DYNAMIC CONTACT WITH NORMAL COMPLIANCE WEAR AND DISCONTINUOUS FRICTION COEFFICIENT*

KENNETH L. KUTTLER† AND MEIR SHILLOR‡

Abstract. We apply the recent theory of evolution inclusions for set-valued pseudomonotone maps, developed in Kuttler and Shillor [*Commun. Contemp. Math.*, 1 (1999), pp. 87–123] to the problem of dynamic frictional contact with normal compliance and wear. The friction coefficient is assumed to be slip rate dependent, and may be continuous, or discontinuous in the form of a graph with a vertical segment at the origin, representing the transition from the static to the dynamic value. The wear of the contacting surfaces is modeled by the Archard law. We prove the existence of a weak solution for the problem. We establish the uniqueness of the weak solution in the case when the friction coefficient is continuous. We also show that the problem with prescribed wear depends continuously on the wear.

Key words. dynamic frictional contact, set-valued inclusions, existence and uniqueness, discontinuous friction coefficient, normal compliance, wear

1. Introduction.

We use the theory of set-valued pseudomonotone maps, which we have developed in [18], to establish the existence of a weak solution of a dynamic frictional contact problem with wear, when the friction coefficient depends discontinuously on the slip velocity. The problem describes frictional dynamic contact between a deformable body, assumed to be viscoelastic, and a moving foundation and the resulting wear of the contact surface. This paper is a continuation of our investigation in [18], where the contact problem has been considered, however, with continuous coefficient of friction and without wear. The new features in the model are the description of friction with a discontinuous coefficient and inclusion of the wear of the contacting surfaces. We investigate the case when the friction coefficient jumps from a static value, when the contacting surfaces stick together, to the lower dynamic value at the onset of relative motion between them. Such a behavior is often assumed in engineering applications. The contact between the body and a moving rigid foundation is modeled with the normal compliance condition, and friction is modeled with the pressure dependent condition. We use the Archard law to describe the evolution of the wear. The problem is formulated as an abstract inclusion in a Banach space to which the results of [18] apply.

Dynamic frictional contact problems have been considered recently in [5, 6, 9, 19, 21, 26, 31], while quasi-static problems can be found in [2, 4, 7, 27, 30] and references to therein. See also [29] and the papers therein. It is a common assumption in engineering literature that the friction coefficient depends on the slip speed. However, there are only few and very recent mathematical publications which consider dynamic contact with a friction coefficient which depends on the slip velocity of the contacting surface [2, 10, 18, 19]. The last reference deals with a discontinuous slip-dependent

coefficient, but in that problem the contact was assumed to be maintained and there was no wear. A simple one-dimensional dynamic problem was analyzed in [10], where a criterion for the appearance of dynamic instabilities was discovered. Analysis and numerical simulations of thermoelastic frictional contact of a beam were performed in [17]. The quasi-static problem with slip or total slip (over the contact history) dependent coefficient of friction can be found in [2] and the dynamic thermoviscoelastic problem in [3]. Frictional contact problems with wear can be found in [6] and [31].

In section 2, we present preliminary material which includes the abstract existence theorem of [18] that underlies our results here. The classical model for the process, its abstract formulation, the assumptions on the problem data, and the statement of our main result, Theorem 3.2, are given in section 3. Section 4 is devoted to approximate problems, with a known wear function, whose unique solvability, stated in Theorem 4.1, follows from the existence theorem in section 2. A solution of the contact problem with known wear, when the friction coefficient μ is continuous, is obtained as a limit of these approximate solutions in section 5. Under a mild additional assumption on the problem data we show that the solution is unique. We investigate in section 6 the case of a discontinuous friction coefficient. It is found that many of the necessary estimates do not depend on the continuity of μ, and this fact is exploited in establishing the existence of a weak solution in the case when μ has a jump discontinuity at the origin, when slip motion is initiated. The result is stated in Theorem 3.2, in the case when the wear is known. Uniqueness remains an unsolved problem in this case. In section 7, we prove the continuous dependence of the solutions of the problem on the wear function w. The result is stated in Theorem 7.1, and it has some merit on its own. In section 8, we deal with the problem with wear, which is assumed to evolve according to a local version of the Archard law. We use the results up to this point to establish the existence of the weak solution to the problem with wear; however, the questions of uniqueness and stability of the solutions remain open.

2. Preliminaries. The existence results to be presented in this paper are based on our recent theorems [18] for differential inclusions of the form

$$\left(B\left(t\right)u\left(t\right)\right)' + Au \ni f\left(t\right),$$

where A is a set-valued pseudomonotone map. Here, the prime denotes the time derivative which is understood in the sense of distributions. Let $\mathcal{V}$ be a reflexive Banach space, over $\mathbb{C}$, and let $\mathcal{V}'$ denote the space of conjugate linear maps. We start with (see, e.g., [22]) the following definition.

DEFINITION 2.1. *A map $A : \mathcal{V} \to \mathcal{P}\left(\mathcal{V}'\right)$ is said to be pseudomonotone if*

1. *the set Au is nonempty, bounded, closed, and convex for all $u \in \mathcal{V}$;*
2. *if F is a finite-dimensional subspace of $\mathcal{V}$, $u \in F$, and if U is a weakly open set in $\mathcal{V}'$ such that $Au \subseteq U$, then there exists $\delta > 0$ such that if $v \in B_\delta(u) \cap F$, then $Av \subseteq U$;*
3. *if $u_i \to u$ weakly in $\mathcal{V}$ and $u_i^* \in Au_i$ is such that*

$$\limsup_{i\to\infty} \mathrm{Re}\langle u_i^*, u_i - u\rangle_{\mathcal{V}} \leq 0, \tag{2.1}$$

then, for each $v \in \mathcal{V}$, there exists $u^*\left(v\right) \in Au$ such that

$$\liminf_{i\to\infty} \mathrm{Re}\langle u_i^*, u_i - v\rangle_{\mathcal{V}} \geq \mathrm{Re}\langle u^*(v), u - v\rangle_{\mathcal{V}}. \tag{2.2}$$

Here $B_\delta(u)$ denotes the ball of radius δ centered at u.

Our theory of set-valued evolution equations was developed in general reflexive Banach spaces. Here we restrict ourselves to the spaces which we now describe. Let $\Omega \subset \mathbb{R}^N$ $(N = 2, 3)$ be a domain, occupied by the deformable body, with Lipschitz boundary Γ. The surface is divided into three mutually disjoint parts Γ_D, Γ_N, and Γ_C such that $\Gamma_C \neq \emptyset$ is the potential contact surface. Next, we choose the space W as follows: if the body is clamped over Γ_D, with $\operatorname{meas}\Gamma_D > 0$, then we set $W = \{\mathbf{u} \in (H^1(\Omega))^N : \mathbf{u} = 0 \text{ on } \Gamma_D\}$; if the body is not held fixed ($\operatorname{meas}\Gamma_D = 0$), then $W = (H^1(\Omega))^N$. Now we let $q, p \geq 2$, set $D = W \cap (C^\infty(\overline{\Omega}))^N$, and define

$$\widetilde{V}_p = \{\mathbf{u} \in W : \gamma\mathbf{u} \in (L^p(\Gamma_C))^N\}, \tag{2.3}$$

with norm $||\mathbf{u}||_{\widetilde{V}_p} = ||\mathbf{u}||_W + ||\gamma\mathbf{u}||_{(L^p(\Gamma_C))^N}$, where $\gamma : W \to (L^2(\Gamma_C))^N$ is the trace operator. $\widetilde{V}_p$ is a reflexive Banach space since it is isometric to a closed subspace of $W \times (L^p(\Gamma_C))^N$. We denote by V_p the closure of D in $\widetilde{V}_p$. Then V_p is a reflexive Banach space, and for $p < q$

$$V_p \supseteq V_q, \qquad V_q \text{ is dense in } V_p. \tag{2.4}$$

Since V_p is dense in $H = (L^2(\Omega))^N$, we identify H and H' and write $V_p \subseteq H = H' \subseteq V_p'$. Let

$$\mathcal{V}_p = \{\mathbf{u} \in L^2(0, T; V_p) : ||\mathbf{u}||_{\mathcal{V}_p} < \infty\}, \tag{2.5}$$

equipped with norm

$$||\mathbf{u}||_{\mathcal{V}_p} = ||\mathbf{u}||_{L^2(0,T;W)} + ||\gamma\mathbf{u}||_{L^p(0,T;(L^p(\Gamma_C))^N)}. \tag{2.6}$$

$\mathcal{V}_p$ is a reflexive Banach space since it is isometric to a closed subspace of $L^2(0, T; W) \times L^p(0, T; (L^p(\Gamma_C))^N)$, and $\mathcal{V}_q$ is dense in $\mathcal{V}_p$ when $p < q$. Note that $\mathcal{V}_p' \subseteq L^{p'}(0, T; V_p')$ and the inclusion map is continuous.

Next, we define the Banach space X as follows:

$$X = \{\mathbf{u} \in \mathcal{V}_p : \mathbf{u}' \in \mathcal{V}_p'\}, \qquad ||\mathbf{u}||_X = ||\mathbf{u}||_{\mathcal{V}_p} + ||\mathbf{u}'||_{\mathcal{V}_p'}. \tag{2.7}$$

We shall use the following two results.

THEOREM 2.2 (see [20]). *Let $p \geq 1$, $q > 1$, $W \subseteq U \subseteq Y$ with compact inclusion map $i : W \to U$ and continuous inclusion map $i : U \to Y$ and let*

$$S_R = \{\mathbf{u} \in L^p(0, T; W) : \mathbf{u}' \in L^q(0, T; Y),\ ||\mathbf{u}||_{L^p(0,T;W)} + ||\mathbf{u}'||_{L^q(0,T;Y)} < R\}.$$

Then S_R is precompact in $L^p(0, T; U)$.

THEOREM 2.3 (see [28]). *Let W, U, and Y be as above and let*

$$S_{RT} = \{\mathbf{u} : ||\mathbf{u}(t)||_W + ||\mathbf{u}'||_{L^q(0,T;Y)} \leq R, \quad t \in [0, T]\}$$

for $q > 1$. Then S_{RT} is precompact in $C(0, T; U)$.

We now describe the abstract setting we shall use. Let V and W be reflexive Banach spaces over $\mathbb{C}$ and let $I = [a, b]$. We denote $\mathcal{W}_I \equiv L^2(I; W)$ and then $\mathcal{W}_I' = L^2(I; W')$. Also, when $I = [0, T]$, we write $\mathcal{V}$ instead of $\mathcal{V}_I$.

We assume that the family of operators $B(t)$ satisfies $B(t) \in \mathcal{L}(W, W')$ and

$$\langle B(t)\, u,\, v\rangle = \overline{\langle B(t)\, v, u\rangle}, \tag{2.8}$$

$$\langle B(t)\, u,\, u\rangle \geq 0, \tag{2.9}$$

$$B(t) = B(0) + \int_0^t B'(s)\, ds. \tag{2.10}$$

The operator L, associated with B, is defined as

$$D(L) \equiv \{u \in \mathcal{V} : (i^*Bu)' \in \mathcal{V}'\}, \tag{2.11}$$

$$Lu \equiv (i^*Bu)' \quad \text{for } u \in D(L), \tag{2.12}$$

where i is the inclusion map of V into W. The following lemma results from the definitions.

LEMMA 2.4. *L is a closed operator.*

We define

$$X \equiv D(L), \qquad ||u||_X \equiv ||Lu||_{\mathcal{V}'} + ||u||_{\mathcal{V}}.$$

By Lemma 2.4, X is isometric to a closed subspace of a product of reflexive Banach spaces and thus X is also reflexive. Under these conditions the following theorem was proved in [18].

THEOREM 2.5 (see [18]). *Let $u, v \in X$; then the following hold.*

1. *$t \to \langle B(t)u(t), v(t)\rangle_{W',W}$ equals an absolutely continuous function a.e. t, denoted by $\langle Bu, v\rangle(\cdot)$.*
2. *$\mathrm{Re}\langle Lu(t), u(t)\rangle = \frac{1}{2}[\langle Bu, u\rangle'(t) + \langle B'(t)u(t), u(t)\rangle]$ for a.e. t.*
3. *$|\langle Bu, v\rangle(t)| \le C||u||_X ||v||_X$ for some $C > 0$ and for all $t \in [0, T]$.*
4. *$t \to B(t)u(t)$ equals a function in $C(0, T; W')$, a.e. t, denoted by $Bu(\cdot)$.*
5. *$\sup\{||Bu(t)||_{W'},\ t \in [0, T]\} \le C||u||_X$ for some $C > 0$.*

If $K : X \to X'$ is given by

$$\langle Ku, v\rangle_{X',X} \equiv \int_0^T \langle Lu(t), v(t)\rangle dt + \langle Bu,\ v\rangle(0),$$

then

6. *K is linear, continuous, and weakly continuous.*
7. *$\mathrm{Re}\langle Ku, u\rangle = \frac{1}{2}[\langle Bu, u\rangle(T) + \langle Bu, u\rangle(0)] + \frac{1}{2}\int_0^T \langle B'(t)u(t), u(t)\rangle dt$.*

The operator A in the theorem and below is assumed to satisfy

$$A : \mathcal{V} \to \mathcal{P}(\mathcal{V}') \text{ is bounded;} \tag{2.13}$$

$$\liminf_{||u||_{\mathcal{V}} \to \infty} \frac{\{2\mathrm{Re}\langle u^*, u\rangle + \langle B'u, u\rangle + \langle Bu, u\rangle(T) : u^* \in Au\}}{||u||_{\mathcal{V}}} = \infty \tag{2.14}$$

for $u \in X$; and

$$A + K : X \to \mathcal{P}(X') \text{ is pseudomonotone.} \tag{2.15}$$

The following abstract theorem is the basis for the results in this paper.

THEOREM 2.6 (see [18]). *Let the spaces $\mathcal{V}$ and $\mathcal{W}$ be as defined above and let the operators $A : \mathcal{V} \to \mathcal{P}(\mathcal{V}')$ and $B(t)$ satisfy (2.13)–(2.15) and (2.10)–(2.12), respectively. If $f \in \mathcal{V}'$ and $u_0 \in W$, then there exists a solution $u \in \mathcal{V}$ to the initial value problem*

$$(i^*Bu)' + Au \ni f \text{ in } \mathcal{V}', \qquad Bu(0) = Bu_0 \text{ in } W'.$$

Here, i is the inclusion map $i : V \to W$. The proof of the theorem can be found in [18].

3. The model. We describe the classical problem and the assumptions on the data, then we formulate it abstractly, and we state our main results in Theorems 3.2–3.3. We use the isothermal version of the problem in [6] (see also [21, 8]). We refer the reader there for a more detailed description of the model. We use the *normal compliance* contact condition (see, e.g., [6, 5, 15, 13, 21, 27]) to describe the contact, together with a condition for dry friction. Dynamic problems with this condition have been investigated in [15, 5, 9, 6]. We use the Archard law, as has been done in [6], to describe the wear of the contact surface (see also [27, 30, 31]).

A viscoelastic body occupies the reference configuration $\Omega \subset \mathbb{R}^N$, with boundary surface $\Gamma = \partial\Omega$, such that $\Gamma = \overline{\Gamma}_C \cup \overline{\Gamma}_D \cup \overline{\Gamma}_N$. It may come in contact with a deformable moving foundation on the part Γ_C. We set $\Omega_T = \Omega \times (0,T)$ for $0 < T$ and denote the displacements vector by $\mathbf{u} = (u_1, \dots, u_N)$ and the stress tensor by $\sigma = \sigma(\mathbf{u}, \mathbf{u}') = (\sigma_{ij})$, where here and below $i, j = 1, \dots, N$, and a comma separates the components of a vector or tensor from partial derivatives.

The equations of motion, in dimensionless form, are

$$\mathbf{u}'' - \operatorname{Div} \sigma(\mathbf{u}, \mathbf{u}') = \mathbf{f}_B \qquad \text{in } \ \Omega_T, \tag{3.1}$$

where $\mathbf{f}_B$ represents the volume force acting on the body. Initially,

$$\mathbf{u}(\mathbf{x}, 0) = \mathbf{u}_0(\mathbf{x}), \qquad \mathbf{u}'(\mathbf{x}, 0) = \mathbf{v}_0(\mathbf{x}) \ \text{ in } \Omega, \tag{3.2}$$

where $\mathbf{u}_0$ and $\mathbf{v}_0$ are the prescribed displacement and velocity fields, respectively.

The body is held fixed on Γ_D (when $\operatorname{meas} \Gamma_D \neq 0$) and tractions $\mathbf{f}_N$ act on Γ_N, thus

$$\mathbf{u} = 0 \quad \text{on } \Gamma_D, \qquad \sigma\mathbf{n} = \mathbf{f}_N \quad \text{on } \Gamma_N, \tag{3.3}$$

where $\mathbf{n}$ is the unit outward normal to Ω on Γ.

Our interest lies in the process on the contact surface Γ_C. We denote the normal component of the displacements vector on Γ by $u_n = \ \mathbf{u} \cdot \mathbf{n}$, the tangential components by $\mathbf{u}_T = \mathbf{u} - (\mathbf{u} \cdot \mathbf{n})\mathbf{n}$, the normal component of the traction by $\sigma_n = \sigma_{ij} n_j n_i$, and the tangential tractions by $\sigma_{Ti} = \sigma_{ij} n_j - \sigma_n n_i$.

We model the contact between the body and the foundation by the normal compliance condition. Let $g = g(\mathbf{x})$ be a nonnegative function on Γ_C, representing the gap between the body's surface (in the reference configuration) and the foundation, measured along the normal $\mathbf{n}$. We denote by $w = w(\mathbf{x}, t)$ the *wear function* which measures the wear of Γ_C at position $\mathbf{x}$ and time t. It describes the change in the surface, in the (negative) direction of the normal, resulting from material removal because of friction. We assume that the contact pressure is given by

$$\sigma_n = -p(u_n - w - g), \tag{3.4}$$

where $p(\cdot)$ is a nonnegative monotone function which vanishes for negative argument values. Thus, the pressure on the contact surface depends on the interpenetration $u_n - w - g$, when positive. The choice $p(r) = (r)_+^{m_n}$ can be found in [13, 21].

We note that as the wear of the surface increases the normal displacement needed for contact increases, too. In the tangential direction we employ a dry friction condition that is compatible with (3.4) and which has a slip dependent and discontinuous friction coefficient. Let μ^* denote the *friction graph*,

$$\mu^*(r) = \begin{cases} [\mu_d, \mu_s] & \text{when } r = 0, \\ \mu_c(r) & \text{when } r > 0, \end{cases} \tag{3.5}$$

where $r = |\mathbf{u}'_T - \mathbf{v}_*|$ denotes the relative slip between the surface and the foundation. Here, $\mathbf{v}_*$ is the tangential velocity of the foundation, and generally it depends on the location on the surface, thus it is assumed to lie in $L^\infty(0,T;L^\infty\left(\mathbb{R}^N\right))$. If the contact surface is flat, a portion of a plane, we may choose $\mathbf{v}_*$ to be a function of time only, but when the contact surface is not flat, even if the velocity of the foundation is constant, the tangential velocity is not constant and depends on the position and on time.

In the slip state ($0 < r$) the coefficient μ is given by $\mu_c(r)$, and $\mu_d = \lim_{s\to 0}\mu_c(s)$ denotes the dynamic value at zero slip. In the absence of relative slip μ may have any value in the interval $[\mu_d, \mu_s]$. Thus, we do not insist that it has the static value μ_s, although it is likely when the body is in stick state for a while. We assume that $\mu_c(r)$, for $r \geq 0$, is a given positive Lipschitz function which satisfies the conditions below.

Next, we consider the friction condition. As is well known in applications, and explained well in [25, 32], when the contact pressure is low to moderate, the real contact area is a small fraction of the nominal contact area, and the frictional tangential traction is proportional to the contact pressure, given by μp. This is the usual Coulomb's condition which is often used both in engineering and mathematical publications. However, when the contact pressure is very high, such as in metal forming processes, the fraction of the real contact area approaches unity, and the frictional traction reaches saturation and the maximal frictional resistance becomes independent of the contact pressure. Thus, there is a transition from the Coulomb law to the so-called Tresca law; see, e.g., [32]. Such a transition is observed both in elastic and plastic materials. A simple way to model such behavior is to introduce the truncated contact pressure function

$$p_{_R} = \begin{cases} p & \text{if } \ p \leq R, \\ R & \text{if } \ R \leq p. \end{cases}$$

Here, $R = $ const. is the pressure at which the friction traction levels off. We could have used, instead, a more general, and less transparent, function F such that $F = \mu p$ for small p, and asymptotically $F \to \mu R$ as $p \to \infty$.

Then the *friction bound* is defined as $\mu p_{_R}$, and the friction law is

$$\mu(|\mathbf{u}'_T - \mathbf{v}_*|) \in \mu^*(|\mathbf{u}'_T - \mathbf{v}_*|) \qquad \text{a.e. on } \Gamma_C, \tag{3.6}$$

$$|\sigma_T| \leq \mu_s p_{_R}(u_n - w - g), \tag{3.7}$$

$$\sigma_T = -\frac{\mathbf{u}'_T - \mathbf{v}_*}{|\mathbf{u}'_T - \mathbf{v}_*|}\mu_c\left(|\mathbf{u}'_T - \mathbf{v}_*|\right) p_{_R}(u_n - w - g) \quad \text{ if } \ \mathbf{u}'_T - \mathbf{v}_* \neq 0. \tag{3.8}$$

Conditions (3.6)–(3.8) model friction as follows. The tangential part of the traction is bounded by $\mu_s p_{_R}$. Sliding commences when $|\sigma_T|$ reaches the bound $\mu_s p_{_R}$, and then the tangential force has a direction opposite to the relative tangential velocity. The actual value of μ is a selection out of the graph, (3.6).

The contact surface Γ_C is divided, at each time instant, into the *separation*, *slip,* and *stick* zones.

We assume that the wear of the surface is either a given function or else it is proportional to the friction force and to the sliding speed, as in the Archard law,

$$\frac{\partial w}{\partial t} = k_w \mu_c(|\mathbf{u}'_T - \mathbf{v}_*|) p_{_R}(u_n - w - g) s_c(|\mathbf{u}'_T - \mathbf{v}_*|). \tag{3.9}$$

Here, k_w is a positive material constant, very small in practice. The function s_c is a regularization of $|\cdot|$ on $\mathbb{R}^N$ which is uniformly bounded and such that $s_c(r) = 0$ for $r = 0$. Note that we used μ_c in (3.9) since s_c vanishes when there is no slip.

The new features in the model are the dependence, which often can be observed experimentally, of the friction coefficient on the magnitude of the slip, $|\mathbf{u}'_T - \mathbf{v}_*|$, with a jump from a static to a dynamic value at the onset of sliding, and the wear of the contact surface. The problem with Lipschitz μ and without wear was investigated in [18].

Finally, we assume that the material is viscoelastic with constitutive law

$$\sigma = \sigma(\mathbf{u}, \mathbf{u}') = A\mathbf{u} + C\mathbf{u}', \tag{3.10}$$

i.e., $\sigma_{ij} = A_{ijkl}u_{k,l} + C_{ijkl}u'_{k,l}$, where the elasticity tensor A has the components A_{ijkl} and the viscosity tensor C has the components C_{ijkl}.

The classical formulation of the problem of *dynamic frictional contact with normal compliance wear and discontinuous slip dependent friction coefficient* is as follows: Find $\{\mathbf{u}, w\}$ such that (3.1)–(3.10) hold.

We make the following assumptions on the problem data. The normal pressure function $p(\cdot)$ is increasing and satisfies

$$|p(r_1) - p(r_2)| \le K(1 + r_1^{p-2} + r_2^{p-2})|r_1 - r_2|, \tag{3.11}$$

and either

$$0 \le p\,(r) \le K \text{ and } p = 2; \quad p(r) = 0, \qquad r < 0, \tag{3.12}$$

or

$$\delta^2 r^{p-1} - K \le p(r) \le K(1 + r^{p-1}), \qquad r \ge 0; \quad p(r) = 0, \qquad r < 0, \tag{3.13}$$

where $p \ge 2$ is a fixed exponent here and everywhere below, and δ and K are positive constants. Also, p is the exponent and $p(\cdot)$ is the normal compliance function. The choice made in [21] and [13] of $p(r) = r_+^{m_n}$, where $1 < m_T \le m_n$, corresponds to $p - 1 = m_n$ and clearly (3.13) holds for suitable constants K and δ. The function s_c satisfies

$$s_c(r) \le s_c^*, \qquad |s_c(r_1) - s_c(r_2)| \le \delta_c^* |r_1 - r_2|. \tag{3.14}$$

We assume that the coefficient of friction is a graph composed of the vertical segment $[\mu_d,\, \mu_s]$ and the function μ_c is bounded, positive, and Lipschitz continuous,

$$|\mu_c\,(r_1) - \mu_c\,(r_2)| \le \ \mathrm{Lip}_\mu\,|r_1 - r_2|\,, \qquad ||\mu_c||_{L^\infty} \le c_\mu. \tag{3.15}$$

We assume that the elasticity and viscosity coefficients A and C lie in $L^\infty(\Omega)$ and satisfy the following symmetries for $B = A$ or C:

$$B_{ijkl} = B_{ijlk}, \qquad B_{jikl} = B_{ijkl}, \qquad B_{ijkl} = B_{klij}, \tag{3.16}$$

and

$$B_{ijkl}\zeta_{ij}\zeta_{kl} \ge \lambda\zeta_{rs}\zeta_{rs}, \tag{3.17}$$

for all symmetric matrices ζ, where $0 < \lambda$.

We now obtain a weak formulation of problem (3.1)–(3.10) since, generally, the friction law and the set inclusion (3.6) preclude the existence of classical solutions.

We begin by defining the viscosity and elasticity operators $M, A : V_p \to V_p'$ as

$$\langle M\mathbf{u}, \mathbf{v}\rangle = \int_\Omega C_{ijkl}\mathbf{u}_{k,l}\mathbf{v}_{i,j}\,dx, \tag{3.18}$$

$$\langle A\mathbf{u}, \mathbf{v}\rangle = \int_\Omega A_{ijkl}\mathbf{u}_{k,l}\mathbf{v}_{i,j}\,dx. \tag{3.19}$$

It follows from our assumptions and Korn's inequality [23] that both M and A satisfy

$$\langle B\mathbf{u}, \mathbf{u}\rangle \geq \delta^2||\mathbf{u}||_W^2 - \lambda_0|\mathbf{u}|_H^2, \qquad \langle\, B\mathbf{u}, \mathbf{u}\rangle \geq 0, \qquad \langle B\mathbf{u}, \mathbf{v}\rangle = \langle B\mathbf{v}, \mathbf{u}\rangle$$

for $B = M$ or A, for some $\delta > 0$, and for $\lambda_0 \geq 0$.

The *normal compliance* operator $(\mathbf{v}, w) \to P(\mathbf{u}, w)$, which maps $\mathcal{V}_q \times L^p(\Gamma_C)$ to $\mathcal{V}_q'$ (for each $q \geq p$), is given by

$$\langle P(\mathbf{u}, w), \mathbf{z}\rangle = \int_0^T \int_{\Gamma_C} p(u_n - w - g)z_n\,d\Gamma dt, \tag{3.20}$$

where $\mathbf{u}(t) = \mathbf{u}_0 + \int_0^t \mathbf{v}(s)ds$, for $\mathbf{u}_0 \in V_q$. Next, we define $\mathbf{f} \in \mathcal{W}'$ as

$$\langle \mathbf{f}, \mathbf{z}\rangle_{\mathcal{W}',\mathcal{W}} = \int_0^T \int_\Omega \mathbf{f}_B\mathbf{z}\,dxdt + \int_0^T \int_{\partial\Omega} \mathbf{f}_N\gamma\mathbf{z}\,d\Gamma dt \tag{3.21}$$

for all $\mathbf{z} \in \mathcal{W}$. Here $\mathbf{f}_B$ represents a body force in $L^2(0, T; H)$ and $\mathbf{f}_N$ is a traction force in $L^2(0, T; L^2(\partial\Omega)^N)$.

Let $\gamma_T^* : L^{p'}(0, T; L^{p'}(\Gamma_C)^N) \to \mathcal{V}_p'$ be defined as

$$\langle \gamma_T^*\xi, \mathbf{w}\rangle = \int_0^T \int_{\Gamma_C} \xi \cdot \mathbf{w}_T\,d\Gamma dt.$$

The abstract form of the problem for the displacement $\mathbf{u}$, the velocity $\mathbf{v}$, and the wear w, is the following.

Problem $\mathcal{P}$. Find $\mathbf{u}, \mathbf{v} \in \mathcal{V}_p$, $w \in L^p(0, T; L^p(\Gamma_C))$ such that

$$\mathbf{v}' + M\mathbf{v} + A\mathbf{u} + P(\mathbf{u}, w) + \gamma_T^*\xi = \mathbf{f} \quad \text{ in } \quad \mathcal{V}_p', \tag{3.22}$$

$$w' = k_w\mu_c\left(|\mathbf{v}_T - \mathbf{v}_*|\right)p_R\left(u_n - w - g\right)s_c\left(|\mathbf{v}_T - \mathbf{v}_*|\right), \tag{3.23}$$

$$w(0) = 0, \qquad \mathbf{v}(0) = \mathbf{v}_0 \in H, \tag{3.24}$$

$$\mathbf{u}(t) = \mathbf{u}_0 + \int_0^t \mathbf{v}(s)\,ds, \qquad \mathbf{u}_0 \in V_p, \tag{3.25}$$

the inclusion (3.6) holds and for all $\mathbf{w} \in \mathcal{V}_p$,

$$\langle \gamma_T^*\xi, \mathbf{w}\rangle \leq \int_0^T \int_{\Gamma_C} \mu_c p_R\left(|\mathbf{v}_T - \mathbf{v}_* + \mathbf{w}_T| - |\mathbf{v}_T - \mathbf{v}_*|\right)\,d\Gamma dt, \tag{3.26}$$

where $\mu_c = \mu_c(|\mathbf{v}_T - \mathbf{v}_*|)$ and $p_R = p_R(u_n - w - g)$.

When the triplet $\{\mathbf{u}, \mathbf{v}, w\}$ solves the abstract problem (3.22)–(3.26), then $\mathbf{u}$ and w are a weak solution of (3.1)–(3.10).

The main results in this paper are presented according to whether the wear is a given function or is determined by the differential equation (3.23). To begin with, we consider the following basic result, proved in section 5, in the case of a given wear function. We note that it includes all the published versions of the problem, such as [14, 21] or [15].

THEOREM 3.1. *Let $p \geq 2$ and let $w \in L^p(0,T;L^p(\Gamma_C))$, $w' \in L^p(0,T;L^p(\Gamma_C))$, $w' \geq 0$, $\mathbf{u}_0 \in V_p$, $\mathbf{v}_0 \in H$, $\mathbf{f} \in \mathcal{V}_p'$ and assume $\mu^*(r) = \mu_c(r)$, where μ_c is bounded and Lipschitz. Then there exists $\xi \in L^{p'}(0,T;L^{p'}(\Gamma_C)^N)$ and $\mathbf{v} \in L^2(0,T;W)$ such that*

$$(u_n - w - g)_+ \in L^\infty(0,T;L^p(\Gamma_C)), \tag{3.27}$$

$$\mathbf{v}' + M\mathbf{v} + A\mathbf{u} + P(\mathbf{u}, w) + \gamma_T^*\xi = \mathbf{f} \ \text{ in } \ \mathcal{V}_p', \tag{3.28}$$

$$\mathbf{v}(0) = \mathbf{v}_0\ ,\ \mathbf{u}(t) = \mathbf{u}_0 + \int_0^t \mathbf{v}(s)\,ds, \tag{3.29}$$

and

$$\langle \gamma_T^*\xi, \mathbf{w}\rangle \leq \int_0^T \int_{\Gamma_C} \mu_c p_R\left(|\mathbf{v}_T - \mathbf{v}_* + \mathbf{w}_T| - |\mathbf{v}_T - \mathbf{v}_*|\right) d\Gamma\, dt, \tag{3.30}$$

where $\mu_c = \mu_c(|\mathbf{v}_T - \mathbf{v}_*|)$ and $p_R = p_R(u_n - w - g)$.

If, in addition, $p \leq 4$, then the solution $\{\mathbf{u}, \mathbf{v}\}$ is unique.

Next, we consider the case of a set-valued friction coefficient and given wear function. The proof can be found in section 6.

THEOREM 3.2. *Let $p \geq 2$ and let $\mathbf{u}_0 \in V_p$, $\mathbf{v}_0 \in H$, $\mathbf{f} \in \mathcal{V}_p'$, and $w, w' \in L^p(0,T;L^p(\Gamma_C))$ with $w' \geq 0$. Then there exists a pair $\{\mathbf{v}, \xi\}$ such that*

$$\mathbf{v} \in L^2(0,T;W), \qquad (u_n - w - g)_+ \in L^\infty(0,T;L^p(\Gamma_C)), \tag{3.31}$$

$$\mathbf{v}' + M\mathbf{v} + A\mathbf{u} + P(\mathbf{u}, w) + \gamma_T^*\xi = \mathbf{f} \ \text{ in } \ \mathcal{V}_p', \tag{3.32}$$

$$\mathbf{v}(0) = \mathbf{v}_0, \qquad \mathbf{u}(t) = \mathbf{u}_0 + \int_0^t \mathbf{v}(s)\,ds, \tag{3.33}$$

where ξ satisfies the inequality

$$\langle \gamma_T^*\xi, \mathbf{w}\rangle \leq \int_0^T \int_{\Gamma_C} \mu_c p_R\left(|\mathbf{v}_T - \mathbf{v}_* + \mathbf{w}_T| - |\mathbf{v}_T - \mathbf{v}_*|\right) d\Gamma dt, \tag{3.34}$$

and where $\mu_c = \mu_c(|\mathbf{v}_T - \mathbf{v}_*|)$ and $p_R = p_R(u_n - w - g)$, for an element $(|\mathbf{v}_T - \mathbf{v}_*|, \mu(|\mathbf{v}_T - \mathbf{v}_*|))$ from the graph μ^*, a.e., and for all $\mathbf{w} \in \mathcal{V}_p$.

We note that this theorem guarantees only the existence of a solution. Indeed, it seems unreasonable to expect uniqueness when we have a graph in the problem; however, the question remains open.

Finally, we consider the case where the wear is a solution of the differential equation of Archard's law and $\mu^* = \mu_c$. This leads to the following theorem whose proof is in section 8.

THEOREM 3.3. *Assume* (3.12) *and that* $\mu = \mu_c = \mu^*$ *and* s_c *are bounded and Lipschitz continuous. Let* $\mathbf{u}_0 \in V_2, \mathbf{v}_0 \in H$, *and* $\mathbf{f} \in \mathcal{V}_2'$. *Then there exists a unique solution* $\{\mathbf{u}, \mathbf{v}, w\}$ *of problem* (3.22)–(3.26), *and it satisfies*

$$\mathbf{v} \in L^2(0,T;V_2), \quad \mathbf{v}' \in L^2(0,T;V_2'), \quad w,\, w' \in L^\infty(0,T;L^\infty(\Gamma_C)).$$

If we wish to take into account the possible dependence of μ and $p(\cdot)$ on the position x on the contact surface, all we need to do is to assume that both functions are measurable in x, in addition to the other assumptions above. This increase in generality is mainly technical and does not change any of the arguments and conclusions that follow. Therefore, we have omitted an explicit reference to it in the models.

Existence of weak solutions for the problem with friction graph and a wear function that is an unknown of the problem remains an important unresolved problem.

4. Approximate problems with given wear. In this section we consider regularized approximate problems in which w is a given function satisfying

$$w \in L^p(0,T;L^p(\Gamma_C)), \quad w' \in L^p(0,T;L^p(\Gamma_C)), \quad w' \geq 0,$$

and $\mu = \mu_c = \mu^*$ is a given Lipschitz continuous function of $|\mathbf{v}_T - \mathbf{v}_*|$.

First, let $\mathbf{u}_{0\varepsilon}$ be a sequence in D satisfying $\lim_{\varepsilon\to 0} \mathbf{u}_{0\varepsilon} = \mathbf{u}_0$ in V_p. We assume that $q = p^2(p-1)^{-1}$, thus

$$\frac{p-1}{q} + \frac{1}{p} + \frac{1}{q} = 1.$$

Next, let the operator J be defined by

$$\langle J\mathbf{u}, \mathbf{v}\rangle = \int_{\Gamma_C} ||\gamma\mathbf{u}||^{q-2}\gamma\mathbf{u}\cdot\gamma\mathbf{v}\, d\Gamma. \tag{4.1}$$

We use J to regularize problem (3.22)–(3.26) and for each $\varepsilon > 0$ the approximate problem is the following.

Problem $\mathcal{P}(\varepsilon)$. Find $\mathbf{v}_\varepsilon \in \mathcal{V}_q$ such that

$$\mathbf{v}_\varepsilon' + M\mathbf{v}_\varepsilon + A\mathbf{u}_\varepsilon + \varepsilon J\mathbf{v}_\varepsilon + P(\mathbf{u}_\varepsilon, w) + Q(\mathbf{v}_\varepsilon, w) \ni \mathbf{f} \ \text{ in } \mathcal{V}_q', \tag{4.2}$$

$$\mathbf{v}_\varepsilon(0) = \mathbf{v}_0 \in H, \tag{4.3}$$

$$\mathbf{u}_\varepsilon(t) = \mathbf{u}_{0\varepsilon} + \int_0^t \mathbf{v}_\varepsilon(s)\, ds. \tag{4.4}$$

Here, by $\mathbf{v}^* \in Q(\mathbf{v}, w) \subseteq \mathcal{V}_p'$ we mean that there exists $\mathbf{z} \in L^\infty(0,T;L^\infty(\Gamma_C)^N)$ such that

$$\langle \mathbf{v}^*, \mathbf{w}\rangle = \int_0^T \int_{\Gamma_C} \mu\left(|\mathbf{v}_T - \mathbf{v}_*|\right) p_R\left(u_n - w - g\right) \mathbf{z}\cdot\mathbf{w}_T\, d\Gamma dt, \tag{4.5}$$

and $\mathbf{z}$ satisfies

$$\int_0^T \int_{\Gamma_C} \mathbf{z}\cdot\mathbf{w}_T d\Gamma dt \leq \int_0^T \int_{\Gamma_C} \left(|\mathbf{v}_T - \mathbf{v}_* + \mathbf{w}_T| - |\mathbf{v}_T - \mathbf{v}_*|\right) d\Gamma dt, \tag{4.6}$$

for all $\mathbf{w} \in \mathcal{V}_p$.

Below we omit the subscript ε for the sake of simplicity. We have the following result for the approximate problems.

THEOREM 4.1. *Assume that $p(\cdot)$ satisfies* (3.13). *Then for each $\varepsilon > 0$ there exists a solution $\mathbf{v}_\varepsilon \in \mathcal{V}_q$ of $\mathcal{P}(\varepsilon)$.*

The proof of the theorem is accomplished in a number of steps. We begin with the following assertion which follows directly from the definitions.

LEMMA 4.2. *The operators J, Q, M, A, and $P(\cdot, w)$ are bounded maps from $\mathcal{V}_q$ or $\mathcal{V}_q \times L^p(0,T; L^p(\Gamma_C))$ into $\mathcal{V}_q'$ or $\mathcal{P}(\mathcal{V}_q')$.*

Next, we change the dependent variable and set $\mathbf{y}e^{\lambda t} = \mathbf{v}$. Then, in terms of $\mathbf{y}$, the problem $\mathcal{P}(\varepsilon)$ consists of finding $\mathbf{y} \in \mathcal{V}_q$ such that

$$\mathbf{y}' + \lambda\mathbf{y} + M\mathbf{y} + e^{-\lambda(\cdot)}A\mathbf{u} + \varepsilon e^{-\lambda(\cdot)}J(e^{\lambda(\cdot)}\mathbf{y})$$

$$+ e^{-\lambda(\cdot)}P(\mathbf{u}, w) + e^{-\lambda(\cdot)}Q(e^{\lambda(\cdot)}\mathbf{y}, w) \ni e^{-\lambda(\cdot)}\mathbf{f} \qquad \text{in } \mathcal{V}_q', \tag{4.7}$$

$$\mathbf{y}(0) = \mathbf{v}_0 \in H. \tag{4.8}$$

Let X be the space given in (2.7). The next lemma will be used to show the operator Q_λ given by

$$\mathbf{y} \to Q_\lambda(\mathbf{y}, w) \equiv e^{-\lambda(\cdot)}Q(e^{\lambda(\cdot)}\mathbf{y}, w) \tag{4.9}$$

is pseudomonotone.

LEMMA 4.3. *If $\mathbf{v}^k \rightharpoonup \mathbf{v}$ in X, then $\gamma\mathbf{v}^k \to \gamma\mathbf{v}$ in $L^p(0,T;(L^p(\Gamma_C))^N)$.*

Proof. Since $p \geq 2$, it is straightforward to verify that if $\mathbf{v} \in X$, then $\mathbf{v}' \in L^{q'}(0,T;V_q')$ and $\mathbf{v}(t_1) - \mathbf{v}(t_2) = \int_{t_2}^{t_1} \mathbf{v}'(s)\,ds$. Let $W \subseteq U$ be such that the injection $W \to U$ is compact and $\gamma : U \to (L^2(\Gamma_C))^N$ is continuous. Since $\mathcal{V}_q$ embeds continuously into $L^2(0,T;W)$, Theorem 2.2 implies that $\mathbf{v}^k \to \mathbf{v}$ in $L^2(0,T;U)$. It follows that $\gamma\mathbf{v}^k \to \gamma\mathbf{v}$ in $L^2(0,T;(L^2(\Gamma_C))^N)$. Now if the lemma is not true, then there exists a sequence $\{\mathbf{v}^k\} \subseteq X$ such that $\mathbf{v}^k \rightharpoonup \mathbf{v}$ in X but $||\gamma\mathbf{v}^k - \gamma\mathbf{v}||_{L^p(0,T;(L^p(\Gamma_C))^N)} \geq \eta > 0$ for some η. By taking a subsequence, we may assume $\widetilde{\gamma\mathbf{v}}^k(\mathbf{x},t) \to \widetilde{\gamma\mathbf{v}}(\mathbf{x},t)$ a.e. $(\mathbf{x},t) \in \Gamma_C \times (0,T)$, since $\gamma\mathbf{v}^k \to \gamma\mathbf{v}$ in $L^2(0,T;(L^2(\Gamma_c))^N$. Here, " $\sim$ " means a product measurable representative. Since $\widetilde{\gamma\mathbf{v}}^k$ is bounded in $(L^q((0,T)\times\Gamma_C))^N$, the Fatou lemma guarantees that $\widetilde{\gamma\mathbf{v}}$ is also bounded in $L^q((0,T)\times\Gamma_C)$. Thus, the sequence $\{|\widetilde{\gamma\mathbf{v}}^k - \widetilde{\gamma\mathbf{v}}|^p\}$ is uniformly integrable, so it follows from the Vitali convergence theorem that

$$\lim_{k\to\infty} \int_{(0,T)\times\Gamma_C} |\widetilde{\gamma\mathbf{v}}^k - \widetilde{\gamma\mathbf{v}}|^p \, d\Gamma dt = 0.$$

This contradicts the assumption that $||\gamma\mathbf{v}^k - \gamma\mathbf{v}||_{L^p(0,T;(L^p(\Gamma_C))^N)} \geq \eta > 0$ and thus proves the lemma.

LEMMA 4.4. *If $\mathbf{y}^k \rightharpoonup \mathbf{y}$ in X, then*

$$p(u_n^k - w - g) \to p(u_n - w - g) \quad \text{in } L^{p'}(0,T;L^{p'}(\Gamma_C)) \tag{4.10}$$

and

$$\mu\left(|\mathbf{v}_T^k - \mathbf{v}_*|\right) \to \mu\left(|\mathbf{v}_T - \mathbf{v}_*|\right) \quad \text{in } L^p(0,T;L^p(\Gamma_C)). \tag{4.11}$$

Proof. To simplify the notation we let $F = p(u_n - w - g)$, $F^k = p(u_n^k - w - g)$, $\mu = \mu(|\mathbf{v}_T - \mathbf{v}_*|)$, and $\mu^k = \mu(|\mathbf{v}_T^k - \mathbf{v}_*|)$. Now it follows from (3.13) that

$$\left|F^k - F\right| \leq K\left(1 + \left|u_n^k\right|^{p-2} + |u_n|^{p-2}\right)\left|u_n^k - u_n\right|.$$

We will show that $|u_n^k|^{p-2}|u_n^k-u_n| \to 0$ in $L^{p'}(0,T;L^{p'}(\Gamma_C))$ and observe that simpler arguments apply to the other two terms. We have

$$\begin{aligned}
&\int_0^T \int_{\Gamma_C} \left|u_n^k\right|^{(p-2)p'} \left|u_n^k - u_n\right|^{p'} \, d\Gamma dt \\
&\quad \leq \left(\int_0^T \int_{\Gamma_C} \left|u_n^k - u_n\right|^p d\Gamma dt \right)^{p'/p} \left(\int_0^T \int_{\Gamma_C} \left|u_n^k\right|^p \, d\Gamma dt \right)^{(p-p')/p} \\
&\quad \leq c \left(\int_0^T \int_{\Gamma_C} \left|u_n^k - u_n\right|^p d\Gamma dt \right)^{p'/p},
\end{aligned}$$

which converges to zero by Lemma 4.3. Moreover,

$$\int_0^T \int_{\Gamma_C} |\mu^k - \mu|^p \, d\Gamma dt \leq C \ \ \mathrm{Lip}_\mu^p \int_0^T \int_{\Gamma_C} \left|\gamma \mathbf{v}^k - \gamma \mathbf{v}\right|^p \, d\Gamma dt,$$

which also converges to zero by Lemma 4.3. The other terms behave similarly.

LEMMA 4.5. *Let* $\mathbf{y}^k \rightharpoonup \mathbf{y}$ *in* X *and* $\mathbf{z}^k \rightharpoonup \mathbf{z}$ *in* $L^\infty(0,T;L^\infty(\Gamma_C)^N)$. *If* $\mathbf{w} \in L^p(0,T;L^p(\Gamma_C)^N)$, *then*

$$\int_0^T \int_{\Gamma_C} F^k \mu^k \, \mathbf{z}^k \cdot \mathbf{w}_T \, d\Gamma dt \to \int_0^T \int_{\Gamma_C} F\mu \ \ \mathbf{z} \cdot \mathbf{w}_T \, d\Gamma dt. \tag{4.12}$$

Proof. We argue by contradiction. If (4.12) does not hold, then there exist two sequences $\mathbf{y}^k \rightharpoonup \mathbf{y}$ in X and $\mathbf{z}^k \rightharpoonup \mathbf{z}$ in $L^\infty(0,T;L^\infty(\Gamma_C)^N)$ and $\mathbf{w} \in L^p(0,T;L^p(\Gamma_C)^N)$ such that

$$\left| \int_0^T \int_{\Gamma_C} F^k \mu^k \, \mathbf{z}^k \cdot \mathbf{w}_T \, d\Gamma dt - \int_0^T \int_{\Gamma_C} F\mu \, \mathbf{z} \cdot \mathbf{w}_T \, d\Gamma dt \right| \geq 2\hat{\varepsilon}.$$

Since $L^\infty(0,T;L^\infty(\Gamma_C)^N)$ is dense in $L^p(0,T;L^p(\Gamma_C)^N)$, we find that, for $\mathbf{w} \in L^\infty(0,T;L^\infty(\Gamma_C)^N)$,

$$\left| \int_0^T \int_{\Gamma_C} F^k \mu^k \, \mathbf{z}^k \cdot \mathbf{w}_T \, d\Gamma dt - \int_0^T \int_{\Gamma_C} F\mu \, \mathbf{z} \cdot \mathbf{w}_T \, d\Gamma dt \right| \geq \hat{\varepsilon}. \tag{4.13}$$

However, by Lemma 4.4, $\mu(|\mathbf{v}_T^k - \mathbf{v}_*|)p(u_n^k - w - g) \to \mu(|\mathbf{v}_T - \mathbf{v}_*|)p(u_n - w - g)$ in $L^1(0,T;L^1(\Gamma_C))$. Therefore, (4.13) cannot hold for all k, which proves the lemma.

LEMMA 4.6. Q_λ *is a bounded pseudomonotone operator.*

Proof. We have already observed that Q_λ is bounded, and it is straightforward to show that $Q_\lambda(\mathbf{y})$ is convex. Suppose that $Q_\lambda(\mathbf{y}) \subseteq U$, where U is a weakly open set in X', that $\mathbf{y}_k^* \in Q_\lambda(\mathbf{y}) \setminus U$, and that $\mathbf{y}^k \rightharpoonup \mathbf{y}$ in X, where $\mathbf{y}_k^* \in Q_\lambda\left(\mathbf{y}^k\right)$. Let $U_\lambda \equiv e^{\lambda(\cdot)}U$; then U_λ is weakly open in X' containing $Q(\mathbf{v})$, $\mathbf{v}^k \rightharpoonup \mathbf{v}$ in X, and $\mathbf{v}_k^* \equiv e^{\lambda(\cdot)}\mathbf{y}_k^* \in Q(\mathbf{v}^k) \setminus U_\lambda$. Next, let $\{\mathbf{z}^k\}$ be a sequence in $L^\infty(0,T;L^\infty(\Gamma_C)^N)$ as in the definition of Q such that, possibly for a subsequence, $\mathbf{z}^k \rightharpoonup \mathbf{z}$ in $L^\infty(0,T;L^\infty(\Gamma_C)^N)$.

From Lemma 4.3,

$$\begin{aligned}\int_0^T \int_{\Gamma_C} \mathbf{z}\cdot\mathbf{w}_T\, d\Gamma dt &= \lim_{k\to\infty} \int_0^T \int_{\Gamma_C} \mathbf{z}^k\cdot\mathbf{w}_T\, d\Gamma dt \\ &\le \lim_{k\to\infty} \int_0^T \int_{\Gamma_C} \left(|\ \mathbf{v}_T^k - \mathbf{v}_* + \mathbf{w}_T| - |\mathbf{v}_T^k - \mathbf{v}_*|\right)\, d\Gamma dt \\ &\le \int_0^T \int_{\Gamma_C} \left(|\mathbf{v}_T - \mathbf{v}_* + \mathbf{w}_T| - |\mathbf{v}_T - \mathbf{v}_*|\right)\, d\Gamma\, dt.\end{aligned}$$

Now, using the notation $p_{_R}^k = p_{_R}(u_n^k - w - g)$ and $p_{_R} = p_{_R}(u_n - w - g)$, we have

$$\langle \mathbf{v}_k^*, \mathbf{w}\rangle \equiv \int_0^T \int_{\Gamma_C} \mu\left(\left|\mathbf{v}_T^k - \mathbf{v}_*\right|\right) p_{_R}^k\, \mathbf{z}^k\cdot\mathbf{w}_T\, d\Gamma dt,$$

and so from Lemma 4.5 we know that $\mathbf{v}_k^* \rightharpoonup \mathbf{v}^*$, where

$$\langle \mathbf{v}^*, \mathbf{w}\rangle \equiv \int_0^T \int_{\Gamma_C} \mu\left(|\mathbf{v}_T - \mathbf{v}_*|\right) p_{_R}\, \mathbf{z}\cdot\mathbf{w}_T\, d\Gamma dt. \tag{4.14}$$

Thus, $\mathbf{v}^* \in Q(\mathbf{v}) \subseteq U_\lambda$ by the definition of Q. This contradicts the assumption that $\mathbf{v}_k^* \notin U_\lambda$ for all k, and hence $Q(\mathbf{v}^k) \subseteq U_\lambda$ for all large k. This argument also shows that $Q_\lambda(\mathbf{y})$ is closed. It remains to verify conditions (2.1) and (2.2).

To that end let $\mathbf{y}^k \rightharpoonup \mathbf{y}$ and $\mathbf{y}_k^* \in Q_\lambda(\mathbf{y}^k)$. We show that if $\mathbf{w} \in X$, then

$$\liminf_{k\to\infty} \langle \mathbf{y}_k^*, \mathbf{y}^k - \mathbf{w}\rangle \ge \langle \mathbf{y}^*(\mathbf{w}), \mathbf{y} - \mathbf{w}\rangle, \qquad \mathbf{y}^*(\mathbf{w}) \in Q_\lambda(\mathbf{y}).$$

We choose a subsequence $\mathbf{y}^k$ (depending on $\mathbf{w}$) such that

$$\lim_{k\to\infty} \langle \mathbf{y}_k^*, \mathbf{y}^k - \mathbf{w}\rangle = \liminf_{k\to\infty} \langle \mathbf{y}_k^*, \mathbf{y}^k - \mathbf{w}\rangle.$$

For $\mathbf{v}_k^* = e^{\lambda(\cdot)}\mathbf{y}_k^* \in Q\left(\mathbf{v}^k\right)$ we let $\mathbf{z}^k \in L^\infty(0,T;L^\infty(\Gamma_C)^N)$ be as in the definition of Q. We take a further subsequence, if necessary, such that $\mathbf{z}^k \rightharpoonup \mathbf{z}$ in $L^\infty(0,T;L^\infty(\Gamma_C)^N)$. Then $\mathbf{z}$ satisfies (4.6) by Lemma 4.3. It follows from Lemma 4.5 that if we define $\mathbf{y}^*(\mathbf{w})$ by

$$\langle \mathbf{y}^*(\mathbf{w}), \mathbf{b}\rangle = \int_0^T \int_{\Gamma_C} e^{-\lambda t} p_{_R}\left(u_n - w - g\right) \mu\left(|\mathbf{v}_T - \mathbf{v}_*|\right) \mathbf{z}\cdot\mathbf{b}_T\, d\Gamma dt,$$

then

$$\begin{aligned}\liminf_{k\to\infty} \langle \mathbf{y}_k^*, \mathbf{y}^k - \mathbf{w}\rangle &= \lim_{k\ \to\infty} \langle \mathbf{y}_k^*, \mathbf{y}^k - \mathbf{w}\rangle \\ &= \lim_{k\to\infty} \int_0^T \int_{\Gamma_C} e^{-\lambda t}\mu^k\, p_{_R}^k\, \mathbf{z}^k\cdot\left(\mathbf{y}_T^k - \mathbf{w}_T\right) d\Gamma dt \\ &= \int_0^T \int_{\Gamma_C} e^{-\lambda t}\mu\, p_{_R}\, \mathbf{z}\cdot\left(\mathbf{y}_T - \mathbf{w}_T\right) d\Gamma dt = \langle \mathbf{y}^*(\mathbf{w}), \mathbf{y} - \mathbf{w}\rangle.\end{aligned}$$

This proves the lemma.

LEMMA 4.7. *If $\mathbf{v}^k \rightharpoonup \mathbf{v}$ in X, then $P(\mathbf{u}^k, w) \to P(\mathbf{u}, w)$ in $\mathcal{V}_q'$.*

Proof. Let $\mathbf{w} \in \mathcal{V}_q$. Then we have from the definition of P and (3.13) that

$$\begin{aligned}
&\left|\left\langle P(\mathbf{u}^k, w) - P(\mathbf{u}, w), \mathbf{w}\right\rangle\right| \\
&\quad \le K \int_0^T \int_{\Gamma_C} (1 + |u_n^k|^{p-2} + |u_n|^{p-2})|u_n^k - u_n||w_n| \, d\Gamma dt \\
&\quad \le K \int_0^T \left(\int_{\Gamma_C} (1 + |u_n^k|^p + |u_n|^p) \, d\Gamma\right)^{\frac{p-2}{p}} \left(\int_{\Gamma_C} |u_n^k - u_n|^p \, d\Gamma\right)^{\frac{1}{p}} \\
&\qquad\qquad \times \left(\int_{\Gamma_C} |w_n|^p d\Gamma\right)^{\frac{1}{p}} dt \\
&\quad \le K ||u_n^k - u_n||_{L^p(0,T;(L^p(\Gamma_C))^N)} || \, \mathbf{w}||_{\mathcal{V}_q}.
\end{aligned}$$

Thus, $||P(\mathbf{u}^k, w) - P(\mathbf{u}, w)||_{\mathcal{V}_q'} \le K||\gamma \mathbf{u}^k - \gamma \mathbf{u}||_{L^p(0,T;(L^p(\Gamma_C))^N)}$, and the result follows from Lemma 4.3.

Now for each $\lambda \ge 0$ the map $\mathbf{y} \to e^{-\lambda(\cdot)} A\mathbf{u}$ is monotone; in fact,

$$\begin{aligned}
\left\langle e^{-\lambda(\cdot)} A(\mathbf{u}_1 - \mathbf{u}_2), \mathbf{y}_1 - \mathbf{y}_2 \right\rangle &= \frac{1}{2} \int_0^T e^{-2\lambda t} \frac{d}{dt} \left\langle A(\mathbf{u}_1 - \mathbf{u}_2), \mathbf{u}_1 - \mathbf{u}_2 \right\rangle dt \\
&= \frac{1}{2} e^{-2\lambda T} \left\langle A(\mathbf{u}_1(T) - \mathbf{u}_2(T)), \mathbf{u}_1(T) - \mathbf{u}_2(T) \right\rangle \\
&\quad + \lambda \int_0^T \left\langle A(\mathbf{u}_1 - \mathbf{u}_2), \mathbf{u}_1 - \mathbf{u}_2 \right\rangle e^{-2\lambda t} dt.
\end{aligned} \tag{4.15}$$

Also, the map $\mathbf{y} \to \varepsilon e^{-\lambda(\cdot)} J(e^{\lambda(\cdot)} \mathbf{y})$ is monotone. Next, $\mathbf{y}^k \rightharpoonup \mathbf{y}$ in X if and only if $\mathbf{v}^k \rightharpoonup \mathbf{v}$ in X, and Lemma 4.7 implies that the operator $\mathbf{y} \to e^{-\lambda(\cdot)} P(\mathbf{u}, w)$ is completely continuous; and if we let

$$\begin{aligned}
\mathcal{A}_\lambda \mathbf{y} &= \lambda \mathbf{y} + M\mathbf{y} + e^{-\lambda(\cdot)} A(\mathbf{u}) + \varepsilon e^{-\lambda(\cdot)} J(e^{\lambda(\cdot)} \mathbf{y}) \\
&\quad + e^{-\lambda(\cdot)} Q(e^{\lambda(\cdot)} \mathbf{y}) + e^{-\lambda(\cdot)} P(\mathbf{u}, w),
\end{aligned} \tag{4.16}$$

then $\mathcal{A}_\lambda$ is a sum of bounded pseudomonotone operators. Consequently, $\mathcal{A}_\lambda : X \to \mathcal{P}(X')$ is pseudomonotone [22], verifying condition (2.15) for $\mathcal{A}_\lambda$. We now check the coercivity of $\mathcal{A}_\lambda$ (2.14). To this end, we consider the various terms of $\langle \mathcal{A}_\lambda \mathbf{y}, \mathbf{y} \rangle$. Let $\mathbf{y}^* \in Q_\lambda(\mathbf{y})$, which implies that $\mathbf{y}^* \in e^{-\lambda(\cdot)} Q(e^{\lambda(\cdot)} \mathbf{v})$ and so $\mathbf{y}^* = e^{-\lambda(\cdot)} \mathbf{v}^*$, where $\mathbf{v}^* \in Q\left(e^{\lambda(\cdot)} \mathbf{v}\right)$. Therefore,

$$\langle \mathbf{y}^*, \mathbf{y} \rangle = \langle e^{-\lambda(\cdot)} \mathbf{v}^*, e^{\lambda(\cdot)} \mathbf{v} \rangle = \langle \mathbf{v}^*, \mathbf{v} \rangle = \int_0^T \int_{\Gamma_C} \mu p_{_R} \, \mathbf{z} \cdot \mathbf{v}_T \, d\Gamma dt,$$

where $p_{_R} = p_{_R}(u_n - w - g)$ and $\mathbf{z} \in L^\infty(0,T; L^\infty(\Gamma_C)^N)$ satisfies

$$\int_0^T \int_{\Gamma_C} \mathbf{z} \cdot \mathbf{w}_T \, d\Gamma dt \le \int_0^T \int_{\Gamma_C} \left(|e^{\lambda(\cdot)} \mathbf{v}_T - \mathbf{v}_* + \mathbf{w}_T| - |e^{\lambda(\cdot)} \mathbf{v}_T - \mathbf{v}_*| \right) d\Gamma dt, \tag{4.17}$$

and $\mathbf{u}(t) = \mathbf{u}_0 + \int_0^t e^{\lambda s} \mathbf{v}(s) \, ds$. Thus,

$$\begin{aligned}
\langle \mathbf{y}^*, \mathbf{y} \rangle &= \int_0^T \int_{\Gamma_C} e^{-\lambda t} \mu p_{_R} \, \mathbf{z} \cdot \left(e^{\lambda t} \mathbf{v}_T - \mathbf{v}_* \right) d\Gamma dt \\
&\quad + \int_0^T \int_{\Gamma_C} e^{-\lambda t} \mu p_{_R} \, \mathbf{z} \cdot \mathbf{v}_* \, d\Gamma dt.
\end{aligned} \tag{4.18}$$

Now the first integral is nonnegative by a routine argument involving (4.17), and since $\mathbf{v}_* \in L^\infty(0,T;L^p(\Gamma_C)^N)$ we have that the second integral is bounded below by

$$-c - c\int_0^T \left(\int_{\Gamma_C} (u_n - w - g)_+^p \, d\Gamma\right)^{1/p} dt$$

$$\geq -c_\eta - \eta \int_0^T \int_0^t |v_n(s) - w_t(s)|^p_{L^p(\Gamma_C)} \, ds dt \tag{4.19}$$

for $\eta > 0$. Next, we examine the term $\left\langle e^{-\lambda(\cdot)} P(\mathbf{u}, w), \mathbf{y} \right\rangle$. Let $h(r, \mathbf{x}) = \int_{g(\mathbf{x})}^r p(s - g(\mathbf{x}))\, ds$ and define $H : L^2(\Gamma_C) \to [0, \infty)$ by

$$H(u) = \int_{\Gamma_C} h(u, \mathbf{x}) \, d\Gamma. \tag{4.20}$$

Then

$$\frac{d}{dt} H(u_n - w) = \langle DH(u_n - w), v_n - w' \rangle$$

$$= \int_{\Gamma_C} p(u_n - w - g)\,(v_n - w')\, d\Gamma = \langle P(\mathbf{u}, w), \mathbf{v} \rangle - \int_{\Gamma_C} p(u_n - w - g) w' \, d\Gamma. \tag{4.21}$$

Therefore,

$$\left\langle e^{-\lambda(\cdot)} P(\mathbf{u}, w), \mathbf{y} \right\rangle = \int_0^T e^{-2\lambda t} \langle P(\mathbf{u}, w), \mathbf{v} \rangle \, dt$$

$$= \int_0^T e^{-2\lambda t} \frac{d}{dt} H(u_n - w)\, dt + \int_0^T \int_{\Gamma_C} p(u_n - w - g) w' \, d\Gamma \tag{4.22}$$

$$\geq H(u_n(T) - w(T)) e^{-2\lambda T} - H(u_{0\varepsilon n}) + 2\lambda \int_0^T H(\mathbf{u}) e^{-2\lambda t} \, dt,$$

due to the assumptions that $w' \geq 0$ and $p(\cdot) \geq 0$. Similarly,

$$\left\langle e^{-\lambda(\cdot)} A\mathbf{u}, \mathbf{y} \right\rangle = \frac{1}{2} \langle A\mathbf{u}(T), \mathbf{u}(T) \rangle \, e^{-2\lambda T}$$

$$- \frac{1}{2} \langle A\mathbf{u}_{0\varepsilon}, \mathbf{u}_{0\varepsilon} \rangle + \lambda \int_0^T \langle A\mathbf{u}, \mathbf{u} \rangle \, e^{-2\lambda t} \, dt. \tag{4.23}$$

It follows from (4.19), (4.22), and (4.23) that

$$\langle \mathcal{A}_\lambda \mathbf{y}, \mathbf{y} \rangle \geq \delta^2 ||\mathbf{y}||^2_{L^2(0,T;W)} + \varepsilon e^{-2\lambda T} ||\gamma \mathbf{y}||^q_{L^q(0,T;(L^q(\Gamma_C))^N)}$$

$$- c_\eta - \eta \int_0^T \int_0^t |v_n(s) - w'(s)|^p_{L^p(\Gamma_C)} \, ds dt - H(u_{0\varepsilon n}).$$

We conclude that $\mathcal{A}_\lambda$ is coercive when η is sufficiently small and by Lemma 4.2 that $\mathcal{A}_\lambda : \mathcal{V}_q \to \mathcal{V}_q'$ is bounded. All the assumptions of Theorem 2.6 are satisfied now, and the proof of Theorem 4.1 is complete.

We use this result in the following section. However, we note that the theorem has merit of its own.

5. Existence and uniqueness. We obtain a solution for problem $\mathcal{P}$, when w is a known function, by deriving estimates on the solutions of $\mathcal{P}(\varepsilon)$ and passing to the limit $\varepsilon \to 0$, thus proving Theorem 3.1. We are still assuming that μ is Lipschitz continuous.

The proof of Theorem 3.1 is accomplished in a number of steps. We denote by c a generic positive constant which is independent of ε. Multiplying both sides of (4.2) by $\mathbf{v}\chi_{[0,t]}$ and using the above formulas along with the assumption that $w' \geq 0$, and performing routine manipulations, we obtain the following estimates for $\mathbf{v}^* \in Q\mathbf{v}$:

$$\begin{aligned}
&\frac{1}{2}|\mathbf{v}(t)|_H^2 - \frac{1}{2}|\mathbf{v}_0|_H^2 + \delta^2 \int_0^t ||\mathbf{v}||_W^2 \, ds + \frac{1}{2}\langle A\mathbf{u}(t), \mathbf{u}(t)\rangle \\
&\quad + \varepsilon \int_0^t \int_{\Gamma_C} |\gamma\mathbf{v}|^q \, d\Gamma ds + \langle \mathbf{v}^*, \mathbf{v}\chi_{[0,t]}\rangle + H(u_n(t) - w(t)) - H(u_{0\varepsilon n}) \\
&\qquad \leq \int_0^t \langle \mathbf{f}(s), \mathbf{v}(s)\rangle \, ds + \frac{1}{2}\langle A\mathbf{u}_{0\varepsilon}, \mathbf{u}_{0\varepsilon}\rangle. \qquad (5.1)
\end{aligned}$$

Now, when $\lambda = 0$ in (4.18), we obtain

$$\langle \mathbf{v}^*, \mathbf{v}\chi_{[0,t]}\rangle \geq -c - c\int_0^t \int_{\Gamma_C} (u_n - w - g)_+^p \, d\Gamma,$$

thus

$$\begin{aligned}
&\frac{1}{2}|\mathbf{v}(t)|_H^2 + \delta^2 \int_0^t ||\mathbf{v}||_W^2 \, ds + \frac{1}{2}\langle A\mathbf{u}(t), \mathbf{u}(t)\rangle + \varepsilon \int_0^t \int_{\Gamma_C} |\gamma\mathbf{v}|^q \, d\Gamma ds \\
&+ \int_{\Gamma_C} h(u_n(t,\mathbf{x}) - w(t,\mathbf{x}), \mathbf{x}) \, d\Gamma \leq c + \frac{1}{2}|\mathbf{v}_0|_H^2 + \frac{1}{2}\langle A\mathbf{u}_{0\varepsilon}, \mathbf{u}_{0\varepsilon}\rangle + H(u_{0\varepsilon n}) \\
&+ \frac{1}{2\delta^2}\int_0^t ||\mathbf{f}(s)||_{W'}^2 \, ds + \frac{\delta^2}{2}\int_0^t ||\mathbf{v}(s)||_W^2 \, ds + c\int_0^t \int_{\Gamma_C} (u_n - w - g)_+^p \, d\Gamma ds. \qquad (5.2)
\end{aligned}$$

The assumptions on $p(\cdot)$ given in (3.13) imply that if $r \geq g(\mathbf{x})$, then

$$h(r, \mathbf{x}) \geq \int_{g(\mathbf{x})}^r (\delta^2 (s - g)_+^{p-1} - c) \, ds = \frac{\delta^2}{p}(r - g(\mathbf{x}))_+^p - c(r - g(\mathbf{x}))_+. \qquad (5.3)$$

Now, since $p(r) = 0$ for $r \leq 0$, (5.3) holds also when $r < g(\mathbf{x})$. Then (5.2) yields

$$\begin{aligned}
&|\mathbf{v}(t)|_H^2 + \delta^2 \int_0^t ||\mathbf{v}||_W^2 \, ds + \langle A\mathbf{u}(t), \mathbf{u}(t)\rangle + 2\varepsilon \int_0^t \int_{\Gamma_C} |\gamma\mathbf{v}|^q \, d\Gamma ds \\
&\qquad + \frac{2\delta^2}{p}\int_{\Gamma_C} (u_n(t) - w(t) - g)_+^p d\Gamma - 2c\int_{\Gamma_C} (u_n(t) - w(t) - g)_+ \, d\Gamma \\
&\quad \leq c + |\mathbf{v}_0|^2 + \langle A\mathbf{u}_{0\varepsilon}, \mathbf{u}_{0\varepsilon}\rangle + 2H(\mathbf{u}_{0\varepsilon n}) + \frac{1}{\delta^2}\int_0^t ||\mathbf{f}(s)||_{W'}^2 \, ds \\
&\qquad + c\int_0^t \int_{\Gamma_C} (u_n - w - g)_+^p \, d\Gamma ds. \qquad (5.4)
\end{aligned}$$

Applying the Hölder inequality to the sixth term on the right-hand side we obtain

$$
\begin{aligned}
|\mathbf{v}(t)|_H^2 + \delta^2 \int_0^t ||\mathbf{v}||_W^2 \, ds + \langle A\mathbf{u}(t), \mathbf{u}(t)\rangle + 2\varepsilon \int_0^t \int_{\Gamma_C} |\gamma \mathbf{v}|^q \, d\Gamma ds \\
+ \ \frac{\delta^2}{p} \int_{\Gamma_C} (u_n(t) - w - g)_+^p \, d\Gamma \le c + |\mathbf{v}_0|^2 + \langle A\mathbf{u}_{0\varepsilon}, \mathbf{u}_{0\varepsilon}\rangle + 2H(\mathbf{u}_{0\varepsilon}) \\
+ \ \frac{1}{\delta^2} \int_0^t ||\mathbf{f}(s)||_{W'}^2 \, ds + c \int_0^t \int_{\Gamma_C} (u_n - w - g)_+^p \, d\Gamma ds. \qquad (5.5)
\end{aligned}
$$

Now using the Gronwall inequality yields

$$
\begin{aligned}
|\mathbf{v}(t)|_H^2 + \int_0^t ||\mathbf{v}||_W^2 ds + \langle A\mathbf{u}(t), \mathbf{u}(t)\rangle + \varepsilon \int_0^t \int_{\Gamma_C} |\gamma \mathbf{v}|^q \, d\Gamma ds \\
+ \int_{\Gamma_C} (u_n(t) - w - g)_+^p \, d\Gamma \le c, \qquad (5.6)
\end{aligned}
$$

where c does not depend on ε, q (for $q > p$) or w. If $\mathbf{w} \in \mathcal{V}_q$, then (5.6) and the definition of J imply

$$
\begin{aligned}
|\langle \varepsilon J\mathbf{v}, \mathbf{w}\rangle| &\le \varepsilon \langle J\mathbf{v}, \mathbf{v}\rangle^{(1/q')} \langle J\mathbf{w}, \mathbf{w}\rangle^{(1/q)} \\
&\le (\varepsilon \langle J\mathbf{v}, \mathbf{v}\rangle)^{(1/q')} \varepsilon^{(1/q)} ||\mathbf{w}||_{\mathcal{V}_q} \le c\varepsilon^{(1/q)} ||\mathbf{w}||_{\mathcal{V}_q}. \qquad (5.7)
\end{aligned}
$$

Thus, when $\mathbf{v}_\varepsilon$ is a solution of problem $\mathcal{P}(\varepsilon)$ we have

$$
\varepsilon J\mathbf{v}_\varepsilon \to 0 \quad \text{in } \mathcal{V}_q'. \qquad (5.8)
$$

From (5.6) and the growth conditions for $p(\cdot)$ we find that $Q(\mathbf{v}_\varepsilon, w)$ and $P(\mathbf{u}_\varepsilon, w)$ are bounded in $\mathcal{V}_p' \subseteq \mathcal{V}_q'$. Using Theorems 2.2 and 2.3 we find that there exists a subsequence, still denoted by $\varepsilon \to 0$, such that

$$
\begin{aligned}
\mathbf{v}_\varepsilon &\to \mathbf{v} \quad \text{weakly in } L^2(0,T;W), \qquad (5.9)\\
\mathbf{v}_\varepsilon' &\to \mathbf{v}' \quad \text{in } \mathcal{V}_q', \qquad (5.10)\\
\mathbf{u}_\varepsilon &\to \mathbf{u} \quad \text{in } C(0,T;U), \qquad (5.11)\\
\mathbf{v}_\varepsilon &\to \mathbf{v} \quad \text{in } L^2(0,T;U), \qquad (5.12)\\
M\mathbf{v}_\varepsilon &\to M\mathbf{v} \quad \text{weakly in } L^2(0,T;W'), \qquad (5.13)\\
A\mathbf{u}_\varepsilon &\to A\mathbf{u} \quad \text{weakly in } L^2(0,T;W'). \qquad (5.14)
\end{aligned}
$$

Here U denotes a space containing W with compact identity map and such that the trace map $\gamma : U \to L^2(\Gamma_C)^N$ is continuous. Letting $\mathbf{z}_\varepsilon$ be as in (4.5) and (4.6), (5.11) and (5.12) imply that, for a subsequence,

$$
\begin{aligned}
\widetilde{\gamma \mathbf{u}}_\varepsilon(\mathbf{x},t) &\to \widetilde{\gamma \mathbf{u}}(\mathbf{x},t) \quad \text{a.e. in } \Gamma_C \times (0,T), \qquad (5.15)\\
\widetilde{\gamma \mathbf{v}}_\varepsilon(\mathbf{x},t) &\to \widetilde{\gamma \mathbf{v}}(\mathbf{x},t) \text{ a.e. in } \Gamma_C \times (0,T), \qquad (5.16)\\
\mu\left(|\mathbf{v}_{\varepsilon T} - \ \mathbf{v}_*|\right) p_R\left(u_{\varepsilon n} - w - g\right) \mathbf{z}_\varepsilon &\rightharpoonup \xi \\
&\text{weakly in } L^{p'}(0,T;L^{p'}(\Gamma_C)^N). \qquad (5.17)
\end{aligned}
$$

LEMMA 5.1. *$P(\mathbf{u}_\varepsilon, w) \to P(\mathbf{u}, w)$ in $\mathcal{V}_q'$ and $P(\mathbf{u}_\varepsilon, w) \rightharpoonup P(\mathbf{u}, w)$ weakly in $\mathcal{V}_p'$.*

Proof. Let $\mathbf{w} \in \mathcal{V}_q$; then, by (3.13),

$$\begin{aligned}|\langle P(\mathbf{u}_\varepsilon, w) - P(\mathbf{u}, w), \mathbf{w}\rangle| &\leq \int_0^T \int_{\Gamma_C} K(1 + (u_{\varepsilon n} - w - g)_+^{p-2} + (u_n - w - g)_+^{p-2}) \\ &\quad \times |(u_{\varepsilon n} - w - g)_+ - (u_n - w - g)_+|\, |w_n|\, d\Gamma dt \\ &\leq c \int_0^T \left(\int_{\Gamma_C} (1 + (u_{\varepsilon n} - w - g)_+^p + (u_n - w - g)_+^p)\, d\Gamma \right)^{\frac{p-2}{p}} \\ &\quad \times \left(\int_{\Gamma_C} |(u_{\varepsilon n} - w - g)_+ - (u_n - w - g)_+|^r\, d\Gamma \right)^{\frac{1}{r}} \cdot \left(\int_{\Gamma_C} |w_n|^q d\Gamma \right)^{\frac{1}{q}} dt,\end{aligned}$$

where $r = pq(2q-p)^{-1}$. It follows from (5.6) that

$$\begin{aligned}&|\langle P(\mathbf{u}_\varepsilon, w) - P(\mathbf{u}, w), \mathbf{w}\rangle| \\ &\leq c \left(\int_0^T \int_{\Gamma_C} |(u_{\varepsilon n} - w - g)_+ - (u_n - w - g)_+|^r\, d\Gamma dt \right)^{\frac{1}{r}} ||\mathbf{w}||_{\mathcal{V}_q}. \end{aligned} \tag{5.18}$$

Now note that $r < p$ and so estimate (5.6) implies the functions $|(u_\varepsilon - w - g)_+ - (u_n - w - g)_+|^r$ are uniformly integrable. Then (5.15) and the Vitali convergence theorem imply

$$\lim_{\varepsilon \to 0} \int_0^T \int_{\Gamma_C} |(u_{\varepsilon n} - w - g)_+ - (u_n - w - g)_+|^r d\Gamma dt = 0.$$

Now

$$\begin{aligned}&\|P(\mathbf{u}_\varepsilon, w) - P(\mathbf{u}, w)\|_{\mathcal{V}_q'} \\ &\quad \leq c \left(\int_0^T \int_{\Gamma_C} |(u_{\varepsilon n} - w - g)_+ - (u_n - w - g)_+|^r\, d\Gamma\, dt \right)^{\frac{1}{r}},\end{aligned}$$

and hence $P(\mathbf{u}_\varepsilon, w) \to P(\mathbf{u}, w)$ in $\mathcal{V}_q'$.

To obtain the other assertion, we note that $P(\mathbf{u}_\varepsilon, w)$ is bounded in $\mathcal{V}_p'$, and therefore it has a convergent subsequence such that $P(\mathbf{u}_\varepsilon, w) \rightharpoonup \ell$ weakly in $\mathcal{V}_p'$. However, $\mathcal{V}_q$ is dense in $\mathcal{V}_p$ and so $\ell = P(\mathbf{u}, w)$. Since this holds for every weakly convergent subsequence, it follows that $P(\mathbf{u}_\varepsilon, w) \rightharpoonup P(\mathbf{u}, w)$.

LEMMA 5.2. *For each* $\mathbf{w} \in \mathcal{V}_p$,

$$\langle \gamma_T^* \xi, \mathbf{w}\rangle \leq \int_0^T \int_{\Gamma_C} \mu p_R \left(|\mathbf{v}_T - \mathbf{v}_* + \ \mathbf{w}_T| - |\mathbf{v}_T - \mathbf{v}_*| \right) d\Gamma\, dt, \tag{5.19}$$

where $\mu(|\mathbf{v}_T - \mathbf{v}_*|)$ *and* $p_R = p_R(u_n - w - g)$.

Proof. To simplify the notation we let $F = p_R(u_n - w - g)$, $F_\varepsilon = p_R(u_{\varepsilon n} - w - g)$, $\mu = \mu(|\mathbf{v}_T - \mathbf{v}_*|)$, and $\mu_\varepsilon = \mu(|\mathbf{v}_{\varepsilon T} - \mathbf{v}_*|)$. First suppose that $\mathbf{w} \in \mathcal{V}_q$. It follows from the assumptions on $\mathbf{z}_\varepsilon$ that $\mathbf{z}_\varepsilon \cdot \mathbf{w}_T \leq (|\mathbf{v}_{\varepsilon T} - \mathbf{v}_* + \mathbf{w}_T| - |\mathbf{v}_{\varepsilon T} - \mathbf{v}_*|)$ for a.e. t and a.e. $\mathbf{x}$. Therefore,

$$\begin{aligned}\langle \gamma_T^* \xi, \mathbf{w}\rangle &= \lim_{\varepsilon \to 0} \int_0^T \int_{\Gamma_C} F_\varepsilon \mu_\varepsilon \mathbf{z}_\varepsilon \cdot \mathbf{w}_T\, d\Gamma dt \\ &\leq \liminf_{\varepsilon \to 0} \int_0^T \int_{\Gamma_C} F_\varepsilon \mu_\varepsilon \left(|\mathbf{v}_{\varepsilon T} - \mathbf{v}_* + \mathbf{w}_T| - |\mathbf{v}_{\varepsilon T} - \mathbf{v}_*| \right) d\Gamma dt. \end{aligned} \tag{5.20}$$

Now the integrand converges pointwise to $F\mu\left(|\mathbf{v}_T-\mathbf{v}_*+\mathbf{w}_T|-|\mathbf{v}_T-\ \mathbf{v}_*|\right)$ and is bounded in absolute value by $c(1+(u_{\varepsilon n}-w-g)_+^{p-1})|\mathbf{w}_T|$. These functions are bounded in $L^r((0,T)\times\Gamma_C)$, independently of ε, where $r\equiv pq/(pq+p-q)$. Indeed, $(p-1)rq/(q-r)=p$, and thus

$$\begin{aligned}(u_{\varepsilon n}-w-g)_+^{(p-1)r}\,|\mathbf{w}_T|^r &\le (u_{\varepsilon n}-w-g)_+^{\frac{(p-1)rq}{q-r}}+|\mathbf{w}_T|^q\\ &=(u_{\varepsilon n}-w-g)_+^{p}+|\mathbf{w}_T|^q\,,\end{aligned}$$

which is bounded in L^1, independent of ε. Therefore, using the Vitali convergence theorem in (5.20), we may pass to the limit and obtain (5.19) for all $\mathbf{w}\in\mathcal{V}_q$, and since $\mathcal{V}_q$ is dense in $\mathcal{V}_p$ this inequality holds for all $\mathbf{w}\in\mathcal{V}_p$. This proves the lemma.

Next, from (4.2), (5.13), (5.14), (5.9), and Lemma 5.1 we obtain

$$\mathbf{v}'+M\mathbf{v}+A\mathbf{u}+\gamma_T^*\xi+P\left(\mathbf{u},w\right)=\mathbf{f}\ \text{in}\ \mathcal{V}_q'.$$

Since $\gamma_T^*\xi,\ A\mathbf{u},\ M\mathbf{v}$ and $\mathbf{f}$ are all in $\mathcal{V}_p'$, so is $\mathbf{v}'$. This proves the existence part of the theorem.

Proof of uniqueness. Suppose $\mathbf{v}_1$ and $\mathbf{v}_2$ are two solutions of $\mathcal{P}$. Let, for $i=1,2,\ \mathbf{u}_i(t)=\mathbf{u}_0+\int_0^t\mathbf{v}_i(s)\,ds$. It follows that

$$\begin{aligned}&\frac{1}{2}|\mathbf{v}_1(t)-\mathbf{v}_2(t)|_H^2+\int_0^t\langle M\mathbf{v}_1-M\mathbf{v}_2,\mathbf{v}_1-\mathbf{v}_2\rangle\,ds\\ &\quad+\int_0^t\langle A(\mathbf{u}_1-\mathbf{u}_2),\mathbf{v}_1-\mathbf{v}_2\rangle\,ds+\int_0^t\langle\gamma_T^*\xi_1-\gamma_T^*\xi_2,\mathbf{v}_1-\mathbf{v}_2\rangle\,ds\\ &\quad+\int_0^t\langle P\left(\mathbf{u}_1,w\right)-P\left(\mathbf{u}_2,w\right),\mathbf{v}_1-\mathbf{v}_2\rangle\,ds=0.\end{aligned}\tag{5.21}$$

Thus, if we denote by c a positive generic constant, we have

$$\begin{aligned}&\frac{1}{2}|\mathbf{v}_1(t)-\mathbf{v}_2(t)|_H^2+\frac{1}{2}\left\langle A(\mathbf{u}_1(t)-\mathbf{u}_2(t)),\mathbf{u}_1(t)-\mathbf{u}_2(t)\right\rangle\\ &+\int_0^t\left\langle P\left(\mathbf{u}_1,w\right)-P\left(\mathbf{u}_2,w\right),\mathbf{v}_1-\mathbf{v}_2\right\rangle\,ds+\delta^2\int_0^t||\mathbf{v}_1-\mathbf{v}_2||_W^2\,ds\\ &+\int_0^t\langle\gamma_T^*\xi_1-\gamma_T^*\xi_2,\mathbf{v}_1-\mathbf{v}_2\rangle\,ds\le c\int_0^t|\mathbf{v}_1(s)-\mathbf{v}_2(s)|_H^2\,ds.\end{aligned}\tag{5.22}$$

Let $F^i=p_{_R}(u_{in}-w-g)$, $\mu^i=\mu(|\mathbf{v}_{iT}-\mathbf{v}_*|)$, for $i=1,2$; then using condition (5.20) we observe

$$\begin{aligned}&\int_0^t\langle\gamma_T^*\xi_1-\gamma_T^*\xi_2,\mathbf{v}_1-\mathbf{v}_2\rangle\,ds\\ &\quad\ge\int_0^t\int_{\Gamma_C}\left(F^1\mu^1-F^2\mu^2\right)\left(|\mathbf{v}_{1T}-\mathbf{v}_*|-|\mathbf{v}_{2T}-\mathbf{v}_*|\right)\,d\Gamma ds.\end{aligned}$$

Consequently, the last term on the left-hand side in (5.22) dominates

$$-c\int_0^t\int_{\Gamma_C}F^2\,|\mathbf{v}_{1T}-\mathbf{v}_{2T}|^2\,d\Gamma ds-c\int_0^t\int_{\Gamma_C}|F^1-F^2|\,|\mathbf{v}_{1T}-\mathbf{v}_{2T}|\,d\Gamma ds.\tag{5.23}$$

The third term in (5.22) is greater than or equal to

$$-\int_0^t \int_{\Gamma_C} |p(u_{1n}-w-g)-p(u_{2n}-w-g)|\,|v_{1n}-v_{2n}|\,d\Gamma ds. \tag{5.24}$$

From the assumptions on $p(\cdot)$ and from (5.22) we obtain

$$\begin{aligned}
&|\mathbf{v}_1(t)-\mathbf{v}_2(t)|_H^2 + \langle A(\mathbf{u}_1(t)-\mathbf{u}_2(t)), \mathbf{u}_1(t)-\mathbf{u}_2(t)\rangle + \delta^2 \int_0^t ||\mathbf{v}_1-\mathbf{v}_2||_W^2\, ds \\
&\quad \le c\int_0^t \int_{\Gamma_C} (1+|(u_{1n}-w-g)_+|^2+|(u_{2n}-w-g)_+|^2) \\
&\qquad\qquad \times |u_{1n}-u_{2n}|\,|v_{1n}-v_{2n}|\,d\Gamma ds \\
&\quad + c\int_0^t |\mathbf{v}_1(s)-\mathbf{v}_2(s)|_H^2\, ds + c\int_0^t \int_{\Gamma_C} |\mathbf{v}_{1T}-\mathbf{v}_{2T}|^2\, d\Gamma ds.
\end{aligned}$$

Since $(u_n-w-g)_+ \in L^\infty(0,T;L^p(\Gamma_C))$, we obtain, with another c which depends on $\mathbf{u}_1$ and $\mathbf{u}_2$,

$$\begin{aligned}
|\mathbf{v}_1(t)-\mathbf{v}_2(t)|_H^2 + \delta^2 \int_0^t ||\mathbf{v}_1-\mathbf{v}_2||_W^2\, ds &\le c\int_0^t ||\mathbf{v}_1-\mathbf{v}_2||_U^2\, dt \\
&+ c\int_0^t \left(\int_{\Gamma_C} |u_{1n}-u_{2n}|^4 d\Gamma\right)^{\frac14} \left(\int_{\Gamma_C} |v_{1n}-v_{2n}|^4 d\Gamma\right)^{\frac14} ds \\
&+ c\int_0^t |\mathbf{v}_1(s)-\mathbf{v}_2(s)|_H^2\, ds \\
&\le c\int_0^t ||\mathbf{u}_1-\mathbf{u}_2||_W\, ||\mathbf{v}_1-\mathbf{v}_2||_W\, ds + c\int_0^t |\mathbf{v}_1(s)-\mathbf{v}_2(s)|_H^2\, ds \\
&+ K\int_0^t ||\mathbf{v}_1-\mathbf{v}_2||_U^2\, dt,
\end{aligned}$$

where we used the fact that the trace map $W \to L^4(\partial\Omega)$ is continuous. It follows from the compactness of the embedding $U \to W$ that

$$\begin{aligned}
|\mathbf{v}_1(t)-\mathbf{v}_2(t)|_H^2 + \frac{\delta^2}{2}\int_0^t ||\mathbf{v}_1-\mathbf{v}_2||_W^2\, ds &\le c_{\delta T}\int_0^t \int_0^s ||\mathbf{v}_1-\mathbf{v}_2||_W^2\, dr ds + K_\varepsilon \int_0^t |\mathbf{v}_1(s)-\mathbf{v}_2(s)|_H^2\, ds \\
&+ \varepsilon \int_0^t ||\mathbf{v}_1-\mathbf{v}_2||_W^2\, dt.
\end{aligned}$$

Choosing $\varepsilon = \frac{\delta^2}{4}$ and adjusting the constants yields

$$\begin{aligned}
|\mathbf{v}_1(t)-\mathbf{v}_2(t)|_H^2 + \frac{\delta^2}{4}\int_0^t ||\mathbf{v}_1-\mathbf{v}_2||_W^2\, ds &\le c_{\delta T}\int_0^t \left(\int_0^s ||\mathbf{v}_1-\mathbf{v}_2||_W^2\, dr + |\mathbf{v}_1(s)-\mathbf{v}_2(s)|_H^2\right) ds.
\end{aligned}$$

By the Gronwall inequality we obtain $\mathbf{v}_1 = \mathbf{v}_2$. This concludes the proof of Theorem 3.1 in the case that p satisfies (3.13).

In the case when $p(\cdot)$ satisfies (3.12) the proof is much easier, not requiring the consideration of the approximate problems where εJ was added in.

THEOREM 5.3. *Let $p \geq 2$ and let $w \in L^p(0,T;L^p(\Gamma_C))$, $w' \in L^p(0,T;L^p(\Gamma_C))$, $w' \geq 0$, $\mathbf{u}_0 \in V_p$, $\mathbf{v}_0 \in H$, $\mathbf{f} \in \mathcal{V}_p'$ and assume $\mu^*(r) = \mu_c(r)$, where μ_c is bounded and Lipschitz. Then there exists $\xi \in L^{p'}(0,T;L^{p'}(\Gamma_C)^N)$ and $\mathbf{v} \in L^2(0,T;W)$ such that*

$$(u_n - w - g)_+ \in L^\infty(0,T;L^p(\Gamma_C)), \tag{5.25}$$

$$\mathbf{v}' + M\mathbf{v} + A\mathbf{u} + P(\mathbf{u},w) + \gamma_T^*\xi = \mathbf{f} \ \text{ in } \ \mathcal{V}_p', \tag{5.26}$$

$$\mathbf{v}(0) = \mathbf{v}_0\,, \ \mathbf{u}(t) = \mathbf{u}_0 + \int_0^t \mathbf{v}(s)\,ds, \tag{5.27}$$

and

$$\langle \gamma_T^*\xi, \mathbf{w}\rangle \leq \int_0^T \int_{\Gamma_C} \mu p_{_R} \left(|\mathbf{v}_T - \mathbf{v}_* + \mathbf{w}_T| - |\mathbf{v}_T - \mathbf{v}_*|\right) d\Gamma\, dt, \tag{5.28}$$

where $\mu = \mu(|\mathbf{v}_T - \mathbf{v}_*|)$ and $p_{_R} = p_{_R}(u_n - w - g)$.

Moreover, if the function $p(\cdot)$ satisfies (3.12)*, the solution $\{\mathbf{u},\mathbf{v}\}$ is unique.*

We note that (3.28) and the fact that $\mathbf{v}_1 = \mathbf{v}_2$ imply $\gamma_T^*\xi_1 = \gamma_T^*\xi_2$; however, we do not know if $\xi_1 = \xi_2$.

6. Discontinuous friction coefficient. In this section we consider the case when the coefficient of friction is a discontinuous function of the slip speed and establish Theorem 3.2. This is the case often described in elementary courses where it is stated that the coefficient of sliding friction is smaller than the coefficient of static friction. Therefore, we assume that the function μ has a jump discontinuity at zero, becoming smaller when slip takes place, and is represented by the friction graph μ^* (3.5).

To investigate this case when p satisfies (3.13), we regularize the graph μ^* by defining $\mu_c(r) = \mu_d$ for all $r \leq 0$ and

$$\mu_\varepsilon(r) = \mu_c(r) - h_\varepsilon'(r) + \eta,$$

where $2\eta = \mu_s - \mu_d$ and $h_\varepsilon(r) \equiv (\eta^2 r^2 + \varepsilon)^{1/2}$, for $0 < \varepsilon$ small. Thus, η is half the size of the jump at 0 between μ_d and μ_s. From this definition, it follows that

$$\lim_{\varepsilon\to 0} \mu_\varepsilon(r) = \begin{cases} \mu_c(r) \quad \text{if } \ r > 0, \\ \mu_c(r) + 2\eta = \mu_s \quad \text{if } \ r < 0, \\ \mu_d + \eta \text{ if } r = 0 \end{cases}$$

which is a function whose graph has a jump of height $2\eta = \mu_s - \mu_d$ at $r = 0$.

Let $\mathbf{v}_\varepsilon$ be the solution of the approximate problem (4.2)–(4.6) in which μ is replaced with μ_ε. Then, estimate (5.6) holds for $\mathbf{v}_\varepsilon$ and, consequently, there exists a subsequence such that (5.9)–(5.17) hold. Passing to a further subsequence if necessary, we may assume there exists $\psi \in L^\infty(0,T;L^\infty(\Gamma_C))$ such that

$$h_\varepsilon'(|\mathbf{v}_{\varepsilon T} - \mathbf{v}_*|) \to \psi \text{ weak} * \text{ in } L^\infty(0,T;L^\infty(\Gamma_C))\,.$$

We note that Lemma 5.1 still holds. As above, we let $F = p_{_R}(u_n - w - g)$ and

$F_\varepsilon = p_{_R}(u_{\varepsilon n} - w - g)$. Let $\mathbf{w} \in \mathcal{V}_q$,

$$\begin{aligned}
\langle \gamma_T^* \xi, \mathbf{w} \rangle &= \lim_{\varepsilon \to 0} \int_0^T \int_{\Gamma_C} F_\varepsilon \mu_\varepsilon \mathbf{z}_\varepsilon \cdot \mathbf{w}_T \, d\Gamma dt \\
&\leq \liminf_{\varepsilon \to 0} \int_0^T \int_{\Gamma_C} F_\varepsilon \mu_\varepsilon \left(|\mathbf{v}_{\varepsilon T} - \mathbf{v}_* + \mathbf{w}_T| - |\mathbf{v}_{\varepsilon T} - \mathbf{v}_*| \right) d\Gamma dt \\
&= \liminf_{\varepsilon \to 0} \Bigg[\int_0^T \int_{\Gamma_C} F_\varepsilon \left(\mu_c \left(|\mathbf{v}_{\varepsilon T} - \mathbf{v}_*| \right) - \psi + \eta \right) \\
&\qquad \times \left(|\mathbf{v}_{\varepsilon T} - \mathbf{v}_* + \mathbf{w}_T| - |\mathbf{v}_{\varepsilon T} - \mathbf{v}_*| \right) d\Gamma dt \\
&\qquad + \int_0^T \int_{\Gamma_C} F_\varepsilon \left(\psi - h_\varepsilon' \left(|\mathbf{v}_{\varepsilon T} - \mathbf{v}_*| \right) \right) \\
&\qquad \times \left(|\mathbf{v}_{\varepsilon T} - \mathbf{v}_* + \mathbf{w}_T| - |\mathbf{v}_{\varepsilon T} - \mathbf{v}_*| \right) d\Gamma dt \Bigg].
\end{aligned}$$

As in the proof of Lemma 5.2, the first integral on the right-hand side converges to

$$\int_0^T \int_{\Gamma_C} \left(\mu_c \left(|\mathbf{v}_T - \mathbf{v}_*| \right) - \psi + \eta \right) p_{_R} \left(|\mathbf{v}_T - \mathbf{v}_* + \mathbf{w}_T| - |\mathbf{v}_T - \mathbf{v}_*| \right) d\Gamma dt,$$

where $p_{_R} = p_{_R}\left(u_n - w - g\right)$. We need to show that the second integral converges to zero. This follows from the observation that, since $p_{_R}$ is bounded,

$$|p_{_R}(u_{\varepsilon n} - w - g)(|\mathbf{v}_{\varepsilon T} - \mathbf{v}_* + \mathbf{w}_T| - |\ \mathbf{v}_{\varepsilon T} - \mathbf{v}_*|)|$$

is bounded in $L^2((0,T) \times \Gamma_C)$, independently of ε, and converges pointwise to $|F\left(|\mathbf{v}_T - \mathbf{v}_* + \mathbf{w}_T| - |\mathbf{v}_T - \mathbf{v}_*|\right)|$, which lies in $L^2((0,T) \times \Gamma_C)$. Thus, the sequence is uniformly integrable, and by the Vitali convergence theorem it converges strongly in $L^1((0,T) \times \Gamma_C)$. Since $\psi - h_\varepsilon'(|\mathbf{v}_{\varepsilon T} - \mathbf{v}_*|)$ converges weak$*$ in L^∞ to zero, the second integral converges to zero as desired. Next, we consider ψ.

First, note that, from the convexity of h_ε,

$$h_\varepsilon' \left(|\mathbf{v}_{\varepsilon T} - \mathbf{v}_*| \right) z \leq h_\varepsilon \left(|\mathbf{v}_{\varepsilon T} - \mathbf{v}_*| + z \right) - h_\varepsilon \left(|\mathbf{v}_{\varepsilon T} - \mathbf{v}_*| \right),$$

thus for arbitrary $z \in L^1\left(0, T; L^1\left(\Gamma_C\right)\right)$

$$\int_0^T \int_{\Gamma_C} \psi z d\Gamma dt \leq \int_0^T \int_{\Gamma_C} |\eta \left(|\mathbf{v}_T - \mathbf{v}_*| + z \right)| - |\eta(|\mathbf{v}_T - \mathbf{v}_*|)| \, d\Gamma dt$$

which implies that, for a.e. t,

$$\psi z \leq |\eta \left(|\mathbf{v}_T - \mathbf{v}_*| + z \right)| - |\eta(|\mathbf{v}_T - \mathbf{v}_*|)|$$

for a.e. $\mathbf{x}$. Letting $\theta\left(r\right) \equiv |\eta r|$, it follows that, for a.e. $\mathbf{x}, t$,

$$\psi\left(t, \mathbf{x}\right) \in \partial\theta \left(|\mathbf{v}_T - \mathbf{v}_*| \left(t, \mathbf{x}\right) \right).$$

Therefore, for a.e. $t, \mathbf{x}$,

$$\psi\left(t, \mathbf{x}\right) \in \left[-\eta, \eta\right].$$

More particularly, if $|\mathbf{v}_T - \mathbf{v}_*| > 0$, $\psi = \eta$, while if $|\mathbf{v}_T - \mathbf{v}_*| = 0$, the above holds. Therefore, the pair

$$\left(|\mathbf{v}_T - \mathbf{v}_*|,\ \mu_c\left(|\mathbf{v}_T - \mathbf{v}_*|\right) - \psi + \eta\right)$$

is an element of the graph of μ^*, a.e. The proof of Theorem 3.2 is now complete in the case where $p(\cdot)$ satisfies (3.13). Theorem 3.2 holds in the case where $p(\cdot)$ satisfies (3.12) from arguments similar to the above but without the necessity of dealing with the limit as $\varepsilon \to 0$ in the solutions of the approximate problems in which $\varepsilon J\mathbf{v}_\varepsilon$ was added.

The uniqueness of the solution remains an open question.

7. Dependence on w. In this section we investigate the dependence of the solution of (3.27)–(3.30) on w in the situation of (3.12) and $\mu^* = \mu = \mu_c$. Therefore, in this section we do not need to employ the truncation $p_{_R}$. We need to identify the dependence of $\gamma_T^*\xi$ on w and for this reason we write $\gamma_T^*\xi_w$ and rewrite (3.27)–(3.29) as follows:

$$\mathbf{v}' + M\mathbf{v} + A\mathbf{u} + \gamma_T^*\xi_w + P(\mathbf{u}, w) = \mathbf{f} \text{ in } \mathcal{V}_2', \tag{7.1}$$

$$\mathbf{v}(0) = \mathbf{v}_0,\ \mathbf{u}(t) = \mathbf{u}_0 + \int_0^t \mathbf{v}(s)\ ds, \tag{7.2}$$

and

$$\langle \gamma_T^*\xi_w, \mathbf{w}\rangle \le \int_0^T \int_{\Gamma_C} \mu p\left(|\mathbf{v}_T - \ \mathbf{v}_* + \mathbf{w}_T| - |\mathbf{v}_T - \mathbf{v}_*|\right)\ d\Gamma dt, \tag{7.3}$$

where $\mu = \mu(|\mathbf{v}_T - \mathbf{v}_*|)$ and $p = p(u_n - w - g)$.

Now let w_i, for $i = 1, 2$, be two wear functions as above and let $\mathbf{v}^i$ denote the corresponding solutions of problem (7.1)–(7.3). We need the following estimates. From (7.3) we obtain

$$\begin{aligned}
&\int_0^t \langle \gamma_T^*\xi_{w_1} - \gamma_T^*\xi_{w_2}, \mathbf{v}^1 - \mathbf{v}^2\rangle\, ds \\
&\quad \ge -\int_0^t \int_{\Gamma_C} F^1\mu^1 \left(\left|\mathbf{v}_T^2 - \mathbf{v}_*\right| - \left|\mathbf{v}_T^1 - \mathbf{v}_*\right|\right)\ d\Gamma\, ds \\
&\qquad -\int_0^t \int_{\Gamma_C} F^2\mu^2 \left(\left|\mathbf{v}_T^1 - \mathbf{v}_*\right| - \left|\mathbf{v}_T^2 - \mathbf{v}_*\right|\right)\ d\Gamma\, ds \\
&\quad = \int_0^t \int_{\Gamma_C} \left(F^2\mu^2 - F^1\mu^1\right)\left(|\mathbf{v}_T^2 - \mathbf{v}_*| - |\mathbf{v}_T^1 - \mathbf{v}_*|\right)\ d\Gamma\, ds,
\end{aligned}$$

where $F^i = p(u_n^i - w_i - g)$ and $\mu^i = \mu(|\mathbf{v}_T^i - \mathbf{v}_*|)$, for $i = 1, 2$. Let c be a positive constant which depends on Lip_μ, Lip_p, $p(\cdot)$, and the bounds on μ and $p(\cdot)$; then

$$\int_0^t \langle \gamma_T^*\xi_{w_1} - \gamma_T^*\xi_{w_2}, \mathbf{v}^1 - \mathbf{v}^2\rangle ds \ge -c\int_0^t \int_{\Gamma_C} \left|\mathbf{v}_T^1 - \mathbf{v}_T^2\right|^2\ d\Gamma ds$$

$$-\ c\int_0^t \int_{\Gamma_C} \left|\mathbf{v}_T^2 - \mathbf{v}_T^1\right| |w_1 - w_2|\ d\Gamma d - c\int_0^t \int_{\Gamma_C} \left|\mathbf{v}_T^1 - \mathbf{v}_T^2\right| \left|u_n^1 - u_n^2\right|\ d\Gamma ds. \tag{7.4}$$

Next, we consider the term $\int_0^t \langle P\left(\mathbf{u}^1, w_1\right) - P\left(\mathbf{u}^2, w_2\right), \mathbf{v}^1 - \mathbf{v}^2\rangle \, ds$. From (3.11) and (3.20), the definition of $P(\mathbf{u}, w)$, we obtain that this expression is no smaller than

$$-\int_0^t \int_{\Gamma_C} \left(p\left(u_n^1 - w_1 - g\right) - p\left(u_n^2 - w_2 - g\right)\right)\left(v_n^1 - v_n^2\right) \, d\Gamma ds$$

$$\geq -c \int_0^t \int_{\Gamma_C} \left(\left|u_n^1 - u_n^2\right| + |w_1 - w_2|\right)\left|v_n^1 - v_n^2\right| \, d\Gamma ds. \tag{7.5}$$

Now let U be a space in which V_2 embeds compactly and for which the trace map from U to $L^2(\partial\Omega)$ is continuous. Then, after adjusting the constant c and denoting by H_C the Hilbert space $L^2(\Gamma_C)$, we obtain from (7.4) and (7.5)

$$\int_0^t \langle \gamma_T^* \xi_{w_1} - \gamma_T^* \xi_{w_2}, \mathbf{v}^1 - \mathbf{v}^2\rangle \, ds + \int_0^t \langle P\left(\mathbf{u}^1, w_1\right) - P\left(\mathbf{u}^2, w_2\right), \mathbf{v}^1 - \mathbf{v}^2\rangle \, ds$$

$$\geq -c \int_0^t \left|\left|\mathbf{v}^1 - \mathbf{v}^2\right|\right|_U^2 ds - c \int_0^t |w_1 - w_2|_{H_C}^2 \, ds. \tag{7.6}$$

It follows from (7.6) and (7.1) that

$$\begin{aligned}
&\left|\mathbf{v}^1(t) - \mathbf{v}^2(t)\right|_H^2 + \delta^2 \int_0^t \left|\left|\mathbf{v}^1(s) - \mathbf{v}^2(s)\right|\right|_{V_2}^2 ds \\
&\qquad + \frac{1}{2}\langle A\left(\mathbf{u}^1(t) - \mathbf{u}^2(t)\right), \mathbf{u}^1(t) - \mathbf{u}^2(t)\rangle \\
&\leq c \int_0^t \left|\left|\mathbf{v}^1 - \mathbf{v}^2\right|\right|_U^2 ds + c \int_0^t |w_1 - w_2|_{H_C}^2 \, ds \\
&\qquad + \delta^2 \int_0^t \left|\mathbf{v}^1(s) - \mathbf{v}^2(s)\right|_H^2 ds.
\end{aligned}$$

By the compactness of the embedding $V_2 \to U$ we have $||\mathbf{z}||_U^2 \leq \frac{\delta^2}{2} ||\mathbf{z}||_{V_2}^2 + c_\delta |\mathbf{z}|_H^2$; hence,

$$\left|\mathbf{v}^1(t) - \mathbf{v}^2(t)\right|_H^2 + \frac{\delta^2}{2} \int_0^t \left|\left|\mathbf{v}^1(s) - \mathbf{v}^2(s)\right|\right|_{V_2}^2 ds$$

$$\leq c_\delta \int_0^t \left|\mathbf{v}^1(s) - \mathbf{v}^2(s)\right|_H^2 ds + c \int_0^t |w_1 - w_2|_{H_C}^2 \, ds.$$

It follows from the Gronwall inequality that

$$\begin{aligned}
\left|\mathbf{v}^1(t) - \mathbf{v}^2(t)\right|_H^2 + &\int_0^t \left|\left|\mathbf{v}^1(s) - \quad \mathbf{v}^2(s)\right|\right|_{V_2}^2 ds \\
&\leq c(\delta, T) \int_0^t |w_1 - w_2|_{H_C}^2 \, ds,
\end{aligned} \tag{7.7}$$

where the constant c depends on the indicated quantities and the bounds and Lipschitz constants of p and μ but not on the choice of w_i. We conclude with the following theorem.

THEOREM 7.1. *The solutions* $\mathbf{v}$ *of problem* (3.27)–(3.30) *depend continuously on* w.

8. Archard law. We now consider Theorem 3.3. We use a fixed point argument to prove Theorem 3.3, which guarantees the existence and uniqueness of the weak solution. Since $p(\cdot)$ is assumed to be bounded, we do not need to employ the truncation p_R.

The Archard law of wear, in its differential form (3.9), may be written as

$$w' = \Psi(\mathbf{v}_T)\, p(u_n - w - g),$$

where $\Psi(\mathbf{v}_T) \equiv k_w \mu(|\mathbf{v}_T - \mathbf{v}_*|) s_c(|\mathbf{v}_T - \mathbf{v}_*|)$. It follows from our assumptions that Ψ is bounded, nonnegative, and Lipschitz continuous. Let $\mathbf{v}^i \in \mathcal{V}_2$ and w_i, for $i = 1, 2$, be the solutions of the problem

$$w_i, w_i' \in L^2(0, T; H_C), \tag{8.1}$$

$$w_i' = \Psi\left(\mathbf{v}_T^i\right) p\left(u_n^i - w_i - g\right), \tag{8.2}$$

$$w_i(\cdot, 0) = 0. \tag{8.3}$$

Since the function Ψ is bounded, we actually have

$$w, w' \in L^\infty(0, T; L^\infty(\Gamma_C)),$$

and so these functions may be considered as known wear functions in the preceding theory. Thus,

$$\begin{aligned}
&\frac{1}{2}\left|w_1(t) - w_2(t)\right|_{H_C}^2 \\
&\quad \le c(\Psi, R) \int_0^t \left(|u_n^1 - u_n^2|_{H_C} + |w_1 - w_2|_{H_C}\right)\left(|w_1 - w_2|_{H_C}\right) ds \\
&\qquad + c(\ \mathrm{Lip}_\Psi, R, p) \int_0^t \left|\mathbf{v}_T^1 - \mathbf{v}_T^2\right|_{H_C^N} |w_1 - w_2|_{H_C}\, ds,
\end{aligned}$$

where $H_C = L^2(\Gamma_C)$. It follows that

$$\begin{aligned}
&|w_1(t) - w_2(t)|_{H_C}^2 \\
&\quad \le c(\Psi, R, p,\ \mathrm{Lip}_\Psi, T)\left(\int_0^t |w_1 - w_2|_{H_C}^2\, ds + \int_0^t \left|\left|\mathbf{v}^2 - \mathbf{v}^1\right|\right|_U^2\, ds\right),
\end{aligned}$$

where U is an intermediate space. Thus, by the Gronwall inequality,

$$|w_1(t) - w_2(t)|_{H_C}^2 \le c(\Psi, R, p,\ \mathrm{Lip}_\Psi, T) \int_0^t \left|\left|\mathbf{v}^1 - \mathbf{v}^2\right|\right|_U^2\, ds. \tag{8.4}$$

Now we construct the following mapping. Starting with $\mathbf{v} \in \mathcal{V}_2$, we denote by $w(\mathbf{v})$ the solution of problem (8.1)–(8.3), with i omitted. Then we use $w(\mathbf{v})$ as the wear function in the system (7.1)–(7.3). In this manner we define a mapping, $\Lambda : \mathcal{V}_2 \to \mathcal{V}_2$, where $\mathbf{z} = \Lambda\mathbf{v}$, and $\mathbf{z}$ is the solution of (7.1)–(7.3) with the given wear function $w(\mathbf{v})$. Now, from (7.7) and (8.4) we obtain

$$\int_0^t \left|\left|\Lambda\mathbf{v}^1 - \Lambda\mathbf{v}^2\right|\right|_{V_2}^2\, ds \le c(\delta, T, \Psi, R, p,\ \mathrm{Lip}_\Psi) \int_0^t \int_0^s \left|\left|\mathbf{v}^1 - \mathbf{v}^2\right|\right|_{V_2}^2\, dr ds.$$

By iterating this inequality m times we find that every Λ^m is a contraction mapping on $\mathcal{V}_2$ for all sufficiently large m. Consequently, Λ has a unique fixed point, which is the unique solution of problem $\mathcal{P}$. This establishes Theorem 3.3.

UNIQUENESS AND STABILITY OF L^∞ SOLUTIONS FOR TEMPLE CLASS SYSTEMS WITH BOUNDARY AND PROPERTIES OF THE ATTAINABLE SETS*

FABIO ANCONA† AND PAOLA GOATIN‡

Abstract. We consider the initial-boundary value problem for a strictly hyperbolic, genuinely nonlinear, Temple class system of conservation laws

$$u_t + f(u)_x = 0, \qquad u \in \mathbb{R}^n,$$

on the domain $\Omega = \{(t,x) \in \mathbb{R}^2 : t \geq 0,\, x \geq 0\}$. For a class of initial data $\overline{u} \in \mathbf{L}^\infty(\mathbb{R}^+)$ and boundary data $\widetilde{u} \in \mathbf{L}^\infty(\mathbb{R}^+)$ with possibly unbounded variation, we construct a flow of solutions $(\overline{u}, \widetilde{u}) \to u(t) \doteq E_t(\overline{u}, \widetilde{u})$ that depend continuously, in the $\mathbf{L}^1$ distance, both on the initial data and on the boundary data. Moreover, we show that each trajectory $t \mapsto E_t(\overline{u}, \widetilde{u})$ provides the unique weak solution of the corresponding initial-boundary value problem that satisfies an entropy condition of Oleinik type.

Next, we study the initial-boundary value problem for the above equation from the point of view of control theory taking the initial data $\overline{u}$ fixed and considering, in connection with a prescribed set $\mathcal{U}$ of boundary data regarded as admissible controls, the set of attainable profiles at a fixed time $T > 0$, and at a fixed point $\overline{x} > 0$:

$$\mathcal{A}(T, \mathcal{U}) \doteq \left\{E_T(\overline{u}, \widetilde{u})(\cdot)\ ;\ \widetilde{u} \in \mathcal{U}\right\}, \qquad \mathcal{A}(\overline{x}, \mathcal{U}) \doteq \left\{E_{(\cdot)}(\overline{u}, \widetilde{u})(\overline{x})\ ;\ \widetilde{u} \in \mathcal{U}\right\}.$$

We establish closure and compactness of the sets $\mathcal{A}(T, \mathcal{U})$, $\mathcal{A}(\overline{x}, \mathcal{U})$ in the $\mathbf{L}^1_{loc}$ topology for a class $\mathcal{U}$ of admissible controls satisfying convex constraints.

1. Introduction.

Consider the initial-boundary value problem for a nonlinear, strictly hyperbolic system of conservation laws in one space dimension,

$$u_t + f(u)_x = 0, \tag{1.1}$$

$$u(0,x) = \overline{u}(x), \tag{1.2}$$

$$u(t,0) = \widetilde{u}(t), \tag{1.3}$$

on the domain $\Omega = \{(t,x) \in \mathbb{R}^2\ ;\ t \geq 0,\, x \geq 0\}$. Here, $u = u(t,x) \in \mathbb{R}^n$ is the vector of the conserved quantities, and the flux function $f : U \mapsto \mathbb{R}^n$ is a smooth vector field defined on some open set $U \subseteq \mathbb{R}^n$. We recall that, for problems of this type, classical solutions may develop discontinuities in finite time, no matter the regularity of the initial and boundary data. Hence, it is natural to consider weak solutions in the sense of distributions. Moreover, in general, the Dirichlet condition (1.3) cannot be fulfilled pointwise a.e. (see [7, 17]), even when (1.1) is a linear system (cf. [23]).

For this reason, different weaker formulations of the boundary condition have been considered in the literature, both for characteristic boundaries (where the eigenvalues of the Jacobian matrix $Df(u)$ may coincide with the slopes of the boundary profile) and for noncharacteristic ones; see [1, 28] and the references therein.

In this paper we assume that the boundary is noncharacteristic, requiring that, for each ith characteristic family, the ith eigenvalue $\lambda_i(u)$ of $Df(u)$ always has the same sign, which implies that there is a fixed set of characteristic lines entering the interior of the domain Ω at any point of the boundary $x = 0$. Then, following Dubois and LeFloch [17] and Joseph and LeFloch [21], we reformulate (1.3) in the weak form

$$f\big(u(t,0+)\big) \in f\big(\mathcal{V}(\widetilde{u}(t))\big), \qquad \text{for a.e. } t>0, \tag{1.4}$$

where $\mathcal{V}(\widetilde{u}(t)) \subset U$ is a time-dependent set (the set of *admissible boundary values*) that is defined from the boundary data $\widetilde{u}$ using the notion of Riemann problem, while $f(u(t,0+))$ represents the weak trace of the flux $f(u(t,x))$ at $x = 0$. We are concerned with the well-posedness of (1.1)–(1.2), (1.4) within domains of $\mathbf{L}^\infty$ functions with possibly unbounded variations, having in mind to study the initial-boundary value problem (1.1)–(1.2), (1.4) from the point of view of control theory where it is natural to regard the boundary data as varying within a prescribed set of admissible $\mathbf{L}^\infty$ controls.

We recall that, for initial and boundary data with small total variation, the existence of global weak solutions of the corresponding mixed problem for (1.1), with various types of boundary conditions, was studied by Liu [25, 26], Goodman [19], Dubroca and Gallice [18], and Sablé-Tougeron [28], using the Glimm scheme, and by Amadori [1], developing a front tracking algorithm. More recently, the Lipschitz continuous dependence on the initial and boundary data of entropy admissible BV solutions was obtained in [2, 3], for systems of two equations, following the *semigroup approach* developed by Bressan and his collaborators to prove the well-posedness of the Cauchy problem for (1.1) (see [11]).

Notice that, while for scalar conservation laws the well-posedness theory for the mixed problem had been established within domains of $\mathbf{L}^\infty$ functions [23, 24, 29], in the case of systems the available stability results apply only to solutions with small total variation. In the present paper we extend these results to domains of $\mathbf{L}^\infty$ functions for a class of systems introduced by Temple [30, 29] in which rarefaction and Hugoniot curves coincide, under the assumption that all characteristic fields are genuinely nonlinear in the sense of Lax. Namely, for such systems, and for a domain $\mathcal{D}$ of pairs of $\mathbf{L}^\infty$ functions with possibly unbounded variation, we construct a continuous flow of solutions

$$(\,\overline{u},\,\widetilde{u}\,) \mapsto u(t,\,\cdot\,) \doteq E_t(\,\overline{u},\,\widetilde{u}\,)(\cdot), \qquad (\,\overline{u},\,\widetilde{u}\,) \in \mathcal{D} \tag{1.5}$$

of the mixed problem (1.1)–(1.2), (1.4), that, for every fixed $\delta > 0$, satisfy the stability estimate

$$\begin{aligned} &\big\|E_t(\,\overline{u},\,\widetilde{u}\,) - E_t(\,\overline{v},\,\widetilde{v}\,)\big\|_{\mathbf{L}^1([\delta,+\infty[)} \\ &\qquad \leq L_t \cdot \Big\{ \big\|\,\overline{u}-\overline{v}\,\big\|_{\mathbf{L}^1(\mathbb{R}^+)} + \big\|f(\widetilde{u})-f(\widetilde{v})\big\|_{\mathbf{L}^1([0,\,t])} \Big\} \end{aligned} \tag{1.6}$$

for all $t \geq \delta$, where the Lipschitz constant L_t takes the form $L_t = C(1+\log(t/\delta))$, for some constant $C > 0$ depending on the system (1.1). Moreover, relying on a

stability estimate of the same type, established for the map $(\,\overline{u},\,\widetilde{u}\,)\mapsto E_{(\cdot)}(\,\overline{u},\,\widetilde{u}\,)(x)$, $x>0$, we prove that every solution $u(t,x)\doteq E_t(\,\overline{u},\,\widetilde{u}\,)(x)$ actually admits a strong $\mathbf{L}^1$ trace at the boundary $x=0$. In the same spirit of [6, 14], the flow map E_t in (1.5) is constructed as the unique limit of a Cauchy sequence of flow maps E^ν_t whose trajectories are front tracking approximate solutions of (1.1) in the region Ω that satisfy a stability estimate of the same type as (1.6) (with a Lipschitz constant independent of ν and on the total variation).

Concerning the existence of weak solutions of the initial-boundary value problem (1.1)–(1.3) for Temple class systems with $\mathbf{L}^\infty$ data, an earlier result can be found in [16], where it was shown the convergence of the viscous approximate solutions using a compensated compactness argument.

In order to obtain the well-posedness of the mixed problem (1.1)–(1.2), (1.4) with initial and boundary data $(\,\overline{u},\,\widetilde{u}\,)\in\mathcal{D}$, we next show that a distributional solution $u=u(t,x)$ of (1.1)–(1.2), (1.4) coincides with the corresponding trajectory of the flow map E_t if and only if, letting $w=(w_1,\ldots,w_n)$ denote a system of Riemann coordinates for (1.1), and assuming that the characteristic speeds entering the domain Ω are λ_i, $i\in\{n-p+1,\ldots,n\}$, the following conditions hold:

(i) The map $(t,x)\to\big(u(t,\cdot\,),\,u(\cdot\,,x)\big)$ takes values within the domain $\mathcal{D}$.

(ii) u satisfies suitable Oleinik-type conditions on the decay of positive waves in time and in space.

(iii) u admits at $t=0$ and at $x=0$ the essential limits

$$\operatorname*{ess\ sup}_{t\to 0^+}\big\|u(t,\cdot\,)-\overline{u}\,\big\|_{\mathbf{L}^1([0,R])}=0\,,$$

$$\operatorname*{ess\ sup}_{x\to 0^+}\big\|w_i\big(u(\cdot\,,x)\big)-w_i\circ\widetilde{u}\big\|_{\mathbf{L}^1([0,\,\tau])}=0\qquad\forall\ i\in\{n-p+1,\ldots,n\}$$

for any $R>0$, $\tau>0$.

Relying on the formulation of the boundary condition in terms of *boundary entropy pairs*, introduced by Otto [27] for scalar conservation laws, and then extended by Chen and Frid [15, 16] to various classes of systems (including Temple systems), one can recover the regularity conditions (iii) employing the corresponding distributional entropy inequality. We thus prove, in particular, that any weak solution of the mixed problem (1.1)–(1.2), (1.4) constructed by the Glimm scheme or by a front tracking algorithm, which clearly satisfies the Oleinik-type conditions (ii) and any entropy inequality, must coincide with the trajectory of the flow map E_t in (1.5).

The proof of the $\mathbf{L}^1$ stability estimate (1.6) is based on the same homotopy and linearization technique developed in [12, 6, 14]. In order to estimate how the distance between two infinitesimally close solutions varies in time, the basic idea consists of "differentiating" a family of front tracking approximate solutions w.r.t. a parameter which determines the (space) locations of the jumps and in providing a priori bounds on the norm of the resulting "shift differential". In particular, given a piecewise constant solution $u=u(t,x)$ with an initial data $\overline{u}$ and a boundary data $\widetilde{u}$, we may consider a family of perturbed solutions $\theta\mapsto u^\theta(t,\cdot\,)$ obtained from u by shifting the time position t_0 of a single jump in $\widetilde{u}$ at constant rate $\widetilde{\xi}$ (or the space location x_0 of a single jump in $\overline{u}$ at constant rate ξ_0). Call $\widetilde{\sigma}\doteq f(\widetilde{u}(t_0+))-f(\widetilde{u}(t_0-))$ the size of this jump in $f(\widetilde{u})$ (or let $\sigma\doteq\overline{u}(x_0+)-\overline{u}(x_0-)$ denote the size of the jump in $\overline{u}$). As long as the wave-front configuration of the perturbed and unperturbed solutions is the same, for every fixed $\delta>0$, and any $t\geq\delta$, one can estimate the $\mathbf{L}^1$ distance between $u(t,\cdot\,)\restriction_{[\delta,+\infty[}$ and $u^\theta(t,\cdot\,)\restriction_{[\delta,+\infty[}$ by showing that, if the perturbed solution

$u^\theta(t,\cdot)$ contains jumps of size $\sigma_1^\theta,\dots,\sigma_M^\theta$ located at $x_\alpha^\theta \geq \delta$, and shifted at shift rate (in space) $\xi_1^\theta,\dots,\xi_M^\theta$, then there holds

$$\sum_{\alpha=1}^{M} \left|\sigma_\alpha^\theta\, \xi_\alpha^\theta\right| \leq L_t \cdot \left|\widetilde{\sigma}\, \widetilde{\xi}\right| \tag{1.7}$$

for some constant $L_t = L_t(\delta) > 0$ depending on t and on the distance δ from the boundary $x = 0$. The key stability estimate (1.7) is obtained here as in [14], relying on two remarkable properties of genuinely nonlinear systems of Temple class:

(a) By genuine nonlinearity and finite propagation speed, for every fixed $\delta > 0$, the total amount of waves in a solution $u(t,\cdot)$ to the mixed problem (1.1)–(1.2), (1.4), which can be influenced by shifting a single wave-front of the initial data $\overline{u}$ or of the boundary data $\widetilde{u}$, and are located at distance $\geq \delta$ from the boundary $x = 0$, remains uniformly bounded, for all $t \geq \delta$, by some constant depending on t and δ.

(b) For solutions of Temple class systems, the support of perturbations satisfies a special localization property related to the representation formula for the solutions of the nonlinear equation $U_t + f(U_x) = 0$ in terms of envelopes of n families of hyperplanes [29].

Having in mind applications of Temple systems to problems of oil reservoir simulation, multicomponent chromatography, as well as in models for traffic flows, in the last part of the paper we focus our attention on the mixed problem (1.1)–(1.2), (1.4) from the point of view of control theory. Namely, following the same approach adopted by Ancona and Marson [4, 5] for scalar conservation laws, we fix an initial data $\overline{u} \in \mathbf{L}^\infty(\mathbb{R}^+)$, and, in connection with an assigned set $\mathcal{U} \subset \mathbf{L}^\infty(\mathbb{R}^+)$ of boundary data regarded as admissible controls, we consider the sets of attainable profiles at a fixed time T,

$$\mathcal{A}(T,\mathcal{U}) \doteq \big\{E_T(\,\overline{u},\,\widetilde{u}\,)(\cdot)\ ;\ \widetilde{u} \in \mathcal{U}\big\},$$

and at a fixed point in space $\overline{x} > 0$,

$$\mathcal{A}(\,\overline{x},\mathcal{U}) \doteq \big\{E_{(\cdot)}(\,\overline{u},\,\widetilde{u}\,)(\overline{x})\ ;\ \widetilde{u} \in \mathcal{U}\big\}\,.$$

Relying on the well-posedness theory provided by the previous results, we establish here, as in the scalar case [4, 5], the compactness of these sets in the $\mathbf{L}^1{}_{loc}$ topology for a class $\mathcal{U}$ of admissible boundary controls that satisfy convex constraints.

The paper is organized as follows. Section 2 contains the basic definitions and the statement of the main results. In section 3 we provide an outline of the proof of Theorem 2.3 on the existence of a continuous flow of solutions depending continuously, in the $\mathbf{L}^1$ distance, on the initial and on the boundary data. The basic a priori estimates on shift differentials are contained in sections 4 and 5, while the proof of Theorem 2.3 is given in section 6, which also contains the proof of Theorem 2.4. The compactness property of the attainable sets stated in Theorem 2.6 is established in section 7.

2. Preliminaries and statement of the main results.

2.1. Formulation of the problem. Let $f : U \mapsto \mathbb{R}^n$ be the flux function of the strictly hyperbolic system (1.1) defined on a neighborhood of the origin $U \subseteq \mathbb{R}^n$, and denote by $\lambda_1(u) < \cdots < \lambda_n(u)$ the eigenvalues of the Jacobian matrix $Df(u)$.

Choose right and left eigenvectors $r_i(u)$, $l_i(u)$, $i = 1, \dots, n$, of $Df(u)$ normalized so that

$$|r_i(u)| = 1, \qquad l_i(u) \cdot r_j(u) = \begin{cases} 1 & \text{if } i = j, \\ 0 & \text{if } i \neq j. \end{cases} \tag{2.1}$$

By possibly considering a sufficiently small restriction of the domain U, we may assume that a *uniform* strict hyperbolicity condition holds:

(SH1) For every $u, v \in U$, the characteristic speeds at these points satisfy

$$\lambda_j(u) > \lambda_i(v) \qquad \forall\, 1 \leq i < j \leq n\,. \tag{2.2}$$

We also assume that each ith characteristic field r_i is *genuinely nonlinear* in the sense of Lax, i.e., that, by choosing a suitable orientation of the eigenvectors $r_i(u)$, at every point $u \in U$ one has $D\lambda_i \cdot r_i(u) > 0$. Moreover, the system (1.1) is of Temple class in accordance with the following.

Definition 2.1. *A system of conservation laws is of Temple class if there exists a system of coordinates $w = (w_1, \dots, w_n)$ consisting of Riemann invariants and such that the level sets $\{u \in U;\ w_i(u) = \text{constant}\}$ are hyperplanes (see* [29]*).*

It is not restrictive to assume that the Riemann coordinates are chosen so that $(w_1, \dots, w_n)(0) = (0, \dots, 0)$ and

$$\frac{\partial}{\partial w_i}\lambda_i(w) > 0 \qquad \forall\, w = w(u), \quad u \in U, \qquad i = 1, \dots, n. \tag{2.3}$$

Throughout the paper, we will often write $w_i(t,x) \doteq w_i\big(u(t,x)\big)$ to denote the ith Riemann coordinate of a solution $u = u(t,x)$ to (1.1). For a Temple class system, the integral curve of the vector field r_i through a point u_0 is the straight line described by the $n-1$ linear equations

$$w_j(u) = w_j(u_0)\,, \qquad j \neq i. \tag{2.4}$$

In particular, shock and rarefaction curves coincide. Let $\sigma \mapsto R_i(u)[\sigma]$ denote the ith rarefaction curve through $u \in U$. We fix a convex, compact set $K \subset U$ having the form

$$K = \Big\{u \in U; \quad w_i(u) \in [a_i,\ b_i], \qquad i = 1, \dots, n\Big\}, \tag{2.5}$$

and, concerning the boundary, we assume that there is a fixed set of characteristic lines entering the interior of the domain Ω at every point of the boundary $x = 0$, i.e., that, for some index $p \in \{1, \dots, n\}$, there holds

$$\lambda_{n-p}(u) < 0 < \lambda_{n-p+1}(u) \qquad \forall\, u \in K. \tag{2.6}$$

We shall denote by $\lambda^{\min}$, $\lambda^{\max}$ the minimum and maximum characteristic speed so that there holds

$$0 < \lambda^{\min} \leq |\lambda_i(u)| \leq \lambda^{\max} \qquad \forall\, u \in K, \qquad \forall\, i \in \{1, \dots, n\}. \tag{2.7}$$

Remark 2.1. Since the rarefaction curves are straight lines, the existence of Riemann coordinates implies

$$r_k\big(R_i(u)[\sigma]\big) \in \operatorname{span}\big\{r_k(u),\, r_i(u)\big\} \qquad \forall\, u \in U, \quad \forall\, \sigma, \quad \forall\, i, k = 1, \dots, n\,. \tag{2.8}$$

Relying on this property, one can easily verify that a strengthened version of the strict hyperbolicity assumption on the linear independence of the eigenvectors $\{r_1(u), \dots, r_n(u)\}$, $u \in U$, holds, namely:

(SH2) Given any n-tuple of states $u^1, \dots, u^n \in U$, such that

$$u^{i+1} = R_i(u^i)[\sigma_i], \qquad 1 \leq i < n\,,$$

for some $\sigma_1, \dots, \sigma_n$, the eigenvectors $r_1(u^1), \dots, r_n(u^n)$ are linearly independent.

Notice that the strict hyperbolicity condition (SH2) implies the invertibility of the map $f : U \mapsto f(U)$. Indeed, for any given pair of states $u, v \in U$, there will be some values $\sigma_1, \dots, \sigma_n$ so that, setting

$$z^1 \doteq u, \qquad z^{i+1} \doteq z^i + \sigma_i\, r_i(z^i), \qquad 1 \leq i \leq n,$$

we can write

$$v - u = \sum_{i=1}^n \sigma_i\, r_i(z^i). \tag{2.9}$$

In turn, (2.9) yields

$$f(v) - f(u) = \sum_{i=1}^n \sigma_i\, \lambda_i(z^i,\, z^{i+1})\, r_i(z^i), \tag{2.10}$$

where $\lambda_i(z^i,\, z^{i+1})$ denotes the ith eigenvalue of the averaged matrix

$$A(z^i,\, z^{i+1}) = \int_0^{\sigma_i} Df(z^i + \theta r_i(z^i))\; d\theta\,. \tag{2.11}$$

Observing that, by the genuine nonlinearity of the characteristic speeds and because of the assumption (2.6), one has

$$\sigma_i \neq 0 \quad \Longrightarrow \quad \lambda_i(z^i,\, z^{i+1}) \neq 0 \qquad \forall\; i = 1, \dots, n\,,$$

using (SH2) one clearly deduces from (2.9)–(2.10) the injectivity of the flux function f.

We next introduce a definition of weak solution to (1.1)–(1.3) which includes an entropy admissibility condition of Oleinik type on the decay of positive waves. The boundary condition is formulated in terms of the weak trace of $f(u)$ at the boundary $x = 0$ and is related to the notion of Riemann problem in the same spirit of [17]. To this purpose, letting $u(t,x) = W(\xi = x/t;\, u_L, u_R)$, $u_L, u_R \in K$, denote the self-similar solution of the Riemann problem for (1.1) with initial data

$$u(0,x) = \begin{cases} u_L & \text{if } x < 0, \\ u_R & \text{if } x > 0, \end{cases}$$

for any given boundary state $\widetilde{u} \in K$, we define the set of *admissible states at the boundary*

$$\mathcal{V}(\widetilde{u}) := \big\{ W(0+;\, \widetilde{u}, u_R)\;;\; u_R \in K \big\}. \tag{2.12}$$

Definition 2.2. *A function $u : [0,\, T] \times \mathbb{R}^+ \mapsto K$ is an entropy weak solution of the initial-boundary value problem* (1.1)–(1.3) *on $\Omega_T \doteq [0,\, T] \times \mathbb{R}^+$ if it is continuous as a function from $]0,\, T]$ into $\mathbf{L}^1{}_{loc}$ and the following properties hold:*

(i) *u is a distributional solution to the Cauchy problem* (1.1)–(1.2) *on Ω_T in the sense that, for every test function $\phi \in \mathcal{C}^1_c$ with compact support contained in the set $\{(t,x) \in \mathbb{R}^2;\ x > 0,\, t < T\}$, there holds*

$$\int_0^T \int_0^{+\infty} \big(u(t,x)\cdot\phi_t(t,x) + f(u(t,x))\cdot\phi_x(t,x)\big)dx\,dt + \int_0^{+\infty} \overline{u}(x)\cdot\phi(0,x)dx = 0.$$

(ii) *The flux $f(u)$ admits a weak* trace at the boundary $x = 0$; i.e., there exists a measurable function $\Psi : [0,\, T] \mapsto \mathbb{R}^n$ such that*

$$f(u(\cdot,x)) \ \underset{x\to 0^+}{\overset{*}{\longrightarrow}}\ \Psi \qquad \text{in} \quad \mathbf{L}^\infty([0,\,T]), \tag{2.13}$$

and the boundary condition (1.3) *is satisfied in the following sense:*

$$\Psi(t) \in f\big(\mathcal{V}(\widetilde{u}(t))\big) \qquad \text{for a.e.} \quad 0 \le t \le T. \tag{2.14}$$

(iii) *u satisfies the following entropy conditions on the decay of positive waves in time and in space. There exists some constant $C > 0$, depending only on the system* (1.1), *so that*

(a) *for any $0 < t \le T$, and for a.e. $0 < x < y$, there holds*

$$w_i(t,y) - w_i(t,x) \ \le\ C \cdot \frac{y-x}{t} \qquad \text{if} \qquad i \in \{1,\dots,n-p\}, \tag{2.15}$$

$$w_i(t,y) - w_i(t,x) \ \le\ C \cdot \left\{ \frac{y-x}{t} + \log\frac{y}{x} \right\} \text{if } i \in \{n-p+1,\dots,n\}; \tag{2.16}$$

(b) *for a.e. $x > 0$, and for a.e. $0 < \tau_1 < \tau_2 \le T$, there holds*

$$w_i(\tau_2,x) - w_i(\tau_1,x) \ \le\ C \cdot \log\frac{\tau_2}{\tau_1} \qquad \text{if} \qquad i \in \{1,\dots,n-p\}, \tag{2.17}$$

$$w_i(\tau_2,x) - w_i(\tau_1,x) \ \le\ C \cdot \left\{ \frac{\tau_2-\tau_1}{x} + \log\frac{\tau_2}{\tau_1} \right\} \text{if } i \in \{n-p+1,\dots,n\}. \tag{2.18}$$

Remark 2.2. The set of admissible flux values at the boundary $f\big(\mathcal{V}(\widetilde{u})\big)$ can be expressed in Riemann coordinates as

$$f\big(\mathcal{V}(\widetilde{u})\big) = \Big\{ f(u)\ ;\ w_j(u) = w_j(\widetilde{u}) \qquad \forall\ j = n-p+1,\dots,n \Big\}. \tag{2.19}$$

Hence, by the invertibility of the map $f : U \mapsto f(U)$, the above boundary condition (2.14) is equivalent to the set of equalities

$$w_j\big(f^{-1}(\Psi(t))\big) = w_j\big(\widetilde{u}(t)\big) \quad \text{ for a.e.} \quad 0 \le t \le T, \quad j = n-p+1,\dots,n. \tag{2.20}$$

This means that the boundary condition (2.14) guarantees that, at almost every time $t \in [0,\, T]$, the solution to the Riemann problem for (1.1), having left and right

initial states $u^L = \widetilde{u}(t)$, $u^R = f^{-1}(\Psi(t))$, contains only waves with negative speeds and, in particular, its restriction to the region $[t, +\infty]\times]0, +\infty[$ takes constant value $f^{-1}(\Psi(t))$.

Remark 2.3. Several definitions of sets of admissible boundary values that can be used for alternative formulations of the boundary condition (2.14) have been proposed in the literature. (A systematic study of such formulations is contained in [21].) In particular, following Dubois and LeFloch [17] one may consider an admissible set $\mathcal{V}^{\mathcal{E}ntr}$ whose definition is based on the boundary entropy inequalities associated with the artificial vanishing viscosity limit

$$u^\varepsilon_t + f(u^\varepsilon)_x = \varepsilon u^\varepsilon_{xx}, \qquad \varepsilon \to 0\,. \tag{2.21}$$

Namely, in accordance with [17], for any given boundary state $\widetilde{u}$ the set of admissible boundary values $\mathcal{V}^{\mathcal{E}ntr}(\widetilde{u})$ based on the vanishing viscosity limit (2.21) is defined as

$$\begin{aligned}\mathcal{V}^{\mathcal{E}ntr}(\widetilde{u}) \doteq \Big\{ u \ ;\ &\text{for all convex entropy-entropy flux pairs } (\eta, q)\\ &q(u) - q(\widetilde{u}) - D\eta(\widetilde{u})\big(f(u) - f(\widetilde{u})\big) \le 0 \Big\}\,.\end{aligned} \tag{2.22}$$

The resulting boundary condition (2.14), with $f(\mathcal{V}(\widetilde{u}))$ replaced by $f(\mathcal{V}^{\mathcal{E}ntr}(\widetilde{u}))$, is a generalization of the earlier one introduced by Bardos, Leroux, and Nedelec in [7] for scalar (multidimensional) conservation laws, which used only the boundary entropy inequalities associated with the Kruzkov entropies to define the set (2.22). By reformulating the entropy inequalities in terms of Young measures (associated with a sequence of viscous approximates solutions) it is shown in [21] that the boundary condition (2.14) corresponding to the set of admissible boundary data (2.22) is satisfied by any (artificial) vanishing viscosity limit (2.21). Thus, this formulation of the boundary condition is natural at least in the case that no boundary layer develops near the boundary. Moreover, it is proved in [17, 21] that, for linear hyperbolic systems and scalar conservation laws, the two sets of admissible boundary data (2.12), (2.22) are the same, and hence the two formulations of the boundary condition are equivalent. Indeed, as it was conjectured by Dubois and LeFloch [17], the two sets (2.12), (2.22) also coincide in the case of Temple systems. The inclusion $\mathcal{V}(\widetilde{u}) \subseteq \mathcal{V}^{\mathcal{E}ntr}(\widetilde{u})$ was proved by Benabdallh and Serre [8], while the converse inclusion $\mathcal{V}^{\mathcal{E}ntr}(\widetilde{u}) \subseteq \mathcal{V}(\widetilde{u})$ can be established making use of the Kruzkov-type entropies associated with a Temple system, as it is shown in the appendix.

An alternative formulation of the boundary condition (1.3) for $\mathbf{L}^\infty$ boundary data, which is not based on the existence of the trace of the solution (or of the flux of the solution) at the boundary, was proposed by Otto [27], for scalar conservation laws, following the vanishing viscosity approach, and then extended by Chen and Frid [15, 16] to various classes of systems (including Temple systems). In this case, the boundary condition is expressed, requiring that the solution satisfy a family of boundary entropy admissibility integral inequalities that are associated with the *boundary entropy pairs* for the system (1.1). Applying the theory of divergence measure fields, it is shown in [15] that, for scalar conservation laws and for Temple class sytems, a solution satisfying such an integral formulation of the boundary conditions assumes the boundary data also in the sense of our Definition 2.2.

2.2. Stability and uniqueness of weak solutions. Due to the presence of the boundary data, the flow map $u(0,\cdot) \mapsto u(t,\cdot)$ induced by (1.1)–(1.3) is not time homogeneous. To recast the problem in a semigroup framework, it is thus convenient

to incorporate the boundary data $\widetilde{u}$ in the domain of the semigroup. More precisely, in connection with a convex, compact set $K \subset U$ of the form (2.5), we consider the positively invariant domain of pairs of $\mathbf{L}^\infty$ functions, with possibly unbounded variations

$$\mathcal{D} \doteq \Big\{ \mathbf{p} = (\,\overline{u},\, \widetilde{u}\,)\ ;\ \overline{u},\, \widetilde{u} \in \mathbf{L}^1(\mathbb{R}^+, K) \Big\}, \tag{2.23}$$

where $\mathbf{L}^1(\mathbb{R}^+, K)$ denotes the metric space of all $\mathbf{L}^1$ functions $u : \mathbb{R}^+ \mapsto K$, equipped with the usual $\mathbf{L}^1$ distance. Let $\mathcal{T}_t : \mathbf{L}^1(\mathbb{R}^+, K) \mapsto \mathbf{L}^1(\mathbb{R}^+, K)$ be the translation operator, i.e., $(\mathcal{T}_t\widetilde{u})(s) \doteq \widetilde{u}(t+s)$, and denote by $E : \mathbb{R}^+ \times \mathcal{D} \mapsto \mathbf{L}^1(\mathbb{R}^+, K)$ the evolution operator $E_t\mathbf{p} = u(t,\cdot)$, u being a solution to (1.1)–(1.3). With the above notations, we shall construct a semigroup S acting on $\mathcal{D}$, in the sense that

$$\begin{array}{rcl} S : \mathbb{R}^+ \times \mathcal{D} & \mapsto & \mathcal{D}, \\ (\,t\,,\,\mathbf{p}\,) & \mapsto & S_t\mathbf{p}, \end{array} \tag{2.24}$$

where, if $\mathbf{p} = (\,\overline{u},\, \widetilde{u}\,)$, $S_t\mathbf{p} = \big(E_t\mathbf{p},\, \mathcal{T}_t\widetilde{u}\,\big)$.

Our main result is concerned with the existence of an $\mathbf{L}^1$ continuous semigroup of the form (2.24), generated by the system (1.1) on the domain $\mathcal{D}$.

THEOREM 2.3. *Let* (1.1) *be a system of Temple class with all characteristic fields genuinely nonlinear. Assume that* (2.6) *and the strict hyperbolicity condition* (SH1) *are verified. Then there exist a continuous semigroup S of the form* (2.24) *and some constant $C > 0$, depending only on the system* (1.1) *and on the domain K, so that, for every fixed $\delta > 0$, and for all $(\,\overline{u},\, \widetilde{u}\,), (\,\overline{v},\, \widetilde{v}\,) \in \mathcal{D}$, letting $L_t \doteq L_t(\delta) = C(1+\log(t/\delta))$, one has*

$$\begin{aligned} &\big\| E_t(\,\overline{u},\, \widetilde{u}\,) - E_t(\,\overline{v},\, \widetilde{v}\,) \big\|_{\mathbf{L}^1([\delta, +\infty[)} \\ &\qquad \leq L_t \cdot \Big\{ \big\| \,\overline{u} - \overline{v}\, \big\|_{\mathbf{L}^1(\mathbb{R}^+)} + \big\| f(\widetilde{u}) - f(\widetilde{v}) \big\|_{\mathbf{L}^1([0,\,t])} \Big\} \end{aligned} \tag{2.25}$$

for all $t \geq \delta$. Moreover, the map $(t,x) \mapsto E_t(\,\overline{u},\, \widetilde{u}\,)(x)$ yields an entropy weak solution (in the sense of Definition 2.2*) to the initial-boundary value problem* (1.1)–(1.3) *on Ω that admits a strong $\mathbf{L}^1$ trace at the boundary $x = 0$; i.e., there exists a measurable map $\psi : \mathbb{R}^+ \mapsto U$ such that*

$$\lim_{x \to 0^+} \int_0^\tau \big| E_t(\,\overline{u},\, \widetilde{u}\,)(x) - \psi(t) \big|\, dt = 0 \qquad \forall\ \tau \geq 0. \tag{2.26}$$

Remark 2.4. With the same arguments used in section 6 to establish the existence of a strong $\mathbf{L}^1$ trace at the boundary $x = 0$ for the map $(t,x) \mapsto E_t(\,\overline{u},\, \widetilde{u}\,)(x)$ provided by Theorem 2.3, one can show the continuity w.r.t. the $\mathbf{L}^1{}_{loc}$ topology of $t \mapsto E_t(\,\overline{u},\, \widetilde{u}\,)$ at time $t = 0$. However, as in the case of the Cauchy problem [14], the map $t \mapsto E_t(\,\overline{u},\, \widetilde{u}\,)$ may not be Lipschitz continuous at $t = 0$ if the initial condition $\overline{u}$ has unbounded total variation. Moreover, the evolution operator $\mathbf{p} \mapsto E_t\mathbf{p}$ is not, in general, Lipschitz continuous w.r.t. the topology of $\mathbf{L}^1(\mathbb{R}^+, K)$ on the range $E_t(\mathcal{D})$.

Remark 2.5. The trajectories of the flow map E_t provided by Theorem 2.3 are obtained as limits of front tracking approximate solutions whose values are independent of the Riemann coordinates of the boundary data that leave the domain Ω. Thus, the same property holds for the limit map E_t, and hence, given any couple of initial data

and boundary condition $(\,\overline{u},\,\widetilde{u}\,)\in\mathcal{D}$, if we consider the auxiliary boundary condition $\widetilde{u}'$ defined in Riemann coordinates by

$$w_j(\widetilde{u}'(t))\doteq\begin{cases}\overline{c}_j & \text{if}\quad j\le n-p,\\ \\ w_j(\widetilde{u}(t)) & \text{if}\quad j>n-p,\end{cases}\qquad\forall\ t\ge 0\,, \tag{2.27}$$

for some constant values $\overline{c}_j\in[a_i,\,b_i]$, $j=1,\dots,n-p$, one has

$$E_t(\,\overline{u},\,\widetilde{u}\,)=E_t(\,\overline{u},\,\widetilde{u}'\,)\qquad\forall\ t\ge 0\,. \tag{2.28}$$

Therefore, given any $(\,\overline{u},\,\widetilde{u}\,),(\,\overline{v},\,\widetilde{v}\,)\in\mathcal{D}$, by replacing $\widetilde{u},\widetilde{v}$ in (2.25) with two auxiliary boundary data $\widetilde{u}',\widetilde{v}'$ having the property

$$w_j(\widetilde{u}'(t))=w_j(\widetilde{v}'(t))\qquad\forall\ t\ge 0,\qquad j=1,\dots,n-p,$$

we deduce for the flow map E_t the sharper estimate

$$\begin{aligned}&\big\|E_t(\,\overline{u},\,\widetilde{u}\,)\,-\,E_t(\,\overline{v},\,\widetilde{v}\,)\big\|_{\mathbf{L}^1([\delta,+\infty[)}\\ &\qquad\le L_t\cdot\left\{\big\|\,\overline{u}-\overline{v}\,\big\|_{\mathbf{L}^1(\mathbb{R}^+)}+\sum_{j=n-p+1}^{n}\big\|w_j(\widetilde{u})-w_j(\widetilde{v})\big\|_{\mathbf{L}^1([0,\,t])}\right\}.\end{aligned} \tag{2.29}$$

The next result states that every entropy weak solution to (1.1)–(1.3), admitting an essential limit in the $\mathbf{L}^1$ norm at time $t=0$, and at the boundary $x=0$, actually coincides with the corresponding trajectory $t\mapsto E_t(\,\overline{u},\,\widetilde{u}\,)$ of the flow map E_t constructed in Theorem 2.3. As a consequence, we deduce the uniqueness (up to the domain) of a Lipschitz continuous map as E_t having the property that each trajectory provide an entropy weak solution to (1.1)–(1.3) that admits a strong $\mathbf{L}^1$ trace at the boundary $x=0$, and at the initial time $t=0$. Notice that, in order to select a *unique* solution to (1.1)–(1.3), it is crucial to require that such a solution satisfies the decay estimates on positive waves stated in Definition 2.2(ii). For this reason, since in the case of $\mathbf{L}^\infty$ initial and boundary data the currently available results on the convergence of the viscous approximate solutions u^ε do not provide a priori BV bounds on u^ε, it remains an open problem whether or not the vanishing viscosity limit (2.21) coincides with the trajectory of the flow map E_t constructed in Theorem 2.3.

THEOREM 2.4. *Let* (1.1) *be a system of Temple class satisfying the same assumptions as in Theorem* 2.3. *Let* $u=u(t,x)$ *be an entropy weak solution to the mixed problem* (1.1)–(1.3) *on the region* $\Omega_T\doteq[0,\,T]\times\mathbb{R}^+$, *in the sense of Definition* 2.2. *Assume that the following conditions hold:*

(i) *The map* $(t,x)\to\big(u(t,\cdot),\,u(\cdot,x)\big)$ *takes values within the domain*

$$\mathcal{D}_T\doteq\Big\{\mathbf{p}=(\,\overline{u},\,\widetilde{u}\,)\ ;\ \overline{u}\in\mathbf{L}^1(\mathbb{R}^+,K),\,\widetilde{u}\in\mathbf{L}^1([0,T],K)\Big\}. \tag{2.30}$$

(ii) *For every fixed* $R>0$, *there holds*

$$\operatorname*{ess\,sup}_{t\to 0^+}\int_0^R\big|u(t,x)-\overline{u}(x)\big|\,dx=0\,. \tag{2.31}$$

(iii) *There holds*

$$\operatorname*{ess\,sup}_{x\to 0^+}\int_0^T\big|w_i\big(u(t,x)\big)-w_i(\widetilde{u}(t))\big|\,dt=0\qquad\forall\ i\in\{n-p+1,\dots,n\}\,. \tag{2.32}$$

Then u coincides with the corresponding trajectory of the flow map E_t, namely,

$$u(t,\cdot) = E_t(\,\overline{u},\,\widetilde{u}\,)(\cdot) \qquad \forall\ 0 \le t \le T. \tag{2.33}$$

A convenient way to prove that the regularity conditions (2.31)–(2.33) are verified is to employ the distributional entropy inequalities associated with the "boundary entropy pairs" for (1.1), as it is shown by Chen and Frid in [15, 16]. A pair of continuously differentiable functions $\alpha : \mathbb{R}^n \times \mathbb{R}^n \mapsto \mathbb{R}$, $\beta : \mathbb{R}^n \times \mathbb{R}^n \mapsto \mathbb{R}$ is called a *boundary entropy pair* for (1.1) if, for any fixed $v \in \mathbb{R}^n$, $u \mapsto \big(\alpha(u,v),\,\beta(u,v)\big)$ is an entropy pair for (1.1) and there holds

$$\alpha(v,v) = \beta(v,v) = \partial_u \alpha(v,v) = 0 \qquad \forall\ v \in \mathbb{R}^n\,.$$

An immediate application of [15, Theorem 4.1] (or of [16, Theorem 1.1]) and of [15, Theorem 4.3] yields the following.

LEMMA 2.5. *Let $u(t,x)$ be an entropy weak solution to the mixed problem* (1.1)–(1.3) *on the region $\Omega_T \doteq [0,\,T] \times \mathbb{R}^+$, in the sense of Definition* 2.2. *Assume that, given any boundary entropy pair $\big(\alpha(u,v),\,\beta(u,v)\big)$ for* (1.1), *there is a constant $M > 0$ (depending only on $(\alpha,\,\beta)$ and on the domain K) such that, for every nonnegative test function $\phi \in \mathcal{C}^1_c(]-\infty, T[\times\mathbb{R}^+)$, and for any $v \in \mathbb{R}^n$, there holds*

$$\begin{aligned} &\int_0^T \int_0^{+\infty} \Big\{\alpha(u(t,x),\,v)\cdot\phi_t(t,x) + \beta(u(t,x),\,v)\cdot\phi_x(t,x)\Big\}\,dx\,dt \\ &\quad + \int_0^{+\infty} \big|\overline{u}(x) - v\big|\cdot\phi(0,x)\,dx + M\int_0^T \big|\widetilde{u}(t) - v\big|\cdot\phi(t,0)\,dt \ge 0\,. \end{aligned} \tag{2.34}$$

Then the essential limits (2.31)–(2.33) *are verified for any $R > 0$.*

Remark 2.6. By [15, Theorem 4.1] it also follows that, if $u(t,x)$ is an entropy weak solution to the mixed problem (1.1)–(1.3) on Ω_T in the sense of Definition 2.2, and if we assume that

(a) given any (standard) entropy pair $(\eta(u),\,q(u))$, for every test function $\phi \in \mathcal{C}^1_c(\overset{\circ}{\Omega}_T)$, $\phi \ge 0$, one has the usual entropy inequality

$$\int_0^T \int_0^{+\infty} \Big\{\eta(u(t,x))\cdot\phi_t(t,x) + q(u(t,x))\cdot\phi_x(t,x)\Big\}\,dx\,dt \ge 0, \tag{2.35}$$

(b) for every $R > 0$ there holds (2.31),

(c) given any boundary entropy pair $\big(\alpha(u,v),\,\beta(u,v)\big)$, for every function $\gamma \in \mathbf{L}^1([0,T])$, $\gamma \ge 0$ a.e., there holds

$$\operatorname*{ess\ sup}_{x\to 0^+} \int_0^T \beta(u(t,x),\,\widetilde{u}(t))\,\gamma(t)\,dt \le 0, \tag{2.36}$$

then the assumptions of Lemma 2.5 are verified, and hence the essential limits (2.33) hold.

2.3. Properties of the attainable sets. Following [4, 5], we now turn to study the mixed initial-boundary value problem (1.1)–(1.3) from the point of view of control theory, taking a fixed initial data $\overline{u} \in \mathbf{L}^1(\mathbb{R}^+, K)$ and considering, in connection with

a prescribed set $\mathcal{U} \subseteq \mathbf{L}^1(\mathbb{R}^+, K)$ of boundary data regarded as admissible controls, the *attainable sets* for (1.1)–(1.3):

(2.37)
$$\mathcal{A}(T, \mathcal{U}) \doteq \Big\{ E_T(\,\overline{u},\, \widetilde{u}\,)(\cdot)\ ;\ \widetilde{u} \in \mathcal{U} \Big\}, \qquad \mathcal{A}(\,\overline{x}, \mathcal{U}) \doteq \Big\{ E_{(\cdot)}(\,\overline{u},\, \widetilde{u}\,)(\overline{x})\ ;\ \widetilde{u} \in \mathcal{U} \Big\},$$

i.e., the sets of all profiles that can be attained at a fixed time $T > 0$, or at a fixed point in space $\overline{x} > 0$, by entropy weak solutions of (1.1)-(1.3) with initial data $\overline{u}$ and boundary data $\widetilde{u}$ that vary in $\mathcal{U}$. Relying on the well-posedness theory provided by the above results, we establish here the compactness of $\mathcal{A}(T, \mathcal{U})$, $\mathcal{A}(\,\overline{x}, \mathcal{U})$ for a class $\mathcal{U}$ of admissible boundary controls that satisfy convex constraints.

THEOREM 2.6. *Let K be a set of the form* (2.5) *and $J \subseteq \{1, \dots, n\}$ a set of indices such that $J \supseteq \{n-p, \dots, n\}$. Define*

(2.38)
$$\mathcal{U} \doteq \Big\{ \widetilde{u} \in \mathbf{L}^1(\mathbb{R}^+, K)\ ;\ w_j(\widetilde{u}(t)) \in [c_j,\ d_j], \qquad \textit{for a.e. } t \geq 0\,, \qquad \forall\ j \in J \Big\}$$

for some $-\infty < c_j \leq d_j < +\infty$, $j \in J$. Then $\mathcal{A}(T, \mathcal{U})$, $T > 0$, and $\mathcal{A}(\,\overline{x},\mathcal{U})$, $\overline{x} > 0$, are compact subsets of $\mathbf{L}^1{}_{loc}(\mathbb{R}^+, K)$.

3. Outline of the proof of Theorem 2.3. We describe here the basic steps in the proof of Theorem 2.3. All the technical estimates involved in the proof will then be worked out in sections 4–6. As in [14] we shall first construct a sequence of flow maps E^ν whose trajectories are front tracking approximate solutions [6, 10] of (1.1) in the region Ω that depend $\mathbf{L}^1$ continuously on the initial and boundary data. Next, for any fixed $\mathcal{M} > 0$, we shall prove the convergence of such a sequence of flow maps to a continuous flow of solutions $\mathbf{p} \mapsto E_t\,\mathbf{p}$, defined on the domain

$$\mathcal{D}_{\mathcal{M}} \doteq \Big\{ \mathbf{p} \in \mathcal{D};\ \text{Tot.Var.}\{\mathbf{p}\} \leq \mathcal{M} \Big\}, \tag{3.1}$$

where, if $\mathbf{p} = (\,\overline{u},\, \widetilde{u}\,)$,

$$\text{Tot.Var.}(\mathbf{p}) \doteq \text{Tot.Var.}(\overline{u}) + \text{Tot.Var.}(\widetilde{u}). \tag{3.2}$$

Finally, we will show that, for every fixed $\delta > 0$, and for any $t \geq \delta$, the map

$$\mathbf{p} \mapsto E_t\,\mathbf{p}\,\restriction_{[\delta, +\infty[}\,, \qquad \mathbf{p} \in \mathcal{D}_{\mathcal{M}} \tag{3.3}$$

is Lipschitz continuous with a Lipschitz constant depending on δ and t but independent of the bound on the total variation $\mathcal{M}$.

We now describe a front tracking algorithm which represents a natural extension of [14]. Fix an integer $\nu \geq 1$ and consider the discrete set of points in K whose coordinates are integer multiples of $2^{-\nu}$:

$$K^\nu \doteq \Big\{ u \in K\,;\ w_i(u) \in 2^{-\nu}\mathbb{Z}, \quad i = 1, \dots, n \Big\}.$$

Moreover, consider the domain

(3.4)
$$\mathcal{D}^\nu \doteq \Big\{ \mathbf{p} = (u, u') : \mathbb{R}^+ \mapsto K^\nu \times K^\nu; \qquad u,\, u' \in \mathbf{L}^1,\ \ u,\, u' \text{ are piecewise constant} \Big\}.$$

On $\mathcal{D}^\nu$ we now construct a flow map E^ν whose trajectories are front tracking approximate solutions of (1.1). To this end, we first describe how to solve a Riemann problem with left and right initial states $u^L, u^R \in K^\nu$. In Riemann coordinates, assume that

$$w(u^L) \doteq w^L = (w_1^L, \dots, w_n^L), \qquad w(u^R) \doteq w^R = (w_1^R, \dots, w_n^R).$$

Consider the intermediate states

$$z^0 = u^L, \quad \dots, \qquad z^i = u(w_1^R, \dots, w_i^R, w_{i+1}^L, \dots, w_n^L), \quad \dots, \quad z^n = u^R. \tag{3.5}$$

If $w_i^R < w_i^L$, the solution will contain a single i shock connecting the states z^{i-1}, z^i, and travelling with Rankine–Hugoniot speed $\lambda_i(z^{i-1}, z^i)$. Here and in what follows, by $\lambda_i(u, u')$ we denote the ith eigenvalue of the averaged matrix

$$A(u, u') \doteq \int_0^1 Df\big(\theta u + (1-\theta)u'\big)\, d\theta. \tag{3.6}$$

If $w_i^R > w_i^L$, the exact solution of the Riemann problem would contain a centered rarefaction wave. This is approximated by a rarefaction fan as follows. If $w_i^R = w_i^L + p_i\, 2^{-\nu}$ we insert the states

$$z^{i,\ell} = (w_1^R, \dots, w_i^L + \ell\, 2^{-\nu}, w_{i+1}^L, \dots, w_n^L), \qquad \ell = 0, \dots, p_i, \tag{3.7}$$

so that $z^{i,0} = z^{i-1}$, $z^{i,p_i} = z^i$. Our front tracking solution will then contain p_i fronts of the ith family, each connecting a couple of states $z^{i,\ell-1}$, $z^{i,\ell}$ and travelling with speed $\lambda_i\big(z^{i,\ell-1},\ z^{i,\ell}\big)$.

For a given pair of piecewise constant initial and boundary data $\mathbf{p} = (\,\overline{u},\, \widetilde{u}\,) \in \mathcal{D}^\nu$, the approximate solution $u(t,\cdot) \doteq E_t^\nu \mathbf{p}$ is now constructed as follows. At time $t = 0$, for $x > 0$ we solve each of the Riemann problems determined by the jumps in $\overline{u}$ according to the above procedure, while at $x = 0$ we construct the solution to the Riemann problem with left and right initial states $u^L = \widetilde{u}(0+)$, $u^R = \overline{u}(0+)$ and take its restriction to the interior of the domain Ω. This yields a piecewise constant function with finitely many fronts travelling with constant speeds. The solution is then prolonged up to the first time t_1 at which one of the following events takes place:

(a) Two or more discontinuities interact in the interior of Ω.
(b) One or more discontinuities hit the boundary.
(c) The boundary data $\widetilde{u}$ has a jump.

If case (a) occurs, then we solve the resulting Riemann problems, again applying the above procedure, while in cases (b)–(c) we construct the solution to the Riemann problem with left and right initial states $u^L = \widetilde{u}(t_1+)$, $u^R = u(t_1, 0+)$ and take its restriction to the interior of the domain Ω. This determines the solution $u(t,\cdot)$ until the time $t_2 > t_1$ where one of the events (a)–(c) again takes place, etc. Notice that at any time where case (b) occurs but (c) does not take place, no new wave is generated. Therefore, wave-fronts entering the domain Ω at the boundary $x = 0$ are produced only by the jumps of the boundary data $\widetilde{u}$.

As in [6] and [14], one checks that these front tracking approximations are well defined for all times $t \geq 0$. Indeed, the following properties hold:

- The total variation of $u(t,\cdot)$, measured w.r.t. the Riemann coordinates $w_1(t,\cdot), \dots, w_n(t,\cdot)$, is nonincreasing in time.
- The number of wave-fronts in $u(t,\cdot)$ is nonincreasing at each interaction. Hence, the total number of wave-fronts in $u(t,\cdot)$ remains finite.

It is now possible to define a ν-approximate semigroup $S^\nu : \mathbb{R}^+ \times \mathcal{D}^\nu \mapsto \mathcal{D}^\nu$ as in (2.24) by setting

$$S^\nu_t \mathbf{p} \doteq \big(E^\nu_t \mathbf{p},\, \mathcal{T}_t \widetilde{u}\big), \qquad \mathbf{p} = (\,\overline{u},\, \widetilde{u}\,). \tag{3.8}$$

The uniqueness of the definition of the approximate solution $u(t,\cdot) = E^\nu_t \mathbf{p}$ guarantees that S^ν_t satisfy the standard semigroup properties, i.e.,

$$S^\nu_0 = \text{Identity}, \qquad S^\nu_t \circ S^\nu_s = S^\nu_{t+s}.$$

Each trajectory $t \mapsto E^\nu_t \mathbf{p}$ is a weak solution of (1.1) (because all fronts satisfy the Rankine–Hugoniot conditions) but may contain discontinuities that do not satisfy the usual Lax stability conditions (because of the presence of rarefaction fronts).

We next proceed towards an estimate of the Lipschitz constant for $\mathbf{p} \mapsto E^\nu_t\, \mathbf{p}\restriction_{[\delta,+\infty[}$, $\delta > 0$, following the same technique adopted in [14]. The basic idea to estimate the distance between two approximate solutions u, v consists of constructing a continuous path of solutions u^θ connecting u, v and then studying how the length of the path $\theta \to u^\theta(t,\cdot)$ varies in time. In particular, given any two couples of initial and boundary data $\mathbf{p}_1 = (\,\overline{u}_1,\, \widetilde{u}_1\,)$, $\mathbf{p}_2 = (\,\overline{u}_2,\, \widetilde{u}_2\,)$ in $\mathcal{D}^\nu$, we introduce a suitable class of continuous paths (pseudopolygonals) that connect $\mathbf{fp}_1 \doteq (\,\overline{u}_1,\, f(\widetilde{u}_1))$ with $\mathbf{fp}_2 \doteq (\,\overline{u}_2,\, f(\widetilde{u}_2))$ by merely shifting the space and time positions of the jumps in $\overline{u}_1$, $\overline{u}_2$ and in $f(\widetilde{u}_1)$, $f(\widetilde{u}_2)$, respectively. More precisely, we consider a *pseudopolygonal* with values in

$$\mathcal{FD}^\nu \doteq \big\{\mathbf{fp} = (u, f(u')); \quad (u,u') \in \mathcal{D}^\nu\big\},$$

that is, a finite concatenation of *elementary paths* $\gamma : \theta \mapsto \big(\,\overline{u}^\theta,\, f(\widetilde{u}^\theta)\big)$ of the form

$$\begin{aligned} &\overline{u}^\theta(x) = \textstyle\sum_{\alpha=1}^N \overline{\omega}_\alpha \cdot \chi_{]x^\theta_{\alpha-1},\, x^\theta_\alpha]}(x), \qquad x^\theta_\alpha = x_\alpha + \xi_\alpha \theta, \quad x \geq 0, \\ &\qquad\qquad\qquad\qquad\qquad\qquad\qquad\qquad\qquad\qquad\qquad\qquad \theta \in [a,b], \\ &f(\widetilde{u}^\theta(t)) = \textstyle\sum_{\beta=1}^{\widetilde{N}} f(\widetilde{\omega}_\beta) \cdot \chi_{]t^\theta_{\beta-1},\, t^\theta_\beta]}(t), \qquad t^\theta_\beta = t_\beta + \widetilde{\xi}_\beta \theta, \quad t \geq 0, \end{aligned} \tag{3.9}$$

with $x^\theta_{\alpha-1} < x^\theta_\alpha$, $t^\theta_{\alpha-1} < t^\theta_\alpha$, for all $\theta \in [a,\, b]$ and $\alpha = 1, \ldots, N$, $\beta = 1, \ldots, \widetilde{N}$. Here, χ_I is the characteristic function of the interval I, while $\overline{\omega}_\alpha$, $\widetilde{\omega}_\beta \in K^\nu$ are constant states and ξ_α, $\widetilde{\xi}_\beta$ are, respectively, the (space) shift rate of the jump in $\overline{u}^\theta$ at x_α and the (time) shift rate of the jump in $f(\widetilde{u}^\theta)$ at t_β. A simple example of a pseudopolygonal joining two couples of initial data and boundary flux $\mathbf{fp}_1 = (\,\overline{u}_1,\ f(\widetilde{u}_1))$, $\mathbf{fp}_2 = (\,\overline{u}_2,\ f(\widetilde{u}_2))$ is given by

$$\theta \mapsto \big(\,\overline{u}_1 \cdot \chi_{[0,\theta[} + \overline{u}_2 \cdot \chi_{]\theta,+\infty[}\,,\ \ f(\widetilde{u}_1) \cdot \chi_{[0,\theta[} + f(\widetilde{u}_2) \cdot \chi_{]\theta,+\infty[}\,\big).$$

The $\mathbf{L}^1$ length of an elementary path γ of the form (3.9) is then computed by

$$\begin{aligned} \|\gamma\|_{\mathbf{L}^1} &= \int_a^b \left\{ \sum_{\alpha=1}^N \big|\Delta\overline{u}^\theta(x_\alpha)\big| \left|\frac{\partial x^\theta_\alpha}{\partial\theta}\right| + \sum_{\beta=1}^{\widetilde{N}} \big|\widetilde{\Delta}\widetilde{u}^\theta(t_\beta)\big| \left|\frac{\partial t^\theta_\beta}{\partial\theta}\right| \right\} d\theta \\ &= \left\{ \sum_{\alpha=1}^N \big|\sigma_\alpha\big|\,|\xi_\alpha| + \sum_{\beta=1}^{\widetilde{N}} \big|\widetilde{\sigma}_\beta\big|\,|\widetilde{\xi}_\beta| \right\} (b-a), \end{aligned} \tag{3.10}$$

where

$$\sigma_\alpha \doteq \Delta\overline{u}^\theta(x_\alpha) = \overline{\omega}_{\alpha+1} - \overline{\omega}_\alpha, \qquad \widetilde{\sigma}_\beta \doteq \widetilde{\Delta}\widetilde{u}^\theta(t_\beta) = f(\widetilde{\omega}_{\beta+1}) - f(\widetilde{\omega}_\beta). \tag{3.11}$$

If we consider a pseudopolygonal $\gamma_0^\nu : \theta \mapsto \big(\overline{u}^\theta,\, f(\widetilde{u}^\theta)\big)$, $\theta \in [0,\,1]$, with values in $\mathcal{FD}^\nu$, and let $u_\nu^\theta(t,\cdot) = E_t^\nu(\,\overline{u}^\theta,\,\widetilde{u}^\theta)$ be the corresponding solution, since the number of wave-fronts in these solutions is a priori bounded and the locations of the interaction points in the t-x plane are determined by a linear system of equations, it follows that, at any time $t > 0$, the path

$$\gamma_t^\nu : \theta \mapsto \big(u_\nu^\theta(t,\cdot),\, f(\widetilde{u}^\theta)\big), \qquad \theta \in [0,\,1], \tag{3.12}$$

is still a pseudopolygonal with values in $\mathcal{FD}^\nu$. Moreover, there exist finitely many parameter values $0 = \theta_0 < \theta_1 < \cdots < \theta_m = 1$ such that the wave-front configuration of u_ν^θ remains the same as θ ranges on each of the open intervals $I_j \doteq]\theta_{j-1}, \theta_j[$. In this case, the length of the path γ_t^ν is measured by an expression of the form

$$\begin{aligned}\|\gamma_t^\nu\|_{\mathbf{L}^1} =& \sum_{j=1}^m \int_{\theta_{j-1}}^{\theta_j} \sum_\alpha \big|\Delta u_\nu^\theta(t,\, x_\alpha^\theta)\big| \left|\frac{\partial x_\alpha^\theta}{\partial\theta}\right| d\theta \\ &+ \sum_{j=1}^m \int_{\theta_{j-1}}^{\theta_j} \sum_\beta \big|\widetilde{\Delta}\widetilde{u}^\theta(t_\beta^\theta)\big| \left|\frac{\partial t_\beta^\theta}{\partial\theta}\right| d\theta\,.\end{aligned} \tag{3.13}$$

Let $\pi_1(\,\overline{u},\, f(\widetilde{u})) = \overline{u}$, $\pi_2(\,\overline{u},\, f(\widetilde{u})) = f(\widetilde{u})$, and denote the canonical projections for any couple $\mathbf{fp} = (\,\overline{u},\, f(\widetilde{u})) \in \mathcal{FD}^\nu$. In connection with any elementary path γ of the form (3.9), define the paths

$$\rho^i_{s_1,s_2}(\gamma) \;:\; \theta \longmapsto \pi_i(\gamma(\theta)) \restriction_{[s_1,\,s_2]}, \qquad s_1,\, s_2 \geq 0\,, \tag{3.14}$$

and introduce the seminorms

$$\big\|\gamma\big\|_{\delta,t_1,t_2} \doteq \big\|\rho^1_{\delta,+\infty}(\gamma)\big\|_{\mathbf{L}^1} + \big\|\rho^2_{t_1,t_2}(\gamma)\big\|_{\mathbf{L}^1}, \qquad \delta,\, t_i \geq 0. \tag{3.15}$$

Since the second term of the sum in (3.13) is constant in time, we have

$$\big\|\gamma_t^\nu\big\|_{\delta,0,t} = \big\|\rho^1_{\delta,+\infty}(\gamma_t^\nu)\big\|_{\mathbf{L}^1} + \big\|\rho^2_{0,t}(\gamma_0^\nu)\big\|_{\mathbf{L}^1} \qquad \forall\; t \geq 0\,. \tag{3.16}$$

Thus, to estimate the $\mathbf{L}^1$ distance between two approximate solutions $E_t^\nu\mathbf{p}_1$, $E_t^\nu\mathbf{p}_2$, we will provide in Lemma 5.1 an a priori bound on the integrand of the first term in (3.13), which represents the infinitesimal length of a generalized tangent vector to the one-parameter family of pairs of solutions and boundary flux (3.12). Relying on this result, we will show in section 6.1 that, for any fixed $\mathcal{M} > 0$, $\delta > 0$, and for any $t \geq \delta$, there exists some constant $L_{\mathcal{M},t} \doteq c_0(1+\mathcal{M})(1+\log(t/\delta)) > 0$ such that there holds

$$\big\|\rho^1_{\delta,+\infty}(\gamma_t^\nu)\big\|_{\mathbf{L}^1} \leq L_{\mathcal{M},t}\cdot\big\|\gamma_0^\nu\big\|_{0,0,t} \qquad \forall\; t \geq \delta \tag{3.17}$$

for every pseudopolygonal $\gamma_0^\nu : [0,\,1] \to \mathcal{FD}^\nu$ joining two couples of initial data and boundary flux in $\{\mathbf{fp};\;\; \mathbf{p} \in D_\mathcal{M} \cap \mathcal{D}^\nu\}$. Hence, defining the pseudometrics

$$\begin{aligned} d_{\delta,t_1,t_2}(\mathbf{p}_1,\mathbf{p}_2) \doteq& \big\|\,\overline{u}_1 - \overline{u}_2\big\|_{\mathbf{L}^1([\delta,\,+\infty[)} + \big\|\,\widetilde{u}_1 - \widetilde{u}_2\,\big\|_{\mathbf{L}^1([t_1,\,t_2])}, \\ &\mathbf{p}_i = (\,\overline{u}_i,\,\widetilde{u}_i\,), \quad \delta,\, t_i \geq 0, \end{aligned} \tag{3.18}$$

and observing that the $\mathbf{L}^1$ lengths of the paths γ_0^ν, γ_t^ν satisfy

$$\|\gamma_0^\nu\|_{0,0,t} \leq C_0\cdot d_{0,0,t}(\mathbf{fp}_1,\,\mathbf{fp}_2), \tag{3.19}$$

$$\big\|E_t^\nu\mathbf{p}_1 - E_t^\nu\mathbf{p}_2\big\|_{\mathbf{L}^1([\delta,+\infty[)} \leq C_0\cdot\|\gamma_t^\nu\|_{\delta,0,t}\,, \tag{3.20}$$

for some constant $C_0 > 0$ (depending only on the domain $\mathcal{D}$), we deduce from (3.16)–(3.17) a uniform Lipschitz estimate for the flow maps $\mathbf{p} \mapsto E^\nu_t\,\mathbf{p}\restriction_{[\delta,+\infty[}$ of the type

$$\big\|E^\nu_t\mathbf{p}_1 - E^\nu_t\mathbf{p}_2\big\|_{\mathbf{L}^1([\delta,+\infty[)} \leq L'_{\mathcal{M},t}\cdot d_{0,0,t}(\mathbf{fp}_1,\,\mathbf{fp}_2) \qquad \forall\ t\geq\delta\,, \tag{3.21}$$

with $L'_{\mathcal{M},t} \doteq c'_0(1+\mathcal{M})(1+\log(t/\delta))$, for some other constant $c'_0 > 0$ independent of ν, and for any $\mathbf{p}_1, \mathbf{p}_2 \in D_{\mathcal{M}} \cap \mathcal{D}^\nu$. As $\nu\to\infty$, the domain $D_{\mathcal{M}}\cap\mathcal{D}^\nu$ become dense in $\mathcal{D}_{\mathcal{M}}$. In the limit, a continuous flow map E_t is obtained in (6.2), defined on the domain $\mathcal{D}_M$ and satisfying the estimate (2.25).

To extend the flow map E_t to the whole domain $\mathcal{D}$ preserving the property (2.25), by similar arguments as above we will prove in section 6.2 the estimate

$$\big\|E_t\mathbf{p}_1 - E_t\mathbf{p}_2\big\|_{\mathbf{L}^1([\delta,+\infty[)} \leq L''_t\cdot d_{0,0,t}(\mathbf{fp}_1,\,\mathbf{fp}_2) \qquad \forall\ t\geq\delta \tag{3.22}$$

with $L''_t \doteq c''_0(1+\log(t/\delta))$ for some other constant $c''_0 > 0$ independent of the total variation, and for any $\mathbf{p}_1, \mathbf{p}_2 \in \mathcal{D}^\mu$, $\mu \geq 1$. Any trajectory $t\mapsto E_t(\mathbf{p})$ of such a map E_t (defined in (6.12)) is defined as the limit of front tracking approximations, and hence provides a weak solution to problem (1.1)–(1.2).

In order to show that the map $(t,x)\mapsto E_t(\,\overline{u},\,\widetilde{u}\,)(x)$ admits a strong $\mathbf{L}^1$ trace at the boundary $x=0$, we next derive a stability estimate for the map $\mathbf{p}\mapsto f\big(E_{(\cdot)}\mathbf{p}(x)\big)$ following the same homotopy and linearization technique adopted above. Namely, we first establish in Lemma 5.2 an a priori bound on a generalized tangent vector to the one-parameter family of pairs of initial data and fluxes

$$\gamma^\nu_x : \theta\mapsto \big(\,\overline{u}^\theta,\, f\big(u^\theta_\nu(\cdot,\,x)\big)\big), \qquad \theta\in[0,\,1], \tag{3.23}$$

evaluated along the vertical segment of the domain Ω. Next, we show in section 6.3 that, for any $\mathbf{p}_1, \mathbf{p}_2 \in \mathcal{D}^\mu,\ \mu\geq 1$, and for every $\tau_2 > \tau_1 > 0$, there holds

$$\begin{aligned}&\big\|f\big(E_{(\cdot)}\mathbf{p}_1(x)\big) - f\big(E_{(\cdot)}\mathbf{p}_2(x)\big)\big\|_{\mathbf{L}^1([\tau_1,\,\tau_2])} \leq L'''\cdot d_{0,0,\tau_2}(\mathbf{fp}_1,\,\mathbf{fp}_2)\\ &\qquad\qquad \forall\ x\in[0,\,(\lambda^{\min}/2)\,\tau_1]\,,\end{aligned} \tag{3.24}$$

where $\lambda^{\min}$ is the lower bound for the absolute value of all characteristic speeds in (2.7), and $L''' \doteq c'''_0(1+\log(\tau_2/\tau_1))$, for some constant $c'''_0 > 0$ independent of μ. By continuity, and relying on the density of the domains $\mathcal{D}^\mu,\ \mu\geq 1$ in $\mathcal{D}$, we then extend the estimate (3.24) to any pair $\mathbf{p}_1,\ \mathbf{p}_2$ in $\mathcal{D}$. Relying on this property, and thanks to the invertibility of the flux f (see Remark 2.1), we prove in section 6.5 the existence of the strong $\mathbf{L}^1$ trace of $E_t\mathbf{p}(x)$ at $x=0$ for any $\mathbf{p}\in\mathcal{D}$. Finally, we show in (6.24) that $E_t\mathbf{p}$ fulfills the boundary condition (2.20), and we prove in section 6.4 that the Oleinik-type estimates (2.15)–(2.18) on the decay of the positive waves are satisfied, thus completing the proof of Theorem 2.3.

4. Preliminary results. Fix $\nu\geq 1$ and consider a piecewise constant solution $u(t,\cdot\,)\doteq E^\nu_t(\,\overline{u},\,\widetilde{u}\,)$ of (1.1) in the region Ω constructed by the front tracking algorithm described in section 3 for some $(\,\overline{u},\,\widetilde{u}\,)\in\mathcal{D}^\nu$. We may perturb this solution by shifting the (space) locations x_α of the jumps in the initial data $\overline{u}$ at rates ξ_α and the (time) locations t_α of the jumps in the boundary data $\widetilde{u}$ entering the interior of the domain Ω at rates $\widetilde{\xi}_\alpha$ (Figure 1). This means that, if we let $x_\beta = x_\beta(t)$ denote the jumps in the unperturbed solution $u(t,\cdot)$, for θ suitably close to zero, the corresponding perturbed solution $u^\theta(t,\cdot)$ will be a function with jumps at the points $x^\theta_\beta = x_\beta + \theta\xi_\beta$. In the same way, $u^\theta(\cdot,x)$ will have jumps at times $t^\theta_\beta = t_\beta - \theta\widetilde{\xi}_\beta$ with $\widetilde{\xi}_\beta = \xi_\beta/\lambda_{k_\beta}$, where $t_\beta = t_\beta(x)$

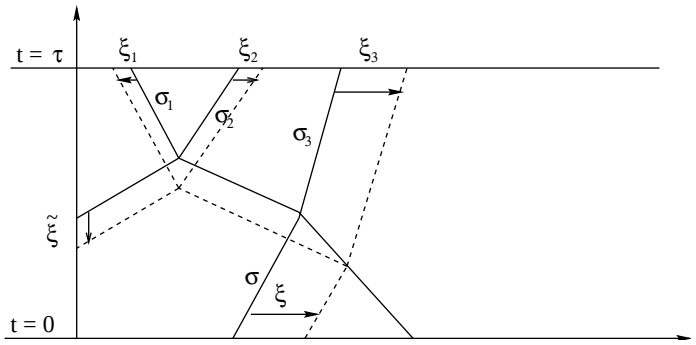

FIG. 1.

denote the locations of all jumps in $u(\cdot, x)$ having nonzero slope λ_{k_β}. As long as the wave-front configuration of the functions u, u^θ is the same, the *space-shifts* $\xi_\beta(t)$ and the *time-shifts* $\widetilde{\xi}_\beta(x)$ are uniquely determined as linear functions of the initial time and space-shifts ξ_α, $\widetilde{\xi}_\alpha$. In this section we collect some basic properties of these *shift differentials* that depend on the special geometric features of Temple class systems and on the fact that the front tracking algorithm described in section 3 guarantees that wave-fronts entering the domain Ω at the boundary $x = 0$ are produced only by the jumps of the boundary data. Such properties can be obtained with entirely similar arguments as for the corresponding results in [14]. Hence, we refer to [14] for most of the proofs of the results presented in this section, limiting ourself to discussing the points that really involve the boundary conditions and to establish in detail the proof of Lemma 4.4 which provides decay estimates on the positive waves of front tracking solutions that are different from the corresponding ones (Lemmas 4 and 5) in [14].

Remark 4.1. We denote by $\sigma_\alpha(t) = u(t, x_\alpha+) - u(t, x_\alpha-)$ the size of a jump in the solution u, occurring at $(t, x_\alpha(t))$, along the space direction (*space-size*) and by $\widetilde{\sigma}_\alpha(x) = f(u(t_\alpha+, x)) - f(u(t_\alpha-, x))$ the size of a jump in the flux $f(u)$ occurring at $(t, x_\alpha(t))$ along the time direction (*time-size*). Since approximate solutions are indeed weak solutions, by the Rankine–Hugoniot equations we have the identity

$$\widetilde{\xi}_\alpha \widetilde{\sigma}_\alpha = \frac{\xi_\alpha}{\lambda_{k_\alpha}} \lambda_{k_\alpha} \sigma_\alpha = \xi_\alpha \sigma_\alpha. \tag{4.1}$$

In the following we will use both notations, depending on convenience.

LEMMA 4.1. *Consider a bounded, open region Γ in Ω. Call σ_α, $\alpha = 1, \dots, M$, the fronts entering Γ and let ξ_α be their space-shifts. Assume that the fronts leaving Γ, say σ_β, $\beta = 1, \dots, M'$, are linearly independent. Then the space-shifts ξ_β of the outgoing fronts are uniquely determined by the linear relation*

$$\sum_{\alpha=1}^{M} \xi_\alpha \sigma_\alpha = \sum_{\beta=1}^{M'} \xi_\beta \sigma_\beta \,. \tag{4.2}$$

A proof of Lemma 4.1, based on an application of the divergence theorem, can be obtained by the same arguments in [14].

Remark 4.2. As observed in [14], according to Lemma 4.1 the shift rates of the outgoing fronts from a given region Γ depend only on the shift rates of the incoming ones and not on the order in which these wave-fronts interact inside Γ. In particular,

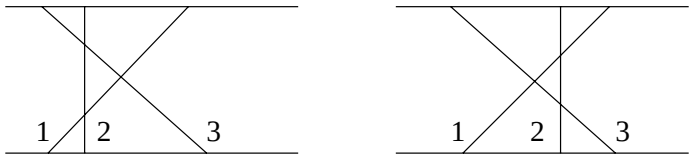

FIG. 2.

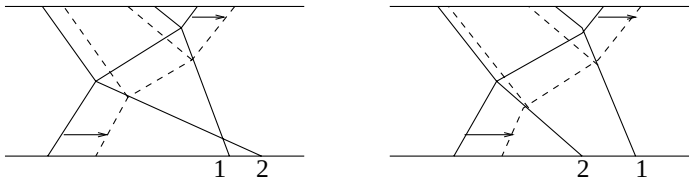

FIG. 3.

one can perform the following two operations, without changing the shift rates of the outgoing fronts:

(O1) Switch the order in which three fronts interact (Figure 2).

(O2) Invert the order of two fronts at $t = 0$ or at $x = 0$, provided that both fronts have zero shift rate (Figure 3).

This property will be used repeatedly in our future estimates. Indeed, in the computation of a shift rate, we can suitably alter the order of wave interactions and thus reduce the problem to a case where the wave-front configuration is particularly simple.

LEMMA 4.2. *Assume that a front tracking solution* $u(t,\cdot) = E^\nu_t(\overline{u}, \widetilde{u})$ *contains two wave-fronts of the same characteristic family, say* $t \mapsto x_{\alpha'}(t)$, $t \mapsto x_{\alpha''}(t)$, *originating at distinct points* $(\tau', \overline{x}')$, $(\tau'', \overline{x}'')$, $\tau' \geq \tau''$, $\overline{x}' \leq \overline{x}''$, *of the boundary of* Ω, *and such that* $x_{\alpha'}(t) \leq x_{\alpha''}(t)$, $t \in [\tau', T]$. *Then it is possible to assign space-shift rates* ξ_α *to all fronts in the initial data* $\overline{u}$ *and in the boundary data* $\widetilde{u}$ *so that the space-shift rate of the front at* $x_{\alpha'}(\tau', \overline{x}')$ *is* $\xi_{\alpha'} = 1$, *and, in the corresponding perturbed solution* u^θ, *all fronts* $x_\beta(t)$ *outside the strip* $\Gamma \doteq \big\{(t,x);\ \ t \in [\tau'', \tau'],\ 0 \leq x \leq x_{\alpha''}(t)\big\} \cup \big\{(t,x);\ \ t \in [\tau',\ T],\ x_{\alpha'}(t) \leq x \leq x_{\alpha''}(t)\big\}$ *have zero shift rate.*

In other words, the perturbation of the initial and boundary data can be chosen so that one particular front shifts at unit rate, but the corresponding solution remains unaffected outside the region Γ (Figure 4). For a proof of the lemma, proceed as in [14].

LEMMA 4.3. *Let* u *be a front tracking solution of* (1.1) *in the region* Ω *and consider two wave-fronts, say* $t \mapsto x(t)$, $t \in [\tau_x, T]$, *and* $t \mapsto y(t)$, $t \in [\tau_y, T]$, *originating at two points* $(\tau_x, \overline{x})$, $(\tau_y, \overline{y})$ *of the boundary of* Ω. *Then there exists a second front tracking solution* $\widehat{u}$ *with two fronts* $t \mapsto \widehat{x}(t)$, $t \in [\tau_x, T]$, $t \mapsto \widehat{y}(t)$, $t \in [\tau_y, T]$, *having the following properties:*

(i) $\widehat{x}(\tau_x) = \overline{x}$, $\widehat{y}(\tau_y) = \overline{y}$, $\widehat{x}(T) = x(T)$, $\widehat{y}(T) = y(T)$.

(ii) $\widehat{u} = u$ *in a neighborhood of these points* $(\tau_x, \overline{x})$, $(\tau_y, \overline{y})$, $(T, x(T))$, $(T, y(T))$.

(iii) *Tot.Var.*$\big\{\big(\widehat{u}(0,\cdot), \widehat{u}(\cdot, 0)\big)\big\} \leq C_1$ *for some constant* C_1 *depending only on the system* (1.1) *and on the set* K.

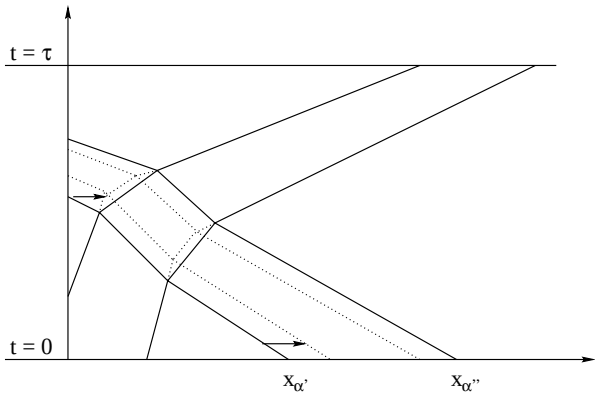

FIG. 4.

Proof. To fix the ideas, assume $\overline{x} = 0$, $\tau_x > 0$, $\overline{y} > 0$, $\tau_y = 0$. Call J_1, J_2, J_3 the three connected components of the set $\big(\{0\}\times\mathbb{R}^+\cup[0,\ T]\times\{0\}\big)\setminus\{(0,\overline{y}\,),\ (\tau_x,0)\}$ and, similarly, let J_1', J_2', J_3', J_4' denote the connected components of the set $\big([0,T]\times\{0\}\cup\{T\}\times\mathbb{R}^+\big)\setminus\{(\tau_x,0),\ (T,x(T)),\ (T,y(T))\}$. Assume that u contains two wave-fronts $t\mapsto z'(t)$, $t\mapsto z''(t)$, of the same kth family and with the same sign, starting at some points ζ_I', ζ_I'' within the same set J_i, and ending at some other points ζ_F', ζ_F'' that lie in the same set J_j'. Then, proceeding as in [14], we may apply Lemma 4.2 and obtain a second front tracking solution u^{θ_1} which has a smaller number of k-fronts than u and coincides with u outside the region bounded by the fronts z', z''. We can repeat this construction as long as the resulting solution contains fronts of the same family and with the same sign, starting at points of the same set J_i and ending within the same set J_j'. In a finite number of steps, we then obtain a new solution $\widehat{u}$ which has the property that, for each $k = 1,\dots,n$, and for any $i = 1,2,3,\quad j = 1,2,3,4$, there exists at most one point $\zeta^0\in J_i$ where a positive k-wave originates, terminating within J_j', and similarly for negative k-waves. This implies that the total variation of $(\widehat{u}(0,\cdot),\,\widehat{u}(\cdot,0)\restriction_{[0,T]})$ is uniformly bounded by a constant C_1 depending only on n and on the diameter of the set K, which completes the proof of the lemma, since we may clearly modify $\widehat{u}(t,\cdot)$ for $t > T$ so that also $\text{Tot.Var.}\big\{\widehat{u}(\cdot,0)\restriction_{[T,+\infty]}\big\}\le C_1$. □

Due to genuine nonlinearity, the amount of positive waves in $u(t,\cdot)$ contained in an interval $[a,\ b]$, measured in Riemann coordinates, decays in time. We have the following result.

LEMMA 4.4. *Consider a front tracking solution $u(t,\cdot) = E_t^{\nu}(\,\overline{u},\,\widetilde{u}\,)$, with $\overline{u}$, $\widetilde{u}$ containing together at most N shock fronts of the kth family. Then there exists some constant C_2 depending only on the system* (1.1) *such that, for each $\tau > 0$, and for every interval $[a,\ b]$, $a > 0$, one has*

$$\text{Tot.Var.}\big\{w_k(\tau,\cdot);\ [a,\ b]\big\}\le 2C_2\frac{b-a}{\tau}+\|w_k\|_{L^\infty}+(N+1)2^{1-\nu} \tag{4.3}$$

for $k = 1,\dots,n-p$,

$$\text{Tot.Var.}\big\{w_k(\tau,\cdot);\ [a,\ b]\big\}\le 2C_2\left\{\frac{b-a}{\tau}+\log\frac{b}{a}\right\}+\|w_k\|_{L^\infty}+(N+1)2^{1-\nu} \tag{4.4}$$

for $k = n-p+1,\dots,n$.

Proof. We give the proof of the statement only for $k \in \{n-p+1, \dots, n\}$, the other case being entirely similar. Relying on Lemma 4.3 and on the uniform strict hyperbolicity assumption (SH1), with the same arguments used in the proof of Lemma 4 in [14] one can show that any two adjacent k-rarefaction fronts $x(t) \leq y(t)$ of u, starting from the boundary $x = 0$, are separated at time $\tau > 0$ by a distance $\geq \kappa(\tau - t_0) \cdot 2^{-\nu}$, where $t_0 \geq 0$ is the beginning time of the rarefaction front $x(t)$, and $\kappa > 0$ denotes some constant depending only on the system. Hence, the distance between rarefaction fronts entering the domain Ω from the boundary $x = 0$ grows at least linearly with the distance from the t-axis. Therefore, the number of rarefaction fronts emanating from the boundary and crossing any interval $[a, b]$, $a > 0$, is bounded by

$$1 + N + \frac{C_2}{2^{-\nu}} \log \frac{b}{a}$$

for some constant $C_2 > 0$ depending on the system (1.1). The positive variation of $w_k(\tau, \cdot)$ on $[a, b]$, i.e., the total amount of upward jumps, thus satisfies

$$\text{Pos.Var.}\big\{w_k(\tau, \cdot);\ [a,\ b]\big\} \leq (1+N)2^{-\nu} + C_2 \cdot \log \frac{b}{a}. \tag{4.5}$$

On the other hand, the same decay estimates in [14, Lemma 5] hold for the waves starting from $t = 0$:

$$\text{Pos.Var.}\big\{w_k(\tau, \cdot);\ [a,\ b]\big\} \leq (1+N)2^{-\nu} + C_2 \cdot \frac{b-a}{\tau}\,. \tag{4.6}$$

In turn, the total variation of $w_k(\tau, \cdot)$ on $[a, b]$ is bounded by $\|w_k\|_{\mathbf{L}^\infty}$ plus twice the positive variation of w_k. Hence (4.3)–(4.4) hold. □

5. Estimates on shift differentials. In this section, relying on the results presented in section 4, we recover the key estimates on shift differentials of paths of approximate solutions. We will use the same technique developed in [14], since we are dealing with front tracking solutions whose wave-fronts emanating from the boundary are produced only by the jumps on the boundary data.

LEMMA 5.1. *Let $u(t, \cdot) = E_t^\nu(\,\overline{u},\, \widetilde{u}\,)$ be a front tracking solution, with $\overline{u}$, $\widetilde{u}$ containing together N shocks. Assume that the fronts of $\overline{u}$ located at x_β (respectively, the fronts of $f(\widetilde{u})$ starting at t_β) are shifted with shift rate ξ_β (respectively, $\widetilde{\xi}_\beta = \xi_\beta/\lambda_{k_\beta}$) and have amplitude σ_β (respectively, $\widetilde{\sigma}_\beta = \lambda_{k_\beta}\,\sigma_\beta$). Then there exists a constant C_3 depending only on the system* (1.1) *and on the domain K such that, for any $\delta > 0$, and for every $\tau \geq \delta$, calling $\xi_\alpha(\tau)$, $\sigma_\alpha(\tau)$ the shift rates and the amplitudes of the fronts in $u(\tau, \cdot)$, we have*

$$\sum_{x_\alpha(\tau) > \delta} \big|\xi_\alpha(\tau)\,\sigma_\alpha(\tau)\big| \leq C_3(1 + N2^{-\nu})(1 + \log(\tau/\delta)) \cdot \left(\sum_\beta \big|\xi_\beta\,\sigma_\beta\big| + \sum_\beta \big|\widetilde{\xi}_\beta\,\widetilde{\sigma}_\beta\big|\right). \tag{5.1}$$

Proof. Assume first that only one single front σ^0 is shifted, starting at time $t = 0$ in the position $x = \overline{x}$ (or leaving the boundary $x = 0$ at time $t = \overline{t}$), say, of the kth family, with shift rate ξ^0. Consider one particular front, say, located at $x_{\alpha^*}(\cdot)$, of the jth family, and call $\overline{y} \doteq x_{\alpha^*}(\tau)$ its terminal point at time τ. We claim that there are

constants C_4, C_5, depending only on the system (1.1) and on the domain K, such that the following properties hold.

(P1) If x_{α^*} is precisely the k-front starting at $\overline{x}$ ($\overline{t}$, respectively), then

$$\left|\xi_{\alpha^*}(\tau)\,\sigma_{\alpha^*}(\tau)\right| \leq C_4|\xi^0\,\sigma^0|. \tag{5.2}$$

(P2) If x_{α^*} is a j-front, with $j \neq k$, and the backward j-characteristics ending at $\overline{y}$ include fronts starting from both sides of $\overline{x}$ ($\overline{t}$, respectively), then (5.2) again holds.

(P3) If x_{α^*} is a j-front, and the j-fronts ending at $\overline{y}$ start all at the same side of $\overline{x}$ ($\overline{t}$, respectively), one then has the sharper estimate

$$\left|\xi_{\alpha^*}(\tau)\right| \leq C_5|\xi^0\,\sigma^0|. \tag{5.3}$$

Properties (P1)–(P2) can be established by the same arguments in [14], with minor changes. Hence, we limit ourselves here to give a proof of (P3). To this end, observe that, besides the fronts starting at $\overline{x}$ (or $\overline{t}$) and the ones ending at $\overline{y}$, one can single out four groups of waves:

(1) the waves starting on the left of $\overline{x}$ (respectively, after $\overline{t}$) and ending on the left of $\overline{y}$;
(2) the waves starting on the right of $\overline{x}$ (respectively, before $\overline{t}$) and ending on the right of $\overline{y}$;
(3) the waves starting on the right of $\overline{x}$ (respectively, before $\overline{t}$) and ending on the left of $\overline{y}$;
(4) the waves starting on the left of $\overline{x}$ (respectively, after $\overline{t}$) and ending on the right of $\overline{y}$.

According to Remark 4.2, in our computation of the shift rate $\xi_{\alpha^*}(\tau)$ of the front reaching $\overline{y}$, it is not restrictive to assume that the sets of waves in (1) and (2) are empty. Indeed, we can otherwise shift the locations of all these fronts of type (1) towards the left, until they all lie outside the domain influenced by the shift at $\overline{x}$. Similarly, fronts of type (2) can be shifted toward the right until they lie completely outside this domain of influence.

Having achieved this simplification, we shall first establish (P3) in the case (Figure 5) where no j-wave ending at $\overline{y}$ crosses the k-wave starting at $\overline{x}$ (or $\overline{t}$). Consider a curve γ running slightly to the right of the minimal backward j-front ending at $\overline{y}$. By

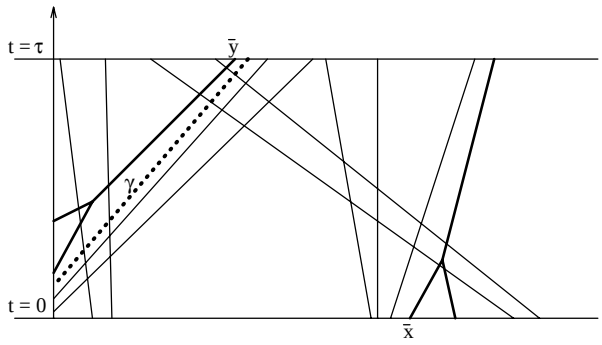

FIG. 5.

Lemmas 4.1 and 4.2, after performing the operations (O1)–(O2) a number of times, we can consider an equivalent configuration with the following properties:

- No front crosses γ from left to right.
- There exists some index $\ell \leq j$ such that only fronts of families $i < \ell$ can cross γ from right to left, and we can assume that the waves of type (1) have zero shift rate at every time in the interval $[0,\ \tau]$.

Applying Remark 4.2 to the region on the right of γ we obtain

$$\sum_{\alpha\in C(\gamma)} \xi_\alpha\,\sigma_\alpha + \sum_{x_\alpha(\tau)>\gamma(\tau)} \xi_\alpha(\tau)\,\sigma_\alpha(\tau) = \xi^0\,\sigma^0. \tag{5.4}$$

Here the first summation extends to all fronts crossing the curve γ with nonzero shift rate. Call u^L and u^R the left and right states across the jump at $\overline{y}$. Observing that the two sums on the left-hand side of (5.4) are contained in

$$\text{span}\big\{r_1(u^R),\dots,r_{\ell-1}(u^R)\big\},\qquad \text{span}\big\{r_\ell(u^R),\dots,r_n(u^R)\big\}, \tag{5.5}$$

using the strict hyperbolicity condition (SH2), we conclude that

$$\left|\sum_{\alpha\in C(\gamma)} \xi_\alpha\sigma_\alpha\right| \leq C'\left|\xi^0\,\sigma^0\right| \tag{5.6}$$

for some constant C', depending only on the system (1.1). We now again apply Remark 4.2 to the region on the left of γ. Observing that the only incoming fronts which carry a nonzero shift rate are those crossing γ from right to left, and that the only outgoing shifted j-front is the one ending at $\overline{y}$, we obtain

$$\sum_{x_\alpha(\tau)<\overline{y}} \xi_\alpha\sigma_\alpha + \xi_{\alpha^*}(\tau)\sigma_{\alpha^*}(\tau) = \sum_{\alpha\in C(\gamma)} \xi_\alpha\sigma_\alpha. \tag{5.7}$$

Recalling the normalization at (2.1), we observe that (5.7) implies

$$\big|\xi_{\alpha^*}(\tau)\sigma_{\alpha^*}(\tau)\big| = l_j(u^L)\cdot\sum_{\alpha\in C(\gamma)} \xi_\alpha\sigma_\alpha. \tag{5.8}$$

On the other hand, one has

$$l_j(u^R)\cdot\sum_{\alpha\in C(\gamma)} \xi_\alpha\sigma_\alpha = 0. \tag{5.9}$$

Together, (5.6), (5.8) and (5.9) imply

$$\big|\xi_{\alpha^*}(\tau)\sigma_{\alpha^*}(\tau)\big| \leq \big|l_j(u^R)-l_j(u^L)\big|\left|\sum_{\alpha\in C(\gamma)} \xi_\alpha\sigma_\alpha\right| \leq C_5\big|\sigma_{\alpha^*}(\tau)\big|\big|\xi^0\,\sigma^0\big| \tag{5.10}$$

for some other constant C_5 depending only on the system (1.1), proving (5.3).

We next establish (P3) in the case where $k > j$ and all j-waves running into $\overline{y}$ cross the k-wave starting from $\bar{t}$, as in Figure 6. In this case, we construct a curve γ slightly to the left of the maximal backward j-front ending at $\overline{y}$. Observe that every wave-front crossing γ from left to right must be of a family $i > j$. Moreover, we can

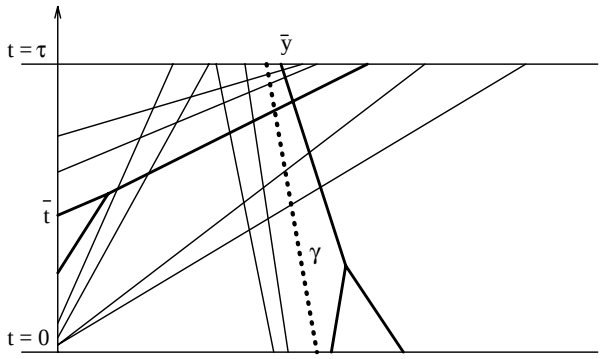

FIG. 6.

assume that no wave crosses γ from right to left. Applying Remark 4.2 to the region on the left of γ we obtain

$$\sum_{\alpha\in C(\gamma)} \xi_\alpha\,\sigma_\alpha + \sum_{x_\alpha(\tau)<\gamma(\tau)} \xi_\alpha(\tau)\,\sigma_\alpha(\tau) = \xi^0\,\sigma^0. \tag{5.11}$$

Since the waves crossing γ must belong to different families from the ones ending inside the interval $[0,\ \gamma(\tau)]$ (recall that interacting waves of the same family produce a single wave-front), (5.11) implies

$$\left|\sum_{\alpha\in C(\gamma)} \xi_\alpha\,\sigma_\alpha\right| \le C''\,|\xi^0\,\sigma^0| \tag{5.12}$$

for some constant C'' depending only on the system (1.1). We now again apply Remark 4.2 to the region on the right of γ, observing that the set of outgoing fronts, crossing the line $t=\tau$, contains the j-front at $\overline{y}$ plus other fronts on the right of $\overline{y}$ of families $i>j$. This yields

$$\xi_{\alpha^*}(\tau)\,\sigma_{\alpha^*}(\tau) + \sum_{x_\alpha(\tau)>\overline{y}} \xi_\alpha(\tau)\,\sigma_\alpha(\tau) = \sum_{\alpha\in C(\gamma)} \xi_\alpha\,\sigma_\alpha \tag{5.13}$$

which, in turn, implies

$$\left|\xi_{\alpha^*}(\tau)\,\sigma_{\alpha^*}(\tau)\right| = l_j(u^R)\cdot \sum_{\alpha\in C(\gamma)} \xi_\alpha\,\sigma_\alpha. \tag{5.14}$$

Observing that

$$l_j(u^L)\cdot \sum_{\alpha\in C(\gamma)} \xi_\alpha\,\sigma_\alpha = 0,$$

we again obtain an estimate of the form (5.10), and hence **(P3)** holds. The other cases are similar or easier.

We now complete the proof of Lemma 5.1. If we assume that only one single front is shifted leaving the boundary $x=0$, say, starting at time $t=\overline{t}$ (or starting at time $t=0$ and located at $x=\overline{x}$), it follows that at a fixed time $\tau>0$ the only fronts with nonzero shift rate can be the ones located inside the interval $[a_0,\ b_0] \doteq [0,\ \lambda^{\max}\cdot(\tau-\overline{t})]$

(or inside the interval $[a_0,\, b_0] \doteq [\max\{0, \overline{x}-\lambda^{\max}\cdot\tau\},\, \overline{x}+\lambda^{\max}\cdot\tau]$), where $\lambda^{\max}$ denotes the upper bound for the absolute value of all characteristic speeds in (2.7). Recalling the estimate (4.3)–(4.4) on the total variation, and using the properties (P1)–(P3), we thus have

$$\begin{aligned}\sum_{x_\alpha(\tau)>\delta} \big|\xi_\alpha(\tau)\,\sigma_\alpha(\tau)\big| &\leq n\,C_4|\xi^0\,\sigma^0| + C_5\big|\xi^0\,\sigma^0\big|\cdot \text{Tot.Var.}\big\{u(\tau)\,;\ [\delta,\ b_0]\big\}\\ &\leq C_3(1+N2^{-\nu})(1+\log(\tau/\delta))\big|\xi^0\,\sigma^0\big|\,,\end{aligned}\tag{5.15}$$

for a suitable constant C_3 depending only on the system (1.1), proving (5.2). Finally, we consider the case where all fronts in $\overline{u}$, $\tilde{u}$ are shifted. More precisely, let $\xi_\alpha(0)$ be the shift rate of the front located at $x_\alpha(0)$ ($t_\alpha(0)$, respectively), having amplitude $\sigma_\alpha(0)$. Call $\xi_\beta(\tau)$ the corresponding shift rate of the front of $u(\tau,\cdot)$ located at $x_\beta(\tau)$. Observing that the shift differential

$$\big(\xi_1(0),\dots\xi_M(0)\big)\mapsto\big(\xi_1(\tau),\dots\xi_{M'}(\tau)\big)$$

is a linear mapping, the estimate (5.2) follows easily from (5.15). □

In order to show that the trajectories of the flow map E_t that we shall construct in section 6 provide solutions with a strong $\mathbf{L}^1$ trace at the boundary $x=0$, we will make use of the following estimates on shift differentials of paths of approximate solutions along vertical segments of the domain Ω.

LEMMA 5.2. *Let $u(t,x)=E^\nu_t(\,\overline{u},\,\widetilde{u}\,)(x)$ be a front tracking solution containing at most N shocks. Assume that the fronts of $\overline{u}$ located at x_β (respectively, the fronts of $f(\widetilde{u})$ entering the interior of the domain Ω and starting at t_β) are shifted with shift rate ξ_β (respectively, $\widetilde{\xi}_\beta=\xi_\beta/\lambda_{k_\beta}$) and have amplitude σ_β (respectively, $\widetilde{\sigma}_\beta=\lambda_{k_\beta}\,\sigma_\beta$). Then there exists some constant C_6 depending only on the system* (1.1) *and on the domain K such that, for any $\tau_2>\tau_1>0$, and for every $0<\rho<(\lambda^{\min}/2)\,\tau_1$, denoting with $\widetilde{\xi}_\alpha(\rho)$, $\widetilde{\sigma}_\alpha(\rho)$ the time-shift rates and the time-sizes of the fronts in $f(u(\cdot,\rho\,))$ crossing the line $\{(t,\rho)\ ;\ t\geq 0\}$ at time $t_\alpha(\rho)$, there holds*

$$\sum_{t_\alpha(\rho)\in[\tau_1,\ \tau_2]}\big|\widetilde{\xi}_\alpha(\rho)\,\widetilde{\sigma}_\alpha(\rho)\big|\leq C_6(1+N2^{-\nu})(1+\log(\tau_2/\tau_1))\cdot\left(\sum_\beta\big|\xi_\beta\,\sigma_\beta\big|+\sum_\beta\big|\widetilde{\xi}_\beta\,\widetilde{\sigma}_\beta\big|\right).\tag{5.16}$$

Proof. We give here only a sketch of the proof, since it is quite similar to the one of Lemma 5.1. The estimates (P1)–(P3) can be recovered with minor modifications. As an example, we establish the estimate (P3) for a front belonging to a family $j\in\{1,\dots n-p\}$, say, (time)-located at $t_{\alpha^*}(\cdot)$, that starts at time $t=0$ and crosses the segment $\{(t,\rho);\ t\in[\tau_1,\ \tau_2]\}$ at $\overline{s}=t_{\alpha^*}(\rho)$. Assume that only a single front of (time)-size $\widetilde{\sigma}^0$ is shifted, leaving the boundary $x=0$ at time $t=\overline{t}$, say, of the family $k\in\{n-p+1,\dots,n\}$, with (time)-shift $\widetilde{\xi}^0$, and no other front of the boundary data $\widetilde{u}$ or of the initial data $\overline{u}$ is shifted. After performing the usual simplifications, we reduce to the situation illustrated in Figure 7. Consider the straight line $t=\overline{s}$ and a curve γ running slightly to the left of the maximal backward j-front passing through $(\,\overline{s},\rho)$. Applying the divergence theorem to the region on the left of γ, and using (4.1), we obtain

$$\widetilde{\xi}^0\,\widetilde{\sigma}^0=\xi^0\,\sigma^0=\sum_{\alpha\in C(\gamma)}\xi_\alpha\,\sigma_\alpha+\sum_{x_\alpha(\overline{s})<\gamma(\overline{s})}\xi_\alpha(\overline{s})\,\sigma_\alpha(\overline{s}).\tag{5.17}$$

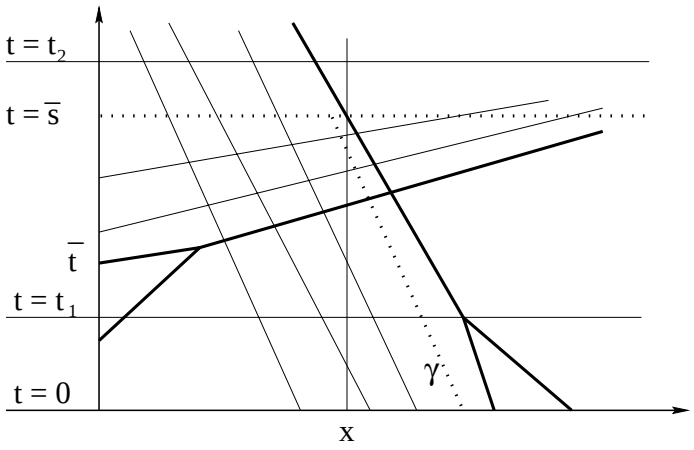

FIG. 7.

By linear independence of the vectors on the right-hand side of (5.17) we derive

$$\left| \sum_{\alpha\in C(\gamma)} \xi_\alpha\,\sigma_\alpha \right| \le C'''\,\big|\widetilde{\xi}^0\,\widetilde{\sigma}^0\big| \tag{5.18}$$

for some constant C''' depending only on the system (1.1). Next, we consider the region on the right of γ, where we compute

$$\sum_{\alpha\in C(\gamma)} \xi_\alpha\,\sigma_\alpha = \widetilde{\xi}_{\alpha^*}(\rho)\,\widetilde{\sigma}_{\alpha^*}(\rho) + \sum_{x_\alpha(\overline{s})>\rho} \xi_\alpha(\overline{s})\,\sigma_\alpha(\overline{s}). \tag{5.19}$$

From (5.18)–(5.19), and because of (2.1), (2.7), letting u^L, u^R denote as usual the left and right states across the jump at $(\overline{s},\rho)$, we obtain

$$\begin{aligned}\big|\widetilde{\xi}_{\alpha^*}(\rho)\,\widetilde{\sigma}_{\alpha^*}(\rho)\big| &= \left| l_j(u^R)\cdot \sum_{\alpha\in C(\gamma)} \xi_\alpha\,\sigma_\alpha \right| \\ &\le \big|l_j(u^R)-l_j(u^L)\big| \left| \sum_{\alpha\in C(\gamma)} \xi_\alpha\,\sigma_\alpha \right| \le \frac{C'^v}{\lambda^{\min}}\,\big|\widetilde{\sigma}_{\alpha^*}(\rho)\big|\big|\widetilde{\xi}^0\,\widetilde{\sigma}^0\big|\,,\end{aligned}$$

for some other constant C'^v depending only on the system (1.1), and we recover (P3).

Therefore, in the case where at the boundary $x=0$ only a single front is shifted, say, starting at time $t=\overline{t}$, observing that the only fronts of the last p characteristic families with nonzero shift rate along a fixed line $\{(t,\rho)\ ;\ t\ge 0\}$ can be the ones located inside the (time)-interval $[s_0,t_0]\doteq[\overline{t}+(\rho/\lambda^{\max}),\,\overline{t}+(\rho/\lambda^{\min})]$, one derives (5.17) relying on the properties (P1)–(P3) and using similar estimates on the total variation as the ones in (4.3)–(4.4). Namely, there will be some positive constant depending only on the system (1.1) that we may call C_2 as the one in (4.3)–(4.4) such that, for every $x>0$, and for any $t>s>0$, there holds

$$\text{Tot.Var.}\big\{w_k(\cdot,x);\ [s,\,t]\big\} \le 2C_2\cdot\log\frac{t}{s} + \|w_k\|_{L^\infty} + (N+1)2^{1-\nu} \tag{5.20}$$

for $k = 1, \dots, n-p$,

$$\text{(5.21)}\quad \text{Tot.Var.}\big\{w_k(\cdot, x);\ [s,\, t]\big\} \leq 2C_2\left\{\frac{t-s}{x} + \log\frac{t}{s}\right\} + \|w_k\|_{L^\infty} + (N+1)2^{1-\nu}$$

for $k = n-p+1, \dots, n$. The proof of the estimates (5.20)–(5.21) is entirely similar to the one of Lemma 4.4. With the same arguments we obtain (5.17) in the case where we assume that a single front is shifted at time $t = 0$ and located at $x = \overline{x}$, observing that, if $\rho > \overline{x}$, the fronts of the first p families with nonzero shift rate along the line $\{(t, \rho)\ ;\ t \geq 0\}$ are located inside the (time)-interval $[s_0, t_0] \doteq [0,\, \rho/\lambda^{\min}]$, while if $\rho < \overline{x}$, such fronts are the ones that interact on the left of $x = \rho$ with the front starting at $x = \overline{x}$, and hence their total strength is at most

$$\log\ \frac{\tau_2}{\tau_1 - \rho/\lambda^{\min}} \leq \log\ \frac{2\,\tau_2}{\tau_1}\,.$$

Finally, the general case where all fronts in $\overline{u}$ and in $\widetilde{u}$ are shifted is treated as in Lemma 5.1. □

Remark 5.1. If we perturb a front tracking solution $u(t, \cdot) \doteq E^\nu_t(\,\overline{u},\, \widetilde{u}\,)$ by shifting only the (time) locations of the jumps in the boundary data $\widetilde{u}$, with the same arguments of the proof of Lemma 5.2, one can show that the stability estimate (5.17) holds with a Lipschitz constant that is independent of τ_1, τ_2. Namely, in the same setting of Lemma 5.2, assuming that the fronts of $f(\widetilde{u})$, with (time)-size $\widetilde{\sigma}_\beta = \lambda_{k_\beta}\,\sigma_\beta$, are shifted with (time)-shift rate $\widetilde{\xi}_\beta = \xi_\beta/\lambda_{k_\beta}$, the following holds. There exists some constant (depending only on the system (1.1) and on the domain K) that we still call C_6 such that, for any fixed $\delta > 0$, and for every $0 < \rho < \lambda^{\min}\delta$, $\tau > \delta$, letting $\widetilde{\xi}_\alpha(\rho)$, $\widetilde{\sigma}_\alpha(\rho)$ be the time-shift rates and the time-sizes of the fronts in $f(u(\cdot, \rho\,))$ crossing the line $\{(t, \rho)\ ;\ t \geq 0\}$ at time $t_\alpha(\rho)$, there holds

$$\text{(5.22)}\qquad \sum_{t_\alpha(\rho)\in[\delta,\ \tau]} \big|\widetilde{\xi}_\alpha(\rho)\,\widetilde{\sigma}_\alpha(\rho)\big| \leq C_6(1 + N2^{-\nu}) \cdot \sum_\beta \big|\widetilde{\xi}_\beta\,\widetilde{\sigma}_\beta\big|.$$

6. Proof of Theorems 2.3 and 2.4.

6.1. Existence of the semigroup on domains of BV functions. In order to construct the semigroup described in Theorem 2.3, we shall first define an $\mathbf{L}^1$ continuous flow map E_t on every domain

$$\mathcal{D}_{\mathcal{M}} \doteq \Big\{\mathbf{p} \in \mathcal{D};\quad \text{Tot.Var.}\{\mathbf{p}\} \leq \mathcal{M}\Big\}, \qquad\qquad \mathcal{M} > 0,$$

obtained as a limit of the approximate flow maps E^ν_t constructed in section 3 on the domains $\mathcal{D}^\nu$. To this end, consider any two piecewise constant couples of initial and boundary data, say $\mathbf{p}_1,\ \mathbf{p}_2 \in \mathcal{D}_{\mathcal{M}} \cap \mathcal{D}^\nu$, and construct a pseudopolygonal path $\gamma^\nu_0 : \theta \mapsto \mathbf{fp}^\theta = (\,\overline{u}^\theta,\, f(\widetilde{u}^\theta))$ connecting $\mathbf{fp}_1$ with $\mathbf{fp}_2$ as described in section 3. All functions $(\,\overline{u}^\theta,\, \widetilde{u}^\theta\,)$ lie in $\mathcal{D}_{\mathcal{M}} \cap \mathcal{D}^\nu$ and have a uniformly bounded number of shocks, say $\leq N$. Call $u^\theta_\nu(t, \cdot) = E^\nu_t(\,\overline{u}^\theta,\, \widetilde{u}^\theta\,)$ the corresponding solution and consider the path $\gamma^\nu_t : \theta \mapsto \big(u^\theta_\nu(t, \cdot),\, f(\widetilde{u}^\theta)\big)$. Writing the length of this path in the form (3.13),

and using Lemma 5.1, for any fixed $\delta > 0$, and for every $t \geq \delta$, we obtain the estimate

$$\begin{aligned}
\big\|\rho^1_{\delta,+\infty}(\gamma^\nu_t)\big\|_{\mathbf{L}^1} &= \sum_{j=1}^m \int_{\theta_{j-1}}^{\theta_j} \sum_{\{\alpha\,:\,x^\theta_\alpha>\delta\}} \big|\Delta u^\theta_\nu(t,x^\theta_\alpha)\big|\left|\frac{\partial x^\theta_\alpha(t)}{\partial\theta}\right| d\theta \\
&\leq \sum_{j=1}^m \int_{\theta_{j-1}}^{\theta_j} C_3(1+N2^{-\nu})(1+\log(t/\delta)) \\
&\quad\cdot\left(\sum_\beta \big|\Delta u^\theta_\nu(0,x^\theta_\beta)\big|\left|\frac{\partial x^\theta_\beta(0)}{\partial\theta}\right| + \sum_{\{\beta'\,:\,t^\theta_{\beta'}<t\}} \big|\widetilde{\Delta} u^\theta_\nu(t^\theta_{\beta'},0)\big|\left|\frac{\partial t^\theta_{\beta'}(0)}{\partial\theta}\right|\right) d\theta \\
&\leq C_3(1+N2^{-\nu})(1+\log(t/\delta))\cdot\big\|\gamma^\nu_0\big\|_{0.0,t}\,, \qquad (6.1)
\end{aligned}$$

where $\rho^1_{\delta,+\infty}$ and $\|\cdot\|_{0,0,t}$ denote the restriction map and the seminorm introduced at (3.14)–(3.15). Observing that any function in $\mathcal{D}_\mathcal{M}\cap\mathcal{D}^\nu$ has at most $2^\nu\mathcal{M}$ jumps, from (6.1) we derive (3.17) with $L_{\mathcal{M},t} = C_3(1+\mathcal{M})(1+\log(t/\delta))$, which, in turn, because of (3.19)–(3.20), clearly implies (3.21).

Once we have established the uniform Lipschitz continuity of the maps $\mathbf{p}\mapsto E^\nu_t\,\mathbf{p}\restriction_{[\delta,+\infty[}$, on the domains $\mathcal{D}_\mathcal{M}\cap\mathcal{D}^\nu$, since the union $\cup_{\nu\geq1}\mathcal{D}_\mathcal{M}\cap\mathcal{D}^\nu$ is dense in $\mathcal{D}_\mathcal{M}$, we will define the map E_t on $\mathcal{D}_\mathcal{M}$ as the limit

$$E_t(\mathbf{p}) \doteq \mathbf{L}^1 - \lim_{\nu\to\infty} E^\nu_t(\mathbf{p}^\nu), \qquad \mathbf{p}^\nu\in\mathcal{D}_\mathcal{M}\cap\mathcal{D}^\nu,\ \mathbf{p}^\nu\to\mathbf{p}\text{ in }\mathbf{L}^1\,. \qquad (6.2)$$

In order to prove that the assignment (6.2) yields a well-defined map, since any sequence $E^\nu_t\mathbf{p}^\nu$ is uniformly bounded in $\mathbf{L}^\infty$, it is sufficient to show that, for every given $\mathbf{p}\in\mathcal{D}_\mathcal{M}$, and for any $\delta>0$, if $\mathbf{p}^\nu\in\mathcal{D}_\mathcal{M}\cap\mathcal{D}^\nu$ is any sequence that converges to $\mathbf{p}$ in $\mathbf{L}^1$, then the sequence $E^\nu_t\mathbf{p}^\nu\restriction_{[\delta,+\infty[}$ is Cauchy in $\mathbf{L}^1$. Indeed, for any $\mu>\nu$, using (3.21) (possibly with a different constant $L'_{\mathcal{M},t}$), we obtain

$$\begin{aligned}
\big\|E^\mu_t\mathbf{p}^\mu - E^\nu_t\mathbf{p}^\nu\big\|_{\mathbf{L}^1([\delta,+\infty[)} &\leq \big\|E^\mu_t\mathbf{p}^\mu - E^\mu_t\mathbf{p}^\nu\big\|_{\mathbf{L}^1([\delta,+\infty[)} + \big\|E^\mu_t\mathbf{p}^\nu - E^\nu_t\mathbf{p}^\nu\big\|_{\mathbf{L}^1([\delta,+\infty[)} \\
&\leq L'_{\mathcal{M},t}\cdot d_{0,0,t}(\mathbf{p}^\mu,\,\mathbf{p}^\nu) + d_{\delta,0,\infty}\big(S^\mu_t\mathbf{p}^\nu,\,S^\nu_t\mathbf{p}^\nu\big), \qquad (6.3)
\end{aligned}$$

where $d_{\delta,0,\infty}$ denotes the pseudometric defined as in (3.18). To estimate the second term in (6.3), we shall use the same type of error estimate established in [11, Theorem 2.9] for the distance between a Lipschitz continuous map and the trajectory of a Lipschitz continuous semigroup which can be restated as follows.

LEMMA 6.1. *Let $(B,\,d_B)$ be a metric space, let $d_{B'}$ be a pseudometric on B, and let $\mathcal{D}$ be a closed subset of B. Let $S:\mathcal{D}\times[0,\,T]\mapsto\mathcal{D}$ be a continuous semigroup and $\Gamma:[0,\,T]\mapsto\mathcal{D}$ a continuous map that satisfy*

$$d_{B'}\big(S_t\mathbf{p}_1,\,S_s\mathbf{p}_2\big)\leq L\cdot\big\{d_B(\mathbf{p}_1,\,\mathbf{p}_2)+|t-s|\big\}, \qquad (6.4)$$

$$d_B\big(\Gamma(t),\,\Gamma(s)\big)\leq L\cdot|t-s| \qquad (6.5)$$

for some constant $L>0$. Then, for any $\tau\in[0,\,T]$, one has the estimate

$$d_{B'}\big(\Gamma(\tau),\,S_\tau\Gamma(0)\big)\leq L\cdot\int_0^\tau\left\{\liminf_{h\to0+}\ \frac{d_{B'}\big(\Gamma(t+h),\,S_h\Gamma(t)\big)}{h}\right\}\,dt. \qquad (6.6)$$

Let B be the metric space $\mathbf{L}^1(\mathbb{R}^+, K) \times \mathbf{L}^1(\mathbb{R}^+, K)$ equipped with the usual $\mathbf{L}^1$ distance, and set

$$d_{B'} \doteq d_{\delta,0,\infty}, \qquad \mathcal{D} \doteq \mathcal{D}_{\mathcal{M}} \cap \mathcal{D}^\mu\,.$$

Observe that, if we let $S \doteq S^\mu$ be the approximate semigroup defined in (3.8), and $\Gamma : [0, T] \to \mathcal{D}_{\mathcal{M}} \cap \mathcal{D}^\nu \subset \mathcal{D}_{\mathcal{M}} \cap \mathcal{D}^\mu$ be the map $\Gamma(t) = S^\nu_t \mathbf{p}^\nu$, then the Lipschitz continuity (3.21) of $\mathbf{p} \mapsto E^\nu_t\, \mathbf{p}\,\restriction_{[\delta,+\infty[}$, together with the uniform bound on the total variation of $t \mapsto E^\nu_t \mathbf{p},\ \mathbf{p} \in \mathcal{D}_{\mathcal{M}} \cap \mathcal{D}^\nu,\ \ t \mapsto E^\mu_t \mathbf{p},\ \mathbf{p} \in \mathcal{D}_{\mathcal{M}} \cap \mathcal{D}^\mu$, clearly implies the estimates (6.4)–(6.5). Thus, we may apply Lemma 6.1 and, from (6.3), (6.6), we derive

$$\begin{aligned}\left\|E^\mu_t \mathbf{p}^\mu - E^\nu_t \mathbf{p}^\nu\right\|_{\mathbf{L}^1([\delta,+\infty[)} &\leq L'_{\mathcal{M},t} \cdot d_{0,0,t}(\mathbf{p}^\mu,\, \mathbf{p}^\nu)\\ &\quad + L \cdot \int_0^t \left\{ \liminf_{h\to 0+} \frac{d_{\delta,0,\infty}\big(S^\nu_{s+h}\, \mathbf{p}^\nu,\ S^\mu_h S^\nu_s \mathbf{p}^\nu\big)}{h} \right\} ds. \end{aligned} \tag{6.7}$$

With the same arguments in [6], letting $\mathbf{q} \doteq S^\nu_s \mathbf{p}^\nu$, we can now estimate the integrand in (6.7) by

$$\frac{1}{h}\, d_{\delta,0,\infty}\big(S^\nu_h\, \mathbf{q},\ S^\mu_h \mathbf{q}\big) = \frac{1}{h}\left\|E^\nu_h\, \mathbf{q} - E^\mu_h \mathbf{q}\right\|_{\mathbf{L}^1([\delta,+\infty[)} \leq C_7 \cdot 2^{-\nu} \mathcal{M} \tag{6.8}$$

for some constant $C_7 > 0$. Hence, (6.7) together with (6.8) yields

$$\left\|E^\mu_t \mathbf{p}^\mu - E^\nu_t \mathbf{p}^\nu\right\|_{\mathbf{L}^1([\delta,+\infty[)} \leq L'_{\mathcal{M},t} \cdot d_{0,0,t}(\mathbf{p}^\mu,\, \mathbf{p}^\nu) + LC_7 \mathcal{M} \cdot 2^{-\nu} t, \tag{6.9}$$

which clearly shows that $E^\nu_t \mathbf{p}^\nu\,\restriction_{[\delta,+\infty[}$ is a Cauchy sequence in the $\mathbf{L}^1$ norm and that this limit does not depend on the choice of the sequence $\mathbf{p}^\nu$. Thus, the map in (6.2) is well defined on every domain $\mathcal{D}_{\mathcal{M}}$ and, passing to the limit in (3.21), we obtain the estimate (2.25) for any couples of initial and boundary data $\mathbf{p}_i = (\,\overline{u}_i,\, \widetilde{u}_i\,) \in D_{\mathcal{M}},\ i = 1, 2$.

6.2. Extension of the semigroup to domains of $\mathbf{L}^\infty$ functions. To ensure the existence of the map E_t on the whole domain $\mathcal{D}$ of functions of possibly unbounded variation, we will now prove the estimate (3.22) for some constant $L''_t > 0$ independent of the total variation. To this purpose, consider any two couples $\mathbf{p}_1,\ \mathbf{p}_2 \in \mathcal{D}^\mu$, and construct as above a pseudopolygonal path $\gamma_0 : \theta \mapsto \mathbf{fp}^\theta = (\overline{u}^\theta,\, f(\widetilde{u}^\theta))$ taking values in $\mathcal{F}\mathcal{D}^\mu$ that connects $\mathbf{fp}_1$ with $\mathbf{fp}_2$ and has the following property. All functions $(\,\overline{u}^\theta,\, \widetilde{u}^\theta\,)$ have a uniformly bounded number of jumps and hence lie in some domain $\mathcal{D}_{\mathcal{M}},\ \mathcal{M} > 0$. Then, calling $u^\theta_\nu(t,\cdot) = E^\nu_t(\,\overline{u}^\theta,\, \widetilde{u}^\theta\,)$ the corresponding ν-approximate solution, since by (6.2) we have

$$E_t(\,\overline{u}^\theta,\, \widetilde{u}^\theta\,) = \lim_{\nu\to\infty} E^\nu_t(\,\overline{u}^\theta,\, \widetilde{u}^\theta\,) = \lim_{\nu\to\infty} u^\theta_\nu(t,\cdot), \tag{6.10}$$

in order to establish (3.22) we will show that the length of the path $\gamma^\nu_t : \theta \mapsto \big(u^\theta_\nu(t,\cdot),\, f(\widetilde{u}^\theta)\big)$ remains a bounded multiple of the length of γ_0, independent of ν. Indeed, for any fixed $\delta > 0$, and for every $\nu \geq \mu$, letting N be a uniform bound on the number of shocks in $(\,\overline{u}^\theta,\, \widetilde{u}^\theta\,)$, and using Lemma 5.1, we obtain by the same arguments in (6.1) the estimate

$$\left\|\rho^1_{\delta,+\infty}\big(\gamma^\nu_t\big)\right\|_{\mathbf{L}^1} \leq C_3(1 + N2^{-\nu})(1 + \log(t/\delta)) \cdot \|\gamma_0\|_{0,0,t} \qquad \forall\ t \geq \delta\,,$$

which, in turn, because of (3.16), (3.19)–(3.20), implies

(6.11)
$$\big\|E^\nu_t\mathbf{p}_1 - E^\nu_t\mathbf{p}_2\big\|_{\mathbf{L}^1([\delta,+\infty[)} \leq C_8(1+N2^{-\nu})(1+\log(t/\delta))\cdot d_{0,0,t}(\mathbf{fp}_1,\,\mathbf{fp}_2) \qquad \forall\, t\geq\delta$$

for some other constant $C_8>0$. Letting $\nu\to\infty$ in (6.12), because of (6.10) we obtain (3.22) for all $\mathbf{p}_1,\ \mathbf{p}_2\in\mathcal{D}^\mu$. Since the domains $\mathcal{D}^\mu,\ \mu\geq 1$, are dense in $\mathcal{D}$, relying on (3.22) we can now extend the map E_t by continuity to the whole domain $\mathcal{D}$ setting

$$E_t(\mathbf{p}) \doteq \mathbf{L}^1\!-\lim_{\mu\to\infty} E_t(\mathbf{p}^\mu), \qquad\qquad \mathbf{p}^\mu\in\mathcal{D}^\mu,\ \mathbf{p}^\mu\to\mathbf{p}\ \text{in}\ \mathbf{L}^1\,. \tag{6.12}$$

Clearly, the map in (6.12) preserves the property (3.22), proving (2.25). Moreover, any trajectory $t\mapsto E_t(\mathbf{p})$, being the limit of front tracking approximations, provides by standard arguments [10, 11] a weak solution to problem (1.1)–(1.2).

6.3. Stability estimates in space. Towards a proof of the existence of a strong $\mathbf{L}^1$ trace of $f(u(t,x))\doteq f\big(E_t\mathbf{p}(x)\big)$ at the boundary $x=0$, we shall first establish the stability estimate (3.24) for the map $\mathbf{p}\mapsto f\big(E_{(\cdot)}\mathbf{p}(x)\big)$. Fix $\tau_2>\tau_1>0$, and observe that, because of (6.2), for every given $\mathbf{p}\in\mathcal{D}_{\mathcal{M}}$, the sequence $E^\nu_{(\cdot)}\mathbf{p}(\cdot)$ converges to $E_{(\cdot)}\mathbf{p}(\cdot)$ in $\mathbf{L}^1\big([0,\,\tau_2]\times\mathbb{R}^+;\,K\big)$. Hence, relying also on the continuity of the maps $x\mapsto E^\nu_{(\cdot)}\mathbf{p}(x),\ x\mapsto E_{(\cdot)}\mathbf{p}(x)$, we deduce that

(6.13)
$$f\big(E_{(\cdot)}(\mathbf{p})(x)\big)\restriction_{[\tau_1,\,\tau_2]} = \mathbf{L}^1-\lim_{\nu\to\infty} f\big(E^\nu_{(\cdot)}(\mathbf{p})(x)\big)\restriction_{[\tau_1,\,\tau_2]} \qquad \forall\, x\in[0,\,(\lambda^{\min}/2)\,\tau_1].$$

Therefore we may proceed as in the proof of (3.22) to establish the estimate (3.24). Given any pair of couples $\mathbf{p}_1,\ \mathbf{p}_2\in\mathcal{D}^\mu$, we construct a pseudopolygonal path $\gamma_0:\theta\mapsto\mathbf{fp}^\theta=(\,\overline{u}^\theta,\,f(\widetilde{u}^\theta))$ taking values in $\mathcal{FD}^\mu$, and connecting $\mathbf{fp}_1$ with $\mathbf{fp}_2$, so that all functions $(\,\overline{u}^\theta,\,\widetilde{u}^\theta)$ have a uniformly bounded number of shocks $\leq N$ and lie in some domain $\mathcal{D}_{\mathcal{M}},\ \mathcal{M}>0$. Then, for every $\nu\geq\mu$, calling $u^\theta_\nu(t,\cdot)\doteq E^\nu_t(\,\overline{u}^\theta,\,\widetilde{u}^\theta\,)(\cdot)$ the corresponding ν-approximate solution, we consider the pseudopolygonal path

$$\gamma^\nu_x:\theta\mapsto\big(\,\overline{u}^\theta,\,f\big(u^\theta_\nu(\cdot,\,x)\big)\big) \tag{6.14}$$

with values in $\mathcal{FD}^\nu$. Let $\rho^i_{\tau_1,\tau_2}$ and $\|\cdot\|_{0,0,\tau_2}$ denote the restriction map and the seminorm defined as in (3.14)–(3.15). Then, using Lemma 5.2, we compute as in (6.1)

$$\begin{aligned}
\big\|\rho^2_{\tau_1,\tau_2}(\gamma^\nu_x)\big\|_{\mathbf{L}^1} &= \sum_{j=1}^m\int_{\theta_{j-1}}^{\theta_j}\sum_{\{\alpha\,:\,t^\theta_\alpha\in[\tau_1,\tau_2]\}}\big|\widetilde{\Delta}u^\theta_\nu(t^\theta_\alpha,x)\big|\left|\frac{\partial t^\theta_\alpha(x)}{\partial\theta}\right|d\theta\\
&\leq \sum_{j=1}^m\int_{\theta_{j-1}}^{\theta_j} C_6(1+N2^{-\nu})(1+\log(\tau_2/\tau_1))\\
&\qquad\cdot\left(\sum_\beta\big|\Delta u^\theta_\nu(0,x^\theta_\beta)\big|\left|\frac{\partial x^\theta_\beta(0)}{\partial\theta}\right|+\sum_{\{\beta'\,:\,t^\theta_{\beta'}<\tau_2\}}\big|\widetilde{\Delta}u^\theta_\nu(t^\theta_{\beta'},0)\big|\left|\frac{\partial t^\theta_{\beta'}(0)}{\partial\theta}\right|\right)d\theta\\
&\leq C_6(1+N2^{-\nu})(1+\log(\tau_2/\tau_1))\cdot\|\gamma_0\|_{0,0.\tau_2}
\end{aligned} \tag{6.15}$$

for every $x\in[0,\,(\lambda^{\min}/2)\,\tau_1]$. Observe that the $\mathbf{L}^1$ length of the path γ^ν_x satisfies

$$\big\|\gamma^\nu_x\big\|_{0,\tau_1,\tau_2} = \big\|\rho^1_{0,+\infty}(\gamma^\nu_0)\big\|_{\mathbf{L}^1}+\big\|\rho^2_{\tau_1,\tau_2}(\gamma^\nu_x)\big\|_{\mathbf{L}^1}\,, \tag{6.16}$$

$$\big\|f\big(E^\nu_{(\cdot)}\mathbf{p}_1(x)\big)-f\big(E^\nu_{(\cdot)}\mathbf{p}_2(x)\big)\big\|_{\mathbf{L}^1([\tau_1,\,\tau_1])}\leq C_9\cdot\|\gamma^\nu_x\|_{0,\tau_1,\tau_2}\,, \tag{6.17}$$

for every $x \in [0,\, (\lambda^{\min}/2)\,\tau_1]$, and for some constant $C_9 > 0$. Hence, recalling also (3.19), we deduce from (6.15) the estimate

$$\begin{aligned}\big\|f\big(E^\nu_{(\cdot)}\mathbf{p}_1(x)\big)-f\big(E^\nu_{(\cdot)}\mathbf{p}_2(x)\big)\big\|_{\mathbf{L}^1([\tau_1,\,\tau_1])}\\ \leq C_{10}(1+N2^{-\nu})(1+\log(\tau_2/\tau_1))\cdot d_{0,0,\tau_2}(\mathbf{fp}_1,\,\mathbf{fp}_2)\end{aligned}\tag{6.18}$$

for some other constant $C_{10} > 0$. Letting $\nu \to \infty$ in (6.18), thanks to (6.14) we obtain (3.24) with $L''' = C_{10}(1 + \log(\tau_2/\tau_1))$. By continuity, and relying on the density of the domains $\mathcal{D}^\mu,\ \mu \geq 1$ in $\mathcal{D}$, we then extend the estimate (3.24) to any pair $\mathbf{p}_1,\ \mathbf{p}_2$ in $\mathcal{D}$.

Remark 6.1. If we fix a piecewise constant initial data $\overline{u} \in \mathbf{L}^1(\mathbb{R}^+, K^\mu)$, and for any given pair of piecewise constant boundary data $\widetilde{u},\, \widetilde{v} \in \mathbf{L}^1(\mathbb{R}^+, K^\nu)$, $\nu \geq \mu$, we construct a pseudopolygonal path $\gamma_0 : \theta \mapsto \mathbf{fp}^\theta = (\,\overline{u},\, f(\widetilde{u}^\theta))$, taking values in $\mathcal{FD}^\mu$, and connecting $\mathbf{fp}_1 \doteq (\,\overline{u},\, f(\widetilde{u}))$ with $\mathbf{fp}_2 \doteq (\,\overline{u},\, f(\widetilde{v}))$, with the same arguments above, and relying on Remark 5.1, we derive the same type of estimate as (3.24) with a Lipschitz constant that is independent on $\tau_1,\, \tau_2$. Thus, by continuity, and by the density of the domains $\mathcal{D}^\mu,\ \mu \geq 1$ in $\mathcal{D}$, we deduce that there exists some constant C', depending only on the system (1.1), so that for any fixed $\tau > \delta > 0$, and for all $(\,\overline{u},\, \widetilde{u}\,), (\,\overline{u},\, \widetilde{v}\,) \in \mathcal{D}$, there holds

$$\begin{aligned}\big\|E_{(\cdot)}\big(\overline{u},\, \widetilde{u}\,\big)(x) - E_{(\cdot)}\big(\overline{u},\, \widetilde{v}\,\big)(x)\big\|_{\mathbf{L}^1([\delta,\,\tau])} \leq C'\cdot\big\|\widetilde{u}-\widetilde{v}\big\|_{\mathbf{L}^1([0,\,\tau])}\\ \forall\ x \in [0,\, \lambda^{\min}\,\delta]\,.\end{aligned}\tag{6.19}$$

6.4. Oleinik-type estimates. Concerning the entropy admissibility conditions (2.15)–(2.16) on the decay of the positive waves, consider a couple of initial data and boundary conditions $(\,\overline{u},\, \widetilde{u}\,) \in \mathcal{D}$ and fix any interval $[a, b]$. Thanks to (3.21)–(3.22), we can now approximate the weak solution constructed as above, $u(t,\cdot) = E_t(\,\overline{u},\, \widetilde{u}\,)$, with a sequence of front tracking solutions $u^\nu(t,\cdot) = E^\nu_t(\,\overline{u}^\nu,\, \widetilde{u}^\nu\,)$, choosing initial and boundary data $(\,\overline{u}^\nu,\, \widetilde{u}^\nu\,) \in \mathcal{D}^\nu$ having a number of shocks $N_\nu \leq \nu$. By (4.5)–(4.6), the total number of positive wave-fronts in $u^\nu(\tau,\cdot) = E^\nu_\tau(\,\overline{u}^\nu,\, \widetilde{u}^\nu\,)$ on $[a, b]$ satisfies

$$\text{Pos.Var.}\big\{w^\nu_k(\tau,\cdot);\ [a,\ b]\big\} \leq C_2\cdot\frac{b-a}{\tau} + (N_\nu+1)2^{1-\nu}\tag{6.20}$$

for $k = 1, \ldots, n-p$,

$$\text{Pos.Var.}\big\{w^\nu_k(\tau,\cdot);\ [a,\ b]\big\} \leq C_2\cdot\left\{\frac{b-a}{\tau} + \log\left(\frac{b}{a}\right)\right\} + (N_\nu+1)2^{1-\nu}\,,\tag{6.21}$$

for $k = n-p+1, \ldots, n$, where $w^\nu_k \doteq w_k(u^\nu)$ denotes as usual the kth Riemann coordinate of u^ν. Letting $\nu \to \infty$ in (6.20)–(6.21), by the lower semicontinuity of the total variation we obtain (2.15)–(2.16). The estimates (2.17)–(2.18) on the decay of the positive variation of $w_k(\cdot\,, x)$ can be established in the entirely similar way relying on the corresponding estimates for $w^\nu_k(\cdot, x)$ which, in turn, are obtained with the same type of arguments used to prove the ones in (5.20)–(5.21).

6.5. Boundary conditions. Let $u(t,x) \doteq E_t\mathbf{p}(x),\ \mathbf{p} = (\,\overline{u},\, \widetilde{u}\,) \in D$, be the weak solution defined at (6.12), and consider a sequence $\mathbf{p}^\nu = (\,\overline{u}^\nu,\, \widetilde{u}^\nu\,) \in \mathcal{D}^\nu$ converging to $\mathbf{p}$ in $\mathbf{L}^1$ as $\nu \to \infty$. Call $u^\nu(t,x) \doteq E_t\mathbf{p}^\nu(x)$ the corresponding solution. Since every $\mathbf{p}^\nu$ is piecewise constant and lies in some domain $D_{\mathcal{M}_\nu}$, one can easily

verify that any function $u^\nu(t,x)$, $\nu \geq 1$, has bounded total variation and pointwise satisfies the boundary condition (2.20); i.e., there holds

$$\lim_{x\to 0+} w_j\big(u^\nu(t,x)\big) = w_j\big(\widetilde{u}^\nu(t)\big) \quad \text{for a.e.} \quad t\geq 0, \quad j = n-p+1,\dots,n. \tag{6.22}$$

Now, fix $\tau_2 > \tau_1 > 0$. By (3.24) and because of the invertibility property of the flux function, f, there will be some constant $C_{11} = C_{11}(\tau_1,\tau_2) > 0$ (depending only on τ_1,τ_2) such that

$$\big\|w_j\big(u^\nu(\cdot,x)\big) - w_j\big(u(\cdot,x)\big)\big\|_{\mathbf{L}^1([\tau_1,\ \tau_2])} \leq C_{11}\cdot d_{0,0,\tau_2}(\mathbf{p}^\nu,\ \mathbf{p}) \tag{6.23}$$

for all $x\in[0,\ (\lambda^{\min}/2)\,\tau_1]$, $\nu\geq 1$. Then, (6.22), (6.23) together imply that, for any $j = n-p+1,\dots,n$, the functions $w_j\big(u(\cdot,x)\big)$, $w_j\big(f(u(\cdot,x))\big)$ have a strong limit as $x\to 0$ and

$$\lim_{x\to 0+}\int_{\tau_1}^{\tau_2} \big|w_j\big(u(t,x)\big) - w_j\big(\widetilde{u}(t)\big)\big|dt = 0\,, \tag{6.24}$$

thus showing that $u(t,x)$ fulfills the boundary condition (2.20). On the other hand, because of the Oleinik-type conditions (2.15) on the decay of the positive waves, also $w_j\big(u(\cdot,x)\big)$, $j=1,\dots,n-p$, have a strong limit as $x\to 0$, which completes the proof of the existence of the strong $\mathbf{L}^1$ trace of $u(t,x)$ at $x=0$, and hence concludes the proof of Theorem 2.3.

6.6. Uniqueness. Let u be an entropy weak solution to (1.1)–(1.3) on the region $\Omega_T \doteq [0,\,T]\times\mathbb{R}^+$ in accordance with Definition 2.2, and assume that conditions (i)–(iii) stated in Theorem 2.4 hold. Let $\lambda^{\max}$ be the upper bound for the absolute value of all characteristic speeds at (2.7), and fix $R > \lambda^{\max}\cdot T$, $0<\delta<(R-\lambda^{\max}\cdot T)/2$. Observe that, because of the entropy conditions (2.15)–(2.16) on the decay of the positive waves, for every fixed $0<s\leq\delta$, the restrictions of $u(t,\cdot)$ to the intervals $J_{\delta,R}(t)\doteq[2\delta,\,R-\lambda^{\max}\cdot t]$, $s\leq t\leq T$, have uniformly bounded total variation. Thus, the same type of uniqueness results in [13] yield

$$u(t,\cdot) = E_{t-s}\big(u(s,\,s+\cdot),\ u(s+\cdot,\,s)\big)(-s+\cdot) \qquad \text{restricted to} \quad J_{\delta,R}(t) \tag{6.25}$$

for every $0<s\leq\delta\leq t\leq T$. Moreover, by the definition of $J_{\delta,R}(t)$, the domain of dependence of a solution to (1.1)–(1.3) along the segment $\{(t,x)\ ;\ x\in J_{\delta,R}(t)\}$ is contained in the set $\{(s,x)\in\mathbb{R}^2\ ;\ 0\leq s\leq t,\quad 0\leq x\leq R\}$. Hence, recalling Remark 2.5, we can restate the Lipschitz estimate (2.25) provided by Theorem 2.3 as

$$\begin{aligned}
&\int_{2\delta-s}^{R-(\lambda^{\max}\cdot t+s)} \Big|E_{t-s}\big(u(s,s+\cdot),u(s+\cdot,s)\big)(x)\\
&\qquad\qquad -E_{t-s}\big(E_s(\overline{u},\widetilde{u})(s+\cdot),\ E_{(s+\cdot)}(\overline{u},\widetilde{u})(s)\big)(x)\Big|dx\\
&\leq C(1+\log(t/\delta))\cdot\Big\{\int_\delta^R \Big|u(s,\,x) - E_s(\overline{u},\widetilde{u})(x)\Big|dx\\
&\qquad\qquad + \sum_{j=n-p+1}^{n}\int_s^t \Big|w_j\big(u(\sigma,\,s)\big) - w_j\big(E_\sigma(\,\overline{u},\,\widetilde{u}\,)(s)\big)\Big|d\sigma\Big\},
\end{aligned} \tag{6.26}$$

which, because of (6.25), yields

$$\begin{aligned}&\int_{J_{\delta,R}(t)} \Big|u(t,x) - E_t(\,\overline{u},\,\widetilde{u}\,)(x)\Big|dx\\ &\le C(1+\log(t/\delta))\cdot\Big\{\int_0^R \Big|u(s,\,x) - E_s(\overline{u},\widetilde{u})(x)\Big|dx\\ &\qquad + \sum_{j=n-p+1}^{n}\int_0^t \Big|w_j\big(u(\sigma,\,s\big) - w_j\big(E_\sigma(\,\overline{u},\,\widetilde{u}\,)(s)\big)\Big|d\sigma\Big\}\end{aligned} \tag{6.27}$$

for every $0 < s \le \delta \le t \le T$. On the other hand, the continuity in $\mathbf{L}^1{}_{loc}$ of the map $t \mapsto E_t(\,\overline{u},\,\widetilde{u}\,)$ at $t = 0$ (see Remark 2.4), and the existence of a strong $\mathbf{L}^1$ trace of $E_t(\,\overline{u},\,\widetilde{u}\,)(x)$ at the boundary $x = 0$ (guaranteed by Theorem 2.3), together with (2.19), imply

$$\begin{aligned}&\lim_{s\to 0^+}\int_0^R \Big|E_s(\overline{u},\widetilde{u})(x) - \overline{u}(x)\Big|dx = 0\,,\\ &\lim_{s\to 0^+}\int_0^t \Big|w_j\big(E_\sigma(\,\overline{u},\,\widetilde{u}\,)(s) - w_j\big(\widetilde{u}(\sigma)\big)\Big|\,d\sigma = 0\,.\end{aligned} \tag{6.28}$$

Thus, taking the essential limit of the right-hand side of (6.27) as $s \to 0^+$, using (6.28), and relying on (2.31)–(2.33), we obtain

$$\int_{2\delta}^{R-\lambda^{\max}\cdot t} \big|u(t,x) - E_t(\,\overline{u},\,\widetilde{u}\,)(x)\big|dx = 0 \qquad \forall\, t\in[0,T]\,. \tag{6.29}$$

Since $\delta \in]0,\, R - \lambda^{\max}\cdot T)/2[\,$, and $R > \lambda^{\max}\cdot T$ were arbitrary, this concludes the proof of Theorem 2.4.

7. Proof of Theorem 2.6. We give here only the proof of the compactness of the attainable sets $\mathcal{A}(T,\mathcal{U})$, $T > 0$, in connection with the sets of admissible boundary controls $\mathcal{U}$ defined in (2.39), the procedure to establish the compactness of $\mathcal{A}(\,\overline{x},\mathcal{U})$, $\overline{x} > 0$, being entirely similar.

Fix $T > 0$. Given $\overline{u} \in \mathbf{L}^1(\mathbb{R}^+, K)$, consider a sequence of boundary data $\{\widetilde{u}^\nu\}_{\nu\ge 0} \subset \mathcal{U}$, and let $u^\nu(t,x) \doteq E_t(\,\overline{u},\,\widetilde{u}^\nu\,)(x)$ be the corresponding solutions. Observe that all solutions $u^\nu(t,x)$, $\nu \ge 0$, are uniformly bounded since they take values in the compact set K. Moreover, thanks to the Oleinik-type estimates (2.15)–(2.16) on the time decay of the positive waves, for every fixed $0 < a < b$, and $0 < \tau \le T$, there exist constants $C' = C'(a,b,\tau) > 0$, $C'' = C''(a,b,\tau) > 0$ such that

$$\text{Tot.Var.}\big\{u^\nu(t,\cdot)\ ;\ [a,\,b]\big\} \le C' \qquad \forall\, t\in[\tau,\,T], \qquad \forall\,\nu\ge 0\,, \tag{7.1}$$

$$\int_a^b |u^\nu(t,x) - u^\nu(s,x)|\,dx \le C''|t-s| \qquad \forall\, t,s\in[\tau,\,T], \qquad \forall\,\nu\ge 0\,. \tag{7.2}$$

Hence, applying Helly's theorem, we deduce that there exists a subsequence $\{u^{\nu_j}\}_{j\ge 0}$ so that $\{u^{\nu_j}(t,\cdot)\restriction_{[a,\,b]}\}_{j\ge 0}$ converges in $\mathbf{L}^1([a,b],\,K)$ to some function $u_{a,b,\tau}(t,\cdot)$ for any $t \in [\tau,\,T]$. Therefore, by considering sequences of real number $a_k \to 0+$, $b_k \to \infty$, $\tau_k \to 0+$, and by using a diagonal procedure, we construct a subsequence $\{u^{\nu'}(t,\cdot)\}_{\nu'\ge 0}$ that converges in $\mathbf{L}^1{}_{loc}(\mathbb{R}^+,K)$ to some function $u(t,\cdot)$ for any $t \in [0,\,T]$. We claim that there exists a boundary data $\widetilde{u} \in \mathcal{U}$ such that

$$u(t,\cdot) = E_t(\,\overline{u},\,\widetilde{u}\,) \qquad \forall\, t\in[0,\,T]\,. \tag{7.3}$$

Notice that, by construction, the map $(t,x) \to \big(u(t,\cdot),\, u(\cdot,x)\big)$ takes values within the domain $\mathcal{D}_T$ defined in (2.30). Moreover, the estimate (7.2) implies the continuity of $u : [0,\, T] \times \mathbb{R}^+ \mapsto U$ as a function from $]0,\, T]$ into $\mathbf{L}^1{}_{loc}(\mathbb{R}^+)$. Hence, thanks to Theorem 2.4 and Lemma 2.5, in order to prove the claim it will be sufficient to show the following:

(1) There exists a boundary data $\widetilde{u} \in \mathcal{U}$ so that $u(t,x)$ is an entropy weak solution to (1.1)–(1.3) on the region $[0,\, T] \times \mathbb{R}^+$, in the sense of Definition 2.2.
(2) Given any boundary entropy pair $\big(\alpha(u,v),\, \beta(u,v)\big)$ for (1.1), there is a constant $M > 0$ (depending only on $(\alpha,\, \beta)$ and on the domain K) for which $u(t,x)$ satisfies the corresponding distributional entropy inequality (2.34).

Towards a proof of (1) observe that, because of (2.26), all fluxes $f(u^\nu)$, $\nu \geq 0$, admit a strong $\mathbf{L}^1$ trace Ψ^ν at $x = 0$, whose essential range is contained in the compact set $f(K)$. Hence, the sequence $\{\Psi^\nu\}_{\nu \geq 0}$ is weak* relatively compact in $\mathbf{L}^\infty(\mathbb{R}^+)$ and, by possibly taking a subsequence, we have

$$\Psi^\nu \,\overset{*}{\rightharpoonup}\, \Psi \qquad \text{in} \quad \mathbf{L}^\infty(\mathbb{R}^+) \tag{7.4}$$

for some function $\Psi \in \mathbf{L}^\infty(\mathbb{R}^+, \mathbb{R}^n)$. Moreover, by Theorem 2.3, every u^ν is a distributional solution of the corresponding initial-boundary value problem on $[0,\, T] \times \mathbb{R}^+$; i.e., there holds

$$\begin{aligned} &\int_0^T \int_0^{+\infty} \Big\{ u^\nu(t,x) \cdot \phi_t(t,x) + f(u^\nu(t,x)) \cdot \phi_x(t,x) \Big\}\, dx\, dt \\ &\qquad + \int_0^{+\infty} \overline{u}(x) \cdot \phi(0,x)\, dx + \int_0^T \Psi^\nu(t) \cdot \phi(t,0)\, dt = 0 \end{aligned} \tag{7.5}$$

for any test function $\phi \in \mathcal{C}^1_c$ with compact support contained in the set $]-\infty,\, T\,[\times\mathbb{R}$. Therefore, passing to the limit as $\nu \to \infty$ in (7.5), we get

$$\begin{aligned} &\int_0^T \int_0^{+\infty} \Big\{ u(t,x) \cdot \phi_t(t,x) + f(u(t,x)) \cdot \phi_x(t,x) \Big\}\, dx\, dt \\ &\qquad + \int_0^{+\infty} \overline{u}(x) \cdot \phi(0,x)\, dx + \int_0^T \Psi(t) \cdot \phi(t,0)\, dt = 0\,. \end{aligned} \tag{7.6}$$

By considering, in particular, test functions $\phi \in \mathcal{C}^1_c$ with compact support contained in the set $]-\infty,\, T\,[\times]0,\, \infty[$, from (7.6) we deduce that $u(t,x)$ is a distributional solution of the Cauchy problem (1.1)–(1.2) on the region $[0,\, T] \times \mathbb{R}^+$, as required by Definition 2.2(i). On the other hand, given any $\mathcal{C}^1$ function $\alpha = \alpha(t)$, writing (7.6) for test functions $\phi^\varepsilon(t,x) = \alpha(t) \cdot \beta^\varepsilon(t,x)$, $\beta^\varepsilon \in \mathcal{C}^1_c$, supported on the semistrips $]0,\, T[\times]-\infty,\, \varepsilon[$, $\varepsilon > 0$, shrinking to the region $]0,\, T[\times]-\infty,\, 0]$ around the boundary $]0,\, T[\times\{0\}$, and such that $\phi^\varepsilon(t,0) = \alpha(t)$, we obtain

$$\lim_{x \to 0^+} \int_0^T f(u(t,x)) \cdot \alpha(t)\, dt = \int_0^T \Psi(t) \cdot \alpha(t)\, dt\,, \tag{7.7}$$

thus proving (2.13).

Now observe that, by Remark 2.2, the definition (2.39) of the set $\mathcal{U}$ of admissible boundary data implies

$$w_j\big(f^{-1}(\Psi^\nu(t))\big) \in [c_j,\, d_j] \qquad \text{for a.e.} \quad t \geq 0, \qquad j = n-p+1, \ldots, n. \tag{7.8}$$

Hence, for every flux trace Ψ^ν, $\nu \geq 0$, one has

(7.9)
$$\Psi^\nu(t) \in \mathcal{G} \doteq \Big\{ f(u) \ ; \ w_j(u) \in [c_j,\, d_j] \qquad \forall\ j = n-p+1, \dots, n \Big\} \qquad \text{for a.e.} \quad t \geq 0.$$

Since, by the properties of the Riemann invariants, the set $\mathcal{G}$ is closed and convex, it follows that the weak limit of Ψ^ν satisfies

$$\Psi(t) \in \mathcal{G} \qquad \text{for a.e.} \quad t \geq 0. \tag{7.10}$$

Therefore, if we consider the boundary data $\widetilde{u}$ defined in Riemann coordinates by

$$w_j(\widetilde{u}(t)) \doteq \begin{cases} \overline{\gamma}_j & \text{if} \quad j \leq n-p, \\ \\ w_j\big(f^{-1}(\Psi(t))\big) & \text{if} \quad j > n-p, \end{cases} \qquad \forall\ t \geq 0\,, \tag{7.11}$$

for some constant values

$$\overline{\gamma}_j \in \begin{cases} [c_j,\, d_j] & \text{if} \quad j \in J, \\ \\ [a_j,\, b_j] & \text{otherwise} \end{cases} \qquad j \leq n-p\,, \tag{7.12}$$

(J denoting the set of indices in the definition (2.39) of $\mathcal{U}$, and a_j, b_j being the constants in the definition (2.5) of the set K), we clearly have $\widetilde{u} \in \mathcal{U}$, and, by Remark 2.2, $u(t,x)$ satisfies the boundary condition (2.14) of Definition 2.2(ii). To complete the proof of (1) observe that the Oleinik-type conditions of Definition 2.2(iii) can be recovered by the lower semicontinuity of the total variation, since the map $u(t,x)$ is obtained as the $\mathbf{L}^1{}_{loc}$ limit of a sequence of maps satisfying (2.15)–(2.18).

Finally, regarding (2) observe that every solution $t \mapsto u^\nu(t,\cdot)$, being a trajectory of the flow map E_t, is obtained as the limit of front tracking approximations, and hence by standard arguments satisfies the distributional entropy inequality (2.34) associated with any boundary entropy pair for (1.1). Clearly, this property is preserved by the $\mathbf{L}^1{}_{loc}$ limit u of the sequence u^ν. This concludes the proof of Theorem 2.6.

8. Appendix. We show here that, if the system (1.1) is of Temple class, the two sets of admissible boundary values $\mathcal{V}^{\mathcal{E}ntr}(\widetilde{u})$, $\mathcal{V}(\widetilde{u})$ defined in (2.12), (2.22) coincide. Indeed, it was already shown in [8] that, if $u \in \mathcal{V}^{\mathcal{E}ntr}(\widetilde{u})$, and η is an entropy for the system (1.1) that is differentiable in $\widetilde{u}$, with $D\eta(\widetilde{u}) = 0$, while q is the corresponding flux associated with η, then u satisfies the entropy inequality that appears in the definition (2.22), since $q(u) \leq q(\widetilde{u})$. Therefore, we deduce that u satisfies all the inequalities in (2.22) associated with entropies η that are differentiable in $\widetilde{u}$, since in this case one can write $\eta = \eta_1 + \eta_2$, with

$$\eta_1(u) \doteq \eta(\widetilde{u}) + D\eta(\widetilde{u}) \cdot (u - \widetilde{u}), \qquad \eta_2(u) \doteq \eta(u) - \eta_1(u)\,, \tag{8.1}$$

where $D\eta_2(\widetilde{u}) = 0$, while η_1 is an affine entropy which trivially verifies the inequality in (2.22). By density it follows that u satisfies all the inequalities in (2.22) associated with any (continuous) convex entropy η, proving

$$\mathcal{V}(\widetilde{u}) \subseteq \mathcal{V}^{\mathcal{E}ntr}(\widetilde{u})\,. \tag{8.2}$$

We will show below that the converse inclusion also holds.

LEMMA 8.1. *Let* (1.1) *be a system of Temple class, and let* K *be a set as in* (2.5). *Assume that the strict hyperbolicity condition* (SH1) *is verified and that, for*

some index $p \in \{1, \dots, n\}$, there holds (2.6). *Then, letting $\mathcal{V}(\widetilde{u})$, $\mathcal{V}^{\mathcal{E}ntr}(\widetilde{u})$ be the sets of admissible boundary values defined, respectively, in* (2.12), *and in* (2.22), *one has*

$$\mathcal{V}^{\mathcal{E}ntr}(\widetilde{u}) \subseteq \mathcal{V}(\widetilde{u}) \qquad \forall\, \widetilde{u} \in K\,. \tag{8.3}$$

Proof. First observe that, by Remark 2.2, if $w = (w_1, \dots, w_n)$ is a system of Riemann coordinates for (1.1), then the inclusion (8.3) is verified if and only if, for every $\widetilde{u} \in K$, there holds

$$u \in \mathcal{V}^{\mathcal{E}ntr}(\widetilde{u}) \qquad \Longrightarrow \qquad w_j(u) = w_j(\widetilde{u}) \qquad \forall\, j = n-p+1, \dots, n\,. \tag{8.4}$$

Next, fix $\widetilde{u} \in K$, and, for every $j > n-p$, consider the following Kruzkow-type entropy-entropy flux pair (see, e.g., [29, Chapter 13]):

$$\begin{aligned} \eta_j(u) &= \big|l_j(\widetilde{u}) \cdot (u - \widetilde{u})\big|\,, \\ q_j(u) &= l_j(\widetilde{u}) \cdot (f(u) - f(\widetilde{u}))\ \mathrm{sgn}\big(l_j(\widetilde{u}) \cdot (u - \widetilde{u})\big)\,, \end{aligned} \tag{8.5}$$

where $l_j(u)$ denotes the left eigenvector of the Jacobian matrix $DF(u)$, normalized as in (2.1). We will show that, if we set

$$\mathcal{E}(\eta,\, q;\, \zeta,\, u) \doteq q(u) - q(\widetilde{u}) - \zeta \cdot \big(f(u) - f(\widetilde{u})\big), \qquad \zeta \in \partial\eta(\widetilde{u}) \tag{8.6}$$

($\partial\eta(\widetilde{u})$ denoting the subdifferential of η at $\widetilde{u}$), then, for any $j > n-p$, there holds

$$\mathcal{E}(\eta_j,\, q_j;\, \zeta,\, u) \le 0 \qquad \forall\, \zeta \in \partial\eta(\widetilde{u}) \qquad \Longrightarrow \qquad l_j(\widetilde{u}) \cdot (u - \widetilde{u}) = 0\,, \tag{8.7}$$

which proves (8.4) since $l_j(\widetilde{u}) \cdot (u - \widetilde{u}) = 0$ is the equation of the hyperplane $\{u \in U\ ;\ w_j(u) = w_j(\widetilde{u})\}$. Observe that $\partial\eta(\widetilde{u}) = \{\gamma\, l_j(\widetilde{u})\ ;\ \gamma \in \partial|\cdot| = [-1,\, 1]\}$, and recall that for Temple class systems there exists a smooth, matrix-valued map $M : \mathbb{R}^n \times \mathbb{R}^n \to M_{n\times n}(\mathbb{R})$ with the following properties (see [20]):

(i) There holds

$$\begin{aligned} f(u) - f(v) &= M(u, v) \cdot (u - v) \qquad \forall\, u,\, v\,, \\ M(u, u) &= Df(u) \qquad \forall\, u. \end{aligned} \tag{8.8}$$

(ii) $M(u, v)$ and $Df(v)$ have the same (left and right) eigenvectors.

Multipling both terms of the first equality in (8.8) on the left by $l_j(v)$, we obtain

$$l_j(v) \cdot (f(u) - f(v)) = \lambda_j(u, v)\, l_j(v) \cdot (u - v) \qquad \forall\, u,\, v\,, \tag{8.9}$$

where $\lambda_j(u, v)$ denotes the ith eigenvalue of $M(u, v)$. Then, using (8.9), by a direct computation we find

$$\begin{aligned} &\mathcal{E}\big(\eta_j,\, q_j;\, \zeta,\, u\big) \\ &\quad = l_j(\widetilde{u}) \cdot (f(u) - f(\widetilde{u}))\ \mathrm{sgn}\big(l_j(\widetilde{u}) \cdot (u - \widetilde{u})\big) - \gamma\, l_j(\widetilde{u}) \cdot (f(u) - f(\widetilde{u})) \\ &\quad = \lambda_j(u, \widetilde{u})\Big(\big|l_j(\widetilde{u}) \cdot (u - \widetilde{u})\big| - \gamma\, l_j(\widetilde{u}) \cdot (u - \widetilde{u})\Big) \qquad \forall\, \gamma \in [-1,\, 1]\,. \end{aligned} \tag{8.10}$$

Since, by (2.6), one has $\lambda_j(u, \widetilde{u}) > 0$ for any $j > n-p$, from (8.10) we deduce (8.7), thus concluding the proof. ∎

A REFINED GLOBAL WELL-POSEDNESS RESULT FOR SCHRÖDINGER EQUATIONS WITH DERIVATIVE*

J. COLLIANDER†, M. KEEL‡, G. STAFFILANI§, H. TAKAOKA¶, AND T. TAO‖

Abstract. In this paper we prove that the one-dimensional Schrödinger equation with derivative in the nonlinear term is globally well-posed in H^s for $s > \frac{1}{2}$ for data small in L^2. To understand the strength of this result one should recall that for $s < \frac{1}{2}$ the Cauchy problem is ill-posed, in the sense that uniform continuity with respect to the initial data fails. The result follows from the method of almost conserved energies, an evolution of the "I-method" used by the same authors to obtain global well-posedness for $s > \frac{2}{3}$. The same argument can be used to prove that any quintic nonlinear defocusing Schrödinger equation on the line is globally well-posed for large data in H^s for $s > \frac{1}{2}$.

Key words. almost conserved energies, global well-posedness, Schrödinger equation with derivative

1. Introduction.

In this paper, using the method of almost conserved energies, we establish a sharp result on global well-posedness for the derivative nonlinear Schrödinger IVP

$$\begin{cases} i\partial_t u + \partial_x^2 u = i\lambda\partial_x(|u|^2 u), \\ u(x,0) = u_0(x), \qquad\qquad x \in \mathbb{R},\ t \in \mathbb{R}, \end{cases} \tag{1}$$

where $\lambda \in \mathbb{R}$.

The first result of this kind was obtained in the context of the KdV and the modified KdV (mKdV) IVPs [11], also using almost conserved energies. Below we will discuss in more detail the "almost conservation method" and its relationship with the "I-method" which was applied to (1) in [9] (see also [10, 11, 20, 21]).

From the point of view of physics the equation in (1) is a model for the propagation of circularly polarized Alfvén waves in magnetized plasma with a constant magnetic field [25, 26, 29].

It is natural to impose the smallness condition

$$\|u_0\|_{L^2} < \sqrt{\frac{2\pi}{|\lambda|}} \tag{2}$$

on the initial data, as this will force the energy to be positive via the sharp Gagliardo–Nirenberg inequality [36]. Note that the L^2 norm is conserved by the evolution. In this paper, we prove the following global well-posedness result.

THEOREM 1.1. *The Cauchy problem* (1) *is globally well-posed in* H^s *for* $s > \frac{1}{2}$, *assuming the smallness condition* (2).

We present here once again [9] a summary of the well-posedness story for (1). Scattering and well-posedness for this Cauchy problem has been studied by many authors [14, 15, 16, 17, 18, 19, 27, 28, 30, 34, 35]. The best local well-posedness result is due to Takaoka [30], where a gauge transformation and the Fourier restriction method are used to obtain local well-posedness in H^s, $s \geq \frac{1}{2}$. In [31], Takaoka showed this result is sharp in the sense that, when $s < \frac{1}{2}$, the nonlinear evolution $u(0) \mapsto u(t)$, thought of as a map from H^s to H^s for some fixed t, fails to be C^3 or even uniformly C^0 in this topology, even when t is arbitrarily close to zero and the H^s norm of the data is small (see also Bourgain [5] and Biagioni–Linares [2]). Therefore, we see that Theorem 1.1 is sharp, in the sense described above, except for the endpoint.

In [27], global well-posedness is obtained for (1) in H^1 assuming the smallness condition (2). The argument there is based on two gauge transformations performed in order to remove the derivative in the nonlinear term and the conservation of the Hamiltonian. This was improved by Takaoka [31], who proved global well-posedness in H^s for $s > \frac{32}{33}$ assuming (2). His method of proof is based on the idea of Bourgain [4, 6] of estimating separately the evolution of low frequencies and of high frequencies of the initial data. In [9], we used the "I-method" to further push the Sobolev exponent for global well-posedness down to $s > \frac{2}{3}$. The main idea of the "I-method" consists of defining a modified H^s norm permitting us to capture some nonlinear cancellations in frequency space during the evolution (1). These cancellations allow us to prove that the modified $H^s(\mathbb{R})$ norm is nearly conserved in time, and an iteration of the local result proves global well-posedness provided $s > \frac{2}{3}$. In this paper, an algorithmic procedure, first developed in the KdV context [11], is applied to better capture the cancellations in frequency space. Successive applications of the algorithm generate higher-order-in-u but lower-order-in-scaling corrections to the modified H^s norm. After one application of our algorithm, we show that the modified H^s norm *with* the generated correction terms changes less in time than the modifed H^s norm itself, so the first application of the algorithm produces an *almost conserved energy.* The improvement obtained allows us to iterate the local result and prove global well-posedness in $H^s(\mathbb{R})$ provided $s > \frac{1}{2}$. In principle, the algorithm may itself be iterated to generate a sequence of almost conserved energies giving further insight into the dynamical properties of (1). The endpoint $s = \frac{1}{2}$ is not obtained here. We speculate, however, that a further refinement of the "almost conservation method" could be a possible way to approach this question.

We conclude this section with the following remark.

Remark 1.2. Consider the one-dimensional quintic nonlinear Schrödinger

$$i\partial_t u = \partial_{xx} u + iau\bar{u}\partial_x u + ibu^2\partial_x \bar{u} + cu^3\bar{u}^2, \tag{3}$$

where a, b, and c are fixed real numbers. If $(a+b)(3a-5b)/48+c/3 < 0$ the equation in (3) is defocusing and, as was remarked in [9], the techniques used to prove Theorem 1.1

apply here too, and one can prove global well-posedness for initial data in $H^s, s > \frac{1}{2}$. Moreover, if $a = b = 0$, we expect our method to give global well-posedness[1] even below $s = 1/2$.

We should point out that Clarkson and Cosgrove [8] (see also [1]) proved that (3) fails the Painlevé test for complete integrability when

$$c \neq \frac{1}{4}b(2b - a).$$

In particular, this shows that our techniques, which do not depend on a, b, c, do not rely on complete integrability.

2. Notation and known facts. To prove Theorem 1.1 we may assume $\frac{1}{2} < s \leq \frac{2}{3}$, since for $s > \frac{2}{3}$ the result is contained in [27, 31] and [9]. Henceforth $\frac{1}{2} < s \leq \frac{2}{3}$ shall be fixed. Also, by rescaling u, we may assume $\lambda = 1$.

We use C to denote various constants depending on s; if C depends on other quantities as well, this will be indicated by explicit subscripting; e.g., $C_{\|u_0\|_2}$ will depend on both s and $\|u_0\|_2$. We use $A \lesssim B$ to denote an estimate of the form $A \leq CB$, and $A \sim B$ for $cB \leq A \leq CB$, where c and C are absolute constants. We also use $A \ll B$ if $A \leq \epsilon B$, where ϵ is a very small absolute constant. We use $a+$ and $a-$ to denote expressions of the form $a + \varepsilon$ and $a - \varepsilon$, where $0 < \varepsilon \ll 1$ depends only on s.

We use $\|f\|_p$ to denote the $L^p(\mathbb{R})$ norm and $L^q_t L^r_x$ to denote the mixed norm

$$\|f\|_{L^q_t L^r_x} := \left(\int \|f(t)\|_r^q \, dt \right)^{1/q}$$

with the usual modifications when $q = \infty$.

We define the spatial Fourier transform of $f(x)$ by

$$\mathcal{F}(f)(\xi) := \hat{f}(\xi) := \int_{\mathbb{R}} e^{-ix\xi} f(x) \, dx$$

and the spacetime Fourier transform $u(t, x)$ by

$$\widetilde{\mathcal{F}}(u)(\tau, \xi) := \tilde{u}(\tau, \xi) := \int_{\mathbb{R}} \int_{\mathbb{R}} e^{-i(x\xi + t\tau)} u(t, x) \, dtdx.$$

Note that the derivative ∂_x is conjugated to multiplication by $i\xi$ by the Fourier transform.

We shall also define D_x to be the Fourier multiplier with symbol $\langle \xi \rangle := 1 + |\xi|$. We can then define the Sobolev norms H^s by

$$\|f\|_{H^s} := \|D_x^s f\|_2 = \|\langle \xi \rangle^s \hat{f}\|_{L^2_\xi}.$$

We also define the spaces $X^{s,b}(\mathbb{R}\times\mathbb{R})$ (first introduced in the context of the Schrödinger equation in [3]; see also [22, 23]) on $\mathbb{R} \times \mathbb{R}$ by

$$\|u\|_{X^{s,b}(\mathbb{R}\times\mathbb{R})} := \|\langle \xi \rangle^s \langle \tau - |\xi|^2 \rangle^b \hat{u}(\xi, \tau)\|_{L^2_\tau L^2_\xi}.$$

[1] Recall that in this case the initial value problem is locally well-posed in H^s for $s \geq 0$; see [7] and [33].

We often abbreviate $\|u\|_{s,b}$ for $\|u\|_{X^{s,b}(\mathbb{R}\times\mathbb{R})}$. For any time interval I, we define the restricted spaces $X^{s,b}(I\times\mathbb{R})$ by

$$\|u\|_{X^{s,b}(I\times\mathbb{R})} := \inf\{\|U\|_{s,b} : U|_{I\times\mathbb{R}} = u\}.$$

We shall take advantage of the Strichartz estimate (see, e.g., [3])

$$\|u\|_{L_t^6 L_x^6} \lesssim \|u\|_{0,\frac{1}{2}+}, \tag{4}$$

which interpolates with the trivial estimate

$$\|u\|_{L_t^2 L_x^2} \lesssim \|u\|_{0,0}, \tag{5}$$

to give

$$\|u\|_{L_t^p L_x^p} \lesssim \|u\|_{0,\alpha(p)} \tag{6}$$

for any $p\in[2,6]$ and $\alpha(p) = \frac{(3+)(p-2)}{4p}$. We also use

$$\|u\|_{L_t^\infty L_x^2} \lesssim \|u\|_{0,\frac{1}{2}+}, \tag{7}$$

which together with Sobolev embedding gives

$$\|u\|_{L_t^\infty L_x^\infty} \lesssim \|u\|_{\frac{1}{2}+,\frac{1}{2}+}. \tag{8}$$

The next lemma introduces two more estimates that are probably less known than the standard Strichartz estimates.

LEMMA 2.1. *For any $b > \frac{1}{2}$ and any function u for which the right-hand side is well defined, we have*

$$\|D_x^{\frac{1}{2}} u\|_{L_x^\infty L_t^2} \lesssim \|u\|_{X^{0,b}} \tag{9}$$

(smoothing effect estimate).

For any $s > \frac{1}{2}$ and $\rho \geq \frac{1}{4}$ we have

$$\|u\|_{L_x^2 L_t^\infty} \lesssim \|u\|_{X^{s,b}}, \tag{10}$$

$$\|u\|_{L_x^4 L_t^\infty} \lesssim \|u\|_{X^{\rho,b}} \tag{11}$$

(maximal function estimates).

Proof. The estimates (9), (10), and (11) come from estimating the solution $S(t)u_0$ of the linear one-dimensional Schrödinger IVP in the norm appearing in the left-hand side and from a standard argument of summation along parabolic curves; see, for example, the expository paper [13]. The smoothing effect and maximal function estimates for $S(t)u_0$ can be found, for example, in [24]. □

We also have the following improved Strichartz estimate (cf. Lemma 7.1 in [9]; see also [4, 28, 32]).

LEMMA 2.2. *For any Schwartz functions u, v with Fourier support in $|\xi| \sim R$, $|\xi| \ll R$, respectively, we have that*

$$\|uv\|_{L_t^2 L_x^2} = \|u\bar{v}\|_{L_t^2 L_x^2} \lesssim R^{-1/2}\|u\|_{0,1/2+}\|v\|_{0,1/2+}.$$

In our arguments we shall be using the trivial embedding

$$\|u\|_{s_1,b_1} \lesssim \|u\|_{s_2,b_2} \quad \text{whenever } s_1 \leq s_2, b_1 \leq b_2$$

so frequently that we will not mention this embedding explicitly.

We now give some useful notation for multilinear expressions. If $n \geq 2$ is an even integer, we define a *(spatial) n-multiplier* to be any function $M_n(\xi_1, \dots, \xi_n)$ on the hyperplane

$$\Gamma_n := \{(\xi_1, \dots, \xi_n) \in \mathbb{R}^n : \xi_1 + \cdots + \xi_n = 0\},$$

which we endow with the standard measure $\delta(\xi_1 + \cdots + \xi_n)$, where δ is the Dirac delta.

If M_n is an n-multiplier and $f_1, \dots, f_n$ are functions on $\mathbb{R}$, we define the *n-linear functional* $\Lambda_n(M_n; f_1, \dots, f_n)$ by

$$\Lambda_n(M_n; f_1, \dots, f_n) := \int_{\Gamma_n} M_n(\xi_1, \dots, \xi_n) \prod_{j=1}^{n} \hat{f}_j(\xi_j).$$

We adopt the notation

$$\Lambda_n(M_n; f) := \Lambda_n(M_n; f, \bar{f}, f, \bar{f}, \dots, f, \bar{f}).$$

Observe that $\Lambda_n(M_n; f)$ is invariant under permutations of the even ξ_j indices or of the odd ξ_j indices.

If M_n is a multiplier of order n, $1 \leq j \leq n$ is an index, and $k \geq 1$ is an even integer, we define the *elongation* $\mathbf{X}_j^k(M_n)$ of M_n to be the multiplier of order $n + k$ given by

$$\mathbf{X}_j^k(M_n)(\xi_1, \dots, \xi_{n+k}) := M_n(\xi_1, \dots, \xi_{j-1}, \xi_j + \ldots + \xi_{j+k}, \xi_{j+k+1}, \dots, \xi_{n+k}).$$

In other words, $\mathbf{X}_j^k$ is the multiplier obtained by replacing ξ_j by $\xi_j + \cdots + \xi_{j+k}$ and advancing all the indices after ξ_j accordingly.

We shall often write ξ_{ij} for $\xi_i + \xi_j$, ξ_{ijk} for $\xi_i + \xi_j + \xi_k$, etc. We also write ξ_{i-j} for $\xi_i - \xi_j$, ξ_{ij-klm} for $\xi_{ij} - \xi_{klm}$, etc. Also, if $m(\xi)$ is a function defined in the frequency space, we use the notation $m(\xi_i) = m_i$, $m(\xi_{ij-k}) = m_{ij-k}$, etc.

In this paper we often use two very elementary tools: the mean value theorem (MVT) and the double mean value theorem (DMVT). While recalling the statement of the MVT will be an embarrassment, we think that doing so for the DMVT is a necessity to avoid later confusion.

LEMMA 2.3 (DMVT). *Assume $f \in C^2(\mathbb{R})$ and that $\max(|\eta|, |\lambda|) \ll |\xi|$; then*

$$|f(\xi + \eta + \lambda) - f(\xi + \eta) - f(\xi + \lambda) + f(\xi)| \lesssim |f''(\theta)||\eta||\lambda|,$$

where $|\theta| \sim |\xi|$.

3. The gauge transformation, energy, and the almost conservation laws. In this section we summarize the main results presented in section 3 and 4 of [9]. Whatever is here simply stated and recalled is fully explained or proved in those sections.

We start by applying the gauge transform used in [27] in order to improve the derivative nonlinearity present in (1).

DEFINITION 3.1. *We define the nonlinear map $\mathcal{G} : L^2(\mathbb{R}) \to L^2(\mathbb{R})$ by*

$$\mathcal{G}f(x) := e^{-i\int_{-\infty}^{x} |f(y)|^2 dy} f(x).$$

The inverse transform $\mathcal{G}^{-1}f$ is then given by

$$\mathcal{G}^{-1}f(x) := e^{i\int_{-\infty}^{x}|f(y)|^2dy}f(x).$$

This transform is a bicontinuous map from H^s to itself for any $s \in [0,1]$.

Set $w_0 := \mathcal{G}u_0$, and $w(t) := \mathcal{G}u(t)$ for all times t. A straightforward calculation shows that the IVP (1) transforms into

$$\begin{cases} i\partial_t w + \partial_x^2 w = -iw^2\partial_x\bar{w} - \frac{1}{2}|w|^4 w, \\ w(x,0) = w_0(x), \qquad\qquad x \in \mathbb{R},\ t \in \mathbb{R}. \end{cases} \tag{12}$$

Also, the smallness condition (2) becomes

$$\|w_0\|_{L^2} < \sqrt{2\pi}. \tag{13}$$

By the bicontinuity we thus see that global well-posedness of (1) in H^s is equivalent to that of (12). From [27, 30, 31], we know that both Cauchy problems are locally well-posed in $H^s, s \geq \frac{1}{2}$, and globally well-posed in H^1 assuming (13). By standard limiting arguments, we thus see that Theorem 1.1 will follow if we can show the following.

PROPOSITION 3.2. *Let w be a global H^1 solution to* (12) *obeying* (13). *Then for any $T > 0$ and $s > \frac{1}{2}$ we have*

$$\sup_{0\leq t\leq T}\|w(t)\|_{H^s} \lesssim C_{(\|w_0\|_{H^s},T)},$$

where the right-hand side does not depend on the H^1 norm of w.

We now pass to the considerations on the energy associated with solutions of (12).

DEFINITION 3.3. *If $f \in H^1(\mathbb{R})$, we define the energy $E(f)$ by*

$$E(f) := \int \partial_x f \partial_x \overline{f}\ dx - \frac{1}{2}\mathrm{Im}\int f\overline{f}f\partial_x\overline{f}\ dx.$$

By the Gagliardo–Nirenberg inequality we have

$$\|\partial_x f\|_2 \leq C_{\|f\|_2}E(f)^{1/2} \tag{14}$$

for any $f \in H^1$ such that $\|f\|_2 < \sqrt{2\pi}$.

By Plancherel, we write $E(f)$ using the Λ notation and Fourier transform properties as

$$E(f) = -\Lambda_2(\xi_1\xi_2; f) - \frac{1}{2}\mathrm{Im}\Lambda_4(i\xi_4; f). \tag{15}$$

Expanding out the second term using $\mathrm{Im}(z) = (z - \bar{z})/2i$, and using symmetry, we may rewrite this as

$$E(f) = -\Lambda_2(\xi_1\xi_2; f) + \frac{1}{8}\Lambda_4(\xi_{13-24}; f). \tag{16}$$

One can use the same notation to rewrite the L^2 norm as

$$\|w(t)\|_2^2 = \Lambda_2(1; w(t)).$$

LEMMA 3.4 (see [27]). *If w is an H^1 solution to* (12) *for $t \in [0,T]$, then we have*

$$\|w(t)\|_2 = \|w_0\|_2$$

and

$$E(w(t)) = E(w_0)$$

for all $t \in [0,T]$.

In [9] this lemma was proved using the following general proposition (cf. [9]).

PROPOSITION 3.5. *Let $n \geq 2$ be an even integer, let M_n be a multiplier of order n, and let w be a solution of* (12). *Then*

$$\begin{aligned}\partial_t \Lambda_n(M_n; w(t)) &= i\Lambda_n\left(M_n \sum_{j=1}^{n}(-1)^j \xi_j^2; w(t)\right)\\ &\quad - i\Lambda_{n+2}\left(\sum_{j=1}^{n} \mathbf{X}_j^2(M_n)\xi_{j+1}; w(t)\right)\\ &\quad + \frac{i}{2}\Lambda_{n+4}\left(\sum_{j=1}^{n}(-1)^{j-1}\mathbf{X}_j^4(M_n); w(t)\right).\end{aligned} \tag{17}$$

We summarize below the idea we used to prove Proposition 3.2 for $s > \frac{2}{3}$ in [9]. Because we do not want to use the H^1 norm of w, we cannot directly use the energy $E(w(t))$ defined above. So we introduced a substitute notion of "energy" that could be defined for a less regular solution and that had a very slow increment in time. In frequency space consider an even C^∞ monotone multiplier $m(\xi)$ taking values in $[0, 1]$ such that

$$m(\xi) := \begin{cases} 1 & \text{if } |\xi| < N, \\ \left(\frac{|\xi|}{N}\right)^{s-1} & \text{if } |\xi| > 2N. \end{cases} \tag{18}$$

Define the multiplier operator $I : H^s \longrightarrow H^1$ such that $\widehat{Iw}(\xi) := m(\xi)\widehat{w}(\xi)$. This operator is smoothing of order $1 - s$; indeed one has

$$\|u\|_{s_0,b_0} \lesssim \|Iu\|_{s_0+1-s,b_0} \lesssim N^{1-s}\|u\|_{s_0,b_0} \tag{19}$$

for any $s_0, b_0 \in \mathbb{R}$. Our substitute energy was defined by

$$E_N(w) := E(Iw).$$

Note that this energy makes sense even if w is only in H^s. In general, the energy $E_N(w(t))$ is not conserved in time, but we showed that the increment was very small in terms of N.

To proceed with the improvement of the "I-method," let us consider a symmetric multiplier $m(\xi)^2$ and let I be the multiplier operator associated with it. Then we write

$$E^1(w) := E(Iw).$$

Clearly, if m is the multiplier in (18), then

$$E^1(w) = E_N(w),$$

so we can think about $E^1(w)$ as the first generation of a family of modified energies. In this paper we introduce the second generation in detail, but formally the method can be used to define an infinite family of modified energies. We write

$$E^2(w) = -\Lambda_2(m_1\xi_1 m_2\xi_2, w) + \frac{1}{2}\Lambda_4\left(M_4(\xi_1, \xi_2, \xi_3, \xi_4), w\right), \tag{20}$$

[2]This eventually will be taken to be exactly the multiplier in (18).

where M_4 will be determined later. Assume now that w is a solution of (12). Because w is fixed we drop it from the definition of E^2. We are interested in the increment of this second generation of energies, and hence we compute $\frac{d}{dt}E^2$. Differentiating $\Lambda_2(m_1\xi_1 m_2\xi_2)$ using Proposition 3.5, using the identity $\xi_1+\cdots+\xi_n=0$ and symmetrizing, we have

$$\begin{aligned}\frac{d}{dt}\Lambda_2(m_1\xi_1 m_2\xi_2) =& -i\Lambda_2(m_1\xi_1 m_2\xi_2(\xi_1^2-\xi_2^2)) - i\Lambda_4(m_{123}\xi_{123}m_4\xi_4\xi_2 + m_1\xi_1 m_{234}\xi_{234}\xi_3)\\ &+\frac{i}{2}\Lambda_6(m_{12345}\xi_{12345}m_6\xi_6 - m_1\xi_1 m_{23456}\xi_{23456})\\ =&\frac{i}{2}\Lambda_4(\sigma_4(\xi_1,\xi_2,\xi_3,\xi_4)) + \frac{i}{6}\Lambda_6(\sigma_6(\xi_1,\xi_2,\xi_3,\xi_4,\xi_5,\xi_6)),\end{aligned}$$

where

$$\sigma_4(\xi_1,\xi_2,\xi_3,\xi_4) = m_1^2\xi_1^2\xi_3 + m_2^2\xi_2^2\xi_4 + m_3^2\xi_3^2\xi_1 + m_4^2\xi_4^2\xi_2 \tag{21}$$

and

$$\sigma_6(\xi_1,\xi_2,\xi_3,\xi_4,\xi_5,\xi_6) = \sum_{j=1}^{6}(-1)^{j-1}m_j^2\xi_j^2. \tag{22}$$

Notice that the contribution of Λ_2 is zero because the factor $(\xi_1^2-\xi_2^2)$ is zero over the set of integration $\xi_1+\xi_2=0$.

Differentiating $\Lambda_4(M_4)$, we have

$$\begin{aligned}&\frac{d}{dt}\Lambda_4(M_4(\xi_1,\xi_2,\xi_3,\xi_4))\\ &= i\Lambda_4\left(M_4\sum_{j=1}^{4}(-1)^j\xi_j^2\right)\\ &\quad - i\Lambda_6(M_4(\xi_{123},\xi_4,\xi_5,\xi_6)\xi_2 + M_4(\xi_1,\xi_{234},\xi_5,\xi_6)\xi_3\\ &\quad + M_4(\xi_1,\xi_2,\xi_{345},\xi_6)\xi_4 + M_4(\xi_1,\xi_2,\xi_3,\xi_{456})\xi_5)\\ &\quad + \frac{i}{2}\Lambda_8(M_4(\xi_{12345},\xi_6,\xi_7,\xi_8) - M_4(\xi_1,\xi_{23456},\xi_7,\xi_8)\\ &\quad + M_4(\xi_1,\xi_2,\xi_{34567},\xi_8) - M_4(\xi_1,\xi_2,\xi_3,\xi_{45678}))\\ &= i\Lambda_4\left(M_4\sum_{j=1}^{4}(-1)^j\xi_j^2\right)\\ &\quad - \frac{i}{36}\sum_{\substack{\{a,c,e\}=\{1,3,5\}\\ \{b,d,f\}=\{2,4,6\}}}\Lambda_6(M_4(\xi_{abc},\xi_d,\xi_e,\xi_f)\xi_b + M_4(\xi_a,\xi_{bcd},\xi_e,\xi_f)\xi_c\\ &\quad + M_4(\xi_a,\xi_b,\xi_{cde},\xi_f)\xi_d + M_4(\xi_a,\xi_b,\xi_c,\xi_{def})\xi_e)\\ &\quad + C\sum_{\substack{\{a,c,e,g\}=\{1,3,5,7\}\\ \{b,d,f,h\}=\{2,4,6,8\}}}\Lambda_8(M_4(\xi_{abcde},\xi_f,\xi_g,\xi_h) + M_4(\xi_a,\xi_b,\xi_{cdefg},\xi_h)\\ &\quad - M_4(\xi_a,\xi_{bcdef},\xi_g,\xi_h) - M_4(\xi_a,\xi_b,\xi_c,\xi_{defgh})).\end{aligned}$$

Then

$$\begin{aligned}\frac{d}{dt}E^2(w) = &-\frac{i}{2}\Lambda_4(\sigma_4(\xi_1,\xi_2,\xi_3,\xi_4)) + \frac{i}{2}\Lambda_4\left(M_4\sum_{j=1}^{4}(-1)^j\xi_j^2\right)\\ &-\frac{i}{6}\Lambda_6(\sigma_6(\xi_1,\xi_2,\xi_3,\xi_4,\xi_5,\xi_6))\\ &-\frac{i}{72}\sum_{\substack{\{a,c,e\}=\{1,3,5\}\\ \{b,d,f\}=\{2,4,6\}}}\Lambda_6(M_4(\xi_{abc},\xi_d,\xi_e,\xi_f)\xi_b + M_4(\xi_a,\xi_{bcd},\xi_e,\xi_f)\xi_c\\ &+M_4(\xi_a,\xi_b,\xi_{cde},\xi_f)\xi_d + M_4(\xi_a,\xi_b,\xi_c,\xi_{def})\xi_e)\\ &+C_1\sum_{\substack{\{a,c,e,g\}=\{1,3,5,7\}\\ \{b,d,f,h\}=\{2,4,6,8\}}}\Lambda_8(M_4(\xi_{abcde},\xi_f,\xi_g,\xi_h) + M_4(\xi_a,\xi_b,\xi_{cdefg},\xi_h)\\ &-M_4(\xi_a,\xi_{bcdef},\xi_g,\xi_h) - M_4(\xi_a,\xi_b,\xi_c,\xi_{defgh})).\end{aligned}$$

We abbreviate the 6-linear and the 8-linear expressions as $\Lambda_6(M_6(\xi_1,\xi_2,\dots,\xi_6))$ and $\Lambda_8(M_8(\xi_1,\xi_2,\dots,\xi_8))$. We are now ready to make our choice for M_4. From our calculations in [9], we realized that the estimates for the different pieces of Λ_n appearing in the right-hand side of $\frac{d}{dt}E_N(w)$ are easier for n larger.[3] We decided to use the freedom of choosing M_4 to cancel the Λ_4 contribution obtained above. Hence, using (21), we set

$$M_4(\xi_1,\xi_2,\xi_3,\xi_4) = -\frac{m_1^2\xi_1^2\xi_3 + m_2^2\xi_2^2\xi_4 + m_3^2\xi_3^2\xi_1 + m_4^2\xi_4^2\xi_2}{\xi_1^2-\xi_2^2+\xi_3^2-\xi_4^2}, \tag{23}$$

which in the set of integration $\xi_1+\xi_2+\xi_3+\xi_4=0$ can also be written as

$$M_4(\xi_1,\xi_2,\xi_3,\xi_4) = -\frac{m_1^2\xi_1^2\xi_3 + m_2^2\xi_2^2\xi_4 + m_3^2\xi_3^2\xi_1 + m_4^2\xi_4^2\xi_2}{2\xi_{12}\xi_{14}}.$$

Remark 3.6. If we assume that $m(\xi)=1$, then $E^2(w)=E(w)$. In fact, on the set $\xi_1+\xi_2+\xi_3+\xi_4=0$ we have

$$\begin{aligned}&m_1^2\xi_1^2\xi_3 + m_2^2\xi_2^2\xi_4 + m_3^2\xi_3^2\xi_1 + m_4^2\xi_4^2\xi_2\\ &= \xi_1^2\xi_3 + \xi_2^2\xi_4 + \xi_3^2\xi_1 + \xi_4^2\xi_2\\ &= (\xi_1+\xi_3)(\xi_1\xi_3 - \xi_2\xi_4)\\ &= (\xi_1+\xi_3)(\xi_1\xi_3 + (\xi_1+\xi_3+\xi_4)\xi_4)\\ &= -(\xi_1+\xi_3)(\xi_1+\xi_4)(\xi_1+\xi_2);\end{aligned}$$

hence

$$M_4(\xi_1,\xi_2,\xi_3,\xi_4) = \frac{1}{2}(\xi_1+\xi_3) \tag{24}$$

and

$$E^2(w) = -\Lambda_2(\xi_1\xi_2) + \frac{1}{4}\Lambda_4(\xi_{13}),$$

[3] Compare, for example, sections 8, 9, and 10 in [9].

which is exactly the value of $E(w)$ in (15).

Once again we recall that we assume throughout the paper that $s \in (\frac{1}{2}, \frac{2}{3}]$ and that the multiplier m is defined as in (18). To stress the fact that with this choice the energy $E^2(w)$ depends on the parameter N, we write $E^2(w) = E^2_N$. We now summarize some of the above observations in the following.

PROPOSITION 3.7. *Let w be an H^1 global solution to* (12). *Then for any $T \in \mathbb{R}$ and $\delta > 0$ we have*

$$E^2_N(w(T+\delta)) - E^2_N(w(T)) = \int_T^{T+\delta} [\Lambda_6(M_6; w(t)) + \Lambda_8(M_8; w(t))]\, dt,$$

where the multipliers M_6 and M_8 are given by

$$\begin{aligned} M_6 :=& -\frac{i}{6}\sigma_6(\xi_1,\xi_2,\xi_3,\xi_4,\xi_5,\xi_6) \\ &- \frac{i}{72} \sum_{\substack{\{a,c,e\}=\{1,3,5\}\\ \{b,d,f\}=\{2,4,6\}}} (M_4(\xi_{abc},\xi_d,\xi_e,\xi_f)\xi_b + M_4(\xi_a,\xi_{bcd},\xi_e,\xi_f)\xi_c \\ &+ M_4(\xi_a,\xi_b,\xi_{cde},\xi_f)\xi_d + M_4(\xi_a,\xi_b,\xi_c,\xi_{def})\xi_e), \\ M_8 :=& C_2 \sum_{\substack{\{a,c,e,g\}=\{1,3,5,7\}\\ \{b,d,f,h\}=\{2,4,6,8\}}} (M_4(\xi_{abcde},\xi_f,\xi_g,\xi_h) + M_4(\xi_a,\xi_b,\xi_{cdefg},\xi_h) \\ &- M_4(\xi_a,\xi_{bcdef},\xi_g,\xi_h) - M_4(\xi_a,\xi_b,\xi_c,\xi_{defgh})), \end{aligned}$$

where C_2 is an absolute constant. Furthermore, if $|\xi_j| \ll N$ for all j, then the multipliers M_6 and M_8 vanish.

We end this section with a lemma that shows the energy $E^2_N(w)$ has the same strength as $\|Iw\|_{H^1}$.

LEMMA 3.8. *Assume that w satisfies $\|w\|_{L^2} < \sqrt{2\pi}$, $\|Iw\|_{H^1} = O(1)$. Then, for $N \gg 1$,*

$$\|\partial_x Iw\|^2_{L^2} \lesssim E^2_N(w). \tag{25}$$

The proof of this lemma relies strongly on the estimate of the multiplier M_4, and it can be found in the next section.

4. Estimates for M_4 and proof of Lemma 3.8. Before we start with our estimates we recall some notation that we used in [9]. Let $n = 4$, 6, or 8 and let $\xi_1, \dots, \xi_n$ be frequencies such that $\xi_1 + \cdots + \xi_n = 0$. Define $N_i := |\xi_i|$, and $N_{ij} := |\xi_{ij}|$. We adopt the notation that

$$1 \le soprano, alto, tenor, baritone \le n$$

are the distinct indices such that

$$N_{soprano} \ge N_{alto} \ge N_{tenor} \ge N_{baritone}$$

are the highest, second highest, third highest, and fourth highest values of the frequencies $N_1, \dots, N_n$, respectively. (If there is a tie in frequencies, we break the tie arbitrarily.) Since $\xi_1 + \cdots + \xi_n = 0$, we must have $N_{soprano} \sim N_{alto}$. Also, from Proposition 3.7 we see that M_n vanishes unless $N_{soprano} \gtrsim N$.

In this section whenever we write $\max|f(\theta)|$ for a function f we understand that the maximum is taken for $|\theta| \sim N_{soprano}$.

LEMMA 4.1. *Assume M_4 is the multiplier defined in* (23) *and $m(\xi)$ is as in* (18). *Then*

$$|M_4(\xi_1, \dots, \xi_4)| \lesssim m^2(N_{soprano})N_{soprano}. \tag{26}$$

Proof. We observe that to prove (26) it suffices to prove

$$|\sigma_4(\xi_1, \dots, \xi_4)| \lesssim |\xi_{12}||\xi_{12}|m^2(N_{soprano})N_{soprano}.$$

Without loss of generality we may assume that $N_{soprano} = N_1$. By symmetry we can assume that $|\xi_{12}| \le |\xi_{14}|$. We divide the analysis into two cases: Case (a) when $N_1 \lesssim |\xi_{14}|$ and Case (b) when $|\xi_{14}| \ll N_1$.

Case (a). We write

$$\begin{aligned} |\sigma_4(\xi_1, \dots, \xi_4)| &= |m_1^2\xi_1^2\xi_3 + m_2^2\xi_2^2(-\xi_{12} - \xi_3) + m_3^2\xi_3^2\xi_1 + m_{12+3}^2\xi_{12+3}^2\xi_2| \\ &= |\xi_3(m_1^2\xi_1^2 - m_{1-12}^2\xi_{1-12}^2) + \xi_1(m_3^2\xi_3 - m_{3+12}^2\xi_{3+12}^2) \\ &\quad - \xi_{12}(m_2^2\xi_2^2 - m_{12+3}^2\xi_{12+3}^2)|. \end{aligned} \tag{27}$$

Then the MVT shows that

$$|\sigma_4(\xi_1, \xi_2, \xi_3, \xi_4)| \lesssim |\xi_{12}|N_1 \max|(m(\xi)^2\xi^2)'|, \tag{28}$$

where $|\xi| \lesssim N_1$. Now it is easy to see that for m defined in (18)

$$(m^2(\xi)\xi^2)' \sim m^2(\xi)\xi$$

and that the function $m^2(\xi)\xi$ is nondecreasing. Then (28) immediately gives (26).

Case (b). We first write σ_4 so that the DMVT in Lemma 2.3 can be applied. For simplicity we write $m^2(\xi)\xi^2 = f(\xi)$. Then in the set $\xi_1 + \cdots + \xi_4 = 0$ we have

$$\begin{aligned} \sigma_4(\xi_1, \dots, \xi_4) &= f(\xi_1)\xi_3 + f(\xi_2)\xi_4 + f(\xi_3)\xi_1 f(\xi_4)\xi_2 \\ &= \xi_3[f(\xi_1) - f(\xi_2)] + \xi_1[f(\xi_3) - f(-\xi_4)] - \xi_{12}[f(\xi_2) - f(-\xi_4)] \\ &= \xi_3[f(\xi_1) - f(\xi_2) + f(\xi_3) - f(-\xi_4)] \\ &\quad + (\xi_1 - \xi_3)[f(\xi_3) - f(\xi_3 - \xi_{12})] - \xi_{12}[f(\xi_2) - f(-\xi_4)] \\ &= \xi_3[f(\xi_1 - \xi_{12} - \xi_{14}) - f(\xi_1 - \xi_{12}) - f(\xi_1 - \xi_{14}) + f(\xi_1)] \\ &\quad + (-\xi_3 + \xi_1)[f(\xi_3) - f(\xi_3 - \xi_{12})] - \xi_{12}[f(\xi_2) - f(\xi_2 + \xi_{14} - \xi_{12})], \end{aligned}$$

where we often used the fact that $f(\xi)$ is an even function. Using the DMVT in the first term of the right-hand side of the inequality and the MVT in the remaining two terms we obtain

$$\sigma_4(\xi_1, \dots, \xi_4) \lesssim |\xi_1||f''(\theta)||\xi_{12}||\xi_{14}| + |\xi_{12}| \max|f'|(|\xi_{3-1}| + |\xi_{14}| + |\xi_{12}|), \tag{29}$$

where $|\theta| \sim N_1$. Now observe that

$$|\xi_{3-1}| = |\xi_{12} + \xi_{14}| \lesssim |\xi_{14}|$$

and that $|f''(\theta)| \lesssim m(N_1)^2$, so inserting (29) in the definition of M_4 we obtain (26). ∎

We need two more local estimates for M_4.

LEMMA 4.2.

- *Assume that* $|\xi_1| \sim |\xi_3| \gtrsim N \gg |\xi_2|, |\xi_4|$*; then*

$$|M_4(\xi_1, \xi_2, \xi_3, \xi_4)| \lesssim m(N_{soprano})^2 N_{tenor}. \tag{30}$$

- *Assume that* $|\xi_1| \sim |\xi_2| \gtrsim N \gg |\xi_3|, |\xi_4|$*; then*

$$M_4(\xi_1, \xi_2, \xi_3, \xi_4) = \frac{m_1^2 \xi_2^2}{2\xi_1} + R(\xi_1, \dots, \xi_4), \tag{31}$$

where

$$|R(\xi_1, \dots, \xi_4)| \lesssim N_{tenor}.$$

Proof. The first part of the lemma follows from the MVT. In fact,

$$\begin{aligned}\left| \frac{m_1^2 \xi_1^2 \xi_3 + \xi_2^2 \xi_4 + m_3^2 \xi_3^2 \xi_1 + \xi_4^2 \xi_2}{\xi_{12} \xi_{14}} \right| &\lesssim \frac{|\xi_1 \xi_3 \xi_{13}| \max |(m(\xi)^2 \xi)'| + |\xi_{24} \xi_2 \xi_4|}{|\xi_1|^2} \\ &\lesssim m(N_{soprano})^2 N_{tenor},\end{aligned}$$

where again we used that $|(m(\xi)^2 \xi)'| \sim |m(\xi)\xi|$.

To prove the second part of the lemma we use the identity

$$\frac{1}{\xi_{14}} = \frac{1}{\xi_1} - \frac{\xi_4}{\xi_{14}} \frac{1}{\xi_1},$$

and we write

$$-2M_4(\xi_1, \xi_2, \xi_3, \xi_4) + \frac{m_1^2 \xi_2^2}{\xi_1} = R_1(\xi_1, \dots, \xi_4) + R_2(\xi_1, \dots, \xi_4),$$

where

$$\begin{aligned}R_1(\xi_1, \dots, \xi_4) &= \frac{m_1^2 \xi_1^2 \xi_3 + m_2^2 \xi_2^2 \xi_4 + \xi_3^2 \xi_1 + \xi_4^2 \xi_2 + m_1^2 \xi_2^2 \xi_{12}}{\xi_{12} \xi_1}, \\ R_2(\xi_1, \dots, \xi_4) &= -\frac{\xi_4}{\xi_{14}} \frac{m_1^2 \xi_1^2 \xi_3 + m_2^2 \xi_2^2 \xi_4 + \xi_3^2 \xi_1 + \xi_4^2 \xi_2}{\xi_{12} \xi_1}.\end{aligned}$$

We first estimate R_1:

$$\begin{aligned}R_1(\xi_1, \dots, \xi_4) &= \frac{m_1^2 \xi_1^2 \xi_3 + m_2^2 \xi_2^2 \xi_4 + \xi_3^2 \xi_1 + \xi_4^2 \xi_2 - m_1^2 \xi_2^2 \xi_{34}}{\xi_{12} \xi_1} \\ &= \frac{m_1^2 \xi_3 (\xi_1^2 - \xi_2^2) + \xi_2^2 \xi_4 (m_2^2 - m_1^2) + \xi_3^2 (\xi_1 + \xi_2) + \xi_2 (\xi_4^2 - \xi_3^2)}{\xi_{12} \xi_1}, \text{ and}\end{aligned}$$

hence, by the MVT,

$$|R_1(\xi_1, \dots, \xi_4)| \lesssim N_{tenor}.$$

On the other hand,

$$R_2(\xi_1, \dots, \xi_4) = -\frac{\xi_4}{\xi_{14}} \frac{m_1^2 \xi_1^2 (\xi_3 + \xi_4) + (m_2^2 \xi_2^2 - m_1^2 \xi_1^2) \xi_4 + \xi_3^2 \xi_{12} + \xi_2 \xi_{34} \xi_{3-4}}{\xi_{12} \xi_1}, \text{ and}$$

hence, again by the MVT,

$$|R_2(\xi_1, \dots, \xi_4)| \lesssim N_{tenor}. \qquad \square$$

Proof of Lemma 3.8.
Proof. We rewrite $E_N^2(w)$ as

$$E_N^2(w) = -\Lambda_2(m_1\xi_1 m_2\xi_2) + \frac{1}{8}\Lambda_4(\xi_{13-24}m_1m_2m_3m_4) + \frac{1}{8}\Lambda_4(4M_4(\xi_1,\xi_2,\xi_3,\xi_4) - \xi_{13-24}m_1m_2m_3m_4).$$

In Lemma 3.6 of [9] we proved the estimate

$$\|\partial_x Iw\|_{L^2}^2 \lesssim -\Lambda_2(m_1\xi_1 m_2\xi_2) + \frac{1}{8}\Lambda_4(\xi_{13-24}m_1m_2m_3m_4)$$

for $\|Iw\|_{L^2} < \sqrt{2\pi}$. Hence we have only to show that

$$|\Lambda_4(4M_4(\xi_1,\xi_2,\xi_3,\xi_4) - \xi_{13-24}m_1m_2m_3m_4)| \lesssim O\left(\frac{1}{N^\alpha}\right)\|Iw\|_{H^1}^4 \tag{32}$$

for some $\alpha > 0$.

We first perform a Littlewood–Paley decomposition of the four factors w so that the ξ_i are essentially the constants N_i, $i = 1,\dots,4$. To recover the sum at the end we borrow a $N_{soprano}^{-\epsilon}$ from the large denominator $N_{soprano}$ and often this will not be mentioned.

If all $|\xi_j|$ are less than $\frac{N}{100}$, the left-hand side of (32) vanishes thanks to (23). Therefore, we may assume $N_{soprano} \gtrsim N$. Also note $N_{alto} \gtrsim N$ on the set $\xi_1+\xi_2+\xi_3+\xi_4 = 0$. Then it is obvious that

$$|\Lambda_4(\xi_{13-24}m_1m_2m_3m_4)| \lesssim \frac{1}{N}\|Iw\|_{H^1}^2\|Iw\|_{L^\infty}^2 \lesssim \frac{1}{N}\|Iw\|_{H^1}^4.$$

Next we control the contribution of $\Lambda_4(M_4)$ in (32). By (26), we have

$$|\Lambda_4(M_4(\xi_1,\xi_2,\xi_3,\xi_4))| \lesssim \frac{1}{N_{soprano}^{1-}m(N_{baritone})^2N_{baritone}}\|Iw\|_{H^1}^4 \lesssim \frac{1}{N^{1-}}\|Iw\|_{H^1}^4,$$

where again we used the fact that $m^2(\xi)\xi$ is nondecreasing. □

5. Local estimates. This section contains a refinement of the results presented in section 5 of [9]. We start with the main result.

THEOREM 5.1. *Let w be a H^1 global solution to* (12) *and let $T \in \mathbb{R}$ be such that*

$$\|Iw(T)\|_{H^1} \le C_0$$

for some $C_0 > 0$. Then we have

$$\|Iw\|_{X^{1,b}([T,T+\delta]\times\mathbb{R})} \lesssim 1$$

for any $\frac{1}{2} < b < \frac{3}{4}$ and for some $\delta > 0$ depending on C_0.

Remark 5.2. This theorem is stronger than the corresponding Theorem 5.1 in [9] because b can be arbitrarily close to $\frac{3}{4}$, and this is essential to obtain our sharp global well-posedness result.

As explained in [9] the proof of Theorem 5.1 is a consequence of the following multilinear estimates.

LEMMA 5.3. *For the Schwartz function w and $\frac{1}{2} < b < \frac{3}{4},\ b' < \frac{3}{4}$, we have*

$$\|I(w\partial_x \overline{w} w)\|_{1,b'-1} \lesssim \|Iw\|^2_{1,\frac{1}{2}+}\|Iw\|_{1,b}, \tag{33}$$

$$\|I(w\overline{w}w\overline{w}w)\|_{1,b'-1} \lesssim \|Iw\|^5_{1,\frac{1}{2}+}. \tag{34}$$

Proof. The proof of (34) follows from the same arguments used to prove (17) in [9], and we do not present it here again. The proof of (33) on the other hand is more delicate than the one given in [9] for (16), so we decided to give all the details. By standard duality arguments in L^2 and renormalization, it is easy to see that (33) is equivalent to

$$\int_* \frac{m_4\langle\xi_4\rangle|\xi_2|\langle\tau_4+\xi_4^2\rangle^{b'-1}}{\sum_{i=1}^3\langle\tau_i+(-1)^i\xi_i^2\rangle^{b-\frac{1}{2}-}\prod_{j=1}^3 m_j\langle\xi_j\rangle\langle\tau_j+(-1)^j\xi_j^2\rangle^{\frac{1}{2}+}}\prod_{j=1}^4 F_j(\tau_j,\xi_j) \lesssim \prod_{j=1}^4\|F_j\|_{L^2}, \tag{35}$$

where all functions F_j are real-valued and nonnegative. If

$$\frac{m_4\langle\xi_4\rangle|\xi_2|}{\prod_{j=1}^3 m_j\langle\xi_j\rangle} \lesssim 1, \tag{36}$$

then the L^2 estimate (5) for F_4 and the Strichartz estimate (6) with $p=6$ for F_1, F_2, F_3 automatically shows (35) for $b > \frac{1}{2},\ b' \le 1$. Then we may assume

$$\frac{m_4\langle\xi_4\rangle|\xi_2|}{\prod_{j=1}^3 m_j\langle\xi_j\rangle} \gg 1,$$

which, one can easily check, can happen only when

$$|\xi_2| \gg 1, \quad |\xi_{12}| \gg 1, \quad |\xi_{14}| \gg 1.$$

We recall (cf. [3] and [9]) the fundamental inequality

$$|\xi_{12}\xi_{14}| \lesssim \max_{j=1,2,3,4}\{\langle\tau_j+(-1)^j\xi_j^2\rangle\}. \tag{37}$$

Then we proceed with a case by case analysis: Case (a) if $\max_{j=1,2,3}\{\langle\tau_4+\xi_4^2\rangle, \langle\tau_j+(-1)^j\xi_j^2\rangle\} = \langle\tau_4+\xi_4^2\rangle$ and Case (b) if $\max_{j=1,2,3}\{\langle\tau_4+\xi_4^2\rangle, \langle\tau_j+(-1)^j\xi_j^2\rangle\} = \langle\tau_i+(-1)^j\xi_i^2\rangle$ for some $i=1,2,3$.

- *Case* (a). In this case we replace in the denominator $\langle\tau_4+\xi_4^2\rangle^{1-b'}$ with $(\langle\xi_{12}\rangle\langle\xi_{14}\rangle)^{1-b'}$. Then, using the same argument that in [9] led us from (16) to (18), we can show that (35) is equivalent to

$$\int_* \frac{\langle\xi_4\rangle^s\langle\xi_2\rangle^{1-s}}{(\langle\xi_{12}\rangle\langle\xi_{14}\rangle)^{1-b'}\langle\xi_1\rangle^s\langle\xi_3\rangle^s\prod_{j=1}^3\langle\tau_j+(-1)^j\xi_j^2\rangle^{\frac{1}{2}+}}\prod_{j=1}^4 F_j(\tau_j,\xi_j) \lesssim \prod_{j=1}^4\|F_j\|_{L^2}. \tag{38}$$

To have an idea of the "numerics" involved while proceeding with the proof, the reader should keep in mind that the interesting case is when $s = \frac{1}{2}+$ and $1 - b' = \frac{1}{4}+$. Since $\xi_{14} = -\xi_{32}$, by symmetry, we may assume that $|\xi_1| \geq |\xi_3|$. Then, using the fact that $\xi_4 = -\xi_3 - \xi_{12}$, we can write

$$\frac{\langle \xi_4 \rangle^s \langle \xi_2 \rangle^{1-s}}{(\langle \xi_{12} \rangle \langle \xi_{14} \rangle)^{1-b'} \langle \xi_1 \rangle^s \langle \xi_3 \rangle^s} = A_1 + A_2, \tag{39}$$

where

$$A_1 \lesssim \frac{\langle \xi_2 \rangle^{1-s}}{(\langle \xi_{12} \rangle \langle \xi_{14} \rangle)^{1-b'} \langle \xi_1 \rangle^s},$$
$$A_2 \lesssim \frac{\langle \xi_{12} \rangle^{s-1+b'} \langle \xi_2 \rangle^{1-s}}{\langle \xi_{14} \rangle^{1-b'} \langle \xi_1 \rangle^s \langle \xi_3 \rangle^s}.$$

We now write $\xi_{12} = -\xi_{14} - \xi_3 + \xi_1$, and we write

$$A_2 = A_2^1 + A_2^2 + A_2^3,$$

where

$$A_2^1 \lesssim \frac{\langle \xi_2 \rangle^{1-s}}{\langle \xi_{14} \rangle^{2(1-b')-s} \langle \xi_1 \rangle^s \langle \xi_3 \rangle^s},$$
$$A_2^2 \lesssim \frac{\langle \xi_2 \rangle^{1-s}}{\langle \xi_{14} \rangle^{1-b'} \langle \xi_3 \rangle^{1-b'} \langle \xi_1 \rangle^s},$$
$$A_2^3 \lesssim \frac{\langle \xi_2 \rangle^{1-s}}{\langle \xi_{14} \rangle^{1-b'} \langle \xi_1 \rangle^{1-b'} \langle \xi_3 \rangle^s}.$$

It is now easy to see that, for $1 - b' \geq \frac{s}{2}$,

$$A_1, A_2^i(\xi_1, \xi_2, \xi_3) \lesssim \frac{\langle \xi_2 \rangle^{\frac{1}{2}}}{\langle \xi_1 \rangle^{\frac{s}{2}} \langle \xi_3 \rangle^{\frac{s}{2}}} \quad \text{for all } i = 1, 2, 3.$$

Then by (9) and (11) we obtain

$$\int_* \frac{\langle \xi_4 \rangle^s \langle \xi_2 \rangle^{1-s}}{(\langle \xi_{12} \rangle \langle \xi_{14} \rangle)^{1-b'} \langle \xi_1 \rangle^s \langle \xi_3 \rangle^s \prod_{j=1}^3 \langle \tau_j + (-1)^j \xi_j^2 \rangle^{\frac{1}{2}+}} \prod_{j=1}^4 F_j(\tau_j, \xi_j)$$
$$\lesssim \|\widetilde{\mathcal{F}}^{-1}(F_4)\|_{L^2_{xt}} \left\| \widetilde{\mathcal{F}}^{-1} \left(\frac{\langle \xi \rangle^{\frac{1}{2}}}{\langle \tau + \xi^2 \rangle^{\frac{1}{2}+}} F_2 \right) \right\|_{L^\infty_x L^2_t} \| \widetilde{\mathcal{F}}^{-1} \left(\frac{\langle \xi \rangle^{-\frac{s}{2}}}{\langle \tau - \xi^2 \rangle^{\frac{1}{2}+}} F_3 \right) \|_{L^4_x L^\infty_t}$$
$$\times \| \widetilde{\mathcal{F}}^{-1} \left(\frac{\langle \xi \rangle^{-\frac{s}{2}}}{\langle \tau - \xi^2 \rangle^{\frac{1}{2}+}} F_1 \right) \|_{L^4_x L^\infty_t} \lesssim \prod_{j=1}^4 \|F_j\|_{L^2}.$$

- *Case* (b). In this case we borrow a power $\alpha = b' - \frac{1}{2}+$ from the large denominator, and we reduce our estimate to

$$\int_* \frac{\langle \xi_4 \rangle^s \langle \xi_2 \rangle^{1-s}}{\langle \xi_1 \rangle^s \langle \xi_3 \rangle^s \prod_{j=1}^4 \langle \tau_j + (-1)^j \xi_j^2 \rangle^{\frac{1}{2}+}} \prod_{j=1}^4 F_j(\tau_j, \xi_j) \lesssim \prod_{j=1}^4 \|F_j\|_{L^2}.$$

Again by symmetry we can assume that $|\xi_1| \geq |\xi_3|$. We first observe that if the exponent of $\langle \xi_4 \rangle$ were $\frac{1}{2}$, then we could simply use (9) for the function F_2 and (10) for the function F_4 to obtain the estimate as we did above. However, in our case $s > \frac{1}{2}$, so we have to do a bit more work. We subdivide the analysis into subcases.

– *Subcase* (1). $|\xi_4| \lesssim |\xi_2|$. In this case we can write

$$\langle \xi_4 \rangle^s \langle \xi_2 \rangle^{1-s} \lesssim \langle \xi_4 \rangle^{\frac{1}{2}} \langle \xi_2 \rangle^{\frac{1}{2}},$$

and we can indeed use (9) and (10).

– *Subcase* (2). $|\xi_2| \ll |\xi_4|$. Because we assumed that $|\xi_3| \leq |\xi_1|$ and we are on the set $\xi_1 + \cdots + \xi_4 = 0$, it follows that $|\xi_4| \lesssim |\xi_1|$. Then the estimate becomes

$$\begin{aligned}
&\int_* \frac{\langle \xi_2 \rangle^{1-s}}{\langle \xi_3 \rangle^s \prod_{j=1}^4 \langle \tau_j + (-1)^j \xi_j^2 \rangle^{\frac{1}{2}+}} \prod_{j=1}^4 F_j(\tau_j, \xi_j) \\
&\lesssim \left\| \widetilde{\mathcal{F}}^{-1} \left(\frac{1}{\langle \tau + \xi^2 \rangle^{\frac{1}{2}+}} F_4 \right) \right\|_{L^4_{xt}} \left\| \widetilde{\mathcal{F}}^{-1} \left(\frac{1}{\langle \tau - \xi^2 \rangle^{\frac{1}{2}+}} F_1 \right) \right\|_{L^4_{xt}} \\
&\times \left\| \widetilde{\mathcal{F}}^{-1} \left(\frac{\langle \xi \rangle^{1-s}}{\langle \tau + \xi^2 \rangle^{\frac{1}{2}+}} F_2 \right) \right\|_{L^\infty_x L^2_t} \\
&\times \left\| \widetilde{\mathcal{F}}^{-1} \left(\frac{\langle \xi \rangle^{-s}}{\langle \tau - \xi^2 \rangle^{\frac{1}{2}+}} F_3 \right) \right\|_{L^2_x L^\infty_t} \lesssim \prod_{j=1}^4 \|F_j\|_{L^2},
\end{aligned}$$

thanks to (6) for $p = 2$, (9), and (10). □

6. Proof of Proposition 3.2. Based on Lemma 3.8, Theorem 5.1, and the arguments presented in [9, section 6] (see also the comments in [9, section 7]), the only result that one needs to obtain is the following.

LEMMA 6.1. *For any Schwartz function w, we have*

$$\left| \int_T^{T+\delta} \Lambda_n(M_n; w(t))\, dt \right| \lesssim \frac{1}{N^{2-}} \|Iw\|^n_{X^{1,3/4-}([T,T+\delta]\times\mathbb{R})} \tag{40}$$

for $n = 6, 8$, where M_6, M_8 are defined in Proposition 3.7.

In [9] we were only able to obtain a decay of N^{-1+}, which is why we could only prove global well-posedness for $s > \frac{2}{3}$.

The proof of this lemma is a corollary of the four lemmas that follow in this section.

LEMMA 6.2 ($n = 8$).

$$|M_8(\xi_1, \xi_2, \ldots, \xi_8)| \lesssim N_{soprano} m^2(N_{soprano}).$$

This is a simple consequence of Lemma 4.1. We now turn to the estimate of $\frac{d}{dt} E^2(Iw)$ involving Λ_8.

LEMMA 6.3.

$$\left| \int_T^{T+\delta} \int \Lambda_8(M_8(\xi_1, \xi_2, \ldots, \xi_8))\, dt \right| \lesssim \frac{1}{N^{2-}} \|Iw\|^8_{1,\frac{1}{2}+}.$$

Proof. As in the proof of Lemma 3.8, also in this case we first perform a Littlewood–Paley decomposition of the eight factors w so that the ξ_i essentially are the constants N_i, $i = 1, \dots, 8$. To recover the sum at the end we borrow a $N_{soprano}^{-\epsilon}$ from the large denominator $N_{soprano}$. Often this will not be mentioned, and it will only be recorded at the end by paying a price equivalent to N^{0+}. Below we often use the set of indices $R = \{soprano, alto, tenor\}$. Again we proceed by analyzing different cases.

- *Case* (a). $N_{soprano} \sim N_{tenor}$. By Lemma 6.2 and the fact that $m(\xi)\langle\xi\rangle^{\frac{1}{2}}$ is increasing, we have

$$\begin{aligned}&\left|\int_T^{T+\delta}\int \Lambda_8(M_8(\xi_1,\xi_2,\dots,\xi_8))\,dt\right|\\ &\lesssim \sum_{R,j}\frac{N_{soprano}}{m(N_{tenor})}\|D_xIw_{soprano}\|_{L^6}\|D_xIw_{alto}\|_{L^6}\|D_xIw_{tenor}\|_{L^6}\\ &\quad\prod_{j,k\notin R}\|D_xIw_j\|_{L^6}\|D_x^{1/2-}Iw_k\|_{L^\infty}^2 \lesssim \frac{1}{N^{2-}}\|Iw\|_{1,\frac{1}{2}+}^8.\end{aligned}$$

- *Case* (b). $N_{soprano} \gg N_{tenor}$. By Lemma 2.2, and again the monotonicity of $m(\xi)\langle\xi\rangle^{1/2}$, we have

$$\begin{aligned}&\left|\int_T^{T+\delta}\int \Lambda_8(M_8(\xi_1,\xi_2,\dots,\xi_8))\,dt\right|\\ &\lesssim N_{soprano}\|Iw_{soprano}w_{tenor}\|_{L^2}\|Iw_{alto}w_{baritone}\|_{L^2}\\ &\times\|w\|_{L^\infty}^4 \lesssim \frac{1}{N^{2-}}\|Iw\|_{1,\frac{1}{2}+}^8. \qquad \square\end{aligned}$$

LEMMA 6.4 ($n = 6$).

- *If* $N_{tenor} \gtrsim N$, *we have*

$$|M_6(\xi_1,\xi_2,\dots,\xi_6)| \lesssim m(N_{soprano})^2 N_{soprano}^2. \tag{41}$$

- *If* $N_{tenor} \ll N$, *we have*

$$|M_6(\xi_1,\xi_2,\dots,\xi_6)| \lesssim N_{soprano}N_{tenor}. \tag{42}$$

Proof. If $N_{soprano} \ll N$, M_6 vanishes. Then we may assume $N_{soprano} \gtrsim N$. Also in the set $\xi_1 + \cdots + \xi_6 = 0$ we have $N_{alto} \sim N_{soprano}$.

The proof of (41) follows from (26). The proof of (42) is more delicate. By symmetry we assume $soprano = 1$, $N_1 \geq N_3 \geq N_5$, $N_2 \geq N_4 \geq N_6$. Again we analyze different cases.

- *Case* (a). $alto = 2$. The MVT shows

$$\begin{aligned}|\sigma_6(\xi_1,\xi_2,\dots,\xi_6)| &\lesssim m(N_1)^2N_1N_{12} + m(N_{tenor})^2N_{tenor}^2\\ &\lesssim m(N_{soprano})^2N_{soprano}N_{tenor}.\end{aligned}$$

Next we estimate the second term in M_6:

$$\sum (M_4(\xi_{abc},\xi_d,\xi_e,\xi_f)\xi_b + M_4(\xi_a,\xi_{bcd},\xi_e,\xi_f)\xi_c + M_4(\xi_a,\xi_b,\xi_{cde},\xi_f)\xi_d + M_4(\xi_a,\xi_b,\xi_c,\xi_{def})\xi_e).$$

Again by (26) one has that

$$|M_4(\xi_{abc},\xi_d,\xi_e,\xi_f)\xi_g| \lesssim m(N_{soprano})^2 N_{soprano} N_{tenor} \tag{43}$$

for every $a,\dots,g \in \{1,\dots,6\}$ and $g \neq soprano, alto$. Thus we have only to consider the contributions

$$\left| \sum_{(a,e)\in\{3,5\}} \sum_{(d,f)\in\{4,6\}} M_4(\xi_{a21},\xi_d,\xi_e,\xi_f)\xi_2 + M_4(\xi_a,\xi_{21d},\xi_e,\xi_f)\xi_1 \right|$$

$$+ \left| \sum_{(a,c)\in\{3,5\}} \sum_{(d,f)\in\{4,6\}} M_4(\xi_a,\xi_{12b},\xi_e,\xi_f)\xi_1 + M_4(\xi_a,\xi_b,\xi_{12e},\xi_f)\xi_2 \right|$$

$$+ \left| \sum_{(a,c)\in\{3,5\}} \sum_{(d,f)\in\{4,6\}} M_4(\xi_a,\xi_b,\xi_{12c},\xi_f)\xi_2 + M_4(\xi_a,\xi_b,\xi_c,\xi_{12f})\xi_1 \right|$$

$$+ \left| \sum_{(a,e)\in\{3,5\}} \sum_{(d,f)\in\{4,6\}} M_4(\xi_{a2c},\xi_d,\xi_1,\xi_f)\xi_2 + M_4(\xi_a,\xi_2,\xi_c,\xi_{d1f})\xi_1 \right| = \sum_{i=1}^{4} I_i.$$

Observe first that all the variables appearing in the function M_4 in $\sum_{i=1}^3 I_i$ are strictly smaller that $\frac{N}{2}$, and hence by (24) it follows that

$$\sum_{i=1}^{3} I_i \lesssim N_{soprano} N_{tenor}.$$

To estimate I_4 we use (30) and the symmetry of M_4. Then also in this case we obtain

$$I_4 \lesssim N_{soprano} N_{tenor}.$$

- *Case* (b). $alto = 3$. In this case we need some cancellation between the large terms coming from $\sigma_6(\xi_1,\dots,\xi_6)$ and the large terms of the sum of the M_4. From (43) it is easy to see that one needs to estimate only

$$\begin{aligned}\widetilde{M}_6(\xi_1,\dots,\xi_6) = &-\frac{1}{6}(m_1^2\xi_1^2 + m_3^2\xi_3^2) \\ &- \frac{\xi_1}{36}\left(\sum_{(b,d,f)\in\{2,4,6\}} M_4(\xi_a,\xi_{b1d},\xi_3,\xi_f) + M_4(\xi_a,\xi_b,\xi_3,\xi_{d1f})\right) \\ &- \frac{\xi_3}{36}\left(\sum_{(b,d,f)\in\{2,4,6\}} M_4(\xi_a,\xi_b,\xi_1,\xi_{d3f}) + M_4(\xi_a,\xi_{b3d},\xi_1,\xi_f)\right).\end{aligned}$$

We now use (31) and the symmetries of M_4 to write

$$\begin{aligned}
\widetilde{M_6}(\xi_1,\dots,\xi_6) = &-\frac{1}{6}(m_1^2\xi_1^2+m_3^2\xi_3^2)\\
&-\frac{\xi_1}{72}\left(\sum_{(b,d,f)\in\{2,4,6\}}\frac{m_3^2(\xi_{b1d}^2+\xi_{b1f}^2)}{\xi_3}\right)+O(N_{soprano}N_{tenor})\\
&-\frac{\xi_3}{72}\left(\sum_{(b,d,f)\in\{2,4,6\}}\frac{m_1^2(\xi_{d3f}^2+\xi_{b3d}^2)}{\xi_1}\right)+O(N_{soprano}N_{tenor})\\
=&-\frac{1}{6}(m_1^2\xi_1^2+m_3^2\xi_3^2)\\
&+\frac{1}{72}\left(\sum_{(b,d,f)\in\{2,4,6\}}m_3^2(\xi_{b1d}^2+\xi_{b1f}^2)\right)+O(N_{soprano}N_{tenor})\\
&+\frac{1}{72}\left(\sum_{(b,d,f)\in\{2,4,6\}}m_1^2(\xi_{d3f}^2+\xi_{b3d}^2)\right)+O(N_{soprano}N_{tenor})\\
=&-\frac{1}{72}m_3^2\sum_{(b,d,f)\in\{2,4,6\}}(\xi_3^2-\xi_{1bd}^2)+(\xi_3^2-\xi_{1fb}^2)\\
&-\frac{1}{72}m_1^2\sum_{(b,d,f)\in\{2,4,6\}}(\xi_1^2-\xi_{3bf}^2)+(\xi_1^2-\xi_{b3d}^2)\\
&+O(N_{soprano}N_{tenor}),
\end{aligned}$$

and now it is clear that also in this case

$$|\widetilde{M_6}(\xi_1,\dots,\xi_6)|\lesssim N_{soprano}N_{tenor}. \qquad \square$$

LEMMA 6.5.

$$\left|\int_T^{T+\delta}\int\Lambda_6(M_6(\xi_1,\xi_2,\dots,\xi_6))\,dt\right|\lesssim\frac{1}{N^{2-}}\|Iw\|_{1,\frac{3}{4}-}^6. \tag{44}$$

Proof. Also in this case one uses a Littlewood–Paley decomposition to start. We divide the proof into three different cases: Case (a) when $N_{baritone}\gtrsim N$, Case (b) when $N_{soprano}\geq N_{tenor}\gtrsim N\gg N_{baritone}$, and Case (c) when $N_{soprano}\sim N_{alto}\gtrsim N\gg N_{tenor}$. Below we often use the two sets of indices $S=\{soprano, alto, tenor, baritone\}$ and $R=\{soprano, alto, tenor\}$. We also recall that thanks to the fact that $m(\xi)|\xi|^{\frac{1}{2}}$ is not decreasing,

$$m(\xi)(1+|\xi|)\gtrsim\begin{cases}N & \text{if } |\xi|>\frac{N}{2},\\ 1 & \text{if } |\xi|\leq\frac{N}{2}.\end{cases} \tag{45}$$

- *Case* (a). $N_{baritone} \gtrsim N$. By Lemma 6.4, (45), and the Strichartz estimate (4), we have

$$\begin{aligned}
&\left| \int_T^{T+\delta} \int \Lambda_6(M_6(\xi_1, \xi_2, \dots, \xi_6))\, dt \right| \\
&\lesssim \sum_{S,j} \frac{1}{N_{soprano} N} m(N_{soprano}) N_{soprano} \|w_{soprano}\|_{L^6} \\
&\times m(N_{alto}) N_{alto} \|w_{alto}\|_{L^6} m(N_{tenor}) N_{tenor} \|w_{tenor}\|_{L^6} \\
&\times m(N_{baritone}) N_{baritone} \|w_{baritone}\|_{L^6} \\
&\times \prod_{j \notin S} \|Iw_j\|_{L^6} \lesssim \frac{1}{N^{2-}} \|Iw\|^6_{1,\frac{1}{2}+}.
\end{aligned}$$

- *Case* (b). $N_{soprano} \geq N_{tenor} \gtrsim N \gg N_{baritone}$. This is the only part in which we need to use the space $X^{1,b}$ with $b \sim \frac{3}{4}-$. By Lemma 6.4 and (45) we have

$$\begin{aligned}
&\left| \int_T^{T+\delta} \int \Lambda_6(M_6(\xi_1, \xi_2, \dots, \xi_6))\, dt \right| \\
&\lesssim \sum_{R,j} \frac{1}{N_{soprano}} m(N_{soprano}) N_{soprano} \|w_{soprano} w_{baritone}\|_{L^2} \\
&\times m(N_{alto}) N_{alto} \|w_{alto}\|_{L^6} m(N_{tenor}) N_{tenor} \|w_{tenor}\|_{L^6} \prod_{j \notin R} \|D_x^{\frac{1}{2}} Iw_j\|_{L^{12}}.
\end{aligned}$$

Using Lemma 2.2 and (45), it is easy to see that

$$\begin{aligned}
&m(N_{soprano}) N_{soprano} \|w_{soprano} w_{baritone}\|_{L^2} \\
&\lesssim N^{-1/2} \|Iw_{soprano}\|_{X^{1,\frac{1}{2}+}} \|Iw_{baritone}\|_{X^{1,\frac{1}{2}+}}.
\end{aligned}$$

Also by the Sobolev inequalities and again (45)

$$\prod_{j \notin R} \|D_x^{\frac{1}{2}} Iw_j\|_{L^{12}} \lesssim \prod_{j \notin R} \|Iw_j\|_{X^{1,\frac{1}{2}+}}.$$

Collecting the above estimates one obtains

$$\left| \int_T^{T+\delta} \int \Lambda_6(M_6(\xi_1, \xi_2, \dots, \xi_6))\, dt \right| \lesssim \frac{1}{N^{\frac{3}{2}-}} \|Iw\|^6_{1,\frac{1}{2}+}.$$

Unfortunately, the decay $N^{-\frac{3}{2}+}$ is not enough for our purposes. Because the local estimate allow us to handle terms of type $\|Iw\|_{1,\frac{3}{4}-}$ (see section 5), we take advantage of the extra denominators. To see this we use the identity

$$\xi_1 + \cdots + \xi_4 = 0 \implies \xi_1^2 - \xi_2^2 + \xi_3^2 - \xi_4^2 = 2\xi_{12}\xi_{14},$$

proved in [9]. We consider only the case $N_1 = N_{soprano}, N_2 = N_{alto}$, and $N_3 = N_{tenor}$. Indeed if $N_5 = N_{tenor}$ the argument is easier. Then in the set $\xi_1 + \cdots + \xi_6 = 0$ we write

$$\begin{aligned}\sum_{i=1}^{6}(-1)^{i-1}\xi_i^2 &= \xi_1^2 - \xi_2^2 + \xi_3^2 - (\xi_4+\xi_5+\xi_6)^2 \\ &\quad +(\xi_4+\xi_5+\xi_6)^2 - \xi_4^2 + \xi_5^2 - \xi_6^2 \\ &= 2\xi_{12}\xi_{1456} + (\xi_4+\xi_5+\xi_6)^2 - \xi_4^2 + \xi_5^2 - \xi_6^2,\end{aligned}$$

which implies that

$$\left|\sum_{i=1}^{6}(-1)^{i-1}\xi_i^2\right| \gtrsim N^2,$$

and for $\lambda_1 + \cdots + \lambda_6 = 0$

$$N^2 \lesssim \max_{i=1,\dots,6} |\lambda_i + (-1)^i \xi_i^2|. \tag{46}$$

If the integral in time were performed on the whole real line instead of $[T, T+\delta]$, then, after paying the price of the extra factor $\max_{i=1,\dots,6} |\lambda_i + (-1)^i\xi_i^2|^{\frac{1}{4}}$, one would obtain

$$\left|\int_T^{T+\delta}\int \Lambda_6(M_6(\xi_1,\xi_2,\dots,\xi_6))\,dt\right| \lesssim \frac{1}{N^{2-}}\|Iw\|^6_{1,\frac{3}{4}-}.$$

This argument has to be modified when the time integral is performed on a finite interval $[T, T+\delta]$, due to the fact that $\chi_{[T,T+\delta]}$, the characteristic function of the interval $[T, T+\delta]$, is not smooth enough. A similar difficulty was encountered also in [9]. We split

$$\chi_{[T,T+\delta]}(t) = a(t) + b(t),$$

where

$$\hat{a}(\tau) = \widehat{\chi_{[T,T+\delta]}}(\tau)\eta(\tau/N^2),$$

and η is supported on a small interval of 0 and equals 1 near 0, so a is smoothing out $\chi_{[T,T+\delta]}$ at scale N^{-2}. If one replaces $\chi_{[T,T+\delta]}(t)$ with $a(t)$, then the argument above works because the Fourier transform of $a(t)$ is supported on $|\tau| \ll N^2$, and one can still obtain the crucial inequality (46). We now have to deal with $b(t)$. It is easy to check that

$$\|b(t)\|_{L^1_t} \lesssim N^{-2}.$$

So we just have to show that

$$\sup_t |\Lambda_6(M_6; w_1(t),\dots,w_6(t))| \lesssim \prod_{j=1}^{6}\|Iw_j\|_{X^{1,\frac{3}{4}-}}. \tag{47}$$

We can crudely use Lemma 6.4 and obtain

$$|\Lambda_6(M_6; w_1(t), \dots, w_6(t))| \lesssim m_{soprano}^2 N_{soprano}^2 \|w_{soprano}\|_{L_t^\infty L_x^2} \|w_{alto}\|_{L_t^\infty L_x^2} \times \|w_{tenor}\|_{L_t^\infty L_x^\infty} \|w_{baritone}\|_{L_t^\infty L_x^\infty} \prod_{j \notin S} \|Iw_j\|_{L_t^\infty L_x^\infty},$$

which gives (47) by the Sobolev embedding theorem.

- *Case* (c). $N_{soprano} \sim N_{alto} \gtrsim N \gg N_{tenor}$. By Lemma 6.4, Lemma 2.2, Sobolev inequality, and (45), we have

$$\begin{aligned} \left| \int\int \Lambda_6(M_6(\xi_1, \xi_2, \dots, \xi_6)) \right| &\lesssim \sum_{S,j} \frac{1}{m_{alto}^2 N_{alto}} N_{soprano} N_{tenor} \\ &\quad \times \|Iw_{soprano} Iw_{tenor}\|_{L^2} \\ &\quad \times N_{alto} \|Iw_{alto} Iw_{baritone}\|_{L^2} \prod_{j \notin S} \|w_j\|_{L^\infty} \\ &\lesssim \frac{1}{N^{2-}} \|Iw\|_{1, \frac{1}{2}+}. \end{aligned}$$

This concludes the proof of the lemma. □

ON THE HÖLDER CONTINUITY OF SOLUTIONS OF A CERTAIN SYSTEM RELATED TO MAXWELL'S EQUATIONS*

KYUNGKEUN KANG† AND SEICK KIM†

Abstract. We study the system $\operatorname{curl}(a(x)\operatorname{curl} u) = 0$, $\operatorname{div} u = 0$ with a bounded measurable coefficient $a(x)$. The main result of this paper is the Hölder continuity of weak solutions of the system above. As an application, we prove the C^α regularity of weak solutions of the Maxwell's equations in a quasi-stationary electromagnetic field.

Key words. interior regularity, Maxwell's equations, measurable coefficients

1. Introduction.

Let Ω be a domain in $\mathbb{R}^3$ and $a \in L^\infty(\Omega)$ be a scalar function bounded by two positive numbers m, M. In this paper we study the regularity problem of the following system:

$$\left.\begin{array}{c} \nabla \times [a(x)\nabla \times u] = f + \nabla \times g \\ \nabla \cdot u = 0 \end{array}\right\} \quad \text{in} \quad \Omega. \tag{1.1}$$

Here we denote $\nabla \times u = \operatorname{curl} u$ and $\nabla \cdot u = \operatorname{div} u$. The question about the regularity of the solution of such a system was raised by Professor M. Giaquinta. The main result of this paper is the Hölder continuity of weak solutions of system (1.1) under appropriate assumptions on the inhomogeneous terms f, g.

The above system arises from Maxwell's equations in a quasi-stationary electromagnetic field where the displacement of electrical current is assumed to be time independent. We are grateful to Professor M. Hong for valuable discussions elucidating the connection between the system (1.1) and Maxwell's equations. In the study of the penetration of a magnetic field in materials, the electrical resistance strongly depends on the temperature, and, by taking the temperature effect into consideration, the classical Maxwell system in a quasi-stationary electromagnetic field reduces to the following mathematical model: find $H(x,t)$ and $u(x,t)$ such that

$$\begin{cases} H_t + \nabla \times [\sigma(u)\nabla \times H] = 0, \\ \nabla \cdot H = 0, \\ u_t - \Delta u = \sigma(u)\,|\nabla \times H|^2, \end{cases} \tag{1.2}$$

where H and u represent, respectively, the strength of the magnetic field and temperature, while $\sigma(u)$ denotes the electrical resistivity of the material (see, e.g., [9], [10]). In particular, in the steady state we have the following steady-state system:

$$\begin{cases} \nabla \times [\sigma(u)\nabla \times H] = 0, \\ \nabla \cdot H = 0, \\ -\Delta u = \sigma(u)\,|\nabla \times H|^2. \end{cases} \tag{1.3}$$

Global existence of a pair of weak solutions (H, u) of the system (1.2) was established by Yin [9]. However, the continuity of weak solutions of the system (1.2) as well as the system (1.3) was unknown. In section 3, we will show that, by using our result on the linear system (1.1), weak solutions of the coupled nonlinear system (1.3) are locally Hölder continuous.

As we mentioned earlier, the motivation for studying the system (1.1) is an interesting question which has been raised by Giaquinta and Hong [4]. The original formulation of the question appears in terms of differential forms. However, in the case when $n = 3$, it can be rephrased as follows: Are weak solutions to the following system locally Hölder continuous?

$$\left.\begin{array}{c} \nabla \times [a(x)\nabla \times u] = 0 \\ \nabla \cdot u = 0 \end{array}\right\} \quad \text{in} \quad \Omega. \tag{1.4}$$

Indeed, the above system (1.4) is a special case of (1.1), and, as we mentioned at the beginning, the answer is positive when $n = 3$. We don't know the answer for higher dimensions $n \geq 4$. In section 4 we will formulate their original question by using differential forms and discuss some related problems. Very recently, we received a preprint by Yin [11], in which a similar result to ours is obtained. It seems [11] used an idea similar to ours, although technical details are different.

2. Main results: Hölder estimates. In this section we shall always assume $n = 3$. First, we will introduce notations.

- For $x \in \mathbb{R}^n$ and $\rho > 0$, we define $B_\rho(x) = \{y \in \mathbb{R}^n : |x - y| < \rho\}$.
- For a measurable set $S \subset \mathbb{R}^n$, we define $\fint_S f = \frac{1}{|S|}\int_S f\,dx$.
- We denote $(f)_{x,\rho} = f_{x,\rho} = \fint_{B_\rho(x)} f\,dx$.
- We denote $B_\rho = B_\rho(x)$ and $f_\rho = f_{x,\rho}$ if x is clear from the context.
- Let $\mathcal{D}(\Omega) = \mathcal{D}(\Omega; \mathbb{R}^n) = \{f \in C^\infty(\Omega; \mathbb{R}^n) : \nabla \cdot f = 0\}$. We denote by $\mathcal{H}^q(\Omega)$, $q \in [1, \infty)$, the completion of $\mathcal{D}(\Omega)$ in the norm of $L^q(\Omega)$.
- $\Omega' \Subset \Omega$ means Ω' is a precompact subset of Ω.
- For $u = (u^1, \dots, u^n)$, we denote by ∇u the gradient matrix: $(\nabla u)_{ij} = D_j u^i$.

Now we will state our main results. Consider the following linear system:

$$\left.\begin{array}{c} \nabla \times [a(x)\nabla \times u] = f \\ \nabla \cdot u = 0 \end{array}\right\} \quad \text{in} \quad \Omega, \tag{2.1}$$

where $f \in \mathcal{H}^q(\Omega; \mathbb{R}^n)$ and $a \in L^\infty(\Omega; \mathbb{R})$ such that $m \leq a \leq M$ for some constants $m, M > 0$. The restriction $f \in \mathcal{H}^q(\Omega; \mathbb{R}^n)$ arises from the consistency condition

$$0 = \nabla \cdot \nabla \times [a(x)\nabla \times u] = \nabla \cdot f$$

in the sense of distribution.

THEOREM 2.1. *Let $u \in W^{1,2}_{loc}(\Omega; \mathbb{R}^n)$ be a weak solution of the system (2.1) with $f \in \mathcal{H}^q_{loc}(\Omega)$, $q > n/2$. Let $B := B_R(x_0) \Subset \Omega$. Then there exist constants $\alpha = \alpha(m, M, q) > 0$ and $C = C(m, M, q, R)$ such that u is Hölder continuous in $B_{R/16}(x_0)$ and*

$$\|u\|_{C^{0,\alpha}(\overline{B}_{R/16})} \leq C\left[\|u\|_{L^2(B)} + \|f\|_{L^q(B)}\right]. \tag{2.2}$$

Next we consider the quasi-linear system

$$\left.\begin{array}{c}\nabla\times[\sigma(x,u)\nabla\times u]=f\\ \nabla\cdot u=0\end{array}\right\}\quad\text{in}\quad\Omega. \tag{2.3}$$

Here we assume $f\in\mathcal{H}^q_{loc}(\Omega)$ and $\sigma:\Omega\times\mathbb{R}^n\to\mathbb{R}$ satisfies the following conditions:

(a) $m\le\sigma\le M$ for positive constants m,M.

(b) σ is Hölder continuous in $\Omega\times\mathbb{R}^n$: $[\sigma]_\mu=[\sigma]_{C^{0,\mu}(\Omega\times\mathbb{R}^n)}<\infty$ for some $\mu\in(0,1)$.

THEOREM 2.2. *Let $u\in W^{1,2}_{loc}(\Omega;\mathbb{R}^n)$ be a weak solution of (2.3) and assume $f\in\mathcal{H}^p_{loc}(\Omega)$, $p>n$. Let $B:=B_R(x_0)\Subset\Omega$. Then, under the above assumptions on σ, ∇u is locally Hölder continuous with exponent $\alpha=\min(\mu,1-n/p)$ and*

$$\|u\|_{C^{1,\alpha}(\overline{B}_{R/4})}\le C,\quad C=C(m,M,p,[\sigma]_\mu,\|u\|_{W^{1,2}(B)},\|f\|_{L^p(B)},R).$$

The following technical lemmas will be used in the proof of theorems.

LEMMA 2.3 (uniqueness). *Let $u\in W^{1,2}_0(\Omega)$ be a weak solution of*

$$\left.\begin{array}{c}\nabla\times[a(x)\nabla\times u]=0\\ \nabla\cdot u=0\end{array}\right\}\quad in\quad\Omega.$$

Then $u\equiv0$ in Ω.

Proof. Since $\nabla\cdot u=0$, integration by parts yields

$$\int_\Omega|\nabla\times u|^2=\int_\Omega|\nabla\times u|^2+|\nabla\cdot u|^2=\int_\Omega|\nabla u|^2.$$

On the other hand, by using u itself as a test function we have

$$m\int_\Omega|\nabla\times u|^2\le\int_\Omega a(x)\,|\nabla\times u|^2=\int_\Omega\nabla\times[a(x)\,\nabla\times u]\cdot u=0.$$

Hence, $\nabla u=0$ in Ω. This completes the proof. □

LEMMA 2.4. *Let $B\subset\mathbb{R}^n$ be a open ball and let $f\in\mathcal{D}(B)$. Then there exists $g\in C^\infty(B;\mathbb{R}^n)\cap\mathcal{D}(B)$ such that $\nabla\times g=f$ in B and $g=0$ on ∂B. Moreover, if $f\in\mathcal{H}^p(B)$, $1<p<\infty$, then $\|\nabla g\|_{L^p(B)}\le C(p)\,\|f\|_{L^p(B)}$.*

Proof. Let g be the unique solution of

$$\left\{\begin{array}{rl}-\Delta g=\nabla\times f & \text{in}\quad B,\\ g=0 & \text{on}\quad\partial B.\end{array}\right.$$

From the following vector identity,

$$\nabla\times(\nabla\times f)=\nabla(\nabla\cdot f)-\Delta f, \tag{2.4}$$

and the representation formula of g in terms of the Green's function, it is easy to see $\nabla\times g=f$ and $\nabla\cdot g=0$ in B. The second part of the lemma follows from the L^p theory of the Laplace operator. □

LEMMA 2.5. *Suppose $F\in C^\infty(B;\mathbb{R}^n)$ satisfies $\nabla\times F=0$ in B. Then there exists $\varphi\in C^\infty(B;\mathbb{R})$ such that $\nabla\varphi=F$ in B and $\varphi=0$ on ∂B. Moreover, if $F\in L^2(B)$, then $\|\varphi\|_{L^2}\le C\,\|F\|_{L^2}$.*

Proof. Let φ be the unique solution of

$$\left\{\begin{array}{rl}\Delta\varphi=\nabla\cdot F & \text{in}\quad B,\\ \varphi=0 & \text{on}\quad\partial B.\end{array}\right.$$

Then $\nabla\varphi = F$ will follow immediately from Lemma 2.3. Also, $\|\nabla\varphi\|_{L^2} \le C\|F\|_{L^2}$. Since $\varphi = 0$ on ∂B, we can use Poincaré inequality to get $\|\varphi\|_{L^2(B)} \le C\|F\|_{L^2}$. □

LEMMA 2.6. *Let $w \in W_0^{1,2}(B_R;\mathbb{R}^n)$ be a weak solution of*

$$\left.\begin{array}{c}\nabla\times(\nabla\times w) = \nabla\times(F+G+H)\\ \nabla\cdot w = 0\end{array}\right\} \quad \text{in} \quad B_R,$$

where $F \in C^{0,\mu}(B_R)$, $\mu > 0$, $G \in L^2(B_R)$, and $H \in L^q(B_R)$, $q > n$. Then

$$\int_{B_R} |\nabla w|^2 \le C\left([F]_\mu^2 R^{n+2\mu} + \|G\|_{L^2}^2 + \|H\|_{L^q}^2 R^{n-2+2\gamma}\right), \qquad \gamma = 1 - n/q > 0.$$

Proof. From the identity (2.4), $w \in W_0^{1,2}$ is a weak solution of

$$-\Delta w = \nabla\times(F+G+H) \quad \text{in} \quad B_R.$$

By using w itself as a test function we get

$$\int_{B_R} \nabla w\cdot\nabla w = \int_{B_R} (F-F_R)\cdot\nabla\times w + \int_{B_R}(G+H)\cdot\nabla\times w.$$

Hence, Schwarz inequality yields

$$\int_{B_R}|\nabla w|^2 \le \int_{B_R}|F-F_R|^2 + \int_{B_R}|G|^2 + \int_{B_R}|H|^2 + \frac{3}{4}\int_{B_R}|\nabla\times w|^2.$$

Since $\nabla\cdot w = 0$, integration by parts yields

$$\int_{B_R}|\nabla\times w|^2 = \int_{B_R}|\nabla\times w|^2 + |\nabla\cdot w|^2 = \int_{B_R}|\nabla w|^2.$$

The lemma follows from obvious inequalities $\int_{B_R}|F-F_R|^2 \le C(n)[F]_\mu^2 R^{n+2\mu}$ and $\|H\|_{L^2}^2 \le \|H\|_{L^q}^2 |B_R|^{1-2/q}$. □

LEMMA 2.7. *Let $u \in W^{1,2}(B_2;\mathbb{R}^n)$ be a weak solution of*

$$\nabla\times[a(x)\nabla\times u] = \nabla\times g \quad \text{in} \quad \Omega.$$

Then $\|\nabla\times u\|_{L^2(B_1)} \le C(\|u\|_{L^2(B_2)} + \|g\|_{L^2(B_2)})$.

Proof. This is a Caccioppoli-type inequality. The proof is straightforward. □

LEMMA 2.8. *Let $\phi(t)$ be a nonnegative and nondecreasing function. Suppose that*

$$\phi(\rho) \le A\left[\left(\frac{\rho}{r}\right)^\alpha + \varepsilon\right]\phi(r) + Br^\beta$$

for all $\rho < r \le R_0$, with A, α, β nonnegative constants, $\beta < \alpha$. Then there exists a constant $\varepsilon_0 = \varepsilon_0(A,\alpha,\beta)$ such that, if $\varepsilon < \varepsilon_0$ for all $\rho < r \le R_0$, we have

$$\phi(\rho) \le c\left[\left(\frac{\rho}{r}\right)^\beta \phi(r) + B\rho^\beta\right],$$

where c is a constant depending on α, β, A.

Proof. See [3, Lemma 2.1, p. 86]. □

Now we are ready to prove our main theorems.

Proof of Theorem 2.1. First, we shall assume that $a \in L^\infty(\Omega) \cap C^\infty(\Omega)$ and $f \in \mathcal{H}^q_{loc}(\Omega) \cap C^\infty(\Omega)$. The constant C which appears in (2.2) will not depend on extra smoothness of data. Since (2.1) is a linear system, the full result will then follow from Lemma 2.3 and standard approximation argument. Also, we will assume without loss of generality that $B = B_{16}(x_0)$. Moreover, we may assume $n/2 < q < n$. The case $q \geq n$ will be recovered by Hölder's inequality.

Since $\nabla \cdot f = 0$, we conclude from Lemma 2.4 that there exists $g \in C^\infty(B_8; \mathbb{R}^n)$ such that $f = \nabla \times g$ and $g = 0$ on ∂B_8. Then Sobolev–Poincaré inequality implies

$$\|g\|_{L^{q^*}(B_8)} \leq C \|\nabla g\|_{L^q(B_8)} \leq C \|f\|_{L^q(B_8)}, \qquad q^* = nq/(n-q) > n. \tag{2.5}$$

Then by Lemma 2.5 there exists $\varphi \in C^\infty(B_8; \mathbb{R})$ such that

$$\nabla \varphi = a(x) \nabla \times u - g \tag{2.6}$$

and

$$\|\varphi\|_{L^2(B_8)} \leq C \Big(\|\nabla \times u\|_{L^2(B_8)} + \|g\|_{L^2(B_8)} \Big). \tag{2.7}$$

From Lemma 2.7 and (2.5), we can estimate $\|\varphi\|_{L^2(B_8)}$ in (2.7):

$$\|\varphi\|_{L^2(B_8)} \leq C \Big(\|u\|_{L^2(B)} + \|f\|_{L^q(B)} \Big). \tag{2.8}$$

By rewriting (2.6) as $\nabla \times u = a^{-1} \nabla \varphi + a^{-1} g$ we conclude

$$0 = \nabla \cdot (\nabla \times u) = \nabla \cdot [a^{-1} \nabla \varphi] + \nabla \cdot (a^{-1} g).$$

Now we have a single elliptic equation

$$-\nabla \cdot [a^{-1} \nabla \varphi] = \nabla \cdot (a^{-1} g). \tag{2.9}$$

It is well known that the following estimate holds:

$$\|\varphi\|_{C^{0,\beta}(B_4)} \leq C \Big(\|\varphi\|_{L^2(B_8)} + \|g\|_{L^{q^*}(B_8)} \Big), \tag{2.10}$$

where $C = C(M/m, q)$ and $\beta = \beta(M/m) > 0$ (see, e.g., [5, Theorem 8.24]).

Also, from (2.9) we have the following Caccioppoli inequality: for all $r \leq 4$

$$\begin{aligned} \int_{B_{r/2}} |\nabla \varphi|^2 &\leq C \left(\frac{1}{r^2} \int_{B_r} |\varphi - (\varphi)_r|^2 + \int_{B_r} |g|^2 \right) \\ &\leq C \Big([\varphi]^2_{C^{0,\beta}(B_4)} r^{n-2+2\beta} + \|g\|^2_{L^{q^*}(B_8)}\, r^{n-2+2\gamma} \Big), \end{aligned} \tag{2.11}$$

where $C = C(M/m)$ and $\gamma = (2 - \frac{n}{q}) > 0$.

Since $\nabla \cdot u = 0$, (2.4) implies

$$-\Delta u = \nabla \times (\nabla \times u) = \nabla \times (a^{-1} \nabla \varphi) + \nabla \times (a^{-1} g).$$

Fix $r \leq 2$ and decompose u into two functions v and $w := u - v$ such that v is the unique solution of

$$\begin{cases} -\Delta v = 0 & \text{in} \quad B_r, \\ v = u & \text{on} \quad \partial B_r. \end{cases}$$

Then $w = 0$ on ∂B_r and solves

$$-\Delta w = \nabla \times (a^{-1}\nabla\varphi) + \nabla \times (a^{-1}g) \quad \text{in} \quad B_r.$$

Hence, from (2.11) and Lemma 2.6 (with $G = a^{-1}\nabla\varphi$ and $H = a^{-1}g$), together with Poincaré inequality, we get

$$\int_{B_r} |w - w_r|^2 \le C \left([\varphi]^2_{C^{0,\beta}(B_4)} r^{n+2\beta} + \|g\|^2_{L^{q^*}(B_8)} r^{n+2\gamma} \right).$$

Then, since v is harmonic, the following estimates hold for all $\rho < r \le 2$:

$$\begin{aligned} \int_{B_\rho} |u - u_\rho|^2 &\le C \left(\frac{\rho}{r}\right)^{n+2} \int_{B_r} |u - u_r|^2 + C \int_{B_r} |w - w_r|^2 \\ &\le C \left(\frac{\rho}{r}\right)^{n+2} \int_{B_r} |u - u_r|^2 \\ &\quad + C \left([\varphi]^2_{C^{0,\beta}(B_4)} r^{n+2\beta} + \|g\|^2_{L^{q^*}(B_8)} r^{n+2\gamma} \right), \end{aligned} \tag{2.12}$$

where $C = C(m, M)$.

Let $\phi(\rho) := \int_{B_\rho} |u - u_\rho|^2$ and $\alpha = \min(\beta, \gamma)$. Combining (2.5), (2.8), and (2.10),

$$\phi(\rho) \le C \left[\left(\frac{\rho}{r}\right)^{n+2} \phi(r) + r^{n+2\alpha} \left(\|u\|^2_{L^2(B)} + \|f\|_{L^q(B)} \right) \right]. \tag{2.13}$$

Since (2.13) holds for any $\rho < r \le 2$, by Campanato's integral characterization of Hölder continuous function, together with Lemma 2.8, we conclude that

$$[u]_{C^{0,\alpha}(B_2)} \le C(m, M, q) \left(\|u\|_{L^2(B)} + \|f\|_{L^q(B)} \right). \tag{2.14}$$

Fix $x \in \overline{B}_1$ and consider a ball $B_1(x) \subset B_2$. Then

$$|u(x)| \le |u(y)| + |u(x) - u(y)| \le |u(y)| + [u]_{C^{0,\alpha}(B_2)} \quad \forall y \in B_1(x). \tag{2.15}$$

Integrating (2.15) with respect to y over $B_1(x)$ we get

$$|u(x)| \le C \left(\|u\|_{L^2(B_2)} + [u]_{C^{0,\alpha}(B_2)} \right) \quad \forall x \in B_1. \tag{2.16}$$

Combining (2.14) and (2.16) we finally obtain

$$\|u\|_{C^{0,\alpha}(\overline{B}_1)} \le C(m, M, q) \left(\|u\|_{L^2(B)} + \|f\|_{L^q(B)} \right).$$

This completes the proof. □

For the proof of Theorem 2.2, we need $C^{1,\alpha}$ estimates of the linear system (2.1) under the assumption that a is Hölder continuous.

LEMMA 2.9. *Let $u \in W^{1,2}_{loc}(\Omega; \mathbb{R}^n)$ be a weak solution of (2.1) where $f \in \mathcal{H}^p_{loc}(\Omega)$ for some $p > n$. Assume further that $a \in C^{0,\mu}(\Omega; \mathbb{R})$. Then, if $B := B_R(x_0) \Subset \Omega$, ∇u is Hölder continuous in $B_{R/4}(x_0)$ and*

$$[\nabla u]_{C^{0,\alpha}(B_{R/4})} \le C \left(\|\nabla u\|_{L^2(B)} + \|f\|_{L^q(B)} \right). \tag{2.17}$$

Here, $\alpha = \min(1 - n/p, \mu)$ *and* $C = C(n, m, M, p, [a]_\mu, R)$.

Proof. The proof relies on the standard perturbation method. As in Theorem 2.1, we may assume that f is smooth and $B = B_4(x_0)$. Then, by Lemma 2.4 there exists g such that $f = \nabla \times g$ and $[g]_{C^{0,\nu}(B)} \le C \|\nabla g\|_{L^p(B)} \le C \|f\|_{L^p(B)}$, $\nu = 1 - n/p > 0$. Let $y \in \overline{B}_2(0)$ and let $R_0 \le 2$ be a fixed number which will be specified later. Then

$$a(y)[\nabla \times (\nabla \times u)] = \nabla \times (\,[a(y) - a(x)]\ \nabla \times u) + \nabla \times g \quad \text{in} \quad B_{R_0}(y) \subset B.$$

Fix an $r \le R_0$ and split u into v and $w := u - v$ such that

$$\begin{cases} -\Delta v = 0 & \text{in} \quad B_r(y), \\ v = u & \text{on} \quad \partial B_r(y). \end{cases}$$

Then $w \in W_0^{1,2}(B_r(y))$ and satisfies

$$-a(y)\Delta w = \nabla \times (\,[a(y) - a(x)]\,\nabla \times u + g) \quad \text{in} \quad B_r(y).$$

Hence, from Lemma 2.6 with $F = g$ and $G = [a(y) - a(x)]\nabla \times u$, we obtain

$$\begin{aligned} \int_{B_r(y)} |\nabla w|^2 &\le C \left([a]_\mu^2 r^{2\mu} \|\nabla \times u\|^2_{L^2(B_r(y))} + [g]_\nu^2\, r^{n+2\nu} \right) \\ &\le C \left(r^{2\mu} \int_{B_r(y)} |\nabla u|^2 + \|f\|^2_{L^p(B)}\ r^{n+2\nu} \right). \end{aligned}$$

Since ∇v is harmonic in $B_r(y)$, the following estimate holds for $\rho < r \le R_0$:

$$\begin{aligned} \int_{B_\rho(y)} |\nabla u|^2 &\le C \left[\left(\frac{\rho}{r}\right)^n \int_{B_r(y)} |\nabla u|^2 + \int_{B_r(y)} |\nabla w|^2 \right] \\ &\le C \left[\left(\frac{\rho}{r}\right)^n + r^{2\mu} \right] \int_{B_r(y)} |\nabla u|^2 + C \|f\|^2_{L^p(B)}\ r^{n+2\nu}. \end{aligned}$$

We will apply Lemma 2.8 to the quantity $\phi(\rho) := \int_{B_\rho(y)} |\nabla u|^2$. Choose R_0 small enough so that $R_0^{2\mu} < \varepsilon_0$. Then Lemma 2.8 implies

$$\int_{B_\rho(y)} |\nabla u|^2 \le c\rho^{n-\mu} \left[\|\nabla u\|^2_{L^2(B)} + \|f\|^2_{L^p(B)} \right] \quad \forall y \in \overline{B}_2, \quad \forall \rho \le R_0.$$

Now set $y = x_0$ and $R_0 = 2$. In the rest of the proof we will denote $B_r := B_r(x_0)$. By using standard covering argument, if necessary, we obtain

$$\int_{B_r} |\nabla u|^2 \le C r^{n-\mu} \left[\|\nabla u\|^2_{L^2(B)} + \|f\|^2_{L^p(B)} \right] \quad \forall r \le 2. \tag{2.18}$$

On the other hand, for all $\rho < r \le 2$,

$$\begin{aligned} \int_{B_\rho} |\nabla u - (\nabla u)_\rho|^2 &\le C \left[\left(\frac{\rho}{r}\right)^{n+2} \int_{B_r} |\nabla u - (\nabla u)_r|^2 + \int_{B_r} |\nabla w|^2 \right] \\ &\le C \left[\left(\frac{\rho}{r}\right)^{n+2} \int_{B_r} |\nabla u - (\nabla u)_r|^2 \right] \\ &\quad + C \left(\|\nabla u\|^2_{L^2(B_r)}\, r^{2\mu} + \|f\|^2_{L^p(B)}\, r^{n+2\nu} \right). \end{aligned} \tag{2.19}$$

Combining (2.18) and (2.19) we conclude that $\nabla u \in C^{0,\gamma}(B_1)$, $\gamma = \min(\nu, \mu/2)$. In particular, as in (2.16) in the proof of Theorem 2.1,

$$\sup_{B_1} |\nabla u| \le C \left(\|\nabla u\|_{L^2(B_2)} + \|f\|_{L^p(B)} \right). \tag{2.20}$$

We may then use inequality (2.19) again for $\rho < r \le 1$, getting

$$[\nabla u]_{C^{0,\alpha}(B_1)} \le C \left(\|\nabla u\|_{L^2(B)} + \|f\|_{L^p(B)} \right), \quad \alpha = \min(\mu, \nu).$$

This completes the proof. □

Proof of Theorem 2.2. First, by Theorem 2.1 we know $u \in C^{0,\beta}_{loc}(\Omega)$ for some $\beta > 0$. Then $a(x) := \sigma(x, u(x))$ is locally Hölder continuous with some exponent $\gamma > 0$. Hence, from Lemma 2.9 we conclude ∇u is locally Hölder continuous. In particular, ∇u is bounded in B. As in (2.20) we have an estimate

$$\sup_{B_{R/2}} |\nabla u| \le C \left(\|\nabla u\|_{L^2(B)} + \|f\|_{L^p(B)} \right).$$

Thus $a(x)$ is Hölder continuous in $B_{R/2}$ with exponent μ and $[a]_{C^{0,\mu}(B_{R/2})} \le K$, where K is a constant that depends on $\|\nabla u\|_{L^2(B)}$, $\|f\|_{L^p(B)}$, $[\sigma]_\mu$, and other prescribed quantities independent of u, f. Now the theorem follows from Lemma 2.9. □

Remark 2.10. *In the proof of Theorem* 2.1 *we actually proved that if* $f \in \mathcal{H}^{q/2}_{loc}(\Omega; \mathbb{R}^n)$ *and* $g \in L^q_{loc}(\Omega; \mathbb{R}^n)$, $q > n$, *then any weak solution of the system*

$$\left.\begin{array}{c} \nabla \times [a(x) \nabla \times u] = f + \nabla \times g \\ \nabla \cdot u = 0 \end{array}\right\} \quad \text{in} \quad \Omega \tag{2.21}$$

satisfies the following estimate in $B := B_R(x_0) \Subset \Omega$:

$$\|u\|_{C^{0,\alpha}(\overline{B}_{R/2})} \le C \left[\|u\|_{L^2(B)} + \|f\|_{L^{q/2}(B)} + \|g\|_{L^q(B)} \right]. \tag{2.22}$$

Also, the proof of Lemma 2.9 *implies that a weak solution of*

$$\left.\begin{array}{c} \nabla \times [\sigma(x,u) \nabla \times u] = f + \nabla \times g \\ \nabla \cdot u = 0 \end{array}\right\} \quad \text{in} \quad \Omega, \tag{2.23}$$

where $f \in \mathcal{H}^p_{loc}(\Omega)$, $p > n$, *and* $g \in C^{0,\beta}_{loc}(\Omega)$, $\beta > 0$, *is locally Hölder continuous with exponent* $\alpha = \min(\mu, 1 - n/p, \beta)$.

Remark 2.11. *In the two-dimensional case, the Hölder continuity of weak solutions of* (2.1) *may follow from Sobolev imbedding. In fact, if* $f \equiv 0$, *then a weak solution* u *belongs to* $W^{1,p}_{loc}(\Omega)$ *for all* $p \in (1, \infty)$. *However, when* $n = 3$, $C^{0,\alpha}$ *regularity is the optimal result. To see this, consider a solution of the form* $u = (0, 0, u_3) : \Omega \to \mathbb{R}^3$. *Let us assume for simplicity that* $f \equiv 0$. *Then the system* (2.1) *becomes*

$$\begin{cases} D_3(a(x) D_1 u_3) = 0, \\ D_3(a(x) D_2 u_3) = 0, \\ D_1(a(x) D_1 u_3) + D_2(a(x) D_2 u_3) = 0, \\ D_3 u_3 = 0. \end{cases} \tag{2.24}$$

From the last equation of (2.24), *we can set* $v(x_1, x_2) := u_3(x_1, x_2, x_3)$. *It also follows that* $a(x)$ *depends only on* x_1 *and* x_2. *Then* v *solves the following equation of*

divergence form in two variables:

$$Lv := \sum_{i=1}^{2} D_i(a(x)D_i v) = 0 \quad in \quad \Omega.$$

The operator L is called an isotropic operator. Piccinini and Spagnolo showed that v is locally Hölder continuous with exponent $\alpha = \frac{4}{\pi} \arctan \sqrt{m/M}$ *(see* [7, Theorem 2, p. 396]*). To see that it is an optimal result, consult Example* 2 *of* [7] *on page* 400.

3. Application to a Maxwell system. As mentioned in the introduction, the problem we have analyzed so far arises from the Maxwell's system in a quasi-stationary electromagnetic field. Especially if the electric conductivity strongly depends on the temperature, then by taking the temperature effect into consideration the classical Maxwell system in a quasi-stationary electromagnetic field reduces to the following mathematical model (see [9, pp. 1029–1032]):

$$\begin{cases} H_t + \nabla \times (\sigma(u)\nabla \times H) = 0, \\ \nabla \cdot H = 0, \\ u_t - \Delta u = \sigma(u) \left|\nabla \times H\right|^2, \end{cases} \tag{3.1}$$

where H and u are unknowns representing, respectively, the strength of magnetic field and temperature, while $\sigma(u)$ denotes the electric resistivity of the material which is assumed to be strictly positive and bounded; i.e., there exist positive numbers m, M such that

$$0 < m \le \sigma(s) \le M \quad \forall s \in \mathbb{R}. \tag{3.2}$$

In [9], Yin proved, under appropriate assumptions on boundary and initial conditions, the existence of a pair of global weak solutions (H, u):

$$\begin{aligned} &H \in L^\infty\left(0, T; L^2(\Omega; \mathbb{R}^3)\right) \cap L^2\left(0, T; W^{1,2}(\Omega; \mathbb{R}^3)\right), \\ &u \in L^\infty\left(0, T; L^1(\Omega; \mathbb{R})\right) \cap L^q\left(0, T; W^{1,q}(\Omega; \mathbb{R})\right), \quad q \in [1, 5/4). \end{aligned}$$

In addition, he showed that if a pair of weak solutions (H, u) are continuous, then they are classical provided that σ is smooth enough. However, as pointed out by him, the continuity of weak solutions is unknown even if σ is smooth. Continuity of weak solutions of (3.1) heavily relies on the regularity theory of the following system with bounded measurable coefficient $a(x, t)$:

$$\left.\begin{array}{c} v_t + \nabla \times [a(x,t)\nabla \times v] = 0 \\ \nabla \cdot v = 0 \end{array}\right\} \quad \text{in} \quad Q, \tag{3.3}$$

where Q is the space-time cylinder $\Omega \times (0, T)$ for some $T > 0$. We don't know at this time whether or not weak solutions of the system (3.3) are Hölder continuous.

In this section, we consider instead the following fully steady-state systems introduced by Yin (see [9, p. 1031]):

$$\left.\begin{array}{c} \nabla \times (\sigma(u)\nabla \times H) = 0 \\ \nabla \cdot H = 0 \\ -\Delta u = \sigma(u) \left|\nabla \times H\right|^2 \end{array}\right\} \quad \text{in} \quad \Omega. \tag{3.4}$$

Using the results we obtained in previous section, we will show the $C^{0,\alpha}$ regularity of weak solutions of (3.4).

THEOREM 3.1. *Let (H,u) be a pair of weak solutions of (3.4). Then $(H,u) \in C^{0,\alpha}_{loc}(\Omega)$ for some $\alpha > 0$. Moreover, the following estimates hold in $\Omega' \Subset \Omega$:*

$$[H]_{C^{0,\alpha}(\Omega')} + [u]_{C^{0,\alpha}(\Omega')} \le C(m, M, \Omega', \Omega, \|H\|_{L^2}, \|u\|_{L^2}). \tag{3.5}$$

Proof. Let $B := B_{4R} = B_{4R}(x_0) \Subset \Omega$. We will show (u,H) is Hölder continuous in $B_R = B_R(x_0)$. Indeed, from the proof of Theorem 2.1 we have

$$\|H\|_{C^{0,\alpha}(B_{2R})} \le C(m, M, R) \|H\|_{L^2(B)}, \qquad \alpha = \alpha(m/M) > 0. \tag{3.6}$$

It remains to show that u is also Hölder continuous in B_R. Using a vector identity,

$$\nabla \cdot (F \times G) = (\nabla \times F) \cdot G - F \cdot (\nabla \times G), \tag{3.7}$$

together with the first equation $\nabla \times (\sigma(u) \nabla \times H) = 0$ of (3.4), we obtain

$$\nabla \cdot [H \times (\sigma(u) \nabla \times H)] = \sigma(u) |\nabla \times H|^2. \tag{3.8}$$

We rewrite the last equation of (3.4) as follows:

$$-\Delta u = \nabla \cdot [H \times (\sigma(u) \nabla \times H)]. \tag{3.9}$$

As before, fix $r \le R$ and split u into two parts v and $w := u - v$ such that

$$\begin{cases} -\Delta v = 0 & \text{in} \quad B_r, \\ v = u & \text{on} \quad \partial B_r. \end{cases}$$

Then, as in (2.12), the following estimate holds for $\rho < r \le R$:

$$\int_{B_\rho} |u - u_\rho|^2 \le C \left(\frac{\rho}{r}\right)^{n+2} \int_{B_r} |u - u_r|^2 + Cr^2 \int_{B_r} |\nabla w|^2. \tag{3.10}$$

We need to estimate $\|\nabla w\|^2_{L^2(B_r)}$. Since $w \in W^{1,2}_0(B_r)$ and satisfies

$$-\Delta w = \nabla \cdot [H \times (\sigma(u) \nabla \times H)] \quad \text{in} \quad B_r,$$

integration by parts and Schwarz inequality yields

$$\int_{B_r} |\nabla w|^2 \le 2 \int_{B_r} \sigma(u)^2 |H|^2 |\nabla \times H|^2 \le 2M^2 \int_{B_r} |H|^2 |\nabla \times H|^2. \tag{3.11}$$

Since H is continuous, it is bounded in B_r and thus from (3.11)

$$\int_{B_r} |\nabla w|^2 \le C \sup_{B_{2R}} |H|^2 \int_{B_r} |\nabla \times H|^2. \tag{3.12}$$

On the other hand, from the fact that H solves the first equation of (3.4) it follows that

$$\int_{B_r} |\nabla \times H|^2 \le \frac{C}{r^2} \int_{B_{2r}} |H - H_{2r}|^2 \le C [H]^2_{C^{0,\alpha}(B_{2R})} r^{n-2+2\alpha}. \tag{3.13}$$

Combining (3.12) and (3.13) together with (3.6) we obtain the required estimate

$$\|\nabla w\|^2_{L^2(B_r)} \le C(m, M, R) \|H\|^4_{L^2(B)} r^{n-2+2\alpha}. \tag{3.14}$$

Finally, by inserting (3.14) into (3.10) we conclude from Lemma 2.8

$$[u]_{C^{0,\alpha}(B_R)} \le C(m, M, R)\left(\|u\|_{L^2(B)} + \|H\|^2_{L^2(B)}\right). \tag{3.15}$$

Theorem 3.1 follows from (3.6), (3.15), and standard covering argument. □

THEOREM 3.2. *Let (H, u) be a pair of weak solutions of* (3.4). *Assume further that σ is Hölder continuous with exponent $\mu \in (0, 1)$. Then $H \in C^{1,\mu}_{loc}(\Omega)$ and $u \in C^{2,\mu}_{loc}(\Omega)$.*

Proof. First, by Theorem 2.1 we have $(u, H) \in C^{0,\alpha}_{loc}(\Omega)$, which in turn implies $\sigma(u)$ is Hölder continuous with exponent $\beta = \alpha\mu$. Then $H \in C^{1,\beta}_{loc}(\Omega)$ by Lemma 2.9 and thus $\sigma(u)\,|\nabla \times H|^2 \in C^{0,\beta}_{loc}(\Omega)$. Since u solves

$$-\Delta u = \sigma(u)\,|\nabla \times H|^2 \quad \text{in} \quad \Omega, \tag{3.16}$$

it follows from the theory of the Laplace operator that $u \in C^{2,\beta}_{loc}(\Omega)$. In particular, ∇u is locally bounded and thus $\sigma(u) \in C^{0,\mu}_{loc}(\Omega)$. By Lemma 2.9 again, $H \in C^{1,\mu}_{loc}(\Omega)$. Therefore $\sigma(u)\,|\nabla \times H|^2 \in C^{0,\mu}_{loc}(\Omega)$ and $u \in C^{2,\mu}_{loc}(\Omega)$ by (3.16). This completes the proof. □

REMARK 3.3. *Let (H, u) be a pair of weak solutions of* (3.4). *Suppose that $\sigma \in C^{k,\alpha}$, where k is a nonnegative integer and $0 < \alpha < 1$. Then*

$$H \in C^{k+1,\alpha}_{loc}(\Omega), \quad u \in C^{k+2,\alpha}_{loc}(\Omega). \tag{3.17}$$

In particular, if $\sigma \in C^{1,\alpha}$, then (H, u) is a pair of classical solutions.

4. Remarks on the case $n \ge 4$. First, we introduce some notations. Let Ω be a domain in $\mathbb{R}^n$, $n \ge 3$. Denote by $\Lambda^k := \Lambda^k(\Omega)$ the class of k-forms in Ω. Let $* : \Lambda^k \to \Lambda^{n-k}$ be the Hodge star linear operator, defined by setting

$$*(dx^{i_1} \wedge \cdots \wedge dx^{i_k}) = (dx^{j_1} \wedge \cdots \wedge dx^{j_{n-k}})$$

and extending it linearly, where $(i_1, \dots, i_k, j_1, \dots, j_{n-k})$ is an even permutation of $(1, 2, \dots, n)$ so that $dx^{i_1} \wedge \cdots \wedge dx^{i_k} \wedge dx^{j_1} \wedge \cdots \wedge dx^{j_{n-k}} = d\text{vol}$. Let $d^* : \Lambda^k \to \Lambda^{k-1}$ be the adjoint of the exterior differential operator $d : \Lambda^{k-1} \to \Lambda^k$ with respect to the *Hodge inner product*:

$$\langle \alpha, \beta \rangle := \int_\Omega \alpha \wedge *\beta, \quad \text{where} \quad \alpha, \beta \in L^2(\Omega; \Lambda^k). \tag{4.1}$$

More precisely, it is defined by $\langle d\alpha, \beta \rangle = \langle \alpha, d^*\beta \rangle$ for smooth forms $\alpha \in \Lambda^{k-1}(\Omega)$, $\beta \in \Lambda^k(\Omega)$, one of which with compact support in Ω. From the Stokes theorem, it follows that $d^* = (-1)^{nk+n+1} * d *$.

Let $u = (u^1, \dots, u^n) \in W^{1,2}(\Omega; \mathbb{R}^n)$. For the sake of simplicity, we will use the same notation u for the corresponding 1-form $\sum_{i=1}^n u^i(x)dx^i$. In this context, we denote its exterior differential du by

$$du := \sum_{i<j} (D_i u^j - D_j u^i) dx^i \wedge dx^j.$$

A celebrated result by De Giorgi [1] states that weak solutions to linear elliptic equations with L^∞ coefficients are Hölder continuous. In contrast to this, as it is well known, weak solutions of linear elliptic systems with L^∞ coefficients may have

singularities. For example, De Giorgi [2] constructed a weak solution to an elliptic system with L^∞ coefficients which belongs to $W^{1,2}(B_1(0);\mathbb{R}^n)$, $n \geq 3$, but is not bounded.

Related to those results, Giaquinta and Hong [4] raised an interesting question: Are weak solutions of the following system locally Hölder continuous?

$$\left.\begin{array}{c} d^*[a(x)du] = 0 \\ d^*u = 0 \end{array}\right\} \quad \text{in} \quad \Omega. \tag{4.2}$$

Here $a(x) \in L^\infty(\Omega)$ is assumed to be bounded by two positive numbers m, M. More generally, consider the following inhomogeneous system:

$$\left.\begin{array}{c} d^*[a(x)du] = f + d^*g \\ d^*u = 0 \end{array}\right\} \quad \text{in} \quad \Omega, \tag{4.3}$$

where $f \in \mathcal{H}^p_{loc}(\Omega;\mathbb{R}^n)$ and $g \in L^q_{loc}(\Omega;\Lambda^2) \cong L^q_{loc}(\Omega;\mathbb{R}^{n(n-1)/2})$.

When $n = 3$ the above system (4.3) is identical to the system (2.1), and Theorem 2.1 states the answer to their question is positive when $n = 3$. However, our method used in the proof of Theorem 2.1 cannot be applied to the case when $n \geq 4$, and we don't know the answer in that case.

Let us briefly mention why the case $n = 3$ is special. In the proof of Theorem 2.1, we made use of the fact that de Rham cohomology of a ball $B \in \mathbb{R}^n$ is trivial in the sense that if $\alpha \in \Lambda^2(B)$ satisfies $d^*\alpha = 0$, then there exists a $\beta \in \Lambda^{n-3}(B)$ such that $d\beta = *\alpha$. In the case when $n = 3$, β is a scalar function so that we may apply the well-known result of De Giorgi [1] to get the $C^{0,\alpha}$ estimate.

The aim of this section is to compile known results from general theory of elliptic systems which can be applied to the system (4.3). We have the following identity similar to (2.4) (see, e.g., [8, p. 33]):

$$-\Delta\alpha = d^*(d\alpha) + d(d^*\alpha) \quad \forall\alpha \in \Lambda^1(\Omega). \tag{4.4}$$

Hence, if $a(x)$ is continuous, then the perturbation method used in Lemma 2.9 can be applied here without any change. Also, if the ratio M/m is sufficiently close to 1, then it can be shown that weak solutions u of the system (4.3) satisfy $u \in W^{1,p}_{loc}$ for some $p > n$. Hölder continuity of u will then follow from Sobolev imbedding.

We again emphasize that most of results in this section can be inferred from the general theories of elliptic systems, so we will provide proofs only when the situation is not quite obvious.

PROPOSITION 4.1. *Let $u \in W^{1,2}_{loc}(\Omega;\mathbb{R}^n)$ be a weak solution of (4.3). Suppose $f \in \mathcal{H}^p_{loc}(\Omega;\mathbb{R}^n)$, $p > n/2$, and $g \in L^q_{loc}(\Omega;\Lambda^2)$, $q > n$. If $a(x)$ is continuous, then u is locally Hölder continuous with exponent $\alpha = \alpha(n, m, M, p, q) > 0$.*

Proof. See Theorem 3.1 in [3] and the following remark on page 87. □

PROPOSITION 4.2. *Let $u \in W^{1,2}_{loc}(\Omega;\mathbb{R}^n)$ be a weak solution of (4.3). Suppose $f \in \mathcal{H}^{q/2}_{loc}(\Omega;\mathbb{R}^n)$ and $g \in L^q_{loc}(\Omega;\Lambda^2)$, $q > n$. Then there exists a number $\epsilon_0 > 1$ such that if $M/m < \epsilon_0$, then $\nabla u \in L^p_{loc}(\Omega;\mathbb{R}^{n^2})$ for some $p > n$. In particular, u is locally Hölder continuous in Ω.*

Proof. The proof relies on the L^p theory for the Laplace operator and a perturbation argument (see, e.g., [6] and Theorem 2.5 (page 154) in [3]). □

PROPOSITION 4.3. *Let $u \in W^{1,2}_{loc}(\Omega;\mathbb{R}^n)$ be a weak solution of (4.3). Assume $f \in \mathcal{H}^p_{loc}(\Omega;\mathbb{R}^n)$, $p > n$, and $g \in C^{0,\beta}_{loc}(\Omega;\Lambda^2)$, $\beta > 0$. If $a(x)$ is $C^{0,\mu}$-continuous, then ∇u is locally Hölder continuous with exponent $\alpha = \min(\mu, 1 - n/p, \beta)$.*

Proof. See Theorem 3.2 (page 88) in [3] and also Lemma 2.9 in section 2. □

LEMMA 4.4 (Caccioppoli inequality). *Let $u \in W^{1,2}_{loc}(\Omega;\mathbb{R}^n)$ be a weak solution of the system* (4.3) *with $f \in \mathcal{H}^{2n/(n+2)}_{loc}(\Omega;\mathbb{R}^n)$ and $g \in L^2_{loc}(\Omega;\Lambda^2)$. Let $B_R := B_R(x_0) \Subset \Omega$. Then, for any $\lambda \in \mathbb{R}^n$,*

$$\int_{B_{R/2}} |\nabla u|^2 \le C\left(\frac{1}{R^2}\int_{B_R}|u-\lambda|^2 + \|f\|^2_{L^{2n/(n+2)}(B_R)} + \|g\|^2_{L^2(B_R)}\right), \tag{4.5}$$

where $C = C(n,m,M)$.

Sketch of proof. As in Lemma 2.4, there exists $h \in W^{1,2}_0(B_R;\Lambda^2)$ such that

$$f = d^*h \quad \text{in} \quad B_R; \qquad \|h\|_{L^2(B_R)} \le C\,\|f\|_{L^{2n/(n+2)}(B_R)}. \tag{4.6}$$

Let $\eta \in C^\infty_0(B_R;\mathbb{R})$ be a cut-off function such that $0 \le \eta \le 1$, $\eta \equiv 1$, in $B_{R/2}$ and $|\nabla\eta| \le 4/R$. By choosing $(u-\lambda)\eta^2$ as a test function it is easy to see that

$$\int_{B_R}\eta^2\,|du|^2 \le C\left(\frac{1}{R^2}\int_{B_R}|u-\lambda|^2 + \int_{B_R}|h|^2 + \int_{B_R}|g|^2\right). \tag{4.7}$$

Since $d^*u = 0$ in Ω, (4.4) implies

$$\begin{aligned}\big\langle -\Delta u, \eta^2(u-\lambda)\big\rangle &= \big\langle du, d\left(\eta^2(u-\lambda)\right)\big\rangle \\ &= \langle du, 2\eta\,d\eta\wedge(u-\lambda)\rangle + \big\langle du, \eta^2 du\big\rangle.\end{aligned}$$

On the other hand, integration by parts yields

$$\begin{aligned}\big\langle -\Delta u, \eta^2(u-\lambda)\big\rangle &= \int_\Omega \nabla u\cdot\nabla\left(\eta^2(u-\lambda)\right) \\ &= \int_\Omega 2\eta\,D_j u^i D_j\eta(u^i-\lambda^i) + \int_\Omega \eta^2\,|\nabla u|^2.\end{aligned}$$

Therefore

$$\int_{B_R}\eta^2\,|\nabla u|^2 \le C\left(\frac{1}{R^2}\int_{B_R}|u-\lambda|^2 + \int_{B_R}\eta^2\,|du|^2\right). \tag{4.8}$$

Combining (4.6), (4.7), and (4.8) we obtain (4.5). □

LEMMA 4.5 (L^p estimates). *Suppose $f \in \mathcal{H}^q_{loc}(\Omega;\mathbb{R}^n)$, $q > 2n/(n+2)$, and $g \in L^r_{loc}(\Omega;\Lambda^2)$, $r > 2$. Let $u \in W^{1,2}_{loc}(\Omega)$ be a weak solution of the system* (4.3). *Then $\nabla u \in L^p_{loc}(\Omega;\mathbb{R}^{n^2})$ for some $p > 2$. More precisely, let $B := B_R(x_0) \Subset \Omega$; then*

$$\|\nabla u\|_{L^p(B_{R/2})} \le C\left(\|\nabla u\|_{L^2(B)} + \|f\|_{L^{np/(n+p)}(B)} + \|g\|_{L^p(B)}\right). \tag{4.9}$$

Sketch of proof. Let h be as in (4.6). Setting $\lambda = (u)_R$ and then using Sobolev–Poincaré inequality, we obtain from (4.7) and (4.8)

$$⨍_{B_{R/2}}|\nabla u|^2 \le C\left[\left(⨍_B|\nabla u|^s\right)^{2/s} + ⨍_B|h|^2 + ⨍_B|g|^2\right], \quad s = \frac{2n}{n+2}. \tag{4.10}$$

It is so-called reverse Hölder inequality. It is well known that higher integrability of ∇u follows from (4.10) (see, e.g., Proposition 1.1 (page 122) of [3]). Also, as mentioned

in Proposition 4.2, (4.9) can be derived by a perturbation argument based on the L^p theory of the Laplace operator. □

With the preceding lemmas at hand, let us consider the quasi-linear system

$$\left.\begin{array}{c} d^*[\sigma(x,u)du] = f + d^*g \\ d^*u = 0 \end{array}\right\} \quad \text{in} \quad \Omega, \tag{4.11}$$

where $f \in \mathcal{H}^p_{loc}(\Omega)$ and $g \in L^q_{loc}(\Omega;\Lambda^2)$.

By using general theory of elliptic systems, it is again more or less straightforward to show partial $C^{0,\alpha}$ (or $C^{1,\alpha}$) regularity for weak solutions of the system (4.11) under appropriate continuity assumptions on σ. We denote k-dimensional Hausdorff measure of $\Sigma \subset \mathbb{R}^n$ by $H^k(\Sigma)$.

PROPOSITION 4.6 ($C^{0,\alpha}$-partial regularity). *Suppose $f \in \mathcal{H}^{q/2}_{loc}(\Omega)$ and $g \in L^q_{loc}(\Omega)$, for some $q > n$, and let $u \in W^{1,2}_{loc}(\Omega)$ be a weak solution of the system* (4.11). *Assume that σ is continuous. Then there exists an open set $\Omega_0 \subset \Omega$ such that u is locally Hölder continuous with exponent $1 - n/q$ in Ω_0. Moreover, $H^{n-s}(\Omega \setminus \Omega_0) = 0$ for some $s > 2$.*

Proof. See Theorem 1.1 (page 166) in [3]. □

PROPOSITION 4.7 ($C^{1,\alpha}$-partial regularity). *Suppose σ is locally $C^{0,\alpha}$-continuous for some $\alpha \in (0,1)$. Let $u \in W^{1,2}_{loc}(\Omega)$ be a weak solution of the system* (4.11) *and let $f \in \mathcal{H}^p_{loc}(\Omega;\mathbb{R}^n)$, $p = n/(1-\alpha)$, $g \in C^{0,\alpha}_{loc}(\Omega;\mathbb{R}^n)$. Then there exists an open set $\Omega_0 \subset \Omega$ such that $u \in C^{1,\alpha}_{loc}(\Omega_0)$ and $H^{n-s}(\Omega \setminus \Omega_0) = 0$ for some $s > 2$.*

Proof. The proof follows from Proposition 4.6 and Lemma 2.9. □

FUNCTIONS AND DOMAINS HAVING MINIMAL RESISTANCE UNDER A SINGLE-IMPACT ASSUMPTION*

M. COMTE† AND T. LACHAND-ROBERT†

Abstract. We are looking for the domains $\Omega \subset \mathbb{R}^2$ tiling the plane and for functions $u : \Omega \to \mathbb{R}$ satisfying the simple impact assumption introduced by G. Buttazzo, V. Ferone, and B. Kawohl [*Math. Nach.*, 173 (1993), pp. 71–89.] about Newton's problem of the body of minimal resistance, which minimizes functionals $F(u;\Omega) = \frac{1}{|\Omega|}\int_\Omega f(|\nabla u|)$, with f decreasing.

We prove that only some convex polygons are minimizers, and we give explicitly the corresponding functions u. In the case of the Newton's functional $f(t) = 1/(1+t^2)$, all optimal domains are squares or regular hexagons.

1. Introduction.

Newton's problem of the body of minimal resistance, first stated in [6], has been widely studied, and new interest has recently been raised, particularly since the minimizer has been proven to not have the symmetry of the domain. This problem can be mathematically stated as follows: minimize

$$G(u) = \int_\Omega \frac{dx}{1 + |\nabla u(x)|^2}$$

in an appropriate class of functions $u : \Omega \to \mathbb{R}$. Here $\Omega \subset \mathbb{R}^2$ is a bounded domain, and the functional expresses the resistance of the body in $\{(x,z) \in \Omega \times \mathbb{R};\ z \le u(x)\}$ to a uniform stream of particles coming downward in the vertical direction. It is assumed that each particle's shock on the body is perfectly elastic and that each particle hits the body at most once. The elastic assumption leads on the given value of the functional [2]. Since the infimum of G is clearly zero, if we can consider very long and thin bodies, it is necessary to restrict the class of admissible functions u by fixing the surface area, or fixing the maximal height as a number $M > 0$, a given parameter. This last requirement was first proposed by Newton and is the most frequently considered one.

The single impact assumption is classically enforced by considering only concave functions u. On the other hand, it was shown in [2] that this requirement is not necessary. More precisely, it is sufficient to consider the unknown function u in the class of maps $u : \Omega \to [-M, 0]$ satisfying the geometrical condition

$$(1)\quad \forall x \in \mathrm{dom}(\nabla u),\ \forall \tau > 0,\ \text{such that } x - \tau\nabla u(x) \in \overline{\Omega},$$
$$\frac{u(x - \tau\nabla u(x)) - u(x)}{\tau} \le \frac{1}{2}\left(1 - |\nabla u(x)|^2\right).$$

Here $\mathrm{dom}(\nabla u)$ is merely the dense subset of Ω where u is differentiable; we will define it more precisely later.

This constraint has been studied in [4] and [3], where it is shown that a radial minimizer exists (but there is generally no uniqueness), but in the general class the minimum is not attained. This comes from the presence of a boundary, which induces special effects, and, in particular, allows oscillations near it. This leads us to the idea that without a boundary, the problem would be more "stable," and a global minimizer could exist with no radial symmetry assumption.

In this paper we investigate this problem. In order to make sense, we consider an infinite body with periodicity; that is, let Ω be a domain *tiling the plane* (meaning that there exists a finitely generated subgroup $\mathcal{G}_\Omega \subset \mathcal{O}_2$ such that $\bigcup_{g\in\mathcal{G}_\Omega} g(\overline{\Omega}) = \mathbb{R}^2$, and $g_1(\Omega) \cap g_2(\Omega) = \emptyset$ if $g_1 \neq g_2$); let $\bar{u} : \mathbb{R}^2 \to \mathbb{R}$ be a function with the same periodicity ($\bar{u} \circ g = \bar{u}$ for all $g \in \mathcal{G}_\Omega$); and let u be the restriction of $\bar{u}$ to Ω. We are looking to the body $\{(x, z) \in \mathbb{R}^3;\ z \leq \bar{u}(x)\}$ minimizing the mean value of G, that is, we minimize

$$F(u;\Omega) := \frac{1}{|\Omega|}\int_\Omega \frac{dx}{1+|\nabla u(x)|^2} \tag{2}$$

with respect to all domains Ω tiling the plane and to all functions $u : \Omega \to [-M, 0]$ having periodicity Ω.

Note that Ω is not well defined in general if only $\bar{u}$ is given. In order to fix the notations, we choose Ω such that $u(x) = 0$ for all $x \in \partial\Omega$ and $u < 0$ in Ω.

The natural topology associated with (1) is $W^{1,\infty}(\Omega)$. However it has been shown in [3] that the set of admissible functions must be restricted to a strict subset of $W^{1,\infty}(\Omega)$. Moreover, the minimizing functions must be *regular* in the following sense: these are continuous, C^2 by parts, functions; that is, they are obtained by a finite number of min or max operations on C^2 functions. In this paper, we do not enter these technicalities, and we restrain ourselves to this smaller class of regular functions. Since $u = 0$ on $\partial\Omega$, this implies also some regularity on Ω itself.

Our main result reads as follows.

THEOREM 1. *Among all regular functions and regular domains tiling the plane, the minimum of F is attained in only two cases, up to a similitude (with the same minimal value):*

1. *Ω is a square, $\Omega = (-a, a) \times (-a, a)$ with $a \leq 4M/3$, and u is the function*

$$u(x_1, x_2) := \max[\phi_a(|x_1|), \phi_a(|x_2|)], \tag{3}$$

   where $\phi_a(x) := \frac{(x+a)^2}{4a} - a$.
2. *Ω is a regular convex hexagon with diameter $4a/\sqrt{3}$, with center $O = (0, 0)$, and two vertices $A = (a, a/\sqrt{3})$, $B = (a, -a/\sqrt{3})$; then u is the function invariant by rotation of $\pi/3$ whose restriction to the triangle OAB is $\phi_a(x_1)$.*

In both cases, the optimal value for F is given by

$$F_{\text{opt}} := \pi + 12\ln 2 - 4\ln 5 - 4\arctan 2 \simeq 0.5930123.$$

Hence the resistance of the infinite tiling is less than 60% of the resistance of the plane (which has maximal resistance).

The proof of this theorem constitutes the rest of the paper. It relies on the following properties: first of all, any minimizing domain Ω is convex. This is proved in Theorem 2 hereafter, even for a more general functional $\frac{1}{|\Omega|}\int_\Omega f(|\nabla u|)$, with f decreasing. Section 2 states this theorem and gives the proof.

Since Ω should also tile the plane, it is a polygon. In section 3, we restrict ourselves to the functional of (2), give additional properties of optimal polygons, and characterize the corresponding function u. This allows us to restrict ourselves to a small set of admissible polygons. We end by using some explicit computations to distinguish the minimizers.

2. Convexity of the optimal domains. The first fact of interest is that any minimizer u of (2) saturates everywhere in $\mathrm{dom}(\nabla u)$; that is, for all $x \in \mathrm{dom}(\nabla u)$ there exists $\tau_x > 0$ such that

$$\frac{u(x - \tau_x \nabla u(x)) - u(x)}{\tau_x} = \frac{1}{2}\left(1 - |\nabla u(x)|^2\right), \tag{4}$$

and for all $\tau \in (0, \tau_x)$ inequality (1) is strict. This has been proved in [4], using a small variation with a fast oscillating function. Since the proof is quite lengthy and technical and works similarly here, we don't repeat it.

Note that (4) implies that

$$|\nabla u| \le 1 \tag{5}$$

and $x - \tau_x \nabla u \in \overline{\Omega}$ if $x \in \Omega$. Indeed, x is an interior point of the bounded set Ω; hence there exists $\tau_1 > 0$ such that $x - \tau_1 \nabla u(x)$ belongs to $\partial\Omega$. Since we assume $u = 0$ on $\partial\Omega$, we get $u(x - \tau_1 \nabla u(x)) = 0 \ge u(x)$. Putting this inequality into (1) yields (5) as claimed. Now if $\tau > \tau_1$,

$$\begin{aligned} u(x) + \frac{\tau}{2}\left(1 - |\nabla u(x)|^2\right) &> u(x) + \frac{\tau_1}{2}\left(1 - |\nabla u(x)|^2\right) \\ &\ge u(x - \tau_1 \nabla u(x)) = 0. \end{aligned}$$

This implies $\tau_x \le \tau_1$ since u takes values in $[-M, 0]$; hence $x - \tau_x \nabla u(x) \in \overline{\Omega}$.

Also this implies that

$$|\nabla u(x)| = 1 \qquad \forall x \in \partial\Omega \cap \mathrm{dom}(\nabla u). \tag{6}$$

Indeed, for $x \in \partial\Omega$, $u(x) = 0$, so the left-hand side of (4) is nonpositive. Hence $|\nabla u(x)| \ge 1$ and (6) follows since $|\nabla u| \le 1$.

Remark 2.A. First we have that if $x \in \partial\Omega \cap \mathrm{dom}(\nabla u)$, then $u(x) = 0$ and $u(x - \tau_x \nabla u(x)) = 0$, and from the definition of Ω, $x - \tau_x \nabla u(x) \in \partial\Omega$.

We also obtain that (5) implies

$$1 \ge F(u; \Omega) \ge \frac{1}{2} \tag{7}$$

for all admissible $(u; \Omega)$.

The main theorem relies primarily on the following result, which can be stated for a more general functional.

THEOREM 2. *Let $(u; \Omega)$ be a local minimizer pair for a functional in the form $\Upsilon(u; \Omega) := \frac{1}{|\Omega|}\int_\Omega f(|\nabla u|)$, where $f \in C^1(\mathbb{R}_+)$ is decreasing. Then Ω is convex.*

Proof. Assume that Ω is not convex. Then there exists $x_0 \in \partial\Omega$, a straight line Δ containing x_0, and a neighborhood V of x_0 such that, if P_1, P_2 are the two open half-planes limited by Δ,

$$V \cap P_1 \subset \Omega \quad \text{and} \quad V \cap P_2 \cap \Omega \ne \emptyset. \tag{8}$$

Choosing the appropriate center of coordinates, we can assume that $x_0 = 0$; also we can assume that 0 is an exposed point on the boundary of $\mathbb{R}^2 \setminus \Omega$, that $0 \in \mathrm{dom}(\nabla u)$, and that

$$\Delta \cap V \cap \partial\Omega = \{0\}. \tag{9}$$

We recall that $u(0) = 0$ and, since $|\nabla u(0)| = 1$, we can assume $\nabla u(0) = -e_1$ again by choosing the appropriate coordinate system, which is the unit outward normal vector to Ω at 0. Let τ_0 be the value of τ_x corresponding to $x = 0$.

Step 1. Let us first assume that u is not differentiable near 0. More precisely, V can be divided in two zones V_1, V_2, and there exists two functions u_1, u_2 of class $C^2(V)$ such that $u = u_i$ on V_i, $i = 1, 2$. Since u is continuous, $u_1 = u_2$ on the common boundary of V_1, V_2. We have $(u_1 - u_2)(0) = 0$, but the assumption that u is not differentiable at 0 implies in particular that $\nabla u_1(0) \neq \nabla u_2(0)$. Since $u_1 - u_2$ is C^2, the line $u_1 = u_2$ is a differentiable curve containing 0. Let us choose a coordinate system such that e_1 is tangent to this curve, pointing inside Ω at 0.

Since $|\nabla u| = 1$ on $\partial\Omega$, we can write that

$$u_1(x) = -\cos\alpha\ x_1 - \sin\alpha\ x_2 + o(|x_1| + |x_2|)$$

in V. Also

$$u_2(x) = -\cos\alpha\ x_1 + \sin\alpha\ x_2 + o(|x_1| + |x_2|)$$

in V, taking into account that $u_1 = u_2$ on the line $x_2 = 0$. Moreover, $\cos\alpha > 0$ since e_1 points inside Ω. Hence, if the direction of the axis x_2 is chosen appropriately, we have $u(x) = -\cos\alpha\ x_1 - \sin\alpha\ |x_2| + o(|x_1| + |x_2|)$ near 0.

Let us now define $\theta_0(x) = -\cos\beta\, x_1 - \sin\beta\, |x_2|$, where β satisfies $\cos\beta \in (0, \cos\alpha)$ and $\cos(\alpha - \beta) > 0$. For any $\varepsilon > 0$, we define $\theta_\varepsilon(x) := (1 - \delta_\varepsilon)\theta_0(x_1 + \varepsilon, x_2)$, where $\delta_\varepsilon > 0$ satisfies $\lim_{\varepsilon\to 0} \delta_\varepsilon = 0$ and $\lim \frac{\varepsilon}{\delta_\varepsilon} = 0$.

We extend u outside Ω by zero, and define V_ε as the connected part of $\{x; \theta_\varepsilon(x) < u(x)\}$ containing 0. Note that V_ε is approximately equal to the set

$$T_\varepsilon := \Big\{ x \in \mathbb{R}^2; \\ \max(0, -\cos\alpha\ x_1 - \sin\alpha\ |x_2|) > -(1 - \delta_\varepsilon)(\cos\beta\ (x_1 + \varepsilon) + \sin\beta\, |x_2|) \Big\},$$

which is a triangle symmetric with respect to $\{x_2 = 0\}$. Note that the edges of T_ε have length of order ε, so that $|V_\varepsilon| \sim |T_\varepsilon| \sim c\varepsilon^2$ for some constant c. Also we can assume that there exists $C_1 > 0$ such that $V_\varepsilon \subset B(0, C_1\varepsilon)$ for ε small enough. In particular there exists $C_2 > 0$

$$\forall x \in V_\varepsilon, \qquad |\theta_\varepsilon(x)| < C_2\varepsilon. \tag{10}$$

We now define $\Omega_\varepsilon := \Omega \cup V_\varepsilon$, and

$$u_\varepsilon = \begin{cases} \theta_\varepsilon & \text{in } V_\varepsilon, \\ u & \text{in } \Omega \setminus V_\varepsilon. \end{cases} \tag{11}$$

Let us prove that u_ε satisfies the constraint (1) if ε is small enough and if δ_ε is chosen appropriately.

If x and y belong to $\Omega \setminus \overline{V}_\varepsilon$, then $u_\varepsilon \equiv u$ near x and y, so the constraint for u_ε follows from (1). If x and y belong to V_ε, then u_ε is affine near x and y; hence it satisfies (1).

If $x \in \Omega \setminus \overline{V}_\varepsilon$, $y \in V_\varepsilon$, then $u_\varepsilon(y) = \theta_\varepsilon(y) \le u(y)$, and $u_\varepsilon \equiv u$ near x, so the constraint follows from (1) again.

The last case to consider is $x \in V_\varepsilon$, $y \in \Omega \setminus V_\varepsilon$. We have $\nabla\theta_0(x) = -\cos\beta\ e_1 - \sin\beta\ \operatorname{sgn}(x_2)e_2$; hence

$$\frac{d}{dt}u(x - t\nabla\theta_0(x))\Big|_{t=0} = -\nabla u(x)\cdot\nabla\theta_0(x) = -\cos(\alpha-\beta) < 0$$

by assumption. Hence, reducing V if necessary, we can assume that for all $x \in V$ the map $t \mapsto u(x - t\nabla\theta_0(x))$ is decreasing for $t > 0$ satisfying $x - t\nabla\theta_0(x) \in V$.

Now if $x \in V_\varepsilon$, $y = x - \tau\nabla\theta_\varepsilon(x) = x - t\nabla\theta_0(x)$, where $t = \tau(1-\delta_\varepsilon)$, we distinguish two cases: if $\tau > C_2\varepsilon/\delta_\varepsilon(1-\delta_\varepsilon)$, we have, using (10), that

$$\theta_\varepsilon(x) + \tau(1 - |\nabla\theta_\varepsilon|^2) > -C_2\varepsilon + \tau\left(\delta_\varepsilon - \frac{1}{2}\delta_\varepsilon^2\right) > 0 \ge u_\varepsilon(y);$$

hence the constraint is satisfied.

In the other case, using $V_\varepsilon \subset B(0, C_1\varepsilon)$,

$$|y| \le |x| + |x-y| \le C_1\varepsilon + \tau(1-\delta_\varepsilon) = \varepsilon C_1 + C_2\frac{\varepsilon}{\delta_\varepsilon} \longrightarrow 0 \text{ as } \varepsilon \to 0.$$

Therefore, if ε is small enough, that will imply $y \in V$. We recall that this implies that the map $t \mapsto u(x - t\nabla\theta_0(x))$ is decreasing. Since $y \notin V_\varepsilon$, there exists $t' \in (0,t)$ such that $z := x - t'\nabla\theta_0(x)$ belongs to the boundary of V_ε; then

$$u_\varepsilon(y) = u(y) \le u(z) = \theta_\varepsilon(z) \le \theta_\varepsilon(x).$$

Hence u_ε satisfies the constraint since $\frac{1}{2}(1 - |\nabla u_\varepsilon(x)|^2) > 0$.

We now compute $\delta\Upsilon := \Upsilon(u_\varepsilon;\Omega_\varepsilon) - \Upsilon(u;\Omega)$. In the following, we note $W_\varepsilon := V_\varepsilon \cap \Omega$, and $X_\varepsilon := V_\varepsilon \setminus W_\varepsilon$. Then $|\Omega_\varepsilon| = |\Omega| + |X_\varepsilon|$. We have $|V_\varepsilon| \sim c\varepsilon^2$ as $\varepsilon \to 0$, as explained before, and also $|X_\varepsilon| \sim c_1\varepsilon^2$, $|W_\varepsilon| \sim (c - c_1)\varepsilon^2$ for some constant c_1.

We have

$$\begin{aligned}
\delta\Upsilon &= \frac{1}{|\Omega_\varepsilon|}\left(\int_{V_\varepsilon} f(|\nabla\theta_\varepsilon|) + \int_{\Omega\setminus V_\varepsilon} f(|\nabla u|)\right) - \frac{1}{|\Omega|}\int_\Omega f(|\nabla u|) \\
&= \frac{1}{|\Omega_\varepsilon|}\left[\int_{X_\varepsilon} f(|\nabla\theta_\varepsilon|) + \int_{W_\varepsilon} f(|\nabla\theta_\varepsilon|) - f(|\nabla u|)\right] + \left[\frac{1}{|\Omega_\varepsilon|} - \frac{1}{|\Omega|}\right]\int_\Omega f(|\nabla u|) \\
&= \frac{|X_\varepsilon|}{|\Omega_\varepsilon|}\left[\frac{1}{|X_\varepsilon|}\int_{X_\varepsilon} f(|\nabla\theta_\varepsilon|) - \frac{1}{|\Omega|}\int_\Omega f(|\nabla u|) + R_\varepsilon\right] \\
&= \frac{|X_\varepsilon|}{|\Omega_\varepsilon|}\left[\Upsilon(\theta_\varepsilon; X_\varepsilon) - \Upsilon(u;\Omega) + R_\varepsilon\right],
\end{aligned}$$

where

$$R_\varepsilon := \frac{1}{|X_\varepsilon|}\int_{W_\varepsilon} f(|\nabla\theta_\varepsilon|) - f(|\nabla u|).$$

We deduce that $\lim_{\varepsilon\to 0} R_\varepsilon = 0$. Indeed, $|W_\varepsilon| / |X_\varepsilon|$ is bounded, and, since $\nabla\theta_\varepsilon = -(1-\delta_\varepsilon)e_1$ and $\nabla u = -e_1 + o(1)$ on V_ε, the result follows directly.

Going back to $\delta\Upsilon$, we note that

$$\lim_{\varepsilon\to 0} \Upsilon(\theta_\varepsilon; X_\varepsilon) = f(1)$$

since $|\nabla\theta_\varepsilon| = 1 + o(1)$ in V_ε. We conclude that there exists a constant $C > 0$ such that

$$\delta\Upsilon = C[f(1) - \Upsilon(u;\Omega)]\ \varepsilon^2 + o(\varepsilon^2).$$

Since u is a minimizer, $\delta\Upsilon \geq 0$; hence $\Upsilon(u;\Omega) \leq f(1)$. On the other hand, $|\nabla u| \leq 1$ in Ω and f is decreasing, so $f(|\nabla u|) \geq f(1)$. We deduce that $|\nabla u| = 1$ almost everywhere in Ω. This implies $u \geq 0$ in Ω from (1) and the fact that $u = 0$ on $\partial\Omega$ (consider a $\tau > 0$ such that $x - \tau\nabla u(x) \in \partial\Omega$). We already know that $u \leq 0$, so $u \equiv 0$, a contradiction.

This ends the proof of the theorem in the case where u is not differentiable at 0.

Step 2. Let us now assume that u is C^2 near 0. Then we can write it in the form

$$u(x_1, x_2) = -x_1 + \frac{1}{2}\alpha_1 x_1^2 + \frac{1}{2}\alpha_2 x_2^2 + o(x_1^2 + x_2^2). \tag{12}$$

We have taken into account that 0 is an exposed point, that we have (8), (9), and the fact that $u = 0$ on $\partial\Omega$ and $u < 0$ in Ω. Moreover, Δ is the tangent line to $\partial\Omega$ at 0, and from (8) we have $\alpha_2 < 0$. Since $|\nabla u(x_1, 0)| = |1 - \alpha_1 x_1 + o(x_1)| < 1$ for $x_1 > 0$, we also have $\alpha_1 > 0$.

Let θ_0 be the function defined by

$$\theta_0(x_1, x_2) = \begin{cases} -x_1 + \frac{1}{2}\beta x_1^2 & \text{if } x_1 < \frac{2}{\beta}, \\ 0 & \text{otherwise,} \end{cases}$$

where β is a number to be chosen later satisfying $\beta > \alpha_1$. As this is the negative part of a parabola whose focus point is at $(\frac{1}{\beta}, 0)$, θ_0 satisfies the constraint for every $x \in \mathbb{R}^2$ with $x_1 \geq 0$ and for every $\tau > 0$.

For any $\varepsilon > 0$, let $\theta_\varepsilon(x_1, x_2) := \theta_0(x_1 + \varepsilon^2, x_2)$. We claim that there exists $\varepsilon_0 > 0$, and, for any $\varepsilon \in (0, \varepsilon_0)$, a neighborhood $V_\varepsilon \subset V$ of 0 such that

$$\limsup_{\varepsilon\to 0} \frac{\operatorname{diam} V_\varepsilon}{\varepsilon} < \infty, \quad u > \theta_\varepsilon \text{ in } V_\varepsilon \cap \Omega, \quad \text{and} \quad u = \theta_\varepsilon \text{ on } \partial V_\varepsilon \cap \overline{\Omega}. \tag{13}$$

Let us extend u by the constant value 0 outside Ω and consider V_ε the connected component of $\{u > \theta_\varepsilon\}$ containing 0. Notice first that

$$V_\varepsilon \cap (\mathbb{R}^2 \setminus \Omega) \subset \{x_1 > -\varepsilon^2\}$$

since u was extended by zero.

We now consider $W_\varepsilon := V_\varepsilon \cap \overline{\Omega}$. Using the Taylor expansion of u, we have

$$\begin{aligned} u(x_1, x_2) - \theta_\varepsilon(x_1, x_2) = \varepsilon^2(1 - \beta x_1) - \frac{1}{2}(\beta - \alpha_1)x_1^2 \\ + \frac{1}{2}\alpha_2 x_2^2 - \frac{1}{2}\beta\varepsilon^4 + o(x_1^2 + x_2^2). \end{aligned} \tag{14}$$

Hence this vanishes for x_1, x_2 of order ε, and the set $u > \theta_\varepsilon$ is described by the equation

$$\varepsilon^2 + o(\varepsilon^2) > \frac{1}{2}(\beta - \alpha_1)\left(x_1 + \frac{\beta}{\beta - \alpha_1}\varepsilon^2\right)^2 - \frac{1}{2}\alpha_2 x_2^2.$$

Except for the $o(\varepsilon^2)$ term, this is the interior of an ellipse with center $(-\frac{\beta}{\beta-\alpha_1}\varepsilon^2, 0)$ and diameter of order ε. That proves that $\operatorname{diam} W_\varepsilon$ is of order ε. Moreover, V_ε is included in the intersection of the ellipse and $\{x_1 > -\varepsilon^2\}$. This ends the proof of (13). Notice also that (14) implies that $|u - \theta_\varepsilon| \le c\varepsilon^2$ on V_ε for some $c > 0$.

Step 3. We now define $\Omega_\varepsilon := \Omega \cup V_\varepsilon$, and

$$u_\varepsilon = \begin{cases} \theta_\varepsilon & \text{in } V_\varepsilon, \\ u & \text{in } \Omega \setminus V_\varepsilon. \end{cases} \tag{15}$$

We claim that

$$\Upsilon(u_\varepsilon; \Omega_\varepsilon) < \Upsilon(u; \Omega) \tag{16}$$

for ε small enough: this will contradict the minimality of $(u; \Omega)$ and ends the proof of the theorem.

Let us first prove that u_ε satisfies the constraints in Ω_ε. Let $x \in \Omega_\varepsilon \cap \operatorname{dom}(\nabla u_\varepsilon)$, and $\tau > 0$ such that $y := x - \tau \nabla u_\varepsilon(x) \in \overline{\Omega}_\varepsilon$. We have to prove that

$$\frac{u_\varepsilon(y) - u_\varepsilon(x)}{\tau} \le \frac{1}{2}(1 - |\nabla u_\varepsilon(x)|^2). \tag{17}$$

If x and y belong to $\Omega \setminus \overline{V}_\varepsilon$, then $u_\varepsilon \equiv u$ near x and y, and so (17) follows from (1). If x and y belong to V_ε, then $u_\varepsilon \equiv \theta_\varepsilon$ near x and y, and so (17) is obvious.

If $x \in \Omega \setminus \overline{V}_\varepsilon$, $y \in V_\varepsilon$, then $u_\varepsilon(y) = \theta_\varepsilon(y) \le u(y)$, and $u_\varepsilon \equiv u$ near x, and so (17) follows from (1) again.

The last case to consider is $x \in V_\varepsilon$, $y \in \Omega \setminus V_\varepsilon$.

Let us define, for all $x \in V$ and any $\varepsilon > 0$,

$$\Sigma_\varepsilon(x) := \left\{ y \in x - \mathbb{R}_+(\nabla u(x) + \sqrt{\varepsilon} B_1);\, \frac{u(y) - u(x)}{|y - x|} \ge \frac{1 - |\nabla u(x)|^2}{2\,|\nabla u(x)|} - \sqrt{\varepsilon} \right\},$$

where B_1 is the unit ball of $\mathbb{R}^2$. This is nonempty since it contains $x - \tau_x \nabla u(x)$. We now define $Q_\varepsilon := \Sigma_\varepsilon(V_\varepsilon)$. We claim that there exist $\varepsilon_0 > 0$ and $k > 0$ such that for all $\varepsilon \in (0, \varepsilon_0)$, $Q_\varepsilon \subset \{x_1 > k\}$. Indeed, if not, we can find sequences $(\varepsilon^n)_n$ going to 0, $(k^n)_n$ going to zero, and $x^n \in V_{\varepsilon^n}$, $y^n \in \Sigma(x_n)$ such that $y_1^n \le k_n$. This implies that x^n converges to 0; hence $\nabla u(x^n) \to -e_1$. Since $y^n \in x^n - \mathbb{R}_+(\nabla u(x^n) + \sqrt{\varepsilon^n} B_1)$, we deduce $(y_2^n - x_2^n)/(y_1^n - x_1^n) \to 0$ and $y_1^n \in [x_1^n, k^n]$ goes to zero for n large. So x^n and y^n are in V for n large, and using (12), we get

$$u(y^n) - u(x^n) = x_1^n - y_1^n + o(\varepsilon^n) \qquad \text{and} \qquad |y^n - x^n| = y_1^n - x_1^n + o(\varepsilon^n).$$

Since $y^n \in \Sigma_{\varepsilon^n}(x_n)$, we get

$$-1 + o(1) = \frac{u(y^n) - u(x^n)}{|y^n - x^n|} \ge \frac{1 - |\nabla u(x^n)|^2}{2\,|\nabla u(x^n)|} - \sqrt{\varepsilon^n} = o(1)$$

since $|\nabla u(x^n)| \to 1$. This is a contradiction.

The parameters β and k and linked together in our construction, but we can increase β without changing k. This is permitted by the monotonicity properties associated with these parameters: if β is increased (to a new value $\tilde{\beta} > \beta$, say), the corresponding function $\tilde{\theta}_0$ satisfies $\tilde{\theta}_0 \geq \theta_0$. This implies $\tilde{V}_\varepsilon \subset V_\varepsilon$ and $\tilde{Q}_\varepsilon \subset Q_\varepsilon \subset \{x_1 > k\}$.

In the following, we will assume that $\beta > 2/k$.

Let us now assume that we can find $x_\varepsilon \in V_\varepsilon$, $\tau_\varepsilon > 0$ such that the constraint is not satisfied for u_ε at x_ε, $y_\varepsilon := x_\varepsilon - \tau_\varepsilon \nabla u_\varepsilon(x_\varepsilon) = x_\varepsilon - \tau_\varepsilon \nabla \theta_\varepsilon(x_\varepsilon)$; that is,

$$\frac{u(y_\varepsilon) - \theta_\varepsilon(x_\varepsilon)}{\tau_\varepsilon} > \frac{1}{2}(1 - |\nabla \theta_\varepsilon(x_\varepsilon)|^2). \tag{18}$$

Note that $y_1^\varepsilon = x_1^\varepsilon + \tau_\varepsilon(1 - \beta(x_1^\varepsilon + \varepsilon^2))$, $y_2^\varepsilon = x_2^\varepsilon$.

Extracting a subsequence, we can assume that $\tau_\varepsilon \to \tau_0$. We have $\tau_0 > 0$ since if not, y_ε goes to 0 as x_ε does; hence y_ε belongs to V for ε small enough. Using a Taylor expansion of u near 0 in (18) and the particular form of the coordinates of y_ε, we get

$$\beta x_1^\varepsilon - 1 + o(|x^\varepsilon|) = \frac{1}{\tau_\varepsilon}(-y_1^\varepsilon + o(|y^\varepsilon|) - x_1^\varepsilon + o(|x^\varepsilon|)) > \beta x_1^\varepsilon + o(|x^\varepsilon|),$$

which is a contradiction. This proves $\tau_0 > 0$.

Using (18), we get

$$\begin{aligned}\frac{u(y_\varepsilon) - u(x_\varepsilon)}{\tau_\varepsilon} - \frac{1}{2}(1 - |\nabla u(x_\varepsilon)|^2) \\ > - \frac{u(x_\varepsilon) - \theta_\varepsilon(x_\varepsilon)}{\tau_\varepsilon} + \frac{1}{2}(|\nabla u(x_\varepsilon)|^2 - |\nabla \theta_\varepsilon(x_\varepsilon)|^2).\end{aligned}$$

Note that both terms in the right are $O(\varepsilon)$, so $y_\varepsilon \in \Sigma_\varepsilon(x_\varepsilon)$ for ε small enough. In particular, this implies $y_1^\varepsilon > k > 2/\beta$. Hence $\theta_\varepsilon(y^\varepsilon) \geq 0 \geq u(y^\varepsilon)$. From (18) we deduce that

$$\frac{\theta_\varepsilon(y_\varepsilon) - \theta_\varepsilon(x_\varepsilon)}{\tau_\varepsilon} > \frac{1}{2}(1 - |\nabla \theta_\varepsilon(x_\varepsilon)|^2).$$

Hence the pair $(x^\varepsilon, y^\varepsilon)$ violates the constraint for θ_ε, which is impossible from its definition. This ends the proof that u_ε satisfies the constraint.

We now compute $\delta\Upsilon := \Upsilon(u_\varepsilon; \Omega_\varepsilon) - \Upsilon(u; \Omega)$. In the following, we note $W_\varepsilon := V_\varepsilon \cap \Omega$ and $X_\varepsilon := V_\varepsilon \setminus W_\varepsilon$. Then $|\Omega_\varepsilon| = |\Omega| + |X_\varepsilon|$. From the definition of V_ε, the boundary of X_ε has two parts, one included in $\{x_1 = -\varepsilon^2\}$, the other one in $\partial\Omega$. Note that the boundary of Ω can be defined by the equation $u(x_1, x_2) = 0$; that is, using (12),

$$x_1 = \frac{1}{2}\alpha_2 x_2^2 + o(x_2^2).$$

We deduce that

$$|X_\varepsilon| \sim \int_{-\varepsilon^2}^0 2 \int_0^{\sqrt{2x_1/\alpha_2}} dx_2 \, dx_1 = \frac{4}{3}\sqrt{\frac{-2}{\alpha_2}} \, \varepsilon^3 + o(\varepsilon^3).$$

Note that $|V_\varepsilon| = O(\varepsilon^2)$ from (13).

We have

$$\begin{aligned}\delta\Upsilon &= \frac{1}{|\Omega_\varepsilon|}\left(\int_{V_\varepsilon} f(|\nabla\theta_\varepsilon|) + \int_{\Omega\setminus V_\varepsilon} f(|\nabla u|)\right) - \frac{1}{|\Omega|}\int_\Omega f(|\nabla u|)\\ &= \frac{1}{|\Omega_\varepsilon|}\left[\int_{X_\varepsilon} f(|\nabla\theta_\varepsilon|) + \int_{W_\varepsilon} f(|\nabla\theta_\varepsilon|) - f(|\nabla u|)\right] + \left[\frac{1}{|\Omega_\varepsilon|} - \frac{1}{|\Omega|}\right]\int_\Omega f(|\nabla u|)\\ &= \frac{|X_\varepsilon|}{|\Omega_\varepsilon|}\left[\frac{1}{|X_\varepsilon|}\int_{X_\varepsilon} f(|\nabla\theta_\varepsilon|) - \frac{1}{|\Omega|}\int_\Omega f(|\nabla u|) + R_\varepsilon\right]\\ &= \frac{|X_\varepsilon|}{|\Omega_\varepsilon|}\left[\Upsilon(\theta_\varepsilon; X_\varepsilon) - \Upsilon(u;\Omega) + R_\varepsilon\right],\end{aligned}$$

where

$$R_\varepsilon := \frac{1}{|X_\varepsilon|}\int_{W_\varepsilon} f(|\nabla\theta_\varepsilon|) - f(|\nabla u|).$$

We claim that $\lim_{\varepsilon\to 0} R_\varepsilon = 0$. Indeed, since $\nabla\theta_\varepsilon = -e_1 + o(1)$ and $\nabla u = -e_1 + o(1)$ on V_ε, we have $\lim R_\varepsilon = \lim \bar{R}_\varepsilon$, where

$$\bar{R}_\varepsilon := \frac{1}{|X_\varepsilon|}\int_{V_\varepsilon} f(|\nabla\theta_\varepsilon|) - f(|\nabla u|) = R_\varepsilon + \frac{1}{|X_\varepsilon|}\int_{X_\varepsilon} f(|\nabla\theta_\varepsilon|) - f(|\nabla u|).$$

Let us define $U(x) := \nabla u(x) + e_1$, $\Theta_\varepsilon(x) := \nabla\theta_\varepsilon(x) + e_1$. We note that there exists $c > 0$ such that $|U(x)| + |\Theta_\varepsilon(x)| < c\varepsilon$ for all $x \in V_\varepsilon$. Hence using a Taylor expansion of f near $-e_1$ in the form

$$f(|-e_1 + U|) = f(1) + \Phi\cdot U + O(|U|^2),$$

we get

$$\bar{R}_\varepsilon = \frac{1}{|X_\varepsilon|}\left[\int_{V_\varepsilon} \Phi\cdot(\Theta_\varepsilon(x) - U(x)) + O(\varepsilon^2)\,|V_\varepsilon|\right].$$

The integral vanishes since it is equal to $\int \Phi\cdot\nabla(\theta_\varepsilon - u)$, which is zero from the Green formula and the fact that $u = \theta_\varepsilon$ on ∂V_ε. Hence $\bar{R}_\varepsilon = O(\varepsilon)$ from our previous estimates and goes to zero as claimed.

Going back to $\delta\Upsilon$, we note that

$$\lim_{\varepsilon\to 0}\Upsilon(\theta_\varepsilon; X_\varepsilon) = f(1)$$

since $|\nabla\theta_\varepsilon| = 1 + o(1)$ in V_ε. We conclude that there exists a constant $C > 0$ such that

$$\delta\Upsilon = C[f(1) - \Upsilon(u;\Omega)]\,\varepsilon^3 + o(\varepsilon^3).$$

Using the same argument as used in the end of Step 1, we are led again to a contradiction.

This ends the proof of Theorem 2. □

3. Newton's functional. The remaining part of the proof of the main theorem relies more precisely on the exact value of the functional in (2). We divide it into a few lemmas.

LEMMA 3.1. *If (u, Ω) satisfies the constraint, with Ω convex and u saturating the constraints everywhere, then Ω is a convex polygon having at most six vertices and satisfying the following properties:*

1. *For every side $[A, B]$ of the polygon, and for any vertex C, the orthogonal projection of C on the line (AB) does not lie on the open segment (A, B).*
2. *All inner angles of the polygon are $\geq \pi/2$.*

Proof. We already know that Ω is convex from Theorem 2. Since Ω tiles the plane with a locally finite tiling, Ω is the interior of a convex polygon with at most six vertices (cf. [1]). Of course this gives us that u is C^2 on $\partial\Omega$ except at the vertices. We note that $A_0, \dots, A_{p-1}$ are the vertices of $\partial\Omega$, $p \leq 6$.

Step 4. Since u is constant ($= 0$) on $\partial\Omega$, $\nabla u(x)$ is orthogonal to $\partial\Omega$ at x; in particular, since $x - y(x) \in \mathbb{R}\nabla u(x)$, we have

$$\forall x \in \partial\Omega \cap \mathrm{dom}(\nabla u), \quad x - y(x) \text{ is orthogonal to } \partial\Omega \text{ at } x. \tag{19}$$

We recall that we assumed u to be C^2 by parts; the map $x \mapsto y(x) := x - \tau_x \nabla u(x)$ is defined almost everywhere. Let $x_0 \in \partial\Omega \setminus \{A_0, \dots, A_{p-1}\}$ and V be a neighborhood of x_0 such that u is $C^2(\overline{\Omega} \cap V)$. We assume by contradiction that $y(x_0) \notin \mathrm{dom}(\nabla u)$, that is, $y(x_0) \in \{A_0, \dots, A_{p-1}\}$, say $y(x_0) = A_0$, for instance.

We note that the map y is $C^1(V \cap \Omega)$. Indeed, since $u(x - \tau_x \nabla u(x)) = 0$, we have, using (4),

$$-2u(x) = \tau_x(1 - |\nabla u(x)|^2).$$

For any $x \in \Omega \cap \mathrm{dom}(\nabla u)$, we have $u(x) < 0$; since there exists $t \in \mathbb{R}$ such that $x - t\nabla u(x) \in \partial\Omega$, so that $u(x - t\nabla u(x)) = 0$, we get from (4) that $|\nabla u(x)| < 1$. Consequently τ is $C^1(V \cap \Omega)$, and so is y.

For $\varepsilon > 0$ small enough, the equation $u(x) = -\varepsilon$ defines a C^1-line $\mathcal{L}_\varepsilon$ in $V \cap \Omega$ with a parametric representation $s \in I_\varepsilon \subset \mathbb{R} \to \xi_\varepsilon(s)$. The map

$$y(\xi_\varepsilon(s)) = \xi_\varepsilon(s) - \tau(\xi_\varepsilon(s))\nabla u(\xi_\varepsilon(s))$$

takes values in $\partial\Omega$ near A_0. On the other hand, it is a C^1 map; hence it takes images in $[A_{p-1}, A_0]$ or $[A_0, A_1]$.

Moreover, $\mathcal{L}_\varepsilon$ is continuous with respect to ε and converges to $\mathcal{L}_0 := V \cap \partial\Omega \ni x_0$. From (19) and the convexity of Ω, $y(\mathcal{L}_0) \cap (A_{p-1}, A_0) \neq \emptyset$ and $y(\mathcal{L}_0) \cap (A_0, A_1) \neq \emptyset$. This is a contradiction, and this proves the first assertion of the lemma.

Step 5. We now prove that every interior angle at the vertices $A_0, \dots, A_{p-1}$ is $\geq \pi/2$. Since Ω is a convex polygon tiling the plane, that implies also that $p > 3$.

Indeed, let us assume by contradiction that the angle at, say, A_1 is $< \pi/2$. Let us consider $x \in (A_0, A_1)$ near A_1; from the previous step, $y(x)$ belongs to the orthogonal line to $[A_0, A_1]$ at x and to $\partial\Omega$, that is, $y(x) \in (A_1, A_2)$. As x varies continuously from A_1 to A_0, $y(x)$ still belongs to the same segment as proved before. Let B_0 be the limit of $y(x)$ as $x \to A_0$, so that $B_0 \in [A_1, A_2]$. Then the triangle $[A_0, A_1, B_0]$ is rectangular in A_0 and not flat. This implies

$$|A_1 - A_0| < |A_1 - B_0| \leq |A_1 - A_2|\,.$$

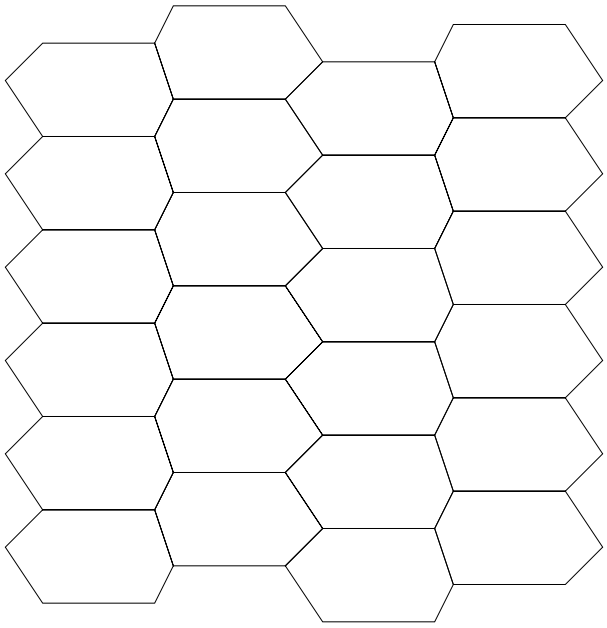

FIG. 1. *Tiling the plane with an irregular hexagon.*

On the other hand, A_2 obeys the same rule on the other side, and so $|A_1 - A_2| < |A_1 - A_0|$, which is a contradiction.

This ends the proof of the lemma. □

LEMMA 3.2. *The polygons obeying the properties of Lemma* 3.1 *and tiling the plane are*

1. *all the rectangles;*
2. *the regular hexagon;*
3. *all convex hexagons such that $A_1A_2A_4A_5$ is a rectangle, $\widehat{A}_0 \geq \pi/2$, $\widehat{A}_3 \geq \pi/2$, and $A_1A_2 > A_iA_{i+1}$ for $i = 2, 3, 5, 0$ (see Figure* 1*).*

Proof. Let us number the vertices such that A_1A_2 is one of the largest sides of the polygon. We shall write the indices modulo p, that is, $A_p = A_0$, etc. We call $\widehat{A}_i$ the inner angle at A_i.

Step 6. We claim that there exists $k > 1$ such that $A_1A_2A_kA_{k+1}$ is a rectangle.

Indeed, for any i, the orthogonal projection P_i of A_i on the line $\Delta = (A_1A_2)$ does not belong to (A_1, A_2), that is, belong to $\Delta_1 := \{A_1 + t(A_1 - A_2); t \in \mathbb{R}_+\}$ or $\Delta_2 := \{A_2 + t(A_2 - A_1); t \in \mathbb{R}_+\}$. Moreover, $P_0 \in \Delta_1$ since the inner angle at A_1 is $\geq \pi/2$; similarly, $P_3 \in \Delta_2$. Therefore, there exists k such that $P_k \in \Delta_2$ and $P_{k+1} \in \Delta_1$. Since the projection is 1-Lipschitz,

$$|A_k - A_{k+1}| \geq |P_k - P_{k+1}| \geq |A_1 - A_2|.$$

Since A_1A_2 is one of largest sides, there is equality here, and $P_k = A_2$, $P_{k+1} = A_1$.

Step 7. If $\widehat{A}_1 = \pi/2$, then the polygon is a rectangle. Indeed, $\widehat{A}_1 = \pi/2$ implies $A_{k+1} = A_0$, that is, $k = p-1$. If we suppose $\widehat{A}_2 > \pi/2$, then $k > 3$, and the projection of A_3 on (A_0, A_1) belongs to the interior of (A_0, A_1) from the convexity of the polygon and the fact that $A_0A_1A_2A_{p-1}$ is a rectangle. This contradicts Lemma 3.1.

Step 8. Let us now assume that the polygon is not a rectangle. From the previous

step, $\widehat{A}_i > \pi/2$ for $i = 1, 2, k, k+1$ since all four vertices of the rectangle $A_1A_2A_kA_{k+1}$ are equivalent. Consequently $k > 3$ and $k+1 < p$; since $p \leq 6$, this implies $p = 6$ and $k = 4$.

Let us first assume that $|A_2 - A_3| = |A_1 - A_2|$. Then using the same argument as in the first step, we get that $A_2A_3A_5A_0$ is a rectangle. Since this rectangle has a common diagonal (A_2A_5) with $A_1A_2A_4A_5$, both have the same center O. Therefore, A_i and A_{i+3} are symmetrical with respect to O for $i = 0, 1, 2$. The polygon is a regular hexagon.

Step 9. The last case to consider is $|A_1 - A_2| = |A_4 - A_5| > |A_i - A_{i+1}|$ for $i = 0, 2, 3, 5$.

Since Ω tiles the plane, there is a deplacement R such that A_1A_2 is a side of $R(\Omega)$; hence it must be $R(A_1A_2)$ or $R(A_4A_5)$. That implies that R is a translation or a rotation with angle π or a symmetry with respect to a line parallel to (A_1, A_2). Moreover, $R(A_1A_2A_4A_5)$ is a rectangle with parallel sides, the longest side being parallel to A_1A_2. More generally, this property is true for any $R' \in G$, where G is the group of deplacements generating the tiling.

The additional requirements stated in the lemma come from Lemma 3.1. □

LEMMA 3.3. *Let Ω be a convex polygon with vertices $\{A_0, \dots, A_{p-1}\}$. Then if u is optimal, $u = \max(u_0, \dots, u_{p-1})$, where u_k has the form*

$$u_k(x_1, x_2) = \frac{1}{2\gamma}(X_2^2 - \gamma^2) \quad \text{or} \quad u_k(x_1, x_2) = \cosh\beta\ X_1 + \sinh\beta\ \sqrt{X_1^2 + X_2^2}$$

with $X := Rx + X_0$, where $R \in SO_2$, $X_0 \in \mathbb{R}^2$, and $\gamma, \beta \in \mathbb{R}$ are constant.

Proof. Let A_kA_{k+1} be one of the sides of the polygon. There exists u_k of class C^2 such that $u \equiv u_k$ in a neighborhood V of this side. Also there exists another side A_iA_{i+1} such that for all x, $y(x) \in [A_i, A_{i+1}]$.

There exists $R \in SO_2$, $X_0 \in \mathbb{R}^2$ such that, in the new coordinates system $X = Rx + X_0$, (A_iA_{i+1}) is included in the line $\{X_2 = 0\}$ and either A_kA_{k+1} is parallel to A_iA_{i+1} or the line A_kA_{k+1} contains $X = 0$. Since $u(Y(x)) = 0$, where $Y(x) = Ry(x) + X_0$ and

$$y(x) = x - \tau_x \nabla u(x) = x + 2\frac{u(x)}{1 - |\nabla u(x)|^2}\ \nabla u(x), \tag{20}$$

the fact that $Y_2(x) = 0$ is equivalent to the equation

$$X_2\,(|\nabla u(X)|^2 - 1) = 2u(X)\ \partial_2 u(X). \tag{21}$$

Therefore u_k must be a regular solution of this equation, satisfying $u_k \equiv 0$ on the segment A_kA_{k+1}; that is, either $u(X_1, \gamma) = 0$ for some γ or $u(\delta X_2, X_2) = 0$ for some δ. Since (21) is a Hamilton–Jacobi equation, there is uniqueness of the solution near this line. In the first case, one can check that the solution is $\frac{1}{2\gamma}(X_2^2 - \gamma^2)$, and in the other case, it is

$$\cosh\beta\ X_1 + \sinh\beta\ \sqrt{X_1^2 + xX_2^2},$$

where β is defined by $\sinh\beta = -\delta$. These solutions can be found using the methods described in [5].

Since all these functions are convex, u coincides with them near the sides and satisfies the constraints only if $u \geq U := \max(u_k)$. Moreover, if $u > U$, then $|\nabla u| <$

$|\nabla U|$ in the zone $\{u > U\}$; hence $F(u;\Omega) > F(U;\Omega)$, contradicting the optimality of u. □

In order to conclude the proof of the main theorem, we have to compute explicitly the value of the functional for the polygons given in Lemma 3.2, using the explicit functions given in Lemma 3.3. It turns out that the case of the nonregular hexagons leads to a larger value of the functional. This is shown, with complicated computations, in the appendix.

Let us first present the computation for the rectangle $[-1,1]\times[-k,k]$, where $k \geq 1$ is a given number. We will prove that the value of the functional attains a strict minimum for $k = 1$, that is, for a square.

From Lemma 3.3, since reflection occurs on parallel lines, we have u in the form $\max(u_1,u_2,u_3,u_4)$ with each u_i in the form $u_i(x_1,x_2) = (\pm x_j+\gamma)^2/4\gamma - \gamma$, where $j = 1$ or $j = 2$ and $\gamma = 1$ or $\gamma = k$ in an appropriate coordinate system. If we restrict ourselves to the positive quadrant $x_1 > 0$, $x_2 > 0$, we have

$$u(x_1,x_2) = \max(u_1(x_1),u_2(x_2))$$
$$\text{with} \qquad u_1(x_1) := \frac{(1+x_1)^2}{4} - 1, \quad u_2(x_2) := \frac{(k+x_2)^2}{4k} - k.$$

For any value of $x_1 \in [0,1]$, there exists a unique positive root $x_2 = h(x_1)$ of the equation $u_1(x_1) = u_2(x_2)$, given by

$$h(x_1) = \sqrt{k(4(k-1)+(x_1+1)^2)} - k.$$

Moreover, if $x_2 > h(x_1)$, then $u_2(x_2) > u_1(x_1)$, and hence $u = u_2$; conversely, $u = u_1$ if $x_2 < h(x_1)$. Therefore the value of the functional is given by

$$\begin{aligned} F(u) &= \frac{1}{k}\int_0^1 \left(\int_0^{h(x_1)} f(u_1'(x_1))\,dx_2 + \int_{h(x_1)}^k f(u_2'(x_2))\,dx_2 \right) dx_1 \\ &= 4\int_0^1 \frac{\sqrt{k(4(k-1)+(x_1+1)^2)} - k}{k((x_1+1)^2+4)}\,dx_1 \\ &\quad + \frac{\pi}{2} - 2\int_0^1 \arctan\left[\frac{\sqrt{4(k-1)+(x_1+1)^2}}{2\sqrt{k}}\right] dx_1. \end{aligned}$$

Differentiating with respect to k, using the change of variable $x = (1+x_1)/2$, and writing $k = 1+\beta^2$, we get

$$\frac{dF(u)}{dk} = \frac{\beta^2\sqrt{1+\beta^2}}{2}\int_{\frac{1}{2}}^1 \frac{(x^2-1)^2\,dx}{(1+x^2)(1+2\beta^2+x^2)\sqrt{\beta^2+x^2}} > 0$$

for $\beta \neq 0$; hence $F(u)$ is increasing as claimed.

This proves that the minimum among all rectangles is achieved for a square. The minimal value is given by $k = 1$; that is,

$$F_{\text{square}} := \pi + 12\ln 2 - 4\ln 5 - 4\arctan 2 \simeq 0.5930123.$$

For the regular hexagon, we put the vertices as indicated in Theorem 1. Using symmetries, we have to compute the value of the functional for the triangle OAI,

where $I = (a, 0)$, whose area is $a^2/2\sqrt{3}$. The restriction of u in this triangle is equal to $\phi_a(x_1)$ (defined in Theorem 1); hence the corresponding value of the functional is

$$\begin{aligned} F_{\text{hexagon}} &= \frac{2\sqrt{3}}{a^2} \int_0^a \int_0^{x_1/\sqrt{3}} f(\phi_a'(x_1))\, dx_2\ dx_1 \\ &= \pi + 12 \ln 2 - 4 \ln 5 - 4 \arctan 2 = F_{\text{square}}. \end{aligned}$$

This ends the proof of Theorem 1.

Appendix. Nonregular hexagons. We consider here a hexagon with vertices A, B, C, A', B', C'. We assume that $C'A$ is the longest side of the hexagon; then $C'ACA'$ is a rectangle from Lemma 3.2. We choose a coordinate system where $A = (a, -1)$, $C = (a, 1)$, $B = (a+\alpha, \beta)$ with $\alpha > 0$, and $A' = -A$, $C' = -C$ (see Figure 2). In the following, we consider only the part in $\Omega_+ := \{x \in \Omega;\ x_1 > 0\}$. Indeed, it suffices to minimize the functional on each half part of the hexagon.

We use the auxiliary functions $\phi_a(t) = (t + a)^2/(4a) - a$,

$$\psi_b(x) = x_1 \sqrt{1 + b^2} + b \sqrt{x_1^2 + x_2^2},$$

and the parameters $p := \alpha/(1 + \beta)$, $q := \alpha/(1 - \beta)$. Hence $\alpha = 2pq/(p + q)$, $\beta = (q - p)/(q + p)$. Then the line (AB) crosses $\{x_2 = 1\}$ at $L := (a + 2p, 1)$, and (BC) crosses $\{x_2 = -1\}$ at $K := (a + 2q, -1)$.

Here $u = \max(u_1, u_2, u_3, u_4)$, where

$$\begin{aligned} u_1(x) &= \phi_1(x_2) = \frac{1}{4}(1 + x_2)^2 - 1, \\ u_2(x) &= \phi_1(-x_2) = \frac{1}{4}(1 - x_2)^2 - 1, \\ u_3(x) &= \psi_q(x_1 - a - 2q, 1 + x_2), \\ u_4(x) &= \psi_p(x_1 - a - 2p, 1 - x_2). \end{aligned}$$

We note that $\Omega_i := \text{interior}\{x \in \Omega_+, u(x) = u_i(x)\}$.

THEOREM 3. *Assume that there exists an irregular hexagon H such that $F(u_H, H) < F_{\text{square}}$. Then there exists a symmetrical hexagon H' such that $F(u_{H'}, H') \le F(u_H, H)$.*

Proof. For a symmetrical hexagon, we have $\beta = 0$ or, equivalently, $q = p$. In the following, we assume that $q > p$, and we will prove that the value of F is increasing with respect to q; we note it shortly as $F(q)$:

$$F(q) := \frac{G(q)}{\sum_i |\Omega_i|}, \quad \text{where} \quad G(q) := \sum_{i=1}^4 \int_{\Omega_i} f(\nabla u_i).$$

Let us assume that $F(q)$ is optimal and, in particular, is not greater than F_{square}. Then we have a smaller value if $q = 1/a$. Indeed, we must in general have $qa \ge 1$ since the angle OCB must be not smaller than $\pi/2$ from Lemma 3.1. This implies that the scalar product $OC.CB \ge 0$, that is, $qa \ge 1$, or equivalently the line perpendicular to CB at C must cross the x_1-axis at some point D having a nonnegative first coordinate d. Let $U_1 = \{x \in \Omega_+; |x_1| < d\}$, $U_2 = \Omega_+ \setminus U_1$. If $qa > 1$, then U_1 is nonempty; then

$$F(u; \Omega_+) = tF(u; U_1) + (1 - t)F(u; U_2), \quad \text{where} \quad t := \frac{|U_1|}{|U_1| + |U_2|} \in (0, 1).$$

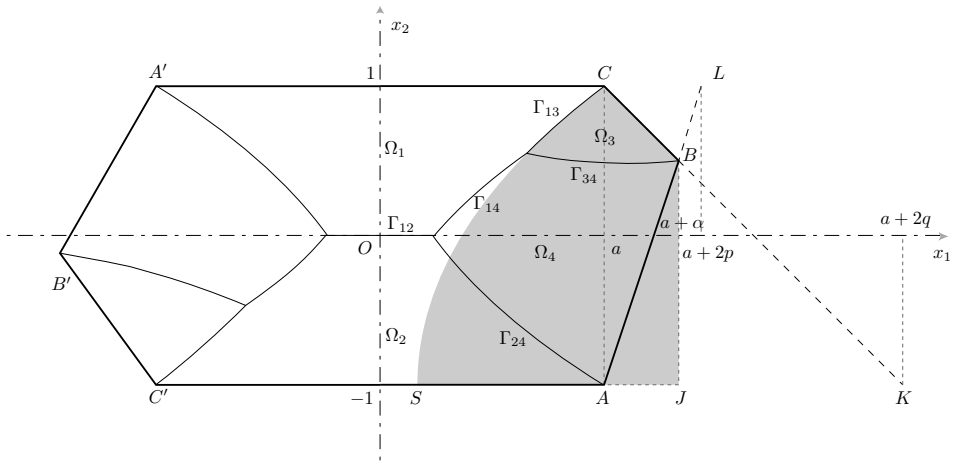

FIG. 2. *Nonsymmetrical hexagon.*

On the other hand, $F(u;U_1) > F_{\text{square}}$ as shown from an explicit computation, using $u = \phi_1(|x_2|)$ in U_1. Therefore, if the optimal value for F is not greater than F_{square}, then $F(u;U_2) \le F_{\text{square}}$; hence F is minimal when we have $U_1 = \emptyset$; that is, $qa = 1$ as claimed.

We are now going to study the variation of $F(q)$ with respect to q, assuming that $qa \equiv 1$. We recall that $F(q) = G(q)/A(q)$, where $A(q) := |\Omega|/2 = 2a + \beta$. We will prove that

$$\frac{\partial A}{\partial q} < 0 \quad \text{and} \quad \frac{\partial G}{\partial q} > 0 \tag{22}$$

under the assumption that $q > p$. (The partial derivatives are understood with p constant.) This implies that F is minimal for $q = p$, that is, for a symmetrical hexagon as claimed.

We note that the angle ABC must be not smaller than $\pi/2$ from Lemma 3.1, that is, $\alpha^2 + \beta^2 \le 1$ or, equivalently, $pq \le 1$. Under the assumption that $p < q$, this implies $p < 1$; since we have $A(q) = 2a + \beta = \frac{2}{q} + \frac{q-p}{q+p}$, we get

$$\frac{\partial A}{\partial q} = -\frac{2}{q^2} + \frac{2p}{(q+p)^2} < -\frac{2}{q^2} + \frac{2}{(q+p)^2} < 0.$$

This proves the first inequality in (22).

Let us turn to the proof of the second one. We note that only u_3 depends on q. Therefore, if we define $g_{ij} = u_i - u_j$, $\Gamma_{ij} = g_{ij}^{-1}(0)$ for $i, j \in \{1, \dots, 4\}$, we have

$$\frac{\partial G}{\partial q} = \int_{\Omega_3} \frac{\partial}{\partial q} f(\nabla u_3) + R_{43} + R_{13},$$

where

$$R_{ij} := \int_{\Gamma_{ij}} \frac{\partial g_{ij}}{\partial q} \, \frac{1}{|\nabla g_{ij}|} \left[f(\nabla u_i) - f(\nabla u_j) \right].$$

We prove that all three terms in $\frac{\partial G}{\partial q}$ are positive. Let us begin with R_{43}.

Let $x \in \Omega_3$ be given, and $y := x - \tau_x \nabla u(x) = x - \tau_x \nabla u_3(x)$. From the definition of u_3, we have $y \in C'A$ and $u(y) = 0$. From (4), we have

$$u_3(x) = -\frac{\tau_x}{2}(1 - |\nabla u_3(x)|^2).$$

A similar relation holds if $x \in \Omega_4$, and $y \in A'C$. For $x \in \Gamma_{43} \subset \overline{\Omega}_3 \cap \overline{\Omega}_4$, there exists τ_3, τ_4 such that

$$-\frac{\tau_3}{2}(1 - |\nabla u_3(x)|^2) = u_3(x) = u_4(x) = -\frac{\tau_4}{2}(1 - |\nabla u_4(x)|^2),$$

and $y_3 := x - \tau_3 \nabla u_3(x) \in C'A$, $y_4 := x - \tau_4 \nabla u_4(x) \in A'C$. Since $\Gamma_{43} \subset \{x_2 > 0\}$, we have $t_3 := |x - y_3| > t_4 := |x - y_4|$; notice also that $t_i = \tau_i |\nabla u_i(x)|$, and, in particular,

$$t_3 \left(\frac{1}{|\nabla u_3(x)|} - |\nabla u_3(x)| \right) = t_4 \left(\frac{1}{|\nabla u_4(x)|} - |\nabla u_4(x)| \right).$$

Since $t_3 > t_4$, this implies that $|\nabla u_3(x)| > |\nabla u_4(x)|$; hence

$$\forall x \in \Gamma_{43}, \qquad f(\nabla u_3(x)) < f(\nabla u_4(x)). \tag{23}$$

Similarly, if $x \in \Gamma_{13}$, y_1 is the orthogonal projection of x on $C'A$; hence $t_1 < t_3$. This implies that

$$\forall x \in \Gamma_{13}, \qquad f(\nabla u_3(x)) < f(\nabla u_1(x)). \tag{24}$$

Moreover, $\frac{\partial}{\partial q} g_{43}(x) = -\frac{\partial}{\partial q} u_3(x) = \frac{\partial}{\partial q} g_{13}(x)$ since $u_4(x)$ and $u_1(x)$ do not depend on q. In what follows, we will use the following coordinates:

$$X_1 := a + 2q - x_1, \qquad X_2 = 1 + x_2, \qquad R := \sqrt{X_1^2 + X_2^2}.$$

We recall that $x \in \overline{\Omega}_3$ in the expression of $\partial G/\partial q$. We need to describe the domain of variation of (X_1, R) for $x \in \overline{\Omega}_3$.

We have

$$\overline{\Omega}_3 \subset \{x; \quad u_3(x) \geq u_1(x) \text{ and } u_3(x) \leq 0 \text{ and } x_1 \leq a + \alpha \text{ and } x_2 \geq -1\};$$

that is, $\overline{\Omega}_3$ is included in the gray zone $SJBC$ indicated on Figure 2. This yields first $R \geq X_1$. Then $x_1 \leq a + \alpha$ implies $X_1 \geq 2q^2/(q + p) \geq q$ since we assume $q > p$. The condition $u_3 \leq 0$ implies $qR \leq X_1\sqrt{1 + q^2}$. And $u_3 \geq u_1$ leads to $(X_1 - 2\sqrt{1 + q^2})^2 \geq (R - 2q)^2$; taking into account that $X_1 \leq R$, this yields $R + X_1 \leq 2(q + \sqrt{1 + q^2})$, and, in particular, $X_1 \leq q + \sqrt{1 + q^2}$. Therefore, in (X_1, R) coordinates, $\overline{\Omega}_3$ is included in the polygon $\widetilde{B}\widetilde{C}\widetilde{S}\widetilde{J}$ pictured in Figure 3.

We have

$$\begin{aligned} -\frac{\partial}{\partial q} u_3(x) &= -\frac{\partial}{\partial q} \psi_q(a + 2q - x_1, 1 + x_2) \\ &= -\frac{\partial \psi_q}{\partial q}(a + 2q - x_1, 1 + x_2) - 2\frac{\partial \psi_q}{\partial x_1}(a + 2q - x_1, 1 + x_2) \\ &= \frac{-R^2 + R\,(X_1 q + 2(1 + q^2)) - 2qX_1\sqrt{1 + q^2}}{R\sqrt{1 + q^2}}. \end{aligned}$$

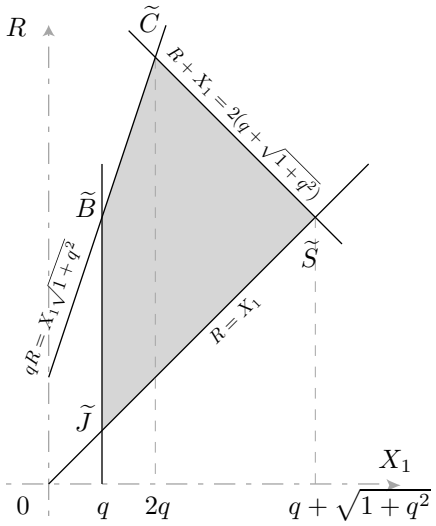

FIG. 3. *Zone including* $\overline{\Omega}_3$ *in* (X_1, R) *coordinates..*

Hence the sign of $\frac{\partial}{\partial q}u_3(x)$ is the same as the sign of

$$n_3(X_1, R) := -R^2 + R\,(X_1 q + 2(1+q^2)) - 2qX_1\sqrt{1+q^2}.$$

This is a concave expression in R, and so it is minimal for the extremal values of R, when X_1 is given. That is, we have to check that $n_3 \geq 0$ on $[\widetilde{J}\widetilde{S}]$, $[\widetilde{C}\widetilde{S}]$, $[\widetilde{B}\widetilde{C}]$.

On $[\widetilde{J}\widetilde{S}]$, we have $R = X_1$; using $m := q + \sqrt{1+q^2}$, we get

$$\begin{aligned} n_3(X_1, X_1) &= X_1(X_1(q-1) + 2(1+q^2) - 2q\sqrt{1+q^2}) \\ &= X_1 m^{-2}(-X_1 m + m^2 + 1) \geq 0, \end{aligned}$$

since $X_1 \leq m$.

On $[\widetilde{C}\widetilde{S}]$, we have $R = 2m - X_1$, and

$$n_3(X_1, 2m - X_1) = -m^4 + 2X_1 m^3 - X_1^2 m^2 + 1.$$

This is again a concave expression on X_1, so it is minimal for $X = m$ or $X = 2q = m - 1/m$; since $n_3(m, m) = 1$ and $n_3(m, m + 1/m) = 0$, we conclude that $n_3 \geq 0$ on $[\widetilde{C}\widetilde{S}]$.

On $[\widetilde{B}\widetilde{C}]$, $q \leq X_1 \leq 2q$, $R = X_1\sqrt{1+q^2}/q$; hence

$$n_3(X_1, X_1\sqrt{1+q^2}/q) = -2mX_1(1+m^2)\frac{X_1 m - m^2 + 1}{(m^2-1)^2} \geq 0.$$

This proves that $n_3 \geq 0$; hence $\frac{\partial}{\partial q}g_{43}(x) = \frac{\partial}{\partial q}g_{13}(x) \geq 0$. This proves that $R_{43} > 0$ and $R_{13} > 0$, taking (23) and (24) into account.

To conclude the proof that $\partial G/\partial q > 0$, we prove that $\frac{\partial}{\partial q}f(\nabla u_3) > 0$ or, equivalently, that $\frac{\partial}{\partial q}\left|\nabla u_3\right|^2 < 0$. We have

$$\begin{aligned} \left|\nabla u_3\right|^2 = &\left[\frac{q(a+2q-x_1)}{\sqrt{(a+2q-x_1)^2 + (1+x_2)^2}} - \sqrt{1+q^2}\right]^2 \\ &+ \frac{q^2(1+x_2)^2}{(a+2q-x_1)^2 + (1+x_2)^2}. \end{aligned}$$

Hence, using the notations X_1, X_2, R,

$$\frac{\partial}{\partial q}\left|\nabla u_3\right|^2 = \frac{2N(X_1,R)}{R^3\sqrt{1+q^2}},$$

where

$$N(X_1,R) := 2qX_1^2(1+q^2) - (2q^2+1)R^2X_1 - 2q(1+q^2)R^2 + 2q\sqrt{1+q^2}R^3.$$

We have to prove that $N \leq 0$; since this is a convex function of X_1, it is enough to prove that for the extremal values of X_1.

Let us first examine the value on $[\widetilde{S}\widetilde{J}]$, where $X_1 = R$. We have

$$N(R,R) = R^3(2q\sqrt{1+q^2} - 2q^2 - 1) < 0$$

since $2q\sqrt{1+q^2} < 2q^2+1$ for any $q > 0$.

On $[\widetilde{B}\widetilde{J}]$, we have $X_1 = q$, and

$$N(q,R) := 2q\sqrt{1+q^2}R^3 - (4q^2+3)qR^2 + 2q^3(1+q^2).$$

Since $\frac{d}{dR}N(q,R)$ has the form $R(c_1R - c_2)$, with $c_1, c_2 > 0$, $N(q,R)$ is decreasing, then increasing on $\mathbb{R}_+$. Hence, to prove $N(q,R) < 0$, it is enough to check on the boundary values for R, that is, $R = q$ (for $\widetilde{J}$) and $R = \sqrt{1+q^2}$ (for $\widetilde{B}$). We already know that $N(q,q) < 0$ and

$$N(q,\sqrt{1+q^2}) = -q(1+q^2) < 0.$$

On $[\widetilde{B}\widetilde{C}]$, we have $R = X_1\sqrt{1+q^2}/q$ and then

$$N(X_1, X_1\sqrt{1+q^2}/q) := \frac{X_1^2}{q^2}(1+q^2)[X_1 - 2q] \leq 0,$$

since $X_1 \leq 2q$ on $[\widetilde{B}\widetilde{C}]$.

On $[\widetilde{C}\widetilde{S}]$, we have $R = 2m - X_1$, where $m := q + \sqrt{1+q^2}$ and $X_1 \in [2q, m]$. Using $t := m(X - 2q)$, we have $t \in [0,1]$; thus,

$$N(X_1, 2m - X_1) = N\left(2q + \frac{t}{m}, 2m - 2q - \frac{t}{m}\right) = \frac{t}{m^3}\widetilde{N}(t),$$

where

$$\widetilde{N}(t) = -m^2t^2 + (2m^4 + 3m^2 - 1)t - 3m^4 - 2m^2 + 1.$$

We have $\widetilde{N}'(t) = -2tm^2 + 2m^4 + 3m^2 - 1 > 0$ since $m \geq 1$ and $t \in [0,1]$. Hence

$$\widetilde{N}(t) \leq \widetilde{N}(1) = -m^4 < 0.$$

This concludes the proof of (22) and the proof of Theorem 3. □

We now consider the case of a symmetrical hexagon, that is, $\beta = 0$, $p = q = \alpha$. For the reason given in the beginning of the proof of Theorem 3, it is sufficient to consider the case $a = 1/\alpha$, with $a \geq 1$.

THEOREM 4. *Let $F(a)$ be the value of $F(u_{H_a}; H_a)$, where H_a is the symmetrical hexagon ($\beta = 0$) with parameters $a \geq 1$, $\alpha = 1/a$. Then $F(a)$ is increasing with respect to $a \geq 1$, and its minimal value $F(1)$ is greater than F_{square}.*

Proof. We prove the theorem by an explicit computation of $F(a)$ and then by a differentiation with respect to a.

Since $\beta = 0$, the point B in Figure 2 lies on the x_1-axis, and H_a and u_{H_a} are symmetrical with respect to x_1 and x_2. Therefore, if we define $\Omega_a := H_a \cap \{x_1 > 0, x_2 > 0\}$ and u_a as the restriction of u_{H_a} to Ω_a, we have $F(a) = F(u_a, \Omega_a)$. In Ω_a, we have $u_a = \max(u_1, u_3)$, where $u_1(x) = \phi_1(x_2)$ and $u_3(x) = \psi_{1/a}(x_1 - a - 2/a, 1 + x_2)$.

We have $\overline{\Omega}_a = \overline{\Omega}_1 \cup \overline{\Omega}_3$ with $u_a = u_i$ in Ω_i, $i = 1, 3$. We still note by Γ_{13} the common boundary of Ω_1 and Ω_3. It is defined by the equation

$$\begin{aligned}\frac{1}{4}(1 + x_2)^2 - 1 = u_1(x) &= u_3(x) \\ &= \sqrt{1 + a^{-2}} \left(x_1 - a - \frac{2}{a} \right) + \frac{\sqrt{(x_1 - a - 2/a)^2 + (1 + x_2)^2}}{a},\end{aligned}$$

which can be solved in the form

$$x_1 = w(x_2) = \frac{(s - 1)(2s^2 + 2 + (x_2 + 1)^2 s)}{4s(s + 1)},$$

where $s := \exp(\operatorname{asinh} a) = a + \sqrt{1 + a^2}$.

We have

$$F(a) = \frac{G_1(a) + G_3(a)}{|\Omega_a|}, \quad \text{where} \quad G_i(a) := \int_{\Omega_i} f(\nabla u_i). \tag{25}$$

Now

$$G_3(a) = \int_0^1 \int_{w(x_2)}^{a + \frac{1 - x_2}{a}} f_3(x_1, x_2)\, dx_1\, dx_2$$

$$\text{with} \quad f_3(x_1, x_2) := f(\nabla u_3(x)) = \frac{1}{2} \frac{a^2 \sqrt{X^2 + Y^2}}{\sqrt{1 + a^2} X + (1 + a^2)\sqrt{X^2 + Y^2}},$$

where $X := x_1 - a - 2/a$, $Y := x_2 + 1$.

Using the change of variable $X = Y \sinh t$, we have that

$$J_3 := \int_{w(x_2)}^{a + \frac{1 - x_2}{a}} f_3(x_1, x_2)\, dx_1 = \frac{a^2 Y}{2} \int_W^{-\operatorname{asinh} \frac{1}{a}} \frac{\cosh^2 t\, dt}{(a^2 + 1)\cosh t + \sqrt{1 + a^2} \sinh t},$$

where $\sinh W = (aw(Y - 1) - 2 - a^2)/(aY)$, that is,

$$W = \log \left(\frac{Y(s - 1)}{2(s + 1)} \right),$$

taking into account the value of w and using $s = a + \sqrt{1 + a^2}$. We explicitly get

$$\begin{aligned}8(s^4 - 1) J_3 = (1 + s^4 + 6s^2)(4 - Y^2) + 4s(s^2 + 1)(Y - 2)^2 \\ + 32 s^2 Y \arctan \left(\frac{Y - 2}{2 + Y} \right).\end{aligned}$$

Integrating for $Y \in [1,2]$, we get

$$G_3(a) = \frac{5s^4 + 4s^3 + (144\arctan 3 + 384\arctan 2 - 66 - 168\pi)s^2 + 4s + 5}{24(s^4-1)}.$$

Since u_1 does not depend on x_1, we have

$$\begin{aligned} G_1(a) &= \int_0^1 w(x_2) f(\nabla u_1(x_2))\, dx_2 \\ &= \frac{(s-1)((4\arctan 2 - \pi)(s-1)^2 + 4s)}{4(s+1)s}. \end{aligned}$$

Finally, $|\Omega_a| = a + 1/(2a) = (1+s^4)/(2s(s^2-1))$, so

$$F(a) = \frac{2s(s^2-1)}{1+s^4}\left[G_1(a) + G_3(a)\right].$$

Hence,

$$F'(a) = \frac{ds}{da}\ \frac{(s^2-1)^2 N(s)}{12(1+s^4)^2(s^2+1)^2}$$

has the sign of

$$\begin{aligned} N(s) := 96\left(1 - 9s^5 - 6s^4 - 9s^3 - 6s^6 - 6s^2 - 3s - 3s^7 + s^8\right)\arctan 2 \\ - 144s^2(3 + 4s^2 + 3s^4)\arctan 3 \\ - 24(1 - 18s^4 - 9s^5 - 9s^3 - 15s^2 - 3s^7 + s^8 - 3s - 15s^6)\pi \\ - 29 + 88s + 54s^2 + 264s^3 + 88s^7 + 14s^4 + 264s^5 - 29s^8 + 54s^6. \end{aligned}$$

Since $a \geq 1$, $s \geq 1 + \sqrt{2}$. Computing the coefficients explicitly, we get for $t > 0$,

$$\begin{aligned} N(1+\sqrt{2}+t) \simeq 1.88805320\, t^8 + 31.8011496\, t^7 + 236.968636\, t^6 \\ + 1013.948295\, t^5 + 2708.11097\, t^4 + 4589.26377\, t^3 \\ + 4768.4986\, t^2 + 2727.7799\, t + 634.0078 > 0. \end{aligned}$$

Hence $F(a)$ is increasing as claimed. The minimal value of $F(a)$ is

$$\begin{aligned} F(1) &= ((528\sqrt{2} + 768)\arctan 2 + (180\sqrt{2} + 252)\arctan 3 \\ &\quad - (222\sqrt{2} + 318)\pi + 53 + 41\sqrt{2}) \Big/ (36(10 + 7\sqrt{2})) \\ &\simeq 0.60771279 > F_{\text{square}}. \end{aligned}$$

This concludes the proof of the theorem. □

ON THE CAUCHY PROBLEM FOR STOCHASTIC STOKES EQUATIONS*

R. MIKULEVICIUS†

Abstract. We extend Krylov's L_p-solvability theory of the second order quasi-linear parabolic stochastic differential equations to the stochastic Stokes equation. Some additional integrability and regularity properties are also presented.

Key words. stochastic partial differential equations, Stokes equation, Cauchy problem

1. Introduction.

In this paper we study the stochastic Stokes equation. Specifically, we are considering in $\mathbf{R}^d$ the system of equations for $\mathbf{u}=(u^l)_{1\le l\le d}$ and scalar functions p, $\tilde{p}$:

$$\begin{aligned} \partial_t u^l &= \partial_i(a^{ij}(t,x)\partial_j u^l)+D^l(\mathbf{u},t,x)+\partial_l p \\ &\quad +[\sigma^k(t,x)\partial_k u^l+Q^l(\mathbf{u},t,x)+\partial_l\tilde{p}]\cdot\dot{W}, \\ u^l(0,x) &= u_0^l(x), \quad l=1,\dots,d, \quad x\in\mathbf{R}^d, \\ \operatorname{div}\mathbf{u} &= 0, \end{aligned} \tag{1.1}$$

where W is a cylindrical Wiener process in a Hilbert space. Here and everywhere below, the summation with respect to the repeated indices is assumed.

Our interest was motivated by stochastic fluid mechanics (see, e.g., [3], [4]). While the assumptions imposed below exclude the "typical" nonlinearity $u^k\partial_k u$, they allow us to construct suitable approximations to the solution of stochastic Navier–Stokes equations.

In [1], [2], Krylov developed a comprehensive theory of second order quasi-linear parabolic stochastic differential equations in Bessel classes $H_p^s(\mathbf{R}^d)$. In [7], Krylov's results were extended to parabolic systems of quasi-linear stochastic PDEs on $\mathbf{R}^d$ for $\mathbf{u}=(u^l)_{1\le l\le d}$:

$$\begin{aligned} \partial_t u^l &= \partial_i(a^{ij}(t,x)\partial_j u^l)+D^l(\mathbf{u},t,x) \\ &\quad +[\sigma^k(t,x)\partial_k u^l+Q^l(\mathbf{u},t,x)]\cdot\dot{W}, \\ u^l(0,x) &= u_0^l(x), \quad l=1,\dots,d, \quad x\in\mathbf{R}^d. \end{aligned}$$

We prove the existence and uniqueness of solutions to (1.1) in the spaces of Bessel potentials.

The structure of the paper is as follows. In section 2 we introduce the notation and state the main result about the existence and uniqueness of solutions to (1.1). In section 3 we present some auxiliary results needed for the investigation of the Stokes equation in $\mathbb{R}^d$. They regard pointwise multipliers in $\mathbf{R}^d$ and solenoidal and potential

projections of vector fields. In section 4, following Krylov's ideas and [7], we prove the main results about the existence and uniqueness of solutions to (1.1). Also, some additional integrability and regularity properties of solutions are investigated.

2. Notation and the main results. Let Y be a separable Hilbert space with a norm $|\cdot|_Y$. The scalar product of $x, y \in Y$ will be denoted by $x \cdot y$.

Let $\mathbf{R}^d$ be a d-dimensional Euclidean space with elements $x = (x_1, \dots, x_d)$; if $x, y \in \mathbf{R}^d$, we write

$$(x, y) = \sum_{i=1}^{d} x_i y_i, \qquad |x| = \sqrt{(x, x)}.$$

If u is a function on $\mathbf{R}^d$, the following notational conventions will be used for its partial derivatives: $\partial_i u = \partial u/\partial x_i$, $\partial_{ij}^2 = \partial^2 u/\partial x_i \partial x_j$, $\partial_t u = \partial u/\partial t$, $\nabla u = \partial u = (\partial_1 u, \dots, \partial_d u)$, and $\partial^2 u = (\partial_{ij}^2 u)$ denotes the Hessian matrix of second derivatives. Let $\alpha = (\alpha_1, \dots, \alpha_d)$ be a multi-index; then $\partial_x^\alpha = \Pi_{i=1}^d \partial_{x_i}^{\alpha_i}$.

Let $C_0^\infty = C_0^\infty(\mathbf{R}^d)$ be the set of all infinitely differentiable functions on $\mathbf{R}^d$ with compact support.

For $s \in (-\infty, \infty)$, write $\Lambda^s = \Lambda_x^s = (1 - \sum_{i=1}^d \partial^2/\partial x_i^2)^{s/2}$.

For $p \in [1, \infty]$ and $s \in (-\infty, \infty)$, we define the space $H_p^s = H_p^s(\mathbf{R}^d)$ as the space of generalized functions u with the finite norm

$$|u|_{s,p} = |\Lambda^s u|_p,$$

where $|\cdot|_p$ is the L_p norm. Obviously, $H_p^0 = L_p$. Note that if $s \geq 0$ is an integer, the space H_p^s coincides with the Sobolev space $W_p^s = W_p^s(\mathbf{R}^d)$.

If $p \in [1, \infty]$ and $s \in (-\infty, \infty)$, $H_p^s(Y) = H_p^s(\mathbf{R}^d, Y)$ denotes the space of Y-valued functions on $\mathbf{R}^d$ so that the norm $||g||_{s,p} = |\,|\Lambda^s g|_Y\,|_p < \infty$. We also write $L_p(Y) = L_p(\mathbf{R}^d, Y) = H_p^0(Y) = H_p^0(\mathbf{R}^d, Y)$. Let $C_0^\infty(Y)$ be the space of Y-valued infinitely differentiable functions on $\mathbf{R}^d$ with compact support.

Obviously, the spaces $C_0^\infty, C_0^\infty(Y)$, $H_p^s(\mathbf{R}^d)$, and $H_p^s(\mathbf{R}^d, Y)$ can be extended to vector functions (denoted with boldfaced letters). For example, the space of all vector functions $\mathbf{u} = (u^1, \dots, u^d)$ such that $\Lambda^s u^l \in L_p$, $l = 1, \dots, d$, with the finite norm

$$|\mathbf{u}|_{s,p} = \left(\sum_l |u^l|_{s,p}^p \right)^{1/p},$$

we denote by $\mathbb{H}_p^s = \mathbb{H}_p^s(\mathbf{R}^d)$. Similarly, we denote by $\mathbb{H}_p^s(Y) = \mathbb{H}_p^s(\mathbf{R}^d, Y)$ the space of all vector functions $g = (g^l)_{1 \leq l \leq d}$, with Y-valued components g^l, $1 \leq l \leq d$, so that $||g||_{s,p} = (\sum_l |g^l|_{s,p}^p)^{1/p} < \infty$. The set of all infinitely differentiable vector functions $u = (u^1, \dots, u^d)$ on $\mathbf{R}^d$ with compact support will be denoted by $\mathbb{C}_0^\infty$. We denote by $\mathbb{C}_0^\infty(Y)$ the set of all infinitely differentiable vector functions $u = (u^1, \dots, u^d)$ on $\mathbf{R}^d$ with compact support. (All u^l are Y-valued.)

When $s = 0$, $\mathbb{H}_p^s(Y) = \mathbb{L}_p(Y) = \mathbb{L}_p(\mathbf{R}^d, Y)$. Also, in this case, the norm $||g||_{0,p}$ is denoted more briefly by $||g||_p$. To forcefully distinguish L_p norms in spaces of Y-valued functions, we write $||\cdot||_p$, while in all other cases a norm is denoted by $|\cdot|$.

The duality $\langle \cdot, \cdot \rangle_s$ between $\mathbb{H}_p^s(\mathbf{R}^d, Y)$ and $\mathbb{H}_q^{-s}(\mathbf{R}^d, Y)$, $p \geq 2$, $s \in (-\infty, \infty)$, and

$q = p/(p-1)$, is defined by

$$\langle \boldsymbol{\phi}, \boldsymbol{\psi} \rangle_{\mathbb{H}^s_p(Y),\mathbb{H}^{-s}_q(Y)} = \sum_{i=1}^{d} \int_{\mathbf{R}^d} \left[\Lambda^s \phi^i\right](x) \cdot \Lambda^{-s}\psi^i(x)\, dx$$

$$= \sum_{i=1}^{d} \int_{\mathbf{R}^d} \left[\tilde{\Lambda}_s \phi^i\right](x) \cdot \tilde{\Lambda}_{-s}\psi^i(x)\, dx, \quad \boldsymbol{\phi} \in \mathbb{H}^s_p(Y), \quad \boldsymbol{\psi} \in \mathbb{H}^{-s}_q(Y).$$

If $Y = \mathbf{R}$, i.e., $\mathbb{H}^s_p(Y) = \mathbb{H}^s_p$, we denote $\langle \boldsymbol{\phi}, \boldsymbol{\psi} \rangle_{\mathbb{H}^s_p(Y),\mathbb{H}^{-s}_q(Y)} = \langle \boldsymbol{\phi}, \boldsymbol{\psi} \rangle_s = \langle \boldsymbol{\phi}, \boldsymbol{\psi} \rangle_{s,p}$. If $\mathbf{f} \in \mathbb{H}^s_q(\mathbf{R}^d, Y)$ and $\boldsymbol{\phi} \in \mathbb{H}^{-s}_p(\mathbf{R}^d)$, $p \geq 2$, $s \in (-\infty, \infty)$, and $q = p/(p-1)$, we write

$$\langle \mathbf{f}, \boldsymbol{\phi} \rangle_{s,Y} = \langle \mathbf{f}, \boldsymbol{\phi} \rangle_{s,p,Y} = \sum_{l=1}^{d} \int_{\mathbf{R}^d} \left[\Lambda^s f^l(x)\right] \Lambda^{-s}\phi^l(x)\, dx$$

$$= \sum_{l=1}^{d} \int_{\mathbf{R}^d} \left[\tilde{\Lambda}_s f^l(x)\right] \tilde{\Lambda}_{-s}\phi^l(x)\, dx.$$

Obviously, the function $\boldsymbol{\phi} \longrightarrow \langle \mathbf{f}, \boldsymbol{\phi} \rangle_{s,Y}$ is a linear mapping from H^{-s}_p into Y, and $|\langle \mathbf{f}, \boldsymbol{\phi} \rangle_s|_Y \leq ||\mathbf{f}||_{s,q} |\boldsymbol{\phi}|_{-s,p}$. Similar notation, $\langle \phi, \psi \rangle_s$ and $\langle f, \phi \rangle_{s,Y}$, will be used for scalar functions.

We define the subspace of the divergence free vector fields $\mathcal{S}(\mathbb{H}^s_p(Y)) = \{\mathbf{v} \in \mathbb{H}^s_p(Y) : \operatorname{div} \mathbf{v} = 0\} \subseteq \mathbb{H}^s_p(Y)$ and the subspace of gradient vector fields

$$\mathcal{G}(\mathbb{H}^s_p(Y)) = \{\mathbf{v} \in \mathbb{H}^s_p(Y) : \langle \mathbf{v}, \mathbf{g} \rangle_{\mathbb{H}^s_p(Y),\mathbb{H}^{-s}_q(Y)} = 0 \ \forall\ \mathbf{g} \in \mathcal{S}(\mathbb{H}^{-s}_q(Y))\},$$

where $p \geq 2$, $q = p/(p-1)$, $s \in (-\infty, \infty)$.

Also, we will need some spaces of Y-valued continuous functions. For $m = 1, 2, 3, \ldots$, we define

$$C^m(Y) = \{u : \partial^\alpha u \text{ is uniformly continuous on } \mathbf{R}^d \ \forall\ |\alpha| \leq m\},$$

with the norm $||u||_{C^m} = \sum_{|\alpha| \leq m} ||\partial^\alpha u||_\infty$. For a noninteger $s > 0$, we define

$$\mathcal{C}^s(Y) = \left\{ u \in C^{[s]} : ||u||_{\mathcal{C}^s} = ||u||_{C^{[s]}} + \sum_{|\alpha|=[s]} \sup_{x \neq y} \frac{|\partial^\alpha u(x) - \partial^\alpha u(y)|_Y}{|x-y|^{\{s\}}} < \infty \right\},$$

where $s = [s] + \{s\}$, s is an integer, and $0 \leq \{s\} < 1$. For an integer $s > 0$, we denote

$$\mathcal{C}^s(Y) = \left\{ u \in C^{s-1} : ||u||_{\mathcal{C}^s} = ||u||_{C^{s-1}} + \sum_{|\alpha|=[s]^-} \sup_{x \neq y} \frac{|\partial^\alpha u(x) - \partial^\alpha u(y)|_Y}{|x-y|} < \infty \right\},$$

where $s = [s]^- + 1$. If $Y = \mathbf{R}^d$, we write simply $C^m, \mathcal{C}^s$.

Remark 2.1 (*see, for example, Lemma* 6 *in* [7]). Let $s > 0$. Then

(a) $H^s_\infty(Y) \subseteq \mathcal{C}^s(Y)$, if s is not an integer;

(b) $\mathcal{C}^{s+\varepsilon}(Y) \subseteq H^s_\infty(Y)$ for each $\varepsilon > 0$.

Let

$$B^s(Y) = \begin{cases} H^s_\infty(Y) & \text{if } s > 0 \text{ is not an integer,} \\ \mathcal{C}^s(Y) & \text{if } s > 0 \text{ is an integer,} \\ L_\infty(Y) & \text{if } s = 0, \end{cases}$$

and denote the corresponding norms by $|\cdot|_{B^s}$. If $Y=\mathbf{R}^d$, we write simply B^s.

It is shown (see Lemma 7 in [7]) that for $b\in B^{|s|}(Y)$, $s\in(-\infty,\infty)$, $p\in(1,\infty)$, there is a constant N so that

$$||b\mathbf{v}||_{s,p}\le N||b||_{B^{|s|}}|\mathbf{v}|_{s,p} \tag{2.1}$$

for all $\mathbf{v}\in\mathbb{H}^s_p$, where $b\mathbf{v}=(bv^1,\dots,bv^d)$.

Let $(\Omega,\mathcal{F},\mathbf{P})$ be a probability space with a filtration $\mathbb{F}$ of right continuous σ-algebras $(\mathcal{F}_t)_{t\ge0}$. All the σ-algebras are assumed to be $\mathbf{P}$-completed. Let $W(t)$ be an $\mathbb{F}$-adapted cylindrical Brownian motion in Y; i.e., we have a family of continuous martingales $W_t(v)$, $v\in Y$, with the quadratic variation

$$\langle W(v),W(v')\rangle_t=t\ v\cdot v'\qquad\forall\, v,\,v'\in Y.$$

Let $p\ge2$, $s\in(-\infty,\infty)$. Denote by $\mathcal{I}_{s,p}$ the set of all measurable $\mathbb{F}$-adapted $\mathbb{H}^s_p(Y)$-valued functions such that for every t,

$$\int_0^t||\mathbf{g}(r)||^p_{s,p}\,dr<\infty,\quad\mathbf{P}\text{ a.s.}$$

It is shown (see Theorem 2.1 in [7]) that for each $\mathbf{g}\in\mathcal{I}_{s,p}$ there is a unique $\mathbb{H}^s_p(Y)$-valued continuous martingale $\mathbf{M}(t)=\int_0^t\mathbf{g}(r)\cdot dW(r)$ such that for all $\boldsymbol{\phi}\in\mathbb{H}^{-s}_q$,

$$\left\langle\int_0^t\mathbf{g}(r)\cdot dW(r),\boldsymbol{\phi}\right\rangle_s=\int_0^t\langle\mathbf{g}(r),\boldsymbol{\phi}\rangle_{s,Y}\cdot dW(r)\quad\forall t>0,\mathbf{P}\text{ a.s.}$$

Moreover, for each $T>0$ there exists a constant C not depending on g so that for any stopping time $\tau\le T$,

$$\mathbf{E}\sup_{r\le\tau}|\mathbf{M}(r)|^p_{s,p}\le C\mathbf{E}\int_0^\tau||\mathbf{g}(r)||^p_{s,p}\,dr. \tag{2.2}$$

Consider the Stokes system (1.1) in vector form:

$$\begin{aligned}\partial_t\mathbf{u}(t,x)&=\partial_i(a^{ij}(t,x)\partial_j\mathbf{u})+\mathbf{D}(\mathbf{u},t,x)-\nabla p(t,x)\\&\qquad[\sigma^k(t,x)\partial_k\mathbf{u}(t,x)+\mathbf{Q}(\mathbf{u},t,x)-\nabla\tilde p(t,x)]\cdot\dot W,\\\mathbf{u}(0,x)&=\mathbf{u}_0(x),\qquad\operatorname{div}\mathbf{u}=0.\end{aligned} \tag{2.3}$$

Let $s\in(-\infty,\infty)$, $p\ge2$. For $\mathbf{v}\in\mathbb{H}^{s+1}_p$, let $\mathbf{Q}(\mathbf{v},t)=\mathbf{Q}(\mathbf{v},t,x)$ be a predictable $\mathbb{H}^s_p(Y)$-valued function and $\mathbf{D}(\mathbf{v},t)=\mathbf{D}(\mathbf{v},t,x)$ a predictable $\mathbb{H}^{s-1}_p$-valued function. Let $a=a(t)=(a^{ij}(t,x))_{1\le i,j\le d}$ be a symmetric $\mathbb{F}$-adapted matrix. Let $\sigma=\sigma(t)=(\sigma^k(t,x))_{1\le k\le d}$ be an $\mathbb{F}$-adapted vector function with Y-valued components σ^k, and let $\mathbf{u}_0=(u^l_0)_{1\le l\le d}$ be an $\mathcal{F}_0$-measurable $\mathbb{H}^{s+1-2/p}_p$-valued function so that $\mathbf{E}||\mathbf{u}_0||^p_{s+1-2/p,p}<\infty$, $\operatorname{div}\mathbf{u}_0=0$.

The following assumptions will be made:

A. For all $t\ge0$, $x,\lambda\in R^d$,

$$K|\lambda|^2\ge\left[a^{ij}(t,x)-\frac12\sigma^i(t,x)\cdot\sigma^j(t,x)\right]\lambda^i\lambda^j\ge\delta|\lambda|^2,$$

where K,δ are fixed strictly positive constants.

A1(s,p). For all $t,x,y,\mathbf{P}$ a.s.,

$$|a^{ij}(t,x)-a^{ij}(t,y)|+|\sigma^i(t,x)-\sigma^i(t,y)|_Y\le K|x-y|$$

and

$$\begin{cases} |a^{ij}(t)|_{B^s}\le K & \text{if } s\ge 1,\\ |a(t,x)|\le K & \text{if } -1<s<1,\\ |a^{ij}(t)|_{B^{-s+\varepsilon}}\le K & \text{if } s\le -1, \end{cases}$$

where $\varepsilon\in(0,1)$.

For all i,t,x,

$$\begin{cases} ||\sigma^i(t)||_{B^s}\le K & \text{if } s\ge 1,\\ |\sigma^i(t,x)|_Y\le K & \text{if } s\in(-1,1),\\ ||\sigma^i(t)||_{B^{-s+\varepsilon}}\le K & \text{if } s\le -1, \end{cases}$$

where $\varepsilon\in(0,1)$.

A2(s,p). For $\mathbf{v}\in\mathbb{H}^{s+1}_p$, $\mathbf{Q}(\mathbf{v},t)=\mathbf{Q}(\mathbf{v},t,x)$ is a predictable $\mathbb{H}^s_p(Y)$-valued function and $\mathbf{D}(\mathbf{v},t)=\mathbf{D}(\mathbf{v},t,x)$ is a predictable $\mathbb{H}^{s-1}_p$-valued function, and $\mathbf{P}$ a.s. for each t

$$\int_0^t(|\mathbf{D}(\mathbf{0},r)|^p_{s-1,p}+||\mathbf{Q}(\mathbf{0},r)||^p_{s,p})\,dr<\infty\quad\forall t>0,\mathbf{P}\text{ a.s.},$$

where $\mathbf{0}=(0,\dots,0)$.

A3(s,p). For every $\varepsilon>0$, there exists a constant K_ε such that for any $\mathbf{u},\mathbf{v}\in\mathbb{H}^{s+1}_p$,

$$|\mathbf{D}(\mathbf{u},t,x)-\mathbf{D}(\mathbf{v},t,x)|_{s-1,p}+||\mathbf{Q}(\mathbf{u},t,x)-\mathbf{Q}(\mathbf{v},t,x)||_{s,p}$$

$$\le\varepsilon|\mathbf{u}-\mathbf{v}|_{s+1,p}+K_\varepsilon|\mathbf{u}-\mathbf{v}|_{s-1,p},\quad\mathbf{P}\text{ a.s.}$$

Given a stopping time τ, we consider a stochastic interval

$$[[0,\tau]]=\begin{cases}[0,\tau(\omega)] & \text{if } \tau(\omega)<\infty,\\ [0,\infty) & \text{otherwise.}\end{cases}$$

DEFINITION 2.2. *Given a stopping time τ, an $\mathbb{H}^s_p(\mathbf{R}^d)$-valued $\mathbb{F}$-adapted function $\mathbf{u}(t)$ on $[0,\infty)$ is called an $\mathbb{H}^s_p$-solution of* (2.3) *in $[[0,\tau]]$ if it is strongly continuous in t with probability* 1,

$$\mathbf{u}(t\wedge\tau)=\mathbf{u}(t),\quad\operatorname{div}\mathbf{u}(t)=0,\quad\int_0^{t\wedge\tau}|\mathbf{u}(r)|^p_{s+1,p}\,dr<\infty\quad\forall t>0,\mathbf{P}\text{ a.s.},\tag{2.4}$$

and there exist two gradient vector fields, an $\mathbb{F}$-adapted $\mathcal{G}(\mathbb{H}^{s-1}_p(\mathbf{R}^d))$-valued process $\mathbf{G}(t)$ and an $\mathbb{F}$-adapted $\mathcal{G}(\mathbb{H}^{s-1}_p(\mathbf{R}^d,Y))$-valued process $\tilde{\mathbf{G}}(t)$, such that

$$\mathbf{G}=1_{[[0,\tau]]}\mathbf{G},\tilde{\mathbf{G}}=1_{[[0,\tau]]}\tilde{\mathbf{G}},\qquad dtd\mathbf{P}\text{ a.e.},$$

$$\int_0^{t\wedge\tau}[|\mathbf{G}(r)|^p_{s-1,p}+||\tilde{\mathbf{G}}(r)||^p_{s-1,p}]\,dr<\infty\quad\forall t>0,\ \mathbf{P}\text{ a.s.},$$

and the equality

$$\mathbf{u}(t\wedge\tau)=\mathbf{u_0}+\int_0^{t\wedge\tau}[\partial_i(a^{ij}(r)\partial_j\mathbf{u})+\mathbf{D}(\mathbf{u},r)-\mathbf{G}(r)]\,dr$$

$$+\int_0^{t\wedge\tau}[\sigma^k(r)\partial_k\mathbf{u}\,(r)+\mathbf{Q}(\mathbf{u},r)-\tilde{\mathbf{G}}(r)]\cdot dW\,(r) \tag{2.5}$$

holds in $\mathbb{H}_p^{s-1}(\mathbf{R}^d)$ *for every* $t>0$, $\mathbf{P}$ *a.s.*

If $\tau=\infty$, *we simply say* $\mathbf{u}$ *is an* $\mathbb{H}_p^s$*-solution of* (2.3).

The main result of the paper is the following statement.

THEOREM 2.3. *Let* $s\in(-\infty,\infty)$, $p\geq 2$. *Assume* A, A1(s,p)–A3(s,p) *are satisfied and* $\mathbf{E}|\mathbf{u}_0|^p_{s+1-2/p,p}<\infty$. *Then for each stopping time* τ, *the Cauchy problem* (1.1) *has a unique* $\mathbb{H}_p^s$*-solution in* $[[0,\tau]]$. *Moreover, the gradient processes in* (2.5) *are uniquely determined, and for each* $T>0$ *there is a constant* C *such that for each stopping time* $\bar\tau\leq T\wedge\tau$

$$\mathbf{E}\left[\sup_{r\leq\bar\tau}|\mathbf{u}(r)|^p_{s,p}+\int_0^{\bar\tau}(|\partial^2\mathbf{u}(r)|^p_{s-1,p}+|\mathbf{G}(r)|^p_{s-1,p}+||\tilde{\mathbf{G}}(r)||^p_{s,p})\,dr\right]$$

$$\leq C\mathbf{E}\left[|\mathbf{u}_0|^p_{s+1-2/p,p}+\int_0^{\bar\tau}(|\mathbf{D}(\mathbf{0},r)|^p_{s-1,p}+|\mathbf{Q}(\mathbf{0},r)|^p_{s,p})\,dr\right].$$

3. Some properties of function spaces.

3.1. Pointwise multipliers in $\mathbb{H}_p^s$. We will need the following statement about Hilbert space valued multipliers in $\mathbb{H}_p^s$, proved in [7].

LEMMA 3.1 (see Lemma 7 in [7]). (a) *Let* $a\in B^{|s|}(Y)$, $s\in(-\infty,\infty)$, $p\in(1,\infty)$. *Then there is a constant* N *so that*

$$||a\mathbf{u}||_{s,p}\leq N||a||_{B^{|s|}}|\mathbf{u}|_{s,p}$$

for all $\mathbf{u}\in\mathbb{H}_p^s$, *where* $a\mathbf{u}=(au^1,\dots,au^d)$.

(b) *Assume,* $p\in(1,\infty)$, $\kappa>0$, *and*

$$a\in\begin{cases}B^s(Y) & \text{if } s\geq 0,\\ B^{|s|+\kappa}(Y) & \text{if } s<0.\end{cases}$$

Let $\bar a_s=|a|_{B^s}$ *if* $s\geq 0$, *and* $\bar a_s=|a|_{B^{|s|+\kappa}}$ *if* $s<0$.

Then for every s *there exist constants* $s_0<s$ *and* N *such that*

$$||a\mathbf{u}||_{s,p}\leq N(||a||_\infty|\mathbf{u}|_{s,p}+\bar a_s|\mathbf{u}|_{s_0,p})$$

for all $\mathbf{u}\in\mathbb{H}_p^s$.

3.2. Solenoidal and potential projections of vector fields. First of all we decompose square integrable vector fields $\mathbf{v}\in\mathbb{L}_2(Y)=\mathbb{L}_2(\mathbf{R}^d,Y)$ (Y is a separable Hilbert space). Let

$$\mathcal{S}(\mathbb{L}_2(Y))=\{\mathbf{g}\in\mathbb{L}_2(Y):\operatorname{div}\mathbf{g}=0\},$$

where $\operatorname{div} \mathbf{g} = \partial_l g^l$. (All the component functions g^l are Y-valued.) Obviously, $\mathcal{S}(\mathbb{L}_2(Y))$ is a Hilbert subspace of $\mathbb{L}_2(Y)$, and

$$\mathbb{L}_2(Y) = \mathcal{G}(\mathbb{L}_2(Y)) \oplus \mathcal{S}(\mathbb{L}_2(Y)), \tag{3.1}$$

where $\mathcal{G}(\mathbb{L}_2(Y))$ is the orthogonal complement of $\mathcal{S}(\mathbb{L}_2(Y))$. Vector fields from $\mathcal{S}(\mathbb{L}_2(Y))$ are usually referred to as solenoidal or divergence free.

We will use a Riesz transform for the definition of solenoidal and gradient projections of a vector field. We set for $f \in L_p(\mathbf{R}^d, Y), 1 \le p < \infty$,

$$R_j(f)(x) = \lim_{\varepsilon \to 0} c_* \int_{|y| \ge \varepsilon} \frac{y_j}{|y|^{d+1}} f(x-y)\, dy, \quad j = 1, \dots, d,$$

with $c_* = G(\frac{n+1}{2})/\pi^{(n+1)/2}$ (G is the Gamma function). R_j is called a Riesz transform. According to [6, Chapter III, formula (8), p. 58],

$$(R_j \hat{f})(x) = -i \frac{\xi_j}{|\xi|} . \hat{f}, \tag{3.2}$$

where

$$\hat{f}(\xi) = \mathcal{F}(f) = (2\pi)^{-d/2} \int e^{-i(\xi, x)} f(x)\, dx.$$

Given a function $f \in L_p(\mathbf{R}^d, Y)$, we define a vector Riesz transform $Rf = (R_1 f, \dots, R_d f)$.

The following identity (see [6, Chapter III, Proposition 3, p. 59]) holds for each $u \in C_0^\infty(\mathbf{R}^d)$:

$$\partial_{jl}^2 u(x) = -R_l R_j \Delta u(x). \tag{3.3}$$

(The identity follows easily if we take the Fourier transform of (3.3) and use (3.2).)

LEMMA 3.2. *Let $\mathcal{G}$ be a projection of $\mathbb{L}_2(Y)$ onto $\mathcal{G}(\mathbb{L}_2(Y))$, and $\mathcal{S}$ be a projection of $\mathbb{L}_2(Y)$ onto $\mathcal{S}(\mathbb{L}_2(Y))$. Then*

$$\mathcal{G}(\mathbf{v}) = -RR_j v^j, \qquad \mathcal{S}(\mathbf{v}) = \mathbf{v} - \mathcal{G}(\mathbf{v}), \quad \mathbf{v} \in \mathbb{L}_2(Y).$$

Proof. By the Calderon–Zygmund theorem (see [6, Chapter II, Theorem 5, p. 46]) the Riesz transform is a bounded linear operator on L_2. Obviously, for each $\mathbf{v} \in \mathbb{L}_2(Y)$,

$$\mathbf{v} = -RR_j v^j + (\mathbf{v} + RR_j v^j).$$

Let us assume that $\mathbf{v}, \mathbf{g}, \partial \mathbf{g} \in \mathbb{L}_2(Y)$, $\operatorname{div} \mathbf{g} = 0$. Then

$$\mathcal{F}(\operatorname{div}(\mathbf{v} + RR_j v^j)) = i\xi_k \mathcal{F}(v^k) - i\xi_k \frac{\xi_k}{|\xi|} \frac{\xi_j}{|\xi|} \mathcal{F}(v^j) = 0,$$

and (by Parseval's equality)

$$\begin{aligned} \int \mathcal{G}(\mathbf{v}) \cdot \mathbf{g}\, dx &= \int \mathcal{F}(\mathcal{G}(\mathbf{v})) \cdot \bar{\mathcal{F}}(\mathbf{g})\, d\xi \\ &= \int \left(\frac{\xi}{|\xi|} \frac{\xi_k}{|\xi|} \mathcal{F}(v^k), \bar{\mathcal{F}}(\mathbf{g}) \right) d\xi = 0. \end{aligned}$$

So, the statement follows. □

Remark 3.3. If $f \in C_0^\infty(\mathbf{R}^d)$, it is known (see, e.g., [8]) that the classical solution to

$$\Delta u(x) = f(x), \quad x \in \mathbf{R}^d, \tag{3.4}$$

is given by the formula

$$u(x) = \int \Gamma(x-y) f(y)\, dy, \tag{3.5}$$

where

$$\Gamma(x-y) = \begin{cases} |x-y|^{2-d}/d(2-d)\omega_d, & d > 2, \\ \frac{1}{2\pi} \ln|x-y|, & d = 2, \end{cases}$$

and ω_d is the volume of the unit ball in $\mathbf{R}^d$. If $\mathbf{f} \in \mathbb{C}_0^\infty(Y)$, it is rather straightforward to show that

$$\mathcal{G}(\mathbf{f}) = \nabla \int \Gamma_{x_i}(x-y) f^i(y)\, dy = -RR_j f^j. \tag{3.6}$$

The functions $\mathcal{G}(\mathbf{v})$ and $\mathcal{S}(\mathbf{v})$ are usually referred to as the potential and the solenoidal, respectively, projections, of the vector field $\mathbf{v}$.

COROLLARY 3.4. *For any* $\mathbf{v}, \mathbf{u} \in \mathbb{L}_2(Y)$,

$$\int \mathcal{G}(\mathbf{u}) \cdot \mathbf{v}\, dx = \int \mathbf{u} \cdot \mathcal{G}(\mathbf{v})\, dx. \tag{3.7}$$

Proof. Indeed, because of orthogonality, both integrals are equal to $\int \mathcal{G}(\mathbf{u}) \cdot \mathcal{G}(\mathbf{v})\, dx$. □

Remark 3.5. Let $p \in (1, \infty)$. Note that, by Calderón–Zygmund's inequality [6, Chapter II, Theorem 5, p. 46], the Riesz transform is bounded on $\mathbb{L}_p(Y)$. Therefore, the function $\mathcal{G}(\mathbf{f}) = \nabla \int \Gamma_{x_i}(x-y) f^i(y)\, dy = -RR_i f^i$ is defined for all $\mathbf{f} \in \mathbb{L}_p(Y)$, and there is a constant C such that

$$||\mathcal{G}(\mathbf{f})||_p \le C||\mathbf{f}||_p, \quad \mathbf{f} \in \mathbb{L}_p(Y). \tag{3.8}$$

LEMMA 3.6. *Let* $1 < p < \infty$. *Then for each* $\mathbf{v} \in \mathbb{C}_0^\infty(Y)$ *we have* $\mathcal{G}(\mathbf{v}), \mathcal{S}(\mathbf{v}) \in \cap_s \mathbb{H}_p^s(Y)$ *and*

$$\begin{aligned} (1-\Delta)^{s/2}\mathcal{G}(\mathbf{v}) &= \mathcal{G}((1-\Delta)^{s/2}\mathbf{v}), \\ (1-\Delta)^{s/2}\mathcal{S}(\mathbf{v}) &= \mathcal{S}((1-\Delta)^{s/2}\mathbf{v}). \end{aligned} \tag{3.9}$$

Moreover, there is a constant C *so that for all* $\mathbf{v} \in \mathbb{C}_0^\infty(Y)$

$$||\mathcal{G}(\mathbf{v})||_{s,p} \le C||\mathbf{v}||_{s,p}, ||\mathcal{S}(\mathbf{v})||_{s,p} \le C||\mathbf{v}||_{s,p}$$

for any $s \in (-\infty, \infty)$ *and* $\mathcal{G}, \mathcal{S}$ *can be extended by continuity to all* $\mathbb{H}_p^s(Y)$, $s \in (-\infty, \infty)$.

Also, for each $\mathbf{v} \in \mathbb{H}_p^s(Y)$,

$$\mathcal{G}(\mathbf{v}) = (1-\Delta)^{-s/2}\mathcal{G}((1-\Delta)^{s/2}\mathbf{v}).$$

Proof. For $\mathbf{v} \in \mathbb{C}_0^\infty(Y)$, we have

$$\mathcal{F}((1-\Delta)^{s/2}\mathcal{G}(\mathbf{v})) = (1+|\xi|^2)^{s/2}\frac{\xi}{|\xi|}\frac{\xi_k}{|\xi|}\mathcal{F}(v^k) \in \mathbb{L}_2(Y)$$

for each s, and $\mathcal{F}((1-\Delta)^{s/2}\mathcal{G}(\mathbf{v})) = \mathcal{F}(\mathcal{G}((1-\Delta)^{s/2}\mathbf{v}))$. Therefore, (3.9) holds. According to Remark 3.5 and (3.8),

$$||\mathcal{G}(\mathbf{v})||_{s,p} = ||\mathcal{G}((1-\Delta)^{s/2}\mathbf{v})||_p \le C||(1-\Delta)^{s/2}\mathbf{v}||_p = C||\mathbf{v}||_{s,p}.$$

Since $\mathcal{S}(\mathbf{v}) = \mathbf{v} - \mathcal{G}(\mathbf{v})$, we can immediately obtain the extensions to $\mathbb{H}_p^s(Y)$. ∎

The following statement is the direct consequence of Lemma 3.6.

LEMMA 3.7. *Suppose $p \in (1,\infty)$ and $s \in (-\infty,\infty)$. Then the space $\mathbb{H}_p^s(Y)$ can be decomposed into the direct sum*

$$\mathbb{H}_p^s(Y) = \mathcal{G}(\mathbb{H}_p^s(Y)) \oplus \mathcal{S}(\mathbb{H}_p^s(Y)).$$

Moreover, if $1/q + 1/p = 1$, $\mathbf{f} \in \mathcal{G}(\mathbb{H}_p^s(Y))$, $\mathbf{g} \in \mathcal{S}(\mathbb{H}_q^{-s}(Y))$, then

$$\langle \mathbf{f}, \mathbf{g}\rangle_{\mathbb{H}_p^s(Y),\mathbb{H}_q^{-s}(Y)} = 0. \tag{3.10}$$

Also,

$$\mathcal{S}(\mathbb{H}_p^s(Y)) = \{\mathbf{v} \in \mathbb{H}_p^s(Y) : \operatorname{div}\mathbf{v} = \mathbf{0}\}, \tag{3.11}$$

$$\mathcal{G}(\mathbb{H}_p^s(Y)) = \{\mathbf{v} \in \mathbb{H}_p^s(Y) : \langle \mathbf{v}, \mathbf{g}\rangle_{\mathbb{H}_p^s(Y),\mathbb{H}_q^{-s}(Y)} = 0 \quad \forall \mathbf{g} \in \mathcal{S}(\mathbb{H}_{\mathbf{q}}^{-\mathbf{s}}(\mathbf{Y}))\}. \tag{3.12}$$

Proof. Let $1/q + 1/p = 1$, $\tilde{\mathbf{f}} \in \mathbb{H}_p^s(Y)$, $\tilde{\mathbf{g}} \in \mathbb{H}_q^{-s}(Y)$ and $\mathbf{f} = \mathcal{G}(\tilde{\mathbf{f}})$, $\mathbf{g} = \mathcal{S}(\tilde{\mathbf{g}})$. By Lemma 3.6, there are some sequences $\mathbf{f}_n \in \mathbb{C}_0^\infty$ and $\mathbf{g}_n \in \mathbb{C}_0^\infty$ such that

$$|\mathbf{f}_n - \tilde{\mathbf{f}}|_{s,p} + |\mathbf{g}_n - \tilde{\mathbf{g}}|_{-s,q} \to 0.$$

Then

$$|\mathcal{G}(\mathbf{f}_n) - \mathcal{G}(\tilde{\mathbf{f}})|_{s,p} + |\mathcal{S}(\mathbf{g}_n) - \mathcal{S}(\tilde{\mathbf{g}})|_{-s,q} \to 0,$$

and, by Lemmas 3.6 and 3.2,

$$\begin{aligned}\langle \mathbf{f}, \mathbf{g}\rangle_{\mathbb{H}_p^s(Y),\mathbb{H}_q^{-s}(Y)} &= \int (1-\Delta)^{s/2}\mathcal{G}(\tilde{\mathbf{f}})(1-\Delta)^{-s/2}\mathcal{S}(\tilde{\mathbf{g}})\,dx \\ &= \lim_n \int (1-\Delta)^{s/2}\mathcal{G}(\mathbf{f}_n)(1-\Delta)^{-s/2}\mathcal{S}(\mathbf{g}_n)\,dx \\ &= \lim_n \int \mathcal{G}((1-\Delta)^{s/2}\mathbf{f}_n)\mathcal{S}((1-\Delta)^{-s/2}\mathbf{g}_n)\,dx = 0.\end{aligned}$$

So (3.10) holds.

If $\mathbf{f} \in \mathbb{H}_p^s(Y)$, we have, obviously, $\mathbf{f} = \mathcal{G}(\mathbf{f}) + [\mathbf{f} - \mathcal{G}(\mathbf{f})] = \mathcal{G}(\mathbf{f}) + \mathcal{S}(\mathbf{f})$. Now we prove that

$$\mathcal{G}(\mathbb{H}_p^s(Y)) \cap \mathcal{S}(\mathbb{H}_p^s(Y)) = \{\mathbf{0}\}.$$

Suppose $\mathbf{f} \in \mathcal{G}(\mathbb{H}^s_p(Y)) \cap \mathcal{S}(\mathbb{H}^s_p(Y))$. Then for each $\mathbf{v} \in \mathbb{C}^\infty_0(Y)$ we have by Lemma 3.6 and (3.10) that

$$\int (1-\Delta)^{s/2}\mathbf{f}\cdot(1-\Delta)^{-s/2}\mathcal{S}(\mathbf{v})\,dx = \int (1-\Delta)^{s/2}\mathbf{f}\cdot\mathcal{S}((1-\Delta)^{-s/2}\mathbf{v})\,dx$$

$$= \langle \mathbf{f}, \mathcal{S}(\mathbf{v})\rangle_{\mathbb{H}^s_p(Y),\mathbb{H}^{-s}_q(Y)} = 0.$$

Also,

$$\int (1-\Delta)^{s/2}\mathbf{f}\cdot(1-\Delta)^{-s/2}\mathcal{G}(\mathbf{v})\,dx = \int (1-\Delta)^{s/2}\mathbf{f}\cdot\mathcal{G}((1-\Delta)^{-s/2}\mathbf{v})\,dx$$

$$= \langle \mathbf{f}, \mathcal{G}(\mathbf{v})\rangle_{\mathbb{H}^s_p(Y),\mathbb{H}^{-s}_q(Y)} = 0.$$

Therefore, $\langle \mathbf{f}, \mathbf{v}\rangle_{\mathbb{H}^s_p(Y),\mathbb{H}^{-s}_q(Y)} = \langle \mathbf{f}, \mathcal{G}(\mathbf{v}) + \mathcal{S}(\mathbf{v})\rangle_{\mathbb{H}^s_p(Y),\mathbb{H}^{-s}_q(Y)} = 0$. Thus, $\mathbf{f} = \mathbf{0}$.

Now, we prove (3.11). Let $\mathbf{v} \in \mathbb{H}^s_p(Y)$, $\operatorname{div}\mathbf{v} = 0$. Let $\varphi \in C^\infty_0(\mathbf{R}^d)$ be a scalar nonnegative function so that $\int \varphi\,dx = 1$. For $\varepsilon > 0$, write $\varphi_\varepsilon(x) = \varepsilon^{-d}\varphi(x/\varepsilon)$. Set

$$\mathbf{v}_k(x) = (1-\Delta)^{-s/2}\int \varphi_{1/k}(x-y)(1-\Delta)^{s/2}\mathbf{v}(y)$$

$$= \int (1-\Delta)^{-s/2}\varphi_{1/k}(x-y)(1-\Delta)^{s/2}\mathbf{v}(y)\,dy$$

$$= \int (1-\Delta)^{-s/2}\varphi_{1/k}(y)(1-\Delta)^{s/2}\mathbf{v}(x-y)\,dy.$$

Obviously, $\mathbf{v}_k \in \mathbb{H}^{s+1}_p(Y)$, $\operatorname{div}\mathbf{v}_k = 0$, and $|\mathbf{v}_k - \mathbf{v}|_{n,p} \to 0$ as $k \to \infty$. By Corollary 3.4, $\mathcal{G}(\mathbf{v}_k) = \mathbf{0}$. Therefore, $\mathcal{G}(\mathbf{v}) = \mathbf{0}$ and $\mathbf{v} = \mathcal{S}(\mathbf{v})$.

Let $\mathbf{v} \in \mathbb{H}^s_p(Y)$ and $\langle \mathbf{v}, \mathbf{g}\rangle_{\mathbb{H}^s_p(Y),\mathbb{H}^{-s}_q(Y)} = 0$ for all $\mathbf{g} \in \mathcal{S}(\mathbb{H}^{-\mathbf{s}}_{\mathbf{q}}(\mathbf{Y}))$. Then for any $\mathbf{h} \in \mathbb{H}^{-\mathbf{s}}_{\mathbf{q}}(\mathbf{Y})$

$$0 = \langle \mathbf{v}, \mathcal{S}(\mathbf{h})\rangle_{\mathbb{H}^s_p(Y),\mathbb{H}^{-s}_q(Y)} = \langle \mathcal{S}(\mathbf{v}), \mathbf{h}\rangle_{\mathbb{H}^s_p(Y),\mathbb{H}^{-s}_q(Y)}.$$

Therefore, $\mathcal{S}(\mathbf{v}) = \mathbf{0}$, i.e., $\mathbf{v} = \mathcal{G}(\mathbf{v})$, and equality (3.12) follows. □

LEMMA 3.8. *Assume* $\mathbf{v} \in \mathbb{H}^{s+1}_p(Y)$, $p \in (1,\infty)$. *Then*

$$\mathcal{G}(\partial_l \mathbf{v}) = \partial_l \mathcal{G}(\mathbf{v}) = -(1-\Delta)^{-s/2}\mathbf{R}R_l((1-\Delta)^{s/2}\operatorname{div}\mathbf{v}). \tag{3.13}$$

There is a constant C *such that for all* $\mathbf{v} \in \mathbb{H}^{s+1}_p(Y)$

$$||\partial\mathcal{G}(\mathbf{v})||_{s,p} \le C||\operatorname{div}\mathbf{v}||_{s,p},$$

and for all $\mathbf{v} \in \mathbb{H}^s_p(Y)$

$$||\mathcal{G}(\mathbf{v})||_{s,p} \le C||\operatorname{div}\mathbf{v}||_{s-1,p} + ||\mathbf{v}||_{s-1,p}.$$

Proof. By Lemma 3.6 and Remark 3.5, we have for $\tilde{\mathbf{v}} = \partial_l \mathbf{v}$ that

$$\mathcal{G}(\tilde{\mathbf{v}}) = -(1-\Delta)^{-s/2}RR_k((1-\Delta)^{s/2}\tilde{v}^k)$$
$$= -(1-\Delta)^{-s/2}RR_k((1-\Delta)^{s/2}\partial_l v^k).$$

Notice that

$$\begin{aligned} &-(1-\Delta)^{-s/2}RR_k((1-\Delta)^{s/2}\partial_l v^k) \\ &= -(1-\Delta)^{-s/2}RR_l((1-\Delta)^{s/2}\operatorname{div}\mathbf{v}) \\ &= -\partial_l(1-\Delta)^{-s/2}RR_k((1-\Delta)^{s/2}v^k). \end{aligned} \tag{3.14}$$

Indeed, if $\mathbf{v}\in\mathbb{C}_0^\infty(Y)$, taking the Fourier transform of each term in (3.14), we have

$$\frac{\xi}{|\xi|}\frac{\xi_k}{|\xi|}i\xi_l\mathcal{F}(v^k)=\frac{\xi}{|\xi|}\frac{\xi_l}{|\xi|}i\xi_k\mathcal{F}(v^k)=i\xi_l\frac{\xi}{|\xi|}\frac{\xi k}{|\xi|}\mathcal{F}(v^k).$$

So, the first part of the statement follows, and we have, obviously, the first inequality. Since s is arbitrary, we have

$$||\mathcal{G}(\mathbf{v})||_{s,p}\le C\bigg(\sum_l||\partial_l\mathcal{G}(\mathbf{v})||_{s-1,p}+||\mathbf{v}||_{s-1,p}\bigg)\le C(||\operatorname{div}\mathbf{v}||_{s-1,p}+||\mathbf{v}||_{s-1,p})$$

by (3.13) and Remark 3.5. □

Later we will need L_p-estimates of the function $\mathcal{G}(\mathbf{h})$, where $\mathbf{h}=c^j\partial_j\mathbf{v}$.

LEMMA 3.9. *Let* $\mathbf{h}=c^j(x)\partial_j\mathbf{v}(x)$, *where* $c=(c^j)$ *is a measurable d-vector of Hilbert space* Y*-valued functions,* $\mathbf{v}\in\mathbb{H}_p^{s+1}$, $\operatorname{div}\mathbf{v}=0$, $\varepsilon\in(0,1)$. *Assume*

$$\begin{aligned} ||c||_{B^{|s|}}&<\infty \text{ if } s\ge 1,\\ ||c||_{B^1}&<\infty \text{ if } s\in(-1,1),\\ ||c||_{B^{-s+\varepsilon}}&<\infty \text{ if } s\le -1. \end{aligned}$$

Then

$$||\mathcal{G}(\mathbf{h})||_{s,p}\le\begin{cases} C(||\partial_l c^j\partial_j\mathbf{v}||_{s-1,p}+||c^j\partial_j\mathbf{v}||_{s-1,p}) & \text{if } s>0,\\ C(||\partial_l c^j v^l||_{s,p}+||\operatorname{div}\mathrm{c}\,\mathbf{v}||_{s,p}] & \text{if } s\le 0. \end{cases}$$

Proof. Let $s>0$. Then, by inequality (3.13) of Lemma 3.8,

$$||\mathcal{G}(\mathbf{h})||_{s,p}\le C(||\operatorname{div}\mathbf{h}||_{s-1,p}+||\mathbf{h}||_{s-1,p})$$

and $\operatorname{div}\mathbf{h}=\partial_l c^j\partial_j v^l$. Let $s\le 0$. Since

$$c^j\partial_j\mathbf{v}=\partial_j(c^j\mathbf{v})-\partial_j\,c^j\mathbf{v},$$

it follows by Lemma 3.8 and Remark 3.5 that

$$\begin{aligned} ||\mathcal{G}(\mathbf{h})||_{s,p}&\le||\partial_j\mathcal{G}(c^j\mathbf{v})||_{s,p}+||\mathcal{G}(\partial_j c^j\mathbf{v})||_{s,p}\\ &\le C(||\partial_l c^j v^l||_{s,p}+||\partial_j c^j\,\mathbf{v}||_{s,p}), \end{aligned}$$

and the second inequality follows. □

Also we will need L_p-estimates of the function $\mathcal{G}(\mathbf{h})$, where $\mathbf{h}=\partial_i(c^{ij}(x)\partial_j\mathbf{v})$.

COROLLARY 3.10. *Let* $\mathbf{h}=\partial_i(c^{ij}(x)\partial_j\mathbf{v})$, *where* $c=(c^{ij})$ *is a measurable function,* $\mathbf{v}\in\mathbb{H}_p^{s+1}$, $\operatorname{div}\mathbf{v}=0$, $\varepsilon\in(0,1)$. *Assume*

$$\begin{aligned} |c|_{B^{|s|}}&<\infty \text{ if } s\ge 1,\\ |c|_{B^1}&<\infty \text{ if } s\in(-1,1),\\ |c|_{B^{-s+\varepsilon}}&<\infty \text{ if } s\le -1. \end{aligned}$$

Then

$$|\mathcal{G}(\mathbf{h})|_{s-1,p} \le \begin{cases} C(|\partial_l c^{ij}\partial_j v^l|_{s-1,p} + |c^{ij}\partial_j v^l|_{s-1,p}) & \text{if } s > 0, \\ C(|\partial_l c^{ij} v^j|_{s,p} + |\partial_j c^{ij}\,\mathbf{v}|_{s,p}] & \text{if } s \le 0. \end{cases}$$

Proof. Indeed,

$$|\mathcal{G}(\mathbf{h})|_{s-1,p} \le C\sum_i |\mathcal{G}\left(c^{ij}(x)\partial_j \mathbf{v}\right)|_{s,p},$$

and the inequality follows by Lemma 3.9. □

4. Stochastic Stokes equation. We rewrite (2.3) in an equivalent form:

$$\begin{aligned} \partial_t \mathbf{u}(t,x) &= \mathcal{S}(\partial_i(a^{ij}(t,x)\partial_j \mathbf{u}) + \mathbf{D}(\mathbf{u},t,x)) \\ &\quad \mathcal{S}(\sigma^k(t,x)\partial_k \mathbf{u}(t,x) + \mathbf{Q}(\mathbf{u},t,x))\cdot \dot{W}, \\ \mathbf{u}(0,x) &= \mathbf{u}_0(x). \end{aligned} \tag{4.1}$$

We use the following equivalent definition of an $\mathbb{H}^s_p$-solution of (2.3) (or (4.1)).

DEFINITION 4.1. *Given a stopping time τ, an $\mathbb{H}^s_p(\mathbf{R}^d)$-valued $\mathbb{F}$-adapted function $\mathbf{u}(t)$ on $[0,\infty)$ is called an $\mathbb{H}^s_p$-solution of* (2.3) (*or* (4.1)) *in $[[0,\tau]]$ if it is strongly continuous in t with probability* 1,

$$\mathbf{u}(t\wedge\tau) = \mathbf{u}(t), \qquad \int_0^{t\wedge\tau} |\mathbf{u}(r)|^p_{s+1,p}\,dr < \infty \quad \forall t > 0, \mathbf{P}\ \textit{a.s.}, \tag{4.2}$$

and the equality

$$\begin{aligned} \mathbf{u}(t\wedge\tau) = \mathbf{u_0} &+ \textstyle\int_0^{t\wedge\tau} \mathcal{S}(\partial_i(a^{ij}(r)\partial_j \mathbf{u}) + \mathbf{D}(\mathbf{u},r))dr \\ &+ \textstyle\int_0^{t\wedge\tau} \mathcal{S}(\sigma^k(r)\partial_k \mathbf{u}\,(r) + \mathbf{Q}(\mathbf{u},r))\cdot dW\,(r) \end{aligned} \tag{4.3}$$

holds in $\mathbb{H}^{s-1}_p(\mathbf{R}^d)$ for every $t > 0$, $\mathbf{P}$ a.s.

If $\tau = \infty$, we simply say $\mathbf{u}$ is an $\mathbb{H}^s_p$-solution of (2.3).

It is readily checked that all the integrals in (4.3) are well defined. For example, let us consider the stochastic integral. By (4.2),

$$\int_0^{t\wedge\tau} |\mathbf{u}(r)|^p_{s+1,p}\,dr < \infty \quad \forall t > 0, \mathbf{P}\text{ a.s.} \tag{4.4}$$

Since ∂_i is a bounded operator from $\mathbb{H}^m_p$ into $\mathbb{H}^{m-1}_p$ (see [5]), by Lemma 5.2 in [2] and assumption A1(s,p), we have $||\mathcal{S}(\sigma^k(r)\partial_k \mathbf{u}(r))||_{s,p} \le C||\mathbf{u}(r)||_{s+1,p}$. By assumptions A2$(s,p)$ and A3(s,p),

$$\int_0^{t\wedge\tau} ||\mathcal{S}(\mathbf{Q}(\mathbf{u},r))||^p_{s,p}\,dr \le C\int_0^{t\wedge\tau} (||\mathbf{Q}(\mathbf{0},r)||^p_{s,p} + |\mathbf{u}\,(r)\,|^p_{s+1,p})dr.$$

Thus, the integral is defined according to (2.2).

Remark 4.2. It is not difficult to show that (4.3) can be replaced by the equality

$$\begin{aligned} &\left\langle u^l(t\wedge\tau), \phi^l\right\rangle_s = \left\langle u^l_0, \phi^l\right\rangle_s + \textstyle\int_0^{t\wedge\tau} -\left\langle \mathcal{S}(a^{ij}(r)\partial_i u^l), \partial_j \phi^l\right\rangle_s \\ &+ \langle \Lambda^{-1} D^l(\mathbf{u},r), \Lambda\phi^l\rangle_s dr + \textstyle\int_0^{t\wedge\tau} \langle \mathcal{S}(\sigma^k(r)\partial_k u^l + Q^l(\mathbf{u},r)), \phi^l\rangle_{s,Y}\cdot dW\,(r) \\ &\qquad \forall t > 0, \mathbf{P}\text{ a.s.}, \end{aligned} \tag{4.5}$$

which holds for all $\boldsymbol{\phi} = (\phi^l)_{1\leq l\leq d}$ such that $\phi^l \in C_0^\infty, l = 1, \dots, d$.

Indeed, owing to (2.5), we have

(4.6)
$$\left(u^l(t\wedge\tau),\phi^l\right)_{s-1} = \left(u_0^l,\phi^l\right)_{s-1} + \int_0^{t\wedge\tau}\left(\mathcal{S}(\partial_j(a^{ij}(r)\partial_i u^l) + D^l(\mathbf{u},r)),\phi^l\right)_{s-1} dr$$

$$+\int_0^{t\wedge\tau}\left(\mathcal{S}(\sigma^k(r)\partial_k u^l + Q^l(\mathbf{u},r)),\phi^l\right)_{s-1,Y}\cdot dW(r) \quad \forall t>0, \mathbf{P}\text{ a.s.}$$

On the other hand, since $\mathbf{u}\in\mathbb{H}_p^s$, $\mathbf{u}_0\in\mathbb{H}_p^{s+1-2/p}$, and for almost all r, $\sigma^k(r)\partial_k\mathbf{u}(r)+Q^l(\mathbf{u},r)\in\mathbb{H}_p^s$, $\mathbf{P}$ a.s., we have that

$$\left(u^l(t),\phi^l\right)_{s-1} = \left(u^l(t),\phi^l\right)_s, \left(u_0^l,\phi^l\right)_{s-1} = \left(u_0^l,\phi^l\right)_{s+1-2/p},$$

and for almost all s,

$$\left(\sigma^k(r)\partial_k u^l(r) + Q^l(\mathbf{u},r),\phi^l\right)_{s-1,Y} = \left(\sigma^k(r)\partial_k u^l(r) + Q^l(\mathbf{u},r),\phi^l\right)_{s,Y}$$

$\mathbf{P}$ a.s. It is readily checked that $dr\times d\mathbf{P}$ a.e.

$$\left(\partial_j(a^{ij}(r)\partial_i u^l),\phi^l\right)_{s-1} = \left(\partial_j(a^{ij}(r)\partial_i u^l),\phi^l\right)_{s-1}$$

$$= -\left(\Lambda^s(a^{ij}(r)\partial_i u^l),\Lambda^{-s}\partial_j\phi^l\right)_0 = -\left((a^{ij}(r)\partial_i u^l),\partial_j\phi^l\right)_s.$$

Note that to prove the first equality, one should first establish it for smooth functions and then prove it in the general case by approximations. Thus, (4.6) implies (4.5). Now by reversing the order of our arguments, one could easily show that (4.3) follows from (4.5).

The main existence theorem will be proved in several steps. We begin with a simple particular case.

THEOREM 4.3 (cf. Theorem 4.10 in [2]). *Assume* A, A1(s,p)–A3(s,p). *Suppose that* $\mathbf{D}$ *and* $\mathbf{Q}$ *are independent of* $\mathbf{u}$, a^{ij} *and* σ^k *are independent of* x, $\mathbf{u}_0 = \mathbf{0}$, *and* $\operatorname{div}\mathbf{D}(t) = \operatorname{div}\mathbf{Q}(t) = 0$.

Then for each stopping time τ *there is a unique* $\mathbb{H}_p^s$*-solution* $\mathbf{u}$ *of* (4.1) *in* $[[0,\tau]]$. *Moreover,*

(i) *for each stopping time* $\bar\tau\leq\tau$,

$$\mathbf{E}\int_0^{\bar\tau}|\partial^2\mathbf{u}(r)|_{s-1,p}^p\,dr \leq N\mathbf{E}\int_0^{\bar\tau}(|\mathbf{D}(r)|_{s-1,p}^p + ||\mathbf{Q}(r)||_{s,p}^p)\,dr, \tag{4.7}$$

where $N = N(d,p,\delta,K)$ *does not depend on* τ;

(ii) *for each finite* T *and each stopping time* $\bar\tau\leq T\wedge\tau$,

$$\mathbf{E}\sup_{r\leq\bar\tau}|\mathbf{u}(r)|_{s,p}^p \leq e^T C\mathbf{E}\int_0^{\bar\tau}(|\mathbf{D}(r)|_{s-1,p}^p + ||\mathbf{Q}(r)||_{s,p}^p)\,dr, \tag{4.8}$$

where $C = C(d,p,\delta,K)$ *does not depend on* T *and* $\bar\tau,\tau$.

Proof. Consider the system

$$\begin{aligned}\partial_t\mathbf{v}(t,x) &= \partial_i(a^{ij}(t)\partial_j\mathbf{v}) + \mathbf{D}(t,x)\\ &\quad + [\sigma^k(t)\partial_k\mathbf{v}(t,x) + \mathbf{Q}(t,x)]\cdot\dot W,\\ \mathbf{v}(0,x) &= \mathbf{0}.\end{aligned} \tag{4.9}$$

According to [7], there is a unique $\mathbb{H}^s_p$-valued continuous $\mathbb{F}$-adapted solution to (4.9) in $[[0,\tau]]$ such that the estimates (4.7) and (4.8) hold. Then $\mathbf{u}(t)=\mathcal{S}(\mathbf{v}(t))$ is $\mathbb{H}^s_p$-valued continuous $\mathbb{F}$-adapted and (4.7) holds. According to our assumptions, $\mathbf{u}(t)$ satisfies the same equation (4.9). Therefore, $\mathbf{u}(t)=\mathcal{S}(\mathbf{v}(t))=\mathbf{v}(t)$, and the statement follows. □

To prove the general Theorem 2.3 we will rely on the two fundamental techniques: partition of unity and the method of continuity. The same technique was used in [2] for scalar equations.

The next step is to derive a priori L_p-estimates for a solution of (4.1).

LEMMA 4.4. *Assume* A, A1(s,p)–A3(s,p). *Suppose that* $\mathbf{u}$ *is an* $\mathbb{H}^s_p$*-solution of* (2.3) *in* $[[0,\tau]]$ *with* $\mathbf{u}_0=\mathbf{0}$.

Then for each T *there is a constant* $C=C(d,p,\delta,K,T)$ *such that for each stopping time* $\bar\tau\le T\wedge\tau$,

$$\begin{aligned}&\mathbf{E}[\sup_{r\le\bar\tau}|\mathbf{u}(r)|^p_{s,p}+\textstyle\int_0^{\bar\tau}|\partial^2\mathbf{u}(r)|^p_{s-1,p}\,dr]\\&\le C\mathbf{E}\textstyle\int_0^{\bar\tau}(|\mathbf{D}(\mathbf{0},r)|^p_{s-1,p}+|\mathbf{Q}(\mathbf{0},r)|^p_{s,p})\,dr.\end{aligned}\tag{4.10}$$

Proof. In order to use Theorem 4.3 we start with a standard partition of unity. Let $\psi\in C_0^\infty(\mathbf{R})$ be $[0,1]$-valued and such that $\psi(s)=1$, if $|s|\le 5/8$, and $\psi(s)=0$, if $|s|>6/8$. For an arbitrary but fixed $\kappa>0$ there we choose m such that $\kappa<2^{-m}$. Consider a grid in $\mathbf{R}^d$ consisting of $x_k=k2^{-m}$, $k=(k_1,\dots,k_d)\in\mathbf{Z}^d$, where $\mathbf{Z}$ is the set of all integers. Given $k\in\mathbf{Z}^d$, we define a function on $\mathbf{R}^d$ as

$$\bar\eta_k(x)=\prod_{l=1}^d\psi((x^l-x^l_k)2^m).$$

Notice that $0\le\bar\eta_k\le 1,\bar\eta_k=1$ in the cube $v_k=\{x:|x^l-x^l_k|\le(5/8)2^{-m},l=1,\dots,d\}$, and $\bar\eta_k=0$ outside the cube $V_k=\{x:|x^l-x^l_k|\le(6/8)2^{-m},l=1,\dots,d\}$. Obviously,

1. $\cup_k v_k=\mathbf{R}^d$ and

$$1\le\sum_k 1_{V_k}\le 2^d;$$

2. for all multi-indices γ

$$|\partial^\gamma\bar\eta_k|\le N(d,|\gamma|)2^{m|\gamma|}<N(d)\kappa^{-|\gamma|}.$$

Denote

$$\eta_k(x)=\bar\eta_k(x)\Big(\sum_k\bar\eta_k(x)\Big)^{-1},\qquad k=1,\dots.$$

Obviously, $\sum_k\eta_k=1$ in $\mathbf{R}^d$, and for all k and multi-indices μ,

$$|\partial^\mu\eta_k|\le N(d,|\mu|)\kappa^{-|\mu|},$$

and for each $p\ge 1,\mu$,

$$\sum_k\eta_k(x)^p\le N(p,d),\qquad\sum_k|\partial^\mu\eta_k|^p\le N(p,d,|\mu|)\kappa^{-p|\mu|}.\tag{4.11}$$

So, by Lemma 6.7 in [2], for any n there exist constants $c = c(d,p,\kappa)$, $C = C(d,p,\kappa)$ such that for all $\mathbf{f} \in \mathbb{H}^n_p, \mathbf{g} \in \mathbb{H}^n_p(Y)$

$$c|\mathbf{f}|^p_{n,p} \le \sum_k |\eta_k \mathbf{f}|^p_{n,p} \le C|\mathbf{f}|^p_{n,p}, \tag{4.12}$$

$$c||\mathbf{g}||^p_{n,p} \le \sum_k ||\eta_k \mathbf{g}||^p_{n,p} \le C||\mathbf{g}||^p_{n,p}.$$

Multiplying (4.1) by η_k and taking a solenoidal projection, we have

$$\begin{aligned} \partial_t \mathcal{S}(\eta_k \mathbf{u}) = {} & \partial_i(a^{ij}(t,x_k)\partial_j \mathcal{S}(\eta_k \mathbf{u})) + \mathcal{S}(\mathbf{D}_k(\mathbf{u},t,x)) \\ & + [\sigma^i(t,x_k)\partial_i \mathcal{S}(\eta_k \mathbf{u}) + \mathcal{S}(\mathbf{Q}_k(\mathbf{u},t,x))] \cdot \dot{W}, \end{aligned} \tag{4.13}$$

where

$$\begin{aligned} \mathbf{D}_k(\mathbf{u},t,x) = {} & \eta_k[\mathcal{S}(\mathbf{D}(\mathbf{u},t)) + \mathcal{S}(\partial_i(a^{ij}(t) - a^{ij}(t,x_k))\partial_j \mathbf{u}(t))] \\ & - \partial_i(a^{ij}(t,x_k)\partial_j \eta_k \mathbf{u}) - a^{ij}(t,x_k)\partial_i \eta_k \partial_j \mathbf{u}, \\ \mathbf{Q}_k(\mathbf{u},t,x) = {} & \eta_k[\mathcal{S}(\mathbf{Q}(\mathbf{u},t)) + \mathcal{S}((\sigma^i(t) - \sigma^i(t,x_k))\partial_i \mathbf{u}(t))] \\ & - \sigma^i(t,x_k)\partial_i \eta_k \mathbf{u}. \end{aligned}$$

We have

$$\sum_k |\eta_k \mathcal{G}(\partial_i[(a^{ij}(t) - a^{ij}(t,x_k))\partial_j \mathbf{u}(t)])|^p_{s-1,p}$$

$$\le C|\mathcal{G}(\partial_i[(a^{ij}(t) - a^{ij}(t,x_k))\partial_j \mathbf{u}(t)])|^p_{s-1,p},$$

and

$$\sum_k |\eta_k \mathcal{G}((\sigma^i(t) - \sigma^i(t,x_k))\partial_i \mathbf{u}(t))|^p_{s,p}$$

$$\le C|\mathcal{G}((\sigma^i(t) - \sigma^i(t,x_k))\partial_i \mathbf{u}(t))|^p_{s,p}.$$

Also,

$$\begin{aligned} & \sum_k |\eta_k \partial_i(a^{ij}(t) - a^{ij}(t,x_k)\partial_j \mathbf{u}(t))|^p_{s-1,p} \\ & \le 2^{p-1} \sum_k |\partial_i \eta_k (a^{ij}(t) - a^{ij}(t,x_k))\partial_j \mathbf{u}(t)|^p_{s-1,p} \\ & + 2^{p-1} \sum_k |\partial_i[\eta_k(a^{ij}(t) - a^{ij}(t,x_k))\tilde{\eta}_k \partial_j \mathbf{u}(t)]|^p_{s-1,p}, \end{aligned}$$

where $\tilde{\eta}_k(x) = \bar{\eta}_k(5x/6)$. (Notice that $\tilde{\eta}_k(x) = 1$ in V_k and $\tilde{\eta}_k(x) = 0$ if there is l such that $|x^l - x^l_k| > 0.9 \cdot 2^{-m}$.) According to Lemma 3.1, there is a constant C and $s_0 < s$ such that

$$\begin{aligned} & \sum_k |\partial_i[\eta_k(a^{ij}(t) - a^{ij}(t,x_k))\tilde{\eta}_k \partial_j \mathbf{u}(t)]|^p_{s-1,p} \\ & \le \sum_k |\eta_k(a^{ij}(t) - a^{ij}(t,x_k))\tilde{\eta}_k \partial_j \mathbf{u}(t)|^p_{s,p} \\ & \le C \sum_k [\sup_{x,k} |\tilde{\eta}_k(a^{ij}(t) - a^{ij}(t,x_k))|^p |\partial \mathbf{u}(t)|^p_{s,p} + |\eta_k \partial_j \mathbf{u}(t)|^p_{s_0,p}]. \end{aligned}$$

Similarly, by Lemma 3.1 there is $s_0 < s$ so that

$$\sum_k ||\eta_k(\sigma^i(t) - \sigma^i(t,x_k))\partial_i \mathbf{u}(t)||^p_{s,p}$$
$$= \sum_k ||\tilde{\eta}_k(\sigma^i(t) - \sigma^i(t,x_k))\eta_k \partial_i \mathbf{u}(t)||^p_{s,p}$$
$$\le C \sum_k [\sup_x |\tilde{\eta}_k(\sigma^i(t) - \sigma^i(t,x_k))|^p_Y |\eta_k \partial_i \mathbf{u}(t)|^p_{s,p} + |\eta_k \partial_i \mathbf{u}(t)|^p_{s_0,p}].$$

It follows by the assumptions, equation (4.12), Lemma 3.9, Corollary 3.10, and the interpolation theorem (see Lemma 6.7 in [2]) that for each ε there is $\kappa > 0$ and a constant $C = C(\varepsilon, \kappa, d, p, \delta, K)$ such that

$$\sum_k |\mathcal{S}(\mathbf{D}_k(\mathbf{u},t))|^p_{s-1,p} \le \varepsilon |\partial^2 \mathbf{u}(t)|^p_{s-1,p} + C(|\mathbf{u}(t,\cdot)|^p_{s-1,p} + |\mathbf{D}(\mathbf{0},t)|^p_{s-1,p}),$$

$$\sum_k ||\mathcal{S}(\mathbf{Q}_k(\mathbf{u},t,\cdot))||^p_{s,p} \le \varepsilon |\partial^2 \mathbf{u}(t)|^p_{s-1,p} + C(|\mathbf{u}(t)|^p_{s-1,p} + ||\mathbf{Q}(\mathbf{0},t)||^p_{s,p}).$$

Choosing ε sufficiently small and applying (4.12) and Theorem 4.3 to $\eta_k \mathbf{u}$ (it is a solution to (4.13)), we obtain that

(i) for each stopping time τ

$$\mathbf{E} \int_0^\tau |\partial^2 \mathbf{u}(t)|^p_{s-1,p}\, dt \le N \mathbf{E} \int_0^\tau (|\mathbf{u}(t)|^p_{s-1,p} + |\mathbf{D}(\mathbf{0},t)|^p_{s-1,p} + ||\mathbf{Q}(\mathbf{0},t)||^p_{s,p})\, dt,$$

where $N = N(p,d,\delta,K)$ does not depend on τ;

(ii) for each $T > 0$ and each stopping time $\tau \le T$

$$\mathbf{E} \sup_{t \le \tau} |\mathbf{u}(t)|^p_{s,p} \le N e^T \mathbf{E} \int_0^\tau (|\mathbf{u}(t)|^p_{s-1,p} + |\mathbf{D}(\mathbf{0},t)|^p_{s-1,p} + ||\mathbf{Q}(\mathbf{0},t)||^p_{s,p})\, dt. \tag{4.14}$$

Fix an arbitrary $\tau \le T$ such that

$$\mathbf{E}\left[\sup_{t \le \tau} |\mathbf{u}(t)|^p_{s,p} + \int_0^\tau (|\mathbf{u}(t)|^p_{s-1,p} + |\mathbf{D}(\mathbf{0},t)|^p_{s-1,p} + ||\mathbf{Q}(\mathbf{0},t)||^p_{s,p})\, dt\right] < \infty.$$

Then for each $t \le T$

$$\mathbf{E} \sup_{r \le t \wedge \tau} |\mathbf{u}(r)|^p_{s,p} \le N e^T \mathbf{E} \int_0^t \sup_{\bar{r} \le r \wedge \tau} |\mathbf{u}(\bar{r})|^p_{s,p}\, dr$$
$$+ \mathbf{E} \int_0^\tau |\mathbf{D}(\mathbf{0},t)|^p_{s-1,p} + ||\mathbf{Q}(\mathbf{0},t)||^p_{s,p}\, dt,$$

and the statement follows by Gronwall's inequality. □

Now we can prove the uniqueness of solutions of (4.1).

COROLLARY 4.5. *Let* A, A1(s,p)–A3(s,p) *hold,* $p \ge 2$. *Then there is at most one* $\mathbb{H}^s_p(\mathbf{R}^d)$*-solution to* (4.1) *in* $[[0,\tau]]$.

Proof. Assume that $\mathbf{u}_1, \mathbf{u}_2$ are $\mathbb{H}^s_p(\mathbf{R}^d)$-valued continuous solutions to (2.3) such that $\mathbf{P}$ a.s. for all t,

$$\int_0^{t \wedge \tau} |\partial^2 \mathbf{u}_l(r)|^p_{s-1,p}\, dr < \infty, \quad l = 1,2.$$

Then $\mathbf{v} = \mathbf{u}_2 - \mathbf{u}_1$ satisfies the equation

$$\begin{aligned}\partial_t \mathbf{v}(t,x) &= \partial_i(a^{ij}(t,x)\partial_j \mathbf{v}) + \mathbf{D}(\mathbf{v}+\mathbf{u}_1,t,x) - \mathbf{D}(\mathbf{u}_1,t,x)\\ &\quad + [\sigma^k(t,x)\partial_k \mathbf{v}(t,x) + \mathbf{Q}(\mathbf{v}+\mathbf{u}_1,t,x) - \mathbf{Q}(\mathbf{u}_1,t,x)]\cdot \dot{W},\\ \mathbf{v}(0,x) &= \mathbf{0}.\end{aligned}$$

Applying Lemma 4.4 to this equation and $\mathbf{v}$, we have $\mathbf{v} = \mathbf{0}$ by (4.10). □

To complete the proof of Theorem 2.3 we apply the standard method of continuity (see Theorem 5.1 in [2], Theorem 2 in [7]).

Proof of Theorem 2.3. The uniqueness follows by Corollary 4.5. So, we prove the existence of a solution to (4.1). Without any loss of generality we can assume $\mathbf{u}_0 = \mathbf{0}$ (see the proof of Theorem 5.1 in [2]), $\tau = \infty$. Then we introduce a parameter $\lambda \in [0,1]$ and consider the equation

$$\begin{aligned}\partial_t \mathbf{u}(t,x) &= \mathcal{S}\{\partial_i[\lambda\delta_{ij} + (1-\lambda)a^{ij}\partial_j \mathbf{u}] + \mathbf{D}(\mathbf{u},t,x)\}\\ &\quad + \mathcal{S}[(1-\lambda)\sigma^k \partial_k \mathbf{u} + \mathbf{Q}(\mathbf{u},t,x)]\cdot \dot{W},\\ \operatorname{div}\mathbf{u} &= 0,\end{aligned} \tag{4.15}$$

with zero initial condition. By Lemma 4.4 the a priori estimate (4.10) holds with the same constant C. Assume that for $\lambda = \lambda_0$ equation (4.15) for any $\mathbf{D}, \mathbf{Q}$ satisfying A3(s,p) has a unique continuous in t $\mathbb{H}^s_p$-valued solution such that $\mathbf{P}$ a.s. for all t,

$$\int_0^t |\partial^2 \mathbf{u}(r)|^p_{s-1,p}\, dr < \infty.$$

For other $\lambda \in [0,1]$ we rewrite (4.15) as

$$\begin{aligned}\partial_t \mathbf{u}(t,x) &= \mathcal{S}\{\partial_i[(\lambda_0\delta_{ij} + (1-\lambda_0)a^{ij})\partial_j \mathbf{u}] + \mathbf{D}(\mathbf{u},t,x)\\ &\quad + (\lambda-\lambda_0)\partial_i[(\delta_{ij}+a^{ij})\partial_j \mathbf{u}]\}\\ &\quad + \mathcal{S}[(1-\lambda_0)\sigma^i\partial_i \mathbf{u} + (\lambda-\lambda_0)\sigma^i\partial_i \mathbf{u} + \mathbf{Q}(\mathbf{u},t,x)]\cdot \dot{W},\\ \operatorname{div}\mathbf{u} &= 0\end{aligned}$$

and solve it by iterations. Define $\mathbf{u}_0 = \mathbf{0}$ and

$$\begin{aligned}\partial_t \mathbf{u}_{k+1}(t,x) &= \mathcal{S}\{\partial_i[(\lambda_0\delta_{ij} + (1-\lambda_0)a^{ij})\partial_j \mathbf{u}_{k+1}] + \mathbf{D}(\mathbf{u}_{k+1},t,x)\\ &\quad + (\lambda-\lambda_0)\partial_i[(\delta_{ij}+a^{ij})\partial_j \mathbf{u}_k]\}\\ &\quad + \mathcal{S}[(1-\lambda_0)\sigma^k\partial_k \mathbf{u}_{k+1} + (\lambda-\lambda_0)\sigma^i\partial_i \mathbf{u}_k + \mathbf{Q}(\mathbf{u}_{k+1},t,x)]\cdot \dot{W},\\ \operatorname{div}\mathbf{u} &= 0.\end{aligned} \tag{4.16}$$

So $\bar{\mathbf{u}}_{k+1} = \mathbf{u}_{k+1} - \mathbf{u}_k$ is a solution of the equation

$$\begin{aligned}\partial_t \bar{\mathbf{u}}_{k+1}(t,x) &= \mathcal{S}\{\partial_i[\lambda_0\delta_{ij} + (1-\lambda_0)a^{ij}\partial_j \bar{\mathbf{u}}_{k+1}] + \mathbf{D}(\mathbf{u}_k+\bar{\mathbf{u}}_{k+1},t,x) - \mathbf{D}(\mathbf{u}_k,t,x)\}\\ &\quad + \mathcal{S}\{(\lambda-\lambda_0)\partial_i[(\delta_{ij}+a^{ij})\partial_j \bar{\mathbf{u}}_k]\} + \mathcal{S}\{(\lambda-\lambda_0)\sigma^i\partial_i \bar{\mathbf{u}}_k\}\cdot \dot{W}\\ &\quad + \mathcal{S}[(1-\lambda_0)\sigma^k\partial_k \bar{\mathbf{u}}_{k+1} + \mathbf{Q}(\mathbf{u}_k+\bar{\mathbf{u}}_{k+1},t,x) - \mathbf{Q}(\mathbf{u}_k,t,x)]\cdot \dot{W},\end{aligned}$$

$\operatorname{div}\mathbf{u} = 0$. By our assumptions for each $T > 0$, there is a constant $C = C(d,p,\delta,K,T)$

such that for all stopping times $\tau \le T$

$$\begin{aligned}
&\mathbf{E}\left[\sup_{r\le\tau}|\bar{\mathbf{u}}_{k+1}(r)|^p_{s,p}+\int_0^\tau|\partial^2\bar{\mathbf{u}}_{k+1}(r)|^p_{s-1,p}\,dr\right]\\
&\le C'|\lambda-\lambda_0|^p\mathbf{E}\int_0^\tau(|\partial\bar{\mathbf{u}}_k(r)|_{s,p}+|\partial^2\bar{\mathbf{u}}_k(r)|^p_{s-1,p})\,dr\\
&\le C|\lambda-\lambda_0|^p\mathbf{E}\left[\sup_{r\le\tau}|\bar{\mathbf{u}}_k(r)|^p_{s,p}+\int_0^\tau|\partial^2\bar{\mathbf{u}}_k(r)|^p_{s-1,p}\,dr\right].
\end{aligned}$$

Fix an arbitrary stopping time $\tau \le T$ such that

$$I(\tau)=\mathbf{E}\left[\sup_{r\le\tau}|\mathbf{u}_1(r)|^p_{s,p}+\int_0^\tau|\partial^2\mathbf{u}_1(r)|^p_{s-1,p}\,dr\right]<\infty.$$

Notice that $\mathbf{u}_1$ and τ do not depend on λ (only on λ_0). Let $|\lambda-\lambda_0|<C^{-1/p}/2$. Then

$$\mathbf{E}\left[\sup_{r\le\tau}|\bar{\mathbf{u}}_{k+1}(r)|^p_{s,p}+\int_0^\tau|\partial^2\bar{\mathbf{u}}_{k+1}(r)|^p_{s-1,p}\,dr\right]^{1/p}\le(1/2)^kI(\tau)^{1/p},$$

and $(\mathbf{u}_k)$ is a Cauchy sequence on $[0,\tau]$. Therefore, there is a continuous in t $\mathbb{H}^s_p$-valued process $\mathbf{u}$ such that

$$\mathbf{E}\left[\sup_{r\le\tau}|\mathbf{u}_k(r)-\mathbf{u}(r)|^p_{s,p}+\int_0^\tau|\partial^2(\mathbf{u}_k(r)-\mathbf{u}(r))|^p_{s-1,p}\,dr\right]\to0$$

as $k\to\infty$. Obviously $\mathbf{u}$ is a solution to (4.15) on $[0,\tau]$. Since τ is any stopping time such that $I(\tau)$ is finite, it follows that we have a solution for any $|\lambda-\lambda_0|<C^{-1/p}/2$ (assuming we have one for λ_0). For $\lambda=1$ it exists by Theorem 4.3. So, in a finite number of steps starting with $\lambda=1$, we get to $\lambda=0$. This proves Theorem 2.3.

COROLLARY 4.6 (cf. Corollary 5.11 in [2]). *Let* A, A1(s,p)–A3(s,p), A1(s,q)–A3(s,q) *hold,* $p,q\ge2$, *and let* $|\mathbf{u}_0|_{s+1-2/p,p}+|\mathbf{u}_0|_{s+1-2/q,q}<\infty$ $\mathbf{P}$ *a.s. Then the* $\mathbb{H}^s_p$*-solution* $\mathbf{u}$ *from Theorem* 2.3 *is also an* $\mathbb{H}^s_q$*-solution, i.e., for each* $T>0$, *there is a constant* C *such that for each stopping time* $\tau\le T, A\in\mathcal{F}_0$,

$$\begin{aligned}
&\mathbf{E}1_A\left[\sup_{r\le\tau}|\mathbf{u}(r)|^l_{r,l}+\int_0^\tau|\partial^2\mathbf{u}(r)|^l_{s-1,l}\,dr\right]\\
&\quad\le C\mathbf{E}1_A\left[|\mathbf{u}_0|^l_{s+1,l}+\int_0^\tau(|\mathbf{D}(\mathbf{0},r)|^l_{s-1,l}+||\mathbf{Q}(\mathbf{0},r)||^l_{s,l})\,dr\right],
\end{aligned}$$

$l=p,q$.

Proof. We follow the lines of the proof of Theorem 2.3 by introducing the parameter $\lambda\in[0,1]$ and by considering (4.15). We can assume that $\mathbf{u}_0=\mathbf{0}$. The statement holds for $\lambda=1$ by Lemma 5.11 in [2] applied to each component of $\mathbf{u}$. If it is true for λ_0, then (4.16) defines a sequence $\mathbf{u}_k$ of $\mathbb{H}^s_p$-valued continuous processes that are $\mathbb{H}^s_q$-valued and continuous as well, and $\mathbf{P}$ a.s. for all t,

$$\int_0^t|\partial^2\mathbf{u}(r)|^l_{s-1,l}\,dr<\infty,\quad l=p,q.$$

For each $T>0$ there are constants $C_l=C(d,l,\delta,K,T)$, $l=p,q$, such that for all stopping times $\tau\le T$

$$\begin{aligned}&\mathbf{E}\left[\sup_{r\le\tau}|\bar{\mathbf{u}}_{k+1}(r)|_{s,l}^l+\int_0^\tau|\partial^2\bar{\mathbf{u}}_{k+1}(r)|_{s-1,l}^l\,dr\right]\\&\le C'|\lambda-\lambda_0|^p\mathbf{E}\int_0^\tau(|\partial\bar{\mathbf{u}}_k(r)|_{s,p}+|\partial^2\bar{\mathbf{u}}_k(r)|_{s-1,p}^p)\,dr\\&\le C_l|\lambda-\lambda_0|^p\mathbf{E}\left[\sup_{r\le\tau}|\bar{\mathbf{u}}_k(r)|_{s,l}^l+\int_0^\tau|\partial^2\bar{\mathbf{u}}_k(r)|_{s-1,l}^l\,dr\right],\end{aligned}$$

$l=p,q$. Fix an arbitrary stopping time $\tau\le T$ such that

$$I(\tau)=\mathbf{E}\left[\sup_{r\le\tau}(|\mathbf{u}_1(r)|_{s,p}^p+|\mathbf{u}_1(r)|_{s,q}^q)+\int_0^\tau(|\partial^2\mathbf{u}_1(r)|_{s-1,p}^p+|\partial^2\mathbf{u}_1(r)|_{s-1,q}^q)\,dr\right]<\infty.$$

Let $C=\max\{C_p,C_q\}$, $|\lambda-\lambda_0|<C^{-1/p}/2$. Then

$$\mathbf{E}\left[\sup_{r\le\tau}|\bar{\mathbf{u}}_{k+1}(r)|_{s,l}^l+\int_0^\tau|\partial^2\bar{\mathbf{u}}_{k+1}(r)|_{n-1,l}^l\,dr\right]^{1/p}\le(1/2)^kI(\tau)^{1/p},$$

$l=p,q$. Therefore, there is a continuous in t $\mathbb{H}_p^s\cap\mathbb{H}_q^s$-valued process $\mathbf{u}$ such that

$$\mathbf{E}\left[\sup_{r\le\tau}|\mathbf{u}_k(r)-\mathbf{u}(r)|_{s,l}^l+\int_0^\tau|\partial^2(\mathbf{u}_k(r)-\mathbf{u}(r))|_{s-1,l}^l\,dr\right]\to0,$$

$l=p,q$, and the statement follows. □

If s is large positive, assumption A3(s,p) is rarely satisfied even in the scalar case (see the example below). The following proposition helps to circumvent this problem in many important cases.

PROPOSITION 4.7. *Assume that for each* $\mathbf{v}\in\mathbb{H}_p^{s+1}$, $\mathbf{Q}(\mathbf{v},t)$ *is a predictable* $\mathbb{H}_p^{s+1}$*-valued process and* $\mathbf{D}(\mathbf{v},t)$ *is a predictable* $\mathbb{H}_p^s$*-valued process. Let* A, A1(s,p)–A3(s,p), A1$(s+1,p)$, A2$(s+1,p)$ *be satisfied,* $\mathbf{E}(|\mathbf{u}_0|_{s+2-2/p,p}^p)<\infty$, *and for all* $t>0,\mathbf{v}\in\mathbb{H}_p^{s+1}$,

$$\begin{aligned}||\mathbf{Q}(\mathbf{v},t)||_{s+1,p}&\le||\mathbf{Q}(\mathbf{0},t)||_{s+1,p}+C|\mathbf{v}|_{s+1,p},\\|\mathbf{D}(\mathbf{v},t)|_{s,p}&\le|\mathbf{D}(\mathbf{0},t)|_{s,p}+C|\mathbf{v}|_{s+1,p}.\end{aligned}$$

Suppose also that

$$\int_0^t(||\mathbf{Q}(\mathbf{0},r)||_{s+1,p}^p+|\mathbf{D}(\mathbf{0},r)|_{s,p}^p)\,dr<\infty$$

$\mathbf{P}$ *a.s. for all* t. *Then* (2.3) *has a unique continuous* $\mathbb{H}_p^{s+1}$*-solution.*

Moreover, for each $T>0$ *there is a constant* C *such that for each stopping time* $\tau\le T$,

$$\begin{aligned}&\mathbf{E}\left[\sup_{r\le\tau}|\mathbf{u}(r)|_{s+1,p}^p+\int_0^\tau|\partial^2\mathbf{u}(r)|_{s,p}^p\,dr\right]\\&\le C\mathbf{E}\left[|\mathbf{u}_0|_{s+2,p}^p+\int_0^\tau(|\mathbf{D}(\mathbf{0},r)|_{s,p}^p+||\mathbf{Q}(\mathbf{0},r)||_{s+1,p}^p)\,dr\right].\end{aligned}$$

Proof. Since the assumptions A, A1(s,p)–A3(s,p) are satisfied, the existence and uniqueness of $\mathbb{H}^s_p$-solution $\mathbf{u}$ is guaranteed by Theorem 2.3. By the same theorem, the linear equation

$$\begin{aligned}\partial_t \xi(t,x) &= \partial_i(a^{ij}(t,x)\partial_j\xi(t,x)) + \mathbf{D}(\mathbf{u},t,x)\\ &\quad + [\sigma^k(t,x)\partial_k\xi(t,x) + \mathbf{Q}(\mathbf{u},t,x)]\cdot \dot{W},\\ \xi(0,x) &= \mathbf{u}_0(x),\end{aligned}$$

has a unique $\mathbb{H}^{s+1}_p$-solution. Thus, $\xi = \mathbf{u}$ $\mathbf{P}$ a.s. Moreover, for each T there is a constant C such that for all stopping times $\tau \le T$,

$$\begin{aligned}&\mathbf{E}\left[\sup_{r\le t\wedge\tau}|\mathbf{u}(r)|^p_{s+1,p} + \int_0^{t\wedge\tau}|\partial^2\mathbf{u}(r)|^p_{s,p}\,dr\right]\\ &\le C\mathbf{E}\left[|\mathbf{u}_0|^p_{s+2,p} + \int_0^{t\wedge\tau}(|\mathbf{u}(r)|^p_{s+1,p} + |\mathbf{D}(\mathbf{0},r)|^p_{s,p} + ||\mathbf{Q}(\mathbf{0},r)||^p_{s+1,p})\,dr\right].\end{aligned}$$

Now the estimate of the statement follows by Gronwall's inequality. □

Example. Let us consider the following scalar equation:

$$\begin{aligned}\partial_t u &= \mathcal{S}[\Delta u + D(u)] + \mathcal{S}(u)\cdot\dot{W},\\ u(0,x) &= 0,\end{aligned}$$

where $W(t)$ is a one-dimensional Wiener process, $D(u) = \partial[f(u(x))] = \partial f(u(x))\partial u(x)$, and f is a scalar Lipschitz function on R^1. Then A3(1,p) would require the following estimate:

$$\begin{aligned}|D(u) - D(v)|_p &= |\nabla f(u(x))\partial u(x) - \nabla f(v(x))\partial v(x)|_p\\ &\le \varepsilon|u-v|_{2,p} + K_\varepsilon|u-v|_p,\end{aligned}$$

which is false in general even if ∇f is Lipschitz.

On the other hand, the assumptions of the proposition are satisfied for $s = 0$. Indeed,

$$|D(u)|_p = |\nabla f(u)\partial u|_p \le C|\partial u|_p,$$

where C is the Lipschitz constant of f.

Now, since ∂ is a bounded operator from $\mathbb{H}^s_p$ into $\mathbb{H}^{s+1}_p$, we have

$$\begin{aligned}&|D(u) - D(v)|_{-1,p} = |\partial[f(u)] - \partial[f(v)]|_{-1,p}\\ &\le C|f(u) - f(v)|_p \le C'|u-v|_p\\ &\qquad \le \varepsilon|u-v|_{1,p} + K_\varepsilon|u-v|_{-1,p}.\end{aligned}$$

(The latter inequality follows from Remark 5.5 in [2].) Thus assumption A3(0,p) is verified.

WEAK STABILITY OF NONUNIFORMLY STABLE MULTIDIMENSIONAL SHOCKS*

JEAN-FRANÇOIS COULOMBEL†

Abstract. The aim of this paper is to investigate the linear stability of multidimensional shock waves that violate the uniform stability condition derived by Majda [*Mem. Amer. Math. Soc.*, 41 (1983)]. Two examples of such shock waves are studied: (1) planar Lax shocks in isentropic gas dynamics and (2) phase transitions in an isothermal van der Waals fluid. In both cases we prove an energy estimate on the resulting linearized system. Special attention is paid to the losses of derivatives arising from the failure of the uniform stability condition.

Key words. conservation laws, multidimensional shocks, phase transitions, stability of shock waves

1. Introduction.

The stability of multidimensional shock waves in gas dynamics has been an active field of mathematical research since the late 1940's; see, e.g., [10, 12, 13, 19, 33]. The first results proved on this subject were giving some necessary conditions of stability by means of a normal modes analysis. In [21] (see also the review [22]), Lax formulated the definition of a shock wave for an arbitrary system of conservation laws in space dimension one: the definition was also dictated by some kind of "stability" argument. More precisely, the number of characteristics impinging on the shock front curve is imposed by the size of the system in order to avoid under- (or over-) determinacy of the resulting free boundary problem. Regarding ideal gas dynamics, this definition is known to be equivalent to the requirement that the physical entropy increases upon crossing the shock front curve; see [10].

Using the extensive study of initial boundary value problems for linear hyperbolic systems (see, e.g., [16, 17, 20]), Majda succeeded in the early 1980's in deriving a necessary and sufficient strong stability condition for multidimensional shock waves [25]. The resulting estimates on the linearized problem enabled him to prove a nonlinear existence theorem [24]. We also refer to [26, 37] for a general overview of the method and its application to isentropic gas dynamics. It is worth noting that a different approach developed at the same time by Blokhin [6, 7] gave rise to similar results. However, Majda's approach, which has been slightly improved in [27, 30] by using the new ideas of paradifferential calculus introduced by Bony and Meyer, seems appropriate to our purpose, and we shall adopt it for our analysis.

In the study of initial boundary value problems for linear hyperbolic systems, many physically relevant boundary data are found to violate the uniform stability condition, namely the so-called Kreiss–Lopatinskii condition. A list of such boundary conditions for physical systems can be found in [11]. Nevertheless, many authors have overcome this difficulty in various cases by using particular properties of the involved (linear or nonlinear) system; see, e.g., [3, 15, 35] for results on fluid dynamics and [29, 34] for results on elastodynamics. In a more general setting, Ohkubo and

Shirota derived in [31] a sufficient condition for linear initial boundary value problems to ensure L^2 well-posedness with respect to the "interior source term." (Initial and boundary data are homogeneous.)

Although Majda's result has the great advantage of dealing with any system of conservation laws, examples of multidimensional shocks are not that numerous, and the verification of the uniform stability condition often gives rise to very tedious computations. However, such verification can be carried out for the system of gas dynamics. Two cases of nonuniformly stable shocks arise and motivate the present study. The first example, which is briefly addressed in [25], is the one of planar Lax shocks in isentropic gas dynamics that violate Majda's inequality (see [25, p. 10]). This inequality is recalled in section 2. The second example comes from the theory of phase transitions in isothermal van der Waals fluids. These planar discontinuities are undercompressive shocks. They require an additional jump relation to select the relevant ones. Various admissibility criteria have been proposed over the last two decades; see [39] for phase transitions in the context of gas dynamics or [38, 40] and references therein for phase transitions in the context of elastodynamics. We base our analysis on the viscosity-capillarity criterion proposed in [39] under the assumption that the viscosity coefficient is neglected and taken to be zero. In other words, the additional jump relation is written as a generalized equal area rule. It has been shown in [4] that the uniform stability condition is violated because of surface waves. (Taking viscosity into account would yield uniform stability; see [5].) It is worth noting that the failure of the uniform stability condition in isentropic gas dynamics can rise only from the appearance of boundary waves (but we shall get back to this in the next sections); for a precise statement of the distinction between these two types of waves, we refer the reader to the very nice survey [11].

The purpose of the paper is the derivation of a complete energy estimate on the linearized system resulting from the study of these two problems. Since the *classical* energy estimate is known to be equivalent to the uniform stability condition, as proved in [25], losses of derivatives are to be expected. As shown in Theorems 3.5 and 4.5, and this is no real surprise, losses of derivatives are more severe when boundary waves occur than when surface waves occur. We point out that this kind of phenomenon had already been mentioned in previous works [11, 34]. Despite the impossibility of using some "dissipativeness" arguments on the boundary conditions in our context, we shall see that the derivation of an energy estimate can be carried out by a suitable modification in the ordinary construction of a Kreiss symmetrizer. This point will be emphasized in both problems we shall detail.

This paper is divided as follows. In section 2, we recall Majda's method for multidimensional shock waves and introduce some notations. Note that Lax shocks for isentropic Euler equations are uniformly stable in one space dimension, and we shall therefore deal with two- or three-dimensional problems. (The one-dimensional case is treated in [23].) We warn the reader that many calculations cannot be reproduced here to avoid overloading the paper, and we shall often refer to previous works on this subject where some details are available. However, special attention will be paid to detailing the normal modes analysis on which relies the entire construction of the symbolic symmetrizer. In section 3, we treat the first example, i.e., nonuniformly stable Lax shocks for isentropic Euler equations. We show in section 4 how the method developed in section 3 applies in the study of phase transitions in a van der Waals fluid and even gives slightly better results. Once again, we shall focus on two- or three-dimensional problems, since phase transitions are known to be uniformly

stable in one space dimension, and their existence has already been studied in [14]. Section 5 is devoted to the proof of several technical lemmas used in the construction of Kreiss symmetrizers. Eventually, we make in section 6 some general remarks on the possible advances for these two problems.

2. General considerations. We study the Euler equations governing the motion of an inviscid isentropic fluid in $\mathbb{R}^d$:

$$\begin{cases} \partial_t \rho + \nabla \cdot (\rho \mathbf{u}) = 0 \,, \\ \partial_t (\rho \mathbf{u}) + \nabla \cdot (\rho \mathbf{u} \otimes \mathbf{u}) + \nabla p = 0 \,. \end{cases} \tag{2.1}$$

We have adopted the following standard notations that will be used throughout this paper: ρ denotes the density, $\mathbf{u}$ the velocity field, and c the sound speed given by the pressure law $p(\rho)$ that the fluid is assumed to obey,

$$c(\rho) = \sqrt{p'(\rho)} \,.$$

Since smooth solutions generally develop singularities in finite time, we look for particular weak solutions of the form of functions which are smooth on both sides of a (variable) hypersurface of $\mathbb{R}^d$. A first step in the proof of the existence of such solutions is the study of the linear stability of piecewise constant solutions defined by a relation of the form

$$\overline{U} = \begin{cases} U_l = (\rho_l, \mathbf{u}_l) & \text{if } x \cdot \nu < \sigma t, \\ U_r = (\rho_r, \mathbf{u}_r) & \text{if } x \cdot \nu > \sigma t. \end{cases}$$

Such a function $\overline{U}$ is a weak solution of the Euler equations (2.1) if and only if it satisfies the Rankine–Hugoniot jump relations which can be written in the following way:

$$\begin{cases} \rho_r(\mathbf{u}_r \cdot \nu - \sigma) = \rho_l(\mathbf{u}_l \cdot \nu - \sigma) =: j \,, \\ j[\mathbf{u}] + [p]\nu = 0 \,. \end{cases} \tag{2.2}$$

We consider dynamical discontinuities and thus assume that the mass transfer j across the hyperplane $\{x \cdot \nu = \sigma t\}$ is not zero. By symmetry arguments, one can therefore assume $j > 0$. We first assume that $\overline{U}$ defines a compressive 1-Lax shock or, in other words, that the following inequalities hold:

$$M_r = \frac{\mathbf{u}_r \cdot \nu - \sigma}{c(\rho_r)} < 1, \quad M_l = \frac{\mathbf{u}_l \cdot \nu - \sigma}{c(\rho_l)} > 1, \quad \text{and} \quad \rho_r > \rho_l \,.$$

Note that the above assumptions immediately imply that the shock is noncharacteristic: the propagation speed of the interface σ is different from the characteristic speeds of system (2.1) on both sides of the interface. With the above notations, we have the following statement.

PROPOSITION 2.1 (Majda [25]). *The shock $\overline{U}$ is uniformly stable if and only if*

$$M_r^2 \left(\frac{\rho_r}{\rho_l} - 1 \right) < 1 \,. \tag{2.3}$$

If inequality (2.3) *does not hold, then the shock $\overline{U}$ is only weakly stable.*

Inequality (2.3) holds as long as p is a convex function of the density ρ which is the case for the classical gamma-law but not for more complicated laws (like, for instance, an isothermal van der Waals pressure law). We shall investigate in section 3 the case where the opposite *strict* inequality holds. We shall also detail why the equality case cannot be treated by the techniques used in this paper.

If we now assume that p is a nonmonotone function of ρ (this hypothesis can be viewed as a model of isothermal liquid-vapor phase transitions; see [18]), it is known that subsonic discontinuities can appear for which we have

$$M_r = \frac{\mathbf{u}_r \cdot \nu - \sigma}{c(\rho_r)} < 1, \quad M_l = \frac{\mathbf{u}_l \cdot \nu - \sigma}{c(\rho_l)} < 1, \quad \text{and} \quad \rho_r > \rho_l \,.$$

Such inequalities occur if p is, for instance, given by an isothermal van der Waals pressure law with a temperature below the so-called critical temperature (see [4, 5, 39]). To avoid the natural instability of $\overline{U}$ with respect to small perturbations, one needs to specify an additional jump relation to the Rankine–Hugoniot conditions. The analysis developed in section 4 is based on the capillarity criterion proposed in [39]. (The admissibility criterion proposed in [40] is the analogue for elastodynamics, and the main idea governing both criteria is that there is no entropy dissipation upon crossing the shock.) Together with the Rankine–Hugoniot conditions, this criterion requires that $\overline{U}$ satisfies the generalized equal area rule

$$\int_{v_r}^{v_l} p(v)\, dv \;=\; (v_l - v_r)\, \frac{p(v_r) + p(v_l)}{2}\,, \tag{2.4}$$

where $v = 1/\rho$ is the specific volume of the fluid. Such phase transitions which differ from Maxwell equilibrium states are noncharacteristic.

We are now able to develop Majda's method to study the linear stability of such multidimensional shocks. First note that, by a change of observer, one can always assume that the unit vector ν is the last vector of the canonical basis of $\mathbb{R}^d$. Since the mass transfer j is not zero, equations (2.2) show that the tangential components of the velocity are the same on both sides of the shock front curve. Performing another change of observer one can assume from now on that

$$(\mathbf{u}_1^r, \dots, \mathbf{u}_{d-1}^r) = (\mathbf{u}_1^l, \dots, \mathbf{u}_{d-1}^l) = \mathbf{0} \quad \text{and} \quad \sigma = 0\,,$$

which is of no consequence on the stability of the particular solution $\overline{U}$. Note that these operations yield a simplified expression of the mass transfer j across the interface (defined by system (2.2)): $j = \rho_r u_r = \rho_l u_l$.

We adopt in all that follows the following notations: all space vectors x in $\mathbb{R}^d$ are decomposed as $x = (y, x_d)$, where y is a vector in $\mathbb{R}^{d-1}$ and x_d is a scalar. Similarly, all velocity vectors $\mathbf{u}$ are decomposed as $\mathbf{u} = (\check{u}, u)$, where $\check{u} \in \mathbb{R}^{d-1}$ is the tangential part of the velocity and $u \in \mathbb{R}$ is the normal velocity.

We are now led to search a weak solution U of (2.1) defining a compressive 1-Lax shock (or an admissible phase transition) across a smooth hypersurface $\Sigma(t) = \{x_d = \varphi(t, y)\}$ close to the hyperplane $\{x_d = 0\}$. Since $\Sigma(t)$ is part of the unknowns of the problem, one first fixes the front by the following well-known transformation in free boundary problems:

$$\big(U :\, (t, y, x_d) \longrightarrow \mathbb{R}^N\,\big) \longrightarrow (U_\pm :\, (t, y, z) \longmapsto U(t, y, \varphi(t, y) \pm z)\,)\,,$$

both applications $U_+ = (\rho_+, \mathbf{u}_+)$ and $U_- = (\rho_-, \mathbf{u}_-)$ being defined on the same half-space $\{z > 0\}$. The quasi-linear form of Euler equations is linearized on both sides

of $\Sigma(t)$ around the piecewise constant solution $\overline{U}$ (see [25, 37]). The resulting linear system reads

$$\begin{cases} \partial_t U_+ + \sum_{j=1}^{d-1} A_j(U_r)\,\partial_{x_j} U_+ + A_d(U_r)\,\partial_z U_+ = f_+\,, \\ \partial_t U_- + \sum_{j=1}^{d-1} A_j(U_l)\,\partial_{x_j} U_- - A_d(U_l)\,\partial_z U_- = f_-\,, \end{cases} \tag{2.5}$$

where $A_j(U_{r,l})$ are $(d+1)\times(d+1)$ matrices corresponding to the quasi-linear form of isentropic Euler equations; see [9, 10, 36].

The linearization of the jump conditions across the interface $\Sigma(t)$ yields the boundary conditions on $\{z=0\}$. When one deals with a compressive Lax shock, the jump conditions are nothing but the Rankine–Hugoniot relations, and their linearized form reads

$$\begin{aligned} u_r\rho_+ + \rho_r u_+ - u_l\rho_- - \rho_l u_- - [\rho]\partial_t\varphi = g_1\,, \\ \rho_r u_r \check{u}_+ - \rho_l u_l \check{u}_- - [p]\nabla_y\varphi = \check{g}\,, \\ (u_r^2+c_r^2)\rho_+ + 2\rho_r u_r u_+ - (u_l^2+c_l^2)\rho_- - 2\rho_l u_l u_- = g_{d+1}\,. \end{aligned} \tag{2.6}$$

When one deals with a subsonic phase transition in a van der Waals fluid, the complete boundary conditions for the linearized problem are obtained by linearizing (2.4) and adding this new relation to the linearized Rankine–Hugoniot relations (2.6). The complete set of boundary conditions in this case reads

$$\begin{aligned} u_r\rho_+ + \rho_r u_+ - u_l\rho_- - \rho_l u_- - [\rho]\partial_t\varphi = g_1\,, \\ \rho_r u_r \check{u}_+ - \rho_l u_l \check{u}_- - [p]\nabla_y\varphi = \check{g}\,, \\ (u_r^2+c_r^2)\rho_+ + 2\rho_r u_r u_+ - (u_l^2+c_l^2)\rho_- - 2\rho_l u_l u_- = g_{d+1}\,, \\ c_r^2\frac{\rho_+}{\rho_r} + u_r u_+ - c_l^2\frac{\rho_-}{\rho_l} - u_l u_- - [u]\partial_t\varphi = g_{d+2}\,. \end{aligned} \tag{2.7}$$

It is now clear that, even though both examples rise from two different research areas, they are exactly of the same kind. In both cases, we are led to study a non-standard mixed initial boundary value problem

$$\begin{cases} \partial_t U + \sum_{j=1}^{d-1} \mathcal{A}_j\,\partial_{x_j} U + \mathcal{A}_d\,\partial_z U = f & \text{for } z>0, \\ \partial_t\varphi\, b_0 + \sum_{j=1}^{d-1} \partial_{x_j}\varphi\, b_j + M\,U = g & \text{for } z=0. \end{cases} \tag{2.8}$$

The boundary conditions for the study of compressive Lax shocks are given by (2.6), and the boundary conditions for the study of subsonic phase transitions are given by (2.7). To write system (2.8), we have let

$$U = \begin{pmatrix} U_+ \\ U_- \end{pmatrix}, \quad f = \begin{pmatrix} f_+ \\ f_- \end{pmatrix}, \quad g = \begin{pmatrix} g_1 \\ \check{g} \\ g_{d+1} \end{pmatrix}, \quad \text{or } g = \begin{pmatrix} g_1 \\ \check{g} \\ g_{d+1} \\ g_{d+2} \end{pmatrix},$$

$$\mathcal{A}_j = \begin{pmatrix} A_j(U_r) & \mathbf{0} \\ \mathbf{0} & A_j(U_l) \end{pmatrix} \text{ for } 1\le j\le d-1, \quad \mathcal{A}_d = \begin{pmatrix} A_d(U_r) & \mathbf{0} \\ \mathbf{0} & -A_d(U_l) \end{pmatrix}.$$

In both examples, M represents the matrix of the linearized jump conditions (Rankine–Hugoniot relations and the generalized equal area rule in the case of phase transitions). The vectors $b_0, \dots, b_{d-1}$ come from (2.6) and (2.7). They belong to $\mathbb{R}^{d+1}$ in the study of Lax shocks, while they belong to $\mathbb{R}^{d+2}$ in the study of subsonic phase transitions.

The derivation of an energy estimate for system (2.8) relies on the introduction of a positive weight γ (see [20, 25]). More precisely, we perform a change of unknown functions

$$v(t,y,z) = e^{-\gamma t}\, U(t,y,z) \quad \text{and} \quad \psi(t,y) = e^{-\gamma t}\, \varphi(t,y)\,,$$

where γ is a nonnegative parameter. We now perform a Fourier transform in the variables t and y. (The corresponding dual variables will be respectively denoted δ and η.) These operations yield the system of ordinary differential equations

$$\begin{cases} \dfrac{dV}{dz} = \mathcal{A}(\delta,\eta,\gamma)\, V(z) + F & \text{for } z > 0, \\ \chi\, b(\delta,\eta,\gamma) + M\, V(0) = G & \text{for } z = 0, \end{cases} \tag{2.9}$$

with

$$\mathcal{A}(\delta,\eta,\gamma) = -\mathcal{A}_d^{-1} \left(\tau + i \sum_{j=1}^{d-1} \eta_j \mathcal{A}_j \right) \quad \text{and} \quad b(\delta,\eta,\gamma) = \tau b_0 + i \sum_{j=1}^{d-1} \eta_j b_j\,.$$

For convenience we have let $\tau = \gamma + i\delta$. Note that inverting $\mathcal{A}_d$ is legitimate, since the shock is in both examples noncharacteristic. We now turn to the description of the method: in both examples, we show that the boundary conditions in problem (2.9) can be rewritten so that χ appears only in the last scalar boundary condition. The remaining part of the work consists of deriving an a priori estimate on the resulting initial boundary value problem for U where the boundary conditions take the form of a pseudodifferential operator.

Because of the decoupled nature of system (2.5), it is clear that matrix $\mathcal{A}(\delta,\eta,\gamma)$ has a block diagonal structure: its first block corresponds to the linearized system ahead of the shock, and its second block corresponds to the linearized system before the shock (see [25, 26, 37]). The eigenmodes of the first block are $\omega_2^r = -\tau/u_r$, and the roots of the second order polynomial equation are

$$(\tau + u_r\, \omega)^2 = c_r^2 (\omega^2 - |\eta|^2)\,. \tag{2.10}$$

In a similar way, the eigenmodes of the second block are $\omega_2^l = \tau/u_l$, and the roots of the second order polynomial equation are

$$(\tau - u_l\, \omega)^2 = c_l^2 (\omega^2 - |\eta|^2)\,. \tag{2.11}$$

We briefly analyze the eigenmodes of $\mathcal{A}$ and begin with the eigenmodes of the first block. In both problems analyzed in sections 3 and 4, the shock $\overline{U}$ is subsonic with respect to the right state ($M_r < 1$). It is clear that ω_2^r is of negative real part when τ has positive real part (that is, when γ is positive). Moreover, (2.10) has one root ω_3^r of negative real part when τ has positive real. The other root of (2.10) is denoted ω_1^r and has positive real part when τ has positive real part. The parametrization of the corresponding eigenspaces, which we use in sections 3 and 4, can be found in [4, 37]. One crucial property of the eigenmodes $\omega_{1,3}^r$ is that they can be extended up

to imaginary values of τ. Note that ω_3^r has negative real part if $|\tau| < |\eta|\sqrt{c_r^2 - u_r^2}$ and is purely imaginary if $|\tau| \geq |\eta|\sqrt{c_r^2 - u_r^2}$.

In the case of a compressive 1-Lax shock, that is, when the shock is supersonic with respect to the left state, then the second dynamical system does not give any contribution to the stable subspace $\mathcal{E}^-$ of $\mathcal{A}$. Indeed, ω_2^l is of positive real part when τ has positive real part. Furthermore, (2.11) has two roots ω_1^l and ω_3^l of positive real part when τ has positive real part. One easily checks that the continuous extension of ω_1^l and ω_3^l for purely imaginary values of τ are always distinct.

In the case of a subsonic phase transition, (2.11) has the same behavior as (2.10). More precisely, (2.11) has exactly one root ω_1^l of negative real part when τ has positive real part. The other root of (2.11) is denoted ω_3^l. It has positive real part when τ has positive real part. When τ is a purely imaginary number, ω_1^l has negative real part if $|\tau| < |\eta|\sqrt{c_l^2 - u_l^2}$ and is purely imaginary if $|\tau| \geq |\eta|\sqrt{c_l^2 - u_l^2}$.

3. Nonuniformly stable shocks in gas dynamics. We begin by describing the failure of the uniform stability condition for compressive Lax shocks in isentropic gas dynamics. Let $\overline{U}$ define a compressive 1-Lax shock for isentropic Euler equations (2.1) as described in the previous section. We study the nonstandard initial boundary value problem (2.8) with boundary conditions given by (2.6). We assume that $\overline{U}$ violates Majda's inequality (2.3) in the following way:

$$M_r^2 \left(\frac{\rho_r}{\rho_l} - 1 \right) > 1 \,.$$

Note that the previous simplifications imply that this inequality is equivalent to

$$u_r u_l > c_r^2 + u_r^2 \,. \tag{3.1}$$

This remark will be useful to complete the proof of Lemma 3.3. Under the assumptions made on $\overline{U}$, the normal modes analysis of problem (2.9) is summarized in the following result.

LEMMA 3.1. *There exists a positive number V_1 such that, for all $(\delta, \eta, \gamma) \in \mathbb{R}^{d+1}$ satisfying $\gamma \geq 0$ and $(\delta, \gamma) \neq (\pm i V_1 |\eta|, 0)$, one has*

$$\big\{ (Z, \chi) \in \mathcal{E}^-(\delta, \eta, \gamma) \times \mathbb{C} \ \text{ so that (s.t.) } \ \chi\, b(\delta, \eta, \gamma) + M\, Z = 0 \big\} = \{0\} \,,$$

and, for $\eta \neq 0$, the set

$$\big\{ (Z, \chi) \in \mathcal{E}^-(\pm V_1 |\eta|, \eta, 0) \times \mathbb{C} \ \text{ s.t. } \ \chi\, b(\pm V_1 |\eta|, \eta, 0) + M\, Z = 0 \big\}$$

is a one-dimensional subspace of $\mathbb{C}^{2d+3}$.

By definition, V_1^2 is the smallest root of the polynomial

$$P_1(X) = (c_r^2 - u_r^2)(X^2 + u_r^2 u_l^2) + \big[4 u_r^2 c_r^2 - 2 u_r u_l (c_r^2 + u_r^2) \big]\, X \,,$$

which has two real positive roots under assumption (3.1). *(The greatest is denoted V_2^2.) Furthermore, we have*

$$c_r^2 - u_r^2 < V_1^2 < u_r u_l \frac{c_r^2 - u_r^2}{c_r^2 + u_r^2} < V_2^2 \,.$$

Proof. This is a basic extension of the calculations already done in [25] (which can also be found in [37]). First of all, we note that the stable subspace of the dynamical system

$$\frac{dV}{dz} = \mathcal{A}(\delta, \eta, \gamma)\, V$$

consists of all vectors $Z = (Z_r, Z_l)$ such that

$$(u_r\tau - (c_r^2 - u_r^2)\omega_3^r, \rho_r u_r i\eta^T, -\rho_r\tau) \cdot Z_r = 0 \quad \text{and} \quad Z_l = 0\,.$$

With this parametrization of the stable subspace, one easily computes the Lopatinskii determinant associated with (2.9):

$$\Delta(\delta, \eta, \gamma) = \rho_r^d u_r^{d-1} \left[(c_r^2 - u_r^2)[p]|\eta|^2 + (c_r^2 + u_r^2)[\rho]\tau^2 + 2u_r[\rho]\tau a_3^r\right]\,,$$

where we have let $a_3^r = u_r\tau - (c_r^2 - u_r^2)\omega_3^r$. It is clear that $\Delta(\delta, 0, \gamma)$ does not vanish for any $(\delta, \gamma) \neq (0, 0)$. One can therefore factor the expression of $\Delta(\delta, \eta, \gamma)$ by $|\eta|^2$ and use the reduced variables

$$V = \frac{\tau}{i|\eta|}, \quad A_3^r = \frac{a_3^r}{i|\eta|}\,.$$

Some simplifications using the Rankine–Hugoniot relations lead to the expression

$$\Delta(\delta, \eta, \gamma) = \rho_r^d u_r^{d-1}|\eta|^2[\rho]\left[(c_r^2 - u_r^2)u_r u_l - (c_r^2 + u_r^2)V^2 - 2u_r V A_3^r\right]\,.$$

Let $\mathcal{R}$ denote the complex square root mapping defined by

$$\begin{aligned}\mathcal{R}\ : \mathbb{C} \setminus \mathbb{R}_+ &\longrightarrow \{\zeta \in \mathbb{C} \text{ s.t. } \operatorname{Im}\zeta > 0\},\\ w &\longmapsto \mathcal{R}(w) \quad \text{with} \quad \mathcal{R}(w)^2 = w\,.\end{aligned}$$

Then analyzing equation (2.10) shows that for $\gamma > 0$ (or, equivalently, for V of negative imaginary part) we have

$$A_3^r = -c_r\mathcal{R}(V^2 - (c_r^2 - u_r^2)),$$

and therefore, if the Lopatinskii determinant vanishes at some point (τ, η), V^2 has to be a root of the polynomial P_1 defined in the lemma. Note that the assumption (3.1) made on the shock $\overline{U}$ implies that P_1 has two distinct positive roots V_1^2 and V_2^2 that satisfy the properties given in the lemma. This already proves that the possible zeros of $\Delta(\delta, \eta, \gamma)$ have to satisfy

$$\eta \neq 0\,,\ \gamma = 0 \quad \text{and} \quad \delta^2 > (c_r^2 - u_r^2)|\eta|^2\,,$$

and those requirements imply that V is a real number such that $V^2 > c_r^2 - u_r^2$. One therefore has to extend the previous definition of A_3^r to such values of V. This is achieved by using the Cauchy–Riemann relations on holomorphic functions (see [4, 37] for the details):

$$\begin{cases} A_3^r = c_r\sqrt{V^2 - (c_r^2 - u_r^2)} & \text{if } V > \sqrt{c_r^2 - u_r^2},\\ A_3^r = -c_r\sqrt{V^2 - (c_r^2 - u_r^2)} & \text{if } V < -\sqrt{c_r^2 - u_r^2}. \end{cases}$$

Furthermore, the previous analysis shows that $\Delta(\delta,\eta,0)$ vanishes if and only if

$$\begin{cases} 2u_rc_rV\sqrt{V^2-(c_r^2-u_r^2)} = -(c_r^2+u_r^2)V^2 + u_ru_l(c_r^2-u_r^2) & \text{if } V > \sqrt{c_r^2-u_r^2}, \\ 2u_rc_rV\sqrt{V^2-(c_r^2-u_r^2)} = (c_r^2+u_r^2)V^2 - u_ru_l(c_r^2-u_r^2) & \text{if } V < -\sqrt{c_r^2-u_r^2}, \end{cases}$$

and these relations imply $P_1(V^2)=0$.

If the Lopatinskii determinant vanishes at $V=V_2$, then we must have

$$2u_rc_rV_2\sqrt{V_2^2-(c_r^2-u_r^2)} = -(c_r^2+u_r^2)V_2^2 + u_ru_l(c_r^2-u_r^2)\,.$$

However, the left-hand term of the equality is positive, and the right-hand term is negative. Therefore the Lopatinskii determinant cannot vanish at $V=V_2$ (and neither at $V=-V_2$ by a similar argument). Since $P_1(V_1^2)=0$ we have

$$2u_rc_rV_1\sqrt{V_1^2-(c_r^2-u_r^2)} = -(c_r^2+u_r^2)V_1^2 + u_ru_l(c_r^2-u_r^2)\,,$$

because both terms in the equality are positive. Therefore the Lopatinskii determinant vanishes at $V=V_1$ (and similarly at $V=-V_1$). This completes the proof of the existence and the characterization of points where the uniform stability condition fails. The last assertion on the dimension of the corresponding kernel follows directly from the shape of the boundary conditions (2.6). □

Note that if in the special case $u_ru_l = c_r^2+u_r^2$, then $P_1(c_r^2-u_r^2)=0$. In other words, the uniform stability condition fails exactly at the points where (2.10) has a double root. At such points, the symbol $\mathcal{A}$ is not diagonalizable, and a 2×2 Jordan block arises in the reduction of $\mathcal{A}$ which is used to construct a Kreiss symmetrizer (see the proof of Proposition 3.4). At the present time, we have not been able to overcome this difficulty. This case is left to a future work.

3.1. Elimination of the front. The first step in the derivation of an energy estimate for the mixed problem (2.8) is to work in the Fourier space and to isolate the front χ in the last boundary condition for problem (2.9). This operation can be summarized in the following terms.

LEMMA 3.2. *There exists a C^∞ mapping Q defined on the half-space $\mathbb{R}^d\times\mathbb{R}^+\setminus\{0\}$, homogeneous of degree 0, with values in the set of square $(d+1)\times(d+1)$ invertible matrices such that, for all $X\in\mathbb{R}^d\times\mathbb{R}^+\setminus\{0\}$, the first d components of the vector $Q(X)\,b(X)$ vanish.*

Proof. The Rankine–Hugoniot jump relations together with (2.6) yield the relations

$$b(\delta,\eta,\gamma) = \begin{pmatrix} -\tau[\rho] \\ -iu_ru_l[\rho]\eta \\ 0 \end{pmatrix} \text{ if } d=2 \quad \text{and} \quad b(\delta,\eta,\gamma) = \begin{pmatrix} -[\rho]\tau \\ -iu_ru_l[\rho]\eta_1 \\ -iu_ru_l[\rho]\eta_2 \\ 0 \end{pmatrix} \text{ if } d=3.$$

To preserve the homogeneity of the physical quantities we handle in the calculations, we fix a reference velocity $\widetilde{V}$ and a reference frequency $\widetilde{\gamma}$, and we define Σ_+ as the hemisphere

$$\Sigma_+ = \left\{ (\delta,\eta,\gamma)\in\mathbb{R}^d\times\mathbb{R}_+ \text{ s.t. } \gamma^2+\delta^2+\widetilde{V}^2|\eta|^2 = \widetilde{\gamma}^2 \right\}.$$

We first define the mapping Q on the hemisphere Σ_+ and then extend it as a homogeneous mapping of degree 0. One easily checks that, for $d = 2$, the matrix

$$Q(\delta,\eta,\gamma) = \begin{pmatrix} 0 & 0 & 1 \\ iu_r u_l \eta & -\tau & 0 \\ u_r u_l \overline{\tau} & -i\widetilde{V}^2\eta & 0 \end{pmatrix}$$

satisfies all required properties. For $d = 3$, one can choose, for instance,

$$Q(\delta,\eta,\gamma) = \begin{pmatrix} 0 & 0 & 0 & 1 \\ iu_r u_l \eta_1 & -\tau & 0 & 0 \\ iu_r u_l \eta_2 & 0 & -\tau & 0 \\ u_r u_l \overline{\tau} & -i\widetilde{V}^2\eta_1 & -i\widetilde{V}^2\eta_2 & 0 \end{pmatrix}$$

which also satisfies all required properties. This completes the proof. □

We can therefore write boundary conditions for the linearized problem (2.8) in the equivalent way

$$\begin{pmatrix} B(\delta,\eta,\gamma) \\ \ell(\delta,\eta,\gamma) \end{pmatrix} V(0) + \chi \begin{pmatrix} \mathbf{0}_d \\ \alpha(\delta,\eta,\gamma) \end{pmatrix} = Q(\delta,\eta,\gamma)\, G\,,$$

where $\alpha(\delta,\eta,\gamma)$ is given by

$$\alpha(\delta,\eta,\gamma) = -u_r u_l [\rho] \widetilde{\gamma} \sqrt{\gamma^2 + \delta^2 + \widetilde{V}^2|\eta|^2} \neq 0\,,$$

and this relation holds for $d = 2$ and $d = 3$.

Lemma 3.1 ensures that the restriction of $B(X)$ to the stable subspace $\mathcal{E}^-(X)$ is invertible except at the points X where the uniform stability condition fails. We thus have to study the behavior of the restriction of $B(X)$ to the stable subspace $\mathcal{E}^-$ in the neighborhood of those points. Lemma 3.3 asserts that the Lopatinskii determinant vanishes *at order* 1 or, in other words, that the roots exhibited in Lemma 3.1 are simple.

For all vectors Z belonging to the stable subspace $\mathcal{E}^-$ we denote by Z_3^r and Z_2^r the components of Z on the eigenspaces associated with the eigenmodes ω_3^r and ω_2^r. In other words, we decompose Z as

$$Z = \begin{pmatrix} Z_r \\ \mathbf{0}_{d+1} \end{pmatrix} \quad \text{with} \quad Z_r = Z_3^r \begin{pmatrix} \rho_r(\tau + u_r\,\omega_3^r) \\ -c_r^2\, i\eta \\ -c_r^2\,\omega_3^r \end{pmatrix} + \begin{pmatrix} 0 \\ -\omega_2^r Z_2^r \\ i\eta \cdot Z_2^r \end{pmatrix}.$$

Then we have the following microlocal estimate.

LEMMA 3.3. *There exists a neighborhood $\mathcal{V}$ of $(V_1|\eta|,\eta,0)$ in Σ_+ and a constant $c > 0$ such that, for all $X \in \mathcal{V}$ and for all $Z \in \mathcal{E}^-(X)$, one has*

$$|B(X)\,Z|^2 \geq c\,\gamma^2 \left(|Z_3^r|^2 + |Z_2^r|^2\right).$$

An analogous estimate holds in a neighborhood of points $(-V_1|\eta|,\eta,0)$.

Proof. According to Lemma 3.1 we know that the kernel of the restriction of B to the stable subspace $\mathcal{E}^-$ at the point $(V_1|\eta|,\eta,0)$ is a one-dimensional space. Therefore, in order to prove Lemma 3.3, we need only to show that 0 is a *simple root* of the determinant of the restriction of B to $\mathcal{E}^-$ or, more precisely, that the partial derivative of this determinant with respect to γ calculated at $\gamma = 0$ is not zero.

We first deal with the case $d = 2$, and we keep the notation a_3^r introduced in the proof of Lemma 3.1. After a few simplifications, for $Z \in \mathcal{E}^-$, we get

$$B(\delta,\eta,\gamma)\, Z = \begin{pmatrix} \rho_r(c_r^2\tau + u_r a_3^r) & 2ij\eta \\ \dfrac{ij\eta\widetilde{\gamma}(c_r^2\tau + u_l a_3^r)}{\sqrt{\gamma^2+\delta^2+\widetilde{V}^2\eta^2}} & \dfrac{-\rho_r\widetilde{\gamma}(\tau^2 + u_r u_l \eta^2)}{\sqrt{\gamma^2+\delta^2+\widetilde{V}^2\eta^2}} \end{pmatrix} \begin{pmatrix} Z_3^r \\ Z_2^r \end{pmatrix}.$$

Note that this expression involves $\widetilde{\gamma}$ and some square roots because of the homogeneity property of the mapping Q. The determinant of the restriction of B to the stable subspace $\mathcal{E}^-$ is therefore given by

$$\det B^- = \frac{i\widetilde{\gamma}\rho_r^2|\eta|^3}{\sqrt{\gamma^2+\delta^2+\widetilde{V}^2\eta^2}} \underbrace{\left[c_r^2 V(V^2+2u_r^2-u_r u_l) + u_r A_3^r (V^2+u_r u_l)\right]}_{f(V)},$$

where V and A_3^r denote the same reduced quantities as those defined in the proof of Lemma 3.1. One can check that $f(V)$ vanishes at the points where the uniform stability condition fails (thanks to the expression of the Lopatinskii determinant). The final step consists of calculating the partial derivative of $\det B^-$ with respect to γ at $\gamma = 0$. Proving that this derivative is not zero is equivalent to proving that the derivative (with respect to V) of the function $f(V)$ calculated at $V = \pm V_1$ is not zero. We have

$$f'(V) = c_r(3V^2 + 2u_r^2 - u_r u_l) + \frac{c_r u_r V\left[3V^2 + u_r u_l - 2(c_r^2 - u_r^2)\right]}{u_r V A_3^r},$$

and thus, using the expression of VA_3^r at $(V_1|\eta|,\eta,0)$, we find the expression

$$f'(V_1) = c_r^2(3V_1^2 + 2u_r^2 - u_r u_l) - \frac{2c_r^2 u_r^2 V_1^2\left[3V_1^2 + u_r u_l - 2(c_r^2 - u_r^2)\right]}{(c_r^2+u_r^2)V_1^2 - (c_r^2-u_r^2)u_r u_l}.$$

Eventually, $f'(V_1) = 0$ if and only if V_1^2 is a root of the polynomial

$$Q_1(X) = 3(c_r^2-u_r^2)X^2 + 2\left[u_r^2(3c_r^2-u_r^2) - 2u_r u_l c_r^2\right]X + u_r u_l(c_r^2-u_r^2)(u_r u_l - 2u_r^2).$$

Assume that $Q_1(V_1^2) = 0$. Since V_1^2 is also a root of the polynomial P_1 defined in Lemma 3.1, we get the relation

$$\left[u_r u_l(c_r^2+3u_r^2) - u_r^2(3c_r^2+u_r^2)\right]V_1^2 - u_r u_l(c_r^2-u_r^2)(u_r u_l + u_r^2) = 0,$$

and one easily checks that the previous term between brackets is positive, since $u_r u_l > c_r^2 + u_r^2$. Plugging this explicit expression of V_1^2 into the definition of P_1 implies that $S := u_r u_l / c_r^2$ is a root of the following polynomial:

$$Q_2(X) = (1-M_r^2)X^3 + (2M_r^4 + 3M_r^2 - 1)X^2 - M_r^2(M_r^4 + 5M_r^2 + 2)X + M_r^4(3+M_r^2).$$

One easily checks that $Q_2(1) = 0$, and we have assumed that $S > 1 + M_r^2$. We thus deduce that S is a root of the polynomial

$$Q_3(X) = (1-M_r^2)X^2 + 2M_r^2(1+M_r^2)X - M_r^4(3+M_r^2) = 0.$$

However, the value of $Q_3(1+M_r^2)$ is greater than 1, so S is always larger than the greatest root of Q_3. We are thus led to a contradiction. Therefore V_1^2 cannot be a root of the polynomial Q_1 which means exactly that $f'(V_1) \neq 0$.

If $d = 3$ and Z is a vector in the stable subspace $\mathcal{E}^-$, we have the relation

$$B(\delta,\eta,\gamma)\,Z = \begin{pmatrix} \rho_r(c_r^2\tau + u_r a_3^r) & 2ij\eta_1 & 2ij\eta_2 \\ \dfrac{ij\eta_1\widetilde{\gamma}(c_r^2\tau + u_l a_3^r)}{\sqrt{\gamma^2+\delta^2+\widetilde{V}^2|\eta|^2}} & \dfrac{-\rho_r\widetilde{\gamma}(\tau^2 + u_r u_l \eta_1^2)}{\sqrt{\gamma^2+\delta^2+\widetilde{V}^2|\eta|^2}} & \dfrac{-\rho_r\widetilde{\gamma}u_r u_l \eta_1\eta_2}{\sqrt{\gamma^2+\delta^2+\widetilde{V}^2|\eta|^2}} \\ \dfrac{ij\eta_2\widetilde{\gamma}(c_r^2\tau + u_l a_3^r)}{\sqrt{\gamma^2+\delta^2+\widetilde{V}^2|\eta|^2}} & \dfrac{-\rho_r\widetilde{\gamma}u_r u_l \eta_1\eta_2}{\sqrt{\gamma^2+\delta^2+\widetilde{V}^2|\eta|^2}} & \dfrac{-\rho_r\widetilde{\gamma}(\tau^2 + u_r u_l \eta_1^2)}{\sqrt{\gamma^2+\delta^2+\widetilde{V}^2|\eta|^2}} \end{pmatrix} \begin{pmatrix} Z_3^r \\ \\ Z_2^r \end{pmatrix},$$

from which we get the expression

$$\det B^- = \frac{i\widetilde{\gamma}^2\rho_r^3 V^2|\eta|^5}{\gamma^2+\delta^2+\widetilde{V}^2\eta^2}\, f(V)\,.$$

Therefore the previous analysis made in the case $d = 2$ applies, and the conclusion of the lemma follows. □

In order to simplify what follows, we assume that the reference speed $\widetilde{V}$ and the reference frequency $\widetilde{\gamma}$ are *normalized* and taken to be equal to 1. This is of pure convenience and does not affect the following results, but it will clarify the introduction of weighted Sobolev spaces.

3.2. A priori estimate on the linearized equations. We begin with a result of existence of a microlocal Kreiss symmetrizer for system (2.8). The proof of this result is detailed in the next subsection. Except at the particular points where the uniform stability condition fails, the method is the one developed in [20] (see also [8]) whose first purpose was the resolution of mixed initial boundary value problems for strictly hyperbolic systems when the boundary conditions do not have any "dissipativeness" property. We point out that this method was later used in [25] (see also [27, 30]) to deal with multidimensional shock waves where no "dissipativeness" argument holds, since the boundary conditions B take the form of a pseudodifferential operator of order 0. In our case, since we have limited the study to constant coefficients systems, these boundary conditions take the simpler form of a Fourier multiplier.

We shall see in the proof of Theorem 3.5 that the failure of the uniform stability condition in the so-called hyperbolic region gives rise to some poor energy estimates compared to the maximal L^2 estimates obtained under the uniform stability condition. In fact, we can state the following result.

PROPOSITION 3.4. *For all $X_0 \in \Sigma_+$, there exists an open neighborhood $\mathcal{V}$ of X_0 and matrices $r(X)$, $T(X)$ of class C^∞ with respect to $X \in \mathcal{V}$ which satisfy the following:*

$r(X)$ is hermitian.

$T(X)$ is invertible, and, defining $a(X) = T(X)^{-1}\mathcal{A}(X)\,T(X)$, $\widetilde{B}(X) = B(X)\,T(X)$, there exist two positive constants C and $c > 0$ such that

$$\operatorname{Re}\,(r(X)\,a(X)) \geq c\gamma I\,,$$
$$r(X) + C\widetilde{B}(X)^*\widetilde{B}(X) \geq cI\,,$$

if the Lopatinskii determinant does not vanish at X_0, and

$$\text{Re } (r(X)\, a(X)) \geq c\gamma^3 I\,,$$
$$r(X) + C\widetilde{B}(X)^*\widetilde{B}(X) \geq c\gamma^2 I\,,$$

if X_0 is a root of the Lopatinskii determinant. In this latter case, $r(X)$ can be chosen under the following diagonal form:

$$r(X) = \begin{pmatrix} -\gamma^2 I_d & 0 \\ 0 & \lambda I_{d+2} \end{pmatrix},$$

where λ is a real number greater than 1.

Recall that, under the uniform stability condition, one can construct a Kreiss symmetrizer R that satisfies

$$\text{Re } (R(X)\mathcal{A}(X)) \geq c\gamma I\,,$$
$$R(X) + CB(X)^*B(X) \geq cI\,.$$

Proposition 3.4 enables us to derive an energy estimate on system (2.8) in some appropriate weighted spaces. We define two domains Ω and ω as

$$\Omega = \mathbb{R}\times\mathbb{R}^d_+ = \{(t,y,z)\in\mathbb{R}^{d+1} \text{ s.t. } z>0\} \quad \text{and} \quad \omega = \mathbb{R}\times\mathbb{R}^{d-1} = \partial\overline{\Omega}\,.$$

For $\gamma>0$ and $s\in\mathbb{R}$ we define the following symbols:

$$\forall \xi\in\mathbb{R}^d, \quad \lambda^{s,\gamma}(\xi) = (\gamma^2+|\xi|^2)^{s/2}\,.$$

The usual Sobolev spaces $H^s(\omega)$ are equipped with the following weighted norms (depending on the positive parameter γ):

$$\|u\|^2_{s,\gamma} = \frac{1}{(2\pi)^d}\int_{\mathbb{R}^d} \lambda^{2s,\gamma}(\xi)\,|\widehat{u}(\xi)|^2\,d\xi\,.$$

These weighted norms enable us to construct a parameter version of the classical pseudodifferential calculus which is of constant use in the study of mixed initial boundary value problems for hyperbolic systems; see [1, 20, 25].

For all integer k, we equip the usual Sobolev space $H^k(\Omega)$ with the following norm:

$$|\!|\!| U |\!|\!|^2_{k,\gamma} = \sum_{j=0}^{k}\int_0^{+\infty} \|\partial_z^j U(.,z)\|^2_{k-j,\gamma}\,dz\,.$$

We now define two operators $\mathcal{L}$ and $\mathcal{B}$ by

$$\mathcal{L}(U) = \partial_t U + \sum_{j=1}^{d-1}\mathcal{A}_j\,\partial_{x_j}U + \mathcal{A}_d\,\partial_z U \quad \text{for } z>0,$$

$$\mathcal{B}(\varphi,U) = \partial_t\varphi\, b_0 + \sum_{j=1}^{d-1}\partial_{x_j}\varphi\, b_j + M\,U \quad \text{for } z=0.$$

The change of unknown functions described in section 2 leads to the introduction of the "weighted" operators

$$\mathcal{L}^\gamma(U) = \mathcal{L}(U) + \gamma U \quad \text{and} \quad \mathcal{B}^\gamma(\varphi,U) = \mathcal{B}(\varphi,U) + \gamma\varphi\, b_0\,.$$

These notations enable us to state our first weak stability theorem.

THEOREM 3.5. *There exists a constant $C > 0$ such that, for all $U \in H^2(\Omega)$, for all $\varphi \in H^2(\omega)$, and for all $\gamma \geq 1$, the following estimate holds:*

$$\gamma |\!|\!| U |\!|\!|_{0,\gamma}^2 + \|U\|_{0,\gamma}^2 + \|\varphi\|_{1,\gamma}^2 \leq C \left(\frac{1}{\gamma^3} |\!|\!| \mathcal{L}^\gamma U |\!|\!|_{1,\gamma}^2 + \frac{1}{\gamma^2} \|\mathcal{B}^\gamma(\varphi, U)\|_{1,\gamma}^2 \right).$$

We recall that, under the uniform stability condition, one deduces from the existence of a global Kreiss symmetrizer the following maximal L^2 estimate:

$$\gamma |\!|\!| U |\!|\!|_{0,\gamma}^2 + \|U\|_{0,\gamma}^2 + \|\varphi\|_{1,\gamma}^2 \leq C \left(\frac{1}{\gamma} |\!|\!| \mathcal{L}^\gamma U |\!|\!|_{0,\gamma}^2 + \|\mathcal{B}^\gamma(\varphi, U)\|_{1,\gamma}^2 \right).$$

Comparing to the result of Theorem 3.5, we see that losses of derivatives appear both in the interior domain and on the boundary. This is quite a remarkable difference between our study and previous works such as [11, 34], where derivatives were lost only on the boundary.

Proof. The result is a consequence of the existence of a symbolic symmetrizer r given by Proposition 3.4. Since Σ_+ is a compact set, we can fix a finite covering $(\mathcal{V}_i)_{1 \leq i \leq I}$ of Σ_+ by open sets defined in Proposition 3.4. Let $(\psi_i)_{1 \leq i \leq I}$ be a partition of unity associated with this covering. More precisely, the functions ψ_i are nonnegative, C^∞, and satisfy

$$\forall i = 1, \dots, I, \quad \text{Supp } \psi_i \subset \mathcal{V}_i \quad \text{and} \quad \sum_{i=1}^{I} \psi_i^2 \equiv 1 .$$

Now let $U \in H^2(\Omega)$ and $\varphi \in H^2(\omega)$. We denote $\widehat{U}(\xi, z)$ the Fourier transform of $U(t, y, z)$ with respect to the d first variables (t, y). We also define

$$F(t, y, z) = \mathcal{L}^\gamma U(t, y, z) \in H^1(\Omega) ,$$
$$G(t, y) = \mathcal{B}^\gamma(\varphi, U) \in H^1(\omega) .$$

Lemma 3.2 ensures that there exists a constant $C > 0$ such that

$$\lambda^{2,\gamma}(\xi) \, |\widehat{\varphi}(\xi)|^2 \leq C \left(|\widehat{U}(\xi, 0)|^2 + |\widehat{G}(\xi)|^2 \right) ,$$

with $\xi = (\delta, \eta)$. Integrating with respect to ξ and using Plancherel's theorem yield the inequalities

$$\begin{aligned} \|\varphi\|_{1,\gamma}^2 &\leq C \left(\|U\|_{0,\gamma}^2 + \|\mathcal{B}^\gamma(\varphi, U)\|_{0,\gamma}^2 \right) \\ &\leq C \left(\|U\|_{0,\gamma}^2 + \gamma^{-2} \|\mathcal{B}^\gamma(\varphi, U)\|_{1,\gamma}^2 \right) . \end{aligned}$$

We now need to estimate the norms $\|U\|_{0,\gamma}^2$ and $|\!|\!| U |\!|\!|_{0,\gamma}^2$ in terms of $\|G\|_{1,\gamma}^2$ and $|\!|\!| F |\!|\!|_{1,\gamma}^2$. We define

$$V_i(X, z) = \psi_i(X) \, T_i(X)^{-1} \, \widehat{U}(\xi, z) .$$

Since ψ_i has compact support in $\mathcal{V}_i$, we extend the mappings r_i and T_i on all Σ_+, assuming them to be constant outside of $\mathcal{V}_i$. (This is of pure convenience since only the value of these mappings on Supp ψ_i will be involved in what follows.) Then we extend r_i and T_i (and thus a) as homogeneous functions of degree 0 in $X = (\xi, \gamma)$. (This is the method developed in [8, 20, 30].)

Using the definition of the matrix $a(X)$, we know that $V_i(X,z)$ satisfies the ordinary differential equation

$$\frac{dV_i}{dz} = a(X)\,V_i + \psi_i(X)\,T_i(X)^{-1}\,\mathcal{A}_d^{-1}\,\widehat{F}\,.$$

We first deal with the case where $\mathcal{V}_i$ is a neighborhood of a root of the Lopatinskii determinant. We take the scalar product of the previous equation by $\lambda^{2,\gamma}(\xi)\,r_i(X)V_i$ and integrate with respect to $\xi=(\delta,\eta)\in\mathbb{R}^d$. Then we integrate with respect to z from 0 to $+\infty$. Using the properties of the symmetrizer r_i, we get

$$\begin{aligned}-2\ \mathrm{Re}\ \left\langle\left\langle r_i(X)\,V_i, \psi_i(X)\,\lambda^{2,\gamma}(\xi)\,T_i(X)^{-1}\,\mathcal{A}_d^{-1}\widehat{F}\right\rangle\right\rangle&\\ \geq c\gamma^2\left\|\psi_i\widehat{U}\right\|_{0,\gamma}^2 - C\left\|\psi_i B\,\widehat{U}\right\|_{1,\gamma}^2 + 2\ \mathrm{Re}\ \langle\langle V_i, \lambda^{2,\gamma}\,r_i(X)\,a(X)\,V_i\rangle\rangle\,.&\end{aligned}$$

Define a matrix Σ as

$$\Sigma = \begin{pmatrix} \dfrac{\gamma}{\sqrt{\gamma^2+|\xi|^2}} & \mathbf{0} \\ \mathbf{0} & \sqrt{\lambda} \end{pmatrix},$$

where λ is a real number greater than 1 as stated in Proposition 3.4. We clearly have $\mathrm{Re}\ r_i(X)\,a(X)\geq c\gamma\Sigma^2$ for X in the support of ψ_i. Since a and r_i are diagonal matrices on $\mathcal{V}_i$, we have

$$2\ \mathrm{Re}\ \langle\langle V_i, \lambda^{2,\gamma}\,r_i(X)\,a(X)\,V_i\rangle\rangle \geq c\gamma|\!|\!|\lambda^{1,\gamma}\,\Sigma V_i|\!|\!|_{0,\gamma}^2\,,$$

and the Cauchy–Schwarz inequality yields the estimate

$$\begin{aligned}-2\ \mathrm{Re}\ \left\langle\left\langle r_i(X)\,V_i, \psi_i(X)\,\lambda^{2,\gamma}(\xi)\,T_i(X)^{-1}\,\mathcal{A}_d^{-1}\widehat{F}\right\rangle\right\rangle &\leq c\gamma|\!|\!|\lambda^{1,\gamma}\,\Sigma V_i|\!|\!|_{0,\gamma}^2 + \frac{C}{\gamma}\left|\!\left|\!\left|\lambda^{1,\gamma}\,\Sigma\widehat{F}\right|\!\right|\!\right|_{0,\gamma}^2\\ &\leq c\gamma|\!|\!|\lambda^{1,\gamma}\,\Sigma V_i|\!|\!|_{0,\gamma}^2 + +\frac{C}{\gamma}|\!|\!|F|\!|\!|_{1,\gamma}^2\,.\end{aligned}$$

Eventually, we get the following estimate:

$$c\gamma^2\left\|\psi_i\widehat{U}\right\|_{0,\gamma}^2 + c\gamma|\!|\!|\lambda^{1,\gamma}\,\Sigma V_i|\!|\!|_{0,\gamma}^2 \leq \frac{C}{\gamma}|\!|\!|F|\!|\!|_{1,\gamma}^2 + C\left\|\psi_i B\,\widehat{U}\right\|_{1,\gamma}^2\,,$$

from which we finally obtain

$$\gamma^2\left\|\psi_i\widehat{U}\right\|_{0,\gamma}^2 + \gamma^3\left\|\psi_i\widehat{U}\right\|_{0,\gamma}^2 \leq \frac{C}{\gamma}|\!|\!|F|\!|\!|_{1,\gamma}^2 + C\left\|\psi_i B\,\widehat{U}\right\|_{1,\gamma}^2\,.$$

When $\mathcal{V}_i$ is a neighborhood of a point X_0, where the Lopatinskii determinant does not vanish, the result is directly obtained by the analysis made by Kreiss [20] (see also [8, 30]) which gives the maximal L^2 estimate. All these inequalities give an estimate on U in terms of $\mathcal{L}^\gamma(U)$ and $\mathcal{B}^\gamma(\varphi,U)$. The previous estimate on the front φ added to this estimate on U gives the result. □

Note that, when $\mathcal{L}^\gamma(U)=0$, we recover Majda's statement on weakly stable shocks (see [25, p. 10]). However, Theorem 3.5 is a little more precise, since it indicates two types of loss of derivatives arising in this problem. Some regularity is lost on the boundary, as pointed out in Majda's work. However, in addition, a very severe loss of regularity occurs in the domain Ω.

3.3. Construction of a Kreiss symmetrizer: Proof of Proposition 3.4. In this subsection, we prove Proposition 3.4 and construct a microlocal symmetrizer. This construction relies on the so-called block structure of the symbol $\mathcal{A}$ which was introduced by Kreiss in the case of strictly hyperbolic systems [20]. In [25], Majda extended this property in a general definition and proved that isentropic Euler equations (2.1) met all the requirements. We point out that, in a recent paper [28], Métivier succeeded in proving that Majda's definition of the block structure condition was a property satisfied by all hyperbolic systems of conservation laws with constant multiplicity eigenvalues.

We need to distinguish four cases corresponding to the different behaviors of the eigenmodes $\omega_k^{l,r}$. We recall that, when $\gamma = 0$, the eigenmodes ω_1^l and ω_3^l are always distinct (see section 2).

Construction of r in the elliptic region. Let $X_0 \in \Sigma_+$ such that $\gamma > 0$. The symbol $\mathcal{A}(X_0)$ has no purely imaginary eigenvalue, and one can therefore choose two closed curves C^- (resp., C^+) lying in the half-plane $\{\text{Re } z < 0\}$ (resp., $\{\text{Re } z > 0\}$) such that the eigenvalues of negative (resp., positive) real part of $\mathcal{A}(X_0)$ stand in the domain delimited by C^- (resp., C^+). Using the generalized eigenprojectors associated with $C^\pm$, one gets the existence of a C^∞ mapping $T(X)$ with values in the set of $2(d+1) \times 2(d+1)$ invertible matrices, defined on a neighborhood of X_0, such that

$$\forall X \in \mathcal{V}\,, \quad T(X)^{-1}\mathcal{A}(X)\,T(X) = \begin{pmatrix} a^-(X) & \mathbf{0} \\ \mathbf{0} & a^+(X) \end{pmatrix},$$

and the spectrum of $a^-(X)$ (resp., $a^+(X)$) is contained in the half-space $\{\text{Re } z < 0\}$ (resp., $\{\text{Re } z > 0\}$).

Now define the positive definite hermitian matrices

$$H^- = 2\int_0^{+\infty} \exp(ta^-(X_0))^* \exp(ta^-(X_0))\,dt$$

and

$$H^+ = 2\int_0^{+\infty} \exp(-ta^+(X_0))^* \exp(-ta^+(X_0))\,dt\,.$$

One easily checks that

$$\begin{aligned} \text{Re } (H^+\,a^+(X_0)) &:= (H^+\,a^+(X_0) + a^+(X_0)^* H^+)/2 = I\,, \\ \text{Re } (H^-\,a^-(X_0)) &:= (H^-\,a^-(X_0) + a^-(X_0)^* H^-)/2 = -I\,. \end{aligned}$$

This is the classical Lyapunov matrix theorem; see [2]. In a neighborhood $\mathcal{V}$ of X_0, one has

$$\forall\, X \in \mathcal{V}\,, \quad \text{Re } H^- a^-(X) \le -\frac{1}{2} I \quad \text{and} \quad \text{Re } H^+ a^+(X) \ge \frac{1}{2} I\,.$$

We now define

$$r = \begin{pmatrix} -H^- & 0 \\ 0 & \lambda H^+ \end{pmatrix},$$

where λ will be a real number fixed greater than 1 in what follows. It is clear that r satisfies the first property of the lemma. Moreover, if Z denotes any vector of $\mathbb{C}^{2(d+1)}$, we can write

$$\widetilde{B}(X_0)\, Z = \widetilde{B}(X_0) \begin{pmatrix} Z^- \\ 0 \end{pmatrix} + \widetilde{B}(X_0) \begin{pmatrix} 0 \\ Z^+ \end{pmatrix} .$$

Since the Lopatinskii determinant does not vanish at any point of $\mathcal{V}$, there exists a constant $C > 0$ such that

$$|Z^-|^2 \leq C \left(|Z^+|^2 + |\widetilde{B}(X_0)\, Z|^2 \right) .$$

Following [8, 20], one can check that, for sufficiently large λ, we have

$$r + C\widetilde{B}(X_0)^* \widetilde{B}(X_0) \geq cI\,,$$

for some constant $c > 0$, and this estimate holds in all $\mathcal{V}$ by a continuity argument (replacing c by $c/2$).

Construction of r at a hyperbolic diagonalization point. Let $X_0 \in \Sigma_+$ such that $\gamma = 0$, $\eta \neq 0$, and $\delta \neq \pm|\eta|\sqrt{c_{r,l}^2 - u_{r,l}^2}$. We also assume that the Lopatinskii determinant does not vanish at X_0 and therefore does not vanish in a suitable neighborhood of X_0. Using the parametrization of the eigenspaces associated with the eigenmodes $\omega^{l,r}$, it is clear that one can construct a C^∞ mapping T such that, for all X in a neighborhood $\mathcal{V}$ of X_0, one has

$$\forall X \in \mathcal{V}\,, \quad T(X)^{-1} \mathcal{A}(X)\, T(X) = \begin{pmatrix} \omega_3^r & & & & & \\ & \omega_2^r I_{d-1} & & & \mathbf{0} & \\ & & \omega_1^r & & & \\ & & & \omega_1^l & & \\ & \mathbf{0} & & & \omega_2^l I_{d-1} & \\ & & & & & \omega_3^l \end{pmatrix} .$$

To achieve the construction of the symmetrizer in this case, we first need to study the behavior of ω_1^r and ω_3^r near X_0. We shall prove in section 5 that there exists a constant $c > 0$ such that

$$\forall\, X \in \mathcal{V}\,, \quad \begin{cases} -\mathrm{Re}\ \omega_3^r \geq c\gamma\,, \\ \ \ \mathrm{Re}\ \omega_1^r \geq c\gamma\,. \end{cases}$$

Similar results hold for the behavior of the eigenmodes ω_1^l and ω_3^l. Then it is sufficient to choose r under diagonal form

$$r = \begin{pmatrix} -1 & & & & & \\ & -I_{d-1} & & & \mathbf{0} & \\ & & \lambda & & & \\ & & & \lambda & & \\ & \mathbf{0} & & & \lambda I_{d-1} & \\ & & & & & \lambda \end{pmatrix} ,$$

and performing the same analysis as in the elliptic region yields the required properties on the symmetrizer r.

Construction of r in the neighborhood of Jordan points. Let $X_0 \in \Sigma_+$ such that $\gamma = 0$ and $\delta = \pm|\eta|\sqrt{c_r^2 - u_r^2}$. Using the same type of arguments as in the case $\gamma > 0$, one can prove that there exists a C^∞ mapping $T(X)$ with values in the set of $2(d+1) \times 2(d+1)$ invertible matrices, defined on a neighborhood of X_0, such that

$$\forall X \in \mathcal{V}\,, \quad T(X)^{-1}\mathcal{A}(X)\,T(X) = \begin{pmatrix} \omega_2^r I_{d-1} & & & & \\ & a_r(X) & & \mathbf{0} & \\ & & \omega_1^l & & \\ & \mathbf{0} & & \omega_2^l I_{d-1} & \\ & & & & \omega_3^l \end{pmatrix},$$

with $a_r(X)$ some 2×2 matrix satisfying

$$a_r(X_0) = \begin{pmatrix} \lambda_r & i \\ 0 & \lambda_r \end{pmatrix},$$

$\lambda_r = i\kappa_r$ being the double (purely imaginary) root of the polynomial

$$(c_r^2 - u_r^2)X^2 \pm 2i|\eta|u_r\sqrt{c_r^2 - u_r^2}X - u_r^2|\eta|^2\,,$$

which is nothing but (2.10) at point X_0. We shall show in section 5 that T can be chosen such that, for all $X \in \mathcal{V} \cap \{\gamma = 0\}$, $a_r(X)$ has purely imaginary coefficients. Furthermore, if $D_r(X)$ denotes the partial derivative of $a_r(X)$ with respect to γ, the lower left corner coefficient α_r of $D_r(X_0)$ is a nonzero real number.

We define $r(X)$ in the following way:

$$r(X) = \begin{pmatrix} -1 & & & & \\ & -I_{d-1} & & \mathbf{0} & \\ & & h_r(X) & & \\ & \mathbf{0} & & \lambda I_{d-1} & \\ & & & & \lambda \end{pmatrix},$$

λ once again being some real number greater than 1 fixed in what follows. Following the analysis of Kreiss [8, 20], we choose h_r of the form

$$h_r(X) = \underbrace{\begin{pmatrix} 0 & e_1 \\ e_1 & e_2 \end{pmatrix}}_{E} + \underbrace{\begin{pmatrix} f(X) & 0 \\ 0 & 0 \end{pmatrix}}_{F(X)} - i\gamma \underbrace{\begin{pmatrix} 0 & -g \\ g & 0 \end{pmatrix}}_{G},$$

where e_1, e_2, and g are real numbers and f is a C^∞ real-valued function that we shall fix in what follows. The Taylor expansion of $a_r(X)$ reads

$$a_r(X) = i\left(\kappa_r I + N - iB_r\left(\widetilde{X}\right)\right) + \gamma D_r\left(\widetilde{X}\right) + \gamma^2 M(X)\,,$$

where $\widetilde{X} = (\delta, \eta, 0)$ if $X = (\delta, \eta, \gamma)$, and $B_r(\widetilde{X}) = a_r(\widetilde{X}) - a_r(X_0)$; in the previous relation, N denotes the nilpotent matrix

$$N = \begin{pmatrix} 0 & 1 \\ 0 & 0 \end{pmatrix}.$$

We know that B_r reads

$$B_r\left(\widetilde{X}\right) = i\begin{pmatrix} b_{11} & b_{12} \\ b_{21} & b_{22} \end{pmatrix},$$

with real-valued C^∞ functions b_{ij} vanishing at X_0. We fix f by the following formula:

$$f(X) = \frac{e_1(b_{11} - b_{22}) + e_2 b_{21}}{1 + b_{12}}$$

so that f has the required property. Moreover, this choice of f implies that

$$(E + F(X))\left(N - iB_r\left(\widetilde{X}\right)\right)$$

is a real symmetric matrix. As a consequence, one gets

$$\text{Re}\,(h_r(X)\,a_r(X)) = \gamma\ \text{Re}\,\left(G\,N\,+\,E\,D_r\left(\widetilde{X}\right)\right) + \gamma\,L(X)\,,$$

where L is a C^∞ hermitian matrix which vanishes at X_0. The shape of E and G yields

$$\text{Re}\,(G\,N\,+\,E\,D_r(X_0)) = \begin{pmatrix} 0 & 0 \\ 0 & g \end{pmatrix} + \begin{pmatrix} e_1\alpha_r & * \\ * & * \end{pmatrix},$$

where quantities denoted by $*$ depend only on e_1 and e_2. We fix $e_1 = 1/\alpha_r$ and g sufficiently large so that

$$\text{Re}\,(h_r(X)\,a_r(X)) \geq c\gamma I\,.$$

This is possible as long as the choice of e_2 does not depend on g. In fact, e_2 will be fixed in order to give the estimate with respect to the boundary conditions $\widetilde{B}$, and the choice will not involve g. Indeed, the choice of h_r implies that

$$r(X_0) = \begin{pmatrix} -I_{d-1} & & & & & \\ & 0 & e_1 & & \mathbf{0} & \\ & e_1 & e_2 & & & \\ & & & \lambda & & \\ & \mathbf{0} & & & \lambda I_{d-1} & \\ & & & & & \lambda \end{pmatrix},$$

and a rather tedious analysis (essentially based on the Cayley–Hamilton theorem) shows that the stable subspace $\mathcal{E}^-(X_0)$ is spanned by the d first vectors of our new basis. Since the Lopatinskii determinant does not vanish in $\mathcal{V}$, we can therefore fix sufficiently large e_2 and λ (independently of g) to get an estimate of the type

$$r + C\widetilde{B}(X_0)^*\widetilde{B}(X_0) \geq cI\,.$$

An appropriate choice of g achieves the construction.

We now turn to the last case of points where the uniform stability condition fails. Note that the previous result on the behavior of the eigenmodes still hold because of

the properties of V_1^2. Indeed, one can diagonalize the symbol $\mathcal{A}$ in a neighborhood of $(V_1|\eta|, \eta, 0)$; in other words, we still have the existence of a C^∞ mapping T satisfying

$$\forall X \in \mathcal{V}\,, \quad T(X)^{-1}\mathcal{A}(X)\,T(X) = \begin{pmatrix} \omega_3^r & & & & & \\ & \omega_2^r I_{d-1} & & & \mathbf{0} & \\ & & \omega_1^r & & & \\ & & & \omega_1^l & & \\ & \mathbf{0} & & & \omega_2^l I_{d-1} & \\ & & & & & \omega_3^l \end{pmatrix}.$$

To recover the estimate of r with respect to the boundary conditions B, one has to choose r of the form

$$r = \begin{pmatrix} -\gamma^2 & & & & & \\ & -\gamma^2 I_{d-1} & & & \mathbf{0} & \\ & & \lambda & & & \\ & & & \lambda & & \\ & \mathbf{0} & & & \lambda I_{d-1} & \\ & & & & & \lambda \end{pmatrix}.$$

Using Lemma 3.3 and performing the same analysis as in the elliptic region yield the estimate

$$r(X) + C\widetilde{B}(X)^*\widetilde{B}(X) \geq c\gamma^2 I$$

for sufficiently large λ. Since r is diagonal, we immediately have the estimate

$$\text{Re}\,(r\,a(X)) \geq c\gamma^3 I\,,$$

and this completes the proof of Proposition 3.4.

4. Subsonic phase transitions in a van der Waals fluid. In this section, we consider the nonstandard initial boundary value problem (2.8) with boundary conditions given by (2.7). We follow the method adopted in section 3 and begin by recalling the main result of [4].

LEMMA 4.1 (Benzoni-Gavage [4]). *There exists a positive number V_0 such that, for all $(\delta, \eta, \gamma) \in \mathbb{R}^{d+1}$ satisfying $\gamma \geq 0$ and $(\delta, \gamma) \neq (\pm iV_0|\eta|, 0)$, one has*

$$\big\{(Z, \chi) \in \mathcal{E}^-(\delta, \eta, \gamma) \times \mathbb{C} \ \text{ s.t. } \ \chi\, b(\delta, \eta, \gamma) + M\,Z = 0\big\} = \{0\}\,,$$

and, for $\eta \neq 0$, the set

$$\big\{(Z, \chi) \in \mathcal{E}^-(\pm V_0|\eta|, \eta, 0) \times \mathbb{C} \ \text{ s.t. } \ \chi\, b(\pm V_0|\eta|, \eta, 0) + M\,Z = 0\big\}$$

is a one-dimensional subspace of $\mathbb{C}^{2d+3}$. If (Z, χ) belongs to this subspace, then

$$Z_r \in \mathbb{C}\begin{pmatrix} \rho_r(\tau + u_r\,\omega_3^r) \\ -c_r^2\, i\eta \\ -c_r^2\,\omega_3^r \end{pmatrix} \quad \textit{and} \quad Z_l \in \mathbb{C}\begin{pmatrix} \rho_l(\tau - u_l\,\omega_1^l) \\ -c_l^2\, i\eta \\ c_l^2\,\omega_1^l \end{pmatrix};$$

that is, Z_r has no component on the eigenspace associated with the eigenvalue ω_2^r. At all points of the form $(\pm V_0|\eta|, \eta, 0)$, both eigenmodes ω_3^r and ω_1^l have negative real part (which explains the designation "surface waves").

By definition, V_0^2 is the positive root of the polynomial

$$P_2(X) = \frac{c_r^2 c_l^2 - u_r^2 u_l^2}{u_r^2 u_l^2} X^2 + (c_r^2 - u_r^2 + c_l^2 - u_l^2) X - (c_r^2 - u_r^2)(c_l^2 - u_l^2)\,,$$

and the following inequalities hold:

$$V_0^2 < \min(c_r^2 - u_r^2, c_l^2 - u_l^2) \quad \textit{and} \quad V_0^2 < u_r u_l\,.$$

4.1. Elimination of the front. As we did in section 3 we begin by isolating the shock front in the last boundary condition of (2.9). This is stated as follows.

LEMMA 4.2. *There exists a C^∞ mapping Q defined on the half-space $\mathbb{R}^d \times \mathbb{R}^+ \setminus \{0\}$, homogeneous of degree 0, with values in the set of square $(d+2) \times (d+2)$ invertible matrices such that, for all $X \in \mathbb{R}^d \times \mathbb{R}^+ \setminus \{0\}$, the first $d+1$ components of the vector $Q(X)\, b(X)$ vanish.*

Proof. The Rankine–Hugoniot jump relations together with (2.7) yield the relations

$$b(\delta,\eta,\gamma) = \begin{pmatrix} -\tau[\rho] \\ ij[u]\eta \\ 0 \\ -\tau[u] \end{pmatrix} \text{ if } d=2 \quad \text{and} \quad b(\delta,\eta,\gamma) = \begin{pmatrix} -\tau[\rho] \\ ij[u]\eta_1 \\ ij[u]\eta_2 \\ 0 \\ -\tau[u] \end{pmatrix} \text{ if } d=3.$$

The mapping Q is first defined on the hemisphere Σ_+ and then extended by homogeneity. Note that we go back to the first definition of Σ_+ with a reference velocity $\widetilde{V}$ and a reference frequency $\widetilde{\gamma}$ to take the physical dimension of the quantities into account.

One easily checks that, for $d=2$, the matrix

$$Q(\delta,\eta,\gamma) = \begin{pmatrix} [u] & 0 & 0 & -[\rho] \\ 0 & \tau & 0 & ij\eta \\ 0 & 0 & 1 & 0 \\ 0 & i\widetilde{V}^2\eta & 0 & j\overline{\tau} \end{pmatrix}$$

satisfies all required properties. For $d=3$, one can choose, for instance,

$$Q(\delta,\eta,\gamma) = \begin{pmatrix} [u] & 0 & 0 & 0 & -[\rho] \\ 0 & \tau & 0 & -i\widetilde{V}\eta_2 & ij\eta_1 \\ 0 & 0 & \tau & i\widetilde{V}\eta_1 & ij\eta_2 \\ 0 & -i\widetilde{V}\eta_2 & i\widetilde{V}\eta_1 & \overline{\tau} & 0 \\ 0 & i\widetilde{V}^2\eta_1 & i\widetilde{V}^2\eta_2 & 0 & j\overline{\tau} \end{pmatrix}$$

which also satisfies all required properties. This completes the proof. ∎

We can therefore write boundary conditions for the linearized problem (2.8) in the equivalent way

$$\begin{pmatrix} B(\delta,\eta,\gamma) \\ \ell(\delta,\eta,\gamma) \end{pmatrix} V(0) + \chi \begin{pmatrix} \mathbf{0}_{d+1} \\ \beta(\delta,\eta,\gamma) \end{pmatrix} = Q(\delta,\eta,\gamma)\, G\,,$$

where $\beta(\delta,\eta,\gamma)$ is given by

$$\beta(\delta,\eta,\gamma) = -j[u]\widetilde{\gamma}\sqrt{\gamma^2 + \delta^2 + \widetilde{V}^2|\eta|^2} \neq 0\,,$$

and this relation holds for $d = 2$ and $d = 3$. We now turn to the study of the behavior of the restriction of $B(\delta, \eta, \gamma)$ to the stable subspace $\mathcal{E}^-$ in the neighborhood of the points where the uniform stability condition fails. According to Lemma 4.1, the symbol $\mathcal{A}$ is diagonalizable in the neighborhood of such points.

We decompose all vectors Z belonging to the stable subspace $\mathcal{E}^-$ on the three different eigenspaces, denoting by Z_3^r, Z_2^r, and Z_1^- the components of Z on the eigenspaces associated with the eigenmodes ω_3^r, ω_2^r, and ω_1^l. More precisely, we decompose Z as

$$Z = \begin{pmatrix} Z_r \\ Z_l \end{pmatrix} \quad \text{with} \quad Z_r = Z_3^r \begin{pmatrix} \rho_r(\tau + u_r\,\omega_3^r) \\ -c_r^2\, i\eta \\ -c_r^2\,\omega_3^r \end{pmatrix} + \begin{pmatrix} 0 \\ -\omega_2^r Z_2^r \\ i\eta \cdot Z_2^r \end{pmatrix}$$

$$\text{and} \quad Z_l = Z_1^l \begin{pmatrix} \rho_l(\tau - u_l\,\omega_1^l) \\ -c_l^2\, i\eta \\ c_l^2\,\omega_1^l \end{pmatrix}.$$

Then we have the following microlocal estimate.

LEMMA 4.3. *There exists a neighborhood $\mathcal{V}$ of $(V_0|\eta|, \eta, 0)$ and a constant $c > 0$ such that, for all $X \in \mathcal{V}$ and for all $Z \in \mathcal{E}^-(X)$, one has*

$$|B(X)\,Z|^2 \geq c\,\gamma^2 \left(|Z_3^r|^2 + |Z_1^l|^2\right) + c|Z_2^r|^2\,.$$

An analogous estimate holds in a neighborhood of points of the form $(-V_0|\eta|, \eta, 0)$.

Proof. According to Lemma 4.1 we know that the kernel of the restriction of B to the stable subspace $\mathcal{E}^-$ is a one-dimensional space whose vectors have no Z_2^r component. Therefore, in order to prove the stated result, it is again sufficient to prove that 0 is a *simple root* of the determinant of the restriction of B to $\mathcal{E}^-$.

To avoid overloading this paper, we shall detail only the different steps of the proof in the two-dimensional case. The three-dimensional case is carried out by similar arguments, but the calculations are much more complicated due to the expression of the mapping Q defined at the previous lemma which involves the complex conjugate $\overline{\tau}$ (which was not the case in section 3).

Let $d = 2$ and define (as in the proof of Lemma 3.1) the following quantities:

$$a_3^r = \tau u_r - (c_r^2 - u_r^2)\omega_3^r, \quad a_1^l = \tau u_l + (c_l^2 - u_l^2)\omega_1^l\,.$$

Keeping the definition of the complex square root $\mathcal{R}$ introduced in the proof of Lemma 3.1, we also define two quantities $W_{r,l}(V)$ as

$$W_{r,l}(V) = \mathcal{R}(V^2 - (c_{r,l}^2 - u_{r,l}^2))\,.$$

Because of the properties of V_0 (see Lemma 4.1), both expressions W_r and W_l depend analytically on V in a neighborhood of V_0, and it is shown in [4] that V_0 also satisfies

$$c_r^2 c_l^2 V_0^2 + u_r u_l W_l(V_0) W_r(V_0) = 0\,.$$

A direct calculation shows that V_0 is a simple root of the above analytical function (as mentioned in [5]).

Now let Z be any vector in the stable subspace $\mathcal{E}^-(\delta,\eta,\gamma)$ with components Z_3^r, Z_2^r, and Z_1^l on the eigenspaces associated with the eigenmodes ω_3^r, ω_2^r, and ω_1^l. We have

$$B(\delta,\eta,\gamma)\,Z = \begin{pmatrix} \rho_r[u]a_3^r - c_r^2[\rho]\tau & i(\rho_l+\rho_r)[u]\eta & c_l^2[\rho]\tau - \rho_l[u]a_1^l \\ 0 & j\widetilde{\gamma}\dfrac{\tau^2/u_r - u_r\eta^2}{\sqrt{\gamma^2+\delta^2+\widetilde{V}^2\eta^2}} & 0 \\ \rho_r(c_r^2\tau + u_r a_3^r) & 2ij\eta & -\rho_l(c_l^2\tau + u_l a_1^l) \end{pmatrix} \begin{pmatrix} Z_3^r \\ Z_2^r \\ Z_1^- \end{pmatrix},$$

from which we get the expression of the restriction of B to the stable subspace $\mathcal{E}^-$. Letting $X=(\delta,\eta,\gamma)$, one gets the expression of the determinant of the above matrix:

$$\det B^-(X) = h_2(\gamma)\left[c_r^2c_l^2V^2 + u_ru_lW_l(V)W_r(V)\right],$$

where h_2 is given by

$$h_2(\gamma) = \frac{-j\widetilde{\gamma}c_rc_l[\rho]^2|\eta|^4(V^2+u_r^2)}{u_r\sqrt{\gamma^2+V_0^2|\eta|^2+\widetilde{V}^2|\eta|^2}}.$$

With the preceding remarks, it is now a straightforward verification that the partial derivative of this determinant with respect to γ calculated at $\gamma=0$ is not zero, simply because $h_2(0)\neq 0$.

For the three-dimensional case ($d=3$), one proceeds in the same way. The expression of the determinant of the restriction B^- is

$$\det B^-(X) = h_3(\gamma)\left[c_r^2c_l^2V^2 + u_ru_lW_l(V)W_r(V)\right],$$

where h_3 is given by

$$h_3(\gamma) = \frac{j^2\widetilde{\gamma}^3c_rc_l[\rho]^2|\eta|^6\,\overline{\tau}}{(\gamma^2+V_0^2|\eta|^2+\widetilde{V}^2|\eta|^2)^{3/2}}\left[\frac{V^4}{u_r^2}+V^2-\widetilde{V}^2\left(\frac{V^2}{u_r^2}+1\right)\frac{\tau}{\overline{\tau}}\right].$$

Once again (since $h_3(0)\neq 0$) the partial derivative of the determinant with respect to γ calculated at $\gamma=0$ is not zero. ∎

4.2. A priori estimate on the linearized equations. We begin with a result of existence of a global Kreiss symmetrizer for system (2.8).

PROPOSITION 4.4. *There exist a C^∞ mapping R defined on the half-space $\mathbb{R}^d\times\mathbb{R}_+\setminus\{0\}$, homogeneous of degree 0, and two positive constants c and C such that*

$$\text{Re }(R(X)\mathcal{A}(X)) \geq \frac{c\gamma^2}{\sqrt{\gamma^2+\delta^2+|\eta|^2}},$$
$$R(X)+CB(X)^*B(X) \geq \frac{c\gamma^2}{\gamma^2+\delta^2+|\eta|^2}$$

for all $X=(\delta,\eta,\gamma)\in\mathbb{R}^d\times\mathbb{R}_+\setminus\{0\}$.

This result will be directly derived from the microlocal analysis developed in the next subsection. We simply make the following remark: as in the study of nonuniformly stable Lax shocks for isentropic Euler equations, the failure of the uniform

stability condition yields two types of losses of derivatives. Some regularity is lost in the interior domain, and some is lost on the boundary.

The previous result enables us to derive the second main result of this paper, namely the complete energy estimate on the linearized problem (2.8) in the case of subsonic phase transitions. We keep the notations introduced in subsection 3.2 for the domains Ω, for its boundary ω, and for the linearized operators $\mathcal{L}^\gamma$ and $\mathcal{B}^\gamma$.

THEOREM 4.5. *There exists a constant $C > 0$ such that, for all $U \in H^2(\Omega)$, for all $\varphi \in H^{3/2}(\omega)$, and for all $\gamma \geq 1$, the following estimate holds:*

$$\gamma^2(|\!|\!| U |\!|\!|^2_{0,\gamma} + \|U\|^2_{-1/2,\gamma} + \|\varphi\|^2_{1/2,\gamma}) \leq C\left(\frac{1}{\gamma^2}|\!|\!| \mathcal{L}^\gamma U |\!|\!|^2_{1,\gamma} + \|\mathcal{B}^\gamma(\varphi, U)\|^2_{1/2,\gamma}\right).$$

Proof. The result is a direct consequence of the existence of a symbolic symmetrizer R given by Proposition 4.4. Let $U \in H^2(\Omega)$ and $\varphi \in H^{3/2}(\omega)$. We denote $\widehat{U}(\xi, z)$ the Fourier transform of $U(t, y, z)$ with respect to the d first variables (t, y). We also define

$$F(t, y, z) = \mathcal{L}^\gamma U(t, y, z) \in H^1(\Omega)\,,$$
$$G(t, y) = \mathcal{B}^\gamma(\varphi, U) \in H^{1/2}(\omega)\,.$$

Then Lemma 4.1 ensures that there exists a constant $C_1 > 0$ such that

$$\lambda^{1,\gamma}(\xi)\,|\widehat{\varphi}(\xi)|^2 \leq C_1 \lambda^{-1,\gamma}(\xi)\left(|\widehat{U}(\xi, 0)|^2 + |\widehat{G}(\xi)|^2\right),$$

with $\xi = (\delta, \eta)$. Integrating with respect to ξ and using Plancherel's theorem yield the estimates

$$\begin{aligned}\|\varphi\|^2_{1/2,\gamma} &\leq C_1(\|U\|^2_{-1/2,\gamma} + \|\mathcal{B}^\gamma(\varphi, U)\|^2_{-1/2,\gamma}) \\ &\leq C_1(\|U\|^2_{-1/2,\gamma} + \gamma^{-2}\|\mathcal{B}^\gamma(\varphi, U)\|^2_{1/2,\gamma})\,.\end{aligned}$$

Furthermore, $\widehat{U}$ satisfies the ordinary differential equation

$$\frac{d\widehat{U}}{dz} = \mathcal{A}(\xi, \gamma)\,\widehat{U} + \mathcal{A}_d^{-1}\,\widehat{F}\,.$$

We take the scalar product of this equation by $\lambda^{1,\gamma}(\xi)\,R(\xi, \gamma)\,\widehat{U}$ and integrate with respect to $\xi = (\delta, \eta) \in \mathbb{R}^d$. Then we integrate with respect to z from 0 to $+\infty$ and take the real part of the corresponding equality. Using the properties of the symmetrizer R, we get

$$-2\ \mathrm{Re}\ \left\langle\left\langle \widehat{U}, \lambda^{1,\gamma}(\xi)\,\mathcal{A}_d^{-1}\widehat{F}\right\rangle\right\rangle \geq 2c\gamma^2|\!|\!| U |\!|\!|^2_{0,\gamma} + 2c\gamma^2\|U\|^2_{-1/2,\gamma} - C_2\|\mathcal{B}^\gamma(\varphi, U)\|^2_{1/2,\gamma}\,.$$

The Cauchy–Schwarz inequality yields the estimate

$$-2\ \mathrm{Re}\ \left\langle\left\langle \widehat{U}, \lambda^{1,\gamma}(\xi)\,\mathcal{A}_d^{-1}\widehat{F}\right\rangle\right\rangle \leq c\gamma^2|\!|\!| U |\!|\!|^2_{0,\gamma} + \frac{C_3}{\gamma^2}|\!|\!| \mathcal{L}^\gamma U |\!|\!|^2_{1,\gamma}\,.$$

This last inequality added to the previous estimate on the front φ enables us to conclude. ∎

4.3. Construction of a Kreiss symmetrizer. We first construct a microlocal symmetrizer from which we will deduce the result of Proposition 4.4.

PROPOSITION 4.6. *For all $X_0 \in \Sigma_+$, there exists an open neighborhood $\mathcal{V}$ of X_0 and matrices $r(X)$, $T(X)$ of class C^∞ with respect to $X \in \mathcal{V}$ which satisfy the following:*

$r(X)$ is hermitian,

$T(X)$ is invertible, and, defining $a(X) = T(X)^{-1}\mathcal{A}(X)\,T(X)$, $\widetilde{B}(X) = B(X)\,T(X)$, there exist two positive constants C and c such that

$$\begin{aligned} &\text{Re }(r(X)\,a(X)) \geq c\gamma^2 I\,,\\ &r(X) + C\widetilde{B}(X)^*\widetilde{B}(X) \geq c\gamma^2 I\,. \end{aligned}$$

Proof. Many steps of the proof are identical to what has been done in the case of Lax shocks, and we shall not repeat them: in the so-called elliptic region $\{\gamma > 0\}$ and at Jordan points, the construction is entirely similar. Note that the equality $c_r^2 - u_r^2 = c_l^2 - u_l^2$ is not precluded in the context of phase transitions, though it is highly unlikely. In such a case, the reduction of $\mathcal{A}$ would involve two distinct Jordan blocks, but the microlocal construction of r would be a direct extension of what has been done in the case of a single.

The only difference relies on the properties of the symbol $\mathcal{A}$ in the neighborhood of the points where the uniform stability condition fails. Let $X_0 = (\pm V_0|\eta|, \eta, 0)$ be a point where the Lopatinskii determinant vanishes. We already know that $\mathcal{A}$ is diagonalizable in a neighborhood $\mathcal{V}$ of X_0 and that $\mathcal{V}$ may be suitably chosen so that ω_3^r and ω_1^l have negative real part in $\mathcal{V}$. We thus choose r of the form

$$r(X) = \begin{pmatrix} -\gamma^2 & & & & & \\ & -I_{d-1} & & & \mathbf{0} & \\ & & -\gamma^2 & & & \\ & & & \lambda & & \\ & \mathbf{0} & & & \lambda I_{d-1} & \\ & & & & & \lambda \end{pmatrix},$$

where λ is a real number greater than 1 which will be fixed in what follows. Since there exists a C^∞ invertible matrix $T(X)$ such that

$$\forall X \in \mathcal{V}\,, \quad T(X)^{-1}\mathcal{A}(X)\,T(X) = \begin{pmatrix} \omega_3^r & & & & & \\ & \omega_2^r I_{d-1} & & & \mathbf{0} & \\ & & \omega_1^l & & & \\ & & & \omega_3^l & & \\ & \mathbf{0} & & & \omega_2^l I_{d-1} & \\ & & & & & \omega_1^r \end{pmatrix},$$

we have Re $(r(X)\,a(X)) \geq c\gamma^2 I$ for all X in $\mathcal{V}$. We now have to fix λ in order to get the estimate on the boundary conditions. For this, we let $Z \in \mathbb{C}^{2(d+1)}$ and define Z^- (resp., Z^+) as the vector formed by the $(d+1)$ first (resp., last) components of Z. Writing $Z^- = (Z_1^-, \check{Z}^-, Z_{d+1}^-)$, Lemma 4.3 ensures that there exists a constant $c > 0$ which does not depend on Z such that

$$c\gamma^2\left(|Z_1^-|^2 + |Z_{d+1}^-|^2\right) + c|\check{Z}^-|^2 \leq C\left(|Z^+|^2 + |\widetilde{B}(X)\,Z|^2\right).$$

By the same techniques as used in the construction of the symmetrizer in the elliptic region, it is clear that, for a sufficiently large λ, there exists a constant $C > 0$ such that the following estimate holds:

$$r(X) + C\widetilde{B}(X)^*\widetilde{B}(X) \geq c\gamma^2 I\,.$$

This completes the proof of Proposition 4.6.

We can now turn to the proof of Proposition 4.4, using the gluing technique developed in [8, 30]. We fix a finite covering $(\mathcal{V}_i)_{1\leq i\leq I}$ of Σ_+ by open sets defined in Proposition 4.6. Let $(\psi_i)_{1\leq i\leq I}$ be a partition of unity associated with this covering (with the same properties as stated in section 3). We define a C^∞ mapping R on Σ_+ by the following formula:

$$\forall X \in \Sigma_+, \quad R(X) = \sum_{i=1}^{I} \psi_i^2(X) \left(T_i(X)^{-1}\right)^* r_i(X)\, T_i(X)^{-1}$$

so that R has values in the set of hermitian matrices. Moreover, we have

$$\begin{aligned}
\text{Re } (R(X)\mathcal{A}(X)) &\geq c\gamma^2 \sum_{i=1}^{I} \psi_i^2(X) \left(T_i(X)^{-1}\right)^* T_i(X)^{-1}\,,\\
R(X) + CB(X)^*B(X) &\geq c\gamma^2 \sum_{i=1}^{I} \psi_i^2(X) \left(T_i(X)^{-1}\right)^* T_i(X)^{-1}
\end{aligned}$$

for some positive constants c and C. It is clear that, for all X in the compact set Σ_+, the matrix

$$\sum_{i=1}^{I} \psi_i^2(X) \left(T_i(X)^{-1}\right)^* T_i(X)^{-1}$$

is hermitian positive definite. We can therefore conclude that there exists positive constants c and C such that, for all X in Σ_+,

$$\begin{aligned}
\text{Re } (R(X)\,\mathcal{A}(X)) &\geq c\gamma^2 I\,,\\
R(X) + CB(X)^*B(X) &\geq c\gamma^2 I\,.
\end{aligned}$$

The result of Proposition 4.4 follows by extending R in a homogeneous function of degree 0 and using the homogeneity properties of symbols $\mathcal{A}$ and B. □

We point out that the result of Theorem 4.5 is not optimal in the sense that we could define new spaces to get a refined estimate, since only 1/2 of a derivative is lost in the interior domain (and only in the tangential variables). However, we have preferred to state the result in this way to make it easier to visualize. Furthermore, the proof of the theorem appears much more simple than the proof of Theorem 3.5 where attention needs to be paid to get the best result possible.

5. Some technical lemmas. In this section, we prove three results used in the proof of Propositions 3.4 and 4.6. Though our proof uses some particular properties of system (2.1), they are essentially the same as in the general case; see [8, 20, 32].

We first begin by studying the behavior of the eigenmodes ω_1^r and ω_3^r in a neighborhood of points $X_0 = (\delta, \eta, 0)$.

LEMMA 5.1. *Let $X_0 \in \Sigma_+$ such that $\gamma = 0$, $\eta \neq 0$, and $\delta \neq \pm|\eta|\sqrt{c_r^2 - u_r^2}$. There exists a neighborhood $\mathcal{V}$ of X_0 in Σ_+ and a positive constant c such that*

$$\forall\, X \in \mathcal{V}\,, \quad \begin{cases} -\mathrm{Re}\ \omega_3^r \geq c\gamma\,, \\ \mathrm{Re}\ \omega_1^r \geq c\gamma\,. \end{cases}$$

Proof. Let $X_0 = (\delta_0, \eta_0, 0)$ satisfy the assumptions of the lemma. Using the proof of Proposition 3.4, we already know that $\mathcal{A}$ is diagonalizable in a neighborhood $\mathcal{V}$ of X_0:

$$\forall X \in \mathcal{V}\,, \quad T(X)^{-1}\mathcal{A}(X)\,T(X) = \begin{pmatrix} \omega_3^r & & & & & \\ & \omega_2^r I_{d-1} & & & \mathbf{0} & \\ & & \omega_1^r & & & \\ & & & \omega_1^l & & \\ & \mathbf{0} & & & \omega_2^l I_{d-1} & \\ & & & & & \omega_3^l \end{pmatrix}.$$

If both eigenmodes ω_1^r and ω_3^r are not purely imaginary at X_0, the result comes from a simple continuity argument. We shall therefore assume that both eigenmodes are purely imaginary at X_0. We fix $\eta = \eta_0$ and define

$$Q(\delta, \gamma, \omega) = (\omega + i\omega_1^r(X))(\omega + i\omega_3^r(X))(\omega + i\omega_2^r(X))^{d-1}\,. \tag{5.1}$$

For $\tau = \gamma + i\delta$ close to $i\delta_0$, the eigenmodes ω_k^r are pairwise distinct, and the hyperbolicity of the system (2.1) shows that, for all $\xi \in \mathbb{R}$, Q is given by

$$\begin{aligned} Q(\delta, \gamma, \xi) = \alpha \Big[\delta - i\gamma + \Big(\xi u_r + c_r\sqrt{|\eta_0|^2 + \xi^2}\Big)\Big] \\ \Big[\delta - i\gamma + \Big(\xi u_r - c_r\sqrt{|\eta_0|^2 + \xi^2}\Big)\Big]\,(\delta - i\gamma + \xi u_r)^{d-1} \end{aligned}$$

for some real constant $\alpha \neq 0$. Thus, for all real ξ, we have

$$Q(\delta, 0, \xi) \in \mathbb{R} \quad \text{and} \quad \frac{\partial Q}{\partial \gamma}(\delta, 0, \xi) \in i\mathbb{R}\,. \tag{5.2}$$

Moreover, the definition of Q gives the relation

$$\frac{\partial Q}{\partial \gamma}(\delta_0, 0, -i\omega_1^r(X_0)) = i\frac{\partial \omega_1^r}{\partial \gamma}(X_0)(-i\omega_1^r(X_0) + i\omega_3^r(X_0))(-i\omega_1^r(X_0) + i\omega_2^r(X_0))^{d-1}\,,$$

from which we conclude that the partial derivative $\partial_\gamma \omega_1^r(X_0)$ is a real number. A similar result holds for ω_3^r. We are now going to prove that this partial derivative is not zero. Equation (2.10) reads

$$(c_r^2 - u_r^2)(\omega_1^r)^2 - 2\tau u_r \omega_1^r - \tau^2 - c_r^2|\eta_0|^2 = 0\,,$$

and thus differentiating with respect to γ yields the equality

$$(c_r^2 - u_r^2)2\omega_1^r \frac{\partial \omega_1^r}{\partial \gamma} - 2u_r\omega_1^r - 2\tau u_r \frac{\partial \omega_1^r}{\partial \gamma} - 2\tau = 0\,.$$

Since ω_1^r and ω_2^r are distinct, for all $X \in \mathcal{V}$, it is clear that $\partial_\gamma \omega_1^r$ does not vanish at X_0. The end of the proof relies on a simple Taylor expansion of ω_1^r at X_0, using the fact that ω_1^r is of positive real part for $\gamma > 0$. ∎

We now turn to the study of the reduced symbol in the neighborhood of Jordan points. Let $X_0 = (\delta_0, \eta_0, 0)$ be such that

$$\delta_0 = |\eta_0|\sqrt{c_r^2 - u_r^2}$$

so that, according to the proof of Proposition 3.4, we have

$$T(X)^{-1}\mathcal{A}(X)\,T(X) = \begin{pmatrix} \omega_2^r I_{d-1} & & & \\ & a_r(X) & \mathbf{0} & \\ & & \omega_1^l & \\ & \mathbf{0} & & \omega_2^l I_{d-1} \\ & & & & \omega_3^l \end{pmatrix},$$

with $a_r(X)$ some 2×2 matrix satisfying

$$a_r(X_0) = \begin{pmatrix} \lambda_r & i \\ 0 & \lambda_r \end{pmatrix} = \lambda_r I_2 + iN\,.$$

Recall that $\lambda_r = i\kappa_r$ is the double root of the polynomial

$$(c_r^2 - u_r^2)X^2 \pm 2i|\eta|u_r\sqrt{c_r^2 - u_r^2}X - u_r^2|\eta|^2\,.$$

With these notations, we have the following result.

LEMMA 5.2. *Defining $D_r(X) = \frac{\partial a_r}{\partial \gamma}(X)$ for X close to X_0, then the lower left corner coefficient α_r of $D_r(X_0)$ is a nonzero real number.*

Proof. We fix $\eta = \eta_0$ and let $\tau = \gamma + i\delta$ be close to $i\delta_0$. We define a polynomial Q by (5.1) (see the proof of Lemma 5.1) and two polynomials Q_r and $\widetilde{Q}$ by the following formulas:

$$\begin{aligned} Q_r(\delta, \gamma, \omega) &= \det\left[\omega I_2 + i a_r(\delta, \eta_0, \gamma)\right], \\ \widetilde{Q}(\delta, \gamma, \omega) &= (\omega + i\omega_2^+)^{d-1} = (\omega - i\tau/u_r)^{d-1} \end{aligned}$$

so that $Q = Q_r\widetilde{Q}$. We already know by relation (5.2) that, for all real ξ,

$$Q(\delta, 0, \xi) \in \mathbb{R} \quad \text{and} \quad \frac{\partial Q}{\partial \gamma}(\delta, 0, \xi) \in i\mathbb{R}\,.$$

It is also clear that, for $\xi \in \mathbb{R}$, one has $\widetilde{Q}(\delta, 0, \xi) \in \mathbb{R}$.

For δ close to δ_0, $Q(\delta, 0, \omega)$ seen as a polynomial in ω has real coefficients and therefore has real roots or conjugate complex roots. Moreover, $\widetilde{Q}(\delta, 0, \omega)$ has exactly one real root, so $Q_r(\delta, 0, \omega)$ has two real roots or two conjugate complex roots. Thus, for δ close to δ_0, we have

$$\forall\, \xi \in \mathbb{R}\,, \quad Q_r(\delta, 0, \xi) \in \mathbb{R}\,. \tag{5.3}$$

The definition of λ_r yields

$$\frac{\partial Q}{\partial \gamma}(\delta_0, 0, -i\lambda_r) = \widetilde{Q}(\delta_0, 0, -i\lambda_r)\,\frac{\partial Q_r}{\partial \gamma}(\delta_0, 0, -i\lambda_r)\,,$$

and since $\lambda_r \neq -i\delta_r/u_r$ we can conclude that $\partial_\gamma Q_r(\delta_0, 0, -i\lambda_r)$ is a purely imaginary number. It is clear that 0 is a simple root of the polynomial $Q(\delta_0, \cdot, -i\lambda_r)$,

and therefore the partial derivative $\partial_\gamma Q_r(\delta_0, 0, -i\lambda_r)$ is a nonzero purely imaginary number.

To complete the proof, we note that

$$ia_r(X_0) = i\lambda_r I_2 \begin{pmatrix} 0 & -1 \\ 0 & 0 \end{pmatrix},$$

from which we get

$$\frac{\partial Q_r}{\partial \gamma}(\delta_0, 0, -i\lambda_r) = i\alpha_r \in i\mathbb{R} \setminus \{0\}. \qquad \square$$

The last thing to check is the invertible matrix $T(X)$ may be chosen in such a way that $a_r(X)$ has purely imaginary coefficients for $X \in \mathcal{V} \cap \{\gamma = 0\}$. We base our proof of this result on a technique developed in [32]. Let X_0 be the triple $(|\eta_0|\sqrt{c_r^2 - u_r^2}, \eta_0, 0)$. For $X = (\delta, \eta, \gamma)$ close to X_0, we define $\widetilde{X} = (\delta, \eta, 0)$. With these notations, we have the following result.

LEMMA 5.3. *There exists a C^∞ change of basis of $\mathbb{C}^2$ such that, for all X close to X_0, $a_r(\widetilde{X})$ has purely imaginary coefficients.*

Proof. Let (f_1, f_2) be the canonical basis of $\mathbb{C}^2$. For X close to X_0, define

$$N = \begin{pmatrix} 0 & 1 \\ 0 & 0 \end{pmatrix}, \quad B_r(X) = a_r(X) - a_r(X_0).$$

Since $B_r(X_0)$ is zero, the couple of vectors $(f_1' = (N - iB_r(\widetilde{X}))\, f_2, f_2)$ forms a basis of $\mathbb{C}^2$ for X close to X_0, and f_1' is a C^∞ vector-valued function of X. In this new basis, $N - iB_r(\widetilde{X})$ reads

$$\begin{pmatrix} b_1 & 1 \\ b_2 & 0 \end{pmatrix},$$

and the characteristic polynomial of $N - iB_r(\widetilde{X})$ is therefore

$$P(\xi) = \xi^2 - b_1\xi - b_2.$$

We also have the relation $N - iB_r(\widetilde{X}) = -ia_r(\widetilde{X}) - \kappa_r I_2$, from which we get

$$P(\xi) = \det\left[ia_r(\widetilde{X}) + (\kappa_r + \xi)I_2\right],$$

and relation (5.3) asserts that P has real coefficients. This completes the proof. $\square$

6. Concluding remarks. In both problems detailed in this paper, a weak stability result has been proved. Though the present study is just a constant coefficients analysis, it indicates the way to follow in order to get a nonlinear existence result. (We warn the reader that such a result is not guaranteed at the present time.)

Since both problems give rise to losses of derivatives on the solution of the corresponding linearized system, special attention should be paid when dealing with a variable coefficients linearized system. The usual linearized system (2.8) used in [25, 27, 30] is not appropriate in this case, since the right-hand side would involve some terms whose Sobolev norm needs to be controlled when one wants to construct an iterative scheme. Higher order terms in the Taylor expansion should therefore

be taken into account when linearizing equations (2.1) around a variable coefficients state $\overline{U}$.

It appears from Theorem 4.5 that the case of phase transitions in a van der Waals fluid is rather similar to the problem treated in [34]. The study of the variable linearized system should be carried out by using a parameter version of paradifferential calculus as introduced in [30].

To conclude, it is known since Majda's work that planar discontinuities for a multidimensional scalar conservation law are only weakly stable: since our method relies first on the elimination of the shock front, it cannot apply in the context of scalar conservation laws. Moreover, instability in this case is associated with the shock front symbol which is a second reason why we cannot deal with such equations. Nevertheless, we postpone the extension of the previous results to the general case of a multidimensional system to a future work.

SMOOTHNESS OF CENTER MANIFOLDS FOR MAPS AND FORMAL ADJOINTS FOR SEMILINEAR FDES IN GENERAL BANACH SPACES*

TERESA FARIA†, WENZHANG HUANG‡, AND JIANHONG WU§

Abstract. We develop a formal adjoint theory for retarded linear functional differential equations in Banach spaces and establish the existence and smoothness of center manifolds for nonlinearly perturbed equations. The hypotheses imposed here are significantly weaker than those that usually appear in the literature referring to semigroups for abstract functional differential equations, and the smoothness of the center manifolds for nonlinear perturbed equations is derived from our general results on the smoothness of center manifolds for maps in infinite-dimensional Banach spaces.

Key words. functional differential equations in Banach spaces, formal adjoint equations, resolvent compact operators, perturbations, center manifolds, smoothness

1. Introduction.

We consider the autonomous linear functional differential equations (FDEs) of retarded type,

$$\dot{u}(t) = A_T u(t) + L(u_t), \qquad u(t) \in X, \tag{1.1}$$

and the nonlinearly perturbed systems

$$\dot{u}(t) = A_T u(t) + L(u_t) + F(u_t), \tag{1.2}$$

where X is a Banach space, $r > 0$, $C := C([-r, 0]; X)$ is the Banach space of continuous mappings from $[-r, 0]$ to X with the sup norm, $u_t \in C$ is defined by $u_t(\theta) = u(t + \theta)$ for $t \in \mathbb{R}$ and $\theta \in [-r, 0]$, $L : C \longrightarrow X$ is a bounded linear operator, $A_T : D(A_T) \subset X \longrightarrow X$ is the infinitesimal generator of a compact C_0-semigroup of linear operators on X, and F is a sufficiently smooth nonlinear map with $F(0) = 0, DF(0) = 0$.

In the last two decades, there has been an increasing interest in retarded FDEs in Banach spaces. Typically, these equations depend on both spatial and temporal variables, with the time-dependence involving discrete or distributed delays. Such equations arise from a variety of situations in population dynamics and take the abstract form (1.1) or (1.2), where a diffusion term $d\Delta v(t, x)$ with $d = (d_1, \ldots, d_n) \in \mathbb{R}^n$ defines $A_T u(t) = d\Delta v(t, x)$ for $u(t)(x) := v(t, x), x \in \mathbb{R}^n$. See Wu [21] for more details.

The purpose of the present work is to establish two necessary technical tools—a formal adjoint theory for equations of type (1.1) and the existence and smoothness of center manifolds for nonlinearly perturbed equation (1.2)—in order to develop a normal form theory on invariant manifolds of (1.2).

Several extensions of the formal adjoint and invariant manifold theory for FDEs in $\mathbb{R}^n$ (see Hale [8]) to infinite-dimensional Banach spaces have been developed in different frameworks. Related to our present work is the paper of Travis and Webb [18], where the authors initiated a formal adjoint theory for linear equations of the form (1.1); other related work includes Arino and Sanchez [1], Huang [9], Nakagiri [13], Schumacher [15], Shin and Naito [16], Wu [21], and Yamamoto and Nakagiri [22], to mention a few. We should particularly remark that a quite complete theory has also been developed for FDEs in Banach spaces of type (1.1) and (1.2) regarding duality, formal adjoint theory, and invariant manifolds (cf., e.g., Memory [12], Lin, So, and Wu [11], Wu [21], and Faria [5]) under some quite severe constraints. In fact, assume that the eigenvectors of A_T form a basis for X in the following sense: if $\mu_k, k \in \mathbb{N}$, are the eigenvalues of A_T with associated eigenvectors $\beta_k, k \in \mathbb{N}$, then every $x \in X$ is written in a unique way as $x = \sum_{k\in\mathbb{N}} x_k$, where $x_k \in span\{\beta_k\}, k \in \mathbb{N}$, with $A_T x = \sum_{k\in\mathbb{N}} \mu_k x_k$. Assume also that $L(\varphi\beta_k) \in span\{\beta_k\}$ for all $\varphi \in C([-r, 0]; \mathbb{R})$ and all eigenvectors β_k. Then it is possible to decompose the characteristic equation of the abstract FDE into a sequence of characteristic equations in $\mathbb{R}$. This decomposition yields a decomposition of (1.1) into a sequence of scalar FDEs, to which the standard formal adjoint theory for FDEs in $\mathbb{R}^n$ of Hale [8] can be applied (see [11], [12], [21], and other references therein). A slightly weaker hypothesis was considered in [5], as follows. In addition to the assumption that the eigenvectors of A_T form a basis for X, suppose now that the set of eigenvalues of A_T can be written as $\{\mu_k^{i_k} : k \in \mathbb{N}, i_k = 1, \dots, p_k\}$; for each $k \in \mathbb{N}$, let B_k be the generalized eigenspace for A_T associated with the block of eigenvalues $\{\mu_k^{i_k} : i_k = 1, \dots, p_k\}$, and assume that $L(\mathcal{B}_k) \subset B_k$, where $\mathcal{B}_k = \{\varphi \in C : \varphi(\theta) \in B_k \text{ for } \theta \in [-r, 0]\}$. This means that the eigenvalues of A_T can be organized by blocks in such a way that L does not mix the modes of the generalized eigenspaces associated with the eigenvalues in each block. Under these conditions, (1.1) is decomposed into a sequence of FDEs in finite-dimensional spaces (whose dimensions are now equal to the dimensions of the generalized eigenspaces B_k associated with each block $\{\mu_k^{i_k} : i_k = 1, \dots, p_k\}$), and again one can apply the adjoint theory for FDEs in $\mathbb{R}^n$. However, these hypotheses impose severe restrictions on the applicability of the approach to a wide range of problems arising from population dynamics. For instance, even if A_T is an n-dimensional elliptic operator with $n > 1$, it is unknown whether the eigenfunctions of A_T form a basis of X. Moreover, the above assumption that the linear operator L does not mix the modes of the eigenfunction spaces of the operator A_T is not realistic, for this almost implies that the operator L is a scalar multiplication.

Our goal is to develop a complete formal adjoint theory and center manifold theory without the aforementioned restrictions. The main sources of inspiration for our work on adjoint theory presented here are the work of Travis and Webb [18] for (1.1) and the work of Arino and Sanchez [1] for equations of the form $\dot{u}(t) = L(u_t)$, with $L : C \longrightarrow X$ being a bounded linear operator. More specifically, Travis and Webb [18] set the basis for an adjoint theory by introducing an adequate bilinear form $\langle\langle \cdot, \cdot \rangle\rangle$, which serves as the formal duality between C and its dual C^*, as well as an adequate definition of formal adjoint equation for (1.1). However, their theory was not completed in the following sense: in order to set a suitable framework to construct normal forms for

perturbed FDE (1.2), a formal adjoint theory should eventually provide an analytic formula for the decomposition of the phase space C by a nonempty finite set Λ of characteristic values for (1.1). Here, we present results that enable us to decompose C by Λ as the direct sum $C = P \oplus Q$, where P is the generalized eigenspace associated with Λ and $Q = \{\varphi \in C : \langle\langle \psi, \varphi \rangle\rangle = 0 \text{ for all } \psi \in P^*\}$, where P^* is the generalized eigenspace associated with Λ for the formal adjoint equation.

Since we deal with infinite-dimensional Banach spaces X, rather than finite-dimensional ones, our main difficulty is to use the formal duality to relate the generalized eigenspaces of the infinitesimal generator for the semigroup induced by the solutions of (1.1) with the generalized eigenspaces of its formal adjoint. Without having to impose further hypotheses on X or on the operators A_T and L, we succeeded in expressing the kernel and range for these generalized eigenspaces in terms of the kernel and range for some auxiliary operators. (This is a generalization of the operators introduced by Hale [8] for the case $X = \mathbb{R}^n$.) It turns out that these auxiliary operators are crucial for deriving the decomposition $C = P \oplus Q$ by a nonempty finite set Λ of characteristic eigenvalues because, as we shall prove, they have compact resolvents and closed ranges.

For the sake of exposition, we include some definitions and results from [18]. But we should emphasize that some results about duality in [18] were proven under stronger hypotheses than the ones assumed in this paper. Namely, in the present work the Banach space X is not required to be reflexive; also in [18, Propositions 4.14 and 4.15], some conditions on the characteristic operator were imposed in order to derive some results, such as that the point spectra for the infinitesimal generator of the semigroup defined by the mild solutions of (1.1) and for its formal adjoint coincide. Our techniques and results on formal adjoints are different from those in [1] for equations of type $\dot{u}(t) = L(u_t)$ (i.e., where A_T is absent). In [1] the authors considered only elements in Λ that are not in the essential spectrum, so that their auxiliary operators are Fredholm operators, while in the present paper we prove that the corresponding auxiliary operators have compact resolvents and closed ranges (two key points in establishing a Fredholm alternative result) from which the decomposition $C = P \oplus Q$ is deduced. Also, potential applications of the results in the present paper are much different from those of [1]. For instance, as we have already mentioned, (1.1) includes reaction-diffusion equations with delays as special cases.

As mentioned above, our second goal is to obtain the existence and smoothness of the center manifold. We notice that center manifolds are of particular interest in applications since the qualitative behavior of the solutions of a nonlinear equation in a neighborhood of an equilibrium can be described by the flow on these manifolds. See, for example, Carr [3]. See also Vanderbauwhede and van Gils [20], Vanderbauwhede and Iooss [19], and Diekmann et al. [4] for the theory of center manifolds for FDEs in $\mathbb{R}^n$. As already observed in the aforementioned papers, the phase space for FDE (1.2) is a Banach space which does not admit a smooth cut-off function, and thus it is a very challenging task to obtain the smoothness of center manifolds. Such a difficult issue was addressed for FDEs in $\mathbb{R}^n$ by Vanderbauwhede and van Gils [20], and the details are presented by Diekmann et al. [4]. In the recent work of Krisztin, Walther, and Wu [10], the existence and C^1-smoothness of various invariant manifolds for C^1-maps in general Banach spaces were established. Here we utilize some of the ideas in [10] and prove general C^k-smoothness for C^k-maps, with k being an arbitrary positive integer, and we apply this general smoothness result for maps to obtain the existence and C^k-smoothness of center manifolds for the semiflow generated by (1.2). Such a general

smoothness result is necessary for the normal form theory to be developed later, as the normal forms usually involve Taylor series expansions of various nonlinear maps involved in the center manifold reduction.

Although our final goal is to use formal adjoints and center manifolds as basic tools to develop a normal form theory for equations in the form (1.2), we note that the results presented here are important by themselves, and a decomposition of the phase space for linear equations and center manifolds for semilinear equations could be applied in different frameworks of qualitative theory for FDEs.

The paper is organized as follows. In section 2, some definitions and results are recalled, most of them from [18]. Sections 3 and 4 address a complete formal adjoint theory for FDEs (1.1): the auxiliary operators are introduced in section 3, and we derive some important properties of their spectra and resolvents; in section 4, a Fredholm alternative result is presented, and the phase space C is decomposed by a nonempty finite set Λ of characteristic eigenvalues of (1.1) by using the formal adjoint equation. Section 5 develops general results for the smoothness of center-stable and center-unstable manifolds for maps in Banach spaces, and section 6 applies these results to obtain the existence and regularity of center manifolds for perturbed FDE (1.2) at the zero equilibrium.

Because of space limitations, other important properties of the center manifold, such as the local invariance and attractivity, will be studied in a separate paper.

We now list notation that will be used throughout the paper. For a given Banach space X and for a linear operator A from its domain in X to X, we shall use $D(A)$, $R(A)$, and $N(A)$ to denote the domain, range, and kernel of A, respectively. The spectrum, point spectrum, and resolvent of A are considered as subsets of $\mathbb{C}$ and are denoted by $\sigma(A)$, $\sigma_P(A)$, and $\rho(A)$, respectively. If $\lambda \in \sigma_P(A)$, then $\mathcal{M}_\lambda(A)$ is the generalized eigenspace associated with λ.

2. Preliminary results and definitions. Consider

$$\dot{u}(t) = A_T u(t) + L(u_t), \qquad t \geq 0, \quad u(t) \in X, \tag{2.1}$$

where X is a Banach space over the field $\mathbb{C}$, $r > 0$, $C := C([-r, 0]; X)$ is the Banach space of continuous mappings from $[-r, 0]$ to X with the sup norm, $L : C \longrightarrow X$ is a bounded linear operator, and $A_T : D(A_T) \subset X \longrightarrow X$ is linear. As usual, $u_t \in C$ denotes the shifted restriction of u to $[t - r, t]$, i.e., $u_t(\theta) = u(t + \theta)$ for $-r \leq \theta \leq 0$. We require the following assumptions:

(H1) A_T generates a C_0-semigroup of linear operators $\{T(t)\}_{t\geq 0}$ on X, with $\|T(t)\| \leq Me^{\omega t}$ $(t \geq 0)$ for some $M \geq 1$, $\omega \in \mathbb{R}$.

(H2) $T(t)$ is a compact operator for each $t > 0$.

For $u \in C([-r, \infty); X)$, u is said to be a *mild solution* of (2.1) with initial condition $\varphi \in C$ if it satisfies

$$\begin{cases} u(t) = T(t)\varphi(0) + \int_0^t T(t - s)L(u_s)ds, & t \geq 0, \\ u_0 = \varphi. \end{cases} \tag{2.2}$$

(See, e.g., [23, p. 75] for the definition of integral used here.) It is known that the initial value problem (2.2) has a unique solution denoted by $u(\varphi)(t), t \in [-r, \infty)$. Moreover, for the operators $U(t), t \geq 0$, given by

$$U(t) : C \longrightarrow C, \qquad U(t)\varphi = u_t(\varphi), \tag{2.3}$$

from Propositions 2.4, 3.1, and 3.2 in Travis and Webb [18], we have the following proposition.

PROPOSITION 2.1. *Assume* (H1). *Then* $\{U(t)\}_{t\geq 0}$ *is a* C_0*-semigroup of bounded linear operators on* C. *Its infinitesimal generator* $A_U : C \longrightarrow C$ *is given by*

$$\begin{aligned} &A_U\varphi = \dot{\varphi}, \\ &D(A_U) = \{\varphi \in C : \dot{\varphi} \in C, \varphi(0) \in D(A_T), \dot{\varphi}(0) = A_T\varphi(0) + L(\varphi)\}. \end{aligned} \tag{2.4}$$

Moreover, if (H2) *holds, then* $U(t)$ *is a compact operator for each* $t > r$.

Since $\{U(t)\}_{t\geq 0}$ is eventually compact (i.e., there exists $t_0 > 0$ such that $U(t)$ is a compact operator for every $t > t_0$), from Greiner [7, p. 209] the next result follows.

PROPOSITION 2.2. *Assume* (H1), (H2) *and let* A_U *be defined by* (2.4). *Then we have the following:*

(i) $\sigma(A_U) = \sigma_P(A_U)$ *and every* $\lambda \in \sigma(A_U)$ *is a pole of finite order of the resolvent* $R(\lambda; A_U) = (\lambda I - A_U)^{-1}$;
(ii) *for each* $\lambda \in \sigma(A_U)$, *the generalized eigenspace* $\mathcal{M}_\lambda(A_U)$ *is finite-dimensional;*
(iii) *for each* $\alpha \in \mathbb{R}$, *the set* $\{\lambda \in \sigma(A_U) : \mathrm{Re}\lambda \geq \alpha\}$ *is finite.*

From the general theory of C_0-semigroups and compact operators, we also conclude the following.

PROPOSITION 2.3. *Assume* (H1), (H2) *and let* $\lambda \in \mathbb{C}$. *If* $\lambda \in \sigma(A_U)$, *then the ascent and descent of* $A_U - \lambda I$ *are both equal to* m, *where* m *is the order of* λ *as a pole of the resolvent* $R(\lambda; A_U)$. *Furthermore,*

$$C = N[(A_U - \lambda I)^m] \oplus R[(A_U - \lambda I)^m], \tag{2.5}$$

where $N[(A_U - \lambda I)^m] = \mathcal{M}_\lambda(A_U)$ *and* $R[(A_U - \lambda I)^m]$ *is a closed subspace of* C.

Proof. The first part follows directly from Theorem V.10.1 of Taylor and Lay [17, p. 330]. Now, let $k \in \mathbb{N}$, $t > r$. Since $U(t)$ is compact, $N[(U(t) - \mu I)^k]$ is finite-dimensional for $\mu \in \sigma(U(t))$. On the other hand, from the general theory of C_0-semigroups,

$$N[(U(t) - \mu I)^k] = \bigoplus_{\lambda \in S_\mu} N[(A_U - \lambda I)^k], \quad \text{where } S_\mu = \{\lambda \in \sigma(A_U) : e^{\lambda t} = \mu\}.$$

Thus, for m the ascent of λ, $N[(A_U - \lambda I)^m] = \mathcal{M}_\lambda(A_U)$ is finite-dimensional and Theorem IV.5.10 of Taylor and Lay [17, p. 217] implies that $R[(A_U - \lambda I)^m]$ is closed. ∎

For $\lambda \in \mathbb{C}$, we say that λ is a *characteristic value* for (2.1) if λ satisfies the *characteristic equation* given by

$$\Delta(\lambda)x = 0, \qquad x \in D(A_T) \setminus \{0\}, \tag{2.6}$$

where $\Delta(\lambda) : D(A_T) \subset X \longrightarrow X$ is defined by

$$\Delta(\lambda)x := A_T x + L(e^{\lambda \cdot} x) - \lambda x, \qquad x \in D(A_T), \tag{2.7}$$

and $e^{\lambda \cdot} x \in C$ is given by $(e^{\lambda \cdot} x)(\theta) = e^{\lambda\theta} x$ for $\theta \in [-r, 0]$ and $x \in X$. It is easy to see that $\lambda \in \sigma(A_U)$ if and only if λ is a characteristic value for (2.1), in which case

$$N(A_U - \lambda I) = \{e^{\lambda \cdot} x : x \in N(\Delta(\lambda))\}.$$

Note also that for $\psi \in C$, the equation $\psi = (A_U - \lambda I)\varphi$ has a solution $\varphi \in D(A_U)$ if and only if there is a $b \in D(A_T)$ satisfying the equation

$$\Delta(\lambda)b = \psi(0) - L\left(\int_0^\theta e^{\lambda(\theta - \xi)}\psi(\xi)d\xi\right). \tag{2.8}$$

In this case, the solution φ of $\psi = (A_U - \lambda I)\varphi$ is given by

$$\varphi(\theta) = e^{\lambda\theta}b + \int_0^\theta e^{\lambda(\theta-\xi)}\psi(\xi)d\xi, \qquad \theta \in [-r, 0]. \tag{2.9}$$

Here and throughout the remainder of this paper, for the sake of simplicity, we abuse notation and write explicitly the value of $\varphi \in C$ at an arbitrary given $\theta \in [-r, 0]$ in the evaluation of $L(\varphi)$. Namely, $L(\int_0^\theta e^{\lambda(\theta-\xi)}\psi(\xi)d\xi)$ should be understood as the value of L acting on the mapping $[-r, 0] \ni \theta \mapsto \int_0^\theta e^{\lambda(\theta-\xi)}\psi(\xi)d\xi \in X$.

We now assume that the linear operator L can be expressed in integral form by means of a function of bounded variation:

(H3) There is $\eta : [-r, 0] \longrightarrow \mathcal{L}(X, X)$ of bounded variation such that

$$L(\varphi) = \int_{-r}^0 d\eta(\theta)\varphi(\theta), \qquad \varphi \in C,$$

where $\mathcal{L}(X, X)$ denotes the Banach space of bounded linear operators from X into X.

Following Travis and Webb [18], we define the formal duality, the formal adjoint operator of L, and the formal adjoint equation of (2.1) below.

Let X^* be the dual of X and $C^* := C([0, r]; X^*)$. The *formal duality* between C^* and C is the bilinear form $\langle\langle\cdot, \cdot\rangle\rangle$ from $C^* \times C$ to the scalar field, defined by

$$\langle\langle\alpha, \varphi\rangle\rangle = \langle\alpha(0), \varphi(0)\rangle - \int_{-r}^0 \int_0^\theta \langle\alpha(\xi - \theta), d\eta(\theta)\varphi(\xi)\rangle d\xi \tag{2.10}$$

for $\alpha \in C^*, \varphi \in C$, where $\langle\cdot, \cdot\rangle$ is the usual duality between X^* and X. For $f \in C([0, r]; \mathbb{R})$ and $u^* \in X^*$, we use fu^* to denote $f \otimes u^*$ in C^*, i.e., $(fu^*)(s) = f(s)u^*$ for $0 \le s \le r$. We remark that

$$\langle\langle fu^*, \varphi\rangle\rangle = \langle u^*, f(0)\varphi(0)\rangle - \left\langle u^*, L\left(\int_0^\theta f(\xi - \theta)\varphi(\xi)d\xi\right)\right\rangle. \tag{2.11}$$

To avoid possible confusion, throughout this paper we adopt the following notation: given a densely defined linear operator B in a Banach space, we denote by B^* the (true) adjoint of B, also called the dual of B; and by ${}^*B$ we denote the formal adjoint of B relative to the formal duality $\langle\langle\cdot, \cdot\rangle\rangle$ defined above, in a sense that will soon be more clearly defined. The *formal adjoint operator* ${}^*L$ of L is given by

$${}^*L : C^* \longrightarrow X^*, \qquad {}^*L(\alpha) = \int_{-r}^0 d\eta^*(\theta)\alpha(-\theta), \tag{2.12}$$

where $\eta^*(\theta)$ is the adjoint of $\eta(\theta)$. Since η is of bounded variation, its adjoint operator $\eta^* : [-r, 0] \longrightarrow \mathcal{L}(X^*, X^*)$ is also of bounded variation. For (2.1), the *formal adjoint equation* is defined as

$$\dot\alpha(t) = -A_T^*\alpha(t) - {}^*L(\alpha^t), \qquad t \le 0, \tag{2.13}$$

where A_T^* is the adjoint of A_T and $\alpha^t \in C^*$ is given by $\alpha^t(s) = \alpha(t + s)$ for $s \in [0, r]$.

Consider the *mild solution* $\alpha^t(\psi)$ for (2.13) with initial condition $\psi \in C^*$, i.e., the solution of the integral equation

$$\begin{cases} \alpha(t) = T^*(-t)\psi(0) + \int_0^t T^*(s - t){}^*L(\alpha^s)ds, & t \le 0, \\ \alpha^0(\psi) = \psi. \end{cases}$$

As for (2.1), equation (2.13) generates a C_0-semigroup of linear operators $\{{}^*U(t)\}_{t\geq 0}$ on C^* defined by ${}^*U(t)\psi = \alpha^{-t}(\psi)$, whose infinitesimal generator ${}^*A_U$ is given by

$$\begin{aligned} &{}^*A_U\alpha = -\dot{\alpha}, \\ &D({}^*A_U) = \{\alpha \in C^* : \dot{\alpha} \in C^*, \alpha(0) \in D(A_T^*), -\dot{\alpha}(0) = A_T^*\alpha(0) + {}^*L(\alpha)\} \end{aligned} \tag{2.14}$$

and has the following properties (see Travis and Webb [18]):

$$\langle\langle {}^*A_U\alpha, \varphi\rangle\rangle = \langle\langle \alpha, A_U\varphi\rangle\rangle \quad \text{for } \alpha \in D({}^*A_U),\ \varphi \in D(A_U), \tag{2.15}$$

$$\langle\langle \alpha, \varphi\rangle\rangle = 0 \quad \text{for } \alpha \in N({}^*A_U - \mu I),\ \varphi \in N(A_U - \lambda I),\ \text{with } \lambda \neq \mu. \tag{2.16}$$

Note that (2.15) justifies the designation of ${}^*A_U$ as the formal adjoint of A_U, since its behavior relative to the formal duality $\langle\langle \cdot, \cdot\rangle\rangle$ is similar to the behavior of the (true) adjoint of an operator relative to the usual duality between a Banach space and its dual.

3. The point spectrum of ${}^*A_U$. The classic (formal) adjoint theory for FDEs in $\mathbb{R}^n$ will now be generalized to FDEs in Banach spaces, completing the theory initiated by Travis and Webb [18] and following the ideas of Arino and Sanchez [1], Busenberg and Huang [2], and Huang [9].

Similarly to what is done in section 7.3 of Hale [8] (see also [1]), we introduce some auxiliary operators that allow us to express the null space and range for $(A_U - \lambda I)^m,\ \lambda \in \mathbb{C}, m \in \mathbb{N}$, in terms of the null space and range of those auxiliary operators. For $\lambda \in \mathbb{C}, j \in \mathbb{N}_0, m \in \mathbb{N}$, we define the following linear operators:

$$L_\lambda^j : X \longrightarrow X, \quad L_\lambda^j(x) = L\left(\frac{\theta^j}{j!}e^{\lambda\theta}x\right), \tag{3.1}$$

$$\mathcal{L}_\lambda^{(m)} : [D(A_T)]^m \longrightarrow X^m, \quad \mathcal{L}_\lambda^{(m)} = \begin{pmatrix} \Delta(\lambda) & L_\lambda^1 - I & L_\lambda^2 & \dots & L_\lambda^{m-1} \\ 0 & \Delta(\lambda) & L_\lambda^1 - I & \dots & L_\lambda^{m-2} \\ \vdots & \vdots & \ddots & \ddots & \vdots \\ 0 & 0 & \dots & \Delta(\lambda) & L_\lambda^1 - I \\ 0 & 0 & \dots & 0 & \Delta(\lambda) \end{pmatrix}, \tag{3.2}$$

$$\mathcal{R}_\lambda^{(m)} : C \longrightarrow X^m, \quad \mathcal{R}_\lambda^{(m)}(\psi) = \begin{pmatrix} -L\Big(\int_0^\theta e^{\lambda(\theta-\xi)}\frac{(\theta-\xi)^{m-1}}{(m-1)!}\psi(\xi)d\xi\Big) \\ \vdots \\ -L\Big(\int_0^\theta e^{\lambda(\theta-\xi)}(\theta-\xi)\psi(\xi)d\xi\Big) \\ \psi(0) - L\Big(\int_0^\theta e^{\lambda(\theta-\xi)}\psi(\xi)d\xi\Big) \end{pmatrix}. \tag{3.3}$$

With the definitions above, it is clear that $\Delta(\lambda) = \mathcal{L}_\lambda^{(1)} = A_T + L_\lambda^0 - \lambda I$. Moreover, from (2.8) and (2.9) it follows that $\psi \in R(A_U - \lambda I)$ if and only if there exists $b \in D(A_T)$ such that $\Delta(\lambda)b = \mathcal{R}_\lambda^{(1)}(\psi)$.

As in [1] and [8], we can carry out direct computations to obtain an explicit characterization of the spaces $N[(A_U - \lambda I)^m],\ R[(A_U - \lambda I)^m],\ m \in \mathbb{N}$. So we state the following proposition without a proof.

PROPOSITION 3.1. *Assume* (H1), (H2) *and let* $\lambda \in \mathbb{C}, m \in \mathbb{N}$. *Then*
(i) $\varphi \in N[(A_U - \lambda I)^m]$ *if and only if*

$$\varphi(\theta) = \sum_{j=0}^{m-1} \frac{\theta^j}{j!} e^{\lambda\theta} u_j, \qquad \theta \in [-r, 0], \qquad \text{with} \quad \begin{pmatrix} u_0 \\ \vdots \\ u_{m-1} \end{pmatrix} \in N(\mathcal{L}_\lambda^{(m)});$$

(ii) $\psi \in R[(A_U - \lambda I)^m]$ *if and only if* $\mathcal{R}_\lambda^{(m)}(\psi) \in R(\mathcal{L}_\lambda^{(m)})$.
From the definition of ${}^*L$ in (2.12), one can see that

$$\langle {}^*L(fu^*), u\rangle = \langle u^*, L(\hat{f}u)\rangle$$

for $u^* \in X^*, u \in X, f \in C([0, r]; \mathbb{R})$, where $\hat{f} \in C([-r, 0]; \mathbb{R})$ is given by $\hat{f}(\theta) := f(-\theta)$ for $\theta \in [-r, 0]$. Therefore, the adjoint $(L_\lambda^j)^*$ of L_λ^j ($j \in \mathbb{N}_0, \lambda \in \mathbb{C}$) is given by

$$(L_\lambda^j)^* u^* = {}^*L\left(\frac{(-\theta)^j}{j!} e^{-\lambda\theta} u^*\right), \qquad u^* \in X^*. \tag{3.4}$$

Similar to Proposition 3.1, we have an explicit characterization of $N[({}^*A_U - \lambda I)^m]$.
PROPOSITION 3.2. *Assume* (H1)–(H3). *For* $m \in \mathbb{N}, \lambda \in \mathbb{C}$,

$$\alpha \in N[({}^*A_U - \lambda I)^m] \quad \text{if and only if } \alpha(s) = \sum_{j=0}^{m-1} \frac{(-s)^j}{j!} e^{-\lambda s} x^*_{m-j-1}, \qquad s \in [0, r],$$

with $(x_0^*, \ldots, x_{m-1}^*)^T \in N((\mathcal{L}_\lambda^{(m)})^*)$. *In particular,* $\alpha \in N({}^*A_U - \lambda I)$ *if and only if* $\alpha(s) = e^{-\lambda s} x^*, s \in [0, r]$, *with* $x^* \in N(\Delta(\lambda)^*)$.

Proof. We have

$$(\mathcal{L}_\lambda^{(m)})^* = \begin{pmatrix} \Delta(\lambda)^* & 0 & \ldots & 0 \\ (L_\lambda^1)^* - I & \Delta(\lambda)^* & \ldots & 0 \\ (L_\lambda^2)^* & (L_\lambda^1)^* - I & \ldots & 0 \\ \vdots & \ddots & \ddots & \vdots \\ (L_\lambda^{m-1})^* & \ldots & (L_\lambda^1)^* - I & \Delta(\lambda)^* \end{pmatrix},$$

with $(L_\lambda^j)^*$ given by (3.4). Using this and direct computations in the same spirit as in section 7.3 in Hale [8], we can complete the verification of Proposition 3.2. □

Now, we want to present a Fredholm alternative result relative to the formal adjoint. The following lemmas will establish some properties of the operators $\mathcal{L}_\lambda^{(m)}$ that will play an important role in this setting.

LEMMA 3.3. *Assume* (H1), (H2) *and let* $\lambda \in \mathbb{C}$. *Then* $\lambda \in \rho(A_U)$ *if and only if* $0 \in \rho(\Delta(\lambda))$.

Proof. For $\lambda \in \mathbb{C}$, it has been shown in section 2 that $\lambda \in \rho(A_U)$ if and only if $N(\Delta(\lambda)) = \{0\}$. On the other hand, $\Delta(\lambda) = A_T + L_\lambda^0 - \lambda I$, where A_T generates a compact C_0-semigroup of bounded linear operators and $L_\lambda^0 - \lambda I$ is linear and bounded. Hence, $\Delta(\lambda)$ is also the infinitesimal generator of a compact C_0-semigroup (see Proposition III.1.4 of Pazy [14, p. 79]). From the note in p. 51 of the same book, it follows that $0 \in \rho(\Delta(\lambda))$ if and only if 0 is not an eigenvalue of $\Delta(\lambda)$, or, equivalently, if and only if $N(\Delta(\lambda)) = \{0\}$. □

LEMMA 3.4. *Assume* (H1), (H2) *and let* $\lambda \in \mathbb{C}$ *and* $m \in \mathbb{N}$. *Then*

(i) *if* $\mu \in \rho(\Delta(\lambda))$, *then* $\mu \in \rho(\mathcal{L}_\lambda^{(m)})$ *and* $(\mathcal{L}_\lambda^{(m)} - \mu I)^{-1}$ *is a compact operator;*

(ii) $R(\mathcal{L}_\lambda^{(m)})$ *is a closed subspace of* X^m.

Proof. The proof of (i) is given by induction. For $m = 1$, $\mathcal{L}_\lambda^{(1)} = \Delta(\lambda)$. We have already observed that $\Delta(\lambda)$ is the infinitesimal generator of a compact C_0-semigroup. Hence, for $\mu \in \rho(\Delta(\lambda))$ the resolvent $[\Delta(\lambda) - \mu I]^{-1}$ is compact (see Theorem II.3.3 of Pazy [14, p. 48]).

We now consider $\lambda \in \mathbb{C}, \mu \in \rho(\Delta(\lambda))$ and suppose that (i) is true for m. Since

$$\mathcal{L}_\lambda^{(m+1)} - \mu I = \begin{pmatrix} \mathcal{L}_\lambda^{(m)} - \mu I & \begin{pmatrix} L_\lambda^m \\ \vdots \\ L_\lambda^2 \\ L_\lambda^1 - I \end{pmatrix} \\ O & \Delta(\lambda) - \mu I \end{pmatrix},$$

$$(\mathcal{L}_\lambda^{(m+1)} - \mu I)^{-1} = \begin{pmatrix} (\mathcal{L}_\lambda^{(m)} - \mu I)^{-1} & -(\mathcal{L}_\lambda^{(m)} - \mu I)^{-1} \begin{pmatrix} L_\lambda^m \\ \vdots \\ L_\lambda^2 \\ L_\lambda^1 - I \end{pmatrix} (\Delta(\lambda) - \mu I)^{-1} \\ O & (\Delta(\lambda) - \mu I)^{-1} \end{pmatrix}$$

exists and is bounded. Now, let $(y_n) \subset X^m, (z_n) \subset X$ be bounded sequences. The compactness of the operators $(\mathcal{L}_\lambda^{(m)} - \mu I)^{-1}$ and $(\Delta(\lambda) - \mu I)^{-1}$ implies that there are subsequences $(y_{n_k}), (z_{n_k})$ such that

$$(\mathcal{L}_\lambda^{(m)} - \mu I)^{-1} y_{n_k} \to w \in X^m, \qquad (\Delta(\lambda) - \mu I)^{-1} z_{n_k} \to x \in X.$$

Then $(\mathcal{L}_\lambda^{(m+1)} - \mu I)^{-1} \binom{y_{n_k}}{z_{n_k}}$ converges, proving that $(\mathcal{L}_\lambda^{(m+1)} - \mu I)^{-1}$ is a compact operator.

To prove (ii), let $(x_n) \subset [D(A_T)]^m$, $\mathcal{L}_\lambda^{(m)} x_n \to y \in X^m$. For $\mu \in \rho(\Delta(\lambda)), \mu \neq 0$,

$$\left[\frac{I}{\mu} + (\mathcal{L}_\lambda^{(m)} - \mu I)^{-1}\right] x_n = \frac{1}{\mu}(\mathcal{L}_\lambda^{(m)} - \mu I)^{-1} \mathcal{L}_\lambda^{(m)} x_n \to \frac{1}{\mu}(\mathcal{L}_\lambda^{(m)} - \mu I)^{-1} y.$$

The space $R[\frac{I}{\mu} + (\mathcal{L}_\lambda^{(m)} - \mu I)^{-1}]$ is closed, because $(\mathcal{L}_\lambda^{(m)} - \mu I)^{-1}$ is compact (see Theorem V.7.8 of Taylor and Lay [17, p. 300]). Thus, there exists $x \in X^m$ such that

$$\frac{1}{\mu}(\mathcal{L}_\lambda^{(m)} - \mu I)^{-1} y = \left[\frac{I}{\mu} + (\mathcal{L}_\lambda^{(m)} - \mu I)^{-1}\right] x,$$

i.e., $\mathcal{L}_\lambda^{(m)} x = y \in R(\mathcal{L}_\lambda^{(m)})$. □

The characterization of the point spectrum of ${}^*A_U$ relies on the next lemma.

LEMMA 3.5. *Assume* (H1)–(H3). *Consider* $\lambda \in \mathbb{C}, m \in \mathbb{N}$. *Then*

$$\dim N(\mathcal{L}_\lambda^{(m)}) = \dim N((\mathcal{L}_\lambda^{(m)})^*).$$

Proof. We may assume that $\lambda \in \sigma(A_U)$, i.e., $0 \in \sigma(\Delta(\lambda))$ (cf. Lemma 3.3). For $\mu \in \rho(\Delta(\lambda))$, then $\mu \in \rho(\mathcal{L}_\lambda^{(m)})$ by Lemma 3.4, and we conclude that

$$N(\mathcal{L}_\lambda^{(m)}) = N\left((\mathcal{L}_\lambda^{(m)} - \mu I)^{-1} + \frac{I}{\mu}\right),$$
$$N((\mathcal{L}_\lambda^{(m)})^*) = N\left([(\mathcal{L}_\lambda^{(m)})^* - \mu I]^{-1} + \frac{I}{\mu}\right).$$

Since $\mathcal{L}_\lambda^{(m)}$ is densely defined, we also conclude that $\mu \in \rho((\mathcal{L}_\lambda^{(m)})^*)$ and $[(\mathcal{L}_\lambda^{(m)} - \mu I)^{-1}]^* = [(\mathcal{L}_\lambda^{(m)})^* - \mu I]^{-1}$ (cf. Lemma I.10.2 of Pazy [14, p. 38]). It remains to be proved that $N((\mathcal{L}_\lambda^{(m)} - \mu I)^{-1} + \frac{I}{\mu})$ and $N([(\mathcal{L}_\lambda^{(m)} - \mu I)^{-1}]^* + \frac{I}{\mu})$ have the same dimension. Since $(\mathcal{L}_\lambda^{(m)} - \mu I)^{-1}$ is a compact operator, so is its adjoint $[(\mathcal{L}_\lambda^{(m)} - \mu I)^{-1}]^*$, and the result now follows from Theorem V.7.14 of Taylor and Lay [17, p. 303]. □

As an immediate and most relevant consequence of this lemma, we can now derive the following result.

PROPOSITION 3.6. *Assume* (H1)–(H3). *Then*

(i) $\sigma_P(A_U) = \sigma_P({}^*A_U)$;

(ii) $\dim N[(A_U - \lambda I)^m] = \dim N[({}^*A_U - \lambda I)^m], m \in \mathbb{N}$;

(iii) *the ascent of* $A_U - \lambda I$ *and* ${}^*A_U - \lambda I$ *are equal.*

Proof. Propositions 3.1 and 3.2 and Lemma 3.5 imply (ii), from which (i) and (iii) follow. □

Remark 3.1. We note that (i) of Proposition 3.6 was proven in Proposition 4.14 of Travis and Webb [18] under the additional hypothesis $N(\Delta(\lambda)) \neq \{0\}$ if and only if $N(\Delta(\lambda)^*) \neq \{0\}$.

Remark 3.2. In the literature dealing with adjoint semigroups for FDEs in Banach spaces (cf., e.g., Nakagiri [13] and Travis and Webb [18, p. 412]), it is often assumed that the Banach space X is reflexive in order to have nice properties for adjoint semigroups. Here, we are able to develop the adjoint theory without imposing such a condition. Of course, if this condition holds, further properties for ${}^*A_U$ and ${}^*U(t)$ are obtained. For example, if the Banach space X is reflexive, then the adjoint A_T^* of A_T is the infinitesimal generator of the adjoint C_0-semigroup $\{T(t)^*\}_{t\geq 0}$ (cf. Pazy [14, p. 39]). For $t > 0$, $T(t)$ is a compact operator, and hence its adjoint $T(t)^*$ is also compact. Since (H1) and (H2) are fulfilled with $A_T, T(t)$ replaced by $A_T^*, T(t)^*$, respectively, the conclusions of Propositions 2.1, 2.2, and 2.3 hold for ${}^*A_U, {}^*U(t)$ $(t > 0)$ instead of $A_U, U(t)$ $(t > 0)$. In particular, $\sigma_P({}^*A_U) = \sigma({}^*A_U)$.

Remark 3.3. In Arino and Sanchez [1], a formal adjoint theory was established for equations of the form $\dot{u}(t) = L(u_t)$, where $L : C \longrightarrow X$ is a bounded linear operator. Since $A_T = 0$, the C_0-semigroup $\{U(t)\}_{t\geq 0}$ associated with the solutions of this equation is not eventually compact in general. For this reason, in [1] the authors restricted their study to eigenvalues of the infinitesimal generator that are not in the essential spectrum. With this restriction, the corresponding operators $\mathcal{L}_\lambda^{(m)}$ are Fredholm operators, instead of having compact resolvent. However, for our purposes and in view of applications, it is more interesting to consider equations of type (2.1) rather than $\dot{u}(t) = L(u_t)$, and in this situation no restrictions on the eigenvalues have to be assumed.

4. Decomposition of the phase space by using the formal adjoint theory. In this section, we always assume (H1)–(H3). The Fredholm alternative is stated

in the next result.

PROPOSITION 4.1. *Consider $\lambda \in \sigma(A_U)$ and $m \in \mathbb{N}$. Then $\psi \in R[(A_U - \lambda I)^m]$ if and only if $\langle\langle \alpha, \psi \rangle\rangle = 0$ for all $\alpha \in N[({}^*A_U - \lambda I)^m]$. In particular, $\psi \in R(A_U - \lambda I)$ if and only if*

$$\langle\langle e^{-\lambda \cdot} u^*, \psi \rangle\rangle = 0 \quad \text{for all } u^* \in N(\Delta(\lambda)^*).$$

Proof. Since $R(\mathcal{L}_\lambda^{(m)})$ is closed (Lemma 3.4), we have

$$R(\mathcal{L}_\lambda^{(m)}) = N((\mathcal{L}_\lambda^{(m)})^*)^\perp.$$

Thus, Proposition 3.1 implies that

$$\psi \in R[(A_U - \lambda I)^m] \quad \text{if and only if } \langle Y^*, \mathcal{R}_\lambda^{(m)}(\psi) \rangle = 0$$

for all $Y^* \in N((\mathcal{L}_\lambda^{(m)})^*)$. For $Y^* = (y_0^*, \dots, y_{m-1}^*)^T \in (X^*)^m$, from (2.11) and (3.3) we have

$$\begin{aligned}
&\langle Y^*, \mathcal{R}_\lambda^{(m)}(\psi) \rangle \\
&= -\sum_{j=0}^{m-1} \left\langle y_j^*, L\left(\int_0^\theta e^{\lambda(\theta-\xi)} \frac{(\theta-\xi)^{m-j-1}}{(m-j-1)!} \psi(\xi) d\xi \right) \right\rangle + \langle y_{m-1}^*, \psi(0) \rangle \\
&= \sum_{j=0}^{m-1} \left\langle \left\langle e^{-\lambda s} \frac{(-s)^{m-j-1}}{(m-j-1)!} y_j^*, \psi \right\rangle \right\rangle,
\end{aligned}$$

and the result follows from Proposition 3.2. □

We note that the above result was established in Proposition 4.15 of Travis and Webb [18] only for the particular situation $m = 1$ and with the additional hypothesis that $\Delta(\lambda)$ has a closed range. In Proposition 4.1, the most important case is the case m equal to the ascent of $A_U - \lambda I$. For $\lambda \in \sigma(A_U)$, denote by $\mathcal{M}_\lambda(A_U)$ and $\mathcal{M}_\lambda({}^*A_U)$ the generalized eigenspaces for A_U and ${}^*A_U$ associated with λ, respectively.

PROPOSITION 4.2. *Let $\lambda \in \sigma(A_U)$ and m be the ascent of $A_U - \lambda I$. Then $C = \mathcal{M}_\lambda(A_U) \oplus Q_\lambda$, with $\mathcal{M}_\lambda(A_U) = N[(A_U - \lambda I)^m]$, $\mathcal{M}_\lambda({}^*A_U) = N[({}^*A_U - \lambda I)^m]$, and*

$$Q_\lambda = \{\psi \in C : \langle\langle \alpha, \psi \rangle\rangle = 0 \quad \text{for all } \alpha \in \mathcal{M}_\lambda({}^*A_U)\}. \tag{4.1}$$

Proof. From Proposition 3.6, m is also the ascent of ${}^*A_U - \lambda I$. On the other hand, Proposition 4.1 implies that $\psi \in R[(A_U - \lambda I)^m]$ if and only if $\langle\langle \alpha, \psi \rangle\rangle = 0$ for all $\alpha \in \mathcal{M}_\lambda({}^*A_U)$. Decomposition (2.5) is therefore written as $C = \mathcal{M}_\lambda(A_U) \oplus Q_\lambda$, with $Q_\lambda = R[(A_U - \lambda I)^m]$ defined by (4.1). □

LEMMA 4.3. *For $\lambda, \mu \in \sigma(A_U)$, $\lambda \neq \mu$, and $m, r \in \mathbb{N}$,*

$$\langle\langle \alpha, \varphi \rangle\rangle = 0 \quad \text{for all } \alpha \in N[({}^*A_U - \lambda I)^m] \quad \text{and} \quad \varphi \in N[(A_U - \mu I)^r].$$

Proof. This lemma generalizes formula (2.16) for $m \in \mathbb{N}$. It relies on the identity (2.15) and is easily verified by using arguments as in Lemma 9 of Arino and Sanchez [1], so we omit the details here. □

Let $\lambda \in \sigma(A_U)$ and choose bases

$$\Phi_\lambda = (\varphi_1, \dots, \varphi_{p_\lambda}), \qquad \Psi_\lambda = (\psi_1, \dots, \psi_{p_\lambda})^T$$

of $\mathcal{M}_\lambda(A_U)$ and $\mathcal{M}_\lambda({}^*A_U)$, respectively, where $p_\lambda = \dim \mathcal{M}_\lambda(A_U) = \dim \mathcal{M}_\lambda({}^*A_U)$. Define a $p_\lambda \times p_\lambda$ matrix

$$\langle\langle \Psi_\lambda, \Phi_\lambda \rangle\rangle := [\langle\langle \psi_i, \varphi_j \rangle\rangle]_{i,j=1,\dots,p_\lambda}.$$

Suppose that $\langle\langle \Psi, \Phi \rangle\rangle c = 0$ for some constant vector $c = (c_1, \dots, c_{p_\lambda})^T$. Then, $\langle\langle \alpha, c_1\varphi_1 + \cdots + c_{p_\lambda}\varphi_{p_\lambda} \rangle\rangle = 0$ for all $\alpha \in \mathcal{M}_\lambda({}^*A_U)$, and Proposition 4.2 implies that $c_1\varphi_1 + \cdots + c_{p_\lambda}\varphi_{p_\lambda} \in Q_\lambda \cap \mathcal{M}_\lambda(A_U) = \{0\}$ for Q_λ as in (4.1). This shows that $\langle\langle \Psi_\lambda, \Phi_\lambda \rangle\rangle$ is nonsingular. Therefore, we can always choose bases $\Psi_\lambda, \Phi_\lambda$ such that

$$\langle\langle \Psi_\lambda, \Phi_\lambda \rangle\rangle = I_{p_\lambda}, \qquad p_\lambda = \dim \mathcal{M}_\lambda(A_U). \tag{4.2}$$

If the bases are normalized in such a way that (4.2) is fulfilled, then there is a $p_\lambda \times p_\lambda$ constant matrix B_λ, with $\sigma(B_\lambda) = \{\lambda\}$, that satisfies simultaneously

$$\dot{\Phi}_\lambda = \Phi_\lambda B_\lambda \quad \text{and} \quad -\dot{\Psi}_\lambda = B_\lambda \Psi_\lambda. \tag{4.3}$$

Furthermore,

$$U(t) = \Phi_\lambda e^{B_\lambda t}, \qquad t > 0. \tag{4.4}$$

We are now in the position to decompose C by a finite set of characteristic eigenvalues of (2.1), using the formal duality $\langle\langle \cdot, \cdot \rangle\rangle$. Consider a nonempty finite set $\Lambda = \{\lambda_1, \dots, \lambda_s\} \subset \sigma(A_U)$ and define $\Phi_\Lambda = (\Phi_{\lambda_1}, \dots, \Phi_{\lambda_s}), \Psi_\Lambda = (\Psi_{\lambda_1}, \dots, \Psi_{\lambda_s})^T$, where $\Phi_{\lambda_j}, \Psi_{\lambda_j}$ are bases of the generalized eigenspaces $\mathcal{M}_{\lambda_j}(A_U), \mathcal{M}_{\lambda_j}({}^*A_U)$, respectively, such that (4.2) holds ($j = 1, \dots, s$). From Lemma 4.3, it follows that $\langle\langle \Psi_\Lambda, \Phi_\Lambda \rangle\rangle = I_p$, where $p = p_{\lambda_1} + \cdots + p_{\lambda_s}$.

PROPOSITION 4.4. *Assume* (H1)–(H3), *let* $\Lambda = \{\lambda_1, \dots, \lambda_s\} \subset \sigma(A_U)$, *define*

$$P_\Lambda = \mathcal{M}_{\lambda_1}(A_U) \oplus \cdots \oplus \mathcal{M}_{\lambda_s}(A_U),$$
$$P_\Lambda^* = \mathcal{M}_{\lambda_1}({}^*A_U) \oplus \cdots \oplus \mathcal{M}_{\lambda_s}({}^*A_U),$$

and consider bases $\Phi_\Lambda, \Psi_\Lambda$ *for* P_Λ, P_Λ^* *such that* $\langle\langle \Psi_\Lambda, \Phi_\Lambda \rangle\rangle = I_p$, $p = \dim P_\Lambda$. *Then there exists a subspace* Q_Λ *of* C, *invariant under* A_U *and* $U(t)$, $t \geq 0$, *such that*

$$C = P_\Lambda \oplus Q_\Lambda \tag{4.5}$$

with

$$Q_\Lambda = \{\varphi \in C : \langle\langle \Psi_\Lambda, \varphi \rangle\rangle = 0\}, \tag{4.6}$$

where $\langle\langle \Psi_\Lambda, \varphi \rangle\rangle := (\langle\langle \Psi_{\lambda_1}, \varphi \rangle\rangle, \dots, \langle\langle \Psi_{\lambda_s}, \varphi \rangle\rangle)^T$. *Moreover,* $\varphi \in C$ *is written according to decomposition* (4.6) *as* $\varphi = \varphi_{P_\Lambda} + \varphi_{Q_\Lambda}$, *where* $\varphi_{P_\Lambda} = \Phi_\Lambda \langle\langle \Psi_\Lambda, \varphi \rangle\rangle$ *and* $\varphi_{Q_\Lambda} \in Q_\Lambda$.

5. Center manifolds for maps in general Banach spaces: Smoothness. We start with the following general results on smooth center-stable manifolds for maps.

THEOREM 5.1. *Let* $f : U \to E$ *be a* C^1*-map on an open subset* U *of a Banach space* E *over* $\mathbb{R}$, *with a fixed point* p. *Let* $L = Df(p)$ *and assume that* E *has the following decomposition:*

$$E = E_s \oplus E_c \oplus E_u,$$

where E_s is a closed subspace, E_c and E_u are finite-dimensional, $L(E_s) \subset E_s$, $L(E_c) \subset E_c$, and $L(E_u) \subset E_u$. We further assume that

$$\sigma_s = \sigma(L|_{E_s} : E_s \to E_s) \text{ is contained in a compact subset of } \{z \in \mathbb{C} : |z| < 1\}$$

and

$$\begin{aligned}\sigma_c =& \sigma(L|_{E_c} : E_c \to E_c) \subset S^1_{\mathbb{C}},\\ \sigma_u =& \sigma(L|_{E_u} : E_u \to E_u) \subset \{z \in \mathbb{C} : |z| > 1\}.\end{aligned}$$

Let $E_{sc} = E_s \oplus E_c$. Then

(i) *there exist open neighborhoods N_{sc} of 0 in E_{sc}, N_u of 0 in E_u, N of p in U, and a C^1-map $w : N_{sc} \to E_u$ with $w(0) = 0$, $Dw(0) = 0$, and $w(N_{sc}) \subset N_u$ so that the shifted graph $W = p + \{z + w(z) : z \in N_{sc}\}$ satisfies $f(W \cap N) \subset W$ and $\cap_{n=0}^{\infty} f^{-n}(p + N_{sc} + N_u) \subset W$;*

(ii) *if f is C^k-smooth for an integer $k \geq 2$, then so is w.*

Part (i) was proved in [10]. Our argument for the general smoothness in (ii), given below, will be based on the following general C^1-smoothness result for fixed points of contractions depending on a parameter developed in [10].

LEMMA 5.2. *Let Y, Λ be Banach spaces over $\mathbb{R}$ and let an open set $P \subset \Lambda$, a map $h : Y \times P \to Y$, and a constant $\kappa \in [0, 1)$ be given with $|h(y, p) - h(\tilde{y}, p)| \leq \kappa |y - \tilde{y}|$ for all $y, \tilde{y}$ in Y and all $p \in P$. Consider a convex subset $M \subset Y$ and a map $\Phi : P \to M$ so that for every $p \in P$, $\Phi(p)$ is the unique fixed point of $h(\cdot, p) : Y \to Y$. Suppose the following hold:*

(i) *the restriction $h_0 = h|_{M \times P}$ has a partial derivative $D_2 h_0 : M \times P \to L(\Lambda, Y)$ and the map $D_2 h_0$ is continuous;*

(ii) *there are a Banach space Y_1 over $\mathbb{R}$ and a continuous injective linear map $j : Y \to Y_1$ so that the map $k = j \circ h_0$ is continuously differentiable with respect to Y in the sense that there is a continuous map $A : M \times P \to L(Y, Y_1)$ so that for every $(y, p) \in M \times P$ and every $\epsilon^* > 0$, there exists $\tilde{\delta} > 0$ with $|k(\tilde{y}, p) - k(y, p) - A(y, p)(\tilde{y} - y)| \leq \epsilon^* |\tilde{y} - y|$ for all $\tilde{y} \in M$ with $|\tilde{y} - y| \leq \tilde{\delta}$;*

(iii) *there exist maps $h^{(1)} : M \times P \to L(Y, Y)$ and $h_1^{(1)} : M \times P \to L(Y_1, Y_1)$ such that*

$$A(y, p)\hat{y} = j h^{(1)}(y, p)\hat{y} = h_1^{(1)}(y, p) j\hat{y} \quad \text{on } M \times P \times Y$$

and

$$|h^{(1)}(y, p)| \leq \kappa,\ |h_1^{(1)}(y, p)| \leq \kappa \quad \text{on } M \times P;$$

(iv) *the map $(y, p) \in M \times P \to j \circ h^{(1)}(y, p) \in L(Y, Y_1)$ is continuous.*

Then the map $j \circ \Phi : P \to Y_1$ is C^1-smooth and

$$D(j \circ \Phi)(p) = h_1^{(1)}(\Phi(p), p) \circ D(j \circ \Phi)(p) + j \circ D_2 h_0(\Phi(p), p) \quad \text{for all } p \in P.$$

For a given positive integer k and for given Banach spaces $Y_1, \ldots, Y_k$ and Y, let $\mathcal{L}^{(k)}(Y_1 \times \cdots \times Y_k, Y)$ be the Banach space of all continuous k-linear maps from $Y_1 \times \cdots \times Y_k$ to Y, equipped with the operator norm. If $Y_i = Y_1$ for all $1 \leq i \leq k$, we write $\mathcal{L}^{(k)}(Y_1, Y)$ for $\mathcal{L}^{(k)}(Y_1 \times \cdots \times Y_k, Y)$. Also, we will denote the kth derivative of a given map by D^k if it exists.

We now briefly recall some results and associated notation in [10] as a preparation for the proof of Theorem 5.1. Set $b = \inf_{\lambda \in \sigma_u} |\lambda|, a = \sup_{\lambda \in \sigma_s} |\lambda|$ and fix $\epsilon > 0$ with

$a+\epsilon<1<1+\epsilon<(1+\epsilon)^k<b-\epsilon$. Let P_s, P_c, P_u denote the projections of E onto E_s along $E_c\oplus E_u$, onto E_c along $E_s\oplus E_u$, and onto E_u along $E_c\oplus E_s$, respectively. Whenever convenient, we shall use abbreviations like

$$x_s=P_sx,\qquad x_c=P_cx,\qquad x_u=P_ux,\qquad P_{sc}=P_s+P_c,\qquad x_{cu}=x_c+x_u.$$

There exists a norm $|\cdot|$ on E which is equivalent to the originally given one and satisfies

$$\begin{aligned}&|x|=|x_s|+|x_c|+|x_u|,\\&|LP_sx|\le(a+\epsilon)|P_sx|,\\&|LP_cx|\le(1+\epsilon)|P_cx|,\\&|LP_ux|\ge(b-\epsilon)|P_ux|\end{aligned}$$

for all $x\in E$.

Set $V=U-p$. Consider the transformed map $g^*: x\in V\to f(x+p)-p\in E$ with fixed point 0 and $Dg^*(0)=L$. Define $r^*: V\to E$ as the nonlinear part of g^* by $r^*(x)=g^*(x)-Lx$, and then extend r^* to a map $r: E\to E$ by $r(x)=0$ for all $x\in E\setminus V$. Finally, let $g=L+r$.

To construct small Lipschitz continuous modifications of g which are smooth on strips containing the center-unstable space E_{cu}, we fix a norm $|\cdot|_{cu}$ on E_{cu} which is C^∞-smooth on $E_{cu}\setminus\{0\}$. The norm $||\cdot||: x\in E\to\max\{|x_s|,|x_{cu}|_{cu}\}\in\mathbb{R}$ is equivalent to $|\cdot|$. For $\delta>0$, set $E(\delta)=\{x\in E: ||x||<\delta\}$. Choose a C^∞-function $\rho:\mathbb{R}\to\mathbb{R}$ with $\rho([0,\infty))\subset[0,1], \rho(t)=1$ for $0\le t\le 1$, $\rho(t)=0$ for $t\ge 2$. For every $\delta>0$, define $r_\delta: E\to E$ by

$$r_\delta(x)=\rho\left(\frac{|x_{cu}|_{cu}}{\delta}\right)\rho\left(\frac{|x_s|}{\delta}\right)r(x)$$

and set $g_\delta=L+r_\delta$.

Fix $\delta_0>0$ so that $\overline{E(3\delta_0)}\subset V$ and that $r|_{E(3\delta_0)}$ is C^k-smooth and all lth derivatives, $1\le l\le k$, of $r|_{E(3\delta_0)}$ are bounded. Observing that for every $\delta\in(0,\delta_0)$ the restriction $r_\delta|_{\{x\in E:|x_s|<\delta\}}$ is given by $\rho(\frac{|x_{cu}|_{cu}}{\delta})r(x)$, it follows that $r_\delta|_{\{x\in E:|x_s|<\delta\}}$ is C^k-smooth and that the restriction of r_δ to $\{x\in E; |x_s|\le\frac{\delta}{2}\}$ has all lth derivatives bounded, $1\le l\le k$.

It was shown in [10] that there exist $\delta_1\in(0,\delta_0)$ and a nondecreasing function $\lambda:[0,\delta_1]\to[0,1]$ with $\lim_{\delta\to 0^+}\lambda(\delta)=0=\lambda(0)$ so that for each $\delta\in(0,\delta_1]$ and for all x,y in E, $|r_\delta(x)|\le\delta\lambda(\delta)$ and $|r_\delta(x)-r_\delta(y)|\le\lambda(\delta)|x-y|$.

For $\eta>0$, let E_η denote the Banach space of all sequences $\chi=(x_n)_0^\infty\in E^{\mathbb{N}}$ with

$$\sup_{j\in\mathbb{N}}|x_j|\eta^{-j}<\infty$$

and norm

$$||\chi||_\eta=\sup_{j\in\mathbb{N}}|x_j|\eta^{-j}.$$

Consider

$$\begin{cases}x_{n+1}=Lx_n+f_n & \text{for } n\ge 0,\\ P_{sc}x_0=z\end{cases}\tag{5.1}$$

for given $z\in E_{sc}$, $\phi=(f_n)_0^\infty\in E_\eta$, and $\eta\in(1+\epsilon,b-\epsilon)$.

Let $L_{sc} = L|_{E_{sc}} : E_{sc} \to E_{sc}$. It was shown in [10] that for fixed $z \in E_{sc}, 1+\epsilon < \eta < b-\epsilon$, and $\phi \in E_\eta$, if $\chi \in E_\eta$ satisfies (5.1), then

$$x_n = \sum_{j=0}^{n-1} L_{sc}^{n-j-1} P_{sc} f_j - \sum_{j=n}^{\infty} L_u^{n-j-1} P_u f_j + L_{sc}^n z \quad \text{for } n \geq 1$$

and

$$x_0 = z - \sum_{j=0}^{\infty} L_u^{-j-1} P_u f_j.$$

In particular, given $z \in E_{sc}$ and $\phi = (f_j)_0^\infty \in E_\eta$, there is at most one solution of (5.1) in E_η. Let

$$K : \{\chi \in E^{\mathbb{N}} : \chi \in E_\eta \text{ for some } \eta \in (1+\epsilon, \mathrm{b}-\epsilon)\} \to \mathrm{E}^{\mathbb{N}}$$

be given by

$$(K\phi)_n = \sum_{j=0}^{n-1} L_{sc}^{n-j-1} P_{sc} f_j - \sum_{j=n}^{\infty} L_u^{n-j-1} P_u f_j \quad \text{for } n \geq 1$$

and

$$(K\phi)_0 = -\sum_{j=0}^{\infty} L_u^{-j-1} P_u f_j.$$

Also, let

$$c(\eta) = \frac{1}{\eta - 1 - \epsilon} + \frac{1}{b - \epsilon - \eta}.$$

Then the linear map $K_\eta : E_\eta \to E_\eta$ given by $K_\eta \phi = K\phi$ is continuous with $|K_\eta| \leq c(\eta)$. Furthermore, for every $\eta \in (1+\epsilon, b-\epsilon)$, $z \in E_{sc}$, and $\phi \in E_\eta$, the sequence $\chi = K_\eta \phi + (L_{sc}^n z)_0^\infty \in E_\eta$ solves (5.1).

Consider the substitution operator

$$R_\delta : E^{\mathbb{N}} \to E^{\mathbb{N}} \quad \text{by } R_\delta(\chi) = (r_\delta(x_n))_0^\infty \quad \text{for } \chi = (x_n)_0^\infty \in E^{\mathbb{N}}.$$

For every $\eta \in (1+\epsilon, b-\epsilon)$, choose $\delta_\eta \in (0, \delta_1]$ with $\lambda(\delta_\eta) c(\eta) < 1$. Let $\eta \in (1+\epsilon, b-\epsilon)$ and $\delta \in (0, \delta_\eta)$. It was shown in [10] that $R_\delta(E_\eta) \subset E_\eta$, and the induced map $\gamma_{\delta\eta} : E_\eta \ni \chi \mapsto R_\delta(\chi) \in E_\eta$ is Lipschitz continuous with a Lipschitz constant $\lambda(\delta)$.

Therefore, for every $z \in E_{sc}$ and $\chi = (x_n)_0^\infty \in E_\eta$ the properties

$$x_{n+1} = g_\delta(x_n) \quad \text{for all } n \geq 0, \qquad P_{sc} x_0 = z$$

are equivalent to the fixed point equation $\chi = T_{\delta\eta}(\chi, z)$, where the map $T_{\delta\eta} : E_\eta \times E_{sc} \to E_\eta$ is given by

$$T_{\delta\eta}(\chi, z) = K_\eta(\gamma_{\delta\eta}(\chi)) + (L_{sc}^j z)_0^\infty.$$

As

$$|T_{\delta\eta}(\chi, z) - T_{\delta\eta}(\chi^*, z)|_\eta \leq c(\eta)\lambda(\delta)|\chi - \chi^*|_\eta$$

for all $\chi, \chi^* \in E_\eta$ and for all $z \in E_{sc}$, there is exactly one fixed point $\chi_{\delta\eta}(z) \in E_\eta$ of the contraction $T_{\delta\eta}(\cdot, z) : E_\eta \to E_\eta$ for every $z \in E_{sc}$. Moreover, $P_{sc}(\chi_{\delta\eta}(z))_0 = z$. In summary, $\chi \in E_\eta$ is a trajectory of g_δ with $P_{sc}x_0 = z$ if and only if $\chi = \chi_{\delta\eta}(z)$.

It was shown in [10] that the map $\chi_{\delta\eta} : z \in E_{sc} \to \chi_{\delta\eta}(z) \in E_\eta$ is Lipschitz continuous, and thus $w_{\delta\eta} : z \in E_{sc} \to P_u(\chi_{\delta\eta}(z))_0 \in E_u$ is Lipschitz continuous. To obtain the differentiability of $w_{\delta\eta}$, [10] proved the following important properties: if $0 < \delta < \delta_\eta$ and $\lambda(\delta) < \frac{(1-a-\epsilon)^2}{2}$, then for every $z \in E_{sc}$ with $|P_s z| < \frac{\delta}{2}$ and for all integers $j \geq 0$,

$$|P_s(\chi_{\delta\eta}(z))_j| < \frac{\delta}{2}. \tag{5.2}$$

We can now give the following proof.

Proof of Theorem 5.1. We divide the long proof into several steps. The first step concerns the proof of the C^1-smoothness. Except for the last remark, all results in Step 1 belong to [10].

Step 1. Fix $\eta, \tilde{\eta}, \overline{\eta}$ so that $1 + \epsilon < \eta < \tilde{\eta} \leq \overline{\eta}$ with $\overline{\eta} \in (\eta^k, b - \epsilon)$, and fix $\delta > 0$ so that

$$\delta < \delta_\eta, \qquad \lambda(\delta) < \frac{(1-a-\epsilon)^2}{2}, \qquad \kappa := \sup_{\tilde{\eta} \in [\eta, \overline{\eta}]} \lambda(\delta) c(\tilde{\eta}) < 1.$$

Let

$$P = \left\{ x \in E_{sc} : |x_s| < \frac{\delta}{2} \right\}.$$

P is an open set in the Banach space $\Lambda = E_{sc}$.

Recall that $r_\delta|_{\{x \in E : |x_s| < \delta\}}$ is C^k-smooth and $\sup\{|D^1 r_\delta(x)| : |x_s| < \delta\} \leq \lambda(\delta)$. It was shown in [10] that for any $\tilde{\eta} \in (\eta, \overline{\eta}]$, the linear map

$$A^{(1)}_{r_\delta}(\chi) : E^{\mathbb{N}} \ni \hat{\chi} = (\hat{x}_j)_0^\infty \mapsto (D^1 r_\delta(x_j)\hat{x}_j)_0^\infty \in E^{\mathbb{N}}, \quad \chi = (x_j)_0^\infty, \quad |P_s x_j| < \frac{\delta}{2}, \quad j \in \mathbb{N},$$

induces a continuous map $A^{(1)}_{r_\delta \tilde{\eta}\eta}$ from the convex set

$$M = \left\{ \chi \in E_\eta : |P_s x_j| < \frac{\delta}{2} \text{ for all } j \in \mathbb{N} \right\} \subset E_\eta$$

into $\mathcal{L}(E_\eta, E_{\tilde{\eta}})$.

Let $Y = E_\eta, h = T_{\delta\eta}|_{Y \times P}$. It is important to keep in mind that $\chi_{\delta\eta}(P) \subset M$. Define $\Phi : P \to M$ by $\Phi(z) = \chi_{\delta\eta}(z)$; we have $h(\Phi(p), p) = \Phi(p)$ for all $p \in P$. The map $h_0 = h|_{M \times P}$ is given by

$$h_0(\chi, z) = T_{\delta\eta}(\chi, z) = K(R_\delta(\chi)) + (L^j_{sc} z)_0^\infty,$$

so for every $(\chi, z) \in M \times P$ the derivative $D_2 h_0(\chi, z)$ exists and is given by

$$D_2 h_0(\chi, z)\tilde{z} = (L^j_{sc}\tilde{z})_0^\infty \in E_\eta.$$

This derivative is constant on $M \times P$ and therefore is continuous.

Set $Y_1 = E_{\tilde{\eta}}$ and define $j_{\tilde{\eta}\eta} : Y \to Y_1$ by

$$j_{\tilde{\eta}\eta}(\chi) = \chi.$$

Then $j_{\tilde{\eta}\eta}$ is continuous and injective, and the map $k = j_{\tilde{\eta}\eta} \circ h_0$ is given by

$$k(\chi, z) = T_{\delta_{\tilde{\eta}}}(\chi, z) = K_{\tilde{\eta}}(\gamma_{\delta_{\tilde{\eta}}}(\chi)) + (L^j_{sc} z)^\infty_0.$$

It was shown in [10] that the map $A : M \times P \ni (\chi, z) \mapsto K_{\tilde{\eta}} \circ A_{r_\delta \tilde{\eta}\eta}(\chi) \in L(Y, Y_1)$ is continuous, and each $A^{(1)}_{r_\delta}(\chi), \chi \in M$, defines elements

$$A^{(1)}_{r_\delta \eta\eta}(\chi) \in \mathcal{L}(Y, Y) \quad \text{with } |A^{(1)}_{r_\delta \eta\eta}(\chi)| \le \lambda(\delta)$$

and

$$A^{(1)}_{r_\delta \tilde{\eta}\tilde{\eta}}(\chi) \in \mathcal{L}(Y_1, Y_1) \quad \text{with } |A^{(1)}_{r_\delta \tilde{\eta}\tilde{\eta}}(\chi)| \le \lambda(\delta).$$

Define

$$h^{(1)} : M \times P \to \mathcal{L}(Y, Y) \quad \text{by } h^{(1)}(\chi, z) = K_\eta \circ A^{(1)}_{r_\delta \eta\eta}(\chi)$$

and

$$h^{(1)}_1 : M \times P \to \mathcal{L}(Y_1, Y_1) \quad \text{by } h^{(1)}_1(\chi, z) = K_{\tilde{\eta}} \circ A^{(1)}_{r_\delta \tilde{\eta}\tilde{\eta}}(\chi).$$

It was shown in [10] that

$$\max\{|h^{(1)}(\chi, z)|, |h^{(1)}_1(\chi, z)|\} \le \max\{c(\eta), c(\tilde{\eta})\}\lambda(\delta) = \kappa,$$

and all other conditions in Lemma 5.2 are satisfied. Therefore, $j_{\tilde{\eta}\eta} \circ \Phi = j_{\tilde{\eta}\eta} \circ (\chi_{\delta\eta}|_P)$ is C^1-smooth and $j_{\tilde{\eta}\eta} \circ \Phi = \chi_{\delta_{\tilde{\eta}}}|_P$. Moreover, $D^1(j_{\tilde{\eta}\eta} \circ \Phi)$ satisfies

$$D^1(j_{\tilde{\eta}\eta} \circ \Phi)(z) = K_{\tilde{\eta}} \circ A^{(1)}_{r_\delta \tilde{\eta}\tilde{\eta}}(\Phi(z)) \circ D^1(j_{\tilde{\eta}\eta} \circ \Phi)(z) + j_{\tilde{\eta}\eta} \circ (L^j_{sc} \cdot)^\infty_0, \qquad z \in P.$$

The final remark of this step is essential for the general smoothness to be proved in later steps. Recall that for any $\tilde{\eta} \in [\eta, \bar{\eta}]$, $K_{\tilde{\eta}} \circ A^{(1)}_{r_\delta \tilde{\eta}\tilde{\eta}}(\Phi(z)) \in \mathcal{L}(E_{\tilde{\eta}}, E_{\tilde{\eta}})$ and

$$|K_{\tilde{\eta}} \circ A^{(1)}_{r_\delta \tilde{\eta}\tilde{\eta}}(\Phi(z))|_{\mathcal{L}(E_{\tilde{\eta}}, E_{\tilde{\eta}})} \le c(\tilde{\eta})\lambda(\delta) \le \kappa < 1.$$

Therefore, $K_{\tilde{\eta}} \circ A^{(1)}_{r_\delta \tilde{\eta}\tilde{\eta}}(\Phi(z)) \in \mathcal{L}(E_{\tilde{\eta}}, E_{\tilde{\eta}})$ is a uniform contraction and the map

$$K_{\tilde{\eta}} \circ A^{(1)}_{r_\delta \tilde{\eta}\tilde{\eta}}(\Phi(z))L + j_{\tilde{\eta}\eta} \circ (L^j_{sc} \cdot)^\infty_0, \qquad z \in P,\ L \in \mathcal{L}(\Lambda, E_{\tilde{\eta}}),$$

has a unique fixed point $\Psi^{(1)}_{\tilde{\eta}}(z)$ in $\mathcal{L}(\Lambda, E_{\tilde{\eta}})$. Since $j_{\tilde{\eta}\eta} \circ \Psi^{(1)}_\eta(z) \in \mathcal{L}(\Lambda, E_{\tilde{\eta}})$, the uniqueness of a fixed point in $\mathcal{L}(\Lambda, E_{\tilde{\eta}})$ implies

$$\Psi^{(1)}_{\tilde{\eta}}(z) = j_{\tilde{\eta}\eta} \circ \Psi^{(1)}_\eta(z).$$

In particular,

$$D^1(j_{\tilde{\eta}\eta} \circ \Phi)(z) = \Psi^{(1)}_{\tilde{\eta}}(z) = j_{\tilde{\eta}\eta} \circ \Psi^{(1)}_\eta(z), \qquad z \in P.$$

Step 2. We now assume $k \geq 2$. For any given integer l with $1 \leq l \leq k$, consider the operator $A^{(l)}_{r_\delta}$ given by

$$A^{(l)}_{r_\delta}(\chi)(\chi^1, \ldots, \chi^l) = (D^l r_\delta(x_j)(x^1_j, \ldots, x^l_j))^\infty_0,$$
$$\chi = (x_j)^\infty_0, \quad \chi^i = (x^i_j)^\infty_0 \in E^{\mathbb{N}}, \qquad 1 \leq i \leq l.$$

Note that $A^{(l)}_{r_\delta}$ with $l = 1$ was introduced in Step 1. The operators $A^{(l)}_{r_\delta}$ with $1 \leq l \leq k$ are the substitution operators of $D^l r_\delta$; they can be regarded as the Nemytskii operators induced by $D^l r_\delta$ in the appropriate spaces.

As $r_\delta|_{\{z \in E; |z_s| \leq \frac{\delta}{2}\}}$ has all lth derivatives bounded, $1 \leq l \leq k$, we can show that

$$A^{(l)}_{r_\delta}(\chi)(E_{\eta^{r_1}} \times \cdots \times E_{\eta^{r_l}}) \subset E_{\eta^{r_1+\cdots+r_l}}, \qquad \chi \in M,\ 1 \leq r_i \leq l.$$

We are going to use induction on p with $1 \leq p \leq k$. (Note that for the remainder of this proof, p is not the fixed point of f.) The strategy is to show that the order of the smoothness of $j_{\tilde\eta\eta} \circ \Phi : P \to E_{\tilde\eta}$ is increased by at least one as $\tilde\eta$ passes η^{p-1}, from $(\eta, \eta^{p-1}]$ to $(\eta^{p-1}, \eta^p]$, and to construct higher order derivatives inductively.

Suppose $1 \leq p < k$ and suppose that for all integers q with $1 \leq q \leq p$ and for all $\tilde\eta \in [\eta^q, \bar\eta]$, the mapping $j_{\tilde\eta\eta} \circ \Phi : P \to E_{\tilde\eta}$ is C^q-smooth with

(i) $D^q(j_{\tilde\eta\eta} \circ \Phi) = j_{\tilde\eta\eta} \circ \Psi^{(q)}_\eta$;

(ii) $\Psi^{(q)}_\eta(z) \in \mathcal{L}^{(q)}(\Lambda, E_{\eta^q})$ as the unique solution of

$$F = KA^{(1)}_{r_\delta}(\Phi(z))F + H_q(z), \qquad F \in \mathcal{L}^{(q)}(\Lambda, E_{\eta^q}), \qquad z \in P,$$

with $H_1(z)\tilde z = (L^j_{sc}\tilde z)^\infty_0, \tilde z \in \Lambda$, and for $q \geq 2$,

$$H_q(z) = \sum_{2 \leq l \leq q, 1 \leq i \leq l, 1 \leq r_i \leq l, r_1+\cdots+r_l = q} KA^{(l)}_{r_\delta}(\Phi(z))(\Psi^{(r_1)}_\eta(z), \ldots, \Psi^{(r_l)}_\eta(z));$$

(iii) $j_{\tilde\eta\eta} \circ \Psi^{(q)}_\eta : P \to \mathcal{L}^{(q)}(\Lambda, E_{\tilde\eta})$ being continuous.

We want to show that the above statement is true for $q = p + 1$.

Step 3. Fix $\tilde\eta \in [\eta^{p+1}, \bar\eta]$ and let $X = \mathcal{L}^{(p)}(\Lambda, E_{\tilde\eta})$. For $F \in \mathcal{L}^{(p)}(\Lambda, E_{\eta^p})$ and $z \in P$, let

$$H(F, z) = KA^{(1)}_{r_\delta}(\Phi(z))F + H_p(z).$$

By the induction hypotheses in Step 2 and the estimates in Step 1, for any $\eta^* \in [\eta^p, \overline{\eta}]$, $F \in \mathcal{L}^{(p)}(\Lambda, E_{\eta^*}), z \in P$, we have $H(F, z) \in E_{\eta^*}$ and

$$|H(\tilde F, z) - H(F, z)| \leq c(\eta^*)\lambda(\delta)|\tilde F - F| \leq \kappa|\tilde F - F|, \qquad \tilde F, F \in \mathcal{L}^{(p)}(\Lambda, E_{\eta^*}).$$

Therefore, $H(\cdot, z)$ has a unique fixed point in $\mathcal{L}^{(p)}(\Lambda, E_{\eta^*})$. Note also that for $\eta^* = \eta^p$ this fixed point is given by $\Psi^{(p)}_\eta(z)$. From now on, we restrict $H : X \times P \to X$ and let $N = \mathcal{L}^{(p)}(\Lambda, E_{\eta^p})$, $H_0 = H|_{N \times P}$.

Step 4. Let $e_j : E^{\mathbb{N}} \to E$ be given by

$$e_j((z_i)^\infty_0) = z_j, \qquad (z_i)^\infty_0 \in E^{\mathbb{N}}.$$

Define $\Phi_j = e_j \circ \Phi : P \to E$ and $\Psi^{(l)}_{\eta j}(z)\tilde z = e_j \circ \Psi^{(l)}_\eta(z)\tilde z$ for $1 \leq l \leq p, z \in P$, and $\tilde z \in \Lambda$. We claim that Φ_j is C^1-smooth and $D\Phi_j(z)\tilde z = \Psi^{(1)}_{\eta j}(z)\tilde z$. In fact,

$\Phi_j = e_j \circ \Phi = e_j \circ j_{\tilde{\eta}\eta}\Phi$, and thus Φ_j is C^1-smooth since $j_{\tilde{\eta}\eta} \circ \Phi$ is. Moreover, $D(j_{\tilde{\eta}\eta} \circ \Phi) = j_{\tilde{\eta}\eta} \circ \Psi^{(1)}_\eta$, and thus

$$e_j(j_{\tilde{\eta}\eta}\Psi^{(1)}_\eta(z)\tilde{z}) = e_j D(j_{\tilde{\eta}\eta} \circ \Phi)(z)\tilde{z}.$$

This shows that $\Psi^{(1)}_{\eta j}(z)\tilde{z} = D\Phi_j(z)\tilde{z}$.

Step 5. We now prove that for any fixed $F \in \mathcal{L}^{(p)}(\Lambda, E_{\eta^p})$ and $\tilde{\eta} > \eta^{p+1}$, the mapping $P \ni z \mapsto KA^{(1)}_{r_\delta}(\Phi(z))F \in \mathcal{L}^{(p)}(\Lambda, E_{\tilde{\eta}})$ has a derivative, which is given by $KA^{(2)}_{r_\delta}(\Phi(z))(\Psi^{(1)}_\eta(z)\cdot, F)$, and the map

$$P \times \mathcal{L}^{(p)}(\Lambda, E_{\eta^p}) \ni (z, F) \mapsto KA^{(2)}_{r_\delta}(\Phi(z))(\Psi^{(1)}_\eta(z)\cdot, F) \in \mathcal{L}(\Lambda, \mathcal{L}^{(p)}(\Lambda, E_{\tilde{\eta}}))$$

is continuous.

Let

$$|D^l r_\delta|_\infty = \sup\left\{|D^l r_\delta(z)|; z \in E, |z_s| \le \frac{\delta}{2}\right\}.$$

Note that for $1 \le l \le k$, $|D^l r_\delta|_\infty < \infty$.

For any $z_i \in \Lambda$ with $1 \le i \le p$, let

$$F_j(z_1, \dots, z_p) = e_j(F(z_1, \dots, z_p)).$$

Then for $\tilde{z}, z \in P$ we have

$$\begin{aligned}
&\tilde{\eta}^{-j}|D^1 r_\delta(\Phi_j(\tilde{z}))F_j(z_1, \dots, z_p) - D^1 r_\delta(\Phi_j(z))F_j(z_1, \dots, z_p) \\
&\quad - D^2 r_\delta(\Phi_j(z))(\Psi^{(1)}_{\eta j}(z)(\tilde{z} - z), F_j(z_1, \dots, z_p))| \\
&\le \tilde{\eta}^{-j}|D^1 r_\delta(\Phi_j(\tilde{z})) - D^1 r_\delta(\Phi_j(z)) - D^2 r_\delta(\Phi_j(z))\Psi^{(1)}_{\eta j}(z)(\tilde{z} - z)|\eta^{pj}|F||z_1| \cdots |z_p|.
\end{aligned}$$

Therefore, for any $\epsilon > 0$ there exists an integer $J_0 \ge 0$ so that if $j \ge J_0$ and if $|\tilde{z} - z| \le 1$, then

$$\begin{aligned}
&\tilde{\eta}^{-j}|D^1 r_\delta(\Phi_j(\tilde{z}))F_j(z_1, \dots, z_p) - D^1 r_\delta(\Phi_j(z))F_j(z_1, \dots, z_p) \\
&\quad - D^2 r_\delta(\Phi_j(z))(\Psi^{(1)}_{\eta j}(z)(\tilde{z} - z), F_j(z_1, \dots, z_p))| \\
&\le [(\tilde{\eta}\eta^{-p})^{-j} 2|D^1 r_\delta|_\infty |F| + (\tilde{\eta}\eta^{-p})^{-j}|D^2 r_\delta|_\infty \eta^j |\Psi^{(1)}_{\eta j}(z)(\tilde{z} - z)||F|]|z_1| \cdots |z_p| \\
&\le \frac{\epsilon}{c(\tilde{\eta}) + 1}|z_1| \cdots |z_p|.
\end{aligned}$$

As $r_\delta|_{\{x \in E; |x_s| < \delta\}}$ is C^k-smooth, $k \ge 2$, $\Phi_i : P \to E$ is C^1-smooth and $D\Phi_j(z)\tilde{z} = \Psi^{(1)}_{\eta j}(z)\tilde{z}$ for $z \in P$ and $\tilde{z} \in \Lambda$. For any $\epsilon > 0$, there exists $\delta > 0$ so that when $\tilde{z} \in P$ and $|\tilde{z} - z| < \delta$, then for $0 \le j \le J_0$ we have

$$|Dr_\delta(\Phi_j(\tilde{z})) - Dr_\delta(\Phi_j(z)) - D^2 r_\delta(\Phi_j(z))\Psi^{(1)}_{\eta j}(z)(\tilde{z} - z)| < \frac{\tilde{\eta}^j \eta^{-pj}}{|F| + 1} \frac{\epsilon}{c(\tilde{\eta}) + 1},$$

and hence

$$\begin{aligned}
&\tilde{\eta}^{-j}|D^1 r_\delta(\Phi_j(\tilde{z}))F_j(z_1, \dots, z_p) - D^1 r_\delta(\Phi_j(z))F_j(z_1, \dots, z_p) \\
&\quad - D^2 r_\delta(\Phi_j(z))(\Psi^{(1)}_{\eta j}(z)(\tilde{z} - z), F_j(z_1, \dots, z_p))| \\
&< \tilde{\eta}^{-j} \frac{\tilde{\eta}^j \eta^{-pj}}{|F| + 1} \frac{\epsilon}{c(\tilde{\eta}) + 1} \eta^{pj}|F||z_1| \cdots |z_p| \\
&\le \frac{\epsilon}{c(\tilde{\eta}) + 1}|z_1| \cdots |z_p|.
\end{aligned}$$

Therefore,

$$\begin{aligned}
&|KA^{(1)}_{r_\delta}(\Phi(\tilde z))F - KA^{(1)}_{r_\delta}(\Phi(z))F - KA^{(2)}_{r_\delta}(\Phi(z))(\Psi^{(1)}_\eta(z)(\tilde z - z), F)|\\
&\le c(\tilde\eta) \sup_{z_i\in\Lambda,|z_i|\le 1,1\le i\le p,j\ge 0} \tilde\eta^{-j}|[D^1 r_\delta(\Phi_j(\tilde z))F_j(z_1,\dots,z_p)\\
&\qquad - D^1 r_\delta(\Phi_j(z))F_j(z_1,\dots,z_p) - D^2 r_\delta(\Phi_j(z))(\Psi^{(1)}_{\eta j}(z)(\tilde z - z), F_j(z_1,\dots,z_p))]|\\
&< c(\tilde\eta)\frac{\epsilon}{c(\tilde\eta)+1} \le \epsilon.
\end{aligned}$$

This proves the differentiability.

We now prove that the map

$$P\times N \ni (z,F) \mapsto KA^{(2)}_{r_\delta}(\Phi(z))(\Psi^{(1)}_\eta(z)\cdot, F) \in \mathcal{L}(\Lambda, \mathcal{L}^{(p)}(\Lambda, E_{\tilde\eta})) = \mathcal{L}^{(p+1)}(\Lambda, E_{\tilde\eta})$$

is continuous. Fix $(z,F)\in P\times N$. Then for any $(\tilde z,\tilde F)\in P\times N$, we have

$$\begin{aligned}
&|KA^{(2)}_{r_\delta}(\Phi(\tilde z))(\Psi^{(1)}_\eta(\tilde z)\cdot,\tilde F) - KA^{(2)}_{r_\delta}(\Phi(z))(\Psi^{(1)}_\eta(z)\cdot, F)|\\
&\le |KA^{(2)}_{r_\delta}(\Phi(\tilde z))(\Psi^{(1)}_\eta(\tilde z)\cdot,\tilde F) - KA^{(2)}_{r_\delta}(\Phi(z))(\Psi^{(1)}_\eta(z)\cdot,\tilde F)|\\
&\quad + |KA^{(2)}_{r_\delta}(\Phi(z))(\Psi^{(1)}_\eta(z)\cdot,\tilde F) - KA^{(2)}_{r_\delta}(\Phi(z))(\Psi^{(1)}_\eta(z)\cdot, F)|
\end{aligned}$$

and

$$\begin{aligned}
&|KA^{(2)}_{r_\delta}(\Phi(\tilde z))(\Psi^{(1)}_\eta(\tilde z)\cdot,\tilde F) - KA^{(2)}_{r_\delta}(\Phi(z))(\Psi^{(1)}_\eta(z)\cdot,\tilde F)|\\
&= \sup_{z_i\in\Lambda,|z_i|\le 1,1\le i\le p+1} |KA^{(2)}_{r_\delta}(\Phi(\tilde z))(\Psi^{(1)}_\eta(\tilde z)z_{p+1},\tilde F(z_1,\dots,z_p))\\
&\qquad\qquad - KA^{(2)}_{r_\delta}(\Phi(z))(\Psi^{(1)}_\eta(z)z_{p+1},\tilde F(z_1,\dots,z_p))|_{E_{\tilde\eta}}\\
&= \sup_{z_i\in\Lambda,|z_i|\le 1,1\le i\le p+1} |K_{\tilde\eta}[A^{(2)}_{r_\delta}(\Phi(\tilde z))(\Psi^{(1)}_\eta(\tilde z)z_{p+1},\tilde F(z_1,\dots,z_p))\\
&\qquad\qquad - A^{(2)}_{r_\delta}(\Phi(z))(\Psi^{(1)}_\eta(z)z_{p+1},\tilde F(z_1,\dots,z_p))]|_{E_{\tilde\eta}}.
\end{aligned}$$

Moreover,

$$\begin{aligned}
&|A^{(2)}_{r_\delta}(\Phi(\tilde z))(\Psi^{(1)}_\eta(\tilde z)z_{p+1},\tilde F(z_1,\dots,z_p)) - A^{(2)}_{r_\delta}(\Phi(z))(\Psi^{(1)}_\eta(z)z_{p+1},\tilde F(z_1,\dots,z_p))|_{E_{\tilde\eta}}\\
&= \sup_{j\in\mathbb{N}} \tilde\eta^{-j}|D^2 r_\delta(\Phi_j(\tilde z))(\Psi^{(1)}_{\eta j}(\tilde z)z_{p+1},\tilde F_j(z_1,\dots,z_p))\\
&\qquad - D^2 r_\delta(\Phi_j(z))(\Psi^{(1)}_{\eta j}(z)z_{p+1},\tilde F_j(z_1,\dots,z_p))|.
\end{aligned}$$

Note that for any $\eta^*\in(\eta,\bar\eta]$, the mapping $j_{\eta^*\eta}\circ\Psi^{(1)}_\eta : P\to E_{\eta^*}$ is continuous. Fix $\eta^*\in(\eta,\frac{\bar\eta}{\eta^p})$. There exists $\delta_1>0$ so that if $\tilde z\in P$ and $|\tilde z - z|<\delta_1$, then

$$|j_{\eta^*\eta}\circ\Psi^{(1)}_\eta(\tilde z) - j_{\eta^*\eta}\circ\Psi^{(1)}_\eta(z)|\le 1.$$

Therefore, $\eta^{*-j}|\Psi^{(1)}_{\eta j}(\tilde z) - \Psi^{(1)}_{\eta j}(z)|\le 1$ for all $j\in\mathbb{N}$. In particular, $|\Psi^{(1)}_{\eta j}(\tilde z) - \Psi^{(1)}_{\eta j}(z)|\le \eta^{*j}$ for all $j\in\mathbb{N}$.

Find an integer $J_0\ge 0$ so that if $j\ge J_0$, then

$$|D^2 r_\delta|_\infty\left(\frac{\tilde\eta}{\eta^p}\right)^{-j}[2\eta^j|\Psi^{(1)}_\eta(z)| + (\eta^*)^j] < \frac{\epsilon}{2(c(\eta^*)+1)(|F|+1)}.$$

Therefore, for $j \geq J_0$, we have

$$\begin{aligned}
&\tilde{\eta}^{-j}|D^2 r_\delta(\Phi_j(\tilde{z}))(\Psi_\eta^{(1)}(\tilde{z})z_{p+1}, \tilde{F}_j(z_1,\dots,z_p)) - D^2 r_\delta(\Phi_j(z))(\Psi_{\eta j}^{(1)}(z)z_{p+1}, \tilde{F}_j(z_1,\dots,z_p))| \\
&\leq |D^2 r_\delta|_\infty \tilde{\eta}^{-j}[2|\Psi_{\eta j}^{(1)}(z)| + \eta^{*j}]\eta^{pj}|\tilde{F}||z_1|\cdots|z_p||z_{p+1}| \\
&\leq |D^2 r_\delta|_\infty \left(\frac{\tilde{\eta}}{\eta^p}\right)^{-j} [2\eta^j|\Psi_\eta^{(1)}(z)| + \eta^{*j}]|\tilde{F}||z_1|\cdots|z_{p+1}|.
\end{aligned}$$

For $0 \leq j \leq J_0$, as $\Phi_j = e_j\Phi$ and $\Psi_{\eta j}^{(1)} = e_j j_{\eta^*\eta}\Psi_{\eta j}^{(1)}$ are continuous, we can find $\delta_2 > 0$ so that when $\tilde{z} \in P$ and $|\tilde{z} - z| < \delta_2$, we have

$$\begin{aligned}
&\tilde{\eta}^{-j}|D^2 r_\delta(\Phi_j(\tilde{z}))(\Psi_{\eta j}^{(1)}(\tilde{z})z_{p+1}, \tilde{F}_j(z_1,\dots,z_p)) - D^2 r_\delta(\Phi_j(z))(\Psi_{\eta j}^{(1)}(z)z_{p+1}, \tilde{F}_j(z_1,\dots,z_p))| \\
&\quad < \frac{\epsilon}{2(c(\tilde{\eta})+1)(|F|+1)}|\tilde{F}||z_1|\cdots|z_{p+1}|.
\end{aligned}$$

Therefore, if $|\tilde{F} - F| \leq 1$ and $|\tilde{z} - z| < \min\{\delta_1, \delta_2\}$, we have

$$\begin{aligned}
&|KA_{r_\delta}^{(2)}(\Phi(\tilde{z}))(\Psi_\eta^{(1)}(\tilde{z})\cdot, \tilde{F}) - KA_{r_\delta}^{(2)}(\Phi(z))(\Psi_\eta^{(1)}(z)\cdot, \tilde{F})| \\
&\quad \leq c(\tilde{\eta})\frac{\epsilon}{2(c(\tilde{\eta})+1)} < \frac{\epsilon}{2}.
\end{aligned}$$

In a similar fashion, we get

$$\begin{aligned}
&|KA_{r_\delta}^{(1)}(\Phi(z))(\Psi_\eta^{(1)}(z), \tilde{F})_K A_{r_\delta}^{(2)}(\Phi(z))(\Psi_\eta^{(1)}(z), F)| \\
&= \sup_{z_i\in\Lambda, |z_i|\leq 1, 1\leq i\leq p+1} |KA_{r_\delta}^{(2)}(\Psi_\eta^{(1)}(z)z_{p+1}, (\tilde{F} - F)(z_1,\dots,z_p))|_{E_{\tilde{\eta}}} \\
&\leq c(\tilde{\eta}) \sup_{z_i\in\Lambda, |z_i|\leq 1, 1\leq i\leq p+1, j\geq 0} \tilde{\eta}^{-j}|D^2 r_\delta|_\infty \eta^{-j}|\Psi_\eta^{(1)}(z)|\eta^{-pj}|\tilde{F} - F||z_1|\cdots|z_{p+1}| \\
&\leq c(\tilde{\eta})|D^2 r_\delta|_\infty |\Psi_\eta^{(1)}(z)||\tilde{F} - F|.
\end{aligned}$$

Therefore, if $|\tilde{z} - z| < \min\{\delta_1, \delta_2\}$ and if $|\tilde{F} - F| < \min\{1, \frac{\epsilon}{2c(\tilde{\eta})|D^2 r_\delta|_\infty |\Psi^{(1)}(z)|+1}\}$, then $|KA_{r_\delta}^{(1)}(\Phi(\tilde{z})\cdot, \tilde{F}) - KA_{r_\delta}^{(1)}(\Phi(z)\cdot, F)| < \epsilon$. This completes the proof of the required continuity.

For the sake of later reference, let us summarize the main idea of the arguments involved in this step. To estimate

$$|KA_{r_\delta}^{(1)}(\Phi(\tilde{z}))F - KA_{r_\delta}^{(1)}(\Phi(z))F - KA_{r_\delta}^{(2)}(\Phi(z))(\Psi_\eta^{(1)}(z)(\tilde{z} - z), F)|$$

in the proof of the differentiability of the mapping $P \ni z \mapsto KA_{r_\delta}^{(1)}(\Phi(z))F \in \mathcal{L}^{(p)}(\Lambda, E_{\tilde{\eta}})$, we used the definition of the operator norm for multilinear operators $KA_{r_\delta}^{(1)}(\Phi(z))F$ and the definition of the norm in $E_{\tilde{\eta}}$ and were led to the estimation of the expression

$$\begin{aligned}
&\tilde{\eta}^{-j}|[D^1 r_\delta(\Phi_j(\tilde{z}))F_j(z_1,\dots,z_p) - D^1 r_\delta(\Phi_j(z))F_j(z_1,\dots,z_p) \\
&\qquad - D^2 r_\delta(\Phi_j(z))(\Psi_{\eta j}^{(1)}(z)(\tilde{z} - z), F_j(z_1,\dots,z_p))|
\end{aligned}$$

for each given nonnegative integer j. The above term can be made arbitrarily small if j is sufficiently large, thanks to the choice of $\tilde{\eta} > \eta^{p+1}$ (the essential gradient of the proof). When j is restricted to a finite set, the smallness of the above expression

follows from the continuity of the involved operators and mappings. Similar arguments were used to estimate

$$|KA^{(2)}_{r_\delta}(\Phi(\tilde z))(\Psi^{(1)}_\eta(\tilde z)\cdot,\tilde F)-KA^{(2)}_{r_\delta}(\Phi(z))(\Psi^{(1)}_\eta(z)\cdot,F)|$$

in the proof of the continuity of the map

$$P\times N\ni(z,F)\mapsto KA^{(2)}_{r_\delta}(\Phi(z))(\Psi^{(1)}_\eta(z)\cdot,F)\in\mathcal{L}(\Lambda,\mathcal{L}^{(p)}(\Lambda,E_{\tilde\eta})).$$

Step 6. Let $2\le l\le p, 1\le r_i<l$ with $r_1+\cdots+r_l=p$. For any integer $j\ge 0$, $z\in\Lambda$, and $\hat z_{r_i}\in\Lambda^{r_i}$, let

$$\Psi^{(r_i)}_{\eta j}(z)\hat z_{r_i}=e_j(\Psi^{(r_i)}_\eta(z)\hat z_{r_i}).$$

Then for $z,\tilde z\in\Lambda$ we have

$$\begin{aligned}
&\Big|KA^{(l)}_{r_\delta}(\Phi(\tilde z))(\Psi^{(r_1)}_\eta(\tilde z),\dots,\Psi^{(r_l)}_\eta(\tilde z))-KA^{(l)}_{r_\delta}(\Phi(z))(\Psi^{(r_1)}_\eta(z),\dots,\Psi^{(r_l)}_\eta(z))\\
&\quad-\sum_{k=1}^{l}KA^{(l)}_{r_\delta}(\Phi(z))(\Psi^{(r_1)}_\eta(z),\dots,\Psi^{(r_k+1)}_\eta(z)(\tilde z-z),\dots,\Psi^{(r_l)}_\eta(z))\\
&\quad-KA^{(l+1)}_{r_\delta}(\Phi(z))(\Psi^{(1)}_\eta(z)(\tilde z-z),\Psi^{(r_1)}_\eta(z),\dots,\Psi^{(r_l)}_\eta(z))\Big|\\
&\le c(\tilde\eta)\sup_{\hat z_{r_i}\in\Lambda^{r_i},|z_{r_i}|\le 1,1\le i\le p,j\ge 0}\tilde\eta^{-j}\Big|D^l r_\delta(\Phi_j(\tilde z))(\Psi^{(r_1)}_{\eta j}(\tilde z)\hat z_{r_1},\dots,\Psi^{(r_l)}_{\eta j}(\tilde z)\hat z_{r_l})\\
&\quad-D^l r_\delta(\Phi_j(z))(\Psi^{(r_1)}_{\eta j}(z)\hat z_{r_1},\dots,\Psi^{(r_l)}_{\eta j}(z)\hat z_{r_l})\\
&\quad-\sum_{k=1}^{l}D^l r_\delta(\Phi_j(z))(\Psi^{r_1}_{\eta j}(z)\hat z_{r_1}\dots,\Psi^{(r_k+1)}_{\eta j}(z)(\tilde z-z,\hat z_{r_k}),\dots,\Psi^{(r_l)}_{\eta j}(z)z_{r_l})\\
&\quad-D^{l+1}r_\delta(\Phi_j(z))(\Psi^{(1)}_{\eta j}(z)(\tilde z-z),\Psi^{(r_1)}_{\eta j}(z)\hat z_{r_1},\dots,\Psi^{(r_l)}_{\eta j}(z)\hat z_{r_l})\Big|.
\end{aligned}$$

Now we can use the fact that $|D^l r_\delta|_\infty<\infty$ for $1\le l\le p$, and the induction hypothesis implies that the mapping

$$P\ni z\mapsto\Psi^{(r_i)}_{\eta j}(z)\in\mathcal{L}^{(r_i)}(\Lambda,E_{\eta^{r_i}})$$

is differentiable, and we apply an argument similar to that for the first part of Step 5 to show that for any $2\le l\le p$, $1\le r_i<l$ with $r_1+\cdots+r_l=p$, the map $P\ni z\mapsto KA^{(l)}_{r_\delta}(\Phi(z))(\Psi^{(r_1)}_\eta(z),\dots,\Psi^{(r_l)}_\eta(z))\in\mathcal{L}^{(p)}(\Lambda,E_{\tilde\eta})$ is differentiable and the derivative is given by

$$\begin{aligned}
&\sum_{j=1}^{l}KA^{(l)}_{r_\delta}(\Phi(z))(\Psi^{(r_1)}_\eta(z),\dots,\Psi^{(r_j+1)}_\eta(z),\dots,\Psi^{(r_l)}_\eta(z))\\
&\quad+KA^{(l+1)}_{r_\delta}(\Phi(z))(\Psi^{(1)}_\eta(z),\Psi^{(r_1)}_\eta(z),\dots,\Psi^{(r_l)}_\eta(z)).
\end{aligned}$$

The continuity of the above derivative, with respect to $z \in P$, can also be verified by using an argument similar to that for the second part of Step 5 and by noting that the induction hypothesis implies that the mapping

$$P \ni z \mapsto \Psi_{\eta j}^{(r_i+1)}(z) \in \mathcal{L}^{(r_i+1)}(\Lambda, E_{\eta^{r_i}})$$

is continuous.

Step 7. Let $\hat{\eta}$ be given so that $\hat{\eta} \in (\tilde{\eta}, \bar{\eta}]$. Define the continuous linear injective map $J : X \to X_1 = \mathcal{L}^{(p)}(\Lambda, E_{\hat{\eta}})$ by

$$J(L)(z_1, \ldots, z_p) = j_{\hat{\eta}\tilde{\eta}} L(z_1, \ldots, z_p), \qquad z_1, \ldots, z_p \in \Lambda, \quad L \in X.$$

Then

$$JH_0(F, z) = j_{\hat{\eta}\tilde{\eta}} K A_{r_\delta}^{(1)}(\Phi(z))F + j_{\hat{\eta}\eta} H_p(z), \qquad z \in P, \quad F \in \mathcal{L}^{(p)}(\Lambda, E_{\eta^p}).$$

Let $A : P \to \mathcal{L}(X, X_1)$ be given by

$$(A(z)F)(z_1, \ldots, z_p) = j_{\hat{\eta}\tilde{\eta}} K \circ A_{r_\delta}(\Phi(z))F(z_1, \ldots, z_p), \qquad z \in P, \ F \in X, \ x_1, \ldots, z_p \in \Lambda.$$

Again, we can use arguments similar to those in Step 5 (see the remarks at the end of Step 5) to show that A is continuous. Moreover, we have

$$JH_0(\tilde{F}, z) - JH_0(F, z) = A(z)(\tilde{F} - F), \qquad z \in P, \quad \tilde{F}, F \in N.$$

Note that for any $\eta^* \geq \eta$, $KA_{r_\delta}^{(1)}(\Phi(z))$ induces a bounded linear map from $\mathcal{L}^{(p)}(\Lambda, E_{\eta^*})$ into itself by

$$Q_{\eta^*}(L)(z_1, \ldots, z_p) = K_{\eta^*} A_{r_\delta \eta^* \eta^*}^{(1)}(\Phi(z)) L(z_1, \ldots, z_p)$$

and

$$|Q_{\eta^*}| \leq c(\eta^*)\lambda(\delta).$$

Define $H^{(1)} : P \to \mathcal{L}(X, X)$ and $H_1^{(1)} : P \to \mathcal{L}(X_1, X_1)$ by

$$H^{(1)}(z) = Q_{\tilde{\eta}}, \quad H_1^{(1)}(z) = Q_{\hat{\eta}}, \qquad z \in P.$$

Clearly, we have for $F \in X$ the following:

$$\begin{aligned} A(z)F &= j_{\hat{\eta}\tilde{\eta}} K A_{r_\delta}^{(1)}(\Phi(z))F \\ &= j_{\hat{\eta}\tilde{\eta}} Q_{\tilde{\eta}} F = JH_1^{(1)}(z)F \\ &= Q_{\hat{\eta}} j_{\hat{\eta}\tilde{\eta}} F = H_1^{(1)}(z)JF \end{aligned}$$

and

$$|H^{(1)}(z)| \leq c(\tilde{\eta})\lambda(\delta) \leq \kappa, \qquad |H_1^{(1)}(z)| \leq c(\hat{\eta})\lambda(\delta) \leq \kappa.$$

Moreover, the mapping

$$P \ni z \mapsto J \circ H^{(1)}(z) = j_{\hat{\eta}\tilde{\eta}} \circ Q_{\tilde{\eta}} = J_{\hat{\eta}\tilde{\eta}} K_{\tilde{\eta}} A_{r_\delta \tilde{\eta}\tilde{\eta}}^{(1)}(\Phi(z)) = A \in \mathcal{L}(X, X_1)$$

is continuous. Therefore, by Lemma 5.2, the map $j_{\hat{\eta}\eta}\circ\Psi_\eta^{(p)} = j_{\hat{\eta}\tilde{\eta}}\circ j_{\tilde{\eta}\eta}\circ\Psi_\eta^{(p)} : P \to X_1$ is C^1-smooth and

$$D(j_{\hat{\eta}\eta}\circ\Psi_\eta^{(p)})(z) = KA_{r_\delta}^{(1)}(\Phi(z))D(j_{\hat{\eta}\tilde{\eta}}\circ\Psi_\eta^{(p)}) + j_{\hat{\eta}\tilde{\eta}}\circ D_2H_0(\Psi_\eta^{(p)}, z), \qquad z \in P.$$

Step 8. We now prove that the mapping $j_{\hat{\eta}\eta}\circ\Phi : P \to E_{\hat{\eta}}$ is C^{p+1}-smooth. Indeed, as $\hat{\eta} > \eta^{p+1} > \eta^p$, $j_{\hat{\eta}\eta}\circ\Phi : P \to E_{\hat{\eta}}$ is C^p-smooth and

$$D^p(j_{\hat{\eta}\eta}\circ\Phi) = j_{\hat{\eta}\eta}\circ\Psi_\eta^{(p)}.$$

Since $j_{\hat{\eta}\eta}\circ\Psi_\eta^{(p)}$ is C^1-smooth, we conclude that $j_{\hat{\eta}\eta}\circ\Phi$ is C^{p+1}-smooth and $D^{p+1}(j_{\hat{\eta}\eta}\circ\Phi) = D(j_{\hat{\eta}\eta}\circ\Psi_\eta^{(p)})$. Let $H_{p+1}(z) = D_2H_0(\Psi_\eta^p(z), z)$ and let $\Psi_\eta^{(p+1)}(z)$ be the unique fixed point of the contraction

$$\mathcal{L}^{(p+1)}(\Lambda, E_{\eta^{p+1}}) \ni F \mapsto K_{\eta^{p+1}}A^{(1)}_{r_\delta\eta^{p+1}\eta^{p+1}}(\Phi(z))F + H_{p+1}(z) \in \mathcal{L}^{(p+1)}(\Lambda, E_{\eta^{p+1}});$$

then $D^{p+1}(j_{\hat{\eta}\eta}\circ\Phi) = j_{\hat{\eta}\eta}\Psi_\eta^{(p+1)}$. This proves all conclusions in the case of $p+1$.

Therefore, we have proved that for a fixed $\tilde{\eta} > \eta^k$ the mapping $j_{\tilde{\eta}\eta}\circ\Phi : P \to E_{\eta^k}$ is C^k-smooth, and hence $\chi_{\delta_{\tilde{\eta}}}|_P = j_{\tilde{\eta}\eta}\Phi$ is C^k smooth. Consequently, $w_{\delta_{\tilde{\eta}}}|_P = P_u \circ e_0\chi_{\delta_{\tilde{\eta}}}|P$ is C^k-smooth. □

Similarly, we have the following center-unstable manifold theorem.

THEOREM 5.3. *Let $f : U \to E$ be a C^1-map on an open subset U of a Banach space E over $\mathbb{R}$, with a fixed point p. Let $L = Df(p)$ and assume that E has the following decomposition:*

$$E = E_s \oplus E_c \oplus E_u,$$

where E_s is a closed subspace, E_c and E_u are finite-dimensional, $L(E_s) \subset E_s$, $L(E_c) \subset E_c$, and $L(E_u) \subset E_u$. We further assume that

$$\sigma_s = \sigma(L|_{E_s} : E_s \to E_s) \text{ is contained in a compact subset of } \{z \in \mathbb{C} : |z| < 1\}$$

and

$$\sigma_c = \sigma(L|_{E_c} : E_c \to E_c) \subset S^1_{\mathbb{C}},$$
$$\sigma_u = \sigma(L|_{E_u} : E_u \to E_u) \subset \{z \in \mathbb{C} : |z| > 1\}.$$

Let $E_{cu} = E_u \oplus E_c$. Then

(i) *there exist open neighborhoods N_{cu} of 0 in E_{cu}, N_s of 0 in E_s, N of p in U, and a C^1-map $w : N_{cu} \to E_s$ with $w(0) = 0$, $Dw(0) = 0$, and $w(N_{cu}) \subset N_s$ so that the shifted graph $W = p + \{z + w(z) : z \in N_{cu}\}$ satisfies $f(W \cap N) \subset W$ and $\{x \in E;$ there exists a trajectory $(x_n)_{-\infty}^0$ of f in $p + N_{cu} + N_s$ with $x_0 = x\} \subset W$;*

(ii) *if f is C^k-smooth for an integer $k \geq 2$, then so is w.*

We can now state the following smoothness theorem for center manifolds in general Banach spaces.

THEOREM 5.4. *Let $f : U \to E$ be a C^1-map on an open subset U of a Banach space E over $\mathbb{R}$, with a fixed point p. Let $L = Df(p)$ and assume that E has the following decomposition:*

$$E = E_s \oplus E_c \oplus E_u,$$

where E_s is a closed subspace, E_c and E_u are finite-dimensional, $L(E_s) \subset E_s$, $L(E_c) \subset E_c$, and $L(E_u) \subset E_u$. We further assume that

$$\sigma_s = \sigma(L|_{E_s} : E_s \to E_s) \text{ is contained in a compact subset of } \{z \in \mathbb{C} : |z| < 1\}$$

and

$$\begin{aligned}\sigma_c =& \sigma(L|_{E_c} : E_c \to E_c) \subset S^1_{\mathbb{C}},\\ \sigma_u =& \sigma(L|_{E_u} : E_u \to E_u) \subset \{z \in \mathbb{C} : |z| > 1\}.\end{aligned}$$

Let $E_{su} = E_s \oplus E_c$. Then

(i) *there exist open neighborhoods N_c of 0 in E_c, N_{su} of 0 in E_{su}, N of p in U, and a C^1-map $w : N_c \to E_{su}$ with $w(0) = 0$, $Dw(0) = 0$, and $w(N_c) \subset N_{su}$ so that the shifted graph $W = p + \{z + w(z) : z \in N_c\}$ satisfies $f(W \cap N) \subset W$, and if there exists $(x_n)_{-\infty}^{\infty}$ such that $x_n = f(x_{n-1})$ and $x_n \in p + N_c + N_{su}$ for every integer n, then $x_0 \in W$;*

(ii) *if f is C^k-smooth for an integer $k \geq 2$, then so is w.*

Proof. Without loss of generality, we may assume $p = 0$. By Theorem 5.1, there exist convex open neighborhoods $\widetilde{N}_{cs}$ of 0 in $E_c + E_s$, $\widetilde{N}_u$ of 0 in E_u, $\widetilde{N}$ of 0 in U, and a C^k-map ($k = 1$ in case of (i) and $k \geq 2$ in case of (ii)) $\widetilde{w}_{cs} : \widetilde{N}_{cs} \to E_u$ with

$$\begin{aligned}&\widetilde{w}_{cs}(0) = 0, \qquad D\widetilde{w}_{cs}(0) = 0;\\ &\widetilde{w}_{cs}(\widetilde{N}_{cs}) \subset \widetilde{N}_u,\end{aligned}$$

and such that the graph

$$\widetilde{W}_{cs} = \{z_{cs} + \widetilde{w}_{cs}(z_{cs}) : z_{cs} \in \widetilde{N}_{cs}\}$$

satisfies

$$f(\widetilde{W}_{cs} \cap \widetilde{N}) \subset \widetilde{W}_{cs}$$

and

$$\cap_{n=0}^{\infty} f^{-n}(\widetilde{N}_{cs} + \widetilde{N}_u) \subset \widetilde{W}_{cs}. \tag{5.3}$$

By Theorem 5.3, there exist open neighborhoods $\widehat{N}_{cu}$ of 0 in $E_c \oplus E_u$, $\widehat{N}_s$ of 0 in E_s, $\widehat{N}$ of 0 in U, and a C^k-map ($k = 1$ in case (i) and $k \geq 2$ in case (ii)) $\widehat{w}_{cu} : \widehat{N}_{cu} \to E_s$ with

$$\begin{aligned}&\widehat{w}_{cu}(0) = 0, \qquad D\widehat{w}_{cu}(0) = 0;\\ &\widehat{w}_{cu}(\widehat{N}_{cu}) \subset \widehat{N}_s,\end{aligned}$$

and the graph

$$\widehat{W}_{cu} = \{z_{cu} + \widehat{w}_{cu}(z_{cu}) : z_{cu} \in \widehat{N}_{cu}\}$$

satisfies

$$f(\widehat{W}_{cu} \cap \widehat{N}) \subset \widehat{W}_{cu}$$

and

$$\begin{aligned}&z \in \widehat{W}_{cu} \text{ if there exists } \{z_n\}_{n=-\infty}^{0} \subset \widehat{N}_{cu} + \widehat{N}_s\\ &\text{such that } z_{n+1} = f(z_n) \text{ for } n \leq -1 \text{ and that } z_0 = z.\end{aligned} \tag{5.4}$$

Choose open neighborhoods N_c^* of 0 in E_c, N_s^* of 0 in E_s, N_c^* of 0 in E_c, N^* of 0 in E such that

$$\begin{cases} N^* \subset \widehat{N} \cap \widetilde{N}; \\ N_c^* + N_s^* \subset \widetilde{N}_{cs}; \\ N_c^* + N_u^* \subset \widehat{N}_{cu}; \\ z_c \in N_c^*, z_s \in N_s^* \text{ if } z \in f(N^*); \\ z_c \in N_c^*, z_u \in N_u^* \text{ if } z \in f(N^*); \\ \widetilde{w}_{cs}(z_c + z_s) \in N_u^* \text{ if } z_c \in N_c^* \text{ and } z_s \in N_s^*. \end{cases}$$

Define

$$W_{cs}^* = \{z_{cs} + \widetilde{w}_{cs}(z_{cs}) : z_{cs} = z_c + z_s \in N_c^* + N_s^*\},$$
$$W_{cu}^* = \{z_{cu} + \widehat{w}_{cu}(z_{cu}) : z_{cu} = z_c + z_u \in N_c^* + N_u^*\},$$

and

$$W^* = W_{cs}^* \cap W_{cu}^*.$$

For $z \in W^*$, we have

$$\begin{aligned} z &= z_c + z_s + \widetilde{w}_{cs}(z_c + z_s) \\ &= z_c + z_u + \widehat{w}_{cu}(z_c + z_u) \end{aligned}$$

with $z_c \in N_c^*, z_s \in N_s^*$, and $z_u \in N_u^*$. Therefore,

$$z_s = \widehat{w}_{cu}(z_c + z_u) = \widehat{w}_{cu}(z_c + \widetilde{w}_{cs}(z_c + z_s)).$$

Consider the equation

$$z_s = \widehat{w}_{cu}(z_c + \widetilde{w}_{cs}(z_c + z_s)). \tag{5.5}$$

As both $\widehat{w}_{cu}$ and $\widetilde{w}_{cs}$ are C^k-smooth and $D\widehat{w}_{cu}(0) = 0, D\widetilde{w}_{cs}(0) = 0$, the implicit function theorem implies that there are open neighborhoods N_c of 0 in N_c^* and N_s of 0 in N_s^* and a C^k-map $w_s : N_c \to N_s$ such that for every $z_c \in N_s$ equation (5.5) has the unique solution $z_s = w_s(z_c)$. It is easy to verify that $w_s(0) = 0$ and $Dw_s(0) = 0$.

We now define $w_c : N_c \to E_s \oplus E_u$ by

$$w_c(z_c) = w_s(z_c) + \widetilde{w}_{cs}(z_c + w_s(z_c)), \qquad z_c \in N_c.$$

Clearly, w_c is C^k-smooth, $w_c(0) = 0$, $Dw_c(0) = 0$, and

$$w_c(N_c) \subset N_s + N_u$$

with

$$N_u = N_u^*.$$

Let

$$W_c = \{z_c + w_c(z_c) : z_c \in N_c\}.$$

We prove that if there exists $\{z_n\}_{n=-\infty}^{\infty} \subset N_c + N_s + N_u$ such that $z_{n+1} = f(z_n)$ for $n \in \mathbf{Z}$, then $z = z_0 \in W_c$. In fact, (5.3) and (5.4) imply that $z \in \widehat{W}_{cu} \cap \widetilde{W}_{cs}$. As $z_c \in N_c \subset N_c^*$, $z_s \in N_s \subset N_s^*$, and $z_u \in N_u = N_u^*$, we have $z \in W^*$ and

$$z_0 = z_c + z_s + \widetilde{w}_{cs}(z_c + z_s) = z_c + z_u + \widehat{w}_{cu}(z_c + z_u),$$

from which it follows that

$$z_s = \widehat{w}_{cu}(z_c + \widetilde{w}_{cs}(z_c + z_s)), \qquad z_s \in N_s, \quad z_c \in N_c.$$

Therefore, we must have $z_s = w_s(z_c)$ and $z_u = \widetilde{w}_{cs}(z_c + w_s(z_c))$. This shows that $z \in W_c$.

Other properties in Theorem 5.4 are straightforward consequences of Theorems 5.1 and 5.3. □

6. Center manifolds for nonlinear FDEs in Banach spaces. We now start to consider semilinear FDEs

$$\dot{u}(t) = A_T u(t) + L(u_t) + F(u_t), \tag{6.1}$$

where we assume A_T, L are as in the previous sections, and, in particular, that (H1)–(H3) are satisfied. We also assume that $F : V_1 \to X$ is a C^k-mapping ($k \geq 1$) from a neighborhood V_1 of $0 \in C$ into X with $F(0) = 0$ and $DF(0) = 0$.

Fix $\omega > r$. Using the arguments of Fitzgibbon [6] (see also Theorems 2.1 and 2.2 in Chapter 2 of Wu [21]), we can find an open neighborhood $V_2 \subset V_1$ of 0 in C such that for any $\phi \in V_2$ there exists a unique continuous function $u^\phi : [-r, \omega] \to X$ such that $u_0^\phi = \phi$ and

$$u^\phi(t) = T(t)\phi(0) + \int_0^t T(t-s)[L(u_s^\phi) + F(u_s^\phi)]ds$$

for $t \in [0, \omega]$. Define $\tilde{f} : V_2 \to C$ by

$$\tilde{f}(\phi) = u_\omega^\phi \quad \text{for } \phi \in V_2.$$

As $\omega > r$, we can show that $\tilde{f}$ is compact (using the argument in Travis and Webb [18]; see also Theorem 1.8 of Chapter 2 of Wu [21]). The next lemma shows that there exists an open neighborhood $V \subset V_2$ of 0 in C such that $f = \tilde{f}|_V : V \to C$ is C^k-smooth and

$$Df(0) = U(\omega) : C \to C.$$

LEMMA 6.1. *There exists an open neighborhood $V \subset V_2$ of 0 in C such that for each $t \in [0, \omega]$, u_t^ϕ is C^k-smooth with respect to $\phi \in V$. Moreover, for each $\psi \in C$, $D_\phi u^\phi(t)\psi$ satisfies the linear variational equation*

$$\begin{cases} v(t) = T(t)\psi(0) + \int_0^t T(t-s)[L(v_s) + DF(u_s^\phi)v_s]ds, \\ v_0 = \psi. \end{cases} \tag{6.2}$$

In particular, $Df(0) = U(\omega)$.

Proof. We are going to apply the same argument as that for Theorem 4.1 in Hale [8] based on [8, Lemma 4.2, p. 46]. Let $\hat{F}(\phi) = L(\phi) + F(\phi)$. Fix $\chi \in V_2$. There exist $M > 0$, $\delta > 0$, and $N > 0$ such that

$$\begin{cases} \|T(t)\| \leq M \quad \text{for } t \in [0, 1]; \\ \overline{B_\delta(\chi)} \subset V_2 \quad \text{with } B_\delta(\chi) = \{\psi \in C : ||\psi - \chi|| < \delta\}; \\ |\hat{F}(\psi)| \leq N, \ |D\hat{F}(\psi)| \leq N \text{ for } \psi \in \overline{B_\delta(\chi)}. \end{cases}$$

Now choose $\epsilon \in (0,1)$ and $\beta \in (0,1)$ so that

$$\begin{cases} \beta < \frac{\delta}{2}; \\ \sup_{\theta,\theta' \in [-r,0], |\theta-\theta'| \le \epsilon} |\chi(\theta) - \chi(\theta')| < \frac{\delta}{8}; \\ \sup_{t \in [0,\epsilon]} |T(t)\chi(0) - \chi(0)| < \frac{\delta}{8}; \\ \epsilon < \frac{\beta}{MN}. \end{cases}$$

Let

$$K(\epsilon,\beta) = \{y \in C([-r,\epsilon];X) : y_0 = 0,\ ||y_t|| \le \beta \text{ for } t \in [0,\epsilon]\}.$$

Clearly, $K(\epsilon,\beta)$ is a closed subset of the Banach space $C_0([-r,\epsilon]) = \{z \in C([-r,\epsilon];X) : z(s) = 0 \text{ for } s \in [-r,0]\}$ equipped with the supremum norm.

For each $\phi \in C$, define $\tilde{\phi} : [-r,\infty) \to X$ by $\tilde{\phi}_0 = \phi$ and $\tilde{\phi}(t) = T(t)\phi(0)$ for $t \ge 0$. Now, for fixed $\phi \in B_{\frac{\delta}{8(1+M)}}(\chi)$ define $A(\phi)$ on $K(\epsilon,\beta)$ by

$$A(\phi)y(t) = \begin{cases} \int_0^t T(t-s)\hat{F}(y_s + \tilde{\phi}_s)ds,\ y \in K(\epsilon,\beta), & t \in [0,\epsilon]; \\ 0, \quad t \in [-r,0]. \end{cases}$$

Clearly, $A(\phi)y \in C([-r,\epsilon];X)$. Moreover, since for $s \in [0,\epsilon]$, $||y_s|| \le \beta$, and

$$\begin{aligned} ||\tilde{\phi}_s - \chi|| &\le ||\tilde{\phi}_s - \tilde{\chi}_s|| + ||\tilde{\chi}_s - \chi|| \\ &\le ||\phi - \chi|| + \sup_{s\in[0,\epsilon]} ||T(s)||\phi(0) - \chi(0)| \\ &\quad + \sup_{\theta\in[-r,0],s\in[0,\epsilon],s+\theta\in[-r,0]} |\chi(\theta+s) - \chi(\theta)| \\ &\quad + \sup_{\theta\in[-r,0],s\in[0,\epsilon],s+\theta\ge 0} |T(s+\theta)\chi(0) - \chi(0)| \\ &\quad + \sup_{\theta\in[-r,0],s\in[0,\epsilon],s+\theta\ge 0} |\chi(\theta) - \chi(0)| \\ &\le (1+M)||\phi - \chi|| + \frac{\delta}{8} + \frac{\delta}{8} + \frac{\delta}{8} < \frac{\delta}{2}, \end{aligned}$$

we have

$$||y_s + \tilde{\phi}_s - \chi|| < \beta + \frac{\delta}{2} < \delta,$$

and hence

$$|\hat{F}(y_s + \tilde{\phi}_s)| \le N \quad \text{for } s \in [0,\epsilon].$$

This implies that

$$|A(\phi)y(t)| \le MN\epsilon < \beta \quad \text{for } t \in [0,\epsilon].$$

So, $A(\phi)y \in K(\epsilon,\beta)$ and $A(\phi)K(\epsilon,\beta) \subset K(\epsilon,\beta)$.

Moreover, using $||D\hat{F}(\psi)|| \le N$ for all $\psi \in \overline{B_\delta(\chi)}$, for $y, \hat{y} \in K(\epsilon,\beta)$ and $t \in [0,\epsilon]$ we have

$$\begin{aligned}
&|A(\phi)y(t) - A(\phi)\hat{y}(t)| \\
&\le \left| \int_0^t T(t-s)[\hat{F}(y_s + \tilde{\phi}_s) - \hat{F}(\hat{y}_s + \tilde{\phi}_s)ds] \right| \\
&\le MN\epsilon \sup_{s\in[0,t]} ||y_s - \hat{y}_s|| \\
&\le MN\epsilon \sup_{s\in[-r,\epsilon]} |y(s) - \hat{y}(s)| \\
&\le \beta \sup_{s\in[-r,\epsilon]} |y(s) - \hat{y}(s)|.
\end{aligned}$$

As $\beta < 1$, we conclude that for each $\phi \in \overline{B_{\frac{\delta}{8(1+M)}}(\chi)}$, the mapping $A(\phi) : K(\epsilon,\beta) \to K(\epsilon,\beta)$ is a contraction. By Lemma 4.2 of Hale [8], for each fixed $\phi \in \overline{B_{\frac{\delta}{8(1+M)}}(\chi)}$, $A(\phi)$ has a unique fixed point $y(\phi) \in K(\epsilon,\beta)$ which is continuous in ϕ.

Note that $\overline{B_{\frac{\delta}{8(1+M)}}(\chi)}$ is the closure of the open set $B_{\frac{\delta}{8(1+M)}}(\chi)$ and $A(\phi)y$ has a continuous kth derivative with respect to $(\phi, y) \in B_{\frac{\delta}{8(1+M)}}(\chi) \times K^0(\epsilon,\beta)$, where

$$K^0(\epsilon,\beta) = \{y \in K(\epsilon,\beta) : ||y_t|| < \beta \text{ for } t \in [0,\epsilon]\}$$

is open in $C_0([-r,\epsilon])$ and $K(\epsilon,\beta) = \overline{K^0(\epsilon,\beta)}$. Therefore, by Lemma 4.2 in Hale [8], $y(\phi)$ is C^k-smooth with respect to $\phi \in B_{\frac{\delta}{8(1+M)}}(\chi)$, and hence $u_t^\phi = \tilde{\phi}_t + (y(\phi))_t$ is C^k-smooth in $\phi \in B_{\frac{\delta}{8(1+M)}}(\chi)$ for each fixed $t \in [0,\epsilon]$. A standard continuation argument then leads to the C^k-smoothness of $u(\phi)$ with respect to ϕ for $t \in [0,\omega]$. The remaining part of the lemma can be easily verified. □

Let

$$\begin{aligned}
\Sigma_s &= \{\lambda \in \sigma_P(A_U) : \mathrm{Re}\lambda < 0\}, \\
\Sigma_u &= \{\lambda \in \sigma_P(A_U) : \mathrm{Re}\lambda > 0\}, \\
\Sigma_c &= \{\lambda \in \sigma_P(A_U) : \mathrm{Re}\lambda = 0\},
\end{aligned}$$

and assume $\Sigma_c \neq \emptyset$. We know that $\Sigma_c \cup \Sigma_u$ is a finite set.

Let

$$\begin{aligned}
C^s &= \bigoplus_{\lambda\in\Sigma_s} \mathcal{M}_\lambda(A_U), \\
C^u &= \bigoplus_{\lambda\in\Sigma_u} \mathcal{M}_\lambda(A_U), \\
C^c &= \bigoplus_{\lambda\in\Sigma_c} \mathcal{M}_\lambda(A_U).
\end{aligned}$$

C^s, C^u, and C^c are realified generalized eigenspaces associated with Σ_s, Σ_u, and Σ_c, respectively. Then C^u and C^c are finitely dimensional and

$$C = C^s \oplus C^u \oplus C^c.$$

Recall that C^s, C^u, and C^c are called the *stable, unstable*, and *center* subspaces of the C_0-semigroup $\{U(t)\}_{t\ge0}$.

We can now state the main result of this section.

THEOREM 6.2. *There exist open neighborhoods N_c of 0 in C^c, N_s of 0 in C^s, N^u of 0 in C^u, and a C^k-map $w_c : N_c \to C^s \oplus C^u$ such that*

(i) $w_c(0) = 0, Dw_c(0) = 0, w_c(N_c) \subset N_s + N_u$;

(ii) *for any $\phi \in V$, if there exists a continuous mapping $u^\phi : \mathbb{R} \to X$ such that $u_0^\phi = \phi$,*

$$u^\phi(t) = T(t-s)u^\phi(s) + \int_s^t T(t-\theta)[L(u_\theta^\phi) + F(u_\theta^\phi)]d\theta$$

for $t, s \in \mathbb{R}$ with $t \geq s$, and $u_t^\phi \in N_s + N_u + N_c$ for all $t \in \mathbb{R}$, then $u_t^\phi \in W_c$ for $t \in \mathbb{R}$, where

$$W_c = \{\phi_c + w_c(\phi_c) : \phi_c \in N_c\}.$$

Proof. Recall that $f : V \to C$ is C^k-smooth, $f(0) = 0$, $Df(0) = U(\omega)$, and

$$\begin{cases} C = C^s \oplus C^u \oplus C^c, \\ U(\omega)C^s \subset C^s,\ U(\omega)C^u \subset C^u,\ U(\omega)C^c \subset C^c, \\ \sigma(U(\omega)|_{C^s}) \text{ is a compact subset of } \{z \in \mathbb{C} : |z| < 1\}, \\ \sigma(U(\omega)|_{C^c}) \subset S^1_{\mathbb{C}}, \\ \sigma(U(\omega)|_{C^u}) \subset \{z \in \mathbb{C} : |z| > 1\}. \end{cases}$$

See Chapter IV.2 in Diekmann et al. [4].

By Theorem 5.4, there exist open neighborhoods N_c of 0 in C^c, N_s of 0 in C^s, N_u of 0 in C^u, and a C^k-map $w : N_c \to C^s \oplus C^u$ such that $w_c(0) = 0$, $Dw_c(0) = 0$, and $w_c(N_c) \subset N_s + N_u$. Moreover, for $W_c = \{\phi_c + w_c(\phi_c) : \phi_c \in N_c\}$, if there exists $(\phi^n)_{-\infty}^{\infty}$ such that $\phi^n = f(\phi^{n-1})$ and $\phi^n \in N_c + N_{su}$ for $n \in \mathbf{Z}$, then $\phi^0 \in W_c$.

Fix $\phi \in V$ such that condition (ii) of this theorem is satisfied. Then for any fixed $t \in \mathbb{R}$, $u_t^\phi \in N_s + N_u + N_c \subset V$, and if we let

$$\phi^n = u_{t+n\omega}^\phi, \qquad n \in \mathbf{Z},$$

then $\phi^{n+1} = f(\phi^n)$ for $n \in \mathbf{Z}$ and $\phi^n \in N_c + N_s + N_u$ for all $n \in \mathbf{Z}$. Therefore, the result in the last step implies that $\phi^0 = u_t^\phi \in W_c$. This completes the proof. ∎

UNIFORM PERSISTENCE, COEXISTENCE, AND EXTINCTION IN ALMOST PERIODIC/NONAUTONOMOUS COMPETITION DIFFUSION SYSTEMS*

GEORG HETZER† AND WENXIAN SHEN†

Dedicated to Professor Paul Waltman on the occasion of his 70th birthday

Abstract. A two species competition model with diffusion is considered. The parameters describing the growth, interaction, and self-limitation of the species are spatially inhomogeneous and temporally almost periodic. The boundary conditions are homogeneous and of Neumann or Dirichlet type. First, a convergence theorem is derived in the single species case. Roughly speaking, it states that one of the following alternatives will occur: either every positive solution converges to a unique strictly positive almost periodic solution, every positive solution converges to the trivial solution, or every positive solution is neither bounded away from the trivial solution nor converges to it. Then appropriate conditions for uniform persistence of both species as well as for extinction of one of the species are established. Moreover, it is shown that uniform persistence implies coexistence in the sense that there is a strictly positive solution whose hull is almost automorphic. The above results generalize earlier work in the time independent and time periodic cases for both single species population models and two species competition models. The approach developed in this paper for dealing with almost periodic equations can be applied to more general nonautonomous equations, as we will indicate by briefly discussing applications where merely time recurrence is supposed.

Key words. almost periodicity, almost automorphy, competition, uniform persistence, coexistence, extinction

1. Introduction.

A central issue in population dynamics is the long-term development of populations, and one finds terms such as uniform persistence (sometimes also called permanence), coexistence, and extinction describing important special types of asymptotic behavior of the solutions of associated model equations. The time independent and time periodic cases have found great interest in the past. Our goal, however, is to investigate possible scenarios for two species populations in the case where the model equations depend on time nonperiodically. The reaction-diffusion system under consideration is given by

$$\begin{cases} u_t = k_1\Delta u + u(a_1(t,x) - b_1(t,x)u - c_1(t,x)v), & x \in \Omega, \\ v_t = k_2\Delta v + v(a_2(t,x) - b_2(t,x)u - c_2(t,x)v), & x \in \Omega, \\ Bu = Bv = 0, & x \in \partial\Omega, \end{cases} \tag{1.1}$$

where k_1, k_2 are positive constants, a_i, b_i, c_i $(i = 1, 2)$ are smooth functions, $\Omega \subset \mathbb{R}^n$ is a smooth bounded region, and $Bu = \frac{\partial u}{\partial n}$, $Bv = \frac{\partial v}{\partial n}$ or $Bu = u$, $Bv = v$.

System (1.1) models the competition between two species. It is sometimes called the Lotka–Volterra competition model. In the context of ecology, k_1, k_2 are the dispersal rates, a_1, a_2 represent growth rates, b_1, c_2 denote self-limitation rates, and c_1, b_2 are the interaction rates. Dirichlet boundary conditions ($u = v = 0$, $x \in \partial\Omega$)

describe a "lethal crossing" boundary, and Neumann boundary conditions ($\frac{\partial u}{\partial n} = \frac{\partial v}{\partial n} = 0$) exclude migration across the boundary.

Ecologically, one is only interested in positive solutions of system (1.1), and it is the objective of this paper to study uniform persistence, coexistence, and extinction for (1.1). Roughly speaking, *uniform persistence* means that there are strictly positive functions $u_*(\cdot)$, $u^*(\cdot)$, $v_*(\cdot)$, and $v^*(\cdot)$ such that, for every positive solution $(u(t,x), v(t,x))$ of (1.1), $u_*(x) \le u(t,x) \le u^*(x)$, and $v_*(x) \le v(t,x) \le v^*(x)$ for $x \in \Omega$ and large t, *coexistence* refers to the existence of certain distinct strictly positive solutions, and *extinction* indicates that at least one of the species eventually dies out. These issues have been studied widely for time independent or time periodic equations under Neumann boundary conditions; cf. [3], [4], [6], [9], [13], [16], [20], [25], [26], [27], [30], [31], [42], [46], [47], [48], etc. In [8], [10], etc., one also finds results in the case of Dirichlet boundary conditions. It turns out that, thanks to the Poincaré map, time periodic equations resemble time independent ones in many aspects.

In nature, populations evolve influenced by external effects which are roughly, but not exactly periodic, or under environmental forcing which exhibits different, noncommensurate periods. This sort of time dependence can arise from the interplay of short-term weather cycles and seasonal climate variations, or from the superposition of daily and annually periodic phenomena, and so on. Growth processes, for example, depend on the length of days and nights which varies during the year. Models with such time dependence are characterized more appropriately by quasi-periodic or almost periodic equations or even by certain nonautonomous equations rather than by periodic ones. Additionally, populations are affected by a wide variety of irregularly occurring phenomena which lead to stochastic or random equations. Both types of equations, time nonperiodic deterministic (e.g., quasi-periodic and almost periodic) equations and time stochastic ones are therefore worth studying. In this paper, we will focus on the first type of equations, in particular, time quasi-periodic, almost periodic, and certain general nonautonomous equations. These equations have found much attention (see [1], [2], [14], [15], [22], [37], etc.). However, in contrast to the time independent and periodic cases, many fundamental questions about general nonautonomous, even about quasi-periodic or almost periodic cases remain open. For example, in the time periodic case, uniform persistence implies the coexistence in the sense that there is a strictly positive periodic solution having the same period as the period of the functions arising in (1.1). However, it is not known yet whether, in the general time quasi-periodic (almost periodic) case, uniform persistence implies the existence of a strictly positive quasi-periodic (almost periodic) solution. If not, which kind of distinct positive solution may result from uniform persistence? Note that quasi periodicity is a special kind of almost periodicity. It is known (see [38]) that in a certain sense quasi-periodic time dependence does not result in "better" dynamics than general almost periodic dependence. Motivated by these facts, we will mainly focus in this paper on (1.1) with general almost periodic time dependence. Typically, studies about periodic equations are carried out in terms of the Poincaré map. A unified framework to study an almost periodic equation is the so-called skew-product (semi)flow generated by the equation (see [35], [36], [38], etc.). We will carry out our study for almost periodic competition models in the skew-product setting, but note that the approach developed in this paper for dealing with almost periodic equations can be applied to more general time dependent settings. Moreover, methodologically this framework can also be considered a precursor for a study of associated stochastic

problems, even if the concept of random dynamical systems would prove to be inadequate due to technical obstacles from stochastic partial differential equations (cocycle property).

From now on, we assume that a_i, b_i, c_i $(i = 1, 2)$ in (1.1) are smooth functions (i.e., continuous in x on $\bar{\Omega}$ and Hölder continuous in t) and that they are uniformly almost periodic in t (see section 2.1 for definition) unless otherwise specified. In such a setting, system (1.1) has been considered under Neumann boundary conditions in [1], [2], [14], etc. In [22], we studied the long-time behavior of positive solutions of (1.1) when a_i, b_i, c_i are spatially homogeneous and Neumann boundary conditions are prescribed. We took advantage of findings for the associated system of ODEs,

$$\begin{cases} \dot{u} = u(a_1(t) - b_1(t)u - c_1(t)v) \\ \dot{v} = v(a_2(t) - b_2(t)u - c_2(t)v), \end{cases} \tag{1.2}$$

by investigating the relation between (1.1) and (1.2) and utilized convergence results from [37] for the single species population model

$$\begin{cases} u_t = k\Delta u + u(a(t,x) - b(t,x)u), & x \in \Omega, \\ Bu = 0, \quad x \in \partial\Omega, \end{cases} \tag{1.3}$$

assuming that $Bu = \frac{\partial u}{\partial n}$, k is a positive constant, a and b are smooth functions which are uniformly almost periodic in t, and Ω has the same meaning as for (1.1).

Clearly, a new approach is required when dealing with (1.1) in the general case. As a first step, we develop a general method for studying the convergence of positive solutions of the single species population model (1.3) when $Bu = u$ or $Bu = \frac{\partial u}{\partial n}$. A solution $u(t,x)$ of (1.3) is said to be *positive* if $u(t,x) \geq 0$ $(u \not\equiv 0)$ for $x \in \Omega$ and $t \geq 0$, and *strictly positive* if in the Neumann case $(Bu = \frac{\partial u}{\partial n})$ one has $u(x,t) > 0$ for $x \in \bar{\Omega}$ and $t \geq 0$, and if in the Dirichlet case $(Bu = u)$ one has $u(x,t) > 0$ for $x \in \Omega$ and $t \geq 0$, $\frac{\partial u}{\partial n} < 0$ for $x \in \partial\Omega$ and $t \geq 0$. A solution $u(t,x)$ of (1.3) is said to *converge* to $u^*(t,x)$ if $u(t,\cdot) - u^*(t,\cdot) \to 0$ in an appropriate function space norm as $t \to \infty$. Denote by $\mathcal{M}(\cdot)$ the frequency module of an almost periodic (almost automorphic) function (see section 2.1 for a definition). We prove the following result.

THEOREM A (Corollary 3.4). *Consider* (1.3) *and assume* $b(t,x) \geq \delta$ *for some* $\delta > 0$. *One and only one of the following alternatives occurs.*

(1) *Every positive solution converges to a unique strictly positive almost periodic solution* $u^*(t,x)$ *with* $\mathcal{M}(u^*) \subset \mathcal{M}(a,b)$.

(2) *Every positive solution converges to the trivial solution* $u = 0$.

(3) *Every positive solution is neither bounded away from the trivial solution nor converges to it.*

Notice that if a, b in (1.3) are actually periodic in t, alternative (3) of Theorem A cannot occur in view of the generic convergence of monotone dynamical systems ([24], [29], [33], [40], etc.). Theorem A extends the convergence results proved for the periodic case in [18], [19], [21], as well as the convergence results for (1.3) which were obtained in [37] for the Neumann case $Bu = \frac{\partial u}{\partial n}$. It should be pointed out that Takáč [43] has obtained some results which partially cover Theorem A, by using the so-called part metric.

Next, we consider positive solutions of (1.1). A solution $(u(t,x), v(t,x))$ of (1.1) is said to be *positive* if $u(t,x) \geq 0$, $v(t,x) \geq 0$ $(u(t,x) \not\equiv 0$, $v(t,x) \not\equiv 0)$ for $x \in \Omega$ and $t \geq 0$, and *strictly positive* if one has in the Neumann case that $u(t,x) > 0$, $v(t,x) > 0$ for $x \in \bar{\Omega}$ and $t \geq 0$, and if one has in the Dirichlet case that $u(t,x) > 0$, $v(t,x) > 0$

for $x \in \Omega$ and $t \geq 0$, $\frac{\partial u}{\partial n} < 0$, $\frac{\partial v}{\partial n} < 0$ for $x \in \partial\Omega$ and $t \geq 0$. A solution $(u(t,x), v(t,x))$ of (1.1) is said to *converge* to $(u^*(t,x), v^*(t,x))$ if, in a certain function space norm, $u(t,x) - u^*(t,x) \to 0$ and $v(t,x) - v^*(t,x) \to 0$ as $t \to \infty$. Let

$$a_{iL(M)} = \inf(\sup)_{t\in\mathbb{R}, x\in\bar{\Omega}} a_i(t,x), \tag{1.4}_1$$

$$b_{iL(M)} = \inf(\sup)_{t\in\mathbb{R}, x\in\bar{\Omega}} b_i(t,x), \tag{1.4}_2$$

$$c_{iL(M)} = \inf(\sup)_{t\in\mathbb{R}, x\in\bar{\Omega}} c_i(t,x). \tag{1.4}_3$$

Assume that a_{iL}, b_{iL}, $c_{iL} > 0$, and $u \equiv 0$ is an unstable solution of

$$\begin{cases} u_t = k_1\Delta u + u(a_1 - b_1 u), & x \in \Omega, \\ Bu = 0, & x \in \partial\Omega \end{cases} \tag{1.5}$$

and $v \equiv 0$ is an unstable solution of

$$\begin{cases} v_t = k_2\Delta v + v(a_2 - c_2 v), & x \in \Omega, \\ Bv = 0, & x \in \partial\Omega. \end{cases} \tag{1.6}$$

Then, by Theorem A(1), (1.5), (1.6) has a globally stable strictly positive almost periodic solution $u^*(t,x)$ $(v^*(t,x))$ with $\mathcal{M}(u^*) \subset \mathcal{M}(a_1, b_1)$ $(\mathcal{M}(v^*) \subset \mathcal{M}(a_2, c_2))$. We show the following results.

THEOREM B (Theorem 5.1). *Consider* (1.1). *Assume that* $Bu = \frac{\partial u}{\partial n}$.

(1) *If* $a_{1L} > \frac{c_{1M}a_{2M}}{c_{2L}}$ *and* $a_{2L} > \frac{a_{1M}b_{2M}}{b_{1L}}$, *then uniform persistence occurs. Moreover, there is a strictly positive solution* $(u_*(t,x), v_*(t,x))$ *whose hull is almost automorphic, and, for each* $(\tilde{u}_*(\cdot,\cdot), \tilde{v}_*(\cdot,\cdot)) \in H(u_*, v_*)$ *with* $\tilde{u}_*(t,x)$, $\tilde{v}_*(t,x)$ *being almost automorphic in* t, $\mathcal{M}(\tilde{u}_*, \tilde{v}_*) \subset \mathcal{M}(a_1, b_1, c_1, a_2, b_2, c_2)$.

(2) *If* $a_{1L} > \frac{c_{1M}a_{2M}}{c_{2L}}$ *and* $a_{2M} \leq \frac{a_{1L}b_{2L}}{b_{1M}}$, *then every positive solution converges to* $(u^*(t,x), 0)$.

(3) *If* $a_{1M} \leq \frac{c_{1L}a_{2L}}{c_{2M}}$ *and* $a_{2L} > \frac{a_{1M}b_{2M}}{b_{1L}}$, *then every positive solution converges to* $(0, v^*(t,x))$.

(4) *If* $a_1 = a_2$, $b_1 = b_2 = c_1 = c_2$, *and also* $k_1 = k_2$ *in the case where* a_i, b_i, c_i $(i = 1, 2)$ *are not spatially homogeneous, then there is a stable continuous family of strictly positive almost periodic solutions connecting* $(u^*(t,x), 0)$ *and* $(0, v^*(t,x))$.

THEOREM C. (Theorem 5.2). *Consider* (1.1). *Assume that* $Bu = u$.

(1) *If* $a_{1L} > \frac{c_{1M}a_{2M}}{c_{2L}}$, $a_{2L} > \frac{a_{1M}b_{2M}}{b_{1L}}$, $k_1 = k_2$, *and* $a_1 = a_2$ *(constant), then uniform persistence occurs. Moreover, there is a strictly positive solution* $(u_*(t,x), v_*(t,x))$ *whose hull is almost automorphic, and one has* $\mathcal{M}(\tilde{u}_*, \tilde{v}_*) \subset \mathcal{M}(a_1, b_1, c_1, a_2, b_2, c_2)$ *for each* $(\tilde{u}_*(\cdot,\cdot), \tilde{v}_*(\cdot,\cdot)) \in H(u_*, v_*)$ *for which* $\tilde{u}_*(\cdot,\cdot)$, $\tilde{v}_*(\cdot,\cdot)$ *are almost automorphic in* t.

(2) *If* $a_{1L} > \frac{c_{1M}a_{2M}}{c_{2L}}$, $a_{2M} \leq \frac{a_{1L}b_{2L}}{b_{1M}}$, $k_2 \geq k_1$, *and* $a_{1L} \geq a_2$, *then every positive solution converges to* $(u^*(t,x), 0)$.

(3) *If* $a_{1M} \leq \frac{c_{1L}a_{2L}}{c_{2M}}$, $a_{2L} > \frac{a_{1M}b_{2M}}{b_{1L}}$, $k_1 \geq k_2$, *and* $a_{2L} \geq a_1$, *then every positive solution converges to* $(0, v^*(t,x))$.

(4) *If* $k_1 = k_2$, $a_1 = a_2$, *and* $b_1 = b_2 = c_1 = c_2$, *then there is a stable continuous family of strictly positive almost periodic solutions connecting* $(u^*(t,x), 0)$ *and* $(0, v^*(t,x))$.

As pointed out before, in the periodic case, uniform persistence implies coexistence in the sense that there is a strictly positive periodic solution with the same period as the period of the functions arising in (1.1). By Theorems B and C, in the almost periodic case, uniform persistence implies the coexistence in the sense that there is a

strictly positive solution whose hull is almost automorphic with the same frequency module as that of the functions arising in (1.1). Note that such a solution is periodic if these functions are actually periodic and all have the same period. Therefore, on the one hand, Theorems B and C shed light on uniform persistence, coexistence, and extinction in the case of almost periodic competition models, and, on the other hand, they generalize most existing results for corresponding time independent or time periodic competition models.

Also, as previously mentioned, the approach which we develop here for dealing with (1.1) and (1.3) in the case of almost periodic time dependence extends to more general situations. For example, if we assume only recurrent time dependence (see section 2.1 for a definition) in the context of (1.1) and (1.3), we obtain the following results.

THEOREM D (Theorem 6.1). *Consider* (1.3) *with a, b being recurrent in t and $b \geq \delta$ for some $\delta > 0$. One and only one of the following alternatives occurs.*

(1) *Every positive solution converges to a unique strictly positive recurrent solution $u^*(t,x)$ whose hull is a* 1*-cover of the hull of (a,b).*

(2) *Every positive solution converges to the trivial solution $u = 0$.*

(3) *Every positive solution is neither bounded away from the trivial solution nor converges to it.*

THEOREM E (Theorem 6.2). Consider (1.1) with a_i, b_i, c_i $(i = 1, 2)$ being recurrent in t. Assume that $Bu = \frac{\partial u}{\partial n} = 0$.

(1) If $a_{1L} > \frac{c_{1M} a_{2M}}{c_{2L}}$ and $a_{2L} > \frac{a_{1M} b_{2M}}{b_{1L}}$, then uniform persistence occurs. Moreover, there is a strictly positive recurrent solution $(u_*(t,x), v_*(t,x))$ whose hull is an almost 1-cover of the hull of $(a_1, b_1, c_1, a_2, b_2, c_2)$.

(2) If $a_{1L} > \frac{c_{1M} a_{2M}}{c_{2L}}$ and $a_{2M} \leq \frac{a_{1L} b_{2L}}{b_{1M}}$, then every positive solution converges to $(u^*(t,x), 0)$, where $u^*(t,x)$ is the unique strictly positive recurrent solution of (1.5) guaranteed by Theorem D(1).

(3) If $a_{1M} \leq \frac{c_{1L} a_{2L}}{c_{2M}}$ and $a_{2L} > \frac{a_{1M} b_{2M}}{b_{1L}}$, then every positive solution converges to $(0, v^*(t,x))$, where $v^*(t,x)$ is the unique strictly positive recurrent solution of (1.6) guaranteed by Theorem D(1).

THEOREM F (Theorem 6.3). *Consider* (1.1) *with a_i, b_i, c_i $(i = 1, 2)$ being recurrent in t. Assume that $Bu = u$.*

(1) *If $a_{1L} > \frac{c_{1M} a_{2M}}{c_{2L}}$, $a_{2L} > \frac{a_{1M} b_{2M}}{b_{1L}}$, $k_1 = k_2$, and $a_1 = a_2$ (constant), then uniform persistence occurs. Moreover, there is a strictly positive recurrent solution $(u_*(t,x), v_*(t,x))$ whose hull is an almost* 1*-cover of the hull of $(a_1, b_1, c_1, a_2, b_2, c_2)$.*

(2) *If $a_{1L} > \frac{c_{1M} a_{2M}}{c_{2L}}$, $a_{2M} \leq \frac{a_{1L} b_{2L}}{b_{1M}}$, $k_2 \geq k_1$, and $a_{1L} \geq a_2$, then every positive solution converges to $(u^*(t,x), 0)$, where $u^*(t,x)$ is the unique strictly positive recurrent solution of* (1.5) *guaranteed by Theorem* D(1).

(3) *If $a_{1M} \leq \frac{c_{1L} a_{2L}}{c_{2M}}$, $a_{2L} > \frac{a_{1M} b_{2M}}{b_{1L}}$, $k_1 \geq k_2$, and $a_{2L} \geq a_1$, then every positive solution converges to $(0, v^*(t,x))$, where $v^*(t,x)$ is the unique strictly positive recurrent solution of* (1.6) *guaranteed by Theorem* D(1).

Let us end the discussion of our results by the following remarks. First, Theorems D, E, and F apply to both the almost periodic and the almost automorphic cases, and, when applied to the almost periodic case, Theorems A, B, and C, respectively, are recovered. In order to be more precise, if a and b are actually uniformly almost periodic (almost automorphic) in t (see section 2.1 for a definition), $u^*(t,x)$ in Theorem D(1) is also almost periodic (almost automorphic) and $\mathcal{M}(u^*) \subset \mathcal{M}(a,b)$. In the case where a_i, b_i, and c_i $(i = 1, 2)$ are uniformly almost periodic (almost automorphic) in t, $u^*(t,x)$ and $v^*(t,x)$ in Theorems E, F(2) and Theorems E, F(3) are almost periodic

(almost automorphic), but $(u_*(t,x), v_*(t,x))$ in Theorems E, F(1) may be neither almost periodic nor almost automorphic; nevertheless, their hull is almost automorphic (see section 2.1 for a definition). Second, we remark that the approach developed in the current paper applies to more general right-hand sides of one species population and two species competition models (see [22] for the spatially homogeneous case). It also has certain implications on the study of stochastic population models (see [23] for one species population models). Finally, we note that the dynamical system framework employed in this paper can also be applied to (two species) competition in stirred and unstirred chemostats, though due to the lack of monotonicity many techniques developed in this paper do not extend to such models, and new techniques need to be introduced. A characteristic feature of such models is a nutrition in- and out-flow explicitly represented by an extra differential equation. Waltman has made numerous contributions to this area, but we refer here only to the monograph [41].

The paper is organized as follows. In section 2, we present some preliminary lemmas. Section 3 is devoted to the investigation of a single almost periodic population model, and Theorem A will be proved in this section. We establish some basic properties of the almost periodic two species competition model in section 4 and establish Theorems B and C in section 5. In section 6, we describe some results which can be obtained for (1.1) and (1.3) in the case of general recurrent time dependence by employing the approach which we have developed in this paper in the context of almost periodic time dependence.

2. Preliminary lemmas. In this section, we present some results about frequency module containment of almost periodic (almost automorphic) functions, ω-limit sets of skew-product semiflows, and spectra of linear scalar parabolic equations for use in later sections.

2.1. Almost periodic, almost automorphic, and recurrent functions. Let $E \subset \mathbb{R}^n$ and $f \in C(\mathbb{R}\times E, \mathbb{R}^m)$ be uniformly almost periodic (almost automorphic) in t. Recall that $f \in C(\mathbb{R}\times E, \mathbb{R}^m)$ is *uniformly almost periodic (almost automorphic) in* t if f is uniformly continuous on $\mathbb{R} \times E_0$ for any bounded subset $E_0 \subset E$ and is almost periodic (almost automorphic) in t for each $x \in E$, and $f(t,x)$ is *almost periodic (almost automorphic) in* t for given $x \in E$ if, for all sequences $\{\alpha_n'\}, \{\beta_n'\} \subset \mathbb{R}$ ($\{\alpha_n'\} \subset \mathbb{R}$), there are subsequences $\{\alpha_n\} \subset \{\alpha_n'\}$, $\{\beta_n\} \subset \{\beta_n'\}$ ($\{\alpha_n\} \subset \{\alpha_n'\}$) such that $\lim_{k\to\infty}\lim_{n\to\infty} f(t+\alpha_n+\beta_k, x) = \lim_{n\to\infty} f(t+\alpha_n+\beta_n, x)$ ($\lim_{k\to\infty}\lim_{n\to\infty} f(t+\alpha_n-\alpha_k, x) = f(t,x)$) pointwise for $t \in \mathbb{R}$ (see [11], [45] for details). The so-called frequency module of f is defined as follows. Let

$$f(t,x) \sim \sum_{\lambda\in\mathbb{R}} a_\lambda(x) e^{i\lambda t} \tag{2.1}$$

be a Fourier series of f (see [44], [45] for the definition and existence of Fourier series). Then $\mathcal{S}(f) = \{\lambda : a_\lambda(x) \not\equiv 0\}$ is called the *Fourier spectrum of* f *associated with the Fourier series* (2.3), and $\mathcal{M}(f) =$ the smallest additive subgroup of $\mathbb{R}$ containing $\mathcal{S}(f)$ is called the *frequency module of* f. We note that $\mathcal{S}(f)$ may depend on the chosen Fourier series (2.1), but $\mathcal{M}(f)$ is independent of that series (see [45]).

Let $E \subset \mathbb{R}^n$ and $f \in C(\mathbb{R}\times E, \mathbb{R}^n)$ be uniformly continuous on $\mathbb{R} \times E_0$ for each bounded subset $E_0 \subset E$. The hull $H(f)$ of f is defined to be $H(f) = cl\{f\cdot\tau | \tau \in \mathbb{R}\}$, where $f\cdot\tau(t,x) = f(t+\tau, x)$, and the closure is taken under the compact open topology. Denote $(H(f), \mathbb{R})$ as the translation flow $(g,t) = g\cdot t$ for each $g \in H(h)$ and $t \in \mathbb{R}$. f is said to have an *almost periodic* (*almost automorphic*) *hull* if $(H(f), \mathbb{R})$

is minimal and there is $g \in H(f)$ such that g is uniformly almost periodic (almost automorphic) in t. f is said to be *recurrent* if $(H(f), \mathbb{R})$ is minimal. Notice that if f is almost periodic (almost automorphic), then $(H(f), \mathbb{R})$ is minimal, and hence f is recurrent.

LEMMA 2.1. *Let $f(t,x)$ and $g(t,y)$ ($f \in C(\mathbb{R} \times E, \mathbb{R}^m)$, $g \in C(\mathbb{R} \times E, \mathbb{R}^k)$) be two uniformly almost automorphic functions in t. Then $\mathcal{M}(g) \subset \mathcal{M}(f)$ iff for each sequence $\{\alpha_n\} \subset \mathbb{R}$, if $\lim_{n\to\infty} f(t+\alpha_n, x) = f(t,x)$ uniformly for t and x in bounded sets, then $\lim_{n\to\infty} g(t+\alpha_n, y) = g(t,y)$ uniformly for t and y in bounded sets.*

Proof. See [45]. □

2.2. Skew-product semiflows. Let $(Y, \mathbb{R})$ be a minimal flow with Y being a compact metric space and $y \cdot t \equiv (y,t)$ for any $y \in Y$ and $t \in \mathbb{R}$. Let Z be a complete metric space and $\leq$ be a partial ordering on Z satisfying that if $z_n^1 \leq z_n^2$ ($n \in \mathbb{N}$), then $\lim_{n\to\infty} z_n^1 \leq \lim_{n\to\infty} z_n^2$ provided that both limits exist. Let $P : Z \times Y \to Y$ be the natural projection and $\pi_t : Z \times Y \to Z \times Y$ be a skew-product semiflow, that is, a semiflow of the form

$$\pi_t(z,y) = (\Psi(t;z,y), y \cdot t)$$

for all $(z,y) \in Z \times Y$ and $t \geq 0$. Given $(z_0, y_0) \in Z \times Y$, if $\{\pi_t(z_0,y_0) | t \geq t_0\}$ is relatively compact for a $t_0 > 0$, then the set

$$\omega(y_0, z_0) = \bigcap_{\tau \geq t_0} cl\{\pi_{t+\tau}(z_0,y_0) | t \geq 0\}$$

is called the *ω-limit set of $\pi_t(z_0,y_0)$*. We say π_t is *partially monotone with respect to* $\leq$ if, for any $y \in Y$ and any z_1, $z_2 \in Z$ with $z_1 \leq z_2$, $\Psi(t;z_1,y) \leq \Psi(t;z_2,y)$ for $t \geq 0$.

LEMMA 2.2. *Assume that, for each $(z,y) \in Z \times Y$, $\pi_t(z,y)$ has at most one backward extension and that $(z_0,y_0) \in Z \times Y$ is such that $\{\pi_t(z_0,y_0) | t \geq t_0\}$ is relatively compact for some $t_0 > 0$.*

(1) π_t has a flow extension on the ω-limit set $\omega(z_0,y_0)$.

(2) There is a residual invariant subset $Y_0 \subset Y$ such that, for all $y^* \in Y_0$, $y \in Y$, and $\{t_n\} \subset \mathbb{R}$ with $y \cdot t_n \to y^*$ and for all $(z^*, y^*) \in P^{-1}(y^*) \cap \omega(z_0,y_0)$, there is a sequence $\{(z_n, y)\} \subset P^{-1}(y) \cap \omega(z_0,y_0)$ such that $\pi_{t_n}(z_n, y) \to (z^*, y^*)$.

(3) If π_t is partially monotone with respect to $\leq$, and $z_0 \leq z$ ($z \leq z_0$) for every $(z, y_0) \in \omega(z_0,y_0)$, then $\omega(z_0,y_0)$ is an almost 1-cover of Y; that is, $P^{-1}(y) \cap \omega(z_0,y_0)$ is a singleton for residually many $y \in Y$.

Proof. (1) The proof follows from [38].

(2) See [39] or [45].

(3) Without loss of generality, assume that $z_0 \leq z$ for every $(z,y_0) \in \omega(z_0,y_0)$. Let $Y_0 \subset Y$ be the set guaranteed by (2). For $y^* \in Y_0$ and (z_1,y^*), $(z_2,y^*) \in \omega(z_0,y_0)$, let $t_n \to \infty$ be such that $\pi_{t_n}(z_0,y_0) \to (z_1,y^*)$. By (2), one finds $(z^n, y_0) \in \omega(z_0,y_0)$ ($n \in \mathbb{N}$) such that $\pi_{t_n}(z^n,y_0) \to (z_2,y^*)$. Since $z_0 \leq z^n$, one has $\pi_{t_n}(z_0,y_0) \leq \pi_{t_n}(z^n,y_0)$ for $n \geq 1$, thus $z_1 \leq z_2$. Similarly, we can prove that $z_2 \leq z_1$. Hence $z_1 = z_2$ and $\omega(z_0,y_0)$ is an almost 1-cover of Y. □

2.3. Spectrum of linear scalar parabolic equations. Given a smooth bounded region $\Omega \subset \mathbb{R}^n$, let $X \subset L^p(\Omega)$ ($p > n$) be a fractional power space of $-\Delta : \mathcal{D} \to L^p(\Omega)$ satisfying $X \hookrightarrow C^1(\bar{\Omega})$, where $\mathcal{D} = \{u \in H^{2,p}(\Omega) | Bu = 0 \text{ for } x \in \partial\Omega\}$ and $Bu = \frac{\partial u}{\partial n}$ or u [17]. Then $\mathrm{Int}X_+ \neq \emptyset$. This is because, in the case that $Bu = \frac{\partial u}{\partial n}$, the set $\{u \in X | u(x) > 0 \text{ for } x \in \bar{\Omega}\} \subset \mathrm{Int}X_+$ is not empty, and, in the case

that $Bu = u$, the set $\{u \in X | u(x) > 0$ for $x \in \Omega$ and $\frac{\partial u}{\partial n} < 0$ for $x \in \partial\Omega\} \subset \mathrm{Int}X_+$ is not empty. Consequently, X_+ defines a strong ordering on X as follows:

$$u_1 \leq u_1 \quad \text{if} \quad u_1(x) \leq u_2(x) \quad \text{for} \quad \text{all} \quad x \in \Omega, \tag{2.2}$$

$$u_1 < u_2 \quad \text{if} \quad u_1 \leq u_2 \quad \text{but} \quad u_1 \neq u_2, \tag{2.3}$$

$$u_1 \ll u_2 \quad \text{if} \quad u_2 - u_1 \in \mathrm{Int}X_+. \tag{2.4}$$

Let $(Y, \mathbb{R})$ be a compact flow and $y \cdot t \equiv (y, t)$. Consider

$$\begin{cases} u_t = k\Delta u + A(y \cdot t, x)u, & x \in \Omega, \\ Bu = 0, & x \in \Omega, \end{cases} \tag{2.5}_y$$

where u is a scalar function, k is a positive constant, $y \in Y$, $A : Y \times \bar{\Omega} \to \mathbb{R}$ is continuous, and $A(y \cdot t, x)$ is Hölder continuous in t uniformly with respect to $y \in Y$ and $x \in \bar{\Omega}$. Then $(2.5)_y$ generates a skew-product semiflow [17], $\Pi_t : X \times Y \to X \times Y$,

$$\Pi_t(u, y) = (\Phi(t; u, y), y \cdot t), \tag{2.6}$$

where $\Phi(t; u, y)$ is the solution of $(2.5)_y$ with $\Phi(0; u, y) = u$. Thanks to the maximum principle for parabolic equations [12], [34], Π_t in (2.6) is strongly monotone in the sense that $\Phi(t; u, y) \gg 0$ for any $t > 0$, $y \in Y$, and $u \in X_+$ with $u \not\equiv 0$. The so-called Sacker–Sell spectrum and upper Lyapunov exponent of (2.6) or $(2.5)_y$ are defined as follows.

For a given $\sigma \in \mathbb{R}$, define $\Pi_t^\sigma : X \times Y \to X \times Y$, $t \geq 0$,

$$\Pi_t^\sigma(u, y) = (\Phi_\sigma(t; u, y), y \cdot t), \tag{2.7}_\sigma$$

where $\Phi_\sigma(t; u, y) = e^{-\sigma t}\Phi(t; u, y)$. Then the set

$$\Sigma(k, Y) = \{\sigma \in \mathbb{R} \mid (2.7)_\sigma \text{ admits no exponential dichotomy}\}$$

is called the *Sacker–Sell (dynamical) spectrum* and the number $\lambda(k, Y) = \sup_{y \in Y} \lambda(k, y)$ is called the *upper Lyapunov exponent* of (2.6), where $\lambda(k, y) = \limsup_{t \to \infty} \frac{\ln \|\Phi(t; \cdot, y)\|}{t}$.

Notice that, for any smooth function $h(t, x)$ which is uniformly almost periodic (almost automorphic, recurrent) in t, the almost periodic (almost automorphic, recurrent) scalar parabolic equation

$$\begin{cases} u_t = k\Delta u + h(t, x)u, & x \in \Omega, \\ Bu = 0, & x \in \partial\Omega, \end{cases} \tag{2.8}$$

can be built into $(2.5)_y$ by letting $Y = H(h)$ and $A : Y \times \bar{\Omega} \to \mathbb{R}$, $A(g, x) = g(0, x)$ for any $g \in Y$ and $x \in \bar{\Omega}$. Moreover, the dynamics of (2.8) is then reflected by that of the skew-product semiflow generated $(2.5)_y$ with $y \in Y = H(h)$. If $h(t, x) = h(x)$ is independent of t, then $\lambda(k, h)$ is the largest eigenvalue of the eigenvalue problem,

$$\begin{cases} k\Delta u + h(x)u = \lambda u, & x \in \Omega, \\ Bu = 0, & x \in \partial\Omega. \end{cases} \tag{2.9}$$

LEMMA 2.3. (1) *Suppose that $h_1(t, x)$ and $h_2(t, x)$ are two smooth functions which are uniformly almost periodic (almost automorphic, recurrent) in t. If $h_1(t, x) \leq h_2(t, x)$, then $\lambda(k, H(h_1)) \leq \lambda(k, H(h_2))$.*

(2) *If h is uniformly almost periodic in t, then $\lambda(k,g)$ is independent of $g \in H(h)$ (consequently, $\lambda(k,H(h)) = \lambda(k,h)$).*

(3) *If h is uniformly almost periodic in t, then $\lambda(k,h) \geq \lambda(k,\bar{h})$, where $\bar{h}(x) = \lim_{t\to\infty} \frac{1}{t}\int_0^t h(s,x)ds$.*

(4) *If h is uniformly almost periodic in t, then there is $\sigma_1 < \lambda(k,h)$ such that $\Sigma(k,H(h)) = \Sigma_1 \cup \{\lambda(k,h)\}$ and $\lambda \leq \sigma_1$ for any $\lambda \in \Sigma_1$.*

(5) *Suppose that $0 < k_1 \leq k_2$ are two constants and $h_1(x) \geq h_2(x)$ are two smooth functions. Then $\lambda(k_1,h_1) \geq \lambda(k_2,h_2)$, and the strict inequality holds if $h_1 \not\equiv h_2$.*

Proof. (1), (2), (3), and (4) follow from the arguments in [28] and the exponential separation theory in [32]. (5) follows from the fact that

$$\lambda(k_i,h_i) = \sup_{u\in X, \|u\|_2=1}\left(-k_i\int_\Omega |\bigtriangledown u(x)|^2dx + \int_\Omega h_i(x)u^2(x)dx\right)$$

$(i = 1,2)$, where $\|u\|_2 = (\int_\Omega u^2(x)dx)^{1/2}$. □

3. Convergence for almost periodic single species population models. In this section, we consider the convergence in the following single species population model:

$$\begin{cases} u_t = k\Delta u + u(a(t,x) - b(t,x)u), & x \in \Omega, \\ Bu = 0, & x \in \partial\Omega, \end{cases} \tag{3.1}$$

where k is a positive constant, $a(t,x)$, $b(t,x)$ $(b(t,x) \geq \delta > 0)$ are smooth functions and are uniformly almost periodic in t, $\Omega \subset \mathbb{R}^n$ is a smooth bounded region, and $Bu = \frac{\partial u}{\partial n}$ or u.

Let $X \hookrightarrow C^1(\bar{\Omega})$ be as in section 2.3, and let $\|\cdot\|$ be the norm of X. Let $P : X\times H(a,b) \to H(a,b)$ be the natural projection and $\Pi_t : X\times H(a,b) \to X\times H(a,b)$ be the (local) skew-product semiflow generated by (3.1); that is,

$$\Pi_t(u_0,a,b) = (u(t,\cdot;u_0,c,d), c\cdot t, d\cdot t), \tag{3.2}$$

where $u(t,\cdot;u_0,c,d)$ is the solution of

$$\begin{cases} u_t = k\Delta u + u(c(t,x) - d(t,x)u), & x \in \Omega, \\ Bu = 0, & x \in \partial\Omega \end{cases} \tag{3.3}_{c,d}$$

with $u(0,\cdot;u_0,c,d) = u_0(\cdot)$ $((c,d) \in H(a,b))$. By the comparison principle for parabolic equations [12], [34], Π_t is partially monotone with respect to the ordering $\leq$ in (2.2).

Definition 3.1. *A set $E \subset X \times H(a,b)$ is said to be trivial if $E \subset \{0\}\times H(a,b)$ and strictly positive if there is $u^+ \in \mathrm{Int}X_+$ such that $u \geq u^+$ for any $(u,c,d) \in E$.*

Notice that, for any $(c,d) \in H(a,b)$, $u \equiv 0$ is a solution of $(3.3)_{c,d}$ and that for sufficiently large $M > 1$, $u(t,x) = M$ is a supersolution of $(3.3)_{c,d}$. Therefore the comparison principle and standard a priori estimates for parabolic equations [12], [17], [18] yield the following result.

Lemma 3.2. *There is $M_0 > 0$ such that, for any $u_0 \in X_+ \setminus \{0\}$ and any $(c,d) \in H(a,b)$, $u(t,\cdot;u_0,c,d)$ exists for all $t \geq 0$ and*

$$u(t,\cdot;u_0,c,d) \gg 0 \quad \text{for} \quad t > 0,$$

$$0 < u(t,x;u_0,c,d) \leq M_0 \quad \text{for} \quad x \in \Omega, \quad t \gg 1.$$

Lemma 3.2 and the theory of parabolic equations [12], [17] imply that $\Pi_t : X_+ \times H(a,b) \to X_+ \times H(a,b)$ is a skew-product semiflow and $\{u(t,\cdot;u_0,c,d)|t \geq t_0\}$ is relatively compact in X for any $u_0 \in X_+$ and $t_0 > 0$. Therefore, the ω-limit set $\omega(u_0,c,d)$ of $\Pi_t(u_0,c,d)$ is well defined for all $(u_0,c,d) \in X_+ \times H(c,d)$. Moreover, Lemma 2.2(1) and the unique backward extensibility for parabolic equations show that Π_t has a flow extension on $\omega(u_0,c,d)$. The main result of this section is the following.

THEOREM 3.3. *Consider* (3.2). *One and only one of the following three alternatives occurs.*

(1) *For any $u_0 \in X_+ \setminus \{0\}$, $\omega(u_0,a,b)$ is strictly positive, a 1-cover of $H(a,b)$ (that is, $P^{-1}(c,d) \cap \omega(u_0,a,b)$ is a singleton for any $(c,d) \in H(a,b)$), and independent of u_0.*

(2) *For any $u_0 \in X_+ \setminus \{0\}$, $\omega(u_0,a,b) = \{0\} \times H(a,b)$.*

(3) *For any $u_0 \in X_+ \setminus \{0\}$, $\omega(u_0,a,b) \cap (\{0\} \times H(a,b)) \neq \emptyset$ and $\omega(u_0,a,b) \cap (\mathrm{Int}X_+ \times H(a,b)) \neq \emptyset$.*

The following corollary directly follows from Theorem 3.3 and Lemma 2.1.

COROLLARY 3.4. *Consider* (3.1). *One and only one of the following three alternatives occurs.*

(1) *There is a strictly positive almost periodic solution $u^*(t,x)$ with $\mathcal{M}(u^*) \subset \mathcal{M}(a,b)$ such that, for any $u_0 \in X_+ \setminus \{0\}$, $u(t,\cdot;u_0,a,b)$ converges to $u^*(t,x)$ in X; i.e.,*

$$\|u(t,\cdot;u_0,a,b) - u^*(t,\cdot)\| \to 0$$

as $t \to \infty$.

(2) *For any $u_0 \in X_+ \setminus \{0\}$, $u(t,\cdot;u_0,a,b)$ converges to $u \equiv 0$.*

(3) *For any $u_0 \in X_+ \setminus \{0\}$, $u(t,\cdot;u_0,a,b)$ is neither bounded away from $u \equiv 0$ nor converges to $u \equiv 0$.*

Before presenting the proof of Theorem 3.3, we establish the following four lemmas.

LEMMA 3.5. *Given $u_0 \in X_+$, $\alpha, \beta \in \mathbb{R}^+$ with $0 < \alpha \leq 1 \leq \beta$, and $(c,d) \in H(a,b)$, then*

$$\alpha u(t,\cdot;u_0,c,d) \leq u(t,\cdot;\alpha u_0,c,d) \leq u(t,\cdot;u_0,c,d)$$

and

$$u(t,\cdot;u_0,c,d) \leq u(t,\cdot;\beta u_0,c,d) \leq \beta u(t,\cdot;u_0,c,d)$$

for $t \geq 0$.

Proof. First of all, the comparison principle for parabolic equations yields

$$u(t,\cdot;\alpha u_0,c,d) \leq u(t,\cdot;u_0,c,d) \leq u(t,\cdot;\beta u_0,c,d) \tag{3.4}$$

for $t \geq 0$.

Next, letting $u_1(t,x) = \alpha u(t,x;u_0,c,d)$, $u_2(t,x) = u(t,x;\alpha u_0,c,d)$, $u_3(t,x) = u(t,x;\beta u_0,c,d)$, and $u_4(t,x) = \beta u(t,x;u_0,c,d)$, one has that $u = u_i(t,x)$ is the solution of

$$\begin{cases} u_t = k\Delta u + h(t,x)u, & x \in \Omega, \\ Bu = 0, & x \in \partial\Omega, \end{cases} \tag{3.5}$$

with $h(t,x) = h_i(t,x)$ and $u(0,x) = u_i(x)$ $(i = 1,2,3,4)$, where

$$h_1(t,x) = h_4(t,x) = c(t,x) - d(t,x)u(t,x;u_0,c,d),$$
$$h_2(t,x) = c(t,x) - d(t,x)u(t,x;\alpha u_0,c,d),$$
$$h_3(t,x) = c(t,x) - d(t,x)u(t,x;\beta u_0,c,d),$$

and

$$u_1(x) = u_2(x) = \alpha u_0(x), \qquad u_3(x) = u_4(x) = \beta u_0(x).$$

By (3.4),

$$h_1(t,x) \le h_2(t,x) \quad \text{and} \quad h_3(t,x) \le h_4(t,x) \quad \text{for} \quad x \in \Omega, \quad t \ge 0.$$

Again, it follows from the comparison principle that

$$u_1(t,\cdot) \le u_2(t,\cdot) \quad \text{and} \quad u_3(t,\cdot) \le u_4(t,\cdot) \tag{3.6}$$

for $t \ge 0$, and (3.4) and (3.6) imply the statements of the lemma. □

LEMMA 3.6. *Suppose that $\omega(u_0^*,a,b)$ is strictly positive for some $u_0^* \in \mathrm{Int}X_+$; then $\omega(u_0,a,b)$ is strictly positive for all $u_0 \in X_+ \setminus \{0\}$.*

Proof. First of all, $u(t,\cdot;u_0,a,b) \in \mathrm{Int}X_+$ for $u_0 \in X_+ \setminus \{0\}$ and $t > 0$. Hence we may assume without loss of generality that $u_0 \in IntX_+$.

Next, for any $u_0 \in \mathrm{Int}X_+$, there is $\alpha > 0$ such that $u_0 \ge \alpha u_0^*$. Then the comparison principle for parabolic equations and Lemma 3.5 imply

$$\alpha u(t,x;u_0^*,a,b) \le u(t,\cdot;u_0,a,b) \quad \text{for} \quad t > 0.$$

Thus, $\omega(u_0,a,b)$ is strictly positive for any $u_0 \in \mathrm{Int}X_+$. □

LEMMA 3.7. *Let $E \subset X_+ \times H(a,b)$ be compact, strictly positive, and invariant under Π_t. Then, for each $\epsilon > 0$, there is $\delta > 0$ such that, for any $(u_1,c,d) \in E$ and $u_2 \in X_+$ with $\|u_2 - u_1\| < \delta$,*

$$|u(t,x;u_2,c,d) - u(t,x;u_1,c,d)| < \epsilon \quad \text{for} \quad x \in \Omega, \quad t \ge 0.$$

Proof. Since E is compact, strictly positive, and invariant under Π_t, there exists a $u_+ \in \mathrm{Int}X_+$ such that $u \ge u_+$ for all $(u,c,d) \in E$. Also, one finds an $M > 0$ such that $|u(x)| \le M$ for every $(u,c,d) \in E$ and $x \in \Omega$. Now let $\epsilon > 0$ and select $0 < \alpha < 1$ with $\alpha M < \epsilon$. We claim that there is $\delta > 0$ such that, for each $(u_1,c,d) \in E$ and $u_2 \in X_+$ with $\|u_2 - u_1\| < \delta$,

$$(1-\alpha)u_1(\cdot) \le u_2(\cdot) \le (1+\alpha)u_1(\cdot). \tag{3.7}$$

Otherwise, let $\delta_n = \frac{1}{n}$. Then there exist $(u_n^1,c_n,d_n) \in E$ and $u_n^2 \in X_+$ with $\|u_n^2 - u_n^1\| < \delta_n$, but (3.7) does not hold for $u_1 = u_n^1$ and $u_2 = u_n^2$. Without loss of generality, assume that $(u_n^1,c_n,d_n) \to (u_1^*,c^*,d^*)$ as $n \to \infty$. We have

$$\frac{1+\alpha/2}{1+\alpha}u_1^* \le u_n^1 \le \frac{1-\alpha/2}{1-\alpha}u_1^*$$

and

$$(1-\alpha/2)u_1^* \le u_n^2 \le (1+\alpha/2)u_1^*$$

for n large enough. This implies that

$$(1-\alpha)u_n^1 \le (1-\alpha/2)u_1^* \le u_n^2 \le (1+\alpha/2)u_1^* \le (1+\alpha)u_n^1$$

for n large enough, a contradiction. Hence (3.7) holds for some $\delta > 0$. Then the comparison principle for parabolic equations and Lemma 3.5 show that

$$(1-\alpha)u(t,\cdot;u_1,c,d) \le u(t,\cdot;u_2,c,d) \le (1+\alpha)u(t,\cdot;u_1,c,d)$$

for all $t \ge 0$ and $(u_1,c,d) \in E$, $u_2 \in X_+$ with $\|u_2 - u_1\| < \delta$, hence

$$|u(t,x;u_2,c,d) - u(t,x;u_1,c,d)| \le \alpha|u(t,x;u_1,c,d)| \le \alpha M < \epsilon$$

for $x \in \Omega$ and $t \ge 0$. □

LEMMA 3.8. *If $\omega(u_0,a,b)$ is strictly positive for $u_0 \in X_+ \setminus \{0\}$, then it is independent of u_0.*

Proof. It is sufficient to prove that, for any $u_1, u_2 \in \mathrm{Int}X_+$ with $u_1 \ll u_2$, $\omega(u_1,a,b) = \omega(u_2,a,b)$.

To this end, fix $u_1^0, u_2^0 \in \mathrm{Int}X_+$ with $u_1^0 \ll u_2^0$. By Lemma 3.6, both $\omega(u_1^0,a,b)$ and $\omega(u_2^0,a,b)$ are strictly positive. Suppose that $\omega(u_1^0,a,b) \ne \omega(u_2^0,a,b)$. Then we may assume that there is $(u_1^*,c,d) \in \omega(u_1^0,a,b) \setminus \omega(u_2^0,a,b)$. Let $t_n \to \infty$ and $(u_2^*,c,d) \in \omega(u_2^0,c,d)$ be such that $\Pi_{t_n}(u_1^0,a,b) \to (u_1^*,c,d)$ and $\Pi_{t_n}(u_2^0,a,b) \to (u_2^*,c,d)$ as $n \to \infty$. By $u_1^0 \ll u_2^0$,

$$u(t,\cdot;u_1^*,c,d) = \lim_{n\to\infty} u(t+t_n,\cdot;u_1^0,a,b) \le \lim_{n\to\infty} u(t,\cdot;u_2^0,a,b) = u(t,\cdot;u_2^*,c,d)$$

for $t \in \mathbb{R}$. Clearly, $u_1^* \ne u_2^*$, and the comparison principle yields

$$u(t,\cdot;u_1^*,c,d) \ll u(t,\cdot;u_2^*,c,d) \quad \text{for} \quad t \in \mathbb{R}.$$

Moreover, we claim that there is $u_+(\cdot) \in \mathrm{Int}X_+$ such that

$$u(t,\cdot;u_2^*,c,d) - u(t,\cdot;u_1^*,c,d) \ge u_+(\cdot) \quad \text{for} \quad t \le 0. \tag{3.8}$$

Otherwise, there are $u_n^+(\cdot) \in \mathrm{Int}X_+$ with $\|u_n^+\| \to 0$ as $n \to \infty$ and $t_n \le 0$ such that (3.8) does not hold for $u_+ = u_n^+$ and $t = t_n$. Without loss of generality, assume that $u(t_n,\cdot;u_i^*,c,d) \to u_i^{**}(\cdot)$ and $(c,d)\cdot t_n \to (c^*,d^*)$. By Lemma 3.7, $u_1^{**} \ne u_2^{**}$, thus $u_1^{**} \ll u_2^{**}$ thanks to the comparison principle for parabolic equations. Hence there is $u_+^*(\cdot) \in \mathrm{Int}X_+$ such that

$$u_2^{**}(\cdot) - u_1^{**}(\cdot) \gg u_+^*(\cdot)$$

and then

$$u(t_n,\cdot;u_2^*,c,d) - u(t_n,\cdot;u_1^*,c,d) \ge \frac{1}{2}u_+^*(\cdot) \ge u_n^+(\cdot)$$

for n large enough, a contradiction. Therefore, (3.8) holds for some $u_+(\cdot) \in \mathrm{Int}X_+$.

Next, select $s_n \to -\infty$ such that

$$u(s_n,\cdot;u_i^*,c,d) \to \tilde{u}_i^*(\cdot) \quad \text{and} \quad (c,d)\cdot s_n \to (a,b),$$

and let $u_i(t,x) = u(t,x;\tilde{u}_i^*,a,b)$ $(i=1,2)$. By (3.8),

$$u_2(t,\cdot) - u_1(t,\cdot) \ge u_+(\cdot) \quad \text{for} \quad t \in \mathbb{R}. \tag{3.9}$$

By the positivity and compactness of $\omega(u_i^0, a, b)$ $(i = 1, 2)$, there is $\alpha > 0$ such that

$$u_2(t, \cdot) \le \alpha u_1(t, \cdot) \quad \text{for} \quad t \in \mathbb{R}. \tag{3.10}$$

Now let $\Phi^1(t, x)$ be the evolution operator of (3.5) with $h(t, x) = a(t, x) - b(t, x)u_1(t, x)$; that is, $\Phi^1(t, s)u_0 = u(t; s, u_0)$, where $u(t; s, u_0)$ is the solution of (3.5) with $h(t, x) = a(t, x) - b(t, x)u_1(t, x)$ and $u(s; s, u_0) = u_0$. We claim that there is $\beta > 0$ such that

$$\Phi^1(s + 1, s)\big(b(s, \cdot)(u_2(s, \cdot) - u_1(s, \cdot))u_2(s, \cdot)\big) \ge \beta u_1(s + 1, \cdot) \tag{3.11}$$

for any $s \in \mathbb{R}$. In fact, otherwise one finds for $\beta_n = \frac{1}{n}$ an $s_n \in \mathbb{R}$ such that

$$\Phi^1(s_n + 1, s_n)\big(b(s_n, \cdot)(u_2(s_n, \cdot) - u_1(s_n, \cdot))u_2(s_n, \cdot)\big) \not\ge \beta_n u_1(s_n + 1, \cdot). \tag{3.12}$$

Without loss of generality, we may assume that

$$u_i(s_n, \cdot) \to \bar{u}_i(\cdot), \qquad (a \cdot s_n, b \cdot s_n) \to (\bar{a}, \bar{b})$$

as $n \to \infty$. Let $\bar{\Phi}^1(t, s)$ be the evolution operator of (3.5) with $h(t, x) = \bar{a}(t, x) - \bar{b}(t, x)\bar{u}_1(t, x)$, where $\bar{u}_1(t, x) = \lim_{n\to\infty} u_1(t + s_n, x)$. Then

$$\begin{aligned}\Phi^1(s_n + 1, s_n)\big(b(s_n, \cdot)(u_2(s_n, \cdot) - u_1(s_n, \cdot))u_2(s_n, \cdot)\big)\\ \to \bar{\Phi}^1(1, 0)\big(\bar{b}(0, \cdot)(\bar{u}_2(\cdot) - \bar{u}_1(\cdot))\bar{u}_2(\cdot)\big)\end{aligned}$$

as $n \to \infty$. By (3.9) and the positivity of $\omega(u_2^0, a, b)$,

$$\bar{\Phi}^1(1, 0)\big(\bar{b}(0, \cdot)(\bar{u}_2(\cdot) - \bar{u}_1(\cdot))\bar{u}_2(\cdot)\big) \gg 0.$$

Hence there is $\bar{\beta} > 0$ such that

$$\bar{\Phi}^1(1, 0)\big(\bar{b}(0, \cdot)(\bar{u}_2(\cdot) - \bar{u}_1(\cdot))\bar{u}_2(\cdot)\big) \gg 2\bar{\beta}\bar{u}_1(1, \cdot).$$

This implies that

$$\Phi^1(s_n + 1, s_n)\big(b(s_n, \cdot)(u_2(s_n, \cdot) - u_1(s_n, \cdot))u_2(s_n, \cdot)\big) \gg \bar{\beta}\bar{u}_1(1, \cdot)$$

for n large enough; consequently, there is $\beta > 0$ such that

$$\Phi^1(s_n + 1, s_n)\big(b(s_n, \cdot)(u_2(s_n, \cdot) - u_1(s_n, \cdot))u_2(s_n, \cdot)\big) \ge \beta u_1(s_n + 1, \cdot)$$

for n large enough, a contradiction to (3.12). Hence there is $\beta > 0$ such that (3.11) holds.

Note that $u_2(t, x)$ is a solution of (3.5) with $h(t, x) = a(t, x) - b(t, x)u_2(t, x) = a(t, x) - b(t, x)u_1(t, x) - b(t, x)\big(u_2(t, x) - u_1(t, x)\big)$. By the variation of constant formula [17] and (3.10), (3.11), for $t \ge 1$,

$$\begin{aligned}u_2(t, x) &= \Phi^1(t, s)u_2(s, \cdot) - \int_0^t \Phi^1(t, s)\big(b(s, \cdot)(u_2(s, \cdot) - u_1(s, \cdot))u_2(s, \cdot)\big)ds\\
&\le \Phi^1(t, s)\alpha u_1(s, \cdot) - \int_0^{t-1} \Phi^1(t, s + 1)\Phi^1(s + 1, s)\big(b(s, \cdot)(u_2(s, \cdot) - u_1(s, \cdot))\\
&\qquad \times u_2(s, \cdot)\big)ds\\
&\le \alpha u_1(t, \cdot) - \int_0^{t-1} \Phi^1(t, s + 1)\beta u_1(s + 1, \cdot)ds\\
&= \alpha u_1(t, \cdot) - \beta \int_0^{t-1} u_1(t, \cdot)ds\\
&= (\alpha - \beta(t - 1))u_1(t, \cdot),\end{aligned}$$

which contradicts the boundedness and positivity of u_1, u_2. Hence $\omega(u_1^0, a, b) = \omega(u_2^0, a, b)$. □

Proof of Theorem 3.3. First of all, fix a $u_0^* \in \mathrm{Int}X_+$. Then $\omega(u_0^*, a, b)$ is either strictly positive, or trivial, or neither strictly positive nor trivial.

Claim 1. $\omega(u_0^*, a, b)$ is strictly positive iff alternative (1) of Theorem 3.3 occurs.

First, if alternative (1) of Theorem 3.3 occurs, clearly, then $\omega(u_0^*, a, b)$ is strictly positive.

Next, suppose that $\omega(u_0^*, a, b)$ is strictly positive. Then, by Lemmas 3.6 and 3.8, $\omega(u_0, a, b)$ is strictly positive and independent of u_0 for any $u_0 \in \mathrm{Int}X_+$. It remains to prove that $\omega(u_0^*, a, b)$ is a 1-cover of $H(a, b)$. Note that there is $u_+ \in \mathrm{Int}X_+$ such that $u(\cdot) \le u_+(\cdot)$ for any $(u, a, b) \in \omega(u_0^*, a, b)$. Hence $u \le u_+$ for any $(u, a, b) \in \omega(u_+, a, b)$. Then by Lemma 2.2(3), $\omega(u_0^*, a, b) = \omega(u_+, a, b)$ is an almost 1-cover of $H(a, b)$. Suppose that $(c_0, d_0) \in H(a, b)$ is such that $\omega(u_0^*, a, b) \cap (X \times \{(c_0, d_0)\}) = \{(u_0, c_0, d_0)\}$ is a singleton. Then one obtains for every (u_1, c, d), $(u_2, c, d) \in \omega(u_0^*, a, b)$ and $s_n \to -\infty$ with $(c, d) \cdot s_n \to (c_0, d_0)$ that

$$\|u(s_n, \cdot; u_1, c, d) - u(s_n, \cdot; u_2, c, d)\| \to 0$$

as $n \to \infty$. By Lemma 3.7, we must have $u_1 = u_2$ and then $\omega(u_0^*, a, b)$ is a 1-cover of $H(a, b)$.

Claim 2. $\omega(u_0^*, a, b)$ is trivial iff alternative (2) of Theorem 3.3 occurs.

First, observe that, if alternative (2) of Theorem 3.3 occurs, then $\omega(u_0^*, a, b)$ is trivial.

Next, suppose that $\omega(u_0^*, a, b)$ is trivial. Note that $u(t, \cdot; u_0, a, b) \gg 0$ for all $t > 0$ and $u_0 \in X_+ \setminus \{0\}$. Hence we need only to prove that $\omega(u_0, a, b)$ is trivial for each $u_0 \in \mathrm{Int}X_+$. Given any $u_0 \in \mathrm{Int}X_+$, let $\alpha > 0$ be such that $\alpha u_0(\cdot) \le u_0^*(\cdot)$. By Lemma 3.5,

$$\alpha u(t, x; u_0, a, b) \le u(t, x; u_0^*, a, b)$$

for $x \in \Omega$ and $t \ge 0$. This implies that $\omega(u_0, a, b)$ is trivial, and hence the claim follows.

Claim 3. $\omega(u_0^*, a, b)$ is neither trivial nor strictly positive iff alternative (3) of Theorem 3.3 occurs.

Clearly, if alternative (3) of Theorem 3.3 holds, then $\omega(u_0^*, a, b)$ is neither trivial nor strictly positive.

Conversely, suppose that $\omega(u_0^*, a, b)$ is neither trivial nor strictly positive. Then we also have $\omega(u_0, a, b)$ is neither trivial nor strictly positive for any $u_0 \in X_+ \setminus \{0\}$. Since $\omega(u_0, a, b) \ne \{0\} \times H(a, b)$, there is $(u^*, c, d) \in \omega(u_0, a, b)$ with $u^* \in X_+ \setminus \{0\}$. Then we must have $u(t, \cdot; u^*, c, d) \in \mathrm{Int}X_+$ for $t > 0$. Hence $\omega(u_0, a, b) \cap (\mathrm{Int}X_+ \times H(a, b)) \ne \emptyset$. Since $\omega(u_0, a, b)$ is not strictly positive, for any $u_n^+ \in \mathrm{Int}X_+$ with $\|u_n^+\| \to 0$, there is t_n such that $u(t_n, \cdot; u_0, a, b) \not\ge u_n^+(\cdot)$. Assume that $u(t_n, \cdot; u_0, a, b) \to u^*(\cdot)$ as $n \to \infty$. Then we must have $u^* = 0$. Hence $\omega(u_0, a, b) \cap (\{0\} \times H(a, b)) \ne \emptyset$.

Theorem 3.3 now follows from Claims 1, 2, and 3. □

Remark 3.1. (1) When a, b are actually periodic, alternative (3) of Theorem 3.3 does not occur (cf. [19], [21]).

(2) In the case where a is almost periodic and homogeneous Neumann boundary conditions are prescribed, the theorem has been proved in [36] by means of a very different approach which is limited to Neumann conditions. Moreover, it has been shown in [36] that each of the alternatives (1), (2), (3) really occurs.

COROLLARY 3.9. *Let* $\bar{a}(x) = \lim_{t\to\infty} \frac{1}{t}\int_0^t a(s,x)ds$. *If* $\lambda(k,a) > 0$ *or* $\lambda(k,\bar{a}) > 0$, *then alternative* (1) *of Theorem* 3.3 *occurs.*

Proof. By Lemma 2.3(4), there is $\sigma_1 < \lambda(k,a)$ such that $\Sigma(k,H(a)) = \Sigma_1 \cup \{\lambda(k,a)\}$ and $\lambda \le \sigma_1$ for any $\lambda \in \Sigma_1$. Hence $u \equiv 0$ is a linearly unstable solution of (3.1), and the invariant manifold theory ([5], [7], etc.) excludes alternatives (2) and (3) of Theorem 3.3, thus alternative (1) holds. □

4. Basic properties of almost periodic two species competition models. In this section, we present some basic properties of the two species competition model:

$$(4.1)\qquad \begin{cases} u_t = k_1\Delta u + u(a_1(t,x) - b_1(t,x)u - c_1(t,x)v), & x \in \Omega,\\ v_t = k_2\Delta v + v(a_2(t,x) - b_2(t,x)u - c_2(t,x)v), & x \in \Omega,\\ Bu = Bv = 0, & x \in \partial\Omega, \end{cases}$$

where k_i, a_i, b_i, c_i $(i = 1,2)$, Ω and Bu, Bv are as in (1.1), and b_1, $c_2 \ge \delta$ for some $\delta > 0$, c_1, $b_2 \ge 0$. Let $f_i(t,x,u,v) = a_i(t,x) - b_i(t,x)u - c_i(t,x)v$ $(i = 1,2)$. Let X be as in section 2.3 and $\Pi_t : X \times X \times H(f_1,f_2) \to X \times X \times H(f_1,f_2)$ be the (local) skew-product semiflow generated by (4.1),

$$(4.2)\qquad \Pi_t(u_0,v_0,g_1,g_2) = (u(t,\cdot;u_0,v_0,g_1,g_2), v(t,\cdot;u_0,v_0,g_1,g_2), g_1\cdot t, g_2\cdot t),$$

where $(u(t,\cdot;u_0,v_0,g_1,g_2), v(t,\cdot;u_0,v_0,g_1,g_2))$ is the solution of

$$(4.3)_{g_1,g_2}\qquad \begin{cases} u_t = k_1\Delta u + ug_1(t,x,u,v), & x \in \Omega,\\ v_t = k_2\Delta v + vg_2(t,x,u,v), & x \in \Omega,\\ Bu = Bv = 0, & x \in \partial\Omega \end{cases}$$

with $(u_0(\cdot), v_0(\cdot)) := (u(0,\cdot;u_0,v_0,g_1,g_2), v(0,\cdot;u_0,v_0,g_1,g_2))$.

Given (u_1,v_1), $(u_2,v_2) \in X_+ \times X_+$, we define

$$(4.4)_1\qquad (u_1,v_1) \le_1 (u_2,v_2) \quad\text{if}\quad u_1 \le u_2, \quad v_1 \le v_2,$$

$$(4.4)_2\qquad (u_1,v_1) <_1 (u_2,v_2) \quad\text{if}\quad (u_1,v_1) \le_1 (u_2,v_2), \quad (u_1,v_1) \ne (u_2,v_2),$$

$$(4.4)_3\qquad (u_1,v_1) \ll_1 (u_2,v_2) \quad\text{if}\quad (u_2-u_1, v_2-v_1) \in \mathrm{Int}(X_+) \times \mathrm{Int}(X_+),$$

$$(4.5)_1\qquad (u_1,v_1) \le_2 (u_2,v_2) \quad\text{if}\quad u_1 \le u_2, \quad v_1 \ge v_2,$$

$$(4.5)_2\qquad (u_1,v_1) <_2 (u_2,v_2) \quad\text{if}\quad (u_1,v_1) \le_2 (u_2,v_2), \quad (u_1,v_1) \ne (u_2,v_2),$$

$$(4.5)_3\qquad (u_1,v_1) \ll_2 (u_2,v_2) \quad\text{if}\quad (u_2-u_1, v_1-v_2) \in \mathrm{Int}(X_+) \times \mathrm{Int}(X_+).$$

For (u_1,v_1,g_1,g_2), $(u_2,v_2,g_1,g_2) \in X_+ \times X_+ \times H(f_1,f_2)$, define

$$(4.6)_1\quad (u_1,u_2,g_1,g_2) \le_1 (<_1,\ll_1)(u_2,v_2,g_1,g_2) \quad\text{if}\quad (u_1,v_1) \le_1 (<_1,\ll_1)(u_2,v_2)$$

and

$$(4.6)_2\quad (u_1,u_2,g_1,g_2) \le_2 (<_2,\ll_2)(u_2,v_2,g_1,g_2) \quad\text{if}\quad (u_1,v_1) \le_2 (<_2,\ll_2)(u_2,v_2).$$

LEMMA 4.1. (1)

$$\Pi_t(X_+ \times \{0\} \times H(f_1,f_2)) \subset X_+ \times \{0\} \times H(f_1,f_2) \quad\text{for}\quad t > 0,$$

$$\Pi_t(\{0\} \times X_+ \times H(f_1,f_2)) \subset \{0\} \times X_+ \times H(f_1,f_2) \quad\text{for}\quad t > 0.$$

(2)

$$\Pi_t(X_+ \times X_+ \times H(f_1, f_2)) \subset X_+ \times X_+ \times H(f_1, f_2) \quad \text{for} \quad t > 0.$$

Proof. These results follow from the standard parabolic theory. □

By Lemma 4.1, $\Pi_t|_{X_+\times X_+\times H(f_1,f_2)}$ ($\Pi|_{X_+\times\{0\}\times H(f_1,f_2)}$, $\Pi|_{\{0\}\times X_+\times H(f_1,f_2)}$) is a skew-product semiflow.

LEMMA 4.2. *If* (u_1, v_1), $(u_2, v_2) \in X_+ \times X_+$ *and* $(u_1, v_1) \leq_2 (u_2, v_2)$, *then*

$$\Pi_t(u_1, v_1, g_1, g_2) \leq_2 \Pi_t(u_2, v_2, g_1, g_2)$$

for all $t > 0$ *and* $(g_1, g_2) \in H(f_1, f_2)$. *Moreover, if* $(u_1, v_1) <_2 (u_2, v_2)$ *and* $(u_1, v_1) \notin X_+ \times \{0\}$, $(u_2, v_2) \notin \{0\} \times X_+$, *then*

$$\Pi_t(u_1, v_1, g_1, g_2) \ll_2 \Pi_t(u_2, v_2, g_1, g_2)$$

for all $t > 0$ *and* $(g_1, g_2) \in H(f_1, f_2)$.

Proof. The proof follows from Lemma 4.1 and the comparison principle for parabolic equations. □

By Lemmas 4.1 and 4.2, $\Pi_t|_{X_+\times X_+\times H(f_1,f_2)}$ is partially monotone with respect to the ordering $\leq_2$ in $(4.5)_1$, and $\Pi_t(u_0, v_0, g_1, g_2)$ is strictly positive for all $(u_0, v_0, g_1, g_2) \in (X_+ \setminus \{0\}) \times (X_+ \setminus \{0\}) \times H(f_1, f_2)$ and $t > 0$; that is,

$$(0, 0, g_1 \cdot t, g_2 \cdot t) \ll_1 \Pi_t(u_0, v_0, g_1, g_2)$$

for $t > 0$.

LEMMA 4.3. *Assume that* $\lambda(k_1, a_1) > 0$ *and* $\lambda(k_2, a_2) > 0$.

(1) *There is* $E_1 \subset X_+ \times \{0\} \times H(f_1, f_2)$, *which is invariant under* Π_t *and has the form*

$$E_1 = \{(u_{g_1}, 0, g_1, g_2) | (g_1, g_2) \in H(f_1, f_2)\}.$$

E_1 *is attracting in the sense that, for each* $u_0 \in X_+ \setminus \{0\}$ *and* $(g_1, g_2) \in H(f_1, f_2)$,

$$\|u(t, \cdot; u_0, 0, g_1, g_0) - u(t, \cdot; u_{g_1}, 0, g_1, g_2)\| \to 0$$

as $t \to \infty$.

(2) *There is* $E_2 \subset \{0\} \times X_+ \times H(f_1, f_2)$, *which is invariant under* Π_t *and has the form*

$$E_2 = \{(0, v_{g_2}, g_1, g_2) | (g_1, g_2) \in H(f_1, f_2)\}.$$

E_2 *is attracting in the sense that, for each* $v_0 \in X_+ \setminus \{0\}$ *and* $(g_1, g_2) \in H(f_1, f_2)$,

$$\|u(t, \cdot; 0, v_0, g_1, g_2) - u(t, \cdot; 0, v_{g_2}, g_1, g_2)\| \to 0$$

as $t \to \infty$.

Proof. The proof follows from Corollary 3.9 and Lemma 4.1(1). □

Unless otherwise specified, we assume throughout the rest of the paper that $\lambda(k_1, a_1) > 0$ and $\lambda(k_2, a_2) > 0$. Let $E \subset X_+ \times X_+ \times H(f_1, f_2)$ be such that

$$E \cap (X \times X \times \{(g_1, g_2)\}) = ([0, u_{g_1}] \times [0, v_{g_2}] \times \{(g_1, g_2)\}) \setminus \{(0, 0, g_1, g_2)\}, \tag{4.7}$$

where $[0, u_{g_1}] = \{u \in X \mid 0 \leq u \leq u_{g_1}\}$ and $[0, v_{g_2}] = \{v \in X \mid 0 \leq v \leq v_{g_2}\}$.

LEMMA 4.4. (1) $\Pi_t E \subset E$ *for each* $t > 0$*;*

(2) $\omega(u_0, v_0, g_1, g_2) \subset E$ *for all* $(u_0, v_0) \in (X_+ \times X_+) \setminus \{(0,0)\}$ *and* $(g_1, g_2) \in H(f_1, f_2)$.

Proof. The proof follows from Lemmas 4.2 and 4.3. □

Let $a_{iL(M)}$, $b_{iL(M)}$, and $c_{iL(M)}$ have the same meaning as in $(1.4)_1$–$(1.4)_3$, and let $(u^{\pm}(t,\cdot;u_0,v_0), v^{\pm}(t,\cdot;u_0,v_0))$ denote the solutions of

$$(4.8)_+ \qquad \begin{cases} u_t = k_1\Delta u + u(a_{1M} - b_{1L}u - c_{1L}v), & x \in \Omega, \\ v_t = k_2\Delta v + v(a_{2L} - b_{2M}u - c_{2M}v), & x \in \Omega, \\ Bu = Bv = 0, & x \in \partial\Omega \end{cases}$$

(this is the case +) and

$$(4.8)_- \qquad \begin{cases} u_t = k_1\Delta u + u(a_{1L} - b_{1M}u - c_{1M}v), & x \in \Omega, \\ v_t = k_2\Delta v + v(a_{2M} - b_{2L}u - c_{2L}v), & x \in \Omega, \\ Bu = Bv = 0, & x \in \partial\Omega \end{cases}$$

satisfying $(u^{\pm}(0,\cdot;u_0,v_0), v^{\pm}(0,\cdot;u_0,v_0)) = (u_0(\cdot), v_0(\cdot))$. The comparison principle for parabolic equations yields the following result.

LEMMA 4.5. *If* $(u_0, v_0) \in X_+ \times X_+$ *and* $(g_1, g_2) \in H(f_1, f_2)$*, then*

$$(u^-(t,\cdot;u_0,v_0), v^-(t,\cdot;u_0,v_0)) \leq_2 (u(t,\cdot;u_0,v_0,g_1,g_2), v(t,\cdot;u_0,v_0,g_1,g_2))$$

and

$$(u(t,\cdot;u_0,v_0,g_1,g_2), v(t,\cdot;u_0,v_0,g_1,g_2)) \leq_2 (u^+(t,\cdot;u_0,v_0), v^+(t,\cdot;u_0,v_0))$$

for $t \geq 0$.

The following lemmas concern the dynamics of (4.1) when a_i, b_i, and c_i $(i = 1, 2)$ are constants.

LEMMA 4.6. *Assume that* a_i, b_i, c_i $(i = 1, 2)$ *are positive constants and that* $\lambda(k_1, a_1) > 0$, $\lambda(k_2, a_2) > 0$. *Then exactly one of the following alternatives holds.*

(1) (4.1) *has a strictly positive equilibrium solution.*

(2) *Every positive solution of* (4.1) *converges to the solution* $(u_{f_1}, 0)$.

(3) *Every positive solution of* (4.1) *converges to the solution* $(0, v_{f_2})$.

Proof. See [25]. □

LEMMA 4.7. *Assume that* a_i, b_i, c_i $(i = 1, 2)$ *are positive constants and* $Bu = \frac{\partial u}{\partial n}$.

(1) *If* $a_1 > \frac{c_1 a_2}{c_2}$ *and* $a_2 > \frac{a_1 b_2}{b_1}$, *then every positive solution of* (4.1) *converges to a unique strictly positive equilibrium.*

(2) *If* $a_1 > \frac{c_1 a_2}{c_2}$ *and* $a_2 \leq \frac{a_1 b_2}{b_1}$, *then every positive solution of* (4.1) *converges to the equilibrium* $(u_{f_1}, 0) \equiv (\frac{a_1}{b_1}, 0)$.

(3) *If* $a_1 \leq \frac{c_1 a_2}{c_2}$ *and* $a_2 > \frac{a_1 b_2}{b_1}$, *then every positive solution of* (4.1) *converges to the equilibrium* $(0, v_{f_2}) \equiv (0, \frac{a_2}{c_2})$.

Proof. (1) The proof follows from [31], [48].

(2) and (3) follow from [3], [31]. □

LEMMA 4.8. *Assume that* a_i, b_i, c_i $(i = 1, 2)$ *are positive constants,* $Bu = u$, *and* $\lambda(k_1, a_1) > 0$, $\lambda(k_2, a_2) > 0$.

(1) *If* $a_1 > \frac{c_1 a_2}{c_2}$, $a_2 > \frac{a_1 b_2}{b_1}$, $k_1 = k_2$, *and* $a_1 = a_2$, *then every positive solution of* (4.1) *converges to a unique strictly positive equilibrium.*

(2) *If* $a_1 > \frac{c_1 a_2}{c_2}$, $a_2 \leq \frac{a_1 b_2}{b_1}$, $k_1 \leq k_2$, *and* $a_1 \geq a_2$, *then every positive solution of* (4.1) *converges to* $(u_{f_1}, 0)$.

(3) *If* $a_1 \le \frac{c_1 a_2}{c_2}$, $a_2 > \frac{a_1 b_2}{b_1}$, $k_1 \ge k_2$, *and* $a_1 \le a_2$, *then every positive solution of* (4.1) *converges to* $(0, v_{f_2})$.

Proof. (1) The proof follows from [8].

(2) First, we show that $(0, v_{f_2})$ is linearly unstable. Since v_{f_2} is a solution of (3.5) with $k = k_2$ and $h = a_2 - c_2 v_{f_2}$, one has $\lambda(k_2, a_2 - c_2 v_{f_2}) = 0$. Linearizing (4.1) around $(0, v_{f_2})$, we obtain

$$\begin{cases} u_t = k_1 \Delta u + (a_1 - c_1 v_{f_2})u, & x \in \Omega, \\ v_t = k_2 \Delta v - b_2 v_{f_2} u + (a_2 - 2c_2 v_{f_2})v, & x \in \Omega, \\ u = v = 0, & x \in \partial\Omega. \end{cases} \tag{4.9}$$

Note that $0 < v_{f_2} \le \frac{a_2}{c_2}$; consequently, $a_1 \ge a_2$ and $a_1 > \frac{c_1 a_2}{c_2}$ yield

$$a_1 - c_1 v_{f_2} = a_1 \left(1 - \frac{c_1}{a_1} v_{f_2}\right) > a_1 \left(1 - \frac{c_2}{a_2} v_{f_2}\right) \ge a_2 \left(1 - \frac{c_2}{a_2} v_{f_2}\right) = a_2 - c_2 v_{f_2}.$$

Therefore $k_1 \le k_2$ and Lemma 2.3(5) imply $\lambda(k_1, a_1 - c_1 v_{f_2}) > 0$. Observe that $\lambda = \lambda(k_1, a_1 - c_1 v_{f_2})$ is an eigenvalue of the following eigenvalue problem which arises from (4.9):

$$\begin{cases} k_1 \Delta u + (a_1 - c_1 v_{f_2})u = \lambda u, & x \in \Omega, \\ k_2 \Delta v - b_2 v_{f_2} u + (a_2 - 2c_2 v_{f_2})v = \lambda v, & x \in \Omega, \\ u = v = 0, & x \in \partial\Omega. \end{cases} \tag{4.10}$$

Hence $(0, v_{f_2})$ is linearly unstable, and therefore alternative (3) of Lemma 4.6 cannot occur.

Next, we prove (4.1) has no strictly positive equilibrium. Suppose that there is a strictly positive equilibrium (u_*, v_*). Then $u = u_*$ is a solution of (3.5) with $k = k_1$ and $h = a_1 - b_1 u_* - c_1 v_*$, and $v = v_*$ is a solution of (3.5) with $k = k_2$ and $h = a_2 - b_2 u_* - c_2 v_*$. Hence $\lambda(k_1, a_1 - b_1 u_* - c_1 v_*) = 0$ and $\lambda(k_2, a_2 - b_2 u_* - c_2 v_*) = 0$. By $a_1 \ge a_2$, $a_1 > \frac{c_1 a_2}{c_2}$, and $a_2 \le \frac{a_1 b_2}{b_1}$, one gets

$$a_1 - b_1 u_* - c_1 v_* > a_1 - \frac{a_1 b_2}{a_2} u_* - \frac{a_1 c_2}{a_2} v_* = \frac{a_1}{a_2}(a_2 - b_2 u_* - c_2 v_*). \tag{4.11}$$

Let $\xi_2(x)$ ($\|\xi_2\|_2 = 1$) be a positive eigenfunction of (2.9) with $k = k_2$, $h = a_2 - b_2 u_* - c_2 v_*$, and $\lambda = \lambda(k_2, a_2 - b_2 u_* - c_2 v_*)$. Then

$$k_2 \int_\Omega |\bigtriangledown \xi_2|^2 dx = \int_\Omega (a_2 - b_2 u_* - c_2 v_*)\xi_2^2 dx > 0. \tag{4.12}$$

By (4.11) and (4.12),

$$\begin{aligned} -k_1 \int_\Omega |\bigtriangledown \xi_2|^2 dx + \int_\Omega (a_1 - b_1 u_* - c_1 v_*)\xi_2^2 dx \\ > -k_2 \int_\Omega |\bigtriangledown \xi_2|^2 dx + \frac{a_1}{a_2} \int_\Omega (a_2 - b_2 - c_2 v_*)\xi_2^2 dx \ge 0. \end{aligned}$$

It then follows from the arguments of Lemma 2.3(5) that $\lambda(k_1, a_1 - b_1 u_* - c_1 v_*) > 0$, a contradiction. Therefore, (4.1) has no strictly positive equilibrium.

Now, by Lemma 4.6, every positive solution of (4.1) converges to $(u_{f_1}, 0)$.

(3) The proof can be derived by arguments similar to those in (2). □

5. Uniform persistence, coexistence, and extinction in almost periodic two species competition models. Let $a_{iL(M)}$, $b_{iL(M)}$, $c_{iL(M)}$ have the same meaning as in $(1.4)_1$–$(1.4)_3$, and let u_{g_1}, v_{g_2} be understood as in Lemma 4.3. Then we obtain for the Neumann case the following result.

THEOREM 5.1. *Consider* (4.1). *Suppose that* $Bu = \frac{\partial u}{\partial n}$ *and* a_{iL}, b_{iL}, *and* c_{iL} $(i = 1, 2)$ *are positive.*

(1) *If* $a_{1L} > \frac{c_{1M}a_{2M}}{c_{2L}}$ *and* $a_{2L} > \frac{a_{1M}b_{2M}}{b_{1L}}$, *then there exist* (u_-, v_-), $(u_+, v_+) \in \mathrm{Int}X_+ \times \mathrm{Int}X_+$ *with* $(u_-, v_-) \ll_2 (u_+, v_+)$ *such that, for each* $(u_0, v_0) \in (X_+ \setminus \{0\}) \times (X_+ \setminus \{0\})$ *and each* $(u, v, g_1, g_2) \in \omega(u_0, v_0, f_1, f_2)$,

$$(u_-, v_-) \leq_2 (u, v) \leq_2 (u_+, v_+)$$

(hence uniform persistence occurs). Moreover, there are (u_*^-, v_*^-), (u_*^+, v_*^+) *with*

$$(u_-, v_-) \leq_2 (u_*^-, v_*^-) \leq_2 (u_*^+, v_*^+) \leq_2 (u_+, v_+)$$

such that $\omega(u_*^-, v_*^-, f_1, f_2)$, $\omega(u_*^+, v_*^+, f_1, f_2)$ *are minimal and almost* 1*-covers of* $H(f_1, f_2)$ *(hence almost automorphic), and* $\mathcal{M}(\tilde{u}_*, \tilde{v}_*) \subset \mathcal{M}(a_1, b_1, c_1, a_2, b_2, c_2)$ *holds if* $(\bar{u}_*, \bar{v}_*, g_1, g_2) \in \omega(u_*^\pm, v_*^\pm, f_1, f_2)$ *is such that* $(\tilde{u}_*(t, x), \tilde{v}_*(t, x)) = (u(t, x; \bar{u}_*, \bar{v}_*, g_1, g_2), v(t, x; \bar{u}_*, \bar{v}_*, g_1, g_2))$ *is almost automorphic in* t. *In addition, if* a_i, b_i, c_i *are spatially homogeneous, then* $(u_*^-, v_*^-) = (u_*^+, v_*^+) = (u_*, v_*)$ *and* $(u(t; u_*, v_*, f_1, f_2), v(t; u_*, v_*, f_1, f_2))$ *is a globally stable positive almost periodic solution of* (4.1).

(2) *If* $a_{1L} > \frac{c_{1M}a_{2M}}{c_{2L}}$ *and* $a_{2M} \leq \frac{a_{1L}b_{2L}}{b_{1M}}$, *then every positive solution of* (4.1) *converges to* $(u_{f_1}(t, x), 0)$.

(3) *If* $a_{1M} \leq \frac{c_{1L}a_{2L}}{c_{2M}}$ *and* $a_{2L} > \frac{a_{1M}b_{2M}}{b_{1L}}$, *then every positive solution of* (4.1) *converges to* $(0, v_{f_2}(t, x))$.

(4) *If* $a_1 = a_2$, $b_1 = b_2 = c_1 = c_2$, *and additionally* $k_1 = k_2$ *in the case where* a_i, b_i, c_i *are not spatially homogeneous, then there exists a stable continuous family of positive almost periodic solutions connecting* $(u_{f_1}(t, x), 0)$ *and* $(0, v_{f_2}(t, x))$.

The following results hold for the Dirichlet case.

THEOREM 5.2. *Consider* (4.1). *Suppose that* $Bu = u$, a_{iL}, b_{iL}, c_{iL} *are positive constants, and* $\lambda(k_1, a_1) > 0$, $\lambda(k_2, a_2) > 0$.

(1) *If* $a_{1L} > \frac{c_{1M}a_{2M}}{c_{2L}}$, $a_{2L} > \frac{a_{1M}b_{2M}}{b_{1L}}$, $k_1 = k_2$, *and* $a_1 = a_2$ *(constant), then there are* (u_-, v_-), $(u_+, v_+) \in \mathrm{Int}X_+ \times \mathrm{Int}X_+$ *with* $(u_-, v_-) \ll_2 (u_+, v_+)$ *such that, for each* $(u_0, v_0) \in (X_+ \setminus \{0\}) \times X_+ \setminus \{0\}$ *and each* $(u, v, g_1, g_2) \in \omega(u_0, v_0, f_1, f_2)$,

$$(u_-, v_-) \leq_2 (u, v) \leq_2 (u_+, v_+)$$

(hence uniform persistence occurs). Moreover, there exist (u_*^-, v_*^-), (u_*^+, v_*^+) *with*

$$(u_-, v_-) \leq_2 (u_*^-, v_*^-) \leq_2 (u_*^+, v_*^+) \leq_2 (u_+, v_+)$$

such that $\omega(u_*^-, v_*^-, f_1, f_2)$, $\omega(u_*^+, v_*^+, f_1, f_2)$ *are minimal and almost* 1*-covers of* $H(f_1, f_2)$ *(hence almost automorphic), and* $\mathcal{M}(\tilde{u}_*, \tilde{v}_*) \subset \mathcal{M}(a_1, b_1, c_1, a_2, b_2, c_2)$ *if* $(\bar{u}_*, \bar{v}_*, g_1, g_2) \in \omega(u_*^\pm, v_*^\pm, f_1, f_2)$ *is such that* $(\tilde{u}_*(t, x), \tilde{v}_*(t, x)) = (u(t, x; \bar{u}_*, \bar{v}_*, g_1, g_2), v(t, x; \bar{u}_*, \bar{v}_*, g_1, g_2))$ *is almost automorphic in* t.

(2) *If* $a_{1L} > \frac{c_{1M}a_{2M}}{c_{2L}}$, $a_{2M} \leq \frac{b_{2L}a_{1L}}{b_{1M}}$, $k_2 \geq k_1$, *and* $a_{1L} \geq a_2$, *then every positive solution converges to* $(u_{f_1}(t, x), 0)$.

(3) *If* $a_{1M} \leq \frac{c_{1L}a_{2L}}{c_{2M}}$, $a_{2L} > \frac{a_{1M}b_{2M}}{b_{1L}}$, $k_1 \geq k_2$, *and* $a_{2L} \geq a_1$, *then every positive solution converges to* $(0, v_{f_2}(t, x))$.

(4) *If* $k_1 = k_2$, $a_1 = a_2$, *and* $b_1 = b_2 = c_1 = c_2$, *then there exists a stable continuous family of positive almost periodic solutions connecting* $(u_{f_1}(t, x), 0)$ *and* $(0, v_{f_2}(t, x))$.

Proof of Theorem 5.1. (1) First, by $a_{1L} > \frac{c_{1M}a_{2M}}{c_{2L}}$ and $a_{2L} > \frac{a_{1M}b_{2M}}{b_{1L}}$, we have

$$\frac{c_{1L}}{c_{2M}} \le \frac{c_{1M}}{c_{2L}} < \frac{a_{1L}}{a_{2M}} \le \frac{a_{1M}}{a_{2L}} < \frac{b_{1L}}{b_{2M}} \le \frac{b_{1M}}{b_{2L}}.$$

Hence, by Lemma 4.7, $(u^{\pm}(t;u_0,v_0), v^{\pm}(t;u_0,v_0))$ converges to a unique strictly positive equilibrium $(u_{\pm}, v_{\pm})$ of $(4.8)_{\pm}$ for each $(u_0,v_0) \in (X_+ \setminus \{0\}) \times (X_+ \setminus \{0\})$.

Next, Lemma 4.5 shows

$$(u^-(t,\cdot;u_0,v_0), v^-(t,\cdot;u_0,v_0)) \le_2 (u(t,\cdot;u_0,v_0,f_1,f_2), v(t,\cdot;u_0,v_0,f_1,f_2))$$

and

$$(u(t,\cdot;u_0,v_0,f_1,f_2), v(t,\cdot;u_0,v_0,f_1,f_2)) \le_2 (u^+(t,\cdot;u_0,v_0), v^+(t,\cdot;u_0,v_0))$$

for $t \ge 0$ and all $(u_0,v_0) \in (X_+ \setminus \{0\}) \times (X_+ \setminus \{0\})$, hence

$$(u_-, v_-) \le_2 (u,v) \le_2 (u_+, v_+)$$

for $(u,v,g_1,g_2) \in \omega(u_0,v_0,f_1,f_2)$.

Now we have $(u_-,v_-) \le_2 (u,v)$ for every $(u,v,g_1,g_2) \in \omega(u_-,v_-,f_1,f_2)$. By Lemma 2.2(3), $\omega(u_-,v_-,\ f_1,f_2)$ is an almost 1-cover of $H(f_1,f_2)$. Similarly, we obtain that $\omega(u_+,v_+,f_1,f_2)$ is an almost 1-cover of $H(f_1,f_2)$. Therefore, there are $(u_*^{\pm},,v_*^{\pm},f_1,f_2) \in \omega(u_{\pm},v_{\pm},f_1,f_2)$ such that

$$(u_-,v_-) \le_2 (u_*^-,v_*^-) \le_2 (u_*^+,v_*^+) \le_2 (u_+,v_+)$$

and $\omega(u_*^{\pm},v_*^{\pm},f_1,f_2)$ are minimal and almost 1-covers of $H(f_1,f_2)$.

Note that if $(\bar u_*,\bar v_*,g_1,g_2) \in \omega(u_*^{\pm},v_*^{\pm},f_1,f_2)$ is such that

$$\{(\bar u_*,\bar v_*,g_1,g_2)\} = \omega(u_*^{\pm},v_*^{\pm},f_1,f_2) \cap (X_+ \times X_+ \times \{(g_1,g_2)\}), \tag{5.1}$$

then, by the definition of almost automorphic functions (see section 2.1),

$$(\tilde u_*(t,x), \tilde v_*(t,x)) = (u(t,x;\bar u_*,\bar v_*,g_1,g_2), v(t,x;\bar u_*,\bar v_*,g_1,g_2)) \tag{5.2}$$

is uniformly almost automorphic in t (hence $\omega(u_*^{\pm},v_*^{\pm},f_1,f_2)$ is almost automorphic). Moreover, by Lemma 2.1, $\mathcal{M}(\tilde u_*,\tilde v_*) \subset \mathcal{M}(a_1,b_1,c_1,a_2,b_2,c_2)$. Conversely, if $(\bar u_*,\bar v_*,g_1,g_2) \in \omega(u_*^{\pm},v_*^{\pm},f_1,f_2)$ is such that $(\tilde u_*(t,x),\ \tilde v_*(t,x))$ in (5.2) is uniformly almost automorphic in t, then (5.1) must hold, and hence one has $\mathcal{M}(\tilde u_*,\tilde v_*) \subset \mathcal{M}(a_1,b_1,c_1,a_2,b_2,c_2)$. Otherwise, there is $(\bar u_*^1,\bar v_*^1,g_1,g_2) \in \omega(u_*^{\pm},v_*^{\pm},f_1,f_2)$ with $(\bar u_*^1,\bar v_*^1) \ne (\bar u_*,\bar v_*)$. Let $(g_1^0,g_2^0) \in H(f_1,f_2)$ be such that

$$\omega(u_*^{\pm},v_*^{\pm},f_1,f_2) \cap (X_+ \times X_+ \times \{(g_1^0,g_2^0)\}) = \{(\bar u_*^0,\bar v_*^0,g_1^0,g_2^0)\}$$

is a singleton. Let $\beta_n \to \infty$ be such that

$$\Pi_{\beta_n}(\bar u_*^0,\bar v_*^0,g_1^0,g_2^0) \to (\bar u_*^1,\bar v_*^1,g_1,g_2)$$

and $\alpha_n = -\beta_n$. Then, given any subsequence $\{\alpha_{n_k}\} \subset \{\alpha_n\}$,

$$\lim_{m\to\infty}\lim_{k\to\infty} \Pi_{-\alpha_{n_m}}\Pi_{\alpha_{n_k}}(\bar u_*,\bar v_*,g_1,g_2) = (\bar u_*^1,\bar v_*^1,g_1,g_2) \ne (\bar u_*,\bar v_*,g_1,g_2),$$

which contradicts the almost automorphy of $(\tilde u^*(t,x),\tilde v^*(t,x))$ (see section 2.1).

Finally, if a_i, b_i and c_i $(i = 1, 2)$ are spatially homogeneous, by [22], $(u_*^-, v_*^-) = (u_*^+, v_*^+) = (u_*, v_*)$ and $(u(t; u_*, v_*, f_1, f_2), v(t; u_*, v_*, f_1, f_2))$ is a globally stable positive almost periodic solution of (4.1).

(2) First, $a_{1L} > \frac{c_{1M}a_{2M}}{c_{2L}}$ and $a_{2M} \le \frac{a_{1L}b_{2L}}{b_{1M}}$ imply

$$\frac{c_{1M}}{c_{2L}} < \frac{a_{1L}}{a_{2M}} \quad \text{and} \quad \frac{a_{1L}}{a_{2M}} \ge \frac{b_{1M}}{b_{2L}}.$$

Therefore, by Lemma 4.7, every positive solution of $(4.8)_-$ converges to $(u_-^*, 0) \equiv (\frac{a_{1L}}{b_{1M}}, 0)$.

Next, let $(u_0, v_0) \in (X_+ \setminus \{0\}) \times (X_+ \setminus \{0\})$. Lemma 4.5 yields

$$(u_-^*, 0) \le_2 (u, v) \le_2 (u_{g_1}, 0)$$

for every $(u, v, g_1, g_2) \in \omega(u_0, v_0, f_1, f_2)$. Assume that $(u_0, v_0) \le_2 (u_-^*, 0)$. Then, by Lemma 2.2(3), $\omega(u_0, v_0, f_1, f_2)$ is an almost 1-cover of $H(f_1, f_2)$. By the arguments of Lemma 3.7, $\omega(u_0, v_0, f_1, f_2)$ is a 1-cover of $H(f_1, f_2)$ and hence is minimal. By Lemma 4.3, we must have $\omega(u_0, v_0, f_1, f_2) = E_1$, and hence $(u(t, x; u_0, v_0, f_1, f_2), v(t, x; u_0, v_0, f_1, f_2))$ converges to $(u_{f_1}(t, x), 0)$.

Finally, for any $(u_0, v_0) \in \mathrm{Int}X_+ \times \mathrm{Int}X_+$, there is $(\tilde{u}_0, \tilde{v}_0) \in \mathrm{Int}X_+ \times \mathrm{Int}X_+$ such that $(\tilde{u}_0, \tilde{v}_0) \ll_2 (u_0, v_0)$ and $(\tilde{u}_0, \tilde{v}_0) \le_2 (u_-^*, 0)$. By the above arguments, $\omega(\tilde{u}_0, \tilde{v}_0, f_1, f_2) = E_1$, and we must have $\omega(u_0, v_0, f_1, f_2) = E_1$, and hence every positive solution of (4.1) converges to $(u_{f_1}(t, x), 0)$.

(3) The proof can be derived by similar arguments as in (2).

(4) If a_i, b_i, c_i are spatially homogeneous, the proof follows from [22]. Otherwise, note that $w = u + v$ satisfies

$$\begin{cases} w_t = k\Delta w + w(a - bw), & x \in \Omega, \\ \dfrac{\partial w}{\partial n} = 0, & x \in \partial\Omega, \end{cases}$$

where $k = k_1 = k_2$, $a = a_1 = a_2$, $b = b_1 = b_2 = c_1 = c_2$. (4) then follows from Theorem 3.3. □

Proof of Theorem 5.2. (1) Since $a_1 = a_2$ are constant, $\lambda(k_i, a_{iL(M)}) > 0$ for $i = 1, 2$. Then, by Lemma 4.8, $(u^{\pm}(t, x; u_0, v_0), v^{\pm}(t, x; u_0, v_0))$ converges to a unique strictly positive equilibrium $(u_{\pm}, v_{\pm})$ of $(4.8)_{\pm}$ for every $(u_0, v_0) \in (X_+ \setminus \{0\}) \times (X_+ \setminus \{0\})$. The rest of the proof now follows by employing the same arguments as in the proof of Theorem 5.1(1).

(2) By $k_2 \ge k_1$, $a_{1L} \ge a_2$ and Lemma 2.3, we have $\lambda(k_1, a_{1L}) \ge \lambda(k_2, a_{1L}) \ge \lambda(k_2, a_2) > 0$ and $\lambda(k_2, a_{2M}) \ge \lambda(k_2, a_2) > 0$. By Lemma 4.8, for each $(u_0, v_0) \in (X_+ \setminus \{0\}) \times (X_+ \setminus \{0\})$, $(u^-(t, x; u_0, v_0), v^-(t, x; u_0, v_0))$ converges to $(u_-^*, 0)$, where u_-^* is the unique positive equilibrium of (3.1) with $k = k_1$, $a = a_{1L}$, $b = b_{1M}$, and $Bu = u$. The rest of the proof then follows from the same arguments as in Theorem 5.1(2).

(3) The proof can be derived by similar arguments as in the proof of (2).

(4) The proof can be derived by similar arguments as in the proof of Theorem 5.1(4). □

6. Single species population and two species competition models with recurrent time dependence. In this section, we state results similar to those of Theorems 3.3, 5.1, and 5.2 for more general time dependent single species population and two species competition models. They can be derived by the approach we have

developed in the previous sections. We deal with the case where the reaction terms in (1.1) and (1.3) exhibit merely recurrent time dependence.

Throughout this section, we assume that a_i, b_i, c_i $(i = 1, 2)$ in (1.1) and a, b in (1.3) are recurrent in t, $b(t, x) \geq \delta$ for some $\delta > 0$. Let $a_{iL(M)}$, $b_{iL(M)}$, and $c_{iL(M)}$ be as in $(1.4)_1$–$(1.4)_3$.

First, by arguments similar to those in the proofs of Theorem 3.3 and Corollary 3.4, one obtains the following result.

THEOREM 6.1. *Consider* (1.3). *One and only one of the following alternatives occurs.*

(1) *Every positive solution converges to a unique strictly positive recurrent solution* $u^*(t, x)$ *whose hull is a* 1*-cover of the hull of* (a, b).

(2) *Every positive solution converges to the trivial solution* $u = 0$.

(3) *Every positive solution is neither bounded away from the trivial solution nor converges to it.*

Next, consider (1.1) with $Bu = \frac{\partial u}{\partial n}$. If $a_{1L} > 0$ and $a_{2L} > 0$, then by Theorem 6.1 and the comparison principle for parabolic equations, (1.3) with $a = a_1$ and $b = b_1$ ($a = a_2$ and $b = c_2$) has a unique strictly positive recurrent solution $u^*_N(t, x)$ ($v^*_N(t, x)$). Following arguments similar to those in proving Theorem 5.1, we have the following result.

THEOREM 6.2. *Consider* (1.1). *Assume that* $Bu = \frac{\partial u}{\partial n}$ *and* a_{iL}, b_{iL}, $c_{iL} > 0$ $(i = 1, 2)$.

(1) *If* $a_{1L} > \frac{c_{1M}a_{2M}}{c_{2L}}$ *and* $a_{2L} > \frac{a_{1M}b_{2M}}{b_{1L}}$, *then uniform persistence occurs. Moreover, there is a strictly positive recurrent solution* $(u_*(t, x), v_*(t, x))$ *whose hull is an almost* 1*-cover of the hull of* $(a_1, b_1, c_1, a_2, b_2, c_2)$.

(2) *If* $a_{1L} > \frac{c_{1M}a_{2M}}{c_{2L}}$ *and* $a_{2M} \leq \frac{a_{1L}b_{2L}}{b_{1M}}$, *then every positive solution converges to* $(u^*_N(t, x), 0)$.

(3) *If* $a_{1M} \leq \frac{c_{1L}a_{2L}}{c_{2M}}$ *and* $a_{2L} > \frac{a_{1M}b_{2M}}{b_{1L}}$, *then every positive solution converges to* $(0, v^*_N(t, x))$.

Finally, consider (1.1) with $Bu = u$. Assume that $\lambda(k_1, H(a_1)) > 0$ and $\lambda(k_1, H(a_2)) > 0$. If $k_2 \geq k_1$ and $a_{1L} \geq a_2$ ($k_1 \geq k_2$ and $a_{2L} \geq a_1$), then $\lambda(k_1, a_{1L}) \geq \lambda(k_2, a_{1L}) \geq \lambda(k_2, H(a_2)) > 0$ ($\lambda(k_2, a_{2L}) \geq \lambda(k_1, a_{2L}) \geq \lambda(k_1, H(a_1)) > 0$). Again, by Theorem 6.1 and the comparison principle for parabolic equations, (1.3) with $a = a_1$ and $b = b_1$ ($a = a_2$ and $b = c_2$) has a unique strictly positive recurrent solution $u^*_D(t, x)$ ($v^*_D(t, x)$). Arguments similar to those in proving Theorem 5.2 yield the following result.

THEOREM 6.3. *Consider* (1.1) *with* a_i, b_i, c_i $(i = 1, 2)$ *being recurrent. Assume that* $Bu = u$, a_{iL}, b_{iL}, $c_{iL} > 0$ $(i = 1, 2)$, *and* $\lambda(k_1, H(a_1)) > 0$, $\lambda(k_2, H(a_2)) > 0$.

(1) *If* $a_{1L} > \frac{c_{1M}a_{2M}}{c_{2L}}$, $a_{2L} > \frac{a_{1M}b_{2M}}{b_{1L}}$, $k_1 = k_1$, *and* $a_1 = a_2$ *(constant), then uniform persistence occurs. Moreover, there is a strictly positive recurrent solution* $(u_*(t, x), v_*(t, x))$ *whose hull is an almost* 1*-cover of the hull of* $(a_1, b_1, c_1, a_2, b_2, c_2)$.

(2) *If* $a_{1L} > \frac{c_{1M}a_{2M}}{c_{2L}}$, $a_{2M} \leq \frac{a_{1L}b_{2L}}{b_{1M}}$, $k_2 \geq k_1$, *and* $a_{1L} \geq a_2$, *then every positive solution converges to* $(u^*_D(t, x), 0)$.

(3) *If* $a_{1M} \leq \frac{c_{1L}a_{2L}}{c_{2M}}$, $a_{2L} > \frac{a_{1M}b_{2M}}{b_{1L}}$, $k_1 \geq k_2$, *and* $a_{2L} \geq a_1$, *then every positive solution converges to* $(0, v^*_D(t, x))$.

TRIPLE VARIATIONAL PRINCIPLES FOR EIGENVALUES OF SELF-ADJOINT OPERATORS AND OPERATOR FUNCTIONS*

DAVID ESCHWÉ† AND HEINZ LANGER†

Abstract. We derive triple variational principles for the eigenvalues of a self-adjoint operator pencil, which also allow a characterization of discrete eigenvalues within a gap of the essential spectrum. In the general case, we can prove only an inequality; the equality sign is shown to hold in four particular situations.

Key words. eigenvalue, variational principle, operator pencil

1. Introduction. It is well known that the discrete eigenvalues of a self-adjoint operator A on some Hilbert space $\mathcal{H}$, which lie below or above the essential spectrum of A, can be characterized by double variational principles applied to the Rayleigh quotients $\frac{(Ax,x)}{(x,x)}$, $x \in \mathcal{H}$, $x \neq 0$. For example, if the eigenvalues below the minimum of the essential spectrum of A are denoted by

$$\lambda_1 \leq \lambda_2 \leq \cdots, \tag{1.1}$$

counted according to their multiplicities, then

$$\lambda_j = \sup_{\substack{\mathcal{V}\subset\mathcal{H}\\ \dim\mathcal{V}=j-1}} \inf_{\substack{x\neq 0\\ x\perp\mathcal{V}}} \frac{(Ax,x)}{(x,x)}, \qquad j = 1,2,\ldots.$$

These formulas have been generalized for sufficiently smooth self-adjoint operator functions L, defined on some interval Δ of the real axis, under the assumption that for some $\alpha \in \Delta$ the operator $L(\alpha)$ is uniformly positive or uniformly negative (see, e.g., [M], [BEL]): in this case the discrete eigenvalues, numbered according to their multiplicity and their distance from α, can be characterized by such double variational principles applied to the zeros of the scalar functions $(L(\,\cdot\,)x,x)$, $x \in \mathcal{H}$, $x \neq 0$. They have been generalized further to the case where $L(\alpha)$ is not definite but has a finite number of positive or of negative eigenvalues (see [BEL]). In the latter case, in the formulas an index shift, corresponding to the number of these eigenvalues, appears.

On the other hand, already in 1970 Phillips [P] and, subsequently, Textorius [T] proved a *triple* variational principle for eigenvalues of positive compact operators on Krein spaces. For example, given a positive self-adjoint operator A on a Krein space $(\mathcal{K},[\,\cdot\,,\,\cdot\,])$ such that below the essential spectrum of A there are isolated eigenvalues as in (1.1), then

$$\lambda_j = \sup_{\mathcal{M}\in\mathbf{M}^{--}} \sup_{\substack{\mathcal{V}\subset\mathcal{M}\\ \dim\mathcal{V}=j-1}} \inf_{\substack{x\neq 0\\ x\perp\mathcal{V}}} \frac{[Ax,x]}{[x,x]}, \qquad j = 1,2,\ldots;$$

here $\mathbf{M}^{--}$ denotes the set of all maximal negative subspaces of $\mathcal{K}$. This result can be understood as corresponding to a situation where the function L is linear in the parameter λ and for a certain α the operator $L(\alpha)$ has infinitely many positive and infinitely many negative spectral points. On the other hand, it is not hard to see that the above mentioned double variational principles with index shift can also be replaced by triple variational principles.

In the present paper we show that such triple variational principles do also hold in other situations for discrete eigenvalues which lie in a gap of the essential spectrum. In section 2 we prove a general triple variational inequality for discrete eigenvalues of a continuous self-adjoint operator function L which satisfies Assumptions 1–3 (listed in section 2 below). These discrete eigenvalues are numbered starting from a certain point $\alpha \in \rho(L)$, and in the variational principle the maximal $L(\alpha)$-nonnegative subspaces play an important role. We do not know if in the general situation of section 2 such a maximal $L(\alpha)$-nonnegative subspace exists for which the inequalities become equalities. This we can show only in particular situations in section 3. Namely, we can show it for the discrete eigenvalues in a gap of the essential spectrum of a self-adjoint operator, for a nonnegative operator in a Krein space (this situation corresponds to the results of Phillips and Textorius mentioned above), for a special class of quadratic operator pencils, and for a self-adjoint block operator matrix

$$\widetilde{A} = \begin{pmatrix} A & B \\ B^* & D \end{pmatrix}.$$

In the latter case, double variational principles for eigenvalues in a certain gap of the essential spectrum of $\widetilde{A}$ were proved by Griesemer and Siedentop [GS] if the numerical ranges of A and D overlap in at most one point. Here we show that triple variational principles also allow us to characterize certain discrete eigenvalues of $\widetilde{A}$ if the numerical ranges of A and D overlap in an interval.

In this paper we restrict ourselves to bounded operators. In a subsequent publication pencils of unbounded self-adjoint operators will be considered. They include Hain–Lüst-type equations for partial or ordinary differential operators; e.g.,

$$-y'' + \lambda y - \frac{qy}{u - \lambda} = 0 \quad \text{on} \quad [0,1], \qquad y(0) = y(1) = 0,$$

with real continuous functions q, u (see [ALM]). Here the essential spectrum consists of the range of the function u, and the eigenvalues $\lambda_1 \le \lambda_2 \le \cdots$ to the right of this essential spectrum should be characterized by triple variational principles from the left. They also include quadratic pencils arising in the consideration of beams with inner and outer damping (so-called Vogt material), e.g., from the equation

$$\alpha \frac{\partial^5 u}{\partial t \partial x^4} + \frac{\partial^4 u}{\partial x^4} + \frac{\partial}{\partial x} g(x) \frac{\partial u}{\partial x} + k(x) \frac{\partial u}{\partial t} + \frac{\partial^2 u}{\partial t^2} = 0$$

with appropriate boundary and initial conditions (see [Pi2]). Finally, these principles can also be applied to the problem considered in [LM].

2. A general inequality. Let $\mathcal{H}$ be a Hilbert space. We make the following assumptions.

Assumption 1. The operator function L is defined and continuous in the operator norm on the interval $[\alpha, \beta)$, and its values are self-adjoint operators on $\mathcal{H}$ and $0 \in \rho(L(\alpha))$.

It follows that for some $\alpha' > \alpha$ the interval $[\alpha, \alpha')$ belongs to $\rho(L)$. We allow $\beta = \infty$. The point $\lambda \in \mathcal{C}$ is an *eigenvalue* of the operator function L if 0 is an eigenvalue of $L(\lambda)$, and a *normal eigenvalue* of L if 0 is a normal eigenvalue of $L(\lambda)$; recall (see [GK]) that the latter means that the algebraic eigenspace $\mathcal{L}$ of $L(\lambda)$ at 0 is finite-dimensional and that the space $\mathcal{H}$ is the direct sum of $\mathcal{L}$ and an invariant subspace $\mathcal{N}$ of $L(\lambda)$ such that $0 \in \rho(L(\lambda)|\mathcal{N})$. Further, the point $\lambda \in \mathcal{C}$ belongs to the *essential spectrum* $\sigma_{ess}(L)$ of the operator function L if $0 \in \sigma_{ess}(L(\lambda))$. If the essential spectrum $\sigma_{ess}(L)$ in $[\alpha, \beta)$ is not empty we set $\lambda_e := \min \sigma_{ess}(L) \cap [\alpha, \beta)$; otherwise, if there is no essential spectrum of L in $[\alpha, \beta)$, then $\lambda_e := \beta$. By definition of the essential spectrum of an operator function and Assumption 1, in the interval (α, λ_e) the spectrum of L is discrete; that is, it consists of normal eigenvalues of $L(\lambda)$, and λ_e is their only possible accumulation point.

If we equip the space $\mathcal{H}$ with the inner product $[\,\cdot\,,\,\cdot\,]_\alpha := (L(\alpha)\cdot\,,\,\cdot\,)$, by Assumption 1 it becomes a Krein space (see [B], [AI]) which we denote by $\mathcal{K}_\alpha$. A natural canonical decomposition of this Krein space is given by $\mathcal{K}_\alpha = \mathcal{H}_+ \oplus \mathcal{H}_-$, where $\mathcal{H}_+$ is the spectral invariant subspace of $L(\alpha)$ corresponding to $(0, +\infty)$ and $\mathcal{H}_-$ is the spectral invariant subspace of $L(\alpha)$ corresponding to $(-\infty, 0)$. In this section, the set of all maximal nonnegative subspaces of this Krein space $\mathcal{K}_\alpha$, which are also called *maximal $L(\alpha)$-nonnegative subspaces* of $\mathcal{H}$, is denoted by $\mathbf{M}_\alpha^+$.

A function φ, considered on a real interval, is said to be *decreasing at value zero* if $\varphi(\lambda_0) = 0$ implies that $\varphi(\lambda) > 0$ if $\lambda < \lambda_0$ and $\varphi(\lambda) < 0$ if $\lambda > \lambda_0$.

Assumption 2. For each $x \in \mathcal{H}$, $x \neq 0$, the function $\varphi_x : \varphi_x(\lambda) := (L(\lambda)x, x)$, $\lambda \in [\alpha, \beta)$, is decreasing at value zero.

It follows that each function φ_x, $x \neq 0$, has at most one zero in the interval $[\alpha, \beta)$; this zero is denoted by $p(x)$. If $\varphi_x(\alpha) > 0$ and the function φ_x does not have a zero in $[\alpha, \beta)$ we put $p(x) = +\infty$. Evidently, if $x \in \mathcal{H}$, $x \neq 0$, and $\gamma \neq 0$ is a complex number, then $p(\gamma x) = p(x)$. Also, the convention $\min \emptyset = +\infty$ is used.

Sometimes we need the following assumption.

Assumption 3. If $\lambda_0 \in (\alpha, \beta)$ is fixed, for each $\varepsilon > 0$ such that $(\lambda_0 - \varepsilon, \lambda_0 + \varepsilon) \subset (\alpha, \beta)$ there exists a $\delta(\varepsilon) > 0$ such that $\|x\| = 1$, $|\varphi_x(\lambda_0)| \leq \delta(\varepsilon)$ implies that φ_x has a zero in the interval $(\lambda_0 - \varepsilon, \lambda_0 + \varepsilon)$.

For any subspace $\mathcal{M}$ of $\mathcal{H}$, by $\mathcal{M}^1$ we denote the unit sphere of $\mathcal{M}$ that is the set of all elements $x \in \mathcal{M}$ with $\|x\| = 1$.

THEOREM 2.1. *Under Assumptions* 1–3, *for each subspace* $\mathcal{M} \in \mathbf{M}_\alpha^+$ *we have*

$$\inf_{x \in \mathcal{M}^1} p(x) \leq \min \sigma(L) \cap [\alpha, \beta).$$

Proof. Denote $a := \min \sigma(L) \cap [\alpha, \beta)$ and assume to the contrary that

$$\inf_{x \in \mathcal{M}^1} p(x) > a. \tag{2.1}$$

First we suppose that a is an eigenvalue of L: $L(a)x_0 = 0$, $\|x_0\| = 1$. Then $p(x_0) = a$ and, by (2.1), $x_0 \notin \mathcal{M}$. We consider $\mathcal{M}' := \operatorname{span}\{\mathcal{M}, x_0\}$. Since $L(a)$ is self-adjoint and $L(a)x_0 = 0$, for an arbitrary element $x \in \mathcal{M}$ we obtain

$$\begin{aligned}(L(a)(x + x_0), x + x_0) &= (L(a)x, x) + (L(a)x_0, x) + (L(a)x, x_0) + (L(a)x_0, x_0)\\ &= (L(a)x, x) \geq 0.\end{aligned}$$

It follows that $(L(\alpha)(x + x_0), x + x_0) \geq 0$, hence $\mathcal{M}'$ is an $L(\alpha)$-nonnegative subspace, a contradiction to the fact that $\mathcal{M}$ is a maximal $L(\alpha)$-nonnegative subspace.

In the general case, for the point a there exists a sequence (y_n) in $\mathcal{H}$, $\|y_n\| = 1$, such that $\|L(a)y_n\| \to 0$ if $n \to \infty$. According to Assumption 3 and (2.1) there exists a $c > 0$ such that $\varphi_x(a) \geq c\|x\|^2$ for all $x \in \mathcal{M}$. Indeed, otherwise in $\mathcal{M}$ there would exist a sequence of elements x_n, $\|x_n\| = 1$, such that $\varphi_{x_n}(a) \downarrow 0$, and Assumption 3 would imply that $p(x_n) \to a$, which is impossible because of (2.1). Now we obtain for $x \in \mathcal{M}$

$$\begin{aligned}(L(a)(x+y_n), x+y_n) &= (L(a)x, x) + (L(a)x, y_n) + (L(a)y_n, x) + (L(a)y_n, y_n)\\ &\geq c\|x\|^2 - 2\|x\|\,\|L(a)y_n\| + (L(a)y_n, y_n)\\ &\geq \left(\sqrt{c}\|x\| - \frac{\|L(a)y_n\|}{\sqrt{c}}\right)^2 - \frac{\|L(a)y_n\|^2}{c} - \|L(a)y_n\|\\ &\geq -\left(\frac{\|L(a)y_n\|^2}{c} + \|L(a)y_n\|\right).\end{aligned}$$

If we choose $\varepsilon > 0$ such that $(a-\varepsilon, a+\varepsilon) \subset [\alpha, \beta)$, $\delta(\varepsilon)$ according to Assumption 3, and, finally, n such that $\frac{\|L(a)y_n\|^2}{c} + \|L(a)y_n\| < \delta(\varepsilon)$, then $\varphi_{x+y_n}(a-\varepsilon) > 0$, which is again a contradiction to the fact that $\mathcal{M}$ is a maximal $L(\alpha)$-nonnegative subspace. ∎

Remark 2.2. The proof of Theorem 2.1 shows that Assumption 3 is needed only if $\sigma(L) \cap (\alpha, \lambda_e) = \emptyset$.

Let $\mathcal{K}$ be a Krein space, and let $\mathcal{K} = \mathcal{H}_+ \oplus \mathcal{H}_-$ be a canonical decomposition of $\mathcal{K}$. We denote the corresponding orthogonal projections onto $\mathcal{H}_\pm$ by $P_\pm$. Each nonnegative subspace $\mathcal{L}$ of $\mathcal{K}$, if it is not maximal nonnegative, is contained in infinitely many maximal nonnegative subspaces. If $\mathcal{M}$ denotes one of these, the dimension of the factor space $\mathcal{M}/\mathcal{L}$ is independent of the choice of the maximal nonnegative subspace $\mathcal{M}$, and it coincides with the dimension of the space $\mathcal{H}_+ \ominus P_+\mathcal{L}$. Moreover, the space $\mathcal{M}_\mathcal{L} := \mathcal{L} \oplus (\mathcal{H}_+ \ominus P_+\mathcal{L})$ is a maximal nonnegative subspace containing $\mathcal{L}$, and $\mathcal{L}$ is the orthogonal complement in $\mathcal{M}_\mathcal{L}$ of the subspace

$$\mathcal{V}_\mathcal{L} := \mathcal{H}_+ \ominus P_+\mathcal{L}. \tag{2.2}$$

The space $\mathcal{M}_\mathcal{L}$ will be called the *standard maximal nonnegative extension* of $\mathcal{L}$.

We also need the following lemma; cf. [M].

LEMMA 2.3. *Suppose that the operator function L, defined on the interval $[\alpha, \beta)$, satisfies Assumptions* 1 *and* 2. *If $\lambda_1 \leq \lambda_2 \leq \cdots \leq \lambda_n$ are eigenvalues of L with corresponding eigenvectors $y_1, y_2, \ldots, y_n$ and $\mathcal{L}$ is a subspace of $\mathcal{H}$ such that $p(x) \geq \lambda_n$ for all $x \in \mathcal{L}$, then $(L(\lambda_1)x, x) \geq 0$ for all $x \in \operatorname{span}\{\mathcal{L}, y_1, y_2, \ldots, y_n\}$.*

Proof. If $y \in \mathcal{L}$, then $(L(\lambda_n)(y+y_n), y+y_n) = (L(\lambda_n)y, y) \geq 0$, and hence also $(L(\lambda_{n-1})(y+y_n), y+y_n) \geq 0$. If $n \geq 2$ the same reasoning yields

$$(L(\lambda_{n-1})(y+y_n+y_{n-1}), y+y_n+y_{n-1}) \geq 0,$$

and repeating this we finally get $(L(\lambda_1)x, x) \geq 0$ for $x \in \operatorname{span}\{\mathcal{L}, y_1, y_2, \ldots, y_n\}$, which implies $(L(\alpha)x, x) \geq 0$ for the same x. ∎

THEOREM 2.4. *Suppose that the operator function L, defined on the interval $[\alpha, \beta)$, satisfies Assumptions* 1 *and* 2. *If L has at least n eigenvalues in (α, λ_e) and we denote the n smallest ones by*

$$\lambda_1 = \cdots = \lambda_{n_1} < \lambda_{n_1+1} = \cdots = \lambda_{n_2} < \cdots < \lambda_{n_k+1} = \cdots = \lambda_{n_{k+1}} < \cdots \leq \lambda_n, \tag{2.3}$$

counted according to their multiplicities, then

$$\sup_{\mathcal{M}\in\mathbf{M}_\alpha^+} \sup_{\substack{\mathcal{V}\subset\mathcal{M}\\ \dim\mathcal{V}=j-1}} \inf_{\substack{x\in\mathcal{M}^1\\ x\perp\mathcal{V}}} p(x) \leq \lambda_j, \qquad j = 1, 2, \ldots, n. \tag{2.4}$$

If the total number of eigenvalues of L in (α, λ_e) is finite, say n, and Assumption 3 is satisfied, then the inequality in (2.4) holds also for $j = n+1, n+2, \dots$ if we define $\lambda_{n+1} = \lambda_{n+2} = \cdots = \lambda_e$.

Proof. Let $y_1, y_2, \dots, y_n$ be a system of linearly independent eigenvectors of L corresponding to the eigenvalues in (2.3). We denote the number on the left-hand side of (2.4) by μ_j. Since the sequence of these numbers is nondecreasing, the relation (2.4) will be proved if we show that $\mu_{n_k} \le \lambda_{n_k}$ for $k = 1, 2, \dots$. We prove this by induction with respect to k.

So for $k = 1$ assume that

$$\lambda_1 = \lambda_{n_1} < \inf_{\substack{x \in \mathcal{M}_0^1 \\ x \perp \mathcal{V}_0}} p(x)$$

for some maximal $L(\alpha)$-nonnegative subspace $\mathcal{M}_0$ and some $(n_1 - 1)$-dimensional subspace $\mathcal{V}_0 \subset \mathcal{M}_0$. Then $(L(\lambda_1)x, x) > 0$ for all $x \in \mathcal{V}_0^\perp \cap \mathcal{M}_0$, $x \neq 0$. If y is any nonzero element of the linear span of $y_1, y_2, \dots, y_{n_1}$, it follows that $y \notin \mathcal{V}_0^\perp \cap \mathcal{M}_0$, and hence $\mathcal{V}_0^\perp \cap \mathcal{M}_0$ and the elements $y_1, y_2, \dots, y_{n_1}$ are linearly independent. Further, we obtain for $x \in \mathcal{V}_0^\perp \cap \mathcal{M}_0$ from Lemma 2.3

$$(L(\lambda_1)(x+y), x+y) = (L(\lambda_1)x, x) \ge 0.$$

Because of Assumption 2,

$$(L(\alpha)u, u) \ge 0 \quad \text{for all} \quad u \in \operatorname{span}\{\mathcal{V}_0^\perp \cap \mathcal{M}_0, \mathrm{y}_1, \mathrm{y}_2, \dots, \mathrm{y}_{\mathrm{n}_1}\},$$

or, in words, this subspace is $L(\alpha)$-nonnegative. However, this is impossible since the defect of $\mathcal{V}_0^\perp \cap \mathcal{M}_0$ with respect to $\mathcal{M}_0$ and hence with respect to any maximal $L(\alpha)$-nonnegative subspace is $n_1 - 1$.

The proof of the step from k to $k+1$ is similar. Suppose that

$$\mu_{n_k} \le \lambda_{n_k}, \tag{2.5}$$

but $\mu_{n_{k+1}} > \lambda_{n_{k+1}}$. Then there exists a maximal $L(\alpha)$-nonnegative subspace $\mathcal{M}_0$ and an $(n_{k+1} - 1)$-dimensional subspace $\mathcal{V}_0$ of $\mathcal{M}_0$ such that

$$\inf_{\substack{x \in \mathcal{M}_0^1 \\ x \perp \mathcal{V}_0}} p(x) > \lambda_{n_{k+1}}.$$

Since $\big(L(\lambda_{n_{k+1}})y, y\big) = 0$ for all y in the linear span of $y_{n_k+1}, y_{n_k+2}, \dots, y_{n_{k+1}}$, these elements are linearly independent of $\mathcal{V}_0^\perp \cap \mathcal{M}_0$. Consider

$$\mathcal{L} := \operatorname{span}\{\mathcal{V}_0^\perp \cap \mathcal{M}_0, y_{n_k+1}, y_{n_k+2}, \dots, y_{n_{k+1}}\}.$$

By the same argument as above, this is an $L(\alpha)$-nonnegative subspace, and its defect to a maximal $L(\alpha)$-nonnegative subspace is $\dim \mathcal{V}_0 - (n_{k+1} - n_k) = n_k - 1$. With the standard maximal $L(\alpha)$-nonnegative extension $\mathcal{M}_\mathcal{L}$ and the corresponding subspace $\mathcal{V}_\mathcal{L}$ from (2.2) it follows that

$$\begin{aligned}\lambda_{n_{k+1}} = \inf_{x \in \mathcal{L}} p(x) = \inf_{\substack{x \in \mathcal{M}_\mathcal{L}^1 \\ x \perp \mathcal{V}_\mathcal{L}}} p(x) &\le \sup_{\substack{\mathcal{V} \subset \mathcal{M}_\mathcal{L} \\ \dim \mathcal{V} = n_k - 1}} \inf_{\substack{x \in \mathcal{M}_\mathcal{L}^1 \\ x \perp \mathcal{V}}} p(x) \\ &\le \sup_{\mathcal{M} \in \mathbf{M}_\alpha^+} \sup_{\substack{\mathcal{V} \subset \mathcal{M} \\ \dim \mathcal{V} = n_k - 1}} \inf_{\substack{x \in \mathcal{M}^1 \\ x \perp \mathcal{V}}} p(x) = \mu_{n_k} \le \lambda_{n_k},\end{aligned}$$

where the last inequality is a consequence of the induction assumption (2.5). On the other hand, $\lambda_{n_{k+1}} > \lambda_{n_k}$, a contradiction.

In order to prove the last statement of the theorem, assume that for some $l > 0$ we have $\mu_{n+l} > \lambda_e$. Then there exists a maximal $L(\alpha)$-nonnegative subspace $\mathcal{M}_0$ and an $(n+l-1)$-dimensional subspace $\mathcal{V}_0$ of $\mathcal{M}_0$ such that

$$\inf_{\substack{x\in\mathcal{M}_0^1\\ x\perp\mathcal{V}_0}} p(x) > \lambda_e.$$

Choose $\varepsilon > 0$ such that

$$\lambda_n < \lambda_e - \varepsilon < \lambda_e < \lambda_e + \varepsilon < \inf_{\substack{x\in\mathcal{M}_0^1\\ x\perp\mathcal{V}_0}} p(x).$$

As above, Assumption 3 implies for $x \in \mathcal{M}_0$, $x \perp \mathcal{V}_0$ that $(L(\lambda_e)x, x) \geq c\|x\|^2$ with some $c > 0$. Since λ_e belongs to the essential spectrum of L, that is, 0 belongs to the essential spectrum of $L(\lambda_e)$, for each $\eta > 0$ there exists an l-dimensional subspace $\mathcal{L}_l^\eta$ such that $\|L(\lambda_e)\big|_{\mathcal{L}_l^\eta}\| \leq \eta$. As in the proof of Theorem 2.1 it follows that for some subspace $\mathcal{L}_l^\eta$ it holds $(L(\lambda_e - \varepsilon)x, x) > 0$ for all $x \neq 0$, $x \in \operatorname{span}\{\mathcal{V}_0^\perp \cap \mathcal{M}_0, \mathcal{L}_1^\eta\}$. Now Lemma 2.3 implies that the subspace $\mathcal{M}_1 := \operatorname{span}\{\mathcal{V}_0^\perp \cap \mathcal{M}_0, \mathcal{L}_l^\eta, y_1, y_2, \ldots, y_n\}$ is $L(\lambda_1)$-nonnegative, and hence also $L(\alpha)$-nonnegative. On the other hand, the dimension of the factor space $\mathcal{M}_1/(\mathcal{V}_0^\perp \cap \mathcal{M}_0)$ equals $l + n$. This is a contradiction since $\dim \mathcal{M}_0/(\mathcal{V}_0^\perp \cap \mathcal{M}_0) = n + l - 1$ and the dimensions of all the complementary spaces of $\mathcal{V}_0^\perp \cap \mathcal{M}_0$ to maximal $L(\alpha)$-nonnegative spaces coincide. □

3. Triple variational principles.

3.1. Self-adjoint operators in Hilbert space with a gap in the essential spectrum. In this subsection a self-adjoint operator A on some Hilbert space $\mathcal{H}$ will be considered for which there exists a semiclosed interval such that $\sigma(A)$ is discrete in this interval. The eigenvalues of A in this interval are characterized by a triple variational principle. By $\mathbf{M}_\alpha^+$ we denote the set of maximal $(A - \alpha I)$-nonnegative subspaces; that is, a subspace $\mathcal{M}$ of $\mathcal{H}$ belongs to $\mathbf{M}_\alpha^+$ if $((A - \alpha)x, x) \geq 0$ for all $x \in \mathcal{M}$ and $\mathcal{M}$ is maximal with respect to this property. The results of section 2 will be applied to the linear pencil $L(\lambda) = A - \lambda I$. Evidently, if $\alpha \in \rho(A)$, then L satisfies Assumptions 1–3.

THEOREM 3.1. *Let A be a self-adjoint operator A such that for some $\alpha \in \rho(A) \cap R$ and $\beta > \alpha$ the spectrum $\sigma(A)$ is discrete in the interval $[\alpha, \beta)$. If A has at least n eigenvalues in $[\alpha, \beta)$ and we denote the smallest n ones by*

$$\lambda_1 = \lambda_2 = \cdots = \lambda_{n_1} < \lambda_{n_1+1} = \cdots = \lambda_{n_2} < \cdots < \lambda_{n_k+1} = \cdots = \lambda_{n_{k+1}} < \cdots \leq \lambda_n,$$

counted according to their multiplicities, then

$$\lambda_j = \max_{\mathcal{M}\in\mathbf{M}_\alpha^+} \sup_{\substack{\mathcal{V}\subset\mathcal{M}\\ \dim\mathcal{V}=j-1}} \inf_{\substack{x\in\mathcal{M}^1\\ x\perp\mathcal{V}}} p(x), \qquad j = 1, 2, \ldots, n. \tag{3.1}$$

If A has finitely many, say n eigenvalues in $[\alpha, \beta)$ and $\sigma_{ess}(A) \cap [\alpha, \beta] \neq \emptyset$, then with $\lambda_e = \min \sigma_{ess}(A) \cap [\alpha, \beta]$ and $\lambda_{n+1} = \lambda_{n+2} = \cdots = \lambda_e$ the relation (3.1) holds also for $j = n + 1, n + 2, \ldots$.

Proof. We apply Theorem 2.4 to the linear pencil

$$L(\lambda) := A - \lambda I, \qquad \lambda \in R, \tag{3.2}$$

and obtain the relation (3.1) with $\geq$ instead of the sign $=$. It remains to find a subspace $\mathcal{M}_0 \in \mathbf{M}_\alpha^+$ such that

$$\lambda_j = \max_{\substack{\mathcal{V}\subset\mathcal{M}_0 \\ \dim\mathcal{V}=j-1}} \inf_{\substack{x\in\mathcal{M}_0^1 \\ x\perp\mathcal{V}}} p(x). \tag{3.3}$$

If we choose for $\mathcal{M}_0$ the spectral subspace of A corresponding to the interval $[\alpha,\infty)$ the relation (3.3) is a consequence of a classical double variational principle of the spectrum of a self-adjoint operator, applied to the operator $A|_{\mathcal{M}_0}$. □

Remark 3.2. In Theorem 3.1 the set $\mathbf{M}_\alpha^+$ can be replaced by the set of all maximal $(A-\alpha I)$-positive subspaces.

3.2. Nonnegative operators on Krein spaces. Let $(\mathcal{K}, [\,\cdot\,,\,\cdot\,])$ be a Krein space. We fix a fundamental symmetry J on $\mathcal{K}$ and introduce the Hilbert space $(\mathcal{H}, (\,\cdot\,,\,\cdot\,))$, which consists of the same elements as $\mathcal{K}$ and with inner product

$$(x,y) := [Jx,y], \qquad x,y\in\mathcal{K}.$$

Let A be a bounded positive operator on $\mathcal{K}$; here positive means that $[Ax,x]>0$ for all $x\in\mathcal{K}$, $x\neq 0$. Then the spectrum $\sigma(A)$ is real, with positive eigenvalues having positive-type and negative eigenvalues having negative-type eigenvectors; see, e.g. [L], [AI]. The spectrum of A on $\mathcal{K}$ and also the eigenvalues, eigenvectors, etc. coincide with the spectrum, the eigenvalues, etc. of the self-adjoint linear pencil $M(\mu) := JA-\mu J$ on the Hilbert space $\mathcal{H}$.

We introduce the pencil

$$L(\lambda) := J-\lambda JA.$$

The spectrum of the pencil L is in general unbounded, the relations

$$\lambda\in\sigma(L) \Longleftrightarrow \mu=\frac{1}{\lambda}\in\sigma(M), \qquad \lambda\in\sigma_p(L) \Longleftrightarrow \mu=\frac{1}{\lambda}\in\sigma_p(M)$$

hold, and the eigenvectors of corresponding eigenvalues of L and M coincide. The pencil L satisfies Assumptions 1–2 with respect to $\alpha=0$ and $\beta=\infty$. Denote by $\mathbf{M}_0^+$ the set of all maximal nonnegative subspaces of $\mathcal{K}$, by $\mathbf{M}_0^{++}$ the set of all maximal positive subspaces of $\mathcal{K}$.

THEOREM 3.3. *Let A be a positive operator on the Krein space $\mathcal{K}$. Suppose that A has at least n eigenvalues which are greater than* $\max\{\sigma_{ess}(A),0\}$ *denoted by*

$$\mu_1=\mu_2=\cdots=\mu_{n_1}>\mu_{n_1+1}=\cdots=\mu_{n_2}>\cdots>\mu_{n_k+1}=\cdots=\mu_{n_{k+1}}>\cdots\geq\mu_n,$$

counted according to their multiplicities. Then

$$\mu_j = \inf_{\mathcal{M}\in\mathbf{M}_0^{++}} \inf_{\substack{\mathcal{V}\subset\mathcal{M} \\ \dim\mathcal{V}=j-1}} \sup_{\substack{x\in\mathcal{M}^1 \\ x\perp\mathcal{V}}} \frac{[Ax,x]}{[x,x]}, \qquad j=1,2,\dots,n. \tag{3.4}$$

Proof. If we apply Theorem 2.4 to the pencil L and the interval $[0,\infty)$ we obtain with $\lambda_j=\mu_j^{-1}$, $j=1,2,\dots,n$,

$$\lambda_j \geq \sup_{\mathcal{M}\in\mathbf{M}_0^+} \sup_{\substack{\mathcal{V}\subset\mathcal{M} \\ \dim\mathcal{V}=j-1}} \inf_{\substack{x\in\mathcal{M}^1 \\ x\perp\mathcal{V}}} \frac{[x,x]}{[Ax,x]}, \qquad j=1,2,\dots,n.$$

Rewriting this relation for the μ_j and positive subspaces $\mathcal{M}$ gives

$$\mu_j \le \inf_{\mathcal{M}\in\mathbf{M}_0^{++}} \inf_{\substack{\mathcal{V}\subset\mathcal{M}\\ \dim\mathcal{V}=j-1}} \sup_{\substack{x\in\mathcal{M}^1\\ x\perp\mathcal{V}}} \frac{[Ax,x]}{[x,x]}, \qquad j=1,2,\dots,n.$$

It remains to find a subspace $\mathcal{M}_0 \in \mathbf{M}_0^{++}$ such that

$$\mu_j = \inf_{\substack{\mathcal{V}\subset\mathcal{M}_0\\ \dim\mathcal{V}=j-1}} \sup_{\substack{x\in\mathcal{M}_0^1\\ x\perp\mathcal{V}}} \frac{[Ax,x]}{[x,x]}, \qquad j=1,2,\dots,n.$$

We choose $\mathcal{M}_0$ to be a maximal nonnegative subspace of $\mathcal{K}$ which is invariant under A and which exists according to [L, Theorem 7.1]. Then $\mathcal{M}_0$ is even a positive subspace: If it contains a neutral element x_0 it follows that $[Ax_0, x_0] = 0$, and hence $x_0 = 0$ since A is positive. Now consider the Hilbert space completion $\mathcal{H}_0$ of $\mathcal{M}_0$ with respect to the inner product $[\,\cdot\,,\,\cdot\,]$. The restriction $A|_{\mathcal{M}_0}$ extends by continuity to a bounded self-adjoint operator A_0 in $\mathcal{H}_0$ which has the same discrete spectrum as the restriction $A|_{\mathcal{M}_0}$. If we apply the classical variational principle to A_0 the claim follows. □

3.3. A class of quadratic operator pencils. In this subsection we consider a self-adjoint quadratic operator pencil

$$L(\lambda) = -\lambda^2 I + \lambda B + C$$

with bounded operators B and C in some Hilbert space $\mathcal{H}$, B being nonpositive. As we have mentioned already, pencils of this form with unbounded operators arise in problems of mechanics; see [Pi1], [Pi2]. Here, however, we shall restrict ourselves to the case of bounded operators.

For convenience it is also assumed that C is boundedly invertible: $0 \in \rho(C)$, and we write C as the difference of its two positive components C_+, C_- : $C = C_+ - C_-$. We shall characterize the smallest discrete positive eigenvalues of L by a variational principle from the left.

The pencil L satisfies Assumptions 1–3 with respect to $\alpha = 0$ and $\beta = \infty$. Denote by $\mathbf{M}_0^+$ the set of all C-nonnegative subspaces of $\mathcal{H}$. For $x \neq 0$ the solutions of the equation

$$\lambda^2\|x\|^2 - \lambda(Bx,x) - (Cx,x) = 0$$

are

$$\lambda = p_\pm(x) = \frac{1}{2\|x\|^2}\left((Bx,x) \pm \sqrt{(Bx,x)^2 + 4(Cx,x)\|x\|^2}\right).$$

Hence this equation has a solution in the right half plane if and only if $(Cx,x) > 0$, and then this solution $p_+(x)$ is unique and real; we denote it for short by $p(x)$. It follows that under the above assumptions the spectrum of L in the right half plane is real.

THEOREM 3.4. *Given the quadratic operator pencil*

$$L(\lambda) = -\lambda^2 I + \lambda B + C$$

with a bounded nonpositive operator B and a bounded self-adjoint operator C such that $0 \in \rho(C)$. Then the spectrum of L in the right half plane is real, and hence

positive, and it is nonempty if and only if $C_+ \neq 0$. *If* L *has at least* n *eigenvalues in the interval* $[0, \lambda_e)$, *where* $\lambda_e := \min \sigma_{ess}(L) \cap R^+$ *and we denote the* n *smallest ones as in* (2.3):

$$\lambda_1 = \cdots = \lambda_{n_1} < \lambda_{n_1+1} = \cdots = \lambda_{n_2} < \cdots < \lambda_{n_k+1} = \cdots = \lambda_{n_{k+1}} < \cdots \leq \lambda_n,$$

counted according to their multiplicities, then

$$\sup_{\mathcal{M} \in \mathbf{M}_0^+} \sup_{\substack{\mathcal{V} \subset \mathcal{M} \\ \dim \mathcal{V} = j-1}} \inf_{\substack{x \in \mathcal{M}^1 \\ x \perp \mathcal{V}}} p(x) = \lambda_j, \qquad j = 1, 2, \ldots, n. \tag{3.5}$$

If the total number of eigenvalues of L *in* $[0, \lambda_e)$ *is finite, say* n, *and* $\operatorname{ran} C_+$ *is infinite-dimensional, then the equality sign in* (3.5) *holds also for* $j = n+1, n+2, \ldots$ *if we define* $\lambda_{n+1} = \lambda_{n+2} = \cdots = \lambda_e$.

Proof. Theorem 2.4 yields immediately the inequalities

$$\sup_{\mathcal{M} \in \mathbf{M}_\alpha^+} \sup_{\substack{\mathcal{V} \subset \mathcal{M} \\ \dim \mathcal{V} = j-1}} \inf_{\substack{x \in \mathcal{M}^1 \\ x \perp \mathcal{V}}} p(x) \leq \lambda_j, \qquad j = 1, 2, \ldots, n. \tag{3.6}$$

We shall find a maximal C-positive subspace $\mathcal{M}_0$ such that

$$\sup_{\substack{\mathcal{V} \subset \mathcal{M}_0 \\ \dim \mathcal{V} = j-1}} \inf_{\substack{x \in \mathcal{M}_0^1 \\ x \perp \mathcal{V}}} p(x) = \lambda_j, \qquad j = 1, 2, \ldots, n.$$

In order to find such a subspace we consider the following linearization of the pencil L. In the space $\widetilde{\mathcal{H}} := \mathcal{H} \oplus \mathcal{H}$ define the operators

$$\widetilde{A} := \begin{pmatrix} B & C \\ I & 0 \end{pmatrix}, \qquad \widetilde{G} := \begin{pmatrix} -I & 0 \\ 0 & C \end{pmatrix}. \tag{3.7}$$

The operator $\widetilde{A}$ is a standard linearization of the pencil L, and it is well known that the spectra of L and of $\widetilde{A}$ coincide. In particular, the spectrum of $\widetilde{A}$ in the right half plane forms a spectral set in the Riesz–Dunford sense. Denote the corresponding spectral subspace of $\widetilde{A}$ by $\widetilde{\mathcal{M}}_0$. The operator $\widetilde{A}$ is $\widetilde{G}$-accretive:

$$\Re\,(\widetilde{G}\widetilde{A}) = \Re \begin{pmatrix} -B & -C \\ C & 0 \end{pmatrix} = \begin{pmatrix} -B & 0 \\ 0 & 0 \end{pmatrix} \geq 0.$$

Therefore this spectral subspace $\widetilde{\mathcal{M}}_0$ is $\widetilde{G}$-nonnegative; see [AI]. It follows that it admits a representation of the form

$$\widetilde{\mathcal{M}}_0 = \left\{ \begin{pmatrix} K P_{\mathcal{M}_0} x \\ P_{\mathcal{M}_0} x \end{pmatrix} : \, x \in \mathcal{H} \right\},$$

where $P_{\mathcal{M}_0}$ is an orthogonal projection in $\mathcal{H} = \operatorname{ran} C_- \oplus \operatorname{ran} C_+$ onto a subspace $\mathcal{M}_0$ of the form

$$\mathcal{M}_0 = \left\{ \begin{pmatrix} K_1 x \\ x \end{pmatrix} : \, x \in \operatorname{ran} C_+ \right\},$$

with a bounded linear operator K_1 from $\operatorname{ran} C_+$ into $\operatorname{ran} C_-$. It is now easy to see that the spectrum of the operator $\widetilde{A}|_{\widetilde{\mathcal{M}}_0}$, which is the spectrum of $\widetilde{A}$ in the right half plane, coincides with the spectrum of the pencil

$$L_{\mathcal{M}_0}(\lambda) := \lambda^2 P_{\mathcal{M}_0} - \lambda P_{\mathcal{M}_0} B P_{\mathcal{M}_0} - P_{\mathcal{M}_0} C P_{\mathcal{M}_0},$$

(which is considered just in the subspace $\mathcal{M}_0$ of $\mathcal{H}$) in the right half plane, and, in particular, the eigenvalues in the right half plane and the corresponding eigenvectors of the pencils L and $L_{\mathcal{M}_0}$ coincide. On the other hand, we have from (3.7) for $\widetilde{x} = \binom{KP_{\mathcal{M}_0}x}{P_{\mathcal{M}_0}x} \in \widetilde{\mathcal{M}}_0$

$$(\widetilde{G}\widetilde{x}, \widetilde{x}) = (CP_{\mathcal{M}_0}x, P_{\mathcal{M}_0}x) - \|KP_{\mathcal{M}_0}x\|^2 \geq 0,$$

and it follows that $P_{\mathcal{M}_0}CP_{\mathcal{M}_0}$ is strictly positive on $\mathcal{M}_0$, or, in other words, the subspace $\mathcal{M}_0$ is $P_{\mathcal{M}_0}CP_{\mathcal{M}_0}$-positive. Therefore the positive eigenvalues of the pencil $L_{\mathcal{M}_0}$ can be characterized by double variational principles, which implies that

$$\sup_{\substack{\mathcal{V}\subset\mathcal{M}_0\\ \dim\mathcal{V}=j-1}} \inf_{\substack{x\in\mathcal{M}_0{}^1\\ x\perp\mathcal{V}}} p(x) = \lambda_j, \qquad j = 1, 2, \ldots, n;$$

that is, for $\mathcal{M} = \mathcal{M}_0$ the equality sign in (3.6) is attained. □

3.4. Block operator matrices. In this subsection we consider a self-adjoint operator $\widetilde{A}$ on the orthogonal sum $\widetilde{\mathcal{H}} = \mathcal{H}_1 \oplus \mathcal{H}_2$ of two Hilbert spaces $\mathcal{H}_1$, $\mathcal{H}_2$ given by the block operator matrix

$$\widetilde{A} = \begin{pmatrix} A & B \\ B^* & D \end{pmatrix}. \tag{3.8}$$

Evidently, A and D are self-adjoint operators on $\mathcal{H}_1$ and $\mathcal{H}_2$, respectively. The spectrum of $\widetilde{A}$ outside of $\sigma(D)$ coincides with the spectrum of the first Schur complement

$$L(\lambda) := A - \lambda I - B(D - \lambda I)^{-1}B^*$$

of $\widetilde{A}$. If $\lambda \notin \sigma(D)$, then $L'(\lambda) = -I - B(D - \lambda I)^{-2}B^* \leq -I$; therefore, if $\alpha > \max\sigma(D)$, $\alpha \in \rho(\widetilde{A})$, and $\beta > \alpha$, then for L and the interval $[\alpha, \beta)$ Assumptions 1–3 are satisfied. In particular, for $x \in \mathcal{H}_1$, $x \neq 0$, the equation $(L(\lambda)x, x) = 0$ has at most one zero in the interval $[\alpha, \infty)$ and has exactly one zero in this interval if $(L(\alpha)x, x) \geq 0$. Denote this zero by $p(x)$. Further, by $\mathbf{M}_\alpha^+$ we denote the set of all maximal $L(\alpha)$-nonnegative subspaces of $\mathcal{H}_1$.

THEOREM 3.5. *Let the self-adjoint block operator matrix $\widetilde{A}$ be given as in* (3.8). *Consider $\alpha \in \rho(\widetilde{A})$ such that $\alpha > \max\sigma(D)$, and denote $\lambda_e := \min\sigma_{ess}(\widetilde{A}) \cap [\alpha, \infty)$. If $\widetilde{A}$ has at least n eigenvalues in (α, λ_e) and we denote the n smallest ones as in* (2.3):

$$\lambda_1 = \cdots = \lambda_{n_1} < \lambda_{n_1+1} = \cdots = \lambda_{n_2} < \cdots < \lambda_{n_k+1} = \cdots = \lambda_{n_{k+1}} < \cdots \leq \lambda_n,$$

counted according to their multiplicities, then

$$\lambda_j = \sup_{\mathcal{M}\in\mathbf{M}_\alpha^+} \sup_{\substack{\mathcal{V}\subset\mathcal{M}\\ \dim\mathcal{V}=j-1}} \inf_{\substack{x\in\mathcal{M}^1\\ x\perp\mathcal{V}}} p(x), \qquad j = 1, 2, \ldots, n. \tag{3.9}$$

If the total number of eigenvalues of L in (α, λ_e) is finite, say n, then the equality in (3.9) *holds also for $j = n+1, n+2, \ldots$ if we define $\lambda_{n+1} = \lambda_{n+2} = \cdots = \lambda_e$.*

Proof. Theorem 2.4 yields immediately the relation (3.9) with the sign $\geq$ instead of the sign $=$. It remains to find a maximal $L(\alpha)$-nonnegative subspace of $\mathcal{H}_1$ such that the equality is attained. To this end we consider the spectral invariant subspace $\widetilde{\mathcal{M}}$

of $\widetilde{A}$ corresponding to the interval $\Delta := [\alpha, \infty)$. According to [LMMT, Theorem 1.2] this invariant subspace is of the form

$$\widetilde{\mathcal{M}} = \left\{ \begin{pmatrix} x \\ K_\Delta x \end{pmatrix} : x \in \mathcal{H}_1^\Delta \right\},$$

where $\mathcal{H}_1^\Delta$ is a subspace of $\mathcal{H}_1$ and K_Δ is a bounded operator from $\mathcal{H}_1^\Delta$ into $\mathcal{H}_2$. Let P_Δ be the orthogonal projection in $\mathcal{H}_1$ onto $\mathcal{H}_1^\Delta$. We introduce the space $\widetilde{\mathcal{H}}^\Delta := \mathcal{H}_1^\Delta \oplus \mathcal{H}_2$ and the compression $\widetilde{A}_\Delta$ of $\widetilde{A}$ to $\widetilde{\mathcal{H}}^\Delta$:

$$\widetilde{A}_\Delta := \begin{pmatrix} P_\Delta A P_\Delta & P_\Delta B \\ B^* P_\Delta & D \end{pmatrix}.$$

Evidently, with the first Schur complement $L_\Delta(\lambda)$ of $\widetilde{A}_\Delta$ it holds that

$$(L(\lambda)x, x) = (L_\Delta(\lambda)x, x), \qquad x \in \mathcal{H}_1^\Delta.$$

Then, according to [LMMT, Theorem 2.6], $\mathcal{M}_0 := \mathcal{H}_1^\Delta$ is a maximal $L(\alpha)$-positive subspace. The discrete eigenvalues of $\widetilde{A}$ and of $\widetilde{A}_\Delta$ in $[\alpha, \infty)$ coincide, and it is well known (see [BEL]) that the latter can be characterized by the formula

$$\lambda_j = \sup_{\substack{\mathcal{V} \subset \mathcal{M}_0 \\ \dim \mathcal{V} = j-1}} \inf_{\substack{x \in \mathcal{M}_0^1 \\ x \perp \mathcal{V}}} p(x), \qquad j = 1, 2, \ldots, n. \qquad \square$$

CRITICAL MAGNETIC FIELD AND ASYMPTOTIC BEHAVIOR OF SUPERCONDUCTING THIN FILMS*

SHIJIN DING† AND QIANG DU‡

Abstract. In this paper, we discuss the vortex structure of the superconducting thin films placed in a magnetic field. The discussion is based on a system of simplified Ginzburg–Landau equations. We obtain the estimate for the lower critical magnetic field H_{c_1}, in the sense that it is the first critical value of h_{ex}, the applied field, for which the minimal energy among vortexless configurations is equal to the minimal energy among single-vortex configurations; moreover, it corresponds to the first phase transition in which vortices appear in the superconductor. We also discuss the location of these vortices and the asymptotic behavior of the local minimizers.

Key words. superconductivity, thin films, vortices, pinning, critical magnetic field

1. Introduction.

Consider a three-dimensional superconducting thin film that occupies the domain $\Omega_\delta = \Omega \times (-\delta a, \delta a)$, where Ω is a bounded smooth planar domain and $a \in C^\infty(\overline{\Omega})$ is a function measuring the variation in the film thickness. Assume that $a(x) \geq a_0 > 0$ for all $x \in \overline{\Omega}$; by taking integral averages along the vertical direction and setting δ going to zero, it was shown in [10] that the three-dimensional Ginzburg–Landau model of superconductivity [16, 26] defined on Ω_δ may be reduced to a two-dimensional one given by the minimization in $H^1(\Omega)$ of the functional

$$J_a(u) = \frac{1}{2}\int_\Omega a(x)\left[|\nabla_{\mathbf{A}_0} u|^2 + \frac{1}{2\varepsilon^2}(1-|u|^2)^2\right], \tag{1.1}$$

where $\mathbf{A}_0(x)$, the in-plane component of the magnetic potential, is determined by

$$\begin{cases} \operatorname{div}(a(x)\mathbf{A}_0) = 0, \quad \mathbf{curl}\mathbf{A}_0 = h_{ex} & \text{in } \Omega, \\ \mathbf{A}_0 \cdot \mathbf{n} = \mathbf{0} & \text{on } \partial\mathbf{\Omega}. \end{cases} \tag{1.2}$$

Here, h_{ex} is the external magnetic field which is applied vertically to the (x_1, x_2)-plane, $\mathbf{n}$ denotes the outward normal to $\partial\Omega$, u is the complex superconducting order parameter with $|u|^2$ representing the density of superconducting electrons ($|u| = 1$ corresponds to the superconducting state, $|u| = 0$ corresponds to the normal state), $\nabla_{\mathbf{A}_0} u = \nabla u - i\mathbf{A}_0 u$, and ε is proportional to the coherence length.

Let u be a critical point of the functional $J_a(u)$ in $H^1(\Omega)$ which satisfies the

Euler–Lagrange (or simplified Ginzburg–Landau) equation

$$\begin{cases} -(\nabla - i\mathbf{A}_0)\cdot a(x)(\nabla u - i\mathbf{A}_0 u) = \dfrac{a(x)}{\varepsilon^2}u(1-|u|^2) \text{ in } \Omega, \\ \partial_{\mathbf{n}} u = 0 \qquad\qquad\qquad \text{on } \partial\Omega. \end{cases} \tag{1.3}$$

The points where the zeros of u appear, with their topological degrees, are called the vortices of the map u. Understanding the vortex structures in the solutions and describing the vortices as h_{ex} varies is of great physical relevance and mathematical interests. Discussions on the vortex state in the thin film geometry have been given in [1, 16, 17, 19, 20, 26]; in particular, the variation in the film thickness is thought to provide an effective vortex pinning mechanism [10]. For works related to the mathematical analysis of the various pinning mechanisms, we refer to [2, 3, 4, 6, 10, 11, 12, 15].

In [7, 8], rigorous mathematical analysis of vortex solutions has been done for a similar problem with $a(x) = 1$, $\mathbf{A}_0 = 0$ and Dirichlet boundary condition $u = g\colon \Omega \to S^1$ of degree d. It was proved that, asymptotically, minimizers have d isolated vortices of degree one and their locations are determined by minimizing a renormalized energy. This result was extended to the case $a(x) \not\equiv 1$, $\mathbf{A}_0 = 0$ with the same Dirichlet boundary conditions in [6] and [15] independently, and the vortices of the minimizers were shown to be located at the minimum of $a(x)$. Some results similar to those in [7] were obtained in [9] for the original Ginzburg–Landau functional $J(u, \mathbf{A})$,

$$J(u,\mathbf{A}) = \frac{1}{2}\int_\Omega \left[|\nabla_{\mathbf{A}} u|^2 + |\mathbf{curlA} - h_{ex}|^2 + \frac{1}{2\varepsilon^2}(1-|u|^2)^2\right],$$

with $h_{ex} = 0$ and the gauge invariant Dirichlet conditions (a name given in [22]). This work was later extended in [14] to the case where a weight (thickness) appears in the functional $J(u, \mathbf{A})$; the corresponding renormalized energy was presented in [13]. Similar analysis based on the functional (1.1) was also presented in [18]. All the available results substantiate the pinning effect of the thickness variation; that is, the vortices turn to stay where the film is thin.

Recently, the minimizers of $J(u, \mathbf{A})$ with nonzero applied fields with natural boundary conditions were studied in [5, 18, 23, 24, 25, 21, 22]. In this case, there is no a priori bound on the number of the vortices for the minimizers in $H^1 \times H^1$. To overcome this difficulty, i.e., to have an a priori control on the numbers of the vortices, in [23, 24], the local minimizers of the functional

$$J(u,\mathbf{A}) = \frac{1}{2}\int_\Omega \left[|\nabla_{\mathbf{A}} u|^2 + |\mathbf{curlA} - h_{ex}|^2 + \frac{1}{2\varepsilon^2}(1-|u|^2)^2\right]$$

in the set $\overline{D_M}$ were studied, where

$$D_M = \left\{(u,\mathbf{A}) \in H^1(\Omega)\times H^1(\Omega) :\ F(u) < M|\ln\varepsilon|\ \right\}$$

and $F(u) = J_1(u) = J(u, 0)$ with $\mathbf{A}_0 = 0$. The minimizers were shown not to be on the boundary of D_M, hence the Ginzburg–Landau equations (the Euler–Lagrange equations for the functional J) are satisfied. Such analysis also provided estimates on the lower critical magnetic field H_{c_1}, the locations of the vortices, and the asymptotic behaviors of the minimizers. The lower critical field H_{c_1} may be defined as the value of h_{ex} for which the minimal energy among vortexless configurations is equal to the

minimal energy among single-vortex configurations. For $h_{ex} \le H_{c_1}$, it was shown in [21] that the global minimizer (in $H^1 \times H^1$) of Ginzburg–Landau functional $J(u, \mathbf{A})$ is the vortexless solution found in [23]. For the case $H_{c_1} \ll h_{ex} \ll H_{c_2}$, in [22], it was shown that as $\varepsilon \to 0$ the energy minimizers have vortices whose density tends to be uniform and proportional to h_{ex}. For other discussions, we refer the reader to [2] and [25] and references therein.

In this paper, we study the minimizers of the functional (1.1) in the set

$$D_M^a = \left\{ u \in H^1(\Omega) : \ F_a(u) < M|\ln\varepsilon| \ \right\}, \tag{1.4}$$

where $F_a(u) = J_a(u)$ with $\mathbf{A}_0 = 0$. The main techniques of this paper come from [23, 24]. We also present the estimate on the lower critical magnetic field H_{c_1} and discuss the impact of the thickness function $a(x)$ and the given applied field $\mathbf{curl}\mathbf{A}_0$ on the vortices: their number and their locations. These new results have not been stated even in the physics literature. Our results also provide rigorous theoretical justification of the pinning mechanism due to the thickness variation based on the simplified Ginzburg–Landau model.

Let us introduce a few notation. By (1.2), there is a function $\xi \in H^2(\Omega)$ such that

$$a(x)\mathbf{A}_0(x) = \nabla^\perp \xi = (-\xi_{x_2}, \xi_{x_1}) \ \text{ in } \Omega.$$

Using the scaling $\xi = \xi_0 h_{ex}$, we have from (1.2) that

$$\begin{cases} -\mathrm{div}(\frac{1}{a(x)}\nabla\xi_0) = -1 & \text{in } \Omega, \\ \xi_0 = 0 & \text{on } \partial\Omega. \end{cases} \tag{1.5}$$

By the maximum principle, we may easily see that $-C \le \xi_0 < 0$ for some constant $C > 0$ and ξ_0 is a smooth function that depends only on Ω and $a = a(x)$. Let

$$\Lambda = \left\{ x \in \Omega, |\xi_0(x)/a(x)| = \max_{y\in\Omega} |\xi_0(y)/a(y)| \right\}. \tag{1.6}$$

To state our main results, the following assumption is made.

Assumption 1.1. *Assume that the constant M in* (1.4) *is chosen so that there is a positive integer $n \in \mathbb{N}$ such that*

$$\left[\frac{M}{\pi \max\limits_{\Lambda} a(x)}, \quad \frac{M}{\pi \min\limits_{\Lambda} a(x)} \right] \subset (n, n+1). \tag{1.7}$$

The above assumption on the existence of $n \in \mathbb{N}$ with the desired property (1.7) is needed in proving (see section 6) that the minimizer of $J_a(u)$ in $\overline{D_M^a}$ is in D_M^a (not on ∂D_M^a) and thus the minimizer is a solution of (1.3). Under the above assumption, we have the following theorem.

Theorem 1.1. *There exists $k_a = \frac{1}{2\max_\Omega |\xi_0(x)/a(x)|}$, $k_2^\varepsilon = O(1)$, $k_3^\varepsilon = o(1)$, and $\varepsilon_0 = \varepsilon_0(M) > 0$ such that*

$$H_{c_1} = k_a|\ln\varepsilon| + k_2^\varepsilon, \tag{1.8}$$

and, for $\varepsilon < \varepsilon_0$, the following holds:

(i) *If* $h_{ex} \le H_{c_1}$, *there exists a solution* u_ε *of* (1.3) *which minimizes* $J_a(u)$ *in* D_M^a, *and it satisfies* $1/2 \le |u_\varepsilon| \le 1$.

(ii) *If* $H_{c_1} + k_3^\varepsilon \le h_{ex} \le H_{c_1} + O(1)$, *there exists a solution* u_ε *of* (1.3) *that minimizes* $J_a(u)$ *in* D_M^a. *The solution has a bounded positive number of vortices* b_i^ε *of degree one such that*

$$\operatorname{dist}(b_i^\varepsilon, \Lambda) \to 0, \quad \text{as } \varepsilon \to 0, \tag{1.9}$$

and there exists a constant $\alpha > 0$ *such that* $\operatorname{dist}(b_i^\varepsilon, b_j^\varepsilon) \ge \alpha$ *for* $i \ne j$.

REMARK 1.1. *The main differences between our results and those in* [23, 24] *are as follows: first,* A_0 *is determined a priori, and it satisfies* (1.2) *and* $\mathbf{curl} A_0(x) = O(|\ln \varepsilon|)$ *so that no London type equation is used; second, with a variable weight* $a = a(x)$ *in the functional, methods developed in* [6] *(see also* [13]*) and in* [23] *are needed to derive the energy lower bound.*

REMARK 1.2. *It follows from the proof of Theorem* 1.1 *that the number of the vortices, under our assumption, is bounded by*

$$N = \min\left\{ \frac{M}{\pi \max_\Lambda a(x)}, \quad \frac{\min_\Lambda a(x)}{\max_\Lambda a(x) - \min_\Lambda a(x)} \right\}.$$

REMARK 1.3. *From* (1.6) *and* (1.9)*, one may conclude that the distribution of the vortex locations are influenced both by the pinning effect due to thickness variation and the effect of the applied magnetic field. A similar phenomenon has also been explored in* [2] *with normal inclusion serving as pinning sites.*

Let us discuss briefly Assumption 1.1 and the results of Theorem 1.1. The parameter M in (1.4) is chosen such that

$$\Big[M/(\pi \max_\Lambda a(x)), M/(\pi \min_\Lambda a(x)) \Big] \subset (n, n+1)$$

for some positive integer n. For Λ defined by (1.6), it is easy to see that the above assumption can be equivalently replaced by

$$\max_\Lambda a(x) < 2 \min_\Lambda a(x). \tag{1.10}$$

Note that if Λ consists of only one point, or if $a(x)$ satisfies

$$\max_{\overline{\Omega}} a(x) < 2 \min_{\overline{\Omega}} a(x),$$

then (1.10) is automatically satisfied. With suitable choices of the domain Ω and the coefficient $a(x)$, it is indeed possible to make Λ a single point. A couple of simple examples are in order; let $\Omega = B(0, R_0)$ be a two-dimensional disc of radius R_0 and $r = |x|$ for $x \in \Omega$. Let $v(x) = \xi_0(x)/a(x)$; (1.5) for ξ_0 may be rewritten, in the polar coordinate system, as

$$\begin{cases} v''(r) + v'(r)/r + v'(r)(\ln a(r))' + v(r)\Delta \ln a(r) = 1 \text{ in } (0, R_0), \\ v'(0) = 0, \quad v(R_0) = 0, \end{cases} \tag{1.11}$$

where $v(r)$ and $a(r)$ represent the functions v and a in the polar coordinates.

Example 1. If $a(r) = e^{-\frac{r^2}{4}}$, then $\Lambda = \{0\}$.

Since $\Delta \ln a(r) = -1$, $(\ln a(r))' = -r/2$, we have

$$v''(r) + (1/r - r/2)v'(r) - v(r) = 1 \text{ in } (0, R_0).$$

One may verify that $v(r) = z(r)/z(R_0) - 1$ is nonpositive in $[0, R_0]$, where

$$z(r) = r^2 + r^3 + \sum_{n=0}^{+\infty} \left(\frac{1}{4^{n+1}(n+2)!} r^{2(n+2)} + \frac{1}{2^{n+1}(2n+5)!!} r^{2n+5} \right).$$

$v(r)$ is a solution of problem (1.11). Since $z(r)$ is strictly increasing in $[0, R_0]$, so is $v(r)$. We know $|v(r)|$ takes its maximum value only at 0, that is, $\Lambda = \{0\}$.

Example 2. If $a(r) = 2(1 + r)$, then $\Lambda = \{0\}$.

In fact, let $\xi_0(r) = \frac{1}{3}r^3 + \frac{1}{2}r^2 - (\frac{1}{3}R_0^3 + \frac{1}{2}R_0^2)$. Then $\xi_0(r)$ is nonpositive in $[0, R_0]$, $\xi_0(R_0) = 0$, and ξ_0 is a solution of (1.11). $\xi_0 = \xi_0(r)$ is strictly increasing in $[0, R_0]$, so is $a = a(r)$. Therefore $|\xi_0(r)|/a(r)$ takes its maximum value only at $\{0\}$, so $\Lambda = \{0\}$.

For both of the above examples, depending on R_0, the thickness function a may take on values of different magnitude at different locations in the domain $B(0, R_0)$. It is interesting to note that the coefficient $a(x)$ takes its minimum value at the boundary in Example 1 but at the origin in Example 2. Based on the analysis given in this paper, near H_{c_1}, the solution of (1.3) with a single vortex in Ω will have its vortex pinned near the origin in both cases for small enough ε even though the origin is the thickest position in Example 1. This illustrates that the vortex pinning phenomenon may be affected by the competition between the applied field and the thickness variation.

We now state the second main theorem.

THEOREM 1.2. *For a solution sequence $u_n = u_{\varepsilon_n}$ of (1.3) given by the part (ii) of Theorem 1.1, up to a subsequence, there exist d points $c_i \in \Lambda$ such that $u_n \to u_*$ weakly in $W^{1,p}$ $(p < 2)$ and strongly in $H^1_{\text{loc}}(\Omega \setminus \cup_{i=1}^d \{c_i\})$, where u_* is a solution of*

$$\begin{cases} -\nabla \cdot (a(x)\nabla u_*) = a(x)u_*|\nabla u_*|^2 \text{ in } \Omega \setminus \cup_{i=1}^d \{c_i\}, \\ \frac{\partial u_*}{\partial \mathbf{n}} = 0 \qquad \text{on } \partial\Omega, \\ |u_*| = 1 \qquad \text{a.e. on } \Omega. \end{cases} \tag{1.12}$$

It is easy to see that the local minimizers in $\overline{D_M^a}$ may not be the solution of (1.3) (if it is on the boundary of $\overline{D_M^a}$). However, the vortex structure is only well defined for solutions that satisfy $|\nabla u| \le C/\varepsilon$. For this reason, similar to [23], we introduce a regularization as follows.

Let $u_\varepsilon^\gamma \in H^1(\Omega, \mathbb{R}^2)$ be a minimizer of the following minimization problem:

$$\min_{v \in H^1(\Omega, \mathbb{R}^2)} \left\{ \int_\Omega a(x) \left[\frac{1}{2}|\nabla v|^2 + \frac{1}{4\varepsilon^2}(1 - |v|^2)^2 \right] + \int_\Omega \frac{|v - u_\varepsilon|^2}{2\varepsilon^{2\gamma}} \right\}, \tag{1.13}$$

where $u_\varepsilon \in \overline{D_M^a}$. u_ε^γ is, in some sense, a regularization of u_ε in $\overline{D_M^a}$ and an a priori bound on the number of the vortices of u_ε^γ can be obtained. This in turn leads to a description of the vortices of u_ε. More careful examination of the minimizers u_ε of $J_a(u)$ in $\overline{D_M^a}$ shows that they are actually not on the boundary of $\overline{D_M^a}$, and hence they solve (1.3). For brevity, in the rest of the paper, unless explicitly stated to avoid ambiguity, the subscript ε is dropped from the notation u_ε and u_ε^γ; i.e., u and u^γ are used instead.

This paper is organized as follows. In the next section we shall give some basic estimates for $J_a(u)$ and for the regularization u^γ. The main ideas are to define the vortices of u^γ and to expand the energy $J_a(u)$. Using the idea of [23] and the estimate in [6], we may then give the lower bound for the energy. In section 3, we shall provide estimates to the critical magnetic field. In section 4, the proof Theorem 1.1 is given, and in section 5 we shall prove the convergence of the sequence of the minimizers, i.e., Theorem 1.2.

In the following discussion, we always consider the case $h_{ex} \le C|\ln\varepsilon|$ for some positive constant C and assume that the Abrikosov estimate $H_{c_1} \le C|\ln\varepsilon|$ holds.

2. Preliminaries. In this section we present technical estimates which can be proved by a slight modification of the results in [6, 23]. The detailed proofs are omitted. We begin by defining

$$J^0 = J_a(1) = \frac{1}{2}\int_\Omega \frac{1}{a(x)}|\nabla\xi|^2 \le Ch_{ex}^2. \tag{2.1}$$

LEMMA 2.1. *For $u \in \overline{D_M^a}$ minimizing $J_a(u)$ in $\overline{D_M^a}$, we have*

$$J_a(u) \le Ch_{ex}^2, \tag{2.2}$$

$$\int_\Omega a(x)|\nabla_{\mathbf{A}_0}u|^2 \le Ch_{ex}^2, \tag{2.3}$$

$$\frac{1}{4\varepsilon^2}\int_\Omega a(x)(1-|u|^2)^2 \le Ch_{ex}^2. \tag{2.4}$$

Proof. Taking $v \equiv 1$ as a comparison function leads to the results. ∎

For any $\tilde{u}$ with $J_a(\tilde{u}) \le Ch_{ex}^2$, let $\eta = |\tilde{u}|$. Since

$$a(x)|\nabla u - i\mathbf{A}_0 u|^2 = a(x)[|\nabla u|^2 + i\mathbf{A}_0(u^*\nabla u - u\nabla u^*) + |\mathbf{A}_0|^2|u|^2],$$

where u^* is the complex conjugate of u, we have the following lemma.

LEMMA 2.2. *For any $\tilde{u}$ with $J_a(\tilde{u}) \le Ch_{ex}^2$, we have*

$$J_a(\tilde{u}) = F_a(\tilde{u}) + \frac{1}{2}\int_\Omega \frac{1}{a(x)}|\nabla\xi|^2 + \int_\Omega (i\tilde{u}, \xi_{x_2}\tilde{u}_{x_1} - \xi_{x_1}\tilde{u}_{x_2}) + o(1).$$

LEMMA 2.3. *For $\tilde{u} \in \overline{D_M^a}$ such that $J_a(\tilde{u}) \le Ch_{ex}^2$, there exists $u \in \overline{D_M^a}$ such that*

$$|u| \le 1, \tag{2.5}$$

$$F_a(u) \le F_a(\tilde{u}), \tag{2.6}$$

$$J_a(u) \le J_a(\tilde{u}) + o(1). \tag{2.7}$$

If, in addition, $\tilde{u} \in \overline{D_M^a}$ is a minimizer of J_a in $\overline{D_M^a}$, then, as $\varepsilon \to 0$, there holds

$$F_a(u) = F_a(\tilde{u}) + o(1), \tag{2.8}$$

$$J_a(u) = J_a(\tilde{u}) + o(1). \tag{2.9}$$

LEMMA 2.4. *For $u \in \overline{D_M^a}$, we have $u^\gamma \in H^3(\Omega)$ (for any $0 < \gamma < 1$) which solves* (1.13) *and satisfies*

$$-\nabla\cdot(a(x)\nabla u^\gamma) = \frac{a(x)}{\varepsilon^2}u^\gamma(1-|u^\gamma|^2) + \frac{u-u^\gamma}{\varepsilon^{2\gamma}}, \tag{2.10}$$

$$F_a(u^\gamma) \le F_a(u) \le M|\ln\varepsilon|, \tag{2.11}$$

$$|u^\gamma| \le 1, |\nabla u^\gamma| \le \frac{C}{\varepsilon}. \tag{2.12}$$

This implies that $u^\gamma \in \overline{D_M^a}$. Taking u as a comparison function in (1.13) gives

$$\int_\Omega \frac{1}{2\varepsilon^{2\gamma}}|u-u^\gamma|^2 + F_a(u^\gamma) \le F_a(u) \le M|\ln\varepsilon|$$

so that $\|u-u^\gamma\|_{L^2(\Omega)} \le C\varepsilon^\gamma|\ln\varepsilon|^{\frac{1}{2}}$. Since $|\nabla u^\gamma| \le \frac{C}{\varepsilon}$, the vortices are well defined in the following sense.

LEMMA 2.5. *There exists $\lambda > 0$ and points a_i^ε $(i \in \mathcal{J}_1)$ in Ω with* $\mathrm{Card}\mathcal{J}_1 \le Ch_{ex}^2$ *such that*

$$|u^\gamma| \ge \frac{1}{2} \quad \text{in} \quad \Omega \setminus \cup_{i\in\mathcal{J}_1} B(a_i^\varepsilon, \lambda\varepsilon).$$

Proof. We know from [7] that there exists $\mu_0 > 0$ such that

$$\frac{1}{\varepsilon^2}\int_{B(a_i^\varepsilon,\lambda\varepsilon)} (1-|u^\gamma|^2)^2 \ge \mu_0 \quad \forall i \in \mathcal{J}_1.$$

Using exactly the same arguments given in [7], this implies that $\mathrm{Card}\mathcal{J}_1 \le Ch_{ex}^2$ since $J_a(u) \le Ch_{ex}^2$. □

The balls $B(a_i^\varepsilon, \lambda\varepsilon)$ are called "bad" discs and a_i^ε together with its degree d_i^ε is called a vortex of "size" $\lambda\varepsilon$. We now pay attention to the minimizer u^γ. Although a weight is added to the functional on u^γ, i.e., (1.13), the proofs of the following four lemmas on the properties of u^γ can still be obtained directly from the corresponding ones in [23] and [24] by replacing the energy density with $e_\varepsilon(u) = \frac{1}{2}a(x)[|\nabla u|^2 + \frac{1}{\varepsilon^2}(1-|u|^2)^2]$. We omit the details.

LEMMA 2.6. *For any $0 < \gamma < \beta < 1$, u^γ has no vortex (i.e., $|u^\gamma| \ge 1/2$) in* $\{x \in \Omega; \mathrm{dist}(x, \partial\Omega) \le \varepsilon^\beta\}$.

LEMMA 2.7. *For small enough ε,* $\mathrm{Card}\mathcal{J}_1$ *is uniformly bounded by a constant N which is independent of ε. Let $0 < \gamma < \beta < \mu < 1$ such that $\overline{\mu} = \mu^{N+1} > \beta$. For ε small enough, there exists a subset $\mathcal{J} \subset \mathcal{J}_1$ and a radius $\rho > 0$ with $\lambda\varepsilon \le \varepsilon^\mu \le \rho \le \varepsilon^{\overline{\mu}} < \varepsilon^\beta$ such that*

$$\begin{aligned}
&|u^\gamma| \ge 1/2 \quad \text{in } \Omega \setminus \cup_{i\in\mathcal{J}} B(a_i^\varepsilon, \rho),\\
&|u^\gamma| \ge 1 - 2|\ln\varepsilon|^{-2} \quad \text{on } \partial B(a_i^\varepsilon, \rho), \ \ i \in \mathcal{J},\\
&\int_{\partial B(a_i^\varepsilon,\rho)} e_\varepsilon(u^\gamma) \le C(\beta,\mu)/\rho, \quad i \in \mathcal{J},\\
&|a_i^\varepsilon - a_j^\varepsilon| \ge 8\rho, \quad i \ne j \in \mathcal{J}.
\end{aligned}$$

Denote $d_i^\varepsilon = \deg(u^\gamma, \partial B(a_i^\varepsilon, \rho))$. We have the following lemma.

LEMMA 2.8. *For small enough ε and $u \in \overline{D_M^a}$, $|d_i^\varepsilon| = O(1)$ for all $i \in \mathcal{J}$.*

Assume for the moment that $|\nabla u| \le C/\varepsilon$ which is true if u is shown to be a solution of (1.3); then, in the sense of [7], the vortices of u are well defined and there exists the same uniform bound on the vortex number. One may also have bigger vortices of size ρ (where "bigger" means $\rho \ge \lambda\varepsilon$), $(b_i^\varepsilon, q_i^\varepsilon)$, such that u satisfies the same conclusions as in Lemma 2.7 for u^γ. As in [23], we may compare $(a_i^\varepsilon, d_i^\varepsilon)$ (the vortices of u^γ) with $(b_i^\varepsilon, q_i^\varepsilon)$ (the vortices of u) by the minimal connection between the vortices.

LEMMA 2.9. *For small ε, there holds* $\mathrm{dist}(a,b) \le C\varepsilon^\gamma|\ln\varepsilon|$

For the definition of $\mathrm{dist}(a,b)$ and the proof of this lemma, we refer to [23]. The following lemma gives the splitting of the energy $J_a(u)$ as in [23].

LEMMA 2.10. *For any $\tilde{u}$ satisfying* (2.2)–(2.4)*, let u be associated to $\tilde{u}$ as in Lemma* 2.3 *and u^γ be associated to u by solving the minimization problem* (1.13) *with vortices (a_i, d_i) satisfying Lemma* 2.7*. Then we have*

$$J_a(u) = F_a(u) + \frac{1}{2}\int_\Omega \frac{1}{a(x)}|\nabla\xi|^2 + 2\pi\sum_{i\in\mathcal{J}} d_i\xi(a_i), \quad as\ \varepsilon\to 0,$$

where $\xi = h_{ex}\xi_0$ and ξ_0 is the unique solution of problem (1.5).

Using this splitting, we have the following lemma.

LEMMA 2.11. *The constant J^0 in* (2.1) *is asymptotically equal to the minimal energy among vortexless configurations; i.e.,* $\inf_{\{u:\mathcal{J}=\emptyset\}} J_a(u) = J^0 + o(1)$ *as $\varepsilon\to 0$.*

Let $e_\varepsilon(u) = \frac{1}{2}a(x)[|\nabla u|^2 + \frac{1}{2\varepsilon^2}(1-|u|^2)^2]$ and $\Omega_\rho = \Omega\setminus\cup_{i\in\mathcal{J}}B(a_i,\rho)$, where $B(a_i,\rho)$'s are defined in Lemma 2.7. We have the following lemma.

LEMMA 2.12. *Assume that $\mathcal{J} = \{1, 2, \dots, k\}$; then*

$$\frac{1}{2}\int_{\Omega_\rho} a(x)|\nabla u^\gamma|^2 \ge \pi\sum_{i\in\mathcal{J}} a(a_i)d_i^2|\ln\rho| + W((a_1,d_1),\dots,(a_k,d_k)) + O(1),$$

where

$$W((a_1,d_1),\dots,(a_k,d_k)) = -\pi\sum_{i\ne j\in\mathcal{J}} a(a_i)d_id_j\ln|a_i-a_j| - \pi\sum_{i\in\mathcal{J}} d_iR_0(a_i)$$

and $R_0(x) = \Phi_0(x) - \sum_{i\in\mathcal{J}} a(a_i)d_i\ln|x-a_i|$ with $\Phi_0(x)$ solves

$$\begin{cases} -\mathrm{div}(\frac{1}{a(x)}\nabla\Phi_0) = 2\pi\sum_{i\in\mathcal{J}} d_i\delta_{a_i} & in\ \Omega,\\ \Phi_0 = 0 \qquad on\ \partial\Omega. \end{cases}$$

In the following lemma, we give a few more precise lower bounds on $F_a(u^\gamma)$.

LEMMA 2.13. *For ε and ρ satisfying Lemma* 2.7*, we have*

$$F_a(u^\gamma) \ge \pi\sum_{i\in\mathcal{J}} a(a_i)[d_i^2|\ln\rho| + |d_i||\ln(\rho/\varepsilon)| + W((a_1,d_1),\dots,(a_k,d_k)) + O(1), \tag{2.13}$$

$$F_a(u^\gamma) \ge \pi\sum_{i\in\mathcal{J}} a(a_i)|d_i||\ln(\rho/\varepsilon)| + O(1). \tag{2.14}$$

3. Obtaining the critical magnetic field H_{c_1}. Using the splitting and the lower bound of $J_a(u)$, we now estimate the critical magnetic field H_{c_1}.

LEMMA 3.1. *Let $h_{ex} = k_a|\ln\varepsilon| + o(|\ln\varepsilon|)$ and $\tilde{u}\in\overline{D_M^a}$ be a minimizer of $J_a(u)$ in $\overline{D_M^a}$ and $\{(a_i,d_i) : i\in\mathcal{J}\}$ be the vortices of u^γ. For ε small enough, if $\mathcal{J}\ne\emptyset$, say, $\mathcal{J} = \{1,\dots,k\}$, then*

(i) *$d_i > 0$ for any $i\in\mathcal{J}$, and*

(ii) *$\mathrm{dist}(a_i,\partial\Omega)\ge\alpha>0$ for some positive constant α, and consequently*

(iii) *$W((a_1,d_1),\dots,(a_k,d_k))\ge C$ for some constant C.*

Proof. We divide the proof into two steps.

Step 1. We first prove that, for ε small enough, $d_i>0$ for $i\in\mathcal{J}$. Since $\tilde{u}\in\overline{D_M^a}$ is a minimizer of $J_a(u)$, it follows from Lemma 2.11 that $J_a(u)\le J^0+o(1)$, i.e.,

$$F_a(u) + J^0 + 2\pi h_{ex}\sum_{i\in\mathcal{J}} d_i\xi_0(a_i) + o(1) \le J^0 + o(1).$$

Therefore

$$F_a(u) \le -2\pi h_{ex} \sum_{i\in\mathcal{J}} d_i \xi_0(a_i) + o(1) \tag{3.1}$$

or equivalently (noting that $\xi_0 < 0$ in Ω)

$$\begin{aligned} F_a(u) &\le 2\pi(k_a|\ln\varepsilon| + o(|\ln\varepsilon|)) \max\left|\frac{\xi_0(x)}{a(x)}\right| \sum_{d_i>0} a(a_i)d_i + o(1) \\ &\le \pi|\ln\varepsilon| \sum_{d_i>0} a(a_i)d_i + o(|\ln\varepsilon|). \end{aligned}$$

This inequality implies

$$F_a(u^\gamma) \le F_a(u) \le \pi|\ln\varepsilon| \sum_{d_i>0} a(a_i)d_i + o(|\ln\varepsilon|). \tag{3.2}$$

Combining (3.2) with (2.14) in Lemma 2.13 we obtain

$$\pi(1-\mu)\left(\sum_{i\in\mathcal{J}} a(a_i)|d_i|\right)|\ln\varepsilon| \le \pi\left(\sum_{d_i>0} a(a_i)d_i\right)|\ln\varepsilon| + o(|\ln\varepsilon|) \tag{3.3}$$

since $\varepsilon^\mu \le \rho \le \varepsilon^{\overline{\mu}}$. This implies

$$(1-\mu)\sum_{d_i<0} a(a_i)|d_i| \le \mu \sum_{d_i>0} a(a_i)d_i + o(1). \tag{3.4}$$

We estimate the first term on the right-hand side of (3.4). By (2.11), (2.14),

$$\mu \sum_{d_i>0} a(a_i)d_i \le \mu \sum_{i\in\mathcal{J}} a(a_i)|d_i| \le M\mu/(\pi(1-\mu)) + o(1).$$

Substituting this into (3.4), we get

$$\sum_{d_i<0} a(a_i)|d_i| \le M\mu/(\pi(1-\mu)^2) + o(1).$$

This means $\{i \in \mathcal{J};\ d_i < 0\} = \emptyset$ if one chooses μ small enough.

Step 2. We prove (ii) and (iii) in this step. It follows from Step 1 that

$$-\pi \sum_{i\ne j} a(a_i)d_i d_j \ln|a_i - a_j| \ge O(1)$$

and then

$$W((a_1,d_1),\dots,(a_k,d_k)) \ge -\pi \sum_{i\in\mathcal{J}} d_i R_0(a_i) + O(1). \tag{3.5}$$

For the proof of $\|R_0\|_{L^\infty(\Omega)} \le C$, similar to [23] and [6], it suffices to prove that $\operatorname{dist}(a_i, \partial\Omega)$ is uniformly bounded from below. Indeed, it can be shown as in [23] that

$$\|R_0(x)\|_{L^\infty(\Omega)} \le C\beta|\ln\varepsilon| + O(1). \tag{3.6}$$

Therefore we deduce

$$W((a_1,d_1),\dots,(a_k,d_k)) \geq -C\beta|\ln\varepsilon|. \tag{3.7}$$

On the other hand, we know from (3.2) and (2.13) (in view of $d_i^2 \geq d_i > 0$) that

$$\begin{aligned} F_a(u^\gamma) &\leq F_a(u) \leq -2\pi h_{ex}\sum_{i\in\mathcal{J}} d_i\xi_0(a_i) + o(1),\\ F_a(u^\gamma) &\geq \pi\sum_{i\in\mathcal{J}} a(a_i)d_i|\ln\varepsilon| + W((a_1,d_1),\dots,(a_k,d_k)) + O(1)\\ &\geq \pi\sum_{i\in\mathcal{J}} a(a_i)d_i|\ln\varepsilon| - C\beta|\ln\varepsilon| + O(1). \end{aligned}$$

Putting these two inequalities together and using

$$h_{ex} = k_a|\ln\varepsilon| + o(|\ln\varepsilon|) = \frac{|\ln\varepsilon|}{2\max_\Omega|\xi_0(x)/a(x)|} + o(|\ln\varepsilon|),$$

we get

$$2\pi h_{ex}\sum_{i\in\mathcal{J}} a(a_i)d_i\left[\frac{\xi_0(a_i)}{a(a_i)} + \max_\Omega\left|\frac{\xi_0(x)}{a(x)}\right|\right] \leq C\beta|\ln\varepsilon| + o(|\ln\varepsilon|). \tag{3.8}$$

Since $d_i \geq 1$ and $a(a_i) \geq \alpha_0 > 0$ for $i \in \mathcal{J}$, the above implies

$$\frac{\xi_0(a_i)}{a(a_i)} + \max_\Omega\left|\frac{\xi_0(x)}{a(x)}\right| \leq C\beta\max_\Omega\left|\frac{\xi_0(x)}{a(x)}\right| \ \ \forall i\in\mathcal{J}. \tag{3.9}$$

Taking $\beta > 0$ such that $C\beta < 1/2$, we get

$$\frac{\xi_0(a_i)}{a(a_i)} \leq -\frac{1}{2}\max_\Omega\left|\frac{\xi_0(x)}{a(x)}\right| < 0. \tag{3.10}$$

Since $\xi_0 = 0$ on $\partial\Omega$, we thus have $\operatorname{dist}(a_i,\partial\Omega)$ being uniformly bounded from below. So, $\|R_0\|_{L^\infty(\Omega)} \leq C$. This implies $W \geq O(1)$ uniformly by (3.5). □

Now, let $\overline{D_0} = \{u \in \overline{D_M^a}; \mathcal{J} = \emptyset\}$, and we have the following lemma.

LEMMA 3.2. *Suppose* $\max_{\overline{\Omega}} a(x)\pi < M$. *There are* $k_2^\varepsilon = O(1)$, $k_3^\varepsilon = o(1)$, *and* $\varepsilon_0 > 0$ *such that, for* $h_{ex} = |\ln\varepsilon|/(2\max_\Omega|\xi_0(x)/a(x)|) + t$, *there holds*

(i) *if* $t < k_2^\varepsilon$ *and* $\tilde{u}$ *is a minimizer of* J_a *in* $\overline{D_M^a}$, *then* $\mathcal{J} = \emptyset$ *and*

$$J_a(\tilde{u}) = \inf_{\overline{D_0}} J_a(u) = J^0 + o(1);$$

(ii) *if* $t = k_2^\varepsilon$, *there is* $u \in \overline{D_M^a}$ *with a simple vortex and* $J_a(u) \leq \inf_{\overline{D_0}} J_a(v)$;

(iii) *if* $t \geq k_2^\varepsilon + k_3^\varepsilon$, *there is* $u \in \overline{D_M^a}$ *with a simple vortex and* $J_a(u) < \inf_{\overline{D_0}} J_a(v)$.

Proof. Let J^0 be as in (2.1). We have

$$J_a(u) = F_a(u) + J^0 + 2\pi h_{ex}\sum_{i\in\mathcal{J}} d_i\xi_0(a_i) + o(1).$$

Clearly, $J^0 = \inf_{\overline{D_0}} J_a(v)$. If $\mathcal{J} \neq \emptyset$, then we consider two cases.

Case 1. $h_{ex} \le (1-\mu^*)k_a|\ln\varepsilon|$ for some $0<\mu^*<1$. Since $\rho \ge \varepsilon^\mu$ for some $\mu>0$, it follows from Lemma 2.13 that

$$F_a(u) \ge F_a(u^\gamma) \ge (1-\mu)\pi \sum_{i\in\mathcal{J}} a(a_i)|d_i||\ln\varepsilon| + O(1), \tag{3.11}$$

and then

$$J_a(u) \ge J^0 + \pi(1-\mu)\sum_{i\in\mathcal{J}} a(a_i)|d_i||\ln\varepsilon| - 2\pi h_{ex}\sum_{i\in\mathcal{J}} a(a_i)|d_i|\left|\frac{\xi_0(a_i)}{a(a_i)}\right| + O(1).$$

Hence, $J_a(u) > \inf_{\overline{D_0}} J_a(v)$ as long as

$$2\pi h_{ex}\sum_{i\in\mathcal{J}} a(a_i)|d_i|\left|\frac{\xi_0(a_i)}{a(a_i)}\right| \le (1-\mu)\pi\sum_{i\in\mathcal{J}} a(a_i)|d_i||\ln\varepsilon| + O(1)$$

which may be valid if we take $\mu<\mu^*$ since

$$h_{ex} \le (1-\mu)\frac{|\ln\varepsilon|}{2\max\limits_{\Omega}|\xi_0(x)/a(x)|}.$$

Case 2. $t<k_2^\varepsilon$ with $|t| = o(|\ln\varepsilon|)$. Then, by Lemma 3.1, we have

$$W((a_1,d_1),\dots,(a_k,d_k)) \ge C$$

for some constant C, thus, by Lemma 2.13, we get

$$F_a(u) \ge F_a(u^\gamma) \ge \pi\sum_{i\in\mathcal{J}} a(a_i)|d_i||\ln\varepsilon| + O(1).$$

Then, similar to Case 1, we have $J_a(u) > \inf_{\overline{D_0}} J_a(v)$ as long as

$$h_{ex} \le \frac{|\ln\varepsilon|}{2\max\limits_{\Omega}|\xi_0(x)/a(x)|} + O(1).$$

This verifies conclusion (i) in the lemma.

Next, let $k_a = 1/(2\max_\Omega|\xi_0(x)/a(x)|)$. As in [23], set

$$Z^\varepsilon = \Big\{ t\in\mathbb{R};\ \text{there exists } u\in\overline{D_M^a} \text{ with at least one vortex}$$
$$\text{and } J_a(u) < \inf_{\{\mathcal{J}=\emptyset\}} J_a \text{ for } h_{ex} = k_a|\ln\varepsilon| + t\Big\}.$$

In the following, we prove $Z^\varepsilon\neq\emptyset$ which would allow us to define $k_2^\varepsilon = \inf Z^\varepsilon$ and to prove that there exists $k_3^\varepsilon = o(1)$ such that $[k_2^\varepsilon + k_3^\varepsilon, +\infty] \subset Z^\varepsilon$.

Let $c\in\Omega$ such that $|\xi_0(c)/a(c)| = \max_\Omega|\xi_0(x)/a(x)|$. Consider the problem

$$\nu_\varepsilon(c) = \min_W \frac{1}{2}\int_{\Omega\setminus B(c,\varepsilon)} a(x)|\nabla u|^2, \tag{3.12}$$

where $W = \{\, u\in H^1(\Omega\setminus B(c,\varepsilon), S^1), \deg(u,\partial B(c,\varepsilon)) = 1\,\}$. Similar as before,

$$\nu_\varepsilon(c) = \pi a(c)|\ln\varepsilon| + O(1).$$

Let u be a minimizer of problem (3.12) which is well defined on $\Omega\setminus B(c,\varepsilon)$. Extending u to the whole domain Ω by defining it on $B(c,\varepsilon)$ as in [23] and denoting it by $\bar{u}$, we may get, as similarly done in [23],

$$F_a(\overline{u},\Omega)=F_a(\overline{u},B(c,\varepsilon))+\frac{1}{2}\int_{\Omega\setminus B(c,\varepsilon)}a(x)|\nabla u|^2\le K+a(c)\pi|\ln\varepsilon|.$$

For $h_{ex}=\frac{1}{2\max|\xi_0(x)/a(x)|}|\ln\varepsilon|+t=-\frac{1}{2\xi_0(c)/a(c)}|\ln\varepsilon|+t$, we have

$$\begin{aligned}J_a(\overline{u})&\le F_a(\overline{u})+J^0+2\pi h_{ex}\xi_0(c)+o(1)\\&=K-2\pi|\xi_0(c)|t+J^0+o(1).\end{aligned}$$

This implies $t\in Z^\varepsilon$ when $2\pi|\xi_0(c)|t\ge K+o(1)$. So, $Z^\varepsilon\neq\emptyset$ and $k_2^\varepsilon=\inf Z^\varepsilon\le K/2\pi|\xi_0(c)|+o(1)$. On the other hand, $h_{ex}\le k_a|\ln\varepsilon|+O(1)$; we thus know $k_2^\varepsilon\ge O(1)$ which gives $k_2^\varepsilon=O(1)$.

Finally, we prove that there exists $k_3^\varepsilon=o(1)$ such that $[k_2^\varepsilon+k_3^\varepsilon,+\infty]\subset Z^\varepsilon$. In fact, let $t\in Z^\varepsilon$ and, for $h_{ex,1}=k_a|\ln\varepsilon|+t$, $J_a(u)<\inf_{\overline{D_0}}J_a(v)$ and u^γ has vortices (a_i,d_i). Assume $t^{'}>t$ and $h_{ex,2}=k_a|\ln\varepsilon|+t^{'}$; we have

$$\begin{aligned}J_a(u)&=F_a(u)+J^0+2\pi h_{ex,2}\sum_{i=1}^k\xi_0(a_i)d_i+o(1)\\&\le J_a(u)+o(1)-(t^{'}-t)\sum_{i=1}^k2\pi|\xi_0(a_i)|d_i.\end{aligned}$$

Thus, if $t^{'}-t\ge k_3^\varepsilon=o(1)$, then $J_a(u)<\inf_{\{\mathcal{J}=\emptyset\}}J_a$, i.e., $[k_2^\varepsilon+k_3^\varepsilon,+\infty]\subset Z^\varepsilon$.

In summary, we have deduced that $H_{c_1}=k_a|\ln\varepsilon|+k_2^\varepsilon$ for the lower critical field. This completes the proof of the lemma. □

4. Proof of Theorem 1.1. By Lemma 3.2 and the bounds in Lemma 2.3 and Lemma 2.11, we see that, for $h_{ex}\le H_{c_1}$, the minimizer of J_a in $\overline{D_M^a}$ has no vortex and it is in the interior of $\overline{D_M^a}$, thus the first part of Theorem 1.1 follows.

To complete the proof of Theorem 1.1, we need the following lemmas.

LEMMA 4.1. *Let $h_{ex}=k_a|\ln\varepsilon|+o(|\ln\varepsilon|)$ and $\tilde{u}\in\overline{D_M^a}$ be a minimizer of $J_a(u)$ in $\overline{D_M^a}$. $\{(a_i,d_i)\}_{i=1}^k$ are the vortices of u^γ. Then $d_i=1$ for any $i\in\mathcal{J}=\{1,\dots,k\}$.*

Proof. Using the lower bound on W proved in Lemma 3.1 and returning to Lemma 2.13, we have

$$\pi\sum_{i\in\mathcal{J}}a(a_i)d_i^2|\ln\rho|+\pi\sum_{i\in\mathcal{J}}a(a_i)d_i\ln\frac{\rho}{\varepsilon}+O(1)\le\pi\sum_{d_i>0}a(a_i)d_i|\ln\varepsilon|+o(|\ln\varepsilon|).$$

This gives

$$\pi\sum_{i\in\mathcal{J}}a(a_i)(d_i^2-d_i)|\ln\rho|\le o(|\ln\varepsilon|).$$

Therefore we have from $\rho\ge\varepsilon^\mu$ that

$$\mu\sum_{i\in\mathcal{J}}a(a_i)(d_i^2-d_i)|\ln\varepsilon|\le\sum_{i\in\mathcal{J}}a(a_i)(d_i^2-d_i)|\ln\rho|\le o(|\ln\varepsilon|),$$

which implies

$$\mu \min_{\Omega} a(x) \sum_{i\in\mathcal{J}} (d_i^2 - d_i) \le o(1).$$

This inequality is impossible if there is a $d_i > 1$ for small ε. So when $\varepsilon \le \varepsilon_0$, we have $d_i = 1$ for all $i \in \mathcal{J}$. The lemma is proved. □

We are now closer to a complete proof of Theorem 1.1. Consider

$$H_{c_1} + k_3^\varepsilon \le h_{ex} \le k_a |\ln\varepsilon| + O(1),$$

where

$$H_{c_1} = k_a |\ln\varepsilon| + k_2^\varepsilon, \qquad k_a = 1/(2\max_{\Omega} |\xi_0(x)/a(x)|),$$

$k_2^\varepsilon = O(1)$, and $k_3^\varepsilon = o(1)$. Let

$$\Lambda = \left\{ x, x \in \Omega : \left| \frac{\xi_0(x)}{a(x)} \right| = \max_{y\in\Omega} \left| \frac{\xi_0(y)}{a(y)} \right| \right\}.$$

The proof of Theorem 1.1 can be obtained by proving the following three lemmas.

LEMMA 4.2. *Let $u \in \overline{D_M^a}$ be a minimizer of $J_a(u)$, and let (a_i, d_i) ($d_i = 1$ for all $i \in \mathcal{J}$) be the vortices of u^γ. Then*

$$\operatorname{dist}(a_i, \Lambda) \to 0, \text{ as } \varepsilon \to 0 \ \forall i \in \mathcal{J}, \tag{4.1}$$

$$\operatorname{dist}(a_i, a_j) \ge \alpha > 0 \ \forall i \ne j \in \mathcal{J}. \tag{4.2}$$

The first result is also true under the assumption $h_{ex} \le k_a |\ln\varepsilon| + o(|\ln\varepsilon|)$.

Proof. If $\mathcal{J} \ne \emptyset$, we have from Lemma 4.1 that $d_i = 1$ for all $i \in \mathcal{J}$. Now let $d = \sum_{i\in\mathcal{J}} d_i = \operatorname{Card}\mathcal{J} = \deg(u^\gamma, \partial\Omega)$. It follows from Step 1 in the proof of Lemma 3.1 and from Lemma 2.13 that

$$W(a_1, \dots, a_k) + \pi \sum_{i\in\mathcal{J}} a(a_i) |\ln\varepsilon| + O(1) \le F_a(u^\gamma) \le -2\pi h_{ex} \sum_{i\in\mathcal{J}} \xi_0(a_i) + o(|\ln\varepsilon|).$$

Then

$$2\pi h_{ex} \sum_{i\in\mathcal{J}} a(a_i) \left(\frac{\xi_0(a_i)}{a(a_i)} + \max_{\Omega} \left| \frac{\xi_0(x)}{a(x)} \right| \right) \le o(|\ln\varepsilon|).$$

Hence we have

$$\sum_{i\in\mathcal{J}} \left(\frac{\xi_0(a_i)}{a(a_i)} + \max_{\Omega} \left| \frac{\xi_0(x)}{a(x)} \right| \right) \le \frac{o(|\ln\varepsilon|)}{h_{ex}} \to 0.$$

This implies the first conclusion

$$\operatorname{dist}(a_i, \Lambda) \to 0, \text{ as } \varepsilon \to 0 \ \forall i \in \mathcal{J}.$$

Moreover, since $W(a_1, \dots, a_k) \ge O(1)$ and

$$W(a_1, \dots, a_k) + \pi \sum_{i\in\mathcal{J}} a(a_i) |\ln\varepsilon| + O(1) \le -2\pi h_{ex} \pi \sum_{i\in\mathcal{J}} \xi_0(a_i) + O(1),$$

we have $W(a_1,\dots,a_k)\le O(1)$ if $h_{ex}\le k_a|\ln\varepsilon|+O(1)$. Therefore we conclude that $|a_i-a_j|$ remains bounded from below uniformly, since as in [7] we could prove that $W\to+\infty$ if $|a_i-a_j|\to 0$ for some $i\neq j$. Lemma 4.2 is proved. □

LEMMA 4.3. *Let M, n satisfy Assumption* 1.1*, and let $\tilde u$ be a minimizer of $J_a(u)$ in $\overline{D_M^a}$; then $\tilde u$ satisfies* (1.3) *and $u=\tilde u$, where u is defined by $\tilde u$ as in Lemma* 2.3.

Proof. It suffices to prove that $\tilde u$ is not on the boundary of $\overline{D_M^a}$. Since we have proved that W is a bounded quantity and $\operatorname{dist}(a_i,a_j)\ge\alpha>0$, we get

$$\begin{aligned}\pi\sum_{i\in\mathcal{J}}a(a_i)|\ln\varepsilon|+O(1)&\le -2\pi h_{ex}\sum_{i\in\mathcal{J}}\xi_0(a_i)+O(1)\\&=2\pi h_{ex}\sum_{i\in\mathcal{J}}a(a_i)\,|\xi_0(a_i)/a(a_i)|+O(1)\\&\le\pi\sum_{i\in\mathcal{J}}a(a_i)|\ln\varepsilon|+O(1).\end{aligned}$$

This inequality and Lemma 2.3 yield that

$$F_a(u)=F_a(\tilde u)+o(1)=\pi\sum_{i\in\mathcal{J}}a(a_i)|\ln\varepsilon|+O(1)\le M|\ln\varepsilon|+O(1).$$

So, $\sum_{i\in\mathcal{J}}a(a_i)\le M/\pi$. It follows from Lemma 4.2 that as $\varepsilon\to0$, $a_i\to c_i\in\Lambda$. Then, for ε small enough, $d\le M/(\pi m_d)$, where $m_d=(\sum_{i\in\mathcal{J}}a(c_i))/d$ and

$$\frac{M}{\pi m_d}\in\left[\frac{M}{\pi\max\limits_{\Lambda}a(x)},\quad\frac{M}{\pi\min\limits_{\Lambda}a(x)}\right]\subset(n,n+1).$$

Thus, $M/(\pi m_d)$ is not an integer which implies $d<M/(\pi m_d)$. Hence $\pi\sum_{i\in\mathcal{J}}a(a_i)<M$ for $\varepsilon\le\varepsilon_0$. Thus, there is a positive number $\eta>0$ such that

$$F_a(\tilde u)\le\pi\sum_{i\in\mathcal{J}}a(a_i)|\ln\varepsilon|+O(1)\le(M-\eta)|\ln\varepsilon|,$$

which means that $\tilde u$ is not on $\partial\overline{D_M^a}$. The lemma is proved. □

REMARK 4.1. *It follows from the proof of Lemma* 4.3 *that $d<M/(\pi\max_\Lambda a(x))$. Otherwise, since we also have $d\min_\Lambda a(x)\le\sum_{i=1}^d a(a_i)\le M/\pi$, this implies that*

$$d\in\left[\frac{M}{\pi\max\limits_{\Lambda}a(x)},\quad\frac{M}{\pi\min\limits_{\Lambda}a(x)}\right]\subset(n,n+1);$$

then d is not an integer. This leads to a contradiction.

Now we may continue the proof of Theorem 1.1 with the following lemma. Once u is a solution of (1.3), we may show that $|\nabla u|\le C/\varepsilon$. Then u has bigger vortices of size ρ: $\{(b_i,q_i)\}_{i\in\mathcal{J}}$. The following lemma compares what we call the bigger vortices of u (i.e., the vortices of u^γ) with the real vortices of u. Its proof follows easily from the same arguments given in [23].

LEMMA 4.4. *For sufficiently small ε, we have*

(i) *if u is a solution of* (1.3) *such that $J_a(u)\le Ch_{ex}^2$, then $|u|\le1$ and there exists a constant $C>0$ such that $|\nabla u|\le C/\varepsilon$;*

(ii) *if u is a solution of* (1.3) *such that u^γ has no vortices (i.e., $|u^\gamma| \geq 1/2$) and $J_a(u) \leq J^0$, then u has no vortices on Ω ($|u| \geq 1/2$);*

(iii) *if u is a solution given in Theorem* 1.1*, then its vortices (of size ρ) satisfy the same conclusions as those of u^γ;*

(iv) *if, in addition, $\{a_i\}_{i\in\mathcal{J}}$ are the vortices of u^γ of degree one, then the vortices $\{b_i\}_{i\in\mathcal{J}}$ are also of degree one and Lemma* 2.7 *(on u^γ) is satisfied by u.*

The following lemma shows that the real vortices of u remain far from the boundary.

LEMMA 4.5. *If $u \in D_M^a$ is an energy minimizer satisfying* (1.3)*, then, for any $0 < \beta < 1$, $|u| \geq 1/2$ on $\{x \in \Omega : \mathrm{dist}(x, \partial\Omega) \leq \varepsilon^\beta\}$. Moreover, u has no zero degree vortex.*

Finally, since $\mathrm{dist}(a_i, \partial\Omega)$, $\mathrm{dist}(b_i, \partial\Omega)$ remain bounded from below by a positive constant and $\mathrm{dist}(a, b) \leq C\varepsilon^\gamma |\ln\varepsilon|$, we have for small ε that $\mathbb{R}^2$ is a hole of null multiplicity. This implies $\sum_i q_i = \sum_i q_i = \mathrm{Card}\mathcal{J}'$, and the b_i's tend to the a_i's with the same multiplicities. However, $\inf_{i\neq j} |a_i - a_j| \leq C|\ln\varepsilon|^{-\frac{1}{2}}$; comparing with $\mathrm{dist}(a, b) \leq C\varepsilon^\gamma |\ln\varepsilon|$, the b_i's must be of multiplicity one, and $q_i = 1$ for all $i \in \mathcal{J}'$. Theorem 1.1 is proved.

5. Proof of Theorem 1.2. In this section we derive the convergence of u_ε and the limit equation of (1.3). The case $d = 0$ is again trivial to consider; we omit the details. Now, for $H_{c_1} + k_3^\varepsilon \leq h_{ex} \leq H_{c_1} + O(1)$, let us consider a sequence $\varepsilon_n \to 0$ and denote $u_n = u_{\varepsilon_n}$ an associated solution of (1.3) given by Theorem 1.1.

We also denote $\{b_i\}_{i\in\mathcal{J}}$ the real vortices of u_n (see Lemma 4.4) of size $\lambda\varepsilon$, and $\{b_i\}_{i\in\mathcal{J}'\subset\mathcal{J}}$ its vortices of size ρ, exactly as we did for u^γ. (Again, the superscript ε in the notation of b_i is removed.) This means

$$|u_n| \geq 1/2 \ \text{ on } \Omega \setminus \cup_{i\in\mathcal{J}} B(b_i, \lambda\varepsilon) \ \text{ and on } \Omega \setminus \cup_{i\in\mathcal{J}'} B(b_i, \rho),$$
$$\cup_{i\in\mathcal{J}} B(b_i, \lambda\varepsilon) \subset \cup_{i\in\mathcal{J}'} B(b_i, \rho).$$

Extracting a subsequence if necessary, we may assume that $\mathrm{Card}\mathcal{J}' \equiv d \geq 1$ and

$$b_i^{\varepsilon_n} \to c_i \in \Lambda \ \text{ for } i \in \mathcal{J}'.$$

Here, we put back the superscript ε_n to avoid ambiguity. First, we prove that

$$|\ln\varepsilon_n|\nabla u_n \to 0, \quad \text{strongly in} \quad L^p(\Omega)\ \forall p < 2.$$

In fact, we may rewrite (1.3) as

$$-\nabla\cdot(a(x)\nabla u) + 2ia(x)A_0\cdot\nabla u = a(x)u\left[|A_0|^2 + \frac{1}{\varepsilon^2}(1 - |u|^2)\right]. \tag{5.1}$$

This equation is equivalent to the following system if we write locally $u = \rho e^{i\varphi}$:

$$\begin{cases} -\nabla\cdot(a(x)\nabla\rho) + a(x)\rho|\nabla\varphi|^2 - 2a\rho A_0\cdot\nabla\varphi = a(x)\rho(|A_0|^2 + \frac{1-\rho^2}{\varepsilon^2}), \\ -\nabla\cdot(a(x)\rho^2\nabla\varphi) + a(x)A_0\cdot\nabla\rho^2 = 0. \end{cases} \tag{5.2}$$

Define

$$\overline{\rho} = \max\{\rho, 1 - |\ln\varepsilon|^{-4}\} \geq 1 - |\ln\varepsilon|^{-4}, \quad K = \{x \in \Omega, \rho \geq 1 - |\ln\varepsilon|^{-4}\};$$

then $\nabla\overline{\rho} = \nabla\rho$ on K, and $\nabla\overline{\rho} = 0$ on $\Omega \setminus K$. It follows from

$$\frac{1}{\varepsilon^2}\int_\Omega (1-\rho)^2 \le \frac{1}{\varepsilon^2}\int_\Omega (1-\rho^2)^2 \le C|\ln\varepsilon|^2$$

that $\mathrm{meas}(\Omega \setminus K) \le C\varepsilon^2|\ln\varepsilon|^{10}$.

Multiplying the first equation in (5.2) by $1-\overline{\rho}$, and integrating over Ω, we get

$$2\int_K a(x)\rho|\nabla\rho|^2 \le C\int_\Omega a(x)(1-\overline{\rho})\rho[|A_0|^2 + |A_0||\nabla u|] \le C\|1-\overline{\rho}\|_{L^\infty}|\ln\varepsilon|^2.$$

This inequality, together with the fact $0 \le 1-\overline{\rho} \le |\ln\varepsilon|^{-4}$, yields

$$\int_K |\nabla\rho|^2 \le C/|\ln\varepsilon|^2 \to 0.$$

On the other hand, we have for $p < 2$

$$\begin{aligned}\int_{\Omega\setminus K}|\nabla\rho|^p &\le \left(\int_{\Omega\setminus K}|\nabla\rho|^2\right)^{p/2}\mathrm{meas}(\Omega\setminus \mathrm{K})^{1-p/2}\\ &\le C\varepsilon^{2-p}|\ln\varepsilon|^{10-4p} \le C/|\ln\varepsilon|^2 \to 0.\end{aligned}$$

Combining the above two estimates, we have

$$\int_\Omega |h_{ex}\nabla\rho|^p \le \frac{C}{|\ln\varepsilon|^{2-p}} \to 0. \tag{5.3}$$

Now we rewrite the second equation of (5.2) as

$$-\nabla\cdot(a(x)\rho^2\nabla\varphi) = f(x),$$

where $f(x) = -a(x)A_0\cdot\nabla\rho^2$. Since $a(x)A_0 = h_{ex}\nabla^\perp\xi_0$ is a smooth function, we have

$$\int_\Omega |f(x)|^p \le C/|\ln\varepsilon|^{2-p}.$$

Hence we have

$$\int_\Omega |h_{ex}\nabla\varphi|^p \le C/|\ln\varepsilon|^{2-p} \to 0. \tag{5.4}$$

The estimates (5.3) and (5.4) yield

$$\int_\Omega |h_{ex}\nabla u|^p \to 0.$$

It follows that, for any smooth test function $\phi \in C_0^\infty(\Omega)$,

$$2i\int_\Omega a\,\phi A_0\cdot\nabla u = 2i\int_\Omega(\phi\nabla^\perp\xi_0)\cdot(h_{ex}\nabla u) \to 0 \tag{5.5}$$

since we may take $(\phi\nabla^\perp\xi_0) \in L^q(\Omega)$ for any $q > 2$.

Let s be a positive integer. As in the proofs of Lemmas 2.12 and 2.13, by solving an auxiliary problem, we may get

$$\int_{B(c_i,\frac{1}{s})\setminus B(b_i,\rho)} a(x)|\nabla u_n|^2 \geq \pi a(b_i)|\ln\rho| + O(1) \qquad \forall i \in \mathcal{J}'$$

and

$$\int_{B(b_i,\rho)} e_\varepsilon(u_n) \geq \pi a(b_i)\ln\frac{\rho}{\varepsilon} + O(1) \qquad \forall i \in \mathcal{J}'.$$

These two inequalities yield

$$\int_{B(c_i,\frac{1}{s})} e_\varepsilon(u_n) \geq \pi a(b_i)|\ln\varepsilon| + O(1) \quad \forall i \in \mathcal{J}'.$$

On the other hand, we have

$$F_a(u) \leq \pi\sum_{i=1}^{d} a(a_i)|\ln\varepsilon| + O(1) \leq \pi\sum_{i=1}^{d} a(b_i)|\ln\varepsilon| + O(1),$$

where we have used $\mathrm{dist}(a,b) \leq C\varepsilon^\gamma|\ln\varepsilon|$ (see Lemma 2.9). We finally get

$$\int_{B(c_i,\frac{1}{s})} |\nabla u_n|^2 \leq C.$$

Extracting a subsequence if necessary, there exists u_* such that

$$u_n \to u_* \text{ weakly in } H^1(\Omega \setminus \cup_{i=1}^d B(c_i,1/s)). \tag{5.6}$$

By standard diagonal extraction, we may find a subsequence such that this is true for any positive integer s. $|u_*| = 1$ follows from

$$\int_\Omega (1-|u_n|^2)^2 \leq C\varepsilon^2|\ln\varepsilon|^2.$$

Taking the cross product of (5.1) with u, we get

$$u_n \times [-\nabla\cdot(a(x)\nabla u_n) + 2ia(x)A_0\cdot\nabla u_n] = 0.$$

Using (5.5) and (5.6), we have from the above that u_* solves

$$u_* \times (\nabla\cdot(a(x)\nabla u_*)) = 0 \ \text{ in } \ \mathcal{D}'(\Omega\setminus\cup\{c_i\}).$$

Now it is easy to get the limit (1.12) from the above inequality. Theorem 1.2 is proved.

Acknowledgment. The authors would like to thank an anonymous referee for helpful suggestions.

THE LIFSHITZ–SLYOZOV–WAGNER EQUATION WITH CONSERVED TOTAL VOLUME*

PHILIPPE LAURENÇOT†

Abstract. The Lifshitz–Slyozov–Wagner theory of coarsening (Ostwald ripening) in alloys describes the time evolution of the sizes of the grains of a new phase growing by diffusional mass transfer from a supersaturated solid solution. The volume distribution function of the grains obeys a nonlinear transport equation with a nonlocal nonlinearity. Global existence of solutions is obtained for a large class of data including the ones derived by Lifshitz and Slyozov [*J. Phys. Chem. Solids*, 19 (1961), pp. 35–50] and Wagner [*Z. Elektrochem.*, 65 (1961), pp. 581–591], and uniqueness of these solutions is proved in some cases.

Key words. Lifshitz–Slyozov model, Ostwald ripening, existence, uniqueness

1. Introduction. The theory of coarsening (Ostwald ripening) in alloys describes the late stages of the formation and growth of grains of a new phase from a supersaturated solid solution. During these stages, no new grains can form and the determining process is the growth of the grains by diffusional mass exchange [6, 11]. More precisely, the grains of the new phase larger than some critical size grow at the expense of smaller ones, the critical size varying in time as a function of the degree of supersaturation. A mean-field approach for this process has been formulated by Lifshitz and Slyozov [6] and Wagner [11]. The resulting model consists of an evolution equation for the volume distribution function f of the grains coupled with the equation of the conservation of matter and reads, for spherical grains,

$$f_t + (\mathcal{V}\ f)_x = 0, \quad (t,x) \in (0,+\infty) \times (0,+\infty),$$
$$u(t) + A \int_0^\infty x\ f(t,x)\ dx = Q, \quad t \in (0,+\infty).$$

Here $x \in (0,+\infty)$ is the volume of the grains, $t \in (0,+\infty)$ is the time variable, Q is the total initial supersaturation, and A is a physical constant [6]. Finally $\mathcal{V} = \mathcal{V}(t,x)$ denotes the rate of growth of the grains and is determined by the mechanism of mass transfer between the grains, e.g., volume diffusion [6, 11] or grain-boundary diffusion [9]. In general one has $\mathcal{V}(t,x) = k(x)u(t) - q(x)$, where k and q are computed from the modeling of the mechanism of mass transfer between the grains [6, 9, 11], and the Lifshitz–Slyozov–Wagner equation reads

$$f_t + ((ku - q)\ f)_x = 0, \quad (t,x) \in (0,+\infty) \times (0,+\infty), \tag{1}$$
$$u(t) + A \int_0^\infty x\ f(t,x)\ dx = Q, \quad t \in (0,+\infty). \tag{2}$$

For instance, in the model considered in [6], the grains are assumed to be widely separated spheres evolving in a quasi-static diffusion field. The interaction between

*Received by the editors April 6, 2001; accepted for publication (in revised form) April 11, 2002; published electronically October 8, 2002.

the grains is ignored and the diffusion field is taken to be close to the degree of supersaturation far from the grains. Assuming the growth rate of the grains to be proportional to the mass flux at the grain boundary, it can be computed explicitly [6] and reads, in dimensionless form,

$$\mathcal{V}(t,x) = 3\ \left(x^{1/3}\ u(t) - 1 \right),$$

that is, $k(x) = 3\ x^{1/3}$ and $q(x) = 3$, $x \in (0,+\infty)$.

For very dilute solutions a physically relevant assumption at large times is that the variation of the degree of supersaturation is small during the time evolution and the equation of conservation of matter (2) becomes [11]

$$\int_0^\infty x\ f(t,x)\ dx = \text{ const.}, \quad t \in (0,+\infty).$$

In that case the function u is determined by requiring that the solution f to (1) comply with the above conservation law, that is,

$$u(t)\ \int_0^\infty k(x)\ f(t,x)\ dx = \int_0^\infty q(x)\ f(t,x)\ dx, \quad t \in (0,+\infty).$$

The aim of this work is thus to investigate the existence and uniqueness of weak solutions to the initial value problem

$$f_t + ((ku - q)\ \ f)_x = 0, \quad (t,x) \in (0,+\infty) \times (0,+\infty), \tag{3}$$

$$u(t)\ \int_0^\infty k(x)\ f(t,x)\ dx = \int_0^\infty q(x)\ f(t,x)\ dx, \quad t \in (0,+\infty), \tag{4}$$

$$f(0,x) = f_0(x), \quad x \in (0,+\infty). \tag{5}$$

The initial value problem (3)–(5) is a nonlinear transport equation with a nonlocal nonlinearity. Observe, however, that the main difference between (2) and (4) is that u is a linear functional of f in the former, while it is a nonlinear functional of f in the latter. It is thus expected that the initial value problem (3)–(5) will be more delicate to handle than the initial value problem (3), (2), and (5). Still, existence and uniqueness of measure-valued solutions are proved by Niethammer and Pego when k and q are given by

$$k(x) = 3\ x^{1/3} \quad \text{and} \quad q(x) = 3, \quad x \in (0,+\infty), \tag{6}$$

the initial datum f_0 being a probability measure with compact support [7]. The extension of this result to an arbitrary probability measure is performed in [8]. To our knowledge these are the only available existence and uniqueness results for (3)–(5), and the purpose of this work is to investigate the existence and uniqueness of solutions to (3)–(5) for a larger class of functions k and q, including the ones derived in [6], which are given by (6), and the ones derived in [11], namely,

$$k(x) = \frac{a\ x^{2/3}}{c\ x^{1/3} + d} \quad \text{and} \quad q(x) = \frac{b\ x^{1/3}}{c\ x^{1/3} + d}, \quad x \in (0,+\infty), \tag{7}$$

where a, b, c, and d are positive real numbers. Our analysis relies on different arguments than the ones developed in [7] and actually includes the following typical example (which generalizes the Lifshitz–Slyozov case (6)):

$$k(x) = a\ x^{\alpha} \quad \text{and} \quad q(x) = b\ x^{\beta}, \quad x \in (0, +\infty), \tag{8}$$

where $0 \le \beta < \alpha \le 1$ and a, b are positive real numbers. We will, however, restrict ourselves to nonnegative and integrable initial data with finite first moment and do not consider the case of measures. Before going further, let us mention that the initial value problem (3), (2), and (5) has been studied recently, and existence and uniqueness of measure-valued and integrable solutions have been obtained in [1, 7] and [1, 4], respectively.

We now briefly outline the contents of the paper and sketch the main ideas of the existence proof as well. In the next section we state the assumptions on the data k, q, and f_0 together with our main results. The case where the functions k and q are given by (8) is included in our analysis, and we prove the existence of a solution to (3)–(5) when $0 \le \beta < \alpha \le 1$ for any nonnegative and integrable initial datum f_0 with finite first moment. In addition, this solution is shown to be unique if $\beta > 0$ or $(\alpha, \beta) = (1, 0)$. Thus, our uniqueness result unfortunately does not apply to the Lifshitz–Slyozov case (6). Nevertheless our results apply when k and q are given by (7) and provide also the existence and uniqueness of a solution to (3)–(5) in that case. The existence proof is inspired by the derivation of (3)–(5) performed in [11] and may be seen somehow as a penalization method. More precisely, we consider $\varepsilon \in (0, 1)$ and denote by $(f^{\varepsilon}, u^{\varepsilon})$ the solution to (3), (2), and (5), where we have chosen

$$A_{\varepsilon} = \varepsilon^{-1} \quad \text{and} \quad Q_{\varepsilon} = \varepsilon^{-1} \int_0^{\infty} x\ f_0(x)\ dx.$$

Then (2) reads

$$\varepsilon\ u^{\varepsilon}(t) = \int_0^{\infty} x\ f_0(x)\ dx - \int_0^{\infty} x\ f^{\varepsilon}(t,x)\ dx, \quad t \in [0, +\infty),$$

and it is easily seen (at least formally) that the above equation yields (4) as $\varepsilon \to 0$. We might thus expect that the sequence $(f^{\varepsilon}, u^{\varepsilon})$ will converge to a solution to (3)–(5), and this turns out to be true as we shall see below. We thus recall in section 3.1 some results for (3), (2), and (5) previously obtained in [4], namely, the existence of solutions together with some estimates which will be needed later. Section 3.2 is devoted to the main step of the existence proof, namely, an L^{∞}-bound for u^{ε} which is uniform with respect to $\varepsilon \in (0, 1)$. Thanks to this bound, we may argue as in [4] and prove that (f^{ε}) enjoys some weak compactness properties in $L^1(0, +\infty; x dx)$ with the help of a refined version of the de la Vallée–Poussin theorem [5]. Equicontinuity with respect to time then follows from (3) and allows us to complete the proof of the existence result in section 3.3. Uniqueness of solutions to (3)–(5) is investigated in the final section and requires stronger assumptions on the functions k and q.

Remark. The above choice of Q_{ε} entails that $u^{\varepsilon}(0) = 0$ and is made throughout the paper for simplicity. However, the convergence of $(f^{\varepsilon}, u^{\varepsilon})$ shown in section 3 is still valid with $Q_{\varepsilon} = Q_{\varepsilon}^0/\varepsilon$, (Q_{ε}^0) being a nondecreasing sequence satisfying

$$\lim_{\varepsilon \to 0} Q_{\varepsilon}^0 = \int_0^{\infty} x\ f_0(x)\ dx.$$

2. Main results. We first describe the class of functions f_0, k, and q to be considered in this paper. More precisely, we assume that the data f_0, k, and q enjoy the following properties:

$$f_0 \in L^1(\mathbb{R}_+;(1+x)dx) \quad \text{and} \quad f_0 \ge 0 \ \text{ a.e. in } \ \mathbb{R}_+, \tag{9}$$

where $\mathbb{R}_+ = (0,+\infty)$.

$$\begin{cases} \text{The function } k \text{ is a nonnegative function in } \mathcal{C}([0,+\infty)) \cap \mathcal{C}^1(\mathbb{R}_+) \\ \text{satisfying } k(0)=0,\ k(r)>0 \text{ if } r>0 \text{ and} \\ \qquad k' \in L^\infty(1,+\infty) \quad \text{and} \quad k' \ge 0, \\ \qquad r \mapsto \dfrac{k(r)}{r} \ \text{ is nonincreasing on } \ \mathbb{R}_+. \end{cases} \tag{10}$$

$$\begin{cases} \text{The function } q \text{ is a nonnegative function in } \mathcal{C}([0,+\infty)) \cap \mathcal{C}^1(\mathbb{R}_+) \\ \text{and satisfies} \\ \qquad q' \in L^\infty(1,+\infty) \quad \text{and} \quad q' \ge 0. \end{cases} \tag{11}$$

In other words the functions k and q are Lipschitz continuous functions for large values of x and might be less regular near $x=0$ but are nondecreasing. Note also that since $k(0)=0$ and q is nonnegative, no boundary condition is needed at $x=0$ to solve (3).

We also assume that for every $U \ge 0$, there exists $x_U \in (0,1]$ such that

$$U\ k(x) - q(x) \le -x\ q'(x), \quad x \in (0,x_U]. \tag{12}$$

In particular, q' being nonnegative by (11), we infer from (12) that

$$\lim_{x\to 0} \frac{q(x)}{k(x)} = +\infty. \tag{13}$$

Let us point out here that the functions k and q given by (6) (see [6]) and (7) (see [11]) fulfill the assumptions (10)–(12) and the functions k and q given by (8) as well (since $0 \le \beta < \alpha \le 1$).

Remark. The assumption that k and q are nondecreasing may actually be relaxed, and the results presented below are also true for Lipschitz continuous perturbations of nondecreasing functions k and q. We restrict ourselves, however, to the framework described above for simplicity and refer to [4], where this more general class of data is considered for the initial value problem (3), (2), and (5).

We are now in a position to state our existence result.

THEOREM 1. *Consider a function f_0 satisfying* (9) *and assume that the functions k and q enjoy the properties* (10)–(12). *There are at least a couple of nonnegative functions (f,u) satisfying*

$$\begin{cases} f \in \mathcal{C}([0,t];L^1(\mathbb{R}_+;xdx)) \cap L^\infty(0,t;L^1(\mathbb{R}_+)), \\ u \in L^\infty(0,t) \end{cases} \tag{14}$$

and

$$\int_0^\infty f(t,x)\ g(x)\ dx = \int_0^\infty f_0(x)\ g(x)\ dx + \int_0^t \int_0^\infty g_x(x)\ \mathcal{V}(s,x)\ f(s,x)\ dxds \tag{15}$$

for each $t \in \mathbb{R}_+$ *and* $g \in \mathcal{C}_0^\infty(\mathbb{R}_+)$, *where*

$$\mathcal{V}(t,x) = k(x)\ u(t) - q(x), \quad x \in \mathbb{R}_+, \tag{16}$$

$$u(t) \int_0^\infty k(x)\ f(t,x)\ dx = \int_0^\infty q(x)\ f(t,x)\ dx, \tag{17}$$

or, equivalently,

$$\int_0^\infty x\ f(t,x)\ dx = \int_0^\infty x\ f_0(x)\ dx. \tag{18}$$

Note that (15) makes sense since the continuity of k, q, and (14) ensure that $\mathcal{V} \in L^\infty((0,T) \times \mathcal{K})$ for every compact subset $\mathcal{K}$ of $\mathbb{R}_+$ and $T \in \mathbb{R}_+$. Let us also mention here that, in the proof of Theorem 1, we first obtain that $f \in \mathcal{C}([0,+\infty); w - L^1(\mathbb{R}_+; xdx))$. Here we use the following notation: if X is a Banach space and $T \in (0,+\infty]$, then $\mathcal{C}([0,T); w - X)$ denotes the space of weakly continuous functions from $[0,T)$ in X. The time continuity (14) of f in the strong topology of $L^1(\mathbb{R}_+; xdx)$ then follows from (3) by arguments similar to those of [3, sections II.1 and II.2].

If we strengthen the assumptions on the data k and q, we are able to show that there is only one solution to (3)–(5) with the properties stated in Theorem 1.

THEOREM 2. *Assume that* f_0, k, *and* q *fulfill* (9)–(12) *and that*

$$\sup_{x \in (0,+\infty)} (U\ k'(x) - q'(x)) < +\infty \tag{19}$$

for each $U \in \mathbb{R}_+$. *Then there are a unique couple of nonnegative functions* (f,u) *satisfying* (14)–(17).

Clearly the functions k and q given by (8) satisfy (19) only if $0 < \beta < \alpha \leq 1$ or $(\alpha,\beta) = (1,0)$, which unfortunately excludes the Lifshitz–Slyozov case (6). The assumption (19) is also fulfilled in the Wagner case (7) and guarantees that $\mathcal{V}_x$ is bounded from above on $(0,T) \times \mathbb{R}_+$ for each $T > 0$.

From now on we assume that f_0, k, and q are given functions satisfying (9)–(12). Since $f \equiv 0$ is clearly a solution to (3)–(5) with initial datum $f_0 \equiv 0$, we further assume that $f_0 \not\equiv 0$ and put

$$M_0 := \int_0^\infty x\ f_0(x)\ dx > 0.$$

In the following we denote by C any positive constant depending only on f_0, k, and q. The dependence of C upon additional parameters will be indicated explicitly.

3. Existence.

3.1. The approximating equation. For $\varepsilon \in (0,1)$ we put

$$A_\varepsilon = \varepsilon^{-1} \quad \text{and} \quad Q_\varepsilon = \varepsilon^{-1} \int_0^\infty x\ f_0(x)\ dx. \tag{20}$$

Owing to (9)–(12) and (20), we are in a position to apply [4, Theorem 2.2, Propositions 3.1 and 3.3] to obtain the existence of a weak solution to (3), (2), and (5) with initial datum f_0 and $(A_\varepsilon, Q_\varepsilon)$ instead of (A,Q). More precisely, we have the following result.

PROPOSITION 3. *For $\varepsilon \in (0,1)$ there is a nonnegative function*

$$f^\varepsilon \in \mathcal{C}([0,+\infty); L^1(\mathbb{R}_+; x dx)) \cap L^\infty(0,+\infty; L^1(\mathbb{R}_+)) \tag{21}$$

satisfying for each $t \in \mathbb{R}_+$ and $g \in \mathcal{C}_0^\infty(\mathbb{R}_+)$

$$A_\varepsilon \int_0^\infty x\ f^\varepsilon(t,x)\ dx \le Q_\varepsilon, \tag{22}$$

$$\begin{aligned} \int_0^\infty f^\varepsilon(t,x)\ g(x)\ dx &= \int_0^\infty f_0(x)\ g(x)\ dx \\ &\quad + \int_0^t \int_0^\infty g_x(x)\ \mathcal{V}^\varepsilon(s,x)\ f^\varepsilon(s,x)\ dxds, \end{aligned} \tag{23}$$

where

$$\mathcal{V}^\varepsilon(t,x) = k(x)\ u^\varepsilon(t) - q(x), \quad x \in \mathbb{R}_+, \tag{24}$$

$$u^\varepsilon(t) + A_\varepsilon \int_0^\infty x\ f^\varepsilon(t,x)\ dx = Q_\varepsilon. \tag{25}$$

In addition,

$$\int_0^\infty f^\varepsilon(t,x)\ dx \le \int_0^\infty f^\varepsilon(s,x)\ dx \le \int_0^\infty f_0(x)\ dx, \quad 0 \le s \le t. \tag{26}$$

Notice that (22) warrants that u^ε is nonnegative, while (25) also reads

$$\varepsilon\ u^\varepsilon(t) + \int_0^\infty x\ f^\varepsilon(t,x)\ dx = \int_0^\infty x\ f_0(x)\ dx, \quad t \in [0,+\infty). \tag{27}$$

From the analysis of [4] we also deduce some estimates on the moments of f^ε, together with some integrability properties. We first introduce the set $\mathcal{J}_\infty$ of nonnegative and convex functions $j : [0,+\infty) \longrightarrow [0,+\infty)$ such that

$$\begin{cases} j \in \mathcal{C}^1([0,+\infty)) \cap W^{2,\infty}_{\rm loc}(\mathbb{R}_+) \text{ with } j(0) = 0 \text{ and } j'(0) \ge 0,\ j' \text{ is a} \\ \text{concave function on } [0,+\infty) \text{ and} \\ \qquad \displaystyle\lim_{r\to+\infty} j'(r) = \lim_{r\to+\infty} \frac{j(r)}{r} = +\infty. \end{cases} \tag{28}$$

The next result follows at once from [4, Lemma 3.4] and provides a control on the propagation of moments of f^ε.

LEMMA 4. *Let $\varepsilon \in (0,1)$ and $T \in \mathbb{R}_+$. Assume that there are a function $j \in \mathcal{J}_\infty$ and a real number U such that*

$$M = \int_0^\infty j(x)\ f_0(x)\ dx < +\infty \quad \text{and} \quad \sup_{t\in[0,T]} \{u^\varepsilon(t)\} \le U. \tag{29}$$

There is a constant K_1 depending only on k, q, f_0, j, M, U, x_U, and T such that

$$\int_0^\infty j(x)\ f^\varepsilon(t,x)\ dx \le K_1, \quad t \in [0,T]. \tag{30}$$

Notice that since j is superlinear at infinity, Lemma 4 allows us to control the behavior of f^ε for large values of x. As for the local behavior of f^ε we have the following result, which is a consequence of [4, Lemma 3.5].

LEMMA 5. *Let $\varepsilon \in (0,1)$ and $T \in \mathbb{R}_+$. Assume that there are a function $j \in \mathcal{J}_\infty$ and a real number U such that*

$$M = \int_0^\infty j\left(f_0(x)\right)\ x\ dx < +\infty \quad \text{and} \quad \sup_{t\in[0,T]} \{u^\varepsilon(t)\} \le U. \tag{31}$$

There is a constant K_2 depending only on k, q, f_0, j, M, U, x_U, and T such that

$$\int_0^\infty j\left(f^\varepsilon(t,x)\right)\ \min(x,1)\ dx \le K_2, \quad t \in [0,T]. \tag{32}$$

Here again the superlinearity of j at infinity ensures that $f^\varepsilon(t)$ cannot concentrate on a small measurable subset of $\mathbb{R}_+$ and thus excludes the formation of Dirac masses. We thus conclude from the previous results that if f_0 enjoys the integrability properties (29) and (31) and if the sequence (u^ε) is uniformly bounded in $L^\infty(0,T)$, the sequence $(f^\varepsilon(t))$ is uniformly integrable in $L^1(\mathbb{R}_+; xdx)$ for $t \in [0,T]$, whence it is weakly compact in $L^1(\mathbb{R}_+; xdx)$ by the Dunford–Pettis theorem. Therefore an L^∞-bound on u^ε seems to be an important step towards the proof of Theorem 1 and is derived in the next section.

3.2. An L^∞-estimate for u^ε. We now turn to the cornerstone of the proof of Theorem 1 and prove the following result.

LEMMA 6. *Let $T \in \mathbb{R}_+$. There are $\varepsilon(T) \in (0,1)$ and $C(T)$ such that there holds*

$$u^\varepsilon(t) \le C(T)$$

for every $\varepsilon \in (0, \varepsilon(T))$ and $t \in [0,T]$.

Proof. The proof of Lemma 6 actually splits into two parts and depends on the compactness or noncompactness of the support of f_0.

Case 1. We first consider the case where

$$\int_x^\infty f_0(y)\ dy > 0 \tag{33}$$

for every $x \in \mathbb{R}_+$ (i.e., f_0 is not compactly supported). It follows from (23), (24), and (25) that

$$\frac{du^\varepsilon}{dt}(t) + \frac{1}{\varepsilon}\ \left(\int_0^\infty k(x)\ f^\varepsilon(t,x)\ dx\right)\ u^\varepsilon(t) = \frac{1}{\varepsilon}\ \int_0^\infty q(x)\ f^\varepsilon(t,x)\ dx.$$

Owing to (11), there holds $q(x) \le C\ (1+x)$ for $x \in \mathbb{R}_+$, and the right-hand side of the above equality can be bounded from above with the help of (25) and (26) by

$$\frac{1}{\varepsilon}\ \int_0^\infty q(x)\ f^\varepsilon(t,x)\ dx \le \frac{C}{\varepsilon}\ \int_0^\infty (1+x)\ f^\varepsilon(t,x)\ dx \le \frac{C}{\varepsilon}\ \int_0^\infty (1+x)\ f_0(x)\ dx.$$

Therefore,

$$\frac{du^\varepsilon}{dt}(t) + \frac{1}{\varepsilon}\ \left(\int_0^\infty k(x)\ f^\varepsilon(t,x)\ dx \right)\ u^\varepsilon(t) \le \frac{C}{\varepsilon}. \tag{34}$$

We now introduce the function F^ε defined by

$$F^\varepsilon(t,x) = \int_x^\infty f^\varepsilon(t,y)\ dy, \quad (t,x) \in [0,+\infty) \times \mathbb{R}_+.$$

Owing to (21) and (23), we have $F_t^\varepsilon = \mathcal{V}^\varepsilon\ f^\varepsilon$, and the nonnegativity of k, u^ε, and f^ε further entails that $F_t^\varepsilon \ge -q\ f^\varepsilon$. Since $q(x) \le C\ (1+x)$ for $x \in \mathbb{R}_+$ by (11) and $f^\varepsilon = -F_x^\varepsilon$, we end up with

$$F_t^\varepsilon \ge C\ (1+x)\ F_x^\varepsilon,$$

whence

$$F^\varepsilon(t,x) \ge F^\varepsilon\left(0, (1+x)\ e^{Ct} - 1\right), \quad (t,x) \in [0,+\infty) \times \mathbb{R}_+.$$

Since k satisfies (10) with $k(0) = 0$, we deduce from the above estimate that

$$\begin{aligned} \int_0^\infty k(x)\ f^\varepsilon(t,x)\ dx &\ge \int_{e^{-Ct}}^\infty k(x)\ f^\varepsilon(t,x)\ dx \\ &\ge k\left(e^{-Ct}\right)\ F^\varepsilon\left(t, e^{-Ct}\right) \\ &\ge k\left(e^{-Ct}\right)\ F^\varepsilon\left(0, e^{Ct}\right) \\ &\ge k\left(e^{-CT}\right)\ \int_{e^{CT}}^\infty f_0(y)\ dy. \end{aligned}$$

Recalling (34), we finally obtain

$$\frac{du^\varepsilon}{dt}(t) + \frac{\delta(T)}{\varepsilon}\ u^\varepsilon(t) \le \frac{C}{\varepsilon}$$

with

$$\delta(T) := k\left(e^{-CT}\right)\ \int_{e^{CT}}^\infty f_0(y)\ dy.$$

Thanks to (10) and (33) we have $\delta(T) > 0$, and the differential inequality satisfied by u^ε yields

$$u^\varepsilon(t) \le \frac{C}{\delta(T)}, \quad t \in [0,T].$$

Recall that $u^\varepsilon(0) = 0$ by (20) and (25). We have thus proved Lemma 6 for noncompactly supported initial data (with $\varepsilon(T) = 1$).

Case 2. We now turn to the case of a compactly supported initial datum f_0 and assume that $f_0(x) = 0$ a.e. in $(R_0, +\infty)$ for some $R_0 > 0$. We first notice that the previous proof does not work in that case as $\delta(T)$ vanishes for T large enough. Since (3) is a transport equation, we actually expect $f^\varepsilon(t)$ to be compactly supported for each $t \geq 0$, and the proof of Lemma 6 relies on an estimate of the growth of the support of f^ε, which we derive now.

LEMMA 7. *There is a unique couple* $(R_\varepsilon, \tau_\varepsilon)$ *in* $\mathcal{C}([0,+\infty)) \times (0,+\infty]$ *satisfying* $R_\varepsilon(0) = R_0$, $R_\varepsilon(t) > 0$ *if* $t \in [0, \tau_\varepsilon)$, $R_\varepsilon \in \mathcal{C}^1([0,\tau_\varepsilon))$, *and*

$$\begin{cases} \dfrac{dR_\varepsilon}{dt}(t) = \mathcal{V}^\varepsilon\left(t, R_\varepsilon(t)\right) & \text{if} \quad t \in [0, \tau_\varepsilon), \\ \\ R_\varepsilon(t) = 0 & \text{if} \quad t \geq \tau_\varepsilon. \end{cases} \tag{35}$$

In addition, the support of $f^\varepsilon(t)$ *is included in* $[0, R_\varepsilon(t)]$ *for each* $t \geq 0$.

Proof of Lemma 7. First we remark that $\mathcal{V}^\varepsilon$ is continuous on $[0,+\infty)^2$ and Lipschitz continuous with respect to x on compact subsets of $[0,+\infty)\times\mathbb{R}_+$. Since $R_0 > 0$, classical results ensure that there is a unique maximal solution $R_\varepsilon \in \mathcal{C}^1([0,\tau_\varepsilon);\mathbb{R}_+)$ to

$$\frac{dR_\varepsilon}{dt}(t) = \mathcal{V}^\varepsilon\left(t, R_\varepsilon(t)\right), \quad R_\varepsilon(0) = R_0,$$

and we have the following alternative: either $\tau_\varepsilon = +\infty$, or $\tau_\varepsilon < +\infty$ and the only possible cluster points of $R_\varepsilon(t)$ as $t \to \tau_\varepsilon-$ are 0 and $+\infty$. In the latter case, notice that (10), (11), and (25) entail that

$$\frac{dR_\varepsilon}{dt}(t) \leq C\ Q_\varepsilon\ \left(1 + R_\varepsilon(t)\right), \quad t \in [0, \tau_\varepsilon),$$

which excludes the possibility of blow-up as $t \to \tau_\varepsilon-$. Consequently $R_\varepsilon(t)$ converges to 0 as $t \to \tau_\varepsilon-$, and we extend R_ε to $[0,+\infty)$ by putting $R_\varepsilon(t) = 0$ for $t \geq \tau_\varepsilon$. The estimate for the support of $f^\varepsilon(t)$ then follows by standard arguments if $t \in [0,\tau_\varepsilon)$. If $\tau_\varepsilon < +\infty$, we further obtain that $f^\varepsilon(\tau_\varepsilon) \equiv 0$, whence $f^\varepsilon(t) \equiv 0$ for $t \geq \tau_\varepsilon$ by (26), and the proof of Lemma 7 is complete. □

We are now in a position to complete the proof of Lemma 6. Let $T \in \mathbb{R}_+$ and consider $t \in [0,T]$ such that $t < \tau_\varepsilon$. We infer from (10) and (27) that

$$\begin{aligned} \int_0^\infty k(x)\ f^\varepsilon(t,x)\ dx &= \int_0^{R_\varepsilon(t)} \frac{k(x)}{x}\ x\ f^\varepsilon(t,x)\ dx \\ &\geq \frac{k\left(R_\varepsilon(t)\right)}{R_\varepsilon(t)}\ \int_0^{R_\varepsilon(t)} x\ f^\varepsilon(t,x)\ dx \\ &\geq \frac{k\left(R_\varepsilon(t)\right)}{R_\varepsilon(t)}\ \int_0^{\infty} x\ f^\varepsilon(t,x)\ dx \\ &\geq \frac{k\left(R_\varepsilon(t)\right)}{R_\varepsilon(t)}\ \left(M_0 - \varepsilon\ u^\varepsilon(t)\right). \end{aligned}$$

Recalling (34) and (35), we obtain the following system of differential inequalities for $(u^\varepsilon, R_\varepsilon)$:

$$\frac{du^\varepsilon}{dt}(t) + \frac{k\left(R_\varepsilon(t)\right)}{R_\varepsilon(t)}\ \left(\frac{M_0}{\varepsilon} - u^\varepsilon(t)\right)\ u^\varepsilon(t) \leq \frac{C}{\varepsilon}, \tag{36}$$

$$\frac{dR_\varepsilon}{dt}(t) \leq \frac{k\left(R_\varepsilon(t)\right)}{R_\varepsilon(t)}\ u^\varepsilon(t)\ R_\varepsilon(t), \tag{37}$$

which is valid for $t \in [0,T] \cap [0,\tau_\varepsilon)$. Since $u^\varepsilon(0) = 0$ by (20), we have

$$\sigma_\varepsilon := \sup \left\{ t \in [0,T] \cap [0,\tau_\varepsilon),\ \ u^\varepsilon(s) \le \frac{M_0}{2\ \varepsilon} \ \text{ for } \ s \in [0,t) \right\} > 0.$$

Assume for contradiction that $\sigma_\varepsilon < \min\{T, \tau_\varepsilon\}$. On the one hand, we infer from (36) that

$$\frac{du^\varepsilon}{dt}(t) + \frac{M_0}{2\ \varepsilon}\ \frac{k\left(R_\varepsilon(t)\right)}{R_\varepsilon(t)}\ u^\varepsilon(t) \le \frac{C}{\varepsilon} \tag{38}$$

for $t \in [0,\sigma_\varepsilon]$, whence, after integration,

$$\begin{aligned} \frac{M_0}{2\ \varepsilon}\ \int_0^t \frac{k\left(R_\varepsilon(s)\right)}{R_\varepsilon(s)}\ u^\varepsilon(s)\ ds &\le \frac{C\ t}{\varepsilon}, \\ \int_0^t \frac{k\left(R_\varepsilon(s)\right)}{R_\varepsilon(s)}\ u^\varepsilon(s)\ ds &\le C\ t, \end{aligned}$$

since u^ε is nonnegative and $u^\varepsilon(0) = 0$. On the other hand, the positivity of R_ε on $[0,\sigma_\varepsilon]$ and (37) entails that

$$R_\varepsilon(t) \le R_0\ \exp\left\{ \int_0^t \frac{k\left(R_\varepsilon(s)\right)}{R_\varepsilon(s)}\ u^\varepsilon(s)\ ds \right\}, \quad t \in [0,\sigma_\varepsilon].$$

Combining the above two estimates finally yields

$$R_\varepsilon(t) \le R_0\ e^{Ct} \le C(T), \quad t \in [0,\sigma_\varepsilon].$$

Recalling that $r \mapsto k(r)/r$ is nonincreasing by (10), we may use the above upper bound on R_ε to estimate the second term of the left-hand side of (38) from below and obtain

$$\frac{du^\varepsilon}{dt}(t) + \frac{C(T)}{\varepsilon}\ \ u^\varepsilon(t) \le \frac{C}{\varepsilon}, \quad t \in [0,\sigma_\varepsilon].$$

The Gronwall lemma then ensures that

$$u^\varepsilon(t) \le C(T), \quad t \in [0,\sigma_\varepsilon],$$

and a contradiction for ε small enough. Therefore $\sigma_\varepsilon = \min\{T,\tau_\varepsilon\}$ for ε small enough, and the above computation entails that

$$u^\varepsilon(t) \le C(T), \quad t \in [0, \min\{T,\tau_\varepsilon\}]. \tag{39}$$

We next argue again by contradiction to show that $\tau_\varepsilon > T$ for ε small enough. Otherwise $\tau_\varepsilon \le T$ for $\varepsilon \in (0,1)$ and $f^\varepsilon(\tau_\varepsilon) \equiv 0$. Therefore $u^\varepsilon(\tau_\varepsilon) = M_0/\varepsilon$ by (25), while (39) ensures that $u^\varepsilon(\tau_\varepsilon) \le C(T)$, whence we obtain a contradiction for ε small enough. Consequently $\tau_\varepsilon > T$ for ε small enough, and Lemma 6 then follows from (39). □

3.3. Proof of Theorem 1. We are now in a position to complete the proof of Theorem 1. As already mentioned, we proceed along the lines of the proof of [4, Theorem 2.2] and aim to prove that the sequence (f^ε) is relatively weakly compact in $L^1((0,T)\times\mathbb{R}_+; x dx dt)$ for each $T\in\mathbb{R}_+$. For that purpose we need to be able to control the behavior of the sequence (f^ε) for large values of x and on small measurable subsets of $(0,T)\times\mathbb{R}_+$. Concerning the latter it is equivalent to obtain an upper bound on the L^1-norm of $j(f^\varepsilon)$ for some function j which is superlinear for large values of its argument. Thanks to the L^∞-bound on u^ε obtained in Lemma 6, both results will follow from Lemma 4 and Lemma 5, respectively. We first recall a refined version of the de la Vallée–Poussin theorem [5, Proposition I.1.1].

THEOREM 8. *If $(\Omega,\mathcal{B},\mu)$ is a measured space and $w\in L^1(\Omega,\mathcal{B},\mu)$, there exists a function $j\in\mathcal{J}_\infty$ (depending only on w) such that*

$$j\left(|w|\right)\in L^1(\Omega,\mathcal{B},\mu).$$

Remark. Theorem 8 is a classical result when $\mu(\Omega)<\infty$ (see, e.g., [2, p. 38]), except for the possibility of choosing j' concave. This last fact has been noticed in [5].

Owing to (9), we may apply Theorem 8 to conclude that there are two functions j_1 and j_2 in $\mathcal{J}_\infty$ such that

$$M:=\int_0^\infty j_1(x)\ f_0(x)\ dx+\int_0^\infty j_2\left(f_0(x)\right)\ x\ dx<\infty. \tag{40}$$

We fix $T\in\mathbb{R}_+$. Owing to (40) and Lemma 6, we may apply Lemmas 4 and 5 and conclude that there holds

$$\int_0^\infty j_1(x)\ f^\varepsilon(t,x)\ dx+\int_0^\infty j_2\left(f^\varepsilon(t,x)\right)\ \min\left(x,1\right)\ dx\le C(T)$$

for every $\varepsilon\in(0,\varepsilon(T))$ and $t\in(0,T)$. Since both j_1 and j_2 are superlinear at infinity, we infer from the above estimates and the Dunford–Pettis theorem that there is a weakly compact subset $\mathcal{K}(T)$ of $L^1(\mathbb{R}_+;xdx)$ such that

$$f^\varepsilon(t)\in\mathcal{K}(T),\quad (t,\varepsilon)\in[0,T]\times(0,\varepsilon(T)). \tag{41}$$

We next study the equicontinuity of (f^ε) with respect to time and claim that

$$\lim_{h\to0}\sup_{t\in[0,T-h]}\sup_{\varepsilon\in(0,\varepsilon(T))}\left|\int_0^\infty\left(f^\varepsilon(t+h,x)-f^\varepsilon(t,x)\right)\ \varphi(x)\ \min\left(x,1\right)\ dx\right|=0 \tag{42}$$

for $\varphi\in W^{1,\infty}(0,+\infty)$. Indeed, consider $\varepsilon\in(0,\varepsilon(T))$, $h\in(0,T)$, and $t\in(0,T-h)$. By (23) we have

$$\begin{aligned}&\left|\int_0^\infty\left(f^\varepsilon(t+h,x)-f^\varepsilon(t,x)\right)\ \varphi(x)\ \min\left(x,1\right)\ dx\right|\\ &\le|\varphi_x|_{L^\infty}\int_t^{t+h}\int_0^\infty|\mathcal{V}^\varepsilon(s,x)|\ f^\varepsilon(s,x)\ \min\left(x,1\right)\ dxds\\ &\quad+|\varphi|_{L^\infty}\int_t^{t+h}\int_0^1|\mathcal{V}^\varepsilon(s,x)|\ f^\varepsilon(s,x)\ dxds.\end{aligned}$$

Now (10)–(11) and Lemma 6 entail that $|\mathcal{V}^\varepsilon(s,x)| \le C(T)\ (1+x)$ for $(s,x) \in (0,T)\times\mathbb{R}_+$. Consequently, thanks to (25) and (26), we have

$$\left|\int_0^\infty (f^\varepsilon(t+h,x)-f^\varepsilon(t,x))\ \varphi(x)\ \min(x,1)\ dx\right|$$
$$\le C(T)\ |\varphi|_{W^{1,\infty}} \int_t^{t+h}\int_0^\infty (1+x)\ f^\varepsilon(s,x)\ dxds \le C(T)\ |\varphi|_{W^{1,\infty}}\ h,$$

from which the claim (42) follows. Furthermore, since an arbitrary function φ in $L^\infty(\mathbb{R}_+)$ is the almost everywhere limit of a sequence of functions in $W^{1,\infty}(\mathbb{R}_+)$ which is bounded in $L^\infty(\mathbb{R}_+)$, it follows from (41) and (42) that (42) is actually valid for every $\varphi \in L^\infty(\mathbb{R}_+)$. We have thus proved that

$$\text{(43)}\qquad \begin{cases}\text{the family } \{f^\varepsilon,\ \ \varepsilon\in(0,\varepsilon(T))\} \text{ is weakly equicontinuous in}\\ L^1(\mathbb{R}_+;\min(x,1)dx) \text{ at every } t\in[0,T] \text{ (see [10, Definition 1.3.1])}.\end{cases}$$

Now, according to a variant of the Arzelà–Ascoli theorem (see, e.g., [10, Theorem 1.3.2]), we infer from (41) and (43) that

$$(f^\varepsilon) \text{ is relatively compact in } \mathcal{C}([0,T];w-L^1(\mathbb{R}_+;\min(x,1)dx)).$$

Once more using (41), we actually obtain that (f^ε) is relatively compact in $\mathcal{C}([0,T];w-L^1(\mathbb{R}_+;xdx))$. This last fact and Lemma 6 yield that there are a sequence (ε_n), $\varepsilon_n\to 0$, and functions

$$f\in\mathcal{C}([0,T];w-L^1(\mathbb{R}_+;xdx)) \quad\text{and}\quad u\in L^\infty(0,T)$$

such that

$$\text{(44)}\qquad \lim_{n\to+\infty}\sup_{t\in[0,T]}\left|\int_0^\infty (f^{\varepsilon_n}(t,x)-f(t,x))\ \varphi(x)\ x\ dx\right| = 0,$$

$$\text{(45)}\qquad u^{\varepsilon_n}\overset{*}{\rightharpoonup} u \text{ in } L^\infty(0,T)$$

for every $\varphi\in L^\infty(\mathbb{R}_+)$. Let $t\in[0,T]$. As $f^{\varepsilon_n}(t)$ is nonnegative a.e. in $\mathbb{R}_+$, a first consequence of (44) is that $f(t)$ is nonnegative a.e. in $\mathbb{R}_+$. Similarly we deduce from (45) that u is nonnegative a.e. in $(0,T)$. It also readily follows from (44) that $f(0)=f_0$ and

$$\lim_{n\to+\infty}\int_0^\infty x\ f^{\varepsilon_n}(t,x)\ dx = \int_0^\infty x\ f(t,x)\ dx$$

for $t\in[0,T]$. We may then pass to the limit in (25) and use (45) to obtain that

$$\int_0^\infty x\ f(t,x)\ dx = \int_0^\infty x\ f_0(x)\ dx, \quad t\in[0,T].$$

Owing to (44) and (45), we may also pass to the limit in (23) to obtain that (f,u) satisfies (15) with $\mathcal{V}$ given by (16). Owing to (9)–(11) and the integrability properties of f, we may take $g(x)=x$ as a test function in (15) and deduce that u satisfies (17). Also, proceeding as in [3] yields that $f\in\mathcal{C}([0,T];L^1(\mathbb{R}_+;xdx))$.

Finally, another consequence of (44) and (26) is that

$$\lim_{n\to+\infty}\int_\delta^\infty f^{\varepsilon_n}(t,x)\ dx = \int_\delta^\infty f(t,x)\ dx \le \int_0^\infty f_0(x)\ dx,$$

and the Fatou lemma guarantees that

$$\int_0^\infty f(t,x)\ dx \le \int_0^\infty f_0(x)\ dx, \quad t \in [0,T].$$

The above analysis being valid for an arbitrary $T \in \mathbb{R}_+$, we may take T to be an arbitrary large integer and perform countably many successive extractions to complete the proof of Theorem 1. □

We conclude this section with a remark on the almost everywhere finiteness of some negative moments of solutions to (3)–(5).

PROPOSITION 9. *Let f_0, k, and q be functions enjoying the properties* (9)–(12) *and denote by f a solution to* (3)–(5) *in the sense of Theorem* 1. *For $\alpha \in (0,1)$ and $T \in \mathbb{R}_+$ there holds*

$$\int_0^T \int_0^\infty x^{\alpha-1}\ q(x)\ f(t,x)\ dxdt < \infty.$$

Proof. Consider $\delta \in (0,1)$ and put $g_\delta(x) = (x+\delta)^\alpha - \delta^\alpha$ for $x \in \mathbb{R}_+$. Owing to (14), we may take g_δ as a test function in (15) and use the nonnegativity of f and u to obtain

$$\begin{aligned}
&\alpha \int_0^T \int_0^\infty (x+\delta)^{\alpha-1}\ q(x)\ f(t,x)\ dxdt \\
&\le \int_0^\infty x^\alpha\ f_0(x)\ dx + \alpha \int_0^T \int_0^\infty (x+\delta)^{\alpha-1}\ k(x)\ u(t)\ f(t,x)\ dxdt \\
&\le \int_0^\infty (1+x)\ f_0(x)\ dx + \alpha\ |u|_{L^\infty(0,T)} \int_0^T \int_0^\infty (x+\delta)^{\alpha-1}\ k(x)\ f(t,x)\ dxdt.
\end{aligned}$$

Recalling (13), there is x_T such that

$$q(x) \ge 2\ |u|_{L^\infty(0,T)}\ k(x)$$

for $x \in (0, x_T)$. Consequently,

$$\begin{aligned}
&\alpha \int_0^T \int_0^\infty (x+\delta)^{\alpha-1}\ q(x)\ f(t,x)\ dxdt \\
&\le C + \frac{\alpha}{2} \int_0^T \int_0^{x_T} (x+\delta)^{\alpha-1}\ q(x)\ f(t,x)\ dxdt \\
&\quad + \alpha\ x_T^{\alpha-1}\ |u|_{L^\infty(0,T)} \int_0^T \int_{x_T}^\infty k(x)\ f(t,x)\ dxdt \\
&\le C(T,\alpha) + \frac{\alpha}{2} \int_0^T \int_0^\infty (x+\delta)^{\alpha-1}\ q(x)\ f(t,x)\ dxdt,
\end{aligned}$$

where we have used (10) and (14) to obtain the last estimate. Therefore,

$$\int_0^T \int_0^\infty (x+\delta)^{\alpha-1}\ q(x)\ f(t,x)\ dxdt \le C(T,\alpha)$$

and we may let $\delta \to 0$ and use the Fatou lemma to complete the proof of Proposition 9. □

Remark. When k and q are given by (6) and $\alpha = 1/3$, Proposition 9 is similar to the last assertion of [7, Corollary 2.5] but stated in a different way.

4. Uniqueness. Throughout this section, f_0 and $\hat{f}_0$ are two functions satisfying (9), while k and q are two functions enjoying the properties (10)–(12) and (19) as well. Let (f,u) and $(\hat{f},\hat{u})$ be two solutions to (3)–(5) in the sense of Theorem 1 with data (f_0,k,q) and $(\hat{f}_0,k,q)$, respectively, with the obvious notation

$$\mathcal{V}(t,x)=k(x)\ u(t)-q(x),\quad \hat{\mathcal{V}}(t,x)=k(x)\ \hat{u}(t)-q(x),\quad (t,x)\in[0,+\infty)\times\mathbb{R}_+.$$

Next we introduce

$$\begin{aligned}&F(t,x)=\int_x^\infty f(t,y)\ dy,\quad \hat{F}(t,x)=\int_x^\infty \hat{f}(t,y)\ dy,\\ &E(t,x)=F(t,x)-\hat{F}(t,x)\end{aligned}$$

for $(t,x)\in[0,+\infty)\times\mathbb{R}_+$. We infer from (14) that

$$F\in W^{1,1}(0,T;L^1(\mathbb{R}_+))\quad\text{with}\quad F_x=-f\in L^\infty(0,T;L^1(\mathbb{R}_+;xdx))$$

and $F_t=\mathcal{V}\ f$ for each $T\in(0,+\infty)$. The function $\hat{F}$ enjoying similar properties, we conclude that, for each $T\in(0,+\infty)$,

$$E\in W^{1,1}(0,T;L^1(\mathbb{R}_+))\quad\text{with}\quad E_x=\hat{f}-f\in L^\infty(0,T;L^1(\mathbb{R}_+;xdx))$$

and

$$E_t=\mathcal{V}\ f-\hat{\mathcal{V}}\ \hat{f}=-\mathcal{V}\ E_x+\left(\mathcal{V}-\hat{\mathcal{V}}\right)\ \hat{f}. \tag{46}$$

Since $k(0)=0$ by (10), we infer from (46) that

$$\begin{aligned}\int_0^\infty |E(t,x)|\ dx\le{}&\int_0^\infty |E(0,x)|\ dx-q(0)\ \int_0^t |E(s,0)|\ ds\\ &+\int_0^t\int_0^\infty \mathcal{V}_x(s,x)\ |E(s,x)|\ dxds\\ &+\int_0^t\int_0^\infty k(x)\ \hat{f}(s,x)\ \left|(u-\hat{u})(s)\right|\ dxds.\end{aligned} \tag{47}$$

A formal proof of (47) follows by multiplying the equation satisfied by E by $sign(E)$ and integrating by parts. We next compute the last term of the right-hand side of (47) as follows. Since $\hat{f}$ and k are nonnegative, we have

$$\begin{aligned}&\int_0^\infty k(x)\ \hat{f}(s,x)\ \left|(u-\hat{u})(s)\right|\ dx\\ &=\left|u(s)\ \int_0^\infty k(x)\ \hat{f}(s,x)\ dx-\int_0^\infty q(x)\ \hat{f}(s,x)\ dx\right|\\ &=\left|u(s)\ \int_0^\infty k(x)\ \left(\hat{f}-f\right)(s,x)\ dx-\int_0^\infty q(x)\ \left(\hat{f}-f\right)(s,x)\ dx\right|\\ &=\left|u(s)\ \int_0^\infty k(x)\ E_x(s,x)\ dx-\int_0^\infty q(x)\ E_x(s,x)\ dx\right|.\end{aligned}$$

Now it readily follows from (10), (11), and (14) that

$$\begin{aligned}&\int_0^\infty k(x)\ E_x(s,x)\ dx=-\int_0^\infty k'(x)\ E(s,x)\ dx,\\ &-\int_0^\infty q(x)\ E_x(s,x)\ dx=q(0)\ E(s,0)+\int_0^\infty q'(x)\ E(s,x)\ dx.\end{aligned}$$

We thus end up with

$$\int_0^\infty k(x)\ \hat{f}(s,x)\ \left|(u-\hat{u})(s)\right|\ dx = \left| q(0)\ E(s,0) - \int_0^\infty \mathcal{V}_x(s,x)\ E(s,x)\ dx \right|.$$

After inserting the above formula in (47), we are led to

$$\begin{aligned}\int_0^\infty |E(t,x)|\ dx \le \int_0^\infty |E(0,x)|\ dx - q(0)\ \int_0^t |E(s,0)|\ ds \\ + \int_0^t \int_0^\infty \mathcal{V}_x(s,x)\ |E(s,x)|\ dxds \\ + q(0)\ \int_0^t |E(s,0)|\ ds + \int_0^t \int_0^\infty |\mathcal{V}_x(s,x)|\ |E(s,x)|\ dxds,\end{aligned}$$

whence

$$\begin{aligned}\int_0^\infty |E(t,x)|\ dx \le \int_0^\infty |E(0,x)|\ dx \\ + \int_0^t \int_0^\infty \left(|\mathcal{V}_x(s,x)| + \mathcal{V}_x(s,x)\right)\ |E(s,x)|\ dxds.\end{aligned} \tag{48}$$

We finally consider $T \in \mathbb{R}_+$ and $t \in [0,T]$. On the one hand, it follows from (14) that $u \in L^\infty(0,T)$. On the other hand, notice that

$$|\mathcal{V}_x(s,x)| + \mathcal{V}_x(s,x) = \begin{cases} 0 & \text{if} \quad \mathcal{V}_x(s,x) \le 0, \\ \\ 2\ \mathcal{V}_x(s,x) & \text{otherwise,} \end{cases}$$

and

$$\mathcal{V}_x(s,x) \le \left(|u|_{L^\infty(0,T)}\ k'(x) - q'(x)\right)$$

in the latter case. The condition (19) then warrants that $(s,x) \to |\mathcal{V}_x(s,x)| + \mathcal{V}_x(s,x)$ belongs to $L^\infty((0,T)\times\mathbb{R}_+)$. We may now apply the Gronwall lemma to (48) and obtain that there is a positive constant γ (depending on T, k, q, and u) such that

$$\int_0^\infty |E(t,x)|\ dx \le \left(\int_0^\infty |E(0,x)|\ dx\right)\ e^{\gamma t}$$

for each $t \in [0,T]$. Theorem 2 then readily follows by taking $f_0 = \hat{f}_0$.

ASYMPTOTIC BEHAVIOR OF A ONE-DIMENSIONAL COMPRESSIBLE VISCOUS GAS WITH FREE BOUNDARY*

TAO PAN†, HONGXIA LIU‡, AND KENJI NISHIHARA§

Abstract. We consider the initial-boundary value problem for a one-dimensional compressible viscous gas with free boundary, which is modeled in the Eulerian coordinate as

$$\text{(IBVP)}\qquad \begin{cases} \rho_t + (\rho u)_x = 0, \quad x > x(t), \quad t > 0, \\ (\rho u)_t + (\rho u^2 + p)_x = \mu u_{xx}, \quad x > x(t), \quad t > 0, \\ (p - \mu u_x)|_{x=x(t)} = p_0, \quad \frac{dx(t)}{dt} = u(x(t), t), \quad t \geq 0, \\ (\rho, u)|_{t=0} = (\rho_0, u_0)(x), \quad x \geq x(0). \end{cases}$$

Here, $\rho\,(> 0)$ is the density, u is the velocity, $p = p(\rho) = \rho^\gamma$ ($\gamma \geq 1$: the adiabatic constant) is the pressure, and $\mu\,(> 0)$ is the viscosity constant. At the boundary the flow is attached to the atmosphere with pressure $p_0\,(> 0)$ and the boundary condition is derived by the balance law. The initial data have constant states (ρ_+, u_+) at $x = \infty$. The flow has no vacuum state so that $\rho_0(x) > 0$ and $\rho_+ > 0$ are assumed. Our main purpose is to investigate the asymptotic behaviors of solutions for (IBVP), which are closely related to those for the corresponding Cauchy problem and hence the corresponding Riemann problem. Depending on p_0 and the endstates (ρ_+, u_+), the solutions are shown to tend to the outgoing rarefaction wave or the outgoing viscous shock wave as t tends to infinity. The proof is given under the weakness assumption of the waves. The analysis will be done by changing (IBVP) into the problem in the Lagrangian coordinate.

Key words. one-dimensional compressible viscous gas, free boundary, asymptotic behavior, rarefaction wave, viscous shock wave

1. Introduction.

A one-dimensional barotropic viscous flow is modeled in the Eulerian coordinate $(\tilde{x}, \tilde{t})$ as

$$\text{(1.1)}\qquad \begin{cases} \tilde{\rho}_{\tilde{t}} + (\tilde{\rho}\tilde{u})_{\tilde{x}} = 0, \\ (\tilde{\rho}\tilde{u})_{\tilde{t}} + (\tilde{\rho}\tilde{u}^2 + \tilde{p})_{\tilde{x}} = \mu \tilde{u}_{\tilde{x}\tilde{x}}, \end{cases}$$

where $\tilde{\rho}$ is the density, $\tilde{u}$ is the velocity, $\tilde{p} = \tilde{p}(\tilde{\rho}) = \tilde{\rho}^\gamma$ ($\gamma \geq 1$: the adiabatic constant) is the pressure, and $\mu\,(> 0)$ is the viscosity constant. If the flow is attached at the boundary to the atmosphere with pressure p_0, then the balance law at the boundary $\tilde{x} = \tilde{x}(\tilde{t})$ gives the condition

$$\text{(1.2)}\qquad (\tilde{p} - \mu \tilde{u}_{\tilde{x}})|_{\tilde{x}=\tilde{x}(\tilde{t})} = p_0 \quad \text{and} \quad \frac{d\tilde{x}(\tilde{t})}{d\tilde{t}} = \tilde{u}(\tilde{x}(\tilde{t}), \tilde{t})$$

by $(1.1)_2$ (second equation of (1.1)), which implies that $\tilde{x} = \tilde{x}(\tilde{t})$ is the free boundary.

We now consider (1.1) on $\tilde{x} > \tilde{x}(\tilde{t})$ with the boundary condition (1.2) and the initial data

$$(\tilde{\rho}, \tilde{u})|_{\tilde{t}=0} = (\tilde{\rho}_0, \tilde{u}_0)(\tilde{x}), \quad \tilde{x} \geq \tilde{x}(0) =: 0. \tag{1.3}$$

The initial data are assumed to be constant as $\tilde{x} \to \infty$:

$$\lim_{\tilde{x}\to\infty} (\tilde{\rho}_0, \tilde{u}_0)(\tilde{x}) = (\rho_+, u_+). \tag{1.4}$$

Also,

$$0 < \tilde{\rho}_0(\tilde{x}) < \infty, \quad \rho_+ > 0, \quad \text{and} \quad p_0 > 0 \tag{1.5}$$

are assumed, so that the flow has no vacuum state.

Our main interest concerns the large-time behaviors of solutions to (1.1)–(1.3). To explore those, we transform the Eulerian coordinate $(\tilde{x}, \tilde{t})$ into the Lagrangian coordinate (x, t) by

$$x = \int_0^{\tilde{x}} \tilde{\rho}_0(y)dy, \quad \tilde{t} = t.$$

Then, (1.1)–(1.3) changes into the problem with fixed boundary in the form of

$$\begin{cases} v_t - u_x = 0, & x \in \mathbf{R}_+ = (0, \infty), \quad t > 0, \\ u_t + p(v)_x = \mu \left(\dfrac{u_x}{v}\right)_x \end{cases} \tag{1.6}$$

with the boundary condition

$$\left(p(v) - \mu \frac{u_x}{v}\right)(0, t) = p_0, \quad t \geq 0, \tag{1.7}$$

and the initial condition

$$(v, u)(x, 0) = (v_0, u_0)(x), \quad x \in \mathbf{R}_+, \tag{1.8}$$

where $\tilde{u}(\tilde{x}, \tilde{t}) = u(x, t)$, etc., and $v = 1/\rho$, so that $p(v) := \tilde{p}(\tilde{\rho}) = v^{-\gamma}$ satisfies

$$p'(v) < 0, \quad p''(v) > 0 \quad \text{for} \quad v > 0. \tag{1.9}$$

The assumptions (1.4) and (1.5) are written as

$$\lim_{x\to\infty} (v_0(x), u_0)(x) = (v_+, u_+), \quad v_+ = 1/\rho_+ \tag{1.10}$$

and

$$0 < v_0(x) < \infty, \quad v_+ > 0, \quad \text{and} \quad p_0 > 0. \tag{1.11}$$

The cases of the Dirichlet boundary

$$u|_{x=0} = u_- := 0 \tag{1.12}$$

instead of (1.7) have been investigated by Matsumura and Mei [3], Pan, Liu, and Nishihara [11], and Matsumura and Nishihara [8]. From those results the behaviors

of solutions closely relate to those for the corresponding Cauchy problem on $\mathbf{R} = (-\infty, \infty)$ for (1.6) with $(v,u)|_{t=0} = (v_0,u_0)(x) \to (v_\pm, u_\pm)$ as $x \to \infty$, and hence the corresponding Riemann problem for (1.6) with $\mu = 0$ for the Riemann data

$$(v_0^R, u_0^R)(x) = \begin{cases} (v_-, u_-), & x < 0, \\ (v_+, u_+), & x > 0. \end{cases}$$

As is well known, the behaviors expected for the Cauchy problem and the Riemann problem divide $\mathbf{R}^2_{(v,u)}$-space into four ranges by the shock curves $S_i(v_-, u_-)$ and the rarefaction curves $R_i(v_-, u_-)$ $(i = 1, 2)$. Refer to [5, 7, 12] and the survey paper [10].

Roughly speaking, it is shown in [3] that if $u_- > u_+$, then there is a constant v_- such that $(v_+, u_+) \in S_2(v_-, u_-)$ (the 2-shock curve) and the solution (v,u) to (1.6), (1.12), (1.8) tends to the 2-viscous shock wave $(V_2, U_2)(x - st + \alpha)$ connecting (v_-, u_-) and (v_+, u_+) as $t \to \infty$ for some shift α determined by the initial data. On the other hand, in [11, 8] they have shown that if $u_- < u_+$, then there is a constant v_- such that $(v_+, u_+) \in R_2(v_-, u_-)$ (the 2-rarefaction curve) and the solution (v,u) tends to the 2-rarefaction wave $(v_2^r, u_2^r)(x/t)$ connecting (v_-, u_-) and (v_+, u_+) as $t \to \infty$.

Summing up their results, all waves are reflected at the boundary and they merge to the outgoing wave, which is the 2-viscous shock wave or the 2-rarefaction wave depending on the data u_- and (v_+, u_+).

Thus, in our problem it is also a key point to determine the value $v_- = v(0,t)$ instead of (1.12). From $(1.6)_1$, the boundary condition (1.7) can be rewritten as

$$\left(p(v) - \mu \frac{v_t}{v}\right)(0,t) = p_0. \tag{1.13}$$

If we define v_- by

$$p(v_-) = p_0 \quad \text{or} \quad v_- = p_0^{1/\gamma}, \tag{1.14}$$

then (1.13) becomes the ordinary differential equation

$$\mu \frac{v_t}{v}(0,t) = p(v(0,t)) - p(v_-). \tag{1.15}$$

The initial data of $v(0,t)$ should be

$$v(0,t)|_{t=0} = v_0(0) \tag{1.16}$$

from the compatibility condition. Solving (1.15)–(1.16) we have

$$\lim_{t \to \infty} v(0,t) = v_-, \tag{1.17}$$

which will be shown in the next section.

Thus, we can expect that if $v_- > v_+$, then u_- is uniquely determined by $(v_+, u_+) \in R_2(v_-, u_-)$ and the solution (v,u) to (1.6)–(1.8) tends to the 2-rarefaction wave $(v_2^r, u_2^r)(x/t)$ connecting (v_-, u_-) and (v_+, u_+) as $t \to \infty$, and that if $v_- < v_+$, then u_- is uniquely determined by $(v_+, u_+) \in S_2(v_-, u_-)$ and the solution (v,u) to (1.6)–(1.8) tends to the 2-viscous shock wave $(V_2, U_2)(x - s_2 t + \alpha)$ as $t \to \infty$ for suitable α. In the results, in each case $u(0,t) \to u_-$ as $t \to \infty$, and hence the free boundary $\tilde{x}(\tilde{t})$ in the Eulerian coordinate satisfies $\frac{d\tilde{x}(\tilde{t})}{d\tilde{t}} = \tilde{u}(\tilde{x}(\tilde{t}), \tilde{t}) \to u_-$ as $\tilde{t} \to \infty$.

Our purpose in this paper is to show these two assertions under some weakness condition, that is, $|v_+ - v_-|$ is suitably small. We note that the weakness conditions

are assumed in [3] and [11]. In [8] any smallness conditions are not assumed. A global result corresponding to [8] will be expected in our problem, which will be investigated in a forthcoming paper.

Related to the boundary effect, we mention about another kind of initial and boundary problems, i.e., the inflow problem and outflow problem. Those problems have been recently proposed by Matsumura, and all behaviors of solutions expected are classified in [2]. In [9] some cases are proved rigorously. Other cases remain open.

The outline of this paper is as follows. In the next section the behavior of $v(0,t)$ will be studied. In section 3 the convergence to the 2-rarefaction wave will be treated, and the convergence to the 2-viscous shock wave will be done in the final section.

2. Preliminaries. We observe the behaviors of the boundary value $v(0,t)$. Denote $v(t) := v(0,t)$ in this section; then $v(t)$ satisfies the ordinary differential equation

$$\begin{cases} \frac{dv}{dt} = \frac{1}{\mu}\left(p\left(v\right) - p\left(v_-\right)\right)v, \\ v\left(0\right) = v_0(0) =: v_0 \end{cases} \tag{2.1}$$

by (1.15)–(1.16). Note that v_- is defined by (1.14) and $v_0(x)$ is a initial value in (1.8).

LEMMA 2.1. *Under the condition* (1.9)*, the global smooth solution* $v = v\left(t\right)$ *for* (2.1) *satisfies the following properties:*

(i) *If* $v_0 = v_-$*, then* $v\left(t\right) \equiv v_-$*. If* $v_0 \neq v_-$*, then* $v(t) \neq v_-$ *for any* $t \in \mathbf{R}_+$*.*

(ii) *If* $v_0 > v_-$*, then* $v_- < v\left(t\right) < v_0$*,* $v'\left(t\right) < 0$*,* $v''\left(t\right) > 0$*.*

(iii) *If* $v_0 < v_-$*, then* $v_0 < v\left(t\right) < v_-$*,* $v'\left(t\right) > 0$*,* $v''\left(t\right) < 0$*.*

(iv) $\lim_{t\to+\infty} v\left(t\right) = v_-$*.*

Proof. (i) If there is a global smooth solution for (2.1), then it is easy to show that the solution is unique. Hence $v(t) \equiv v_-$ if $v_0 = v_-$. If $v_0 > v_-$ and $v(t_0) = v_-$ with $v(t) > v_-$ for $0 \le t < t_0 < \infty$, then

$$\int_0^t \frac{\frac{dv}{d\tau}(\tau)}{v(\tau) - v_-} d\tau = \int_0^t \frac{1}{\mu}\frac{p(v(\tau)) - p(v_-)}{v(\tau) - v_-} v(\tau) d\tau, \quad t < t_0.$$

When $\tau \to t_0 - 0$, the left-hand side tends to $-\infty$, and the right-hand side is larger than

$$-\frac{t_0}{\mu}\max_{[0,t_0]}\left\{\frac{p(v(\tau)) - p(v_-)}{v(\tau) - v_-} v(\tau)\right\} \ (> -\infty),$$

which deduces the contradiction. Hence we obtain the property (i).

(ii) Rewrite (2.1) as

$$\int_{v_0}^{v} \frac{dw}{\left(p\left(w\right) - p\left(v_-\right)\right)w} = \int_0^t \frac{dt}{\mu} = \frac{t}{\mu}. \tag{2.2}$$

By the mean-value theorem

$$\int_{v_0}^{v} \frac{dw}{\left(w - v_-\right)wp'\left(\xi\right)} = \frac{t}{\mu}, \tag{2.3}$$

where ξ is between v_0 and v.

Suppose that there exists $t_0 > 0$ such that $v\left(t_0\right) = \bar{v} \ge v_0 > v_-$; then from (2.3), we have

$$\int_{v_0}^{\bar{v}} \frac{dw}{\left(w - v_-\right)wp'\left(\xi\right)} = \frac{t_0}{\mu}.$$

The left-hand side of the above equality is negative, in which the signs contradict. Hence $v(t) < v_0$. From $v(0) = v_0 \neq v_-$, $v(t) \not\equiv v_-$ for $t \geq 0$. If $v(t) \geq v_-$ is not valid, then there exist $0 < t_0 < t_1$ such that $v(t_0) = v_- > v(t_1)$. Therefore, as $t \geq t_0$, $v(t) \equiv v_-$ is the solution of (2.1). This contradicts $v(t_1) < v_-$. Thus, we have proved that $v_- < v(t) < v_0$. Hence $v'(t) = \frac{1}{\mu}(p(v) - p(v_-))v < 0$ and $v''(t) = \frac{1}{\mu}(p'(v)v + p(v) - p(v_-))v'(t) > 0$.

(iii) The proof is similar to that of (ii).

(iv) We show $\lim_{t\to+\infty} v(t) = v_-$ when $v_0 > v_-$. If not, then there exists $\varepsilon > 0$ such that for any $t > 0$, there is a positive constant $t_1 > t$ such that $v(t_1) \geq v_- + \varepsilon$. Since $(p(v) - p(v_-))v$ is decreasing for $v > v_-$,

$$v'(t_1) = (p(v(t_1)) - p(v_-))\frac{v(t_1)}{\mu} \leq \frac{(v_- + \varepsilon)}{\mu}(p(v_- + \varepsilon) - p(v_-)) \triangleq -\nu.$$

In view of $v''(t) > 0$, we have $v'(t) \leq v'(t_1) \leq -\nu$. Let $t \to +\infty$; then $v(t) \to -\infty$. This generates a contradiction. Thus $\lim_{t\to+\infty} v(t) = v_-$. The proof in the case of $v_0 < v_-$ is similar.

Conversely, we show the global existence and precise behavior for $v(t)$. □

LEMMA 2.2. *Suppose that* (1.9) *holds. Then there exists a unique global smooth solution* $v(t)$ *to* (2.1). *Moreover,* $|v(t) - v_-| = O(1)|v_0 - v_-|e^{-c_0 t}$ *and* $|v'(t)| = O(1)|v_0 - v_-|e^{-c_0 t}$ *as* $t \to +\infty$, *where* $c_0 = \frac{1}{\mu}v_-|p'(v_-)|$.

Proof. The local existence of a smooth solution to (2.1) can be shown in the standard way. Making use of the local existence result and the a priori estimate in Lemma 2.1, we can prove the existence of the unique global smooth solution to (2.1) through the continuation process.

Next, we shall prove $v(t) - v_-$, $v'(t) \to 0$ exponentially as $t \to +\infty$ in the case of $v_0 > v_-$. By Lemma 2.1 $v_- < v(t) < v_0$. By using the Taylor expansion theorem, we can rewrite (2.2) as

$$\int_v^{v_0} \frac{dw}{(w - v_-)\left(1 - \frac{p''(\eta)}{2|p'(v_-)|}(w - v_-)\right)w|p'(v_-)|} = \frac{t}{\mu}, \tag{2.4}$$

where $\eta = v_- + \theta(w - v_-)$, $0 < \theta < 1$.

Put $m_0 = \sup_{v_-\leq v\leq v_0} \frac{p''(\eta)}{2|p'(v_-)|}$ and take $v_1 = v(t_1) > v_-$, $t_1 \gg 1$ such that $1 - m_0(v_1 - v_-) \geq \frac{1}{2}$, and then (2.4) is rewritten as

$$\left(\int_v^{v_1} + \int_{v_1}^{v_0}\right)\frac{v_- dw}{(w - v_-)(1 - m_0(w - v_-))w} \geq \frac{1}{\mu}v_-|p'(v_-)|t = c_0 t,$$

and hence

$$\int_v^{v_1} \frac{v_- dw}{(w - v_-)(1 - m_0(w - v_-))w} \geq c_0 t - c(v_0, v_1),$$

where $c(v_0, v_1) = \int_{v_1}^{v_0} \frac{v_- dw}{(w-v_-)(1-m_0(w-v_-))w}$.

Using the equality

$$\frac{v_-}{(w - v_-)(1 - m_0(w - v_-))w} = \frac{1}{w - v_-} + \frac{B_0 m_0}{1 - m_0(w - v_-)} - \frac{A_0}{w},$$

where $A_0 = \frac{1}{1+m_0 v_-}$, $B_0 = \frac{m_0 v_-}{1+m_0 v_-}$, we obtain

$$\ln \frac{v - v_-}{(1 - m_0 (v - v_-))^{B_0} v^{A_0}} \Bigg|_v^{v_1} \geq c_0 t - c (v_0, v_1),$$

which gives

$$\begin{aligned} v - v_- &\leq (v_1 - v_-) \frac{(1-m_0(v-v_-))^{B_0} v^{A_0}}{(1-m_0(v_1-v_-))^{B_0} v_-^{A_0}} e^{-c(v_0,v_1)} e^{-c_0 t} \\ &\leq \frac{v_0^{A_0}}{(1-m_0(v_1-v_-))^{B_0} v_-^{A_0}} e^{-c(v_0,v_1)} |v_0 - v_-| e^{-c_0 t}. \end{aligned} \tag{2.5}$$

On the other hand, by (2.4),

$$\int_v^{v_0} \frac{v_- dw}{(w - v_-) w} \leq \frac{1}{\mu} v_- |p' (v_-)| t,$$

which implies that

$$\begin{aligned} v - v_- &\geq \frac{(v_0 - v_-) v}{v_0} e^{-c_0 t} \\ &\geq \frac{v_-}{v_0} |v_0 - v_-| e^{-c_0 t}. \end{aligned} \tag{2.6}$$

Thus we have the desired result $|v (t) - v_-| = O (1) |v_0 - v_-| e^{-c_0 t}$ by (2.5) and (2.6). From (2.1) we also have $|v' (t)| = O (1) |v_0 - v_-| e^{-c_0 t}$. □

3. Convergence to rarefaction waves. As stated in the introduction, the asymptotic behavior of the solution to (1.6)–(1.8) depends on the sign of $v_- - v_+$. This section is devoted to studying the case $v_- > v_+$, in which the solution to (1.6)–(1.8) converges to the 2-rarefaction waves.

3.1. Main result. To state our result, we first remember the results for the corresponding Riemann problem on $R = (-\infty, +\infty)$ for given constant states $(v_\pm, u_\pm)$, $v_\pm > 0$:

$$\begin{cases} v_t - u_x = 0, \\ u_t + p (v)_x = 0, \\ (v, u) (x, 0) = \left(v_0^R, u_0^R\right) (x) = \begin{cases} (v_-, u_-), & x < 0, \\ (v_+, u_+), & x > 0, \end{cases} \end{cases} \qquad t > 0, \quad x \in R. \tag{3.1}$$

It is well known that if $(v_+, u_+) \in R_i (v_-, u_-)$ $(i = 1, 2)$, then (3.1) admits an i-rarefaction wave solution

$$(v_i^r, u_i^r) (x/t) = \begin{cases} (v_-, u_-), & -\infty < \xi \leq \lambda_i (v_-), \\ \left(\lambda_i^{-1} (\xi), \ u_- - \int_{v_-}^{\lambda_i^{-1}(\xi)} \lambda_i (s) \, ds\right), & \lambda_i (v_-) \leq \xi \leq \lambda_i (v_+), \\ (v_+, u_+), & \lambda_i (v_+) \leq \xi < +\infty, \end{cases} \tag{3.2}$$

where $\lambda_i (v) = (-1)^i \sqrt{-p' (v)}$ $(i = 1, 2)$ are the eigenvalues for (3.1) and

$$R_i (v_-, u_-) = \left\{ (v, u) \in \Omega \,\middle|\, u = u_- - \int_{v_-}^{v} \lambda_i (s) \, ds, u \geq u_- \right\} \tag{3.3}$$

for a suitable neighborhood Ω of (v_-, u_-) in $R^2_{(v,u)}$.

Since there is a boundary at $x = 0$ in our problem, the backward flow reflects at the boundary and the total flow is eventually expected to move forward and behave as the 2-rarefaction wave for large time if $v_- > v_+$. Therefore, for any given $v_- = p^{-1}(p_0) > v_+ > 0$ and $u_+ \in R$, there is a unique $u_- \in R$ such that

$$(v_+, u_+) \in R_2(v_-, u_-) \tag{3.4}$$

and (3.1) admits the 2-rarefaction wave $(v_2^r, u_2^r)(x/t)$ connecting (v_-, u_-) and (v_+, u_+), and the solution (v, u) of (1.6)–(1.8) is expected to behave as $(v_2^r, u_2^r)(x/t)|_{x\geq 0}$.

We now assume

$$(v_0(\cdot) - v_+, u_0(\cdot) - u_+) \in L^2(R_+), \qquad (v_0(\cdot), u_0(\cdot))_x \in L^2(R_+) \tag{3.5}$$

and set

$$\begin{aligned}\Phi_0^2 = {} & \|(v_0(\cdot) - v_+, u_0(\cdot) - u_+)\|^2 + \|(v_0(\cdot), u_0(\cdot))_x\|^2 \\ & + |(v_+ - v_-, u_+ - u_-)| + |v_0(0) - v_-|.\end{aligned}$$

Then our first main theorem is the following.

THEOREM 3.1. *For given constants (v_+, u_+) and $v_- = p^{-1}(p_0)$ with $0 < v_+ < v_-$ and $u_- \in R$ determined by (3.4), there exists a positive constant ε such that if $\Phi_0 < \varepsilon$, then the initial-boundary value problem (1.6)–(1.8) has a unique global solution $(v, u)(x, t)$ in time satisfying*

$$\begin{cases} (v - v_+, u - u_+) \in C^0([0, +\infty); L^2), \\ (v, u)_x \in C^0([0, +\infty); L^2), \\ u_{xx} \in L^2([0, +\infty); L^2) \end{cases} \tag{3.6}$$

and

$$\lim_{t\to+\infty} \sup_{x\in R_+} |(v, u)(x, t) - (v_2^r, u_2^r)(x/t)| = 0, \tag{3.7}$$

where $(v_2^r, u_2^r)(x/t)$ is given by (3.2).

3.2. Smooth rarefaction wave. To prove Theorem 3.1 we start with the Riemann problem on $R = (-\infty, +\infty)$ for the typical Burgers equation

$$\begin{cases} \omega_t + \omega\omega_x = 0, & (x, t) \in R \times R_+, \\ \omega(0, x) = \omega_0^r(x) = \begin{cases} \omega_-, & x < 0, \\ \omega_+, & x > 0, \end{cases} \end{cases} \tag{3.8}$$

with $\omega_- < \omega_+$. As is well known, the problem (3.8) has the centered rarefaction wave $\omega(x, t) = \omega^r\left(\frac{x}{t}\right)$ given by

$$\omega^r\left(\frac{x}{t}\right) = \begin{cases} \omega_-, & x \leq \omega_- t, \\ \frac{x}{t}, & \omega_- t < x < \omega_+ t, \\ \omega_+, & x \geq \omega_+ t. \end{cases} \tag{3.9}$$

We approximate the rarefaction wave by the solution to the following problem:

$$\begin{cases} \omega_t + \omega\omega_x = 0, \\ \omega(0, x) = \omega_0(x) := \widehat{\omega} + \widetilde{\omega}\tanh x, \end{cases} \tag{3.10}$$

where $\widehat{\omega} = (\omega_+ + \omega_-)/2$, $\widetilde{\omega} = (\omega_+ - \omega_-)/2$.

Now, we state the properties of ω.

LEMMA 3.1. *Suppose $\omega_+ > \omega_- > 0$. Then (3.10) has a unique smooth global solution in time $\omega(x, t)$, which satisfies the following properties:*

(i) $\omega_- < \omega(x,t) < \omega_+, \quad \omega_x(x,t) > 0.$

(ii) *For any p $(1 \le p < +\infty)$, there exists a constant C_p such that for $t \ge 0$,*

$$\|\omega_x(\cdot,t)\|_{L^p} \le C_p \min\left\{\widetilde{\omega}, \widetilde{\omega}^{\frac{1}{p}} t^{-1+\frac{1}{p}}\right\},$$

$$\|\omega_{xx}(\cdot,t)\|_{L^p} \le C_p \min\left\{\widetilde{\omega}, t^{-1}\right\}.$$

(iii) *For any $x \le 0$ and $t \ge 0$,*

$$0 < \omega(x,t) - \omega_- \le \widetilde{\omega} \exp\left\{-2(|x| + \omega_- t)\right\},$$

$$0 < \omega_x(x,t) \le 2\widetilde{\omega} \exp\left\{-2(|x| + \omega_- t)\right\}.$$

(iv) $\lim_{t\to+\infty} \sup_{x\in R} |\omega(x,t) - \omega^r(x/t)| = 0.$

Since the 2-rarefaction waves $(v_2^r, u_2^r)(x,t)$ are constructed in (3.2), their smooth approximation $(V,U)(x,t)$ can be defined by

$$\lambda_2(V) = \omega(x,t), \qquad U = u_- - \int_{v_-}^{V(x,t)} \lambda_2(s)\, ds,$$

where ω is the solution to (3.10) with $\lambda_2(v_\pm) = \omega_\pm$. Then it can be easily seen that (V,U) is a smooth exact solution to $(3.1)_1$–$(3.1)_2$. Moreover, the properties of ω shift to those of (V,U).

LEMMA 3.2. *Let $\delta = |v_+ - v_-| + |u_+ - u_-|$. Then the following hold:*

(i) *There exists a positive constant C such that for any $t \ge 0$, $x \in R_+$, and $0 \le \delta \le \delta_0$,*

$$|V_x| \le CV_t, \qquad 0 < V_t = U_x \le C\delta,$$

$$|U_{xx}| \le C\left(|V_{xx}| + |V_x|^2\right).$$

(ii) *For any p $(1 \le p < +\infty)$, there exists a constant $C_p > 0$ such that for $t \ge 0$ and $0 \le \delta \le \delta_0$,*

$$\|(V_x, U_x)(\cdot,t)\|_{L^p(R_+)} \le C_p \delta^{\frac{1}{p}} (1+t)^{-1+\frac{1}{p}},$$

$$\|(V_{xx}, U_{xx})(\cdot,t)\|_{L^p(R_+)} \le C_p \min\left\{\delta, (1+t)^{-1}\right\}.$$

(iii) *There exist positive constants C and c_- depending only on $\lambda_2(v)$ and $v_\pm$ such that for $t \ge 0$ and $0 \le \delta \le \delta_0$,*

$$|V(0,t) - v_-, V_x(0,t), V_{xx}(0,t)| \le C\delta e^{-c_- t}.$$

(iv) $\lim_{t\to+\infty} \sup_{x\in R_+} \left|(V,U)(x,t) - (v_2^r, u_2^r)\left(\frac{x}{t}\right)\right| = 0.$

The proofs of Lemmas 3.1 and 3.2 are given in [6].

3.3. Reformulation of the problem. Rewrite (1.6)–(1.8) by the change of variables $(v,u) = (V+\phi, U+\psi)$ as follows:

$$\text{(3.11)} \quad \begin{cases} \phi_t - \psi_x = 0, \\ \psi_t + (p(V+\phi) - p(V))_x - \mu\left(\dfrac{\psi_x}{V+\phi}\right)_x = F, \quad F = \mu\left(\dfrac{U_x}{V+\phi}\right)_x, \\ \left(p(V+\phi) - \mu\dfrac{U_x+\psi_x}{V+\phi}\right)|_{x=0} = p_0, \\ (\phi,\psi)(x,0) = (\phi_0,\psi_0)(x) := (v_0(x) - V(0,x), u_0(x) - U(0,x)). \end{cases}$$

Here (V,U) is the smooth approximate solution constructed in section 3.2.

We first choose a positive constant E_0 by virtue of Sobolev's imbedding theorem such that

$$\sup_{x\in R_+}|f(x)|\le\frac{1}{4}v_+ \quad\text{for any}\quad f\in H^1(R_+),\quad \|f\|_1:=\|f\|_{H^1}\le E_0.$$

We look for the solution (ϕ,ψ) of (3.11) in the solution space $X(0,+\infty)$, where

$$\begin{aligned}X(0,T)=\Big\{(\phi,\psi)\,\big|\,&(\phi,\psi)\in C^0\left([0,T];H^1(R_+)\right),\phi_x\in L^2\left([0,T];L^2(R_+)\right)\\ &\psi_x\in L^2\left([0,T];H^1(R_+)\right)\text{and}\sup_{0\le t\le T}\|(\psi,\psi)\|_1\le E_0\Big\}\end{aligned}\tag{3.12}$$

for $0<T\le+\infty$. Note that $V+\phi\ge\frac{3}{4}v_+$ if $(\phi,\psi)\in X(0,T)$.

Similar to the previous papers [9, 6], for the proof of Theorem 3.1 it suffices to show the following theorem.

THEOREM 3.2. *For each fixed constant (v_+,u_+) and $v_-=p^{-1}(p_0)$ $(v_->v_+>0)$ and u_- satisfying* (3.4)*, there exist positive constants ε_0 and C_0 such that if $|(\phi_0,\psi_0)|_1+\delta+|v_0(0)-v_-|\le\varepsilon_0$ $(\delta=|v_+-v_-|+|u_+-u_-|)$, then the problem* (3.11) *has a unique global solution $(\phi,\psi)\in X(0,+\infty)$ which satisfies*

$$\begin{aligned}&\sup_{t\ge0}\|(\phi,\psi)(t)\|_1^2+\int_0^{+\infty}\left(\left\|V_t^{\frac{1}{2}}\phi(\tau)\right\|^2+\|\phi_x(\tau)\|^2+\|\psi_x(\tau)\|_1^2\right)d\tau\\ &\qquad\le C_0\left(\delta^{\frac{1}{6}}+|v_0(0)-v_-|+\|(\phi_0,\psi_0)\|_1^2\right).\end{aligned}\tag{3.13}$$

Along the same lines as in previous papers (see, e.g., [1, 4, 13]), Theorem 3.2 can be shown by the continuation argument combining the local existence with the a priori estimates. For the local existence we define the sequence $\{(\phi^{(n)},\psi^{(n)})\}$ by the iteration

$$(\phi^{(0)},\psi^{(0)})(x)=(\phi_0,\psi_0)(x),$$

$$\begin{cases}\psi_t^{(n+1)}-\mu\left(\dfrac{\psi_x^{(n+1)}}{V+\phi^{(n)}}\right)_x=-(p(V+\phi^{(n)})-p(V))+\mu\left(\dfrac{U_x}{V+\phi^{(n)}}\right)_x,\\ \psi_x^{(n+1)}|_{x=0}=\left\{\dfrac{1}{\mu}(V+\phi^{(n)})(p(V+\phi^{(n)})-p_0)-U_x\right\}\Big|_{x=0},\\ \psi^{(n+1)}(x,0)=\psi_0(x),\end{cases}$$

$$\phi^{(n+1)}(x,t)=\phi_0(x)+\int_0^t\psi_x^{(n+1)}(x,s)ds.$$

Since it is standard to show that $\{(\phi^{(n)},\psi^{(n)})\}$ is the Cauchy sequence in $X(0,t_0)$ for $t_0=t_0(\|(\phi_0,\psi_0)\|_1)>0$ and $\|(\phi_0,\psi_0)\|_1\le E_0$, we omit the details. It now suffices to show the following a priori estimate.

PROPOSITION 3.1 (a priori estimate). *For given constants $(v_\pm,u_\pm)$ in Theorem* 3.2*, suppose that $(\phi,\psi)(x,t)$ is a solution of* (3.11) *in $X(0,T)$ for some $T>0$.*

Then there exist positive constants ε_1 and C_1 independent of T and δ such that if $\sup_{0\le t\le T}\|(\phi,\psi)(t)\|_1+\delta\le\varepsilon_1$, then it holds that

$$\begin{aligned}\sup_{0\le t\le T}\|(\phi,\psi)(t)\|_1^2+\int_0^T\left(\left\|V_t^{\frac12}\phi(\tau)\right\|^2+\|\phi_x(\tau)\|^2+\|\psi_x(\tau)\|_1^2\right)d\tau\\ \le C_1\left(\delta^{\frac16}+|v_0(0)-v_-|+\|(\phi_0,\psi_0)\|_1^2\right).\end{aligned}\tag{3.14}$$

Note that the smallness of $|v_0(0)-v_-|$ in Theorem 3.2 is used in the continuation process.

3.4. A priori estimates. Let $(v_\pm,u_\pm)$ be fixed as in Theorem 3.2 and let $(\phi,\psi)\in X([0,T])$ be a solution of (3.11) for some $T(>0)$ and δ $(0\le\delta<\delta_0)$. Setting $E=\sup_{0\le t\le T}\|(\phi,\psi)(t)\|_1$ and $E(t)=\sup_{0\le\tau\le t}\|(\phi,\psi)(\tau)\|$ we proceed to estimate (ϕ,ψ). Throughout this subsection and later, we write C as generic positive constants independent of T and δ, which may depend on $(v_\pm,u_\pm)$ and v_0.

To prove Proposition 3.1, we need the following estimates at the boundary.

LEMMA 3.3. *Assume $E(t)\le1$. Then it holds for $0\le t\le T$ that*

$$\left|\int_0^t\left(\left(p(V+\phi)-p(V)\right)\psi-\mu\frac{\psi_x\psi}{V+\phi}\right)\Big|_0^{+\infty}d\tau\right|\le\nu\int_0^t\|\psi_x(\tau)\|^2d\tau+C\delta^{\frac43},\tag{3.15}$$

$$\left|\int_0^t\psi(0,\tau)\psi_x(0,\tau)\,d\tau\right|\le\nu\int_0^t\|\psi_x(\tau)\|^2d\tau+C\left(\delta+|v_0-v_-|\right),\tag{3.16}$$

$$\left|\int_0^t\psi_\tau(0,\tau)\psi_x(0,\tau)\,d\tau\right|\le C\left(\delta+|v_0-v_-|\right)\tag{3.17}$$

for any fixed constant $\nu(>0)$.

Proof. Making use of the boundary condition $(3.11)_3$, Lemma 3.2, and Sobolev's inequality, we have

$$\begin{aligned}&\left|\int_0^t\left(\left(p(V+\phi)-p(V)\right)\psi-\mu\tfrac{\psi_x\psi}{V+\phi}\right)\Big|_0^{+\infty}d\tau\right|\\&=\left|\int_0^t\left(p(v(0,\tau))-p(V(0,\tau))-\mu\tfrac{u_x(0,\tau)}{v(0,\tau)}+\mu\tfrac{\mu U_x(0,\tau)}{v(0,\tau)}\right)\psi(0,\tau)\,d\tau\right|\\&=\left|\int_0^t\left(p(v_-)-p(V(0,\tau))+\mu\tfrac{U_x(0,\tau)}{v(0,\tau)}\right)\psi(0,\tau)\,d\tau\right|\\&\le C\int_0^t\left(|v_--V(0,\tau)|+|V_x(0,\tau)|\right)|\psi(0,\tau)|\,d\tau\\&\le C\int_0^t g(\tau)\|\psi(\tau)\|^{\frac12}\|\psi_x(\tau)\|^{\frac12}d\tau\quad\left(\text{where }\ g(t)\triangleq|v_--V(0,t)|+|V_x(0,t)|\right)\\&\le\nu\int_0^t\|\psi_x(\tau)\|^2d\tau+C_\nu\int_0^t g(\tau)^{\frac43}\|\psi(\tau)\|^{\frac23}d\tau\\&\le\nu\int_0^t\|\psi_x(\tau)\|^2d\tau+C_\nu E(t)^{\frac23}\int_0^t g(\tau)^{\frac43}d\tau\\&\le\nu\int_0^t\|\psi_x(\tau)\|^2d\tau+C_\nu\delta^{\frac43},\end{aligned}$$

which shows (3.15). By virtue of (3.15) we derive (3.16) and (3.17) as follows:

$$\begin{aligned}
&\left|\int_0^t \psi(0,\tau)\,\psi_x(0,\tau)\,d\tau\right| \le C\left|\int_0^t \tfrac{\mu\psi(0,\tau)\psi_x(0,\tau)}{v(0,\tau)}d\tau\right| \\
&\le \nu\int_0^t \|\psi_x(\tau)\|^2\,d\tau + C\delta^{\frac{4}{3}} + C\left|\int_0^t (p(V+\phi)-p(V))\,\psi|_0^{+\infty}\,d\tau\right| \\
&\le \nu\int_0^t \|\psi_x(\tau)\|^2\,d\tau + C\delta^{\frac{4}{3}} + C\int_0^t \|\psi(\tau)\|^{\frac{1}{2}}\,\|\psi_x(\tau)\|^{\frac{1}{2}}\,|v(0,\tau)-V(0,\tau)|\,d\tau \\
&\le \nu\int_0^t \|\psi_x(\tau)\|^2\,d\tau + C\delta^{\frac{4}{3}} + CE\int_0^t (|v(0,\tau)-v_-| + |v_- - V(0,\tau)|)\,d\tau \\
&\le \nu\int_0^t \|\psi_x(\tau)\|^2\,d\tau + C\delta^{\frac{4}{3}} + C(|v_0 - v_-| + \delta) \\
&\le \nu\left(\int_0^t \|\psi_x(\tau)\|^2\,d\tau + C(\delta + |v_0 - v_-|)\right)
\end{aligned}$$

and

$$\begin{aligned}
&\left|\int_0^t \psi_\tau(0,\tau)\,\psi_x(0,\tau)\,d\tau\right| \\
&= \left|\int_0^t \psi_\tau(0,\tau)\,(u_x(0,\tau)-U_x(0,\tau))\,d\tau\right| \\
&= \left|\int_0^t \psi_\tau(0,\tau)\,a(\tau)\,d\tau\right| \quad \left(\text{where } a(t) \triangleq \tfrac{1}{\mu}(p(v(0,t))-p(v_-))\,v(0,t) - U_x(0,t)\right) \\
&= \left|a(t)\,\psi(0,t) - a(0)\,\psi(0,0) - \int_0^t \psi(0,\tau)\,a'(\tau)\,d\tau\right| \\
&\le C\left(|a(t)| + |a(0)| + \int_0^t |a'(\tau)|\,d\tau\right)E \\
&\le C(\delta + |v_0(0) - v_-|).
\end{aligned}$$

Thus we complete the proof. □

Using Lemmas 3.2 and 3.3, we can establish the following three lemmas using the same technique as in [11].

LEMMA 3.4. *It follows that for* $0 \le t \le T$,

$$\begin{aligned}
&\|(\phi,\psi)(t)\|^2 + \int_0^t \left(\left\|V_\tau^{\frac{1}{2}}\phi(\tau)\right\|^2 + \|\psi_x(\tau)\|^2\right)d\tau \\
&\le C\left(\delta^{\frac{1}{6}} + \|(\phi_0,\psi_0)\|^2 + E^{\frac{1}{2}}\int_0^t \|(\phi,\psi)_x(\tau)\|^2\,d\tau\right).
\end{aligned}$$

LEMMA 3.5. *It follows that for* $0 \le t \le T$,

$$\begin{aligned}
&\|\phi_x(t)\|^2 + \int_0^t \|\phi_x(\tau)\|^2\,d\tau \\
&\le C\left(\delta^{\frac{1}{2}} + |v_0 - v_-| + \|\phi_{0x}\|^2 + \|\psi_0\|^2 + \|\psi(t)\|^2\right. \\
&\left. + \int_0^t \left(\|\psi_x(\tau)\|^2 + (E+\delta)\,\|\phi_x(\tau)\|^2 + E\,\|\psi_{xx}(\tau)\|^2\right)d\tau\right).
\end{aligned}$$

LEMMA 3.6. *It follows that for* $0 \le t \le T$,

$$\begin{aligned}&\|\psi_x(t)\|^2 + \int_0^t \|\psi_{xx}(\tau)\|^2 d\tau \\ &\le C\left(\delta^{\frac{1}{2}} + |v_0 - v_-| + \|\psi_{0x}\|^2 + \int_0^t \left(\|(\phi,\psi)_x(\tau)\|^2 + E\|\psi_{xx}(\tau)\|^2\right) d\tau\right).\end{aligned}$$

Combining Lemmas 3.4–3.6 yields

$$\begin{aligned}&\|(\phi,\psi)(t)\|_1^2 + \int_0^t \left(\left\|V_\tau^{\frac{1}{2}}\phi(\tau)\right\|^2 + \|\phi_x(\tau)\|^2 + \|\psi_x(\tau)\|_1^2\right) d\tau \\ &\le C\left(\delta^{\frac{1}{6}} + |v_0 - v_-| + \|(\phi_0,\psi_0)\|_1^2\right. \\ &\left. + \int_0^t \left(E^{\frac{1}{2}}\|\psi_x(\tau)\|^2 + \left(E^{\frac{1}{2}} + \delta\right)\|\phi_x(\tau)\|^2 + E\|\psi_{xx}(\tau)\|^2\right) d\tau\right).\end{aligned}$$

Hence, choosing E and δ suitably small as $E + \delta < \varepsilon_1$, we have the a priori estimate (3.14). Thus Proposition 3.1 is completed.

4. Convergence to viscous shock wave. In this section, we discuss the convergence for the solution of (1.6)–(1.8) toward the front viscous shock wave for $p(v) = v^{-\gamma}$ under the condition $v_- < v_+$. Our discussions are largely due to those by Matsumura and Mei [3].

4.1. Viscous shock wave. The viscous shock wave of system (1.6) for the corresponding Cauchy problem is a smooth solution $(V,U)(\xi)$ $(\xi = x - st)$ satisfying (1.6) and $(V,U)(\pm\infty) = (v_\pm, u_\pm)$, namely,

$$\begin{cases} -sV' - U' = 0, \\ -sU' + p(V)' = \mu\left(\frac{U'}{V}\right)', \\ (V,U)(\pm\infty) = (v_\pm, u_\pm), \end{cases} \tag{4.1}$$

where $' = d/d\xi$, s is the shock speed, and $(v_\pm, u_\pm)$ are the given constant states at $\xi = \pm\infty$, satisfying the Rankine–Hugoniot condition

$$\begin{cases} -s(v_+ - v_-) - (u_+ - u_-) = 0, \\ -s(u_+ - u_-) + (p(v_+) - p(v_-)) = 0 \end{cases} \tag{4.2}$$

and the entropy condition

$$\lambda_1(v_+) < s < \lambda_1(v_-)\,(<0) \quad \text{or} \quad (0<)\lambda_2(v_+) < s < \lambda_2(v_-). \tag{4.3}$$

Integrate (4.1) under the Rankine–Hugoniot condition (4.2), and the problem (4.1) is deduced to

$$\begin{cases} \frac{\mu s V'}{V} = -s^2 V - p(V) - b \triangleq h(V), & V(\pm\infty) = v_\pm, \\ U = -s(V - v_\pm) + u_\pm, \end{cases} \tag{4.4}$$

where $b = -s^2 v_\pm - p(v_\pm)$.

In our present problem, the solution to (1.6)–(1.8) is expected to behave as the front viscous shock wave, i.e., $s > 0$, and hence the entropy condition (4.3) yields

$$v_- < v_+. \tag{4.5}$$

Therefore, we have the following lemma on the existence of the front viscous shock wave (see [3]).

LEMMA 4.1. *For any* (v_+, u_+) *and* $v_- = p^{-1}(p_0)$ *with* $0 < v_- < v_+$, *there exist a unique number* $u_- \in R(u_- > u_+)$ *and* $s = \sqrt{-\frac{p(v_+)-p(v_-)}{v_+-v_-}} > 0$ *satisfying* (4.2), *and a unique front viscous shock profile* $(V,U)(\xi)$ $(\xi = x - st)$ *of* (1.6) *up to shift determined by* (4.4), *which satisfies*

$$|V(\xi) - v_\pm, U(\xi) - u_\pm| = O(1)\,|v_+ - v_-, u_+ - u_-|\, e^{-c_\pm|\xi|} \tag{4.6}$$

as $\xi \to \pm\infty$, *where* $c_\pm = v_\pm \left|p'(v_\pm) + s^2\right| / \mu s > 0$.

4.2. Determination of the shift. We first fix a viscous shock wave $(V,U)(x - st)$ mentioned above. Assume that the initial perturbation $(v_0, u_0)(x)$ is given in a neighborhood of the front viscous shock profile $(V,U)(x-\beta)$, where β is a sufficient large constant so that $(V,U)(x-\beta)$ is away from the boundary. Then a shifted front viscous profile $(V,U)(x - st + \alpha - \beta)$ is determined by the data $(v_0, u_0)(x)$ as in [3].

Denote $(V,U) = (V,U)(x - st + \alpha - \beta)$. From $(1.6)_2$ and $(4.1)_2$ we have

$$(u-U)_t = -\left(p(v) - p(V) - \mu\frac{u_x}{v} + \mu\frac{U'}{V}\right)_x. \tag{4.7}$$

Integrating (4.7) over $[0, +\infty)$ with respect to x and using the boundary condition (1.7), we have

$$\begin{aligned} &\frac{d}{dt}\int_0^{+\infty} (u(x,t) - U(x - st + \alpha - \beta))\,dx \\ &= -\left(p(v) - p(V) - \mu\frac{u_x}{v} + \mu\frac{U'}{V}\right)\Big|_0^{+\infty} \\ &= \left(p(v_-) - p(V) + \mu\frac{U'}{V}\right)\Big|_{x=0}. \end{aligned} \tag{4.8}$$

Integrating (4.8) again with respect to t, we get

$$\begin{aligned} &\int_0^{+\infty} (u(x,t) - U(x - st + \alpha - \beta))\,dx \\ &= \int_0^{+\infty} (u_0(x) - U(x + \alpha - \beta))\,dx + \int_0^t \left(p(v_-) - p(V) + \tfrac{\mu U'}{V}\right)\Big|_{x=0} d\tau. \end{aligned} \tag{4.9}$$

If we assume that $u(x,t)$ tends to $U(x - xt + \alpha - \beta)$ in L^1 as $t \to +\infty$, then the right-hand side of (4.9) must go to zero as $t \to +\infty$. Hence, if we set

$$\begin{aligned} I(\alpha) \triangleq &\int_0^{+\infty} (u_0(x) - U(x + \alpha - \beta))\,dx \\ &+ \int_0^{+\infty} \left(p(v_-) - p(V) + \frac{\mu U'}{V}\right)\Big|_{x=0} d\tau, \end{aligned} \tag{4.10}$$

then the shift α must be determined by $I(\alpha) = 0$. Differentiating $I(\alpha)$ with respect to α and using (4.4) yields

$$\begin{aligned} I'(\alpha) &= -\int_0^{\infty} U'(x + \alpha - \beta)\,dx + \int_0^{\infty} (-sU'(-s\tau + \alpha - \beta))\,d\tau \\ &= -u_+ + U(\alpha - \beta) + u_- - U(\alpha - \beta) \\ &= u_- - u_+. \end{aligned} \tag{4.11}$$

Hence $I(\alpha) = I(0) + (u_- - u_+)\alpha$. Thus, the shift $\alpha = \alpha(\beta)$ should be determined explicitly by $I(0) + (u_- - u_+)\alpha = I(\alpha) = 0$, that is,

$$\begin{aligned}\alpha &\triangleq \frac{1}{u_- - u_+}\left(\int_0^\infty (u_0(x) - U(x-\beta))\,dx\right.\\ &\quad\left.+\int_0^\infty (p(v_-) - p(V(-st-\beta)))\,dt + \int_0^\infty \frac{\mu U'}{V}(-st-\beta)\,dt\right)\\ &= \frac{1}{u_- - u_+}\left(\int_0^\infty (u_0(x) - U(x-\beta))\,dx\right.\\ &\quad\left.+\int_0^\infty (p(v_-) - p(V(-st-\beta)))\,dt + \mu\ln\frac{v_-}{V(-\beta)}\right).\end{aligned} \tag{4.12}$$

From (4.9), (4.12), (4.1), and Lemma 4.1 we have heuristically

$$\begin{aligned}&\int_0^\infty (u(x,t) - U(x-st+\alpha-\beta))\,dx\\ &= I(\alpha) - \int_t^\infty \left(p(v_-) - p(V) + \frac{\mu U'}{V}\right)\Big|_{x=0} d\tau\\ &= -\int_t^\infty (p(v_-) - p(V(-s\tau+\alpha-\beta)))\,d\tau - \mu\ln\frac{v_-}{V(-st+\alpha-\beta)}\\ &\to 0 \quad \text{as } t\to\infty.\end{aligned} \tag{4.13}$$

Particularly, note that

$$\begin{aligned}&\int_0^\infty (u_0(x) - U(x+\alpha-\beta))\,dx\\ &= -\int_0^\infty \left(p(v_-) - p(V) + \frac{\mu U'}{V}\right)\Big|_{x=0} dt\\ &= -\int_0^\infty (p(v_-) - p(V(-st+\alpha-\beta)))\,dt + \mu\ln\frac{V(\alpha-\beta)}{v_-}.\end{aligned} \tag{4.14}$$

On the other hand, by the similar argument of $(1.1)_1$ and $(4.1)_1$, the following must hold:

$$\int_0^\infty (v_0(x) - V(x+\alpha-\beta))\,dx + \int_0^\infty (U(-st+\alpha-\beta) - u(0,t))\,dt = 0. \tag{4.15}$$

However, as stated in Matsumura and Mei [3], we expect that $u(0,t)$ is automatically controlled by the effect of boundary so that (4.15) holds with the same shift α defined by (4.12). This situation is really possible because $u(0,t)$ is not specified.

4.3. Main result. Suppose that for some $\beta > 0$,

$$(v_0(x) - V(x-\beta), u_0(x) - U(x-\beta)) \in H^1(R_+) \cap L^1(R_+), \tag{4.16}$$

$$(\Phi_0, \Psi_0)(x) = -\int_x^\infty (v_0(y) - V(y-\beta), u_0(y) - U(y-\beta))\,dy \in L^2(R_+), \tag{4.17}$$

then we have an asymptotic property of the constant shift α as follows.

LEMMA 4.2. *If* (4.16) *and* (4.17) *hold, then* $(\Phi_0, \Psi_0) \in H^2(R_+)$ *and the shift* α *defined by* (4.12) *satisfies that* $\alpha \to 0$ *as* $\|(\Phi_0, \Psi_0)\|_2 \to 0$ *and* $\beta \to +\infty$.

The proof of Lemma 4.2 is easily shown by (4.12).

We now state our second main theorem.

THEOREM 4.1. *For any given* (v_+, u_+), $v_- = p^{-1}(p_0) > 0$ *with* $v_+ > v_-$, *and* u_- *determined in Lemma* 4.1, *suppose the assumptions* (4.16)–(4.17) *and*

$$(\gamma - 1)^2 (v_+ - v_-) < 2\gamma v_-.$$

Then there exists a positive constant ε_2 *such that if* $\|(\Phi_0, \Psi_0)\|_2 + |v_0 - v_-| + \beta^{-1} < \varepsilon_2$, *then* (1.6)–(1.8) *has a unique global solution* $(v, u)(x, t)$ *satisfying*

$$v(x,t) - V(x - st + \alpha - \beta) \in C^0\left([0,\infty); H^1(R_+)\right) \cap L^2\left([0,\infty); H^1(R_+)\right),$$

$$u(x,t) - U(x - st + \alpha - \beta) \in C^0\left([0,\infty); H^1(R_+)\right) \cap L^2\left([0,\infty); H^2(R_+)\right)$$

and, moreover,

$$\sup_{x \in R_+} |(v,u)(x,t) - (V,U)(x - st + \alpha - \beta)| \to 0 \quad \text{as } t \to \infty, \tag{4.18}$$

where $\alpha = \alpha(\beta)$ *is determined by* (4.12).

4.4. Reformulation of the original problem. Define the new unknowns by

$$\begin{cases} \phi(x,t) = -\displaystyle\int_x^\infty (v(y,t) - V(y - st + \alpha - \beta))\, dy, \\ \psi(x,t) = -\displaystyle\int_x^\infty (u(y,t) - U(y - st + \alpha - \beta))\, dy. \end{cases} \tag{4.19}$$

Then the original system (1.6) can be reduced to

$$\begin{cases} \phi_t - \psi_x = 0, \\ \psi_t + (p(V + \phi_x) - p(V)) = \mu\left(\frac{U' + \psi_{xx}}{V + \phi_x} - \frac{U'}{V}\right). \end{cases} \tag{4.20}$$

The initial condition (1.8) is transformed to

$$\begin{aligned} \phi(x,0) &= -\int_x^\infty (v_0(y) - V(y + \alpha - \beta))\, dy \\ &= \Phi_0(x) + \int_x^\infty (V(y + \alpha - \beta) - V(y - \beta))\, dy \\ &= \Phi_0(x) + \int_x^\infty \int_0^\alpha V'(y + \theta - \beta)\, d\theta dy \\ &= \Phi_0(x) + \int_0^\alpha (v_+ - V(x + \theta - \beta))\, d\theta \triangleq \phi_0(x), \end{aligned} \tag{4.21}$$

$$\begin{aligned} \psi(x,0) &= -\int_x^\infty (u_0(y) - U(y + \alpha - \beta))\, dy \\ &= \Psi_0(x) + \int_x^\infty (U(y + \alpha - \beta) - U(y - \beta))\, dy \\ &= \Psi_0(x) + \int_0^\alpha (u_+ - U(x + \theta - \beta))\, d\theta \triangleq \psi_0(x). \end{aligned} \tag{4.22}$$

Then, by the same proof as in [3], we have the following fact for the initial perturbations (4.21) and (4.22) for ϕ and ψ.

LEMMA 4.3. *Under the conditions* (4.16) *and* (4.17)*, the initial perturbation* $(\phi_0, \psi_0) \in H^2(R_+)$ *and satisfies*

$$\|(\phi_0, \psi_0)\|_2 \to 0 \quad \text{as} \quad \|(\Phi_0, \Psi_0)\|_2 \to 0 \text{ and } \beta \to +\infty. \tag{4.23}$$

Concerning the boundary data, from (4.19) and (4.13), it must hold that

$$\begin{aligned} \psi(0,t) &= -\int_0^\infty (u(y,t) - U(y - st + \alpha - \beta))\, dy \\ &= \int_t^\infty (p(v_-) - p(V(-s\tau + \alpha - \beta)))\, d\tau + \mu \ln \tfrac{v_-}{V(-st+\alpha-\beta)} \\ &\triangleq A(t). \end{aligned} \tag{4.24}$$

Thus, by (4.20)–(4.24), we reformulate our problem to

$$\begin{cases} \phi_t - \psi_x = 0, \\ \psi_t - f(V)\phi_x - \frac{\mu}{V}\psi_{xx} = F, \\ (\phi, \psi)(x,0) = (\phi_0, \psi_0)(x) \in H^2(R_+), \ x \geq 0, \\ \psi(0,t) = A(t), \qquad t \geq 0, \end{cases} \tag{4.25}$$

where

$$f(V) = -p'(V) + \frac{\mu s V_x}{V^2} = \frac{h(V) - p'(V)V}{V} \equiv \frac{K(V)}{V}, \tag{4.26}$$

$$F = -(p(V + \phi_x) - p(V) - p'(V)\phi_x) - (\mu\psi_{xx} + h(V)\phi_x)\left(\frac{1}{V + \phi_x} - \frac{1}{V}\right). \tag{4.27}$$

We define the solution space of (4.25) on $I \subset [0, \infty)$ by

$$\begin{aligned} G(I) = \Big\{ &(\phi, \psi) \,\big|\, (\phi, \psi) \in C^0\left(I; H^2(R_+)\right), \ \phi_x \in L^2\left(I; H^1(R_+)\right), \\ &\psi_x \in L^2\left(I; H^2(R_+)\right) \quad \text{with} \quad \sup_{[0,T]} \|(\phi, \psi)(t)\|_2 \leq E_0 \Big\} \end{aligned}$$

for some small constant E_0, so that $\sup_{R_+ \times I}(V + \phi_x)(x,t) \geq \frac{1}{2}v_-$. We also set

$$N(t) = \sup_{0 \leq \tau \leq t} \|(\phi, \psi)(\tau)\|_2, \qquad N_0 = \|\phi_0\|_2 + \|\psi_0\|_2.$$

To prove Theorem 4.1 it suffices to prove the following theorem.

THEOREM 4.2. *Suppose that the assumptions in Theorem* 4.1 *hold. Then there exist positive constants* ε_3 *and* C *such that if* $N_0 + |v_0 - v_-| + \beta^{-1} \leq \varepsilon_3$*, then the initial-boundary value problem* (4.25) *has a unique global solution* $(\phi, \psi) \in G([0, \infty))$ *satisfying*

$$\begin{aligned} &\|(\phi, \psi)(t)\|_2^2 + \int_0^t \left(\|\phi_x(\tau)\|_1^2 + \|\psi_x(\tau)\|_2^2\right) d\tau \\ &\qquad \leq C\left(|v_0 - v_-| + e^{-c_-\beta} + \|(\phi_0, \psi_0)\|_2^2\right), \end{aligned} \tag{4.28}$$

$$\begin{aligned}&\int_0^t \left(\left| \frac{d}{d\tau} \|\phi_x(\tau)\|^2 \right| + \left| \frac{d}{d\tau} \|\psi_x(\tau)\|^2 \right| \right) d\tau \\ &\quad \le C \left(|v_0 - v_-| + e^{-c_-\beta} + \|(\phi_0, \psi_0)\|_2^2 \right)\end{aligned} \tag{4.29}$$

for all $t \ge 0$. Moreover, it holds that the asymptotic stability

$$\sup_{x \in R_+} |(\phi_x, \psi_x)(x,t)| \to 0 \quad \text{as } t \to \infty. \tag{4.30}$$

Similar to Theorem 3.2, Theorem 4.2 can be shown by the continuation argument combining the local existence result together with the a priori estimates. We omit here the local existence result since it is standard. We now give the following a priori estimates which will be shown in the next subsection.

PROPOSITION 4.1 (a priori estimates). *Suppose all assumptions in Theorem* 4.2. *Let $(\phi, \psi) \in G([0,T])$ be a solution to* (4.25) *for $T > 0$. Then there exist positive constants δ_1 and C independent of T such that if $N(T) < \delta_1$, then (ϕ, ψ) satisfies the a priori estimates* (4.28) *and* (4.29) *for $0 \le t \le T$.*

4.5. A priori estimates. Let $(\phi, \psi) \in G([0,T])$ be a solution to (4.25) which satisfies $N(T) < 1$, $\beta > 1$, and $|\alpha| < 1$. In this subsection, we use the letter C to denote some positive constant independent of T, β, and α.

To prove the a priori estimates, we need the following estimates at the boundary.

LEMMA 4.4. *The following inequalities hold for $0 \le t \le T$:*

$$\left| \int_0^t \phi(0,\tau)\psi(0,\tau)\,d\tau \right| \le Ce^{-c_-\beta},$$
$$\left| \int_0^t \psi(0,\tau)\psi_x(0,\tau)\,d\tau \right| \le Ce^{-c_-\beta},$$

$$\left| \int_0^t \phi_x(0,\tau)\psi_x(0,\tau)\,d\tau \right| \le C\left(|v_0 - v_-| + e^{-c_-\beta} \right),$$
$$\left| \int_0^t \psi_x(0,\tau)\psi_t(0,\tau)\,d\tau \right| \le Ce^{-c_-\beta},$$

and

$$\left| \int_0^t \psi_x(0,\tau)\psi_{xx}(0,\tau)\,d\tau \right| \le C\left(|v_0 - v_-| + e^{-c_-\beta} \right),$$
$$\left| \int_0^t \psi_{xt}(0,\tau)\psi_{xx}(0,\tau)\,d\tau \right| \le C\left(|v_0 - v_-| + e^{-c_-\beta} \right).$$

Proof. By Sobolev's inequality, we have

$$\begin{cases} |\phi(0,t)| \le \sup\limits_{x \in R_+} |\phi(x,t)| \le CN(T) \le C, \\ |\psi_x(0,t)| \le \sup\limits_{x \in R_+} |\phi_x(x,t)| \le CN(T) \le C. \end{cases} \tag{4.31}$$

Using Lemma 4.1 gives

$$\begin{aligned}|V(-st + \alpha - \beta) - v_-| &\le Ce^{-c_-|-st+\alpha-\beta|} \\ &= Ce^{-c_-(\beta-\alpha)}e^{-c_-st} \le Ce^{-c_-\beta}e^{-c_-st}.\end{aligned}$$

Thus we have

$$\begin{aligned}|\psi(0,t)| = |A(t)| &\le C\int_t^\infty |V(-s\tau+\alpha-\beta)-v_-|\,d\tau + C\,|V(-st+\alpha-\beta)-v_-| \\ &\le Ce^{-c_-\beta}e^{-c_-st}.\end{aligned}$$

Similarly, we can conclude from (4.4) and Lemma 4.1 that

$$\left|\frac{d^kA(t)}{dt^k}\right| \le Ce^{-c_-\beta}e^{-c_-st}, \qquad k=0,1,2,3. \tag{4.32}$$

From (4.31) and (4.32), it follows that

$$\left|\int_0^t \phi(0,\tau)\,\psi(0,\tau)\,d\tau\right| \le \int_0^t |\phi(0,\tau)|\,|A(\tau)|\,d\tau \le Ce^{-c_-\beta},$$

$$\left|\int_0^t \psi(0,\tau)\,\psi_x(0,\tau)\,d\tau\right| \le \int_0^t |\psi_x(0,\tau)|\,|A(\tau)|\,d\tau \le Ce^{-c_-\beta},$$

$$\left|\int_0^t \psi_x(0,\tau)\,\psi_t(0,\tau)\,d\tau\right| \le \int_0^t |\psi_x(0,\tau)|\,|A'(\tau)|\,d\tau \le Ce^{-c_-\beta}.$$

In light of (4.31), (4.25), (4.32), and Lemma 2.2, we obtain

$$\begin{aligned}\left|\int_0^t \phi_x(0,\tau)\,\psi_x(0,\tau)\,d\tau\right| &\le \int_0^t |v(0,\tau)-V(-s\tau+\alpha-\beta)|\,|\psi_x(0,\tau)|\,d\tau \\ &\le C\int_0^t |v(0,\tau)-V(-s\tau+\alpha-\beta)|\,d\tau \\ &\le C\int_0^t \left(|v(0,\tau)-v_-| + |V(-s\tau+\alpha-\beta)-v_-|\right)d\tau \\ &\le C\left(|v_0-v_-| + e^{-c_-\beta}\right).\end{aligned}$$

By (4.19) and the boundary condition (1.7)

$$\begin{aligned}\psi_{xx}(0,t) &= u_x(0,t) - U'(-st+\alpha-\beta) \\ &= -\tfrac{1}{\mu}v(0,t)\left(p(v(0,t)) - p(v_-)\right) - U'(-st+\alpha-\beta).\end{aligned} \tag{4.33}$$

Hence (4.31) and Lemma 2.2 yield

$$\begin{aligned}\left|\int_0^t \psi_x(0,\tau)\,\psi_{xx}(0,\tau)\,d\tau\right| &\le C\left(\int_0^t \tfrac{1}{\mu}\,|v(0,\tau)|\,|p(v(0,\tau)) - p(v_-)|\,d\tau \right. \\ &\qquad \left. + \int_0^t |U'(-s\tau+\alpha-\beta)|\,d\tau\right) \\ &\le C\left(|v_0-v_-| + e^{-c_-\beta}\right).\end{aligned}$$

Finally, we estimate $|\int_0^t \psi_{xt}(0,\tau)\,\psi_{xx}(0,\tau)\,d\tau|$. Making use of (4.33), (4.31),

Lemma 2.2, (4.4), Lemma 4.1, and the integration of parts, we have

$$\begin{aligned}
&\left|\int_0^t \psi_{xt}(0,\tau)\,\psi_{xx}(0,\tau)\,d\tau\right| \\
=\ &\left|\psi_x(0,t)\,\psi_{xx}(0,t)-\psi_x(0,0)\,\psi_{xx}(0,0)-\int_0^t \psi_x(0,\tau)\,\psi_{xxt}(0,\tau)\,d\tau\right| \\
\le\ &|\psi_x(0,t)\,\psi_{xx}(0,t)|+|\psi_x(0,0)\,\psi_{xx}(0,0)|+\int_0^t |\psi_x(0,\tau)|\,|\psi_{xxt}(0,\tau)|\,d\tau \\
\le\ &C\left(|v_0-v_-|+e^{-c_-\beta}\right)+C\int_0^t \Big(\tfrac{1}{\mu}\,|v_t(0,\tau)|\,|p(v(0,\tau))-p(v_-)| \\
&+\tfrac{1}{\mu}\,|v(0,\tau)|\,|p'(v(0,\tau))\,v_t(0,\tau)|+s\,|U''(-s\tau+\alpha-\beta)|\Big)\,d\tau \\
\le\ &C\left(|v_0-v_-|+e^{-c_-\beta}\right). \qquad \square
\end{aligned}$$

Applying Lemma 4.4, we get the desired a priori estimates (4.28) and (4.29). The proof is the same as that of Proposition 3.4 in [3] except for the boundary values mentioned above, so we omit the details.

EFFECTS OF CERTAIN DEGENERACIES IN THE PREDATOR-PREY MODEL*

E. N. DANCER† AND YIHONG DU‡

Abstract. To demonstrate the influence of spatial heterogeneity on the predator-prey model, we study the effects of the partial vanishing of the nonnegative coefficient functions $b(x)$ and $e(x)$, respectively, in the steady-state predator-prey model

$$\begin{array}{l} -d_1(x)\Delta u = \lambda a_1(x)u - b(x)u^2 - c(x)uv, \\ -d_2(x)\Delta v = \mu a_2(x)c - e(x)v^2 + d(x)uv, \end{array} \qquad u|_{\partial\Omega} = v|_{\partial\Omega} = 0,$$

where all other coefficient functions are strictly positive over the bounded domain Ω in R^N. Critical values of the parameter λ are obtained to show that, in each case, the vanishing has little effect on the behavior of the model when λ is below the critical value, while essential changes occur once λ is beyond the critical value.

Key words. global bifurcation, a priori estimates, predator-prey

1. Introduction.

We are mainly concerned with the nonnegative steady-state solutions of the predator-prey model

$$\left\{ \begin{array}{l} u_t - d_1(x)\Delta u = \lambda a_1(x)u - b(x)u^2 - c(x)uv, \\ v_t - d_2(x)\Delta v = \mu a_2(x)v - e(x)v^2 + d(x)uv, \\ u|_{\partial\Omega\times(0,\infty)} = v|_{\partial\Omega\times(0,\infty)} = 0, \end{array} \right. \tag{1.1}$$

where Ω is a bounded smooth domain in R^N ($N \geq 2$), λ, μ are constants, and $d_1, d_2, a_1, a_2, b, c, d, e$ are nonnegative continuous functions on $\overline{\Omega}$. The dependence on the space variable x of these coefficient functions represents the fact that the prey u and predator v interact in a spatially heterogeneous environment. If the environment is spatially homogeneous, then all these coefficient functions reduce to positive constants, and (1.1) is known as, in this special case, the classical Lotka–Volterra predator-prey model with diffusion, which has attracted extensive study (see, e.g., [BB1, Da1, Da2, KL, Li, LP, Pao, Ya] and the references therein). It is interesting to know whether the model behaves differently when the environment is spatially heterogeneous. When all the coefficient functions are strictly positive over Ω, it is easy to see that (1.1) behaves similarly to the classical Lotka–Volterra case. Thus, we will call (1.1) a *classical* predator-prey model when all the coefficient functions are strictly positive over Ω. A limiting case is when some of the coefficient functions in (1.1) vanish partially over Ω, which we henceforth call a degeneracy. Equation (1.1) with a degeneracy will hence be called a *degenerate* predator-prey model. The main purpose of this paper is to show that the dynamical behavior of (1.1) with certain degeneracies may change drastically from the classical model. This fact shows that the influence of certain

spatial heterogeneity may cause significant changes of behavior for the predator-prey model. A study in the same spirit was carried out recently by Du [Du1, Du2] for the competition model, but the difficulties and the techniques required in the predator-prey model here are very different from those in [Du1, Du2]; the new phenomena revealed are also fundamentally different.

We would like to remark that a degenerate model as described above is a natural limiting problem for the classical model when some of its coefficients are very small on part of the underlying domain. This is an extreme opposite case from all coefficients being constant. Hence a better understanding of the degenerate cases helps the understanding of the more natural classical model with variable coefficients, particularly, the transition of its behavior from a homogeneous environment to an extremely heterogeneous environment. Note that while we understand completely when there is at least one coexistence state for the classical model (see [BB1] or [Da2]), we do not know much about the multiplicity of the coexistence states (except for space dimension 1, where uniqueness is known to hold) and their spatial behavior. To try to understand these problems one is led naturally to degenerate cases. The cases we choose to study here demonstrate considerable differences from the classical homogeneous problem (see, for example, our discussions after Theorem 2.6) and reveal interesting spatial behavior of the coexistence states (see Theorems 2.7 and 3.4). However, they do not seem to lead to multiple coexistence states. It is our hope that this sort of information can also help with the difficult problem of understanding the dynamics of the parabolic predator-prey system.

Let us now describe our results in more detail. We will analyze the effects on the set of steady-state solutions of (1.1) caused by the partial vanishing of $b(x)$ and $e(x)$, respectively. Let us recall that these two functions describe the introspecific pressures of u and v, respectively. The partial vanishing of $b(x)$ implies that in the absence of v, the growth of u is governed by a degenerate logistic law or, more precisely, a mixture of the logistic and Malthusian laws over Ω. The implication of the vanishing of $e(x)$ on v is similar.

When $b(x)$ vanishes partially in Ω, we assume that all the other coefficient functions are positive over Ω. For simplicity, we assume further that all these nonvanishing coefficients are positive constants. It can be easily seen that our arguments work as well without this further assumption. Therefore we lose no generality by doing this. Furthermore, through some simple rescalings of u, v and the coefficients, we see that for the steady-state solutions, we need only consider the following further simplified system:

$$\begin{cases} -\Delta u = \lambda u - b(x)u^2 - cuv, \\ -\Delta v = \mu v - v^2 + duv, \\ u|_{\partial\Omega} = v|_{\partial\Omega} = 0, \end{cases} \tag{1.2}$$

where c, d are positive constants. We assume that $b(x) \equiv 0$ on the closure of some smooth domain Ω_0 satisfying $\overline{\Omega}_0 \subset \Omega$ and $b(x) > 0$ over $\overline{\Omega} \setminus \overline{\Omega}_0$. We will show that there exists a critical value $\lambda^* > 0$ such that (1.2) behaves as if $b(x) \equiv 1$ when $\lambda < \lambda^*$, while essential changes occur once $\lambda \geq \lambda^*$ (see Theorems 2.4 and 2.6 for details). We will also discuss the limiting behavior of the system as $\mu \to -\infty$, where the limiting problem is an interesting free boundary problem (see (2.14), Theorem 2.7, and Remark 2.1 for more details).

Similarly, when $e(x)$ in (1.1) vanishes partially in Ω while all other coefficient functions are positive, then without loss of generality we can consider the following

simplified system:

$$\begin{cases} -\Delta u = \lambda u - u^2 - cuv, \\ -\Delta v = \mu v - e(x)v^2 + duv, \\ u|_{\partial\Omega} = v|_{\partial\Omega} = 0, \end{cases} \tag{1.3}$$

where we assume that $e(x)$ satisfies the same conditions as $b(x)$ given above. Again we will show that there exists a critical number $\lambda_* > 0$ such that (1.3) behaves as if $e(x) \equiv 1$ if $\lambda < \lambda_*$, but drastic changes occur once $\lambda \geq \lambda_*$. However, we will show that the changes now are very different in nature from that for (1.2) (see Theorems 3.2 and 3.3 for details).

The rest of this paper is organized as follows. In section 2 we study (1.2), where for both cases $\lambda < \lambda^*$ and $\lambda \geq \lambda^*$, sufficient and necessary conditions are obtained for the existence of positive solutions of (1.2). Our analysis is based on an a priori estimate result (Theorem 2.1) and a global bifurcation method adapted from [BB2]. When the global bifurcation branch of positive solutions is unbounded, its asymptotic behavior is studied (Theorem 2.7). In section 3 we carry out a similar analysis for (1.3), but as will become clear later, the techniques used and phenomena revealed there are quite different from those in section 2. In the appendix, we collect a few known results used in sections 2 and 3.

2. Degeneracy in the prey equation. This section is devoted to the understanding of the effects of the vanishing of $b(x)$ on the system (1.2). We will, as usual, fix c, d and regard λ and μ as varying parameters. We assume that $b(x)$ possesses the properties described in the introduction.

Clearly $v \equiv 0$ satisfies the second equation in (1.2). In this case u satisfies the so-called degenerate logistic equation

$$-\Delta u = \lambda u - b(x)u^2, \quad u|_{\partial\Omega} = 0. \tag{2.1}$$

It is well known (see [Ou, dP, FKLM]) that (2.1) has only the trivial nonnegative solution $u \equiv 0$ when $\lambda \notin (\lambda_1^\Omega, \lambda_1^{\Omega_0})$, while there is a unique positive solution u_λ when λ belongs to this open interval. Here we use λ_1^ω to denote the first Dirichlet eigenvalue of the Laplacian over the domain ω. For later use, we also introduce the notation $\lambda_1^\omega(\phi)$, which denotes the first eigenvalue of the problem

$$-\Delta u + \phi u = \lambda u, \quad u|_{\partial\omega} = 0.$$

Clearly, $\lambda_1^\omega = \lambda_1^\omega(0)$ under these notations.

It is easily seen that $u_\lambda \to 0$ in $L^\infty(\Omega)$ when $\lambda \to \lambda_1^\Omega$. Moreover, by [DH], as $\lambda \to \lambda_1^{\Omega_0}$,

$$\begin{aligned} &u_\lambda \to \infty && \text{uniformly on } \overline{\Omega}_0, \\ &u_\lambda \to U_{\lambda^{\Omega_0}} && \text{locally uniformly on } \overline{\Omega} \setminus \overline{\Omega}_0, \end{aligned}$$

where U_λ denotes the minimal positive solution of the following boundary blow-up problem:

$$-\Delta U = \lambda U - b(x)U^2, \quad x \in \Omega \setminus \overline{\Omega}_0; \qquad U|_{\partial\Omega} = 0, \quad U|_{\partial\Omega_0} = \infty. \tag{2.2}$$

Here $U|_{\partial\Omega_0} = \infty$ means $\lim_{d(x,\partial\Omega_0)\to 0} U(x) = \infty$. By [DH], (2.2) has a minimal and maximal positive solution for each $\lambda \in (-\infty, \infty)$.

To summarize, for each $\lambda \in (\lambda_1^\Omega, \lambda_1^{\Omega_0})$, (1.2) has a unique semitrivial solution of the form $(u, 0)$ with $u > 0$, namely, $(u_\lambda, 0)$; there is no such semitrivial solution for other λ values.

When $u \equiv 0$, then v satisfies the logistic equation

$$-\Delta v = \mu v - v^2, \quad v|_{\partial\Omega} = 0.$$

It is well known that this equation has no positive solution when $\mu \le \lambda_1^\Omega$, and there is a unique positive solution $v = \theta_\mu$ when $\mu > \lambda_1^\Omega$. Thus (1.2) has a unique semitrivial solution $(0, \theta_\mu)$ of the form $(0, v)$ with $v > 0$ if $\mu > \lambda_1^\Omega$, and there is no such semitrivial solution for other μ values.

The obvious solution $(u, v) = (0, 0)$ of (1.2) is called the trivial solution.

To analyze the set of positive solutions for (1.2) we will need the following a priori estimates.

THEOREM 2.1. *Given an arbitrary positive constant M we can find another positive constant C, depending only on M and b, c, d, Ω in* (1.2)*, such that if (u, v) is a positive solution of* (1.2) *with $|\lambda| + |\mu| \le M$, then*

$$\|u\|_\infty + \|v\|_\infty \le C.$$

Here $\|\cdot\|_\infty = \|\cdot\|_{L^\infty(\Omega)}$.

In the proof of Theorem 2.1, and also in later discussions of the paper, we will need the following result.

LEMMA 2.2. *Suppose $\{u_n\} \subset C^2(\overline{\Omega})$ satisfies*

$$-\Delta u_n \le \lambda u_n, \quad u_n|_{\partial\Omega} = 0, \quad u_n \ge 0, \quad \|u_n\|_\infty = 1,$$

where λ is a positive constant. Then there exists $u_\infty \in L^\infty(\Omega) \cap H_0^1(\Omega)$ such that, subject to a subsequence, $u_n \to u_\infty$ weakly in $H_0^1(\Omega)$, strongly in $L^p(\Omega)$ for all $p \ge 1$, and $\|u_\infty\|_\infty = 1$.

Proof. From the assumption, clearly

$$\int_\Omega |\nabla u_n|^2 dx \le \lambda \int_\Omega u_n^2 dx \le \lambda |\Omega|.$$

Hence $\{u_n\}$ is bounded in $H_0^1(\Omega)$. It follows that by passing to a subsequence, $u_n \to u_\infty$ weakly in $H_0^1(\Omega)$ and strongly in $L^2(\Omega)$. As $\|u_n\|_\infty = 1$, $u_n \to u_\infty$ in $L^2(\Omega)$ implies $u_n \to u_\infty$ in $L^p(\Omega)$ for all $p \ge 1$. Clearly $0 \le u_\infty \le 1$.

It remains to show that $\|u_\infty\|_\infty = 1$. Assume by way of contradiction that $\|u_\infty\|_\infty = 1 - \epsilon < 1$. We are going to prove that this implies $\|u_n\|_\infty < 1$ for all large n, contradicting the assumption that $\|u_n\|_\infty = 1$. This would finish the proof.

From the regularity of the operator $(-\Delta)^{-1}$ we know that

$$w := \lim_{n\to\infty} \lambda(-\Delta)^{-1} u_n = \lambda(-\Delta)^{-1} u_\infty$$

belongs to $C^1(\overline{\Omega})$, and $w = 0$ on $\partial\Omega$. By our assumption, we easily see that $0 \le u_n \le \lambda(-\Delta)^{-1} u_n$. Hence there exists $n_0 \ge 1$ such that for all $n > n_0$, $u_n \le w + 1 - (3/4)\epsilon$. We can now choose a small neighborhood U of $\partial\Omega$ in $\overline{\Omega}$ such that, on U, $u_n < 1 - \epsilon/2$ for $n = 1, \ldots, n_0$ and $w < \epsilon/4$. Thus we have $u_n < 1 - \epsilon/2$ on U for all $n \ge 1$.

In the following, we want to show that for any $x_0 \in \Omega \backslash U$, we can find a small open ball B_{x_0} centered at x_0 such that $u_n \le 1 - \epsilon/2$ on B_{x_0} for all large n. As $\Omega \setminus U$ can

be covered by finitely many such balls, this would eventually mean that $u_n \le 1-\epsilon/2$ on $\Omega \setminus U$ for all large n. Therefore, $\|u_n\|_\infty < 1$ for all large n, as required.

Let us now fix such an x_0. Denote $B_r(x_0) = \{x : |x - x_0| < r\}$ and let

$$v_n(r) = \int_{\partial B_r(x_0)} |u_n(y) - u_\infty(y)| dS_y.$$

We have, for some small positive r_0,

$$\int_0^{r_0} v_n(r)dr = \int_{B_{r_0}(x_0)} |u_n(x) - u_\infty(x)|dx \le \|u_n - u_\infty\|_{L^1(\Omega)} \to 0$$

as $n \to \infty$. Hence, $v_n(r) \to 0$ for almost every $r \in (0, r_0)$.

Choose $r \in (0, r_0)$ very small so that $v_n(r) \to 0$ for this r and that the unique solution to

$$-\Delta w = \lambda, \quad x \in B_r(x_0), \quad w|_{\partial B_r(x_0)} = 0$$

satisfies $\|w\|_\infty < \epsilon/4$. Then let w_n be the unique solution to the problem

$$-\Delta w_n = 0, \quad w_n|_{\partial B_r(x_0)} = u_n.$$

We find that $z_n = w + w_n - u_n$ satisfies

$$-\Delta z_n = \lambda + \Delta u_n \ge \lambda - \lambda u_n \ge 0 \quad \forall x \in B_r(x_0), \quad z_n|_{\partial B_r(x_0)} = 0.$$

Hence, by the maximum principle, $z_n \ge 0$ in $B_r(x_0)$, i.e.,

$$u_n \le w + w_n \quad \forall x \in B_r(x_0).$$

Denote, for $x \in B_r(x_0)$,

$$w_\infty(x) = \frac{r^2 - |x - x_0|^2}{N\omega_N r} \int_{\partial B_r(x_0)} \frac{u_\infty(y)}{|x-y|^N} dS_y,$$

where ω_N stands for the volume of the unit ball in R^N. We clearly have

$$w_\infty(x) \le \frac{r^2 - |x - x_0|^2}{N\omega_N r} \int_{\partial B_r(x_0)} \frac{1-\epsilon}{|x-y|^N} dS_y = 1 - \epsilon \quad \forall x \in B_r(x_0).$$

By the Poisson integral formula, for $x \in B_r(x_0)$,

$$w_n(x) = \frac{r^2 - |x - x_0|^2}{N\omega_N r} \int_{\partial B_r(x_0)} \frac{u_n(y)}{|x-y|^N} dS_y.$$

Therefore, we have, for $x \in B_{r/2}(x_0)$,

$$\begin{aligned} |w_n(x) - w_\infty(x)| &\le \frac{r^2 - |x - x_0|^2}{N\omega_N r} \int_{\partial B_r(x_0)} \frac{|u_n(y) - u_\infty(y)|}{|x-y|^N} dS_y \\ &\le \frac{r^2 - |x - x_0|^2}{N\omega_N r} \int_{\partial B_r(x_0)} \frac{|u_n(y) - u_\infty(y)|}{(r/2)^N} dS_y \\ &\le \frac{2^N}{N\omega_N r^{N-1}} v_n(r) \to 0 \end{aligned}$$

as $n \to \infty$. It follows that for all large n,

$$|w_n(x) - w_\infty(x)| < \epsilon/4 \quad \forall x \in B_{r/2}(x_0).$$

Thus,

$$w_n(x) \le w_\infty(x) + \epsilon/4 \le 1 - (3/4)\epsilon \quad \forall x \in B_{r/2}(x_0).$$

We finally obtain

$$u_n \le w + w_n < \epsilon/4 + 1 - (3/4)\epsilon = 1 - \epsilon/2 \quad \forall x \in B_{r/2}(x_0).$$

This is what we wanted and the proof is thus complete. □

Proof of Theorem 2.1. We use an indirect argument. Suppose the conclusion of our theorem is false. Then we can find a constant $M > 0$ and λ_n, μ_n satisfying

$$|\lambda_n| + |\mu_n| \le M$$

and positive solutions (u_n, v_n) of (1.2) with $\lambda = \lambda_n, \mu = \mu_n$ such that

$$\|u_n\|_\infty + \|v_n\|_\infty \to \infty \quad \text{as } n \to \infty.$$

Since

$$-\Delta v_n = \mu_n v_n - v_n^2 + d u_n v_n \le (M + d\|u_n\|_\infty) v_n - v_n^2,$$

an application of Lemma 2.1 of [DM] (recalled in Lemma A.1 in the appendix) shows that

$$v_n \le M + d\|u_n\|_\infty. \tag{2.3}$$

Therefore we must have $\|u_n\|_\infty \to \infty$.

From the equation for u_n we easily see that $-\Delta u_n \le M u_n$. Hence if we define $\hat{u}_n = u_n/\|u_n\|_\infty$, then

$$-\Delta \hat{u}_n \le M \hat{u}_n. \tag{2.4}$$

Applying Lemma 2.2 we find that, subject to a subsequence, $\hat{u}_n$ converges weakly in $H_0^1(\Omega)$ and strongly in $L^p(\Omega)$ for all $p \ge 1$, to some $\hat{u} \in H_0^1(\Omega)$. Moreover, $\hat{u} \not\equiv 0$.

We claim further that $\hat{u} = 0$ a.e. on $\Omega_+ := \Omega \setminus \overline{\Omega}_0$. To see this, we compare u_n with U_M over Ω_+, where U_M satisfies (2.2) with $\lambda = M$. Clearly we have

$$-\Delta u_n \le M u_n - b(x) u_n^2 \quad \text{over } \Omega_+.$$

Moreover, for each fixed n,

$$\overline{\lim}_{d(x,\partial\Omega_+)\to 0}(u_n - U_M) \le 0.$$

Therefore an application of [DH, Lemma 2.1] gives $u_n \le U_M$ in Ω_+. As $\|u_n\|_\infty \to \infty$, we now easily see that $\hat{u} = 0$ a.e. on Ω_+.

From (2.3), we find that $\hat{v}_n := v_n/\|u_n\|_\infty$ gives rise to a bounded sequence in $L^\infty(\Omega)$. Therefore, by passing to a subsequence, we may assume that $\hat{v}_n$ converges weakly in $L^2(\Omega)$ to some $\hat{v}$. Clearly $\hat{v}$ must be nonnegative and L^∞ bounded.

Choose $\phi \in C_c^\infty(\Omega_0)$ and multiply the equation for u_n by $\phi/\|u_n\|_\infty^2$ and then integrate over Ω_0. We obtain

$$(\|u_n\|_\infty)^{-1} \int_{\Omega_0} \nabla \hat{u}_n \cdot \nabla \phi dx = \int_{\Omega_0} \hat{u}_n(\lambda_n/\|u_n\|_\infty - c\hat{v}_n)\phi dx.$$

Letting $n \to \infty$, we deduce

$$\int_{\Omega_0} \hat{u}\hat{v}\phi dx = 0.$$

This implies

$$\hat{u}\hat{v} = 0 \quad \text{a.e. in } \Omega_0. \tag{2.5}$$

To derive a contradiction, we now look at the equation satisfied by v_n and find that v_n satisfies

$$-\Delta v + \psi v = \mu_n v, \quad v|_{\partial\Omega} = 0,$$

where $\psi = v_n - du_n$. It follows that

$$\mu_n = \lambda_1^\Omega(v_n - du_n). \tag{2.6}$$

By the variational characterization of the first eigenvalue, we have

$$\int_\Omega (|\nabla\phi|^2 + (v_n - du_n)\phi^2)dx \geq \mu_n \int_\Omega \phi^2 dx$$

for any $\phi \in H_0^1(\Omega)$. Choosing $\phi = \hat{u}_n/\sqrt{\|u_n\|_\infty}$, we obtain

$$\int_\Omega |\nabla \hat{u}_n|^2 dx/\|u_n\|_\infty + \int_\Omega (\hat{v}_n - d\hat{u}_n)\hat{u}_n^2 dx \geq \mu_n \int_\Omega \hat{u}_n^2 dx/\|u_n\|_\infty.$$

Letting $n \to \infty$ and recalling $\hat{u}_n \to \hat{u}$ in $L^p(\Omega)$ for any $p \geq 1$, we deduce

$$\int_\Omega (\hat{v}\hat{u}^2 - d\hat{u}^3)dx \geq 0.$$

We already know that $\hat{u} = 0$ a.e. in Ω_+ and $\hat{v}\hat{u} = 0$ a.e. in Ω_0. Therefore $\hat{v}\hat{u}^2 = 0$ a.e. in Ω. It follows that

$$\int_\Omega \hat{u}^3 \leq 0.$$

This can happen only if the nonnegative function $\hat{u}$ is identically zero almost everywhere, which contradicts our earlier observation on $\hat{u}$. This completes the proof of Theorem 2.1. □

We are now ready to study the positive solution set of (1.2). We will adapt the bifurcation approach used by Blat and Brown in [BB2] by fixing λ and using μ as the main bifurcation parameter.

Let us observe that if (1.2) has a positive solution (u, v), then from the first equation in (1.2) we obtain

$$\lambda = \lambda_1^\Omega(bu + cv) > \lambda_1^\Omega(0) = \lambda_1^\Omega.$$

Hence we assume

$$\lambda > \lambda_1^{\Omega}$$

from now on.

Our discussion below is divided into two cases:

$$\text{(i) } \lambda_1^{\Omega} < \lambda < \lambda_1^{\Omega_0} \qquad \text{and} \qquad \text{(ii) } \lambda \geq \lambda_1^{\Omega_0}.$$

In the first case, (1.2) has a unique semitrivial solution of the form $(u, 0)$, namely, $(u_\lambda, 0)$. If (u, v) is a positive solution to (1.2), then u satisfies

$$-\Delta u \leq \lambda u - b(x)u^2, \quad u|_{\partial\Omega} = 0.$$

An application of [DM, Lemma 2.1] (see Lemma A.1) yields

$$0 < u \leq u_\lambda \quad \forall x \in \Omega. \tag{2.7}$$

From the equation for v we find

$$-\Delta v > \mu v - v^2, \quad v|_{\partial\Omega} = 0,$$

which implies, by [DM, Lemma 2.1], that

$$v \geq \theta_\mu \quad \forall x \in \Omega, \tag{2.8}$$

where we make the convention that $\theta_\mu \equiv 0$ whenever $\mu \leq \lambda_1^{\Omega}$.

From the equation for v we also obtain

$$\mu = \lambda_1^{\Omega}(v - du).$$

Therefore, by (2.7) and the well-known monotonicity property of $\lambda_1^{\Omega}(\phi)$, we easily deduce

$$\mu > \lambda_1^{\Omega}(-du_\lambda). \tag{2.9}$$

By the equation for u and (2.8), we deduce

$$\lambda = \lambda_1^{\Omega}(bu + cv) > \lambda_1^{\Omega}(cv) \geq \lambda_1^{\Omega}(c\theta_\mu),$$

that is,

$$\lambda > \lambda_1^{\Omega}(c\theta_\mu). \tag{2.10}$$

Summarizing, we have the following result.

THEOREM 2.3. *In the case that $\lambda_1^{\Omega} < \lambda < \lambda_1^{\Omega_0}$, a necessary condition for* (1.2) *to possess a positive solution is that both* (2.9) *and* (2.10) *hold.*

We will see in the following that (2.9) and (2.10) are also sufficient conditions for the existence of positive solutions. Our argument below is very similar to that of [BB2], and hence we will only sketch it here.

In the (μ, u, v)-space $X := R \times C^1(\overline{\Omega}) \times C^1(\overline{\Omega})$, we have two semitrivial solution curves

$$\Gamma_u := \{(\mu, u_\lambda, 0) : \mu \in (-\infty, \infty)\} \quad \text{and} \quad \Gamma_v := \{(\mu, 0, \theta_\mu) : \lambda_1^{\Omega} < \mu < \infty\}.$$

A local bifurcation analysis along Γ_u shows that a smooth curve of positive solutions $\Gamma' = \{(\mu, u, v)\}$ bifurcates from $(\lambda_1^\Omega(-du_\lambda), u_\lambda, 0) \in \Gamma_u$. A global bifurcation consideration, together with an application of the maximum principle, shows that Γ' is contained in a global branch (i.e., connected set) of positive solutions $\Gamma = \{(\mu, u, v)\}$ which is either unbounded or joins the semitrivial curve Γ_v at exactly $(\mu_0, 0, \theta_{\mu_0}) \in \Gamma_v$, where $\mu_0 > \lambda_1^\Omega$ is determined uniquely by

$$\lambda = \lambda_1^\Omega(c\theta_{\mu_0}). \tag{2.11}$$

It follows from (2.10) that $\mu < \mu_0$ whenever $(\mu, u, v) \in \Gamma$. Therefore, we find that $(\mu, u, v) \in \Gamma$ implies

$$\lambda_1^\Omega(-du_\lambda) < \mu < \mu_0. \tag{2.12}$$

From this, and applying Theorem 2.1, we conclude that Γ is bounded in the space $R \times L^\infty(\Omega) \times L^\infty(\Omega)$. By standard L^p theory for elliptic operators, we conclude that Γ is also bounded in X. Hence Γ must join Γ_v. A local bifurcation analysis near $(\mu_0, 0, \theta_{\mu_0})$ shows that near this point, Γ consists of a smooth curve.

To summarize, we have proved the following result.

THEOREM 2.4. *When $\lambda_1^\Omega < \lambda < \lambda_1^{\Omega_0}$, there is a bounded connected set of positive solutions $\Gamma = \{(\mu, u, v)\}$ in the space X which joins the semitrivial solutions branches Γ_u and Γ_v at $(\lambda_1^\Omega(-du_\lambda), u_\lambda, 0)$ and $(\mu_0, 0, \theta_{\mu_0})$, respectively; moreover, near these two points, Γ consists of smooth curves.*

Clearly, (2.12) is equivalent to (2.9) and (2.10) combined. From Theorems 2.3 and 2.4 the following result now follows.

COROLLARY 2.5. *When $\lambda_1^\Omega < \lambda < \lambda_1^{\Omega_0}$, (1.2) has a positive solution if and only if (2.12) holds.*

The statement in Corollary 2.5 can also be proved by the fixed point index method developed in [Da1, Da2].

In conclusion, we find that our results above are very similar with that for the classical case $b(x) \equiv 1$ obtained in [BB1, BB2] and [Da1, Da2].

Let us now consider the second case where $\lambda \geq \lambda_1^{\Omega_0}$. The striking difference with the classical case now is that we no longer have a semitrivial solution of the form $(u, 0)$. However, the semitrivial solution curve Γ_v is unchanged, and the bifurcation analysis of [BB2] along Γ_v can still be adapted. Again, a local bifurcation analysis shows that a smooth curve of positive solutions $\Gamma' = \{(\mu, u, v)\}$ bifurcates from $(\mu_0, 0, \theta_{\mu_0}) \in \Gamma_v$, where μ_0 is determined by (2.11). As before, a global bifurcation analysis, together with an application of the maximum principle, shows that Γ' is contained in a global branch of positive solutions Γ which is either unbounded in X or joins a semitrivial solution of the form $(u, 0)$. But we already know that there is no semitrivial solution of the form $(u, 0)$. Therefore, Γ must be unbounded.

One easily sees that the arguments leading to (2.10) still work for our present situation. Hence $\mu < \mu_0$ whenever (1.2) has a positive solution. We now apply Theorem 2.1 and conclude that

$$\{\mu : (\mu, u, v) \in \Gamma\} = (-\infty, \mu_0). \tag{2.13}$$

Summarizing the above discussion, we obtain the following result.

THEOREM 2.6. *When $\lambda \geq \lambda_1^{\Omega_0}$, (1.2) has a positive solution if and only if $\mu < \mu_0$. Moreover, there is an unbounded connected set of positive solutions $\Gamma = \{(\mu, u, v)\}$ in X which joins the semitrivial solution branch Γ_v at $(\mu_0, 0, \theta_{\mu_0})$ and satisfies (2.13).*

The fact that (1.2) has a positive solution for arbitrarily large negative μ is strikingly different from the classical case. Biologically, this implies that the prey species can support a predator species of arbitrarily negative growth rate. This is due to the fact that the population of the prey would blow up in the region Ω_0 in the absence of the predator, and hence one might think of Ω_0 as a region where food is abundant for the predator. On the other hand, our above result indicates that the blow-up of the prey population can be avoided by introducing a predator with rather arbitrary growth rate.

It is natural to consider the asymptotic behavior of the positive solutions of (1.2) as $\mu \to -\infty$. For this purpose, we consider a decreasing sequence of negative numbers μ_n which converges to $-\infty$, and we let (u_n, v_n) be an arbitrary positive solution of (1.2) with $\mu = \mu_n$. We show that the following result holds.

THEOREM 2.7. *Let (μ_n, u_n, v_n) be as above. Then the following conclusions are true.*

(i) $\lim_{n\to\infty} \|u_n\|_\infty/|\mu_n| = 1/d$, $\lim_{n\to\infty} \|v_n\|_\infty/|\mu_n| = 0$.

(ii) $u_n/|\mu_n| \to 0$ *and* $v_n \to 0$ *uniformly on any compact subset of* $\overline{\Omega} \setminus \overline{\Omega}_0$.

(iii) $\underline{\lim}_{n\to\infty}\|u_n\|_{L^1(\Omega)}/|\mu_n| > 0$, $\overline{\lim}_{n\to\infty}\|v_n\|_{L^1(\Omega)} < \infty$, *and when* $\lambda > \lambda_1^{\Omega_0}$, $\underline{\lim}_{n\to\infty}\|v_n\|_{L^1(\Omega)} > 0$.

(iv) *If for some* $q > 1$, $\{\|v_n\|_{L^q(\Omega)}\}$ *is bounded, then subject to a subsequence,* $u_n/\|u_n\|_\infty \to \hat{u}$ *weakly in* $H_0^1(\Omega)$, $v_n \to (\lambda/c)\chi_{\{\hat{u}=1\}}$ *weakly in* $L^q(\Omega)$, *where* $\hat{u} = 0$ *a.e. in* $\Omega \setminus \Omega_0$ *and* $\hat{u}|_{\Omega_0}$ *is a positive weak solution* (*with* L^∞ *norm* 1) *of*

$$-\Delta u = \lambda\chi_{\{u<1\}}u, \quad u|_{\partial\Omega_0} = 0. \tag{2.14}$$

Proof. From the equation for v_n we obtain

$$\mu_n > \lambda_1^\Omega - d\|u_n\|_\infty, \tag{2.15}$$

for otherwise,

$$-\Delta v_n \le \lambda_1^\Omega v_n - v_n^2,$$

which gives

$$\int_\Omega |\nabla v_n|^2 dx < \lambda_1^\Omega \int_\Omega v_n^2 dx,$$

contradicting the variational characterization of λ_1^Ω.

From (2.15) we see immediately that $\|u_n\|_\infty \to \infty$ as $n \to \infty$. We can now use (2.4) with $M = \lambda$ and argue as in the proof of Theorem 2.1 to conclude that subject to a subsequence, $\hat{u}_n = u_n/\|u_n\|_\infty \to \hat{u}$ weakly in $H_0^1(\Omega)$ and strongly in $L^p(\Omega)$ for any $p \ge 1$. Moreover, $\hat{u} = 0$ a.e. in Ω_+ and $\hat{u}$ has L^∞ norm 1 over Ω. Furthermore, using standard interior estimates in Ω_+ and boundary estimates near $\partial\Omega$ for the equation satisfied by $\hat{u}_n$, one easily sees that $\hat{u}_n \to 0$ in $C^2(\omega)$ for any compact subset ω of $\overline{\Omega} \setminus \overline{\Omega}_0$. We show next that

$$\lim_{n\to\infty} \mu_n/\|u_n\|_\infty = -d. \tag{2.16}$$

Since

$$-\Delta v_n \le (\mu_n + d\|u_n\|_\infty)v_n - v_n^2,$$

an application of Lemma A.1 shows that

$$v_n \le \mu_n + d\|u_n\|_\infty.$$

It follows that

$$0 \le v_n/\|u_n\|_\infty \le d + \frac{\mu_n}{\|u_n\|_\infty} \le d. \tag{2.17}$$

By passing to a subsequence, we may assume that $\hat{v}_n := v_n/\|u_n\|_\infty$ converges weakly in $L^2(\Omega)$ to $\hat{v}$. The arguments in the proof of Theorem 2.1 which lead to (2.5) work in the same way for our present situation, and hence we still have (2.5), i.e.,

$$\hat{u}\hat{v} = 0 \quad \text{a.e. in } \Omega_0.$$

The identity (2.6) also remains valid and hence

$$\int_\Omega [|\nabla\phi|^2 + (v_n - du_n)\phi^2]dx \ge \mu_n \int_\Omega \phi^2 dx \quad \forall \phi \in H_0^1(\Omega).$$

Dividing the above inequality by $\|u_n\|_\infty$ we obtain, after a simple rearrangement of terms,

$$\int_\Omega \left(\frac{\mu_n}{\|u_n\|_\infty} + d\hat{u}_n - \hat{v}_n\right)\phi^2 dx \le \int_\Omega |\nabla\phi|^2 dx/\|u_n\|_\infty.$$

Letting $n \to \infty$ and denoting $\alpha = \overline{\lim}_{n\to\infty}\mu_n/\|u_n\|_\infty$, we obtain

$$\int_\Omega (\alpha + d\hat{u} - \hat{v})\phi^2 dx \le 0.$$

It follows that

$$\alpha \le -d\hat{u} + \hat{v} \quad \text{a.e. in } \Omega.$$

Since $\hat{u} = 0$ a.e. in Ω_+ and $\hat{u}\hat{v} = 0$ a.e. in Ω_0 and $\|\hat{u}\|_\infty = 1$, we deduce

$$\alpha \le -d.$$

Combining this with (2.15) we find that (2.16) is proved. This finishes the proof of the conclusions about u_n in (i) and (ii). Note that (2.16) holding for a subsequence of an arbitrary subsequence implies that it holds for the entire original sequence.

The second part of (i) follows directly from the first conclusion in (i) and (2.17). We now prove the conclusion about v_n in (ii). By using [DH, Lemma 2.1] we see that $u_n \le U_\lambda$, where U_λ is the minimal positive solution of (2.2). For small $\delta > 0$, define

$$D_\delta = \{x \in \Omega : d(x, \Omega_0) > \delta\}.$$

We find that

$$u_n(x) \le \sup_{x\in D_\delta} U_\lambda(x) = M_\delta < \infty \quad \forall x \in D_\delta.$$

It follows that

$$-\Delta v_n \le (\mu_n + cM_\delta)v_n - v_n^2, \quad x \in D_\delta. \tag{2.18}$$

Denote $a_n = |\mu_n + cM_\delta|$ and define

$$W_n = \frac{\beta}{a_n} d(x)^{-4}, \tag{2.19}$$

where $d(x)$ is a smooth function on $\overline{D}_\delta$ satisfying $d(x) = 0$ on $\partial D_\delta \cap \Omega$ and is positive elsewhere (this is possible if δ is small enough due to the smoothness of $\partial\Omega_0$), and $\beta > 0$ is a constant to be determined later. We calculate

$$\begin{aligned}
&\Delta W_n + (\mu_n + cM_\delta)W_n - W_n^2 \\
&\quad = \frac{\beta}{a_n}\Big(20d(x)^{-6}|\nabla d(x)|^2 - 4d(x)^{-5}\Delta d(x)\Big) - \beta d(x)^{-4} - \frac{\beta^2}{a_n^2} d(x)^{-8} \\
&\quad = \frac{\beta d(x)^{-6}}{a_n}\left(20|\nabla d(x)|^2 - 4d(x)\Delta d(x) - a_n d(x)^2 - \frac{\beta}{a_n} d(x)^{-2}\right) \\
&\quad \le \frac{\beta d(x)^{-6}}{a_n}\Big(20|\nabla d(x)|^2 - 4d(x)\Delta d(x) - 2\sqrt{\beta}\Big) < 0 \quad \forall x \in D_\delta
\end{aligned}$$

if β is chosen large enough.

Thus for such choice of β, for all $n \ge 1$,

$$-\Delta W_n \ge (\mu_n + cM_\delta)W_n - W_n^2 \quad \forall x \in D_\delta.$$

As clearly $W_n > v_n$ on ∂D_δ, we can use (2.18) and Lemma A.1 to conclude that $v_n \le W_n$ on D_δ. Since clearly $W_n \to 0$ uniformly on $D_{2\delta}$, the same is true for v_n. This proves the second part of (ii).

We now consider (iii). If $\underline{\lim}_{n\to\infty} \|u_n\|_{L^1(\Omega)}/|\mu_n| = 0$, then, by passing to a subsequence, we may assume $\|u_n\|_{L^1(\Omega)}/|\mu_n| \to 0$. On the other hand, our previous proof of (i) shows that by passing to a further subsequence, $u_n/|\mu_n| = \hat{u}_n(\|u_n\|_\infty/|\mu_n|) \to \hat{u}/d$ in $L^p(\Omega)$ for all $p \ge 1$, and $\|\hat{u}\|_\infty = 1$. In particular, $\|u_n\|_{L^1(\Omega)}/|\mu_n| \to \|\hat{u}\|_{L^1(\Omega)}/d > 0$. This contradiction shows that we must have $\underline{\lim}_{n\to\infty} \|u_n\|_{L^1(\Omega)}/|\mu_n| > 0$.

If $\overline{\lim}_{n\to\infty} \|v_n\|_{L^1(\Omega)} = \infty$, then by passing to a subsequence, we may assume that $\|v_n\|_{L^1(\Omega)} \to \infty$. As before, by passing to a further subsequence, we have $\hat{u}_n = u_n/\|u_n\|_\infty \to \hat{u}$ in $L^p(\Omega)$ for all $p \ge 1$, and $\|\hat{u}\|_\infty = 1$. Let ϕ be an arbitrary nonnegative function in $C^2(\Omega)$ with compact support in Ω. We multiply the equation for u_n by $\phi/\|u_n\|_\infty$ and integrate over Ω to obtain

$$\int_\Omega \hat{u}_n(-\Delta\phi)dx = \int_\Omega [\lambda\hat{u}_n - b(x)u_n\hat{u}_n - c\hat{u}_n v_n]\phi dx.$$

It follows that

$$\int_\Omega \hat{u}_n v_n \phi dx \le (1/c)\int_\Omega [\lambda\hat{u}_n\phi + \hat{u}_n(\Delta\phi)]dx \to (1/c)\int_\Omega (\lambda\hat{u}\phi + \hat{u}\Delta\phi)dx.$$

Therefore, we can find a positive constant $C_1 = C_1(\phi)$ such that

$$\int_\Omega \hat{u}_n v_n \phi dx \le C_1 \quad \forall n \ge 1. \tag{2.20}$$

Multiplying the equation for v_n by $\phi/|\mu_n|$ and integrating over Ω, we obtain

$$\int_\Omega \frac{v_n}{|\mu_n|}(-\Delta\phi)dx = -\int_\Omega v_n\phi dx + \frac{d\|u_n\|_\infty}{|\mu_n|}\int_\Omega \hat{u}_n v_n\phi dx - \int_\Omega \frac{v_n}{|\mu_n|} v_n\phi dx.$$

Using this identity, (i), and (2.20), we easily deduce

$$\overline{\lim}_{n\to\infty}\int_\Omega v_n\phi dx \le \overline{\lim}_{n\to\infty}\int_\Omega \hat{u}_n v_n\phi dx \le C_1.$$

Thus, there exists some positive constant $C_2 = C_2(\phi)$ such that

$$\int_\Omega v_n\phi dx \le C_2 \quad \forall n \ge 1.$$

By (ii) we know that for any given small closed neighborhood N of $\partial\Omega$ in $\overline{\Omega}$, $v_n \to 0$ uniformly on N. If we choose a particular ϕ in the above discussion such that $\phi \equiv 1$ on $\Omega \setminus N$, then we have

$$\int_{\Omega\setminus N} v_n dx \le \int_\Omega v_n\phi dx \le C_2.$$

Therefore,

$$\|v_n\|_{L^1(\Omega)} = \int_\Omega v_n dx = \int_N v_n dx + \int_{\Omega\setminus N} v_n dx \le C_3 \quad \forall n \ge 1$$

for some positive constant C_3. This contradicts our assumption that $\|v_n\|_{L^1(\Omega)} \to \infty$. Hence we must have $\overline{\lim}_{n\to\infty}\|v_n\|_{L^1(\Omega)} < \infty$.

Suppose now $\lambda > \lambda_1^{\Omega_0}$. To see that $\underline{\lim}_{n\to\infty}\|v_n\|_{L^1(\Omega)} > 0$, we argue indirectly. Suppose this is not true. Then by passing to a subsequence, we may assume that $v_n \to 0$ in $L^1(\Omega)$. Note that on Ω_0, it holds that

$$-\Delta\hat{u}_n = (\lambda - cv_n)\hat{u}_n.$$

We have already proved that subject to a subsequence, $\hat{u}_n \to \hat{u}$ weakly in $H_0^1(\Omega)$, strongly in $L^p(\Omega)$ for all $p \ge 1$, and $\hat{u} \equiv 0$ on Ω_+, and that $\hat{u}$ is positive on a set of positive measure in Ω_0. Moreover, for any $\phi \in C_c^2(\Omega_0)$,

$$\left|\int_\Omega v_n\hat{u}_n\phi dx\right| \le \|\phi\|_\infty \int_\Omega v_n dx \to 0.$$

Thus it is easily seen that $\hat{u}|_{\Omega_0}$ is a weak solution to

$$-\Delta u = \lambda u, \quad u|_{\partial\Omega_0} = 0.$$

As $\hat{u}|_{\Omega_0}$ is nonnegative and not identically zero, we must have $\lambda = \lambda_1^{\Omega_0}$, contradicting our assumption. This finishes the proof for all conclusions in (iii).

It remains to prove (iv). Since by assumption $\{v_n\}$ is bounded in $L^q(\Omega)$, there exists $v \in L^q(\Omega)$ such that, subject to a subsequence, $v_n \to v$ weakly in $L^q(\Omega)$. As before, by passing to a further subsequence, we may assume that $\hat{u}_n = u_n/\|u_n\|_\infty \to \hat{u}$ weakly in $H_0^1(\Omega)$ and strongly in $L^p(\Omega)$ for all $p \ge 1$, and, moreover, $\hat{u} = 0$ a.e. in $\Omega \setminus \Omega_0$ and $\|\hat{u}\|_\infty = 1$. Let ϕ be an arbitrary nonnegative function in $C^2(\Omega)$ with compact support in Ω. Multiply the equation for v_n by $\phi/|\mu_n|$, and integrating over Ω, we deduce

$$\int_\Omega \frac{v_n}{|\mu_n|}(-\Delta\phi)dx = -\int_\Omega v_n\phi dx + \frac{d\|u_n\|_\infty}{|\mu_n|}\int_\Omega \hat{u}_n v_n\phi dx - \int_\Omega \frac{v_n}{|\mu_n|}v_n\phi dx.$$

Making use of (i) and letting $n \to \infty$, we obtain

$$0 = -\int_\Omega v\phi dx + \int_\Omega \hat{u}v\phi dx = -\int_\Omega (1-\hat{u})v\phi dx.$$

As ϕ is arbitrary and $1-\hat{u} \geq 0$ and $v \geq 0$, the above identity implies that $(1-\hat{u})v = 0$ a.e. in Ω. Hence $v = 0$ a.e. in the set $\Omega_1 := \{x \in \Omega : \hat{u}(x) < 1\}$. Since $\hat{u} = 0$ a.e. in $\Omega \setminus \Omega_0$, we find that $\Omega \setminus \Omega_0 \subset \Omega_1$.

Multiplying the equation for u_n by an arbitrary $\psi \in C^2(\Omega_0)$ with compact support in Ω_0 and integrating over Ω_0, we deduce

$$\int_{\Omega_0} \nabla u_n \cdot \nabla \psi dx = \int_{\Omega_0} (\lambda u_n - c u_n v_n)\psi dx.$$

Dividing this identity by $\|u_n\|_\infty$ and letting $n \to \infty$, we obtain

$$\int_{\Omega_0} \nabla \hat{u} \cdot \nabla \psi dx = \int_{\Omega_0} (\lambda - cv)\hat{u}\psi dx.$$

This implies that $\hat{u}|_{\Omega_0}$ is a positive weak solution of the problem

$$-\Delta u = (\lambda - cv)u, \quad u|_{\partial\Omega_0} = 0.$$

Since $(\lambda - cv)\hat{u} \in L^q(\Omega)$, standard elliptic regularity theory implies that $\hat{u}|_{\Omega_0} \in W^{2,q}(\Omega_0)$ and $\Delta\hat{u} = 0$ a.e. in the set $\{x \in \Omega_0 : \hat{u}(x) = 1\}$. Hence $v(x) = \lambda/c$ a.e. in the set $\{x \in \Omega_0 : \hat{u}(x) = 1\}$, which agrees with $\{\hat{u} = 1\} := \{x \in \Omega : \hat{u}(x) = 1\}$, because $\hat{u} = 0$ a.e. in $\Omega \setminus \Omega_0$. Thus,

$$v = (\lambda/c)\chi_{\{\hat{u}=1\}}, \quad 1 - cv = \lambda(1 - \chi_{\{\hat{u}=1\}}) = \lambda\chi_{\{\hat{u}<1\}},$$

and $\hat{u}|_{\Omega_0}$ is a positive weak solution to the problem

$$-\Delta u = \lambda\chi_{\{u<1\}}u, \quad u|_{\partial\Omega_0} = 0.$$

This proves (iv) and hence finishes the proof of Theorem 2.7. □

REMARK 2.1.

(i) *As $\int_\Omega u dx$ and $\int_\Omega v dx$ represent the total population of u and v, respectively, the conclusions in parts* (i) *and* (iii) *of Theorem* 2.7 *imply that, as $\mu \to -\infty$, the total population of u blows up at the rate of $|\mu|$, while the total population of v stays bounded. Moreover, when $\lambda > \lambda_1^{\Omega_0}$, the total population of v is bounded from below by a positive constant independent of μ.*

(ii) *Note that when $\lambda > \lambda_1^{\Omega_0}$, it is easily seen from* (2.14) *that $|\{\hat{u} = 1\}| > 0$ in part* (iv) *of Theorem* 2.7. *Hence $\hat{u}$ has a "flat core." Conversely, if $\lambda = \lambda_1^{\Omega_0}$, then the flat core has measure zero and $\hat{u}$ is the first normalized eigenfunction on Ω_0.*

(iii) *If $\{\|v_n\|_{L^q}\}$ is bounded for some $q > 1$, then from* (2.14) *one sees that $\hat{u} \in C^1(\overline{\Omega_0})$. It is easy to show that $v_n \to 0$ uniformly on any compact subset of the set $\{\hat{u} < 1\}$. However, we were unable to determine whether $\{\|v_n\|_{L^q}\}$ is always bounded for some $q > 1$.*

(iv) *Without the assumption that $\{\|v_n\|_{L^q}\}$ is bounded for some $q > 1$, we can still show that $u_n/\|u_n\|_\infty$ has a subsequence converging to some $\hat{u}$ weakly in $H_0^1(\Omega)$ and that $\hat{u}$ is upper semicontinuous (and hence $\{\hat{u} = 1\}$ is closed) by making use of* [LL, *Theorem* 9.3]. *Moreover, $\hat{u} = 0$ a.e. in $\Omega \setminus \Omega_0$, and on Ω_0, $\hat{u}$ solves $-\Delta u = \lambda\chi_{\{u<1\}}u - m$, where m is a nonnegative measure with support in the boundary of $\{\hat{u} = 1\}$; subject to a subsequence, v_n weak * converges in $C(\Omega)^*$ to $(\lambda/c)\chi_{\{\hat{u}=1\}} + m$.*

(v) *In a forthcoming paper* [DD], *we will show that* $m = 0$ *always, so* $\hat{u}|_{\Omega_0}$ *solves* (2.14). *Moreover, we will show that* (2.14) *has a unique positive solution when* $\lambda \geq \lambda_1^{\Omega_0}$, *and it has no positive solution otherwise. This implies that in part* (iv) *above, the entire sequence* $u_n/\|u_n\|_\infty$ *converges to* $\hat{u}$ *weakly in* $H_0^1(\Omega)$. *A similar comment applies to* v_n.

3. Degeneracy in the predator equation. In this section, we study (1.3). Analogous to the case of (1.2), the semitrivial solutions are easily understood. Now we have a unique semitrivial solution of the form $(0, v)$ for every $\mu \in (\lambda_1^\Omega, \lambda_1^{\Omega_0})$, namely, $(0, v_\mu)$, where v_μ is the unique positive solution of

$$-\Delta v = \mu v - e(x)v^2, \quad v|_{\partial\Omega} = 0; \tag{3.1}$$

and for other values of μ, there is no semitrivial solution of this form.

When $\lambda > \lambda_1^\Omega$, $(\theta_\lambda, 0)$ is the unique semitrivial solution of the form $(u, 0)$, and there is no such semitrivial solution for other λ values.

Our later discussion will require an analysis of $\lambda_1^\Omega(v_\mu)$ as a function of μ.

Let us recall the well-known facts that $\mu \to v_\mu$ is a continuous and strictly increasing function from $(\lambda_1^\Omega, \lambda_1^{\Omega_0})$ to $C(\overline{\Omega})$, $v_\mu \to 0$ as $\mu \to \lambda_1^\Omega$, and as $\mu \to \lambda_1^{\Omega_0}$, by [DH], $v_\mu \to \infty$ uniformly on $\overline{\Omega}_0$ and $v_\mu \to V_{\lambda_1^{\Omega_0}}$ locally uniformly on $\overline{\Omega} \setminus \overline{\Omega}_0$, where V_λ denotes the minimal positive solution of (2.2) with $b(x)$ replaced by $e(x)$.

It follows that

$$\mu \to \Lambda(\mu) := \lambda_1^\Omega(cv_\mu)$$

is a strictly increasing continuous function with $\Lambda(\lambda_1^\Omega - 0) = \lambda_1^\Omega$.

By [Du2, Lemma 3.1] (see Lemma A.2 in the appendix of this paper), we find that

$$\lim_{\mu \to \lambda_1^{\Omega_0}} \Lambda(\mu) = \lambda_* := \lambda_1^{\Omega_+}(cV_{\lambda_1^{\Omega_0}}). \tag{3.2}$$

It follows that

$$\lambda_1^\Omega < \Lambda(\mu) < \lambda_* \quad \forall \mu \in (\lambda_1^\Omega, \lambda_1^{\Omega_0}). \tag{3.3}$$

We will also need the following a priori estimates.

THEOREM 3.1. *Given any positive number* ϵ, *we can find a constant* C, *depending only on* ϵ, c, d, e, *and* Ω, *such that if* (u, v) *is a positive solution of* (1.3) *with* λ, μ *satisfying*

$$|\lambda| + |\mu| \leq \epsilon^{-1}, \quad |\mu - \lambda_1^{\Omega_0}| \geq \epsilon,$$

then

$$\|u\|_\infty + \|v\|_\infty \leq C.$$

Proof. Suppose the conclusion is false. Then we can find some $\epsilon > 0$ and λ_n, μ_n satisfying

$$|\lambda_n| + |\mu_n| \leq \epsilon^{-1}, \quad |\mu_n - \lambda_1^{\Omega_0}| \geq \epsilon \tag{3.4}$$

such that (1.3) with $\lambda = \lambda_n$ and $\mu = \mu_n$ has a positive solution (u_n, v_n) which satisfies

$$\|u_n\|_\infty + \|v_n\|_\infty \to \infty \quad \text{as } n \to \infty.$$

From the equation for u_n we find

$$-\Delta u_n \le \epsilon^{-1} u_n - u_n^2.$$

Comparing u_n with $v \equiv \epsilon^{-1}$ and using Lemma A.1 results in the following:

$$u_n \le \epsilon^{-1} \quad \forall n \ge 1 \quad \forall x \in \Omega. \tag{3.5}$$

Therefore we necessarily have $\|v_n\|_\infty \to \infty$. Let $\hat{v}_n = v_n/\|v_n\|_\infty$. We find, by using the equation for v_n, (3.4), and (3.5), that

$$-\Delta \hat{v}_n \le (1+d)\epsilon^{-1}\hat{v}_n, \quad \hat{v}_n|_{\partial\Omega} = 0.$$

That is, $\hat{v}_n$ satisfies (2.4) with $M = (1+d)\epsilon^{-1}$. Hence we can repeat the argument in the proof of Theorem 2.1 to conclude that, subject to a subsequence, $\hat{v}_n \to \hat{v}$ weakly in $H_0^1(\Omega)$ and strongly in $L^p(\Omega)$ for any $p \ge 1$. Moreover, $\hat{v} = 0$ a.e. in Ω_+ and $\hat{v} > 0$ in a set of positive measure in Ω_0. To show the fact that $\hat{v} = 0$ a.e. in Ω_+, we need the following inequality:

$$-\Delta v_n \le (1+d)\epsilon^{-1} v_n - e(x) v_n^2.$$

Recall that by the smoothness of $\partial\Omega_0$, our above conclusions imply that $w_0 := \hat{v}|_{\Omega_0} \in H_0^1(\Omega_0)$.

By (3.4) and the equation for u_n, we find that u_n satisfies an inequality of the form (2.4), namely,

$$-\Delta u_n \le \epsilon^{-1} u_n.$$

Hence, due to (3.5), subject to a subsequence, $u_n \to u^*$ weakly in $H_0^1(\Omega)$ and strongly in $L^p(\Omega)$ for any $p \ge 1$. It is unclear, however, whether $u^* = 0$ a.e. in Ω.

Let $\phi \in C_c^\infty(\Omega_0)$ and multiply the equation for v_n by $\phi/\|v_n\|_\infty$ and integrate over Ω_0, producing

$$\int_{\Omega_0} \nabla \hat{v}_n \cdot \nabla \phi dx = \mu_n \int_{\Omega_0} \hat{v}_n \phi dx + d \int_{\Omega_0} u_n \hat{v}_n \phi dx.$$

Without loss of generality, we may assume that $\mu_n \to \mu^*$ as $n \to \infty$. We now let $n \to \infty$ in the above identity and deduce

$$\int_{\Omega_0} \nabla \hat{v} \cdot \nabla \phi dx = \int_{\Omega_0} (\mu^* + d u^*) \hat{v} \phi dx.$$

This implies that $w_0 := \hat{v}|_{\Omega_0} \in H_0^1(\Omega)$ is a weak solution to

$$-\Delta w = (\mu^* + d u^*) w, \quad w|_{\partial\Omega_0} = 0. \tag{3.6}$$

Since w_0 is nonnegative and is positive on a set of positive measure, and since $u^* \in L^\infty(\Omega)$, it follows from the Harnack inequality that $w_0 > 0$ in Ω_0.

Let $\psi \in C_c^\infty(\Omega)$ and multiply the equation for u_n by ψ and integrate over Ω. We obtain

$$\int_\Omega \nabla u_n \cdot \nabla \psi dx = \int_\Omega (\lambda_n u_n - u_n^2)\psi dx - c\|v_n\|_\infty \int_\Omega u_n \hat{v}_n \psi dx.$$

It follows easily that

$$\int_\Omega u^* \hat{v} \psi dx = 0.$$

Since $\hat{v}|_{\Omega_0} = w_0 > 0$ in Ω_0, we necessarily have $u^* = 0$ a.e. in Ω_0. Thus (3.6) reduces to

$$-\Delta w_0 = \mu^* w_0, \quad w_0|_{\partial\Omega_0} = 0.$$

This implies that $\mu^* = \lambda_1^{\Omega_0}$, contradicting (3.4).

The proof is complete. □

We are now ready to discuss the set of positive solutions of (1.3). Again we will fix λ and regard μ as the main bifurcation parameter. As before, it is easily seen that when (1.3) has a positive solution, then necessarily, $\lambda > \lambda_1^\Omega$. It turns out that the number $\lambda_* = \lambda_1^{\Omega+}(cV_{\lambda_1^{\Omega_0}})$ is critical in characterizing the behavior of (1.3). So we divide our following discussion into two cases:

$$\text{(i) } \lambda_1^\Omega < \lambda < \lambda_*, \qquad \text{(ii) } \lambda \geq \lambda_*.$$

In case (i), due to the properties of the function $\Lambda(\mu)$, we can find a unique $\mu_0 \in (\lambda_1^\Omega, \lambda_1^{\Omega_0})$ such that

$$\Lambda(\mu_0) = \lambda.$$

A local bifurcation analysis then shows that a smooth curve of positive solutions of (1.3), $\Gamma' = \{(\mu, u, v)\}$, bifurcates from the semitrivial solution curve

$$\Gamma_v := \{(\mu, 0, v_\mu) : \lambda_1^\Omega < \mu < \lambda_1^{\Omega_0}\}$$

at exactly $(\mu_0, 0, v_{\mu_0})$. As before, a global bifurcation consideration, together with an application of the maximum principle, shows that Γ' belongs to a global branch of positive solutions of (1.3), to be denoted by Γ henceforth, which is either unbounded or joins the other semitrivial solution branch

$$\Gamma_u := \{(\mu, \theta_\lambda, 0) : \mu \in (-\infty, \infty)\}$$

at exactly the point $(\lambda_1^\Omega(-d\theta_\lambda), \theta_\lambda, 0) \in \Gamma_u$. Moreover, a local bifurcation analysis shows that when the latter alternative occurs, then Γ consists of a smooth curve near $(\lambda_1^\Omega(-d\theta_\lambda), \theta_\lambda, 0)$.

To determine which alternative occurs for Γ, let us now consider the possible range of μ where (1.3) can have a positive solution. If (u, v) is a positive solution of (1.3), then by using [Du2, Theorem 2.2] for the equation satisfied by v, we deduce

$$\lambda_1^\Omega(-du) < \mu < \lambda_1^{\Omega_0}(-du) < \lambda_1^{\Omega_0}.$$

Since $u \leq \theta_\lambda$, we deduce $\lambda_1^\Omega(-du) \geq \lambda_1^\Omega(-d\theta_\lambda)$. Thus a necessary condition for (1.3) to possess a positive solution is

$$\lambda_1^\Omega(-d\theta_\lambda) < \mu < \lambda_1^{\Omega_0}. \tag{3.7}$$

From the equation for u we obtain

$$\lambda = \lambda_1^\Omega(u + cv).$$

An application of Lemma A.1 for the equation of v gives $v \geq v_\mu$, where we define $v_\mu = 0$ for $\mu \leq \lambda_1^\Omega$. Therefore,

$$\lambda = \lambda_1^\Omega(u + cv) > \lambda_1^\Omega(cv_\mu).$$

This implies $\mu < \mu_0$, and hence the necessary condition (3.7) can be improved to

$$\lambda_1^\Omega(-d\theta_\lambda) < \mu < \mu_0. \tag{3.8}$$

We can now apply Theorem 3.1 to conclude that Γ must be bounded. Hence, we have the following result.

THEOREM 3.2. *When $\lambda_1^\Omega < \lambda < \lambda_*$, (1.3) has a positive solution if and only if (3.8) holds. Moreover, there is a bounded connected set of positive solutions of (1.3), $\Gamma = \{(\mu, u, v)\}$, which joins the semitrivial solution branches Γ_u and Γ_v at $(\lambda_1^\Omega(-d\theta_\lambda), \theta_\lambda, 0)$ and $(\mu_0, 0, v_{\mu_0})$, respectively.*

The above result is clearly very similar to that for the classical case $e(x) \equiv 1$ obtained in [BB1, BB2] and [Da1, Da2]. We show in the following that for the case $\lambda \geq \lambda_*$, very different behavior arises for (1.3).

Suppose from now on that $\lambda \geq \lambda_*$. A local and global bifurcation analysis much as before shows that from the semitrivial solution curve Γ_u, a global bifurcation branch $\Gamma = \{(\mu, u, v)\}$ of positive solutions of (1.3) bifurcates from the point $(\lambda_1^\Omega(-d\theta_\lambda), \theta_\lambda, 0)$, and it is either unbounded or joins the semitrivial solution curve Γ_v. In the latter case, we can find a sequence $(\mu_n, u_n, v_n) \in \Gamma$ such that $(\mu_n, u_n, v_n) \to (\mu, 0, v_\mu) \in \Gamma_v$ in the space $R \times C(\overline{\Omega}) \times C(\overline{\Omega})$. Then, from the equation for u_n and (3.3), we obtain

$$\lambda = \lambda_1^\Omega(u_n + cv_n) \to \lambda_1^\Omega(cv_\mu) = \Lambda(\mu) < \lambda_*.$$

This contradicts our assumption that $\lambda \geq \lambda_*$. Therefore Γ must be unbounded.

One easily checks that the analysis leading to (3.7) is still valid for our present situation. Hence, (3.7) is still a necessary condition and by Theorem 3.1, Γ contains points (μ_n, u_n, v_n) such that $\mu_n \to \lambda_1^{\Omega_0}$. Summarizing, we obtain the following result.

THEOREM 3.3. *When $\lambda \geq \lambda_*$, (1.3) has a positive solution if and only if (3.7) holds. Moreover, there is an unbounded connected set of positive solutions of (1.3), $\Gamma = \{(\mu, u, v)\}$, which joins the semitrivial solution curve Γ_u at $(\lambda_1^\Omega(-d\theta_\lambda), \theta_\lambda, 0)$ and remains bounded until μ approaches $\lambda_1^{\Omega_0}$, where it blows up. Γ does not join the other semitrivial solution curve Γ_v.*

To analyze the blow-up behavior of the positive solutions of (1.3) as $\mu \to \lambda_1^{\Omega_0}$, we make the following further assumption on $e(x)$:

$$\lim_{d(x,\Omega_0)\to 0} \frac{e(x)}{d(x,\Omega_0)^\alpha} = c \quad \text{for some positive constants } \alpha \text{ and } c. \tag{3.9}$$

By [DH, Theorem 2.8], we know that (3.9) guarantees that problem (2.2) with $b(x)$ replaced by $e(x)$ has a unique positive solution V_λ.

Suppose μ_n is an increasing sequence of positive numbers converging to $\lambda_1^{\Omega_0}$ as $n \to \infty$, and (u_n, v_n) is an arbitrary positive solution of (1.3) with $\mu = \mu_n$. We have the following result which describes the asymptotic behavior of (u_n, v_n).

THEOREM 3.4. *Suppose (3.9) holds and $\lambda \geq \lambda_*$. Then the following are true.*

(i) $\lim_{n\to\infty} u_n = 0$ *uniformly on any compact subset of* Ω_0.

(ii) $\lim_{n\to\infty} v_n = \infty$ *uniformly on* $\overline{\Omega}_0$.

(iii) *If* $\lambda = \lambda_*$, *then* $\lim_{n\to\infty}(u_n, v_n)|_{\Omega_+} = (0, V_{\lambda_1^{\Omega_0}})$ *in the space* $C(\overline{\Omega}_+)\times C^1_{\rm loc}(\Omega_+\cup\partial\Omega)$, *where* $C^1_{\rm loc}(\Omega_+\cup\partial\Omega) = \cap_D C^1(D)$ *with* D *running through all the closed subsets of* $\Omega_+\cup\partial\Omega$.

(iv) *If* $\lambda > \lambda_*$, *then, subject to a subsequence,* $\lim_{n\to\infty}(u_n, v_n)|_{\Omega_+} = (u^*, v^*)$ *in the space* $C^1_{\rm loc}(\Omega_+\cup\partial\Omega)\times C^1_{\rm loc}(\Omega_+\cup\partial\Omega)$, *where* (u^*, v^*) *is a positive solution of the boundary blow-up problem*

$$\begin{cases} -\Delta u = \lambda u - u^2 - cuv, \\ -\Delta v = \lambda_1^{\Omega_0} v - e(x)v^2 + duv, \\ u|_{\partial\Omega_+} = 0, \quad v|_{\partial\Omega} = 0, \quad v|_{\partial\Omega_0} = \infty. \end{cases} \quad x \in \Omega_+, \tag{3.10}$$

Proof. Denote $w_n = v_{\mu_n}$. Then it follows from

$$-\Delta v_n \geq \mu_n v_n - e(x)v_n^2, \quad v_n|_{\partial\Omega} = 0,$$

and [DH, Lemma 2.1] that $w_n \leq v_n$. By [DH, Theorem 3.6], $w_n \to \infty$ uniformly on $\overline{\Omega}_0$. Hence so is v_n. This proves (ii).

Denote $\eta_n = \min_{x\in\overline{\Omega}_0} v_n(x)$. The above proved conclusion (ii) implies that $\eta_n \to \infty$ as $n \to \infty$. From the equation for u_n we find

$$-\Delta u_n \leq (\lambda - \eta_n)u_n - u_n^2 \quad \forall x \in \Omega_0. \tag{3.11}$$

Let W_n be defined by (2.19) but with $a_n = |\lambda - \eta_n|$ and D_δ replaced by Ω_0. Then the same calculation as in the proof of Theorem 2.7 shows

$$-\Delta W_n \geq (\lambda - \eta_n)W_n - W_n^2 \quad \forall x \in \Omega_0, \tag{3.12}$$

provided that $\beta > 0$ is chosen large enough.

By (3.11), (3.12), and Lemma A.1, we deduce that $u_n \leq W_n$ and (i) follows.

Since $u_n \leq \theta_\lambda$, much as before, it follows from

$$-\Delta u_n \leq \lambda u_n, \quad u_n|_{\partial\Omega} = 0$$

that, subject to a subsequence, $u_n \to u^*$ weakly in $H_0^1(\Omega)$ and strongly in $L^p(\Omega)$ for any $p \geq 1$. By conclusion (i) we see that $u^* = 0$ a.e. in Ω_0. It follows from the smoothness assumption on $\partial\Omega_0$ that

$$u^*|_{\Omega_+} \in H_0^1(\Omega_+). \tag{3.13}$$

To prove (iii), we assume now that $\lambda = \lambda_*$. We first show that $u^* = 0$ a.e. in Ω. Otherwise, due to (i), $u^* > 0$ on a set of positive measure in Ω_0. Recalling that $v_n \geq w_n$, we deduce from the equation of u_n that

$$\lambda = \lambda_1^\Omega(u_n + cv_n) \geq \lambda_1^\Omega(u_n + cw_n).$$

Using the properties of w_n and applying Lemma A.2 in the appendix, we deduce

$$\lambda_1^\Omega(u_n + cw_n) \to \lambda_1^{\Omega_+}(u^* + cV_{\lambda_1^{\Omega_0}}) > \lambda_*.$$

This implies that $\lambda > \lambda_*$, contradicting our assumption that $\lambda = \lambda_*$. This proves $u^* = 0$ a.e. in Ω. Hence $u_n \to 0$ in $L^p(\Omega)$ for any $p \geq 1$.

We claim further that $u_n \to 0$ in $L^\infty(\Omega)$. Indeed, from $-\Delta u_n \leq u_n$ we deduce

$$0 \leq u_n \leq \lambda(-\Delta)^{-1}u_n.$$

By using the regularity of the operator $(-\Delta)^{-1}$ repeatedly, we easily see from the above inequality that $u_n \to 0$ in $L^p(\Omega)$ for any $p \geq 1$ implies that $u_n \to 0$ in $L^\infty(\Omega)$.

Next we show that $v_n \to V_{\lambda_1^{\Omega_0}}$ in $C^1_{\rm loc}(\Omega_+ \cup \partial\Omega)$. To this end, we consider a sequence of enlarging smooth domains Ω_n given by

$$\Omega_n = \{x \in \Omega_0 : d(x, \partial\Omega_0) > \delta_n\},$$

where δ_n is a decreasing sequence of positive numbers converging to 0. We assume that δ_1 is small enough such that for each $n \geq 1$, Ω_n is not empty and $\partial\Omega_n$ is as smooth as $\partial\Omega_0$.

Let

$$e_n(x) = e(x) + d(x, \Omega_n), \quad x \in \Omega.$$

Clearly $e_n(x)$ has the following properties:

(a) $e_n \to e$ in $L^\infty(\Omega)$,
(b) $e_n(x) > 0$ on $\overline{\Omega} \setminus \overline{\Omega}_n$,
(c) $e_n(x) = 0$ on $\overline{\Omega}_n$, and
(d) $e_n(x) \geq e_{n+1}(x)$ for all $x \in \Omega$.

For fixed $\epsilon > 0$, by [DH, Theorem 2.8], for each n there is a unique positive solution Z_n to the problem

$$-\Delta Z = (\mu_n + \epsilon)Z - e_n(x)Z^2 \quad \text{in } \Omega \setminus \overline{\Omega}_n, \quad Z|_{\partial\Omega} = 0, \quad Z|_{\partial\Omega_n} = \infty.$$

By [DH, Lemma 2.1], we find that on Ω_+, Z_n increases with n, and hence $Z^*(x) = \lim_{n\to\infty} Z_n(x)$ is well defined over Ω_+. A simple regularity consideration reveals that Z^* is a solution to

$$-\Delta Z = (\lambda_1^{\Omega_0} + \epsilon)Z - e(x)Z^2, \quad Z|_{\partial\Omega} = 0, \quad Z|_{\partial\Omega_0} = \infty.$$

As $V_{\lambda_1^{\Omega_0}+\epsilon}$ is the unique positive solution to this problem, we must have $Z^* = V_{\lambda_1^{\Omega_0}+\epsilon}$, that is,

$$\lim_{n\to\infty} Z_n(x) = V_{\lambda_1^{\Omega_0}+\epsilon}(x) \quad \forall x \in \Omega_+. \tag{3.14}$$

Since $\|u_n\|_\infty \to 0$ as $n \to \infty$, for all large n, we obtain from the equation for v_n that

$$-\Delta v_n = (\mu_n + du_n)v_n - e(x)v_n^2 \leq (\mu_n + \epsilon)v_n - e_n(x)v_n^2.$$

Apply [DH, Lemma 2.1], we find $v_n \leq Z_n$ on $\Omega_+ \subset \Omega \setminus \overline{\Omega}_n$ for all large n. Using (3.14), we deduce

$$\overline{\lim}_{n\to\infty} v_n(x) \leq V_{\lambda_1^{\Omega_0}+\epsilon}(x) \quad \forall x \in \Omega_+. \tag{3.15}$$

The uniqueness of V_λ implies that V_λ varies continuously with respect to λ in the norm $C^1_{\rm loc}(\Omega_+ \cup \partial\Omega)$, which follows from a simple regularity and compactness consideration. As (3.15) holds for all small $\epsilon > 0$, letting $\epsilon \to 0$, we deduce

$$\overline{\lim}_{n\to\infty} v_n(x) \leq V_{\lambda_1^{\Omega_0}}(x) \quad \forall x \in \Omega_+.$$

On the other hand, we already know that $v_n(x) \geq w_n(x)$ and $w_n(x) \to V_{\lambda_1^{\Omega_0}}(x)$, so it follows that

$$\underline{\lim}_{n\to\infty} v_n(x) \geq V_{\lambda_1^{\Omega_0}}(x) \quad \forall x \in \Omega_+.$$

Therefore we must have

$$\lim_{n\to\infty} v_n(x) = V_{\lambda_1^{\Omega_0}}(x) \quad \forall x \in \Omega_+.$$

By a simple regularity consideration, we find that $v_n \to V_{\lambda_1^{\Omega_0}}$ in $C^1_{\rm loc}(\Omega_+ \cup \partial\Omega)$. This finishes the proof of (iii).

Finally we consider the case $\lambda > \lambda_*$ and prove (iv). Our first observation is that $u^* > 0$ on a set of positive measure in Ω_0. Otherwise, we can follow the argument in the proof of (iii) above to conclude that $u_n \to 0$ in $L^\infty(\Omega)$ and $v_n \to V_{\lambda_1^{\Omega_0}}$ in $C^1_{\rm loc}(\Omega_+ \cup \partial\Omega)$. Hence, by Lemma A.2,

$$\lambda = \lambda_1^{\Omega}(u_n + cv_n) \to \lambda_1^{\Omega_+}(cV_{\lambda_1^{\Omega_0}}) = \lambda_*.$$

This contradicts our assumption that $\lambda > \lambda_*$.

If $\eta > \lambda_1^{\Omega_0} + d\|\theta_\lambda\|_\infty$, then

$$-\Delta v_n = \mu_n - e(x)v_n^2 + du_nv_n \leq \eta v_n - e(x)v_n^2.$$

Therefore we can use [DH, Lemma 2.1] to conclude that $v_n \leq V_\eta$ on Ω_+, where we recall that V_η is the unique positive solution of (2.2) with $\lambda = \eta$ and $b(x) = e(x)$. This implies that $\{v_n(x)\}$ is uniformly bounded on any compact subset of $\Omega_+ \cup \partial\Omega$. Define $D_n = \{x \in \overline{\Omega} : d(x, \Omega_0) > \delta_n\}$, where δ_n is a decreasing sequence of positive numbers converging to 0; we easily see, using interior and boundary estimates on D_{K+1}, that $\{v_n|_{D_k}\}$ is compact in $C^1(D_k)$. Hence, by a standard diagonal process, $\{v_n|_{\Omega_+}\}$ has a subsequence converging to some v^* in $C^1_{\rm loc}(\Omega_+ \cup \partial\Omega)$. Clearly $v^*|_{\partial\Omega} = 0$. Since $w_n(x) \leq v_n(x)$ and $w_n(x) \to V_{\lambda_1^{\Omega_0}}(x)$ on Ω_+, we deduce $v^* \geq V_{\lambda_1^{\Omega_0}}$ on Ω_+. Thus $v^* > 0$ on Ω_+ and $v^*|_{\partial\Omega_0} = \infty$. By passing to the limit along a proper subsequence in the equations for u_n and v_n, it is now easily seen that $(u^*, v^*)|_{\Omega_+}$ satisfies (3.10). By standard interior and boundary regularity, we find that $u^*|_{\Omega_+}$ belongs to $C^1_{\rm loc}(\Omega_+ \cup \partial\Omega)$, and by applying the Harnack inequality on each compact subset of $\Omega_+ \cup \partial\Omega$, we find that $u^* > 0$ in Ω_+. This proves (iv) and hence completes the proof of Theorem 3.4. □

Theorem 3.4 implies that when the growth rate of the predator approaches a certain critical positive value (i.e., $\lambda_1^{\Omega_0}$), then the predator population blows up in the region Ω_0 and the prey population vanishes in Ω_0 due to the strong presence of the predator in that region. Note, however, that the prey population survives in Ω_+. A positive growth rate of the predator implies that it has other food supplies apart from the prey u, which seems reasonable in many practical situations.

Remark 3.1.

(i) *As in the classical case, we suspect that for* (1.2) *and* (1.3), *there is at most one positive solution, which is the global attractor of the positive solutions of the corresponding parabolic system.*

(ii) *Our results are valid if* Ω *is a finite interval. In this case,* Ω_+ *is no longer connected; instead, it becomes the union of two disconnected intervals. Hence* (2.2) *and* (3.10) *split into problems on these two subintervals. The conclusions remain valid on each subinterval.*

(iii) *A direct adaptation of the argument in* [LP] *shows that in the case* Ω *is a finite interval,* (1.2) *and* (1.3) *have at most one positive solution. It follows that the connected set of positive solutions,* Γ*, in Theorems* 2.4, 2.6, 3.2, *and* 3.3 *is a smooth curve and contains all the positive solutions.*

(iv) *All our existence results can be obtained by the fixed point index approach developed in Dancer* [Da1, Da2].

Appendix. For the convenience of the reader, we state precisely [DM, Lemma 2.1] and [Du2, Lemma 3.1] here.

LEMMA A.1 (see [DM, Lemma 2.1]). *Suppose that* Ω *is a bounded domain in* R^N*,* $\alpha(x)$ *and* $\beta(x)$ *are continuous functions on* Ω *with* $\|\alpha\|_{L^\infty(\Omega)} < \infty$*, and* $\beta(x)$ *is nonnegative and not identically zero. Let* $u_1, u_2 \in C^2(\Omega)$ *be positive in* Ω *and satisfy*

$$Lu_1 + \alpha(x)u_1 - \beta(x)g(u_1) \le 0 \le Lu_2 + \alpha(x)u_2 - \beta(x)g(u_2), \quad x \in \Omega,$$

and $\overline{\lim}_{x\to\partial\Omega}(u_2 - u_1) \le 0$*, where* $Lu = \Sigma_{ij}[a_{ij}(x)u_{x_i}]_{x_j}$ *is a uniformly elliptic operator with smooth coefficients* a_{ij}*, and* $g(u)$ *is continuous and such that* $g(u)/u$ *is strictly increasing for* u *in the range* $\inf_\Omega\{u_1, u_2\} < u < \sup_\Omega \|u_1, u_2\}$*. Then* $u_2 \le u_1$ *in* Ω*.*

Note that the positive functions u_1 and u_2 may not be defined on $\partial\Omega$. Therefore this comparison result can be applied to solutions with boundary blow-ups. The existence of such *positive* functions u_1 and u_2 has hidden restrictions on $\alpha(x)$ and $\beta(x)$.

Let $\lambda_1^\omega(\phi)$ be as defined at the beginning of section 2, and let Ω, Ω_0, and Ω_+ be the same as used in this paper. Then the following result holds.

LEMMA A.2 (see [Du2, Lemma 3.1]). *Suppose that* $\phi_n \in C(\overline{\Omega})$ *and satisfies*

(i) $\phi_n \ge -M$ *for some positive constant* M*,* $\phi_n \to \infty$ *uniformly on* $\overline{\Omega}_0$ *as* $n \to \infty$*, and*

(ii) $\phi_n \to \phi$ *in* $L^p(\Omega')$ *for all* $p > 1$ *and* $\Omega' \subset\subset \Omega_+$*, where* $\phi \in C(\Omega_+ \cup \partial\Omega)$*.*

Then $\lambda_1^\Omega(\phi_n) \to \lambda_1^{\Omega_+}(\phi)$*.*

EXISTENCE OF SOLUTIONS AND A QUASI-STATIONARY LIMIT FOR A HYPERBOLIC SYSTEM DESCRIBING FERROMAGNETISM*

FRANK JOCHMANN†

Abstract. In this paper the transient Landau–Lifschitz equations coupled with Maxwell's equations describing ferromagnetic media without exchange interaction are studied. The main goals are existence of solutions and a quasi-stationary limit.

Key words. ferromagnetism, Maxwell's equations, existence of solutions, quasi-stationary limit

1. Introduction.

The paper is concerned with a nonlinear system consisting of Maxwell's equations

$$\varepsilon\partial_t\mathbf{E} = \operatorname{curl}\mathbf{H} - \sigma\mathbf{E} - \mathbf{J}, \qquad \mu\partial_t\mathbf{H} = -\operatorname{curl}\mathbf{E} - \mu\partial_t\tilde{\mathbf{M}}, \tag{1.1}$$

on $\mathbb{R}^+ \times \mathbb{R}^3$ coupled with the equation

$$\partial_t\mathbf{M} = F(x,\mathbf{M})\cdot\mathbf{H} + \mathbf{a}(x,\mathbf{M}) \tag{1.2}$$

on $\mathbb{R}^+ \times G$. Here $G \subset \mathbb{R}^3$ is an open set. In (1.1) the function $\tilde{\mathbf{M}}$ is the extension of $\mathbf{M}$ on $\mathbb{R}^+ \times \mathbb{R}^3$ defined by zero on the set $\mathbb{R}^+ \times (\mathbb{R}^3 \setminus G)$. This system, which describes the propagation of electromagnetic waves in a ferromagnetic medium occupying the set G, is supplemented by the initial conditions

$$\mathbf{E}(0,x) = \mathbf{E}_0(x), \qquad \mathbf{H}(0,x) = \mathbf{H}_0(x) \tag{1.3}$$

and

$$\mathbf{M}(0,x) = \mathbf{M}_0(x) \text{ on } G. \tag{1.4}$$

The unknown functions are the electric and magnetic field $\mathbf{E}, \mathbf{H}$, which depend on the time $t \geq 0$ and the space-variable $x \in \mathbb{R}^3$, and the magnetization $\mathbf{M}$ defined on $\mathbb{R}^+ \times G$; see [2], [13], [20].

Furthermore, $\varepsilon, \mu \in L^\infty(\mathbb{R}^3)$ denote the dielectric and magnetic permittivities, respectively, which are assumed to be bounded from below by a strictly positive constant. The electrical conductivity is denoted by σ for which the set $\{\sigma > 0\}$ does not necessarily coincide with G. An external current $\mathbf{J}$ is also included. The assumptions on the data $\mathbf{E}_0, \mathbf{H}_0$, and $\mathbf{J}$ are

$$\mathbf{J} \in L^1((0,\infty), L^2(\mathbb{R}^3)), \quad \mathbf{E}_0, \mathbf{H}_0 \in L^2(\mathbb{R}^3), \quad \mathbf{M}_0 \in L^2(G) \cap L^\infty(G). \tag{1.5}$$

Furthermore, the initial state for the magnetic induction $\mathbf{B}_0 \stackrel{\text{def}}{=} \mu[\mathbf{H}_0+\tilde{\mathbf{M}}_0]$ is assumed to be divergence-free, i.e.,

$$\text{div } (\mu[\mathbf{H}_0 + \tilde{\mathbf{M}}_0]) = 0 \text{ on } \mathbb{R}^3. \tag{1.6}$$

It is assumed that the nonlinear functions $\mathbf{a} : G \times \mathbb{R}^3 \to \mathbb{R}^3$ and $F : G \times \mathbb{R}^3 \to \mathbb{R}^{3\times 3}$ satisfy

$$\mathbf{ma}(x, \mathbf{m}) \leq 0 \text{ and } \mathbf{m}(F(x, \mathbf{m})\mathbf{h}) = 0 \text{ for all } x \in G, \mathbf{m} \in \mathbb{R}^3, \text{ and } \mathbf{h} \in \mathbb{R}^3. \tag{1.7}$$

Furthermore, they are assumed to be locally Lipschitz-continuous with respect to $\mathbf{M}$; i.e., for $A \in (0, \infty)$ there exists $L_A \in (0, \infty)$ such that

$$|\mathbf{a}(x, y) - \mathbf{a}(x, z)| + |F(x, y) - F(x, z)| \leq L_A|y - z| \tag{1.8}$$

for all $x \in G, y \in \mathbb{R}^3, \text{ and } z \in \mathbb{R}^3$ with $|y| + |z| \leq A$. Finally,

$$F(\cdot, 0) \in L^\infty(G) \text{ and } \mathbf{a}(\cdot, 0) \in L^2(G) \cap L^\infty(G). \tag{1.9}$$

Here $\mathbf{a}(x, \mathbf{M})$ takes into account a possible anisotropy of the medium, whereas $F(x, \mathbf{M})\mathbf{H}$ describes the interaction between the magnetic dipoles and the magnetic field $\mathbf{H}$. The dominant term is in most cases the torque $\mathbf{M} \wedge \mathbf{H}$, which is perpendicular to $\mathbf{M}$. This motivates assumption (1.7). A physically relevant example for F is

$$F(x, \mathbf{m})\mathbf{h} = -\gamma \mathbf{m} \wedge \mathbf{h} - \alpha|\mathbf{m}|^{-1}\mathbf{m} \wedge (\mathbf{m} \wedge \mathbf{h}) \tag{1.10}$$

including a damping term $\alpha\mathbf{m} \wedge (\mathbf{m} \wedge \mathbf{h})$ with $\alpha \geq 0$.

The main topic of this paper is a proof of existence of solutions $(\mathbf{E}, \mathbf{H}, \mathbf{M})$ of problem (1.1)–(1.4) and a quasi-stationary limit.

In the case $\varepsilon = \mu = 1$ on $\mathbb{R}^3$, the existence of solutions has been proved in [11], where the analysis is based on a compactness property of the commutator between P_H and smooth functions and also on a compensated compactness argument applied to the divergence-free part of $P_H(\mathbf{H}_n - \mathbf{H})$ for a suitable sequence $\{(\mathbf{E}_n, \mathbf{H}_n, \mathbf{M}_n)\}_{n\in\mathbb{N}}$ of approximate solutions. Here P_H denotes the orthogonal projector on the space of all vector fields $\mathbf{h} \in L^2(\mathbb{R}^3)$ with div $(\mu\mathbf{h}) = 0$. In the case $\varepsilon = \mu = 1$ on $\mathbb{R}^3$, Maxwell's equations for the part $P_H\mathbf{H}(\cdot)$ can be reduced to an inhomogeneous scalar wave equation and microlocal defect measures, and compensated compactness techniques (see [6], [16]) can be applied. This reduction to the scalar wave equation is no longer possible in the general case considered here, in which the coefficients ε, μ are not smooth, which often occurs in real situations. Therefore, a new compactness result for Maxwell's equations (Lemma 3.4) concerning local compactness properties of certain time averages of $P_H\mathbf{H}$ is proved in section 3. For the proof of the existence of solutions, in section 4 a sequence of approximate solutions $\{(\mathbf{E}_n, \mathbf{H}_n, \mathbf{M}_n)\}_{n\in\mathbb{N}}$ to a regularized problem is constructed. The subtle part is, due to the nonlinearity (1.2), the limit $n \to \infty$ where the abovementioned compactness result for Maxwell's equations and a lemma concerning the commutator between the projector P_H and suitable weight functions are used. The main ingredient of the proof of the existence of solutions is the strong convergence of $\{\mathbf{M}_n\}_{n\in\mathbb{N}}$ with respect to a weighted norm introduced in [11] in order to deal with the difficulty that $\mathbf{H}$ is generally not bounded. By a similar argument a weak convergence principle is obtained in section 5 which

says that the weak limit of solutions to (1.1)–(1.4) is again a solution provided that the initial data for $\mathbf{M}$ converge strongly.

Section 6 is concerned with the quasi-stationary limit which is of interest if the size of the ferromagnetic medium is very small in comparison to the electromagnetic wave length. After a suitable rescaling this corresponds to a high wave propagation speed $c = (\varepsilon\mu)^{-1/2}$. In this case one expects that the magnetic field is governed by magnetostatics, which means that

$$\text{curl } \mathbf{H} = \mathbf{J} \text{ and div } (\mu[\mathbf{H} + \tilde{\mathbf{M}}]) = 0 \text{ on } \mathbb{R}^+ \times \mathbb{R}^3.$$

For this purpose the external current $\mathbf{J}$ is assumed to be divergence-free. The precise statement concerning the quasi-stationary limit given in this paper is the following theorem.

THEOREM 1.1. *Assume* (1.5)–(1.9). *Suppose that in addition*

$$\mathbf{J} = \mathit{curl}\, \mathbf{g}_0 \tag{1.11}$$

with some $\mathbf{g}_0 \in L^2_{loc}(\mathbb{R}, H_{curl}) \cap W^{1,2}_{loc}(\mathbb{R}, L^2(\mathbb{R}^3))$, *in particular* $\operatorname{div} \mathbf{J} = 0$.

Let α_n *and* β_n *be sequences of positive numbers such that* $\alpha_n \overset{n\to\infty}{\longrightarrow} 0$, $\beta_n \overset{n\to\infty}{\longrightarrow} 0$, *and* α_n/β_n *is bounded as* $n \to \infty$. *With*

$$\varepsilon_n(x) = \alpha_n \varepsilon(x) \text{ and } \mu_n(x) = \beta_n \mu(x)$$

let $(\mathbf{E}_n, \mathbf{H}_n, \mathbf{M}_n)$ *be weak solutions of Landau–Lipschitz–Maxwell equations* (1.1)–(1.4), *where* ε *and* μ *are replaced by* ε_n *and* μ_n, *respectively.*

Then there exist $\mathbf{M} \in W^{1,\infty}_{loc}((0,\infty), L^2(G)) \cap L^\infty((0,\infty), L^\infty(G))$ *and a subsequence,* $(\mathbf{E}_{(n_m)}, \mathbf{H}_{(n_m)}, \mathbf{M}_{(n_m)})$, *such that for all* $T > 0$ *and* $p \in (2, \infty)$ *one has*

$$\mathbf{M}_{(n_m)} \overset{m\to\infty}{\longrightarrow} \mathbf{M} \text{ in } L^\infty((0,T), L^p(G)) \text{ strongly} \tag{1.12}$$

and

$$\mathbf{H}_{(n_m)} \overset{m\to\infty}{\longrightarrow} \mathbf{H} \text{ in } L^\infty((0,T), L^2(\mathbb{R}^3)) \text{ weak} * \tag{1.13}$$

with

$$\mathit{curl}\, \mathbf{H} = \mathbf{J} \text{ and } \operatorname{div}\left(\mu\left[\mathbf{H} + \tilde{\mathbf{M}}\right]\right) = 0. \tag{1.14}$$

Furthermore, $\mathbf{M}$ *and* $\mathbf{H}$ *solve*

$$\partial_t \mathbf{M} = F(x, \mathbf{M}) \cdot \mathbf{H} + \mathbf{a}(x, \mathbf{M}) \text{ on } \mathbb{R}^+ \times G \tag{1.15}$$

and

$$\mathbf{M}(0) = \mathbf{M}_0. \tag{1.16}$$

Here Lemma 3.4 is also applied. In the case where F is given by (1.10) with $\alpha = 0$, i.e., $F(x, \mathbf{m})\mathbf{h} = -\gamma \mathbf{m} \wedge \mathbf{h}$, the solution to problem (1.14)–(1.16) is unique and (1.12), (1.13) hold for the whole sequence.

Existence and the quasi-stationary limit have been carried out in [3] for the Landau–Lipschitz equation for the magnetic moment coupled with Maxwell's equations including the exchange interaction [3], [17], which reads as

$$\partial_t \mathbf{M} + \mathbf{M} \wedge \partial_t \mathbf{M} = 2\mathbf{M} \wedge (\Delta \mathbf{M} + \mathbf{H}) \text{ on } \mathbb{R}^+ \times G.$$

The parabolic structure of this equation simplifies the quasi-stationary limit considerably, since it provides an $H^1(G)$ estimate for the magnetic moment $\mathbf{M}$. This H^1 coercivity yields compactness properties of $\mathbf{M}$, which lets one pass to the limit in the nonlinear equations directly. Furthermore, it is shown in [3] and [4] that all points of the weak ω-limit set are solutions of the corresponding stationary equations. This is also a consequence of the H^1 boundedness of $\mathbf{M}$, which provides the compactness of the orbit with respect to the strong topology. The spatially one-dimensional case is studied in [12].

Other nonlinear models in electromagnetism have been studied, which involve the dielectric polarization $\mathbf{P}$ instead of the magnetic moment $\mathbf{M}$. In [8] and [10] the anharmonic oscillator model is studied, whereas in [5] and [9] the Maxwell–Bloch equations are considered.

2. Basic definitions and notation. Let $G \subset \mathbb{R}^3$ be a nonempty open set.

The dielectric and magnetic susceptibilities $\varepsilon, \mu \in L^\infty(\mathbb{R}^3)$ are assumed to be uniformly positive functions, which means that

$$\varepsilon(x), \mu(x) \geq a_0 \text{ on } \mathbb{R}^3 \text{ with some } a_0 > 0.$$

Furthermore, let $\sigma \in L^\infty(\mathbb{R}^3)$ be a nonnegative function.

Next, let H_{curl} be the space of all $\mathbf{E} \in L^2(\mathbb{R}^3, \mathbb{R}^3)$ with curl $\mathbf{E} \in L^2(\mathbb{R}^3)$. Now, the following operators are defined. As in [7] B is the skew self-adjoint operator

$$B(\mathbf{E}, \mathbf{H}) \stackrel{\text{def}}{=} (\varepsilon^{-1}\text{curl } \mathbf{H}, -\mu^{-1}\text{curl } \mathbf{E}) \text{ for } (\mathbf{E}, \mathbf{H}) \in D(B) \stackrel{\text{def}}{=} H_{curl} \times H_{curl}$$

in the Hilbert space $X \stackrel{\text{def}}{=} L^2(\mathbb{R}^3, \mathbb{C}^6)$ endowed with the scalar product

$$\langle (\mathbf{E}, \mathbf{H}), (\mathbf{F}, \mathbf{G}) \rangle_X \stackrel{\text{def}}{=} \int_{\mathbb{R}^3} \left(\varepsilon \mathbf{E} \cdot \overline{\mathbf{F}} + \mu \mathbf{H} \cdot \overline{\mathbf{G}} \right) dx.$$

The orthogonal decomposition (with respect to the L^2 scalar product without weight)

$$L^2(\mathbb{R}^3) = H_{curl,0} + H_{\text{div},0} \tag{2.1}$$

is well known, where $H_{curl,0}$ and $H_{\text{div},0}$ denote the spaces of all $\mathbf{E} \in L^2(\mathbb{R}^3, \mathbb{R}^3)$ with curl $\mathbf{E} = 0$ and div $\mathbf{E} = 0$, respectively. Let P with $P(\mathbf{e}, \mathbf{h}) = (P_E \mathbf{e}, P_H \mathbf{h})$ denote the orthogonal projector on $(\ker B)^\perp = \overline{\text{ran } B}$ (with respect to the weighted scalar product in X), which means that $(1 - P)$ is the orthogonal projector on $\ker B$. In particular,

$$\text{ran } (1 - P_E) = \text{ ran } (1 - P_H) = H_{curl,0}. \tag{2.2}$$

Since $(\mathbf{f}, \mathbf{g}) \in \ \ker B$ for all $\mathbf{f}, \mathbf{g} \in H_{curl,0}$, a pair $(\mathbf{e}, \mathbf{h}) \in L^2(\mathbb{R}^3)$ belongs to $(\ker B)^\perp = \text{ran } P$ if and only if

$$\int_{\mathbb{R}^3} (\varepsilon \mathbf{ef} + \mu \mathbf{hg}) dx = \langle (\mathbf{e}, \mathbf{h}), (\mathbf{f}, \mathbf{g}) \rangle_X = 0$$

for all $\mathbf{f}, \mathbf{g} \in H_{curl,0}$. By (2.1) this means that $\varepsilon \mathbf{e} \in H_{\text{div},0}$ and also $\mu \mathbf{h} \in H_{\text{div},0}$. Hence

$$\text{ran } P = (\ker B)^\perp = \{(\mathbf{e}, \mathbf{h}) \in L^2(\mathbb{R}^3) : \text{div } (\varepsilon \mathbf{e}) = \text{div } (\mu \mathbf{h}) = 0\} \tag{2.3}$$

in the sense of distributions. In particular,

$$\text{ran } P_H = \{\mathbf{h} \in L^2(\mathbb{R}^3) : \text{div } (\mu\mathbf{h}) = 0\}. \tag{2.4}$$

Next, let $F_\sigma : X \to X$ and $\mathcal{R} : L^2(G) \to X$ be defined by

$$(\mathcal{R}\mathbf{M})(x) \stackrel{\text{def}}{=} (0, \mathbf{M}(x)) \text{ if } x \in G \text{ and } (\mathcal{R}\mathbf{M})(x) \stackrel{\text{def}}{=} 0 \text{ if } x \in \mathbb{R}^3 \setminus G$$

and

$$F_\sigma(\mathbf{e}, \mathbf{h}) \stackrel{\text{def}}{=} \left(\varepsilon^{-1}\sigma\mathbf{e}, 0\right).$$

The aim of section 4 is to prove the existence of weak solutions with the properties

$$(\mathbf{E}, \mathbf{H}) \in C([0,\infty), X) \text{ and } \mathbf{M} \in W^{1,\infty}_{loc}([0,\infty), L^2(G)) \cap L^\infty_{loc}([0,\infty), L^\infty(G)). \tag{2.5}$$

This means that (1.1) is fulfilled in the sense that

$$\frac{d}{dt}\langle(\mathbf{E}(t), \mathbf{H}(t)), \mathbf{u}\rangle_X = -\langle(\mathbf{E}(t), \mathbf{H}(t)), B\mathbf{u}\rangle_X \tag{2.6}$$

$$- \langle \mathcal{R}\partial_t\mathbf{M}(t) + (\varepsilon^{-1}\mathbf{J}(t), 0) + F_\sigma(\mathbf{E}(t), \mathbf{H}(t)), \mathbf{u}\rangle_X \text{ for all } \mathbf{u} \in D(B).$$

This is equivalent to the variation of constant formula

$$(\mathbf{E}(t), \mathbf{H}(t)) = \exp(tB)\mathbf{w}_0 \tag{2.7}$$

$$- \int_0^t \exp((t-s)B)\left[\mathcal{R}\partial_t\mathbf{M}(s) + (\varepsilon^{-1}\mathbf{J}(s), 0) + F_\sigma(\mathbf{E}(s), \mathbf{H}(s))\right] ds,$$

where $\mathbf{w}_0 \stackrel{\text{def}}{=} (\mathbf{E}_0, \mathbf{H}_0) \in X$ and $\mathbf{J}$ are as in (1.5) and $(\exp(tB))_{t\in\mathbb{R}}$ is the unitary group generated by B; see [1], [7], and [14].

3. Some compactness results. One of the main goals of this section is to prove a generalization of the compensated compactness argument in [11] for Maxwell's equations with nonsmooth coefficients (Lemma 3.4). First it is shown that the space of all vector fields with divergence and curl in $L^q(\mathbb{R}^3)$, $q \in (6/5, 2]$, is compactly embedded in $L^2(B_r)$ for all $r > 0$, where $B_r \stackrel{\text{def}}{=} \{|x| < r\}$. Such a compactness result is well known for $q = 2$; see [15], [18], and [19]. This is generalized to the case where $\text{curl}\,\mathbf{h} \in L^q(\mathbb{R}^3)$ and $\text{div}\,(\mu\mathbf{h}) \in L^q(\mathbb{R}^3)$ for some $q \in (6/5, 2]$. Due to the fact that μ may be nonsmooth this does not follow directly from the Sobolev's compactness theorem $W^{1,q}(\mathbb{R}^3) \hookrightarrow L^2(B_r)$ for $q \in (6/5, 2]$.

Next, $H^{(q)}_{curl}$ denotes for $q \in [1, 2]$ the space of all $\mathbf{h} \in L^2(\mathbb{R}^3)$ with $\text{curl}\,\mathbf{h} \in L^q(\mathbb{R}^3) + L^2(\mathbb{R}^3)$; i.e., curl $\mathbf{h}$ admits a decomposition $\text{curl}\,\mathbf{h} = \mathbf{g}_1 + \mathbf{g}_2$ with

$$\mathbf{g}_1 \in L^q(\mathbb{R}^3) \text{ and } \mathbf{g}_2 \in L^2(\mathbb{R}^3).$$

The space $H^{(q)}_{\text{div}}$ is defined analogously. Now, a basic compactness lemma can be proved.

LEMMA 3.1. *Let $q \in (6/5, 2]$ and $r > 0$. Then the space of all $\mathbf{h} \in H^{(q)}_{curl}$ with $\mu\mathbf{h} \in H^{(q)}_{\text{div}}$ is compactly embedded in $L^2(B_r)$.*

Proof. Suppose that $\{\mathbf{h}_n\}_{n\in\mathbb{N}}$ is a bounded sequence in $H_{curl}(q)\cap\mu^{-1}H^{(q)}_{\mathrm{div}}$ which means that $\{\mathbf{h}_n\}_{n\in\mathbb{N}}$ is bounded in $L^2(\mathbb{R}^3)$, whereas $\{\mathrm{curl}\ \mathbf{h}_n\}_{n\in\mathbb{N}}$ and $\{\mathrm{div}\ [\mu\mathbf{h}_n]\}_{n\in\mathbb{N}}$ are bounded in $L^q(\mathbb{R}^3)+L^2(\mathbb{R}^3)$. Let

$$\chi\in C_0^\infty(B_{(2r)}) \text{ with } \chi=1 \text{ on } B_r \text{ and } \mathbf{U}_n \stackrel{\mathrm{def}}{=} \chi\mathbf{h}_n.$$

Then, since $q\le 2$ and supp χ is bounded, $\{\mathrm{curl}\ \mathbf{U}_n\}_{n\in\mathbb{N}}$ and $\{\mathrm{div}\ [\mu\mathbf{U}_n]\}_{n\in\mathbb{N}}$ are bounded in $L^q(\mathbb{R}^3)$ and supp $\mathbf{U}_n\subset B_{(2r)}$. Due to Poincaré's inequality

$$\|\psi\|^2_{H^1(B_{(2r)})}\le K\int_{B_{(2r)}}|\nabla\psi|^2dx$$

on the space

$$Y\stackrel{\mathrm{def}}{=}\left\{\psi\in H^1(B_{(2r)}) \text{ with } \int_{B_{(2r)}}\psi dx=0\right\}$$

there exists some $\psi_n\in Y$ with

$$\int_{B_{(2r)}}\mu\nabla\psi_n\nabla\psi dx=\int_{B_{(2r)}}\mu\mathbf{U}_n\nabla\psi dx \text{ for all } \psi\in Y \tag{3.1}$$

and, thus, for all $\psi\in H^1(B_{(2r)})$ (by adding a suitable constant). By taking $\psi=\psi_n$ in (3.1) it follows from the boundedness of $\mathbf{U}_n$ in $L^2(\mathbb{R}^3)$ that

$$\{\psi_n\}_{n\in\mathbb{N}} \text{ is bounded in } Y\subset H^1(B_{(2r)}). \tag{3.2}$$

Next, define $\mathbf{B}_n\in L^2(\mathbb{R}^3)$ by

$$\mathbf{B}_n(x)\stackrel{\mathrm{def}}{=}\mu(x)[\mathbf{U}_n(x)-\nabla\psi_n(x)] \text{ if } x\in B_{(2r)} \text{ and } \mathbf{B}_n(x)\stackrel{\mathrm{def}}{=}0 \text{ if } \in\mathbb{R}^3\setminus B_{(2r)}. \tag{3.3}$$

Then $\mathrm{div}\ \mathbf{B}_n=0$ on $\mathbb{R}^3$, since

$$\int_{\mathbb{R}^3}\mathbf{B}_n\nabla\varphi dx=\int_{B_{(2r)}}\mu(x)[\mathbf{U}_n(x)-\nabla\psi_n(x)]\nabla\varphi dx=0 \text{ for all } \varphi\in C_0^\infty(\mathbb{R}^3)$$

by (3.1). Furthermore, $\mathbf{B}_n$ is bounded in $L^2(\mathbb{R}^3)\cap L^1(\mathbb{R}^3)$, and hence $\widehat{\mathbf{B}_n}\in L^2(\mathbb{R}^3)\cap L^\infty(\mathbb{R}^3)$, where $\hat{\cdot}$ denotes Fourier-transform. Therefore,

$$\mathbf{g}_n(k)\stackrel{\mathrm{def}}{=}i|k|^{-2}k\wedge\widehat{\mathbf{B}_n}(k)\in L^2(\mathbb{R}^3).$$

Define $\mathbf{A}_n\stackrel{\mathrm{def}}{=}\mathcal{F}^{-1}\mathbf{g}_n\in L^2(\mathbb{R}^3)$. Since $\mathrm{div}\ \mathbf{B}_n=0$ one has $k\cdot\widehat{\mathbf{B}}_n(k)=0$ and thus $k\wedge\mathbf{g}_n(k)=-i\widehat{\mathbf{B}}_n(k)$. Hence

$$\mathrm{curl}\ \mathbf{A}_n=i\mathcal{F}^{-1}(k\wedge\mathbf{g}_n(k))=\mathbf{B}_n \text{ for all } n\in\mathbb{N}. \tag{3.4}$$

Since

$$\|\mathbf{A}_n\|_{H^1(\mathbb{R}^3)}=\|(1+|k|)\mathbf{g}_n\|_{L^2(\mathbb{R}^3)}\le C_1\|(|k|^{-1}+1)\widehat{\mathbf{B}_n}\|_{L^2(\mathbb{R}^3)}$$

$$\le C_2(\|\widehat{\mathbf{B}_n}\|_{L^\infty(\mathbb{R}^3)}+\|\widehat{\mathbf{B}_n}\|_{L^2(\mathbb{R}^3)})\le C_3(\|\mathbf{B}_n\|_{L^1(\mathbb{R}^3)}+\|\mathbf{B}_n\|_{L^2(\mathbb{R}^3)}),$$

it follows that

$$\{\mathbf{A}_n\}_{n\in\mathbb{N}} \text{ is bounded in } H^1(\mathbb{R}^3). \tag{3.5}$$

With supp $\mathbf{U}_n \subset B_{(2r)}$ one obtains from (3.3), (3.4), and Hölder's inequality after partial integration

$$c_0\|\mathbf{U}_n - \mathbf{U}_m\|^2_{L^2(B_{(2r)})} \le \int_{B_{(2r)}} (\mathbf{U}_n - \mathbf{U}_m)\cdot(\mu\mathbf{U}_n - \mu\mathbf{U}_m)dx$$

$$= \int_{B_{(2r)}} (\mathbf{U}_n - \mathbf{U}_m)(\text{curl } \mathbf{A}_n + \mu\nabla\psi_n - \text{curl } \mathbf{A}_m - \mu\nabla\psi_m)dx$$

$$= \int_{B_{(2r)}} [(\text{curl } \mathbf{U}_n - \text{curl } \mathbf{U}_m)(\mathbf{A}_n - \mathbf{A}_m) - \text{div } (\mu[\mathbf{U}_n - \mathbf{U}_m])(\psi_n - \psi_m)]dx$$

$$\le \|\text{curl } (\mathbf{U}_n - \mathbf{U}_m)\|_{L^q(B_{(2r)})}\|\mathbf{A}_n - \mathbf{A}_m\|_{L^{(q^*)}(B_{(2r)})}$$

$$+ \|\text{div } (\mu[\mathbf{U}_n - \mathbf{U}_m])\|_{L^q(B_{(2r)})}\|\psi_n - \psi_m\|_{L^{(q^*)}(B_{(2r)})}.$$

Since $q^* < 6$, the previous estimate, (3.2), (3.5), and Sobolev's embedding theorem $H^1(B_{2r}) \hookrightarrow L^{(q^*)}(B_{2r})$ yield the precompactness of $(\mathbf{U}_n)_{n\in\mathbb{N}}$ in $L^2(B_{2r})$, which completes the proof. □

Now, one obtains from Lemma 3.1, (2.2), and (2.4) the following corollary.

COROLLARY 3.2. *Let $q \in (6/5, 2]$ and $r > 0$. Then $(ran\ P_H) \cap H^{(q)}_{curl}$ is compactly embedded in $L^2(B_r)$.*

COROLLARY 3.3. *Let $\chi \in W^{1,\infty}(\mathbb{R}^3)$. Then the commutators $[\chi, P_E]$ and $[\chi, P_H]$ are compact operators from $L^2(\mathbb{R}^3)$ to $L^2(B_R)$ for all $R > 0$.*

Proof. Suppose $\mathbf{h} \in L^2(\mathbb{R}^3)$. Then $\mathbf{f} \overset{\text{def}}{=} \chi \cdot P_H\mathbf{h} - P_H(\chi\mathbf{h})$ obeys, by (2.4),

$$\text{div } (\mu\mathbf{f}) = \text{div } (\chi\mu P_H\mathbf{h}) = \mu\,(P_H\mathbf{h})\,\nabla\chi \in L^2(\mathbb{R}^3). \tag{3.6}$$

Since $\mathbf{f} = \chi\cdot(P_H - 1)\mathbf{h} - (P_H - 1)(\chi\mathbf{h})$, one obtains from (2.2)

$$\text{curl } \mathbf{f} = ((1 - P_H)\mathbf{h}) \wedge \nabla\chi \in L^2(\mathbb{R}^3).$$

By (3.6) and Lemma 3.1 this completes the proof. □

As a substitute for the compensated compactness argument in [11] the following compactness result for Maxwell's equations is proved.

LEMMA 3.4. *Suppose that $\{\mathbf{G}_n\}_{n\in\mathbb{N}}$, and $\{\mathbf{H}_n\}_{n\in\mathbb{N}}$ are bounded sequences in $L^\infty((0,T), L^2(\mathbb{R}^3))$, and $\{\mathbf{D}_n\}_{n\in\mathbb{N}}$ is bounded in $L^\infty((0,T), L^q(\mathbb{R}^3) + L^2(\mathbb{R}^3))$ with some $q \in (6/5, 2]$ such that*

$$\mathbf{H}_n \overset{n\to\infty}{\longrightarrow} 0 \text{ in } L^\infty((0,T), L^2(\mathbb{R}^3)) \text{ weak} * \tag{3.7}$$

and curl $\mathbf{H}_n(t) = \partial_t\mathbf{D}_n(t)$ on $(0,T)\times\mathbb{R}^3$ in the sense that

$$\int_{\mathbb{R}^3} \mathbf{H}_n(t)\cdot \text{curl } \mathbf{g}dx = \frac{d}{dt}\int_{\mathbb{R}^3} \mathbf{D}_n(t)\cdot\mathbf{g}dx \text{ for all } \mathbf{g} \in C_0^\infty(\mathbb{R}^3). \tag{3.8}$$

In addition, assume that the sequence $\{\mathbf{G}_n\}_{n\in\mathbb{N}}$ *is equicontinuous (from* $[0,T]$ *to* $L^2(\mathbb{R}^3)$*), i.e., for all* $\theta>0$ *there exists some* $\delta>0$ *such that*

(3.9) $\|\mathbf{G}_n(t)-\mathbf{G}_n(s)\|_{L^2(\mathbb{R}^3)}\leq\theta$ *for all* $n\in\mathbb{N}$ *and* $s,t\in(0,T)$ *with* $|s-t|\leq\delta$.

Then

$$\sup_{m\in\mathbb{N}}\int_0^T\int_{B_r}\mathbf{G}_m(t)\cdot P_H\mathbf{H}_n(t)dxdt\overset{n\to\infty}{\longrightarrow}0 \text{ for all radii } r>0.$$

Proof. The main ingredient of the proof is a local compactness property of certain time averages of $P_H\mathbf{H}_n$. For all $\chi\in C_0^\infty(0,T)$ one obtains from the boundedness of $\{\mathbf{G}_n\}_{n\in\mathbb{N}}$ and $\{P_H\mathbf{H}_n(\cdot)\}_{n\in\mathbb{N}}$ in $L^\infty((0,T),L^2(\mathbb{R}^3))$ that

$$\left|\int_0^T\int_{B_r}\mathbf{G}_m(t)\cdot P_H\mathbf{H}_n(t)dxdt-\int_0^T\int_{B_r}\chi(t)\mathbf{G}_m(t)\cdot P_H\mathbf{H}_n(t)dxdt\right|\leq C_1\int_0^T|1-\chi|dt$$

with some constant C_1 independent of $m,n\in\mathbb{N}$ and χ. Thus, it suffices to show for all $\chi\in C_0^\infty(0,T)$ and $r>0$

$$\sup_{m\in\mathbb{N}}\int_0^T\int_{B_r}\chi(t)\mathbf{G}_m(t)\cdot P_H\mathbf{H}_n(t)dxdt\overset{n\to\infty}{\longrightarrow}0. \tag{3.10}$$

Suppose $\chi\in C_0^\infty(0,T)$ and let

$$\mathbf{F}_m^{(h)}(t,x)\overset{\text{def}}{=}h^{-1}\int_0^h\chi(t+s)\mathbf{G}_m(t+s,x)ds \text{ for } h>0 \text{ and } m\in\mathbb{N}. \tag{3.11}$$

Since $\{\chi\mathbf{G}_n\}_{n\in\mathbb{N}}$ is also equicontinuous, one obtains

$$\sup_{t\in(0,T),m\in\mathbb{N}}\|\chi(t)\mathbf{G}_m(t)-\mathbf{F}_m^{(h)}(t)\|_{L^2(\mathbb{R}^3)}\overset{h\to0}{\longrightarrow}0,$$

and hence

$$\sup_{m,n\in\mathbb{N}}\left|\int_0^T\int_{B_r}\chi(t)\mathbf{G}_m(t)\cdot P_H\mathbf{H}_n(t)dxdt\right. \tag{3.12}$$

$$\left.-\int_0^T\int_{B_r}\chi(t)\mathbf{G}_m(t)\cdot P_H\mathbf{H}_n^{(h)}(t)dxdt\right|$$

$$=\sup_{m,n\in\mathbb{N}}\left|\int_0^T\int_{B_r}\Big(\chi(t)\mathbf{G}_m(t)-\mathbf{F}_m^{(h)}(t)\Big)\cdot P_H\mathbf{H}_n(t)dxdt\right|\overset{h\to0}{\longrightarrow}0,$$

where

$$\mathbf{H}_n^{(h)}(t,x)\overset{\text{def}}{=}h^{-1}\int_0^h\mathbf{H}_n(t-s,x)ds \text{ for } h>0,\ t\in\ \text{supp}\ \chi,\ \text{and } n\in\mathbb{N}. \tag{3.13}$$

Hence, it suffices to show that

$$\sup_{m\in\mathbb{N}}\int_0^T\int_{B_r}\chi(t)\mathbf{G}_m(t)\cdot P_H\mathbf{H}_n^{(h)}(t)dxdt\overset{n\to\infty}{\longrightarrow}0 \text{ for all } r>0, h>0. \tag{3.14}$$

Let $\mathbf{g}\in C_0^\infty(\mathbb{R}^3)$. Then it follows from (2.2) and (3.8) that

$$\int_{\mathbb{R}^3}P_H\mathbf{H}_n^{(h)}(t)\text{curl }\mathbf{g}dx=\int_{\mathbb{R}^3}\mathbf{H}_n^{(h)}(t)\text{curl }\mathbf{g}dx$$

$$=h^{-1}\int_0^h\int_{\mathbb{R}^3}\mathbf{H}_n(t-s)\text{curl }\mathbf{g}dxds=h^{-1}\int_{\mathbb{R}^3}[\mathbf{D}_n(t-h)-\mathbf{D}_n(t)]\cdot\mathbf{g}dx.$$

Hence

$$\text{curl }P_H\mathbf{H}_n^{(h)}(t)=h^{-1}[\mathbf{D}_n(t-h)-\mathbf{D}_n(t)]\in L^q(\mathbb{R}^3)+L^2(\mathbb{R}^3),$$

which implies by Corollary 3.2 and the boundedness of $\{\mathbf{D}_n\}_{n\in\mathbb{N}}$ in $L^\infty((0,T),L^q(\mathbb{R}^3)+L^2(\mathbb{R}^3))$ that

$$\{P_H\mathbf{H}_n^{(h)}(t)\}_{n\in\mathbb{N}}\text{ is precompact in }L^2(B_r)\text{ for fixed }t\in(0,T). \tag{3.15}$$

Since $\partial_t\mathbf{H}_n^{(h)}(t)=h^{-1}[\mathbf{H}_n(t)-\mathbf{H}_n(t-h)]$, it follows from the boundedness of $\{\mathbf{H}_n\}_{n\in\mathbb{N}}$ in $L^\infty((0,T),L^2(\mathbb{R}^3))$ that $\{P_H\mathbf{H}_n^{(h)}\}_{n\in\mathbb{N}}$ is bounded in $W^{1,\infty}((0,T),L^2(B_r))$. Hence it follows from (3.15) and Arzela's theorem that this sequence is precompact in $C([0,T],L^2(B_r))$ for all $r>0$. Thus, (3.7) yields

$$\|P_H\mathbf{H}_n^{(h)}(t)\|_{L^2(B_r)}\overset{n\to\infty}{\longrightarrow}0\text{ uniformly on }(0,T),$$

which gives (3.14), since $\{\mathbf{G}_n\}_{n\in\mathbb{N}}$ is bounded in $L^\infty((0,T),L^2(B_r))$. □

In what follows the linear, symmetric regularization operator $R_n: L^2(\mathbb{R}^3)\to L^2(\mathbb{R}^3)$ is defined by

$$(R_nf)(x)\overset{\text{def}}{=}\int_{\mathbb{R}^3}f(y)\omega_n(x-y)dy,\qquad x\in\mathbb{R}^3, \tag{3.16}$$

where $\omega_n\in C_0^\infty(\mathbb{R}^3)$ is a mollifier with supp $\omega_n\subset B_{(1/n)}$ and $\int_{\mathbb{R}^3}\omega_n dx=1$. Then R_n has the following properties:

$$\|F-R_nF\|_{L^2(\mathbb{R}^3)}\overset{n\to\infty}{\longrightarrow}0,\qquad \|R_nF\|_{L^2(\mathbb{R}^3)}\le K\|F\|_{L^2(\mathbb{R}^3)}, \tag{3.17}$$

$$\|R_nF\|_{L^2(B_r)}\le K\|F\|_{L^2(B_{(r+1)})}\text{ and }\|R_nF\|_{L^2(\mathbb{R}^3\setminus B_r)}\le K\|F\|_{L^2(\mathbb{R}^3\setminus B_{(r-1)})} \tag{3.18}$$

for all $r>1$ and $F\in L^2(\mathbb{R}^3)$ with some constant K independent of n, r, and F. For all $T>0$ and $f_\delta\in C_0^\infty((0,T)\times\mathbb{R}^3)$ the commutator between R_n and f_δ obeys

$$\sup_{t\in(0,T)}\|[f_\delta(t),R_n]\|_{B(L^2(\mathbb{R}^3),L^2(\mathbb{R}^3))}\overset{n\to\infty}{\longrightarrow}0. \tag{3.19}$$

For the proof of existence of solutions to (1.1)–(1.4) it is important that

$$R_nF\in L^\infty(\mathbb{R}^3)\text{ and }\|R_nF\|_{L^\infty(\mathbb{R}^3)}\le K_n\|F\|_{L^2(\mathbb{R}^3)}\text{ for all }F\in L^2(\mathbb{R}^3) \tag{3.20}$$

with some constant K_n independent of F but which may depend on n. Of course other regularizations with the properties (3.17)–(3.20) are possible. The following lemma concerns the commutator between the projector P_H and suitable weight functions. Beyond Lemma 3.4 it is also a main ingredient of the proof of the existence of solutions to (1.1)–(1.4) as well as of the proof of Theorem 1.1.

LEMMA 3.5. *Suppose that* $\{\mathbf{F}_n\}_{n\in\mathbb{N}}$ *is a bounded sequence in* $W^{1,\infty}((0,T),L^2(\mathbb{R}^3)) \cap L^\infty((0,T),L^\infty(\mathbb{R}^3))$ *with*

$$\mathbf{F}_n \overset{n\to\infty}{\longrightarrow} 0 \text{ in } L^\infty((0,T),L^2(\mathbb{R}^3)) \text{ weak } *. \tag{3.21}$$

Furthermore, let $\rho \in L^2((0,T),L^2(\mathbb{R}^3)) \cap L^\infty((0,T),L^\infty(\mathbb{R}^3))$. *Then*

$$\int_0^T \left\|\rho(t)^2 R_n(1-P_H)\mathbf{F}_n(t) - \rho(t)R_n(1-P_H)\left\{\rho(t)\mathbf{F}_n(t)\right\}\right\|_{L^1(\mathbb{R}^3)+L^2(\mathbb{R}^3)} dt \overset{n\to\infty}{\longrightarrow} 0$$

and

$$\int_0^T \left\|\rho(t)^2 (1-P_H)\mathbf{F}_n(t) - \rho(t)(1-P_H)\left\{\rho(t)\mathbf{F}_n(t)\right\}\right\|_{L^1(\mathbb{R}^3)+L^2(\mathbb{R}^3)} dt \overset{n\to\infty}{\longrightarrow} 0.$$

Proof. The idea is to approximate ρ by some smooth function $f \in C_0^\infty((0,T)\times\mathbb{R}^3)$ in order to get suitable estimates for the commutator between f and P_H and also for the commutator between f and R_n, since ρ may be nonsmooth.

For all $f \in C_0^\infty((0,T)\times\mathbb{R}^3)$ one obtains from the estimate in (3.17) and the boundedness of the sequence $\{\mathbf{F}_n\}_{n\in\mathbb{N}}$ in $L^\infty((0,T),L^2(\mathbb{R}^3)) \cap L^\infty((0,T),L^\infty(\mathbb{R}^3))$ that

$$\begin{aligned}
&\int_0^T \|\rho(t)\left[\rho(t)-f(t)\right] R_n(1-P_H)\mathbf{F}_n(t)\|_{L^1(\mathbb{R}^3)+L^2(\mathbb{R}^3)}\, dt \qquad (3.22)\\
&\leq \int_0^T \|\rho(t)\left[\rho(t)-f(t)\right] R_n(1-P_H)\mathbf{F}_n(t)\|_{L^1(\mathbb{R}^3)}\, dt\\
&\leq \int_0^T \|\rho(t)\|_{L^\infty(\mathbb{R}^3)} \|f(t)-\rho(t)\|_{L^2(\mathbb{R}^3)} \|R_n(1-P_H)\mathbf{F}_n(t)\|_{L^2(\mathbb{R}^3)}\, dt\\
&\leq C_1 \int_0^T \|f(t)-\rho(t)\|_{L^2(\mathbb{R}^3)} \|\mathbf{F}_n(t)\|_{L^2(\mathbb{R}^3)}\, dt\\
&\leq C_2 \|f-\rho\|_{L^2((0,T),L^2(\mathbb{R}^3))}
\end{aligned}$$

and also

$$\begin{aligned}
&\int_0^T \|\rho(t)R_n(1-P_H)\left\{\left[\rho(t)-f(t)\right]\mathbf{F}_n(t)\right\}\|_{L^1(\mathbb{R}^3)+L^2(\mathbb{R}^3)}\, dt \qquad (3.23)\\
&\leq C_3 \int_0^T \|(f(t)-\rho(t))\mathbf{F}_n(t)\|_{L^2(\mathbb{R}^3)}\, dt
\end{aligned}$$

$$\leq C_3 \int_0^T \|f(t)-\rho(t)\|_{L^2(\mathbb{R}^3)} \|\mathbf{F}_n(t)\|_{L^\infty(\mathbb{R}^3)}\, dt$$

$$\leq C_4 \|f-\rho\|_{L^2((0,T),L^2(\mathbb{R}^3))}$$

with some constants C_1, C_3 independent of n.

Let $\delta > 0$.

By the previous estimates there is some $f_\delta \in C_0^\infty((0,T)\times\mathbb{R}^3)$ such that

$$\int_0^T \big\|\rho(t)^2 R_n(1-P_H)\mathbf{F}_n(t) \tag{3.24}$$

$$-\ \rho(t)R_n(1-P_H)\{\rho(t)\mathbf{F}_n(t)\}\|_{L^1(\mathbb{R}^3)+L^2(\mathbb{R}^3)}\, dt$$

$$\leq \delta + \int_0^T \|\rho(t)f_\delta(t)R_n(1-P_H)\mathbf{F}_n(t) - \rho(t)R_n(1-P_H)\left\{f_\delta(t)\mathbf{F}_n(t)\right\}\|_{L^1(\mathbb{R}^3)+L^2(\mathbb{R}^3)}\, dt.$$

Since $f_\delta \in C_0^\infty((0,T)\times\mathbb{R}^3)$, it follows from (3.19) and the boundedness of the sequence $\{\mathbf{F}_n\}_{n\in\mathbb{N}}$ in $L^\infty((0,T),L^2(\mathbb{R}^3))$ again that we can choose some $N_\delta \in \mathbb{N}$ such that for all $n > N_\delta$

$$\int_0^T \|\rho(t)f_\delta(t)R_n(1-P_H)\mathbf{F}_n(t) \tag{3.25}$$

$$-\ \rho(t)R_n\left\{f_\delta(t)(1-P_H)\mathbf{F}_n(t)\right\}\|_{L^1(\mathbb{R}^3)+L^2(\mathbb{R}^3)}\, dt$$

$$\leq \int_0^T \|\rho(t)[f_\delta(t),R_n](1-P_H)\mathbf{F}_n(t)\|_{L^2(\mathbb{R}^3)}\, dt$$

$$\leq C_4 \|[f_\delta(t),R_n]\|_{B(L^2(\mathbb{R}^3),L^2(\mathbb{R}^3))} \leq \delta.$$

And thus, by (3.18) and (3.24), for all radii $r > 0$

$$\int_0^T \big\|\rho(t)^2 R_n(1-P_H)\mathbf{F}_n(t) \tag{3.26}$$

$$-\ \rho(t)R_n(1-P_H)\{\rho(t)\mathbf{F}_n(t)\}\|_{L^1(\mathbb{R}^3)+L^2(\mathbb{R}^3)}\, dt$$

$$\leq 2\delta + \int_0^T \|\rho(t)R_n\left\{f_\delta(t)(1-P_H)\mathbf{F}_n(t)\right\} - \rho(t)R_n(1-P_H)\left\{f_\delta(t)\mathbf{F}_n(t)\right\}\|_{L^1(\mathbb{R}^3)+L^2(\mathbb{R}^3)}\, dt$$

$$\leq 2\delta + \int_0^T \big(\|\rho(t)R_n\left\{[P_H,f_\delta(t)]\mathbf{F}_n(t)\right\}\|_{L^2(B_r)}$$

$$+\ \|\rho(t)R_n\left\{[P_H,f_\delta(t)]\mathbf{F}_n(t)\right\}\|_{L^1(\mathbb{R}^3\setminus B_r)}\big)\, dt$$

$$\leq 2\delta + C_5 \int_0^T (\|[P_H, f_\delta(t)]\mathbf{F}_n(t)\|_{L^2(B_{(r+1)})}$$

$$+ \|\rho(t)\|_{L^2(\mathbb{R}^3\setminus B_r)}\|R_n\left\{[P_H, f_\delta(t)]\mathbf{F}_n(t)\right\}\|_{L^2(\mathbb{R}^3)}\big)\, dt$$

$$\leq 2\delta + C_6 \int_0^T (\|[P_H, f_\delta(t)]\mathbf{F}_n(t)\|_{L^2(B_{(r+1)})} + \|\rho(t)\|_{L^2(\mathbb{R}^3\setminus B_r)})dt$$

with some constant C_6 independent of $n > N_\delta$ and r. Now, it follows from the boundedness of the sequence $\{\mathbf{F}_n\}_{n\in\mathbb{N}}$ in $L^\infty((0,T), L^2(\mathbb{R}^3))$ and Corollary 3.3 that

(3.27) $\{[P_H, f_\delta(t)]\mathbf{F}_n(t)\}_{n\in\mathbb{N}}$ is precompact in $L^2(B_{(r+1)})$ for fixed $t \in (0,T)$.

It follows from the boundedness of $\{\mathbf{F}_n\}_{n\in\mathbb{N}}$ in $W^{1,2}((0,T), L^2(\mathbb{R}^3))$ that the sequence $\{[P_H, f_\delta(\cdot)]\mathbf{F}_n(\cdot)\}_{n\in\mathbb{N}}$ is bounded in $W^{1,2}((0,T), L^2(B_{(r+1)}))$. Hence it follows from (3.27) and Arzela's theorem that this sequence is precompact in $C([0,T], L^2(B_{(r+1)}))$ for all $r > 0$. Thus, (3.21) yields

(3.28) $$\|[P_H, f_\delta(t)]\mathbf{F}_n(t)\|_{L^2(B_{(r+1)})} \overset{n\to\infty}{\longrightarrow} 0 \text{ uniformly on } (0,T)$$

for all $r > 0$. Now, (3.26) and (3.28) give

$$\limsup_{n\to\infty} \int_0^T \left\|\rho(t)^2 R_n(1-P_H)\mathbf{F}_n(t) - \rho(t)R_n(1-P_H)\left\{\rho(t)\mathbf{F}_n(t)\right\}\right\|_{L^1(\mathbb{R}^3)+L^2(\mathbb{R}^3)} dt$$

$$\leq 2\delta + C_6 \int_0^T \|\rho(t)\|_{L^2(\mathbb{R}^3\setminus B_r)} dt \text{ for all } r > 0.$$

Since $\delta > 0$ has been chosen arbitrarily, this completes the proof of the first assertion by letting $r \to \infty$. The other one is proved analogously. □

4. Existence of solutions. The main result of this section is the following theorem.

THEOREM 4.1. *Assume* (1.5)–(1.9). *Then problem* (1.1)–(1.4) *admits a weak solution* $(\mathbf{E}, \mathbf{H}, \mathbf{M})$ *with the properties* (2.5).

First a regularized problem is considered. Let

(4.1) $$\varepsilon\partial_t\mathbf{E}_n = \operatorname{curl}\mathbf{H}_n - \sigma\mathbf{E}_n - \mathbf{J}, \qquad \mu\partial_t\mathbf{H}_n = -\operatorname{curl}\mathbf{E}_n - \mu\partial_t\tilde{\mathbf{M}}_n,$$

on $\mathbb{R}^+ \times \mathbb{R}^3$, coupled with the equation

(4.2) $$\partial_t\mathbf{M}_n = F(x, \mathbf{M}_n)\cdot R_n(\mathbf{H}_n(\cdot)) + \mathbf{a}(x, \mathbf{M}_n)$$

on $\mathbb{R}^+ \times G$, with initial conditions (1.3) and (1.4). Here R_n is the regularization operator in (3.16). Due to the fact that R_n maps $L^2(\mathbb{R}^3)$ to $L^\infty(\mathbb{R}^3)$, problem (4.1)–(4.2) can be solved using the contraction mapping principle. The difficult part is the limit $n \to \infty$ where Lemmas 3.4 and 3.5 are used.

Suppose that $\mathbf{f} \in C_0(\mathbb{R}\times\mathbb{R}^3, \mathbb{R}^3)$ and let $\mathbf{m}$ be the solution to the ordinary initial value problem

(4.3) $$\partial_t\mathbf{m} = F(x, \mathbf{m})\cdot\mathbf{f} + \mathbf{a}(x, \mathbf{m})$$

(pointwise with respect to x) on $\mathbb{R}^+ \times G$ with initial condition (1.4). By assumption (1.7) multiplication with $\mathbf{m}$ gives $\mathbf{m}\partial_t\mathbf{m} \le 0$, and hence

$$|\mathbf{m}(t,x)| \le |\mathbf{M}_0(x)| \le C_0. \tag{4.4}$$

In particular, the ordinary initial value problem (4.3) and (1.4) admit a global solution $\mathbf{m} \in W^{1,\infty}_{loc}([0,\infty), L^2(G)) \cap L^\infty_{loc}([0,\infty), L^\infty(G))$ defined on $(0,\infty)\times G$.

Let $T > 0$ be arbitrary large and $\mathcal{A}_n : C([0,T],X) \to C([0,T],X)$ be defined by

$$(\mathcal{A}_n(\mathbf{E},\mathbf{H}))(t) = \exp(tB)(\mathbf{E}_0,\mathbf{H}_0)$$

$$-\int_0^t \exp((t-s)B)\left[\mathcal{R}\partial_t\mathbf{M}(s) + F_\sigma(\mathbf{E}(s),\mathbf{H}(s)) + (\varepsilon^{-1}\mathbf{J}(s),0)\right] ds,$$

where $\mathbf{M}$ solves (4.3) with $\mathbf{f}(t) \stackrel{\text{def}}{=} R_n(\mathbf{H}(t))$; i.e.,

$$\partial_t\mathbf{M} = F(x,\mathbf{M})\cdot R_n(\mathbf{H}_n(\cdot)) + \mathbf{a}(x,\mathbf{M}) \tag{4.5}$$

with initial condition (1.4). First, suppose that $(\mathbf{E},\mathbf{H}) \in C([0,T],X)$ and let $\mathbf{M} \in W^{1,2}([0,T], L^2(G,\mathbb{R}^3))$ be the solution to (4.5) and (1.4). Then $(\mathbf{E},\mathbf{H},\mathbf{M})$ solves (4.1), (4.2) on the interval $[0,T]$ with the initial conditions (1.3)–(1.4) (in the sense of (2.7)) if and only if $(\mathbf{E},\mathbf{H}) \in C([0,T],X)$ solves the fixed-point problem

$$\mathcal{A}_n(\mathbf{E},\mathbf{H}) = (\mathbf{E},\mathbf{H}). \tag{4.6}$$

Now suppose $(\mathbf{E},\mathbf{H}) \in C([0,T],X)$ and $(\mathbf{E}^{(1)},\mathbf{H}^{(1)}) \in C([0,T],X)$ and let $\mathbf{M}$ and $\mathbf{M}^{(1)}$ be the corresponding solutions to (4.5) and (1.4). With $R_n(\mathbf{H}(\cdot)) \in C([0,\infty), L^2(\mathbb{R}^3)\cap L^\infty(\mathbb{R}^3))$ by (3.20) one obtains from assumption (1.8), (1.9), the estimate in (3.17), and (4.4) that

$$\|\partial_t\mathbf{M}(t)\|_{L^2(G)} \le C_{1,n}(1 + \|R_n(\mathbf{H}(t))\|_{L^2(G)}) \le C_{2,n}(1 + \|(\mathbf{E}(t),\mathbf{H}(t))\|_X) \tag{4.7}$$

and

$$\begin{aligned}\|\partial_t\mathbf{M}(t) - \partial_t\mathbf{M}^{(1)}(t)\|_{L^2(G)} &\le C_{3,n}\|R_n(\mathbf{H}(t)) - R_n(\mathbf{H}^{(1)}(t))\|_{L^2(\mathbb{R}^3)} \\ &+ C_{3,n}\|\mathbf{M}(t) - \mathbf{M}^{(1)}(t)\|_{L^2(G)}\|R_n(\mathbf{H}(t))\|_{L^\infty(G)} + C_{3,n}\|\mathbf{M}(t) - \mathbf{M}^{(1)}(t)\|_{L^2(G)} \\ &\le C_{4,n}\|(\mathbf{E}(t),\mathbf{H}(t)) - (\mathbf{E}^{(1)}(t),\mathbf{H}^{(1)}(t))\|_X \\ &+ C_{4,n}\|\mathbf{M}(t) - \mathbf{M}^{(1)}(t)\|_{L^2(G)}(1 + \|(\mathbf{E}(t),\mathbf{H}(t))\|_X).\end{aligned} \tag{4.8}$$

The constants $C_{1,n} - C_{4,n}$ are independent of $(\mathbf{E},\mathbf{H})$, $(\mathbf{E}^{(1)},\mathbf{H}^{(1)})$, and t, but they may depend on n at this stage. Note that such an estimate generally does not hold for the original problem (1.1), (1.2) unless $\mathbf{H} \notin L^\infty_{loc}([0,\infty), L^\infty(\mathbb{R}^3))$. By (4.7), (4.8), and the standard energy estimate for weak solutions to the linear inhomogeneous Maxwell equations given by (2.7) it is now routine to show, by using the contraction mapping principle, that the fixed-point problem (4.6) has a unique fixed point $(\mathbf{E},\mathbf{H}) \in C([0,T],X)$. Hence problem (4.1), (4.2) has a unique solution on each finite

time interval $(0,T)$ and, therefore, it has a unique global solution $(\mathbf{E}_n, \mathbf{H}_n, \mathbf{M}_n)$ on $(0,\infty)$ the properties (2.5). It follows from (2.7) that

$$(1-P)(\mathbf{E}_n(t),\mathbf{H}_n(t)) = (1-P)(\mathbf{E}_0,\mathbf{H}_0) \tag{4.9}$$

$$-\int_0^t (1-P)\left[\mathcal{R}\partial_t \mathbf{M}_n(s) + (\varepsilon^{-1}\mathbf{J}(s),0) + F_\sigma(\mathbf{E}_n(s),\mathbf{H}_n(s))\right] ds.$$

In particular, by assumption (1.6) and (2.4),

$$(1-P_H)\left(\mathbf{H}_n(t)+\tilde{\mathbf{M}}_n(t)\right) = (1-P_H)\left(\mathbf{H}_0+\tilde{\mathbf{M}}_0\right) = 0, \tag{4.10}$$

where $\tilde{\mathbf{M}}_n(t)$ denotes the extension of $\mathbf{M}_n(t)$ by zero outside G. This means that the divergence-free condition on $\mathbf{B} \stackrel{\text{def}}{=} (\mu[\mathbf{H}+\tilde{\mathbf{M}}])$ is invariant under the nonlinear flow governed by (1.1), (1.2).

From now on the constants C_j are independent of $(\mathbf{E},\mathbf{H})$, t, and $n \in \mathbb{N}$. By (4.4) we have

$$\mathbf{M}_n \partial_t \mathbf{M}_n \le 0 \text{ and } |\mathbf{M}_n(t,x)| \le |\mathbf{M}_0(x)| \le C_0. \tag{4.11}$$

Now it follows from (4.2), (4.11), and the assumptions on the nonlinear functions that

$$|\partial_t \mathbf{M}_n| \le C_1 |R_n(\mathbf{H}_n(\cdot))| + C_1|\mathbf{M}_0|, \tag{4.12}$$

in particular, by the estimate in (3.17),

$$\|\mathcal{R}\partial_t \mathbf{M}_n(t)\|_X = \|\mu^{1/2}\partial_t \mathbf{M}_n(t)\|_{L^2(G)} \tag{4.13}$$

$$\le C_1(1+\|R_n(\mathbf{H}_n(t))\|_{L^2(G)}) \le C_2(1+\|(\mathbf{E}_n(t),\mathbf{H}_n(t))\|_X).$$

On the other hand, one obtains from (2.7) the energy estimate

$$\frac{1}{2}\frac{d}{dt}\|(\mathbf{E}_n(t),\mathbf{H}_n(t))\|_X^2 \le -\langle \mathcal{R}\partial_t \mathbf{M}_n(t) + (\varepsilon^{-1}\mathbf{J}(t),0), (\mathbf{E}_n(t),\mathbf{H}_n(t))\rangle_X \tag{4.14}$$

$$= -\int_G \mu \mathbf{H}_n(t)\partial_t \mathbf{M}_n(t) dx - \int_{\mathbb{R}^3} \mathbf{E}_n(t)\mathbf{J}(t) dx$$

$$\le \|(\mathbf{E}_n(t),\mathbf{H}_n(t))\|_X^2 + \|(\varepsilon^{-1}\mathbf{J}(t),0)\|_X^2 + \|\mathcal{R}\partial_t \mathbf{M}_n(t)\|_X^2.$$

By (4.11), (4.13), and (4.14) and Gronwall's lemma one obtains

$$\|(\mathbf{E}_n,\mathbf{H}_n)\|_{L^\infty((0,T),X)} + \|\mathbf{M}_n\|_{L^\infty((0,T),L^\infty(G))} \tag{4.15}$$

$$+ \|\partial_t \mathbf{M}_n\|_{L^\infty((0,T),L^2(G))} \le C_3$$

with some constants C_3 independent of n.

Hence there exists a subsequence $\{(\mathbf{E}_{n_m},\mathbf{H}_{n_m},\mathbf{M}_{n_m})\}_{m\in\mathbb{N}}$ such that

$$(\mathbf{E}_{n_m},\mathbf{H}_{n_m}) \stackrel{m\to\infty}{\longrightarrow} (\mathbf{E},\mathbf{H}) \text{ in } L^\infty((0,T),X) \text{ weak } *, \tag{4.16}$$

$$\mathbf{M}_{n_m} \overset{m\to\infty}{\longrightarrow} \mathbf{M} \text{ in } W^{1,2}((0,T),L^2(G)) \text{ weakly,} \tag{4.17}$$

and in $L^\infty((0,T),L^\infty(G))$ weak $*$. Note that it follows from the boundedness of $\partial_t \mathbf{M}_n$ in $L^2((0,T),L^2(G))$ and initial condition (1.4) for $\mathbf{M}_n$ that $\mathbf{M} \in W^{1,2}((0,T),L^2(G)) \subset C([0,T],L^2(G))$ and $\mathbf{M}(0) = \mathbf{M}_0$.

From (2.7), (4.1), (4.16), and (4.17) we obtain

$$(\mathbf{E},\mathbf{H}) = \exp(tB)(\mathbf{E}_0,\mathbf{H}_0) \tag{4.18}$$

$$-\int_0^t \exp((t-s)B)\left[\mathcal{R}\partial_t \mathbf{M}(s) + F_\sigma(\mathbf{E}(s),\mathbf{H}(s)) + (\varepsilon^{-1}\mathbf{J}(s),0)\right] ds;$$

i.e., $(\mathbf{E},\mathbf{H}) \in C([0,T],X)$ is the solution of the Maxwell system (1.1).

The aim of the following considerations is to show strong convergence of $\{\mathbf{M}_{n_m}\}_{m\in\mathbb{N}}$. By assumption (1.8) and the uniform boundedness of $\{\mathbf{M}_{n_m}\}_{m\in\mathbb{N}}$ in (4.11), there is some $L > 0$ such that

$$|F_n(t,x) - F_m(t,x)| \le L|\mathbf{M}_n(t,x) - \mathbf{M}_m(t,x)| \tag{4.19}$$

$$\text{and } |\mathbf{a}(x,\mathbf{M}_n) - \mathbf{a}(x,\mathbf{M}_m)| \le L|\mathbf{M}_n(t,x) - \mathbf{M}_m(t,x)| \text{ for all } n,m \in \mathbb{N}$$

with the abbreviation $F_n(t,x) \overset{\text{def}}{=} F(x,\mathbf{M}_n(t,x))$.

The main difficulty is that $\{\mathbf{H}_{n_m}\}_{m\in\mathbb{N}}$ is not uniformly bounded in general. For this purpose the weighted norm as in [11] is introduced. Let

$$\rho(t,x) \overset{\text{def}}{=} \rho_0(x)\exp\left(-L\int_0^t |\mathbf{H}(s,x)|ds\right) \text{ for } t \in (0,T) \tag{4.20}$$

with some arbitrarily chosen positive function $\rho_0 \in L^2(\mathbb{R}^3) \cap L^\infty(\mathbb{R}^3)$ and $\mathbf{H}$ as in (4.16). Then (4.19) gives

$$\int_G \rho(t)^2(\mathbf{M}_{n_m}(t) - \mathbf{M}_{n_p}(t)) \cdot \left(F_{n_m}(t) - F_{n_p}(t)\right)\mathbf{H}(t)dx \tag{4.21}$$

$$\le L\int_G \rho(t)^2|\mathbf{H}(t)|(\mathbf{M}_{n_m}(t) - \mathbf{M}_{n_p}(t))^2 dx.$$

Now, it follows from assumption (1.8), (4.2), (4.11), (4.20), and (4.21) that

$$\frac{1}{2}\frac{d}{dt}\|\rho(t)(\mathbf{M}_{n_m}(t) - \mathbf{M}_{n_p}(t))\|^2_{L^2(G)} \tag{4.22}$$

$$= \int_G \rho(t)^2(\mathbf{M}_{n_m}(t) - \mathbf{M}_{n_p}(t))\partial_t(\mathbf{M}_{n_m}(t) - \mathbf{M}_{n_p}(t))dx$$

$$- L\int_G \rho(t)^2|\mathbf{H}(t)|(\mathbf{M}_{n_m}(t) - \mathbf{M}_{n_p}(t))^2 dx$$

$$= \int_G \rho(t)^2(\mathbf{M}_{n_m}(t) - \mathbf{M}_{n_p}(t)) \cdot \left(F_{n_m}(t)R_{n_m}(\mathbf{H}_{n_m}(t)) - F_{n_p}(t)R_{n_p}(\mathbf{H}_{n_p}(t)\right) dx$$

$$+\int_G \rho(t)^2(\mathbf{M}_{n_m}(t)-\mathbf{M}_{n_p}(t))\cdot\big(\mathbf{a}(x,\mathbf{M}_{n_m})-\mathbf{a}(x,\mathbf{M}_{n_p})\big)\,dx$$

$$-\ L\int_G \rho(t)^2|\mathbf{H}(t)|(\mathbf{M}_{n_m}(t)-\mathbf{M}_{n_p}(t))^2dx$$

$$\leq \int_G \rho(t)^2(\mathbf{M}_{n_m}(t)-\mathbf{M}_{n_p}(t))\cdot F_{n_m}(t)\left[R_{n_m}(\mathbf{H}_{n_m}(t))-\mathbf{H}(t)\right]dx$$

$$-\int_G \rho(t)^2(\mathbf{M}_{n_m}(t)-\mathbf{M}_{n_p}(t))\cdot F_{n_p}(t)\left[R_{n_p}(\mathbf{H}_{n_p}(t))-\mathbf{H}(t)\right]dx$$

$$+\ C_3\|\rho(t)(\mathbf{M}_{n_m}(t)-\mathbf{M}_{n_p}(t))\|^2_{L^2(G)}$$

$$\leq C_3\|\rho(t)(\mathbf{M}_{n_m}(t)-\mathbf{M}_{n_p}(t))\|^2_{L^2(G)}+\sum_{j=1}^{3}h_{j,m,p}(t)+\sum_{j=1}^{3}h_{j,p,m}(t).$$

Here

$$h_{1,m,p}(t)\stackrel{\text{def}}{=}\int_G \rho(t)^2(\mathbf{M}_{n_m}(t)-\mathbf{M}_{n_p}(t))\cdot F_{n_m}(t)R_{n_m}P_H\left(\mathbf{H}_{n_m}(t)-\mathbf{H}(t)\right)dx, \tag{4.23}$$

$$h_{2,m,p}(t)\stackrel{\text{def}}{=}\int_G \rho(t)^2(\mathbf{M}_{n_m}(t)-\mathbf{M}_{n_p}(t))\cdot F_{n_m}(t)R_{n_m}(1-P_H)\left(\mathbf{H}_{n_m}(t)-\mathbf{H}(t)\right)dx, \tag{4.24}$$

$$h_{3,m,p}(t)\stackrel{\text{def}}{=}\int_G \rho(t)^2(\mathbf{M}_{n_m}(t)-\mathbf{M}_{n_p}(t))\cdot F_{n_m}(t)\left[R_{n_m}(\mathbf{H}(t))-\mathbf{H}(t)\right]dx. \tag{4.25}$$

With (4.15) and the strong convergence in (3.17) it follows easily that

$$\int_0^T |h_{3,m,p}(t)|dt\stackrel{m,p\to\infty}{\longrightarrow}0. \tag{4.26}$$

In analogy to (4.10) it follows from (4.18) that

$$(1-P_H)\left(\mathbf{H}(t)+\tilde{\mathbf{M}}(t)\right)=(1-P_H)\left(\mathbf{H}_0+\tilde{\mathbf{M}}_0\right)=0, \tag{4.27}$$

and hence

$$(1-P_H)\left((\mathbf{H}_{n_m}(t))-\mathbf{H}(t)\right)=-(1-P_H)\left(\tilde{\mathbf{M}}_{n_m}(t)-\tilde{\mathbf{M}}(t)\right).$$

This gives

$$h_{2,m,p}(t) = \int_G \rho(t)^2(\mathbf{M}_{n_m}(t) - \mathbf{M}_{n_p}(t)) \cdot F_{n_m}(t) R_{n_m}(1-P_H)\left(\tilde{\mathbf{M}} - \tilde{\mathbf{M}}_{n_m}(t)\right) dx$$

$$= -\int_{\mathbb{R}^3} \left[\tilde{\mathbf{M}}_{n_m}(t) - \tilde{\mathbf{M}}_{n_p}(t)\right] \cdot \tilde{F}_{n_m}(t)\rho(t)^2 R_{n_m}(1-P_H)\left(\tilde{\mathbf{M}}(t) - \tilde{\mathbf{M}}_{n_m}(t)\right) dx.$$

The idea is to replace $\rho(t)R_{n_m}(1-P_H)(\tilde{\mathbf{M}}(t)-\tilde{\mathbf{M}}_{n_m}(t))$ by $R_{n_m}(1-P_H)\{\rho(t)(\tilde{\mathbf{M}}(t)-\tilde{\mathbf{M}}_{n_m}(t))\}$ in order to obtain an estimate of $h_{2,m,p}(t)$ in terms of the L^2-norm of $\rho(t)(\tilde{\mathbf{M}}(t) - \tilde{\mathbf{M}}_{n_m}(t))$.

Let $\delta > 0$.

By (4.15), (4.17), and Lemma 3.5 with

$$\mathbf{F}_m(t) \overset{\text{def}}{=} \tilde{\mathbf{M}}(t) - \tilde{\mathbf{M}}_{n_m}(t)$$

we can choose some $N_\delta \in \mathbb{N}$ such that for all $m, p > N_\delta$

$$\int_0^T \Big| h_{2,m,p}(t) - \int_{\mathbb{R}^3} \rho(t)\left[\tilde{\mathbf{M}}_{n_m}(t) - \tilde{\mathbf{M}}_{n_p}(t)\right] \tag{4.28}$$

$$\cdot\, \tilde{F}_{n_m}(t) R_{n_m}(1-P_H)\left\{\rho(t)\left(\tilde{\mathbf{M}}(t) - \tilde{\mathbf{M}}_{n_m}(t)\right)\right\} dx \Big| dt$$

$$\le \int_0^T \Big| \int_{\mathbb{R}^3} \tilde{F}_{n_m}(t)^* \left[\tilde{\mathbf{M}}_{n_m}(t) - \tilde{\mathbf{M}}_{n_p}(t)\right] \cdot \Big(\rho(t)^2 R_{n_m}(1-P_H)\left(\tilde{\mathbf{M}}(t) - \tilde{\mathbf{M}}_{n_m}(t)\right)$$

$$-\, \rho(t) R_{n_m}(1-P_H)\left\{\rho(t)\left(\tilde{\mathbf{M}}(t) - \tilde{\mathbf{M}}_{n_m}(t)\right)\right\}\Big) dx \Big| dt$$

$$\le \int_0^T \left\| \tilde{F}_{n_m}(t)^* \left[\tilde{\mathbf{M}}_{n_m}(t) - \tilde{\mathbf{M}}_{n_p}(t)\right] \right\|_{L^\infty(\mathbb{R}^3)\cap L^2(\mathbb{R}^3)}$$

$$\Big\| \rho(t)^2 R_{n_m}(1-P_H)\left(\tilde{\mathbf{M}}(t) - \tilde{\mathbf{M}}_{n_m}(t)\right)$$

$$-\rho(t) R_{n_m}(1-P_H)\left\{\rho(t)\left(\tilde{\mathbf{M}}(t) - \tilde{\mathbf{M}}_{n_m}(t)\right)\right\}\Big\|_{L^1(\mathbb{R}^3)+L^2(\mathbb{R}^3)} dt \le \delta,$$

and hence

$$\int_0^t |h_{2,m,p}(s)| ds \tag{4.29}$$

$$\le \delta + \int_0^t \Big| \int_{\mathbb{R}^3} \rho(s)[\tilde{\mathbf{M}}_{n_m}(s) - \tilde{\mathbf{M}}_{n_p}(s)]$$

$$\cdot\, \tilde{F}_{n_m}(s) R_{n_m}(1-P_H)\left\{\rho(s)\left(\tilde{\mathbf{M}}(s)-\tilde{\mathbf{M}}_{n_m}(s)\right)\right\}dx\Big|ds$$

$$\leq \delta + C_7 \int_0^t \left\|\rho(s)\left[\tilde{\mathbf{M}}_{n_p}(s)-\tilde{\mathbf{M}}_{n_m}(s)\right]\right\|_{L^2(\mathbb{R}^3)}$$

$$\left\|R_{n_m}(1-P_H)\left(\rho(s)\tilde{\mathbf{M}}_{n_m}(s)-\rho(s)\tilde{\mathbf{M}}(s)\right)\right\|_{L^2(\mathbb{R}^3)} ds$$

$$\leq \delta + C_8 \int_0^t \|\rho(s)(\mathbf{M}_{n_m}(s)-\mathbf{M}_{n_p}(s))\|_{L^2(G)} \|\rho(s)(\mathbf{M}_{n_m}(s)-\mathbf{M}(s))\|_{L^2(G)} ds$$

with some constant C_8 independent of t, δ and $m, p > N_\delta$.

It remains to estimate $h_{1,m,p}(t)$. Let

$$\mathbf{G}_{m,p}(t) \stackrel{\text{def}}{=} R_{n_m}\left\{\rho(t)^2 \tilde{F}_{n_m}(t)^*\left[\tilde{\mathbf{M}}_{n_m}(t)-\tilde{\mathbf{M}}_{n_p}(t)\right]\right\}. \tag{4.30}$$

By (4.23) one has

$$h_{1,m,p}(t) = \int_{\mathbb{R}^3} \mathbf{G}_{m,p}(t)\cdot P_H\left(\mathbf{H}_{n_m}(t)-\mathbf{H}(t)\right)dx$$

from which one obtains by (3.18) and (4.15) for all radii $r > 1$,

$$\left|\int_0^t h_{1,m,p}(s)ds\right| \leq \left|\int_0^t \int_{B_r} \mathbf{G}_{m,p}(s)\cdot P_H\left(\mathbf{H}_{n_m}(s)-\mathbf{H}(s)\right)dxds\right| \tag{4.31}$$

$$+ \int_0^T \|\mathbf{G}_{m,p}(s)\|_{L^2(\mathbb{R}^3\setminus B_r)} \|P_H\left(\mathbf{H}_{n_m}(s)-\mathbf{H}(s)\right)\|_{L^2(\mathbb{R}^3\setminus B_r)} ds$$

$$\leq \left|\int_0^t \int_{B_r} \mathbf{G}_{m,p}(s)\cdot P_H\left(\mathbf{H}_{n_m}(s)-\mathbf{H}(s)\right)dxds\right|$$

$$+ C_{10}\int_0^T \left\|\rho(s)^2 \tilde{F}_{n_m}(s)^*\left[\tilde{\mathbf{M}}_{n_m}(s)-\tilde{\mathbf{M}}_{n_p}(s)\right]\right\|_{L^2(\mathbb{R}^3\setminus B_{r-1})} ds$$

$$\leq \left|\int_0^t \int_{B_r} \mathbf{G}_{m,p}(s)\cdot P_H\left(\mathbf{H}_{n_m}(s)-\mathbf{H}(s)\right)dxds\right| + C_{11}\int_0^T \|\rho(s)^2\|_{L^2(\mathbb{R}^3\setminus B_{(r-1)})} ds$$

with some constant C_{11} independent of $m, p > N_\delta$ and r. By (4.1), (2.6), and (4.18), i.e., (1.1), one has

$$\int_{\mathbb{R}^3} (\mathbf{H}_{n_m}(t)-\mathbf{H}(t))\cdot \operatorname{curl}\mathbf{g}\,dx = \frac{d}{dt}\int_{\mathbb{R}^3} \mathbf{D}_{n_m}(t)\cdot\mathbf{g}\,dx \tag{4.32}$$

for all $\mathbf{g} \in C_0^\infty(\mathbb{R}^3)$ with

$$\mathbf{D}_n(t) \stackrel{\text{def}}{=} \varepsilon\left(\mathbf{E}_n(t)-\mathbf{E}(t)\right) + \int_0^t \sigma\left(\mathbf{E}_n(s)-\mathbf{E}(s)\right)ds.$$

By assumption (1.8), (1.9), (4.15), and (4.30) the functions $\{\tilde{\mathbf{M}}_{n_m}\}_{m\in\mathbb{N}}$ and $\{\rho^2\tilde{F}^*_{n_m}\}_{m\in\mathbb{N}}$ are bounded in $L^\infty((0,T),L^\infty(\mathbb{R}^3))$, whereas their time derivatives are bounded in $L^\infty((0,T),L^2(\mathbb{R}^3))$. Hence, by (3.17), there exists some constant K such that

$$\|\mathbf{G}_{m,p}(t)-\mathbf{G}_{m,p}(s)\|_{L^2(\mathbb{R}^3)} \le \Big\|\rho(t)^2\tilde{F}_{n_m}(t)^*\left[\tilde{\mathbf{M}}_{n_m}(t)-\tilde{\mathbf{M}}_{n_p}(t)\right]$$

$$-\,\rho(s)^2\tilde{F}_{n_m}(s)^*\left[\tilde{\mathbf{M}}_{n_m}(s)-\tilde{\mathbf{M}}_{n_p}(s)\right]\Big\|_{L^2(\mathbb{R}^3)} \le K|s-t| \text{ for all } s,t\in(0,T),$$

which means that the sequence $\{\mathbf{G}_{m,p}\}_{m\in\mathbb{N}}$ is equicontinuous. Therefore, it follows from (4.16), (4.32), and Lemma 3.4 that

$$\int_0^t\int_{B_r}\mathbf{G}_{m,p}(s)\cdot P_H\left(\mathbf{H}_{n_m}(s)-\mathbf{H}(s)\right)dxds \overset{m,p\to\infty}{\longrightarrow} 0 \text{ for all } r>1. \tag{4.33}$$

Now, (4.31) and (4.33) give

$$\limsup_{m,p\to\infty}\left|\int_0^t h_{1,m,p}(s)ds\right| \le C_{11}\int_0^T\|\rho(s)^2\|_{L^2(\mathbb{R}^3\setminus B_{(r-1)})}ds \text{ for all } r>1,$$

which implies that

$$\int_0^t h_{1,m,p}(s)ds \overset{m,p\to\infty}{\longrightarrow} 0 \text{ for all } t\in[0,T]. \tag{4.34}$$

It follows from (3.17), (4.15), and (4.23) that the functions $h_{1,m,p}$ are uniformly bounded, and hence the functions $\tilde{h}_{1,m,p}(t)\overset{\text{def}}{=}\int_0^t h_{1,m,p}(s)ds$ are equicontinuous on $[0,T]$. Therefore, the convergence in (4.34) is uniform with respect to $t\in[0,T]$. By (4.22), (4.26), (4.29), and (4.34) there is some $m_\delta>N_\delta$ such that

$$\frac{1}{2}\|\rho(t)(\mathbf{M}_{n_m}(t)-\mathbf{M}_{n_p}(t))\|^2_{L^2(G)} \tag{4.35}$$

$$\le\sum_{j=1}^3\int_0^t h_{j,m,p}(s)ds+\sum_{j=1}^3\int_0^t h_{j,p,m}(s)ds$$

$$+\,C_3\int_0^t\|\rho(s)(\mathbf{M}_{n_m}(s)-\mathbf{M}_{n_p}(s))\|^2_{L^2(G)}ds$$

$$\le 6\delta+C_3\int_0^t\|\rho(s)(\mathbf{M}_{n_m}(s)-\mathbf{M}_{n_p}(s))\|^2_{L^2(G)}ds$$

$$+\,C_8\int_0^t\|\rho(s)(\mathbf{M}_{n_m}(s)-\mathbf{M}_{n_p}(s))\|_{L^2(G)}$$

$$\left(\|\rho(s)(\mathbf{M}_{n_m}(s)-\mathbf{M}(s))\|_{L^2(G)}+\|\rho(s)(\mathbf{M}_{n_p}(s)-\mathbf{M}(s))\|_{L^2(G)}\right)ds$$

$$\leq 6\delta + \frac{C_9}{6}\int_0^t (\|\rho(s)(\mathbf{M}_{n_m}(s)-\mathbf{M}_{n_p}(s))\|^2_{L^2(G)} + \|\rho(s)(\mathbf{M}_{n_m}(s)-\mathbf{M}(s))\|^2_{L^2(G)})ds$$

for all $t \in (0,T)$ and $m,p > m_\delta$. Using the elementary inequality

$$\exp(-C_9 t)C_9\int_0^t f(s)ds \leq \sup_{s\in(0,t)}[\exp(-C_9 s)f(s)] \leq \sup_{s\in(0,T)}[\exp(-C_9 s)f(s)]$$

for all nonnegative functions $f \in C[0,T]$ this gives

$$\sup_{t\in(0,T)}\left[\exp(-C_9 t)\|\rho(t)(\mathbf{M}_{n_m}(t)-\mathbf{M}_{n_p}(t))\|^2_{L^2(G)}\right] \tag{4.36}$$

$$\leq 18\delta + \frac{1}{2}\sup_{t\in(0,T)}\left[\exp(-C_9 t)\|\rho(t)(\mathbf{M}_{n_m}(t)-\mathbf{M}(t))\|^2_{L^2(G)}\right].$$

Letting $p\to\infty$ it follows from (4.17) and (4.36) that

$$\exp(-C_9 t)\|\rho(t)(\mathbf{M}_{n_m}(t)-\mathbf{M}(t))\|^2_{L^2(G)} \tag{4.37}$$

$$\leq \limsup_{p\to\infty}\exp(-C_9 t)\|\rho(t)(\mathbf{M}_{n_m}(t)-\mathbf{M}_{n_p}(t))\|^2_{L^2(G)}$$

$$\leq 18\delta + \frac{1}{2}\sup_{t\in(0,T)}\left[\exp(-C_9 t)\|\rho(t)(\mathbf{M}_{n_m}(t)-\mathbf{M}(t))\|^2_{L^2(G)}\right].$$

This estimate gives

$$\|\rho[\mathbf{M}_{n_m}-\mathbf{M}]\|_{L^\infty((0,T),L^2(\mathbb{R}^3))} \overset{m\to\infty}{\longrightarrow} 0. \tag{4.38}$$

Let $A_k \overset{\text{def}}{=} \{(t,x)\in(0,T)\times G : \rho(t,x) > 1/k\}$. By (4.11) one obtains

$$\|\mathbf{M}_{n_m}-\mathbf{M}\|_{L^2((0,T),L^2(G))} \leq \|\mathbf{M}_{n_m}-\mathbf{M}\|_{L^2(A_k)} + \|2\mathbf{M}_0\|_{L^2([(0,T)\times G]\setminus A_k)}$$

$$\leq k\|\rho[\mathbf{M}_{n_m}-\mathbf{M}]\|_{L^2((0,T),L^2(\mathbb{R}^3))} + \|2\mathbf{M}_0\|_{L^2([(0,T)\times G]\setminus A_k)}.$$

Now (4.38) yields

$$\limsup_{m\to\infty}\|\mathbf{M}_{n_m}-\mathbf{M}\|_{L^2((0,T),L^2(\mathbb{R}^3))} \leq \|2\mathbf{M}_0\|_{L^2([(0,T)\times G]\setminus A_k)} \text{ for all } k\in\mathbb{N}.$$

Since $(0,T)\times G = \bigcup_{k=1}^\infty A_k$, this gives

$$\|\mathbf{M}_{n_m}-\mathbf{M}\|_{L^2((0,T),L^2(\mathbb{R}^3))} \overset{m\to\infty}{\longrightarrow} 0. \tag{4.39}$$

By (3.17), (4.2), and (4.16) it follows from this strong convergence that $(\mathbf{E},\mathbf{H},\mathbf{M})$ also satisfies (1.2). Since T can be chosen arbitrarily large this completes the proof of the existence of solutions.

5. A weak convergence principle. The following theorem says that the weak limit of solutions to (1.1)–(1.4) is again a solution provided that the initial data for $\mathbf{M}$ converge strongly. It will also be used in section 6.

THEOREM 5.1. *Assume* (1.7)–(1.9). *Suppose that* $\{\mathbf{H}_n\}_{n\in\mathbb{N}}$ *is a bounded sequence in* $L^\infty((0,T),L^2(\mathbb{R}^3))$, *and let* $\{\mathbf{M}_n\}_{n\in\mathbb{N}}$ *be a bounded sequence in* $W^{1,\infty}((0,T),L^2(G)) \cap L^\infty((0,T),L^\infty(G))$, *such that*

$$\mathbf{H}_n \overset{n\to\infty}{\longrightarrow} \mathbf{H} \text{ in } L^\infty((0,T),L^2(\mathbb{R}^3)) \text{ weak } *, \tag{5.1}$$

$$\mathbf{M}_n \overset{n\to\infty}{\longrightarrow} \mathbf{M} \text{ in } L^\infty((0,T),L^\infty(G)) \text{ weak } *, \tag{5.2}$$

and

$$\mathbf{M}_n(0) \overset{n\to\infty}{\longrightarrow} \mathbf{M}_0 \text{ in } L^2(G) \text{ strongly }. \tag{5.3}$$

Furthermore, assume that

$$(1-P_H)\mathbf{H}_n(t) = (1-P_H)\tilde{\mathbf{M}}_n(t), \tag{5.4}$$

$$\partial_t \mathbf{M}_n = F(x,\mathbf{M}_n)\cdot\mathbf{H}_n + \mathbf{a}(x,\mathbf{M}_n) \text{ on } \mathbb{R}^+\times G, \tag{5.5}$$

and

$$\int_{\mathbb{R}^3} \mathbf{H}_n(t)\cdot \mathit{curl}\,\mathbf{g}dx = \frac{d}{dt}\int_{\mathbb{R}^3}\mathbf{D}_n(t)\cdot\mathbf{g}dx \text{ for all } \mathbf{g}\in C_0^\infty(\mathbb{R}^3), \tag{5.6}$$

where $\{\mathbf{D}_n\}_{n\in\mathbb{N}}$ *is a bounded sequence in* $L^\infty((0,T),L^q(\mathbb{R}^3)+L^2(\mathbb{R}^3))$ *for some* $q\in(6/5,2]$. *Then*

$$\|\mathbf{M}_n-\mathbf{M}\|_{L^\infty((0,T),L^p(G))} \overset{n\to\infty}{\longrightarrow} 0 \text{ for all } p\in[2\infty), \tag{5.7}$$

$$\partial_t\mathbf{M} = F(x,\mathbf{M})\cdot\mathbf{H} + \mathbf{a}(x,\mathbf{M}) \text{ on } \mathbb{R}^+\times G, \tag{5.8}$$

and

$$\mathbf{M}(0) = \mathbf{M}_0. \tag{5.9}$$

Proof. The basic idea is to show strong convergence of $\{\mathbf{M}_{n_m}\}_{m\in\mathbb{N}}$ by using similar arguments as in the proof of Theorem 4.1.

Let $F_n(t,x) \overset{\text{def}}{=} F(x,\mathbf{M}_n(t))$ and ρ be as in (4.20) with $\mathbf{H}$ as in (5.1). As in (4.22) one obtains

$$\begin{aligned}\frac{1}{2}\|\rho(t)(\mathbf{M}_n(t)-\mathbf{M}_m(t))\|^2_{L^2(G)} &\le \frac{1}{2}\|\rho(t)(\mathbf{M}_n(0)-\mathbf{M}_m(0))\|^2_{L^2(G)} \\ &+ C_1\int_0^t \|\rho(s)(\mathbf{M}_n(s)-\tilde{\mathbf{M}}_m(s))\|^2_{L^2(G)}ds \\ &+ \int_0^t (g_{1,n,m}(s)+g_{2,n,m}(s)+g_{1,m,n}(s)+g_{2,m,n}(s))\,ds.\end{aligned} \tag{5.10}$$

Here

$$g_{1,n,m}(t) \stackrel{\text{def}}{=} \int_G \rho(t)^2[\mathbf{M}_n(t)-\mathbf{M}_m(t)]\cdot F_n(t)P_H\left(\mathbf{H}_n(t)-\mathbf{H}(t)\right)dx, \tag{5.11}$$

$$\begin{aligned} g_{2,n,m}(t) &\stackrel{\text{def}}{=} \int_G \rho(t)^2[\mathbf{M}_n(t)-\mathbf{M}_m(t)]\cdot F_n(t)(1-P_H)\left(\mathbf{H}_n(t)-\mathbf{H}(t)\right)dx \\ &= -\int_{\mathbb{R}^3} \rho(t)\left[\tilde{\mathbf{M}}_n(t)-\tilde{\mathbf{M}}_m(t)\right]\cdot \tilde{F}_n(t)\rho(t)(1-P_H)\left(\tilde{\mathbf{M}}(t)-\tilde{\mathbf{M}}_n(t)\right)dx, \end{aligned} \tag{5.12}$$

by 5.4, where $\tilde{\mathbf{M}}(t)$ denotes the extension of $\mathbf{M}(t)$ by zero outside G. The estimate of $g_{2,n,m}(t)$ can be arranged as in the proof of Theorem 4.1 using (5.2) and Lemma 3.5.

In order to estimate $g_{1,n,m}(t)$ let

$$\mathbf{G}_{n,m}(t) \stackrel{\text{def}}{=} \rho(t)^2\tilde{F}_n(t)^*\left[\tilde{\mathbf{M}}_n(t)-\tilde{\mathbf{M}}_m(t)\right]. \tag{5.13}$$

By (5.11) one has

$$g_{1,n,m}(t) = \int_{\mathbb{R}^3} \mathbf{G}_{n,m}(t)\cdot P_H\left(\mathbf{H}_n(t)-\mathbf{H}(t)\right)dx.$$

In analogy to (4.31) and (4.33) it suffices to show that

$$\int_0^t \int_{B_r} \mathbf{G}_{n,m}(s)\cdot P_H\left(\mathbf{H}_n(s)-\mathbf{H}(s)\right)dxds \stackrel{m,n\to\infty}{\longrightarrow} 0 \tag{5.14}$$

for all $t\in[0,T]$ and $r>0$.

It follows from the boundedness of $\{\mathbf{D}_n\}_{n\in\mathbb{N}}$ there exists some $\mathbf{D}\in L^2((0,T),L^q(\mathbb{R}^3)+L^2(\mathbb{R}^3))$ and a subsequence $\{\mathbf{D}_{n_m}\}_{m\in\mathbb{N}}$ such that

$$\mathbf{D}_{n_m} \stackrel{m\to\infty}{\longrightarrow} \mathbf{D} \text{ in } L^\infty((0,T),L^q(\mathbb{R}^3)+L^2(\mathbb{R}^3)) \text{ weak } -*. \tag{5.15}$$

By (5.1), (5.6), and (5.15) one obtains

$$\int_{\mathbb{R}^3} \mathbf{H}(t)\cdot \operatorname{curl}\mathbf{g}dx = \frac{d}{dt}\int_{\mathbb{R}^3}\mathbf{D}(t)\cdot\mathbf{g}dx,$$

and hence, by (5.6),

$$\int_{\mathbb{R}^3} (\mathbf{H}_n(t)-\mathbf{H}(t))\cdot\operatorname{curl}\mathbf{g}dx = \frac{d}{dt}\int_{\mathbb{R}^3}(\mathbf{D}_n(t)-\mathbf{D}(t))\cdot\mathbf{g}dx \tag{5.16}$$

for all $\mathbf{g}\in C_0^\infty(\mathbb{R}^3)$. From (1.8), (1.9), and the boundedness of $\{\mathbf{M}_n\}_{n\in\mathbb{N}}$ in

$$W^{1,\infty}((0,T),L^2(G))\cap L^\infty((0,T),L^\infty(G))$$

one obtains the equicontinuity of the family $\{\mathbf{G}_{n,m}\}_{n,m\in\mathbb{N}}$ required for Lemma 3.4. Hence (5.14) follows from (5.1), (5.16), and Lemma 3.4. Proceeding as in the proof of Theorem 4.1 one gets (5.7) for $p=2$. By the uniform boundedness of $\{\mathbf{M}_n\}_{n\in\mathbb{N}}$ (5.7) also holds for all $p\in[2,\infty)$. By (5.1), (5.5) it follows from this strong convergence that $(\mathbf{E},\mathbf{H},\mathbf{M})$ satisfies (5.8). □

6. The quasi-stationary limit. In what follows let α_n and β_n be sequences of positive numbers with

$$\alpha_n \overset{n\to\infty}{\longrightarrow} 0,\ \beta_n \overset{n\to\infty}{\longrightarrow} 0,\ \text{and } \alpha_n/\beta_n \le K$$

with some constant K independent of n. Furthermore, let $(\mathbf{E}_n, \mathbf{H}_n, \mathbf{M}_n)$ be a weak solution to (1.1)–(1.4) where ε and μ are replaced by $\varepsilon_n = \alpha_n\varepsilon$ and $\mu_n = \beta_n\mu$, respectively. Setting $\mathbf{h}_n \overset{\text{def}}{=} \mathbf{H}_n - \mathbf{g}_0$ with $\mathbf{g}_0$ as in (1.11) these equations read as

$$\alpha_n\varepsilon\partial_t\mathbf{E}_n = \varepsilon_n\partial_t\mathbf{E}_n = \text{curl } \mathbf{H}_n - \sigma\mathbf{E}_n - \mathbf{J} = \text{curl } \mathbf{h}_n - \sigma\mathbf{E}_n, \tag{6.1}$$

$$\beta_n\mu\partial_t\mathbf{h}_n = \mu_n\partial_t\mathbf{H}_n - \beta_n\mu\partial_t\mathbf{g}_0 = -\text{curl } \mathbf{E}_n - \beta_n\mu\partial_t\tilde{\mathbf{M}}_n - \beta_n\mu\partial_t\mathbf{g}_0, \tag{6.2}$$

on $\mathbb{R}^+ \times \mathbb{R}^3$ coupled with the equation

$$\partial_t\mathbf{M}_n = F(x, \mathbf{M}_n)\cdot\mathbf{H}_n + \mathbf{a}(x, \mathbf{M}_n) \tag{6.3}$$

on $\mathbb{R}^+ \times G$, with initial conditions (1.3) and (1.4).

Proof of Theorem 1.1. Let $T > 0$ be arbitrary large. From (6.1) and (6.2) one obtains the energy balance

$$\frac{1}{2}\frac{d}{dt}\|(\alpha_n^{1/2}\mathbf{E}_n(t), \beta_n^{1/2}\mathbf{h}_n(t))\|_X^2 \tag{6.4}$$

$$= -\int_{\mathbb{R}^3}\mathbf{E}_n(t)\sigma\mathbf{E}_n(t)dx - \beta_n\int_G\mu\mathbf{h}_n(t)\partial_t\mathbf{M}(t)dx - \beta_n\int_{\mathbb{R}^3}\mu\mathbf{h}_n(t)\partial_t\mathbf{g}_0(t)dx.$$

This gives

$$\frac{1}{2}\|(\alpha_n^{1/2}\beta_n^{-1/2}\mathbf{E}_n(t), \mathbf{h}_n(t))\|_X^2 \tag{6.5}$$

$$\le \frac{1}{2}\|(\alpha_n^{1/2}\beta_n^{-1/2}\mathbf{E}_0, \mathbf{h}_0)\|_X^2 - \beta_n^{-1}\int_0^t\int_{\mathbb{R}^3}\mathbf{E}_n(s)\sigma\mathbf{E}_n(s)dxds$$

$$+\int_0^t\left(\|\mu^{1/2}\mathbf{h}_n(s)\|_{L^2(\mathbb{R}^3)}^2 + \|\mu^{1/2}\partial_t\mathbf{M}_n(s)\|_{L^2(G)}^2 + \|\mu^{1/2}\partial_t\mathbf{g}_0(s)\|_{L^2(\mathbb{R}^3)}^2\right)ds.$$

From (1.5), (4.4) one obtains the following bound on $\mathbf{M}_n$:

$$\|\mathbf{M}_n\|_{L^\infty((0,T),L^\infty(G))} + \|\mathbf{M}_n\|_{L^\infty((0,T),L^2(G))} \le C_1. \tag{6.6}$$

By assumption (1.8), (1.9), (6.3), and (6.6) one obtains

$$\int_0^t\|\mu^{1/2}\partial_t\mathbf{M}_n(s)\|_{L^2(G)}^2ds \le C_2\int_0^t(1 + \|F(x, \mathbf{M}_n(s))\|_{L^\infty(G)}\|\mu^{1/2}\mathbf{H}_n(s)\|_{L^2(\mathbb{R}^3)})^2ds$$

$$\le C_3\left(1 + \int_0^t\|\mu^{1/2}\mathbf{h}_n(s)\|_{L^2(\mathbb{R}^3)}^2ds\right).$$

Next, (6.5) and this estimate yield $\|(\alpha_n^{1/2}\beta_n^{-1/2}\mathbf{E}_n(t), \mathbf{h}_n(t))\|_X^2 \leq C_4$, and hence

$$\alpha_n \|\mathbf{E}_n\|_{L^\infty((0,T),L^2(\mathbb{R}^3))} \leq C_5 \alpha_n^{1/2}\beta_n^{1/2}\,, \qquad \|\mathbf{H}_n\|_{L^\infty((0,T),L^2(\mathbb{R}^3))} \leq C_5 \tag{6.7}$$

and

$$\|\sigma \mathbf{E}_n\|_{L^2((0,T),L^2(\mathbb{R}^3))} \leq C_5 \beta_n^{1/2}.$$

Furthermore, assumption (1.8), (1.9), (6.3), (6.6), and (6.7) also give

$$\|\partial_t \mathbf{M}_n\|_{L^\infty((0,T),L^2(G))} \leq C_5 \tag{6.8}$$

with some constant C_5 independent of n.

By (6.6) and (6.7) there exists a subsequence $\{(\mathbf{E}_{n_m}, \mathbf{H}_{n_m}, \mathbf{M}_{n_m})\}_{m\in\mathbb{N}}$ such that

$$\mathbf{H}_{n_m} \overset{m\to\infty}{\longrightarrow} \mathbf{H} \text{ in } L^\infty((0,T),L^2(\mathbb{R}^3)) \text{ weak } *, \tag{6.9}$$

$$\mathbf{M}_{n_m} \overset{m\to\infty}{\longrightarrow} \mathbf{M} \text{ in } L^\infty((0,T),L^\infty(G)) \text{ weak } *, \tag{6.10}$$

and in $W^{1,2}((0,T),L^2(G))$ weakly.

By (2.4), assumption (1.6), (2.6), and (6.2) one has

$$(1-P_H)\left(\mathbf{H}_{n_m}(t) + \tilde{\mathbf{M}}_{n_m}(t)\right) = (1-P_H)\left(\mathbf{H}_0 + \tilde{\mathbf{M}}_0\right) = 0. \tag{6.11}$$

Next, (6.1) and (6.7) imply that

$$\operatorname{curl} \mathbf{H}_n - \mathbf{J} = \alpha_n \varepsilon \partial_t \mathbf{E}_n + \sigma \mathbf{E}_n \overset{n\to\infty}{\longrightarrow} 0 \text{ in } \mathcal{D}'\left((0,\infty)\times\mathbb{R}^3\right).$$

Hence, one obtains from (6.9)–(6.11) that

$$\operatorname{curl} \mathbf{H} = \mathbf{J} \text{ and } \operatorname{div}\left(\mu\left[\mathbf{H} + \tilde{\mathbf{M}}\right]\right) = 0 \text{ on } (0,\infty)\times\mathbb{R}^3. \tag{6.12}$$

Now, Theorem 5.1 will be applied. By (6.9), (6.10), and (6.11) the conditions (5.1)–(5.4) are fulfilled, and by (6.1) and (2.6) one has

$$\int_{\mathbb{R}^3} \mathbf{H}_{n_m}(t)\cdot \operatorname{curl} \mathbf{g}\, dx = \frac{d}{dt}\int_{\mathbb{R}^3} \mathbf{D}_{n_m}(t)\cdot \mathbf{g}\, dx \text{ for all } \mathbf{g}\in C_0^\infty(\mathbb{R}^3),$$

with

$$\mathbf{D}_n(t) \overset{\text{def}}{=} \alpha_n \varepsilon \mathbf{E}_n(t) + \int_0^t (\sigma \mathbf{E}_n(s) + \mathbf{J}(s))\, ds,$$

which is bounded in $L^\infty((0,T),L^2(\mathbb{R}^3))$ by (6.7). Thus, assumption (5.6) is also satisfied. Finally, the assertion follows from (6.12) and Theorem 5.1. □

Remark 1. By (2.2), (2.4), and (1.11) it follows that (1.14) is fulfilled if and only if

$$\mathbf{H}(t) \overset{\text{def}}{=} P_H \mathbf{g}_0(t) - (1-P_H)\tilde{\mathbf{M}}(t) \text{ for all } t\in(0,\infty). \tag{6.13}$$

LEMMA 6.1. *Suppose that in addition F is given by*

$$F(x,\mathbf{m})\mathbf{h} = -\gamma(x)\mathbf{m}\wedge\mathbf{h} \text{ for all } x\in G, \mathbf{m}\in\mathbb{R}^3 \text{ and } \mathbf{h}\in\mathbb{R}^3 \tag{6.14}$$

with some function $\gamma\in L^\infty(G)$. The solution to problem (1.14)–(1.16) *is unique and* (1.12), (1.13) *hold for the whole sequence.*

Proof. Suppose that $(\mathbf{H}^{(1)},\mathbf{M}^{(1)})$ and $(\mathbf{H}^{(2)},\mathbf{M}^{(2)})$ are the solution to problem (1.14)–(1.16). Then, it follows from the boundedness of $\mathbf{M}^{(j)}$ and assumption (1.8) that

$$\begin{aligned}
&\frac{1}{2}\frac{d}{dt}\|\mathbf{M}^{(1)}(t)-\mathbf{M}^{(2)}(t)\|^2_{L^2(G)} \qquad (6.15)\\
&= -\int_G \gamma(\mathbf{M}^{(1)}(t)-\mathbf{M}^{(2)}(t))\cdot(\mathbf{M}^{(1)}(t)\wedge\mathbf{H}^{(1)}(t)-\mathbf{M}^{(2)}(t)\wedge\mathbf{H}^{(2)}(t))dx\\
&\quad+\int_G(\mathbf{M}^{(1)}(t)-\mathbf{M}^{(2)}(t))\cdot(\mathbf{a}(x,\mathbf{M}^{(1)}(t))-\mathbf{a}(x,\mathbf{M}^{(2)}(t)))dx\\
&\le -\int_G \gamma(\mathbf{M}^{(1)}(t)-\mathbf{M}^{(2)}(t))\cdot\mathbf{M}^{(1)}(t)\wedge(\mathbf{H}^{(1)}(t)-\mathbf{H}^{(2)}(t))dx\\
&\quad+C_1\|\mathbf{M}^{(1)}(t)-\mathbf{M}^{(2)}(t)\|^2_{L^2(G)}\\
&\le C_2\|\mathbf{M}^{(1)}(t)-\mathbf{M}^{(2)}(t)\|^2_{L^2(G)}+C_2\|\mathbf{H}^{(1)}(t)-\mathbf{H}^{(2)}(t)\|^2_{L^2(G)}.
\end{aligned}$$

Invoking Remark 1 and (1.14) one obtains

$$\mathbf{H}^{(1)}(t)-\mathbf{H}^{(2)}(t) = -(1-P_H)\left(\tilde{\mathbf{M}}^{(1)}(t)-\tilde{\mathbf{M}}^{(2)}(t)\right),$$

in particular

$$\|\mathbf{H}^{(1)}(t)-\mathbf{H}^{(2)}(t)\|^2_{L^2(\mathbb{R}^3)}\le C_3\|\mathbf{M}^{(1)}(t)-\mathbf{M}^{(2)}(t)\|^2_{L^2(G)}. \tag{6.16}$$

Finally, it follows from (6.15) and (6.16) that $\mathbf{M}^{(1)}=\mathbf{M}^{(2)}$ and also $\mathbf{H}^{(1)}=\mathbf{H}^{(2)}$ by (1.14) again. ∎

THE 2-DIMENSIONAL RIEMANN PROBLEM FOR A 2×2 HYPERBOLIC CONSERVATION LAW I. ISOTROPIC MEDIA*

WOONJAE HWANG† AND W. BRENT LINDQUIST‡

Abstract. We construct the solutions for a two-dimensional (2-D) Riemann problem for a 2×2 hyperbolic nonlinear system based upon the Keyfitz–Kranzer–Isaacson–Temple model. The system is applicable to polymer flooding of an oil reservoir; the parameterization can be adjusted to model either isotropic or anisotropic media. For isotropic media, the solutions are obtained by two methods. The first method utilizes a transformation into a one-dimensional (1-D) Cauchy problem. Such a transformation requires conformity of the x- and y-directional fluxes in the system. The second method involves a 2-D constructive technique which can be used more generally for solving systems. For the isotropic media case, we explicitly construct solutions for the so-called single and four quadrant Riemann problems by both methods and demonstrate the equality of the solutions. This has relevance as a test for the 2-D solution method, as existence and uniqueness results for solutions of systems in 1-D are known, whereas no such results exist for systems in 2-D.

1. Introduction.

The existence and uniqueness theory for the scalar hyperbolic equation in multiple space dimensions is largely complete [4, 15, 26, 27]. The theory gives little insight into the form of the solutions which (e.g., [31, 24]) can possess interesting qualitative behavior. Since the solutions to multidimensional Riemann problems are also important for numerical computation, recent literature has concentrated on finding the solution to the general Riemann problem in two space dimensions. As no general theory exists for systems in multiple space dimensions, the two-dimensional (2-D) Riemann problem for systems must be computed on a case by case basis. Thus, our general interest is the achievement of a 2-D constructive technique which would be generally applicable for systems.

The study of the 2-D Riemann problem was initiated by Guckenheimer [10]. Further analyses of the 2-D scalar conservation law (1.1),

$$s_t + f(s)_x + h(s)_y = 0, \tag{1.1}$$

have appeared in [17, 18, 28, 31, 32, 33]. In a 2-D Riemann problem, the initial data is piecewise constant in wedge-shaped regions surrounding the origin. Wagner [28] constructed the solution for the four quadrant (90 degree regions) Riemann problem in the case of $f \equiv h$, where f, h are convex. Lindquist [17] showed that unique solutions to the arbitrary wedge problems are piecewise smooth when $f \equiv h$ and f has at most one inflection point. In a companion work [18], Lindquist outlined a systematic

method for construction of such solutions in terms of 2-D nonlinear waves. Zhang and Zheng [33] constructed the solution for the four quadrant Riemann problem under the extended condition $f_{ss} \neq 0$, $h_{ss} \neq 0$, and $\partial_s (f_{ss}/h_{ss}) \neq 0$. Chen, Li, and Tan [3] studied the dependence of the structure of the solution on the initial data values as well as wedge angles for the particular case of Riemann data arranged in three wedges.

A body of work has also developed for the important case of the Euler system of conservation laws modeling gas dynamics in two dimensions. A good summary is provided in the book by Chang (Zhang) and Hsiao [1]. Glimm et al. [6] presented a list of generic, steady (in some reference frame) waves (referred to as "nodes" by the authors) expected in 2-D Riemann problem solutions of the Euler equations. In [34], Zhang and Zheng presented conjectures on the classification and structure of the 2-D solutions to the four quadrant Riemann problem for the Euler equations of gas dynamics with a polytropic equation of state. In preparatory work for this conjecture, Tan and Zhang [22, 23] constructed analytic solutions for the simplified model

$$u_t + (u^2)_x + (uv)_y = 0, \tag{1.2}$$

$$v_t + (uv)_x + (v^2)_y = 0. \tag{1.3}$$

Yang and Zhang [29] verified the analytic solutions for (1.2), (1.3) numerically using the maximum-minimum bounds (MmB) preserving scheme. In [19], Schulz-Rinne presented a correction to the conjectured classification for the Euler equations. He showed that one of the solutions classified from the conjecture [34] is impossible. Schulz-Rinne, Collins, and Glaz [20] computed numerical Riemann problem solutions to the Euler equations in gas dynamics using the second order Godunov method and confirmed that, with the exception of one case, the conjectured solutions agree closely with the numerical results. Chang (Zhang), Chen, and Yang [2] performed numerical simulation for the Euler equations in gas dynamics with the MmB scheme to check the conjecture [34]. Lax and Liu [16] demonstrated that the numerical solution for the Euler equations obtained with their positive scheme are strikingly consistent with calculations by Schulz-Rinne, Collins, and Glaz [20]. Zhang and Zheng [35] obtained exact spiral solutions of the 2-D Euler equations. Zhang, Li, and Zhang [30] considered the 2-D Riemann problem for the pressure-gradient equations of the Euler system in the case of four quadrant initial data.

Other related work on Riemann problems has provided qualitative insights on 2-D wave interactions [5]; introduced a new type of nonlinear hyperbolic wave, a delta-shock wave, which is a Dirac delta function supported on a shock [24]; solved the 2-D Riemann problem for the transportation equations in the case of four quadrant initial data [21]; studied the solution of the 2-D Riemann problem of Hamilton Jacobi equations[7]; and examined Riemann problems in higher dimensions [8, 9].

In this paper and in part II [11], our interest is twofold.

The first is to develop the solutions to a class of 2-D Riemann problems for a 2×2 hyperbolic system based upon the Keyfitz–Kranzer–Isaacson–Temple model [14, 12, 25] which provides a model for polymer flood recovery in an oil reservoir with either an isotropic or anisotropic medium. This 2×2 system exhibits the distinctive feature that, regardless of the flux function, the second wave family is linearly degenerate, exhibiting only contact discontinuities and constant states. In this sense the system is the "simplest 2×2 system" beyond a scalar equation.

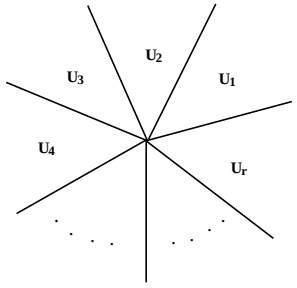

FIG. 1. *General 2-D Riemann problem initial data.*

Our second interest is the continued development of a 2-D Riemann problem solution constructive technique which has been generalized from that used in [18] for scalar equations. Recently, Zhang and Zhang [31] have classified the shock (S) and rarefaction (R) elementary waves into four types, S^+, S^-, R^+ and R^-, discussed the allowed interactions amongst them, and generalized the characteristic based solution construction method. The constructive method is based upon the existence of base points and base curves in the space of variables $\xi = x/t, \eta = y/t$ which govern the location of shocks, rarefactions and contact discontinuities in the self-similar growth of the 2-D Riemann problem solution. In part II of this paper [11] we show the existence of both flux function dependent and flux function independent relationships among these points and curves. In this paper, our interest in the constructive technique is to show, by example, that the technique is capable of providing correct, unique solutions (when they exist) to a 2×2 system Riemann problem.

For the isotropic media parameterization of our model, solutions can be obtained by two methods. The first method utilizes a transformation into a one-dimensional (1-D) Cauchy problem. (Such a transformation requires conformity of the x- and y-directional fluxes in the system.) The second method is via the 2-D constructive technique. For the isotropic media case, we construct solutions by both methods and demonstrate equality. This provides a test for the 2-D solution method, as existence and uniqueness results for solutions of systems in one dimension are known, whereas no such results exist for systems in two dimensions.

The Riemann problem in two spatial dimensions for a system of n conservation laws is the problem

$$U_t + F(U)_x + H(U)_y = 0, \tag{1.4}$$

with solution and flux vectors $U = (u_1, u_2, \ldots, u_n)$, $F = (f_1(U), f_2(U), \ldots, f_n(U))$, $H = (h_1(U), h_2(U), \ldots, h_n(U))$, and initial data that is piecewise constant on a finite number r of wedges centered on the origin $x = 0$, $y = 0$ as shown in Figure 1; i.e.,

$$U(0, x, y) = U_i, \qquad i = 1, \ldots, r,$$

where, for each i, x and y lie in the wedge between the half lines determined by the parametric equations

$$\left[\begin{array}{rcl} x_i & = & \tau \cos(\theta_i), \\ x_{i+1} & = & \tau \cos(\theta_{i+1}), \end{array} \quad \begin{array}{rcl} y_i & = & \tau \sin(\theta_i) \\ y_{i+1} & = & \tau \sin(\theta_{i+1}) \end{array} \right], \qquad 0 \le \tau < \infty, \quad r+1 \equiv 1$$

for r ordered, counterclockwise positive angles $0 \le \theta_1 < \theta_2 < \cdots < \theta_r < 2\pi$. Of particular interest is the four wedge problem with wedges corresponding to the four

quadrants ($\theta_1 = 0, \theta_2 = \pi/2, \theta_3 = \pi, \theta_4 = 3\pi/2$) of the spatial plane, since such initial data is pertinent to numerical finite difference schemes. We also consider the "single quadrant" Riemann problem having $\theta_1 = \pi/2, \theta_2 = \pi$. (The choice of the quadrant is discussed in section 3.1.)

In much of the work on systems [16, 19, 20, 21, 22, 23, 24, 29, 30, 34, 35], the initial Riemann data is restricted so that the presence of a single wave is always guaranteed to develop from each initial discontinuity. This has some physical justification, in that the majority of physical observations involve the study of a single propagating wave type. It is, nonetheless, a restrictive assumption when considering wave interactions, which in general, for an $n \times n$ system, would produce n postinteraction waves. For this reason we make no such restriction on the initial Riemann data in the development of our solutions.

In section 2, we present the specifics of our 2×2 system. In section 3, we consider 2-D Riemann problems for (1.4) for the isotropic media parameterization of our model: $H(U) = \alpha F(U)$, where α is a constant. Both single quadrant and four quadrant initial Riemann data are considered. Solutions are developed by both methods and compared.

2. The model. The Keyfitz–Kranzer–Isaacson–Temple 2×2 system of conservation laws in one space dimension is

$$s_t + f(s,c)_x = 0, \tag{2.1}$$

$$(cs)_t + (cf(s,c))_x = 0, \tag{2.2}$$

where the physical state variables $U = (s, c)$ are

$$\begin{aligned} s &= \text{water saturation}, & 0 \le s \le 1, \\ c &= \text{concentration of polymer}, & 0 \le c \le 1. \end{aligned}$$

This system models the polymer flooding of an oil reservoir by generalizing the Buckley–Leverett equation which models a two phase water-flood process. In the polymer flood, a (generally small) amount of polymer is added to the water to increase the sweep efficiency of oil production. The model assumes the polymer is completely miscible in the water phase and undergoes no mass transfer into the oil phase. See [12] for details of the model.

Regardless of the form of f, this model contains two families of waves, a c-family consisting of a contact discontinuity, and an s-family identical to the scalar family (2.1) with c held a constant. The functional forms for $f(\cdot,\cdot)$ commonly used with this model in enhanced oil recovery [12, 13] and elasticity [14] studies contain a single inflection point, and the s-family thus consists of compound waves composed of a Lax shock and a rarefaction fan.

In order to partially eliminate the complexity introduced by the compound waves in the s-family, we simplify to a convex function f. A representative example for f is

$$f(s,c) = s^2[1 + A(1-c)(1-s)], \qquad 0 < A < 1/2, \qquad 0 \le s, c \le 1, \tag{2.3}$$

having the form shown in Figure 2.

In analyzing the solutions to (2.1), (2.2) it is convenient to introduce the change of variables

$$s,\ c \to s,\ b \equiv sc,$$

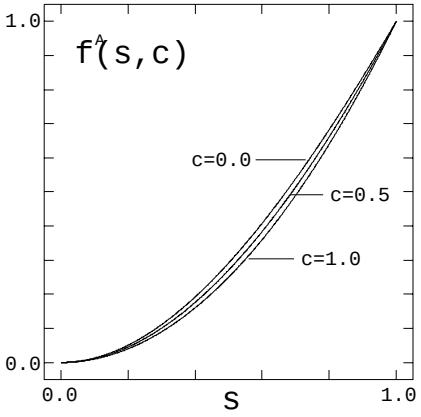

FIG. 2. *The flux function for the model.*

and introduce

$$g \equiv f(s,c)/s.$$

For smooth solutions to (2.1), (2.2) the eigenvalues, right eigenvectors, and Riemann invariants for the two families of waves are

$$\begin{aligned} \lambda^s &= f_s, & \lambda^c &= g, \\ r^s &= (s,b), & r^c &= (-g_b, g_s), \\ W^s &= c, & W^c &= g, \end{aligned}$$

independent of the form of f [12]. The Rankine–Hugoniot relations, also independent of the form of f, are

$$\begin{aligned} c_l &= c_r, & g_l &= g_r, \\ \sigma_s &= \frac{[f]}{[s]}, & \sigma_c &= g_l = g_r. \end{aligned}$$

For convex functions such as (2.3), the system remains strictly hyperbolic; the eigenvalues of the two families coinciding only on the axis $s = 0$. For a strictly hyperbolic system, Figure 3 shows the Hugoniot/rarefaction solution curves for the four general cases of a 1-D Riemann problem $U_L \to U_{R_i}$. U_{M_j} denotes the intermediate state in each solution.

We extend the model (2.1), (2.2) to two space dimensions in a manner that has physical relevance. For spatially isotropic media, the extension is

$$H(U) = \alpha F(U), \qquad F(U) \equiv (f, cf), \tag{2.4}$$

with α = constant. For anisotropic media, having principle axes aligned in the x and y directions, $F(U)$ and $H(U)$ would most likely differ in the value of one or more physical parameters, for example, in the value of A in (2.3). Our model for anisotropic media is then

$$s_t + f^A(s,c)_x + f^B(s,c)_y = 0, \tag{2.5}$$

$$(cs)_t + (cf^A(s,c))_x + (cf^B(s,c))_y = 0, \tag{2.6}$$

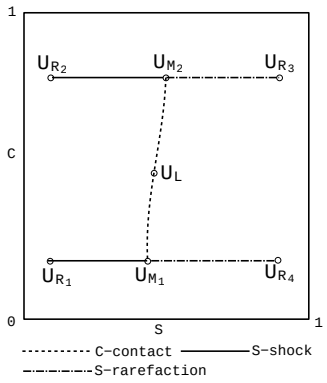

FIG. 3. *The Hugoniot and rarefaction curves for the four general solution cases to the* 1*-D Riemann problem in the model.*

where

$$
\begin{aligned}
f^A(s,c) &= s^2[1 + A(1-c)(1-s)], \qquad \text{with } 0 < A < 1/2, \\
f^B(s,c) &= s^2[1 + B(1-c)(1-s)], \qquad \text{with } 0 < B < 1/2.
\end{aligned} \tag{2.7}
$$

s and c have the same range of values as in the 1-D model.

There are several reasons for considering this model. One is physical, its relevance for flow in porous media. The remainder are mathematical. Note that system (2.5), (2.6) can be written

$$s_t + (sg^A(s,b))_x + (sg^B(s,b))_y = 0, \tag{2.8}$$

$$b_t + (bg^A(s,b))_x + (bg^B(s,b))_y = 0, \tag{2.9}$$

with $g^\alpha(s,b) \equiv f^\alpha(s,b)/s,\ \alpha = A, B$. Any system of this form remains hyperbolic in any spatial direction regardless of the form of the (real-valued) functions g^A and g^B! The model can be viewed as the simplest extension from a scalar equation to a hyperbolic system in the sense that the second family of waves introduced (the c-wave family) is linearly degenerate, producing only contact discontinuity waves. The restrictions (2.7) on the flux functions guarantee $f^A_{ss} \neq 0$, $f^B_{ss} \neq 0$ and $\frac{\partial}{\partial s}(f^A_{ss}/f^B_{ss}) \neq 0$ for any $s \in (0,1]$, $c \in [0,1]$. This in turn guarantees [33] that the s-wave family is genuinely nonlinear in all spatial directions except one (along which it becomes linear).

As we shall see, a result of the linear degeneracy of the second wave family is a division of the solution space t, x, y into regions where the solution is governed by a scalar equation, the boundary between these regions being the contact discontinuity. This will ultimately guarantee the computation of globally unique solutions.

As the 2-D Riemann problem is self-similar, the solution needs to be constructed only in a single t = const plane; the usual choice is $t = 1$. The construction method developed in [18, 31] assembles the global solution in this plane by "joining together" elementary waves (shocks, rarefactions, their composite waves, and contacts). For scalar equations in two dimensions, global uniqueness of the solution results implicitly by ensuring the elementary waves obey local entropy conditions due to Vol'pert [27] or Kruzkov [15]. For systems, no such general local entropy

conditions exist and global uniqueness becomes an issue. In particular, no general uniqueness theory exists that is applicable to the system under consideration here.

The 2-D Riemann problem for the case of isotropic media (2.4) is the $B \to A$ limiting case of anisotropic media. We deal with the isotropic case separately in this paper since it provides information both as to the form and uniqueness of the global solutions for the more general anisotropic problem.

The isotropic case is amenable to two solution methods. Under rotation by $\theta = \tan^{-1}\alpha$, the 2-D problem converts into uncoupled, 1-D Cauchy problems

$$U_t + \sec(\theta)F(U)_\xi = 0, \qquad (x, y) \to (\xi, \eta), \tag{2.10}$$

whose initial data can be described as interacting Riemann problems [17, 18]. Existence and uniqueness for this system in one dimension is known [12]. Thus comparison of the rotated 1-D and direct 2-D construction methods is a check that the direct 2-D construction method is producing the correct unique global solution. In fact, as we shall see for this system, all 2-D solutions consist of two separate solution regions whose common boundary is a contact discontinuity. In each of these two regions the variable c is constant in value; in each region the solution reduces to that of a scalar Riemann problem, to which the existence and uniqueness conditions of Vol'pert and Kruzkov can be applied. The comparison with the rotated 1-D solution thus provides verification that this spatial decomposition into two regions separated by the contact discontinuity is unique. This uniqueness is exploited in part II of this paper [11].

3. Isotropic media. We consider the system

$$s_t + f(s, c)_x + \alpha f(s, c)_y = 0, \tag{3.1}$$

$$(cs)_t + (cf(s, c))_x + \alpha(cf(s, c))_y = 0 \tag{3.2}$$

with the form of f consistent with the behavior of example (2.3). Without loss of generality, we take $\alpha = 1$. Under the transformation

$$\xi = (x + y)/2, \qquad \eta = (y - x)/2$$

(a rotation of $\pi/4 = \tan^{-1}(1)$ combined with a dilation by a factor of $\sqrt{2}$), the system (3.1), (3.2) becomes

$$s_t + f(s, c)_\xi = 0, \tag{3.3}$$

$$(cs)_t + (cf(s, c))_\xi = 0. \tag{3.4}$$

From (3.3), (3.4) we see that the solution can be obtained in each $(\xi, \eta = \text{ const}, t)$ plane independent of other η. In particular, this implies the solutions obtained in the $\eta < 0$ half-space can be obtained independently of the solutions in the $\eta > 0$ half-space. The catalog of solutions in both half-spaces is the same; for any particular 2-D Riemann problem, the solutions in the two half-spaces join in a consistent manner along the $\eta = 0$ axis [17, 18]. We therefore restrict our discussion to the half-space $\eta > 0$ $(y > x)$.

Solution topology depends on initial data values in the Riemann problem wedges. We present the complete catalog of solution topologies for the single and four quadrant Riemann problems in section 3.1 and section 3.2, respectively.

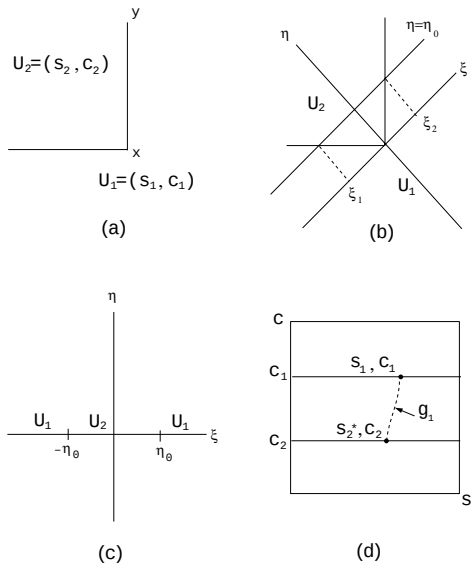

FIG. 4. *The single quadrant Riemann problem:* (a) *the initial Riemann data;* (b) *the wedge geometry;* (c) *the initial* 1*-dim Cauchy data along a line* $\eta = \eta_0$*;* (d) *the solution wave curves for the transition* $(s_1, c_1) \to (\cdot, c_2)$ *producing the intermediate state* (s_{2^*}, c_2).

3.1. The single quadrant Riemann problem. For the single quadrant problem the wedge angles are $\theta_1 = \pi/2$ and $\theta_2 = \pi$. The initial Riemann problem data is shown in Figure 4(a) and the rotated (ξ, η) coordinate system is sketched in Figure 4(b). Figure 4(c) shows the initial 1-D Cauchy data along a line $\eta = \eta_0$. Numbering the four quadrants clockwise from the negative y-axis (see Figure 9(a)) we note that of the four possible single quadrant choices, choosing 2 or 4 will produce equivalent solutions; choosing 1 or 3 leads to trivial solutions as either quadrant choice results in two initial data discontinuities, one above and one below the $\eta = 0$ plane. In this case waves emanating from the discontinuity in the $\eta > 0$ plane propagate independently of those emanating from the discontinuity in the $\eta < 0$ plane.

Avoiding the choice $c_1 = c_2$ which reverts to the scalar problem, there are four possible classes of initial data U_1 and U_2 for the single quadrant problem:

$$\begin{array}{ll} \text{case 1} & c_1 > c_2, \quad s_{2^*} \geq s_2; \\ \text{case 2} & c_1 > c_2, \quad s_{2^*} < s_2; \\ \text{case 3} & c_1 < c_2, \quad s_{2^*} \geq s_2; \\ \text{case 4} & c_1 < c_2, \quad s_{2^*} < s_2, \end{array}$$

where the intermediate state $U_{2^*} = (s_{2^*}, c_2)$ is defined in Figure 4(d). Only the first two cases lead to topologically distinct solutions; cases 1 and 3 have the same structure as cases 2 and 4. We label the two distinct topologies by their structure "at spatial infinity" (i.e., $R \to \infty, R^2 \equiv x^2 + y^2$). Thus case 1 (and case 3) topology is characterized by a contact and a shock wave propagating in the y-direction, a contact and rarefaction wave propagating in the x-direction. This topology is labeled CSCR. Case 2 (and case 4) topology is reversed and is labeled CRCS.

3.1.1. The single quadrant CSCR solution. We first present the solution obtained by rotating into a 1-D Cauchy problem. We will be brief in our discus-

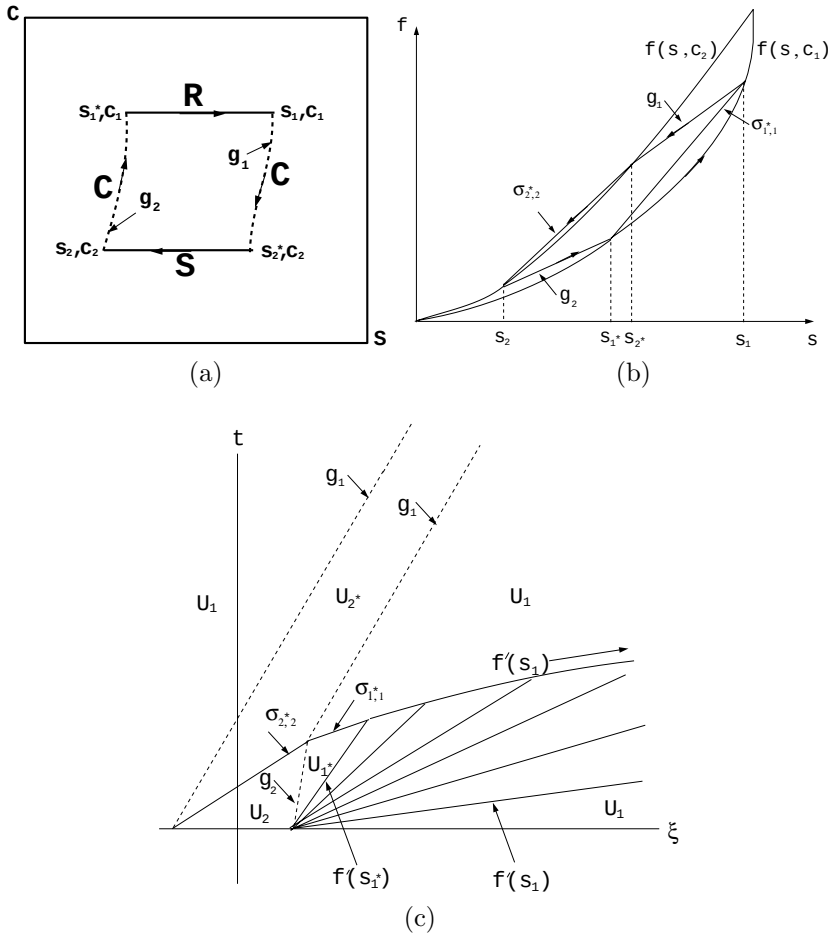

FIG. 5. *CSCR solution of the single quadrant Riemann problem:* (a) *wave curves in phase space for the Riemann problems at* $\xi = \pm\eta_0$ *(C, S, and R represent contact discontinuity, shock, and rarefaction wave, respectively);* (b) *the solution construction on the flux functions for the Riemann problems at* $\xi = \pm\eta_0$ *and for the shock separating the states* U_{1*} *and* U_1*;* (c) *the solution in the* t, ξ, η_0 *plane.*

sion of the solution as it involves well-known general 1-D Cauchy problem solution construction methods based upon the particular Riemann problem solution for this model [12].

On the line $\eta = \eta_0$, the initial data discontinuities are positioned at $\xi = \pm\eta_0$. The $U_1 \to U_2$ transition at $\xi = -\eta_0$ results in a contact (speed g_1) and shock (speed $\sigma_{2^*,2}$) wave and an intermediate state U_{2^*}. The $U_2 \to U_1$ transition at $\xi = \eta_0$ results in a contact (speed g_2) and rarefaction (characteristic speeds between $f'(s_{1^*})$ and $f'(s_1)$) fan and an intermediate state U_{1^*}. Figure 5(a) shows the phase space solution for these two separate Riemann problems. Details on solving for the states $U_{1^*} = (s_{1^*}, c_1)$ and $U_{2^*} = (s_{2^*}, c_2)$ are given in the appendix.

The shock emanating from $\xi = -\eta_0$ and the contact from $\xi = \eta_0$ interact at a later time, resulting in a Riemann problem between the states U_{2^*} and U_{1^*}. This Riemann problem produces a contact (speed g_1) and a shock $\sigma_{1^*,1}$. Figure 5(b) presents the

solution construction on the flux functions for the Riemann problems at $\xi = \pm\eta_0$ for this contact-shock interaction.

The shock of speed $\sigma_{1^*,1}$ interacts with the rarefaction fan. As a result the shock speed increases, approaching an asymptotic speed of $f'(s_1)$. Figure 5(c) shows the entire solution in the t, ξ, η_0 plane. The solution in any other plane t, ξ, $\eta > 0$ is self-similar to this.

Basic principles for the direct 2-D Riemann problem solution construction method are outlined in [18, 31]. (The terminologies are slightly different.) The 2-D solution method is discussed fully in part II of this paper [11] for application to the anisotropic medium model. This discussion carries over to the isotropic model by setting $B = A$. With a view to introducing necessary notation, the relevant principles in the construction method, specialized to the isotropic medium model, are briefly stated here.

• The construction is performed in the $t = 1, x, y$ plane. For brevity, we henceforth suppress the $t = 1$ label for points in this plane.

• If p is a point (in this x, y plane) on a c-family contact discontinuity separating the two states (s_l, c_l) and (s_r, c_r), the tangent line to the contact discontinuity at p passes through the two *contact base points* g_l and g_r having coordinate values

$$g_l = (g(s_l, c_l), g(s_l, c_l)) \quad \text{and} \quad g_r = (g(s_r, c_r), g(s_r, c_r)). \tag{3.5}$$

From the contact discontinuity Rankine–Hugoniot conditions, these two points are identical, $g_l = g_r$.

• If p is a point on an s-family shock separating the two states (s_l, c) and (s_r, c), the tangent line to the shock at p passes through the *shock base point* σ_{lr} having coordinate values

$$\sigma_{lr} = (\sigma(s_l, s_r), \sigma(s_l, s_r)), \tag{3.6}$$

where

$$\sigma(s_l, s_r) \equiv \frac{f(s_l) - f(s_r)}{s_l - s_r}. \tag{3.7}$$

• s-family shocks develop in regions of constant c, i.e., in regions where the problem reduces to being scalar. Thus Kruzkov's entropy conditions are applicable, these are shown in [11] to reduce to familiar Lax shock conditions and become easily verifiable angle restrictions in the case of the isotropic model.

• An s-family level curve (i.e., characteristic in an s-family rarefaction fan) having state value (s_p, c_p) is a straight line segment whose tangent passes through the *characteristic base point* $f'(p)$ having coordinate values

$$f'(p) = (f_s(s_p, c_p), f_s(s_p, c_p)), \tag{3.8}$$

where the subscript represent the differentiation with respect to s.

The 2-D construction of solutions for the case of an isotropic medium simplifies since all base points lie along the line $y = x$ in the $t = 1$ plane. (This is not true in the anisotropic medium case.)

Figure 6 displays the solution obtained by the 2-D construction method in the $t = 1, x, y$ plane. The solution for any other $t > 0$ is self-similar to this. Constant states and relevant base points on the line $y = x$ are labeled. As stated, our interest in this paper is to verify that the 2-D construction method produces the correct globally unique solution by comparing against the rotated 1-D solutions. Thus

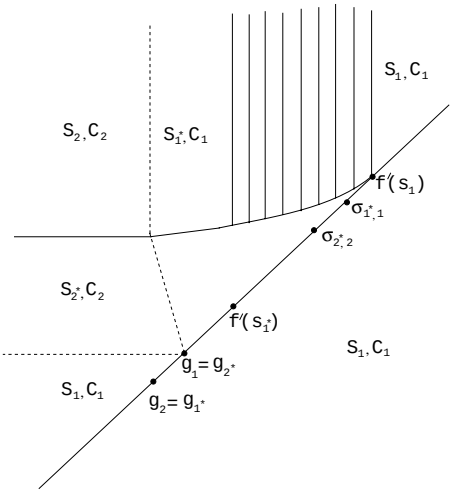

FIG. 6. *Direct 2-D construction of the CSCR solution of the single quadrant Riemann problem in the* $t = 1, x, y$ *plane.*

it is necessary to compare the solution in Figure 5(c) (which is self-similar in η) to the solution in Figure 6 (which is self-similar in t). While a mapping between these two solutions can be formally derived [17], examination of qualitative features of this map are enough to determine that the two solutions are indeed identical. First, a cut through the solution in Figure 6 along the line $y = x + 2\eta_0$ should be identical to a $t = 1$ cut through the solution in Figure 5. A cut through the solution in Figure 6 along any line $y = x + 2\eta$ for $\eta < \eta_0$ should correspond to a constant t cut through the solution in Figure 5 for some $t > 1$. As the value of $\eta \to 0$, the corresponding value for $t \to \infty$. Similarly, a cut through the solution in Figure 6 along any line $y = x + 2\eta$ for $\eta > \eta_0$ should correspond to a constant t cut through the solution in Figure 5 for some $t < 1$. As the value of $\eta \to \infty$, the corresponding value for $t \to 0$. Comparison of such qualitative features between the two figures easily verifies the identical nature of the two solutions.

3.1.2. The single quadrant CRCS solution. Figure 7(a)–(c) presents the analogous 1-D rotated solution construction for the CRCS topology solution. Figure 8 presents the direct 2-D solution construction. Again, qualitative comparison reveals that the direct construction is computing the globally unique solution.

We draw attention to an important characteristic feature of the solutions in Figures 6 and 8. The continuous contact discontinuity wave divides the solution into two regions, each region having constant concentration value c. In each such region, the solution is governed by a scalar equation in two dimensions. *Existence and uniqueness of the construction of the solution in these regions should be governed by multidimensional scalar theory, i.e., by the work of Vol'pert and Kruzkov, and hence the direct construction method employed, which is based upon the Rankine–Hugoniot and entropy conditions of this work, should produce a unique solution in each region.*

It is also interesting to note the physical diffraction present in the solution in Figure 8. The contact discontinuity separates regions of different polymer concentration. The polymer concentration is acting like an index of refraction. Rarefaction waves emerging from one region into the other are diffracted according to a "Snell's law."

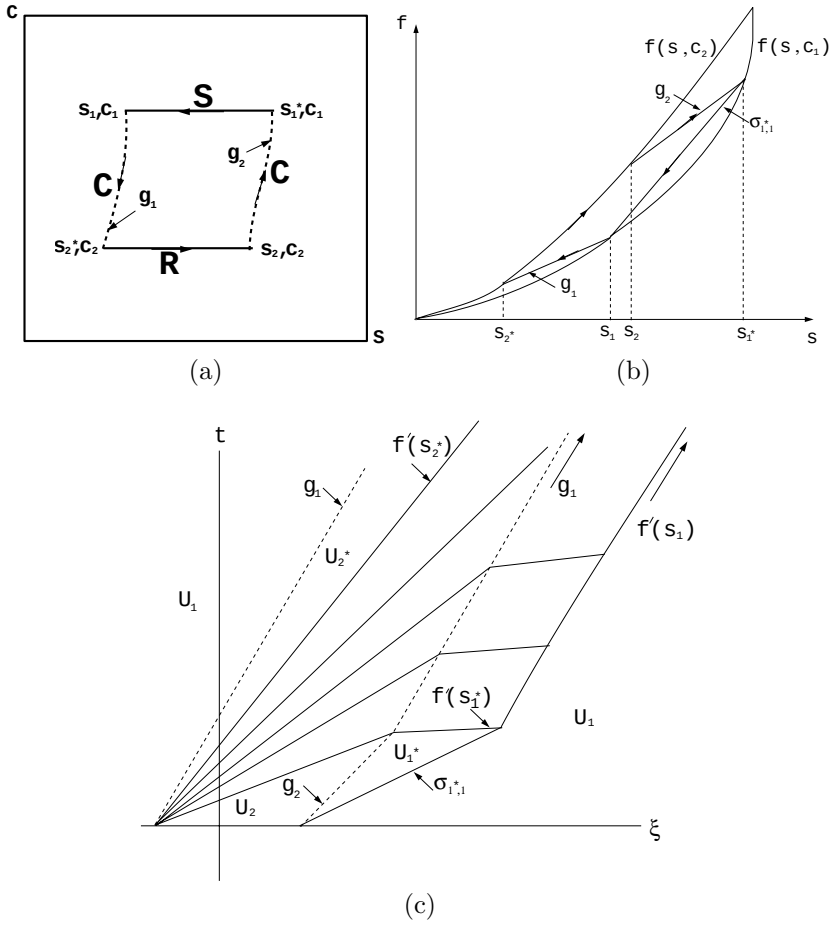

FIG. 7. *CRCS solution of the single quadrant Riemann problem:* (a) *wave curves in phase space for the Riemann problems at* $\xi = \pm\eta_0$ *(C, S, and R represent contact discontinuity, shock, and rarefaction wave, respectively);* (b) *the solution construction on the flux functions for the Riemann problems at* $\xi = \pm\eta_0$ *and for the shock separating the states* U_{1*} *and* U_1*;* (c) *the solution in the* t, ξ, η_0 *plane.*

The situation is dynamic, however, in that the interaction of the rarefaction waves with the contact also dynamically determines not only the strength of the diffraction but the boundary position at which the diffraction occurs.

3.2. The four quadrant Riemann problem. We now turn to the problem of initial data specified in the four quadrants (Figure 9(a)). We will present the solution in the $t = 1, x, y$ plane as computed by the direct 2-D solution method. For brevity, we do not show the 1-D rotated solutions; they are identical to those constructed directly in two dimensions.

As noted previously, we need only catalog the solution forms in the half-space $y \geq x$ ($\eta \geq 0$) as this produces the same catalog of solutions as in the half-space $y \leq x$. Thus we need not consider data in quadrant 4. Given initial data $U_1 = (s_1, c_1)$, $U_2 = (s_2, c_2)$, $U_3 = (s_3, c_3)$, we consider only the cases in which c_1, c_2, and c_3 all differ. There are 36 possible orderings of the initial data U_1, U_2, U_3, but only four topologically distinct solutions for the isotropic model. The four distinct cases, again

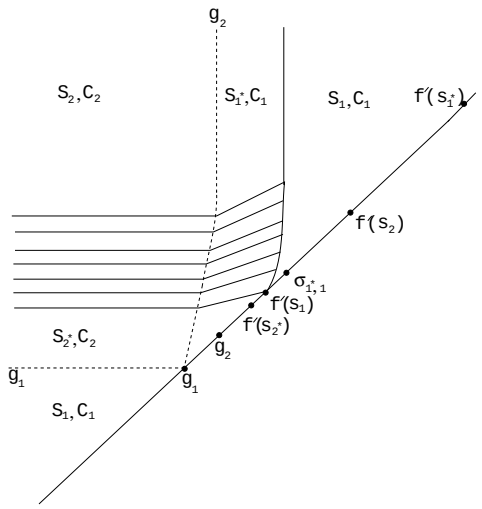

FIG. 8. *Direct 2-D construction of the CRCS solution of the single quadrant Riemann problem in the $t = 1, x, y$ plane.*

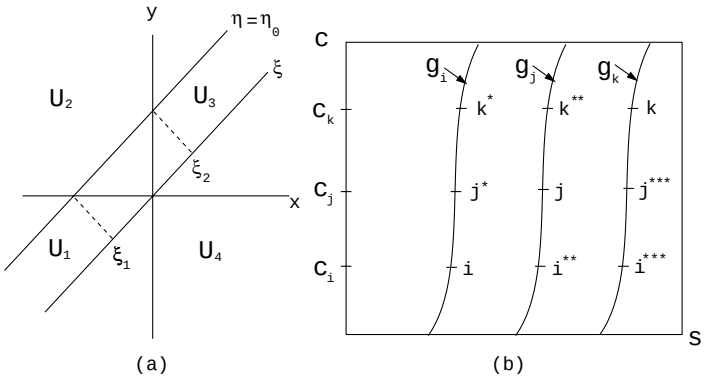

FIG. 9. *The four quadrant Riemann problem:* (a) *the initial Riemann data;* (b) *notation used for states relative to an initial state U_j. The state U_k is a final state having $s_k > s_j$, $c_k > c_j$. The state U_i is a final state having $s_i < s_j$, $c_i < c_j$. All other states are intermediate.*

labeled by the waves which appear "at spatial infinity," are

$$\begin{array}{lllll}
\text{case CRCR} & c_1 < c_2 < c_3, & s_1 \le s_{1^{**}}, & s_{3^{**}} \le s_3; \\
\text{case CSCS} & c_3 < c_2 < c_1, & s_3 \le s_{3^{**}}, & s_{1^{**}} \le s_1; \\
\text{case CSCR} & c_2 < c_1 \le c_3, & s_2 \le s_{2^{**}}, & s_{3^{**}} \le s_3; \\
\text{case CRCS} & c_1 \le c_3 < c_2, & s_1 \le s_{1^{**}}, & s_{2^{**}} \le s_2,
\end{array}$$

where, for $c_i < c_j < c_k$, the states $U_{i^{**}}$, U_j, $U_{k^{**}}$ lie on the c-family Hugoniot locus passing through state U_j as shown in Figure 9(b).

The phase space portrait of the Hugoniot and rarefaction curves for case CRCR are shown in Figure 10(a); relevant wave speed computations are shown in Figure 10(b). The solution in the $t = 1$, x, y plane, showing constant states and relevant base points, is given in Figure 10(c). The intermediate state saturation values s_{2^*}, s_{3^*}, and $s_{3^{**}}$ are found using the same procedure given in the appendix.

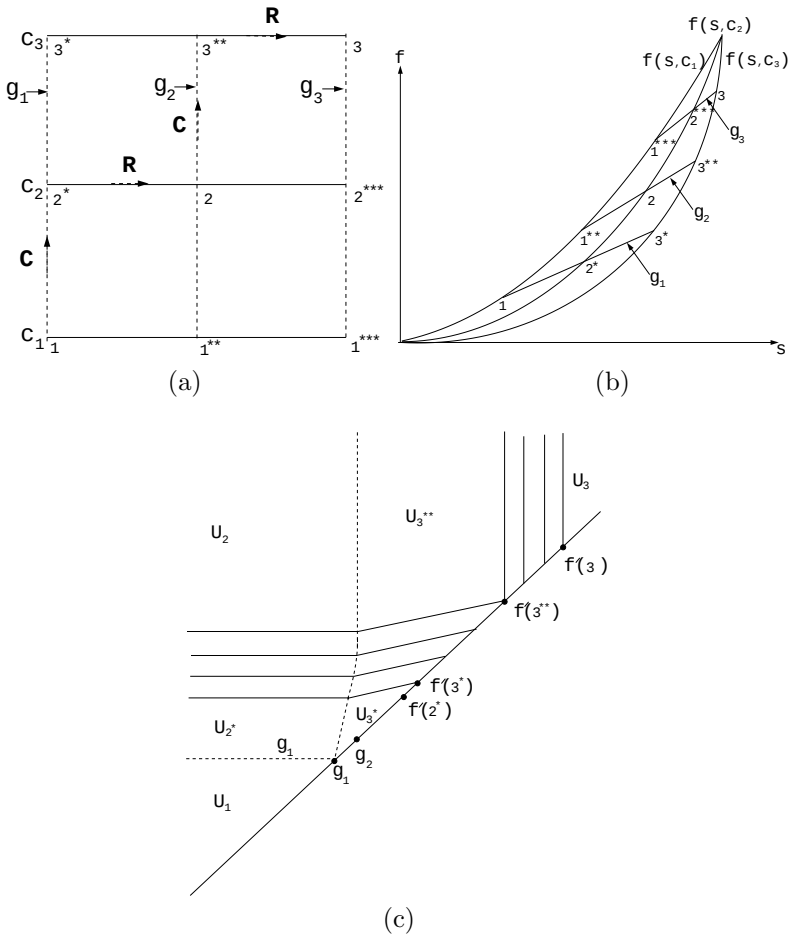

FIG. 10. *CRCR solution of the four quadrant Riemann problem:* (a) *wave curves in phase space and* (b) *solution construction on the flux functions for the relevant Riemann problems encountered in the solution; (C, S, and R represent contact discontinuity, shock, and rarefaction wave, respectively);* (c) *the solution in the* $t = 1, x, y$ *plane.*

Similar plots for the CSCS, CSCR, and CRCS cases are given, respectively, in Figures 11, 12, and 13.

If the $y < x$ solution half of the solution is included, then in the general case where c_1, c_2, c_3, and c_4 are all different in value, the solution will consist of four distinct regions in each of which c remains at the initial concentration value. These regions are separated by a piecewise smooth contact discontinuity boundary. In each region the solution is governed by a scalar equation, and the solution constructed by the direct 2-D method utilizing Rankine–Hugoniot and entropy conditions due to Kruzkov will be unique.

4. Discussion. We have verified that the 2-D Riemann problem construction method outlined in [11] produces the globally unique solution to the isotropic medium model (3.1), (3.2) for single and four quadrant initial data.

From the phase space constructions we note that, in this model, there is no method for introducing values of concentration that are not present in the initial

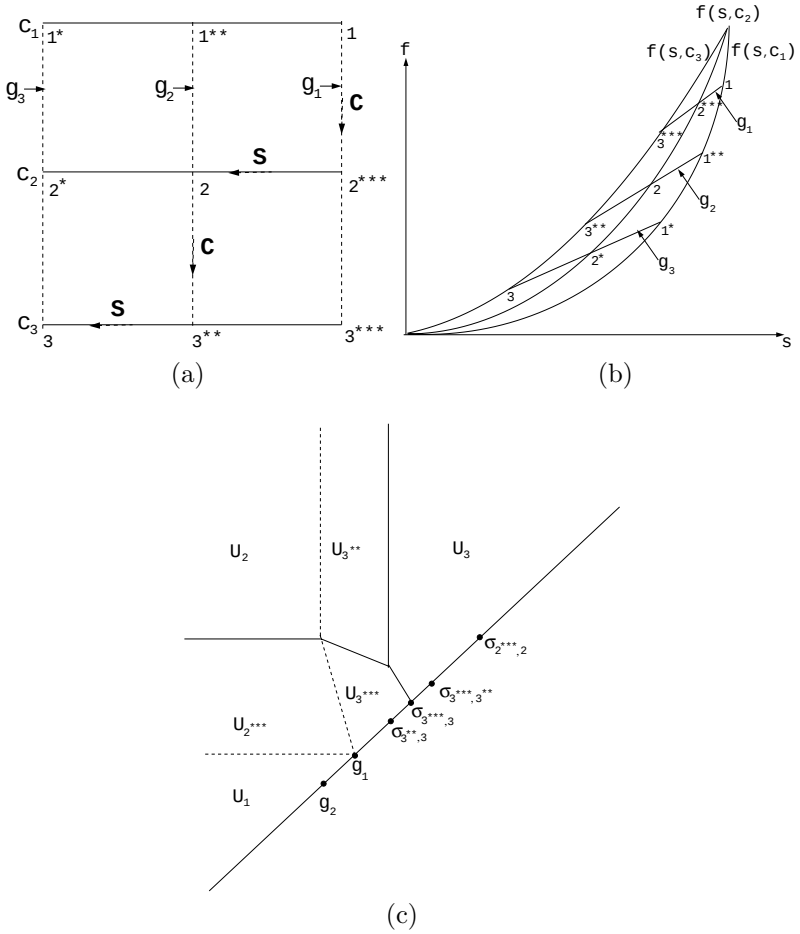

FIG. 11. *CSCS solution of the four quadrant Riemann problem:* (a) *wave curves in phase space and* (b) *solution construction on the flux functions for the relevant Riemann problems encountered in the solution; (C, S, and R represent contact discontinuity, shock, and rarefaction wave, respectively);* (c) *the solution in the* $t = 1, x, y$ *plane.*

data; similarly, there is no mechanism for eliminating a concentration value present in the initial data. This observation would hold for a Riemann problem consisting of a general (finite) number of wedges. Thus the general wedge 2-D Riemann problem solution must consist of r different regions of constant concentration, where r is the number of different concentrations in the initial data. These r regions will be joined by piecewise smooth contact discontinuities. The solution within each region will be governed by a scalar equation, and the solution constructed by the direct 2-D method utilizing Rankine–Hugoniot and entropy conditions due to Kruzkov will be unique.

5. Appendix. Computation of s_{1^*}. The saturation value for the intermediate state U_{1^*} in the single quadrant CSCR topology is computed as follows. For given values s_2, c_1 and c_2, s_{1^*} can be computed from the Rankine–Hugoniot relation

$$g^A(s_{1^*}, c_1) = g^A(s_2, c_2). \tag{A.1}$$

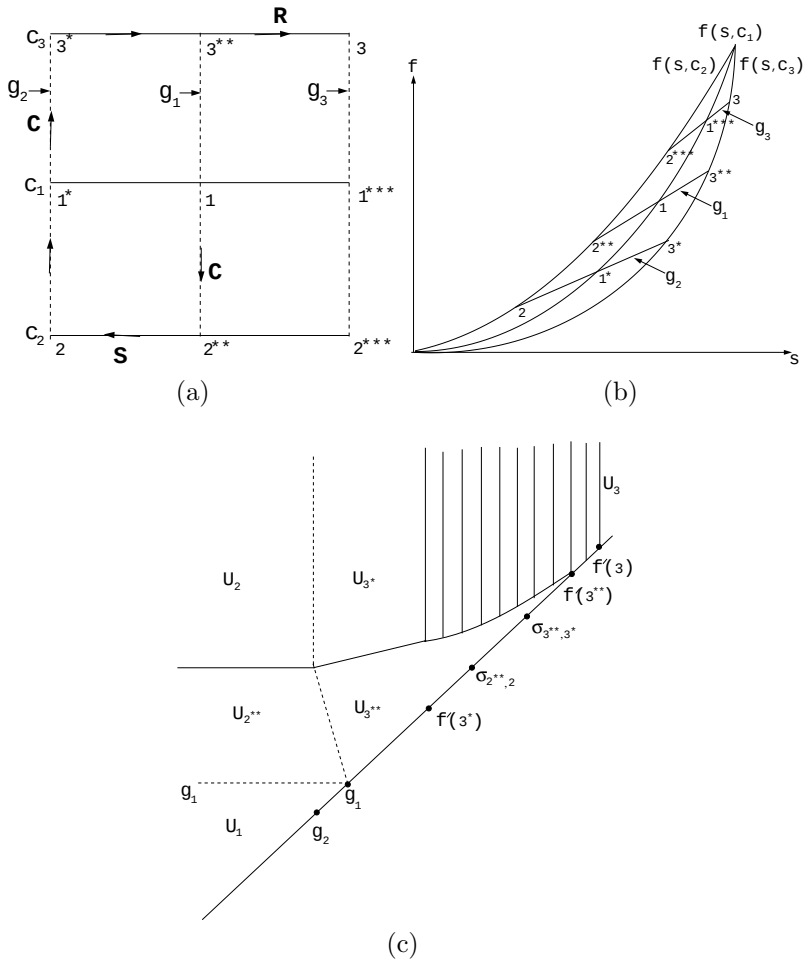

FIG. 12. *CSCR solution of the four quadrant Riemann problem:* (a) *wave curves in phase space and* (b) *solution construction on the flux functions for the relevant Riemann problems encountered in the solution; (C, S, and R represent contact discontinuity, shock, and rarefaction wave, respectively);* (c) *the solution in the* $t = 1, x, y$ *plane.*

Let $g_2^A \equiv g^A(s_2, c_2)$. Solving (A.1) for s_{1^*} produces the quadratic

$$A_1(s_{1^*})^2 - (1 + A_1)s_{1^*} + g_2^A = 0, \tag{A.2}$$

where $A_1 \equiv A(1 - c_1)$. The quadratic has two solutions s_+, s_- where $s_+ > s_-$. As $s_+ > 1$ and $s_- \in (0, 1)$, the appropriate value for s_{1^*} is s_-.

Computation of s_{2^*}. Computation of s_{2^*} proceeds as for s_{1^*} using the relation

$$g^A(s_{2^*}, c_2) = g^A(s_1, c_1). \tag{A.3}$$

Solving for s_{2^*} again results in a quadratic with the appropriate solution value being the unique root lying in the range $(0, 1)$.

THE 2-DIMENSIONAL RIEMANN PROBLEM FOR A 2×2 HYPERBOLIC CONSERVATION LAW II. ANISOTROPIC MEDIA*

WOONJAE HWANG† AND W. BRENT LINDQUIST‡

Abstract. We construct the solutions to a two-dimensional (2-D) Riemann problem for a 2×2 hyperbolic nonlinear system which models polymer flooding in an anisotropic oil reservoir. The construction demonstrates the importance of the shock, rarefaction, and contact "base points" and "base curves" in the determination of the solutions for 2-D Riemann problems. In particular, we establish some new relations between these. While specific details of the base points and curves are applicable only to this model, the existence of the curves and the existence of relationships between these curves are general features to be exploited for any hyperbolic system.

1. Introduction. Early work [1, 17, 8, 9, 21, 22] in two dimensions developed fundamental concepts for Riemann problem solutions for scalar equations. A by-product of this work was the development of a constructive technique for two-dimensional (2-D) Riemann problem solutions. Elements of this technique are still being refined concurrent with its use to obtain and examine solutions for systems where, in contrast to scalar hyperbolic equations, no general existence and uniqueness theory exists in multiple space dimensions. Spearheaded largely by the work of T. Zhang and collaborators, a body of work [7, 10, 11, 12, 13, 14, 18, 19, 23, 24] has since developed for the solution of 2-D Riemann problems for systems, specifically for the Euler system modeling gas dynamics and for simpler gas-dynamics-like models. In this work we consider a 2×2 system which is a 2-D generalization of the one-dimensional (1-D) Keyfitz–Kranzer–Isaacson–Temple model [4, 5, 15], which has been used in studies of material elasticity and flow in porous media. In addition to the particular solutions developed for this system, our emphasis here is on the constructive technique, in particular the fundamental role played by rarefaction, shock, and contact "base points" and "base curves," and the relationship between these elements.

In this and part I of this paper [3] we consider the 2×2 system

$$s_t + f^A(s,c)_x + f^B(s,c)_y = 0, \tag{1.1}$$

$$(cs)_t + (cf^A(s,c))_x + (cf^B(s,c))_y = 0. \tag{1.2}$$

An attractive feature of this model is that, regardless of the form of the flux functions f^A and f^B, the wave family associated with the variable c is always linear, i.e., produces only states of constant c-value separated by contact discontinuities. The other family, associated with the variable s, is identical to the scalar family obtained from (1.1) with c held constant.

The presence of the linear c-family is important in guaranteeing solution uniqueness within a regularity class of functions. Recall [8] that initial data for a 2-D Riemann problem consists of piecewise constant data given on a finite number of wedges centered at the origin. As noted in part I of this paper [3], the system (1.1), (1.2) has no mechanism to remove (create) any constant concentration value $\bar{c}$ which is (is not) in the initial data. Consequently, only regions of constant concentration value exist in the self-similar Riemann problem solution, and these must correspond in an identifiable fashion with each region of constant concentration value in the initial data. These constant concentration regions must be delineated by contact discontinuities of the c-family. Furthermore, the solution within each region of constant concentration is determined by the scalar equation (1.1) for which uniqueness and existence of solutions within the function classes of bounded variation [16] and piecewise smooth [6] have been determined. Thus the only nonuniqueness possible in the solutions may arise from the pattern of contact discontinuities in a solution. As we show in section 4, the Rankine–Hugoniot conditions for the degenerate family lead to a unique pattern of contact discontinuity. The construction method used for the 2-D solutions employs the existence and uniqueness conditions of [6]. Thus within the class of piecewise smooth solutions (in the sense of Kruzkov), the solutions we generate are unique.

Complexity of the solution is governed by the form of the flux functions f^A and f^B and by the number of initial data wedges considered. To minimize complexity, we choose particular forms for the flux functions and limit the number of wedges. Our choice of flux function form is determined by application to flow in porous media. We consider the functions

$$\begin{aligned} f^A(s,c) &= s^2[1 + A(1-c)(1-s)], \qquad 0 < A < 1/2, \\ f^B(s,c) &= s^2[1 + B(1-c)(1-s)], \qquad 0 < B < 1/2, \end{aligned} \tag{1.3}$$

where the physical state variables are

$$\begin{aligned} s &= \text{water saturation}, & 0 \le s \le 1, \\ c &= \text{concentration of polymer}, & 0 \le c \le 1. \end{aligned}$$

This system models polymer flooding of an oil reservoir [4]. In a polymer flood, a small amount of polymer is added to the water to increase the sweep efficiency of oil production. The model assumes the polymer is completely miscible in the water phase and undergoes no mass transfer into the oil phase. In part I of this paper [3] we have developed the solution of this model for the case $A \equiv B$ (i.e., $f^A \equiv f^B$), which is applicable to isotropic media.

In this paper, we develop solutions for the case $A \neq B$. The directional fluxes f^A and f^B differ in those terms of order higher than s^2, as may be appropriate for anisotropic media. In order to restrict the complexity introduced by compound waves in the s-family we simplify to a convex form for the flux functions. The restriction $0 < A < 1/2$ guarantees that the x-direction flux function f^A remains convex for allowed values of $s \in [0,1]$ and $c \in [0,1]$, similarly for the y-direction flux f^B. The following lemma impacts the form of the effective flux function $f_s^{\hat{n}} \equiv \hat{n} \cdot (f_s^A, f_s^B)$ governing flow in an arbitrary 2-D direction $\hat{n}$.

LEMMA 1.1 (see [22]). *For fixed c, if $f_{ss}^A \neq 0, f_{ss}^B \neq 0$, and $\frac{\partial}{\partial s}(f_{ss}^A / f_{ss}^B) \neq 0$ for any s then, for any $\hat{n}$, $f^{\hat{n}}$ has at most one inflection point.*

Lemma 1.1 holds under either the restriction $0 < B < A < 1/2$ or $0 < A < B < 1/2$; without loss of generality we will consider the case $0 < A < B < 1/2$.

The 2-D Riemann problem studies for gas dynamics models have involved initial data on four wedges corresponding to the four quadrants in the plane, as this is pertinent to typical data encountered in 2-D finite difference methods. For general

Riemann data, n waves emerge from an initial discontinuity for an $n \times n$ system. The work on gas dynamics models has typically added an additional restrictive assumption on the initial data values to ensure that only a single wave evolves from each initial discontinuity. In this paper, we relax the single wave restriction; however, we do restrict the initial data to two wedges defined by the angles $\pi/2$ and π (Figure 4.1(a)). As the smaller wedge agrees with one of the quadrants in the plane, we refer to this as a single quadrant Riemann problem.

To analyze system (1.1), (1.2) it is convenient to introduce the change of variables $s, c \to s, b \equiv sc$. The eigenvalues, right eigenvectors, and Riemann invariants for the two families of waves are, respectively,

$$\begin{array}{rlll} \lambda^s = f_s^{\hat{n}}, & \text{where} & f_s^{\hat{n}} \equiv \hat{n} \cdot (f_s^A, f_s^B), & \\ \lambda^c = g^{\hat{n}}, & \text{where} & g^{\hat{n}} \equiv \hat{n} \cdot (g^A, g^B), & g^\alpha \equiv f^\alpha / s, \quad \alpha = A, B, \\ r^s = (s, b), & & r^c = (-g_b^{\hat{n}}, g_s^{\hat{n}}), & \\ W^s = c, & & W^c = g^{\hat{n}}. & \end{array}$$

Here, $\hat{n} \equiv (\mu, \nu)$ denotes a direction vector and subscripts represent partial differentiation.

The solution construction method developed in [1, 9, 17, 22] relies heavily on the existence of so-called base points and curves. We review these in section 2 and establish some new relations between these. While specific details of the base points and curves are applicable only to this model, the existence of the curves and the existence of relationships between these curves are general features to be exploited for any hyperbolic system. In particular, the geometrical nature of the Kruzkov entropy condition (Figure 2.3) and the relationships between the shock and rarefaction base curves place regional restrictions on the allowed s-family waves. This is discussed for this model in section 3. A topological classification of the solutions and a discussion of the generic solution form for the single quadrant Riemann problem for our system is presented in section 4. In section 5 we present the unique canonical Riemann problem solution in each class.

2. Base curves. As the solution to a Riemann problem is self-similar, direct construction of a 2-D Riemann problem solution is done in the plane defined by the self-similar coordinates $\xi = x/t$, $\eta = y/t$ (i.e., in the plane $t = 1, x, y$). Positioning of shock, rarefaction, and contact discontinuity waves in this plane is related to the existence of rarefaction and shock base curves and contact base points. Furthermore, shock and rarefaction waves are each classifiable into two types [22], and possible interactions among the types are limited.

The existence of base points and curves, the existence of relations between them, and the shock and rarefaction wave classifications are general. However, the form of base curves and position of base points depend on the particular choice of flux functions. The flux functions in the model studied here have the following characteristics. For any fixed value of $c \in [0, 1]$ (recall we have chosen $A < B$),

(2.1) $f^\alpha(0, c) = 0, \quad f^\alpha(1, c) = 1, \quad \alpha = A, B;$

(2.2) $f^\alpha(s, c)$ is convex (i.e., $f_s > 0, \quad f_{ss} > 0$ for $s \in [0, 1]$), $\quad \alpha = A, B;$

(2.3) $f_s^A < f_s^B$ for $s \in [0, s_{AB}), \quad f_s^B < f_s^A$ for $s \in (s_{AB}, 1];$

(2.4) $g^\alpha(0, c) = 0, \quad g^\alpha(1, c) = 1, \quad \alpha = A, B;$

(2.5) $g^A(s, c) < g^B(s, c)$ for $s \in [0, 1];$

(2.6) $g^\alpha(s, c) \le f_s^\alpha(s, c)$ for $s \in [0, 1], \quad \alpha = A, B,$ with equality holding only for $s = 0$.

For any fixed value of $s \in [0,1]$,

$$f^\alpha(s,c_1) > f^\alpha(s,c_2) \text{ for } c_1 < c_2, \quad \alpha = A,B; \tag{2.7}$$

$$g^\alpha(s,c_1) > g^\alpha(s,c_2) \text{ for } c_1 < c_2, \quad \alpha = A,B. \tag{2.8}$$

2.1. Rarefaction base curves and wave classification. Consider the scalar equation (1.1) with $c = c_0$ (c_0 a constant).

$$s_t + f^A(s,c_0)_x + f^B(s,c_0)_y = 0. \tag{2.9}$$

Under the change of variables $\xi = x/t$, $\eta = y/t$, (2.9) has the self-similar form

$$-\xi s_\xi - \eta s_\eta + f^A(s,c_0)_\xi + f^B(s,c_0)_\eta = 0, \tag{2.10}$$

where now $s = s(\xi,\eta)$. For $s \in C^1$, (2.10) becomes

$$\left(f^A_s(s,c_0) - \xi\right)s_\xi + \left(f^B_s(s,c_0) - \eta\right)s_\eta = 0 \tag{2.11}$$

whose characteristic form is given by

$$\begin{aligned} d\eta(\xi)/d\xi &= (f^B_s(s,c_0) - \eta)/(f^A_s(s,c_0) - \xi), \\ ds(\xi,\eta(\xi))/d\xi &= 0. \end{aligned} \tag{2.12}$$

From (2.12), the characteristic lines are defined by

$$\frac{\eta - f^B_s(s,c_0)}{\xi - f^A_s(s,c_0)} = \text{const}, \qquad s = \text{const}. \tag{2.13}$$

Remark 2.1. From (2.13) we note that an s-family level curve with $s = s_1$, $c = c_0$ is a straight line segment whose tangent passes through the *characteristic base point* $f_s(s_1;c_0)$ in the ξ,η plane having coordinates

$$f_s(s_1;c_0) \equiv (f^A_s(s_1,c_0), f^B_s(s_1,c_0)), \tag{2.14}$$

as illustrated in Figure 2.1(a). We refer to the curve

$$f_s(s;c_0) \equiv (f^A_s(s,c_0), f^B_s(s,c_0)), \qquad 0 \le s \le 1, \tag{2.15}$$

as the *rarefaction base curve for* c_0.

As a consequence of Remark 2.1, (i) if a single point on a characteristic in a rarefaction wave is known the characteristic can be extended locally as a straight line segment, or (ii) if the direction of a characteristic wave is known the wave can be locally located (as a straight line segment) in the (ξ,η) plane.

For a model with the characteristics (2.1)–(2.2) it is easy to show that the rarefaction base curve is a monotonic increasing, concave curve segment in the (ξ,η) plane extending between the points $(\xi = 0, \eta = 0)$ and $(\xi = f^A_s(1,c), \eta = f^B_s(1,c))$. For the fluxes (1.3) used here, the value s_{AB} in (2.3) is independent of the value of c, A, or B; thus all rarefaction base curves pass through the point $(f^A_s(s_{AB},c), f^B_s(s_{AB},c)) = (4/3, 4/3)$. Two example rarefaction base curves are shown in Figure 2.1(b). The upper termination point $(2 - A(1-c), 2 - B(1-c))$ of any rarefaction base curve must lie within the triangular region delimited by the dotted lines.

Rarefaction waves can be classified [20] according to the direction of the gradient of s across the wave relative to the direction toward the base curve.

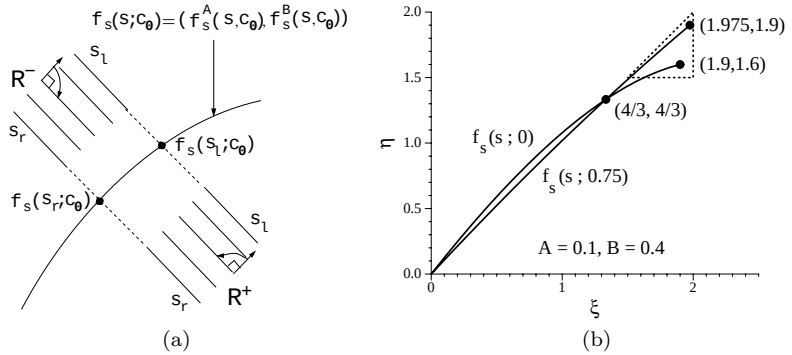

FIG. 2.1. (a) *A rarefaction base curve* $f_s(s) \equiv (f_s^A(s), f_s^B(s))$ *and rarefaction waves* R^+, R^- $(s_l > s_r)$. (b) *Example plots of two rarefaction base curves.*

DEFINITION 2.1 (see [20]). *Classify a rarefaction wave as* R^+ (R^-) *if* $\nabla_{\xi,\eta} s$ *and the direction toward the base curve of the characteristic lines of the wave form a right- (left-) hand system.*

R^+ and R^- rarefaction waves are indicated in Figure 2.1(a). If (s_l, c) and (s_r, c) are the bounding characteristics of a rarefaction wave, the wave will be labeled $R^+_{l,r}$ or $R^-_{l,r}$ as appropriate.

2.2. Shock base curves and wave classification. From (2.10) we have the Rankine–Hugoniot condition for a piecewise smooth shock curve $\eta = \eta(\xi)$,

$$\frac{d\eta}{d\xi} = \frac{\eta - \sigma^B(s_l, s_r; c_0)}{\xi - \sigma^A(s_l, s_r; c_0)}, \tag{2.16}$$

where

$$\sigma^\alpha(s_l, s_r; c_0) \equiv \frac{f^\alpha(s_l, c_0) - f^\alpha(s_r, c_0)}{s_l - s_r}, \qquad \alpha = A, B. \tag{2.17}$$

Remark 2.2. From (2.16) we see that any s-family shock point D in the (ξ, η) plane separating (s_l, c_0) and (s_r, c_0) lies on a curve segment whose tangent at D passes through the *shock base point* $\sigma(s_l, s_r; c_0)$ in the ξ, η plane having coordinates

$$\sigma(s_l, s_r; c_0) \equiv (\sigma^A(s_l, s_r; c_0),\ \sigma^B(s_l, s_r; c_0)). \tag{2.18}$$

The notations $\sigma(s_l, s_r; c)$ and $\sigma(s_r, s_l; c)$ specify the same base point. The curve of base points

$$\sigma(s, s_r; c_0) \equiv (\sigma^A(s, s_r; c_0),\ \sigma^B(s, s_r; c_0)), \qquad 0 \le s \le 1, \tag{2.19}$$

is denoted the *shock base curve* for the state (s_r, c_0).

Shock base points are used analogously to rarefaction base points to locally position shocks involving the states s_r, c_0 and s_l, c_0. For our model with $A < B$ any shock base curve $\sigma(s, s_r; c_0)$ is monotonic increasing and concave in the (ξ, η) plane. A shock base curve $\sigma(s, s_r; c_0)$ is sketched in Figure 2.2(a).

DEFINITION 2.2. *For a point* D *on a shock separating* s_l *and* s_r*, the direction of the normal vector* $\hat{n} \equiv (\mu, \nu)$ *at* D *is defined as pointing from the side having larger to the side having smaller value of* s*; i.e., if* $s_l > s_r$*,* $\hat{n}$ *points from* s_l *to* s_r*.*

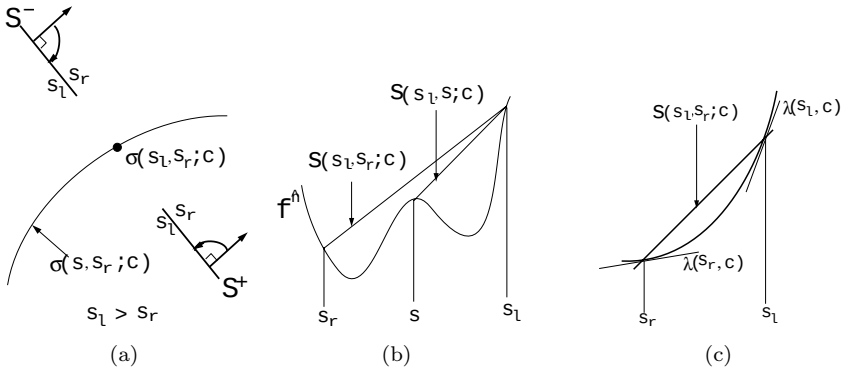

FIG. 2.2. (a) *Illustration of the shock base curve* $\sigma(s, s_r; c)$ *and* S^+ *and* S^- *shock waves. Sketch of the Kruzkov entropy condition for* (b) *general and* (c) *convex flux functions.* $S(\cdot)$ *and* $\lambda(\cdot)$ *refer to the slopes of indicated lines.*

Let

$$\begin{aligned} S(s_l, s_r; c) &\equiv \hat{n} \cdot (\sigma^A(s_l, s_r; c), \sigma^B(s_l, s_r; c)) \\ &= \mu\sigma^A(s_l, s_r; c) + \nu\sigma^B(s_l, s_r; c). \end{aligned} \tag{2.20}$$

The Kruzkov entropy condition for a shock whose normal has the direction (μ, ν) is given by

$$S(s_l, s_r; c) \le S(s_l, s; c) \quad \text{for all} \quad s \in (s_r, s_l). \tag{2.21}$$

This entropy condition for a flux function $f^{\hat{n}}(s, c)$ of general shape is illustrated in Figure 2.2(b); it is the familiar Oleinik construction. If $f^{\hat{n}}$ is convex over the domain (s_r, s_l), the entropy condition reduces to

$$\lambda(s_r, c) < S(s_l, s_r; c) < \lambda(s_l, c), \tag{2.22}$$

i.e.,

$$\hat{n} \cdot (f_s^A, f_s^B)\Big|_{s_r} < \hat{n} \cdot (\sigma^A, \sigma^B) < \hat{n} \cdot (f_s^A, f_s^B)\Big|_{s_l}. \tag{2.23}$$

This convex form of the entropy condition is illustrated in Figure 2.2(c) and is the well-known Lax entropy condition. As shown in Figure 2.3, the Lax entropy inequality (2.23) is equivalent to comparing the lengths of the projections on the direction $\hat{n}$ of the vectors from the origin of the ξ, η plane to the respective rarefaction and shock base points $f_s(s_r; c), \sigma(s_l, s_r; c)$, and $f_s(s_l; c)$.

A shock wave can be classified [22] according to the relative direction of the shock normal and tangent vectors at each point.

DEFINITION 2.3 (see [22]). *A shock wave is classified as* S^+ *(*S^-*) if at each point the normal and tangent (pointing towards the shock base point) vectors of the shock form a right-hand (left-hand) system.*

The two shock types are also illustrated in Figure 2.2(a). If (s_l, c) and (s_r, c) are the states bounding the shock, the shock will be labeled $S_{l,r}^+$ or $S_{l,r}^-$ as appropriate.

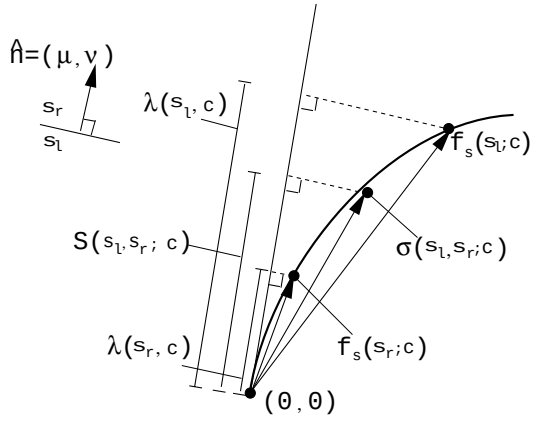

FIG. 2.3. *Geometrical realization in the ξ, η plane of the Kruzkov entropy condition for convex f.*

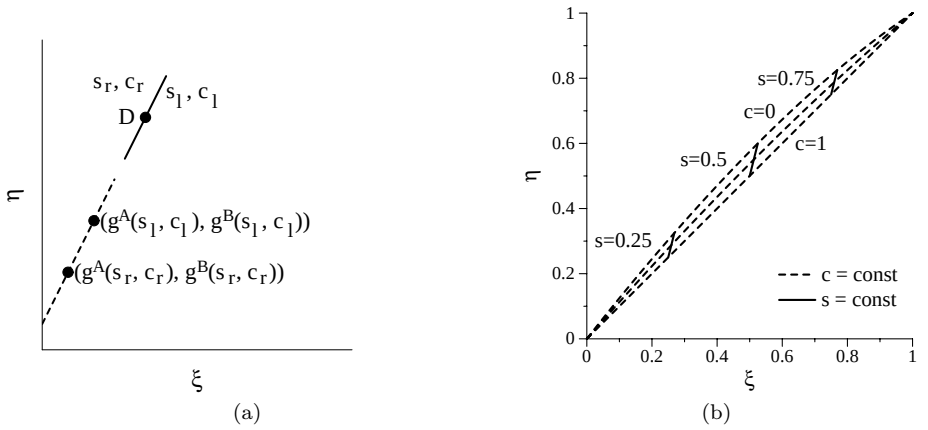

FIG. 2.4. (a) *The tangent (dotted line) to a contact discontinuity point D must pass through two appropriate contact base points $(g^A(s_l, c_l), g^B(s_l, c_l))$ and $(g^A(s_r, c_r), g^B(s_r, c_r))$ as illustrated.* (b) *Illustration of coordinate curves which cover the region of contact base points. Here $s = 0.5$ refers to the coordinate curve $(g^A(0.5, c), g^B(0.5, c))$, while $c = 0$ refers to the coordinate curve $(g^A(s, 0), g^B(s, 0))$, etc.*

2.3. Contact discontinuity base points. Let D be a point on a c-family contact discontinuity curve segment separating the states (s_l, c_l) and (s_r, c_r). The Rankine–Hugoniot condition across a smooth c-family contact discontinuity curve having normal vector $\hat{n} = (\mu, \nu)$ at D is

$$g^{\hat{n}}(s_l, c_l) = g^{\hat{n}}(s_r, c_r), \tag{2.24}$$

where $g^{\hat{n}} \equiv \mu g^A + \nu g^B$.

Remark 2.3. As a consequence of (2.24) a contact discontinuity point D lies on a curve segment whose tangent must pass through the two *contact base points*,

$$(g^A(s_l, c_l), g^B(s_l, c_l)) \quad \text{and} \quad (g^A(s_r, c_r), g^B(s_r, c_r)), \tag{2.25}$$

as illustrated in Figure 2.4(a).

For a model with the characteristics (2.4), (2.5) any contact base point must lie within a region $\Omega_{A,B}$ of the ξ, η plane bounded between the concave curve segments $(g^A(s,1), g^B(s,1))$ and $(g^A(s,0), g^B(s,0))$, both of which terminate at the points (0, 0) and (1, 1). An example region $\Omega_{0.1,0.4}$ for the model studied here is shown in Figure 2.4(b). In this case $(g^A(s,1), g^B(s,1))$ is the straight line segment between (0,0) and (1,1). The set of curve segments $(g^A(s, c = \text{const}),\ g^B(s, c = \text{const}))$ and the set $(g^A(s = \text{const}, c),\ g^B(s = \text{const}, c))$ form a coordinate system over this region. (Thus the contact base point $(g^A(s_l, c_l), g^B(s_l, c_l))$ occurs at the intersection of the $(g^A(s, c_l), g^B(s, c_l))$ and $(g^A(s_l, c), g^B(s_l, c))$ coordinate curves.) The $(g^A(s = \text{const}, c),\ g^B(s = \text{const}, c))$ coordinate curves are straight lines, with slope B/A. A few coordinate curves are also sketched in Figure 2.4(b).

2.4. Relation between rarefaction and shock base curves. For a fixed value of $c = c_0$ and any $s_1 \in (0,1)$, the shock and rarefaction base curves $\sigma(s_1, s; c_0)$ and $f_s(s; c_0)$ are related as indicated in the following two lemmas.

LEMMA 2.4.

$$\frac{d}{ds}\sigma(s_1, s; c_0) = \frac{1}{(s - s_1)}\big[f_s(s; c_0) - \sigma(s_1, s; c_0)\big]. \tag{2.26}$$

Proof. We prove (2.26) componentwise. Consider the ξ-component

$$\begin{aligned}\frac{d}{ds}\sigma^A(s_1, s; c_0) &\equiv \frac{d}{ds}\left(\frac{f^A(s, c_0) - f^A(s_1, c_0)}{s - s_1}\right)\\ &= \frac{1}{(s - s_1)}\left(f_s^A(s, c_0) - \frac{f^A(s, c_0) - f^A(s_1, c_0)}{s - s_1}\right)\\ &= \frac{1}{(s - s_1)}\big(f_s^A(s, c_0) - \sigma^A(s_1, s; c_0)\big).\end{aligned}$$

The computation is identical for the η-component. ∎

LEMMA 2.5.

$$\frac{d\sigma^B(s_1, s; c_0)}{d\sigma^A(s_1, s; c_0)} = \frac{f_s^B(s, c_0) - \sigma^B(s_1, s; c_0)}{f_s^A(s, c_0) - \sigma^A(s_1, s; c_0)}. \tag{2.27}$$

Proof. The proof follows immediately from Lemma 2.4 using the fact that s_1 and c_0 are constant, i.e.,

$$\frac{d\sigma^B(s_1, s; c_0)}{d\sigma^A(s_1, s; c_0)} = \frac{d\sigma^B(s_1, s; c_0)/ds}{d\sigma^A(s_1, s; c_0)/ds}. \qquad ∎$$

Remark 2.4. Two shock base curves $\sigma(s, s_r; c)$ and $\sigma(s_l, s; c)$ pass through each shock base point $\sigma(s_l, s_r; c)$. Lemma 2.5 states that the tangent to the shock base curve $\sigma(s, s_r; c)$ at the shock base point $\sigma(s_l, s_r; c)$ also passes through the rarefaction base curve at the point $f_s(s_l; c)$. Equivalently, the tangent to the shock base curve $\sigma(s_l, s; c)$ at the shock base point $\sigma(s_l, s_r; c)$ passes through the rarefaction base curve at the point $f_s(s_r; c)$. These tangent lines (dashed lines) are shown in Figure 2.5(a).

As a consequence of Remark 2.4, the rarefaction and shock base points $f_s(s_r; c)$ and $\sigma(s_r, s_r; c)$ are coincident and the shock $\sigma(s, s_r; c)$ and the rarefaction $f_s(s; c)$ base curves meet tangentially at this common point (i.e., at the parameter value $s = s_r$). This is also illustrated in Figure 2.5(a).

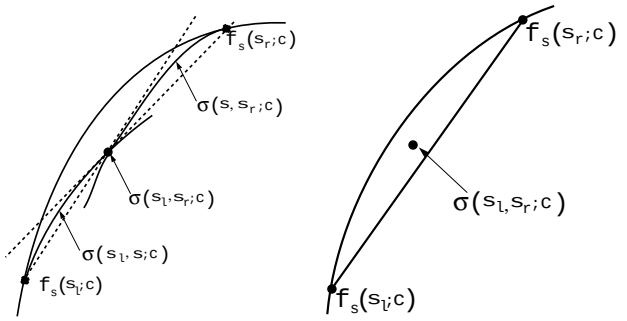

FIG. 2.5. *Illustration of* (a) *the relation between the rarefaction and shock base curves. The dashed lines indicate tangents to the two shock base curves at* $\sigma(s_r, s_l; c)$*;* (b) *the convex hull property of shock base points relative to the rarefaction base curve.*

Lemmas 2.4 and 2.5 and Remark 2.4 hold for any scalar equation with flux functions having sufficient continuity. The following remark is pertinent to the model studied here.

Remark 2.5. The rarefaction $f_s(s; c)$ and shock $\sigma(s_1, s; c)$ base curves have the same curvature sign. This property follows from Remark 2.4

LEMMA 2.6. *For our model, the shock base point* $\sigma(s_l, s_r; c)$ *lies within the convex hull of* $f_s(s; c)$ *between the rarefaction base points* $f_s(s_r; c)$ *and* $f_s(s_l; c)$ *as shown in Figure* 2.5(b). *We refer to this as the* convex hull *property of the rarefaction base curve relative to shock base points.*

Proof. As a consequence of Remark 2.5, the larger of the two angles between the two tangent lines in Remark 2.4 must be less than π. □

2.5. Relation between rarefaction and contact base coordinate curves. Following a proof analogous to that for Lemma 2.5, we have the fundamental relation between the rarefaction base curve for c_0 and the $c = c_0$ contact base coordinate curve.

LEMMA 2.7.

$$\frac{dg^B(s, c_0)}{dg^A(s, c_0)} = \frac{f_s^B(s, c_0) - g^B(s, c_0)}{f_s^A(s, c_0) - g^A(s, c_0)}. \tag{2.28}$$

Note that this lemma depends only on the definition $g(s, c) \equiv f(s, c)/s$ and not on the form of $f(\cdot)$.

Remark 2.6. Lemma 2.7 states that the tangent to the contact base point coordinate curve $(g^A(s, c_0), g^B(s, c_0))$ at the contact base point $(g^A(s_1, c_0), g^B(s_1, c_0))$ passes through the rarefaction base curve at the base point $f_s(s_1; c_0)$.

Remark 2.7. Further, in this model it is easy to show the following.

1. Both the rarefaction base curve $f_s(s; c_0)$ and contact base point coordinate curve $(g^A(s, c_0), g^B(s, c_0))$ have the same curvature sign. For $A < B$ the curvature is negative.
2. For $A < B$ and $s \in (0, 1]$, the coordinate curve $(g^A(s, c_0), g^B(s, c_0))$ lies below the rarefaction base curve $f_s(s; c_0)$.
3. The base points $(g^A(0, c_0), g^B(0, c_0))$ and $f_s(0; c_0)$ are identical, and the contact base coordinate curve and the rarefaction base curve meet tangentially at this common point (which is in fact the point $(\xi = 0, \eta = 0)$).

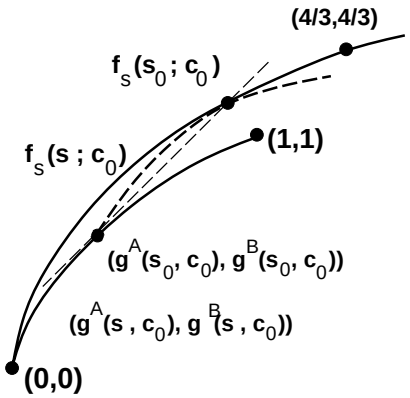

FIG. 2.6. *Illustration of the relationship between the rarefaction base curve $f_s(s;c_0)$ (upper), the contact base coordinate curve $(g^A(s,c_0), g^B(s,c_0))$ (lower), and the shock base curve $\sigma(s_1,s;c_0)$ (dashed). The straight dashed line is tangent to the contact base coordinate curve at $(g^A(s,c_0), g^B(s,c_0))$.*

Figure 2.6 shows a rarefaction base curve and the corresponding contact base point coordinate curve.

2.6. Relation between shock base curves and contact base points. The following lemma establishes a useful relationship between shock base curves and contact base points.

LEMMA 2.8.

$$\left.\begin{array}{ll} g^\alpha(s_0,c_0) = \sigma^\alpha(s_0,0;c_0), & \\ g^\alpha(s_0,c_0) < \sigma^\alpha(s_0,s;c_0), & s\in(0,1], \end{array}\right\} \qquad \alpha = A,B. \tag{2.29}$$

Proof. The equality in the lemma follows from the definitions of g^α and σ^α. The inequality is easily shown geometrically given that the function $f^\alpha(s,c_0)$ is convex. ∎

From Lemma 2.8 we see that the contact base point $(g^A(s_0,c_0), g^B(s_0,c_0))$ is the "lower" termination point of the shock base curve $\sigma(s_0,s;c_0)$. This relationship is also sketched in Figure 2.6.

3. Entropy restrictions for *s*-family shocks. The geometrical nature of the entropy condition (Figure 2.3) and the relationships between the shock and rarefaction base curves place the following regional restrictions on the allowed s-family waves in the ξ,η plane.

Consider a point D on a curve of discontinuity separating states s_l, c and s_r, c with $s_l > s_r$. Assume at D that the normal and tangent (pointing toward the appropriate shock base point) form a right-handed system. If D lies in the lower right, wedge shaped region of the ξ,η plane labeled $S^+_{l,r}$ in Figure 3.1(a) (this region is centered on the shock base point $\sigma(s_l,s_r;c)$, is bounded above by the half line starting from this shock base point and passing through the rarefaction base point $f_s(s_l;c)$, and is bounded to the left by the half line starting from the shock base point and passing through the rarefaction base point $f_s(s_r;c)$), then the local solution to this Riemann problem is an s-family shock of type $S^+_{l,r}$.

It is an easy geometrical exercise to verify the entropy condition for this shock. The verification is sketched in Figure 3.2(a). The projection lengths (2.22) are seen to have the correct ordering along the normal direction $\hat{n}$.

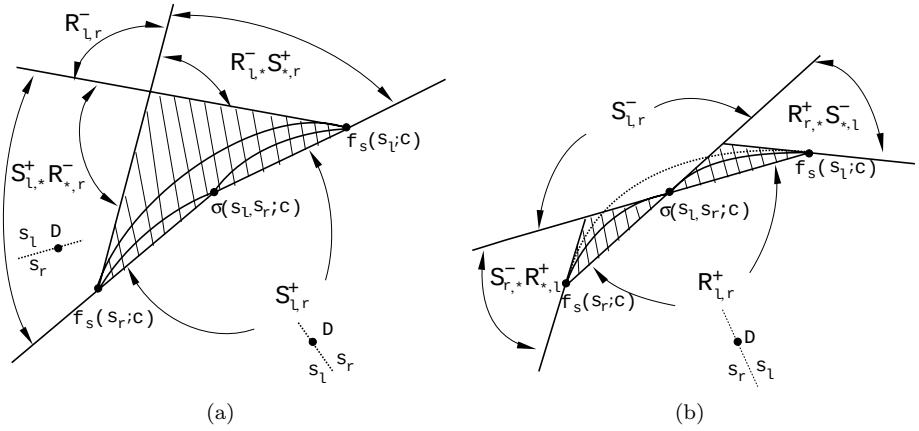

FIG. 3.1. *Regional entropy restrictions for s-family waves. Here* $s_l > s_r$.

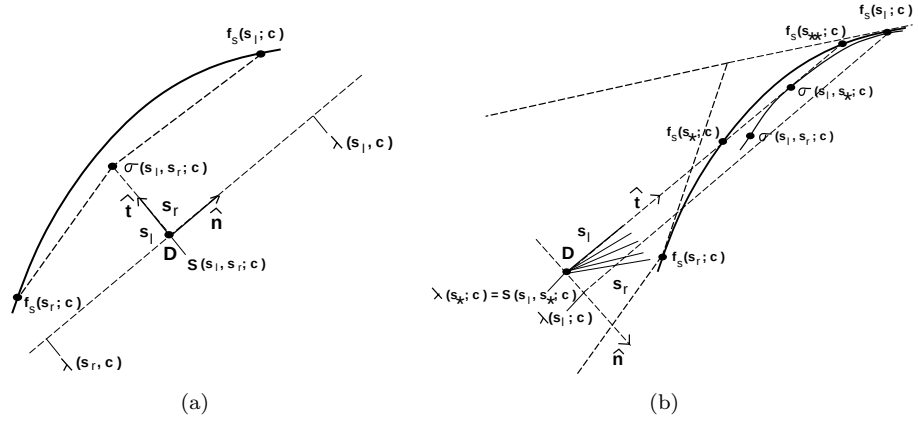

FIG. 3.2. (a) *Detail verifying the Lax entropy condition for an* S^+ *shock in the* $S^+_{l,r}$ *region.* (b) *Detail verifying the Lax entropy condition for the composite* S^+R^- *wave shock in the* $S^+_{l,*}R^-_{*,r}$ *region.*

If D lies in the region labeled $S^+_{l,*}R^-_{*,r}$ (lower left) in Figure 3.1(a), with the orientation of s_l and s_r ($s_l > s_r$) as indicated, the local Riemann problem solution will consist of a composite wave consisting of an $S^+_{l,*}$ shock and an $R^-_{*,r}$ rarefaction fan. Here $*$ denotes the intermediate state common to one side of the shock and the rarefaction fan. The region is bounded by the three dark dashed lines shown in Figure 3.2(b). (The lower dashed line is the extension of the line segment from the shock base point $\sigma(s_l, s_r; c)$ to the rarefaction base point $f_s(s_r; c)$. The middle dashed line is tangent to the rarefaction base curve at $f_s(s_r; c)$. The upper is tangent to the rarefaction base curve at $f_s(s_l; c)$.)

LEMMA 3.1. *There is a unique base point* $\sigma(s_l, s_*; c)$, *with* $s_* < s_l$, *on the shock base curve* $\sigma(s_l, s; c)$ *such that the line segment from* D *to* $\sigma(s_l, s_*; c)$ *is tangent to the shock base curve. This line also passes through a rarefaction base point* $f_s(s_*; c)$ *such that* $\sigma(s_l, s_*; c)$ *lies in the convex hull of* $f_s(s_*; c)$ *and* $f_s(s_l; c)$.

Proof. The existence of the unique shock base point $\sigma(s_l, s_*; c)$ follows by requiring D to remain within the region bounded by the indicated lines and by noting that the shock base curve is concave down. The relations between rarefaction and shock base curves noted in section 2.4 imply that this tangent line passes through the rarefaction base curve $f_s(s; c)$ twice, at base points $f_s(s^*; c)$ and $f_s(s^{**}; c)$ as indicated in Figure 3.2(b). However, only for the smaller (s^*) of the values s^* and s^{**} does $\sigma(s_l, s_*; c)$ lie in the convex hull of $f_s(s; c)$ between $f_s(s_l; c)$ and $f_s(s_*; c)$. ∎

Thus the unique local entropy solution of the Riemann problem at D consists of a shock between the state s_l and the state s_* followed by a rarefaction wave $R^-_{*,r}$. The tangent (and hence normal) to the shock direction at D is determined by the shock base point $\sigma(s_l, s_*; c)$. The characteristics in the rarefaction fan must point to the appropriate rarefaction base points corresponding to values of s lying in the range $[s_*, s_r]$ as sketched in the Figure 3.2(b). Again it is easy to geometrically verify the entropy condition

$$\hat{n} \cdot (f_s^A, f_s^B)\Big|_{s_*} = \hat{n} \cdot (\sigma^A, \sigma^B)\Big|_{l,*} < \hat{n} \cdot (f_s^A, f_s^B)\Big|_{s_l} \tag{3.1}$$

for the $S^+_{l,*}$ shock, as illustrated in Figure 3.2(b).

If D lies in the region labeled $R^-_{l,r}$ (upper left) in Figure 3.1(a), the local Riemann problem solution will consist of an $R^-_{l,r}$ rarefaction fan. If D lies in the region labeled $R^-_{l,*}S^+_{*,r}$ (upper right) in Figure 3.1(a), the local Riemann problem solution will consist of a composite wave consisting of an $R^-_{l,*}$ rarefaction fan followed by an $S^+_{*,r}$ shock. The detailed analysis of the composite wave in this region follows analogously to that for the $S^+_{l,*}R^-_{*,r}$ region.

If s_l and s_r are switched so that now the normal and tangent vectors at D form a left-handed system, four different solution regions in the ξ, η plane develop. These are indicated in Figure 3.1(b).

Note in Figure 3.1 that the occurrence of D in the shaded regions is not investigated. This shaded region is dynamic, depending on the left and right states on each side of the discontinuity. Solutions are constructed by "tracing waves in from infinity." We observe one of two events occurring as a shock point D is "traced in" and approaches the shaded region; either D separates two constant states, in which case the shock remains a straight line with unchanging entropy condition, or the change in saturation s across the shock weakens, and the dynamic shaded region shrinks in a manner that D never reaches it.

4. Solution classification and generic form. A 2-D Riemann problem solution can be partly classified by its solution at infinity in the (ξ, η) plane where it consists of noninteracting 1-D solutions. For the single quadrant problem Figure 4.1(a) investigated here, the solution form at infinity is sketched in Figure 4.1(b). In each direction the solution consists of a contact discontinuity followed by an s-family wave (which cannot be composite as the flux functions $f^A(s, c)$ and $f^B(s, c)$ are convex). It is therefore natural to label the solution behavior at infinity as $\mathrm{CW}_y\mathrm{CW}_x$, where W_y and W_x denote the s-family wave type (either S or R) in the y and x direction, respectively. Given s_1, c_1 there are four cases for the solution at infinity (labeled CSCS, CSCR, CRCS, and CRCR) determined by the location of s_2, c_2 in one of four regions in phase space. These four regions are indicated in Figure 4.2(a). The regions are bounded by the two curves $c^\alpha(s)$ defined implicitly by $g^\alpha(s, c) = g_1^\alpha$, where $g_1^\alpha \equiv f^\alpha(s_1, c_1)/s_1$, $\alpha = A, B$.

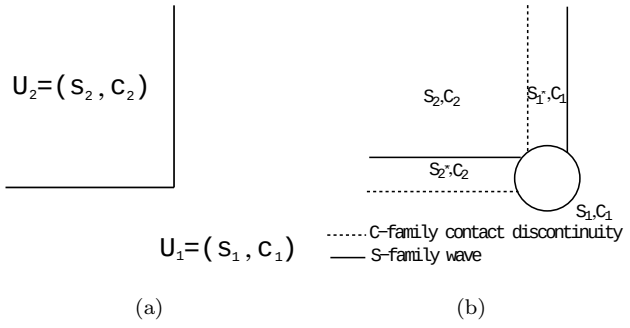

FIG. 4.1. (a) *The initial data for the single quadrant Riemann problem.* (b) *The solution at infinity.*

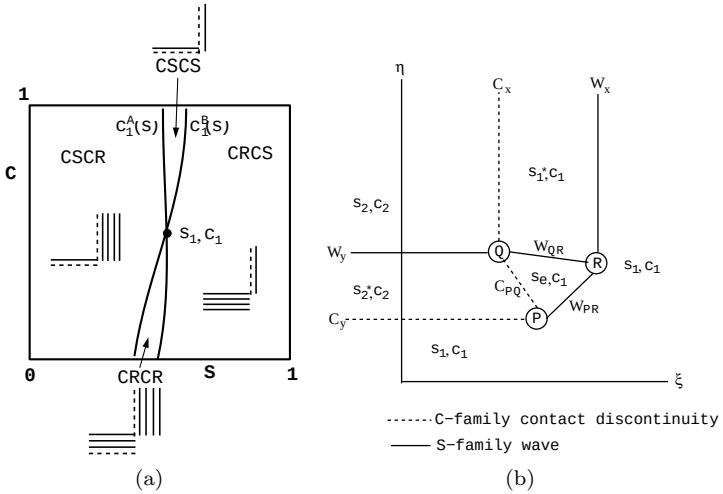

FIG. 4.2. (a) *Phase space classification of the solution at infinity.* (b) *The generic form of the single quadrant Riemann problem solution.*

As discussed earlier, the single quadrant Riemann problem solution must contain a "single" contact discontinuity wave which divides the solution into two separate scalar regions. This contact discontinuity provides the only mechanism for the $c_2 \to c_1$ transition required in the solution. Given this and the solution structure at infinity, all solutions must have the generic form shown in Figure 4.2(b). The existence of the constant state s_e, c_1 is a consequence of the required transition across the contact discontinuity C_{PQ}. Whereas Q and R may denote either an interaction point or interaction region in the solution, P is always an interaction point (since the contact discontinuities C_{PQ} and C_y must meet at P). In fact, P is the contact base point $(g^A(s_{2^*}, c_2), g^B(s_{2^*}, c_2))$.

In the rest of this section we discuss the interactions in regions Q and P. In section 5 we discuss the interaction in region R in the context of completing the entire solution.

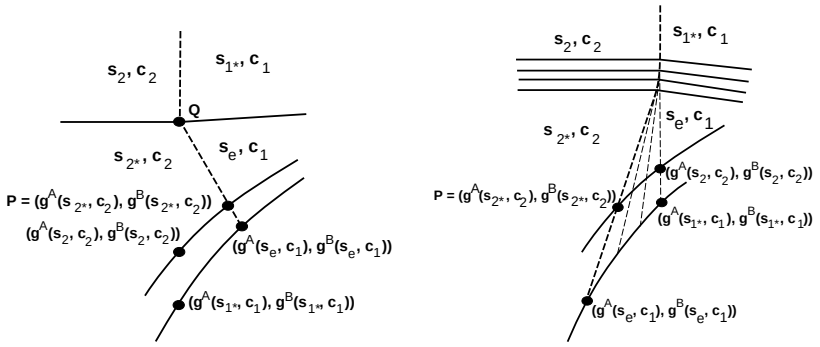

FIG. 4.3. *Illustration of construction in region Q for* (a) *CSCW$_x$ and* (b) *CRCW$_x$ cases. The lighter dashed lines in* (b) *illustrate the behavior of the tangents to the contact discontinuity.*

Interaction at *Q*. The wave W_{QR} is of the same type as W_y. The direction of W_{QR} is determined by the appropriate shock or rarefaction base curve. Our discussion therefore concentrates on the contact discontinuity segment C_{PQ} (Figure 4.2(b)) separating the constant states s_{2^*}, c_2 and s_e, c_1. Let $\hat{n} = (\mu, \nu)$ be the normal to C_{PQ} pointing from the side s_{2^*}, c_2 to s_e, c_1. Let $\theta_{\mu\nu} \equiv \tan^{-1}(\nu/\mu)$ be the angle associated with the normal.

LEMMA 4.1. *For solutions in which W_y is an s-family shock, $0 < \theta_{\mu\nu} < \pi/2$.*

Proof. When W_y is an s-family shock, Q in Figure 4.2(b) is a single point. Figure 4.3(a) illustrates the detail of the construction of this interaction. As W_y and C_y are horizontal lines, the y coordinate of point P is less than that of point Q. The x coordinates of Q and P are, respectively, $g^A(s_2, c_2) \equiv f^A(s_2, c_2)/s_2$ and $g^A(s_{2^*}, c_2) \equiv f^A(s_{2^*}, c_2)/s_{2^*}$. As W_y is a shock, we have $s_2 < s_{2^*}$. Since $f^A(s, c)$ is convex, it follows that $g^A(s_2, c_2) < g^A(s_{2^*}, c_2)$. Thus the components μ and ν of the normal vector are both positive. □

LEMMA 4.2. *For solutions in which W_y is an s-family rarefaction, $-\pi/2 < \theta_{\mu\nu} < 0$.*

Proof. Since W_y is an s-family rarefaction wave, Q in Figure 4.2(b) corresponds to a region over which the contact discontinuity C_x interacts with W_y. Figure 4.3(b) illustrates the details of the construction of this interaction. As W_y is a rarefaction, $s_2 > s_{2^*}$ and $g^A(s_2, c_2) > g^A(s_{2^*}, c_2)$. Given that the $(g^A(s, c_2), g^B(s, c_2))$ contact base coordinate curve is monotonic increasing, concave down, it is clear from the construction in Figure 4.3(b) that the normal to the straight segment of the contact discontinuity separating s_{2^*}, c_2 from s_e, c_1 obeys $-\pi/2 < \theta_{\mu\nu} < 0$. □

Figures 4.3(a) and 4.3(b) also indicate how the saturation values s_{1^*}, s_e and, in the CRCW$_x$ cases, the saturation values in the rarefaction fan W_{QR} are found as crossing points of the appropriate contact discontinuity tangent line with the $(g^A(s, c_1), g^B(s, c_1))$ contact base coordinate curve. (Figures 4.3(a) and 4.3(b) demonstrate this for the case $c_1 > c_2$. For $c_1 < c_2$ the computation is the same.) Lemma 4.3 addresses the computation of these saturation values.

LEMMA 4.3. *s_{1^*} is always the smaller root of the quadratic equation*

$$A_1(s_{1^*})^2 - (1 + A_1)s_{1^*} + g_2^A = 0, \tag{4.1}$$

where $g_2^A \equiv g^A(s_2, c_2)$ and $A_1 \equiv A(1 - c_1)$. s_{2^*} and s_e are computed analogously.

Proof. For given values of s_2, c_1, and c_2, the saturation s_{1^*} is obtained using the Rankine–Hugoniot relation

$$g^A(s_{1^*}, c_1) = g^A(s_2, c_2). \tag{4.2}$$

We easily get the quadratic equation (4.1) from this relation. There are two solutions, s_+, s_- $(s_+ > s_-)$, for s_{1^*}. As $s_+ > 1$ and $s_- \in (0,1)$, the correct choice is $s_{1^*} = s_-$. s_{2^*} can be computed analogously from the Rankine–Hugoniot relation

$$g^B(s_{2^*}, c_2) = g^B(s_1, c_1) \tag{4.3}$$

for given values of s_1, c_1, and c_2.

To compute s_e, let $\hat{n} = (\mu, \nu)$ denote the normal direction to the contact discontinuity C_{PQ}. Given s_{2^*}, c_1, and c_2, the value of s_e is determined from the Rankine–Hugoniot relation

$$g^{\hat{n}}(s_e, c_1) = g^{\hat{n}}(s_{2^*}, c_2), \tag{4.4}$$

where $g^{\hat{n}} = \mu g^A + \nu g^B$. Again (4.4) produces a quadratic equation for s_e with two solutions s_+, s_-. As $s_+ \in (-\infty, 0) \cup (1, \infty)$ and $s_- \in (0,1)$, the correct solution is $s_e = s_-$. ∎

The uniqueness of these saturation values follows from the following remark.

Remark 4.1. The tangent lines of the contact discontinuity C_{PQ} in Figure 4.3 cutting the c_2 contact base coordinate curve also cut the c_1 contact base coordinate curve exactly once. This follows immediately from Lemma 4.3, since there is always a unique $s \in (0,1)$ which satisfies the Rankine–Hugoniot relation (4.4).

Interaction at *P*. The s-family wave W_{PR} is required to provide the transition from the "intermediate state" s_e, c_1 to the initial data state s_1, c_1. We now discuss the determination of this wave type. The wave type depends on the position of the point P, which depends on the relative magnitudes of s_e and s_1, which (Proposition 4.5 below), depends only on the relative magnitudes of c_1 and c_2. We develop first a preparatory lemma needed to prove Proposition 4.5.

Let s_0, c_0 be a fixed state value, $\hat{n} = (\mu, \nu)$ be a unit vector, and $\theta_{\mu\nu} = \tan^{-1}(\nu/\mu)$ as before. Consider the curve in phase space defined by the condition

$$g^{\hat{n}}(s, c) = g^{\hat{n}}(s_0, c_0). \tag{4.5}$$

Using the form for $g^\alpha, \alpha = A, B$, specific to our model, the curve defined by (4.5) can be rewritten explicitly as a function of s,

$$c_0^{\mu,\nu}(s) \equiv \frac{s(\mu + \nu + (\mu A + \nu B)(1-s)) - (\mu g_0^A + \nu g_0^B)}{(\mu A + \nu B) s(1-s)}. \tag{4.6}$$

Note that $c_1^{1,0}(s)$ and $c_1^{0,1}(s)$ correspond, respectively, to the terse notation $c_1^A(s)$ and $c_1^B(s)$ introduced earlier. For our model it is easy to show that $c_0^\alpha(s)$, $\alpha = A, B$, is monotonic increasing on $s \in (0,1)$ for any constant c_0. As noted in Figure 4.2(a), the curves $c_1^A(s)$ and $c_1^B(s)$ divide phase space into the four regions displaying different behaviors at infinity. We consider the relationship between the curves $c_0^A(s)$, $c_0^{\mu,\nu}(s)$, and $c_0^B(s)$.

LEMMA 4.4.

1. *If* $0 < \theta_{\mu\nu} < \pi/2$, *then* $c_0^A(s) > c_0^{\mu,\nu}(s) > c_0^B(s)$ *when* $s > s_0$; $c_0^A(s) < c_0^{\mu,\nu}(s) < c_0^B(s)$ *when* $s < s_0$.

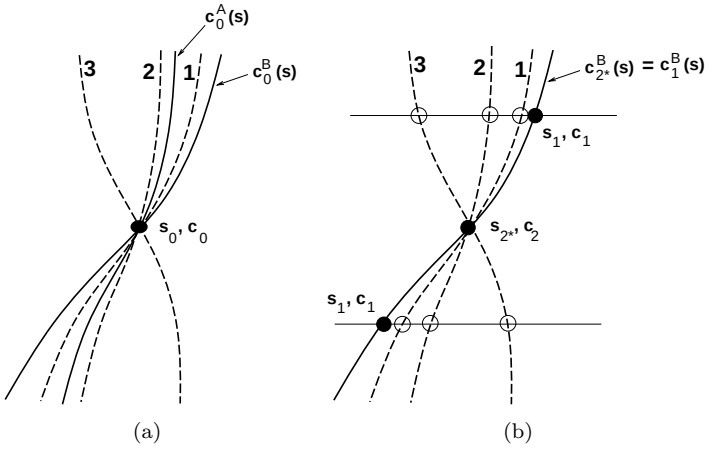

FIG. 4.4. (a) *The behavior of the curve* $c_0^{\mu,\nu}(s)$ *(dashed curves) relative to* $c_0^A(s)$ *and* $c_0^B(s)$ *for the three cases of Lemma* 4.4. (b) *Behavior of the location of the state* s_e, c_1 *(open points) for* $c_2 > c_1$ *and* $c_2 < c_1$.

2. *If* $-\pi/2 < \theta_{\mu\nu} < 0$ *and* $\mu A + \nu B > 0$, *then* $c_0^{\mu,\nu}(s) > c_0^A(s) > c_0^B(s)$ *when* $s > s_0$; $c_0^B(s) > c_0^A(s) > c_0^{\mu,\nu}(s)$ *when* $s < s_0$.
3. *If* $-\pi/2 < \theta_{\mu\nu} < 0$ *and* $\mu A + \nu B < 0$, *then* $c_0^{\mu,\nu}(s) > c_0^B(s) > c_0^A(s)$ *when* $s < s_0$; $c_0^A(s) > c_0^B(s) > c_0^{\mu,\nu}(s)$ *when* $s > s_0$.

Proof. These conclusions follow easily from examination of the equations

$$c_0^B(s) - c_0^{\mu,\nu}(s) = \frac{(A-B)\mu}{Bs(1-s)(\mu A + \nu B)}(s - s_0), \tag{4.7}$$

$$c_0^{\mu,\nu}(s) - c_0^A(s) = \frac{(B-A)\nu}{As(1-s)(\mu A + \nu B)}(s - s_0), \tag{4.8}$$

and noting $0 < A < B < 1/2$, $s \in (0,1)$. ∎

The results of Lemma 4.4 are summarized in Figure 4.4(a).

PROPOSITION 4.5. *If* $c_2 > c_1$, *then* $s_e > s_1$; *if* $c_2 < c_1$, *then* $s_e < s_1$.

Proof. The proof follows from the application of Lemma 4.4 with $s_0, c_0 = s_{2^*}, c_2$. Construction of the contact discontinuity C_y requires $c_1^B(s) = c_{s_2^*}^B(s)$ as shown in Figure 4.4(b). Thus if $c_2 > c_1$, all possible locations for the state s_e, c_1 lie to the right of s_1, c_1; if $c_2 < c_1$, all possible locations for the state s_e, c_1 lie to the left of s_1, c_1. ∎

We now address the nature of the W_{PR} wave.

PROPOSITION 4.6. *For* $c_2 > c_1$, W_{PR} *is an* S^+ *shock.*

Proof. The proof relies on the relationship between the shock base curves and the contact base coordinate lines. Since $c_2 > c_1$, by Proposition 4.5 $s_e > s_1$. Consider Figure 4.5 which shows the rarefaction base points $(f_s(s_1; c_1),\ f_s(s_e; c_1))$, the shock base point $\sigma(s_e, s_1; c_1)$, and the shock base curve $\sigma(s, s_1; c_1)$. This shock base curve ends at the contact base point $(g^A(s_1, c_1), g^B(s_1, c_1))$ which lies on the $c = c_1$ contact base coordinate curve. The c-family contact discontinuity separating the states s_1, c_1 and s_{2^*}, c_2 is a horizontal line (since this Riemann problem is "at infinity") and must pass through the contact base points $(g^A(s_1, c_1), g^B(s_1, c_1))$ and $(g^A(s_{2^*}, c_2), g^B(s_{2^*}, c_2))$. Since $c_2 > c_1$ the $c = c_2$ contact base coordinate curve

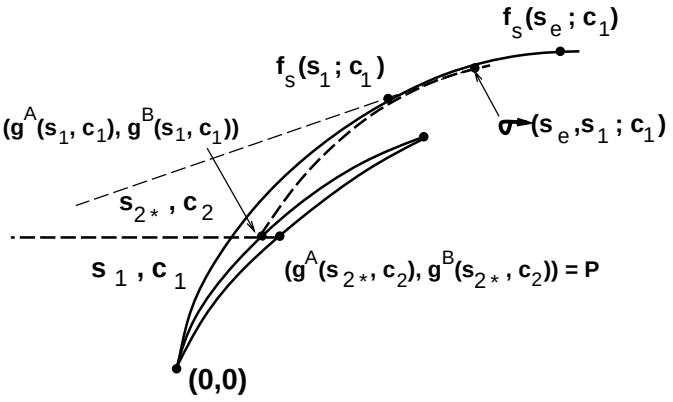

FIG. 4.5. *For $c_2 > c_1$ (i.e., $s_e > s_1$) the contact base point $(g^A(s_{2^*}, c_2), g^B(s_{2^*}, c_2))$ which is the point P in Figure* 4.2(b) *must lie below and to the right of the contact base point $(g^A(s_1, c_1), g^B(s_1, c_1))$. Consequently, W_{PR} must be an S^+ shock.*

must lie to the right of the $c = c_1$ contact base coordinate curve. Hence the contact base point $(g^A(s_{2^*}, c_2), g^B(s_{2^*}, c_2))$ must lie at the intersection of the horizontal line through $(g^A(s_1, c_1), g^B(s_1, c_1))$ and the $c = c_2$ contact base coordinate curve. However, $(g^A(s_{2^*}, c_2), g^B(s_{2^*}, c_2))$ is just the point P in Figure 4.2(b). Part of the boundary of the $S^+_{s_e,s_1}$ region is formed by the half line beginning at $\sigma(s_e, s_1; c_1)$ and passing through the rarefaction base point $f_s(s_1; c_1)$ (light dashed line in Figure 4.5). The relation (see section 2.4) between the rarefaction $f_s(s; c_1)$ and shock base curve $\sigma(s, s_1; c_1)$ guarantees that $(g^A(s_1, c_1), g^B(s_1, c_1))$ lies to the right of this boundary. Consequently, P also lies to the right of this boundary, i.e., P lies within the $S^+_{s_e,s_1}$ region. □

PROPOSITION 4.7. *For $c_2 < c_1$, W_{PR} is either* (i) *an R^+ rarefaction,* (ii) *an S^-R^+ composite, or* (iii) *an S^- shock.*

Proof. As $c_2 < c_1$, by Proposition 4.5 $s_e < s_1$. The resolution of the discontinuity between the states s_e, c_1 and s_1, c_1 involves Figure 3.1(b) where s_1, s_e and c_1 correspond, respectively, to the values s_l, s_r and c in Figure 3.1(b). If $g^B(s_{2^*}, c_2)$ (which is the y coordinate of point P) is less than $f^B_s(s_e, c_1)$ (which is the y coordinate of the rarefaction base point denoted $f_s(s_r; c)$ in Figure 3.1(b)), clearly point P can lie only in the R^+, S^-R^+, or S^- regions indicated in the figure.

We need therefore consider only the case $f^B_s(s_e, c_1) < g^B(s_{2^*}, c_2)$. Since $c_2 < c_1$, the contact base coordinate curve $g(s; c_2)$ lies above the curve $g(s; c_1)$. The contact discontinuity C_{PQ} crosses the contact base coordinate curve $g(s; c_2)$ at the base point $P = (g^A(s_{2^*}, c_2), g^B(s_{2^*}, c_2))$ and the curve $g(s; c_1)$ at the contact base point $(g^A(s_e, c_1), g^B(s_e, c_1))$. The horizontal contact C_y passes through the base points P and $(g^A(s_1, c_1), g^B(s_1, c_1))$. Since the tangent to $g(s; c_1)$ at the base point $(g^A(s_e, c_1), g^B(s_e, c_1))$ has to meet the rarefaction base curve $f_s(s; c_1)$ at the base point $(f^A_s(s_e, c_1), f^B_s(s_e, c_1))$, and since both the rarefaction and contact base coordinate curves are concave down, this rarefaction base point $(f^A_s(s_e, c_1), f^B_s(s_e, c_1))$ has to be on a segment of the rarefaction base curve $f_s(s; c_1)$ lying inside the "triangular" region having vertices P, $(g^A(s_e, c_1), g^B(s_e, c_1))$ and $(g^A(s_1, c_1), g^B(s_1, c_1))$ as shown in Figure 4.6. (Note that we are considering the case $f^B_s(s_e, c_1) < g^B(s_{2^*}, c_2)$.) Since the rarefaction base curve is concave down, point P is located left of the tangent line to the rarefaction base curve $f_s(s; c_1)$ at the point $(f^A_s(s_e, c_1), f^B_s(s_e, c_1))$.

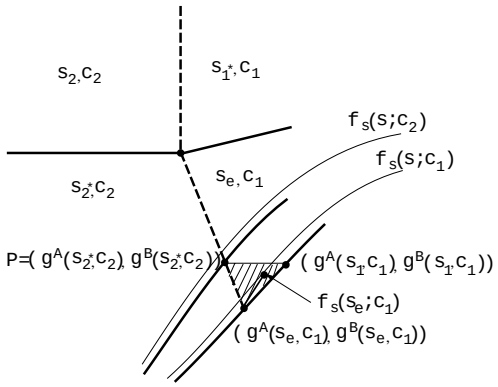

FIG. 4.6. *For $c_2 < c_1$, the rarefaction base point $(f_s^A(s_e, c_1), f_s^B(s_e, c_1))$ has to be on a segment of the rarefaction base curve $f_s(s; c_1)$ lying inside the "triangular" region if $f_s^B(s_e, c_1) < g^B(s_{2*}, c_2)$. This figure is for the $CSCW_x$ case; the $CRCW_x$ case has a similar "triangular" region.*

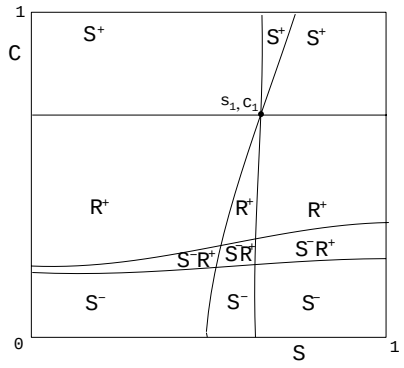

FIG. 4.7. *Identity of the s-family wave W_{PR} as a function of the location in phase space of (s_2, c_2) relative to (s_1, c_1).*

This implies point P can lie only in the S^-R^+ or S^- regions indicated in Figure 3.1(b). □

Figure 4.7 summarizes the results for the identity of the s-family wave W_{PR} according to the location of the initial state s_2, c_2 relative to s_1, c_1 in phase space. There are 12 regions formed by the combined classification of the solution behavior at infinity and the W_{PR} wave type.

This classification is generic with the following exception. Due to the finite limits on the values of s and c in the model, as the value of c_1 is lowered, the S^- and S^-R^+ regions in Figure 4.7 will vanish. Additionally, the width of the S^-R^+ region varies with c_1, increasing in width as c_1 decreases. As $c_1 \to 1$, the S^-R^+, R^+, and S^+ regions shrink to zero area. These observations are based upon numerical computations designed to identify the phase space boundaries of the S^+, R^+, S^-R^+, and S^- regions. The numerical computations vary s_1, c_1 over their full range of values and for each fixed pair s_1, c_1 perform the classification for a extensive choice of values of s_2, c_2 covering phase space on a fine grid ($\Delta s = 2 \cdot 10^{-4}$, $\Delta c = 1 \cdot 10^{-4}$). An illustration of the results for six choices of s_1, c_1 ($s_1 = 0.59$ held fixed, and c_1 varying over the range [0.4,0.95]) is given in Figure 4.8.

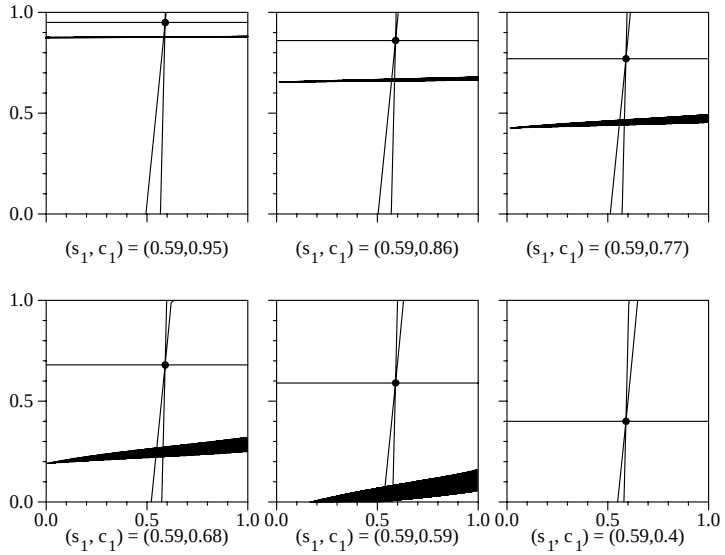

FIG. 4.8. *Due to the finite range of c and s, certain realizations of the wave type W_{PR} may not appear for all values of s_1, c_1.*

5. Solution construction for the single quadrant Riemann problem. In this section, we present the detailed solutions for each of the 12 solution types in Figure 4.7 and discuss the final wave interaction in region R for each case.

For each solution construction the same general steps are used. With reference to Figure 4.2(b), they are as follows:

- From separate 1-D Riemann problems, determine the states s_{1^*} and s_{2^*} (Lemma 4.3) and the s-family waves W_x, W_y "at infinity."
- The interaction at Q of the s-family wave W_y (separating state (s_2, c_2) and (s_{2^*}, c_2)) with the contact discontinuity C_x separating state (s_2, c_2) and (s_{1^*}, c_1) is resolved.
- The location of the point P of intersection of the contact discontinuities C_y and C_{PQ} is determined. It has coordinates $P = (g^A(s_{2^*}, c_2), g^B(s_{2^*}, c_2))$.
- The direction of the contact discontinuity C_{PQ} separating constant states s_{2^*}, c_2 and s_e, c_1 is determined.
- The value of the intermediate state saturation s_e is determined (Lemma 4.3).
- The s-family wave W_{QR} separating constant states (s_{1^*}, c_1) and (s_e, c_1) is resolved.
- The s-family wave W_{PR} separating constant states (s_1, c_1) and (s_e, c_1) is resolved.
- The interaction involving the s-family waves W_x, W_{QR}, and W_{PR} is resolved in the region R.

We present each solution for all 12 cases. However, due to space limitations, we display only simplified figures of each solution in Figure 5.1. For complete figures, we refer to [2]. We focus our discussion on the region R.

5.1. CSCS. The solution contains only contact discontinuities (dashed lines) and s-family shocks (solid). Each contact discontinuity is a straight line whose tangent passes through the two relevant contact base points. Each shock separates two constant states and is therefore a straight line whose tangent passes through the appropriate shock base point. W_y and W_{QR} are S^- shocks. (The shock-contact in-

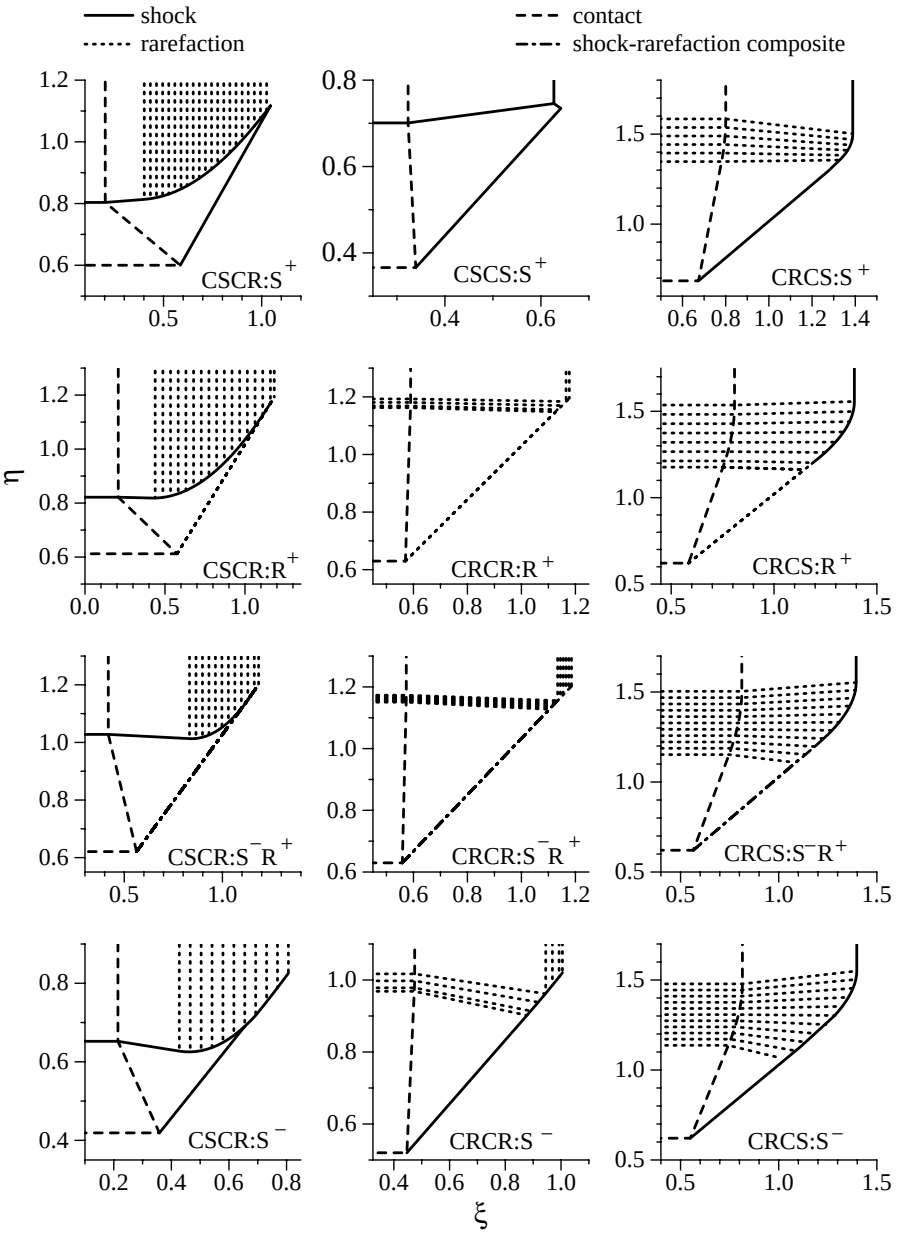

FIG. 5.1. *All* 12 *solutions in the* (ξ, η) *plane.*

teraction at the point Q preserves shock type.) The shock W_x and the short third shock emerging from the W_{QR}, W_x interaction point are also of type S^-. W_{PR} is a shock of type S^+ by Proposition 4.6.

5.2. CSCR. The CSCR case breaks into four subcases, one for $c_2 > c_1$ and three for $c_2 < c_1$.

5.2.1. $\boldsymbol{c_2 > c_1}$**.** As for the CSCS case, the waves W_y and W_{QR} are S^- type shocks; W_{PR} is always a shock of type S^+ by Proposition 4.6. W_x is a rarefaction

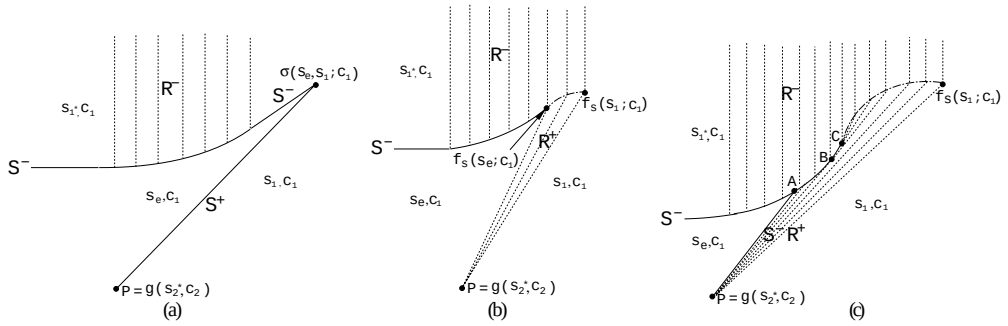

FIG. 5.2. *CSCR solution: Details of the W_{QR} and W_{PR} wave interaction at point R for CSCR solutions when the W_{PR} wave is of type* (a) S^+, (b) R^+, (c) S^-R^+.

fan of type R^-. Each characteristic wave in the R^- fan is a straight half line whose tangent passes through to the appropriate rarefaction base point. Details of the interaction are given in Figure 5.2(a). The interaction of the S^- shock W_{QR} and the R^- rarefaction fan results in a continuously curving shock of decaying strength. As $s_e > s_1$, the S^- shock interacts with the R^- fan and "emerges" from this interaction with a straight segment that ends at the shock base point $\sigma(s_e, s_1; c_1)$. The S^+ shock W_{PR} also terminates at this shock base point.

5.2.2. $c_2 < c_1$. There are three different cases, labeled by the possible type for the W_{PR} wave.

$\mathbf{R}^+$. For a range of values of c_2, W_{PR} is an R^+ rarefaction fan centered at the point P. (P is the contact base point $(g^A(s_{2^*}, c_2), g^B(s_{2^*}, c_2))$.) W_y and W_{QR} are S^- shocks, and W_x is an R^- rarefaction fan. Details of the W_x, W_{QR} and W_{PR} interaction are given in Figure 5.2(b). Upon interacting with the R^- rarefaction, the S^- shock begins to curve and weaken. One edge of the R^+ rarefaction fan centered at P also meets the S^- shock at this base point. Over the range of state values (s_e, c_1) to (s_1, c_1) the characteristic lines of both R^+ and R^- rarefaction fans meet along the section of the rarefaction base curve between the base points $f_s(s_e; c_1)$ and $f_s(s_1; c_1)$.

This $\mathrm{W}_{QR} \leftrightarrow \mathrm{W}_x$ wave interaction is of the type $S^- \leftrightarrow R^-$. Theorem 1 of Zhang and Zhang [20], based upon analysis of the four quadrant Riemann problem for a single conservation law, states that either "the S^- shock will penetrate the R^- wave completely" or "during the penetration, an R^+ wave will form having the S^- shock as an envelope of characteristic lines of the R^+ (i.e., an S^-R^+ composite wave is formed)." In our entropy obeying solution, however, the S^- shock terminates with zero strength at the rarefaction base point $f_s(s_e; c_1)$ and neither "complete penetration" nor "composite wave formation" occurs. It is currently unclear as to whether the presence of the W_{PR} R^+ wave emanating from P is the reason for the behavioral difference between our observed solution and the Zhang–Zhang theorem. (We do, however, find composite waves occurring in $S^- \leftrightarrow R^-$ interactions in our S^-R^+ labeled subcases of CSCR, CRCS, and CRCR.)

$\mathbf{S}^-\mathbf{R}^+$. For a range of values of c_2, W_{PR} becomes an S^-R^+ composite wave with the R^+ fan centered at the point P (the contact base point $(g^A(s_{2^*}, c_2), g^B(s_{2^*}, c_2))$. The S^-R^+ composite wave W_{PR} is very narrow; Figure 5.2(c) gives an enlarged sketch of this wave and the interaction region of the waves W_{QR}, W_x, and W_{PR}. The straight S^- shock begins to curve upon interaction with the upper R^- rarefaction

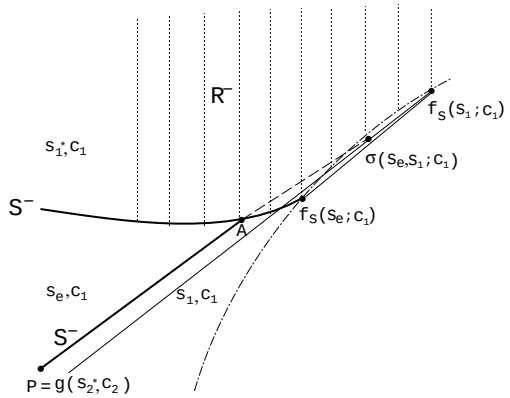

FIG. 5.3. *Details of the W_{QR} and W_{PR} wave interaction at point R for the CSCR solution with $c_2 < c_1$. (The W_{PQ} wave is of type S^-.)*

fan. At point A it also interacts with the S^- shock from the lower S^-R^+ composite wave. The resultant shock (curve segment AB) of S^- type separates the R^- and R^+ rarefaction fans. At point B a characteristic of the R^+ fan meets this S^- shock tangentially. On the segment AB the effective flux function $\hat{n} \cdot (f^A, f^B)$, where $\hat{n}$ is normal to the shock, remains convex. On the segment BC the effective flux develops a single inflection point and a composite S^-R^+ wave forms with the characteristics of this R^+ wave "emerging" tangentially from the S^- shock. This second R^+ fan "merges" continuously with the remainder of the R^+ fan centered on point P. At C the S^- shock decays to zero strength (the characteristic state (s^*, c_1) on both sides of the shock is the same) and meets the rarefaction base curve at the base point $f_s(s^*; c_1)$. Over the segment of rarefaction base curve from C to $f_s(s_1; c_1)$ the characteristics of the upper R^- and lower R^+ rarefaction waves meet continuously. Composite waves of the type generated over the segment BC have been seen in the work of Zhang and Zheng [22] and even as early as the work by Wagner [17]. In these earlier works, however, one side of the "precursor" shock segment (i.e., the shock segment AB) was always a constant state. In our case the state on both sides of the precursor segment is changing continuously.

S^-. For the final range of values of $c_2 < c_1$, W_{PR} is an S^- shock, W_{QR} is an S^- shock, and W_x is an R^- rarefaction.

The following lemma shows that the W_{QR} S^- shock must interact with the W_{PR} S^- shock before W_{QR} has "completed" its interaction with the W_x R^- rarefaction.

LEMMA 5.1. *The W_{PR} and W_{QR} S^- shock waves must interact when the state on the upper side of W_{PR} has a saturation value lying in the range (s_{1^*}, s_e).*

Proof. The proof is geometrical. Figure 5.3 shows the rarefaction base curve, the base points $f_s(s_1; c_1)$, $f_s(s_e; c_1)$, and the shock base point $\sigma(s_1, s_e; c_1)$ which lies in their convex hull. As W_{PR} is an S^- shock, the point P must lie to the left of the straight dashed line which passes through the two base points $f_s(s_1; c_1)$ and $\sigma(s_1, s_e; c_1)$. Assume the S^- shock W_{QR} *does not* interact with W_{PR} but only with the R^- rarefaction fan W_x. Then, as shown in Figure 5.3, the shock W_{QR} must end at zero strength at the rarefaction base point $f_s(s_e; c_1)$. However, we see that this is geometrically impossible without an interaction with the W_{PR} shock. Hence the two shocks W_{PR} and W_{QR} must interact as claimed. □

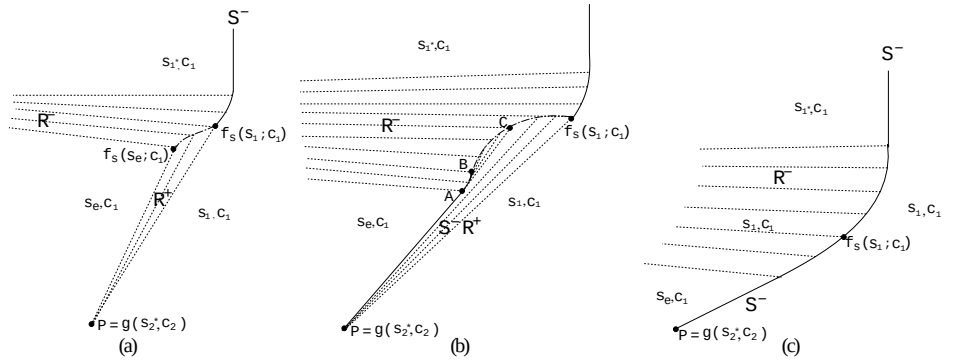

FIG. 5.4. *Details of the W_{QR} and W_{PR} wave interaction at point R for CRCS solutions when the W_{PR} wave is of type* (a) R^+, (b) S^-R^+, (c) S^-.

The shocks W_{PR} and W_{QR} must interact at a point A. From A to $f_s(s_1; c_1)$ an S^- shock separates the R^- rarefaction from the constant state (s_1, c_1). This shock ends with zero strength at the base point $f_s(s_1; c_1)$.

5.3. CRCS. The CRCS case also breaks into four subcases, one for $c_2 > c_1$ and three for $c_2 < c_1$.

5.3.1. $c_2 > c_1$. W_y and W_{QR} are R^- rarefaction fans; W_{PR} is an S^+ shock by Proposition 4.6; W_x is an S^- shock. We note that, as in the isotropic case [3], the contact-rarefaction interaction produces a dynamic diffraction of the W_{QR} rarefaction fan, *in this case focusing the fan.* The S^- shock interacts with the W_{QR} fan; both S^+ and S^- shocks meet at the shock base point $\sigma(s_1, s_e; c_1)$.

5.3.2. $c_2 < c_1$. There are three different cases, again labeled by the possible type for the W_{PR} wave. In all cases the W_y and W_{QR} waves are rarefactions; interaction with the C_x contact discontinuity produces diffraction of the W_{QR} fan.

$\mathbf{R}^+$. For a range of values of $c_2 < c_1$, a centered R^+ rarefaction fan forms at the point P. Details of the W_x, W_{QR} and W_{PR} interaction are given in Figure 5.4(a). The saturations s_e, s_1 and s_{1^*} are ordered $s_e < s_1 < s_{1^*}$. W_x is an S^- shock. Due to the relative ordering of s_e, s_1 and s_{1^*}, W_x interacts with W_{QR} until it decays to zero strength at the rarefaction base point $f_s(s_1; c_1)$. The remainder of the W_{QR} rarefaction and W_{PR} meet continuously along the rarefaction base curve between the points $f_s(s_1; c_1)$ and $f_s(s_e; c_1)$.

$\mathbf{S}^-\mathbf{R}^+$. For the next lowest range of values of $c_2 < c_1$, the W_{PR} wave becomes an S^-R^+ composite wave with the R^+ fan centered at the point P. Details of the interaction is given in Figure 5.4(b). W_x interacts with the W_{QR} fan and terminates tangentially, at zero strength, at the base point $f_s(s_1; c_1)$. The S^- shock in the composite W_{PR} wave interacts with the W_{QR} fan at A. It curves as a result of the interaction; over a segment (AB in Figure 5.4(b)) the effective flux function $\hat{n}\cdot(f^A, f^B)$ continues to have an inflection point and a composite S^-R^+ wave continues to form with the characteristics of the R^+ fan "emerging" tangentially from the shock along the segment AB. This fan merges continuously with the R^+ fan centered on point P. The point B is a rarefaction base point $f_s(\bar{s}; c_1)$ for some saturation $\bar{s}$ in the interval (s_e, s_1). Between the respective characteristics $(\bar{s}, c_1)$ and (s_1, c_1) the $\mathrm{W}_{QR}R^-$ and the R^+ rarefaction fans meet continuously along the rarefaction base curve.

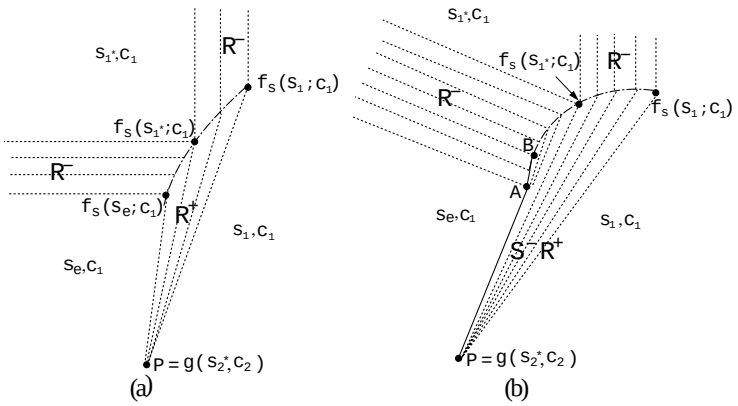

FIG. 5.5. *Details of the W_{QR} and W_{PR} wave interaction at point R for the CRCR solutions when the W_{PR} wave is of type* (a) R^+, (b) S^-R^+.

$\mathbf{S^-}$. For the lowest range of values of c_2, W_{PR} is an S^- shock. The S^- shocks W_x and W_{PR} interact separately with either end of the R^- rarefaction W_{QR}. Both shocks meet tangentially at the rarefaction base point $f_s(s_1; c_1)$, decaying to zero strength at this point. Details of the interaction are given in Figure 5.4(c).

5.4. CRCR. In this case, $c_2 < c_1$. We have the state ordering $s_e < s_{1^*} < s_1$. W_y, W_{QR}, and W_x are all R^- rarefaction fans. Again there are three possibilities for W_{PR}.

$\mathbf{R^+}$. For a range of values of $c_2 < c_1$, a centered R^+ rarefaction fan forms at the point P. Details of the W_x, W_{QR} and W_{PR} interaction are given in Figure 5.5(a). All rarefaction fans meet continuously along the rarefaction base curve between the base points $f_s(s_e; c_1)$ and $f_s(s_1; c_1)$. There are no s-family shocks in the solution.

$\mathbf{S^-R^+}$. For the next range of values of $c_2 < c_1$, W_{PR} forms an S^-R^+ composite wave with the R^+ fan centered at the point P. The W_{PR} R^+ rarefaction meets the upper part of the W_{QR} R^- rarefaction continuously along the rarefaction base curve between the base points $f_s(s_{1^*}; c_1)$ and $f_s(s_1; c_1)$. The interaction of the composite wave W_{PR} and the lower part of the W_{QR} R^- rarefaction is given in Figure 5.5(b) and is the same as in Figure 5.4(b).

$\mathbf{S^-}$. For the lowest range of values of $c_2 < c_1$, W_{PR} forms an S^- shock. It interacts separately with the W_x and W_{QR} rarefaction fans, meeting the base curve tangentially at the base point $f_s(s_1; c_1)$ where it decays to zero strength.

6. Discussion. It is tempting to comment on the generalizability of the construction technique utilized here to Riemann problems involving systems in $\mathbf{R}^2$. In $\mathbf{R}^2$ the integral curves (characteristic lines) for the ith family are given by (see, e.g., (2.12) of this paper, or (2.5) and following in [12])

$$\frac{\partial \eta(\xi)}{\partial \xi} = \lambda_i = \frac{\eta - R_{i,\eta}(U)}{\xi - R_{i,\xi}(U)}. \tag{6.1}$$

Here $U = (u_1, \ldots, u_n)$ denotes the solution. The rarefaction base points associated with this family are the points $(R_{i,\xi}(U), R_{i,\eta}(U))$. An ith family integral curve having state value U_0 must have a tangent line passing through the rarefaction base point $(R_{i,\xi}(U_0), R_{i,\eta}(U_0))$.

If the jth family is a contact discontinuity, the contact base points are similarly defined:

$$\frac{\partial \eta(\xi)}{\partial \xi} = \lambda_j = \frac{\eta - C_{j,\eta}(U)}{\xi - C_{j,\xi}(U)}; \tag{6.2}$$

the contact base points associated with this family are the points $(C_{j,\xi}(U), C_{j,\eta}(U))$. Such a contact discontinuity separating two states U_l and U_r must satisfy $\lambda_j(U_l) = \lambda_j(U_r)$; the tangent line to the contact discontinuity must pass through the two contact base points $(C_{j,\xi}(U_l), C_{j,\eta}(U_l))$ and $(C_{j,\xi}(U_r), C_{j,\eta}(U_r))$.

Finally a (smooth) discontinuity for the ith family satisfies a Rankine–Hugoniot condition

$$\frac{\partial \eta(\xi)}{\partial \xi} = \sigma_i = \frac{\eta - S_{i,\eta}(U_l, U_r)}{\xi - S_{i,\xi}(U_l, U_r)}. \tag{6.3}$$

(See, e.g., (2.16) of this paper, or (2.8.2) in [12].) The shock base points associated with this family are the points $(S_{i,\xi}(U_l, U_r), S_{i,\eta}(U_l, U_r))$; a shock discontinuity separating states U_l and U_r must have a tangent line passing through this shock base point.

Base points provide ODE integration (tangent) directions for the characteristic curves and smooth discontinuity curves, enabling the tracing of such curves in the ξ, η plane. Constant state conditions on characteristic curves or changing state conditions on each side of discontinuity curves implicitly define a (presumably) continuous path through a relevant set of base points. In this paper, the second state variable $u_2 = c$ is a Riemann invariant for the s-family of waves, and the rarefaction base points form curves (parametrized by values of c) vastly simplifying characteristic curve tracing. A simplifying organization of the set of shock base points also follows from the same invariance.

It is, however, the development of relationships between base points of different types (i.e., between the functions R_i, C_i, and S_i above) that seems to be critical in achieving "analytic" solution. The critical question is whether one can find general relationships that hold independent of the model under consideration. It is encouraging that equations such as (2.26) and (2.27) between the R and S functions for the same wave family are somewhat general relationships which hold in any scalar region of the solution and are independent of the form of the flux function f. (By scalar region we mean any region in which the variables associated with all but one wave family are constant.)

ERROR OF THE NETWORK APPROXIMATION FOR DENSELY PACKED COMPOSITES WITH IRREGULAR GEOMETRY*

LEONID BERLYAND† AND ALEXEI NOVIKOV‡

Abstract. We introduce a discrete network approximation to the problem of the effective conductivity of the high contrast, highly packed composites in which inclusions are irregularly (randomly) distributed in a hosting medium so that a significant fraction of them may not participate in the conducting spanning cluster. For this class of spacial arrays of inclusions we derive a discrete network approximation and obtain its a priori error estimate. We obtained an explicit dependence of the network approximation and its error on the irregular geometry of the inclusions' array. We use variational techniques to provide rigorous mathematical justification for the approximation and its error estimate.

Key words. effective conductivity, discrete network, error estimate, variational bounds

1. Introduction.

We study the effective properties such as the effective conductivity or the effective dielectric constant of composite materials in which a large number of inclusions are irregularly (randomly) distributed in a homogeneous hosting medium (matrix). For ease of presentation and clarity we concentrate here on the effective conductivity. We are particularly interested in the case of the high contrast, highly packed particulate composites, that is, when the conductivity of the inclusions is much larger than the conductivity of the hosting medium and the volume fraction of the inclusions is very high. High contrast composites are extremely attractive for the design of new materials with physical properties better than those of their constituents. The case when the concentration of the filling inclusions is high is particularly relevant to polymer/ceramic composites, because a polymer matrix compensates for the brittle nature of ceramics which is their main weakness. A survey on the relevant engineering problems in two and three dimensions (fibers and particles in a matrix) can be found in [3].

Our main tool is (a modification of) the discrete network approximation (DNA) of [3] for a two-dimensional composite, where the inclusions are modeled as identical disks. We focus on the two key issues arising for this approximation. The first is the explicit error estimate of the DNA to the continuum problem of effective conductivity. The second is a quantitative estimate on how the connectivity patterns for various irregular distributions of the inclusions affect the effective conductivity.

The main advantage of our DNA is that it is easy to implement numerically and at the same time it captures geometric patterns of the location of inclusions in the matrix. The importance of the geometric patterns in evaluation of the effective properties of

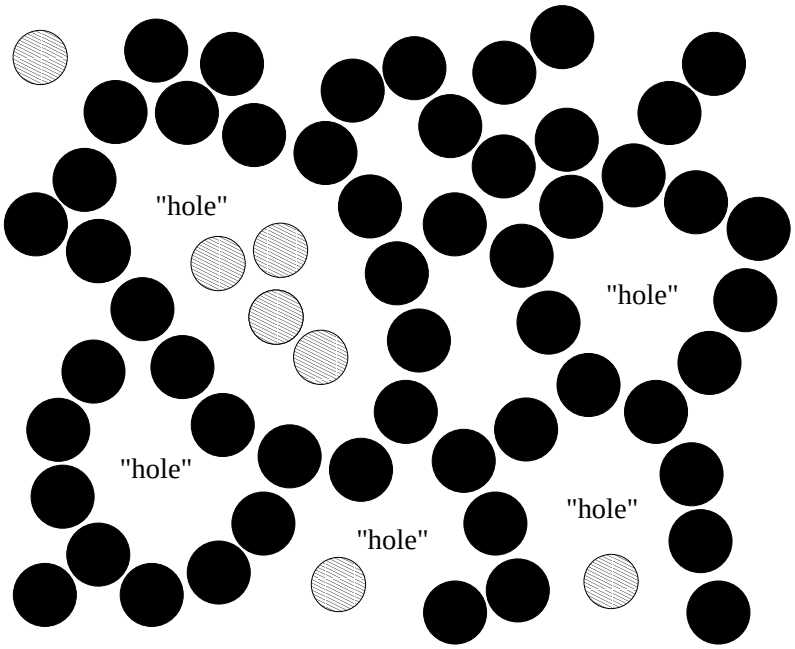
high contrast composites can be seen in the analysis of periodic structures. It was observed that for such periodic composites of moderate volume fraction, that is, away from the almost touching situation, the effective conductivity is of the order of the conductivity of the matrix (see, for example, [2], [16], [17], and references therein). In other words, the filler has almost no effect on the effective conductivity. However, in the case of almost touching inclusions, the effective conductivities of two periodic structures with different locations of inclusions in the matrix can be significantly different for the same volume fraction. For example, if the contrast ratio of the constituents is assumed to be ∞, then for the same volume fraction of disks (equal to $\pi/4$) for the hexagonal lattice, the effective conductivity $\hat{a} = O(1)$ (see [4]), while for the square lattice $\hat{a} = \infty$ (see [13]).

The case of irregularly distributed inclusions is not as well understood as the periodic case. Since the volume fraction of the inclusions is high, the irregular connectivity patterns in the whole composite (percolation effects) determine the behavior of the effective properties. Moreover, it was observed that the irregular connectivity patterns of conducting inclusions can greatly increase the effective conductivity. Therefore, there is a need for a simple model that is still able to capture percolation effects. Also, while for a given periodic structure the volume fraction of the inclusions uniquely determines the distances between the inclusions, this is no longer true for irregular structures, and one should search for a model with a new parameter which describes the local geometry when the inclusions are close to touching. Such a model (the network approximation) was proposed in [3] in two dimensions. The notion of the *interparticle distance parameter* for closely packed ("randomized" hexagonal) patterns, based on the Voronoi tessellation, was introduced there. In the present work we generalize this notion for a broad class of geometrical patterns. This is important in practical applications, because in real composites the array of the inclusions is often highly nonuniform due to the manufacturing process.

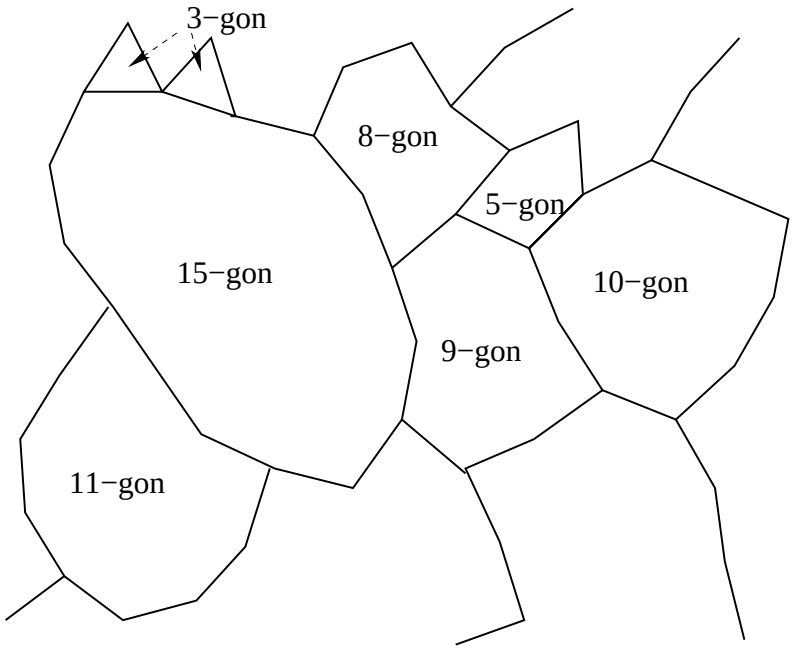
Our new approach allows us to derive an *explicit error estimate* for the DNA. Since most of the existing estimates provide an order of the magnitude of the error only, such explicit estimates are rare in homogenization theory. The class of geometrical patterns that can be handled by our approach includes a nonuniform irregular distribution, when a significant fraction of the inclusions does not participate in the conducting spanning cluster. This approach allows us to relax the close packing condition of [3] so that not all the "neighboring" inclusions (disks) are closely spaced. More specifically, we introduce and study the $\delta - \mathbf{N}$ close packing condition, which loosely speaking allows for "holes" with the perimeter of order $\mathbf{N}\,R$ in the conducting spanning cluster. Here R is the radius of the inclusions, and $\mathbf{N}$ is the number of inclusions in the perimeter of the largest hole in the conducting cluster (see Figure 1.1). Thus we account quantitatively for the presence of these holes in the composite.

The question of error estimates was raised by I. Babuska, because the analysis of [3] is asymptotic in the interparticle distance parameter and does not provide an error estimate. The analysis in the present paper does not use asymptotics, and it holds for any (small) finite value of the *relative* interparticle distance parameter. This enables us to prove the following error estimate for the effective conductivity $\hat{a}$:

$$\frac{|\hat{a} - I|}{I} \le C(\mathbf{N})\sqrt{\frac{\delta}{R}}, \tag{1.1}$$



(a) Black disks form the conducting cluster.
Hatched disks do not participate in the cluster.



(b) The graph that corresponds to the conducting cluster in (a). An **N**-gon $\mathbf{N} \geq 4$ corresponds to a "hole" of size **N**.

FIG. 1.1. *The conducting cluster in a composite with "holes".*

where I is the value of effective conductivity provided by the network approximation, δ/R is the relative interparticle distance, and for the constant $C(\mathbf{N})$ we provide an upper bound $C(\mathbf{N}) \leq 2.56\mathbf{N}^4$.

The discrete network models for various high contrast composites have been used extensively in the physics literature (see [1], [11], [12], [14], [18], [19]); however, the relation between the network and the underlying continuum problem was not studied there. In [15], high contrast conductivity problems were first formulated and analyzed using variational methods. There the high contrast field was of the form

$$e^{S(x)/\epsilon} \tag{1.2}$$

with a *smooth* function $S(x)$. In particular, the asymptotic analysis in the high contrast ratio parameter ϵ has been carried out in [15] for a random checkerboard model.

For the Kozlov's function (1.2) a *network* asymptotic approximation in the high contrast parameter ϵ was developed in [6], [7], [8], [9]. It was *rigorously proved* in [8] that the network approximates the original continuum problem. The analysis of [8] was carried out for high contrast continuum problems arising in imaging, when the materials' properties are not known and it is convenient to model the high contrast in a simple geometric manner by (1.2). In this model the key parameter, which determines the conductivity of the edges in the network, is $\sqrt{k_+/k_-}$, where k_+ and k_- are the principal curvatures at the saddle points of $S(x)$.

Our analysis applies to a class of physical problems where $S(x)$ is *not smooth*. In our case $S(x)$ is the characteristic function of the disks, $S(x) = 1$, $S(x) = 0$, on the inclusions and in the matrix, respectively (see Figure 2.1). Furthermore, in our case the high contrast parameter $\epsilon = 0$ and the analysis is carried out when the relative interparticle distance parameter is sufficiently small. In other words, we consider the infinite contrast material with ideally conducting inclusions. This assumption is valid for a variety of particulate composites (particles or fibers in a matrix), and it is in agreement with bounds [10] which imply that if the contrast ratio is greater than several hundred, then for practical purposes it can be taken to be infinite.

The paper is organized as follows. In section 2 we give the formulation of the problem and construct the modified DNA. In section 3 we formulate and prove the main result: an explicit analytical a priori error estimate for this approximation. We also present there numerical a posteriori error estimates.

2. Formulation.

2.1. Mathematical model. Consider a two-dimensional rectangular two-phase composite that consists of a matrix filled by a large number of inclusions. The inclusions are ideally conducting. Assume that all the inclusions are identical nonoverlapping disks. The centers of the disks are irregularly distributed in the rectangular domain. The distribution of the disks is dense; that is, the characteristic distance between two neighbors is much smaller compared to the radius of the disks.

Denote the domain occupied by the composite by $\Pi = [-L, L] \times [-1, 1]$ (Figure 2.1). Denote the disks that model the inclusions by D_i, $i = 1, \ldots, N$, where N is the total number of disks. Then

$$Q_p = \Pi \backslash \cup_{i=1}^{N} D_i \tag{2.1}$$

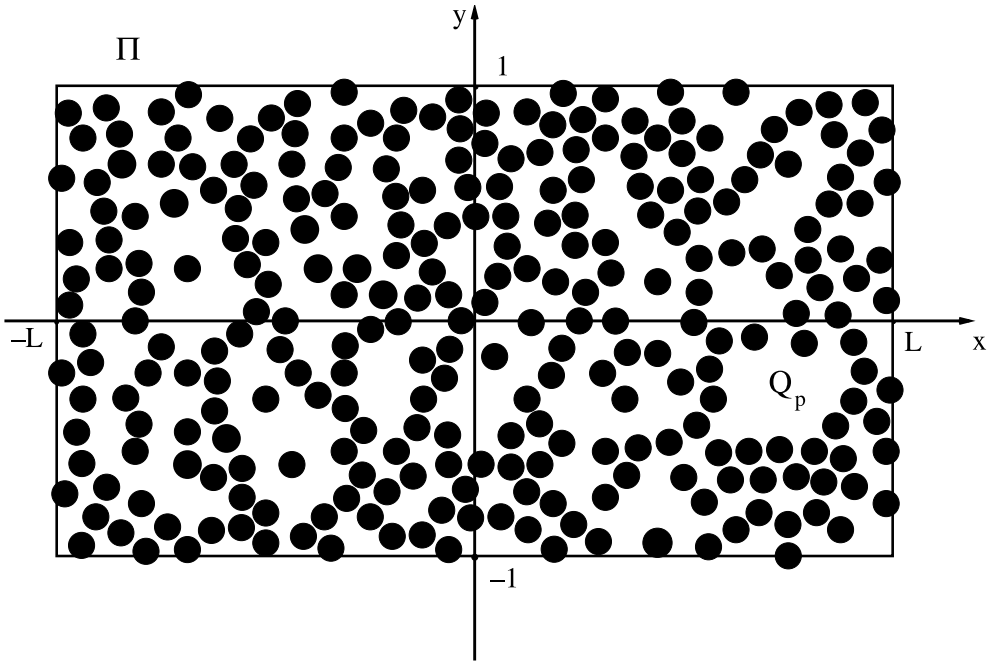


FIG. 2.1. *The composite.*

is the matrix. The potential $\phi(x,y) = \phi(\mathbf{x}), \mathbf{x} = (x,y)$ satisfies

$$\begin{aligned} &\text{(a)} && \Delta\phi = 0 \text{ in } Q_p, \\ &\text{(b)} && \frac{\partial\phi(\pm L, y)}{\partial \mathbf{n}} = 0, \\ &\text{(c)} && \int_{\partial D_i} \partial\phi/\partial\mathbf{n}\, d\mathbf{x} = 0 \text{ for all } i, \\ &\text{(d)} && \phi(\mathbf{x}) = t_i \text{ in } \partial D_i, \\ &\text{(e)} && \phi(x, \pm 1) = \pm 1. \end{aligned} \tag{2.2}$$

We apply the potential ± 1 to the boundaries $y = \pm 1$ (respectively, (2.2)(e)) and assume insulating boundary conditions on the vertical boundaries (2.2)(b). The assumption that the disks are ideally conducting implies (2.2)(c–d), where the constants t_i in (2.2)(d) are arbitrary and they should be determined by solving the system (2.2). The integral condition (2.2)(c) means that the total flux through any disk is zero. If ϕ satisfies (2.2), then the effective conductivity $\hat{a}$ is defined by

$$\hat{a} = \frac{1}{4L} \int_{Q_p} |\nabla\phi|^2 d\mathbf{x}, \tag{2.3}$$

or (see [3])

$$\hat{a} = \frac{1}{2L} \int_{y=1} \nabla\phi \cdot \mathbf{n}\, d\mathbf{x} - \frac{1}{2L} \int_{y=-1} \nabla\phi \cdot \mathbf{n}\, d\mathbf{x} - \frac{1}{4L} \int_{Q_p} |\nabla\phi|^2 d\mathbf{x}, \tag{2.4}$$

because

$$\int_{y=1} \nabla\phi \cdot \mathbf{n}\, d\mathbf{x} - \int_{y=-1} \nabla\phi \cdot \mathbf{n}\, d\mathbf{x} = \int_{Q_p} |\nabla\phi|^2 d\mathbf{x}, \tag{2.5}$$

where $\mathbf{n}$ is the normal to the boundary $y = \pm 1$ and $\int_{y=\pm 1} \nabla\phi \cdot \mathbf{n}\, d\mathbf{x}$ are fluxes through the horizontal boundaries $y = \pm 1$, respectively.

There are two variational definitions (see [3]) of the effective conductivity $\hat{a}$. The first one is given by a minimization problem for the Dirichlet integral

$$\hat{a} = \frac{1}{4L} \min_{\tilde{\phi} \in V_p} \int_{Q_p} |\nabla \tilde{\phi}|^2 d\mathbf{x}, \tag{2.6}$$

where the minimum is taken over a class of all piecewise differentiable potentials $\phi(x, y) \in V_p$, where V_p is defined by

$$V_p = \{\phi \in H^1(Q_p) : \phi(\mathbf{x}) = t_i \text{ on } D_i, \phi(x, \pm 1) = \pm 1\}. \tag{2.7}$$

The Euler–Lagrange equations of the minimization problem (2.6), (2.7) are (2.2). The second variational formulation is given using the dual formulation (2.4):

$$\hat{a} = \frac{1}{2L} \max_{\tilde{\mathbf{v}} \in W_p} \left\{ \int_{y=1} \tilde{\mathbf{v}} \cdot \mathbf{n}\, d\mathbf{x} - \int_{y=-1} \tilde{\mathbf{v}} \cdot \mathbf{n}\, d\mathbf{x} - \frac{1}{2} \int_{Q_p} \tilde{\mathbf{v}}^2 d\mathbf{x} \right\}, \tag{2.8}$$

where the minimum is taken over a class of all fluxes (see [3] for details)

$$W_p = \left\{ \mathbf{v} \in L_2(Q_p) : \mathbf{v}(\pm L, y) \cdot \mathbf{n} = 0, \int_{\partial D_i} \mathbf{v} \cdot \mathbf{n}\, d\mathbf{x} = 0, \nabla \cdot \mathbf{v} = 0 \right\}. \tag{2.9}$$

Hence for any $\phi \in V_p$ and $\mathbf{v} \in W_p$ we have bounds

$$\frac{1}{2L} \left[\int_{y=1} \mathbf{v} \cdot \mathbf{n}\, d\mathbf{x} - \int_{y=-1} \mathbf{v} \cdot \mathbf{n}\, d\mathbf{x} - \frac{1}{2} \int_{Q_p} \mathbf{v}^2 d\mathbf{x} \right] \le \hat{a} \le \frac{1}{4L} \int_{Q_p} |\nabla\phi|^2 d\mathbf{x}. \tag{2.10}$$

Moreover, if $\mathbf{v} = \nabla\phi$, then the upper bound equals the lower bound in (2.10).

2.2. Discrete network. Following [3], we construct the discrete network using the notion of the Voronoi tessellation. We partition the matrix Q_p into simple nonoverlapping geometric figures—necks and triangles. This *triangle-neck partition* is an auxiliary construction, which is used in section 3 as a convenient and efficient tool for the construction of the trial functions for the error estimates.

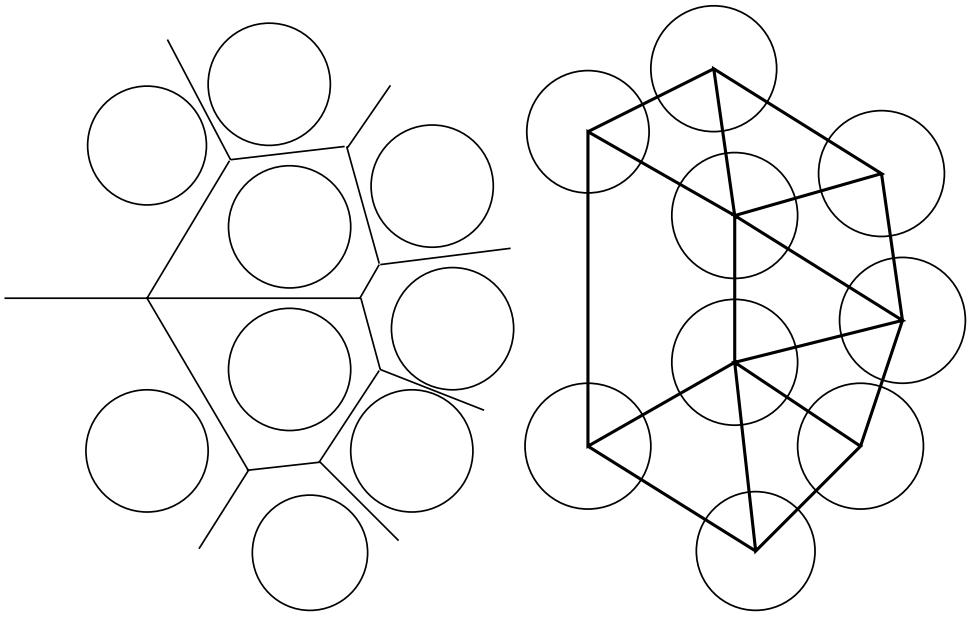
Consider the set of centers x_i, $i = 1, 2, \ldots, N$, of all disks D_i and construct the Voronoi tessellation for the vertices x_i, $i = 1, 2, \ldots, N$.

DEFINITION 2.1. *For a given distribution of vertices x_i, $i = 1, \ldots, N$, in the two-dimensional rectangular domain Π the Voronoi cell V_i associated with x_i is a polygon that consists of all the points in Π at least as close to x_i as to any other vertex. The set of all such Voronoi cells V_i is the Voronoi tessellation of Π.*

Also construct the Delaunay graph (triangulation) dual to the Voronoi tessellation, that is, connect every pair of vertices x_i and x_j by the line segment (edge) e_{ij} if their respective cells share a common edge in the Voronoi tessellation (see Figure 2.2).

DEFINITION 2.2. *Any two disks D_i and D_j are said to be* neighbors *if their centers x_i and x_j are connected by the edge e_{ij}.*

Consider any two neighbors D_i and D_j with the centers x_i and x_j, respectively (see Figure 2.3(a)). Denote by O_n and O_p the endpoints of the common edge of their Voronoi cells V_i and V_j. Then connect the center x_j with all the vertices of its Voronoi



(a) Voronoi tessellation (b) Delaunay graph

FIG. 2.2.

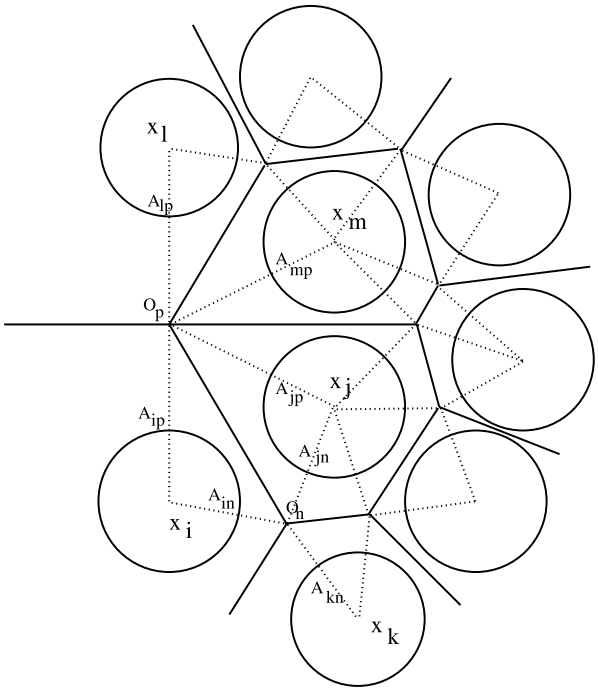
cell V_j by auxiliary line segments (dotted lines in Figure 2.3(a)). Denote by A_{jn} the intersection of the line segment x_jO_n with the circumference of the disk D_j. Finally, define similarly points A_{in} and A_{kn} and connect the points A_{in}, A_{jn}, and A_{kn}.

DEFINITION 2.3. *The* neck Π_{ij} *between the neighbors* D_i *and* D_j *is the curvilinear quadrangle* $A_{in}A_{ip}A_{jp}A_{jn}$*, bounded by the two line segments* $A_{in}A_{jn}$ *and* $A_{ip}A_{jp}$ *and the two arcs* $A_{in}A_{ip}$ *and* $A_{jn}A_{jp}$*.*

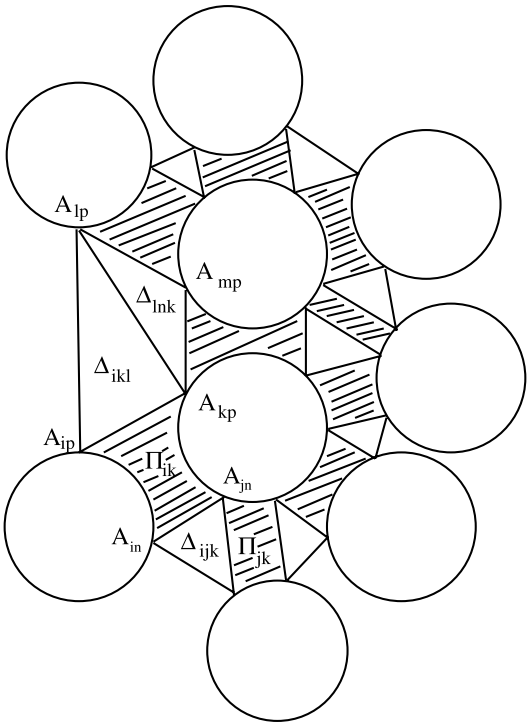
When we apply this algorithm to all neighbors, in general, all these line segments $A_{in}A_{jn}$ partition the domain Q_p into necks Π_{ij} between neighboring disks and triangles Δ_{ijk}. In exceptional cases, instead of triangles we obtain polygons (for example, quadrangle $A_{ip}A_{lp}A_{mp}A_{kp}$ in Figure 2.3(b)) which can be further partitioned into triangles by drawing auxiliary diagonal lines.

The situation at the boundary needs special treatment. For the construction of the partition of Q_p near the boundary $\partial\Pi$ we use reflections about all four parts of $\partial\Pi$. Without loss of generality we assume that all the centers x_i of the disks lie *inside* the domain Π, and hence the centers of the reflected disks will *always* lie outside the domain Π. (The case when the disks lie outside the boundary can also be treated by the model by adding simple but cumbersome modifications.) Consider, for example, the left boundary $x = -L$. The algorithm is shown in Figure 2.4. We reflect symmetrically along the line $x = -L$ *all* the disks, including the disks that intersect the boundary. The latter disks partially overlap with the "ghost" disks (dotted disks in Figure 2.4) which are their mirror images. For the distribution of original disks and the ghost disks we can still apply the Voronoi tessellation and the algorithm proposed for the interior disks. For uniformity of presentation we use, as in [3], a notion of a quasidisk.

DEFINITION 2.4. *A quasidisk* $D_{i''}$*, is the part of a neck* $\Pi_{ii'}$ *that lies on the boundary of* Π*. The radius of a quasidisk is* ∞*.*



(a) Voronoi tessellation



(b) Triangle-neck partition

FIG. 2.3. *Decomposition of a Voronoi cell.*

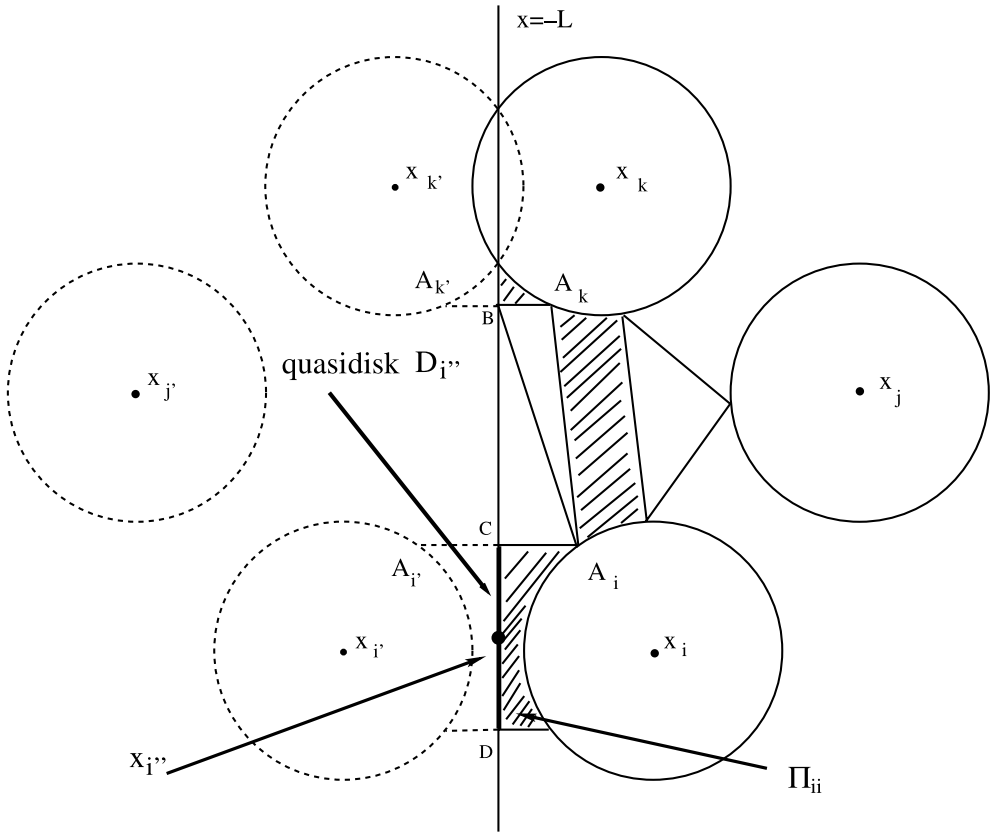


FIG. 2.4. *Vertical boundary.*

An example is the line segment $CD \equiv D_{i''}$ in Figure 2.4. This notion allows us to treat the quasidisks and the original disks uniformly as disks of different radii. In particular, for a quasidisk the definition of a neighbor (Definition 2.2) applies.

DEFINITION 2.5. *The triangle-neck partition $\mathbb{P} = \mathbb{P}(Q_p)$ of the domain Q_p is the set of necks Π_{ij} and triangles Δ_{ijk}.*

The triangle-neck partition is unique up to partitioning of degenerate (exceptional) polygons into triangles. Typically, a neck Π_{ij} is not symmetric with respect to the line connecting the centers of the disks D_i and D_j. An example of a neck is given in Figure 2.5, where we used the local coordinate system when the centers of the both disks lie on the y-axis. In this coordinate system the width of the left half-neck is $|S_1|$, $S_1 < 0$, and the width of the right half-neck is $|S_2|$, $S_2 > 0$. Note that inequalities $S_1 < 0$, $S_2 > 0$ are not true in general, but $S_1 \le S_2$ always by our construction. For uniformity of presentation we view auxiliary diagonals as necks with width zero $S_1 = S_2$. For example, the line segment A_iB in Figure 2.4 corresponds to such a neck.

DEFINITION 2.6. *The maximal and the minimal relative half-neck widths are defined by*

(2.11)
$$\beta_{ij}^{\max} = \max\left(\frac{|S_1|}{R}, \frac{|S_2|}{R}\right), \qquad \beta_{ij}^{\min} = \min\left(\frac{|S_1|}{R}, \frac{|S_2|}{R}\right), 0 \le \beta_{ij}^{\min} \le \beta_{ij}^{\max} < 1.$$

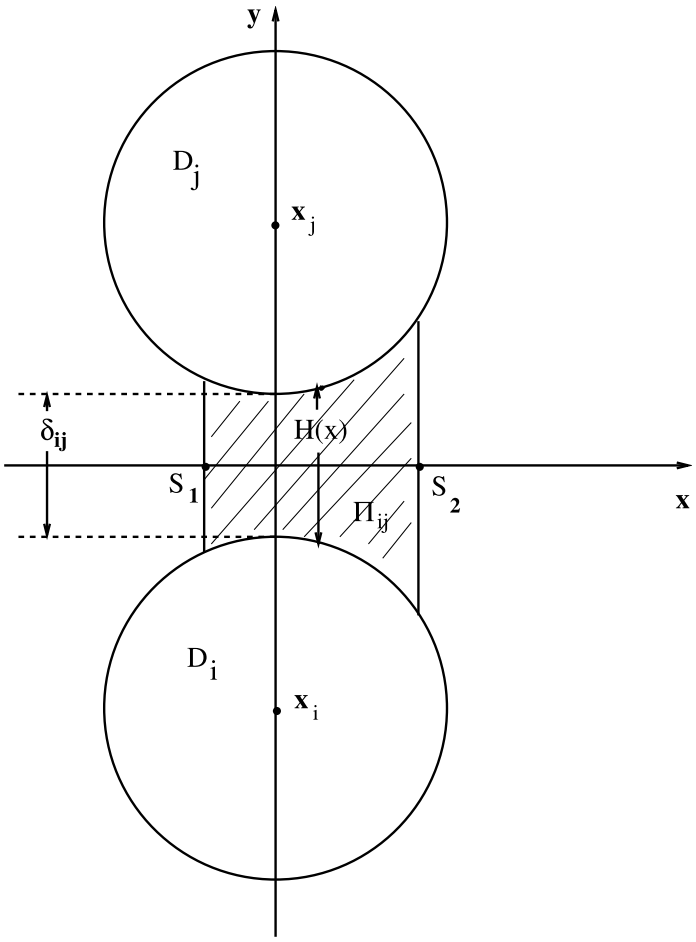

FIG. 2.5. *The hatched region is the neck between two neighbors.*

We use the relative half-neck widths $\beta_{ij}^{\max}$ and $\beta_{ij}^{\min}$ in the error estimates in section 3.

Using the triangle-neck partition we decompose the Dirichlet integral (2.3) into integrals over necks and triangles:

$$\hat{a} = \frac{1}{4L}\int_{Q_p} |\nabla\phi|^2 d\mathbf{x} = \frac{1}{4L}\sum_{\Pi_{ij}} \int_{\Pi_{ij}} |\nabla\phi|^2 d\mathbf{x} + \frac{1}{4L}\sum_{\Delta_{ijk}} \int_{\Delta_{ijk}} |\nabla\phi|^2 d\mathbf{x}. \tag{2.12}$$

The DNA of the effective conductivity is based on the observation in [13] that for high concentration of the disks the fluxes $\nabla\phi$ are significant only in necks Π_{ij} between closely spaced disks,

$$\sum_{\Delta_{ijk}} \int_{\Delta_{ijk}} |\nabla\phi|^2 d\mathbf{x} \ll \sum_{\Pi_{ij}} \int_{\Pi_{ij}} |\nabla\phi|^2 d\mathbf{x}, \tag{2.13}$$

and in these necks the fluxes can be easily computed (as in [13]) by the linear interpolation between the values of the potentials on the disks. More specifically, if we

align the neck Π_{ij} between two neighbors D_i and D_j with the vertical direction as indicated in Figure 2.5, then by the linear interpolation the local flux in Π_{ij} satisfies

$$\nabla\phi = \left(0, \frac{t_i - t_j}{H(x)}\right), \tag{2.14}$$

$$H(x) = \begin{cases} \delta_{ij} + 2R - 2\sqrt{R^2 - x^2} & \text{for disks,} \\ \delta_{ij} + R - \sqrt{R^2 - x^2} & \text{for quasidisks,} \end{cases}$$

where δ_{ij} is given by the following definition.

DEFINITION 2.7. *The length δ_{ij} of a neck Π_{ij} is*

$$\delta_{ij} = \begin{cases} d_{ij} - 2R & \text{if } D_i \text{ and } D_j \text{ are disks,} \\ d_{ij} - R & \text{if one of } D_i \text{ is a quasidisk,} \end{cases} \tag{2.15}$$

where $d_{ij} = |x_i - x_j|$ is the (Euclidean) distance between x_i and x_j.

Using (2.14)

$$\int_{\Pi_{ij}} |\nabla\phi|^2 d\mathbf{x} = \int_{S_1}^{S_2} \frac{(t_i - t_j)^2}{H^2(x)} H(x)dx = g_{ij}(t_i - t_j)^2, \tag{2.16}$$

where

$$g_{ij} = \int_{S_1}^{S_2} \frac{dx}{H(x)}, \tag{2.17}$$

and t_i, t_j are potentials on D_i, D_j, respectively, and S_1, S_2 are as defined in Figure 2.5. If we use (2.16) with (2.17) for all neighbors, then observation (2.13) would imply

$$\hat{a} \equiv \frac{1}{4L} \min_{\phi \in V_p} \int_{Q_p} |\nabla\phi|^2 d\mathbf{x} \sim I \equiv \frac{1}{4L} \min_{\mathbf{t}} \sum_{\Pi_{ij}} g_{ij}(t_i - t_j)^2, \tag{2.18}$$

where $\mathbf{t} = (t_1, t_2, \ldots, t_N)$.

This is our *modified network approximation*. The *energy of the discrete network*

$$I = \frac{1}{4L} \min_{\mathbf{t}} \sum_{\Pi_{ij}} g_{ij}(t_i - t_j)^2 \tag{2.19}$$

is determined by the choice of the *specific fluxes* g_{ij}. Following [13] they were chosen in [3] to be

$$g_{ij} = \pi \sqrt{\frac{2R_iR_j}{R_i + R_j}} \Bigg/ \sqrt{\delta_{ij}} \tag{2.20}$$

for *closely spaced* disks and zero otherwise. Both formulas (2.20) and (2.17) give the same leading term in the power expansion in $\delta_{ij} \to 0$ (see [3], [4] for details), and hence these formulas are asymptotically equivalent as $\delta_{ij} \to 0$. We propose here to use (2.17), instead of (2.20), and use it for *all* neighbors not necessarily closely spaced. Such *modified* choice of the specific fluxes allows us to derive tight variational bounds for the relative error of our modified network approximation. The choice (2.17) validates the approximation (2.18) for much more general nonuniform irregular distributions, when a significant fraction of the inclusions does not participate in the

conducting spanning cluster, whereas in [3] it was shown that (2.20) validates the approximation (2.18) only for arrays of inclusions in which all neighbors are closely spaced ("randomized hexagonal arrays"). The main goal of this paper is to give sufficient conditions for these nonuniform irregular distributions, under which (2.18) is a valid approximation, and provide a rigorous a priori estimate on the relative error of this approximation. The full details of our construction of the modified network approximation can be found in [4].

The relation (2.18) is a DNA, because we approximate the continuum minimization problem with a discrete minimization problem of a quadratic form (2.19). The unknowns of the minimization problem are the values of the discrete potentials t_i on the interior disks, and the quadratic form is defined on a graph (network) where the vertices x_i are the centers of the disks D_i and the edges e_{ij} are the necks Π_{ij}. This graph is the Delaunay triangulation for the centers of the disks, modified by an additional construction at the boundaries. The construction is as follows. If for a vertex x_i its Voronoi cell V_i is adjacent to the boundary (that is, one of the sides of V_i lies on the boundary of Π) and the radius of the disk $R_i = R$ is smaller than the distance from x_i to this boundary, then connect x_i with this boundary by the perpendicular line. Denote the intersection of this perpendicular and the boundary by $x_{i''}$, $i'' > N$, and the line segment between x_i and $x_{i''}$ by the edge $e_{ii''}$. This modification added vertices $x_{i''}$, $i'' > N$, that lie on the boundary of Π (see Figure 2.4). These vertices are in one-to-one correspondence with quasidisks in the triangle-neck partition.

The discrete potentials $\tilde{t}_i$ at the "boundary" vertices x_i, are prescribed on the horizontal boundaries by

$$\tilde{t}_i = \pm 1 \text{ for } x_i \in S^{\pm}, \tag{2.21}$$

where $S^{\pm}$ are the upper/lower boundary vertices defined as follows.

DEFINITION 2.8. *A vertex x_i is an upper (lower/left/right) boundary vertex, if x_i lies on the upper (lower/left/right) boundary (an added vertex $x_{i''}$, $i'' > N$) or x_i is the center of the disk D_i, that intersects the upper (lower/left/right) boundary. The set S^+ ($S^-/S^l/S^r$) is the set of upper (lower/left/right) boundary vertices.*

The minimization problem (2.19)–(2.21) amounts to solving the corresponding linear algebraic system that determines the discrete potentials $\tilde{t}_i$ at the "interior" vertices $x_i \in \mathbb{I}$, $\mathbb{I} = \{x_i, i = 1, \dots, N\} \setminus (S^+ \cup S^-)$. A discrete version of insulating boundary conditions on $S^l \cup S^r$ can be formulated as follows. If a vertex of the discrete network $x_{i''} \notin \mathbb{I} \cup (S^+ \cup S^-)$, then $x_{i''}$ must be a center of a *quasidisk* that lies on the left or the right boundary $x_{i''} \in S^l \cup S^r$. For such vertices $\tilde{t}_{i''} = \tilde{t}_i$, where $\tilde{t}_i$ and $\tilde{t}_{i''}$ are the values of the potential on the disks $D_i \in \mathbb{I} \cup (S^+ \cup S^-)$ and $D_{i''}$, respectively, where D_i is the uniquely determined disk connected with $D_{i''}$ (e.g., in Figure 2.4 $D_{i''} \equiv CD$). Therefore,

$$\sum_{\Pi_{ik}, i'' \text{ fixed}} g_{i''k}(t_{i''} - t_k) = g_{i''i}(t_{i''} - t_i) = 0 \quad \text{for all } x_{i''} \notin \mathbb{I} \cup (S^+ \cup S^-). \tag{2.22}$$

DEFINITION 2.9. *For a given distribution of disks D_i with centers x_i, $i = 1, \dots, N$, the discrete network $\mathbb{D}$ is a set of vertices x_i, $i = 1, \dots, M$, $M \geq N$, and edges e_{ij} between neighbors x_i and x_j of the modified Delaunay graph.*

By [3] a necessary condition for the validity of (2.18) is the existence of a conducting spanning cluster.

DEFINITION 2.10. *For any discrete network $\mathbb{D}$ (or any subgraph $\mathbb{D}'$ of it) a spanning cluster is the (unique) connected component of $\mathbb{D}$ (or $\mathbb{D}'$) that contains at least one path that connects the S^+ and S^- and at least one path that connects S^l and S^r.*

The spanning cluster is conducting if the distance δ_{ij} between every two consecutive vertices of this graph $\delta_{ij} \leq \delta$, where δ is sufficiently small. A sufficient condition for the existence of the conducting spanning cluster is the δ-**N** connectedness property of the discrete network $\mathbb{D}$ which can be formulated in terms of δ-subgraphs of $\mathbb{D}$.

DEFINITION 2.11. *For any $\delta > 0$ the δ-subgraph $\mathbb{D}_\delta$ of the discrete network (graph) $\mathbb{D}$ is the subset of edges e_{ij} and their incident vertices x_i and x_j of $\mathbb{D}$ such that their length $\delta_{ij} \leq \delta$. For any subgraph a vertex is incident if it is an end-vertex of one of its edges.*

The δ-**N** connectedness property of $\mathbb{D}$ is used extensively in this paper; therefore, for completeness, in the rest of this section we give the precise graph-theoretical definitions related to this notion. Most of them are taken from [5].

DEFINITION 2.12. *A path of a graph $\mathbb{D}$ from x_0 to x_n is an alternating sequence of*

$$x_0, e_{01}, x_1, e_{12}, x_2, e_{23}, \ldots, x_{n-1}, e_{n-1n}, x_n$$

of distinct vertices x_i and edges e_{ij}. Such a path has size $\mathbf{n}$*, and the vertices x_0 and x_n are said to be the end-vertices. The vertices $x_1, \ldots, x_{n-1}$ are said to be the interior vertices.*

Conventionally (see [5]), the *size* of a path is called its *length*. Here we do not use this standard notation, because the following definition of the length of a path is more natural in our setting (due to Definition 2.7).

DEFINITION 2.13. *The length of a path is the sum of lengths of its edges e_{ij}. The length of an edge e_{ij} is the length of the corresponding neck Π_{ij} as in Definition* 2.7.

DEFINITION 2.14. *An internal cycle C of $\mathbb{D}$ is an alternating sequence of*

$$x_0, e_{01}, x_1, e_{12}, x_2, e_{23}, \ldots, x_n, e_{n0}, x_0$$

of vertices and edges, such that

$$x_0, e_{01}, x_1, e_{12}, x_2, e_{23}, \ldots, x_n$$

is a path, and e_{n0} connects the vertices x_0 and x_n. Such a cycle has size $\mathbf{n}+1$.

DEFINITION 2.15. *A boundary cycle C of $\mathbb{D}$ is a path*

$$x_0, e_{01}, x_1, e_{12}, x_2, e_{23}, \ldots, x_n$$

such that the end-vertices x_0 and x_n lie on the boundary of the domain Π. Such a boundary cycle has size $\mathbf{n}$.

Note that the end-vertices x_0 and x_n of a boundary cycle may belong to different boundaries, for example S^- and S^l, respectively.

DEFINITION 2.16. *A minimal cycle $C_{\min}$ is an (internal or boundary) cycle such that for any two vertices x_i and x_j of this cycle the shortest path from x_i to x_j is a subset of the cycle $C_{\min}$. If the cycle $C_{\min}$ is a boundary cycle, we also require that for any interior point x_i of this cycle the shortest path from to x_i to any point x_k on the boundary is a subset of the cycle $C_{\min}$.*

Note that we require for a minimal boundary cycle an additional condition. This condition guarantees that a boundary cycle cannot be shortened by connecting an

interior point of this cycle with the boundary. Definition 2.16 is a formalization of an intuitive notion of a hole in a composite. Each hole in a composite is surrounded by a loop of conducting disks (see Figure 1.1(a)). On the modified Delaunay graph this loop corresponds to an **N**-gon, which is a minimal cycle of this graph.

DEFINITION 2.17. *The size* **N** *of the largest minimal cycle of a (sub)graph* $\mathbb{D}_\delta$ *is the upper bound on the size of all its minimal cycles; that is,*

$$\mathbf{N} = \max_{C_{\min} \subset \mathbb{D}_\delta} size(C_{\min}), \tag{2.23}$$

where $C_{\min}$ *is a minimal cycle.*

The interior of a cycle C, denoted Int_C, is a (closed) polygon having the cycle C as its boundary; that is, $\partial \mathrm{Int}_C = C$. However, the definition of the interior of a boundary cycle requires an additional technical construction. Naturally, the interior of a boundary cycle can be defined as a (closed) polygon having the cycle C and some parts of the boundary of the domain Π as its boundary. However, there are exactly two such polygons such that their union is the whole domain Π. Among these two polygons we choose for the interior the one with the smallest area.

The *degree* of the connectedness of the whole graph $\mathbb{D}$ can now be quantified in terms of the two parameters, δ and **N**, and an a priori relative error estimate for the DNA $\mathbb{D}$ is determined in terms of these parameters only.

DEFINITION 2.18. *For a fixed* δ *a discrete network (graph)* $\mathbb{D}$ *is* δ-**N** *connected if*

(i) *the* δ*-subgraph* $\mathbb{D}_\delta$ *contains the spanning cluster as in Definition* 2.10,

(ii) *the size of the largest minimal cycle of* $\mathbb{D}_\delta$ *is* **N**.

In this paper we are interested in δ-**N** connected discrete networks such that the size of the composite is large, compared to the perimeter of the largest minimal cycle:

$$(2R + \delta)\mathbf{N} < \min(2, 2L). \tag{2.24}$$

If (2.24) holds, then (i) is equivalent to the following:

(i') For every point y of the domain Π there exists a minimal cycle $C_{\min}$ of the δ-subgraph $\mathbb{D}_\delta$ such that $y \in \mathrm{Int}_{C_{\min}}$; and if this minimal cycle is a boundary cycle, then its end-vertices either lie on the same (left/right/upper/lower) part of the boundary $\partial\Pi$ or they lie on two adjacent parts of $\partial\Pi$, e.g., left and upper.

The condition (i') is technical, but in the proofs of our main results we use (i') instead of (i). Thus, let us show that these conditions are equivalent. To argue by contradiction we assume that (2.24) holds, but there are no paths on the graph $\mathbb{D}_\delta$ that connect S^+ and S^-. Then there exists a path in the *whole* domain Π that connects S^l and S^r and does not intersect $\mathbb{D}_\delta$. The length of this path, on the one hand, must be larger than the distance between the left and the right boundaries; on the other hand, it cannot be larger than the diameter of the largest minimal cycle. Recall that the distance between any two vertices in $\mathbb{D}$ does not exceed $2R + \delta$, and hence the inequality $2L \le (2R + \delta)\mathbf{N}$ must hold which contradicts (2.24). Suppose now (i) holds. Then the spanning cluster partitions Π into polygons ("holes in the cluster"). Therefore, every point $y \in \Pi$ lies in one of them. These polygons can be chosen to be nonoverlapping and so that their boundaries are interior minimal cycles of $\mathbb{D}_\delta$, or boundary minimal cycles of $\mathbb{D}_\delta$ and some parts of $\partial\Pi$. Hence it is left to check that every boundary minimal cycle satisfies the condition that its end-vertices either lie on the same part of the boundary $\partial\Pi$ or they lie on two adjacent parts of $\partial\Pi$. This follows from (2.24).

Finally, we note that the existence of a path connecting S^+ and S^- implies the existence of a path connecting S^l and S^r. Indeed, suppose (2.24) holds, but there is

no path in $\mathbb{D}_\delta$ that connects S^l and S^r. Then the connected component of $\mathbb{D}_\delta$ that contains the path from S^+ to S^- is not connected to one of the boundaries S^l or S^r. Then there exists a *boundary minimal cycle* in $\mathbb{D}_\delta$ that connects S^+ and S^-. On the one hand, its length is at most $(2R+\delta)\mathbf{N}$; on the other hand, it must exceed 2, the distance between the upper and the lower boundaries. This is impossible, because it contradicts (2.24).

2.3. Properties of the discrete network. Here we collect some results on the properties of the discrete network. The first lemma gives an upper bound on the number of necks and triangles that lie in the interior of any minimal cycle of the δ-subgraph in terms of the size of largest minimal cycle $\mathbf{N}$. Consider a δ-$\mathbf{N}$ connected discrete network $\mathbb{D}$ (Definition 2.18). Let us now consider a minimal cycle $C_{\min}$ of the δ-subgraph $\mathbb{D}_\delta$. Denote by $\#\Delta_{C_{\min}}$ the number of the triangles Δ_{ijk} that lie in the interior of this minimal cycle $\Delta_{ijk} \subset \mathrm{Int}_{C_{\min}}$. Similarly, $\#\Pi_{C_{\min}}$ is the number of the necks Π_{ij} that lie in the interior of this minimal cycle $\Pi_{ij} \subset \mathrm{Int}_{C_{\min}}$, and $\#x_{C_{\min}}$ is the number of the vertices (centers of disks) x_i such that $x_i \subset \mathrm{Int}_{C_{\min}}$.

LEMMA 2.19. *Suppose the discrete network $\mathbb{D}$ is δ-$\mathbf{N}$ connected. Then for any minimal cycle $C_{\min}$ of the δ-subgraph $\mathbb{D}_\delta$ the number of triangles $\#\Delta_{C_{\min}}$, and the number of necks $\#\Pi_{C_{\min}}$ that lie in the interior of $C_{\min}$, satisfy the bounds*

$$\#\Delta_{C_{\min}} \le 2\left(\mathbf{N} + \frac{2}{\pi\sqrt{3}}\mathbf{N}^2\right), \quad \#\Pi_{C_{\min}} \le 3\left(\mathbf{N} + \frac{2}{\pi\sqrt{3}}\mathbf{N}^2\right). \tag{2.25}$$

The proof is basically the isoperimetric inequality together with the Euler's formula. For details see [4].

LEMMA 2.20. *There is a unique solution $\mathbf{t} = \{t_i | x_i \in \mathbb{I}\}$ of the discrete minimization problem* (2.19)–(2.21). *This solution satisfies a discrete analogue of Euler–Lagrange equations (compare to* (2.2)*)*

$$\sum_{\Pi_{ik}, i \text{ fixed}} g_{ik}(t_i - t_k) = 0 \quad \text{for all } x_i \in \mathbb{I}. \tag{2.26}$$

Proof. A solution that satisfies (2.26) exists, because the quadratic form (2.19) is positive definite. The discrete network is a connected graph in the sense that there is a path between each vertex x_i and a boundary vertex $x_j \in S^\pm$. This implies that the solution is unique. □

Similar to the fluxes through the horizontal boundaries on the right-hand side of (2.4), denote by P^+ and P^- the discrete fluxes through the boundaries S^+ and S^-, respectively;

$$P^+ \equiv \sum_{\Pi_{ij}, x_i \in S^+} g_{ij}(t_i - t_j), \qquad P^- \equiv \sum_{\Pi_{ij}, x_i \in S^-} g_{ij}(t_i - t_j). \tag{2.27}$$

Then

$$\frac{1}{4L}(P^+ - P^-) = \frac{1}{4L}\sum_{\Pi_{ij}} g_{ij}(t_i - t_j)^2 \equiv I(\mathbf{t}). \tag{2.28}$$

Formula (2.28) is a discrete analogue of (2.5). For the proof see [3].

LEMMA 2.21 (discrete maximum principle). *Suppose $\mathbf{t} = \{t_1, t_2, \dots, t_M\}$ is the solution of the $\mathbb{D}$ problem* (2.19)–(2.21). *For any (internal or boundary) cycle C of $\mathbb{D}$ define*

$$t_{\max} = \max(t_i), x_i \in C, \qquad t_{\min} = \min(t_i), x_i \in C.$$

Then for any vertex x_k with potential t_k such that $x_k \in \mathrm{Int}_C$, that is, x_k belongs to the interior of the cycle C (as in Definition 2.18), we have

$$t_{\min} \le t_k \le t_{\max}.$$

The proof of the discrete maximum principle is by contradiction; it is fairly standard and it could be found in [3]. As a corollary of the discrete maximum principle we have the following lemma.

LEMMA 2.22. *If the discrete network $\mathbb{D}$ is δ-$\mathbf{N}$ connected, then for any minimal cycle $C_{\min}$ of the δ-subgraph $\mathbb{D}_\delta$ and a vertices $x_k \in \mathrm{Int}_{C_{\min}}$ and $x_l \in \mathrm{Int}_{C_{\min}}$ we have*

$$(t_k - t_l)^2 \le \mathbf{N} \sum_{\Pi_{ij} \in C_{\min}} (t_i - t_j)^2. \tag{2.29}$$

Proof. By the discrete maximum principle

$$(t_k - t_l)^2 \le (t_{\max} - t_{\min})^2, \tag{2.30}$$

where

$$t_{\max} = \max(t_i), x_i \in C_{\min}, \qquad t_{\min} = \min(t_i), x_i \in C_{\min}.$$

Suppose the maximum $t_{\max}$ and the minimum $t_{\min}$ are achieved at the vertices $x' \in C_{\min}$ and $x'' \in C_{\min}$, respectively. Since both vertices belong to the minimal cycle $C_{\min}$, there is a part of this minimal cycle which is a path with the size $\le \mathbf{N}$ that connects them. Therefore, by the triangle inequality for the values of the potentials t_i, $x_i \in C$

$$(t_{\max} - t_{\min})^2 \le \mathbf{N} \sum_{\Pi_{ij} \in C_{\min}} (t_i - t_j)^2$$

which inserted in (2.30) yields (2.22). □

LEMMA 2.23. *Suppose*

$$|g^0_{ij} - g_{ij}| \le C_0 \text{ as } \delta_{ij} \to 0, \tag{2.31}$$

and $I^0(\mathbf{t^0})$ is another DNA with the specific fluxes g^0_{ij} and the energy I^0. Then the bound $\frac{|\hat{a}-I|}{I} \le C_1\sqrt{\delta/R}$ implies $\frac{|\hat{a}-I^0|}{I^0} \le C_2\sqrt{\delta/R}$, where C_2 depends on C_0 and C_1 only.

Lemma 2.23 gives an equivalence of the energy $I(\mathbf{t})$ to the energy of any other discrete network that uses a set of specific fluxes g^0_{ij} that satisfies (2.31). Since (see derivation in [4]) both formulas (2.20) and (2.17) give the same leading term in the power expansion in $\delta_{ij} \to 0$, the previous lemma implies that for the purpose of estimating the effective conductivity of a composite where inclusions are almost touching our model and the model introduced in [3] are equivalently good as $\delta \to 0$. For the proof see [4], which, in particular, shows that under the δ-$\mathbf{N}$ packing condition the relative error of the discrete network I^0 introduced in [3] (when (2.17) are replaced by (2.20)) satisfies

$$\frac{|\hat{a} - I^0|}{I^0} \le 9.82\mathbf{N}^4\sqrt{\frac{\delta}{R}}.$$

3. Variational error estimates.

3.1. The lower bound. Following [3] the test function $\mathbf{v}$ for the lower bound is chosen to be zero everywhere except the necks Π_{ij} between adjacent disks; however, in our case for the specific fluxes we use (2.17) instead of (2.20).

PROPOSITION 3.1. *The lower bound on $\hat{a}$ in terms of g_{ij} and the parameters of the solution of the discrete minimization problem is*

$$I(\mathbf{t}) = \frac{1}{4L} \sum_{\Pi_{ij}} g_{ij}(t_i - t_j)^2 \le \hat{a}, \tag{3.1}$$

where $\mathbf{t} = \{t_1, t_2, \dots, t_M\}$ are the values of the discrete potentials of the solution of the discrete minimization problem (2.19)–(2.21).

The left-hand side in (3.1) is always positive, which reflects the physics of the problem. The analogous lower bound in Proposition 2.1 in [3] is positive and sufficiently tight for the δ-3 close packing condition only. Our bound allows us to handle general distribution of disks that satisfy the δ-$\mathbf{N}$ close packing condition for any $\mathbf{N}$.

Proof. Consider two neighbors centered at x_i and x_j. Suppose the potentials t_i and t_j on the disks D_i and D_j are the solutions to the minimization problem (2.19)–(2.21). Rotate the domain so that in the local coordinates the neck between them is aligned with the direction of the y-axis (as in Figure 2.5). Define

$$\mathbf{v} = \begin{cases} (0, \frac{t_i - t_j}{H(x)}) & \text{in the neck } \Pi_{ij}, \\ (0,0) & \text{otherwise}, \end{cases} \tag{3.2}$$

where $H(x)$ is the distance between the disks. Since for a piecewise constant function the divergence-free condition amounts to checking that the normal components of $\mathbf{v}$ match along the discontinuity, we see that our trial function $\mathbf{v}$ is divergence-free. The matching condition $\int_{\partial D_i} \mathbf{v} \cdot \mathbf{n} d\mathbf{x} = 0$ is satisfied (as in [3]) due to (2.17) and (2.26). The insulating condition $\mathbf{v}(\pm L, y) \cdot \mathbf{n} = 0$ at the vertical boundary is satisfied by (2.22). Hence $\mathbf{v} \in W_p$. Observe that for the trial function (3.2) the fluxes through the upper and the lower boundary of Π are exactly the discrete fluxes P^+ and P^-:

$$P^+ = \int_{y=1} \mathbf{v} \cdot \mathbf{n}\, d\mathbf{x}, \qquad P^- = \int_{y=-1} \mathbf{v} \cdot \mathbf{n}\, d\mathbf{x}.$$

Following [3] we have

$$\int_{Q_p} \mathbf{v}^2 d\mathbf{x} = \sum_{\Pi_{ij}} g_{ij}(t_i - t_j)^2,$$

because $\mathbf{v} \equiv 0$ on every triangle and the Dirichlet integral over a neck

$$\int_{\Pi_{ij}} \mathbf{v}^2 d\mathbf{x} = (t_i - t_j)^2 \int_{S_1}^{S_2} \frac{dx}{H(x)} = g_{ij}(t_i - t_j)^2.$$

Using (2.28) we have

$$\frac{1}{2L} \left[\int_{y=1} \mathbf{v} \cdot \mathbf{n}\, d\mathbf{x} - \int_{y=-1} \mathbf{v} \cdot \mathbf{n}\, d\mathbf{x} - \frac{1}{2} \int_{Q_p} \mathbf{v}^2 d\mathbf{x} \right] = I(\mathbf{t}).$$

By the first inequality in (2.10) we have (3.1). ∎

3.2. The upper bound.

PROPOSITION 3.2. *The upper bound on $\hat{a}$ in terms of g_{ij} and the parameters of the solution of the discrete minimization problem is*

$$\hat{a} \le \frac{1}{4L}\sum_{\Pi_{ij}}[g_{ij}+C_{ij}](t_i-t_j)^2 = I(\mathbf{t}) + \frac{1}{4L}\sum_{\Pi_{ij}} C_{ij}(t_i-t_j)^2, \tag{3.3}$$

where all $C_{ij} = C_{ij}(\beta_{ij}^{\max})$ depend only on the relative neck thicknesses $\beta_{ij}^{\max}$ defined (2.11). *Moreover, if*

$$\beta_{ij}^{\max} \le \beta < 1, \tag{3.4}$$

then $C_{ij} \le C$ with some $C = C(\beta)$.

It was shown in [4] that

$$C_{ij} \le \frac{|\ln(1-\beta_{ij}^{\max})| + \pi + \ln 2}{6} + \frac{4}{\sqrt{1-[\beta_{ij}^{\max}]^2}}.$$

Proof. Consider a piecewise continuous test function ϕ. Similar to [3], the function ϕ is linear in y in the neck Π_{ij} with the values t_i and t_j on the boundary of the disks ∂D_i and ∂D_j (Figure 2.5). Then on the neck Π_{ij}

$$\phi(x,y) = t_i + \frac{(t_j-t_i)(y+H(x)/2)}{H(x)} = t_i + (t_j-t_i)\left[\frac{y}{H(x)}+\frac{1}{2}\right]$$
$$\text{for } y \in \left[-\frac{H(x)}{2}, \frac{H(x)}{2}\right]. \tag{3.5}$$

The function ϕ is linear in the Δ_{ijk} (see Figure 3.1) with the values t_i^0, t_j^0, and t_k^0 at the vertices of Δ_{ijk}. In Figure 3.1 these vertices are the points A, B, and C, respectively. In a neck Π_{ij}

$$\int_{\Pi_{ij}} (\partial\phi/\partial y)^2 dxdy = \int_{S_1}^{S_2} \frac{(t_j-t_i)^2}{H^2(x)} H(x)dx = (t_j-t_i)^2 g_{ij} \tag{3.6}$$

and

$$\int_{\Pi_{ij}} (\partial\phi/\partial x)^2 dxdy = \int_{\Pi_{ij}} (t_j^0-t_i^0)^2 \left[\frac{yH'(x)}{H^2(x)}\right]^2 dxdy$$

$$= \frac{1}{12}(t_j^0-t_i^0)^2 \int_{S_1}^{S_2} \frac{(H')^2(x)}{H(x)}dx.$$

Since $H(x) = \delta + 2R - 2\sqrt{R^2-x^2}$, therefore $H'(x) = \frac{2x}{\sqrt{R^2-x^2}}$, and

$$\frac{H'^2(x)}{H(x)} = \frac{2R}{R^2-x^2} + \frac{2}{\sqrt{R^2-x^2}}.$$

Hence as in [3]

$$\int_{\Pi_{ij}} (\partial\phi/\partial x)^2 dxdy \le C(\beta_{ij}^{\max})(t_j-t_i)^2 \le C(t_j-t_i)^2 \tag{3.7}$$

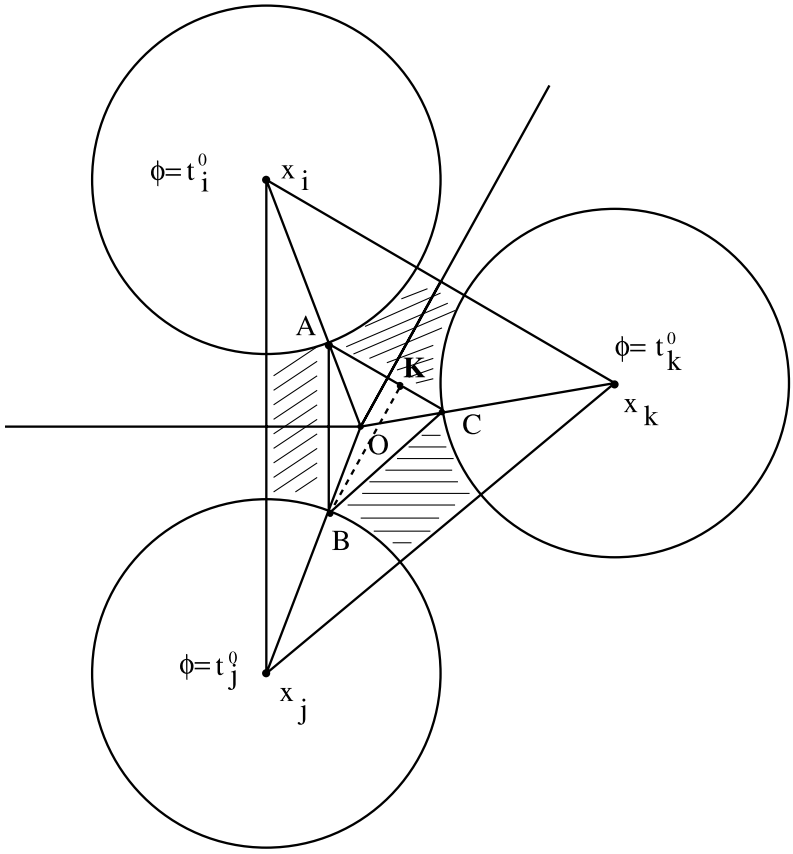

FIG. 3.1. *Typical $\Delta ABC \equiv \Delta_{ijk}$; half-necks are hatched.*

if $\beta_{ij} \le \beta < 1$. Each triangle is bounded by three necks. In Figure 3.1 we show a typical case with three disks centered at x_i, x_j, and x_k, three half-necks, and the $\Delta ABC \equiv \Delta_{ijk}$ bounded by these half-necks. Suppose in ΔABC the side $|AC|$ is the longest, and the side $|BC|$ is the shortest. Then (see details in [4])

$$\int_{ABC} |\nabla\phi|^2 d\mathbf{x} \le \frac{2}{\sin(\angle BAC)}\Big((t_i - t_j)^2 + (t_k - t_i)^2\Big).$$

Since

$$\frac{1}{\sin(\angle BAC)} = \frac{1}{\sin(\pi/2 - \angle x_k x_j O)} \le \frac{1}{\sqrt{1 - (\beta_{jk}^{\max})^2}},$$

therefore

$$\int_{ABC} |\nabla\phi|^2 d\mathbf{x} \le C(\beta_{jk}^{\max})((t_i - t_j)^2 + (t_k - t_i)^2) \le C((t_i - t_j)^2 + (t_k - t_i)^2) \tag{3.8}$$

if $\beta_{jk}^{\max} \le \beta < 1$. Combining (3.6), (3.7), (3.8) and summing over all necks and triangles we have (3.3). □

3.3. The error estimate.

THEOREM 3.3. *If for a distribution of disks D_i, $i = 1, \dots, N$, its discrete network is δ-$\mathbf{N}$ connected, then the relative error*

$$\frac{|\hat{a} - I|}{I} \le C(\mathbf{N})\sqrt{\frac{\delta}{R}}, \tag{3.9}$$

where $\hat{a}$, I are defined in (2.3), (2.19)*, respectively, and*

$$C(\mathbf{N}) \le 2.56\mathbf{N}^4. \tag{3.10}$$

Inequality (3.10) is a very rough upper bound, and it could be significantly improved by more careful analysis. In particular, if $\mathbf{N} = 3$, then $C(\mathbf{3}) \le 3.84$; if $\mathbf{N} = 4$, then $C(\mathbf{4}) \le 12.73$. For simplicity of presentation we do not specify our numerical estimate (3.10). For more details see [4].

Proof. As $\delta_{ij} \to 0$, we know that $g_{ij} = O(\delta^{-1/2})$ and therefore if there is a conducting spanning cluster, then (see [3]) $I(\mathbf{t}) = O(\delta^{-1/2})$. Hence (3.10) will follow if we can "absorb" *all* the $O(1)$ terms in (3.3) as the "smaller order corrections" into $O(\sqrt{\frac{R}{\delta}})$ terms and derive an estimate

$$I(\mathbf{t}) \le \hat{a} \le I(\mathbf{t}) + O(1) \le I(\mathbf{t})\left(1 + C\sqrt{\frac{\delta}{R}}\right), \tag{3.11}$$

where the first inequality in (3.11) follows from (3.1). The second inequality is also immediate if *all* necks are short: $\delta_{ij} \le \delta$. If not all the necks are short, then $g_{ij} = O(1)$ and therefore C_{ij} in (3.3) are compatible in magnitude with g_{ij}. Here we use the assumption that our discrete network is δ-$\mathbf{N}$ connected. The key observation here is that the centers of any two neighbors D_k and D_l must lie inside a minimal cycle $C_{\min}$. Therefore, by Lemma 2.22 the values of the potentials t_k and t_l at these disks satisfy

$$(t_k - t_l)^2 \le \mathbf{N} \sum_{\Pi_{ij} \in C_{\min}} (t_i - t_j)^2.$$

By Lemma 2.19 we have a bound, that depends on $\mathbf{N}$ only, on the total number of vertices, necks, and triangles that lie inside any minimal cycle $C_{\min}$. Therefore, for our trial function ϕ for the upper bound, the Dirichlet integral over the all the triangles and necks that lie inside any $C_{\min}$ is a smaller order correction to the energy of the minimal cycle $C_{\min}$:

$$\sum_{\Pi_{ij}, e_{ij} \in C_{\min}} g_{ij}(t_i - t_j)^2.$$

Thus we have

$$\hat{a} \le \frac{1}{4L}\sum_{\Pi_{ij}} [g_{ij} + C](t_i - t_j)^2 \le \frac{1}{4L} \sum_{\Pi_{ij}, e_{ij} \notin \mathbb{D}_\delta} g_{ij}(t_i - t_j)^2$$

$$+ \frac{1}{4L} \sum_{\Pi_{ij}, e_{ij} \in \mathbb{D}_\delta} [g_{ij} + C(\mathbf{N})](t_i - t_j)^2 \le \frac{1}{4L} \sum_{\Pi_{ij}, e_{ij} \notin \mathbb{D}_\delta} g_{ij}(t_i - t_j)^2$$

$$+ \frac{1}{4L} \sum_{\Pi_{ij}, e_{ij} \in \mathbb{D}_\delta} g_{ij} \left(1 + C(\mathbf{N})\sqrt{\frac{\delta}{R}}\right)(t_i - t_j)^2 \le \left(1 + C(\mathbf{N})\sqrt{\frac{\delta}{R}}\right) \frac{1}{4L} \sum_{\Pi_{ij}} g_{ij}(t_i - t_j)^2.$$

Hence we have proved (3.11). ∎

3.4. A posteriori numerical error. The main goal of this paper is to give a rigorous quantitative justification of discrete network model (2.18) by means of a priori error estimates. However, the use of our trial functions for the upper and the lower bounds also provides us with a numerical a posteriori error. We must solve the discrete network problem (2.19)–(2.21), construct the trial functions $\phi \in V_p$ (see section 3.1) and $\mathbf{v} \in W_p$ (see section 3.2), and evaluate explicitly the left-hand side and the right-hand side of the upper and lower bound (2.10). The evaluation of this dual bound is not computationally expensive, because we use simple trial functions—they are given by explicit analytic formulas in the necks (for derivation see [4]):

$$g_{ij} = \int_{S_1}^{S_2} \frac{dx}{H(x)}$$

$$= \left[-\alpha + 2\frac{\delta_{ij} + R}{\sqrt{\delta_{ij}^2 + 2R\delta_{ij}}} \arctan\left(\frac{\sqrt{\delta_{ij}^2 + 2R\delta_{ij}}\tan(\alpha/2)}{\delta_{ij}} \right) \right] \Bigg|_{\arcsin(S_1/R)}^{\arcsin(S_2/R)},$$

and they are linear interpolations on the triangles. Also the use of the a posteriori error widens the range of the characteristic distance δ, where the discrete network gives a good approximation. This section implements this idea for numerical simulations of a randomized hexagonal lattice. For details see [4].

Our numerical experiments consist of three parts: numerical simulations of a randomized hexagonal distribution of disks; numerical evaluations of the dual variational bounds; and the statistics.

The distribution of disks is implemented by randomization of a periodic hexagonal lattice of disks of equal radii $R_i = R = 0.02$ on a square domain $[-1, 1] \times [-1, 1]$, with a volume fraction f, and then removal of some fraction f_r of these disks from this distribution. For fixed f and f_r this algorithm creates a distribution of disks with the volume fraction $f_0 = f - f_r$.

For a given distribution of disks we compute $I = I(\mathbf{t})$ (formula (2.19)), the energy of the discrete network. After the energy I is computed, we also compute the trial function ϕ for the upper bound as in section 3.2, and then we compute $I_\phi = \frac{1}{4L}\int_{Q_p} |\nabla\phi|^2 d\mathbf{x}$ for this trial function. Therefore, by construction in sections 3.1 and 3.2 we have $I \le \hat{a} \le I_\phi$. Hence I and I_ϕ are a posteriori lower and upper bounds, respectively, for the effective conductivity of a composite with a given distribution of disks.

The simulations are done with the 0.05 increments of f_r. For fixed f and f_r there were 80 simulations. For the mean we use the notation $\mathbb{E}(I) = 1/n \sum_{k=1}^{n} I^k$, where I^k is the result of kth simulation with fixed f and f_r and the number of simulations $n = 80$. Here we present the results of the numerical simulations that show the dependence of the effective conductivity on the presence of holes in the matrix.

In Figure 3.2 we plot $\mathbb{E}(I)$ (solid lines) and $\mathbb{E}(I_\phi)$ (dotted lines) as functions of the volume fraction $f_0 = 0.105, \ldots, 0.905$. For the lower two lines the volume fraction of removed disks $f_r = 0$ is fixed, for the upper two lines the initial volume fraction $f = 0.905$ is fixed, and $f_r = f - f_0$. If the total volume fraction of the inclusions is fixed, then the increase of the volume fraction of holes in the material implies that the interparticle distance δ decreases. Hence the percolation effects play a more significant role. Indeed, we observe that for the *same* volume fraction $f_0 = 0.605$ a distribution of disks with holes has the effective conductivity at least two times larger

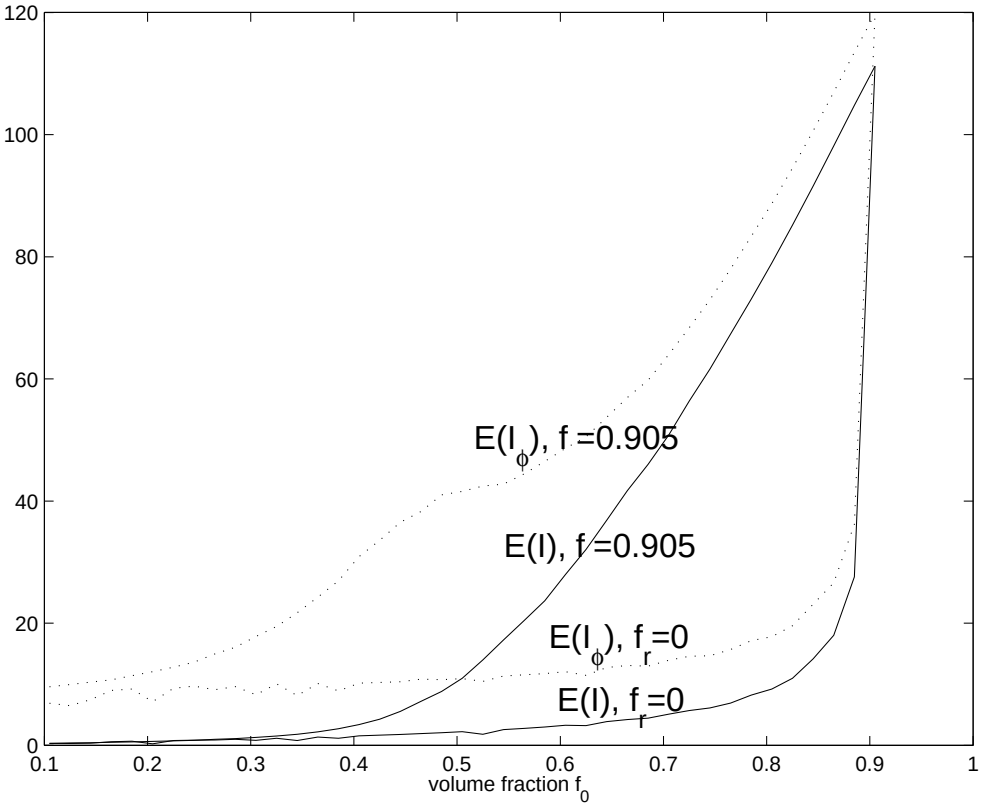

FIG. 3.2. $\mathbb{E}(I)$ *(solid lines) and* $\mathbb{E}(I_\phi)$ *(dotted lines) as functions of the volume fraction* $f_0 = 0.105, \ldots, 0.905$. *Lower two lines for the case with no holes. Upper two lines for the case with holes.*

than a distribution of disks without holes. (The lower bound in the first case is more than two times larger than the upper bound in the composite with no holes.)

When $f_0 \leq .35$ the effective conductivities of a material with holes and of a material without holes are numerically very close, at least the computed a posteriori error does not allow us to distinguish between these composites. For such volume fractions there are no percolation effects in both cases.

Observe that in the presence of holes the a posteriori error of the network approximation $I_\phi - I$ is significantly larger than in the case when there are no holes. For example, when $f_0 = .5$ in the presence of holes the a posteriori error is 3.5 times larger than the error in the case when there are no holes; however, for the same volume fraction of inclusions the *relative* a posteriori error estimate is better in the presence of holes. For example, when $f = .6$ the relative a posteriori error estimate in the presence of holes in the conducting cluster is up to 8 times better than for uniformly highly packed composites. Hence, we observe numerically that our network approximation works better for irregular geometric patterns, which are not quasi-hexagonal, that is, when a typical number of nearest neighbors can vary significantly.

Finally, let us compare the a posteriori error estimates discussed in this section and the a priori error estimates given in section 3.3 for a quasi-hexagonal case, $\mathbf{N} = 3$. Since $C(3) \leq 3.84$ in (3.9), a straightforward calculation shows that 10% accuracy is achieved when δ is about 1500 and 250 times smaller than the disk's radius R for the

a priori and a posteriori estimates, respectively.

4. Conclusions. In this paper we introduced and justified the modified network approximation which generalizes the network approximation from [3]. This modified network approximation is no longer asymptotic in nature. We decompose the Dirichlet integral (2.6) for the effective conductivity into two parts: the network approximation, which is a quadratic form, and the error term. Our modified network approximation accounts for *all* fluxes between the neighboring particles, where neighbors are defined via Voronoi tessellation. If the fluxes are small (neighbors are not closely spaced), then the corresponding coefficients in the modified network approximation g_{ij} are not significant, but unlike [3] we do not need to introduce any cut-off distance in the numerical implementation. For the network approximation the error term is explicitly estimated based on the construction of the trial functions using the triangle-neck partition of the domain. The approach developed in this paper allowed us to consider generic geometrical arrays of the particles which satisfy the so-called δ-$\mathbf{N}$ close packing condition. This condition allows for strongly nonuniform geometrical arrays when a significant fraction of the particles does not participate in the conducting cluster. We have shown numerically how such nonuniformity affects the error estimate and therefore the quality of the approximation. We observe that irregularity in the geometrical distribution of the inclusions in all simulations consistently lead to a significant (up to 10 times) increase in the effective conductivity at the same total volume fraction of the inclusions.

Thus we conclude that our approximation provides a very efficient computational tool for evaluation of the effective properties of high contrast composites, which is capable of capturing the effects of irregular geometrical arrays with a good control of the approximation error. We expect that the method developed in this work will be generalized for more complicated problems of highly packed elastic and fluid composites.

Acknowledgment. We are grateful to Ivo Babuska for raising the question of the error estimate.

PHASE-FIELD MODELS WITH HYSTERESIS IN ONE-DIMENSIONAL THERMOVISCOPLASTICITY*

PAVEL KREJČÍ†, JÜRGEN SPREKELS‡, AND ULISSE STEFANELLI§

Abstract. This paper introduces a combined one-dimensional model for thermoviscoplastic behavior under solid-solid phase transformations that incorporates the occurrence of hysteresis effects in both the strain-stress law and the phase transition described by the evolution of a *phase-field* (which is usually closely related to an order parameter of the phase transition). Hysteresis is accounted for using the mathematical theory of *hysteresis operators* developed in the past thirty years. The model extends recent works of the first two authors on phase-field models with hysteresis to the case when mechanical effects can no longer be ignored or even prevail. It leads to a strongly nonlinear coupled system of partial differential equations in which hysteresis nonlinearities occur at several places, even under time and space derivatives. We show the thermodynamic consistency of the model, and we prove its well-posedness.

Key words. phase-field systems, phase transitions, hysteresis operators, thermoviscoplasticity, thermodynamic consistency

1. Introduction and physical motivation.

In this paper, we study initial-boundary value problems for systems of partial differential equations of the form

$$\rho u_{tt} - \mu u_{xxt} = \sigma_x + f(x,t) \quad \text{a.e. in } \Omega_T, \tag{1.1}$$

$$\sigma = \mathcal{H}_1[u_x, w] + \theta\, \mathcal{H}_2[u_x, w] \quad \text{a.e. in } \Omega_T, \tag{1.2}$$

$$\Big(C_V\theta + \mathcal{F}_1[u_x, w]\Big)_t - \kappa\theta_{xx} = \mu u_{xt}^2 + \sigma u_{xt} + g(x,t,\theta) \quad \text{a.e. in } \Omega_T, \tag{1.3}$$

$$\nu w_t = -\psi \quad \text{a.e. in } \Omega_T, \tag{1.4}$$

$$\psi = \mathcal{H}_3[u_x, w] + \theta\, \mathcal{H}_4[u_x, w] \quad \text{a.e. in } \Omega_T, \tag{1.5}$$

$$u(\cdot,0) = u_0, \quad u_t(\cdot,0) = u_1, \quad \theta(\cdot,0) = \theta_0, \quad w(\cdot,0) = w_0 \quad \text{a.e. in } \Omega, \tag{1.6}$$

$$u(0,t) = 0, \quad \mu\, u_{xt}(1,t) + \sigma(1,t) = 0, \quad \theta_x(0,t) = \theta_x(1,t) = 0 \quad \text{a.e. in } (0,T), \tag{1.7}$$

where $\Omega := (0,1)$, $T > 0$ denotes some final time, and where $\Omega_t := \Omega \times (0,t)$ for $t \in (0,T]$.

The system (1.1)–(1.7) constitutes a model for the one-dimensional thermomechanical developments in a linearly viscous piece of wire of unit length in which a solid-solid phase transition takes place. In this connection, the unknowns u, θ, σ, w, ψ denote displacement, absolute (Kelvin) temperature, elastoplastic stress, phase variable (usually a so-called *generalized freezing index*; cf. [15]), and the thermodynamic force driving the phase transition, respectively. The positive physical constants ρ, μ, C_V, κ, ν denote mass density, viscosity, specific heat, heat conductivity, and a relaxation coefficient, in that order. For the sake of notational convenience, we will always assume without loss of generality that $\rho = \mu = C_V = \kappa = \nu = 1$. Finally, the expressions $\mathcal{H}_j$, $1 \le j \le 4$, and $\mathcal{F}_1$ are nonlinearities of *hysteresis type* (to be specified below).

The equations (1.1), (1.3), (1.4) represent the equation of motion, the balance of internal energy, and the phase evolution equation, in that order (see below); equation (1.2) is the constitutive law relating strain and phase variable to the elastoplastic stress, and (1.4) expresses that the phase variable evolves into the opposite direction of the thermodynamic force driving the phase transition. In addition, the boundary conditions (1.7) indicate that the wire is thermally insulated at both ends, fixed at $x = 0$, and stress-free at $x = 1$.

The motivation to study systems of the above type is twofold. On the one hand, it is well known that for many materials the macroscopic strain-stress (ε-σ, where $\varepsilon = u_x$ is the linearized strain and u is the displacement) relations measured in uniaxial load-deformation experiments strongly depend on the absolute (Kelvin) temperature θ and, at the same time, exhibit a strong elastoplasticity witnessed by the occurrence of *hysteresis loops* that are *rate-independent*, i.e., independent of the speed with which there are traversed. Due to the hysteresis, which reflects the presence of a *rate-independent memory* in the material, the stress-strain relation can no longer be expressed in terms of a simple single-valued function. Among the materials showing very strong temperature-dependent hysteretic effects are the so-called *shape memory alloys* (see Figure 1 below and Chapter 5 in [2]); but even quite ordinary steels are well known to exhibit this kind of behavior (cf. [21]), although to a smaller extent.

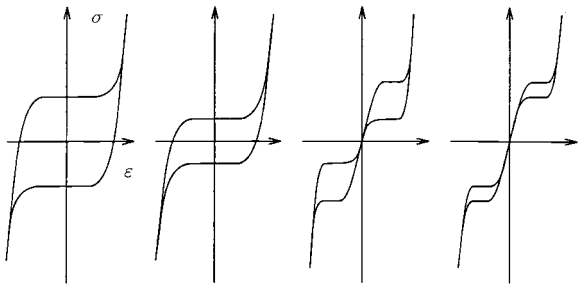

FIG. 1. *Schematic load-deformation curves in shape memory alloys, with temperature increasing from left to right.*

Usually the occurrence of a hysteresis in the macroscopic stress-strain relations is accompanied (or even triggered) by changes between different configurations of the crystal lattice within the solid. It thus makes sense to complement macroscopic equations of thermoelastoplasticity by field equations accounting for such phase trans-

formations on the micro- and/or mesoscales.

On the other hand, phase transition phenomena are often accompanied by macroscopic hysteresis effects that are caused by thermal and/or mechanical stresses acting on the micro- and/or mesoscales. It then makes sense to complement the field equations describing the macroscopic phase transition by equations modeling such micro- or mesoscopic stresses.

A classical approach to such problems would be the following. One first tries to construct a local *free energy function* of the form

$$F(\varepsilon, w, \theta) = \theta(1 - \log(\theta)) + F_1(\varepsilon, w) + \theta\, F_2(\varepsilon, w) \tag{1.8}$$

in such a way that the experimentally observed ε-σ and/or w-ψ hysteresis loops are approximately matched using the relations

$$\sigma = \frac{\partial F}{\partial \varepsilon}(\varepsilon, w, \theta), \quad \psi = \frac{\partial F}{\partial w}(\varepsilon, w, \theta), \tag{1.9}$$

then determines the corresponding *internal energy* U and *entropy* S,

$$\begin{aligned} U(\varepsilon, w, \theta) &:= F(\varepsilon, w, \theta) - \theta\, \frac{\partial F}{\partial \theta}(\varepsilon, w, \theta) = \theta + F_1(\varepsilon, w), \\ S(\varepsilon, w, \theta) &:= -\frac{\partial F}{\partial \theta}(\varepsilon, w, \theta) = \log(\theta) - F_2(\varepsilon, w), \end{aligned} \tag{1.10}$$

and finally inserts these expressions in the governing field equations: equation of motion,

$$u_{tt} - \tilde{\sigma}_x = f \quad (\tilde{\sigma} = \text{total stress} = \sigma + \text{viscous stress}), \tag{1.11}$$

balance of internal energy,

$$U_t - \theta_{xx} = \tilde{\sigma} u_{xt} + g \quad (U = \text{internal energy}), \tag{1.12}$$

and phase evolution equation (1.4).

We then obtain (1.1), (1.3), (1.4) if we put

$$\begin{aligned} &\mathcal{H}_1[\varepsilon, w] := \frac{\partial F_1}{\partial \varepsilon}(\varepsilon, w), \quad \mathcal{H}_2[\varepsilon, w] := \frac{\partial F_2}{\partial \varepsilon}(\varepsilon, w), \\ &\mathcal{H}_3[\varepsilon, w] := \frac{\partial F_1}{\partial w}(\varepsilon, w), \quad \mathcal{H}_4[\varepsilon, w] := \frac{\partial F_2}{\partial w}(\varepsilon, w), \\ &\mathcal{F}_1[\varepsilon, w] := F_1(\varepsilon, w). \end{aligned} \tag{1.13}$$

In order that an ε-σ (or w-ψ, respectively) hysteresis be modeled by (1.9), $F(\cdot, w, \theta)$ ($F(\varepsilon, \cdot, \theta)$, respectively) needs to be a nonconvex function within the range of interesting temperatures.

This approach has advantages: if the nonlinearities involved in (1.1)–(1.7) are smooth functions, then the vast literature on one-dimensional thermoviscoelasticity (we just refer to the fundamental papers [4], [5]) can be applied to derive results concerning well-posedness and asymptotic behavior. However, while this approach is capable of correctly predicting many of the experimentally observed phenomena, it also has certain disadvantages from the phenomenological (engineering) point of view: the use of a nonconvex free energy does not guarantee that a hysteresis actually occurs; one only observes that unstable branches are traversed with a very high speed, which

may look like a hysteresis if the speed is interpreted as infinite. For the moment, there is no mathematical theory which would allow us to rigorously justify this singular transition and give a correct account of the inherent memory structures that are responsible for the complicated loopings in the interior of the external hysteresis loops that are observed in experiments.

To avoid these difficulties, the first two authors have recently proposed a different approach using the theory of *hysteresis operators* developed in the past thirty years (let us at least refer to the monographs [8], [20], [22], [2], [9] devoted to this subject). In this approach, we replace the relations (1.9) by the identities (1.2), (1.5), where the expressions $\mathcal{H}_j$, $1 \le j \le 4$, and $\mathcal{F}_1$ are no longer real-valued *functions* but *hysteresis operators* acting between suitable function spaces. This approach has been successfully carried out for the two cases when either we have one-dimensional thermoelastoplastic hysteresis without the order parameter evolution (that is, we have (1.1)–(1.3) with no dependence on w; cf. the papers [10], [11]) or we have a multidimensional phase transition without mechanical effects (that is, we have (1.3)–(1.5) with no dependence on u, σ; see [7], [12], [13], [14], [15], [16], [17]). In this paper, we want to extend some of these results to the fully coupled problem.

At this point we remark that in [10], [11] a more general constitutive law than (1.2) has been treated in that there the hysteresis operators could also depend on θ. However, no dependence on w was admitted in [10], [11]. It is in fact this additional dependence that forces us to assume σ in the form (1.2) which, on the other hand, is quite typical in the Landau theory of phase transitions (cf. Chapter 4 in [2]). The extension of the results of this paper to more general temperature-dependent hysteresis operators seems to be a very difficult unsolved problem.

We also note that in [18] the present authors have studied a related version of system (1.1)–(1.7): there, an additional curvature term was added on the left of (1.1), and the boundary conditions for u were of the form $u(0,t) = u(1,t) = u_{xx}(0,t) = u_{xx}(1,t) = 0$. Let us stress the fact that the mathematical analysis carried out in [18] differs considerably from that used in this paper. In fact, the problem investigated here is more difficult than that studied in [18]: if the smoothing term γu_{xxxx} is present in (1.1), then already the first a priori estimate (see below) yields an $L^\infty(L^2)$-bound for the strain gradient u_{xx} and thus an $L^\infty(L^\infty)$-bound for u_x. This means that the Andrews transformation (see (3.1) below) used in this paper to eventually bound u_x is not needed. As a consequence, the solution established in this paper enjoys less smoothness than that in [18]. On the other hand, our analysis does not apply to the case when (1.1) is complemented with zero boundary conditions at both ends of the wire: we have to assume a stress-free regime at one of the ends in order to take advantage of the Andrews transformation.

Let us now recall some basic facts about the notion of hysteresis operators (for details, we refer to the monographs mentioned above). Let $T > 0$ denote some (final) time. A mapping $\mathcal{H}$ from the set $\mathrm{Map}[0,T] := \{w : [0,T] \to \mathbb{R}\}$ into itself is called a *hysteresis operator* if it is *causal*, that is, if for all $w_1, w_2 \in \mathrm{Map}[0,T]$ and $t \in [0,T]$ we have the implication

$$w_1(\tau) = w_2(\tau) \quad \forall\, \tau \in [0,t] \;\Rightarrow\; \mathcal{H}[w_1](t) = \mathcal{H}[w_2](t),$$

and if it is *rate-independent*, that is, if for every $w \in \mathrm{Map}[0,T]$ and every continuous increasing mapping α of $[0,T]$ onto $[0,T]$ we have

$$\mathcal{H}[w \circ \alpha](t) = \mathcal{H}[w](\alpha(t)) \quad \forall\, t \in [0,T].$$

In the case of partial differential equations, when the input functions not only depend on a time variable $t \in [0,T]$ but also on a space variable $x \in [0,1]$, it is necessary to extend the above notion. In this situation, it is natural to associate with a hysteresis operator $\mathcal{H}$ defined on $\mathrm{Map}[0,T]$ in the above sense an operator $\hat{\mathcal{H}}$ acting on $\mathrm{Map}([0,1] \times [0,T])$ by simply putting

$$\hat{\mathcal{H}}[w](x,t) := \mathcal{H}[w(x,\cdot)](t). \tag{1.14}$$

It is customary to identify the operators $\mathcal{H}$ and $\hat{\mathcal{H}}$. The hysteresis operators appearing in (1.1)–(1.7) have to be understood in this way.

The advantage of this approach is that an operator equation like (1.2), (1.5), is suited much better than a relation like (1.9) to keep track of the memory effects imprinted on the material in the past history. In fact, the output at any time $t \in [0,T]$ may depend on the whole evolution of the input in the time interval $[0,t]$. Observe that the rate-independence implies that the hysteresis behavior cannot be expressed in terms of an integral operator of convolution type; i.e., we are not dealing with a model with fading memory.

Unfortunately, there are also disadvantages: the input-output behavior of hysteresis operators usually cannot be described explicitly, and they have, as a rule, only very restricted smoothness properties. In fact, nontrivial hysteresis operators are, as a rule, *not differentiable*, but at best only (possibly locally) *Lipschitz continuous* in suitable function spaces; in addition, they carry a *nonlocal memory* with respect to time.

Both nondifferentiability and presence of a memory are unpleasant features from the mathematical point of view. For instance, the classical method of deriving higher order a priori estimates for w (namely, differentiation of (1.4) with respect to t and testing with w_t) does not immediately work, since there is no chain rule for the hysteretic nonlinearities; also, we may not simply differentiate (1.2) or (1.5) with respect to x. These facts result in a lack of compactness and thus in difficulties in existence proofs.

However, hysteresis operators usually dissipate energy which typically is proportional to the area of closed traversed loops in the hysteresis diagram. Let us explain this fact for one fundamental hysteresis operator which plays a most prominent role in the theory, namely the so-called *stop operator* or *Prandtl's normalized elastic–perfectly plastic element*. To this end, let $r > 0$ (the yield limit) and $\sigma_r^0 \in [-r,r]$ (the initial stress) be given. For any input function $\varepsilon \in W^{1,1}(0,T)$, we define the output $\sigma_r \in W^{1,1}(0,T)$ as the solution to the variational inequality (the index t denotes time differentiation)

$$\sigma_r(t) \in [-r,r] \quad \forall\, t \in [0,T], \quad \sigma_r(0) = \sigma_r^0, \tag{1.15}$$

$$(\varepsilon_t(t) - \sigma_{r,t}(t))(\sigma_r(t) - \eta) \geq 0 \quad \forall\, \eta \in [-r,r] \quad \text{a.e. in } (0,T). \tag{1.16}$$

In Figure 2, the typical input-output behavior is depicted.

It can easily be proved (see, for instance, [9], where also the multidimensional case is treated) that (1.15)–(1.16) admits a unique solution $\sigma_r \in W^{1,1}(0,T)$ for every $\varepsilon \in W^{1,1}(0,T)$ and $\sigma_r^0 \in [-r,r]$. The corresponding solution operator

$$s_r : [-r,r] \times W^{1,1}(0,T) \to W^{1,1}(0,T) : (\sigma_r^0, \varepsilon) \mapsto \sigma_r \tag{1.17}$$

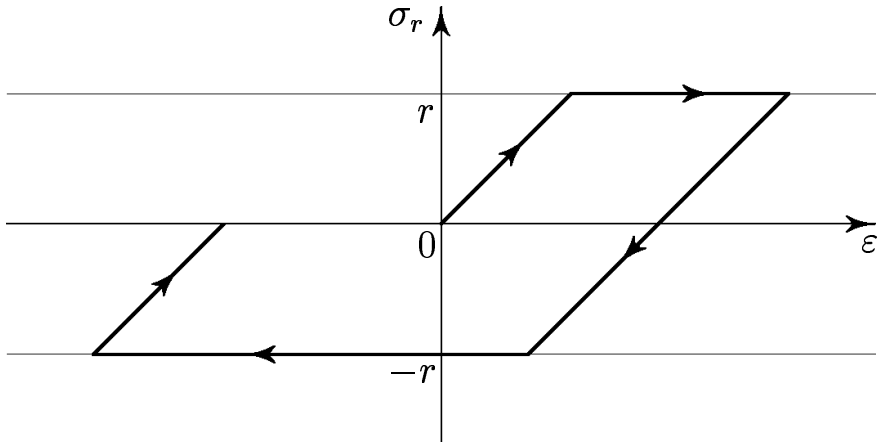

FIG. 2. *Prandtl's normalized elastic–perfectly plastic element.*

is just the stop operator. It has the well-known property (cf. [2], [9]) that for any $r_1, r_2 \in [0, +\infty)$, $\sigma^0_{r_j} \in [-r_j, +r_j]$, $j = 1, 2$, $t \in [0, T]$, and $\varepsilon_1, \varepsilon_2 \in C[0, T]$, it holds that

$$\begin{aligned} &\big|s_{r_1}[\sigma^0_{r_1}, \varepsilon_1](t) - s_{r_2}[\sigma^0_{r_2}, \varepsilon_2](t)\big| \\ &\le |\varepsilon_1(t) - \varepsilon_2(t)| + \max\Big\{|r_1 - r_2| + \max_{0\le\tau\le t} |\varepsilon_1(\tau) - \varepsilon_2(\tau)|, \big|\sigma^0_{r_1} - \sigma^0_{r_2}\big|\Big\}. \end{aligned} \tag{1.18}$$

In addition, it holds for any $\varepsilon \in W^{1,1}(0, T)$ that

$$\big\|s_r[\sigma^0_r, \varepsilon]\big\|_\infty \le r, \quad s_r[\sigma^0_r, \varepsilon]_t(t) = \varepsilon_t(t) \quad \text{if} \quad \big|s_r[\sigma^0_r, \varepsilon](t)\big| < r, \tag{1.19}$$

$$\big|s_r[\sigma^0_r, \varepsilon]_t\big|^2 = s_r[\sigma^0_r, \varepsilon]_t \varepsilon_t \quad \text{a.e. in } (0, T). \tag{1.20}$$

For each fixed initial condition σ^0_r, the stop operator is a hysteresis operator in the sense of the above definition, where the value of σ^0_r accounts for some previous memory. On the other hand, the value at $t = 0$ of the output of any rate-independent operator can be represented as a function of the initial value of the input. For the operators occurring in our model, we will not make any special assumptions about their initial configurations, except for those that follow from the general analytic conditions imposed below in hypothesis (H4), like, e.g., Lipschitz continuous input-output relation.

We now describe the intrinsic dissipation property of the stop operator. It results if we insert $\eta = 0$ in (1.16). We then obtain that the energy $\mathcal{P}_r := \frac{1}{2} s_r^2$ of the stop element satisfies the inequality

$$\frac{d}{dt}\, \mathcal{P}_r[\sigma^0_r, \varepsilon](t) \le s_r[\sigma^0_r, \varepsilon](t)\, \varepsilon_t(t) \quad \text{a.e. in } (0, T) \tag{1.21}$$

for all $(\sigma^0_r, \varepsilon) \in [-r, r] \times W^{1,1}(0, T)$, and the difference between the right and the left of (1.21) is the dissipated energy. Equation (1.21) can also be interpreted as a *chain rule inequality* for the energy operator $\mathcal{P}_r$ where the stop operator s_r plays the role of the "derivative" of $\mathcal{P}_r$ with respect to ε (only formally, since $\mathcal{P}_r$ is certainly not differentiable with respect to ε).

Chain rule inequalities of the form (1.21) have proven to be crucial for a successful study of differential equations with hysteresis (for this, see the cited literature). In the case of system (1.1)–(1.7), an appropriate form of such a condition is to postulate the existence of a further hysteresis operator $\mathcal{F}_2$ such that for any $(\varepsilon, w) \in W^{1,1}(0,T) \times W^{1,1}(0,T)$ it holds, for a.e. $t \in (0,T)$, that

$$\begin{aligned} &\frac{d}{dt}\,\mathcal{F}_1[\varepsilon,w](t) \le \mathcal{H}_1[\varepsilon,w](t)\,\varepsilon_t(t) + \mathcal{H}_3[\varepsilon,w](t)\,w_t(t), \\ &\frac{d}{dt}\,\mathcal{F}_2[\varepsilon,w](t) \le \mathcal{H}_2[\varepsilon,w](t)\,\varepsilon_t(t) + \mathcal{H}_4[\varepsilon,w](t)\,w_t(t). \end{aligned} \tag{1.22}$$

We then can associate with system (1.1)–(1.7) free energy, entropy, and internal energy *hysteresis operators* by putting (compare (1.8), (1.10))

$$\begin{aligned} &\mathcal{F}[\varepsilon,w,\theta] := \theta(1-\log(\theta)) + \mathcal{F}_1[\varepsilon,w] + \theta\,\mathcal{F}_2[\varepsilon,w], \\ &\mathcal{S}[\varepsilon,w,\theta] := \log(\theta) - \mathcal{F}_2[\varepsilon,w], \\ &\mathcal{U}[\varepsilon,w,\theta] := \theta + \mathcal{F}_1[\varepsilon,w], \end{aligned} \tag{1.23}$$

where $[\varepsilon, w, \theta] \in \mathrm{Map}[0,T] \times \mathrm{Map}[0,T] \times (0,+\infty)$. Indeed, if we associate σ and ψ as given by (1.2) and (1.5), respectively, with the "derivatives" of $\mathcal{F}$ with respect to ε and w (only formally, as they do not exist), respectively, then we arrive at system (1.1)–(1.5) as field equations. It will turn out later that the validity of (1.22) (rather, of a generalized version thereof; see below) will guarantee the thermodynamic consistency of the model, that is, the temperature stays positive during the evolution, and the *Clausius–Duhem inequality*, which in view of (1.12) can be written in the form

$$\theta\,\frac{d}{dt}\,\mathcal{S}[\varepsilon,w,\theta] - \frac{d}{dt}\,\mathcal{U}[\varepsilon,w,\theta] \ge -\tilde{\sigma}\varepsilon_t \quad \text{a.e. in } \Omega_T, \tag{1.24}$$

where $\tilde{\sigma} = \sigma + \varepsilon_t$ again denotes the total stress, will be satisfied.

The rest of the paper is organized as follows: In section 2, we give a detailed statement of the mathematical problem and of the main mathematical result. Section 3 brings the proof of local existence and global uniqueness, and in the concluding section 4 we prove global existence for system (1.1)–(1.7).

In what follows, the norms of the standard Lebesgue spaces $L^p(\Omega)$ for $1 \le p \le \infty$ will be denoted by $\|\cdot\|_p$. Finally, we shall use the usual denotations $W^{m,p}(\Omega)$ and $H^m(\Omega)$, $m \in \mathbb{N}$, $1 \le p \le \infty$, for the standard Sobolev spaces.

2. Statement of the problem. We make the following general assumptions on the data of the system.

(H1) $u_0 \in H^2(\Omega)$, $u_1 \in H^1(\Omega)$, $\theta_0 \in H^1(\Omega)$, $w_0 \in H^1(\Omega)$, it holds that $\theta_0(x) \ge \delta > 0$ for all $x \in \bar{\Omega}$, and the compatibility condition $u_0(0) = u_1(0) = 0$ is satisfied.

(H2) It holds that $f \in H^1(0,T;L^2(\Omega))$.

(H3) We assume that $g : \Omega \times (0,T) \times \mathbb{R} \to \mathbb{R}$ is a Carathéodory function such that

$$\exists\, g_0 \in L^\infty(\Omega_T) : \quad \theta \le 0 \;\Rightarrow\; g(x,t,\theta) = g_0(x,t), \tag{2.1}$$

$$\begin{aligned} &\exists\, K_1 > 0 : \quad |g(x,t,\theta_1) - g(x,t,\theta_2)| \le K_1|\theta_1 - \theta_2| \quad \text{for a.e.} \\ &(x,t) \in \Omega \times (0,T) \text{ and } \forall \theta_1, \theta_2 \in \mathbb{R}, \end{aligned} \tag{2.2}$$

$$g_0(x,t) \geq 0 \qquad \text{a.e. in } \Omega_T. \tag{2.3}$$

(H4) The operators $\mathcal{H}_j$, $1 \leq j \leq 4$, and $\mathcal{F}_1$ are causal and map $C[0,T] \times C[0,T]$ continuously into $C[0,T]$, and $W^{1,1}(0,T) \times W^{1,1}(0,T)$ into $W^{1,1}(0,T)$. In addition, the following conditions are satisfied:

(i) $\exists\, K_2 > 0 :\ \forall\, \varepsilon, w \in C[0,T]$ it holds that

$$\max_{j\in\{2,4\}} \|\mathcal{H}_j[\varepsilon,w]\|_\infty \leq K_2, \quad \mathcal{F}_1[\varepsilon,w](t) \geq -K_2 \quad \forall\, t \in [0,T]. \tag{2.4}$$

(ii) $\exists\, K_3 > 0 :\ \forall\, \varepsilon, w \in W^{1,1}(0,T)$ it holds, for a.e. $t \in (0,T)$, that

$$\max_{1\leq j\leq 4} |\mathcal{H}_j[\varepsilon,w]_t(t)| + |\mathcal{F}_1[\varepsilon,w]_t(t)| \leq K_3\Big(|\varepsilon_t(t)| + |w_t(t)|\Big). \tag{2.5}$$

(iii) $\exists\, K_4 > 0 :\ \forall\, \varepsilon_1, w_1, \varepsilon_2, w_2 \in C[0,T]$ it holds, for every $t \in [0,T]$, that

$$\begin{aligned} &\max_{1\leq j\leq 4} |\mathcal{H}_j[\varepsilon_1,w_1](t) - \mathcal{H}_j[\varepsilon_2,w_2](t)| \\ &\leq K_4 \max_{0\leq r\leq t}\Big(|\varepsilon_1(r) - \varepsilon_2(r)| + |w_1(r) - w_2(r)|\Big), \end{aligned} \tag{2.6}$$

and $\forall\, \varepsilon_1, w_1, \varepsilon_2, w_2 \in W^{1,1}(0,T)$ it holds, for every $t \in [0,T]$, that

$$\begin{aligned} |\mathcal{F}_1[\varepsilon_1,w_1](t) - \mathcal{F}_1[\varepsilon_2,w_2](t)| \leq K_4\Big[&|\varepsilon_1(0) - \varepsilon_2(0)| + |w_1(0) - w_2(0)| \\ &+ \int_0^t \Big(|\varepsilon_{1,t}(r) - \varepsilon_{2,t}(r)| + |w_{1,t}(r) - w_{2,t}(r)|\Big)\, dr\Big]. \end{aligned} \tag{2.7}$$

(H5) There exist causal operators $\mathcal{F}_2 : W^{1,1}(0,T) \times W^{1,1}(0,T) \to W^{1,1}(0,T)$, $\mathcal{G} : W^{1,1}(0,T) \to W^{1,1}(0,T)$, and a constant $K_5 > 0$ such that the following conditions are satisfied:

(i) For every $\varepsilon, w \in W^{1,1}(0,T)$ it holds that

$$\mathcal{F}_1[\varepsilon,w]_t \leq \varepsilon_t\, \mathcal{H}_1[\varepsilon,w] + \mathcal{G}[w]_t\, \mathcal{H}_3[\varepsilon,w] \quad \text{a.e. in } (0,T), \tag{2.8}$$

$$\mathcal{F}_2[\varepsilon,w]_t \leq \varepsilon_t\, \mathcal{H}_2[\varepsilon,w] + \mathcal{G}[w]_t\, \mathcal{H}_4[\varepsilon,w] \quad \text{a.e. in } (0,T). \tag{2.9}$$

(ii) For every $w \in W^{1,1}(0,T)$ it holds that

$$|\mathcal{G}[w]_t(t)|^2 \leq K_5 w_t(t)\, \mathcal{G}[w]_t(t) \quad \text{for a.e. } t \in (0,T). \tag{2.10}$$

Remark 1. Owing to (H4)(iii) we have, in particular, that for any $\varepsilon, w \in H^1(0,T)$ and $t \in [0,T]$ the following holds:

$$\begin{aligned} &|\mathcal{H}_1[\varepsilon,w](t)| + |\mathcal{H}_3[\varepsilon,w](t)| \\ &\leq |\mathcal{H}_1[\varepsilon,w](0)| + |\mathcal{H}_3[\varepsilon,w](0)| + 2K_4 \max_{0\leq r\leq t} (|\varepsilon(r) - \varepsilon(0)| + |w(r) - w(0)|) \\ &\leq |\mathcal{H}_1[\varepsilon,w](0)| + |\mathcal{H}_3[\varepsilon,w](0)| + 2K_4 \int_0^t \Big(|\varepsilon_t(r)| + |w_t(r)|\Big)\, dr \\ &\leq |\mathcal{H}_1[\varepsilon,w](0)| + |\mathcal{H}_3[\varepsilon,w](0)| + 2K_4\sqrt{t} \left(\int_0^t \Big(|\varepsilon_t(r)|^2 + |w_t(r)|^2\Big)\, dr\right)^{1/2}. \end{aligned} \tag{2.11}$$

In addition, a linear growth of $\mathcal{H}_1$ and $\mathcal{H}_3$ with respect to both ε and w is admitted, which, in particular, includes the case of simple linear elasticity. It also follows that for any $\varepsilon, w \in H^1(\Omega; C[0,T])$ it holds, for a.e. $(x,t) \in \Omega_T$, that

$$\max_{1\le j\le 4} \Big| \Big(\mathcal{H}_j[\varepsilon, w]\Big)_x (x,t)\Big| \le K_4 \max_{0\le r\le t} \Big(|\varepsilon_x(x,r)| + |w_x(x,r)|\Big). \tag{2.12}$$

Indeed, we only have to apply (2.6) with $\varepsilon_1(x,t) := \varepsilon(x+h,t)$, $\varepsilon_2(x,t) := \varepsilon(x,t)$, $w_1(x,t) := w(x+h,t)$, $w_2(x,t) := w(x,t)$, with some $h > 0$, and then let $h \searrow 0$. Consequently, we may consider first order spatial derivatives of $\mathcal{H}_j[\varepsilon, w]$, and we have $(\mathcal{H}_j[\varepsilon, w])_x \in L^2(\Omega_T)$, $1 \le j \le 4$.

Remark 2. A typical example where (H4), (H5) are fulfilled is given by *Prandtl–Ishlinskii operators* of the form

$$\begin{aligned} \mathcal{H}_j[\varepsilon, w] &:= \int_0^\infty \varphi_j(r)\, s_r\left[\sigma_r^{0,j}, \varepsilon\right]\, dr, \quad j = 1,2, \\ \mathcal{H}_j[\varepsilon, w] &:= \int_0^\infty \varphi_j(r)\, s_r\left[\sigma_r^{0,j}, w\right]\, dr, \quad j = 3,4, \end{aligned} \tag{2.13}$$

where $\sigma_r^{0,j} \in [-r, +r]$, $1 \le j \le 4$, are given initial values for the operators s_r defined in (1.17), and the weight functions φ_j are nonnegative on $[0, +\infty)$ and satisfy

$$\max_{1\le j\le 4} \int_0^\infty (1+r^2)\, \varphi_j(r)\, dr < +\infty. \tag{2.14}$$

Indeed, defining the (energy) operators

$$\begin{aligned} \mathcal{F}_1[\varepsilon, w] &:= \frac{1}{2}\int_0^\infty \Big(\varphi_1(r)\, s_r^2\left[\sigma_r^{0,1}, \varepsilon\right] + \varphi_3(r)\, s_r^2\left[\sigma_r^{0,3}, w\right]\Big)\, dr, \\ \mathcal{F}_2[\varepsilon, w] &:= \frac{1}{2}\int_0^\infty \Big(\varphi_2(r)\, s_r^2\left[\sigma_r^{0,2}, \varepsilon\right] + \varphi_4(r)\, s_r^2\left[\sigma_r^{0,4}, w\right]\Big)\, dr, \end{aligned} \tag{2.15}$$

choosing $\mathcal{G}[w] = w$, and invoking the properties (1.21)–(1.24) of the stop operators s_r, we easily verify the validity of (H4), (H5). Other examples, where the dependence on ε, w is no longer decoupled as in (2.13), can be constructed using multidimensional stop operators as basic elements (cf. [15], [16]). For examples where the $\mathcal{H}_j$ are not Prandtl–Ishlinskii operators and $\mathcal{G}$ differs from the identity operator, we refer to [14], [15].

We can now formulate the main result of this paper.

THEOREM 2.1. *Suppose that the hypotheses* (H1) *to* (H5) *are satisfied. Then the system* (1.1)–(1.7) *admits a unique strong solution* (u, θ, w) *such that* (1.1)–(1.5) *hold a.e. in* Ω_T*, and such that*

$$\begin{aligned} &u \in H^2(0,T; L^2(\Omega)) \cap H^1(0,T; H^2(\Omega)),\ w \in H^2(0,T; L^2(\Omega)) \cap H^1(0,T; H^1(\Omega)), \\ &\theta \in H^1(0,T; L^2(\Omega)) \cap L^2(0,T; H^2(\Omega)). \end{aligned} \tag{2.16}$$

In addition, with the finite norms $\beta_1 := \|u_{xt}\|_{L^1(0,T;L^\infty(\Omega))}$ *and* $\beta_2 := \|w_t\|_{C(\overline{\Omega_T})}$ *it holds that*

$$\theta(x,t) \ge \delta e^{-((K_1 + K_2K_5\beta_2)t + K_2\beta_1)} \quad \forall (x,t) \in \overline{\Omega_T}. \tag{2.17}$$

Remark 3. We note at this point that Theorem 2.1 also implies that the second principle of thermodynamics is satisfied for the system (1.1)–(1.7). Indeed, we have

$\theta > 0$ in $\overline{\Omega_T}$, and the validity of the Clausius–Duhem inequality (1.24) follows from the simple calculation

$$\begin{aligned} &\theta\,\mathcal{S}[\varepsilon,w,\theta]_t - \mathcal{U}[\varepsilon,w,\theta]_t + \tilde{\sigma}\varepsilon_t = -\theta\,\mathcal{F}_2[\varepsilon,w]_t - \mathcal{F}_1[\varepsilon,w]_t + \sigma\varepsilon_t + \varepsilon_t^2 \\ &\geq -\Big(\mathcal{H}_1[\varepsilon,w] + \theta\,\mathcal{H}_2[\varepsilon,w]\Big)\varepsilon_t - \Big(\mathcal{H}_3[\varepsilon,w] + \theta\,\mathcal{H}_4[\varepsilon,w]\Big)\mathcal{G}[w]_t + \sigma\varepsilon_t + \varepsilon_t^2 \\ &\geq \varepsilon_t^2 + w_t\,\mathcal{G}[w]_t \geq 0 \quad \text{a.e. in } \Omega_T, \end{aligned} \tag{2.18}$$

where $\mathcal{F}, \mathcal{S}, \mathcal{U}$ are given by (1.23). We may therefore claim that our system is thermodynamically consistent.

The proof of Theorem 2.1 will be given in the following sections. During its course, we will make repeated use of *Young's inequality*,

$$ab \leq \frac{\delta}{2}a^2 + \frac{1}{2\delta}b^2 \quad \forall\, a,b \in \mathbb{R},\ \delta > 0, \tag{2.19}$$

of the elementary inequality,

$$|z(t)|^2 \leq 2|z(0)|^2 + 2t\int_0^t z_t^2(r)\,dr \quad \forall\, t \in (0,T) \quad \forall\, z \in H^1(0,T), \tag{2.20}$$

and of the one-dimensional *Gagliardo–Nirenberg inequality*,

$$\|w\|_p \leq K_0\Big(\|w\|_q^{1-\omega}\|w_x\|_r^{\omega} + \|w\|_q\Big) \quad \forall\, w \in W^{1,r}(\Omega) \cap L^q(\Omega), \tag{2.21}$$

where $K_0 > 0$ is a constant depending only on p, q, r, and where

$$1 \leq r \leq +\infty, \quad 1 \leq q \leq p \leq +\infty, \quad \omega\left(\frac{1}{q} - \frac{1}{r} + 1\right) = \frac{1}{q} - \frac{1}{p}. \tag{2.22}$$

3. Local existence. We rewrite the system (1.1)–(1.7), using the transformation due to Andrews [1],

$$u_x = p + q, \quad \text{where } p(x,t) := \int_1^x u_t(\xi,t)\,d\xi. \tag{3.1}$$

We easily find that (1.1)–(1.6) is equivalent to the system

$$p_t - p_{xx} = \sigma + \int_1^x f(\xi,t)\,d\xi, \tag{3.2}$$

$$p(1,t) = p_x(0,t) = 0, \quad p(x,0) = \int_1^x u_1(\xi)\,d\xi, \tag{3.3}$$

$$\sigma = \mathcal{H}_1[p+q,w] + \theta\,\mathcal{H}_2[p+q,w], \tag{3.4}$$

$$q_t = -\sigma - \int_1^x f(\xi,t)\,d\xi, \tag{3.5}$$

$$q(x,0) = u_0'(x) - \int_1^x u_1(\xi)\,d\xi, \tag{3.6}$$

$$\Big(\theta + \mathcal{F}_1[p+q,w]\Big)_t - \theta_{xx} = p_{xx}^2 + \sigma p_{xx} + g(x,t,\theta), \tag{3.7}$$

$$w_t = -\psi, \tag{3.8}$$

$$\psi = \mathcal{H}_3[p+q,w] + \theta\,\mathcal{H}_4[p+q,w], \tag{3.9}$$

$$\theta(x,0) = \theta_0(x), \quad w(x,0) = w_0(x), \quad \theta_x(0,t) = \theta_x(1,t) = 0. \tag{3.10}$$

Let $V_0 := \{z \in H^1(\Omega); z(1) = 0\}$, and let V_0^* denote its dual space. We are going to show the following result.

THEOREM 3.1. *Suppose that the hypotheses* (H1) *to* (H4) *are fulfilled. Then there is some* $\hat\tau > 0$ *such that the initial-boundary value problem* (3.2)–(3.10) *admits a unique solution quadruple* (p,q,θ,w) *on* $\bar\Omega \times [0,\hat\tau]$ *satisfying*

$$p \in H^2(0,\hat\tau;V_0^*) \cap H^1(0,\hat\tau;H^1(\Omega)) \cap L^2(0,\hat\tau;H^3(\Omega)), \tag{3.11}$$

$$q, w \in H^2(0,\hat\tau;L^2(\Omega)) \cap H^1(0,\hat\tau;H^1(\Omega)) \cap C^1([0,\hat\tau];C(\bar\Omega)), \tag{3.12}$$

$$\theta \in H^1(0,\hat\tau;L^2(\Omega)) \cap L^2(0,\hat\tau;H^2(\Omega)) \cap C(\overline{\Omega_{\hat\tau}}), \tag{3.13}$$

$$\theta(x,t) \ge \frac{\delta}{2} > 0 \quad \textit{for every } (x,t) \in \bar\Omega \times [0,\hat\tau]. \tag{3.14}$$

Proof of Theorem 3.1. We divide the proof of Theorem 3.1 into several steps, each formulated as a separate lemma. The existence part of the proof is based on the following special case of the *Schauder–Tikhonov fixed point principle* (cf., for instance, Theorem 3.6.1 in [6]).

LEMMA 3.2. *Let the operator* $\mathcal{T}$ *map the nonempty, closed, convex, and weakly compact subset* $\mathcal{M}$ *of the separable Hilbert space* X *into itself, and suppose that* $\mathcal{T}$ *is weakly sequentially continuous on* $\mathcal{M}$*; that is, it holds that* $\mathcal{T}(v_n) \to \mathcal{T}(v)$ *weakly in* X *whenever* $v_n \to v$ *weakly in* X *for some sequence* $\{v_n\} \subset \mathcal{M}$*. Then* $\mathcal{T}$ *has a fixed point in* $\mathcal{M}$*.*

We aim to apply Lemma 3.2 to the following setting. Consider for $\tau \in (0,T]$ the separable Hilbert spaces

$$\begin{aligned} P_\tau &:= H^2(0,\tau;V_0^*) \cap H^1(0,\tau;H^1(\Omega)) \cap L^2(0,\tau;H^3(\Omega)),\\ Q_\tau &:= H^2(0,\tau;L^2(\Omega)) \cap H^1(0,\tau;H^1(\Omega)),\\ Z_\tau &:= H^1(0,\tau;L^2(\Omega)) \cap L^2(0,\tau;H^2(\Omega)),\\ W_\tau &:= H^2(0,\tau;L^2(\Omega)) \cap H^1(0,\tau;H^1(\Omega)),\\ X_\tau &:= P_\tau \times Q_\tau \times Z_\tau \times W_\tau \end{aligned} \tag{3.15}$$

and introduce the sets

$$\mathcal{M}_\tau := \Big\{ (p,q,\theta,w) \in X_\tau;\ (3.3),\ (3.6),\ (3.10) \text{ hold},\ p_t + q_t = p_{xx} \quad \text{a.e. in } \Omega_\tau,$$

$$\int_0^\tau \int_\Omega \Big(\theta_t^2 + \theta_{xx}^2\Big)\,dx\,dt + \max_{0\le t\le\tau} \int_\Omega |\theta_x(x,t)|^2\,dx \le M_1, \tag{3.16}$$

$$\max_{(x,t)\in\overline{\Omega_\tau}} |\theta(x,t)| \le M_2, \tag{3.17}$$

$$\max_{0\le t\le\tau} \int_\Omega \Big(|q_t(x,t)|^2 + |w_t(x,t)|^2\Big)\,dx \le M_3, \tag{3.18}$$

$$\int_0^\tau \int_\Omega \Big(q_{xt}^2 + w_{xt}^2 \Big)\, dx\, dt \le M_4, \tag{3.19}$$

$$\int_0^\tau \int_\Omega \Big(p_t^2 + p_{xx}^2 \Big)\, dt + \max_{0\le t\le\tau} \int_\Omega |p_x(x,t)|^2\, dx \le M_5, \tag{3.20}$$

$$\max_{0\le t\le\tau} \int_\Omega \Big(|q_x(x,t)|^2 + |w_x(x,t)|^2 \Big)\, dx \le M_6, \tag{3.21}$$

$$\|p_t\|^2_{H^1(0,\tau;V_0^*)} + \int_0^\tau \int_\Omega p_{xt}^2\, dx\, dt + \max_{0\le t\le\tau} \int_\Omega |p_t(x,t)|^2\, dx \le M_7, \tag{3.22}$$

$$\max_{0\le t\le\tau} \int_\Omega |p_{xx}(x,t)|^2\, dx \le M_8, \tag{3.23}$$

$$\int_0^\tau \int_\Omega p_{xxx}^2\, dx\, dt \le M_9, \tag{3.24}$$

$$\int_0^\tau \int_\Omega (q_{tt}^2 + w_{tt}^2)\, dx\, dt \le M_{10}, \tag{3.25}$$

$$\min_{(x,t)\in\overline{\Omega_\tau}} \theta(x,t) \ge \frac{\delta}{2} > 0 \Big\}, \tag{3.26}$$

where the positive constants M_i, $i = 1, \dots, 10$, will have to be specified later. Obviously, $\mathcal{M}_\tau$ is a nonempty, closed, convex, and bounded (hence weakly compact) subset of the separable Hilbert space X_τ.

Next, we introduce the operator $\mathcal{T}$ on $\mathcal{M}_\tau$ by $\mathcal{T}(\bar p, \bar q, \bar\theta, \bar w) := (p, q, \theta, w)$, where for $(\bar p, \bar q, \bar\theta, \bar w) \in \mathcal{M}_\tau$ the quadruple (p, q, θ, w) is the unique solution to the linear initial-boundary value problem

$$p_t - p_{xx} = \bar\sigma + \int_1^x f(\xi, t)\, d\xi, \tag{3.27}$$

$$p(1,t) = p_x(0,t) = 0, \quad p(x,0) = \int_1^x u_1(\xi)\, d\xi, \tag{3.28}$$

$$\bar\sigma = \mathcal{H}_1[\bar p + \bar q, \bar w] + \bar\theta\, \mathcal{H}_2[\bar p + \bar q, \bar w], \tag{3.29}$$

$$q_t = -\bar\sigma - \int_1^x f(\xi, t)\, d\xi, \tag{3.30}$$

$$q(x,0) = u_0'(x) - \int_1^x u_1(\xi)\, d\xi, \tag{3.31}$$

$$\theta_t - \theta_{xx} = -\mathcal{F}_1[\bar p + \bar q, \bar w]_t + \bar p_{xx}^2 + \bar\sigma \bar p_{xx} + g(x, t, \bar\theta), \tag{3.32}$$

$$w_t = -\bar\psi, \tag{3.33}$$

$$\bar\psi = \mathcal{H}_3[\bar p + \bar q, \bar w] + \bar\theta\, \mathcal{H}_4[\bar p + \bar q, \bar w], \tag{3.34}$$

$$\theta(x,0) = \theta_0(x), \quad w(x,0) = w_0(x), \quad \theta_x(0,t) = \theta_x(1,t) = 0. \tag{3.35}$$

We have the following result.

LEMMA 3.3. *There exist* $\hat\tau \in (0,T]$ *and positive constants* M_i, $i = 1,\dots,10$, *such that* $\mathcal{T}(\mathcal{M}_\tau) \subset \mathcal{M}_\tau$ *for any* $\tau \in (0,\hat\tau]$.

Proof. Let $\tau \in (0,T]$ be given. Without loss of generality, we may assume that $\tau \le 1$. We have $p_t + q_t = p_{xx}$ a.e. in Ω_τ, and we infer from the general hypotheses that $p_t, p_{xx}, q_t, w_t, \theta_t, \theta_{xx} \in L^2(\Omega_\tau)$. Therefore, $\theta \in Z_\tau$. Also, since $(\bar p, \bar q, \bar\theta, \bar w) \in \mathcal{M}_\tau$, it follows from Remark 1 that the right-hand sides of both (3.30) and (3.33) belong to $H^1(\Omega_\tau)$ so that $q \in Q_\tau$ and $w \in W_\tau$.

Next, we consider the parabolic initial-boundary value problem

$$z_t - z_{xx} = v := \bar\sigma_t + \int_1^x f_t(\xi,t)\,d\xi, \tag{3.36}$$

$$z_x(0,t) = z(1,t) = 0, \quad z(x,0) = u_1'(x) + \bar\sigma(0) + \int_1^x f(\xi,0)\,d\xi. \tag{3.37}$$

Since $z(\cdot,0) \in L^2(\Omega)$, and since the right-hand side v of (3.36) belongs to $L^2(\Omega_\tau)$, it follows from general linear parabolic theory (cf. Lions and Magenes [19]) that (3.36)–(3.37) admits a unique weak solution $z \in L^2(0,\tau;H^1(\Omega)) \cap H^1(0,\tau;V_0^*) \cap C([0,\tau];L^2(\Omega))$, and there is some constant $\hat C > 0$, not depending on $\tau \in (0,T]$, such that

$$\begin{aligned} &\|z\|^2_{H^1(0,\tau;V_0^*)} + \int_0^\tau\int_\Omega z_x^2\,dx\,dt + \max_{0\le t\le\tau}\int_\Omega |z(x,t)|^2\,dx \\ &\le \hat C\left(\int_\Omega |z(x,0)|^2\,dx + \int_0^\tau\int_\Omega v^2\,dx\,dt\right). \end{aligned} \tag{3.38}$$

Invoking the compatibility condition $u_1(0) = 0$, we easily verify that

$$p(x,t) = \int_1^x u_1(\xi)\,d\xi + \int_0^t z(x,r)\,dr, \tag{3.39}$$

so that $p \in H^2(0,\tau;V_0^*) \cap H^1(0,\tau;H^1(\Omega)) \cap C^1([0,\tau];L^2(\Omega))$, and (3.38) holds for $z = p_t$. Hence, using (3.27), we can conclude that $p_{xxx} \in L^2(\Omega_\tau)$, and also $p_{xx} \in C([0,\tau];L^2(\Omega))$. In conclusion, $p \in P_\tau$, and we have shown that $\mathcal{T}(\mathcal{M}_\tau) \subset X_\tau$.

Now let $(p,q,\theta,w) = \mathcal{T}(\bar p,\bar q,\bar\theta,\bar w)$ for some $(\bar p,\bar q,\bar\theta,\bar w) \in \mathcal{M}_\tau$, where the constants $M_1,\dots,M_{10}$ and $\tau \in (0,T]$ are assumed to be fixed. We are going to derive a number of estimates for (p,q,θ,w) in terms of $M_1,\dots,M_{10}$ and of the data of the system. In what follows, we denote by C_i, $i \in \mathbb{N} \cup \{0\}$, positive constants which may depend on the given data u_0, u_1, θ_0, w_0, f, g_0, and on the constants K_i, $0 \le i \le 4$, but neither on τ nor on $M_1,\dots,M_{10}$.

At first, we conclude from (2.11), (2.4), and (2.5) that

$$\begin{aligned} &\int_\Omega \Big(|\bar\sigma|^2 + |\bar\psi|^2\Big)(x,t)\,dx \\ &\le 2\int_\Omega \Big(\mathcal{H}_1^2[\bar p + \bar q, \bar w] + \mathcal{H}_3^2[\bar p + \bar q, \bar w] + \bar\theta^2(\mathcal{H}_2^2[\bar p + \bar q, \bar w] + \mathcal{H}_4^2[\bar p + \bar q, \bar w])\Big)(x,t)\,dx \\ &\le 4K_2^2M_2^2 + C_0\left[1 + t\int_0^t\int_\Omega \Big(\bar p_t^2 + \bar q_t^2 + \bar w_t^2\Big)\,dx\,dr\right] \\ &\le 4K_2^2M_2^2 + C_0\Big(1 + t(M_3 + M_7)\Big) \quad \forall t \in [0,\tau], \end{aligned} \tag{3.40}$$

$$|\bar\sigma_t| + |\bar{\psi}_t| \le 2K_3(1+M_2)(|\bar p_t| + |\bar q_t| + |\bar w_t|) + 2K_2|\bar\theta_t| \quad \text{a.e. in } \Omega_\tau. \tag{3.41}$$

Also, it follows from (2.12) that for $1 \le i \le 4$ and a.e. $(x,t) \in \Omega_\tau$ we have

$$\Big|\Big(\mathcal{H}_i[\bar p + \bar q, \bar w]\Big)_x(x,t)\Big| \le K_4 \max_{0\le r\le t}\Big(|\bar p_x(x,r)| + |\bar q_x(x,r)| + |\bar w_x(x,r)|\Big). \tag{3.42}$$

In addition, owing to (2.5),

$$|\mathcal{F}_1[\bar p + \bar q, \bar w]_t| \le K_3(|\bar p_t| + |\bar q_t| + |\bar w_t|) \quad \text{a.e. in } \Omega_\tau, \tag{3.43}$$

as well as, by virtue of (H3),

$$|g(x,t,\bar\theta(x,t))| \le g_0(x,t) + K_1 M_2. \tag{3.44}$$

Now multiply (3.32) first by θ_t and then by $-\theta_{xx}$; add the resulting equations and integrate over $\Omega\times[0,t]$ for any $t\in(0,\tau]$. Using Young's inequality and invoking (3.40), (3.43), and (3.44), we find that

$$\begin{aligned} &\int_0^t\int_\Omega \Big(\theta_t^2 + \theta_{xx}^2\Big)\,dx\,dr + \int_\Omega |\theta_x(x,t)|^2\,dx \\ &\le C_1\left[1 + tM_2^2 + \int_0^t\int_\Omega\Big(\bar p_t^2 + \bar q_t^2 + \bar w_t^2\Big)\,dx\,dr \right. \\ &\qquad \left. + \int_0^t\int_\Omega \bar p_{xx}^4\,dx\,dr + \int_0^t\int_\Omega \bar\sigma^2\,\bar p_{xx}^2\,dx\,dr\right]. \end{aligned} \tag{3.45}$$

Invoking the Gagliardo–Nirenberg inequality (2.21) for $p=+\infty$, $q=r=2$, $\omega=1/2$, we infer that

$$\begin{aligned} \int_0^t \|\bar p_{xx}(\cdot,r)\|_\infty^2\,dr &\le 2K_0^2\left(\int_0^t\int_\Omega \bar p_{xx}^2\,dx\,dr \right. \\ &\qquad \left. + \max_{0\le r\le t}\|\bar p_{xx}(\cdot,r)\|_2 \int_0^t \|\bar p_{xxx}(\cdot,r)\|_2\,dr\right) \\ &\le 2K_0^2\Big(tM_8 + \sqrt{M_8}\sqrt{t}\sqrt{M_9}\Big) \le 2K_0^2\sqrt{t}\Big(M_8 + \sqrt{M_8M_9}\Big). \end{aligned} \tag{3.46}$$

It follows that

$$\begin{aligned} \int_0^t\int_\Omega \bar p_{xx}^4\,dx\,dr &\le \max_{0\le r\le t}\|\bar p_{xx}(\cdot,r)\|_2^2 \int_0^t \|\bar p_{xx}(\cdot,r)\|_\infty^2\,dr \\ &\le 2K_0^2\sqrt{t}\Big(M_8^2 + M_8^{3/2}\sqrt{M_9}\Big). \end{aligned} \tag{3.47}$$

In addition, by (3.40),

$$\begin{aligned} &\int_0^t\int_\Omega \bar\sigma^2\bar p_{xx}^2\,dx\,dr \le \max_{0\le r\le t}\|\bar\sigma(\cdot,r)\|_2^2 \int_0^t \|\bar p_{xx}(\cdot,r)\|_\infty^2\,dr \\ &\le 2K_0^2\sqrt{t}\Big(M_8 + \sqrt{M_8M_9}\Big)\Big(4K_2^2M_2^2 + C_0(1+t(M_3+M_7))\Big). \end{aligned} \tag{3.48}$$

In conclusion, we have shown the estimate

$$\begin{aligned} &\int_0^\tau\int_\Omega \Big(\theta_t^2 + \theta_{xx}^2\Big)\,dx\,dr + \max_{0\le t\le\tau}\int_\Omega |\theta_x(x,t)|^2\,dx \\ &\le C_2\Big[1 + \sqrt{\tau}\big(M_2^2 + M_3 + M_7 + M_8^2 + M_8^{3/2}M_9^{1/2} \\ &\qquad + \big(M_8 + M_8^{1/2}M_9^{1/2}\big)\big(1 + M_2^2 + M_3 + M_7\big)\big)\Big]. \end{aligned} \tag{3.49}$$

Next, we consider (3.30) and (3.33). By the general hypotheses and (3.40), we have

$$\max_{0\le t\le\tau}\int_\Omega \Big(|q_t(x,t)|^2+|w_t(x,t)|^2\Big)\,dx \le C_3\Big(1+M_2^2+t(M_3+M_7)\Big). \tag{3.50}$$

Now differentiate (3.30) and (3.33) with respect to x. Then, by (3.42),

$$|\bar\sigma_x(x,t)|+|\bar\psi_x(x,t)| \le 2K_2|\bar\theta_x(x,t)|+2K_4(1+M_2)\max_{0\le r\le t}\Big((|\bar p_x|+|\bar q_x|+|\bar w_x|)(x,r)\Big) \tag{3.51}$$

for a.e. $(x,t)\in\Omega_\tau$. Therefore, using (2.20), we can conclude that

$$\begin{aligned}&\int_0^\tau\int_\Omega\Big(q_{xt}^2+w_{xt}^2\Big)\,dx\,dt \le C_4\Big(1+\int_0^\tau\int_\Omega\Big(|\bar\sigma_x|^2+|\bar\psi_x|^2\Big)\,dx\,dt\Big)\\ &\le C_5\left[1+M_2^2+\int_0^\tau\int_\Omega|\bar\theta_x|^2\,dx\,dt+(1+M_2^2)\tau\int_0^\tau\int_\Omega\Big(\bar p_{xt}^2+\bar q_{xt}^2+\bar w_{xt}^2\Big)\,dx\,dt\right]\\ &\le C_5\Big(1+M_2^2+\tau\big(M_1+(1+M_2^2)(M_4+M_7)\big)\Big).\end{aligned} \tag{3.52}$$

But then also

$$\begin{aligned}&\max_{0\le t\le\tau}\int_\Omega\Big(|q_x(x,t)|^2+|w_x(x,t)|^2\Big)\,dx\\ &\le C_6\Big(1+M_2^2+\tau\left(M_1+(1+M_2^2)(M_4+M_7)\right)\Big).\end{aligned} \tag{3.53}$$

Next, we consider the linear parabolic system (3.27)–(3.28). Standard parabolic estimates, using the general hypotheses and (3.40), yield that

$$\begin{aligned}&\int_0^\tau\int_\Omega\Big(p_t^2+p_{xx}^2\Big)\,dx\,dt \le C_7\Big(1+\int_0^\tau\int_\Omega|\bar\sigma|^2\,dx\,dt\Big)\\ &\le C_8\Big(1+\tau(M_2^2+M_3+M_7)\Big).\end{aligned} \tag{3.54}$$

Moreover, since (3.38) is valid for $z=p_t$, we can infer from (H2) and from (3.41) that

$$\begin{aligned}&\|p\|^2_{H^2(0,\tau;V_0^*)}+\int_0^\tau\int_\Omega p_{xt}^2\,dx\,dt+\max_{0\le t\le\tau}\int_\Omega|p_t(x,t)|^2\,dx\\ &\le C_9\left(1+\int_0^\tau\int_\Omega\Big(\bar\theta_t^2+(1+M_2^2)\Big(\bar p_t^2+\bar q_t^2+\bar w_t^2\Big)\Big)\,dx\,dt\right)\\ &\le C_9\Big(1+M_1+\tau(1+M_2^2)(M_3+M_7)\Big).\end{aligned} \tag{3.55}$$

But then we obtain from (3.27), also using (3.29) and (H2), that

$$\begin{aligned}\max_{0\le t\le\tau}\int_\Omega|p_{xx}(x,t)|^2\,dx &\le 2\max_{0\le t\le\tau}\int_\Omega|p_t(x,t)|^2\,dx+2C_{10}\left(1+\max_{0\le t\le\tau}\int_\Omega|\bar\sigma(x,t)|^2\,dx\right)\\ &\le C_{11}\Big(1+M_1+M_2^2+\tau(1+M_2^2)(M_3+M_7)\Big).\end{aligned} \tag{3.56}$$

In addition, employing (3.51) and (3.55), and arguing as in the derivation of (3.52), we can deduce the estimate

$$\begin{aligned}\int_0^\tau\int_\Omega p_{xxx}^2\,dx\,dt &\le 2\int_0^\tau\int_\Omega p_{xt}^2\,dx\,dt+2\int_0^\tau\int_\Omega|\bar\sigma_x+f|^2\,dx\,dt\\ &\le C_{12}\Big(1+M_1+M_2^2+\tau(M_1+(1+M_2^2)(M_3+M_4+M_7))\Big).\end{aligned} \tag{3.57}$$

Next, we differentiate (3.30) and (3.33), respectively, with respect to t, and invoke (H2) and (3.41) to obtain the bound

$$\int_0^\tau \int_\Omega (q_{tt}^2 + w_{tt}^2)\,dx\,dt \le C_{13}(1 + (1 + M_2^2)(M_3 + M_5) + M_1). \tag{3.58}$$

Finally, since Ω is one-dimensional, $H^1(0,\tau;L^2(\Omega)) \cap L^2(0,\tau;H^2(\Omega))$ is continuously imbedded in $C(\overline{\Omega_\tau})$. Hence, there is some $C_{14} > 0$ such that

$$\max_{(x,t)\in\overline{\Omega_\tau}} |\theta(x,t)| \le C_{14}\left(1 + \sqrt{\hat{M}_1}\right), \tag{3.59}$$

where $\hat{M}_1$ is equal to the expression on the right-hand side of (3.49).

Now, we can define the constants $M_1 \dots, M_{10}$. We make the choices

$$\begin{aligned}
&M_1 := 2C_2, \quad M_2 := C_{14}\left(1 + \sqrt{\hat{M}_1}\right), \quad M_3 := 2C_3 + C_3 M_2^2,\\
&M_4 := 2C_5 + C_5 M_2^2, \quad M_5 := 2C_8, \quad M_6 := 2C_6 + C_6 M_2^2,\\
&M_7 := 2C_9 + C_9 M_1, \quad M_8 := 2C_{11} + C_{11}(M_1 + M_2^2),\\
&M_9 := 2C_{12} + C_{12}(M_1 + M_2^2),\ M_{10} := C_{13}(1 + (1 + M_2^2)(M_3 + M_5) + M_1).
\end{aligned} \tag{3.60}$$

It then follows from the estimates (3.49)–(3.50), (3.52)–(3.57), and (3.59) that there exists some $\tau_0 \in (0,T]$ such that the inequalities (3.16)–(3.27) are fulfilled for any $\tau \in (0,\tau_0]$. In particular, (3.16) implies that the assumptions of Lemma 3.2.2 in [2] are satisfied. Therefore, we have $\theta \in C^{\frac{1}{2},\frac{1}{6}}(\overline{\Omega_{\tau_0}})$, and there is some constant $C_{15} > 0$, depending only on M_1 and τ_0, such that for every $(x,t),(y,s) \in \overline{\Omega_{\tau_0}}$ it holds that

$$|\theta(x,t) - \theta(y,s)| \le C_{15}\left(|t-s|^{1/6} + |x-y|^{1/2}\right). \tag{3.61}$$

Consequently, for sufficiently small $\hat{\tau} \in (0,\tau_0]$,

$$\theta(x,t) \ge \theta_0(x) - |\theta(x,t) - \theta_0(x)| \ge \delta - C_{15} t^{1/6} \ge \frac{\delta}{2} \tag{3.62}$$

for all $(x,t) \in \Omega \times [0,\hat{\tau}]$. With this, the proof of the lemma is complete. ∎

LEMMA 3.4. *The operator $\mathcal{T}$ is weakly sequentially continuous in $\mathcal{M}_{\hat{\tau}}$.*

Proof. Suppose a sequence $\{(\bar{p}_n, \bar{q}_n, \bar{\theta}_n, \bar{w}_n)\} \subset \mathcal{M}_{\hat{\tau}}$ is given such that

$$(\bar{p}_n, \bar{q}_n, \bar{\theta}_n, \bar{w}_n) \to (\bar{p}, \bar{q}, \bar{\theta}, \bar{w}) \quad \text{weakly in } X_{\hat{\tau}} \quad \text{as } n \to \infty. \tag{3.63}$$

Since $\mathcal{M}_{\hat{\tau}}$ is weakly closed, it holds that $(\bar{p}, \bar{q}, \bar{\theta}, \bar{w}) \in \mathcal{M}_{\hat{\tau}}$. Now, let

$$(p_n, q_n, \theta_n, w_n) := \mathcal{T}(\bar{p}_n, \bar{q}_n, \bar{\theta}_n, \bar{w}_n), \quad n \in \mathbb{N}, \quad (p,q,\theta,w) := \mathcal{T}(\bar{p}, \bar{q}, \bar{\theta}, \bar{w}). \tag{3.64}$$

We have to show that

$$(p_n, q_n, \theta_n, w_n) \to (p, q, \theta, w) \quad \text{weakly in } X_{\hat{\tau}} \quad \text{as } n \to \infty. \tag{3.65}$$

Clearly, as $(p_n, q_n, \theta_n, w_n) \in \mathcal{M}_{\hat{\tau}}$ for all $n \in \mathbb{N}$, we have, on a subsequence which is again indexed by n,

$$(p_n, q_n, \theta_n, w_n) \to (\hat{p}, \hat{q}, \hat{\theta}, \hat{w}) \quad \text{weakly in } X_{\hat{\tau}} \quad \text{as } n \to \infty \tag{3.66}$$

for some $(\hat{p},\hat{q},\hat{\theta},\hat{w}) \in \mathcal{M}_{\hat{\tau}}$. It remains to show that $(\hat{p},\hat{q},\hat{\theta},\hat{w}) = (p,q,\theta,w)$. The uniqueness of the limit point then entails that (3.66), and thus (3.65) holds for the entire sequence. To this end, note that we have the convergences

$$\begin{aligned}&\bar{\theta}_{n,t} \to \bar{\theta}_t,\ \ \bar{\theta}_{n,xx} \to \bar{\theta}_{xx},\ \ \bar{p}_{n,t} \to \bar{p}_t,\ \ \bar{p}_{n,xx} \to \bar{p}_{xx},\ \ \bar{p}_{n,xxx} \to \bar{p}_{xxx},\ \ \bar{p}_{n,xt} \to \bar{p}_{xt},\\ &\bar{w}_{n,t} \to \bar{w}_t,\ \ \bar{w}_{n,xt} \to \bar{w}_{xt},\ \ \bar{q}_{n,t} \to \bar{q}_t,\ \ \bar{q}_{n,xt} \to \bar{q}_{xt},\ \text{ all weakly in } L^2(\Omega_{\hat{\tau}}).\end{aligned} \tag{3.67}$$

By compact imbedding, we may also assume that

$$\bar{\theta}_n \to \bar{\theta},\quad \bar{p}_{n,x} \to \bar{p}_x,\quad \text{both uniformly in } \overline{\Omega_{\hat{\tau}}}, \tag{3.68}$$

$$\bar{p}_n \to \bar{p},\quad \bar{q}_n \to \bar{q},\quad \bar{w}_n \to \bar{w},\quad \text{all strongly in } L^2(\Omega; C[0,\hat{\tau}]). \tag{3.69}$$

But then, owing to (H4), it follows that

$$\begin{aligned}&\bar{\sigma}_n \to \bar{\sigma},\quad \bar{\psi}_n \to \bar{\psi},\quad \mathcal{F}_1[\bar{p}_n + \bar{q}_n, \bar{w}_n] \to \mathcal{F}_1[\bar{p}+\bar{q},\bar{w}],\\ &\text{all strongly in } L^2(\Omega; C[0,\hat{\tau}]),\end{aligned} \tag{3.70}$$

where $\bar{\sigma}_n$, $\bar{\psi}_n$ have obvious meaning. Also,

$$g(\cdot,\cdot,\bar{\theta}_n) \to g(\cdot,\cdot,\bar{\theta}) \quad \text{strongly in } L^\infty(\Omega_{\hat{\tau}}), \tag{3.71}$$

$$\bar{\sigma}_n \bar{p}_{n,xx} \to \bar{\sigma}\bar{p}_{xx} \quad \text{weakly in } L^2(\Omega_{\hat{\tau}}). \tag{3.72}$$

In addition, owing to (3.18), (3.22), and (3.43), the sequence $\{\mathcal{F}_1[\bar{p}_n + \bar{q}_n, \bar{w}_n]_t\}$ is bounded in $L^\infty(0,\hat{\tau}; L^2(\Omega))$, so that we may assume that

$$\mathcal{F}_1[\bar{p}_n + \bar{q}_n, \bar{w}_n]_t \to y \quad \text{weakly-star in } L^\infty(0,\hat{\tau}; L^2(\Omega)) \tag{3.73}$$

for some $y \in L^\infty(0,\hat{\tau}; L^2(\Omega))$. But then it follows from (3.70) that $y = \mathcal{F}_1[\bar{p}+\bar{q},\bar{w}]_t$. Finally, we conclude from (3.67) and (3.68) that

$$\bar{p}^2_{n,xx} \to \bar{p}^2_{xx} \quad \text{weakly in } L^2(\Omega_{\hat{\tau}}). \tag{3.74}$$

Indeed, we have for any test function $\eta \in C_0^\infty(\Omega_{\hat{\tau}})$ that

$$\begin{aligned}&\lim_{n\to\infty} \int_0^{\hat{\tau}} \int_\Omega \bar{p}^2_{n,xx}\eta \,dx\,dt\\ &= -\lim_{n\to\infty} \int_0^{\hat{\tau}} \int_\Omega \Big(\bar{p}_{n,xxx}\bar{p}_{n,x}\eta + \bar{p}_{n,xx}\bar{p}_{n,x}\eta_x\Big)\,dx\,dt\\ &= -\int_0^{\hat{\tau}} \int_\Omega \Big(\bar{p}_{xxx}\bar{p}_x\eta + \bar{p}_{xx}\bar{p}_x\eta_x\Big)\,dx\,dt = \int_0^{\hat{\tau}} \int_\Omega \bar{p}^2_{xx}\eta\,dx\,dt.\end{aligned} \tag{3.75}$$

Since $C_0^\infty(\Omega_{\hat{\tau}})$ is a dense subset of $L^2(\Omega_{\hat{\tau}})$, and since $\{\bar{p}^2_{n,xx}\}$ is bounded in $L^2(\Omega_{\hat{\tau}})$ (cf. (3.47)), we conclude (3.74) from the Banach–Steinhaus theorem.

Now observe that (3.66) implies, in particular, the convergences

$$\theta_{n,t} \to \hat{\theta}_t,\ \ \theta_{n,xx} \to \hat{\theta}_{xx},\ \ p_{n,t} \to \hat{p}_t,\ \ p_{n,xx} \to \hat{p}_{xx},\ \ q_{n,t} \to \hat{q}_t,\ \ w_{n,t} \to \hat{w}_t, \tag{3.76}$$

all weakly in $L^2(\Omega_{\hat{\tau}})$. Combining all the above convergences, and letting $n \to \infty$, we finally can infer that $(\hat{p},\hat{q},\hat{\theta},\hat{w}) = \mathcal{T}(\bar{p},\bar{q},\bar{\theta},\bar{w})$. This concludes the proof of the lemma. □

By virtue of Lemmas 3.3 and 3.4, we deduce from Lemma 3.2 that $\mathcal{T}$ has a fixed point in $\mathcal{M}_{\hat\tau}$ which then is a solution to the system (3.2)–(3.10). To conclude the proof of Theorem 3.1, we still need to show the uniqueness. We achieve this through the following result, which even shows global uniqueness.

LEMMA 3.5. *Let the assumptions of Theorem* 3.1 *be fulfilled, and let* $\tau \in (0,T]$ *be arbitrary. Then the system* (3.2)–(3.10) *has at most one solution in* X_τ.

Proof. Suppose that $(p_i, q_i, \theta_i, w_i) \in X_\tau$, $i = 1, 2$, are two solutions to (3.2)–(3.10) on Ω_τ for some $\tau \in (0,T]$. Let $p := p_1 - p_2$, $q := q_1 - q_2$, $\theta := \theta_1 - \theta_2$, $w := w_1 - w_2$, and put $\sigma_i := \mathcal{H}_1[p_i + q_i, w_i] + \theta_i\, \mathcal{H}_2[p_i + q_i, w_i]$, $\psi_i := \mathcal{H}_3[p_i + q_i, w_i] + \theta_i\, \mathcal{H}_4[p_i + q_i, w_i]$ for $i = 1, 2$. Then it holds that

$$p_t - p_{xx} = \sigma_1 - \sigma_2, \tag{3.77}$$

$$q_t = \sigma_2 - \sigma_1, \tag{3.78}$$

$$\begin{aligned} \theta_t - \theta_{xx} = {} & -\mathcal{F}_1[p_1 + q_1, w_1]_t + \mathcal{F}_1[p_2 + q_2, w_2]_t + p_{1,xx}^2 - p_{2,xx}^2 \\ & + \sigma_1 p_{1,xx} - \sigma_2\, p_{2,xx} + g(x,t,\theta_1) - g(x,t,\theta_2), \end{aligned} \tag{3.79}$$

$$w_t = \psi_1 - \psi_2, \tag{3.80}$$

with corresponding zero initial and boundary conditions. Owing to (H4)(iii), we have for every $(x,t) \in \overline{\Omega_\tau}$

$$\begin{aligned} & \max\{|\sigma_1(x,t) - \sigma_2(x,t)|, |\psi_1(x,t) - \psi_2(x,t)|\} \\ & \le C_1\Big(|\theta(x,t)| + \max_{0\le r\le t}(|p(x,r)| + |q(x,r)| + |w(x,r)|)\Big) \\ & \le C_1\left(|\theta(x,t)| + \int_0^t \Big(|p_t(x,r)| + |q_t(x,r)| + |w_t(x,r)|\Big)\, dr\right), \end{aligned} \tag{3.81}$$

where by C_i, $i \in \mathbb{N}$, we denote positive constants that depend only on the data of the system and on the X_τ-norms of $(p_i, q_i, \theta_i, w_i)$, $i = 1, 2$. Hence, we may multiply (3.77) by p_t, and by $-p_{xx}$, respectively, (3.78) by q_t, and (3.80) by w_t, respectively, add the four resulting equations, integrate over space and time, and apply Young's inequality appropriately to arrive at the estimate

$$\begin{aligned} \int_0^t \int_\Omega \Big(p_t^2 + p_{xx}^2 + q_t^2 + w_t^2\Big)\, dx\, ds \le {} & C_2 \int_0^t \int_0^s \int_\Omega \Big(p_t^2 + q_t^2 + w_t^2\Big)\, dx\, dr\, ds \\ & + C_3 \int_0^t \int_\Omega \theta^2\, dx\, ds. \end{aligned} \tag{3.82}$$

Next, we integrate (3.79) over $[0,s]$ for some $s > 0$. We obtain

$$\begin{aligned} \theta - \int_0^s \theta_{xx}\, dr = {} & -\mathcal{F}_1[p_1 + q_1, w_1] + \mathcal{F}_1[p_2 + q_2, w_2] + \int_0^s \Big(p_{1,xx}^2 - p_{2,xx}^2\Big)\, dr \\ & + \int_0^s \Big(\sigma_1 p_{1,xx} - \sigma_2 p_{2,xx}\Big)\, dr + \int_0^s \Big(g(x,r,\theta_1) - g(x,r,\theta_2)\Big)\, dr. \end{aligned} \tag{3.83}$$

Our aim is to multiply (3.83) by θ, and integrate over $\Omega \times [0,t]$ for some $t \in [0,\tau]$. In what follows, we first estimate the terms resulting from the right-hand side individually. To this end, let $\gamma > 0$ (to be specified later). First, we note that for a.e. $(x,t) \in \Omega_\tau$ it holds that

$$|\mathcal{F}_1[p_1+q_1,w_1](x,t)-\mathcal{F}_1[p_2+q_2,w_2](x,t)| \le C_4 \int_0^t \Big(|p_t|+|q_t|+|w_t|\Big)(x,r)\,dr, \tag{3.84}$$

so that, using Young's inequality,

$$\begin{aligned} &\int_0^t \int_\Omega |\theta(x,s)|\,|\mathcal{F}_1[p_1+q_1,w_1](x,s)-\mathcal{F}_1[p_2+q_2,w_2](x,s)|\,dx\,ds \\ &\le \frac{\gamma}{2}\int_0^t\int_\Omega \theta^2\,dx\,ds + \frac{C_5}{2\gamma}\int_0^t\int_0^s\int_\Omega \Big(p_t^2+q_t^2+w_t^2\Big)\,dx\,dr\,ds. \end{aligned} \tag{3.85}$$

Moreover, owing to (H3), we have

$$\begin{aligned} &\int_0^t \int_\Omega |\theta(x,t)| \int_0^s |g(x,r,\theta_1(x,r))-g(x,r,\theta_2(x,r)|\,dr\,dx\,ds \\ &\le C_6 \int_0^t \int_\Omega |\theta(x,t)| \int_0^s |\theta(x,r)|\,dr\,dx\,ds \\ &\le \frac{\gamma}{2}\int_0^t\int_\Omega \theta^2\,dx\,ds + \frac{C_6}{2\gamma}\int_0^t\int_0^s\int_\Omega \theta^2\,dx\,dr\,ds. \end{aligned} \tag{3.86}$$

Next, we estimate

$$\begin{aligned} &\int_0^t \int_\Omega |\theta(x,s)| \int_0^s |\sigma_1 p_{1,xx}-\sigma_2 p_{2,xx}|(x,r)\,dr\,dx\,ds \\ &\le \int_0^t \int_\Omega |\theta(x,s)| \int_0^s |\sigma_2(x,r)|\,|p_{xx}(x,r)|\,dr\,dx\,ds \\ &\quad + \int_0^t \int_\Omega |\theta(x,s)| \int_0^s \Big(|p_{1,xx}|\,|\sigma_1-\sigma_2|\Big)(x,r)\,dr\,dx\,ds \\ &=: B_1 + B_2. \end{aligned} \tag{3.87}$$

By the boundedness of σ_2,

$$B_1 \le \frac{\gamma}{2}\int_0^t\int_\Omega \theta^2\,dx\,ds + \frac{C_7}{2\,\gamma}\int_0^t\int_0^s\int_\Omega p_{xx}^2\,dx\,dr\,ds. \tag{3.88}$$

Next, we employ the Gagliardo–Nirenberg inequality (2.21) with $p=+\infty$, $q=r=2$, $\omega=1/2$, to conclude that, for $i=1,2$ and every $x \in \bar\Omega$,

$$\begin{aligned} &\int_0^s |p_{i,xx}(x,r)|^2\,dr \le \int_0^s \|p_{i,xx}(\cdot,r)\|_\infty^2\,dr \\ &\le 2K_0^2 \int_0^s \Big(\|p_{i,xx}(\cdot,r)\|_2^2 + \|p_{i,xx}(\cdot,r)\|_2 \|p_{i,xxx}(\cdot,r)\|_2\Big)\,dr \\ &\le C_8 \max_{0\le r\le s} \|p_{i,xx}(\cdot,r)\|_2^2 + C_9 \max_{0\le r\le s} \|p_{i,xx}(\cdot,r)\|_2 \left(\int_0^s\int_\Omega |p_{i,xxx}|^2\,dx\,dr\right)^{1/2} \\ &\le C_{10}. \end{aligned} \tag{3.89}$$

Hence, we have

$$\int_0^s \Big(|\sigma_1-\sigma_2|\,|p_{1,xx}|\Big)(x,r)\,dr \le \bigg(\int_0^s |(\sigma_1-\sigma_2)(x,r)|^2\,dr\bigg)^{1/2}\bigg(\int_0^s |p_{1,xx}(x,r)|^2\,dr\bigg)^{1/2}$$
$$\le \sqrt{C_{10}}\,\bigg(\int_0^s |(\sigma_1-\sigma_2)(x,r)|^2\,dr\bigg)^{1/2}, \tag{3.90}$$

so that, by virtue of (3.81) and of Young's inequality,

$$\begin{aligned} B_2 &\le \frac{\gamma}{2}\int_0^t\int_\Omega \theta^2\,dx\,ds + \frac{C_{11}}{2\gamma}\int_0^t\int_0^s\int_\Omega |\sigma_1-\sigma_2|^2\,dx\,dr\,ds \\ &\le \frac{\gamma}{2}\int_0^t\int_\Omega \theta^2\,dx\,ds + \frac{C_{12}}{2\gamma}\int_0^t\int_0^s\int_\Omega \Big(\theta^2+p_t^2+q_t^2+w_t^2\Big)\,dx\,dr\,ds. \end{aligned} \tag{3.91}$$

Finally, using (3.89), we estimate

$$\begin{aligned} &\int_0^t\int_\Omega |\theta(x,s)|\int_0^s \Big(p_{1,xx}^2-p_{2,xx}^2\Big)(x,r)\,dr\,dx\,ds \\ &\le \int_0^t\int_\Omega |\theta(x,s)|\int_0^s \Big(|p_{xx}|\,|p_{1,xx}+p_{2,xx}|\Big)(x,r)\,dr\,dx\,ds \\ &\le \int_0^t\int_\Omega |\theta(x,s)|\bigg(\int_0^s |p_{xx}(x,r)|^2 dr\bigg)^{1/2}\bigg(\int_0^s |(p_{1,xx}+p_{2,xx})(x,r)|^2 dr\bigg)^{1/2} dx\,ds \\ &\le C_{13}\int_0^t\int_\Omega |\theta(x,s)|\,\bigg(\int_0^s |p_{xx}(x,r)|^2\,dr\bigg)^{1/2}\,dx\,ds \\ &\le \frac{\gamma}{2}\int_0^t\int_\Omega \theta^2\,dx\,ds + \frac{C_{14}}{2\gamma}\int_0^t\int_0^s\int_\Omega p_{xx}^2\,dx\,dr\,ds. \end{aligned} \tag{3.92}$$

Now, we multiply (3.83) by θ and integrate over $\Omega\times[0,t]$ for some $t\in[0,\tau]$. Combining the estimates (3.85)–(3.92) and choosing $\gamma>0$ appropriately small, we obtain the inequality

$$\int_0^t\int_\Omega \theta^2\,dx\,ds \le C_{15}\int_0^t\int_0^s\int_\Omega \Big(\theta^2+p_{xx}^2+p_t^2+q_t^2+w_t^2\Big)\,dx\,dr\,ds. \tag{3.93}$$

Consequently, combining inequalities (3.82) and (3.93), we have finally shown that

$$\begin{aligned} &\int_0^t\int_\Omega \Big(\theta^2+p_t^2+p_{xx}^2+q_t^2+w_t^2\Big)\,dx\,ds \\ &\le C_{16}\int_0^t\int_0^s\int_\Omega \Big(\theta^2+p_t^2+p_{xx}^2+q_t^2+w_t^2\Big)\,dx\,dr\,ds, \end{aligned} \tag{3.94}$$

whence, by Gronwall's lemma, $p_t=q_t=w_t=\theta=0$ a.e. in Ω_τ, so that the assertion follows. With this, the proof of Theorem 3.1 is complete. □

4. Global existence. Suppose now that the hypotheses (H1) to (H5) hold so that (3.2)–(3.11) has a unique solution (p,q,θ,w) on $\Omega_{\hat\tau}$ which satisfies (3.11)–(3.14). Using the compatibility condition $u_0(0)=0$, we then easily verify that (u,θ,w), where

$$u(x,t) = \int_0^x \Big(p(\xi,t)+q(\xi,t)\Big)\,d\xi, \tag{4.1}$$

solves (1.1)–(1.7) on $\Omega_{\hat\tau}$ and satisfies (2.16). Now let $\tau \in (0,T]$ be arbitrary such that (u,θ,w) can be extended to a solution of (1.1)–(1.7) on Ω_τ and satisfies $\theta(x,t) \geq \bar\theta$ for some $\bar\theta > 0$, as well as the smoothness properties (2.16). Owing to the global uniqueness result of Lemma 3.5, this solution is unique. We are now going to derive a number of global a priori estimates. To this end, we denote by C_i, $i \in \mathbb{N}$, positive constants which may depend on the given data of system (1.1)–(1.7), but neither on τ nor on the lower bound $\bar\theta$ for the temperature. For notational convenience, we put $\varepsilon := u_x$.

First estimate. We multiply (1.1) by u_t, add the result to (1.3), and then integrate over Ω_t, $t \in (0,\tau]$, and by parts. In light of (H1), we have

$$\begin{aligned} &\frac12 \int_\Omega u_t^2(x,t)\,dx + \int_\Omega \Big(\theta(x,t) + \mathcal{F}_1[\varepsilon,w](x,t)\Big)\,dx \\ &\leq C_1 + \int_0^t \int_\Omega g(x,r,\theta(x,r))\,dx\,dr + \int_0^t \int_\Omega f u_t\,dx\,dr. \end{aligned} \tag{4.2}$$

Invoking (2.2), (2.4), (H2), (H4)(i), the positivity of θ, and Gronwall's lemma, we find that

$$\max_{0\leq t\leq\tau} \Big(\|\theta(\cdot,t)\|_1 + \|u_t(\cdot,t)\|_2 \Big) \leq C_2. \tag{4.3}$$

Second estimate. We multiply (1.3) by $-\theta^{-1}$ and integrate over Ω_t, $t \in (0,\tau]$. (Note that θ^{-1} is actually bounded, since $\theta \geq \bar\theta > 0$.) It follows that

$$\begin{aligned} \int_0^t \int_\Omega \left(\frac{\theta_x^2}{\theta^2} + \frac{\varepsilon_t^2}{\theta} \right) dx\,dr &\leq C_3 + \int_0^t \int_\Omega \frac{1}{\theta} \Big(\mathcal{F}_1[\varepsilon,w]_t - \sigma\varepsilon_t - g(x,r,\theta) \Big)\,dx\,dr \\ &\quad + \int_\Omega \log(\theta(x,t))\,dx. \end{aligned} \tag{4.4}$$

In light of (4.3) and of the elementary inequality $\log(\theta) \leq \theta$ for $\theta > 0$, the second integral on the right-hand side is bounded. Also, we obtain from (1.2), (1.4), (H3), (H5), and Young's inequality that a.e. in Ω_τ it holds that

$$\begin{aligned} &\mathcal{F}_1[\varepsilon,w]_t - \sigma\varepsilon_t - g(x,r,\theta) \leq \mathcal{H}_3[\varepsilon,w]\,\mathcal{G}[w]_t - \theta\,\mathcal{H}_2[\varepsilon,w]\,\varepsilon_t - g_0(x,r) + K_1\theta \\ &\leq -(\theta\,\mathcal{H}_4[\varepsilon,w] + w_t)\,\mathcal{G}[w]_t + K_2\theta|\varepsilon_t| + K_1\theta \leq K_1\theta + K_2\theta|\varepsilon_t| + \frac{K_5}{4} K_2^2\theta^2. \end{aligned} \tag{4.5}$$

Therefore, using (4.3), we find from Young's inequality that

$$\begin{aligned} \int_0^t \int_\Omega \frac{1}{\theta} \Big(\mathcal{F}_1[\varepsilon,w]_t - \sigma\varepsilon_t - g(x,r,\theta) \Big)\,dx\,dr &\leq C_4 \Big(1 + \int_0^t \int_\Omega |\varepsilon_t|\,dx\,dr \Big) \\ &\leq C_5 + \frac12 \int_0^t \int_\Omega \frac{\varepsilon_t^2}{\theta}\,dx\,dr. \end{aligned} \tag{4.6}$$

In conclusion, we have shown the estimate

$$\int_0^\tau \int_\Omega \left(\frac{\theta_x^2}{\theta^2} + \frac{\varepsilon_t^2}{\theta} \right) dx\,dt \leq C_6. \tag{4.7}$$

But then, using Schwarz's inequality for a fixed $t \in (0,\tau)$,

$$\begin{aligned}\int_\Omega \left|\Big(\sqrt{\theta}\Big)_x\right|(x,t)\,dx &= \int_\Omega \left|\frac{\theta_x(x,t)}{2\sqrt{\theta(x,t)}}\right| dx \\ &\le \frac{1}{2}\left(\int_\Omega \theta(x,t)\,dx\right)^{1/2}\left(\int_\Omega \frac{\theta_x^2(x,t)}{\theta^2(x,t)}\,dx\right)^{1/2},\end{aligned} \tag{4.8}$$

whence, using the Gagliardo–Nirenberg inequality (2.21) with $w = \sqrt{\theta}$, $p = +\infty$, $q = 2$, $r = 1$, and $\omega = 1$, and invoking (4.3), we obtain

$$\int_0^\tau \|\theta(\cdot,t)\|_\infty\,dt \le C_7 + C_8\int_0^\tau\int_\Omega \frac{\theta_x^2}{\theta^2}\,dx\,dt \le C_9. \tag{4.9}$$

Hence,

$$\int_0^\tau\int_\Omega \theta^2\,dx\,dt \le \max_{0\le t\le\tau}\|\theta(\cdot,t)\|_1\int_0^\tau \|\theta(\cdot,t)\|_\infty\,dt \le C_{10}. \tag{4.10}$$

Third estimate. We now exploit the decomposition (3.1). We have $u_x = \varepsilon = p + q$, where, owing to (4.3), $\|p\|_{L^\infty(\Omega_\tau)} \le C_{11}$. Therefore, invoking (H4) and (2.11), it holds that for every $(x,t) \in \overline{\Omega_\tau}$,

$$|\sigma(x,t)| + |\psi(x,t)| \le C_{12} + 2K_2\,\theta(x,t) + 2K_4\max_{0\le r\le t}\Big(|q(x,r)| + |w(x,r)|\Big). \tag{4.11}$$

Now multiply (3.5) by q, and (3.8) by w, respectively, add the resulting equations, and integrate over $[0,t]$, where $t \in (0,\tau]$. Using Young's inequality and invoking (4.9), we obtain from (4.11) the estimate

$$\begin{aligned}&\frac{1}{2}\Big(q^2(x,t) + w^2(x,t)\Big)\\ &\le C_{13}\left[1 + \max_{0\le r\le t}\Big(|q(x,r)| + |w(x,r)|\Big)\left(1 + \int_0^t\Big(|q(x,r)| + |w(x,r)|\Big)\,dr\right)\right]\\ &\le C_{14} + \frac{1}{4}\max_{0\le r\le t}\Big(q^2(x,r) + w^2(x,r)\Big) + C_{15}\int_0^t\Big(q^2(x,r) + w^2(x,r)\Big)\,dr.\end{aligned} \tag{4.12}$$

Taking the maximum with respect to t on both sides, we obtain from Gronwall's lemma that

$$\|q\|_{L^\infty(\Omega_\tau)} + \|w\|_{L^\infty(\Omega_\tau)} \le C_{16}, \tag{4.13}$$

whence also

$$\|\varepsilon\|_{L^\infty(\Omega_\tau)} + \max_{j\in\{1,3\}}\|\mathcal{H}_j[\varepsilon,w]\|_{L^\infty(\Omega_\tau)} \le C_{17}, \tag{4.14}$$

and we obtain from (3.5) and (3.8), using (4.9)–(4.11), that

$$\begin{aligned}&\|q_t\|_{L^1(0,\tau;L^\infty(\Omega))\cap L^2(\Omega_\tau)\cap L^\infty(0,\tau;L^1(\Omega))}\\ &\qquad + \|w_t\|_{L^1(0,\tau;L^\infty(\Omega))\cap L^2(\Omega_\tau)\cap L^\infty(0,\tau;L^1(\Omega))} \le C_{18}.\end{aligned} \tag{4.15}$$

Moreover, (4.10) and (4.14) imply that the right-hand side of (3.2) is bounded in $L^2(\Omega_\tau)$; hence, using standard parabolic estimates, we can conclude that

$$\|p\|_{H^1(0,\tau;L^2(\Omega))\cap L^2(0,\tau;H^2(\Omega))\cap C([0,\tau];H^1(\Omega))} \le C_{19}, \tag{4.16}$$

which yields, in particular, that $u_{xt} = p_{xx}$ is bounded in $L^2(\Omega_\tau)$.

Fourth estimate. In the next step, we perform a classical estimate (cf. [5]); namely, we multiply (1.3) by $-\theta^{-1/3}$ and integrate over Ω_t for $t \in (0,\tau]$. It then follows from (4.5) that

$$\int_0^t \int_\Omega \left(\theta^{-4/3}\theta_x^2 + \theta^{-1/3}\varepsilon_t^2\right) dx\, dr \le C_{20}\left(1 + \int_\Omega \theta^{2/3}(x,t)\, dx + \int_0^t \int_\Omega \theta^{2/3}\, dx\, dr\right)$$
$$+ C_{21}\left(\int_0^t \int_\Omega \theta^{2/3}|\varepsilon_t|\, dx\, dr + \int_0^t \int_\Omega \theta^{5/3}\, dx\, dr\right). \tag{4.17}$$

Owing to (4.3) and (4.10), the first, second, and fourth integrals on the right of (4.17) are bounded, and the remaining expression is estimated as follows:

$$\begin{aligned}\int_0^t \int_\Omega \theta^{2/3}|\varepsilon_t|\, dx\, dr &= \int_0^t \int_\Omega \theta^{5/6}\theta^{-1/6}|\varepsilon_t|\, dx\, dr \\ &\le \frac{1}{2}\int_0^t \int_\Omega \theta^{-1/3}\varepsilon_t^2\, dx\, dr + \frac{1}{2}\int_0^t \int_\Omega \theta^{5/3}\, dx\, dr.\end{aligned} \tag{4.18}$$

Since the second summand on the right of (4.18) is again bounded, we have shown the estimate

$$\int_0^\tau \int_\Omega \left(\theta^{-4/3}\theta_x^2 + \theta^{-1/3}\varepsilon_t^2\right) dx\, dt \le C_{22}. \tag{4.19}$$

But then $\theta^{1/3}$ is bounded in $L^\infty(0,\tau;L^3(\Omega)) \cap L^2(0,\tau;H^1(\Omega))$, and the Gagliardo–Nirenberg inequality (2.21), with $p = +\infty$, $r = 2$, $q = 3$, and $\omega = 2/5$, yields that

$$\int_0^\tau \|\theta(\cdot,t)\|_\infty^{5/3}\, dt \le C_{23}, \tag{4.20}$$

whence, using (4.3) once more, we obtain

$$\int_0^\tau \int_\Omega \theta^{8/3}\, dx\, dt \le C_{24}. \tag{4.21}$$

Thus, the right-hand sides of (3.2), (3.5), and (3.8), respectively, are bounded in $L^{8/3}(\Omega_\tau)$, and we can infer from standard parabolic estimates, using $\varepsilon_t = p_{xx}$, that

$$\|p_t\|_{L^{8/3}(\Omega_\tau)} + \|\varepsilon_t\|_{L^{8/3}(\Omega_\tau)} + \|q_t\|_{L^{8/3}(\Omega_\tau)} + \|w_t\|_{L^{8/3}(\Omega_\tau)} \le C_{25}. \tag{4.22}$$

Fifth estimate. We now turn our attention to (1.3). By virtue of (4.21) and (4.22), and invoking (2.5), we easily verify that $\mathcal{F}_1[\varepsilon,w]_t$ and the right-hand side of (1.3) are bounded in $L^{4/3}(\Omega_\tau)$. Therefore, multiplying (1.3) by θ, integrating over Ω_τ for $t \in (0,\tau]$, and applying Young's inequality and (4.3), we see that for any $\gamma > 0$ it holds that

$$\begin{aligned}\|\theta(\cdot,t)\|_2^2 + \int_0^t \int_\Omega \theta_x^2\, dx\, dr &\le C_{26}\left(1 + \gamma^{-1}\right) + \gamma \int_0^t \int_\Omega \theta^4\, dx\, dr \\ &\le C_{27}\left(1 + \gamma^{-1} + \gamma \int_0^t \|\theta(\cdot,r)\|_\infty^3\, dr\right).\end{aligned} \tag{4.23}$$

Now we use (4.3) and the Gagliardo–Nirenberg inequality (2.21) with $p = +\infty$, $q = 1$, $r = 2$, and $\omega = 2/3$ in order to obtain that

$$\int_0^t \|\theta(\cdot,r)\|_\infty^3\, dr \le C_{28}\left(1 + \int_0^t \int_\Omega \theta_x^2\, dx\, dr\right). \tag{4.24}$$

Hence, choosing $\gamma > 0$ small enough, we have shown the estimate

$$\|\theta\|_{L^\infty(0,\tau;L^2(\Omega))\cap L^2(0,\tau;H^1(\Omega))} \le C_{29}, \tag{4.25}$$

whence, using interpolation once more, we obtain

$$\|\theta\|_{L^6(\Omega_\tau)} \le C_{30}. \tag{4.26}$$

Thus, just as in the derivation of (4.22), we have

$$\|p_t\|_{L^6(\Omega_\tau)} + \|\varepsilon_t\|_{L^6(\Omega_\tau)} + \|q_t\|_{L^6(\Omega_\tau)} + \|w_t\|_{L^6(\Omega_\tau)} \le C_{31}. \tag{4.27}$$

But then $\mathcal{F}_1[\varepsilon, w]_t$ and the right-hand side of (1.3) are bounded in $L^2(\Omega_\tau)$, and standard parabolic estimates, also using the continuous imbeddings $H^1(0,\tau;L^2(\Omega)) \cap L^2(0,\tau;H^2(\Omega)) \hookrightarrow C([0,\tau];H^1(\Omega)) \hookrightarrow C(\overline{\Omega_\tau})$, yield that

$$\|\theta\|_{H^1(0,\tau;L^2(\Omega))\cap L^2(0,\tau;H^2(\Omega))\cap C([0,\tau];H^1(\Omega))\cap C(\overline{\Omega_\tau})} \le C_{32}. \tag{4.28}$$

This implies, in particular, that σ_t and ψ_t are bounded in $L^2(\Omega_\tau)$, so that

$$\|q_{tt}\|_{L^2(\Omega_\tau)} + \|w_{tt}\|_{L^2(\Omega_\tau)} \le C_{33}. \tag{4.29}$$

In addition, we may argue as in the derivation of (3.38) to conclude that also

$$\|p\|_{H^2(0,\tau;V_0^*)\cap H^1(0,\tau;H^1(\Omega))} \le C_{34}. \tag{4.30}$$

Sixth estimate. In light of the above estimates, we have, for a.e. $(x,t) \in \Omega_\tau$,

$$\begin{aligned} |\sigma_x(x,t)| + |\psi_x(x,t)| &\le C_{35}\Big(|\theta_x(x,t)| + \max_{0\le r\le t}((|p_x| + |q_x| + |w_x|)(x,r))\Big) \\ &\le C_{36}\left(1 + |\theta_x(x,t)| + \int_0^t \Big(|p_{xt}(x,r)| + |q_{xt}(x,r)| + |w_{xt}(x,r)|\Big)\,dr\right). \end{aligned} \tag{4.31}$$

Hence, differentiating (3.5) and (3.8), respectively, with respect to x, and invoking the estimates (4.28) and (4.30), we easily derive the estimate

$$\|q_{xt}\|_{L^2(\Omega_t)} + \|w_{xt}\|_{L^2(\Omega_t)} \le C_{37}\left(1 + \int_0^t \Big(\|q_{xt}\|_{L^2(\Omega_r)} + \|w_{xt}\|_{L^2(\Omega_r)}\Big)\,dr\right), \tag{4.32}$$

whence, using Gronwall's lemma, we have

$$\|q_{xt}\|_{L^2(\Omega_\tau)} + \|w_{xt}\|_{L^2(\Omega_\tau)} \le C_{38}. \tag{4.33}$$

Finally, we conclude from the above estimates that also

$$\|p_{xxx}\|_{L^2(\Omega_\tau)} \le C_{39}. \tag{4.34}$$

In conclusion, combining all previously shown estimates, we have shown that

$$\|(p,q,\theta,w)\|_{X_\tau} \le C_{40}, \tag{4.35}$$

where X_τ is the space introduced in (3.15).

Conclusion of the proof of Theorem 2.1. So far we have shown that (4.35) holds as long as there is some $\bar\theta > 0$ such that $\theta \ge \bar\theta$ on $\overline{\Omega_\tau}$. To conclude the proof of the assertion, we still have to prove the validity of (2.17). To this end, first observe that we have shown above that $\varepsilon_t = p_{xx}$ is bounded in $L^6(\Omega_\tau) \cap L^2(0,\tau;H^1(\Omega))$. In particular, there is some $\beta_1 > 0$, independent of τ, such that

$$\int_0^t \|\varepsilon_t(\cdot,r)\|_\infty \, dr \le \beta_1 \quad \forall t \in (0,\tau]. \tag{4.36}$$

Besides, there is some $\beta_2 > 0$, independent of τ, such that

$$\max_{(x,t)\in\overline{\Omega_\tau}} |w_t(x,t)| \le \beta_2. \tag{4.37}$$

Now test (1.3) with an arbitrary function $z \in H^1(\Omega_\tau)$ satisfying $z \le 0$ a.e. in Ω_τ. In view of (2.10), (4.5), and (4.37) it follows, for a.e. $t \in (0,T)$, that

$$\begin{aligned}
&\int_\Omega \Big(z\theta_t + z_x\theta_x\Big)(x,t)\,dx \le \int_\Omega |z(x,t)|\Big((\mathcal{F}[\varepsilon,w]_t - \sigma\varepsilon_t - g(\cdot,\cdot,\theta))(x,t)\Big)\,dx \\
&\le \int_\Omega |z(x,t)|\Big((-\theta\,\mathcal{H}_4[\varepsilon,w] - w_t)\,\mathcal{G}[w]_t + K_2\theta|\varepsilon_t| + K_1\theta\Big)(x,t)\,dx \\
&\le \Big(K_1 + K_2K_5\beta_2 + K_2\|\varepsilon_t(\cdot,t)\|_\infty\Big)\int_\Omega |z(x,t)|\,\theta(x,t)\,dx \\
&\le \varphi(t)\int_\Omega |z(x,t)|\,\theta(x,t)\,dx,
\end{aligned} \tag{4.38}$$

where $\varphi(t) := (K_1 + K_2K_5\beta_2 + K_2\|\varepsilon_t(\cdot,t)\|_\infty)$ is by (4.36) bounded in $L^1(0,\tau)$ by a constant which does not depend on $\tau \in (0,T]$. Now, put

$$z(x,t) := -\left(\delta\exp\left(-\int_0^t \varphi(s)\,ds\right) - \theta(x,t)\right)^+ \quad \text{for } (x,t)\in\Omega_\tau. \tag{4.39}$$

Then it follows from inequality (4.38) that

$$\begin{aligned}
&\int_\Omega \left(z\left(z + \delta\exp\left(-\int_0^t \varphi(s)\,ds\right)\right)_t + z_x^2\right)(x,t)\,dx \\
&\le \varphi(t)\int_\Omega |z|\left(|z| + \delta\exp\left(-\int_0^t \varphi(s)\,ds\right)\right)(x,t)\,dx.
\end{aligned} \tag{4.40}$$

This yields, in particular,

$$\frac{1}{2}\,\frac{d}{dt}\int_\Omega z^2(x,t)\,dx + \int_\Omega z_x^2(x,t)\,dx \le \varphi(t)\int_\Omega z^2(x,t)\,dx. \tag{4.41}$$

Therefore, by Gronwall's lemma, $z = 0$, and thus

$$\theta(x,t) \ge \delta e^{-((K_1+K_2K_5\beta_2)t + K_2\beta_1)} \quad \forall (x,t)\in\overline{\Omega_\tau}. \tag{4.42}$$

Therefore, we can claim that $\tau = T$, and the assertion of Theorem 2.1 is completely proved. □

Remark 4. It does not present any major difficulties to extend the above proof to the more general case when $\mathcal{H}_3$ and $\mathcal{H}_4$ are *vector* hysteresis operators and, accordingly, (1.4) is a vector differential equation (then, of course, the hypotheses (H4) and (H5) have to be appropriately modified).

Remark 5. It is easy to see that the solution (u, θ, w) depends Lipschitz continuously on the data of the system. Indeed, a closer look at the proof of Lemma 3.5 reveals that $L^2(\Omega)$-variations of u_0, u_1, θ_0, w_0 and $L^2(\Omega_T)$-variations of f lead to Lipschitz variations of (p, q, θ, w) in the norm of the space $(H^1(0,T;L^2(\Omega)) \cap L^2(0,T;H^2(\Omega))) \times H^1(0,T;L^2(\Omega)) \times L^2(\Omega_T) \times H^1(0,T;L^2(\Omega))$. A similar result holds for variations of g. As the line of arguments should be clear, we leave the explicit formulation and the proof of the corresponding result to the reader.

Remark 6. It seems natural to discuss the asymptotic behavior of system (1.1)–(1.7) as $\mu \searrow 0$. As our method of proof strongly relies on the presence of the viscous term $-\mu u_{xxt}$ in (1.1), our analysis does not cover this problem, which seems to be very difficult.

ON THE INITIAL VALUE PROBLEM FOR THE ONE DIMENSIONAL QUASI-LINEAR SCHRÖDINGER EQUATIONS*

WEE KEONG LIM† AND GUSTAVO PONCE†

Abstract. We study the local in time solvability of the initial value problem (IVP) of the one dimensional fully nonlinear Schrödinger equation. Under appropriate assumptions on the nonlinearity (regularity and ellipticity) and on the initial data (regularity and decay at infinity), we establish the existence and uniqueness of solutions of the IVP in weighted Sobolev spaces. The equation can be reduced to its quasi-linear version by taking space derivative. The desired results are obtained by combining a change of variables, energy estimates, and the artificial viscosity method.

Key words. quasi-linear Schrödinger equations, a priori estimates

1. Introduction.

This paper is concerned with the initial value problem (IVP) for the general quasi-linear Schrödinger equation in one space dimension

$$\begin{cases} \partial_t u = ia(u,\bar{u},\partial_x u,\partial_x\bar{u})\partial_x^2 u + ib(u,\bar{u},\partial_x u,\partial_x\bar{u})\partial_x^2\bar{u} \\ \qquad\qquad + c(u,\bar{u},\partial_x u,\partial_x\bar{u})\partial_x u + d(u,\bar{u},\partial_x u,\partial_x\bar{u})\partial_x\bar{u} + f(u,\bar{u}), \\ u(x,0) = u_0(x), \end{cases} \tag{1.1}$$

where $u = u(x,t)$, $(x,t) \in \mathbb{R}^2$, $a, b, c, d : \mathbb{C}^4 \to \mathbb{C}$, and $f : \mathbb{C}^2 \to \mathbb{C}$ are smooth functions with $a(\cdot)$ a real-valued function. We shall assume the following ellipticity condition:

$$\begin{cases} \text{for any } R > 0, \text{ there exists } \lambda = \lambda(R) > 0 \text{ such that if} \\ \|(z_1,z_2,z_3,z_4)\| = \left(\sum_{j=1}^{4} |z_j|^2\right)^{\frac{1}{2}} \le R, \\ \text{then} \quad \pm a(z_1,z_2,z_3,z_4) - |b(z_1,z_2,z_3,z_4)| \ge \lambda. \end{cases} \tag{1.2}$$

Our goal is to establish a local theory (including existence and uniqueness) in the classical Sobolev spaces $H^s(\mathbb{R})$ or its weighted version $H^s(\mathbb{R}) \cap L^2(|x|^r dx)$, depending on the degree of nonlinearity of a, b, c, d.

Equations of this kind arise in several fields in physics (see [1], [2], and references therein) and have received considerable attention in recent publications.

In [2], de Bouard, Hayashi, and Saut proved local wellposedness for the IVP associated with the equation

$$\partial_t u = i\Delta u - 2iuh'(|u|^2)\Delta(h(|u|^2)) + iug(|u|^2) \tag{1.3}$$

in space dimensions $n = 1, 2, 3$ corresponding to small data u_0 in $H^6(\mathbb{R})$. They also deduced in dimensions $n = 2, 3$ sufficient conditions of the data u_0 which guarantee that the local solution extends to a global one.

The first author's research was conducted while on leave from Multimedia University, Department of Engineering, Jalan Multimedia, 63100 Cyberjaya, Selangor, Malaysia. The second author was supported in part by an NSF grant.

In [18], Poppenberg studied the IVP for the equation of the form

$$\partial_t u = i(\Delta - V(x))u + iuh'(|u|^2)\Delta(h(|u|^2)) + iug(|u|^2). \tag{1.4}$$

Under certain conditions on the potential V and on h and g, he showed that the corresponding IVP is locally wellposed in $H^\infty(\mathbb{R}^n)$ for any dimension n. His proof is based on the Nash–Moser implicit function theorem.

In [5] and [6], Colin removed the smallness condition on the data assumed in [2] to establish the local wellposedness of the IVP for (1.4) in any dimension in $H^s(\mathbb{R}^n)$, $s \geq s_0(n)$.

For the one dimensional case, Poppenberg [19] showed that the IVP associated with the fully nonlinear Schrödinger equation

$$\begin{cases} i\partial_t u = F(t, x, u, \bar{u}, u_x, \bar{u}_x, u_{xx}, \bar{u}_{xx}), \\ u(x, 0) = u_0(x) \end{cases} \tag{1.5}$$

is locally wellposed in $H^\infty(\mathbb{R})$, under appropriate assumptions on F. As in [18], the proof in [19] is based on the Nash–Moser implicit function theorem, which allows it to overcome "the loss of derivatives" introduced by the nonlinearity.

The assumptions in [19] include ellipticity and a "cubic" character of the nonlinearity. For example, the assumptions in [19] exclude equations of the form

$$(a)\ F = u_{xx} + uu_x \ \text{ or } \ (b)\ F = (1 + |u|^2)u_{xx} + i\mathrm{Re}(u)u_x. \tag{1.6}$$

The case (a) above was considered by Ozawa [17]. The implicit "cubic" assumption on the nonlinearity in [19] can be explained by the Mizohata condition [16] which we now describe.

It was shown in [16] that for the local wellposedness of

$$\begin{cases} \partial_t u = i\Delta u + \vec{b}(x) \cdot \nabla u, \quad x \in \mathbb{R}^n, t \in \mathbb{R}, \\ u(x, 0) = u_0(x) \in L^2(\mathbb{R}^n) \end{cases} \tag{1.7}$$

the following condition is necessary:

$$\sup_{x \in \mathbb{R}^n, \omega \in \mathbb{S}^{n-1}} \left| \int_0^\infty Im\ \vec{b}(x + s\omega) \cdot \omega ds \right| < \infty. \tag{1.8}$$

In the one dimensional case, the condition (1.8) applied to the equations in (1.6) (a) suggests that $u(\cdot, t) \in L^1(\mathbb{R})$ for $t \in [0, T]$. However, this does not follow directly from the initial data since even the group $\{e^{it\partial_x^2} : t \in \mathbb{R}\}$ does not preserve the L^1-class.

Notice that when the "nonlinearity" is "cubic," e.g., $F = u_{xx} + u^2 u_x$, the condition (1.8) is "fulfilled" if $u(\cdot, t) \in L^2(\mathbb{R})$.

To state our result, we first need some definition. Let μ_j, $j = 1, 2, 3, 4$, be the smallest integer such that

$$\begin{cases} \partial_z^\alpha a(0,0,0,0) \neq 0, & 0 < |\alpha| \leq \mu_1, \\ \partial_z^\beta b(0,0,0,0) \neq 0, & 0 < |\beta| \leq \mu_2 \ \text{ if } \ b \not\equiv 0, \\ \partial_z^\gamma c(0,0,0,0) \neq 0,\ c(0,0,0,0) = 0, & 0 < |\gamma| \leq \mu_3 \ \text{ if } \ c \not\equiv 0, \\ \partial_z^\sigma d(0,0,0,0) \neq 0,\ d(0,0,0,0) = 0, & 0 < |\sigma| \leq \mu_4 \ \text{ if } \ d \not\equiv 0, \\ f(0,0) = 0, \end{cases} \tag{1.9}$$

where $a = a(z_1, z_2, z_3, z_4)$, similarly for b, c, d and $z = (z_1, z_2, z_3, z_4)$. Let

$$\mu = \min\{\mu_1, \mu_2, \mu_3, \mu_4\}. \tag{1.10}$$

Thus the case $\mu = 1$ corresponds to the "quadratic" case in (1.1) and $\mu \geq 2$ to at least the cubic case in (1.1). Consider the following examples:

Example 1. $a = 1 + z_1^2 + z_2^2 + z_3^2 z_4^2$, $b = z_1 z_2$, $c = z_1 + z_2^2$, $d = z_1 + z_1 z_2 z_3$; then $\mu_1 = \mu_2 = 2$, $\mu_3 = \mu_4 = 1$, so $\mu = 1$, which is a quadratic case.

Example 2. $a = 1 + \text{Re } u + (\text{Re } u)^2$, $b = c = d = 0$ is "quadratic," i.e., $\mu = 1$.

Example 3. $a = 1 + |u_x|^2$, $b = c = d = 0$ is "cubic," i.e., $\mu = 2$.

THEOREM 1. *Assuming* (1.2) *and* (1.9) *with* $\mu \geq 2$, *there exists* $k \in \mathbb{Z}^+$ *such that for any* $u_0 \in H^k(\mathbb{R})$ *there exist* $T = T(\|u_0\|_{H^k})$ *and a unique solution* $u = u(x,t)$ *of the IVP* (1.1) *on the time interval* $[-T, T]$ *such that*

$$u \in C([-T,T] : H^{k-1}(\mathbb{R})) \cap C^1([-T,T] : H^{k-3}(\mathbb{R})).$$

THEOREM 2. *Assuming* (1.2) *and* (1.9) *with* $\mu = 1$, *there exist* $k, r \in \mathbb{Z}^+$ *such that the condition of Theorem* 1 *holds in the space* $H^{k-1}(\mathbb{R}) \cap L^2(|x|^r dx)$ *instead of* $H^{k-1}(\mathbb{R})$.

Remarks.

1. It will follow from our proof that under appropriate assumptions the same results apply to the IVP for the fully nonlinear Schrödinger equation

$$\partial_t w = iF(w, \bar{w}, w_x, \bar{w}_x, w_{xx}, \bar{w}_{xx}). \tag{1.11}$$

   One has to observe that just by taking derivative in (1.11) and using the notation $u = \partial_x w$, one gets an equation similar to (1.1).
   The same applies to the more general form

$$F = F(x, t, w, \bar{w}, w_x, \bar{w}_x, w_{xx}, \bar{w}_{xx}). \tag{1.12}$$

2. As mentioned above, Theorem 2 deals with quadratic nonlinearity for which one "needs" the weighted Sobolev spaces to handle the integrability conditions in (1.8).
3. Our ellipticity assumption (1.2) allows us to consider equations of the form $a(\cdot) = \frac{1}{1+|u|^2} = 1 - \frac{|u|^2}{1+|u|^2}$, $b = c = d = f = 0$ which are not "uniformly elliptic."
4. Once the results in Theorem 1 and 2 are established, one can obtain the persistence property by combining these results with those found in [15]. The solution u in Theorems 1 and 2 satisfies $u \in C([-T,T] : H^k(\mathbb{R}))$, and some kind of stability (continuous dependence of the solution upon the initial data) can be established. However, to simplify the exposition, we shall not pursue these results here.
5. We do not attempt to get the optimal value of the parameter s (in H^s) and r (in $L^2(|x|^r dx)$) in Theorems 1 and 2 provided by our arguments below.

Our method of proof consists of several steps.

First we differentiate j times the equation in (1.1) to obtain an equation for $v_j = \partial_x^j u = \frac{\partial^j u}{\partial x^j}$, $j = 0, 1, \ldots, k-1$, whose coefficients for the second order derivatives are similar to those in (1.1).

We perform energy estimates in these equations which depend on one higher derivative, i.e., $v_{j+1} = \partial_x^{j+1} u$. To close the estimate we need to bound $v_k = \partial_x^k u$. To

do this, we shall use the "gauge transformation" introduced by Hayashi and Ozawa in [11]. However, this process presents the difficulty of working with $\phi\partial_x^k u$ instead of $\partial_x^k u$, where ϕ is the factor arising from the "gauge transformation" which has exponential form and depends only on some derivatives $\partial_x^j u$, $j = 0, 1, 2, 3$.

To overcome this difficulty, we used ϕ as part of our unknown and show that both norms for $\phi\partial_x^k u$ and $\partial_x^k u$ are equivalent in some time interval.

Putting all these together we get an a priori estimate of the form

$$\frac{d}{dt}h(t) \leq \left((h(t))^2 + (h(t))^l\right) e^{(h(t))^2+(h(t))^l}, \tag{1.13}$$

at least the cubic case (Theorem 1), with l depending on the highest nonlinearity considered.

From (1.13) it follows that there exists $T = T(\|u_0\|_{H^k}) > 0$ such that, for $t \in [0, T]$, $h(t) \leq 100h(0)$ and in this time interval $h(t) \cong \|u(t)\|_{H^k}$. This provides to the norm an a priori estimate.

To prove existence we rely on the artificial viscosity method, so we need to check that the previous argument is preserved for the one parameter family of parabolic equations whose solutions converge as the parameter defining the parabolic character goes to zero.

At this point we explain the restriction of the dimension. In [14], Kenig, Ponce, and Vega established the local wellposedness of the IVP associated with the equation

$$\partial_t u = i\Delta u + P(u, \bar{u}, \nabla_x u, \nabla_x \bar{u}), \tag{1.14}$$

where $P : \mathbb{C}^{2n+2} \to \mathbb{C}$ is a polynomial without constant or linear terms, under the smallness assumption for the data. In [11], Hayashi and Ozawa used a gauge transformation to remove in one dimension the smallness assumption on the data in [14].

In [3] and [4], using ideas due to Doi [8], Chihara was able to remove the smallness condition in [14] in any dimension. Roughly speaking, in [4], Chihara relied on a symmetrization process based on the ellipticity of the dispersive factor in (1.14) and the gauge transformation, which in the case $n \geq 2$ involves pseudodifferential operators. In the one dimensional case, this symmetrization process is not necessary. Also the fact that the "gauge transformation" is exact, i.e., it does not involve pseudodifferential operator, is crucial in our result. The results of Chihara in [4] have been improved by Hayashi and Kaikina [10].

The proof in [14] is based on the following smoothing effects of the solution of the lineal IVP:

$$\begin{cases} \partial_t u = i\Delta u + f(x,t), \\ u(x,0) = u_0(x). \end{cases}$$

If $f \equiv 0$, then

$$\int_0^T \int_{\mathbb{R}^n} |D_x^{1/2} e^{it\Delta} u_0|^2 \lambda(x) dx dt \leq c\|u_0\|_{L^2}, \tag{1.15}$$

and if $u_0 \equiv 0$, then

$$\int_0^T \int_{\mathbb{R}^n} \left| \partial_x \int_0^t e^{i(t-t')\Delta} f(\cdot, t') dt' \right|^2 \lambda(x) dx dt \leq c \int_0^T \int_{\mathbb{R}^n} |f(x)|^2 \lambda^{-1}(x) dx dt, \tag{1.16}$$

where $\lambda(x)$ is a weight with appropriate decay at ∞. The inequality (1.15) was proved simultaneously in [7], [20], [21], and (1.16) in [13].

We do not need to establish the smoothing effect in our solutions as part of the proof to get the existence of solutions. The fact that the solutions provided by Theorems 1 and 2 satisfy the "smoothing effect" of the kind described in (1.13)–(1.14) (gain $\frac{1}{2}$-derivative with respect to the initial data and 1-derivative with respect to the inhomogeneous part) follow immediately by the results in [15]; see also [8], [9]. The main point is that once the existence of a (smooth enough) solution has been established, the proof of the corresponding smoothing effect reduces to a linear problem treated in [8], [9], and [15].

The rest of this paper is organized as follows. We will prove Theorem 1 in section 2 and Theorem 2 in section 3. The appendix includes some technical details. All the integrations are with respect to x and over the whole real line $\mathbb{R}$ unless otherwise mentioned.

2. Proof of Theorem 1. We shall divide the proof in several steps.

2.1. Step 1: Formal energy estimate for lower derivatives. Consider the general quasi-linear Schrödinger equation

$$\begin{cases} \partial_t u = ia(u,\bar{u},\partial_x u,\partial_x\bar{u})\partial_x^2 u + ib(u,\bar{u},\partial_x u,\partial_x\bar{u})\partial_x^2\bar{u} \\ \qquad\qquad + c(u,\bar{u},\partial_x u,\partial_x\bar{u})\partial_x u + d(u,\bar{u},\partial_x u,\partial_x\bar{u})\partial_x\bar{u} + f(u,\bar{u}), \\ u(x,0) = u_0(x) \in H^k(\mathbb{R}), \end{cases} \tag{2.1}$$

where $u = u(x,t), (x,t) \in \mathbb{R}^2$. We recall our hypotheses:

1. a, b, c, d, f are smooth functions of its arguments.
2. a is a real-valued function.
3. For any $\lambda > 0$, there exist $m_1, M_1 > 0$ such that if $\|(z_1,z_2,z_3,z_4)\| \le \lambda$, then we have
$$m_1 \le a(z_1,z_2,z_3,z_4) - |b(z_1,z_2,z_3,z_4)| \le M_1,$$
thus there exist $m_2, M_2 > 0$ such that $m_2 \le \frac{1}{a \pm |b|} \le M_2$. (It will be clear from the proof below that the case $-a(z_1,z_2,z_3,z_4) - |b(z_1,z_2,z_3,z_4)|$ is similar.)
4. $a(z_1,z_2,z_3,z_4) - a(0,0,0,0) = O(|z_1|^\alpha + |z_2|^\alpha + |z_3|^\alpha + |z_4|^\alpha)$, $\alpha \ge \mu \ge 2$, similarly for $b(z_1,z_2,z_3,z_4) - b(0,0,0,0)$, $c(z_1,z_2,z_3,z_4), d(z_1,z_2,z_3,z_4)$.
5. We consider only the case $t \in [0,T]$. (The case $t < 0$ follows by a similar argument.)

To perform the energy estimate on $\partial_x^j u$, we need to take the jth derivative of (2.1), $j = 0, 1, \ldots, k$. With the notation $\partial_x^j u = v_j$, we have from (4.8) (Appendix 1) that (2.1) is rewritten as

$$\partial_t v_j = ia\partial_x^2 v_j + ib\partial_x^2\bar{v}_j \ + c_j\partial_x v_j + d_j\partial_x\bar{v}_j + f_j, \tag{2.2}$$

where $a'_j = \partial_{z_j} a(z_1,z_2,z_3,z_4)$, similarly for b'_j, c'_j, d'_j, $j = 1,2,3,4$; $a' = \partial_x(a) = \frac{\partial a}{\partial x}$, where $a = a(u(x,t),\bar{u}(x,t),\partial_x u(x,t),\partial_x\bar{u}(x,t))$ is implicitly a function of x,t, similarly for b', c', d' and

$$\begin{cases} c_j = ija' + ia'_3 v_2 + ib'_3\bar{v}_2 + c + c'_3 v_1 + d'_3\bar{v}_1, \\ d_j = ijb' + ia'_4 v_2 + ib'_4\bar{v}_2 + d + c'_4 v_1 + d'_4\bar{v}_1, \\ f_j = f_{aj} + f_{bj} + f_{cj} + f_{dj} + \partial_x^j f, \end{cases} \tag{2.3}$$

where $f_{aj}, f_{bj}, f_{cj}, f_{dj}$ are described in (4.7) and depend only on at most jth derivatives of the unknown u, i.e., on $v_0, \bar{v}_0, \dots, v_j, \bar{v}_j$. Thus,

$$\begin{cases} c_j = c_j(v_0, \bar{v}_0, v_1, \bar{v}_1, v_2, \bar{v}_2), \\ d_j = d_j(v_0, \bar{v}_0, v_1, \bar{v}_1, v_2, \bar{v}_2), \\ f_j = f_j(v_0, \bar{v}_0, v_1, \bar{v}_1, \dots, v_j, \bar{v}_j). \end{cases} \tag{2.4}$$

Notice that c_j and d_j depend on j only as a multiplicative constant.

For $j \le k-1$, we perform the standard energy estimate on (2.2), i.e., multiply the equation by $\bar{v}_j$, integrate with respect to x over $\mathbb{R}$, and take the real part of the result. After integration by parts, we have

$$\begin{aligned} \frac{d}{dt}\int |v_j|^2 dx =\ & i\int a(\bar{v}_j\partial_x^2 v_j - v_j\partial_x^2\bar{v}_j)dx + i\int(\bar{v}_j b\partial_x^2\bar{v}_j - v_j\bar{b}\partial_x^2 v_j)dx \\ & + \int(c_j\bar{v}_j\partial_x v_j + \bar{c}_j v_j\partial_x\bar{v} + d_j\bar{v}_j\partial_x\bar{v}_j + \bar{d}_j v_j\partial_x v_j)dx + \int(v_j f_j + \bar{v}_j\bar{f}_j)dx \\ =\ & -2i\mathrm{Re}\int \bar{v}_j a' v_{j+1}dx - 2i\mathrm{Re}\int b(\bar{v}_{j+1})^2 dx + i\mathrm{Re}\int b''\bar{v}_j^2 dx \\ & + 2\mathrm{Re}\int c_j\bar{v}_j v_{j+1}dx - \mathrm{Re}\int d_j'\bar{v}_j^2 dx + 2\mathrm{Re}\int v_j f_j dx. \end{aligned} \tag{2.5}$$

Thus, we obtain the following estimate:

$$\begin{aligned} \frac{d}{dt}\|v_j\|_{L^2}^2 \le\ & 2\|b\|_{L^\infty}\|v_{j+1}\|_{L^2}^2 + 2(\|a'\|_{L^\infty} + \|c_j\|_{L^\infty})\|v_j\|_{L^2}\|v_{j+1}\|_{L^2} \\ & + (\|b''\|_{L^\infty} + \|d_j'\|_{L^\infty})\|v_j\|_{L^2}^2 + 2\|f_j\|_{L^2}\|v_j\|_{L^2}. \end{aligned} \tag{2.6}$$

We shall use that $a' = a_1'\partial_x u + a_2'\partial_x\bar{u} + a_3'\partial_x^2 u + a_4'\partial_x^2\bar{u}$ can be viewed as a first order polynomial of $u, \bar{u}, \partial_x u, \partial_x\bar{u}, \partial_x^2 u, \partial_x^2\bar{u}$, i.e., $v_0, \bar{v}_0, v_1, \bar{v}_1, v_2, \bar{v}_2$; similarly, c_j, d_j, and b'' can be viewed as first and second order polynomials of $v_0, \bar{v}_0, v_1, \bar{v}_1, v_2, \bar{v}_2$. Observe that the estimate in (2.6) depends on v_{j+1}. However, for $j = k$, $\frac{d}{dt}\int |v_k|^2 dx$ depends on v_{k+1}. To have the estimate close within $H^k(\mathbb{R})$, we need to consider a gauge transformation.

2.2. Step 2: Estimate for $v_k = \partial_x^k u$, the gauge transformation. In this section, we will use a gauge transformation to get the desired estimate for $v_k = \partial_x^k u$. It is performed as follows: consider the kth derivative of the quasi-linear Schrödinger equation (1.1) and its conjugate as a system and rewrite them in a matrix form. The ellipticity (1.2) $a^2 - |b|^2 > 0$ will guarantee the nonsingularity of the matrix $A = \left(\begin{smallmatrix} a & b \\ -\bar{b} & -a \end{smallmatrix}\right)$. The equation is rewritten in the form which after introducing a weight function ϕ we are able to close the estimate within $H^k(\mathbb{R})$ with some equivalent "norm."

From (2.2) with $j = k$ and its conjugate, we get

$$\begin{cases} \partial_t v_k = ia\partial_x^2 v_k + ib\partial_x^2\bar{v}_k + c_k\partial_x v_k + d_k\partial_x\bar{v}_k + f_k, \\ \partial_t\bar{v}_k = -ia\partial_x^2\bar{v}_k - i\bar{b}\partial_x^2 v_k + \bar{c}_k\partial_x\bar{v}_k + \bar{d}_k\partial_x v_k + \bar{f}_k, \end{cases} \tag{2.7}$$

which can be written as the system

$$\partial_t\begin{pmatrix} v_k \\ \bar{v}_k \end{pmatrix} = i\begin{pmatrix} a & b \\ -\bar{b} & -a \end{pmatrix}\partial_x^2\begin{pmatrix} v_k \\ \bar{v}_k \end{pmatrix} + \begin{pmatrix} c_k & d_k \\ \bar{d}_k & \bar{c}_k \end{pmatrix}\partial_x\begin{pmatrix} v_k \\ \bar{v}_k \end{pmatrix} + \begin{pmatrix} f_k \\ \bar{f}_k \end{pmatrix}. \tag{2.8}$$

Let

$$A=\begin{pmatrix} a & b \\ -\bar{b} & -a \end{pmatrix}, \quad \tilde{a}=\tfrac{a}{a^2-|b|^2}, \quad \tilde{b}=\tfrac{b}{a^2-|b|^2}$$
$$\text{so } A^{-1}=\begin{pmatrix} \tilde{a} & \tilde{b} \\ -\bar{\tilde{b}} & -\tilde{a} \end{pmatrix}. \tag{2.9}$$

Notice that ellipticity guarantees that $a^2-|b|^2>0$.

So (2.8) is equivalent to

$$A^{-1}\partial_t \begin{pmatrix} v_k \\ \bar{v}_k \end{pmatrix} = i\partial_x^2 \begin{pmatrix} v_k \\ \bar{v}_k \end{pmatrix} + A^{-1}\begin{pmatrix} c_k & d_k \\ \bar{d}_k & \bar{c}_k \end{pmatrix}\partial_x \begin{pmatrix} v_k \\ \bar{v}_k \end{pmatrix} + A^{-1}\begin{pmatrix} f_k \\ \bar{f}_k \end{pmatrix}. \tag{2.10}$$

Write

$$\begin{cases} A^{-1}\begin{pmatrix} c_k & d_k \\ \bar{d}_k & \bar{c}_k \end{pmatrix} = \begin{pmatrix} \tilde{a}c_k+\tilde{b}\bar{d}_k & \tilde{a}d_k+\tilde{b}\bar{c}_k \\ -\bar{\tilde{b}}c_k-\tilde{a}\bar{d}_k & -\bar{\tilde{b}}d_k-\tilde{a}\bar{c}_k \end{pmatrix} = \begin{pmatrix} \alpha_{11}^k & \alpha_{12}^k \\ \alpha_{21}^k & \alpha_{22}^k \end{pmatrix}, \\ A^{-1}\begin{pmatrix} f_k \\ \bar{f}_k \end{pmatrix} = \begin{pmatrix} \tilde{a}f_k+\tilde{b}\bar{f}_k \\ -\bar{\tilde{b}}f_k-\tilde{a}\bar{f}_k \end{pmatrix} = \begin{pmatrix} F_k \\ -\bar{F}_k \end{pmatrix}. \end{cases} \tag{2.11}$$

Thus (2.10) becomes

$$\begin{pmatrix} \tilde{a} & \tilde{b} \\ -\bar{\tilde{b}} & -\tilde{a} \end{pmatrix}\partial_t \begin{pmatrix} v_k \\ \bar{v}_k \end{pmatrix} = i\partial_x^2 \begin{pmatrix} v_k \\ \bar{v}_k \end{pmatrix} + \begin{pmatrix} \alpha_{11}^k & \alpha_{12}^k \\ \alpha_{21}^k & \alpha_{22}^k \end{pmatrix}\partial_x \begin{pmatrix} v_k \\ \bar{v}_k \end{pmatrix} + \begin{pmatrix} F_k \\ \bar{F}_k \end{pmatrix}. \tag{2.12}$$

Since c_k, d_k depend on k only as a multiplicative constant, then α_{mn}^k, $m,n=1,2$, depend on k also as a multiplicative constant.

We now apply a gauge transformation to (2.12), i.e., multiply a function ϕ (which will be determined later) to the system (2.12) and write the system in the following form:

$$\begin{aligned} \begin{pmatrix} \tilde{a} & \tilde{b} \\ -\bar{\tilde{b}} & -\tilde{a} \end{pmatrix}\left[\partial_t \begin{pmatrix} v_k\phi \\ \bar{v}_k\phi \end{pmatrix} - \partial_t\phi \begin{pmatrix} v_k \\ \bar{v}_k \end{pmatrix}\right] = {} & i\partial_x^2 \begin{pmatrix} v_k\phi \\ \bar{v}_k\phi \end{pmatrix} - 2i\partial_x\phi\partial_x \begin{pmatrix} v_k \\ \bar{v}_k \end{pmatrix} \\ & - i\partial_x^2\phi \begin{pmatrix} v_k \\ \bar{v}_k \end{pmatrix} + \begin{pmatrix} \alpha_{11}^k & \alpha_{12}^k \\ \alpha_{21}^k & \alpha_{22}^k \end{pmatrix}\phi\partial_x \begin{pmatrix} v_k \\ \bar{v}_k \end{pmatrix} + \phi \begin{pmatrix} F_k \\ \bar{F}_k \end{pmatrix}. \end{aligned} \tag{2.13}$$

Consider the first equation of (2.13),

$$\begin{aligned} \tilde{a}\partial_t(v_k\phi)+\tilde{b}\partial_t(\bar{v}_k\phi)-\partial_t\phi(\tilde{a}v_k+\tilde{b}\bar{v}_k) = {} & i\partial_x^2(v_k\phi)-2i\partial_x\phi\partial_x v_k \\ & - i(\partial_x^2\phi)v_k+(\alpha_{11}^k\partial_x v_k+\alpha_{12}^k\partial_x\bar{v}_k)\phi+\phi F_k, \end{aligned} \tag{2.14}$$

which is equivalent to

$$\begin{aligned} \tilde{a}\partial_t(v_k\phi)+\tilde{b}\partial_t(\bar{v}_k\phi) = {} & i\partial_x^2(v_k\phi)+(-2i\partial_x\phi+\alpha_{11}^k\phi)\partial_x v_k \\ & + \alpha_{12}^k\phi\partial_x\bar{v}_k+\partial_t\phi(\tilde{a}v_k+\tilde{b}\bar{v}_k)-i(\partial_x^2\phi)v_k+\phi F_k. \end{aligned} \tag{2.15}$$

We want to eliminate the term having $\partial_x v_k$ as a factor so we can perform an appropriate energy estimate. Hence we should choose ϕ such that

$$-2i\partial_x\phi+\alpha_{11}^k\phi=0.$$

Thus

$$\begin{aligned}\phi = \phi(x,t) &= \exp\left(\frac{1}{2i}\int_0^x \left(\alpha_{11}^k\right)(x',t)dx'\right)\\ &= \exp\left(\frac{1}{2i}\int_0^x \left(\tilde{a}c_k + \tilde{b}\bar{d}_k\right)(x',t)dx'\right)\\ &= \exp\left\{\frac{1}{2i}\int_0^x \Big(\tilde{a}(ika' + ia_3'v_2 + ib_3'\bar{v}_2 + \ c + c_3'v_1 + d_3'\bar{v}_1)\right.\\ &\qquad \left.+ \tilde{b}(-ia_4'\bar{v}_2 - ik\bar{b}' - i\bar{b}_4'v_2 + \bar{c}_4'\bar{v}_1 + \bar{d} + \bar{d}_4'v_1)\Big)(x',t)dx'\right\}.\end{aligned} \tag{2.16}$$

Observe the following:

1. $\phi = \phi(v_0, \bar{v}_0, v_1, \bar{v}_1, v_2, \bar{v}_2)$, since a, b, c, d are functions of $v_0, \bar{v}_0, v_1, \bar{v}_1,\ v_2, \bar{v}_2$ and the expression in the exponential involves only one derivative.
2. $\phi = \phi_k$ depends on k only as a multiplicative constant.
3. $\phi^{-1} = \frac{1}{\phi}$.
4. If $b \equiv 0$, then $\phi = e^{\frac{1}{2i}\int_0^x \left(\frac{c_k}{a}\right)(x',t)dx'}$.
5. $\phi = e^{\frac{1}{2i}\int_0^x \left(\tilde{a}c_k + \tilde{b}d_k\right)(x',t)dx'} = e^{\rho + i\nu}$, which gives $|\bar{\phi}\phi^{-1}| = |\phi\bar{\phi}^{-1}| = 1$.
6. For $\mu \geq 2$, $\tilde{a}c_k + \tilde{b}d_k$ is at least quadratic, which means
$$|\phi| \leq e^{C\int |\tilde{a}c_k + \tilde{b}d_k|dx} \leq e^{C(\|u\|_{H^3}^2 + \|u\|_{H^3}^l)},$$
where l depends on the order of a, b, c, d.

With this choice of ϕ, (2.15) is reduced to

$$\begin{aligned}\tilde{a}\partial_t(v_k\phi) + \tilde{b}\partial_t(\bar{v}_k\phi) = i\partial_x^2(v_k\phi) + \alpha_{12}^k\phi\partial_x\bar{v}_k + \partial_t\phi(\tilde{a}v_k + \tilde{b}\bar{v}_k)\\ - i(\partial_x^2\phi)v_k + \phi F_k.\end{aligned} \tag{2.17}$$

We rewrite (2.17) in the following form:

$$\begin{aligned}\tilde{a}\partial_t(v_k\phi) + \tilde{b}\partial_t(\bar{v}_k\phi) &= i\partial_x^2(v_k\phi) + \alpha_{12}^k\phi\bar{\phi}^{-1}\partial_x(\bar{v}_k\bar{\phi}) + (\partial_t\phi)\tilde{a}\phi^{-1}(v_k\phi)\\ &\quad + (\partial_t\phi)\tilde{b}\bar{\phi}^{-1}(\bar{v}_k\bar{\phi}) - \alpha_{12}^k\phi\bar{\phi}^{-2}\partial_x\bar{\phi}(\bar{v}_k\bar{\phi})\\ &\quad - i(\partial_x^2\phi)\phi^{-1}(v_k\phi) + \phi F_k.\end{aligned} \tag{2.18}$$

Performing the energy estimate on (2.18), i.e., multiplying (2.18) by $\bar{v}_k\bar{\phi}$, integrating with respect to x over $\mathbb{R}$, and taking the real part, we have

$$\begin{aligned}&\int [2\tilde{a}\partial_t(|v_k\phi|^2) + \tilde{b}(\bar{v}_k\bar{\phi})\partial_t(\bar{v}_k\phi) + \bar{\tilde{b}}(v_k\phi)\partial_t(v_k\bar{\phi})]dx\\ &\quad = \int i\left[(\bar{v}_k\bar{\phi})\partial_x^2(v_k\phi) - (v_k\phi)\partial_x^2(\bar{v}_k\bar{\phi})\right]dx\\ &\quad\quad + \int \left[\alpha_{12}^k\phi\bar{\phi}^{-1}(\bar{v}_k\bar{\phi})\partial_x(\bar{v}_k\bar{\phi}) + \bar{\alpha}_{12}^k\bar{\phi}\phi^{-1}(v_k\phi)\partial_x(v_k\phi)\right]dx\\ &\quad\quad + 2\mathrm{Re}\int \partial_t\phi\left[\tilde{a}\phi^{-1}(\bar{v}_k\bar{\phi})(v_k\phi) + \tilde{b}\bar{\phi}^{-1}(\bar{v}_k\bar{\phi})(\bar{v}_k\bar{\phi})\right]dx\\ &\quad\quad - 2\mathrm{Re}\int \alpha_{12}^k\phi\bar{\phi}^{-2}\partial_x\bar{\phi}(\bar{v}_k\bar{\phi})(\bar{v}_k\bar{\phi})dx\\ &\quad\quad - 2\mathrm{Re}\int \left[i(\partial_x^2\phi)\phi^{-1}(\bar{v}_k\bar{\phi})(v_k\phi) + \phi(\bar{v}_k\bar{\phi})F_k\right]dx.\end{aligned} \tag{2.19}$$

Using that

$$\tilde{b}(\bar{v}_k\bar{\phi})\partial_t(\bar{v}_k\phi) = \tilde{b}\bar{\phi}\phi^{-1}(\bar{v}_k\phi)\partial_t(\bar{v}_k\phi) = \frac{\tilde{b}\bar{\phi}\phi^{-1}}{2}\partial_t\left((\bar{v}_k\phi)^2\right),$$
$$\bar{\tilde{b}}(v_k\phi)\partial_t(v_k\bar{\phi}) = \frac{\bar{\tilde{b}}\phi\bar{\phi}^{-1}}{2}\partial_t\left((v_k\bar{\phi})^2\right),$$

the left-hand side of (2.19) becomes

$$\begin{aligned}
&\int\left[\tilde{a}\partial_t(|v_k\phi|^2) + \tilde{b}(\bar{v}_k\bar{\phi})\partial_t(\bar{v}_k\phi) + \bar{\tilde{b}}(v_k\phi)\partial_t(v_k\bar{\phi})\right]dx\\
&\quad= \int\left[\tilde{a}\partial_t(|v_k\phi|^2) + \frac{\tilde{b}\bar{\phi}\phi^{-1}}{2}\partial_t\left((\bar{v}_k\phi)^2\right) + \frac{\bar{\tilde{b}}\phi\bar{\phi}^{-1}}{2}\partial_t\left((v_k\bar{\phi})^2\right)\right]dx \qquad (2.20)\\
&\quad= \frac{d}{dt}\int\left[\tilde{a}(|v_k\phi|^2) + \mathrm{Re}[\tilde{b}\bar{\phi}\phi^{-1}(\bar{v}_k\phi)^2]\right]dx\\
&\qquad- \int(\partial_t\tilde{a}|v_k\phi|^2 + \mathrm{Re}[\partial_t(\tilde{b}\bar{\phi}\phi^{-1})(\bar{v}_k\phi)^2])dx.
\end{aligned}$$

Combining (2.20) and integration by parts on the right-hand side of (2.19), it follows that

$$\begin{aligned}
\frac{d}{dt}\int\left[\tilde{a}|v_k\phi|^2 + \mathrm{Re}(\tilde{b}\bar{\phi}\phi^{-1}(\bar{v}_k\phi)^2)\right]dx &= -\mathrm{Re}\int\left[\partial_x\left(\alpha_{12}^k\phi\bar{\phi}^{-1}\right)(\bar{v}_k\bar{\phi})^2\right]dx\\
&+ 2\mathrm{Re}\int\partial_t\phi\left[\tilde{a}\phi^{-1}|v_k\phi|^2 + \tilde{b}\bar{\phi}^{-1}(\bar{v}_k\bar{\phi})^2\right]dx\\
&- 2\mathrm{Re}\int\alpha_{12}^k\phi\bar{\phi}^{-2}\partial_x\bar{\phi}(\bar{v}_k\bar{\phi})^2dx \qquad (2.21)\\
&- 2\mathrm{Re}\int\left[i(\partial_x^2\phi)\phi^{-1}|v_k\phi|^2 + \phi(\bar{v}_k\bar{\phi})F_k\right]dx\\
&+ \int\partial_t\tilde{a}|v_k\phi|^2dx + \mathrm{Re}\int\partial_t(\tilde{b}\bar{\phi}\phi^{-1})(\bar{v}_k\phi)^2dx.
\end{aligned}$$

Note that $\partial_t a, \partial_t b, \partial_t\bar{b}$ can be expressed in terms of a, b, c, d, f, their first order derivatives (i.e., a_1', a_2', a_3', a_4', and so on), and their conjugates. Also, observe that $\partial_t a, \partial_t b, \partial_t\bar{b}$ depend only on $v_0, \bar{v}_0, \ldots, v_3, \bar{v}_3$ (Appendix 2). Thus we have the following estimate:

$$\begin{aligned}
\frac{d}{dt}\int\left[\tilde{a}|v_k\phi|^2 + \mathrm{Re}[\tilde{b}\bar{\phi}\phi^{-1}(\bar{v}_k\phi)^2]\right]dx \;&\le 2\Big\{\|\partial_x\left(\alpha_{12}^k\phi\bar{\phi}^{-1}\right)\|_{L^\infty}\\
&+ \|\partial_t\phi\tilde{a}\phi^{-1}\|_{L^\infty} + \|\partial_t\phi\tilde{b}\bar{\phi}^{-1}\|_{L^\infty} + \|\alpha_{12}^k\phi\bar{\phi}^{-2}\partial_x\bar{\phi}\|_{L^\infty}\\
&+ \|(\partial_x^2\phi)\phi^{-1}\|_{L^\infty} + \|\partial_t\left(b\bar{\phi}\phi^{-1}\right)\|_{L^\infty} + \frac{1}{2}\|\partial_t\tilde{a}\|_{L^\infty}\Big\}\|v_k\phi\|_{L^2}^2 \qquad (2.22)\\
&+ 2\int|\phi F_k\bar{v}_k\bar{\phi}|dx\\
&= J_1\|v_k\phi\|_{L^2}^2.
\end{aligned}$$

The expressions for J_1 depend only on $v_j, \bar{v}_j$ for $j \le 5$ and $|\phi|$ which depend only on $v_0, \bar{v}_0, v_1, \bar{v}_1, v_2, \bar{v}_2$ (Appendix 2); this guarantees an appropriate boundedness of J_1 since $|\phi| \le e^{C(\|u\|_{H^3}^2 + \|u\|_{H^3}^l)}$. Thus, with these properties, we consider the expression

$$|||v|||^2 = \sum_{j=0}^{k-1}\|v_j\|_{L^2}^2 + \left(\int\left[\tilde{a}|v_k\phi|^2 + \mathrm{Re}(\tilde{b}\bar{\phi}\phi^{-1}(\bar{v}_k\phi)^2)\right]dx\right). \qquad (2.23)$$

From our hypothesis $m_2 \leq \frac{1}{a\pm|b|} \leq M_2$, as long as $\|(z_1,z_2,z_3,z_4)\| \leq \lambda$ with $\lambda = 100\|u_0\|_{H^k}$, using that $|\bar{\phi}\phi^{-1}| = 1$, we have

$$\int \left[\tilde{a}|v_k\phi|^2 + \mathrm{Re}(\tilde{b}\bar{\phi}\phi^{-1}(\bar{v}_k\phi)^2)\right]dx \geq \int \left[\tilde{a}|v_k\phi|^2 - |\tilde{b}||v_k\phi|^2\right]dx \tag{2.24}$$
$$= \int \frac{a-|b|}{a^2-|b|^2}|v_k\phi|^2dx \geq m_2\int |v_k\phi|^2dx = m_2\|v_k\phi\|_{L^2}^2.$$

Collecting (2.6), (2.22)–(2.24), we conclude that

$$\frac{d}{dt}|||v||| \leq C(|||v|||^2 + |||v|||^l)e^{C(|||v|||^2+|||v|||^l)}, \tag{2.25}$$

which shows that there exists $T = T(\|u_0\|_{H^k}) > 0$ such that

$$|||v(t)||| \leq 100|||v(0)|||,$$

and, within this range,

$$|||\cdot||| \sim \|\cdot\|_{H^k}. \tag{2.26}$$

At this point, we have only established an a priori estimate for the L^2-norm of $v_0, v_1, \ldots, v_k$. We shall obtain the existence of $v_0, v_1, \ldots, v_k$ by introducing two viscosity terms to our IVP (1.1). This will be done in the next section.

2.3. Step 3: Estimate for v_k in the equation with viscosity. To establish the local existence of (1.1) in $H^k(\mathbb{R})$, we shall consider first a parabolic version of (1.1). The energy estimate for this new equation can be obtained using an argument similar to that provided above. So we should consider only the additional terms coming from the added parabolic part.

To show existence, we need to introduce a modified version of (1.1) with two viscosity terms: for $\varepsilon \in (0,1]$,

$$\begin{cases} \partial_t u = -\varepsilon\partial_x^4 u + \varepsilon\delta\partial_x^2 u + ia\partial_x^2 u + ib\partial_x^2\bar{u} + c\partial_x u + d\partial_x\bar{u} + f, \\ u(x,0) = u_0(x), \end{cases} \tag{2.27}$$

where $\delta > 0$ will be determined.

As before, to establish the energy estimate within $H^k(\mathbb{R})$, we need to take the jth derivative of (2.27) to get the same expression as in (2.2) with two extra terms:

$$\partial_t v_j = -\varepsilon\partial_x^4 v_j + \varepsilon\delta\partial_x^2 v_j + ia\partial_x^2 v_j + ib\partial_x^2\bar{v}_j \ + c_j\partial_x v_j + d_j\partial_x\bar{v}_j + f_j. \tag{2.28}$$

For $j \leq k-1$, perform the energy estimate for (2.27): take the jth derivative of (2.27), multiply by $\bar{v}_j$, integrate with respect to x, and take the real part:

$$\begin{aligned} \frac{d}{dt}\int |v_j|^2dx &= -\varepsilon\int(\bar{v}_j\partial_x^4 v_j + v_j\partial_x^4\bar{v}_j)dx + \varepsilon\delta\int(\bar{v}_j\partial_x^2 v_j + v_j\partial_x^2\bar{v}_j)dx \\ &\quad - 2i\mathrm{Re}\int \bar{v}_j a' v_{j+1}dx - 2i\mathrm{Re}\int b(\bar{v}_{j+1})^2dx + i\mathrm{Re}\int b''\bar{v}^2dx \\ &\quad + 2\mathrm{Re}\int c_j\bar{v}_j v_{j+1}dx - \mathrm{Re}\int d_j'\bar{v}_j^2dx + 2\mathrm{Re}\int v_j f_j dx \\ &= -\varepsilon\int(\bar{v}_j\partial_x^4 v_j + v_j\partial_x^4\bar{v}_j)dx + \varepsilon\delta\int(\bar{v}_j\partial_x^2 v_j + v_j\partial_x^2\bar{v}_j)dx + P_j. \end{aligned} \tag{2.29}$$

We have already discussed all the terms in P_j in (2.6), so we just need to consider the first two terms in the right-hand side of (2.29). After integration by parts, (2.29) becomes

$$\partial_t \int |v_j|^2 dx = -2\varepsilon \int |\partial_x^2 v_j|^2 dx - 2\varepsilon\delta \int |\partial_x v_j|^2 dx + P_j. \tag{2.30}$$

Since $-2\varepsilon \int |\partial_x^2 v_j|^2 dx - 2\varepsilon\delta \int |\partial_x v_j|^2 dx \le 0$, the estimate for the jth equations, for $j \le k-1$, can be handled exactly as in (2.5)–(2.6). For $j = k$, again, we need to consider other alternatives: we will rewrite the equation for $j = k$ and its conjugate in matrix form and again use a gauge transformation to get the desired estimate.

Consider (2.28) when $j = k$ and its conjugate,

$$\begin{cases} \partial_t v_k = -\varepsilon\partial_x^4 v_k + \varepsilon\delta\partial_x^2 v_k + ia\partial_x^2 v_k + ib\partial_x^2 \bar v_k \\ \qquad\qquad + c_k \partial_x v_k + d_k \partial_x \bar v_k + f_k, \\ \partial_t \bar v_k = -\varepsilon\partial_x^4 \bar v_k + \varepsilon\delta\partial_x^2 \bar v_k - ia\partial_x^2 \bar v_k - i\bar b\partial_x^2 v_k \\ \qquad\qquad + \bar c_k \partial_x \bar v_k + \bar d_k \partial_x v_k + \bar f_k. \end{cases} \tag{2.31}$$

Rewrite the equations in matrix form by using (2.9)–(2.11):

$$\begin{aligned} \begin{pmatrix} \tilde a & \tilde b \\ -\bar{\tilde b} & -\tilde a \end{pmatrix} \partial_t \begin{pmatrix} v_k \\ \bar v_k \end{pmatrix} &= \begin{pmatrix} \tilde a & \tilde b \\ -\bar{\tilde b} & -\tilde a \end{pmatrix} (-\varepsilon\partial_x^4 + \varepsilon\delta\partial_x^2) \begin{pmatrix} v_k \\ \bar v_k \end{pmatrix} \\ &\quad + i\partial_x^2 \begin{pmatrix} v_k \\ \bar v_k \end{pmatrix} + \begin{pmatrix} \alpha_{11}^k & \alpha_{12}^k \\ \alpha_{21}^k & \alpha_{22}^k \end{pmatrix} \partial_x \begin{pmatrix} v_k \\ \bar v_k \end{pmatrix} + \begin{pmatrix} F_k \\ -\bar F_k \end{pmatrix}. \end{aligned} \tag{2.32}$$

Consider the first equation of (2.32):

$$\begin{aligned} \tilde a\partial_t v_k + \tilde b\partial_t \bar v_k = \tilde a(-\varepsilon\partial_x^4 + \varepsilon\delta\partial_x^2)v_k + \tilde b(-\varepsilon\partial_x^4 + \varepsilon\delta\partial_x^2)\bar v_k \\ + i\partial_x^2 v_k + (\alpha_{11}^k \partial_x v_k + \alpha_{12}^k \partial_x \bar v_k) + F_k. \end{aligned}$$

Using gauge transformation with the same ϕ as in (2.16), we have

$$\begin{aligned} \tilde a\partial_t(v_k\phi) + \tilde b\partial_t(\bar v_k\phi) = \ & \phi\tilde a(-\varepsilon\partial_x^4 + \varepsilon\delta\partial_x^2)v_k + \phi\tilde b(-\varepsilon\partial_x^4 + \varepsilon\delta\partial_x^2)\bar v_k \\ & + i\partial_x^2(v_k\phi) + \alpha_{12}^k \phi\partial_x \bar v_k + \partial_t\phi(\tilde a v_k + \tilde b\bar v_k) - i(\partial_x^2\phi)v_k + \phi F_k. \end{aligned} \tag{2.33}$$

Perform the energy estimate on the last equation (in divergent form): multiplying by $\bar v_k\bar\phi$, integrating with respect to x over $\mathbb{R}$ and taking the real part, we have

$$\begin{aligned} \frac{d}{dt}\int \left[\tilde a|v_k\phi|^2 + \mathrm{Re}(\tilde b\bar\phi\phi^{-1}(\bar v_k\phi)^2)\right] dx &= 2\mathrm{Re}\int (\bar v_k\bar\phi)\tilde a(-\varepsilon\phi\partial_x^4 v_k + \varepsilon\delta\phi\partial_x^2 v_k)dx \\ &+ 2\mathrm{Re}\int (\bar v_k\bar\phi)\tilde b(-\varepsilon\phi\partial_x^4 \bar v_k + \varepsilon\delta\phi\partial_x^2 \bar v_k)dx - \mathrm{Re}\int \left[\partial_x\left(\alpha_{12}^k\phi\bar\phi^{-1}\right)(\bar v_k\bar\phi)^2\right] dx \\ &+ 2\mathrm{Re}\int \partial_t\phi\left[\tilde a\phi^{-1}|v_k\phi|^2 + \tilde b\bar\phi^{-1}(\bar v_k\bar\phi)^2\right] dx - 2\mathrm{Re}\int \alpha_{12}^k\phi\bar\phi^{-2}\partial_x\bar\phi(\bar v_k\bar\phi)^2 dx \\ &- 2\mathrm{Re}\int \left[i(\partial_x^2\phi)\phi^{-1}|v_k\phi|^2 + \phi(\bar v_k\bar\phi)F_k\right] dx + \int \partial_t\tilde a|v_k\phi|^2 dx \\ &+ \mathrm{Re}\int \partial_t\left(\tilde b\bar\phi\phi^{-1}\right)(\bar v_k\phi)^2 dx. \end{aligned} \tag{2.34}$$

Only the terms

$$2\mathrm{Re}\int(\bar{v}_k\bar{\phi})\tilde{a}(-\varepsilon\phi\partial_x^4 v_k+\varepsilon\delta\phi\partial_x^2 v_k)dx+2\mathrm{Re}\int(\bar{v}_k\bar{\phi})\tilde{b}(-\varepsilon\phi\partial_x^4\bar{v}_k+\varepsilon\delta\phi\partial_x^2\bar{v}_k)dx$$

need to be considered since the other terms have been dealt with in (2.6) and (2.22). It can be shown (Appendix 3) that with an appropriate choice of δ, the terms in (2.34) generated by the two viscosity terms can be absorbed into the energy estimate. Thus we have the following proposition.

PROPOSITION 2.1. *There exist $\delta=\delta(\|u_0\|_{H^k})>0$, $C=C(\delta,\|u_0\|_{H^k})$ such that for $\varepsilon\in(0,1]$*

$$\begin{aligned}(2.35)\qquad 2\mathrm{Re}\int(\bar{v}_k\bar{\phi})\tilde{a}(-\varepsilon\phi\partial_x^4 v_k+\varepsilon\delta\phi\partial_x^2 v_k)dx\\ +2\mathrm{Re}\int(\bar{v}_k\bar{\phi})\tilde{b}(-\varepsilon\phi\partial_x^4\bar{v}_k+\varepsilon\delta\phi\partial_x^2\bar{v}_k)dx\le C\|v_k\phi\|_{L^2}^2.\end{aligned}$$

Gathering (2.6), (2.22), and Proposition 2.1, we have the a priori estimate of the norm $|||\cdot|||$ similar to (2.26) for the solution u^ε of (2.27); i.e., there exists $T=T(\|u_0\|_{H^k})>0$ such that if $u^\varepsilon\in C([0,T]:H^k(\mathbb{R}))$ is a solution of (2.27), then $\|u^\varepsilon(t)\|_{H^k}\le 100\|u_0\|_{H^k}$ for $t\in[0,T]$.

2.4. Step 4: The local existence of a solution with viscosity terms. With the a priori estimate discussed above, we are ready to show the local existence and uniqueness of the IVP (2.27). Consider

$$\begin{aligned}(2.36)\qquad \partial_t u&=-\varepsilon\partial_x^4 u+\varepsilon\delta\partial_x^2 u+ia\partial_x^2 u+ib\partial_x^2\bar{u}+c\partial_x u+d\partial_x\bar{u}+f\\ &=(-\varepsilon\partial_x^4+\varepsilon\delta\partial_x^2)u+F(u,\bar{u},\partial_x u,\partial_x\bar{u},\partial_x^2 u,\partial_x^2\bar{u}).\end{aligned}$$

2.4.1. The linear equation. We will first look at some properties of the operator of the linear homogeneous equation

$$(2.37)\qquad\begin{cases}\partial_t w=-\varepsilon\partial_x^4 w+\varepsilon\delta\partial_x^2 w, & x\in\mathbb{R},t>0,\\ w(0,x)=w_0(x),\end{cases}$$

where $w=w(t,x)$. The IVP (2.37) has the solution

$$(2.38)\qquad \hat{w}(t,\xi)=(e^{(-\varepsilon(2\pi\xi)^4+\varepsilon\delta(2\pi\xi)^2)t})\hat{w}_0(\xi)=(e^{-\varepsilon(2\pi\xi)^4 t}e^{\varepsilon\delta(2\pi\xi)^2 t})\hat{w}_0(\xi).$$

If $\widehat{K}_{\varepsilon\delta t}=e^{\varepsilon\delta(2\pi\xi)^2 t}$ and $\widehat{G}_{\varepsilon t}(\xi)=e^{-\varepsilon(2\pi\xi)^4 t}$, then the solution of (5.2) can be written as

$$(2.39)\qquad w(x,t)=(G_{\varepsilon t}*(K_{\varepsilon\delta t}*w_0))(x).$$

Note that

$$(2.40)\qquad G_{\varepsilon t}(x)=\int_{\mathbb{R}}e^{2\pi i x\xi}e^{-\varepsilon t(2\pi)^4\xi^4}d\xi,$$

so the change of variable $\eta=\xi(\varepsilon t)^{1/4}$ gives

$$\begin{aligned}(2.41)\qquad G_{\varepsilon t}(x)&=\int_{\mathbb{R}}e^{2\pi i x\eta/(\varepsilon t)^{1/4}}e^{-(2\pi\eta)^4}\frac{d\eta}{(\varepsilon t)^{1/4}}\\ &=\frac{1}{(\varepsilon t)^{1/4}}(e^{-(2\pi\eta)^4})^\vee\left(\frac{x}{(\varepsilon t)^{1/4}}\right)\end{aligned}$$

and

$$\partial_x^\alpha G_{\varepsilon t}(x) = \int_{\mathbb{R}} \frac{(2\pi\eta)^\alpha}{(\varepsilon t)^{\alpha/4}} e^{2\pi i x\eta/(\varepsilon t)^{1/4}} e^{-(2\pi\eta)^4} \frac{d\eta}{(\varepsilon t)^{1/4}}. \tag{2.42}$$

We introduce the notation

$$\mathcal{W}(t)f = (e^{-\varepsilon(2\pi\xi)^4 t}\widehat{f}(\xi))^\vee(x). \tag{2.43}$$

2.4.2. The existence of a solution of (2.27). We will prove the existence and uniqueness of a solution to the IVP

$$\begin{cases} \partial_t u = (-\varepsilon\partial_x^4 + \varepsilon\delta\partial_x^2)u + F(u, \bar{u}, \partial_x u, \partial_x\bar{u}, \partial_x^2 u, \partial_x^2\bar{u}), \\ u(x,0) = u_0(x), \end{cases} \tag{2.44}$$

as the fixed point for the operator

$$\begin{aligned} \Phi_\varepsilon(u(t)) &= \mathcal{W}(t)(K_{\varepsilon\delta t} * u_0) + \int_0^t e^{(-\varepsilon\partial_x^4 + \varepsilon\delta\partial_x^2)(t-t')} F(x,t')dt' \\ &= \mathcal{W}(t)(K_{\varepsilon\delta t} * u_0) + \int_0^t \mathcal{W}(t-t')(K_{\varepsilon\delta t} * F)(x,t')dt'. \end{aligned} \tag{2.45}$$

We observe that

$$\begin{aligned} \partial_x^s \Phi_\varepsilon(u(t)) &= \mathcal{W}(t)(K_{\varepsilon\delta t} * \partial_x^s u_0) \\ &\quad + \int_0^t \partial_x^2 \mathcal{W}(t-t')(K_{\varepsilon\delta t} * \partial_x^{s-2} F)(x,t')dt', \end{aligned} \tag{2.46}$$

so from (2.42)–(2.43) one has the following estimates:

$$\begin{aligned} \sup_{[0,T]} \|\Phi_\varepsilon(u(t))\|_{H^k} &\le C\|w_0\|_{H^k} + C\int_0^t (\varepsilon(t-t'))^{-\frac{1}{2}} \|F\|_{H^{k-2}} dt' \\ &\le C\|w_0\|_{H^k} + C\varepsilon^{-\frac{1}{2}} T^{\frac{1}{2}} \sup_{[0,T]} \|F(t)\|_{H^{k-2}} \\ &\le C\|w_0\|_{H^k} + C\varepsilon^{-\frac{1}{2}} T^{\frac{1}{2}} \sup_{[0,T]} \left(\|u(t)\|_{H^k}^2 + \|u(t)\|_{H^k}^l\right) \end{aligned} \tag{2.47}$$

and

$$\begin{aligned} \sup_{[0,T]} \|(\Phi_\varepsilon(u) - \Phi_\varepsilon(v))(t)\|_{H^s} &\le \varepsilon^{-\frac{1}{2}} T^{\frac{1}{2}} \sup_{[0,T]} \|(F(u) - F(v))(t)\|_{H^{s-2}} \\ &\le \varepsilon^{-\frac{1}{2}} T^{\frac{1}{2}} \sup_{[0,T]} \Big(\|u(t)\|_{H^k} + \|v(t)\|_{H^k} + \|u(t)\|_{H^k}^{l-1} \\ &\qquad + \|v(t)\|_{H^k}^{l-1} \Big) \sup_{[0,T]} \|(u-v)(t)\|_{H^{k-2}}. \end{aligned} \tag{2.48}$$

Collecting the above information we have the following proposition.

PROPOSITION 2.2. *There exists $T_\varepsilon = T_\varepsilon(\varepsilon, \|u_0\|_{H^k})$ such that*

$$\Phi : C([0,T_\varepsilon] : H^k(\mathbb{R})) \to C([0,T_\varepsilon] : H^k(\mathbb{R}))$$

is a contraction mapping.

Our next goal is to remove the dependence on ε of the time interval of existence. We have that for each $\varepsilon > 0$ there exists $T_\varepsilon = T_\varepsilon(\varepsilon, \|u_0\|_{H^k}) = O(\varepsilon)$ such that the unique solution $u^\varepsilon(x,t)$ of

$$\begin{cases} \partial_t u = -\varepsilon\partial_x^4 u + \varepsilon\delta\partial_x^2 u + ia\partial_x^2 u + ib\partial_x^2\bar{u} + c\partial_x u + d\partial_x\bar{u} + f, \\ u(x,0) = u_0(x) \end{cases}$$

satisfies $u^\varepsilon \in C([0,T_\varepsilon] : H^k(\mathbb{R}))$.

Using the a priori estimate obtained in section 2.3, we can reapply the local existence argument given above to extend the local solution u^ε to $C([0,T] : H^k(\mathbb{R}))$ for every $\varepsilon > 0$ with T independent of ε. Therefore, we have shown that for every $u_0 \in H^k(\mathbb{R})$ there exists a $T = T(\|u_0\|_{H^k}) > 0$ independent of ε and a unique solution u^ε of

$$\begin{cases} \partial_t u = -\varepsilon\partial_x^4 u + \varepsilon\delta\partial_x^2 u + ia\partial_x^2 u + ib\partial_x^2\bar{u} + c\partial_x u + d\partial_x\bar{u} + f, \\ u(x,0) = u_0(x) \end{cases}$$

satisfying $u^\varepsilon \in C([0,T] : H^k)$ with

$$\sup_{[0,T]} \|u^\varepsilon(t)\|_{H^k} \le C(\|u_0\|_{H^k}), \tag{2.49}$$

with $C(\|u_0\|_{H^k})$ independent of ε.

Next we shall establish the convergence of u^ε to u, which will be a solution of (1.1) as $\varepsilon \to 0$.

To establish this convergence, we consider the equation for u^ε and $u^{\varepsilon'}$:

$$\begin{cases} \partial_t u^\varepsilon = -\varepsilon\partial_x^4 u^\varepsilon + \delta\varepsilon\partial_x^2 u^\varepsilon + ia(u^\varepsilon, \bar{u}^\varepsilon, \partial_x u^\varepsilon, \partial_x\bar{u}^\varepsilon)\partial_x^2 u^\varepsilon \\ \qquad + ib(u^\varepsilon, \bar{u}^\varepsilon, \partial_x u^\varepsilon, \partial_x\bar{u}^\varepsilon)\partial_x^2\bar{u}^\varepsilon + c(u^\varepsilon, \bar{u}^\varepsilon, \partial_x u^\varepsilon, \partial_x\bar{u}^\varepsilon)\partial_x u^\varepsilon \\ \qquad + d(u^\varepsilon, \bar{u}^\varepsilon, \partial_x u^\varepsilon, \partial_x\bar{u}^\varepsilon)\partial_x\bar{u}^\varepsilon + f(u^\varepsilon, \bar{u}^\varepsilon) \\ \partial_t u^{\varepsilon'} = -\varepsilon'\partial_x^4 u^{\varepsilon'} + \delta\varepsilon'\partial_x^2 u^{\varepsilon'} + ia(u^{\varepsilon'}, \bar{u}^{\varepsilon'}, \partial_x u^{\varepsilon'}, \partial_x\bar{u}^{\varepsilon'})\partial_x^2 u^{\varepsilon'} \\ \qquad + ib(u^{\varepsilon'}, \bar{u}^{\varepsilon'}, \partial_x u^{\varepsilon'}, \partial_x\bar{u}^{\varepsilon'})\partial_x^2\bar{u}^{\varepsilon'} + c(u^{\varepsilon'}, \bar{u}^{\varepsilon'}, \partial_x u^{\varepsilon'}, \partial_x\bar{u}^{\varepsilon'})\partial_x u^{\varepsilon'} \\ \qquad + d(u^{\varepsilon'}, \bar{u}^{\varepsilon'}, \partial_x u^{\varepsilon'}, \partial_x\bar{u}^{\varepsilon'})\partial_x\bar{u}^{\varepsilon'} + f(u^{\varepsilon'}, \bar{u}^{\varepsilon'}) \end{cases} \tag{2.50}$$

and consider that for the difference of $u^\varepsilon, u^{\varepsilon'}, w = w^{\varepsilon,\varepsilon'} = u^\varepsilon - u^{\varepsilon'}$,

$$\begin{aligned} \partial_t w =& -\varepsilon\partial_x^4 w + \varepsilon\delta\partial_x^2 w - (\varepsilon - \varepsilon')\partial_x^4 u^\varepsilon + (\varepsilon - \varepsilon')\delta\partial_x^2 u^\varepsilon \\ &+ ia(u^\varepsilon, \bar{u}^\varepsilon, \partial_x u^\varepsilon, \partial_x\bar{u}^\varepsilon)\partial_x^2 w + ib(u^\varepsilon, \bar{u}^\varepsilon, \partial_x u^\varepsilon, \partial_x\bar{u}^\varepsilon)\partial_x^2\bar{w} \\ &+ i\big(a(u^\varepsilon, \bar{u}^\varepsilon, \partial_x u^\varepsilon, \partial_x\bar{u}^\varepsilon) - a(u^{\varepsilon'}, \bar{u}^{\varepsilon'}, \partial_x u^{\varepsilon'}, \partial_x\bar{u}^{\varepsilon'})\big)\partial_x^2 u^{\varepsilon'} \\ &+ i\big(b(u^\varepsilon, \bar{u}^\varepsilon, \partial_x u^\varepsilon, \partial_x\bar{u}^\varepsilon) - b(u^{\varepsilon'}, \bar{u}^{\varepsilon'}, \partial_x u^{\varepsilon'}, \partial_x\bar{u}^{\varepsilon'})\big)\partial_x^2\bar{u}^{\varepsilon'} \\ &+ c(u^\varepsilon, \bar{u}^\varepsilon, \partial_x u^\varepsilon, \partial_x\bar{u}^\varepsilon)\partial_x w + d(u^\varepsilon, \bar{u}^\varepsilon, \partial_x u^\varepsilon, \partial_x\bar{u}^\varepsilon)\partial_x\bar{w} \\ &+ \big(c(u^\varepsilon, \bar{u}^\varepsilon, \partial_x u^\varepsilon, \partial_x\bar{u}^\varepsilon) - c(u^{\varepsilon'}, \bar{u}^{\varepsilon'}, \partial_x u^{\varepsilon'}, \partial_x\bar{u}^{\varepsilon'})\big)\partial_x u^{\varepsilon'} \\ &+ \big(d(u^\varepsilon, \bar{u}^\varepsilon, \partial_x u^\varepsilon, \partial_x\bar{u}^\varepsilon) - d(u^{\varepsilon'}, \bar{u}^{\varepsilon'}, \partial_x u^{\varepsilon'}, \partial_x\bar{u}^{\varepsilon'})\big)\partial_x\bar{u}^{\varepsilon'} \\ &+ f(u^\varepsilon, \bar{u}^\varepsilon) - f(u^{\varepsilon'}, \bar{u}^{\varepsilon'}). \end{aligned} \tag{2.51}$$

By expressing the factors

$$a^\varepsilon - a^{\varepsilon'} = a(u^\varepsilon, \bar{u}^\varepsilon, \partial_x u^\varepsilon, \partial_x\bar{u}^\varepsilon) - a(u^{\varepsilon'}, \bar{u}^{\varepsilon'}, \partial_x u^{\varepsilon'}, \partial_x\bar{u}^{\varepsilon'}), \tag{2.52}$$

similarly for $b^\varepsilon - b^{\varepsilon'}, c^\varepsilon - c^{\varepsilon'}, d^\varepsilon - d^{\varepsilon'}$ in an appropriate manner, we can rewrite (2.51) in the following form:

$$\partial_t w = ia^\varepsilon \partial_x^2 w + ib^\varepsilon \partial_x^2 \bar{w} + \tilde{c}\partial_x w + \tilde{d}\partial_x \bar{w} + \tilde{q}_1 w + \tilde{q}_2 \bar{w} + (\varepsilon + \varepsilon')\Psi, \tag{2.53}$$

where $\tilde{c} = \tilde{c}(u^\varepsilon, \bar{u}^\varepsilon, \partial_x u^\varepsilon, \partial_x \bar{u}^\varepsilon, \partial_x^2 u^\varepsilon, \partial_x^2 \bar{u}^\varepsilon, u^{\varepsilon'}, \bar{u}^{\varepsilon'}, \partial_x u^{\varepsilon'}, \partial_x \bar{u}^{\varepsilon'}, \partial_x^2 u^{\varepsilon'}, \partial_x^2 \bar{u}^{\varepsilon'})$, similarly for $\tilde{d}, \tilde{q}_1, \tilde{q}_2, \Psi$. We notice that the last three terms in the right-hand side of (2.53) can be easily handled by the energy estimate. So we will concentrate on the second to the fourth terms. For this we repeat the argument in section 2.2 used to obtain the gauge transformation. The weight function here

$$\phi_{\varepsilon,\varepsilon'} = \phi_{\varepsilon,\varepsilon'}(u^\varepsilon, \ldots, \partial_x^2 \bar{u}^\varepsilon, u^{\varepsilon'}, \ldots, \partial_x^2 \bar{u}^{\varepsilon'}) \tag{2.54}$$

is as in (2.11)–(2.16) such that

$$-2i\partial_x \phi_{\varepsilon,\varepsilon'} + \left(\tilde{a}^\varepsilon \tilde{c} + \tilde{b}^\varepsilon \bar{\tilde{d}}\right)\phi_{\varepsilon,\varepsilon'} = 0, \tag{2.55}$$

where $\tilde{a}^\varepsilon = \frac{a^\varepsilon}{(a^\varepsilon)^2 - |b^\varepsilon|^2}$, $\tilde{b}^\varepsilon = \frac{b^\varepsilon}{(a^\varepsilon)^2 - |b^\varepsilon|^2}$. Thus

$$\phi_{\varepsilon,\varepsilon'} = \exp\left\{\frac{1}{2i}\int_0^x \left(\tilde{a}^\varepsilon \tilde{c} + \tilde{b}^\varepsilon \bar{\tilde{d}}\right)(x', t)dx'\right\}. \tag{2.56}$$

Using that

$$\sup_{[0,T]} \|u^\varepsilon\|_{H^k} \le 100\|u_0\|_{H^k}, \tag{2.57}$$

we know that $\phi_{\varepsilon,\varepsilon'}$ is bounded uniformly on $\varepsilon, \varepsilon' \in (0, 1]$. Combining again the argument in section 2.2 and (2.57), we have

$$\begin{aligned}\frac{d}{dt}\int \left[\tilde{a}^\varepsilon |w\phi_{\varepsilon,\varepsilon'}|^2 + \mathrm{Re}(\tilde{b}^\varepsilon \bar{\phi}_{\varepsilon,\varepsilon'}\phi_{\varepsilon,\varepsilon'}^{-1}(\bar{w}\phi_{\varepsilon,\varepsilon'})^2)\right]dx \\ \le C\|w\phi_{\varepsilon,\varepsilon'}\|_{L^2} + C(\varepsilon - \varepsilon').\end{aligned} \tag{2.58}$$

Using Gronwall inequality, the fact from (2.16), i.e.,

$$\int \left[\tilde{a}^\varepsilon |w\phi_{\varepsilon,\varepsilon'}|^2 + \mathrm{Re}(\tilde{b}^\varepsilon \bar{\phi}_{\varepsilon,\varepsilon'}\phi_{\varepsilon,\varepsilon'}^{-1}(\bar{w}\phi_{\varepsilon,\varepsilon'})^2)\right] dx \ge m_2 \int |w\phi_{\varepsilon,\varepsilon'}|^2 dx, \tag{2.59}$$

where m_2 is independent of $\varepsilon, \varepsilon' \in (0, 1]$ and that $w(0) = 0$, we obtain

$$\lim_{\varepsilon,\varepsilon' \to 0} \sup_{[0,T]} \|w(t)\|_{L^2} = 0. \tag{2.60}$$

Hence $\sup_{[0,T]} \|(u^\varepsilon - u^{\varepsilon'})(t)\|_{L^2} \to 0$ as $\varepsilon, \varepsilon' \to 0$. Consequently, by interpolation, we have

$$\begin{aligned}&\sup_{[0,T]} \|(u^\varepsilon - u^{\varepsilon'})(t)\|_{H^{k-1}} \\ &\qquad \le \sup_{[0,T]} \|(u^\varepsilon - u^{\varepsilon'})(t)\|_{L^2}^{\frac{1}{k}} \sup_{[0,T]} \|(u^\varepsilon - u^{\varepsilon'})(t)\|_{H^k}^{\frac{k-1}{k}}\end{aligned} \tag{2.61}$$

which implies that $\sup_{[0,T]} \|(u^\varepsilon - u^{\varepsilon'})(t)\|_{H^{k-1}} \to 0$; i.e., $\{u^\varepsilon\}_{\varepsilon>0}$ is a Cauchy sequence in the space $C([0,T] : H^{k-1}(\mathbb{R}))$. So there exists $u \in C([0,T] : H^{k-1}(\mathbb{R}))$ which is the limit of the u^ε's as $\varepsilon \to 0$. One also has that $u^\varepsilon(t)$ converges weakly to $u(t)$ in $H^k(\mathbb{R})$ for each $t \in [0,T]$, so $u \in L^\infty([0,T] : H^k(\mathbb{R}))$. Since $k \geq 4$, it is clear that u solves the IVP (1.1).

The proof of the uniqueness in the class described in Theorem 1 follows the same argument given above for the convergence without involving the viscosity part; i.e., if u, v are solutions, we replace u^ε by u and $u^{\varepsilon'}$ by v in (2.51) with $\varepsilon = \varepsilon' = 0$ and repeat the argument.

3. Proof of Theorem 2. The proof of Theorem 2 follows in the same manner as that of Theorem 1; i.e., we establish formal energy estimate for the jth derivative of (1.1) for $j = 1, 2, \ldots, k-1$. For the case $j = k$, we again use a gauge transformation and introduce the same function ϕ in (2.16) to obtain the estimate of the expression (2.24) which is equivalent to $\|\cdot\|_{H^k}$ for some range $|||v(t)||| \leq 100|||v(0)|||$. The problem comes in when the gauge transformation is introduced: ϕ might have some linear terms due to the fact that $a = a(u, \bar{u}, \partial_x u, \partial_x \bar{u})$ or b, c, d may be linear. The weighted $L^2(|x|^r dx)$-norm will allow us to bound $\|\phi\|_{L^\infty}$. We need to consider $H^k \cap L^2(|x|^r dx)$ instead of H^k. Observe that f does not have any influence in the form of ϕ.

In order to proceed, we need the following interpolation lemma.

LEMMA 3.1. *If $u \in H^k(\mathbb{R}) \bigcap L^2(|x|^r dx)$, then $x^\beta \partial_x^\alpha u \in L^2(\mathbb{R})$ with $0 \leq \alpha + \beta \leq r$.*

Next, we observe that the weighted norm $\|\cdot\|_{L^2(|x|^r dx)}$ guarantees the boundedness of $\|\phi\|_{L^\infty}$ for $\mu = 1$; i.e., a, b, c, d might be linear; e.g., let g be some linear term in $ac_k + bd_k$, and then

$$\begin{aligned} \int g(u, \bar{u}, \partial_x u, \partial_x \bar{u}, \partial_x^2 u, \partial_x^2 \bar{u}) dx &= \int \frac{(1+x^2)^{r/2} g}{(1+x^2)^{r/2}} dx \\ &\leq \|(1+x^2)^{r/2} g\|_{L^2} \|(1+x^2)^{-r/2}\|_{L^2} \\ &\leq C \sum_{j=0}^{2} \big(\|\partial_x^j u\|_{L^2(|x|^{2r} dx)} + \|\partial_x^j u\|_{L^2} \big). \end{aligned} \tag{3.1}$$

Hence, for some $l \geq 0$,

$$\begin{aligned} \|\phi\|_{L^\infty} &\leq e^{C \int |ac_k + bd_k| dx} \\ &\leq e^{C \sum_{j \leq 2} \left(\|\partial_x^j u\|_{L^2(|x|^r dx)} + \|\partial_x^j u\|^l_{L^2(|x|^r dx)} \right) + C\left(\|u\|_{H^k} + \|u\|^l_{H^k} \right)}. \end{aligned} \tag{3.2}$$

We will perform the energy estimate for $\|x \partial_x^j u\|_{L^2}$, $j = 0, 1, 2, 3, 4$. We multiply by x the equation in (2.1) to obtain

$$\begin{aligned} \partial_t (xu) = {} & ia \partial_x^2 (xu) - 2ia \partial_x u + ib \partial_x^2 (x\bar{u}) - 2ib \partial_x \bar{u} \\ & + c \partial_x (xu) - cu + d \partial_x (x\bar{u}) - d\bar{u} + xf. \end{aligned} \tag{3.3}$$

To perform energy estimates for xu, we multiply (3.3) by $x\bar{u}$, integrate with respect to x over $\mathbb{R}$ and take the real part:

$$\begin{aligned}\partial_t \int |xu|^2 dx = &-2\mathrm{Re}\int ia' x\bar{u}\partial_x(xu)dx - 4\mathrm{Re}\int iax\bar{u}\partial_x u\ dx\\ &-2\mathrm{Re}\int ib(\partial_x(x\bar{u}))^2 dx - \mathrm{Re}\int ib''(x\bar{u})^2 dx - 4\mathrm{Re}\int ibx\bar{u}\partial_x\bar{u}\ dx\\ &+2\mathrm{Re}\int cx\bar{u}\partial_x(xu)dx - 2\mathrm{Re}\int cx\bar{u}u\ dx\\ &+\mathrm{Re}\int d'(x\bar{u})^2 dx - 2\mathrm{Re}\int dx\bar{u}\bar{u}\ dx - 2\mathrm{Re}\int x\bar{u}xf\ dx\end{aligned} \tag{3.4}$$

which gives

$$\begin{aligned}\partial_t \int |xu|^2 dx \le\ & 2\|a'\|_{L^\infty}\|xu\|_{L^2}\|\partial_x(xu)\|_{L^2} + 4\|a\|_{L^\infty}\|xu\|_{L^2}\|\partial_x u\|_{L^2}\\ &+2\|b\|_{L^\infty}\|\partial_x(xu)\|_{L^2}^2 + \|b''\|_{L^\infty}\|xu\|_{L^2}^2 + 4\|b\|_{L^\infty}\|xu\|_{L^2}\|\partial_x u\|_{L^2}\\ &+2\|c\|_{L^\infty}\|xu\|_{L^2}\|\partial_x(xu)\|_{L^2} + 2\|c\|_{L^\infty}\|xu\|_{L^2}\|u\|_{L^2}\\ &+\|d'\|_{L^\infty}\|xu\|_{L^2}^2 + 2\|d\|_{L^\infty}\|xu\|_{L^2}\|u\|_{L^2} + 2\|xu\|_{L^2}\|xf\|_{L^2}.\end{aligned} \tag{3.5}$$

Thus we can establish the following estimate:

$$\frac{d}{dt}\|xu\|_{L^2} \le C(\|u\|_{H^4} + \|u\|_{H^4}^l)(\|xu\|_{L^2}^2 + \|x\partial_x u\|_{L^2}^2) + C(\|u\|_{H^k}^2 + \|u\|_{H^k}^l) \tag{3.6}$$

for some $l \ge 0$ which depends on the nonlinearity. Similarly, we have

$$\begin{cases}\dfrac{d}{dt}\|x\partial_x u\|_{L^2}^2 \le C(\|u\|_{H^4} + \|u\|_{H^4}^l)(\|xu\|_{L^2}^2 + \|x\partial_x u\|_{L^2}^2 + \|x\partial_x^2 u\|_{L^2}^2)\\ \qquad\qquad + C(\|u\|_{H^k}^2 + \|u\|_{H^k}^l),\\ \dfrac{d}{dt}\|x\partial_x^2 u\|_{L^2}^2 \le C(\|u\|_{H^4} + \|u\|_{H^4}^l)\big(\|xu\|_{L^2}^2 + \|x\partial_x u\|_{L^2}^2\\ \qquad\qquad + \|x\partial_x^2 u\|_{L^2}^2 + \|x\partial_x^3 u\|_{L^2}^2\big) + C(\|u\|_{H^k}^2 + \|u\|_{H^k}^l),\\ \dfrac{d}{dt}\|x\partial_x^3 u\|_{L^2}^2 \le C(\|u\|_{H^4} + \|u\|_{H^4}^l)\big(\|xu\|_{L^2}^2 + \|x\partial_x u\|_{L^2}^2 + \|x\partial_x^2 u\|_{L^2}^2\\ \qquad\qquad + \|x\partial_x^3 u\|_{L^2}^2 + \|x\partial_x^4 u\|_{L^2}^2\big) + C(\|u\|_{H^k}^2 + \|u\|_{H^k}^l),\end{cases} \tag{3.7}$$

which depends on $\|x\partial_x^4 u\|_{L^2}$, i.e., one derivative higher. Thus the estimate for $x\partial_x^4 u$ depends on $x\partial_x^5 u$. We need to consider a gauge transformation to enable the estimate to close within itself which allows us to obtain the desired a priori estimate. We proceed as in section 2.2; consider the equation for $x\partial_x^4 u = xv_4$,

$$\begin{aligned}\partial_t(xv_4) = &\ ia\partial_x^2(xv_4) - 2ia\partial_x v_4 + ib\partial_x^2(x\bar{v}_4) - 2ib\partial_x\bar{v}_4\\ &+ c_4\partial_x(xv_4) - c_4 v_4 + d_4\partial_x(x\bar{v}_4) - d_4\bar{v}_4 + xf_4,\end{aligned} \tag{3.8}$$

where

$$
\begin{aligned}
c_4 &= 4ia' + ia_3'v_2 + ib_3'\bar{v}_2 + c + c_3'v_1 + d_3'\bar{v}_1,\\
d_4 &= 4ib' + ia_4'v_2 + ib_4'\bar{v}_2 + d + c_4'v_1 + d_4'\bar{v}_1,\\
f_4 &= f_{a4} + f_{b4} + f_{c4} + f_{d4} + \partial_x^4 f,\\
f_{a4} &= iv_2\partial_x^3(a_1'v_1 + a_2'\bar{v}_1) + i\sum_{l=2}^{3}\binom{4}{l}(\partial_x^l a)v_{6-l},\\
&\quad + i\sum_{l=1}^{3}\binom{3}{l}v_2\big(\partial_x^l(a_3')v_{5-l} + \partial_x^l(a_4')\bar{v}_{5-l}\big),\\
&\text{similarly for } f_{b4}, f_{c4}, f_{d4} \text{ (Appendix 1)},
\end{aligned}
\tag{3.9}
$$

and its conjugate and write them as the system

$$
\begin{aligned}
\partial_t\begin{pmatrix} xv_4\\ x\bar{v}_4\end{pmatrix} &= i\begin{pmatrix} a & b\\ -\bar{b} & -a\end{pmatrix}\partial_x^2\begin{pmatrix} xv_4\\ x\bar{v}_4\end{pmatrix} + \begin{pmatrix} -2ia + c_4 & -2ib + d_4\\ 2i\bar{d} + \bar{d}_4 & 2ia + \bar{c}_4\end{pmatrix}\partial_x\begin{pmatrix} xv_4\\ x\bar{v}_4\end{pmatrix}\\
&\quad + \begin{pmatrix} -2iav_4 + 2ib\bar{v}_4 - c_4v_4 - d_4\bar{v}_4u + xf_4\\ -2ia\bar{v}_4 - 2i\bar{b}v_4 - \bar{c}_4\bar{v}_4 - \bar{d}_4v_4 + x\bar{f}_4\end{pmatrix}.
\end{aligned}
\tag{3.10}
$$

Using the A as in (2.9) and

$$
A^{-1}\begin{pmatrix} -2ia + c_4 & -2ib + d_4\\ 2i\bar{d} + \bar{d}_4 & 2ia + \bar{c}_4\end{pmatrix} = \begin{pmatrix} \alpha_{11}^4 & \alpha_{12}^4\\ \alpha_{21}^4 & \alpha_{22}^4\end{pmatrix},
\tag{3.11}
$$

the system is written as

$$
A^{-1}\partial_t\begin{pmatrix} xv_4\\ x\bar{v}_4\end{pmatrix} = i\partial_x^2\begin{pmatrix} xv_4\\ x\bar{v}_4\end{pmatrix} + \begin{pmatrix} \alpha_{11}^4 & \alpha_{12}^4\\ \alpha_{21}^4 & \alpha_{22}^4\end{pmatrix}\partial_x\begin{pmatrix} xv_4\\ x\bar{v}_4\end{pmatrix} + A^{-1}\begin{pmatrix} F\\ \bar{F}\end{pmatrix}.
\tag{3.12}
$$

To perform gauge transformation, we multiply a function ϕ_4, which will be determined later to the system, and consider the first equation of the system:

$$
\begin{aligned}
\tilde{a}\partial_t(xv_4\phi_4) + \tilde{b}\partial_t(x\bar{v}_4\phi_4) = {}& i\partial_x^2(xv_4\phi_4) + (\alpha_{11}^4\phi_4 - 2i\partial_x\phi_4)\partial_x(xv_4)\\
&+ \alpha_{12}^4\phi_4\partial_x(x\bar{v}_4) + i(\partial_x^2\phi_4)xv_4 + \phi_4F + \partial_t\phi_4(\tilde{a}xv_4 + \tilde{b}x\bar{v}_4).
\end{aligned}
\tag{3.13}
$$

With the choice of ϕ_4 such that

$$
\begin{cases}\alpha_{11}^4\phi_4 - 2i\partial_x\phi_4 = 0,\\ \phi_4 = \exp\left\{\dfrac{1}{2i}\displaystyle\int_0^x \alpha_{11}^4(x',t)dx'\right\} = e^{\frac{1}{2i}\int_0^x(\tilde{a}(c_4-2ia)+\tilde{b}(d_4+2i\bar{b}))(x',t)dx'},\end{cases}
\tag{3.14}
$$

(3.13) is reduced to

$$
\begin{aligned}
\tilde{a}\partial_t(xv_4\phi_4) + \tilde{b}\partial_t(x\bar{v}_4\phi_4) = {}& i\partial_x^2(xv_4\phi_4) + \alpha_{12}\phi_4\partial_x(x\bar{v}_4) + i(\partial_x^2\phi_4)xv_4\\
&+ \phi_4F + \partial_t\phi_4(\tilde{a}xv_4 + \tilde{b}x\bar{v}_4).
\end{aligned}
\tag{3.15}
$$

Basically ϕ_4 is similar to ϕ in (2.16) except for some extra terms due to the commutator. Also, it has the same properties as ϕ listed after (2.16).

Now we perform the energy estimate: multiply $x\bar{v}_4\bar{\phi}_4$ to (3.15), integrate with respect to x over $\mathbb{R}$ and take the real part. After integration by parts, we have

$$\begin{aligned}\frac{d}{dt}\int \Big[\tilde{a}|xv_4\phi_4|^2 + \mathrm{Re}(\tilde{b}\bar{\phi}\phi_4^{-1}(x\bar{v}_4\phi_4)^2)\Big]dx &= \int(\partial_t\tilde{a})|xu\phi_4|^2dx \\ &+ \int \partial_t(\tilde{b}\bar{\phi}_4\phi_4^{-1})(x\bar{v}_4\phi_4)^2dx - \mathrm{Re}\int \partial_x(\alpha_{12}\bar{\phi}_4\phi_4\bar{\phi}^{-2})(x\bar{v}_4\bar{\phi})^2dx \\ &+ 2\mathrm{Re}\int i(\partial_x^2\phi_4)\phi_4^{-1}|xu\phi_4|^2dx + \int(x\bar{v}_4\bar{\phi}_4)\phi_4F\ dx \\ &+ \int(\partial_t\phi_4)(\tilde{a}\phi_4^{-1}|xu\phi_4|^2 + \tilde{b}\bar{\phi}_4^{-1}(x\bar{v}_4\bar{\phi}_4)^2)dx\end{aligned} \tag{3.16}$$

which gives the following estimate:

$$\frac{d}{dt}\int \Big[\tilde{a}|xv_4\phi_4|^2 + \mathrm{Re}(\tilde{b}\bar{\phi}_4\phi_4^{-1}(x\bar{v}_4\phi_4)^2)\Big]dx \le C(\|xv_4\phi_4\|_{L^2} + \|xv_4\phi_4\|_{L^2}^2). \tag{3.17}$$

With this estimate, we consider the expression

$$\begin{aligned}|||\cdot|||_*^2 = &\sum_{j=0}^{k-1}\|v_j\|_{L^2}^2 + \int \tilde{a}|v_k\phi|^2 + \mathrm{Re}(\tilde{b}\bar{\phi}\phi^{-1}(\bar{v}_k\phi)^2)dx \\ &+ \sum_{j=0}^{3}\|xv_j\|_{L^2}^2 + \int \tilde{a}|xv_4\phi_4|^2 + \mathrm{Re}(\tilde{b}\bar{\phi}_4\phi_4^{-1}(x\bar{v}_4\phi_4)^2)dx.\end{aligned} \tag{3.18}$$

Thus we have that

$$\frac{d}{dt}|||v|||_* \le C(|||v|||_* + |||v|||_*^l)(e^{C(|||v|||_* + |||v|||_*^l)} + 1) \tag{3.19}$$

which shows there exists $T_* > 0$ such that

$$|||v(t)|||_* \le 100|||v(0)|||_* \tag{3.20}$$

and within this range

$$|||\cdot|||_* \sim \sum_{j=0}^{k}\|\partial_x^j u\|_{L^2} + \sum_{j=0}^{4}\|x\partial_x^j u\|_{L^2}. \tag{3.21}$$

Once we obtain this a priori estimate, it is easier to return to the equation (assuming the existence of the solution) to prove that the solution belongs to the space in the statement in Theorem 2. To establish local existence, we again introduce two viscosity terms and proceed exactly as in sections 2.3 and 2.4 with the same argument as above when dealing with gauge transformation for the case $j = k$.

The rest of the proof follows by the method in the previous proof, in the previous section, thus it will be omitted here.

4. Appendix. We would use that for $f, g \in H^r(\mathbb{R})$, $r \ge 1$, then $fg \in H^r(\mathbb{R})$ (i.e., $H^r(\mathbb{R})$ is a Banach algebra under the pointwise product) and

$$\|fg\|_{H^r} \le C_r(\|f\|_{L^\infty}\|g\|_{H^r} + \|g\|_{L^\infty}\|f\|_{H^r}) \tag{4.1}$$

for some $C_r > 0$.

4.1. Appendix 1. Consider the jth derivative of (2.1):

$$\begin{aligned}\partial_x^j\partial_t u &= \partial_x^j\big(ia\partial_x^2 u + ib\partial_x^2\bar{u} + c\partial_x u + d\partial_x\bar{u} + f\big)\\ &= i\partial_x^j(a\partial_x^2 u) + i\partial_x^j(b\partial_x^2\bar{u}) + \partial_x^j(c\partial_x u) + \partial_x^j(d\partial_x\bar{u}) + \partial_x^j f.\end{aligned} \tag{4.2}$$

Write $\partial_x a = a'$, $\frac{\partial}{\partial z_l}a(z_1,z_2,z_3,z_4) = a_l'$, $l = 1,2,3,4$, similarly for b, c, d.

In order to rewrite the jth derivative of (2.1) such that the energy estimate can be evaluated effectively, the terms involving the highest and the second highest derivatives are essential. Thus we need the following:

$$\begin{aligned}\partial_x^j(ia\partial_x^2 u) = \partial_x^j(iav_2) &= i\sum_{l=0}^{j}\binom{j}{l}(\partial_x^l a)(\partial_x^{j-l}v_2)\\ &= ia\partial_x^2 v_j + ija'\partial_x v_j + i(\partial_x^j a)v_2 + i\sum_{l=2}^{j-1}\binom{j}{l}(\partial_x^l a)(\partial_x^{j-l}v_2).\end{aligned} \tag{4.3}$$

Examine $\partial_x^j a$:

$$\begin{aligned}\partial_x^j a = \partial_x^{j-1}(\partial_x a) &= \partial_x^{j-1}(a_1'\partial_x u + a_2'\partial_x\bar{u} + a_3'\partial_x^2 u + a_1'\partial_x^2\bar{u})\\ &= \partial_x^{j-1}(a_1'v_1 + a_2'\bar{v}_1) + a_3'\partial_x v_j + a_4'\partial_x\bar{v}_j\\ &\quad + \sum_{l=1}^{j-1}\binom{j-1}{l}\big((\partial_x^l(a_3'))(\partial_x^{j-1-l}v_2) + (\partial_x^l(a_4'))(\partial_x^{j-1-l}\bar{v}_2)\big),\end{aligned} \tag{4.4}$$

and thus

$$\begin{aligned}\partial_x^j(ia\partial_x^2 u) &= ia\partial_x^2 v_j + ija'\partial_x v_j + ia_3'v_2\partial_x v_j + ia_4'v_2\partial_x\bar{v}_j\\ &\quad + iv_2\partial_x^{j-1}(a_1'v_1 + a_2'\bar{v}_1) + i\sum_{l=2}^{j-1}\binom{j}{l}(\partial_x^l a)v_{j+2-l}\\ &\quad + i\sum_{l=1}^{j-1}\binom{j-1}{l}v_2\big((\partial_x^l(a_3'))v_{j+1-l} + (\partial_x^l(a_4'))\bar{v}_{j+1-l}\big),\end{aligned} \tag{4.5}$$

similarly for $\partial_x^j(ib\partial_x^2\bar{u})$, $\partial_x^j(c\partial_x u)$, $\partial_x^j(d\partial_x\bar{u})$. Write

$$\begin{cases}\partial_x^j(ia\partial_x^2 u) &= ia\partial_x^2 v_j + ija'\partial_x v_j + ia_3'v_2\partial_x v_j + ia_4'v_2\partial_x\bar{v}_j + f_{aj},\\ \partial_x^j(ib\partial_x^2\bar{u}) &= ib\partial_x^2\bar{v}_j + ijb'\partial_x\bar{v}_j + ib_3'\bar{v}_2\partial_x v_j + ib_4'\bar{v}_2\partial_x\bar{v}_j + f_{bj},\\ \partial_x^j(c\partial_x u) &= c\partial_x v_j + c_3'v_1\partial_x v_j + c_4'v_1\partial_x\bar{v}_j + f_{cj},\\ \partial_x^j(d\partial_x\bar{u}) &= d\partial_x\bar{v}_j + d_3'\bar{v}_1\partial_x v_j + d_4'\bar{v}_1\partial_x\bar{v}_j + f_{dj},\end{cases} \tag{4.6}$$

where

$$
\begin{aligned}
f_{aj} &= iv_2\partial_x^{j-1}(a_1'v_1 + a_2'\bar v_1) + i\sum_{l=2}^{j-1}\binom{j}{l}(\partial_x^l a)v_{j+2-l}\\
&\quad + i\sum_{l=1}^{j-1}\binom{j-1}{l}v_2\big((\partial_x^l(a_3'))v_{j+1-l} + (\partial_x^l(a_4'))\bar v_{j+1-l}\big),\\
f_{bj} &= i\bar v_2\partial_x^{j-1}(b_1'v_1 + b_2'\bar v_1) + i\sum_{l=2}^{j-1}\binom{j}{l}(\partial_x^l b)\bar v_{j+2-l}\\
&\quad + i\sum_{l=1}^{j-1}\binom{j-1}{l}\bar v_2\big((\partial_x^l(b_3'))v_{j+1-l} + (\partial_x^l(b_4'))\bar v_{j+1-l}\big),\\
f_{cj} &= v_1\partial_x^{j-1}(c_1'v_1 + c_2'\bar v_1) + \sum_{l=1}^{j-1}\binom{j}{l}(\partial_x^l c)\bar v_{j+1-l}\\
&\quad + \sum_{l=1}^{j-1}\binom{j-1}{l}\big((\partial_x^l c_3')v_{j+1-l} + (\partial_x^l c_4')\bar v_{j+1-l}\big)v_1,\\
f_{dj} &= \bar v_1\partial_x^{j-1}(d_1'v_1 + d_2'\bar v_1) + \sum_{l=1}^{j-1}\binom{j}{l}(\partial_x^l d)\bar v_{j+1-l}\\
&\quad + \sum_{l=1}^{j-1}\binom{j-1}{l}\big((\partial_x^l d_3')v_{j+1-l} + (\partial_x^l d_4')\bar v_{j+1-l}\big)\bar v_1.
\end{aligned}
\tag{4.7}
$$

Combine all of the above and write the jth derivative of (2.1)

$$
\begin{aligned}
\partial_t v_j &= \partial_x^j(ia\partial_x^2 u) + \partial_x^j(ib\partial_x^2\bar u) + \partial_x^j(c\partial_x u) + \partial_x^j(d\partial_x\bar u) + \partial_x^j f\\
&= ia\partial_x^2 v_j + ija'\partial_x v_j + ia_3'v_2\partial_x v_j + ia_4'v_2\partial_x\bar v_j + f_{aj}\\
&\quad + ib\partial_x^2\bar v_j + ijb'\partial_x\bar v_j + ib_3'\bar v_2\partial_x v_j + ib_4'\bar v_2\partial_x\bar v_j + f_{bj}\\
&\quad + c\partial_x v_j + c_3'v_1\partial_x v_j + c_4'v_1\partial_x\bar v_j + f_{cj}\\
&\quad + d\partial_x\bar v_j + d_3'\bar v_1\partial_x v_j + d_4'\bar v_1\partial_x\bar v_j + f_{dj} + \partial_x^j f\\
&= ia\partial_x^2 v_j + ib\partial_x^2\bar v_j + c_j\partial_x v_j + d_j\partial_x\bar v_j + f_j,
\end{aligned}
\tag{4.8}
$$

where

$$
\begin{cases}
c_j = ija' + ia_3'v_2 + ib_3'\bar v_2 + c + c_3'v_1 + d_3'\bar v_1,\\
d_j = ia_4'v_2 + ijb' + ib_4'\bar v_2 + c_4'v_1 + d + d_4'\bar v_1,\\
f_j = f_{aj} + f_{bj} + f_{cj} + f_{dj} + \partial_x^j f.
\end{cases}
\tag{4.9}
$$

4.2. Appendix 2. Let $P(\alpha; z_1, z_2, \dots, z_n)$ represent the polynomial of α-degree in $z_1, z_2, \dots, z_n$.

In order to obtain the estimates (2.6) and (2.22), we need to examine the terms involving a, its jth derivative with respect to x, its derivative with respect to t, and its derivatives with respect to its arguments, e.g., a_l', $l = 1, 2, 3, 4$ etc., similarly for b, c, d and their conjugates. Also, since the expressions $f_{aj}, f_{bj}, f_{cj}, f_{dj}$ in (4.7), F_k, and their conjugates involve the terms mentioned above, they can be considered in

the similar manner. Other terms worth mentioning are α_{12}^k, ϕ and its derivatives with respect to x and t.

Recall that

$$\begin{cases} \tilde{a} = \dfrac{a}{a^2-|b|^2}, \quad \tilde{b} = \dfrac{b}{a^2-|b|^2}, \\ c_j = ija' + ia_3'v_2 + ib_3'\bar{v}_2 + c + c_3'v_1 + d_3'\bar{v}_1, \\ d_j = ijb' + ib_4'v_2 + ib_4'\bar{v}_2 + d + c_4'v_1 + d_4'\bar{v}_1, \\ \alpha_{12}^k = \tilde{a}d_k + \tilde{b}\bar{c}_k, \\ f_j = f_{aj} + f_{bj} + f_{cj} + f_{dj} + \partial_x^j f, \\ F_k = \tilde{a}f_k + \tilde{b}\bar{f}_k. \end{cases} \tag{4.10}$$

We now investigate the terms above in more detail, especially the order with respect to u, $\bar{u}$ and their derivatives. It is enough to look at a and its derivatives; the cases for b, c, d are similar.

$$\begin{aligned} a' &= a_1'\partial_x u + a_2'\partial_x\bar{u} + a_3'\partial_x^2 u + a_4'\partial_x^2\bar{u} \\ &= P(1;\partial_x u, \partial_x\bar{u}, \partial_x^2 u, \partial_x^2\bar{u}), \\ a'' &= P(2;\partial_x u, \partial_x\bar{u}, \partial_x^2 u, \partial_x^2\bar{u}, \partial_x^3 u, \partial_x^3\bar{u}), \\ \partial_x\tilde{a} &= \partial_x\Big(\frac{a}{a^2-|b|^2}\Big) = \frac{a'(a^2-|b|^2) - a(2aa' - \bar{b}b' - b\bar{b}')}{(a^2-|b|^2)^2} \\ &= P(1;u,\bar{u},\dots,\partial_x^2 u, \partial_x^2\bar{u}), \\ \partial_t a &= a_1'\partial_t u + a_2'\partial_t\bar{u} + a_3'\partial_x\partial_t u + a_4'\partial_x\partial_t\bar{u} \\ &= a_1'(ia\partial_x^2 u + ib\partial_x^2\bar{u} + c\partial_x u + d\partial_x\bar{u} + f) \\ &\quad + a_2'(-ia\partial_x^2\bar{u} - i\bar{b}\partial_x^2 u + \bar{c}\partial_x\bar{u} + \bar{d}\partial_x u + \bar{f}) \\ &\quad + a_3'\partial_x(ia\partial_x^2 u + ib\partial_x^2\bar{u} + c\partial_x u + d\partial_x\bar{u} + f) \\ &\quad + a_4'\partial_x(-ia\partial_x^2\bar{u} - i\bar{b}\partial_x^2 u + \bar{c}\partial_x\bar{u} + \bar{d}\partial_x u + \bar{f}) \\ &= P(2;u,\bar{u},\partial_x u,\partial_x\bar{u},\partial_x^2 u,\partial_x^2\bar{u},\partial_x^3 u,\partial_x^3\bar{u}) \\ \partial_t\tilde{a} &= P(2;u,\bar{u},\partial_x u,\partial_x\bar{u},\partial_x^2 u,\partial_x^2\bar{u},\partial_x^3 u,\partial_x^3\bar{u}). \end{aligned} \tag{4.11}$$

Other expressions worth mentioning are c_j, d_j and their derivatives. Again, it is enough to consider c_j:

$$\begin{aligned} \partial_t c_j &= \partial_t(ija' + ia_3'v_2 + ib_3'\bar{v}_2 + c + c_3'v_1 + d_3'\bar{v}_1) \\ &= ij\partial_x\partial_t a + i\partial_t(a_3')\partial_x^2 u + a_3'\partial_x^2\partial_t u + i\partial_t(b_3')\partial_x^2\bar{u} + b_3'\partial_x^2\partial_t\bar{u} \\ &\quad + \partial_t c + \partial_t(c_3')\partial_x u + c_3'\partial_x\partial_t u + \partial_t(d_3')\partial_x\bar{u} + d_3'\partial_x\partial_t\bar{u} \\ &= P(3;u,\bar{u},\dots,\partial_x^4 u,\partial_x^4\bar{u}). \end{aligned} \tag{4.12}$$

We would also consider α_{12}^k since it is an important component of ϕ:

$$\begin{cases} \alpha_{12}^k = \tilde{a}c_k + \tilde{b}d_k = \dfrac{ac_k + b\bar{d}_k}{a^2-|b|^2} = P(u,\bar{u},\partial_x u,\partial_x\bar{u},\partial_x^2 u,\partial_x^2\bar{u}), \\ \partial_x\alpha_{12}^k = d_k\partial_x\tilde{a} + \tilde{a}\partial_x d_k + \bar{c}_k\partial_x\tilde{b} + \tilde{b}\partial_x\bar{c}_k = P(2;u,\bar{u},\dots,\partial_x^3 u,\partial_x^3\bar{u}). \end{cases} \tag{4.13}$$

The boundedness of ϕ and its derivatives play an important role in the energy estimates, thus a closer look at the terms involved is necessary:

$$\begin{aligned}
\phi =& \exp\left\{\frac{1}{2i}\int_0^x (\tilde{a}c_k+\tilde{b}d_k)(x',t)dx'\right\},\\
\partial_x\phi =& \frac{1}{2i}\phi(\tilde{a}c_k+\tilde{b}\bar{d}_k) = P(u,\bar{u},\dots,\partial_x^2 u,\partial_x^2\bar{u}),\\
\partial_x^2\phi =& -\frac{1}{4}\phi(\tilde{a}c_k+\tilde{b}\bar{d}_k)^2+\frac{1}{2i}\phi\partial_x(\tilde{a}c_k+\tilde{b}\bar{d}_k) = P(u,\bar{u},\dots,\partial_x^3 u,\partial_x^3\bar{u}),\\
\partial_t\phi =& \phi\left(\frac{1}{2i}\int_0^x \partial_t\left(\frac{ac_k+b\bar{d}_k}{a^2-|b|^2}\right)(x',t)dx'\right) = P(u,\bar{u},\dots,\partial_x^4 u,\partial_x^4\bar{u});
\end{aligned} \tag{4.14}$$

higher derivatives of ϕ can be derived similarly.

4.2.1. Estimate (2.22). To obtain estimate (2.22), i.e., the boundedness of J_1, we need the following:

$$\begin{aligned}
\|\phi(t)\|_{L^\infty} &\le \exp\left\{\frac{1}{2}\int_{\mathbb{R}}|(\tilde{a}c_k-\tilde{b}d_k)(x,t)|dx\right\}\\
&\le \exp\left\{C\int |ac_k|+|bd_k|dx\right\}\\
&\le \exp\left\{C(\|u\|_{H^k}^2+\|u\|_{H^k}^l)(t)\right\}
\end{aligned} \tag{4.15}$$

for some constant $C>0$, where a,b,c,d are not linear and l depends on the highest order of ac_k+bd_k.

Since $F_k\bar{v}_k=(\tilde{a}f_k+\tilde{b}\bar{f}_k)\bar{v}_k$ is not linear and involves only at most $v_k,\bar{v}_k$, the right-hand side of (2.22) is

$$\begin{aligned}
&2\Big\{\|\partial_x\big(\alpha_{12}^k\phi\bar{\phi}^{-1}\big)\|_{L^\infty}+\|\partial_t\phi\tilde{a}\phi^{-1}\|_{L^\infty}+\|\partial_t\phi\tilde{b}\bar{\phi}^{-1}\|_{L^\infty}\\
&\quad+\|\alpha_{12}^k\phi\bar{\phi}^{-2}\partial_x\bar{\phi}\|_{L^\infty}+\|(\partial_x^2\phi)\phi^{-1}\|_{L^\infty}+\|\partial_t\left(b\bar{\phi}\phi^{-1}\right)\|_{L^\infty}\\
&\quad+\frac{1}{2}\|\partial_t\tilde{a}\|_{L^\infty}\Big\}\|v_k\phi\|_{L^2}^2+2\int|\phi F_k\bar{v}_k\bar{\phi}|dx\le J_1\|v_k\|_{L^2}^2
\end{aligned} \tag{4.16}$$

with

$$J_1\le e^{C(\|u\|_{H^k}^2+\|u\|_{H^k}^l)}\Big(\|u\|_{H^k}^2+\|u\|_{H^k}^{l-1}\Big). \tag{4.17}$$

4.3. Appendix 3.

4.3.1. Proof of Proposition 2.1. The proof of Proposition 2.1 is based on the following equations:

$$\phi\partial_x^2 v_k=\partial_x^2(v_k\phi)-2\partial_x\phi\phi^{-1}\partial_x(v_k\phi)+[2(\partial_x\phi)^2\phi^{-2}-\partial_x^2\phi\phi^{-1}](v_k\phi), \tag{4.18}$$

$$\begin{aligned}
\phi\partial_x^3 v_k=&\partial_x^3(v_k\phi)-3\partial_x\phi\phi^{-1}\partial_x^2(v_k\phi)+[6(\partial_x\phi)^2\phi^{-1}-3\partial_x^2\phi]\phi^{-1}\partial_x(v_k\phi)\\
&+(-(6(\partial_x\phi)^2\phi^{-1}-3\partial_x^2\phi)\phi^{-1}\partial_x\phi-\partial_x^3\phi)\phi^{-1}(v_k\phi),
\end{aligned} \tag{4.19}$$

$$\begin{aligned}
\phi\partial_x^4 v_k=&\partial_x^4(v_k\phi)-4\partial_x\phi\phi^{-1}\partial_x^3(v_k\phi)+[12(\partial_x\phi)^2\phi^{-1}-6\partial_x^2\phi]\phi^{-1}\partial_x^2(v_k\phi)\\
&+[-24(\partial_x\phi)^3\phi^{-1}+24\phi^{-1}\partial_x^2\phi\partial_x\phi-4\partial_x^3\phi]\phi^{-1}\partial_x(v_k\phi)\\
&+\{24(\partial_x\phi)^4\phi^{-2}-12[2\phi^{-2}+\phi^{-1}]\partial_x^2\phi(\partial_x\phi)^2+8\phi^{-1}\partial_x\phi\partial_x^3\phi\\
&+6\phi^{-1}(\partial_x^2\phi)^2-\partial_x^4\phi\}\phi^{-1}(v_k\phi)\\
=&\partial_x^4(v_k\phi)+\gamma_3\partial_x^3(v_k\phi)+\gamma_2\partial_x^2(v_k\phi)+\gamma_1\partial_x(v_k\phi)+\gamma_0 v_k\phi.
\end{aligned} \tag{4.20}$$

We would want to show that for some choice of $\delta > 0$ we are able to bound the following four terms within $H^k(\mathbb{R})$:

(4.21)
$$2\mathrm{Re}\int(\bar{v}_k\bar{\phi})\tilde{a}(-\varepsilon\phi\partial_x^4 v_k+\varepsilon\delta\phi\partial_x^2 v_k)dx+2\mathrm{Re}\int(\bar{v}_k\bar{\phi})\tilde{b}(-\varepsilon\phi\partial_x^4\bar{v}_k+\varepsilon\delta\phi\partial_x^2\bar{v}_k)dx.$$

Using (4.18)–(4.20) and after integration by parts, we have

$$\begin{aligned}
&2\mathrm{Re}\int(\bar{v}_k\bar{\phi})\tilde{a}(-\varepsilon\phi\partial_x^4 v_k+\varepsilon\delta\phi\partial_x^2 v_k)dx\\
&\qquad+2\mathrm{Re}\int(\bar{v}_k\bar{\phi})\tilde{b}(-\varepsilon\phi\partial_x^4\bar{v}_k+\varepsilon\delta\phi\partial_x^2\bar{v}_k)dx\\
&\le-2\varepsilon\int(\tilde{a}-|\tilde{b}|)|\partial_x^2(v_k\phi)|^2dx-2\varepsilon\delta\int(\tilde{a}-|\tilde{b}|)|\partial_x(v_k\phi)|^2dx\\
&\quad+\varepsilon C_1\|\partial_x^2(v_k\phi)\|_{L^2}\|\partial_x(v_k\phi)\|_{L^2}+\varepsilon C_2\|\partial_x(v_k\phi)\|_{L^2}\|v_k\phi\|_{L^2}\\
&\quad+\varepsilon C_3\|\partial_x(v_k\phi)\|_{L^2}^2+\varepsilon C_4\|v_k\phi\|_{L^2}^2.
\end{aligned}\tag{4.22}$$

Thus for $p,q>0$, we have

$$\begin{aligned}
&2\mathrm{Re}\int(\bar{v}_k\bar{\phi})\tilde{a}(-\varepsilon\phi\partial_x^4 v_k+\varepsilon\delta\phi\partial_x^2 v_k)dx\\
&\qquad+2\mathrm{Re}\int(\bar{v}_k\bar{\phi})\tilde{b}(-\varepsilon\phi\partial_x^4\bar{v}_k+\varepsilon\delta\phi\partial_x^2\bar{v}_k)dx\\
&\le-2\varepsilon m_2\|\partial_x^2(v_k\phi)\|_{L^2}^2-2\varepsilon\delta m_2\|\partial_x(v_k\phi)\|_{L^2}^2\\
&\quad+\varepsilon C_1\left(\frac{1}{p}\|\partial_x^2(v_k\phi)\|_{L^2}^2+p\|\partial_x(v_k\phi)\|_{L^2}^2\right)\\
&\quad+\varepsilon C_2\left(\frac{1}{q}\|\partial_x(v_k\phi)\|_{L^2}^2+q\|v_k\phi\|_{L^2}^2\right)+\varepsilon C_3\|\partial_x(v_k\phi)\|_{L^2}^2+\varepsilon C_4\|v_k\phi\|_{L^2}^2\\
&=\varepsilon\left(-2m_2+C_1p^{-1}\right)\|\partial_x^2(v_k\phi)\|_{L^2}^2\\
&\quad+\varepsilon\left(-2\delta c_3+C_1p+C_2q^{-1}+C_3\right)\|\partial_x(v_k\phi)\|_{L^2}^2+\varepsilon(C_2q+\delta C_4)\|v_k\phi\|_{L^2}^2,
\end{aligned}\tag{4.23}$$

where

$$\begin{aligned}
C_1&=2\|\tilde{a}\gamma_2\|_{L^\infty},\\
C_2&=\|\partial_x^2(\tilde{a}\gamma_3)\|_{L^\infty}+2\varepsilon\|\partial_x(\tilde{a}\gamma_2)\|_{L^\infty}+2\varepsilon\|\tilde{a}\gamma_1\|_{L^\infty}+4\varepsilon\delta\|\tilde{a}\partial_x\phi\phi^{-1}\|_{L^\infty},\\
C_3&=4\|\partial_x^2\tilde{a}\|_{L^\infty}+2\|\partial_x(\tilde{a}\gamma_3)\|_{L^\infty}+2\|\tilde{a}\gamma_2\|_{L^\infty}\\
&\quad+2\|\tilde{b}\bar{\phi}^{-1}\phi\bar{\gamma}_2\|_{L^\infty}+4\|\partial_x^2(\tilde{b}\bar{\phi}^{-1}\phi)\|_{L^\infty},\\
C_4&=\|\partial_x^4\tilde{a}\|_{L^\infty}+2\|\tilde{a}\gamma_0\|_{L^\infty}+2\delta\|\tilde{a}[2(\partial_x\phi)^2\phi^{-2}-\partial_x^2\phi\phi^{-1}]\|_{L^\infty}\\
&\quad+2\|\partial_x^4(\tilde{b}\bar{\phi}^{-1}\phi)\|_{L^\infty}+2\|\partial_x^3(\tilde{b}\bar{\phi}^{-1}\phi\bar{\gamma}_3)\|_{L^\infty}+\|\partial_x^2(\tilde{b}\bar{\phi}^{-1}\phi\bar{\gamma}_2)\|_{L^\infty}\\
&\quad+2\|\partial_x(\tilde{b}\bar{\phi}^{-1}\phi\bar{\gamma}_1)\|_{L^\infty}+2\|\tilde{b}\bar{\phi}^{-1}\phi\bar{\gamma}_2\|_{L^\infty}+2\delta\Big[\|\partial_x^2(\tilde{b}\bar{\phi}^{-1}\phi)\|_{L^\infty}\\
&\quad+\|\partial_x(\tilde{b}\bar{\phi}^{-2}\phi\partial_x\bar{\phi})\|_{L^\infty}+\|\tilde{b}(2\partial_x\bar{\phi})^2\bar{\phi}^{-2}-(\partial_x^2\bar{\phi})\bar{\phi}^{-1}\|_{L^\infty}\Big].
\end{aligned}\tag{4.24}$$

To obtain the desired result in Proposition 2.1, we choose p such that $2m_2 \geq C_1 p^{-1}$, or, $p \geq \frac{C_1}{2m_2}$, and then choose δ such that $-2\delta m_2 + C_1 p + C_2 q^{-1} + C_3 \leq 0$, or $\delta \geq \frac{C_1 p + C_2 q^{-1} + C_3}{2m_2}$. Thus

$$2\mathrm{Re}\int (\bar{v}_k\bar{\phi})\tilde{a}(-\varepsilon\phi\partial_x^4 v_k + \varepsilon\delta\phi\partial_x^2 v_k)dx + 2\mathrm{Re}\int (\bar{v}_k\bar{\phi})\tilde{b}(-\varepsilon\phi\partial_x^4 \bar{v}_k + \varepsilon\delta\phi\partial_x^2 \bar{v}_k)dx \leq C\|v_k\phi\|_{L^2}^2 \tag{4.25}$$

for $\varepsilon \in (0,1]$, where $C = C(\delta, \|u\|_{H^k}) > 0$ is independent of ε.

Acknowledgment. The authors would like to thank the referees for several suggestions which improved the presentation of this work.

A DUALITY APPROACH FOR THE BOUNDARY VARIATION OF NEUMANN PROBLEMS*

DORIN BUCUR† AND NICOLAS VARCHON‡

Abstract. In two dimensions, we study the stability of the solution of an elliptic equation with Neumann boundary conditions for nonsmooth perturbations of the geometric domain. Using harmonic conjugates, we relate this problem to the shape stability of the solution of an elliptic equation with Dirichlet boundary conditions. As a particular case, we prove the stability of the solution under a topological constraint (uniform number of holes), which is analogous to Šverák's result for Dirichlet boundary conditions.

Key words. boundary variation, Neumann problem, shape optimization, stability

1. Introduction.

An interesting question arising in shape optimization concerns the stability of the solution of a partial differential equation (PDE) for nonsmooth variations of the geometric domain. Various papers in the literature deal with PDEs with Dirichlet boundary conditions, while very few results can be found for PDEs with Neumann boundary conditions. Several reasons may explain this situation, but maybe the most important is that for a nonsmooth open set Ω a function of the Sobolev space $H^1(\Omega)$ might not have an extension outside Ω.

The purpose of this paper is to give a quite general method, based on duality, for the study of the shape stability of the weak solution of a linear elliptic problem with homogeneous Neumann boundary conditions. Given two bounded open sets $\Omega \subseteq D \subseteq \mathbb{R}^2$, $a \in L^\infty(D), a \geq 0$, and $h \in L^2(D)$, we consider the following problem:

$$\left\{ \begin{array}{rl} -\triangle u_{\Omega,h} + a(x) u_{\Omega,h} = h & \text{in} \quad \Omega, \\ \frac{\partial u_{\Omega,h}}{\partial n} = 0 & \text{on} \quad \partial\Omega. \end{array} \right. \tag{1}$$

In order to handle easily the compatibility conditions on regions where a vanishes, we suppose that $h(x) = a(x)f(x) + g(x)$, where $f \in L^2(D)$ and $g \in L^2(D)$, supp $g \subseteq \Omega$, and $\int_C g dx = 0$ for every connected component C of Ω.

We study the stability of the solution $u_{\Omega,h}$ for perturbations of the geometric domain Ω inside D, i.e., the "continuity" of the mapping $\Omega \mapsto u_{\Omega,h}$. We point out that we consider only *weak* solutions of (1) (see the precise definition in section 2); those solutions are classical only if Ω, a, and h are regular enough.

The family of domains is endowed with the Hausdorff complementary topology (see [7, 24, 25]), which has good compactness properties and allows nonsmooth perturbations of the boundaries. We are particularly interested in dealing with nonsmooth domains, like domains with cracks or with boundaries of strictly positive measure. For this reason, the functional spaces where the weak solutions are defined play a

crucial role; one has to pay attention to the fact that extension operators may fail to exist as soon as Ω is not smooth (for example, if Ω has a crack, there is no extension operator from $H^1(\Omega)$ to $H^1(\mathbb{R}^2)$).

In order to compare two solutions on two different domains, the following convention is applied: extending by zero on $D\setminus\Omega$, we see $u_{\Omega,h}$ and $\nabla u_{\Omega,h}$ as functions defined on D. The exact sense of those extensions is given in section 2 once the functional spaces where the solutions belong are introduced.

Several results can be found in the literature concerning (1) for $a \equiv 1$, which has a variational solution in the Sobolev space $H^1(\Omega)$. We refer to [10] for a pioneering continuity result obtained under geometric constraints on the variable domains (uniform Lipschitz boundary), which particularly imply the existence of uniformly bounded extension operators from $H^1(\Omega)$ to $H^1(\mathbb{R}^2)$; the existence of extension operators across the boundary is the key result for the shape continuity. In [23] the shape continuity is established for the same equation in a class of domains satisfying weaker geometric constraints which still insure the existence of a dense set of functions having extensions.

A different point of view, still for $a \equiv 1$, based on the Mosco convergence of H^1-spaces, was followed by Chambolle and Doveri in [9]. (In the last section we recall the definition of the Mosco convergence and the main lines of this issue.) Here, the extension property is replaced by an approximability one: the family of functions of $H^1(\Omega)$ which can be written as strong limits of elements of $H^1(\Omega_n)$ is dense in $H^1(\Omega)$. They proved (in two dimensions) that if Ω_n converges in the Hausdorff complementary topology to Ω and the lengths of the boundaries $\mathcal{H}^1(\partial\Omega_n)$ and the number of the connected components of $\partial\Omega_n$ are uniformly bounded, then $u_{\Omega_n,h}$ converges to $u_{\Omega,h}$. In [6] a more general result is proved for the same equation (i.e., $a \equiv 1$): if Ω_n converges in the Hausdorff complementary topology to Ω such that the number of the connected components of $\mathbb{R}^2 \setminus \Omega_n$ is uniformly bounded, then shape continuity holds if and only if the Lebesgue measure is stable, i.e., $|\Omega_n| \to |\Omega|$.

The purpose of this paper is to investigate the case $a \not\equiv 1$ and, in particular, the case when a vanishes on some regions of the plane. For example if $a \equiv 0$, we observe that the stability of the Lebesgue measure is not anymore a necessary condition for the shape stability of the solutions. We give a set of conditions which is equivalent to the shape stability of (1). The major condition, which in concrete examples is the one difficult to check, is reduced by a duality argument to the study of the shape stability of an elliptic equation with Dirichlet boundary conditions. In particular, we prove the following.

THEOREM 1.1. *Let $\{\Omega_n\}_{n\in\mathbb{N}}$ such that $\Omega_n \subseteq D$ and the number of the connected components of Ω_n^c is uniformly bounded. If Ω_n^c converges into the Hausdorff metric to Ω^c, then, for every admissible right-hand side h in* (1)*, we have that $u_{\Omega_n,h}$ converges to $u_{\Omega,h}$ if and only if $|\Omega_n \cap \{a > 0\}| \to |\Omega \cap \{a > 0\}|$.*

The sense of the convergence is defined in section 2. In the extremal case $a \equiv 0$, this result is analogous to the compactness-continuity result of Šverák [25] for Dirichlet boundary conditions.

In section 2 we introduce the main notation. Section 3 is devoted to the case $a \equiv 0$ and to the duality argument. The general case $a \geq 0$ is discussed in section 4. We finish the paper with an example and some remarks.

2. Notation and preliminaries. In this section we set the main notation and recall some facts about the (weak) variational solutions of (1). For this purpose, we introduce the functional spaces in which the solutions are searched.

Let D be a bounded open set in $\mathbb{R}^2$ (called design region). Let $a \in L^\infty(D), a \geq 0$, be a fixed function. For every open set $\Omega \subseteq D$ we introduce the following functional space:

$$\mathcal{L}^{1,2}_a(\Omega) = \left\{ u \in L^2_{loc}(\Omega) : \nabla u \in L^2(\Omega, \mathbb{R}^2), \int_\Omega u^2 a dx < +\infty \right\}, \tag{2}$$

where the gradient of u is taken in the sense of distributions. Introducing the equivalence relation

$$u \mathcal{R}_a v \text{ if } \int_\Omega |\nabla(u-v)|^2 dx + \int_\Omega (u-v)^2 a dx = 0,$$

the quotient space $\mathcal{L}^{1,2}_a(\Omega)_{/\mathcal{R}_a} := L^{1,2}_a(\Omega)$ is a Hilbert space for the scalar product

$$(u,v)_{L^{1,2}_a(\Omega)} = \int_\Omega \nabla u \nabla v dx + \int_\Omega uva dx.$$

Let C be a connected component of Ω and let $u, v \in \mathcal{L}^{1,2}_a(\Omega)$ such that $u \mathcal{R}_a v$. Note that if $|C \cap \{a > 0\}| = 0$, then $u - v$ is constant a.e. on C. If $|C \cap \{a > 0\}| > 0$, this constant is zero, i.e., $u = v$ a.e. on C.

If $a \equiv 1$, then $L^{1,2}_a(\Omega)$ is nothing else but the usual Sobolev space $H^1(\Omega)$ (see [2]). If $a \equiv 0$, then $\mathcal{L}^{1,2}_a(\Omega)$ is the usual Dirichlet space (see [20]). In our paper, if $a \equiv 0$, the spaces $\mathcal{L}^{1,2}_a(\Omega)$, $L^{1,2}_a(\Omega)$ will simply be denoted $\mathcal{L}^{1,2}(\Omega)$, $L^{1,2}(\Omega)$, respectively. Note that if $a_1 \leq a_2$, then the natural injection $L^{1,2}_{a_2}(\Omega) \hookrightarrow L^{1,2}_{a_1}(\Omega)$ is a contraction.

Following [19, Corollary 2.2], if Ω is smooth enough (e.g., with Lipschitz continuous boundary and with a finite number of connected components), then $\mathcal{L}^{1,2}(\Omega) = H^1(\Omega)$. If Ω is not smooth, then $H^1(\Omega)$ might be strictly contained in $\mathcal{L}^{1,2}(\Omega)$. Observe also that if Ω is not smooth enough, several "well-known" properties of H^1-spaces fail to be true, as, for example, the Poincaré–Wirtinger inequality. Moreover, there does not exist an extension operator from $H^1(\Omega)$ to $H^1(D)$, even though the density of $C^\infty(\Omega) \cap H^1(\Omega)$ in $H^1(\Omega)$ remains true (see [18]). In fact, $C^\infty(\overline{\Omega})$ is no longer dense in $H^1(\Omega)$.

Let $h \in L^2(D)$ be such that $h(x) = a(x)f(x) + g(x)$, where $f \in L^2(D)$ and $g \in L^2(D)$, supp $g \subseteq \Omega$, and $\int_C g dx = 0$ for every connected component C of Ω. Then (1) has a weak variational solution $u_{\Omega,h} \in L^{1,2}_a(\Omega)$ obtained by the minimization of the energy functional

$$L^{1,2}_a(\Omega) \ni u \mapsto F(u) = \frac{1}{2}\int_\Omega |\nabla u|^2 dx + \frac{1}{2}\int_\Omega u^2 a dx - \int_\Omega hu dx.$$

This is an immediate consequence of the Lax–Milgram theorem (see [2, Corollary V.8]). The only point to be verified is the strong continuity of the mapping

$$L^{1,2}_a(\Omega) \ni u \mapsto \int_\Omega afu + gu dx.$$

Indeed,

$$\left| \int_\Omega afu + gu dx \right| \leq \int_\Omega |afu| dx + \left| \int_U gu dx \right|$$

$$\leq \Big(\int_\Omega au^2 dx \Big)^{\frac{1}{2}} \Big(\int_\Omega af^2 dx \Big)^{\frac{1}{2}} + C \Big(\int_U |\nabla u|^2 dx \Big)^{\frac{1}{2}} \Big(\int_U g^2 dx \Big)^{\frac{1}{2}} \leq C' |u|_{L^{1,2}_a(\Omega)},$$

where C is the constant given by the Poincaré–Wirtinger inequality applied in $H^1(U)_{/\mathbb{R}}$; the smooth set U is chosen such that supp $g \subseteq \mathrm{U} \subseteq \Omega$.

If Ω, a, and h are smooth enough, every representative in $\mathcal{L}^{1,2}_a(\Omega)$ of the weak variational solution is also classical. In view of the equivalence relation $\mathcal{R}_a$, on each connected component C of Ω, two classical solutions of (1) are identical if $|\{a > 0\} \cap C| > 0$ and differ by a constant if $|\{a > 0\} \cap C| = 0$. It is not our purpose to find the minimal assumptions such that the weak solution is classical (see e.g., [2]); if Ω is of class C^3 and a, h are of class $C^1(\overline{\Omega})$, then every representative of the weak solution is classical. If Ω is not smooth, the sense of the Neumann condition on $\partial\Omega$ is only *weak*; it is implicitly contained in the variational formulation of the problem.

One of the main ideas of this paper is to introduce a new equation which is easier to study from the point of view of the shape stability, but which carries most of the information concerning the shape stability of (1). Let $B = B(0, r)$ be such that $B(0, r + \delta) \subseteq \Omega \subseteq D$ for some $\delta > 0$ and $\gamma \in H^{\frac{1}{2}}(\partial B)$ such that $\int_{\partial B} \gamma d\sigma = 0$. Note that under this last assumption, γ is also an element of the dual of $H^{\frac{1}{2}}(\partial B)_{/\mathbb{R}}$. We consider the following equation:

$$\text{(3)} \qquad \begin{cases} -\triangle v_{\Omega,\gamma} = 0 & \text{in} \quad \Omega \setminus \overline{B}, \\ \frac{\partial v_{\Omega,\gamma}}{\partial n} = 0 & \text{on} \quad \partial\Omega, \\ \frac{\partial v_{\Omega,\gamma}}{\partial n} = \gamma & \text{on} \quad \partial B. \end{cases}$$

Equation (3) has a unique variational solution in $L^{1,2}(\Omega \setminus \overline{B})$ obtained by the minimization of the energy functional

$$\text{(4)} \qquad L^{1,2}(\Omega \setminus \overline{B}) \ni v \mapsto F(v) = \frac{1}{2} \int_{\Omega \setminus \overline{B}} |\nabla v|^2 dx - \int_{\partial B} \gamma v d\sigma.$$

This is a consequence of the Lax–Milgram theorem and, again, the only point to be verified is the continuity of the mapping

$$v \mapsto \int_{\partial B} \gamma v d\sigma.$$

This is a direct consequence of the trace theorem and the Poincaré–Wirtinger inequality applied in $H^1(B(0, r + \delta) \setminus \overline{B})$.

The main interest in relating the shape stability of the solution of (1) to the shape stability of the solution of (3) relies on the fact that all solutions of (3) (even in open sets with nonsmooth boundaries) have harmonic conjugates which satisfy a Dirichlet boundary condition, which is easier to handle on varying domains. Several results for the boundary variation of Dirichlet problems, such as those of [4, 7, 15, 25], can be applied. Observe that a new difficulty (of different type) appears, since the traces of the conjugate functions on the boundary are constant on connected components, but the constants may vary. Nevertheless, in concrete examples, this seems easier to handle, as opposed to directly investigating the stability of the original problem.

The sense in which we investigate the continuity of the mappings

$$\Omega \mapsto u_{\Omega,h} \qquad \text{and} \qquad \Omega \mapsto v_{\Omega,\gamma}$$

is the following. For simplicity, we denote by $L^2_a(D)$ the usual space of square integrable functions with respect to the measure of density $a(x)$ with respect to the

Lebesgue measure, endowed with the scalar product $(u,v)=\int_D uv\ adx$. Since the space to which $u_{\Omega,h}$ belongs varies with Ω, the following convention is used. We embed the space $L^{1,2}_a(\Omega)$ into the following space, which is not dependent on Ω:

$$L^{1,2}_a(\Omega)\hookrightarrow L^2_a(D)\times L^2(D,\mathbb{R}^2) \tag{5}$$

by

$$u\mapsto(\tilde{u},\widetilde{\nabla u}), \tag{6}$$

where $\tilde{u}(x)=u(x)$ if $x\in\Omega$ and $\tilde{u}(x)=0$ if $x\in D\setminus\Omega$. In the same way $\widetilde{\nabla u}(x)=\nabla u(x)$ if $x\in\Omega$ and $\widetilde{\nabla u}(x)=0$ if $x\in D\setminus\Omega$. Note that $\widetilde{\nabla u}$ is not the distributional gradient of $\tilde{u}$.

Since $L^{1,2}_a(\Omega)$ is a quotient space, one has to check that $\tilde{u}$ and $\widetilde{\nabla u}$ do not depend on the choice of the representative of u. This is true since all representatives of u have the same gradient and coincide on $\Omega\cap\{a>0\}$. If $a\equiv 0$, of course the space $L^{1,2}(\Omega)$ is embedded in $L^2(D,\mathbb{R}^2)$, since $L^2_a(\Omega)\equiv\{0\}$.

We denote

$$\mathcal{O}(D)=\{\Omega\subseteq D:\Omega\text{ open}\}\qquad\text{and}\qquad\mathcal{O}_l(D)=\{\Omega\subseteq D:\Omega\text{ open }\sharp\Omega^c\leq l\}.$$

Here $l\in\mathbb{N}$ is fixed, and $\sharp\Omega^c$ denotes the number of the connected components of the complement of Ω.

The Hausdorff distance in the family of open subsets of D (called the Hausdorff complementary distance) is given by the following metric:

$$d_{H^c}(\Omega_1,\Omega_2)=d_H(\overline{D}\setminus\Omega_1,\overline{D}\setminus\Omega_2),$$

where

$$d_H(K_1,K_2)=\max\left\{\sup_{x\in K_1}\inf_{y\in K_2}|x-y|,\sup_{y\in K_2}\inf_{x\in K_1}|x-y|\right\}$$

is the usual Hausdorff distance between two closed sets. It is well known that $\mathcal{O}(D)$ is compact in the Hausdorff complementary topology. Moreover, if $\Omega_n\xrightarrow{H^c}\Omega$, then

$$\forall K\subset\subset\Omega,\ \ \exists n=n_K\in\mathbb{N}\quad\text{such that }\ \forall n\geq n_K\text{ we have }K\subseteq\Omega_n. \tag{7}$$

This property has a geometric character and does not require any regularity on Ω (see [24, Lemma 3, p. 32]). A direct consequence is the following:

$$\forall\phi\in C^\infty_0(\Omega)\quad\exists n=n_\phi\in\mathbb{N}\quad\text{such that }\ \forall n\geq n_\phi\text{ we have }\phi\in C^\infty_0(\Omega_n). \tag{8}$$

The characteristic function of a set E is denoted 1_E and its Lebesgue measure is denoted $|E|$. The capacity of a set E is denoted $cap(E)$; we refer to [20] for details concerning capacity and quasi-continuous functions in Sobolev spaces.

3. The shape stability in the case $a\equiv 0$. In this section we discuss the particular case $a\equiv 0$. We give, in a first step, a proposition relating the shape stability of (1) to the shape stability of (3). In a second step we present the duality method. Using the harmonic conjugates associated to the solutions of (3), we prove the shape stability of (3) for the H^c-topology in the family of domains for which the complements have a uniformly bounded number of connected components.

3.1. Relation between shape stability of (1) with $a \equiv 0$ and (3).

PROPOSITION 3.1. *Let $\Omega_n, \Omega \in \mathcal{O}(D)$ such that $\Omega_n \xrightarrow{H^c} \Omega$. The following assertions are equivalent:*

1. *For $a \equiv 0$ and for every admissible $h := g$, we have $\widetilde{\nabla u_{\Omega_n,g}} \overset{L^2(D,\mathbb{R}^2)}{\longrightarrow} \widetilde{\nabla u_{\Omega,g}}$.*
2. *For every ball B such that $\overline{B} \subseteq \Omega$ and for every $\gamma \in H^{\frac{1}{2}}(\partial B)$ with $\int_{\partial B} \gamma d\sigma = 0$ we have $\widetilde{\nabla v_{\Omega_n,\gamma}} \overset{L^2(D,\mathbb{R}^2)}{\longrightarrow} \widetilde{\nabla v_{\Omega,\gamma}}$,*
3. *For every $u \in L^{1,2}(\Omega)$ there exists $u_n \in L^{1,2}(\Omega_n)$ such that $\widetilde{\nabla u_n} \overset{L^2(D,\mathbb{R}^2)}{\longrightarrow} \widetilde{\nabla u}$.*

We list condition 3 in Proposition 3.1 because it is useful in the proof of the equivalence between conditions 1 and 2.

Proof. $1 \Rightarrow 3$. Let us denote

$$Y = \left\{ \psi \in L^{1,2}(\Omega) : \exists \psi_n \in L^{1,2}(\Omega_n) \quad \text{such that } \widetilde{\nabla \psi_n} \overset{L^2(D,\mathbb{R}^2)}{\longrightarrow} \widetilde{\nabla \psi} \right\}.$$

It is sufficient to prove that Y is dense in $L^{1,2}(\Omega)$; then 3 follows straightforwardly by a usual diagonal procedure. Let $\Psi \in L^{1,2}(\Omega)$ such that

$$\Psi \perp_{L^{1,2}(\Omega)} Y,$$

i.e., $\int_\Omega \nabla\Psi\nabla v dx = 0$ for all $v \in Y$. Let us fix a representative of $\psi \in \mathcal{L}^{1,2}(\Omega)$. Following property (8) of the Hausdorff convergence, the equivalence class generated by $C_0^\infty(\Omega)$ in $L^{1,2}(\Omega)$ is contained in Y. Hence, for all $v \in C_0^\infty(\Omega)$ we have $\int_\Omega \nabla\Psi\nabla v dx = 0$, and therefore $-\Delta\Psi = 0$ in $\mathcal{D}'(\Omega)$. Now let B be a ball such that $\overline{B} \subset \Omega$. For every $g \in L^2(D)$, with supp $g \subset \bar{B}$ and $\int_B g dx = 0$ we have, following condition 1, $\int_B g\Psi dx = 0$, so Ψ is constant in B; hence $\nabla\Psi = 0$ in the connected component of Ω which contains B. Applying this argument to every connected component of Ω, we deduce that $\nabla\Psi = 0$ in Ω, i.e., $\Psi \equiv 0$ in $L^{1,2}(\Omega)$.

$3 \Rightarrow 1$. Let $g \in L^2(\Omega)$ and $K =$ supp g. Let U be a smooth open set such that $K \subset U \subset\subset \Omega$. Taking $u_{\Omega_n,g}$ as a test function in (1) and applying the Poincaré inequality in $H^1(U)$, we obtain that the sequence

$$\|\widetilde{\nabla u_{\Omega_n,g}}\|_{L^2(D,\mathbb{R}^2)}$$

is bounded. Up to a subsequence denoted by the same index we have

$$\widetilde{\nabla u_{\Omega_n,g}} \overset{L^2(D)}{\rightharpoonup} (u_1, u_2).$$

From property (7) of the H^c-convergence, we get that

$$\forall \overline{q} \in C_0^\infty(\Omega, \mathbb{R}^2), \quad \text{div } \overline{q} = 0, \qquad \langle (u_1, u_2)|_\Omega, \overline{q} \rangle_{H^{-1}(\Omega,\mathbb{R}^2)\times H_0^1(\Omega,\mathbb{R}^2)} = 0.$$

Applying successively De Rham's theorem [19, Theorem 2.3] on an increasing sequence of smooth sets covering Ω, there exists $u \in L^2_{loc}(\Omega)$ such that $(u_1, u_2)|_\Omega = \nabla u$ in the distributional sense in Ω. Moreover, from the compact injection $H^1(U) \hookrightarrow L^2(U)$ we have $u_{\Omega_n,g} \overset{L^2(U)}{\longrightarrow} u$. Following condition 3, for every $v \in L^{1,2}(\Omega)$ we have

$$\int_\Omega \nabla u \nabla v dx = \int_D \langle (u_1, u_2), \widetilde{\nabla v} \rangle dx = \lim_{n\to\infty} \int_D \widetilde{\nabla u_n}\widetilde{\nabla v_n} dx = \lim_{n\to\infty} \int_{\Omega_n} g v_n dx = \int_\Omega g v dx. \tag{9}$$

Hence $u|_\Omega = u_{\Omega,g}$ and, moreover,

$$\int_D |\widetilde{\nabla u_{\Omega,g}}|^2 dx = \int_U g u_{\Omega,g} dx \longleftarrow_{n\to\infty} \int_U g u_{\Omega_n,g} dx = \int_D |\widetilde{\nabla u_{\Omega_n,g}}|^2 dx. \tag{10}$$

By the uniqueness of the solution of (1), the whole sequence $\widetilde{\nabla u_{\Omega_n,g}}$ converges to $\widetilde{\nabla u_{\Omega,g}}$ in $L^2(D,\mathbb{R}^2)$.

$2 \Rightarrow 3$. Let C be a connected component of Ω and denote

$$Y = \{\psi \in L^{1,2}(C\backslash\overline{B}) : \exists \psi_n \in L^{1,2}(\Omega_n\backslash\overline{B}) \text{ such that } \widetilde{\nabla\psi_n} \overset{L^2(D,\mathbb{R}^2)}{\longrightarrow} \widetilde{\nabla\psi}\} \subseteq L^{1,2}(C\backslash\overline{B}).$$

Let $\Psi \in L^{1,2}(C \setminus \overline{B})$, $\Psi \perp Y$, i.e., $\int_{C\setminus\overline{B}} \nabla\Psi\nabla v dx = 0$ for all $v \in Y$; let us fix a representative of Ψ in $\mathcal{L}^{1,2}(C \setminus \overline{B})$. Using property (8) of the H^c-convergence we deduce, as above, that $-\Delta\Psi = 0$ in $\mathcal{D}'(C \setminus \overline{B})$. Since every solution $v_{\Omega,\gamma}$ belongs to Y, writing the orthogonality property we get

$$0 = \int_{C\setminus\overline{B}} \nabla\Psi\nabla v_{\Omega,\gamma} dx = \int_{\partial B} \gamma\Psi d\sigma.$$

This relation holds for every $\gamma \in H^{\frac{1}{2}}(\partial B)$ such that $\int_{\partial B}\gamma d\sigma = 0$. Since $H^{\frac{1}{2}}(\partial B)$ is dense in $L^2(\partial B)$ we get that Ψ is constant on ∂B. Now let $\bar\Psi \in L^{1,2}(C)$ such that $\bar\Psi = \Psi$ in $C \setminus \bar B$ and $\bar\Psi = c$ a.e. on B. Since $\Omega_n \overset{H^c}{\longrightarrow} \Omega$, for every function $\varphi \in C_0^\infty(C)$ the restriction $\varphi_{|\Omega\setminus\bar B}$ belongs to Y, and hence we have

$$\int_\Omega \nabla\bar\Psi\nabla\varphi dx = 0.$$

Therefore the extension of Ψ by the same constant on B gives a harmonic function constant on a set of strictly positive measure; hence $\nabla\Psi = 0$ on $\Omega \setminus \overline{B}$. We conclude that Y is dense in $L^{1,2}(C \setminus \bar B)$.

To prove that for all $u \in L^{1,2}(C)$, there exists $u_n \in L^{1,2}(\Omega_n)$ such that $\widetilde{\nabla u_n} \overset{L^2(D,\mathbb{R}^2)}{\longrightarrow} \widetilde{\nabla u}$ we use an argument based on the partition of unity of D. Let $\varphi \in C_0^\infty(C)$ such that $\varphi = 1$ on B. Let $u_n = \tilde u\varphi + (1-\varphi)\tilde v_n$, where $v_n \in L^{1,2}(\Omega\setminus\bar B)$ and $\widetilde{\nabla v_n} \overset{L^2(D,\mathbb{R}^2)}{\longrightarrow} \widetilde{\nabla u_{|C\setminus\bar B}}$. So $u_n \in L^{1,2}(\Omega_n)$ and $\widetilde{\nabla u_n} \overset{L^2(D,\mathbb{R}^2)}{\longrightarrow} \widetilde{\nabla u}$.

Now let $(C_i)_{i\in\mathbb{N}}$ be the family of all connected components of Ω. Since the set

$$\{u \in L^{1,2}(\Omega) \text{ such that } \nabla u = 0 \text{ on } C_i \text{ except for a finite number of } i\}$$

is dense in $L^{1,2}(\Omega)$ assertion 3 follows.

$3 \Rightarrow 2$. The proof follows the same arguments as $3 \Rightarrow 1$ with the remark that every function of $L^{1,2}(\Omega \setminus \overline{B})$ has an extension on $L^{1,2}(\Omega)$. □

3.2. Sufficient topological constraints for the shape stability of (3). In what follows, we use the harmonic conjugates of the solutions of (3) in order to transform the shape continuity problem for (3) into a shape continuity problem of an elliptic equation with Dirichlet boundary conditions. The main reason for doing this is that the study of the domain variation for Dirichlet problems has a complete answer in the case that the Dirichlet boundary condition is zero (or a restriction of some fixed H^1-function). Either necessary and sufficient conditions for shape stability are given

in this case (see [7, 5, 14]) or relaxation results can be established (see [8, 15]). In the latter case, one can describe exactly the "lack" of continuity. Unfortunately, in our case, the Dirichlet boundary condition is not zero, and the values of the functions on different connected components of the boundaries are constants which *vary* with the domains.

That is why we restrict ourselves to the case that for every $n \in \mathbb{N}$ the set $\mathbb{R}^2 \setminus \Omega_n$ has a uniformly bounded number of connected components. In this particular case, we can establish a continuity result for the Dirichlet problem even if the constants are different on each connected component. Nevertheless, some of the results of this section are true without any restriction.

THEOREM 3.2. *If $\{\Omega_n\}_{n\in\mathbb{N}} \in \mathcal{O}_l(D)$ is such that $\Omega_n \xrightarrow{H^c} \Omega$, then for every ball B such that $\overline{B} \subseteq \Omega$ and for every $\gamma \in H^{\frac{1}{2}}(\partial B)$ such that $\int_{\partial B} \gamma d\sigma = 0$, we have*

$$\widetilde{\nabla v_{\Omega_n,\gamma}} \xrightarrow{L^2(D,\mathbb{R}^2)} \widetilde{\nabla v_{\Omega,\gamma}}.$$

Proof. The proof is divided into three steps. We use the duality argument to transform the Neumann problem into a Dirichlet problem, then use continuity results for the domain variation of a Dirichlet problem (such as, for example, a Šverák-type result adapted to different constants), and then return to the Neumann problem.

Step 1. *Passage from the Neumann problem to the Dirichlet problem.* For the existence of the conjugate function into a smooth domain with a finite number of (smooth) holes, we refer to [19, Theorem 3.1]. Since we do not impose any regularity of the boundary (besides the constraint on the number of connected components), we prove in what follows that if on the nonsmooth part of the boundary the normal derivative is zero in the weak sense given by the variational formulation, one can still use a duality argument and modify the result of [19] in order to find a conjugate function with a constant trace on the connected components of the complementary. The sense of the trace on a nonsmooth set is understood as the usual restriction of a quasi-continuous representative of an $H_0^1(D)$-function, this restriction being defined quasi-everywhere (q.e.). (See [20] for details concerning capacity.)

Let $\Omega \in \mathcal{O}_l(D)$ such that $\overline{B} \subseteq \Omega$ and denote by $K_1, \dots, K_l$ the connected components of its complement. Consider (3) on $\Omega \setminus \overline{B}$:

$$\begin{cases} -\Delta v_{\Omega,\gamma} = 0 & \text{in} \quad \Omega \setminus \overline{B}, \\ \frac{\partial v_{\Omega,\gamma}}{\partial n} = 0 & \text{on} \quad \partial\Omega, \\ \frac{\partial v_{\Omega,\gamma}}{\partial n} = \gamma & \text{on} \quad \partial B. \end{cases} \tag{11}$$

If Ω is not connected in every connected component which does not contain B, the solution is set to be 0.

LEMMA 3.3. *There exist a function $\phi \in H_0^1(D)$ and constants $c_1, \dots, c_l \in \mathbb{R}$ such that $\nabla v_{\Omega,g} = \operatorname{curl}\phi$ in $\Omega \setminus \overline{B}$ and*

$$\begin{cases} -\Delta\phi = 0 & \text{in} \quad \Omega \setminus \overline{B}, \\ \phi = c_i & \text{q.e. on} \quad K_i, \quad i = 1, \dots, l, \\ \phi = G & \text{on} \quad \partial B, \end{cases} \tag{12}$$

where $G \in H^{\frac{3}{2}}(\partial B)$ is such that $G' = \gamma$ in the sense of distribution on ∂B.

The equality $\phi = c_i$ q.e. on K_i means that the usual restriction (defined q.e.) of a quasi-continuous representative of ϕ in $H_0^1(D)$ is equal to c_i on K_i.

Proof. We suppose that for every $i = 1, \dots, l$, $diam(K_i) > 0$; if not, we simply ignore K_i since it has zero capacity. If $\partial\Omega$ were Lipschitz, then the result of this lemma would be a straightforward consequence of [19, Theorem 3.1]. Since no assumption on the regularity of the $\partial\Omega$ is made, we consider a sequence of smooth open sets $\{U_n\}_{n\in\mathbb{N}}$ such that $\sharp U_n^c \leq l$, $B(0, r+\delta) \subseteq U_n \subseteq U_{n+1} \subseteq \Omega$, and $\Omega = \bigcup_{n\in\mathbb{N}} U_n$. Let us denote by v_n the solution of the following problem:

$$\left\{\begin{array}{rcl} -\Delta v_n = 0 & \text{in} & U_n \setminus \overline{B}, \\ \frac{\partial v_n}{\partial n} = 0 & \text{on} & \partial U_n, \\ \frac{\partial v_n}{\partial n} = \gamma & \text{on} & \partial B. \end{array}\right. \tag{13}$$

Following [19], there exists a function $\phi_n \in H_0^1(D)$ (obtained by extension with zero on the infinite connected component of $\mathbb{R}^2 \setminus U_n$) such that $\nabla v_n = \mathrm{curl}\phi_n$ in $U_n \setminus \overline{B}$ and

$$\left\{\begin{array}{rcl} -\Delta \phi_n = 0 & \text{in} & U_n \setminus \overline{B}, \\ \phi_n = c_i^n & \text{on} & K_i^n, \quad i = 1, \dots, l, \\ \phi_n = G + c_n & \text{on} & \partial B. \end{array}\right. \tag{14}$$

Taking v_n as a test function in (13) and using the trace theorem and the Poincaré inequality in $H^1(B(0, r+\delta) \setminus \overline{B})$, there exists a constant C independent of n such that

$$\Big(\int_{U_n \setminus B} |\nabla v_n|^2 dx \Big)^{\frac{1}{2}} \leq C |\gamma|_{L^2(\partial B)}.$$

In the connected components of U_n not containing B we have $\nabla v_n = \nabla \phi_n = 0$. Hence $\nabla \phi_n$ is bounded in $L^2(D, \mathbb{R}^2)$. Since ϕ_n is defined up to a constant in each connected component of $U_n \setminus \overline{B}$, we choose the constants such that ϕ_n extended by these constants on each connected component of $\overline{D} \setminus (\Omega \setminus \overline{B})$ belongs to $H_0^1(D)$ (see [20]). These extended functions are denoted by the same symbols. The Poincaré inequality in $H_0^1(D)$ gives that the sequence $\{\phi_n\}_{n\in\mathbb{N}}$ is bounded in $H_0^1(D)$. There exists a function $\phi \in H_0^1(D)$ such that for a subsequence (still denoted with the same index) we can write

$$\nabla \phi_n \overset{L^2(D,\mathbb{R}^2)}{\rightharpoonup} \nabla \phi.$$

As a consequence of the H^c-convergence, property (8), we obtain that $-\Delta\phi = 0$ in $\Omega \setminus \overline{B}$, and by the Banach–Saks theorem we get that $\phi = c_i$ q.e. on K_i, $\phi = G + c$ on ∂B. These equalities hold, since $\{c_i^n\}_{n\in\mathbb{N}}$ is bounded and $cap(K_n^i)$ does not converge to zero (in fact we have $\liminf_{n\to\infty} cap(K_n^i) \geq cap(K) > 0$).

Let us prove that $\nabla v_{\Omega,\gamma} = \mathrm{curl}\phi$ in $\Omega \setminus \overline{B}$. It is sufficient to prove that

$$\widetilde{\nabla v_n} \overset{L^2(D,\mathbb{R}^2)}{\rightharpoonup} \widetilde{\nabla v_{\Omega,\gamma}}.$$

This comes back to proving that the Neumann problem is shape stable to increasing sequences of domains. For a subsequence (still denoted by the same index) we can write

$$\widetilde{\nabla v_n} \overset{L^2(D,\mathbb{R}^2)}{\rightharpoonup} (v_1, v_2).$$

Since U_n is increasing, we get $\partial_2 v_1 = \partial_1 v_2$ in $\Omega \setminus \overline{B}$, and by the De Rham theorem there exists $\bar{v} \in L^2_{loc}(\Omega \setminus \overline{B})$ such that $\nabla \bar{v} = (v_1, v_2)$; hence $\bar{v} \in L^{1,2}(\Omega \setminus \overline{B})$. Moreover, we have that $\bar{v}$ is a weak variational solution of (13) on $\Omega \setminus \overline{B}$ since

$$\begin{aligned}\frac{1}{2}\int_{\Omega\setminus\overline{B}} |\nabla \bar{v}|^2 dx - \int_{\partial B} \gamma \bar{v} d\sigma &\leq \liminf_{n\to\infty} \frac{1}{2}\int_{U_n\setminus\overline{B}} |\nabla v_n|^2 dx - \int_{\partial B} \gamma v_n d\sigma \\ &\leq \liminf_{n\to\infty} \frac{1}{2}\int_{U_n\setminus\overline{B}} |\nabla \xi|^2 dx - \int_{\partial B} \gamma \xi d\sigma \\ &= \frac{1}{2}\int_{\Omega\setminus\overline{B}} |\nabla \xi|^2 dx - \int_{\partial B} \gamma \xi d\sigma,\end{aligned}$$

where $\xi \in L^{1,2}(\Omega \setminus \overline{B})$ is an arbitrary element. Consequently, we get that $\bar{v} = v_{\Omega,\gamma}$. □

Step 2. *Continuity with respect to the domain variation for the associated Dirichlet problems.* We give without proofs two technical lemmas. The first one is an immediate consequence of [4, 7], while the second one can be proved using circular rearrangements (see [13]) and noticing that in one dimension the step functions are not in $H^{\frac{1}{2}}(\mathbb{R})$.

LEMMA 3.4. *Let $\{\phi_n\}_{n\in\mathbb{N}} \subseteq H^1_0(D)$, let $\{K_n\}_{n\in\mathbb{N}}$ be a sequence of compact connected sets in D, and let $\{c_n\}_{n\in\mathbb{N}}$ be a sequence of constants such that $\phi_n(x) = c_n$ q.e. on K_n. If*

$$K_n \xrightarrow{H} K \qquad \text{and} \qquad \phi_n \overset{H^1_0(D)}{\rightharpoonup} \phi,$$

there exists a constant $c \in \mathbb{R}$ such that $c_n \longrightarrow c$ and $\phi(x) = c$ q.e. on K.

LEMMA 3.5. *Let $\phi \in H^1_0(D)$ and let K_1, K_2 be two compact connected sets in D with positive diameter. If there exist two constants $c_1, c_2 \in \mathbb{R}$ such that $\phi(x) = c_1$ q.e. on K_1 and $\phi(x) = c_2$ q.e. on K_2, then $K_1 \cap K_2 = \emptyset$.*

Let us assume that $\{\Omega_n\}_{n\in\mathbb{N}}$ is a sequence satisfying the hypotheses of Theorem 3.2. As in the previous step, we denote by ϕ_n, ϕ the corresponding functions found by Lemma 3.3 applied to $v_{\Omega_n,\gamma}$ on Ω_n and $v_{\Omega,\gamma}$ on Ω, respectively. We denote the connected components of $\overline{D} \setminus \Omega_n$ by $K^n_1, \ldots, K^n_l$, some of them perhaps being empty.

LEMMA 3.6. *There exist a subsequence $\{\phi_{n_k}\}_{k\in\mathbb{N}}$ such that*

$$\phi_{n_k} \overset{H^1_0(D)}{\rightharpoonup} \phi$$

and a function $v \in L^{1,2}(\Omega \setminus \overline{B})$ such that $\operatorname{curl}\phi = \nabla v$ *in* $\Omega \setminus \overline{B}$.

Proof. Since the extension by constants of ϕ_n does not increase the norm of the gradient, and since we have $\int_{\Omega_n\setminus\overline{B}} |\nabla \phi_n|^2 dx = \int_{\Omega_n\setminus\overline{B}} |\nabla u_n|^2 dx$, we get that $\{\widetilde{\nabla\phi_n}\}_{n\in\mathbb{N}}$ is bounded in $L^2(D, \mathbb{R}^2)$. Hence for a subsequence we have

$$\phi_{n_k} \overset{H^1_0(D)}{\rightharpoonup} \phi.$$

From the Hausdorff convergence we get $-\Delta\phi = 0$ in $\Omega \setminus \overline{B}$.

Without losing the generality, we can suppose that for a subsequence (still denoted by the same index) and for all $i = 1, \ldots, l$ we have $K^{n_k}_i \xrightarrow{H} K_i$. Using Lemma 3.4 we also get $c_{n_k,i} \to c_i$ and $\phi = c_i$ q.e. on K_i. If there exist two compact sets with positive diameter K_{i_1} and K_{i_2} and nonempty intersection, then from Lemma 3.5 we get that $c_{i_1} = c_{i_2}$.

Since $\overline{D}\setminus\Omega = \cup_{i=1}^{l} K_i$ we get that ϕ is constant q.e. on every connected component of $\overline{D}\setminus\Omega$. Using property (7) of the H^c-convergence, there exists $v \in L^{1,2}(\Omega)$ such that

$$\widetilde{\nabla v_{\Omega_n,\gamma}} \overset{L^2(D,\mathbb{R}^2)}{\rightharpoonup} (v_1, v_2)$$

and $\nabla v = (v_1, v_2)$ in Ω. The relation $\nabla v_{\Omega_n,\gamma} = \mathrm{curl}\phi_n$ in Ω_n gives (again from property (7)) that $\nabla v = \mathrm{curl}\phi$ in $\Omega \setminus \overline{B}$. □

Step 3. *Passage from the Dirichlet problem to Neumann problem under the rotational hypothesis.* The result obtained in the previous step asserts that the weak limit ϕ is such that $-\Delta\phi = 0$ in $\Omega\setminus\overline{B}$ and ϕ is q.e. constant on each connected component of $\overline{D}\setminus\Omega$. In what follows we prove that ϕ has a conjugate; i.e., ϕ is exactly the function obtained by applying Lemma 3.3 to $v_{\Omega,\gamma}$ on $\Omega\setminus\overline{B}$.

LEMMA 3.7. *Let O be a smooth open connected set and K a compact connected set such that $K \subseteq O$. Let us denote by θ the capacitary potential of K in O, i.e., the function $\theta \in H_0^1(O)$ such that*

$$\begin{cases} -\Delta\theta = 0 & \text{in} \quad O\setminus K, \\ \theta = 0 & \text{on} \quad \partial O, \\ \theta = 1 & \text{q.e. on} \quad \partial K. \end{cases} \tag{15}$$

There does not exist a function $\xi \in L^{1,2}(O\setminus K)$ such that $\mathrm{curl}\theta = \nabla\xi$, *unless* $diam(K) = 0$.

Proof. Suppose $diam(K) > 0$. Since O is smooth and θ attains its minimum in all the points of ∂O, we get by the Hopf maximum principle that $\frac{\partial\theta}{\partial n} \neq 0$ in any point of ∂O. There exists a neighborhood of ∂O of the form $\{\theta \le c\}$ with $c > 0$ in which $|\nabla\theta| \neq 0$. Indeed, supposing that there exists x_n such that $\theta(x_n) = c_n \to 0$ and $\nabla\theta(x_n) = 0$, we have by compactness that for a subsequence (still denoted with the same index) $x_n \to x$; therefore, $\theta(x) = 0$, and hence $x \in \partial O$. On the other side, the gradient is also continuous up to the boundary, which yields $\nabla\theta(x) = 0$, contrary to the previous assertion.

Let us denote $U = \{x \in O : \theta(x) < c\}$. The open set U has a smooth boundary, $\partial O \cup \{\theta = c\}$. Computing

$$\int_U |\nabla\theta|^2 dx = \int_{\partial O\cup\{\theta=c\}} \theta\frac{\partial\theta}{\partial n} d\sigma - \int_U \theta\Delta\theta dx = \int_{\{\theta=c\}} \theta\frac{\partial\theta}{\partial n} d\sigma.$$

Using the hypothesis $\mathrm{curl}\theta = \nabla\xi$, we can write

$$\int_{\{\theta=c\}} \theta\frac{\partial\theta}{\partial n} d\sigma = \int_{\{\theta=c\}} c\frac{\partial\xi}{\partial t} d\sigma = 0.$$

Here $\frac{\partial\xi}{\partial t}$ denotes the tangential derivative of ξ to the smooth curve $\{\theta = c\}$. Therefore, we would get that θ vanishes on U, contrary to the maximum principle. □

LEMMA 3.8. *Let $\Omega \in \mathcal{O}_l(D)$ such that $\overline{B} \subseteq \Omega$. Suppose that there exist a function $\phi \in H_0^1(D)$ and a function $u \in L^{1,2}(\Omega\setminus\overline{B})$ such that $\nabla u = \mathrm{curl}\phi$ in $\Omega\setminus\overline{B}$ and*

$$\begin{cases} -\Delta\phi = 0 & \text{in} \quad \Omega\setminus\overline{B}, \\ \phi = c_i & \text{on} \quad K_i, \quad i = 1,\dots,l, \\ \phi = G + c & \text{on} \quad \partial B. \end{cases} \tag{16}$$

Then u is the weak solution of (11) *on $\Omega\setminus\overline{B}$.*

Proof. Since $u \in L^{1,2}(\Omega \setminus \overline{B})$ it suffices to prove that for any $\xi \in L^{1,2}(\Omega \setminus \overline{B})$ we have

$$\int_{\Omega\setminus\overline{B}} \nabla u \nabla \xi dx = \int_{\partial B} \gamma \xi d\sigma.$$

Considering smooth neighborhoods O_i of K_i, by an argument of partition of unity, it suffices to prove that for any function $\xi \in H^1(O_i \setminus K_i)$ vanishing q.e. on ∂O_i we have

$$\int_{O_i\setminus K_i} \nabla u \nabla \xi dx = 0.$$

It suffices actually to prove that u is a solution of the following problem on $O_i \setminus K_i$:

$$\left\{ \begin{array}{rcl} -\Delta u = 0 & \text{in} & O_i \setminus K_i, \\ \frac{\partial u}{\partial n} = 0 & \text{on} & \partial K_i, \\ \frac{\partial u}{\partial n} = \frac{\partial \phi}{\partial t} & \text{on} & \partial O_i. \end{array} \right. \tag{17}$$

To the solution u^* of this equation we associate the function ϕ^* given by Lemma 3.3. We have that $-\Delta\phi^* = 0$ in $O_i \setminus K_i$, $\phi^* = \phi$ on ∂O_i, $\phi^* = c^*$ on K_i. Denoting $\theta = \phi - \phi^*$, we get that $\nabla\theta = \text{curl}(u - u^*)$, $-\Delta\theta = 0$ in $O_i \setminus K_i$, $\theta = 0$ on ∂O_i, $\theta = c - c^*$ on K_i. Following Lemma 3.7, since $diam(K_i) > 0$, we get $c = c^*$, and hence $u = u^*$. □

Remark that Step 1 is in general true, without any assumption on the number of connected components. Indeed, when taking the approximating sequence $\{u_n\}_{n\in\mathbb{N}}$ of smooth functions, on each set U_n, [19, Theorem 3.1] can be applied. Step 2 fails to be true in general.

4. The general case $a \geq 0$. The following result establishes the relation between the shape stability of problems (1) and (3). This result is general and does not require any geometrical or topological constraints on Ω_n.

THEOREM 4.1. *Given a sequence of open sets $\{\Omega_n\}_{n\in\mathbb{N}}$ converging in the Hausdorff complementary topology to Ω, assertions* (A) *and* (B) *are equivalent:*

(A) *For every admissible h, we have*

$$(\tilde{u}_{\Omega_n,h}, \widetilde{\nabla u_{\Omega_n,h}}) \overset{L^2_a(D)\times L^2(D,\mathbb{R}^2)}{\longrightarrow} (\tilde{u}_{\Omega,h}, \widetilde{\nabla u_{\Omega,h}}).$$

(B) *The following three conditions hold:*

(B.1) *For every ball B such that $\overline{B} \subseteq \Omega$ and for every $\gamma \in H^{\frac{1}{2}}(\partial B)$ with $\int_{\partial B} \gamma d\sigma = 0$, we have*

$$\widetilde{\nabla v_{\Omega_n,\gamma}} \overset{L^2(D,\mathbb{R}^2)}{\longrightarrow} \widetilde{\nabla v_{\Omega,\gamma}}.$$

(B.2) *For every $u \in L^{1,2}_a(\Omega)$ such that $\nabla u = 0$, there exist*

$$u_n \in L^{1,2}_a(\Omega_n) \quad \text{such that} \quad (\tilde{u}_n, \widetilde{\nabla u_n}) \overset{L^2_a(D)\times L^2(D,\mathbb{R}^2)}{\longrightarrow} (\tilde{u}, 0).$$

(B.3) $|\Omega \cap \{a > 0\}| = \lim_{n\to\infty} |\Omega_n \cap \{a > 0\}|$.

When investigating the shape stability of (1), condition (B.1) is, in general, the difficult one. As seen in section 3, the duality argument can be applied successfully

in some particular situations. Condition (B.2) is easy to handle as soon as Ω is connected, and condition (B.3) is trivial to check in concrete examples.

Proof. (A) $\Rightarrow$ (B) For proving (B.1) it is enough to prove assertion 3 of Proposition 3.1. Take $u \in L^{1,2}(\Omega)$ and define for every $M > 0$

$$u_M := \min\{\max\{u^*, -M\}, M\},$$

where u^* is a representative of u in $\mathcal{L}^{1,2}(\Omega)$. Then u_M converges in $L^{1,2}(\Omega)$ to u when $M \to +\infty$ and, moreover, u_M belongs to $L^{1,2}_a(\Omega)$.

Let us denote

$$Y = \{u_{\Omega,h} : h \text{ admissible}\} \subseteq L^{1,2}_a(\Omega)$$

and prove that this set is dense in $L^{1,2}_a(\Omega)$. Suppose for contradiction that $u \in L^{1,2}_a(\Omega)$ is orthogonal on Y, i.e.,

$$\int_\Omega \nabla u \nabla u_{\Omega,h} + a u u_{\Omega,h} dx = 0.$$

Consequently

$$\int_\Omega u(af + g)dx = 0.$$

Taking $f = 0$, we get that u is constant on every connected component of Ω, and taking $g = 0$ we get that $au = 0$; hence $\int_\Omega |\nabla u|^2 + au^2 dx = 0$, i.e., $u \equiv 0$ in $L^{1,2}_a(\Omega)$. So, for every $M > 0$ and for every $\varepsilon > 0$ there exists $h_{M,\varepsilon}$ such that

$$\int_\Omega |\nabla u_{\Omega,h_{M,\varepsilon}} - \nabla u_M|^2 dx + \int_\Omega (u_{\Omega,h_{M,\varepsilon}} - u_M)^2 a(x) dx \le \varepsilon.$$

Since from hypothesis (A)

$$\int_D |\widetilde{\nabla u_{\Omega,h_{M,\varepsilon}}} - \widetilde{\nabla u_{\Omega_n,h_{M,\varepsilon}}}|^2 dx + \int_D (\tilde{u}_{\Omega,h_{M,\varepsilon}} - \tilde{u}_{\Omega_n,h_{M,\varepsilon}})^2 a(x) dx \to 0,$$

by a usual diagonal procedure we find a sequence of the form $\{(\tilde{u}_{\Omega_n,h_{M,\varepsilon_n}}, \widetilde{\nabla u_{\Omega_n,h_{M,\varepsilon_n}}})\}$ which converges in $L^2_a(D) \times L^2(D,\mathbb{R}^2)$ to $(\tilde{u}_M, \widetilde{\nabla u_M})$. We finish the proof by taking $M \to \infty$ and observing that for every open set U the injection $L^{1,2}_a(U) \hookrightarrow L^{1,2}(U)$ is a contraction.

To prove (B.2) let us consider $u \in L^{1,2}_a(\Omega)$ such that $\nabla u = 0$. Take $g = 0$ and $f = u$. Then $u = u_{\Omega,h}$, and hypothesis (A) gives the conclusion.

In order to prove (B.3) take $g = 0$ and $f = 1$. Then $u_{\Omega_n,h} = 1_{\Omega_n}$, and hypothesis (A) gives

$$\int_{\Omega_n} a dx \to \int_\Omega a dx. \tag{18}$$

From the H^c-convergence we have $1_\Omega \le \liminf_{n\to\infty} 1_{\Omega_n}$ a.e. in D, and hence

$$\liminf_{n\to\infty} 1_{\Omega_n \cap \{a>0\}} \ge 1_{\Omega \cap \{a>0\}}. \tag{19}$$

From (18) and (19) we get $1_{\Omega_n \cap \{a>0\}} \overset{L^1(D)}{\longrightarrow} 1_{\Omega \cap \{a>0\}}$; therefore (B.3) holds.

(B) $\Rightarrow$ (A) Assume in a first step that the set

$$Y = \{\phi \in L^{1,2}_a(\Omega) : \exists \phi_n \in L^{1,2}_a(\Omega_n) \text{ such that } (\tilde{\phi}_n, \widetilde{\nabla \phi_n}) \to (\tilde{\phi}, \widetilde{\nabla \phi}) \quad L^2_a(D) \times L^2(D, \mathbb{R}^2) - \text{strongly}\} \tag{20}$$

is dense in $L^{1,2}_a(\Omega)$. Then (A) follows straightforwardly. Indeed, by the boundedness of $\{(\tilde{u}_{\Omega_n,h}, \widetilde{\nabla u_{\Omega_n,h}})\}$ in $L^2_a(D) \times L^2(D, \mathbb{R}^2)$ there exists a subsequence (still denoted by the same index) such that

$$(\tilde{u}_{\Omega_n,h}, \widetilde{\nabla u_{\Omega_n,h}}) \rightharpoonup (u, u_1, u_2) \quad \text{in} \quad L^2_a(D) \times L^2(D, \mathbb{R}^2) - \text{weakly}. \tag{21}$$

From property (8) of the Hausdorff convergence and the De Rham theorem, we get that $\nabla u = (v_1, v_2)$ on Ω. Let us fix $\phi \in Y$. Writing the fact that $u_{\Omega_n,h}$ is a solution on Ω_n with ϕ_n as a test function (where ϕ_n is given by (20)) and passing to the limit for $n \to \infty$, by the usual pairing (weak, strong)-convergence we get

$$\int_D \langle (u_1, u_2), \widetilde{\nabla \phi} \rangle dx + \int_D u \tilde{\phi} a dx = \int_D h \tilde{\phi} dx.$$

Since $\widetilde{\nabla \phi}(x) = 0$ on $D \setminus \Omega$ and $\tilde{\phi} = 0$ on $D \setminus \Omega$, we have

$$\int_\Omega \nabla u \nabla \phi dx + \int_\Omega u \phi dx = \int_\Omega h \phi dx. \tag{22}$$

Because (22) holds for every $\phi \in Y$ and Y is dense in $L^{1,2}_a(\Omega)$, we get that $u|_\Omega = u_{\Omega,h}$ and $(u_1, u_2)|_\Omega = \nabla u_{\Omega,h}$. Taking $u_{\Omega_n,h}$ as a test function on Ω_n and passing to the limit for $n \to \infty$, we have

$$\int_{\Omega_n} |\nabla u_{\Omega_n,h}|^2 + a u^2_{\Omega_n,h} dx = \int_{\Omega_n} h u_{\Omega_n,h} dx = \int_D h \tilde{u}_{\Omega_n,h} dx \to \int_D h u dx. \tag{23}$$

We wrote in the previous equality $\int_D h u dx = \int_\Omega h u dx$. Indeed, $\int_D g u dx = \int_\Omega g u dx$ because supp $g \subseteq \Omega$, and $\int_D f u a dx = \int_\Omega f u a dx$ because $au = 0$ on $\Omega^c \cap \{a > 0\}$. The last inequality is a direct consequence of hypothesis (B.3). Since $u = u_{\Omega,h}$ on Ω, using relation (23) we get

$$|(u, u_1, u_2)|_{L^2_a(D) \times L^2(D,\mathbb{R}^2)} \geq |(\tilde{u}_{\Omega,h}, \widetilde{\nabla u_{\Omega,h}})|_{L^2_a(D) \times L^2(D,\mathbb{R}^2)}$$

$$= \lim_{n \to \infty} |(\tilde{u}_{\Omega_n,h}, \widetilde{\nabla u_{\Omega_n,h}})|_{L^2_a(D) \times L^2(D,\mathbb{R}^2)} \geq |(u, u_1, u_2)|_{L^2_a(D) \times L^2(D,\mathbb{R}^2)}.$$

Consequently, we get that $(u, u_1, u_2) = (\tilde{u}_{\Omega,h}, \widetilde{\nabla u_{\Omega,h}})$ and that convergence (21) is strong. The continuity $u_{\Omega_n,h} \to u_{\Omega,h}$ was proved for a subsequence, but since the limit is unique, it holds for the whole sequence.

To finish, let us prove that Y is dense in $L^{1,2}_a(\Omega)$. By linearity and a truncation argument, we can fix $\phi \in L^{1,2}_a(\Omega)$ such that $\phi \in L^\infty(\Omega)$ and $\phi = 0$ on $\Omega \setminus C$, where C is one connected component of Ω. From now on, we fix one representative of ϕ in $\mathcal{L}^{1,2}_a(\Omega)$. Following (B.1) there exists $u_n \in L^{1,2}(\Omega_n)$ such that

$$\widetilde{\nabla u_n} \overset{L^2(D,\mathbb{R}^2)}{\longrightarrow} \widetilde{\nabla \phi}.$$

Let us fix a ball B such that $\overline{B} \subseteq C$, and choosing the representative of u_n in $\mathcal{L}^{1,2}(\Omega_n)$ by adding a suitable constant, we can assume that $\int_B u_n dx = \int_B \phi dx$. Let M be a positive constant such that $\|\phi\|_\infty < M$ and define

$$u_n^M = \max\{\min\{u_n, M\}, -M\}.$$

We notice that $u_n^M \in L_a^{1,2}(\Omega_n)$ and

$$\widetilde{\nabla u_n^M} \overset{L^2(D,\mathbb{R}^2)}{\longrightarrow} \widetilde{\nabla \phi}.$$

Moreover, since $\{\tilde{u}_n^M\}_n$ is uniformly bounded in $L^\infty(D)$, we can write (for a subsequence)

$$\tilde{u}_{n_k}^M \overset{L^2(D)}{\longrightarrow} v,$$

where $\nabla v = \nabla \phi$ on Ω and $v = \phi$ on C. Using the Poincaré inequality on smooth open subsets compactly contained in C, we have that the convergence is strong in $L^2_{loc}(C)$.

Following (B.2), there exists $v_{n_k} \in L_a^{1,2}(\Omega_{n_k})$ such that

$$(\tilde{v}_{n_k}, \widetilde{\nabla v_{n_k}}) \overset{L_a^2(D)\times L^2(D,\mathbb{R}^2)}{\longrightarrow} (\tilde{v}_{|\Omega} - \tilde{\phi}, 0).$$

It is obvious that v_{n_k} can be chosen such that $\|v_{n_k}\|_\infty \leq 2M$. Let us define $\phi_{n_k} := u_{n_k}^M - v_{n_k} \in L_a^{1,2}(\Omega_{n_k})$. We have

$$\widetilde{\nabla \phi_{n_k}} \overset{L^2(D,\mathbb{R}^2)}{\longrightarrow} \widetilde{\nabla \phi}.$$

Let us prove that $\int_D a(\tilde{\phi}_{n_k} - \tilde{\phi})^2 dx \to 0$. First, we have

$$\int_\Omega a(\tilde{\phi}_{n_k} - \tilde{\phi})^2 dx \to 0$$

since on every compact set $\omega \subseteq \Omega$ we have that $\tilde{\phi}_{n_k} - \tilde{\phi}$ weakly converges to 0 in $L^2(\omega)$, the gradient converges to zero strongly, and the sequence is uniformly bounded in $L^\infty(D)$. Second,

$$\int_{D\setminus\Omega} a(\tilde{\phi}_{n_k} - \tilde{\phi})^2 dx \leq 4M^2 \int_{D\setminus\Omega} a 1_{\Omega_{n_k}} dx,$$

the last term converging to zero from (B.3).

Notice that we found a subsequence $\{\phi_{n_k}\}$ and not a sequence converging to ϕ. Suppose for contradiction that there does not exist a sequence $\{\phi_n\}$ strongly converging to ϕ. For a subsequence, we would have that the distance in $L_a^2(D) \times L^2(D,\mathbb{R}^2)$ from ϕ to $L_a^{1,2}(\Omega_{n_k})$ would be bounded below by a positive number. This is absurd since, using the same arguments, there exists a subsequence of this subsequence for which the property cannot hold. □

An immediate consequence of Theorems 4.1 and 3.2 is Theorem 1.1 announced in the introduction.

Proof of Theorem 1.1.

Necessity. Following Theorem 4.1, condition (B.3) holds.

Sufficiency. Let us prove that (B.1), (B.2), and (B.3) hold. Condition (B.1) is a consequence of Theorem 3.2, and condition (B.3) is assumed by hypothesis. One has

only to verify condition (B.2) of Theorem 4.1. If Ω is connected, this is trivial, since every function with zero gradient in Ω is constant, say $c1_\Omega$. Therefore, the sequence $c1_{\Omega_n}$ solves (B.2) using the hypothesis on the convergence of the measures in the region where a is positive. If Ω is not connected, then condition (B.2) is a consequence of the more involved geometric argument relating the Hausdorff convergence to the capacity. We recall this result from [6].

LEMMA 4.2. *If $\{\Omega_n\}_{n\in\mathbb{N}}$ is a sequence of simply connected open sets in D such that $\Omega_n \xrightarrow{H^c} \Omega_a \cup \Omega_b$, where $\Omega_a \cap \Omega_b = \emptyset$, then there exist a subsequence (still denoted by the same index) and two sequences of simply connected open sets $\{\Omega_n^a\}_{n\in\mathbb{N}}$, $\{\Omega_n^b\}_{n\in\mathbb{N}}$ such that $\Omega_n^a \cap \Omega_n^b = \emptyset$, $\Omega_n^a \cup \Omega_n^b \subseteq \Omega_n$, $cap(\Omega_n \setminus (\Omega_n^a \cup \Omega_n^b)) \to 0$, and $\Omega_n^a \xrightarrow{H^c} \Omega_a$, $\Omega_n^b \xrightarrow{H^c} \Omega_b$.*

Using this lemma, condition (B.2) can be proved using a partition of the unity and localizing around the boundary of $\partial\Omega$, as in [9]. □

5. Further remarks. In what follows we give a simple example showing the influence of the positivity of the function a on the shape stability of (1).

Example 5.1. Let

$$\Omega_n = (-1,1)\times(0,1) \setminus (-1,0] \times \left\{ \frac{k}{n} : k = 1, \dots, n-1 \right\}.$$

Note that $\Omega_n \xrightarrow{H^c} \Omega := (0,1)\times(0,1)$.

Take $a_1 = 1_{[0,1]^2}$. Then, following Theorem 1.1, shape stability holds for every admissible h. For example, if $h = 1_{[0,1]^2}$, then $u_{\Omega_n,h} = 1_{\Omega_n}$. Clearly, $u_{\Omega_n,h}$ converges in $L^2_{a_1}(D) \times L^2(D,\mathbb{R}^2)$ to $u_{\Omega,h}$. This can be directly verified, since $\widetilde{\nabla 1_{\Omega_n}} \equiv 0$ and $1_{\Omega_n}|_{\{a_1>0\}} \to 1_\Omega|_{\{a_1>0\}}$ strongly in $L^2(\{a_1 > 0\})$.

If $a_2 = 1_{[-1,1]\times[0,1]}$, then, for the same h,

$$u_{\Omega_n,h}(x,y) = \begin{cases} \frac{e^2}{2(1+e^2)}e^x + \frac{1}{2(1+e^2)}e^{-x} & \text{if } (x,y) \in \Omega_n \cap (-1,0]\times(0,1), \\ -\frac{1}{2(1+e^2)}e^x - \frac{e^2}{2(1+e^2)}e^{-x} + 1 & \text{if } (x,y) \in \Omega_n \cap [0,1)\times(0,1), \end{cases}$$

while $u_{\Omega,h} = 1_\Omega$. Clearly, $u_{\Omega_n,h}$ does not converge to $u_{\Omega,h}$.

Remark 5.2 (shape stability and Mosco convergence). In general, when investigating the shape continuity of the solution of some variational PDE, one has to refer to the Mosco convergence of the associated functional spaces. A general result relating the Mosco convergence of functional spaces and the convergence of minima of some functionals is contained in [1, Theorem 3.6.6]. We briefly recall the definitions of the Kuratowski limits and Mosco convergence.

Let X be a Hilbert space and let $\{G_n\}_{n\in\mathbb{N}}$ be a sequence of subsets of X. The weak upper and the strong lower limits in the sense of Kuratowski are defined as follows:

$$w - \limsup_{n\to\infty} G_n = \left\{ u \in X : \exists \{n_k\}_k, \exists u_{n_k} \in G_{n_k} \text{ such that } u_{n_k} \overset{w-X}{\rightharpoonup} u \right\},$$

$$s - \liminf_{n\to\infty} G_n = \left\{ u \in X : \exists u_n \in G_n \text{ such that } u_n \xrightarrow{s-X} u \right\}.$$

If $\{G_n\}_{n\in\mathbb{N}}$ are closed subspaces in X, it is said that G_n converges in the sense of Mosco to G if

(M_1) $G \subseteq s - \liminf_{n\to\infty} G_n$,
(M_2) $w - \limsup_{n\to\infty} G_n \subseteq G$.
Note that in general $s - \liminf_{n\to\infty} G_n \subseteq w - \limsup_{n\to\infty} G_n$. Therefore, if G_n converges in the sense of Mosco to G, then

$$s - \liminf_{n\to\infty} G_n = G = w - \limsup_{n\to\infty} G_n.$$

For our purpose, the space X is, following the embedding given by relations (5)–(6), $L^2_a(D) \times L^2(D, \mathbb{R}^2)$.

It can be easily proved that if $L^{1,2}_a(\Omega_n)$ converges in the sense of Mosco to $L^{1,2}_a(\Omega)$, then for every admissible h, $u_{\Omega_n,h}$ converges to $u_{\Omega,h}$. Moreover, if $a(x) > 0$ a.e. in D, it can be proved that if $\Omega_n \overset{H^c}{\to} \Omega$, then the Mosco convergence is *equivalent* to the shape stability of the solution for every admissible h; this was proved in [6] for $a \equiv 1$. We notice that if a vanishes on some regions, this equivalence fails. We may have shape stability without Mosco convergence. Indeed, in the example above it is enough to take, with $a_1 = 1_{[0,1]^2}$, the sequence of functions $u_n(x, y) = x$. The second Mosco condition is not satisfied, since the weak limit in $L^2_{a_1}(D) \times L^2(D, \mathbb{R}^2)$ of this sequence has a nonvanishing gradient on $D \setminus \Omega$. Although the second Mosco condition is not satisfied in general, we note that it is satisfied for every sequence of solutions.

The first Mosco condition, i.e., every function $u \in L^{1,2}_a(\Omega)$ is a strong limit (in the sense of extensions) of a sequence of functions of $L^{1,2}_a(\Omega_n)$, is implicitly present in Proposition 3.1, condition 3 and in the proof of Theorem 4.1. In concrete situations, this condition is the one that is difficult to handle. If Ω would have a smooth boundary, then the restrictions to Ω_n of any extension of u would straightforwardly give (M_1). However, in general we deal with nonsmooth sets and u might not possess an extension in $L^{1,2}(D)$. If Ω has a crack, the "traces" of the function may be different on each side of the crack.

Remark 5.3. Theorem 1.1 remains valid if the operator $-\Delta$ in (1) is replaced by a general operator A in the divergence form

$$Au = -\sum_{i,j=1}^{2} \frac{\partial}{\partial x_i}\Big(a_{ij}(x)\frac{\partial}{\partial x_j}u\Big),$$

with $(a_{ij}) \in L^\infty(D, \mathbb{R}^4)$, uniformly elliptic.

Of course, the duality argument is no longer valid for this operator; for proving Theorem 1.1 one can use assertion 3 of Proposition 3.1.

For other approaches of the shape stability of (1), through homogenization or relaxation techniques, we refer the reader to [3, 16, 17, 21, 22] and [11], respectively. The notion of weak connected domains of [21], even if it does not appear explicitly here, is strongly related through Lemma 4.2 to the convergence in the sense of Kuratowski of the families of locally constant functions. The general relaxed form of (1) is not known.

Largely studied in the literature is also the continuity with respect to the domain variation of the solution of an elliptic problem with homogeneous Dirichlet boundary conditions (in (1) the Neumann condition is replaced by $u = 0$ on $\partial\Omega$). The complete relaxation result for this problem was obtained in [15]. In a certain way, the study of the shape continuity for Dirichlet problems is easier, mainly because the H^1_0-Sobolev spaces enjoy a very natural extension property, but also because many results of potential theory relating the oscillations of harmonic functions on the boundary to the Wiener criterion can be applied.

Another interesting question is to find whether the spectrum of the Neumann–Laplacian is stable for perturbations of the geometric domain. As shown in the classical example of Courant and Hilbert [12], the spectrum is not stable in the case when a fixed square is perturbed by a small square connected by a channel. Consequently, the resolvent operators do not converge in the operator norm topology, but following Theorem 1.1 they converge strongly.

NONLINEAR STABILITY IN L^p FOR A CONFINED SYSTEM OF CHARGED PARTICLES*

MARÍA J. CÁCERES†, JOSÉ A. CARRILLO†, AND JEAN DOLBEAULT‡

Abstract. We prove the nonlinear stability in L^p, with $1 \le p \le 2$, of particular steady solutions of the Vlasov–Poisson system for charged particles in the whole space $\mathbb{R}^6$. Our main tool is a functional associated to the relative entropy or Casimir-energy functional.

Key words. kinetic equations, Vlasov–Poisson system, nonlinear stability, relative entropy, Csiszár–Kullback inequality, interpolation inequalities

1. Introduction.

We consider a gas of charged particles described by a distribution function $f(t,x,v) \ge 0$ which represents the probability density of particles at position x with velocity v at time t. The evolution of f is governed by the Liouville evolution equation

$$\frac{\partial f}{\partial t} + v \cdot \nabla_x f + F(t,x) \cdot \nabla_v f = 0 \tag{1.1}$$

in $\mathbb{R}_0^+ \times \mathbb{R}^3 \times \mathbb{R}^3$, where the electric field $F(t,x)$ is given by an external potential ϕ_e and by a mean field potential ϕ according to

$$F(t,x) \;=\; -q\left(\nabla_x \phi(t,x) + \nabla_x \phi_e(x)\right) . \tag{1.2}$$

The electrostatic potential $\phi \ge 0$ is self-consistently computed by

$$\phi = K * \rho(f) \tag{1.3}$$

with $K = \frac{q}{4\pi\epsilon_0}|x|^{-1}$, where $\rho(f)$ is the spatial density of particles, which is defined by

$$\rho(f)(t,x) \;=\; \int_{\mathbb{R}^3} f(t,x,v)\; dv\ .$$

As usual, ϵ_0 and q are, respectively, the permittivity of the vacuum and the elementary charge of the particles that, in what follows, we assume to be unity without loss of generality. We shall consider the initial value problem corresponding to

$$f(0,x,v) \;=\; f_0(x,v) \ge 0\ . \tag{1.4}$$

This system is called the *Vlasov–Poisson system for charged particles*. The main feature we add to standard versions of the Vlasov–Poisson system is an external

potential that confines particles and allows the existence of steady states. For this reason, we will refer to $\phi_e(x)$ as a *confinement potential*.

The aim of this paper is to establish the nonlinear stability of special stationary solutions in $L^p(\mathbb{R}^6)$ with $p \in [1,2]$ and explicit constants, at least in some cases (see section 3). For this purpose, we shall use an entropy, which is also called Casimir-energy, free energy, relative entropy, or Lyapunov functional in the literature. The stationary solution is a minimizer, under constraints, of the entropy; or, reciprocally, the entropy functional is determined by the shape in energy of the stationary solution. Our first main result corresponds to a p which is fixed by the entropy.

THEOREM 1.1. *Let ϕ_e be a bounded-from-below function on $\mathbb{R}^3$ with $\phi_e(x) \to \infty$ as $|x| \to +\infty$ such that $(x,s) \mapsto s^{3/2-1}\gamma(s+\phi_e(x))$ belongs to $L^1 \cap L^\infty(\mathbb{R}^3, L^1(\mathbb{R}))$. Here γ is the inverse of $-\sigma'$, eventually extended by 0, where σ is a bounded-from-below and strictly convex function of class C^2.*

Let f be a weak solution of the Vlasov–Poisson system corresponding to a nonnegative initial data f_0 in $L^1 \cap L^{p_0}$, $p_0 = (12+3\sqrt{5})/11$, such that $\sigma(f_0)$ and $(|\phi_e|+|v|^2)f_0$ belong to $L^1(\mathbb{R}^6)$. If $\inf_{s\in(0,+\infty)} \sigma''(s)/s^{p-2} > 0$ for some $p \in [1,2]$, then there exists an explicit constant $C > 0$, which depends only on f_0, such that for any $t > 0$, $f = f(t)$ satisfies

$$\|f-f_\infty\|_{L^p}^2 \le C \int_{\mathbb{R}^6} [\sigma(f_0)-\sigma(f_\infty)-\sigma'(f_\infty)(f_0-f_\infty)]\, d(x,v) + \frac{1}{2}\int_{\mathbb{R}^3} |\nabla(\phi_0-\phi_\infty)|^2\, dx\,,$$

where $\big(f_\infty(x,v) = \gamma(\frac{1}{2}|v|^2 + \phi_e(x) + \phi_\infty(x)), \phi_\infty\big)$ is a stationary solution of the Vlasov–Poisson system and ϕ_0 is given by (1.3) *at $t = 0$.*

The value of p_0 arises from the paper [34] by Hörst and Hunze in order to define weak solutions (see section 2 for more details). Note that some of our results can be extended to weaker notions of solutions, like the renormalized solutions introduced by DiPerna and Lions in [26], as we shall see later.

Also, let us point out that assumptions over σ in Theorem 1.1 can be translated into assumptions over γ if needed. We remark that our stationary states are obtained as minimizers of entropy functionals; thus hypotheses over σ are more natural.

Our second main result is a stability result in L^2, which can be written as follows in the case of Maxwellian stationary solutions.

THEOREM 1.2. *Under the same assumptions as in Theorem* 1.1*, except that we assume now $p_0 = 2$ and $\sigma(s) = s\log s - s$, there exists a convex functional $\mathcal{F}$ reaching its minimum at $f = f_\infty$ such that any weak solution to* (1.1)–(1.4) *satisfies*

$$\|f(t,\cdot) - f_\infty\|_{L^2}^2 \le \mathcal{F}[f_0]\,.$$

With the notation of Theorem 1.1, $p = 1$, $\gamma(s) = e^{-s}$, and (f_∞, ϕ_∞) is given by $f_\infty(x,v) = \frac{e^{-|v|^2/2}}{(2\pi)^{3/2}}\,\rho_\infty(x)$ with $-\Delta\phi_\infty = \rho_\infty = \|f_0\|_{L^1}\frac{e^{-(\phi_\infty+\phi_e)}}{\int e^{-(\phi_\infty+\phi_e)}\,dx}$. More general statements will be given in the rest of the paper.

Theorem 1.1 is based on a somehow canonical method to relate entropies and special stationary solutions, at least for $p = 1$ or $p = 2$. Here we get an L^p-nonlinear stability result, $1 \le p \le 2$, for a whole family of stationary solutions. It is also possible to take advantage of the uniform boundedness of the stationary solution to introduce new possible choices of the entropy functional and get stability results in L^q with $q \ne p$: for instance, $q = 2$ and $p = 1$ in Theorem 1.2. Note that Theorem 1.2 provides an L^2-stability result for the Maxwellian stationary solutions, which is not included in Theorem 1.1 (see section 4).

Similar ideas have been used previously in various contexts: for gravitational systems (without confinement) in [42, 44, 30, 31, 32] using the Casimir-energy method, and for systems in bounded domains in [6, 7], using entropy fluxes involving Darrozès–Guiraud-type estimates. For confinement, we shall refer to [27] and also to [11, 24, 10] in the case of models with a Fokker–Planck term. Entropy methods have recently been adapted to nonlinear diffusions: see, for instance, [2] in the linear case and [13, 14, 20, 21, 39, 23, 22] in the nonlinear case, with applications to models where a Poisson coupling is involved [2, 8, 9] (also see references therein for earlier works). The estimates of Csiszár–Kullback type are indeed exactly the same in kinetic and parabolic frameworks.

In the electrostatic case of the Vlasov–Poisson system, the most relevant reference for our paper is [12] (also see [4, 5, 29] for earlier results in plasma physics). In [12], Braasch, Rein, and Vukadinović consider compactly supported classical solutions to the Cauchy problem and stationary solutions which are compactly supported in the energy variable and depending on additional invariants of the particle motion. The scope of our paper is to extend their approach to general weak solutions and to emphasize the interplay of the regularity of the initial data and the various possible functionals and norms. We improve and complement results in [12] in several ways. We generalize stationary states in two directions: (1) We allow them to be not compactly supported in energy variable (Maxwellian stationary states), and (2) the dependence on energy and on other invariants of motion includes states which have not been factorized (see section 6 for details). Theorems 1.1 and 1.2 are valid for either weak or renormalized solutions (see below for details). And finally, we obtain stability bounds in L^q spaces $1 \le q \le 2$ (while in [12] only for $q = 2$).

We are going to work in the framework of weak [34, 36] or renormalized [26, 38] solutions, which of course contains the case of classical solutions. As we shall see below, there is a natural class of stationary solutions and L^p norms with respect to which the stability can be studied, but we will also consider other L^q norms. For instance, Maxwellian steady states are known to be asymptotically stable in $L^1(\mathbb{R}^6)$ for the Vlasov–Poisson–Fokker–Planck (VPFP) system [11, 10, 27, 24]. It turns out that they are stable for the Vlasov–Poisson system, in L^1 of course, but also in other norms. This question initially motivated our study and has been used to extend [12] (see Theorem 1.2).

This paper is organized as follows. We start our discussion with an overview of the definitions and properties of the solutions to the Vlasov–Poisson system. We also introduce in section 2 the family of stationary solutions we are dealing with and some of their properties. Section 3 contains the proof of a generalized version of Theorem 1.1. Theorem 1.2 is proved in section 4. In section 5, we establish some relations among various nonlinear stability results and generalize Theorem 1.2. Finally, in section 6 we consider more general steady states depending on additional invariants, for which we prove an extension of Theorem 1.2.

2. Notions of solution and stationary solutions.

2.1. Weak and renormalized solutions to the Cauchy problem. A *classical solution* [41, 43, 33, 28] is a solution to the Cauchy problem (1.1)–(1.4) for which the derivatives hold in the classical sense and the force term F satisfies a Lipschitz condition. Our approach applies to weaker notions of solutions. By *weak solution* [3, 34, 36], we mean a solution in the distributional sense, for which the force field F is not smooth enough to apply the classical characteristics theory (see below for a precise definition). Essentially, we are going to use the framework of *weak solutions* ($\mathcal{W}$)

of Hörst and Hunze [34] and, as a special case, that of Lions and Perthame [36], for which further interpolations identities are available. These last solutions are sometimes called *strong solutions* [40], and we shall denote them by $(\mathcal{S})$. For solutions corresponding to initial data with very low regularity, we shall use the *renormalized solutions* $(\mathcal{R})$ of DiPerna and Lions [26, 38].

Before making these notions of solution precise, let us introduce some notation and a basic hypothesis on the initial data. We shall refer to the Cauchy problem for the Vlasov–Poisson system with initial data f_0 as the *initial value problem* (1.1)–(1.4). We assume

(H1) $\qquad f_0$ *is a nonnegative function in* $L^1(\mathbb{R}^6)$

and denote by $M := \|f_0\|_{L^1}$ its *mass*. Let ϕ_0 be the solution to the Poisson equation at $t = 0$, corresponding to $f = f_0$ in (1.3).

Throughout this paper, we consider global in time solutions: $\mathbb{R}_0^+ = [0, \infty)$ is the time interval. As a preliminary step, we can state the following result (see the appendix for a proof).

PROPOSITION 2.1. *For any nonnegative function* f_0 *in* $L^1(\mathbb{R}^6)$*, there exists a nonnegative strictly convex function* σ *such that* $\lim_{s\to+\infty} \sigma(s)/s = +\infty$ *and* $\sigma(f_0) \in L^1(\mathbb{R}^6)$.

To obtain stability results, we are going to impose further constraints on σ, which will be strongly related to the choice of the entropy or to the choice of a special stationary solution. However, we first have to define a precise notion of solution.

DEFINITION 2.2. *Let* $p \in [1, \infty]$. *A function* $f \in L^\infty(\mathbb{R}_0^+, L^p(\mathbb{R}^6))$ *is a global* weak solution *of* (1.1)–(1.4) *with initial data* f_0 *if and only if the following hold:*

1. f *is continuous on* $\mathbb{R}_0^+$ *with values in* $L^s(\mathbb{R}^6)$*, where* $s \in [1, p)$ *(*$s = 1$ *if* $p = 1$*), with respect to the* $\sigma(L^p, L^{p'})$ *topology (weak topology for* $p < \infty$ *and weak* $*$ *topology for* $p = \infty$*). Here* p *and* p' *are the Hölder conjugates.*
2. $f(0, \cdot) = f_0$.
3. *The function* $(x, v) \mapsto f(t, x, v)F(t, x)$ *is locally integrable over* $\mathbb{R}^6$ *for all* $t \geq 0$*. (Since* $f(t) \in L^1(\mathbb{R}^6)$ *for any fixed* t*,* $F(t, \cdot)$ *is defined almost everywhere on* $\mathbb{R}^3$ *and is locally integrable.)*
4. *For all test functions* $\chi \in {C_c}^1(\mathbb{R}^6)$*, the function* $\varrho(t) := \int \chi(x, v) f(t, x, v)\, d(x, v)$ *is continuously differentiable on* $\mathbb{R}_0^+$ *and*

$$\varrho'(t) = \int v \cdot \nabla_x \chi(x, v)\, f(t, x, v)\, d(x, v) + \int F(t, x) \cdot \nabla_v \chi(x, v)\, f(t, x, v)\, d(x, v)\,.$$

Note that a weak solution for $p > 1$ is a weak solution for all $q \in [1, p]$. According to Hörst and Hunze [34], such *weak solutions* exist in the case $\phi_e \equiv 0$ globally in time if we assume that f_0 satisfies

$(\mathcal{W})$ $f_0 \geq 0$, $f_0 \in L^1(\mathbb{R}^6) \cap L^p(\mathbb{R}^6)$, $p \geq p_0 = (12 + 3\sqrt{5})/11 = 1.70075\ldots$, and

$$\int_{\mathbb{R}^6} \Big(|v|^2 + \phi_e(x)\Big) f_0(x, v)\, d(x, v) < \infty\,.$$

We shall also consider the subcase of the so-called *strong solutions* of Lions and Perthame [36]:

$(\mathcal{S})$ $f_0 \geq 0$, $f_0 \in L^1(\mathbb{R}^6) \cap L^\infty(\mathbb{R}^6)$, and for some $m > 3$,

$$\int_{\mathbb{R}^6} \Big(|v|^m + \phi_e(x)\Big) f_0(x, v)\, d(x, v) < \infty\,.$$

Remark 2.3. In case $(\mathcal{W})$, $\nabla\phi_0 \in L^2(\mathbb{R}^3)^3$ [34] as a consequence of the interpolation inequality, $\|\rho\|_{L^q} \le C\,\|f\|_{L^p}^{\theta}\,\|\,|v|^2 f\|_{L^1}^{1-\theta}$ with $q = \frac{5p-3}{3p-1}$, $\theta \in (0,1)$; and of the Hardy–Littlewood–Sobolev inequality, $\|\nabla\phi\|_{L^r} \le C\,\|\rho\|_{L^q}$ with $\frac{1}{q} - \frac{1}{r} = \frac{1}{3}$. The case $p = p_0$ is obtained by imposing $r = p'$.

Without assumptions on the initial energy, it is still possible to give global existence results [15, 16]. Also note that if $(\mathcal{W})$ is satisfied, $f_0 \log f_0 \in L^1(\mathbb{R}^6)$, as we shall see in section 4, provided $e^{-\beta\,\phi_e} \in L^1(\mathbb{R}^3)$ for some $\beta > 0$.

In this paper, we will also consider weaker notions of solutions.

DEFINITION 2.4. *Assume that*

$(\mathcal{R})$ *f_0 is a nonnegative function in $L^1(\mathbb{R}^6)$ such that $f_0 \log f_0 \in L^1(\mathbb{R}^6)$ and*

$$\int_{\mathbb{R}^6} \Big(\frac{1}{2}|v|^2 + \phi_e(x)\Big) f_0(x,v)\; d(x,v) + \frac{1}{2}\int_{\mathbb{R}^3} |\nabla_x \phi_0|^2\; dx < \infty\;.$$

We shall say that $f \in C^0(\mathbb{R}_0^+, L^1(\mathbb{R}^6))$ is a renormalized solution *of* (1.1)–(1.4) *on $\mathbb{R}_0^+$ with initial data f_0 if and only if*

1. *the quantities*

$$\int_{\mathbb{R}^6} \Big(\frac{1}{2}|v|^2 + \phi_e(x) + \phi(x,t)\Big)\, f(t,x,v)\; d(x,v)$$
$$\text{and}\ \int_{\mathbb{R}^6} f(t,x,v)\,\log f(t,x,v)\; d(x,v)$$

   are bounded from above, uniformly in $t \ge 0$;

2. *$\beta(f) = \log(1+f)$ is a weak solution of*

$$\frac{\partial}{\partial t}\beta(f) + v\cdot\nabla_x\beta(f) + F(t,x)\cdot\nabla_v\beta(f) = 0$$

   considered in the distributional sense, where F is defined according to (1.2) *and* (1.3).

In the case in which $e^{-\beta\,\phi_e} \in L^1(\mathbb{R}^3)$ for some $\beta > 0$, weak solutions for $p > 1$ are also renormalized solutions (see Lemma 4.1).

PROPOSITION 2.5. *Let f_0 verify $(\mathcal{R})$ and assume that ϕ_e is a nonnegative potential such that $\lim_{|x|\to+\infty} \phi_e(x) = +\infty$. If ϕ_e is in $W^{1,1}_{loc}(\mathbb{R}^3)$, then* (1.1)–(1.4) *admits a global in time renormalized solution. If, moreover, ϕ_e belongs to $W^{1,q}_{loc}$ for $q \ge \frac{5p-3}{2(p-1)}$ and if $(\mathcal{W})$ holds, then* (1.1)–(1.4) *admits a weak solution.*

Proof. This result can be obtained by adapting the proofs of [34, 36, 26, 38]. For renormalized solutions, characteristics can be defined according to [25, 35] as soon as ϕ_e is in $W^{1,1}_{loc}(\mathbb{R}^3)$. Details are left to the reader. □

Weak or renormalized solutions have the following properties:

1. The distribution function is nonnegative for all $t \ge 0$.
2. Conservation of mass: for any $t \ge 0$,

$$\int_{\mathbb{R}^6} f(t,x,v)\; d(x,v) \;=\; \int_{\mathbb{R}^6} f_0(x,v)\; d(x,v) \;=\; M\;.$$

3. Finite kinetic energy, potential energy, and entropy: for any $t \ge 0$,

$$\int_{\mathbb{R}^6} \left(\frac{1}{2}|v|^2 + \phi_e(x) + \phi(x)\right) f\; d(x,v) \le \int_{\mathbb{R}^6} \left(\frac{1}{2}|v|^2 + \phi_e(x) + \phi_0(x)\right) f_0\; d(x,v)$$
$$\text{and}\quad \int_{\mathbb{R}^6} f\,\log f\; d(x,v) \le \int_{\mathbb{R}^6} f_0\,\log f_0\; d(x,v)\;,$$

with equality in the case of classical solutions (see Corollary 2.8 for an application).

4. In case $(\mathcal{S})$, for any $t \geq 0$,

$$\|f(t,\cdot)\|_{L^\infty(\mathbb{R}^6)} \leq \|f_0\|_{L^\infty(\mathbb{R}^6)} .$$

5. Moreover, if we assume that

$$\int_{\mathbb{R}^6} \sigma(f_0)\ d(x,v) < \infty \tag{H2}$$

for some strictly convex continuous function $\sigma : \mathbb{R}_0^+ \to \mathbb{R}$, then for any $t \geq 0$,

$$\int_{\mathbb{R}^6} \sigma(f)\ d(x,v)\ \leq\ \int_{\mathbb{R}^6} \sigma(f_0)\ d(x,v)\ ,$$

with equality in the case of classical solutions (see Corollary 2.8 for an application).

2.2. Stationary solutions and entropy functionals. Let us introduce further notation. For any function $f \in L^1(\mathbb{R}^6)$, let $\phi = \phi[f]$ be the solution of $-\Delta\phi = \int_{\mathbb{R}^3} f\ dv$ in $L^{3,\infty}(\mathbb{R}^3)$ given by the convolution with the Green function of the Laplacian. The operator ϕ is linear and satisfies

$$\int_{\mathbb{R}^6} f\,\phi[g]\ d(x,v) = \int_{\mathbb{R}^6} g\,\phi[f]\ d(x,v)\ .$$

Any function $f_{\infty,\sigma}$ such that

$$f_{\infty,\sigma}(x,v) = \gamma\left(\frac{1}{2}|v|^2 + \phi[f_{\infty,\sigma}](x) + \phi_e(x) - \alpha\right) \tag{2.1}$$

is a stationary solution of the Vlasov–Poisson system. Such a solution exists if and only if

$$-\Delta\phi_{\infty,\sigma} = G_\sigma(\phi_{\infty,\sigma} + \phi_e - \alpha) \quad \text{with} \quad G_\sigma(\phi) = 4\pi\sqrt{2}\int_0^{+\infty} \sqrt{s}\ \gamma(s+\phi)\ ds$$

has a solution $\phi_{\infty,\sigma} = \phi[f_{\infty,\sigma}]$ such that $\int_{\mathbb{R}^6} f_{\infty,\sigma}\ d(x,v) = M$. The constant α is therefore determined by the total mass M. Under assumptions that we are going to specify now, we will prove that such a stationary solution exists and is unique (see Lemma 2.7).

Let us consider σ such that γ is the generalized inverse of $-\sigma'$ (eventually extended by 0): σ is convex (resp., strictly convex) if and only if γ is monotone nonincreasing (resp., decreasing in its support). With these notations, we assume that σ and ϕ_e verify the following:

(H3) $\sigma \in C^2(\mathbb{R}^+) \cap C^0(\mathbb{R}_0^+)$ *is a bounded-from-below strictly convex function such that*

$$\lim_{s\to+\infty} \frac{\sigma(s)}{s} = +\infty\ ;$$

(H4) $\phi_e : \mathbb{R}^3 \to \mathbb{R}$ *is a measurable bounded-from-below function such that*

$$\lim_{|x|\to+\infty} \phi_e(x) = +\infty$$

and $x \mapsto G_\sigma(\phi_e(x)) = 4\pi\sqrt{2}\int_0^{+\infty} \sqrt{s}\ \gamma(s+\phi_e(x))\ ds$ *belongs to* $L^1 \cap L^\infty(\mathbb{R}^3)$.

The conditions on the growth of ϕ_e and on the decay of γ will be referred to as *confinement conditions*. We are going to adapt the proofs given in [27] for the case $\gamma(s) = e^{-s}$ and in [6, 7] for the bounded domain case to prove the existence of a stationary solution $f_{\infty,\sigma}$. The existence of $\alpha = \alpha(M)$ will be a consequence of the proof.

Let $M > 0$ and consider on $L^1_M(\mathbb{R}^6) = \{f \in L^1(\mathbb{R}^6) \ : \ f \geq 0 \text{ a.e., } \|f\|_{L^1} = M\}$ the functional

$$K_\sigma[f] = \int_{\mathbb{R}^6} \left[\sigma(f) + \left(\frac{1}{2}|v|^2 + \phi_e(x) \right) f \right] \, d(x,v) + \frac{1}{2} \int_{\mathbb{R}^3} |\, \nabla\phi[f]\,|^2 \, dx \, .$$

DEFINITION 2.6. *Given f and g in $L^1_M(\mathbb{R}^6)$, the relative entropy of f with respect to g is*

$$\Sigma_\sigma[f|g] := \int_{\mathbb{R}^6} [\sigma(f) - \sigma(g) - \sigma'(g)(f-g)]\, d(x,v) + \frac{1}{2} \int_{\mathbb{R}^3} |\nabla\phi[f-g]|^2 \, dx \tag{2.2}$$

LEMMA 2.7. *Under assumptions* (H3)–(H4)*, K_σ is a strictly convex bounded-from-below functional on $L^1_M(\mathbb{R}^6)$. It has a unique global minimum, $f_{\infty,\sigma}$, which takes the form* (2.1) *and is therefore a stationary solution of the Vlasov–Poisson system. Moreover $\Sigma_\sigma[f|f_{\infty,\sigma}]$ can be written as*

$$\Sigma_\sigma[f|f_{\infty,\sigma}] = K_\sigma[f] - K_\sigma[f_{\infty,\sigma}] \, . \tag{2.3}$$

and $\sigma(f_{\infty,\sigma})$ and $\sigma'(f_{\infty,\sigma})f_{\infty,\sigma}$ belong to $L^1(\mathbb{R}^6)$.

Proof. Assumption (H4) gives that $K_\sigma[f]$ is bounded from below by Jensen's inequality. By hypothesis (H3) K_σ is convex, so we may pass to the limit in a minimizing sequence involving the semicontinuity property. The limit $f_{\infty,\sigma}$ belongs to $L^1_M(\mathbb{R}^6)$ because of the Dunford–Pettis criterion. Equation (2.1) is the corresponding Euler–Lagrange (where α enters as the Lagrange multiplier associated to the constraint on the L^1 norm). Identity (2.2) easily follows by a direct computation using (2.1). ∎

Note that $\Sigma_\sigma[f|f_{\infty,\sigma}]$ is obviously nonnegative, since $K_\sigma[f]$ attains its unique minimum at $f = f_{\infty,\sigma}$.

COROLLARY 2.8. *Consider a renormalized or weak solution f of* (1.1)–(1.4) *under assumptions* (H1), (H2), (H3), *and* (H4). *Then $\Sigma_\sigma[f(t)|f_{\infty,\sigma}] \leq \Sigma_\sigma[f_0|f_{\infty,\sigma}]$.*

The proof relies on standard semicontinuity arguments and is left to the reader.

Example 2.9. (1) Let $\sigma_q(s) = s^q$, with $\gamma_q(s) = (-s/q)_+^{1/(q-1)}$, for some given $q > 1$. With the notation $f_{\infty,q} = f_{\infty,\sigma_q}$ and $\phi_{\infty,q} = \phi[f_{\infty,\sigma_q}]$, this stationary solution satisfies the nonlinear Poisson equation

$$-\Delta\phi_{\infty,q} = C_q \, (\alpha(M) - \phi_e - \phi_{\infty,q})_+^{\frac{3}{2} + \frac{1}{q-1}} \ ,$$

where $C_q = (2\pi)^{3/2} \, q^{-\frac{1}{q-1}} \, \Gamma(\frac{q}{q-1})/\Gamma(\frac{5q-3}{2(q-1)})$.

(2) The limit case as $q \to 1$ corresponds to $\sigma_1(s) = s\log s - s$ and $\gamma_1(s) = e^{-s}$. In this case we obtain the Maxwellian stationary solution

$$f_{\infty,1}(x,v) \ = \ m(x,v) \ = \ M \, \frac{e^{-\frac{1}{2}|v|^2}}{(2\pi)^{3/2}} \, \frac{e^{-(\phi_{\infty,1}(x)+\phi_e(x))}}{\int_{\mathbb{R}^3} e^{-(\phi_{\infty,1}(x)+\phi_e(x))} \, dx} \, , \tag{2.4}$$

where $\phi_{\infty,1}$ is given by the Poisson–Boltzmann equation

$$-\Delta_x \phi_{\infty,1} \ = \ \int_{\mathbb{R}^3} m(x,v) \, dv \ = \ M \, \frac{e^{-(\phi_{\infty,1}+\phi_e)}}{\int_{\mathbb{R}^3} e^{-(\phi_{\infty,1}+\phi_e)} \, dx} \, . \tag{2.5}$$

(3) A less standard case is given by

$$\sigma(t) = \begin{cases} 2\int_1^{\sqrt{-\log t}} s^2 e^{-s^2}\ ds & \text{if } 0 < t \le 1\ , \\ 0 & \text{if } t > 1\ , \end{cases}$$

which corresponds to $\gamma(t) = e^{-t^2}$.

In the following sections, the various cases of this example will be analyzed. They will motivate a more general treatment. For simplicity, we shall write $\Sigma_q[f|f_{\infty,q}]$ instead of $\Sigma_{\sigma_q}[f|f_{\infty,\sigma_q}]$ for $q \ge 1$.

3. L^p-nonlinear stability. In this section, we give an L^p-nonlinear stability result for $f_{\infty,\sigma}$, $1 \le p \le 2$, with minimal convexity assumptions on the initial data and an explicit stability constant. It is based on the following result.

PROPOSITION 3.1. *Let f and g be two nonnegative functions in $L^1(\mathbb{R}^6) \cap L^p(\mathbb{R}^6)$, $p \in [1,2]$, and consider a strictly convex function $\sigma : \mathbb{R}_0^+ \to \mathbb{R}$ in $C^2(\mathbb{R}^+) \cap C^0(\mathbb{R}_0^+)$. Let $A = \inf\left\{\sigma''(s)/s^{p-2} :\ s \in (0,\infty)\right\}$. If $A > 0$, then the following inequality holds:*

$$\Sigma_\sigma[f|g] \ge 2^{-2/p} A \left[\max\left(\|f\|_{L^p}^{2-p}, \|g\|_{L^p}^{2-p}\right)\right]^{-1} \|f-g\|_{L^p}^2 + \frac{1}{2}\int_{\mathbb{R}^3} |\nabla_x(\phi[f]-\phi[g])|^2\ dx\ . \tag{3.1}$$

Proof. The case $p = 1$ is the well-known Csiszár–Kullback inequality (see, for instance, [1]) that we are going to adapt to the case $p \ge 1$.

Assume first that $f > 0$. By a Taylor development at order 2 of σ we deduce that we can write the relative entropy for f and g as

$$\begin{aligned} \Sigma_\sigma[f|g] &= \frac{1}{2}\int_{\mathbb{R}^6} \sigma''(\xi)|f-g|^2\ d(x,v) + \frac{1}{2}\int_{\mathbb{R}^3} |\nabla_x(\phi[f]-\phi[g])|^2\ dx \\ &\ge \frac{A}{2}\int_{\mathbb{R}^6} \xi^{p-2}|f-g|^2\ d(x,v) + \frac{1}{2}\int_{\mathbb{R}^3} |\nabla_x(\phi[f]-\phi[g])|^2\ dx\ , \end{aligned} \tag{3.2}$$

where ξ lies between f and g. If $p = 2$, the result is obvious. Let $1 \le p < 2$. By Hölder's inequality, for any $h > 0$ and for any measurable set $\mathcal{A} \subset \mathbb{R}^6$, we get

$$\int_{\mathcal{A}} |f-g|^p\, h^{-\alpha}\, h^\alpha\ d(x,v) \le \left(\int_{\mathcal{A}} |f-g|^2\, h^{p-2}\ d(x,v)\right)^{p/2} \left(\int_{\mathcal{A}} h^{\alpha s}\ d(x,v)\right)^{1/s}$$

with $\alpha = p\,(2-p)/2$, $s = 2/(2-p)$. Thus

$$\left(\int_{\mathcal{A}} |f-g|^2\, h^{p-2}\ d(x,v)\right)^{p/2} \ge \left(\int_{\mathcal{A}} |f-g|^p\ d(x,v)\right)\ \left(\int_{\mathcal{A}} h^p\ d(x,v)\right)^{(p-2)/2}\ .$$

We apply this formula to two different sets.

(i) On $\mathcal{A} = \mathcal{A}_1 = \{(x,v) \in \mathbb{R}^6 : f(x,v) > g(x,v)\}$, use $\xi^{p-2} > f^{p-2}$ and take $h = f$:

$$\left(\int_{\mathcal{A}_1} |f-g|^2 \xi^{p-2}\ d(x,v)\right)^{p/2} \ge \left(\int_{\mathcal{A}_1} |f-g|^p\ d(x,v)\right)\ \|f\|_{L^p}^{-(2-p)\,p/2}\ .$$

(ii) On $\mathcal{A} = \mathcal{A}_2 = \{(x,v) \in \mathbb{R}^6 : f(x,v) \le g(x,v)\}$, use $\xi^{p-2} \ge g^{p-2}$ and take $h = g$:

$$\left(\int_{\mathcal{A}_2} |f-g|^2 \xi^{p-2}\ d(x,v)\right)^{p/2} \ge \left(\int_{\mathcal{A}_2} |f-g|^p\ d(x,v)\right)\ \|g\|_{L^p}^{-(2-p)\,p/2}\ .$$

To prove (3.1) in the case $f > 0$, we just add the two previous inequalities in (3.2) and use the inequality $(a+b)^r \le 2^{r-1}(a^r+b^r)$ for any $a, b \ge 0$ and $r \ge 1$. To handle the case $f \ge 0$, we proceed by a density argument: apply (3.1) to $f_\epsilon(x,v) = f(x,v) + \epsilon\, e^{-|x|^2-|v|^2}$ and let $\epsilon \to 0$ using Lebesgue's convergence theorem. □

This proposition can be applied to weak or renormalized solutions, thus proving the first main result of this paper, which is a more detailed version of Theorem 1.1.

THEOREM 3.2. *Let f_0 verify* (H1), (H2), *and either* $(\mathcal{R})$ *or* $(\mathcal{W})$. *Assume* (H3) *and* (H4). *If f is a weak or renormalized solution of* (1.1)–(1.4) *with initial value f_0, then*

$$\|\nabla\phi - \nabla\phi_{\infty,\sigma}\|^2_{L^2} \quad \le \quad 2\,\Sigma_\sigma[f_0|f_{\infty,\sigma}]\,.$$

Assume that $A = \inf\left\{\sigma''(s)/s^{p-2} \ :\ s \in (0,\infty)\right\}$ *is positive for some* $p \in [1,2]$. *If* $p = 1$, *assume moreover that* $e^{-\phi_e} \in L^1$. *Then* $f_0 \in L^p(\mathbb{R}^6)$ *and*

$$\|f(t) - f_{\infty,\sigma}\|^2_{L^p} \le C(f_0,\sigma)\,\Sigma_\sigma[f_0|f_{\infty,\sigma}]$$

for any $t \ge 0$, *where* $C(f_0,\sigma)$ *is a constant, which takes the explicit form*

$$C(f_0,\sigma) = \begin{cases} \frac{2^{2/p}}{A}\max\left(\|f_0\|^{2-p}_{L^p}, \|f_{\infty,\sigma}\|^{2-p}_{L^p}\right) & \text{if } p > 1\,, \\ \\ \frac{4}{A}M & \text{if } p = 1\,. \end{cases}$$

In case $(\mathcal{S})$, $C(f_0,\sigma)$ *is also bounded by* $\frac{2^{2/p}}{A}\,M^{(2-p)/p}\,\mathcal{M}^{(2-p)(p-1)/p}$ *with* $\mathcal{M} = \max\left(\|f_0\|_{L^\infty}, \|f_{\infty,\sigma}\|_{L^\infty}\right)$.

Proof. The proof is a straightforward consequence of Lemma 2.7, Corollary 2.8, and Proposition 3.1 once it is known that $C(f_0,\sigma)$ is finite. Although we directly prove an estimate of $\|f(t) - f_{\infty,\sigma}\|^2_{L^p}$ in terms of $\Sigma_\sigma[f_0|f_{\infty,\sigma}]$, we may notice that, for $p > 1$, two integrations give the inequality

$$\sigma(s) - \sigma(s_0) - \sigma'(s_0)\,(s - s_0) \ge \frac{A}{p\,(p-1)}\left[s^p - s_0^p - p\,s_0^{p-1}\,(s - s_0)\right]$$

for any $(s, s_0) \in (0+\infty)^2$. Applied to f and $f_{\infty,\sigma}$, this means that on $\mathbb{R}^6$

$$\sigma(f) - \sigma(f_{\infty,\sigma}) - \sigma'(f_{\infty,\sigma})\,(f - f_{\infty,\sigma}) \ge \frac{A}{p\,(p-1)}\left[f^p - f^p_{\infty,\sigma} - p\,f^{p-1}_{\infty,\sigma}\,(f - f_{\infty,\sigma})\right]\,, \tag{3.3}$$

which proves that f belongs to $L^\infty(\mathbb{R}^+, L^p(\mathbb{R}^6))$ (by $\|f_0\|_{L^p}$, according to Corollary 2.8 applied with $\sigma(s) = \sigma_p(s) = s^p$). The constant $C(f_0,\sigma)$ involves $\|f_0\|_{L^p}$, which is therefore itself bounded in terms of $\sigma(f_0)$ and $f_0\,\sigma'(f_0)$.

If $p = 1$, the condition that $e^{-\phi_e} \in L^1$ shows that $f_{\infty,\sigma}$ also belongs to L^1. In that case, inequality (3.3) is replaced by

$$\sigma(f) - \sigma(f_{\infty,\sigma}) - \sigma'(f_{\infty,\sigma})\,(f - f_{\infty,\sigma}) \ge A\left[f\log\left(\frac{f}{f_{\infty,\sigma}}\right) - (f - f_{\infty,\sigma})\right]\,.$$

The details of the proof are left to the reader. □

Remark 3.3. Note that $A = p\,(p-1)$ if $\sigma = \sigma_p$, $p > 1$, and $A = 1$ if $p = 1$ and $C(f_0,\sigma_2) = 1$. The expression of $C(f_0,\sigma)$ is optimal at least for $\sigma = \sigma_p$ in the limit $\|f_0 - f_{\infty,\sigma}\|_{L^p} \to 0$ (see [1] for a discussion in the case $p = 1$).

For $p > 2$, Hölder's inequality holds in the reverse sense: $\|f(t) - f_{\infty,\sigma}\|^2_{L^p} + \|\nabla\phi - \nabla\phi_{\infty,\sigma}\|^2_{L^2}$ controls $\Sigma_\sigma[f_0|\sigma]$.

For $p = 1$, we recover the classical Csiszár–Kullback inequality in Proposition 3.1 and a stability result in L^1 (see [1, 2]) which is natural in the framework of renormalized solutions (if $f\log f$ belongs to L^1: see Lemma 4.1 below).

4. L^2-nonlinear stability of Maxwellian steady states. In [12], Braasch, Rein, and Vukadinović introduce modified Lyapunov functionals for proving L^2-stability for certain steady states (see section 5 for more details). In this section, we shall extend this approach to the Maxwellian case. The main idea is the following: Although $\sigma''(s) = 1/s$ is not bounded from below uniformly away from 0 (which would be the condition to apply directly Proposition 3.1 in L^2), since $f_{\infty,1}$ is bounded in L^∞ by a constant $\bar{s}$, it is sufficient to consider the infimum of σ'' in $(0, \bar{s})$.

In the Maxwellian case, we first notice that (H2) follows from the other assumptions.

LEMMA 4.1. *Assume that $e^{-\beta\,\phi_e}$ belongs to $L^1(\mathbb{R}^3)$ for some $\beta > 0$. Let f be a nonnegative function in $L^1 \cap L^q(\mathbb{R}^6)$, $q > 1$, such that $(x,v) \mapsto (|v|^2 + \phi_e(x))f(x,v) \in L^1(\mathbb{R}^6)$. Then $f \log f$ belongs to $L^1(\mathbb{R}^6)$.*

Proof. Depending on the sign of $\log f$, we are going to consider two cases.

(1) Define $g(x,v) = e^{-\frac{\beta}{2}|v|^2 - \beta\,\phi_e(x)}$. On $\mathcal{A} = \{(x,v) \in \mathbb{R}^6 \ : \ f(x,v) < 1\}$, using Jensen's inequality, we get

$$0 \geq \int_{\mathcal{A}} \left[f \log f + \beta \left(\frac{1}{2}|v|^2 + \phi_e \right) f \right] \, d(x,v) = \int_{\mathcal{A}} f \, \log\left(\frac{f}{g}\right) \, d(x,v)$$
$$\geq \|f\|_{L^1(\mathcal{A})} \log\left(\frac{\|f\|_{L^1(\mathcal{A})}}{\|g\|_{L^1(\mathcal{A})}} \right) .$$

(2) On $\mathbb{R}^6 \setminus \mathcal{A}$, we conclude using the next lemma. ∎

LEMMA 4.2. *Let f be a nonnegative function in $L^1 \cap L^q(\Omega)$, $q > 1$, for some arbitrary domain $\Omega \subset \mathbb{R}^d$, $d \geq 1$. Then*

$$\int_\Omega f(z) \, \log f(z) \, dz \leq \frac{1}{q-1} \, \|f\|_{L^1(\Omega)} \, \log\left(\frac{\|f\|^q_{L^q(\Omega)}}{\|f\|_{L^1(\Omega)}} \right) .$$

Proof. According to Hölder's inequality,

$$\|f\|^r_{L^r} \leq \|f\|_{L^1}^{\frac{q-r}{q-1}} \, \|f\|_{L^q}^{\frac{q(r-1)}{q-1}}$$

for $1 \leq r \leq q$. At $r = 1$, this is an equality and thus we may derive the inequality with respect to r at $r = 1$. ∎

Let ϕ_e and f_0 verify, respectively, (H4) for $\sigma_1(s) = s \log s - s$, and (H1), $(\mathcal{W})$. Consider a weak or renormalized solution f of (1.1)–(1.4) with initial value f_0 and the corresponding stationary solution $f_{\infty,1} = m$ given by (2.4)–(2.5). According to Theorem 3.2, m is L^1-stable:

$$\Sigma_1[f|m] \geq \frac{1}{4M} \|f - m\|^2_{L^1} \, .$$

We shall now prove an L^2-stability result for m using an appropriate cut-off functional as in [12]. Let $E_1(x,v) := \frac{1}{2}|v|^2 + \phi_{\infty,1}(x) + \phi_e(x)$. According to (H4),

$$E_{min} := \inf\{E_1(x,v) \ : \ (x,v) \in \mathbb{R}^6\} \geq \inf\{\phi_e(x) \ : \ x \in \mathbb{R}^3\} > -\infty \, .$$

Denote $m = \varphi \circ E_1$ with $\varphi(s) = \kappa \, e^{-s}$, where

$$\kappa = \frac{M}{(2\pi)^{3/2}} \left[\int e^{-\phi_{1,\infty} - \phi_e} \, dx \right]^{-1} . \tag{4.1}$$

Consider $\bar s = \varphi(E_{min})$ and define

$$\tau_1(s) := \begin{cases} s\log s - s & \text{if } s \in [0,\bar s]\,, \\ \frac{1}{2\kappa}\, e^{E_{min}}\,(s-\bar s)^2 \;-\; (E_{min} - \log\kappa)(s-\bar s) + \bar s\log\bar s - \bar s & \text{if } s \in (\bar s, +\infty)\,. \end{cases}$$

The function τ_1 is of class $C([0,\infty))\cap C^2((0,\infty))$, with $\min(\tau_1'') = e^{E_{min}}/\kappa > 0$. Since $0 \le m(x,v) \le \varphi(E_{min}) = \bar s$ for any $(x,v)\in\mathbb{R}^6$ and φ is decreasing, m is a minimizer of the modified free energy (or Casimir) functional $\Sigma_{\tau_1}[f|m] = K_{\tau_1}[f] - K_{\tau_1}[m]$, where

$$K_{\tau_1}[f] = \int_{\mathbb{R}^6} \left(\frac12\,|v|^2 + \frac12\,\phi + \phi_e\right) f\; d(x,v) \;+\; \int_{\mathbb{R}^6} \tau_1(f)\; d(x,v)\,,$$

and we can apply Theorem 3.2 with $p = 2$. This proves a refined version of Theorem 1.2. Since f belongs to L^2, $\tau_1(f)$ makes sense in L^1 according to Lemma 4.1. Let us remark that the construction of τ_1 is done in such a way that $K_{\tau_1}[m] = K_{\sigma_1}[m]$, and then Corollary 2.8 can be applied. In this framework, it is natural to work with weak rather than renormalized solutions.

THEOREM 4.3. *Assume* (H1), (H3), (H4) *for* $\sigma = \sigma_1$ *and* $(\mathcal{W})$ *for* $p = 2$. *Consider the stationary solution given by* (2.4)–(2.5). *With the above notation, every weak solution* f *of* (1.1)–(1.4) *with initial data* $f_0 \in L^1\cap L^2(\mathbb{R}^6)$ *verifies*

$$\Sigma_{\tau_1}[f_0|m] \ge \Sigma_{\tau_1}[f(t)|m] \ge \frac{1}{2\,\bar s}\,\|f(t) - m\|_{L^2}^2 \quad \textit{for all}\;\; t \ge 0\,.$$

Remark 4.4. (1) A simpler version of Theorem 4.3 holds for solutions satisfying $(\mathcal{S})$. In this case, it is not necessary to modify σ, since $\sigma_1''(s) = \frac{1}{s}$ is bounded from below in $(0, \max(\|f_0\|_{L^\infty}, \|m\|_{L^\infty})]$ by $\max(\|f_0\|_{L^\infty}, \|m\|_{L^\infty})^{-1}$.

(2) Theorem 4.3 can be generalized to any stationary solution $f_{\infty,\sigma}$ and any L^q norm with $p \ne q \in (1,2]$; see the next section.

(3) Note that in the Maxwellian case the value of κ defined by (4.1) is $e^{-\alpha(M)}$, where $\alpha = \alpha(M)$ is the constant in (2.1) which is fixed by the mass constraint.

5. General nonlinear stability results. In this section, we generalize to L^q, $1 \le q \le 2$, and to arbitrary steady states $f_{\infty,\sigma}$ the stability results of sections 3–4. We are also going to generalize the techniques used in the L^2-stability result of Braasch, Rein, and Vukadinović in [12], which can be summarized as follows. *Let* γ *be a* C^1 *function on* $\mathbb{R}$ *such that* $\gamma' < 0$ *on* $(-\infty, E_{\max})$ *and* $\gamma \equiv 0$ *on* $[E_{max}, +\infty)$ *and define* σ *as a primitive of* $-(\gamma^{-1})$, *which is well defined at least on some subinterval in* $\mathbb{R}^+$ (see, for instance, [14] for more details). *Then* $f_{\infty,\sigma}$ *is a compactly supported steady state which is* L^2*-stable among weak or renormalized solutions of* (1.1)–(1.4).

For $q > p$, the main idea is again to bound $\sigma''(s)/s^{q-2}$ from below only on the interval $(0, \bar s = \|f_{\infty,\sigma}\|_{L^\infty})$ and to modify σ on $(\bar s, +\infty)$. In this case, let us establish a useful consequence of Proposition 3.1. Let $E_\sigma(x,v) := \frac12|v|^2 + \phi_{\infty,\sigma}(x) + \phi_e(x)$ and $E_{min} := \inf\{E_\sigma(x,v) \;:\; (x,v)\in\mathbb{R}^6\}$, which is finite by assumption (H4). With the notation of sections 2–3, $f_{\infty,\sigma} = \gamma\circ(E_\sigma - \alpha)$, where α is such that $\|f_{\infty,\sigma}\|_{L^1} = M$. Take $\bar s = \gamma(E_{min} - \alpha)$ and define

$$\tau_\sigma(s) := \begin{cases} \sigma(s) & \text{if } s \in [0,\bar s]\,, \\ \psi(s) & \text{if } s \in (\bar s, +\infty) \end{cases}$$

with $\psi(s) = \frac{\sigma''(\bar s)}{\sigma_q''(\bar s)}\sigma_q(s) + (\sigma'(\bar s) - \frac{\sigma''(\bar s)}{\sigma_q''(\bar s)}\,\sigma_q'(\bar s))(s-\bar s) + \sigma(\bar s) - \frac{\sigma''(\bar s)}{\sigma_q''(\bar s)}\,\sigma_q(\bar s)$ and $\sigma_q(t) = t^q$. With the truncated Lyapunov functional $\Sigma_{\tau_\sigma}[f|f_{\infty,\sigma}] = K_{\tau_\sigma}[f] - K_{\tau_\sigma}[f_{\infty,\sigma}]$, we immediately get the following variant of Proposition 3.1.

COROLLARY 5.1. *Let f and g be two nonnegative functions in $L^1(\mathbb{R}^6) \cap L^q(\mathbb{R}^6)$, $q \in [1,2]$, and consider a strictly convex function $\sigma : \mathbb{R}_0^+ \to \mathbb{R}$ in $C^2(\mathbb{R}^+) \cap C^0(\mathbb{R}_0^+)$. With the above notation, let $B = \inf\left\{\sigma''(s)/s^{q-2} \ : \ s \in (0,\bar{s})\right\}$. If $B > 0$, then there exists a constant $C > 0$ such that*

$$\Sigma_{\tau_\sigma}[f|g] \geq C \, \|f-g\|_{L^q}^2 + \frac{1}{2}\|\nabla\phi - \nabla\phi_{\infty,\sigma}\|_{L^2}^2 \ .$$

As in the case of section 4, this estimate can be applied to get nonlinear stability results.

THEOREM 5.2. *Let f_0 verify* (H1), (H2), *and either* $(\mathcal{R})$ *or* $(\mathcal{W})$. *Assume that σ and ϕ_e satisfy* (H3) *and* (H4). *Assume that* $\inf\left\{\sigma''(s)/s^{p-2} : s \in (0,\bar{s})\right\}$ *is positive for some $p \in [1,2]$, where $\bar{s}$ is defined as above. Then $f_{\infty,\sigma}$ is L^q-nonlinearly stable among weak or renormalized solutions of* (1.1)–(1.4) *for any $q \in (1,2]$, provided $f_0 \in L^q(\mathbb{R}^6)$ if $q > p$.*

Proof. The case $q = p$ is covered by Theorem 3.2. In the case $q > p$, the proof is an easy application of Corollary 5.1: $f_{\infty,\sigma}$ is L^q-stable in the sense that there exists a constant $C > 0$ such that for any $t \geq 0$,

$$\|f(t) - f_{\infty,\sigma}\|_{L^q} \leq C \, \Sigma_{\tau_\sigma}[f_0|f_{\infty,\sigma}] \ .$$

The case $1 < q < p$ relies on Hölder's inequality and Theorem 3.2:

$$\|f(t) - f_{\infty,\sigma}\|_{L^q} \leq (2M)^{\frac{p-q}{q\,(p-1)}} \left(C(f_0,\sigma)\,\Sigma_\sigma[f_0|f_{\infty,\sigma}]\right)^{\frac{p\,(q-1)}{2q\,(p-1)}} \ . \qquad \square$$

The case $p = q = 1$ is covered by Theorem 3.2. Only the case $1 = q < p$ is left open. In the case $q > p$, notice that the L^q norm is bounded in terms of $\Sigma_{\tau_\sigma}[f_0|f_{\infty,\sigma}]$ and not in terms of $\Sigma_\sigma[f_0|f_{\infty,\sigma}]$ (as is also the case in Theorem 4.3, with $p = 1$, $q = 2$).

6. Steady states depending on additional invariants. In the previous sections, we dealt with stationary solutions depending only on the energy. Our stability analysis can be extended to steady states which depend on additional invariants of the particle motion. To avoid lengthy statements, we shall state only the generalization of Theorem 4.3. In order to emphasize the connection with the previous results, we shall abuse the same notations.

Consider the ODE system

$$\dot{X} = V \ , \quad \dot{V} = -\nabla_x\phi(t,X) - \nabla_x\phi_e(X) \ ,$$

which describes the characteristics of the Vlasov equation (1.1). We shall assume that either both ϕ and ϕ_e are locally Lipschitz (classical solutions), or both ϕ and ϕ_e are at least in $W^{1,1}_{loc}$ (using the generalized characteristics of DiPerna and Lions; see [25, 35]). A function $I : \mathbb{R}^6 \to \mathbb{R}^m$ is an *invariant of the motion* if and only if

$$\frac{d}{dt} I(X(t),V(t)) = 0$$

in an appropriate sense. Classical examples of invariants are, for instance, the angular momentum $I(x,v) = x \times v$ in the case of a central force motion (i.e., if $\phi + \phi_e$ is radially symmetric), its modulus, or one of its components: $I(x,v) \cdot \nu$, in the axisymmetric case with axis of direction $\nu \in S^2$, corresponding to a system invariant under rotations of axis ν. References on existence results of classical solutions with symmetries can be found in [28] (for stationary solutions, see [18]).

Consider stationary solutions in the form

$$f_{\infty,\sigma}(x,v) = \mu\big(E(x,v) - \alpha_M[\phi_{\infty,\sigma},\phi_e,I], I(x,v)\big)\ , \tag{6.1}$$

where α_M is a constant to be determined by $\|f_{\infty,\sigma}\|_{L^1} = M$, E is the energy, and I is an invariant of the motion. Note that E depends on $\phi_{\infty,\sigma} = \phi[f_{\infty,\sigma}]$. For simplicity, we suppose that I is a scalar quantity.

In [12], Braasch, Rein, and Vukadinović consider the case where μ can be factorized as

$$\mu(E,I) = \gamma(E-\alpha)\,\nu(I) \quad \text{for all} \ \ (E,I) \in \mathbb{R}^2\ ,$$

where γ is compactly supported and $\alpha \in \mathbb{R}$. If γ satisfies (H3) and (H4) and if ν is a C^1 uniformly positive function, our previous results can easily be extended. In this section, we are going to consider general steady states corresponding to functions μ which cannot be factorized in terms of two functions γ and ν (such an extension has already been considered by Guo and Rein in [32] for gravitational systems) or which do not necessarily have a compact support in E.

In order to obtain the existence of these stationary solutions, we have to assume the following hypotheses on μ and ϕ_e, which are generalizations of (H3) and (H4) of section 2.

(H3′) *Let $\sigma:\ \mathbb{R}_0^+ \times \mathbb{R} \to \mathbb{R}$ be such that $\frac{\partial\sigma}{\partial s}(s,I) = -\mu^{-1}(s,I)$ and assume that for any fixed $I \in \mathbb{R}$, $\sigma(.,I)$ has a $C^0({\mathbb{R}_0}^+) \cap C^2(\mathbb{R}^+)$ regularity and is bounded from below, strictly convex, and such that $\lim_{s\to+\infty} \sigma(s,I)/s = +\infty$. Here μ^{-1} is the generalized inverse of $s \mapsto \mu(s,I)$ for fixed I.*

(H4′) *The external potential $\phi_e : \mathbb{R}^3 \to \mathbb{R}$ is a measurable bounded-from-below function such that $\lim_{|x|\to+\infty} \phi_e(x) = +\infty$ and*

$$x \mapsto \int_{\mathbb{R}^3} \mu\left(\frac{1}{2}|v|^2 + \phi_e(x), I(x,v)\right)\ dv$$

belongs to $L^1 \cap L^\infty(\mathbb{R}^3)$.

The stationary solution $f_{\infty,\sigma}$ is characterized as the unique nonnegative critical point of a strictly convex coercive functional K_σ, with

$$K_\sigma[f] = \int_{\mathbb{R}^6} \left[\sigma(f,I) + \left(\frac{1}{2}|v|^2 + \phi_e(x)\right) f\right]\ d(x,v) + \frac{1}{2}\int_{\mathbb{R}^3} |\nabla\phi[f]|^2\ dx\ ,$$

under the constraint $\int_{\mathbb{R}^6} f_{\infty,\sigma}\ d(x,v) = M$ for some given $M > 0$. As in section 2, α_M in (6.1) is the Lagrange multiplier associated to the constraint on the mass and is uniquely determined by the condition $\int_{\mathbb{R}^6} f_{\infty,\sigma}\ d(x,v) = M$. To σ we associate a relative entropy functional defined by

$$\begin{aligned}\Sigma_\sigma[f|f_{\infty,\sigma}] &:= K_\sigma[f] - K_\sigma[f_{\infty,\sigma}]\\ &= \int_{\mathbb{R}^6} \left[\sigma(f,I) - \sigma_\infty - \frac{\partial\sigma_\infty}{\partial s}\,(f - f_{\infty,\sigma})\right] d(x,v) + \frac{1}{2}\int_{\mathbb{R}^3} |\nabla_x(\phi[f] - \phi_{\infty,\sigma})|^2 dx\end{aligned}$$

with $\sigma_\infty = \sigma(f_{\infty,\sigma}, I)$ and $\phi_{\infty,\sigma} = \phi[f_{\infty,\sigma}]$.

If there exists a function $A_\sigma(I) > 0$ such that $\frac{\partial^2\sigma}{\partial s^2}(s,I) \ge A_\sigma(I)$ for any $(s,I) \in \mathbb{R}_0^+ \times \mathbb{R}$, by Taylor expansion it follows that

$$\Sigma_\sigma[f|f_{\infty,\sigma}] \ge \int_{\mathbb{R}^6} A_\sigma(I)|f - f_{\infty,\sigma}|^2\ d(x,v)\ ,$$

which proves a weighted L^2-stability result. Exactly as before, we can use a cut-off argument and get a generalization of Theorem 4.3.

Let $E_\sigma(x,v) := \frac{1}{2}|v|^2 + \phi_{\infty,\sigma}(x) + \phi_e(x)$ and $E_{min} := \inf\{E_\sigma(x,v) \ : \ (x,v) \in \mathbb{R}^6\}$, which is finite by assumption (H4′). With evident notation, $f_{\infty,\sigma} = \mu(E_\sigma(\cdot) - \alpha_M, I(\cdot,\cdot))$. Take $\bar{s}(I) = \mu(E_{min} - \alpha_M, I)$ and define for any $I \in \mathbb{R}$

$$\tau_\sigma(s,I) := \begin{cases} \sigma(s,I) & \text{if } s \in [0,\bar{s}(I)] \ , \\ \psi(s,I) & \text{if } s \in (\bar{s}(I),+\infty) \end{cases} \tag{6.2}$$

with $\psi(s,I) = \frac{\sigma''(\bar{s},I)}{\sigma_2''(\bar{s})}\sigma_2(s) + (\sigma'(\bar{s},I) - \frac{\sigma''(\bar{s},I)}{\sigma_2''(\bar{s})}\,\sigma_2'(\bar{s}))(s-\bar{s}) + \sigma(\bar{s},I) - \frac{\sigma''(\bar{s},I)}{\sigma_2''(\bar{s})}\,\sigma_2(\bar{s})$, $\bar{s} = \bar{s}(I)$, and $\sigma_2(s) = s^2$. With the truncated Lyapunov functional $\Sigma_{\tau_\sigma}[f|f_{\infty,\sigma}] = K_{\tau_\sigma}[f] - K_{\tau_\sigma}[f_{\infty,\sigma}]$, we immediately get the following variant of Theorem 4.3.

THEOREM 6.1. *Let I be a function in $C^1(\mathbb{R}^6)$ and assume that ϕ_e, μ verify* (H3′)–(H4′). *Assume, moreover, that*

$$B_\sigma(I) = \inf\left\{ s \in [E_{min} - \alpha_M, \mu^{-1}(0,I)] \ : \ \frac{\partial^2\sigma}{\partial s^2}(s,I) \right\} > 0 \quad \textit{for any } I \in \mathbb{R} \ .$$

Let f_0 be a nonnegative function in $L^1(\mathbb{R}^6) \cap L^2(\mathbb{R}^6, B_\sigma(I(x,v))\,d(x,v))$ such that $(x,v) \mapsto \sigma(f_0(x,v), I(x,v))$ belongs to $L^1(\mathbb{R}^6)$ and consider a weak (resp., renormalized) solution of the Vlasov–Poisson system with initial data f_0 satisfying $(\mathcal{W})$ (resp., $(\mathcal{R})$). Then for any $t \geq 0$

$$\Sigma_{\tau_\sigma}[f_0|f_{\infty,\sigma}] \geq \Sigma_{\tau_\sigma}[f(t)|f_{\infty,\sigma}] \geq \int_{\mathbb{R}^6} B_\sigma(I(x,v))\,|f(t,x,v) - f_{\infty,\sigma}(x,v)|^2 \ d(x,v) \ .$$

Weighted L^q estimates can also be established if one replaces σ_2 by σ_q in (6.2), under the condition that $\inf\{s \in [E_{min} - \alpha, \mu^{-1}(0,I)] \ : \ s^{2-q}\frac{\partial^2\sigma}{\partial s^2}(s,I)\} > 0$ for any $I \in \mathbb{R}$.

Remark 6.2. Equation (1.1) is a special case (parabolic-band approximation) of the Vlasov–Poisson system for semiconductors

$$\frac{\partial f}{\partial t} + v(p)\cdot\nabla_x f + F(t,x)\cdot\nabla_p f = 0$$

on $\mathbb{R}_0^+ \times \mathbb{R}^3 \times \mathbb{R}^3$, with $v(p) = \nabla_p \epsilon(p)$. If we assume that ϵ is a nonnegative C^1 function such that $e^{-\epsilon(p)} \in L^1(\mathbb{R}^3)$, then abusing the same notations as for (1.1) (which corresponds to the special case $\epsilon(p) = \frac{1}{2}p^2$), one can, for instance, prove that there exists a Maxwellian-type stationary solution given by

$$m(x,p) \ = \ M\,\frac{e^{-\epsilon(p) - q\,(\phi(x) + \phi_e(x))}}{\int_{\mathbb{R}^6} e^{-\epsilon - q\,(\phi+\phi_e)}\ d(x,p)} \ ,$$

where ϕ is given by (1.3) with $\rho(f)(t,x) = \int_{\mathbb{R}^3} f(t,x,p)\ dp$. Nonlinear stability results for m and more general stationary states can be easily obtained using the previous ideas. Realistic models include collisions, which usually determine a special class of stationary solutions (and the appropriate Lyapunov functional is then decreasing even for classical solutions). We refer to [37, 6, 7, 17, 19] for more details on this subject.

7. Appendix: A convexity property of L^1 functions. Let f_0 be a nonnegative function in $L^1(\Omega)$ for some (not necessarily bounded) domain Ω in $\mathbb{R}^d$, $d \geq 1$. It is straightforward to check that $\sigma(f_0) \in L^1(\Omega)$ if σ is a C^2 convex function on $\mathbb{R}^+$

such that $s \mapsto \sigma(s)/s$ is bounded (consider, for example, $\sigma(s) = 2s + e^{-s} - 1$). The result of Proposition 2.1, which is a special case of the following Proposition, is much stronger.

PROPOSITION 7.1. *Let $(E, d\mu)$ be a measurable space. For any nonnegative function f_0 in $L^1(E, d\mu)$, there exists a nonnegative strictly convex function σ of class C^2 such that $\lim_{s\to+\infty} \sigma(s)/s = +\infty$ and $\sigma(f_0) \in L^1(E, d\mu)$.*

This result is more or less standard. For completeness, we are going to give a proof which is based on the following elementary lemma.

LEMMA 7.2. *Consider a sequence $\{\alpha_n\}$ with $\alpha_n > 0$ for any n and $\sum \alpha_n < \infty$. Then there exists an increasing sequence $\{\beta_n\}$ with $\beta_n > 0$ for any $n \in \mathbb{N}$, and $\lim_{n\to\infty} \beta_n = +\infty$ such that $\sum \alpha_n\beta_n < \infty$.*

Proof of Lemma 7.2. We prove this result by an explicit construction of β_n. Let $\epsilon_n = \sum_{m\geq n} \alpha_m$ and take $\beta_n = \frac{1}{2\sqrt{\epsilon_n}}$:

$$\alpha_n\beta_n = (\epsilon_n - \epsilon_{n+1}) \frac{1}{2\sqrt{\epsilon_n}} \leq \sqrt{\epsilon_n} - \sqrt{\epsilon_{n+1}} \, ,$$

which immediately gives $\sum_{m\geq n} \alpha_m\beta_m \leq \sqrt{\epsilon_n}$. □

Proof of Proposition 7.1. Let $\alpha_n = \int_{n\leq f_0<n+1} f_0 \, d\mu$ and take β_n given by Lemma 7.2. One can find a convex function σ with $s \mapsto \sigma(s)/s$ nondecreasing such that $\sigma(n + 1) = (n + 1)\beta_n$. Thus

$$\int_{n\leq f_0<n+1} \sigma(f_0) \, d\mu \leq \int_{n\leq f_0<n+1} f_0 \, d\mu \cdot \frac{\sigma(n+1)}{n+1} = \alpha_n\beta_n \, ,$$

which ends the proof. □

Remark 7.3. From Proposition 7.1, it is clear that there is no optimal convex function σ corresponding to a given initial data f_0 (reapply the Proposition to $\sigma(f_0)$). To any σ, one can, however, associate a function γ. Is there an optimal condition on the growth of ϕ_e so that both the stationary solution and the relative entropy are well defined? This would indeed define a notion of *confinement* which would depend only on f_0. On the other hand, if the growth condition is not satisfied, is it possible to give some dispersion estimate (as in the case $\phi_e \equiv 0$, or $(x - x_0) \cdot \nabla\phi_e \geq 0$ for some given $x_0 \in \mathbb{R}^3$)?

Acknowledgment. The authors thank Bernt Wennberg for a comment which led us to include the results stated in the appendix.

LOCAL STRESS REGULARITY IN SCALAR NONCONVEX VARIATIONAL PROBLEMS*

CARSTEN CARSTENSEN† AND STEFAN MÜLLER‡

Abstract. In light of applications to relaxed problems in the calculus of variations, this paper addresses convex but not necessarily strictly convex minimization problems. A class of energy functionals is described for which any stress field σ in $L^q(\Omega)$ with $\operatorname{div}\sigma$ in $W^{1,p'}(\Omega)$ belongs to $W^{1,q}_{loc}(\Omega)$. The condition on $\operatorname{div}\sigma$ holds, for example, for solutions of the Euler–Lagrange equations involving additional lower-order terms. Applications include the scalar double-well potential, an optimal design problem, a vectorial double-well problem in a compatible case, and Hencky elastoplasticity with hardening. If the energy density depends only on the modulus of the gradient, we also show regularity up to the boundary.

Key words. nonconvex minimization, regularization, relaxed problem, stress regularity

1. Introduction.

Consider a volume term $f \in L^q_{loc}(\Omega)$, Dirichlet data $u_0 \in W^{1,p}(\Omega)$, and a nonvoid, closed, convex set $\mathcal{A}$ of admissible displacements, which satisfies $u_0 + W^{1,p}_0(\Omega) \subseteq \mathcal{A} \subseteq W^{1,p}(\Omega)$. The problem

$$\text{minimize } E(u) := \int_\Omega W(Du)\,dx - \int_\Omega f\,u\,dx \quad \text{among } u \in \mathcal{A} \tag{1.1}$$

may fail to have a solution in $\mathcal{A}$. Typically, infimizing sequences exist and are bounded in the seminorm of $W^{1,p}(\Omega)$ and weakly convergent towards some u in $\mathcal{A}$. The limit u, however, may fail to minimize the energy E since the functional $E : \mathcal{A} \to \mathbb{R}$ is not (sequentially) weakly lower semicontinuous owing to its nonconvexity.

Nevertheless, u describes the macroscopic, space-averaged state and is therefore of interest. Relaxation results in the calculus of variations show that u can be computed as a solution of the relaxed problem

$$\text{minimize } RE(u) := \int_\Omega \varphi(Du)\,dx - \int_\Omega f\,u\,dx \quad \text{among } u \in \mathcal{A}. \tag{1.2}$$

In the general case φ is the quasi-convexification of W [Dac89, Rou97]. The arguments of this paper are essentially restricted to the situation where φ is the convex envelope of W.

It was observed in [Fri94, Cel93a, Cel93b, CP97b] for scalar problems and recently in [BKK00] in the general case that the stress fields $\sigma_j := DW(Du_j)$ of an infimizing sequence u_j converge in a weak sense. The limit σ is given as the stress of a relaxed

energy φ, i.e., $\sigma = D\varphi(Du)$. Hence the stress field associated with (1.1) can be computed from (1.2); for the regularity of σ it suffices to study (1.2).

This paper establishes local regularity of the stress variable σ under minimal conditions on u. We consider a class of convex (but not necessarily strictly convex) C^1 functions φ with

$$|D\varphi(A) - D\varphi(B)|^2 \le c_1\,(1 + |A|^s + |B|^s) \times (D\varphi(A) - D\varphi(B)) : (A - B) \tag{1.3}$$

for all $A, B \in \mathbb{M}^{m\times n}$ ($\mathbb{M}^{m\times n}$ denotes the real $m \times n$ matrices) and a multiplicative constant c_1. Note that (1.3) implies convexity of φ but not strict convexity.

Theorem 2.1 of section 2 asserts that the monotonicity condition (1.3) and the identity $\operatorname{div} D\varphi(Du) = f$ in $W^{1,q}(\Omega)$, which is the Euler–Lagrange equation corresponding to (1.2), together yield $\sigma = D\varphi(Du)$ in $W^{1,q}_{loc}(\Omega)$. Examples include the scalar two-well potential (see section 3) and a relaxed energy density of an optimal design problem (see section 4).

A symmetric variant of (1.1)–(1.2), where $n = m$ and where Du is replaced by the symmetric part $\varepsilon(u) := \operatorname{sym} Du$, is given by

$$\text{minimize } RE(u) := \int_\Omega \varphi(\varepsilon(u))\,dx - \int_\Omega f\,u\,dx \quad \text{among } u \in \mathcal{A} \tag{1.4}$$

and is discussed in section 5. Emphasis is put on the robustness of the stress estimate as $\lambda \to \infty$, where λ is the Lamé constant related to volume changes. Applications to Hencky elastoplasticity and a vector two-well example in sections 6 and 7, respectively, conclude this paper.

Throughout this paper $\mathbb{M}^{m\times n}$ denotes the real $m \times n$ matrices endowed with the Euclidean scalar product $A : B := \sum_{j=1}^m \sum_{k=1}^n A_{jk}B_{jk}$ and the induced (Frobenius matrix) norm $|\cdot|$, $|A| := (A : A)^{1/2}$. We use standard notation for Sobolev and Lebesgue spaces and their norms and seminorms.

2. Abstract stress regularity result. Let Ω be an open set in $\mathbb{R}^n$, let $\varphi : \mathbb{M}^{m\times n} \to \mathbb{R}$ be a C^1 function, and let $D\varphi$ be its derivative. Suppose that there exist constants $1 < p < \infty$, $1 < r < \infty$, $0 \le s < \infty$, and $0 < c_2$ such that, for all $A, B \in \mathbb{M}^{m\times n}$,

$$|D\varphi(A) - D\varphi(B)|^r \le c_2\,(1 + |A|^s + |B|^s) \times (D\varphi(A) - D\varphi(B)) : (A - B). \tag{2.1}$$

THEOREM 2.1. *Assume furthermore that*

$$u \in W^{1,p}(\Omega;\mathbb{R}^m) \quad \textit{and} \quad \sigma := D\varphi(Du)$$

satisfy

$$\sigma \in L^q_{loc}(\Omega;\mathbb{M}^{m\times n}) \quad \textit{and} \quad \operatorname{div}\sigma \in W^{1,p'}_{loc}(\Omega;\mathbb{R}^m)$$

for $p' := p/(p-1)$ *and* $q := r/(1 + s/p)$. *Suppose* $p' \le q$ *and* $r \le 2$. *Then*

$$\sigma \in W^{1,q}_{loc}(\Omega;\mathbb{M}^{m\times n}).$$

Remark 2.1. (a) The point is that (2.1) implies that φ is convex; nonetheless, φ need not to be strictly convex since the lower bound is in terms of stress differences but not in terms of $|A - B|$.

(b) The assumptions on u can be localized to $u \in W^{1,p}_{loc}(\Omega;\, \mathbb{R}^n)$ by applying the result to subsets of Ω.

Proof. Let ω be an open, bounded set which is compactly contained in Ω, i.e., $\omega \subset \overline{\omega} \subset \Omega$. Fix $\eta \in \mathcal{D}(\omega)$ and a direction $M \in \mathbb{M}^{m\times n}$ with $|M| = 1$. Set $\alpha := 1/(r-1)$ and $\beta := r/(r-1)$. For $0 < h < h_0 := \operatorname{dist}(\operatorname{supp}\eta; \partial\omega)$ consider the difference quotients

$$\begin{aligned} \tau(x) &:= (\sigma(x+hM) - \sigma(x))/h, \\ e(x) &:= (u(x+hM) - u(x))/h, \\ \delta(x) &:= De(x). \end{aligned}$$

A standard argument in the approximation of weak derivatives by difference quotients shows that

$$\|e\|_p := \|e\|_{L^p(\omega)} \le c_3\, \|u\|_{W^{1,p}(\Omega)}. \tag{2.2}$$

Here and throughout the proof $\|\cdot\|_t := \|\cdot\|_{L^t(\omega)}$ denotes the $L^t(\omega)$-norm with respect to the subdomain ω of Ω.

Since $u \in W^{1,p}(\Omega)$ the expression $\|e\|_{L^p(\omega)}$ is bounded uniformly in h. A careful use of Hölder's inequality in combination with $q' \le p$,

$$\operatorname{div}\sigma \in W^{1,p'}(\omega; \mathbb{M}^{m\times n}) \quad \text{and} \quad \sigma \in L^{p'}(\omega; \mathbb{M}^{m\times n}),$$

yields the uniform bound

$$\|\, \varrho^{q/r}\, \|^{r/q}_{1+p/s} + \|e\|_p + \|e\|_{q'} + \|\eta^\beta \operatorname{div}\tau\|_{p'} + \|\,\eta\,\|_{W^{1,\infty}(\Omega)} \le c_4, \tag{2.3}$$

where $\varrho(x) := 1 + |Du(x)|^s + |Du(x+hM)|^s$.

To verify the assertion, we have to bound $|\tau|_{L^q(K)}$ uniformly in h for each compact set $K \subset \Omega$ (below K is a compact subset of the interior of $\operatorname{supp}\eta$).

Applying (2.1) with $A := Du(x+hM)$ and $B := Du(x)$, we obtain

$$|\tau|^r \le c_2\, h^{2-r}\, \varrho\, \tau : \delta \quad \text{a.e. in } \omega. \tag{2.4}$$

Raising (2.4) to the power q/r, multiplying with $\eta^{\alpha q}$, and finally integrating the result over Ω, we infer that

$$\|\eta^\alpha \tau\|_q^q \le c_2^{q/r}\, h^{q(2-r)/r} \int_\Omega \eta^{\alpha q}\, \varrho^{q/r}\, (\tau:\delta)^{q/r} dx. \tag{2.5}$$

Applying Hölder's inequality (with r/q and $(r/q)' = 1 + p/s$), raising the result to the power r/q, and using the fact that $0 \le \tau : \delta$ and $\alpha r = \beta$, we derive

$$\|\eta^\alpha \tau\|_q^r \le c_2\, h^{2-r}\, \|\, \varrho^{q/r}\, \|^{r/q}_{1+p/s} \int_\Omega \eta^\beta\, \tau : \delta\, dx. \tag{2.6}$$

Since $\delta = De$ on ω and $h \le h_0$, an integration by parts proves that

$$\begin{aligned} \int_\Omega \eta^\beta\, \tau : \delta\, dx &= -\int_\Omega e \cdot \operatorname{div}(\eta^\beta \tau) dx \\ &\le \beta \|\,\eta\,\|_{1,\infty}\, \|\, \eta^{\beta-1}\, \tau\, e\,\|_1 + \|\, e\,\|_p \|\, \eta^\beta \operatorname{div}\tau\,\|_{p'}. \end{aligned} \tag{2.7}$$

Hölder's inequality and the relation $\beta - 1 = \alpha$ lead to

$$\| \eta^{\beta-1} \tau e \|_1 \leq \| e \|_{q'} \| \eta^{\alpha} \tau \|_q. \tag{2.8}$$

The combination of (2.6)–(2.8) with (2.3) and the hypothesis $r \leq 2$ proves that

$$\|\eta^{\alpha}\tau\|_q^r \leq c_2 c_4^3 h_0^{2-r}(1 + \| \eta^{\alpha}\tau \|_q). \tag{2.9}$$

With Young's inequality $ab \leq (ac)^r/r + (b/c)^{r'}/r'$ for positive a, b, c we deduce from (2.9) and the assumptions $r \leq 2$ and $q > 1$ that $\|\eta^{\alpha}\tau\|_q$ is bounded uniformly in h. Hence,

$$\limsup_{h\to 0} \|\eta^{\alpha}\tau\|_{L^q(\Omega)} < \infty \quad \text{for all } \eta \in \mathcal{D}(\Omega).$$

The proof is finished. □

To illustrate the growth condition in (2.1) we consider the simple example of the p-Laplace equation.

Example 2.1. Let $m = 1$, let $2 \leq p < \infty$, and consider $\varphi(F) := |F|^p/p$ for $F \in \mathbb{R}^n$. Then $D\varphi(F) = |F|^{p-2} F$, and for fixed $B \in \mathbb{R}^n$ and $A \in \mathbb{R}^n$ with $|A| \to \infty$, we have

$$\frac{|D\varphi(A) - D\varphi(B)|^2}{(D\varphi(A) - D\varphi(B) \cdot (A - B)} \approx |D\varphi(A)|/|A| = |A|^{p-2}.$$

Indeed, it is known (e.g., by a combination of Lemmas 2.1 to 2.3 in [CK01]) that for any $A, B \in \mathbb{R}^n$,

$$\frac{|D\varphi(A) - D\varphi(B)|^2}{(D\varphi(A) - D\varphi(B) \cdot (A - B)} \leq (1 + \max\{1, p-2\}^2)(|A|^{p-2} + |B|^{p-2}).$$

We therefore obtain, as a corollary of Theorem 2.1, local regularity of the stress field, i.e., $\sigma := D\varphi(Du) \in W^{1,p'}_{loc}(\Omega; \mathbb{R}^n)$ for a minimizer $u \in W^{1,p}(\Omega)$ of (1.2) with $f \in W^{1,p'}_{loc}(\Omega)$.

3. An application to the scalar two-well problem. This section concerns the scalar double-well problem, where

$$W : \mathbb{R}^n \to \mathbb{R}, \quad F \mapsto |F - F_1|^2 \, |F - F_2|^2 \tag{3.1}$$

and where the energy wells $F_1, F_2 \in \mathbb{R}^n$, $F_1 \neq F_2$, are given. The scalar problem (1.1) with (3.1) (for $m = 1$) can be deduced from the Ericksen–James energy density in an antiplane shear model; the version for $n = 1$, due to Bolza [Bol06]) (cf. also [You69]), is the model example in nonconvex minimization.

PROPOSITION 3.1 (see [CP97b]). *Let $a := (F_2 - F_1)/2$ and $b := (F_1 + F_2)/2$. The convex envelope φ of W given by* (3.1) *is*

$$\varphi(F) := \max\{|F - b|^2 - |a|^2, 0\}^2 + 4(|a|^2 \, |F - b|^2 - [a \cdot (F - b)]^2)$$

and satisfies (2.1) *with $r = 2$, $s = 2$, and $c_2 = 4 \max\{2, |F_1 - F_2|^2\}$.*

COROLLARY 3.2. *Adopt the notation of Proposition* 3.1 *and let u be a minimizer of* (1.2) *with $f \in W^{1,4/3}$. Then $\sigma := D\varphi(Du) \in W^{1,4/3}_{loc}(\Omega; \mathbb{R}^n)$.*

Proof. The assertion follows from Theorem 2.1 and Proposition 3.1 since the Euler–Lagrange equations of the minimization problem (1.2) imply that $-\operatorname{div}\sigma = f \in W^{1,4/3}(\Omega)$. □

Remark 3.1. Further estimates in [CP97b] allow one to control other quantities. In particular,

$$\max\{0, |B - Du|^2 - |A|^2\} \in H^1_{loc}(\Omega) \quad \text{and} \quad M \cdot Du \in H^1_{loc}(\Omega)$$

for all directions M perpendicular to A.

4. An application to an optimal design problem. The relaxed model for an optimal design problem derived in [GKR86] has the form (1.2), where $\varphi(F) = \psi(|F|)$. Given positive parameters $0 < t_1 < t_2$ and $0 < \mu_2 < \mu_1$ with $t_1\mu_1 = t_2\mu_2$, the C^1 function $\psi : [0,\infty) \to [0,\infty)$ is defined by $\psi(0) = 0$ and

$$\psi'(t) := \begin{cases} \mu_1\, t & \text{if } 0 \le t \le t_1, \\ t_1\mu_1 = t_2\mu_2 & \text{if } t_1 \le t \le t_2, \\ \mu_2\, t & \text{if } t_2 \le t. \end{cases}$$

PROPOSITION 4.1 (see [CP97b]). *The function $\varphi(F) = \psi(|F|)$ satisfies (2.1) with $r = 2$, $s = 0$, and $c_2 = 1/\mu_1$.*

Therefore Theorem 2.1 yields local stress regularity for minimizers of (1.2) when $f \in H^1_{loc}(\Omega)$.

COROLLARY 4.2. *Adopt the notation of Proposition 4.1 and let u be a minimizer of (1.2) in $\mathcal{A} := H^1_0(\Omega)$. Then $\sigma := D\varphi(Du) \in W^{1,2}_{loc}(\Omega;\mathbb{R}^n)$.*

Global regularity of the variable $u \in C^\alpha(\overline{\Omega}) \cap W^{1,\infty}(\Omega)$ and of the level sets has been analyzed in [KSW91].

The rest of this section is devoted to establishing stress regularity up to the boundary.

THEOREM 4.3. *Suppose that $f \in W^{1,2}_0(\Omega)$ and that Ω is a $C^{2,1}$ domain. If u is a minimizer of (1.2), then $\sigma := D\varphi(Du) \in W^{1,2}(\Omega;\mathbb{R}^n)$.*

The remaining part of this section is devoted to a proof of Theorem 4.3 via a local reflection argument. Owing to the local regularity of Corollary 4.2, it remains to prove $\sigma \in W^{1,2}(\Omega \cap B(x_0,\delta);\mathbb{R}^n)$ for each point x_0 on the boundary $\partial\Omega$ and some small $\delta > 0$. Without loss of generality, we suppose $x_0 = 0$ and that the Cartesian coordinate system at hand directly allows a $C^{2,1}$ parameterization.

DEFINITION 4.1. *Let $\chi : B'_0 \to \mathbb{R}$ be a (scalar) $C^{2+\alpha}$ function, where $B_0 := B(0,\delta_0) \subset \mathbb{R}^n$ and $B'_0 := \{x' \in \mathbb{R}^{n-1} : |x'| < \delta_0\} \subset \mathbb{R}^{n-1}$ denote the δ_0-ball around $x_0 = 0$ in n and $(n-1)$ dimensions, respectively. Suppose that χ parameterizes the boundary $\Gamma := \partial\Omega$ near $x_0 = 0$, i.e.,*

$$\begin{aligned} \Gamma \cap B_0 &= \{(x', \chi(x')) \in B_0 : x' \in B'_0\}, \\ \Omega \cap B_0 &= \{(x', x_n) \in B_0 : x' \in B', x_n > \chi(x')\}, \\ B_0 \backslash \overline{\Omega} &= \{(x', x_n) \in B_0 : x' \in B', x_n < \chi(x')\}. \end{aligned}$$

Let ν be the unit normal vector on Γ and set

$$\Psi(x) := (x', \chi(x')) - x_n\, \nu(x', \chi(x')) \quad \text{for all } x =: (x', x_n) \in B_0 \subset B'_0 \times \mathbb{R}.$$

LEMMA 4.4. *The pull-back metric $g := D\Psi^T D\Psi : B_0 \to \mathbb{M}^{n\times n}_{sym}$ is of class $C^{1+\alpha}$. Let I_{n-1} denote the $n\times(n-1)$ unit matrix (i.e., the first $n-1$ columns of $\sum_{j=1}^{n-1} e_j \otimes e_j$)*

and let $E := I_{n-1} + e_n \otimes D\chi(x') - x_n D_{x'}\nu(x', \chi(x')) \in \mathbb{M}^{n\times(n-1)}$. *Then*

$$g(x) = \begin{pmatrix} E^T E & 0 \\ 0 & 1 \end{pmatrix} \in \mathbb{M}^{n\times n}_{sym} \text{ for } (x', x_n) \in B.$$

Proof. We have $D\Psi = E - \nu \otimes e_n$. Hence $\Psi \in C^{1+\alpha}$. Moreover $E^T E e_n = 0$ and

$$E^T \nu = \sum_{j=1}^{n} \big(\nu_j + (\partial_{x_j}\chi)\nu_n - x_n(\partial_{x_j}\nu)\cdot\nu_n\big)\, e_j.$$

Since ν is normal to the surface $x' \mapsto (x', \chi(x'))$ we have $(\nu_j + \partial_{x_j}\chi) = \partial_{x_j}(x', \chi(x'))\cdot \nu = 0$. Moreover $\partial_{x_j}\nu\cdot\nu = 0$ since $|\nu|^2 = 1$. This establishes the desired block structure of g. ∎

DEFINITION 4.2. *Suppose that* δ *is small enough,* $0 < \delta < \delta_0$, *such that* $\Psi(B_+) =: \omega \subset \Omega$, $B_\pm := \{(x', x_n) \in B : \pm x_n > 0\}$, *where* $B := B(0, \delta)$ *and* $B' := \{x' \in \mathbb{R}^{n-1} : |x'| < \delta\}$ *denote the* δ*-ball around* $x_0 = 0$ *in* n *and* $(n-1)$ *dimensions, respectively. For any* $x = (x', x_n) \in B_+$ *set* $Sx := (x', -x_n) \in B_-$ *and*

$$\begin{aligned}
\tilde u(x) &= -\tilde u(Sx) := u(\Psi(x)),\\
\tilde\sigma(x) &= -\tilde\sigma(Sx)S := \sigma(\Psi(x))\ \operatorname{cof} D\Psi,\\
\tilde f(x) &= -\tilde f(Sx) := (\det g(x))^{1/2}\, f(\Psi(x)),\\
\tilde g(x) &= \tilde g(Sx) := g(x).
\end{aligned}$$

LEMMA 4.5. *There holds* $\tilde u \in W^{1,2}(B)$, $\tilde f \in W^{1,2}(B)$, $\tilde\sigma \in H(\operatorname{div}, B)$,

$$\tilde\sigma = D\varphi(\nabla\tilde u\, \tilde g^{-1/2}) \operatorname{cof} \tilde g^{1/2} \text{ in } B, \quad \text{and} \quad \operatorname{div}\tilde\sigma = \tilde f \text{ in } \mathcal{D}'(B).$$

Proof. A polar decomposition $QU = D\Psi(x)$ shows that $g(x) = U^2$, $g(x)^{1/2} = U$. Since $Q = D\Psi(x) g(x)^{-1/2}$ is orthonormal we have

$$|\nabla u(\Psi(x))| = |\nabla u(\Psi(x))\, D\Psi(x)\, g(x)^{-1/2}| = |\nabla\tilde u(x)\, g(x)^{-1/2}|.$$

The function $\varphi(\cdot) = \psi(|\cdot|)$ solely depends on the modulus, and this implies that for $\xi := \Psi(x)$ and $x \in B_+$,

$$\begin{aligned}
\sigma(\xi) &= D\varphi(\nabla u(\xi))\\
&= \psi'(|\nabla u(\xi)|)\, \nabla u(\xi)/|\nabla u(\xi)|\\
&= \psi'(|\nabla\tilde u(x)\, g(x)^{-1/2}|)(\nabla\tilde u(x)\, D\Psi^{-1}(x))/|\nabla\tilde u(x)\, D\Psi^{-1}(x)|\\
&= D\varphi(\nabla\tilde u(x)\, g^{-1/2}(x))\, Q^T.
\end{aligned}$$

Using $\operatorname{adj} D\psi(x) = \operatorname{cof} g^{1/2}(x)\, Q^T$ we obtain the asserted identity for $\tilde\sigma$ in B_+.

By assumption $\operatorname{div}\sigma = f$ in $\mathcal{D}'(\Omega)$. Using the test function $\eta\circ\Psi^{-1}$, where $\eta \in \mathcal{D}(B_+)$, and the change of variables formula we get

$$\begin{aligned}
\int_{B_+} \tilde f(x)\, \eta(x)\, dx &= \int_\omega f(\xi)\eta(\Psi^{-1}(\xi))\, d\xi\\
&= -\int_\omega \nabla\eta(\Psi^{-1}(\xi))\cdot\big(D\Psi^{-1}(\xi)\sigma(\xi)\big)\, d\xi.
\end{aligned}$$

The substitution of $\tilde\sigma$ and a retransformation give

$$\int_{B_+} \tilde f(x)\, \eta(x)\, dx = \int_{B_+} \tilde\sigma(x)\cdot\nabla\eta(x)\, dx.$$

This proves $\operatorname{div}\tilde\sigma = \tilde f$ in $\mathcal{D}'(B_+)$.

The block structure of g shows that g^α commutes with $S = \operatorname{diag}(1,\dots,1,-1)$, i.e., $Sg^\alpha = g^\alpha S$ for $\alpha\in\mathbb{R}$. Since $\varphi(\cdot)$ depends solely on the modulus, $D\varphi$ commutes with S as well, i.e., $D\varphi(-S\cdot) = -SD\varphi(\cdot)$. Then, for $x\in B_-$, $\xi\in B_+$, $x = S\xi$,

$$\begin{aligned}&\operatorname{cof}\tilde g^{1/2}(x)\, D\varphi(\tilde g^{-1/2}(x)\,\nabla\tilde u(x))\\ &= \operatorname{cof}\tilde g^{1/2}(\xi)\, D\varphi(-\tilde g^{-1/2}(\xi)\, S\nabla\tilde u(\xi))\\ &= -S\operatorname{cof}\tilde g^{1/2}(\xi)\, D\varphi(\tilde g^{-1/2}(\xi)\,\nabla\tilde u(\xi))\\ &= -\tilde\sigma(\xi)S = \tilde\sigma(x).\end{aligned}$$

Thus $\tilde\sigma = \operatorname{cof}(\tilde g^{1/2})\, D\varphi(\tilde g^{-1/2}\,\nabla\tilde u)$ holds a.e. in B.

Since $\tilde f = 0 = \tilde u$ on $\overline{B}_+\cap\overline{B}_- = B\cap(B'\times\{0\})$ the maps $\tilde u$ and $\tilde f$ belong to $W^{1,2}(B)$. Notice that $g\in C(B)$. Clearly $\tilde\sigma\in L^2(B)$ and $\tilde\sigma|_{B_\pm}\in H(\operatorname{div},B_\pm)$. Hence it remains to prove $\operatorname{div}\tilde\sigma = \tilde f$ in $\mathcal{D}'(B)$. Given $\eta\in\mathcal{D}(B)$, set $\alpha := (\eta+\eta\circ S)/2$ and $\beta := (\eta-\eta\circ S)/2$. Since $\nabla\alpha(x) = (\nabla\eta(x)+\nabla\eta(Sx)S)/2 = \nabla\alpha(Sx)S$ we get

$$\int_B \tilde\sigma\cdot\nabla\alpha\,dx = \int_{B_+}(\tilde\sigma(x)+\tilde\sigma(Sx))\cdot\nabla\alpha(x)\,dx = 0.$$

We have $\beta = 0$ on $B'\times\{0\}$ and $\nabla\beta(Sx) = -\nabla\beta(x)S$. Thus a transformation to B_+ and an integration by parts in B_+ lead to

$$\begin{aligned}&\int_B \tilde\sigma\cdot\nabla\eta\,dx = \int_{B_+}\tilde\sigma(x)\cdot\nabla\beta(x)\,dx + \int_{B_+}\tilde\sigma(Sx)\cdot\nabla\beta(Sx)\,dx\\ &= 2\int_{B_+}\tilde\sigma(x)\cdot\nabla\beta(x)\,dx = 2\int_{B_+}\tilde f(x)\beta(x)\,dx = \int_B\tilde f(x)\beta(x)\,dx.\end{aligned}$$

Hence $-\operatorname{div}\tilde\sigma = \tilde f$ in $\mathcal{D}'(B)$, and the proof of Lemma 4.5 is finished. □

If we can show that the transformed stress $\tilde\sigma$ satisfies $\tilde\sigma\in W^{1,2}_{loc}(B;\mathbb{M}^{n\times n})$, then we easily conclude that $\sigma\in W^{1,2}(\Omega\cap B(x_0,\delta/2);\mathbb{R}^n)$, and we are done. To establish the regularity of $\tilde\sigma$ we cannot directly appeal to Theorem 2.1 since $\tilde\sigma$ is not of the form $D\varphi(\nabla\tilde u)$ but is given by the inhomogeneous expression $\operatorname{cof}(\tilde g^{1/2})\, D\varphi(\tilde g^{-1/2}\,\nabla\tilde u)$. To conclude we thus adopt the strategy of the proof of Theorem 2.1 for the present situation with variable coefficients.

Proof of Theorem 4.3. Let $x\in B$, $h>0$, and let $M\in\mathbb{R}^n$ with $|M| = 1$. We use the abbreviations $x_2 := x+hM$, $x_0 := x-h\,M$, $x_1 := x$ and define, for $j = 1,2$,

$$\begin{aligned}&F_j := \nabla\tilde u(x_j),\quad \sigma_j := \tilde\sigma(x_j),\quad U_j := \tilde g^{-1/2}(x_j),\\ &V_j := \operatorname{cof}U_j^{-1},\quad \Sigma_j := \sigma_j\,\det U_j,\quad T_j := \Sigma_jU_j^{-1}.\end{aligned}$$

We write $a\lesssim b$ to denote $a\le C\,b$ if C is a generic constant that is independent of $\delta>0$, $h>0$ (as long as they are sufficiently small). The constant $C>0$ may, however, depend on g, U_j, V_j, e.g., through $\|\tilde g\|_{W^{1,\infty}(B)}$, $\|\operatorname{cof}\tilde g\|\|_{W^{1,\infty}(B)}$, $\|\tilde g^{-1}\|_{W^{1,\infty}(B)}$, $\|\operatorname{cof}\tilde g^{-1}\|_{W^{1,\infty}(B)}$, or $\|\eta\|_{W^{1,\infty}(B)}$. With this notation we have

$$\begin{aligned}|\sigma_2-\sigma_1|^2 &= |D\varphi(F_2U_2)V_2 - D\varphi(F_1U_1)V_1)|^2\\ &\lesssim |V_2-V_1|^2|D\varphi(F_1U_1)|^2 + |D\varphi(F_2U_2)-D\varphi(F_1U_1)|^2.\end{aligned}$$

Using Proposition 4.1 and the identity $T_jU_j = \Sigma_j$ we infer

$$\begin{aligned}
&|D\varphi(F_2U_2) - D\varphi(F_1U_1)|^2 \\
&\lesssim (D\varphi(F_2U_2) - D\varphi(F_1U_1)) \cdot (F_2U_2 - F_1U_1) \\
&= (T_2 - T_1) \cdot (F_2U_2 - F_1U_1) \\
&= (\Sigma_2 - \Sigma_1) \cdot (F_2 - F_1) + (T_2 - T_1) \cdot (F_1 + F_2)(U_2 - U_1) \\
&\quad + T_1 \cdot F_1(U_2 - U_1) - T_2 \cdot F_2(U_2 - U_1).
\end{aligned}$$

Consider $\eta \in \mathcal{D}(B)$, $0 \le \eta \le 1$, which equals one in a neighborhood of $x_0 = 0$, and assume that $|h|$ is sufficiently small. Multiply the combination of the last two estimates by η^2/h^2 and integrate over $\operatorname{supp}\eta$. With the notation $\tilde\tau(x) := (\tilde\sigma(x_2) - \tilde\sigma(x_1))/h$ and $\tilde e(x) := (\tilde u(x_2) - \tilde u(x_1))/h$, we deduce that

$$\begin{aligned}
&\int \eta^2(x)|\tilde\tau(x)|^2\,dx \lesssim \int \eta^2|\tilde\sigma(x)|^2\,dx \\
&+ 1/h^2 \int \eta^2(\Sigma_2 - \Sigma_1) \cdot (F_2 - F_1)\,dx \\
&+ 1/h \int \eta^2|T_2 - T_1|\,(|\nabla\tilde u(x)| + |\nabla\tilde u(x + h\,M)|)\,dx \\
&+ 1/h^2 \int \eta^2 T_1(U_2 - U_1) \cdot F_1\,dx \\
&- 1/h^2 \int \eta^2 T_2(U_2 - U_1) \cdot F_2\,dx \\
&=: \text{ I } + \text{ II } + \text{ III } + \text{ IV} - \text{V}.
\end{aligned}$$

Term I is bounded since $\tilde\sigma \in L^2(B)$. Term II is recast into the form

$$\begin{aligned}
\text{II} &= 1/h^2 \int \eta^2(\Sigma_2 - \Sigma_1) \cdot (F_2 - F_1)\,dx \\
&= \int \eta^2(x)\,\det\tilde g^{-1/2}(x)\,\tilde\tau(x) \cdot \nabla\tilde e(x)\,dx \\
&\quad + \int \eta^2(x)\left(\det\tilde g^{-1/2}(x_2) - \det\tilde g^{-1/2}(x_1)\right)/h \\
&\qquad \times \tilde\sigma(x_2) \cdot \nabla\tilde e(x)\,dx.
\end{aligned}$$

Since $\tilde e\eta^2\,\det\tilde g^{-1/2} \in H^1(B)$ is a feasible test function we have

$$\begin{aligned}
&\int \eta^2 \det\tilde g^{-1/2}\tilde\tau \cdot \nabla\tilde e\,dx = -\int \tilde e\tilde\tau \cdot \nabla(\eta^2 \det\tilde g^{-1/2})\,dx \\
&+ \int \tilde e(x)\eta^2(x) \det g^{-1/2}(x)\,(f(x_2) - f(x_1))\,/h\,dx \\
&\lesssim \|\tilde u\|_{1,2}(\|f\|_{1,2} + \|\eta\tilde\tau\|_2)
\end{aligned}$$

with the abbreviations $\|\cdot\|_p := \|\cdot\|_{L^p(B)}$ and $\|\cdot\|_{1,p} := \|\cdot\|_{W^{1,p}(B)}$. To estimate the other term in II we write out $\nabla\tilde e(x) = 1/h\,(\nabla\tilde u(x + hM) - \nabla\tilde u(x))$, split the integral into two integrals, and perform a change of variables $x \mapsto x - hM$ in the first integral

(summation by parts). This yields

$$\begin{aligned}
&\int \eta^2(x)\big(\det \tilde g^{-1/2}(x_2) - \det \tilde g^{-1/2}(x_1)\big)/h\,\tilde\sigma(x_2)\cdot\nabla\tilde e(x)\,dx\\
&= -\int (\eta^2(x_1)-\eta^2(x_0))/h\\
&\qquad \times\ (\det \tilde g^{-1/2}(x_1) - \det \tilde g^{-1/2}(x_0))/h\,\tilde\sigma(x)\cdot\nabla\tilde u(x)\,dx\\
&\quad -\int \eta^2(x)(\det \tilde g^{-1/2}(x_2) - \det \tilde g^{-1/2}(x))/h\,\tilde\tau(x)\cdot\nabla\tilde u(x)\,dx\\
&\quad -\int \eta^2(x)\Big(\det \tilde g^{-1/2}(x_2) - 2\det \tilde g^{-1/2}(x_1)\\
&\qquad\qquad + \det \tilde g^{-1/2}(x_0)\Big)/h^2\,\tilde\sigma(x)\cdot\nabla\tilde u(x)\,dx\\
&\lesssim (\|\tilde\sigma\|_2 + \|\eta\tilde\tau\|_2)\cdot\|\tilde u\|_{1,2}.
\end{aligned}$$

In the last step we used $g\in C^{1,1}$. It is at this point that the assumption $\partial\Omega$ is $C^{2,1}$ enters. Combining the previous estimates, we get

$$\text{II} \ \lesssim \|\tilde u\|_{1,2}(\|f\|_{1,2} + \|\tilde\sigma\|_{1,2} + \|\eta\tilde\tau\|_2).$$

Since $T_j = D\varphi(\nabla\tilde u(x_j)) = \sigma_j \operatorname{cof} U_j$, similar arguments lead to

$$\begin{aligned}
\text{III} \ &= 1/h\int \eta^2|T_2 - T_1|(|\nabla\tilde u(x_1)| + |\nabla\tilde u(x_2)|)\,dx\\
&\lesssim (\|\eta\tilde\tau\|_2 + \|\tilde\sigma\|_2)\|u\|_{1,2}.
\end{aligned}$$

A shift in the variable x_2 in term V leads similarly to the estimate

$$\begin{aligned}
\text{IV} - \text{V} &= \int \eta^2 T_1(\tilde g^{-1/2}(x_2) - 2\tilde g^{-1/2}(x_1) + \tilde g^{-1/2}(x_0)/h^2\cdot\nabla\tilde u(x)\,dx\\
&\quad + \int (\eta^2(x_1) - \eta^2(x_2)/h\,T_1\,(\tilde g^{-1/2}(x) - \tilde g^{-1/2}(x_0)/h\cdot\nabla\tilde u(x)\,dx\\
&\lesssim \|\tilde\sigma\|_2\,\|\tilde u\|_{1,2}.
\end{aligned}$$

Absorbing $\|\eta\tau\|_2$ in terms II and III concludes the proof. ∎

5. A symmetric variant for geometrically linear models. This section concerns a variation of Theorem 2.1 for symmetrized gradients. Some (geometrically) linear models in elasticity involve the symmetric Green strain

$$\varepsilon(u) := \operatorname{sym} Du := ((\partial u_j/\partial x_k + \partial u_k/\partial x_j) :\ j,k = 1,\dots,n)$$

for $m = n$. For ease of presentation we focus on $p = r = q = 2$ and $s = 0$ as in linear elasticity but emphasize robustness with respect to the limit $\lambda\to\infty$, where λ is one of the Lamé constants (see below).

Let $\mathbb{M}^{n\times n}_{sym}$ denote the symmetric real $n\times n$ matrices. The fourth-order elasticity tensor $\mathbb{C}:\mathbb{M}^{n\times n}_{sym}\to\mathbb{M}^{n\times n}_{sym}$ is defined by

$$\mathbb{C}E := \lambda\ \operatorname{tr}(E)\,\mathbb{I} + 2\mu\,E \quad \text{for } E\in\mathbb{M}^{n\times n}_{sym}.$$

Here the positive scalars λ,μ are the Lamé constants, $\mathbb{I}$ is the identity matrix, and $\operatorname{tr}(E) := \sum_{j=1}^n E_{jj}$. Since $\mathbb{C}$ is symmetric and positive definite, there exist an inverse $\mathbb{C}^{-1}$ and the square roots $\mathbb{C}^{1/2}$ and $\mathbb{C}^{-1/2}$. The norm

$$|\,E\,|_{\mathbb{C}} := (E : \mathbb{C}E)^{1/2} = |\,\mathbb{C}^{1/2}E\,| \quad \text{for } E\in\mathbb{M}^{n\times n}_{sym}$$

is induced by the energy scalar product with respect to $\mathbb{C}$ in $\mathbb{M}^{n\times n}_{sym}$.

Suppose that $\varphi : \mathbb{M}^{n\times n}_{sym} \to \mathbb{R}$ is C^1 and that there exists a constant c_5 such that for all $A, B \in \mathbb{M}^{n\times n}_{sym}$,

$$|D\varphi(A) - D\varphi(B)|^2_{\mathbb{C}^{-1}} \le c_5\,(D\varphi(A) - D\varphi(B)) : (A - B). \tag{5.1}$$

THEOREM 5.1. *Assume furthermore that*

$$u \in H^1(\Omega;\mathbb{R}^n) \quad \textit{and} \quad \sigma := D\varphi(\varepsilon(u))$$

satisfy

$$\sigma \in L^2_{loc}(\Omega;\mathbb{M}^{n\times n}_{sym}) \quad \textit{and} \quad \operatorname{div}\sigma \in H^1_{loc}(\Omega;\mathbb{R}^n).$$

Then

$$\sigma \in H^1_{loc}(\Omega;\mathbb{M}^{n\times n}_{sym}).$$

Moreover, if $\omega_0 \subset\subset \omega_1 \subset\subset \Omega$ for nonvoid open sets ω_0 and ω_1, there exists a λ-independent constant $c_6 > 0$ such that

$$\|\,\sigma\,\|_{H^1(\omega_0)} \le c_6\,(\|\,u\,\|_{H^1(\omega_1)} + \|\,\sigma\,\|_{L^2(\omega_1)} + \|\,\operatorname{div}\sigma\,\|_{H^1(\omega_1)}). \tag{5.2}$$

Remark 5.1. (a) Korn's inequality does not play an explicit role in the proof. It is used, however, in applications to guarantee $u \in H^1(\Omega)$ (and so the boundedness of e in $L^2_{loc}(\Omega)$ in the proof).

(b) The fourth-order elasticity tensor could be more general; for the assertion $\sigma \in H^1_{loc}(\Omega;\mathbb{M}^{n\times n}_{sym})$ it is sufficient that $\mathbb{C}$ is a linear, continuous, and positive definite operator.

(c) The constant c_6 in (5.2) depends on c_5, μ, ω_0, and ω_1, but on neither σ nor u.

(d) The functional $\varphi : \mathbb{M}^{n\times n}_{sym} \to \mathbb{R}$ may depend on $\mathbb{C}$ and λ; the constant c_6 depends on φ only through c_5 and stays independent of λ as long as c_5 does.

Proof of Theorem 5.1. The proof follows the arguments of the proof of Theorem 2.1, but the differential operator D is replaced by the symmetric variant ε. In particular, $\delta := \varepsilon(e)$. This results in the estimate

$$\begin{aligned}
\|\,\eta\,\mathbb{C}^{-1/2}\tau\,\|_2^2 &\le c_7 \int_\omega \eta^2\,\varepsilon(e) : \tau\,dx = -c_7 \int_\omega e\,\operatorname{div}(\tau\eta^2)\,dx \\
&\le c_7\,\|\,e\,\|_2\,\|\,\eta\,\|_{W^{1,\infty}(\Omega)}(2\|\,\eta\,\tau\,\|_2 + \|\,\eta\,\operatorname{div}\tau\,\|_2) \\
&\le c_8(\|\,u\,\|^2_{H^1(\omega)} + \|\,\operatorname{div}\sigma\,\|^2_{H^1(\omega)} + \|\,\eta\,\tau\,\|_2)^2
\end{aligned} \tag{5.3}$$

for some (h,λ,μ)-independent constant $c_8 > 0$. The first assertion follows (with a constant depending on λ) from (5.3) and the estimate

$$\|\,\eta\,\tau\,\|_2 \le (2\mu + \lambda)^{1/2}\|\,\eta\,\mathbb{C}^{-1/2}\tau\,\|_2.$$

In order to prove (5.2) fix $\omega_0 \subset\subset \omega_1$ and suppose that ω is a bounded Lipschitz domain between ω_0 and ω_1, $\omega_0 \subset\subset \omega \subset\subset \omega_1$. Assume that $\eta \in \mathcal{D}(\omega)$ satisfies $0 \le \eta \le 1$ and equals $\eta = 1$ on ω_0. Then we introduce the deviator $\operatorname{dev}(\tau) := \tau - \operatorname{tr}(\tau)/n\,\mathbb{I}$ and rewrite (5.3) as

$$\begin{aligned}
\|\,\eta\,\mathbb{C}^{-1/2}\tau\,\|_2^2 &= \frac{\|\,\operatorname{dev}(\eta\tau)\,\|_2^2}{2\mu} + \frac{\|\,\operatorname{tr}(\eta\tau)\,\|_2^2}{n^2(2\mu/n + \lambda)} \\
&\le c_8\Big(\|\,u\,\|^2_{H^1(\omega)} + \|\,\operatorname{div}\sigma\,\|^2_{H^1(\omega)} + \|\,\operatorname{dev}(\eta\tau)\,\|_2^2 + \|\,\operatorname{tr}(\eta\tau)\,\|_2^2\Big).
\end{aligned} \tag{5.4}$$

The λ-independent bound requires an extra argument using results for the Stokes problem [BF91, GR86]. To apply this we first reduce to a situation with zero mean. Let ξ be the center of mass of ω. We write $|\omega|$ for the measure of ω, and we set $e_1 = (1, 0, \dots, 0)$. Define the constant

$$\tau_0 := \int_\omega \operatorname{tr}(\eta\,\tau) dx/|\omega| \in \mathbb{R}$$

and consider the function $v_1 \in H^1(\omega; \mathbb{R}^n)$ defined by

$$v_1(x) := \tau_0((x - \xi) \cdot e_1)\, e_1 \quad \text{for } x \in \omega.$$

Then $\operatorname{div} v_1 = \tau_0$ and $\int_\omega (\tau_0 - \operatorname{tr}(\eta\,\tau))dx = 0$. The solvability of the Stokes equations guarantees the existence of $v_2 \in H^1_0(\omega; \mathbb{R}^n)$, which satisfies $\operatorname{div} v_2 = \tau_0 - \operatorname{tr}(\eta\tau)$ and the bound

$$\| v_2 \|_{H^1(\omega)} \le c_9 \| \tau_0 - \operatorname{tr}(\eta\,\tau) \|_2 \le c_9 \| \operatorname{tr}(\eta\,\tau) \|_2.$$

Thus there exists $c_{10} > 0$ such that $v := v_1 - v_2 \in H^1(\omega; \mathbb{R}^n))$ satisfies

$$\operatorname{div} v = \operatorname{tr}(\eta\,\tau) \quad \text{and} \quad \| v \|_{H^1(\omega)} \le c_{10} \| \operatorname{tr}(\eta\,\tau) \|_2. \tag{5.5}$$

Recall that $\operatorname{tr}(\eta\,\tau)/n\,\mathbb{I} := \eta\,\tau - \operatorname{dev}(\eta\,\tau)$. Hence

$$\begin{aligned} \| \operatorname{tr}(\eta\,\tau) \|_2^2 &= \int_\omega \operatorname{tr}(\eta\,\tau) \operatorname{div} v\, dx = \int_\omega \operatorname{tr}(\eta\,\tau)\mathbb{I} : Dv\, dx \\ &= n \int_\omega (\eta\,\tau - \operatorname{dev}(\eta\,\tau)) : Dv\, dx. \end{aligned}$$

Multiple applications of Cauchy's inequality and integration by parts yield

$$\begin{aligned} \frac{1}{n} \| \operatorname{tr}(\eta\,\tau) \|_2^2 &\le \| Dv \|_2 \| \operatorname{dev}(\eta\,\tau) \|_2 - \int_\Omega v \cdot (\tau \nabla\eta + \eta \operatorname{div}\tau) dx \\ &\le \| v \|_{H^1(\omega)} \Big(\| \operatorname{dev}(\eta\,\tau) \|_2 + \| \eta \operatorname{div}\tau \|_2 \Big) \\ &\quad - \int_\Omega v \cdot \tau \nabla\eta\, dx. \end{aligned} \tag{5.6}$$

To rewrite the last term using a summation by parts, let $\otimes$ denote the dyadic product and set

$$V_h(x) := \frac{1}{h} \Big((v \otimes \nabla\eta)(x) - (v \otimes \nabla\eta)(x - hM) \Big) \in \mathbb{M}^{n\times n} \quad \text{for a.e. } x \in \omega.$$

Now $(v \otimes \nabla\eta)_{jk} = v_j\, \partial\eta/\partial x_k$ belongs to $H^1(\omega)$, and we have

$$\lim_{h\to 0} \| V_h \|_2 \le | v \otimes \nabla\eta |_{H^1(\omega_1)} \le \| v \|_{H^1(\omega)} \| \eta \|_{W^{2,\infty}(\omega)}. \tag{5.7}$$

Since $\eta \in \mathcal{D}(\omega)$ is fixed we infer (for sufficiently small h) from (5.7) that

$$\begin{aligned} &- \int_\Omega v \cdot \tau \nabla\eta\, dx = \int_\Omega V_h : \sigma\, dx \\ &\le \| \sigma \|_{L^2(\omega_1)} \| V_h \|_{L^2(\omega_1)} \le c_{11} \| \sigma \|_{L^2(\omega_1)} \| v \|_{H^1(\omega)}. \end{aligned}$$

Using this in (5.6) and applying the estimate (5.5) to bound $\| v \|_{H^1(\omega)}$, we deduce

$$c_{12} \| \operatorname{tr}(\eta\,\tau) \|_2 \le \| \operatorname{dev}(\eta\,\tau) \|_2 + \| \operatorname{div} \tau \|_2 + \| \sigma \|_{L^2(\omega_1)}. \tag{5.8}$$

We return to (5.4) and substitute $\| \operatorname{tr}(\eta\,\tau) \|_2$ with the bound (5.8) on the right-hand side of (5.4). The resulting estimate reads

$$\begin{aligned} &\frac{\| \operatorname{dev}(\eta\tau) \|_2^2}{2\mu} + \frac{\| \operatorname{tr}(\eta\tau) \|_2^2}{n^2(2\mu/n+\lambda)} \\ &\le c_{13}\Big(\| u \|_{H^1(\omega)}^2 + \| \operatorname{div} \sigma \|_{H^1(\omega)}^2 + \| \sigma \|_{L^2(\omega_1)}^2 + \| \operatorname{dev}(\eta\tau) \|_2^2 \Big) \end{aligned}$$

and allows us to absorb $\| \operatorname{dev}(\eta\tau) \|_2$ using Young's inequality. Hence

$$c_{14} \| \eta\, \mathbb{C}^{-1/2} \tau \|_2 \le \| u \|_{H^1(\omega)} + \| \operatorname{div} \sigma \|_{H^1(\omega)} + \| \sigma \|_{L^2(\omega_1)}.$$

Another application of (5.8) finally yields

$$c_{15} \| \eta\, \tau \|_2 \le \| u \|_{H^1(\omega)} + \| \operatorname{div} \sigma \|_{H^1(\omega)} + \| \sigma \|_{L^2(\omega_1)}.$$

The proof is then concluded as in Theorem 2.1. □

6. An application to Hencky elastoplasticity with hardening. One time step within an elastoplastic evolution problem leads to Hencky's model. For various hardening laws and von-Mises yield conditions, the minimization problem takes the form (1.4). After an elimination of internal variables [ACZ99] the energy function becomes, in the notation of the previous section,

$$\varphi(E) := \frac{1}{2}\, E : \mathbb{C}E - \frac{1}{4\mu}\, \max\{0, |\operatorname{dev} \mathbb{C}E| - \sigma_y\}^2/(1+\eta) \tag{6.1}$$

for $E \in \mathbb{M}^{n\times n}_{sym}$. Here $\mathbb{C}$ is the fourth-order elasticity tensor, $\sigma_y > 0$ is the yield stress, and $\eta > 0$ is the modulus of hardening. The model of perfect plasticity corresponds to $\eta = 0$ [Tem83].

PROPOSITION 6.1. *We have, for all $A, B \in \mathbb{M}^{n\times n}_{sym}$,*

$$|D\varphi(A) - D\varphi(B)|^2_{\mathbb{C}^{-1}} \le (D\varphi(A) - D\varphi(B)) : (A - B). \tag{6.2}$$

Proof. Set $\xi(x) := 1 - \max\{0, 1 - \sigma_y/(2\mu\, x)\}/(1+\eta)$ to define the continuous and monotonously decreasing function $\xi : [0,\infty) \to (0,1]$ with $\xi(0) = 1 \ge \xi(x) > \eta/(1+\eta) > 0$ for $0 < x < \infty$. Then

$$D\varphi(E) = (\lambda + 2\mu/n)\, \operatorname{tr}(E)\, \mathbb{I} + 2\mu\, \xi(|\operatorname{dev} E|)\, \operatorname{dev} E \quad \text{for all } E \in \mathbb{M}^{n\times n}_{sym}.$$

Without loss of generality, we suppose that $a := |\operatorname{dev} A| \le b := |\operatorname{dev} B|$ and abbreviate $\alpha := \xi(a)$ and $\beta := \xi(b)$. First, we calculate

$$2\mu\, \delta := |D\varphi(A) - D\varphi(B)|^2_{\mathbb{C}^{-1}} - (D\varphi(A) - D\varphi(B)) : (A - B).$$

Then we have to show that

$$\delta = |\operatorname{dev}(\xi(a)A - \xi(b)B)|^2 - \operatorname{dev}(\xi(a)A - \xi(b)B) : \operatorname{dev}(A - B)$$

is nonpositive. To see that $\delta \le 0$ observe that $0 \le (1-\alpha)\beta + \alpha(1-\beta)$. Expanding the squares and collecting terms, we infer in combination with Cauchy's inequality that

$$\begin{aligned}\delta &= (\xi(a)a - \xi(b)b)^2 - (\xi(a)a - \xi(b)b)(a-b)\\ &\quad + (\operatorname{dev}(A) : \operatorname{dev}(B) - ab)\Big((1-\alpha)\beta + \alpha(1-\beta)\Big)\\ &\le (\xi(a)a - \xi(b)b)^2 - (\xi(a)a - \xi(b)b)(a-b)\\ &= (\xi(a)a - \xi(b)b)\Big((\alpha-1)a - (\beta-1)b\Big).\end{aligned}$$

An elementary analysis shows that $x\xi(x) \ge 0$ is monotonously increasing in $0 \le x < \infty$, while $x(\xi(x)-1) \le 0$ is monotonously decreasing. As a consequence, $a \le b$ implies $\xi(a)a \le \xi(b)b$ and $(\xi(a)-1)a \ge (\xi(b)-1)b$. Taking this into account in the last estimate of δ, we conclude that $\delta \le 0$. ∎

We therefore have the following consequence of Theorem 5.1.

COROLLARY 6.2. *If u is a minimizer of (1.2) in $\mathcal{A} \subseteq H^1(\Omega)$ and $f \in H^1_{loc}(\Omega)$, then $\sigma := D\varphi(\varepsilon(u)) \in W^{1,2}_{loc}(\Omega;\mathbb{R}^n)$.* ∎

Remark 6.1. (a) The corollary is essentially due to Seregin [Ser93].

(b) The case $\eta = 0$ corresponds to perfect plasticity [Tem83] and is excluded from our analysis. Then u belongs only to $BD(\Omega)$, the space of bounded deformations.

7. An application to a vector two-well problem. Given two distinct wells E_1 and E_2 in $\mathbb{M}^{n\times n}_{sym}$ with minimal energies W_1^0 and W_2^0 in $\mathbb{R}$, we consider the quadratic elastic energies

$$W_j(E) := \frac{1}{2}(E-E_j) : \mathbb{C}(E-E_j) + W_j^0 \quad \text{for all } E \in \mathbb{M}^{n\times n}_{sym}. \tag{7.1}$$

Energy minimization leads to an optimal choice of the configuration of the two phases, and so the strain energy density W is modeled by the minimum

$$W(E) = \min\{W_1(E), W_2(E)\} \quad \text{for all } E \in \mathbb{M}^{n\times n}_{sym}. \tag{7.2}$$

The two wells (transformation strains) are said to be compatible if the following condition holds:

$$E_1 = E_2 + \frac{1}{2}(a\otimes b + b\otimes a) \quad \text{for some } a, b \in \mathbb{R}^n. \tag{7.3}$$

The constant γ used below is determined by a certain projection onto the space of symmetric matrices and satisfies $0 < \gamma \le \frac{1}{2}|E_2 - E_1|^2_{\mathbb{C}}$. In the compatible case (7.3) it attains its upper bound, i.e., $\gamma = \frac{1}{2}|E_2 - E_1|^2_{\mathbb{C}}$. The quasi-convexification φ of W is given by [Koh91]:

$$\varphi(E) = \begin{cases} W_2(E) & \text{if } W_2(E) + \gamma \le W_1(E),\\ \frac{1}{2}(W_2(E)+W_1(E)) - \frac{1}{4\gamma}(W_2(E)-W_1(E))^2 - \frac{\gamma}{4} & \\ \qquad\qquad \text{if } |W_2(E) - W_1(E)| \le \gamma,\\ W_1(E) & \text{if } W_1(E) + \gamma \le W_2(E).\end{cases} \tag{7.4}$$

LEMMA 7.1 (see [CP97a]). *In the compatible case (7.3) we have, for all $A, B \in \mathbb{M}^{n\times n}_{sym}$,*

$$|D\varphi(A) - D\varphi(B)|^2_{\mathbb{C}^{-1}} \le \Big(D\varphi(A) - D\varphi(B)\Big) : (A-B). \tag{7.5}$$

Thus Theorem 5.1 implies the following result.

COROLLARY 7.2 (see [Ser96]). *If u is a minimizer of (1.4) in $\mathcal{A} \subseteq H^1(\Omega)$ and $f \in H^1_{loc}(\Omega)$, then $\sigma := D\varphi(\varepsilon(u)) \in W^{1,2}_{loc}(\Omega; \mathbb{M}^{n\times n})$.* □

Remark 7.1. (a) The corollary is due to Seregin [Ser96, Theorem 2.2]. In addition to the local stress regularity, he shows that the strain tensor locally has bounded mean oscillation, and he investigates the pure phase area.

(b) In the case of incompatible wells (i.e., if (7.3) fails) Lemma 7.1 fails (as it guarantees convexity of φ). Seregin [Ser99] showed that the quasi-convex envelope $\varphi(\operatorname{sym} F)$ can be rewritten as the sum of a convex function (which then satisfies an estimate of the form (7.5)) and a linear combination of second-order minors of F. The integral $\int_\Omega \operatorname{cof} Du\, dx$ depends only on the boundary values of u and can hence be neglected in the pure Dirichlet problem. Then, up to cofactor matrices of the gradient F, the stress belongs to $W^{1,2}_{loc}(\Omega; \mathbb{M}^{n\times n}_{sym})$. Formally one may interpret the term $\int_\Omega \operatorname{cof} Du\, dx$ as a constant pressure (as the model is in material coordinates). Such an interpretation is, however, doubtful if one keeps in mind that (7.1) is based on a linearization. Thus material and spatial coordinates coincide and incompressibility reads $\operatorname{div} u = 0$ and *not* $\det Du = 1$.

(c) A time-discretized model for hysteresis in [MTL] leads to a similar variational problem. From a stress estimate in [CP00] we obtain an analogue of Lemma 7.1 and can conclude $\sigma \in W^{1,2}_{loc}(\Omega; \mathbb{M}^{n\times n})$ as well.

ON A NONLINEAR PARTIAL DIFFERENTIAL EQUATION ARISING IN MAGNETIC RESONANCE ELECTRICAL IMPEDANCE TOMOGRAPHY*

SUNGWHAN KIM†‡, OHIN KWON§, JIN KEUN SEO†, AND JEONG-ROCK YOON¶

Abstract. This paper considers the fundamental questions, such as existence and uniqueness, of a mathematical model arising in the MREIT system, which is an electrical impedance tomography technique integrated with magnetic resonance imaging. The mathematical model for MREIT is the Neumann problem of a nonlinear elliptic partial differential equation $\nabla \cdot (\frac{a(x)}{|\nabla u(x)|}\nabla u(x)) = 0$. We show that this Neumann problem belongs to one of two cases: either infinitely many solutions exist or no solution exists. This explains rigorously the reason why we have used the modified model in [O. Kwon, E. J. Woo, J. R. Yoon, and J. K. Seo, *IEEE Trans. Biomed. Engrg.*, 49 (2002), pp. 160–167], which is a system of the Neumann problem associated with two different Neumann data. For this modified system, we prove a uniqueness result on the edge detection of a piecewise continuous conductivity distribution.

1. Introduction.

Magnetic resonance electrical impedance tomography (MREIT) is a new imaging technique of reconstructing the cross-sectional conductivity distribution of a human body by means of the electrical impedance tomography (EIT) technique integrated with the magnetic resonance imaging (MRI) technique. The EIT technique to estimate the conductivity distribution uses data obtained by injecting a known current into the body through electrodes placed on the surface and measuring the resulting voltage difference recorded on the electrodes. The EIT problem is known as a highly ill-posed inverse problem due to its low sensitivity of data to the change in conductivity value. (See [14].) MREIT is designed to overcome this severe ill-posedness of the EIT problem by making good use of a recent MRI technique, so-called current density imaging (CDI), which measures the internal current density distribution. (For related works see [4, 6, 10, 11, 12, 15].)

In the recent paper [7], a new reconstruction algorithm for MREIT was developed to provide a high-resolution conductivity image. This algorithm is based on a new mathematical modeling which is involved with a nonlinear partial differential equation instead of the linear conductivity equation. Although the algorithm has achieved

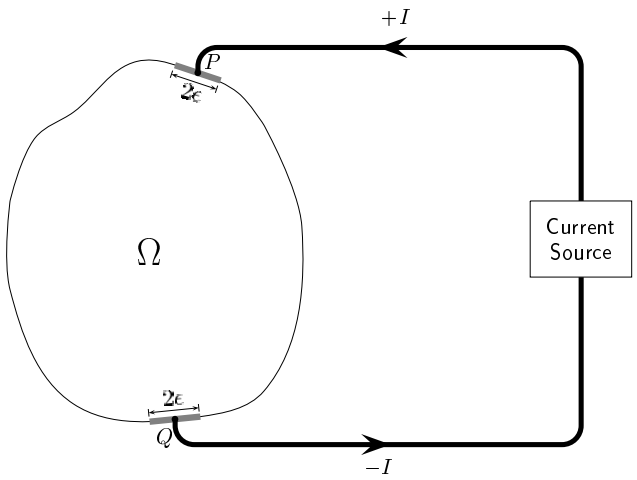

FIG. 1.1. *An illustration of the model where the current I is applied through a pair of electrodes attached to the boundary.*

successful numerical results in simulations, there has been no related mathematical theory for the new model such as existence and uniqueness. This paper is intended to provide answers to those questions.

Let us explain the mathematical model for MREIT, which was introduced in [7]. Let the cross-section of the cylindrical body occupy a bounded domain $\Omega \subset \mathbb{R}^2$. When a current is injected transversely through the outer surface of the body, it induces an electrical potential distribution u that satisfies the two-dimensional conductivity equation

$$\nabla \cdot (\sigma \nabla u) = 0 \quad \text{in } \Omega, \tag{1.1}$$

where σ denotes the conductivity coefficient of the body which we want to reconstruct. This unknown two variable function σ may be regarded as a piecewise continuous positive function. In the MREIT model, the current is applied through a pair of electrodes attached on the boundary $\partial\Omega$: If both electrodes of width 2ϵ are attached at points $P, Q \in \partial\Omega$, respectively, then the current density on the boundary can be approximated by a function

$$g(x) = \begin{cases} +\frac{I}{2\epsilon} & \text{on } \{|x-P| < \epsilon\} \cap \partial\Omega, \\ -\frac{I}{2\epsilon} & \text{on } \{|x-Q| < \epsilon\} \cap \partial\Omega, \\ 0 & \text{otherwise,} \end{cases} \tag{1.2}$$

where I is the current sent to both electrodes at P and Q; see Figure 1.1. For more details, see the ave-gab model in [3, 9].

With this current g, the resulting internal current density vector $\mathbf{J} = -\sigma\nabla u$ is divergence-free and satisfies the boundary condition

$$\sigma \frac{\partial u}{\partial \nu} = -\mathbf{J} \cdot \nu = g \qquad \text{on } \partial\Omega, \tag{1.3}$$

where ν denotes the outward unit normal vector to $\partial\Omega$. Moreover, the MREIT system furnishes the internal data $a = |\mathbf{J}| = \sigma|\nabla u|$, which is measured and processed in the

MRI system [7, 15]. We want to utilize this acquisition data a by substituting

$$\sigma(x) = \frac{a(x)}{|\nabla u(x)|}, \qquad x \in \Omega, \tag{1.4}$$

into the conductivity equation (1.1) and the Neumann boundary condition (1.3). As a result, the linear boundary value problem (1.1) and (1.3) with two unknowns σ and u is reduced to the following nonlinear Neumann boundary value problem with one unknown u:

$$\begin{aligned} \nabla\cdot\left(\frac{a}{|\nabla u|}\nabla u\right) &= 0 \quad \text{in } \Omega, \\ \frac{a}{|\nabla u|}\frac{\partial u}{\partial \nu} &= g \quad \text{on } \partial\Omega, \quad \text{and} \quad \int_{\partial\Omega} u\, ds = 0, \end{aligned} \tag{1.5}$$

where the last condition means the potential reference condition. To be precise, the electric potential $u \in H^1(\Omega)$ can be viewed as a weak solution satisfying

$$\int_\Omega \frac{a}{|\nabla u|}\nabla u \cdot \nabla\phi\, dx = \int_{\partial\Omega} g\phi\, ds \qquad \text{for all} \quad \phi \in H^1(\Omega)$$

with a constraint $\int_{\partial\Omega} u\, ds = 0$.

It is natural to investigate the fundamental mathematical issue of the nonlinear boundary value problem (1.5), such as existence and uniqueness. In practice, the existence may not be a serious problem, but the uniqueness must be seriously taken into account. In the case in which we have not one but several different solutions, there will be several corresponding distinct conductivity images, and we cannot judge which one would be the actual image.

Unfortunately, in section 3 we will prove that once (1.5) has a solution, then it always has infinitely many solutions under a practically acceptable assumption that will be precisely defined in section 3. Hence the model (1.5) using one measurement is insufficient for the reconstruction of the conductivity distribution. A numerical example is presented in section 5 to show how different conductivity images can be reconstructed with the same data (a, g). Moreover, we also prove in section 3 that (1.5) in general does not have an existence result even if a is smooth. We think that the existence of the solution to (1.5) is related to some complicated connection between a and g, because the internal current density a depends on the choice of the injected current g.

Thus the model should be modified in order to guarantee the uniqueness. In section 4, we apply two different currents g_1 and g_2 approximated in the same manner as in (1.2), attaching two different pairs of electrodes $\{P_1, Q_1\}$ and $\{P_2, Q_2\}$. Since the conductivity distribution σ is independent of the change of injected currents, from the relation (1.4) we may assume

$$\frac{a_1(x)}{|\nabla u_1(x)|} = \frac{a_2(x)}{|\nabla u_2(x)|}, \qquad x \in \Omega,$$

where u_j is a solution to the nonlinear Neumann boundary value problem (1.5) when g and a are replaced by g_j and a_j $(j = 1, 2)$. This leads to the following nonstandard

system of equations:

$$
\begin{aligned}
\nabla\cdot\left(\frac{a_j}{|\nabla u_j|}\nabla u_j\right) &= 0 \quad \text{in } \Omega,\\
\frac{a_1}{|\nabla u_1|} &= \frac{a_2}{|\nabla u_2|} \quad \text{in } \Omega,\\
\frac{a_j}{|\nabla u_j|}\frac{\partial u_j}{\partial \nu} &= g_j \quad \text{on } \partial\Omega,\\
\int_{\partial\Omega} u_j\, ds &= 0
\end{aligned}
\tag{1.6}
$$

for $j = 1, 2$. With this modified model and a practically acceptable assumption, in section 4 we are able to establish an important uniqueness result which may look strange at a glance.

In section 2, we define a space for physically meaningful conductivity distributions and recall some regularity properties of elliptic partial differential equations for further usage.

2. Definitions and preliminary. We assume that $\Omega \subset \mathbb{R}^2$, a cross-section of the human body, is a simply connected bounded domain with a $\mathcal{C}^2$ boundary. The conductivity distribution σ on the cross-section Ω may be regarded as a piecewise continuous function because distinct tissues have different conductivities. So, we may assume that σ belongs to the following class:

$$
\Sigma := \left\{ \sigma = \sigma_0 + \sum_{k=1}^{M} \sigma_k \chi_{D_k} \;\middle|\; M \in \mathbb{N},\ 0 < \sigma < \infty,\ \bar{D}_k \subset \Omega,\ \bar{D}_k \cap \bar{D}_\ell = \emptyset \text{ for } k \neq \ell, \right.
$$
$$
\left. \sigma_0 \in \mathcal{C}^\alpha(\bar{\Omega}),\ \sigma_k \in \mathcal{C}^\alpha(\bar{D}_k),\ \sigma_k \neq 0 \text{ on } \partial D_k,\ \partial D_k \text{ is a } \mathcal{C}^2 \text{ boundary} \right\},
$$

where χ_{D_k} denotes the characteristic function for D_k and $0 < \alpha < 1$ is not an important number. With this setting, for any $\sigma = \sigma_0 + \sum_{k=1}^{M} \sigma_k \chi_{D_k} \in \Sigma$, we easily see that

$$
\sigma \in \mathcal{C}^\alpha\left(\cup_{k=1}^{M} \bar{D}_k\right) \cap \mathcal{C}^\alpha\left(\Omega \setminus \cup_{k=1}^{M} D_k\right), \tag{2.1}
$$

$$
\{x \in \Omega \,|\, \sigma \text{ is discontinuous at } x\} = \bigcup_{k=1}^{M} \partial D_k. \tag{2.2}
$$

For a given current g in (1.2) and $\sigma = \sigma_0 + \sum_{k=1}^{M} \sigma_k \chi_{D_k} \in \Sigma$, let u be the solution of the classical Neumann boundary value problem

$$
\begin{aligned}
\nabla\cdot(\sigma\nabla u) &= 0 \quad \text{in } \Omega,\\
\sigma\frac{\partial u}{\partial \nu} &= g \quad \text{on } \partial\Omega, \quad \text{and} \quad \int_{\partial\Omega} u\, ds = 0.
\end{aligned}
\tag{2.3}
$$

From the basic theory of standard elliptic partial differential equations [5, 8], we know

$$
\begin{aligned}
&\text{(a)} \quad u \in \mathcal{C}(\bar{\Omega}),\\
&\text{(b)} \quad \nabla u \in \mathcal{C}^\alpha\left(\cup_{k=1}^{M} \bar{D}_k\right) \cap \mathcal{C}^\alpha\left(\Omega \setminus \cup_{k=1}^{M} D_k\right),\\
&\text{(c)} \quad \sigma_0(\xi)\nabla u^+(\xi)\cdot\nu(\xi) = (\sigma_0(\xi) + \sigma_k(\xi))\nabla u^-(\xi)\cdot\nu(\xi) \ \text{ if } \xi \in \partial D_k,\\
&\text{(d)} \quad \nabla u^+(\xi)\cdot\tau(\xi) = \nabla u^-(\xi)\cdot\tau(\xi) \ \text{ if } \xi \in \partial D_k,
\end{aligned}
\tag{2.4}
$$

where ν and τ are the outward unit normal vector and the unit tangent vector to ∂D_k, respectively, and u^+, u^- are defined by

$$u^+ = u|_{\Omega \setminus \bigcup_{k=1}^M \bar{D}_k} \quad \text{and} \quad u^- = u|_{\bigcup_{k=1}^M D_k}.$$

Moreover, owing to the choice of g as in (1.2), we can show that

$$\nabla u(x) \neq 0 \quad \text{for all } x \in \Omega, \tag{2.5}$$

the proof of which can be found in [1, 2, 13]. Indeed, (2.5) holds if nonzero g satisfies the following condition: there exist two disjoint arcs Γ^+ and Γ^- contained in $\partial\Omega$ such that

$$\Gamma^+ \cup \Gamma^- = \partial\Omega, \quad \text{and} \quad \Gamma^+ \subset \{g \geq 0\}, \quad \Gamma^- \subset \{g \leq 0\},$$

the detailed proof of which will be given in Remark 4.2 for completeness.

3. Nonexistence and nonuniqueness. In this section, we will prove that the nonlinear Neumann boundary value problem (1.5) under a practically acceptable assumption is generally not uniquely solvable by constructing infinitely many different solutions from one solution and by giving an example for nonexistence.

From the relation (1.4) between the conductivity distribution σ and the measured current density a, we may assume that a practically meaningful solution u of the Neumann problem (1.5) satisfies

$$\frac{a(x)}{|\nabla u(x)|} \in \Sigma, \tag{3.1}$$

since Σ contains almost all cases of piecewise continuous conductivities that may happen in the real situation. So, the practical solution u can be considered as a $H^1(\Omega)$ solution of the more complicated problem where g is given as in (1.2),

$$\begin{aligned} &\nabla\cdot\left(\frac{a}{|\nabla u|}\nabla u\right) = 0 \quad \text{in } \Omega, \quad \frac{a}{|\nabla u|} \in \Sigma, \\ &\frac{a}{|\nabla u|}\frac{\partial u}{\partial \nu} = g \quad \text{on } \partial\Omega, \quad \text{and} \quad \int_{\partial\Omega} u\, ds = 0. \end{aligned} \tag{3.2}$$

Hence, if u is a solution of (3.2), it satisfies (2.5) and the properties (a)–(d) in (2.4). By the property (b) in (2.4) and (3.1), $a = \frac{a}{|\nabla u|}|\nabla u|$ must be also a piecewise continuous function in Ω.

We can easily construct a solution for (3.2): For any $\sigma \in \Sigma$, there exists a unique solution u_σ to the classical Neumann problem (2.3), and this u_σ is also a solution to (3.2) when a is given by $a = \sigma|\nabla u_\sigma|$. To our surprise, (3.2) with this a has infinitely many solutions, and u_σ is just one of them. The following theorem states this nonuniqueness result.

THEOREM 3.1. *If the nonlinear problem* (3.2) *has a solution, then it has infinitely many solutions.*

Proof. Suppose u is a solution of the problem (3.2). We will construct infinitely many solutions by means of u. Since u satisfies the property (a) in (2.4) and (2.5), we have $\min_{x\in\bar{\Omega}} u(x) < \max_{x\in\bar{\Omega}} u(x)$. For any $t \in (\min_{\bar{\Omega}} u, \max_{\bar{\Omega}} u)$ and $\lambda > 0$, we define

$$u_{t,\lambda} := \begin{cases} u + c & \text{in} \quad \Omega_t^+, \\ \lambda u + (1-\lambda)t + c & \text{in} \quad \Omega_t^-, \end{cases}$$

where the number c is chosen so that $\int_{\partial\Omega} u_{t,\lambda}\, ds = 0$ and

$$\Omega_t^+ := \{x \in \Omega \,|\, u(x) \geq t\} \quad \text{and} \quad \Omega_t^- := \{x \in \Omega \,|\, u(x) < t\}.$$

Then it is easy to see that $u_{t,\lambda} \in \mathcal{C}(\bar{\Omega})$ and

$$\frac{\nabla u_{t,\lambda}(x)}{|\nabla u_{t,\lambda}(x)|} = \frac{\nabla u(x)}{|\nabla u(x)|} \quad \text{for all } x \in \Omega.$$

Since the possible discontinuity regions of $a/|\nabla u_{t,\lambda}|$ are $\{x \in \Omega \,|\, u(x) = t\}$ and those of $a/|\nabla u|$, we easily verify that $a/|\nabla u_{t,\lambda}| \in \Sigma$. Therefore $u_{t,\lambda}$ is also a solution to (3.2), which completes the proof. □

In section 5, we will present two distinct (numerically obtained) solutions that will arise in a complicated real situation and which solve the same problem (3.2).

Now we investigate the existence question. For simplicity, we confine ourselves to a unit square domain $\Omega = (0,1) \times (0,1)$ in $\mathbb{R}^2$. Let $x = (x_1, x_2)$ denote a point in Ω and let the current pattern g on $\partial\Omega$ be given by

$$g(x) = \begin{cases} -1 & \text{if } x_1 = 0, \\ 1 & \text{if } x_1 = 1, \\ 0 & \text{otherwise.} \end{cases} \tag{3.3}$$

The next theorem furnishes an example for the nonexistence of (3.2).

THEOREM 3.2. *Let $\Omega = (0,1) \times (0,1)$ and g be given in* (3.3)*. Assume that a in* (3.2) *depends only on the x_1-variable, that is, $a(x_1, x_2) = a(x_1)$. The necessary and sufficient condition for the existence of solution to* (3.2) *is $a \equiv 1$.*

Proof. If $a \equiv 1$, then clearly $u(x) = x_1 - \frac{1}{2}$ is a solution of (3.2) which would be one of the infinitely many solutions. This proves the sufficiency.

To show the necessity, suppose that the problem (3.2) has a solution u. First, we will prove that $a(t) \geq 1$ for all $t \in (0,1)$. For convenience, we denote

$$l_1 = \{x \in \partial\Omega \,|\, x_2 = 0\}, \qquad l_2 = \{x \in \partial\Omega \,|\, x_1 = 1\},$$
$$l_3 = \{x \in \partial\Omega \,|\, x_2 = 1\}, \qquad l_4 = \{x \in \partial\Omega \,|\, x_1 = 0\},$$

and let $R_t := \{x \in \Omega \,|\, 0 < x_1 < t\}$ be a rectangle on the left side of the line $\{x_1 = t\}$.

Applying the divergence theorem on R_t, we obtain

$$\begin{aligned} 0 &= \int_{\partial R_t} \frac{a}{|\nabla u|} \frac{\partial u}{\partial \nu}\, ds \\ &= \int_{\partial R_t \cap \partial\Omega} g\, ds + \int_{\partial R_t \cap \{x_1 = t\}} \frac{a}{|\nabla u|} \nabla u \cdot \nu\, ds \\ &= -\int_{l_4} ds + a(t) \int_{\partial R_t \cap \{x_1 = t\}} \frac{\nabla u \cdot \nu}{|\nabla u|}\, ds \\ &\leq -1 + a(t), \end{aligned} \tag{3.4}$$

since $a(x) = a(t)$ on $\partial R_t \cap \{x_1 = t\}$ and $\nabla u \cdot \nu \leq |\nabla u|$, where ν denotes the outward unit normal to R_t. Hence we have $a(t) \geq 1$ for all $t \in (0,1)$.

Now, we will show that the level curve $\Gamma_t := \{x \in \Omega \,|\, u(x) = u(t,0)\}$ is the vertical line $\{x \in \Omega \,|\, x_1 = t\}$ for all $t \in (0,1)$. Since $a \geq 1$, the choice of g in (3.3) and the Neumann boundary condition in (3.2) yield $\partial u/\partial\nu(t,0) = 0$, which implies

$$\min_{x \in \bar{\Omega}} u(x) < u(t,0) < \max_{x \in \bar{\Omega}} u(x).$$

Thus $\Omega_t := \{x \in \Omega \,|\, u(x) < u(t,0)\}$ is a nonempty open subset of Ω and $(t,0) \in \partial\Omega_t$. It is easy to see that

$$\mathcal{H}^1(\partial\Omega_t \cap l_4) \,<\, \mathcal{H}^1(\partial\Omega_t \setminus (l_1 \cup l_3 \cup l_4)) \quad \text{if } \Gamma_t \neq \{x \in \Omega \,|\, x_1 = t\}, \tag{3.5}$$

where $\mathcal{H}^1(L)$ denotes the arclength of the curve L.

Applying the divergence theorem on Ω_t, we have

$$\begin{aligned} 0 &= \int_{\partial\Omega_t} \frac{a}{|\nabla u|}\frac{\partial u}{\partial \nu}\, ds \\ &= \int_{\partial\Omega_t \cap \partial\Omega} g\, ds + \int_{\partial\Omega_t \setminus \partial\Omega} \frac{a}{|\nabla u|}\frac{\partial u}{\partial \nu}\, ds \\ &= -\mathcal{H}^1(\partial\Omega_t \cap l_4) + \mathcal{H}^1(\partial\Omega_t \cap l_2) + \int_{\partial\Omega_t \setminus \partial\Omega} a\frac{\nabla u \cdot \nu}{|\nabla u|}\, ds, \end{aligned} \tag{3.6}$$

where ν denotes the outward unit normal to Ω_t. Since $u(x) < u(t,0)$ in Ω_t and $u(x) = u(t,0)$ on $\partial\Omega_t \setminus \partial\Omega$, we have $\nu = \nabla u/|\nabla u|$ on $\partial\Omega_t \setminus \partial\Omega$, which implies

$$\frac{\nabla u \cdot \nu}{|\nabla u|} = 1 \quad \text{on } \partial\Omega_t \setminus \partial\Omega.$$

By the above identity and the fact that $a \geq 1$, from (3.6) we get

$$\begin{aligned} \mathcal{H}^1(\partial\Omega_t \cap l_4) &= \mathcal{H}^1(\partial\Omega_t \cap l_2) + \int_{\partial\Omega_t \setminus \partial\Omega} a\, ds \\ &\geq \mathcal{H}^1(\partial\Omega_t \cap l_2) + \mathcal{H}^1(\partial\Omega_t \setminus \partial\Omega) \\ &= \mathcal{H}^1(\partial\Omega_t \setminus (l_1 \cup l_3 \cup l_4)). \end{aligned}$$

Hence, from (3.5) it must be $\Gamma_t = \{x \in \Omega \,|\, x_1 = t\}$, that is, $u(t,x_2) = u(t,0)$ for $0 < x_2 < 1$, which implies $(\nabla u \cdot \nu)/|\nabla u| = \pm 1$ on $\partial R_t \cap \{x_1 = t\}$ in (3.4). Thus from (3.4), we have

$$0 = \int_{\partial R_t} \frac{a}{|\nabla u|}\frac{\partial u}{\partial \nu}\, ds = -1 \pm a(t).$$

By the knowledge of $a \geq 1$, we conclude that $a(t) = 1$ for all $t \in (0,1)$, which proves the necessity. ∎

4. Uniqueness of edge in a modified system. In order not to go astray from the main point of MREIT, we must focus on the final goal of MREIT, which aims to reconstruct the conductivity image σ. In section 3, we have observed that the model (3.2) may have infinitely many solutions u, and so has infinitely many distinct conductivity images $\sigma = a/|\nabla u|$. Thus, the model (3.2) is not appropriate for making a reconstruction algorithm. This is the main reason why the modified system (1.6) was introduced in [7] for the reconstruction algorithm that has been successfully demonstrated to provide accurate high-resolution conductivity images.

Although in numerical simulations in [7] the system (1.6) seems to have uniqueness, we were not able to prove the uniqueness rigorously as of this writing, but we could prove a practically useful uniqueness result which guarantees the unique detection of the edges of the conductivity image. This means that the system (1.6) uniquely determines the interface where the conductivity distribution σ is discontinuous.

As discussed at the beginning of section 3, if we assume that (u_1, u_2) is a practically acceptable solution of the system (1.6), we may impose the assumption

$$\sigma = \frac{a_1}{|\nabla u_1|} = \frac{a_2}{|\nabla u_2|} \in \Sigma,$$

which is the two-measurement analogue of the assumption (3.1). By plugging this assumption into the system (1.6), we have the following system, which will be considered in this section:

$$\begin{aligned} \nabla\cdot\left(\frac{a_j}{|\nabla u_j|}\nabla u_j\right) &= 0 \quad \text{in } \Omega, \\ \frac{a_1}{|\nabla u_1|} &= \frac{a_2}{|\nabla u_2|} \in \Sigma, \\ \frac{a_j}{|\nabla u_j|}\frac{\partial u_j}{\partial \nu} &= g_j \quad \text{on } \partial\Omega, \\ \int_{\partial\Omega} u_j\, ds &= 0 \end{aligned} \tag{4.1}$$

for $j = 1, 2$. For the uniqueness of (4.1), we need to choose an appropriate pair of current patterns g_1 and g_2 to have

$$|\nabla u_1(x) \times \nabla u_2(x)| > 0 \quad \text{for all } x \in \Omega. \tag{4.2}$$

In practice, each current g_j $(j = 1, 2)$ is applied through one pair of electrodes attached at points $P_j, Q_j \in \partial\Omega$. Here, the points P_1, P_2, Q_1, and Q_2 are situated along the boundary $\partial\Omega$ in this order and separated by a distance greater than 2ϵ. (See [7].) Hence we can assume, as in (1.2), the current g_j is approximated by

$$g_j(x) = \begin{cases} +\frac{I}{2\epsilon} & \text{on } \{|x - P_j| < \epsilon\} \cap \partial\Omega, \\ -\frac{I}{2\epsilon} & \text{on } \{|x - Q_j| < \epsilon\} \cap \partial\Omega, \\ 0 & \text{otherwise,} \end{cases} \tag{4.3}$$

where I is the current sent to both electrodes at P_j and Q_j, and 2ϵ is the width of each electrode. With these currents g_1 and g_2 as the Neumann data, from (2.5) we can easily see that the solution $(u_1, u_2) \in H^1(\Omega) \times H^1(\Omega)$ to the nonlinear system (4.1) satisfies

$$\nabla u_j(x) \neq 0 \quad \text{for all } x \in \Omega, \quad j = 1, 2.$$

More generally, in this case we can prove that (4.2) holds as the following lemma.

LEMMA 4.1. *Suppose that $(u_1, u_2) \in H^1(\Omega) \times H^1(\Omega)$ is a solution to the nonlinear system* (4.1) *with the Neumann data g_1 and g_2 defined in* (4.3). *Then we have*

$$|\nabla u_1(x) \times \nabla u_2(x)| > 0 \quad \textit{for all } x \in \Omega.$$

Proof. To derive a contradiction, suppose that there exists a point $\xi \in \Omega$ such that

$$|\nabla u_1(\xi) \times \nabla u_2(\xi)| = 0.$$

Then there exists a nonzero vector $(c_1, c_2) \in \mathbb{R}^2$ so that $c_1 \nabla u_1(\xi) + c_2 \nabla u_2(\xi) = 0$. Consider the function $w := c_1 u_1 + c_2 u_2$, which satisfies $\nabla w(\xi) = 0$ and

$$\nabla \cdot \left(\frac{a_1}{|\nabla u_1|} \nabla w \right) = 0 \quad \text{in } \Omega,$$
$$\frac{a_1}{|\nabla u_1|} \frac{\partial w}{\partial \nu} = \tilde{g} \quad \text{on } \partial\Omega, \quad \text{and} \quad \int_{\partial\Omega} w \, ds = 0,$$

where $\tilde{g} = c_1 g_1 + c_2 g_2$. By the assumption of

$$\frac{a_1(x)}{|\nabla u_1(x)|} = \frac{a_2(x)}{|\nabla u_2(x)|} \in \Sigma,$$

we may regard w as a solution to the classical Neumann problem (2.3) with the conductivity coefficient in the set Σ. Then all the properties in (2.4) hold for w.

On the other hand, the definition of g_j in (4.3) yields

$$\tilde{g}(x) = \begin{cases} +c_1 \frac{I}{2\epsilon} & \text{on } \{|x - P_1| < \epsilon\} \cap \partial\Omega, \\ +c_2 \frac{I}{2\epsilon} & \text{on } \{|x - P_2| < \epsilon\} \cap \partial\Omega, \\ -c_1 \frac{I}{2\epsilon} & \text{on } \{|x - Q_1| < \epsilon\} \cap \partial\Omega, \\ -c_2 \frac{I}{2\epsilon} & \text{on } \{|x - Q_2| < \epsilon\} \cap \partial\Omega, \\ 0 & \text{otherwise.} \end{cases}$$

Hence, by the ordering of the points P_1, P_2, Q_1, and Q_2, we easily see that for any nonzero vector (c_1, c_2), $\tilde{g} \neq 0$ and there exist two disjoint arcs Γ^+ and Γ^- contained in $\partial\Omega$ such that

$$\Gamma^+ \cup \Gamma^- = \partial\Omega, \quad \text{and} \quad \Gamma^+ \subset \{\tilde{g} \geq 0\}, \quad \Gamma^- \subset \{\tilde{g} \leq 0\}. \tag{4.4}$$

Therefore, it follows from (2.5) that $\nabla w(x) \neq 0$ for all $x \in \Omega$. In particular, $\nabla w(\xi) \neq 0$, and hence it is a contradiction. This completes the proof. ∎

For the sake of clarity, we will give in the following remark more detailed proof for the reason why the property (4.4) of nonzero $\tilde{g}$ implies $\nabla w \neq 0$ in Ω, although it can also be found in [1, 2, 13].

Remark 4.2. Suppose that $\nabla w(\xi) = 0$; then by the maximum principle the level set $\{x \in \Omega \,|\, w(x) = w(\xi)\}$ divides Ω into more than four disjoint connected components $\Omega_1^{\pm}, \ldots, \Omega_m^{\pm}$ $(m \geq 2)$ such that (see Figure 4.1)

$$\bigcup_{k=1}^{m} \Omega_k^+ = \{x \in \Omega \,|\, w(x) > w(\xi)\} \quad \text{and} \quad \bigcup_{k=1}^{m} \Omega_k^- = \{x \in \Omega \,|\, w(x) < w(\xi)\}.$$

Applying the maximum principle again, we find that the boundary of each component $\Omega_k^{\pm}$ must occupy a portion $\gamma_k^{\pm}$ of $\partial\Omega$, that is, $\gamma_k^{\pm} := \partial\Omega_k^{\pm} \cap \partial\Omega \neq \emptyset$: if not, $\partial\Omega_k^{\pm}$ is a subset of the level curve $\{x \in \Omega \,|\, w(x) = w(\xi)\}$ and therefore by maximum principle w is the constant equal to $w(\xi)$ in $\Omega_k^{\pm}$. By the unique continuation, $\nabla w = 0$ in the whole domain Ω, and therefore $\tilde{g} = 0$, which is a contradiction.

From the maximum-minimum principle

$$\sup_{\Omega_k^+} w = \sup_{\partial\Omega_k^+} w = \sup_{\gamma_k^+} w \quad \text{and} \quad \inf_{\Omega_k^-} w = \inf_{\partial\Omega_k^-} w = \inf_{\gamma_k^-} w,$$

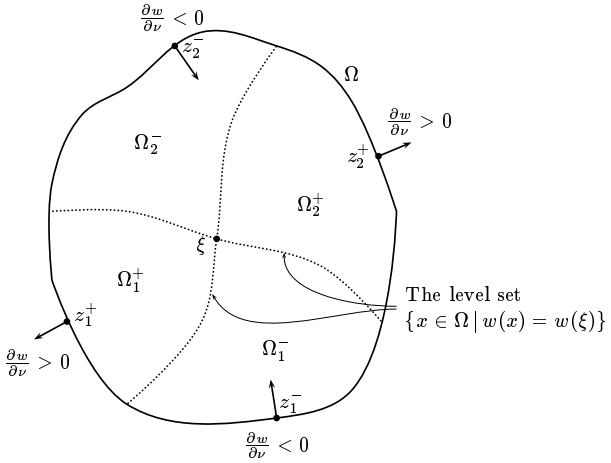

FIG. 4.1. *An illustration for Remark* 4.2 *when* $m = 2$.

there exist points $z_k^+ \in \gamma_k^+$ and $z_k^- \in \gamma_k^-$ so that

$$w(z_k^+) = \sup_{\Omega_k^+} w, \quad w(z_k^-) = \inf_{\Omega_k^-} w.$$

By Hopf's lemma, we have $\tilde{g}(z_k^+) > 0$ and $\tilde{g}(z_k^-) < 0$ for $k = 1, \ldots, m$. Since $m \geq 2$, $\tilde{g}$ cannot satisfy the property (4.4), which is a contradiction.

Lemma 4.1 tells us that two gradient vector fields ∇u_1 and ∇u_2 are neither vanishing nor parallel to each other at any points in Ω. Based on this fact, we can prove the following uniqueness result for the inverse problem with two measurements.

THEOREM 4.3. *Suppose that* $(u_1, u_2), (\tilde{u}_1, \tilde{u}_2) \in H^1(\Omega) \times H^1(\Omega)$ *are solutions to the nonlinear system* (4.1) *with the Neumann data* g_1 *and* g_2 *defined in* (4.3). *Then the edge of the conductivity image is uniquely determined by* (a_1, a_2) *in such a way that*

$$\left\{ x \in \Omega \;\middle|\; \frac{a_j}{|\nabla u_j|} \text{ is discontinuous at } x \right\} = \left\{ x \in \Omega \;\middle|\; \frac{a_j}{|\nabla \tilde{u}_j|} \text{ is discontinuous at } x \right\}.$$

Proof. Since (u_1, u_2) satisfies

$$\frac{a_1}{|\nabla u_1|} = \frac{a_2}{|\nabla u_2|} \in \Sigma,$$

there exist $\sigma_0 \in \mathcal{C}^\alpha(\bar{\Omega})$ and $\{(\sigma_k, D_k) \,|\, \sigma_k \in \mathcal{C}^\alpha(\bar{D}_k), \bar{D}_k \subset \Omega\}_{k=1}^M$ for some $M \in \mathbb{N}$, which satisfy

$$\frac{a_j}{|\nabla u_j|} = \sigma_0 + \sum_{k=1}^M \sigma_k \chi_{D_k} \in \Sigma. \tag{4.5}$$

Hence, from (2.1) we have

$$\sigma := \sigma_0 + \sum_{k=1}^M \sigma_k \chi_{D_k} \in \mathcal{C}^\alpha\left(\cup_{k=1}^M \bar{D}_k\right) \cap \mathcal{C}^\alpha\left(\Omega \setminus \cup_{k=1}^M D_k\right), \tag{4.6}$$

and u_j can be viewed as a solution of (2.3) when g is substituted by g_j. Thus, from (b) in (2.4) we get

$$\nabla u_j \in \mathcal{C}^\alpha\left(\cup_{k=1}^M \bar{D}_k\right) \cap \mathcal{C}^\alpha\left(\Omega \setminus \cup_{k=1}^M D_k\right). \tag{4.7}$$

From (4.5), we have $a_j(x) = \sigma(x)|\nabla u_j(x)|$, which implies that

$$a_j \in \mathcal{C}^\alpha\left(\cup_{k=1}^M \bar{D}_k\right) \cap \mathcal{C}^\alpha\left(\Omega \setminus \cup_{k=1}^M D_k\right) \qquad \text{for } j = 1, 2$$

by the aid of (4.6) and (4.7). Therefore, we get

$$A := \{x \in \Omega \,|\, a_1 \text{ or } a_2 \text{ is discontinuous at } x\} \subset \bigcup_{k=1}^M \partial D_k. \tag{4.8}$$

For the converse of (4.8), fix any $\xi \in \partial D_k$ for any $k = 1, \ldots, M$. It follows from Lemma 4.1 that either

$$\frac{\partial u_1^+}{\partial \tau}(\xi) \neq 0 \quad \text{or} \quad \frac{\partial u_2^+}{\partial \tau}(\xi) \neq 0, \tag{4.9}$$

where $u_j^+ := u_j|_{\Omega \setminus \bar{D}_k}$ for $j = 1, 2$, and $\partial/\partial\tau$ denotes the tangential derivative on ∂D_k. By the properties (c) and (d) in (2.4), we get

$$\sigma_0(\xi)\frac{\partial u_j^+}{\partial \nu}(\xi) = (\sigma_0(\xi) + \sigma_k(\xi))\frac{\partial u_j^-}{\partial \nu}(\xi) \quad \text{and} \quad \frac{\partial u_j^+}{\partial \tau}(\xi) = \frac{\partial u_j^-}{\partial \tau}(\xi),$$

where $u_j^- := u_j|_{D_k}$ and ν denotes the outward unit normal to ∂D_k. Considering $a_j = \sigma|\nabla u_j|$, a simple calculation yields that

$$|a_j^-(\xi)|^2 = |a_j^+(\xi)|^2 + \left((\sigma_0(\xi) + \sigma_k(\xi))^2 - (\sigma_0(\xi))^2\right)\left|\frac{\partial u_j^+}{\partial \tau}(\xi)\right|^2, \tag{4.10}$$

where $a_j^- := a_j|_{D_k}$ and $a_j^+ := a_j|_{\Omega \setminus \bar{D}_k}$. Since $\sigma_k(\xi) \neq 0$ by definition of Σ, by the aid of (4.9) the second term on the right-hand side of (4.10) is nonzero for either $j = 1$ or $j = 2$. Thus we show that a_1 or a_2 is discontinuous at ξ, and so $\xi \in A$. This proves that $\cup_{k=1}^M \partial D_k \subset A$. Hence, from (4.8) we conclude that $\cup_{k=1}^M \partial D_k = A$.

On the other hand, from (4.5) and (2.2), we can easily see that

$$\left\{x \in \Omega \;\middle|\; \frac{a_j}{|\nabla u_j|} \text{ is discontinuous at } x\right\} = \bigcup_{k=1}^M \partial D_k = A. \tag{4.11}$$

Because we have used only the fact that (u_1, u_2) is a solution to the nonlinear system (4.1), we can derive the same conclusion as (4.11) for $(\tilde{u}_1, \tilde{u}_2)$

$$\left\{x \in \Omega \;\middle|\; \frac{a_j}{|\nabla \tilde{u}_j|} \text{ is discontinuous at } x\right\} = \bigcup_{k=1}^{\tilde{M}} \partial \tilde{D}_k = A \tag{4.12}$$

for some mutually disjoint domains $\tilde{D}_k \subset \Omega$. Since the set A is completely determined by the data (a_1, a_2), the proof is completed by (4.11) and (4.12). □

Theorem 4.3 shows that the region where the conductivity distribution has jumps can be uniquely detected by the observation of discontinuities of the measured data

(a_1, a_2). In the following theorem, we show that the conductivity values as well as the unknown inclusions can be determined in a simple case when the conductivity distribution $\sigma \in \Sigma$ is known to be piecewise constant.

THEOREM 4.4. *Suppose that* $(u_1, u_2), (\tilde{u}_1, \tilde{u}_2) \in H^1(\Omega) \times H^1(\Omega)$ *are solutions to the nonlinear system* (4.1) *with the Neumann data* g_1 *and* g_2 *defined in* (4.3). *Suppose that* $\frac{a_j}{|\nabla u_j|}$ *and* $\frac{a_j}{|\nabla \tilde{u}_j|}$ *are piecewise constants, that is,*

$$\frac{a_j}{|\nabla u_j|} = 1 + \sum_{k=1}^{M} \mu_k \chi_{D_k} \quad \text{and} \quad \frac{a_j}{|\nabla \tilde{u}_j|} = 1 + \sum_{k=1}^{\tilde{M}} \tilde{\mu}_k \chi_{\tilde{D}_k}, \tag{4.13}$$

where $\mu_k, \tilde{\mu}_k$ *are nonzero constants satisfying* $-1 < \mu_k, \tilde{\mu}_k < \infty$. *Then* (u_1, u_2) *and* $(\tilde{u}_1, \tilde{u}_2)$ *are the same.*

Proof. First, we will prove that

$$\frac{a_j}{|\nabla u_j|} = \frac{a_j}{|\nabla \tilde{u}_j|}. \tag{4.14}$$

From (4.13), and (4.11), (4.12) in the proof of Theorem 4.3, the edge of the conductivity image is uniquely determined, that is, $M = \tilde{M}$ and $\bigcup_{k=1}^{M} D_k = \bigcup_{k=1}^{\tilde{M}} \tilde{D}_k$. Thus, for (4.14) it only remains to prove that $\mu_k = \tilde{\mu}_k$ for $k = 1, \ldots, M$. For this, it suffices to show that μ_k can be uniquely determined by the measured data (a_1, a_2) analogously as explained in the proof of Theorem 4.3. To be precise, μ_k will be shown to be determined by

$$\mu_k = \sqrt{1 + m_k} - 1, \quad k = 1, \ldots, M, \tag{4.15}$$

where the number m_k is defined by

$$m_k := \begin{cases} \max\limits_{\xi \in \partial D_k} \left\{ \left| \dfrac{a_1^-(\xi)}{a_1^+(\xi)} \right|^2 - 1 \right\} & \text{if } a_1^- \geq a_1^+ \text{ on } \partial D_k, \\ \\ \min\limits_{\xi \in \partial D_k} \left\{ \left| \dfrac{a_1^-(\xi)}{a_1^+(\xi)} \right|^2 - 1 \right\} & \text{if } a_1^- \leq a_1^+ \text{ on } \partial D_k. \end{cases} \tag{4.16}$$

Here, $a_1^- := a_1|_{D_k}$ and $a_1^+ := a_1|_{\Omega \setminus \bar{D}_k}$.

From (4.13), we have $a_1^+ = |\nabla u_1^+|$ on ∂D_k, and thus it follows that

$$\left| \frac{a_1^-(\xi)}{a_1^+(\xi)} \right|^2 - 1 = \frac{|\, a_1^-(\xi)|^2 - |\, a_1^+(\xi)|^2}{|\nabla u_1^+(\xi)|^2}, \quad \xi \in \partial D_k. \tag{4.17}$$

By the aid of (4.10) (in our case, $\sigma_0(\xi) = 1$ and $\sigma_k(\xi) = \mu_k$), we easily observe that either $a_1^- \geq a_1^+$ or $a_1^- \leq a_1^+$ on ∂D_k. In the case in which $a_1^- \geq a_1^+$, from (4.17) and (4.10) we have

$$\left| \frac{a_1^-(\xi)}{a_1^+(\xi)} \right|^2 - 1 \leq \frac{|\, a_1^-(\xi)|^2 - |\, a_1^+(\xi)|^2}{\left|\, \partial u_1^+ / \partial \tau(\xi) \,\right|^2} = \mu_k(\mu_k + 2)$$

for all $\xi \in \partial D_k$. In the case in which $a_1^- \leq a_1^+$, we get a similar result given by

$$\left| \frac{a_1^-(\xi)}{a_1^+(\xi)} \right|^2 - 1 \geq \mu_k(\mu_k + 2).$$

Now we will find the optimizer $z \in \partial D_k$ of (4.16). Applying the divergence theorem on $\Omega \setminus \bar{D}_k$, we get

$$0 = \int_{\partial\Omega} \frac{a_1}{|\nabla u_1|} \frac{\partial u_1}{\partial \nu}\, ds - \int_{\partial D_k} \frac{\partial u_1^+}{\partial \nu}\, ds = -\int_{\partial D_k} \frac{\partial u_1^+}{\partial \nu}\, ds,$$

noting that u_1 belongs to $\mathcal{C}^{1,\alpha}(\Omega \setminus \cup_{k=1}^M D_k)$ from (2.4) and $a_1^+/|\nabla u_1^+| = 1$ on ∂D_k. Hence there exists a point $z \in \partial D_k$ satisfying $\partial u_1^+/\partial \nu(z) = 0$, and by Lemma 4.1 we have

$$\left| \frac{\partial u_1^+}{\partial \tau}(z) \right| = |\nabla u_1^+(z)| > 0. \tag{4.18}$$

From (4.17), (4.18), and the jump relation (4.10), we obtain

$$\left| \frac{a_1^-(z)}{a_1^+(z)} \right|^2 - 1 = \mu_k(\mu_k + 2),$$

which implies that the point $z \in \partial D_k$ is the optimizer of (4.16). Thus it is clear that the number m_k defined in (4.16) is given by $m_k = \mu_k(\mu_k + 2) > -1$ because $\mu_k > -1$. Therefore we conclude that $\mu_k = \sqrt{1 + m_k} - 1$, which proves (4.15) and hence (4.14).

Finally, from (4.13) and (4.14) we see that u_j and $\tilde{u}_j$ can be viewed as the solutions of (2.3) when g is substituted by g_j and $\sigma := 1 + \sum_{k=1}^M \mu_k \chi_{D_k}$, since both (u_1, u_2) and $(\tilde{u}_1, \tilde{u}_2)$ are solutions to the nonlinear system (4.1). Hence by the uniqueness of the classical Neumann problem (2.3), we verify that $u_1 = \tilde{u}_1$ and $u_2 = \tilde{u}_2$, which completes the proof. ∎

5. Conclusion and numerical examples. A new reconstruction algorithm, the so-called *J-substitution algorithm*, was presented in [7] without uniqueness proofs to provide an impressively high-resolution conductivity image σ in simulations based on internal current density a obtained from the MRI system. For this algorithm, two different internal current densities a_1 and a_2 induced by two different applied currents g_1 and g_2 defined in (4.3) were used. In this paper, Theorem 4.3 has proved the uniqueness of the edge detection for piecewise continuous conductivities, and Theorem 4.4 has shown that a piecewise constant conductivity distribution can be completely reconstructed from a_1 and a_2.

On the other hand, it is worth investigating whether one could recover the conductivity distribution with only one internal current density, which means equivalently whether the nonlinear Neumann boundary value problem (3.2) could be solved uniquely. Theorem 3.1 has given a negative answer to this question.

In this section, we will present a numerically obtained example of nonuniqueness with one measurement which has been discussed in section 3. Suppose that Figure 5.1 represents an internal current density $a(x)$ on a cross-section $\Omega = (-1, 1) \times (-1, 1)$ of the human body induced by the applying the current

$$g(x) = \begin{cases} 1 & \text{if } x_1 = 1, \\ -1 & \text{if } x_1 = -1, \\ 0 & \text{otherwise,} \end{cases} \tag{5.1}$$

which can be viewed as an electrode attachment model in (1.2) when $P = (1, 0)$, $Q = (-1, 0)$, $I = 2$, and $\epsilon = 1$. We have numerically obtained this current density

$$a(x) := \sigma(x)|\nabla u(x)| \tag{5.2}$$

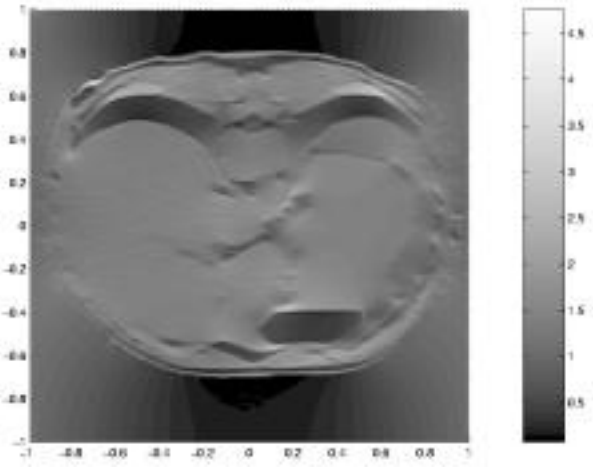

FIG. 5.1. *Simulated current density* $a(x)$.

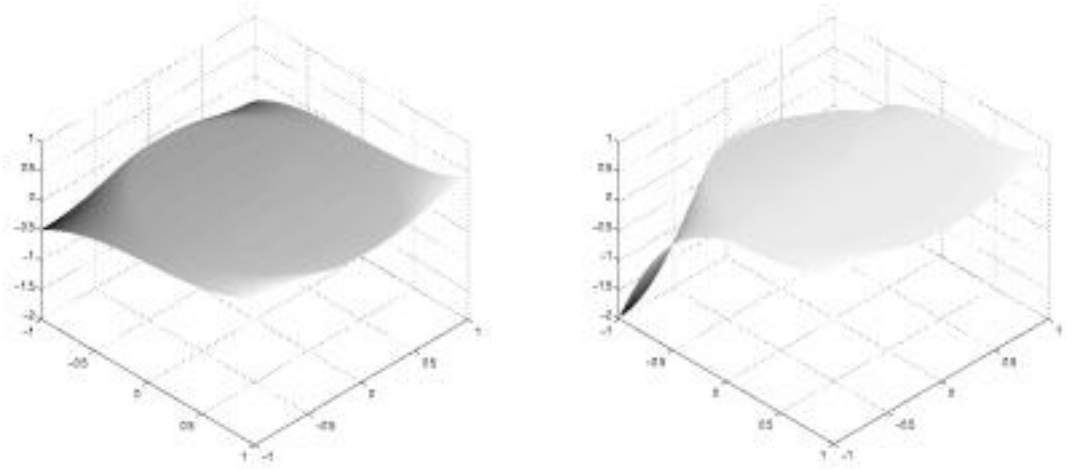
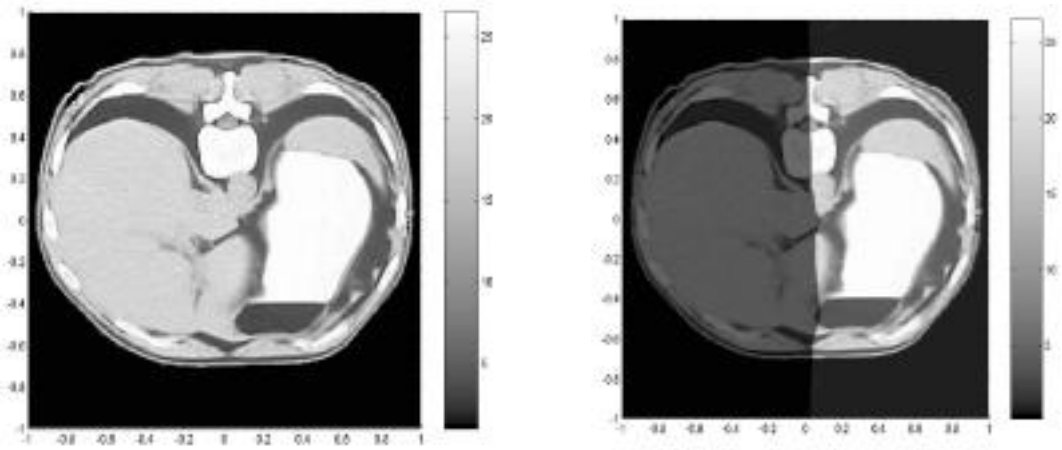


$u_1(x)$ $u_2(x)$

FIG. 5.2. *Two different solutions* u_1 *and* u_2 *to the problem* (3.2).

by assuming a conductivity distribution σ (in our experiment, σ is assumed to be σ_1 in Figure 5.3) and numerically solving the classical Neumann problem (2.3) with Neumann data g in (5.1) to calculate $|\nabla u(x)|$. As a numerical solver for (2.3), we have adopted the cell-centered finite difference scheme explained in [7]. In a real situation, the current density $a(x)$ is provided by a suitable MRI experiment called current density imaging [4, 6, 10, 11, 12, 15].

With this a and g, we can construct infinitely many solutions of the nonlinear Neumann boundary value problem (3.2) by virtue of Theorem 3.1. Here we present two different solutions u_1 and u_2, respectively given in Figure 5.2. Indeed, u_1 is equal to u that has been used to generate the simulated current density a in (5.2), and u_2 corresponds to $u_{t,\lambda}$ defined in the proof of Theorem 3.1 in the case in which $t = 0$



$\sigma_1(x)$ $\sigma_2(x)$

FIG. 5.3. *Two distinct conductivity images generated by* u_1 *and* u_2.

and $\lambda = 5$. These two different solutions yield two distinct conductivity images,

$$\sigma_1(x) = \frac{a(x)}{|\nabla u_1(x)|} \quad \text{and} \quad \sigma_2(x) = \frac{a(x)}{|\nabla u_2(x)|},$$

which are respectively shown in Figure 5.3. Hence, we conclude that only one internal current density information is insufficient for the unique determination of conductivity distributions.

A FREE BOUNDARY PROBLEM FOR A HYPOPLASTIC MODEL OF PLANE SHEAR WAVES IN A FULLY SATURATED GRANULAR MATERIAL*

MICHAEL S. GORDON†

Abstract. A one-dimensional system describing small shearing disturbances in a semi-infinite, fully saturated granular medium is studied. The system is fully nonlinear as a result of the incrementally nonlinear constitutive law for the material. In particular, there are two different wave speeds corresponding to loading or unloading of the material. A free boundary problem for the boundary between loading and unloading regions is derived and solved globally. The solution is then applied to the investigation of two specific boundary value problems for the full system.

Key words. saturated granular material, hypoplastic flow rule, shear waves, free boundary problem, loading and unloading, characteristic analysis, functional equation

1. Introduction.

The following system of equations was derived by Osinov and Gudehus [7] as the key equations in a simplified model for plane shear waves in a saturated granular body:

$$\begin{aligned} \partial_t v &= \partial_x \sigma, \\ \partial_t \sigma &= a\partial_x v + b|\partial_x v|. \end{aligned} \tag{1.1}$$

Here a and b are constants satisfying $0 < b < a$. The dependent variables are v and σ; v is velocity and σ is a component of stress. Notice that, in regions where $\partial_x v$ (or, equivalently, $\partial_t \sigma$) does not change sign, the system (1.1) reduces to a linear wave equation with wave speed $\sqrt{a+b}$ or $\sqrt{a-b}$. Osinov and Gudehus derive the system (1.1) from a full three-dimensional system of equations for the deformation of a saturated granular material with a hypoplastic flow rule. (See [1], [4], [5], [6].) They linearize this system about a static state (i.e., zero strain rate) with constant stress tensor T^0; further, they assume that the incremental variables depend only on t and x_1 and that v_2 is the only nonzero component of velocity. The equations for $v = v_2$ and $\sigma = T_{12} - T^0_{12}$ (the perturbation of the shear stress) decouple from the other equations, leading to the system (1.1). We should point out that the constant b is positive because we assume that $T^0_{12} < 0$; the sign of b changes if $T^0_{12} > 0$. (See [7].) A consequence of $T^0_{12} < 0$ is that increasing σ decreases the magnitude of the total shear stress and thus unloads the material. Similarly, decreasing σ loads the material. Thus we will refer to regions where $\partial_t \sigma < 0$ (or, equivalently, $\partial_x v < 0$) as *loading* regions and those where $\partial_t \sigma > 0$ ($\partial_x v > 0$) as *unloading*.

A physical context for this model is shown in Figure 1.1. The figure shows a saturated granular material resting on an inclined solid mass. Plane shear waves described by (1.1) propagate in the direction perpendicular to the interface between the solid and the granular material, while the velocity vector is parallel to it. Boundary

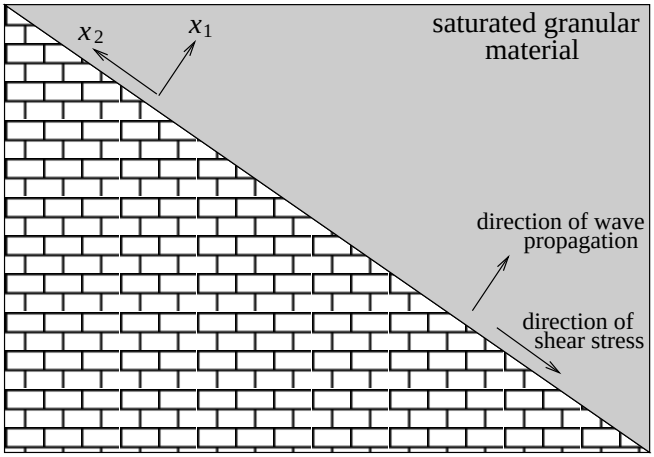

FIG. 1.1. *Physical setting for the model equations.*

disturbances could be created by waves propagating through the solid. A negative shear stress T_{12}^0 is created by the weight of the granular material.

We consider the system (1.1) in the quarter plane $x \geq 0$, $t \geq 0$ with initial data

$$v(x,0) = \sigma(x,0) = 0 \tag{1.2}$$

and stress-controlled boundary data

$$\sigma(0,t) = -\phi(t), \tag{1.3}$$

where $\phi(0) = 0$, $\lim_{t\to\infty} \phi(t) = 0$, ϕ is continuous, nonnegative, nondecreasing on $[0, t_s]$, and nonincreasing on $[t_s, \infty)$. (Two examples of such ϕ are shown in Figures 6.1 and 6.2.) Notice that (1.3) implies that σ decreases initially and then increases so that the resulting traveling pulse consists of a loading front followed by an unloading front. The form of the solution in the xt-plane (near $t = t_s$) is shown in Figure 1.2. Velocity and stress are zero in A_0 due to (1.2), A_1 is a loading region, and A_2 is an unloading region. Finding the solution in A_0 and A_1 is a straightforward application of the method of characteristics to (1.2) and (1.3). However, the solution in A_2 and the interface between A_1 and A_2 are interdependent, resulting in a free boundary problem. Gordon, Shearer, and Schaeffer [3] solve (1.1), (1.2), (1.3) with piecewise linear boundary data so that the resulting interface between loading and unloading regions is a straight line whose slope is the solution of a quadratic. In our case, this interface will be the solution of a difficult functional equation similar to the one solved in [2], and we find solutions with a similar iterative technique. The solution in [2] is local, and the iterations shrink the domain so that some effort is needed to show that it does not vanish to a point in the limit. In this work, we find a local solution and show that the iterations actually enlarge the domain, leading to a global solution.

In section 2, we use characteristic analysis to reduce the boundary value problem to an equation for the loading/unloading interface. In sections 3 and 4, we consider two cases: (i) ϕ has a corner at t_s and (ii) ϕ is smooth at t_s. The main challenge in the smooth case is finding a suitable function space, closed under our iterating operator, in which to seek a solution.

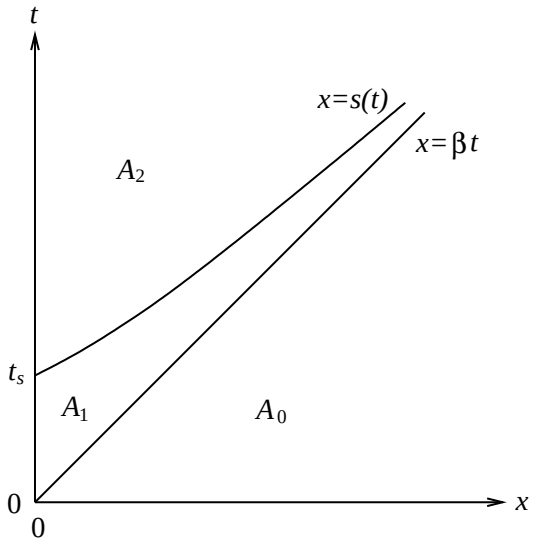

FIG. 1.2. *Form of the solution in xt-space.*

We had hoped to show in this work that the long-time solution of (1.1), (1.2), (1.3) was the same as was shown for a piecewise linear boundary pulse in [3], i.e., a decaying pulse which consists of a leading loading front and a trailing unloading front for all time. In fact, our derivation in section 2 of the equation for the loading/unloading interface assumes that our solution also has this form for all time. (See Figure 1.2.) However, if the solution begins to load somewhere in the unloading region after the loading/unloading interface has passed, it will invalidate that derivation. Unfortunately, this can happen for some choices of ϕ, as we show by example in section 6. In that section, we consider two examples of possible boundary data ϕ. We use analysis and numerical computations to show that, in one case, the solution of the interface equation does not lead to a global solution of (1.1), (1.2), (1.3), while in the other it does. In the second case, we show that the behavior of the solution is, as expected, qualitatively the same as for the stress-controlled problem in [3]. In section 5, we show that the solution of the interface equation leads to a solution of (1.1), (1.2), (1.3) that is at least locally valid.

2. Derivation of loading/unloading interface equation. In deriving an equation for the interface between loading and unloading regions, we will assume that the solution of (1.1), (1.2), (1.3) has the form shown in Figure 1.2; $v = \sigma = 0$ in $A_0 = \{(x,t) : x > \beta t\}$; $A_1 = \{(x,t) : s(t) < x < \beta t\}$ is a loading region, and $A_2 = \{(x,t) : x < s(t)\}$ is unloading. (We will show later that this assumption is at least locally valid and that σ and v are continuous across the loading/unloading interface $x = s\,(t)$.) This means that

$$\begin{aligned} \partial_t v &= \partial_x \sigma, \\ \partial_t \sigma &= \beta^2 \partial_x v \end{aligned} \tag{2.1}$$

in A_1, where $\beta = \sqrt{a-b}$ is the slow wave speed associated with loading, and

$$\begin{aligned} \partial_t v &= \partial_x \sigma, \\ \partial_t \sigma &= \alpha^2 \partial_x v \end{aligned} \tag{2.2}$$

in A_2, where $\alpha = \sqrt{a+b}$ is the fast wave speed associated with unloading. The curve $x = s(t)$ must satisfy the entropy condition discussed in [3]:

$$\beta \leq \frac{s(t+h) - s(t)}{h} \leq \alpha. \tag{2.3}$$

We will use characteristic analysis to derive an equation for the loading/unloading interface. First, notice that $v = \sigma = 0$ in A_0 because of (1.2) and the fact that every point in A_0 is connected to the x-axis by a pair of characteristics. Each point in A_1 is reached by one characteristic emanating from the x-axis and one from the t-axis, so the solution there is determined by (1.2) and (1.3). To see this, we rewrite (2.1) as

$$\begin{aligned} (\partial_t - \beta \partial_x)(\sigma + \beta v) &= 0, \\ (\partial_t + \beta \partial_x)(\sigma - \beta v) &= 0. \end{aligned} \tag{2.4}$$

Equations (2.4) and (1.2) imply that $\sigma + \beta v = 0$ in A_1, so

$$v = -\sigma/\beta \text{ in } A_1. \tag{2.5}$$

Combining (2.5) with (1.3), we have

$$v(0,t) = \phi(t)/\beta \quad \text{for } t \leq t_s.$$

This, (1.3), and (2.4) now imply that

$$(\sigma - \beta v)(0,t) = -2\phi(t) \quad \text{for } t \leq t_s. \tag{2.6}$$

Equation (2.6), combined with (2.4), determines $\sigma - \beta v$ on all of A_1; using (2.5), the entire solution σ, v is then determined on all of A_1. Notice that, if the loading/unloading interface $x = s(t)$ was known, characteristic analysis could then be used to find the entire solution on A_2, since two characteristics enter A_2 from the interface. Since this would also determine the known boundary condition $\sigma = \phi(t)$ on the t-axis for $t > t_s$, it seems reasonable to expect that we can set up an equation relating $s(t)$ to $\phi(t)$. Figure 2.1 shows how this will be accomplished. Referring to that figure, we let $(s(t), t)$ be a point on the interface and

$$\begin{aligned} t_\alpha &= t - s(t)/\alpha = \tilde{t} + s(\tilde{t})/\alpha, \\ t_\beta &= t - s(t)/\beta, \quad \tilde{t}_\beta = \tilde{t} - s(\tilde{t})/\beta. \end{aligned} \tag{2.7}$$

From (2.6) and (2.4), we have

$$(\sigma - \beta v)(s(t), t) = (\sigma - \beta v)(0, t_\beta) = -2\phi(t_\beta). \tag{2.8}$$

By (2.5),

$$(\sigma - \beta v)(s(t), t) = 2\sigma(s(t), t). \tag{2.9}$$

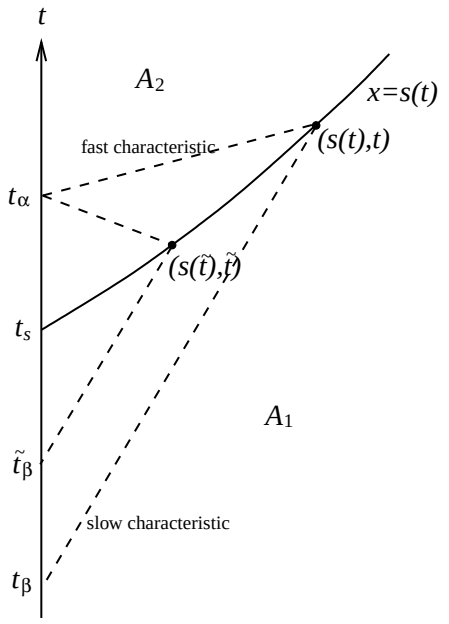

FIG. 2.1. *Derivation of the interface equation.*

Combining (2.5), (2.8), and (2.9), we have

$$\begin{aligned} \sigma(s(t),t) &= -\phi(t_\beta), \\ v(s(t),t) &= \phi(t_\beta)/\beta. \end{aligned} \tag{2.10}$$

Similarly,

$$\begin{aligned} \sigma(s(\tilde{t}),\tilde{t}) &= -\phi(\tilde{t}_\beta), \\ v(s(\tilde{t}),\tilde{t}) &= \phi(\tilde{t}_\beta)/\beta. \end{aligned} \tag{2.11}$$

Notice that (2.2) can be written as (2.4) with α in place of β:

$$\begin{aligned} (\partial_t - \alpha\partial_x)(\sigma + \alpha v) &= 0, \\ (\partial_t + \alpha\partial_x)(\sigma - \alpha v) &= 0. \end{aligned} \tag{2.12}$$

This implies

$$\begin{aligned} (\sigma - \alpha v)(s(t),t) &= (\sigma - \alpha v)(0,t_\alpha) = -\phi(t_\alpha) - \alpha v(0,t_\alpha), \\ (\sigma + \alpha v)(s(\tilde{t}),\tilde{t}) &= (\sigma + \alpha v)(0,t_\alpha) = -\phi(t_\alpha) + \alpha v(0,t_\alpha). \end{aligned}$$

Adding these gives

$$(\sigma - \alpha v)(s(t),t) + (\sigma + \alpha v)(s(\tilde{t}),\tilde{t}) = -2\phi(t_\alpha). \tag{2.13}$$

Notice that (2.10) and (2.12) imply

$$(\sigma - \alpha v)(s(t),t) + (\sigma + \alpha v)(s(\tilde{t}),\tilde{t}) = -(\alpha/\beta + 1)\,\phi(t_\beta) + (\alpha/\beta - 1)\,\phi(\tilde{t}_\beta). \tag{2.14}$$

Combining (2.13) and (2.14), we have the equation we seek:

$$-(\alpha/\beta+1)\,\phi(t_\beta)+(\alpha/\beta-1)\,\phi(\tilde{t}_\beta)=-2\phi(t_\alpha).$$

For simplicity, we rewrite this equation as

$$\mu\phi(t_\beta)-\phi(\tilde{t}_\beta)=(\mu-1)\phi(t_\alpha), \tag{2.15}$$

where $\mu=(\alpha+\beta)/(\alpha-\beta)>1$.

It becomes easier to see (2.15) in terms of the unknown interface if we make a change in coordinates so that the characteristics in A_2 become coordinate directions: $\xi=t-x/\alpha$, $\zeta=t+x/\alpha$. We let $\zeta=\rho(\xi)$ be the loading/unloading interface in the new variables, where ρ is defined implicitly in terms of s:

$$\rho\left(t-s\left(t\right)/\alpha\right)=t+s\left(t\right)/\alpha \quad \text{for } t>t_s. \tag{2.16}$$

The point $(t,s(t))$ becomes $(\xi,\rho(\xi))$ in the new coordinates. We let $\tilde{\xi}=\tilde{t}-s(\tilde{t})/\alpha$; then $(\tilde{t},s(\tilde{t}))$ becomes $(\tilde{\xi},\rho(\tilde{\xi}))$ in the new coordinates. Notice that (2.16) implies

$$\xi=t-s(t)/\alpha=t_\alpha \ \text{ by (2.7)}, \tag{2.17}$$

$$\rho\left(\xi\right)=t+s\left(t\right)/\alpha, \tag{2.18}$$

$$\rho(\tilde{\xi})=\tilde{t}+s(\tilde{t})/\alpha=t_\alpha \ \text{ by (2.7)}. \tag{2.19}$$

We solve (2.17) and (2.18) for t and $s\left(t\right)$ to get

$$\begin{aligned} t&=\left(\rho\left(\xi\right)+\xi\right)/2,\\ s\left(t\right)&=\alpha\left(\rho\left(\xi\right)-\xi\right)/2. \end{aligned} \tag{2.20}$$

We use (2.20) to rewrite t_β in terms of the new variables:

$$t_\beta=t-s(t)/\beta=\left(\rho\left(\xi\right)+\xi\right)/2-\frac{\alpha}{2\beta}\left(\rho\left(\xi\right)-\xi\right)=\frac{\mu\xi-\rho(\xi)}{\mu-1}. \tag{2.21}$$

A similar calculation with $\tilde{t}$ and $\tilde{\xi}$ in place of t and ξ gives

$$\tilde{t}_\beta=\tilde{t}-s(\tilde{t})/\beta=\frac{\mu\tilde{\xi}-\rho(\tilde{\xi})}{\mu-1}. \tag{2.22}$$

Notice that (2.17) and (2.19) imply

$$\xi=\rho(\tilde{\xi})\Rightarrow\tilde{\xi}=\rho^{-1}(\xi),$$

provided that ρ is invertible. Combining this with (2.22), we have

$$\tilde{t}_\beta=\frac{\mu\rho^{-1}(\xi)-\xi}{\mu-1}. \tag{2.23}$$

Using (2.17), (2.21), and (2.23) to make appropriate substitutions into (2.15), we now have

$$\mu\phi\left(\frac{\mu\xi-\rho(\xi)}{\mu-1}\right)-\phi\left(\frac{\mu\rho^{-1}(\xi)-\xi}{\mu-1}\right)=(\mu-1)\phi(\xi). \tag{2.24}$$

We have reduced the boundary value problem to solving (2.24) for the loading/unloading interface $\zeta = \rho(\xi)$. We seek a solution ρ, defined on $[t_s, \infty)$, satisfying the entropy condition (2.3) or, equivalently,

$$D_\ell \rho(\xi) \geq \mu \tag{2.25}$$

for all $\xi \geq t_s$, where

$$D_\ell \rho(\xi) = \liminf_{h \to 0^+} \frac{\rho(\xi + h) - \rho(\xi)}{h}$$

is the lower Dini derivative. The upper Dini derivative is defined by

$$D_u \rho(\xi) = \limsup_{h \to 0^+} \frac{\rho(\xi + h) - \rho(\xi)}{h}.$$

We will also show that the loading/unloading interface $x = s\,(t)$ approaches but never intersects the leading edge of the front $x = \beta t$, or, equivalently,

$$\rho(\xi) < \mu\xi \tag{2.26}$$

for all $\xi \geq t_s$, and

$$\lim_{\xi \to \infty} (\mu\xi - \rho(\xi)) = 0. \tag{2.27}$$

Notice that (2.27) and (2.25) imply that

$$\lim_{\xi \to \infty} D_\ell \rho(\xi) = \mu. \tag{2.28}$$

3. Corner case. In this section, we solve (2.24), assuming that there is a jump in the derivative of ϕ at t_s. More precisely, we let $\phi_1 = \phi|_{[0,t_s]}$ and $\phi_2 = \phi|_{[t_s,\infty)}$. We assume that $\phi_1 \in C^1\,[t_s - \delta_0, t_s]$, $\phi_2 \in C^1[t_s, t_s + \delta_0]$ for some $\delta_0 > 0$, and

$$\phi_1' > 0 \text{ on } [t_s - \delta_0, t_s] \text{ and } \phi_2' \leq 0 \text{ on } [t_s, t_s + \delta_0]. \tag{3.1}$$

The solution of (2.24) will be obtained by an iterative procedure defined as follows. Given a continuous function ρ satisfying (2.25) and $\rho(t_s) = t_s$, let $\Psi(\rho)$ be the function satisfying

$$\mu\phi_1\left(\frac{\mu\xi - \Psi(\rho)(\xi)}{\mu - 1}\right) - \phi_1\left(\frac{\mu\rho^{-1}(\xi) - \xi}{\mu - 1}\right) = (\mu - 1)\phi_2(\xi)$$

or, equivalently,

$$\Psi(\rho)(\xi) = \mu\xi - (\mu - 1)\phi_1^{-1}\left[(1 - 1/\mu)\phi_2(\xi) + \frac{1}{\mu}\phi_1\left(\frac{\mu\rho^{-1}(\xi) - \xi}{\mu - 1}\right)\right]. \tag{3.2}$$

Notice that a function ρ which is a fixed point of Ψ is a solution of (2.24). We will show that $\Psi^n(\rho)$ converges to a fixed point of Ψ as $n \to \infty$.

Before we continue, however, we pause to give some motivation for the choice of Ψ. Consider the case, solved in [3], where the boundary data ϕ is piecewise linear. As mentioned in the introduction, the loading/unloading interface in this case is a

straight line. Let $\phi_1'(t) = \omega_1 > 0$, $\phi_2'(t) = -\omega_2 \leq 0$, and $\rho'(\xi) = \rho_0$. It is not difficult to show that (2.24) reduces to

$$\mu\omega_1\left(\frac{\mu-\rho_0}{\mu-1}\right) - \omega_1\left(\frac{\mu/\rho_0-1}{\mu-1}\right) = -(\mu-1)\omega_2, \tag{3.3}$$

which then reduces to a quadratic in ρ_0. We examine what happens when we employ the iterative method described above to (3.3). Ψ is now defined by

$$\begin{aligned}\Psi(\rho_0) &= \mu - \frac{\mu-1}{\omega_1}\left[-(1-1/\mu)\omega_2 + \frac{\omega_1}{\mu}\left(\frac{\mu/\rho_0-1}{\mu-1}\right)\right] \\ &= \mu + \frac{\omega_2(\mu-1)^2}{\omega_1\mu} + 1/\mu - 1/\rho_0.\end{aligned}$$

Notice that $\Psi : [\mu, k] \to [\mu, k]$, where

$$k = \mu + \frac{\omega_2(\mu-1)^2}{\omega_1\mu} + 1/\mu. \tag{3.4}$$

Suppose $\rho_0, \bar{\rho}_0 \in [\mu, k]$. Then

$$|\Psi(\bar{\rho}_0) - \Psi(\rho_0)| = |1/\rho_0 - 1/\bar{\rho}_0| = \frac{|\bar{\rho}_0 - \rho_0|}{\bar{\rho}_0\rho_0} \leq \frac{|\bar{\rho}_0 - \rho_0|}{\mu^2}.$$

This shows that Ψ is a contraction on $[\mu, k]$, and so $\Psi^n(\rho_0)$ converges to a solution of (3.3) for any $\rho_0 \in [\mu, k]$. This is the strategy we use in solving the general problem in this and the following section. In both cases, we will show that Ψ is a contraction in the supremum norm on a suitably chosen function space. In the corner case, the space chosen is analogous to the interval used above in the piecewise linear case, placing upper and lower bounds on $D_u\rho$ and $D_\ell\rho$. The choice is more difficult in the smooth case; more discussion precedes that section.

In this and the following section, we let

$$t_\beta(\xi) = \frac{\mu\xi - \Psi(\rho)(\xi)}{\mu-1} = \phi_1^{-1}\left[(1-1/\mu)\phi_2(\xi) + \frac{1}{\mu}\phi_1\left(\tilde{t}_\beta(\xi)\right)\right]. \tag{3.5}$$

$\tilde{t}_\beta(\xi)$ is as defined in (2.23). (See Figure 3.1.) The following lemma motivates the definition of the function space for the corner case.

LEMMA 3.1. *Suppose* $\rho \in C[t_s, t_s+\delta]$, $\delta > 0$, $\rho(t_s) = t_s$, $\rho(\xi) \leq \mu\xi$, *and* ρ *satisfies* (2.25). *Then* $\Psi(\rho) \in C[t_s, \rho(t_s+\delta)]$, $\Psi(\rho)(t_s) = t_s$, $\Psi(\rho)(\xi) \leq \mu\xi$, *and* $\Psi(\rho)$ *satisfies* (2.25).

Proof. Suppose $\rho \in C[t_s, t_s+\delta]$, $\rho(t_s) = t_s$, $\rho(\xi) \leq \mu\xi$, and ρ satisfies (2.25). It is clear from (3.2) that $\Psi(\rho)(t_s) = t_s$. It follows from $\rho(\xi) \leq \mu\xi$ and (2.25) that

$$\xi \leq \mu\rho^{-1}(\xi) \leq \mu t_s + (\xi - t_s) \Rightarrow 0 \leq \tilde{t}_\beta(\xi) = \frac{\mu\rho^{-1}(\xi) - \xi}{\mu-1} \leq t_s$$

for all $\xi \in [t_s, \rho(t_s+\delta)]$. Notice then that

$$0 \leq (1-1/\mu)\phi_2(\xi) + \phi_1\left(\tilde{t}_\beta(\xi)\right)/\mu \leq \phi(t_s)$$

for all $\xi \in [t_s, \rho(t_s+\delta)]$. It then follows from (3.2) that $\Psi(\rho) \in C[t_s, \rho(t_s+\delta)]$ and that $\Psi(\rho)(\xi) \leq \mu\xi$. It follows from (2.25) that $\tilde{t}_\beta(\xi)$ is nonincreasing, and so

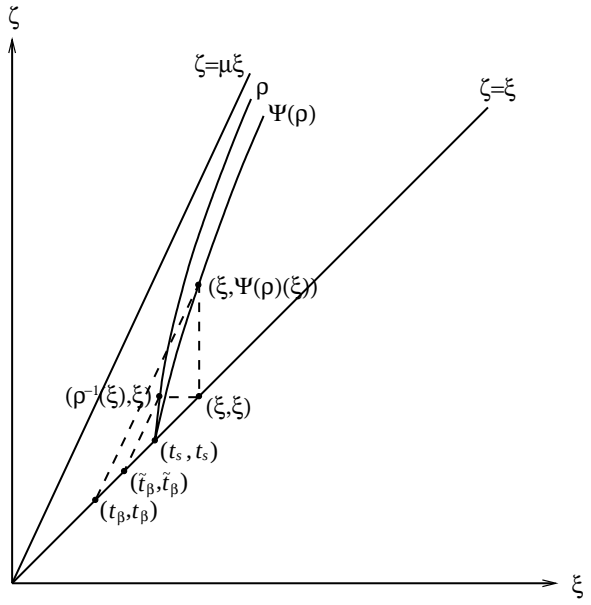

FIG. 3.1. *Iterative procedure for finding the interface.*

$\phi_1\left(\tilde{t}_\beta(\xi)\right)$ is nonincreasing. Since ϕ_2 is also nonincreasing, (3.5) implies that $t_\beta(\xi)$ is nonincreasing, and so

$$D_\ell \Psi(\rho)(\xi) = \mu - (\mu-1) D_u t_\beta(\xi) \geq \mu.$$

Hence $\Psi(\rho)$ satisfies (2.25). ∎

Let $K = \mu + (\mu-1)^2 K_1 K_2/\mu + K_1 K_2/\mu$, where $K_1 = \sup\left\{1/\phi_1'(t) : t_s - \delta_0 \leq t \leq t_s\right\}$ and $K_2 = \sup\left\{\left|\phi'(t)\right| : t_s - \delta_0 \leq t \leq t_s + \delta_0\right\}$. Notice that K_1 exists by (3.1). Define $\Gamma(\delta)$ to be the set of functions $\rho \in C[t_s, t_s+\delta]$ such that $\rho(t_s) = t_s$, $\rho(\xi) \leq \mu\xi$, ρ satisfies (2.25), and

$$D_u \rho(\xi) \leq K \tag{3.6}$$

for $\xi \in [t_s, t_s+\delta]$. We note that K is a generalization of the bound in (3.4).

We now show that $\Gamma(\delta)$ is closed under Ψ.

THEOREM 3.2. *$\Psi : \Gamma(\delta) \to \Gamma(\delta)$ for $\delta \leq \delta_0$.*

Proof. Suppose $\rho \in \Gamma(\delta_0)$. By Lemma 3.1, we need only show that $\Psi(\rho)$ satisfies (3.6). Differentiating (3.2), we have

$$\begin{aligned} D_u \Psi(\rho)(\xi) &= \mu - \frac{(\mu-1)^2}{\mu} \frac{\phi_2'(\xi)}{\phi_1'\left(t_\beta(\xi)\right)} + \frac{\phi_1'(\tilde{t}_\beta(\xi))}{\phi_1'\left(t_\beta(\xi)\right)} \left(\frac{1}{\mu} - \frac{1}{D_u \rho\left(\rho^{-1}(\xi)\right)}\right) \\ &\leq \mu + \frac{(\mu-1)^2}{\mu} K_1 K_2 + K_1 K_2/\mu = K. \end{aligned} \tag{3.7}$$

∎

THEOREM 3.3. *There is some $\delta_1 \in (0, \delta_0]$ such that Ψ is a contraction in the supremum norm on $\Gamma(\delta_1)$.*

Proof. Suppose $\rho_1, \rho_2 \in \Gamma(\delta_0)$. Let $\|\cdot\|_\delta$ denote the supremum norm on $\Gamma(\delta)$, and

let $t_{1,2}$, $\tilde{t}_{1,2}$ be defined as t_β, $\tilde{t}_\beta$ with $\rho_{1,2}$ in place of ρ. Then, by (3.2),

$$\begin{aligned}\Psi(\rho_1)(\xi) - \Psi(\rho_2)(\xi) &= (\mu-1)\left(t_2(\xi) - t_1(\xi)\right)\\ &= \frac{\mu-1}{\mu\phi_1'(\tau)}\left(\phi_1\left(\tilde{t}_2(\xi)\right) - \phi_1\left(\tilde{t}_1(\xi)\right)\right), \text{ where } \tau \text{ is between } t_1, t_2\\ &= \frac{(\mu-1)\,\phi_1'(\tilde{\tau})}{\mu\phi_1'(\tau)}\left(\tilde{t}_2(\xi) - \tilde{t}_1(\xi)\right), \text{ where } \tilde{\tau} \text{ is between } \tilde{t}_1, \tilde{t}_2\\ &= \frac{\phi_1'(\tilde{\tau})}{\phi_1'(\tau)}\left(\rho_2^{-1}(\xi) - \rho_1^{-1}(\xi)\right)\\ &= \frac{\phi_1'(\tilde{\tau})}{\phi_1'(\tau)}\frac{\rho_2^{-1}(\xi) - \rho_1^{-1}(\xi)}{\rho_1\left(\rho_2^{-1}(\xi)\right) - \rho_1\left(\rho_1^{-1}(\xi)\right)}\left(\rho_1\left(\rho_2^{-1}(\xi)\right) - \rho_2\left(\rho_2^{-1}(\xi)\right)\right).\end{aligned}$$

Thus, by (2.25),

$$|\Psi(\rho_1)(\xi) - \Psi(\rho_2)(\xi)| \le \frac{\phi_1'(\tilde{\tau})}{\mu\phi_1'(\tau)}\left|\rho_1\left(\rho_2^{-1}(\xi)\right) - \rho_2\left(\rho_2^{-1}(\xi)\right)\right|. \tag{3.8}$$

Choose $\kappa \in (1, \sqrt{\mu})$. By (3.1), we can choose $\delta_1 \in (0, \delta_0]$ so that

$$\nu/\kappa \le \phi_1'(t) \le \nu\kappa \quad \text{for } t \in [t_s, t_s + \delta_1(K-\mu)/(\mu-1)], \tag{3.9}$$

where $\nu = \phi_1'(t_s)$. By (3.6),

$$\rho(\xi) \le K(\xi - t_s) + t_s \tag{3.10}$$

for all $\rho \in \Gamma(\delta_1)$. Since $\tilde{t}_\beta$ is nonincreasing and $\rho(\xi) > \xi$, we have that $\tilde{t}_\beta(\xi) \ge \tilde{t}_\beta(\rho(\xi))$ which implies

$$t_s - \tilde{t}_\beta(\xi) \le t_s - \tilde{t}_\beta(\rho(\xi)) = t_s - \frac{\mu\xi - \rho(\xi)}{\mu-1}.$$

Combining this with (3.10), we have

$$t_s - \tilde{t}_\beta(\xi) \le \frac{K-\mu}{\mu-1}(\xi - t_s) \tag{3.11}$$

for all $\rho \in \Gamma(\delta_1)$. By Theorem 3.2, $\Psi(\rho) \in \Gamma(\delta_1)$, so $\Psi(\rho)$ satisfies (3.10). Thus, since

$$t_s - t_\beta(\xi) = t_s - \frac{\mu\xi - \Psi(\rho)(\xi)}{\mu-1},$$

t_β satisfies (3.11) for all $\rho \in \Gamma(\delta_1)$, and so $t_{1,2}$, $\tilde{t}_{1,2}$, τ, $\tilde{\tau}$ all satisfy (3.11) for $\xi \in [t_s, t_s + \delta_1]$. This, along with (3.9) and (3.8), implies that

$$\|\Psi(\rho_1) - \Psi(\rho_2)\|_{\delta_1} \le \frac{\nu\kappa}{\mu\nu/\kappa}\|\rho_1 - \rho_2\|_{\delta_1} = \frac{\kappa^2}{\mu}\|\rho_1 - \rho_2\|_{\delta_1},$$

from which the theorem follows. □

From Theorems 3.2 and 3.3 and the completeness of $\Gamma(\delta_1)$ in the supremum norm, we have the following theorem.

THEOREM 3.4. *$\Psi^n(\rho)$ converges to a unique solution of* (2.24) *in $\Gamma(\delta_1)$ for any $\rho \in \Gamma(\delta_1)$.*

We now show that the iterative procedure used to solve (2.24) locally actually leads to a global solution.

THEOREM 3.5. *There is a unique solution of* (2.24) *defined on* $[t_s, \infty)$ *satisfying* (2.25), (2.26), *and* (2.27).

Proof. Let $\rho_1 \in \Gamma(\delta_1)$ be a solution of (2.24), and let $\rho_n = \Psi(\rho_{n-1})$ for $n \geq 2$. Define δ_n by

$$t_s + \delta_n = \rho_{n-1}(t_s + \delta_{n-1}) \tag{3.12}$$

for $n \geq 2$. Notice that the proofs of Lemma 3.1 and Theorem 3.2 imply that $\rho_n \in \Gamma(\delta_n)$ for $n \geq 2$. By (2.25), $\delta_n \geq \mu\delta_{n-1}$, and so $\delta_n \to \infty$ as $n \to \infty$, and so ρ_n converges to a function ρ_* solving (2.24) on $[t_s, \infty)$ and satisfying (2.25).

We now show that ρ_* satisfies (2.26). Clearly there is some $\delta > 0$ such that $\rho_*(\xi) < \mu\xi$ for $\xi \in [t_s, t_s + \delta]$. This implies

$$\xi < \mu\rho_*^{-1}(\xi) \Rightarrow \tilde{t}_\beta(\xi) = \frac{\mu\rho_*^{-1}(\xi) - \xi}{\mu - 1} > 0$$

for all $\xi \in [t_s, \rho_*(t_s + \delta)]$. Thus

$$(1 - 1/\mu)\phi_2(\xi) + \frac{1}{\mu}\phi_1\left(\frac{\mu\rho_*^{-1}(\xi) - \xi}{\mu - 1}\right) > 0$$

for all $\xi \in [t_s, \rho_*(t_s + \delta)]$ since ϕ_1 is positive on $(0, t_s]$. Thus, by (3.2), $\rho_*(\xi) < \mu\xi$ for $\xi \in [t_s, \rho_*(t_s + \delta)]$. By (3.12), $\rho_*^n(t_s + \delta) = t_s + \delta_n \to \infty$ as $n \to \infty$, so $\rho_*(\xi) < \mu\xi$ for $\xi \in [t_s, \infty)$.

We now show that ρ_* satisfies (2.27). Equations (2.25) and (2.26) imply that $\mu\xi - \rho_*(\xi)$ is nonincreasing and bounded below by zero. Thus $\varepsilon = \lim_{\xi\to\infty}(\mu\xi - \rho_*(\xi)) \geq 0$. Letting $\xi \to \infty$ in (2.24), we have

$$\mu\phi_1\left(\frac{\varepsilon}{\mu - 1}\right) - \phi_1\left(\frac{\varepsilon}{\mu - 1}\right) = 0 \Rightarrow \phi_1\left(\frac{\varepsilon}{\mu - 1}\right) = 0 \Rightarrow \varepsilon = 0. \qquad \square$$

The following theorem shows that the solution ρ is differentiable if the boundary data ϕ is differentiable except at $t = t_s$.

THEOREM 3.6. *Suppose that* ϕ_1 *is differentiable on* $[0, t_s]$ *and* ϕ_2 *is differentiable on* $[t_s, \infty)$. *Then the solution* ρ *of* (2.24) *is differentiable on* $[t_s, \infty)$ *and*

$$\lim_{\xi\to\infty} \rho'(\xi) = \mu. \tag{3.13}$$

Proof. Let ρ be a solution of (2.24). Using (3.2) and differentiating, we have

$$\rho'(\xi) = \mu - \frac{(\mu - 1)^2}{\mu}\frac{\phi_2'(\xi)}{\phi_1'(t_\beta(\xi))} + \frac{\phi_1'(\tilde{t}_\beta(\xi))}{\phi_1'(t_\beta(\xi))}\left(\frac{1}{\mu} - \frac{1}{\rho'(\rho^{-1}(\xi))}\right), \tag{3.14}$$

which implies that if ρ is differentiable on $[t_s, t_s + \delta_1]$, then ρ is differentiable on $[t_s, \rho^n(t_s + \delta_1)]$, and hence on $[t_s, \infty)$. Thus we need only show that ρ is differentiable on $[t_s, t_s + \delta_1]$. Notice that $D_\ell\rho$ and $D_u\rho$ satisfy (3.14). Taking the difference, we have

$$\begin{aligned} D_u\rho(\xi) - D_\ell\rho(\xi) &= -\frac{\phi_1'(\tilde{t}_\beta(\xi))}{\phi_1'(t_\beta(\xi))}\left(\frac{1}{D_u\rho(\rho^{-1}(\xi))} - \frac{1}{D_\ell\rho(\rho^{-1}(\xi))}\right) \\ &= \frac{\phi_1'(\tilde{t}_\beta(\xi))}{\phi_1'(t_\beta(\xi))}\left(\frac{D_u\rho(\rho^{-1}(\xi)) - D_\ell\rho(\rho^{-1}(\xi))}{D_u\rho(\rho^{-1}(\xi))\, D_\ell\rho(\rho^{-1}(\xi))}\right). \end{aligned}$$

Combining this with (2.25) and (3.9), we have

$$|D_u\rho(\xi) - D_\ell\rho(\xi)| \le \frac{\kappa^2}{\mu^2}\left|D_u\rho\left(\rho^{-1}(\xi)\right) - D_\ell\rho\left(\rho^{-1}(\xi)\right)\right|$$

for $\xi \in [t_s, t_s + \delta_1]$. By induction,

$$|D_u\rho(\xi) - D_\ell\rho(\xi)| \le \frac{\kappa^{2n}}{\mu^{2n}}\left|D_u\rho\left(\rho^{-n}(\xi)\right) - D_\ell\rho\left(\rho^{-n}(\xi)\right)\right| \le \frac{\kappa^{2n}}{\mu^{2n}}K \to 0 \text{ as } n \to \infty,$$

and so $D_u\rho = D_\ell\rho$ on $[t_s, t_s + \delta_1]$. Equation (3.13) follows from (2.28). □

4. Smooth case. We now assume in place of (3.1) that ϕ is differentiable at t_s. Specifically, $\phi \in C^1[t_s - \delta_0, t_s + \delta_0]$ for some $\delta_0 > 0$ (so $\phi'(t_s) = 0$) and $\phi''(t_s)$ exists and is nonzero. Thus we may write

$$\phi(\xi) = \phi(t_s) - (\xi - t_s)^2(\lambda + \phi_0(\xi)), \tag{4.1}$$

where $\phi_0 \in C^1\left([t_s - \delta_0, t_s + \delta_0] - \{t_s\}\right)$, $\lim_{\xi\to t_s}\phi_0(\xi) = 0$, $\lim_{\xi\to t_s}(\xi - t_s)\,\phi_0'(\xi) = 0$, and $\lambda = -\frac{1}{2}\phi''(t_s) > 0$. We note that Lemma 3.1 still holds in this setting.

Before we begin, we remark on the difficulties of this case as compared to the corner case. The corner case relies on the Lipschitz continuity of ϕ_1 and its inverse to find a space of Lipschitz continuous functions which is complete and closed under our iterating operator. In the smooth case, ϕ_1^{-1} is not Lipschitz continuous, but we are still able to find a similar space of Lipschitz continuous functions by modifying the upper bound on difference quotients in (3.6). (See (4.2).) However, it is more difficult to show closure (Lemma 4.2) and requires a bound on the modulus of continuity of difference quotients of ρ at $\xi = t_s$ (see (4.3)), forcing another condition on the function space which must be preserved under Ψ (Lemma 4.1).

Let $\rho_0 = \mu - 1 + \sqrt{\mu^2 - \mu + 1} > \mu$. It will be apparent from the construction that follows that if ρ is a solution of (2.24) under the above assumptions, then $\rho'(t_s) = \rho_0$. Choose $\tilde{K} > \mu + 1/\mu + (\mu-1)^3/\left(\mu\rho_0 - \mu^2\right) > \rho_0$.

Define $\bar{\phi}_0(\xi) = \sup\{|\phi_0(\zeta)| : |\zeta - t_s| \le |\xi - t_s|\}$ and

$$\tilde{t}^*_\beta(\xi) = \frac{\mu t_s - \xi}{\mu - 1} = t_s - \frac{\xi - t_s}{\mu - 1},$$
$$t^*_\beta(\xi) = \phi_1^{-1}\left[(1 - 1/\mu)\phi_2(\xi) + \frac{1}{\mu}\phi_1\left(\tilde{t}^*_\beta(\xi)\right)\right].$$

Notice that $\tilde{t}^*_\beta$, t^*_β are lower bounds (independent of ρ) of $\tilde{t}_\beta$, t_β. Choose $c \in (1/\rho_0^3, 1)$ and define

$$\epsilon(h) = \frac{4(\rho_0 - \mu)\bar{\phi}_0(\tilde{t}^*_\beta(t_s + h))}{\lambda\mu\left(2\rho_0 - \mu\right)^2(1 - c)} + \frac{4(\rho_0 - \mu)\bar{\phi}_0(t^*_\beta(t_s + h))}{\lambda(1 - c)} + \frac{(\mu - 1)^3\bar{\phi}_0(t_s + h)}{\lambda\mu(\rho_0 - \mu)(1 - c)}.$$

Notice that ϵ is nondecreasing and $\lim_{h\to 0}\epsilon(h) = 0$.

Define $\Omega(\delta)$ to be the set of functions $\rho \in C[t_s, t_s + \delta]$ such that $\rho(t_s) = t_s$,

$$D_\ell\rho(\xi) \ge \mu, \quad D_u\rho(\xi) \le \tilde{K} \tag{4.2}$$

for $\xi \in [t_s, t_s + \delta]$, and

$$|D(\rho, h) - \rho_0| \le \epsilon(h) \tag{4.3}$$

for $h \in (0, \delta]$, where

$$D(\rho, h) = \frac{\rho(t_s + h) - \rho(t_s)}{h} = \frac{\rho(t_s + h) - t_s}{h}.$$

Notice that (4.3) and $\lim_{h \to 0} \epsilon(h) = 0$ imply that $\rho'(t_s) = \rho_0$ for all $\rho \in \Omega(\delta)$.

The following two lemmas, along with Lemma 3.1, establish the closure of Ω under Ψ.

LEMMA 4.1. *There is some $\delta_1 \in (0, \delta_0]$ such that $|D(\Psi(\rho), h) - \rho_0| \leq \epsilon(h)$ for all $\rho \in \Omega(\delta_1)$, $h \in (0, \delta_1]$.*

Proof. Let $\rho \in \Omega(\delta_0)$. Letting $\xi = t_s + h$ in (4.1) and substituting into (2.24), we have

$$\mu (t_\beta - t_s)^2 (\lambda + \phi_0(t_\beta)) - \left(\tilde{t}_\beta - t_s\right)^2 \left(\lambda + \phi_0\left(\tilde{t}_\beta\right)\right) = (\mu - 1) h^2 (\lambda + \phi_0(t_s + h)),$$

where $t_\beta = t_\beta(t_s + h)$, $\tilde{t}_\beta = \tilde{t}_\beta(t_s + h)$. Using (2.21) and (3.5), we have

$$\frac{\mu}{(\mu - 1)^2} (\Psi(\rho)(t_s + h) - t_s - h\mu)^2 (\lambda + \phi_0(t_\beta)) - \frac{1}{(\mu - 1)^2} \left(\mu\rho^{-1} - \mu t_s - h\right)^2 \left(\lambda + \phi_0\left(\tilde{t}_\beta\right)\right) = (\mu - 1) h^2 (\lambda + \phi_0(t_s + h))$$

which implies

$$\mu (D(\Psi(\rho), h) - \mu)^2 (\lambda + \phi_0(t_\beta)) - \left(1 - \mu D(\rho^{-1}, h)\right)^2 \left(\lambda + \phi_0\left(\tilde{t}_\beta\right)\right) = (\mu - 1)^3 (\lambda + \phi_0(t_s + h)).$$

Using the fact that $D(\rho^{-1}, h) = 1/D(\rho, \rho^{-1}(t_s + h) - t_s)$, this implies

$$\mu (D_1 - \mu)^2 (\lambda + \phi_0(t_\beta)) - (1 - \mu/D_2)^2 \left(\lambda + \phi_0\left(\tilde{t}_\beta\right)\right) = (\mu - 1)^3 (\lambda + \phi_0(t_s + h)), \tag{4.4}$$

where $D_1 = D(\Psi(\rho), h)$ and $D_2 = D(\rho, \rho^{-1}(t_s + h) - t_s)$. It is not hard to show that ρ_0 satisfies

$$\mu (\rho_0 - \mu)^2 - (1 - \mu/\rho_0)^2 = (\mu - 1)^3. \tag{4.5}$$

Multiplying (4.5) by λ and subtracting the result from (4.4), we have

$$\lambda\mu (D_1 - \rho_0)(D_1 + \rho_0 - 2\mu) + \mu (D_1 - \mu)^2 \phi_0(t_\beta) + \lambda\mu (1/\rho_0 - 1/D_2)(2 - \mu/\rho_0 - \mu/D_2) - (1 - \mu/D_2)^2 \phi_0\left(\tilde{t}_\beta\right) = (\mu - 1)^3 \phi_0(t_s + h),$$

and so

$$D_1 - \rho_0 = \frac{(D_2 - \rho_0)(\mu D_2 + \mu\rho_0 - 2\rho_0 D_2)}{\rho_0^2 D_2^2 (D_1 + \rho_0 - 2\mu)} + \frac{(1 - \mu/D_2)^2 \phi_0\left(\tilde{t}_\beta\right)}{\lambda\mu (D_1 + \rho_0 - 2\mu)} - \frac{(D_1 - \mu)^2 \phi_0(t_\beta)}{\lambda (D_1 + \rho_0 - 2\mu)} + \frac{(\mu - 1)^3 \phi_0(t_s + h)}{\lambda\mu (D_1 + \rho_0 - 2\mu)}.$$

Notice that

$$\frac{\mu D_2 + \mu\rho_0 - 2\rho_0 D_2}{\rho_0^2 D_2^2 (D_1 + \rho_0 - 2\mu)} \to -\frac{1}{\rho_0^3} \quad \text{as} \quad D_1, D_2 \to \rho_0.$$

Choose $\varepsilon \in (0, \rho_0 - \mu)$ such that

$$\left| \frac{\mu D_2 + \mu\rho_0 - 2\rho_0 D_2}{\rho_0^2 D_2^2 \left(D_1 + \rho_0 - 2\mu\right)} \right| < c \text{ when } |D_{1,2} - \rho_0| < \varepsilon. \tag{4.6}$$

Now, solving (4.4) for D_1, we have

$$D_1 = \mu + \left[\frac{(\mu-1)^3}{\mu} \cdot \frac{\lambda + \phi_0\left(t_s + h\right)}{\lambda + \phi_0\left(t_\beta\right)} + \frac{1}{\mu}\left(1 - \mu/D_2\right)^2 \cdot \frac{\lambda + \phi_0\left(\tilde{t}_\beta\right)}{\lambda + \phi_0\left(t_\beta\right)} \right]^{1/2}. \tag{4.7}$$

Equation (2.25) implies that $\rho^{-1}(t_s + h) - t_s \leq h/\mu < h$, and so, by (4.3),

$$|D_2 - \rho_0| \leq \epsilon(h). \tag{4.8}$$

Combining (4.7) and (4.8) we have upper and lower bounds on D_1 given by

$$\mu + \left[\frac{(\mu-1)^3}{\mu} \cdot \frac{\lambda \pm \bar{\phi}_0\left(t_s + h\right)}{\lambda \mp \bar{\phi}_0(t^*_\beta)} + \frac{1}{\mu}\left(1 - \frac{\mu}{\rho_0 \pm \epsilon(h)}\right)^2 \cdot \frac{\lambda \pm \bar{\phi}_0(\tilde{t}^*_\beta)}{\lambda \mp \bar{\phi}_0(t^*_\beta)} \right]^{1/2}, \tag{4.9}$$

where $t^*_\beta = t^*_\beta\left(t_s + h\right)$, $\tilde{t}^*_\beta = \tilde{t}^*_\beta\left(t_s + h\right)$. From (4.5) we have

$$\rho_0 = \mu + \left[\frac{(\mu-1)^3}{\mu} + \frac{1}{\mu}\left(1 - \frac{\mu}{\rho_0}\right)^2 \right]^{1/2}. \tag{4.10}$$

Equations (4.8), (4.9), and (4.10) imply that there is some $\delta_1 > 0$ such that $|D_{1,2} - \rho_0| < \varepsilon$ for all $\rho \in \Omega(\delta_1)$. Thus, by (4.6),

$$\begin{aligned} |D_1 - \rho_0| &\leq c\,|D_2 - \rho_0| + \frac{\left(1 - \mu/D_2\right)^2 \bar{\phi}_0\left(\tilde{t}_\beta\right)}{\lambda\mu\left(D_1 + \rho_0 - 2\mu\right)} + \frac{\left(D_1 - \mu\right)^2 \bar{\phi}_0\left(t_\beta\right)}{\lambda\left(D_1 + \rho_0 - 2\mu\right)} \\ &\qquad + \frac{(\mu-1)^3 \bar{\phi}_0\left(t_s + h\right)}{\lambda\mu\left(D_1 + \rho_0 - 2\mu\right)} \\ &\leq c\,|D_2 - \rho_0| + \frac{\left(1 - \mu/\left(\rho_0 + \varepsilon\right)\right)^2 \bar{\phi}_0(\tilde{t}^*_\beta)}{\lambda\mu\left(2\rho_0 - 2\mu - \varepsilon\right)} + \frac{\left(\rho_0 - \mu + \varepsilon\right)^2 \bar{\phi}_0(t^*_\beta)}{\lambda\left(2\rho_0 - 2\mu - \varepsilon\right)} \\ &\qquad + \frac{(\mu-1)^3 \bar{\phi}_0\left(t_s + h\right)}{\lambda\mu\left(2\rho_0 - 2\mu - \varepsilon\right)}. \end{aligned}$$

Using (4.8) and the fact that $\varepsilon < \rho_0 - \mu$, we have

$$\begin{aligned} |D_1 - \rho_0| &\leq c\epsilon(h) + \frac{4\left(\rho_0 - \mu\right)\bar{\phi}_0(\tilde{t}^*_\beta)}{\lambda\mu\left(2\rho_0 - \mu\right)^2} + \frac{4\left(\rho_0 - \mu\right)\bar{\phi}_0(t^*_\beta)}{\lambda} + \frac{(\mu-1)^3 \bar{\phi}_0\left(t_s + h\right)}{\lambda\mu\left(\rho_0 - \mu\right)} \\ &= \epsilon(h) \end{aligned}$$

for all $\rho \in \Omega(\delta_1)$. □

LEMMA 4.2. *There is some $\delta_2 \in (0, \delta_1]$ such that $D_u\Psi\left(\rho\right)\left(\xi\right) \leq \tilde{K}$ for all $\rho \in \Omega(\delta_2)$, $\xi \in [t_s, t_s + \delta_2]$.*

Proof. Let $\rho \in \Omega(\delta_1)$. From (3.7) we have

$$D_u\Psi(\rho)(\xi) \leq \mu + \frac{(\mu-1)^2}{\mu} \cdot \frac{\left|\phi_2'(\xi)\right|}{\phi_1'\left(t_\beta(\xi)\right)} + \frac{\phi_1'(\tilde{t}_\beta(\xi))}{\mu\phi_1'\left(t_\beta(\xi)\right)}. \tag{4.11}$$

Notice that

$$\tilde{t}_\beta(\xi) = t_s - \frac{\xi - t_s}{\mu - 1}\left(1 - \mu D(\rho^{-1}, \xi - t_s)\right) = t_s - \frac{\xi - t_s}{\mu - 1}\left(1 - \mu / D(\rho, \rho^{-1}(\xi) - t_s)\right),$$

so, by (4.8),

$$\tilde{t}_\beta(\xi) \geq t_s - \frac{\xi - t_s}{\mu - 1}\left(1 - \frac{\mu}{\rho_0 + \epsilon(\xi - t_s)}\right). \tag{4.12}$$

Also, from (3.5),

$$\begin{aligned} t_\beta(\xi) &= t_s - \frac{\xi - t_s}{\mu - 1}\left(D(\Psi(\rho), \xi - t_s) - \mu\right) \\ &\leq t_s - \frac{\xi - t_s}{\mu - 1}\left(\rho_0 - \epsilon(\xi - t_s) - \mu\right) \end{aligned} \tag{4.13}$$

by Lemma 4.1. Given (4.12), (4.13), and

$$1 - \mu/\rho_0 < \rho_0 - \mu, \tag{4.14}$$

we can choose $\delta_3 \in (0, \delta_1]$ such that

$$t_\beta(\xi) \leq \tilde{t}_\beta(\xi) \text{ for all } \rho \in \Omega(\delta_3),\ \xi \in [t_s, t_s + \delta_3]. \tag{4.15}$$

Choose $\delta_4 \in (0, \delta_3]$ such that ϕ_1' is decreasing on $[t_\beta^*(t_s + \delta_4), t_s]$. Then, by (4.15), we have

$$\frac{\phi_1'\left(\tilde{t}_\beta(\xi)\right)}{\phi_1'\left(t_\beta(\xi)\right)} \leq 1 \text{ for all } \rho \in \Omega(\delta_4),\ \xi \in [t_s, t_s + \delta_4]. \tag{4.16}$$

Differentiating (4.1), we have

$$\begin{aligned} \frac{\left|\phi_2'(\xi)\right|}{\phi_1'(t_\beta)} &= \frac{(\xi - t_s)\left(2\lambda + 2\phi_0(\xi) + (\xi - t_s)\phi_0'(\xi)\right)}{(t_s - t_\beta)\left(2\lambda + 2\phi_0(t_\beta) + (t_\beta - t_s)\phi_0'(t_\beta)\right)} \\ &= \frac{\mu - 1}{D(\Psi(\rho), \xi - t_s) - \mu} \cdot \frac{2\lambda + 2\phi_0(\xi) + (\xi - t_s)\phi_0'(\xi)}{2\lambda + 2\phi_0(t_\beta) + (t_\beta - t_s)\phi_0'(t_\beta)} \\ &\leq \frac{\mu - 1}{\rho_0 - \epsilon(\xi - t_s) - \mu} \cdot \frac{2\lambda + 2\phi_0(\xi) + \varphi_0(\xi)}{2\lambda - 2\phi_0(t_\beta^*) - \varphi_0(t_\beta^*)} \to \frac{\mu - 1}{\rho_0 - \mu} \text{ as } \xi \to t_s, \end{aligned}$$

where $t_\beta = t_\beta(\xi)$, $t_\beta^* = t_\beta^*(\xi)$, and $\varphi_0(\xi) = \sup\left\{\left|(\zeta - t_s)\phi_0'(\zeta)\right| : |\zeta - t_s| \leq |\xi - t_s|\right\}$. Combining this with (4.11) and (4.16), we can now choose $\delta_2 \in (0, \delta_4]$ such that $D_u\Psi(\rho)(\xi) \leq \tilde{K}$ for all $\rho \in \Omega(\delta_2)$, $\xi \in [t_s, t_s + \delta_2]$. □

From Lemmas 3.1, 4.1, and 4.2, we have the following theorem.

THEOREM 4.3. *$\Psi : \Omega(\delta) \to \Omega(\delta)$ for $\delta \leq \delta_2$.*

THEOREM 4.4. *There is some $\delta_* \in (0, \delta_2]$ such that Ψ is a contraction in the supremum norm on $\Omega(\delta_*)$.*

Proof. Suppose $\rho_1, \rho_2 \in \Omega(\delta_2)$, and let $t_{1,2}$, $\tilde{t}_{1,2}$ be defined as in the proof of Theorem 3.3. From (4.12), (4.13), and (4.14), we deduce that there is some $\delta_* \in (0, \delta_2]$ such that $t_{1,2} < \tilde{t}_{1,2}$ for any pair $\rho_1, \rho_2 \in \Omega(\delta_2)$. Thus $\tau < \tilde{\tau}$, which implies that $\phi_1'(\tilde{\tau}) < \phi_1'(\tau)$. Combining this with (3.8) gives

$$\|\Psi(\rho_1) - \Psi(\rho_2)\|_{\delta_*} \leq \frac{1}{\mu}\|\rho_1 - \rho_2\|_{\delta_*},$$

from which the theorem follows. ∎

From Theorems 4.3 and 4.4 and the completeness of $\Omega(\delta_*)$ in the supremum norm, we have the following theorem.

THEOREM 4.5. *$\Psi^n(\rho)$ converges to a unique solution of* (2.24) *in $\Omega(\delta_*)$ for any $\rho \in \Omega(\delta_*)$.*

Theorems 3.5 and 3.6 follow as before, except that, in the proof of Theorem 3.6, we can use 1 in place of κ.

5. Verification of loading/unloading near $t = t_s$. Throughout this section, we let $\rho(\xi)$ be the solution of (2.24) and $\sigma(x,t)$, $v(x,t)$ be continuous functions satisfying (1.2), (1.3), (2.1) on A_1 and A_0, and (2.2) on A_2. As mentioned in section 2, characteristic analysis can be used to find σ and v on A_1 and, once the interface $\zeta = \rho(\xi)$ between A_1 and A_2 is determined, on A_2. The goal of this section is to carry out such analysis and use it to verify that σ and v satisfy the original system (1.1) for at least a short time after the loading/unloading interface forms, i.e., that the solution is loading on A_1 and unloading on A_2. For simplicity, we assume in this section that ϕ is differentiable (except possibly at $t = t_s$). Then, by Theorem 3.6, ρ is differentiable, and it is not hard to show that σ and v are also then differentiable on A_1 and A_2. The following theorem shows that the solution is loading on A_1.

THEOREM 5.1. *$\partial_t \sigma(x,t) \le 0$ on $A_1 = \{(x,t) : s(t) < x < \beta t\}$.*

Proof. From (2.4), we have

$$(\sigma - \beta v)(x,t) = (\sigma - \beta v)(0, t - x/\beta)$$

on A_1. Combining this with (1.3) and (2.5), we have

$$\sigma(x,t) = -\phi(t - x/\beta) \tag{5.1}$$

on A_1. The theorem follows from (5.1) since ϕ is nondecreasing on $(0, t_\beta)$ and $0 < t - x/\beta < t_\beta$ on A_1. ∎

The following lemma gives a necessary and sufficient condition for the solution σ, v to be unloading in A_2. We should note that the condition can be checked only after the solution ρ of (2.24) is determined.

LEMMA 5.2. *$\partial_t \sigma(\xi,\zeta) \ge 0$ on $A_2 = \{(\xi,\zeta) : \xi < \zeta < \rho(\xi)\}$ iff*

$$\phi_1'(t_\beta(\xi))\left[\rho'(\xi) - \mu\right] \ge \phi_1'(\tilde{t}_\beta(\zeta))\left[\frac{1}{\mu} - \frac{1}{\rho'(\rho^{-1}(\zeta))}\right] \tag{5.2}$$

on A_2 or, equivalently,

$$\phi_1'(t_\beta(\xi))\left[\rho'(\xi) - \mu\right] \ge \phi_1'(t_\beta(\zeta))\left[\rho'(\zeta) - \mu\right] + \frac{(\mu-1)^2}{\mu}\phi_2'(\zeta) \tag{5.3}$$

on A_2. (See Figure 5.1.*)*

Proof. From (2.12), we have

$$\partial_\xi(\sigma + \alpha v) = 0,$$
$$\partial_\zeta(\sigma - \alpha v) = 0$$

on A_2. Combining this with (2.10), we have

$$(\sigma + \alpha v)(\xi,\zeta) = (\sigma + \alpha v)\left(\rho^{-1}(\zeta), \zeta\right) = \frac{2}{\mu - 1}\phi_1\left(\tilde{t}_\beta(\zeta)\right), \tag{5.4}$$
$$(\sigma - \alpha v)(\xi,\zeta) = (\sigma - \alpha v)(\xi, \rho(\xi)) = -\frac{2\mu}{\mu - 1}\phi_1(t_\beta(\xi)).$$

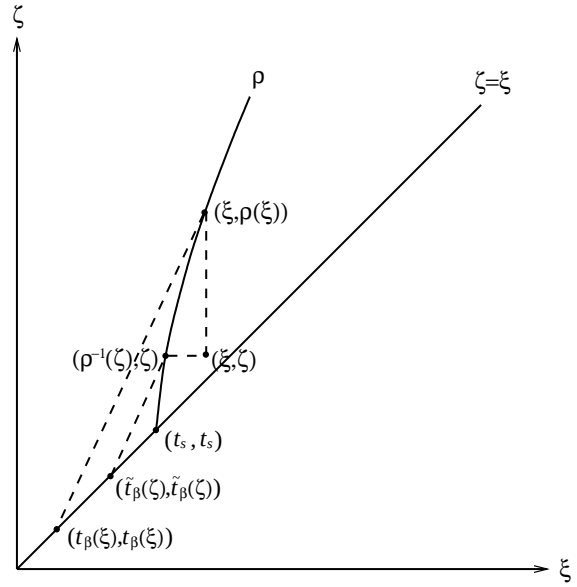

FIG. 5.1. *Derivation of the unloading condition.*

Adding these gives

$$\sigma(\xi,\zeta)=\frac{\phi_1\left(\tilde{t}_\beta(\zeta)\right)-\mu\phi_1\left(t_\beta(\xi)\right)}{\mu-1}. \tag{5.5}$$

Notice that $\partial_t=\partial_\xi+\partial_\zeta$, so

$$\begin{aligned}\partial_t\sigma(\xi,\zeta)&=\frac{\phi_1'\left(\tilde{t}_\beta(\zeta)\right)\tilde{t}_\beta'(\zeta)-\mu\phi_1'\left(t_\beta(\xi)\right)t_\beta'(\xi)}{\mu-1}\\&=\frac{\phi_1'\left(\tilde{t}_\beta(\zeta)\right)\left[\mu/\rho'\left(\rho^{-1}(\zeta)\right)-1\right]-\mu\phi_1'\left(t_\beta(\xi)\right)\left[\mu-\rho'(\xi)\right]}{(\mu-1)^2}\\&=\frac{\mu}{(\mu-1)^2}\left(\phi_1'\left(t_\beta(\xi)\right)\left[\rho'(\xi)-\mu\right]-\phi_1'\left(\tilde{t}_\beta(\zeta)\right)\left[\frac{1}{\mu}-\frac{1}{\rho'\left(\rho^{-1}(\zeta)\right)}\right]\right),\end{aligned}$$

from which (5.2) follows. From (3.14),

$$\phi_1'(\tilde{t}_\beta(\zeta))\left[\frac{1}{\mu}-\frac{1}{\rho'\left(\rho^{-1}(\zeta)\right)}\right]=\phi_1'(t_\beta(\zeta))\left[\rho'(\zeta)-\mu\right]+\frac{(\mu-1)^2}{\mu}\phi_2'(\zeta),$$

which implies (5.3). □

The following theorem shows that the solution is locally unloading on A_2.

THEOREM 5.3. *σ, v satisfy (1.1) on $\{(x,t):0<t<t_s+\delta\}$ for some $\delta>0$ in both the corner case and the smooth case.*

Proof. By Theorem 5.1 and Lemma 5.2, we need only show that (5.2) is satisfied on $\{(\xi,\zeta):\xi<\zeta<\rho(\xi),\ t_s<\xi<t_s+\delta\}$ for some $\delta>0$. Note that, in both the corner and smooth cases,

$$\rho'(t_s)-\mu\geq\frac{1}{\mu}-\frac{1}{\rho'(t_s)}.$$

The result then follows in the corner case from the fact that $\lim_{\xi \to t_s} \phi_1'(\xi) = \nu$ and in the smooth case from (4.16). □

6. Examples. In this section we apply the previously described iterative technique to (2.24) with $\mu = 3$ and specific boundary data; first,

$$\phi(t) = \begin{cases} \frac{1}{2} + \frac{1}{2}\sin\pi\left(t - \frac{1}{2}\right) & 0 \le t < 2, \\ 0 & t \ge 2; \end{cases} \tag{6.1}$$

then

$$\phi(t) = \frac{t}{t^2 + 1}. \tag{6.2}$$

(See Figures 6.1 and 6.2.) Notice that both fall under the smooth case and $t_s = 1$ for both. Our computations show that, with boundary data (6.1), $\partial_t \sigma(\xi, \zeta) < 0$ in part of A_2, and so σ, v do *not* satisfy (1.1) globally, while with boundary data (6.2), σ, v (as defined in section 5) satisfy (1.1) globally.

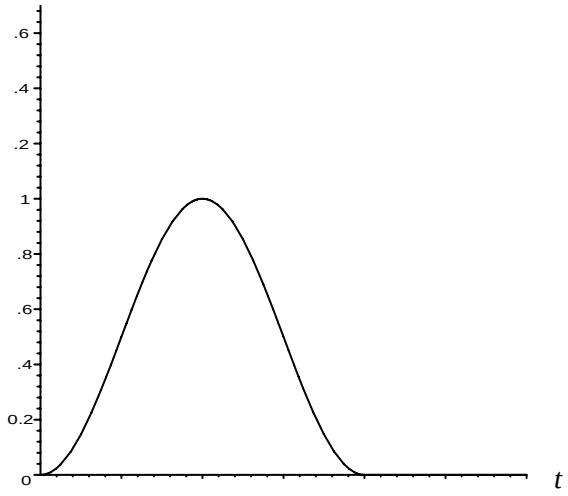

FIG. 6.1. *Boundary data* (6.1).

First, we use Maple V and the iterative technique described previously to compute the solution ρ of (2.24), (6.1). Figure 6.3 shows the graphs of $\mu\xi$ and ρ.

CLAIM 1. *Let σ, v be the solution of* (2.2) *with $\mu = 3$ satisfying* (1.3), (6.1), *and* (2.10). *Then $\partial_t \sigma(\xi, \zeta) < 0$ on a subset of $A_2 = \{(\xi, \zeta) : \xi < \zeta < \rho(\xi)\}$.*

Let

$$G(\xi) = \phi_1'(t_\beta(\xi))\left[\rho'(\xi) - \mu\right] \tag{6.3}$$

$$H(\xi) = \phi_1'(t_\beta(\xi))\left[\rho'(\xi) - \mu\right] + \frac{(\mu - 1)^2}{\mu}\phi_2'(\xi). \tag{6.4}$$

Graphs of G and H for (6.1) are shown in Figure 6.4. Notice that $G(\xi) = H(\xi)$ for $\xi \ge 2$ (this is because $\phi_2'(\xi) = 0$) and G is increasing for $\xi \ge 2$. This implies that $G(\xi) < H(\zeta) = G(\zeta)$ for $2 \le \xi < \zeta$, but, according to (5.3) and Lemma 5.2, $\partial_t \sigma(\xi, \zeta) \ge 0$ iff $G(\xi) \ge H(\zeta)$. This demonstrates the claim.

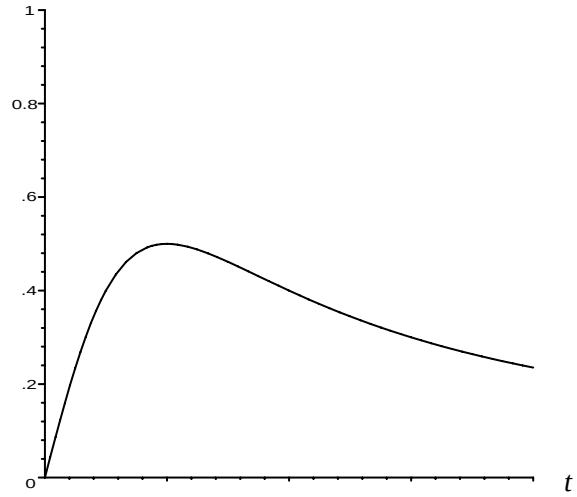

FIG. 6.2. *Boundary data* (6.2).

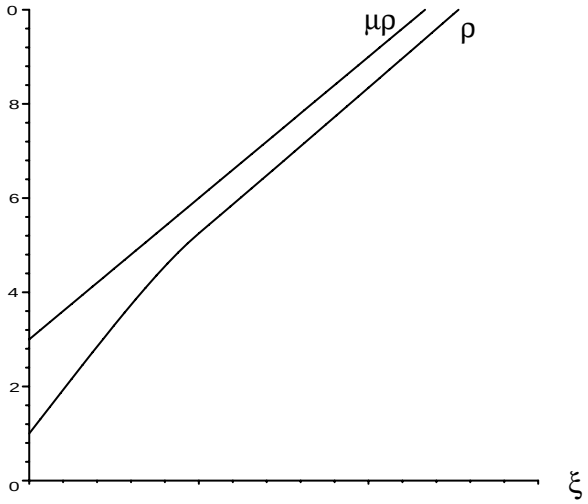

FIG. 6.3. *Solution of* (2.24), (6.1) *with* $\mu = 3$.

The claim is also illustrated by Figures 6.5 and 6.6. Figure 6.5 shows the graph of v (derived from (5.4)) at $t = 1.5$, 2, 2.5. The portion of each graph following the corner corresponds to the region A_2 and was derived assuming that the solution is unloading there. However, closer inspection of v at $t = 2.5$ (Figure 6.6) shows that $\partial_x v < 0$ (loading) on part of that region, thus invalidating the solution. Figure 6.7 shows the corresponding graphs of σ.

Next, we compute the solution ρ of (2.24), (6.2). Figure 6.8 shows the graphs of $\mu\xi$ and ρ.

CLAIM 2. *Let* σ, v *be the solution of* (2.2) *with* $\mu = 3$ *satisfying* (1.3), (6.2), *and* (2.10). *Then* $\partial_t \sigma(\xi, \zeta) \geq 0$ *on all of* $A_2 = \{(\xi, \zeta) : \xi < \zeta < \rho(\xi)\}$.

Graphs of G and H for (6.2) are shown in Figure 6.9. Notice that $G(\xi) > H(\xi)$

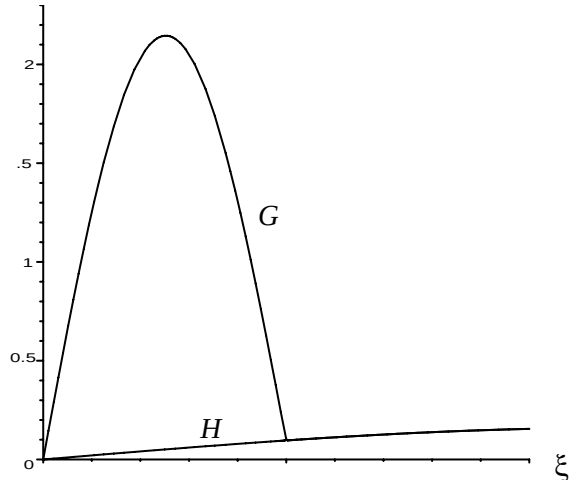

FIG. 6.4. *g and h with boundary data* (6.1).

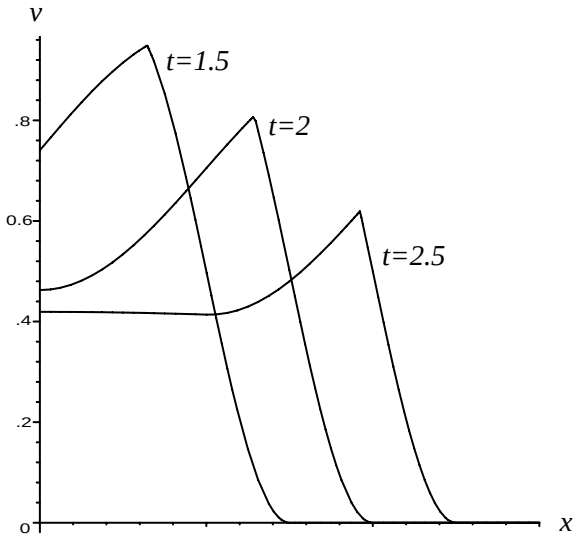

FIG. 6.5. *Solution of* (1.1), (1.2) *with boundary data* (6.1) *and* $\mu = 3$.

for $\xi \geq 1$ since $\phi_2'(\xi) < 0$ for $\xi \geq 1$. Let $H_{\max}(\xi) = \max\{H(\zeta) : \xi \leq \zeta \leq \rho(\xi)\}$. The claim is equivalent to $G(\xi) > H_{\max}(\xi)$ for $\xi > 1$. Figure 6.10 shows graphs of G and $H_{\max}$ for $1 \leq \xi \leq 10$, demonstrating the claim for ξ in that interval. Notice that $H = H_{\max}$ once H begins decreasing, so if we can show that H is decreasing for $\xi \geq 10$, the claim will follow. Toward that end, we will prove the following theorem.

THEOREM 6.1. *Suppose* ρ *is the solution of* (2.24), (6.2). *There is some* M *such that, if* $\xi_0 \geq M$ *and* H *is decreasing on* $[\xi_0, \rho(\xi_0)]$ *and*

$$H(\xi) \leq \frac{(\mu-1)^2 \ln \xi}{\mu \xi^2 \ln \mu} \tag{6.5}$$

on $[\xi_0, \rho(\xi_0)]$, *then* H *is decreasing on* $[\xi_0, \infty)$.

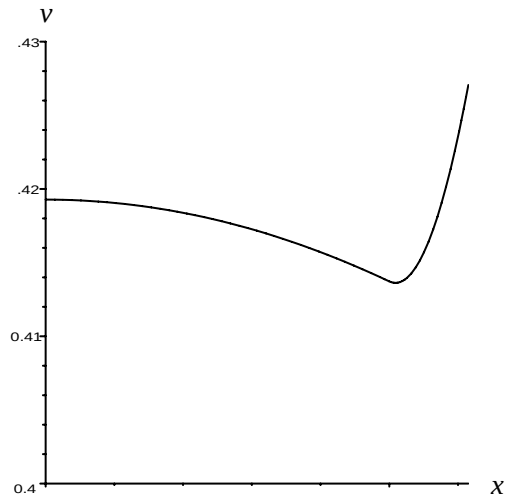

FIG. 6.6. $v(x, 2.5)$.

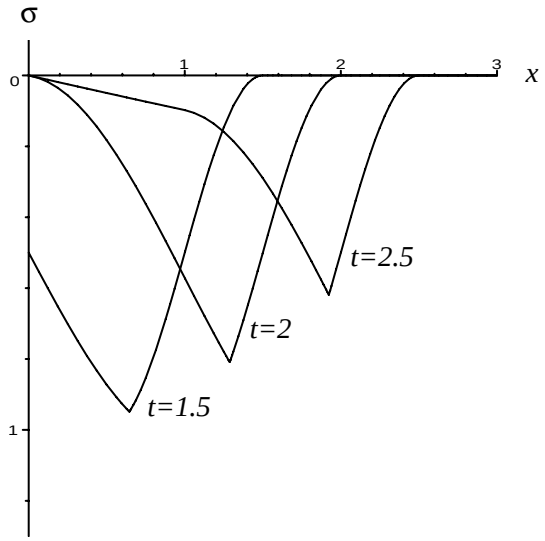

FIG. 6.7. *Solution* σ *of* (1.1), (1.2) *with boundary data* (6.1) *and* $\mu = 3$.

We begin with two lemmas.

LEMMA 6.2. *Suppose* ρ *is the solution of* (2.24), (6.2). *If* $\xi \geq \sqrt{e}$ *and* H *satisfies* (6.5) *on* $[\xi_0, \rho(\xi_0)]$, *then* H *satisfies* (6.5) *on* $[\xi_0, \infty)$.

Proof. Differentiating (2.24), we have

$$\mu\phi_1'(t_\beta)\left(\mu - \rho'(\xi)\right) - \phi_1'(\tilde{t}_\beta)\left(\frac{\mu - \rho'(\rho^{-1}(\xi))}{\rho'(\rho^{-1}(\xi))}\right) = (\mu - 1)^2\phi_2'(\xi).$$

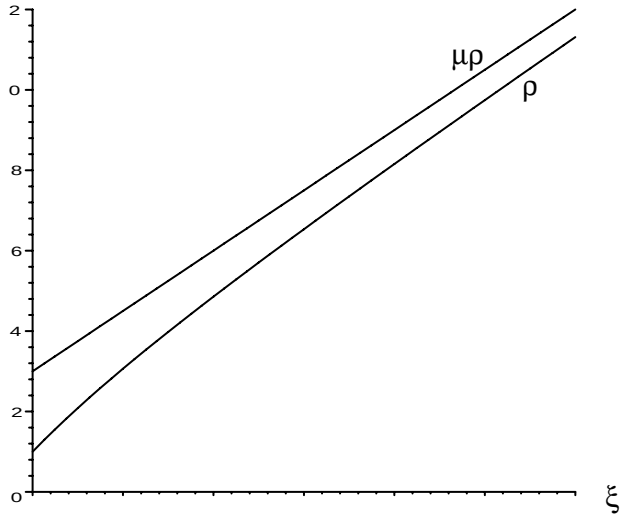

FIG. 6.8. *Solution of* (2.24), (6.2) *with* $\mu = 3$.

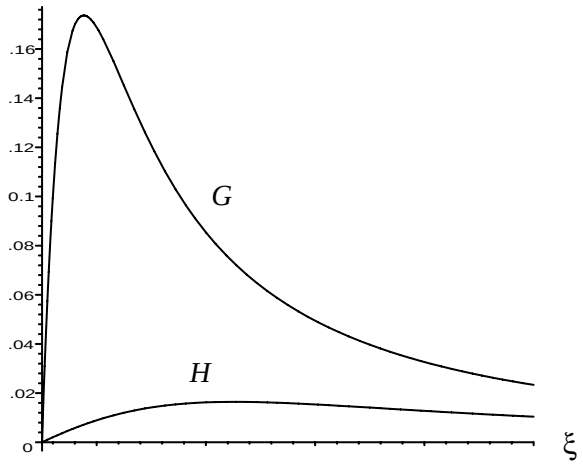

FIG. 6.9. *G and H with boundary data* (6.2).

Combining this with (6.4), we have

$$H(\xi) = \frac{\mu H(\rho^{-1}(\xi)) - (\mu-1)^2\phi_2'(\rho^{-1}(\xi))}{\mu^2\rho'(\rho^{-1}(\xi))},$$

which implies

$$H(\rho(\xi)) = \frac{\mu H(\xi) - (\mu-1)^2\phi_2'(\xi)}{\mu^2\rho'(\xi)} \leq \frac{\mu H(\xi) + (\mu-1)^2/\xi^2}{\mu^3} \tag{6.6}$$

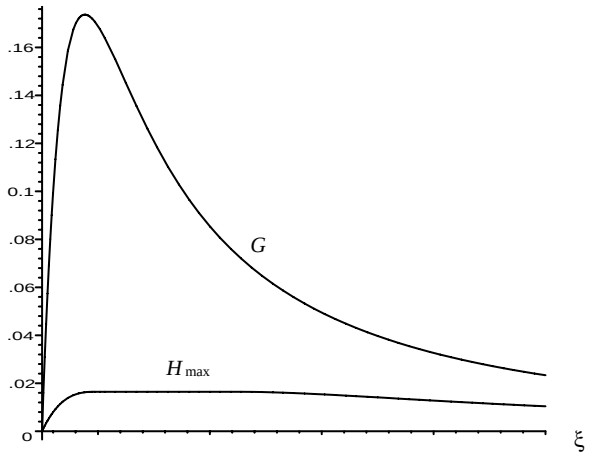

FIG. 6.10. *G and $H_{\max}$.*

by (2.25) and

$$-\phi_2'(\xi) = \frac{\xi^2 - 1}{\left(\xi^2 + 1\right)^2} < \frac{1}{\xi^2}. \tag{6.7}$$

Combining (6.5) and (6.6), we have

$$H(\rho(\xi)) \le \frac{(\mu-1)^2 \ln \xi}{\mu^3 \xi^2 \ln \mu} + \frac{(\mu-1)^2}{\mu^3 \xi^2} = \frac{(\mu-1)^2 \ln \mu\xi}{\mu(\mu\xi)^2 \ln \mu}.$$

Thus

$$H(\rho(\xi)) \le \frac{(\mu-1)^2 \ln \rho(\xi)}{\mu \rho(\xi)^2 \ln \mu}$$

for $\xi \ge \sqrt{e}/\mu$ by (2.26) and the fact that $(\ln \xi)/\xi^2$ is decreasing for $\xi \ge \sqrt{e}$. This means that H satisfies (6.5) on $\left[\rho(\xi_0), \rho^2(\xi_0)\right]$. Notice that (2.25) implies that $\lim_{n\to\infty} \rho^n(\xi_0) = \infty$ for $\xi_0 > 1$, so the result follows by induction. ∎

LEMMA 6.3. *Suppose ρ is the solution of* (2.24), (6.2) *satisfying* (6.5). *Then there is some M_1 such that*

$$\rho'(\xi) - \mu \le \frac{2(\mu-1)^2 \ln \mu\xi}{\mu \xi^2 \ln \mu}$$

for $\xi \ge M_1$.

Proof. From (6.4), we have

$$\rho'(\xi) - \mu = \frac{\mu H(\xi) - (\mu-1)^2 \phi_2'(\xi)}{\mu \phi_1'(t_\beta(\xi))}. \tag{6.8}$$

It is not hard to show that

$$\phi_1'(\xi) = \frac{1 - \xi^2}{\left(\xi^2 + 1\right)^2} \ge 1 - 3\xi^2 \ge \frac{1}{2} \quad \text{for } \xi \le \frac{1}{\sqrt{6}}. \tag{6.9}$$

Since t_β is decreasing by (2.25) and $\lim_{\xi\to\infty} t_\beta(\xi) = 0$ by (2.27), there is some M_1 such that

$$t_\beta(\xi) \le \frac{1}{\sqrt{6}} \quad \text{for } \xi \ge M_1. \tag{6.10}$$

Combining this with (6.7), (6.8), and (6.9) gives

$$\rho'(\xi) - \mu \le \frac{\mu H(\xi) + (\mu-1)^2/\xi^2}{\mu\left(1 - 3t_\beta(\xi)^2\right)} \le 2H(\xi) + \frac{2(\mu-1)^2}{\mu\xi^2}$$

for $\xi \ge M_1$. Combining this with (6.5) gives

$$\rho'(\xi) - \mu \le \frac{2(\mu-1)^2 \ln\xi}{\mu\xi^2 \ln\mu} + \frac{2(\mu-1)^2}{\mu\xi^2} = \frac{2(\mu-1)^2 \ln\mu\xi}{\mu\xi^2\ln\mu}$$

for $\xi \ge M_1$. □

We now give the proof of Theorem 6.1.

Proof. Assume that, on $[\xi_0, \rho(\xi_0)]$, H is decreasing and satisfies (6.5). Let $\xi_0 \le \xi < \zeta \le \rho(\xi_0)$. From (6.3), (6.4), and (6.6) we have

$$H(\rho(\xi)) = \frac{G(\xi)}{\mu\rho'(\xi)},$$

so

$$\begin{aligned} H(\rho(\xi)) - H(\rho(\zeta)) &= \frac{G(\xi)}{\mu\rho'(\xi)} - \frac{G(\zeta)}{\mu\rho'(\zeta)} = \frac{G(\xi)-G(\zeta)}{\mu\rho'(\xi)} + \frac{G(\zeta)}{\mu\rho'(\xi)\rho'(\zeta)}\left(\rho'(\zeta)-\rho'(\xi)\right) \\ &= \frac{G(\xi)-G(\zeta)}{\mu\rho'(\xi)} + \frac{G(\zeta)}{\mu\rho'(\xi)\rho'(\zeta)}\left(\frac{G(\zeta)}{\phi_1'(t_\beta(\zeta))} - \frac{G(\xi)}{\phi_1'(t_\beta(\xi))}\right) \quad \text{by (6.3)} \\ &= \frac{G(\xi)-G(\zeta)}{\mu\rho'(\xi)}\left[1 - \frac{G(\zeta)}{\rho'(\zeta)\phi_1'(t_\beta(\xi))}\right] + \frac{G(\zeta)^2\left(\phi_1'(t_\beta(\xi)) - \phi_1'(t_\beta(\zeta))\right)}{\mu\rho'(\xi)\rho'(\zeta)\phi_1'(t_\beta(\zeta))\phi_1'(t_\beta(\xi))}. \end{aligned}$$

The last term is negative since ϕ_1' and t_β are decreasing, so

$$H(\rho(\xi)) - H(\rho(\zeta)) \ge \frac{G(\xi)-G(\zeta)}{\mu\rho'(\xi)}\left(1 - 2G(\zeta)/\mu\right) - \frac{4G(\zeta)^2}{\mu^2}\left(\phi_1'(t_\beta(\zeta)) - \phi_1'(t_\beta(\xi))\right) \tag{6.11}$$

for $\xi \ge M_1$ by (2.25), (6.9), and (6.10). By (6.3), (6.4), (6.5), and (6.7), we have

$$G(\zeta) \le \frac{(\mu-1)^2\ln\zeta}{\mu\zeta^2\ln\mu} + \frac{(\mu-1)^2}{\mu\zeta^2} = \frac{(\mu-1)^2\ln\mu\zeta}{\mu\zeta^2\ln\mu}. \tag{6.12}$$

Combining this with Lemma 6.3, we can choose $M_2 \ge M_1$ such that

$$G(\zeta) \le \frac{\mu}{4} \text{ and } \rho'(\xi) \le \mu + 2\left(\frac{\mu}{4}\right) = \frac{3\mu}{2} \tag{6.13}$$

when $\xi \geq M_2$. Then, from (6.11), we have

$$\begin{aligned} H(\rho(\xi)) - H(\rho(\zeta)) &\geq \frac{G(\xi)-G(\zeta)}{3\mu^2} - \frac{4G(\zeta)^2}{\mu^2}\left(\phi_1'(t_\beta(\zeta)) - \phi_1'(t_\beta(\xi))\right) \\ &= \frac{H(\xi)-H(\zeta)}{3\mu^2} + \frac{(\mu-1)^2\left(\phi_2'(\zeta)-\phi_2'(\xi)\right)}{3\mu^3} \\ &\quad - \frac{4G(\zeta)^2}{\mu^2}\left(\phi_1'(t_\beta(\zeta)) - \phi_1'(t_\beta(\xi))\right) \\ &= \frac{H(\xi)-H(\zeta)}{3\mu^2} + \frac{(\mu-1)^2\phi_2''(c_1)(\zeta-\xi)}{3\mu^3} \\ &\quad - \frac{4G(\zeta)^2\phi_1''(c_2)t_\beta'(c_3)(\zeta-\xi)}{\mu^2}, \end{aligned} \tag{6.14}$$

where $\xi < c_1$, $c_3 < \zeta$, and $t_\beta(\zeta) < c_2 < t_\beta(\xi)$. It is not hard to show from (6.2) that

$$\phi_2''(\xi) \geq \frac{1}{\xi^3} \quad \text{for } \xi \geq \sqrt{12}, \tag{6.15}$$

$$\phi_1''(\xi) \geq -6\xi. \tag{6.16}$$

Combining (6.14), (6.15), and (6.16), we have

$$H(\rho(\xi)) - H(\rho(\zeta)) \geq \frac{H(\xi)-H(\zeta)}{3\mu^2} + \left[\frac{(\mu-1)^2}{3\mu^3 c_1^3} + \frac{24G(\zeta)^2 c_2 t_\beta'(c_3)}{\mu^2}\right](\zeta-\xi) \tag{6.17}$$

when $\xi \geq M_2, \sqrt{12}$. From (2.21) and Lemma 6.3, we have

$$t_\beta'(c_3) = \frac{\mu-\rho'(c_3)}{\mu-1} \geq -\frac{2(\mu-1)\ln \mu c_3}{\mu c_3^2 \ln \mu} \geq -\frac{2(\mu-1)\ln \mu\xi}{\mu\xi^2 \ln \mu}.$$

We now use this and (6.12) to estimate the quantity in brackets in (6.17):

$$\begin{aligned} \frac{(\mu-1)^2}{3\mu^3 c_1^3} + \frac{24G(\zeta)^2 c_2 t_\beta'(c_3)}{\mu^2} &\geq \frac{(\mu-1)^2}{3\mu^3 c_1^3} - \frac{48c_2(\mu-1)^5 \ln^2 \mu\zeta \ln \mu\xi}{\mu^5\zeta^4\xi^2 \ln^3 \mu} \\ &\geq \frac{(\mu-1)^2}{3\mu^3\zeta^3} - \frac{48t_\beta(\xi)(\mu-1)^5 \ln^2 \mu\zeta \ln \mu\xi}{\mu^5\zeta^4\xi^2 \ln^3 \mu} \\ &\geq \frac{(\mu-1)^2}{3\mu^3\zeta^3} - \frac{8\sqrt{6}(\mu-1)^5 \ln^2 \mu\zeta \ln \mu\xi}{\mu^5\zeta^4\xi^2 \ln^3 \mu} \end{aligned}$$

for $\xi \geq M_2, \sqrt{12}$ by (6.10). Combining this with (6.17), we have

$$\begin{aligned} H(\rho(\xi)) - H(\rho(\zeta)) &\geq \frac{H(\xi)-H(\zeta)}{3\mu^2} + \frac{(\mu-1)^2}{3\mu^3\zeta^3}\left[1 - \frac{24\sqrt{6}(\mu-1)^3 \ln^2 \mu\zeta \ln \mu\xi}{\mu^2\zeta\xi^2 \ln^3 \mu}\right](\zeta-\xi) \\ &\geq \frac{H(\xi)-H(\zeta)}{3\mu^2} + \frac{(\mu-1)^2}{3\mu^3\zeta^3}\left[1 - \frac{24\sqrt{6}(\mu-1)^3 \ln^3 \mu\xi}{\mu^2\xi^3 \ln^3 \mu}\right](\zeta-\xi) \end{aligned} \tag{6.18}$$

for $\xi \geq e^2/\mu$ since $(\ln^2 \mu\zeta)/\zeta$ is then decreasing. Since the function in brackets is increasing for $\xi \geq e/\mu$ and approaches 1 as $\xi \to \infty$, we can choose $M \geq M_2, \sqrt{12}, e^2/\mu$

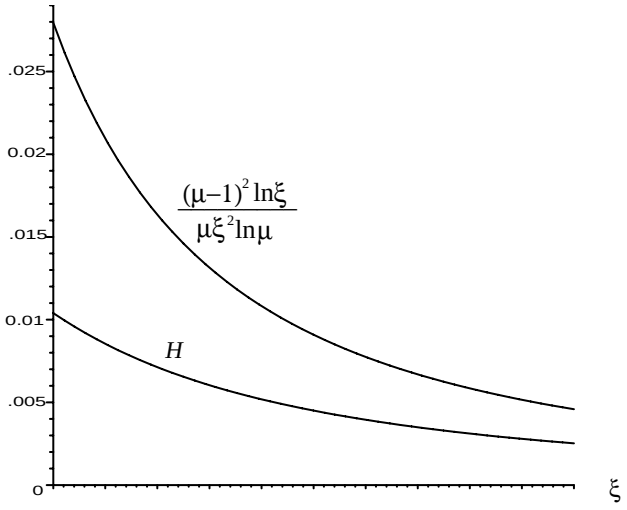

FIG. 6.11. *Bound on H.*

so that

$$1 - \frac{24\sqrt{6}(\mu-1)^2 \ln^3 \mu\xi}{\mu^2 \xi^3 \ln^3 \mu} > 0 \tag{6.19}$$

for $\xi \geq M$. Since H is decreasing on $[\xi_0, \rho(\xi_0)]$, (6.18) implies that H is decreasing on $[\rho(\xi_0), \rho^2(\xi_0)]$ if $\xi_0 \geq M$. The result follows by induction and Lemma 6.2. ∎

Our computations with $\mu = 3$ show that (6.10), (6.13), and (6.19) all hold for $\xi \geq 10 > \sqrt{12}, e^2/\mu$, so we can let $M = 10$. Figure 6.11 shows that (6.5) holds on $[10, \rho(10)]$ and that H is decreasing on $[10, \rho(10)]$, and so Theorem 6.1 implies that H is decreasing on $[10, \infty)$, from which Claim 2 follows.

Figures 6.12 and 6.13 show the graphs of v and σ at $t = 2, 5, 10$. The solution of (1.1), (1.2), (1.3), (6.2) with $\mu = 3$ is qualitatively the same as for the stress-controlled problem in [3], i.e., a decaying pulse of increasing length consisting of a loading front followed by an unloading front. We prove the decay in the following theorem.

THEOREM 6.4. *Let σ, v be the solution of* (2.2) *with $\mu = 3$ satisfying* (1.3), (6.2)*, and* (2.10). *Then*

$$\lim_{t\to\infty} \max_x \{|v(x,t)|, |\sigma(x,t)|\} = 0.$$

Proof. Since $\partial_x v$ changes sign only at the loading/unloading interface, we have

$$\max_x |v(x,t)| = v(s(t), t) = \phi(t - s(t)/\beta)/\beta \tag{6.20}$$

by (2.10). Equation (2.27) implies that $\lim_{t\to\infty}(t - s(t)/\beta) = 0$, and hence

$$\lim_{t\to\infty} \max_x |v(x,t)| = 0.$$

Now, from (5.1), we have

$$\partial_x \sigma(x,t) = \phi'(t - x/\beta)/\beta$$

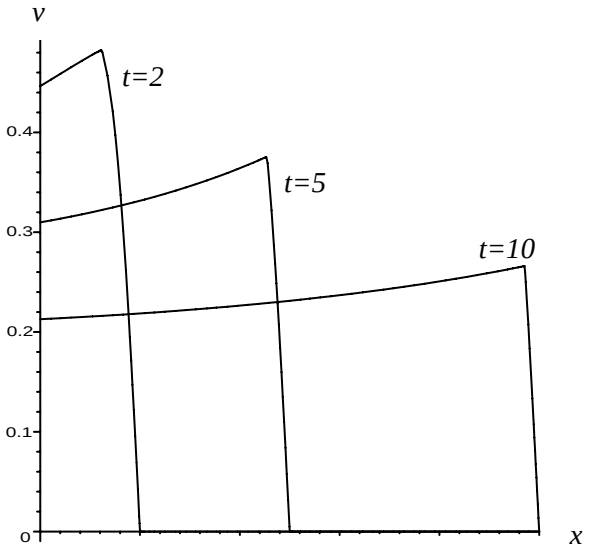

FIG. 6.12. *Solution v of* (1.1), (1.2) *with boundary data* (6.2) *and* $\mu = 3$.

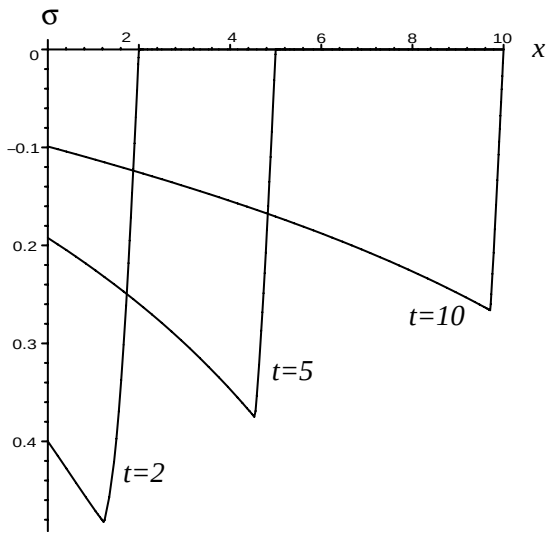

FIG. 6.13. *Solution σ of* (1.1), (1.2) *with boundary data* (6.2) *and* $\mu = 3$.

which is nonnegative on A_1 since

$$t - x/\beta \le t - s(t)/\beta = t_\beta \le t_s$$

on A_1. This implies that

$$0 \ge \sigma(x,t) \ge \sigma(s(t),t) = -\phi(t - s(t)/\beta)$$

by (2.10), and so

$$\lim_{t\to\infty} \max_{x\ge s(t)} |\sigma(x,t)| = 0.$$

We now focus on A_2. Combining (5.5) and (2.24), we have

$$\sigma(\xi,\zeta) = \frac{\mu}{\mu-1}\left[\phi_1\left(t_\beta(\zeta)\right) - \phi_1\left(t_\beta(\xi)\right)\right] - \phi_2(\zeta), \tag{6.21}$$

which is negative on A_2 since t_β is nonincreasing (by (2.21) and (2.25)), ϕ_1 is nondecreasing, and $\zeta > \xi$. Also, (6.21) implies that

$$\begin{aligned}\sigma(\xi,\zeta) &\geq -\frac{\mu}{\mu-1}\phi_1\left(t_\beta(\xi)\right) - \phi_2(\zeta)\\ &= -\frac{\mu}{\mu-1}\phi_1\left(t_\beta(t-x/\alpha)\right) - \phi_2(t+x/\alpha)\\ &\geq -\frac{\mu}{\mu-1}\phi_1\left(t_\beta(t-s(t)/\alpha)\right) - \phi_2(t)\end{aligned}$$

on A_2 since ϕ_2 and t_β are nonincreasing and ϕ_1 is nondecreasing. By (2.7),

$$t_\beta(t-s(t)/\alpha) = t - s(t)/\beta,$$

so

$$0 \geq \sigma(x,t) \geq -\frac{\mu}{\mu-1}\phi_1\left(t-s(t)/\beta\right) - \phi_2(t).$$

The right-hand side goes to zero as $t \to \infty$ by (2.27), so

$$\lim_{t\to\infty}\max_{0\leq x\leq s(t)}|\sigma(x,t)| = 0. \qquad \square$$

Acknowledgments. We thank David Schaeffer and Michael Shearer for their many helpful comments made on an earlier draft of this paper.

ASYMPTOTIC STABILITY OF TRAVELING WAVES TO A CERTAIN DISCRETE VELOCITY MODEL OF THE BOLTZMANN EQUATION IN THE HALF SPACE*

SHINYA NISHIBATA†

Dedicated to Professors Takaaki Nishida and Masayasu Mimura on their 60th birthdays

Abstract. The present paper studies the asymptotic stability of a traveling wave for the Broadwell model in a half space. This model admits the traveling wave which connects two distinct Maxwellian states at the spatial asymptotic points. The traveling wave is shown to be time asymptotically stable if the fluid dynamical velocity is less than a certain positive value. This stability theorem is proved by applying the standard energy method. Here, the location of the traveling wave, which should be a time asymptotic state, is shifted by boundary effect. This shift is estimated by utilizing the property that the traveling wave converges to the Maxwellian states exponentially fast.

Key words. Broadwell model, boundary effect, initial boundary value problem, energy method

1. Introduction.

1.1. Problems. We study the asymptotic stability of a traveling wave solution to the Broadwell model system

$$\partial_t F_1 + v\partial_x F_1 = q(F), \tag{1.1a}$$

$$4\partial_t F_2 = -2q(F), \tag{1.1b}$$

$$\partial_t F_3 - v\partial_x F_3 = q(F) \tag{1.1c}$$

in the first half space $\mathbb{R}_+ := \{x > 0\}$. Here,

$$q(F) := F_2^2 - F_1 F_3, \quad F := (F_1, F_2, F_3),$$

v is a positive constant, and unknown functions $F_i > 0$ for $i = 1, 2, 3$ represent the mass densities for gas particles moving with the speed v, 0, and $-v$ in the x-direction, respectively.

We prescribe the initial condition

$$F(x,0) = F_0(x) = (F_{1,0}, F_{2,0}, F_{3,0})(x), \tag{1.2a}$$

$$F_0(x) \to M^+ = (M_1^+, M_2^+, M_3^+) \quad \text{as} \quad x \to \infty, \tag{1.2b}$$

where M^+ is a Maxwellian state. The Maxwellian state $M := (M_1, M_2, M_3)$ is an equilibrium state of (1.1) with positive entries

$$q(M) = 0, \quad M_i > 0 \text{ for } i = 1,\ 2,\ 3. \tag{1.3}$$

Since the characteristic speed v of F_1 is positive, it is necessary to set one condition on the boundary $\{x = 0\}$ for the well-posedness of the initial and boundary value problem (1.1) and (1.2). Then we adopt the pure diffusion boundary condition as

$$F_1(0,t) = B_1, \quad B_1 > 0, \tag{1.4}$$

where B_1 is a constant. The compatibility condition of order zero is supposed to hold:

$$F_{1,0}(0) = B_1. \tag{1.5}$$

The traveling wave to the system (1.1) is a solution in the form of $\tilde{F}(\xi) := (\tilde{F}_1, F_2, F_3)(\xi)$ interpolating two distinct Maxwellian states $M^{\pm} = (M_1^{\pm}, M_2^{\pm}, M_3^{\pm})$:

$$\tilde{F}(\xi) \to M^{\pm} = (M_1^{\pm}, M_2^{\pm}, M_3^{\pm}) \text{ as } \xi \to \pm\infty, \quad M^+ \neq M^-, \tag{1.6}$$

where $\xi := x - st$ and s is a constant called the traveling wave speed. The main purpose of the present paper is to show the asymptotic stability of the traveling wave with $s > 0$ in the first half space $\mathbb{R}_+$. It is shown in Lemma 1.1 that for a positive constant B_1 and a Maxwellian state M^+, if $B_1 > M_1^+$, then we can find a unique Maxwellian state $M^- = (M_1^-, M_2^-, M_3^-)$ such that there exists a traveling wave $\tilde{F}(x - st)$, with $s > 0$, which satisfies (1.6) with $M_1^- = B_1$.

1.2. Equations for traveling waves. Substituting $\tilde{F}(\xi)$ in (1.1) yields that

$$(v - s)\tilde{F}_1' = \tilde{F}_2^2 - \tilde{F}_1\tilde{F}_3, \tag{1.7a}$$

$$-4s\tilde{F}_2' = -2(\tilde{F}_2^2 - \tilde{F}_1\tilde{F}_3), \tag{1.7b}$$

$$-(v + s)\tilde{F}_3' = \tilde{F}_2^2 - \tilde{F}_1\tilde{F}_3. \tag{1.7c}$$

Here and hereafter, the superscript " $'$ " denotes the differentiation with respect to ξ. From (1.7), it holds that

$$\{(v - s)\tilde{F}_1 - 4s\tilde{F}_2 - (v + s)\tilde{F}_3\}' = 0, \tag{1.8a}$$

$$\{(v - s)\tilde{F}_1 + (v + s)\tilde{F}_3\}' = 0. \tag{1.8b}$$

Suppose that the traveling wave solution $\tilde{F}(\xi)$, $\xi \in \mathbb{R}$, satisfying (1.6) with (1.3), exists for the moment. Integrating (1.8) over $(-\infty, \infty)$ and $(-\infty, \xi]$, respectively, we have

$$(v - s)\tilde{F}_1 - 4s\tilde{F}_2 - (v + s)\tilde{F}_3 = r_1, \quad r_1 := (v - s)M_1^{\pm} - 4sM_2^{\pm} - (v + s)M_3^{\pm}, \tag{1.9a}$$

$$(v - s)\tilde{F}_1 + (v + s)\tilde{F}_3 = r_2, \quad r_2 := (v - s)M_1^{\pm} + (v + s)M_3^{\pm}. \tag{1.9b}$$

The right equalities in (1.9) are the Rankine–Hugoniot condition. It is easy to see from (1.7) that $s \neq \pm v$, 0. Represent $\tilde{F}_2$ and $\tilde{F}_3$ in terms of $\tilde{F}_1$ by solving (1.9) and then substitute the resultant expressions in (1.7a). Apply the same procedure to $\tilde{F}_2$ and $\tilde{F}_3$, too. The results are

$$\tilde{F}_1' = \frac{v^2 + 3s^2}{4s^2(v + s)}(\tilde{F}_1 - M_1^-)(\tilde{F}_1 - M_1^+), \tag{1.10a}$$

$$\tilde{F}_2' = \frac{v^2 + 3s^2}{4s(v + s)(v - s)}(\tilde{F}_2 - M_2^-)(\tilde{F}_2 - M_2^+), \tag{1.10b}$$

$$\tilde{F}_3' = -\frac{v^2 + 3s^2}{4s^2(v - s)}(\tilde{F}_3 - M_3^-)(\tilde{F}_3 - M_3^+). \tag{1.10c}$$

Since $\tilde{F}(\xi)$ satisfies (1.6), we arrive at the inequality

$$0 < s < v \tag{1.11a}$$

$$\text{or} \quad -v < s < 0. \tag{1.11b}$$

It is easy to see from (1.10) that the traveling wave is monotonic. Especially, $\tilde{F}_1(\xi)$ is monotonically decreasing and thus $M_1^+ < M_1^-$. $\tilde{F}_2(\xi)$ is monotonically decreasing if and only if (1.11a) holds.

The above observation means that the condition (1.11) is necessary for the existence of the traveling wave $\tilde{F}(\xi)$. Moreover, it is proved in [2], the condition (1.11) is sufficient for the existence of the traveling wave. This fact is also proved by the straightforward computation with (1.10). In the next lemma, we summarize the results concerning the existence of the traveling wave in a convenient formulation to the present paper. The proof follows from algebraic computations with (1.3), (1.9), and (1.11).

LEMMA 1.1. (i) *If there exists a traveling wave* $\tilde{F}(\xi)$, $\xi := x - st \in \mathbb{R}$, *interpolating two distinct Maxwellian states* $M^{\pm}$, *then* (1.11) *hold. Moreover, if* $s \lesseqgtr 0$, *then* $M_2^- \lesseqgtr M_2^+$.

(ii) *Suppose that a positive constant* B_1 *and a Maxwellian state* $M^+ = (M_1^+, M_2^+, M_3^+)$ *satisfy* $B_1 > M_1^+$. *If* $|B_1 - M_1^+|$ *is sufficiently small, then there exists a unique Maxwellian state* $M^- = (M_1^-, M_2^-, M_3^-)$ *such that* $M_1^- = B_1$, $M_2^- > M_2^+$, *and the Rankine–Hugoniot condition in* (1.9) *holds. Therefore, there exists a traveling wave* $\tilde{F}(x - st)$, *uniquely up to a shift, which interpolates* $M^{\pm}$ *and satisfies* (1.11a).

Due to Lemma 1.1, we assume that

$$M_1^+ < B_1 \tag{1.12}$$

and (1.11a) hold, here and hereafter. For a given Maxwellian state M^+ and B_1 satisfying (1.12), M^- is determined by the algebraic relation (1.9) and (1.3) with $M_1^- = B_1$. Therefore, it holds that

$$|M_i^+ - M_i^-| \le C\delta_M, \quad \delta_M := |M_1^+ - B_1| \quad \text{for } i = 1, 2, 3. \tag{1.13}$$

We often call the quantity δ_M the shock strength.

1.3. Fluid dynamical equations. We rewrite the system (1.1) in terms of the fluid dynamical quantities, following the context of [3]. The density ρ and the momentum m are defined by

$$\rho := F_1 + 4F_2 + F_3, \quad m := v(F_1 - F_3). \tag{1.14a}$$

In addition, we denote

$$z := v^2(F_1 + F_3). \tag{1.14b}$$

From (1.1) and (1.14), we have the system of equations for the fluid dynamical quantities

$$\rho_t + m_x = 0, \tag{1.15a}$$

$$m_t + z_x = 0, \tag{1.15b}$$

$$z_t + v^2 m_x = \frac{(v^2\rho - z)^2 - 4(z^2 - v^2 m^2)}{8v^2}. \tag{1.15c}$$

The initial data for the above system (1.15) is derived from (1.14) and written as

$$\begin{aligned} \rho(x,0) &= \rho_0(x) := (F_{1,0} + 4F_{2,0} + F_{3,0})(x), \\ m(x,0) &= m_0(x) := v(F_{1,0} - F_{3,0})(x), \\ z(x,0) &= z_0(x) := v^2(F_{1,0} + F_{3,0})(x). \end{aligned} \tag{1.16}$$

The spatial asymptotic states for the fluid dynamical quantities are given by

$$\rho^\pm = M_1^\pm + 4M_2^\pm + M_3^\pm > 0, \quad m^\pm := v(M_1^\pm - M_3^\pm), \quad z^\pm := v^2(M_1^\pm + M_3^\pm) > 0. \tag{1.17}$$

The above inequalities follow from the positivity of each $M_i^\pm$. The condition (1.3) for the Maxwellian state M is rewritten in the fluid dynamical quantities as

$$|u| < v, \quad z = \rho\sigma(u), \quad \sigma(u) := \frac{v^2}{3}\left(2\sqrt{1 + \frac{3u^2}{v^2}} - 1\right), \tag{1.18}$$

where $u := m/\rho$ is called the fluid dynamical velocity. Since the asymptotic states $(\rho_\pm, m_\pm, z_\pm)$ are Maxwellian states, $(\rho_\pm, m_\pm, z_\pm)$ satisfy (1.18).

We express the traveling wave solution to (1.15) by

$$(\tilde\rho, \tilde m, \tilde z) := (\tilde F_1 + 4\tilde F_2 + \tilde F_3, v(\tilde F_1 - \tilde F_3), v^2(\tilde F_1 + \tilde F_3)), \tag{1.19}$$

which satisfies

$$-s\tilde\rho' + \tilde m' = 0, \tag{1.20a}$$

$$-s\tilde m' + \tilde z' = 0, \tag{1.20b}$$

$$-s\tilde z' + v^2\tilde m' = \frac{(v^2\tilde\rho - \tilde z)^2 - 4(\tilde z^2 - v^2\tilde m^2)}{8v^2}. \tag{1.20c}$$

The existence of the traveling wave $(\tilde\rho,\ \tilde m,\ \tilde z)$ immediately follows from (1.19) and the existence of the traveling wave $(\tilde F_1, \tilde F_2, \tilde F_3)$ to (1.7) in Lemma 1.1. Substituting (1.19) in (1.9), we have the Rankine–Hugoniot condition

$$-s(\rho^+ - \rho^-) + (m^+ - m^-) = 0, \tag{1.21a}$$

$$-s(m^+ - m^-) + (z^+ - z^-) = 0. \tag{1.21b}$$

Apparently, from (1.13),

$$|(\rho^+ - \rho^-, m^+ - m^-, z^+ - z^-)| \le C\delta_M. \tag{1.22}$$

It is shown in [3] that the condition (1.11) is equivalent to the Lax entropy condition

$$\lambda_-(u^+) < s < \lambda_+(u^-) \quad \text{or} \quad \lambda_+(u^+) < s < \lambda_-(u^-), \tag{1.23}$$

where

$$\lambda_\pm(u) := \frac{u \pm \sqrt{\sigma(u)}}{\sqrt{1 + 3(u^2/v^2)}}, \quad u^\pm := \frac{m^\pm}{\rho^\pm}. \tag{1.24}$$

Here, $\lambda_\pm(u)$ are the characteristics of the corresponding Euler equation

$$\rho_t + m_x = 0, \tag{1.25a}$$

$$m_t + (\rho\sigma(u))_x = 0. \tag{1.25b}$$

The system (1.25) is derived from (1.15) through the Chapman–Enskog expansion.

1.4. Assumptions and the main result. To handle the boundary terms, the given Maxwellian state M^+ is supposed to satisfy

$$M_1^+ - M_3^+ < 2M_2^+. \tag{1.26}$$

The condition (1.26) apparently holds if the fluid dynamical momentum is negative at the Maxwellian state M^+. The condition (1.26) with M^+ replaced by $\tilde{F}(\xi)$ also holds, provided that the traveling wave $\tilde{F}(\xi)$ interpolates M^- and M^+ with sufficiently small shock strength, $\delta_M \ll 1$. The condition (1.26) is rewritten in the fluid dynamical quantities as

$$u^+ < \frac{2-\sqrt{2}}{2} v, \tag{1.26$'$}$$

where we have used (1.18).

Since the traveling wave $\tilde{F}(\xi)$ converges to M^+ exponentially fast as ξ tends to infinity, we can define the antiderivatives of the initial perturbations from the traveling wave if $F_0 - M_+ \in L^1(\mathbb{R}_+)$. Thus, we define

$$\hat{\Phi}_0(x) := -\int_x^\infty \hat{\phi}_0(x)dy, \quad \hat{\Psi}_0(x) := -\int_x^\infty \hat{\psi}_0(x)dy, \tag{1.27a}$$

$$\begin{aligned} &\hat{\phi}_0(x) := \rho_0(x) - \tilde{\rho}(x-\beta), \quad \hat{\psi}_0(x) := m_0(x) - \tilde{m}(x-\beta), \\ &\hat{\omega}_0(x) := z_0(x) - \tilde{z}(x-\beta), \end{aligned} \tag{1.27b}$$

where β is a positive constant. The parameter β is determined later and utilized to handle the boundary terms in subsection 2.3.

THEOREM 1.2. *Suppose that* (1.5) *and* (1.26) *hold. Let* $F_0 - M^+ \in (L^1 \cap H^1)(\mathbb{R}_+)$ *and* $(\hat{\Phi}_0, \hat{\Psi}_0) \in L^2(\mathbb{R}_+)$. *Then there exists a constant* $\bar{\delta}_0$ *with the following property: if* $\delta_M \le \bar{\delta}_0$, *then one can find a positive constant* β_0 *such that whenever* $\beta \ge \beta_0$ *and* $\|(\hat{\Phi}_0, \hat{\Psi}_0)\| + \|F_0(\cdot) - \tilde{F}(\cdot - \beta)\|_1$ *is sufficiently small, the initial boundary value problem* (1.1), (1.2), *and* (1.4) *has a unique solution* $F(x,t)$ *globally in time. Moreover, the solution* $F(x,t)$ *satisfies that for a certain constant* x_∞,

$$\sup_{x \in \mathbb{R}_+} |F(x,t) - \tilde{F}(x - st + x_\infty)| \to 0 \quad as \quad t \to \infty. \tag{1.28}$$

The Broadwell model (1.1) is a simple but typical model of the Boltzmann equation. The existence of the traveling wave to the model is established by Caflish [2]. It is proved by Kawashima and Matsumura in [3] that the traveling wave is asymptotically stable in the full space $\mathbb{R}$. In [3], the energy method is employed to obtain the a priori estimate. In the present research, we also use this method and follow some computations of their research. Due to Lemma 1.1, we have to assume $B_1 > M_1^+$ for the existence of the traveling wave. The opposite case $B_1 < M_1^+$ gives the solution which converges to the rarefaction wave in the half space $\mathbb{R}_+$. It has been recently proved by Nikkuni and Kawashima in [9].

The half space problem for general systems of the Boltzmann equation with discrete velocities is considered in [4], [5], [8], and [10]. These papers are concerned with the stationary wave, which is the traveling wave with zero speed. The research in [10] and [4] shows the existence of the stationary wave with the pure diffusive boundary condition. The stability of this stationary wave is proved in [8]. The existence and the stability of the stationary wave with the reflective boundary condition are proved in [4].

Following these results, the present research studies the stability of the traveling wave with positive speed, $s > 0$. Although these two types of waves, the traveling wave and the stationary wave, look similar, the positivity of the traveling wave speed gives rise to some essential difficulties. For example, it has been enough to consider a certain part of the stationary wave in [4] and [8]. As the traveling wave moves in a positive direction, the present research needs to handle the whole shape of the wave. Thus, we have to introduce the antiderivatives of perturbations from the traveling wave. Furthermore, we cannot determine the asymptotic location of the traveling wave by the initial condition. Namely, the boundary effect causes a shift of the location. This difficulty is resolved by employing the idea in Matsumura and Mei [7], where the same kind of problem is considered for the viscous p-system.

The plan of the present paper is as follows. In the next section, we discuss the property of the traveling wave and then derive the system of equations to the antiderivatives of perturbations in terms of fluid dynamical quantities. Then we show the time exponential decay of a certain linear combination of the boundary data by utilizing the decay property of the traveling wave at the spatial asymptotic points. In section 3, we obtain the a priori estimates by the energy method applied to the fluid dynamical equations. In these computations, the decay property of the boundary condition plays an essential role. Here, we are indebted to some ideas in the preceding research in [3] and [7].

Notation. For $1 \le p \le \infty$, $L^p(\Omega)$ denotes the usual Lebesgue space over Ω with the norm $|\cdot|_p$. For an arbitrary integer $l \ge 0$, H^l denotes the lth order Sobolev space in the L^2-sense, equipped with the norm $\|\cdot\|_l$. We note $H^0 = L^2$ and $\|\cdot\| := \|\cdot\|_0 = |\cdot|_2$. We also denote by $C^k(I; H^l(\Omega))$ the space of k-times continuously differentiable functions on the interval I with values in $H^l(\Omega)$. Finally, by c and C we denote several constants without confusion.

2. Preliminary calculation.

2.1. Properties of traveling waves. In this subsection, we summarize the property of the traveling wave satisfying (1.11a). We first normalize the traveling wave as

$$\tilde{F}_1(0) = \frac{1}{2}(M_1^+ + M_1^-) \tag{2.1}$$

for clarity. Then it holds from (1.10a) that, for $\xi \in \mathbb{R}$,

$$\begin{cases} 0 < M_1^- - \tilde{F}_1(\xi) \le (M_1^- - M_1^+)e^{\sigma\xi}/2 & \text{for} \quad \xi \ge 0, \\ 0 < \tilde{F}_1(\xi) - M_1^+ \le (M_1^- - M_1^+)e^{-\sigma\xi}/2 & \text{for} \quad \xi < 0, \end{cases} \tag{2.2a}$$

$$\sigma := \frac{v^2 + 3s^2}{4s^2(v+s)}(M_1^- - M_1^+) > 0, \tag{2.2b}$$

where we have used $s > 0$. From (1.9) and (1.14), we have

$$-s\tilde{\rho} + \tilde{m} = -s\rho_\pm + m_\pm, \quad -s\tilde{m} + \tilde{z} = -sm_\pm + z_\pm. \tag{2.3}$$

Substituting (2.3) in (1.20) yields that

$$\tilde{\rho}' = C_\rho(\tilde{\rho} - \rho_+)(\tilde{\rho} - \rho_-), \quad C_\rho := \frac{v^2 + 3s^2}{8sv^2} > 0, \tag{2.4}$$

where we have used (1.11a). It holds from (1.22), (2.2a), and (2.4) that

$$\tilde{\rho}' < 0, \quad \tilde{m}' = s\tilde{\rho}' < 0, \quad \tilde{z}' = s^2\tilde{\rho}' < 0, \tag{2.5a}$$

$$|\tilde{\rho}(\xi) - \rho_+| \le \begin{cases} (|\rho_- - \rho_+|/2)e^{-\sigma\xi} \le C\delta_M e^{-\sigma\xi} & \text{for} \quad \xi \ge 0, \\ |\rho_- - \rho_+|/2 \le C\delta_M & \text{for} \quad \xi < 0, \end{cases} \tag{2.5b}$$

$$|\tilde{m}(\xi) - m_+| \le \begin{cases} (|m_- - m_+|/2)e^{-\sigma\xi} \le C\delta_M e^{-\sigma\xi} & \text{for} \quad \xi \ge 0, \\ |m_- - m_+|/2 \le C\delta_M & \text{for} \quad \xi < 0. \end{cases} \tag{2.5c}$$

2.2. The equations for the perturbations. The difficulty of the stability problem in the half space comes from the fact that the location of the traveling wave, which should be the asymptotic state for the initial boundary value problem, is shifted owing to the boundary effects. To overcome this difficulty, we employ the idea in [7] and consider the traveling wave in the form of $\tilde{F}(x-st+\alpha-\beta)$, where the parameters, α and β, are to be determined later. Then putting

$$f(x,t) := F(x,t) - \tilde{F}(x - st + \alpha - \beta), \tag{2.6}$$

we have from (1.1) that

$$\partial_t f_1 + v\partial_x f_1 = q(F) - q(\tilde{F}), \tag{2.7a}$$

$$4\partial_t f_2 \qquad\quad = -2(q(F) - q(\tilde{F})), \tag{2.7b}$$

$$\partial_t f_3 - v\partial_x F_3 = q(F) - q(\tilde{F}). \tag{2.7c}$$

The initial and boundary data for (2.7) are given by

$$f_0(x) := f(x,0) = F_0(x) - \tilde{F}(x + \alpha - \beta), \quad f_1(0,t) = B_1 - \tilde{F}_1(-st + \alpha - \beta). \tag{2.8}$$

The local existence theorem for the above system is proved by the standard argument using the characteristic method and the contraction principle.

LEMMA 2.1. *Suppose that $f_0 \in H^1(\mathbb{R}_+)$ and the compatibility condition* (1.5) *holds. Then there exists a positive constant T_0, depending only on $\|f_0\|_1$, such that the initial boundary value problem* (2.7) *and* (2.8) *has a unique solution $f(x,t)$ in the space $C^0([0,T_0];H^1(\mathbb{R}_+)) \cap C^1([0,T_0];L^2(\mathbb{R}_+))$.*

In order to prove the existence of the solution to (2.7) (and thus (1.1)) globally in time, it is convenient to handle the system (1.15) for the fluid dynamical quantities. We regard the solution $(\rho, m, z)(x,t)$ as the perturbation from the traveling wave $(\tilde{\rho}, \tilde{m}, \tilde{z})(x - st + \alpha - \beta)$ and introduce the new unknown functions,

$$\begin{aligned} (\phi,\psi,\omega)(x,t) :&= (\rho, m, z)(x,t) - (\tilde{\rho}, \tilde{m}, \tilde{z})(x - st + \alpha - \beta) \\ &= (f_1 + 4f_2 + f_3, v(f_1 - f_3), v^2(f_1 + f_3))(x,t). \end{aligned} \tag{2.9}$$

From (2.7) (or (1.15)), we have

$$\phi_t + \psi_x = 0, \tag{2.10a}$$

$$\psi_t + \omega_x = 0, \tag{2.10b}$$

$$\omega_t + v^2\psi_x - \tilde{a}\phi - \tilde{m}\psi + \tilde{b}\omega = \Gamma(\phi,\psi,\omega), \tag{2.10c}$$

where the quantities in (2.10c) are given by

$$\tilde{a} := \frac{v^2\tilde{\rho} - \tilde{z}}{4}, \quad \tilde{b} := \frac{v^2\tilde{\rho} + 3\tilde{z}}{4v^2}, \quad \Gamma(\phi,\psi,\omega) := \frac{(v^2\phi - \omega)^2 - 4(\omega^2 - v^2\psi^2)}{8v^2}. \tag{2.11}$$

It holds from (2.5a) with (1.11a) that

$$\tilde{a}' = \frac{1}{4}(v^2 - s^2)\tilde{\rho}' < 0, \quad \tilde{b}' = \frac{1}{4v^2}(v^2 + 3s^2)\tilde{\rho}' < 0. \tag{2.12}$$

Thus, $\tilde{a}$ and $\tilde{b}$ are monotonically decreasing. Using (1.17), (1.11a), and (2.5a), it holds that

$$c \le a^+ \le \tilde{a} \le a^- \le C, \quad c \le b^+ \le \tilde{b} \le b^- \le C \tag{2.13}$$

for certain positive constants c and C, where $a^\pm := \lim_{\eta\to\pm\infty} \tilde{a}(\eta)$, $b^\pm := \lim_{\eta\to\pm\infty} \tilde{b}(\eta)$.

The initial and boundary data for (2.10) are derived from (2.8):

$$(\phi_0, \psi_0, \omega_0)(x) := (\rho_0, m_0, z_0)(x) - (\tilde{\rho}, \tilde{m}, \tilde{z})(x + \alpha - \beta), \tag{2.14}$$

$$\left(\psi + \frac{1}{v}\omega\right)(0,t) = 2v\left(M_1 - \tilde{F}_1(-st + \alpha - \beta)\right). \tag{2.15}$$

We see from (2.10) that we can define the antiderivatives of perturbations ϕ and ψ if $(\phi_0, \psi_0) \in (L^1 \cap H^1)(\mathbb{R}_+)$:

$$\Phi(x,t) := -\int_x^\infty \phi(y,t)\,dy, \quad \Psi(x,t) := -\int_x^\infty \psi(y,t)\,dy. \tag{2.16}$$

Then, integrating (2.10a) and (2.10b) over $[x,\infty)$ for $x > 0$ and multiplying by -1, we have

$$\Phi_t + \Psi_x = 0, \tag{2.17a}$$

$$\Psi_t + \omega = 0, \tag{2.17b}$$

$$\omega_t + v^2\Psi_{xx} - \tilde{a}\Phi_x - \tilde{m}\Psi_x + \tilde{b}\omega = \Gamma(\Phi_x, \Psi_x, \omega). \tag{2.17c}$$

Substituting $\omega = -\Psi_t$ in (2.17c), we obtain the system

$$\Phi_t + \Psi_x = 0, \tag{2.18a}$$

$$\Psi_{tt} - v^2\Psi_{xx} + \tilde{a}\Phi_x + \tilde{m}\Psi_x + \tilde{b}\Psi_t = -\Gamma(\Phi_x, \Psi_x, -\Psi_t). \tag{2.18b}$$

Here, the nonlinear term Γ in (2.18b) is estimated as

$$|\Gamma(\Phi_x, \Psi_x, -\Psi_t)| \le C(|\Phi_x|^2 + |\Psi_x|^2 + |\Psi_t|^2), \tag{2.19a}$$

$$|\partial_t\Gamma(\Phi_x, \Psi_x, -\Psi_t)| \le C(|\Phi_x| + |\Psi_t| + |\Psi_x|)(|\Phi_{xt}| + |\Psi_{tt}| + |\Psi_{xt}|). \tag{2.19b}$$

The initial data for the system (2.18) is derived from (2.14):

$$\Phi_0(x) := -\int_x^\infty \phi_0(y)\,dy, \quad \Psi_0(x) := -\int_x^\infty \psi_0(y)\,dy, \quad \Psi_t(x,0) = -\omega_0(x). \tag{2.20}$$

The boundary condition to be satisfied by (Φ, Ψ) is discussed in the next subsection.

2.3. Boundary estimates. In this subsection, we derive the estimate for the boundary data on $\{x = 0\}$. Divide (2.7b) by 2 and add the resultant equality to (2.7a). This computation yields that

$$(f_1 + 2f_2)_t + v(f_1)_x = 0. \tag{2.21}$$

Integrating (2.21) over $(0,\infty)\times[0,t]$ for $t>0$, we obtain

$$\int_0^\infty (f_1+2f_2)(x,t)\,dx = \int_0^\infty (f_1+2f_2)(x,0)\,dx + v\int_0^t M_1^- - \tilde{F}_1(-s\tau+\alpha-\beta)\,d\tau, \tag{2.22}$$

where we have used (2.8). The left-hand side of (2.22) converges to zero as t tends to infinity, provided that the stability of the traveling wave holds. Thus, it is necessary that the right-hand side of (2.22) converges to zero as t tends to infinity. Therefore, we have

$$\int_0^\infty (f_1+2f_2)(x,0)\,dx + v\int_0^\infty M_1^- - \tilde{F}_1(-s\tau+\alpha-\beta)\,d\tau = 0. \tag{2.23}$$

Thus, it is necessary to chose α so that (2.23) holds. We derive the explicit formula of α following the idea in [7]. We regard the left-hand side of (2.23) as the function of α. Let $I(\alpha)$ denote it. Differentiate $I(\alpha)$ with respect to α using (2.6) and then apply the Rankine–Hugoniot condition in (1.9). The result is $I'(\alpha) = (M_1^- - M_1^+) + 2(M_2^- - M_2^+)$. Integrating this equality in α, we have the identity $I(\alpha) = I(0) + \{(M_1^- - M_1^+) + 2(M_2^- - M_2^+)\}\alpha$. Consequently, we see that (2.23) holds if and only if α is given by

$$\begin{aligned}\alpha &= C_M\left\{\int_0^\infty (F_1+2F_2)(x,0) - (\tilde{F}_1+2\tilde{F}_2)(x-\beta)\,dx \right.\\ &\qquad\left. + v\int_0^\infty M_1^- - \tilde{F}_1(-s\tau-\beta)\,d\tau\right\}\\ &= C_M\left\{-\frac{1}{2}(\hat{\Phi}_0(0)+\frac{1}{v}\hat{\Psi}_0(0)) + v\int_0^\infty M_1^- - \tilde{F}_1(-s\tau-\beta)\,d\tau\right\},\\ C_M &:= \{(M_1^+ - M_1^-) + 2(M_2^+ - M_2^-)\}^{-1}.\end{aligned} \tag{2.24}$$

Notice that the right-hand side of (2.24) is determined by the initial and boundary data. The above observation means that it is necessary to chose α by (2.24) for the stability of the traveling wave. Thus, here and hereafter, we determine α by (2.24) and regard it as the function of the other parameter β. Namely, $\alpha = \alpha(\beta)$. The essential property of $\alpha(\beta)$ is that $\alpha(\beta)$ is bounded even if the parameter β becomes large. Moreover, the following lemma holds.

LEMMA 2.2. *For an arbitrary positive constant ε, there exists a constant δ such that if $\beta>0$ and $\|(\hat{\Phi}_0,\hat{\Psi}_0)\|_1 + 1/\beta \le \delta$, then $|\alpha(\beta)|\le\varepsilon$.*

Proof. Estimating (2.24) by using (2.2), we have

$$|\alpha(\beta)| \le C(|\hat{\Phi}_0|_\infty + |\hat{\Psi}_0|_\infty + e^{-\sigma\beta}). \tag{2.25}$$

The proof immediately follows from (2.25) by applying the Sobolev inequality. ∎

Subtracting (2.23) from (2.22), and using (2.9) and (2.16), we have that

$$\left(\Phi + \frac{1}{v}\Psi\right)(0,t) = B(t), \tag{2.26a}$$

$$B(t) := 2v\int_t^\infty M_1^- - \tilde{F}_1(-s\tau+\alpha(\beta)-\beta)\,d\tau \tag{2.26b}$$

for $t > 0$. Suppose that $\beta > 0$ is sufficiently large. Substitute (2.2) in (2.26b) and apply Lemma 2.2 as well as (2.2). The result is the estimate for boundary data:

$$0 < B(t) < Ce^{-\sigma(st+\beta)} < Ce^{-\sigma\beta}. \tag{2.27}$$

Square (2.27) and integrate in t. The result is

$$0 < \int_0^t B(\tau)^2\,d\tau < C\int_0^t e^{-2\sigma(s\tau+\beta)}\,d\tau < Ce^{-2\sigma\beta}. \tag{2.28}$$

Apply ∂_t^i on (2.26a), for $i = 1, 2$, and use (2.26b). Then we have

$$|\partial_t^i B(t)| < Ce^{-\sigma\beta}, \quad 0 < \int_0^t |\partial_t^i B(\tau)|^2\,d\tau < Ce^{-2\sigma\beta}. \tag{2.29}$$

The existence and the asymptotic state of a time global solution is obtained in the next section by the energy method. In this method, we make the integration by parts, but it gives rise to the integrations in t along the boundary $\{x = 0\}$. These integrations are estimated by utilizing the inequalities (2.27), (2.28), and (2.29).

We conclude this section by showing the next lemma, which we prove using the idea in [7]. Here, we recover a certain gap between the assumptions on initial data in Theorem 1.2 and Proposition 3.1. Precisely, we need to prove that the smallness assumption on the initial data in Theorem 1.2, which is equivalent to the smallness of $(\hat{\Phi}_0, \hat{\Psi}_0, \hat{\omega}_0)$, implies that of $(\Phi_0, \Psi_0, \omega_0)$.

LEMMA 2.3. *For an arbitrary positive constant ε, there exists a positive constant δ such that if $\beta > 0$ and $(\beta+1)(\|(\hat{\Phi}_0, \hat{\Psi}_0)\|_2^2 + \|\hat{\omega}_0\|_1^2) + 1/\beta \le \delta$, then $\|(\Phi_0, \Psi_0)\|_2^2 + \|\omega_0\|_1^2 \le \varepsilon$.*

Proof. Subtracting the first equality in (2.20) from (1.27) yields that

$$\begin{aligned}\hat{\Phi}_0(x) - \Phi_0(x) &= -\int_x^\infty \tilde{\rho}(y-\beta) - \rho_+\,dy + \int_x^\infty \tilde{\rho}(y+\alpha-\beta) - \rho_+\,dy \\ &= \int_\alpha^0 \tilde{\rho}(y+\theta-\beta) - \rho_+\,d\theta =: \chi(x).\end{aligned}$$

Then we compute $\|\chi\|$ with the aid of the estimate (2.5b) assuming $\alpha \ge 0$. The other case, $\alpha < 0$, is computed similarly. Divide the integration region $(0, \infty)$ into three parts and apply (2.5b), respectively. Consequently, we have

$$\begin{aligned}\|\chi\|^2 &= \int_0^{\beta-\alpha} |\chi(x)|^2\,dx + \int_{\beta-\alpha}^{\beta} |\chi(x)|^2\,dx + \int_\beta^\infty |\chi(x)|^2\,dx \\ &\le C(\alpha^2\beta + o(\alpha) + o(1/\beta)),\end{aligned}$$

where $o(\alpha) \to 0$ as $\alpha \to 0$. The first term on the right-hand side of the above inequality is estimated as

$$|\alpha^2\beta| \le C(\|\hat{\Phi}_0\|_1^2 + \|\hat{\Psi}_0\|_1^2 + e^{-2\sigma\beta})|\beta|,$$

where we have used (2.25) and the Sobolev inequality. These computations and Lemma 2.2 yield the estimate

$$\|\Phi_0\|^2 \le \|\hat{\Phi}_0\|^2 + C(\|\hat{\Phi}_0\|_1^2 + \|\hat{\Psi}_0\|_1^2)|\beta| + o(1/\beta).$$

This estimate gives the proof of the assertion concerning $\|\Phi_0\|$. The estimates for the first and the second derivatives of Φ_0 are obtained by direct computation with (2.20) and (1.27). The other terms are handled similarly. □

Note that the assumptions in Lemma 2.3 hold if we choose β sufficiently large and then take the initial data $\|(\hat{\Phi}_0, \hat{\Psi}_0)\|_2 + \|\hat{\omega}_0\|_1$ small enough.

3. Energy estimate. In this section, we prove the a priori estimate in Proposition 3.1 by the energy method following the context of [3]. Theorem 1.2 follows from combining Proposition 3.1 and the local existence of the initial boundary value problem (2.18), (2.20), and (2.26a) with the aid of Lemma 2.3. Precisely, we show the existence of the global solution $(\phi,\psi,\omega)(x,t)$ to (2.10). This immediately means the global existence of the solution $F(x,t)$. The asymptotic convergence (1.28) follows from the standard discussion on the uniform estimate (3.3). (See [7], for example.)

The local existence of the solution $(\phi,\psi,\omega)(x,t)$ to the problem (2.18), (2.20), and (2.26a) follows from Lemma 2.1 and it verifies

$$(\phi,\psi,\omega)\in C^0([0,T_0];H^1(\mathbb{R}_+))\cap C^1([0,T_0];L^2(\mathbb{R}_+)), \tag{3.1}$$

where the existence time T_0 depends only on the initial data $\|(\phi_0,\psi_0,\omega_0)\|_1$. Moreover, if $(\phi_0,\psi_0)\in L^1(\mathbb{R}_+)$, then the antiderivatives $(\Phi,\Psi)(x,t)$ can be defined by (2.16) for $t\in[0,T_0]$ and satisfy (2.18). Furthermore, we see from (2.17) that $(\Phi,\Psi)(\cdot,t)\in L^2(\mathbb{R}_+)$ if $(\Phi_0,\Psi_0)\in L^2(\mathbb{R}_+)$.

We introduce some notations.

$$N(t)=\sup_{0\le\tau\le t}\{\|(\Phi,\Psi)(\tau)\|_2+\|\Psi_t(\tau)\|_1\},$$
$$M(t)^2=\int_0^t\|(\Phi_x,\Phi_{xt},\Psi_x,\Psi_t,\Psi_{xt},\Psi_{tt})(\tau)\|^2\,d\tau,$$
$$|||\phi|||_1:=(\|\phi\|_1^2+\|\phi_t\|^2)^{1/2}.$$

L_1 and L_2 denote the left-hand sides of (2.18), respectively. Namely,

$$L_1(\Phi,\Psi):=\Phi_t+\Psi_x,\quad L_2(\Phi,\Psi):=\Psi_{tt}-v^2\Psi_{xx}+\tilde{a}\Phi_x+\tilde{m}\Psi_x+\tilde{b}\Psi_t. \tag{3.2}$$

Here, we state the a priori estimate. Since the proof is divided in several lemmas, we complete it at the end of this section.

PROPOSITION 3.1. *Let (ϕ,ψ,ω) be a solution to the problem* (2.10), (2.14), *and* (2.15), *which satisfies* (3.1) *with T_0 replaced by T. Then (Φ,Ψ) defined by* (2.16) *is located in $C^0([0,T];H^2(\mathbb{R}_+))$ and satisfies* (2.18), (2.20), *and* (2.26). *Moreover, let δ_M be sufficiently small and then $\beta>0$ be sufficiently large. Then there is a positive constant δ independent of T such that if $N(T)\le\delta$, then we have the uniform estimate*

$$\begin{aligned}&|||(\Phi,\Psi)(t)|||_1^2+\|(\Phi_{xx},\Phi_{xt},\Psi_{xx},\Psi_{xt},\Psi_{tt})(t)\|^2\\&\quad+\int_0^t\|(|\tilde{\rho}'|^{1/2}\Psi)(\tau)\|^2+|||(\Phi_x,\Psi_x,\Psi_t)(\tau)|||_1^2\,d\tau\\&\qquad\le C(\|(\Phi_0,\Psi_0)\|_2+\|\omega_0\|_1^2+e^{-2\sigma\beta})\end{aligned} \tag{3.3}$$

for $0\le t\le T$, where C is a positive constant independent of T.

By the standard argument employing a mollifier with respect to t, we may assume without loss of generality that $(\Phi,\Psi)\in C^\infty([0,T];H^2(\mathbb{R}_+))$.

LEMMA 3.2. *Suppose that the same assumptions as in Proposition* 3.1 *hold. If $N(T)<\delta$, then it holds that*

$$\begin{aligned}&\|\Phi(t)\|^2+|||\Psi(t)|||_1^2\\&\quad+\int_0^t\|(|\tilde{\rho}'|^{1/2}\Psi,\Psi_x,\Psi_t)(\tau)\|^2+\Psi^2(0,\tau)+\Psi_t^2(0,\tau)\,d\tau+\Psi^2(0,t)\\&\qquad\le C(\|\Phi(0)\|^2+|||\Psi(0)|||_1^2+N(t)M(t)^2+e^{-2\sigma\beta})\end{aligned} \tag{3.4}$$

for $0 \le t \le T$, where C is a positive constant independent of T.

Proof. Multiply (2.18a) and (2.18b) by $-\Psi_x$ and $\tilde{a}^{-1}\Psi_t$, respectively. Adding these two resultant equalities yields that

$$-\Psi_x L_1(\Phi,\Psi) + \tilde{a}^{-1}\Psi_t L_2(\Phi,\Psi) = -\tilde{a}^{-1}\Psi_t\Gamma, \tag{3.5}$$

where we have used the notations in (3.2). Precisely, (3.5) gives that

$$\begin{aligned} -\Psi_x^2 + \left\{\tilde{a}^{-1}\left(\frac{1}{2}\Psi_t^2 + \frac{v^2}{2}\Psi_x^2\right) - \Psi_x\Phi\right\}_t + \tilde{a}^{-1}\tilde{b}\Psi_t^2 + \{-v^2\tilde{a}^{-1}\Psi_t\Psi_x + \Psi_t\Phi\}_x \\ - s(\tilde{a}^{-1})'\left(\frac{1}{2}\Psi_t^2 + \frac{v^2}{2}\Psi_x^2\right) + \tilde{a}^{-1}\tilde{m}\Psi_t\Psi_x + (\tilde{a}^{-1})'v^2\Psi_t\Psi_x = -\tilde{a}^{-1}\Psi_t\Gamma. \end{aligned} \tag{3.6}$$

Successively, multiply (2.18a) and (2.18b) by Φ and $\tilde{a}^{-1}\Psi$, respectively, and add the resultant equalities to obtain that

$$\Phi L_1(\Phi,\Psi) + \tilde{a}^{-1}\Psi L_2(\Phi,\Psi) = -\tilde{a}^{-1}\Psi\Gamma. \tag{3.7}$$

Namely,

$$\begin{aligned} \left\{\frac{1}{2}\Phi^2 + \tilde{a}^{-1}\Psi\Psi_t + s(\tilde{a}^{-1})'\frac{1}{2}\Psi^2 + \frac{1}{2}\tilde{a}^{-1}\tilde{b}\Psi^2\right\}_t + \tilde{a}^{-1}(-\Psi_t^2 + v^2\Psi_x^2) \\ + \left\{-\frac{1}{2}\{\tilde{a}^{-1}(\tilde{m} - s\tilde{b})\}' + \frac{1}{2}(s^2 - v^2)(\tilde{a}^{-1})''\right\}\Psi^2 \\ + \left\{\Phi\Psi - v^2\tilde{a}^{-1}\Psi\Psi_x + \frac{1}{2}\tilde{a}^{-1}\tilde{m}\Psi^2 + \frac{v^2}{2}(\tilde{a}^{-1})'\Psi^2\right\}_x = -\tilde{a}^{-1}\Psi\Gamma. \end{aligned} \tag{3.8}$$

Then multiply (3.8) by λ, which is a positive constant to be determined later. Add the resultant equality to (3.6). The result is

$$(E_1 + E_2 + \hat{E}_2)_t + E_3 + E_4 + G + \hat{B}_x = -\tilde{a}^{-1}(\Psi_t + \lambda\Psi)\Gamma, \tag{3.9}$$

where

$$E_1(\Phi,\Psi_x) := \tilde{a}^{-1}\left(\frac{\lambda}{2}\tilde{a}\Phi^2 - \tilde{a}\Phi\Psi_x + \frac{v^2}{2}\Psi_x^2\right), \tag{3.10a}$$

$$E_2(\Psi,\Psi_t) := \tilde{a}^{-1}\left(\frac{\lambda}{2}\tilde{b}\Psi^2 + \lambda\Psi\Psi_t + \frac{1}{2}\Psi_t^2\right), \tag{3.10b}$$

$$\hat{E}_2(\Psi) := \frac{\lambda s}{2}(\tilde{a}^{-1})'\Psi^2, \tag{3.10c}$$

$$E_3(\Psi_t,\Psi_x) := \tilde{a}^{-1}\{(\tilde{b} - \lambda)\Psi_t^2 + \tilde{m}\Psi_t\Psi_x + (\lambda v^2 - \tilde{a})\Psi_x^2\}, \tag{3.10d}$$

$$E_4(\Psi) := \frac{\lambda}{2}\left\{-\{\tilde{a}^{-1}(\tilde{m} - s\tilde{b})\}' + (s^2 - v^2)(\tilde{a}^{-1})''\right\}\Psi^2, \tag{3.10e}$$

$$G(\Psi_t,\Psi_x) := (\tilde{a}^{-1})'\left\{-s\left(\frac{1}{2}\Psi_t^2 + \frac{v^2}{2}\Psi_x^2\right) + v^2\Psi_t\Psi_x\right\}, \tag{3.10f}$$

$$\begin{aligned} \hat{B} := -v^2\tilde{a}^{-1}\Psi_t\Psi_x + \Psi_t\Phi \\ + \lambda\left\{\Phi\Psi - v^2\tilde{a}^{-1}\Psi\Psi_x + \frac{1}{2}\tilde{a}^{-1}\tilde{m}\Psi^2 + \frac{v^2}{2}(\tilde{a}^{-1})'\Psi^2\right\}. \end{aligned} \tag{3.10g}$$

Then, integrating (3.9) over $(0,\infty)\times(0,t)$ we have

$$\begin{aligned}(3.11)\quad &\int_0^\infty (E_1+E_2+\hat{E}_2)(x,t)\,dx\\ &\quad+\int_0^t\int_0^\infty (E_3+E_4+G)(x,\tau)\,dx\,d\tau-\int_0^t \hat{B}(0,\tau)\,d\tau\\ &\quad=\int_0^\infty (E_1+E_2+\hat{E}_2)(x,0)\,dx-\int_0^t\int_0^\infty \tilde{a}^{-1}(\Psi_t+\lambda\Psi)\Gamma\,dx\,d\tau.\end{aligned}$$

Next, we need to estimate the integrands above, respectively. If the shock strength δ_M is sufficiently small, then we have

$$(3.12a)\qquad c(\Phi^2+\Psi_x^2)\le E_1\le C(\Phi^2+\Psi_x^2),$$

$$(3.12b)\qquad c(\Psi^2+\Psi_t^2)\le E_2\le C(\Psi^2+\Psi_t^2),$$

$$(3.12c)\qquad c(\Psi_t^2+\Psi_x^2)\le E_3\le C(\Psi_t^2+\Psi_x^2)$$

by choosing the constant λ suitably, where c and C are positive constants. These equivalences are obtained by computing the determinants of the quadratic forms E_1, E_2, and E_3. For example, if we take λ to be

$$(3.13)\qquad \lambda=\frac{\rho_+-\rho_-}{8}+\frac{z_+-z_-}{8v^2},$$

then (3.12) holds. For details, see [3].

Owing to (2.12) and (2.13), we have

$$(3.14)\qquad 0\le\hat{E}_2(\Psi)\le C|\tilde{\rho}'|\Psi^2,$$

where C is a positive constant. Next, it follows from (2.12) that

$$(3.15)\qquad \{\tilde{a}^{-1}(\tilde{m}-s\tilde{b})\}'=-\frac{v^2-s^2}{4\tilde{a}^2}\rho_\pm(u_\pm-s)\rho'<0,\quad \tilde{a}''=\frac{v^2-s^2}{4}\rho''.$$

The first inequality in (3.15) follows from the inequality

$$(3.16)\qquad -\frac{v^2-s^2}{4\tilde{a}^2}\rho_\pm(u_\pm-s)>c\gneq 0,$$

where c is a positive constant. Here, (3.16) is obtained by using (1.11a). For details, see [3]. Estimating (3.15) using (2.4) and (3.16) and substituting the resultant estimation in (3.10e), we have that

$$(3.17)\qquad E_4\ge c|\tilde{\rho}'|\Psi^2.$$

We also have, from (2.12), that

$$(3.18)\qquad |G|\le C|\tilde{\rho}'|(\Psi_t^2+\Psi_x^2).$$

The last term in (3.11) is estimated by (2.19a) as

$$\begin{aligned}(3.19)\qquad |(\tilde{a}^{-1}(\Psi_t+\lambda\Psi)\Gamma)|&\le C(\|\Psi\|_1+\|\Psi_t\|_1)(\Phi_x^2+\Psi_x^2+\Psi_t^2)\\ &\le C\delta(\Phi_x^2+\Psi_x^2+\Psi_t^2),\end{aligned}$$

where we have used the Sobolev inequality. Substitute the estimates (3.14), (3.17), (3.18), and (3.19) in (3.11). These computations give the desired estimate (3.4) except the boundary integration along $\{x = 0\}$.

Therefore, it remains to estimate the boundary terms. By virtue of (2.26a) and (2.17a), we have

$$\Phi(0,t) = B(t) - \frac{1}{v}\Psi(0,t), \quad \Psi_x(0,t) = -B_t(t) + \frac{1}{v}\Psi_t(0,t). \tag{3.20}$$

Substituting (3.20) in (3.10g) yields that

$$\begin{aligned} -\hat{B}(0,\tau) = \lambda\left\{\frac{1}{v} - \frac{\tilde{m}}{2\tilde{a}} + \frac{v(s-v)}{2}(\tilde{a}^{-1})'\right\}\Psi^2 + \frac{v}{\tilde{a}}\Psi_t^2 \\ + \left\{\left(\frac{1}{2v} + \frac{v\lambda}{2\tilde{a}}\right)\Psi^2\right\}_t - (\lambda\Psi + \Psi_t)(B + v^2\tilde{a}^{-1}B_t), \end{aligned} \tag{3.21}$$

where we have also used (2.13). Then we estimate each term on the right-hand side of (3.21), respectively. The coefficient of Ψ^2 in the first term is strictly positive due to (1.26) with (1.19) if the shock strength δ_M is sufficiently small (see (2.12) and (2.13)). So is the coefficient of Ψ_t^2 in the second term owing to (2.13). We integrate the third term in t to obtain that

$$\left\{\left(\frac{1}{2v} + \frac{v\lambda}{2\tilde{a}}\right)\Psi^2\right\}(0,t) - \left\{\left(\frac{1}{2v} + \frac{v\lambda}{2\tilde{a}}\right)\Psi^2\right\}(0,0). \tag{3.22}$$

Owing to (2.13), the first term in (3.22) appears on the left-hand side of (3.4). The second term is majorized by $\|\Psi_0\|_1$. At last, we estimate the fourth term by using (2.27) and (2.29). The absolute value of the fourth term is less than

$$\varepsilon(|\Psi(0,\tau)|^2 + |\Psi_t(0,\tau)|^2) + C_\varepsilon(|B(\tau)|^2 + |B_t(\tau)|^2), \tag{3.23}$$

where ε is an arbitrary positive number. We take ε so small that the first term in (3.23) is absorbed in the first and the second terms on the right-hand side of (3.21). The second term in (3.23) is estimated by using (2.28) and (2.29). The above computations give the estimates for boundary terms in (2.13) and complete the proof. □

LEMMA 3.3. *Suppose that the same assumptions as in Proposition* 3.1 *hold. If* $N(T) < \delta$*, then it holds that*

$$\begin{aligned} \|\Phi_x(t)\|^2 + \int_0^t \|\Phi_x(\tau)\|^2\,d\tau \\ - c\left\{\|(\Psi_x,\Psi_t)(t)\|^2 + \int_0^t \|(\Psi_x,\Psi_t)(\tau)\|^2 + \Psi_t^2(0,\tau)\,d\tau\right\} \\ \le C(\|(\Phi_x,\Psi_x,\Psi_t)(0)\|^2 + N(t)M(t)^2 + e^{-2\sigma\beta}) \end{aligned} \tag{3.24}$$

for $0 \le t \le T$*, where* c *and* C *are positive constants independent of* T*.*

Proof. Differentiate (2.18a) in x and then multiply by $\Psi_t + v^2\Phi_x$. Then multiply (2.18b) by Φ_x. Adding these two resultant equalities yields that

$$(\Psi_t + v^2\Phi_x)L_1(\Phi_x,\Psi_x) + \Phi_x L_2(\Phi,\Psi) = -\Phi_x\Gamma, \tag{3.25}$$

since $\partial_x L_1(\Phi,\Psi) = L_1(\Phi_x,\Psi_x)$. Precisely, (3.25) gives that

$$\left(\frac{1}{2}v^2\Phi_x^2 + \Psi_t\Phi_x - \frac{1}{2}\Psi_x^2\right)_t + (\Psi_t\Psi_x)_x + \tilde{a}\Phi_x^2 + \Phi_x(\tilde{m}\Psi_x + \tilde{b}\Psi_t) = -\Phi_x\Gamma. \tag{3.26}$$

Then we integrate (3.26) over $(0,\infty)\times(0,t)$ and estimate each term, respectively. The first term on the left-hand side of (3.26) is handled by the Schwarz inequality. The second term gives the boundary integration, which is estimated by the Schwarz inequality as

$$\begin{aligned}\int_0^t |(\Psi_t\Psi_x)(0,\tau)|\,d\tau &\le C\int_0^t B_t^2(\tau) + \Psi_t^2(0,\tau)\,d\tau \\ &\le C(e^{-2\sigma\beta} + \int_0^t \Psi_t^2(0,\tau)\,d\tau),\end{aligned} \tag{3.27}$$

where we have used (3.20) and (2.29). The third term gives the desired term since $\tilde{a} \ge a^+ > 0$ (see (2.13)). The fourth term is handled by the Schwarz inequality again as well as (2.5c) and (2.13):

$$|\Phi_x\Psi_x| \le \varepsilon\Phi_x^2 + C_\varepsilon\Psi_x^2, \quad |\Phi_x\Psi_t| \le \varepsilon\Phi_x^2 + C_\varepsilon\Psi_t^2,$$

where ε is an arbitrary positive constant. We take ε so small that $\varepsilon < a^+$. Finally, the right-hand side of (3.26) is estimated by the argument, using (2.19b), similar to that in deriving (3.19). The above computations yield the desired estimate (3.24). □

Then we need to derive the estimate for the higher derivatives. For this purpose, it is convenient to compute the time derivatives to take advantage of the time decay of the boundary data in (2.27), (2.28), and (2.29). Thus, we differentiate the linear operators $L_1(\Phi,\Psi)$ and $L_2(\Phi,\Psi)$ in t, respectively, to obtain that

$$\partial_t L_1(\Phi,\Psi) = L_1(\Phi_t,\Psi_t), \quad \partial_t L_2(\Phi,\Psi) = L_2(\Phi_t,\Psi_t) - R(\Phi_x,\Psi_x,\Psi_t), \tag{3.28a}$$

$$R(\Phi_x,\Psi_x,\Psi_t) := s(\tilde{a}'\Phi_x + \tilde{m}'\Psi_x + \tilde{b}'\Psi_t). \tag{3.28b}$$

LEMMA 3.4. *Suppose that the same assumptions as in Proposition* 3.1 *hold. If* $N(T) < \delta$, *then it holds that*

$$\begin{aligned}&\|\Phi_t(t)\|^2 + |||\Psi_t(t)|||_1^2 + \int_0^t \|(\Psi_{xt},\Psi_{tt})(\tau)\|^2 + \Psi_t^2(0,\tau) + \Psi_{tt}^2(0,\tau)\,d\tau \\ &\qquad + \Psi_t^2(0,t) - c\int_0^t \|(\Phi_x,\Psi_x,\Psi_t)(\tau)\|^2\,d\tau \\ &\qquad\qquad \le C(\|\Phi_t(0)\|^2 + |||\Psi_t(0)|||_1^2 + N(t)M(t)^2 + e^{-2\sigma\beta})\end{aligned} \tag{3.29}$$

for $0 \le t \le T$, *where* c *and* C *are positive constants independent of* T.

Proof. We first differentiate (2.18a) in t and multiply by $-\Psi_{xt}$. Successively, differentiate (2.18b) in t and multiply by $\tilde{a}^{-1}\Psi_{tt}$. Adding these two resultant equalities using (3.28), we have

$$-\Psi_{xt}L_1(\Phi_t,\Psi_t) + \tilde{a}^{-1}\Psi_{tt}L_2(\Phi_t,\Psi_t) = -\tilde{a}\Psi_{tt}\Gamma_t + \tilde{a}^{-1}\Psi_{tt}R. \tag{3.30}$$

Next, differentiate (2.18a) in t and multiply by Φ_t. Then, differentiate (2.18b) in t and multiply $\tilde{a}^{-1}\Psi_t$. Adding these two equalities yields that

$$\Phi_t L_1(\Phi_t,\Psi_t) + \tilde{a}^{-1}\Psi_t L_2(\Phi_t,\Psi_t) = -\tilde{a}^{-1}\Psi_t\Gamma_t + \tilde{a}^{-1}\Psi_t R. \tag{3.31}$$

It is easy to see that the left-hand sides of (3.30) and (3.31) take the forms of the left-hand sides of (3.5) and (3.7) with (Φ_t, Ψ_t) in place of (Φ, Ψ), respectively. Thus, we apply the computation in deriving (3.4) to the left-hand sides of (3.30) and (3.31). Since the nonlinear terms including Γ_t in (3.30) and (3.31) are estimated, using (2.19b), by the same method as (3.19), it suffices to estimate the last terms on the right-hand sides of (3.30) and (3.31). In fact, they are handled by using the inequalities

$$|\tilde{a}^{-1}\Psi_{tt}R| \le \varepsilon\Psi_{tt}^2 + C_\varepsilon(\Phi_x^2 + \Psi_x^2 + \Psi_t^2), \quad |\tilde{a}^{-1}\Psi_t R| \le C(\Phi_x^2 + \Psi_x^2 + \Psi_t^2), \tag{3.32}$$

where ε is an arbitrarily small positive constant. In deriving (3.32), we have used (2.5a) and (2.12). Consequently, we have the desired estimate (3.29). □

LEMMA 3.5. *Suppose that the same assumptions as in Proposition* 3.1 *hold. If* $N(T) < \delta$, *then it holds that*

$$\begin{aligned} &\|(\Phi_{xt}, \Psi_{xx})(t)\|^2 + \int_0^t \|(\Phi_{xt}, \Psi_{xx})(\tau)\|^2\, d\tau \\ &\quad - c\left\{\|(\Psi_{xt}, \Psi_{tt})(t)\|^2 + \int_0^t \|(\Phi_x, \Psi_x, \Psi_t, \Psi_{xt}, \Psi_{tt})(\tau)\|^2 + \Psi_{tt}^2(0,\tau)\, d\tau\right\} \\ &\qquad\qquad \le C(\|\Phi_{xt}, \Psi_{xt}, \Psi_{tt})(0)\|^2 + N(t)M(t)^2) \end{aligned} \tag{3.33}$$

for $0 \le t \le T$, *where* c *and* C *are positive constants independent of* T.

Proof. Differentiate (2.18) with respect to t, respectively. Then, apply the procedure in deriving (3.25). The result is

$$(\Psi_{tt} + v^2\Phi_{xt})L_1(\Phi_{xt}, \Psi_{xt}) + \Phi_{xt}L_2(\Phi_t, \Psi_t) = -\Phi_{xt}\Gamma_t + \Phi_{xt}R. \tag{3.34}$$

Here, notice that the left-hand side of (3.34) takes the form of the left-hand side of (3.25) with (Φ_t, Ψ_t) in place of (Φ, Ψ). Thus, the left-hand side of (3.34) is handled by the same procedure as that in the proof of Lemma 3.3. Since the first term on the right-hand side of (3.34) is estimated by using (2.19b) with the Sobolev and the Schwarz inequalities, it suffices to drive the estimation on the last term in (3.34). It is handled by applying the Schwarz inequality on (3.28b) as

$$|\Phi_{xt}R| \le \varepsilon\Phi_{xt}^2 + C_\varepsilon(\Phi_x^2 + \Psi_x^2 + \Phi_t^2),$$

where ε is an arbitrarily small positive constant. Finally, use the equality $|\Phi_{tx}| = |\Psi_{xx}|$, which follows from (2.18a). Consequently, we have the desired estimate (3.33). □

In order to complete the proof of the a priori estimate (3.3), we derive the estimates for the other remaining terms.

LEMMA 3.6. *Suppose that the same assumptions as in Proposition* 3.1 *hold. If* $N(T) < \delta$, *then it holds that*

$$\begin{aligned} &\|\Phi_{xx}(t)\|^2 + \int_0^t \|\Phi_{xx}(\tau)\|^2\, d\tau \\ &\quad - c\left\{\|\Psi_{xt}(t)\|^2 + \int_0^t \|(\Phi_x, \Psi_x, \Psi_t, \Phi_{xt}, \Psi_{xt})(\tau)\|^2\, d\tau\right\} \le C\|(\Phi_{xx}, \Psi_{xt})(0)\|^2 \end{aligned} \tag{3.35}$$

for $0 \le t \le T$, *where* c *and* C *are positive constants independent of* T.

Proof. Differentiating (2.7b) in x, we have

$$f_{2\,tx} + \tilde{F}_2 f_{2\,x} = -(f_{2\,x} + \tilde{F}_{2\,x}) f_2 + H, \tag{3.36a}$$

$$H := \frac{1}{2}(f_1 f_3 + \tilde{F}_3 f_1 + \tilde{F}_1 f_3 + \tilde{F}_1 f_{3\,x})_x. \tag{3.36b}$$

Multiplying (3.36a) by $f_{2\,x}$ yields that

$$\frac{1}{2}(f_{2\,x}^2)_t + \tilde{F}_2 f_{2\,x}^2 = -(f_{2\,x} + \tilde{F}_{2\,x}) f_2 f_{2\,x} + H f_{2\,x} \tag{3.37a}$$

$$\leq (c_1\delta + \varepsilon) f_{2\,x}^2 + C_\varepsilon (f_2^2 + H^2), \tag{3.37b}$$

where ε is an arbitrary positive constant and c_1 is a certain positive constant. In deriving the inequality (3.37b), we have used the Schwarz inequality and the fact that

$$|f_2|_\infty \leq c_1(\|\Phi_x\|_1 + \|\Psi_t\|_1) \leq c_1\delta, \tag{3.38}$$

which follows from (2.9). In addition, we have from (2.9) that

$$f_2^2 \leq C(\Phi_x^2 + \Psi_t^2), \quad H^2 \leq C(\Psi_x^2 + \Psi_t^2 + \Psi_{xx}^2 + \Psi_{xt}^2). \tag{3.39}$$

Substitute the estimates (3.39) in (3.37b), take ε and δ so small that $c_1\delta + \varepsilon < M_2^+ = \min_{\xi\in\mathbb{R}} \tilde{F}_2(\xi)$, and successively integrate the resultant inequality to obtain that

$$\|f_{2\,x}(t)\|^2 + \int_0^t \|f_{2\,x}(\tau)\|^2\, d\tau \leq C\left\{\|f_{2\,x}(0)\|^2 + \int_0^t \|(\Phi_x, \Psi_x, \Psi_t, \Psi_{xx}, \Psi_{tx})(\tau)\|^2\, dt\right\}. \tag{3.40}$$

From (2.9), we have

$$c(|\Phi_{xx}|^2 - |\Psi_{xt}|^2) \leq |f_{2\,x}|^2 \leq C(|\Phi_{xx}|^2 + |\Psi_{xt}|^2), \tag{3.41}$$

where c and C are positive constants. Substituting (3.41) in (3.40) yields the desired estimate (3.35). ∎

Proof of Proposition 3.1. Multiply the estimates (3.4), (3.24), (3.29), (3.33), and (3.35) by suitably chosen positive constants, respectively, sum up the resultant inequalities, and then take δ sufficiently small. Consequently, it holds that

$$\begin{aligned} &|||(\Phi,\Psi)(t)|||_1^2 + \|(\Phi_{xx}, \Phi_{xt}, \Psi_{xx}, \Psi_{xt}, \Psi_{tt})(t)\|^2 \\ &\quad + \int_0^t \|(|\tilde{\rho}'|^{1/2}\Psi)(\tau)\|^2 + |||(\Phi_x, \Psi_x, \Psi_t)(\tau)|||_1^2\, d\tau \\ &\quad \leq C(|||(\Phi,\Psi)(0)|||_1^2 + \|(\Phi_{xt}, \Phi_{xx}, \Psi_{xx}, \Psi_{xt}, \Psi_{tt})(0)\|^2 + e^{-2\sigma\beta}). \end{aligned} \tag{3.42}$$

From (2.17) and (2.18), we see that the right-hand side of (3.42) is equivalent to $(\|\Phi_0, \Psi_0)\|_2^2 + \|\omega_0\|_1^2 + e^{-2\sigma\beta})$. These procedures yield the desired estimate (3.3). ∎

Acknowledgments. The author would like to express his deepest gratitude to Professor Shuichi Kawashima and Professor Akitaka Matsumura for stimulating discussions and helpful comments.

TIME DISCRETIZATION OF TRANSITION LAYER DYNAMICS IN ONE-DIMENSIONAL VISCOELASTIC SYSTEMS*

H. LIM†

Abstract. We investigate how evolution occurs as the strain u_x of a viscoelastic system $u_{tt} - (\sigma(u_x) + u_{xt})_x + u = 0$ goes towards a state of equilibrium. The time limit of u_x eventually shows a finite number of discontinuous interfaces if the strain starts from the continuous initial data whose transition layers are steep enough and the initial energy is sufficiently small. The number of phases is conserved and the transition layers stay in the initial position of interfaces. The results are obtained by using the implicit time discretization method and the Andrews–Pego transformed equations.

Key words. implicit time discretization, viscous dissipation, transition layers, Andrews–Pego transformed equations, nonconvex energy

Introduction. There are various results on the phase transitions of microstructured elastic crystals [2, 5, 12, 16, 25, 27, 30, 32, 33]. Nonconvex double-well free energy induces hysteretic behavior of the fine microstructures of the material. The usual approach involves the minimization of the elastic energy. Due to the nonconvexity of the free energy, every minimizing sequence fails to attain a minimizer and induces the formation of finer and finer oscillations of the sequence [5, 6, 30]. However, under the presence of the energy dissipation, such a behavior is prevented and the solution converges to the minimizer of the energy [3, 15, 27].

This article focuses on the one-dimensional viscoelastic system

$$u_{tt} - (\sigma(u_x) + u_{xt})_x + u = 0, \tag{0.1}$$

where u is a mapping from $(0,1) \times (0,\infty) \subset \mathbb{R} \times \mathbb{R}$ to $\mathbb{R}$ under appropriate initial and boundary conditions and $\sigma(x) = W'(x)$ for some stored energy function $W : \mathbb{R} \to \mathbb{R}$.

The system describes a time-dependent elastic bar with a nonconvex energy W and a viscous stress u_{xxt} with the zero displacement boundary conditions. The bar interacts with an elastic foundation u. In other words, the bar is placed on a system of linearly elastic springs [32].

Many global existence results for the solutions of similar systems are available [1, 3, 4, 7, 9, 11, 13, 14, 15, 16, 17, 18, 21, 24, 26, 27, 28]. The existence of a weak solution for the viscoelastic-type materials was developed for the cases without assuming the ellipticity of the free energy W [27], the convexity of W, or the Lipschitz continuity of σ [15]. In either case, the viscous dissipation plays a significant role in the strong convergence of the minimizing sequences. In the higher-dimensional case, Friesecke and Dolzmann [15] approached the results by an approximation, called the time discretized solution, on each sufficiently small time interval and using the Andrews–Pego transformed equations which were introduced in [1, 25].

The dynamics of the transition layers on the viscoelastic system (0.1) is the main topic in this paper. The transition layers are defined by the part of the strain u_x

*Received by the editors November 27, 2001; accepted for publication (in revised form) April 29, 2002; published electronically December 13, 2002.

where the norm of u_x is less than a sufficiently small number. For the dynamics, we need the following two assumptions:

(I) The continuous initial data u_0 must have steep enough transition layers; that is, the norm of $(u_0)_{xx}$ should be sufficiently large at the position of transition layers of the initial data.

(II) The initial energy where the energy functional is defined by

$$E(u,v) = \int_0^1 \left[\frac{1}{2}(u(x))^2 + W((u_x(x)) + \frac{1}{2}(v(x))^2\right] dx$$

must be sufficiently small.

Under these assumptions, the time limit of u_x experiences a discontinuity at a finite number of points. More precisely, the transition layers get steeper and eventually become discontinuous at the time limit. Away from these finitely many points, the solution remains continuous and converges to a steady state. The number of transition layers remains the same and the transition layers of the solution are always within the intervals of initial layers, which is comparable to the results of stick-slip motion of layers in a system with the time-dependent displacement boundary conditions [33]. It was proven in [33] that the dynamics exhibits a different behavior than our main results. The layers do not stay in the initial intervals and will move both forward and backward.

Some important physical applications include a phase transformation in microstructured elastic crystals caused by changes in temperature, stresses, or incident electromagnetic waves. The nonconvex elastic energy functional induces finer and finer oscillations, but under the given initial state, the dynamics prevents the nucleation of more phases.

Friesecke and McLeod [16] proved the dynamics of transition layers employing the semigroup approach. In this paper, we use the method of time discretization to show the results. The time discretization theory has a long history [8, 10, 15, 19]. The scheme has been used for the nonlinear diffusion equations [8] and for the parabolic equations [19]. The second order time discretization on a related problem was first introduced in [10].

The existence of the solution was achieved in [16] by proving the existence of the Andrews–Pego transformations under an appropriate fractional power space. However, in [15], the variational approach was utilized for the proof of existence. It was proven that the time discretized functional

$$J^{m,j}[u] := \int_0^1 \left[\frac{1}{2m^2}|u - 2u^{m,j-1} + u^{m,j-2}|^2 + W(u_x) + \frac{1}{2m}|u_x - u_x^{m,j-1}|^2 + \frac{1}{2}|u|^2\right] dx$$

for each time interval $((j-1)m,\ jm],\ \ j \in \mathbb{N}$, where $m > 0$ is a fixed and sufficiently small time stepsize, has a minimizer $u^{m,j}$ which is a weak solution to the following discretized version of (0.1):

$$\frac{1}{m^2}(u - 2u^{m,j-1} + u^{m,j-2}) - (\sigma(u_x))_x - \frac{1}{m}(u_x - u_x^{m,j-1})_x + u = 0 \tag{0.2}$$

on $((j-1)m,\ jm],\ \ j \in \mathbb{N}$. The key idea of the approach is the following: The nonconvexity of the stored energy function W is compensated by the discretized viscous damping term $\frac{1}{2m}|u_x - u_x^{m,j-1}|^2$ to provide the convexity of the functional. It was also proven in [15] that the $W_0^{1,p}$ limit of the time discretized solutions is the weak

solution of (0.1) as the time stepsize m approaches zero. The time discretization scheme naturally applies to the proof of the dynamics of the phase transition in this paper. The method is rather straightforward since it does not introduce any new space. There is nevertheless still a question whether the asymptotic behaviors of (0.1) and (0.2) commute or not. Is there any equivalence between $jm \to \infty$ for fixed m and then $m \to 0$ for the discretized problem, and $t \to \infty$ for the original problem? The question is discussed in the last section of the paper.

As in previous works [16, 27], the decay of the energy functional $E(u, v)$ is the crucial point of the proof. We prove in section 4 that the discretized energy functional is nonincreasing and bounded by the initial energy. A priori estimates are also proved in this section. We show next the existence and the equilibrium state as the limit $u_\star^m$ (as $j \to \infty$) of the discretized solution for fixed m in section 5. The main proof of the dynamics is conducted in section 6. We prove in this section that the transition layers approach a jump discontinuity as $j \to \infty$ by showing that a finite number of intervals where the strain is steep enough are decreasing to a finite number of isolated points. Unfortunately, the intervals in $(0, 1)$ where the norm of the strain $u_x^{m,j}$ is sufficiently small (denote the intervals as $I(u_x^{m,j})$) do not decrease monotonically as $j \to \infty$ in general. Instead, we introduce the time discretized version of Andrews–Pego transformed equations,

$$p^{m,j}(x) := \frac{1}{m}\int_0^x [u^{m,j}(y) - u^{m,j-1}(y)]dy - \frac{1}{m}\int_0^1 \int_0^z [u^{m,j}(y) - u^{m,j-1}(y)]dydz,$$
$$q^{m,j}(x) := u_x^{m,j}(x) - p^{m,j}(x),$$

and consider the finite number of intervals in $(0, 1)$ where the norm of $q^{m,j}$ is sufficiently small (denote them as $I(q^{m,j})$). We show that the $I(q^{m,j})$ decrease monotonically and exponentially to the isolated points as $j \to \infty$, and the intervals $I(u_x^{m,j})$ are contained in the $I(q^{m,j})$. The solution at the limit exhibits a jump discontinuity because of the decrease of the $I(q^{m,j})$ and the fact that the $I(u_x^{m,j})$ are contained in the $I(q^{m,j})$. In the last section, we summarize the relationship between the asymptotic behaviors of (0.1) and (0.2).

The interaction of the bar with an elastic foundation u induces a finely layered microstructure [12]. It has also been shown using the bifurcation analysis that the elastic foundation induces oscillations in the one-dimensional case of the static problem [32]. Nevertheless, under the assumption of low initial energy, the results still hold without the elastic foundation, and only minor change of the proof is required.

Another advantage is that the method is also useful in the practical implementation of the numerical solution of the system. The numerical results for the related problems have been discussed [4, 20, 29, 30, 31]. An implicit finite difference scheme for the homogeneous boundary conditions was achieved in [29], and the numerical methods for the time-dependent boundary conditions were investigated in [31]. In [20], the efficient numerical algorithms for the system in both one- and two-dimensional cases were developed. Applications to the microscale heat transfer equations will also appear in the near future.

The dynamics on similar problems was investigated in [22, 23]. The stability of the incompressible viscoelastic non-Newtonian fluid flows was observed in these papers. Investigating this type of spurt phenomena using the method of time discretization would be very interesting for future work.

1. The initial-boundary value problem and hypotheses. Consider the initial-boundary value problem

$$
\begin{aligned}
&u_{tt} - (\sigma(u_x) + u_{xt})_x + u = 0 \qquad (x \in (0,1), \quad t \in (0,\infty)),\\
&u|_{x=0} = u|_{x=1} = 0 \qquad (t \in [0,\infty)),\\
&u|_{t=0} = u_0, \quad u_t|_{t=0} = v_0 \qquad (x \in [0,1]),
\end{aligned} \tag{1.1}
$$

where u is a function from $(0,1)\times(0,\infty) \subset \mathbb{R}\times\mathbb{R}$ to $\mathbb{R}$, $\sigma = W^{'}$, and W is a stored energy function satisfying the following conditions:

(H1) $W \in C^2(\mathbb{R}), W^{'} = \sigma$.

(H2) There exist $c > 0,\ C > 0$, and $p \geq 2$ such that $c|z|^p - C \leq W(z) \leq C(|z|^p + 1),\ \ |\sigma(z)| \leq C(|z|^{p-1} + 1)$ (coercivity).

(H3) W: double-well potential, that is, there exist $z_- < z_1 < 0 < z_2 < z_+$ such that $W(z_\pm) = 0, W > 0$ elsewhere, $W^{'}(0) = 0, W^{''}|_{(z_1,z_2)} < 0, W^{''}|_{\mathbb{R}\setminus[z_1,z_2]} > 0$.

The stored energy function W is usually a fourth order nonconvex polynomial, and the most common example is $W(z) = \frac{1}{4}(z^2-1)^2$. Moreover, assume

(A1) (smoothness and a priori bounds) $u_0 \in C^2, v_0 \in W_0^{1,2}, ||(u_0)_x||_{L^\infty} + ||v_0||_{W^{1,2}} \leq M$;

(A2) (low initial energy) $E(u_0, v_0) < \epsilon$, where

$$E(u,v) := \int_0^1 \left(\frac{1}{2}u^2 + W(u_x) + \frac{1}{2}v^2\right) dx;$$

(A3) (no transition layers at $x = 0, 1$) $\mathcal{L}_\rho(0) := \{x \in [0,1] : |(u_0)_x(x)| \leq \rho\} \subset (0,1)$;

(A4) (steepness of transition layers) $|(u_0)_{xx}(x)| \geq K$ in $\mathcal{L}_\rho(0)$

for some $M, \epsilon, \rho, K > 0$. Here, $\epsilon,\ \rho$ are sufficiently small numbers and K is a sufficiently large number.

Let the connected components of $\mathcal{L}_\rho(0)$ be denoted by $[(a_0)_i, (b_0)_i]$, $i = 1, \ldots, N$ $(0 < (a_0)_1 < (b_0)_1 < \cdots < (a_0)_N < (b_0)_N < 1)$. Note that by assumption (A4), there exists only one zero of $(u_0)_x$ in each interval $[(a_0)_i, (b_0)_i]$. Let the zeros of $(u_0)_x$ be $(x_0)_i, (x_0)_i \in [(a_0)_i, (b_0)_i], i = 1, \ldots, N$.

2. The time discrete scheme for the solution. Let $m > 0,\ m \ll 1$ be the time stepsize of our problem. The m will be fixed throughout the paper except for the last section. Let $u^{m,0} := u_0, v^{m,0} := v_0, u^{m,-1} := u_0 - mv_0$. For each time interval $((j-1)m,\ jm], j \in \mathbb{N}$, define the following functional inductively:

$$J^{m,j}[u] := \int_0^1 \left[\frac{1}{2m^2}|u - 2u^{m,j-1} + u^{m,j-2}|^2 + W(u_x) + \frac{1}{2m}|u_x - u_x^{m,j-1}|^2 + \frac{1}{2}|u|^2\right] dx$$

on the Sobolev space $W_0^{1,p}((0,1),\mathbb{R})$, where p is the coercivity exponent of W in (H2). It was shown that $J^{m,j}$ attains a minimum $u^{m,j}$ if W satisfies the hypotheses (H1), (H2), and (H3) since the first and the fourth integrands are convex and the nonconvex term $W(u_x)$ combined with the viscous dissipation term $\frac{1}{2m}|u_x - u_x^{m,j-1}|^2$ provides the weakly lower semicontinuity [15]. It can be easily verified that for each time interval $((j-1)m,\ jm],\ j \in \mathbb{N}$, $u^{m,j}(x)$ is the weak solution of

$$\frac{1}{m^2}(u - 2u^{m,j-1} + u^{m,j-2}) - (\sigma(u_x))_x - \frac{1}{m}(u_x - u_x^{m,j-1})_x + u = 0, \tag{2.1}$$

which is the time approximated equation of (1.1). The $u^{m,j}$ is thus called the time discretized solution of the problem (1.1). Assume that $u^{m,j}$ satisfies the boundary

conditions of (1.1) for each $j \in \mathbb{N}$. On the time interval $((j-1)m,\ jm],\ j \in \mathbb{N}$, we define the linear interpolation function $u^j(x,t)$ of $u^{m,j}(x)$ as follows:

$$u^j(x,t) := \left(\frac{mj-t}{m}\right) u^{m,j-1}(x) + \left(\frac{t-m(j-1)}{m}\right) u^{m,j}(x). \tag{2.2}$$

It is now important to define the functions which are called the Andrews–Pego transformed equations. The equations will play a crucial role for the proof of the main results. Define

$$\begin{aligned}
p_0(x) &:= \int_0^x v_0(y)dy - \int_0^1 \int_0^z v_0(y)dydz,\\
q_0(x) &:= (u_0)_x(x) - p_0(x),\\
p^{m,j}(x) &:= \frac{1}{m}\int_0^x [u^{m,j}(y) - u^{m,j-1}(y)]dy - \frac{1}{m}\int_0^1 \int_0^z [u^{m,j}(y) - u^{m,j-1}(y)]dydz,\\
q^{m,j}(x) &:= u_x^{m,j}(x) - p^{m,j}(x)
\end{aligned}$$

for all $j \in \mathbb{N}$. Note that $p_x^{m,j}(x) = \frac{u^{m,j}(x)-u^{m,j-1}(x)}{m} =: v^{m,j}(x)$. For all $j \in \mathbb{N}$ and $(j-1)m < t \le jm$, define the interpolation functions of $p^j(x,t),\ q^j(x,t)$, and $v^j(x,t)$ of $p^{m,j}(x),\ q^{m,j}(x)$, and $v^{m,j}(x)$, respectively, in the same way as (2.2).

3. Main results. The following theorem describes the dynamical behavior of the transition layers.

THEOREM 3.1. *Suppose the stored energy function W and the initial data $(u_0,\ v_0) \in W_0^{1,\infty} \times L^2$ are assumed to satisfy* (H1)–(H3), (A1)–(A4). *Then the following hold:*

(P1) (Preservation of number of zeros.) *The number of zeros of $u_x^{m,j}$, denoted by $N(j)$, is finite, is positive for all $j \in \{0\} \cup \mathbb{N}$, and is independent of j. Let the zeros be denoted by $0 < x_1^m(j) < \cdots < x_N^m(j) < 1$.*

(P2) (Preservation of intervals of transition layers.) *The number of connected components of $\mathcal{L}_{\frac{\rho}{2}}(j) := \{x \in (0,1) : |u_x^j(x,t)| \le \frac{\rho}{2}\}$ is finite, is positive for all $j \in \mathbb{N}$, and is independent of j, and in each connected component, $u_x^j(x,t)$ is strictly monotone and has exactly one zero. Let the connected components of $\mathcal{L}_{\frac{\rho}{2}}(j)$ be denoted by $[a_i^m(j), b_i^m(j)],\ i = 1, \dots, N$ $(0 < a_1^m(j) < b_1^m(j) < \cdots < a_N^m(j) < b_N^m(j) < 1)$.*

(P3) (Lock-in and exponential steepening of transition layers.) *For all $j \in \mathbb{N}$, $i = 1, \dots, N$, and for some $K_0 > 0$,*

$$x_i^m(j) \in [a_i^m(j), b_i^m(j)] \subset [(a_0)_i, (b_0)_i],$$

$$|u_{xx}^j(x,t)| \ge \frac{K_0}{2} e^{\sigma_0 jm} \quad \forall x \in \mathcal{L}_{\frac{\rho}{2}}(j) = \bigcup_{i=1}^N [a_i^m(j), b_i^m(j)],$$

$$|b_i^m(j) - a_i^m(j)| \le \frac{2\rho}{K_0} e^{-\sigma_0 jm},$$

where $\sigma_0 := \min_{[-\rho,\rho]} |\sigma'| > 0$.

(P4) (Convergence of phases.) $\lim_{j\to\infty} x_i^m(j) =: (x_\star)_i^m$ *exists for all $i = 1, \dots, N$ and $(x_\star)_i^m \in [(a_0)_i, (b_0)_i]$ (in particular, $0 < (x_\star)_1^m < \cdots < (x_\star)_N^m < 1$).*

(P5) (Jump discontinuity of the limit state.) $\lim_{j\to\infty} u_x^{m,j} =: (u_\star^m)_x$ *(which exists as an L^p limit) is continuous on $(0,1)\backslash\{(x_\star)_1^m, \dots, (x_\star)_N^m\}$ but discontinuous at every $(x_\star)_i^m$ for all $i = 1, \dots, N$.*

4. Energy decay and a priori estimates. Let $t \in ((j-1)m,\ jm],\ j \in \mathbb{N}$. We first prove the decay of the energy functional:

$$E(t) = E(u^j, v^j) = \int_0^1 \left[\frac{1}{2}(u^j(x,t))^2 + W(u_x^j(x,t)) + \frac{1}{2}(v^j(x,t))^2\right] dx.$$

LEMMA 4.1. *$E(t)$ is nonincreasing, bounded by the initial data on $((j-1)m,\ jm]$ for all $j \in \mathbb{N}$.*

Proof. Recall that $u^{m,j},\ j \in \mathbb{N}$, satisfies (2.1). That is, the equation

$$v_t^j - \sigma(u_x^{m,j})_x - v_{xx}^{m,j} + u^{m,j} = 0 \tag{4.1}$$

is satisfied for all $j \in \mathbb{N}$. Then the following holds:

$$\begin{aligned}\frac{d}{dt}E(t) = &\int_0^1 [v^{m,j}\cdot v_t^j + \sigma(u_x^{m,j})\cdot u_{xt}^j + u^{m,j}\cdot u_t^j + (v^j - v^{m,j})v_t^j \\ &+ (\sigma(u_x^j) - \sigma(u_x^{m,j}))\cdot u_{xt}^j + (u^j - u^{m,j})\cdot u_t^j]dx \qquad (4.2)\\ = &\int_0^1 [v^{m,j}\{v_t^j - \sigma(u_x^{m,j})_x + u^{m,j}\} + (v^j - v^{m,j})v_t^j \\ &+ (\sigma(u_x^j) - \sigma(u_x^{m,j}))\cdot u_{xt}^j + (u^j - u^{m,j})\cdot u_t^j]dx \qquad (4.3)\\ = &\int_0^1 \left[v^{m,j}\cdot v_{xx}^{m,j} + \frac{(t-jm)}{m^2}\cdot|v^{m,j} - v^{m,j-1}|^2\right. \\ &\left. + (\sigma(u_x^j) - \sigma(u_x^{m,j}))\cdot u_{xt}^j + \frac{(t-jm)}{m^2}\cdot|u^{m,j} - u^{m,j-1}|^2\right] dx \\ = &-\int_0^1 |v_x^{m,j}|^2 dx + \frac{(t-jm)}{m^2}\int_0^1 |v^{m,j} - v^{m,j-1}|^2 dx \\ &+ \int_0^1 (\sigma(u_x^j) - \sigma(u_x^{m,j}))\cdot u_{xt}^j dx + (t-jm)\int_0^1 |v^{m,j}|^2 dx \qquad (4.4)\end{aligned}$$

for $(j-1)m < t \le jm$. The first three terms of (4.2) are the same as the first term of (4.3) by the integration by parts and the boundary conditions of (1.1). By using the mean value theorem, and by the fact that the function σ' is bounded below by a negative number, that is, for all $y \in \mathbb{R}$, $\sigma'(y) \ge -L$ for some $L > 0$, the integrand of the third term of (4.4) is estimated in the following way:

$$\begin{aligned}(\sigma(u_x^j) - \sigma(u_x^{m,j}))\cdot u_{xt}^j &\le \sigma'(c^*)(u_x^j - u_x^{m,j})\cdot u_{xt}^j \\ &= (jm-t)\{-\sigma'(c^*)\}\frac{(u_x^{m,j} - u_x^{m,j-1})^2}{m^2} \\ &\le m\cdot\max_{y\in\mathbb{R}}\{-\sigma'(y)\}\frac{(u_x^{m,j} - u_x^{m,j-1})^2}{m^2} \\ &= mL(v_x^{m,j})^2 \qquad (4.5)\end{aligned}$$

for some c^* between u_x^j and $u_x^{m,j}$. Moreover, both the second and the fourth term of (4.4) are negative since $t - jm \le 0$. Now the following inequalities on the energy $E(t)$ are derived:

$$\begin{aligned}\frac{d}{dt}E(t) &\le (-1+mL)\int_0^1 |v_x^{m,j}|^2 dx \\ &\le -\frac{1}{2}\|v_x^{m,j}\|_{L^2}^2\end{aligned}$$

for all $t \in ((j-1)m, jm]$. ∎

Note that by taking an integral from $(j-1)m$ to jm on both sides of the above inequality, we get

$$E(jm) - E((j-1)m) \le -\frac{1}{2} m \|v_x^{m,j}\|_{L^2}^2,$$

and after taking a summation from $j = 1$ to $j = S$, the following estimate is established:

$$E(Sm) - E(0) \le -\frac{m}{2} \sum_{j=1}^{S} \|v_x^{m,j}\|_{L^2}^2.$$

Therefore,

$$\frac{m}{2} \sum_{j=1}^{S} \|v_x^{m,j}\|_{L^2}^2 \le E(0) - E(Sm) < E(0) < \epsilon \tag{4.6}$$

for all $S \in \mathbb{N}$. Next, we show the several estimates on the functions which will play a significant role for the proof of Theorem 3.1.

LEMMA 4.2. *The following a priori estimates hold:*

(a) $\sup_{j\in\mathbb{N}} \sup_{(j-1)m<t\le jm} \|p^j(\cdot,t)\|_{L^\infty} \le \eta$,

(b) $\sup_{j\in\mathbb{N}} \sup_{(j-1)m<t\le jm} \|\pi_a(\int_0^x u^j(y,t)dy)\|_{L^\infty} \le \sigma_0\eta$, *where* $\pi_a(f) := f - \int_0^1 f$,

(c) $\sup_{j\in\mathbb{N}} \sup_{(j-1)m<t\le jm} \|q^j(\cdot,t)\|_{L^\infty} \le \tilde{K}$,

(d) $\sup_{j\in\mathbb{N}} \sup_{(j-1)m<t\le jm} \|u^j(\cdot,t)\|_{L^\infty} \le \tilde{K}$,

(e) $\sup_{j\in\mathbb{N}} \sup_{(j-1)m<t\le jm} |\int_0^1 \sigma(u_x^j(x,t))dx| \le \sigma_0\eta$,

(f) $\sup_{j\in\mathbb{N}} \sup_{(j-1)m<t\le jm} \|v^j(\cdot,t)\|_{L^\infty} = \sup_{j\in\mathbb{N}} \sup_{(j-1)m<t\le jm} \|p_x^j(\cdot,t)\|_{L^\infty} \le \tilde{K}$

for some constants $\tilde{K},\ \eta > 0,\ \eta \ll 1$.

Proof. Since $\int_0^1 p^j(x,t)dx = 0$, $p^j(x',t) = 0$ for some x' in $(0,1)$. Hence, the following holds:

$$|p^j(x,t)| = \left| \int_{x'}^{x} p_x^j(y,t)dy \right| \le \left(\int_0^1 |p_x^j(y,t)|^2 dy \right)^{\frac{1}{2}}.$$

Since $\|p_x^j(\cdot,t)\|_{L^2} = \|v^j(\cdot,t)\|_{L^2} \le \sqrt{E(u^j,v^j)} \le \sqrt{E(u_0,v_0)} \le \sqrt{\epsilon}$, (a) is accomplished by choosing $\eta > 0$ such that $\eta > \max\{\sqrt{\epsilon}, 2\sqrt{\epsilon}/\sigma_0, C_5\sqrt{\epsilon}/\sigma_0\}$, where C_5 will be chosen later.

Similarly,

$$\begin{aligned}
\left\| \int_0^x u^j(y,t)dy \right\|_{L^\infty} &= \left\| \int_0^x \int_0^y (p^j(z,t) + q^j(z,t))dzdy \right\|_{L^\infty} \\
&\le \left\| \int_0^x (p^j(y,t) + q^j(y,t))dy \right\|_{L^2} \\
&= \|u^j(\cdot,t)\|_{L^2} \\
&\le \sqrt{\epsilon} \le \frac{\sigma_0\eta}{2},
\end{aligned}$$

which proves (b).

By using (4.1),

$$q_t^j = \frac{u_x^{m,j}(x) - u_x^{m,j-1}(x)}{m} - \int_0^x v_t^j + \int_0^1 \int_0^x v_t^j$$

$$= -\pi_a(\sigma(u_x^{m,j})) + \pi_a\left(\int_0^x u^{m,j}\right) \tag{4.7}$$

$$= -\sigma(p^{m,j} + q^{m,j}) + e_1^{m,j}, \tag{4.8}$$

where $e_1^{m,j} = \int_0^1 \sigma(u_x^{m,j}(x))dx + \pi_a(\int_0^x u^{m,j}(y)dy)$. From the hypotheses (H2) and (H3), $\sigma(z) \le W(z) + C_1$ for some $C_1 > 0, z \in \mathbb{R}$. This and estimate (b) imply

$$|e_1^{m,j}| \le \int_0^1 [|W(u_x^{m,j})| + C_1]dx + \sigma_0\eta \le \epsilon + C_1 + \sigma_0\eta < C_2 \tag{4.9}$$

for some $C_2 > 0$. Since $\|p^j\|_{L^\infty} < \eta$, from (4.8), $q_t^j < 0$ when $q^j \ge K_1$ and $q_t^j > 0$ when $q^j \le -K_1$ for some sufficiently large $K_1 > 0$. Hence, q^j is bounded. Let $\tilde{K} > \max\{\eta + K_1, K_2\}$, where K_2 will be chosen later. This completes the proof of (c).

Note that

$$\|u_x^j\|_{L^\infty} \le \|p^j\|_{L^\infty} + \|q^j\|_{L^\infty} \le \eta + K_1 < \tilde{K}. \tag{4.10}$$

Now, (d) clearly follows from (4.10).

Note that by (4.10),

$$|\sigma(u_x^j)| \le C_3 \tag{4.11}$$

for some $C_3 > 0$. Since q_t^j satisfies (4.8), (4.11) combined with (4.9) implies that q_t^j is uniformly bounded for all $j \in \mathbb{N}$ in L^∞ norm. Also, note that

$$|\sigma'(u_x^j)| \le C_4 \tag{4.12}$$

for some $C_4 > 0$. From the coercivity condition (H2) on W and σ and by estimate (4.10),

$$C_5 := \sup_{z \in [-\tilde{K}, \tilde{K}] \setminus \{z_-, z_+\}} \frac{|\sigma(z)|}{\sqrt{W(z)}}$$

is well defined and

$$\left|\int_0^1 \sigma(u_x^j(x,t))dx\right| \le \|\sigma(u_x^j)\|_{L^2} \le C_5\left(\int_0^1 |W(u_x^j)|\right)^{\frac{1}{2}} < C_5\sqrt{\epsilon} \le \sigma_0\eta,$$

which proves (e).

It will be shown next that $\|p_{xx}^j\|_{L^2}$ is uniformly bounded for all $j \in \mathbb{N}$ in order to prove (f).

Since

$$p_{xx}^j(x,t) = r^j(x,t) + s^j(x,t),$$

where

$$
\begin{aligned}
r^j(x,t) &:= \left(\frac{mj-t}{m}\right) p_t^{j-1}(x) + \left(\frac{t-m(j-1)}{m}\right) p_t^j(x),\\
s^j(x,t) &:= \left(\frac{mj-t}{m}\right) q_t^{j-1}(x) + \left(\frac{t-m(j-1)}{m}\right) q_t^j(x),
\end{aligned}
\tag{4.13}
$$

and $\|q_t^j\|_{L^\infty}$ is uniformly bounded for all $j \in \mathbb{N}$, one would only need to show that $\|p_t^j\|_{L^2}$ is uniformly bounded for all $j \in \mathbb{N}$. By (4.7) and the identity $u_{xt}^j = p_{xx}^{m,j}$, p_t^j satisfies the following equation:

$$
p_t^j = p_{xx}^{m,j} + \pi_a \left[\sigma(p^{m,j} + q^{m,j}) - \int_0^x \int_0^{x'} (p^{m,j} + q^{m,j})\right]. \tag{4.14}
$$

Let $f(p^{m,j}) := -q_t^j$. Note that

$$
\|f(p^{m,j})\|_{L^\infty} < M_1 \tag{4.15}
$$

for some $M_1 > 0$ since q_t^j is uniformly bounded. From (4.14),

$$
p^{m,j} - p^{m,j-1} = m\Delta p^{m,j} + mf(p^{m,j}),
$$

which implies

$$
\begin{aligned}
p^{m,j} &= \frac{p^{m,j-1}}{(1-m\Delta)} + \frac{m}{(1-m\Delta)} f(p^{m,j})\\
&= \frac{1}{(1-m\Delta)}\left[\frac{p^{m,j-2}}{(1-m\Delta)} + \frac{m}{(1-m\Delta)} f(p^{m,j-1})\right] + \frac{m}{(1-m\Delta)} f(p^{m,j})\\
&= \frac{p^{m,j-2}}{(1-m\Delta)^2} + m\left[\frac{f(p^{m,j-1})}{(1-m\Delta)^2} + \frac{f(p^{m,j})}{(1-m\Delta)}\right]\\
&\quad \cdots\\
&= \frac{p_0}{(1-m\Delta)^j} + m\left[\frac{f(p^{m,1})}{(1-m\Delta)^j} + \cdots + \frac{f(p^{m,j})}{(1-m\Delta)}\right].
\end{aligned}
$$

Therefore,

$$
p_t^j = \frac{p^{m,j} - p^{m,j-1}}{m} = \frac{\Delta p_0}{(1-m\Delta)^j} + m\sum_{k=1}^{j-1} \frac{\Delta f(p^{m,k})}{(1-m\Delta)^{j+1-k}} + \frac{f(p^{m,j})}{(1-m\Delta)}.
$$

By incorporating the inequality $\|\frac{\Delta}{(1-m\Delta)}\|_{L^2} \le 1$ and (4.15), the following inequalities occur:

$$
\begin{aligned}
\|p_t^j\|_{L^2} &\le \|\Delta p_0\|_{L^2} + m\sum_{k=1}^{j-1} \left\| \frac{1}{(1-m\Delta)^{j-k}} \cdot \frac{\Delta}{(1-m\Delta)} \cdot f(p^{m,k}) \right\|_{L^2} + \|f(p^{m,j})\|_{L^2}\\
&\le \|\Delta p_0\|_{L^2} + mM_1 \cdot \sum_{k=1}^{j-1} \frac{1}{(1-m\lambda_1)^{j-k}} + M_1\\
&\le \|\Delta p_0\|_{L^2} + \frac{M_1}{\lambda_1} \cdot \left[\frac{1}{(1-m\lambda_1)^{j-1}} - 1\right] + M_1\\
&\le \|\Delta p_0\|_{L^2} + \left(-\frac{1}{\lambda_1} + 1\right) \cdot M_1.
\end{aligned}
$$

Here, $\lambda_1 < 0$ is the largest eigenvalue of Δ. Therefore, $\|p_t^j\|_{L^2}$ is uniformly bounded for all $j \in \mathbb{N}$ and $\|p_x^j\|_{L^\infty} < K_2$ for some $K_2 > 0$. Proof of Lemma 4.2 is now complete. □

Remark. One can see from the proofs of Lemmas 4.1 and 4.2 that the energy decay and a priori estimates are independent of m for sufficiently small $m > 0$.

5. Equilibrium state as the limit of the solution as $j \to \infty$. We now introduce the function φ, which is called the phase function. This function will play an important role in proving the equilibrium state of the solution at the limit as $j \to \infty$. Fix $r > 0$, $r \ll 1$ such that for $\lambda \in [-r, r]$, the equation $\sigma(z) = \lambda$ has three different solutions $z_1(\lambda) < z_2(\lambda) < z_3(\lambda)$. Define

$$\varphi(z) = \begin{cases} i, & z \in \bigcup_{\lambda \in [-r,\, r]} z_i(\lambda), \quad i = 1, 2, 3, \\ \infty & \text{elsewhere.} \end{cases}$$

The next proposition states that the discretized solution $u^{m,j}$ converges in $W_0^{1,p}$ to an equilibrium state as j goes to infinity.

PROPOSITION 5.1. *Suppose* (H1)–(H3), (A1)–(A4) *hold. Then the solution* $(u^{m,j}, v^{m,j})$ *of* (2.1) *converges strongly in* $W_0^{1,p} \times L^2$ $(1 \le p < \infty)$ *to some equilibrium state* $(u_\star^m, 0) \in W_0^{1,\infty} \times L^2$ *as* $j \to \infty$.

Proof. The proof consists of several lemmas. The following lemma states that under some appropriate conditions on the elastic stress $\sigma(u_x^{m,j}(x)) - \int_0^x u^{m.j}$ and the phase function φ, the strain $u_x^{m,j}$ converges to an equilibrium state. We must be careful when choosing the pointwise representatives of $u_x^{m,j}$ since in the measure zero sets of $(0,1)$, we never know the behavior of the strain $u_x^{m,j}$. It is important to choose a good representative so that the limit state is continuous except for the finitely many points which are the zeros of the limit state.

LEMMA 5.2. *Assume there exists a full measure subset* $\tilde{\Omega} \in (0,1)$ *(measure of* $\tilde{\Omega}$ *is* 1*) and pointwise representatives* $\bar{w}^{m,j}$ *of* $u_x^{m,j}$ *such that*

(B1) $\sigma(\bar{w}^{m,j}(x)) - \int_0^x u^{m,j} =: \lambda_j^m(x) \to \lambda^m$ *as* $j \to \infty$ *for some* $\lambda^m \in (-r, r)$ *and all* $x \in \tilde{\Omega}$;

(B2) $\lim_{j\to\infty} \varphi(\bar{w}^{m,j}(x))$ *exists and is finite for all* $x \in \tilde{\Omega}$.

Then $\lim_{j\to\infty} \bar{w}^{m,j}(x) =: \bar{w}^m(x)$ *exists for all* $x \in \tilde{\Omega}$. *Moreover, the equivalence class* $\hat{w}^m$ *of* $\bar{w}^m$ *satisfies*

$$\|\hat{w}^m\|_{L_\infty} \le \tilde{K} \qquad \text{and} \qquad u_\star^m(x) := \int_0^x \hat{w}^m \quad \text{is in} \quad W_0^{1,\infty}.$$

Also,

$$\sigma((u_\star^m)_x(x)) - \int_0^x u_\star^m \equiv \lambda^m \ \ a.e., \qquad \varphi((u_\star^m)_x(x)) = \lim_{j\to\infty} \varphi(u_x^{m,j}(x)) \ \ a.e.$$

and

$$u^{m,j} \to u_\star^m \ \ in \ \ W_0^{1,p} \qquad (1 \le p < \infty).$$

Proof. Recall that $\sup_{j\in\mathbb{N}} \|u_x^j\|_{L^\infty} < \tilde{K}$ by (4.10). Define

$$\chi_i^{m,j}(x) := \begin{cases} 1, & x \in \tilde{\Omega} \ \text{ and } \ \varphi(\bar{w}^{m,j}(x)) = i \in \{1,2,3\}, \\ 0 & \text{else,} \end{cases}$$

$$\chi_\infty^{m,j}(x) := \begin{cases} 1, & x \in \tilde{\Omega} \text{ and } \varphi(\bar{w}^{m,j}(x)) = \infty, \\ 0 & \text{else.} \end{cases}$$

Let $x \in \tilde{\Omega}$. Since $\bar{w}^{m,j}(x) = z_i(\int_0^x u^{m,j} + \lambda_j^m(x))$ and $\chi_\infty^{m,j}(x) = 0$ if $\varphi(\bar{w}^{m,j}(x)) = i$, $i = 1, 2, 3$, the following equation holds:

$$\begin{aligned} &\bar{w}^{m,j}(x) - \bar{w}^{m,k}(x) \\ &\quad = \sum_{i=1}^{3} \left[\chi_i^{m,j}(x) \cdot z_i \left(\int_0^x u^{m,j} + \lambda_j^m(x) \right) - \chi_i^{m,k}(x) \cdot z_i \left(\int_0^x u^{m,k} + \lambda_k^m(x) \right) \right] \\ &\qquad + \chi_\infty^{m,j}(x) \cdot \bar{w}^{m,j}(x) - \chi_\infty^{m,k}(x) \cdot \bar{w}^{m,k}(x). \end{aligned} \tag{5.1}$$

Note that since $1 = \frac{d}{d\lambda^m}(\sigma(z_i(\lambda^m))) = \sigma'(z_i(\lambda^m)) \cdot z_i'(\lambda^m)$,

$$\begin{aligned} |z_i(a) - z_i(b)| &\le \sup_{x \in [-r,\, r]} |z_i'(x)| \cdot |a - b| \\ &= \sup_{x \in [-r,\, r]} \frac{1}{|\sigma'(z_i(x))|} \cdot |a - b| \le \frac{1}{\bar{M}} |a - b|, \end{aligned} \tag{5.2}$$

where $\bar{M} := \min_{z \in \sigma^{-1}([-r,r])} |\sigma'(z)|$. Let $\xi_{j,k}^m(x) = \int_0^x |u^{m,j} - u^{m,k}|$, $j, k \in \mathbb{N}$. Then

$$\begin{aligned} 0 \le \frac{d}{dx} \xi_{j,k}^m(x) &= \left| \int_0^x (u_x^{m,j} - u_x^{m,k}) \right| \\ &= \left| \int_0^x \left[\sum_{i=1}^{3} \left\{ \chi_i^{m,j}(x') \cdot z_i \left(\int_0^{x'} u^{m,j} + \lambda_j^m(x') \right) \right. \right. \right. \\ &\qquad \left. - \chi_i^{m,k}(x') \cdot z_i \left(\int_0^{x'} u^{m,k} + \lambda_k^m(x') \right) \right\} \\ &\qquad \left. + \chi_\infty^{m,j}(x') \cdot \bar{w}^{m,j}(x') - \chi_\infty^{m,k}(x') \cdot \bar{w}^{m,k}(x') \right] dx' \Bigg| \\ &= \left| \int_0^x \left[\sum_{i=1}^{3} \chi_i^{m,k}(x') \{ \bar{w}^{m,j}(x') - \bar{w}^{m,k}(x') \} + \sum_{i=1}^{3} \{ \chi_i^{m,j}(x') - \chi_i^{m,k}(x') \} \bar{w}^{m,j}(x') \right. \right. \\ &\qquad \left. \left. + \chi_\infty^{m,j}(x') \cdot \bar{w}^{m,j}(x') - \chi_\infty^{m,k}(x') \cdot \bar{w}^{m,k}(x') \right] dx' \right| \end{aligned} \tag{5.3}$$

holds for $j, k \in \mathbb{N}$. Note that

$$\int_0^x \left[\sum_{i=1}^{3} (\chi_i^{m,j} - \chi_i^{m,k}) \bar{w}^{m,j} \right] \le 2\tilde{K} |\{x \in (0,1) : \varphi(\bar{w}^{m,j}(x)) \ne \varphi(\bar{w}^{m,k}(x))\}|$$

and

$$\begin{aligned} \int_0^x \left(\chi_\infty^{m,j} \cdot \bar{w}^{m,j} - \chi_\infty^{m,k} \cdot \bar{w}^{m,k} \right) &\le \tilde{K} |\{x \in (0,1) : \varphi(\bar{w}^{m,j}(x)) \ne \varphi(\bar{w}^{m,k}(x))\}| \\ &\quad + 2\tilde{K} |\{x \in (0,1) : \varphi(\bar{w}^{m,j}(x)) = \varphi(\bar{w}^{m,k}(x)) = \infty\}|. \end{aligned}$$

Therefore, the last three terms in (5.3) are dominated by

$$\begin{aligned} &3\tilde{K} |\{x \in (0,1) : \varphi(\bar{w}^{m,j}(x)) \ne \varphi(\bar{w}^{m,k}(x))\}| \\ &+ 2\tilde{K} |\{x \in (0,1) : \varphi(\bar{w}^{m,j}(x)) = \varphi(\bar{w}^{m,k}(x)) = \infty\}| =: \delta_{j,k}^m. \end{aligned}$$

Let $x \in (0,1)$ be fixed. By assumption (B2), $\varphi(\bar{w}^{m,j}(x)) = \varphi(\bar{w}^{m,k}(x)) = i(x)$ for some $i(x) = 1,2,3$ if j,k are sufficiently large. Therefore, $\delta^m_{j,k} \to 0$ as $\min\{j,k\} \to \infty$. For each $i \in \{1,2,3\}$,

$$\int_0^x \chi_i^{m,k}(x')(\bar{w}^{m,j}(x') - \bar{w}^{m,k}(x'))dx' \le \int_{J_1(i)} |\bar{w}^{m,j}(x') - \bar{w}^{m,k}(x')|dx' + \int_{J_2(i)} |\bar{w}^{m,j}(x') - \bar{w}^{m,k}(x')|dx',$$

where

$$J_1(i) := \{x' \in (0,x) : \chi_i^{m,j}(x') = \chi_i^{m,k}(x') = 1\},$$

$$J_2(i) := \{x' \in (0,x) : \chi_i^{m,j}(x') = 0,\ \chi_i^{m,k}(x') = 1\}.$$

In the set $J_1(i)$,

$$\begin{aligned}|\bar{w}^{m,j}(x') - \bar{w}^{m,k}(x')| &= \left| z_i\left(\int_0^{x'} u^{m,j}(s)ds + \lambda_j^m(x')\right) - z_i\left(\int_0^{x'} u^{m,k}(s)ds + \lambda_k^m(x')\right)\right| \\ &\le \frac{1}{\bar{M}}\left[\int_0^{x'} |u^{m,j}(s) - u^{m,k}(s)|ds + |\lambda_j^m(x') - \lambda_k^m(x')|\right] \\ &= \frac{1}{\bar{M}}[\xi^m_{j,k}(x') + |\lambda_j^m(x') - \lambda_k^m(x')|].\end{aligned}$$

Note that $J_2(i) \subset \{x \in (0,1) : \varphi(\bar{w}^{m,j}(x)) \ne \varphi(\bar{w}^{m,k}(x))\}$, $i = 1,2,3$. Hence,

$$\begin{aligned}\frac{d}{dx}\xi^m_{j,k}(x) &\le 2\cdot\delta^m_{j,k} + \frac{1}{\bar{M}}\int_0^1 |\lambda_j^m(x') - \lambda_k^m(x')|dx' + \int_0^x \frac{1}{\bar{M}}\xi^m_{j,k}(x')dx' \\ &\le 2\cdot\delta^m_{j,k} + \frac{1}{\bar{M}}\|\lambda_j^m - \lambda_k^m\|_{L^1} + \frac{1}{\bar{M}}\xi^m_{j,k}(x) \\ &\le \epsilon^m_{j,k} + \frac{1}{\bar{M}}\xi^m_{j,k}(x),\end{aligned}$$

where $\epsilon^m_{j,k} := 2\cdot\delta^m_{j,k} + \frac{1}{\bar{M}}\|\lambda_j^m - \lambda_k^m\|_{L^1}$. By assumption (B1), $\epsilon^m_{j,k} \to 0$ as $\min\{j,k\} \to \infty$. By Gronwall's inequality,

$$\xi^m_{j,k}(x) \le \epsilon^m_{j,k}\cdot\bar{M}\cdot\left(\exp\left(\frac{1}{\bar{M}}x\right) - 1\right) \to 0 \ \text{ as } \ \min\{j,k\} \to \infty.$$

Therefore,

$$\left|\int_0^x u^{m,j} - \int_0^x u^{m,k}\right| \le \xi^m_{j,k}(x) \to 0$$

as $\min\{j,k\} \to \infty$. By combining this with assumption (B1), we get

$$\left|\left(\int_0^x u^{m,j} + \lambda_j^m(x)\right) - \left(\int_0^x u^{m,k} + \lambda_k^m(x)\right)\right| \to 0 \ \text{ a.e.}$$

as $\min\{j,k\} \to \infty$. By assumption (B2), $\chi_i^{m,j}(x) = \chi_i^{m,k}(x) = 1$ for some $i(x) = 1,2,3$, and $\chi_\infty^{m,j}(x) = \chi_\infty^{m,k}(x) = 0$ for sufficiently large $j,k \in \mathbb{N}$. This implies that

the right-hand side of (5.1) converges to zero, and thus $\bar{w}^{m,j}(x) - \bar{w}^{m,k}(x) \to 0$ for all $x \in \tilde{\Omega}$ as $\min\{j,k\} \to \infty$. Hence,

$$\lim_{j\to\infty} \int_0^x u^{m,j} =: U^m \quad \text{exists } \forall\ x \in [0,1],$$
$$\lim_{j\to\infty} \bar{w}^{m,j} =: \bar{w}^m \quad \text{exists } \forall\ x \in \tilde{\Omega}.$$

This implies that $u_x^{m,j}$ converges to the equivalence class $\hat{w}^m$ of $\bar{w}^m$ in L^1. Let $u_\star^m(x) := \int_0^x \hat{w}^m$. Since

$$u_\star^m(1) = \int_0^1 \hat{w}^m = \lim_{j\to\infty} \int_0^1 u_x^{m,j} = \lim_{j\to\infty} (u^{m,j}(1) - u^{m,j}(0)) = 0,$$

$u_\star^m$ satisfies the boundary conditions of (1.1). Moreover, since

$$u^{m,j}(x) = \int_0^x u_x^{m,j} \to \int_0^x \hat{w}^m = u_\star^m(x) \ \text{ in } \ C([0,1]),$$

$U^m = \int_0^x u_\star^m$. Hence,

$$u^{m,j} \to u_\star^m \ \text{ in } \ W^{1,p}, \qquad 1 \le p < \infty.$$

Since $u^{m,j},\ u_x^{m,j}$ are uniformly bounded, $u_\star^m \in W_0^{1,\infty}$. Therefore,

$$u_x^{m,j} \to (u_\star^m)_x \quad \text{boundedly a.e.}$$

Since $\sigma(u_x^{m,j}) - \int_0^x u^{m,j} \to \sigma((u_\star^m)_x) - \int_0^x u_\star^m$ boundedly a.e. by assumption (B1),

$$\lambda^m = \sigma((u_\star^m)_x) - \int_0^x u_\star^m \quad \text{a.e.} \tag{5.4}$$

Since $(u_\star^m)_x$ lies in one of the three intervals $\bigcup_{\lambda\in[-r,\,r]} z_i(\lambda),\ \ i \in \{1,2,3\}$ a.e., we can choose the nice pointwise representatives $\bar{w}^{m,j}$ of $u_x^{m,j}$ such that (5.4) holds for the set $(0,1)$ except for the finitely many points which are the limits $(x_\star)_i^m$ of finitely many zeros $x_i^m(j), i = 1,\dots,N$, of $u_x^{m,j}$ in (P4). Hence, we can conclude that $(u^{m,j}, v^{m,j})$ converges to an equilibrium state $(u_\star^m, 0)$ strongly in $W_0^{1,p} \times L^2$. ∎

In the lemmas to follow, we will show that under the low initial energy, the assumptions (B1) and (B2) are satisfied. Lemma 5.3 shows that the convergence of mean elastic stress $\int_0^1 (\sigma(u_x^{m,j}) - \int_0^x u^{m,j})dx$ implies the convergence of elastic stress $\sigma(u_x^{m,j}) - \int_0^x u^{m,j}$.

LEMMA 5.3. *Let $u^{m,j},\ j \in \mathbb{N}$, be a solution of* (2.1). *Assume that*

$$\lim_{j\to\infty} \int_0^1 \left(\sigma(u_x^{m,j}) - \int_0^x u^{m,j}\right) dx =: \lambda^m \quad \textit{exists.}$$

Then

$$\sigma(u_x^{m,j}) - \int_0^x u^{m,j} \to \lambda^m \ \ \textit{a.e. as} \ \ j \to \infty.$$

Proof. By (4.7), the sufficient condition to the conclusion is when q_t^j goes to zero a.e. as $j \to \infty$. Define the following modification of the energy functional $E(t)$:

$$\widetilde{E}(t) := \int_0^1 \left[W(u_x^j(x,t)) + \frac{1}{2}(u^j(x,t))^2 + p^j(x,t)s^j(x,t)\right] dx,$$

where $s^j(x,t)$ is the interpolation function defined in (4.13). Note that $\widetilde{E}(t)$ is uniformly bounded and, moreover, sufficiently small since the first two terms are the part of energy functional $E(t)$ and the third term is small since $p^j(x,t)$ is small enough by estimate (a) of Lemma 4.2 and $s^j(x,t)$ is uniformly bounded since q_t^j is uniformly bounded for all $j \in \mathbb{N}$. By (4.1) and the integration by parts,

$$
\begin{aligned}
\frac{d}{dt}\widetilde{E}(t) &= \int_0^1 [\,\sigma(u_x^j)\cdot u_{xt}^j + u^j \cdot u_t^j + p_t^j \cdot q_t^j + p_t^j(s^j - q_t^j) + p^j \cdot s_t^j]dx \\
&= \int_0^1 \Bigg[(\sigma(u_x^j) - \sigma(u_x^{m,j}))\cdot u_{xt}^j + (u^j - u^{m,j})\cdot u_t^j \\
&\qquad + \sigma(u_x^{m,j})\cdot u_{xt}^j + u^{m,j}\cdot u_t^j + u_{xt}^j \cdot q_t^j - (q_t^j)^2 \\
&\qquad + \ p_t^j\left(\left(\frac{mj-t}{m}\right)q_t^{m,j-1} + \left(\frac{t-m(j-1)-m}{m}\right)q_t^{m,j}\right) + p^j s_t^j\Bigg]\,dx \\
&\le mL\|v_x^{m,j}\|_{L^2}^2 + (t-mj)\|v^{m,j}\|_{L^2}^2 - \int_0^1 (q_t^j)^2 dx \\
&\qquad + \int_0^1 \Bigg[(v_{xx}^{m,j} - v_t^j)\cdot u_t^j + u_{xt}^j u_{xt}^j - u_{xt}^j p_t^j \\
&\qquad\qquad + \ p_t^j\left(\frac{t-mj}{m}\right)\cdot(q_t^{m,j} - q_t^{m,j-1}) + p^j s_t^j\Bigg]\,dx \qquad (5.5) \\
&\le mL\|v_x^{m,j}\|_{L^2}^2 - \int_0^1 (q_t^j)^2 dx \\
&\qquad + \int_0^1 [-u_{xt}^j v_x^{m,j} - u_t^j v_t^j + u_{xt}^j u_{xt}^j + u_t^j p_{xt}^j + p_t^j\cdot(t-mj)\cdot s_t^j + p^j s_t^j]dx \qquad (5.6) \\
&= mL\|v_x^{m,j}\|_{L^2}^2 - \int_0^1 (q_t^j)^2 dx + \int_0^1 s_t^j\left[(t-mj)\cdot\left(\frac{p^{m,j} - p^{m,j-1}}{m}\right)\right. \\
&\qquad \left. + \left(\frac{mj-t}{m}\right)p^{m,j-1} + \left(\frac{t-m(j-1)}{m}\right)p^{m,j}\right]dx \\
&= mL\|v_x^{m,j}\|_{L^2}^2 - \int_0^1 (q_t^j)^2 dx + 2\cdot\int_0^1 s_t^j\cdot p^j dx - \int_0^1 s_t^j \cdot p^{m,j} dx.
\end{aligned}
$$

The first term of (5.5) is followed from estimate (4.5). The first four terms of the integrand of the third term of (5.6) vanish because of the identities $u_{xt}^j = v_x^{m,j}$, $p_{xt}^j = v_t^j$. Since

$$
\begin{aligned}
\left|\int_0^1 s_t^j \cdot p^{m,j} dx\right| &\le \|p_{xx}^{m,j}\|_{L^2}\cdot\|s_t^j\|_{L^2} \\
&= \|v_x^{m,j}\|_{L^2}\cdot\left\|\frac{q_t^j - q_t^{j-1}}{m}\right\|_{L^2} \\
&\le \|v_x^{m,j}\|_{L^2}\cdot\left(\left\|\pi_a\left(\sigma'(c^{**})\cdot\frac{u_x^{m,j} - u_x^{m,j-1}}{m}\right)\right\|_{L^2} + \left\|\frac{u_x^{m,j} - u_x^{m,j-1}}{m}\right\|_{L^2}\right) \\
&\le M_2\cdot\|v_x^{m,j}\|_{L^2}^2,
\end{aligned}
$$

$$\left|\int_0^1 s_t^j \cdot p^j dx\right| \le \|v_x^j\|_{L^2} \cdot \|s_t^j\|_{L^2}$$
$$\le M_3 \cdot (\|v_x^{m,j-1}\|_{L^2} + \|v_x^{m,j}\|_{L^2}) \cdot \|v_x^{m,j}\|_{L^2},$$

and

$$\|v_x^{m,j-1}\|_{L^2} \cdot \|v_x^{m,j}\|_{L^2} \le M_4 \cdot (\|v_x^{m,j-1}\|_{L^2}^2 + \|v_x^{m,j}\|_{L^2}^2)$$

for some c^{**} between $u_x^{m,j}$ and $u_x^{m,j-1}$, M_2, M_3, and $M_4 > 0$, the following estimate on $\frac{d}{dt}\widetilde{E}(t)$ holds:

$$\frac{d}{dt}\widetilde{E}(t) \le mL\|v_x^{m,j}\|_{L^2}^2 - \int_0^1 (q_t^j)^2 dx + M_5 \cdot (\|v_x^{m,j-1}\|_{L^2}^2 + \|v_x^{m,j}\|_{L^2}^2) \tag{5.7}$$

for some $M_5 > 0$. By taking an integral from $(j-1)m$ to jm on both sides of (5.7), we get

$$\widetilde{E}(jm) - \widetilde{E}((j-1)m) \le -m\int_0^1 (q_t^j)^2 + (mL + M_5)m\|v_x^{m,j}\|_{L^2}^2 + mM_5\|v_x^{m,j-1}\|_{L^2}^2.$$

By taking the summation $j = 1, \dots, S$, we get the following estimate:

$$\widetilde{E}(Sm) - \widetilde{E}(0) \le -m\sum_{j=1}^{S}\int_0^1 (q_t^j)^2 + (mL + M_6)\sum_{j=1}^{S} m\|v_x^{m,j}\|_{L^2}^2 + mM_5\|(v_0)_x\|_{L^2}^2$$

for some $M_6 > 0$. By (4.6),

$$m\sum_{j=1}^{S}\int_0^1 (q_t^j)^2 \le \widetilde{E}(0) - \widetilde{E}(Sm) + 2(mL + M_6)\epsilon + M_5 m\|(v_0)_x\|_{L^2}^2$$
$$\le |\widetilde{E}(0)| + |\widetilde{E}(Sm)| + 2(mL + M_6)\epsilon + \epsilon_1$$
$$\le \delta$$

for some $\epsilon_1, \delta \ll 1$. Therefore, $m\sum_{j=1}^{\infty}\int_0^1 (q_t^j)^2 \le \delta$, and this implies $q_t^j \to 0$ a.e. as $j \to \infty$. ∎

The next lemma shows the convergence of the phase function under the assumptions of the low initial energy and the convergence of mean elastic stress.

LEMMA 5.4. *Let $u^{m,j}$, $j \in \mathbb{N}$, be the solution of* (2.1). *Then the assumption* (B2) *in Lemma* 5.2 *holds.*

Proof. By (b) and (e) of Lemma 4.2, mean elastic stress $\int_0^1 \left(\sigma(u_x^{m,j}) - \int_0^x u^{m,j}\right) dx$ is sufficiently small. Then by Lemma 5.3, $\limsup_{j\to\infty}\left|\sigma(u_x^{m,j}) - \int_0^x u^{m,j}\right|$ is sufficiently small a.e. Combining this and estimate (b) of Lemma 4.2, $\limsup_{j\to\infty}\left|\sigma(u_x^j)\right| \le \frac{2r}{3}$ a.e. This implies that for almost every x, there exists $J(x) \in \mathbb{N}$ such that

$$\{u_x^j(x,t) : j \ge J(x)\} \subseteq \sigma^{-1}([-r,\ r]) = \bigcup_{i=1}^{3}\bigcup_{\lambda\in[-r,\ r]} z_i(\lambda).$$

Since $\{u_x^j(x,t) : j \ge J(x)\}$ is connected, $u_x^j(x,t) \in \bigcup_{\lambda\in[-r,\ r]} z_i(\lambda)$ for all $j \ge J(x)$ and for some $i(x) = 1, 2$, or 3. This implies that $\lim_{j\to\infty}\varphi(u_x^j(x,t))$ exists and is finite a.e. Consequently, $\lim_{j\to\infty}\varphi(u_x^{m,j}(x))$ also exists and is finite a.e. ∎

The next lemma shows the convergence of mean elastic stress.

LEMMA 5.5. *Let $u^{m,j}$ be the solution of* (2.1). *Then*

$$\lim_{j\to\infty} \underbrace{\left[\int_0^1 \left(\sigma(u_x^{m,j}) - \int_0^x u^{m,j}\right) dx\right]}_{=:\, c(j)} \quad \textit{exists.}$$

Proof. Suppose this fails. Then there exists a subsequence $j_k \to \infty$ such that $c(j_k) \to \lambda^m$ and another subsequence $j_s \to \infty$ such that $c(j_s) \to \bar{\lambda}^m$ for some $\lambda^m,\ \bar{\lambda}^m \in [-\frac{2r}{3}, \frac{2r}{3}]$ and $\lambda^m < \bar{\lambda}^m$. Then by Lemma 5.3, $\sigma(u_x^{m,j_k}) - \int_0^x u^{m,j_k} \to \lambda^m$ a.e. as $j_k \to \infty$ and $\sigma(u_x^{m,j_s}) - \int_0^x u^{m,j_s} \to \bar{\lambda}^m$ a.e. as $j_s \to \infty$. Also by Lemma 5.4, $\lim_{j_k\to\infty} \varphi(u_x^{m,j_k})$, $\lim_{j_s\to\infty} \varphi(u_x^{m,j_s})$ exist and are finite, respectively. Hence, these satisfy the assumptions (B1), (B2) of Lemma 5.2, and therefore there exist $u^m,\ \bar{u}^m \in W^{1,\infty}$ such that

$$\sigma(u_x^m)_x - \int_0^x u^m \equiv \lambda^m \ \text{ a.e.}, \quad \sigma(\bar{u}_x^m)_x - \int_0^x \bar{u}^m \equiv \bar{\lambda}^m \ \text{ a.e.},$$

$$\varphi(u_x^m(x)) = \lim_{j_k\to\infty} \varphi(u_x^{m,j_k}(x)) \ \text{ a.e.}, \quad \text{and} \quad \varphi(\bar{u}_x^m(x)) = \lim_{j_s\to\infty} \varphi(u_x^{m,j_s}(x)) \ \text{ a.e.}$$

Note that $\varphi(u_x^m(x)) = \varphi(\bar{u}_x^m(x)) =: \varphi_\infty(x)$ since the limit of the phase function is independent of λ^m and $\bar{\lambda}^m$.

Consider the case where $\varphi_\infty(x) \in \{1, 3\}$ a.e. That is, the measure of the set $\Omega_u := \{x \in (0,1) : \varphi_\infty(x) = 2\}$ is zero. Now we introduce the following principle, whose proof was done in [16].

Comparison principle for weak solutions of the ordinary differential equation $\boldsymbol{\sigma(u_x)_x = u}$. Assume that $u,\ \bar{u} \in W^{1,\infty}$ satisfy

$$\sigma(u_x)_x - \int_0^x u \equiv \lambda \ \text{ a.e.}, \quad \sigma(\bar{u}_x)_x - \int_0^x \bar{u} \equiv \bar{\lambda} \ \text{ a.e.},$$

$\lambda < \bar{\lambda}$, $u(0) = \bar{u}(0) = 0$, $\sigma(u_x),\ \sigma(\bar{u}_x) \in [-r, r]$ a.e., $\varphi(u_x) = \varphi(\bar{u}_x)$ a.e., and $\varphi(u_x) \in \{1, 3\}$ a.e. Then $u(x) < \bar{u}(x)$ for all $x \in (0, 1]$.

Since u^m and $\bar{u}^m$ satisfy the assumptions of the above comparison principle, $u^m(1) < \bar{u}^m(1)$. This contradicts the boundary conditions of (1.1). In the case when the measure of Ω_u is not zero, contradiction arises from the following modified principle, which was also proven in [16].

Refined comparison principle for weak solutions of the ordinary differential equation $\boldsymbol{\sigma(u_x)_x = u}$. Under the same assumptions as the comparison principle, but with the condition $\varphi(u_x) \in \{1, 3\}$ a.e. replaced by $\int_0^1 W(u_x) < \epsilon$ and $|\Omega_u| \neq 0$, the inequality

$$u(1) < \bar{u}(1)$$

holds. □

Now Proposition 5.1 is complete. □

6. Dynamical behavior of the transition layers. If the set

$$\mathcal{L}_{\frac{\rho}{2}}(j) = \left\{x \in (0,1) : |u_x^j(x,t)| \le \frac{\rho}{2}\right\}$$

is monotonically decreasing to the finitely many isolated points as $j \to \infty$, we obtain the desired conclusion, since this is equivalent to the fact that the layers get steeper and eventually become discontinuous as j approaches infinity. However, the set $\mathcal{L}_{\frac{\rho}{2}}(j)$ is not decreasing as $j \to \infty$. We define the following set $\widetilde{\mathcal{L}}(j)$ instead and show that the set $\mathcal{L}_{\frac{\rho}{2}}(j)$ is contained in $\widetilde{\mathcal{L}}(j)$. We will then show that the set $\widetilde{\mathcal{L}}(j)$ is decreasing to the finitely many isolated points. Let $\eta \in (0, \frac{\rho}{4})$. Set $\rho_0 := \rho - \eta$. Define

$$\widetilde{\mathcal{L}}(j) := \{x \in (0,1) : |q^j(x,t)| \le \rho_0\}.$$

The following lemma states that the set of transition layers are always in the set $\widetilde{\mathcal{L}}(j)$ and furthermore in the set of initial transition layers $\mathcal{L}_\rho(0)$. This lemma plays an important role in showing the preservation of the number of transition layers.

LEMMA 6.1.

$$\mathcal{L}_{\frac{\rho}{2}}(j) \subseteq \widetilde{\mathcal{L}}(j) \subseteq \mathcal{L}_\rho(0) \quad \forall j \in \mathbb{N}.$$

Proof. If $x \in \mathcal{L}_{\frac{\rho}{2}}(j)$, then $|u_x^j(x,t)| \le \frac{\rho}{2}$. Therefore, by estimate (a) of Lemma 4.2,

$$|q^j(x,t)| = |u_x^j - p^j| \le \frac{\rho}{2} + \eta < \frac{\rho}{2} + \frac{\rho}{4} < \rho - \eta = \rho_0.$$

Now, $\widetilde{\mathcal{L}}(j) \subseteq \mathcal{L}_\rho(0)$ clearly follows. ∎

Next we show that the set $\widetilde{\mathcal{L}}(j)$ is exponentially decreasing to the finitely many isolated points.

LEMMA 6.2. *Assume $K > 4\tilde{K}$. Then for all $j \in \mathbb{N}$ and for some $C_0 > 0$,*

(i) $|q_x^j(x,t)| \ge C_0 e^{jm\sigma_0}|(q_0)_x|$ *if* $x \in \widetilde{\mathcal{L}}(j)$ *(exponential growth),*

(ii) $\widetilde{\mathcal{L}}(j+1) \subseteq \widetilde{\mathcal{L}}(j)$ *(monotonicity).*

Proof. We will show (i) by induction. Fix $j \in \mathbb{N}$ and fix $x \in \widetilde{\mathcal{L}}(j)$. Then $x \in \mathcal{L}_\rho(0)$ by Lemma 6.1. By hypothesis (A4), $|(u_0)_{xx}(x)| \ge K$. Suppose $(u_0)_{xx}(x) \ge K$. Since $(p_0)_x(x) < \tilde{K}$ by estimate (f) of Lemma 4.2, $(q_0)_x(x) = (u_0)_{xx}(x) - (p_0)_x(x) > 0$. By differentiating (4.7) with respect to x for $j = 1$, and by using the estimates (d), (f) of Lemma 4.2 and (4.12), we get the following estimate:

$$\begin{aligned} q_x^{m,1}(x) - q_x^{m,0}(x) &= \{-[\sigma(u_x^{m,1}(x))]_x + u^{m,1}(x)\}m \\ &= \{-\sigma'(u_x^{m,1}(x))(p_x^{m,1}(x) + q_x^{m,1}(x)) + u^{m,1}(x)\}m \\ &\ge -\sigma'(u_x^{m,1}(x))q_x^{m,1}(x)m - C_6 m \end{aligned}$$

for some $C_6 > 0$. Hence,

$$(1 + \sigma'(u_x^{m,1}(x))m)q_x^{m,1}(x) \ge q_x^{m,0}(x) - C_6 m.$$

Since m is sufficiently small and $q_x^{m,0} = (q_0)_x > 0$, $q_x^{m,1}$ is also positive. Therefore, the inequality

$$(1 - \sigma_0 m)q_x^{m,1}(x) \ge (1 + \sigma'(u_x^{m,1}(x))m)q_x^{m,1}(x) \ge q_x^{m,0}(x) - C_6 m$$

holds. Recall that $\sigma_0 = \min_{[-\rho,\rho]} |\sigma'|$. By induction, suppose $q_x^{m,j-1} > 0$. Then $q_x^{m,j} > 0$ and

$$(1-\sigma_0 m) q_x^{m,j}(x) \geq q_x^{m,j-1}(x) - C_6 m.$$

By iterating this, we obtain

$$\begin{aligned}
q_x^{m,j} &\geq \frac{1}{1-\sigma_0 m} \cdot q_x^{m,j-1} - C_6 m \cdot \frac{1}{1-\sigma_0 m} \\
&\geq \frac{1}{1-\sigma_0 m} \cdot \left[\frac{1}{1-\sigma_0 m} \cdot q_x^{m,j-2} - C_6 m \cdot \frac{1}{1-\sigma_0 m} \right] - C_6 m \cdot \frac{1}{1-\sigma_0 m} \\
&= \frac{1}{(1-\sigma_0 m)^2} \cdot q_x^{m,j-2} - C_6 m \left[\frac{1}{1-\sigma_0 m} + \frac{1}{(1-\sigma_0 m)^2} \right] \\
&\cdots \\
&= \frac{1}{(1-\sigma_0 m)^j} \cdot (q_0)_x - C_6 m \left[\frac{1}{1-\sigma_0 m} + \cdots + \frac{1}{(1-\sigma_0 m)^j} \right] \\
&= \frac{1}{(1-\sigma_0 m)^j} \cdot \left((q_0)_x - \frac{C_6}{\sigma_0} \right) + \frac{C_6}{\sigma_0}.
\end{aligned}$$

This implies

$$q_x^{m,j} \geq e^{jm\sigma_0} \cdot (q_0)_x.$$

Therefore, we can establish the exponential growth of q_x^j, that is,

$$|q_x^j(x,t)| \geq C_0 e^{jm\sigma_0} \cdot |(q_0)_x|$$

for some $C_0 > 0$. Similarly, we get the same conclusion for the case $(u_0)_{xx}(x) \leq -K$, and this proves (i) of Lemma 6.2.

Note that for $K > 4\tilde{K}$,

$$|q_x^j(x,t)| \geq C_0 e^{jm\sigma_0} \cdot |(q_0)_x| \geq C_0 e^{jm\sigma_0} (|(u_0)_{xx}| - \tilde{K}) \geq 3K_0 e^{jm\sigma_0}. \tag{6.1}$$

Here, $K_0 = \tilde{K} C_0$. If $q^j = \rho_0$, then $u_x^j = p^j + q^j = p^j + \rho_0 \geq -\eta + \rho_0 > 0$, and if $q^j = -\rho_0$, then $u_x^j = p^j - \rho_0 \leq \eta - \rho_0 < 0$, which implies $sign(u_x^j) = sign(q^j)$ at $|q^j| = \rho_0$. By using this and (4.7), and also by using estimates (b), (e) of Lemma 4.2, we have the estimate

$$\begin{aligned}
\frac{d}{dt}|q^j(x,t)| &= sign(q^j(x,t)) \cdot \left[\frac{q^{m,j}(x) - q^{m,j-1}(x)}{m} \right] \\
&= sign(u_x^j(x,t)) \cdot \left[\sigma(0) - \sigma(u_x^{m,j}(x)) + \int_0^1 \sigma(u_x^{m,j}) + \pi_a \left(\int_0^x u^{m,j} \right) \right] \\
&\geq -\sigma'(c') \cdot u_x^j \cdot sign(u_x^j) - \sigma'(c') \cdot (u_x^{m,j} - u_x^j) \cdot sign(u_x^j) - 2\sigma_0 \eta \\
&\geq \sigma_0 \cdot |u_x^j| - 2\sigma_0 \eta - \sigma'(c') \cdot sign(u_x^j) \cdot \frac{jm-t}{m} (u_x^{m,j} - u_x^{m,j-1}) \\
&\geq \sigma_0 \cdot (\rho - 4\eta) - \sigma'(c') \cdot sign(u_x^j) \cdot \frac{jm-t}{m} (u_x^{m,j} - u_x^{m,j-1}) \qquad (6.2)
\end{aligned}$$

at $|q^j| = \rho_0$ and for some c' between 0 and $u_x^{m,j}(x)$. Note that $|\frac{jm-t}{m}| < 1$. By estimate (a) of Lemma 4.2, $|p^{m,j} - p^{m,j-1}| \leq 2\eta \ll 1$. By (4.15), $|q^{m,j} - q^{m,j-1}| = m|q_t^j| \leq$

$mM_1 \ll 1$ when $m \ll 1$. Hence, $|u_x^{m,j} - u_x^{m,j-1}| \ll 1$, and this enables the second term of (6.2) to be small. Therefore,

$$\frac{d}{dt}|q^j(x,t)| \geq 0,$$

which implies $|q^j(x,t)| \leq |q^{j+1}(x,t)|$ for all $j \in \mathbb{N}$ when $|q^j(x,t)| = \rho_0$. By (i), q^j is strictly increasing or decreasing on $\widetilde{\mathcal{L}}(j)$, which implies (ii). □

From part (i) of Lemma 6.2, estimate (f) of Lemma 4.2, and the hypothesis (A4),

$$\begin{aligned} |u_{xx}^j(x,t)| &\geq |q_x^j(x,t)| - |p_x^j(x,t)| \\ &\geq C_0 e^{jm\sigma_0} \cdot |(q_0)_x| - \tilde{K} \\ &\geq C_0 e^{jm\sigma_0} \cdot (|(u_0)_{xx}| - 2\tilde{K}) \\ &\geq \frac{1}{2} K_0 e^{jm\sigma_0} \end{aligned} \tag{6.3}$$

if $x \in \mathcal{L}_{\frac{\rho}{2}}(j)$ and $K > 4\tilde{K}$.

From (6.3) and the fact that $\|u^{m,j}\|_{C^2} < \infty$ for all $j \in \mathbb{N}$, $\mathcal{L}_{\frac{\rho}{2}}(j)$ has a finite number of components $[a_i^m(j), b_i^m(j)]$, $0 < a_1^m(j) < b_1^m(j) < \cdots < a_N^m(j) < b_N^m(j) < 1$, in each of which $u_x^j(x,t)$ is strictly monotone and has exactly one zero $x_i^m(j)$. Also, $N(j) \geq 1$ since $u^j(0,t) = u^j(1,t) = 0$ for all $j \in \mathbb{N}$.

LEMMA 6.3. *$N(j) \equiv$ const. for all $j \in \mathbb{N}$.*

Proof. For all $j \in \mathbb{N}$, define

$$g^j(x,t) := u_x^j(x,t), \quad (j-1)m < t \leq jm.$$

Since $g^j, g_x^j \in C((0,1) \times ((j-1)m, jm])$ and at each zero (x_0,t_0) of g^j, $|g_x^j(x,t)| \geq \frac{K_0}{2} > 0$ by inequality (6.3), $\{g^j(x_0,t_0) | (x_0,t_0)$ is a zero of $g^j\}$ does not contain a critical value of $g^j(\cdot,t)$ for each t_0. By the implicit function theorem, the number of zeros of $g^j(\cdot,t)$ is independent of t for $(j-1)m < t \leq jm$ for all $j \in \mathbb{N}$. □

Similarly, by defining

$$g^j(x,t) := u_x^j(x,t) - \frac{\rho}{2} \quad \text{and} \quad g^j(x,t) := u_x^j(x,t) + \frac{\rho}{2},$$

the number of connected components of $\mathcal{L}_{\frac{\rho}{2}}(j)$ is independent of j. Now, the proof of (P1) and (P2) is complete.

From Lemma 6.1, $[a_i^m(j), b_i^m(j)] \subseteq [(a_0)_i, (b_0)_i]$, $i = 1, \ldots, N$. Moreover,

$$\begin{aligned} \rho &= |u_x^j(b_i^m(j),t) - u_x^j(a_i^m(j),t)| \\ &= \int_{a_i^m(j)}^{b_i^m(j)} |u_{xx}^j| dx \\ &\geq \frac{1}{2} K_0 e^{jm\sigma_0} \cdot |b_i^m(j) - a_i^m(j)|, \end{aligned}$$

which implies

$$|b_i^m(j) - a_i^m(j)| \leq \frac{2\rho}{K_0} \cdot e^{-jm\sigma_0} \quad \text{for all } i = 1, \ldots, N$$

for fixed j and $K > 4\tilde{K}$. This proves the last part of (P3). The rest of (P3) was already proved.

From (6.1) and from similar analysis as in the case $\mathcal{L}_{\frac{\rho}{2}}(j)$, $\widetilde{\mathcal{L}}(j)$ has a finite number of components $[\alpha_i^m(j), \beta_i^m(j)]$, $0 < \alpha_1^m(j) < \beta_1^m(j) < \cdots < \alpha_N^m(j) < \beta_N^m(j) < 1$. By Lemma 6.1, $x_i^m(j) \in [a_i^m(j), b_i^m(j)] \subseteq [\alpha_i^m(j), \beta_i^m(j)] \subseteq [a_i^0, b_i^0]$. By (ii) of Lemma 6.2, $[\alpha_i^m(j+1), \beta_i^m(j+1)] \subseteq [\alpha_i^m(j), \beta_i^m(j)]$. Therefore, the set of $[\alpha_i^m(j+1), \beta_i^m(j+1)]$ forms a nested family of intervals. Hence,

$$\begin{aligned} 2\rho > 2\rho_0 &= |q^j(\beta_i^m(j), t) - q^j(\alpha_i^m(j), t)| \\ &= \int_{\alpha_i^m(j)}^{\beta_i^m(j)} |q_x^j| dx \\ &\geq 3K_0 |\beta_i^m(j) - \alpha_i^m(j)| \cdot e^{jm\sigma_0}, \end{aligned}$$

which concludes the proof of (P4).

(P3) and (P4) automatically imply that $(u_\star^m)_x$ is discontinuous at every $(x_\star)_i^m$. It remains now to show that $(u_\star^m)_x$ is continuous on $(0,1)\backslash\{(x_\star)_1^m, \ldots, (x_\star)_N^m\}$. Since $u_\star^m$ is an equilibrium state, it satisfies the equation

$$\sigma((u_\star^m)_x(x)) = \int_0^x (u_\star^m) + \lambda^m$$

for some constant $\lambda^m > 0$. We know that the first term on the right-hand side of the above equation is small by estimate (b) of Lemma 4.2. Furthermore, λ^m is sufficiently small on $(0,1)\backslash\{(x_\star)_1^m, \ldots, (x_\star)_N^m\}$. Therefore, $(u_\star^m)_x$, the inverse image of σ, is continuous on those intervals, which proves (P5). Theorem 3.1 is finally complete.

Remark. The results of transition layer dynamics work for the discretized viscoelastic system without the elastic foundation term u, that is, for the system

$$\frac{1}{m^2}(u - 2u^{m,j-1} + u^{m,j-2}) - (\sigma(u_x))_x - \frac{1}{m}(u_x - u_x^{m,j-1})_x = 0.$$

The proof is similar to the proof for the system with the elastic foundation. Only the minor change of the proof of energy decay (Lemma 4.1), the proof of Lemma 5.3, and the estimate of $q^j(x,t)$ is needed.

7. Asymptotic behavior of the original system. In this section, we answer the following question: How do our results relate to the asymptotic behavior of the original system (1.1)?

We proved in section 5 that $u^{m,j}$ converges strongly in $W_0^{1,p}$ to a steady state $u_\star^m$ as $j \to \infty$ for fixed $m \ll 1$. Therefore, $u_\star^m$ satisfies

$$-(\sigma(u_x))_x + u = 0.$$

We will show next the existence of a weak limit of $u_\star^{m_k}$ in $W_0^{1,p}$ as $m_k \to 0$ for some sequence $m_k \ll 1$, $k \in \mathbb{N}$, in the following theorem.

THEOREM 7.1. *There is a sequence $m_k \ll 1$, $k \in \mathbb{N}$, and $m_k \to 0$ as $k \to \infty$ such that the steady state $u_\star^{m_k}$ in Proposition* 5.1 *converges in $W_0^{1,p}$ to a weak limit $u_\star$ as $k \to \infty$.*

Proof. The difficulty arises due to the nonlinearity of σ. However, by the fact that $(u_\star^m)_x$ is uniformly bounded by $\tilde{K} > 0$ and the coercivity condition for σ in (H2), the inequalities

$$\begin{aligned} \int_0^1 \sigma((u_\star^{m_k})_x) \cdot \zeta_x dx &\leq \hat{M} \int_0^1 (|(u_\star^{m_k})_x|^{p-1} + 1) \cdot \zeta_x dx \\ &\leq \hat{M} \int_0^1 (\tilde{K}^{p-1} + 1) \cdot \zeta_x dx \end{aligned}$$

hold for some $\hat{M} > 0$ and for any test function $\zeta \in C_0^\infty((0,1),\mathbb{R})$. The result follows from the dominated convergence theorem. ∎

Note that we can assume that σ is globally Lipschitz continuous since $u_x^{m,j}$ is uniformly bounded for all $j \in \mathbb{N}$ and for any $m \ll 1$. Then by [15, section 5.1], the weak solution of the system (1.1) is unique. Combining this with the results shown in [15, Theorem 4.1] and [16, Theorem 3.1] , the discretized solution $u^{m,j}$ converges in $W_0^{1,p}$ to a unique weak solution u of (1.1) as $m \to 0$, and u converges strongly in $W_0^{1,p}$ to a unique equilibrium state u_∞ as $t \to \infty$.

If the weak limit $u_\star$ is unique and is the same as u_∞, the same asymptotic behavior will hold for the system (1.1). However, we do not know the answer to this question and it remains as an open problem.

Acknowledgments. The author thanks Professor Zhengfang Zhou from Michigan State University for his valuable advice on this paper. The author also thanks the referees for their helpful comments and suggestions.

CONVERGENCE OF VISCOSITY SOLUTIONS FOR ISOTHERMAL GAS DYNAMICS*

FEIMIN HUANG† AND ZHEN WANG‡

Abstract. We study the hyperbolic system of Euler equations for an isothermal, compressible fluid. The *strong convergence theorem* of approximate solutions is proved by the theory of compensated compactness. The existence of a weak entropy solution to Cauchy problems with large L^∞ initial data which may include a vacuum is also obtained. We note that we establish the commutation relations not only for the *weak* entropies but also for the *strong* ones by using the *analytic extension theorem*.

Key words. isothermal gas dynamics, compensated compactness, analytic extension theorem

1. Introduction.

The one-dimensional Euler equations of compressible fluid read

$$\begin{cases} \rho_t + (\rho u)_x = 0, \\ (\rho u)_t + (\rho u^2 + p(\rho))_x = 0, \end{cases} \tag{1.1}$$

where the unknown variable $\rho \geq 0$ denotes the density of the mass, u the velocity. Usually, it is convenient to study (1.1) by a new variable, the momentum $m = \rho u$. Thus (1.1) becomes

$$\begin{cases} \rho_t + m_x = 0, \\ m_t + \left(\dfrac{m^2}{\rho} + p(\rho) \right)_x = 0. \end{cases} \tag{1.2}$$

For polytropic perfect gas, $p = p_0 \rho^\gamma$ with γ the adiabatic exponent. Equation (1.1) is called isentropic gas dynamics for $\gamma > 1$, while it is called isothermal gas dynamics for $\gamma = 1$. Without loss of generality, p_0 is normalized to be 1 here.

One of the main difficulties for the mathematical analysis of (1.1) is the singularity at the vacuum $\rho = 0$. It is noted that the term ρu^2 is only Lipschitz continuous for $\gamma > 1$ near the vacuum, while it is not even Lipschitz continuous for $\gamma = 1$ due to the infiniteness of the velocity u. This shows that the isothermal case is completely different from the isentropic one. Another difficulty is the development of a shock wave in solutions of (1.1) no matter how smooth the initial data are.

‡Wuhan Institute of Physics and Mathematics, The Chinese Academy of Sciences, P.O. Box 71010, Wuhan 430071, China (mazwang@cityu.edu.hk).

Away from the vacuum, the first result on the existence of BV solutions with large initial data in the BV space was obtained in Nishida [18] by using the Glimm scheme [11] for $\gamma = 1$. Poupaud, Rascle, and Vila [20] made a great simplification and improved the results of [18] to the isothermal Euler–Poisson system. For the case of $\gamma > 1$, the existence of a BV solution was established in Nishida and Smoller [19] for large total variation with small $\gamma - 1$.

When a vacuum occurs, the first global existence for (1.1) with large initial data in L^∞ was established in Diperna [10] for $\gamma = 1 + \frac{2}{2n+1}, n \geq 2$, by the theory of compensated compactness. For the interval $(1, \frac{5}{3}]$, the existence was solved by Ding, Chen, and Luo [6, 7] and Chen [2]. Lions, Perthame, and Tadmor [14] and Lions, Perthame, and Souganidis [15] treated this problem for $\gamma > \frac{5}{3}$. More recently, Chen and Le Floch [4] studied the existence problem for general pressure, where p acts like γ-law $(1 < \gamma < 3)$ near the vacuum $\rho = 0$. The approach of [4] further simplified the proofs for the case of $\gamma > 1$.

The purpose of the present paper is to prove the existence of a global weak L^∞ solution for isothermal gas dynamics with large initial data by the theory of compensated compactness. Our initial data are

$$(\rho(0,x), m(0,x)) = (\rho_0(x), m_0(x)) \in L^\infty, \tag{1.3}$$

where the vacuum may occur. It is known that all effective approaches for isentropic gas dynamics are based on the subtle analysis for the Euler–Poisson–Darboux (EPD) equation, while the entropy equation of $\gamma = 1$ is not governed by the EPD equation. Therefore all previous approaches [2, 4, 6, 7, 10, 14, 15] fail here. We shall use a new approach to achieve our goal. We establish the commutation relations for some strong entropies even though we do not know whether these strong waves satisfy the H^{-1} compact condition or not. It should be noted here that the strong entropy is useless for isentropic gas dynamics (see Lions, Perthame, and Tadmor [14]).

In addition, we note that the vacuum may disappear in the solution to the Riemann problem for isothermal flow. It is well known that the centered rarefaction wave may disappear in the solution of the Riemann problem for the scalar conservation laws, but initial value problems are still investigated when the initial data includes the centered rarefaction wave for the scalar equation. Similarly, the Cauchy problem for isothermal gas dynamics with the vacuum initial data is also important (see [1]) and has been long standing for many years. According to our experience with the Riemann problem, we conjecture that the solution we get here for the Cauchy problem may not contain the vacuum when $t > 0$. However, it seems that it is not easy to prove the above conjecture.

Now we recall the definition of the weak entropy solution.

DEFINITION 1.1. *$(\rho, m)(x,t) \in L^\infty(R^2_+)$ is called a weak entropy solution of* (1.2) *if it holds, for any test function $\phi \in C_0^\infty(R^2_+)$, that*

$$\begin{cases} \displaystyle\iint_{t>0} (\rho\phi_t + m\phi_x)\, dxdt + \int_R \rho_0(x)\phi(x,0)\, dx = 0, \\ \displaystyle\iint_{t>0} m\phi_t + \left(\frac{m^2}{\rho} + p(\rho)\right)\phi_x\, dxdt + \int_R m_0(x)\phi(x,0)\, dx = 0, \end{cases} \tag{1.4}$$

and for any weak entropy pair $(\eta, q)(\rho, m)$ with convex $\eta(\rho, m)$,

$$\eta(\rho, m)_t + q(\rho, m)_x \leq 0 \tag{1.5}$$

holds in the sense of distributions. Here the entropy pair (η, q) *is determined by the additional conservation law*

$$\eta(\rho, m)_t + q(\rho, m)_x = 0 \tag{1.6}$$

for any smooth solution of (1.2), *and* weak *entropy is an entropy that vanishes at the vacuum.*

Our main results follow.

THEOREM 1.2 (existence theorem). *Let* $\gamma = 1$, *and assume that the initial data satisfy*

$$0 \le \rho_0(x) \le M, \quad |m_0(x)| \le \rho_0(x)(M + |\log \rho_0(x)|) \quad a.e.; \tag{1.7}$$

then there exists a global weak entropy solution of (1.2), (1.3) *satisfying*

$$0 \le \rho(x,t) \le C, \quad |m(x,t)| \le \rho(x,t)(C + |\log \rho(x,t)|) \quad a.e., \tag{1.8}$$

where C *only depends on* M.

Remark 1.3. It is known that Nishida [18] had established the existence of global BV solutions for the isothermal gas dynamics if the initial data $(\rho_0, u_0) \in BV(R)$ and $\rho_0 > c > 0$. But here our initial data is more rough, i.e., $(\rho_0, u_0) \in L^\infty(R)$. Furthermore, our initial data may include the vacuum.

THEOREM 1.4 (compactness framework). *Let* $\gamma = 1$ *and let* $(\rho^\varepsilon, m^\varepsilon)$ *be a sequence of approximate solutions of* (1.2) *satisfying* (1.8) *uniformly in* ε. *Assume that*

$$\partial_t \eta(\rho^\varepsilon, m^\varepsilon) + \partial_x q(\rho^\varepsilon, m^\varepsilon) \quad \text{is compact in} \quad H^{-1}_{loc} \tag{1.9}$$

holds for some (not all) weak entropies (η, q) *with*

$$\eta = \rho^{\frac{1}{1-\xi^2}} e^{\frac{\xi}{1-\xi^2} u}, \quad q = (u + \xi)\eta, \quad \xi \in (-1, 1); \tag{1.10}$$

then there exists a function $(\rho(x,t), m(x,t))$ *satisfying* (1.8) *such that, extracting a subsequence if necessary,*

$$(\rho^\varepsilon(x,t), m^\varepsilon(x,t)) \to (\rho(x,t), m(x,t)) \quad \text{in } L^p_{loc}(R^2_+) \tag{1.11}$$

for all $p \in [1, +\infty)$.

Remark 1.5. Theorem 1.4 is useful for studying the existence of a global weak L^∞ solution of (1.1) with source term for $\gamma = 1$; for instance, the compressible Euler equations with damping, the Euler–Poisson system, etc.

Before we explain our ideas, it is worthwhile to briefly recall the theory of compensated compactness. To prove the existence, one usually constructs a sequence of approximate solutions $(\rho^\varepsilon, m^\varepsilon)$ by using viscosity perturbation or a finite difference scheme, then extracts a strong subsequence of $(\rho^\varepsilon, m^\varepsilon)$, if necessary, to get the desired results. However, it is very difficult to get a strong convergent subsequence for (1.2). Usually it is easy to obtain the uniform boundness estimates for $(\rho^\varepsilon, m^\varepsilon)$, which indicates that extracting a weak convergent subsequence is available. It is well known that weak convergence alone is not sufficient for implying the existence of a weak solution due to the nonlinearity of (1.2). So some information on the derivative of $(\rho^\varepsilon, m^\varepsilon)$ is needed. Tartar [22] first applied the Young measure to introduce the commutation relations

$$\langle \nu_{x,t}, q_1\eta_2 - q_2\eta_1 \rangle = \langle \nu_{x,t}, q_1 \rangle \langle \nu_{x,t}, \eta_2 \rangle - \langle \nu_{x,t}, q_2 \rangle \langle \nu_{x,t}, \eta_1 \rangle, \tag{1.12}$$

with any two entropy pairs $(\eta_i, q_i), i = 1, 2$, for almost every (x, t) if

$$\eta_i(\rho^\varepsilon, m^\varepsilon) + q_i(\rho^\varepsilon, m^\varepsilon) \tag{1.13}$$

lie in a compact subset of H^{-1}_{loc} as ε vanishes. If the Young measure satisfying (1.12) reduces to a point mass for almost every (x, t), then the weak convergence becomes strong, and the existence of a weak solution is established. Therefore the H^{-1} compact condition is essential to the theory of compensated compactness.

For strictly hyperbolic systems with smooth flux, the H^{-1} compact condition is easy due to the uniform boundness of approximate solutions and Murat's lemma [17], provided that the system has a strictly convex entropy. However, for isentropic gas dynamics, not all entropy pairs can be applied to Tartar commutation relations (1.12), since only weak entropy pairs are known to satisfy the H^{-1} compact condition. As pointed out by Lions, Perthame, and Tadmor [14], strong entropies are useless for the isentropic case. Fortunately, since all weak entropies obey famous EPD equation, people (see [2, 6, 7, 10, 14, 15]) are able to imply that the Young measure is either a single point or a subset of the vacuum by careful entropy analysis for the EPD equation, and then prove the existence of a weak solution for the isentropic case. More precisely, in the proof of [2, 6, 7, 10], the heart of the matter is to construct the special weak entropies and apply them to the commutation relations. This is possible because (1.12) represents an imbalance of regularity: the operator on the left is more regular than the one on the right due to cancellation. The novel idea of applying the technique of fractional derivatives was introduced in [6, 7, 8]. A new analysis of (1.12) was proposed by Lions, Perthame, and Tadmor [14] and Lions, Perthame, and Souganidis [15] for $\gamma > 1$. Motivated by a kinetic formulation of (1.1), they made the crucial observation that the use of special weak entropies could be bypassed and (1.12) be directly expressed with the entropy kernel of EPD equation. We refer to [2, 6, 7, 10, 14, 15] for details. Even though only weak entropy pairs are used in the case $\gamma > 1$, Diperna [10] conjectured that it may be possible to establish the commutation relations for all entropy pairs, weak and strong ones. If it is true, the proof is quite simple (see [10]).

In general, to exploit the classical theory of compensated compactness, the following steps are necessary

(1) *to construct a sequence of approximate solutions and obtain the uniform boundness of approximate solutions;*

(2) *to establish the H^{-1} compact condition for infinite entropy pairs;*

(3) *to apply the* div-curl *lemma into all entropy pairs satisfying* (2) *to establish the commutation relations;*

(4) *to apply the commutation relations to reduce Young measure to a point mass for almost every (x, t).*

Similar to the isentropic case, it is also difficult for $\gamma = 1$ to prove the H^{-1} compact condition for strong entropy pairs (step 2). In fact, we do not know whether the strong entropy pairs satisfy the H^{-1} compact condition or not. Compared with the isentropic case, the main difficulties for the isothermal flow arise on the following two aspects: the infiniteness of eigenvalues due to the presence of a vacuum, and the fact that the entropy equation is not of EPD type. Among them, the second one is essential. Thus all approaches of [2, 6, 7, 10, 14, 15] fail here.

Since only weak entropies are known to satisfy H^{-1} compact condition for $\gamma = 1$, it seems that the strong entropies are useless, as in the isentropic case. However, the use of strong entropies is the key point of our proofs. The main novelty of this paper

is that we establish the commutation relations not only for the *weak* entropies but also for the *strong* ones by using the *analytic extension theorem* even though we do not know whether or not strong entropies satisfy H^{-1} compact conditions.

To achieve our goal, we first choose a special formula of entropies parameterized by a complex variable ξ. The formula includes both weak and strong entropies determined by the value of ξ. Then we prove that there exists a segment such that for any ξ belonging to the segment, the entropy pair is of weak type and satisfies the H^{-1} compact condition. Therefore the commutation relations are established for some weak entropies in this segment. It is observed that the two sides of (1.12) are regular for ξ. In fact, they are analytic functions with respect to ξ. So the commutation relations exactly hold for the whole complex space except two points $(-1, 0)$ and $(1, 0)$ due to the analytic extension theorem. It is noted that the entropies are strong if $|\xi| > 1$ (see (2.9)). Therefore Diperna's conjecture [10] is partially verified for isothermal flow; i.e., the commutation relations hold for some weak and strong entropy pairs. We note that the H^{-1} compact condition for strong entropies (step 2) can be bypassed. Since both weak and strong entropy pairs are applied to (1.12), we establish a strong convergence theorem of approximate solutions and prove the existence of a weak entropy solution for isothermal gas dynamics. Finally, it is worthwhile to point out that our approximate solutions are constructed by adding the viscosity perturbation to (1.1) due to the infiniteness of eigenvalues. It is observed that the eigenvalues $\lambda_1 = u - 1$ and $\lambda_2 = u + 1$ increase with the speed of $|\ln \rho|$. This indicates the possibility of constructing approximate solutions by numerical scheme. We will discuss this in the future.

This paper is organized as follows: In section 2, we give a formula of entropy pairs, parameterized by a complex variable ξ. In section 3, we study the viscosity solutions $(\rho^\varepsilon, m^\varepsilon)$ and prove that the weak entropy fields lie in a compact subset of H^{-1}_{loc} when $\xi \in (-1, 1)$ as ε vanishes. In section 4, we prove a strong convergence theorem of approximate solutions and obtain the existence of a weak solution for isothermal gas dynamics.

2. Entropy waves. This section is devoted to the entropy for isothermal flow. We recall that (η, q) is an entropy-flux pair if for any smooth solutions of (1.1), it satisfies an additional equation,

$$\eta_t(\rho, u) + q_x(\rho, u) = 0. \tag{2.1}$$

By definition, weak entropy is an entropy η that vanishes at the vacuum.

Let $\gamma = 1$. Equation (2.1) yields $\nabla\eta\nabla f = \nabla q$ with the flux $f = (\rho u, \rho u^2 + \rho)^T$, i.e.,

$$q_\rho = u\eta_\rho + \frac{1}{\rho}\eta_u, \quad q_u = \rho\eta_\rho + u\eta_u, \tag{2.2}$$

which indicates

$$\eta_{\rho\rho} = \frac{1}{\rho^2}\eta_{uu}. \tag{2.3}$$

We choose the form $\eta = h(\rho)e^{ku}$; then (2.3) implies

$$h'' - \frac{k^2}{\rho^2}h = 0. \tag{2.4}$$

Thus, we have $h(\rho)=\rho^m$ with $m(m-1)=k^2$. Now we consider the parameter k in the complex space. Let $k=\frac{\xi}{1-\xi^2}$, $\xi\in\mathbf{C}$; then $m=\frac{1}{1-\xi^2}$. Therefore we have the following formula of entropy pairs:

$$\begin{aligned}\eta&=\rho^{\frac{1}{1-\xi^2}}e^{\frac{\xi}{1-\xi^2}u},\\ q&=(u+\xi)\eta.\end{aligned}\tag{2.5}$$

We note that these entropies are analytic functions with respect to ξ. It is easy to see that the points $(-1,0)$ and $(1,0)$ are singular for (η,q).

On the other hand, it is convenient to introduce a coordinate system of Riemann invariants (w,z) with

$$\nabla w\cdot r_1=0,\quad \nabla z\cdot r_2=0,\tag{2.6}$$

where $r_1=(1,u-1)^T$, $r_2=(1,u+1)^T$ are the right eigenvectors of the Jacobian matrix of f: $\nabla f r_i=\lambda_i r_i$, $i=1,2$. In the setting of isothermal flow, the Riemann invariants read

$$w=\rho e^u,\qquad z=\rho e^{-u}.\tag{2.7}$$

Thus we rewrite (2.5) as

$$\begin{aligned}\eta&=w^{\frac{1}{2(1-\xi)}}z^{\frac{1}{2(1+\xi)}},\\ q&=(u+\xi)\eta.\end{aligned}\tag{2.8}$$

It is observed that the formula (2.8) includes two kinds of entropies determined by the new complex variable ξ. By definition, η is a weak entropy if and only if the following hold:

$$\mathrm{Re}\frac{1}{2(1-\xi)}>0,\qquad \mathrm{Re}\frac{1}{2(1+\xi)}>0,\tag{2.9}$$

i.e., $\xi\in\Omega_w=\{\xi\in\mathbf{C};-1<\mathrm{Re}\xi<1\}$.

In fact, we can get more information from (2.8). If we consider ξ in the real space, the entropies defined in (2.8) form a fundamental set of weak entropies for isothermal flow. In other words, we have the following.

LEMMA 2.1. *Let $\gamma=1$; then for any $\varphi(\xi)\in C_0^\infty(-1,1)$,*

$$\begin{aligned}\eta&=\int_{-1}^{1}\varphi(\xi)w^{\frac{1}{2(1-\xi)}}z^{\frac{1}{2(1+\xi)}}\,d\xi,\\ q&=\int_{-1}^{1}\varphi(\xi)(u+\xi)w^{\frac{1}{2(1-\xi)}}z^{\frac{1}{2(1+\xi)}}\,d\xi\end{aligned}\tag{2.10}$$

is a weak entropy-flux pair of (1.1).

3. Viscosity solutions. We consider the viscous perturbation of the isothermal flow,

$$\begin{cases}\rho^\varepsilon_t+m^\varepsilon_x=\varepsilon\rho^\varepsilon_{xx},\\ m^\varepsilon_t+\left(\dfrac{(m^\varepsilon)^2}{\rho^\varepsilon}+\rho^\varepsilon\right)_x=\varepsilon m^\varepsilon_{xx},\end{cases}\tag{3.1}$$

with initial data

$$(\rho^\varepsilon, m^\varepsilon)|_{t=0} = (\rho_0^\varepsilon(x), m_0^\varepsilon(x)), \tag{3.2}$$

where $(\rho_0^\varepsilon(x), m_0^\varepsilon(x))$ satisfy

$$\varepsilon \le \rho_0^\varepsilon(x) \le M, \qquad |m_0^\varepsilon(x)| \le M. \tag{3.3}$$

It is easy to see that (3.3) holds if $\rho_0^\varepsilon(x)$ is given by smoothing out $\rho_0(x)$ with a standard mollifier and adding ε.

In terms of the theory of the positive invariant region in Chueh, Conley, and Smoller [5, 21], it is easy to see that $\{(w,z);\ w \le \text{const},\ \ z \le \text{const}\}$ is the invariant region of (3.1), which indicates that the Riemann invariants w^ε, z^ε are uniformly bounded in L^∞. This implies that $(\rho^\varepsilon, m^\varepsilon)$ are also uniformly bounded in L^∞. It is noted that there always exists a local smooth solution for (3.1) due to Diperna [10]. In order to prove the existence of a smooth solution for (3.1) and (3.2), it is also important to obtain an a priori estimate of the lower bound for the density ρ^ε. Diperna first gave the lower bound by his Lemma 4.1 (see [10]), even though this lemma was stated in an incorrect way. Chen [3] fixed this lemma. On the other hand, Lu [16] also studied the lower bound for general pressure $p(\rho)$ by maximum principle in which the restriction of initial data on the infinity was not needed. Thus the uniform L^∞ estimates and the lower bound of ρ^ε adding the local existence theorem gives the following global existence result.

LEMMA 3.1. *If the initial data satisfy the condition* (3.3), *then for any fixed* $\varepsilon > 0$, *there exists a smooth solution for the Cauchy problem* (3.1), (3.2) *in* $R_T = R \times [0,T]$ *(for arbitrary* T*) which satisfies*

$$0 < c(\varepsilon,t) \le \rho^\varepsilon(x,t) \le C, \qquad |m^\varepsilon(x,t)| \le \rho^\varepsilon(x,t)(C + |\log \rho^\varepsilon(x,t)|), \tag{3.4}$$

where $c(\varepsilon,t)$ *is an appropriate function and* C *depends only on* M.

In order to apply the theory of compensated compactness, it is necessary to prove the divergence of weak entropy-flux pair is in a compact subset of H^{-1} as ε vanishes.

Take the form (η, q) as in (2.8), and let $\xi \in (-1,1)$; we compute

$$\begin{aligned}
\eta_{\rho\rho} &= \frac{\xi^2}{(1-\xi^2)^2}(1 - 2\xi u + u^2)\rho^{\frac{\xi^2}{1-\xi^2}-1} e^{\frac{\xi}{1-\xi^2}u} > 0,\\
\eta_{\rho m} &= \frac{\xi^2}{(1-\xi^2)^2}(\xi - u)\rho^{\frac{\xi^2}{1-\xi^2}-1} e^{\frac{\xi}{1-\xi^2}u},\\
\eta_{mm} &= \frac{\xi^2}{(1-\xi^2)^2}\rho^{\frac{\xi^2}{1-\xi^2}-1} e^{\frac{\xi}{1-\xi^2}u} > 0,
\end{aligned} \tag{3.5}$$

and

$$\eta_{\rho\rho}\eta_{mm} - \eta_{\rho m}^2 = \frac{\xi^4}{(1-\xi^2)^3}\rho^{\frac{2\xi^2}{1-\xi^2}-2} e^{\frac{2\xi}{1-\xi^2}u} > 0, \tag{3.6}$$

which indicates that η is strictly convex for any $\xi \in (-1,1)$. This implies that

$$\eta(\rho^\varepsilon, m^\varepsilon)_t + q(\rho^\varepsilon, m^\varepsilon)_x$$

is compact in H_{loc}^{-1} due to Diperna [9, 10]. Therefore we have the following lemma.

LEMMA 3.2. *Assume that* $(\rho^\varepsilon, m^\varepsilon)$ *are the solutions of* (3.1), (3.2); *then for any* $\xi \in (-1,1)$,

$$\eta_t(\rho^\varepsilon, m^\varepsilon) + q_x(\rho^\varepsilon, m^\varepsilon) \text{ is compact in } H_{loc}^{-1}, \tag{3.7}$$

where (η, q) *is defined as in* (2.8).

4. Convergence of approximate solutions. This section is devoted to the existence of a weak solution of isothermal gas dynamics. Choose $(\rho^\varepsilon, m^\varepsilon)$ as in (3.4); there exists a subsequence of $(\rho^\varepsilon, m^\varepsilon)$ (still denoted by $(\rho^\varepsilon, m^\varepsilon)$) such that, as $\varepsilon \to 0$,

$$\rho^\varepsilon(x,t) \rightharpoonup \rho(x,t), \quad m^\varepsilon(x,t) \rightharpoonup m(x,t) \tag{4.1}$$

in $L^\infty((0,T)\times R)$ weak star for some measurable functions $\rho(x,t), m(x,t)$.

Let us denote $\nu_{x,t}$ to be the Young measure associated to the weak limits (4.1). For any two entropy pairs in (2.8),

$$\eta_1 = w^{\frac{1}{2(1-\xi_1)}} z^{\frac{1}{2(1+\xi_1)}}, \qquad \eta_2 = w^{\frac{1}{2(1-\xi_2)}} z^{\frac{1}{2(1+\xi_2)}},$$
$$q_1 = (u+\xi_1)\eta_1, \qquad q_2 = (u+\xi_2)\eta_2, \qquad \xi_1, \xi_2 \in (-1,1),$$

Lemma 3.2 gives

$$\begin{aligned}\langle \nu_{x,t}, q_1\eta_2 - q_2\eta_1\rangle = {} & \langle \nu_{x,t}, q_1\rangle\langle \nu_{x,t}, \eta_2\rangle \\ & -\langle \nu_{x,t}, q_2\rangle\langle \nu_{x,t}, \eta_1\rangle \quad \text{for almost every} \quad x,t,\end{aligned} \tag{4.2}$$

i.e.,

$$\begin{aligned}(\xi_1-\xi_2)\langle \nu_{x,t}, \eta_1\eta_2\rangle = {} & \langle \nu_{x,t}, (u+\xi_1)\eta_1\rangle\langle \nu_{x,t}, \eta_2\rangle \\ & -\langle \nu_{x,t}, (u+\xi_2)\eta_2\rangle\langle \nu_{x,t}, \eta_1\rangle \quad \text{for almost every} \quad x,t.\end{aligned} \tag{4.3}$$

We shall show that $\nu_{x,t}$ is either a point mass or concentrated in the vacuum. To this end, we show that (4.2) holds for any $\xi_1, \xi_2 \in \mathbf{C}$, except the two points $(-1,0)$ and $(1,0)$, through analytic extension theorem. In other words, we establish the commutation relations for both weak and strong waves.

Since w, z is bounded, it is convenient to study (4.2) in the $w-z$ plane. Let

$$\Omega = \{(w,z); 0 \le w_- \le w \le w_+,\ 0 \le z_- \le z \le z_+\}$$

be the smallest rectangle containing the support of a fixed $\nu_{x,t}$. It is easy to see, if $w_+ = 0$ or $z_+ = 0$, that Ω is supported in the vacuum. So we assume that $w_- < w_+$, $z_- < z_+$ in what follows.

Let $\xi_1 = 1 - \frac{1}{2n}$; then $\eta_1 = \eta_n = w^n z^{\frac{n}{4n-1}}$. From (4.2), we have

$$\langle \nu_{x,t}, q_n\eta - q\eta_n\rangle = \langle \nu_{x,t}, q_n\rangle\langle \nu_{x,t}, \eta\rangle - \langle \nu_{x,t}, q\rangle\langle \nu_{x,t}, \eta_n\rangle. \tag{4.4}$$

We define probability measure μ_z as follows: for any $h \in C_0(R^2)$,

$$\langle \mu_z, h\rangle = \lim_{n\to\infty} \frac{\langle \nu_{x,t}, hw^n z^{\frac{n}{4n-1}}\rangle}{\langle \nu_{x,t}, w^n z^{\frac{n}{4n-1}}\rangle}. \tag{4.5}$$

Similar to [9], it is easy to check that the support of the probability measure μ_z is contained in the line $w = w_+$.

On the other hand, (4.4) yields

$$\frac{\langle \nu_{x,t}, q_n\eta - q\eta_n\rangle}{\langle \nu_{x,t}, \eta_n\rangle} = \frac{\langle \nu_{x,t}, q_n\rangle}{\langle \nu_{x,t}, \eta_n\rangle}\langle \nu_{x,t}, \eta\rangle - \langle \nu_{x,t}, q\rangle. \tag{4.6}$$

Let $n \to \infty$; then we have

$$\langle \mu_z, q - \lambda_2\eta\rangle = \langle \nu_{x,t}, q - \lambda_2^+\eta\rangle, \tag{4.7}$$

where $\lambda_2^+ = \langle \mu_z, \lambda_2 \rangle$ is finite even though $\lambda_2 = u + 1 = \frac{\ln w - \ln z}{2} + 1$ may go to infinity. In fact, since the left term of (4.7) is finite and $\langle \nu_{x,t}, \eta \rangle$ is positive, λ_2^+ must be bounded. In the same way, let $\xi = -1 + \frac{1}{2n}$; then we have

$$\langle \mu_w, q - \lambda_1 \eta \rangle = \langle \nu_{x,t}, q - \lambda_1^+ \eta \rangle, \tag{4.8}$$

with

$$\begin{aligned} &\langle \mu_w, h \rangle = \lim_{n\to\infty} \frac{\langle \nu_{x,t}, h w^{\frac{n}{4n-1}} z^n \rangle}{\langle \nu_{x,t}, w^{\frac{n}{4n-1}} z^n \rangle} \quad \forall h \in C_0(R^2). \\ &\lambda_1^+ = \langle \mu_w, \lambda_1 \rangle. \end{aligned} \tag{4.9}$$

Combining (4.7) and (4.8), we have the following lemma.

LEMMA 4.1. *Let* $\eta = w^{\frac{1}{2(1-\xi)}} z^{\frac{1}{2(1+\xi)}}, q = (u + \xi)\eta, \xi \in (-1, 1)$*; then the following holds:*

$$\begin{aligned} (\lambda_2^+ - \lambda_1^+) \frac{\langle \nu_{x,t}, \eta \rangle}{\eta(w^+, z^+)} &= (1 + \xi) \left\langle \mu_w, \left(\frac{w}{w^+} \right)^{\frac{1}{2(1-\xi)}} \right\rangle \\ &\quad + (1 - \xi) \left\langle \mu_z, \left(\frac{z}{z^+} \right)^{\frac{1}{2(1+\xi)}} \right\rangle. \end{aligned} \tag{4.10}$$

In view of Lemma 4.1, we can prove $\nu_{x,t}(\{\rho > 0\}) = 1$ for almost every x, t. This means that there is no positive mass concentrated in the vacuum for the measure $\nu_{x,t}$. In fact, by the definitions of μ_w and μ_z, it is easy to check that $\mu_w(\{w > 0\}) = \mu_z(\{z > 0\}) = 1$, and thus (4.10) can be rewritten as

$$\begin{aligned} (\lambda_2^+ - \lambda_1^+) \frac{\langle \nu_{x,t}, \eta \rangle}{\eta(w^+, z^+)} &= \left\langle \mu_w, (1 + \xi) \left[\left(\frac{w}{w^+} \right)^{\frac{1}{2(1-\xi)}} - 1 \right] \right\rangle \\ &\quad + \left\langle \mu_z, (1 - \xi) \left[\left(\frac{z}{z^+} \right)^{\frac{1}{2(1+\xi)}} - 1 \right] \right\rangle + 2. \end{aligned} \tag{4.11}$$

Letting $\operatorname{Im} \xi \to \infty$, we get

$$\begin{aligned} (\lambda_2^+ - \lambda_1^+) \nu_{x,t}(\{\rho > 0\}) &= -\frac{1}{2} \left\langle \mu_w, \ln \left(\frac{w}{w^+} \right) \right\rangle - \frac{1}{2} \left\langle \mu_z, \ln \left(\frac{z}{z^+} \right) \right\rangle + 2 \\ &= (\lambda_2^+ - \lambda_1^+) \end{aligned} \tag{4.12}$$

due to $\langle \mu_w, \ln w_+ \rangle = \langle \mu_z, \ln w_+ \rangle = \ln w_+$ and $0 \le \frac{w}{w_+}, \frac{z}{z_+} \le 1$. This implies $\nu_{x,t}(\{\rho > 0\}) = 1$.

Since the functions $\langle \nu_{x,t}, \eta \rangle$, $\langle \mu_w, w^{\frac{1}{2(1-\xi)}} \rangle$, and $\langle \mu_z, z^{\frac{1}{2(1+\xi)}} \rangle$ are analytic in the domain Ω_w and (4.10) holds in the segment $(-1, 1)$, (4.10) must hold for all $\xi \in \Omega_w = \{\xi;\ -1 < \operatorname{Re} \xi < 1\}$ due to analytic extension theorem. We now establish the commutation relations for the whole complex space except the two singular points $(-1, 0)$ and (1,0); i.e., (4.10) holds not only for weak entropies but also for the strong ones.

For any function $h \in C_0(R^2)$, we define a probability measure as follows:

$$\langle \overline{\mu}_z, h \rangle = \lim_{n\to\infty} \frac{\langle \nu_{x,t}, h w^n \rangle}{\langle \nu_{x,t}, w^n \rangle}. \tag{4.13}$$

In the same way as in [9], it is easy to check supp $\overline{\mu}_z \subset \{(w,z); w = w^+\}$. We compute that, for all $h \in C_0(R^2)$,

$$\begin{aligned}\langle \mu_z, h\rangle &= \lim_{n\to\infty} \frac{\langle \nu_{x,t}, hw^n z^{\frac{n}{4n-1}}\rangle}{\langle \nu_{x,t}, w^n\rangle} \lim_{n\to\infty} \frac{\langle \nu_{x,t}, w^n\rangle}{\langle \nu_{x,t}, w^n z^{\frac{n}{4n-1}}\rangle} \\ &= \frac{\langle \overline{\mu}_z, hz^{\frac{1}{4}}\rangle}{\langle \overline{\mu}_z, z^{\frac{1}{4}}\rangle},\end{aligned} \tag{4.14}$$

which implies that $\langle \mu_z, z^{\frac{1}{2(1+\xi)}}\rangle$ is analytic in the domain Re $\frac{1}{2(1+\xi)} > -\frac{1}{4}$. In the same way, $\langle \mu_w, w^{\frac{1}{2(1-\xi)}}\rangle$ is also analytic in the domain Re $\frac{1}{2(1-\xi)} > -\frac{1}{4}$. Thus, the right term of (4.10) is analytic in the domain $\Omega_0 = \{\xi \in \mathbf{C}; \mathrm{Re}\frac{1}{2(1+\xi)} > -\frac{1}{4}, \quad \mathrm{Re}\frac{1}{2(1-\xi)} > -\frac{1}{4}\}$. Next we show that (4.10) holds for any $\xi \in \bar{\Omega}_0 = \{\xi \in \mathbf{C}; |\xi| > 3\} \subset \Omega_0$ by the analytic extension theorem. Since $\eta = w^{\frac{1}{2(1-\xi)}} z^{\frac{1}{2(1+\xi)}}$ may be unbounded in $\bar{\Omega}_0$, it is necessary to show that $\langle \nu_{x,t}, \eta\rangle$ is well defined for any $\xi \in \bar{\Omega}_0$.

We compute

$$\begin{aligned} f(\xi; w, z) &= \left(\frac{w}{w_+}\right)^{\frac{1}{2(1-\xi)}} \left(\frac{z}{z_+}\right)^{\frac{1}{2(1+\xi)}} + \left(\frac{w}{w_+}\right)^{\frac{1}{2(1+\xi)}} \left(\frac{z}{z_+}\right)^{\frac{1}{2(1-\xi)}} \\ &= \mathrm{e}^{\frac{\ln\frac{w}{w_+}+\ln\frac{z}{z_+}}{2(1-\xi^2)}} \left[\mathrm{e}^{\frac{(\ln\frac{w}{w_+}-\ln\frac{z}{z_+})\xi}{2(1-\xi^2)}} + \mathrm{e}^{\frac{-(\ln\frac{w}{w_+}-\ln\frac{z}{z_+})\xi}{2(1-\xi^2)}}\right] \\ &= 2\left\{1 + \sum_{k=1}^{\infty} \frac{\left(-\ln\frac{w}{w_+} - \ln\frac{z}{z_+}\right)^k}{2^k k!} \left(\frac{\frac{1}{\xi^2}}{1-\frac{1}{\xi^2}}\right)^k\right\} \\ &\quad \times \left\{1 + \sum_{j=1}^{\infty} \frac{\left(\ln\frac{w}{w_+} - \ln\frac{z}{z_+}\right)^{2j}}{4^j (2j)!} \left(\frac{\frac{1}{\xi}}{1-\frac{1}{\xi^2}}\right)^{2j}\right\} \\ &= 2\left\{1 + \sum_{m=1}^{\infty} \left[\sum_{k=1}^{m} \frac{\left(-\ln\frac{w}{w_+} - \ln\frac{z}{z_+}\right)^k}{2^k k!} \binom{m-1}{k-1}\right] \frac{1}{\xi^{2m}}\right\} \\ &\quad \times \left\{1 + \sum_{l=1}^{\infty} \left[\sum_{j=1}^{l} \frac{\left(\ln\frac{w}{w_+} - \ln\frac{z}{z_+}\right)^{2j}}{4^j (2j)!} \binom{l+j-1}{2j-1}\right] \frac{1}{\xi^{2l}}\right\} \\ &= \sum_{p=0}^{\infty} \frac{c_{2p}(w,z)}{\xi^{2p}}. \end{aligned} \tag{4.15}$$

It is observed that $\ln\frac{w}{w_+} + \ln\frac{z}{z_+} \le 0$, we have $c_{2p}(w,z) \ge 0$ in supp $\nu_{x,t}$.

From (4.10), we have

$$
\begin{aligned}
(\lambda_2^+ - \lambda_1^+)\langle \nu_{x,t}, f(\xi; w, z)\rangle &= \langle \mu_w, f(\xi; w, z)\rangle + \langle \mu_z, f(\xi; w, z)\rangle \\
&\quad + \left\langle \mu_w, \xi \left[\left(\frac{w}{w_+}\right)^{\frac{1}{2(1-\xi)}} - \left(\frac{w}{w_+}\right)^{\frac{1}{2(1+\xi)}} \right] \right\rangle \\
&\quad + \left\langle \mu_z, \xi \left[\left(\frac{z}{z_+}\right)^{\frac{1}{2(1-\xi)}} - \left(\frac{z}{z_+}\right)^{\frac{1}{2(1+\xi)}} \right] \right\rangle .
\end{aligned} \tag{4.16}
$$

Similar to (4.15), we expand the last two terms of (4.16) to the Laurent series. We compute

$$
\begin{aligned}
g(\xi; w) &= \xi \left[\left(\frac{w}{w_+}\right)^{\frac{1}{2(1-\xi)}} - \left(\frac{w}{w_+}\right)^{\frac{1}{2(1+\xi)}} \right] \\
&= \xi \left[\mathrm{e}^{\frac{\ln \frac{w}{w_+}}{2(1-\xi^2)}} \left(\mathrm{e}^{\frac{\xi \ln \frac{w}{w_+}}{2(1-\xi^2)}} - \mathrm{e}^{\frac{-\xi \ln \frac{w}{w_+}}{2(1-\xi^2)}} \right) \right] \\
&= \left\{ 1 + \sum_{m=1}^{\infty} \left[\sum_{k=1}^{m} \frac{\left(-\ln \frac{w}{w_+}\right)^k}{2^k k!} \begin{pmatrix} m-1 \\ k-1 \end{pmatrix} \right] \frac{1}{\xi^{2m}} \right\} \\
&\quad \times \left\{ \sum_{l=0}^{\infty} \left[\sum_{j=0}^{l} \frac{-\left(\ln \frac{w}{w_+}\right)^{2j+1}}{4^j (2j+1)!} \begin{pmatrix} l+j \\ 2j \end{pmatrix} \right] \frac{1}{\xi^{2l}} \right\} \\
&= \sum_{p=0}^{\infty} \frac{h_{2p}(\frac{w}{w_+})}{\xi^{2p}}.
\end{aligned} \tag{4.17}
$$

It is obvious that $h_{2p}(\frac{w}{w_+}) \geq 0$. We note that $\langle \mu_w, f(\xi; w, z)\rangle$, $\langle \mu_w, g(\xi; w)\rangle$, $\langle \mu_z, g(\xi; z)\rangle$, and $\langle \mu_z, f(\xi; w, z)\rangle$ are analytic in Ω_0 due to (4.14). Thus $\langle \mu_w, c_{2p}(w, z)\rangle$, $\langle \mu_w, h_{2p}(\frac{w}{w_+})\rangle$, $\langle \mu_z, h_{2p}(\frac{z}{z_+})\rangle$, and $\langle \mu_z, c_{2p}(w, z)\rangle$ are bounded. Now we choose $\xi \in R$ and $|\xi| > 3$; then Levi's lemma gives

$$
\begin{aligned}
\langle \mu_w, f(\xi; w, z)\rangle &= \sum_{p=0}^{\infty} \frac{\langle \mu_w, c_{2p}(w, z)\rangle}{\xi^{2p}}, \\
\langle \mu_z, f(\xi; w, z)\rangle &= \sum_{p=0}^{\infty} \frac{\langle \mu_z, c_{2p}(w, z)\rangle}{\xi^{2p}}, \\
\langle \mu_w, g(\xi; w)\rangle &= \sum_{p=0}^{\infty} \frac{\langle \mu_w, h_{2p}(\frac{w}{w_+})\rangle}{\xi^{2p}}, \\
\langle \mu_z, g(\xi; z)\rangle &= \sum_{p=0}^{\infty} \frac{\langle \mu_z, h_{2p}(\frac{z}{z_+})\rangle}{\xi^{2p}}
\end{aligned} \tag{4.18}
$$

due to the fact that $c_{2p}(w,z), h_{2p}(\frac{w}{w_+}), h_{2p}(\frac{z}{z_+}) \geq 0$. This yields that

$$\sum_{p=0}^{\infty} \frac{\langle \mu_w, c_{2p}(w,z)\rangle}{\xi^{2p}} \tag{4.19}$$

is absolutely convergent for any $\xi \in \bar{\Omega}_0$ because $\langle \mu_w, f(\xi; w, z)\rangle$ is analytic in $\bar{\Omega}_0$. In the same way,

$$\sum_{p=0}^{\infty} \frac{\langle \mu_z, c_{2p}(w,z)\rangle}{\xi^{2p}}, \quad \sum_{p=0}^{\infty} \frac{\langle \mu_w, h_{2p}(\frac{w}{w_+})\rangle}{\xi^{2p}}, \quad \text{and} \quad \sum_{p=0}^{\infty} \frac{\langle \mu_z, h_{2p}(\frac{z}{z_+})\rangle}{\xi^{2p}} \tag{4.20}$$

are also convergent in $\bar{\Omega}_0$.

Thus, from (4.10) and (4.16)–(4.20), we have

$$\begin{aligned}(\lambda_2^+ - \lambda_1^+)\langle \nu_{x,t}, f(\xi; w, z)\rangle = &\sum_{p=0}^{\infty} \frac{\langle \mu_w, c_{2p}(w,z) + h_{2p}(\frac{w}{w_+})\rangle}{\xi^{2p}} \\ &+ \sum_{p=0}^{\infty} \frac{\langle \mu_z, c_{2p}(w,z) + h_{2p}(\frac{z}{z_+})\rangle}{\xi^{2p}}\end{aligned} \tag{4.21}$$

if $\xi \in \Omega_w$. We define

$$\begin{aligned}g_p^{(n)}(w,z) &= (-1)^p n^{2p}\left(f(ni; w, z) - \sum_{s=0}^{p-1}(-1)^s \frac{c_{2s}(w,z)}{n^{2s}}\right), \\ &= \sum_{s=p}^{\infty}(-1)^{p+s}\frac{c_{2s}(w,z)}{n^{2(s-p)}}, \qquad p = 1, 2, \ldots .\end{aligned} \tag{4.22}$$

It is easy to see that $g_p^{(n)}(w,z) \geq 0$, and it converges to $c_{2p}(w,z)$ for almost every $\nu_{x,t}$ as $n \to \infty$. We note that $c_0(w,z) = 2$, and $\langle \nu_{x,t}, c_0(w,z)\rangle$ is well defined. Furthermore, direct computation yields

$$\begin{aligned}&(\lambda_2^+ - \lambda_1^+)\langle \nu_{x,t}, c_0(w,z)\rangle \\ &= \langle \mu_w, c_0(w,z) + h_0(\tfrac{w}{w_+})\rangle + \langle \mu_z, c_0(w,z) + h_0(\tfrac{z}{z_+})\rangle.\end{aligned} \tag{4.23}$$

Now we assume that $\langle \nu_{x,t}, c_{2s}(w,z)\rangle$ are well defined and

$$\begin{aligned}&(\lambda_2^+ - \lambda_1^+)\langle \nu_{x,t}, c_{2s}(w,z)\rangle \\ &= \left\langle \mu_w, c_{2s}(w,z) + h_{2s}\left(\frac{w}{w_+}\right)\right\rangle \\ &\quad + \left\langle \mu_z, c_{2s}(w,z) + h_{2s}\left(\frac{z}{z_+}\right)\right\rangle\end{aligned} \tag{4.24}$$

for $s = 0, 1, \ldots, p-1$. We shall show $\langle \nu_{x,t}, c_{2p}(w,z)\rangle$ is also well defined and (4.24) holds for $s = p$.

From (4.21), (4.22), and (4.24), it is easy to check that $\lim_{n\to\infty}\langle \nu_{x,t}, g_p^{(n)}(w,z)\rangle$ exists. By Fatou's lemma, we have

$$\langle \nu_{x,t}, c_{2p}(w,z)\rangle \leq \lim_{n\to\infty}\langle \nu_{x,t}, g_p^{(n)}(w,z)\rangle, \tag{4.25}$$

which, together with (4.24), implies

$$\begin{aligned}&(\lambda_2^+ - \lambda_1^+)\langle \nu_{x,t}, c_{2p}(w,z)\rangle \\ &\le \left\langle \mu_w, c_{2p}(w,z) + h_{2p}\left(\frac{w}{w_+}\right)\right\rangle + \left\langle \mu_z, c_{2p}(w,z) + h_{2p}\left(\frac{z}{z_+}\right)\right\rangle.\end{aligned} \tag{4.26}$$

To prove (4.24) for $s = p$, we use the way of contradiction. We assume that

$$\begin{aligned}&(\lambda_2^+ - \lambda_1^+)\langle \nu_{x,t}, c_{2p}(w,z)\rangle \\ &< \left\langle \mu_w, c_{2p}(w,z) + h_{2p}\left(\frac{w}{w_+}\right)\right\rangle + \left\langle \mu_z, c_{2p}(w,z) + h_{2p}\left(\frac{z}{z_+}\right)\right\rangle.\end{aligned} \tag{4.27}$$

It is observed that

$$g_p^{(n)}(w,z) = c_{2p}(w,z) - \frac{1}{n^2} g_{p+1}^{(n)}(w,z). \tag{4.28}$$

Thus, we have

$$\begin{aligned}&(\lambda_2^+ - \lambda_1^+)\left\langle \nu_{x,t}, \frac{1}{n^2} g_{p+1}^{(n)}(w,z)\right\rangle \\ &= (\lambda_2^+ - \lambda_1^+)\langle \nu_{x,t}, c_{2p}(w,z)\rangle - \left\langle \mu_w, c_{2p}(w,z) + h_{2p}\left(\frac{w}{w_+}\right)\right\rangle \\ &\quad - \left\langle \mu_z, c_{2p}(w,z) + h_{2p}\left(\frac{z}{z_+}\right)\right\rangle \\ &\quad + \sum_{s=p+1}^{\infty} (-1)^{p+s+1} \frac{\langle \mu_w, c_{2s}(w,z) + h_{2s}(\frac{w}{w_+})\rangle}{\xi^{2(s-p)}} \\ &\quad + \sum_{s=p+1}^{\infty} (-1)^{p+s+1} \frac{\langle \mu_z, c_{2s}(w,z) + h_{2s}(\frac{z}{z_+})\rangle}{\xi^{2(s-p)}},\end{aligned} \tag{4.29}$$

which yields $\lim_{n\to\infty}\langle \nu_{x,t}, \frac{1}{n^2} g_{p+1}^{(n)}(w,z)\rangle < 0$. This contradicts the fact that $g_{p+1}^{(n)}(w,z) > 0$.

By the induction principle, $\langle \nu_{x,t}, c_{2p}(w,z)\rangle$ are well defined and (4.24) holds for all $p = 0, 1, \ldots$. Therefore the Laurent series

$$\sum_{p=0}^{\infty} \frac{\langle \nu_{x,t}, c_{2p}(w,z)\rangle}{\xi^{2p}} \tag{4.30}$$

is convergent for any $\xi \in \bar{\Omega}_0$.

Now we construct a sequence of $\nu_{x,t}$-measurable functions

$$f_m(\xi; w, z) = \sum_{p=0}^{m} \frac{c_{2p}(w,z)}{\xi^{2p}} \tag{4.31}$$

which converges to $f(\xi; w, z)$ in $\{w > 0, z > 0\}$. Since

$$\langle \nu_{x,t}, |f_m(\xi; w, z)|\rangle \le \sum_{p=0}^{\infty} \frac{\langle \nu_{x,t}, c_{2p}(w,z)\rangle}{|\xi|^{2p}} < \infty \tag{4.32}$$

for $\xi \in \bar{\Omega}_0$, again using Fatou's lemma, we have $f(\xi; w, z) \in \mathbf{L}(d\nu_{x,t})$ if $\xi \in \bar{\Omega}_0$. In particular, $w^{-\alpha} z^{\frac{\alpha}{4\alpha+1}} + z^{-\alpha} w^{\frac{\alpha}{4\alpha+1}} \in \mathbf{L}(d\nu_{x,t})$ for any $0 < \alpha < \frac{1}{4}$. Therefore, again using the analytic extension theorem, (4.10) holds in the domain $\bar{\Omega}_0$. We note that η is exactly a strong entropy if $\xi \in \bar{\Omega}_0/\Omega_w$; thus we establish (4.10) for some strong entropies.

Choosing any constant $\alpha \in (0, \frac{1}{4})$, we define a probability measure μ_{1z} like (4.13); i.e., for any $h \in C_0(R^2)$,

$$\langle \mu_{1z}, h\rangle = \lim_{n\to\infty} \frac{\langle \nu_{x,t}, h w^n z^{-\alpha}\rangle}{\langle \nu_{x,t}, w^n z^{-\alpha}\rangle}. \tag{4.33}$$

We compute

$$\begin{aligned} \langle \mu_z, h\rangle &= \lim_{n\to\infty} \frac{\langle \nu_{x,t}, h w^n z^{\frac{n}{4n-1}}\rangle}{\langle \nu_{x,t}, w^n z^{-\alpha}\rangle} \lim_{n\to\infty} \frac{\langle \nu_{x,t}, w^n z^{-\alpha}\rangle}{\langle \nu_{x,t}, w^n z^{\frac{n}{4n-1}}\rangle} \\ &= \frac{\langle \mu_{1z}, h z^{\frac{1}{4}+\alpha}\rangle}{\langle \mu_{1z}, z^{\frac{1}{4}+\alpha}\rangle}. \end{aligned} \tag{4.34}$$

In terms of previous argument, we have (4.10) for any $\xi \in \bar{\Omega}_1 = \{\xi \in \mathbf{C}; |\xi| > \frac{2}{1+4\alpha} + 1\} \subset \Omega_1 = \{\xi \in \mathbf{C}; \mathrm{Re}\frac{1}{2(1+\xi)} > -\frac{1}{4} - \alpha \quad \text{and} \quad \mathrm{Re}\frac{1}{2(1-\xi)} > -\frac{1}{4} - \alpha\}$. Thus, repeating the above arguments, we can establish (4.10) for any $\xi \in \bar{\Omega}_k = \{\xi \in \mathbf{C}; |\xi| > \frac{2}{1+4k\alpha} + 1\} \subset \Omega_k = \{\xi \in \mathbf{C}; \mathrm{Re}\frac{1}{2(1+\xi)} > -\frac{1}{4} - k\alpha \quad \text{and} \quad \mathrm{Re}\frac{1}{2(1-\xi)} > -\frac{1}{4} - k\alpha\}$, where k is an arbitrary positive integer. Therefore we have the following lemma.

LEMMA 4.2. *For any $\xi_1, \xi_2 \in C/\{(-1,0),(0,1)\}$, the following holds:*

$$\begin{aligned} \langle \nu_{x,t}, q_1\eta_2 - q_2\eta_1\rangle = &\langle \nu_{x,t}, q_1\rangle\langle \nu_{x,t}, \eta_2\rangle \\ &-\langle \nu_{x,t}, q_2\rangle\langle \nu_{x,t}, \eta_1\rangle \quad \textit{for almost every} \quad x, t, \end{aligned} \tag{4.35}$$

where $\eta_i, q_i, i = 1, 2$, are chosen as in (2.8).

Remark 4.3. Lemma 4.2 indicates that the Tartar commutation relations hold for both weak and strong waves chosen in (2.8).

Proof of Theorem 1.4. To prove Theorem 1.4, it is sufficient to show that $\nu_{x,t}$ is a point mass.

Let $\xi_1 = 1 - \frac{1}{2n}$ and $\xi_2 = 1 + \frac{1}{2n}$ in (4.35). We then have

$$\frac{\langle \nu_{x,t}, q(\xi_1)\eta(\xi_2) - q(\xi_2)\eta(\xi_1)\rangle}{\langle \nu_{x,t}, \eta(\xi_1)\rangle\langle \nu_{x,t}, \eta(\xi_2)\rangle} = \frac{\langle \nu_{x,t}, q(\xi_1)\rangle}{\langle \nu_{x,t}, \eta(\xi_1)\rangle} - \frac{\langle \nu_{x,t}, q(\xi_2)\rangle}{\langle \nu_{x,t}, \eta(\xi_2)\rangle}. \tag{4.36}$$

Letting $n \to \infty$ gives

$$\lim_{n\to\infty} \frac{\langle \nu_{x,t}, q(\xi_2)\rangle}{\langle \nu_{x,t}, \eta(\xi_2)\rangle} = \lambda_2^+. \tag{4.37}$$

On the other hand, let $\xi \in \Omega_w, \xi_2 = 1 + \frac{1}{2n}$ in (4.35). Similar to (4.6) and (4.7), we have, as $n \to \infty$,

$$\langle \mu_{-z}, q - \lambda_2\eta\rangle = \langle \nu_{x,t}, q - \lambda_2^+\eta\rangle, \tag{4.38}$$

due to (4.37), where the probability measure μ_{-z} is defined for any $h \in C_0(R^2)$, by

$$\langle \mu_{-z}, h\rangle = \lim_{n\to\infty} \frac{\langle \nu_{x,t}, h w^{-n} z^{\frac{n}{4n+1}}\rangle}{\langle \nu_{x,t}, w^{-n} z^{\frac{n}{4n+1}}\rangle}. \tag{4.39}$$

It is easy to see that the support of the measure μ^{-z} is contained in the line $\{w = w_-\}$.

By (4.7) and (4.38), we have

$$\langle \mu_z, q - \lambda_2 \eta \rangle = \langle \mu_{-z}, q - \lambda_2 \eta \rangle \tag{4.40}$$

for any $\xi \in \Omega_w$.

Let $\eta = w^n z^{\frac{n}{4n-1}}, q = (u + 1 - \frac{1}{2n})\eta$. We then compute

$$w_+^n \langle \mu_z, z^{\frac{n}{4n-1}} \rangle = w_-^n \langle \mu_{-z}, z^{\frac{n}{4n-1}} \rangle, \tag{4.41}$$

which implies $w_- = w_+$ as $n \to \infty$. In the same way, we also have $z_- = z_+$. Thus $\nu_{x,t}$ is either a point mass or supported in the vacuum. This indicates Theorem 1.4 due to the standard theory of compensated compactness.

Proof of Theorem 1.2. Choose $(\rho^\varepsilon, m^\varepsilon)$ as in (3.4); then Lemma 3.1 gives, for any test function $\phi \in C_0^\infty(R_+^2)$,

(4.42)

$$\iint_{t>0} (\rho^\varepsilon \phi_t + m^\varepsilon \phi_x)\, dxdt + \int_R \rho_0^\varepsilon(x)\phi(x,0)\, dx = -\iint_{t>0} \varepsilon \rho^\varepsilon \phi_{xx} dxdt,$$

$$\iint_{t>0} m^\varepsilon \phi_t + \left(\frac{(m^\varepsilon)^2}{\rho^\varepsilon} + \rho^\varepsilon \right) \phi_x\, dxdt + \int_R m_0^\varepsilon(x)\phi(x,0)\, dx = -\iint_{t>0} \varepsilon m^\varepsilon \phi_{xx} dxdt.$$

By Theorem 1.4, there exists a strong convergent subsequence of $(\rho^\varepsilon, m^\varepsilon)$ (still denoted by $(\rho^\varepsilon, m^\varepsilon)$) such that

$$(\rho^\varepsilon(x,t), m^\varepsilon(x,t)) \to (\rho(x,t), m(x,t)) \quad \text{a.e.} \tag{4.43}$$

Letting $\varepsilon \to 0$, (1.4) holds from (4.42). Thus $(\rho(x,t), m(x,t))$ is a weak solution of (1.1) and (1.3) with $\gamma = 1$. Since $(\rho(x,t), m(x,t))$ is the limit of the viscosity solutions $(\rho^\varepsilon, m^\varepsilon)$, it is easy to check that (1.5) holds for any weak convex entropy. Therefore we complete the proof of Theorem 1.2.

Acknowledgments. The authors wish to thank Prof. Xiaqi Ding for kindly suggesting this problem. The authors are also very grateful to Prof. Guiqiang Chen for kindly pointing out a gap in our first proofs. Finally, the first author wishes to thank Prof. Alberto Bressan for his kind hospitality.

ON A FREE BOUNDARY PROBLEM FOR A STRONGLY DEGENERATE QUASI-LINEAR PARABOLIC EQUATION WITH AN APPLICATION TO A MODEL OF PRESSURE FILTRATION*

RAIMUND BÜRGER†, HERMANO FRID‡, AND KENNETH H. KARLSEN§

Abstract. We consider a free boundary problem of a quasi-linear strongly degenerate parabolic equation arising from a model of pressure filtration of flocculated suspensions. We provide definitions of generalized solutions of the free boundary problem in the framework of L^2 divergence-measure fields. The formulation of boundary conditions is based on a Gauss–Green theorem for divergence-measure fields on bounded domains with Lipschitz deformable boundaries and avoids referring to traces of the solution. This allows one to consider generalized solutions from a larger class than BV. Thus it is not necessary to derive the usual uniform estimates of spatial *and* time derivatives of the solutions of the corresponding regularized problem, as required by the BV approach. We first prove the existence and uniqueness of the solution of the regularized parabolic free boundary problem and then apply the vanishing viscosity method to prove the existence of a generalized solution to the degenerate free boundary problem.

Key words. free boundary problem, strongly degenerate parabolic equation, divergence-measure field, pressure filtration

1. Introduction.

Conventional analyses of initial-boundary value problems of strongly degenerate parabolic equations, which includes first-order conservation laws, are usually based on the concept of generalized solutions in $BV(Q_T)$, where $Q_T := \Omega \times [0,T]$, $\Omega \subset \mathbb{R}$, is the computational domain (for simplicity, assumed to be cylindrical here) [2, 4, 5, 25, 26, 27]. To prove that a generalized solution u of a conservation law or of a strongly degenerate parabolic equation belongs to $BV(Q_T)$, it is necessary to derive estimates of $\|\partial_x u_\varepsilon\|_{L^1(Q_T)}$ and $\|\partial_t u_\varepsilon\|_{L^1(Q_T)}$ which are uniform with respect to the regularization parameter ε, where u_ε denotes the smooth solution of the corresponding regularized initial-boundary value problem. These estimates (and a uniform L^∞ bound on u_ε) imply that the family $\{u_\varepsilon\}_{\varepsilon>0}$ is compact in $L^1(Q_T)$; i.e., there exists a sequence $\varepsilon = \varepsilon_n$ with $\varepsilon_n \to 0$ for $n \to \infty$ such that $\{u^{\varepsilon_n}\}$ converges in $L^1(Q_T)$ to a limit $u \in L^\infty(Q_T) \cap BV(Q_T)$. It is usually straightforward to verify that this limit is indeed a generalized solution.

The importance of the choice of the space $BV(Q_T)$ lies in the existence of traces of the limit function u with respect to the lateral boundaries of Q_T. This well-known property of BV functions is stated, e.g., in [11, sect. 5.32, Thm. 1]. As has become

apparent in [4], traces are needed in the proof of uniqueness of generalized solutions.

For several reasons, the BV approach unfortunately imposes some severe limitations on the analysis of initial-boundary value problems of hyperbolic and strongly degenerate parabolic equations. The most obvious one is the apparent difficulty in actually deriving the required uniform estimates of $\|\partial_x u_\varepsilon\|_{L^1(Q_T)}$ and $\|\partial_t u_\varepsilon\|_{L^1(Q_T)}$. This worked out, e.g., for the spatially one-dimensional problems analyzed in [4]. However, for only marginally more involved equations (but still in one space dimension), and in particular for different boundary conditions, it seems no longer possible to derive a uniform estimate of $\|\partial_t u_\varepsilon\|_{L^1(Q_T)}$. An example of such an initial-boundary problem is given in [24]. When passing to several space dimensions, i.e., to equations of the type

$$\partial_t u + \nabla_{\mathbf{x}} \cdot \mathbf{f}(u) = \Delta A(u), \quad (\mathbf{x}, t) \in Q_T := \Omega \times [0, T], \quad \Omega \subset \mathbb{R}^n, \tag{1.1}$$

together with initial and boundary conditions and where the function $A(u)$ is nonnegative, increasing, and Lipschitz continuous, it seems virtually impossible to derive the required uniform estimates, where the estimate on the spatial derivative has to be replaced, of course, by a uniform estimate of $\|\nabla_{\mathbf{x}} u_\varepsilon\|_{L^1(Q_T)}$.

In the cases where only a uniform estimate of $\|\nabla_{\mathbf{x}} u_\varepsilon\|_{L^1(Q_T)}$ (but not of the time derivative) is feasible, one can utilize Kružkov's "interpolation lemma" [14, Lem. 5] in order to conclude that the sequence u_ε converges to a limit function u belonging to the wider class $BV_{1,1/2}(Q_T) \supset BV(Q_T)$. This means that there exists a constant K such that

$$\iint_{Q_T} \big|u(\mathbf{x} + \Delta\mathbf{x}, t) - u(\mathbf{x}, t)\big| d\mathbf{x}dt \le K|\Delta\mathbf{x}|,$$
$$\iint_{Q_T} \big|u(\mathbf{x}, t + \Delta t) - u(\mathbf{x}, t)\big| d\mathbf{x}dt \le K|\Delta t|^{1/2}.$$

Note that the $BV_{1,1/2}$ estimates of $\{u_\varepsilon\}$ are entirely sufficient to apply Kolmogorov's compactness criterion in order to show existence of a limit function. The problem is with boundary conditions and uniqueness, since it is not ensured that a function $u \in BV_{1,1/2}(Q_T)$ possesses traces at the boundaries of Q_T, such that boundary conditions need to be defined in a fashion that avoids these traces; however, it is then not obvious how to prove uniqueness.

Another general limitation of the BV approach has become apparent in [4] and is due to the restriction that the initial datum u_0 of that paper belongs to the class

$$\mathcal{B} := \Big\{ u \in BV(\Omega) : \ u(x) \in \mathcal{U}_0 \ \forall x \in \overline{\Omega};\ \mathrm{TV}_\Omega(\partial_x A_\varepsilon(u)) < M_0 \text{ uniformly in } \varepsilon \Big\},$$

where $A'_\varepsilon(u) = a_\varepsilon(u)$ and a_ε is an appropriately regularized, positive diffusion coefficient. The condition $u_0 \in \mathcal{B}$ is required to ensure that $\|\partial_t u_\varepsilon(\cdot, t)\|_{L^1(\Omega)}$ or $\|\partial_t u_\varepsilon\|_{L^1(Q_T)}$ remain uniformly bounded. For a given, in general discontinuous function u_0, membership in $\mathcal{B}$ is difficult to verify due to the discontinuity of the diffusion coefficient $a(u)$, so $\mathcal{B}$ denotes a possibly very narrow class.

The mentioned difficulties associated with the BV approach make it desirable to consider generalized solutions from a wider class. This wider class is associated here with the notion of divergence-measure fields, which is a class of vector fields that was first considered by Anzellotti [1]. This paper is based on the recent formulation by Chen and Frid [9].

The main idea is to replace the requirement $u \in L^\infty(Q) \cap BV(Q)$, where we consider $Q \subset \mathbb{R}^N$ and which can be expressed as

$$\|u\|_{BV(Q)} < \infty, \quad \|u\|_{BV(Q)} := \sup\left\{ \int_Q u \nabla \cdot \varphi \, d\mathbf{x} : \varphi \in \left(C_0^1(Q)\right)^N, \ \|\varphi\|_{L^\infty(Q)} \le 1 \right\},$$

by the requirement that a vector field $F \in L^p(Q, \mathbb{R}^N)$ associated with the sought solution u satisfy

$$|\operatorname{div} F|(Q) < \infty, \quad |\operatorname{div} F|(Q) := \sup\left\{ \int_Q F \cdot \nabla \varphi \, d\mathbf{x} : \varphi \in C_0^1(Q; \mathbb{R}), \ \|\varphi\|_{L^\infty(Q)} < 1 \right\}.$$

We define the class of L^p divergence-measure vector fields over Q by

$$\mathcal{DM}^p(Q) := \left\{ F \in L^p(Q; \mathbb{R}^N) : \ |\operatorname{div} F|(Q) < \infty \right\}.$$

We see that if $F \in \mathcal{DM}^p(Q)$, then $\operatorname{div} F$ is a Radon measure over Q. If we assume that the components of F are Lipschitz continuous functions of u, as in the application to conservation laws (see below), then it becomes clear that $u \in L^\infty(Q) \cap BV(Q)$ implies $F \in \mathcal{DM}^\infty(Q)$.

Properties of divergence-measure fields for the case $p = \infty$ are derived by Chen and Frid in [9]. Most important, it is possible to prove a generalized Gauss–Green formula for divergence-measure fields in bounded domains using the concept of domains with deformable Lipschitz boundaries, which allows the definition of traces. For the case of scalar conservation laws, the importance of divergence-measure fields accrues from the fact that any convex entropy pair actually forms an L^∞ divergence-measure field over $Q \subset \mathbb{R}^N$ if we consider a bounded spatial domain $\Omega \subset \mathbb{R}^{N-1}$. Utilizing the Gauss–Green formula, Chen and Frid [9] provide an appropriate formulation for L^∞ (not BV) solutions of conservation laws with boundary conditions. They are able to derive a formulation of an entropy boundary condition which was proposed previously by Otto [17, 19, 20, 21] by advancing the concept of entropy boundary fluxes.

Most properties of L^p, $p = \infty$, divergence-measure fields derived in [9] also hold for $1 \le p < \infty$, as is detailed in [10]. The case $p = 2$ is of particular interest for the analysis of degenerate parabolic equations, since in light of standard a priori estimates, it is possible to show that the appropriately defined entropy pair of a strongly degenerate parabolic equation is an L^2 divergence-measure field over $Q_T \subset \mathbb{R}^{N-1} \times [0, T]$. (More general domains can be considered, but we may limit the discussion here to cylindrical domains.) This was first exploited in a recent paper by Mascia, Porretta, and Terracina [18], who proved existence and uniqueness of L^∞ solutions to nonhomogeneous Dirichlet initial-boundary value problems of (1.1), which in particular includes entropy boundary conditions.

In [6] entropy boundary conditions for strongly degenerate parabolic equations in the context of an application to sedimentation with compression are derived. However, the definition of traces of the solution with respect to the lateral boundary of the computational domain is only possible if the diffusion coefficient $a(u)$ is, for example, Lipschitz continuous. This assumption does not hold for the cases we are interested in here. Moreover, although Dirichlet boundary conditions in the context of solid-liquid separation models lead to mathematically well-posed initial-boundary value problems, their physical significance is questionable due to violation of a conservation principle. Rather, kinematic "flux-type" or "wall" boundary conditions (such as that

of Problem B of [4]) should be employed. In fact, it turned out that these boundary conditions are satisfied in an a.e. pointwise sense on the lateral boundaries of Q_T, that is, in a much stronger sense than are entropy boundary conditions, although they also involve the concept of traces.

The above discussion motivates our interest in applying the recently developed divergence-measure theory to initial-boundary value problems of strongly degenerate parabolic equations. We could now treat again the initial-boundary value problems studied, e.g., in [4] in an appropriate divergence-measure framework and obtain an existence and uniqueness result. However, since the BV calculus is indeed applicable to those problems, the chief gain in using the more general divergence-measure concept would merely consist of the relaxation of the condition $u_0 \in \mathcal{B}$. Instead, the theory of L^2 divergence-measure fields is applied here to a free boundary problem, which is a slight modification of a model of pressure filtration presented in [3]. The problem is still one-dimensional, and its boundary conditions are of "flux-type," similar to those of [4]. Since the flux contains the derivative of the degenerate parabolic term which is only bounded in L^2, we cannot consider strong traces for this term. Moreover, there is reason to believe that the mentioned BV estimate of $\partial_t u_\varepsilon$ cannot be derived. This conjecture is based on the observation that in many other analyses it was necessary to differentiate the corresponding regularized viscous equation with respect to t, to multiply it with a suitable sign-type function, and to use integration by parts. The problem with the filtration problem is the occurrence of the derivative (with respect to t) of the free boundary as a coefficient in the equation, such that differentiating the entire equation with respect to t would entail the necessity to estimate $h''(t)$. Due to the coupling condition with the solution evaluated at one of the boundaries, however, we have no control over this quantity. This seems to preclude the necessary uniform estimate of $\partial_t u$.

The remainder of this paper is organized as follows. In section 2 we briefly recall the mathematical model of pressure filtration, state the free boundary problem, and provide a brief definition of L^2 divergence-measure fields together with the properties relevant for the subsequent analysis. In section 3 generalized solutions of the free boundary problem are defined, where an equivalent problem transformed to fixed boundaries is also considered. In section 4 we state the corresponding regularized viscous free boundary problems and show that they have a unique solution for fixed values of the regularization parameter. Finally we conclude in section 5 by the viscosity method that there exists a generalized solution to the free boundary problem in the sense of section 3.

The analysis of the free boundary problem has not yet been completed, since a uniqueness proof is still lacking. It is, however, not obvious, for instance, how the uniqueness proof for a comparable free boundary problem by Zhao and Li [28], which is based on establishing a fixed boundary initial-boundary value problem for a suitably complemented generalized solution of the free boundary problem, can be extended to the free boundary problem studied in this paper.

2. Statement of the problem and preliminaries.

2.1. Pressure filtration of flocculated suspensions. To motivate the free boundary problem, we briefly recall the one-dimensional mathematical model of pressure filtration formulated in [3]. We consider a filter column closed at height $z = 0$ by a filter medium, which lets only the liquid pass, and at a variable height $z = h(t)$ by a piston which moves downwards due to an applied pressure $\sigma(t)$. The material behavior of the suspension is described by two model functions, the flux density function

or hindered settling factor f and the effective solid stress function σ_e, both functions only of the local solids concentration u. Here f is a nonpositive Lipschitz continuous function with compact support in $[0, u_{\max}]$, where $u_{\max} \le 1$ is the maximum concentration, and the function σ_e satisfies $\sigma_e = 0$ for $u \le u_c$, where $0 \le u_c \le u_{\max}$ is a critical concentration value, and $\sigma_e'(u) > 0$ for $u > u_c$. According to the phenomenological sedimentation-consolidation theory [3, 7, 8], the evolution of the concentration distribution is given by the equation

$$\partial_t u + \partial_z\big(h'(t)u + f(u)\big) = \partial_z^2 A(u), \quad 0 \le z \le h(t), \quad 0 < t \le T, \tag{2.1}$$
$$A(u) := \int_0^u a(s)\,ds, \quad a(u) := Cu^{-1} f(u)\sigma_e'(u),$$

where the parameter $C < 0$ expresses the solid-fluid density difference. Observe that (2.1) is hyperbolic for $u \le u_c$ and $u \ge u_{\max}$ and parabolic for $u_c < u < u_{\max}$ and thus of strongly degenerate parabolic type since the degeneration to hyperbolic type takes place on an interval of solution values of positive length. Specifically for the filtration problem, we assume that the solids flux through the moving piston and through the filter medium is zero. Since (2.1) is derived from the solids continuity equation, this implies the kinematic boundary conditions

$$\big(f(u) - \partial_z A(u)\big)\big(h(t), t\big) = 0, \quad \big(h'(t)u + f(u) - \partial_z A(u)\big)(0, t) = 0, \quad t > 0.$$

At time $t = 0$, the column is filled with a suspension of the local initial volumetric concentration $u(z, 0) = u_0(z)$ for $0 \le z \le h(0) := 1$.

The salient mathematical difficulty of the pressure filtration model arises from the coupling between the applied pressure $\sigma = \sigma(t)$ and the piston trajectory $h(t)$. Resistance to the movement of the piston, i.e., to the flow rate of filtrate leaving the filter, is exerted by the filter medium and by the so-called filter cake forming above the medium. While the resistance of the filter medium is constant, that of the filter cake depends on its thickness and composition, that is, on the solution u. The growth of the filter cake during the initial stages of the filtration process therefore slows down the downward movement of the piston if the applied pressure is kept constant. Specifically, a vertical stress balance and an application of Darcy's law yield the following coupling equation between $\sigma(t)$ and $h(t)$ [3, 16], which is written here as an ordinary differential equation for h:

$$h'(t) + \beta(t)h(t) + \gamma\big(t, u(0,t)\big) = 0, \quad 0 < t \le T, \tag{2.2}$$
$$\beta(t) := \frac{g\varrho_f}{\mu_f R}, \quad \gamma\big(t, u(0,t)\big) := \frac{1}{\mu_f R}\big[g\big(m_0 - \varrho_f\big) + \sigma(t) - \sigma_e\big(u(0,t)\big)\big].$$

Here g is the acceleration of gravity, ϱ_f the density of the fluid, μ_f its viscosity, R the resistance of the filter medium, and m_0 the initial suspension mass divided by the cross-sectional area of the filter column.

The observation that γ depends on $\sigma_e(u(0,t))$ and not on some arbitrary function of $u(0,t)$ is essential to making the problem amenable to mathematical analysis. In fact, both functions σ_e and A vanish for $u \le u_c$, strictly increase for $u_c < u < u_{\max}$, and remain constant for $u \ge u_{\max}$. Thus we can express $\sigma_e(u)$ as a function of $A(u)$, and the function γ takes the form

$$\gamma\big(t, u(0,t)\big) = \tilde{\gamma}(t) + \alpha\big(A(u(0,t))\big), \tag{2.3}$$

where α is a monotonous function on $[u_c, u_{\max}]$ having an inverse α^{-1}.

For numerical examples and applications to experimental data we refer to [3, 12].

2.2. Statement of the free boundary problem. A natural property of any solution u of the free boundary problem in the context of the pressure filtration model should be $0 \le u \le 1$; i.e., solution values should be physically relevant as concentration values. However, due to the presence of the linear transport term $h'(t)u$ in combination with the kinematic boundary condition prescribed at $z = 0$, we cannot exclude that boundary layers involving nonphysical solution values form. This can be avoided if we consider that from a physical point of view, the piston stops immediately as soon as the filter is "clogged," i.e., when the solid particles at $z = 0$ form a dense packing. We consider this effect by replacing the coupling condition (2.2) by the condition

$$h'(t) + c\big(A(u(0,t))\big)\big[\beta(t)h(t) + \gamma\big(t, u(0,t)\big)\big] = 0, \quad 0 < t \le T, \tag{2.4}$$

where $c(\rho) = 1$ for $\rho \in (0, A(u_{\max}))$ and $c(\rho) = 0$ otherwise.

Finally, we introduce a new space coordinate $x = h(t) - z$. Then $x = 0$ corresponds to the piston and $x = h(t)$ to the filter medium. Observing that $\partial_t(u(x,t)) = \partial_t u(z,t) + h'(t)\partial_z u$ and replacing $f(u)$ by $-f(u)$, we get the following free boundary value problem:

$$\partial_t u + \partial_x f(u) = \partial_x^2 A(u), \quad (x,t) \in Q(h,T), \tag{2.5a}$$

$$u(x,0) = u_0(x), \quad 0 \le x \le 1, \tag{2.5b}$$

$$\big(f(u) - \partial_x A(u)\big)(0,t) = 0, \quad 0 < t \le T, \tag{2.5c}$$

$$\big(f(u) - \partial_x A(u)\big)\big(h(t),t\big) = h'(t)u\big(h(t),t\big), \quad 0 < t \le T, \tag{2.5d}$$

$$h'(t) + c\Big(A\big(u\big(h(t),t\big)\big)\Big)\Big[\beta(t)h(t) + \gamma\Big(t, u\big(h(t),t\big)\Big)\Big] = 0, \quad 0 < t \le T, \tag{2.5e}$$

$$h(0) = 1, \tag{2.5f}$$

where $Q(h,T) := \{(x,t) \in (0,1) \times (0,T] : 0 < x < h(t)\}$.

Also, after the change of variables above, the relation (2.3) becomes

$$\gamma\big(t, u(h(t),t)\big) = \tilde{\gamma}(t) + \alpha\big(A(u(h(t),t))\big). \tag{2.6}$$

Since we are interested here exclusively in solutions that take values in the interval $[0, u_{\max}] \subset [0,1]$ of admissible concentrations, we may assume that $a(u) = 0$ for $u \le u_c$ and $u \ge u_{\max}$ such that $A(u) = A(u_{\max})$ for $u \ge u_{\max}$ and $A(u) = 0$ for $u \le u_c$. In particular, we have $0 = \alpha(0) \le \alpha(A(u(0,t))) \le \alpha(A(u_{\max})) =: K_\alpha$ for all times. Since, moreover, $\widetilde{\gamma}$ is a control function given a priori, we may assume that there exist positive constants $k_{\tilde{\gamma}}$ and $K_{\tilde{\gamma}}$ with $k_{\tilde{\gamma}} \le \widetilde{\gamma}(t) \le K_{\tilde{\gamma}}$ for all $t \in [0,T]$ and thus that there exist $k_\gamma, K_\gamma > 0$ with $k_\gamma \le \gamma \le K_\gamma$ for all $t \in [0,T]$. Similarly, we may assume that there exist $k_\beta, K_\beta > 0$ with $k_\beta \le \beta(t) \le K_\beta$ for all $t \in [0,T]$. Finally, to establish well-posedness of the free boundary problem, we assume that $T < 1/K_\gamma$.

2.3. Divergence-measure fields. Here we briefly recall the basic facts of the theory of divergence-measure fields as developed in [9, 10]. Since we will be interested only in the L^2 divergence-measure fields, we will focus our discussion on that case.

Let $\Omega \subset \mathbb{R}^N$ be an open bounded subset. We denote by $\mathcal{DM}^2(\Omega)$ the space of all $L^2(\Omega)$ vector fields whose divergence is a bounded Radon measure on Ω:

$$\mathcal{DM}^2(\Omega) := \left\{ F \in (L^2(\Omega))^N : \exists C > 0 : \forall \varphi \in C_0^\infty(\Omega), \ \left| \int_\Omega F \cdot \nabla\varphi \, d\mathbf{x} \right| \le C\|\varphi\|_\infty \right\},$$

where, as usual, $C_0^\infty(\Omega)$ denotes the space of the infinitely differentiable functions with compact support contained in Ω. Analogously, one may define $\mathcal{DM}^p(\Omega)$, $1 \le p \le \infty$, replacing L^2 by L^p, and $\mathcal{DM}^{\rm ext}(\Omega)$ replacing $L^2(\Omega)^N$ by $\mathcal{M}(\Omega)^N$, the space of vector-valued Radon measures over Ω with N components.

DEFINITION 2.1. *We say that $\partial\Omega$ is a* deformable Lipschitz boundary *provided that the following hold:*

(a) *For all $x \in \partial\Omega$ there exists a number $r > 0$ and a Lipschitz map $h : \mathbb{R}^{N-1} \to \mathbb{R}$ such that, after rotating and relabeling coordinates if necessary,*

$$\Omega \cap Q(x,r) = \left\{ y \in \mathbb{R}^N : h(y_1, \dots, y_{N-1}) < y_N \right\} \cap Q(x,r),$$

where $Q(x,r) := \{ y \in \mathbb{R}^N : |x_i - y_i| \le r,\ i = 1, \dots, N \}$.

(b) *There exists a mapping $\Psi : \partial\Omega \times [0,1] \to \overline{\Omega}$ such that Ψ is a homeomorphism bi-Lipschitz over its image and $\Psi(\omega, 0) = \omega$ for all $\omega \in \partial\Omega$. The map Ψ is called a* Lipschitz deformation *of the boundary $\partial\Omega$. We denote $\Psi_s(\omega) = \Psi(\omega, s)$ and $\partial\Omega_s = \Psi_s(\partial\Omega)$. We also denote by Ω_s the bounded open set whose boundary is $\partial\Omega_s$.*

The following theorem is a particular case of a general result proved in [10], following the guidelines in [9]; we refer to [10] for the proof. If $\mathcal{C}$ is a closed set, we denote by $\mathrm{Lip}(\mathcal{C})$ the space of Lipschitz functions defined on $\mathcal{C}$, equipped with the norm $\|f\|_{\rm Lip} = \|f\|_\infty + \mathrm{Lip}(f)$.

THEOREM 2.2. *Let $F \in \mathcal{DM}^2(\Omega)$, with Ω a bounded open set with Lipschitz deformable boundary. Then there exists a continuous linear functional $F \cdot \nu|_{\partial\Omega}$ over $\mathrm{Lip}(\partial\Omega)$ such that, for any $\phi \in \mathrm{Lip}(\mathbb{R}^N)$,*

$$\langle F \cdot \nu|_{\partial\Omega}, \phi|_{\partial\Omega} \rangle = \int_\Omega \phi \,\mathrm{div}\, F + \int_\Omega \nabla\phi \cdot F. \tag{2.7}$$

Moreover, let $\nu : \Psi(\partial\Omega \times [0,1]) \to \mathbb{R}^N$ be such that $\nu(x)$ is the outer unit normal to $\partial\Omega_s$ at $x \in \partial\Omega_s$, defined for almost every $x \in \Psi(\partial\Omega \times [0,1])$. Then, for any $\psi \in \mathrm{Lip}(\partial\Omega)$,

$$\langle F \cdot \nu|_{\partial\Omega}, \psi \rangle = \operatorname*{ess\,lim}_{s \to 0} \frac{1}{s} \int_0^s \left(\int_{\partial\Omega_s} \mathcal{E}(\psi) F \cdot \nu \, d\mathcal{H}^{N-1} \right) ds,$$

where $\mathcal{E}(\psi)$ denotes any Lipschitz extension of ψ to all $\mathbb{R}^N$ and $\mathcal{H}^{N-1}$ is the $(N-1)$-dimensional Hausdorff measure.

As an example, below we will consider a domain Ω of the form

$$\Omega = \{ (x,t) \in \mathbb{R}^2 : 0 < x < h(t),\ 0 < t < T \},$$

where h is a nonincreasing Lipschitz function satisfying $h(t) > h_0$ for some constant $h_0 > 0$. Clearly, in this case Ω satisfies (a) of Definition 2.1. We may also easily define a Lipschitz deformation for $\partial\Omega$. Indeed, since Ω is convex, given any point (x_*, t_*) in its interior, we may define the map $\Psi((x,t), s) = (x + s\delta(x_* - x), t + s\delta(t_* - t))$, from $\partial\Omega \times [0,1]$ to $\overline{\Omega}$, which, for $\delta > 0$ sufficiently small, certainly gives a Lipschitz deformation. But we will prefer to use deformations which, given $\delta > 0$ sufficiently small, on $\{(x,t) : x = 0,\ \delta < t < T - \delta\}$ are given by $\Psi_\delta((0,t), s) = (\delta s, t)$, and on $\{(x,t) : x = h(t),\ \delta < t < T - \delta\}$ are given by $\Psi_\delta((h(t),t), s) = (h(t) - \delta s, t)$. Clearly, Ψ_δ may be extended to all $\partial\Omega \times [0,1]$ in order to provide Lipschitz deformations

for $\partial\Omega$. By the above theorem, if $F \in \mathcal{DM}^2(\Omega)$ and $\phi \in \mathrm{Lip}(\mathbb{R}^2)$ is such that $\operatorname{supp}\phi \cap \partial\Omega \subset \{x = 0\}$, then, for $\delta > 0$ sufficiently small,

$$\langle F \cdot \nu|_{\partial\Omega}, \phi\rangle = \operatorname*{ess\,lim}_{s\to 0} \frac{1}{s}\int_0^s \left(\int_0^T \phi(\delta s, t) F_1(\delta s, t)\, dt\right) ds. \tag{2.8}$$

On the other hand, if $\phi \in \mathrm{Lip}(\mathbb{R}^2)$ is such that $\operatorname{supp}\phi \cap \partial\Omega \subset \{(h(t), t), 0 < t < T\}$, then, for $\delta > 0$ sufficiently small,

$$\langle F \cdot \nu|_{\partial\Omega}, \phi\rangle = \operatorname*{ess\,lim}_{s\to 0} \frac{1}{s}\int_0^s \left(\int_0^T \phi(h(t) - \delta s, t)(F_1 - h'(t)F_2)(h(t) - \delta s, t)\, dt\right) ds. \tag{2.9}$$

3. Definition of generalized solutions. In what follows let K be a sufficiently large constant, e.g., $K = 2u_{\max}$. As above, for fields $F(x,t) = (F_1(x,t), F_2(x,t))$ defined over domains of $\mathbb{R}^2$, which are distributions on these domains, the operator div is defined as $\operatorname{div} F = \partial_x F_1 + \partial_t F_2$ in the sense of distributions.

DEFINITION 3.1. *A pair of functions (u, h) with $h \in C[0,T]$ and $u \in L^\infty(Q(h,T))$ is called a* generalized solution *of the free boundary problem (2.5) if the following conditions are satisfied:*

(a) *The function $h(\cdot)$ is nonincreasing and Lipschitz continuous on $(0,T)$ with $h(0) = 1$, and there exists a positive constant h_0 such that $h(t) > h_0$.*

(b) *The following regularity properties hold:*

$$A(u) \in L^2\big(0,T; H^1(0, h(\cdot))\big), \tag{3.1}$$

$$\forall k \in \mathbb{R}: \ \Big(\operatorname{sgn}(u-k)\big(f(u) - f(k)\big) - \partial_x\big|A(u) - A(k)\big|, |u-k|\Big) \in \mathcal{DM}^2\big(Q(h,T)\big). \tag{3.2}$$

(c) *The boundary conditions are satisfied in the following sense: For $(F_1, F_2) = (f(u) - \partial_x A(u), u)$, $\delta > 0$ sufficiently small, and every test function $\varphi \in C_0^1(\Pi_T)$, with $\Pi_T = \mathbb{R} \times (0,T)$, we have*

$$\operatorname*{ess\,lim}_{s\to 0} \frac{1}{s}\int_0^s \left(\int_0^T \varphi(\delta s, t) F_1(\delta s, t)\, dt\right) ds = 0, \tag{3.3}$$

$$\operatorname*{ess\,lim}_{s\to 0} \frac{1}{s}\int_0^s \left(\int_0^T \varphi(h(t) - \delta s, t)(F_1 - h'(t)F_2)(h(t) - \delta s, t)\, dt\right) ds = 0. \tag{3.4}$$

(d) *Let $\gamma_{x\to h(t)}A(u)$ denote the trace of $A(u)$ for $x \to h(t)$ in the sense of traces in $L^2(0,T; H^1(0,h(\cdot)))$. Then (2.5e) is satisfied a.e. in $(0,T)$, where in $c(A(u(h(t),t)))$ and in $\gamma(t, u(h(t),t))$, given by (2.6), $A(u(h(t),t))$ must be replaced by $\gamma_{x\to h(t)}A(u)$.*

(e) *The initial condition is valid in the sense that*

$$\lim_{t\to 0}\int_0^{h(t)} \big|u(x,t) - u_0(x)\big|\, dx = 0.$$

(f) *The following entropy inequality is satisfied for all nonnegative test functions $\varphi \in C_0^\infty(Q(h,T))$ and all $k \in \mathbb{R}$:*

$$\iint_{Q(h,T)} \Big\{|u-k|\partial_t\varphi + \operatorname{sgn}(u-k)\big[f(u) - f(k) - \partial_x A(u)\big]\partial_x\varphi\Big\}\, dtdx \geq 0. \tag{3.5}$$

It is convenient to transform the free boundary value problem (2.5) to an equivalent initial-boundary value problem with fixed boundaries by introducing a new space coordinate $\xi := x/h(t)$. Wherever notationally convenient, the argument t in $h(t)$ is omitted, and we denote by h^{-1} the function $1/h(t)$, etc. Then we can rewrite (2.5) as the following initial-boundary value problem with fixed boundaries for $v(\xi,t) := u(h(t)\xi,t)$, where $Q_T := (0,1)\times(0,T)$:

$$\partial_\xi v + h^{-1}h'\big(-\partial_\xi(\xi v)+v\big) + h^{-1}\partial_\xi f(v) = h^{-2}\partial_\xi^2 A(v), \quad (\xi,t)\in Q_T, \tag{3.6a}$$

$$v(\xi,0) = u_0(\xi), \quad \xi\in[0,1], \tag{3.6b}$$

$$\big(f(v) - h^{-1}\partial_\xi A(v)\big)(0,t) = 0, \quad t\in(0,T], \tag{3.6c}$$

$$\big(f(v) - h^{-1}\partial_\xi A(v)\big)(1,t) = h'(t)v(1,t), \quad t\in(0,T], \tag{3.6d}$$

$$h'(t) + c\Big(A\big(v\big(1,t\big)\big)\Big)\Big[\beta(t)h(t) + \gamma\Big(t, v\big(1,t\big)\Big)\Big] = 0, \quad 0<t\le T, \tag{3.6e}$$

$$h(0) = 1, \tag{3.6f}$$

while the relation (2.6) becomes

$$\gamma\big(t, v(1,t)\big) = \tilde\gamma(t) + \alpha\big(A(v(1,t))\big). \tag{3.7}$$

In what follows we use $h' := h'(t)$, $h^{-1} := 1/h(t)$, $h^{-2} := 1/(h(t))^2$, and similar notation for the function $h_\varepsilon(t)$ to be defined below. Moreover, we set $g(v,\xi,t) := -h^{-1}h'(t)\xi v + h^{-1}f(v)$.

The appropriate definition of entropy solution in terms of v is as follows.

DEFINITION 3.2. *A pair of functions (v,h) with $h\in C[0,T]$ and $v\in L^\infty(Q_T)$ is called a* generalized solution *of the transformed free boundary problem* (3.6) *if the following conditions are satisfied:*

(a) *The function $h(\cdot)$ is nonincreasing and Lipschitz continuous on $(0,T)$ with $h(0)=1$, and there exists a positive constant h_0 such that $h(t)>h_0$.*

(b) *The following regularity properties hold:*

$$h^{-2}A(v)\in L^2\big(0,T;H^1(0,1)\big), \tag{3.8}$$

$$\forall k\in\mathbb{R}:\ \Big(\operatorname{sgn}(v-k)\big(g(v,\xi,t)-g(k,\xi,t)\big) - h^{-2}\partial_\xi\big|A(v)-A(k)\big|, |v-k|\Big)\in\mathcal{DM}^2(Q_T). \tag{3.9}$$

(c) *The boundary conditions are satisfied in the following sense: For $(F_1,F_2) = (g(v,\xi,t) - h^{-2}\partial_\xi A(v), v)$, $\delta>0$ sufficiently small, and every test function $\varphi\in C_0^1(\Pi_T)$, we have*

$$\operatorname*{ess\,lim}_{s\to0}\frac{1}{s}\int_0^s\left(\int_0^T\varphi(\delta s,t)F_1(\delta s,t)\,dt\right)ds = 0, \tag{3.10}$$

$$\operatorname*{ess\,lim}_{s\to0}\frac{1}{s}\int_0^s\left(\int_0^T\varphi(1-\delta s,t)F_1(1-\delta s,t)\,dt\right)ds = 0. \tag{3.11}$$

(d) *Let $\gamma_{\xi\to1}A(v)$ denote the trace of $A(v)$ for $\xi\to1$ in the sense of traces in $L^2(0,T;H^1(0,1))$. Then* (3.6e) *is satisfied a.e. in $(0,T)$, where in $c(A(v(1,t)))$ and in $\gamma(t,v(1,t))$, given by* (3.7)*, we must replace $A(v(1,t))$ by $\gamma_{x\to1}A(v)$.*

(e) *The initial condition is valid in the sense that*

$$\lim_{t\to0}\int_0^1\big|v(\xi,t)-u_0(\xi)\big|\,d\xi = 0. \tag{3.12}$$

(f) *The following inequality holds for all nonnegative test functions* $\varphi \in C_0^\infty(Q_T)$ *and all* $k \in \mathbb{R}$*:*

$$\begin{aligned}\iint_{Q_T} \Big\{ |v-k|\partial_t\varphi + \big[\operatorname{sgn}(u-k)\big(g(v,\xi,t)-g(k,\xi,t)\big) \\ - \partial_\xi\big|A(v)-A(k)\big|\big]\partial_\xi\varphi\Big\}\,d\xi dt \ge 0.\end{aligned} \tag{3.13}$$

4. Regularized free boundary problem. As in [4] we prove the existence of entropy solutions by the vanishing viscosity method. To this end, we consider the regularized strictly parabolic free boundary problem

$$\partial_t u_\varepsilon + \partial_x f_\varepsilon(u_\varepsilon) = \partial_x^2 A_\varepsilon(u_\varepsilon), \quad (x,t) \in Q(h_\varepsilon, T), \tag{4.1a}$$

$$u_\varepsilon(x,0) = u_0^\varepsilon(x), \quad 0 \le x \le 1, \tag{4.1b}$$

$$\big(f_\varepsilon(u_\varepsilon) - \partial_x A_\varepsilon(u_\varepsilon)\big)(0,t) = 0, \quad 0 < t \le T, \tag{4.1c}$$

$$\big(f_\varepsilon(u_\varepsilon) - \partial_x A_\varepsilon(u_\varepsilon)\big)\big(h_\varepsilon(t),t\big) = h_\varepsilon'(t) u_\varepsilon\big(h_\varepsilon(t),t\big), \quad 0 < t \le T, \tag{4.1d}$$

(4.1e)

$$h_\varepsilon'(t) + c_\varepsilon\Big(A_\varepsilon\big(u_\varepsilon\big(h_\varepsilon(t),t\big)\big)\Big)\Big[\beta_\varepsilon(t)h_\varepsilon(t) + \gamma_\varepsilon\Big(t, u_\varepsilon\big(h_\varepsilon(t),t\big)\Big)\Big] = 0, \quad 0 < t \le T,$$

$$h_\varepsilon(0) = 1. \tag{4.1f}$$

The regularized functions and initial and boundary data are assumed to satisfy first-order compatibility conditions. Problem (4.1) is equivalent to the following initial-boundary value problem with fixed boundaries for $v_\varepsilon(\xi,t) := u_\varepsilon\big(h_\varepsilon(t)\xi, t\big)$ with $(\xi,t) \in Q_T := (0,1)\times(0,T)$:

$$\partial_t v_\varepsilon + h_\varepsilon^{-1}h_\varepsilon'(t)\big[-\partial_\xi(\xi v_\varepsilon) + v_\varepsilon\big] + h_\varepsilon^{-1}\partial_\xi f_\varepsilon(v_\varepsilon) = h_\varepsilon^{-2}\partial_\xi^2 A_\varepsilon(v_\varepsilon), \quad (\xi,t) \in Q_T, \tag{4.2a}$$

$$v_\varepsilon(\xi,0) = u_0^\varepsilon(\xi), \quad 0 \le \xi \le 1, \tag{4.2b}$$

$$\big(f_\varepsilon(v_\varepsilon) - h_\varepsilon^{-1}\partial_\xi A_\varepsilon(v_\varepsilon)\big)(0,t) = 0, \quad 0 < t \le T, \tag{4.2c}$$

$$\big(f_\varepsilon(v_\varepsilon) - h_\varepsilon^{-1}\partial_\xi A_\varepsilon(v_\varepsilon)\big)(1,t) = h_\varepsilon'(t) v_\varepsilon(1,t), \quad 0 < t \le T, \tag{4.2d}$$

$$h_\varepsilon'(t) + c_\varepsilon\big(A\big(v_\varepsilon(1,t)\big)\big)\Big[\beta_\varepsilon h_\varepsilon(t) + \gamma_\varepsilon\big(t, v_\varepsilon(1,t)\big)\Big] = 0, \quad 0 < t \le T, \tag{4.2e}$$

$$h_\varepsilon(0) = 1. \tag{4.2f}$$

We choose the regularization c_ε such that c_ε is smooth, nonnegative, $c_\varepsilon(\rho) = 1$ for $\varepsilon \le \rho \le A(u_{\max}) - \varepsilon$, and $c_\varepsilon(\rho) = 0$ for $\rho \notin (0, A(u_{\max}))$. We assume that the regularization $f_\varepsilon \ge 0$ is also compactly supported, that $a_\varepsilon(u) \ge \varepsilon$, and that $a_\varepsilon(u) - \varepsilon$ is also compactly supported. We assume $\operatorname{supp} f_\varepsilon \cup \operatorname{supp} c_\varepsilon \subset \overline{\mathcal{U}} = [0, u_{\max}]$ and $\operatorname{supp}(a_\varepsilon - \varepsilon) \subset \overline{\mathcal{U}}$. Moreover, we define $g_\varepsilon(u,\xi,t) := -h_\varepsilon^{-1}h_\varepsilon'\xi u + h_\varepsilon^{-1}f_\varepsilon(u)$ and assume that there exist constants ν_ε, L_ε, and $\tilde{L}$ such that

$$\frac{A_\varepsilon(u) - A_\varepsilon(v)}{u - v} \ge \nu_\varepsilon > 0, \quad \big|g_\varepsilon(u,\xi,t) - g_\varepsilon(v,\xi,t)\big| \le L_\varepsilon|u-v| \quad \text{for } u,v \in \mathbb{R}. \tag{4.3}$$

LEMMA 4.1. *Any solution* u_ε *of the regularized free boundary problem* (4.1) *satisfies* $u_\varepsilon(x,t) \in \overline{\mathcal{U}}$ *for all* $(x,t) \in \overline{Q(h_\varepsilon, T)}$*. Equivalently, any solution* v_ε *of* (4.2) *satisfies* $v_\varepsilon(x,t) \in \overline{\mathcal{U}}$ *for all* $(x,t) \in \overline{Q_T}$*. In particular, there exists a constant* M_0 *independent of* ε *such that for all sufficiently small* $\varepsilon > 0$*,*

$$\|u_\varepsilon\|_{L^\infty(Q(h_\varepsilon,T))} \le M_0. \tag{4.4}$$

Proof. Consider the regularized problem (4.1), perturbed by adding to the right-hand member the term $\lambda N(u_\varepsilon)$, where $\lambda > 0$ and $N(u) = u_{\max}/2 - u$. We may assume h_ε to be a given smooth function, so the problem is in fact given by the first four equations of (4.1), with the first one perturbed. If we prove the result for the perturbed problem, then by the well-known stability for quasi-linear strictly parabolic scalar equations, with respect to coefficients, the desired result will follow sending $\lambda \to 0$. Now, if the result is not true for the perturbed problem, there is a time t_0 at which the solution v_ε leaves $\overline{\mathcal{U}}$ for the first time, that is, $t_0 = \inf\{t : v_\varepsilon(x,t) \notin \overline{\mathcal{U}} \text{ for some } x \in [0,h(t)]\}$. In this case, there exists $x_0 \in [0,h(t_0)]$ such that $u_\varepsilon(x_0,t_0) \in \{0,u_{\max}\}$, say, $u_\varepsilon(x_0,t_0) = u_{\max}$. If $x_0 \in (0,h(t_0))$, as usual, we get a contradiction using that $\partial_x u_\varepsilon = 0$, $\partial_t u_\varepsilon \geq 0$, $\partial_x^2 u_\varepsilon \leq 0$, $a_\varepsilon(u) > 0$, and $N(u_{\max}) < 0$. On the other hand, if $x_0 \in \{0,h(t_0)\}$, using (4.1c)–(4.1e), we again conclude that $\partial_x u_\varepsilon = 0$. Hence, we must again have $\partial_t u_\varepsilon \geq 0$, $\partial_x^2 u_\varepsilon \leq 0$, and so we get a contradiction in the same way. ∎

LEMMA 4.2. *Suppose that $T < 1/K_\gamma$ and that the coefficients of the regularized problem* (4.1) *satisfy compatibility conditions. Then this problem has a unique solution $(u_\varepsilon, h_\varepsilon)$ such that $u_\varepsilon \in C^{2+\alpha,1+\alpha/2}(\overline{Q}(h_\varepsilon,T))$ and $h_\varepsilon \in C^{1+\alpha/2}[0,T]$. Precisely, the function h_ε satisfies the following estimates uniformly in ε:*

$$0 < h_0 \leq h_\varepsilon(t) \leq 1, \quad \|h_\varepsilon'\|_{L^\infty(0,T)} \leq M_h := K_\beta + K_\gamma. \tag{4.5}$$

Proof. Suppose that $(u_\varepsilon, h_\varepsilon)$ with $u_\varepsilon \in C^{2,1}(\overline{Q}(h_\varepsilon,T))$ and $h_\varepsilon \in C^1(0,T)$ is a solution of problem (4.1) or, equivalently, that v_ε satisfies the initial-boundary value problem with fixed boundaries (4.2). In addition, consider for a fixed function $h_\varepsilon \in C^1[0,T]$ the initial-boundary value problem (4.2′) consisting of (4.2a) and the initial and boundary conditions (4.2b)–(4.2d).

The proof of the following lemma is standard and can be found, e.g., in [15, Chap. V].

LEMMA 4.3. *Under the assumptions of Lemma* 4.2*, the solution w_ε of the initial-boundary value problem* (4.2′) *satisfies the following estimates, where the constant K_1 is independent of ε:*

$$0 \leq w_\varepsilon \leq K_1, \quad \|w_\varepsilon\|_{C^\beta(Q_T)} \leq K_2, \quad \|\partial_\xi w_\varepsilon\|_{C^{1,1/2}(\overline{Q_T})} \leq K_2, \quad \|w_\varepsilon\|_{W^{2,1}_\infty(\overline{Q}_T)} \leq K_2.$$

To prove the existence of a solution to problem (4.2), we follow Zhao and Li [28] and use the Schauder fixed point theorem. To this end, define the set

$$H := \big\{h \in C^1(0,T) : \|h'\|_\infty \leq M_h,\ h(0) = 1,\ h \text{ is nonincreasing}\big\},$$

where the constant M_h is defined in (4.5). Note that H is a compact convex set in the Banach space $C^0[0,T]$. Moreover, let $\widehat{\beta}_\varepsilon(t,u) := \chi_\varepsilon(A_\varepsilon(u))\beta_\varepsilon(t)$ and $\widehat{\gamma}_\varepsilon(t,u) := \chi_\varepsilon(u)\gamma_\varepsilon(t,u)$.

LEMMA 4.4. *Let the operator $\mathcal{T} : H \to C^0[0,T]$ be defined by*

$$(\mathcal{T}h)(t) := \exp\Big(\widehat{B}_\varepsilon\big(t; w_\varepsilon(1,\cdot)\big)\Big)\left[1 - \int_0^t \exp\Big(-\widehat{B}_\varepsilon\big(\tau; w_\varepsilon(1,\cdot)\big)\Big)\widehat{\gamma}_\varepsilon\big(\tau, w_\varepsilon(1,\tau)\big)\,d\tau\right],$$

$$\widehat{B}_\varepsilon(t;w) := -\int_0^t \widehat{\beta}_\varepsilon\big(\tau, w(\tau)\big)\,d\tau,$$

where w_ε is the solution of the initial-boundary value problem (4.2′) *corresponding to h. Then $\mathcal{T}h \in H$, i.e., the operator $\mathcal{T}$ maps H into itself.*

Proof. Since we consider a fixed value of the regularization parameter ε, we simplify notation in the remainder of the proof of Lemma 4.2 (including the proofs of Lemmas 4.4 and 4.5) by omitting ε wherever possible.

Obviously, we have $(\mathcal{T}h)(0) = 1$. Since the functions $\widehat{B}(\cdot; w)$ and $\widehat{\gamma}\big(\cdot, w(1,\cdot)\big)$ are smooth, as stated in Lemma 4.3, we see that $\mathcal{T}h \in C^1[0,T]$. Furthermore, we have

$$
\begin{aligned}
(\mathcal{T}h)'(t) = &-\widehat{\beta}\big(t, w(1,t)\big) \exp\Big(\widehat{B}\big(t, w(1,t)\big)\Big) \\
&\times \left[1 - \int_0^t \exp\Big(-\widehat{B}\big(\tau; w(1,\cdot)\big)\Big)\widehat{\gamma}\big(\tau, w(1,\tau)\big)\, d\tau\right] - \widehat{\gamma}\big(t, w(1,t)\big).
\end{aligned} \tag{4.6}
$$

Since $\widehat{\gamma}(t, w(1,t)) \le K_\gamma$ for $\varepsilon > 0$ sufficiently small, the expression in the square brackets in (4.6) is nonnegative, and thus $\mathcal{T}h$ is nonincreasing, if the condition $T < 1/K_\gamma$ is satisfied. Moreover, this assumption implies that $|(\mathcal{T}h)'(t)| \le K_\beta + K_\gamma$. We conclude that indeed $\mathcal{T}h \in H$. ∎

To apply the Schauder fixed point theorem, and thus to show existence of the solution, we have to prove the following lemma.

LEMMA 4.5. *Suppose that* $\{h_n\}_{n\in\mathbb{N}} \subset H$ *and* $\|h_m - h_n\|_{C^0[0,T]} \to 0$ *as* $m, n \to \infty$. *Then* $\|\mathcal{T}h_m - \mathcal{T}h_n\|_{C^0[0,T]} \to 0$ *as* $m, n \to \infty$.

Proof. Assume that $h_n \to h$ uniformly in $[0,T]$. Since $\|h_n'\|_\infty \le M_h$, we can conclude that $h' \in L^\infty[0,T]$ and $h_n' \to h'$ weakly in $L^1[0,T]$. Let w_n and w denote the solutions of the initial-boundary value problem (4.2′) associated with the functions h_n and h, respectively. From Lemma 4.3 it follows that there exist subsequences $\{w_{n_j}\}_{j\in\mathbb{N}}$ and $\{\partial_x w_{n_j}\}_{j\in\mathbb{N}}$ of $\{w_n\}_{n\in\mathbb{N}}$ and $\{\partial_x w_n\}_{n\in\mathbb{N}}$, respectively, converging uniformly on $\overline{Q_T}$ to limit functions $\overline{w}$ and $\overline{w}_x$. Multiplying (4.2a), with v replaced by w_{n_j}, by a test function $\varphi \in C_0^2(Q_T)$, integrating over Q_T, and using integration by parts, we obtain

$$
\iint_{Q_T} \Big\{ w_{n_j}\partial_t\varphi + h_{n_j}^{-1}h_{n_j}' w_{n_j}(\varphi + \xi\partial_\xi\varphi) + \big(h_{n_j}^{-1} f(w_{n_j}) - h_{n_j}^{-2}\partial_\xi A(w_{n_j})\big)\partial_\xi\varphi \Big\}\, d\xi dt = 0.
$$

Letting $j \to \infty$, we get

$$
\iint_{Q_T} \Big\{ \overline{w}\partial_t\varphi + h^{-1}h'\overline{w}(\varphi + \xi\partial_\xi\varphi) + \big(h^{-1} f(\overline{w}) - h^{-2}\partial_\xi A(\overline{w})\big]\partial_\xi\varphi \Big\}\, d\xi dt = 0.
$$

Since solutions of the initial-boundary value problem (4.2′) are unique, we obtain $\overline{w} = w$; hence the sequences $\{w_n\}_{n\in\mathbb{N}}$ and $\{\partial_x w_n\}_{n\in\mathbb{N}}$ converge uniformly on $\overline{Q_T}$. Lemma 4.5 is then an immediate consequence of

$$
\begin{aligned}
&(\mathcal{T}h_n - \mathcal{T}h_m)(t) \\
&= \exp\Big(\widehat{B}\big(t, w(1,\cdot)\big)\Big)\int_0^t \exp\Big(-\widehat{B}\big(\tau, w(1,\cdot)\big)\Big)\Big[\widehat{\gamma}\big(\tau, w_m(1,\tau)\big) - \widehat{\gamma}\big(\tau, w_n(1,\tau)\big)\Big]\, d\tau.
\end{aligned}
$$

∎

We continue with the proof of Lemma 4.2. By Lemma 4.5, $\mathcal{T}$ is a continuous operator on H. We are now in a position to conclude from the Schauder fixed point theorem that $\mathcal{T}$ has a fixed point $h \in H$; in particular $h \in C^{1+\alpha/2}[0,T]$. This also proves the estimates (4.5).

Substituting the fixed point h into the initial-boundary value problem (4.2′) produces a solution $w \in C^{2+\alpha,1+\alpha/2}(Q_T)$ with the property that the pair (w,h) also satisfies the fixed point equation $\mathcal{T}h = h$, which is equivalent to (2.5f). Consequently,

$(v \equiv w, h)$ is a solution of the initial-boundary value problem (4.2), and setting $u(x,t) = v(x/h(t),t)$ produces a solution (u,h) of the regularized free boundary problem (4.1) with $u \in C^{2+\alpha,1+\alpha/2}(\overline{Q}(h,T))$. Thus the existence part of Lemma 4.2 is proved.

We now turn to the uniqueness part. From boundary condition (4.1d) we get

$$\frac{1}{2}h^2(t) = \int_0^t h(s)h'(s)\,ds + \frac{1}{2} = \int_0^t \frac{h(s)}{u}\big(f(u) - \partial_x A(u)\big)\big(h(s),s\big)\,ds + \frac{1}{2}.$$

We now choose a test function $\omega \in C^2(\mathbb{R})$ satisfying $\omega(x) = 0$ for $x \le h_0/2$ and $\omega(x) = 1$ for $x \ge 3h_0/4$. We then get

$$\begin{aligned}
&\int_0^t \frac{h(s)}{u}\big(f(u) - \partial_x A(u)\big)\big(h(s),s\big)\,ds = \iint_{Q(h,t)} \partial_x\left(\frac{x\omega(x)}{u}\big(f(u) - \partial_x A(u)\big)\right) dxds\\
&= \iint_{Q(h,t)} \left\{\big(\omega(x) + x\omega'(x)\big)\frac{f(u) - \partial_x A(u)}{u} + x\omega(x)\partial_x\left(\frac{f(u) - \partial_x A(u)}{u}\right)\right\} dxds\\
&= \iint_{Q(h,t)} \big(\omega(x) + x\omega'(x)\big)\frac{f(u) - \partial_x A(u)}{u}\,dxds\\
&\quad + \iint_{Q(h,t)} x\omega(x)\big(f(u) - \partial_x A(u)\big)\partial_x\Big(\frac{1}{u}\Big)\,dxds + \iint_{Q(h,t)} \frac{x\omega(x)}{u}(-\partial_s u)\,dxds\\
&=: I_1 + I_2 + I_3.
\end{aligned}$$

Defining

$$\widetilde{A}(u) := \int_0^u \frac{a(r)}{r}dr, \quad p(u) := \int_0^u \frac{f'(r)}{r}dr, \quad q(u) := \int_{u_0}^u \frac{f(r)}{r^2}dr,$$

with $u_0 > 0$, we obtain by using integration by parts and the boundary condition

$$\begin{aligned}
I_2 &= \iint_{Q(h,t)} x\omega(x)\partial_x\left(\frac{f(u) - \partial_x A_\varepsilon(u)}{u}\right) dxds\\
&\quad - \iint_{Q(h,t)} \frac{x\omega(x)}{u}\partial_x\big(f(u) - \partial_x A_\varepsilon(u)\big)\,dxds\\
&= \int_0^t h(s)\left(\frac{f(u) - \partial_x A_\varepsilon(u)}{u}\right) ds\\
&\quad - \iint_{Q(h,t)} \big(\omega(x) + x\omega'(x)\big)\big(-p(u) + q(u) - \partial_x \widetilde{A}_\varepsilon(u)\big)\,dxds\\
&\quad + \iint_{Q(h,t)} \frac{x\omega(x)}{u}\partial_s u\,dxds\\
&= \int_0^t h(s)\Big\{-p\big(u(h(s),s)\big) + q\big(u(h(s),s)\big) - \partial_x \widetilde{A}\big(u(h(s),s)\big)\Big\}\,ds\\
&\quad - \iint_{Q(h,t)} \Big\{\big(2\omega'(x) + x\omega''(x)\big)\widetilde{A}(u) + \big(\omega(x) + x\omega'(x)\big)\big(p(u) - q(u)\big)\Big\}\,dxds\\
&\quad + \iint_{Q(h,t)} \frac{x\omega(x)}{u}\partial_s u\,dxds + \int_0^t \widetilde{A}_\varepsilon\big(u\big(h(s),s\big)\big)\,ds.
\end{aligned}$$

Consequently,

$$\begin{aligned}
&\frac{1}{2}h^2(t) = \frac{1}{2} + \iint_{Q(h,t)} (\omega + x\omega')\frac{f(u) - \partial_x A(u)}{u}\,dxds \\
&+ \int_0^t h(s)\Big\{-p\big(u(h(s),s)\big) + q\big(u(h(s),s)\big) - \partial_x \widetilde{A}\big(u(h(s),s)\big)\Big\}\,ds \\
&+ \int_0^t \widetilde{A}\big(u(h(s),s)\big)\,ds - \iint_{Q(h,t)} \Big\{(\omega + x\omega')\big(p(u) - q(u)\big) + (2\omega' + x\omega'')\widetilde{A}\Big\}\,dxds.
\end{aligned}$$

Now let (u^1, h^1) and (u^2, h^2) be two solutions of the regularized free boundary problem (4.1). Let

$$t_1 := \max\big\{t \in [0,T] :\ h^1(\tau) = h^2(\tau) \text{ for } \tau \in [0,t]\big\}.$$

We now show that $t_1 = T$. To this end, we first suppose that $t_1 < T$. Without loss of generality, we suppose that $t_1 = 0$. Moreover, define $h^-(t) := \min\{h^1(t), h^2(t)\}$, $h^+(t) := \max\{h^1(t), h^2(t)\}$, $j(t) := 1$ if $h^1(t) > h^2(t)$ and $j(t) := 2$ if $h^1(t) \le h^2(t)$, and $i(t) := 3 - j(t)$. Then we obtain

$$\begin{aligned}
&\frac{1}{2}\big((h^1)^2(t) - (h^2)^2(t)\big) \\
&= \iint_{Q(h^-,t)} (\omega + x\omega')\left[\frac{f(u^1) - \partial_x A(u^1)}{u^1} - \frac{f(u^2) - \partial_x A(u^2)}{u^2}\right] dxds \\
&\quad - \int_0^t (-1)^{j(s)} \int_{h^-(s)}^{h^+(s)} (\omega + x\omega')\frac{f(u^{j(s)}) - \partial_x A(u^{j(s)})}{u^{j(s)}}\,dxds \\
&\quad + \int_0^t \Big\{h^1(s)\Big[-p\big(u^1(h^1(s),s)\big) + q\big(u^1(h^1(s),s)\big) - \partial_x \widetilde{A}\big(u^1(h^1(s),s)\big)\Big] \\
&\qquad\qquad - h^2(s)\Big[-p\big(u^2(h^2(s),s)\big) + q\big(u^2(h^2(s),s)\big) - \partial_x \widetilde{A}\big(u^2(h^2(s),s)\big)\Big]\Big\}\,ds \\
&\quad + \int_0^t \Big\{\widetilde{A}\big(u^1(h^1(s),s)\big) - \widetilde{A}\big(u^2(h^2(s),s)\big)\Big\}\,ds \\
&\quad + \iint_{Q(h^-,t)} \Big\{(\omega + x\omega')\big(-p(u^1) + q(u^1) + p(u^2) - q(u^2)\big) \\
&\qquad\qquad - (2\omega' + x\omega'')\big(\widetilde{A}(u^1) - \widetilde{A}(u^2)\big)\Big\}\,dxds \\
&\quad - \int_0^t (-1)^{j(s)} \int_{h^-(s)}^{h^+(s)} \Big\{\big(\omega(x) + x\omega'(x)\big)\Big(-p\big(u^{j(s)}\big) + q\big(u^{j(s)}\big)\Big) \\
&\qquad\qquad - (2\omega' + x\omega'')\widetilde{A}\big(u^{j(s)}\big)\Big\}\,dxds \\
&=: I_4 + \cdots + I_9.
\end{aligned}$$

We now set $\delta(t) := |h^1(t) - h^2(t)|$. First note that

$$\big|(h^1)^2(t) - (h^2)^2(t)\big| = \big|h^1(t) + h^2(t)\big|\delta(t) \ge M_1\delta(t), \quad M_1 := 2h(0).$$

We now estimate the integrals I_4 to I_9. In light of

$$\begin{aligned} I_4 = &\iint_{Q(h^-.t)} (\omega + x\omega')\left(\frac{f(u^1)}{u^1} - \frac{f(u^2)}{u^2}\right) dxds \\ &- \int_0^t \left\{\widetilde{A}\big(u^1(h^-(s),s)\big) - \widetilde{A}\big(u^2(h^-(s),s)\big)\right\} ds \\ &+ \iint_{Q(h^-,t)} (2\omega' + \omega'')\big(\widetilde{A}(u^1) - \widetilde{A}(u^2)\big)\, dxds \end{aligned}$$

and the inequality

$$\big|\widetilde{A}\big(u^1(h^-(s),s)\big) - \widetilde{A}\big(u^2(h^-(s),s)\big)\big| \le \varepsilon^{-1}\|a\|_\infty \big|u^1(h^-(s),s) - u^2(h^-(s),s)\big|,$$

it is easy to see that there exist constants C_2 and C_3 such that

$$|I_4| \le C_2 \int_0^t \big|u^1(h^-(s),s) - u^2(h^-(s),s)\big| ds + C_3 \int_0^t \int_0^{h^-(t)} \big|u^1(x,s) - u^2(x,s)\big|\, dxds.$$

Next, noting that in light of boundary condition (4.1c)

$$\begin{aligned} &\big|f\big(u^{j(s)}(x,s)\big) - \partial_x A\big(u^{j(s)}(x,s)\big)\big| \\ &= \big|f\big(u^{j(s)}(x,s)\big) - f\big(u^{j(s)}(h^+(s),s)\big) \\ &\qquad - \partial_x A\big(u^{j(s)}(x,s)\big) + \partial_x A\big(u^{j(s)}(h^+(s),s)\big)\big| \\ &\le \Big(\|f'\|_\infty \|\partial_x u(\cdot,s)\|_\infty + \|a'\|_\infty \|\partial_x u(\cdot,s)\|_\infty \\ &\qquad + \|a\|_\infty \|\partial_x^2 u(\cdot,s)\|_\infty\Big)\big|x - h^+(s)\big|, \end{aligned} \tag{4.7}$$

we obtain that there exists a constant C_4 satisfying $|I_5| \le C_4\delta^2(t)$. Observe that

$$\begin{aligned} &\big|\widetilde{A}\big(u^1\big(h^1(s),s\big)\big) - \widetilde{A}\big(u^2\big(h^2(s),s\big)\big)\big| \\ &\le \big|\widetilde{A}\big(u^{j(s)}(h^+(s),s)\big) - \widetilde{A}\big(u^{j(s)}(h^-(s),s)\big)\big| \\ &\qquad + \big|\widetilde{A}\big(u^{j(s)}(h^-(s),s)\big) - \widetilde{A}\big(u^{i(s)}(h^-(s),s)\big)\big| \\ &\le \varepsilon^{-1}\|a\|_\infty \|\partial_x u(\cdot,s)\|_\infty \delta(t) \\ &\qquad + \varepsilon^{-1}\|a\|_\infty \big|u^{j(s)}\big(h^-(s),s\big) - u^{i(s)}\big(h^-(s),s\big)\big|. \end{aligned}$$

From this inequality and similar ones for the functions $\partial_x\widetilde{A}$, p, and q, we obtain that there exist constants C_5 and C_6 such that

$$|I_6| + |I_7| \le C_5 \int_0^t \delta(\tau)\, d\tau + C_6 \int_0^t \big|u^1\big(h^-(s),s\big) - u^2\big(h^-(s),s\big)\big|\, ds.$$

By similar arguments it follows that there exist constants C_7 and C_8 satisfying

$$|I_8| \le C_7 \int_0^t \delta(\tau)\, d\tau + C_8 \int_0^t \int_0^{h^-(s)} \big|u^1(x,s) - u^2(x,s)\big|\, dxds.$$

Finally, since the integrand of I_9 is bounded, there exists a constant C_9 such that

$$|I_9| \le C_9 \int_0^t \delta(\tau)\, d\tau.$$

Summarizing the estimates of I_4 to I_9, we obtain

$$\begin{aligned}\delta(t) \le C_4\delta^2(t) + C_{10}\int_0^t \big|u^1\big(h^-(s),s\big) - u^2\big(h^-(s),s\big)\big|\,ds \\ + C_{11}\int_0^t \delta(s)\,ds + C_{12}\int_0^t\int_0^{h^-(s)} \big|u^1(x,s) - u^2(x,s)\big|\,dxds\end{aligned} \tag{4.8}$$

with suitable new constants C_{10} to C_{12}. To estimate the right-hand part of (4.8), let $z(x,s) := u^1(x,s) - u^2(x,s)$. This function satisfies in $Q(h^-,t)$ the linear equation

$$\partial_t z - \widetilde{a}\partial_x^2 z + \widetilde{b}\partial_x z + \widetilde{c}z = 0,$$

where the coefficients $\widetilde{a}$ to $\widetilde{c}$ are given by (the argument (x,s) is omitted wherever appropriate)

$$\widetilde{a} = a(u^1), \quad \widetilde{b} = a'(\partial_x u^1 + \partial_x u^2) + f'(u^1), \quad \widetilde{c} = \partial_x^2 u^2 \overline{a'} + (\partial_x u^2)^2 \overline{a''} + \partial_x u^2 \overline{f''},$$

where

$$\overline{g}(x,s) := \int_0^1 g\big(\lambda u^1(x,s) + (1-\lambda)u^2(x,s)\big)d\lambda, \quad g \in \Big\{a', a'', f', f'', \partial_2\widehat{\gamma}, \partial_2\widehat{\beta}\Big\}.$$

The function z satisfies the initial condition $z(x,0) = 0$ for $0 \le x \le 1$. From boundary condition (4.1c) and estimate (4.7) we obtain

$$\big((\overline{f'} - \partial_x u^2 \overline{a'})z - a\big(u^1\big)\partial_x z\big)(0,s) = \psi^1(s).$$

Similarly, boundary condition (4.1d) implies

$$\begin{aligned}\Big(\Big[\overline{f'} + \big[\widehat{\beta}\big(s,u^1\big)h^1(s) + \widehat{\gamma}\big(s,u^1\big)\big] + \overline{\partial_2\widehat{\beta}}h^2(s)u^2 \\ + \overline{\partial_2\widehat{\gamma}}u^2 + \overline{a'}(\partial_x u)^2\Big]z - a(u^1)\partial_x z\Big)\big(h^-(s),s\big) = \psi^2(s), \\ \psi^2(s) := -\widehat{\beta}\big(s,u^1(h^-(s),s)\big)\big(h^1(s) - h^2(s)\big)u^2\big(h^-(s),s\big).\end{aligned}$$

Since the functions $\widetilde{a}$ to $\widetilde{c}$ are bounded and since there exist constants C_{13} to C_{15} such that $|\widetilde{d}(x,s)| \le C_{13}\delta(t)$, $|\psi^1(s)| \le C_{14}\delta(s)$, and $|\psi^2(s)| \le C_{15}\delta(s)$, we obtain from the maximum principle that there exists a constant C_{16} independent of t with

$$\big|z(x,t)\big| \le C_{16}\max_{0\le s\le t}\delta(s);$$

hence inequality (4.8) reduces to

$$\delta(t) \le C_4\delta^2(t) + C_{17}\int_0^t \max_{0\le\tau\le s}\delta(\tau)\,ds.$$

Since $\delta(0) = 0$ and $\delta'(s)$ is uniformly bounded, we can choose a time $t_0 \in (0,T]$ such that $C_4\delta(t) \le 1/2$ for all $t \in (0,t_0]$. Thus

$$\delta(t) \le \frac{1}{2}\max_{0\le\tau\le t}\delta(\tau) + C_{17}\int_0^t \max_{0\le\tau\le s}\delta(\tau)\,ds \quad \text{for } 0 \le t \le t_0.$$

Consequently, there exists a constant C_{18} such that

$$\delta(t) \le C_{18} \int_0^t \max_{0\le\tau\le s} \delta(\tau)\, ds \quad \text{for } 0 \le t \le t_0.$$

This shows that $\delta(t) = 0$, i.e., $h^1(t) = h^2(t) =: h(t)$ for $0 \le t \le t_0$. The maximum principle then implies $u^1(x,t) = u^2(x,t)$ for $(x,t) \in Q(h,t_0)$, which contradicts the definition of t_1. Consequently, we obtain $u^1(x,t) = u^2(x,t)$ in $Q(h,T)$. This concludes the proof of Lemma 4.2. □

5. Existence of generalized solutions. To prove the existence of a generalized solution, we have to establish uniform estimates (with respect to the regularization parameter ε) of the solutions u_ε of the regularized free boundary problem (4.1). It is convenient to formulate these estimates in terms of the solutions $\{v_\varepsilon\}_{\varepsilon>0}$ of the problem (4.2) with fixed boundaries.

LEMMA 5.1. *Let $(v_\varepsilon, h_\varepsilon)$ be a solution of the regularized boundary problem* (4.2). *Then the following uniform estimates are valid, where the constant M_2 is independent of ε:*

$$\sup_{t\in[0,T]} \|\partial_x v_\varepsilon(\cdot,t)\|_{L^1(0,1)} \le M_2. \tag{5.1}$$

Proof. The proof closely follows that of Lemma 11 in [4]. Define approximations sgn_η and $|\cdot|_\eta$ of the sign and modulus functions by

$$\operatorname{sgn}_\eta(\tau) := \begin{cases} \operatorname{sgn}(\tau) & \text{if } |\tau| > \eta, \\ \tau/\eta & \text{if } |\tau| \le \eta, \end{cases} \quad |x|_\eta := \int_0^x \operatorname{sgn}_\eta(\zeta) d\zeta, \quad \eta > 0.$$

Setting $y_\varepsilon := \partial_\xi v_\varepsilon$, we obtain the following by differentiating (4.2a) with respect to ξ, multiplying it by $\operatorname{sgn}_\eta(y_\varepsilon)$, integrating over Q_{T_0}, where $0 < T_0 \le T$, and using integration by parts:

$$\begin{aligned} &\iint_{Q_{T_0}} \operatorname{sgn}_\eta(y_\varepsilon)\partial_t y_\varepsilon \, d\xi dt = \int_0^{T_0} \operatorname{sgn}_\eta(y_\varepsilon)\big(-\partial_\xi g_\varepsilon(v_\varepsilon,\xi,t) + h_\varepsilon^{-2}\partial_\xi^2 A_\varepsilon(v_\varepsilon)\big)\Big|_{\xi=0}^{\xi=1} dt \\ &\quad + \iint_{Q_{T_0}} \operatorname{sgn}'_\eta(y_\varepsilon)\partial_\xi y_\varepsilon \Big\{-h_\varepsilon^{-1}h'_\varepsilon\xi + h_\varepsilon^{-1}f'_\varepsilon(v_\varepsilon) - h_\varepsilon^{-2}a'_\varepsilon(v_\varepsilon)y_\varepsilon\Big\} y_\varepsilon \, d\xi dt \\ &\quad - \iint_{Q_{T_0}} \operatorname{sgn}'_\eta(y_\varepsilon) a_\varepsilon(v_\varepsilon)(\partial_\xi y_\varepsilon)^2 \, d\xi dt - \iint_{Q_{T_0}} \operatorname{sgn}_\eta(y_\varepsilon) h_\varepsilon^{-1} h'_\varepsilon y_\varepsilon \, d\xi dt \\ &=: I_\eta^1 + I_\eta^2 + I_\eta^3 + I_\eta^4. \end{aligned} \tag{5.2}$$

We now estimate the integrals I_η^1 to I_η^4. Using (4.2a), we see that

$$I_\eta^1 = \int_0^{T_0} \Big\{ \operatorname{sgn}_\eta\big(\partial_\xi v_\varepsilon(1,t)\big)\partial_t v_\varepsilon(1,t) - \operatorname{sgn}_\eta\big(\partial_\xi v_\varepsilon(0,t)\big)\partial_t v_\varepsilon(0,t)\Big\}\, dt.$$

The boundary conditions (4.2c) and (4.2d) imply that

$$\partial_\xi v_\varepsilon(0,t) = \frac{h_\varepsilon f_\varepsilon(v_\varepsilon(0,t))}{a_\varepsilon(v_\varepsilon(0,t))} \ge 0, \quad \partial_\xi v_\varepsilon(1,t) = \frac{h_\varepsilon[f_\varepsilon(v_\varepsilon(1,t)) - h'_\varepsilon v_\varepsilon(1,t)]}{a_\varepsilon(v_\varepsilon(1,t))} \ge 0. \tag{5.3}$$

In light of Lemma 4.1, we see from (5.3) that $\partial_\xi v_\varepsilon(0,t) = 0$ implies that $v_\varepsilon(0,t)$ assumes the constant value $v_{\varepsilon\min} := \inf \mathcal{U}^\varepsilon$ or $v_{\varepsilon\max} := \sup \mathcal{U}^\varepsilon$. Letting $\mathcal{E}_0 := \{t \in [0,T] : v_\varepsilon(0,t) = v_{\varepsilon\min} \text{ or } v_\varepsilon(0,t) = v_{\varepsilon\max}\}$, we see that $\partial_t v_\varepsilon(0,t) = 0$ a.e. in $\mathcal{E}_0$. We therefore conclude that

$$-\int_0^{T_0} \operatorname{sgn}_\eta\bigl(y_\varepsilon(0,t)\bigr)\partial_t v_\varepsilon(0,t)\,dt \overset{\eta\to 0}{\longrightarrow} -\int_0^{T_0} \partial_t v_\varepsilon(0,t)\,dt = v_\varepsilon(0,0) - v_\varepsilon(0,T_0).$$

Applying a similar argument to the boundary condition (4.2d), we obtain

$$I_\eta^1 \overset{\eta\to 0}{\longrightarrow} v_\varepsilon(1,T_0) - v_\varepsilon(1,0) + v_\varepsilon(0,0) - v_\varepsilon(0,T_0).$$

From Saks' lemma [2, 22] we infer that $I_\eta^2 \to 0$ for $\eta \to 0$. In light of $I_\eta^3 \le 0$ and

$$I_\eta^4 \overset{\eta\to 0}{\longrightarrow} -\iint_{Q_{T_0}} h_\varepsilon^{-1} h_\varepsilon' |y_\varepsilon|\,d\xi dt,$$

we get from (5.2)

$$\begin{aligned}\bigl\|\partial_x v_\varepsilon(\cdot,T_0)\bigr\|_{L^1(0,1)} \le{}& \|(u_\varepsilon^0)'\|_{L^1(0,1)} - v_\varepsilon(1,0) + v_\varepsilon(1,T_0) - v_\varepsilon(0,T_0)\\ &+ v_\varepsilon(0,0) + \int_0^{T_0} \bigl\|\partial_x v_\varepsilon(\cdot,t)\bigr\|_{L^1(0,1)}\,dt.\end{aligned}$$

An application of Gronwall's lemma yields estimate (5.1). ∎

For the present problem it is probably impossible to obtain a uniform $L^1(Q_T)$ estimate of the time derivative $\partial_t v_\varepsilon$, in contrast to several analyses of problems with fixed boundaries [4, 5]. For example, in [4] such an estimate was derived by differentiating the regularized parabolic equation with respect to t, multiplying the resulting equation by $\operatorname{sgn}_\eta(\partial_x v_\varepsilon)$, integrating the result over the computational domain, and using the boundary conditions and Gronwall's lemma. In the present case, differentiating (4.2a) with respect to t will produce an equation with a coefficient involving $h_\varepsilon''(t)$. However, we cannot bound this quantity, since differentiating the coupling equation (4.2f) with respect to t will lead to an equation for $h_\varepsilon''(t)$ in terms of $\partial_t v_\varepsilon$, and we cannot control the variation of v_ε with respect to t along the boundary $\xi = 0$.

To apply the compactness criterion to the family of regularized solutions $\{v_\varepsilon\}_{\varepsilon>0}$, we apply the following variant of Kružkov's [14] interpolation lemma (see, e.g., [13] for a proof).

LEMMA 5.2. *Assume that there exist finite constants c_1 and c_2 such that the function $u : (0,1)\times[0,T] \to \mathbb{R}$ satisfies $\|u(\cdot,t)\|_{L^\infty(0,1)} \le c_1$ and $\mathrm{TV}_{(0,1)}(u(\cdot,t)) \le c_2$ for all $t \in [0,T]$, and that u is weakly Lipschitz continuous with respect to t in the sense that*

$$\left|\int_0^1 \bigl(u(x,t_2) - u(x,t_1)\bigr)\varphi(x)\,dx\right| \le \mathcal{O}(t_2 - t_1)\sum_{i=0}^n \|\varphi^{(i)}\|_{L^\infty(0,1)}$$

for all $\varphi \in C_0^n(0,1)$, $0 \le t_1 \le t_2 \le T$. Then there exists a constant C, depending in particular on c_1 and c_2, such that the following interpolation result is valid:

$$\bigl\|u(\cdot,t_2) - u(\cdot,t_1)\bigr\|_{L^1(0,1)} \le C(t_2 - t_1)^{1/(n+1)}, \quad 0 \le t_1 \le t_2 \le T.$$

We calculate here that

$$\begin{aligned}
&\int_0^1 \big(v_\varepsilon(\xi,t_2)-v_\varepsilon(\xi,t_1)\big)\varphi(\xi)\,d\xi\\
&=\int_{t_1}^{t_2}\int_0^1 \Big\{h_\varepsilon^{-1}h_\varepsilon'(\xi\partial_\xi v_\varepsilon - v_\varepsilon) - h_\varepsilon^{-1}\partial_\xi f_\varepsilon(v_\varepsilon) + h_\varepsilon^{-2}\partial_\xi^2 A_\varepsilon(v_\varepsilon)\Big\}\varphi(\xi)\,d\xi dt\\
&=\int_{t_1}^{t_2}\int_0^1 \Big\{h_\varepsilon^{-1}h_\varepsilon' v_\varepsilon\varphi(\xi) + \big(-h_\varepsilon^{-1}h_\varepsilon'(t)\xi v_\varepsilon + h_\varepsilon^{-1}f_\varepsilon(v_\varepsilon) - h_\varepsilon^{-2}a_\varepsilon(v_\varepsilon)\partial_\xi v_\varepsilon\big)\varphi'(\xi)\Big\}\,d\xi dt.
\end{aligned}$$

From the proof of Lemma 4.4 it follows that there exists a constant $\widetilde{M}_h$ such that the estimate $\|1/h_\varepsilon^2\|_{L^\infty(0,T)} + \|h_\varepsilon'/h_\varepsilon\|_{L^\infty(0,T)} \le \widetilde{M}_h$ holds uniformly in ε. Using the estimate (5.1), we get

$$\begin{aligned}
&\left|\int_0^1 \big(v_\varepsilon(\xi,t_2)-v_\varepsilon(\xi,t_1)\big)\varphi(\xi)\,d\xi\right|\\
&\quad\le (t_2-t_1)\widetilde{M}_h\Big[M_0\|\varphi\|_{L^\infty(0,1)} + \big(\|f_\varepsilon\|_\infty + \|a_\varepsilon\|_\infty M_2 + M_0\big)\|\varphi'\|_{L^\infty(0,1)}\Big].
\end{aligned}$$

Thus we have proved the following.

LEMMA 5.3. *Let $(v_\varepsilon, h_\varepsilon)$ be a solution of the regularized boundary problem* (4.2). *Then the following uniform estimates are valid, where the constant M_3 is independent of ε:*

$$\big\|v_\varepsilon(\cdot,t_2)-v_\varepsilon(\cdot,t_1)\big\|_{L^1(0,1)} \le M_3(t_2-t_1)^{1/2}, \quad 0\le t_1\le t_2\le T. \tag{5.4}$$

In light of estimates (4.4), (5.1), and (5.4) of v_ε, a standard application of Kolmogorov's compactness criterion [23] yields that the family $\{v_\varepsilon\}$ is compact in $L^1(Q_T)$. Thus there exists a sequence $\varepsilon_n \to 0$ such that $\{v_{\varepsilon_n}\}$ converges in $L^1(Q_T)$ to a function $v \in BV_{1,1/2}(Q_T)$. Moreover, since the estimates of h_ε in (4.5) are uniform in ε, there exists a subsequence $\{h_{\varepsilon_n}\}$ of $\{h_\varepsilon\}$ and a function h such that $|h(t_2)-h(t_1)| \le M_h(t_2-t_1)$ for $0\le t_1\le t_2\le T$, $h(0)=1$ and h is nonincreasing.

We now have to prove that the limit pair (v,h) is indeed a generalized solution of the initial-boundary value problem (3.6). Obviously, the function h satisfies part (a) of Definition 3.2.

LEMMA 5.4. *The limit function v of solutions v_ε of the regularized problem* (4.2) *has the regularity properties stated in part* (b) *of Definition* 3.2.

Proof. Multiplying (4.2a) by v_ε and integrating the result over Q_T, we get

$$\begin{aligned}
\iint_{Q_T} h_\varepsilon^{-2}a_\varepsilon(v_\varepsilon)(\partial_\xi v_\varepsilon)^2 d\xi dt &= -\frac{1}{2}\int_0^1 v_\varepsilon^2\Big|_{t=0}^{t=T} d\xi - \int_{Q_T} h_\varepsilon^{-1}h_\varepsilon' v_\varepsilon^2\,d\xi dt\\
&\quad + \iint_{Q_T} g_\varepsilon(v_\varepsilon,\xi,t)\partial_\xi v_\varepsilon\,d\xi dt,
\end{aligned}$$

and thus

$$\big\|\partial_x A^\varepsilon(v_\varepsilon)\big\|_{L^2(Q_T)} \le \|a_\varepsilon\|_\infty\big\{M_0^2 + TM_h(2M_0^2 + M_2\|f_\varepsilon\|_\infty)\big\} =: M_4^\varepsilon.$$

The stated regularity of $A(u)$ follows by letting $\varepsilon\to 0$ and observing that M_4^ε is uniformly bounded for ε sufficiently small. To show the stated $\mathcal{DM}^2$ property, we

rewrite the regularized equation (4.2a) as follows, where $|k| \le K$ and K is a suitable large constant:

(5.5)
$$\partial_t(v_\varepsilon - k) + \partial_\xi\big(g_\varepsilon(v_\varepsilon,\xi,t) - g_\varepsilon(k,\xi,t)\big) + h_\varepsilon^{-1}h_\varepsilon'(v_\varepsilon - k) = h_\varepsilon^{-2}\partial_\xi^2\big(A_\varepsilon(v_\varepsilon) - A_\varepsilon(k)\big).$$

Multiplying (5.5) by $\operatorname{sgn}_\eta(A_\varepsilon(v_\varepsilon) - A_\varepsilon(k))\zeta$, where $k \in \mathbb{R}$ and $\zeta \in C^\infty(\overline{Q_T})$ is an arbitrary test function, and integrating by parts over Q_T then yields

$$\begin{aligned}
&\iint_{Q_T} h_\varepsilon^{-2}\big[\partial_\xi\big(A_\varepsilon(v_\varepsilon) - A_\varepsilon(k)\big)\big]^2 \operatorname{sgn}_\eta'\big(A_\varepsilon(v_\varepsilon) - A_\varepsilon(k)\big)\zeta\, d\xi dt \\
&= \int_0^T \big(h_\varepsilon^{-2}\partial_\xi A_\varepsilon(v_\varepsilon) - g_\varepsilon(v_\varepsilon,\xi,t)\big)\operatorname{sgn}_\eta\big(A_\varepsilon(v_\varepsilon) - A_\varepsilon(k)\big)\zeta\Big|_{\xi=0}^{\xi=1} dt \\
&\quad + \int_0^T g_\varepsilon(k,\xi,t)\operatorname{sgn}_\eta\big(A_\varepsilon(v_\varepsilon) - A_\varepsilon(k)\big)\zeta\Big|_{\xi=0}^{\xi=1} dt \\
&\quad + \iint_{Q_T}\Big\{\big(g_\varepsilon(v_\varepsilon,\xi,t) - g_\varepsilon(k,\xi,t)\big) - h_\varepsilon^{-2}\partial_\xi\big(A_\varepsilon(v_\varepsilon) - A_\varepsilon(k)\big)\Big\} \\
&\qquad \times \operatorname{sgn}_\eta\big(A_\varepsilon(v_\varepsilon) - A_\varepsilon(k)\big)\partial_\xi\zeta\, d\xi dt \\
&\quad + \iint_{Q_T}\big(g_\varepsilon(v_\varepsilon,\xi,t) - g_\varepsilon(k,\xi,t)\big)\operatorname{sgn}_\eta'\big(A_\varepsilon(v_\varepsilon) - A_\varepsilon(k)\big) \\
&\qquad \times \partial_\xi\big(A_\varepsilon(v_\varepsilon) - A_\varepsilon(k)\big)\zeta\, d\xi dt \\
&\quad - \iint_{Q_T} h_\varepsilon^{-1}h_\varepsilon' v_\varepsilon \operatorname{sgn}_\eta\big(A_\varepsilon(v_\varepsilon) - A_\varepsilon(k)\big)\zeta\, d\xi dt + \int_0^1 |v_\varepsilon - k|_\eta\zeta\Big|_{t=0}^{t=T} d\xi \\
&\quad - \iint_{Q_T}(v_\varepsilon - k)\operatorname{sgn}_\eta'\big(A_\varepsilon(v_\varepsilon) - A_\varepsilon(k)\big)\partial_t\big(A_\varepsilon(v_\varepsilon) - A_\varepsilon(k)\big)\zeta d\xi dt \\
&\quad - \iint_{Q_T}(v_\varepsilon - k)\operatorname{sgn}_\eta\big(A_\varepsilon(v_\varepsilon) - A_\varepsilon(k)\big)\partial_t\zeta\, d\xi dt =: I_\eta^5 + \cdots + I_\eta^{12}.
\end{aligned} \tag{5.6}$$

We now consider the limit of the right-hand side of (5.6) for $\eta \to 0$. First note that $I_\eta^5 = 0$ due to the boundary conditions (4.2c) and (4.2d). By Lebesgue's theorem, we get

$$I_\eta^6 \xrightarrow{\eta\to 0} I_0^6 := \int_0^T g_\varepsilon(k,\xi,t)\operatorname{sgn}\big(A_\varepsilon(v_\varepsilon(\xi,t)) - A_\varepsilon(k)\big)\zeta(\xi,t)\Big|_{\xi=0}^{\xi=1} dt,$$

which implies $|I_0^6| \le T\|g_\varepsilon\|_\infty\|\zeta\|_\infty$. Using the properties of sgn_η, Lebesgue's theorem, $\partial_\xi A(k) = 0$, and the fact that $\operatorname{sgn}(v_\varepsilon - k) = \operatorname{sgn}(A_\varepsilon(v_\varepsilon) - A_\varepsilon(k))$ due the monotonicity of $A_\varepsilon(\cdot)$, we get

$$I_\eta^7 \xrightarrow{\eta\to 0} \iint_{Q_T}\Big\{\operatorname{sgn}(v_\varepsilon - k)\big(g_\varepsilon(v_\varepsilon,\xi,t) - g_\varepsilon(k,\xi,t)\big) - h_\varepsilon^{-2}\partial_\xi\big|A_\varepsilon(v_\varepsilon) - A_\varepsilon(k)\big|\Big\}\,\partial_\xi\zeta d\xi dt.$$

Precisely as in [18], using that $u\operatorname{sgn}_\eta'(u) \le \chi_{\{u:\,0<|u|\le\eta\}}$ and recalling from assumption (4.3) that the inverse function A_ε^{-1} is for fixed ε Lipschitz continuous with constant $1/\nu_\varepsilon$, we get that

$$\begin{aligned}
&\big|\big(g_\varepsilon(v_\varepsilon,\xi,t) - g_\varepsilon(k,\xi,t)\big)\operatorname{sgn}_\eta'\big(A_\varepsilon(v_\varepsilon) - A_\varepsilon(k)\big)\partial_\xi\big(A_\varepsilon(v_\varepsilon) - A_\varepsilon(k)\big)\big| \\
&\qquad\qquad \le \frac{L_\varepsilon}{\nu_\varepsilon}\big|\partial_\xi\big(A_\varepsilon(v_\varepsilon) - A_\varepsilon(k)\big)\big|\chi_{\mathcal{I}(\varepsilon,\eta)},
\end{aligned}$$

where $\mathcal{I}(\varepsilon,\eta) := \{(\xi,t):\ 0 \le |A_\varepsilon(v_\varepsilon(\xi,t)) - A_\varepsilon(k)| \le \eta\}$. Consequently,

$$|I_\eta^8| \le \frac{L_\varepsilon}{\nu_\varepsilon}\|\zeta\|_{L^\infty(Q_T)} \iint_{\mathcal{I}(\varepsilon,\eta)} \big|\partial_\xi\big(A_\varepsilon(v_\varepsilon) - A_\varepsilon(k)\big)\big|\, d\xi dt.$$

Observe that $\operatorname{meas}\mathcal{I}(\varepsilon,\eta) \to 0$ as $\eta \to 0$, since this measure converges to that of the empty set. Thus $I_\eta^8 \to 0$ as $\eta \to 0$. Next, we see that

$$I_\eta^9 \overset{\eta\to 0}{\longrightarrow} I_0^9 := -\iint_{Q_T} h_\varepsilon^{-1} h_\varepsilon'(t) v_\varepsilon \operatorname{sgn}\big(A_\varepsilon(v_\varepsilon) - A_\varepsilon(k)\big)\zeta\, d\xi dt$$

with $|I_0^9| \le T M_h M_0 \|\zeta\|_{L^\infty(Q_T)}$. Furthermore,

$$I_\eta^{10} \overset{\eta\to 0}{\longrightarrow} I_0^{10} := \int_0^1 \Big\{\big|v_\varepsilon(\xi,T) - k\big|\zeta(\xi,T) - \big|u_0^\varepsilon(\xi) - k\big|\zeta(\xi,0)\Big\} d\xi,$$

and thus $|I_0^{10}| \le 2(M_0 + K)\|\zeta\|_{L^\infty(Q_T)}$. The integrand of I_η^{11} satisfies

$$\begin{aligned}
&\big|(v_\varepsilon - k)\operatorname{sgn}_\eta'\big(A_\varepsilon(v_\varepsilon) - A_\varepsilon(k)\big)\partial_t\big(A_\varepsilon(v_\varepsilon) - A_\varepsilon(k)\big)\zeta\big| \\
&= \big|(v_\varepsilon - k)\operatorname{sgn}_\eta'(v_\varepsilon - k)\partial_t\big(A_\varepsilon(u_\varepsilon) - A_\varepsilon(k)\big)\zeta\big| \\
&\le \big|\partial_t\big(A_\varepsilon(v_\varepsilon) - A_\varepsilon(k)\big)\big|\chi_{\{(\xi,t):\, 0\le|v_\varepsilon(\xi,t)-k|\le\eta\}}.
\end{aligned}$$

An argument similar to that employed for I_η^8 reveals that $I_\eta^{11} \to 0$ as $\eta \to 0$. Finally, we obtain

$$I_\eta^{12} \overset{\eta\to 0}{\longrightarrow} I_0^{12} := -\iint_{Q_T} |v_\varepsilon - k|\partial_\xi\zeta\, d\xi dt.$$

Collecting the estimates of I_η^5 to I_η^{12} yields that all terms of the right-hand part of (5.6) possess a limit as $\eta \to 0$ and are in particular uniformly bounded with respect to η. Thus, taking $\zeta \equiv 1$ we see that there exists a constant C_1, depending possibly on ε (but not on η), such that

$$\iint_{Q_T} h_\varepsilon^{-2}\big[\partial_\xi\big(A_\varepsilon(v_\varepsilon) - A_\varepsilon(k)\big)\big]^2 \operatorname{sgn}_\eta'\big(A_\varepsilon(v_\varepsilon) - A_\varepsilon(k)\big)\, d\xi dt \le C_1(\varepsilon).$$

Consequently, the sequence

$$\{E_{\varepsilon,\eta}\}_{\eta>0} := \Big\{\big(h_\varepsilon(t)\big)^{-2}\big[\partial_\xi\big(A_\varepsilon(v_\varepsilon) - A_\varepsilon(k)\big)\big]^2 \operatorname{sgn}_\eta'\big(A_\varepsilon(v_\varepsilon) - A_\varepsilon(k)\big)\Big\}_{\eta>0}$$

is bounded in $L^1(Q_T)$ with respect to η and therefore also in $C(\overline{Q_T})'$, the dual of the space $C(\overline{Q_T})$ of continuous functions on $\overline{Q_T}$. By compactness of the weak-$\star$ topology of $C(\overline{Q_T})'$ we deduce that, up to subsequences, the sequence $\{E_{\varepsilon,\eta}\}_\eta$ converges towards an element $E_\varepsilon \in C(\overline{Q_T})'$ in the weak-$\star$ topology. Thus for any $\zeta \in C^\infty(\overline{Q_T})$

we can pass to the limit $\eta \to 0$ in (5.6) to obtain

$$
\begin{aligned}
\langle E_\varepsilon, \zeta\rangle = &\int_0^T g_\varepsilon(k,\xi,t)\,\mathrm{sgn}\big(A_\varepsilon(v_\varepsilon(\xi,t)) - A_\varepsilon(k)\big)\zeta(\xi,t)\Big|_{\xi=0}^{\xi=1} dt \\
&- \iint_{Q_T} h_\varepsilon^{-1} h_\varepsilon'(t) v_\varepsilon\,\mathrm{sgn}\big(A_\varepsilon(v_\varepsilon) - A_\varepsilon(k)\big)\zeta\,d\xi dt \\
&+ \iint_{Q_T} \Big\{\mathrm{sgn}(v_\varepsilon - k)\big(g_\varepsilon(v_\varepsilon,\xi,t) - g_\varepsilon(k,\xi,t)\big) \\
&\qquad - h_\varepsilon^{-2}\partial_\xi\big|A_\varepsilon(v_\varepsilon) - A_\varepsilon(k)\big|\Big\}\partial_\xi\zeta\,d\xi dt \\
&+ \int_0^1 \Big\{\big|v_\varepsilon(\xi,T) - k\big|\zeta(\xi,T) - \big|u_0^\varepsilon(\xi) - k\big|\zeta(\xi,0)\Big\}d\xi \\
&- \iint_{Q_T} |v_\varepsilon - k|\partial_t\zeta\,d\xi dt.
\end{aligned}
\tag{5.7}
$$

On the other hand, due to the properties of the function sgn_η, we have $E_{\varepsilon,\eta} \geq 0$ for every $\varepsilon, \eta > 0$. Therefore we get

$$
\begin{aligned}
&\frac{|\langle E_\varepsilon, \zeta\rangle|}{\|\zeta\|_{L^\infty(Q_T)}} \\
&= \lim_{\eta\to 0} \frac{1}{\|\zeta\|_{L^\infty(Q_T)}} \left| \iint_{Q_T} h_\varepsilon^{-2}\big[\partial_\xi\big(A_\varepsilon(v_\varepsilon) - A_\varepsilon(k)\big)\big]^2\,\mathrm{sgn}_\eta'\big(A_\varepsilon(v_\varepsilon) - A_\varepsilon(k)\big)\zeta\,d\xi dt \right| \\
&\leq \limsup_{\eta\to 0} \iint_{Q_T} h_\varepsilon^{-2}\big[\partial_\xi\big(A_\varepsilon(v_\varepsilon) - A_\varepsilon(k)\big)\big]^2\,\mathrm{sgn}_\eta'\big(A_\varepsilon(v_\varepsilon) - A_\varepsilon(k)\big)d\xi dt.
\end{aligned}
$$

Thus we get from (5.7) with $\zeta \equiv 1$

$$
\begin{aligned}
\frac{|\langle E_\varepsilon, \zeta\rangle|}{\|\zeta\|_{L^\infty(Q_T)}} \leq &- \iint_{Q_T} h_\varepsilon^{-1} h_\varepsilon'(t) v_\varepsilon\,\mathrm{sgn}\big(A_\varepsilon(v_\varepsilon) - A_\varepsilon(k)\big)\,d\xi dt \\
&+ \int_0^T g_\varepsilon(k,\xi,t)\,\mathrm{sgn}\big(A_\varepsilon(v_\varepsilon(\xi,t)) - A_\varepsilon(k)\big)\Big|_{\xi=0}^{\xi=1} dt \\
&+ \int_0^1 \Big\{\big|v_\varepsilon(\xi,T) - k\big| - \big|u_0^\varepsilon(\xi) - k\big|\Big\}d\xi.
\end{aligned}
\tag{5.8}
$$

Using the estimate (4.4) we deduce that there exists a constant C_2, which does not depend on ε, such that $|\langle E_\varepsilon, \zeta\rangle| \leq C_2\|\zeta\|_{L^\infty(Q_T)}$ for all $\varepsilon > 0$. Consequently, E_ε is bounded in $C(\overline{Q_T})'$, and up to a subsequence E_ε converges in the weak-$\star$ topology to a functional $E \in C(\overline{Q_T})'$, i.e., a Radon measure. We now pass to the limit $\varepsilon \to 0$ in (5.7). Since $g_\varepsilon(k,\xi,t)$ converges strongly to $g(k,\xi,t)$ and $\mathrm{sgn}(A_\varepsilon(v_\varepsilon) - A_\varepsilon(k))$ is bounded, $g_\varepsilon(k,\xi,t)\,\mathrm{sgn}(A_\varepsilon(v_\varepsilon(\xi,t)) - A_\varepsilon(k))$ converges weakly in $L^1(\{\xi\}\times(0,T))$, where $\xi = 0$ or $\xi = 1$, to $g(k,\xi,t)\,\mathrm{sgn}(A(v(\xi,t)) - A(k))$. Moreover, $|v_\varepsilon - k|$ converges strongly to $|v-k|$ in $C(0,T;L^1(0,1))$, $g_\varepsilon(v_\varepsilon,\xi,t)$ converges strongly to $g(v,\xi,t)$ in $L^q(Q_T)$ for every $q < \infty$, and $\partial_x|A_\varepsilon(v_\varepsilon) - A_\varepsilon(k)|$ converges weakly in $L^2(Q_T)$ to $\partial_\xi|A(v) - A(k)|$. Passing to the limit $\varepsilon \to 0$ in (5.7) we conclude that for all $\varphi \in C_0^\infty(Q_T)$,

$$
\begin{aligned}
\langle E, \varphi\rangle = &- \iint_{Q_T} h^{-1}h' v\,\mathrm{sgn}\big(A(v) - A(k)\big)\varphi\,d\xi dt - \iint_{Q_T} |v-k|\partial_t\varphi\,d\xi dt \\
&+ \iint_{Q_T} \Big\{\mathrm{sgn}(v-k)\big(g(v,\xi,t) - g(k,\xi,t)\big) - h^{-2}\partial_\xi\big|A(v) - A(k)\big|\Big\}\partial_\xi\varphi\,d\xi dt.
\end{aligned}
\tag{5.9}
$$

Since g, $\operatorname{sgn}(A(v)-A(k))$, and $\partial_\xi|A(v)-A(k)|$ are all functions in $L^1(Q_T)$, and since E is a Radon measure, we obtain from (5.9) that for all $\varphi \in C_0^\infty(Q_T)$,

$$\left| \iint_{Q_T} \Big\{ |v-k|\partial_t\varphi + \Big(\operatorname{sgn}(v-k)\big(g(v,\xi,t)-g(k,\xi,t)\big) - h^{-2}\partial_\xi\big|A(v)-A(k)\big|\Big)\partial_\xi\varphi \Big\}\, d\xi dt \right| \le C\|\varphi\|_{L^\infty(Q_T)}.$$

This in particular implies the stated $\mathcal{DM}^2$ property (3.9). ∎

LEMMA 5.5. *The limit function v of solutions v_ε of the regularized initial-boundary value problem satisfies the boundary conditions* (3.3) *and* (3.4) *stated in Definition* 3.1.

Proof. First of all we have from Lemma 4.2, passing to a subsequence if necessary, that h_ε converges uniformly to a certain Lipschitz function h, which satisfies $h(0)=1$, $h(t)\ge h_0>0$. Multiplying (4.1a) by $\varphi \in C_0^1(\Pi_T)$, integrating over $Q(h_\varepsilon,T)$, using integration by parts and the boundary conditions (4.1c), (4.1d), and then letting $\varepsilon \to 0$, we get

$$\iint_{Q(h,T)} \Big\{ u\partial_t\varphi + \big(f(u)-\partial_x A(u)\big)\partial_x\varphi \Big\}\, dx\, dt = 0. \tag{5.10}$$

From (5.10) there follow two conclusions about the $\mathcal{DM}^2$ field $F=(F_1,F_2)=(f(u)-\partial_x A(u),u)$: $\operatorname{div} F = 0$ (this is the obvious one) and $\langle F\cdot\nu|_{\partial Q(h,T)},\varphi\rangle = 0$, as a consequence of the generalized Gauss–Green formula (2.7). Hence, using (2.8) and (2.9) we deduce (3.3) and (3.4). ∎

LEMMA 5.6. *The limit function (u,h) of solutions $(u_\varepsilon,h_\varepsilon)$ of the regularized problem* (4.1) *satisfies* (2.5e) *in the sense stated in* (d) *of Definition* 3.1.

Proof. First, we observe that $A_\varepsilon(u_\varepsilon(x,t))$ converges to $A(u(x,t))$ in $L^1_{\mathrm{loc}}(Q(h,T))$. This follows by the convergence of $A_\varepsilon(v_\varepsilon(\xi,t))$ to $A(v(\xi,t))$ in $L^1(Q_T)$, the uniform convergence of h_ε to h, and the uniform boundedness of $\partial_\xi A_\varepsilon(v_\varepsilon(\xi,t))$ in $L^2(Q_T)$. More specifically, for any compact $K\subset Q(h,T)$, for ε sufficiently small,

$$\begin{aligned}
&\iint_K \big|A_\varepsilon\big(u_\varepsilon(x,t)\big)-A\big(u(x,t)\big)\big|\,dx\,dt\\
&= \iint_{K'} \big|A_\varepsilon\big(u_\varepsilon(h(t)\xi,t)\big)-A\big(u(h(t)\xi,t)\big)\big|h(t)\,d\xi\,dt\\
&\le \iint_{K'} \Big\{ \big|A_\varepsilon\big(v_\varepsilon(\xi,t)\big)-A\big(v(\xi,t)\big)\big| + \big|A_\varepsilon\big(u_\varepsilon(h(t)\xi,t)\big)-A_\varepsilon\big(u_\varepsilon(h_\varepsilon(t)\xi,t)\big)\big| \Big\} h(t)\,d\xi dt\\
&\le \iint_{K'} \big|A_\varepsilon\big(v_\varepsilon(\xi,t)\big)-A\big(v(\xi,t)\big)\big|h(t)\,d\xi\,dt\\
&\quad + C\|h_\varepsilon-h\|_\infty \sup_\varepsilon \|\partial_x A_\varepsilon(u_\varepsilon)\|_{L^2(Q(h_\varepsilon,T))} \overset{\varepsilon\to0}{\longrightarrow} 0,
\end{aligned}$$

where K' denotes the image of K by the transformation $(x,t)\mapsto(\xi,t)$. Now, we prove that $A_\varepsilon(u_\varepsilon(h_\varepsilon(t),t)) \to \gamma_{x\to h(t)}A(u(\cdot,t))$ in $L^1(0,T)$ as $\varepsilon\to0$, after passing to a suitable subsequence if necessary. Given any $\delta>0$, we have $h(t)-\delta<h_\varepsilon(t)<h(t)+\delta$, $0<t<T$, for ε sufficiently small, due to the uniform convergence $h_\varepsilon\to h$. We may also assume that $A_\varepsilon(u_\varepsilon(h(t)-\delta,t))\to A(u(h(t)-\delta,t))$ in $L^1(0,T)$ due to the convergence of $A_\varepsilon(u_\varepsilon(x,t))$ to $A(u(x,t))$ in $L^1_{\mathrm{loc}}(Q(h,T))$. Then, setting

$B_\varepsilon(x,t) := A_\varepsilon(u_\varepsilon(x,t))$, $B(x,t) := A(u(x,t))$, and $x_\delta(t) := h(t) - \delta$, we have

$$\begin{aligned}\int_0^T \big|B_\varepsilon\big(h_\varepsilon(t),t\big) - \gamma_{x\to h(t)}B(\cdot,t)\big|\,dt &\le \int_0^T \big|B_\varepsilon\big(x_\delta(t),t\big) - B\big(x_\delta(t),t\big)\big|\,dt \\ &\quad + \int_0^T \big|B_\varepsilon\big(x_\delta(t),t\big) - B_\varepsilon\big(h_\varepsilon(t),t\big)\big|\,dt + \int_0^T \big|B\big(x_\delta(t),t\big) - \gamma_{x\to h(t)}B(\cdot,t)\big|\,dt \\ &\le \int_0^T \big|B_\varepsilon\big(x_\delta(t),t\big) - B\big(x_\delta(t),t\big)\big|\,dt + C\sqrt{\delta}.\end{aligned}$$

Since $\delta > 0$ may be taken arbitrarily small, the assertion follows. Finally, by passing to a further subsequence of ε's if necessary, we see that, except for $h'_\varepsilon(t)$, all other terms in (4.1e) converge a.e. in $(0,T)$ to the corresponding terms in (2.5e), replacing $A(u(h(t),t))$ by $\gamma_{x\to h(t)}A(u(\cdot,t))$. Therefore, $h'_\varepsilon(t)$ also converges a.e. in $(0,T)$, and since it clearly converges weakly to $h'(t)$, we have $h'_\varepsilon(t) \to h(t)$ a.e. in $(0,T)$, and the lemma is proved. □

It is standard to conclude from Lemma 5.2 that the limit function v satisfies the initial condition (3.12), and to prove that the entropy inequality (3.13) is satisfied by multiplying (4.2a) by $\operatorname{sgn}_\eta(v_\varepsilon - k)\varphi$, $k \in \mathbb{R}$, $\varphi \in C_0^\infty(Q_T)$, $\varphi \ge 0$, and letting $\eta \to 0$ and $\varepsilon \to 0$. Thus we have shown the following.

THEOREM 5.7. *The initial-boundary value problem* (3.6) *admits an entropy solution* (v,h).

Since $h(t) > 0$ and h' is bounded, we conclude that the following holds.

COROLLARY 5.8. *The free boundary problem* (2.5) *admits an entropy solution* (u,h).

A GENERAL FRAMEWORK FOR DIFFRACTIVE OPTICS AND ITS APPLICATIONS TO LASERS WITH LARGE SPECTRUMS AND SHORT PULSES*

KAREN BARRAILH† AND DAVID LANNES‡

Abstract. The aim of this article is to generalize the usual tools of diffractive optics in order to allow the study of phenomena which are out of their range. This generalization relies on the algebra of oscillations with a continuous oscillatory spectrum, which is wider than the usual spaces of periodic or almost-periodic functions. We perform the analysis for general nonlinear hyperbolic systems, both in the dispersive and in the nondispersive cases, and particularly focus on the behavior of the nonlinearities. Our tools yield considerable simplifications in these nonlinearities, which allows us to point out qualitative differences between the dispersive and the nondispersive cases. Finally, we study in detail two physical examples which can be modeled with the present tools: lasers with large spectrums, and those with ultrashort pulses.

Key words. nonlinear hyperbolic systems, Maxwell equations, diffractive optics, continuous oscillatory spectrum, large spectrum, short pulse, nonlinear Schrödinger equation

1. General comment.

1.1. Introduction.

Maxwell equations and many of the physical systems encountered in optics may be written in the form

$$\begin{cases} L^\varepsilon(\partial)\mathbf{u}^\varepsilon + f(\mathbf{u}^\varepsilon) = 0, \\ \mathbf{u}^\varepsilon|_{T=0}(X,Y,Z) = \mathbf{u}^0_\varepsilon(X,Y,Z), \end{cases} \tag{1.1}$$

where $\mathbf{u}^\varepsilon$ takes its values in R^n, and $L^\varepsilon(\partial)$ is a hyperbolic symmetric operator which one writes as

$$L^\varepsilon(\partial) = A_0\partial_T + A_1\partial_X + A_2\partial_Y + A_3\partial_Z + \frac{L_0}{\varepsilon},$$

the matrices A_i being symmetric and L_0 skew-symmetric.

In the study of the propagation of a diffractive laser beam with frequency ω_l and wavenumber $\overrightarrow{k_l} = (0,0,k_l)$, an approximate solution u^ε of $\mathbf{u}^\varepsilon$ is generally sought in the form

$$u^\varepsilon(T,X,Y,Z) = \varepsilon^p(\mathcal{U}_0(\varepsilon T,T,X,Y,Z)e^{i(\omega_l T - k_l Z)/\varepsilon} + \text{c.c.}), \tag{1.2}$$

the exponent p being chosen in order for the nonlinear and diffractive effects to come into play at the same time scale. The method of diffractive optics (see [8], for instance) consists of finding some equations which determine the *profile* $\mathcal{U}_0$.

The object of this article is to introduce a general framework for diffractive optics, which generalizes classical studies in both dispersive and nondispersive diffractive

optics, as shown in [10] and [11], for instance, and allows us also, without added difficulty, to treat more pathological situations. Among these, we study here two physical problems which cannot be modeled by oscillations of type (1.2). These physical phenomena are *large-spectrum lasers* and *ultrashort pulses*.

Large spectrum. The oscillatory spectrum of a classical oscillation of type (1.2) is located at two points, $\{\pm(\omega_l, -\overrightarrow{k_l})\}$. Experimentally, such a localization for the spectrum is never realized. Physically, the spectrum is concentrated around $\{\pm(\omega_l, -\overrightarrow{k_l})\}$, but it never reduces to these two points. These variations are generally taken into account in the amplitude $\mathcal{U}_0$. However, modifying $\mathcal{U}_0$ can only make the spectrum of u^ε expand around $\{\pm(\omega_l, -\overrightarrow{k_l})\}$ in an $O(\varepsilon)$ range. Lasers with large spectrum typically have a spectrum of width $O(1)$ and therefore cannot be modeled with usual oscillations of type (1.2). Direct computations for lasers with large spectrums have been carried out by Morice [13]. Here, we choose another approach and seek an approximate solution of (1.1) in the form

$$u^\varepsilon(T,X,Y,Z) = \varepsilon^p\big(\mathcal{U}_{0,I,1}(\varepsilon T,T,X,Y,Z)e^{i(\omega_l T - k_l Z)/\varepsilon} + \text{c.c.}\big) + \varepsilon^p\,\mathcal{U}_{0,II}\left(\varepsilon T,T,X,Y,Z,\frac{T}{\varepsilon},\frac{Z}{\varepsilon}\right),$$

where $\mathcal{U}_{0,II}$ is an oscillation with a *purely continuous spectrum*. We introduce this notion in Proposition 1.10 below; for the moment, just assume that $\mathcal{U}_{0,II}$ is smooth and decaying in its last two variables.

Considering a model of nonlinear Maxwell equations (system (M) in section 4.1), we prove that the amplitude $\mathcal{E}_{0,I,1}$ of the oscillating component of the electric field satisfies the usual nonlinear Schrödinger (NLS) equation

$$\partial_\tau \mathcal{E}_{0,I,1} + i\frac{\omega'(k_l)}{2k_l}(\partial_X^2+\partial_Y^2)\mathcal{E}_{0,I,1} + i\frac{\omega''(k_l)}{2}\partial_Z^2\mathcal{E}_{0,I,1} = \text{Cst}\ |\mathcal{E}_{0,I,1}|^2\mathcal{E}_{0,I,1},$$

while the corrective term $\mathcal{E}_{0,II}$ satisfies a linear equation,

$$\partial_\tau\partial_{z_0}\mathcal{E}_{0,II} - \frac{\omega'(D_{z_0})}{2}(\partial_X^2+\partial_Y^2)\mathcal{E}_{0,II} - \frac{D_{z_0}\omega''(D_{z_0})}{2}\partial_Z^2\mathcal{E}_{0,II} = 0.$$

The main interest of this latter equation is that all the nonlinearities one would find by a direct computation have been dropped, making this equation linear when it was a priori nonlinear. This fact is a striking consequence of the general results proved thereafter.

Ultrashort pulses. Seeking an approximate solution in the form (1.2) supposes that the profile $\mathcal{U}_0$ varies little compared with the scale of an oscillation. This condition is satisfied for almost all lasers because the length of the pulse is great compared with the wavelength. For the ultrashort pulses, obtained by recent lasers, this is no longer the case (see Figure 1). We refer to [4] and the references therein for a brief history of the study of short pulses in geometric optics. For diffractive time scales, the most general studies we know have been performed by Alterman and Rauch; see [1], [2], [3], and [15]. In the *nondispersive* case, these authors proved rigorously, using asymptotic techniques, that the Schrödinger approximation used for wave trains must be replaced by another approximation for short pulses,

$$2\partial_{z_0}\partial_\tau\mathcal{V} = v(\partial_X^2+\partial_Y^2)\mathcal{V} + \partial_{z_0}f(\mathcal{V}), \tag{1.3}$$

where $v\overrightarrow{e}_Z$ denotes the group velocity.

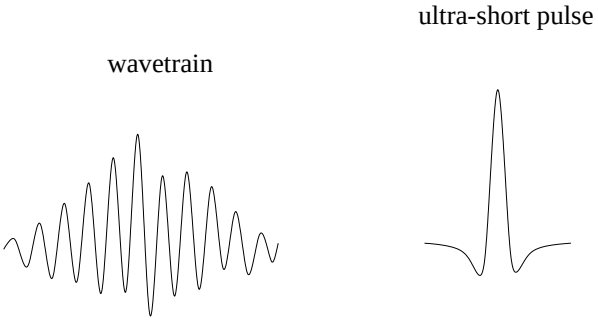

FIG. 1. *Example of a wave train and a short pulse.*

One of the main interests of [1], [3], and [15] is that these papers address pulses which may not have vanishing mean, as was the case in earlier papers [16], [17]. We use here Alterman's technique of infrared cutoffs to obtain this generality, but otherwise our approach is completely different since it is based on oscillations with continuous spectrum. We see three main interests in our method. First, it generalizes the usual methods of diffractive optics [8], [10], [11], so that short pulses do not appear as a pathological case, and "mixed" cases, such as the above lasers with large spectrums, can be addressed without added difficulty. The second interest resides in the study of the nonlinearities, since we prove that most of them can be dropped because their influence is negligible. Finally, we are able to address dispersive models, which are physically the most relevant.

More precisely, an approximate solution for the short pulse is sought in the form

$$u^\varepsilon(T,X,Y,Z) = \varepsilon^p \mathcal{U}_{0,II}\left(\varepsilon T, T, X, Y, Z, \frac{T}{\varepsilon}, \frac{Z}{\varepsilon}\right),$$

where $\mathcal{U}_{0,II}$ is a profile with a purely continuous oscillatory spectrum. Indeed, the pulse here is too short for a sinusoidal oscillation to appear. In the nondispersive case, we find of course that $\mathcal{U}_{0,II}$ must satisfy Alterman and Rauch's equation (1.3). The dispersive case is both simpler and more complicated because if the nonlinearities of (1.3) can be neglected, the group velocity $v\overrightarrow{e}_Z$ then depends on the frequency.

Remark 1.1. As the common formalism suggests, short pulses and large spectrum corrections to wave trains are essentially the same. The former focus on the time domain, while the latter look at the Fourier domain.

1.2. The spaces. We seek approximate solutions of (1.1) for diffractive time scales. Therefore, three scales of variables are used in this study:

- the fast scale $O(\frac{1}{\varepsilon})$ of the oscillations,
- the intermediate scale $O(1)$ of geometrical optics,
- the slow scale $O(\varepsilon)$ related to diffractive effects.

In order to identify clearly the variations of the solutions in these scales, auxiliary functions named *profiles* are introduced as in [8], and we look for exact solutions of (1.1) in the form

$$\mathbf{u}^\varepsilon = \varepsilon^p \mathbf{U}^\varepsilon\left(\varepsilon T, T, X, Y, Z, \frac{T}{\varepsilon}, \frac{Z}{\varepsilon}\right).$$

The factor ε^p is chosen to have both nonlinear and diffractive effects on the same time scale.

Before introducing the spaces associated to the profiles $\mathcal{V}(\tau, T, X, Y, Z, t_0, z_0)$ that we use to represent the exact and approximate solutions of (1.1), let us set some notation.

Notation. From now on, we write $\theta := (\omega_l t_0 - k_l z_0)$ and denote by $\xi := (\omega, k)$ and $\eta := (\eta_1, \eta_2, \eta_3)$ the Fourier dual variable of (t_0, z_0) and (X, Y, Z), respectively. The letter s will always denote a positive real number $s > 3/2$.

We also denote by $\mathcal{F}$ and by $\widehat{\ }$ the Fourier transforms with respect to the variables (t_0, z_0) and (X, Y, Z), respectively.

Throughout this paper constants are invariably denoted by C.

The space we choose for the profiles must contain oscillations with a discrete spectrum such as $U(\tau, T, X, Y, Z)e^{i\theta}$ and oscillations with a purely continuous spectrum. The spaces used here are a generalization to diffractive scales of those which have been introduced in [12] to describe Raman scattering.

DEFINITION 1.1. (i) *We denote by A_0^s the set of the functions defined on $\mathbb{R}^3_{X,Y,Z} \times \mathbb{R}^2_{t_0,z_0}$ with values in $\mathbb{C}^n$ whose Fourier transform with respect to (t_0, z_0) belongs to the set $\mathcal{BV}(\mathbb{R}^2_\xi, H^s(\mathbb{R}^3_{X,Y,Z})^n)$ of bounded variation Borel measures defined on $\mathbb{R}^2_\xi$ and with values in $H^s(\mathbb{R}^3)^n$. This space is endowed with the norm*

$$||\mathcal{V}||_{A_0^s} := |\mathcal{F}\mathcal{V}|_{\mathcal{BV}} \qquad \forall \mathcal{V} \in A_0^s;$$

(ii) *We denote by $E^s_{\tau *}$ the set of the functions defined on $[0, \tau^*] \times \mathbb{R}_T \times \mathbb{R}^3_{X,Y,Z} \times \mathbb{R}^2_{t_0,z_0}$ with values in $\mathbb{C}^n$ whose Fourier transform with respect to (t_0, z_0) belongs to $\mathcal{C}([0, \tau^*] \times \mathbb{R}_T, \mathcal{BV}(\mathbb{R}^2_\xi, H^s(\mathbb{R}^3_{X,Y,Z})^n))$. Moreover, for all $T \in \mathbb{R}$, we define*

$$||\mathcal{V}(T)||_{E^s_{\tau^*}} := \sup_{0 \le \tau \le \tau^*} |\mathcal{F}\mathcal{V}(\tau, T)|_{\mathcal{BV}} \qquad \forall \mathcal{V} \in E^s_{\tau^*};$$

(iii) *We denote by $A^s_{\tau^*}$ the subspace of $E^s_{\tau *}$ composed by all the functions of $E^s_{\tau *}$ bounded on $[0, \tau^*] \times \mathbb{R}_T$ and endow this space with the norm*

$$||\mathcal{V}||_{A^s_{\tau^*}} := \sup_{0 \le \tau \le \tau^*} \sup_{T \in \mathbb{R}} |\mathcal{F}\mathcal{V}(\tau, T)|_{\mathcal{BV}} = \sup_{T \in \mathbb{R}} ||\mathcal{V}(T)||_{E^s_{\tau^*}} \qquad \forall \mathcal{V} \in A^s_{\tau^*};$$

(iv) *We denote by $B^s_{\tau^*}$ the subspace of $A^s_{\tau^*}$ composed by all the functions of $A^s_{\tau^*}$ which do not depend on T.*

The well-known notion of the oscillatory spectrum of an (almost-)periodic function [9] can then be generalized as follows.

DEFINITION 1.2. *If $\mathcal{V} \in E^s_{\tau^*}$, then for all $(\tau, T) \in [0, \tau^*] \times \mathbb{R}$, the spectrum* Sp $\mathcal{V}(\tau, T)$ *of $\mathcal{V}(\tau, T)$ is the support of the Fourier transform $\mathcal{F}\mathcal{V}(\tau, T)$.*

We also define the spectrum of $\mathcal{V}$ as Sp $\mathcal{V} = \bigcup_{(\tau,T) \in [0,\tau^*] \times \mathbb{R}}$ Sp $\mathcal{V}(\tau, T)$.

The following proposition [12] states the main properties of these functional spaces.

PROPOSITION 1.3. (i) *The two normed spaces $(A_0^s, ||.||_{A_0^s})$ and $(A^s_{\tau^*}, ||.||_{A^s_{\tau^*}})$ are complete.*

(ii) *Any J-linear mapping G defined on $(\mathbb{C}^n)^J$ and with values in $\mathbb{C}^n$ extends to a continuous J-linear mapping defined on A_0^s (resp., $A^s_{\tau^*}$) and with values in A_0^s (resp., $A^s_{\tau^*}$). Moreover, there exists a constant $l > 0$ such that for all J-uplet $(\mathcal{V}_1, \dots, \mathcal{V}_J) \in A_0^s$ (resp., $A^s_{\tau^*}$), one has*

$$||G(\mathcal{V}_1, \dots, \mathcal{V}_J)|| \le l||\mathcal{V}_1|| \dots ||\mathcal{V}_J||,$$

where $||.||$ represents the norm of A_0^s (resp., $A^s_{\tau^*}$).

(iii) *Let $\mathcal{V}$ be in A^s_0 (resp., $A^s_{\tau^*}$). Then $\mathcal{V}$ is also in $\mathcal{C}(\mathbb{R}^5)^n$ (resp., $\mathcal{C}([0,\tau^*]\times\mathbb{R}^6)^n$). Moreover, $\mathcal{V}$ is bounded, and there exists a positive number l' such that*

$$||\mathcal{V}||_\infty \leq l'||\mathcal{V}||_{A^s_0} \quad (resp., \quad ||\mathcal{V}||_\infty \leq l'||\mathcal{V}||_{A^s_{\tau^*}}).$$

(iv) *Let $\mathcal{V} \in A^s_0$ (resp., $A^s_{\tau^*}$). Then the function v^ε defined on $\mathbb{R}^3$ (resp., $[0,\frac{\tau^*}{\varepsilon}]\times\mathbb{R}^3$) as $v^\varepsilon(X,Y,Z) = \mathcal{V}(X,Y,Z,0,\frac{Z}{\varepsilon})$ (resp., $v^\varepsilon(T,X,Y,Z) = \mathcal{V}(\varepsilon T,T,X,Y,Z,\frac{T}{\varepsilon},\frac{Z}{\varepsilon})$) belongs to $L^2(\mathbb{R}^3)^n$ (resp., $\mathcal{C}([0,\frac{\tau^*}{\varepsilon}],L^2(\mathbb{R}^3)^n)$). Moreover, one has*

$$||v^\varepsilon||_{L^2(\mathbb{R}^3)} \leq ||\mathcal{V}||_{A^s_0} \quad (resp., \sup_{0\leq T\leq\tau^*/\varepsilon} ||v^\varepsilon(T,.)||_{L^2(\mathbb{R}^3)} \leq ||\mathcal{V}||_{A^s_{\tau^*}}).$$

Examples.

Example 1. Oscillations with a discrete spectrum such as $U(\tau,T,X,Y,Z)e^{i\theta}$, with $\theta = \omega_l t_0 - k_l z_0$ and $U \in \mathcal{C}([0,\tau^*]\times\mathbb{R}_T, H^s(\mathbb{R}^3)^n)$, are in $E^s_{\tau^*}$. Indeed, taking the Fourier transform of such oscillations yields

$$\mathcal{F}(Ue^{i\theta}) = U\delta_{(\omega_l,-k_l)},$$

which belongs to $\mathcal{C}([0,\tau^*]\times\mathbb{R}_T, \mathcal{BV}(\mathbb{R}^2_\xi, H^s(\mathbb{R}^3_{X,Y,Z})^n))$.

Example 2. Let $\mathcal{M}$ be a submanifold of $\mathbb{R}^2$ and α an L^1 function defined on $\mathcal{M}$ and with values in $\mathcal{C}([0,\tau^*]\times\mathbb{R}_T, H^s(\mathbb{R}^3)^n)$. Then the density function [12] defined as

$$\mathcal{V}(\tau,T,X,Y,Z,t_0,z_0) = \int_{\mathcal{M}} e^{i(t_0,z_0)\cdot(\omega,k)}\alpha(\omega,k)(\tau,T,X,Y,Z)\sigma(d\omega,dk),$$

where σ denotes the Lebesgue measure of $\mathcal{M}$, is in $E^s_{\tau^*}$, and its oscillatory spectrum is $\mathcal{M}$.

1.3. Solving the Cauchy problem (1.1). We recall that (1.1) is written as

$$\begin{cases} L^\varepsilon(\partial)\mathbf{u}^\varepsilon + f(\mathbf{u}^\varepsilon) = 0, \\ \mathbf{u}^\varepsilon|_{T=0}(X,Y,Z) = \mathbf{u}^0_\varepsilon(X,Y,Z). \end{cases}$$

We now make precise the assumptions we make on $L^\varepsilon(\partial)$.

ASSUMPTION 1.1. *The system* (1.1) *is symmetric hyperbolic. More accurately, the operator $L^\varepsilon(\partial)$ can be written*

$$L^\varepsilon(\partial) = A_0\partial_T + A_1\partial_X + A_2\partial_Y + A_3\partial_Z + \frac{L_0}{\varepsilon},$$

where the A_i are real symmetric matrices and A_0 is strictly positive. Moreover the system (1.1) *is conservative in the sense that $(L_0)^* = -L_0$.*

Remark 1.2. Since A_0 is strictly positive, we can take $A_0^{-1/2}\mathbf{u}^\varepsilon$ as a new unknown. Multiplying (1.1) by $A_0(0)^{-1/2}$, the resulting system has the same properties as system (1.1) and satisfies $A_0(0) = Id$. *Thus herein, we always consider that $A_0 = Id$.*

The following hypothesis gives the kind of nonlinearity f we study here.

ASSUMPTION 1.2. *There exists a trilinear mapping F such that for all $u \in \mathbb{C}^n$, $f(u) = F(u,u,u)$.*

Remark 1.3. In this paper, we consider nonlinearities of order 3 since the two examples we gave in the last section belong to this class. This limitation on the order of the nonlinearity is only due to technical reasons, and the interested reader could easily generalize our results to nonlinearities of different orders.

The initial conditions for (1.1) must be general enough to allow a model of both large spectrums and ultrashort pulses. The spaces introduced in the previous part are adapted to such a general point of view, and we therefore consider initial conditions of the form

$$\mathbf{u}^0_\varepsilon(X,Y,Z) = \varepsilon^p \mathbf{U}^0\left(X,Y,Z,0,\frac{Z}{\varepsilon}\right), \tag{1.4}$$

with $\mathbf{U}^0 \in A^s_0$.

Choice of the size of the solutions. The choice of p is given [8] by the order of the nonlinearity, $p = 1/2$. With this choice, nonlinear and diffractive effects occur simultaneously.

The following theorem proves that the unique solution L^2 of the Cauchy problem (1.1) with initial condition (1.4) can be written using profiles from $B^s_{\tau^*}$.

THEOREM 1.4. *Let $R > 0$ and $\mathbf{U}^0$ in A^s_0 be such that $\|\mathbf{U}^0\|_{A^s_0} \le R$. There exists a positive real number $\tau^*_1 > 0$, which depends on $\mathbb{R}$ but not on ε, such that for all $\varepsilon > 0$, the Cauchy problem*

$$\begin{cases} L^\varepsilon(\partial)\mathbf{u}^\varepsilon + f(\mathbf{u}^\varepsilon) = 0, \\ \mathbf{u}^\varepsilon|_{T=0}(X,Y,Z) = \varepsilon^{\frac{1}{2}}\mathbf{U}^0(X,Y,Z,0,Z/\varepsilon) \end{cases}$$

has a unique solution $\mathbf{u}^\varepsilon$ in $\mathcal{C}([0,\frac{\tau^*_1}{\varepsilon}]\times\mathbb{R}^3)^n \cap \mathcal{C}([0,\frac{\tau^*_1}{\varepsilon}], L^2(\mathbb{R}^3)^n)$.

Moreover, $\mathbf{u}^\varepsilon$ can be written $\mathbf{u}^\varepsilon(T,X,Y,Z) := \varepsilon^{\frac{1}{2}}\mathbf{U}^\varepsilon(\varepsilon T, X, Y, Z, \frac{T}{\varepsilon}, \frac{Z}{\varepsilon})$, where $\mathbf{U}^\varepsilon \in B^s_{\tau^*_1}$ is uniquely determined by the so-called singular equation*,*

$$\begin{cases} \partial_\tau \mathbf{U}^\varepsilon + \varepsilon^{-1}(A_1\partial_X + A_2\partial_Y + A_3\partial_Z)\mathbf{U}^\varepsilon + \varepsilon^{-2}(\partial_{t_0} + A_3\partial_{z_0} + L_0)\mathbf{U}^\varepsilon + f(\mathbf{U}^\varepsilon) = 0, \\ \mathbf{U}^\varepsilon_{|\tau=0} = \mathbf{U}^0, \end{cases} \tag{1.5}$$

and for all $\varepsilon \in (0,1)$, $\mathbf{U}^\varepsilon$ satisfies the uniform bound $\|\mathbf{U}^\varepsilon\|_{B^s_{\tau^*_1}} \le 2R$.

Proof. The proof of this theorem is similar to the proof of the existence theorem of [12], and we give only a sketch of it. First, we prove that the existence of $\mathbf{u}^\varepsilon$ is a consequence of the existence of a profile $\mathbf{U}^\varepsilon$ satisfying (1.5). This latter result is obtained by Picard iterates using the following lemma, which gives linear estimates.

LEMMA 1.5. *Let $\mathcal{V}^0 \in A^s_0$ and $\mathcal{W} \in B^s_{\tau^*_1}$. The linear problem*

$$\begin{cases} \partial_\tau \mathcal{V} + \varepsilon^{-1}(A_1\partial_X + A_2\partial_Y + A_3\partial_Z)\mathcal{V} + \varepsilon^{-2}(\partial_{t_0} + A_3\partial_{z_0} + L_0)\mathcal{V} = \mathcal{W}, \\ \mathcal{V}_{|\tau=0} = \mathcal{V}^0 \end{cases}$$

has a unique solution in $B^s_{\tau^*_1}$. Moreover, one has

$$||\mathcal{V}||_{B^s_{\tau^*_1}} = ||\mathcal{V}^0||_{A^s_0} + \tau^*_1||\mathcal{W}||_{B^s_{\tau^*_1}}.$$

The existence of $\mathbf{u}^\varepsilon$ being established, one proves uniqueness using a classical L^2-uniqueness argument. ∎

1.4. General method. We seek an approximate solution u^ε of the exact solution $\mathbf{u}^\varepsilon$ of (1.1) using the tools of diffractive optics. The approximate solution u^ε is sought in the form

$$u^\varepsilon = \varepsilon^{\frac{1}{2}}\mathcal{U}^\varepsilon\left(\varepsilon T, T, X, Y, Z, \frac{T}{\varepsilon}, \frac{Z}{\varepsilon}\right), \qquad \text{with} \quad \mathcal{U}^\varepsilon = \mathcal{U}_0 + \varepsilon\mathcal{U}_1 + \varepsilon^2\mathcal{U}_2, \tag{1.6}$$

and $\mathcal{U}_0, \mathcal{U}_1, \mathcal{U}_2 \in E^s_{\tau^*}$.

The expansion of $L^\varepsilon(\partial)u^\varepsilon + f(u^\varepsilon)$ in powers of ε yields

$$L^\varepsilon(\partial)u^\varepsilon + f(u^\varepsilon) = \sum_{j=-1}^{7} \varepsilon^{\frac{1}{2}+j}\mathcal{R}_j(\tau, T, X, Y, Z, t_0, z_0)|_{\tau=\varepsilon T, t_0=T/\varepsilon, z_0=Z/\varepsilon}, \tag{1.7}$$

where

$$\begin{aligned}
\mathcal{R}_{-1}(\tau, T, X, Y, Z, t_0, z_0) &= i\mathcal{L}(D_{t_0,z_0})\mathcal{U}_0,\\
\mathcal{R}_0(\tau, T, X, Y, Z, t_0, z_0) &= i\mathcal{L}(D_{t_0,z_0})\mathcal{U}_1 + L_1(\partial)\mathcal{U}_0,\\
\mathcal{R}_1(\tau, T, X, Y, Z, t_0, z_0) &= i\mathcal{L}(D_{t_0,z_0})\mathcal{U}_2 + L_1(\partial)\mathcal{U}_1 + \partial_\tau\mathcal{U}_0 + f(\mathcal{U}_0),\\
\mathcal{R}_2(\tau, T, X, Y, Z, t_0, z_0) &= L_1(\partial)\mathcal{U}_2 + \partial_\tau\mathcal{U}_1 + \langle f(\mathcal{U}^\varepsilon)\rangle_{1/2+2},\\
\mathcal{R}_3(\tau, T, X, Y, Z, t_0, z_0) &= \partial_\tau\mathcal{U}_2 + \langle f(\mathcal{U}^\varepsilon)\rangle_{1/2+3},\\
\mathcal{R}_{j\geq 4}(\tau, T, X, Y, Z, t_0, z_0) &= \langle f(\mathcal{U}^\varepsilon)\rangle_{1/2+j},
\end{aligned} \tag{1.8}$$

with the notation

$$\begin{aligned}
&\mathcal{L}(D_{t_0,z_0}) := D_{t_0} + A_3 D_{z_0} + L_0/i, \qquad D_{t_0} = -i\partial_{t_0}, \quad D_{z_0} = -i\partial_{z_0}\\
&L_1(\partial) := \partial_T + A_1\partial_X + A_2\partial_Y + A_3\partial_Z := \partial_T + A(\partial_{X,Y,Z}),
\end{aligned}$$

while $\langle f(\mathcal{U}^\varepsilon)\rangle_k$ denotes the coefficient of the monomial ε^k in the expansion into powers of ε of $f(\mathcal{U}^\varepsilon)$.

Notation. We used the pseudodifferential notation $D_{t_0} = -i\partial_{t_0}$ and $D_{z_0} = -i\partial_{z_0}$ to define the operator $\mathcal{L}(D_{t_0,z_0})$. This explains the factor i which appears in front of it in expansion (1.8). Recalling that (ω, k) denote the dual variables of (t_0, z_0), the symbol of this operator reads $\mathcal{L}(\omega, k) = \omega Id + kA_3 + L_0/i$.

The strategy of diffractive optics consists of seeking $\mathcal{U}_0$, $\mathcal{U}_1$, and $\mathcal{U}_2$ in order to cancel the profiles $\mathcal{R}_m(\tau, T, X, Y, Z, t_0, z_0)$, $m = -1, 0, 1$. We then prove that the associated function u^ε given by (1.6) is indeed an approximate solution of (1.1) and give a stability theorem.

1.5. A few tools. The following definition introduces some concepts of diffractive optics.

DEFINITION 1.6. (i) *The characteristic variety associated to the operator $\mathcal{L}$ is the set*

$$\mathcal{C}_\mathcal{L} = \{(\omega, k) \in \mathbb{R}^2, \det(\mathcal{L}(\omega, k)) = \det(\omega Id + kA_3 + L_0/i) = 0\}.$$

(ii) *We denote by $\pi(\omega, k)$ the orthogonal projector onto* $\ker \mathcal{L}(\omega, k)$ *and by $\mathcal{L}^{-1}(\omega, k)$ the partial inverse of $\mathcal{L}(\omega, k)$ defined as*

$$\mathcal{L}^{-1}(\omega, k)\pi(\omega, k) = 0 \quad \text{and} \quad \mathcal{L}^{-1}(\omega, k)\mathcal{L}(\omega, k) = Id - \pi(\omega, k).$$

(iii) *Near every smooth point $(\underline{\omega}, \underline{k})$ of $\mathcal{C}_\mathcal{L}$, we denote by $\omega(k)$ a local parameterization of $\mathcal{C}_\mathcal{L}$.*

The following lemma expresses the resolubility condition of a linear equation with the tools introduced in the previous definition.

LEMMA 1.7. *Let $a, b \in \mathbb{C}^n$. Then the following two assertions are equivalent:*
(i) $\mathcal{L}(\omega, k)a = b$;
(ii) $\pi(\omega, k)b = 0$ *and* $(Id - \pi(\omega, k))a = \mathcal{L}^{-1}(\omega, k)b$.

We want to generalize these resolubility conditions to equations of type $\mathcal{L}(D_{t_0,z_0})\mathcal{V} = \mathcal{W}$, where $\mathcal{V}$ and $\mathcal{W}$ are in $E^s_{\tau *}$. Following [12], we first have to introduce the notion of $\mathcal{L}^{-1}$-regularity.

DEFINITION 1.8. *Let $\mathcal{V} \in E^s_{\tau^*}$ and $\mu(\tau, T) := \mathcal{F}\mathcal{V}(\tau, T)$. We say that $\mathcal{V}$ is $\mathcal{L}^{-1}$-regular if for all $(\tau, T) \in [0, \tau^*] \times \mathbb{R}_T$, $\mathcal{L}^{-1}$ is $\mu(\tau, T)$-integrable.*

We can now generalize Lemma 1.7 in the following way.

LEMMA 1.9. *Let $\mathcal{V}$ and $\mathcal{W}$ be in $E^s_{\tau^*}$. The following assertions are equivalent:*

(i) $\mathcal{L}(D_{t_0,z_0})\mathcal{V} = \mathcal{W}$;

(ii) $\pi(D_{t_0,z_0})\mathcal{W} = 0$, $\mathcal{W}$ *is* $\mathcal{L}^{-1}$*-regular, and* $(Id - \pi(D_{t_0,z_0}))\mathcal{V} = \mathcal{L}^{-1}(D_{t_0,z_0})\mathcal{W}$.

Remark 1.4. The $\mathcal{L}^{-1}$-regularity condition may not be satisfied in the physical phenomena we are interested in here. Indeed, the mapping $(\omega, k) \to \mathcal{L}^{-1}(\omega, k)$ is not bounded at the neighborhood of the origin. When low frequencies are excluded, as in most applications in optics, $\mathcal{L}^{-1}$ remains bounded for the frequencies considered, and the $\mathcal{L}^{-1}$-regularity condition is easily satisfied. But when low frequencies are allowed, as they have to be here, $\mathcal{L}^{-1}$ effectively blows up and the $\mathcal{L}^{-1}$-regularity condition is in general not satisfied. In that case, we have to use tools similar to those introduced by Alterman [1].

It is also interesting to decompose the profiles of $E^s_{\tau^*}$ into a discrete spectrum (sinusoidal) component and a purely continuous one. Such a decomposition is assured by the foregoing proposition.

PROPOSITION 1.10. *Let $\mathcal{V} \in A^s_0$ (resp., $E^s_{\tau^*}$). The profile $\mathcal{V}$ is written uniquely as $\mathcal{V} = \mathcal{V}_I + \mathcal{V}_{II}$, with $\mathcal{V}_I$, $\mathcal{V}_{II} \in A^s_0$ (resp., $E^s_{\tau^*}$) such that*

(i) $\mathcal{V}_I$ *(resp., $\mathcal{V}_I(\tau, T, .)$ for all $(\tau, T) \in [0, \tau^*] \times \mathbb{R}_T$) has a discrete spectrum;*

(ii) $\mathcal{V}_{II}$ *has a purely continuous spectrum, i.e., every point of $\mathbb{R}^2$ has zero measure for $\mathcal{F}\mathcal{V}_{II}$ (resp., for $\mathcal{F}\mathcal{V}_{II}(\tau, T, .)$ for all $(\tau, T) \in [0, \tau^*] \times \mathbb{R}_T$).*

Notation. From now on, and for every profile $\mathcal{V}$ of A^s_0 or $E^s_{\tau^*}$, we denote by $\mathcal{V}_I$ the component with a discrete spectrum and by $\mathcal{V}_{II}$ the component with a purely continuous one.

Proof. First, the existence of the decomposition of a profile $\mathcal{V} \in E^s_{\tau^*}$ is proved. We introduce

$$\mu(\tau, T) := \mathcal{F}\mathcal{V}(\tau, T) \qquad \forall (\tau, T) \in [0, \tau^*] \times \mathbb{R}_T,$$

and $S_{\tau,T}$ the set of points with nonzero measure for $\mu(\tau, T)$,

$$S_{\tau,T} = \{p \in \mathbb{R}^2, \mu(\tau, T)(\{p\}) \neq 0\}.$$

We decompose $\mu(\tau, T)$ in the form

$$\mu(\tau, T) = \mathbb{I}_{S_{\tau,T}}\mu(\tau, T) + (1 - \mathbb{I}_{S_{\tau,T}})\mu(\tau, T),$$

and the proposition will be proved if we can show that $\mathcal{F}^{-1}(\mathbb{I}_{S_{\tau,T}}\mu(\tau, T))$ and $\mathcal{F}^{-1}[(1 - \mathbb{I}_{S_{\tau,T}})\mu(\tau, T)]$ are in $E^s_{\tau^*}$. Indeed, one would then have for all (τ, T),

$$\mathcal{V}_I(\tau, T) = \mathcal{F}^{-1}(\mathbb{I}_{S_{\tau,T}}\mu(\tau, T)) \quad \text{and} \quad \mathcal{V}_{II}(\tau, T) = \mathcal{F}^{-1}([1 - \mathbb{I}_{S_{\tau,T}}]\mu(\tau, T)).$$

It is clear that for all $(\tau, T) \in [0, \tau^*] \times \mathbb{R}_T$, the measures $\mathbb{I}_{S_{\tau,T}}\mu(\tau, T)$ and $(1 - \mathbb{I}_{S_{\tau,T}})\mu(\tau, T)$ belong to $\mathcal{BV}(\mathbb{R}^2_\xi, H^s(\mathbb{R}^3)^n)$. The main difficulty is to prove the continuous dependence on (τ, T) of these two measures. As the mapping $(\tau, T) \mapsto \mu(\tau, T)$ is continuous by assumption, it is sufficient to prove that the mapping

$$\begin{aligned} [0, \tau^*] \times \mathbb{R}_T &\longrightarrow \mathcal{BV}(\mathbb{R}^2, H^s(\mathbb{R}^3)^n), \\ (\tau, T) &\longmapsto \mathbb{I}_{S_{\tau,T}}\mu(\tau, T) \end{aligned}$$

is continuous, i.e., that $\mathbb{I}_{S_{\tau,T}}\mu(\tau,T) - \mathbb{I}_{S_{\tau',T'}}\mu(\tau',T')$ tends to 0 in $\mathcal{BV}(\mathbb{R}^2_\xi, H^s(\mathbb{R}^3)^n)$ when (τ',T') tends to (τ,T). One has

$$\mathbb{I}_{S_{\tau,T}}\mu(\tau,T) - \mathbb{I}_{S_{\tau',T'}}\mu(\tau',T') = (\mathbb{I}_{S_{\tau,T}} - \mathbb{I}_{S_{\tau',T'}})\mu(\tau,T) + \mathbb{I}_{S_{\tau',T'}}(\mu(\tau,T) - \mu(\tau',T')).$$

The second term of the right-hand side of this equation tends to 0 when (τ',T') tends to (τ,T) thanks to the continuity of the mapping $(\tau,T) \mapsto \mu(\tau,T)$. Moreover, the first term of the right-hand side of the equation reads

$$(\mathbb{I}_{S_{\tau,T}} - \mathbb{I}_{S_{\tau',T'}})\mu(\tau,T) = \mathbb{I}_{S_{\tau,T}\setminus S_{\tau',T'}}\mu(\tau,T) - \mathbb{I}_{S_{\tau',T'}\setminus S_{\tau,T}}\mu(\tau,T).$$

But one has $\mathbb{I}_{S_{\tau',T'}\setminus S_{\tau,T}}\mu(\tau,T) = 0$, because if $p \in S_{\tau',T'} \setminus S_{\tau,T}$, then $\mu(\tau,T)(\{p\}) = 0$. On the other hand, one has $\mathbb{I}_{S_{\tau,T}\setminus S_{\tau',T'}}(\{p\}) \to 0$ for all $p \in \mathbb{R}^2$ when $(\tau',T') \to (\tau,T)$. Indeed, for all $p \in S_{\tau,T}$, $\mu(\tau,T)(\{p\}) \neq 0$. By continuity of the mapping $(\tau,T) \mapsto \mu(\tau,T)$, one has $\mu(\tau',T')(\{p\}) \longrightarrow \mu(\tau,T)(\{p\})$ in $H^s(\mathbb{R}^3)^n$ when $(\tau',T') \to (\tau,T)$. Consequently, $\mu(\tau',T')(\{p\}) \neq 0$ if (τ',T') is close enough to (τ,T). In other words, $p \in S_{\tau',T'}$, and hence $p \notin S_{\tau,T} \setminus S_{\tau',T'}$. The proof of the continuous time dependence is then achieved by a dominated convergence argument.

The existence of the decomposition for every profile of $E^s_{\tau *}$, and a fortiori of A^s_0, is thus proved. The proof of the uniqueness of the decomposition is straightforward. □

1.6. Organization of the paper. We first address in section 2 general dispersive hyperbolic systems. Section 2.1 is devoted to the derivation of the profile equations under a simplifying assumption of absence of low frequencies. In section 2.2, we perform a sharp analysis of the nonlinearities found for the profile equations. We show that many of these nonlinearities vanish, which is of crucial importance for the resolubility theorems given in section 2.3. The fact that the approximate solution associated to the profiles found in the previous sections converges towards the exact solution of (1.1) is then proved in section 2.4. The general case (presence of low frequencies) is addressed in section 2.5. Using Alterman's technique of infrared cutoffs, we use the results of the previous sections to give profile equations in the general case, as well as a stability theorem which generalizes the one given in section 2.4.

In section 3, we treat the nondispersive case. Since the methods used in this section are the same as in the dispersive case, we do not extend the proofs. However, the main difference between both cases is by itself interesting enough to justify this section: *nonlinear interactions between components with a purely continuous spectrum can be observed in the nondispersive case*, while they are negligible in the dispersive case.

The two physical examples used as guidelines throughout this paper are studied in section 4. These examples are lasers with large spectrums and short pulses and illustrate the notable simplifications yielded by our general theory with respect to direct computations.

Finally, an intermediate case between dispersive and nondispersive systems, called weakly dispersive, is briefly commented on in section 5. In particular, we find that for large-spectrum lasers, equations for the continuous spectrum component are still linear but, as opposed to the dispersive case, coupled with the discrete spectrum component.

2. Dispersive case. In this part, we consider problems of type (1.1) which are dispersive. More precisely, we suppose that the following assumption is satisfied.

ASSUMPTION 2.1. *One has* $\{0, \pm(\omega_l, -k_l)\} \subset \mathcal{C}_\mathcal{L}$*, but for all* $j \in Z \setminus \{0, \pm 1\}$*, the point* $j(\omega_l, -k_l)$ *is not on* $\mathcal{C}_\mathcal{L}$*. We also assume that* $\mathcal{C}_\mathcal{L}$ *is a union of smooth curves which are never parallel, asymptotic, nor tangent to one another, and which intersect only on the vertical axis* $(O\omega)$.

Remark 2.1. The different nonlinear models whose linearization gives the Maxwell–Lorentz equations (see the last section for an example) do not exactly satisfy this assumption since $\mathcal{C}_\mathcal{L}$ then contains three horizontal lines, which are a fortiori parallel. Moreover, two of these lines are also tangent to curved sheets of the characteristic variety. However, this is not important since the horizontal lines are excluded by the divergence-free conditions one has to add to these systems. Therefore, the Maxwell–Lorentz model, and its nonlinear versions, fall into the range of this assumption.

2.1. The ansatz in the absence of infrared frequencies. As we have said in Remark 1.4, low frequencies make the analysis far more difficult because $\mathcal{L}^{-1}$-regularity of the profiles may fail. That is why in this section we focus on profiles $\mathcal{U}_0$ whose spectrum is outside the band $\{(\omega, k), |k| \leq \delta\}$. More precisely, we assume throughout this section that the continuous spectrum component of the leading term $\mathcal{U}_0$ satisfies the following assumption.

ASSUMPTION 2.2. *The spectrum* $\mathrm{Sp}\ \mathcal{U}_{0,II}$ *of the continuous spectrum component of* $\mathcal{U}_0$ *is in* $\{(\omega, k), |k| > \delta\}$*, where* $\delta > 0$.

The following lemma makes the link between absence of low frequencies and $\mathcal{L}^{-1}$-regularity.

LEMMA 2.1. *Let* $\mathcal{V}_{II}$ *be a profile of* $E^s_{\tau^*}$ *such that* $\mathrm{Sp}\ \ \mathcal{V}_{II} \subset \mathcal{C}_\mathcal{L}$.

If, moreover, $\mathrm{Sp}\ \mathcal{V}_{II} \subset \{(\omega, k), |k| > \delta\}$*, then* $\mathcal{V}_{II}$ *is* $\mathcal{L}^{-1}$*-regular, and for all* $T \in \mathbb{R}$*,*

$$\|\mathcal{L}^{-1}\mathcal{V}_{II}(T)\|_{E^s_{\tau^*}} \leq \frac{C}{\delta}\|\mathcal{V}_{II}(T)\|_{E^s_{\tau^*}}.$$

In particular, if $\mathcal{V}_{II} \in A^s_{\tau^*}$*, one has*

$$\|\mathcal{L}^{-1}\mathcal{V}_{II}\|_{A^s_{\tau^*}} \leq \frac{C}{\delta}\|\mathcal{V}_{II}\|_{A^s_{\tau^*}}.$$

Proof. For all $(\omega, k) \in \mathbb{R}^2$, $\mathcal{L}^{-1}(\omega, k)$ reads

$$\mathcal{L}^{-1}(\omega, k) = \sum_{j, \omega_j(k) \neq \omega} \frac{1}{\omega - \omega_j(k)} \pi(\omega_j(k), k),$$

where the ω_j are parameterizations of the different sheets of $\mathcal{C}_\mathcal{L}$. If $(\omega, k) \in \mathcal{C}_\mathcal{L}$, i.e., if there exists j_0 such that $(\omega, k) = (\omega_{j_0}(k), k)$, then

$$\mathcal{L}^{-1}(\omega, k) = \mathcal{L}^{-1}(\omega_{j_0}(k), k) = \sum_{j \neq j_0} \frac{1}{\omega_{j_0}(k) - \omega_j(k)} \pi(\omega_j(k), k). \tag{2.1}$$

Saying that $\mathcal{V}_{II}$ is $\mathcal{L}^{-1}$-regular means that for all $(\tau, T) \in [0, \tau^*] \times \mathbb{R}$, $\mathcal{L}^{-1}(\omega, k)$ is integrable for $\mu(\tau, T) := \mathcal{F}\mathcal{V}_{II}(\tau, T)$. As we have supposed that $\mathrm{Sp}\ \mathcal{V}_{II} \subset \mathcal{C}_\mathcal{L}$, we must prove that the expression given by (2.1) is integrable for $\mu(\tau, T)$.

Since we supposed in Assumption 2.1 that the different sheets of $\mathcal{C}_\mathcal{L}$ are not asymptotic, (2.1) is bounded for large $|k|$. The only points where this expression is not bounded are those where the different sheets intersect. Thanks to Assumption 2.1,

these points are all on the axis $(O\omega)$. We now consider what happens in the neighborhood of such a point. Consider j and j_0 such that $\lim_{k\to 0}\omega_{j_0}(k)=\lim_{k\to 0}\omega_j(k)=\omega_0$. Near 0, one has

$$\frac{1}{\omega_{j_0}(k)-\omega_j(k)}=\frac{1}{(\omega_{j_0}(k)-\omega_0)-(\omega_j(k)-\omega_0)}\sim\frac{1}{k(v_0-v)},$$

where $v_0=\lim_{k\to 0}\omega'_{j_0}(k)$ and $v=\lim_{k\to 0}\omega'_j(k)$. We know that $v_0-v\neq 0$ since Assumption 2.1 assures us that two different sheets are never tangent.

Therefore, the expression given by (2.1) can be bounded for $|k|>\delta$ by C/δ, which yields both the $\mathcal{L}^{-1}$-regularity result for $\mathcal{V}_{II}$ and the estimate of the lemma. ∎

2.1.1. Annihilating $\mathcal{R}_{-1}$. Annihilating the $\varepsilon^{-\frac{1}{2}}$ term in expansion (1.7) is equivalent to $\mathcal{L}(D_{t_0,z_0})\mathcal{U}_0=0$. Thanks to Lemma 1.7, this equation is equivalent to the *polarization condition*

$$\pi(D_{t_0,z_0})\mathcal{U}_0=\mathcal{U}_0.$$

Moreover, thanks to Proposition 1.10, $\mathcal{U}_0$ can be decomposed in the form $\mathcal{U}_0=\mathcal{U}_{0,I}+\mathcal{U}_{0,II}$, where $\mathcal{U}_{0,I}$ has a discrete spectrum and $\mathcal{U}_{0,II}$ a purely continuous one.

Looking for $\mathcal{U}_{0,I}$ of the form $\mathcal{U}_{0,I,1}(\tau,T,X,Y,Z)e^{i\theta}$ + c.c., the polarization condition $\pi(D_{t_0,z_0})\mathcal{U}_0=\mathcal{U}_0$ gives

$$\pi(\omega_l,-k_l)\mathcal{U}_{0,I,1}=\mathcal{U}_{0,I,1}\quad\text{and}\quad\pi(D_{t_0,z_0})\mathcal{U}_{0,II}=\mathcal{U}_{0,II}. \tag{2.2}$$

Remark 2.2. The notation *c.c.* used above denotes the complex conjugate of the preceding expression. As we are concerned with real-valued solutions of (1.1) and (1.5), we always assume that in the Fourier expansion of the discrete spectrum components, one has $\mathcal{U}_{j,I,k}=\overline{\mathcal{U}_{j,I,-k}}$.

2.1.2. Annihilating $\mathcal{R}_0$. Annihilating the $\varepsilon^{\frac{1}{2}}$ term in expansion (1.7) reads $i\mathcal{L}(D_{t_0,z_0})\mathcal{U}_1+L_1(\partial)\mathcal{U}_0=0$.

As for $\mathcal{U}_0$, decompose $\mathcal{U}_1$ in the form $\mathcal{U}_1=\mathcal{U}_{1,I}+\mathcal{U}_{1,II}$, where $\mathcal{U}_{1,I}$ has a discrete spectrum and $\mathcal{U}_{1,II}$ a purely continuous one. We also look for $\mathcal{U}_{1,I}$ in the form $\mathcal{U}_{1,I,1}(\tau,T,X,Y,Z)e^{i\theta}+c.c.$, so that the equation $\mathcal{R}_0=0$ may read

$$\begin{cases} i\mathcal{L}(\omega_l,-k_l)\mathcal{U}_{1,I,1}+L_1(\partial)\mathcal{U}_{0,I,1}=0,\\ i\mathcal{L}(D_{t_0,z_0})\mathcal{U}_{1,II}+L_1(\partial)\mathcal{U}_{0,II}=0.\end{cases} \tag{2.3}$$

With the polarization condition (2.2) and Lemma 1.7, the first equation of (2.3) is equivalent to

$$\begin{cases} \pi(\omega_l,-k_l)L_1(\partial)\pi(\omega_l,-k_l)\mathcal{U}_{0,I,1}=0,\\ (Id-\pi(\omega_l,-k_l))\mathcal{U}_{1,I,1}=i\mathcal{L}^{-1}(\omega_l,-k_l)A(\partial_{X,Y,Z})\mathcal{U}_{0,I,1}.\end{cases} \tag{2.4}$$

Since Assumption 2.2 and Lemma 2.1 assure us that $A(\partial_{X,Y,Z})\mathcal{U}_{0,II}$ is $\mathcal{L}^{-1}$-regular, we know, thanks to Lemma 1.9, that the second equation of (2.3) is equivalent to

$$\begin{cases} \pi(D_{t_0,z_0})L_1(\partial)\pi(D_{t_0,z_0})\mathcal{U}_{0,II}=0,\\ (Id-\pi(D_{t_0,z_0}))\mathcal{U}_{1,II}=i\mathcal{L}^{-1}(D_{t_0,z_0})A(\partial_{X,Y,Z})\mathcal{U}_{0,II}.\end{cases} \tag{2.5}$$

Remark 2.3. At this stage, only the component $(Id-\pi(\omega_l,-k_l))\mathcal{U}_{1,I,1}$ is determined. We can therefore choose to take the other component equal to zero, i.e.,

$$\pi(\omega_l,-k_l)\mathcal{U}_{1,I,1}=0. \tag{2.6}$$

We cannot do the same thing for $\pi(D_{t_0,z_0})\mathcal{U}_{1,II}$ because this component will play an important role in the solvability of the profile equations.

2.1.3. Annihilating $\mathcal{R}_1$. Annihilating the $\varepsilon^{\frac{3}{2}}$ term in expansion (1.7) yields $i\mathcal{L}(D_{t_0,z_0})\mathcal{U}_2+L_1(\partial)\mathcal{U}_1+\partial_\tau\mathcal{U}_0+f(\mathcal{U}_0)=0$. Thanks to Proposition 1.10, this equation can be decomposed into a discrete spectrum component,

$$-i\mathcal{L}(\omega_l,-k_l)\mathcal{U}_{2,I}=L_1(\partial)\mathcal{U}_{1,I}+\partial_\tau\mathcal{U}_{0,I}+f(\mathcal{U}_0)_I, \tag{2.7}$$

and a purely continuous one,

$$-i\mathcal{L}(D_{t_0,z_0})\mathcal{U}_{2,II}=L_1(\partial)\mathcal{U}_{1,II}+\partial_\tau\mathcal{U}_{0,II}+f(\mathcal{U}_0)_{II}. \tag{2.8}$$

The nonlinearity $f(\mathcal{U}_0)_I$ in (2.7) is given by $f(\mathcal{U}_0)_I=f(\mathcal{U}_{0,I})$, which is a trigonometric polynomial,

$$f(\mathcal{U}_{0,I})=f'(\mathcal{U}_{0,I,1})(\overline{\mathcal{U}_{0,I,1}})e^{i\theta}+f(\mathcal{U}_{0,I,1})e^{i3\theta}+\text{c.c.} \tag{2.9}$$

Since the third harmonic is created by the nonlinearity, we must seek $\mathcal{U}_{2,I}$ in the form

$$\mathcal{U}_{2,I}(\tau,T,X,Y,Z,\theta)=\mathcal{U}_{2,I,1}(\tau,T,X,Y,Z)e^{i\theta}+\mathcal{U}_{2,I,3}(\tau,T,X,Y,Z)e^{i3\theta}+\text{c.c.}$$

According to Assumption 2.1, the component $\mathcal{U}_{2,I,3}$ can be found by elliptic inversion since $\mathcal{L}(3\omega_l,-3k_l)$ is then nonsingular,

$$\mathcal{U}_{2,I,3}=\mathcal{L}(3\omega_l,-3k_l)^{-1}f(\mathcal{U}_{0,I,1}). \tag{2.10}$$

The remaining component $\mathcal{U}_{2,I,1}$ satisfies

$$i\mathcal{L}(\omega_l,-k_l)\mathcal{U}_{2,I,1}+L_1(\partial)\mathcal{U}_{1,I,1}+\partial_\tau\mathcal{U}_{0,I,1}+f'(\mathcal{U}_{0,I,1})(\overline{\mathcal{U}_{0,I,1}})=0,$$

and thanks to Lemma 1.7, we get

$$\begin{cases}\pi(\omega_l,-k_l)\big(L_1(\partial)\mathcal{U}_{1,I,1}+\partial_\tau\mathcal{U}_{0,I,1}+f'(\mathcal{U}_{0,I,1})(\overline{\mathcal{U}_{0,I,1}})\big)=0,\\ (Id-\pi(\omega_l,-k_l))\mathcal{U}_{2,I,1}=i\mathcal{L}^{-1}(\omega_l,-k_l)\big(L_1(\partial)\mathcal{U}_{1,I,1}+\partial_\tau\mathcal{U}_{0,I,1}+f'(\mathcal{U}_{0,I,1})(\overline{\mathcal{U}_{0,I,1}})\big).\end{cases}$$

Using the polarization condition (2.2) and equations (2.4) and (2.6), the first equation of the previous system reads

$$\begin{aligned}&\partial_\tau\mathcal{U}_{0,I,1}+i\pi(\omega_l,-k_l)A(\partial_{X,Y,Z})\mathcal{L}^{-1}(\omega_l,-k_l)A(\partial_{X,Y,Z})\pi(\omega_l,-k_l)\mathcal{U}_{0,I,1}\\ &\qquad+\pi(\omega_l,-k_l)f'(\mathcal{U}_{0,I,1})(\overline{\mathcal{U}_{0,I,1}})=0,\end{aligned} \tag{2.11}$$

while the second equation gives $(Id-\pi(\omega_l,-k_l))\mathcal{U}_{2,I,1}$ in terms of $\mathcal{U}_{0,I,1}$,

$$\begin{aligned}&(I-\pi(\omega_l,-k_l))\mathcal{U}_{2,I,1}\\ &=i\mathcal{L}^{-1}(\omega_l,-k_l)\big(iL_1(\partial)\mathcal{L}^{-1}(\omega_l,-k_l)A(\partial_{X,Y,Z})\mathcal{U}_{0,I,1}+f'(\mathcal{U}_{0,I,1})(\overline{\mathcal{U}_{0,I,1}})\big).\end{aligned} \tag{2.12}$$

While the analysis of the discrete and the continuous spectrum components was formally the same in section 2.1.2, this is no longer true here. This is due to the fact that Assumption 2.2 cannot ensure that the right-hand side of (2.8) is $\mathcal{L}^{-1}$-regular. Therefore, Lemma 1.9 cannot be invoked to solve this equation.

Because of this difficulty, we cannot in general find $\mathcal{U}_2$ in $E^s_{\tau^*}$ such that $\mathcal{R}_1=0$. However, $\mathcal{U}_2\in E^s_{\tau^*}$ may be chosen in such a way that $\mathcal{R}_1$ is very small. We first introduce Alterman's infrared cutoff filter.

Definition 2.2. *Let ψ be defined as follows: $\psi(k)=1$ for $|k|>1$ and $\psi(k)=0$ otherwise. For all $k\in\mathbb{R}$, $\psi^\delta(k)$ is defined as $\psi^\delta(k)=\psi(k/\delta)$, where $\delta>0$ is the same as in Assumption* 2.2.

Remark 2.4. The function ψ introduced above is not smooth, while Alterman's filter is smooth. Since our framework allows it, we have made this choice in order to lighten a few equations. In particular, we have the equivalence $\mathrm{Sp}\ \mathcal{V} \subset \{(\omega,k), |k| > \delta\} \iff \psi^\delta(D_{z_0})\mathcal{V} = \mathcal{V}$.

Since no condition has been found at this stage on $\pi(D_{t_0,z_0})\mathcal{U}_{1,II}$, we can impose a condition of absence of low frequencies on this component and, more precisely, that

$$\psi^\delta(D_{z_0})\pi(D_{t_0,z_0})\mathcal{U}_{1,II} = \pi(D_{t_0,z_0})\mathcal{U}_{1,II}. \tag{2.13}$$

Instead of solving (2.8), we solve the approximate equation $(2.8)_\delta$ defined as

$$-i\mathcal{L}(D_{t_0,z_0})\mathcal{U}_{2,II} = L_1(\partial)\mathcal{U}_{1,II} + \partial_\tau \mathcal{U}_{0,II} + \psi^\delta(D_{z_0})f(\mathcal{U}_0)_{II}.$$

Using (2.5), this equation reads

$$\begin{aligned} -i\mathcal{L}(D_{t_0,z_0})\mathcal{U}_{2,II} = {} & iL_1(\partial)\mathcal{L}^{-1}(D_{t_0,z_0})A(\partial_{X,Y,Z})\mathcal{U}_{0,II} + L_1(\partial)\pi(D_{t_0,z_0})\mathcal{U}_{1,II} \\ & + \partial_\tau \mathcal{U}_{0,II} + \psi^\delta(D_{z_0})f(\mathcal{U}_0)_{II}. \end{aligned} \tag{2.14}$$

Thanks to the presence of the filter ψ^δ, to (2.13), and to Assumption 2.2, the right-hand side of this equation is $\mathcal{L}^{-1}$-regular, so that (2.14) is equivalent to

$$\begin{aligned} & \partial_\tau \mathcal{U}_{0,II} + i\pi(D_{t_0,z_0})A(\partial_{X,Y,Z})\mathcal{L}^{-1}(D_{t_0,z_0})A(\partial_{X,Y,Z})\pi(D_{t_0,z_0})\mathcal{U}_{0,II} \\ & \quad + \pi(D_{t_0,z_0})L_1(\partial)\pi(D_{t_0,z_0})\mathcal{U}_{1,II} \\ & \quad + \pi(D_{t_0,z_0})\psi^\delta(D_{z_0})[f(\mathcal{U}_0)]_{II} = 0 \end{aligned} \tag{2.15}$$

and

$$\begin{aligned} (Id - \pi(D_{t_0,z_0}))\mathcal{U}_{2,II} = {} & -\mathcal{L}^{-1}(D_{t_0,z_0})L_1(\partial)\mathcal{L}^{-1}(D_{t_0,z_0})A(\partial_{X,Y,Z})\mathcal{U}_{0,II} \\ & + i\mathcal{L}^{-1}(D_{t_0,z_0})A(\partial_{X,Y,Z})\pi(D_{t_0,z_0})\mathcal{U}_{1,II} \\ & + i\mathcal{L}^{-1}(D_{t_0,z_0})\psi^\delta(D_{z_0})f(\mathcal{U}_0)_{II}. \end{aligned} \tag{2.16}$$

Remark 2.5. (i) As said above, $\mathcal{R}_1 = 0$ is not solved exactly. If we can find $\mathcal{U}_0$, $\mathcal{U}_1$, and $\mathcal{U}_2$ solutions of (2.2), (2.4)–(2.6), (2.10), (2.11)–(2.12), (2.13), and (2.15)–(2.16), we then have $\mathcal{R}_{-1} = \mathcal{R}_0 = 0$ but only

$$\mathcal{R}_1 = (1 - \psi^\delta(D_{z_0}))f(\mathcal{U}_0)_{II}. \tag{2.17}$$

We will see later that this term tends towards zero as $\delta \to 0$.

(ii) Only the components $(Id - \pi(\omega_l, -k_l))\mathcal{U}_{2,I,1}$ and $(Id - \pi(D_{t_0,z_0}))\mathcal{U}_{2,II}$ of $\mathcal{U}_{2,I,1}$ and $\mathcal{U}_{2,II}$ are determined. We can therefore choose to take

$$\pi(\omega_l, -k_l)\mathcal{U}_{2,I,1} = 0 \quad \text{and} \quad \pi(D_{t_0,z_0})\mathcal{U}_{2,II} = 0. \tag{2.18}$$

2.1.4. Simplification of the profile equations. According to the previous results, one has

$$\mathcal{U}_0(\tau,T,X,Y,Z,t_0,z_0) = \mathcal{U}_{0,I,1}(\tau,T,X,Y,Z)e^{i\theta} + c.c. + \mathcal{U}_{0,II}(\tau,T,X,Y,Z,t_0,z_0),$$

with

$$\pi(\omega_l, -k_l)\mathcal{U}_{0,I,1} = \mathcal{U}_{0,I,1} \quad \text{and} \quad \pi(D_{t_0,z_0})\mathcal{U}_{0,II} = \mathcal{U}_{0,II}. \tag{2.19}$$

Moreover $\mathcal{U}_{0,I,1}$ must satisfy

$$(2.20)\quad \begin{cases} \pi(\omega_l,-k_l)L_1(\partial)\pi(\omega_l,-k_l)\mathcal{U}_{0,I,1}=0,\\ \partial_\tau\mathcal{U}_{0,I,1}+i\pi(\omega_l,-k_l)A(\partial_{X,Y,Z})\mathcal{L}^{-1}(\omega_l,-k_l)A(\partial_{X,Y,Z})\pi(\omega_l,-k_l)\mathcal{U}_{0,I,1}\\ \qquad +\pi(\omega_l,-k_l)f'(\mathcal{U}_{0,I,1})(\overline{\mathcal{U}_{0,I,1}})=0, \end{cases}$$

and the purely continuous spectrum component $\mathcal{U}_{0,II}$ must satisfy

$$(2.21)\quad \begin{cases} \pi(D_{t_0,z_0})L_1(\partial)\pi(D_{t_0,z_0})\mathcal{U}_{0,II}=0,\\ \partial_\tau\mathcal{U}_{0,II}+i\pi(D_{t_0,z_0})A(\partial_{X,Y,Z})\mathcal{L}^{-1}(D_{t_0,z_0})A(\partial_{X,Y,Z})\pi(D_{t_0,z_0})\mathcal{U}_{0,II}\\ \qquad +\pi(D_{t_0,z_0})L_1(\partial)\pi(D_{t_0,z_0})\mathcal{U}_{1,II}+\pi(D_{t_0,z_0})\psi^\delta(D_{z_0})[f(\mathcal{U}_0)]_{II}=0, \end{cases}$$

where we recall that $\pi(D_{t_0,z_0})\mathcal{U}_{1,II}$ must satisfy the condition of absence of low frequencies (2.13).

Before these systems are simplified, a new symbol, $\mathcal{M}$, is introduced.

DEFINITION 2.3. *We denote by $\mathcal{M}(\omega,K)$ the symbol defined for all $(\omega,K)\in\mathbb{R}^{1+3}$ as*

$$\mathcal{M}(\omega,K)=wId+K_1A_1+K_2A_2+K_3A_3+L_0/i,$$

where $K=(K_1,K_2,K_3)$.

We also define the orthogonal projector $\pi_{\mathcal{M}}(\omega,K)$ onto $\ker\mathcal{M}(\omega,K)$, the partial inverse $\mathcal{M}^{-1}(\omega,K)$ of $\mathcal{M}(\omega,k)$, and denote by $\mathcal{C}_{\mathcal{M}}$ the characteristic variety associated to $\mathcal{M}$, i.e., the set of points (ω,K) where $\mathcal{M}(\omega,K)$ is singular.

We also make the following assumption, satisfied, for instance, by Maxwell systems in isotropic media.

ASSUMPTION 2.3. *$\mathcal{C}_{\mathcal{M}}$ is axisymmetric around $(O\omega)$.*

We can now state the following proposition.

PROPOSITION 2.4. *Suppose that Assumption* 2.3 *is satisfied and that $\{(\omega_l,-k_l)\}$ is a smooth point of $\mathcal{C}_{\mathcal{L}}$. One then has the following:*

(i) $\pi(\omega_l,-k_l)L_1(\partial)\pi(\omega_l,-k_l)=\pi(\omega_l,-k_l)(\partial_T+\omega'(k_l)\partial_Z)$;

(ii)
$$\begin{aligned}&\pi(\omega_l,-k_l)A(\partial_{X,Y,Z})\mathcal{L}^{-1}(\omega_l,-k_l)A(\partial_{X,Y,Z})\pi(\omega_l,-k_l)\\ &\quad=\tfrac{\omega'(k_l)}{2k_l}\pi(\omega_l,-k_l)(\partial_X^2+\partial_Y^2)+\tfrac{\omega''(k_l)}{2}\pi(\omega_l,-k_l)\partial_Z^2.\end{aligned}$$

(iii) *If $\mathcal{V}_{II}$ is a profile with a purely continuous spectrum, then one also has*

$$\pi(D_{t_0,z_0})L_1(\partial)\pi(D_{t_0,z_0})\mathcal{V}_{II}=\pi(D_{t_0,z_0})\big(\partial_T-\omega'(D_{z_0})\partial_Z\big)\mathcal{V}_{II}.$$

(iv) *If, moreover, $A(\partial_{X,Y,Z})\pi(D_{t_0,z_0})\mathcal{V}_{II}$ is $\mathcal{L}^{-1}$-regular, then*

$$\begin{aligned}&\pi(D_{t_0,z_0})A(\partial_{X,Y,Z})\mathcal{L}^{-1}(D_{t_0,z_0})A(\partial_{X,Y,Z})\pi(D_{t_0,z_0})\mathcal{V}_{II}\\ &=\frac{\omega'(D_{z_0})}{2D_{z_0}}\pi(D_{t_0,z_0})(\partial_X^2+\partial_Y^2)\mathcal{V}_{II}+\frac{\omega''(D_{z_0})}{2}\partial_Z^2\mathcal{V}_{II}.\end{aligned}$$

Proof. If $(\underline{\omega},\underline{K})$ is a smooth point of $\mathcal{C}_{\mathcal{M}}$, then we can define a local parameterization $\omega_{\mathcal{M}}(K)$ of $\mathcal{C}_{\mathcal{M}}$ near $(\underline{\omega},\underline{K})$. We know [8] that

$$\pi_{\mathcal{M}}(\underline{\omega},\underline{K})A_j\pi_{\mathcal{M}}(\underline{\omega},\underline{K})=-\partial_j\omega_{\mathcal{M}}(\underline{K})\pi_{\mathcal{M}}(\underline{\omega},\underline{K}),\qquad j=1,2,3.$$

As $(\omega_l,-k_l)\in\mathcal{C}_{\mathcal{L}}$, it is easy to see that $(\omega_l,(0,0,-k_l))\in\mathcal{C}_{\mathcal{M}}$. Moreover, since $(\omega_l,-k_l)$ is a smooth point of $\mathcal{C}_{\mathcal{L}}$, $(\omega_l,(0,0,-k_l))$ is a smooth point of $\mathcal{C}_{\mathcal{M}}$ thanks to

Assumption 2.3. Thanks to the same assumption, a local parameterization may be used to write $\omega_{\mathcal{M}}(K) = \omega(|K|)$, where $\omega(\cdot)$ is a local parameterization of $\mathcal{C}_{\mathcal{L}}$ near $(\omega_l, -k_l)$.

Taking $\underline{K} = (0, 0, -k_l)$, one therefore has

$$\pi_{\mathcal{M}}(\omega_l, (0,0,-k_l))A_j\pi_{\mathcal{M}}(\omega_l, (0,0,-k_l)) = -\frac{\underline{K}_j}{k_l}\omega'(k_l).$$

Since $\underline{K}_1 = \underline{K}_2 = 0$, $\underline{K}_3 = -k_l$, and $\pi_M(\omega_l, \underline{K}) = \pi(\omega_l, -k_l)$, we obtain

$$\begin{aligned}
&\pi(\omega_l, -k_l)A_1\pi(\omega_l, -k_l) = 0,\\
&\pi(\omega_l, -k_l)A_2\pi(\omega_l, -k_l) = 0,\\
&\pi(\omega_l, -k_l)A_3\pi(\omega_l, -k_l) = \omega'(k_l),
\end{aligned}$$

which proves point (i).

The same proof shows that $\pi(\omega,k)A_1\pi(\omega,k) = \pi(\omega,k)A_2\pi(\omega,k) = 0$ and similarly $\pi(\omega,k)A_3\pi(\omega,k) = -\omega'(k)$ for every smooth point (ω,k) of $\mathcal{C}_{\mathcal{L}}$. Since we know by Assumption 2.1 that the set of the singular points of $\mathcal{C}_{\mathcal{L}}$ is discrete and hence has zero measure for $\mathcal{F}\mathcal{V}_{II}$ (because the spectrum of $\mathcal{V}_{II}$ is purely continuous), we can conclude that

$$\pi(D_{t_0,z_0})A_1\pi(D_{t_0,z_0})\mathcal{V}_{II} = \pi(D_{t_0,z_0})A_2\pi(D_{t_0,z_0})\mathcal{V}_{II} = 0$$

and that $\pi(D_{t_0,z_0})A_3\pi(D_{t_0,z_0})\mathcal{V}_{II} = -\omega'(D_{z_0})\mathcal{V}_{II}$, which proves point (iii).

For (ii), we still write $(0,0,-k_l) = \underline{K}$. Thanks to [8], we know that

$$\begin{aligned}
&\pi_{\mathcal{M}}(\omega_l, \underline{K})A_i\mathcal{M}^{-1}(\omega_l, \underline{K})A_j\pi_{\mathcal{M}}(\omega_l, \underline{K}) = \frac{1}{2}\pi_{\mathcal{M}}(\omega_l, \underline{K})\partial_{ij}^2\omega_{\mathcal{M}}(\underline{K})\\
&= \frac{1}{2}\pi_{\mathcal{M}}(\omega_l, \underline{K})\left(-\frac{\underline{K}_i\underline{K}_j}{|\underline{K}|^3}\omega'(|\underline{K}|) + \frac{\underline{K}_i\underline{K}_j}{|\underline{K}|^2}\omega''(|\underline{K}|) + \frac{\delta_{ij}}{|\underline{K}|}\omega'(|\underline{K}|)\right),
\end{aligned}$$

where δ_{ij} denotes Kronecker's symbol, $\delta_{ij} = 1$ if $i = j$ and 0 otherwise.

Since $\underline{K}_1 = \underline{K}_2 = 0$, one has

$$\begin{aligned}
&\pi_{\mathcal{M}}(\omega_l, \underline{K})A_1\mathcal{M}^{-1}(\omega_l, \underline{K})A_2\pi_{\mathcal{M}}(\omega_l, \underline{K}) = 0,\\
&\pi_{\mathcal{M}}(\omega_l, \underline{K})A_2\mathcal{M}^{-1}(\omega_l, \underline{K})A_1\pi_{\mathcal{M}}(\omega_l, \underline{K}) = 0,
\end{aligned}$$

and since $\underline{K}_3 = -k_l$,

$$\begin{aligned}
\pi_{\mathcal{M}}A_1\mathcal{M}^{-1}(\omega_l, \underline{K})A_1\pi_{\mathcal{M}} &= \pi_{\mathcal{M}}A_2\mathcal{M}^{-1}(\omega_l, \underline{K})A_2\pi_{\mathcal{M}}\\
&= \frac{\omega'(k_l)}{2k_l}\pi_{\mathcal{M}}(\omega_l, \underline{K})
\end{aligned}$$

and $\pi_{\mathcal{M}}A_3\mathcal{M}^{-1}(\omega_l, \underline{K})A_3\pi_{\mathcal{M}} = \frac{\omega''(k_l)}{2}\pi_{\mathcal{M}}$.

Since $\pi_{\mathcal{M}}(\omega_l, \underline{K}) = \pi(\omega_l, -k_l)$ and $\mathcal{M}^{-1}(\omega_l, \underline{K}) = \mathcal{L}^{-1}(\omega_l, -k_l)$ we obtain (ii).

The same reasoning as in (iii) yields (iv). ∎

Therefore, according to Proposition 2.4 and systems (2.20), (2.21), the leading term $\mathcal{U}_0(\tau, T, X, Y, Z, t_0, z_0) = \mathcal{U}_{0,I,1}(\tau, T, X, Y, Z)e^{i\theta} + \text{c.c.} + \mathcal{U}_{0,II}(\tau, T, X, Y, Z, t_0, z_0)$ is found by solving (if possible)

$$\left\{\begin{aligned}
&\pi(\omega_l, -k_l)\mathcal{U}_{0,I,1} = \mathcal{U}_{0,I,1},\\
&(\partial_T + \omega'(k_l)\partial_Z)\mathcal{U}_{0,I,1} = 0,\\
&\partial_\tau\mathcal{U}_{0,I,1} + i\frac{\omega'(k_l)}{2k_l}(\partial_X^2 + \partial_Y^2)\mathcal{U}_{0,I,1} + i\frac{\omega''(k_l)}{2}\partial_Z^2\mathcal{U}_{0,I,1}\\
&\qquad\qquad +\pi(\omega_l, -k_l)f'(\mathcal{U}_{0,I,1})(\overline{\mathcal{U}_{0,I,1}}) = 0
\end{aligned}\right. \tag{2.22}$$

and

$$
(2.23)\quad \begin{cases} \pi(D_{t_0,z_0})\mathcal{U}_{0,II} = \mathcal{U}_{0,II}, \\ (\partial_T - \omega'(D_{z_0})\partial_Z)\mathcal{U}_{0,II} = 0, \\ \partial_\tau \mathcal{U}_{0,II} + (\partial_T - \omega'(D_{z_0})\partial_Z)\pi(D_{z_0})\mathcal{U}_{1,II} + i\dfrac{\omega'(D_{z_0})}{2D_{z_0}}(\partial_X^2 + \partial_Y^2)\mathcal{U}_{0,II} \\ \qquad\qquad +i\dfrac{\omega''(D_{z_0})}{2}\partial_Z^2\mathcal{U}_{0,II} + \psi^\delta(D_{z_0})\pi(D_{t_0,z_0})[f(\mathcal{U}_0)]_{II} = 0. \end{cases}
$$

Remark 2.6. (i) The notation $\frac{\omega'(D_{z_0})}{2D_{z_0}}$ is ambiguous since one could think that this Fourier multiplier does not depend on D_{t_0}. In fact, for any $k \in \mathbb{R}$, there are several ω_j such that $(\omega_j, k) \in \mathcal{C}_\mathcal{L}$. In Fourier variables, $\omega'(D_{z_0})$ therefore reads $\mathcal{F}\omega'(D_{z_0})(\omega, k) = \omega_j'(k)$, where the subscript j is such that $(\omega_j, k) = (\omega, k)$ and thus depends on w.

(ii) In general $\frac{\omega'(D_{z_0})}{2D_{z_0}}$ is not a Fourier multiplier of $E^s_{\tau^*}$. However, it is well defined here since it is applied to $\mathcal{U}_{0,II}$, which satisfies Assumption 2.2.

2.2. Analysis of the nonlinearity. We have to work more on these profile equations before trying to solve them. In particular, it is essential to simplify the nonlinearity $[f(\mathcal{U}_0)]_{II}$ which appears in (2.23). In this section, we show a striking result. *The nonlinearity* $[f(\mathcal{U}_0)]_{II}$ *is in fact linear.*

We recall that there exists a trilinear mapping F such that $F(u,u,u) = f(u)$ for all $u \in C^n$. The nonlinearity $f(\mathcal{U}_0)_{II}$ which appears in the evolution equation of $\mathcal{U}_{0,II}$ therefore reads

$$
\begin{aligned}
&F(\mathcal{U}_{0,I} + \mathcal{U}_{0,II}, \mathcal{U}_{0,I} + \mathcal{U}_{0,II}, \mathcal{U}_{0,I} + \mathcal{U}_{0,II})]_{II} = F(\mathcal{U}_{0,II}, \mathcal{U}_{0,II}, \mathcal{U}_{0,II}) \\
&+ F(\mathcal{U}_{0,I}, \mathcal{U}_{0,II}, \mathcal{U}_{0,II}) + F(\mathcal{U}_{0,II}, \mathcal{U}_{0,I}, \mathcal{U}_{0,II}) + F(\mathcal{U}_{0,II}, \mathcal{U}_{0,II}, \mathcal{U}_{0,I}) \\
&+ \big(F(\mathcal{U}_{0,I,1}, \mathcal{U}_{0,I,1}, \mathcal{U}_{0,II}) + F(\mathcal{U}_{0,II}, \mathcal{U}_{0,I,1}, \mathcal{U}_{0,I,1}) + F(\mathcal{U}_{0,I,1}, \mathcal{U}_{0,II}, \mathcal{U}_{0,I,1})\big)e^{2i\theta} \\
&+ \big(F(\overline{\mathcal{U}_{0,I,1}}, \overline{\mathcal{U}_{0,I,1}}, \mathcal{U}_{0,II}) + F(\mathcal{U}_{0,II}, \overline{\mathcal{U}_{0,I,1}}, \overline{\mathcal{U}_{0,I,1}}) + F(\overline{\mathcal{U}_{0,I,1}}, \mathcal{U}_{0,II}, \overline{\mathcal{U}_{0,I,1}})\big)e^{-2i\theta} \\
&+ F(\mathcal{U}_{0,I,1}, \overline{\mathcal{U}_{0,I,1}}, \mathcal{U}_{0,II}) + F(\overline{\mathcal{U}_{0,I,1}}, \mathcal{U}_{0,I,1}, \mathcal{U}_{0,II}) + F(\mathcal{U}_{0,I,1}, \mathcal{U}_{0,II}, \overline{\mathcal{U}_{0,I,1}}) \\
&+ F(\overline{\mathcal{U}_{0,I,1}}, \mathcal{U}_{0,II}, \mathcal{U}_{0,I,1}) + F(\mathcal{U}_{0,II}, \mathcal{U}_{0,I,1}, \overline{\mathcal{U}_{0,I,1}}) + F(\mathcal{U}_{0,II}, \overline{\mathcal{U}_{0,I,1}}, \mathcal{U}_{0,I,1}).
\end{aligned}
$$

This expression can be simplified a lot because the role of the components with a purely continuous spectrum in the nonlinearity is not often efficient. This is the object of the following lemma.

LEMMA 2.5. *Suppose Assumption* 2.1 *is satisfied and let* $\mathcal{V}_{II} \in E^s_{\tau^*}$ *be a profile with purely continuous spectrum and such that* $\mathrm{Sp}\ \mathcal{V}_{II} \subset \mathcal{C}_\mathcal{L}$. *Take also* $a, b \in \mathbb{C}^n$. *Then one has*

(i) $\pi(D_{t_0,z_0})F(\mathcal{V}_{II}, \mathcal{V}_{II}, \mathcal{V}_{II}) = 0$;
(ii) $\pi(D_{t_0,z_0})F(ae^{i\theta}, \mathcal{V}_{II}, \mathcal{V}_{II}) = \pi(D_{t_0,z_0})F(ae^{-i\theta}, \mathcal{V}_{II}, \mathcal{V}_{II}) = 0$;
(iii) $\pi(D_{t_0,z_0})F(ae^{i\theta}, be^{i\theta}, \mathcal{V}_{II}) = \pi(D_{t_0,z_0})F(ae^{-i\theta}, be^{-i\theta}, \mathcal{V}_{II}) = 0$.

Proof. Let $\mathcal{V}_{II} \in E^s_{\tau^*}$ be as in the lemma. For (τ, T) fixed, we introduce $\mu := \mathcal{F}\mathcal{V}_{II}(\tau, T)$ and denote by $v(\mu)$ the total variation of μ. Thanks to the Radon–Nikodým property, we can write, for all Borel sets E of $\mathbb{R}^2$,

$$
\mu(E) = \int_E r_\mu(\xi) v(\mu)(d\xi),
$$

where r_μ is an $H^s(\mathbb{R}^3)^n$-valued integrable function such that $||r_\mu(\xi)||_{H^s} = 1$ for $v(\mu)$ for almost all ξ.

Introducing $\nu := \mathcal{F}(\pi(D_{t_0,z_0})F(\mathcal{V}_{II}, \mathcal{V}_{II}, \mathcal{V}_{II}))$, the first point of the lemma will be proved if we can show that $\nu = 0$, i.e., that $v(\nu)(\mathbb{R}^2) = 0$. One has

$$v(\nu)(\mathbb{R}^2) = \int_{\mathbb{R}^2}\int_{\mathbb{R}^2}\int_{\mathbb{R}^2} ||\pi(\xi_1+\xi_2+\xi_3)F(r_\mu(\xi_1), r_\mu(\xi_2), r_\mu(\xi_3))||_{H^s(\mathbb{R}^3)^n} \times v(\mu)(d\xi_1)v(\mu)(d\xi_2)v(\mu)(d\xi_3).$$

Since Sp $\mathcal{V}_{II} \subset \mathcal{C}_\mathcal{L}$, one can take $r_\mu(\xi) = 0$ if $\xi \notin \mathcal{C}_\mathcal{L}$. Hence,

$$\begin{aligned} v(\nu)(\mathbb{R}^2) &= \int_{\mathcal{C}_\mathcal{L}}\int_{\mathcal{C}_\mathcal{L}}\int_{\mathcal{C}_\mathcal{L}} ||\pi(\xi_1+\xi_2+\xi_3)F(r_\mu(\xi_1), r_\mu(\xi_2), r_\mu(\xi_3))||_{H^s(\mathbb{R}^3)^n} \\ &\qquad \times v(\mu)(d\xi_1)v(\mu)(d\xi_2)v(\mu)(d\xi_3) \\ &= \int_{\mathcal{C}_\mathcal{L}}\int_{\mathcal{C}_\mathcal{L}}\left[\int_{\mathcal{C}_\mathcal{L}} ||\pi(\xi_1+\xi_2+\xi_3)F(r_\mu(\xi_1), r_\mu(\xi_2), r_\mu(\xi_3))||_{H^s(\mathbb{R}^3)^n} v(\mu)(d\xi_3)\right] \\ &\qquad \times v(\mu)(d\xi_1)v(\mu)(d\xi_2). \end{aligned}$$

Notice that if $\xi_1+\xi_2 \neq 0$, then the set of $\xi \in \mathcal{C}_\mathcal{L}$ such that $\xi_1+\xi_2+\xi \in \mathcal{C}_\mathcal{L}$ is discrete. Indeed following [6] and [5], the set of $\xi \in \mathcal{C}_\mathcal{L}$ such that $\xi_1+\xi_2+\xi \in \mathcal{C}_\mathcal{L}$ is either a sheet of $\mathcal{C}_\mathcal{L}$ or an algebraic submanifold of $\mathcal{C}_\mathcal{L}$ of strictly lower dimension. Since $\mathcal{C}_\mathcal{L}$ is an algebraic manifold of dimension one, the set of $\xi \in \mathcal{C}_\mathcal{L}$ such that $\xi_1+\xi_2+\xi \in \mathcal{C}_\mathcal{L}$ is then either a sheet of $\mathcal{C}_\mathcal{L}$ or a discrete set. The first case is not possible thanks to Assumption 2.1 because we would have two parallel sheets of $\mathcal{C}_\mathcal{L}$. Therefore, the set of points $\xi \in \mathcal{C}_\mathcal{L}$ such that $\xi_1+\xi_2+\xi \in \mathcal{C}_\mathcal{L}$ is discrete if $\xi_1+\xi_2 \neq 0$. Since $v(\mu)(\{\xi\}) = 0$ for all $\xi \in \mathbb{R}^2$, we can conclude that

$$\int_{\mathcal{C}_\mathcal{L}} ||\pi(\xi_1+\xi_2+\xi_3)F(r_\mu(\xi_1), r_\mu(\xi_2), r_\mu(\xi_3))||_{H^s(\mathbb{R}^3)^n} v(\mu)(d\xi_3) = 0,$$

when $\xi_1+\xi_2 \neq 0$.

Therefore, one has

$$v(\nu)(\mathbb{R}^2) = \int_{\mathcal{C}_\mathcal{L}}\int_{\mathcal{C}_\mathcal{L}} ||\pi(\xi_3)F(r_\mu(\xi_1), r_\mu(-\xi_1), r_\mu(\xi_3))||_{H^s(\mathbb{R}^3)^n} v(\mu)(\{-\xi_1\}) \times v(\mu)(d\xi_1)v(\mu)(d\xi_3).$$

Since $v(\mu)(\{\xi\}) = 0$ for all $\xi \in \mathbb{R}^2$, the above quantity is equal to 0, i.e., $v(\nu)(\mathbb{R}^2) = 0$, which proves point (i).

For (ii), introduce $\lambda := \mathcal{F}(\pi(D_{t_0,z_0})F(ae^{i\theta}, \mathcal{V}_{II}, \mathcal{V}_{II}))$. One has

$$v(\lambda)(\mathbb{R}^2) = \int_{\mathcal{C}_\mathcal{L}}\int_{\mathcal{C}_\mathcal{L}} ||\pi((\omega_l, -k_l)+\xi_1+\xi_2)F(a, r_\mu(\xi_1), r_\mu(\xi_2))||_{H^s(\mathbb{R}^3)^n} \times v(\mu)(d\xi_1)v(\mu)(d\xi_2).$$

With the same reasoning as in (i), one can prove that this expression vanishes, thus yielding point (ii).

Point (iii) is a direct consequence of Assumption 2.1 and, more precisely, of the fact that two different sheets of $\mathcal{C}_\mathcal{L}$ are never parallel. □

Remark 2.7. Lemma 2.5 can easily be generalized to N-linear nonlinear functions F. When $\mathcal{V}_{II}$ appears twice or more in the arguments of F, the term vanishes. When it appears once only, the spectrum of this nonlinear term is a translation of the spectrum of $\mathcal{V}_{II}$, and hence this nonlinear term vanishes unless the intersection of this spectrum with $\mathcal{C}_\mathcal{L}$ has the same dimension as $\mathcal{C}_\mathcal{L}$.

Thanks to Lemma 2.5, many terms vanish when we apply the operator $\pi(D_{t_0,z_0})$ to the nonlinearity. One then finds $\pi(D_{t_0,z_0})[f(\mathcal{U}_0)]_{II} = \pi(D_{t_0,z_0})F^S(\mathcal{U}_{0,I,1},\overline{\mathcal{U}_{0,I,1}},\mathcal{U}_{0,II})$, where the symmetrized function F^S associated to F is defined as

$$F^S(a,b,c) = F(a,b,c) + F(a,c,b) + F(b,a,c) + F(c,a,b) + F(b,c,a) + F(c,b,a)$$

for all $a,b,c \in \mathbb{C}^n$.

The equations for the profile $\mathcal{U}_{0,II}$ are thus

$$\text{(2.24)}\quad \begin{cases} \pi(D_{t_0,z_0})\mathcal{U}_{0,II} = \mathcal{U}_{0,II}, \\ (\partial_T - \omega'(D_{z_0})\partial_Z)\mathcal{U}_{0,II} = 0, \\ \partial_\tau \mathcal{U}_{0,II} + (\partial_T - \omega'(D_{z_0})\partial_Z)\mathcal{U}_{1,II} + i\dfrac{\omega'(D_{z_0})}{2D_{z_0}}(\partial_X^2 + \partial_Y^2)\mathcal{U}_{0,II} \\ \qquad +i\frac{\omega''(D_{z_0})}{2}\partial_Z^2\mathcal{U}_{0,II} + \psi^\delta(D_{z_0})\pi(D_{t_0,z_0})F^S(\mathcal{U}_{0,I,1},\overline{\mathcal{U}_{0,I,1}},\mathcal{U}_{0,II}) = 0, \end{cases}$$

and are therefore coupled with the equations found above for the amplitude $\mathcal{U}_{0,I,1}$,

$$\text{(2.25)}\quad \begin{cases} \pi(\omega_l,-k_l)\mathcal{U}_{0,I,1} = \mathcal{U}_{0,I,1}, \\ (\partial_T + \omega'(k_l)\partial_Z)\mathcal{U}_{0,I,1} = 0, \\ \partial_\tau \mathcal{U}_{0,I,1} + i\dfrac{\omega'(k_l)}{2k_l}(\partial_X^2 + \partial_Y^2)\mathcal{U}_{0,I,1} + i\dfrac{\omega''(k_l)}{2}\partial_Z^2\mathcal{U}_{0,I,1} \\ \qquad +\pi(\omega_l,-k_l)f'(\mathcal{U}_{0,I,1})(\overline{\mathcal{U}_{0,I,1}}) = 0. \end{cases}$$

Remark 2.8. One can see that the evolution equation for the oscillating mode is the usual *uncoupled* NLS equation. The evolution equation of $\mathcal{U}_{0,II}$ is in turn *linear* but *coupled* with $\mathcal{U}_{0,I,1}$. The next step is to prove that this coupling is not efficient. This is the object of the next section.

2.3. Solving the profile equations in absence of low frequencies. If system (2.25) can easily be solved by standard Picard iterates (see [8], for instance), this is not the case for system (2.24), which deals with the continuous spectrum component of $\mathcal{U}_0$. Moreover, one can see that it is not possible to take $\pi(D_{t_0,z_0})\mathcal{U}_{1,II} = 0$ as for the discrete spectrum component, since the term $F^S(\mathcal{U}_{0,I,1},\overline{\mathcal{U}_{0,I,1}},\mathcal{U}_{0,II})$ makes the last equation of (2.24) obviously incompatible with the transport equation $(\partial_T - \omega'(D_{z_0})\partial_Z)\mathcal{U}_{0,II} = 0$.

In fact, as in the papers where various group velocities are studied [10], [11], only a good choice of $\pi(D_{t_0,z_0})\mathcal{U}_{1,II} = 0$ can allow the solubility for (2.24). Inspired by the method and arguments of [10] and [11] (i.e., interactions between components traveling at different speeds do not affect the main profile), we decompose (2.24) as follows:

$$\text{(2.26)}\quad \begin{cases} \pi(D_{t_0,z_0})\mathcal{U}_{0,II} = \mathcal{U}_{0,II}, \\ (\partial_T - \omega'(D_{z_0})\partial_Z)\mathcal{U}_{0,II} = 0, \\ \partial_\tau \mathcal{U}_{0,II} + i\dfrac{\omega'(D_{z_0})}{2D_{z_0}}(\partial_X^2 + \partial_Y^2)\mathcal{U}_{0,II} + i\dfrac{\omega''(D_{z_0})}{2}\partial_Z^2\mathcal{U}_{0,II} = 0, \\ (\partial_T - \omega'(D_{z_0})\partial_Z)\mathcal{U}_{1,II} = -\psi^\delta(D_{z_0})\pi(D_{t_0,z_0})F^S(\mathcal{U}_{0,I,1},\overline{\mathcal{U}_{0,I,1}},\mathcal{U}_{0,II}). \end{cases}$$

We can now state a solubility result, provided that the function $\mathbf{U}_{II}^0$ has no low frequencies.

PROPOSITION 2.6. *Let $\sigma \geq s$, and let $R > 0$ be such that $\mathbf{U}^0 = \mathbf{U}^0_I + \mathbf{U}^0_{II} \in A^\sigma_0$ and $\|\mathbf{U}^0\|_{A^\sigma_0} \leq R$. Suppose, moreover, that $\mathbf{U}^0_I = \mathbf{U}^0_{I,1} e^{i\theta} + c.c.$ and*

$$\pi(\omega_l, -k_l)\mathbf{U}^0_{I,1} = \mathbf{U}^0_{I,1}, \qquad \pi(D_{t_0,z_0})\mathbf{U}^0_{II} = \mathbf{U}^0_{II},$$

and that there exists $\delta > 0$ such that Sp $\mathbf{U}^0_{II} \subset \{(\omega, k), |k| > \delta\}$.

Then there exists $\tau_2^* > 0$, which depends on R but not on ε nor on δ, such that there exists

- *a unique $\mathcal{U}_{0,I,1} = \pi(\omega_l, -k_l)\mathcal{U}_{0,I,1} \in \mathcal{C}_b([0,\tau_2^*] \times \mathbb{R}_T, H^\sigma(\mathbb{R}^3)^n)$ solving*

$$\begin{cases} (\partial_T + \omega'(k_l)\partial_Z)\mathcal{U}_{0,I,1} = 0, \\ \partial_\tau \mathcal{U}_{0,I,1} + i\dfrac{\omega'(k_l)}{2k_l}(\partial_X^2 + \partial_Y^2)\mathcal{U}_{0,I,1} + i\dfrac{\omega''(k_l)}{2}\partial_Z^2 \mathcal{U}_{0,I,1} \\ \qquad\qquad + \pi(\omega_l, -k_l) f'(\mathcal{U}_{0,I,1})(\overline{\mathcal{U}_{0,I,1}}) = 0, \\ \mathcal{U}_{0,I,1}|_{\tau=T=0} = \mathbf{U}^0_{I,1}; \end{cases} \tag{2.27}$$

- *a unique $\mathcal{U}_{0,II} = \pi(D_{t_0,z_0})\mathcal{U}_{0,II} \in A^\sigma_{\tau_2^*}$ solving*

$$\begin{cases} (\partial_T - \omega'(D_{z_0})\partial_Z)\mathcal{U}_{0,II} = 0, \\ \partial_\tau \mathcal{U}_{0,II} + i\dfrac{\omega'(D_{z_0})}{2D_{z_0}}(\partial_X^2 + \partial_Y^2)\mathcal{U}_{0,II} + i\dfrac{\omega''(D_{z_0})}{2}\partial_Z^2 \mathcal{U}_{0,II} = 0, \\ \mathcal{U}_{0,II}|_{\tau=T=0} = \mathbf{U}^0_{II}; \end{cases} \tag{2.28}$$

- *a unique $\mathcal{U}_{1,II} \in E^\sigma_{\tau_2^*}$ solving*

$$\begin{cases} (Id - \pi(D_{t_0,z_0}))\mathcal{U}_{1,II} = i\mathcal{L}^{-1}(D_{t_0,z_0})A(\partial_{X,Y,Z})\mathcal{U}_{0,II}, \\ \psi^\delta(D_{z_0})\pi(D_{t_0,z_0})\mathcal{U}_{1,II} = \pi(D_{t_0,z_0})\mathcal{U}_{1,II}, \\ (\partial_T - \omega'(D_{z_0})\partial_Z)\pi(D_{z_0,t_0})\mathcal{U}_{1,II} \\ \qquad\qquad = -\psi^\delta(D_{z_0})\pi(D_{t_0,z_0})F^S(\mathcal{U}_{0,I,1}, \overline{\mathcal{U}_{0,I,1}}, \mathcal{U}_{0,II}), \\ \mathcal{U}_{1,II}|_{\tau=T=0} = 0. \end{cases} \tag{2.29}$$

Moreover $\mathcal{U}_{0,II}$ satisfies Assumption 2.2 *with the same δ as above, and we have the upper bound $\|\mathcal{U}_0\|_{A^\sigma_{\tau_2^*}} \leq 2R$.*

Proof. The proof of the existence and the uniqueness of the solution of (2.27) is done by standard Picard iterates, as in [8], for instance. Since $\mathcal{U}_{0,I,1}$ must solve the transport equation $(\partial_T + \omega'(k_l)\partial_Z)\mathcal{U}_{0,I,1} = 0$, there exists $\mathtt{U}_{0,I,1} \in \mathcal{C}([0,\tau_2^*], H^s(\mathbb{R}^3)^n)$ such that

$$\mathcal{U}_{0,I,1}(\tau, T, X, Y, Z) = \mathtt{U}_{0,I,1}(\tau, Z - \omega'(k_l)T, X, Y). \tag{2.30}$$

Moreover, the Schrödinger equation that $\mathcal{U}_{0,I,1}$ must satisfy implies, for $\mathtt{U}_{0,I,1}$,

$$\partial_\tau \mathtt{U}_{0,I,1} + i\frac{\omega'(k_l)}{2k_l}(\partial_X^2 + \partial_Y^2)\mathtt{U}_{0,I,1} + i\frac{\omega''(k_l)}{2}\partial_Z^2 \mathtt{U}_{0,I,1} + \pi(\omega_l, -k_l) f'(\mathtt{U}_{0,I,1})(\overline{\mathtt{U}_{0,I,1}}) = 0.$$

Existence and uniqueness of such a $\mathtt{U}_{0,I,1} \in \mathcal{C}([0,\tau_2^*], H^s(\mathbb{R}^3)^n)$ can be proved by standard Picard iterates, and we thus obtain point (i) of the theorem.

In order to prove (ii), introduce $\lambda := \mathcal{F}\mathcal{U}_{0,II}$ and $\lambda_0 := \mathcal{F}\mathbf{U}^0_{II}$. There is a unique solution of (2.28) in the sense of distributions, given by

$$\widehat{\lambda}(\tau, T) = e^{-i\tau(\frac{\omega'(k)}{2k}(\eta_1^2 + \eta_2^2) + \frac{\omega''(k)}{2}\eta_3^2)} e^{iT\omega'(k)\eta_3}\widehat{\lambda}_0, \tag{2.31}$$

where $\widehat{\ }$ denotes the Fourier transform with respect to the variables (X, Y, Z), and the measure $\widehat{\lambda}$ is defined for all Borel sets E of $\mathbb{R}^2$ by $\widehat{\lambda}(E) := \widehat{\lambda(E)}$.

The distribution λ defined above is in $\mathcal{C}_b([0,\tau_2^*]\times\mathbb{R}_T, \mathcal{BV}(\mathbb{R}^2_\xi, H^\sigma(\mathbb{R}^3)^n))$, as one can prove with the same arguments as in Theorem 4 of [12], which proves point (ii) of the theorem.

By the explicit expression (2.31) and under the assumption made on $\mathbf{U}^0_{II}$, we also know that $\mathcal{U}_{0,II}$ satisfies Assumption 2.2 and that $||\mathcal{U}_{0,II}||_{A^\sigma_{\tau_2^*}} \leq \mathbb{R}$.

Before solving the next equation, notice that $\pi(D_{t_0,z_0})F^S(\mathcal{U}_{0,I,1}, \overline{\mathcal{U}_{0,I,1}}, \mathcal{U}_{0,II}) \in A^\sigma_{\tau_2^*}$, thanks to the above results and to Proposition 1.3 . We denote by μ the Fourier transform of this profile and also denote by ν the Fourier transform of the profile $\mathcal{U}_{1,II}$. The last equation of system (2.29) has a unique solution in the sense of the distributions, which reads

$$\widehat{\nu}(\tau, T) = -\int_0^T e^{i(T-u)\omega'(k)}\eta_3\psi^\delta(k)\widehat{\mu}(\tau,u)du. \tag{2.32}$$

Here again, we can prove that ν is in $\mathcal{C}([0,\tau_2^*]\times\mathbb{R}_T, \mathcal{BV}(\mathbb{R}^2_\xi, H^\sigma(\mathbb{R}^3)^n))$ so that $\mathcal{U}_{1,II} \in E^\sigma_{\tau_2^*}$. From this expression it is also clear that $\mathrm{Sp}\,\mathcal{U}_{1,II} \subset \{(\omega,k), |k| > \delta\}$, i.e., that the first equation of (2.29) is also satisfied. □

Remark 2.9. (i) The profile equations are solved in $E^\sigma_{\tau_2^*}$ for all $\sigma \geq s$, not only in $E^s_{\tau_2^*}$, because if one wants the residual term $\mathcal{R}^\varepsilon$ to be in $E^s_{\tau_2^*}$, $\mathcal{U}_0$ must be in $E^{s+4}_{\tau_2^*}$, as we will see in the next section.

(ii) The remaining profiles $(Id - \pi(\omega_l, -k_l))\mathcal{U}_{1,I,1}$, $(Id - \pi(D_{t_0,z_0}))\mathcal{U}_{1,II}$, and $\mathcal{U}_2$ can be found in terms of the profiles given by the above theorem, thanks to the expressions given by (2.4)–(2.5), (2.12), (2.16), and (2.18).

2.4. Stability in the absence of low frequencies. In this part, we want to prove that the solution of diffractive optics gives a good approximation of the exact solution of (1.1), provided that low frequencies are excluded. To get this result, we prove that the residual associated to the approximate solution is small and that the approximate solution is close to the exact solution $\mathbf{u}^\varepsilon$ of (1.1).

Suppose $\mathcal{U}_0$ and $\pi(D_{t_0,z_0})\mathcal{U}_{1,II}$ are given by Proposition 2.6 with initial condition $\mathbf{U}^0$ without frequencies lower than $\delta > 0$. $\mathcal{U}_{0,II}$ then satisfies Assumption 2.2, $\pi(D_{t_0,z_0})\mathcal{U}_{1,II}$ fulfills condition (2.13), and $\mathcal{U}_{2,I}$ and $\mathcal{U}_{2,II}$ can then be constructed with the results of section 2.1. Before proving that $\mathcal{U}^\varepsilon = \mathcal{U}_0 + \varepsilon\mathcal{U}_1 + \varepsilon^2\mathcal{U}_2$ is an approximate solution of the singular equation (1.5) in the sense that the residual remains small, we need estimates of the profiles $\mathcal{U}_j$, $j = 0, 1, 2$, and of the residual terms $\mathcal{R}_j$, $j \geq 2$.

LEMMA 2.7. *Let $\sigma \geq s+4$, $\sigma' \geq s$, and $\delta \in (0,1)$ and suppose $\mathcal{U}_0 \in A^\sigma_{\tau_2^*}$ and $\pi(D_{t_0,z_0})\mathcal{U}_{1,II} \in E^\sigma_{\tau_2^*}$ are given by Proposition* 2.6. *Take $\mathcal{U}_{1,I}$, $(Id - \pi(D_{t_0,z_0}))\mathcal{U}_{1,II}$ and $\mathcal{U}_2$ as computed in section* 2.1. *Then*

(i) *the two components $\mathcal{U}_{1,I}$ and $\mathcal{U}_{1,II}$ of $\mathcal{U}_1$ are controlled as follows:*

$$\|\mathcal{U}_{1,I}\|_{A^{\sigma'}_{\tau_2^*}} \leq C\|\mathcal{U}_{0,I}\|_{A^{\sigma'+1}_{\tau_2^*}}, \quad \|(Id - \pi(D_{t_0,z_0}))\mathcal{U}_{1,II}\|_{A^{\sigma'}_{\tau_2^*}} \leq \frac{C}{\delta}\|\mathcal{U}_{0,II}\|_{A^{\sigma'+1}_{\tau_2^*}},$$

and

$$\|\pi(D_{t_0,z_0})\mathcal{U}_{1,II}(T)\|_{E^{\sigma'}_{\tau_2^*}} \leq CT\|\mathcal{U}_{0,I}\|^2_{A^{\sigma'}_{\tau_2^*}}\|\mathcal{U}_{0,II}\|_{A^{\sigma'}_{\tau_2^*}} \qquad \forall T \geq 0;$$

(ii) *the discrete spectrum component* $\mathcal{U}_{2,I}$ *of* $\mathcal{U}_2$ *is controlled as follows:*

$$\|\mathcal{U}_{2,I}\|_{A^{\sigma'}_{\tau_2^*}} \leq C\left(\|\mathcal{U}_{0,I}\|_{A^{\sigma'+2}_{\tau_2^*}} + \|\mathcal{U}_{0,I}\|^3_{A^{\sigma'}_{\tau_2^*}}\right),$$

while $\mathcal{U}_{2,II}$ *satisfies*

$$\|\mathcal{U}_{2,II}\|_{A^{\sigma'}_{\tau_2^*}} \leq \frac{C}{\delta}\left(\frac{1}{\delta}\|\mathcal{U}_{0,II}\|_{A^{\sigma'+2}_{\tau_2^*}} + \|\mathcal{U}_0\|^3_{A^{\sigma'}_{\tau_2^*}} + T\|\mathcal{U}_{0,I}\|^2_{A^{\sigma'+1}_{\tau_2^*}}\|\mathcal{U}_{0,II}\|_{A^{\sigma'+1}_{\tau_2^*}}\right);$$

(iii) *rough estimates of the profiles* $\mathcal{R}_{j\geq 2}$ *are given by*

$$\|\mathcal{R}_{j,I}\|_{A^{\sigma'}_{\tau_2^*}} \leq h_1\left(\|\mathcal{U}_{0,I}\|_{A^{\sigma'+4}_{\tau_2^*}}\right) \quad \text{and} \quad \|\mathcal{R}_{j,II}(T)\|_{E^{\sigma'}_{\tau_2^*}} \leq \frac{T}{\delta^6}h_2\left(\|\mathcal{U}_0\|_{A^{\sigma'+4}_{\tau_2^*}}\right) \quad \forall T \geq 0,$$

where h_1 *and* h_2 *are smooth positive functions defined on* $\mathbb{R}^+$ *and independent of* $\delta \in (0,1)$ *and of* $T \geq 0$.

Proof. The estimate of $\mathcal{U}_{1,I}$ is easily deduced from (2.4) and (2.6), while Lemma 2.1 and (2.5)–(2.6) yield the estimate of $(Id - \pi(D_{t_0,z_0}))\mathcal{U}_{1,II}$. The estimate of $\pi(D_{t_0,z_0})\mathcal{U}_{1,II}$ is a consequence of (2.32).

The modes ± 3 of $\mathcal{U}_{2,I}$ are controlled using (2.10) together with the algebra properties of $A^{\sigma'}_{\tau_2^*}$. The modes ± 1 are controlled as stated in the lemma as a consequence of (2.12) and (2.18). Lemma 2.1 and (2.16), (2.18) are used to estimate $\mathcal{U}_{2,II}$.

The estimates of the profiles $\mathbb{R}_j$ follow directly from the explicit formulae of these profiles given in (1.8), from Lemma 2.1 and the equations satisfied by $\mathcal{U}_{1\leq j\leq 3}$, and from the estimates of these profiles computed above. ∎

PROPOSITION 2.8. *Let* $\sigma \geq s+4$ *and* $\delta \in (0,1)$ *and suppose* $\mathcal{U}_0$ *and* $\pi(D_{t_0,z_0})\mathcal{U}_{1,II}$ *are as given by Proposition* 2.6. *Take* $\mathcal{U}_{1,I}$, $(Id - \pi(D_{t_0,z_0}))\mathcal{U}_{1,II}$ *and* $\mathcal{U}_2$ *as computed in section* 2.1 *and let* $\mathcal{U}^\varepsilon = \mathcal{U}_0 + \varepsilon\mathcal{U}_1 + \varepsilon^2\mathcal{U}_2 \in E^{s+2}_{\tau_2^*} \subset E^s_{\tau_2^*}$.

Then the profile $\underline{\mathcal{U}}^\varepsilon$ *defined as* $\underline{\mathcal{U}}^\varepsilon(\tau, X, Y, Z, t_0, z_0) = \mathcal{U}^\varepsilon(\tau, \tau/\varepsilon, X, Y, Z, t_0, z_0)$ *is in* $B^{s+2}_{\tau_2^*}$ *and is bounded uniformly in* $\varepsilon \in (0,1)$.

If δ *is small enough,* $\underline{\mathcal{U}}^\varepsilon$ *is an approximate solution of the singular equation* (1.5). *More precisely, for any* $\mu > 0$ *there exists* $\delta(\mu) > 0$ *such that if* $0 < \delta < \delta(\mu)$, $\underline{\mathcal{U}}^\varepsilon$ *satisfies*

$$\limsup_{\varepsilon\to 0} \|\partial_\tau\underline{\mathcal{U}}^\varepsilon + \varepsilon^{-1}(A_1\partial_X + A_2\partial_Y + A_3\partial_Z)\underline{\mathcal{U}}^\varepsilon + \varepsilon^{-2}(\partial_{t_0} + A_3\partial_{z_0} + L_0)\underline{\mathcal{U}}^\varepsilon + f(\underline{\mathcal{U}}^\varepsilon)\| < \mu/3,$$

where the norm is taken in $B^s_{\tau_2^*}$.

Proof. Define, for $j = 1,2,3$, $\underline{\mathcal{U}}^\varepsilon_j(\tau, X, Y, Z, t_0, z_0) = \mathcal{U}_j(\tau, \tau/\varepsilon, X, Y, Z, t_0, z_0)$. One has $\underline{\mathcal{U}}^\varepsilon_0 \in B^{s+2}_{\tau_2^*}$ since $\mathcal{U}_0 \in A^{s+2}_{\tau_2^*}$. Similarly, $\underline{\mathcal{U}}^\varepsilon_{1,I}$ and $(Id - \pi(D_{t_0,z_0}))\underline{\mathcal{U}}^\varepsilon_{1,II}$ are in $B^{s+2}_{\tau_2^*}$. Their norm in this space is obviously uniformly bounded in $\varepsilon \in (0,1)$.

Since $\pi(D_{t_0,z_0})\mathcal{U}_{1,II} \notin A^{s+2}_{\tau_2^*}$, we cannot apply the same reasoning for this component. However, point (i) of Lemma 2.7 asserts that $\varepsilon\pi(D_{t_0,z_0})\mathcal{U}_{1,II}$ satisfies, for all $T \geq 0$,

$$\|\varepsilon\pi(D_{t_0,z_0})\mathcal{U}_{1,II}(T)\|_{E^{s+2}_{\tau_2^*}} \leq \varepsilon T\|\mathcal{U}_{0,I}\|^2_{A^{s+2}_{\tau_2^*}}\|\mathcal{U}_{0,II}\|_{A^{s+2}_{\tau_2^*}},$$

and since one has

$$\|\pi(D_{t_0,z_0})\underline{\mathcal{U}}^\varepsilon_{1,II}\|_{B^{s+2}_{\tau_2^*}} \leq \sup_{T\in[0,\tau_2^*/\varepsilon]} \|\pi(D_{t_0,z_0})\mathcal{U}_{1,II}(T)\|_{E^{s+2}_{\tau_2^*}},$$

we can conclude that

$$\|\varepsilon\pi(D_{t_0,z_0})\underline{\mathcal{U}}^\varepsilon_{1,II}\|_{B^{s+2}_{\tau_2^*}} \le \tau_2^*\|\mathcal{U}_{0,I}\|^2_{A^{s+2}_{\tau_2^*}}\|\mathcal{U}_{0,II}\|_{A^{s+2}_{\tau_2^*}}.$$

Thus, $\varepsilon\pi(D_{t_0,z_0})\underline{\mathcal{U}}^\varepsilon_{1,II}$ is in $B^{s+2}_{\tau_2^*}$ and is uniformly bounded with respect to $\varepsilon \in (0,1)$. The same thing can be said about $\underline{\mathcal{U}}^\varepsilon_{2,II}$, which proves that $\underline{\mathcal{U}^\varepsilon} \in B^{s+2}_{\tau_2^*}$, with uniformly bounded norm.

We recall that

$$\partial_\tau\underline{\mathcal{U}}^\varepsilon + \varepsilon^{-1}(A_1\partial_X + A_2\partial_Y + A_3\partial_Z)\underline{\mathcal{U}}^\varepsilon + \varepsilon^{-2}(\partial_{t_0} + A_3\partial_{z_0} + L_0)\underline{\mathcal{U}}^\varepsilon + f(\underline{\mathcal{U}}^\varepsilon) = \sum_{j=-1}^{7}\varepsilon^{j-1}\underline{\mathcal{R}}^\varepsilon_j,$$

where the profiles $\underline{\mathcal{R}}^\varepsilon_j$ are defined as $\underline{\mathcal{R}}^\varepsilon_j(\tau, X, Y, Z, t_0, z_0) = \mathcal{R}_j(\tau, \tau/\varepsilon, X, Y, Z, t_0, z_0)$ with $\mathcal{R}_j$ given in (1.8).

Thanks to the results of the previous section, we know that $\underline{\mathcal{R}}^\varepsilon_{-1} = \underline{\mathcal{R}}^\varepsilon_0 = 0$ and that $\underline{\mathcal{R}}^\varepsilon_1 = (1-\psi^\delta(D_{z_0}))F^S(\mathcal{U}_{0,I,1}, \overline{\mathcal{U}_{0,I,1}}, \mathcal{U}_{0,II})$. Therefore,

$$\|\underline{\mathcal{R}}^\varepsilon_1\|_{B^s_{\tau_2^*}} \le \|\mathcal{U}_{0,I}\|^2_{A^s_{\tau_2^*}}\|(1-\psi^\delta(D_{z_0}))\underline{\mathcal{U}}^\varepsilon_{0,II}\|_{B^s_{\tau_2^*}}.$$

The following lemma says that this term goes to zero as $\delta \to 0$ uniformly in $\varepsilon \in (0,1)$.

LEMMA 2.9. *Let $\sigma \ge s$ and $\mathcal{U}_{0,II} \in A^\sigma_{\tau_2^*}$ be as given by Proposition* 2.6; *let $\underline{\mathcal{U}}^\varepsilon_{0,II} \in B^\sigma_{\tau_2^*}$ be defined as $\underline{\mathcal{U}}^\varepsilon_{0,II}(\tau, X, Y, Z, t_0, z_0) = \mathcal{U}_{0,II}(\tau, \tau/\varepsilon, X, Y, Z, t_0, z_0)$.*

Then one has $(1-\psi^\delta(D_{z_0}))\underline{\mathcal{U}}^\varepsilon_{0,II} \to 0$ in $B^\sigma_{\tau_2^*}$ as $\delta \to 0$ uniformly in $\varepsilon \in (0,1)$.

Proof. Let $\lambda^\varepsilon := \mathcal{F}\underline{\mathcal{U}}^\varepsilon_{0,II} \in \mathcal{C}([0,\tau_2^*], \mathcal{BV}(\mathbb{R}^2_\xi, H^\sigma(\mathbb{R}^3_{X,Y,Z})^n))$ and $\lambda_0 := \mathcal{F}\mathbf{U}^0_{II}$. Thanks to (2.31), we have

$$\widehat{\lambda}^\varepsilon(\tau) = e^{-i\tau(\frac{\omega'(k)}{2k}(\eta_1^2+\eta_2^2)+\frac{\omega''(k)}{2}\eta_3^2)}e^{i\frac{\tau}{\varepsilon}\omega'(k)\eta_3}\widehat{\lambda}_0.$$

We also know by the Radon–Nikodým property that there exists an H^σ-valued integral function r_0 such that $\|r_0(\xi)\| = 1$ for $v(\lambda_0)$ for almost all $\xi = (\omega, k)$ and such that for all Borel sets $E \subset \mathbb{R}^2$,

$$\lambda_0(E) = \int_E r_0(\xi)v(\lambda_0)(d\xi),$$

where $v(\lambda_0)$ denotes the total variation measure associated to λ_0. Hence,

$$\widehat{\lambda}^\varepsilon(\tau)(E) = \int_E e^{-i\tau(\frac{\omega'(k)}{2k}(\eta_1^2+\eta_2^2)+\frac{\omega''(k)}{2}\eta_3^2)}e^{i\frac{\tau}{\varepsilon}\omega'(k)\eta_3}\widehat{r}_0(\xi)v(\lambda_0)(d\xi), \tag{2.33}$$

and also

$$(1-\psi^\delta(k))\widehat{\lambda}^\varepsilon(\tau)(E) = \int_E (1-\psi^\delta(k))e^{-i\tau(\frac{\omega'(k)}{2k}(\eta_1^2+\eta_2^2)+\frac{\omega''(k)}{2}\eta_3^2)}e^{i\frac{\tau}{\varepsilon}\omega'(k)\eta_3} \times\widehat{r}_0(\xi)v(\lambda_0)(d\xi).$$

Therefore

$$\|(1-\psi^\delta(D_{z_0}))\underline{\mathcal{U}}^\varepsilon_{0,II}\|_{B^\sigma_{\tau_2^*}} = \sup_{\tau\in[0,\tau_2^*]}|(1-\psi^\delta(k))\widehat{\lambda}^\varepsilon|_{\mathcal{B}V} \le \int_E (1-\psi^\delta(k))v(\lambda_0)(d\xi)$$

and hence tends to zero as $\delta \to 0$ uniformly in $\varepsilon \in (0,1)$ as a consequence of the dominated convergence theorem. ∎

We now turn to investigating the residual terms $\varepsilon^{j-1}\underline{\mathcal{R}}_j^\varepsilon$ for $j \geq 2$.

Using point (iii) of Lemma 2.7 and with the same techniques used above to prove that $\varepsilon\pi(D_{t_0,z_0})\underline{\mathcal{U}}_{1,II}^\varepsilon$ is uniformly bounded in $B^{s+2}_{\tau_2^*}$, one can prove that $\varepsilon\underline{\mathcal{R}}_j^\varepsilon$ is uniformly bounded in $B^s_{\tau_2^*}$ with respect to $\varepsilon \in (0,1)$. Therefore, if $j \geq 3$, then the residual terms $\varepsilon^{j-1}\underline{\mathcal{R}}_j^\varepsilon$ tend to 0 in $B^s_{\tau_2^*}$ when $\varepsilon \to 0$ (and with $\delta > 0$ being fixed).

The only remaining term to treat is therefore $\varepsilon\underline{\mathcal{R}}_2^\varepsilon$. In fact, only its continuous spectrum component needs care; so far, we know only that it is uniformly bounded in $B^s_{\tau_2^*}$. We recall that $\mathcal{R}_{2,II}$ is given by

$$\begin{aligned}\mathcal{R}_{2,II} = &-L_1(\partial)\mathcal{L}^{-1}(D_{t_0,z_0})A(\partial_{X,Y,Z})\mathcal{U}_{0,II} + L_1(\partial)\mathcal{L}^{-1}(D_{t_0,z_0})\psi^\delta(D_{z_0})f(\mathcal{U}_0)_{II}\\ &+iL_1(\partial)\mathcal{L}^{-1}(D_{t_0,z_0})A(\partial_{X,Y,Z})\pi(D_{t_0,z_0})\mathcal{U}_{1,II} + i\mathcal{L}^{-1}(D_{t_0,z_0})A(\partial_{X,Y,Z})\partial_\tau\mathcal{U}_{0,II}\\ &+\partial_\tau\pi(D_{t_0,z_0})\mathcal{U}_{1,II} + \big(f'(\mathcal{U}_0)(\mathcal{U}_1)\big)_{II}.\end{aligned}$$

In this expression, all the terms which do not involve $\pi(D_{t_0,z_0})\mathcal{U}_{1,II}$ are in $A^s_{\tau_2^*}$, and their contribution to $\underline{\mathcal{R}}_2^\varepsilon$ is therefore in $B^s_{\tau_2^*}$. Hence, the only possible problems come from the terms which involve $\pi(D_{t_0,z_0})\mathcal{U}_{1,II}$. We need the following lemma.

LEMMA 2.10. *Let $\sigma \geq s+4$ and $\pi(D_{t_0,z_0})\mathcal{U}_{1,II} \in E^\sigma_{\tau_2^*}$ be as given by Proposition* 2.6.

Then one has

$$\lim_{\varepsilon\to 0}\varepsilon\|\underline{\mathcal{U}}_{1,II}^\varepsilon\|_{B^\sigma_{\tau_2^*}} = 0 \quad \text{and} \quad \lim_{\varepsilon\to 0}\varepsilon\|\partial_\tau\underline{\mathcal{U}}_{1,II}^\varepsilon\|_{B^{\sigma-2}_{\tau_2^*}} = 0.$$

Proof. For all $\tau \in [0,\tau_2^*]$, let $\nu^\varepsilon(\tau) := \mathcal{F}\underline{\mathcal{U}}_{1,II}^\varepsilon(\tau)$. Thanks to (2.32), one then has

$$\widehat{\nu^\varepsilon}(\tau) = -\int_0^{\tau/\varepsilon} e^{-(\frac{\tau}{\varepsilon}-t)\omega'(k)\eta_3}\psi^\delta(k)\widehat{\mu}(\tau,t)dt, \tag{2.34}$$

where, for all (τ,T), $\mu(\tau,T)$ is defined as $\mu(\tau,T) := \mathcal{F}\big(F^S(\mathcal{U}_{0,I,1},\overline{\mathcal{U}_{0,I,1}},\mathcal{U}_{0,II})(\tau,T)\big)$. We also recall that $\widehat{\ }$ denotes the Fourier transform with respect to the variables (X,Y,Z).

As with (2.33), we can write $\lambda(\tau,T) := \mathcal{F}\mathcal{U}_{0,II}(\tau,T)$ in the form

$$\widehat{\lambda}(\tau,T) = \int_E e^{-i\tau(\frac{\omega'(k)}{2k}(\eta_1^2+\eta_2^2)+\frac{\omega''(k)}{2}\eta_3^2)}e^{iT\omega'(k)\eta_3}\widehat{r_0(\xi)}v(\lambda_0)(d\xi)$$

for all Borel sets $E \subset \mathbb{R}^2$.

Hence, $\widehat{\mu}(\tau,T)(E) \in H^\sigma(\mathbb{R}^3)$ is given, for all Borel sets $E \subset \mathbb{R}^2$ and $\eta \in \mathbb{R}^3$, by

$$\begin{aligned}\widehat{\mu}(\tau,T)(E)(\eta) = \int_E\int_{\mathbb{R}^3\times\mathbb{R}^3} F^S\Big(&\widehat{\mathcal{U}_{0,I,1}}(\eta-\eta'),\widehat{\overline{\mathcal{U}_{0,I,1}}}(\eta''-\eta'),\\ &e^{-i\tau(\frac{\omega'(k)}{2k}(\eta_1'^2+\eta_2'^2)+\frac{\omega''(k)}{2}\eta_3'^2)}e^{iT\omega'(k)\eta_3'}\widehat{r_0(\xi)}(\eta')\Big)\,d\eta'd\eta''v(\lambda_0)(d\xi).\end{aligned}$$

Combining this equation with (2.34) then yields

$$\begin{aligned}|\widehat{\nu^\varepsilon}(\tau)|_{\mathcal{BV}} \leq &\int_{\mathbb{R}^2}\|\int_{\mathbb{R}^3\times\mathbb{R}^3}\int_0^{\tau/\varepsilon} F^S\Big(\Big(\widehat{\mathcal{U}_{0,I,1}}(\cdot-\eta'),\widehat{\overline{\mathcal{U}_{0,I,1}}}(\eta''-\eta'),\\ &e^{-i\tau(\frac{\omega'(k)}{2k}(\eta_1'^2+\eta_2'^2)+\frac{\omega''(k)}{2}\eta_3'^2)}e^{it\omega'(k)\eta_3'}\widehat{r_0(\xi)}(\eta')\Big)\,dtd\eta'd\eta''\|_{\mathcal{F}(H^\sigma)}v(\lambda_0)(d\xi)\\ := &\int_{\mathbb{R}^2} G^\varepsilon(\xi)v(\lambda_0)(d\xi).\end{aligned}$$

The family $\varepsilon G^\varepsilon(\xi)$ can be bounded by a constant (and constants are $v(\lambda_0)$-integrable); thanks to Lemma 6 of [11], we also know that $\varepsilon G^\varepsilon(\xi) \to 0$ as $\varepsilon \to 0$, provided that $\omega'(k) \neq \omega'(k_l)$. Since this equality occurs only when $k = k_l$, and since $v(\lambda_0)(\{k_l\}) = 0$, we thus have $\varepsilon G^\varepsilon(\xi) \to 0$ $v(\lambda_0)$ almost everywhere, so that the first part of the lemma follows from the dominated convergence theorem.

The second part of the lemma can be established with the same techniques. ∎

From the above lemma, it is clear that $\varepsilon \underline{\mathcal{R}}_2^\varepsilon = o(1)$, which achieves the last step of the proof of the proposition. ∎

We know that u^ε almost solves (1.1), but we have not yet proved that the difference $\mathbf{u}^\varepsilon - u^\varepsilon$ remains small. This is what the following theorem shows.

THEOREM 2.11. *Suppose the characteristic variety $\mathcal{C}_\mathcal{L}$ is as in Assumptions* 2.1 *and* 2.3.

Let $\mathbf{U}^0 = \mathbf{U}_I^0 + \mathbf{U}_{II}^0 \in A_0^{s+4}$ such that $\mathbf{U}_I^0 = \mathbf{U}_{I,1}^0 e^{i\theta} + c.c.$ and suppose, moreover, that

$$\pi(\omega_l, -k_l)\mathbf{U}_{I,1}^0 = \mathbf{U}_{I,1}^0 \quad \textit{and} \quad \pi(D_{t_0,z_0})\mathbf{U}_{II}^0 = \mathbf{U}_{II}^0,$$

and that Sp $\mathbf{U}_{II}^0 \subset \{(\omega,k), |k| > \delta\}$ *for a given $\delta > 0$.*

Then, for $0 < \tau^* \leq \inf(\tau_1^*, \tau_2^*)$, the following holds:

(i) *The profile $\mathcal{U}_0 = \mathcal{U}_{0,I} + \mathcal{U}_{0,II}$ given by Propostion* 2.6 *satisfies Assumption* 2.2, *and the associated profile $\underline{\mathcal{U}}_0^\varepsilon \in B_{\tau^*}^s$ approximates the singular equation* (1.5) *in the sense that for all $\mu > 0$ there exists a $\delta(\mu)$ such that if $0 < \delta < \delta(\mu)$, then*

$$\|\mathbf{U}_I^\varepsilon - \underline{\mathcal{U}}_{0,I}^\varepsilon\|_{B_{\tau^*}^s} = O(\varepsilon) \quad \textit{and} \quad \limsup_{\varepsilon\to 0} \|\mathbf{U}_{II}^\varepsilon - \underline{\mathcal{U}}_{0,II}^\varepsilon\|_{B_{\tau^*}^s} < \mu/3,$$

where we have decomposed the profile $\mathbf{U}^\varepsilon$ of the exact solution $\mathbf{u}^\varepsilon$, given by Theorem 1.4, *into $\mathbf{U}^\varepsilon = \mathbf{U}_I^\varepsilon + \mathbf{U}_{II}^\varepsilon$.*

(ii) *We also have stability of the approximate solution defined with $\mathcal{U}_0$,*

$$\|\mathbf{u}_I^\varepsilon - u_{0,I}^\varepsilon\| = O(\varepsilon^{3/2}) \quad \textit{and} \quad \limsup_{\varepsilon\to 0} \frac{1}{\sqrt{\varepsilon}} \|\mathbf{u}_{II}^\varepsilon - u_{0,II}^\varepsilon\| < \mu/3,$$

where the norm can be taken either in $\mathcal{C}([0, \frac{\tau^*}{\varepsilon}] \times \mathbb{R}^3)^n$ or in $\mathcal{C}([0, \frac{\tau^*}{\varepsilon}], L^2(\mathbb{R}^3)^n)$.

Notation. We have used in this theorem the notation

$$\mathbf{u}_I^\varepsilon = \sqrt{\varepsilon}\mathbf{U}_I^\varepsilon(\varepsilon T, X, Y, Z, T/\varepsilon, Z/\varepsilon), \quad u_{0,I}^\varepsilon = \sqrt{\varepsilon}\underline{\mathcal{U}}_{0,I}^\varepsilon(\varepsilon T, X, Y, Z, T/\varepsilon, Z/\varepsilon),$$

and similarly

$$\mathbf{u}_{II}^\varepsilon = \sqrt{\varepsilon}\mathbf{U}_{II}^\varepsilon(\varepsilon T, X, Y, Z, T/\varepsilon, Z/\varepsilon), \quad u_{0,II}^\varepsilon = \sqrt{\varepsilon}\underline{\mathcal{U}}_{0,II}^\varepsilon(\varepsilon T, X, Y, Z, T/\varepsilon, Z/\varepsilon).$$

Proof. (i) Since $\underline{\mathcal{R}}_{-1}^\varepsilon = \underline{\mathcal{R}}_0^\varepsilon = 0$, the error profile $\mathcal{W}^\varepsilon = \mathbf{U}^\varepsilon - \underline{\mathcal{U}}^\varepsilon$ satisfies

$$\begin{aligned}\partial_\tau \mathcal{W}^\varepsilon + \varepsilon^{-1}(A_1\partial_X + A_2\partial_Y + A_3\partial_Z)\mathcal{W}^\varepsilon + \varepsilon^{-2}(\partial_{t_0} + A_3\partial_{z_0} + L_0)\mathcal{W}^\varepsilon \\ = f(\underline{\mathcal{U}}^\varepsilon) - f(\mathbf{U}^\varepsilon) + \underline{\mathcal{R}}_1^\varepsilon + \sum_{j=2}^7 \varepsilon^{j-1}\underline{\mathcal{R}}_j^\varepsilon.\end{aligned}$$

Thanks to Taylor's theorem, there exists a regular function G such that $f(\underline{\mathcal{U}}^\varepsilon) - f(\mathbf{U}^\varepsilon) = G(\underline{\mathcal{U}}^\varepsilon, \mathbf{U}^\varepsilon)\mathcal{W}^\varepsilon$. Therefore, the profile $\mathcal{W}^\varepsilon$ satisfies

$$\begin{aligned}\partial_\tau \mathcal{W}^\varepsilon + \varepsilon^{-1}(A_1\partial_X + A_2\partial_Y + A_3\partial_Z)\mathcal{W}^\varepsilon + \varepsilon^{-2}(\partial_{t_0} + A_3\partial_{z_0} + L_0)\mathcal{W}^\varepsilon \\ - G(\underline{\mathcal{U}}^\varepsilon, \mathbf{U}^\varepsilon)\mathcal{W}^\varepsilon = \underline{\mathcal{R}}_1^\varepsilon + \sum_{j=2}^7 \varepsilon^{j-1}\underline{\mathcal{R}}_j^\varepsilon.\end{aligned} \tag{2.35}$$

Let $R > 0$ such that $\|\mathbf{U}^0\|_{A^{s+4}_{\tau^*}} \leq R$. We recall that τ_1^* and τ_2^* are chosen (in Theorem 1.4 and Proposition 2.6, respectively) in such a way that $\|\mathbf{U}^\varepsilon\|_{A^s_{\tau_1^*}} \leq 2R$ and $\|\mathcal{U}_0\|_{A^{s+4}_{\tau_2^*}} \leq 2R$. Since $\tau^* \leq \inf(\tau_1^*, \tau_2^*)$, we can replace $\tau_{1,2}^*$ by τ^* in these inequalities. Hence, we can deduce from Lemma 2.7 that

$$\|\underline{\mathcal{U}}^\varepsilon\|_{B^s_{\tau^*}} \leq CR\left(R^2 + \varepsilon\left(1 + \frac{1+R^2}{\delta}\right) + \varepsilon^2(1+R^2)\left(\frac{1}{\delta} + \frac{1}{\delta^2}\right)\right).$$

Thus

$$\|G(\underline{\mathcal{U}}^\varepsilon, \mathbf{U}^\varepsilon)\|_{B^s_{\tau^*}} \leq h\left(R\left(R^2 + \varepsilon\left(1 + \frac{1+R^2}{\delta}\right) + \varepsilon^2(1+R^2)\left(\frac{1}{\delta} + \frac{1}{\delta^2}\right)\right), R\right),$$

where $h(\cdot,\cdot)$ is a smooth positive function which does not depend on R, δ, nor ε.

By a Gronwall-type argument, we can therefore deduce from (2.35) that
