$$\|\mathcal{W}^\varepsilon\|_{B^s_{\tau^*}} \leq \tau^* \left(\|\underline{\mathcal{R}}_1^\varepsilon\|_{B^s_{\tau^*}} + \sum_{j=2}^{7} \varepsilon^{j-1}\|\underline{\mathcal{R}}_j^\varepsilon\|_{B^s_{\tau^*}}\right) e^{h\left(R(R^2+\varepsilon(1+\frac{1+R^2}{\delta})+\varepsilon^2(1+R^2)(\frac{1}{\delta}+\frac{1}{\delta^2})),R\right)\tau^*}. \tag{2.36}$$

It is now easy to deduce from (2.36), Lemma 2.7(iii), and Proposition 2.8 that $\underline{\mathcal{U}}^\varepsilon = \underline{\mathcal{U}}_0^\varepsilon + \varepsilon\underline{\mathcal{U}}_1^\varepsilon + \varepsilon^2\underline{\mathcal{U}}_2^\varepsilon$ satisfies the asymptotic properties of point (i) of the theorem. This point will be proved if we can replace $\underline{\mathcal{U}}^\varepsilon$ by $\underline{\mathcal{U}}_0^\varepsilon$. This is obviously the case since, as a consequence of Lemmas 2.7 and 2.10, $\varepsilon\underline{\mathcal{U}}_1^\varepsilon + \varepsilon^2\underline{\mathcal{U}}_2^\varepsilon$ goes to 0 in $B^s_{\tau^*}$ as $\varepsilon \to 0$.

Taking the discrete spectrum component of (2.35) yields the usual equations of diffractive optics (in particular, $\mathcal{R}_{1,I} = 0$) so that the techniques of [8], [10], and [11] can be used to obtain a better estimate $O(\varepsilon)$ of the error term.

(ii) This point is a direct consequence of (i) and of the embedding results of Proposition 1.3. ∎

2.5. Stability in the general case. In this section, we consider the general case, i.e., we allow low frequencies. Therefore, we consider initial conditions with profile $\mathbf{U}^0 = \mathbf{U}_I^0 + \mathbf{U}_{II}^0 \in A_0^{s+4}$ without making any assumption on the spectrum of $\mathbf{U}_{II}^0$. Alterman's methods [1] are used to relax this assumption. We first introduce the following notation.

Notation. We denote by $\mathbf{U}_{II}^{0,\delta}$ and $\mathbf{U}^{0,\delta}$ the "filtered" profiles

$$\mathbf{U}_{II}^{0,\delta} = \psi^\delta(D_{z_0})\mathbf{U}_{II}^0 \quad \text{and} \quad \mathbf{U}^{0,\delta} = \mathbf{U}_I^0 + \mathbf{U}_{II}^{0,\delta}, \tag{2.37}$$

where $0 < \delta < 1$.

The exact solution of (1.1) with initial condition $\sqrt{\varepsilon}\mathbf{U}^{0,\delta}(X,Y,Z,0,Z/\varepsilon)$ determined by Theorem 1.4 is denoted by $\mathbf{u}^{\varepsilon,\delta}$ and its associated profile by $\mathbf{U}^{\varepsilon,\delta}$, so that one has $\mathbf{u}^{\varepsilon,\delta}(T,X,Y,Z) = \sqrt{\varepsilon}\mathbf{U}^{\varepsilon,\delta}(\varepsilon T, X, Y, Z, T/\varepsilon, Z/\varepsilon)$.

The dominated convergence theorem shows that $\mathbf{U}_{II}^{0,\delta} \to \mathbf{U}_{II}^0$ in A_0^s. We also have convergence of the exact solutions of (1.1) associated to these initial conditions, as the following proposition shows.

PROPOSITION 2.12. *Let $\mathbf{U}^0 = \mathbf{U}_I^0 + \mathbf{U}_{II}^0 \in A_0^s$ and $\mathbf{U}^{0,\delta} = \mathbf{U}_I^0 + \psi^\delta(D_{z_0})\mathbf{U}_{II}^0$.*

There exists $\tau_1^* > 0$, independent of ε and δ, such that the exact solutions $\mathbf{U}^\varepsilon$ and $\mathbf{U}^{\varepsilon,\delta}$ of the singular equation (1.5) *with initial conditions $\mathbf{U}^0$ and $\mathbf{U}^{0,\delta}$, respectively, exist in $B^s_{\tau_1^*}$. Moreover, one has*

$$\mathbf{U}^\varepsilon - \mathbf{U}^{\varepsilon,\delta} \to 0 \quad \text{in } B^s_{\tau_1^*} \quad \text{as } \delta \to 0$$

uniformly in $\varepsilon \in (0,1)$.

Proof. It is easy to see that $\|\mathbf{U}^{0,\delta}\|_{B^s_{\tau_1^*}} \leq \|\mathbf{U}^0\|_{B^s_{\tau_1^*}}$. Hence, if R is such that $\|\mathbf{U}^0\|_{B^s_{\tau_1^*}} \leq R$, one also has $\|\mathbf{U}^{0,\delta}\|_{B^s_{\tau_1^*}} \leq R$. Therefore, Theorem 1.4 implies that the profile $\mathbf{U}^{\varepsilon,\delta}$ also exists on the existence interval $[0,\tau_1^*]$ of $\mathbf{U}^\varepsilon$, since this interval depends only on R.

Moreover, on $[0,\tau_1^*]$, the difference $\mathbf{W}^\delta = \mathbf{U}^\varepsilon - \mathbf{U}^{\varepsilon,\delta}$ satisfies

$$\begin{aligned}\partial_\tau \mathbf{W}^\delta + \varepsilon^{-1}(A_1\partial_X + A_2\partial_Y + A_3\partial_Z)\mathbf{W}^\delta + \varepsilon^{-2}(\partial_{t_0} + A_3\partial_{z_0} + L_0)\mathbf{W}^\delta \\ = G(\mathbf{U}^{\varepsilon,\delta}, \mathbf{U}^\varepsilon)\mathbf{W}^\delta,\end{aligned}$$

where, as for (2.35), G is a regular function satisfying $G(\mathbf{U}^{\varepsilon,\delta}, \mathbf{U}^\varepsilon)\mathbf{W}^\delta = f(\mathbf{U}^{\varepsilon,\delta}) - f(\mathbf{U}^\varepsilon)$.

As in the proof of Theorem 2.11, we obtain

$$\|G(\mathbf{U}^{\varepsilon,\delta}, \mathbf{U}^\varepsilon)\|_{B^s_{\tau_1^*}} \leq h(R,R),$$

where $h(\cdot,\cdot)$ is a smooth positive function independent of δ and ε.

A Gronwall-type argument then yields

$$\|\mathbf{W}^\delta\|_{B^s_{\tau_1^*}} \leq \|\mathbf{W}^{0,\delta}\|_{A^s_0} e^{h(R,R)\tau_1^*},$$

so that the desired result is now a consequence of the dominated convergence theorem. ∎

We now study the convergence of the approximate solutions. If we take $\mathbf{U}^{0,\delta}$ as the initial condition, all the results of sections 2.1–2.4 remain valid. In particular, we can construct an approximate profile $\underline{\mathcal{U}}^{\varepsilon,\delta} = \underline{\mathcal{U}}_0^{\varepsilon,\delta} + \varepsilon\underline{\mathcal{U}}_1^{\varepsilon,\delta} + \varepsilon^2\underline{\mathcal{U}}_2^{\varepsilon,\delta}$ of $\mathbf{U}^{\varepsilon,\delta}$. The leading term $\underline{\mathcal{U}}_0^{\varepsilon,\delta}$ satisfies

$$\underline{\mathcal{U}}_0^{\varepsilon,\delta}(\tau, X, Y, Z, t_0, z_0) = \mathcal{U}_0^\delta(\tau, \tau/\varepsilon, X, Y, Z, t_0, z_0),$$

with $\mathcal{U}_0^\delta = \mathcal{U}_{0,I} + \mathcal{U}_{0,II}^\delta$. The discrete spectrum component $\mathcal{U}_{0,I}$ (which does not depend on δ) is given as before by system (2.27), while $\mathcal{U}_{0,II}^\delta = \pi(D_{t_0,z_0})\mathcal{U}_{0,II}^\delta$ is found solving

$$\left\{\begin{array}{l}(\partial_T - \omega'(D_{z_0})\partial_Z)\mathcal{U}_{0,II}^\delta = 0,\\ \partial_\tau \mathcal{U}_{0,II}^\delta + i\frac{\omega'(D_{z_0})}{2D_{z_0}}(\partial_X^2 + \partial_Y^2)\mathcal{U}_{0,II}^\delta + i\frac{\omega''(D_{z_0})}{2}\partial_Z^2\mathcal{U}_{0,II}^\delta = 0,\\ \mathcal{U}_{0,II}^\delta|_{\tau=T=0} = \mathbf{U}_{II}^{0,\delta}.\end{array}\right. \tag{2.38}$$

The following proposition shows that when $\delta \to 0$, the profile $\mathcal{U}_{0,II}^\delta$ tends to the profile $\mathcal{U}_{0,II}$ obtained formally by taking $\delta = 0$ in (2.38).

PROPOSITION 2.13. *Let $\sigma \geq s$ such that $\mathbf{U}_{II}^0 \in A_0^\sigma$. Suppose, moreover, that $\pi(D_{t_0,z_0})\mathbf{U}_{II}^0 = \mathbf{U}_{II}^0$.*

Then there exists $\tau_2^* > 0$ such that the solution $\mathcal{U}_{0,II}^\delta$ of (2.38) exists in $A^\sigma_{\tau_2^*}$ for all $0 < \delta < 1$ and such that the limit system

$$\left\{\begin{array}{l}(\partial_T - \omega'(D_{z_0})\partial_Z)\mathcal{U}_{0,II} = 0,\\ \partial_\tau\partial_{z_0}\mathcal{U}_{0,II} - \frac{\omega'(D_{z_0})}{2}(\partial_X^2 + \partial_Y^2)\mathcal{U}_{0,II} - \frac{D_{z_0}\omega''(D_{z_0})}{2}\partial_Z^2\mathcal{U}_{0,II} = 0,\\ \mathcal{U}_{0,II}|_{\tau=T=0} = \mathbf{U}_{II}^0\end{array}\right. \tag{2.39}$$

admits a unique solution in $A^\sigma_{\tau_2^*}$.

Moreover, $\mathcal{U}^\delta_{0,II} \to \mathcal{U}_{0,II}$ *in* $A^\sigma_{\tau_2^*}$ *as* $\delta \to 0$.

Proof. The results of the proposition are easily obtained from the explicit expression of $\mathcal{U}^\delta_{0,II}$ given by (2.31) and from the dominated convergence theorem. ∎

Remark 2.10. (i) Since $\omega'(k)$ is an even function and $\omega''(k)$ an odd function of (ω, k), the Fourier multipliers $\omega'(D_{z_0})$ and $D_{z_0}\omega''(D_{z_0})$ transform real functions of the variable (t_0, z_0) into real functions.

(ii) System (2.39) is formally obtained by differentiating (2.38) and letting $\delta \to 0$. In (2.39), there is no D_{z_0} inverse (which is not a Fourier multiplier), and therefore this system can be solved explicitly in the Fourier domain.

We are now ready to state our main theorem.

THEOREM 2.14. *Suppose the characteristic variety* $\mathcal{C}_\mathcal{L}$ *is as in Assumptions* 2.1 *and* 2.3.

Let $\mathbf{U}^0 = \mathbf{U}^0_I + \mathbf{U}^0_{II} \in A^{s+4}_0$ *such that* $\mathbf{U}^0_I = \mathbf{U}^0_{I,1} e^{i\theta} + c.c.$ *and suppose, moreover, that*

$$\pi(\omega_l, -k_l)\mathbf{U}^0_{I,1} = \mathbf{U}^0_{I,1} \quad \textit{and} \quad \pi(D_{t_0,z_0})\mathbf{U}^0_{II} = \mathbf{U}^0_{II}.$$

Then for $\tau_3^* = \min\{\tau_1^*, \tau_2^*\}$ *we have*

(i) *the exact solution* $\mathbf{u}^\varepsilon$ *of* (1.1) *exists on* $[0, \tau_3^*/\varepsilon]$ *and can be written* $\mathbf{u}^\varepsilon(T, X, Y, Z) = \sqrt{\varepsilon}\mathbf{U}^\varepsilon(\varepsilon T, X, Y, Z, T/\varepsilon, Z/\varepsilon)$, *with* $\mathbf{U}^\varepsilon = \mathbf{U}^\varepsilon_I + \mathbf{U}^\varepsilon_{II} \in B^{s+4}_{\tau_3^*}$;

(ii) $\mathcal{U}_{0,I,1}$ *is defined in* $\mathcal{C}_b([0, \tau_3^*] \times \mathbb{R}_T, H^{s+4}(\mathbb{R}^3)^n)$ *as the unique solution of* (2.27);

(iii) $\mathcal{U}_{0,II}$ *is defined in* $A^{s+4}_{\tau_3^*}$ *as the unique solution of* (2.39);

(iv) *the profile* $\underline{\mathcal{U}}^\varepsilon_0 \in B^s_{\tau_3^*}$ *associated to* $\mathcal{U}_0 = \mathcal{U}_{0,I} + \mathcal{U}_{0,II} \in A^s_{\tau_3^*}$, *with* $\mathcal{U}_{0,I} = \mathcal{U}_{0,I,1}e^{i\theta} + c.c.$, *approximates the singular equation* (1.5) *in the sense that*

$$\|\mathbf{U}^\varepsilon_I - \underline{\mathcal{U}}^\varepsilon_{0,I}\|_{B^s_{\tau_3^*}} = O(\varepsilon) \quad \textit{and} \quad \|\mathbf{U}^\varepsilon_{II} - \underline{\mathcal{U}}^\varepsilon_{0,II}\|_{B^s_{\tau_3^*}} = o(1) \quad \textit{as } \varepsilon \to 0;$$

(v) *we also have stability of the approximate solution* u^ε_0 *defined with* $\mathcal{U}_0$,

$$\|\mathbf{u}^\varepsilon_I - u^\varepsilon_{0,I}\| = O(\varepsilon^{3/2}) \quad \textit{and} \quad \|\mathbf{u}^\varepsilon_{II} - u^\varepsilon_{0,II}\| = o(\sqrt{\varepsilon}) \quad \textit{as } \varepsilon \to 0,$$

where the norm can be taken either in $\mathcal{C}([0, \frac{\tau_3^*}{\varepsilon}] \times \mathbb{R}^3)^n$ *or in* $\mathcal{C}([0, \frac{\tau_3^*}{\varepsilon}], L^2(\mathbb{R}^3)^n)$.

Notation. We have used the same notation $\mathbf{u}^\varepsilon_I$, $\mathbf{u}^\varepsilon_{II}$, $u^\varepsilon_{0,I}$, and $u^\varepsilon_{0,II}$ as in Theorem 2.11.

Proof. (i)–(iii) The first three points have been proved in Theorem 1.4, Proposition 2.6, and Proposition 2.13.

(iv) Convergence of the discrete spectrum components is exactly the same as in Theorem 2.11 since the assumption of the absence of low frequencies only affects the continuous spectrum components.

We now want to prove that $\mathbf{U}^\varepsilon_{II} \to \underline{\mathcal{U}}^\varepsilon_{0,II}$ in $B^s_{\tau_3^*}$, i.e., for all $\mu > 0$, there exists $\varepsilon_0 > 0$ such that for $0 < \varepsilon < \varepsilon_0$, $\|\mathbf{U}^\varepsilon_{II} - \underline{\mathcal{U}}^\varepsilon_{0,II}\|_{B^s_{\tau_3^*}} < \mu$.

Now, write

$$\|\mathbf{U}^\varepsilon_{II} - \underline{\mathcal{U}}^\varepsilon_{0,II}\|_{B^s_{\tau_3^*}} \le \|\mathbf{U}^\varepsilon_{II} - \mathbf{U}^{\varepsilon,\delta}_{II}\|_{B^s_{\tau_3^*}} + \|\mathbf{U}^{\varepsilon,\delta}_{II} - \underline{\mathcal{U}}^{\varepsilon,\delta}_{0,II}\|_{B^s_{\tau_3^*}} + \|\underline{\mathcal{U}}^{\varepsilon,\delta}_{0,II} - \underline{\mathcal{U}}^\varepsilon_{0,II}\|_{B^s_{\tau_3^*}},$$

where $\delta > 0$ and $\mathbf{U}^{\varepsilon,\delta}_{II}$ and $\underline{\mathcal{U}}^{\varepsilon,\delta}_{0,II}$ are defined as usual.

Thanks to Propositions 2.12–2.13, we know that for $\delta \le \delta_0$ small enough and for all $\varepsilon \in (0, 1)$, one has

$$\|\mathbf{U}^\varepsilon_{II} - \mathbf{U}^{\varepsilon,\delta}_{II}\|_{B^s_{\tau_3^*}} < \mu/3 \quad \text{and} \quad \|\underline{\mathcal{U}}^{\varepsilon,\delta}_{0,II} - \underline{\mathcal{U}}^\varepsilon_{0,II}\|_{B^s_{\tau_3^*}} \le \|\mathcal{U}^\delta_{0,II} - \mathcal{U}_{0,II}\|_{A^s_{\tau_3^*}} < \mu/3.$$

Moreover, the profile $\underline{\mathcal{U}}_{0,II}^{\varepsilon,\delta}$ satisfies all the assumptions required to apply Theorem 2.11. Therefore, taking $0 < \delta < \inf\{\delta_0, \delta(\mu)\}$, we know that for ε small enough,

$$\|\mathbf{U}_{II}^{\varepsilon,\delta} - \underline{\mathcal{U}}_{0,II}^{\varepsilon,\delta}\|_{B^s_{\tau_3^*}} < \mu/3.$$

The above three inequalities thus yield

$$\|\mathbf{U}_{II}^{\varepsilon} - \underline{\mathcal{U}}_{0,II}^{\varepsilon}\|_{B^s_{\tau_3^*}} < \mu,$$

which proves the result.

(v) This point is a direct consequence of point (iv) and of the embedding properties of Proposition 1.3. ∎

3. Nondispersive case. In section 2, we have considered dispersive systems. If most of the physical applications fall into this class, nondispersive systems are also physically relevant. Ultrashort pulses, for instance, are often modeled with such a framework. There is also a mathematical reason why we study nondispersive problems in this section: We have seen in the previous section that interactions between oscillations with a purely continuous spectrum are not possible. The proof of this result relies strongly on the dispersive properties of the characteristic variety. We show in this section that when these properties do not hold, nonlinearities can be observed on the continuous spectrum components.

As already mentioned, this nondispersive framework has already been investigated by Alterman and Rauch in [1], [2], [3], and [15]. Of course, our results coincide with theirs, but our method is completely different, and the nondispersive case appears to be a particular case of the general framework presented in this paper and does not require an ad hoc analysis.

The systems we consider here are in the form

$$\left\{ \begin{array}{l} L(\partial)\mathbf{u}^\varepsilon + f(\mathbf{u}^\varepsilon) = 0, \mathbf{u}^\varepsilon|_{T=0}(X,Y,Z) = \mathbf{u}_\varepsilon^0(X,Y,Z), \end{array} \right.$$

with $L(\partial) = A_0\partial_T + A_1\partial_X + A_2\partial_Y + A_3\partial_Z$. We thus consider problems of type (1.1) with $L_0 = 0$. As we have seen in Remark 1.2, we can suppose that $A_0 = Id$.

The symbol $\mathcal{L}(\omega, k)$ then reads $\mathcal{L}(\omega, k) = \omega Id + A_3 k$ and is therefore homogeneous of degree one in (ω, k) so that Assumption 2.1 is never realized. Nevertheless without any additional hypothesis on $L(\partial)$, we know some properties on the characteristic variety $\mathcal{C}_\mathcal{L}$. Since $\mathcal{L}(\omega, k)$ is homogeneous of degree one, $\mathcal{C}_\mathcal{L}$ is a union of lines which all go through the origin. Moreover, if (ω, k) and (ω', k') are on the same line of $\mathcal{C}_\mathcal{L}$, then one has $\pi(\omega, k) = \pi(\omega', k')$. From this point onward, we use the following notation.

Notation. We denote by $\mathcal{D}_1, \ldots, \mathcal{D}_N$ the lines such that $\mathcal{C}_\mathcal{L} = \mathcal{D}_1 \cup \cdots \cup \mathcal{D}_N$. We denote by $-v_j$ the slope of line $\mathcal{D}_j$. If $(\omega, k) \in \mathcal{D}_j$, write $\pi_j := \pi(\omega, k)$ and $\mathcal{L}_j^{-1} := \mathcal{L}^{-1}(\omega, k)$. Up to a renumbering, we can also suppose that $(\omega_l, -k_l) \in \mathcal{D}_1$.

As the study of the nondispersive case does not raise many other difficulties than in the dispersive case, most of the following results are given without proof.

3.1. The profile equations. As in section 2, an approximate solution is sought in the form

$$u^\varepsilon(T, X, Y, Z) = \sqrt{\varepsilon}\mathcal{U}^\varepsilon\left(\varepsilon T, T, X, Y, Z, \frac{T}{\varepsilon}, \frac{Z}{\varepsilon}\right),$$

where the profile $\mathcal{U}^\varepsilon$ is written

$$\mathcal{U}^\varepsilon = \mathcal{U}_0 + \varepsilon \mathcal{U}_1 + \varepsilon^2 \mathcal{U}_2,$$

with $\mathcal{U}_0, \mathcal{U}_1, \mathcal{U}_2 \in E^s_{\tau^*}$.

Thanks to Proposition 1.10, these profiles are decomposed into a component with a discrete spectrum and a component with a purely continuous one,

$$\mathcal{U}_j = \mathcal{U}_{j,I} + \mathcal{U}_{j,II}, \qquad j = 0, 1, 2.$$

We recall that the profiles which are labeled I always have a discrete spectrum and the profiles which are labeled II always have a purely continuous one.

The analysis of the discrete spectrum components slightly differs from the analysis performed for the dispersive case. Indeed, the superior harmonics created by the nonlinearity are noncharacteristic in the dispersive case and thus do not play any important role because they are not propagated; conversely, in the nondispersive case, the superior harmonics are characteristic, and so we must seek $\mathcal{U}_{0,I}, \mathcal{U}_{1,I}$, and $\mathcal{U}_{2,I}$ as periodic functions. Since the nonlinearity is odd, only odd harmonics are created by the nonlinearity, if no even harmonic is present initially. Therefore, we look for profiles of the form

$$\mathcal{U}_{l,I}(\tau, T, X, Y, Z, \theta) = \sum_{j \in Z} \mathcal{U}_{l,I,2j+1}(\tau, T, X, Y, Z) e^{i(2j+1)\theta}, \qquad l = 0, 1, 2.$$

In order for these profiles to be in $E^s_{\tau^*}$, one must have normal convergence of the harmonics, and that is why we introduce the following spaces.

DEFINITION 3.1. *We denote by D^s_0 (resp., $D^s_{\tau^*}$) the set of the sequences of profiles $(\mathcal{V}_{2j+1})_{j \in Z}$, with $\mathcal{V}_{2j+1} \in H^s(\mathbb{R}^3)^n$ (resp., $\mathcal{C}_b([0, \tau^*] \times \mathbb{R}_T, H^s(\mathbb{R}^3)^n)$) and such that*

$$\sum_{j \in Z} ||\mathcal{V}_{2j+1}|| < \infty,$$

where $||.||$ represents the norm of $H^s(\mathbb{R}^3)^n$ (resp., $\mathcal{C}_b([0, \tau^*] \times \mathbb{R}_T, H^s(\mathbb{R}^3)^n)$).

This finite positive number endows D^s_0 (resp., $D^s_{\tau^*}$) with a norm, denoted by $\|\cdot\|_{D^s_0}$ (resp., $\|\cdot\|_{D^s_{\tau^*}}$).

Annihilating $\mathcal{R}_{-1,I}$ yields as usual the polarization condition

$$\pi_1 \mathcal{U}_{0,I,2j+1} = \mathcal{U}_{0,I,2j+1} \quad \forall j \in Z. \tag{3.1}$$

As in section 2.1.2 and thanks to Lemma 1.7, the annihilation of $\mathcal{R}_{0,I}$ is equivalent to

$$\begin{cases} \pi_1 L_1(\partial) \pi_1 \mathcal{U}_{0,I,2j+1} = 0, \\ (Id - \pi_1) \mathcal{U}_{1,I,2j+1} = \dfrac{i}{2j+1} \mathcal{L}_1^{-1} A(\partial_{X,Y,Z}) \mathcal{U}_{0,I,2j+1}, \end{cases} \tag{3.2}$$

and as in the dispersive case, we can impose

$$\pi_1 \mathcal{U}_{1,I,2j+1} = 0 \quad \forall j \in Z. \tag{3.3}$$

When we annihilate $\mathcal{R}_{1,I}$ the need for periodic functions appears clearly. Indeed, in the dispersive case, all harmonics different from $\pm\theta$ are solved by elliptic inversion.

This kind of inversion is not possible in the nondispersive case because all harmonics are characteristic. Since all harmonics are odd, the nonlinearity $f(\mathcal{U}_0)_I$ can be written

$$f(\mathcal{U}_0)_I = \Lambda(\mathcal{U}_{0,I,.}) = \sum_{j\in Z} \Lambda_{2j+1}(\mathcal{U}_{0,I,.})e^{i(2j+1)\theta}, \tag{3.4}$$

where the notation $\mathcal{U}_{0,I,.}$ stands for the sequence $(\mathcal{U}_{0,I,2j+1})_{j\in Z}$. The annihilation of $\mathcal{R}_{1,I}$ is then equivalent to

$$\begin{aligned} i(2j+1)\mathcal{L}(\omega_l,-k_l)\mathcal{U}_{2,I,2j+1} + L_1(\partial)\mathcal{U}_{1,I,2j+1} + \partial_\tau \mathcal{U}_{0,I,2j+1} \\ + \Lambda_{2j+1}(\mathcal{U}_{0,I,.}) = 0 \end{aligned}$$

for all $j \in Z$. These equations are decomposed, thanks to Lemma 1.7 and (3.2)–(3.3), into

$$\begin{aligned} (Id-\pi_1)\mathcal{U}_{2,I,2j+1} = &-\frac{1}{(2j+1)^2}\mathcal{L}_1^{-1}L_1(\partial)\mathcal{L}_1^{-1}A(\partial_{X,Y,Z})\mathcal{U}_{0,I,2j+1} \\ &+ \frac{i}{2j+1}\mathcal{L}_1^{-1}\big(\partial_\tau \mathcal{U}_{0,I,2j+1} + \Lambda_{2j+1}(\mathcal{U}_{0,I,.})\big) \end{aligned}$$

and

$$\partial_\tau \mathcal{U}_{0,I,2j+1} + i\pi_1 A(\partial_{X,Y,Z})\mathcal{L}_1^{-1}A(\partial_{X,Y,Z})\pi_1\mathcal{U}_{0,I,2j+1} + \pi_1\Lambda_{2j+1}(\mathcal{U}_{0,I,.}) = 0.$$

Under Assumption 2.3, the same simplifications as in section 2.1.4 can be made using (3.1)–(3.3) and Proposition 2.4, so that $\mathcal{U}_{0,I,.}$ is found solving

$$\begin{cases} \pi_1\mathcal{U}_{0,I,.} = \mathcal{U}_{0,I,.}, \\ (\partial_T + v_1\partial_Z)\mathcal{U}_{0,I,.} = 0, \\ \partial_\tau \mathcal{U}_{0,I,.} + i\dfrac{v_1}{2k_l}(\partial_X^2+\partial_Y^2)\mathcal{U}_{0,I,.} + \pi_1\Lambda(\mathcal{U}_{0,I,.}) = 0 \end{cases} \tag{3.5}$$

in $D^s_{\tau^*}$.

If the nonlinearities are not studied in detail, the analysis of the components with a purely continuous spectrum is strictly the same as in the dispersive case. Provided that the continuous spectrum component $\mathcal{U}_{0,II}$ of $\mathcal{U}_0$ satisfies Assumption 2.2 (absence of low frequencies), we find as in section 2 that $\mathcal{U}_{0,II}$ must satisfy

$$\begin{cases} \pi(D_{t_0,z_0})\mathcal{U}_{0,II} = \mathcal{U}_{0,II}, \\ (\partial_T - \omega'(D_{z_0})\partial_Z)\mathcal{U}_{0,II} = 0, \\ \partial_\tau \mathcal{U}_{0,II} + i\dfrac{\omega'(D_{z_0})}{2D_{z_0}}(\partial_X^2+\partial_Y^2)\mathcal{U}_{0,II} + (\partial_T - \omega'(D_{z_0})\partial_Z)\pi(D_{t_0,z_0})\mathcal{U}_{1,II} \\ \qquad +\pi(D_{t_0,z_0})\psi^\delta(D_{z_0})[f(\mathcal{U}_0)]_{II} = 0, \end{cases} \tag{3.6}$$

where ψ^δ denotes the infrared cutoff introduced in Definition 2.2.

Yet, we can still simplify these equations in decomposing $\mathcal{U}_{0,II}$ in the form

$$\mathcal{U}_{0,II} = \mathcal{U}_{0,II,1} + \cdots + \mathcal{U}_{0,II,N}$$

such that the spectrum of $\mathcal{U}_{0,II,j}$ is included in $\mathcal{D}_j$ for all $j = 1,\dots,N$.

Hence, (3.6) read

$$\begin{cases} \pi_j \mathcal{U}_{0,II,j} = \mathcal{U}_{0,II,j}, \quad j = 1, \dots, N, \\ (\partial_T + v_j \partial_Z)\mathcal{U}_{0,II,j} = 0, \quad j = 1, \dots, N, \\ \partial_\tau \mathcal{U}_{0,II,j} - i\dfrac{v_j}{2D_{z_0}}(\partial_X^2 + \partial_Y^2)\mathcal{U}_{0,II,j} + (\partial_T + v_j\partial_Z)\pi_j \mathcal{U}_{1,II,j} \\ \qquad + \pi_j \psi^\delta(D_{z_0})[f(\mathcal{U}_0)]_{II,j} = 0, \quad j = 1, \dots, N, \end{cases}$$

where we recall that $-v_j$ is the slope of line $\mathcal{D}_j$.

We now study the nonlinearity $\pi_j[f(\mathcal{U}_0)]_{II,j}$ which appears in the profile equations. With the same kind of argument as in the proof of Lemma 2.5, we can obtain the following lemma.

LEMMA 3.2. *Let $\mathcal{V}_{II,j} \in A^s_{\tau^*}$, $j = 1, \dots, N$, be N profiles with a purely continuous spectrum such that* Sp $\mathcal{V}_{II,j} \subset \mathcal{D}_j$. *Take also $a, b \in \mathbb{C}^n$. Then one has*

(i) $\pi_j F(\mathcal{V}_{II,k}, \mathcal{V}_{II,l}, \mathcal{V}_{II,m}) = 0$, *unless $j = k = l = m$;*
(ii) $\pi_j F(ae^{ik\theta}, \mathcal{V}_{II,l}, \mathcal{V}_{II,m}) = 0$ *for all $k \in Z$ unless $j = k = l = m = 1$;*
(iii) $\pi_j F(ae^{ik\theta}, be^{il\theta}, \mathcal{V}_{II,m}) = 0$ *for all $(k, l) \in Z^2$, unless $l + k = 0$ and $j = m$.*

Remark 3.1. The main difference between the dispersive and nondispersive cases is that we can have nonzero interactions between oscillations with a purely continuous spectrum in the nondispersive case. What the lemma says is that, in order to produce a nonzero interaction, these oscillations must have support on the same line as the characteristic variety. Therefore, the evolution equations of the modes $\mathcal{U}_{0,II,j}$ can be nonlinear.

Thanks to Lemma 3.2, the nonlinearity $\pi_j[f(\mathcal{U}_0)]_{II,j}$ may be written in the form

$$\begin{aligned} \pi_1[f(\mathcal{U}_0)]_{II,1} = \sum_{k\in Z} \pi_1 F^S(\mathcal{U}_{0,I,2k+1}, \overline{\mathcal{U}_{0,I,2k+1}}, \mathcal{U}_{0,II,1}) \\ + \pi_1 f'(\mathcal{U}_{0,II,1})(\mathcal{U}_{0,I}) + \pi_1 f(\mathcal{U}_{0,II,1}), \end{aligned}$$

and, when $j \geq 2$,

$$\pi_j[f(\mathcal{U}_0)]_{II,j} = \sum_{k\in Z} \pi_j F^S(\mathcal{U}_{0,I,2k+1}, \overline{\mathcal{U}_{0,I,2k+1}}, \mathcal{U}_{0,II,1}) + \pi_j f(\mathcal{U}_{0,II,j}).$$

3.2. Solving the profile equations. Inspired here again by [10] and [11], and using the expression of the nonlinearities given above, we decompose the equations on $\mathcal{U}_{0,II,j}$ as follows:

$$\begin{cases} \pi_1 \mathcal{U}_{0,II,1} = \mathcal{U}_{0,II,1}, \\ (\partial_T + v_1\partial_Z)\mathcal{U}_{0,II,1} = 0, \\ \partial_\tau \mathcal{U}_{0,II,1} - i\dfrac{v_1}{2D_{z_0}}(\partial_X^2 + \partial_Y^2)\mathcal{U}_{0,II,1} \\ \qquad + \psi^\delta(D_{z_0})\pi_1 \displaystyle\sum_{k\in Z} F^S(\mathcal{U}_{0,I,2k+1}, \overline{\mathcal{U}_{0,I,2k+1}}, \mathcal{U}_{0,II,1}) \\ \qquad + \psi^\delta(D_{z_0})\pi_1 f'(\mathcal{U}_{0,II,1})(\mathcal{U}_{0,I}) + \psi^\delta(D_{z_0})\pi_1 f(\mathcal{U}_{0,II,1}) = 0 \\ (\partial_T + v_1\partial_Z)\mathcal{U}_{1,II,1} = 0 \end{cases} \tag{3.7}$$

and for $j \geq 2$,

$$
(3.8)\quad \begin{cases} \pi_j \mathcal{U}_{0,II,j} = \mathcal{U}_{0,II,j}, \\ (\partial_T + v_j \partial_Z)\mathcal{U}_{0,II,j} = 0, \\ \partial_\tau \mathcal{U}_{0,II,j} - i\dfrac{v_j}{2D_{z_0}}(\partial_X^2 + \partial_Y^2)\mathcal{U}_{0,II,j} + \psi^\delta(D_{z_0})\pi_j f(\mathcal{U}_{0,II,j}) = 0 \\ (\partial_T + v_j \partial_Z)\pi_j \mathcal{U}_{1,II,j} = -\psi^\delta(D_{z_0})\pi_j \displaystyle\sum_{k\in Z} F^S(\mathcal{U}_{0,I,2k+1}, \overline{\mathcal{U}_{0,I,2k+1}}, \mathcal{U}_{0,II,1}). \end{cases}
$$

These profile equations can be solved. However, we will restrict ourselves to the case where $\mathcal{U}_{0,II} = \mathcal{U}_{0,II,1}$, i.e., where the spectrum of $\mathcal{U}_{0,II}$ is included in $\mathcal{D}_1$. The general case would be technically more difficult and is irrelevant for the physical examples considered in this paper.

PROPOSITION 3.3. *Let $\sigma \geq s$ and $\mathbb{R} > 0$ such that $\mathbf{U}^0 = \mathbf{U}^0_I + \mathbf{U}^0_{II,1} \in A^\sigma_0$ and $\|\mathbf{U}^0\|_{A^\sigma_0} \leq R$. Suppose, moreover, that $\mathbf{U}^0_I = \sum_{j\in Z} \mathbf{U}^0_{I,2j+1} e^{i(2j+1)\theta}$ with $\mathbf{U}^0_{I,\cdot} \in D^\sigma_0$. Assume finally that*

$$
\pi_1 \mathbf{U}^0_{I,1,\cdot} = \mathbf{U}^0_{I,1,\cdot}, \quad \text{Sp } \mathbf{U}^0_{II,1} \subset \mathcal{D}_1, \quad \text{and} \quad \pi_1 \mathbf{U}^0_{II,1} = \mathbf{U}^0_{II,1}.
$$

Then there exists $\tau_2^* > 0$, which depends only on R, such that there exists:

- *a unique $\mathcal{U}_{0,I,\cdot} = \pi_1 \mathcal{U}_{0,I,\cdot} \in D^\sigma_{\tau_2^*}$ solution of*

$$
(3.9)\quad \begin{cases} (\partial_T + v_1 \partial_Z)\mathcal{U}_{0,I,\cdot} = 0, \\ \partial_\tau \mathcal{U}_{0,I,\cdot} + i\dfrac{v_1}{2k_l}(\partial_X^2 + \partial_Y^2)\mathcal{U}_{0,I,1} + \pi_1 \Lambda(\mathcal{U}_{0,I,\cdot}) = 0, \\ \mathcal{U}_{0,I,\cdot}|_{\tau=T=0} = \mathbf{U}^0_{I,\cdot}, \end{cases}
$$

where $\Lambda(\mathcal{U}_{0,I,\cdot})$ is given by (3.4)*;*

- *a unique $\mathcal{U}^\delta_{0,II,1} = \pi_1 \mathcal{U}^\delta_{0,II,1} \in A^\sigma_{\tau_2^*}$ solution of*

$$
(3.10)\quad \begin{cases} (\partial_T + v_1 \partial_Z)\mathcal{U}^\delta_{0,II,1} = 0, \\ \partial_\tau \mathcal{U}^\delta_{0,II,1} - i\dfrac{v_1}{2D_{z_0}}(\partial_X^2 + \partial_Y^2)\mathcal{U}^\delta_{0,II,1} \\ \qquad + \psi^\delta(D_{z_0})\pi_1 \displaystyle\sum_{k\in Z} F^S(\mathcal{U}_{0,I,2k+1}, \overline{\mathcal{U}_{0,I,2k+1}}, \mathcal{U}^\delta_{0,II,1}) \\ \qquad + \psi^\delta(D_{z_0})\pi_1 f'(\mathcal{U}^\delta_{0,II,1})(\mathcal{U}_{0,I}) + \psi^\delta(D_{z_0})\pi_1 f(\mathcal{U}^\delta_{0,II,1}) = 0 \\ \mathcal{U}^\delta_{0,II,1}|_{\tau=T=0} = \psi^\delta(D_{z_0})\mathbf{U}^0_{II,1}. \end{cases}
$$

Proof. The first equation of (3.9) is automatically solved by looking for $\mathcal{U}_{0,I,\cdot}$ in the form $\mathcal{U}_{0,I,2j+1}(\tau, T, X, Y, Z) = \mathtt{U}_{0,I,2j+1}(\tau, Z - v_1 T, X, Y)$ for all $j \in Z$. System (3.9) then reduces to the Cauchy problem

$$
\begin{cases} \partial_\tau \mathtt{U}_{0,I,\cdot} + i\dfrac{v_1}{2k_l}(\partial_X^2 + \partial_Y^2)\mathtt{U}_{0,I,1} + \pi_1 \Lambda(\mathtt{U}_{0,I,\cdot}) = 0, \\ \mathtt{U}_{0,I,\cdot}|_{\tau=0} = \mathbf{U}^0_{I,\cdot}, \end{cases}
$$

which is easily solved by Picard iterates in $\mathcal{C}([0, \tau_2^*], D^\sigma_0)$ since its linear part defines a unitary group on D^σ_0, which is a Banach algebra.

For the continuous spectrum component, we cannot give an explicit expression of the solution as in Proposition 2.6, because we have to deal with the nonlinearities. However, the presence of nonlinearities is counterbalanced by the simple form of the transport equation. (We have here a common group velocity for all the frequencies.) In order for $\mathcal{U}^\delta_{0,II,1}$ to satisfy this transport equation, we look for it in the form

$$\mathcal{U}^\delta_{0,II,1}(\tau,T,X,Y,Z,t_0,z_0)=\mathtt{U}^\delta_{0,II,1}(\tau,Z-v_1T,X,Y,t_0,z_0),$$

so that (3.10) reduces to the Cauchy problem

$$\begin{cases}\partial_\tau \mathtt{U}^\delta_{0,II,1}-i\dfrac{v_1}{2D_{z_0}}(\partial_X^2+\partial_Y^2)\mathtt{U}^\delta_{0,II,1}\\ \qquad\quad+\psi^\delta(D_{z_0})\pi_1\displaystyle\sum_{k\in Z}F^S(\mathtt{U}_{0,I,2k+1},\overline{\mathtt{U}_{0,I,2k+1}},\mathtt{U}^\delta_{0,II,1})\\ \qquad\quad+\psi^\delta(D_{z_0})\pi_1 f'(\mathtt{U}^\delta_{0,II,1})(\mathtt{U}_{0,I})+\psi^\delta(D_{z_0})\pi_1 f(\mathtt{U}^\delta_{0,II,1})=0\\ \mathtt{U}^\delta_{0,II,1}|_{\tau=0}=\psi^\delta(D_{z_0})\mathbf{U}^0_{II,1}.\end{cases}$$

This Cauchy problem is solved in $B^\sigma_{\tau_2^*}$ by Picard iterates, using estimates similar to those of Lemma 1.5. □

Remark 3.2. (i) With $\mathcal{U}_0$ being given by Proposition 3.3, system (3.7) is then solved by taking $\pi_1\mathcal{U}_{1,II,1}=0$.

(ii) The results of Proposition 3.3 also hold for $\delta=0$, i.e., there exists a unique solution $\mathcal{U}_{0,II}=\mathcal{U}_{0,II,1}=\pi_1\mathcal{U}_{0,II,1}$ to

$$\begin{cases}(\partial_T+v_1\partial_Z)\mathcal{U}_{0,II,1}=0,\\ \partial_\tau\partial_{z_0}\mathcal{U}_{0,II,1}+\dfrac{v_1}{2}(\partial_X^2+\partial_Y^2)\mathcal{U}_{0,II,1}\\ \qquad\quad+\pi_1\displaystyle\sum_{k\in Z}\partial_{z_0}F^S(\mathcal{U}_{0,I,2k+1},\overline{\mathcal{U}_{0,I,2k+1}},\mathcal{U}_{0,II,1})\\ \qquad\quad+\pi_1\partial_{z_0}f'(\mathcal{U}_{0,II,1})(\mathcal{U}_{0,I})+\pi_1\partial_{z_0}f(\mathcal{U}_{0,II,1})=0,\\ \mathcal{U}_{0,II,1}|_{\tau=T=0}=\mathbf{U}^0_{II,1},\end{cases}\tag{3.11}$$

and the convergence property of Proposition 2.13 can easily be extended to the present case.

3.3. Validity of the approximation. We show here that the approximate solution

$$u^\varepsilon(T,X,Y,Z)=\sqrt{\varepsilon}\mathcal{U}^\varepsilon\left(\varepsilon T,T,X,Y,Z,\frac{T}{\varepsilon},\frac{Z}{\varepsilon}\right),$$

with $\mathcal{U}^\varepsilon=\mathcal{U}_0+\varepsilon\mathcal{U}_1+\varepsilon^2\mathcal{U}_2$, is a good approximation of the exact solution of (1.1). As in section 2, the proof cannot be direct because the presence of low frequencies and $\mathcal{L}^{-1}$-regularity are not compatible. But we can mimic the reasoning of section 2 to obtain a stability result. Before stating the theorem, we recall that to any profile $\mathcal{V}\in A^\sigma_{\tau^*}$, we associate the profile $\underline{\mathcal{V}}^\varepsilon$ defined as

$$\underline{\mathcal{V}}^\varepsilon(\tau,X,Y,Z,t_0,z_0):=\mathcal{V}\left(\tau,\frac{\tau}{\varepsilon},X,Y,Z,t_0,z_0\right).$$

THEOREM 3.4. *Suppose the characteristic variety $\mathcal{C}_\mathcal{L}$ is as in Assumption* 2.3.

Let $\mathbf{U}^0 = \mathbf{U}^0_I + \mathbf{U}^0_{II,1} \in A^{s+4}_0$ *such that* $\mathbf{U}^0_I = \sum_{j\in Z} \mathbf{U}^0_{I,2j+1} e^{i(2j+1)\theta}$, *with* $\mathbf{U}^0_{I,\cdot} \in D^{s+4}_0$, *and suppose that*

$$\pi_1 \mathbf{U}^0_{I,\cdot} = \mathbf{U}^0_{I,\cdot}, \quad \text{Sp } \mathbf{U}^0_{II,1} \subset \mathcal{D}_1, \quad \text{and} \quad \pi_1 \mathbf{U}^0_{II,1} = \mathbf{U}^0_{II,1}.$$

Then for $\tau^*_3 = \min\{\tau^*_1, \tau^*_2\}$, *we have the following:*

(i) *The exact solution* $\mathbf{u}^\varepsilon$ *of* (1.1) *exists on* $[0, \tau^*_3/\varepsilon]$ *and can be written* $\mathbf{u}^\varepsilon(T, X, Y, Z) = \sqrt{\varepsilon}\mathbf{U}^\varepsilon(\varepsilon T, X, Y, Z, T/\varepsilon, Z/\varepsilon)$, *with* $\mathbf{U}^\varepsilon = \mathbf{U}^\varepsilon_I + \mathbf{U}^\varepsilon_{II} \in B^{s+4}_{\tau^*_3}$.

(ii) $\mathcal{U}_{0,I,\cdot}$ *is defined in* $D^{s+4}_{\tau^*_3}$ *as the unique solution of* (3.9), *and we define* $\mathcal{U}_{0,I}$ *as* $\mathcal{U}_{0,I} = \sum_{j\in Z} \mathcal{U}_{0,I,2j+1} e^{i(2j+1)\theta}$.

(iii) $\mathcal{U}_{0,II} = \mathcal{U}_{0,II,1}$ *is defined in* $A^{s+4}_{\tau^*_3}$ *as the unique solution of* (3.11).

(iv) *The profile* $\underline{\mathcal{U}}^\varepsilon_0 \in B^s_{\tau^*_3}$ *associated to* $\mathcal{U}_0 = \mathcal{U}_{0,I} + \mathcal{U}_{0,II} \in A^s_{\tau^*_3}$ *approximates the singular equation* (1.5) *in the sense that*

$$\|\mathbf{U}^\varepsilon_I - \underline{\mathcal{U}}^\varepsilon_{0,I}\|_{B^s_{\tau^*_3}} = O(\varepsilon) \quad \text{and} \quad \|\mathbf{U}^\varepsilon_{II} - \underline{\mathcal{U}}^\varepsilon_{0,II}\|_{B^s_{\tau^*_3}} = o(1).$$

(v) *We also have stability of the approximate solution* u^ε_0 *defined with* $\mathcal{U}_0$,

$$\|\mathbf{u}^\varepsilon_I - u^\varepsilon_{0,I}\| = O(\varepsilon^{3/2}) \quad \text{and} \quad \|\mathbf{u}^\varepsilon_{II} - u^\varepsilon_{0,II}\| = o(\sqrt{\varepsilon}),$$

where the norm can be taken either in $\mathcal{C}([0, \frac{\tau^*_3}{\varepsilon}] \times \mathbb{R}^3)^n$ *or in* $\mathcal{C}([0, \frac{\tau^*_3}{\varepsilon}], L^2(\mathbb{R}^3)^n)$.

4. Examples.

4.1. Lasers with large spectrums. As said in the introduction, we want to study the effects due to the fact that certain lasers have frequencies and wavenumbers which dribble around the theoretical value in a range greater than $O(\varepsilon)$ (typically $O(1)$). In order to make a model out of this phenomenon, we add to the theoretical (sinusoidal) oscillations a corrector with a purely continuous spectrum.

To describe the evolution of the electromagnetic field we use Maxwell equations coupled to a response of the medium by the polarization $\mathbf{p}$, which is described by the anharmonic oscillator model [14]. Once nondimensionalized [7], and omitting the divergence-free equations, the system reads

$$(M) \qquad \begin{cases} \partial_T \mathbf{e}^\varepsilon - \mathbf{curl}\, \mathbf{b}^\varepsilon + \dfrac{\sqrt{\gamma_a}}{\varepsilon}\mathbf{g}^\varepsilon & = 0, \\ \partial_T \mathbf{b}^\varepsilon + \mathbf{curl}\, \mathbf{e}^\varepsilon & = 0, \\ \partial_T \mathbf{p}^\varepsilon - \dfrac{\eta_a}{\varepsilon}\mathbf{q}^\varepsilon & = 0, \\ \partial_T \mathbf{q}^\varepsilon - \dfrac{1}{\varepsilon}(\sqrt{\gamma_a}\mathbf{e}^\varepsilon - \eta_a \mathbf{p}^\varepsilon) - \alpha\gamma_a^{3/2}|\mathbf{p}^\varepsilon|^2\mathbf{p}^\varepsilon & = 0. \end{cases}$$

This system (M) is of type (1.1),

$$L^\varepsilon(\partial)\mathbf{u}^\varepsilon + f(\mathbf{u}^\varepsilon) = 0,$$

with

$$\mathbf{u}^\varepsilon = (\mathbf{e}^\varepsilon, \mathbf{b}^\varepsilon, \mathbf{p}^\varepsilon, \mathbf{q}^\varepsilon)^T \in C^{12},$$

and the nonlinearity is of order 3 and reads

$$f(\mathbf{e}^\varepsilon, \mathbf{b}^\varepsilon, \mathbf{p}^\varepsilon, \mathbf{q}^\varepsilon) = (0, 0, 0, \alpha\gamma_a^{3/2}|\mathbf{p}^\varepsilon|^2\mathbf{p}^\varepsilon)^T.$$

Remark 4.1. The fact that the mapping F associated to f is not trilinear as in Assumption 1.2—since it is semilinear in one of its variables—is not important. Indeed, considering $\tilde{\mathbf{u}}^\varepsilon = (\mathbf{u}^\varepsilon, \overline{\mathbf{u}^\varepsilon}) \in C^{24}$ brings us back to this case.

The operator $L^\varepsilon(\partial)$ reads $L^\varepsilon(\partial) = \partial_T + A_1\partial_X + A_2\partial_Y + A_3\partial_Z + L_0/\varepsilon$, with

$$A_1\partial_X + A_2\partial_Y + A_3\partial_Z = \begin{pmatrix} 0 & -\mathbf{curl} & 0 & 0 \\ \mathbf{curl} & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \end{pmatrix}$$

and

$$L_0 = \begin{pmatrix} 0 & 0 & 0 & \sqrt{\gamma_a} Id \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & -\eta_a Id \\ -\sqrt{\gamma_a} Id & 0 & \eta_a Id & 0 \end{pmatrix}.$$

The characteristic variety $\mathcal{C}_\mathcal{L}$ associated to the symbol $\mathcal{L}(\omega, k) = \omega Id + kA_3 + L_0/i$ is defined by the algebraic equation

$$\omega^2(\omega^2 - 1 - \gamma_a)[(\omega^2 - \eta_a^2)(\omega^2 - k^2) - \gamma_a\omega^2]^2 = 0.$$

This characteristic variety has three singular points which are all of abscissa $k = 0$ and ordinate $0; \pm\sqrt{1+\gamma_a}$. If $(\omega_l, -k_l)$ is on a curved sheet of $\mathcal{C}_\mathcal{L}$, i.e., if $(\omega_l^2 - \eta_a^2)(\omega_l^2 - k_l^2) - \gamma_a\omega_l^2 = 0$, then the group velocity $\omega'(k_l)$ is given by

$$\omega'(k_l) = \frac{k_l}{\omega_l} \frac{\omega_l^2 - \eta_a^2}{(\omega_l^2 - k_l^2) + (\omega_l^2 - \eta_a^2) - \gamma_a}, \tag{4.1}$$

while the dispersive factor $\omega''(k_l)$ reads

$$\omega''(k_l) = \omega'(k_l)\frac{\omega_l - \omega'(k_l)}{\omega_l k_l} - 4\frac{\omega_l\omega'(k_l)^2}{k_l}\frac{\omega_l\omega'(k_l) - k_l}{\omega_l^2 - \eta_a^2}. \tag{4.2}$$

Notice that $\mathcal{C}_\mathcal{L}$ contains three plane sheets, so that Assumption 2.1 is not satisfied since these sheets are parallel. However, as mentioned earlier, the divergence-free conditions satisfied by the electromagnetic field allow us to consider that Assumption 2.1 is fulfilled.

We consider initial conditions of the form

$$\mathbf{u}_\varepsilon^0 = \varepsilon^{1/2}\mathbf{U}^0(X, Y, Z, 0, Z/\varepsilon) = \varepsilon^{1/2}(\mathbf{E}^0, \mathbf{B}^0, \mathbf{P}^0, \mathbf{Q}^0)(X, Y, Z, 0, Z/\varepsilon),$$

where $\mathbf{U}^0$ is written $\mathbf{U}^0(X, Y, Z, t_0, z_0) = \mathbf{U}_{I,1}^0(X, Y, Z)e^{i\theta} + \text{c.c.} + \mathbf{U}_{II}^0(X, Y, Z, t_0, z_0)$, with the component $\mathbf{U}_{II}^0$ having a purely continuous spectrum. As mentioned above, $\mathbf{U}_{I,1}^0$ corresponds to the usual (small-spectrum) laser, i.e., the laser with time-space wavenumber equal to $(\omega_l, -k_l)$, while $\mathbf{U}_{II}^0$ corresponds to the large dribbling.

Moreover, the initial conditions are polarized,

$$\pi(\omega_l, -k_l)\mathbf{U}_{I,1}^0 = \mathbf{U}_{I,1}^0 \quad \text{and} \quad \pi(D_{t_0,z_0})\mathbf{U}_{II}^0 = \mathbf{U}_{II}^0.$$

The solution of diffractive optics reads

$$\begin{aligned} u^\varepsilon(T, X, Y, Z) = \varepsilon^{1/2}(&\mathcal{U}_{0,I,1}(\varepsilon T, T, X, Y, Z)e^{i(\omega_l\frac{T}{\varepsilon} - k_l\frac{Z}{\varepsilon})} + \text{c.c.} \\ &+ \mathcal{U}_{0,II}\left(\varepsilon T, T, X, Y, Z, \frac{T}{\varepsilon}, \frac{Z}{\varepsilon}\right), \end{aligned}$$

and the results of section 2 state that the profile $\mathcal{U}_{0,I,1}$ is given by

$$\partial_\tau \mathcal{U}_{0,I,1} + i\frac{\omega'(k_l)}{2k_l}(\partial_X^2+\partial_Y^2)\mathcal{U}_{0,I,1} + i\frac{\omega''(k_l)}{2}\partial_Z^2\mathcal{U}_{0,I,1} + \pi(\omega_l,-k_l)f'(\mathcal{U}_{0,I,1})(\overline{\mathcal{U}_{0,I,1}}) = 0,$$

with here

$$f'(\mathcal{U}_{0,I,1})(\overline{\mathcal{U}_{0,I,1}}) = \left(0,0,0,\alpha\gamma_a^{3/2}\left(2|\overrightarrow{\mathcal{P}}_{0,I,1}|^2\overrightarrow{\mathcal{P}}_{0,I,1} + (\overrightarrow{\mathcal{P}}_{0,I,1}.\overrightarrow{\mathcal{P}}_{0,I,1})\overline{\overrightarrow{\mathcal{P}}_{0,I,1}}\right)\right)^T$$

and ω' and ω'' given by (4.1)–(4.2).

As the waves which we consider here propagate along (OZ) with a wavenumber $\overrightarrow{k_l} = (0,0,k_l)$, the electric field is polarized on the plane (OXY). We can assume that it is polarized along (OX), i.e., $\overrightarrow{\mathcal{E}}_{0,I,1} = (\mathcal{E}_{0,I,1},0,0)^T$. Since $\pi(\omega_l,-k_l)\mathcal{U}_{0,I,1} = \mathcal{U}_{0,I,1}$, one therefore has $\overrightarrow{\mathcal{P}}_{0,I,1} = \eta_a\chi(\omega_l)\overrightarrow{\mathcal{E}}_{0,I,1}$, where the dielectric susceptibility $\chi(\omega_l)$ is given by

$$\chi(\omega_l) = \frac{\sqrt{\gamma_a}}{\eta_a^2-\omega_l^2}.$$

The nonlinearity therefore reads

$$f'(\mathcal{U}_{0,I,1})(\overline{\mathcal{U}_{0,I,1}}) = (0,0,0,3\alpha\gamma_a^{3/2}\eta_a^3\chi(\omega_l)^3|\mathcal{E}_{0,I,1}|^2\mathcal{E}_{0,I,1},0,0)^T.$$

In order to obtain the evolution equation on $\mathcal{E}_{0,I,1}$, one needs to compute the nonlinearity $\pi(\omega_l,-k_l)f'(\mathcal{U}_{0,I,1})(\overline{\mathcal{U}_{0,I,1}})$ (in fact, computing its first component is enough). For all vectors $a = (a_1,0,0)^T \in C^3$, one has

$$\pi(\omega_l,-k_l)\begin{pmatrix}0\\0\\0\\a\end{pmatrix} = -\frac{i\omega_l\sqrt{\gamma_a}}{\eta_a^2-\omega_l^2}\begin{pmatrix}\frac{a_1}{N^2}\\.\\.\\.\end{pmatrix}$$

with

$$\begin{aligned} N^2 &= 1+\frac{k_l^2}{\omega_l^2}+\eta_a^2\chi^2(\omega_l)+\omega_l^2\chi^2(\omega_l)\\ &= \sqrt{\gamma_a}\left(\frac{k_l^2+\omega_l^2}{k_l^2-\omega_l^2}+\frac{\eta_a^2+\omega_l^2}{\eta_a^2-\omega_l^2}\right)\chi(\omega_l)\\ &:= \sqrt{\gamma_a}\beta(\omega_l,k_l)\chi(\omega_l). \end{aligned}$$

We thus find

$$\pi(\omega_l,-k_l)f'(\mathcal{U}_{0,I,1})(\overline{\mathcal{U}_{0,I,1}}) = -3i\alpha\gamma_a\eta_a^3\frac{\omega_l}{\beta(\omega_l,k_l)}\chi(\omega_l)^3(|\mathcal{E}_{0,I,1}|^2\mathcal{E}_{0,I,1},\ldots),$$

and the evolution equation on $\mathcal{E}_{0,I,1}$ is therefore

$$\begin{aligned} &\partial_\tau\mathcal{E}_{0,I,1} + i\frac{\omega'(k_l)}{2k_l}(\partial_X^2+\partial_Y^2)\mathcal{E}_{0,I,1} + i\frac{\omega''(k_l)}{2}\partial_Z^2\mathcal{E}_{0,I,1}\\ &= -3i\alpha\gamma_a\eta_a^3\frac{\omega_l}{\beta(\omega_l,k_l)}\chi(\omega_l)^3|\mathcal{E}_{0,I,1}|^2\mathcal{E}_{0,I,1}. \end{aligned}$$

The purely continuous spectrum component of $\mathcal{U}_0$ is found solving

$$\partial_\tau \partial_{z_0} \mathcal{U}_{0,II} - \frac{\omega'(D_{z_0})}{2}(\partial_X^2 + \partial_Y^2)\mathcal{U}_{0,II} - \frac{D_{z_0}\omega''(D_{z_0})}{2}\partial_Z^2 \mathcal{U}_{0,II} = 0.$$

Supposing as above that $\mathcal{E}_{0,II}$ is polarized along (OX), i.e., $\overrightarrow{\mathcal{E}}_{0,II} = (\mathcal{E}_{0,II}, 0, 0)^T$, we obtain

$$\partial_\tau \partial_{z_0} \mathcal{E}_{0,II} - \frac{\omega'(D_{z_0})}{2}(\partial_X^2 + \partial_Y^2)\mathcal{E}_{0,II} - \frac{D_{z_0}\omega''(D_{z_0})}{2}\partial_Z^2 \mathcal{E}_{0,II} = 0.$$

Remark 4.2. A usual direct computation of this equation without the help of the general results proved above would have led to a nonlinear equation. It was not obvious a priori that all the nonlinear terms would be negligible.

4.2. Short pulses. The second application we study concerns short-pulse lasers. Normally, the length of the pulse of a laser is long enough to contain many oscillations so that the phenomena considered can be described well enough by knowing the evolution of the envelope of these oscillations. For ultrashort pulses, this is no longer true (see Figure 1) since there may even be less than an oscillation. The profile we use to make a model of this phenomenon therefore has only a purely continuous spectrum component: the sinusoidal one (discrete spectrum) does not have time to appear. More precisely, we consider an initial condition for (M) of the form

$$\mathbf{u}_\varepsilon^0 = \varepsilon^{1/2}\mathbf{U}^0(X, Y, Z, 0, Z/\varepsilon) = \varepsilon^{1/2}(\mathbf{E}^0, \mathbf{B}^0, \mathbf{P}^0, \mathbf{Q}^0)(X, Y, Z, 0, Z/\varepsilon),$$

where $\mathbf{U}^0 \in A_0^s$ has a purely continuous spectrum. Moreover the initial condition is polarized as follows:

$$\pi(D_{t_0,z_0})\mathbf{U}^0 = \mathbf{U}^0.$$

In accordance with the results of section 2, the profile $\mathcal{U}_0 = \mathcal{U}_{0,II}$ of the approximate solution is found solving

$$\partial_\tau \partial_{z_0} \mathcal{U}_0 - \frac{\omega'(D_{z_0})}{2}(\partial_X^2 + \partial_Y^2)\mathcal{U}_0 - \frac{D_{z_0}\omega''(D_{z_0})}{2}\partial_Z^2 \mathcal{U}_0 = 0.$$

Considering the same model (M) as in the previous section and using the same notation thus yield the following equation for the nonzero component $\mathcal{E}_0$ of the electric field:

$$\partial_\tau \partial_{z_0} \mathcal{E}_0 - \frac{\omega'(D_{z_0})}{2}(\partial_X^2 + \partial_Y^2)\mathcal{E}_0 - \frac{D_{z_0}\omega''(D_{z_0})}{2}\partial_Z^2 \mathcal{E}_0 = 0,$$

where ω' and ω'' are given by (4.1)–(4.2).

Remark 4.3. Here again the fact that we would obtain a linear equation is not obvious. We also point out the fact that our framework allows us to find this equation in the physical *dispersive* case.

In a nondispersive framework, the nonlinearities would not have vanished. Assuming that the spectrum of $\mathcal{U}_0 = \mathcal{U}_{0,II}$ is located on the line $\mathcal{D}_1$ of $\mathcal{C}_\mathcal{L}$ to which $(\omega_l, -k_l)$ belongs, we would find

$$\partial_\tau \partial_{z_0} \mathcal{U}_0 + \frac{v_1}{2}(\partial_X^2 + \partial_Y^2)\mathcal{U}_0 + \pi_1 \partial_{z_0} f(\mathcal{U}_0) = 0,$$

where $-v_1$ is the slope of D_1. This is Alterman and Rauch's equation [1], [2], [3].

5. Weakly dispersive case. We have seen in the previous sections that there is a radical difference between the behavior of the approximate solution of the dispersive case and that of the nondispersive case. In the former, the evolution of the continuous spectrum mode is uncoupled with the discrete spectrum mode and is linear; in the latter, it is coupled and nonlinear.

This behavioral gap means that the estimate $o(1)$ of Theorem 2.14 is somewhat critical for weakly dispersive systems.We propose in this section a few hints to improve this result.

In terms of BKW strategy, solving (2.23) or the following equations is equivalent:

$$\left\{\begin{array}{l} \pi(D_{t_0},D_{z_0})\mathcal{U}_{0,II}=\mathcal{U}_{0,II},\\ (\partial_T+\omega'(k_l)\partial_Z)\mathcal{U}_{0,II}=0,\\ \partial_\tau\mathcal{U}_{0,II}+i\dfrac{\omega'(D_{z_0})}{2D_{z_0}}(\partial_X^2+\partial_Y^2)\mathcal{U}_{0,II}+\dfrac{-\omega'(k_l)-\omega'(D_{z_0})}{\varepsilon}\partial_Z\mathcal{U}_{0,II}\\ \qquad +i\dfrac{\omega''(D_{z_0})}{2}\partial_Z^2\mathcal{U}_{0,II}=6\pi(D_{t_0},D_{z_0})F^S(\mathcal{U}_{0,I,1},\overline{\mathcal{U}_{0,I,1}},\mathcal{U}_{0,II}). \end{array}\right. \tag{5.1}$$

Note that the nonlinearity has been simplified according to the results of Lemmas 2.5 and 3.2, and that here $\pi_1(D_{t_0},D_{z_0})\mathcal{U}_{1,II}=0$.

In general, the Fourier multiplier $\frac{-\omega'(k_l)-\omega'(D_{z_0})}{\varepsilon}$ is of size $O(1/\varepsilon)$ and solving (2.23) is much more relevant than solving (5.1) since this former system does not involve ε. However, if the model considered is weakly dispersive in the sense that one can choose ω_0' in such a way that $\frac{-\omega'(k_l)-\omega'(D_{z_0})}{\varepsilon}=O(1)$, system (5.1) becomes more interesting because the transport equation is the same for all frequencies, as in the nondispersive case. Since it is also reasonable to suppose that such weakly dispersive systems also satisfy $\omega''(D_{z_0})=O(\varepsilon)$, system (5.1) is equivalent in terms of BKW strategy to

$$\left\{\begin{array}{l} \pi(D_{t_0},D_{z_0})\mathcal{U}_{0,II}=\mathcal{U}_{0,II},\\ (\partial_T+\omega'(k_l)\partial_Z)\mathcal{U}_{0,II}=0,\\ \partial_\tau\partial_{z_0}\mathcal{U}_{0,II}+\dfrac{\omega'(k_l)}{2}(\partial_X^2+\partial_Y^2)\mathcal{U}_{0,II}+\dfrac{-\omega'(k_l)-\omega'(D_{z_0})}{\varepsilon}\partial_Z\partial_{z_0}\mathcal{U}_{0,II}\\ \qquad =6\pi(D_{t_0},D_{z_0})\partial_{z_0}F^S(\mathcal{U}_{0,I,1},\overline{\mathcal{U}_{0,I,1}},\mathcal{U}_{0,II}), \end{array}\right. \tag{5.2}$$

where we also have differentiated the last equation with respect to z_0.

Therefore, in the weakly dispersive case, one can obtain profile equations for $\mathcal{U}_{0,II}$ which are linear but coupled with the evolution equation of the discrete spectrum mode $\mathcal{U}_{0,I,1}$. System (5.2) thus provides an intermediate model between the dispersive case of section 2 and the nondispersive case of section 3, and hence partially fills the behavioral gap between these two situations.

Example. With the same notation as in section 4.1, the equation for the electric field $\mathcal{E}_{0,II}$ associated to a large-spectrum laser reads

$$\begin{aligned}\partial_\tau\partial_{z_0}\mathcal{E}_{0,II}+\frac{\omega'(k_l)}{2}(\partial_X^2+\partial_Y^2)\mathcal{E}_{0,II}+\frac{-\omega'(k_l)-\omega'(D_{z_0})}{\varepsilon}\partial_Z\partial_{z_0}\mathcal{E}_{0,II}\\ =-6i\alpha\gamma_a\eta_a^3\chi_{\omega_l}^2\frac{D_{t_0}\chi(D_{z_0})}{\beta(D_{t_0},D_{z_0})}|\mathcal{E}_{0,I,1}|^2\mathcal{E}_{0,II},\end{aligned}$$

which is still linear but coupled with $\mathcal{E}_{0,I,1}$. We recall that by weakly dispersive we mean that $\frac{-\omega'(k_l)-\omega'(D_{z_0})}{\varepsilon}=O(1)$, and that we must simultaneously solve $(\partial_T+\omega'(k_l)\partial_Z)\mathcal{E}_{0,II}=0$.

Acknowledgments. The authors want to give warm thanks to T. Colin and G. Gallice for fruitful discussions. They are also grateful to J. Rauch and E. Dumas for their remarks and advice on a previous version of this work.

THE TRANSITION FROM ZELDOVICH–VON NEUMANN–DORING TO CHAPMAN–JOUGUET THEORIES FOR A NONCONVEX SCALAR COMBUSTION MODEL*

JIEQUAN LI† AND PENG ZHANG‡

Abstract. We study the transition from the Zeldovich–von Neumann–Doring (ZND) theory to the Chapman–Jouguet (CJ) theory as the reaction rate tends to infinity for a nonconvex scalar combustion model. The Riemann solution of the nonconvex ZND combustion model is constructed, and the limit of solutions as the reaction rate goes to infinity is investigated. We classify the reaction solutions of the ZND combustion model as detonation and deflagration waves according to the essential difference that the former contains the von Neumann spike but the latter does not. Based on the analysis of this limit, we propose a set of entropy conditions for combustion and noncombustion waves to the nonconvex CJ combustion model, which is the indispensable preparation for the study of multidimensional combustion problems.

Key words. Zeldovich–von Neumann–Doring theory, Chapman–Jouguet theory, detonation, deflagration, von Neumann spike, reaction entropy condition

1. Introduction.

The Zeldovich–von Neumann–Doring (ZND) theory and the Chapman–Jouguet (CJ) theory play an important role in gas dynamics combustion theory. The former describes the combustible gas with a finite reaction rate and the latter with an infinite reaction rate or, equivalently, the infinitely thin reaction region. Formally the CJ theory is regarded as the limit of the ZND theory as the reaction rate tends to infinity [1]. Interesting discussions on this transition can be found in [3, 16]. The Riemann problem for the CJ gas dynamic combustion is constructively solved in [22] to display rich combustion wave patterns satisfying the so-called geometrical entropy conditions. Yet, the study of combustion waves of gas dynamics based on the ZND theory is notoriously complex and difficult, and far from being complete [21]. This motivates us to consider simpler combustion models.

In [2, 14], Fickett and Majda independently proposed a simplified model to study combustion waves, as the Burgers equation models in gas dynamics,

$$\begin{aligned} &(u+qz)_t + f(u)_x = \mu u_{xx}, \\ &z_t + k\phi(u)z = 0, \end{aligned} \tag{1.1}$$

where $x \in \mathbb{R}$, $t > 0$. This model corresponds to the ZND model in gas dynamics. The first equation resembles the conservation law of energy in gas dynamics, leading to nonlinear phenomena such as shocks; the second is the reaction equation, which

may give rise to a linear discontinuity in the solution. The dependent variable u is a lumped quantity, representing density, velocity, or temperature, but not the chemical binding energy, which is represented by q. z is the percentage of unburned gas, k is the reaction rate, and $\phi(u)$ is the standard Heaviside function. We take the ignition point $u = 0$ for simplicity. That is, the material begins to burn just as the temperature becomes higher than zero. Using this model, combustion problems were extensively investigated, such as the stability and asymptotic behavior of combustion waves (see [5, 9, 10, 11] and the references therein). The well-posedness of the general Cauchy problem and the zero viscosity limit of (1.1) was studied in [5]. Ying and Teng [17] studied the Riemann solution of (1.1) at $\mu = 0$ and obtained the limit of the solution as k tends to infinity and defined the limit function as the solution of the Riemann problem for the corresponding CJ model

$$\begin{aligned} &(u+qz)_t + f(u)_x = 0, \\ &z(x,t) = \begin{cases} z(x,0) & \text{if } \max\limits_{0\le\tau\le t} u(x,\tau) \le 0, \\ 0 & \text{otherwise.} \end{cases} \end{aligned} \tag{1.2}$$

In [13], Liu and Zhang extracted from the properties of CJ solutions in [17] to propose a set of entropy conditions, under which the existence and uniqueness of the Riemann solutions were shown constructively and the ignition and extinction problems were investigated as well. A slightly different model was considered in [7, 8, 12, 15]. All of these results were obtained under the assumption that $f(u)$ is strictly convex.

Based on these results in one dimension, one would naturally wish to study combustion phenomena in several dimensions. The generalization of (1.1) may be a reasonable trial in this aspect, for which the theory of well-posedness of a multidimensional scalar ZND model was established in [6]. As is well known, the fluxes must be nonconvex in some directions at this moment [4]. Therefore, it is interesting to investigate scalar combustion models with nonconvex fluxes $f(u)$ so as to make a good preparation for the study of structure of multidimensional combustion waves.

To this end, the Riemann problem for (1.2) with nonconvex fluxes $f(u)$ was solved constructively in [18] under the entropy restriction that mimics those in [13] and generalizes the classical Oleinik entropy condition for scalar conservation laws. A crucial issue here is just how to propose and justify entropy conditions to single out physically admissible solutions. There are some plausible ways: One is, most naturally, to consider the viscosity vanishing limit for corresponding models like (1.1) with nonconvex fluxes, which is found to be a very difficult issue, even only to discuss traveling wave solutions. Another is, as in the classical gas dynamics combustion theory [1], to investigate the limit of the nonviscous Fickett–Majda model (1.1) as the reaction rate k goes to infinity. This is what we do in this paper.

The self-similar combustion model corresponding to (1.1) with sufficiently large reaction rates reads

$$\begin{aligned} &(u+qz)_t + f(u)_x = 0, \\ &z_t + \tfrac{k}{t}\phi(u)z = 0, \end{aligned} \tag{1.3}$$

where $f(u)$ is nonconvex. The second author began to study this model and announced the very partial results in [19]; the Riemann problem was discussed there for some cases and the large reaction rate limit was taken into account to get the associated Riemann solutions of the corresponding CJ model (1.2). However, this result is far

from understanding the entropy combustion solutions which we clarify below. As pointed out in [13], even the Riemann solution to (1.3) is not unique, provided that it is restricted by the classical Oleinik-type entropy condition (2.7). Motivated by the physical consideration that the temperature in the combustion wave front is as high as possible or, equivalently, the propagation speed of combustion wave front is as small as possible, we propose in this paper a reaction entropy condition to guarantee the uniqueness of solutions, under which the Riemann solution to (1.3) is uniquely constructed. Since we focus our attention on the transition from the ZND theory to the CJ theory as the reaction rate k goes to infinity, we mainly display the structure of solutions with the large reaction rate k. Our main contribution is to clarify the reaction solution as detonation and deflagration waves in accord with the essential difference that the former has a von Neumann spike in the reaction region while the latter does not, although it was already noticed earlier, e.g., in [1, 22, 16, 19]. Indeed, the temperature (the lumped variable u) is not monotone for the former but is monotone increasing for the latter. Then we study the limit of solutions by letting the reaction rate k tends to infinity. It is found that although both of these combustion waves in the limit become jump-ups, they still inherit the above intrinsic difference. Finally we formulate a set of entropy conditions based on the analysis of limit solutions, which enables us to greatly improve the result in [18] to get the unique entropy solution of (1.2) with nonconvex flux $f(u)$. Indeed, this entropy condition can be used to justifiably construct two-dimensional Riemann solutions for the CJ combustion model associated with (1.2); see [20].

The rest of this paper consists of three parts. In section 2, we give some preliminaries containing the general property of smooth solutions, the Rankine–Hugoniot jump conditions of combustion waves, and the reaction entropy condition. The Riemann solutions of (1.3) are constructed in section 3 for two typically distinct fluxes with just one inflection point. The limit behavior of solutions is also studied as the reaction rate goes to infinity. We propose the entropy condition from the limit behavior of solutions in the preceding sections for the CJ nonconvex combustion model (1.2) in section 4.

2. Self-similar solutions to the ZND model. This section serves as a preliminary for the forthcoming sections. We will discuss the general properties of smooth solutions, the Rankine–Hugoniot jump conditions of combustion waves, and the reaction entropy condition.

We begin by considering the Riemann problem for (1.3) with initial data

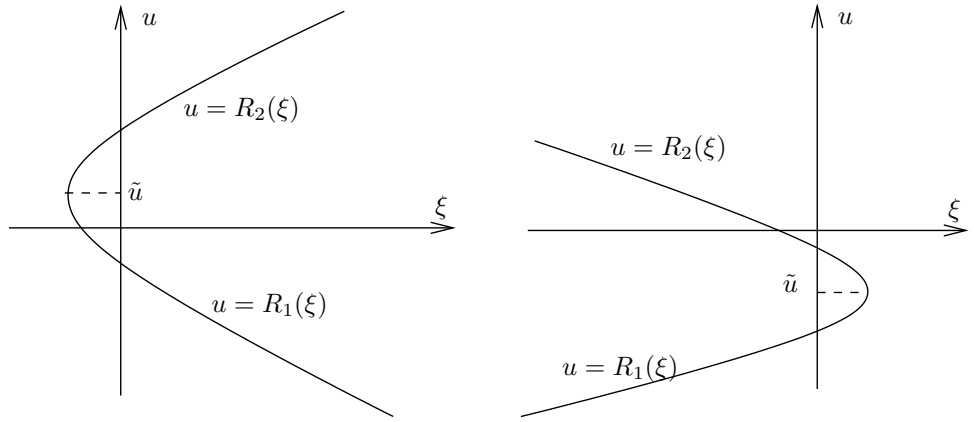
$$(u,z)|_{t=0} = \begin{cases} (u^-, z^-), & x < 0, \\ (u^+, z^+), & x > 0, \end{cases} \tag{2.1}$$

where (u^-, z^-) and (u^+, z^+) are two different states. For the self-similar solutions $(u(\xi), z(\xi))$, $\xi = x/t$, the Riemann problem for (1.3) becomes a boundary value problem with boundary values at infinity,

$$\begin{aligned} &(f'(u) - \xi)\frac{du}{d\xi} = qk\phi(u)z, \\ &\xi\frac{dz}{d\xi} = k\phi(u)z, \end{aligned} \tag{2.2}$$

and

$$(u,z)|_{\xi=\pm\infty} = (u^\pm, z^\pm). \tag{2.3}$$



(a) The branches with assumption (A_1). (b) The branches with assumption (A_2).

FIG. 2.1. *The branches of the inverse function of* $\xi = f'(u)$.

Without loss of generality, we consider this Riemann problem with the data

$$z^- = 1,\ z^+ = 0; \qquad u^- \le 0 < u^+. \tag{2.4}$$

The left state $(u^-, 1)$ is unburned and the right state $(u^+, 0)$ is burnt. For clarity of presentation, we restrict $f(u)$ to be the following two typical cases since the general case for $f(u)$ with a finite number of isolated inflection points is treated similarly without substantial difficulties.

ASSUMPTIONS.

(A_1) *$f(u)$ has one inflection point $\tilde{u}$ and $f'(\pm\infty) = +\infty$;*

(A_2) *$f(u)$ has one inflection point $\tilde{u}$ and $f'(\pm\infty) = -\infty$.*

These assumptions are reasonable in the application to the multidimensional generalization. Consider a two-dimensional counterpart of (1.1) (see [6]),

$$\begin{aligned} &(u + qz)_t + f(u)_x + g(u)_y = \epsilon \Delta u, \\ &z_t + k\phi(u)z = 0, \end{aligned} \tag{2.5}$$

where Δ is the Laplacian, the fluxes $f(u)$ and $g(u)$ satisfy that $f''(u) > 0$, $g''(u) > 0$, and $(f''(u)/g''(u))' > 0$. It is easily shown that for any given direction $(\mu, \nu) \in S^1$, the directional flux $F(u; \mu, \nu) = \mu f(u) + \nu g(u)$ has at most one inflection point.

For each case of these assumptions, the inverse function of $\xi = f'(u)$ has two branches, denoted by $R_1(\xi)$ and $R_2(\xi)$, where $R_1(\xi) < R_2(\xi)$. More specifically, with assumption (A_1), the flux $f(u)$ is convex when $u > \tilde{u}$, while it is concave when $u < \tilde{u}$. Therefore, $u = R_1(\xi)$ is defined via $\xi = f'(u)$ as $u < \tilde{u}$ and $u = R_2(\xi)$ via $\xi = f'(u)$ as $u > \tilde{u}$. Thus, $u = R_1(\xi)$ is decreasing while $u = R_2(\xi)$ is increasing. For (A_2), we have converse statements. See Figure 2.1 for the graphs of $R_1(\xi)$ and $R_2(\xi)$.

Thus, the smooth solutions of (2.2) are in the following:

(1) Constant states, $(u, z) =$ (constant, constant).

(2) $(u, z) = (R_i(\xi),$ constant), where $i = 1$ or 2.

(3) $z(\xi) = |\frac{\xi}{\eta}|^k$, where η is an arbitrary constant, $u(\xi) > 0$ satisfies

$$(f'(u) - \xi)\frac{du}{d\xi} = qk\left|\frac{\xi}{\eta}\right|^k.$$

We now turn to discuss discontinuous solutions. At this moment, we have to understand (2.2) in the sense of distributions. Let $(u(\xi), z(\xi))$ be a piecewise smooth solution with a discontinuity point at $\xi = \sigma$. Then we get the Rankine–Hugoniot jump condition

$$\begin{aligned} &-\sigma[u] + [f] = 0, \\ &\sigma[z] = 0. \end{aligned} \tag{2.6}$$

Throughout this paper, we fix the notation $[u]$ to be the jump of u across $\xi = \sigma$, etc. Then the Rankine–Hugoniot condition (2.6) provides two possibilities: (i) if $[z] \neq 0$, then $\sigma = 0$ and $[f] = 0$; (ii) if $[z] = 0$, then $\sigma = \frac{[f]}{[u]}$. The first corresponds to a slip line and the second a shock wave, provided that it satisfies the following Oleinik-type entropy condition:

$$\frac{f(u) - f(u_l)}{u - u_l} \geq \frac{f(u_r) - f(u_l)}{u_r - u_l} \quad \text{for } (u - u_l)(u - u_r) \leq 0. \tag{2.7}$$

The pair (u, z) is an entropy solution of (2.2) and (2.4) if the equations are satisfied at smooth points in the classical sense and the requirement of Oleinik-type entropy condition (2.7) is met at discontinuity points. This solution has the following property.

LEMMA 2.1. *Let $(u(\xi), z(\xi))$ be an entropy solution of* (2.2) *and* (2.4). *Then there exists $\eta \in (-\infty, 0]$ such that $z(\xi)$ has the structure*

$$z(\xi) = \begin{cases} 1, & \xi < \eta, \\ (\frac{\xi}{\eta})^k, & \eta \leq \xi \leq 0, \\ 0, & 0 < \xi. \end{cases} \tag{2.8}$$

Proof. With the above arguments and the Oleinik-type entropy condition (2.7), $z(\xi)$ consists of some constants and functions with the form $|\frac{\xi}{\eta}|^k$. The only possible discontinuity point of $z(\xi)$ is $\xi = 0$. Since $z(+\infty) = 0$, $z(\xi) \equiv 0$ for $\xi > 0$. Note that $z(-\infty) = 1$. We assert $z(\xi) \equiv 1$ in a neighborhood of negative infinity. If $z(\xi) \equiv 1$ for all $\xi < 0$, then $z(\xi)$ has the structure of (2.8) with $\eta = 0$. Otherwise, there exists a constant $\eta < 0$ satisfying the Rankine–Hugoniot condition $\sigma = \eta = (f(u(\eta - 0)) - f(u(\eta + 0))/(u(\eta - 0)) - u(\eta + 0))$, where u undergoes a jump (shock wave). Since z is continuous there, we conclude that $z(\eta) = 1$, and so $z(\xi) = (\xi/\eta)^k$ for $\xi \in (\eta, 0)$ by (2.2). Thus $z(\xi)$ has three different stages as expressed in (2.8). ∎

Lemma 2.1 gives the following corollary.

COROLLARY 2.2. *The entropy solution $(u(\xi), z(\xi))$ of* (2.2) *and* (2.4) *has the structure*

$$(u(\xi), z(\xi)) = \begin{cases} (A(\xi), 1), & -\infty < \xi < \eta, \\ (B(\xi), (\frac{\xi}{\eta})^k), & \eta \leq \xi \leq 0, \\ (C(\xi), 0), & 0 < \xi < +\infty, \end{cases} \tag{2.9}$$

where A, B, and C satisfy the following equations at smooth points:

$$\begin{aligned} &(f'(A)-\xi)\frac{dA}{d\xi}=0, \quad \xi\in(-\infty,\eta),\\ &A(-\infty)=u^-, \quad A(\eta-0)\le 0, \end{aligned} \tag{2.10}$$

$$\begin{aligned} &(f'(B)-\xi)\frac{dB}{d\xi}=qk\left(\frac{\xi}{\eta}\right)^k, \quad \xi\in[\eta,0],\\ &B(\xi)\ge 0, \end{aligned} \tag{2.11}$$

and

$$\begin{aligned} &(f'(C)-\xi)\frac{dC}{d\xi}=0, \quad \xi\in(0,+\infty),\\ &C(+\infty)=u^+. \end{aligned} \tag{2.12}$$

The states $A(\xi)$, $B(\xi)$, and $C(\xi)$ are called the unburned, burning, and burnt parts of $u(\xi)$, respectively. The pair (u,z) is a combustion solution if it contains a burning part; otherwise, it is a noncombustion solution.

Analogous to [13], where $f(u)$ is convex (or concave), it can be shown that the entropy solution of (2.2) and (2.4) is not unique for some binding energy q and initial data (2.4) even though we impose the requirement of the entropy condition (2.7). Motivated by the physical consideration that the temperature in the wave front is as high as possible or, equivalently, the propagation speed of combustion wave front is as small as possible (cf. [22]), we propose the following *reaction entropy condition* to guarantee the uniqueness of solutions, in addition to the Oleinik-type entropy condition (2.7).

Reaction entropy condition (BE). *If the Riemann problem of* (2.2) *and* (2.4) *has several entropy solutions, we choose a solution so that its speed η in the wave front of the burning part achieves the absolute minimum value.*

A solution (u,z) is *admissible* if it satisfies both the Oleinik-type entropy condition (2.7) and the reaction entropy condition (BE). We call (2.7) and (BE) together as the entropy condition of the reaction solution of (2.2) and (2.4).

3. The entropy solution and the limit of the infinite reaction rate. In this section, we seek the entropy solution to (2.2) and (2.4) when the flux $f(u)$ satisfies the assumptions in the last section. We not only prove the solvability of this problem but display the explicit structure of solutions as well. Furthermore, we consider the limit behavior of entropy solutions as the reaction rate k goes to infinity. We achieve our goals through two cases according to the shape of flux $f(u)$ in the assumptions in the preceding section.

3.1. The solution of (2.2) and (2.4) when $f(u)$ satisfies (A_1). We consider the solution of (2.2) and (2.4) when $f(u)$ has only one inflection point and the slope at infinity is positive infinity. The main results are stated in Theorems 3.7–3.9. We investigate this problem using three cases depending on the position of u^+.

Let $\tilde{u}$ be the inflection point of $f(u)$. If $f'(\tilde{u})\ge 0$, then $f(u)$ is a monotone increasing function. It is easy to verify that the Riemann problem of (2.2) and (2.4) has a unique noncombustion solution (cf. [13]). Therefore, the admissible solution exists and is unique subject to the above entropy conditions. In the following, we

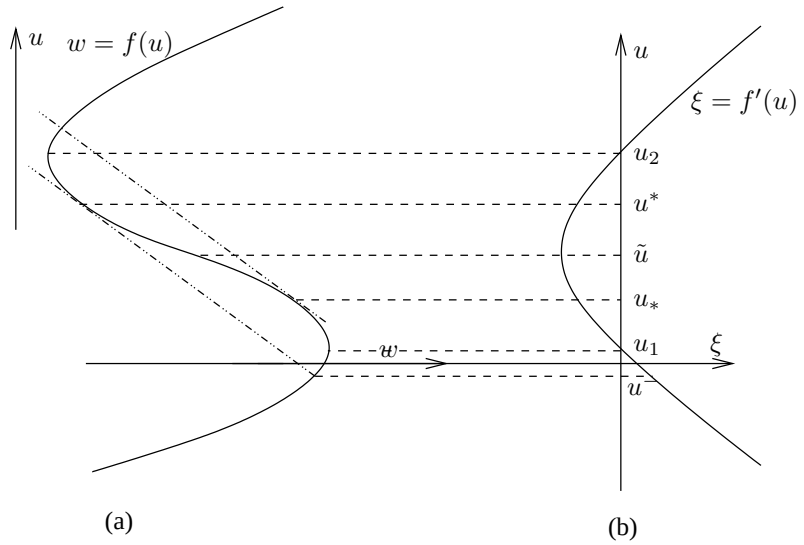


FIG. 3.1. *The graphs of* $w = f(u)$ *and* $\xi = f'(u)$ *when* $f'(\pm\infty) = +\infty$.

consider the case that $f'(\tilde{u}) < 0$. Then there are two critical points $u_1 < u_2$ such that $f'(u_1) = f'(u_2) = 0$ since $f'(\tilde{u}) < 0$ and $f'(\pm\infty) = +\infty$. For definiteness, we assume $u_1 > 0$. The graphs of $w = f(u)$ in the (w, u) plane and $\xi = f'(u)$ in the (ξ, u) plane are shown in Figures 3.1(a) and (b).

Let $u^- < 0$ be a given state. Since our attention in this paper is paid on nonconvex cases, we assume that $u^- < u_1$. If $f(u^-) \le f(u_2)$, then we have a unique admissible noncombustion solution consisting of a forward wave (a shock or a compound wave—a sonic shock plus a rarefaction wave),

$$(u(\xi), z(\xi)) = \begin{cases} (u^-, 1), & \xi < 0, \\ (u^-, 0), & \xi \in (0, \bar{\xi}), \\ (u^+, 0), & \xi > \bar{\xi}, \end{cases}$$

where $\bar{\xi} = \frac{f(v)-f(u^-)}{v-u^-} = f'(v)$. Therefore, it is sufficient to consider the case that $f(u^-) > f(u_2)$.

First, we fix the notation $\bar{u}$, u^*, u_*, $\bar{q}$, q_*, a_0, a_1, and a_2. Let $\bar{u}$, u^*, u_* be so defined that $u_1 < \bar{u} < u_2$, $u^* > u_*$, $f(\bar{u}) = f(u^-)$, and

$$f'(u^*) = \frac{f(u^*) - f(u^-)}{u^* - u^-} = f'(u_*). \tag{3.1}$$

Let $\bar{q}$, q_* be such that

$$\bar{q} = \bar{u} - u^-, \qquad \frac{f(u_*) - f(u^-)}{u_* - (u^- + q_*)} = f'(u_*). \tag{3.2}$$

Then we have $u^* > \bar{u}$ and $\bar{q} < q_*$. Note that q_* is the distance between the tangential lines of $f(u)$ at $(u^*, f(u^*))$ and at $(u_*, f(u_*))$ vertically. We restrict ourselves to dealing with the case where $u_* > \bar{u}$ and $0 < q < q_*$ since the other cases can be treated similarly.

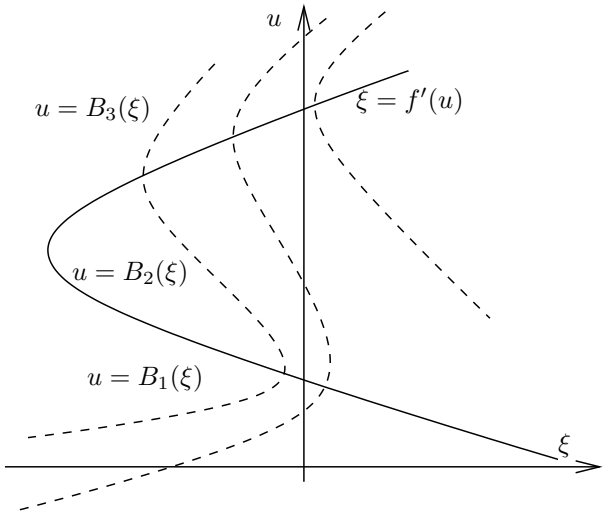

FIG. 3.2. *The branches of integral curve of* (3.3).

Draw a straight line $w - f(u^-) = f'(u^*)(u - (u^- + q))$ in the (u, w) plane, which intersects $w = f(u)$ at three points $(a_i, f(a_i)), i = 0, 1, 2$, $a_0 < a_1 < a_2$. Then we have the relation

$$u_2 > u^* > a_1 > u_* > a_0 > u_-.$$

We also denote $\eta^* = f'(u^*)$.

Fix u^- and q. Then the structure of solution will strongly depend on the value of u^+. Therefore we discuss the issue by the following three cases.

Case 3.1.1. $u^+ \in (a_1, +\infty)$.

Case 3.1.2. $u^+ \in (\bar{u}, a_1]$.

Case 3.1.3. $u^+ \in (0, \bar{u})$.

Before proceeding to discuss these cases, some lemmas are given in the following.

LEMMA 3.1. *All integral curves of the ordinary differential equation*

$$(f'(u) - \xi)\frac{du}{d\xi} = qk\left(\frac{\xi}{\eta}\right)^k \tag{3.3}$$

intersecting with $\xi = f'(u)$ *in the* (ξ, u) *plane are shown in Figure* 3.2. *Each of the integral curves consists of three branches:* $u = B_i(\xi)$, $i = 1, 2, 3$, *having the property that* $B_3(\xi) > R_2(\xi) > B_2(\xi) > R_1(\xi) > B_1(\xi)$.

Proof. Denote the integral curve of (3.3) by $u = B(\xi)$. Let (ξ_0, u_0) be the intersection point of $u = B(\xi)$ and $u = R_2(\xi)$. Then (ξ_0, u_0) is the singularity point of (3.3).

Denote by $u = B_3(\xi)$ the branch that lies in the upper side of $u = R_2(\xi)$ in the neighborhood of (ξ_0, u_0), i.e., $B_3(\xi) > R_2(\xi)$. Then it suffices to show that $B_3(\xi)$ will not intersect with $R_2(\xi)$ for the finite reaction rate $k < \infty$ as $\xi > \xi_0$. Indeed, using

(3.3), we obtain

$$\frac{d}{d\xi}(B_3(\xi)-R_2(\xi))=\frac{kq(\frac{\xi}{\eta})^k}{f'(B_3(\xi))-\xi}-\frac{1}{f''(R_2(\xi))}$$
$$=\frac{kq(\frac{\xi}{\eta})^k f''(R_2(\xi))-(f'(B_3(\xi))-\xi)}{(f'(B_3(\xi))-\xi)f''(R_2(\xi))}.$$

Recall that $u=R_2(\xi)$ is the branch associated with the convex part of $f(u)$. Then $f''(R_2(\xi))>0$. Observe that once $u=B_3(\xi)$ is close to $u=R_2(\xi)$, $f'(B_3(\xi))-\xi$ becomes small. Therefore, at this moment, the numerator is positive, which forces $u=B_3(\xi)$ to leave away $u=B_2(\xi)$ for the upper side of $R_2(\xi)$.

Similarly, we can prove the lemma for $u=B_2(\xi)$ and $u=B_1(\xi)$. □

The solution $u=B_i(\xi)$ $(i=1,2,3)$ of (3.3) depends on the parameters η and k. When there is no risk of confusion, we suppress the dependence of B_i on η and k. Otherwise, we denote $u=B_i(\xi;\eta,k)$.

LEMMA 3.2. *Let $u=B_i(\xi)$, $i=2,3$, be the branches of integral curve of* (3.3) *through the point (η^*,u^*). Then*

(a) $\lim_{k\to+\infty}B_3(\xi)=\max\{a_2,R_2(\xi)\}$ *for all* $\xi\in(\eta^*,0]$;

(b) $\lim_{k\to+\infty}B_2(\xi)=\max\{a_1,R_1(\xi)\}$ *for all* $\xi\in(\eta^*,0]$.

Proof. We prove in two steps part (a) only. Part (b) can be treated in the same way. Note that $B_3(\xi)$ depends on k.

(i) The first step is to prove

$$\underline{\lim_{k\to+\infty}}B_3(\xi)\geq\max\{a_2,R_2(\xi)\}.$$

We write $\underline{\lim_{k\to+\infty}}=:\underline{\lim}$ for short. Since $B_3(\xi)\geq R_2(\xi)$, it suffices to prove $\underline{\lim}B_3(\xi)\geq a_2$. Assume to the contrary that this inequality is not true. Then there exists $\xi_0\in(\eta^*,0]$ such that $\underline{\lim}B_3(\xi_0)<a_2$. Setting $\eta=\eta^*$, $B_3(\eta^*)=u^*$ in (3.3), and integrating (3.3), from η^* to ξ_0, we get

(3.4)
$$f(B_3(\xi_0))-f(u^*)-\xi_0B_3(\xi_0)+\eta^*u^*+\int_{\eta^*}^{\xi_0}B_3(\xi)d\xi=\frac{qk\eta^*}{k+1}\left[\left(\frac{\xi_0}{\eta^*}\right)^{k+1}-1\right].$$

Since $B_3(\xi)$ is increasing, we have

$$\int_{\eta^*}^{\xi_0}B_3(\xi)d\xi<B_3(\xi_0)(\xi_0-\eta^*).$$

Letting $k\to+\infty$ in (3.4) gives

$$f(\underline{B})-f(u^*)-\eta^*(\underline{B}-u^*-q)\geq 0, \tag{3.5}$$

where $\underline{B}=\underline{\lim}B_3(\xi_0)$. Since a_2 is so defined that

$$f(a_2)-f(u^-)=f'(u^*)(a_2-(u^-+q)),$$

we get from (3.5)

$$f(a_2)-f(\underline{B})-\eta^*(a_2-\underline{B})\leq 0, \tag{3.6}$$

where we use the definition of u^*, $f'(u^*)(u^*-u^-)=f(u^*)-f(u^-)<0$.

On the other hand, it follows from $u^*\le \underline{B}=\underline{\lim}B_3(\xi_0)<a_2$ and the convexity of $f(u)$ that

$$\frac{f(a_2)-f(\underline{B})}{a_2-\underline{B}}>\eta^*, \tag{3.7}$$

which contradicts (3.6). Hence $\underline{\lim}B_3(\xi)\ge a_2$ for all $\xi\in(\eta^*,0]$.

(ii) The second step is to verify

$$\overline{\lim_{k\to+\infty}}B_3(\xi)\le\max\{a_2,R_2(\xi)\}.$$

For any $\xi_0\in(\eta^*,0]$, we get from (3.4) that

$$\begin{aligned}f(B_3(\xi_0))&\le f(u^*)+\xi_0B_3(\xi_0)-\int_{\eta^*}^{\xi_0}B_3(\xi)d\xi-\eta^*(u^*+q)\\&\le f(u^*)+\xi_0B_3(\xi_0)-u^*(\xi_0-\eta^*)-\eta^*(u^*+q)\\&<f(u^*)-\eta^*q,\end{aligned}$$

since $\xi_0<0$ and $B_3(\xi_0)>u^*$. This implies that $\{B_3(\xi_0)\}$ is bounded uniformly. Hence $\overline{\lim}B_3(\xi_0):=\overline{\lim_{k_i\to+\infty}}B_3(\xi_0)$ exists for any $\xi_0\in(\eta^*,0]$, denoted by $\overline{B}(\xi_0)$. Choose a subsequence $\{k_i\}$ from $\{k\}$ such that

$$\lim_{k_i\to+\infty}B_3(\xi_0)=\overline{B}(\xi_0).$$

Using Fatou's lemma, we get

$$\begin{aligned}\overline{\lim_{k_i\to+\infty}}\int_{\eta^*}^{\xi_0}B_3(\xi)d\xi&\ge\varlimsup_{k_i\to+\infty}\int_{\eta^*}^{\xi_0}B_3(\xi)d\xi\ge\int_{\eta^*}^{\xi_0}\varlimsup_{k_i\to+\infty}B_3(\xi)d\xi\\&\ge\int_{\eta^*}^{\xi_0}\max(a_2,R_2(\xi))d\xi.\end{aligned}\tag{3.8}$$

Setting $k_i\to+\infty$ in (3.4) and noting (3.8), we arrive at

$$f(\overline{B}(\xi_0))-f(u^*)-\xi_0\overline{B}(\xi_0)+\eta^*u^*+\int_{\eta^*}^{\xi_0}\max\{a_2,R_2(\xi)\}d\xi\le-q\eta^*. \tag{3.9}$$

By the definition of a_2, we have $a_2>u^*$. Let $\bar\xi\in(\eta^*,\xi_0]$ such that $R_2(\bar\xi)=a_2$. (If $a_2>R_2(\xi)$ for all $\xi\in(\eta^*,\xi_0]$, then we take $\bar\xi=\xi_0$.) Then

$$\int_{\eta^*}^{\bar\xi}a_2d\xi=(\bar\xi-\eta^*)a_2$$

and

$$\int_{\bar\xi}^{\xi_0}R_2(\xi)d\xi=f(a_2)-\bar\xi a_2-(f(R_2(\xi_0))-\xi_0R_2(\xi_0)).$$

Note that

$$f(u^*)-f(u^-)=\eta^*(u^*-u^-),\qquad f(a_2)=f(u^-)+\eta^*(a_2-(u^-+q)).$$

Then it is calculated that

$$(\bar{\xi}-\eta^*)a_2 = f(u^*) - f(a_2) + \bar{\xi}a_2 - \eta^*(u^*+q).$$

Consequently, we obtain

$$\begin{aligned}(3.10)\qquad &\int_{\eta^*}^{\xi_0} \max\{a_2, R_2(\xi)\}d\xi \\ &= f(u^*) - f(\max\{a_2, R_2(\xi_0)\}) + \xi_0 \max\{a_2, R_2(\xi_0)\} - \eta^*(u^*+q),\end{aligned}$$

which, combining with (3.9), provides

$$(3.11)\qquad f(\overline{B}(\xi_0)) - f(\max\{a_2, R_2(\xi_0)\}) - \xi_0(\overline{B}(\xi_0) - \max\{a_2, R_2(\xi_0)\}) \le 0.$$

Then there is $\theta \in (\max\{a_2, R_2(\xi_0)\}, \overline{B}(\xi_0))$ such that

$$f(\overline{B}(\xi_0)) - f(\max\{a_2, R_2(\xi_0)\}) = f'(\theta)(\overline{B}(\xi_0) - \max\{a_2, R_2(\xi_0)\}).$$

Note that $f''(u) > 0$ for all $u > \tilde{u}$ and $\overline{B}(\xi_0) > \theta > \max\{a_2, R_2(\xi_0)\} > \tilde{u}$. We have

$$f'(\theta) - \xi_0 = f'(\theta) - f'(R_2(\xi_0)) > 0.$$

Hence, (3.11) implies $\overline{B}(\xi_0) - \max\{a_2, R_2(\xi_0)\} < 0$. □

LEMMA 3.3. *Let $u = B_2(\xi)$ be the integral curve of* (3.3) *through* $(0, u^+)$, *where* $u_1 < u^+ < u_2$. *Then*

$$(3.12)\qquad \lim_{k\to+\infty} B_2(\xi) = \max\{u^+, R_1(\xi)\} \quad \textit{for all } \xi \in (f'(u^+), 0].$$

Proof. By Lemma 3.1, we have for a finite reaction rate k,

$$B_2(\xi) > u^+, \quad B_2(\xi) > R_1(\xi) \quad \text{for all } \xi \in (f'(u^+), 0],$$

and $B_2(\xi)$ is decreasing. Note that $u^+ > R_1(\xi)$ for all $\xi \in (f'(u^+), 0)$. Hence it suffices to prove that

$$(3.13)\qquad \lim_{r\to\infty} B_2(\xi) = u^+.$$

Assume to the contrary that there exists $\xi_0 \in (f'(u^+), 0)$ such that $\underline{\lim}_{k\to\infty} B_2(\xi_0) =: v > u^+$. Then we integrate (3.3) from ξ_0 to 0 and obtain

$$f(u^+) - f(B_2(\xi_0)) + \xi_0 B_2(\xi_0) + \int_{\xi_0}^0 B_2(\xi)d\xi = \frac{kq\xi_0}{k+1}\left(\frac{\xi_0}{\eta}\right)^k.$$

Since

$$\int_{\xi_0}^0 B_2(\xi)d\xi > -\xi_0 u^+,$$

we obtain that as k goes to infinity,

$$f(u^+) - f(v) + \xi_0(v - u^+) < 0,$$

i.e.,

$$\frac{f(u^+)-f(v)}{u^+-v}>\xi_0.$$

Therefore, there exists $\theta\in(u^+,v)$ such that

$$f'(\theta)=\frac{f(u^+)-f(v)}{u^+-v}>\xi_0. \tag{3.14}$$

(a) If $\theta\in(u_1,\tilde{u})$, then since $f''(u)<0$ and $v>\theta>u^+$, we have $f'(v)<f'(\theta)<f'(u^+)$. This contradicts the fact that $f'(\theta)>\xi_0>f'(u^+)$.

(b) If $\theta\in[\tilde{u},u_2)$, then $f'(v)>f'(\theta)$ since $f''(u)>0$ for all $u\in(\tilde{u},u_2)$. Note that $\xi_0>f'(v)$. We obtain the contradiction to (3.14). □

In the remainder of this section, we will suppress the subscript of B when doing so causes no confusion.

LEMMA 3.4. *Let $\eta\in(\eta^*,0)$ and $B(0;\eta,k)=u^+\in(\bar{u},a_1)$. Then there exists a constant $k_0>0$ such that whenever $k>k_0$,*

$$B(\xi;\eta,k)<u^* \quad \textit{uniformly for all } \ \xi\in[\eta,0],\ \eta\in(\eta^*,0). \tag{3.15}$$

Proof. If (3.15) fails, then for any $n>0$ there exist $k_n>n$, $\eta_n\in(\eta^*,0)$, and $\xi_n\in[\eta_n,0]$ such that $B(\xi;\eta_n,k_n)>u^*$ for all $\xi\in(\xi_n,0]$ and $B(\xi_n;\eta_n,k_n)=u^*$.

Since $\eta_n\in(\eta^*,0)$, we choose a convergent subsequence from $\{\eta_n\}$, still denoted by $\{\eta_n\}$. Set $\overline{\eta}=\lim\eta_n$, $\overline{\xi}=\lim\xi_n$. Substituting η, k, and u by η_n, k_n, and $B(\xi;\eta_n,k_n)$ in (3.3), respectively, and then integrating it from ξ_n to 0, we obtain

$$f(u^+)-f(u^*)+\xi_n u^*+\int_{\xi_n}^{0}B(\xi;\eta_n,k_n)d\xi=-q\xi_n\frac{k_n}{k_n+1}\left(\frac{\xi_n}{\eta_n}\right)^{k_n}. \tag{3.16}$$

Letting $n\to+\infty$ and noting $B(\xi;\eta_n,k_n)\geq u^+$, we have from (3.16) that

$$\frac{f(u^*)-f(u^+)}{u^*+q-u^+}\geq\overline{\xi}. \tag{3.17}$$

On the other hand, when $u^+\in(\bar{u},a_1)$,

$$\frac{f(u^*)-f(u^+)}{u^*+q-u^+}<\eta^*. \tag{3.18}$$

Then $\eta^*>\overline{\xi}$, which contradicts $\overline{\xi}\geq\overline{\eta}\geq\eta^*$. Thus, we complete the proof. □

LEMMA 3.5. *Let $B(0;\eta_1,k)=B(0;\eta_2,k)=u^+\in(\bar{u},a_1)$. If $\eta_1\geq\eta_2>\eta^*$, then, for sufficiently large k,*

$$B(\xi;\eta_1,k)>B(\xi;\eta_2,k) \textit{ for all } \xi\in[\eta_1,0]. \tag{3.19}$$

Proof. Letting $w(\xi;\eta,k)=\frac{\partial B(\xi;\eta,k)}{\partial\eta}$, and differentiating (3.3) with respect to ξ, we obtain

$$\begin{cases}\dfrac{dw}{d\xi}+\dfrac{f''(B)qk(\frac{\xi}{\eta})^k}{(f'(B)-\xi)^2}w=\dfrac{-qk(\frac{\xi}{\eta})^k}{\eta(f'(B)-\xi)}, \quad \eta<\xi<0,\\ w(0;\eta,k)=0.\end{cases}$$

From Lemma 3.1, it follows that $f'(B(\xi;\eta,k))-\xi<0$. Then the fact that the right-hand side of the above equation is negative implies $w>0$ for all $\xi\in(\eta,0)$. Hence, $B(\xi;\eta,k)$ increases in η. Thus we obtain (3.19). ∎

LEMMA 3.6. *Let $B(0;\eta,k)=u^+\in(\bar{u},a_1)$. Then, for sufficiently large k, there exists $\eta_k\in(\eta^*,0)$ such that*

$$\eta_k=\frac{f(B(\eta_k;\eta_k,k))-f(u^-)}{B(\eta_k;\eta_k,k)-u^-}. \tag{3.20}$$

Proof. Let $H_k(\eta)=f(B(\eta;\eta,k))-f(u^-)-\eta(B(\eta;\eta,k)-u^-)$. By Lemma 3.1, we have $u^+<B(\eta^*;\eta^*,k)<u^*$. Then

$$H_k(\eta^*)=f(B(\eta^*;\eta^*,k))-f(u^-)-\eta^*(B(\eta^*;\eta^*,k)-u^-)>0$$

and

$$H_k(0)=f(u^+)-f(u^-)-0(u^+-u^-)<0,$$

which implies the existence of η_k satisfying (3.20). ∎

Now we turn to consider the admissible solution of (2.2) and (2.4) corresponding to Cases 3.1.1–3.1.3. In the following arguments, we need to notice the dependence of solutions $(u(\xi),z(\xi))$ of (2.2) and (2.4) on the reaction rate k.

Case 3.1.1. $u^+\in(a_1,+\infty)$.

THEOREM 3.7. *For Case* 3.1.1, *the Riemann problem* (2.2) *and* (2.4) *has a unique admissible solution $(u(\xi),z(\xi))$,*

$$(u(\xi),z(\xi))=\begin{cases}(u^-,1), & \xi<\eta^*,\\ (B(\xi;\eta^*,k),(\frac{\xi}{\eta^*})^k), & \xi\in[\eta^*,0],\\ (C(\xi),0), & \xi>0,\end{cases} \tag{3.21}$$

where $C(\xi)$ is the solution of the following boundary value problem:

$$\begin{cases}(f'(C)-\xi)\frac{dC}{d\xi}=0, C(\xi)\geq 0, \quad \xi\in(0,+\infty),\\ C(0)=B(0;\eta^*,k),\\ C(+\infty)=u^+.\end{cases} \tag{3.22}$$

The infinite reaction rate limit is

$$\lim_{k\to+\infty}(u(\xi),z(\xi))=\begin{cases}(u^-,1), & \xi<\eta^*,\\ (U(\xi),0), & \xi\geq\eta^*,\end{cases} \tag{3.23}$$

where $U(\xi)$ is the solution of

$$\begin{cases}(f'(U)-\xi)\frac{dU}{d\xi}=0, \eta^*<\xi<+\infty,\\ U(\eta^*)=a_2, \quad U(+\infty)=u^+.\end{cases} \tag{3.24}$$

Note that here $\eta^*=\frac{f(a_2)-f(u^-)}{a_2-(u^-+q)}<f'(a_2)$.

Proof. Note that $B_3(0;\eta^*,k)>u_2$ and $\lim_{k\to\infty}B_3(\xi;\eta^*,k)=\max\{R_2(\xi),a_2\}$ for $\xi\in[\eta^*,0]$. Also note that

$$\frac{f(u_2)-f(u)}{u_2-u}\geq 0 \quad \text{for } u\in[u_2,\infty) \tag{3.25}$$

and

$$\frac{f(u_2)-f(u)}{u_2-u}<0 \quad \text{for } u\in(a_1,u_2). \tag{3.26}$$

Then there exists $v\in(a_1,u_2)$ such that for the sufficiently large k, $f(B_3(0;\eta^*,k))=f(v)$. Thus we have two subcases:

(i) $u^+\in[v,\infty)$. Then

$$\frac{f(B_3(0;\eta^*,k))-f(u)}{B_3(0;\eta^*,k))-u}\geq 0 \quad \text{for all } u\in[v,\infty). \tag{3.27}$$

Hence the boundary problem (3.22) has the unique solution $C(\xi)$ for all $\xi>0$ with $C(0+0)=B_3(0;\eta^*,k)$. Thus the solution $(u(\xi),z(\xi))$ can be expressed as in (3.21), where $u(\xi)=B_3(\xi;\eta^*,k)$ as $\xi\in[\eta^*,0)$. This is obviously the admissible solution of (2.2) and (2.4), as shown in Figure 3.3(a).

Next we prove the uniqueness. Let $(u(\xi),z(\xi))$ be the solution of (2.2) and (2.4) for this case. According to Lemma 2.1, $z(\xi)$ has the structure (2.8). When $\xi<\eta$, u satisfies (2.10), of which the unique solution is $u=u^-$. When $\xi\geq 0$, u satisfies (2.12). When $u^+>u_2$, there exists a unique solution of (2.12) for a fixed $u(0+0)$ if $u(0+0)>u_2$. So, we only need to prove $\eta=\eta^*$ and $u(\xi)=B(\xi;\eta^*,k)$, as $\xi\in(\eta^*,0)$.

Indeed, we know from the Rankine–Hugoniot jump condition (2.6) that $\eta\geq\eta^*$. If $\eta>\eta^*$, then the Rankine–Hugoniot jump condition (2.6) and the Oleinik-type entropy condition (2.7) imply $u(\eta+0)<u^*$. Therefore the solution of (2.11) must be continuous and decreasing. Thus, $u(0-0)<u^*$. However, the discontinuity, which is the jump at $\xi=0$ from $u(0-0)<u^*$ to $u(0+0)>u_2$, does not satisfy the Oleinik-type entropy condition (2.7). Therefore, $\eta=\eta^*$ and $u(\eta^*+0)=u^*$. Note from (2.9) that $u(\xi)=B_3(\xi;\eta^*,k)$ lies in the right-hand side of η^*. We conclude that $u(\xi)$ is continuous in $(\eta^*,0)$. Otherwise, suppose ξ_0 to be a discontinuity point of $u(\xi)$. Then, by the Oleinik-type entropy condition (2.7) (observe Figure 3.1), it is easy to see that $u(\xi_0+0)<u^*$, which, combined with the entropy condition, implies that $u(\xi)$ is decreasing and continuous in $(\eta^*,0)$. Consequently, $u(0-0)<u^*$. However, the discontinuity at $\xi=0$ does not satisfies the Oleinik-type entropy condition (2.7). This is a contradiction.

By Lemma 3.2, we have

$$\lim_{k\to\infty} B_3(\xi;\eta^*,k)=\max\{a_2,R_2(\xi)\},\quad \xi\in(\eta^*,0),$$

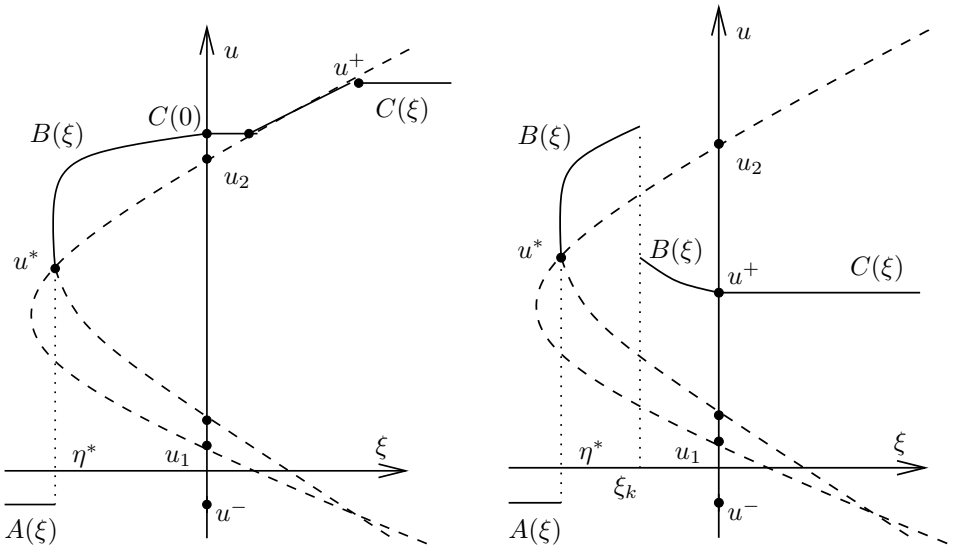
which is the same as the solution of (3.24) for $\xi\in(\eta^*,0)$.

(ii) $u^+\in[a_1,v)$. Note that

$$\frac{f(B_3(0;\eta^*,k))-f(u)}{B_3(0;\eta^*,k))-u}<0 \quad \text{for all } u\in[a_1,v). \tag{3.28}$$

Then we cannot find a solution to (3.22) such that $C(0+0)=B_3(0;\eta^*,k)$. Instead, we construct a solution in the form of (3.21), in which $B(\xi;\eta^*,k)$, at this moment, becomes

$$B(\xi;\eta^*,k)=\begin{cases}B_3(\xi;\eta^*,k), & \xi\in[\eta^*,\xi_k),\\ B_2(\xi;\eta^*,k), & \xi\in[\xi_k,0),\end{cases} \tag{3.29}$$



(a) The solution when $u^+ \in (v, +\infty)$.

(b) The solution when $u^+ \in (a_1, v)$.

FIG. 3.3. *The structure of the entropy solution to the ZND model when* $u^+ \in (a_1, \infty)$.

where $B_3(\xi;\eta^*,k) =: B_3(\xi)$ and $B_2(\xi;\eta^*,k) =: B_2(\xi)$ are defined in Lemmas 3.2 and 3.3, respectively, and $\xi_k \in [\eta^*, 0)$ is to be determined. Next we show that this is indeed the solution of (2.2) and (2.4) for a suitable ξ_k.

In fact, set $\eta = \eta^*$ in (3.3). Then we integrate (3.3) from η^* to ξ_k and from ξ_k to 0, respectively, to obtain

(3.30)
$$f(B_3(\xi_k)) - f(u^*) - \xi_k B_3(\xi_k) + \eta^* u^* + \int_{\eta^*}^{\xi_k} B_3(\xi)d\xi = \frac{kq\eta^*}{k+1}\left(\left(\frac{\xi_k}{\eta^*}\right)^{k+1} - 1\right)$$

and

$$f(u^+) - f(B_2(\xi_k)) + \xi_k B_2(\xi_k) + \int_{\xi_k}^{0} B_2(\xi)d\xi = -\frac{kq\eta^*}{k+1}\left(\frac{\xi}{\eta^*}\right)^{k+1}. \tag{3.31}$$

We add these two identities to get

$$\begin{aligned} &f(B_2(\xi_k)) - f(B_2(\xi_k)) - \xi_k(B_3(\xi_k) - B_2(\xi_k)) \\ &+ f(u^+) - f(u^*) + \eta^* u^* + \frac{kq\eta^*}{k+1} + \int_{\eta^*}^{\xi_k} B_3(\xi)d\xi + \int_{\xi_k}^{0} B_2(\xi)d\xi = 0. \end{aligned} \tag{3.32}$$

Set

$$H(\xi) = f(B_3(\xi)) - f(B_2(\xi)) - \xi(B_3(\xi) - B_2(\xi)). \tag{3.33}$$

Then

$$\frac{dH}{d\xi} = B_2(\xi) - B_3(\xi) < 0. \tag{3.34}$$

Note that

$$\frac{f(a_2)-f(u^+)}{a_2-u^+}>\eta^*. \tag{3.35}$$

Hence, in light of Lemmas 3.2 and 3.3, for the sufficiently large k, there exists $\eta^*<\bar{\xi}<0$ such that $H(\bar{\xi})>0$. Since $f(B_3(0))=f(v)<f(u^+)$, $H(0)<0$. Therefore, there exists a unique $\xi_k\in(\bar{\xi},0)$ such that $H(\xi_k)=0$. Take

$$\xi_k=\frac{f(B_3(\xi_k))-f(B_2(\xi_k))}{B_3(\xi_k)-B_2(\xi_k)}. \tag{3.36}$$

Then the solution $u=u(\xi)$ has a discontinuity at $\xi=\xi_k$, which satisfies the Oleinik entropy condition (2.7) since $B_3(\xi_k)>B_2(\xi_k)$ and $B_3(\xi_k)>u^*$.

In light of (3.32), the solution $(u(\xi),z(\xi))$ constructed above satisfies (2.2) and (2.4) in the sense of distributions and therefore is admissible. We display this solution in Figure 3.3(b).

The uniqueness can be proved similarly to that in (i).

By Lemmas 3.2 and 3.3, the limit of this solution as the reaction rate k goes to infinity is expressed in (3.23). □

Case 3.1.2. $u^+\in(\bar{u},a_1]$.

THEOREM 3.8. *When k is sufficiently large, then*

(1) *there exists $\eta_k\in(\eta^*,0)$ such that the Riemann problem for Case* 3.1.2 *has the unique admissible solution*

$$(u(\xi),z(\xi))=\begin{cases}(u^-,1), & \xi\in(-\infty,\eta_k),\\ (B(\xi;\eta_k,k),(\frac{\xi}{\eta_k})^k), & \xi\in(\eta_k,0),\\ (u^+,0), & \xi\in(0,+\infty),\end{cases} \tag{3.37}$$

where $B(\xi;\eta_k,k)$ satisfies (3.3) *with $B(0;\eta_k,k)=u^+\in(\bar{u},a_1]$ and*

$$\eta_k=\frac{f(B(\eta_k;\eta_k,k))-f(u^-)}{B(\eta_k;\eta_k,k)-u^-};$$

(2) *there holds*

$$\lim_{k\to+\infty}(u(\xi),z(\xi))=\begin{cases}(u^-,1), & \xi\in(-\infty,\eta_0),\\ (U(\xi),0), & \xi\in(\eta_0,+\infty),\end{cases} \tag{3.38}$$

where $U(\xi)=\max\{R_1(\xi),u^+\}$ and η_0 satisfies

$$\eta_0=\frac{f(U(\eta_0))-f(u^-)}{U(\eta_0)-u^--q}\geq f'(U(\eta_0)). \tag{3.39}$$

Proof. (1) If $(u(\xi),z(\xi))$ is the solution of (2.2) and (2.4), then $u(\xi)$ satisfies (2.10) and (2.12) when $\xi\in(-\infty,\eta)$ and $\xi\in(0,+\infty)$, respectively. By the Oleinik-type entropy condition (2.7) and under the assumption that $u^-<a_0$ and $u^+\in(\bar{u},a_1]$, we have $u(\xi)=u^-$ for $\xi\in(-\infty,\eta)$ and $u(\xi)=u^+$ for $\xi\in(0,+\infty)$. By Lemma 3.6, there exists $\eta_k\in(\eta^*,0)$ such that

$$\eta_k=\frac{f(B(\eta_k;\eta_k,k))-f(u^-)}{B(\eta_k;\eta_k,k)-u^-}.$$

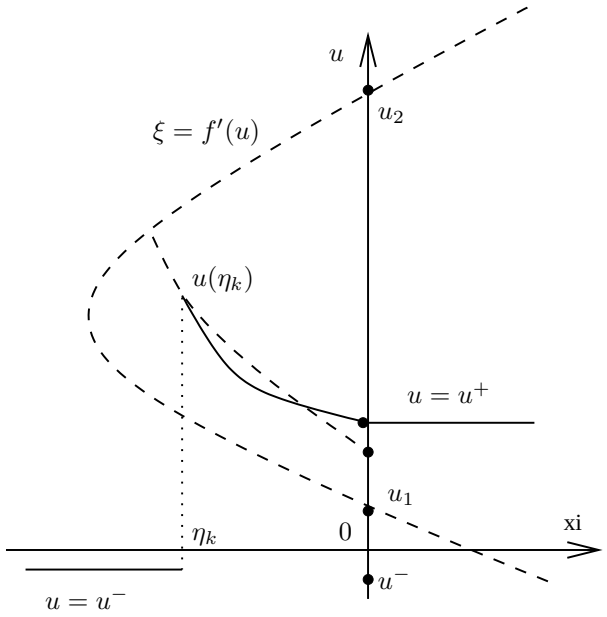


FIG. 3.4. *The structure of entropy solution to the ZND model when* $u^+ \in (\bar{u}, a_1)$.

It is evident that the entropy condition (2.7) is satisfied at the jump $\xi = \eta_k$. Thus, the admissible solution exists (see Figure 3.4). Arguments similar to those in Theorem 3.7 show that such a solution is unique.

(2) Integrating (3.3) from η_k to 0, we have

$$f(u^+) - f(B(\eta_k;\eta_k,k)) + \eta_k B(\eta_k;\eta_k,k) + \int_{\eta_k}^{0} B(\xi;\eta_k,k)d\xi + q\eta_k \frac{k}{k+1} = 0. \tag{3.40}$$

Substituting $H(\eta_k) = 0$ (where $H(\eta_k)$ is defined in Lemma 3.6) into (3.40) gives

$$f(u^+) - f(u^-) + \eta_k u^- + q\eta_k \frac{k}{k+1} + \int_{\eta_k}^{0} B(\xi;\eta_k,k)d\xi = 0. \tag{3.41}$$

Let $\bar{\eta}_0 = \overline{\lim_{k\to+\infty}}\eta_k$. Then, in light of Lemma 3.3, we get from (3.41)

$$f(u^+) - f(u^-) + \bar{\eta}_0 u^- + q\bar{\eta}_0 + \int_{\bar{\eta}_0}^{0} U(\xi)d\xi = 0, \tag{3.42}$$

where $U(\xi) = \max\{u^+, R_1(\xi)\}$. Therefore, we have

$$\int_{\bar{\eta}_0}^{0} U(\xi)d\xi = \begin{cases} -\bar{\eta}_0 u^+, & \bar{\eta}_0 > f'(u^+), \\ -\bar{\eta}_0 U(\bar{\eta}_0) - f(u^+) + f(U(\bar{\eta}_0)), & \bar{\eta}_0 \le f'(u^+). \end{cases} \tag{3.43}$$

Equations (3.42) and (3.43) imply that $\bar{\eta}_0$ satisfies (3.39).

Analogously, it is proved that $\underline{\eta}_0 = \lim_{\overline{k\to+\infty}}\eta_k$ satisfies (3.39). Therefore, $\eta_0 = \lim_{\overline{k\to+\infty}}\eta_k = \bar{\eta}_0 = \underline{\eta}_0$ and satisfies (3.39).

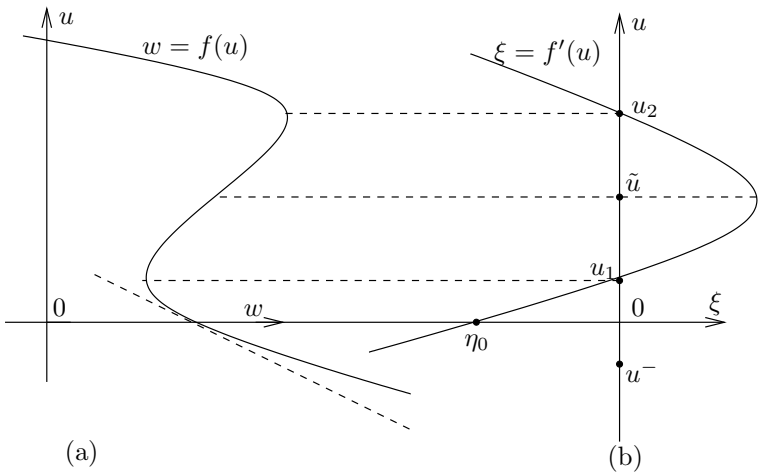

FIG. 3.5. *The graphs of* $w = f(u)$ *and* $\xi = f'(u)$ *when of* $f'(\pm\infty) = -\infty$.

For any given $\xi_0 \in (\eta_0, 0)$, choose a small $\epsilon > 0$ so that $\eta_0 + \epsilon < \xi_0$. Then we have $\eta_k < \eta_0 + \epsilon < \xi_0$ for sufficiently large k. From Lemma 3.6, we get

$$U(\xi_0) < B(\xi_0; \eta_k, k) < B(\xi_0; \eta_0 + \epsilon, k).$$

Thus, letting $k \to +\infty$, we obtain

$$\lim_{k\to\infty} B(\xi_0; \eta_k, k) = U(\xi_0).$$

Due to the arbitrariness of ξ_0, $\lim_{k\to\infty} B(\xi; \eta_k, k) = U(\xi)$ for all $\xi \in (\eta_0, 0)$. □

Case 3.1.3. $\boldsymbol{u^+ \in (0, \bar{u}]}$**.** For this case, we have the following theorem.

THEOREM 3.9. *For Case* 3.1.3, *the unique admissible solution of* (2.2) *and* (2.4) *is the noncombustion solution*

$$(u(\xi), z(\xi)) = \begin{cases} (u^-, 1), & \xi < \frac{f(u^-)-f(u^+)}{u^- - u^+}, \\ (u^+, 0), & \xi > \frac{f(u^-)-f(u^+)}{u^- - u^+}. \end{cases} \tag{3.44}$$

3.2. The solution of (2.2) and (2.4) when $\boldsymbol{f(u)}$**satisfies** $\boldsymbol{(A_2)}$**.** Parallel to section 3.1, we solve (2.2) and (2.4) as $f(u)$ has just one inflection point and the slope at infinity is negative infinity. The results are stated in Theorems 3.12 and 3.13. We omit some proofs because they are similar to those in section 3.1.

Let $\tilde{u}$ be the inflection point of $f(u)$. When $f'(\tilde{u}) \le 0$, there is no combustion solution (cf. [13]). Therefore, we only need to consider $f'(\tilde{u}) > 0$. Let u_1, u_2, and u_3 be such that $u_3 > u_2 > u_1 > 0$ and $f'(u_1) = f'(u_2) = 0$. Recall that $u = 0$ is assumed to be the ignition point and therefore plays an important role in the current context. We set $\hat{q}$ to satisfy $f'(0) = \frac{f(u_2)-f(0)}{u_2-\hat{q}}$. The value of the binding energy q is distinguished into two classes: $0 < q < \hat{q}$ and $q \ge \hat{q}$. We restrict our study to the solution to the case that $q \in (0, \hat{q})$. The case that $q \ge \hat{q}$ can be treated similarly.

Draw the straight line $w - f(0) = f'(0)(u - q)$ in the (u, w) plane. Then it intersects $w = f(u)$ at three points $(a_i, f(a_i))$, $i = 1, 2, 3$, where $a_2 > a_1 > a_0$. It is evident that $a_2 > u_2 > a_1 > 0 > a_0$.

For the fixed $q \in (0, \hat{q})$ and $u^- \in (-\infty, 0)$, the structure of the solution of the Riemann problem (2.2) and (2.4) will depend on the value of u^+. We proceed our discussion through two cases.

Case 3.2.1. $u^+ \in (0, a_2)$.

Case 3.2.2. $u^+ \in [a_2, \infty)$.

Case 3.2.1. $u^+ \in (0, a_2)$. The main result is stated in Theorem 3.12 by following Lemmas 3.10 and 3.11.

LEMMA 3.10. *Let $B(\xi; \eta_0, k)$ be the smooth solution of the problem*

$$\begin{aligned} &(f'(B) - \xi)\frac{dB}{d\xi} = qk\left(\frac{\xi}{\eta_0}\right)^k, \qquad \eta_0 < \xi \le 0, \\ &B(\eta_0; \eta_0, k) = 0, \end{aligned} \tag{3.45}$$

where $\eta_0 = f'(0)$. Then $u = B(\xi; \eta_0, k)$ does not increase until it intersects with $\xi = f'(u)$ and $\lim_{k\to\infty} B(\xi; \eta_0, k) = \max\{a_1, R_1(\xi)\}$, $\xi \in (\eta_0, 0]$.

LEMMA 3.11. *Let $B(\xi; \eta_0, k)$ be the smooth solution of the problem*

$$\begin{cases} (f'(B) - \xi)\dfrac{dB}{d\xi} = qk\left(\dfrac{\xi}{\eta_0}\right)^k, \qquad \xi < 0, \\ B(0; \eta_0, k) = u^+. \end{cases} \tag{3.46}$$

Then for all $u^+ \in (u_2, a_2)$ or $u^+ \in (0, u_1)$, $f'(B(\xi; \eta_0, k) < \xi$, and therefore $B(\xi; \eta_0, k)$ does not decrease until it intersects with $\xi = f'(u)$. Furthermore, the limit of $B(\xi; \eta_0, k)$ as the reaction rate goes to infinity is

$$\lim_{k\to\infty} B(\xi; \eta_0, k) = u^+ \tag{3.47}$$

for all $\xi \in (f'(u^+), 0)$.

Note that $B(\eta_0; \eta_0, k)$ does not need to be zero, which is different from Lemma 3.10.

The proof of Lemmas 3.10 and 3.11 is similar to that of Lemmas 3.1 and 3.3. Using a method similar to that in Theorem 3.7, we can construct the solution of (2.2) and (2.4) for Case 3.2.1.

THEOREM 3.12. *When k is large enough, the Riemann problem of* (2.2) *and* (2.4) *for Case* 3.2.1 *has the unique admissible solution with the structure*

$$(u(\xi), z(\xi)) = \begin{cases} (\max\{u^-, R_1(\xi)\}, 1), & -\infty < \xi < \eta_0, \\ (B(\xi; \eta_0, k), (\frac{\xi}{\eta_0})^k), & \eta_0 < \xi < 0, \\ (C(\xi; \eta_0, k), 0), & 0 \le \xi < +\infty \end{cases} \tag{3.48}$$

and

$$\lim_{k\to\infty}(u(\xi), z(\xi)) = \begin{cases} (\max\{u^-, R_1(\xi)\}, 1), & -\infty < \xi \le \eta_0, \\ (C(\xi), 0), & \eta_0 < \xi < +\infty, \end{cases} \tag{3.49}$$

where $C(\xi)$ is the solution of

$$\begin{cases} (f'(C) - \xi)\frac{dC}{d\xi} = 0, \quad \eta_0 \le \xi < +\infty, \\ C(\eta_0) = a_1, \quad C(+\infty) = u^+. \end{cases} \tag{3.50}$$

Note here that $\eta_0 = \frac{f(a_1)-f(0)}{a_1-q} < f'(a_1)$.

Proof. Let $(u(\xi), z(\xi)) = (\max\{u^-, R_1(\xi)\}, 1)$ when $\xi \in (-\infty, \eta_0)$. Let $B_1(\xi;\eta_0,k)$ and $B_2(\xi;\eta_0,k)$ be the solutions of (3.45) and (3.46), respectively.

(i) If $\frac{f(u^+)-f(B_1(0;\eta_0,k))}{u^+-B_1(0;\eta_0,k)} \geq 0$, then we choose $u(\xi) = B_1(\xi;\eta_0,k)$ as the smooth solution of equation (3.45) when $\eta_0 < \xi < 0$. By Lemma 3.10, $\lim_{k\to\infty} B_1(\xi;\eta_0,k) = \max\{a_1, R_1(\xi)\}$, as $\xi \in (\eta_0, 0]$. Thus we have $u_1 < B(0;\eta_0,k) < u_2$, as k is large enough, due to $u_1 < a_1 < u_2$. Then the problem

$$\begin{cases} (f'(C)-\xi)\frac{dC}{d\xi} = 0, \quad 0 \leq \xi < +\infty, \\ C(0) = B_1(0;\eta_0,k), \quad C(+\infty;\eta_0,k) = u^+ \end{cases} \tag{3.51}$$

has a unique entropy solution since $\frac{f(u^+)-f(B_1(0;\eta_0,k))}{u^+-B_1(0;\eta_0,k)} \geq 0$.

(ii) If $\frac{f(u^+)-f(B_1(0;\eta_0,k))}{u^+-B_1(0;\eta_0,k)} < 0$, then we choose $u(\xi) = u^+$ as $\xi \geq 0$, $u(\xi) = B_1(\xi;\eta_0,k)$ as $\xi \in (\eta_0, \xi_k)$, and $u(\xi) = B_2(\xi;\eta_0,k)$ as $\xi \in (\xi_k, 0)$, where ξ_k is to be determined. Note that now $u^+ \notin (u_1, u_2)$ since $B_1(0;\eta_0,k) \in (u_1, u_2)$ and $\frac{f(B_1(0;\eta_0,k)-f(v)}{B_1(0;\eta_0,k)-v} > 0$ for all $v \in (u_1, u_2)$.

The summation of the integration of (3.45) from η_0 to ξ_k and the integration (3.46) from ξ_k to 0 results in

$$\begin{aligned} &[f(B_1(\xi_k;\eta_0,k)) - f(B_2(\xi_k;\eta_0,k))] \\ &- \xi_k[B_1(\xi_k;\eta_0,k) - B_2(\xi_k;\eta_0,k)] - [f(0) - f(u^+)] + q\eta_0\frac{k}{k+1} \\ &+ \int_{\eta_0}^{\xi_k} B_1(\xi;\eta_0,k)d\xi + \int_{\xi_k}^{0} B_2(\xi;\eta_0,k)d\xi = 0. \end{aligned} \tag{3.52}$$

Set

$$\begin{aligned} H(\xi) = &[f(B_1(\xi;\eta_0,k)) - f(B_2(\xi;\eta_0,k))] \\ &- \xi[B_1(\xi;\eta_0,k) - B_2(\xi;\eta_0,k)]. \end{aligned} \tag{3.53}$$

When $u^+ \in (0, u_1)$, we have

$$\frac{dH}{d\xi} = B_2(\xi;\eta_0,k) - B_1(\xi;\eta_0,k) < 0 \quad \text{for all } \xi \in (f'(u^+), 0) \tag{3.54}$$

and

$$H(0) = f(B_1(0;\eta_0,k)) - f(u^+) < 0. \tag{3.55}$$

In light of Lemmas 3.10 and 3.11, $\lim_{k\to\infty} B_1(\xi;\eta_0,k) = \max\{a_1, R_1(\xi)\}$ and $\lim_{k\to\infty} B_2(\xi;\eta_0,k) = u^+$ as $\xi \in (f'(u^+), 0)$. Since

$$\frac{f(a_1) - f(u^+)}{a_1 - u^+} > f'(u^+),$$

$H(\xi) > 0$ for sufficiently large k as $\xi > f'(u^+)$, and ξ is close to $f'(u^+)$. Therefore, there exists $\xi_k \in (f'(u^+), 0)$ such that $H(\xi_k) = 0$.

When $u^+ \in (u_2, a_2)$, we have

$$H(0) = f(B_1(0;\eta_0,k)) - f(u^+) > 0$$

and

$$H(\eta_0) = f(0) - f(B_2(\eta_0;\eta_0,k)) - \eta_0(0 - B_2(\eta_0;\eta_0,k) < 0;$$

there also exists $\xi_k \in (\eta_0, 0)$ such that $H(\xi_k) = 0$. Thus, define

$$\xi_k = \frac{f(B_1(\xi_k;\eta_0,k)) - f(B_2(\xi_k;\eta_0,k))}{B_1(\xi_k;\eta_0,k) - B_2(\xi_k;\eta_0,k)}. \tag{3.56}$$

By Lemmas 3.10 and 3.11, we have

$$\lim_{k\to\infty} B_1(\xi;\eta_0,k) = \max\{a_1, R_1(\xi)\}, \quad \lim_{k\to\infty} B_2(\xi;\eta_0,k) = u^+.$$

Then, as k is sufficiently large, $B_1(\xi_k;\eta_0,k)$ is close to $\max\{a_1, R_1(\xi_k)\}$ and $B_2(\xi_k;\eta_0,k)$ is close to u^+. Therefore, the discontinuity of u at $\xi = \xi_k$ satisfies the Oleinik entropy condition (2.7). By (3.52), we conclude that this solution satisfies (2.2) and (2.4) in the sense of distributions. Thus we have constructed the admissible solution. The uniqueness is obvious.

Using Lemmas 3.10 and 3.11, the limit of the solution is obtained. □

Case 3.2.2. $u^+ \in [a_2, +\infty)$. Set

$$(u(\xi), z(\xi)) = \begin{cases} (\max\{u^-, R_1(\xi)\}, 1), & \xi \in (-\infty, \eta_k), \\ (B(\xi;\eta_k,k), (\frac{\xi}{\eta_k})^k), & \xi \in (\eta_k, 0], \\ (u^+, 0), & \xi \in (0, +\infty), \end{cases} \tag{3.57}$$

where η_k is to be determined, and $B(\xi;\eta_k,k)$ satisfies

$$\begin{aligned} &(f'(B) - \xi)\frac{dB}{d\xi} = qk\left(\frac{\xi}{\eta_k}\right)^k, \quad \eta_k < \xi < 0, \\ &B(0;\eta_k,k) = u^+. \end{aligned} \tag{3.58}$$

Since $u^+ \geq a_2$, the Riemann problem of (2.2) and (2.4) does not have the same kind of solution as that in Case 3.2.1. This implies that $\eta_k < \eta_0$. Denote $\eta^- = f'(u^-)$. The summation of the integration of (3.3) from η^- to η_k when $q = 0$ and the integration from η_k to 0 when $q > 0$ is

$$\begin{aligned} &f(\max\{u^-, R_1(\eta_k)\}) - f(B(\eta_k;\eta_k,k)) - \eta_k(\max\{u^-, R_1(\eta_k)\} - B(\eta_k;\eta_k,k)) \\ &+ f(u^+) - f(u^-) + \eta^- u^- + \int_{\eta^-}^{\eta_k} \max\{u^-, R_1(\xi)\}d\xi + \int_{\eta_k}^{0} B(\xi;\eta_k,k)d\xi + \frac{kq\eta_k}{k+1} = 0. \end{aligned} \tag{3.59}$$

Set

$$\begin{aligned} H(\eta) = {} & f(B(\eta;\eta,k)) - f(\max\{u^-, R_1(\eta)\}) \\ & - \eta[B(\eta;\eta,k) - \max\{u^-, R_1(\eta)\}]. \end{aligned} \tag{3.60}$$

Then we claim that there exists $\eta_k < \eta_0$ such that $H(\eta_k) = 0$.

Draw a line $w - f(u^-) = f'(u^-)(u - (u^- + q))$. It has an intersection point, denoted by $(b_1, f(b_1))$, $b_1 > a_2$, with $w = f(u)$. Then we prove the above claim using two cases.

(i) $u^+ \in [a_2, b_1)$. Then we can find $u^* \in (u^-, 0]$ such that

$$f'(u^*) = \frac{f(u^+) - f(u^*)}{u^+ - (u^* + q)} =: \eta^*. \tag{3.61}$$

In light of Lemma 3.11, for sufficiently large k, the solution $B(\eta; \eta, k)$ of (3.58) is close to u^+. Therefore,

$$H(\eta^*) = f(u^*) - f(B(\eta^*; \eta^*, k)) - \eta^*(u^* - B(\eta^*; \eta^*, k)) > 0. \tag{3.62}$$

On the other hand,

$$H(\eta^-) = f(u^-) - f(B(\eta^-; \eta^-, k)) - \eta^-(u^- - B(\eta^-; \eta^-, k)) < 0. \tag{3.63}$$

Hence, there exists $\eta_k \in (\eta^-, \eta^*)$ such that $H(\eta_k) = 0$.

(ii) $u^+ \in [b_1, +\infty)$. Now we set

$$\eta^* = \frac{f(u^+) - f(u^-)}{u^+ - (u^- + q)}. \tag{3.64}$$

Then we assert

$$\eta^- > \eta^* > \eta^+ := f'(u^+). \tag{3.65}$$

Making use of (3.59), we can conclude that

$$H(\eta^+) < 0 \quad \text{and} \quad H(\eta^-) > 0. \tag{3.66}$$

Therefore, there also exists $\eta_k \in (\eta^+, \eta^-)$ such that $H(\eta_k) = 0$.

Thus we construct an admissible solution of (2.2) and (2.4) for Case 3.2.2. The uniqueness is obvious. Therefore, we summarize to obtain the following theorem.

THEOREM 3.13. *The Riemann problem for Case* 3.2.2 *has a unique admissible solution with the structure*

$$(u(\xi), z(\xi)) = \begin{cases} (\max\{u^-, R_1(\xi)\}, 1), & \xi \in (-\infty, \eta_k), \\ (B(\xi; \eta_k, k), (\frac{\xi}{\eta_k})^k), & \xi \in (\eta_k, 0), \\ (u^+, 0), & \xi \in [0, +\infty) \end{cases} \tag{3.67}$$

and

$$\lim_{k \to +\infty} (u(\xi), z(\xi)) = \begin{cases} (\max\{u^-, R_1(\xi)\}, 1), & \xi \in (-\infty, \eta^*), \\ (u^+, 0), & \xi \in (\eta^*, +\infty). \end{cases} \tag{3.68}$$

4. Entropy condition for combustion waves of the CJ model. In this section, we will propose the entropy condition for combustion waves of the CJ model (1.2) with nonconvex fluxes $f(u)$ by taking into account the limit behavior of the solutions $(u(\xi), z(\xi))$ of (2.2) and (2.4) as the reaction rate goes to infinity. As we discussed in section 3, the Riemann solutions are essentially classified into two kinds: noncombustion solutions and combustion solutions. The combustion solutions have two types.

(i) For Type 1, as shown in Cases 3.1.2 and 3.2.2, the gas is ignited through a shock at $\xi = \eta_k$. The position of the reaction wave front depends on the reaction rate

k. The solution u is increasing as $\xi < \eta_k$, while it is decreasing as $\xi > \eta_k$. There is a von Neumann spike $u = B(\eta_k; \eta_k, k)$ on the curve of $u = u(\xi)$ in a neighborhood of $\xi = \eta_k$. Denote $\bar{\eta} = \lim_{k\to+\infty} \eta_k$, $\bar{u}(\xi) = \lim_{k\to+\infty} B(\xi; \eta_k, k)$ for $\xi \in (\bar{\eta}, 0)$ and $\bar{u}_R = \lim_{k\to+\infty} B(\eta_k; \eta_k, k)$.

Then, at $\xi = \bar{\eta}$, we have the relation

$$\bar{\eta} = \frac{f(\bar{u}_r) - f(\bar{u}_l)}{\bar{u}_r - \bar{u}_l - q} < 0, \qquad f'(\bar{u}_l) \geq \bar{\eta} \geq f'(\bar{u}_r), \tag{4.1}$$

and $\bar{u}_R > \bar{u}_r$ such that

$$\frac{f(\bar{u}_R) - f(\bar{u}_l)}{\bar{u}_R - \bar{u}_l} = \frac{f(\bar{u}_r) - f(\bar{u}_l)}{\bar{u}_r - \bar{u}_l - q} \leq \frac{f(u) - f(\bar{u}_l)}{u - \bar{u}_l} \quad \text{for all } u \in (\bar{u}_l, \bar{u}_R), \tag{4.2}$$

where $\bar{u}_r = \bar{u}(\bar{\eta} + 0)$, $\bar{u}_l = \bar{u}(\bar{\eta} - 0)$.

(ii) For Type 2, as shown in Cases 3.1.1 and 3.2.1, the gas will burn when its temperature reaches the ignition point continuously at $\xi = \eta_0$ or jumps over the ignition point through a shock at $\xi = \eta^*$. The position of the reaction wave front $\xi = \eta_0$ (or $\xi = \eta^*$) does not depend on the reaction rate k. In the neighborhood of $\xi = \eta_0$ or $\xi = \eta^*$, u is increasing. There is no von Neumann spike on the curve of $u = u(\xi)$ in the neighborhood of $\xi = \eta_0$ or $\xi = \eta^*$. Denote $\bar{\eta} = \eta_0$ or η^*, $\bar{u}(\xi) = \lim_{k\to+\infty} B(\xi; \bar{\eta}, k)$ for $\xi \in (\bar{\eta}, 0)$, and $\bar{u}_R = \lim_{k\to+\infty} B(\bar{\eta}; \bar{\eta}, k)$. Then, at $\xi = \bar{\eta}$, we have the relation

$$\bar{\eta} = \frac{f(\bar{u}_r) - f(\bar{u}_l)}{\bar{u}_r - \bar{u}_l - q} < 0, \qquad \bar{\eta} \leq f'(\bar{u}_r), \tag{4.3}$$

and $\bar{u}_R \in [0, \bar{u}_r)$ such that

$$\frac{f(\bar{u}_R) - f(\bar{u}_l)}{\bar{u}_R - \bar{u}_l} = \frac{f(\bar{u}_r) - f(\bar{u}_l)}{\bar{u}_r - \bar{u}_l - q} \geq \frac{f(u) - f(\bar{u}_l)}{u - \bar{u}_l} \quad \text{for all } u \in (\bar{u}_l, \bar{u}_r), \tag{4.4}$$

where $\bar{u}_r = \bar{u}(\bar{\eta} + 0)$, $\bar{u}_l = \bar{u}(\bar{\eta} - 0)$.

DEFINITION 4.1. *For the CJ combustion model* (1.2), *we define the limit of the interface between the unburned and reaction states in Type* I *as a generalized detonation wave and in Type* II *as the generalized deflagration wave.*

From this definition, we extract the following entropy condition on combustion waves for the nonconvex CJ combustion model (1.2).

ENTROPY CONDITION. *Let $x = x(t)$ be a combustion wave of the CJ combustion model* (1.2). *Let $u_l = u(x(t) - 0, t)$ and $u_r = u(x(t) + 0, t)$ be the limit values of u in the wave front and the wave back, respectively. Then*

(1) *$x = x(t)$ is a generalized CJ deflagration wave if*

$$\frac{dx}{dt} = \frac{f(u_r) - f(u_l)}{u_r - u_l - q} < 0, \quad \frac{dx}{dt} \leq f'(u_r), \tag{4.5}$$

and there exists $u_R \in [0, u_r)$ such that

$$\frac{f(u_R) - f(u_l)}{u_R - u_l} = \frac{f(u_r) - f(u_l)}{u_r - u_l - q} \geq \frac{f(u) - f(u_l)}{u - u_l} \quad \textit{for all } u \in (u_l, u_r); \tag{4.6}$$

(2) *$x = x(t)$ is a generalized detonation wave if*

$$\frac{dx}{dt} = \frac{f(u_r) - f(u_l)}{u_r - u_l - q} < 0, \qquad f'(u_l) \geq \frac{dx}{dt} \geq f'(u_r), \tag{4.7}$$

and there exists $u_R \in (u_r, +\infty)$ *such that*

$$\frac{f(u_R)-f(u_l)}{u_R-u_l}=\frac{f(u_r)-f(u_l)}{u_r-u_l-q}\le\frac{f(u)-f(u_l)}{u-u_l}\quad \textit{for all } u\in(u_l,u_R). \tag{4.8}$$

Furthermore the detonation wave is a CJ detonation wave if $\frac{dx}{dt}=f'(u_r)$*; otherwise, it is a strong detonation wave.*

As we have seen, this entropy condition for the nonconvex CJ combustion model (1.2) inherits the essential difference between detonation and deflagration waves in that the former contains a von Neumann spike in the finite reaction rate region but the latter does not, which reflects the intrinsic feature of combustion waves in gas dynamics (cf. [1, 22]). With this, we can improve the results in [18] greatly to justify the (entropy) solutions of the Riemann problem for (1.2). Actually this entropy condition can be used in the construction of two-dimensional Riemann problems for the counterpart of (1.2), the generalization of (1.2) in two-dimensions; see [20]. Therefore, to some extent, this entropy condition lays a foundation and gives insight into the study of the structure of multidimensional combustion solutions.

Acknowledgments. The authors are grateful to Professor Tong Zhang for stimulating discussions, and also thank the referees for pointing out unclear statements and errors and improving the presentation of this paper. The second author is also grateful to the Institute of Mathematics, the Hebrew University of Jerusalem, whose hospitality and Professor Matania Ben-Artzi's invitation are greatly appreciated.

WIGNER MEASURE AND THE SEMICLASSICAL LIMIT OF SCHRÖDINGER–POISSON EQUATIONS*

PING ZHANG†

Abstract. The wave function $\{\psi^\epsilon(t,x)\}$ of single particle approximation, which is used in the study of quantum transportation in some semiconductive devices, satisfies Schrödinger–Poisson equations. It is well known that the Wigner transformation $f^\epsilon(t,x,\xi)$ of the corresponding wave function $\psi^\epsilon(t,x)$ satisfies the so-called Wigner–Poisson equations. We prove here that in any space dimension, with the initial data of the form $\sqrt{\rho_0^\epsilon(x)}\exp(\frac{i}{\epsilon}S^\epsilon(x))$ to the wave function, and before the formation of vortices, the Wigner measure $f(t,x,\xi)$, which is the weak limit of $f^\epsilon(t,x,\xi)$ as the normalized Planck constant ϵ approaches 0, satisfies Vlasov–Poisson equations, and the limits of the quantum density and momentum to the Schrödinger–Poisson equations satisfy the pressureless Euler–Poisson equations.

Key words. Schrödinger–Poisson, Euler–Poisson, Vlasov–Poisson, Wigner measure, Wigner transformation, pseudodifferential operator

1. Introduction.

In this paper, we consider the local-in-time semiclassical limit of Schrödinger–Poisson equations in any space dimension. The wave function $\{\psi^\epsilon(t,x)\}$ of single particle approximation, which is used in the study of quantum transportation in some semiconductive devices, satisfies Schrödinger–Poisson equations,

$$\begin{cases} i\epsilon\partial_t\psi^\epsilon = -\frac{\epsilon^2}{2}\triangle\psi^\epsilon + V^\epsilon\psi^\epsilon, \qquad x\in\mathbb{R}^d, \quad t\geq 0, \\ \psi^\epsilon(t=0,x) = \sqrt{\rho_0^\epsilon(x)}\exp(\frac{i}{\epsilon}S^\epsilon(x)), \end{cases} \tag{1.1}$$

where ϵ is the normalized Planck constant, and the potential $V^\epsilon(t,x)$ is assumed to be given self-consistently by Poisson's equation,

$$-\triangle V^\epsilon = \rho^\epsilon - b(x), \quad \rho^\epsilon(t,x) = |\psi^\epsilon(t,x)|^2, \tag{1.2}$$

where V^ϵ and $\nabla_x V$ vanish as $|x|\to\infty$, and the function $b(x)$ denotes the doping profile in the semiconductor applications, and, in general, it denotes a fixed background charge. One may see [17] or [5] for more physical explanations..

As was commented in [5], it is a fundamental principle in quantum mechanics that when the time and distance scales are large enough relative to the Planck's constant, the quantum density, $|\psi^\epsilon|^2$, and the quantum momentum, $\epsilon\mathrm{Im}(\overline{\psi^\epsilon}\nabla\psi^\epsilon)$, will approximately obey the laws of classical, Newtonian mechanics. And the quantum-mechanical pressure disappears in the semiclassical limit, and Euler equations for an isentropic compressible flow are formally recovered from the nonlinear Schrödinger equation. In one space dimension with $V^\epsilon = |\psi^\epsilon|^2 - 1$, the global character of the semiclassical limit was established by Jin, Levermore, and McLaughlin [10], [11] using

the inverse scattering method; for $d \geq 2$, $V^\epsilon = f(|\psi^\epsilon|^2)$ with $f' > 0$, before the formation of singularities in the limit system, Grenier [9] solved the limit by applying the symmetric hyperbolic equation theory. The semiclassical limit of the general modified nonlinear Schrödinger equation (see [3]) can be compared to the similar strategy of Grenier's. But we will see that this method does not work for the semiclassical limit of the Schrödinger–Poisson equations if we follow the idea of [9], as the resulting limit equations are not a symmetric hyperbolic system; thus the standard energy estimate which works well there fails here.

Traditional method suggests that, at least for short time, the wave function $\psi^\epsilon(t,x)$ for (1.1) will be of the following form:

$$\psi^\epsilon(t,x) = \sqrt{\rho^\epsilon(t,x)} \exp\left(\frac{i}{\epsilon} S^\epsilon(t,x)\right). \tag{1.3}$$

Then by substituting (1.3) to (1.1) and separating the real and imaginary part in (1.1), the irrotational flow equations

$$\begin{cases} \partial_t \rho^\epsilon + \operatorname{div} J^\epsilon = 0, \\ \partial_t J^\epsilon + \operatorname{div}\left(\frac{J^\epsilon \otimes J^\epsilon}{\rho^\epsilon}\right) + \rho^\epsilon \nabla V^\epsilon = \frac{\epsilon^2}{2} \rho^\epsilon \nabla\left[\frac{1}{\sqrt{\rho^\epsilon}} \triangle \sqrt{\rho^\epsilon}\right], \end{cases} \tag{1.4}$$

where $J^\epsilon = \rho^\epsilon \nabla S^\epsilon = \epsilon \operatorname{Im}(\overline{\psi^\epsilon} \nabla \psi^\epsilon)$ and $\otimes$ denotes the tensor product of vectors (see the notation at the end of the introduction), are obtained in [12]. Equations (1.4) represent a fluid dynamic formulation of (1.1) and are known as Madelung's fluid equations [15]. The semiclassical limit of (1.1) just means the vanishing dispersion limit to (1.4). Unfortunately, we can do almost nothing for the vanishing dispersion limit due to the strong singularity on the set $\{(t,x) | \rho^\epsilon(t,x) = 0\}$.

Motivated by recent work of Brenier [1], where the author proved the local-in-time convergence of the scaled Vlasov–Poisson equations to the incompressible Euler equations, we are going to use the Wigner measure approach to study the semiclassical limit of (1.1). In 1932, Wigner [23] introduced the following transformation in quantum mechanics:

$$f^\epsilon(t,x,\xi) = \frac{1}{(2\pi)^d} \int_{\mathbb{R}^d} e^{-i\xi y} \psi^\epsilon\left(t, x + \frac{\epsilon y}{2}\right) \overline{\psi^\epsilon\left(t, x - \frac{\epsilon y}{2}\right)}\, dy. \tag{1.5}$$

Then trivial calculation shows that $f^\epsilon(t,x,\xi)$ satisfies the equation

$$\begin{cases} \partial_t f^\epsilon + \xi \nabla f^\epsilon + \theta[V^\epsilon] f^\epsilon = 0, \\ f^\epsilon(t=0,x,\xi) = f_I^\epsilon(x,\xi), \end{cases} \tag{1.6}$$

where $\theta[V^\epsilon] f^\epsilon(t,x,\xi)$ is the pseudodifferential operator

$$\theta[V^\epsilon] f^\epsilon(t,x,\xi) = \frac{i}{(2\pi)^d} \int_{\mathbb{R}^d} \int_{\mathbb{R}^d} \frac{V^\epsilon(t, x + \frac{\epsilon y}{2}) - V^\epsilon(t, x - \frac{\epsilon y}{2})}{\epsilon} f^\epsilon(t,x,\eta) e^{-i(\xi-\eta)y}\, d\eta\, dy. \tag{1.7}$$

Formally passing $\epsilon \to 0$ in (1.6), we get

$$\begin{cases} \partial_t f + \xi \nabla_x f - E \nabla_\xi f = 0, \qquad E = \nabla \triangle^{-1}(b(x) - \rho), \\ f(t=0,x,\xi) = f_0(x,\xi), \end{cases} \tag{1.8}$$

where $f(t,x,\xi)$ is the weak limit of $f^\epsilon(t,x,\xi)$, which is a nonnegative Radon measure (see [14] or [7] for more details). Recently we [25] rigorously justified the limit

from (1.6) to (1.8) in one space dimension with very general initial data to the wave function.

On the other hand, with the initial data of the form $\psi_0^\epsilon(x) = \sqrt{\rho_0^\epsilon(x)}\exp(\frac{i}{\epsilon}S^\epsilon(x))$, and assuming that $\{\rho_0^\epsilon(x)\}, \{\nabla S^\epsilon(x)\}$ converge to $\rho_0(x)$ and $u_0(x)$ in some sense (see assumption (A3) below), we can easily calculate that the corresponding Wigner measure $f_0(x,\xi)$ is $\rho_0(x)\delta(\xi - u_0(x))$. Taking this $f_0(x,\xi)$ as initial data for (1.8), formally we can expect that there is a positive constant T^* such that (1.8) has a solution of the form $\rho(t,x)\delta(\xi - u(t,x))$ for $t < T^*$, and $(\rho(t,x), u(t,x))$ is smooth for $t < T^*$. Then by the velocity average to (1.8), we find

$$\left\{\begin{array}{l} \partial_t\rho + \mathrm{div}(\rho u) = 0, \\ \partial_t(\rho u) + \mathrm{div}(\rho u\otimes u) + \rho\nabla V = 0, \qquad \triangle V = b(x) - \rho. \end{array}\right. \tag{1.9}$$

In the following, we will give a rigorous justification to the above formal explanation. It should be noticed that this idea has been used by Gasser and Markowich [4] in the study of the semiclassical limit of the linear Schrödinger equation, where the limit from (1.6) to (1.8) was proved in [14].

Before the presentation of the main result of this paper, let us first make the following assumptions:

(A1) $b(x), \sqrt{\rho_0^\epsilon(x)}, S^\epsilon(x) \in H^s(\mathbb{R}^d)$ for $s \in \mathbb{Z}^+$ and $s > \frac{d}{2} + 2$;

(A2) $b(x) \in L^1(\mathbb{R}^d)$, $\rho_0^\epsilon(x)$ is uniformly bounded in $L^1(\mathbb{R}^d)\cap L^2(\mathbb{R}^d)$, and $\nabla\sqrt{\rho_0^\epsilon}(x)$ and $\sqrt{\rho_0^\epsilon}\nabla S^\epsilon(x)$ are uniformly bounded in $L^2(\mathbb{R}^d)$;

(A3) $\nabla\triangle^{-1}(\rho_0^\epsilon - \rho_0)(x) \to 0$, $\sqrt{\rho_0^\epsilon}(\nabla S^\epsilon - u_0)(x) \to 0$ in $L^2(\mathbb{R}^d)$, and $\rho_0(x) \in H^{s-1}(\mathbb{R}^d), u_0(x) \in H^s(\mathbb{R}^d)$, with $s \in \mathbb{Z}^+$ and $s > \frac{d}{2} + 2$;

(A4) when $d = 1$, 2, we further need that

$$\int_{\mathbb{R}^d} \rho_0^\epsilon(x)\,dx = \int_{\mathbb{R}^d} b(x)\,dx = \int_{\mathbb{R}^d} \rho_0(x)\,dx,$$
$$\int_{\mathbb{R}^d} |x||\rho_0^\epsilon(x) - b(x)|\,dx < C,$$

with C an ϵ-independent positive constant.

From now on, let us denote by (ρ, u) the local smooth solution to the following equations:

$$\left\{\begin{array}{l} \partial_t\rho + \mathrm{div}(\rho u) = 0, \\ \partial_t u + u\nabla u + \nabla V = 0, \quad \triangle V = b(x) - \rho, \\ \rho(t=0,x) = \rho_0, \quad u(t=0,x) = u_0, \end{array}\right. \tag{1.10}$$

where V and $\nabla_x V$ vanish as $|x| \to \infty$. Notice that any smooth solution of (1.10) must be a smooth solution of (1.9). Because of the degeneracy of the second equation of (1.9) on the set $\{(t,x) : \rho(t,x) = 0\}$, we will consider (1.10) as the limit system instead of (1.9).

For the convenience of the reader, let us recall the test function space from [14],

$$\mathcal{A} = \left\{\phi \in C_c^\infty(\mathbb{R}^d_x \times \mathbb{R}^d_\xi)|, \quad (\mathcal{F}_\xi\phi)(x,\eta) \in L^1(\mathbb{R}^d_\eta, C_c(\mathbb{R}^d_x))\right\}, \tag{1.11}$$

with the norm

$$\|\phi(x,\xi)\|_{\mathcal{A}} = \int_{\mathbb{R}^d} \sup_x |(\mathcal{F}_\xi\phi)(x,\eta)|\,d\eta, \tag{1.12}$$

where $(\mathcal{F}_\xi \phi)(x,\eta)$ is the Fourier transformation of $\phi(x,\xi)$ with respect to ξ.

DEFINITION 1.1. *We call* $f^\epsilon(t,x,\xi)$ *the* Wigner transformation *of* $\psi^\epsilon(t,x)$ *for any fixed* t. *The corresponding weak limit* $f(t,x,\xi)$, *which we will detail in what follows, of* $f^\epsilon(t,\cdot,\cdot)$ *as* $\epsilon \to 0$ *is called the* Wigner measure *of* $\psi^\epsilon(t,x)$.

Remark 1.1. The Wigner measure $f(t,x,\xi)$ is in fact a nonnegative Radon measure for any fixed time t. See [14] and [7] for more details. Moreover, $f(t,x,\xi)$ has a very close relation with the H-measure of $\{\psi^\epsilon(t,x))\}$ (see [20], [6], or [14]).

Then we have the following theorem.

THEOREM 1.1. *Let* $(\rho_0^\epsilon(x), S^\epsilon(x)), (\rho_0(x), u_0(x))$ *satisfy* (A1)–(A4), *and let* $\psi^\epsilon(t,x)$, $(\rho(t,x), u(t,x))$ *be the solutions of* (1.1)–(1.2) *and* (1.10), *respectively. Then there exists a positive constant* T^* *such that for all* $T < T^*$, $\rho(t,x) \in L^\infty([0,T], H^{s-1}(\mathbb{R}^d))$, $u(t,x) \in L^\infty([0,T], H^s(\mathbb{R}^d))$. *Moreover, for any fixed* $t < T^*$, *the following hold:*

(1)

$$f^\epsilon(t,x,\xi) \rightharpoonup f(t,x,\xi) =: \rho(t,x)\delta(\xi - u(t,x)) \quad in \quad \mathcal{A}'(\mathbb{R}^{2d}), \tag{1.13}$$

$$|\psi^\epsilon(t,x)|^2 \rightharpoonup \rho(t,x) \quad in \quad \mathcal{M}^+(\mathbb{R}^d), \tag{1.14}$$

$$\epsilon \mathrm{Im}\left(\overline{\psi^\epsilon}(t,x)\nabla\psi^\epsilon(t,x)\right) \rightharpoonup (\rho u)(t,x) \quad in \quad \mathcal{M}(\mathbb{R}^d), \tag{1.15}$$

as ϵ *tends to* 0, *and* T^* *is the first time such that*

$$\lim_{T \to T^*} \|\nabla u(t,\cdot)\|_{L^\infty([0,T]\times\mathbb{R}^d)} = \infty. \tag{1.16}$$

(2) $f(t,x,\xi) \in Lip([0,T^*), H^{-s}(\mathbb{R}^{2d}))$ *for* $s > d+1$ *and* $f(t,x,\xi)$ *satisfies* (1.8) *on* $[0,T^*) \times \mathbb{R}^{2d}$ *in the sense of distribution.*

Remark 1.2. When $d = 1$ and $\rho_0^\epsilon(x)$, $S^\epsilon(x)$ are smooth, we can prove that the Wigner measure $f(t,x,\xi)$ globally solves the one-dimensional Vlasov–Poisson equations (see [25] for more details). Then by (3.35) and the proof of (3.41), up to a subsequence of $\{\psi^\epsilon\}$, which we denote by $\{\psi^{\epsilon_j}\}$ for any fixed $t \geq T^*$, there holds

$$\begin{aligned} &f^\epsilon(t,x,\xi) \rightharpoonup f(t,x,\xi) \quad \text{in} \quad \mathcal{A}'(\mathbb{R}^{2d}), \\ &\epsilon \mathrm{Im}\left(\overline{\psi^\epsilon}(t,x)\nabla\psi^\epsilon(t,x)\right) \rightharpoonup \int_{\mathbb{R}} \xi f(t,x,d\xi) \quad \text{in} \quad \mathcal{M}(\mathbb{R}^d) \end{aligned}$$

as $\epsilon \to 0$, where $f(t,x,\xi)$ is the global weak solution of the one-dimensional Vlasov–Poisson equations

$$\begin{cases} \partial_t f + \xi \partial_\xi - E\partial_\xi f = 0, \quad x \in \mathbb{R}, t \geq 0, \\ \partial_x E = b(x) - \int_{\mathbb{R}} f(t,x,d\xi), \\ f(t=0,x,\xi) = \rho_0(x)\delta(\xi - u_0(x)). \end{cases} \tag{1.17}$$

But from [11], we cannot expect that the limits of the quantum density and momentum to the Schrödinger–Poisson equations satisfy (1.9) after the formation of singularities in the limit system.

Remark 1.3. Recently Lin and Zhang [13] rigorously proved that before the formation of singularities in the limit system, the limit equation obtained by the hydrodynamic limit of Ginzburg–Landau wave vortices is again (1.10).

Notation used throughout this paper. Let $a = (a_1, a_2, \ldots, a_d)$, $b = (b_1, b_2, \ldots, b_d)$ be two vectors; then we denote

$$a \otimes b = (a_i b_j)_{n\times n}.$$

Let $M^k(x) = \big(m^k_{ij}(x)\big)_{n\times n}$, $k = 1, 2$, be two $C^1(\mathbb{R}^d)$ matrix functions; then

$$M^1 : M^2 = \sum_{i,j=1}^{d} m^1_{ij} m^2_{ij}, \quad \nabla : M^1(x) = \begin{pmatrix} \mathrm{div}\vec{m}^1_1(x) \\ \cdot \\ \cdot \\ \cdot \\ \mathrm{div}\vec{m}^1_d(x) \end{pmatrix},$$

with $\vec{m}^1_i(x) = \big(m^1_{i1}(x), m^1_{i2}(x), \ldots, m^1_{id}(x)\big)$.

We denote by $\mathcal{M}\ (\mathbb{R}^d)$ the Radon measure space over $\mathbb{R}^d$, by $\hat{f}(\xi)$ the Fourier transform of $f(x)$, by $\alpha = (\alpha_1, \alpha_2, \ldots, \alpha_d)$ the multi-index, $D_x = \frac{1}{i}\nabla_x$, and by the letter C a uniform constant, which may change from line to line.

2. Preliminaries. In this section, we will present some uniform estimates to the smooth solution of the quantum Schrödinger–Poisson equations and prove the local existence of the smooth solution to (1.10).

LEMMA 2.1. *Let $(\rho^\epsilon_0(x), S^\epsilon(x))$ satisfy* (A1); *then for any fixed ϵ,* (1.1)–(1.2) *has a unique global smooth solution $\psi^\epsilon(t,x) \in L^\infty([0,T], H^s(\mathbb{R}^d))$ for any $T < \infty$. Moreover, the following hold:*

(1)

$$\|\psi^\epsilon(t,\cdot)\|_{L^2} = \|\rho^\epsilon_0\|^{\frac{1}{2}}_{L^1}; \tag{2.1}$$

(2)

$$\frac{d}{dt}\left\{\frac{\epsilon^2}{2}\|\nabla\psi^\epsilon(t,\cdot)\|^2_{L^2} + \|\nabla V^\epsilon(t,\cdot)\|^2_{L^2}\right\} = 0. \tag{2.2}$$

Proof. First, for any fixed ϵ, by modifying the method in [8] or [2], we easily obtain that (1.1) has a global smooth solution $\psi^\epsilon(t,x) \in L^\infty([0,T], H^s(\mathbb{R}^d))$ for any $T < \infty$, with initial data $\sqrt{\rho^\epsilon_0(x)}\exp(\frac{i}{\epsilon}S^\epsilon(x))$. Details are omitted.

By multiplying $\overline{\psi^\epsilon}(t,x)$ by both sides of (1.1), then integrating with respect to x over $\mathbb{R}^d$ and taking integration by parts, we obtain part (1) of Lemma 2.1.

Next, let us multiply $\partial_t\overline{\psi^\epsilon}(t,x)$ by both sides of (1.1), then integrating with respect to x and integrating by parts again, we have

$$i\epsilon\int_{\mathbb{R}^d}|\partial_t\psi^\epsilon|^2\,dx = \frac{\epsilon^2}{2}\int_{\mathbb{R}^d}\nabla\psi^\epsilon\partial_t\nabla\overline{\psi^\epsilon}\,dx + \int_{\mathbb{R}^d}V^\epsilon\psi^\epsilon\partial_t\overline{\psi^\epsilon}\,dx. \tag{2.3}$$

Taking the real part of (2.3), we find

$$\begin{aligned}\frac{\epsilon^2}{2}\frac{d}{dt}\int_{\mathbb{R}^d}|\nabla\psi^\epsilon(t,\cdot)|^2\,dx &= -\int_{\mathbb{R}^d}V^\epsilon\partial_t|\psi^\epsilon(t,\cdot)|^2\,dx \\ &= \int_{\mathbb{R}^d}V^\epsilon\partial_t\triangle V^\epsilon\,dx = -\frac{d}{dt}\int_{\mathbb{R}^d}|\nabla V^\epsilon(t,\cdot)|^2\,dx,\end{aligned} \tag{2.4}$$

where we used (1.2) in the next-to-last step of (2.4). Then (2.2) is a direct consequence of (2.4), which completes the proof of the lemma. ∎

Remark 2.1. By (A2) and (A4), we can prove that $\{\nabla V^\epsilon(0,x)\}$ is uniformly bounded in $L^2(\mathbb{R}^d)$. In fact, for $d \geq 3$, for any fixed positive constant M, we have

$$\begin{aligned}
\|\nabla V^\epsilon(0,x)\|_{L^2} &= \left(\int_{\mathbb{R}^d} |\nabla \triangle^{-1}(\rho_0^\epsilon - b)(x)|^2\, dx\right)^{\frac{1}{2}} \\
&= \left(\int_{\mathbb{R}^d} \left|\frac{\xi}{|\xi|^2}(\hat{\rho_0^\epsilon} - \hat{b})(\xi)\right|^2 d\xi\right)^{\frac{1}{2}} \\
&\leq \left(\int_{|\xi|\leq M} \frac{1}{|\xi|^2}|(\hat{\rho_0^\epsilon} - \hat{b})(\xi)|^2\, d\xi\right)^{\frac{1}{2}} + \frac{1}{M}\left(\int_{\mathbb{R}^d} |(\hat{\rho_0^\epsilon} - \hat{b})(\xi)|^2\, d\xi\right)^{\frac{1}{2}} \\
&\leq CM^{\frac{d-2}{2}}\|(\hat{\rho_0^\epsilon} - \hat{b})\|_{L^\infty} + \frac{1}{M}\|\rho_0^\epsilon - b\|_{L^2}, \qquad (2.5)
\end{aligned}$$

but by [19], we have

$$\|(\hat{\rho_0^\epsilon} - \hat{b})\|_{L^\infty} \leq \|\rho_0^\epsilon - b\|_{L^1}. \qquad (2.6)$$

By combining (A2) and (2.5) with (2.6), we get the estimate for $\|\nabla V^\epsilon(0,x)\|_{L^2}$ for $d \geq 3$, while for $d = 1, 2$, by (A4), we have $\int_{\mathbb{R}^d}(\rho_0^\epsilon - b)(x)\, dx = 0$, which directly implies that

$$(\hat{\rho_0^\epsilon} - \hat{b})(0) = 0;$$

then by the calculations in (2.5), we have

$$\begin{aligned}
\|\nabla V^\epsilon(0,x)\|_{L^2} &= \left(\int_{\mathbb{R}^d} \left|\frac{\xi}{|\xi|^2}\{(\hat{\rho_0^\epsilon} - \hat{b})(\xi) - (\hat{\rho_0^\epsilon} - \hat{b})(0)\}\right|^2 d\xi\right)^{\frac{1}{2}} \\
&\leq CM^{\frac{d}{2}}\|\nabla_\xi(\hat{\rho_0^\epsilon} - \hat{b})(\xi)\|_{L^\infty} + \frac{1}{M}\|\rho_0^\epsilon - b\|_{L^2} \\
&\leq CM^{\frac{d}{2}}\int_{\mathbb{R}^d} |x||\rho_0^\epsilon - b|\, dx + \frac{1}{M}\|\rho_0^\epsilon - b\|_{L^2}, \qquad (2.7)
\end{aligned}$$

which, together with (A2) and (A4), provides the estimate for $\|\nabla V^\epsilon(0,x)\|_{L^2}$.

LEMMA 2.2. *Let $s \in \mathbb{Z}^+, s > \frac{d}{2} + 2$, $(\rho_0(x), u_0(x))$ satisfy* (A3); *then there exists a positive constant $T^* > 0$ such that* (1.10) *has a unique solution $\rho(t,x) \in L^\infty([0,T], H^{s-1}(\mathbb{R}^d))$, $u(t,x) \in L^\infty([0,T], H^s(\mathbb{R}^d))$ for all $T < T^*$; moreover,*

$$\frac{d}{dt}\int_{\mathbb{R}^d} (\rho|u|^2 + |\nabla V|^2)(t,x)\, dx = 0, \qquad t < T^*, \qquad (2.8)$$

where T^* is the first time such that

$$\lim_{T\to T^*} \|\nabla u(t,x)\|_{L^\infty([0,T]\times\mathbb{R}^d)} = \infty. \qquad (2.9)$$

Proof. From the standard theory on the hyperbolic system of equations [16], we know that we can find a positive constant T such that (1.10) has a local solution (ρ, u) with $\rho(t,x) \in L^\infty([0,T], H^{s-1}(\mathbb{R}^d))$, $u(t,x) \in L^\infty([0,T], H^s(\mathbb{R}^d))$; moreover, it holds that

$$\|\rho(t,\cdot)\|_{L^\infty([0,T],H^{s-1}(\mathbb{R}^d))} + \|u(t,\cdot)\|_{L^\infty([0,T],H^s(\mathbb{R}^d))} \leq C(T, \|\rho_0\|_{H^{s-1}}, \|u_0\|_{H^s}). \qquad (2.10)$$

Hence to complete the lemma, we only need to show that if $\|\nabla u(t,x)\|_{L^\infty([0,T]\times\mathbb{R}^d)} < \infty$, then (2.8) and (2.10) hold for $t \le T$. As a convention in the rest of this section, we always assume that all the calculations are to be done for $t \le T$.

First, by multiplying (ρu) by the second equation of (1.10) and integrating over $\mathbb{R}^d$, we find

$$\frac{1}{2}\frac{d}{dt}\int_{\mathbb{R}^d}\rho|u|^2\,dx + \int_{\mathbb{R}^d}\rho u\nabla V\,dx = 0, \tag{2.11}$$

where we used the first equation of (1.10); then by integration by parts and (1.10) again, we have

$$\begin{aligned}\int_{\mathbb{R}^d}\rho u\nabla V\,dx &= -\int_{\mathbb{R}^d}\mathrm{div}(\rho u)V\,dx = \int_{\mathbb{R}^d}\partial_t\rho V\,dx = -\int_{\mathbb{R}^d}\partial_t\triangle V V\,dx\\ &= \frac{1}{2}\frac{d}{dt}\int_{\mathbb{R}^d}|\nabla V|^2\,dx.\end{aligned} \tag{2.12}$$

By summing up (2.11) and (2.12) together, we prove (2.8).

On the other hand, by (A2), (A4), and Fatou's lemma, we have

$$\begin{aligned}&\|\rho_0 - b\|_{L^1} \le \lim_{\epsilon\to 0}\|\rho_0^\epsilon - b\|_{L^1},\\ &\int_{\mathbb{R}^d}|x||\rho_0 - b|\,dx \le \overline{\lim}_{\epsilon\to 0}\int_{\mathbb{R}^d}|x||\rho_0^\epsilon - b|\,dx \quad \text{for} \quad d = 1,2.\end{aligned} \tag{2.13}$$

Thus by exactly the same proof as that of Remark 2.1, we get $\nabla V(0,x) \in L^2(\mathbb{R}^d)$. This together with (2.8) shows that

$$\int_{\mathbb{R}^d}\left(\frac{1}{2}\rho|u|^2 + |\nabla V|^2\right)(t,x)\,dx \le \int_{\mathbb{R}^d}\left(\frac{1}{2}\rho_0|u_0|^2 + |\nabla V(0,x)|^2\right)dx \le C. \tag{2.14}$$

Next we multiply (ρ, u) by (1.10) and integrate over $\mathbb{R}^d$ to obtain

$$\begin{aligned}&\frac{1}{2}\frac{d}{dt}\int_{\mathbb{R}^d}(\rho^2 + |u|^2)(t,x)\,dx\\ &\le \frac{1}{2}\|\mathrm{div}u\|_{L^\infty}\int_{\mathbb{R}^d}(\rho^2 + |u|^2)\,dx + \|\nabla V(t,\cdot)\|_{L^2}\|u(t,\cdot)\|_{L^2}.\end{aligned} \tag{2.15}$$

On the other hand, by taking $\partial_x^{\alpha-1}$ (resp., ∂_x^α) to the first (resp., second) equation of (1.10) for $|\alpha| \le s$, and multiplying $\partial_x^{\alpha-1}\rho(t,x)$ (resp., $\partial_x^\alpha u(t,x)$) to the resulting equation and integrating over $\mathbb{R}^d$, we find

$$\begin{aligned}&\frac{1}{2}\frac{d}{dt}\left(\|\partial_x^{\alpha-1}\rho(t,\cdot)\|_{L^2}^2 + \|\partial_x^\alpha u(t,\cdot)\|_{L^2}^2\right)\\ &\le \left|\int_{\mathbb{R}^d}\left\{\partial_x^{\alpha-1}\mathrm{div}(\rho u)\partial_x^{\alpha-1}\rho + \partial_x^\alpha(u\nabla u)\partial_x^\alpha u + \partial_x^\alpha\nabla V\partial_x^\alpha u\right\}dx\right|;\end{aligned} \tag{2.16}$$

however, by a Moser-type calculus inequality (see [16]), we find

$$\begin{aligned}&\left|\int_{\mathbb{R}^d}\partial_x^{\alpha-1}\mathrm{div}(\rho u)\partial_x^{\alpha-1}\rho\,dx\right|\\ &= \left|\int_{\mathbb{R}^d}u\nabla\partial_x^{\alpha-1}\rho\partial_x^{\alpha-1}\rho\,dx + \int_{\mathbb{R}^d}(\partial_x^{\alpha-1}\mathrm{div}(\rho u) - u\nabla\partial_x^{\alpha-1}\rho)\partial_x^{\alpha-1}\rho\,dx\right|\\ &\le \frac{1}{2}\|\nabla u\|_{L^\infty}\|\partial_x^{\alpha-1}\rho\|_{L^2}^2 + \{\|\nabla u\|_{L^\infty}\|\partial_x^{|\alpha|-1}\rho\|_{L^2} + \|\rho\|_{L^\infty}\|\partial_x^{|\alpha|}u\|_{L^2}\}\|\partial_x^{\alpha-1}\rho\|_{L^2}.\end{aligned} \tag{2.17}$$

Exactly as in the proof of (2.17), we have

$$\left|\int_{\mathbb{R}^d} \partial_x^\alpha(u\nabla u)\partial_x^\alpha u\,dx\right| \le \frac{1}{2}\|\nabla u\|_{L^\infty}\|\partial_x^\alpha u\|_{L^2}^2 + 2\|\nabla u\|_{L^\infty}\|\partial_x^{|\alpha|}u\|_{L^2}\|\partial_x^\alpha u\|_{L^2}, \tag{2.18}$$

and, trivially,

$$\begin{aligned}\left|\int_{\mathbb{R}^d} \partial_x^\alpha \nabla V \partial_x^\alpha u\,dx\right| &= \left|\int_{\mathbb{R}^d} \partial_x^\alpha \nabla\triangle^{-1}(\rho-b)\partial_x^\alpha u\,dx\right| \\ &\le (C + \|\partial_x^{\alpha-1}\rho\|_{L^2})\|\partial_x^\alpha u\|_{L^2}.\end{aligned} \tag{2.19}$$

By summing up (2.15)–(2.19), and doing summation for $|\alpha| \le s$, we finally get

$$\frac{d}{dt}\left(\|\rho(t,\cdot)\|_{H^{s-1}}^2 + \|u(t,\cdot)\|_{H^s}^2\right) \le C(1+\|\nabla u\|_{L^\infty})\left(\|\rho(t,\cdot)\|_{H^{s-1}}^2 + \|u(t,\cdot)\|_{H^s}^2\right). \tag{2.20}$$

Equation (2.20) together with the Gronwall inequality implies that if

$$\|\nabla u(t,\cdot)\|_{L^\infty([0,T]\times\mathbb{R}^d)} < \infty,$$

then (2.10) holds. This completes the proof of the lemma. □

3. Proof of Theorem 1.1. With the fundamental lemmas, Lemmas 2.1 and 2.2, motivated by [1], for $t < T^*$, let us define

$$H_u^\epsilon(t) = \frac{1}{2}\int_{\mathbb{R}^d}\int_{\mathbb{R}^d} |\xi - u(t,x)|^2 f^\epsilon(t,x,\xi)\,d\xi\,dx + \frac{1}{2}\int_{\mathbb{R}^d} |\nabla\triangle^{-1}(\rho^\epsilon - \rho)|^2\,dx, \tag{3.1}$$

where (ρ, u) is the unique local smooth solution of (1.10), and T^* is the positive constant determined by Lemma 2.2. In the following, we are going to show that $\lim_{\epsilon\to 0} H_u^\epsilon(t) = 0$ for $0 \le t < T^*$, which directly implies that the Wigner measure $f(t,x,\xi)$, which is the weak limit of $f^\epsilon(t,x,\xi)$ in some sense (see [14] or [7]), equals $\rho(t,x)\delta(\xi - u(t,x))$. The idea of the proof is somewhat similar to that used in [22] and [24], where we needed to control the variance of the L^p Young measures associated with the approximate solution sequences to the problems there. So now we need to derive an evolution equation for $H_u^\epsilon(t)$.

To begin, let us calculate the first two moment equations of (1.6).

LEMMA 3.1. *Let* $\rho^\epsilon(t,x) =: |\psi^\epsilon(t,x)|^2$, $J^\epsilon(t,x) =: \epsilon Im(\overline{\psi^\epsilon}\nabla\psi^\epsilon)(t,x)$; *then the following hold:*

(1)

$$\partial_t\rho^\epsilon + \mathrm{div}J^\epsilon = 0, \tag{3.2}$$

$$\partial_t J^\epsilon + \nabla_x : \int_{\mathbb{R}^d} \xi\otimes\xi f^\epsilon\,d\xi + \nabla V^\epsilon\rho^\epsilon = 0; \tag{3.3}$$

(2)

$$\frac{d}{dt}\left\{\frac{1}{2}\int_{\mathbb{R}^d}\int_{\mathbb{R}^d} f^\epsilon|\xi|^2\,dx\,d\xi + \int_{\mathbb{R}^d}|\nabla V^\epsilon|^2\,dx\right\} = 0. \tag{3.4}$$

Proof. First, notice by [14] (or [7]) that we have $\int_{\mathbb{R}^d} f^\epsilon(t,x,\xi)\,d\xi = \rho^\epsilon(t,x)$, and by Lemma 2.1, for any fixed $\epsilon>0, t, x$, $D_y\{\psi^\epsilon(t,x+\frac{\epsilon y}{2})\overline{\psi^\epsilon(t,x-\frac{\epsilon y}{2})}\} \in (L^1_y\cap H^s_y)(\mathbb{R}^d)$ with $s>\frac{d}{2}+1$. Thus by Remark 3.1, we have

$$\begin{aligned}\int_{\mathbb{R}^d}\xi f^\epsilon(t,x,\xi)\,d\xi &= \frac{1}{(2\pi)^d}\int_{\mathbb{R}^d}\int_{\mathbb{R}^d} e^{-i\xi y}\xi\psi^\epsilon\left(t,x+\frac{\epsilon y}{2}\right)\overline{\psi^\epsilon\left(t,x-\frac{\epsilon y}{2}\right)}\,dy\,d\xi\\ &= \frac{1}{(2\pi)^d}\int_{\mathbb{R}^d}\int_{\mathbb{R}^d} e^{-i\xi y}D_y\left\{\psi^\epsilon\left(t,x+\frac{\epsilon y}{2}\right)\overline{\psi^\epsilon\left(t,x-\frac{\epsilon y}{2}\right)}\right\}\,dy\,d\xi\\ &= D_y\left\{\psi^\epsilon\left(t,x+\frac{\epsilon y}{2}\right)\overline{\psi^\epsilon\left(t,x-\frac{\epsilon y}{2}\right)}\right\}\Big|_{y=0} = J^\epsilon(t,x). \end{aligned}\tag{3.5}$$

And by (1.7), we have

(3.6)

$$\begin{aligned}&\int_{\mathbb{R}^d}\xi^\alpha\theta[V^\epsilon]f^\epsilon(t,x,\xi)\,d\xi\\ &= \frac{i}{(2\pi)^d}\int_{\mathbb{R}^d} f^\epsilon(t,x,\eta)\int_{\mathbb{R}^d}\int_{\mathbb{R}^d} e^{-i(\xi-\eta)y}\xi^\alpha\frac{V^\epsilon(t,x+\frac{\epsilon y}{2})-V^\epsilon(t,x-\frac{\epsilon y}{2})}{\epsilon}\,dy\,d\xi\,d\eta\\ &= \frac{i}{(2\pi)^d}\int_{\mathbb{R}^d} f^\epsilon(t,x,\eta)\int_{\mathbb{R}^d}\int_{\mathbb{R}^d} e^{-i\xi y}D_y^\alpha\left(\frac{V^\epsilon(t,x+\frac{\epsilon y}{2})-V^\epsilon(t,x-\frac{\epsilon y}{2})}{\epsilon}e^{-i\eta y}\right)\,dy\,d\xi\,d\eta.\end{aligned}$$

In particular, by taking $|\alpha|=0$ and $|\alpha|=1$ in (3.6), Remark 3.1 directly implies that

$$\begin{aligned}&\int_{\mathbb{R}^d}\theta[V^\epsilon]f^\epsilon(t,x,\xi)\,d\xi = 0,\\ &\int_{\mathbb{R}^d}\xi\theta[V^\epsilon]f^\epsilon(t,x,\xi)\,d\xi = \int_{\mathbb{R}^d} f^\epsilon(t,x,\eta)\nabla V^\epsilon(t,x)\,d\eta = (\rho^\epsilon\nabla V^\epsilon)(t,x).\end{aligned}\tag{3.7}$$

With (3.5)–(3.7), by integrating (1.6) over $\mathbb{R}^d$ with respect to ξ, we get (3.2), and by multiplying (1.6) by ξ and integrating over $\mathbb{R}^d$ with respect to ξ again, we find that (3.3) holds.

On the other hand, exactly as in the proof of (3.5), we have

$$\begin{aligned}\int_{\mathbb{R}^d}\int_{\mathbb{R}^d}|\xi|^2 f^\epsilon(t,x,\xi)\,d\xi\,dx &= -\frac{\epsilon^2}{4}\int_{\mathbb{R}^d}\{\overline{\psi^\epsilon}\triangle\psi^\epsilon - 2\nabla\psi^\epsilon\nabla\overline{\psi^\epsilon}+\psi^\epsilon\triangle\overline{\psi^\epsilon}\}\,dx\\ &= \epsilon^2\int_{\mathbb{R}^d}|\nabla\psi^\epsilon|^2\,dx.\end{aligned}\tag{3.8}$$

Equation (2.2) together with (3.8) shows that (3.4) holds. This completes the proof of Lemma 3.1. □

Remark 3.1. Let $s>\frac{d}{2}$, $f(y)\in(L^1\cap H^s)(\mathbb{R}^d)$; then we claim that

$$\frac{1}{(2\pi)^d}\int_{\mathbb{R}^d}\int_{\mathbb{R}^d} e^{-i\xi y}f(y)\,dy\,d\xi = f(0).\tag{3.9}$$

In fact, as $f(y)\in L^1(\mathbb{R}^d)$, by [19], $\hat{f}(\xi) = \frac{1}{(2\pi)^d}\int_{\mathbb{R}^d} e^{-i\xi y}f(y)\,dy$. On the other hand, by the fact that $f(y)\in H^s(\mathbb{R}^d)$ for $s>\frac{d}{2}$, we have

$$\hat{f}(\xi) = \frac{1}{(1+|\xi|^2)^{\frac{s}{2}}}\widehat{\psi^s(D)f}(\xi)\in L^1(\mathbb{R}^d),\tag{3.10}$$

where $\psi^s(D)$ is the pseudodifferential operator (see [21]) with symbol $(1+|\xi|^2)^{\frac{s}{2}}$. Hence by (3.10) and [19] again, we have

$$f(y) = \int_{\mathbb{R}^d} e^{i\xi y}\hat{f}(\xi)\,d\xi. \tag{3.11}$$

In particular, by taking $y=0$ in (3.11), we prove (3.9).

Next let us derive the evolution equation for $H_u^\epsilon(t)$.

LEMMA 3.2. *For $H_u^\epsilon(t)$ defined in* (3.1), *there holds*

$$\begin{aligned}\frac{d}{dt}H_u^\epsilon(t) = &-\int_{\mathbb{R}^d} Du : \int_{\mathbb{R}^d}(\xi-u)\otimes(\xi-u)f^\epsilon\,d\xi\,dx - \frac{1}{2}\int_{\mathbb{R}^d}\mathrm{div}u|\nabla\triangle^{-1}(\rho-\rho^\epsilon)|^2\,dx\\ &+\int_{\mathbb{R}^d} Du : \left(\nabla\triangle^{-1}(\rho^\epsilon-\rho)\otimes\nabla\triangle^{-1}(\rho^\epsilon-\rho)\right)\,dx.\end{aligned} \tag{3.12}$$

Proof. First, by (3.4), we find

$$\begin{aligned}\frac{d}{dt}H_u^\epsilon(t) = &\frac{1}{2}\frac{d}{dt}\int_{\mathbb{R}^d}|u|^2\rho^\epsilon\,dx - \frac{d}{dt}\int_{\mathbb{R}^d}uJ^\epsilon\,dx\\ &+\frac{1}{2}\frac{d}{dt}\int_{\mathbb{R}^d}|\nabla\triangle^{-1}(\rho-b)|^2\,dx - \frac{d}{dt}\int_{\mathbb{R}^d}\nabla\triangle^{-1}(\rho^\epsilon-b)\nabla\triangle^{-1}(\rho-b)\,dx.\end{aligned} \tag{3.13}$$

In the following, we are going to calculate the above four terms separately. First, by (3.2), we have

$$\begin{aligned}\frac{1}{2}\frac{d}{dt}\int_{\mathbb{R}^d}|u|^2\rho^\epsilon\,dx &= \int_{\mathbb{R}^d}\left\{u\partial_t u\rho^\epsilon + \frac{1}{2}|u|^2\partial_t\rho^\epsilon\right\}dx\\ &= \int_{\mathbb{R}^d}\left\{\partial_t u\rho^\epsilon u - \frac{1}{2}|u|^2\mathrm{div}J^\epsilon\right\}dx\\ &= \int_{\mathbb{R}^d}\left\{\partial_t u\rho^\epsilon u + \frac{1}{2}J^\epsilon\nabla|u|^2\right\}dx,\end{aligned} \tag{3.14}$$

and by (3.3), we have

$$\begin{aligned}-\frac{d}{dt}\int_{\mathbb{R}^d}J^\epsilon u\,dx &= \int_{\mathbb{R}^d}\{-\partial_t J^\epsilon u - J^\epsilon\partial_t u\}\,dx\\ &= \int_{\mathbb{R}^d}\left\{\left(\nabla_x : \int_{\mathbb{R}^d}\xi\otimes\xi f^\epsilon\,d\xi + \nabla V^\epsilon\rho^\epsilon\right)u - J^\epsilon\partial_t u\right\}dx\\ &= -\int_{\mathbb{R}^d}Du : \int_{\mathbb{R}^d}\xi\otimes\xi f^\epsilon\,d\xi\,dx + \int_{\mathbb{R}^d}\nabla V^\epsilon\rho^\epsilon u\,dx - \int_{\mathbb{R}^d}J^\epsilon\partial_t u\,dx,\end{aligned} \tag{3.15}$$

while by (1.10), we have

$$\begin{aligned}\frac{1}{2}\frac{d}{dt}\int_{\mathbb{R}^d}|\nabla\triangle^{-1}(\rho-b)|^2\,dx &= \int_{\mathbb{R}^d}\nabla\triangle^{-1}(\rho-b)\nabla\triangle^{-1}\partial_t\rho\,dx\\ &= -\int_{\mathbb{R}^d}\nabla\triangle^{-1}(\rho-b)\nabla\triangle^{-1}\mathrm{div}(\rho u)\,dx\\ &= \int_{\mathbb{R}^d}\triangle^{-1}(\rho-b)\mathrm{div}(\rho u)\,dx\\ &= -\int_{\mathbb{R}^d}\rho u\nabla\triangle^{-1}(\rho-b)\,dx.\end{aligned} \tag{3.16}$$

Then by (1.10), (3.2), and a calculation similar to that in (3.16), we have

$$
\begin{aligned}
&-\frac{d}{dt}\int_{\mathbb{R}^d}\nabla\triangle^{-1}(\rho^\epsilon-b)\nabla\triangle^{-1}(\rho-b)\,dx\\
&=-\int_{\mathbb{R}^d}\nabla\triangle^{-1}\partial_t\rho^\epsilon\nabla\triangle^{-1}(\rho-b)\,dx-\int_{\mathbb{R}^d}\nabla\triangle^{-1}(\rho^\epsilon-b)\nabla\triangle^{-1}\partial_t\rho\,dx\\
&=\int_{\mathbb{R}^d}J^\epsilon\nabla\triangle^{-1}(\rho-b)\,dx+\int_{\mathbb{R}^d}\rho u\nabla\triangle^{-1}(\rho^\epsilon-b)\,dx. \qquad (3.17)
\end{aligned}
$$

By summing (3.13)–(3.17), we get

$$
\begin{aligned}
\frac{d}{dt}H_u^\epsilon(t)&=\int_{\mathbb{R}^d}\Big\{\big(\partial_t u+u\nabla u-\nabla\triangle^{-1}(\rho-b)\big)\rho^\epsilon u-u\nabla u\rho^\epsilon u+\nabla\triangle^{-1}(\rho-b)\rho^\epsilon u\\
&\quad+\frac{1}{2}J^\epsilon\nabla|u|^2-Du:\int_{\mathbb{R}^d}\xi\otimes\xi f^\epsilon\,d\xi+\nabla V^\epsilon\rho^\epsilon u\\
&\quad-J^\epsilon\big(\partial_t u+u\nabla u-\nabla\triangle^{-1}(\rho-b)\big)+u\nabla uJ^\epsilon+\rho u\nabla\triangle^{-1}(\rho^\epsilon-\rho)\Big\}\\
&=\int_{\mathbb{R}^d}\Big\{-u\nabla u\rho^\epsilon u-Du:\int_{\mathbb{R}^d}\xi\otimes\xi f^\epsilon\,d\xi+\frac{1}{2}J^\epsilon\nabla|u|^2+u\nabla uJ^\epsilon\\
&\quad+\nabla\triangle^{-1}(\rho-b)\rho^\epsilon u+\nabla V^\epsilon\rho^\epsilon u+\rho u\nabla\triangle^{-1}(\rho^\epsilon-\rho)\Big\}\,dx\\
&=-\int_{\mathbb{R}^d}Du:\int_{\mathbb{R}^d}(\xi-u)\otimes(\xi-u)f^\epsilon\,d\xi\,dx \qquad (3.18)\\
&\quad+\int_{\mathbb{R}^d}\big\{\nabla\triangle^{-1}(\rho-b)\rho^\epsilon u-\nabla\triangle^{-1}(\rho^\epsilon-b)\rho^\epsilon u+\rho u\nabla\triangle^{-1}(\rho^\epsilon-\rho)\big\}\,dx,
\end{aligned}
$$

where in the second step of the above derivation, we used (1.10).

On the other hand, notice that for any $a(x)\in C^1(\mathbb{R}^d)$, it holds that

$$
\nabla:(\nabla a\otimes\nabla a)-\frac{1}{2}\nabla|\nabla a|^2=\nabla a\triangle a,
$$

and we get

$$
\begin{aligned}
&-\int_{\mathbb{R}^d}\nabla\triangle^{-1}(\rho^\epsilon-b)\rho^\epsilon u\,dx+\int_{\mathbb{R}^d}\nabla\triangle^{-1}(\rho^\epsilon-b)bu\,dx\\
&=-\int_{\mathbb{R}^d}\nabla:\big(\nabla\triangle^{-1}(\rho^\epsilon-b)\otimes\nabla\triangle^{-1}(\rho^\epsilon-b)\big)\,u\,dx\\
&+\frac{1}{2}\int_{\mathbb{R}^d}\nabla\big(|\nabla\triangle^{-1}(\rho^\epsilon-b)|^2\big)\,u\,dx\\
&=\int_{\mathbb{R}^d}Du:\big(\nabla\triangle^{-1}(\rho^\epsilon-b)\otimes\nabla\triangle^{-1}(\rho^\epsilon-b)\big)\,dx-\frac{1}{2}\int_{\mathbb{R}^d}\mathrm{div}u|\nabla\triangle^{-1}(\rho^\epsilon-b)|^2\,dx.
\end{aligned}
\qquad (3.19)
$$

Exactly as in the proof of (3.19), we have

$$
\begin{aligned}
&-\int_{\mathbb{R}^d}\nabla\triangle^{-1}(\rho-b)\rho u\,dx+\int_{\mathbb{R}^d}\nabla\triangle^{-1}(\rho-b)bu\,dx\\
&=\int_{\mathbb{R}^d}Du:\big(\nabla\triangle^{-1}(\rho-b)\otimes\nabla\triangle^{-1}(\rho-b)\big)\,dx-\frac{1}{2}\int_{\mathbb{R}^d}\mathrm{div}u|\nabla\triangle^{-1}(\rho-b)|^2\,dx.
\end{aligned}
\qquad (3.20)
$$

Moreover, for any two $C^1(\mathbb{R}^d)$ functions $a(x), b(x)$, it holds that

$$\nabla : (\nabla a \otimes \nabla b) + \nabla : (\nabla b \otimes \nabla a) - \nabla(\nabla a \cdot \nabla b) = \nabla a \triangle b + \nabla b \triangle a,$$

and we have

$$\begin{aligned}
&\int_{\mathbb{R}^d} \left\{\nabla\triangle^{-1}(\rho - b)\rho^\epsilon u + \nabla\triangle^{-1}(\rho^\epsilon - b)\rho u\right\} dx \\
&- \int_{\mathbb{R}^d} \left\{\nabla\triangle^{-1}(\rho - b) + \nabla\triangle^{-1}(\rho^\epsilon - b)\right\} bu\, dx \\
&= \int_{\mathbb{R}^d} \{\nabla : \left(\nabla\triangle^{-1}(\rho - b) \otimes \nabla\triangle^{-1}(\rho^\epsilon - b)\right) \\
&+ \nabla : \left(\nabla\triangle^{-1}(\rho^\epsilon - b) \otimes \nabla\triangle^{-1}(\rho - b)\right)\} u\, dx \\
&- \int_{\mathbb{R}^d} \nabla\left(\nabla\triangle^{-1}(\rho^\epsilon - b) \cdot \nabla\triangle^{-1}(\rho - b)\right) u\, dx \qquad (3.21) \\
&= -\int_{\mathbb{R}^d} \{\left(\nabla\triangle^{-1}(\rho - b) \otimes \nabla\triangle^{-1}(\rho^\epsilon - b)\right) \\
&\qquad + \left(\nabla\triangle^{-1}(\rho^\epsilon - b) \otimes \nabla\triangle^{-1}(\rho - b)\right)\} : Du\, dx \\
&+ \int_{\mathbb{R}^d} \mathrm{div} u \nabla\triangle^{-1}(\rho^\epsilon - b) \cdot \nabla\triangle^{-1}(\rho - b)\, dx.
\end{aligned}$$

Then by summing up (3.19)–(3.21) and an appropriate rearrangement, we have

(3.22)

$$\begin{aligned}
&\int_{\mathbb{R}^d} \left\{\nabla\triangle^{-1}(\rho - b)\rho^\epsilon u - \nabla\triangle^{-1}(\rho^\epsilon - b)\rho^\epsilon u + \rho u \nabla\triangle^{-1}(\rho^\epsilon - \rho)\right\} dx \\
&= \int_{\mathbb{R}^d} Du : \left(\nabla\triangle^{-1}(\rho^\epsilon - \rho) \otimes \nabla\triangle^{-1}(\rho^\epsilon - \rho)\right) dx - \frac{1}{2}\int_{\mathbb{R}^d} \mathrm{div} u |\nabla\triangle^{-1}(\rho^\epsilon - \rho)|^2\, dx.
\end{aligned}$$

From (3.18) and (3.22), we get (3.12). □

With (3.12), now we can prove that the Wigner measure of $\psi^\epsilon(t,x)$ is $\rho(t,x)\delta(\xi - u(t,x))$ before the formation of singularities in (1.10).

LEMMA 3.3. *Let $f^\epsilon(t,x,\xi)$ be the Wigner transformation of $\psi^\epsilon(t,x)$; then for any fixed $t < T^*$, it holds that*

$$f^\epsilon(t,x,\xi) \rightharpoonup f(t,x,\xi) =: \rho(t,x)\delta(\xi - u(t,x)) \quad \text{in} \quad \mathcal{A}'(\mathbb{R}^{2d}) \quad \text{as} \quad \epsilon \to 0. \tag{3.23}$$

Proof. Compared with the situation in [1], a new difficulty arising here is the sign changing of the Wigner transformation $f^\epsilon(t,x,\xi)$. However, by the following elementary calculations, we fortunately find that $H_u^\epsilon(t)$ keeps its positive sign. In fact, by (3.5) and (3.8), we have

$$\begin{aligned}
&\int_{\mathbb{R}^d}\int_{\mathbb{R}^d} f^\epsilon(t,x,\xi)|\xi - u(t,x)|^2\, dx\, d\xi \\
&= \int_{\mathbb{R}^d}\int_{\mathbb{R}^d} f^\epsilon(t,x,\xi)|\xi|^2\, d\xi\, dx + \int_{\mathbb{R}^d} |u|^2|\psi^\epsilon|^2\, dx - 2\int_{\mathbb{R}^d} uJ^\epsilon\, dx \\
&= \int_{\mathbb{R}^d} \left\{\epsilon^2|\nabla\psi^\epsilon|^2 - 2\epsilon\mathrm{Im}(\overline{\psi^\epsilon}\nabla\psi^\epsilon)u + |u|^2|\psi^\epsilon|^2\right\} dx \\
&= \int_{\mathbb{R}^d} |(u - \epsilon D)\psi^\epsilon|^2\, dx, \qquad (3.24)
\end{aligned}$$

with $D = \frac{1}{i}\nabla_x$, while by a calculation similar to that of (3.8), we have

$$\int_{\mathbb{R}^d} \xi_i\xi_j f^\epsilon \, d\xi = -\frac{\epsilon^2}{4}\left(\partial_i\partial_j\psi^\epsilon\overline{\psi^\epsilon} - \partial_i\psi^\epsilon\partial_j\overline{\psi^\epsilon} - \partial_i\overline{\psi^\epsilon}\partial_j\psi^\epsilon + \psi^\epsilon\partial_i\partial_j\overline{\psi^\epsilon}\right),$$

from which we get

(3.25)
$$\begin{aligned}
&\left|\int_{\mathbb{R}^d} \partial_i u_j \int_{\mathbb{R}^d} (\xi-u)_i(\xi-u)_j f^\epsilon \, d\xi\, dx\right| \\
&= \left|\int_{\mathbb{R}^d} \left\{\partial_i u_j \left(\epsilon^2 \mathrm{Re}(\partial_i\psi^\epsilon\partial_j\overline{\psi^\epsilon}) - \epsilon u_i \mathrm{Im}(\overline{\psi^\epsilon}\partial_j\psi^\epsilon) - \epsilon u_j \mathrm{Im}(\overline{\psi^\epsilon}\partial_i\psi^\epsilon) + u_iu_j|\psi^\epsilon|^2\right)\right. \\
&\left. + \frac{\epsilon^2}{2}\partial_i^2 u_j \mathrm{Re}(\overline{\psi^\epsilon}\partial_j\psi^\epsilon)\right\} dx\Big|.
\end{aligned}$$

Then by rearranging the above, we immediately get

(3.26)
$$\begin{aligned}
&\left|\int_{\mathbb{R}^d} Du : \int_{\mathbb{R}^d} (\xi-u)\otimes(\xi-u) f^\epsilon \, d\xi\, dx\right| \\
&\le \sum_{i,j=1}^d \left|\int_{\mathbb{R}^d} \partial_i u_j \int_{\mathbb{R}^d} (\xi-u)_i(\xi-u)_j f^\epsilon \, d\xi\, dx\right| \\
&= \left|\sum_{i,j=1}^d \left\{\int_{\mathbb{R}^d} \partial_i u_j \mathrm{Re}\left((u_i - \epsilon D_i)\psi^\epsilon \overline{(u_j-\epsilon D_j)\psi^\epsilon}\right) dx + \frac{\epsilon^2}{2}\int_{\mathbb{R}^d} \partial_i^2 u_j \mathrm{Re}(\overline{\psi^\epsilon}\partial_j\psi^\epsilon)\, dx\right\}\right| \\
&\le C\left\{\|\nabla u\|_{L^\infty}\|(u-\epsilon D)\psi^\epsilon\|_{L^2}^2 + \epsilon\|\nabla_x^2 u\|_{L^\infty}\|\psi^\epsilon\|_{L^2}\|\epsilon\nabla\psi^\epsilon\|_{L^2}\right\}.
\end{aligned}$$

By summing up Lemma 2.1, (3.12), (3.24), and (3.26), we find, for any $0 \le t < T^*$, it holds that

$$\frac{d}{dt}H_u^\epsilon(t) \le C\|\nabla u(t,\cdot)\|_{L^\infty} H_u^\epsilon(t) + C\epsilon. \tag{3.27}$$

And by (A2), (A3) in the introduction and (3.24), we have

$$\begin{aligned}
H_u^\epsilon(t)|_{t=0} &= \frac{1}{2}\int_{\mathbb{R}^d} |(u_0-\epsilon D)\psi_0^\epsilon|^2\, dx + \int_{\mathbb{R}^d} |\nabla\triangle^{-1}(\rho_0^\epsilon - \rho_0)|^2\, dx \\
&\le \int_{\mathbb{R}^d} \rho_0^\epsilon |u_0 - \nabla S^\epsilon|^2\, dx + \epsilon\int_{\mathbb{R}^d} |\nabla\sqrt{\rho_0^\epsilon}|^2\, dx + \int_{\mathbb{R}^d} |\nabla\triangle^{-1}(\rho_0^\epsilon-\rho_0)|^2\, dx \\
&= o(1). \qquad (3.28)
\end{aligned}$$

By summing up (3.27), (3.28), and Gronwall's inequality, we find

$$\lim_{\epsilon\to 0} H_u^\epsilon(t) = 0 \qquad \text{for all} \qquad t < T^*. \tag{3.29}$$

Now let us take a smooth cut-off function $\chi(x,\xi) \in C_c^\infty(\mathbb{R}^d\times\mathbb{R}^d)$ with

$$\chi(x,\xi) = 1 \quad \text{for} \quad |x|+|\xi| \le 1, \quad \mathrm{supp}\chi \subset B(0,2); \tag{3.30}$$

then by Proposition 1.1 of [7], we get

$$\int_{\mathbb{R}^d}\int_{\mathbb{R}^d}\chi^2\left(\frac{x}{R},\frac{\xi}{R}\right)|\xi-u(t,x)|^2 f^\epsilon(t,x,\xi)\,dx\,d\xi$$

$$= \int_{\mathbb{R}^d}\left|\chi\left(\frac{x}{R},\frac{\epsilon D}{R}\right)[(u(t,x)-\epsilon D)\psi^\epsilon(t,x)]\right|^2 dx + r_\epsilon, \tag{3.31}$$

where $|r_\epsilon| \le \epsilon C(\chi,u)\|\psi^\epsilon\|_{L^2}^2$, and by Lemma 0.5 D of [21], we have

$$\left\|\chi\left(\frac{x}{R},\frac{\epsilon D}{R}\right)[(u(t,x)-\epsilon D)\psi^\epsilon(t,x)]\right\|_{L^2} \le C\|(u(t,x)-\epsilon D)\psi^\epsilon(t,x)\|_{L^2}. \tag{3.32}$$

On the other hand, by [14] (or [7]), for any fixed $t < T^*$ there is a subsequence $\{f^\epsilon(t,x,\xi)\}$ (we still denote it by $\{f^\epsilon\}$ for convenience) and a nonnegative Radon measure $f(t,x,\xi)$, which is called the Wigner measure of $\{\psi^\epsilon(t,x)\}$, such that

$$f^\epsilon(t,x,\xi) \rightharpoonup f(t,x,\xi) \quad \text{in} \quad \mathcal{A}'(\mathbb{R}^{2d}) \quad \text{as} \quad \epsilon\to 0. \tag{3.33}$$

Furthermore, by (A2), Lemma 2.1, and Remark 2.1, we have

$$\epsilon\|\nabla_x\psi^\epsilon(t,x)\|_{L^2} \le C, \tag{3.34}$$

which together with [14, Theorem III.1, Remark III.13] (or [7]) shows that

$$\rho^\epsilon(t,x) = \int_{\mathbb{R}^d} f^\epsilon(t,x,\xi)\,d\xi \rightharpoonup \int_{\mathbb{R}^d} f(t,x,d\xi) \quad \text{in} \quad \mathcal{M}^+(\mathbb{R}^d), \tag{3.35}$$

while by (3.29), we have $\rho^\epsilon(t,x)\to\rho(t,x)$ in $L^\infty([0,T],H^{-1}_{\mathrm{loc}}(\mathbb{R}^d))$ for any $T<T^*$, which together with (3.35) shows that

$$\int_{\mathbb{R}^d} f(t,x,d\xi) = \rho(t,x) \tag{3.36}$$

for any fixed $t<T^*$.

In particular, by (3.32)–(3.33) for the cut-off function $\chi(x,\xi)$ chosen as above, we have

$$\int_{\mathbb{R}^d}\int_{\mathbb{R}^d}\chi^2\left(\frac{x}{R},\frac{\xi}{R}\right)|\xi-u(t,x)|^2 f(t,dx,d\xi) \tag{3.37}$$

$$= \lim_{\epsilon\to 0}\int_{\mathbb{R}^d}\chi^2\left(\frac{x}{R},\frac{\xi}{R}\right)|\xi-u(t,x)|^2 f^\epsilon(t,x,\xi)\,dx\,d\xi$$

$$\le C\lim_{\epsilon\to 0}\|(u(t,x)-\epsilon D)\psi^\epsilon(t,x)\|_{L^2}^2 \le C\lim_{\epsilon\to 0} H_u^\epsilon(t) = 0. \tag{3.38}$$

Notice that $f(t,\cdot,\cdot)\in\mathcal{M}^+(\mathbb{R}^{2d})$, and Fatou's lemma implies that

$$\int_{\mathbb{R}^d}\int_{\mathbb{R}^d}|\xi-u(t,x)|^2 f(t,dx,d\xi) = 0. \tag{3.39}$$

Thus for any test function $\phi(x,\xi)\in C_c^\infty(\mathbb{R}^d\times\mathbb{R}^d)$, it holds that

$$\left|\int_{\mathbb{R}^d}\int_{\mathbb{R}^d}\phi(x,\xi)\,df(t,x,\xi) - \int_{\mathbb{R}^d}\phi(x,u(t,x))\int_{\mathbb{R}^d} df(t,x,d\xi)\right|$$

$$\le \sup_{x,\xi\in\mathbb{R}^d}|\nabla_\xi\phi|\int_{\mathbb{R}^d}\int_{\mathbb{R}^d}|\xi-u(t,x)|\,df(t,x,\xi)$$

$$\le \sup_{x,\xi\in\mathbb{R}^d}|\nabla_\xi\phi|\left(\int_{\mathbb{R}^d}\int_{\mathbb{R}^d} df(t,x,\xi)\right)^{\frac12}\left(\int_{\mathbb{R}^d}\int_{\mathbb{R}^d}|\xi-u(t,x)|^2\,df(t,x,\xi)\right)^{\frac12},$$

$$= 0,$$

which together with (3.36) implies that

$$\int_{\mathbb{R}^d}\int_{\mathbb{R}^d}\phi(x,\xi)\,df(t,x,\xi)=\int_{\mathbb{R}^d}\phi(x,u(t,x))\int_{\mathbb{R}^d}df(t,x,d\xi)$$
$$=\int_{\mathbb{R}^d}\phi(x,u(t,x))\rho(t,x)\,dx=\left(\phi(x,\xi),\quad \rho(t,x)\delta(\xi-u(t,x))\right),$$

that is,

$$f(t,x,\xi)=\rho(t,x)\delta(\xi-u(t,x)). \tag{3.40}$$

But as (ρ,u) is the unique local solution of (1.10), the above argument in fact implies that we do not need to take the subsequence of $\{f^\epsilon(t,x,\xi)\}$; that is, (3.23) holds for any fixed $t<T^*$. This completes the proof of the lemma. □

LEMMA 3.4. *Let $f(t,x,\xi)$ be the measure defined in* (3.23); *then for every fixed $t<T^*$, it holds that*

$$\epsilon\mathrm{Im}(\overline{\psi^\epsilon}\nabla\psi^\epsilon)(t,x)\rightharpoonup\int_{\mathbb{R}^d}\xi f(t,x,d\xi)=(\rho u)(t,x)\quad in\quad \mathcal{M}(\mathbb{R}^d)\quad as\quad \epsilon\to 0. \tag{3.41}$$

Proof. For a clear presentation, as in [7], let us define

$$W^\epsilon(f,g)=\frac{1}{(2\pi)^d}\int_{\mathbb{R}^d}e^{-iz\xi}f\left(x+\frac{\epsilon z}{2}\right)\overline{g\left(x-\frac{\epsilon z}{2}\right)}\,dz. \tag{3.42}$$

Then for any test function $\phi(x)\in C_c^\infty(\mathbb{R}^d)$ and any cut-off function $\chi(\xi)\in C_c^\infty(\mathbb{R}^d)$, with

$$\chi(\xi)=1\quad\text{for}\quad|\xi|\le 1,\quad \mathrm{supp}\chi(\cdot)\subset B(0,2), \tag{3.43}$$

we claim that for $f(x),g(x)\in H^s(\mathbb{R}^d)$ for $s>\frac{d}{2}$, it holds that

$$\left(W^\epsilon(f,g),\phi(x)\left(1-\chi\left(\frac{\xi}{R}\right)\right)\right)=\left(f\phi,\left(1-\chi\left(\frac{\epsilon D}{R}\right)\right)g\right)+r_\epsilon, \tag{3.44}$$

where $\chi(\frac{\epsilon D}{R})$ is the pseudodifferential operator with symbol $\chi(\frac{\epsilon\xi}{R})$ (see [21]), (a,b) denotes the (complex) L^2 inner product, and

$$|r_\epsilon|\le\frac{C\epsilon}{R}\|\nabla\phi\|_{L^\infty}\|f\|_{L^2}\|g\|_{L^2}. \tag{3.45}$$

In fact, by (3.42) and the change of variables that $x'=x+\frac{\epsilon z}{2}$, we have

(3.46)

$$\left(W^\epsilon(f,g),\phi(x)\left(1-\chi\left(\frac{\xi}{R}\right)\right)\right)$$
$$=\frac{1}{(2\pi)^d}\int_{\mathbb{R}^d}\int_{\mathbb{R}^d}\int_{\mathbb{R}^d}e^{-iz\xi}f(x')\overline{g(x'-\epsilon z)}\phi\left(x'-\frac{\epsilon z}{2}\right)\left(1-\chi\left(\frac{\xi}{R}\right)\right)\,dz\,dx'\,d\xi$$
$$=\int_{\mathbb{R}^d}f(x')\phi(x')\frac{1}{(2\pi)^d}\overline{\int_{\mathbb{R}^d}\int_{\mathbb{R}^d}e^{iz\xi}\left(1-\chi\left(\frac{\xi}{R}\right)\right)g(x'-\epsilon z)\,dz\,d\xi\,dx'}$$
$$-\frac{1}{2(2\pi)^d}\int_{\mathbb{R}^d}f(x')\int_{-1}^0\epsilon z\nabla\phi\left(x'+\frac{\epsilon\theta z}{2}\right)\,d\theta\int_{\mathbb{R}^d}\int_{\mathbb{R}^d}e^{-iz\xi}\left(1-\chi\left(\frac{\xi}{R}\right)\right)\overline{g(x'-\epsilon z)}\,dz\,d\xi\,dx'$$
$$=\left(f\phi,\left(1-\chi\left(\frac{\epsilon D}{R}\right)\right)g\right)+r_\epsilon.$$

But by Remark 3.1 again, we have

$$\begin{aligned}
&\frac{1}{2(2\pi)^d}\int_{\mathbb{R}^d} f(x')\int_{-1}^{0}\epsilon z\nabla\phi\left(x'+\frac{\epsilon\theta z}{2}\right)d\theta\int_{\mathbb{R}^d}\int_{\mathbb{R}^d} e^{-iz\xi}\overline{g(x'-\epsilon z)}\,dz\,d\xi\,dx'\\
&=\frac{\epsilon}{2}\int_{\mathbb{R}^d}\int_{-1}^{0} f(x')\frac{1}{(2\pi)^d}\int_{\mathbb{R}^d}\int_{\mathbb{R}^d} e^{-iz\xi}z\nabla\phi\left(x'+\frac{\epsilon\theta z}{2}\right)\overline{g(x'-\epsilon z)}\,dz\,d\xi\,d\theta\,dx'\\
&=0. \qquad (3.47)
\end{aligned}$$

And for $\chi(\xi)\in C_c^\infty(\mathbb{R}^d)$, we can use integration by parts to obtain

(3.48)

$$\begin{aligned}
|r_\epsilon| &= \left|\frac{\epsilon}{2(2\pi)^d}\int_{\mathbb{R}^d} f(x')\int_{-1}^{0}\nabla\phi\left(x'+\frac{\epsilon\theta z}{2}\right)d\theta\int_{\mathbb{R}^d}\int_{\mathbb{R}^d} e^{-iz\xi}\frac{1}{R}\chi'\left(\frac{\xi}{R}\right)\overline{g(x'-\epsilon z)}\,dz\,d\xi\,dx'\right|\\
&=\left|\frac{\epsilon}{2}\int_{\mathbb{R}^d}\int_{\mathbb{R}^d} f(x')\int_{-1}^{0}\nabla\phi\left(x'+\frac{\epsilon\theta z}{2}\right)d\theta\overline{g(x'-\epsilon z)}R^{d-1}\hat{\chi}'(Rz)\,dx'\,dz\right|\\
&\le\frac{\epsilon}{2}R^{d-1}\int_{\mathbb{R}^d}|\hat{\chi}'(Rz)|\,dz\|f\|_{L^2}\|g\|_{L^2}\|\nabla\phi\|_{L^\infty}\\
&\le\frac{C\epsilon}{R}\|\nabla\phi\|_{L^\infty}\|f\|_{L^2}\|g\|_{L^2}.
\end{aligned}$$

By summing up (3.46)–(3.48), we complete the proof of (3.44) and (3.45). And if we use the change of variables $x'=x-\frac{\epsilon z}{2}$ in (3.46), then by the same proof as the above, we get

$$\left(W^\epsilon(f,g),\phi(x)\left(1-\chi\left(\frac{\xi}{R}\right)\right)\right)=\left(\left(\left(1-\chi\left(\frac{\epsilon D}{R}\right)\right)f,\phi g\right)+r_\epsilon, \qquad (3.49)$$

with r_ϵ satisfying (3.45).

On the other hand, by the definition of $f^\epsilon(t,x,\xi)$, we have

$$\begin{aligned}
\xi_i f^\epsilon(t,x,\xi)=\frac{\epsilon}{2(2\pi)^d}\int_{\mathbb{R}^d} e^{-iz\xi}\Bigg(&D_{x_i}\psi^\epsilon\left(t,x+\frac{\epsilon z}{2}\right)\overline{\psi^\epsilon\left(t,x-\frac{\epsilon z}{2}\right)}\\
&-\psi^\epsilon\left(t,x+\frac{\epsilon z}{2}\right)D_{x_i}\overline{\psi^\epsilon\left(t,x-\frac{\epsilon z}{2}\right)}\Bigg)\,d\xi; \qquad (3.50)
\end{aligned}$$

hence by (3.44), (3.45), (3.49), and (3.50), we get

(3.51)

$$\begin{aligned}
&\left|\int_{\mathbb{R}^d}\int_{\mathbb{R}^d}\phi(x)\left(1-\chi\left(\frac{\xi}{R}\right)\right)\xi_i f^\epsilon(t,x,\xi)\,dx\,d\xi\right|\\
&=\frac{\epsilon}{2}\left\{\left(W^\epsilon(D_{x_i}\psi^\epsilon,\psi^\epsilon),\phi\left(1-\chi\left(\frac{\xi}{R}\right)\right)\right)-\left(W^\epsilon(\psi^\epsilon,D_{x_i}\psi^\epsilon),\phi\left(1-\chi\left(\frac{\xi}{R}\right)\right)\right)\right\}\\
&\le\left|\left(\phi\epsilon D_{x_i}\psi^\epsilon,\left(1-\chi\left(\frac{\epsilon D}{R}\right)\right)\psi^\epsilon\right)\right|+2r_\epsilon,
\end{aligned}$$

but by (3.34), we have

$$\begin{aligned}\left\|\left(1-\chi\left(\frac{\epsilon D}{R}\right)\right)\psi^\epsilon\right\|_{L^2} &\le \int_{\mathbb{R}^d}\left(1-\chi\left(\frac{\epsilon\xi}{R}\right)\right)^2|\hat{\psi^\epsilon}(t,\xi)|^2\,d\xi\\ &\le \int_{|\xi|\ge\frac{R}{\epsilon}}|\hat{\psi^\epsilon}(t,\xi)|^2\,d\xi\\ &\le \frac{1}{R^2}\int_{|\xi|\ge\frac{R}{\epsilon}}|\epsilon\xi|^2|\hat{\psi^\epsilon}(t,\xi)|^2\,d\xi \le \frac{C}{R^2}.\end{aligned}\tag{3.52}$$

By summing up (3.51) and (3.52), we get

$$\lim_{R\to\infty}\sup_{\epsilon>0}\left|\int_{\mathbb{R}^d}\int_{\mathbb{R}^d}\phi(x)\left(1-\chi\left(\frac{\xi}{R}\right)\right)\xi_i f^\epsilon(t,x,\xi)\,dx\,d\xi\right| = 0,\tag{3.53}$$

while by (3.33) and any $\chi(\xi)$ chosen as that in (3.43), we have trivially that

$$\lim_{\epsilon\to0}\int_{\mathbb{R}^d}\int_{\mathbb{R}^d}\phi(x)\chi\left(\frac{\xi}{R}\right)\xi f^\epsilon(t,x,\xi)\,dx\,d\xi = \int_{\mathbb{R}^d}\int_{\mathbb{R}^d}\phi(x)\chi\left(\frac{\xi}{R}\right)\xi f(t,dx,d\xi).\tag{3.54}$$

On the other hand, by taking $u=0$ in (3.31), we then infer from (2.2) and the proof of (3.38)–(3.39) that

$$\int_{\mathbb{R}^d}\int_{\mathbb{R}^d}|\xi|^2 f(t,dx,d\xi)\le C,$$

which implies that

$$\lim_{R\to\infty}\left|\int_{\mathbb{R}^d}\int_{\mathbb{R}^d}\phi(x)\left(1-\chi\left(\frac{\xi}{R}\right)\right)\xi_i f(t,dx,d\xi)\right| = 0.\tag{3.55}$$

Thus by (3.23) and (3.53), for any fixed $t<T^*$ we pass $R\to\infty$ in (3.54) to obtain

$$\begin{aligned}\lim_{\epsilon\to0}\int_{\mathbb{R}^d}\phi(x)J^\epsilon(t,x)\,dx &= \int_{\mathbb{R}^d}\phi(x)\int_{\mathbb{R}^d}\xi\rho(t,x)\delta(\xi-u(t,x))\,d\xi\,dx\\ &= \int_{\mathbb{R}^d}\phi(x)\rho(t,x)u(t,x)\,dx.\end{aligned}\tag{3.56}$$

This proves (3.41), which completes the proof of the lemma. □

Now we are in a position to complete the proof of Theorem 1.1.

Proof. By Lemma 2.2, (3.23), (3.35), (3.36), and (3.41), to complete the proof of Theorem 1.1, we only need to show part (2) of the theorem. In fact, by (1.10) and Lemma 2.2, for any test function $\phi(x,\xi)\in C_c^\infty(\mathbb{R}^{2d})$, we have

$$\begin{aligned}&\left|\frac{d}{dt}\int_{\mathbb{R}^d}\int_{\mathbb{R}^d}\phi(x,\xi)\rho(t,x)\delta(\xi-u(t,x))\,dx\,d\xi\right|\\ &=\left|\frac{d}{dt}\int_{\mathbb{R}^d}\phi(x,u(t,x))\rho(t,x)\,dx\right|\\ &=\left|\int_{\mathbb{R}^d}\{\nabla_\xi\phi(x,u)\partial_t u\rho+\phi(x,u)\partial_t\rho\}\,dx\right|\\ &\le\left(\|\partial_t u\|_{L^2}\|\rho\|_{L^2}+\|\partial_t\rho\|_{L^2}\right)\|\phi\|_{W^{1,\infty}}\\ &\le C\|\phi\|_{H^s},\quad s>d+1\quad\text{for}\quad 0\le t<T^*.\end{aligned}\tag{3.57}$$

This implies that $f(t,x,\xi) \in \mathrm{Lip}([0,T^*), H^{-s}(\mathbb{R}^{2d}))$ for $s > d+1$. On the other hand, to show that $f(t,x,\xi)$ is a distribution solution of (1.6) on $[0,T^*)\times\mathbb{R}^{2d}$, we need only prove that

$$\int_0^{T^*}\int_{\mathbb{R}^d} \{(\partial_t\phi)(t,x,u) + u(\nabla_x\phi)(t,x,u) - E(\nabla_\xi\phi)(t,x,u)\}\,\rho\,dx\,dt = 0 \tag{3.58}$$

for any test function $\phi(t,x,\xi) \in C_c^\infty((0,T^*)\times\mathbb{R}^{2d})$. Notice that by Lemma 2.2, $(\rho(t,x), u(t,x))$ is the unique local smooth solution of (1.10), and we have

$$\int_0^{T^*}\int_{\mathbb{R}^d} \phi(t,x,u)(\partial_t\rho + \mathrm{div}(\rho u))\,dx\,dt = 0 \tag{3.59}$$

and

$$\int_0^{T^*}\int_{\mathbb{R}^d} \nabla_\xi\phi(t,x,u)\{\partial_t u + u\nabla u + E\}\rho\,dx\,dt = 0. \tag{3.60}$$

By summing up (3.59), (3.60) and using integration by parts, we get (3.58). This completes the proof of Theorem 1.1. ∎

Acknowledgments. I am indebted to Professor Brenier, who suggested the idea of using the modulated energy method introduced in [1] for the Vlasov–Poisson system. Later, he mentioned to me the different but related work of Marjolaine Puel [18], who addressed in her Ph.D., with similar methods, the combined classical and neutral limit of the Wigner–Poisson system to the incompressible Euler equations. Also I would like to thank Professors Fanghua Lin, P. A. Markowich, and N. J. Mauser for profitable discussions, with special thanks to Professor Markowich for first introducing me to this problem.

BOUNDARY DETERMINATION OF CONDUCTIVITIES AND RIEMANNIAN METRICS VIA LOCAL DIRICHLET-TO-NEUMANN OPERATOR*

HYEONBAE KANG† AND KIHYUN YUN†

Abstract. We consider the inverse problem to identify an anisotropic conductivity from the Dirichlet-to-Neumann (DtN) map. We first find an explicit reconstruction of the boundary value of less regular anisotropic (transversally isotropic) conductivities and their derivatives. Based on the reconstruction formula, we prove Hölder stability, up to isometry, of the inverse problem using a local DtN map.

Key words. inverse boundary value problem, Dirichlet-to-Neumann map, anisotropic conductivity, boundary determination

1. Introduction and statements of results.

The results of this paper are twofold. We first find an explicit reconstruction of boundary values of anisotropic conductivities and their derivatives. We then derive Hölder stability estimates for the inverse problem to identify Riemannian metrics (up to isometry) on the boundary via the local Dirichlet-to-Neumann (DtN) map using the same ideas and methods.

Boundary reconstruction. Let Ω be a bounded domain in $\mathbb{R}^n$ $(n \geq 2)$ with the smooth boundary. If we recover the conductivity up to mth derivatives, then it is enough to assume that $\partial\Omega$ is C^{m+2}-smooth. We consider the inverse problem of identifying the positive definite symmetric matrix $\gamma = (\gamma^{ij})$ entering the equation

$$L_\gamma u := \sum_{i,j=1}^{n} \frac{\partial}{\partial x_i}\left(\gamma^{ij}\frac{\partial u}{\partial x_j}\right) = 0 \quad \text{in } \Omega \tag{1.1}$$

by the DtN map. The DtN map $\Lambda_\gamma : H^{1/2}(\partial\Omega) \to H^{-1/2}(\partial\Omega)$ is defined to be

$$\langle \Lambda_\gamma f, h\rangle = \int_\Omega (\gamma\nabla u)\cdot\nabla v dx, \quad f, h \in H^{1/2}(\partial\Omega),$$

where $u \in H^1(\Omega)$ is the solution to (1.1) with the Dirichlet data $u|_{\partial\Omega} = f$, and $v \in H^1(\Omega)$ is such that $v|_{\partial\Omega} = h$. Here $\langle\ ,\ \rangle$ denotes the $H^{-1/2}(\partial\Omega)$-$H^{1/2}(\partial\Omega)$ pairing.

In this paper we are first concerned with an explicit reconstruction of the conductivity at the boundary. Quite recently, Nakamura and Tanuma [13, 14] obtained an explicit formula to reconstruct conductivity and its normal derivatives at the boundary. We will discuss more about their formula since the first main result of this paper is an improvement of it.

Let us suppose that $\partial\Omega$ is flat around $x_0 = 0 \in \partial\Omega$, namely, there exists $\delta > 0$ such that

$$\Omega \cap B_\delta(0) = \{x = (x', x_n) \in B_\delta(0) \mid x_n > 0\}, \tag{1.2}$$

and in $\overline{\Omega} \cap B_\delta(0)$, γ is given by

$$\gamma = \begin{pmatrix} & & & 0 \\ & \gamma^{ij} & & \vdots \\ & & & 0 \\ 0 & \cdots & 0 & \gamma^{nn} \end{pmatrix}. \tag{1.3}$$

In fact, using the boundary normal coordinates [9], we can locally transform the general conductivity γ to one of the form (1.2). One can even take $\gamma^{nn} = 1$. Here we keep γ^{nn} in order to see how much we can recover.

Let $t' \in \mathbb{R}^{n-1}$, i.e., $(t', 0)$ is a tangent vector to $\partial\Omega$ at x_0. Let $\eta(x') \in C_0^\infty(\mathbb{R}^{n-1})$ be such that

$$0 \le \eta \le 1, \quad \|\eta\|_{L^2} = 1, \quad \text{supp } \eta \subset \{|x'| < 1\}.$$

For each large positive integer N, let

$$\phi_N(x') = \exp(iNx' \cdot t')\eta(N^{1/2}x'), \tag{1.4}$$

and for $z \in \partial\Omega \cap B_\delta(0)$, let

$$\phi_N^z(x') = \phi_N(x' - z'). \tag{1.5}$$

The function ϕ_N plays the role of Dirichlet data and test functions. Observe that ϕ_N oscillates rapidly as N becomes large. Kohn and Vogelius first used rapidly oscillating boundary data in their proof of uniqueness of the boundary determination [6]. The use of explicit functions such as ϕ_N for boundary reconstruction is due to Brown [3] and Nakamura and Tanuma [13].

Let $\gamma^k \in C^m(\overline{\Omega})$ be an anisotropic conductivity such that

$$\gamma^k(x) := \gamma(x', 0) + \partial_n\gamma(x', 0)x_n + \cdots + \frac{1}{(k-1)!}\partial_n^{k-1}\gamma(x', 0)x_n^{k-1} \tag{1.6}$$

near $\partial\Omega \cap B_\delta(0)$. Let

$$C_\gamma(z) := \sqrt{\gamma^{nn}(z)^{-1}\sum_{i,j=1}^{n-1}\gamma^{ij}(z)t_it_j}. \tag{1.7}$$

Nakamura and Tanuma proved that for $k \le \frac{m}{2}$,

$$\begin{aligned} &\lim_{N\to\infty} N^{\frac{n-3}{2}+k}\langle(\Lambda_\gamma - \Lambda_{\gamma^k})\phi_N^z, \overline{\phi_N^z}\rangle \\ &\quad = C_k C_\gamma(z)^{-a_n-1}\left(\sum_{i,j=1}^{n-1}\partial_{x_n}^k\gamma^{ij}(z)t_it_j + C_\gamma(z)^2\partial_{x_n}^k\gamma^{nn}(z)\right) \end{aligned} \tag{1.8}$$

for some explicit constant C_k. (Even if they wrote the formula only for the isotropic γ, the proof gives (1.8).) If γ is isotropic and $|t'| = 1$, then $C_\gamma \equiv 1$, and hence the formula (1.8) reads

$$\lim_{N\to\infty} N^{\frac{n-3}{2}+k}\langle(\Lambda_\gamma - \Lambda_{\gamma^k})\phi_N^z, \overline{\phi_N^z}\rangle = 2C_k\partial_{x_n}^k\gamma(z). \tag{1.9}$$

However, the reconstruction formula (1.8) is valid only for $k \le \frac{m}{2}$. Moreover, in the inductive reconstruction (1.8) or (1.9), it is required to know $\partial_{x_n}^{k-1}\gamma(x)$ for all $x \in \partial\Omega \cap B_\delta(0)$ in order to recover $\partial_{x_n}^k\gamma(z)$. It is also worth noting that in the formula (1.8) or (1.9), stable recovery of the tangential derivatives does not seem possible: If we take $N^{\frac{n-3}{2}+k}\langle(\Lambda_\gamma - \Lambda_{\gamma_k})\phi_N^z, \overline{\phi_N^z}\rangle$ as an approximation of $2C_k\partial_{x_n}^k\gamma(z)$ in (1.9), then its tangential derivatives do not seem to be good approximations of those of $2C_k\partial_{x_n}^k\gamma(z)$. It is our intention to improve these points.

The reason for the above-mentioned drawbacks in the formula (1.8) is that $N^{1/2}$ is used in the definition (1.4). We use instead the following boundary data:

$$\phi_N(x') = \exp(iNx'\cdot t')\eta(N^{\alpha_1}x_1, \dots, N^{\alpha_{n-1}}x_{n-1}), \tag{1.10}$$

where α_j's are specified shortly. The definition (1.10) amounts to assigning each partial differential operator $\frac{\partial}{\partial x_j}$ with the weight α_j $(j = 1, \dots, n)$ so that we can distinguish each direction x_j. The numbers α_j are chosen as follows: throughout this paper conductivities under consideration are $C^{m,p}$-smooth $(m \ge 0,\ p > 0)$, and $C^{m,p}$, m nonnegative integer and $0 \le p \le 1$, denotes the usual Hölder space. Choose λ so that $\lambda = \frac{1}{l}$ for some integer l and satisfies the following: if $m \ge 1$, then

$$\lambda < p, \quad (1 - m^{n-1}\lambda)(m + p) \ge m + \lambda. \tag{1.11}$$

We then define a multi-index α by

$$\alpha = (\alpha_1, \dots, \alpha_n) := (1 - m^{n-1}\lambda, 1 - m^{n-2}\lambda, \dots, 1 - m\lambda, 1). \tag{1.12}$$

If $m = 0$, choose λ so that $\lambda < p$ and define α by

$$\alpha = (\alpha_1, \dots, \alpha_n) := (1 - (n-1)\lambda, 1 - (n-2)\lambda, \dots, 1). \tag{1.13}$$

We choose α and λ in this way so that they possess the following properties: $|\alpha_i - \alpha_j| \ge \lambda$ if $i \ne j$. If a and b are multi-indices with $|a| \le m$ and $|b| \le m$, then $a\cdot\alpha \ne b\cdot\alpha$ if and only if $a \ne b$. Thanks to these properties, we can define a linear ordering of multi-indices: Let $a = (a_1, \dots, a_n)$ and $b = (b_1, \dots, b_n)$ be two multi-indices. We define $a < b$ if $a\cdot\alpha < b\cdot\alpha$. Using the linear ordering, we are able to recover γ and its derivatives inductively.

For the function η in the definition (1.10), we further assume that for each $a' = (a_1, \dots, a_{n-1})$ with $|a'| \le m$

$$\int_{|y'|\le 1} (y')^{a'}\eta(y')^2 dy' \ne 0,$$

and we define $C(a)$ for a multi-index $a = (a', a_n)$ to be

$$C(a) := \frac{1}{a!}\int_0^\infty y_n^{a_n} e^{-2y_n} dy_n \int_{|y'|\le 1} (y')^{a'}\eta(y')^2 dy'. \tag{1.14}$$

For a given anisotropic conductivity γ and a multi-index a with $|a| \le m$, define $\gamma^{a,z}$ to be a positive definite matrix-valued smooth function on Ω such that

$$\gamma^{a,z}(x) := \sum_{b<a} \frac{\partial^b \gamma(z)}{b!}(x-z)^b \quad \text{near } z. \tag{1.15}$$

Then the DtN map $\Lambda_{\gamma^{a,z}}$ corresponding to $\gamma^{a,z}$ is well defined. If $a = 0$, let $\Lambda_{\gamma^0} = 0$. Here and throughout this paper $\partial^b\gamma$ denotes $\partial^b\gamma = \partial_{x_1}^{b_1} \cdots \partial_{x_n}^{b_n}\gamma$.

Then we have the following reconstruction formula.

THEOREM 1.1. *Suppose that $\gamma \in C^{m,p}(\overline{\Omega} \cap B_\delta(0))$. For $z = (z', 0) \in \partial\Omega \cap B_\delta(0)$, a multi-index $a = (a', a_n)$, and $k \le m$, we have*

$$\begin{aligned} &N^{-2+|\alpha|+a\cdot\alpha}\langle(\Lambda_\gamma - \Lambda_{\gamma^{a,z}})\phi_N^z, \overline{\phi_N^z}\rangle \\ &\quad = C(a)C_\gamma(z)^{-a_n-1}\left(\sum_{i,j=1}^{n-1} \partial^a\gamma^{ij}(z)t_it_j + C_\gamma(z)^2\partial^a\gamma^{nn}(z)\right) + O(N^{-\lambda}), \end{aligned} \tag{1.16}$$

where $O(N^{-\lambda})$ is independent of z. If $a = 0$, then $C(0) = \frac{1}{2}$, and hence we have

$$N^{-2+|\alpha|}\langle\Lambda_\gamma\phi_N^z, \overline{\phi_N^z}\rangle = \sqrt{\gamma^{nn}(z)\sum_{i,j=1}^{n-1}\gamma^{ij}(z)t_it_j} + O(N^{-\lambda}). \tag{1.17}$$

The formula (1.16) says that the boundary values of γ and its derivatives up to order m can be recovered in a stable way (modulo γ^{nn}-terms).

In particular, if γ is isotropic, namely, $\gamma = \gamma(\delta_{ij})$, and $|t'| = 1$, then $C_z \equiv 1$, and hence we have the following corollary.

COROLLARY 1.2. *If $\gamma \in C^{m,p}(\overline{\Omega} \cap B_\delta(0))$ is an isotropic conductivity, then for all multi-index a with $|a| \le m$, we have*

$$N^{-2+|\alpha|+a\cdot\alpha}\langle(\Lambda_\gamma - \Lambda_{\gamma^{a,z}})\phi_N^z, \overline{\phi_N^z}\rangle = C(a)\partial^a\gamma(z) + O(N^{-\lambda}). \tag{1.18}$$

We note that Brown proved a reconstruction formula for γ and the normal derivative on $\partial\Omega$ [3]. In [2], Alessandrini and Gaburro considered reconstruction of special types of anisotropic conductivity.

It turns out that a slight variance of the reconstruction (1.18) gives an interesting stability result, which is the second subject of this paper.

Boundary determination of Riemannian metrics-stability. Let Ω be a bounded domain in $\mathbb{R}^n$ $(n \ge 3)$ with the smooth boundary. We consider the inverse problem of identifying a Riemannian metric or an anisotropic conductivity at the boundary $\partial\Omega$ via the (local) DtN map. Let (g_{ij}) be a Riemannian metric on $\overline{\Omega}$ and $g = (g^{ij}) := (g_{ij})^{-1}$. Then the corresponding DtN map $\Lambda_g : H^{1/2}(\partial\Omega) \to H^{-1/2}(\partial\Omega)$ is defined to be

$$\langle\Lambda_g f, h\rangle = \int_\Omega (|g|^{-1/2}g\nabla u)\cdot\nabla v dx, \quad f, h \in H^{1/2}(\partial\Omega), \tag{1.19}$$

where $u \in H^1(\Omega)$ is the solution to the problem

$$\begin{aligned} \Delta_g u := |g|^{1/2}\sum_{i,j=1}^n \frac{\partial}{\partial x_i}\left(|g|^{-1/2}g^{ij}\frac{\partial u}{\partial x_j}\right) = 0 \quad &\text{in } \Omega, \\ u = f \quad &\text{on } \partial\Omega, \end{aligned}$$

and $v \in H^1(\Omega)$ is such that $v|_{\partial\Omega} = h$. Here $|g|$ denotes the determinant of g.

There is a well-known obstacle in identifying g: Let $\Psi : \overline{\Omega} \to \overline{\Omega}$ be a C^1 diffeomorphism which is the identity on $\partial\Omega$. Then it is well known that

$$\Lambda_{\Psi^* g} = \Lambda_g,$$

where $\Psi^* g$ is the pull-back of g. So the general conjecture of the uniqueness in three dimensions is that if $\Lambda_{g_1} = \Lambda_{g_2}$, then there exists a diffeomorphism Ψ on $\overline{\Omega}$ such that $\Psi|_{\partial\Omega}$ is the identity on $\partial\Omega$ and

$$\Psi^* g_2 = g_1.$$

Lee and Uhlmann proved the conjecture for three dimensions under some restrictions when conductivities are real analytic in $\overline{\Omega}$ [9]. Recently, Lassas and Uhlmann extended the result to the case when g is real analytic up to a portion of $\partial\Omega$ and removed the restrictions [8]. There are also similar kinds of uniqueness theorems for two dimensions. See [15, 10, 8]. When γ is a scalar function, i.e., γ is isotropic, the inverse problem has been extensively studied [4, 5, 6, 7, 11, 12, 16, 17].

In this paper we prove the following Hölder stability estimates for the boundary determination: Let Γ be an open connected subset of $\partial\Omega$. Define the localized DtN map Λ_g^Γ by

$$\Lambda_g^\Gamma(f) := \Lambda_g(f)|_\Gamma, \quad f \in H^{1/2}(\partial\Omega), \quad \operatorname{supp}(f) \subset \Gamma.$$

We will use the following notation: Let f be a C^k function in a neighborhood of a compact set K. Then $\|f\|_{C_E^k(K)} := \sum_{|\alpha|=0}^k \sup_{x\in K} |\partial^\alpha f(x)|$. So, $C_E^k(\partial\Omega)$-norm involves not only the tangential derivatives but also the normal derivative.

THEOREM 1.3. *Suppose that g_1 and g_2 are Riemannian metrics on a domain Ω such that they are $C^{m,p}$ $(m \geq 1, p > 0)$ in a neighborhood of Γ and the $C^{m,p}$-norms are bounded by M and*

$$g_j \xi \cdot \xi \geq A|\xi|^2 \quad \text{for all } \xi \in \mathbb{R}^n \quad (j = 1, 2). \tag{1.20}$$

Let K be a compact subset of Γ. Then there are a neighborhood U of Γ, a C^m diffeomorphism Ψ in $U \cap \overline{\Omega}$ with $\Psi|_\Gamma$ = Identity, and a positive constant $C = C(m, p, \Gamma, K, A, M)$ such that for $k = 0, 1, \ldots, m$,

$$\|g_2 - \Psi^* g_1\|_{C_E^k(K)} \leq C \|\Lambda_{g_1}^\Gamma - \Lambda_{g_2}^\Gamma\|^{2^{-k/\lambda}}. \tag{1.21}$$

The norm on the right-hand side of (1.21) *is the operator norm from $H^{1/2}(\Gamma)$ into $H^{-1/2}(\Gamma)$.*

Thus the Riemannian metrics can be recovered at the boundary in a stable way via the local DtN map.

Using the boundary normal coordinates, we may assume that $\partial\Omega$ is flat around $x_0 = 0 \in \partial\Omega$, and g is given by

$$g = \begin{pmatrix} & & & 0 \\ & g^{ij} & & \vdots \\ & & & 0 \\ 0 & \cdots & 0 & 1 \end{pmatrix}. \tag{1.22}$$

We prove stability estimates for the Riemannian metrics of the form (1.22) by using methods similar to Theorem 1.1. Then Theorem 1.3 follows.

As was observed in [9], if we take

$$g_{ij} := |\gamma|^{1/(n-2)}\gamma^{-1} \quad (n \geq 3),$$

then $\gamma = |g|^{-1/2}g$ ($g = (g_{ij})^{-1}$) and $\Lambda_g = \Lambda_\gamma$. Hence, we have the same stability estimates for anisotropic conductivities.

A similar proof yields the following stability for the boundary determination of isotropic conductivities.

THEOREM 1.4. *Suppose that γ_1 and γ_2 are isotropic conductivities. Let m, p, Γ, K, A, M ($m \geq 0$) be as before. Then there exists a positive constant $C = C(m, \Gamma, K, A, M)$ such that for $k = 0, 1, \dots, m$,*

$$\|\gamma_2 - \gamma_1\|_{C_E^k(K)} \leq C\|\Lambda_{\gamma_1}^\Gamma - \Lambda_{\gamma_2}^\Gamma\|^{2^{-k/\lambda}}. \tag{1.23}$$

Alessandrini proved the following stability for isotropic conductivities using singular solutions [1] (see also [18]):

$$\|\gamma_2 - \gamma_1\|_{C_E^k(\partial\Omega)} \leq C\|\Lambda_{\gamma_1} - \Lambda_{\gamma_2}\|^{\frac{1}{2k+1}}.$$

This stability estimate is better than (1.23). However, the stability estimate (1.23) uses the *local* DtN map.

This paper is organized as follows: In section 2, we construct approximate solutions of $L_\gamma u = 0$ with $u|_{\partial\Omega} = \phi_N^z$ on which the proof of Theorem 1.1 is based. The proof of Theorem 1.1 is given in section 3. Theorem 1.3 is proved in section 4.

2. Approximate solutions. Suppose that Ω and γ are of the forms (1.2) and (1.3) and that $\gamma \in C^{m,p}(\overline{\Omega} \cap B_\delta(0))$ for some integer $m \geq 0$. Let

$$\Omega_N := \left\{ x \mid |x_j| < N^{-\alpha_j} \ (j = 1, \dots, n-1),\ 0 \leq x_n < \frac{1}{\sqrt{N}} \right\}.$$

The following lemma and its proof are based on an idea in [13].

LEMMA 2.1. *For each integer N there is an approximate solution Φ_N of the form*

$$\Phi_N(x) = \exp(iNx' \cdot t') \exp(-C_\gamma(z)Nx_n) \sum_{k=0}^{m/\lambda} N^{-k\lambda} v_k(y) \tag{2.1}$$

$$(y_j = N^{\alpha_j} x_j, \quad j = 1, \dots, n), \tag{2.2}$$

where $v_0(y', y_n) = \eta(y')$, and $v_l(y', y_n)$ are polynomials of y_n whose coefficients are C^∞ functions of y' compactly supported in $\{|y'| < 1\}$, so that Φ_N satisfies

$$\Phi_N|_{\partial\Omega} = \phi_N^z$$

and

$$|\nabla \cdot (\gamma \nabla \Phi_N)(x)| \leq CN^{(2-m)-\lambda} p(y_n) e^{-C_\gamma(z)y_n} \quad \text{for all } x \in \Omega_N \tag{2.3}$$

for some constant $C = C(m)$. Here $p(y_n)$ is a polynomial with positive coefficients.

Proof. Without loss of generality, assume that $z = 0$. Put $C_0 := C_\gamma(0)$. We seek a solution $\Phi_N(x)$ of the form

$$\Phi_N(x) = \exp(iNx' \cdot t') V(N^{\alpha_1} x_1, \dots, N^{\alpha_n} x_n).$$

Then straightforward computations show that

$$\begin{aligned}
\nabla_x(\gamma(\nabla_x\Phi_N)) &= \sum_{i,j=1}^{n} \partial_{x_i}(\gamma^{ij}\partial_{x_j}\Phi_N) \\
&= \left[\sum_{i,j=1}^{n-1} \gamma^{ij}\partial_{x_i}\partial_{x_j} + \gamma^{nn}\partial_{x_n}^2 + \sum_{i,j=1}^{n-1} \partial_{x_i}\gamma^{ij}\partial_{x_j} + \partial_{x_n}\gamma^{nn}\partial_{x_n}\right]\Phi_N \\
&= \exp(iNx'\cdot t')\left[-N^2\sum_{i,j=1}^{n-1}\gamma^{ij}t_it_j + \sqrt{-1}N\sum_{i,j=1}^{n-1}\gamma^{ij}(t_i\partial_{x_j} + t_j\partial_{x_i})\right. \\
&\quad + \sum_{i,j=1}^{n-1}\gamma^{ij}\partial_{x_i}\partial_{x_j} + \gamma^{nn}\partial_{x_n}^2 + \sqrt{-1}N\sum_{i,j=1}^{n-1}(\partial_{x_i}\gamma^{ij})t_j \\
&\quad \left. + \sum_{i,j=1}^{n-1}(\partial_{x_i}\gamma^{ij})\partial_{x_j} + (\partial_{x_n}\gamma^{nn})\partial_{x_n}\right] V(N^{\alpha_1}x_1,\dots,N^{\alpha_n}x_n).
\end{aligned}$$

After the scaling (2.2), we have $\partial_{x_j} = N^{\alpha_j}\partial_{y_j}$ $(i = 1, 2, \dots, n)$, and hence

$$\begin{aligned}
\nabla_x(\gamma(\nabla_x\Phi_N)) = \exp(iNx'\cdot t')\Bigg[&N^2\left(\gamma^{nn}\partial_{y_n}^2 - \sum_{i,j=1}^{n-1}\gamma^{ij}t_it_j\right) \\
&+ 2\sum_{j=1}^{n-1} N^{1+\alpha_j}\left(\sum_{i=1}^{n-1}\gamma^{ij}t_i\right)\partial_{y_j} \\
&+ \sum_{i,j=1}^{n-1} N^{\alpha_i+\alpha_j}\gamma^{ij}\partial_{y_i}\partial_{y_j} \\
&+ N\left(\sqrt{-1}\sum_{i,j=1}^{n-1}(\partial_{x_i}\gamma^{ij})t_j + (\partial_{x_n}\gamma^{nn})\partial_{y_n}\right) \\
&+ \sum_{j=1}^{n-1} N^{\alpha_j}\left(\sum_{i=1}^{n-1}\partial_{x_i}\gamma^{ij}\right)\partial_{y_j}\Bigg] V(y', y_n).
\end{aligned} \tag{2.4}$$

Note that all the powers of N in the formula (2.4) are of the form $2 - k\lambda$ for some integer k with $0 \le k \le 2/\lambda$.

We now expand γ in Taylor series in Ω_N:

$$\gamma(x) = \sum_{|a|\le m}\frac{1}{a!}\partial^a\gamma(0)x^a + O(|x|^{m+p}).$$

By the condition (1.11) imposed on λ, we have

$$\alpha_1(m+p) \ge m + \lambda. \tag{2.5}$$

Thus, after the scaling (2.2), we have

$$\gamma(x) = \sum_{|a|\le m}\frac{1}{a!}\partial^a\gamma(0)N^{-\alpha\cdot a}y^a + E_1(y), \tag{2.6}$$

where

$$|E_1(y)| \le CN^{-\alpha_1(m+p)} \sum_{k=0}^{m+1} y_n^k \le CN^{-m-\lambda} \sum_{k=0}^{m+1} y_n^k. \tag{2.7}$$

Similarly, we have, for $j = 1, 2, \dots, n$,

$$\partial_{x_j}\gamma(x) = \sum_{|a|\le m-1} \frac{1}{a!}\partial^a \partial_{x_j}\gamma(0) N^{-\alpha\cdot a} y^a + E_2(y), \tag{2.8}$$

where

$$|E_2(y)| \le CN^{-m+1-\lambda} \sum_{k=0}^{m} y_n^k. \tag{2.9}$$

Note that this expansion holds uniformly for all $x \in \Omega_N$ and hence for all $y \in \{|y'| < 1,\ 0 \le y_n \le N^{\frac{1}{2}}\}$. Note also that the powers of N in the expansions in (2.6) and (2.8) are of the form $-k\lambda$ for some integer k.

It then follows from (2.4), (2.6), and (2.8) that

$$\nabla_x(\gamma(\nabla_x \Phi_N)) = \exp(iNx'\cdot t') \left[\sum_{k=0}^{m/\lambda} N^{2-k\lambda} L_k + L_R\right] V(y', y_n), \tag{2.10}$$

where L_k are at most second order differential operators in y' and y_n whose coefficients are polynomials in y' and y_n, and L_R is also a second order differential operator in y' and y_n whose coefficients are of the form $O(N^{2-m-\lambda})\times$polynomial in y_n with positive coefficients, and

$$L_0 = \gamma^{nn}(0)\partial_{y_n}^2 - \sum_{i,j=1}^{n-1} \gamma^{ij}(0) t_i t_j. \tag{2.11}$$

We look for $V(y', y_n)$ of the form

$$V(y', y_n) = \sum_{k=0}^{m/\lambda} N^{-k\lambda} V_k.$$

We have from (2.10) that

$$\begin{aligned} \nabla_x(\gamma(\nabla_x\Phi_N)) &= \exp(iNx'\cdot t') \left[\left(\sum_{k=0}^{m/\lambda} N^{2-k\lambda} L_k\right)\left(\sum_{j=0}^{m/\lambda} N^{-j\lambda} V_j\right) + L_R V\right] \\ &= \exp(iNx'\cdot t') \left[\sum_{l=0}^{m/\lambda} N^{2-l\lambda} \sum_{k+j=l} L_k V_j + E\right], \end{aligned} \tag{2.12}$$

where

$$E := \sum_{l=m/\lambda+1}^{2m/\lambda} N^{2-l\lambda} \sum_{k+j=l} L_k V_j + L_R V. \tag{2.13}$$

We solve the system of differential equations

$$\sum_{k+j=l} L_k V_j = 0 \quad (l = 0, 1, 2, \dots, m/\lambda), \tag{2.14}$$

namely,

$$\begin{aligned} L_0 V_0 &= 0, \\ L_0 V_1 + L_1 V_0 &= 0, \\ &\cdots \\ L_0 V_{m/\lambda} + \cdots + L_{m/\lambda} V_0 &= 0, \end{aligned}$$

with the boundary conditions

$$\begin{aligned} V_0|_{y_n=0} &= \eta_N(x') = \eta(y'), \\ V_l|_{y_n=0} &= 0 \quad (l = 1, \dots, m/\lambda). \end{aligned}$$

We remark that this boundary value problem is underdetermined. Because of (2.11), this system of equations can be solved iteratively from top to bottom:

$$\begin{aligned} V_0(y', y_n) &= \eta(y') \exp(-C_0 y_n), \\ V_1(y', y_n) &= \sum_{k=0}^{1} P_1^k(y') y_n^k \exp(-C_0 y_n), \\ &\cdots \\ V_{m/\lambda}(y', y_n) &= \sum_{k=1}^{m/\lambda} P_{m/\lambda}^k(y') y_n^k \exp(-C_0 y_n) \end{aligned}$$

for some N_j $(j = 1, \dots, m/\lambda)$, where $P_j^k(y')$ are C^∞ functions supported in $\{|y'| < 1\}$. It then follows from (2.12) that

$$\nabla_x(\gamma(\nabla_x \Phi_N)) = \exp(iNx' \cdot t')E.$$

Recall that the coefficients of L_R are of the form $O(N^{2-m-\lambda}) \times$ polynomial in y_n. Thus there exists $C = C(m)$ such that

$$|E| \le C N^{2-m-\lambda} p(y_n) \exp(-C_0 y_n)$$

for some polynomial p. This completes the proof. □

The following lemma can be proved by straightforward computations. Recall that ϕ_N is defined in (1.10).

LEMMA 2.2. *For each $s \ge 0$, there exists a constant C_s such that*

$$\|\phi_N\|_{H^s(\partial\Omega)} + \|\Phi_N\|_{H^{s+1/2}(\Omega_N)} \le C_s N^{s+\frac{1}{2}-\frac{|\alpha|}{2}}. \tag{2.15}$$

For each multi-index a, there exists a constant C_a such that

$$\|x^a \nabla \Phi_N\|_{L^2(\Omega_N)} \le C_a N^{1-a\cdot\alpha-\frac{|\alpha|}{2}}. \tag{2.16}$$

3. Proof of Theorem 1.1. In this section we prove Theorem 1.1. Our proof is parallel to that of [13].

Without loss of generality we assume that $z = 0$. Put $C_0 := C_\gamma(0)$ for convenience. Let $\zeta(x_n) \in C^\infty([0,\infty))$ be such that $\zeta(x_n) = 1$ for $0 \le x_n \le 1/2$ and 0 for $1 \le x_n$. Put

$$\zeta_N(x_n) = \zeta(\sqrt{N}x_n).$$

Let a be a multi-index such that $|a| \le m$. Let $u_N \in H^1(\Omega)$ be the solution of

$$\begin{aligned} \nabla_x(\gamma\nabla_x u_N) &= 0 \quad \text{in } \Omega, \\ u_N|_{\partial\Omega} &= \phi_N, \end{aligned}$$

and let $v_N \in H^1(\Omega)$ be the solution of

$$\begin{aligned} \nabla_x(\gamma^a\nabla_x v_N) &= 0 \quad \text{in } \Omega, \\ v_N|_{\partial\Omega} &= \phi_N. \end{aligned}$$

Here $\gamma^a = \gamma^{a,0}$. Let Φ_N and Ψ_N be the extensions of ϕ_N given in Lemma 2.1 corresponding to γ and γ^a, respectively. Note that since $\langle \Lambda_{\gamma^a}\phi_N, \overline{\phi}_N\rangle$ is real, we have

$$\langle \Lambda_{\gamma^a}\phi_N, \overline{\phi_N}\rangle = \langle \overline{\Lambda_{\gamma^a}\phi_N}, \phi_N\rangle,$$

and hence

$$\begin{aligned} &\langle (\Lambda_\gamma - \Lambda_{\gamma^a})\phi_N, \overline{\phi_N}\rangle \\ &= \int_\Omega (\gamma\nabla_x u_N)\cdot\nabla_x\overline{(\zeta_N\Psi_N)}dx - \int_\Omega (\gamma^a\nabla_x\overline{v_N})\cdot\nabla_x(\zeta_N\Phi_N)dx. \end{aligned}$$

Put

$$u_N := \Phi_N + s_N \quad \text{and} \quad v_N := \Psi_N + r_N. \tag{3.1}$$

Then we have

$$\begin{aligned} &\langle (\Lambda_\gamma - \Lambda_{\gamma^a})\phi_N, \overline{\phi_N}\rangle \\ &= \int_\Omega \left[(\gamma\nabla_x\Phi_N)\cdot\nabla_x\overline{(\zeta_N\Psi_N)} - (\gamma^a\nabla_x\overline{\Psi_N})\cdot\nabla_x(\zeta_N\Phi_N)\right] dx \\ &\quad + \int_\Omega (\gamma\nabla_x s_N)\cdot\nabla_x\overline{(\zeta_N\Psi_N)}dx - \int_\Omega (\gamma^a\nabla_x\overline{r_N})\cdot\nabla_x(\zeta_N\Phi_N)dx \\ &:= I + II + III. \end{aligned} \tag{3.2}$$

We estimate I, II, and III separately.

Estimates of I. Put

$$\Omega'_N := \left\{ x : \ |x'| \le N^{-\alpha_j} \ (j = 1,\dots,n-1), \ \frac{1}{2\sqrt{N}} \le x_n \le \frac{1}{\sqrt{N}} \right\}.$$

Since $\zeta_N = 1$ on $0 \le x_n \le \frac{1}{2\sqrt{N}}$, we can rewrite I as

$$\begin{aligned} I &= \int_{\Omega_N\setminus\Omega'_N} (\gamma - \gamma^a)\nabla_x\Phi_N\cdot\nabla_x\overline{\Psi_N}dx \\ &\quad + \int_{\Omega'_N} \left[(\gamma\nabla_x\Phi_N)\cdot\nabla_x\overline{(\zeta_N\Psi_N)} - (\gamma^a\nabla_x\overline{\Psi_N})\cdot\nabla_x(\zeta_N\Phi_N)\right] dx \\ &:= I_1 + I_2. \end{aligned}$$

By (2.1), there exists a constant C such that

$$|\Psi_N| + |\Phi_N| \le C \exp(-C_0 N x_n).$$

Therefore it is easy to see that

$$|I_2| \le C \exp\left(-\frac{C_0}{2} N^{\frac{1}{2}}\right). \tag{3.3}$$

From (2.1), we get

$$\nabla_x \Phi_N = \left[N \begin{pmatrix} it' \\ -C_0 \end{pmatrix} \exp(iNx' \cdot t') \eta_N(x') + O(N^{1-\lambda}) \right] \exp(-C_0 N x_n).$$

Likewise, we have

$$\nabla_x \Psi_N = \left[N \begin{pmatrix} it' \\ -C_0 \end{pmatrix} \exp(iNx' \cdot t') \eta_N(x') + O(N^{1-\lambda}) \right] \exp(-C_0 N x_n).$$

It then follows that

$$\begin{aligned} I_1 = N^2 \int_0^{\frac{1}{2\sqrt{N}}} \int_{|x'| \le \frac{1}{\sqrt{N}}} & \left((\gamma(x) - \gamma^a(x)) \begin{pmatrix} it' \\ -C_0 \end{pmatrix} \right) \cdot \begin{pmatrix} -it' \\ -C_0 \end{pmatrix} \\ & \times e^{-2C_0 N x_n} \eta_N(x')^2 dx' dx_n \\ & + O(N^{2-\lambda}) \int_0^{\frac{1}{2\sqrt{N}}} \int_{|x'| \le \frac{1}{\sqrt{N}}} e^{-2C_0 N x_n} |\gamma(x) - \gamma^a(x)| dx' dx_n. \end{aligned}$$

Note that if two multi-indices a and b satisfy $a < b$, then

$$a \cdot \alpha + \lambda \le b \cdot \alpha.$$

Thus, applying the change of variables $y_j = N^{\alpha_j} x_j$, $j = 1, \dots, n$, we obtain

$$\begin{aligned} \gamma(x) - \gamma^a(x) &= \frac{\partial^a \gamma(0)}{a!} x^a + \sum_{b > a, |b| \le m} \frac{\partial^b \gamma(0)}{b!} x^b + O(|x|^{m+1}) \\ &= \frac{\partial^a \gamma(0)}{a!} N^{-a \cdot \alpha} y^a + O(N^{-a \cdot \alpha - \lambda}) \sum_{k=0}^{m+1} y_n^k. \end{aligned}$$

Therefore, we have

$$\begin{aligned} I_1 = {} & \frac{N^{2-a\cdot\alpha-|\alpha|}}{a!} \int_0^{\frac{\sqrt{N}}{2}} \int_{|y'| \le 1} y^a \partial^a \gamma(0) \begin{pmatrix} it' \\ -C_0 \end{pmatrix} \cdot \begin{pmatrix} -it' \\ -C_0 \end{pmatrix} e^{-2C_0 y_n} \eta(y')^2 dy' dy_n \\ & + O(N^{2-a\cdot\alpha-\lambda-|\alpha|}) \int_0^{\frac{\sqrt{N}}{2}} \int_{|y'| \le 1} y^a e^{-2C_0 y_n} [\eta(y')^2 + 1] \sum_{k=0}^{m+1} y_n^k dy' dy_n \\ = {} & N^{2-a\cdot\alpha-|\alpha|} \left(\sum_{i,j=1}^{n-1} \partial^a \gamma^{ij}(0) t_i t_j + C_0^2 \partial^a \gamma^{nn}(0) \right) \\ & \times \frac{1}{a!} \int_0^{\infty} \int_{|y'| \le 1} y^a e^{-2C_0 y_n} \eta(y')^2 dy' dy_n + O(N^{2-a\cdot\alpha-\lambda-|\alpha|}). \end{aligned}$$

From these estimates and (3.3), we obtain

$$N^{-2+a\cdot\alpha+|\alpha|}I = C(a)C_0^{-a_n-1}\left(\sum_{i,j=1}^{n-1}\partial^a\gamma^{ij}(0)t_it_j + C_0^2\partial^a\gamma^{nn}(0)\right) + O(N^{-\lambda}), \tag{3.4}$$

where $C(a)$ is the quantity defined in (1.14).

Estimates of II and III. We prove that

$$|II| + |III| \le CN^{2-m-|\alpha|-\lambda}. \tag{3.5}$$

Once (3.5) is proved, then Theorem 1.1 follows from (3.2), (3.4), and (3.5).

We only give the proof of (3.5) for II. Equation (3.5) for III can be proved in the same way. Note that

$$\begin{aligned}
II &= \int_\Omega (\gamma\nabla_x s_N)\cdot\overline{\nabla(\zeta_N\Psi_N)}dx\\
&= \int_{\Omega_N\setminus\Omega'_N}(\gamma\nabla_x s_N)\cdot\nabla_x\overline{\Psi_N}dx + \int_{\Omega'_N}(\gamma\nabla_x s_N)\cdot\nabla_x(\overline{\zeta_N\Psi_N})dx\\
&= \int_{\Omega_N\setminus\Omega'_N}(\gamma\nabla_x s_N)\cdot\nabla_x\overline{\Phi_N}dx + \int_{\Omega_N\setminus\Omega'_N}(\gamma\nabla_x s_N)\cdot\nabla_x\overline{(\Psi_N-\Phi_N)}dx\\
&\quad + \int_{\Omega'_N}(\gamma\nabla_x s_N)\cdot\nabla_x(\overline{\zeta_N\Psi_N})dx\\
&:= II_1 + II_2 + II_3.
\end{aligned}$$

In the same way as for (3.3), one can show that

$$|II_3| \le C\exp\left(-\frac{C_0}{4}N^{\frac12}\right). \tag{3.6}$$

We now estimate II_1. Set $D_N := \Omega_N\setminus\Omega'_N$ for convenience. By the definition (3.1) of s_N and Lemma 2.2, we have

$$\begin{aligned}
\|s_N\|_{H^1(D_N)} &\le \|\Phi_N\|_{H^1(D_N)} + \|u_N\|_{H^1(D_N)}\\
&\le \|\Phi_N\|_{H^1(D_N)} + \|\phi_N\|_{H^{1/2}(\partial\Omega)}\\
&\le CN^{1-\frac{|\alpha|}{2}}.
\end{aligned} \tag{3.7}$$

Put $\Gamma_1 := \{|x_j| = N^{-\alpha_j} \text{ for some } j\ (j=1,\dots,n-1),\ 0\le x_n\le\frac{1}{2\sqrt{N}}\}$ and $\Gamma_2 := \{|x_j|\le N^{-\alpha_j}\ (j=1,\dots,n-1),\ x_n=\frac{1}{2\sqrt{N}}\}$. Then $\partial D_N = \Gamma\cup\Gamma_1\cup\Gamma_2$. Since

$$s_N\left(x',\frac{1}{2\sqrt{N}}\right) = \int_0^{\frac{1}{2\sqrt{N}}}\partial_{x_n}s_N(x',t)dt,$$

it follows from the Cauchy–Schwarz inequality and (3.7) that

$$\|s_N\|_{L^2(\Gamma_2)} \le \left(\frac{1}{2\sqrt{N}}\right)^{1/2}\|s_N\|_{H^1(D_N)} \le CN^{\frac34-\frac{|\alpha|}{2}}. \tag{3.8}$$

Observe that $\nabla_x \Phi_N|_{\Gamma_1} = 0$ and $\nabla_x \Phi_N|_{\Gamma_2} = O(e^{-\frac{1}{2}C_0 N^{1/2}})$. Since $s_N = 0$ on Γ, it follows from the divergence theorem that

$$\begin{aligned} II_1 &= \int_{D_N} (\gamma \nabla_x s_N) \cdot \nabla \overline{\Phi_N} dx \\ &= -\int_{D_N} s_N \nabla_x \left(\gamma \nabla_x \overline{\Phi_N}\right) dx + O(e^{-\frac{1}{4}C_0 N^{1/2}}). \end{aligned}$$

Note that

$$\left| \int_{D_N} s_N \nabla_x \left(\gamma \nabla_x \overline{\Phi_N}\right) dx \right| \leq \|x_n \nabla_x (\gamma \nabla_x \overline{\Phi_N})\|_{L^2(D_N)} \|x_n^{-1} s_N\|_{L^2(D_N)}.$$

By the Hardy inequality and (3.7), we have

$$\|x_n^{-1} s_N\|_{L^2(D_N)} \leq C \|s_N\|_{H^1(D_N)} \leq C N^{1-\frac{|\alpha|}{2}}.$$

On the other hand, we obtain from (2.3) that

$$\begin{aligned} \|x_n \nabla_x (\gamma \nabla_x \overline{\Phi_N})\|_{L^2(D_N)} &\leq C N^{2-m-\lambda} \|x_n p(y_n) e^{-C_0 y_n}\|_{L^2(D_N)} \\ &\leq C N^{1-m-\lambda-\frac{|\alpha|}{2}}. \end{aligned} \tag{3.9}$$

It thus follows that

$$|II_1| \leq C N^{2-m-|\alpha|-\lambda}.$$

We now estimate II_2. Note that

$$(\Phi_N - \Psi_N)|_{\Gamma \cup \Gamma_1} = 0, \qquad (\Phi_N - \Psi_N)|_{\Gamma_2} = O\left(e^{-\frac{1}{2}C_0 N^{1/2}}\right).$$

Hence, an integration by parts yields

$$II_2 = -\int_{D_N} \nabla_x (\gamma \nabla_x s_N)(\Psi_N - \Phi_N) dx + O(e^{-\frac{1}{4}C_0 N^{1/2}}).$$

Since $\nabla \cdot (\gamma \nabla u_N) = 0$, we have

$$II_2 = \int_{D_N} \nabla_x (\gamma \nabla_x \Phi_N)(\Psi_N - \Phi_N) dx + O(e^{-\frac{1}{4}C_0 N^{1/2}}).$$

In the same way as for II_1, one can show that

$$|II_2| \leq C N^{2-m-|\alpha|-\lambda}.$$

This completes the proof of (3.5).

4. Proof of Theorem 1.3. In this section we prove Theorem 1.3. Suppose that Ω and g are of the form (1.2) and (1.22). For such a metric g and a multi-index a with $|a| \leq m$, define $g^{a,z}$ to be a positive definite symmetric matrix-valued smooth function on Ω such that

$$g^{a,z}(x) := \sum_{b<a} \frac{\partial^b g(z)}{b!} (x-z)^b \tag{4.1}$$

near z. We then define $\Lambda_{g^{a,z}}$ by

$$\langle \Lambda_{g^{a,z}} f, h\rangle = \int_\Omega (|g|^{-1/2} g^{a,z}\nabla u)\cdot \nabla v dx, \quad f,h\in H^{1/2}(\partial\Omega), \tag{4.2}$$

where $u\in H^1(\Omega)$ is the solution to the problem

$$\begin{aligned} \nabla\cdot(|g|^{-1/2}g^{a,z}\nabla u) &= 0 \quad \text{in } \Omega,\\ u &= f \quad \text{on } \partial\Omega, \end{aligned}$$

and $v\in H^1(\Omega)$ is such that $v|_{\partial\Omega}=h$. If $a=0$, let $\Lambda_{g_0}=0$. Note that $\Lambda_{g^{a,z}}$ is *not* a DtN map corresponding to an invariant Laplacian. Consider it as a DtN map corresponding to a divergence equation.

THEOREM 4.1. *Suppose that $g\in C^{m,p}(\overline{\Omega}\cap B_\delta(0))$. For $z=(z',0)\in\partial\Omega\cap B_\delta(0)$, let*

$$C_g(z) := \sqrt{\sum_{i,j=1}^{n-1} g^{ij}(z)t_i t_j}. \tag{4.3}$$

Then for a multi-index $a=(a',a_n)$ and $k\le m$, we have

$$\begin{aligned} &N^{-2+|\alpha|+a\cdot\alpha}\langle(\Lambda_g-\Lambda_{g^{a,z}})\phi_N^z, \overline{\phi_N^z}\rangle \\ &\quad = C(a)C_g(z)^{-a_n-1}|g(z)|^{-1/2}\sum_{i,j=1}^{n-1}\partial^a g^{ij}(z)t_it_j + O(N^{-\lambda}), \end{aligned} \tag{4.4}$$

where $O(N^{-\lambda})$ is independent of z. In particular, when $a=0$, $C(0)=\frac{1}{2}$, and hence we have

$$N^{-2+|\alpha|}\langle\Lambda_g\phi_N^z,\overline{\phi_N^z}\rangle = 2\sqrt{|g(z)|^{-1}\sum_{i,j=1}^{n-1} g^{ij}(z)t_it_j} + O(N^{-\lambda}). \tag{4.5}$$

Despite a slight difference between Theorem 4.1 and Theorem 1.1, it can be proved in the same way, and so we omit the proof. We are now ready to prove Theorem 1.3.

Proof of Theorem 1.3. Suppose first that g_1 and g_2 are of the forms (1.22) ($j=1,2$) and Ω is of the form (1.2). Let K be a compact subset of Γ such that $\operatorname{dist}(K,\partial\Gamma)>\delta_0$ for some $\delta_0>0$. If N is large enough so that $\operatorname{supp}\phi_N^z\subset\Gamma$ for all $z\in K$, then we have from (2.15) that

$$\begin{aligned} N^{-2+|\alpha|}|\langle(\Lambda_1-\Lambda_2)\phi_N^z,\overline{\phi_N^z}\rangle| &\le N^{-2+|\alpha|}\|\Lambda_1-\Lambda_2\|\|\phi_N^z\|^2_{H^{1/2}(\partial\Omega)}\\ &\le \|\Lambda_1-\Lambda_2\|, \end{aligned}$$

where the norm in the last term is the operator norm from $H^{1/2}(\Gamma)$ into $H^{-1/2}(\Gamma)$. It follows from (4.5) that

$$\left|\sqrt{|g_1(z)|^{-1}\sum_{i,j=1}^{n-1} g_1^{ij}(z)t_it_j} - \sqrt{|g_2(z)|^{-1}\sum_{i,j=1}^{n-1} g_2^{ij}(z)t_it_j}\right| \le C\|\Lambda_1-\Lambda_2\| + O(N^{-\lambda}).$$

Since t' is arbitrary and g_j satisfies (1.20), we have

$$||g_1(z)|^{-1}g_1(z) - |g_2(z)|^{-1}g_2(z)| \le C\|\Lambda_1 - \Lambda_2\| + O(N^{-\lambda}). \tag{4.6}$$

Then, by taking determinants, we have

$$||g_1(z)|^{2-n} - |g_2(z)|^{2-n}| \le C\|\Lambda_1 - \Lambda_2\| + O(N^{-\lambda}),$$

and hence

$$||g_1(z)| - |g_2(z)|| \le C\|\Lambda_1 - \Lambda_2\| + O(N^{-\lambda}). \tag{4.7}$$

It then follows from (4.6) and (4.7) that

$$|g_1(z) - g_2(z)| \le C\|\Lambda_1 - \Lambda_2\|. \tag{4.8}$$

Suppose now that a is a multi-index and $|a| > 0$. Note that

$$\begin{aligned}\langle(\Lambda_1 - \Lambda_2)\phi_N^z, \overline{\phi_N^z}\rangle = \langle(\Lambda_1 - \Lambda_{g_1^{a,z}})\phi_N^z, \overline{\phi_N^z}\rangle - \langle(\Lambda_2 - \Lambda_{g_2^{a,z}})\phi_N^z, \overline{\phi_N^z}\rangle \\ + \langle(\Lambda_{g_1^{a,z}} - \Lambda_{g_2^{a,z}})\phi_N^z, \overline{\phi_N^z}\rangle.\end{aligned}$$

Thus it follows from (4.4) that

$$\begin{aligned}&\left|\frac{\sum_{i,j=1}^{n-1}\partial^a g_1^{ij}(z)t_it_j}{C_{g_1}(z)^{a_n+1}|g_1(z)|^{1/2}} - \frac{\sum_{i,j=1}^{n-1}\partial^a g_2^{ij}(z)t_it_j}{C_{g_2}(z)^{a_n+1}|g_2(z)|^{1/2}}\right| \\ &\le CN^{-2+|\alpha|+a\cdot\alpha}\|\Lambda_1 - \Lambda_2\|\|\phi_N^z\|^2_{H^{1/2}(\partial\Omega)} \\ &\quad + CN^{-2+|\alpha|+a\cdot\alpha}|\langle(\Lambda_{g_1^{a,z}} - \Lambda_{g_2^{a,z}})\phi_N^z, \overline{\phi_N^z}\rangle| + CN^{-\lambda}.\end{aligned} \tag{4.9}$$

Let Φ_N^j be approximate solutions of $\nabla\cdot(|g_j|^{-1/2}g_j^{a,z}\nabla u) = 0$ with the boundary value ϕ_N^z on $\partial\Omega$. Then in the same way as the proof of Theorem 1.1, we can show that

$$\langle(\Lambda_{g_1^{a,z}} - \Lambda_{g_2^{a,z}})\phi_N^z, \overline{\phi_N^z}\rangle = \int_{D_N}|g|^{-1/2}(g_1^{a,z} - g_2^{a,z})\nabla\Phi_N^1\cdot\nabla\overline{\Phi_N^2}dx + O(N^{2-m-|\alpha|-\lambda}).$$

Since

$$g_1^{a,z} - g_2^{a,z} = |g_1|^{-1/2}\sum_{b<a}\frac{\partial^b g_1(z)}{b!}(x-z)^b - |g_2|^{-1/2}\sum_{b<a}\frac{\partial^b g_2(z)}{b!}(x-z)^b,$$

we have

$$\begin{aligned}&\left|\int_{D_N}(g_1^{a,z} - g_2^{a,z})\nabla\Phi_N^1\cdot\nabla\overline{\Phi_N^2}dx\right| \\ &\le C\left||g_1|^{-1/2} - |g_2|^{-1/2}\right|\|\nabla\Phi_N^1\|_{L^2(D_N)}\|\nabla\Phi_N^2\|_{L^2(D_N)} \\ &\quad + C\sum_{b<a}\left|\partial^b g_1(z) - \partial^b g_2(z)\right|\left|\int_{D_N}(x-z)^b\nabla\Phi_N^1\cdot\nabla\overline{\Phi_N^2}dx\right|.\end{aligned}$$

By (2.15) and (2.16), we have

$$\begin{aligned}|\langle(\Lambda_{g_1^{a,z}} - \Lambda_{g_2^{a,z}})\phi_N^z, \overline{\phi_N^z}\rangle| \le C(\|\Lambda_1 - \Lambda_2\| + O(N^{-\lambda}))N^{2-|\alpha|} \\ + C\sum_{b<a}|\partial^b g_1(z) - \partial^b g_2(z)|N^{2-|\alpha|-b\cdot\alpha} + CN^{2-m-|\alpha|-\lambda}.\end{aligned}$$

It then follows from (4.9) and the above estimates that

$$\left|\frac{\sum_{i,j=1}^{n-1}\partial^a g_1^{ij}(z)t_it_j}{C_{g_1}(z)^{a_n+1}|g_1(z)|^{1/2}}-\frac{\sum_{i,j=1}^{n-1}\partial^a g_2^{ij}(z)t_it_j}{C_{g_2}(z)^{a_n+1}|g_2(z)|^{1/2}}\right|$$
$$\leq C\left(\|\Lambda_1-\Lambda_2\|N^{a\cdot\alpha}+\sum_{b<a}|\partial^b g_1(z)-\partial^b g_2(z)|N^{(a-b)\cdot\alpha}+N^{-\lambda}\right).$$

It then follows from (4.8) that

$$|\partial^a g_1(z)-\partial^a g_2(z)| \tag{4.10}$$
$$\leq C\left(\|\Lambda_1-\Lambda_2\|N^{a\cdot\alpha}+\sum_{b<a}|\partial^b g_1(z)-\partial^b g_2(z)|N^{(a-b)\cdot\alpha}+N^{-\lambda}\right).$$

From (4.10), one can show that there exists $C=C(m,\lambda)$ such that

$$|\partial^a g_1(z)-\partial^a g_2(z)|\leq C\|\Lambda_1-\Lambda_2\|^{2^{-a\cdot\alpha/\lambda}}. \tag{4.11}$$

We will give a proof of (4.11) at the end of this paper.

If $|a|=k$, then $a\cdot\alpha\leq k$, and hence we have the following stability: If K is a subset of Γ such that $\operatorname{dist}(K,\Gamma)>\delta_0$ for some $\delta_0>0$, then we have

$$\|g_1-g_2\|_{C_E^k(K)}\leq C\|\Lambda_1-\Lambda_2\|^{2^{-k/\lambda}}. \tag{4.12}$$

We now deal with the general case. Suppose that Γ is an open portion of $\partial\Omega$ and K is a compact subset of Γ. For each $x\in K$, there exists an open neighborhood U_x of x and a diffeomorphism (boundary normal coordinates) $\Phi_{j,x}$ on $U_x\cap\overline{\Omega}_N$ such that $\Phi_{j,x}(U_x\cap\overline{\Omega}_N)$ is of the form (1.2) and $(\Phi_{j,x}^{-1})^*g_j$ is of the form (1.22). Moreover $\Phi_{1,x}(z)=\Phi_{2,x}(z)$ for all $z\in U_x\cap\partial\Omega$. Let K_x be a relatively compact subset of $U_x\cap\Gamma$. Then by (4.8) we have

$$\|(\Phi_{1,x}^{-1})^*g_1-(\Phi_{2,x}^{-1})^*g_2\|_{C_E^k(K_x)}\leq C\|\Lambda_{(\Phi_{1,x}^{-1})^*g_1}-\Lambda_{(\Phi_{2,x}^{-1})^*g_2}\|^{2^{-k/\lambda}}.$$

Put $\phi_x(z):=\Phi_{1,x}(z)=\Phi_{2,x}(z)$ for $z\in U_x\cap\partial\Omega$. Then

$$\Lambda_{(\Phi_{j,x}^{-1})^*g_j}=(\phi_x)_*\Lambda_{g_j}.$$

For the proof of this relation, see [15]. Therefore, we have

$$\|g_1-(\Phi_{2,x}^{-1}\circ\Phi_{1,x})^*g_2\|_{C_E^k(K_x)}\leq C\|(\phi_x)_*(\Lambda_{g_1}-\Lambda_{g_2})\|^{2^{-k/\lambda}}.$$

Put $\Psi_x:=\Phi_{2,x}^{-1}\circ\Phi_{1,x}$. Then we have

$$\|g_1-(\Psi_x)^*g_2\|_{C_E^k(K_x)}\leq C\|\Lambda_{g_1}-\Lambda_{g_2}\|^{2^{-k/\lambda}}.$$

By using a partition of unity, we have the theorem. Note that $\Psi_x=Id$ on $U_x\cap\partial\Omega$ for each x. This completes the proof. □

Derivation of (4.11). Since two multi-indices a,b satisfy $b<a$ if and only if $b\cdot\alpha<a\cdot\alpha$, and $b\cdot\alpha=k\lambda$ for some integer k, we may assign a one-to-one relation from multi-indices a with $|a|\leq m$ into the set $\{0,1,\dots,m/\lambda\}$. Let

$$a(k):=|\partial^b g_1(z)-\partial^b g_2(z)|$$

if $b \cdot \alpha = k\lambda$. Put $a(0) := \|\Lambda_1 - \Lambda_2\|$. Then (4.10) reads

$$a(l) \le C\left(\sum_{k<l} a(k)(N^\lambda)^{l-k} + N^{-\lambda}\right) \quad \text{for all large } N.$$

From this one can show inductively that

$$a(l) \le Ca(0)^{2^{-l}}.$$

Thus (4.11) is obtained. □

Acknowledgments. We would like to express our gratitude to the referees, who read the paper thoroughly and offered several invaluable suggestions.

FUNCTIONAL EQUATIONS AND POINCARÉ INVARIANT MECHANICAL SYSTEMS*

J. G. B. BYATT-SMITH† AND H. W. BRADEN†

Abstract. We study the following functional equation that has arisen in the context of mechanical systems invariant under the Poincaré algebra:

$$\sum_{i=1}^{n+1} \frac{\partial}{\partial x_i} \prod_{j \neq i} f(x_i - x_j) = 0, \qquad n \geq 2.$$

New techniques are developed and the general solution within a certain class of functions is given. New solutions are found.

Key words. functional equation, mechanics

1. Introduction.

The differential equation

$$\begin{vmatrix} 1 & 1 & 1 \\ f(u) & f(v) & f(w) \\ f'(u) & f'(v) & f'(w) \end{vmatrix} = 0 \quad \text{subject to } u + v + w = 0 \tag{1.1}$$

is one form of the first of a series of differential equations that can be written as

$$\sum_{i=1}^{n+1} \frac{\partial}{\partial x_i} \prod_{j \neq i} f(x_i - x_j) = 0, \qquad n \geq 2, \tag{1.2}$$

subject to the constraint that f is an even function. Equation (1.1) appeared in the context of a three-body integrable quantum mechanical problem and was studied by Buchstaber and Perelomov [7] and later by Braden and Byatt-Smith [2]. Equations (1.2), which have appeared in the context of constructing mechanical systems with certain invariances, are the focus of this paper. (We will later review these connections between functional equations and mechanical systems.) When $n = 2$, (1.2) gives

$$\begin{aligned} &\frac{\partial}{\partial x_1}\left(f(x_1 - x_2) f(x_1 - x_3)\right) + \frac{\partial}{\partial x_2}\left(f(x_2 - x_3) f(x_2 - x_1)\right) \\ &\qquad + \frac{\partial}{\partial x_3}\left(f(x_3 - x_1) f(x_3 - x_2)\right) = 0. \end{aligned} \tag{1.3}$$

Using the evenness of f we may express this as

$$\begin{aligned} &\frac{\partial}{\partial x_1}\left(f(x_1 - x_2) f(x_3 - x_1)\right) + \frac{\partial}{\partial x_2}\left(f(x_2 - x_3) f(x_1 - x_2)\right) \\ &\qquad + \frac{\partial}{\partial x_3}\left(f(x_3 - x_1) f(x_2 - x_3)\right) = 0. \end{aligned} \tag{1.4}$$

†Department of Mathematics and Statistics, The University of Edinburgh, Edinburgh, UK (Byatt @ed.ac.uk, hwb@ed.ac.uk).

Equation (1.1) can be written in this form if we put $u = x_1 - x_2, v = x_2 - x_3$, and $w = x_3 - x_1$, which automatically satisfies the constraint, although the assumption of evenness is not required.

Braden and Byatt-Smith [2] proved, as part of a more general theorem, that the complete solution set for the function f which satisfies (1.1) is

$$f(u) = a + bu \text{ or } a + b\, e^{cu} \tag{1.5a}$$

or

$$f(u) = a + b\,\wp(cu + d, g_2, g_3)\,. \tag{1.5b}$$

Here $\wp$ is the Weierstrass $\wp$-function. Equation (1.5b) has six constants associated with it, namely, $\{a, b, c, d, g_2, g_3\}$, where g_2 and g_3 are the two constants which relate to the two periods of $\wp(z)$, and d is one-third of any period. However, $\wp(z)$ satisfies the equation $\wp'^2 = 4\wp^3 - g_2\wp - g_3$, with $z^2\wp(z) \to 1$ as $z \to 0$. Hence $\wp$ satisfies the scaling law $\wp(cu, g_2, g_3) \equiv c^{-2}\wp\left(u, c^4 g_2, c^6 g_3\right)$, so that without loss of generality we may take $c = 1$ in (1.5b). The solution set represented by (1.5a), which is a subset of (1.5b), does not require the constraint $u + v + w = 0$ to be satisfied and is the general solution of the differential equation

$$f' f''' - f''^2 = 0. \tag{1.6}$$

The solution set (1.5b) only satisfies (1.1) provided the constraint is satisfied and is the general solution of

$$f'^2 + Af^3 + Bf^2 + Cf + D = 0, \tag{1.7}$$

or, upon eliminating the arbitrary constants A, B, C, and D,

$$f'^2 f^{(v)} - 3f' f'' f^{(iv)} + 3f''^2 f''' - f' f'''^2 = 0. \tag{1.8}$$

When we consider (1.5b) as the general solution of (1.7) or (1.8), d appears as an arbitrary constant. However, if (1.5b) is also to satisfy (1.1), then d is not arbitrary and, by substituting the solution back into (1.1), can be shown to be either zero or any integer multiple of one-third of any period of $\wp(z)$. A simpler proof that all of the solutions of (1.1) are contained in the solution set of (1.5a, b), subject to the above condition on d, can be obtained by eliminating the functions $f(v)$ and $f(w)$ by taking suitable combinations of derivatives of (1.1). At various points in the proof the equation factorizes to give (1.6) or (1.7) as factors. (This was the approach of [2].)

For the last 15 years the nature of the solutions to (1.2) has remained open. One can show [13] that (1.5b), with $d = 0$ to ensure the evenness of f, satisfy (1.2), and it has been conjectured that such were the only solutions. Though the method of eliminating functions just noted above for the case of (1.1) should be applicable in the general case, the algebra involved to completely define the solution set is quite considerable. In the case of (1.2), when $n \geq 3$ the amount of algebra appears to be so large that even a Maple calculation cannot handle the details necessary to provide a definition of the solution set. Here we shall develop new techniques to handle the equation. Our main result contains a surprise. To describe this let us introduce the following.

DEFINITION 1. *Let $\mathcal{A}$ and $\mathcal{A}'$ denote the class of meromorphic functions $f(z)$ with the following properties:*

(1) *$f(z)$ is an even function of z.*

(2) *The only singularity of $f(z)$ in the strip $|\mathcal{I}m(z)| < a$ for some $a > 0$ is a double pole at the origin. And (respectively)*

(3) *$\frac{z^2 f(z)}{2a^2+z^2}$ is L_1 along any line $|\mathcal{I}m(z)| = t,\ -\infty < \mathcal{R}e(z) < \infty$, where $|t| < a$.*

(3′) (a) *Either $z^2 f(z)$ is L_1 along any line $|\mathcal{I}m(z)| = t,\ -\infty < \mathcal{R}e(z) < \infty$, where $|t| < a$, or* (b) *there exists a constant c such that $z^2 f(z) - c$ is L_1 along any line $|\mathcal{I}m(z)| = t,\ -\infty < |\mathcal{R}e(z) < \infty$, where $|t| < a$.*

DEFINITION 2. *Let $\mathcal{A}_p$ denote the class of periodic, meromorphic functions $f(z)$ whose period is p (where p is real) with the following properties:*

(1) *$f(z)$ is an even function of z.*

(2) *The only singularities of $f(z)$ in the strip $|\mathcal{I}m(z)| < a$ for some $a > 0$ are a periodic array of double poles of the form $1/(z - 2n\pi)^2$ at the points $z = 2n\pi$, $n \in \mathbb{Z}$, on the real axis.*

With these definitions in hand we find the following.

THEOREM 1. *For functions $f(z) \in \mathcal{A}' \cup \mathcal{A}_p$ the general even solution of* (1.2) *is*

(a) *for all even $n \geq 2$ given by* (1.5b) *with $d = 0$, while*

(b) *for odd $n \geq 3$ there are in addition to the solutions* (1.5b) *with $d = 0$ the following:*

$$h_1(z) = \sqrt{(\wp(z) - e_2)(\wp(z) - e_3)} = \frac{\sigma_2(z)\sigma_3(z)}{\sigma^2(z)} = \frac{\theta_3(v)\theta_4(v)}{\theta_1^2(v)} \frac{\theta_1'^2(0)}{4\omega^2\theta_3(0)\theta_4(0)} = b\frac{\mathrm{dn}(u)}{\mathrm{sn}^2(u)},$$

$$h_2(z) = \sqrt{(\wp(z) - e_1)(\wp(z) - e_3)} = \frac{\sigma_1(z)\sigma_3(z)}{\sigma^2(z)} = \frac{\theta_2(v)\theta_4(v)}{\theta_1^2(v)} \frac{\theta_1'^2(0)}{4\omega^2\theta_2(0)\theta_4(0)} = b\frac{\mathrm{cn}(u)}{\mathrm{sn}^2(u)},$$

$$h_3(z) = \sqrt{(\wp(z) - e_1)(\wp(z) - e_2)} = \frac{\sigma_1(z)\sigma_2(z)}{\sigma^2(z)} = \frac{\theta_2(v)\theta_3(v)}{\theta_1^2(v)} \frac{\theta_1'^2(0)}{4\omega^2\theta_2(0)\theta_3(0)} = b\frac{\mathrm{cn}(u)\,\mathrm{dn}(u)}{\mathrm{sn}^2(u)}.$$

Here

$$\sigma_\alpha(z) = \frac{\sigma(z + \omega_\alpha)}{\sigma(\omega_\alpha)} e^{-z\zeta(\omega_\alpha)}, \qquad u = \sqrt{e_1 - e_3}\, z, \qquad v = \frac{z}{2\omega}, \qquad b = e_1 - e_3,$$

with $\omega_1 = \omega$, $\omega_2 = -\omega - \omega'$, and $\omega_3 = \omega'$, and we have given representations in terms of the Weierstrass elliptic functions, theta functions, and the Jacobi elliptic functions [16]. For appropriate ranges of z the solutions are real. These exhaust the even periodic solutions of (1.2), and their degenerations yield all the even solutions with only a double pole at $x = 0$ on the real axis. The assumption of only a double pole at the origin comes from an elementary singularity analysis of (1.2). When $n = 2$, 3 the theorem can be proved without the assumption that $f(z) \in \mathcal{A}' \cup \mathcal{A}_p$, provided it is assumed that f is meromorphic with a double pole at the origin. We also conjecture this latter assumption is all that is required for $n \geq 4$ but have been unable to prove this. The surprise is the appearance of these new solutions for odd n, which in turn yield new Poincaré invariant mechanical systems.

Our paper is arranged as follows. First we will describe the origin of (1.2) and of the several connections between functional equations and mechanical systems in section 2. Section 3 is the heart of the paper where we introduce our new method. Here we take a (suitable) Fourier transform of (1.2), turning that functional equation into a functional equation for the transform. It is in taking this Fourier transform that we encounter the class $\mathcal{A}$, which is sufficient for the transform to exist. The

functional equation we produce has a remarkable property: we can reduce the general n equation to a consideration of the $n = 2$ and $n = 3$ cases. Subject to one or two assertions proven in sections 4 and 5, we have essentially proven the theorem. Section 4 considers the case of the $n = 2$ equation and section 5 considers the case of the $n = 3$, which yields the new solutions. It is only at this stage in solving these equations do we need the more restricted class $\mathcal{A}'$. At this stage we have proven our theorem, and the remaining two sections are included for completeness. In section 6 we consider using our *Fourier transform method* to rederive the general solution of (1.1) found in [2]. Finally in section 7 we consider the more common series methods for solving functional equations, as used, for example, in [2]. These methods yield either a Laurent series for the solution set or a set of differential equations, whose common solution the solution set must satisfy. The advantage of these methods is that they define the solution set, or the differential equations that the set must satisfy, for (1.2) when $n = 2$ or $n = 3$. Even though these methods appear intractable for larger values of n, the equations derived for $n = 2$ and 3 can be solved, and we can prove theorem 1 for cases $n = 2$ and 3 only, but under weaker conditions than those required for the *Fourier transform method*.

2. Some mechanical systems. Some years ago Ruijsenaars and Schneider [13] initiated the study of mechanical systems exhibiting an action of Poincaré algebra:

$$\{H, B\} = P, \qquad \{P, B\} = H, \qquad \{H, P\} = 0. \tag{2.1}$$

Here H is the Hamiltonian of the system generating time-translations, P is a space-translation generator, and B is the generator of boosts. The models they discovered were found to posses other nice features: they were in fact integrable and a quantum version of them naturally existed. These models also appear in various field theoretic contexts (see [5]). Ruijsenaars and Schneider began with the ansatz for a system of $n + 1$ particles interacting on the line,

$$H = \sum_{j=1}^{n+1} \cosh p_j \prod_{k \neq j} F(x_j - x_k), \qquad P = \sum_{j=1}^{n+1} \sinh p_j \prod_{k \neq j} F(x_j - x_k),$$

and

$$B = -\sum_{j=1}^{n+1} x_j.$$

With this ansatz and the canonical Poisson bracket $\{x_i, p_j\} = \delta_{ij}$ the first two Poisson brackets of (2.1) involving the boost operator B are automatically satisfied. Supposing further that $F(x) = \pm F(-x)$, then the final Poisson bracket is equivalent to the functional equation

$$\{H, P\} = 0 \Longleftrightarrow \sum_{j=1}^{n+1} \partial_j \prod_{k \neq j} F^2(x_j - x_k) = 0. \tag{2.2}$$

With $f(x) = F(x)\,F(-x)$ this is precisely (1.2), and so solutions of this equation yield Poincaré invariant mechanical systems. At the time, Ruijsenaars and Schneider were able to show that (1.5b) (with $d = 0$) gave solutions to these equations for all n. These solutions in fact yield $n+1$ independent, mutually Poisson commuting conserved

quantities, and so are a completely integrable mechanical system. A scaling limit of the Ruijsenaars–Schneider model yields the Calogero–Moser system with Hamiltonian

$$H = \frac{1}{2}\sum_{i=1}^{n+1} p_i^2 + \frac{1}{6}\sum_{i\neq j} \wp\left(q_i - q_j\right), \tag{2.3}$$

which is another well-studied completely integrable system [15].

We note that many connections exist between functional equations and integrable quantum and classical systems [3, 4, 6, 7, 8, 9, 11, 12]. Functional equation (1.1) (without any assumptions on the parity of the function f) arises, for example, when characterizing quantum mechanical potentials whose ground state wavefunction (of a given form) is factorizable [10, 14]. Buchstaber and Perelomov solved this equation in [7]. More recently, it has been shown to characterize the Calogero–Moser system [1]. Several functional equations appearing in this setting and whose general solutions have still to be found are given in [4].

3. The Fourier transform method. Our strategy to solve (1.2) will be to derive a functional equation for the Fourier transform of this equation, which we then proceed to solve. Indeed, we will show that in order to solve the functional equation for the Fourier transform, it suffices to solve for the $n = 2$ and $n = 3$ cases, and this is done in later sections. In deriving the functional equation for the Fourier transform we need to assume that $f \in \mathcal{A}$. However, in order to derive the solutions to the $n = 2$ and $n = 3$ equations via this Fourier transform method, we need to assume the more restrictive condition $f \in \mathcal{A}'$. (In section 7 we see that this further restriction is unnecessary.)

Let us then look first to the problem of deriving the equation for the Fourier transform of the solution of (1.1) and (1.2) for general integer n. There are a variety of difficulties which are not immediately apparent. These will be treated as they arise. They include requiring an appropriate generalized Fourier transform for functions of x which are unbounded either at infinity or at points on the real axis, and the consideration of distributional solutions both of (1.2), (1.3), and (1.4) and of the transformed equation. We first consider the even solutions of (1.2) for a general integer n. It will be convenient to write (1.2) as

$$g\left(\mathbf{x}, x_{n+1}\right) = \sum_{p=1}^{n+1} \frac{\partial}{\partial x_p} \prod_{q\neq p} f\left(x_p - x_q\right), \tag{3.1}$$

where f is even and $\mathbf{x}$ is the vector $(x_1, x_2, \ldots, x_n)$. We then define the n-dimensional Fourier transform $\widehat{g}(\mathbf{k}, x_{n+1})$ of $g\left(\mathbf{x}, x_{n+1}\right)$ by

$$\widehat{g}\left(\mathbf{k}, x_{n+1}\right) = \int_{\mathbb{R}^n} g\left(\mathbf{x}, x_{n+1}\right) e^{-i\mathbf{k}.\mathbf{x}} d\mathbf{x}. \tag{3.2}$$

However, there are problems with the double pole of f at the origin. Away from these singularities g is identically zero for these solutions. However, to interpret (3.2) correctly we find that g acts as a distribution over any plane through the origin, and the 2-dimensional Fourier transform of g over this plane gives a nonzero contribution. The contribution from all of these singularities becomes difficult to deal with. To overcome this we assume that the arguments of g are complex, and we replace x_j by

$x_j + i\epsilon_j$, where $\epsilon_{n+1} > \epsilon_n > \cdots > \epsilon_1 > 0$, and assume that ϵ_{n+1} is small. In other words

$$g = \sum_{p=1}^{n+1} \frac{\partial}{\partial x_p} \prod_{q \neq p} f\left(x_p - x_q + i\left(\epsilon_p - \epsilon_q\right)\right). \tag{3.3}$$

We then assume that in the definition of $\widehat{g}$, (3.2), we integrate along the real axis in the complex $x_j + iy_j$ plane. If the function $f(z)$ has double poles on the $x = Re\ z$ axis and no other singularities in the neighborhood of the x-axis, then, provided ϵ_{n+1} is small enough, there will be no singularities of g within the domain of integration of the integral occurring in (3.2). This is the motivation for item (2) in Definitions 1 and 2.

To calculate $\widehat{g}$ we make some changes of variables. Set $\xi_q = x_1 - x_q + i\left(\epsilon_1 - \epsilon_q\right)$ for $2 \leq q \leq n+1$ and $\xi_1 = x_1 - x_{n+1} + i\left(\epsilon_1 - \epsilon_{n+1}\right)$. Then $\xi_1 = \xi_{n+1}$. Further set $X_q = x_1 - x_q$. Then focusing first on the $p = 1$ term in (3.2) consider

$$\begin{aligned} I &= \int_{x_1=-\infty}^{\infty} \int_{\mathbb{R}^{n-1}} \prod_{q=2}^{n+1} f\left(\xi_q\right) e^{-i\mathbf{k}.\mathbf{x}} d^{n-1}x\, dx_1 \\ &= \int_{x_1=-\infty}^{\infty} f(\xi_1) e^{-ik_1x_1} \left(\prod_{q=2}^{n} \int_{x_q=-\infty}^{\infty} f\left(\xi_q\right) e^{-ik_qx_q} dx_q \right) dx_1 \\ &= \int_{x_1=-\infty}^{\infty} f(\xi_1) e^{-ik_1x_1} \left(\prod_{q=2}^{n} \int_{X_q=-\infty}^{\infty} f\left(\xi_q\right) e^{ik_q(X_q - x_1)} dX_q \right) dx_1. \end{aligned} \tag{3.4}$$

Now since $\epsilon_q > \epsilon_1$ the singularities of $f\left(z_1\right)$ at $z_1 = i(\epsilon_{n+1} - \epsilon_1)$, and (for $q > 1$) of $f\left(z_q\right)$ at $z_q = i(\epsilon_q - \epsilon_1)$ lie in the upper half plane.

For functions $f(z)$ which are analytic in the neighborhood of the $Re\ z$ axis but have a pole at $z = 0$ we define Fourier transforms $\widehat{f}_U$ and $\widehat{f}_L$ by

$$\widehat{f}_U(k) = \int\!\!\!\!\!\!\uparrow_{-\infty}^{\infty} f(x) e^{-ikx} dx \tag{3.5}$$

and

$$\widehat{f}_L(k) = \int\!\!\!\!\!\!\downarrow_{-\infty}^{\infty} f(x) e^{-ikx} dx, \tag{3.6}$$

which are suitably indented to go above and below the singularity at the origin. With these definitions we have, in the limit as $\epsilon_{n+1} \to 0$,

$$\begin{aligned} I &= \int_{-\infty}^{\infty} f\left(x_1 - x_{n+1} + i\left(\epsilon_1 - \epsilon_{n+1}\right)\right) e^{-i\left(\sum_{q=1}^{n} k_q\right)x_1} dx_1 \prod_{q=2}^{n} \widehat{f}_L(-k_q) \\ &= e^{-i\left(\sum_{q=1}^{n} k_q\right)x_{n+1}} \widehat{f}_L\left(\sum_{q=1}^{n} k_q\right) \prod_{q=2}^{n} \widehat{f}_L(-k_q). \end{aligned} \tag{3.7}$$

Assuming condition (3) of Definition 1, the Fourier transform of f exists and is continuous. Thus the first term in the sum in (3.3) contributes a term ik_1I to $\widehat{g}$. A

similar calculation gives

$$\widehat{g} = \left(\sum_{j=1}^{n}\left[k_j\left(\prod_{q=1}^{j-1}\widehat{f}_U(-k_q)\right)\left(\prod_{q=j+1}^{n}\widehat{f}_L(-k_q)\right)\right]\widehat{f}_L\left(\sum_{q=1}^{n}k_q\right) - \left(\sum_{j=1}^{n}k_j\right)\left(\prod_{q=1}^{n}\widehat{f}_U(-k_q)\right)\right) ie^{-i\left(\sum_{q=1}^{n}k_q\right)x_{n+1}}, \tag{3.8}$$

so that $\widehat{g}=0$ gives

$$\sum_{j=1}^{n}\left[k_i\left(\prod_{q=1}^{j-1}\widehat{f}_U(-k_q)\right)\left(\prod_{q=j+1}^{n}\widehat{f}_L(-k_q)\right)\right]\widehat{f}_L\left(\sum_{q=1}^{n}k_q\right)-\left(\sum_{j=1}^{n}k_j\right)\left(\prod_{q=1}^{n}\widehat{f}_U(-k_q)\right)=0. \tag{3.9}$$

We now define the Fourier transform of $f(z)$ to be $\frac{1}{2}(\widehat{f}_U(k)+\widehat{f}_L(k))$. Also we have the result that the difference $\widehat{f}_L(k)-\widehat{f}_U(k)$ is $2\pi i$ multiplied by the residue of the functions $f(z)\,e^{-ikz}$ at the origin, assuming that the only singularity of $f(z)$ on the real axis is at the origin. We further make the assumption that $f(z)$ is an even function of z with a double pole of the form $1/z^2$ at the origin. Hence with

$$\widehat{f}(k)=\frac{1}{2}\left(\widehat{f}_U(k)+\widehat{f}_L(k)\right) \tag{3.10}$$

and

$$\widehat{f}_L(k)-\widehat{f}_U(k)=2\pi i\times\ \text{Residue}\left(f(z)\,e^{-ikz}\right)=2\pi k, \tag{3.11}$$

we have

$$\widehat{f}_L(k)=\widehat{f}(k)+\pi k \tag{3.12}$$

and

$$\widehat{f}_U(k)=\widehat{f}(k)-\pi k. \tag{3.13}$$

Hence the equation $\widehat{g}=0$, (3.9) gives

$$\begin{aligned} S_n &\equiv \sum_{j=1}^{n}\left[k_j\prod_{q=1}^{j-1}\left(\widehat{f}(-k_q)+\pi k_q\right)\prod_{q=j+1}^{n}\left(\widehat{f}(-k_q)-\pi k_q\right)\right]\left(\widehat{f}\left(\sum_{q=1}^{n}k_q\right)+\pi\sum_{q=1}^{n}k_q\right) \\ &\qquad -\left(\sum_{j=1}^{n}k_j\right)\left(\prod_{q=1}^{n}\left(\widehat{f}(-k_q)+\pi k_q\right)\right) \\ &= \sum_{j=1}^{n}\left[k_j\prod_{q=1}^{j-1}\left(\widehat{f}(k_q)+\pi k_q\right)\prod_{q=j+1}^{n}\left(\widehat{f}(k_q)-\pi k_q\right)\right]\left(\widehat{f}\left(\sum_{q=1}^{n}k_q\right)+\pi\sum_{q=1}^{n}k_q\right) \\ &\qquad -\left(\sum_{j=1}^{n}k_j\right)\left(\prod_{q=1}^{n}\left(\widehat{f}(k_q)+\pi k_q\right)\right)=0, \end{aligned} \tag{3.14}$$

the final expression being obtained using the fact that $\widehat{f}(k)$ is an even function of k. This equation is to be regarded as one which determines $\widehat{f}(k)$ and must be satisfied for all $\{k_q\}$ in $\mathbb{R}^n$. This is the desired functional equation for the Fourier transform of our equation.

We note that, by inspection, $\widehat{f}(k) = \pm\pi|k|$ satisfies (3.14) for all n, and we may also show that $\widehat{f}(k) = t\pi|k|$ satisfies (3.4) for all values of t which satisfy $(1+t)^n(t-1) = (t-1)^n(1+t)$. Apart from $t = \pm 1$, these are $t = i\cot\frac{j\pi}{n-1}$, $j = 1, \ldots, n-2$. However, to satisfy the requirement that the inverse $f(z)$ is such that $z^2 f(z) \to 1$ as $z \to 0$, we require the solution above with $t = -1$. This problem recurs throughout the rest of the paper, and from now on it will be assumed that we take only the multiple of $\widehat{f}(k)$ which satisfies the criterion that it has the correct double pole either at the origin or at the sequence of double poles when $f(z)$ is periodic.

At this stage we have identified a solution to (3.14), the Fourier transform of (1.2). The following lemmas prove useful in finding the complete solution to (3.14) for all n. We begin with a definition.

DEFINITION 3. *For each n let $\mathcal{F}_n$ be the solution set of $S_n = 0$, and let $\mathcal{G}_n$ be the solution set of $S_n = 0$ and $\widehat{f}(0) \neq 0$.*

LEMMA 1. *For $n \geq 4$ and even, $\mathcal{F}_n \subseteq \mathcal{F}_2$.*

LEMMA 2. *For $n \geq 3$, $\mathcal{G}_n \subseteq \mathcal{G}_2$.*

Proof of Lemma 1. In S_{n+2} we put $k_{n+2} = -k_{n+1}$, and using the fact that $\widehat{f}$ is even, we find

$$S_{n+2}\Big|_{k_{n+2}=-k_{n+1}} = \left(\widehat{f}^2(k_{n+1}) - \pi^2 k_{n+1}^2\right) S_n. \tag{3.15}$$

The factor $\widehat{f}^2(k) - \pi^2 k^2$ produces the solutions $\widehat{f}(k) = \pm\pi|k|$ if $\widehat{f}$ is even. This function we have already shown belongs to all the solution sets $\mathcal{F}_n$. Since the solution set $\mathcal{F}_{n+2}$ must be contained in the solution set of $S_{n+2}\big|_{k_{n+2}=-k_{n+1}}$, (3.15) shows that $\mathcal{F}_{n+2} \subseteq (\widehat{f}(k) = \pm\pi|k|) \cup \mathcal{F}_n \subseteq \mathcal{F}_n$. The result now follows by induction.

Proof of Lemma 2. In S_{n+1} we put $k_{n+1} = 0$ and obtain

$$S_{n+1}\Big|_{k_{n+1}=0} = \widehat{f}(0)\, S_n. \tag{3.16}$$

Again if $\widehat{f}(0) \neq 0$, the result follows by induction.

DEFINITION 4. *Let $\mathcal{B}$ denote the class of functions whose generalized Fourier transform $\widehat{f}(k)$ arise from functions $f(z) \in \mathcal{A}'$.*

Although we have derived (3.14) for the class of functions $\mathcal{A}$, only for the subclass of functions given by $\mathcal{A}'$ are we able to show the following theorem.

THEOREM 2. *For solutions with $\widehat{f} \in \mathcal{B}$, then $\mathcal{F}_n = \mathcal{F}_2$ for all even n.*

Proof. By Lemma 1 $\mathcal{F}_n \subseteq \mathcal{F}_2$. In section 4 we will prove that $\mathcal{F}_2$ is the one parameter family $\widehat{f}(k) = \pi k \coth(\pi k/a_0)$, together with its limit as $a_0 \to 0$, $\pm\pi|k|$. It can be verified by substitution that these satisfy $S_n = 0$, as we show in section 5 (see 5.9). This gives $\mathcal{F}_2 \subseteq \mathcal{F}_n$, and the result now follows.

THEOREM 3. *For solutions with $\widehat{f} \in \mathcal{B}$, then $\mathcal{G}_n = \mathcal{G}_2$ for all n.*

The proof of Theorem 3 follows by the same method as the proof of Theorem 2. However, we cannot exclude the possibility that there exist solutions of $S_n = 0$, with $n \geq 3$ and odd, which have $\widehat{f}(0) = 0$ but are not contained in the solutions of $S_2 = 0$. This will be the way our new solutions arise. At this stage, subject to our assertions regarding the $n = 2$ solutions to be proven, we have reduced the problem of solution of the functional equation of the Fourier transform to the cases of $n = 2$ and $n = 3$

with $\widehat{f}(0) = 0$. Before we look at these cases we conclude this section by considering the extensions of Lemmas 1 and 2 and the corresponding theorems about the solution sets to functions $f(z)$ which are periodic. This requires $f(z)$ to have a periodic array of double poles of the form $1/(z - 2n\pi)^2$ at the points $z = 2n\pi$, $n \in \mathbb{Z}$.

To cater for the even periodic solutions of (1.5b) that are also bounded on the real axis, apart from a periodic sequence of double poles, we assume that the solutions $f(x)$ are 2π-periodic and write

$$f(x) = \frac{1}{2\pi} \sum_{p=-\infty}^{\infty} a_p e^{ipx}, \quad \text{with } a_{-p} = a_p. \tag{3.17}$$

The factor 2π is introduced so that the Fourier transform takes the form

$$\widehat{f}(k) = \sum_{p=-\infty}^{\infty} a_p \delta(k - p). \tag{3.18}$$

The Fourier coefficients for a well-behaved function are defined in the usual way in terms of an integral over a period. The corresponding generalized definition for functions with singularities is defined in the same way as the Fourier transform f_U and f_L via (3.5) and (3.6) by taking the integrals, suitably indented, over a period. The pole contributions to the Fourier series in (3.5) and (3.6) then give rise to a term $\sum_{p=-\infty}^{\infty} \pi k_p \delta(k - p)$, which replaces the corresponding term πk_p in (3.14), using the same interpretation as that in (3.18). We introduce these expressions into (3.14) and then recognize that $\widehat{f}(k)$ is only nonzero when k is an integer. Thus, by replacing $\widehat{f}(k_q)$ by $a_{K_q}\delta(k_q - K_q)$ and the pole contribution by $K_q\delta(k_q - K_q)$, in the neighborhood of the point $\{k_p = K_p,\, p = 1, \ldots, n\}$ we obtain

$$\begin{aligned} S_n = \sum_{j=1}^{n} \Bigg[K_j \prod_{q=1}^{j-1} \left((a_{K_q} + \pi K_q)\delta(k_q - K_q) \right) \prod_{q=j+1}^{n} \left((a_{K_q} - \pi K_q)\delta(k_q - K_q) \right) \Bigg] \\ \times \left(\left(a_{\sum_{q=1}^{n} K_q} + \pi \sum_{q=1}^{n} K_q \right) \delta\left(\sum_{q=1}^{n} (k_q - K_q) \right) \right) \\ - \left(\sum_{j=1}^{n} K_j \right) \left(\prod_{q=1}^{n} \left((a_{K_q} + \pi K_q)\delta(k_q - K_q) \right) \right) = 0. \end{aligned} \tag{3.19}$$

This is a distribution supported at $k_q = K_q$ $(q = 1, \ldots, n)$ and is identically zero if

$$\begin{aligned} \sum_{j=1}^{n} \Bigg[K_j \prod_{q=1}^{j-1} \left(a_{K_q} + \pi K_q \right) \prod_{q=j+1}^{n} \left(a_{K_q} - \pi K_q \right) \Bigg] \left(a_{\sum_{q=1}^{n} K_q} + \pi \sum_{q=1}^{n} K_q \right) \\ - \left(\sum_{j=1}^{n} K_j \right) \left(\prod_{q=1}^{n} \left(a_{K_q} + \pi K_q \right) \right) = 0 \end{aligned} \tag{3.20}$$

for all integer values of K_q. Since $\widehat{f}(k)$ satisfy the continuous version of (3.20), it is clear that the solution $a_K = \widehat{f}(K)$, $K \neq 0$ with a_0 arbitrary, will satisfy (3.20). It is

also easy to construct the corresponding function $f(x)$ that satisfies (1.4). If $f(x)$ is the function whose Fourier transform is $\widehat{f}(k)$, then we define

$$h(x) = \sum_{p=-\infty}^{\infty} f(x - 2\pi p). \tag{3.21}$$

This function is 2π-periodic and has Fourier series $\frac{1}{2\pi}\sum_{K=-\infty}^{\infty} a_K e^{iKx}$, where

$$a_K = \int_0^{2\pi} \sum_{p=-\infty}^{\infty} f(x - 2p\pi)\, e^{-iKx} dx = \int_{-\infty}^{\infty} f(x)\, e^{-iKx} dx = \widehat{f}(K). \tag{3.22}$$

The above solution for a_K can also be obtained directly from (3.20) by successively solving all equations with $1 \le |K_q| \le N$, $q = 1, \ldots, n$, for $N = 1, 2, 3, \ldots$, the equations where $K_q = 0$ being automatically satisfied. All the solutions to (3.20) are obtained in section 4.

The conclusions can be summed up in the following theorem, which incorporates the result of Braden and Byatt-Smith [2] for even functions as a special case.

DEFINITION 5. *Let $\mathcal{B}_{2\pi}$ denote the class of functions whose generalized Fourier transform $\widehat{f}(k)$ arises from 2π-periodic meromorphic functions $f(z)$, bounded on the real axis apart from double poles at $1/(z - 2\pi n)^2$, $n \in \mathbb{Z}$.*

THEOREM 4. *For $\widehat{f} \in \mathcal{B} \cup \mathcal{B}_{2\pi}$,*

1. *the only even solutions of* (1.2) *with n even are those of* (1.5b) *with $d = 0$;*

2. *the only even solutions of* (1.2) *with n odd and for which $\widehat{f}(0) \neq 0$ are those of* (1.5b) *with $d = 0$.*

4. Even solutions of the transformed equation and their inverses. Theorems 1–4 state that the only even solutions of (1.2) with $\widehat{f}(0) \neq 0$ are those of (1.5b) with $d = 0$. We complete the proof of these theorems in this section and section 5 by deriving these solutions for the case $n = 2$ and then in section 5 by showing that these solutions also satisfy (1.2) for arbitrary n; see (5.5)–(5.9). If there are no poles of f on the real axis, then (3.14) for the Fourier transform, when $n = 2$, now reads

$$\left(k\widehat{f}(l) + l\widehat{f}(k)\right)\widehat{f}(k+l) = (k+l)\,\widehat{f}(k)\,\widehat{f}(l), \tag{4.1}$$

where for convenience we have written $k_1 = k$ and $k_2 = l$. Clearly if $\widehat{f}(k)$ is a function not identically zero, then (4.1) implies that $k/\widehat{f}(k)$ is linear so that $\widehat{f}(k)$ is constant. This, however, gives only the distributional solution where $f(x)$ is a constant multiple of $\delta(x)$. If we allow distributions, then $\widehat{f}(k) = a\delta(k)$ is also a solution of (4.1), as is $\widehat{f}(k) = a\delta(k) + b$ with the corresponding $f(x) = b\delta(x) + a$. These are the only even solutions of (4.1).

When we allow f to have a double pole at the origin, (3.14) for the Fourier transform, when $n = 2$, becomes

$$\left(k\widehat{f}(l) + l\widehat{f}(k)\right)\widehat{f}(k+l) = (k+l)\,\widehat{f}(k)\,\widehat{f}(l) + \pi^2 kl\,(k+l). \tag{4.2}$$

The Fourier transform of $1/x^2$ is $-\pi|k|$, and the identity

$$(k|l| + l|k|)\,|k+l| = (k+l)\,(|k|\,|l| + kl) \tag{4.3}$$

for all k, l ensures that the even functions $\widehat{f}(k) = \pm\pi|k|$ satisfy (4.2), with the minus sign required to satisfy the pole condition. However, $\widehat{f}(k) = \pm\pi|k|$ are not the only solutions of (4.2). We wish to consider only even functions, but also wish to include functions like $|k|$ which are not differentiable at $k = 0$. Hence we consider (4.2) defined on the subspace $k \geq 0, l \geq 0$, with all derivatives at the origin defined by one-sided derivatives. Thus in the interval $k \geq 0$, $|k|$ is defined as k with derivative 1 at the origin. Writing (4.2) as

$$\widehat{f}(l)\left(k\left(\widehat{f}(k+l) - \widehat{f}(k)\right) - l\widehat{f}(k)\right) + l\widehat{f}(k)\,\widehat{f}(k+l) = \pi^2 kl\,(k+l) \tag{4.4}$$

and then dividing by l and taking the limit as $l \to 0$ gives

$$a_0 k\widehat{f}'(k) - a_0\widehat{f}(k) + \widehat{f}^2(k) = \pi^2 k^2, \tag{4.5}$$

where $a_0 = \widehat{f}(0)$, and the solution of (4.5) with $\widehat{f}(0) = a_0$, when $a_0 \neq 0$, is

$$\widehat{f}(k) = \pi k \coth(\pi k/a_0). \tag{4.6}$$

We note here that (4.6) requires only $k^{-1}(\widehat{f}(k) - \widehat{f}(0) - k\widehat{f}'(0)) = o(1)$ as $k \to 0$. This will be the case if $\widehat{f}'(k)$ is continuous at the origin. This is provided for by property (3′a) of Definition 1, which ensures that $\widehat{f}(k)$ has a continuous second derivative. Of course for an even function with this property, $\widehat{f}'(0) \equiv 0$. The function appearing in (4.6) is the Fourier transform of the function

$$f(x) = -\frac{1}{4}a_0|a_0| / \sinh^2\left(\frac{a_0 x}{2}\right). \tag{4.7}$$

Again, apart from the addition of a constant and a scaling of x, this produces the unique (degeneration of a) $\wp$ function of imaginary period π and real period infinity.

As $a_0 \to 0$ the solution (4.6) tends to $\pm\pi|k|$, which is also the solution of (4.5) when $a_0 = 0$. This requires $k^{-1}(\widehat{f}(k) - \widehat{f}(0) - |k|\widehat{f}'(0+)) = o(1)$ as $k \to 0$, where $\widehat{f}'(0+)$ is defined to be the limit of $\widehat{f}'(k)$ as k tends to zero through positive values. This is provided for by the stronger property (3′b) of Definition 1.

For even functions $f(x)$ which are 2π-periodic in addition to having a double pole of the form $1/x^2$ at the origin following (3.18), we write $\widehat{f}(k)$ in the form

$$\widehat{f}(k) = \sum_{p=-\infty}^{\infty} a_p \delta(k-p), \quad \text{with } a_{-p} = a_p, \tag{4.8}$$

to obtain the recurrence relation for the set $\{a_K\}$,

$$(Ka_L + La_K)\,a_{K+L} = (K+L)\,a_K a_L + \pi^2 KL(K+L). \tag{4.9}$$

When $K = 0$, (4.9) is automatically satisfied with a_0 arbitrary. Writing $a_K = \pi K b_K$ for $K = 1, 2, \ldots$, we obtain

$$(b_L + b_K)\,b_{K+L} = b_K b_L + 1, \tag{4.10}$$

and with $b_1 = \frac{\beta+1}{1-\beta}$ and $L = 1$, we have

$$b_{K+1} = (b_K(\beta+1) + 1 - \beta) / (b_K(1-\beta) + \beta + 1). \tag{4.11}$$

This is easily solved to yield

$$b_K = \frac{1+\beta^K}{1-\beta^K} \qquad \text{or} \qquad a_K = \pi\,|K|\left(\frac{1+\beta^{|K|}}{1-\beta^{|K|}}\right). \tag{4.12}$$

This reproduces the result that $a_K = \widehat{f}\,(K)$ at integer values of K, where $\widehat{f}\,(K)$ is given by the continuous equation. Also the Fourier series $\sum_{-\infty}^{\infty} \pi\,|K|\,\big(\frac{1+q^{2|K|}}{1-q^{2|K|}}\big)e^{iKx}$ can be recognized as the Fourier series for the $\wp$ function again (up to the addition of a constant). Here $q = \beta^{1/2}$ is the usual notation for the nome.

At this stage we have found the solution set $\mathcal{F}_2$. The conclusion is that the only even solutions of (1.2) with $n = 2$ are those of (1.5b) with $d = 0$.

5. New solutions. We now look at the solutions of (1.2) which have $\widehat{f}\,(0) = 0$ to see if there are solutions which do not belong to the set $\mathcal{F}_2$. Lemma 1 and Theorem 2 can be easily adapted to prove that when n is odd, $\mathcal{F}_n \subseteq \mathcal{F}_3$. We first find this solution set and then prove that when n is odd, $\mathcal{F}_n = \mathcal{F}_3$. Hence we look for solutions of (3.14), with $\widehat{f}\,(0) = 0$, when $n = 3$. We wish to consider only even functions but again wish to include functions like $|k|$ which are not differentiable at $k = 0$. Hence we consider (3.14) defined on the subspace $k_q \geq 0$ $(q = 1, 2, 3)$ with all derivatives at the origin defined by one-sided derivatives. Thus in the interval $k \geq 0$, $|k|$ is defined as k with derivative 1 at the origin.

In (3.14) we write $k_1 = k$ and $k_2 = k_3 = l$ and let $l \to 0$. Then (3.14) gives

$$a_0\left(a_0 k\widehat{f}\,'(k) - a_0\widehat{f}\,(k) + \widehat{f}^{\,2}(k) - \pi^2 k^2\right) = 0, \tag{5.1}$$

where $a_0 = \widehat{f}\,(0)$. When $a_0 \neq 0$ this gives the same equation as (4.5) but is automatically satisfied when $a_0 = 0$. So in addition to the solution given in (4.6), which belongs to $\mathcal{F}_2$, we can also allow $a_0 = 0$.

When $a_0 = 0$ the next term in the expansion of (3.14) gives

$$a_1\left(\widehat{f}^{\,2}(k) - \pi^2 k^2\right) = 0, \tag{5.2}$$

where $a_1 = \widehat{f}\,'(0)$. If $a_1 \neq 0$, then (5.2) gives $\widehat{f}\,(k) = \pm\pi\,|k|$ as the only even solution. This is also the solution of (4.6) when $a_0 = 0$ and hence also belongs to $\mathcal{F}_2$. Now if we assume that $a_1 = 0$, we can write the third term in the expansion of (3.14) as

$$2\pi^2 k\widehat{f}\,'(k) + a_2\widehat{f}^{\,2}(k) - 2\pi^2\widehat{f}\,(k) = \pi^2 a_2 k^2, \tag{5.3}$$

where $a_2 = \widehat{f}\,''(0)$. The derivation of this solution requires $k^{-2}(\widehat{f}(k) - \widehat{f}(0) - k\widehat{f}\,'(0) - k^2\widehat{f}\,''(0)/2) = o(1)$ as $k \to 0$. This will be the case if $\widehat{f}\,''(k)$ is continuous at the origin and is provided for by the property (3′a) of Definition 1. Again for an even function with this property, $\widehat{f}\,'(0) \equiv 0$.

The only even solution of this equation is

$$\widehat{f}\,(k) = \pi k \tanh\left(\frac{ka_2}{2\pi}\right), \tag{5.4}$$

which automatically has $f''(0) = a_2$. This of course is a necessary requirement, and we need to check that this is a solution of (3.14).

We rewrite (3.14) as

(5.5)
$$\widehat{S}_n \equiv \left(\sum_{j=1}^{n} \frac{k_j}{\widehat{f}\,(k_j)+\pi k_j} \prod_{q=j+1}^{n} \left(\frac{\widehat{f}\,(k_q)-\pi k_q}{\widehat{f}\,(k_q)+\pi k_q}\right)\right) \frac{\left(\widehat{f}\left(\sum\limits_{j=1}^{n} k_j\right)+\pi \sum\limits_{j=1}^{n} k_j\right)}{\sum\limits_{j=1}^{n} k_j} - 1 = 0.$$

Substituting $\widehat{f}\,(k) = \pi k \tanh(ak)$ into $\widehat{S}_n$ gives

$$\widehat{S}_n = -\left(\sum_{j=1}^{n} \left(e^{2ak_j}+1\right) \prod_{q=j}^{n} \left(-e^{-2ak_q}\right)\right) \frac{\exp\left(2a \sum\limits_{j=1}^{n} k_j\right)}{\exp\left(2a \sum\limits_{j=1}^{n} k_j\right)+1} - 1. \tag{5.6}$$

The first part of this expression can be written as

$$\widehat{S}_n^{(1)} = \sum_{j=1}^{n} a_{j+1} - a_j \equiv a_{n+1} - a_1, \tag{5.7}$$

where $a_j = \prod_{q=j}^{n} \left(-e^{-2ak_q}\right)$, so that $\widehat{S}_n^{(1)} = (-1)^{n+1} \exp\left(-2a \sum_{j=1}^{n} k_q\right) + 1$. Hence

$$\widehat{S}_n = \frac{\left((-1)^{n+1}-1\right)}{\exp\left(2a \sum\limits_{j=1}^{n} k_j\right)+1}. \tag{5.8}$$

This immediately gives $\widehat{S}_n \equiv 0$ whenever n is odd. Hence $\widehat{f}\,(k) = \pi k \tanh(ak)$, with a arbitrary, is a solution for all equations $S_n = 0$ when n is odd. It is also evident from (5.8) that this solution does not satisfy $S_n = 0$ for n even.

We also note that substituting $\widehat{f}\,(k) = \pi k \coth(ak)$ into (5.5) changes (5.6) to

$$\widehat{S}_n = \left(\sum_{j=1}^{n} \left(e^{2ak_j}-1\right) \prod_{q=j}^{n} e^{-2ak_q}\right) \frac{\exp \sum\limits_{j=1}^{n} (2ak_j)}{\exp\left(\sum\limits_{j=1}^{n} 2ak_j\right)-1} - 1. \tag{5.9}$$

The change in signs now means that $\widehat{S}_n \equiv 0$ for all n, showing that $\widehat{f}_1\,(k) = \pi k \coth(ak)$, with a arbitrary, satisfies (3.14) for all n, as claimed earlier.

If we write $a = \frac{1}{2}\pi/\alpha$ so that $\widehat{f}\,(k) = \pi k \tanh\left(\frac{1}{2}\pi k/\alpha\right)$, then this is the Fourier transform of the function $f(z) = -\alpha|\alpha|\cosh \alpha z/\sinh^2 \alpha z$, so α must be negative to satisfy the pole condition that $z^2 f(z) \to 1$ as $z \to 0$. However, since the coefficient of the double pole is in fact arbitrary, we have $f(z) = \beta \cosh \alpha z/\sinh^2 \alpha z$ satisfying (1.2) for all odd values of n. (We will give an alternate way of discovering this solution in section 7.)

The even periodic solutions, which satisfy the modification of (3.14) when $f(z)$ has an array of double poles of the form $(z-2p\pi)^{-2}$ at the points $z = p\pi$, $p = 0$,

$\pm 1, \pm 2, \ldots$, can be written as

$$\widehat{f}(k) = \sum_{p=-\infty}^{\infty} a_p \delta(k-p), \quad \text{with } a_{-p} = a_p, \tag{5.10}$$

as in (3.18). Again, (3.14) is now to be satisfied at all integer values of $\{k_q\}$ with $\widehat{f}(k_q)$ replaced by a_{k_q}. Hence

$$\widehat{S}_n \equiv \sum_{j=1}^{n} \left[K_j \prod_{q=1}^{j-1} \left(a_{K_q} + \pi K_q\right) \prod_{q=j+1}^{n} \left(a_{K_q} - \pi K_q\right) \right] \left(a_{\sum_{q=1}^{n} K_q} + \pi \sum_{q=1}^{n} K_q \right) - \left(\sum_{j=1}^{n} K_j \right) \left(\prod_{q=1}^{n} \left(a_{K_q} + \pi K_q\right) \right) = 0. \tag{5.11}$$

To solve (5.11) to obtain the solutions for $\widehat{S}_3 = 0$, we proceed as in section 4. If a_0 is not equal to zero, we can put $K_3 = 0$ and recover the solutions (4.12). However, if $a_0 = 0$, then $\widehat{S}_3 \equiv 0$ for all K_1 and K_2 if $K_3 = 0$. Writing down all the equations for $K_j \geq 1$ we find that if $a_1 = \pi(\beta+1)/(1-\beta)$, the odd terms are given by

$$a_{2K+1} = \pi(2K+1) \frac{\left(1+\beta^{2K+1}\right)}{1-\beta^{2K+1}}, \qquad K \geq 0. \tag{5.12}$$

This is established in the same way that (4.12) is obtained from (4.9). Writing $a_K = \pi K b_K$ for $K = 1, 2, \ldots$, and with $K_1 = K_2 = 1$ and $K_3 = 2K+1$ we obtain

$$b_{2K+1} = \left(b_{2K-1}\left(\beta^2+1\right) + 1 - \beta^2\right) / \left(b_{2K-1}\left(1-\beta^2\right) + \beta^2 + 1\right), \tag{5.13}$$

which is solved to get (5.12). However, the even terms depend on the choice of a_2, which must take one of the values

$$a_2 = 2\pi \frac{\left(1+\beta^2\right)}{1-\beta^2} \tag{5.14a}$$

or

$$2\pi \frac{\left(1-\beta^2\right)}{1+\beta^2}. \tag{5.14b}$$

This is obtained by choosing $K_1 = 1, K_2 = 2$, and $K_3 = 2$, with a_1 and a_5 given from (5.12). This yields a quadratic for a_2 with (5.14) as solution. The first choice in (5.14) gives

$$a_{2K} = 2\pi K \frac{\left(1+\beta^{2K}\right)}{1-\beta^{2K}}, \qquad K \geq 0, \tag{5.15}$$

and the second

$$a_{2K} = 2\pi K \frac{\left(1-\beta^{2K}\right)}{1+\beta^{2K}}, \qquad K \geq 0. \tag{5.16}$$

Again these results are obtained from the choice of $K_1 = K_2 = 1$ and $K_3 = 2K$, which, using the definition of b_K, gives

$$b_{2K+2} = (2b_1 + b_{2K} + b_1^2 b_{2K})/(2b_1 b_{2K} + 1 + b_1^2), \tag{5.17}$$

which is solved to give (5.15) or (5.16), depending on the choice of a_2.

The results (5.14a) and (5.15) are equivalent to (4.12), while writing $\beta = -\tilde{\beta}$ shows that (5.14b) and (5.16) are equivalent to

$$a_K = \pi |K| \left(\frac{1 - \beta^{|K|}}{1 + \beta^{|K|}} \right) \qquad \text{for all } K. \tag{5.18}$$

This reproduces the result of (5.4) at integer values of k. The proof that $\{a_K\}$ satisfies $\widehat{S}_n$ for all n is identical to the proof in the continuous case (see (5.5)–(5.8)).

The corresponding inverse $f(z)$, obtained from $\widehat{f}(k)$, can be constructed either by taking the Fourier inverse of $\widehat{f}(k)$ or by the infinite sum defined by (3.21) using the function $\beta \cosh \alpha z / \sinh^2 \alpha z$. This function must be one of $\mathrm{cn}/\mathrm{sn}^2$, $\mathrm{dn}/\mathrm{sn}^2$, or $\mathrm{cndn}/\mathrm{sn}^2$. There are two reasons why there are three functions representing the solution set. The first is that if all the parameters defining the elliptic function are real, then the transformation $z \to iz$ permutes these three functions according to Jacobi's imaginary transformation $\mathrm{sn}(iz, k) \to i\ \mathrm{sn}\left(z, 1-k^2\right)/\mathrm{cn}\left(z, 1-k^2\right)$, $\mathrm{cn}(iz, k) \to 1/\mathrm{cn}\left(z, 1-k^2\right)$, and $\mathrm{dn}(iz, k) \to \mathrm{dn}\left(z, 1-k^2\right)/\mathrm{cn}\left(z, 1-k^2\right)$. Second, Jacobi's real transformation defines the elliptic function for the parameter $k < 0$ or $k > 1$ in terms of elliptic functions with a scaled independent variable and parameter k in the range $0 < k < 1$. Again the effect is to permute the three functions.

The conclusion is that the even solutions of (1.2) with n odd fall into two categories. One is the set defined by (1.5b) with $d = 0$, which satisfy (1.8) subject to $z^2 f(z) \to$ a constant as $z \to 0$. There is also a further set which may be expressed in terms of the $\wp$ function and also in terms of the Jacobian elliptic functions as given in Theorem 1. We have now proven Theorem 1.

6. Noneven solutions. At this stage we have established the theorem. For completeness we show how the general solutions of (1.1) may be obtained using the Fourier transform method. The even solutions have already been obtained, and now we consider the noneven solutions. We now assume that the function f in (1.4) is not necessarily even but is bounded on the real axis, but otherwise satisfies the conditions given in definition 1. Then the method of section 3 can be adapted to give the equation

$$k\widehat{f}(-l)\,\widehat{f}(-k-l) + l\widehat{f}(k)\,\widehat{f}(k+l) - (k+l)\,\widehat{f}(-k)\,\widehat{f}(l) = 0. \tag{6.1}$$

Equation (6.1) is a rather complicated functional equation when $\widehat{f}(-k) \neq \widehat{f}(k)$. A Taylor series method produces a three-parameter family of solutions. Two parameters are as a consequence of the fact that if $\hat{g}(k)$ is a solution, so is $\widehat{f}(k) = a\widehat{g}(bk)$ for all constants a and b. This is as a result of the scaling symmetries of the original equation (6.1). So essentially there is a one parameter family of solutions. However, it is not easy to recognize the solution from its series. The method which appears to give the most simple solution is the following. We decompose $\widehat{f}$ into an even and odd function of the form

$$\widehat{f}(k) = f_1(k) + tk f_2(k), \tag{6.2}$$

where f_1 and f_2 are even functions of k and t can be ± 1. Substituting this expression into (1.4) yields an equation of the form

$$A(k,l) + tB(k,l) + t^2 C(k,l) = 0, \tag{6.3}$$

and since t can be either ± 1 this gives two equations

$$A + C = 0 \qquad \text{and} \qquad B = 0. \tag{6.4}$$

Now we assume that l is small and expand (6.4) as a power series in l. Equating the coefficients of the powers of l to zero gives a series of differential equations involving $f_1(k)$ and $f_2(k)$. From the first two equations we obtain

$$2(f_2(k) - a_2) f_1(k) = k\, a_1\, f_2'(k) \tag{6.5}$$

and

$$ka_1 f_1'(k) + f_1^2(k) + k^2 f_2^2(k) - f_1(k)\, a_1 + 2k^2 a_2 f_2(k) = 0, \tag{6.6}$$

where

$$a_1 = f_1(0) \qquad \text{and} \qquad a_2 = f_2(0). \tag{6.7}$$

Eliminating $f_1(k)$ we obtain

$$a_1^2 \left(2(f_2 - a_2) f_2'' - f_2'^2\right) + 4f_2\left(f_2^3 - 3a_2^2 f_2 - 2a_2^3\right) = 0, \tag{6.8}$$

and one integration yields

$$3a_1^2 f_2'^2 = 4(a_2 - f_2)\left(ca_2^3 + f_2^3 + 3a_2 f_2^2\right), \tag{6.9}$$

where c is an arbitrary constant. This constant is the third parameter referred to above. Examination of the cubic in (6.9) shows that for all (real) constants c other than $c = 0$ or -4 we have an oscillatory solution for f_2. These solutions must be rejected on the grounds that if the original function $f(x)$ is bounded, $\widehat{f}(k)$ must tend to zero as $k \to \pm\infty$. When $c = -4$, $f_2 \equiv a_2$, and (6.5) is automatically satisfied, (6.6) then yields

$$f_1(k) = \sqrt{3} a_2 k \cot\left(\sqrt{3} a_2 k / a_1\right). \tag{6.10}$$

Again this does not represent the Fourier transform of a bounded function $f(x)$. However, it does illustrate the general feature of all periodic solutions of (6.9). When $c \neq 0$ the solution of (6.9) with $f_2(0) = a_2$ is an elliptic function which is even. Clearly, when $c \neq -4$, $f_2(k) - a_2$ has zeros when $k = 0$ or an integer multiple of the period of f_2. Since (6.9) implies that $f_2' = 0$ and $f_2'' \neq 0$ when $f_2 = a_2$, at each zero other than $k = 0$, $f_1(k)$ has a simple pole. Hence f_1 has a periodic array of poles, apart from $k = 0$, where the singularity is removable. This feature is illustrated by the function appearing in (6.10).

When $c = 0$, we can solve (6.9) with $f_2(0) = a_2$ to get

$$f_2(k) = \frac{3a_2}{2\cosh 2\alpha k + 1}, \tag{6.11}$$

where $\alpha = a_2/a_1$, so that

$$f_1(k) = \frac{3a_2 k \cosh \alpha k}{\sinh \alpha k \,(2\cosh \alpha k + 1)}. \tag{6.12}$$

The two possibilities for $\widehat{f}\,(k)$ are then

$$\widehat{f}\,(k) = f_1\,(k) \pm k f_2\,(k)\,, \tag{6.13}$$

giving

$$\widehat{f_1}\,(k) = \frac{6a_2 k e^{4\alpha k}}{e^{6\alpha k} - 1} \qquad \text{and} \qquad \widehat{f_2}\,(k) = \frac{6a_2 k e^{2\alpha k}}{e^{6\alpha k} - 1}\,. \tag{6.14}$$

If we normalize by choosing $6a_2 = \pi a_1$ and $a_1 = -2$, then $\widehat{f_1}$ is the Fourier transform of the function $1/\sinh^2(x - i\pi/3)$ and $\widehat{f_2}$ is the Fourier transform of $1/\sinh^2(x + i\pi/3)$. Apart from the addition of a constant these are $\wp$ functions, with periods (∞, π), and a double pole at the origin.

Thus, apart from the double pole at the origin and the shift by one-third and two-thirds of the imaginary period of the $\wp$ function, there is a unique solution of (1.4) which is bounded on $(-\infty, \infty)$ and tends to zero at ∞. An interesting limit is $a_2 \to 0$, which gives $f_2 \equiv 0$ and $f_1 = a_1$. This is also seen to be the only solution of (6.5) and (6.6) when $a_2 = 0$, subject to the condition that $f_1(0) = a_1$, $f_2\,(0) = a_2 = 0$, and $f_2 \to 0$ as $k = \infty$. The inverse of the Fourier transform $\widehat{f}\,(k) \equiv a_1$ is no longer a function but the distribution $a_1\delta\,(x)$ which can be viewed as the limit

$$a_1\delta\,(x) = \lim_{\alpha \to 0} -\frac{a_2}{\alpha \sinh^2(-x/\alpha + \pi i/3)},$$

where $\pi a_1 \alpha = 6a_2$.

The only other regular solutions of (1.4), on the real axis, are ones that are either not bounded at ∞ or are oscillatory. Such functions have either distributional Fourier transforms or are such that the no conventional Fourier transform exists. For example, the Fourier transform of $e^{i\alpha x}$ is $2\pi\delta\,(k - \alpha)$ and as a distribution $f = 2\pi\delta\,(k - \alpha)$ satisfies (6.1), since

$$\begin{aligned} 4\pi^2 k\delta\,(-l-\alpha)\ \delta\,(-k-l-\alpha) + 4\pi^2 l\delta\,(k-\alpha)\,\delta\,(k+l-\alpha) \\ - 4\pi^2\,(k+l)\,\delta\,(-k-\alpha)\,\delta\,(l-\alpha) \equiv 0. \end{aligned} \tag{6.15}$$

This is because $k\ \delta\,(-l-\alpha)\ \delta\,(-k-l-\alpha)$ is zero unless $l + \alpha = l + k + \alpha = 0$ or $k = 0,\ l = -\alpha$, when the coefficient of the product of δ functions is zero. A more formal proof can be obtained by defining the inner products $\langle u, v\rangle_{k,l}$ and $\langle u, v\rangle_k$ by

$$\langle u, v\rangle_{k,l} \equiv \iint_{\mathbb{R}^2} u\ v\ dkdl \qquad \text{and} \qquad \langle u, v\rangle_k \equiv \int_{\mathbb{R}} u\ v\ dk, \tag{6.16}$$

with a similar definition for $\langle u, v\rangle_l$. Then

$$\begin{aligned} \langle k\delta\,(-l-\alpha)\,\delta\,(-k-l-\alpha)\,,\ F\,(k,l)\rangle_{k,l} &= \langle \delta\,(-l-\alpha)\,\delta\,(-k-l-\alpha)\,,\ \ kF\,(k,l)\rangle_{k,l} \\ &= \langle \delta\,(-l-\alpha)\,,\ \ -(l+\alpha)\ F\,(-l-\alpha,l)\rangle_l \\ &= 0. \end{aligned} \tag{6.17}$$

Although this only shows that $e^{i\alpha x}$ is a solution of (1.4) by analogy, we can also have $e^{\alpha x}$, although this does not have a Fourier transform, except formally by analytic continuation.

The Fourier transform of x is $2\pi i\delta'(k)$, and using (6.16) it is straightforward to prove that $k\delta'(-l)\,\delta'(-k-l)+l\delta'(k)\,\delta'(k+l)$ and $(k+l)\,\delta'(-k)\,\delta'(l)$ are identical distributions. For example

$$\begin{aligned}\langle (k+l)\,\delta'(-k)\,\delta'(l)\,,\ \ F(k,l)\rangle_{k,l} &= \langle \delta'(-k)\,\delta'(l)\,,(k+l)\,F(k,l)\rangle_{k,l}\\ &= \langle \delta'(-k)\,,-F(k,0)-kF_l(k,0)\rangle_k\\ &= -F_k(0,0)-F_l(0,0)\,.\end{aligned}\tag{6.18}$$

A similar calculation shows that

$$\langle k\delta'(-l)\,\delta'(-k-l)\,,\ F(k,l)\rangle_{k,l}+\langle l\delta'(k)\,\delta'(k+l)\,,\ F(k,l)\rangle_{k,l}\ =-F_k(0,0)-F_l(0,0)\,.\tag{6.19}$$

In addition, we can also see that if $\widehat{f}(k)$ is not continuous, $\widehat{f}(0)$ can be arbitrary since (6.1) is satisfied automatically when either k, l, or $k+l$ equals zero. In particular, we can add an arbitrary multiple of $\delta(k)$ to any solution of (6.1). This corresponds to adding a constant to any solution of (1.4).

The above distributional solutions cover the solutions of (1.5a). To cater to the noneven periodic solutions of (1.5b) that are also bounded on the real axis, we assume that the solutions $f(x)$ are 2π-periodic, and following (3.17) we write

$$f(x)=\frac{1}{2\pi}\sum_{p=-\infty}^{\infty}a_p e^{ipx}\tag{6.20}$$

to obtain

$$Ka_{-L}a_{-K-L}+La_Ka_{K+L}-(K+L)\,a_{-K}a_L=0\tag{6.21}$$

for all integer values of (K,L). Since $\widehat{f_1}(k)$ and $\widehat{f_2}(k)$ defined by (6.13) satisfy the continuous version of (6.21), it is clear that the solution $a_K=\widehat{f_1}(K)$, $K\neq 0$ with a_0 arbitrary, will satisfy (6.21). This solution for a_K can also be obtained directly from (6.21) by successively solving all equations with $1\le|K|\le N$, $1\le|L|\le N$ for $N=1,2,3,\ldots$, the equations where $K=0$ or $L=0$ being automatically satisfied. Apart from the fact that a_0 is undetermined and is thus arbitrary, this process, as in the continuous case, produces a three-parameter family of solutions with a_{-2},a_{-1}, and a_1 arbitrary. If we choose $a_{-1}=\beta\alpha^2/\left(\alpha^6-1\right)$ and $a_1=\beta\alpha^4/\left(\alpha^6-1\right)$, then the choice $a_{-2}=\beta\alpha^4/\left(\alpha^{12}-1\right)$ yields $a_K=\beta K\alpha^{4K}/\left(\alpha^{6K}-1\right)$, which is clearly equivalent to $\widehat{f_1}(K)$ when $\beta=6a_2$ and $\alpha=\exp(a_2/a_1)$. Since all continuous solutions $\widehat{f}(k)$ give a corresponding solution $a_K=\widehat{f}(K)$, via (3.22), we presume that other choices of a_{-2} give solutions for a_K which are oscillatory and do not tend to zero as $K\to\infty$. As in the continuous case this gives Fourier series which do not come from a continuous function of x.

It is also easy to show that there are additional solutions of (6.21). If the set $S_1=\{a_K\}$ solves (6.21), then so does the set $S=\left\{\gamma^K a_K\right\}$, provided $\gamma^{3K}=1$ for all integer values of K. This gives two additional solutions $\left\{e^{2\pi Ki/3}a_K\right\}$ and $\left\{e^{4\pi Ki/3}a_K\right\}$. If $f_1(x)$ is the 2π-periodic function whose Fourier series is given by the set S_1, then

these two solutions are from the functions $f_1\left(x+\frac{2}{3}\pi\right)$ and $f_1\left(x+\frac{4}{3}\pi\right)$, which are the original function shifted by one-third and two-thirds of its period, respectively.

In this section we have shown that by requiring f to be bounded on any compact subset of the real axis, we can recover all the solutions of (1.5a,b) that have this boundedness property by taking the appropriate Fourier transform of (1.4). We have also shown that there are no other solutions f which have this boundedness property. However, by taking the appropriate limit we have also shown that the δ function is also a solution and have recovered this from the transformed equation. We have not obtained the $\wp$ function solutions, which have double poles on the real axis. This is because the transforms of these functions do not satisfy the transformed equation (6.1). These follow from an analysis similar to that given in section 4.

7. Series solution approaches. We conclude this paper by describing two methods based on a series approximation for studying (1.2). Although they are incomplete, and this was the reason for developing the new methods already described, it is helpful to see how our new solutions arise in this setting. In doing this, we see that the $n = 2$ and 3 solutions can be derived assuming just the meromorphic nature, pole assumptions, and evenness of the solutions contained in the first two items of Definitions 1 and 2.

Method 1: Obtaining a series solution. One method of attempting to prove the conjecture is to assume all the $x_i, i = 1, \ldots, n+1$, are small and of the same order, so that we write $x_i = t\zeta_i$. Then we assume that all the even functions, such as $f(t\zeta)$, can be expressed as a power series in t with ζ as an order-one parameter in the form

$$f(t\zeta) = \sum_{j=0}^{\infty} a_j c_{2j-2} (t\zeta)^{2j-2}. \tag{7.1}$$

The constants c_j are given by $c_j = 1$ if $j < 0$ and $c_j = 1/j!$ if $j \geq 0$ and are included for convenience. The series (7.1) allows for a double pole at the origin, which can easily be shown to be the only allowable singularity. The coefficients a_j are determined by equating to zero the coefficients of the powers of t^{2j} in the subsequent expansion of (1.2). These coefficients are of course functions of ζ_i as well as a_j. However, each coefficient factorizes into a product of homogeneous polynomials in ζ_i, independent of a_j and a factor dependent on the a_j only. Equating this coefficient to zero successively determines a_j for all $j \geq 4$ in terms of a_0, a_1, a_2, and a_3, which are arbitrary. This process can be completed to any desired order, J, if the expansion (7.1) is truncated at a suitable finite value. Substitution of this finite polynomial into (1.7) shows, for the cases where the method works, that for a suitable choice of $\{A,\ B,\ C,\ D\}$, (1.7) can be satisfied to any desired order.

The proof of the above statement is, of course, incomplete: the form of the general term, a_j, is not obtained, and hence we cannot show that the full expansion (7.1) satisfies (1.7). This method works for $n = 2$ and $n = 4$, but for values of $n \geq 5$ the amount of algebra involved becomes so large that even a Maple calculation cannot handle the details. When $n = 3$, this method does not work completely in that it leaves a_4 arbitrary. Our earlier analysis has shown that this is not the case.

It is interesting to note that the same procedure works for solutions of (1.1),

although the assumption of evenness is not required. Hence we look for a solution

$$f(t\zeta) = \sum_{j=0}^{\infty} a_j c_{j-2} (t\zeta)^{j-2}. \tag{7.2}$$

If we take $a_0 \neq 0$, the process automatically gives $a_{2j+1} \equiv 0$, producing the same even function as obtained via (7.1) for the solutions of (1.2). However, if we take $a_0 = 0$, then we find that $a_1 \equiv 0$, and (7.2) is then a Taylor series. We proceed as above to produce the coefficients a_j for all $j \geq 7$ in terms of a_2 to a_6 and show that (1.7) can be satisfied to any order. However, a_5 is not arbitrary and is given by

$$a_3 a_5 = a_4^2. \tag{7.3}$$

This condition is automatically satisfied for all functions in the set (1.5a). However (7.3) is also equivalent to the condition $\wp''^2(d) = 12\wp(d)\wp'^2(d)$, which is satisfied when d is one-third or two-thirds of any period of $\wp(z)$. This gives the required condition on the constant d appearing in (1.5b) when f belongs to this solution set.

Method 2: Obtaining a series of differential equations. An alternative method is to assume that one variable, for example x_1, is not small and write $x_1 = x$ and $x_i = t\zeta_i$, $2 \leq i \leq n+1$, together with (7.1), although x_1 can be replaced by any linear combination of the x_i, as long as n variables are scaled by t. The expansion of $f(x - t\zeta)$ then naturally produces coefficients of t^j, which are functions of f and its higher derivatives. The coefficients of t^j, in the expansion of (1.2) when equated to zero, now yield differential equations which must be satisfied by $f(x)$ but contain the "arbitrary" constants a_j.

For the case $n = 2$ the first equation is

$$a_0 f''' + 12 a_1 f' - 12 f f' = 0. \tag{7.4}$$

This proves to be sufficient to determine a differential equation for f in the sense that the elimination of the constants a_0 and a_1 by differentiation gives (1.8). The higher order coefficients of t^j produce equations similar to (7.4) but contain the constants a_j with $j \geq 4$, which are not arbitrary. In this case eliminating all the constants by differentiation will yield an equation which is still necessary but not sufficient to determine f. If we seek a series solution to (7.4) by looking for a series solution of the form $f(x) = \sum_{j=0}^{\infty} b_j c_{2j-2} x^{2j-2}$, then we obtain $b_0 = a_0$ and $b_1 = a_1$, with b_2 and b_3 arbitrary. The coefficients $b_j, j \geq 4$, are then determined by these four constants, the recurrence relation being the same as in Method 1. The equations which contain a_2 and a_3 also require $b_2 = a_2$ and $b_3 = a_3$ and so also reproduce the series (7.1).

This method is more complete than the previous method in that it does yield a necessary differential equation, namely, (1.8), that all even solutions of (1.2) for $n = 2$ must satisfy. However, we cannot prove that all the differential equations produced by the expansion are satisfied. But this is not a problem since it is easy to verify, by substitution, that all even solutions of (1.5b) satisfy (1.2) for this case.

Again, the method can be adapted to obtain the solution of (1.1), which are not even, using (7.2) with $a_0 = a_1 = 0$. The procedure is the same except that because $f(\zeta)$ is not even, we obtain differential equations containing $f(\zeta)$ and $f(-\zeta)$. When one of these functions is eliminated we can then show that either (1.6) or (1.8) is satisfied. However, the differentiations required to eliminate the constants a_j mean that the necessary condition (7.3) is not recovered.

For the case $n = 3$ the situation is more complicated since the series of equations similar to (7.4) only produce necessary equations for f. In order to show that f satisfies (1.7) we need to take two equations similar to (7.4) and find the set of solutions common to both differential equations. The algebraic details are quite complicated and require a Maple calculation. The details are not repeated here, but a summary of the results is given. A copy of the Maple program which produces these results with further explanation can be obtained by contacting the first author.

The two equations, whose common solution satisfies (1.2) for $n = 3$ are given by

$$120\,a_2\,f'\,f + 5\,a_0\,f'''\,f'' + 60\,f''\,f'\,a_1 - a_0\,f^{(5)}\,f = 0 \tag{7.5}$$

and

$$\begin{aligned} 0 = {} & 504\,a_3\,f'\,f^2 + 1080\,f'\,a_2\,f''\,f + 36\,f^{(iv)}\,f'\,a_1\,f + 15\,f'\,a_0\,f'''^2 + 180\,f'\,f''^2\,a_1 \\ & + 180\,f'''\,f'^2\,a_1 - 3\,a_0\,f^{(v)}\,f'^2 + 360\,f'^3\,a_2 + 15\,f'\,a_0\,f^{(iv)}\,f'' - 60\,f''\,a_1\,f'''\,f \\ & - 12\,a_0\,f^{(iv)}\,f'''\,f + 240\,f'''\,a_2\,f^2 + +a_0\,f^{(v)}\,f''\,f. \end{aligned} \tag{7.6}$$

To determine the equation or equations for these common solutions, we effectively eliminate the arbitrary constants a_0, a_1, a_2, and a_3. These constants are the ones that appear in the expansion (7.1) used to derive (7.5) and (7.6).

Before we consider the common solution to these equations, we investigate the form of these solutions by looking for a common solution of the form (7.1) but with the constants a_j replaced by b_j. The result again shows that $b_0 = a_0, b_1 = a_1, b_2 = a_2$, and $b_3 = a_3$. Initially b_4 is not determined, but b_5 and b_6 are determined in terms of $b_j, j \le 4$. However, we get two different values of b_7, and equating these values gives an equation which has two solutions, namely,

$$b_3 = \frac{60\left(2b_1^2 - b_0 b_2\right)}{7b_0^2} \tag{7.7a}$$

or

$$b_4 = \frac{60b_2^2}{b_0}. \tag{7.7b}$$

If we choose (7.7b), then in turn we find both equations require a common value for b_j for $j \ge 7$, and the series generates, as in the previous method, a solution of (1.7) or (1.8) and so belongs to the solution set (1.5).

However, if we choose (7.7a) to be satisfied, then the two equations have different solutions for b_8, and equating these values determines b_4. This value differs from that given in (7.5b) and hence generates a solution $f(z) = f_1(z)$, with three arbitrary constants, which is not a solution of (1.7) or (1.8), unless

$$b_2 = \frac{6b_1^2}{5b_0}\,. \tag{7.8}$$

It is easy to verify that when (7.8) is satisfied, any finite truncation of the series is equal to the same truncation of the solution

$$f_2(z) = b_1 \wp\left(\sqrt{\frac{b_1}{b_0}}z, 12, 8\right) + b_1. \tag{7.9}$$

This is a subset of the general solution of (1.8), which may be expressed as

$$f_2(z) = 3b_1/\sin^2\left(\sqrt{\frac{3b_1}{b_0}}z\right) \qquad \text{or} \qquad f_2(z) = -3b_1/\sinh^2\left(\sqrt{-\frac{3b_1}{b_0}}z\right),$$

depending on whether $\frac{3b_1}{b_0}$ is greater than, or less than, zero, respectively. Since the choice of (7.7a) requires a specific choice of b_3 and hence a_3, it may be thought that this solution fails to be a solution of the full equation (1.2). This supposition proves, however, to be erroneous.

We can also determine the equation for the common solution of (7.5) and (7.6) by effectively eliminating the arbitrary constants a_0, a_1, a_2, and a_3. The details are contained in the Maple program referred to earlier and are not given here. Eliminating these constants results in an equation which factorizes into a number of terms, similar to the factorization encountered in [2]. One finds that f must satisfy one of the equations

$$f' = 0 \qquad \text{or} \qquad f = \text{constant}, \tag{7.10}$$

clearly a solution, but not one of interest, and

$$f'''f - f'f'' = 0 \qquad \text{or} \qquad f''/f = \text{constant}. \tag{7.11}$$

We find that this equation satisfies (7.5) and (7.6) only if the constant appearing in (7.11) is zero. Thus the only even solution again is $f =$ constant. A further factor may be recognized as (1.8) with solution (1.5b), with $d = 0$ for an even solution.

The final factor is found to be a fifth order nonlinear, ordinary differential equation which is cubic in $f^{(v)}$ and contains over one hundred terms. It is easily verified that the series solution $f = f_1(z)$ defined earlier by taking the choice of (7.7a) for b_3 satisfies this equation. While at first sight it would seem unlikely that we could obtain the most general even solution which has a double pole at $z = 0$ of such an equation, we have shown in section 5 that the Fourier transform of the nonperiodic solution is simple and easily inverted to give

$$f(z) = a\cosh bz/\sinh^2 bz \tag{7.12}$$

for arbitrary constants a and b. This coincides with the series for $f_1(z)$ upon choosing $a = 6b_1$ and $b = \sqrt{6b_1/b_0}$. (This further requires the choice $b_2 = -7ab^2/60 \equiv -21b_1^2/5b_0$.) With this knowledge, one may guess that the periodic solutions are of the form $a\ \mathrm{cn}(bz,k)\,\mathrm{sn}^2(bz,k)$, $a\ \mathrm{dn}(bz,k)/\mathrm{sn}^2(bz,k)$, or $a\ \mathrm{cn}(bz,k)\,\mathrm{dn}(bz,k)/\mathrm{sn}^2(bz,k)$, or the alternate forms given in Theorem 1. These are all periodic equivalents of (7.12), where cn, dn, and sn are the Jacobian elliptic functions and k is the modulus. It is then possible to verify by substitution that the most general solution of the fifth order equation of the form required may be expressed as

$$f_1(z) = \sqrt{b_0^2 W^2(z) + 2b_0b_1W(z) - b_1^2 + \frac{5}{3}b_0b_2}, \tag{7.13}$$

where

$$W(z) = \wp\left(z, -\frac{20\left(b_0b_2 - 3b_1^2\right)}{3b_0^2}, \frac{8b_1\left(5b_0b_2 - 3b_1^2\right)}{3b_0^3}\right). \tag{7.14}$$

The quadratic in (7.13) has a double root when $6b_1^2 = 5b_0b_2$, which corresponds to the condition (7.8), which gives the function $f_2(z)$, defined by (7.9). Thus $f_2(z)$ is the two-parameter family of common solutions to (1.8) and the fifth order equation coming from elimination, which includes the solution b_0z^{-2} in the limit $b_1 \to 0$.

If the equation for the $\wp$ function is written as

$$\wp'^2 = 4\wp^3 - g_2\wp - g_3 \equiv 4(\wp - e_1)(\wp - e_2)(\wp - e_3) \tag{7.15}$$

in the usual notation, then the quadratic in (7.13) divides the cubic on the right-hand side of (7.15). When e_1 and e_3 are the common roots, (7.13) can be simplified to give the solution $f_1(z) = a\ \mathrm{cn}(bz,k)/\mathrm{sn}^2(bz,k)$ for suitable choices of a, b, and k in terms of b_0, b_1, and b_2. When e_2 and e_3 are the common roots, we recover the solution $f_1(z) = a\ \mathrm{dn}(bz,k)/\mathrm{sn}^2(bz,k)$, while the third choice (e_1, e_2) gives $f_1 = a\ \mathrm{cn}(bz,k)\,\mathrm{dn}(bz,k)/\mathrm{sn}^2(bz,k)$. These are our new solutions.

Acknowledgments. We wish to thank A. M. Davie for helpful discussions and for sharing his insight. One of the authors (H. W. B.) wishes to thank the Newton Institute for support during the completion of this work.

ON THE EIGENVALUES OF ZAKHAROV–SHABAT SYSTEMS*

M. KLAUS† AND J. K. SHAW†

Abstract. We consider the eigenvalues of a Zakharov–Shabat system on the real line with a complex-valued L^1 potential and show that $\pi/2$ is the threshold L^1 norm of the potential for the formation of eigenvalues. We obtain best possible lower bounds on the number of eigenvalues for a real potential of one sign. This lower bound is exact for the class of single lobe potentials, that is, positive potentials with a single local maximum that is also global.

Key words. Zakharov–Shabat systems, eigenvalue thresholds, number of eigenvalues

1. Introduction. Zakharov–Shabat (ZS) systems are non-self-adjoint coupled differential equations of the form [1, 2, 3, 4]

$$v_1' = -i\xi v_1 + q(t)v_2, \quad v_2' = i\xi v_2 - q(t)^* v_1, \tag{1.1}$$

where ξ is a complex-valued eigenvalue (EV) parameter, $q(t)$ is a locally integrable function of the real-variable t, $-\infty < t < \infty$, and the asterisk denotes the complex conjugate. ZS systems have their origin in inverse scattering theory for the nonlinear Schrödinger equation, which in normalized form is [1]

$$iu_z + (1/2)u_{tt} + |u|^2 u = 0, \quad u = u(z,t). \tag{1.2}$$

In (1.2) we can think of $u(z,t)$ as the slowly varying field of a light pulse propagating in an optical fiber under the influence of chromatic dispersion and material nonlinearity [5]; t is normalized local pulse time and z is normalized length along the fiber. The connection between (1.1) and (1.2) is that (1.2) can be formally solved by setting $q(t) = u(0,t)$ and finding $u(z,t)$ by the inverse scattering procedure associated with (1.1) [6, 1, 2]. A further connection is that the EVs of (1.1) correspond to optical solitons of (1.2), that is, particular solutions of (1.2) whose amplitudes are either constant or periodic in z [6, 2]. Both fundamental (constant amplitude) and higher order (periodic) solitons have a functional form involving hyperbolic secants. The EVs are defined as those complex numbers ξ, $\mathrm{Im}(\xi) > 0$, for which (1.1) has a solution $\vec{v}(t) = \binom{v_1(t)}{v_2(t)}$ of integrable square on the real line; that is,

$$\int_{-\infty}^{\infty} (|v_1(t)|^2 + |v_2(t)|^2)\, dt < \infty. \tag{1.3}$$

The initial shape $u(0,t) = q(t)$ does not have to be a hyperbolic secant in order for (1.2) to support solitons, at least in the asymptotic sense. If the initial pulse has enough energy, as measured by the integral

$$E = \int_{-\infty}^{\infty} |q(t)|\, dt, \tag{1.4}$$

*Received by the editors February 22, 2002; accepted for publication (in revised form) July 30, 2002; published electronically February 6, 2003.

then solitons will evolve, as components of $u(z,t)$, with increasing z [2]. Specifically, if E is sufficiently large for (1.1) to have EVs, then those EVs completely determine the asymptotic behavior of $u(z,t)$ as $z \to \infty$ [1, 2].

For conventional real, symmetric, and monomodal pulse shapes $q(t)$ in (1.1), such as Gaussians, hyperbolic secants, and rectangles, the EVs are purely imaginary. This is significant because EVs with the same real part can combine to form a higher order, periodic soliton [2]. The property of having purely imaginary EVs has actually been claimed for many years as a general property of real symmetric potentials but is false [3, 4]. The present authors [4] have established that "single lobe" potentials $q(t)$, functions which increase until t reaches a central concentration point and then decrease, do have purely imaginary EVs only. Single lobe potentials will also be important in this paper.

Specifically, in computable cases ([7, 8]; see [3, 4] for additional references) EVs appear when E in (1.4) exceeds certain threshold levels. For example, if $q(t)$ is a positive constant on a compact interval and 0 elsewhere (rectangular pulse), then successive EVs appear as E crosses the levels $E = (2n-1)\pi/2$ $(n = 1, 2, 3, \dots)$ [7]. Similarly, $\pi/2$ is the threshold for potentials which are constant multiples of $\operatorname{sech}(t)$ [8]. In general, the best known bound on $q(t)$ which rules out EVs is $E < 1.32$ [2] ($E < 0.904$ in [1]). There seem to be no general lower bounds on E in the literature which guarantee the existence of EVs.

Let us state our principal results. Unless stated specifically otherwise, we will assume throughout that

$$q \text{ is real-valued and } q \in L^1(-\infty, \infty); \tag{1.5}$$

that is, $E < \infty$ in (1.4). We are going to improve the 1.32 bound to $\pi/2$ and show that $\pi/2$ is best possible in a wider sense than is provided by the computable examples cited above. In section 3 we prove that if $E \le \pi/2$, then there are no purely imaginary EVs of (1.1). Later, in section 4 we strengthen this to claim that there are no EVs at all for complex potentials satisfying $E \le \pi/2$. Define

$$I = \int_{-\infty}^{\infty} q(t)\, dt. \tag{1.6}$$

In section 3 we show for real potentials $q(t)$ that there are at least N purely imaginary EVs, where N is the largest nonnegative integer such that $(2N-1)\pi/2 < |I|$. For $N = 1$ this reduces, of course, to $|I| > \pi/2$, rendering $\pi/2$ as the EV formation threshold for essentially all physically interesting potentials. For single lobe potentials we will prove that there are exactly N EVs if N is defined as above. For single sign potentials (section 4) we show that the largest magnitude of an EV on the imaginary axis strictly dominates the imaginary part of any other EV in the complex plane. In particular, if there are no imaginary EVs, then there are no EVs at all. Moreover, if $|q|$ (for $q(t)$ complex-valued) has no EVs on the imaginary axis, then q has no EVs at all.

In section 2 we establish most of our results on imaginary EVs in the case where q has compact support, because this situation is concrete and sufficiently interesting, physically speaking, to stand on its own. (All real optical pulses have compact support.) Since potentials of noncompact support, such as hyperbolic secants, are also important, we consider noncompact support in section 3; this will be independent of section 2. We treat single sign and complex-valued potentials in section 4. In section 5

we summarize the paper and discuss some applications giving practical criteria under which initial pulses induce solitons.

We want to clarify that E in (1.4) is not technically the energy contained in the initial pulse $q(t) = u(0,t)$; the energy is given instead by the integral of $|q|^2$. However, (1.4) can be still regarded as an indicator. We note, moreover, that theoretical solitons require conservation of energy and therefore do not actually exist in real fibers. Soliton based fiber communication systems use the soliton effect, whereby a launched pulse that is nearly a perfect soliton gradually degrades due to fiber attenuation which can be as low as 5% per kilometer [5].

2. Compact support case. In this section we suppose in addition to (1.5) that $q(t) = 0$ outside an interval $[-d, d]$, $d > 0$. In the scattering theory of (1.1) one defines the Jost solutions $\vec{\psi}(t,\xi)$ and $\vec{\varphi}(t,\xi)$ by the asymptotic properties [1]

$$\vec{\psi}(t,\xi) \cong \begin{pmatrix} 0 \\ 1 \end{pmatrix} e^{i\xi t}, \quad t \to \infty, \quad \vec{\varphi}(t,\xi) \cong \begin{pmatrix} 1 \\ 0 \end{pmatrix} e^{-i\xi t}, \quad t \to -\infty,$$

which guarantee exponentially small solutions, unique up to constant multiples, at $\pm\infty$ for $\operatorname{Im}(\xi) > 0$. Eigenfunctions of (1.1) are multiples of both Jost solutions. Outside $[-d, d]$, where $q(t) = 0$, (1.1) can be solved in closed form and the EV condition (1.3) gives

$$v_1(-d) = 1, \quad v_2(-d) = 0, \quad v_1(d) = 0, \tag{2.1}$$

where the first of these is actually a normalization and the last is a condition for the existence of an EV. That is, the first two of (2.1) hold for all ξ and the last holds when ξ is an EV.

Since the objects of our investigation are the purely imaginary EVs of (1.1), we set

$$\xi = is, \quad s \geq 0.$$

We employ a Prüfer transformation in (1.1),

$$\begin{pmatrix} v_1 \\ v_2 \end{pmatrix} = \begin{pmatrix} \rho\cos\theta \\ \rho\sin\theta \end{pmatrix}, \tag{2.2}$$

so that $\rho = \rho(t;s)$ and $\theta = \theta(t;s)$ satisfy

$$\theta' = -q(t) - s\,\sin(2\theta) \tag{2.3}$$

and

$$\rho' = s\,\rho\cos(2\theta), \tag{2.4}$$

along with the initial conditions $\theta(-d;s) = 0$, $\rho(-d;s) = 1$ (by (2.1)). The primes in (2.3) and (2.4) denote differentiation with respect to t. The relevant equation for us will be (2.3) because $\theta(t;s)$ contains all the important information about the location of EVs on the imaginary axis. Note that $\xi = is$ is an EV if and only if

$$\theta(d;s) = \frac{(2k-1)\pi}{2}$$

for some integer k.

LEMMA 2.1. *We have* $\theta(d;s) \to 0$ *as* $s \to \infty$.

Proof. We write (2.3) in the form

$$\theta' + 2s\theta = -q(t) - s[\sin(2\theta) - 2\theta]$$

and convert it to an integral equation

$$\theta(t;s) = -e^{-2st}\int_{-d}^{t} e^{2s\tau} q(\tau)\,d\tau - se^{-2st}\int_{-d}^{t} e^{2s\tau}[\sin(2\theta(\tau;s)) - 2\theta(\tau;s)]\,d\tau, \tag{2.5}$$

where the initial condition $\theta(-d;s) = 0$ has been taken into account. Let

$$\eta(s) = \sup_{-d\le t\le d}\left(e^{-2st}\int_{-d}^{t} e^{2s\tau}|q(\tau)|\,d\tau\right)$$

and note that $\eta(s) \to 0$ as $s \to \infty$. Let $\varepsilon > 0$ and suppose without loss of generality that $\varepsilon < 1/2$. Choose s_0 so large that

$$\eta(s) < 2\varepsilon/3, \quad s > s_0. \tag{2.6}$$

We will show that this implies $\sup_{-d\le t\le d}|\theta(t;s)| < \varepsilon$. Fix $s > s_0$ and let

$$m(t;s) = \sup_{-d\le\tau\le t}|\theta(\tau;s)|.$$

Using the inequality $|\sin(z) - z| \le |z|^3/6$, for real z, the estimate

$$s\int_{-d}^{t} e^{-2s(t-\tau)}\,d\tau \le 1/2$$

in (2.5) implies

$$m(t;s) < \frac{2\varepsilon}{3} + \frac{2}{3}m(t;s)^3. \tag{2.7}$$

The function $f(x) = x - (2/3)x^3 - (2\varepsilon/3)$ has two positive roots r_1 and r_2, $0 < r_1 < (1/\sqrt{2}) < r_2$; note that $f(x)$ has a positive maximum at $x = 1/\sqrt{2}$ because $\varepsilon < (1/2) < 1/\sqrt{2}$. Inequality (2.7) says that $f(m(t;s)) < 0$. Since $m(-d;s) = 0$ and $m(t;s)$ is continuous in t, it follows that $m(t;s) \le r_1$, and so $m(t;s) \le 1/\sqrt{2}$. Substituting $m(t;s) \le 1/\sqrt{2}$ into the right side of (2.7) yields

$$m(t;s) < \frac{2\varepsilon}{3} + \frac{1}{3}m(t;s), \quad -d \le t \le d,$$

which is to say $m(t;s) < \varepsilon$. Then $|\theta(t;s)| < \varepsilon$ and the proof is complete.

THEOREM 2.2. *Let* N *be the largest nonnegative integer such that* $(2N-1)\pi/2 < |I|$, *where* I *is given by* (1.6) *(integrated over* $[-d,d]$*). Then* (1.1) *has at least* N *purely imaginary EVs. In particular, if* $|I| > \pi/2$, *then there is at least one purely imaginary EV.*

Proof. For $s = 0$ (2.3) implies that $I = -\theta(d;0)$, and so $|\theta(d;0)| > (2N-1)\pi/2$. By continuity of $\theta(d;s)$ and Lemma 2.1, there must be N values $0 < s_1 < s_2 < \cdots < s_N$ such that $|\theta(d;s_k)| = (2(N-k)+1)\pi/2$, meaning that each $\xi_k = is_k$ is an EV.

Define

$$q_+(t) = \max[q(t),0], q_-(t) = \max[-q(t),0]$$

so that $q = q_+ - q_-$.

We will need the following result.

COMPARISON THEOREM (see [9, p. 122]). *Let the function $f(t, y)$ satisfy a local Lipschitz condition in y and define the operator P by $P(g) = g' - f(t, g)$. Let g_1 and g_2 be absolutely continuous functions on $[t_1, t_2]$ such that $g_1(t_1) \le g_2(t_1)$ and $P(g_1) \le P(g_2)$ almost everywhere on $[t_1, t_2]$. Then either $g_1(t) < g_2(t)$ everywhere in $[t_1, t_2]$ or there exists a point c, $t_1 \le c \le t_2$, such that $g_1(t) = g_2(t)$ in $[t_1, c]$ and $g_1(t) < g_2(t)$ in $(c, t_2]$.*

THEOREM 2.3. *Suppose that*

$$\int_{-d}^{d} q_+(\tau)\, d\tau \le \pi/2 \quad \text{and} \quad \int_{-d}^{d} q_-(\tau)\, d\tau \le \pi/2. \tag{2.8}$$

Then there are no imaginary EVs. In particular, this is true if $\int_{-d}^{d} |q(\tau)|\, d\tau \le \pi/2$.

Proof. We will show that $|\theta(d; s)| < \pi/2$ for $s > 0$. Note that when $s = 0$, (2.3) and (2.8) imply that $|\theta(t, 0)| \le \pi/2$, $-d \le t \le d$. Let $w_\pm(t; s)$ be the solutions of

$$w'_\pm = \pm q_\mp(t) - s \sin[2w_\pm], \quad w_\pm(-d; s) = 0. \tag{2.9}$$

For application of the comparison theorem cited above let $f(t, g) = -q(t) - s \sin[2g(t)]$. Then $P(g) = g' + q(t) + s \sin[2g(t)]$ and so $P(\theta) = 0$. Furthermore,

$$\begin{aligned} P(w_-) &= w'_- + q(t) + s \sin[2w_-] \\ &= w'_- + q_+(t) - q_-(t) + s \sin[2w_-] \\ &= w'_- + q_+(t) + s \sin[2w_-] - q_-(t) \\ &= 0 - q_-(t) \le 0, \end{aligned}$$

and we conclude that $w_-(t; s) \le \theta(t; s)$ for $-d \le t \le d$, $s > 0$. Analogously, one shows $\theta(t; s) \le w_+(t; s)$. Since the initial value problem $z' = -s \sin(2z)$, $z(-d) = 0$, has the unique solution $z = 0$, then we have $w_-(t; s) \le 0 \le w_+(t; s)$, also by the comparison theorem. By (2.9) and the second condition in (2.8),

$$w_+(t; s) \le \int_{-d}^{t} q_-(\tau)\, d\tau, \quad -d \le t \le d. \tag{2.10}$$

Unless $q_-(t) \equiv 0$, then strict inequality holds in (2.10); that is,

$$w_+(d; s) < \int_{-d}^{d} q_-(\tau)\, d\tau. \tag{2.11}$$

For otherwise if equality held, then it would follow that

$$w_+(t; s) = \int_{-d}^{t} q_-(\tau)\, d\tau, \quad -d \le t \le d,$$

by the comparison theorem, and thus $w'_+(t; s) = q_-(t)$. Therefore $\sin[2w_+(t; s)] \equiv 0$, $w_+(t; s) \equiv 0$, and $q_-(t) \equiv 0$, a contradiction. So (2.11) and (2.8) together imply $\theta(d; s) \le w_+(t; s) < \pi/2$ for $s > 0$. If $q_-(t) \equiv 0$, then $w_+(t; s) \equiv 0$ and $\theta(d; s) < \pi/2$ is obviously true. Similarly, using $w_-(t; s)$ we deduce that $\theta(d; s) > -\pi/2$, $s > 0$, and so $|\theta(d; s)| < \pi/2$, $s > 0$, in all cases. Therefore purely imaginary EVs do not exist.

We note that the true number of EVs may be strictly larger than N due to the fact that $\theta(d;s)$ need not be monotone decreasing in general. That is, there can be multiple crossing events $\theta(d;s) = (2k-1)\pi/2$ without monotonicity. As an example, let $q(t) = h$ for $1 \le |t| \le 2$ and $q(t) = 0$ otherwise. As h increases, the first EV appears at $\xi = 0$ for $h = \pi/4$ (so that $I = \pi/2$ in (1.6)) and moves up the imaginary axis. According to Theorem 2.2 there is at least one imaginary EV when $\pi/4 < h < 3\pi/4$. However, a detailed analysis of this example shows that for $h = 2.2$ there are three purely imaginary EVs at approximately $\xi = 0.28i$, $0.63i$, and $1.03i$. The reason is that as $h \to h_c = 2.178$ (approximately) a pair of EVs having opposite nonzero real parts converge to and collide on the imaginary axis at about $\xi = 0.44i$. After the collision the two complex EVs become a pair of purely imaginary EVs so that there are a total of three imaginary EVs for h slightly larger than h_c. The occurrence of EVs colliding on the imaginary axis means that $\theta(d;s)$ need not be monotone in general. In this example we have with $h = 2.2$ that $\theta(2;s_1) = \theta(2;s_2) = -3\pi/2$ at $s_1 = 0.28$ and $s_2 = 0.63$, approximately.

We now show that for single lobe potentials, as mentioned in the introduction, Theorem 2.2 can be strengthened to assert that there are exactly N EVs. To be specific, $q(t)$ is called a single lobe potential if q satisfies (1.5), is bounded, piecewise smooth, and nondecreasing to the left of $t = 0$ and nonincreasing to the right of $t = 0$. By piecewise smooth we mean that $q(t)$ and $q'(t)$ have left- and right-hand limits for all t and that in any bounded interval $q(t)$ has at most finitely many jump discontinuities. Since (1.1) is invariant under shifts in the t variable, there is no loss of generality in taking $t = 0$ to be the point of energy concentration. Our results for single lobe potentials are also true if $q(t) < 0$ and $-q(t)$ is single lobe.

THEOREM 2.4. *In addition to the hypotheses of Theorem* 2.2 *assume that* $q(t)$ *is single lobe. Then there are exactly* N *purely imaginary EVs and no nonimaginary EVs.*

Proof. The statement claiming no nonimaginary EVs is proved in [4]. Putting $\xi = is$ in (1.1) gives the system

$$v_1' = sv_1 + q(t)v_2, \quad v_2' = -sv_2 - q(t)v_1. \tag{2.12}$$

We will show that multiple crossing events $\theta(d;s) = (2k-1)\pi/2$ are ruled out by the condition $\frac{d}{ds}\theta(d;s) > 0$, when s is an EV, for single lobe potentials. To this end, differentiate (2.12) with respect to s, using an overdot to denote the s derivative, to obtain

$$\dot{v}_1' = v_1 + s\dot{v}_1 + q(t)\dot{v}_2, \quad \dot{v}_2' = -v_2 - s\dot{v}_2 - q(t)\dot{v}_1. \tag{2.13}$$

Substitute (2.13) into $(\dot{v}_1 v_2 - v_1\dot{v}_2)'$, where the prime denotes differentiation with respect to t, expand, and simplify to obtain $(\dot{v}_1 v_2 - v_1\dot{v}_2)' = 2v_1 v_2$. The conditions (2.1) yield $\dot{v}_1(-d) = \dot{v}_2(-d) = 0$, and following integration we obtain

$$(\dot{v}_1 v_2 - v_1\dot{v}_2)(d) = 2\int_{-d}^{d} v_1(\tau)v_2(\tau)\,d\tau. \tag{2.14}$$

Noting (2.2) the quotient rule derivative (with respect to s) of $(v_2/v_1) = \tan(\theta)$ gives by (2.14)

$$\dot{\theta}(d;s) = \frac{-2}{v_1^2(d) + v_2^2(d)} \int_{-d}^{d} v_1(\tau)v_2(\tau)\,d\tau, \tag{2.15}$$

where $v_1(d) = 0$ if s is an EV. In [4] the authors have shown that the integral in (2.15) is negative for single lobe potentials. For completeness we give the gist of the argument, which comes from multiplying the first of (2.12) by v_1, solving for $v_1 v_2$, and integrating over $[0, d]$ to obtain

$$\int_0^d v_1(\tau)v_2(\tau)\,d\tau = -\frac{v_1^2(0)}{2q(0)} + \frac{1}{2}\int_0^d \frac{v_1^2(\tau)q'(\tau)}{q^2(\tau)}\,d\tau - s\int_0^d \frac{v_1^2(\tau)}{q(\tau)}\,d\tau. \tag{2.16}$$

Convergence of the integrals on the right of (2.16) can be justified for a single lobe $q(t)$. Since $q'(t) \le 0$ for $t \ge 0$, the right side of (2.16) is negative. Working with the other term in (2.12) shows similarly that the corresponding integral over $[-d, 0]$ is also negative. Therefore $\dot\theta(d; s) > 0$ at EV crossings, and the proof of Theorem 2.2 shows that there are exactly N purely imaginary EVs.

3. Noncompact support case. The Prüfer transformation (2.2) can also be applied if the potential $q(t)$ does not have compact support. The extension of the Prüfer method to the full line may be of independent interest. In this section we assume (1.5) only.

Equation (2.3) is still the most significant, but now the solution is required to satisfy

$$\operatorname*{Lim}_{t\to-\infty}\ \theta(t; s) = 0. \tag{3.1}$$

The integral equation corresponding to (2.5) now reads

$$\theta(t; s) = -e^{-2st}\int_{-\infty}^t e^{2s\tau}q(\tau)\,d\tau - se^{-2st}\int_{-\infty}^t e^{2s\tau}[\sin(2\theta(\tau; s)) - 2\theta(\tau; s)]\,d\tau. \tag{3.2}$$

Equation (3.2) can be solved by iteration, and it follows by standard arguments that (3.2) is the unique solution to (2.3) on $-\infty < t < \infty$ satisfying (3.1). Our goal now is to describe the behavior of $\theta(t; s)$ as $t \to \infty$.

LEMMA 3.1. *For each integer k and for each $s \ge 0$ there is a unique solution $\varphi_k(t; s)$ of* (2.3) *such that*

$$\operatorname*{Lim}_{t\to\infty}\ \varphi_k(t; s) = \frac{(2k-1)\pi}{2} \tag{3.3}$$

uniformly in s.

Proof. It suffices to prove the lemma for $k = 0$, in view of the fact that $\varphi_k(t; s) = \varphi_0(t; s) + k\pi$, which may be verified by substitution in (2.3). To this end define $\chi_0(t; s)$ as the unique solution satisfying

$$\chi_0'(t; s) = q(-t) - s\,\sin[2\chi_0(t; s)], \quad \chi_0(t; s) \to 0 \text{ as } t \to -\infty.$$

This is the same differential equation as (2.3) but with $q(t)$ replaced by $-q(-t)$. Then

$$\varphi_0(t; s) = \chi_0(-t; s) - \pi/2$$

satisfies the first conclusion of the lemma with $k = 0$. To prove the uniformity in s we use the integral equation for $\chi_0(t; s)$ and mimic the proof of Lemma 2.1. Given $\varepsilon > 0$ we can find a number T_ε such that

$$\left|e^{-2st}\int_{-\infty}^t e^{2s\tau}q(-\tau)\,d\tau\right| \le \int_{-\infty}^{-T_\varepsilon} |q(-\tau)|\,d\tau \le 2\varepsilon/3$$

for $t < -T_\varepsilon$ and $s \geq 0$. Proceeding as in the proof of Lemma 2.1 we conclude that $|\chi_0(t;s)| \leq \varepsilon$ for $t < -T_\varepsilon$ and $s \geq 0$. Hence (3.3) is valid uniformly in s.

Note that $\xi = is$ is an EV if and only if $\theta(t;s)$ of (3.1) and (3.2) is a multiple of one of the functions $\varphi_k(t;s)$.

THEOREM 3.2. *Suppose that $q(t)$ satisfies* (1.5) *and that $y(t;s)$ is any solution of* (2.3) *with $s > 0$. Then the limit*

$$L_y(s) = \operatorname*{Lim}_{t \to \infty} y(t;s) \tag{3.4}$$

exists and, moreover, $L_y(s) = k\pi/2$ for some integer k.

Proof. The idea is to exploit the fact that the term $s\sin[2y(t;s)]$ dominates the right side of (2.3) when t is large. Note that if $q(t) = 0$, then (2.3) has the constant solutions $y(t;s) = k\pi/2$, with k an integer.

If $y(0;s) = \varphi_k(0;s)$ for some k, then $y(t;s) = \varphi_k(t;s)$ by uniqueness of solutions and the conclusion follows from Lemma 3.1. Thus we can suppose that $y(0;s) \neq \varphi_k(0;s)$ for any k. Suppose first that $\varphi_0(0;s) < y(0;s) < \varphi_1(0;s)$. We will show that $y(t;s) \to 0$, $t \to \infty$. By the uniqueness part of Lemma 3.1, $y(t;s)$ cannot converge to either $\pm\pi/2$ (by uniqueness of the φ_k). Suppose that $y(t;s)$ does not converge to 0. Then there is a $\delta > 0$ and a sequence $t_n \to \infty$ such that for all n either

$$\delta < y(t_n;s) < (\pi/2) - \delta \quad \text{or} \quad -(\pi/2) + \delta < y(t_n;s) < -\delta.$$

Without loss of generality, assume the former. We will derive a contradiction. Pick N so large that

$$\int_{t_N}^{\infty} |q(\tau)|\, d\tau < \delta/2 \tag{3.5}$$

and note that on the interval $(\delta/2) < z < (\pi - \delta)/2$ we have

$$\sin(2z) > c_\delta \tag{3.6}$$

for some $c_\delta > 0$. Using (3.6) in (2.3) we obtain

$$y'(t;s) \leq -q(t) - c_\delta s$$

so long as $(\delta/2) < y(t;s) < (\pi - \delta)/2$. Therefore, if $y(t;s)$ satisfies these bounds for $\alpha \leq t \leq \beta$, then

$$y(t;s) \leq y(\alpha;s) - c_\delta s(t-\alpha) - \int_\alpha^t q(\tau)\, d\tau, \quad \alpha \leq t \leq \beta. \tag{3.7}$$

We first claim that $(\delta/2) < y(t;s) < (\pi - \delta)/2$ for all $t \geq t_N$. Otherwise, one of the following situations must occur:

(a) there is an interval $[\alpha, \beta]$ with $\alpha > t_N$ such that $y(\alpha;s) = (\pi/2) - \delta < y(t;s) < (\pi - \delta)/2$, for $\alpha < t < \beta$, and $y(\beta;s) = (\pi - \delta)/2$;

(b) there is an interval $[\alpha, \beta]$ with $\alpha > t_N$ such that $y(\alpha;s) = \delta/2 < y(t;s) < \delta$, for $\alpha < t < \beta$, and $y(\beta;s) = \delta$.

In case (a), (3.7) implies $y(t;s) < (\pi/2) - \delta + (\delta/2) = (\pi - \delta)/2$, for $\alpha \leq t \leq \beta$, and this contradicts $y(\beta;s) = (\pi - \delta)/2$. In case (b), we conclude that $y(t;s) < (\delta/2) + (\delta/2) = \delta$, contradicting $y(\beta;s) = \delta$. Thus $(\delta/2) < y(t;s) < (\pi - \delta)/2$ for all $t \geq t_N$. However, then (3.7) leads to an obvious contradiction since it says that $y(t;s)$ becomes negative

for large enough t since $s > 0$. Similarly, one argues that there are no sequences t_n such that $-(\pi/2) + \delta < y(t_n; s) < -\delta$. Therefore $y(t; s) \to 0$.

For solutions $y(t; s)$ satisfying $\varphi_k(0; s) < y(0; s) < \varphi_{k+1}(0; s)$ we use the fact that $\tilde{y}(t; s) = y(t; s) - k\pi$ satisfies $\varphi_0(0; s) < \tilde{y}(0; s) < \varphi_1(0; s)$ so that $\tilde{y}(t; s) \to 0$ as $t \to \infty$; i.e., $y(t; s) \to k\pi$ as $t \to \infty$. This completes the proof of Theorem 3.2. Note that the φ_k have limits $L_{\varphi_k}(s) = (2k-1)\pi/2$ which are odd multiples of $\pi/2$, while all other solutions $y(t; s)$ have limits which are even multiples of $\pi/2$.

THEOREM 3.3. *The conclusions of Theorems* 2.2 *and* 2.3 *hold for general* $q(t)$ *satisfying* (1.5).

Proof. We prove only the extension of Theorem 2.2; the proof of the extension of Theorem 2.3 is similar. For the extension of Theorem 2.2 it suffices to show that $L_\theta(s) \to 0$, $s \to \infty$, without skipping any odd multiples of $\pi/2$. That is, if $|L_\theta(0)| > \frac{(2N-1)\pi}{2}$, we will show that for $k = 1, 2, \ldots, N$ there are s_k such that $|L_\theta(s_k)| = \frac{(2(N-k)+1)\pi}{2}$. Note that $\theta(t; 0) = -\int_{-\infty}^{t} q(\tau)\, d\tau$ and so $L_\theta(0) = -I$ (from (1.6)).

In showing $L_\theta(s) \to 0$ we will actually prove that $L_\theta(s) = 0$ for $s > \tilde{s}$, with $\tilde{s}$ sufficiently large. Let

$$\delta = |L_\theta(0)| - \frac{(2N-1)\pi}{2},$$

where N is defined as in Theorem 2.2. Note that $0 < \delta \leq \pi$ by the definition of N. Pick $\tilde{t}$ so large that $|\varphi_0(\tilde{t}; s) + (\pi/2)| < (\delta/4)$, $|\varphi_1(\tilde{t}; s) - (\pi/2)| < (\delta/4)$, for $s \geq 0$, and $|\theta(\tilde{t}; 0)| > \frac{(2N-1)\pi}{2} + (\delta/4)$. By a slight extension of Lemma 2.1 to the case $d = \infty$ we can conclude that there is an $\tilde{s} > 0$ such that $|\theta(\tilde{t}; s)| < \pi/4$ for $s > \tilde{s}$. Therefore $\varphi_0(\tilde{t}; s) < \theta(\tilde{t}; s) < \varphi_1(\tilde{t}; s)$ if $s > \tilde{s}$. As in the proof of Theorem 3.2 it follows that $\theta(t; s) \to 0$, $t \to \infty$; that is, $L_\theta(s) = 0$, $s > \tilde{s}$.

Suppose now that $L_\theta(0) > \frac{(2N-1)\pi}{2}$; the case $L_\theta(0) < -\frac{(2N-1)\pi}{2}$ is handled similarly. Since $\theta(t; s)$ is continuous in s there are at least N crossings s_k, where $\theta(\tilde{t}; s_k) = \varphi_{N-k+1}(\tilde{t}; s_k)$, so that $\theta(t; s_k) = \varphi_{N-k+1}(t; s_k)$ for all t. Each s_k corresponds to an imaginary EV, which proves the extension of Theorem 2.2.

THEOREM 3.4. *Suppose* $q(t)$ *satisfies* (1.5) *and is an odd function. Then there are no imaginary EVs.*

Proof. Suppose $\xi = is$ is an EV with eigenfunction $\theta(t; s)$ such that $L_\theta(s) = \frac{(2m-1)\pi}{2}$ for some integer m. By substitution $w(t; s) = \theta(-t; s) + \frac{(2m-1)\pi}{2}$ is also a solution of (2.3) since $q(t)$ is odd. Since $\theta(-t; s) \to 0$, $t \to \infty$, then $\mathrm{Lim}_{t\to\infty} w(t; s) = \frac{(2m-1)\pi}{2} = L_\theta(s)$ and therefore $w(t; s) \equiv \theta(t; s)$. Since $w(0; s) = \theta(0; s) + \frac{(2m-1)}{2} \neq \theta(0; s)$, we have a contradiction.

We close the section with an alternate proof of Theorem 3.4. Let $\xi = is$ be an EV with eigenfunction $\vec{v}(t)$. By the odd symmetry of $q(t)$ the function $\eta(t) = \binom{-v_2(-t)}{v_1(-t)}$ is an eigenfunction. Thus $\vec{\eta} = K\vec{v}$ for some constant K. Then $-v_2(0) = Kv_1(0)$ and $v_1(0) = Kv_2(0)$, neither of which is possible unless $\vec{v}(t) \equiv 0$.

4. More general potentials. In this section we suppose that

$$q \in L^1(-\infty, \infty) \tag{4.1}$$

and allow $q(t)$ to be nonreal for some of our results. We begin with the observation that if ξ ($\mathrm{Im}(\xi) > 0$) is an EV for (1.1), then the eigenfunction $\vec{v}(t)$ satisfies

$$\begin{aligned} v_1(t) &= -e^{-i\xi t}\int_t^\infty e^{i\xi\tau}q(\tau)v_2(\tau)\,d\tau, \\ v_2(t) &= -e^{i\xi t}\int_{-\infty}^t e^{-i\xi\tau}q(\tau)^*v_1(\tau)\,d\tau. \end{aligned} \tag{4.2}$$

Equation (4.2) is obtained by converting (1.1) to a system of integral equations using the fact that $v_1, v_2 \in L^2(-\infty,\infty)$. It is convenient to recast (4.2) as an EV problem for a compact operator which will play a role analogous to that of the Birman–Schwinger kernel [10, p. 98] for the Schrödinger equation. To this end we put

$$q(t) = |q(t)|e^{i\sigma(t)}, \quad -\pi < \sigma(t) \le \pi,$$

and let

$$U(t) = \begin{pmatrix} e^{-i\sigma(t)} & 0 \\ 0 & e^{i\sigma(t)} \end{pmatrix}. \tag{4.3}$$

We also introduce the matrix integral kernel

$$A_\xi(t,\tau) = \begin{pmatrix} e^{i\xi(\tau-t)}H(\tau-t) & 0 \\ 0 & e^{i\xi(t-\tau)}H(t-\tau) \end{pmatrix}, \tag{4.4}$$

where H denotes the Heaviside step function, and we put

$$\vec{w} = |q|^{1/2}\vec{v}, \quad J = \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}. \tag{4.5}$$

Then (4.2) can be written as

$$\vec{w}(t) = \int_{-\infty}^\infty K_\xi(t,\tau)\vec{w}(\tau)\,d\tau, \tag{4.6}$$

where

$$K_\xi(t,\tau) = -|q(t)|^{1/2}A_\xi(t,\tau)J|q(\tau)|^{1/2}U(\tau). \tag{4.7}$$

We denote by K_ξ the integral operator induced by the kernel $K_\xi(t,\tau)$. Note that every EV ξ of (1.1) with corresponding eigenfunction $\vec{v}$ gives rise to an eigenfunction $\vec{w}$ for the EV 1 of K_ξ. Conversely, if $\vec{w}(t)$ is a square integrable solution of (4.6), then

$$\vec{v}(t) = \int_{-\infty}^\infty A_\xi(t,\tau)J|q(\tau)|^{1/2}U(\tau)\vec{w}(\tau)\,d\tau$$

is an eigenfunction of (1.1) for the EV ξ. This connection is known as the Birman–Schwinger principle.

LEMMA 4.1. *Suppose q satisfies* (4.1) *and let* $\mathrm{Im}(\xi) \ge 0$. *Then K_ξ is Hilbert–Schmidt. If q is real and of one sign, then K_ξ is unitarily equivalent to $-K_\xi$, and if $\xi = is$ $(s > 0)$, then K_{is} is self-adjoint. Moreover, $\|K_{is}\| \to 0$, $s \to \infty$.*

Proof. The Hilbert–Schmidt norm of K_ξ is given by

$$\|K_\xi\|^2_{H.S.} = \iint_{\Re^2} Tr[K^+_\xi(t,\tau)K_\xi(t,\tau)]\,dt\,d\tau,$$

where the superscript "+" denotes the matrix adjoint and "Tr" the matrix trace. From (4.4) and (4.7) we obtain (putting $\mathrm{Im}(\xi) = s$)

$$\|K_\xi\|^2_{H.S.} = \int_{-\infty}^{\infty}\left(\int_{-\infty}^{t}|q(\tau)|e^{2s\tau}\,d\tau\right)|q(t)|e^{-2st}\,dt \le \left(\int_{-\infty}^{\infty}|q(t)|\,dt\right)^2 < \infty \tag{4.8}$$

by (4.1), proving the first part of the lemma. If q is real and of one sign, then $\sigma(t) = 0$ ($\sigma(t) = \pi$) if $q(t) \ge 0$ ($q(t) \le 0$), and hence by (4.3) $U(t) = \pm I$, where I is the identity matrix. Let $S = \left(\begin{smallmatrix}1 & 0\\ 0 & -1\end{smallmatrix}\right)$. Then $SK_\xi S^{-1} = -K_\xi$, proving that K_ξ is unitarily equivalent to $-K_\xi$. Using $U(t) = \pm I$, $\xi = is$ in (4.7) and the fact that $A^*_{is} = JA_{is}J$, we conclude that $K^*_{is} = K_{is}$. The last statement follows from (4.8) and the Lebesgue dominated convergence theorem.

From (4.8) it follows that $\|K_\xi\|_{H.S.} < \|q\|_{L^1}$ if $\mathrm{Im}(\xi) = s > 0$. Hence there can be no EVs if $\|q\|_{L^1} \le 1$. However, $\|q\|_{L^1} \le 1$ is not as strong as the bound $\|q\|_{L^1} \le 1.32$ mentioned in the introduction, and the latter is not best possible. The optimal L^1 bound on q that guarantees the absence of EVs is obtained in the next theorem.

THEOREM 4.2. *Suppose that q is complex-valued and satisfies* (4.1). *If*

$$\int_{-\infty}^{\infty}|q| \le \pi/2, \tag{4.9}$$

then (1.1) *has no EVs.*

Proof. Put $\xi = \mu + is$, $s > 0$, and

$$W_\mu(t) = \begin{pmatrix} e^{-i\mu t} & 0\\ 0 & e^{i\mu t}\end{pmatrix}.$$

Then we can write $K_\xi(t,\tau)$ given in (4.7) as

$$K_\xi(t,\tau) = W_\mu(t)K_{is}(t,\tau)W_\mu(\tau).$$

Here we have used $A_\xi(t,\tau) = W_\mu(t)A_{is}(t,\tau)W^*_\mu(\tau)$ and $W^*_\mu(\tau)J = JW_\mu(\tau)$. The unitarity of W_μ and U implies that

$$\|K_\xi\| = \|K_{is}\| = \|\tilde K_{is}\|, \tag{4.10}$$

where $\tilde K_{is}$ is the self-adjoint operator with kernel

$$\tilde K_{is}(t,\tau) = -|q(t)|^{1/2}A_{is}(t,\tau)J|q(\tau)|^{1/2}.$$

We are going to use the Birman–Schwinger principle for the potential $|q|$. Now (4.9) together with Theorem 3.3 imply that (1.1) with $|q|$ in place of q has no EV on the imaginary axis. Hence $\|\tilde K_{is}\| < 1$, $s > 0$, for if not, then by Lemma 4.1 there would exist a point $s_0 > 0$ such that $\|\tilde K_{is_0}\| = 1$. This would imply that $\tilde K_{is_0}$ has EV 1, which by the Birman–Schwinger principle implies further that $\xi = is_0$ is an EV of (1.1) for the potential $|q|$, a contradiction. Then $\|K_\xi\| < 1$ by (4.10) and K_ξ does not have an EV 1 for any ξ. The conclusion of the theorem follows.

By Theorem 2.2 the bound $\pi/2$ is optimal as claimed.

Note that the ZS system (1.1) for $|q|$ satisfies (4.9) if it has no imaginary EVs, by Theorems 2.3 and 3.3. This proves the following corollary.

COROLLARY 4.3. *Suppose that q is complex-valued and satisfies* (4.1) *and that* (1.1) *with $|q|$ in place of q has no imaginary EVs. Then* (1.1) *for q has no EVs.*

Corollary 4.3 implies that if q is of one sign with a complex EV $\xi_1 = \mu_1 + is_1$ such that $\mu_1 \neq 0$ and $s_1 > 0$, then there must exist a purely imaginary EV $\xi_0 = is_0$. The next theorem says that there is such an EV with $s_0 > s_1$. That is, there is a purely imaginary EV which dominates the magnitudes of the imaginary parts of all other EVs.

THEOREM 4.4. *Suppose that q satisfies* (4.1) *and either $q(t) \geq 0$ or $q(t) \leq 0$. If* (1.1) *has EVs, then there is a purely imaginary EV whose imaginary part is strictly larger than the imaginary part of any other EV.*

Proof. Suppose that $\xi_1 = \mu_1 + is_1$, with $\mu_1 \neq 0$ and $s_1 > 0$, is an EV. Let $\vec{u} = \binom{u_1}{u_2}$ be the normalized eigenfunction for the EV 1 of K_{ξ_1}. Let $\vec{u}_{abs}$ be the vector whose components are $|u_1|$ and $|u_2|$, respectively. Define

$$\begin{aligned} G_{12}(t,\tau) &= -u_1^*|q(t)|^{1/2}e^{i\xi_1(\tau-t)}H(\tau-t)|q(\tau)|^{1/2}e^{-i\sigma(\tau)}u_2(\tau), \\ G_{21}(t,\tau) &= -u_2^*|q(t)|^{1/2}e^{i\xi_1(t-\tau)}H(t-\tau)|q(\tau)|^{1/2}e^{i\sigma(\tau)}u_1(\tau) \end{aligned} \tag{4.11}$$

so that

$$1 = (\vec{u}, K_{\xi_1}\vec{u}) = \iint_{\Re^2} G_{12}(t,\tau)\,dt\,d\tau + \iint_{\Re^2} G_{21}(t,\tau)\,dt\,d\tau$$

and

$$|(\vec{u}_{abs}, \tilde{K}_{is_1}\vec{u}_{abs})| = \iint_{\Re^2} |G_{12}(t,\tau)|\,dt\,d\tau + \iint_{\Re^2} |G_{21}(t,\tau)|\,dt\,d\tau.$$

We obviously have $(\vec{u}, K_{\xi_1}\vec{u}) \leq (\vec{u}_{abs}, \tilde{K}_{is_1}\vec{u}_{abs})$ and equality holds if and only if

$$\iint_{\Re^2} G_{rs}(t,\tau)\,d\tau\,dt = \iint_{\Re^2} |G_{rs}(t,\tau)|\,d\tau\,dt \tag{4.12}$$

for $(r,s) = (1,2)$ or $(2,1)$. Now (4.12) holds if and only if $G_{rs}(t,\tau) = e^{i\beta_{rs}}|G_{rs}(t,\tau)|$ for some real number β_{rs} [11, p. 174]. Putting $u_k(t) = e^{i\varphi_k(t)}|u_k(t)|$ $(k = 1,2)$ we see from (4.11) that (4.12) can hold only if

$$\begin{aligned} e^{-i(\varphi_1(t)+\mu_1 t)}e^{i(\varphi_2(\tau)+\mu_1\tau-\sigma(\tau)+\pi)} &= e^{i\beta_{12}}, \quad t < \tau, \\ e^{-i(\varphi_2(t)-\mu_1 t)}e^{i(\varphi_1(\tau)-\mu_1\tau+\sigma(\tau)+\pi)} &= e^{i\beta_{21}}, \quad t > \tau. \end{aligned}$$

It follows by a separation of variables argument that each of the exponentials on the left side must be constant. However, this is possible only if $\mu_1 = 0$, which contradicts our assumption. We conclude that in (4.12) equality cannot hold; that is, we have

$$1 = (\vec{u}, K_{\xi_1}\vec{u}) < (\vec{u}_{abs}, \tilde{K}_{is_1}\vec{u}_{abs})$$

and therefore $\|\tilde{K}_{is_1}\| > 1$. By Lemma 4.1 there exists $s_0 > s_1$ such that $\|\tilde{K}_{is_0}\| = 1$. In view of (4.10) $\|K_{is_0}\| = 1$ and thus K_{is_0} has EV 1. Then $\xi_0 = is_0$ is an EV of (1.1) whose imaginary part is strictly larger than s_1. It follows that the purely imaginary EV of largest modulus has an imaginary part that is strictly larger than that of any other EV.

5. Summary and discussion. We have established $\pi/2$ as the threshold L^1 norm of the potential (complex-valued) for the formation of EVs in a ZS system. Bounds for the number of imaginary EVs were obtained and shown to be best possible for the class of single lobe potentials. For real, single signed potentials, an imaginary EV of largest magnitude dominates the magnitudes of the imaginary parts of all other EVs, imaginary or not. ZS systems with odd L^1 potentials are free of imaginary EVs.

Theorem 3.3 provides a way to extend criteria for soliton formation found in the current literature. In (1.2) let $q(t) = u(0,t) = N\ \mathrm{sech}(t)$. Since $\int_{-\infty}^{\infty} \mathrm{sech}(t)\,dt = \pi$, then by Theorem 3.3 the condition for a fundamental soliton is $\frac{1}{2} < N < \frac{3}{2}$, which agrees exactly with [5]. This extends to an order K soliton, K a positive integer, when $K - \frac{1}{2} < N < K + \frac{1}{2}$.

The discussion in [5] takes place in the context of normalized, dimensionless units. In physical units the nonlinear Schrödinger equation is

$$iA_z = \frac{\beta_2}{2} A_{TT} - \gamma |A|^2 A, \quad A(0,T) = f(T), \tag{5.1}$$

with $f(T)$ specified, where $A = A(z,T)$ is the "slowly varying" field, z is physical length, T is local pulse physical time, $\beta_2 < 0$ is the fiber dispersion constant, and γ is the material nonlinearity constant [5]. Here $f(T)$ is assumed real-valued. Solitons occur only in the anomalous dispersion case $\beta_2 < 0$ [5]. The units of $|A|^2$ are expressed in terms of power, typically in milliwatts (mW); since the units of $A(z,T)$ appear in each term, they always cancel and thus $A(z,T)$ need not be assigned units. To express (5.1) in dimensionless form, choose a reference power level P_0 and define $U(z,T) = A(z,T)/\sqrt{P_0}$; here P_0 might be $P_0 = A(0,0)^2 = f(0)^2$ (the "peak" power) or some arbitrary base level such as 1 mW. Next select some reference pulse width T_0, which could be the root mean square width of $f(T)$, the bit period, the full width half-maximum [5], or something else. The corresponding dispersion and nonlinear lengths L_D and L_{NL} are defined by $L_D = T_0^2/|\beta_2|$ and $L_{NL} = 1/(\gamma P_0)$. It is convenient to define dimensionless length and time by $\zeta = z/L_D$ and $t = T/T_0$ [5]. Introducing the constant $N = \sqrt{L_D/L_{NL}}$ and making the appropriate substitutions in (5.1) we obtain the dimensionless nonlinear Schrödinger equation

$$iU_\zeta + \frac{1}{2} U_{tt} + N^2 |U|^2 U = 0, \quad U(0,0) = f(0)/\sqrt{P_0}. \tag{5.2}$$

The N can be removed from (5.2) by making the substitution $u(\zeta,t) = NU(\zeta,t)$, $u(0,t) = q(t)$, bringing (5.2) to the form (1.2). The connection between the physical and dimensionless versions of (1.6) is

$$I = \int_{-\infty}^{\infty} q(t)\,dt = \frac{N}{T_0\sqrt{P_0}} \int_{-\infty}^{\infty} f(T)\,dT, \tag{5.3}$$

in which the reference parameters P_0 and T_0 cancel, since $N^2 = T_0^2 \gamma P_0/|\beta_2|$, leaving

$$I = \int_{-\infty}^{\infty} q(t)\,dt = \sqrt{\frac{\gamma}{|\beta_1|}} \int_{-\infty}^{\infty} f(T)\,dT. \tag{5.4}$$

For single lobe potentials the exact soliton formation criterion is thus $\sqrt{\gamma/|\beta_2|}$ $\int_{-\infty}^{\infty} f(T)\,dT > \pi/2$ by (5.4). Using Theorem 3.3 this extends to higher order solitons using the thresholds $(2n-1)\pi/2$. If $f(T)$ is complex-valued, Corollary 4.3 applies.

Note that (5.4) depends on the physical constants of the fiber and the pulse shape, and not on the particular choices of P_0 and T_0 used in the normalization.

The criterion $\frac{1}{2} < N < \frac{3}{2}$ [5] mentioned above for the hyperbolic secant pulse is only approximate for other shapes. If $f(T)$ is given, $f(0) = \sqrt{P_0}$, and T_0 is the intensity half width at $1/e$ [5], then we can derive specific criteria using (5.3) and (5.4), and detailed knowledge of $\int_{-\infty}^{\infty} f(T)\,dT$. As examples, for Gaussian pulses $f(T) = \sqrt{P_0}\exp\{-\frac{t^2}{2T_0^2}\}$ in (5.2) [5] a fundamental soliton will evolve if $N > \sqrt{\pi/8} \cong 0.6267$, while for a rectangular pulse of height $f(0) = \sqrt{P_0}$ and total width $2T_0$ the corresponding condition is $N > \pi/4 \cong 0.7854$. Analogous threshold levels can be obtained for higher order solitons.

We need to mention some related literature. Kivshar [12] established the $\pi/2$ threshold result for the special case where all EVs corresponding to the potential $\alpha q(t)$ appear on the imaginary axis at $\xi = 0$ as the real parameter α is varied. This approach reduces to analytically solving (1.1) for $\xi = 0$. In general, however, EVs can hop onto the imaginary axis from the upper half plane, without passing through $\xi = 0$ [3]. Kivshar's paper was intended to extend results of Burzlaff [13] which established the bounds in our Theorem 3.3 for the positive "box" and two-sided exponential potentials. Kaup and Scacca [14] also studied potentials made from combining boxes, both positive and negative, a special case of which is the odd potential. They found for odd potentials that EVs are very near the imaginary axis but with definitely nonzero real parts, in contrast to earlier numerical studies which could not confirm that the EVs were not actually on the imaginary axis; see the references in [14]. Theorem 3.4 rules out imaginary EVs for general odd $q(t)$.

Desaix et al. [15] have provided a variational method for approximating ZS EVs. Problems analogous to those discussed in this paper have also been addressed in [16] in connection with the modified KdV equation.

Acknowledgment. We would like to thank a referee for pointing out a paper of Beals and Coifman [17] which treats a more general system than (1.1) and obtains an upper bound on E in (1.4) that rules out EVs. For the particular case of (1.1) the bound in [17] reduces to $E < 1/\sqrt{2}$.

THE EXISTENCE AND LARGE TIME BEHAVIOR OF SOLUTIONS TO A SYSTEM RELATED TO A PHASE TRANSITION PROBLEM*

HARUMI HATTORI†

Abstract. We discuss the existence and the asymptotic behavior of weak solutions to a hyperbolic-elliptic mixed type system related to a phase transition problem. As in the hyperbolic case, the weak solutions are not unique. To select the admissible solution, we need to impose admissibility criteria. One of the criteria we use is the entropy rate admissibility criterion. The question is how it can be applied. We examine two alternatives, and the result is used to study the existence and large time behavior of solutions to the perturbed Riemann problem.

1. Introduction.

In this paper, we consider the existence and large time behavior of weak solutions to a hyperbolic-elliptic mixed system related to a phase transition problem. The system is given by

$$\begin{aligned} v_t - u_x &= 0, \\ u_t - f(v)_x &= 0, \end{aligned} \tag{1.1}$$

where v, u, and f are strain, velocity, and stress, respectively. We assume that f is a smooth nonmonotone function of v, as depicted in Figure 1.1. The horizontal line for which the areas A and B are equal is called the Maxwell stress, and the strains in the α- and β-phases corresponding to the Maxwell stress are denoted by v_α and v_β, respectively. It is important to note that, if f' is nonnegative, the system is hyperbolic, and f' is negative, then the system is elliptic. In our case, there are two intervals $(0,\alpha]$ and $[\beta,\infty)$, where the system is hyperbolic. They are called the α-phase and β-phase, respectively. In thermodynamics, the states $(0,v_\alpha]$ and $[v_\beta,\infty)$ are said to be stable, $(v_\alpha,\alpha]$ and $[\beta,v_\beta)$ are said to be metastable, and (α,β) is called the spinodal region and is physically unobservable. This is one of the simplest systems capable of explaining a phase transition problem.

One goal is to examine the entropy rate admissibility criterion. As in the hyperbolic systems of conservation laws, the weak solutions for the above mixed type problem are not unique. Therefore, to select a physically relevant solution, the admissibility criteria should be imposed. In section 2, we discuss the main admissibility criteria we use in this paper. They are the entropy condition and the entropy rate admissibility criterion. The entropy rate admissibility criterion, proposed by Dafermos [8], [9] for the hyperbolic systems of conservation laws, roughly says that the rate of (mathematical) entropy production is the smallest for the admissible solution. This criterion is also used in crack dynamics [38], and the effort should be made to extend

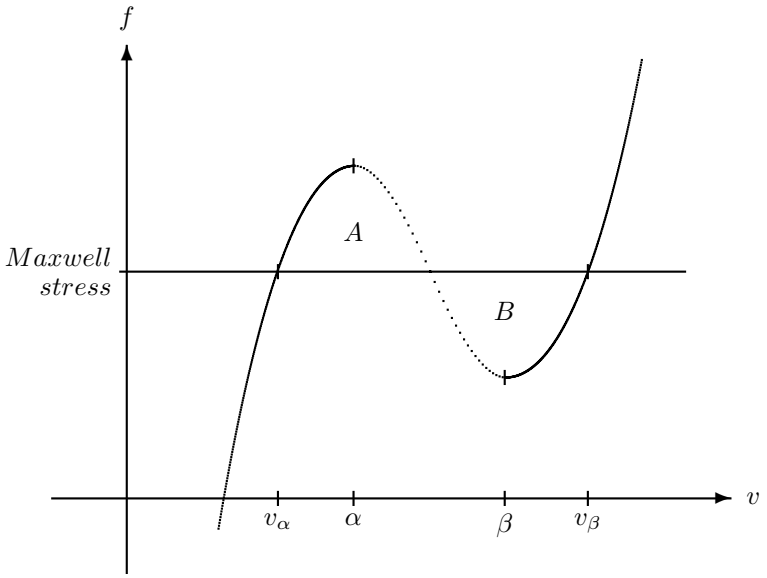

FIG. 1.1.

it to the conservation laws of mixed type. We apply it to the Riemann problem involving the phase boundary. In this case, there are at least two different ways to apply the criterion. Should it be applied to all waves combined or to the phase boundary only? To see the relation, in section 3, we apply the criterion to all of the waves in the Riemann problem to obtain the existence of global weak solutions, and, in section 4, we analyze its consequence to the Riemann problem. We show that, if we apply the criterion in the above fashion to the Riemann problem and take the hyperbolic limit, we obtain the solution to the Riemann problem, where the criterion is applied to the phase boundary only.

Another goal is to discuss the existence and large time behavior of solutions to (1.1) in the space of bounded variations. The initial data are given by

$$U(x,0) = (v,u)(x,0) = (v,u)_{oo}(x) \equiv \begin{cases} U_L = (v_L, u_L), & x \le -M, \\ U_l(x) = (v_l(x), u_l(x)), & -M < x < 0, \\ U_r(x) = (v_r(x), u_r(x)), & 0 < x < M, \\ U_R = (v_R, u_R), & M < x, \end{cases} \tag{1.2}$$

where (v_L, u_L) and (v_R, u_R) are constant states and M is a positive constant. This problem is called the perturbed Riemann problem, and the corresponding Riemann problem is given by

$$(v,u)(x,0) = \begin{cases} U_L = (v_L, u_L), & x < 0, \\ U_R = (v_R, u_R), & 0 < x. \end{cases} \tag{1.3}$$

In what follows, the vector notation U (or V) and the component notation (v,u) are used interchangeably, and the Riemann problem with initial data 1.3 is denoted by (U_L, U_R). We assume the following conditions for the initial data:

1. $U_l(x)$ and $U_r(x)$ are close to U_L and U_R, respectively, in the total variation norm.

2. $v_l(x)$ and v_L are in the α-phase and close to v_α, $v_r(x)$ and v_R are in the β-phase and close to v_β, and $u_{oo}(x)$ is small in total variation.

Therefore, we assume that

$$\begin{aligned}\eta = {} & TV_{x<0}|U_l(x) - U_L| + TV_{x>0}|U_r(x) - U_R| \\ & + |v_L - v_\alpha| + |v_R - v_\beta| + |u_L - u_c| + |u_R - u_c|\end{aligned} \tag{1.4}$$

is small, where u_c is a constant. In particular, we assume that $\eta < 1$. The above initial data will ensure that the speed of the phase boundary is subsonic; namely, its speed is smaller than those of characteristics. We use the Glimm scheme with the admissibility criteria discussed above. A crucial step in the Glimm scheme is to estimate the strengths of outgoing waves for the wave interactions involving the phase boundary. We need to select the outgoing waves so that both the entropy condition and the entropy rate admissibility criterion are satisfied. Concerning the asymptotic behavior, we show that, among other things, the solution approaches the solution of the corresponding Riemann problem modulo shift. The details will be discussed in sections 3 and 5.

It is now a common practice to use the nonmonotone constitutive relation to formulate the conservation laws with phase change. In the inviscid approach, the Riemann problem of system (1.1) was discussed in various literature. James [23] initiated the Riemann problem for this type of problem. Different admissibility criteria were used to select a physically relevant solution. Abeyaratne and Knowles [1], [2] discussed it using the kinetic relation and the initiation criterion. Hattori [17], [18] used the entropy rate admissibility criterion proposed by Dafermos [8], [9] for hyperbolic systems. Shearer [33] considered the problem, assuming that all of the stationary phase boundaries are admissible. Keyfitz [24] discussed the Riemann problem from the point of view of the "hysteresis" approach. Mercier and Piccoli [29] classified the initial data using the kinetic relation. As far as the Cauchy problem is concerned, Le Floch [26] has shown the existence of global solutions for a trilinear system in the space of bounded variations. Asakura [4] considered the nonlinear case. Pego and Serre [31] considered the instability of the Glimm scheme. Colombo and Corli [6] studied the continuous dependence of solutions. Corli and Sablé-Tougeron [7] discussed the sonic phase boundary problem. Another approach is to add the higher spatial derivatives of v and u to smooth out the shock discontinuities and phase boundaries. Slemrod [35], [36] discussed the effects of viscosity and capillarity and proposed the viscosity-capillarity criterion. Shearer [34] considered the issue of nonuniqueness for the Riemann problem using this criterion. Slemrod [37] also discussed the limiting viscosity approach. Fan extended this approach and obtained a series of results [11], [12], [13]. The results of Fan and Slemrod are summarized in [14]. Hattori and Mischaikow [20] considered the soft loading problem with viscosity and capillarity. Hsiao [22], Hoff and Khodja [21], and Pego [30] considered the role of the viscosity.

This paper consists of five sections. In section 2, we describe the admissibility criteria that we use in this paper. They are the entropy condition, the entropy rate admissibility criterion, and the initiation criterion. We then study the Riemann problem with single phase boundary using these criteria. In section 3, we discuss the wave interactions in a diamond and construct the interaction potential. Then we show the existence of weak solutions in the space of bounded variations. In section 4, we revisit the Riemann problem and show that asymptotic states occur immediately in the Riemann problem. We study the large time behavior of weak solutions in section 5.

2. The Riemann problem. In this section, we first describe the waves appearing in the Riemann problem and the admissibility criteria, and then we study the Riemann problem for (1.1) with single phase boundary.

2.1. Waves in the Riemann problem.

1. *Elementary waves.* We call the rarefaction wave and the shock wave the elementary waves. The 1-rarefaction curve $R_1^r(U_o)$ and the 1-shock curve $S_1^r(U_o)$ through U_o are the set of U connected to U_o on the right by the respective waves. They satisfy the following relations:

$$\text{rarefaction curve:} \quad u = u_o + \int_{v_o}^{v} \lambda(w)dw, \qquad \begin{cases} v \le v_o & \text{if } f \text{ is convex,} \\ v \ge v_o & \text{if } f \text{ is concave,} \end{cases}$$

$$\text{shock curve:} \quad u = u_o - \sigma_b(v_o, v)(v - v_o), \qquad \begin{cases} v \ge v_o & \text{if } f \text{ is convex,} \\ v \le v_o & \text{if } f \text{ is concave,} \end{cases}$$

where $\lambda(w) = \sqrt{f'(w)}$ and $\sigma_b(v_o, v) = -\sqrt{\frac{f(v)-f(v_o)}{v-v_o}}$. The combined wave curve is denoted by $T_1^r(U_o)$. The 2-rarefaction, 2-shock, and combined curves $R_2^r(U_o)$, $S_2^r(U_o)$, and $T_2^r(U_o)$ are defined in a similar manner:

$$\text{rarefaction curve:} \quad u = u_o - \int_{v_o}^{v} \lambda(w)dw, \qquad \begin{cases} v \ge v_o & \text{if } f \text{ is convex,} \\ v \le v_o & \text{if } f \text{ is concave,} \end{cases}$$

$$\text{shock curve:} \quad u = u_o - \sigma_f(v_o, v)(v - v_o), \qquad \begin{cases} v \le v_o & \text{if } f \text{ is convex,} \\ v \ge v_o & \text{if } f \text{ is concave,} \end{cases}$$

where $\sigma_f(v_o, v) = \sqrt{\frac{f(v)-f(v_o)}{v-v_o}}$. We define $R_1^l(U_o)$, $S_1^l(U_o)$, $T_1^l(U_o)$, $R_2^l(U_o)$, $S_2^l(U_o)$, and $T_2^l(U_o)$ as the sets of U connected to U_o on the left by the corresponding waves. If the above inequalities are reversed, we obtain the corresponding relations. We measure the wave strength of the elementary waves by $\pm|\lambda(v) - \lambda(v_o)|$, where the plus sign is for the rarefaction waves and the minus sign is for the shock waves. A collection of the 1-waves or 2-waves is called a family of waves.

2. *Phase boundary.* A phase boundary is the line of discontinuity in the xt-plane across which the phase changes. It satisfies the Rankine–Hugoniot condition. The phase boundary curve $P^r(U_o)$ (or $P^l(U_o)$) is the set of U connected to U_o on the right (or left) by the phase boundary and satisfies the relation

$$u = u_o - \sigma_p(v_o, v)(v - v_o),$$

where $\sigma_p(v_o, v) = \pm\sqrt{\frac{f(v)-f(v_o)}{v-v_o}}$ and v_o and v are in the different phases. We measure the wave strength of the phase boundary by $|v - v_o|$. This gives the variation of phase boundary and is equivalent to the wave strengths for shocks and rarefaction waves.

2.2. Admissibility criteria. The weak solutions for (1.1) are not unique, and we use admissibility criteria to choose a physically relevant solution. There are three criteria that we use in this paper. They are the entropy condition, the entropy rate admissibility criterion, and the initiation criterion. The entropy (physically, the energy) for (1.1) is given by

$$H = \frac{1}{2}u^2 + \int f(v)dv.$$

The rate of decay of the total energy is given by

$$D_+H = \sum_{\text{jump discontinuties}} \sigma(v_-, v_+)A(v_-, v_+), \tag{2.1}$$

where $\sigma(v_-, v_+)$ is the speed of the jump discontinuity and

$$A(v_-, v_+) = \left[\frac{1}{2}(f(v_-) + f(v_+))(v_+ - v_-) - \int_{v_-}^{v_+} f(w)dw\right].$$

Here v_- and v_+ are the values of v on the left and right of a jump discontinuity. We denote

$$E(v_-, v_+) = \sigma(v_-, v_+)A(v_-, v_+).$$

The entropy condition requires that $E(v_-, v_+) \leq 0$ is satisfied across a shock or a phase boundary.

The entropy rate admissibility criterion is the criterion that was proposed by Dafermos [8], [9]. This criterion roughly says that the rate of entropy production is the smallest for the admissible solution. Specifically, this criterion postulates that the solution is admissible if it solves (1.1) and minimizes (2.1).

The initiation criterion has been used in [1], [4], and [26]. This criterion imposes that no new phase occurs from any point except when no solution exists without the creation of a new phase. This ensures that spontaneous initiation of a new phase cannot occur from two nearby initial states in the same phase.

As discussed in the introduction, there are at least two ways to apply the entropy rate admissibility criterion in the Riemann problem. Before the separation ($t = 0_-$) of the waves, they influence each other. Therefore, it can be applied to all jump discontinuities in the Riemann problem. In other words, we compute

$$\min \sum_i E(v_{i-}, v_{i+}), \tag{2.2}$$

where the index i runs for all of the jump discontinuities in the Riemann problem and v_{i-} and v_{i+} are the values of v at the ith discontinuity. If the criterion is applied this way, we say that the entropy rate admissibility criterion is applied before the separation. Also, it can be applied to each phase boundary after the separation. In this case, if we take the adjacent states to a phase boundary as the initial data, the solution to the Riemann problem produces that phase boundary only. In other words, the phase boundary is stable in the sense that by itself it is the admissible solution of the Riemann problem if the adjacent states are the initial data. Note that the shocks are stable in this sense. Once the waves in the Riemann problem are separated, it may not be reasonable to apply the criterion to all of the jump discontinuities. If the criterion is applied this way, we say that the entropy rate admissibility criterion is applied after the separation. In what follows, we apply the entropy rate admissibility criterion to all of the jump discontinuities in the Riemann problem where the phase boundary is involved and obtain the existence and asymptotic behavior of weak solutions. Then we discuss the relation between the two.

2.3. The Riemann problem. In this subsection, we discuss the Riemann problem, where the entropy rate admissibility criterion is applied to all discontinuities. The initial data are given by (U_l, U_r), where v_l and v_r are given in the different phases.

We assume that v_l is in the α-phase and v_r is in the β-phase. We require that v_l and v_r are close to v_α and v_β, respectively, and that u_l and u_r are close. We look for a self-similar solution in which the constant states U_l, U_1, U_2, and U_r are separated by the 1-wave, the phase boundary, and the 2-wave. This is based on the fact that, if there are three or more phase boundaries in the solution of the Riemann problem, at least one of them violates the entropy condition [1], [19]. From the entropy condition, we impose $\sigma_p A(v_1, v_2) \le 0$ across the phase boundary. This condition is necessary because it has been shown in [19] that, unlike the hyperbolic conservation laws, the entropy rate admissibility criterion is not consistent with the entropy condition. We also require that the speed of the phase boundary in absolute value be less than or equal to that of the 1- and 2-waves. If this condition is violated, we may have a geometrically inconsistent solution. The above considerations motivate the following minimization problem:

$$\min \{E_b + E_p + E_f\} \tag{2.3}$$

subject to the entropy condition

$$\sigma_p A(v_1, v_2) \le 0, \tag{2.4}$$

the characteristic condition

$$\sigma_b \text{ or } -\lambda_1 \le \sigma_p \le \sigma_f \text{ or } \lambda_2, \tag{2.5}$$

and

$$\begin{aligned} u_l + \left\{ \begin{array}{l} -\sigma_b(v_1 - v_l),\ v_l > v_1 \\ \int_{v_l}^{v_1} \lambda_1(w)dw,\ v_l \le v_1 \end{array} \right\} \\ - \sigma_p(v_2 - v_1) - \left\{ \begin{array}{l} \sigma_f(v_r - v_2),\ v_r < v_2 \\ \int_{v_2}^{v_r} \lambda_2(w)dw,\ v_r \ge v_2 \end{array} \right\} = u_r, \end{aligned} \tag{2.6}$$

where

$$E_p = \sigma_p A(v_1, v_2),$$

$$E_b = \left\{ \begin{array}{ll} \sigma_b A(v_l, v_1), & v_l > v_1, \\ 0, & v_l \le v_1, \end{array} \right.$$

$$E_f = \left\{ \begin{array}{ll} \sigma_f A(v_2, v_r), & v_r < v_2, \\ 0, & v_r \ge v_2. \end{array} \right.$$

The condition (2.6) states the way in which U_l, U_1, U_2, and U_r are connected. We choose v_1 as the independent variable and derive the differential equations governing v_2 and the entropy rate. The admissible solution is the solution to the Riemann problem (2.3)–(2.6). We say that a solution is feasible if it satisfies (2.4) and (2.5). In [32], this type of problem was discussed in the case where there are no shock waves. The region of U_1 where (2.4) and (2.5) are satisfied for a given 2-wave curve $T^l(U_r)$ is called the feasible region. The v-coordinate of the intersection between the 1-wave curve and the feasible region gives the interval of v_1 in which the solution satisfies (2.4) and (2.5). Corresponding to the equality signs in (2.4) and (2.5), we define the following curves.

DEFINITION 2.1. *The stationary phase boundary curve (SC): This is the set of U_1 satisfying $\sigma_p = 0$ and is given by*

$$f(v_1) = f(v_2), \quad u_1 = u_2 \tag{2.7}$$

as U_2 moves along the 2-wave curve.

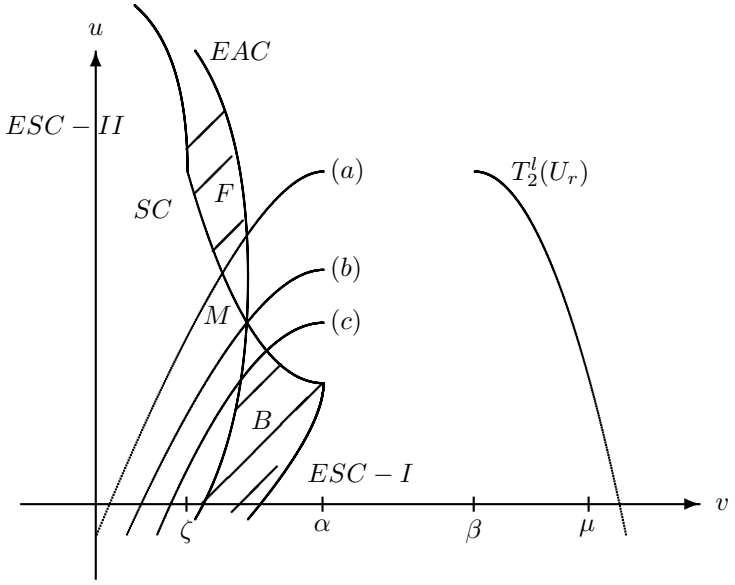

FIG. 2.1.

DEFINITION 2.2. *The equal area curve (EAC): This is the set of* U_1 *satisfying*

$$A(v_1, v_2) = 0, \quad u_1 = u_2 + \sigma_p(v_2 - v_1) \tag{2.8}$$

as U_2 *moves along the* 2*-wave curve.*

DEFINITION 2.3. *The equal speed curve-I (ESC-I): This is the set of* U_1 *satisfying*

$$\sigma_p = \begin{cases} -\lambda_1, & v_1 \geq v_l, \\ \sigma_b, & v_1 < v_l, \end{cases} \tag{2.9}$$

$$u_1 = u_2 + \sigma_p(v_2 - v_1) \tag{2.10}$$

as U_2 *moves along the* 2*-wave curve. This curve starts from* (α, u_1)*, where*

$$u_1 = u_r + \begin{cases} \sigma_f(v_r - \mu), & v_r < \mu, \\ \int_\mu^{v_r} \lambda_2(w)dw, & v_r \geq \mu. \end{cases}$$

If $v_1 < v_l$*, the line segment in the strain-stress plane joining* $(v_2, f(v_2))$ *and* $(v_1, f(v_1))$ *passes through* $(v_l, f(v_l))$*.*

DEFINITION 2.4. *The equal speed curve-II (ESC-II): This is the set of* U_1 *satisfying*

$$\sigma_p = \begin{cases} \lambda_2, & v_2 \leq v_r, \\ \sigma_f, & v_2 > v_r, \end{cases} \tag{2.11}$$

$$u_1 = u_2 + \sigma_p(v_2 - v_1) \tag{2.12}$$

as U_2 *moves along the* 2*-wave curve. This curve starts from* (γ, u_1)*, where* $u_1 = u_r + \int_\beta^{v_r} \lambda_2(w)dw$*. If* $v_r < v_2$*, the line segment in the strain-stress plane joining* $(v_2, f(v_2))$ *and* $(v_1, f(v_1))$ *passes through* $(v_r, f(v_r))$*.*

The curves satisfying the above definitions for the 2-wave curve $T_2^l(U_r)$ are depicted in Figure 2.1. The feasible regions are shaded regions. Depending on how the 1-wave curve $T_1^r(U_l)$ intersects with the shaded regions, we obtain three cases.

(a) The 1-wave curve intersects with the region F in Figure 2.1.

(b) The 1-wave curve goes through the point M in Figure 2.1.

(c) The 1-wave curve intersects with the region B in Figure 2.1.

The v-coordinate of M is v_α, and F (or B) stands for the fact that the phase boundary moves forward (or backward) if the 1-wave curve intersects these regions. For example, in case (a), the solutions are feasible if U_1 is on the intersection of the curve (a) with the shaded region, and we seek a solution to (2.3) and (2.6) for the values of v_1 on the interval where the 1-wave curve (a) intersects with F.

The following theorem shows the existence of solutions satisfying (2.3) and (2.6).

THEOREM 2.5 (Hattori [19]). *There exists an absolute minimum for the Riemann problem* (2.3)–(2.6). *Furthermore, there exists a neighborhood of* $v_l = v_\alpha$, $v_r = v_\beta$, $u_l = u_c$, *and* $u_r = u_c$ *such that the problem has a unique admissible solution.*

3. Existence of weak solutions. This section consists of three subsections. First, we briefly describe the Glimm scheme and its two main ingredients. Then, in subsections 3.2 and 3.3, we discuss the details of the ingredients leading to the proof of the existence of weak solutions.

3.1. Glimm scheme. We choose a sequence $\omega = \{\omega_n\}$ of random and equidistributed numbers in $(-1, 1)$ and define

$$N_{m,n} = ((m + \omega_n)\triangle x, n\triangle t), \quad n \geq 0,$$

as the sample points, where m and n are integers satisfying $m + n =$ odd. Here $\triangle x$ and $\triangle t$ are positive numbers satisfying the Lax–Friedrichs condition

$$\frac{\triangle x}{\triangle t} = r > \max_{v \in V_{v_\alpha} \cup V_{v_\beta}} \lambda(v),$$

where V_{v_α} and V_{v_β} are closed neighborhoods of v_α and v_β, respectively, relevant to our discussion. The upper xt-plane is divided by diamond-shaped domains $\triangle_{m,n}$ with vertices $N_{m,n+1}$, $N_{m-1,n}$, $N_{m,n-1}$, $N_{m+1,n}$. An I-curve is a space-like piecewise-linear curve composed of line segments joining vertices. We define J_0 to be the I-curve consisting of the line segments joining $N_{m-1,0}$, $N_{m,1}$, $N_{m+1,0}$ with m even. It is possible to have a partial ordering of the I-curves. If J_2 lies in the future of J_1, it is denoted by $J_1 \leq J_2$. We say that J_1 and J_2 are consecutive if $J_1 \leq J_2$ and there is only one diamond between them.

The approximate solution $U_{\triangle x,\omega}$ is defined as follows. We choose

$$U_{\triangle x,\omega}(N_{m,o}) = U_{oo}((m + \omega_o)\triangle x).$$

Assuming that $U_{\triangle x,\omega}$ is defined at $N_{m-1,n-1}$ and $N_{m+1,n-1}$, we solve the Riemann problem of (1.1) with the initial data

$$U(x, (n-1)\triangle t) = \begin{cases} U_{\triangle x,\omega}(N_{m-1,n-1}), & (m-1)\triangle x \leq x < m\triangle x, \\ U_{\triangle x,\omega}(N_{m+1,n-1}), & m\triangle x < x \leq (m+1)\triangle x, \end{cases}$$

and the solution is denoted as $U(x, t)$. We then define the solution on the next time level by

$$U_{\triangle x,\omega}(N_{m,n+1}) = U(N_{m,n+1}),$$

$$U_{\triangle x,\omega}(x,t) = U(x,t), \quad (m-1)\triangle x \le x \le (m+1)\triangle x, \quad n\triangle t < t < (n+1)\triangle t.$$

The wave strengths of the solution to the Riemann problem are denoted as

$$a = (a_1, a_2) \quad \text{if there is no phase boundary, and}$$
$$a = (a_1, P, a_2) \quad \text{if there is a phase boundary,}$$

where the subscripts 1 and 2 denote the 1- and 2-waves, respectively. The outgoing waves c are the waves in the solution of the Riemann problem in $\triangle_{m,n}$. The incoming waves a and b to $\triangle_{m,n}$ are the outgoing waves from $\triangle_{m-1,n-1}$ and $\triangle_{m+1,n-1}$, respectively, and entering $\triangle_{m,n}$. If $a = (a_1, a_2)$ and $b = (b_1, b_2)$ cross J and a is lying to the left of b, we say that a_i and b_j are approaching provided that either (i) $i > j$ or (ii) $i = j$ and at least one of them is a shock.

Let $P(J)$ be the strength of phase boundary crossing J, and let $W(J)$ be the collection of the elementary waves crossing J. We define

$$L(J) = \sum_{a \in W(J)} |a| .$$

Then $L(J) + P(J)$ measures the total variation of $U_{\triangle x,\omega}(x,t)$ on J. The Glimm scheme consists of two steps. The first step is to estimate the strengths of outgoing waves in terms of incoming waves in a diamond. The second step is to show that the total variation of the solutions is bounded. Since the total variation is not necessarily monotonically decreasing, we define the interaction potential $Q(J)$ decreasing in J. With this Q we show that the inequality

$$L(J_2) + P(J_2) + Q(J_2) \le L(J_1) + P(J_1) + Q(J_1)$$

holds for $J_1 < J_2$. The details of these steps are discussed in the next two subsections.

3.2. Local wave interaction. We consider the wave interaction in a diamond $\triangle_{m,n}$ and estimate the strengths of outgoing waves in terms of those of incoming waves. There are two cases depending on whether the phase boundary enters the diamond. First, consider the case where the phase boundary does not enter the diamond. This case is treated in the same way as in the previous literature. Let (a_1, a_2) and (b_1, b_2) be the strengths of incoming waves from $\triangle_{m-1,n-1}$ and $\triangle_{m+1,n-1}$, respectively, and let (c_1, c_2) be the strengths of outgoing waves.

LEMMA 3.1 (Glimm [15] and Liu [27]). *Suppose that the phase boundary P does not enter the diamond. Then we have*

$$c_i = a_i + b_i + Q(\triangle_{m,n}), \quad i = 1, 2, \tag{3.1}$$

where $Q(\triangle_{m,n})$ is defined as

$$Q(\triangle_{m,n}) = Q_s(\triangle_{m,n}) + Q_d(\triangle_{m,n}), \tag{3.2}$$

where

$$Q_s(\triangle_{m,n}) = \begin{cases} 0, & a_i \ge 0,\ b_i \ge 0, \\ |a_i|^3, & |a_i| \le |b_i|,\ a_i < 0,\ b_i \ge 0, \\ |a_i||b_i|^2, & |a_i| \le |b_i|,\ b_i < 0, \\ |a_i|^2|b_i|, & |a_i| \ge |b_i|,\ a_i < 0, \\ |b_i|^3, & |a_i| \ge |b_i|,\ a_i \ge 0,\ b_i < 0, \end{cases} \tag{3.3}$$

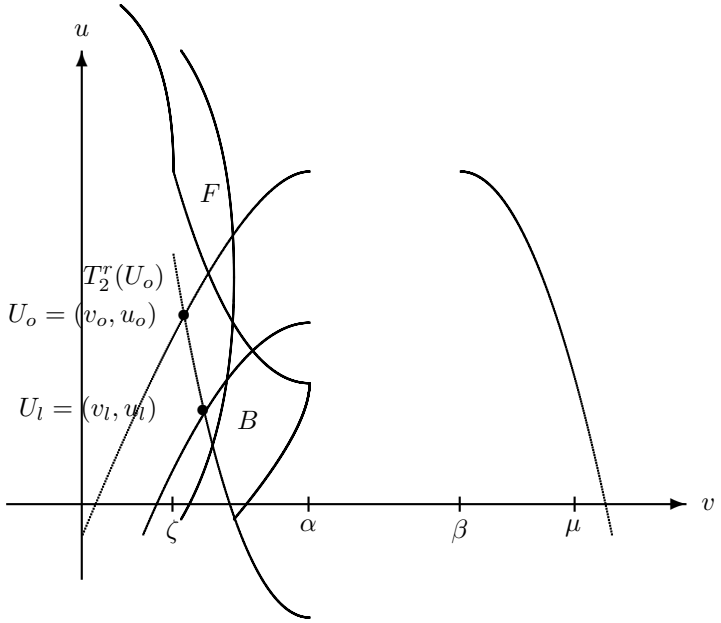

FIG. 3.1.

or

$$= \begin{cases} 0, & a_i \geq 0,\ b_i \geq 0, \\ |a_i||b_i|(|a_i| + |b_i|), & \textit{otherwise,} \end{cases} \tag{3.4}$$

$$Q_d(\triangle_{m,n}) = |a_2 b_1|.$$

Next, we consider the case where the phase boundary enters the diamond $\triangle_{m,n}$. Without loss of generality, we assume that the phase boundary enters $\triangle_{m,n}$ from $\triangle_{m+1,n-1}$. The wave strengths of the incoming waves from $\triangle_{m-1,n-1}$ and $\triangle_{m+1,n-1}$ are denoted by (a_1, a_2) and (b_1, P_i, b_2), respectively, and (c_1, P_o, c_2) for the outgoing waves. There are two subcases to consider. One subcase is that the 2-wave from $\triangle_{m+1,n-1}$ enters the diamond, or it is a rarefaction wave. Another subcase is that the 2-wave from $\triangle_{m+1,n-1}$ does not enter the diamond, and it is a shock. The estimates are given in Lemmas 3.2 and 3.4, respectively. Note that, in the first subcase, the incoming waves from $\triangle_{m+1,n-1}$ are the admissible solution to the Riemann problem (2.3)–(2.6), but, in the second subcase they are not. This makes the estimate more complicated.

LEMMA 3.2. *Suppose that all of the outgoing waves from the diamond $\triangle_{m+1,n-1}$ enter $\triangle_{m,n}$, or the 2-wave from $\triangle_{m+1,n-1}$ which (or a portion of which) does not enter $\triangle_{m,n}$ is a rarefaction wave. Then the outgoing waves from $\triangle_{m,n}$ satisfy the following estimates:*

$$\begin{aligned} c_1 &= b_1 + O(1)|a_2|, \\ c_2 &= b_2 + O(1)|a_2|, \\ P_o &= P_i + O(1)|a_2|. \end{aligned} \tag{3.5}$$

Proof. Note that the wave entering $\triangle_{m,n}$ from $\triangle_{m-1,n-1}$ is a_2 only. Denote the constant states of the incoming waves by U_o, U_l, U_1, U_2, and U_r. The wave

a_2 is between U_o and U_l. As we change U_l along the 2-wave curve through U_o, the minimum point U_1 moves along the composite curve consisting of the SC, the EAC, or the curve lying between the SC and the EAC; see Figures 2.1 and 3.1. In what follows, we prove the case in which all of the elementary waves are rarefaction waves. The other cases are proved similarly. If U_1 is on the SC, we have

$$u_o - \int_{v_o}^{v_l} \lambda(w)dw + \int_{v_l}^{v_1} \lambda(w)dw = u_1 = u_2 = u_r + \int_{v_2}^{v_r} \lambda(w)dw,$$

$$f_1 = f_2.$$

If U_1 is on the EAC, we have

$$u_o - \int_{v_o}^{v_l} \lambda(w)dw + \int_{v_l}^{v_1} \lambda(w)dw = u_1 = \sigma_p(v_2 - v_1) + u_r + \int_{v_2}^{v_r} \lambda(w)dw,$$

$$\frac{1}{2}(f(v_1) + f(v_2))(v_2 - v_2) - \int_{v_1}^{v_2} f(w)dw = 0.$$

Also, if U_1 is between the SC and the EAC, we see that

$$u_o - \int_{v_o}^{v_l} \lambda(w)dw + \int_{v_l}^{v_1} \lambda(w)dw = u_1 = \sigma_p(v_2 - v_1) + u_r + \int_{v_2}^{v_r} \lambda(w)dw,$$

$$\frac{dE}{dv_1} = \frac{1}{4\sigma_p}\left\{\frac{dv_2}{dv_1}(\lambda_2^2 - \sigma_p^2)A_{21} - (\lambda_1^2 - \sigma_p^2)A_{12}\right\} = 0.$$

In each case, the mapping from U_l to U_1 is differentiable. Since it can be shown that $\frac{du_1}{dv_l} \le 0$ in each case, U_1 moves monotonically along a Lipschitz curve as we move U_l along the 2-wave curve through U_o. Therefore, we have (3.5). □

To prepare for the second subcase, we need the following lemma.

LEMMA 3.3. *Suppose that $a = 0$ and $b = (b_1, P_i, \bar{b}_2)$, where $\bar{b}_2$ from $\triangle_{m+1,n-1}$ is a shock wave, and it does not enter $\triangle_{m,n}$. If we solve the Riemann problem* (2.3)–(2.6) *with the initial data U_l and U_2, the wave strengths of the outgoing waves from $\triangle_{m,n}$ satisfy*

$$|c_1 - b_1| = O(1)|\bar{b}_2|^2, \quad |P_o - P_i| = O(1)|\bar{b}_2|^2, \quad |c_2| = O(1)|\bar{b}_2|^2. \tag{3.6}$$

Suppose that $a = (\bar{a}_1, P_i, a_2)$ and $b = 0$, where $\bar{a}_1$ from $\triangle_{m-1,n-1}$ is a shock wave, and it does not enter $\triangle_{m,n}$. If we solve the Riemann problem (2.3) *and* (2.6) *with the initial data U_1 and U_r, the wave strengths of the outgoing waves from $\triangle_{m,n}$ satisfy*

$$|c_1| = O(1)|\bar{a}_1|^2, \quad |P_o - P_i| = O(1)|\bar{a}_1|^2, \quad |c_2 - a_2| = O(1)|\bar{a}_1|^2. \tag{3.7}$$

Proof. We prove (3.7) so that we can use v_1 as the independent variable. The case (3.6) is proved similarly. Assume that the Riemann problem with the initial data U_1 and U_r has U_1' and U_2' as the intermediate constant states.

Depending on the location of U_1 relative to the feasible region, we have three cases, as in the previous lemma. We prove the case in which U_1 is on the EAC. The cases in which U_1 is on the SC and between the EAC and the SC can be shown in a similar manner. Since U_l is connected to U_1 by a 1-shock wave, $v_l > v_1$ and $u_l > u_1$ must hold. We treat the case in which the 2-wave is a rarefaction wave and the 1-wave

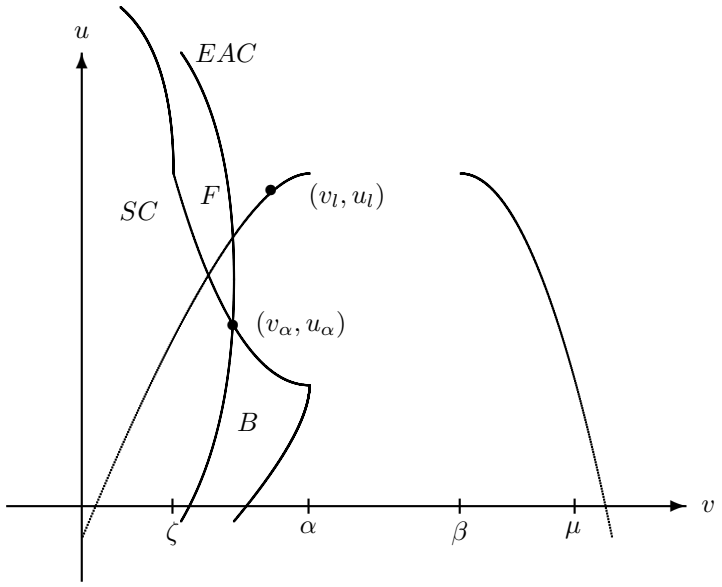

FIG. 3.2.

curve from U_l goes through U_α or above; see Figure 3.2. In this case, we observe the forward phase boundary. The other case is treated in a similar manner. In this case,

$$\frac{dE_b}{dv_1} + \frac{dE_p}{dv_1} + \frac{dE_f}{dv_1}\bigg|_{v_1=v_1} < 0 \quad \text{and} \quad \frac{dE_b}{dv_1}\bigg|_{v_1=v_1} > 0.$$

This implies that

$$A_1 = \frac{dE_p}{dv_1} + \frac{dE_f}{dv_1}\bigg|_{v_1=v_1} < 0.$$

Compare this with

$$A_1' = \frac{dE_p}{dv_1'} + \frac{dE_f}{dv_1'}\bigg|_{v_1'=v_1}.$$

From

$$A_1 = \frac{\partial E_p}{\partial v_1} + \frac{\partial E_p}{\partial v_2}\frac{dv_2}{dv_1} + \frac{\partial E_f}{\partial v_2}\frac{dv_2}{dv_1}\bigg|_{v_1=v_1},$$

$$A_1' = \frac{\partial E_p}{\partial v_1'} + \frac{\partial E_p}{\partial v_2'}\frac{dv_2'}{dv_1'} + \frac{\partial E_f}{\partial v_2'}\frac{dv_2'}{dv_1'}\bigg|_{v_1'=v_1},$$

$$\frac{dv_2}{dv_1}\bigg|_{v_1=v_1} = \frac{(\lambda_1^2 + \sigma_b\sigma_p)(\sigma_b - \sigma_p)}{\sigma_b(\lambda_2 - \sigma_p)^2},$$
$$\frac{dv_2'}{dv_1'}\bigg|_{v_1'=v_1} = \frac{(\lambda_1 - \sigma_p)^2}{(\lambda_2 - \sigma_p)^2},$$

we see that

$$A_1' - A_1 = \left\{ \frac{\partial E_p}{\partial v_2} + \frac{\partial E_f}{\partial v_2} \right\} \frac{\sigma_p(\lambda_1 + \sigma_b)^2}{\sigma_b(\lambda_2 - \sigma_p)^2} = O(1)|\sigma_p||v_1 - v_l|^2.$$

This shows that, if $A_1' < 0$, the configuration does not change, and if $A_1' > 0$,

$$0 < A_1' = A_1 + O(1)|\sigma_p||v_1 - v_l|^2 \le O(1)|\sigma_p||v_1 - v_l|^2.$$

Since $\frac{d^2 E_p}{dv_1'^2} = O(1)$ near the Maxwell construction, we see that

$$|v_1' - v_1| = O(1)|v_1 - v_l|^2.$$

From this we obtain (3.7). □

LEMMA 3.4. *Suppose the 2-wave from $\triangle_{m+1,n-1}$ is a shock and it does not enter $\triangle_{m,n}$. Denote its wave strength by $\bar{b}_2$. Then the outgoing waves from $\triangle_{m,n}$ satisfy the following estimates:*

$$\begin{aligned} c_1 &= b_1 + O(1)|a_2| + O(1)|\bar{b}_2|^2, \\ c_2 &= O(1)|a_2| + O(1)|\bar{b}_2|^2, \\ P_o &= P_i + O(1)|a_2| + O(1)|\bar{b}_2|^2. \end{aligned}$$

Proof. From Lemma 3.3, we see that the wave strengths of the Riemann problem with initial data (v_l, u_l) and (v_3, u_3) corresponding to the waves of the right family $b = \{b_1, P_e, 0\}$ are given by $\{b_1 + O(1)|\bar{b}_2|^2, P_e + O(1)|\bar{b}_2|^2, O(1)|\bar{b}_2|^2\}$. Now we use Lemma 3.2 to obtain the strengths of the outgoing waves. Since the admissible solution is unique, this completes the proof. □

3.3. Existence of global solutions. Let $W(J)$ be the collection of the elementary waves crossing J, and let $W_a(J)$ be the subset of $W(J)$ approaching the phase boundary P. Also, let $W^-(J)$ be the collection of shocks crossing J. We define

$$A(J) = \sum_{a \in W_a(J)} |a|. \tag{3.8}$$

Also, if the phase boundary P crosses J, we define $\triangle_J$ to be the diamond from which P leaves.

Now we define the interaction potential Q as

$$Q(J) = Q_s(J) + N_1\{Q_a(J) + Q_d(J)\} + N_1^2 Q_{aa}(J) + N_2 Q_{sp}(\triangle_J), \tag{3.9}$$

where the quantities on the right-hand side are given by

$$\begin{aligned} Q_s(J) = {} & \textstyle\sum\{|a|^3 : a \in W^-(J)\} \\ & + 4\textstyle\sum\{|bd||b+d| : b,\ d \in W^-(J),\ b \ne d, \text{ and of the same family}\} \\ & + 8\textstyle\sum\{|bde| : b,\ d,\ e \in W^-(J), \text{ distinct, and of the same family}\} \end{aligned} \tag{3.10}$$

or

$$\begin{aligned} Q_s(J) = {} & \textstyle\sum\{|bd||b+d| : b,\ d \text{ are any } j\text{-waves in } W(J) \\ & \text{and not both are } j\text{-rarefaction waves}\}, \end{aligned} \tag{3.11}$$

$$
\begin{aligned}
Q_a(J) &= \sum\{|ab| : a \in W_a(J),\ b \in W(J), \text{ and } a \neq b\},\\
Q_d(J) &= \sum\{|ab| : a,\ b \in W(J) \text{ and } a \text{ is any } i\text{-wave}\\
&\qquad \text{lying toward the left of a } j\text{-wave } b \text{ with } i > j\},\\
Q_{aa}(J) &= \tfrac{1}{2}\sum\{|a|^2 : a \in W_a(J)\} + \sum\{|ab| : a,\ b \in W_a(J) \text{ and } a \neq b\},\\
Q_{sp}(\triangle_J) &= \sum\{|a|^2 : a \text{ is an outgoing wave from } \triangle_J\}.
\end{aligned}
$$

Note that $Q_s(J)$ measures the interaction potential of the waves of the same family, $Q_d(J)$ measures the interaction potential of the waves of the different families, $Q_a(J)$ and $Q_{aa}(J)$ are related to the approaching waves, and $Q_{sp}(\triangle_J)$ is related to the elementary waves leaving from $\triangle_J$. The constants N_1 and N_2 will be determined so that

$$
Q(\triangle_{m,n}) \leq 2(Q(J) - Q(J')) \tag{3.12}
$$

is satisfied, where J and J' are consecutive I-curves with $J \leq J'$, $\triangle_{m,n}$ is the diamond between them, and $Q(\triangle_{m,n})$ is the measure of the wave interactions in $\triangle_{m,n}$. The specific forms of $Q(\triangle_{m,n})$ are given in Lemmas 3.5, 3.6, and 3.7, where the proofs of (3.12) are carried out. Also, let K be a bound on the $O(1)$ coefficients (or a finite multiple of them) appearing in Lemmas 3.1, 3.2, and 3.4.

LEMMA 3.5. *If the phase boundary does not enter $\triangle_{m,n}$, we have*

$$
Q(J') - Q(J) \leq \{-1 + (K + KN_1 + KN_1^2)L(J)\}Q(\triangle_{m,n}), \tag{3.13}
$$

where $Q(\triangle_{m,n})$ is defined in (3.2).

Since $\triangle_J = \triangle_{J'}$ in this case, the proof is reduced to Asakura [3] and Chern [5]. Hence it is omitted. The next two lemmas are similar in proof. Therefore, we prove only Lemma 3.7.

LEMMA 3.6. *If the phase boundary enters $\triangle_{m,n}$ and the 2-wave from $\triangle_J$ $(= \triangle_{m+1,n-1})$ enters $\triangle_{m,n}$ or it is a rarefaction wave, then we have*

$$
Q(J') - Q(J) \leq -Q(\triangle_{m,n}), \tag{3.14}
$$

where $Q(\triangle_{m,n}) = |a_2|\,|b_1| + |a_2|\,|b_2|$.

LEMMA 3.7. *If the phase boundary enters $\triangle_{m,n}$ and the 2-wave with strength $\bar{b}_2$ from $\triangle_J$ $(= \triangle_{m+1,n-1})$ is a shock and it does not enter $\triangle_{m,n}$, then we have*

$$
Q(J') - Q(J) \leq -Q(\triangle_{m,n}), \tag{3.15}
$$

where $Q(\triangle_{m,n}) = |a_2|\,|b_1| + |\bar{b}_2|^2$.

Proof. Let the strengths of the incoming waves from $\triangle_J$ be $b = \{b_1, P_i, 0\}$. Let $A(\triangle_{m,n}) = |a_2|$ be the strength of the approaching wave entering $\triangle_{m,n}$. We prove the case in which both c_i are shocks.

$$
\begin{aligned}
Q_s(J') = {} & \left|b_1 + O(1)|a_2| + O(1)|\bar{b}_2|^2\right|^3\\
& +4 \sum_{d_1 \neq c_1} \left|d(b_1 + O(1)|a_2| + O(1)|\bar{b}_2|^2)\right| \left|d + b_1 + O(1)|a_2| + O(1)|\bar{b}_2|^2\right|\\
& +8 \sum_{d_1, e_1 \neq c_1} \left|de(b_1 + O(1)|a_2| + O(1)|\bar{b}_2|^2)\right|\\
& + \left|O(1)|a_2| + O(1)|\bar{b}_2|^2\right|^3
\end{aligned}
$$

$$
\begin{aligned}
&+4\sum_{d_2\neq c_2}\left|d(O(1)|a_2|+O(1)|\bar{b}_2|^2)\right|\left|d+O(1)|a_2|+O(1)|\bar{b}_2|^2\right|\\
&+8\sum_{d_2,e_2\neq c_2}\left|de(O(1)|a_2|+O(1)|\bar{b}_2|^2)\right|+O.T.\\
&\leq Q_s(J)+K\sum_{e\in W(J)}|e|A(\triangle_{m,n})+K\sum_{e\in W(J)}|e||\bar{b}_2|^2+O.T.,
\end{aligned}
$$

where $O.T.$ represents the potentials not involving the waves in $\triangle_{m,n}$ and canceling out when we estimate $Q_s(J')-Q_s(J)$. Since Q_s is the third order term, we can get the above type estimates easily in the other cases. In what follows, we omit the $O.T.$'s. The estimates of Q_a are given by

$$
\begin{aligned}
Q_a(J')\leq&\sum_{e\in W_a(J_l\cup J_r)}|eb_1|+\sum_{e\in W_a(J_l\cup J_r)}|eb_2|\\
&+K\sum_{e\in W_a(J_l\cup J_r)}|e|A(\triangle_{m,n})+K\sum_{e\in W_a(J_l\cup J_r)}|e||\bar{b}_2|^2\\
\leq& Q_a(J)-|a_2b_1|-|a_2b_2|-\sum_{e\in W(J_l\cup J_r)}|ea_2|\\
&+K\sum_{e\in W_a(J_l\cup J_r)}|e|A(\triangle_{m,n})+K\sum_{e\in W_a(J_l\cup J_r)}|e||\bar{b}_2|^2.
\end{aligned}
$$

For Q_d we obtain

$$
\begin{aligned}
Q_d(J')=&\sum_{e_2\in W_a(J_l)}|e_2c_1|+\sum_{e_1\in W_a(J_r)}|e_1c_2|\\
=&\sum_{e_2\in W_a(J_l)}\left|e_2(b_1+O(1)|a_2|+O(1)|\bar{b}_2|^2)\right|\\
&+\sum_{e_1\in W_a(J_r)}\left|e_1(O(1)|a_2|+O(1)|\bar{b}_2|^2)\right|\\
\leq& Q_d(J)-|a_2b_1|-\sum_{e_1\in W_a(J_r)}|e_1a_2|+K\sum_{e\in W_a(J_l\cup J_r)}|e|(|a_2|+|\bar{b}_2|^2).
\end{aligned}
$$

The estimates of Q_{aa} are given by

$$
Q_{aa}(J')=0,\quad Q_{aa}(J)=\frac{1}{2}|a_2|^2+\sum_{e\in W_a(J_l\cup J_r)}|ea_2|.
$$

For Q_{sp} we have

$$
\begin{aligned}
Q_{sp}(\triangle_{J'})&=N_2\{c_1^2+c_2^2\}\\
&\leq Q_{sp}(\triangle_J)+N_2Ka_2^2.
\end{aligned}
$$

Combining the above estimates, we have

$$
\begin{aligned}
Q(J')-Q(J)\leq&-(N_1^2-K-KN_2)|a_2|^2\\
&-(N_1-K-KN_2)\sum_{e\in W(J),e\neq a_2}|e|A(\triangle_{m,n})\\
&-(N_1^2-KN_1)\sum_{e\in W_a(J_l\cup J_r)}|e|A(\triangle_{m,n})\\
&-\{N_2(1-L(J))-3KL(J)\}|\bar{b}_2|^2.
\end{aligned}
$$

From the above inequality, we can easily find N_1 and N_2 satisfying the inequality (3.15). □

From Lemmas 3.5, 3.6, and 3.7, we obtain the following lemma.

LEMMA 3.8. *Suppose J and J' are two consecutive I-curves with $J \le J'$ and $\triangle$ is the diamond between them. Then we have*

$$Q(\triangle) \le 2(Q(J) - Q(J')), \tag{3.16}$$

provided $N_1^2 - K - KN_2 > 0$, $N_1 - K - KN_2 > \frac{1}{2}$, $N_1^2 - KN_1 > 0$, $N_2(1 - L(J)) - 3KL(J) > \frac{1}{2}$, and $L(J) < \frac{1}{2(K+KN_1+KN_1^2)}$.

Let Λ_{J_1,J_2} be the diamonds between J_1 and J_2, and let $A(J_1, J_2)$ be the change in the amount of the approaching waves between J_1 and J_2. The following theorem shows that the total variation of the solution is bounded.

THEOREM 3.9. *Let J_1 and J_2 be the I-curves satisfying $J_1 \le J_2$. Then we have*

$$Q(\Lambda_{J_1,J_2}) \le 2(Q(J_1) - Q(J_2)), \tag{3.17}$$

$$A(J_1, J_2) \le A(J_1) - A(J_2) + KQ(\Lambda_{J_1,J_2}), \tag{3.18}$$

$$L(J_2) - L(J_1) \le K\{A(J_1) - A(J_2) + Q(J_1) - Q(J_2)\}, \tag{3.19}$$

$$P(J_2) - P(J_1) \le K\{A(J_1) - A(J_2) + Q(J_1) - Q(J_2)\}, \tag{3.20}$$

$$L(J) + P(J) \le N_0\{L(J_0) + P(J_0)\}, \tag{3.21}$$

where N_0 is a positive constant. In particular, (3.21) *implies that the global weak solutions exist.*

Proof. The inequality (3.17) is an easy consequence of Lemma 3.8. For (3.18), assume that J and J' are consecutive, $J \le J'$, and $\triangle$ is the diamond between them. If the phase boundary enters $\triangle$, we have

$$A(\triangle) = |a_2| = A(J) - A(J'),$$

and if the phase boundary does not enter $\triangle$, then, assuming as before that P is to the right of $\triangle$, we have

$$\begin{aligned} A(\triangle) &\le |a_2| + |b_2| - |c_2| + KQ(\triangle) \\ &\le A(J) - A(J') + KQ(\triangle). \end{aligned}$$

If the phase boundary enters the diamond between J and J', from Lemma 3.1 we see that, in the case of Lemma 3.6,

$$\begin{aligned} L(J') - L(J) &= |c_1| + |c_2| - |a_2| - |b_1| - |b_2| \\ &\le O(1)|a_2|, \end{aligned}$$

and, in the case of Lemma 3.7,

$$L(J') - L(J) \le O(1)|a_2| + O(1)|\bar{b}_2|^2.$$

Therefore, we have

$$L(J') - L(J) < K\{A(J) - A(J') + Q(J) - Q(J')\}.$$

If the phase boundary does not enter the diamond, from Lemma 3.1 we have that

$$L(J') - L(J) \le K\{Q(J) - Q(J')\}.$$

Repeating this from J_1 to J_2, we obtain (3.19). We can prove (3.20) in a similar manner. Adding (3.19) and (3.20) from J_0 to J, we have

$$\begin{aligned} L(J) + P(J) &\le L(J_0) + P(J_0) + 2K\{A(J_0) + Q(J_0)\} \\ &\le L(J_0) + P(J_0) + 2KA(J_0) + 2K(L(J_0))^2. \end{aligned}$$

From this we obtain (3.21). □

We now define the cancelation. For a diamond into which the phase boundary does not enter,

$$C_i(\triangle) = \frac{1}{2}(|a_i| + |b_i| - |a_i + b_i|).$$

From this we have the following lemma.

LEMMA 3.10. *The following conservation laws hold provided that* Λ *does not contain the phase boundary.*

$$L_i^{\pm}(\Lambda) = E_i^{\pm}(\Lambda) \mp C_i(\Lambda) + O(1)Q(\Lambda), \quad i = 1, 2. \tag{3.22}$$

For a diamond into which the phase boundary enters, assuming that the phase boundary is in the right family of waves entering the diamond, we define

$$C_i(\triangle) = \kappa_i |a_2|,$$

where κ_i is a nonnegative number, so that the following relation holds:

$$L_i(\triangle) = E_i(\triangle) \pm C_i(\triangle), \quad i = 1, 2,$$

where the signs are chosen so that the above equality holds.

The generalized i-characteristics $\chi_i^{\triangle x}(t)$ were introduced in Glimm and Lax [16]. These are the curves consisting of either an i-characteristic or an i-shock issuing from the center of each diamond. They are straight-line segments in each strip $(n-1)\triangle t < t < n\triangle t$ $(n = 0, 1, 2, \ldots)$ and are continued from the center of the diamonds they enter. They showed that $\chi_i^{\triangle x}(t)$ converges uniformly to a Lipschitz function $\chi_i(t)$ as $\triangle x$ approaches zero on any bounded time interval and that the derivatives $\dot{\chi}_i^{\triangle x}(t)$ of the i-generalized characteristics converge pointwise to $\dot{\chi}_i(t)$ except a set of measure zero. Similar results can be obtained for the phase boundary; i.e., the phase boundary $\chi(t)$ is Lipschitz continuous and subsonic, as shown in [4], [26].

4. Initial value problem with the Riemann initial data. We revisit the Riemann problem with the initial data (1.3) and show that the asymptotic states occur immediately for the solution to the Riemann problem.

First, we study the basic estimates concerning the waves in the limit solution. We define the regions Ω_i $(i = 0, 1, 2, 3)$ and Ω_p in the xt-plane as

$$\begin{aligned} \Omega_0 &= \{(x,t) : x < \mu_0 t\}, \\ \Omega_1 &= \{(x,t) : \mu_0 t < x < \mu_1 t\}, \\ \Omega_p &= \{(x,t) : \mu_1 t < x < \mu_2 t\}, \\ \Omega_2 &= \{(x,t) : \mu_2 t < x < \mu_3 t\}, \\ \Omega_3 &= \{(x,t) : \mu_3 t < x\}, \end{aligned}$$

where μ_i $(i = 0, 1, 2, 3)$ satisfy

$$\begin{aligned} \mu_0 &< -\lambda_1(v) - \delta, \\ -\lambda_1(v) + \delta < \mu_1 &< -|\sigma_p| - \delta, \\ |\sigma_p| + \delta < \mu_2 &< \lambda_2(v) - \delta, \\ \lambda_2(v) + \delta &< \mu_3 \end{aligned}$$

for some positive δ and for all of the values of v in the neighborhoods N_{v_α} and N_{v_β}.

Let $\chi_1^1(t)$ and $\chi_1^2(t)$ be the generalized 1-characteristic curves starting from $(\mu_0 t, t)$ and $(\mu_1 t, t)$, respectively. Similarly, define $\chi_2^1(t)$ and $\chi_2^2(t)$ to be the generalized 2-characteristic curves starting from $(\mu_2 t, t)$ and $(\mu_3 t, t)$, respectively. Note that $\chi_i^j(t)$ $(i, j = 1, 2)$ will be redefined in the next section. We define the following:

$$\begin{array}{lcl} \Lambda_i(t) & = & \text{the region between } \chi_i^1(t) \text{ and } \chi_i^2(t), \\ Q(t,s) & = & \text{amount of interaction between } t < t' < s, \\ Q(t) & = & \text{amount of interaction at } t, \\ X_i^{\pm}(s;t) & = & \text{amount of } i\text{-waves in the interior of } \Lambda_i(t) \text{ at time } s, \\ \tilde{X}_i(s;t) & = & \text{amount of } i\text{-waves outside of } \Lambda_i(t) \text{ at time } s, \\ Str.\chi_i^k(s;t) & = & \text{strength of } \chi_i^k(t) \text{ at time } s, \\ D_i(s;t) & = & \text{distance between } \chi_i^1(t) \text{ and } \chi_i^2(t) \text{ at time } s. \end{array} \tag{4.1}$$

Then we obtain the following lemma.

LEMMA 4.1. *The solution to the Cauchy problems* (1.1) *and* (1.3) *converges to the solution to the Riemann problem where the phase boundary does not generate any wave.*

Proof. Suppose that we use an equidistributed sequence $\{\omega_n\}$. In the case of the Riemann initial data, for $t = 0$, we solve a nontrivial Riemann problem in $\triangle_{0,0}$ only, and all of the other Riemann problems are trivial. We solve the same Riemann problem in $\triangle_{0,0}$ for any mesh size. Then, in the next time level, we solve nontrivial Riemann problems in $\triangle_{-1,1}$ and $\triangle_{1,1}$ only, and they do not depend on the mesh size. This implies the following. Suppose that the mesh size is $(\triangle x, \triangle t)$, and we solve a Riemann problem at the mesh point $(m\triangle x, n\triangle t)$. Then, if we change the mesh size to $(\frac{\triangle x}{p}, \frac{\triangle t}{p})$, we solve the above Riemann problem at the mesh point $(\frac{m\triangle x}{p}, \frac{n\triangle t}{p})$ provided that we use the same sequence $\{\omega_n\}$. From the result of the previous section, the Cauchy problem converges. Since $Q(\Lambda_{J_1,J_\infty})$ is finite, all interactions $Q(\triangle_{m,n})$ approach zero as $n \to \infty$. This also implies that the phase boundary is stable in the sense that there are no waves generated from the phase boundary. As $\triangle x$ and $\triangle t$ approach zero maintaining $\frac{\triangle x}{\triangle t} = r$, all of the interactions will take place at the origin, and what remains after taking the limit is the solution where $Q(t)$ is zero for $t > 0$ and all of the waves start from the origin since the phase boundary and all waves of the approximate solutions start from the origin and they are Lipschitz continuous. Since $Q(t) = 0$, the middle states are constant states. Since the waves of the same family interact except when they are both rarefaction waves, either rarefaction waves or shock waves remain in the limiting solutions. Consider the forward wave. We have

$$\frac{dD_i(s;t_o)}{ds} = \sigma_i(U_i^{+2}, U_i^{-2}) - \sigma_i(U_i^{+1}, U_i^{-1}), \tag{4.2}$$

where $i = 2$ and $U_i^{\pm k}$ are the limits of U from the right and left of $\chi_i^k(t)$, $(k = 1, 2)$. Since each characteristic field is genuinely nonlinear, there exists $\theta = \theta(s)$ $(0 < \theta < 1)$

such that

$$\begin{aligned}\frac{dD_i(s;t_o)}{ds} &= \theta(\lambda_i^{-2}(s)-\lambda_i^{+1}(s))+(1-\theta)(\lambda_i^{+2}(s)-\lambda_i^{-1}(s))\\ &= (\lambda_i^{-2}(s)-\lambda_i^{+1}(s))+(1-\theta)(\lambda_i^{+2}(s)-\lambda_i^{-2}(s)+\lambda_i^{+1}(s)-\lambda_i^{-1}(s))\\ &= X_i^+(s;t_o)+X_i^-(s;t_o)+(1-\theta)(Str.\ \chi_i^1(s;t_o)+Str.\ \chi_i^2(s;t_o)).\end{aligned} \tag{4.3}$$

Denote the constant states to the left and right of the phase boundary by U_1^a and U_2^a, respectively. Then, if $\lambda_2(v_R)-\lambda_2(v_2^a)<0$, the forward wave is dominated by shock waves, and, if there are rarefaction waves, they must have interacted with shock waves and canceled out. Therefore, in this case,

$$X_i^+(s;t_o)=0.$$

So, using the above relations and integrating (4.3), we see that

$$D_i(s;t_o)=D_i(t_o;t_o)+\int_{t_o}^{s}\{X_i^-(\tau;t_o)+(1-\theta)(Str.\ \chi_i^1(\tau;t_o)+Str.\ \chi_i^2(\tau;t_o))\}d\tau.$$

Taking the limit as $t_o\to 0$ and noting that $D_i(t_o;t_o)\to 0$, we obtain

$$D_i(s;0)=\int_0^s\{X_i^-(\tau;0)+(1-\theta)(Str.\ \chi_i^1(\tau;0)+Str.\ \chi_i^2(\tau;0))\}d\tau.$$

Note that the integrand is negative, and it is a constant because there is no interaction and cancelation in (3.22). This implies that, if $\lambda_2(v_R)-\lambda_2(v_2^a)<0$ holds, there is a single discontinuity. This discontinuity is a shock because we solve the Riemann problems for the approximate solutions. Since each side of a shock is a constant state, it is a straight line starting from the origin.

If $\lambda_2(v_R)-\lambda_2(v_2^a)>0$, the forward wave is dominated by rarefaction waves, and if there are shock waves, they must have interacted with rarefaction waves and canceled out. Therefore, in this case, for all $\tau>t_o$,

$$X_i^-(\tau;t_o)=0,\ Str.\ \chi_i^1(\tau;t_o)=0,\ Str.\ \chi_i^2(\tau;t_o)=0.$$

Using the conservation laws (3.22) of the rarefaction waves and noting that there is no cancelation, after taking the limit as $t_o\to 0$, we see that

$$D_i(s;0)=sX_i^+(0;0).$$

Since both $Str.\ \chi_i^1(\tau;t_o)$ and $Str.\ \chi_i^2(\tau;t_o)$ are zero, they are the characteristics, and the outsides are constant states. Using the result of Lax [25], we see that the forward wave is a centered rarefaction wave.

If $\lambda_2(v_R)-\lambda_2(v_2^a)=0$, neither is dominant. If both the shocks and rarefactions are present, there should be interactions. If the shocks or rarefaction waves become dominant, we have a contradiction with $\lambda_2(v_R)-\lambda_2(v_2^a)=0$. Therefore, in this case, there is no shock or rarefaction wave for the forward wave. □

The above result implies that the solution to the Riemann problem consists of the constant states U_L, U_1^a, U_2^a, and U_R separated by the backward wave, the phase boundary, and the forward wave, where the middle constant states U_1^a and U_2^a satisfy the following conditions:

$$(4.4)\qquad (1)\qquad \sigma_b \text{ or } -\lambda_1 \le \sigma_p(v_1^a, v_2^a) \le \sigma_f \text{ or } \lambda_2,$$

$$(4.5)\qquad \begin{aligned} u_L + \left\{ \begin{array}{l} -\sigma_b(v_1^a - v_L),\ v_L > v_1^a \\ \int_{v_L}^{v_1^a} \lambda_1(w)dw,\ v_L \le v_1^a \end{array} \right\} \\ -\sigma_p(v_2^a - v_1^a) - \left\{ \begin{array}{l} \sigma_f(v_R - v_2^a),\ v_R < v_2^a \\ \int_{v_2^a}^{v_R} \lambda_2(w)dw,\ v_R \ge v_2^a \end{array} \right\} = u_R; \end{aligned}$$

(2) the admissible solution to the Riemann problem with the initial data U_1^a and U_2^a consists of the phase boundary only.

The following lemma shows that the solution to the Riemann problem satisfying the above conditions exists.

LEMMA 4.2. *If v_L and v_R are close to the Maxwell strains and $u_L \approx u_R$, then U_1^a and U_2^a satisfying* (1) *and* (2) *exist and are unique.*

Proof. Consider case (a) in Figure 2.1. Let the intermediate constant states be $\bar{U}_1 = (\bar{v}_1, \bar{u}_1)$ and $\bar{U}_2 = (\bar{v}_2, \bar{u}_2)$. First, examine condition (2). This condition reduces to the Riemann problem

$$(4.6)\qquad \min\{E_b(v_1^a, \bar{v}_1) + E_p(\bar{v}_1, \bar{v}_2) + E_f(\bar{v}_2, v_2^a)\}$$

subject to

$$(4.7)\qquad \sigma_p A(\bar{v}_1, \bar{v}_2) \le 0,$$

$$(4.8)\qquad \sigma_b \text{ or } -\lambda_1 \le \sigma_p(\bar{v}_1, \bar{v}_2) \le \sigma_f \text{ or } \lambda_2,$$

and

$$(4.9)\qquad \begin{aligned} u_1^a + \left\{ \begin{array}{l} -\sigma_b(\bar{v}_1 - v_1^a),\ v_1^a > \bar{v}_1 \\ \int_{v_1^a}^{\bar{v}_1} \lambda_1(w)dw,\ v_1^a \le \bar{v}_1 \end{array} \right\} \\ -\sigma_p(\bar{v}_2 - \bar{v}_1) - \left\{ \begin{array}{l} \sigma_f(v_2^a - \bar{v}_2),\ v_2^a < \bar{v}_2 \\ \int_{\bar{v}_2}^{v_2^a} \lambda_2(w)dw,\ v_2^a \ge \bar{v}_2 \end{array} \right\} = u_2^a, \end{aligned}$$

where the intermediate states satisfy $\bar{U}_1 = U_1^a$ and $\bar{U}_2 = U_2^a$. Note that $E_b(v_1^a, \bar{v}_1) = O(|v_1^a - \bar{v}_1|^3)$ and $E_f(\bar{v}_2, v_2^a) = O(|\bar{v}_2 - v_2^a|^3)$. First, evaluate $\frac{dE}{d\bar{v}_1}$ at $\bar{v}_1 = v_1^a$. Then

$$(4.10)\qquad \begin{aligned} \left.\frac{dE}{d\bar{v}_1}\right|_{\bar{v}_1 = v_1^a} &= \left.\frac{dE_p}{d\bar{v}_1}\right|_{\bar{v}_1 = v_1^a} \\ &= \left.\frac{1}{4\sigma_p}\left\{\frac{d\bar{v}_2}{d\bar{v}_1}\{\lambda_2^2 - (\sigma_p)^2\}A_{21} - \{\lambda_1^2 - (\sigma_p)^2\}A_{12}\right\}\right|_{\bar{v}_1 = v_1^a}, \end{aligned}$$

where A_{21} and A_{12} are the same as in Theorem 2.5 with the appropriate change of arguments. From (4.9), we see that

$$\left.\frac{d\bar{v}_2}{d\bar{v}_1}\right|_{\bar{v}_1 = v_1^a} = \frac{(\lambda_1^a + \sigma_p^a)^2}{(\lambda_2^a - \sigma_p^a)^2}.$$

Substituting this into (4.10), we have

$$\left.\frac{dE}{d\bar{v}_1}\right|_{\bar{v}_1 = v_1^a} = \frac{\lambda_1^a + \sigma_p^a}{\lambda_2^a - \sigma_p^a}\left\{(\lambda_1^a + \lambda_2^a)A(v_1^a, v_2^a)/(v_2^a - v_1^a) + (v_2^a - v_1^a)(\lambda_1^a\lambda_2^a + (\sigma_p^a)^2)\sigma_p^a\right\},$$

where $\lambda_1^a = \lambda(v_1^a)$, $\lambda_2^a = \lambda(v_2^a)$. If U_1^a is on SC,

$$\left.\frac{dE}{d\bar{v}_1}\right|_{\bar{v}_1 = v_1^a} < 0,$$

and, if U_1^a is on EAC,

$$\left.\frac{dE}{d\bar{v}_1}\right|_{\bar{v}_1 = v_1^a} > 0.$$

Therefore, from the intermediate value theorem and Theorem 2.5, we see that the minimum of E in (4.6) takes place when v_1^a and v_2^a satisfy

$$F_1 = (\lambda_1^a + \lambda_2^a)A(v_1^a, v_2^a)/(v_2^a - v_1^a) + (v_2^a - v_1^a)(\lambda_1^a \lambda_2^a + (\sigma_p^a)^2)\sigma_p^a = 0. \tag{4.11}$$

Also, from (4.9) and the Rankine–Hugoniot condition, we have

$$F_2 = \sigma_p^a(v_2^a - v_1^a) + u_2^a - u_1^a = 0, \tag{4.12}$$

$$F_3 = \sigma_p^a(u_2^a - u_1^a) + f(v_2^a) - f(v_1^a) = 0, \tag{4.13}$$

where U_1^a and U_2^a satisfy

$$F_4 = u_1^a - u_L - \left\{ \begin{array}{l} -\sigma_b(v_1^a - v_L),\ v_1^a \le v_L \\ \int_{v_L}^{v_1^a} \lambda_1(w)dw,\ v_1^a > v_L \end{array} \right\} = 0, \tag{4.14}$$

$$F_5 = u_2^a - u_R - \left\{ \begin{array}{l} \sigma_f(v_R - v_2^a),\ v_R > v_2^a \\ \int_{v_2^a}^{v_R} \lambda_2(w)dw,\ v_R \le v_2^a \end{array} \right\} = 0. \tag{4.15}$$

Hence the problem (4.4)–(4.9) is reduced to (4.11)–(4.15) provided that $v_L \approx v_\alpha$, $v_R \approx v_\beta$, and $u_L \approx u_R$. It can be shown that $U_1^a = (v_\alpha, u_L)$ and $U_2^a = (v_\beta, u_R)$ are the solution if $v_L = v_\alpha$, $v_R = v_\beta$, and $u_L = u_R$, and that the determinant of the Jacobian of $F = (F_1, F_2, F_3, F_4, F_5)$ with respect to $(v_1^a, u_1^a, v_2^a, u_2^a, \sigma_p^a)$ is not zero at $(v_1^a, u_1^a, v_2^a, u_2^a, \sigma_p^a) = (v_L, u_L, v_R, u_L, 0)$. Therefore, the implicit function theorem applies. Case (b) can be shown in a similar manner. □

From the above lemmas, we have the following theorem.

THEOREM 4.3. *The solution to the Riemann problem* (2.3)–(2.6) *with* $U_l = U_L$ *and* $U_r = U_R$ *converges to* (4.11)–(4.15).

Remark 4.1. Since in the Riemann problem the asymptotic states occur immediately after $t = 0$, it is natural to ask if the entropy rate admissibility criterion could have been applied after the separation from the beginning. However, this should be proved, and a proof is provided here. Also, this result does not mean that the criterion can be applied after the separation to all of the Riemann problems. If the strains are specified in the same phase, the hyperbolic solutions and the double phase boundary solutions are two possible solution configurations. In this case, it may be more reasonable to apply the criterion first before the separation to choose the solution configuration and then apply it after the separation to find the stable phase boundaries.

The above result shows that we can solve (4.11)–(4.15) instead of (2.3)–(2.6). In what follows, we apply the entropy rate admissibility criterion after the separation. Then it is not difficult to see that we can go through section 3 to show the existence

of weak solutions. Since the phase boundary is now admissible in each time interval, proceeding in the same manner as [16], we have the following theorem.

THEOREM 4.4. *If η is small, then the weak global solution exists. Furthermore, at the phase boundary, the limit*

$$\lim_{y\to\pm 0} U(\chi(t)+y,t) = U_{\pm}(t) \tag{4.16}$$

exists except for countable t. At the points where the above limit exists, the Riemann problem (4.11)–(4.15) *is solved with the above limits as the initial data. Therefore, the Rankine–Hugoniot conditions are satisfied across the phase boundary, and the entropy condition and the entropy rate admissibility criterion are satisfied at these points.*

5. Large time behavior of solutions. In this section, we study the asymptotic behavior of the solution to (1.1) and (1.2) and compare it with the solution of (1.1) and (1.3). For this purpose, we define ζ_i to be the strength of the i-wave in the solution of the Riemann problem (4.11)–(4.15) with initial data U_L and U_R. We also define $\mathcal{S}$ and $\mathcal{R}$ to be the sets of i's for which the i-wave is a shock and a rarefaction wave, respectively.

Let $\{\chi_L(t),t\}$ and $\{\chi_R(t),t\}$ be the generalized 1- and 2-characteristic curves issuing from $(-M,0)$ and $(M,0)$, respectively, such that $U(x,t)=U_L$ for $x<\chi_L(t)$ and $U(x,t)=U_R$ for $x>\chi_R(t)$. Let $X_i^+(t)$ and $X_i^-(t)$ denote the amount of i-rarefaction and i-shock at time t, respectively. We redefine $\chi_i^1(t)$ and $\chi_i^2(t)$ to be the generalized i-characteristic curves through $\{\chi_L(t),t\}$ and $\{\chi_R(t),t\}$, respectively. Since the phase boundary χ is subsonic, there exists $t_*>t$ such that both $\chi_2^1(t)$ and $\chi_1^2(t)$ finish intersecting with the phase boundary by the time t_* and $t_*=O(1)t$. We set $t_*=t_*(t)$. We also set $T_*=t_*(0)$. For each $t\ge t_*$, $s>t_*$, and $i=1,2$, the above characteristic curves and the phase boundary divide the xt-plane into the following regions:

$$\begin{aligned}
&\Lambda_i(t) = \text{the region between } \chi_i^1(t) \text{ and } \chi_i^2(t),\\
&\Gamma_1(t) = \text{the region between } \chi_2^1(t) \text{ and } \chi_1^2(t) \text{ satisfying } x<\chi(t),\\
&\Gamma_2(t) = \text{the region between } \chi_2^1(t) \text{ and } \chi_1^2(t) \text{ satisfying } x>\chi(t).
\end{aligned}$$

Note that there exists a constant C $(C>1)$ depending only on the system and P_o such that t_* satisfies

$$t_* = Ct. \tag{5.1}$$

We set

$$\begin{aligned}
&X_i(t) = X_i^+(t) + \left|X_i^-(t)\right|, \qquad i=1,2,\\
&X(t) = \sum_{i=1,2} X_i(t).
\end{aligned}$$

In addition to the quantities defined in (4.1), we define

$$\begin{aligned}
A(t,s) &= \text{amount of approaching waves between } t<t'<s,\\
H(t,s) &= \text{amount of } j\text{-waves } (j\neq i) \text{ crossing } \chi_i^1(t) \text{ and } \chi_i^2(t)\\
&\quad \text{between } t<t'<s.
\end{aligned}$$

Then we obtain the following lemma.

LEMMA 5.1. *There exist bounds $O(1)$ such that, for every $s \geq t_*$,*

$$A(s, s') = O(1)Q(t) \text{ for } s' > s, \tag{5.2}$$

$$H(t, s) = O(1)Q(t), \tag{5.3}$$

$$\tilde{X}_i(s; t) = O(1)Q(t), \tag{5.4}$$

$$P(s') - P(s) = O(1)Q(t). \tag{5.5}$$

Proof. Applying the approximate conservation laws to the region outside of $\Lambda_i(t)$, we obtain (5.2), (5.3), and (5.4). From (3.20) we see that

$$|P(s') - P(s)| \leq O(1)A(s, s').$$

This implies (5.5). □

LEMMA 5.2 (Liu [28]). *For $j \in \mathcal{S}$, there exists T_j such that $\chi_i^1(t; t_0)$ and $\chi_i^2(t; t_0)$ impinge to form a shock wave with strength $\zeta_j(t)$. Furthermore, for $t > O(1)|\zeta_j|t > T_j$, we have*

$$|X_j(t) - \zeta_j(t)| \leq Q(O(1)|\zeta_j|t), \qquad j \in \mathcal{S}. \tag{5.6}$$

In what follows, using (3.3) and (3.4), we define

$$Q_s^{\mathcal{R}} = \sum_{i \in \mathcal{R}} O(1)|X_i^-(t)|^3,$$

$$Q_s^{\mathcal{S}} = \sum_{j \in \mathcal{S}} O(1)\zeta_j^2 |X_j(t) - |\zeta_j(t)||,$$

respectively, and then we define

$$Q(t) = Q_s^{\mathcal{R}} + Q_s^{\mathcal{S}} + O(1) \sum_{k=1,2} \eta \tilde{X}_k(t).$$

LEMMA 5.3. *There exist $O(1)$ bounds such that, for every $s \geq t_*$ and for every $(x_1, t_1) \in \Gamma_1(t)$ and $(x_2, t_2) \in \Gamma_2(t)$,*

$$|U(x_1, t_1) - U_1^a| = O(1)Q(O(1)|\zeta_j|t), \tag{5.7}$$

$$|U(x_2, t_2) - U_2^a| = O(1)Q(O(1)|\zeta_j|t). \tag{5.8}$$

Proof. We claim from [10] that there exist constant states $\widetilde{U}_1^a$, $\widetilde{U}_2^a$, and $\widetilde{U}_R$ satisfying

$$\widetilde{U}_1^a \in T_1^r(U_L),\ \widetilde{U}_2^a \in P^r(\widetilde{U}_1^a),\ \widetilde{U}_R \in T_2^r(\widetilde{U}_2^a),$$

and

$$\begin{aligned} &|U(x_1, t_1) - \widetilde{U}_1^a| \\ &= O(1)Q(t) + \sum_{i \in \mathcal{R}} O(1)|X_i^-(t)|^3 + \sum_{j \in \mathcal{S}} O(1)|X_j(t) - |\zeta_j(t)||, \end{aligned} \tag{5.9}$$

$$\begin{aligned} &|U(x_2, t_2) - \widetilde{U}_2^a| \\ &= O(1)Q(t) + \sum_{i \in \mathcal{R}} O(1)|X_i^-(t)|^3 + \sum_{j \in \mathcal{S}} O(1)|X_j(t) - |\zeta_j(t)||, \end{aligned} \tag{5.10}$$

$$|U_R - \widetilde{U}_R| = O(1)Q(t) + \sum_{i \in \mathcal{R}} O(1)|X_i^-(t)|^3 + \sum_{j \in \mathcal{S}} O(1)|X_j(t) - |\zeta_j(t)||, \tag{5.11}$$

where $\widetilde{U}_1^a$ and $\widetilde{U}_2^a$ verify (4.11)–(4.13). From

$$\widetilde{U}_1^a \in T_1^r(U_L)$$

and

$$U(x_1,t_1) \in T_1^r(U_L) + \sum_{i=1,2} O(1)\tilde{X}_i(s;t) + \sum_{i\in\mathcal{R}} O(1)|X_i^-(t)|^3 + \sum_{j\in\mathcal{S}} O(1)|X_j(t) - |\zeta_j(t)||,$$

we obtain the claim (5.9). The other claims are similarly obtained. Since the solution to the Riemann problem (4.4)–(4.9) is differentiable and unique, after moving $\widetilde{U}_R$ to U_R, we obtain the results. □

The following lemma gives the important decay rates of the solutions. Since the proof is lengthy and slightly different from [28], it is postponed until the appendix.

LEMMA 5.4. *Suppose that η is small. Then the Cauchy problem* (1.1), (1.2) *has a global solution satisfying*

$$Q(t) = O(1)t^{-\frac{3}{2}} \text{ as } t \to \infty, \tag{5.12}$$

$$\max_i |X_i^-(t)| = O(1)t^{-\frac{1}{2}}, \quad i \in \mathcal{R}. \tag{5.13}$$

Now we obtain the following result for the asymptotic behavior of solutions.

THEOREM 5.5. *If η is small, then the initial value problem* (1.1), (1.2) *has a global solution satisfying the following estimates as $t \to \infty$. First, in the region outside Λ_i,*

$$\sum_{k=1,2} \tilde{X}_k(t) = O(1)t^{-3/2}. \tag{5.14}$$

If ζ_j is a shock, we have

$$|X_j(t) - \zeta_j(t)| = O(1)t^{-3/2}, \tag{5.15}$$

$$Dist\ \{U(x,t), T_j(U_j^a)\} = O(1)t^{-3/2}, \tag{5.16}$$

where $\zeta_j(t)$ is the strength of the j-shock at t. Furthermore, for $(x_j,t),\ (\bar{x}_j,t) \in \Omega_j$, where (x_j,t) and $(\bar{x}_j,t)$ are on the left and right of the j-shock,

$$|U(x_j,t) - U_{jl}^a| + |U(\bar{x}_j,t) - U_{j_r}^a| = O(1)t^{-3/2}. \tag{5.17}$$

If ζ_i is a rarefaction wave, for $(x,t) \in \Omega_i$, we obtain

$$|U(x,t) - U^a(x,t)| = O(1)t^{-1/2}. \tag{5.18}$$

For $(x_p,t),\ (\bar{x}_p,t) \in \Omega_p$, where (x_p,t) and $(\bar{x}_p,t)$ are on the left and right of the phase boundary, it holds that

$$|U(x_p,t) - U_1^a| + |U(\bar{x}_p,t) - U_2^a| = O(1)t^{-3/2}, \tag{5.19}$$

$$|P(t) - P^a| = O(1)t^{-3/2}, \tag{5.20}$$

where $P(t)$ and P^a are the wave strengths of the phase boundary at t and the phase boundary for the Riemann problem (4.11)–(4.15), *respectively.*

Proof. The proof is similar to Liu [28]. Hence we describe the basic idea of the proof here. The lemmas and theorems referred to from [28] are listed in the appendix. From Theorem 5.4, we see that

$$Q(t) = O(1)t^{-3/2}.$$

Therefore, (5.4) implies that

$$\tilde{X}_i(t) = O(1)Q(t).$$

If $\zeta_j < 0$, it is possible to show that there exists t_0 such that $D_j(t;t_0) = 0$ and $\chi_j^1(t_0)$ and $\chi_j^2(t_0)$ will collide to form shocks with strengths $\zeta_j(t)$. Since outside $\chi_j^1(t_0)$ and $\chi_j^2(t_0)$ the wave strengths of the j-family are $\tilde{X}_j(t)$, (5.15) can be shown from

$$|X_j(t) - |\zeta_j(t)|| = O(1)Q(t) = O(1)t^{-3/2}.$$

From Lemma 5.3 and $\tilde{X}_j(t) = O(1)Q(t)$, we see that (5.17) holds.

For the phase boundary, after $t > T_*$, the strengths of all of the elementary waves entering and leaving are at most $O(1)Q(t)$. From this and Lemma 5.3, we obtain (5.19) and (5.20).

If $\zeta_i > 0$, for (x_i, t) and $(\bar{x}_i, t)$ in Ω_i, (x_j, t) left of $\chi_i^1(t)$, and $(\bar{x}_i, t)$ right of $\chi_i^2(t)$,

$$|u(x_i,t) - u_i^a| + |u(\bar{x}_i,t) - \bar{u}_i^a| = O(1)Q(t^{1/2}) = O(1)t^{-3/4}.$$

Also, from (5.13) we see that the speed of characteristic χ_i in Ω_j for $\tau > t$ is $\lambda_i + O(1)\tau^{-1/2}$. Therefore, the distance $F_i(t)$ between $\chi_i^1(t)$ and the left (or the right) end of the i-rarefaction wave expand at the rate

$$F_i(t) = O(1)t^{1/2}.$$

On the other hand, the centered rarefaction wave is a function of x/t. Therefore, the shift of order $t^{1/2}$ causes the difference of order $t^{-1/2}$. □

Appendix. Here we provide the proof of Lemma 5.4 and list the lemmas used to prove it.

Proof of Lemma 5.4. Since there are several places where the proof is different from [3] and [28], it is presented here. The proof is done by induction. We show that, for some $\bar{T} > 0$, there exist the sequences $\{K_m\}$, $\{L_m\}$, and $\{\gamma_m\}$, $m = 0, 1, 2, \ldots$, such that

$$\max_{i\in\mathcal{R}} |X_i^-(t)| \le K_m t^{-\frac{1}{2}} \quad \text{for} \quad t \le C^m\bar{T}, \tag{A.1}$$

$$Q(t) \le L_m t^{-\frac{3}{2}} \quad \text{for} \quad t \le C^m\bar{T}, \tag{A.2}$$

$$\begin{aligned} K_{m+1} &= K_m[\{1 + O(1)\gamma_m + O(1)K_m^{\rho-1}(C^m\bar{T})^{\xi-\frac{1}{2}} + O(1)K_m^{2\rho-1}(C^m\bar{T})^{2\xi-3/2}\} \\ &\quad \times \left\{1 + O(1)K_m^{\rho}(C^m\bar{T})^{\xi-1}\right\} C^{O(1)\gamma_m} + O(1)K_m^{2-\frac{3\rho}{2}}(C^m\bar{T})^{-\frac{3\xi}{2}+\frac{1}{2}}], \end{aligned} \tag{A.3}$$

$$\gamma_m \le C^{-\delta}\gamma_{m-1} < 1, \tag{A.4}$$

$$L_m = O(1)(K_m)^3, \tag{A.5}$$

where ρ, ξ, and δ are positive numbers chosen later. We show that $K = \overline{\lim}_{m\to\infty} K_m$ and $L = \overline{\lim}_{m\to\infty} L_m$ exist and are finite.

First, we prove (A.1) along with (A.3) and (A.4). For this purpose, we set

$$\bar{T} = (N_0\eta)^{-11/5}\tilde{T}, \quad K_0 = (N_0\eta)^{-1/10}\tilde{T}^{1/2}, \quad L_0 = K_0^3,$$

where $\tilde{T}$ is the time t at which

$$\sum_{j\in\mathcal{S}}\{X_j(t) - |\zeta_j(t)|\} + \sum_{i=1,2}\tilde{X}_i(t) \le \frac{1}{2}\min_{j\in\mathcal{S}}\zeta_j.$$

Note that $\tilde{T}$ may depend on η. Since $K_0\bar{T}^{-\frac{1}{2}} = (N_0\eta)$, (A.1), (A.2), and (A.5) hold for $m = 0$. Now suppose that (A.1)–(A.5) hold for $m = h$. We set

$$T_h = K_h^{\rho}(C^h\bar{T})^{\xi}, \quad \gamma_h = K_h T_h^{-1/2}. \tag{A.6}$$

Note that

$$\gamma_0 = K_0^{(1-\frac{\rho}{2})}(\bar{T})^{-\xi/2} = (N_0\eta)^{-\frac{(1-\frac{\rho}{2})}{10}+\frac{11\xi}{10}}\tilde{T}^{\frac{(1-\frac{\rho}{2})}{2}-\frac{\xi}{2}}.$$

As we will see, we choose $\rho = \frac{6}{5}$, $\xi = \frac{2}{5}$, and $\delta = \frac{3}{20}$ as one choice, and, in this case, we have

$$\gamma_0 = (N_0\eta)^{\frac{19}{50}} \tag{A.7}$$

so that γ_0 is independent of $\tilde{T}$. The induction hypothesis implies that

$$\begin{aligned} &\max_{i\in\mathcal{R}}|X_i^-(t)| \le \gamma_h, \\ &Q(t) \le L_h T_h^{-3/2} = L_h K_h^{-3}\gamma_h^3 = O(1)\gamma_h^3. \end{aligned} \tag{A.8}$$

For $i \in \mathcal{R}$, we have

$$X_i^+(t;T_h) + X_i^-(t;T_h) + Str.\ \chi_i^1(t;T_h) + Str.\ \chi_i^2(t;T_h) = \zeta_i + O(1)\gamma_h^3. \tag{A.9}$$

From this we have

$$|Str.\ \chi_i^1(t;T_h)| + |Str.\ \chi_i^2(t;T_h)| \le X_i^+(t;T_h) - \zeta_i + O(1)\gamma_h^3. \tag{A.10}$$

Using

$$\sigma_i(U_i^{+k}, U_i^{-k}) = \frac{1}{2}(\lambda_i^{+k} + \lambda_i^{-k}) + O(1)|U_i^{+k} - U_i^{-k}|^2, \quad k = 1, 2,$$

in (4.2), we have

$$\begin{aligned} \frac{dD_i(t;T_h)}{dt} &= \frac{1}{2}(\lambda_i^{+2} + \lambda_i^{-2}) + O(1)|U_i^{+2} - U_i^{-2}|^2 \\ &\quad -\frac{1}{2}(\lambda_i^{+1} + \lambda_i^{-1}) + O(1)|U_i^{+1} - U_i^{-1}|^2 \\ &= \lambda_i^{+2} - \lambda_i^{-1} - \frac{1}{2}(\lambda_i^{+2} - \lambda_i^{-2} + \lambda_i^{+1} - \lambda_i^{-1}) \\ &\quad +O(1)|U_i^{+2} - U_i^{-2}|^2 + O(1)|U_i^{+1} - U_i^{-1}|^2 \\ &= \lambda_i^{+2} - \lambda_i^{-1} + \left\{\frac{1}{2} + O(1)|Str.\ \chi_i^1(t;T_h) + Str.\ \chi_i^2(t;T_h)|\right\} \\ &\quad \times \left\{|Str.\ \chi_i^1(t;T_h) + Str.\ \chi_i^2(t;T_h)|\right\}. \end{aligned} \tag{A.11}$$

Since $\lambda_i^{+2} - \lambda_i^{-1} = \lambda_i^{+2}(U_i^a) - \lambda_i^{-1}(U_{i-1}^a) + O(1)\gamma_h^3 = (U_L, U_R)_{r_i} + O(1)\gamma_h^3$, from this and the induction hypotheses (A.1) and (A.8) we have

$$\frac{dD_i(t;T_0)}{dt} = \left(\frac{1}{2} + O(1)\gamma_h\right) K_h t^{-\frac{1}{2}} + \zeta_i + O(1)\gamma_h^3.$$

Integrating this from CT_h to C^hT, we have

$$\begin{aligned} D_i(C^hT;T_h) \le 2\left(\frac{1}{2} + O(1)\gamma_h\right) K_h\{(C^hT)^{1/2} - (CT_h)^{1/2}\} \\ +O(1)\gamma_h^3(C^hT - CT_h) + D_i(CT_h;T_h). \end{aligned} \tag{A.12}$$

Also, from (A.10) and (A.11), we obtain

$$\begin{aligned} \frac{dD_i(t;T_h)}{dt} &\le \left(\frac{1}{2} + O(1)\gamma_h\right)\{X_i^+(t;T_h) - \zeta_i + O(1)\gamma_h^3\} + O(1)\gamma_h^3 \\ &\le \left(\frac{1}{2} + O(1)\gamma_h\right)\left\{\frac{D_i(t;T_h)}{t - CT_h} - \zeta_i\right\} + \zeta_i + O(1)\gamma_h^3. \end{aligned}$$

Integrating this inequality from $C^h\bar{T}$ to t, where $C^h\bar{T} \le t \le C^{h+1}\bar{T}$, and substituting the result into (A.20), we have

$$\begin{aligned} &X_i^+(t) \\ &\le \frac{1}{(t - CT_h)^{\frac{1}{2}}}\left[(1 + O(1)\gamma_h)K_h\frac{\{(C^h\bar{T})^{1/2} - (CT_h)^{1/2}\}}{(C^h\bar{T} - CT_h)^{\frac{1}{2}}} + \frac{D_{r_i}(CT_h;T_h)}{(C^h\bar{T} - CT_h)^{\frac{1}{2}}}\right] \\ &\quad \times\left\{\frac{t - CT_h}{C^h\bar{T} - CT_h}\right\}^{O(1)\gamma_h} + \zeta_i + O(1)\gamma_h^3 \\ &\le t^{-1/2}\left[(1 + O(1)\gamma_h)K_h + \frac{D_{r_i}(CT_h;T_h)}{(C^h\bar{T} - CT_h)^{\frac{1}{2}}}\right] \\ &\quad \times\left(\frac{t}{C^h\bar{T}}\right)^{O(1)\gamma_h}\left\{\frac{1 - \frac{CT_h}{t}}{1 - \frac{CT_h}{C^h\bar{T}}}\right\}^{O(1)\gamma_h}\left(1 - \frac{CT_h}{t}\right)^{-\frac{1}{2}} + \zeta_i + O(1)\gamma_h^3, \end{aligned}$$

where $C^h\bar{T} \le t \le C^{h+1}\bar{T}$. We estimate the terms in the above inequality. For this purpose, we express every term in terms of γ_h, C and show that there exist positive ρ, ξ, and δ satisfying (A.3) and (A.4). From (A.6) we have

$$K_h = \gamma_h^{\frac{1}{1-\frac{\rho}{2}}}(C^h\bar{T})^{\frac{\xi}{2(1-\frac{\rho}{2})}}.$$

The estimates of the terms in the above inequality are given by

$$\frac{CT_h}{C^h\bar{T}} = \frac{CK_h^\rho(C^h\bar{T})^\xi}{C^h\bar{T}} = CK_h^\rho(C^h\bar{T})^{\xi-1} = C\gamma_h^{\frac{\rho}{1-\frac{\rho}{2}}}(C^h\bar{T})^{\frac{\rho\xi}{2(1-\frac{\rho}{2})}}(C^h\bar{T})^{\xi-1},$$

$$\frac{1}{(1-\frac{CT_h}{C^h\bar{T}})^{\frac{1}{2}}} = 1 + O(1)K_h^{\rho}(C^h\bar{T})^{\xi-1},$$

$$\frac{\{(C^h\bar{T})^{1/2} - (CT_h)^{1/2}\}}{(C^h\bar{T} - CT_h)^{\frac{1}{2}}} \le 1,$$

$$\frac{D_i(CT_h;T_h)}{(C^h\bar{T}-CT_h)^{\frac{1}{2}}} = \frac{O(1)T_h}{(C^h\bar{T}-CT_h)^{\frac{1}{2}}} = \frac{O(1)K_h^{\rho}(C^h\bar{T})^{\xi-\frac{1}{2}}}{(1-\frac{CT_h}{C^h\bar{T}})^{\frac{1}{2}}}$$
$$\le O(1)K_h^{\rho}(C^h\bar{T})^{\xi-\frac{1}{2}}\{1 + O(1)K_h^{\rho}(C^h\bar{T})^{\xi-1}\}.$$

From (A.7), $O(1)\gamma_0 < \frac{1}{2}$ is possible if we choose η to be small. Assuming that $O(1)\gamma_h < \frac{1}{2}$ is possible as a part of the induction hypothesis, we see that

$$\begin{aligned}
&\left\{\frac{1-\frac{CT_h}{t}}{1-\frac{CT_h}{C^h\bar{T}}}\right\}^{O(1)\gamma_h}\left(1-\frac{CT_h}{t}\right)^{-\frac{1}{2}}\\
&\le \left(1-\frac{CT_h}{C^h\bar{T}}\right)^{-(\frac{1}{2}+O(1)\gamma_h)}\\
&= \{1-O(1)(\gamma_h)^{\frac{\rho}{1-\frac{\rho}{2}}}(C^h\bar{T})^{\frac{\rho\xi}{2(1-\frac{\rho}{2})}}(C^h\bar{T})^{\xi-1}\}^{-(\frac{1}{2}+O(1)\gamma_h)}\\
&\le 1 + O(1)(\gamma_h)^{\frac{\rho}{1-\frac{\rho}{2}}}(C^h\bar{T})^{\frac{\rho\xi}{2(1-\frac{\rho}{2})}}(C^h\bar{T})^{\xi-1}.
\end{aligned}$$

Hence

$$\begin{aligned}
&X_i^+(t)\\
&\le K_h t^{-1/2}[\{1 + O(1)\gamma_h + O(1)K_h^{\rho-1}(C^h\bar{T})^{\xi-\frac{1}{2}}(1+O(1)K_h^{\rho}(C^h\bar{T})^{\xi-1})\}\\
&\quad\times\left\{1+O(1)K_h^{\rho}(C^h\bar{T})^{\xi-1}\right\}C^{O(1)\gamma_h} + O(1)K_h^{2-\frac{3\rho}{2}}(C^h\bar{T})^{-\frac{3\xi}{2}+\frac{1}{2}}] + \zeta_i.
\end{aligned}$$

We define

$$\begin{aligned}
&K_{h+1}\\
&= K_h[\{1 + O(1)\gamma_h + O(1)K_h^{\rho-1}(C^h\bar{T})^{\xi-\frac{1}{2}}(1+O(1)K_h^{\rho}(C^h\bar{T})^{\xi-1})\}\\
&\quad\times\left\{1+O(1)K_h^{\rho}(C^h\bar{T})^{\xi-1}\right\}C^{O(1)\gamma_h} + O(1)K_h^{2-\frac{3\rho}{2}}(C^h\bar{T})^{-\frac{3\xi}{2}+\frac{1}{2}}]
\end{aligned} \tag{A.13}$$

and examine the inequality (A.4).

$$\begin{aligned}
\frac{\gamma_{h+1}}{\gamma_h} &= \left(\frac{K_{h+1}}{K_h}\right)^{(1-\frac{\rho}{2})}C^{-\xi/2}\\
&= [\{1 + O(1)\gamma_h + O(1)\gamma_h^{\frac{\rho-1}{1-\frac{\rho}{2}}}(C^h\bar{T})^{\frac{\xi(\rho-1)}{2(1-\frac{\rho}{2})}}(C^h\bar{T})^{\xi-\frac{1}{2}}\\
&\quad\times(1+O(1)C\gamma_h^{\frac{\rho}{1-\frac{\rho}{2}}}(C^h\bar{T})^{\frac{\rho\xi}{2(1-\frac{\rho}{2})}}(C^h\bar{T})^{\xi-1})\}\\
&\quad\times\{1+O(1)C\gamma_h^{\frac{\rho}{1-\frac{\rho}{2}}}(C^h\bar{T})^{\frac{\rho\xi}{2(1-\frac{\rho}{2})}}(C^h\bar{T})^{\xi-1}\}C^{O(1)\gamma_h}\\
&\quad+\gamma_h^{\frac{2-\frac{3\rho}{2}}{1-\frac{\rho}{2}}}(C^h\bar{T})^{\frac{\xi(2-\frac{3\rho}{2})}{2(1-\frac{\rho}{2})}}(C^h\bar{T})^{-\frac{3\xi}{2}+\frac{1}{2}}]^{(1-\frac{\rho}{2})}C^{-\xi/2}.
\end{aligned} \tag{A.14}$$

Assuming that the induction hypothesis $\gamma_h < C^{-\delta h}\gamma_0$ holds, we obtain the condition under which $\frac{\gamma_{h+1}}{\gamma_h} < C^{-\delta}$ is satisfied. After substituting $\gamma_h < C^{-\delta h}\gamma_0$ in (A.14), we see that, if the following inequality is satisfied, $\frac{\gamma_{h+1}}{\gamma_h} < C^{-\delta}$ is satisfied.

$$
\begin{aligned}
(A.15)\quad & [\{1+O(1)C^{-\delta h}\gamma_0 \\
& +O(1)C^{\{\frac{\rho-1}{1-\frac{\rho}{2}}(\frac{\xi}{2}-\delta)+\xi-\frac{1}{2}\}h}(\gamma_0)^{\frac{\rho-1}{1-\frac{\rho}{2}}}(\bar{T})^{\frac{\xi(\rho-1)}{2(1-\frac{\rho}{2})}}(\bar{T})^{\xi-\frac{1}{2}} \\
& \times(1+O(1)C^{\{\frac{\rho}{1-\frac{\rho}{2}}(\frac{\xi}{2}-\delta)+\xi-1\}h}(\gamma_0)^{\frac{\rho}{1-\frac{\rho}{2}}}(\bar{T})^{\frac{\rho\xi}{2(1-\frac{\rho}{2})}}(\bar{T})^{\xi-1})\} \\
& \times\{1+O(1)C^{\{\frac{\rho}{1-\frac{\rho}{2}}(\frac{\xi}{2}-\delta)+\xi-1\}h}(\gamma_0)^{\frac{\rho}{1-\frac{\rho}{2}}}(\bar{T})^{\frac{\rho\xi}{2(1-\frac{\rho}{2})}}(\bar{T})^{\xi-1}\}C^{O(1)C^{-\delta h}\gamma_0} \\
& +O(1)C^{\{\frac{2-\frac{3\rho}{2}}{1-\frac{\rho}{2}}(\frac{\xi}{2}-\delta)-\frac{3\xi}{2}+\frac{1}{2}\}h}(\gamma_0)^{\frac{2-\frac{3\rho}{2}}{1-\frac{\rho}{2}}}(\bar{T})^{\frac{\xi(2-\frac{3\rho}{2})}{2(1-\frac{\rho}{2})}}(\bar{T})^{-\frac{3\xi}{2}+\frac{1}{2}]^{(1-\frac{\rho}{2})}} \\
& < C^{-\delta+\frac{\xi}{2}}.
\end{aligned}
$$

Examining the terms in (A.15), we see that a sufficient condition for (A.15) is that the power of C^h is negative, the power of $(N_0\eta)$ is positive, and the power of $\tilde{T}$ is nonpositive. To make the power of C^h negative, we take $\frac{1}{3} < \xi < \frac{1}{2}$, $\frac{1}{3} < \rho < \frac{4}{3}$, and $\frac{\xi}{2} - \delta > 0$. Observe that the powers of $\tilde{T}$ in the above expressions are proportional to $(\rho + 2\xi - 2)$. We choose ρ and ξ so that $\rho + 2\xi - 2 = 0$. One example satisfying the above restrictions is $\rho = \frac{6}{5}$, $\xi = \frac{2}{5}$, and $\delta = \frac{3}{20}$. Then we have

$$
X_i^+(t) \le K_{h+1}t^{-\frac{1}{2}} + \zeta_i, \quad i \in \mathcal{R}, \tag{A.16}
$$

and we obtain from (A.13) the following estimate for the sequence $\{K_m\}$:

$$
K_h < (1+O(1)C^{-\nu h})^h C^{O(1)\sum_h \gamma_h} K_0,
$$

where ν is a positive constant. This shows that $K = \overline{\lim}_{m\to\infty} K_m$ exists and is finite. Therefore, we see that the estimates (A.1), (A.3), and (A.4) hold for $m = h+1$.

Next, we prove (A.2) and (A.5). From (A.21), (A.1), and (A.4), we have for $m \le h$

$$
\begin{aligned}
Q(t) &= Q_s(t) + \sum_{k=1}^{h}(O(1)\eta)^k Q_s(C^{-k}t) + (O(1)\eta)^h Q_d(C^{-p}t) \\
&= Q_s(t) + O(1)\sum_{k=1}^{h}(O(1)\eta)^k K_h^3 (C^{-k}t)^{-3/2}, \quad C^h\bar{T} \le t \le C^{h+1}\bar{T}. \qquad (A.17)
\end{aligned}
$$

The estimate of $Q_s(t)$ is made in the following way. For $i \in \mathcal{R}$, from (A.1) and (A.16), we have for $m \le h+1$

$$
Q_s^{\mathcal{R}}(t) = \sum_{i\in\mathcal{R}} |X_i^-(t)|^3 = O(1)K_{h+1}^3 t^{-3/2}. \tag{A.18}
$$

For $j \in \mathcal{S}$, there exists $t' < t$ such that $x_j^1(t')$ and $x_j^2(t')$ meet before time t. Since $t \le O(1)t'/|\zeta_j|$ and $K_h < K_{h+1}$,

$$
\begin{aligned}
Q_s^{\mathcal{S}}(t) &= \sum_{j\in\mathcal{S}} O(1)\zeta_j^2 |X_j(t) - \zeta_j(t)| \\
&= \sum_{j\in\mathcal{S}} O(1)\zeta_j^2 Q(t') \\
&= \sum_{j\in\mathcal{S}} O(1)|\zeta|_j^{1/2} K_{h+1}^3 t^{-3/2}. \qquad (A.19)
\end{aligned}
$$

Therefore, (A.17), (A.18), and (A.19) imply (A.2) and (A.5). □

LEMMA A.1 (Glimm and Lax [16]). *For a genuinely nonlinear i-characteristic family and $\tau \geq t > t_*$, we have*

$$X_i^+(\tau;t) \leq \frac{D_i(\tau;t)}{\tau - t_*} + O(1)Q(t). \tag{A.20}$$

LEMMA A.2 (Liu [28]). *For the constant C defined in* (5.1),

$$Q(C^m t) = \sum_{k=0}^{m} (O(1)\eta)^k Q_s(C^{m-k}t) + (O(1)\eta)^m Q_d(t), \tag{A.21}$$

where η is defined as in (1.4).

ON COMPLEX-VALUED SOLUTIONS TO A TWO-DIMENSIONAL EIKONAL EQUATION. II. EXISTENCE THEOREMS*

ROLANDO MAGNANINI† AND GIORGIO TALENTI†

Abstract. The equation $w_x^2 + w_y^2 + n^2(x,y) = 0$, which arises in generalizations of geometrical optics, is investigated from a theoretical point of view. Here x and y denote rectangular coordinates in the Euclidean plane, and n is real-valued and strictly positive. A framework is set up that involves a Bäcklund transformation relating $\mathrm{Re}(w)$ and $\mathrm{Im}(w)$, second-order partial differential equations in divergence and nondivergence form governing $\mathrm{Re}(w)$, a variational integral, and related free boundary problems, boundary value problems, and viscosity solutions. The present paper is a continuation of a preceding one [R. Magnanini and G. Talenti, *Contemp. Math.* 283, AMS, Providence, RI, 1999, pp. 203–229], where qualitative properties of smooth solutions are offered. Here the existence of the real part of solutions, which need not be smooth, is derived.

1. Introduction.

1.1. General. Let x and y denote rectangular coordinates in the Euclidean plane $\mathbb{R}^2$, and let n be a *real-valued* function of x and y. Let n be sufficiently smooth and strictly positive; should the range of x and y be unbounded, let n decay fast enough at infinity. The present paper, its predecessor [26], and forthcoming others are devoted to a tentative theory of the partial differential equation

$$\left(\frac{\partial w}{\partial x}\right)^2 + \left(\frac{\partial w}{\partial y}\right)^2 + n^2(x,y) = 0, \tag{1.1}$$

all of whose solutions are *complex-valued.*

Versions of (1.1) arise in acoustics and optics. Suppose that a two-dimensional isotropic nondissipative medium is under consideration and that n represents the relevant refractive index. Since (1.1) turns into

$$w_x^2 + w_y^2 = n^2(x,y)$$

on replacing w by $\pm iw$, the solutions to (1.1) whose real part is zero call for processes of classical geometrical optics. (We denote $\sqrt{-1}$ by i throughout and denote differentiations either by $\partial/\partial x$ and $\partial/\partial y$ or by subscripts.) On the other hand, solutions to (1.1) whose real part is different from zero are alleged to account for an optical process that is inherently excluded from geometrical optics—the development of *evanescent waves.* Evanescent waves occur beyond a caustic, on the dark side where the geometric optical rays do not penetrate, or else on the optically thinner side of

†Dipartimento di Matematica U. Dini, Università di Firenze, viale Morgagni 67/A, 50134 Firenze, Italy (magnanin@math.unifi.it, talenti@math.unifi.it).

an interface that disconnects two different media and totally reflects a wave incident from the optically denser side. A theory, put forward by Felsen and coworkers some twenty years ago and sometimes called evanescent wave tracking (EWT), claims that features of evanescent waves can be portrayed by retaining the asymptotic expansion

$$\text{electromagnetic field} \sim \exp[-i\nu \cdot (\text{time})] \cdot (\text{amplitude}) \cdot \exp[i\nu \cdot (\text{eikonal})],$$

which lies at the very root of geometrical optics, but allowing the eikonal and the components of the amplitude to take *complex values*; here the amplitude and the eikonal are functions of space coordinates only, and ν, the wave number, tends to infinity. A key to EWT amounts precisely to (1.1) and its three-dimensional analogue. By the way, these same objects appear also in a more exhaustive asymptotic analysis of the electromagnetic field, which leads to uniform expansions near caustics, and in modeling deeper diffraction processes. More information can be found in [4], [5], [10], [11], [14], [15], [18], [20], [21], [24], [25], [23], and in the recent surveys [3] and [6].

1.2. Preparatory results. We warm up by recollecting some material from [26]. Let u and v be *real-valued* functions of x and y, and let

$$w = u + iv$$

be the *complex-valued* function of x and y whose real and imaginary parts are u and v, respectively. w is a solution to (1.1) if and only if u and v obey the following system:

$$\begin{aligned} u_x^2 + u_y^2 - v_x^2 - v_y^2 + n^2 &= 0, \\ u_x v_x + u_y v_y &= 0. \end{aligned} \tag{1.2}$$

u and v obey (1.2) if and only if either

$$u_x = u_y = 0 \quad \text{and} \quad v_x^2 + v_y^2 = n^2$$

or the condition

$$u_x^2 + u_y^2 > 0$$

and the following equations

$$\begin{bmatrix} v_x \\ v_y \end{bmatrix} = \pm\sqrt{1 + \frac{n^2}{u_x^2 + u_y^2}} \begin{bmatrix} -u_y \\ u_x \end{bmatrix}, \tag{1.3}$$

$$\frac{\partial}{\partial x}\left\{\sqrt{1 + \frac{n^2}{u_x^2 + u_y^2}}\, u_x\right\} + \frac{\partial}{\partial y}\left\{\sqrt{1 + \frac{n^2}{u_x^2 + u_y^2}}\, u_y\right\} = 0 \tag{1.4}$$

prevail.

Equations (1.3), which result from algebraic manipulations of (1.2), define a *Bäcklund transformation.* (An account of Bäcklund transformations which fits well into the present context is in [30].) Equation (1.4), which amounts to the integrability of (1.3), is a second-order partial differential equation in *divergence form.* If sufficiently smooth solutions are considered whose gradient is different from 0, (1.4) can be recast in the form

$$\begin{aligned} &[(u_x^2 + u_y^2)^2 + n^2 u_y^2] u_{xx} - 2n^2 u_x u_y u_{xy} + [(u_x^2 + u_y^2)^2 + n^2 u_x^2] u_{yy} \\ &\qquad + n\left(u_x^2 + u_y^2\right)(n_x u_x + n_y u_y) = 0, \end{aligned} \tag{1.5}$$

a *semilinear* second-order partial differential equation with *polynomial nonlinearities.* Equations (1.4) and (1.5) are *elliptic-parabolic* or *degenerate elliptic.* A real-valued solution u to either (1.4) or (1.5) is *elliptic* if $u_x^2 + u_y^2 > 0$; a *degeneracy* occurs at any point where $u_x = u_y = 0$.

It should be stressed that (1.4) and (1.5) are *not* equivalent. First, perfectly smooth solutions to (1.5) exist, whose gradients vanish exclusively in a set of measure 0, and that *do not* satisfy (1.4) in the sense of distributions; they make the left-hand side (l.h.s.) of (1.4) a well-defined distribution which is supported by the set of the critical points but is *not* zero. The identity

$$\text{l.h.s. of (1.5)} = (n^2 + u_x^2 + u_y^2)^{\frac{1}{2}}(u_x^2 + u_y^2)^{\frac{3}{2}} \times \{ \text{ l.h.s. of (1.4)}\}$$

gives evidence to such a statement. In the case in which $n \equiv 1$, one of the last mentioned solutions is constructed by selecting a constant C such that $0 < C < 1$ (e.g., $C = 10^{-10}$) and letting

$$\begin{aligned} &\text{domain of } u = \{(x,y) : x^2/(1-C^2) - y^2/C^2 < 1\}, \\ &\sqrt{2}\cdot u(x,y) = (((1-x^2-y^2)^2 + 4y^2)^{1/2} + 1 - x^2 - y^2)^{1/2}; \end{aligned} \tag{1.6}$$

see [26, Proposition 2.2.1]. Second, we shall demonstrate in the present paper that a conventional boundary condition need not determine a solution to (1.4) in the whole of a domain prescribed in advance, whereas the same boundary condition does suit appropriate solutions to (1.5).

The two theorems below, which bring *critical points* into relation with *rays,* express distinctive properties of the equations in hand. Recall the following. A point where the gradient vanishes is qualified as *critical.* A critical point where the Hessian determinant vanishes is qualified as *degenerate.* (The implicit function theorem states that the gradient of a sufficiently smooth real-valued function acts as a diffeomorphism from a neighborhood of a nondegenerate critical point into a neighborhood of the origin. Therefore, any nondegenerate critical point is isolated, and, conversely, all nonisolated critical points are degenerate.) The geodesics belonging to the Riemannian metric

$$n(x,y)\sqrt{(dx)^2 + (dy)^2}, \tag{1.7}$$

i.e., the paths making

$$\int n(x,y)\sqrt{(dx/ds)^2 + (dy/ds)^2}\, ds$$

either stationary or a minimum, are nicknamed *rays* and are characterized by the differential equation

$$(\text{gradient of } \log n)\cdot(\text{principal normal}) = 1. \tag{1.8}$$

THEOREM 1.1. *Assume n is strictly positive and w is a smooth solution to* (1.1). *If the gradient of* $\mathrm{Re}(w)$ *vanishes at some point, then the same gradient vanishes everywhere on a ray passing through that point.*

THEOREM 1.2. *Suppose n is smooth and strictly positive. Suppose u is smooth and real-valued and satisfies either* (1.4) *or* (1.5) *in every open subset of its domain where $u_x^2 + u_y^2 > 0$. We make the following assertions:*

(i) *Any critical point of u is degenerate.*

(ii) *If* $u_x = u_y = 0$ *and* $u_{xx}^2 + 2u_{xy}^2 + u_{yy}^2 > 0$ *at some point, then* $u_x = u_y = 0$ *everywhere on a smooth curve passing through that point.*

(iii) *If* $u_x = u_y = 0$ *and* $u_{xx}^2 + 2u_{xy}^2 + u_{yy}^2 > 0$ *at every point of a smooth curve, then this curve is a ray.*

Theorem 1.1 makes arguments from [14] rigorous. It also offers a proof of the following statement, which plays a role in the so-called *theory of complex rays* and was alleged in [11, section 3.2]. Let w be a solution to (1.1); if a point obeys the principle of locality, i.e., is a critical point of $\mathrm{Re}(w)$, then the phase path crossing that point, i.e., the level line of $\mathrm{Re}(w)$ containing the point in question, is a ray.

Theorem 1.2 basically shows that (1.5), unlike more conventional second-order partial differential equations, prevents its solutions from having *isolated critical points.* The degeneracy at critical points is a feature of (1.5) that causes critical points to cluster.

Another relevant feature is the architecture of (1.5), which exhibits geometric ingredients. If critical points are ignored and h is defined by either

$$h = -\left(u_x^2 + u_y^2\right)^{-3/2}\left(u_y^2 u_{xx} - 2u_x u_y u_{xy} + u_x^2 u_{yy}\right)$$

or

$$h = -\mathrm{div}\left(\frac{\nabla u}{|\nabla u|}\right),$$

then (1.5) reads both

$$|\nabla u|\ \Delta u - n^2\left\{h - \nabla \log n \cdot \frac{\nabla u}{|\nabla u|}\right\} = 0$$

and

$$\left(\frac{u_x}{|\nabla u|}\frac{\partial}{\partial x} + \frac{u_y}{|\nabla u|}\frac{\partial}{\partial y}\right)\log\sqrt{n^2 + |\nabla u|^2} = h.$$

(We denote the divergence operator by div and the gradient operator by ∇. We denote the length of a vector by vertical bars and the scalar product of two vectors by either a dot or parentheses. For instance, we let

$$|\nabla u| = \sqrt{u_x^2 + u_y^2} \quad \text{and} \quad \nabla u \cdot \nabla v = (\nabla u, \nabla v) = u_x v_x + u_y v_y$$

in case that u and v are real-valued. As usual,

$$\Delta = \partial^2/\partial x^2 + \partial^2/\partial^2 y,$$

the Laplace operator.) Observe the following. First, the principal normal to the level lines of u is

$$(1/h)\frac{\nabla u}{|\nabla u|};$$

in other words, the value of h at any point (x, y) is a *signed curvature* at (x, y) of the *level line* of u crossing (x, y). Second, the value of

$$\nabla \log n \cdot \frac{\nabla u}{|\nabla u|}$$

at (x, y) equals a *signed curvature* at (x, y) of the *ray* which is tangent at (x, y) to a level line of u. Third,

$$\frac{u_x}{|\nabla u|}\frac{\partial}{\partial x} + \frac{u_y}{|\nabla u|}\frac{\partial}{\partial y}$$

is a directional derivative along the *lines of steepest descent* of u. (The first statement follows from Frenet's formulas; the second statement is a consequence of the differential equation (1.8), which characterizes rays; the third one amounts to saying that the lines of steepest descent are the trajectories of the gradient.)

1.3. Background. The present paper rests upon a background that we fix now. We borrow terminology from [1], [28], [29], [31], [33], [34], and the theory of distributions and offer apropos details in the next paragraphs.

Equation (1.4) is reminiscent of the *Euler–Lagrange equation* of a variational integral. Let

$$\Omega = \text{some open nonempty subset of } \mathbb{R}^2, \tag{1.9}$$

let a real function f be defined by

$$f(\rho) = \frac{1}{2}[\rho\sqrt{\rho^2+1} + \log(\rho + \sqrt{\rho^2+1})] \tag{1.10}$$

for every nonnegative ρ, and let a functional J be defined by

$$J(u) = \int_\Omega f\left(\frac{|\nabla u|}{n}\right) n^2 dxdy \tag{1.11}$$

for every u from some set of nice real-valued functions of x and y.

Observe that, if the Riemannian metric (1.7) is in force, the expressions

$$\frac{|\nabla u|}{n} \quad \text{and} \quad n^2 dxdy,$$

which appear in (1.11), equal the Riemannian length of the covariant derivative of u and the Riemannian area element, respectively. As will be clear presently, the right-hand side (r.h.s.) of (1.11) would become the Riemannian area of the graph of u if f were replaced by its derivative f'.

Equation (1.10) gives $f(0) = 0$,

$$f'(\rho) = \sqrt{\rho^2+1},$$

and

$$f''(\rho) = \rho/f'(\rho)$$

for every nonnegative ρ; moreover, $f''' = (f')^{-3}$. We infer that f is nonnegative, vanishes only at 0, and is strictly increasing and strictly convex—a good *Young function.* Therefore, functional J is *strictly convex,* provided a convex domain is supplied to it.

Roughly, a domain that fits J well consists of real-valued functions defined in Ω whose first-order derivatives are square-integrable in Ω. In fact, the formula

$$2f(\rho) = \inf\{\lambda + \rho^2 \cdot \coth\lambda : \lambda > 0\},$$

which holds for every nonnegative ρ and follows from (1.10), implies either

$$2J(u) \le \lambda \cdot \int n^2 dxdy + \coth\lambda \cdot \int |\nabla u|^2 dxdy$$

for every u and every positive λ or

$$J(u) \le \int n^2 dxdy \times f\left(\sqrt{\frac{\int |\nabla u|^2 dxdy}{\int n^2 dxdy}}\right)$$

for every u. Moreover, an appropriate analysis shows that

$$\sup\left\{\frac{f(\rho_1)-f(\rho_2)}{\rho_1-\rho_2} : 0 \le \rho_1 < \rho_2, \rho_1^2+\rho_2^2 = 2M^2\right\} = f'(M),$$

provided M is positive; hence

$$|J(u_1)-J(u_2)|^2 \le \int |\nabla u_1 - \nabla u_2|^2 dxdy \times \left\{\int n^2 dxdy + \frac{1}{2}\int |\nabla u_1|^2 dxdy + \frac{1}{2}\int |\nabla u_2|^2 dxdy\right\}$$

for every u_1 and u_2.

As a working hypothesis, we propose any member of the domain of J to additionally obey a *boundary condition*, e.g., to take prescribed values on the boundary, $\partial\Omega$, of Ω. (On occasion, ∂ denotes either differentiation or the operation which results in the boundary of a point set.) Formal definitions follow.

(i) $W^{1,2}(\Omega)$ = completion of $C^\infty(\Omega)$ under the norm defined by

$$\|u\|^2_{W^{1,2}(\Omega)} = 4\int_\Omega u^2(x^2+y^2+4)^{-2}\, dxdy + \int_\Omega |\nabla u|^2 dxdy.$$

$W_0^{1,2}(\Omega)$ = closure of $C_0^\infty(\Omega)$ in $W^{1,2}(\Omega)$, i.e., the subset of $W^{1,2}(\Omega)$ consisting of those functions that vanish on $\partial\Omega$ in a generalized sense. (As usual, $C^\infty(\Omega)$ is the set of infinitely differentiable real-valued functions defined in Ω, and $C_0^\infty(\Omega)$ is the subset of $C^\infty(\Omega)$ consisting of those functions that vanish out of a compact subset of Ω.)

(ii) Let j be any given member of $W^{1,2}(\Omega)$; define

$$\text{domain of } J = j + W_0^{1,2}(\Omega), \tag{1.12}$$

i.e., the set of functions u from $W^{1,2}(\Omega)$ such that $u-j$ belongs to $W_0^{1,2}(\Omega)$.

The following assumptions will be made throughout. First, the measure of Ω in Riemannian metric (1.7) is *finite*; i.e.,

$$\int_\Omega n^2 dxdy < \infty. \tag{1.13}$$

Second, Ω is *essentially different* from $\mathbb{R}^2$; i.e.,

$$\text{measure of } (\mathbb{R}^2 \setminus \Omega) > 0. \tag{1.14}$$

Note that Ω is allowed to be either bounded or unbounded. (Relevantly to the present context, Ω may be an *exterior domain,* i.e., an open connected set whose complement is compact.) In the former case, the measure $(x^2+y^2+4)^{-2}dxdy$, appearing

in (i) above, may be virtually replaced by the standard Lebesgue measure $dxdy$; hence $W^{1,2}(\Omega)$ coincides with the collection of functions that are square-integrable in Ω and whose first-order weak derivatives are square-integrable in Ω—a standard Sobolev space. In any case, the measure in question can be thought of as the area element on the two-dimensional unit sphere $\mathbb{S}^2$ parametrized via a stereographic projection; hence $W^{1,2}(\Omega)$ can be identified with a space of standard Sobolev functions defined in an open subset of $\mathbb{S}^2$.

Theorem 2.1 below claims that J does possess a minimum and that the relevant minimizer is unique within the domain specified above.

Since J was born convex, a necessary and sufficient condition for a member of the domain of J to render J a minimum is the Euler–Lagrange equation. J fails to be smoothly differentiable, however. Therefore, the Euler–Lagrange equation of J involves a set-valued subdifferential and must be cast in the form of an inclusion. Details follow.

Let u belong to the domain of J. If φ is any test function, i.e., any member of $W_0^{1,2}(\Omega)$, we have

$$J(u+\varphi)-J(u)=\int_{\{(x,y):\nabla u(x,y)\neq 0\}}\left[f\left(\frac{|\nabla u+\nabla\varphi|}{n}\right)-f\left(\frac{|\nabla u|}{n}\right)\right]n^2dxdy$$
$$+\int_{\{(x,y):\nabla u(x,y)=0\}}f\left(\frac{|\nabla\varphi|}{n}\right)n^2dxdy;$$

moreover,

$$t^{-1}\int_{\{(x,y):\nabla u(x,y)\neq 0\}}\left[f\left(\frac{|\nabla u+t\nabla\varphi|}{n}\right)-f\left(\frac{|\nabla u|}{n}\right)\right]n^2dxdy$$
$$\to\int_{\{(x,y):\nabla u(x,y)\neq 0\}}\frac{n}{|\nabla u|}f'\left(\frac{|\nabla u|}{n}\right)(\nabla u,\nabla\varphi)\,dxdy$$

as t approaches 0, and

$$t^{-1}\int_{\{(x,y):\nabla u(x,y)=0\}}f\left(\frac{t|\nabla\varphi|}{n}\right)n^2dxdy$$
$$\to f'(0)\cdot\int_{\{(x,y):\nabla u(x,y)=0\}}|\nabla\varphi|\;n\;dxdy$$

as t approaches 0 through *positive* values. Therefore,

$$\lim_{t\downarrow 0}\left[J(u+t\varphi)-J(u)\right]/t,$$

the *one-sided directional derivative* of J at u with respect to φ, equals

$$\int_{\{(x,y):\nabla u(x,y)\neq 0\}}\sqrt{1+n^2|\nabla u|^{-2}}\,(\nabla u,\nabla\varphi)\,dxdy+\int_{\{(x,y):\nabla u(x,y)=0\}}|\nabla\varphi|\;n\;dxdy.$$

Recall that the *subdifferential* of J, ∂J, may be characterized thusly: (i) $\partial J(u)$ is a *convex set* of distributions; (ii) a distribution T belongs to $\partial J(u)$ if and only if the directional derivative of J at u with respect to φ is greater than or equals $T(\varphi)$ for

every test function φ. Consequently, $\partial J(u)$ is the collection of those distributions T satisfying

$$\int_{\{(x,y):\nabla u(x,y)\neq 0\}} \sqrt{1+n^2|\nabla u|^{-2}}\,(\nabla u,\nabla\varphi)\,dxdy + \int_{\{(x,y):\nabla u(x,y)=0\}} |\nabla\varphi|\ n\ dxdy \geq T(\varphi)$$

for every test function, φ. Such a formula implies that $\partial J(u)\neq\emptyset$, i.e., that J is *everywhere subdifferentiable*, and, moreover, that any member T of $\partial J(u)$ obeys

$$T=-\mathrm{div}\{\sqrt{1+n^2|\nabla u|^{-2}}\nabla u\}$$

in any open set $\mathcal{O}$ contained in Ω and essentially contained in

$$\{(x,y)\in\Omega;\nabla u(x,y)\neq 0\},$$

i.e., satisfying

$$\text{measure of } \mathcal{O}\cap\{(x,y)\in\Omega:\nabla u(x,y)=0\}=0.$$

We see, in particular, that J is *differentiable* at u if the set of the critical points of u has measure *zero; J fails* to be differentiable at u if the set of the critical points of u has a *positive* measure.

The analysis provided may be summarized in this way. The appropriate *Euler–Lagrange equation* of J reads

$$\partial J(u)\ni 0,$$

an *inclusion* that implies the following: (1.4) holds in the sense of distributions in any open subset of Ω which is essentially contained in $\{(x,y)\in\Omega:\nabla u(x,y)\neq 0\}$.

In other words, a solution u to the Euler–Lagrange equation of J solves a *free boundary problem* for (1.4), the relevant *free boundary* being

$$\Omega\cap\partial\{(x,y)\in\Omega:\nabla u(x,y)\neq 0\}.$$

(Let a manifold $\mathfrak{M}$, a class of nice functions defined in $\mathfrak{M}$, and a differential equation be given. Suppose a member u of the given function class and a subset $\mathfrak{N}$ of $\mathfrak{M}$ are sought such that (i) u solves the given equation in any open subset of $\mathfrak{N}$ or in any open set which is essentially contained in $\mathfrak{N}$; (ii) u obeys special conditions either on $\partial\mathfrak{N}\cap\mathfrak{M}$ or out of $\mathfrak{N}$. It is usual to say that a free boundary problem is in hand. $\partial\mathfrak{N}\cap\mathfrak{M}$, the boundary of $\mathfrak{N}$ relative to $\mathfrak{M}$, is called the free boundary. [16] and [19] are exhaustive references on this matter.)

What is the geometry and the physical meaning of these free boundaries? The results recorded in the present paper, though not equal to a full proof, give evidence to the following statements. The free boundaries in question (i) either are empty or are genuine *curves*—rather than collections of isolated points; and (ii) separate regions where evanescent waves develop from regions where geometrical optics prevails—hence coincide with *caustics.* (Recall that the envelopes of rays are nicknamed caustics, and thus caustics are precisely the contours near and beyond which geometrical optics break down.)

Samples of free boundaries, which affect solutions to (1.4), appear in [26, section 2.4] or can be detected in Figure 1.1.

1.4. Summary of results. We have sketched an existence result that is a key to our investigations; i.e., the *minimizer u of an apposite functional both takes prescribed boundary values and solves a free boundary value problem for* (1.4). The main issues of the present paper, which are detailed in section 2, can be summarized as follows.

Suppose n is differentiable and its first-order derivatives belong to $L^2_{\mathrm{loc}}(\Omega)$. (As usual, $L^2(\Omega)$ is the space of the real-valued functions that are square-integrable in Ω, and $L^2_{\mathrm{loc}}(\Omega)$ is the space of functions φ such that $\varphi \cdot \psi$ belongs to $L^2(\Omega)$ for every ψ from $C_0^\infty(\Omega)$. Occasionally, we will need to replace 2 by some exponent p larger than or equal to 1.)

(i) u is locally twice differentiable in a suitable generalized sense and obeys (1.5) *in the whole* of domain Ω.

(ii) u is a *viscosity solution* to (1.5).

We loosely imitate ideas from [7], [8], [12], and [13, Chapter 10] and mean the following: u_ε approaches u in an appropriate topology as ε approaches zero. Here ε is a strictly positive constant parameter, and u_ε is the twice differentiable real-valued function that obeys a *restored version* of (1.5) and takes the relevant boundary values. Such a version results from adding the extra term

$$\varepsilon \cdot n^2 \left(n^2 + |\nabla u|^2\right) \cdot \Delta u$$

to the l.h.s. of (1.5), i.e., reads

$$\begin{aligned} &\varepsilon \cdot n^2 \left(n^2 + |\nabla u|^2\right) \cdot \Delta u \\ &+ \left\{|\nabla u|^4 + n^2 u_y^2\right\} \cdot u_{xx} - 2n^2 u_x u_y \cdot u_{xy} + \left\{|\nabla u|^4 + n^2 u_x^2\right\} \cdot u_{yy} \\ &+ n|\nabla u|^2 (\nabla n \cdot \nabla u) = 0. \end{aligned} \tag{1.15}$$

Observe that (1.15) is *uniformly elliptic* and that its leading part balances the first-order terms properly; in other words, the injection of viscosity cures degeneracy. In fact, if a_{11}, a_{12}, and a_{22} denote the coefficients of u_{xx}, u_{xy}, and u_{yy} in (1.15) and ρ and ω are defined by

$$|\nabla u| = n\rho, \quad u_x : \cos\omega = u_y : \sin\omega,$$

then

$$\begin{bmatrix} a_{11} & a_{12} \\ a_{12} & a_{22} \end{bmatrix}$$

$$= n^4 \begin{bmatrix} \cos\omega & -\sin\omega \\ \sin\omega & \cos\omega \end{bmatrix} \begin{bmatrix} \rho^4 + \varepsilon(1+\rho^2) & 0 \\ 0 & (1+\rho^2)(\varepsilon+\rho^2) \end{bmatrix} \begin{bmatrix} \cos\omega & \sin\omega \\ -\sin\omega & \cos\omega \end{bmatrix}. \tag{1.16}$$

Therefore, the eigenvalues of $[a_{ij}]$ obey

$$\frac{\text{smaller eigenvalue}}{\text{larger eigenvalue}} \geq \sqrt{\varepsilon} \cdot (2 + \sqrt{\varepsilon})(1 + \sqrt{\varepsilon})^{-2},$$

and we have

$$\frac{|\text{first-order term}|}{\text{larger eigenvalue}} \leq (1 + \sqrt{\varepsilon})^{-2} \times \frac{|\nabla n|}{n} \times \text{the first power of } |\nabla u|.$$

Viscosity solutions are focused on in section 5, where we show that (i) a viscosity solution to (1.5) is uniquely determined by its boundary values; (ii) a smooth solution to the same equation need not do the same—therefore, a smooth solution to (1.5) need not be a viscosity solution.

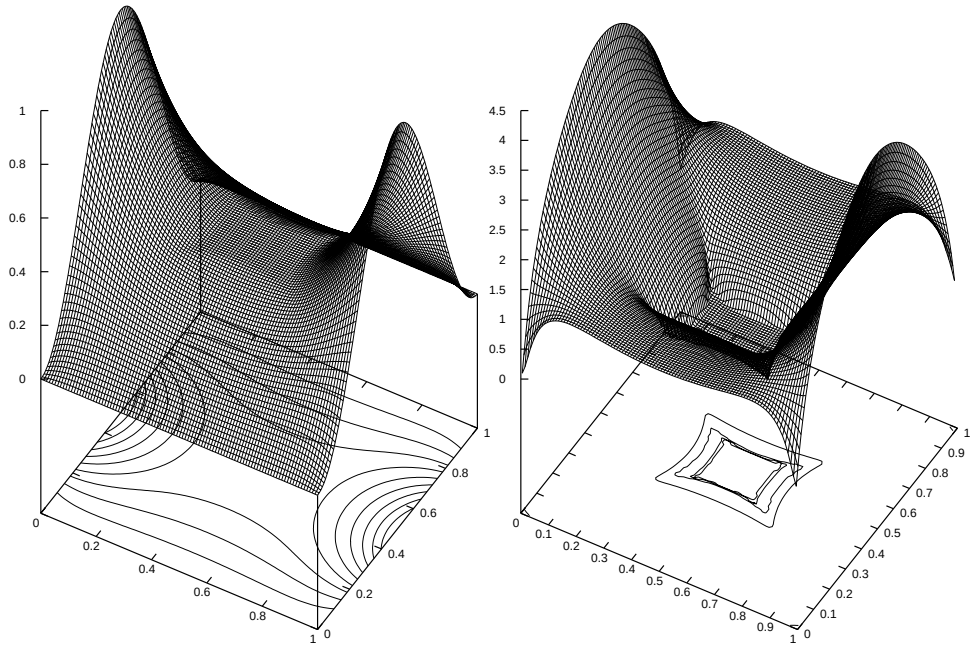

FIG. 1.1. *Typical plots of u and $|\nabla u|$. Here u is a viscosity solution to* (1.5).

1.5. Future developments. Viscosity solutions to (1.5) can be computed efficiently either by finite difference methods or by finite element methods. Details and relevant codes will appear elsewhere.

By way of an example, let u be the viscosity solution that obeys (1.5) in the domain

$$]0,1[\times]0,1[$$

and satisfies the following boundary conditions:

$$\begin{aligned} u(x,0) = u(x,1) &= 0 \qquad \text{if } \ 0 \le x \le 1, \\ u(0,y) = u(1,y) &= [\sin(\pi y)]^2 \ \text{ if } \ 0 \le y \le 1. \end{aligned}$$

Figure 1.1 shows plots of u and $|\nabla u|$, respectively. There, u is approximated by the solution to (1.15) that takes the boundary values in hand, $\varepsilon = 10^{-8}$, finite differences are used, and a 200×200 uniform grid is involved. Note a peculiarity—the solution in question develops caustics, i.e., an inner plateau.

In part three of our work, which will be assembled in a future paper, we will show how the present results, Bäcklund trasformations, and suitable extra ingredients supply solutions to either (1.1) or (1.2) and guarantee their uniqueness.

The referees pointed out that Theorem 9.3 from [9] should be referenced here. Such a theorem claims that if Ω is any open subset of $\mathbb{R}^2$, φ is any Lipschitz continuous map from Ω into $\mathbb{R}^2$, and n is real-valued and continuous, then system (1.2) admits solutions that are Lipschitz continuous in Ω and equal to φ on $\partial\Omega$.

This theorem departs from our point of view for a couple of reasons. First, we are interested in tractable solutions, i.e., smooth enough, unique, and actually computable. Second, we do not address system (1.2) in the present paper. Treating (1.2)

by the present methods cannot be done in few words and deserves further investigation.

2. Main results. Let J be defined by (1.9), (1.10), (1.11), and (1.12). Assume conditions (1.13) and (1.14).

Let ε be a parameter satisfying

$$0 < \varepsilon \le 1/2.$$

Let a real function f_ε be defined by

$$f_\varepsilon(\rho) = \int_0^\rho t \left(\frac{1+t^2}{\varepsilon + t^2} \right)^{\frac{1}{2(1-\varepsilon)}} dt \tag{2.1}$$

for every nonnegative ρ; let a functional J_ε be defined by

$$\begin{aligned} &\text{domain of } J_\varepsilon = \text{domain of } J, \\ &J_\varepsilon(u) = \int_\Omega f_\varepsilon \left(\frac{|\nabla u|}{n} \right) n^2 dxdy. \end{aligned} \tag{2.2}$$

THEOREM 2.1. *Functional J achieves a minimum and has a unique minimizer.*

THEOREM 2.2. (i) *Functional J_ε achieves a minimum and has a unique minimizer.*

(ii) *Let u and u_ε denote the minimizer of J and the minimizer of J_ε, respectively; then u_ε converges to u both in $L^2_{\mathrm{loc}}(\Omega)$ and weakly in $W^{1,2}(\Omega)$ as ε approaches 0.*

THEOREM 2.3. *Suppose n is differentiable and the first-order derivatives of n belong to $L^2_{\mathrm{loc}}(\Omega)$; let u and be u_ε be as above. We make the following assertions:*

(i) *u_ε is twice differentiable in the usual generalized sense, the second-order derivatives of u_ε belong to $L^2_{\mathrm{loc}}(\Omega)$, and u_ε obeys* (1.15).

(ii) *u_ε converges to u uniformly on every compact subset of Ω as ε approaches* 0; *∇u_ε converges to ∇u in $L^p_{\mathrm{loc}}(\Omega) \times L^p_{\mathrm{loc}}(\Omega)$ for every p larger than or equal to* 1.

(iii) *u is twice differentiable in a generalized sense and obeys the inequality*

$$\begin{aligned} &\left\{ \int_{\{(x,y):\mathrm{dist}((x,y),\mathbb{R}^2\setminus K)\ge r\}} \frac{|\nabla u|^2}{n^2+|\nabla u|^2} \left(u_{xx}^2 + 2u_{xy}^2 + u_{yy}^2 \right) \, dxdy \right\}^{\frac{1}{2}} \\ &\qquad \le 6 \left\{ \int_K |\nabla n|^2 \, dxdy \right\}^{\frac{1}{2}} + 2r^{-1} \left\{ \int_K \left(n^2 + |\nabla n|^2 \right) \, dxdy \right\}^{\frac{1}{2}} \end{aligned} \tag{2.3}$$

provided that K is a nice compact subset of Ω and r is a positive number. Moreover, u makes

$$(n^2 + |\nabla u|^2)^{-\frac{3}{2}} \times \{\text{l.h.s. of (1.5)}\}$$

both locally integrable in Ω and equal to 0*; in other words, u obeys* (1.5) *in the whole of Ω.*

3. Proofs of Theorems 2.1 and 2.2.

3.1. An inequality. A proof of Theorem 2.1 relies upon the following lemma.

LEMMA 3.1. *Let Ω obey* (1.9) *and* (1.14), *and let C be any constant such that*

$$C \ge \left\{ \frac{4}{\pi} \int_{\mathbb{R}^2\setminus\Omega} \frac{dxdy}{(x^2+y^2+4)^2} \right\}^{-1}.$$

Then

$$4\int_{\mathbb{R}^2}\varphi^2(x^2+y^2+4)^{-2}\,dxdy \le (C-1)\int_{\mathbb{R}^2}\left(\varphi_x^2+\varphi_y^2\right)\,dxdy$$

provided that φ is smooth enough and real-valued, and

$$\textit{support of } \varphi \subseteq \Omega.$$

Proof. The metric induced by

$$\frac{(dx)^2+(dy)^2}{\left[1+(x^2+y^2)/4\right]^2}$$

makes $\mathbb{R}^2$ a Riemannian manifold $\mathfrak{M}$ that is locally conformal to a unit sphere and enjoys the following properties. First, the Riemannian area element equals

$$\left[1+(x^2+y^2)/4\right]^{-2}\,dxdy.$$

Second, the length of the Riemannian gradient of any smooth scalar field equals

$$\left[1+(x^2+y^2)/4\right]\times \text{length of the Euclidean gradient.}$$

Thus the Riemannian area of $\mathbb{R}^2$ equals 4π, and

$$\text{Riemannian area of } \Omega \le 4\pi(1-1/C);$$

moreover,

$$\int_{\mathbb{R}^2}\varphi^2\left[1+(x^2+y^2)/4\right]^{-2}\,dxdy=\int_{\mathfrak{M}}\varphi^2,$$

and

$$\int_{\mathbb{R}^2}\left(\varphi_x^2+\varphi_y^2\right)\,dxdy=\int_{\mathfrak{M}}|\text{Riemannian gradient of } \varphi|^2.$$

We must show that

$$\int_{\mathfrak{M}}\varphi^2 \le 4(C-1)\int_{\mathfrak{M}}|\text{Riemannian gradient of } \varphi|^2. \tag{3.1}$$

Let μ and φ^* be the distribution function and the decreasing rearrangement of φ, respectively. μ is the map from $[0,\infty[$ into $[0,4\pi]$ such that

$$\mu(t)=\text{Riemannian area of } \{(x,y):|\varphi(x,y)|>t\}$$

for every nonnegative t. φ^* can be defined as the map from $[0,4\pi]$ into $[0,\infty[$ which is right-continuous, decreasing, and equidistributed with φ, i.e., such that

$$\text{length of } \{s\in[0,4\pi]:\varphi^*(s)>t\}=\mu(t)$$

for every nonnegative t.

We have

$$\int_{\mathfrak{M}}\varphi^2=\int_0^{4\pi}\left[\varphi^*(s)\right]^2 ds \tag{3.2}$$

since the very definitions of μ and φ^* ensure that both sides equal $\int_0^\infty t^2[-d\mu(t)]$. On the other hand, a version of an important inequality (see, e.g., [2, section 4]) tells us that φ^* is locally absolutely continuous in $]0, 4\pi[$ and satisfies

$$\int_{\mathfrak{M}} |\text{Riemannian gradient of } \varphi|^2 \geq \int_0^{4\pi} s(4\pi - s) \left[-\frac{d\varphi^*}{ds}(s) \right]^2 \, ds. \tag{3.3}$$

The support of φ^* is an interval whose endpoints are 0 and the Riemannian area of the support of φ. Therefore, our hypotheses yield

$$\text{support of } \varphi^* \subseteq [0, 4\pi(1 - 1/C)].$$

Such an inclusion informs us that φ^* vanishes in a neighborhood of 4π. Thus an integration by parts and a Schwarz inequality give successively

$$\int_0^{4\pi} [\varphi^*(s)]^2 \, ds = 2 \int_0^{4\pi} \varphi^*(s) s \left[-\frac{d\varphi^*}{ds}(s) \right] \, ds$$

and

$$\int_0^{4\pi} [\varphi^*(s)]^2 \, ds \leq 4 \int_0^{4\pi} s^2 \left[-\frac{d\varphi^*}{ds}(s) \right]^2 \, ds.$$

The same inclusion also implies that

$$\int_0^{4\pi} s^2 \left[-\frac{d\varphi^*}{ds}(s) \right]^2 \, ds \leq (C-1) \int_0^{4\pi} s(4\pi - s) \left[-\frac{d\varphi^*}{ds}(s) \right]^2 \, ds.$$

We infer

$$\int_0^{4\pi} [\varphi^*(s)]^2 \, ds \leq 4(C-1) \int_0^{4\pi} s(4\pi - s) \left[-\frac{d\varphi^*}{ds}(s) \right]^2 \, ds. \tag{3.4}$$

Equation (3.2) and inequalities (3.3) and (3.4) result in (3.1). □

3.2. Proof of Theorem 2.1. Uniqueness of the minimizer results from the strict convexity of functional J, while existence follows from the items below via standard arguments of the calculus of variations.

(i) *Boundedness of sublevel sets of J.* The formula

$$f(\rho) = \sup \left\{ \rho \cdot \frac{\lambda}{\sinh \lambda} + \rho^2 \cdot \frac{\sinh(2\lambda) - 2\lambda}{4(\sinh \lambda)^2} : \lambda > 0 \right\},$$

which holds for every nonnegative ρ and follows from (1.10), gives successively

$$J(u) \geq \frac{\lambda}{\sinh \lambda} \cdot \int |\nabla u| \; n \; dxdy + \frac{\sinh(2\lambda) - 2\lambda}{4(\sinh \lambda)^2} \cdot \int |\nabla u|^2 dxdy$$

for every u and every positive λ and either

$$J(u) \geq \frac{\left(\int |\nabla u| n dxdy \right)^2}{\int |\nabla u|^2 dxdy} \times f \left(\frac{\int |\nabla u|^2 dxdy}{\int |\nabla u| n dxdy} \right)$$

or

$$J(u) \geq \int |\nabla u| n dx dy,$$

or else

$$J(u) \geq \frac{1}{2} \int |\nabla u|^2 dx dy \tag{3.5}$$

for every u.

Lemma 3.1 implies that every u from $j + W_0^{1,2}(\Omega)$ obeys

$$\|u\|_{W^{1,2}(\Omega)} \leq (1 + \sqrt{C}) \cdot \|j\|_{W^{1,2}(\Omega)} + \sqrt{C} \cdot \left\{ \int |\nabla u|^2 dx dy \right\}^{1/2}. \tag{3.6}$$

Inequality (3.5) tells us that J is *coercive.* Inequalities (3.5) and (3.6) imply that the sublevel sets of J, i.e., the function classes

$$\{u \in \text{domain of } J : J(u) \leq \text{Constant}\},$$

are all *bounded* in the metric of $W^{1,2}(\Omega)$.

(ii) *Compactness.* The classical Riesz compactness theorem or an oversimplified version of the Rellich–Kondrachov theorem (see, e.g., [1, Chapter V] or [34, section 2.5]) ensures that any sequence which is bounded in $W^{1,2}(\Omega)$ contains some subsequence which converges in $L^2_{\text{loc}}(\Omega)$. The structure of the appropriate dual space (see, e.g., [1, Chapter III] or [34, section 4.3]) ensures that any sequence which is bounded in $W^{1,2}(\Omega)$ and converges in $L^2_{\text{loc}}(\Omega)$ does converge in the weak topology of $W^{1,2}(\Omega)$.

(iii) *Lower semicontinuity of J.* The real function g defined by

$$\begin{aligned} g(\rho) &= 0 && \text{if} \quad 0 \leq \rho \leq 1, \\ &= \tfrac{1}{2}[\rho\sqrt{\rho^2 - 1} - \log(\rho + \sqrt{\rho^2 - 1})] && \text{if} \quad \rho > 1 \end{aligned}$$

is the *Young conjugate* of f, i.e., obeys

$$f(\rho) = \sup\{\rho \cdot \lambda - g(\lambda) : \lambda \geq 0\}$$

for every nonnegative ρ. Therefore, either an inspection or a theorem from [29] gives

$$J(u) = \sup \left\{ \int (\nabla u, \varphi)\, dx dy - \int g\left(\frac{|\varphi|}{n}\right) n^2 dx dy : \varphi \in L^2(\Omega) \times L^2(\Omega) \right\} \tag{3.7}$$

for every u.

Since $C_0^\infty(\Omega)$ is dense in $L^2(\Omega)$, the former can replace the latter in the preceding formula. Hence an integration by parts gives

$$J(u) = \sup \left\{ -\int u \cdot \operatorname{div} \varphi \; dx dy - \int g\left(\frac{|\varphi|}{n}\right) n^2 dx dy : \varphi \in C_0^\infty(\Omega) \times C_0^\infty(\Omega) \right\} \tag{3.8}$$

for every u.

The supremum of a family of continuous functionals is lower semicontinuous. Thus (3.7) and (3.8) imply that J is *lower semicontinuous* with respect to both the weak topology of $W^{1,2}(\Omega)$ and the topology of $L^2_{\text{loc}}(\Omega)$. □

3.3. Proof of Theorem 2.2. Proposition (i) is a replica of Theorem 2.1 and can be demonstrated similarly. Ad hoc ingredients, such as the convexity and the coerciveness of functional J_ε, are provided by (2.1) and (2.2) and by propositions (i), (ii), and (iii) of Lemma A.1.

Proposition (ii) is straightforward. Since (1.11) and (2.2) give

$$|J(\varphi) - J_\varepsilon(\varphi)| \le \int_\Omega n^2 \, dxdy \times \sup\{|f(\rho) - f_\varepsilon(\rho)| : 0 \le \rho < \infty\}$$

for every φ, proposition (iv) of Lemma A.1 implies that

$$\sup\left\{|J(\varphi) - J_\varepsilon(\varphi)| : \varphi \in W^{1,2}(\Omega)\right\} = O(\sqrt{\varepsilon}); \tag{3.9}$$

that is, J_ε converges *uniformly* to J as ε approaches 0.

On the other hand,

$$0 \le J(u_\varepsilon) - \min J \le 2 \cdot \sup\left\{|J(\varphi) - J_\varepsilon(\varphi)| : \varphi \in W^{1,2}(\Omega)\right\}. \tag{3.10}$$

Formulas (3.9) and (3.10) imply that

$$\lim_{\varepsilon \to 0} J(u_\varepsilon) = \min J;$$

therefore,

$$\{u_{\varepsilon_k}\}_{k=1,2,3,\ldots}$$

is a *minimizing sequence* relative to functional J whenever $\{\varepsilon_k\}_{k=1,2,3,\ldots}$ obeys $0 < \varepsilon_k \le 1/2$ for every k and

$$\lim_{k \to \infty} \varepsilon_k = 0.$$

Suppose, by contradiction, that u_ε fails to approach u either in $L^2_{\mathrm{loc}}(\Omega)$ or in the weak topology of $W^{1,2}(\Omega)$ as ε approaches 0. Then a neighborhood of u and a sequence $\{\varepsilon_k\}_{k=1,2,3,\ldots}$ exist such that u_{ε_k} is out of this neighborhood and $0 < \varepsilon_k \le 1/(2k)$ for every k.

The analysis made in section 3.2, while proving Theorem 2.1, shows that every minimizing sequence relative to J contains a subsequence which converges to a minimizer of J both in $L^2_{\mathrm{loc}}(\Omega)$ and in the weak topology of $W^{1,2}(\Omega)$.

Therefore, a minimizer of J exists which is out of some neighborhood of u and thus is different from u.

This is impossible because J is strictly convex, and a strictly convex functional cannot have two different minimizers. □

4. Proof of Theorem 2.3.

4.1. Proof of proposition (i) of Theorem 2.3. The proof is patterned on conventional arguments of the calculus of variations and consists of the three items below.

(i) *Euler–Lagrange equation of J_ε—weak form.* Proposition (v) of Lemma A.1 tells us that

$$\mathbb{R}^2 \ni (p, q) \mapsto n^2 \cdot f_\varepsilon(n^{-1} \cdot \sqrt{p^2 + q^2})$$

is twice continuously differentiable. If ρ and ω are defined by

$$p = n\rho \cdot \cos\omega \quad \text{and} \quad q = n\rho \cdot \sin\omega,$$

then the gradient of the above function equals

$$f'_\varepsilon(\rho) \cdot \begin{bmatrix} \cos\omega \\ \sin\omega \end{bmatrix},$$

and its Hessian matrix, H, is given by

$$H = \begin{bmatrix} \cos\omega & -\sin\omega \\ \sin\omega & \cos\omega \end{bmatrix} \begin{bmatrix} f''_\varepsilon(\rho) & 0 \\ 0 & f'_\varepsilon(\rho)/\rho \end{bmatrix} \begin{bmatrix} \cos\omega & \sin\omega \\ -\sin\omega & \cos\omega \end{bmatrix}. \tag{4.1}$$

Proposition (vi) of Lemma A.1 tells us that the eigenvalues involved obey

$$0 < \text{ eigenvalues } \le \varepsilon^{-\frac{1}{2(1-\varepsilon)}}.$$

Therefore, Taylor's formula gives

$$J_\varepsilon(u+\varphi) - J_\varepsilon(u) = \int_\Omega \frac{n}{|\nabla u|} \cdot f'_\varepsilon\left(\frac{|\nabla u|}{n}\right) \cdot (\nabla u, \nabla\varphi)\ dxdy + \text{ a remainder},$$

$$0 \le 2 \cdot (\text{remainder}) \le \varepsilon^{-\frac{1}{2(1-\varepsilon)}} \int_\Omega |\nabla\varphi|^2\ dxdy$$

provided that u and φ are endowed with square-integrable first-order derivatives. We infer that J_ε is differentiable at every u from its domain, and

$$J'_\varepsilon(u)(\varphi) = \int_\Omega \frac{n}{|\nabla u|} \cdot f'_\varepsilon\left(\frac{|\nabla u|}{n}\right) \cdot (\nabla u, \nabla\varphi)\ dxdy$$

for every φ from $W^{1,2}_0(\Omega)$; in other words,

$$J'_\varepsilon(u) = -\mathrm{div}\left\{ n \cdot f'_\varepsilon\left(\frac{|\nabla u|}{n}\right) \cdot \frac{\nabla u}{|\nabla u|} \right\}$$

in the sense of distributions.

The analysis provided shows that the minimizer of J_ε obeys the equation

$$\mathrm{div}\left\{ n \cdot f'_\varepsilon\left(\frac{|\nabla u|}{n}\right) \cdot \frac{\nabla u}{|\nabla u|} \right\} = 0 \tag{4.2}$$

in the sense of distributions. Thus the *Euler–Lagrange equation* of functional J_ε amounts precisely to (4.2).

(ii) *Extra regularity of extremals.* Now we resort to the hypothesis made on n and claim that, if u is a distributional solution to (4.2) and

$$\nabla u \in L^2_{\mathrm{loc}}(\Omega) \times L^2_{\mathrm{loc}}(\Omega),$$

then u is twice differentiable and its second-order derivatives are in $L^2_{\mathrm{loc}}(\Omega)$.

A proof of such a claim can be outlined in this way.

Let ρ and ω be defined by

$$p = n\rho \cdot \cos\omega \quad \text{and} \quad q = n\rho \cdot \sin\omega,$$

let H be defined as in (4.1), and let either

$$F = [f'_\varepsilon(\rho) - \rho f''_\varepsilon(\rho)] \cdot \frac{\partial n}{\partial x} \cdot \begin{bmatrix} \cos\omega \\ \sin\omega \end{bmatrix}$$

or

$$F = [f'_\varepsilon(\rho) - \rho f''_\varepsilon(\rho)] \cdot \frac{\partial n}{\partial y} \cdot \begin{bmatrix} \cos\omega \\ \sin\omega \end{bmatrix};$$

consider the partial differential equation

$$\operatorname{div}(H \cdot \nabla v) = \operatorname{div} F. \tag{4.3}$$

Proposition (ii) of Lemma 4.1 tells us that certain constants, depending only upon ε, exist such that

$$0 < \text{ Constant } \leq \text{ eigenvalues of } H \leq \text{ Constant},$$

and

$$|F| \leq \text{ Constant} \cdot |\nabla n|.$$

As a consequence, it can be shown that another constant, depending upon ε, exists such that

$$\begin{aligned} &\int_{\{(x,y):\operatorname{dist}((x,y),\mathbb{R}^2\setminus K)\geq r\}} |\nabla v|^2 \, dxdy \\ &\leq \text{ Constant} \cdot \left[\int_K |\nabla n|^2 \, dxdy + r^{-2} \int_K v^2 \, dxdy \right] \end{aligned} \tag{4.4}$$

provided that v is any distributional solution to (4.3), K is a nice compact subset of Ω, and r is a positive number.

Inequality (4.4), which is sometimes referred to as *Caccioppoli's inequality,* plus an appropriate use of finite differences allow one to conclude that, if either

$$v = \partial u/\partial x$$

or

$$v = \partial u/\partial y,$$

then v actually obeys (4.3) in the sense of distributions and

$$\nabla v \in L^2_{\text{loc}}(\Omega) \times L^2_{\text{loc}}(\Omega).$$

Details can be found, e.g., in [17, section 2.1], [22, sections 4.3 and 4.5], [27, seciton 1.10 and 1.11]. The claim is demonstrated.

(iii) *Euler–Lagrange equation of J_ε—strong form.* An appropriate smoothness and appropriate symbols of relevant ingredients having been established, (4.3) can be recast in the following form:

$$\begin{aligned} &\left[f''_\varepsilon(\rho)(\cos\omega)^2 + \frac{f'_\varepsilon(\rho)}{\rho}(\sin\omega)^2 \right] u_{xx} + 2\left[f''_\varepsilon(\rho) - \frac{f'_\varepsilon(\rho)}{\rho} \right] \cos\omega \ \sin\omega \ u_{xy} \\ &+ \left[f''_\varepsilon(\rho)(\sin\omega)^2 + \frac{f'_\varepsilon(\rho)}{\rho}(\cos\omega)^2 \right] u_{yy} + \left[\frac{f'_\varepsilon(\rho)}{\rho} - f''_\varepsilon(\rho) \right] \nabla u \cdot \nabla \log n = 0. \end{aligned} \tag{4.5}$$

As observed in the appendix, (2.1) implies (A.1) and (A.2); these equations give

$$\frac{f'_\varepsilon(\rho)}{\rho} \ : \ \big[(1+\rho^2)(\varepsilon+\rho^2)\big] = \left[\frac{f'_\varepsilon(\rho)}{\rho} - f''_\varepsilon(\rho)\right] \ : \ \rho^2 = (1+\rho^2)^{-\frac{1-2\varepsilon}{2(1-\varepsilon)}}(\varepsilon+\rho^2)^{-\frac{3-2\varepsilon}{2(1-\varepsilon)}}$$

for every nonnegative ρ.

Consequently, (4.5) coincides with (1.15). In other words, (1.15) is another form of the Euler–Lagrange equation for J_ε. □

4.2. Two lemmas. A proof of proposition (ii) of Theorem 2.3 relies upon the following lemmas.

LEMMA 4.1. *Suppose A and B are 2×2 real symmetric matrices. Let A be positive definite, and let*

$$\kappa = \frac{\textit{smaller eigenvalue}}{\textit{larger eigenvalue}},$$

a condition number of A. Then

$$\frac{(\mathrm{tr}AB)^2}{\det A} - 2\cdot\det B \geq \kappa\cdot\mathrm{tr}(B^2). \tag{4.6}$$

(Here tr *and* det *stand for trace and determinant, respectively.)*

Proof. Denote the entries of A and B by a_{ij} and b_{ij}, respectively; let

$$\boldsymbol{M} = \frac{1}{a_{11}a_{22}-a_{12}^2}\begin{bmatrix} a_{11}^2 & \sqrt{2}a_{11}a_{12} & a_{12}^2 \\ \sqrt{2}a_{11}a_{12} & a_{11}a_{22}+a_{12}^2 & \sqrt{2}a_{12}a_{22} \\ a_{12}^2 & \sqrt{2}a_{12}a_{22} & a_{22}^2 \end{bmatrix}$$

and

$$\boldsymbol{m} = \begin{bmatrix} b_{11} \\ \sqrt{2}b_{12} \\ b_{22} \end{bmatrix}.$$

We have

$$\frac{(\mathrm{tr}AB)^2}{\det A} - 2\cdot\det B = (\boldsymbol{M}\boldsymbol{m},\boldsymbol{m}), \quad \mathrm{tr}(B^2) = (\boldsymbol{m},\boldsymbol{m}).$$

An inspection shows that the eigenvalues of $\boldsymbol{M}$ are $1/\kappa, 1, \kappa$. Inequality (4.6) follows. □

LEMMA 4.2. *Let a real-valued function t be defined by*

$$t(\rho) = \tan\left(\frac{1}{2}\arctan\rho\right) \tag{4.7}$$

for every nonnegative ρ, and let a mapping T be defined by

$$T\varphi = t\left(\frac{|\nabla\varphi|}{n}\right)\ \nabla\varphi \tag{4.8}$$

for every φ from a space of sufficiently smooth real-valued functions of x and y. Assume $\nabla(T\varphi)$ stands for the Jacobian matrix of $T\varphi$ and

$$|\nabla(T\varphi)| = \sqrt{\mathrm{tr}\,[(\nabla(T\varphi))(\nabla(T\varphi))^T]},$$

a norm for such a matrix.

(i) *If ρ and ω are defined by $|\nabla\varphi| = n\ \rho$, $\varphi_x : \cos\omega = \varphi_y : \sin\omega$, the following equations hold:*

$$\begin{aligned}\nabla(T\varphi) = &-2\left(\sin\left(\frac{1}{2}\arctan\rho\right)\right)^2 \begin{bmatrix} n_x\cos\omega & n_y\cos\omega \\ n_x\sin\omega & n_y\sin\omega \end{bmatrix} \\ &+ \begin{bmatrix} \cos\omega & -\sin\omega \\ \sin\omega & \cos\omega \end{bmatrix} \begin{bmatrix} 1 & 0 \\ 0 & \frac{1}{2}+\frac{1}{2}(t(\rho))^2 \end{bmatrix} \begin{bmatrix} \cos\omega & \sin\omega \\ -\sin\omega & \cos\omega \end{bmatrix} \\ &\times \frac{|\nabla\varphi|}{\sqrt{n^2+|\nabla\varphi|^2}} \begin{bmatrix} \varphi_{xx} & \varphi_{xy} \\ \varphi_{xy} & \varphi_{yy} \end{bmatrix}, \end{aligned} \tag{4.9}$$

$$\begin{aligned} t\left(\frac{|\nabla\varphi|}{n}\right) &\begin{bmatrix} \varphi_{xx} & \varphi_{xy} \\ \varphi_{xy} & \varphi_{yy} \end{bmatrix} = (t(\rho))^2 \begin{bmatrix} n_x\cos\omega & n_y\cos\omega \\ n_x\sin\omega & n_y\sin\omega \end{bmatrix} \\ &+ \begin{bmatrix} \cos\omega & -\sin\omega \\ \sin\omega & \cos\omega \end{bmatrix} \begin{bmatrix} \frac{1}{2}+\frac{1}{2}(t(\rho))^2 & 0 \\ 0 & 1 \end{bmatrix} \begin{bmatrix} \cos\omega & \sin\omega \\ -\sin\omega & \cos\omega \end{bmatrix} \nabla(T\varphi). \end{aligned} \tag{4.10}$$

(ii) *The following inequalities hold:*

$$|\nabla(T\varphi)| \le |\nabla n| + \frac{|\nabla\varphi|}{\sqrt{n^2+|\nabla\varphi|^2}}\sqrt{\varphi_{xx}^2+2\varphi_{xy}^2+\varphi_{yy}^2}, \tag{4.11}$$

$$\frac{|\nabla\varphi|}{2\sqrt{n^2+|\nabla\varphi|^2}}\sqrt{\varphi_{xx}^2+2\varphi_{xy}^2+\varphi_{yy}^2} \le |\nabla n| + |\nabla(T\varphi)|. \tag{4.12}$$

(iii) *If φ_1 and φ_2 are real-valued and sufficiently smooth, then*

$$|T\varphi_1 - T\varphi_2| \le |\nabla\varphi_1 - \nabla\varphi_2| \tag{4.13}$$

and

$$|\nabla\varphi_1 - \nabla\varphi_2| \le |T\varphi_1 - T\varphi_2|^{\frac{1}{2}} \cdot (4n + |T\varphi_1 - T\varphi_2|)^{\frac{1}{2}}. \tag{4.14}$$

Proof. Equation (4.7) provides us with the properties

$$t(\rho) = \frac{\rho}{1+\sqrt{1+\rho^2}},$$

$$\begin{aligned} t(\rho) = \frac{\rho}{2\sqrt{1+\rho^2}}\left[1+(t(\rho))^2\right], &\quad t(\rho) = \frac{\rho}{2}\left[1-(t(\rho))^2\right], \\ 0 \le t(\rho) < 1, &\quad \frac{\rho}{2\sqrt{1+\rho^2}} \le t(\rho) < \frac{\rho}{\sqrt{1+\rho^2}}, \\ \rho^2 t'(\rho) = 2\left(\sin\left(\frac{1}{2}\arctan\rho\right)\right)^2, &\quad (\rho t(\rho))' = \frac{\rho}{\sqrt{1+\rho^2}}, \end{aligned} \tag{4.15}$$

which hold for every nonnegative ρ and play a role below.

Differentiating both sides of (4.8) gives

$$\nabla(T\varphi) = -\rho^2 t'(\rho) \begin{bmatrix} n_x \cos\omega & n_y \cos\omega \\ n_x \sin\omega & n_y \sin\omega \end{bmatrix}$$

$$+ \begin{bmatrix} \cos\omega & -\sin\omega \\ \sin\omega & \cos\omega \end{bmatrix} \begin{bmatrix} (\rho t(\rho))' & 0 \\ 0 & t(\rho) \end{bmatrix} \begin{bmatrix} \cos\omega & \sin\omega \\ -\sin\omega & \cos\omega \end{bmatrix} \begin{bmatrix} \varphi_{xx} & \varphi_{xy} \\ \varphi_{xy} & \varphi_{yy} \end{bmatrix}.$$

Equation (4.9) follows because of equations that appear in (4.15).

Inequalities (4.11) and (4.12) are easily derived from (4.9) and (4.10), respectively, via some matrix algebra and inequalities that appear in (4.15).

Suppose $\nabla\varphi_1 \neq \nabla\varphi_2$. Define ρ_1 and ρ_2 by

$$|\nabla\varphi_1| = n\ \rho_1 \quad \text{and} \quad |\nabla\varphi_2| = n\ \rho_2,$$

respectively; let θ be the angle between $\nabla\varphi_1$ and $\nabla\varphi_2$, i.e., be such that

$$0 \le \theta \le \pi, \quad |\nabla\varphi_1||\nabla\varphi_2|\ \cos\theta = (\nabla\varphi_1, \nabla\varphi_2).$$

Equation (4.8) gives successively

$$\frac{|T\varphi_1 - T\varphi_2|^2}{|\nabla\varphi_1 - \nabla\varphi_2|^2} = \frac{(\rho_1 t(\rho_1))^2 + (\rho_2 t(\rho_2))^2 - 2\rho_1\rho_2 t(\rho_1)t(\rho_2)\ \cos\theta}{\rho_1^2 + \rho_2^2 - 2\rho_1\rho_2\ \cos\theta}$$

and

$$\frac{\partial}{\partial\theta}\frac{|T\varphi_1 - T\varphi_2|^2}{|\nabla\varphi_1 - \nabla\varphi_2|^2} = -2\rho_1\rho_2 \frac{(t(\rho_1) - t(\rho_2))(\rho_1^2 t(\rho_1) - \rho_2^2 t(\rho_2))}{(\rho_1^2 + \rho_2^2 - 2\rho_1\rho_2\ \cos\theta)^2}\ \sin\theta.$$

We have either $t(\rho_1) \le t(\rho_2)$ and $\rho_1^2 t(\rho_1) \le \rho_2^2 t(\rho_2)$ or $t(\rho_1) > t(\rho_2)$ and $\rho_1^2 t(\rho_1) > \rho_2^2 t(\rho_2)$ since both (4.7) and equations in (4.15) show that t is increasing. We infer successively that

$$\frac{\partial}{\partial\theta}\frac{|T\varphi_1 - T\varphi_2|^2}{|\nabla\varphi_1 - \nabla\varphi_2|^2} \le 0$$

and

$$\frac{\rho_1 t(\rho_1) + \rho_2 t(\rho_2)}{\rho_1 + \rho_2} \le \frac{|T\varphi_1 - T\varphi_2|}{|\nabla\varphi_1 - \nabla\varphi_2|} \le \frac{\rho_1 t(\rho_1) - \rho_2 t(\rho_2)}{\rho_1 - \rho_2}.$$

On the other hand, we have

$$t\left(\frac{\rho_1 + \rho_2}{2}\right) \le \frac{\rho_1 t(\rho_1) + \rho_2 t(\rho_2)}{\rho_1 + \rho_2} \quad \text{and} \quad \frac{\rho_1 t(\rho_1) - \rho_2 t(\rho_2)}{\rho_1 - \rho_2} \le 1$$

since equations in (4.15) show that $0 \le \rho \to \rho t(\rho)$ is convex and contractive. Therefore,

$$t\left(\frac{|\nabla\varphi_1| + |\nabla\varphi_2|}{2n}\right) \le \frac{|T\varphi_1 - T\varphi_2|}{|\nabla\varphi_1 - \nabla\varphi_2|} \le 1.$$

We conclude with (4.13) and the inequality

$$t\left(\frac{|\nabla\varphi_1 - \nabla\varphi_2|}{2n}\right)|\nabla\varphi_1 - \nabla\varphi_2| \le |T\varphi_1 - T\varphi_2|,$$

which leads to (4.14) via algebraic manipulations. □

4.3. Proof of proposition (ii) of Theorem 2.3. Suppose K is a compact subset of Ω whose interior is not empty and whose boundary is sufficiently smooth; let $r > 0$, and define

$$\mathcal{K}(r) = \{(x, y) : \mathrm{dist}((x, y), \mathbb{R}^2 \setminus K) \geq r\}.$$

Let T be as in Lemma 4.2.

The following bounds hold.

Bound 1.

$$\int_{\mathcal{K}(r)} \frac{|\nabla u_\varepsilon|^2}{n^2 + |\nabla u_\varepsilon|^2} \left[\left(\frac{\partial^2 u_\varepsilon}{\partial x^2} \right)^2 + 2 \left(\frac{\partial^2 u_\varepsilon}{\partial x \partial y} \right)^2 + \left(\frac{\partial^2 u_\varepsilon}{\partial y^2} \right)^2 \right] dxdy$$

$$\leq \int_K |\nabla n|^2 \, dxdy + r^{-2} \int_K \left(n^2 + |\nabla u_\varepsilon|^2 \right) \, dxdy. \tag{4.16}$$

Bound 2.

$$\left\{ \int_{\mathcal{K}(r)} |\nabla (T u_\varepsilon)|^2 dxdy \right\}^{\frac{1}{2}}$$

$$\leq 2 \left\{ \int_K |\nabla n|^2 \, dxdy \right\}^{\frac{1}{2}} + r^{-1} \left\{ \int_K \left(n^2 + |\nabla u_\varepsilon|^2 \right) \, dxdy \right\}^{\frac{1}{2}}, \tag{4.17}$$

$$\int_K |T u_\varepsilon|^2 \, dxdy \leq \int_K |\nabla u_\varepsilon|^2 \, dxdy. \tag{4.18}$$

Bound 3. If $p \geq 1$, then

$$\left\{ \int_K |\nabla u_{\varepsilon'} - \nabla u_{\varepsilon''}|^p \, dxdy \right\}^2$$

$$\leq \int_K |T u_{\varepsilon'} - T u_{\varepsilon''}|^p \, dxdy \times \int_K (4n + |T u_{\varepsilon'} - T u_{\varepsilon''}|)^p \, dxdy. \tag{4.19}$$

Bound 4.

$$\int_\Omega |\nabla u_\varepsilon|^2 \, dxdy \leq \text{Constant independent of } \varepsilon. \tag{4.20}$$

Proof of Bound 1. For notational convenience, we temporarily drop the subscript ε and denote u_ε by u in short.

We have shown in proposition (i) of Theorem 2.3 that such a u obeys (1.15). Equation (1.15) implies

$$|a_{11} u_{xx} + 2 a_{12} u_{xy} + a_{22} u_{yy}| \leq n \cdot |\nabla u|^3 \cdot |\nabla n|,$$

where a_{11}, a_{12}, and a_{22} are given by (1.16). Equation (1.16) tells us that, in addition to the inequalities appearing in section 1.4, $[a_{ij}]$ satisfies

$$\frac{\text{smaller eigenvalue}}{\text{larger eigenvalue}} \geq \frac{|\nabla u|^2}{n^2 + |\nabla u|^2}$$

and

$$a_{11}a_{22} - a_{12}^2 \geq n^2 \cdot |\nabla u|^6.$$

Therefore, Lemma 4.1 gives

$$\frac{|\nabla u|^2}{n^2 + |\nabla u|^2} \left(u_{xx}^2 + 2u_{xy}^2 + u_{yy}^2\right) \leq 2\left(u_{xy}^2 - u_{xx}u_{yy}\right) + |\nabla n|^2, \tag{4.21}$$

an instance of what is often called *Bernstein's inequality*—see, e.g., [32].

An inspection shows that $u_{xx}u_{yy} - u_{xy}^2$, the Hessian determinant of u, obeys

$$2\left(u_{xy}^2 - u_{xx}u_{yy}\right) = \operatorname{div} \begin{bmatrix} u_{yy} & -u_{xy} \\ -u_{xy} & u_{xx} \end{bmatrix} \cdot \nabla u; \tag{4.22}$$

equivalently,

$$2\left(u_{xy}^2 - u_{xx}u_{yy}\right) dx \wedge dy = d \begin{vmatrix} u_x & u_y \\ du_x & du_y \end{vmatrix}. \tag{4.23}$$

Inequality (4.21) and either (4.22) or (4.23) give

$$\begin{aligned} &\int_{\mathcal{K}(r)} \frac{|\nabla u|^2}{n^2 + |\nabla u|^2} \left(u_{xx}^2 + 2u_{xy}^2 + u_{yy}^2\right) \, dxdy \\ &\quad \leq \left\{ \int_{\partial\mathcal{K}(r)} \left(n^2 + |\nabla u|^2\right) \sqrt{(dx)^2 + (dy)^2} \right\}^{\frac{1}{2}} \\ &\quad \times \left\{ \int_{\partial\mathcal{K}(r)} \frac{|\nabla u|^2}{n^2 + |\nabla u|^2} \left(u_{xx}^2 + 2u_{xy}^2 + u_{yy}^2\right) \, \sqrt{(dx)^2 + (dy)^2} \right\}^{\frac{1}{2}} \\ &\quad + \int_{\mathcal{K}(r)} |\nabla n|^2 \, dxdy \end{aligned} \tag{4.24}$$

via the Gauss–Green formulas and the Cauchy–Schwarz inequality.

If we define two real-valued functions φ and ψ by

$$\varphi(r) = \int_{\mathcal{K}(r)} \frac{|\nabla u|^2}{n^2 + |\nabla u|^2} \left(u_{xx}^2 + 2u_{xy}^2 + u_{yy}^2\right) \, dxdy - \int_K |\nabla n|^2 \, dxdy$$

and

$$\psi(r) = \int_{\mathcal{K}(r)} \left(n^2 + |\nabla u|^2\right) \, dxdy,$$

then a version of the coarea formula (see, e.g., [34, section 2.7] and the equation

$$|\nabla \operatorname{dist}((x,y), \mathbb{R}^2 \setminus K)| = 1 \text{ for almost every } (x,y) \in K$$

yield

$$-\varphi'(r) = \int_{\partial\mathcal{K}(r)} \frac{|\nabla u|^2}{n^2 + |\nabla u|^2} \left(u_{xx}^2 + 2u_{xy}^2 + u_{yy}^2\right) \, \sqrt{(dx)^2 + (dy)^2}$$

and

$$-\psi'(r) = \int_{\partial\mathcal{K}(r)} \left(n^2 + |\nabla u|^2\right) \sqrt{(dx)^2 + (dy)^2}$$

for almost every positive r. Thus (4.24) yields

$$\varphi(r) \le \sqrt{[-\varphi'(r)]\,[-\psi'(r)]} \tag{4.25}$$

for almost every positive r.

As is easy to see, (4.25) implies

$$\text{positive part of } \varphi(r) \le \left\{ \int_0^r \frac{dt}{[-\psi'(t)]} \right\}^{-1}$$

for every positive r. Since

$$r^2 \le \psi(0) \int_0^r \frac{dt}{[-\psi'(t)]},$$

we conclude that

$$\text{positive part of } \varphi(r) \le r^{-2}\psi(0) \tag{4.26}$$

for every positive r.

The inequality

$$\begin{aligned}\int_{\mathcal{K}(r)} \frac{|\nabla u|^2}{n^2 + |\nabla u|^2} \left[\left(\frac{\partial^2 u}{\partial x^2} \right)^2 + 2 \left(\frac{\partial^2 u}{\partial x \partial y} \right)^2 + \left(\frac{\partial^2 u}{\partial y^2} \right)^2 \right] dxdy \\ \le \int_K |\nabla n|^2 \, dxdy + r^{-2} \int_K \left(n^2 + |\nabla u|^2\right) dxdy\end{aligned}$$

follows from (4.26). Bound 1 is demonstrated.

Proof of Bound 2. Inequality (4.17) follows from Bound 1 and proposition (ii) of Lemma 4.2. Inequality (4.18) follows from proposition (iii) of Lemma 4.2.

Proof of Bound 3. Such a bound follows from proposition (iii) of Lemma 4.2 and the Cauchy–Schwarz inequality.

Proof of Bound 4. The inequalities

$$\frac{\rho^2}{2} + \frac{1}{4}\log(1 + 2\rho^2) \le f_\varepsilon(\rho) \le f(\rho),$$

which hold for every nonnegative ρ and appear in Lemma A.1, tell us that

$$J_\varepsilon \le J$$

and

$$\frac{1}{2} \int_\Omega |\nabla u_\varepsilon|^2 dxdy \le J_\varepsilon(u_\varepsilon).$$

Since

$$J_\varepsilon(u_\varepsilon) = \min J_\varepsilon,$$

we obtain the inequality

$$\frac{1}{2}\int_\Omega |\nabla u_\varepsilon|^2 dxdy \le \min J,$$

which proves (4.20).

Bound 2, Bound 4, and the Rellich–Kondrachov compactness theorem (see, e.g., [1, Chapter VI] or [34, section 2.5]) ensure that a sequence $\{\varepsilon_k\}_{k=1,2,3,\dots}$ exists such that $0 < \varepsilon_k \le 1/2$ for every k, $\varepsilon_k \to 0$ as $k \to \infty$, and

$$\{Tu_{\varepsilon_k}\}_{k=1,2,3,\dots} \text{ converges in } L^p_{\mathrm{loc}}(\Omega) \times L^p_{\mathrm{loc}}(\Omega)$$

for every p larger than or equal to 1. Consequently, Bound 3 ensures that

$$\{\nabla u_{\varepsilon_k}\}_{k=1,2,3,\dots} \text{ converges in } L^p_{\mathrm{loc}}(\Omega) \times L^p_{\mathrm{loc}}(\Omega)$$

for every p larger than or equal to 1. We now profit by a Sobolev inequality (see, e.g., [1, Chapter V] or [34, section 2.4] and infer that if K is any compact subset of Ω and

$$m_k = (\text{measure of } K)^{-1} \cdot \int_K u_{\varepsilon_k} dxdy,$$

then

$$\{u_{\varepsilon_k} - m_k\}_{k=1,2,3,\dots}$$

converges uniformly in K.

Applying proposition (ii) of Theorem 2.2 leads to the conclusion. □

4.4. Proof of proposition (iii) of Theorem 2.3. Proposition (ii) of Theorem 2.3, proposition (iii) of Lemma 4.2, and Bounds 2 and 4 (appearing in the preceding subsection) show that

$$\{\nabla(Tu_\varepsilon)\}_{k=1,2,3,\dots} \text{ converges weakly in } \left(L^2_{\mathrm{loc}}(\Omega)\right)^4 \tag{4.27}$$

as ε approaches 0.

Having (4.27) in hand, we are in a position to resume a former notation, u, and to establish the ultimate properties of u.

(i) *Second-order derivatives.* Previous ingredients, which include proposition (ii) of Theorem 2.3, Bound 2, and (4.27), guarantee that Tu is differentiable and obeys

$$\begin{aligned} &\left\{\int_{\{(x,y):\mathrm{dist}((x,y),\mathbb{R}^2\setminus K)\ge r\}} |\nabla Tu|^2 dxdy\right\}^{\frac{1}{2}} \\ &\le 2\left\{\int_K |\nabla n|^2 dxdy\right\}^{\frac{1}{2}} + r^{-1}\left\{\int_K \left(n^2 + |\nabla u|^2\right) dxdy\right\}^{\frac{1}{2}} \end{aligned} \tag{4.28}$$

if K is a nice compact subset of Ω and $r > 0$. Propositions (i) and (ii) of Lemma 4.2 and inequality (4.28) show that u is twice differentiable and obeys (2.3).

(ii) *Differential equation.* The underlying idea is recasting both (1.5) and (1.15) in a form in which second-order derivatives of u are replaced by the entries of $\nabla(Tu)$ and then letting ε approach zero. Details follow.

Combining proposition (i) of Lemma 4.2 and the identity

$$|\nabla\varphi|^2\cdot\nabla\left\{n\cdot f_\varepsilon'\left(\frac{|\nabla\varphi|}{n}\right)\cdot\frac{\nabla\varphi}{|\nabla\varphi|}\right\}=n\rho^2[f_\varepsilon'(\rho)/\rho-f_\varepsilon''(\rho)]\begin{bmatrix}n_x\varphi_x & n_y\varphi_x\\ n_x\varphi_y & n_y\varphi_y\end{bmatrix}$$
$$+\begin{bmatrix}\varphi_x & -\varphi_y\\ \varphi_y & \varphi_x\end{bmatrix}\begin{bmatrix}f_\varepsilon''(\rho) & 0\\ 0 & f_\varepsilon'(\rho)/\rho\end{bmatrix}\begin{bmatrix}\varphi_x & \varphi_y\\ -\varphi_y & \varphi_x\end{bmatrix}\begin{bmatrix}\varphi_{xx} & \varphi_{xy}\\ \varphi_{xy} & \varphi_{yy}\end{bmatrix}$$

results in

$$\frac{|\nabla\varphi|^3}{\sqrt{n^2+|\nabla\varphi|^2}}\cdot\nabla\left\{n\cdot f_\varepsilon'\left(\frac{|\nabla\varphi|}{n}\right)\cdot\frac{\nabla\varphi}{|\nabla\varphi|}\right\}$$
$$=n\rho^2t(\rho)\left\{\frac{2f_\varepsilon'(\rho)/\rho}{1+(t(\rho))^2}-f_\varepsilon''(\rho)\right\}\begin{bmatrix}n_x\varphi_x & n_y\varphi_x\\ n_x\varphi_y & n_y\varphi_y\end{bmatrix}$$
$$+\begin{bmatrix}\varphi_x & -\varphi_y\\ \varphi_y & \varphi_x\end{bmatrix}\begin{bmatrix}f_\varepsilon''(\rho) & 0\\ 0 & \frac{2f_\varepsilon'(\rho)/\rho}{1+(t(\rho))^2}\end{bmatrix}\begin{bmatrix}\varphi_x & \varphi_y\\ -\varphi_y & \varphi_x\end{bmatrix}\nabla(T\varphi);\tag{4.29}$$

here φ stands for any sufficiently smooth real-valued function, $\rho=|\nabla\varphi|:n$, and t is given by (4.7).

As observed in the proof of Lemma A.1, (2.1) implies

$$\frac{\rho f_\varepsilon''(\rho)}{f_\varepsilon'(\rho)}=1-\frac{\rho^2}{(1+\rho^2)(\varepsilon+\rho^2)}$$

for every nonnegative ρ. Therefore,

$$0<\rho\cdot\left[\frac{\rho f_\varepsilon''(\rho)}{f_\varepsilon'(\rho)}-\frac{\rho^2}{1+\rho^2}\right]\le\frac{\sqrt{\varepsilon}}{2}\tag{4.30}$$

for every nonnegative ρ. In other words, $\rho^2f_\varepsilon''(\rho)/f_\varepsilon'(\rho)$ converges to $\rho^3/(1+\rho^2)$ *uniformly* with respect to ρ as ε approaches 0.

Mimicking the proof of proposition (iii) of Lemma 4.2 shows that

$$\left|\frac{n}{\sqrt{n^2+|\nabla u_\varepsilon|^2}}\,\nabla u_\varepsilon-\frac{n}{\sqrt{n^2+|\nabla u|^2}}\,\nabla u\right|\le|\nabla u_\varepsilon-\nabla u|.\tag{4.31}$$

Proposition (ii) of Theorem 2.3, (4.27), (4.29), and inequalities (4.30) and (4.31) enable us to conclude that

$$\frac{n^{-4}|\nabla u_\varepsilon|^4}{[1+n^{-2}|\nabla u_\varepsilon|^2]^{3/2}}\cdot\frac{|\nabla u_\varepsilon|}{f_\varepsilon'\left(n^{-1}|\nabla u_\varepsilon|\right)}\cdot\operatorname{div}\left\{n\cdot f_\varepsilon'\left(\frac{|\nabla u_\varepsilon|}{n}\right)\cdot\frac{\nabla u_\varepsilon}{|\nabla u_\varepsilon|}\right\}\tag{4.32}$$

approaches

$$\frac{|\nabla u|}{n^2+|\nabla u|^2}\cdot\operatorname{tr}\left\{n\rho^2t(\rho)\left[\frac{2}{1+(t(\rho))^2}-\frac{\rho^2}{1+\rho^2}\right]\begin{bmatrix}n_xu_x & n_yu_x\\ n_xu_y & n_yu_y\end{bmatrix}\right.$$
$$\left.+\begin{bmatrix}u_x & -u_y\\ u_y & u_x\end{bmatrix}\begin{bmatrix}\frac{\rho^2}{1+\rho^2} & 0\\ 0 & \frac{2}{1+(t(\rho))^2}\end{bmatrix}\begin{bmatrix}u_x & u_y\\ -u_y & u_x\end{bmatrix}\nabla(Tu)\right\}\tag{4.33}$$

in $L^1_{\mathrm{loc}}(\Omega)$ as ε approaches 0.

If expression (4.33) is named A and

$$U = \text{l.h.s. of (1.5)},$$

then (4.7) and (4.8) cause the following equation to hold:

$$A = |\nabla u|^2 \times (n^2 + |\nabla u|^2)^{-\frac{5}{2}} \times U.$$

Proposition (i) of Theorem 2.3 implies (4.2); hence expression (4.32) is zero. We infer

$$A = 0.$$

Now we let

$$B = (n^2 + |\nabla u|^2)^{-\frac{3}{2}} \times U$$

and claim that

$$B = 0.$$

In fact, if

$$C = \sqrt{2} \cdot |\nabla u| \cdot \sqrt{u_{xx}^2 + 2u_{xy}^2 + u_{yy}^2} + n \cdot |\nabla n|,$$

then inequality (2.3) informs us that C is locally integrable. We have

$$|B| \le \frac{|\nabla u|}{\sqrt{n^2 + |\nabla u|^2}} \times C$$

because of the Cauchy–Schwarz inequality; moreover,

$$A = \frac{|\nabla u|^2}{n^2 + |\nabla u|^2} \times B.$$

Thus A is locally integrable, irrespective of whether it is zero or not; B is locally integrable too, and the following inequality holds:

$$|B| \le |A|^{1/3} \cdot |C|^{2/3},$$

which proves the claim.

Equation (1.5) follows. The proof of Theorem 2.3 is complete. □

5. Remarks on viscosity solutions.

THEOREM 5.1. *A viscosity solution to* (1.5) *is uniquely determined by its boundary values. A smooth solution to* (1.5) *need not be uniquely determined by its boundary values.*

Proof. Theorems 2.2 and 2.3 demonstrate the following property: any viscosity solution to (1.5) which takes the relevant boundary values minimizes the functional J. The former assertion results. The latter results via the analysis of an ad hoc example, as shown below.

Suppose $n \equiv 1$ and u is given by (1.6). (For the sake of brevity, we denote the domain of u by Ω.) Arguments from [26, section 2.2] tell us the following. First, u is a smooth solution to (1.5). Second,

$$-\operatorname{div}\left(\sqrt{1 + |\nabla u|^2}\, \frac{\nabla u}{|\nabla u|}\right)$$

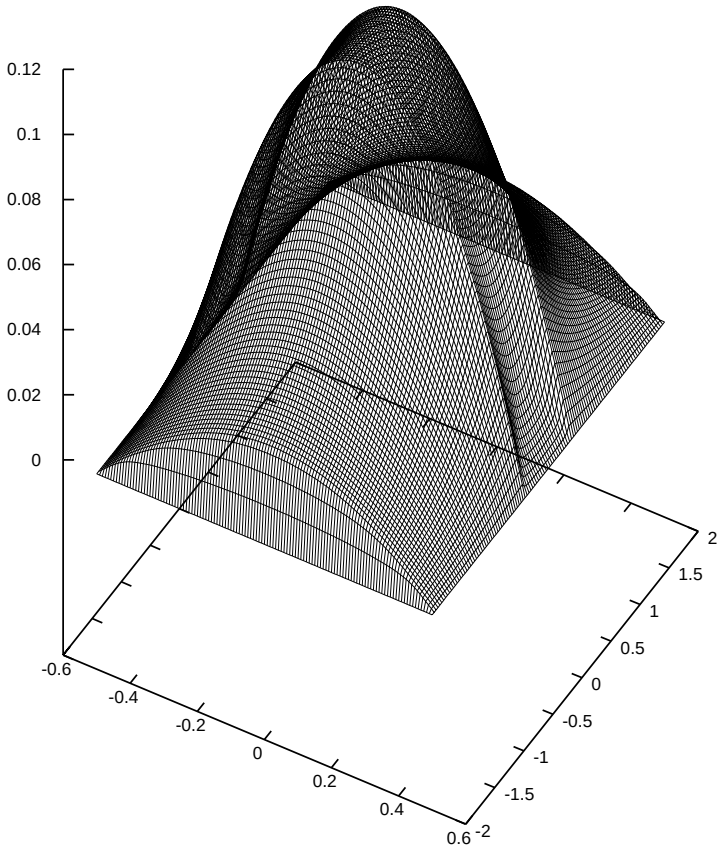

FIG. 5.1. *A plot of the difference between function u given by* (1.6) *and a viscosity solution to* (1.5) *that takes the same boundary values as u.*

equals

$$C_0^\infty(\Omega) \ni \varphi \mapsto 2\int_{-\infty}^{\infty} \varphi(0,y)dy$$

in the sense of distributions. The latter statement informs us that, provided that the domain of J is adjusted as $u + W_0^{1,2}(\Omega)$, the subdifferential of J at u consists of a nonzero measure supported by the y-axis. Therefore, u does not minimize J. It follows that u is not a viscosity solution to (1.5). In other words, u obeys (1.5) but differs from the viscosity solution to (1.5) which is defined in Ω and equals u on $\partial\Omega$. □

Figure 5.1 helps one to visualize the proof above. It displays the difference between the function u given by (1.6) and the viscosity solution to (1.5) that is defined in $]-\frac{1}{2},\frac{1}{2}[\times]-2,2[$ and takes the same values of u on the boundary of such a rectangle. As a matter of fact, such a viscosity solution has been approximated by the solution u_ε to (1.15) with $\varepsilon = 10^{-8}$. Observe the scale in Figure 5.1; we stress that the difference between the u_ε's with $\varepsilon = 10^{-8}$ and $\varepsilon = 10^{-4}$ has order of magnitude 10^{-9}.

Appendix. The following lemma, which analyzes (2.1) closely, is instrumental in proving Theorem 2.2 and proposition (i) of Theorem 2.3.

LEMMA A.1. (i) *f_ε is nonnegative, vanishes only at 0, and is strictly increasing and strictly convex.*

(ii) $$\rho\,\frac{1+\rho^2}{1/2+\rho^2} \le f_\varepsilon'(\rho) \le f'(\rho),$$

and

$$\frac{\rho^2}{2}+\frac{1}{4}\log(1+2\rho^2) \le f_\varepsilon(\rho) \le f(\rho)$$

for every nonnegative ρ.

(iii) *If C_ε is defined by*

$$2C_\varepsilon = \varepsilon^{\frac{1-2\varepsilon}{2(1-\varepsilon)}} + \log(1+\sqrt{\varepsilon}) - \varepsilon - \frac{1}{2}\int_\varepsilon^1 \frac{t^{-\frac{1}{2(1-\varepsilon)}}-\sqrt{t}}{1-t}\,dt,$$

then

$$f_\varepsilon(\rho) = f(\rho) - C_\varepsilon + O(\rho^{-2})$$

as $\rho\to\infty$.

(iv) *f_ε converges uniformly to f on $[0,\infty[$ as ε approaches zero. In effect,*

$$\sup\{|f(\rho)-f_\varepsilon(\rho)| : 0\le\rho<\infty\} = O(\sqrt{\varepsilon}).$$

(v) *f_ε' has a zero of multiplicity one at 0. In effect,*

$$f_\varepsilon'(\rho) = \varepsilon^{-\frac{1}{2(1-\varepsilon)}}\cdot\rho\cdot\left[1-\frac{1}{2\varepsilon}\rho^2+\frac{3+2\varepsilon}{8\varepsilon^2}\rho^4-\frac{15+14\varepsilon+8\varepsilon^2}{48\varepsilon^3}\rho^6+\cdots\right]$$

if $0\le\rho<\sqrt{\varepsilon}$.

(vi) $$\frac{f_\varepsilon'(\rho)}{\rho} < \varepsilon^{-\frac{1}{2(1-\varepsilon)}}$$

and

$$f_\varepsilon''(\rho) < \frac{f_\varepsilon'(\rho)}{\rho}$$

if $\rho>0$;

$$f_\varepsilon''(\rho) \ge \frac{4\varepsilon^{\frac{1-2\varepsilon}{4(1-\varepsilon)}}\,\left[4+\sqrt{\varepsilon(12+\varepsilon)}+\varepsilon\right]}{\left[2+\sqrt{\varepsilon(12+\varepsilon)}+\varepsilon\right]^{\frac{1-2\varepsilon}{2(1-\varepsilon)}}\,\left[\sqrt{12+\varepsilon}+3\sqrt{\varepsilon}\right]^{\frac{3-2\varepsilon}{2(1-\varepsilon)}}}$$

and

$$f_\varepsilon'(\rho)-\rho f_\varepsilon''(\rho) \le \frac{\sqrt{2}\;\varepsilon^{-\frac{\varepsilon}{4(1-\varepsilon)}}\,\left[\sqrt{12+\varepsilon}+\sqrt{\varepsilon}\right]^{\frac{3}{2}}}{\left[2+\sqrt{\varepsilon(12+\varepsilon)}+\varepsilon\right]^{\frac{1-2\varepsilon}{2(1-\varepsilon)}}\left[\sqrt{12+\varepsilon}+3\sqrt{\varepsilon}\right]^{\frac{3-2\varepsilon}{2(1-\varepsilon)}}}$$

if $\rho\ge 0$.

Proof. Equation (2.1) gives successively $f_\varepsilon(0)=0$, and

(A.1) $$f_\varepsilon'(\rho) = \rho\left(\frac{1+\rho^2}{\varepsilon+\rho^2}\right)^{\frac{1}{2(1-\varepsilon)}},$$

$$f_\varepsilon''(\rho) = (1+\rho^2)^{-\frac{1-2\varepsilon}{2(1-\varepsilon)}}(\varepsilon+\rho^2)^{-\frac{3-2\varepsilon}{2(1-\varepsilon)}}(\rho^4+\varepsilon\rho^2+\varepsilon) \tag{A.2}$$

for every nonnegative ρ. Thus $f_\varepsilon'(\rho)$ equals zero if ρ equals zero and is positive if ρ is positive; $f_\varepsilon''(\rho)$ is positive if ρ is nonnegative. Proposition (i) follows.

Equation (A.1) yields

$$\frac{\partial}{\partial\varepsilon}\log f_\varepsilon'(\rho) = \frac{1}{2(1-\varepsilon)^2}\left[\log\left(1+\frac{1-\varepsilon}{\varepsilon+\rho^2}\right) - \frac{1-\varepsilon}{\varepsilon+\rho^2}\right];$$

hence

$$\frac{\partial}{\partial\varepsilon}f_\varepsilon'(\rho) < 0$$

for every positive ρ. In other words, $\varepsilon \mapsto f_\varepsilon'(\rho)$ *decreases* if $\rho > 0$. Since the range of ε is $]0, 1/2]$, proposition (ii) follows. (Incidentally, one might also show that $\varepsilon \mapsto f_\varepsilon'(\rho)$ is *log-convex* for every positive ρ. Observe also that the difference between the r.h.s. and the l.h.s. of the second inequality in (ii) increases as ρ increases from 0 to ∞, approaches $(1+\log 2)/4$ as ρ approaches ∞, and thus is smaller than $0.423286\ldots$.)

Equation (2.1) reads

$$2f_\varepsilon(\rho) = (1-\varepsilon)\int_\varepsilon^{(\varepsilon+\rho^2)/(1+\rho^2)} \frac{t^{\frac{1}{2(1-\varepsilon)}}}{(1-t)^2}\,dt.$$

Integrations by parts and manipulations give

$$2f_\varepsilon(\rho) = (1+\rho^2)^{\frac{1}{2(1-\varepsilon)}}(\varepsilon+\rho^2)^{\frac{1-2\varepsilon}{2(1-\varepsilon)}} - \varepsilon^{\frac{1-2\varepsilon}{2(1-\varepsilon)}}$$

$$+\log\frac{\sqrt{1+\rho^2}+\sqrt{\varepsilon+\rho^2}}{1+\sqrt{\varepsilon}} + \frac{1}{2}\int_\varepsilon^{(\varepsilon+\rho^2)/(1+\rho^2)} \frac{t^{-\frac{1}{2(1-\varepsilon)}} - t^{-\frac{1}{2}}}{1-t}\,dt$$

for every nonnegative ρ. Proposition (iii) follows.

Proposition (ii) ensures that $f - f_\varepsilon$ is nonnegative and increasing, and proposition (iii) ensures that $f(\rho) - f_\varepsilon(\rho)$ approaches C_ε as $\rho \to \infty$. Hence

$$\sup\{|f(\rho) - f_\varepsilon(\rho)| : 0 \le \rho < \infty\} = C_\varepsilon.$$

Proposition (iv) follows.

Proposition (v) follows from manipulations of (A.1).

Equation (A.1) tells us that $f_\varepsilon'(\rho)/\rho$ decreases strictly from $\varepsilon^{-1/(2(1-\varepsilon))}$ to 1 as ρ increases from 0 to ∞. Equations (A.1) and (A.2) imply that

$$\frac{\rho f_\varepsilon''(\rho)}{f_\varepsilon'(\rho)} = 1 - \frac{\rho^2}{(1+\rho^2)(\varepsilon+\rho^2)}$$

if $\rho > 0$ and

$$f_\varepsilon'''(\rho) = (1+\rho^2)^{-\frac{3-4\varepsilon}{2(1-\varepsilon)}}(\varepsilon+\rho^2)^{-\frac{5-4\varepsilon}{2(1-\varepsilon)}}\rho(\rho^4-\varepsilon\rho^2-3\varepsilon)$$

if $\rho \ge 0$. Therefore, $f_\varepsilon''(\rho)$ is less than $f_\varepsilon'(\rho)/\rho$ if ρ is positive; if $\rho = 0$, then $f_\varepsilon'''(\rho)$ and $f_\varepsilon'(\rho) - \rho f_\varepsilon'''(\rho)$ are an absolute maximum and an absolute minimum, respectively; if

$$\rho = \sqrt{\varepsilon/2 + \sqrt{3\varepsilon+\varepsilon^2/4}},$$

then $f_\varepsilon'''(\rho)$ and $f_\varepsilon'(\rho) - \rho f_\varepsilon'''(\rho)$ are an absolute minimum and an absolute maximum, respectively. Proposition (vi) follows. □

NONLINEAR WAVES IN NETWORKS OF NEURONS WITH DELAYED FEEDBACK: PATTERN FORMATION AND CONTINUATION*

LIHONG HUANG† AND JIANHONG WU‡

Abstract. An on-center off-surround network of three identical neurons with delayed feedback is considered, and the effect of synaptic delay of signal transmission on the pattern formation and global continuation of nonlinear waves is described. The spontaneous bifurcation of multiple branches of periodic solutions is discussed, and their spatio-temporal patterns and mode interactions are studied by using the symmetric bifurcation theory of delay differential equations coupled with representation theory of standard dihedral groups, Liapunov's direct method, LaSalle's invariance principle, a priori estimates, and differential inequalities.

Key words. wave, neural network, delay, bifurcation, global continuation

1. Introduction.

We consider the system of delay differential equations

$$\epsilon\dot{x}_j = -x_j(t) + h(x_j(t-1)) - [g(x_{j-1}(t-1)) + g(x_{j+1}(t-1)) - 2g(x_j(t-1))], \tag{1.1}$$

where $j = 1, 2, 3 (\mathrm{mod}\ 3), \epsilon = \tau^{-1} > 0, \dot{x}_j(t) = \frac{d}{dt}x_j(t), h, g \in C^2(\mathbb{R};\mathbb{R})$ with $h(0) = g(0) = 0$, or, equivalently, we consider

$$\dot{x}_j(t) = -x_j(t) + f(x_j(t-\tau)) - [g(x_{j-1}(t-\tau)) + g(x_{j+1}(t-\tau))] \tag{1.2}$$

with $f = h + 2g$ and $\tau = \epsilon^{-1} > 0$.

Such a system models the evolution of a network of three identical neurons with delayed feedback. There are several reasons why we are particularly interested in such a system. First, if h and g are monotonically increasing, then the network modeled by (1.2) has the property that the self-feedback is excitatory (positive) and the feedback from other neurons is inhibitory (negative). This property is called the on-center off-surround characteristic of a network, and such networks have been found in a variety of neural structures such as neocortex [1], cerebellum [2], and hippocampus [3]. The network described by system (1.2) is of the minimal size among all possible networks with such an on-center off-surround characteristic, and examples of a network of three neurons include the basic rhythm generating circuits of central

pattern generators [4, 5] and the canonical cortical circuit proposed in [1, 6]. See also [7] for the motivation of the study of small neural populations. Second, much progress has been made for the theory of dynamics (and, in particular, for the local bifurcation and global continuation of periodic solutions) of scalar delay differential equations (see, for example, [8, 9, 10]), and it is natural to see how the results and methods for scalar delay differential equations can be extended to systems of delay differential equations. Some progress has been made in this direction for a network of two neurons without self-feedback and with delayed interaction (see, for example, [11, 12, 13, 14]). An important factor to the progress in [11, 12, 13] is the fact that such a system can be changed to the so-called unidirectional cyclic system of delay differential equations to which the recently developed powerful theory of Mallet-Paret and Sell [15, 16] and the geometric method developed in [17] can be applied. System (1.2), however, is bidirectional in the sense that the growth rate for the ith cell (component) depends on the feedback from the $(i-1)$th and $(i+1)$th cells, and *both* with a delay. We hope this detailed case study can provide motivation for a more general geometric theory for the global dynamics of bidirectional cyclic systems of delay differential equations. Third, we would like to use this detailed case study to demonstrate how systems with time delay can be used for coupled oscillators. In particular, we note that, in the classical work (see [18] for references), for a ring of cells coupled by diffusion along the sides of a polygon, it was observed that if the coupling is instantaneous, then Hopf bifurcations occur only when the state of each cell is described by at least two variables, and our case study here provides an example in which a ring of cells coupled by delayed nonlinear diffusion exhibits multiple symmetric Hopf bifurcations even when the state of each cell is described by a single variable.

According to the Cohen–Grossberg–Hopfield convergence theorem [19, 20], under standard assumptions on the sigmoid signal functions h and g and if $\tau = 0$, then every solution of system (1.2) is convergent to the set of equilibria. Such a convergence has important applications to a number of areas such as content addressable memory and pattern identification. On the other hand, it was observed in [21] and later confirmed in a number of papers (see [14, 22, 23] and references therein) that large delay may cause nonlinear oscillations in the network. Most of these nonlinear oscillations appear in the form of periodic solutions with certain spatio-temporal structures and, if stable under small perturbation, may represent memory of the network to be stored and retrieved. Therefore, it is important to discuss the spatio-temporal patterns of these periodic solutions and to describe the mode interaction along multiple branches of such periodic solutions.

Needless to say, this is a very difficult task due to the infinite-dimensional nature of the problem caused by the synaptic delay and the possible spatial structure of the system (equivariant with respect to a D_3-action). Some general theorems are available about the existence and global continuation of periodic solutions in symmetric delay differential equations; see [23] for local bifurcation and [24] for global continuation. However, applications of these general results to concrete systems such as (1.1) involve several highly nontrivial tasks: (i) distribution of zeros in characteristic equations which are usually transcendental and depend on parameters; (ii) symmetry analysis on certain generalized eigenspaces of the generator of a linearized system and identification of these spaces with a direct sum of two identical absolute irreducible representations of D_3; (iii) calculation of the so-called crossing numbers which are related to the usual transversality condition in a standard Hopf bifurcation theory (see section 2 for details); (iv) a priori estimation of the period and of the norm of a

periodic solution.

In this paper, we show the following:

(a) The model equation (1.1) is equivariant with respect to a D_3-action.
(b) There exists a sequence of critical values $\{\tau_k\}$ at which the linearization of (1.1) at the zero solution has a pair of purely imaginary eigenvalues.
(c) The generalized eigenspace of the above eigenvalues is four-dimensional and is the direct sum of two identical absolutely irreducible representations of D_3.
(d) Near each τ_k, there exist eight branches of periodic solutions, two of which are phase-locked, three are standing waves, and three are mirror-reflecting waves.
(e) These bifurcations of periodic solutions exist for all $\tau > \tau_k$ (global continuation); the branches of mirror-reflecting waves and the branches of phase-locked oscillations do not coincide, but coincidence of some branches of mirror-reflecting waves and some branches of standing waves may occur through periodic doubling.

The local bifurcation and the asymptotic forms of the aforementioned waves will be described in section 2, and their global continuation will be studied in section 3.

2. The local existence and asymptotic forms of waves. We start by stating a general result due to [23]. Let C denote the Banach space of continuous mappings from $[-1, 0]$ into $\mathbb{R}^n$ equipped with the supremum norm $||\phi|| = \sup_{-1\le\theta\le 0} |\phi(\theta)|$ for $\phi \in C$. In what follows, if $\sigma \in \mathbb{R}$, $A \ge 0$, and $x : [\sigma - 1, \sigma + A] \to \mathbb{R}^n$ is a continuous mapping, then $x_t \in C$, $t \in [\sigma, \sigma + A]$, is defined by $x_t(\theta) = x(t + \theta)$ for $-1 \le \theta \le 0$.

Suppose that $F : C \to \mathbb{R}^n$ is C^2-smooth with $F(0) = 0$. Consider the delay differential equation

$$\dot{x}(t) = \tau F(x_t),$$

where $\tau > 0$. Let $L\phi = DF(0)\phi$ with $\phi \in C$. It is well known that the linear system

$$\dot{x}(t) = \tau L x_t$$

generates a strongly continuous semigroup of linear operators with an infinitesimal generator $A(\tau)$. Moreover, the spectrum $\sigma(A(\tau))$ of $A(\tau)$ consists of eigenvalues which are solutions of the characteristic equation

$$\det \Delta(\tau, \lambda) = 0, \quad \lambda \in \mathbb{C},$$

where $\mathbb{C}$ is the set of all complex numbers, and the characteristic matrix $\Delta(\tau, \lambda)$ is given by

$$\Delta(\tau, \lambda) = \lambda I_n - \tau L(e^{\lambda \cdot} I_n),$$

where I_n is the identity matrix on $\mathbb{C}^n$, $e^{\lambda \cdot} z$ is the mapping from $[-1, 0]$ into $\mathbb{C}^n$ given by $e^{\lambda \cdot} z(\theta) = e^{\lambda\theta} z$ for $z \in \mathbb{C}^n$ and $\theta \in [-1, 0]$, and $L(e^{\lambda \cdot} I_n) = (L(e^{\lambda \cdot} e_1), \dots, L(e^{\lambda \cdot} e_n))$ with $(e_1, \dots, e_n)$ being the standard basis of $\mathbb{R}^n$ and $L(e^{\lambda \cdot} e_j)$ the image of $e^{\lambda \cdot} e_j$ under the complexification of the linear mapping L for each $j = 1, \dots, n$.

We assume the following.

(G1) The characteristic matrix is continuously differentiable in $\tau \in (0, \infty)$, and there exist $\tau_0 \in (0, \infty)$ and $\beta_0 > 0$ such that (i) $A(\tau_0)$ has eigenvalues $\pm i\beta_0$; (ii) the generalized eigenspace, denoted by $U_{(i\beta_0, -i\beta)}(A(\tau_0))$, of these eigenvalues $\pm i\beta_0$

consists of only eigenvectors of $A(\tau_0)$ associated with $\pm i\beta_0$; (iii) all other eigenvalues of $A(\tau_0)$ are not integer multiples of $\pm i\beta_0$.

To state the next assumption that describes the possible (spatial) symmetry of the system considered, we need to introduce some group-theoretic preliminaries. We refer to [18, 25] for more details.

In what follows, by a (compact) Lie group Γ, we mean a closed subgroup of $GL(\mathbb{R}^n)$, the group of all invertible linear transformations of the vector space $\mathbb{R}^n$ into itself. Note that the space of $n\times n$ matrices may be identified with $\mathbb{R}^{n^2}$, which contains $GL(\mathbb{R}^n)$ as an open subset. We say that Γ is a closed subgroup of $GL(\mathbb{R}^n)$ if it is a closed subset of $GL(\mathbb{R}^n)$ as well as a subgroup of $GL(\mathbb{R}^n)$. A specific example of a Lie group is the special orthogonal group $SO(n)$ that consists of all $n \times n$ matrices A such that $AA^T = I_n$ and $\det A = 1$, where A^T is the transpose of A. In particular, $SO(2)$ consists precisely of the planar rotations

$$R_\theta = \begin{pmatrix} \cos\theta & -\sin\theta \\ \sin\theta & \cos\theta \end{pmatrix}.$$

In this way, $SO(2)$ may be identified with the circle group S^1, the identification being $R_\theta \to e^{i\theta}$. Two other Lie groups will be used in this paper. The first is Z_n, the cyclic group of order n. (The order of a finite group is the number of elements that it contains.) The second is the dihedral group D_n of order $2n$ that is generated by Z_n together with an element (called the flip) of order 2 that does not communicate with Z_n.

Let V be a topological vector space over the field of complex numbers $\mathbb{C}$ or the field of real numbers $\mathbb{R}$, and let $GL(V)$ be the group of isomorphisms of V onto itself. We say that a compact Lie group Γ acts on V if there is a continuous mapping $\Gamma \times V \ni (\gamma, v) \mapsto \gamma \cdot v \in V$ such that (a) for each $\gamma \in \Gamma$, the mapping $\rho_\gamma : V \to V$ given by $\rho_\gamma(v) = \gamma \cdot v$ is linear; (b) if $\gamma_1, \gamma_2 \in \Gamma$, then $\gamma_1 \cdot (\gamma_2 \cdot v) = (\gamma_1\gamma_2) \cdot v$. The mapping that sends $\gamma \in \Gamma$ to $\rho_\gamma \in GL(V)$ is called a representation of Γ on V. In what follows, we shall write γv for $\gamma \cdot v$ for all $\gamma \in \Gamma$ and $v \in V$.

If Γ acts on both V and W and if there is a linear isomorphism $A : V \to W$ such that $A(\gamma v) = \gamma(Av)$ for all $v \in V$ and $\gamma \in \Gamma$, then we say the Γ actions on V and W are isomorphic, and such a linear isomorphism is called a Γ-isomorphism.

Let Γ act on V, and let W be a subspace of V. We say that W is Γ-invariant if $\gamma w \in W$ for every $\gamma \in \Gamma$ and $w \in W$. We thus obtain a Γ-action on W called the restricted action of Γ on W.

Finally, if Γ acts on V, we say a linear mapping $F : V \to V$ is Γ-equivariant if $F(\gamma v) = \gamma F(v)$ for all $\gamma \in \Gamma$ and $v \in V$. A representation of Γ on V is absolutely irreducible if the only linear mappings on V that are Γ-equivariant are scalar multiples of the identity. A Γ-invariant subspace W of V is Γ-irreducible if the only invariant subspaces of W are $\{0\}$ and W. It is known that up to a Γ-isomorphism there are only a finite number of distinct Γ-irreducible subspaces, denoted by $U_1, \dots, U_s$. If we define W_k as the sum of all Γ-irreducible subspaces of V that are Γ-isomorphic to U_k, then $V = W_1 \oplus \cdots W_s$, and this is called an isotypical decomposition of V. In the case in which $\Gamma = Z_N$ and $V = \mathbb{C}^n$ for two fixed positive integers n and N, every irreducible subspace must be one-dimensional, and the restricted action of Γ to any such irreducible subspace is Γ-isomorphic to the Γ-action on $\mathbb{C}$ defined by $\rho \cdot z = \rho^j z$ for some nonnegative integer j and for all $z \in \mathbb{C}$, where ρ is the generator of $Z_N \le S^1$.

With this short introduction to group-theoretic preliminaries, we can now state the next set of assumptions.

(G2) There exists a compact Lie group Γ acting on $\mathbb{R}^n$ such that F is Γ-equivariant; i.e., $F(\gamma\phi) = \gamma F(\phi)$ for $(\gamma, \phi) \in \Gamma \times C$, where $\gamma\phi \in C$ is given by $(\gamma\phi)(\theta) = \gamma\phi(\theta),\ \theta \in [-1, 0]$.

Note that the real Γ-action on $\mathbb{R}^n$ can be naturally extended to a Γ-action on $\mathbb{C}^n$ by

$$\gamma(u + iv) = \gamma u + i\gamma v, \qquad \gamma \in \Gamma, u, v \in \mathbb{R}^n.$$

This action is called the complexification of the Γ-action on $\mathbb{R}^n$. In what follows, we will simply call the complexification of Γ on $\mathbb{C}^n$ the Γ-action on $\mathbb{C}^n$. Due to the Γ-equivariance of F, we can easily show that $\mathrm{Ker}\Delta(\tau_0, i\beta_0)$ is an invariant subspace of $\mathbb{C}^n$ with respect to the complexification of the Γ-action on $\mathbb{R}^n$. We need the following assumption.

(G3) There exists a real m-dimensional absolutely irreducible representation of Γ on V such that the restricted action of Γ on $\mathrm{Ker}\Delta(\tau_0, i\beta_0)$ is isomorphic to the action of Γ on $V \oplus V$ defined by $\gamma(v_1, v_2) = (\gamma v_1, \gamma v_2)$ for $\gamma \in \Gamma, v_1, v_2 \in V$.

Let $\{b_{j1} + ib_{j2}\}_{j=1}^m$ be a basis for $\mathrm{Ker}\Delta(\tau_0, i\beta_0)$, and for any $\beta > 0$ define $\sin_\beta,\ \cos_\beta \in \mathrm{C}([-1, 0]; \mathbb{R})$ by

$$\sin_\beta(\theta) = \sin(\beta\theta),\ \cos_\beta(\theta) = \cos(\beta\theta),\ \theta \in [-1, 0].$$

Then the columns of $\Phi_{\tau_0} = (\varepsilon_1, \ldots, \varepsilon_{2m})$ form a basis for $U_{(i\beta_0, -i\beta_0)}(A(\tau_0))$, where

$$\begin{aligned}
&\varepsilon_j = \sin_{\beta_0} b_{\mathrm{j1}} + \cos_{\beta_0} b_{\mathrm{j2}},\\
&\varepsilon_{m+j} = \cos_{\beta_0} b_{\mathrm{j1}} - \sin_{\beta_0} b_{\mathrm{j2}}, \quad 1 \le j \le m.
\end{aligned}$$

It can be shown (see Lemma 2.1 of [23]) that there exist $\delta_0 > 0$ and a continuously differentiable function $\lambda : (\tau_0 - \delta_0, \tau_0 + \delta_0) \to \mathbb{C}$ such that $\lambda(\tau_0) = i\beta_0,\ \lambda(\tau)$ is an eigenvalue of $A(\tau)$, $U_{(\lambda(\tau), \overline{\lambda(\tau)})}(A(\tau))$ consists of eigenvectors of $A(\tau)$ associated with these eigenvalues, and $\dim U_{(\lambda(\tau), \overline{\lambda(\tau)})}(A(\tau)) = \dim U_{(i\beta_0, -i\beta_0)}(A(\tau_0))$.

We will require the following transversality condition.

(G4) $\frac{d}{d\tau}\mathrm{Re}\lambda(\tau)\,|_{\tau=\tau_0} \neq 0$.

Let $\omega = \frac{2\pi}{\beta_0}$. Denote by P_ω the Banach space of all continuous ω-periodic mappings $x : \mathbb{R} \to \mathbb{R}^n$. Then $\Gamma \times S^1$ acts on P_ω by

$$(\gamma, e^{i\theta})x(t) = \gamma x\left(t + \frac{\theta}{2\pi}\omega\right), \quad (\gamma, e^{i\theta}) \in \Gamma \times S^1,\ x \in P_\omega.$$

Denote by SP_ω the subspace of P_ω consisting of all ω-periodic solutions of $\dot{x}(t) = \tau_0 L x_t$. Then, for each subgroup $\Sigma \le \Gamma \times S^1$, the fixed point set

$$Fix(\Sigma, SP_\omega) = \{x \in SP_\omega; \quad (\gamma, \theta)x = x \text{ for all } (\gamma, \theta) \in \Sigma\}$$

is a subspace.

Under assumption (G1), the columns of $U(t) = \Phi_{\tau_0}(0)e^{B(\tau_0)t},\ t \in \mathbb{R}$, form a basis for SP_ω, where

$$B(\tau_0) = \begin{pmatrix} 0 & -\beta_0 I_m \\ \beta_0 I_m & 0 \end{pmatrix}.$$

Also, SP_ω is a $\Gamma \times S^1$-invariant subspace of P_ω (see Lemma 2.3 of [23]). We can now state the general symmetric local Hopf bifurcation theorem (Theorem 2.1 of [23]).

LEMMA 2.1. *Assume that* (G1)–(G4) *are satisfied and* $\dim Fix(\Sigma, SP_\omega) = 2$ *for some* $\Sigma \le \Gamma \times S^1$. *Then, for a chosen basis* $\{\delta_1, \delta_2\}$ *of* $Fix(\Sigma, SP_\omega)$, *there exist constants* $a_0 > 0$, $\tau_0^* > 0$, $\sigma_0 > 0$, C^1*-smooth functions* $\tau^* : \mathbb{R}^2_{a_0} \to \mathbb{R}$, $\omega^* : \mathbb{R}^2_{a_0} \to (0, \infty)$, *and a* C^1*-smooth mapping* $x^* : \mathbb{R}^2_{a_0} \to C(\mathbb{R}; \mathbb{R}^n)$, *where* $\mathbb{R}^2_{a_0} = \{a \in \mathbb{R}^2; |a| < a_0\}$ *and* $C(\mathbb{R}; \mathbb{R}^n)$ *is the Banach space of all continuous mappings from* $\mathbb{R}$ *into* $\mathbb{R}^n$ *equipped with the supremum norm such that, for each* $a \in \mathbb{R}^2_{a_0}$, $x^*(a)$ *is an* $\omega^*(a)$*-periodic solution of* $\dot{x}(t) = \tau F(x_t)$ *with* $\tau = \tau^*(a)$, *and*

$$\begin{aligned} &\gamma x^*(a)(t) = x^*(a)\left(t - \frac{\omega^*(a)}{\omega}\theta\right), \quad (\gamma, \theta) \in \Sigma, \\ &x^*(0) = 0,\ \omega^*(0) = \omega,\ \tau^*(0) = \tau_0^*, \\ &x^*(a) = (\delta_1, \delta_2)a + o(|a|) \text{ as } |a| \to 0. \end{aligned}$$

Furthermore, for $|\tau - \tau_0| < \tau_0^*$, $|\tilde{\omega} - \frac{2\pi}{\beta_0}| < \sigma_0$, *every* $\tilde{\omega}$*-periodic solution of* $\dot{x}(t) = \tau F(x_t)$ *with* $\|x_t\| < \sigma_0$, $\gamma x(t) = x(t - \frac{\tilde{\omega}}{\omega}\theta)$ *for* $(\gamma, \theta) \in \Sigma$, *and* $t \in \mathbb{R}$ *must be of the above type.*

We now consider the system (1.1). It arises from

$$\dot{y}_j(t) = -y_j(t) + h(y_j(t-\tau)) - [g(y_{j-1}(t-\tau)) + g(y_{j+1}(t-\tau)) - 2g(y_j(t-\tau))]$$

with $\epsilon = \tau^{-1}$ and by the change of variable $x_j(t) = y_j(\tau t)$. We will apply Lemma 2.1 to (1.1) with $F : C \to \mathbb{R}^3$ by

$$(F(\phi))_j = -\phi_j(0) + h(\phi_j(-1)) - [g(\phi_{j-1}(-1)) + g(\phi_{j+1}(-1)) - 2g(\phi_j(-1))]$$

for $\phi \in C := C([-\tau, 0]; \mathbb{R}^3)$ and $j (\mathrm{mod}\ 3)$.

PROPOSITION 2.2. *Let* $\Gamma = D_3$ *be the dihedral group of order* 2×3. *Denote by* ρ *the generator of the cyclic subgroup* $Z_3 \le D_3$ *and by* κ *the flip. Define the action of* Γ *on* $\mathbb{R}^3$ *by*

$$\left\{ \begin{array}{l} (\rho x)_j = x_{j+1}, \quad j (\mathrm{mod}\, 3), \\ (\kappa x)_2 = x_3, (\kappa x)_3 = x_2, (\kappa x)_1 = x_1, x \in \mathbb{R}^3. \end{array} \right. \tag{2.1}$$

Then F *is* Γ*-equivariant.*

Proof. For $\phi \in C$ and $j (\mathrm{mod}\, 3)$, we have

$$\begin{aligned} &(F(\rho\phi))_j \\ &= -(\rho\phi)_j(0) + h((\rho\phi)_j(-1)) - [g((\rho\phi)_{j-1}(-1)) + g((\rho\phi)_{j+1}(-1)) - 2g((\rho\phi)_j(-1))] \\ &= -\phi_{j+1}(0) + h(\phi_{j+1}(-1)) - [g(\phi_j(-1)) + g(\phi_{j+2}(-1)) - 2g(\phi_{j+1}(-1))] \\ &= ((\rho F)(\phi))_j \end{aligned}$$

and

$$\begin{aligned} &(F(\kappa\phi))_1 \\ &= -(\kappa\phi)_1(0) + h((\kappa\phi)_1(-1)) - [g((\kappa\phi)_3(-1)) + g((\kappa\phi)_2(-1)) - 2g((\kappa\phi)_1(-1))] \\ &= -\phi_1(0) + h(\phi_1(-1)) - [g(\phi_2(-1)) + g(\phi_3(-1)) - 2g(\phi_1(-1))] \\ &= ((\kappa F)(\phi))_1. \end{aligned}$$

Moreover,

$$\begin{aligned} &(F(\kappa\phi))_2 \\ &= -(\kappa\phi)_2(0) + h((\kappa\phi)_2(-1)) - [g((\kappa\phi)_1(-1)) + g((\kappa\phi)_3(-1)) - 2g((\kappa\phi)_2(-1))] \\ &= -\phi_3(0) + h(\phi_3(-1)) - [g(\phi_1(-1)) + g(\phi_2(-1)) - 2g(\phi_3(-1))] \\ &= ((\kappa F)(\phi))_2. \end{aligned}$$

Similarly, $(F(\kappa\phi))_3 = ((\kappa F)(\phi))_3$. This completes the proof. □

Let

$$\gamma = h'(0), \qquad \beta = g'(0). \tag{2.2}$$

Then the linearization of (1.1) at $x = 0 \in \mathbb{R}^3$ is

$$\frac{1}{\tau}\dot{X}_j(t) = -X_j(t) + \gamma X_j(t-1) - \beta[X_{j-1}(t-1) + X_{j+1}(t-1) - 2X_j(t-1)], \tag{2.3}$$

where $j = 1, 2, 3 (\mathrm{mod}\, 3)$. The characteristic equation takes the form

$$\det \Delta(\tau, \lambda) = 0,$$

where

$$\Delta(\tau, \lambda) = (\lambda + \tau)I_3 - \tau M e^{-\lambda}, \quad \lambda \in \mathbb{C}, \tag{2.4}$$

and

$$M = \begin{pmatrix} \gamma + 2\beta & -\beta & -\beta \\ -\beta & \gamma + 2\beta & -\beta \\ -\beta & -\beta & \gamma + 2\beta \end{pmatrix}. \tag{2.5}$$

PROPOSITION 2.3. $\det \Delta(\tau, \lambda) = (\lambda + \tau - \gamma\tau e^{-\lambda})[\lambda + \tau - (\gamma + 3\beta)\tau e^{-\lambda}]^2$.

Proof. Let $\chi = e^{i\frac{2\pi}{3}}$ and

$$v_k = (1, \chi^k, \chi^{2k})^T, \quad k = 0, 1, 2. \tag{2.6}$$

Clearly, $v_0 = (1, 1, 1)^T$ and $v_2 = \overline{v}_1$. Let

$$\mathbb{C}_k = \{v_k z; z \in \mathbb{C}\}, \quad k = 0, 1, 2.$$

Then

$$\mathbb{C}^3 = \mathbb{C}_0 \oplus \mathbb{C}_1 \oplus \mathbb{C}_2$$

and

$$\begin{aligned}
&(\Delta(\tau, \lambda)v_k)_j \\
&= (\lambda + \tau - (\gamma + 2\beta)\tau e^{-\lambda})(v_k)_j + \tau\beta e^{-\lambda}(e^{i\frac{2\pi}{3}k} + e^{-i\frac{2\pi}{3}k})(v_k)_j \\
&= \left[\lambda + \tau - \tau(\gamma + 2\beta)e^{-\lambda} + 2\beta\tau\cos\left(\frac{2\pi}{3}k\right)e^{-\lambda}\right](v_k)_j \\
&= \left[\lambda + \tau - \left(\gamma + 4\beta\sin^2\left(\frac{\pi}{3}k\right)\right)\tau e^{-\lambda}\right](v_k)_j.
\end{aligned}$$

That is,

$$\begin{aligned}
&\Delta(\tau, \lambda)|_{\mathbb{C}_k} \\
&= \lambda + \tau - \left(\gamma + 4\beta\sin^2\left(\frac{\pi}{3}k\right)\right)\tau e^{-\lambda} \\
&= \begin{cases} \lambda + \tau - \gamma\tau e^{-\lambda} & \text{if } k = 0, \\ \lambda + \tau - (\gamma + 3\beta)\tau e^{-\lambda} & \text{if } k = 1, 2. \end{cases}
\end{aligned}$$

This completes the proof. □

We now make the following assumption.

(H1) $|\gamma| < 1, \gamma + 3\beta > 1$.

The critical values of τ where the characteristic equation has purely imaginary zeros are described in the following.

PROPOSITION 2.4. *Let $A(\tau)$ denote the infinitesimal generator of the semigroup generated by system* (2.3). *Assume that* (H1) *is satisfied. Define*

$$\begin{cases} \beta_k = 2k\pi - \arccos\ \dfrac{1}{\gamma + 3\beta}, \\ \tau_k = -\beta_k \cot\ \beta_k, \quad k \geq 1. \end{cases}$$

Then the following hold.

(i) *For every fixed $\tau \geq 0$, all zeros of $\lambda + \tau - \gamma\tau e^{-\lambda}$ have negative real parts.*

(ii) *At (and only at) $\tau = \tau_k$, $A(\tau)$ has purely imaginary eigenvalues. These eigenvalues are given by $\pm i\beta_k$ with $\beta_k \in (2k\pi - \frac{\pi}{2}, 2k\pi)$.*

(iii) *All other eigenvalues of $A(\tau_k)$ are not integer multiples of $\pm i\beta_k$.*

(iv) *The generalized eigenspace $U_{(i\beta_k, -i\beta_k)}(A(\tau_k))$ consists of eigenvectors of $A(\tau_k)$ associated with $\pm i\beta_k$ only and*

$$U_{(i\beta_k, -i\beta_k)}(A(\tau_k)) = \left\{ \sum_{i=1}^{4} x_i \epsilon_i; \quad x_i \in \mathbb{R}, i = 1, \dots, 4 \right\},$$

where, for $\theta \in [-1, 0]$,

$$\begin{aligned} \epsilon_1(\theta) &= \mathrm{Re}(e^{i\beta_k\theta} v_1) = \cos(\beta_k\theta)\mathrm{Re}v_1 - \sin(\beta_k\theta)\mathrm{Im}v_1, \\ \epsilon_2(\theta) &= \mathrm{Im}(e^{i\beta_k\theta} v_1) = \sin(\beta_k\theta)\mathrm{Re}v_1 + \cos(\beta_k\theta)\mathrm{Im}v_1, \\ \epsilon_3(\theta) &= \mathrm{Re}(e^{i\beta_k\theta} v_2) = \cos(\beta_k\theta)\mathrm{Re}v_1 + \sin(\beta_k\theta)\mathrm{Im}v_1, \\ \epsilon_4(\theta) &= \mathrm{Re}(e^{i\beta_k\theta} v_2) = \sin(\beta_k\theta)\mathrm{Re}v_1 - \cos(\beta_k\theta)\mathrm{Im}v_1. \end{aligned}$$

Proof. (i) Let $\lambda = u + iv$ be a zero of $\lambda + \tau - \gamma\tau e^{-\lambda}$. Then we get $v = -\gamma\tau e^{-u}\mathrm{sin}v$ and $u + \tau = \gamma\tau e^{-u}\mathrm{cos}v$, from which it follows that

$$\gamma^2\tau^2 e^{-2u} = v^2 + (u + \tau)^2.$$

Consequently, $u < 0$, for otherwise the left-hand side of the above equality is strictly less than τ^2, while the right-hand side is larger than or equal to τ^2.

To verify (ii)–(iv), let $\lambda = iv$ with $v > 0$ be a solution of $\lambda + \tau - (\gamma + 3\beta)\tau e^{-\lambda} = 0$. Then

$$\begin{cases} \tau = (\gamma + 3\beta)\tau \mathrm{cos}v, \\ v = -(\gamma + 3\beta)\tau \mathrm{sin}v. \end{cases}$$

So

$$\tan v = -\frac{v}{\tau},$$

from which it follows that $\tan v < 0$, and hence $v \notin [0, \frac{\pi}{2}] + \mathbb{Z}\pi$; here $\mathbb{Z}$ is the set of all integers. Therefore, we must have

$$v = 2k\pi - \arccos \frac{1}{\gamma + 3\beta} = \beta_k, \quad k \geq 1,$$

and

$$\tau = -\beta_k \cot \beta_k = \tau_k.$$

Therefore, $\lambda + \tau - (\gamma + 3\beta)\tau e^{-\lambda} = 0$ has purely imaginary roots (given by $i\beta_k$) if and only if $\tau = \tau_k$ for some $k \geq 1$.

It is well known that $\phi \in C([-1, 0]; \mathbb{C}^3)$ is an eigenvector of $A(\tau_k)$ associated with the eigenvalue $i\beta_k$ if and only if $\phi(\theta) = e^{i\beta_k\theta}z, -1 \leq \theta \leq 0$, for some vector $z \in \mathbb{C}^3$ such that $\Delta(\tau_k, i\beta_k)z = 0$ (see, for example, pp. 198 in [9]). From the proof of Proposition 2.3, we then have $v \in \langle v_1, v_2\rangle$, the complex space spanned by v_1 and v_2. Similar arguments apply to $-i\beta_k$. Therefore, the eigenspace of $A(\tau_k)$ associated with $\pm i\beta_k$ is spanned by $e^{i\beta_k\theta}v_1, e^{i\beta_k\theta}v_2, e^{-i\beta_k\theta}v_1$, and $e^{-i\beta_k\theta}v_2$. Therefore, this space has the real basis $\{\epsilon_1, \epsilon_2, \epsilon_3, \epsilon_4\}$. On the other hand, the eigenspace of $A(\tau_k)$ associated with $i\beta_k$ is of dimension 2 and the algebraic multiplicity of $\lambda = i\beta_k$ as a zero of $\det \Delta(\tau_k, \lambda) = 0$ is also 2. So the well-known folk theorem in functional differential equations (see [26] or Theorem 4.2 in [9]) implies that $U_{(i\beta_k, -i\beta_k)}(A(\tau_k))$ must coincide with the eigenspace of $A(\tau_k)$ associated with $\pm i\beta_k$. This completes the proof. □

PROPOSITION 2.5. *Let $\Gamma = D_3$ act on $\mathbb{R}^2$ by*

$$\rho\begin{pmatrix} x_1 \\ x_2 \end{pmatrix} = \begin{pmatrix} -\frac{1}{2} & -\frac{\sqrt{3}}{2} \\ \frac{\sqrt{3}}{2} & -\frac{1}{2} \end{pmatrix}\begin{pmatrix} x_1 \\ x_2 \end{pmatrix},$$
$$\kappa\begin{pmatrix} x_1 \\ x_2 \end{pmatrix} = \begin{pmatrix} x_1 \\ -x_2 \end{pmatrix}, \quad \begin{pmatrix} x_1 \\ x_2 \end{pmatrix} \in \mathbb{R}^2.$$

Then $\mathbb{R}^2$ is an absolutely irreducible representation of Γ, and the restricted action of Γ on $\mathrm{Ker}\Delta(\tau_k, i\beta_k)$ is isomorphic to the action of Γ on $\mathbb{R}^2 \oplus \mathbb{R}^2$.

Proof. The proof for the absolute irreducibility of the representation of Γ on $\mathbb{R}^2$ is straightforward and can be found in, for example, [18]. Clearly,

$$\mathrm{Ker}\Delta(\tau_k, i\beta_k) = \{(x_1 + ix_2)v_1 + (x_3 + ix_4)v_2; \quad x_i \in \mathbb{R}, i = 1, \ldots, 4\}.$$

Define

$$J((x_1 + ix_2)v_1 + (x_3 + ix_4)v_2) = (x_1 + x_3, x_2 - x_4, x_2 + x_4, x_3 - x_1)^T.$$

Clearly, $J : \mathrm{Ker}\Delta(\tau_k, i\beta_k) \cong \mathbb{R}^4$ is a linear isomorphism. Note that

$$\begin{aligned}
&\rho[(x_1 + ix_2)v_1 + (x_3 + ix_4)v_2] \\
&= (x_1 + ix_2)e^{i\frac{2\pi}{3}}v_1 + (x_3 + ix_4)e^{-i\frac{2\pi}{3}}v_2 \\
&= \left[\left(-\frac{1}{2}x_1 - \frac{\sqrt{3}}{2}x_2\right) + i\left(-\frac{1}{2}x_2 + \frac{\sqrt{3}}{2}x_1\right)\right]v_1 \\
&\quad + \left[\left(-\frac{1}{2}x_3 + \frac{\sqrt{3}}{2}x_4\right) + i\left(-\frac{1}{2}x_4 - \frac{\sqrt{3}}{2}x_3\right)\right]v_2
\end{aligned}$$

and

$$\kappa[(x_1 + ix_2)v_1 + (x_3 + ix_4)v_2] = (x_1 + ix_2)v_2 + (x_3 + ix_4)v_1.$$

Therefore,

$$\begin{aligned}
&J(\rho[(x_1+ix_2)v_1+(x_3+ix_4)v_2])\\
&=\left(-\frac{1}{2}(x_1+x_3)-\frac{\sqrt{3}}{2}(x_2-x_4),-\frac{1}{2}(x_2-x_4)+\frac{\sqrt{3}}{2}(x_1+x_3),\right.\\
&\qquad\left.-\frac{1}{2}(x_2+x_4)-\frac{\sqrt{3}}{2}(x_3-x_1),-\frac{1}{2}(x_3-x_1)+\frac{\sqrt{3}}{2}(x_2+x_4)\right)^T\\
&=\rho J((x_1+ix_2)v_1+(x_3+ix_4)v_2)
\end{aligned}$$

and

$$\begin{aligned}
&J(\kappa[(x_1+ix_2)v_1+(x_3+ix_4)v_2])\\
&=(x_3+x_1,x_4-x_2,x_4+x_2,x_1-x_3)^T\\
&=\kappa J[(x_1+ix_2)v_1+(x_3+ix_4)v_2].
\end{aligned}$$

This completes the proof. ∎

PROPOSITION 2.6. *For each fixed $k\geq 1$, there exist $\delta_k>0$ and a C^1-mapping $\lambda_k:(\tau_k-\delta_k,\tau_k+\delta_k)\to\mathbb{C}$ such that $\lambda_k(\tau_k)=i\beta_k$ and $\lambda_k(\tau)+\tau-(\gamma+3\beta)\tau e^{-\lambda_k(\tau)}=0$ for all $\tau\in(\tau_k-\delta_k,\tau_k+\delta_k)$. Moreover, $\frac{d}{d\tau}\mathrm{Re}\lambda_k(\tau)|_{\tau=\tau_k}>0$.*

Proof. The existence of δ_k and the mapping λ_k follow from the implicit function theorem. We now substitute $\lambda=\lambda_k(\tau)$ into $\lambda+\tau-(\gamma+3\beta)\tau e^{-\lambda}=0$, differentiating the equality with respect to τ, to get

$$\begin{aligned}
&\frac{d}{d\tau}\mathrm{Re}\lambda_k(\tau)|_{\tau=\tau_k}\\
&=\mathrm{Re}\frac{-1+(\gamma+3\beta)e^{-\lambda}}{1+\tau(\gamma+3\beta)e^{-\lambda}}\bigg|_{\lambda=i\beta_k,\tau=\tau_k}\\
&=\mathrm{Re}\frac{\lambda/\tau}{1+(\lambda+\tau)}\bigg|_{\lambda=i\beta_k,\tau=\tau_k}\\
&=\frac{\beta_k^2}{\tau_k[(1+\tau_k)^2+\beta_k^2]}.
\end{aligned}$$

This completes the proof. ∎

Fix $k\geq 1$. Let $\omega=\frac{2\pi}{\beta_k}$, and let P_ω be the Banach space of continuous ω-periodic mappings $x:\mathbb{R}\to\mathbb{R}^3$. $\Gamma\times S^1$ acts on P_ω by

$$(\gamma,e^{i\theta})x(t)=\gamma x(t+\theta),\quad e^{i\theta}\in S^1, x\in P_\omega,\gamma\in\Gamma.$$

We will write γx for $(\gamma,1)x$ when $\gamma\in\Gamma$ and $x\in P_\omega$. Let SP_ω denote the subspace of P_ω consisting of all ω-periodic solutions of (2.3) with $\tau=\tau_k$. Then

$$SP_\omega=\{x_1\epsilon_1^*+x_2\epsilon_2^*+x_3\epsilon_3^*+x_4\epsilon_4^*;\quad x_i\in\mathbb{R}, i=1,\dots,4\},$$

where

$$\begin{cases}
\epsilon_1^*(t)=\cos(\beta_k t)w_1-\sin(\beta_k t)w_2,\\
\epsilon_2^*(t)=\sin(\beta_k t)w_1+\cos(\beta_k t)w_2,\\
\epsilon_3^*(t)=\cos(\beta_k t)w_1+\sin(\beta_k t)w_2,\\
\epsilon_4^*(t)=\sin(\beta_k t)w_1-\cos(\beta_k t)w_2,
\end{cases}$$

and

$$w_1 = \left(1, -\frac{1}{2}, -\frac{1}{2}\right)^T, \quad w_2 = \left(0, \frac{\sqrt{3}}{2}, -\frac{\sqrt{3}}{2}\right)^T.$$

PROPOSITION 2.7. *With ϵ_i^* given above, we have*

(i) $\kappa\epsilon_1^* = \epsilon_3^*, \kappa\epsilon_2^* = \epsilon_4^*, \kappa\epsilon_3^* = \epsilon_1^*, \kappa\epsilon_4^* = \epsilon_2^*$;

(ii) $\rho\epsilon_1^* = -\frac{1}{2}\epsilon_1^* - \frac{\sqrt{3}}{2}\epsilon_2^*, \rho\epsilon_2^* = -\frac{1}{2}\epsilon_2^* + \frac{\sqrt{3}}{2}\epsilon_1^*, \rho\epsilon_3^* = -\frac{1}{2}\epsilon_3^* + \frac{\sqrt{3}}{2}\epsilon_4^*, \rho\epsilon_4^* = -\frac{1}{2}\epsilon_4^* - \frac{\sqrt{3}}{2}\epsilon_3^*$.

Proof. (i) is obvious from the definition of the action of κ in Proposition 2.2. To prove (ii), we note that

$$\rho\begin{pmatrix} 1 \\ -\frac{1}{2} \\ -\frac{1}{2} \end{pmatrix} = \begin{pmatrix} -\frac{1}{2} \\ -\frac{1}{2} \\ 1 \end{pmatrix} = -\frac{1}{2}\begin{pmatrix} 1 \\ -\frac{1}{2} \\ -\frac{1}{2} \end{pmatrix} - \frac{\sqrt{3}}{2}\begin{pmatrix} 0 \\ \frac{\sqrt{3}}{2} \\ -\frac{\sqrt{3}}{2} \end{pmatrix},$$

$$\rho\begin{pmatrix} 0 \\ \frac{\sqrt{3}}{2} \\ -\frac{\sqrt{3}}{2} \end{pmatrix} = \begin{pmatrix} \frac{\sqrt{3}}{2} \\ -\frac{\sqrt{3}}{2} \\ 0 \end{pmatrix} = \frac{\sqrt{3}}{2}\begin{pmatrix} 1 \\ -\frac{1}{2} \\ -\frac{1}{2} \end{pmatrix} - \frac{1}{2}\begin{pmatrix} 0 \\ \frac{\sqrt{3}}{2} \\ -\frac{\sqrt{3}}{2} \end{pmatrix}.$$

So

$$\rho\epsilon_1^* = \cos(\beta_k t)\left[-\frac{1}{2}w_1 - \frac{\sqrt{3}}{2}w_2\right] - \sin(\beta_k t)\left[\frac{\sqrt{3}}{2}w_1 - \frac{1}{2}w_2\right] = -\frac{1}{2}\epsilon_1^* - \frac{\sqrt{3}}{2}\epsilon_2^*,$$

$$\rho\epsilon_2^* = \sin(\beta_k t)\left[-\frac{1}{2}w_1 - \frac{\sqrt{3}}{2}w_2\right] + \cos(\beta_k t)\left[\frac{\sqrt{3}}{2}w_1 - \frac{1}{2}w_2\right] = \frac{\sqrt{3}}{2}\epsilon_1^* - \frac{1}{2}\epsilon_2^*,$$

$$\rho\epsilon_3^* = \cos(\beta_k t)\left[-\frac{1}{2}w_1 - \frac{\sqrt{3}}{2}w_2\right] + \sin(\beta_k t)\left[\frac{\sqrt{3}}{2}w_1 - \frac{1}{2}w_2\right] = -\frac{1}{2}\epsilon_3^* + \frac{\sqrt{3}}{2}\epsilon_4^*,$$

$$\rho\epsilon_4^* = \sin(\beta_k t)\left[-\frac{1}{2}w_1 - \frac{\sqrt{3}}{2}w_2\right] - \cos(\beta_k t)\left[\frac{\sqrt{3}}{2}w_1 - \frac{1}{2}w_2\right] = -\frac{\sqrt{3}}{2}\epsilon_3^* - \frac{1}{2}\epsilon_4^*.$$

This completes the proof. □

Note that, if x is a periodic solution of (1.1), then so is $(\gamma, e^{i\theta})x$ for every $(\gamma, e^{i\theta}) \in \Gamma \times S^1$. If the symmetry of x is Σ_x for a subgroup of $\Gamma \times S^1$, that is, $\Sigma_x = \{(\gamma, e^{i\theta}) \in \Gamma \times S^1; (\gamma, e^{i\theta})x = x\}$, then the symmetry of $(\gamma, e^{i\theta})x$ is given by $(\gamma, e^{i\theta})\Sigma_x(\gamma, e^{i\theta})^{-1}$, which is conjugate to Σ_x. It is known that the subgroups of $D_3 \times S^1$, up to conjugacy, that describe the symmetry of periodic solutions of (1.1) which exhibit certain spatial-temporal patterns are given below (see, for example, p. 368 in [18]):

$$\Sigma_{(2,3)}^{\pm} = \langle(\kappa, \pm 1)\rangle,$$
$$\Sigma_{\rho}^{\pm} = \langle(\rho, e^{\pm i\frac{2\pi}{3}})\rangle.$$

More specifically, for example, $\Sigma_{(2,3)}^{-}$ is a group generated by $(\kappa, -1) \in D_3 \times S^1$.

PROPOSITION 2.8.

$$Fix(\Sigma_{(2,3)}^{+}, SP_\omega) = \{y\cos(\beta_k t)w_1 + z\sin(\beta_k t)w_1; \quad y, z \in \mathbb{R}\},$$
$$Fix(\Sigma_{(2,3)}^{-}, SP_\omega) = \{y\cos(\beta_k t)w_2 + z\sin(\beta_k t)w_2; \quad y, z \in \mathbb{R}\},$$
$$Fix(\Sigma_{\rho}^{-}, SP_\omega) = \{y\epsilon_1^* + z\epsilon_2^*; \quad y, z \in \mathbb{R}\},$$
$$Fix(\Sigma_{\rho}^{=}, SP_\omega) = \{y\epsilon_3^* + z\epsilon_4^*; \quad y, z \in \mathbb{R}\}.$$

Proof. First, $x \in Fix(\Sigma^+_{(2,3)}, SP_\omega)$ if and only if $\kappa x = x$. However, for $x = \sum_{i=1}^4 x_i\epsilon_i^*$, we have

$$\kappa x = x_1\epsilon_3^* + x_2\epsilon_4^* + x_3\epsilon_1^* + x_4\epsilon_2^*.$$

Therefore, $x \in Fix(\Sigma^+_{(2,3)}, SP_\omega)$ if and only if $x_1 = x_3$ and $x_2 = x_4$. This shows that $Fix(\Sigma^+_{(2,3)}, SP_\omega)$ is spanned by $\epsilon_1^* + \epsilon_3^*$ and $\epsilon_2^* + \epsilon_4^*$.

Second, $x \in Fix(\Sigma^-_{(2,3)}, SP_\omega)$ if and only if $\kappa x(t) = x(t + \frac{\omega}{2})$ for $t \in \mathbb{R}$. Let $x = \sum_{i=1}^4 x_i\epsilon_i^*$. Then, as $\cos(\beta_k t + \beta_k \frac{\omega}{2}) = -\cos(\beta_k t)$ and $\sin(\beta_k t + \beta_k \frac{\omega}{2}) = -\sin(\beta_k t)$, we get $\epsilon_i^*(t + \frac{\omega}{2}) = -\epsilon_i^*(t)$, and thus $x(t + \frac{\omega}{2}) = -\sum_{i=1}^4 x_i\epsilon_i^*$. This implies that $\kappa x(t) = x(t + \frac{\omega}{2})$ if and only if $x_1 = -x_3$ and $x_2 = -x_4$. Therefore, $Fix(\Sigma^-_{(2,3)}, SP_\omega)$ is spanned by $\epsilon_1^* - \epsilon_3^*$ and $\epsilon_2^* - \epsilon_4^*$.

Third, for $x = \sum_{i=1}^4 x_i\epsilon_i^*$, we have

$$\begin{aligned}\rho x = &\left(-\frac{1}{2}x_1 + \frac{\sqrt{3}}{2}x_2\right)\epsilon_1^* + \left(-\frac{\sqrt{3}}{2}x_1 - \frac{1}{2}x_2\right)\epsilon_2^* \\ &+ \left(-\frac{1}{2}x_3 - \frac{\sqrt{3}}{2}x_4\right)\epsilon_3^* + \left(\frac{\sqrt{3}}{2}x_3 - \frac{1}{2}x_4\right)\epsilon_4^*.\end{aligned}$$

On the other hand, we have

$$\begin{aligned}\cos\left(\beta_k\left(t \pm \frac{\omega}{3}\right)\right) &= \cos\left(\beta_k t \pm \frac{2\pi}{3}\right) = -\frac{1}{2}\cos(\beta_k t) \mp \frac{\sqrt{3}}{2}\sin(\beta_k t), \\ \sin\left(\beta_k\left(t \pm \frac{\omega}{3}\right)\right) &= \sin\left(\beta_k t \pm \frac{2\pi}{3}\right) = \pm\frac{\sqrt{3}}{2}\cos(\beta_k t) - \frac{1}{2}\sin(\beta_k t).\end{aligned}$$

This, together with the expression of each ϵ_i^* and $x = \sum_{i=1}^4 x_i\epsilon_i^*$, leads to

$$\begin{aligned}&x\left(t \pm \frac{\omega}{3}\right) \\ &= \left(-\frac{1}{2}x_1 \pm \frac{\sqrt{3}}{2}x_2\right)\epsilon_1^* + \left(\mp\frac{\sqrt{3}}{2}x_1 - \frac{1}{2}x_2\right)\epsilon_2^* \\ &\quad + \left(-\frac{1}{2}x_3 \pm \frac{\sqrt{3}}{2}x_4\right)\epsilon_3^* + \left(\mp\frac{\sqrt{3}}{2}x_3 - \frac{1}{2}x_4\right)\epsilon_4^*.\end{aligned}$$

Thus $x \in Fix(\Sigma^\pm_\rho, SP_\omega)$, i.e., $\rho x(t \pm \frac{\omega}{3}) = x(t)$, if and only if

$$\begin{cases} -\frac{1}{2}x_1 + \frac{\sqrt{3}}{2}x_2 = -\frac{1}{2}x_1 \mp \frac{\sqrt{3}}{2}x_2, \\ -\frac{\sqrt{3}}{2}x_1 - \frac{1}{2}x_2 = \pm\frac{\sqrt{3}}{2}x_1 - \frac{1}{2}x_2, \\ -\frac{1}{2}x_3 - \frac{\sqrt{3}}{2}x_4 = -\frac{1}{2}x_3 \mp \frac{\sqrt{3}}{2}x_4, \\ \frac{\sqrt{3}}{2}x_3 - \frac{1}{2}x_4 = \pm\frac{\sqrt{3}}{2}x_3 - \frac{1}{2}x_4. \end{cases}$$

That is, $\rho x(t) = x(t+\frac{\omega}{3})$ if and only if $x_3 = x_4 = 0$, and $\rho x(t) = x(t-\frac{\omega}{3})$ if and only if $x_1 = x_2 = 0$. Therefore, $Fix(\Sigma_\rho^-, SP_\omega)$ is spanned by ϵ_1^* and ϵ_2^*, and $Fix(\Sigma_\rho^+, SP_\omega)$ is spanned by ϵ_3^* and ϵ_4^*. This completes the proof. □

We can now apply Lemma 2.1 to obtain the following main result of this section.

THEOREM 2.9. *Assume that* (H1) *is satisfied. Then, near $\tau = \tau_k$ for each $k \geq 1$, system* (1.1) *has eight distinct branches of periodic solutions bifurcated from the trivial solution $x = 0$. More precisely, we have the following.*

(i) *There exist $\epsilon_0^m > 0$ and $\delta_0^m > 0$ such that, for each $\theta \in [0, 2\pi], \alpha \in (0, \epsilon_0^m)$, system* (1.1) *with $\tau = \tau_k + \tau^m(\alpha, \theta)$ has a periodic solution $x^m = x^m(t; \alpha, \theta)$ with period $\omega^m(\alpha, \theta)$ such that*

$$x_2^m(t;\alpha,\theta) = x_3^m(t;\alpha,\theta),$$
$$x^m(t;\alpha,\theta) = \alpha\cos(\beta_k t + \theta)\left(1, -\frac{1}{2}, -\frac{1}{2}\right)^{\mathrm{T}} + o(|\alpha|) \text{ as } \alpha \to 0.$$

The mapping $(x^m, \tau^m, \omega^m) : (0, \epsilon^m) \times [0, 2\pi] \to C(\mathbb{R}; \mathbb{R}^3) \times \mathbb{R} \times \mathbb{R}$ is C^1-smooth, and

$$\omega^m(0,\theta) = \frac{2\pi}{\beta_k}, \quad \tau^m(0,\theta) = 0.$$

Furthermore, if $|\tau - \tau_k| < \delta_0^m$ and $|\omega - \frac{2\pi}{\beta_k}| < \delta_0^m$, then every ω-periodic solution of (1.1) *satisfying $x_2(t) = x_3(t)$ and $\sup_{t\in\mathbb{R}} |x(t)| < \delta_0^m$ must be given by $x^m(t; \alpha, \theta)$ for some $\alpha \in (0, \epsilon_0^m)$ and $\theta \in [0, 2\pi)$. Similar results hold when we replace $(2, 3)$ by $(1, 2)$ or $(1, 3)$.*

(ii) *There exist $\epsilon_0^s > 0$ and $\delta_0^s > 0$ such that, for each $\theta \in [0, 2\pi], \alpha \in (0, \epsilon_0^s)$, system* (1.1) *with $\tau = \tau_k + \tau^s(\alpha, \theta)$ has a periodic solution $x^s = x^s(t; \alpha, \theta)$ with period $\omega^s = \omega^s(\alpha, \theta)$ such that*

$$x_1^s(t) = x_1^s\left(t - \frac{\omega^s}{2}\right), x_2^s(t) = x_3^s\left(t - \frac{\omega^s}{2}\right), x_3^s(t) = x_3^s(t + \omega^s),$$
$$x^s(t;\alpha,\theta) = \alpha\cos(\beta_k t + \theta)\left(0, -\frac{\sqrt{3}}{2}, -\frac{\sqrt{3}}{2}\right)^{\mathrm{T}} + o(|\alpha|) \text{ as } \alpha \to 0.$$

The mapping $(x^s, \tau^s, \omega^s) : (0, \epsilon_0^s) \times [0, 2\pi] \to C(\mathbb{R}; \mathbb{R}^3) \times \mathbb{R} \times \mathbb{R}$ is C^1-smooth, and

$$\omega^s(0,\theta) = \frac{2\pi}{\beta_k}, \quad \tau^s(0,\theta) = 0.$$

Furthermore, if $|\tau - \tau_k| < \delta_0^s$ and $|\omega - \frac{2\pi}{\beta_k}| < \delta_0^s$, then every ω-periodic solution of (1.1) *satisfying $x_1(t) = x_1(t - \frac{\omega}{2}), x_2(t) = x_3(t - \frac{\omega}{2})$, and $\sup_{t\in\mathbb{R}} |x(t)| < \delta_0^s$ must be given by $x^s(t; \alpha, \theta)$ for some $\alpha \in (0, \epsilon_0^s)$ and $\theta \in [0, 2\pi)$. Similar results hold when we replace $(1, 2, 3)$ by $(2, 1, 3)$ or $(3, 2, 1)$.*

(iii) *There exist $\epsilon_0^d > 0$ and $\delta_0^d > 0$ such that, for each $\theta \in [0, 2\pi], \alpha \in (0, \epsilon_0^d)$, system* (1.1) *with $\tau = \tau_k + \tau^d(\alpha, \theta)$ has a periodic solution $x^d = x^d(t; \alpha, \theta)$ with period $\omega^d = \omega^d(\alpha, \theta)$ such that*

$$x_1^d(t) = x_2^d\left(t \pm \frac{\omega^d}{3}\right), x_2^d(t) = x_3^d\left(t \pm \frac{\omega^d}{3}\right),$$
$$x^d(t;\alpha,\theta) = \alpha\left(\cos(\beta_k t + \theta), \cos\left(\beta_k t + \theta \mp \frac{2\pi}{3}\right), \cos\left(\beta_k t + \theta \mp \frac{4\pi}{3}\right)\right)^T + o(|\alpha|)$$

as $\alpha \to 0$. *The mapping* $(x^d, \tau^d, \omega^d) : (0, \epsilon_0^d) \times [0, 2\pi] \to C(\mathbb{R}; \mathbb{R}^3) \times \mathbb{R} \times \mathbb{R}$ *is* C^1*-smooth, and*

$$\omega^d(0, \theta) = \frac{2\pi}{\beta_k}, \quad \tau^d(0, \theta) = 0.$$

Furthermore, if $|\tau - \tau_k| < \delta_0^d$ *and* $|\omega - \frac{2\pi}{\beta_k}| < \delta_0^d$, *then every* ω*-periodic solution of* (1.1) *satisfying* $x_1(t) = x_2(t \pm \frac{\omega}{3}), x_2(t) = x_3(t \pm \frac{\omega}{3})$, *and* $\sup_{t \in \mathbb{R}} |x(t)| < \delta_0^d$ *must be given by* $x^d(t; \alpha, \theta)$ *for some* $\alpha \in (0, \epsilon_0^d)$ *and* $\theta \in [0, 2\pi)$. *Similar results hold when we replace* $(1, 2, 3)$ *by* $(2, 1, 3)$ *or* $(3, 2, 1)$.

We call periodic solutions in (i)–(iii) *mirror-reflecting waves, standing waves*, and *discrete waves*, respectively. Note that Theorem 2.9 does not rule out the case in which $\tau^l(\alpha, \theta) \leq 0$ $(l = m, s, d)$. In next section, we will use the global bifurcation theory to rule out this case. In fact, we will show that all eight branches of waves are *supercritical* and *global*; i.e., all eight branches of waves exist for $\tau > \tau_k$.

3. Global continuation of waves. We will need a general global symmetric Hopf bifurcation theorem developed in [24]. Namely, we consider the one-parameter family of retarded functional differential equations

$$\dot{x}(t) = \tau F(x_t), \tag{3.1}$$

where $x \in \mathbb{R}^n$, $\tau \in (0, \infty)$, and $F : C([-\tau, 0]; \mathbb{R}^n) \to \mathbb{R}^n$ is continuously differentiable and completely continuous. Furthermore, we assume the following.

(A1) $\Gamma := Z_N$ for some integer N acts on $\mathbb{R}^n$ and $F : C \to \mathbb{R}^n$ is Γ-equivariant.

(A2) For every $x_0 \in M^\Gamma := \{x \in \mathbb{R}^n; \gamma x = x \text{ for } \gamma \in \Gamma, F(\bar{x}) = 0\}$, where $\bar{x} \in C$ is the constant mapping with the constant value $x \in \mathbb{R}^n$, $\det D\hat{F}(x_0) \neq 0$, where $\hat{F}$ is the C^1 mapping from $\mathbb{R}^n$ into $\mathbb{R}^n$, induced by F according to $\hat{F}(x) = F(\bar{x})$ for $x \in \mathbb{R}^n$.

(A3) For every $\tau_0 > 0$ and $x_0 \in M^\Gamma$ such that the generator $A(\tau_0, x_0)$ of the linearized system of (3.1) with $\tau = \tau_0$ at $x = x_0$ has a pair of purely imaginary eigenvalues $\pm i\beta_0$, there exist positive constants b, c, and δ such that (i) the only possible eigenvalue $u + iv$ of $A(\tau_0, x_0)$ with $(u, v) \in \partial\Omega$ is $i\beta_0$, where $\Omega := (0, b) \times (\beta_0 - c, \beta_0 + c)$; (ii) for $(\tau, \beta) \in [\tau_0 - \delta, \tau_0 + \delta] \times [\beta_0 - c, \beta_0 + c]$, $i\beta$ is an eigenvalue of $A(\tau, x_0)$ if and only if $\tau = \tau_0, \beta = \beta_0$.

(A4) $M^* := \{(\tau, x, \beta) \in (0, \infty) \times M^\Gamma \times (0, \infty); \pm i\beta \text{ are eigenvalues of } A(\tau, x)\}$ is a discrete set.

Note that the action of Γ on $\mathbb{R}^n$ induces an action on $\mathbb{C}^n = \mathbb{R}^n + i\mathbb{R}^n$, with respect to which we have the isotypical decomposition

$$\mathbb{C}^n = \mathbb{C}_0^n \oplus \mathbb{C}_1^n \oplus \cdots \oplus \mathbb{C}_j^n \oplus \cdots,$$

where $\mathbb{C}_j^n, j \geq 0$, is the direct sum of all one-dimensional Γ-irreducible subspaces V of $\mathbb{C}^n$ such that the restricted action Γ on V is isomorphic to the Γ-action on $\mathbb{C}$ defined by $\rho \cdot z = \rho^j z$ for the generator $\rho \in Z_N \leq S^1$ and for $z \in \mathbb{C}$. Let

$$\Delta_{x_0}(\tau, \lambda) := \lambda I_n - \tau D_\phi F(\bar{x}_0)(e^{\lambda \cdot} I_n) \tag{3.2}$$

for $\tau > 0, x_0 \in M^\Gamma$, and $\lambda \in \mathbb{C}$. By assumption (A1), we have $\Delta_{x_0}(\tau, \lambda)\mathbb{C}_j^n \subset \mathbb{C}_j^n$ for $j \geq 0$ and for $\lambda \in \mathbb{C}$. Put

$$\Delta_{x_0, j}(\tau, \lambda) = \Delta_{x_0}(\tau, \lambda)|_{\mathbb{C}_j^n}, \quad j \geq 0. \tag{3.3}$$

Clearly, $\Delta_{x_0}(\tau,\lambda)$ is analytic in $\lambda\in\mathbb{C}$ and continuous in $\tau>0$. So, under assumption (A3), we may assume that $\det\Delta_{x_0}(\tau_0\pm\delta,u+iv)\neq 0$ for $(u,v)\in\partial\Omega$. Therefore, $\det\Delta_{x_0,j}(\tau_0\pm\delta,u+iv)\neq 0$ for $(u,v)\in\partial\Omega$ and for $j\geq 0$. Consequently, the following integers are well defined:

$$c_j(x_0,\tau_0,\beta_0)=\deg_B(\det\Delta_{x_0,j}(\tau_0-\delta,\cdot),\Omega)-\deg_B(\det\Delta_{x_0,j}(\tau_0+\delta,\cdot),\Omega), \tag{3.4}$$

where $\deg_B$ is the Brouwer degree. Let

$$\epsilon(x_0)=(-1)^n sign\det D\hat{F}(x_0). \tag{3.5}$$

We have the following global symmetric Hopf bifurcation theorem due to [24].

LEMMA 3.1. *Assume that* (A1)–(A4) *are satisfied and* $c_j(x_0,\tau_0,\beta_0)\neq 0$ *for some integer* $j\geq 0$ *and some* $(\tau_0,x_0,\beta_0)\in(0,\infty)\times M^\Gamma\times(0,\infty)$. *Let* S_j *denote the closure in* $[0,\infty)\times C(\mathbb{R};\mathbb{R}^n)\times[0,\infty)$ *of the set of all* $(\tau,z,\beta)\in[0,\infty)\times C(\mathbb{R};\mathbb{R}^n)\times\mathbb{R}\setminus M^*$ *such that* $x(t):=z(\frac{\beta}{2\pi}t)$ *is a* $\frac{2\pi}{\beta}$*-periodic solution of* (3.1) *with* $\rho x(t)=x(t-\frac{2\pi}{\beta}\frac{j}{N})$ *for* $t\in\mathbb{R}$. *Then* $S_j\neq\emptyset$, *and, for every bounded connected component* E_j *of* S_j, $(\Gamma\times S^1)E_j\cap M^*$ *is finite and*

$$\sum_{(\tau,x,\beta)\in(\Gamma\times S^1)E_j\cap M^*}\epsilon(x)c_j(x,\tau,\beta)=0; \tag{3.6}$$

here a set $E\subset(0,\infty)\times C(\mathbb{R};\mathbb{R}^n)\times(0,\infty)$ *is bounded if*

$$\sup\left\{\frac{1}{\tau}+\tau+\frac{1}{\beta}+\beta+\sup_{t\in\mathbb{R}}|x(t)|;\quad(\tau,x,\beta)\in E\right\}<\infty.$$

We now begin to apply the above result to discuss the global continuation of wave solutions of system (1.1). We need the following assumptions.

(H2) $\sup_{y\in\mathbb{R}}|h'(y)|<1$.

(H3) $g'(x)>0$ for all $x\in\mathbb{R}$.

PROPOSITION 3.2. *Assume that* (H1)–(H3) *are satisfied. Then system* (1.1) *has no nonconstant* 1*-periodic solution.*

Proof. By way of contradiction, let x be a nonconstant periodic solution of system (1.1) with $x_i(t)=x_i(t-1)$ for all $t\in\mathbb{R}$ and $i=1,2,3$. Then we obtain a system of ordinary differential equations

$$\begin{cases}\frac{1}{\tau}\dot{x}_1(t)=-x_1(t)+h(x_1(t))+2g(x_1(t))-g(x_2(t))-g(x_3(t)),\\ \frac{1}{\tau}\dot{x}_2(t)=-x_2(t)+h(x_2(t))+2g(x_2(t))-g(x_1(t))-g(x_3(t)),\\ \frac{1}{\tau}\dot{x}_3(t)=-x_3(t)+h(x_3(t))+2g(x_3(t))-g(x_2(t))-g(x_1(t)).\end{cases} \tag{3.7}$$

Note that the above equation is exactly the model equation for the Hopfield net [20] of three identical neurons with self-feedback, and thus

$$\begin{aligned}&V(x_1,x_2,x_3)\\&=-\frac{1}{2}\sum_{1\leq i<j\leq 3}[g(x_i)-g(x_j)]^2+\sum_{k=1}^{3}\int_0^{x_k}[s-h(s)]g\prime(s)ds\\&=g(x_1)g(x_2)+g(x_2)g(x_3)+g(x_3)g(x_1)\\&\quad-g^2(x_1)-g^2(x_2)-g^2(x_3)\\&\quad+\int_0^{x_1}[s-h(s)]g\prime(s)ds+\int_0^{x_2}[s-h(s)]g\prime(s)ds+\int_0^{x_3}[s-h(s)]g\prime(s)ds\end{aligned}$$

is the so-called energy function. For such an energy function, we have

$$\begin{aligned}
&\dot{V}_{(15)}(x_1,x_2,x_3)\\
&= g\prime(x_1)\dot{x}_1[g(x_2)+g(x_3)-2g(x_1)+x_1-h(x_1)]\\
&\quad + g\prime(x_2)\dot{x}_2[g(x_1)+g(x_3)-2g(x_2)+x_2-h(x_2)]\\
&\quad + g\prime(x_3)\dot{x}_3[g(x_1)+g(x_2)-2g(x_3)+x_3-h(x_3)]\\
&= -\tau\sum_{i=1}^{3} g\prime(x_i)(\dot{x}_i)^2 \le 0
\end{aligned}$$

and

$$\dot{V}_{(15)}(x_1,x_2,x_3)=0 \text{ if and only if } \dot{x}_1=\dot{x}_2=\dot{x}_3=0.$$

The LaSalle invariance principle [27] then implies that every solution of (3.6) converges to an equilibrium as $t\to\infty$. In particular, every 1-periodic solution of (1.1) must be constant. This completes the proof. □

PROPOSITION 3.3. *Under assumptions* (H1)–(H3)*, system* (1.1) *has no nonconstant* 2*-periodic solution.*

Proof. Assume that $x(t)$ is a 2-periodic solution. Let $x_4(t)=x_1(t-1), x_5(t)=x_2(t-1)$, and $x_6(t)=x_3(t-1)$. Then we obtain

$$\begin{cases}
\epsilon\dot{x}_1 = -x_1+h(x_4)-g(x_5)-g(x_6)+2g(x_4),\\
\epsilon\dot{x}_2 = -x_2+h(x_5)-g(x_4)-g(x_6)+2g(x_5),\\
\epsilon\dot{x}_3 = -x_3+h(x_6)-g(x_4)-g(x_5)+2g(x_6),\\
\epsilon\dot{x}_4 = -x_4+h(x_1)-g(x_2)-g(x_3)+2g(x_1),\\
\epsilon\dot{x}_5 = -x_5+h(x_2)-g(x_1)-g(x_3)+2g(x_2),\\
\epsilon\dot{x}_6 = -x_6+h(x_3)-g(x_1)-g(x_2)+2g(x_3).
\end{cases}$$

Then

$$\begin{cases}
\frac{1}{\tau}[x_1-x_4]\prime = -[x_1-x_4]+[h(x_4)-h(x_1)]\\
\qquad\qquad + [g(x_2)-g(x_5)+g(x_3)-g(x_6)-2(g(x_1)-g(x_4))],\\
\frac{1}{\tau}[x_2-x_5]\prime = -[x_2-x_5]+[h(x_5)-h(x_2)]\\
\qquad\qquad + [g(x_1)-g(x_4)+g(x_3)-g(x_6)-2(g(x_2)-g(x_5))],\\
\frac{1}{\tau}[x_3-x_6]\prime = -[x_3-x_6]+[h(x_6)-h(x_3)]\\
\qquad\qquad + [g(x_1)-g(x_4)+g(x_2)-g(x_5)-2(g(x_3)-g(x_6))].
\end{cases}$$

Let D^+ denote the upper right Dini derivative; then

$$\begin{cases}
\frac{1}{\tau}D^+|x_1-x_4| \le -|x_1-x_4|-2|g(x_1)-g(x_4)|+|h(x_1)-h(x_4)|\\
\qquad\qquad + |g(x_2)-g(x_5)|+|g(x_3)-g(x_6)|,\\
\frac{1}{\tau}D^+|x_2-x_5| \le -|x_2-x_5|-2|g(x_2)-g(x_5)|+|h(x_2)-h(x_5)|\\
\qquad\qquad + |g(x_1)-g(x_4)|+|g(x_3)-g(x_6)|,\\
\frac{1}{\tau}D^+|x_3-x_6| \le -|x_3-x_6|-2|g(x_3)-g(x_6)|+|h(x_3)-h(x_6)|\\
\qquad\qquad + |g(x_1)-g(x_4)|+|g(x_2)-g(x_5)|.
\end{cases}$$

Therefore,

$$\begin{aligned}
&\frac{1}{\tau}D^+[|x_1-x_4|+|x_2-x_5|+|x_3-x_6|]\\
&\le -[|x_1-x_4|+|x_2-x_5|+|x_3-x_6|]\\
&\qquad +|h(x_1)-h(x_4)|+|h(x_2)-h(x_5)|+|h(x_3)-h(x_6)|\\
&\le -\left[1-\sup_{\theta\in\mathbb{R}}|h\prime(\theta)|\right][|x_1-x_4|+|x_2-x_5|+|x_3-x_6|].
\end{aligned}$$

This implies that

$$|x_1(t)-x_4(t)|+|x_2(t)-x_5(t)|+|x_3(t)-x_6(t)|\to 0 \quad \text{as } t\to\infty.$$

Therefore, for a 2-periodic solution x of (1), we must have $x_1(t)=x_1(t-1), x_2(t)=x_2(t-1)$, and $x_3(t)=x_3(t-1)$. So Proposition 3.2 can be applied to conclude that x must be constant. This completes the proof. □

It remains to obtain a priori bounds for the norm of periodic solutions of (1.1). We need the following assumption.

(H4) $\sup_{y\in\mathbb{R}}[|h(y)|+|g(y)|]<\infty$.

PROPOSITION 3.4. *Assume* (H1)–(H4) *are satisfied. Then there exists* $M=M(h,g)>0$ *such that* $|x_1(t)|+|x_2(t)|+|x_3(t)|\le M$ *for all* $t\in\mathbb{R}$ *and for every periodic solution* x *of* (1.1).

Proof. Let $t^*\in\mathbb{R}$ and $j\in\{1,2,3\}$ be given so that $|x_j(t^*)|=\max_{t\in\mathbb{R}}\max_{1\le i\le 3}|x_i(t)|$. Then $\dot{x}_j(t^*)=0$. That is,

$$x_j(t^*)=h(x_j(t^*-1))-[g(x_{j-1}(t^*-1))+g(x_{j+1}(t^*-1))-2g(x_j(t^*-1))],$$

from which it follows that

$$|x_j(t^*)|\le\sup_{y\in\mathbb{R}}|h(y)|+4\sup_{y\in\mathbb{R}}|g(y)|:=\frac{M}{3}<\infty.$$

This completes the proof. □

We now apply Lemma 3.1 to investigate the global continuation of standing, mirror-reflecting, and discrete waves.

First, note that near $\tau=\tau_k$ system (1.1) has two bifurcations of discrete waves satisfying $x_{i-1}(t)=x_i(t\pm\frac{\omega}{3})$, where ω is a period. To look at the global continuation of such local bifurcations, we regard system (1.1) as a functional differential equation equivariant with respect to the action of $\Gamma=Z_3$, where the action is the cyclic permutation. We have

$$\begin{aligned}
M^\Gamma&=\{x\in\mathbb{R}^3;\gamma x=x \text{ for } \gamma\in\Gamma, F(\bar{x})=0\}\\
&=\{x\in\mathbb{R}^3;x_1=x_2=x_3 \text{ and } x_1=h(x_1)\}=\{0\}
\end{aligned}$$

under assumption (H2). Clearly, (A1) and (A2) are satisfied.

Under assumption (H1), the discussions in the last section show that

$$M^*=\{(\tau_k,0,\beta_k);\quad k\ge 1\}.$$

Therefore, M^* is discrete in $\mathbb{R}^3$.

Using Proposition 2.4 (ii), for a fixed integer k, we can choose positive constants b,c, and δ so that the only possible eigenvalue $u+iv$ of $A(\tau_k)$ with $(u,v)\in\partial\Omega$ is $i\beta_k$,

where $\Omega = (0, b) \times (\beta_k - c, \beta_k + c)$, and if $(\tau, \beta) \in [\tau_k - \delta, \tau_k + \delta] \times [\beta_k - c, \beta_k + c]$, then $i\beta$ is an eigenvalue of $A(\tau)$ if and only if $\tau = \tau_k$ and $\beta = \beta_k$. Then, using Proposition 2.4 (i), we can conclude that the analytic function $p_\tau(\lambda) := \lambda + \tau - \gamma\tau e^{-\lambda}$ has no zero in $\bar{\Omega}$ for $\tau = \tau_k \pm \delta$. Also, by Propositions 2.4 and 2.6, the above b, c, and δ can be chosen so that, for the analytic function

$$q_\tau(\lambda) = \lambda + \tau - (\gamma + 3\beta)\tau e^{-\lambda},$$

we have that $q_{\tau_k - \delta}$ has no zero in $\bar{\Omega}$, while $q_{\tau_k + \delta}$ has exactly one zero in $\bar{\Omega}$, and this zero is simple and is in the interior of $\bar{\Omega}$. Therefore,

$$\deg_B(q_{\tau_k - \delta}, \Omega) = 0,$$

and

$$\deg_B(q_{\tau_k + \delta}, \Omega) = 1.$$

With respect to the complexification of the above ($\Gamma = Z_3$)-action in $\mathbb{R}^3$, we have the isotypical decomposition

$$\mathbb{C}^3 = \mathbb{C}^3_0 \oplus \mathbb{C}^3_1 \oplus \mathbb{C}^3_2,$$

where

$$\mathbb{C}^3_j = \{(1, e^{i\frac{2\pi}{3}j}, e^{i\frac{4\pi}{3}j})x; \quad x \in \mathbb{C}\}.$$

We have shown that

$$\begin{aligned} \Delta_{0,j} &:= \Delta_0(\tau, \lambda)|_{\mathbb{C}^3_j} = \Delta(\tau, \lambda)|_{\mathbb{C}^3_j} \\ &= \begin{cases} \lambda + \tau - \gamma\tau e^{-\lambda} & \text{if } j = 0, \\ \lambda + \tau - (\gamma + 3\beta)\tau e^{-\lambda} \text{ if} & j = 1, 2. \end{cases} \end{aligned}$$

Therefore, from the above discussions, we get

$$c_0(0, \tau_k, \beta_k) = \deg_B(p_{\tau_k - \delta}, \Omega) - \deg_B(p_{\tau_k + \delta}, \Omega) = 0,$$

and, for $j = 1, 2$,

$$c_j(0, \tau_k, \beta_k) = \deg_B(q_{\tau_k - \delta}, \Omega) - \deg_B(q_{\tau_k + \delta}, \Omega) = -1.$$

Let $S_j, j = 1, 2$, denote the closure in $[0, \infty) \times C(\mathbb{R}; \mathbb{R}^3) \times [0, \infty)$ of the set of all triples $(\tau, z, \beta) \notin M^*$ such that $x(t) := z(\frac{\beta}{2\pi}t)$ is a $\frac{2\pi}{\beta}$-periodic solution of (1.1) with $x_{k+1}(t) = x_k(t - \frac{2\pi}{\beta}\frac{j}{3})$ for $t \in \mathbb{R}$ and $k = 1, 2, 3 (\mathrm{mod}\, 3)$. Then Lemma 3.1 implies that S_j must have a nonempty connected component E_j passing through $(\tau_k, 0, \beta_k)$, and this component must be unbounded in the sense that

$$\sup_{(\tau, x, \beta) \in E_j} \left\{ \tau + \frac{1}{\tau} + \beta + \frac{1}{\beta} + \sup_{t \in \mathbb{R}} |z(t)| \right\} = \infty,$$

for otherwise, the summation (3.6) must hold, and this is clearly impossible as $c_j(0, \tau_k, \beta_k)$ has the same sign for all positive integers k.

The projection of E_j onto the space $C(\mathbb{R};\mathbb{R}^3)$ is bounded due to Proposition 3.4. Near τ_k, (ii) of Proposition 2.4 shows that, for $(\tau,z,\beta)\in E_j$, we have

$$\frac{2\pi}{\beta}\in\left(\frac{2\pi}{2k\pi},\frac{2\pi}{2k\pi-\frac{\pi}{2}}\right)\subset\left(\frac{1}{k},\frac{1}{k-\frac{1}{4}}\right)\subset\left(\frac{1}{k},\frac{4}{3}\right)\subset\left(\frac{1}{k},2\right).$$

On the other hand, Propositions 3.2 and 3.3 imply that the projection of E_j onto the β-plane can never reach the lines $\frac{2\pi}{\beta}=\frac{1}{k}$ (note that (1.1) has no $\frac{1}{k}$-periodic solution as it does not have a 1-periodic solution) and $\frac{2\pi}{\beta}=2$. Therefore, the projection of E_j onto the β-plane always satisfies $\pi<\beta<2k\pi$.

On the other hand, the result of [28] shows that there exists $\alpha^*>0$ such that any period p of a periodic solution of (1.2) must satisfy $p\geq\alpha^*$. Consequently, for $(\tau,z,\beta)\in E_j$, we must have $\tau\frac{2\pi}{\beta}\geq\alpha^*$. That is, $\tau\geq\frac{\beta\alpha^*}{2\pi}>\frac{\alpha^*}{2}$ for every $\tau\in I$, the projection of E_j onto the τ-axis which must be an interval. Therefore, I must be unbounded from above. Clearly, I contains τ_k. This proves the following.

THEOREM 3.5. *For each $\tau>\tau_k$, system (1.1) always has two discrete waves satisfying $x_{j+1}(t)=x_j(t\pm\frac{\omega}{3})$ for $t\in\mathbb{R}$ and $j(\mathrm{mod}\,3)$, where ω is a period of $x(t)$ and $\frac{1}{k}<\omega<2$.*

Let us now consider the global continuation of mirror-reflecting waves and standing waves. For this purpose, we consider (1.1) as a functional differential equation equivariant with respect to the action of $\Gamma=Z_2$ on $\mathbb{R}^3$ defined by

$$\rho\begin{pmatrix}x_1\\x_2\\x_3\end{pmatrix}=\begin{pmatrix}x_1\\x_3\\x_2\end{pmatrix},\quad x_i\in\mathbb{R},i=1,2,3,Z_2=\langle\rho\rangle.$$

In this case,

$$M^\Gamma=\{x\in\mathbb{R}^3;\quad x_2=x_3,x_i=h(x_i)-g(x_{i-1})-g(x_{i+1})+2g(x_i),i(\mathrm{mod}\,3)\}.$$

The structure of M^Γ is explicitly described in the following proposition under the following assumption.

(H5) $yh''(y)<0$ and $yg''(y)<0$ for $y\neq0$.

PROPOSITION 3.6. *Under* (H1)–(H5)*, the system of equations*

$$x_i=h(x_i)-g(x_{i-1})-g(x_{i+1})+2g(x_i),\quad i(\mathrm{mod}\,3),\tag{3.8}$$

and

$$x_2=x_3\tag{3.9}$$

for $x=(x_1,x_2,x_3)^T$ has exactly three solutions. They are

$$(0,0,0)^T,\quad(z^-,y^+,y^+)^T,\quad(z^+,y^-,y^-)^T,$$

where $y^+>0,y^-<0,z^+>0,z^-<0$ are the unique solutions of

$$\begin{cases}y^\pm-h(y^\pm)=u^\pm,\\ z^\mp-h(z^\mp)=-2u^\pm\end{cases}\tag{3.10}$$

and $u^+>0$ and $u^-<0$ are the unique positive and negative solutions of

$$u+g[G^{-1}(-2u)]-g[G^{-1}(u)]=0\tag{3.11}$$

with $G : \mathbb{R} \to \mathbb{R}$ being given by the equation

$$G(\theta) = \theta - h(\theta), \quad \theta \in \mathbb{R}. \tag{3.12}$$

In other words,

$$M^\Gamma = \{(0,0,0)^T, (z^-, y^+, y^+)^T, (z^+, y^-, y^-)^T\}.$$

Proof. Under assumption (H2), $G : \mathbb{R} \to \mathbb{R}$ defined by (3.12) is an increasing function. Define

$$u = G(y), \quad v = G(z). \tag{3.13}$$

Then $x = (x_1, x_2, x_3)^T$ with $x_1 = z$ and $x_2 = x_3 = y$ satisfies (3.8) if and only if

$$u = g[G^{-1}(u)] - g[G^{-1}(v)] \tag{3.14}$$

and

$$v = -2u. \tag{3.15}$$

In other words, (u, v) is given by $v = -2u$ and $u = g[G^{-1}(u)] - g[G^{-1}(-2u)]$. Let

$$H(u) = u + g[G^{-1}(-2u)] - g[G^{-1}(u)], \quad u \in \mathbb{R}.$$

Then

$$H(0) = 0, \quad H(\pm\infty) = \pm\infty.$$

Note that

$$\begin{aligned} H'(u) &= 1 + g'[G^{-1}(-2u)](G^{-1})'(-2u)(-2) - g'[G^{-1}(u)](G^{-1})'(u) \\ &= 1 - 2g'[G^{-1}(-2u)](G^{-1})'(-2u) - g'[G^{-1}(u)](G^{-1})'(u). \end{aligned}$$

Implicitly differentiating $F(\theta) = \theta - h(\theta)$, we get

$$(G^{-1})'(\theta) = \frac{1}{1 - h'[G^{-1}(\theta)]}.$$

Therefore,

$$H'(u) = 1 - \frac{2g'[G^{-1}(-2u)]}{1 - h'[G^{-1}(-2u)]} - \frac{g'[G^{-1}(u)]}{1 - h'[G^{-1}(u)]}.$$

In particular, with $h'(0) = \gamma$ and $g'(0) = \beta$ and under assumption (H1), we have

$$H'(0) = 1 - \frac{2\beta}{1-\gamma} - \frac{\beta}{1-\gamma} = \frac{1 - (\gamma + 3\beta)}{1-\gamma} < 0.$$

Therefore, there must be $u^+ > 0$ and $u^- < 0$ such that $H(u^\pm) = 0$.

It remains to show that there exists no other nonzero zero of H. By way of contradiction, if there exists $u^* > 0$ (the case in which $u^* < 0$ can be dealt with

similarly) such that $H(u^*) = 0$ and $u^* \neq u^+$, then there must be $\theta > 0$ so that $H''(\theta) = 0$. However, we have

$$\begin{aligned} H''(u) &= -2g''[G^{-1}(-2u)][(G^{-1})'(-2u)]^2(-2) \\ &\quad -2g'[G^{-1}(-2u)](G^{-1})''(-2u)(-2) \\ &\quad -g''[G^{-1}(u)][(G^{-1})'(u)]^2 - g'[G^{-1}(u)](G^{-1})''(u) \\ &= 4g''[G^{-1}(-2u)][(G^{-1})'(-2u)]^2 + 4g'[G^{-1}(-2u)](G^{-1})''(-2u) \\ &\quad -g''[G^{-1}(u)][(G^{-1})'(u)]^2 - g'[G^{-1}(u)](G^{-1})''(u). \end{aligned}$$

Under assumption (H5), for $u > 0$ we have

$$g''[G^{-1}(-2u)] > 0, \quad g''[G^{-1}(u)] < 0.$$

Therefore, $H''(u) > 0$ if we can show that

$$(G^{-1})''(-2u) > 0 \text{ and } (G^{-1})''(u) < 0 \text{ for } u > 0. \tag{3.16}$$

The above holds by using (H5) since

$$(G^{-1})''(u) = \frac{h''(G^{-1}(u))(G^{-1})'(u)}{[1 - h'(G^{-1}(u))]^2}$$

has the opposite sign from u. (Recall that $G^{-1}(u)$ has the same sign as u.)

This completes the proof. □

To verify (A2) and (A4) in the case in which $\Gamma = Z_2$, we need the following condition.

(H6) $h'(\alpha) > 0, h'(\alpha) + 3g'(\alpha) < 1$, where $\alpha = y^{\pm}, z^{\pm}$.

The linearization of (1.1) at (z^*, y^*, y^*) with $z^* = z^{\mp}, y^* = y^{\pm}$ takes the form

$$\begin{cases} \frac{1}{\tau}\dot{X}_1(t) = -X_1(t) + h_1'(z^*)X_1(t-1) \\ \qquad\qquad -[g'(y^*)X_2(t-1) + g'(y^*)X_3(t-1) - 2g'(z^*)X_1(t-1)], \\ \frac{1}{\tau}\dot{X}_2(t) = -X_2(t) + h_1'(y^*)X_2(t-1) \\ \qquad\qquad -[g'(y^*)X_3(t-1) + g'(z^*)X_1(t-1) - 2g'(y^*)X_2(t-1)], \\ \frac{1}{\tau}\dot{X}_3(t) = -X_3(t) + h_1'(y^*)X_3(t-1) \\ \qquad\qquad -[g'(z^*)X_1(t-1) + g'(y^*)X_2(t-1) - 2g'(y^*)X_3(t-1)], \end{cases}$$

and the characteristic matrix becomes

$$\begin{aligned} &\Delta_{(z^*,y^*,y^*)}(\tau,\lambda) \\ &= \begin{pmatrix} A & \tau g'(y^*)e^{-\lambda} & \tau g'(y^*)e^{-\lambda} \\ \tau g'(z^*)e^{-\lambda} & B & \tau g'(y^*)e^{-\lambda} \\ \tau g'(z^*)e^{-\lambda} & \tau g'(y^*)e^{-\lambda} & B \end{pmatrix}, \end{aligned}$$

where

$$\begin{aligned} A &= \lambda + \tau - \tau[h'(z^*) + 2g'(z^*)]e^{-\lambda}, \\ B &= \lambda + \tau - \tau[h'(y^*) + 2g'(y^*)]e^{-\lambda}. \end{aligned}$$

The isotypical decomposition of $\mathbb{C}^3$ with respect to the above $\Gamma = Z_2$ action is

$$\mathbb{C}^3 = \mathbb{C}_0^3 \oplus \mathbb{C}_1^3,$$

where

$$\mathbb{C}_0^3 = \{(x, y, y)^T; x, y \in \mathbb{C}\},$$
$$\mathbb{C}_1^3 = \{(0, z, -z)^T; z \in \mathbb{C}\}.$$

Therefore,

$$\Delta_{(z^*,y^*,y^*)}(\tau,\lambda)|_{\mathbb{C}_0^3} = \begin{pmatrix} \lambda + \tau - \tau[h'(z^*) + 2g'(z^*)]e^{-\lambda} & \tau g'(z^*)e^{-\lambda} \\ 2\tau g'(y^*)e^{-\lambda} & \lambda + \tau - \tau[h'(y^*) + g'(y^*)]e^{-\lambda} \end{pmatrix}$$

and

$$\Delta_{(z^*,y^*,y^*)}(\tau,\lambda)|_{\mathbb{C}_1^3} = \lambda + \tau - \tau[h'(y^*) + 3g'(y^*)]e^{-\lambda\tau}.$$

It is already shown in the proof of Proposition 2.4 (i) that, under assumption (H6), every zero of $\Delta_{(z^*,y^*,y^*)}(\tau,\lambda)|_{\mathbb{C}_1^3}$ has negative real part. Note that $\Delta_{(z^*,y^*,y^*)}(\tau,\lambda)|_{\mathbb{C}_0^3}$ is the characteristic matrix for the following linear system of delay differential equations:

$$\begin{cases} \frac{1}{\tau}\dot{u}_1(t) = -u_1(t) + [h'(z^*) + 2g'(z^*)]u_1(t-1) - g'(z^*)u_2(t-1), \\ \frac{1}{\tau}\dot{u}_2(t) = -u_2(t) + [h'(y^*) + g'(y^*)]u_2(t-1) - 2g'(y^*)u_1(t-1). \end{cases} \tag{3.17}$$

Let $V(u_1, u_2) = \max\{|u_1|, |u_2|\}$. For a given solution of (3.17), if at some $t \geq 0$ we have $V(u_1(t-1), u_2(t-1)) \leq V(u_1(t), u_2(t)) = |u_1(t)|$, then

$$\begin{aligned} &\frac{1}{\tau}D^+V(u_1(t), u_2(t)) \\ &\leq -|u_1(t)| + [h'(z^*) + 2g'(z^*)]|u_1(t-1)| + g'(z^*)|u_2(t-1)| \\ &\leq -|u_1(t)| + [h'(z^*) + 3g'(z^*)]|u_1(t)| \\ &= -[1 - h'(z^*) - 3g'(z^*)]V(u_1(t), u_2(t)). \end{aligned}$$

Similarly, for a given solution of (3.17), if at some $t \geq 0$ we have $V(u_1(t-1), u_2(t-1)) \leq V(u_1(t), u_2(t)) = |u_2(t)|$, then

$$\frac{1}{\tau}D^+V(u_1(t), u_2(t)) \leq -[1 - h'(y^*) - 3g'(y^*)]V(u_1(t), u_2(t)).$$

Therefore, using assumption (H6) and the Razumikhin-type LaSalle invariance principle in [27, 29], we can conclude that all solutions of (3.17) converge to zero as $t \to \infty$. This shows that all zeros of $\det\Delta_{(z^*,y^*,y^*)}(\tau,\lambda)|_{\mathbb{C}_0^3}$ have negative real parts. In particular, $\det\Delta_{(z^*,y^*,y^*)}(\tau,0)|_{\mathbb{C}_0^3} \neq 0$, and this determinant is exactly the determinant of the derivative of the corresponding F at (z^*, y^*, y^*). This shows that (A2) is satisfied and that (A3) is trivial.

Therefore, even in the case in which $\Gamma = Z_2$, we have

$$M^* = \{(\tau_k, 0, \beta_k); \quad k \geq 1\}.$$

Thus M^* is discrete and (A4) holds. Using similar arguments as for Theorem 3.5, we can get the following theorems.

THEOREM 3.7. *For each $\tau > \tau_k, k \geq 1$, system (1.1) has one standing wave satisfying $x_1(t) = x_1(t - \frac{\omega}{2})$ and $x_2(t) = x_3(t - \frac{\omega}{2})$ for $t \in \mathbb{R}$, where ω is a period of x and $\frac{1}{k} < \omega < 2$.*

THEOREM 3.8. *For each $\tau > \tau_k, k \geq 1$, system (1.1) has one mirror-reflecting wave satisfying $x_2(t) = x_3(t)$ and $x_i(t) = x_i(t + \omega)$ for $t \in \mathbb{R}, i = 1, 2, 3$, where $\frac{1}{k} < \omega < 2$.*

Remark 1. Due to the D_3-symmetry, Theorems 3.5–3.8 in fact imply the existence of three standing waves, three mirror-reflecting waves, and two discrete waves for each $\tau > \tau_k$. Note also that

$$\tau_1 < \tau_2 < \tau_3 < \cdots .$$

The above results establish the existence of $3k$ standing waves, $3k$ mirror-reflecting waves, and $2k$ discrete waves. It should be mentioned that, in the above theorems, ω is not necessarily the minimal period, and several branches of waves may coincide at some values of τ. In terms of the following five remarks, we can claim that for $\tau > \tau_1$, system (1.1) has three orbits of waves—one orbit of discrete waves, one orbit of standing waves, and one orbit of mirror-reflecting waves—and only the last two orbits may coincide through the mechanism of periodic doubling. Discounting the above possible coincidence, system (1.1) has at least five wave solutions for each $\tau > \tau_1$.

Remark 2. A branch of nontrivial discrete waves and a branch of mirror-reflecting waves cannot coincide at any value of τ, for otherwise there exists a nontrivial ω-periodic solution x of (1.1) such that $x_i(t) = x_{i-1}(t \pm \frac{\omega}{3})$ for $i (\mathrm{mod}\, 3)$ and $x_j(t) = x_k(t)$ for some $j \neq k$. For simplicity, let $x_2(t) = x_3(t)$. Then $x_2(t) = x_3(t \pm \frac{\omega}{3})$ implies that $\frac{\omega}{3}$ is also a period of $x_2 = x_3$, and thus $x_1(t) = x_2(t \pm \frac{\omega}{3}) = x_2(t) (= x_3(t))$. So x must be spatially homogeneous. As $\sup_{x \in \mathbb{R}} |h'(x)| < 1$ implies that $y = 0$ is the global attractor of the scalar equation $y'(t) = -y(t) + h(y(t - \tau))$ for any $\tau \geq 0$ (see, for example, [16]), we have $x = 0$, which is a contradiction.

Remark 3. A branch of nontrivial discrete waves and a branch of standing waves cannot coincide at any value of τ, for otherwise there exists a nontrivial ω-periodic solution x of (1.1) such that $x_i(t) = x_{i-1}(t \pm \frac{\omega}{3})$ for $i (\mathrm{mod}\ 3)$ and, say, $x_1(t) = x_1(t + \frac{\omega}{2}), x_2(t) = x_3(t + \frac{\omega}{2})$. Then $x_2(t) = x_3(t + \frac{\omega}{3}) = x_3(t + \frac{\omega}{2})$. (The other case in which $x_2(t) = x_3(t - \frac{\omega}{3})$ can be dealt similarly.) Therefore, $\frac{\omega}{6}$ is also a period of x_3 (and thus x_2). Consequently, $x_2(t) = x_3(t + \frac{\omega}{3}) = x_3(t)$ and $x_1(t) = x_2(t + \frac{\omega}{3}) = x_2(t) = x_3(t)$. Again, x must be spatially homogeneous, and thus $x = 0$, which is a contradiction.

Remark 4. A branch of nontrivial discrete waves of the form $x_i(t) = x_{i-1}(t - \frac{\omega}{3})$ and a branch of discrete waves of the form $x_i(t) = x_{i-1}(t + \frac{\omega}{3})$ for $i (\mathrm{mod}\, 3)$ and $t \in \mathbb{R}$ cannot coincide at any value of τ. Again, this can be verified by way of contradiction. Namely, if there is a discrete wave satisfying simultaneously $x_i(t) = x_{i-1}(t + \frac{\omega}{3}) = x_{i-1}(t - \frac{\omega}{3})$ for $i (\mathrm{mod}\, 3)$, then $\frac{2\omega}{3}$ and ω are periods of x, and so is $\frac{\omega}{3}$. This, together with $x_i(t) = x_{i-1}(t - \frac{\omega}{3})$, implies that x is spatially homogeneous, and thus $x = 0$, which is a contradiction.

Remark 5. As no nontrivial spatially homogeneous periodic solution exists, it is clear that a branch of nontrivial mirror-reflecting waves satisfying $x_i(t) = x_j(t)$ for some $i \neq j$ and a branch of mirror-reflecting waves satisfying $x_l(t) = x_m(t)$ for some $l \neq m$ cannot coincide at any value of τ if $(i, j) \neq (l, m)$. Similarly, a branch of nontrivial standing waves with $x_i(t) = x_i(t + \frac{\omega}{2}), x_j(t) = x_k(t + \frac{\omega}{2})$ for $i \neq j \neq k$ and a branch of nontrivial standing waves with $x_{i^*}(t) = x_{j^*}(t + \frac{\omega}{2}), x_{j^*}(t) = x_{k^*}(t + \frac{\omega}{2})$ for $i^* \neq j^* \neq k^*$ cannot coincide at any value of τ if $(i, j, k) \neq (i^*, j^*, k^*)$.

Remark 6. Unfortunately, the above arguments cannot be extended to rule out the possibility of the coincidence of a branch of nontrivial ω-periodic mirror-reflecting waves with $x_i(t) = x_j(t)$ for some $i \neq j$ and a branch of ω-periodic standing waves with $x_i(t) = x_j(t + \frac{\omega}{2})$ for some $i \neq j$. In fact, such a coincidence may occur at some value of τ where periodic doubling happens: $x_i(t) = x_i(t + \frac{\omega}{2}), i(\mathrm{mod}\, 3), t \in \mathbb{R}$.

Acknowledgment. We wish to thank one reviewer for her or his valuable comments that led to truly significant improvement of the manuscript.

DYNAMIC BOUNDARY CONDITIONS FOR HAMILTON–JACOBI EQUATIONS*

C. M. ELLIOTT†, Y. GIGA‡, AND S. GOTO§

Abstract. A nonstandard dynamic boundary condition for a Hamilton–Jacobi equation in one space dimension is studied in the context of viscosity solutions. A comparison principle, and hence uniqueness, is proved by consideration of an equivalent notion of viscosity solution for an alternative formulation of the boundary condition. The relationship with a Neumann condition is established. Global existence is obtained by consideration of a related parabolic approximation with a dynamic boundary condition. The problem is motivated by applications in superconductivity and interface evolution.

Key words. Hamilton–Jacobi equation, dynamic boundary condition, viscosity solution

1. Introduction.

We consider the first order equation

$$u_t - F\left(u_x^2 + \gamma^2\right)^{1/2} = 0 \quad \text{in } \Omega \times (0,\infty) \tag{1.1}$$

supplemented with the dynamic boundary condition

$$u_t - F\alpha = 0 \quad \text{on } \partial\Omega \times (0,\infty), \tag{1.2}$$

where Ω is a bounded open interval. The functions F and α are given continuous functions on $\overline{\Omega} \times [0,\infty)$, $\partial\Omega \times [0,\infty)$, respectively, and $\gamma \geq 0$ is a constant.

There are at least two sources of this problem. Consider the mean field vortex density model in a cylinder $D \times \mathbb{R}$ ($D \subset \mathbb{R}^2$) when the magnetic field $\vec{H}$ is orthogonal to the axis of the cylinder; see Chapman [3]. The vorticity field $\vec{\omega} = (\nabla^\perp \psi, 0)$, $\nabla^\perp = (-\partial_{x_2}, \partial_{x_1})$ is required to satisfy the conservation of vorticity

$$\vec{\omega}_t + \operatorname{curl}(\vec{\omega} \times \vec{v}) = 0.$$

If the velocity field $\vec{v}$ is of the form

$$\vec{v} = \operatorname{curl}\vec{H} \times \vec{\omega}/|\vec{\omega}|$$

and $\vec{H}$ is given, then the conservation of vorticity yields

$$\psi_t = |\nabla\psi| F,$$

where F is a given function. Our equation (1.1) is derived by assuming that $\partial_{x_2}\psi = \gamma$ is a constant on $D = \Omega \times \mathbb{R}$ if we set $u(x_1, t) = \psi(x_1, x_2, t) - \gamma x_2$. The quantity $-\psi_t$ on the boundary corresponds to the flux $\vec{n} \times (\vec{\omega} \times \vec{v})$ on $\partial D \times \mathbb{R}$. The condition $\psi_t = F\alpha$ is considered as a special case of assigning the value of flux, and we obtain (1.1), (1.2). A full system with a different boundary condition $\vec{\omega} \cdot \vec{n} = 0$ is studied by Elliott, Schätzle, and Stoth [6].

Another source of the problem is a surface evolution problem with dynamic boundary condition. Consider (1.1) with $\gamma = 1$. Then (1.1) is equivalent to requiring that the upward normal velocity V of the graph $\Gamma_t = \{y = u(x, t)\}$ equal F, i.e., $V = F$. The boundary condition (1.2) is equivalent to saying that the upward velocity v of Γ_t on $\partial\Omega \times \mathbb{R}$ is equal to $F\alpha$, i.e., $v = F\alpha$. In [1] Angenent and Gurtin derive a dynamic boundary condition for the mean curvature flow equation. It is of the form $v = A\cos\theta + B$, where v is the normal velocity of $\partial\Gamma_t$ in $\partial\Omega$ and θ is the contact angle of Γ_t and $\partial\Omega$; A and B are constants. Our boundary condition corresponds to the case $A = 0$.

Our goal is to study the unique global-in-time solvability of (1.1), (1.2) for a given initial data. Since the problem is of first order, it is convenient to handle this problem in the realm of viscosity solutions; see, e.g., Barles [2]. We establish the comparison principle (section 3) for (1.1) and (1.2) by deriving an equivalent definition (section 2) of solutions. Although the dynamic boundary value problem is studied in [2, p. 102, (4.23)], it is essentially of Neumann type and does not include (1.2). We further prove (section 5) that the solution of (1.1) and (1.2) solves the Neumann problem for (1.1) with

$$\partial u/\partial\nu = (\mathrm{Sign}F)\left\{(\alpha - \gamma)_+(\alpha + \gamma)\right\}^{1/2} \tag{1.3}$$

in the viscosity sense, where β_+ denotes the positive part of β and $\mathrm{Sign}F$ denotes the sign of F, i.e., $\mathrm{Sign}F = \pm 1$ if $F \gtrless 0$ and $\mathrm{Sign}F = 0$ if $F = 0$. It might be possible to prove the comparison principle for (1.1) with the inhomogeneous data $\partial u/\partial\nu = p(t)$ when p is continuous; see Claisse [4]. However, our comparison principle for (1.1) and (1.2) still holds when F changes sign, in which case the Neumann data in (1.3) is discontinuous and hence is not included in the literature. Moreover, our proof is more direct and does not use (1.3). Our comparison principle yields the uniqueness of viscosity solutions for (1.1) and (1.2).

We also prove the global existence (section 4) of a solution for (1.1), (1.2) when the initial data a is a Lipschitz function in $\overline{\Omega}$ by using the approximate equation

$$u_t - \varepsilon u_{xx} - F\left(u_x^2 + \gamma^2\right)^{1/2} = 0 \quad \text{in } \Omega \times (0, \infty) \tag{1.4}$$

with the dynamic boundary condition

$$u_t - F\alpha + \varepsilon\partial u/\partial\nu = 0 \quad \text{on } \partial\Omega \times (0, \infty), \tag{1.5}$$

where ε is a positive parameter. The dynamic boundary condition for uniformly parabolic equations is well studied, for example, by Hinterman [10] and Escher [7, 8]. Their results may be applied to (1.4) and (1.5) in order to yield at least a local solution. However, since the global existence of solutions is easy to show, we give a proof for global solvability of (1.4), (1.5) in the appendix. By the maximum principle we derive a priori bounds (section 4) for the sup norms of u_t^ε, u_x^ε, u^ε in $\overline{\Omega} \times [0, T]$ for the solutions of (1.4), (1.5) independent of $\varepsilon \in (0, 1)$. This yields the solution of (1.1), (1.2) as a limit as $\varepsilon \to 0$. The presence of the term $\varepsilon\partial u/\partial\nu$ in (1.5) is crucial in order to obtain the a priori bound.

Finally, we warn the reader that the boundary condition (1.2) cannot be replaced by a formally equivalent Dirichlet boundary condition

$$u(x,t) = \int_0^t F(x,\tau)\alpha(x,\tau)d\tau + a(x) \tag{1.6}$$

even in the viscosity sense. We give in section 5 an explicit solution of (1.1) which solves (1.2) (resp., (1.6)) but does not solve (1.6) (resp., (1.2)) when $\alpha \equiv 1$, $F \equiv 1$, and $\alpha > \gamma$.

2. Definitions and equivalent notions of solutions. Let Ω be a bounded interval $(0, L) \subset \mathbb{R}$ and let $T > 0$ be a constant. For brevity we set $Q = \Omega \times (0, T)$, $\hat{Q} = \overline{\Omega} \times (0, T)$ and their closure $\overline{Q} = \overline{\Omega} \times [0, T]$. Given a mapping $k := k(x, t, \tau, p) : \hat{Q} \times \mathbb{R} \times \mathbb{R} \to \mathbb{R}$ we recall the following definitions of viscosity sub- and supersolutions $u \in C(\hat{Q})$ for k.

DEFINITION 2.1. *A function u is said to be a viscosity subsolution of k (in $\hat{Q}$) provided for any $(\hat{x}, \hat{t}, \phi) \in \hat{Q} \times C^1(\hat{Q})$ such that*

$$(u - \phi)(\hat{x}, \hat{t}) = \sup_{\hat{Q}}(u - \phi);$$

then the inequality

$$k(\hat{x}, \hat{t}, \tau, p) \le 0$$

holds where $\tau = \phi_t(\hat{x}, \hat{t})$ and $p = \phi_x(\hat{x}, \hat{t})$.

DEFINITION 2.2. *A function u is said to be a viscosity supersolution of k (in $\hat{Q}$) provided for any $(\hat{x}, \hat{t}, \phi) \in \hat{Q} \times C^1(\hat{Q})$ such that*

$$(u - \phi)(\hat{x}, \hat{t}) = \inf_{\hat{Q}}(u - \phi);$$

then the inequality

$$k(\hat{x}, \hat{t}, \tau, p) \ge 0$$

holds where $\tau = \phi_t(\hat{x}, \hat{t})$ and $p = \phi_x(\hat{x}, \hat{t})$.

Let F and α be given functions in $C(\overline{Q})$, $C(\partial\Omega \times [0, T])$, respectively, and let $\gamma \ge 0$ be a given constant. We use the notation, since $\partial\Omega = \{0, L\}$, that $\frac{\partial}{\partial\nu} = \nu\frac{\partial}{\partial x}$ on $\partial\Omega$ with $\nu = -1$ for $x = 0$ and $\nu = +1$ for $x = L$. The initial boundary value problem is

$$\begin{cases} u_t - F\left(u_x^2 + \gamma^2\right)^{1/2} = 0 & \text{in} \quad Q, \\ u_t - F\alpha = 0 & \text{on} \quad \partial\Omega \times (0, T), \\ u|_{t=0} = a & \text{on} \quad \Omega. \end{cases} \tag{2.1}$$

In order to formulate the definition of a viscosity solution to (2.1) we define, for $(x, t, \tau, p) \in \hat{Q} \times \mathbb{R} \times \mathbb{R}$,

$$E(x,t,\tau,p) := \tau - F(x,t)\left(p^2 + \gamma^2\right)^{1/2},$$

$$F_{\min}(x,t,\tau,p) := \begin{cases} E(x,t,\tau,p) & \text{if} \quad x \in \Omega, \\ \min\{\tau - F(x,t)\alpha(x,t), E(x,t,\tau,p)\} & \text{if} \quad x \in \partial\Omega, \end{cases}$$

$$F_{\max}(x,t,\tau,p) := \begin{cases} E(x,t,\tau,p) & \text{if} \quad x \in \Omega, \\ \max\{\tau - F(x,t)\alpha(x,t), E(x,t,\tau,p)\} & \text{if} \quad x \in \partial\Omega. \end{cases}$$

DEFINITION 2.3. *We say that $u \in C(\overline{Q})$ is a viscosity solution of* (2.1) *provided $u(x,0) = a(x)$, $x \in \overline{\Omega}$, and u is a viscosity subsolution for $F_{\min}$ and a viscosity supersolution for $F_{\max}$.*

This is the usual notion of viscosity solution for boundary value problems (cf. [5]). We give an equivalent notion of solution by introducing, for $(x,t,\tau,p) \in \hat{Q} \times \mathbb{R} \times \mathbb{R}$,

$$G(x,t,\tau,p) := \begin{cases} E(x,t,\tau,p) & \text{if} \quad x \in \Omega, \\ \tau - F(x,t) \max\left\{\alpha(x,t), \left(([p\nu \mathrm{Sign} F]_-)^2 + \gamma^2\right)^{1/2}\right\} & \text{if} \quad x \in \partial\Omega, \end{cases}$$

where f_- is the negative part of f. Set

$$G_B(x,t,\tau,p) = \tau - F(x,t) \max\left\{\alpha(x,t), \left(([p\nu \mathrm{Sign} F]_-)^2 + \gamma^2\right)^{1/2}\right\}.$$

An alternative expression for G_B is

$$G_B(x,t,\tau,p) = \tau - F(x,t)\left([(\mathrm{Sign} F)p\nu - \delta][(\mathrm{Sign} F)p\nu + \delta]_- + \gamma^2 + \delta^2\right)^{1/2},$$

where $\delta = (\max(\alpha,\gamma)^2 - \gamma^2)^{1/2}$. This identity follows from

$$\max\left\{\alpha, ((\eta_-)^2 + \gamma^2)^{1/2}\right\} = \left((\eta - \delta)(\eta + \delta)_- + \gamma^2 + \delta^2\right)^{1/2}$$

for $\eta \in \mathbb{R}$, which is easy to prove. The main purpose of this section is to prove the following proposition.

PROPOSITION 2.4. *A function u is a viscosity solution of* (2.1) *if and only if $u \in C(\overline{Q})$, $u(x,0) = a(x)$, $x \in \Omega$, and u is both a viscosity subsolution and a viscosity supersolution for G.*

It is sufficient to prove the following lemmas.

LEMMA 2.5. *A function u is a viscosity supersolution for G if and only if u is a viscosity supersolution for $F_{\max}$.*

Proof. We use the notation for $(\hat{x},\hat{t},\phi,\tau,p)$ introduced in Definition 2.2, and $\hat{F} = F(\hat{x},\hat{t})$ and $\hat{\alpha} = \alpha(\hat{x},\hat{t})$. Clearly there is nothing to prove if $\hat{x} \in \Omega$ since G and $F_{\max}$ agree in Ω. Furthermore, without loss of generality we may assume $\hat{x} = L \in \partial\Omega$ so that $\nu = 1$. We suppress the word *viscosity* in the proof.

If u is a supersolution for G, then $\tau \geq \hat{F}\hat{\alpha}$ so that, trivially, u is a supersolution for $F_{\max}$. Thus the proof parts are concluding the situation that u is a supersolution for $F_{\max}$ and proving that this implies u is a supersolution for G. We have that

$$\max\left\{\tau - \hat{F}\hat{\alpha}, \tau - \hat{F}(p^2 + \gamma^2)^{1/2}\right\} \geq 0.$$

We may assume that $(L,\hat{t})$, by modifying ϕ if necessary, is a unique minimizer of $u - \phi$. It is convenient to make the following observation.

Observation 1. The following device shifts the minimizer into the interior. Let $h \in C^1(0,\infty)$ be a nonincreasing function such that $h(\sigma) = 0$ for all $\sigma \geqslant 1$, and that $h(\sigma) \to +\infty$ as $\sigma \to 0$. Set $d(x) := L - x$ and $\phi^\varepsilon(x,t) := \phi(x,t) - \varepsilon h(\frac{d(x)}{\varepsilon})$. Let $(x_\varepsilon, t_\varepsilon)$ be a minimum point of $u - \phi^\varepsilon$ on $\hat{Q}$. Since

$$\liminf_{\varepsilon\to 0 *}(u - \phi^\varepsilon) = u - \phi$$

on $\hat{Q}$, we see that $(x_\varepsilon, t_\varepsilon) \to (L,\hat{t})$ as $\varepsilon \to 0$. Here $\liminf_*$ is the relaxed limit as in [2], i.e.,

$$\liminf_{\varepsilon\to 0 *} f^\varepsilon(x,t) = \liminf_{\varepsilon\to 0}\{f^\delta(y,s); |y-x| < \varepsilon, |s-t| < \varepsilon, 0 < \delta < \varepsilon, (y,s) \in \hat{Q}\}.$$

Furthermore, since $h(\sigma) \to \infty$ as $\sigma \to 0$ we have that, for ε sufficiently small, $x_\varepsilon < L$ and $x_\varepsilon \in \Omega$. Because u is a supersolution for $F_{\max}$, this implies that

$$\phi_t^\varepsilon(x_\varepsilon, t_\varepsilon) \geq F(x_\varepsilon, t_\varepsilon) \left(\phi_x^\varepsilon(x_\varepsilon, t_\varepsilon)^2 + \gamma^2\right)^{1/2},$$

which yields

$$\phi_t(x_\varepsilon, t_\varepsilon) \geq F(x_\varepsilon, t_\varepsilon) \left(\left(\phi_x(x_\varepsilon, t_\varepsilon) + h'\left(\frac{d(x_\varepsilon)}{\varepsilon}\right)\right)^2 + \gamma^2\right)^{1/2}.$$

Observation 2. Set for $A > 0$, $\psi(x,t) := \phi(x,t) - Ad(x)$. Clearly

$$(u - \psi)(x,t) = (u - \phi)(x,t) + Ad(x) \geq (u - \psi)(L, \hat{t})$$

for all $(x,t) \in \hat{Q}$. Since u is a supersolution for $F_{\max}$, we have

$$\max\left\{\tau - \hat{F}\hat{\alpha}, \tau - \hat{F}\left((p + A)^2 + \gamma^2\right)^{1/2}\right\} \geq 0.$$

We consider separately the cases $\hat{F} > 0$ and $\hat{F} < 0$ since the case $\hat{F} = 0$ leads to $G = F_{\max}$.

Case I. $\hat{F} > 0$. Again we discuss three cases.

(i) $\gamma \geq \hat{\alpha}$ and $p \geq 0$. This is immediately treated by Observation 1. Sending ε to zero we have

$$\tau \geq \hat{F}\gamma = \hat{F} \max\left\{\hat{\alpha}, \left([p\nu]_-\right)^2 + \gamma^2\right)^{1/2}\right\}.$$

(ii) $p\nu + \delta < 0$. Using Observation 1 we set that for small ε, we have

$$\phi_x^\varepsilon(x_\varepsilon, t_\varepsilon) = \phi_x(x_\varepsilon, t_\varepsilon) + h'\left(\frac{d(x_\varepsilon)}{\varepsilon}\right) \leq \phi_x(x_\varepsilon, t_\varepsilon) < 0$$

so that

$$\phi_t(x_\varepsilon, t_\varepsilon) \geq F(x_\varepsilon, t_\varepsilon)(\phi_x(x_\varepsilon, t_\varepsilon)^2 + \gamma^2)^{1/2},$$

and sending ε to zero,

$$\tau \geq \hat{F}(p^2 + \gamma^2)^{1/2} = \hat{F}((p\nu - \delta)(p\nu + \delta)_- + \gamma^2 + \delta^2)^{1/2}.$$

(iii) $p\nu + \delta \geq 0$, $\gamma < \hat{\alpha}$. This is the remaining case. From Observation 2, by choosing A large we find

$$\tau \geq \hat{F}\hat{\alpha} = \hat{F}((p\nu - \delta)(p\nu + \delta)_- + \gamma^2 + \delta^2)^{1/2}.$$

Case II. $\hat{F} < 0$.

(i) $\gamma \geq \hat{\alpha}$, $p \geq 0$. This case leads to $F_{\max} = \tau - \hat{F}(p^2 + \gamma^2)^{1/2} = G_B$.

(ii) $\gamma \geq \hat{\alpha}$, $p < 0$. Use Observation 2 and set $A = -p > 0$, which yields $F_{\max} = \tau - \hat{F}\gamma = G_B$.

(iii) $\gamma < \hat{\alpha}$, $p \leq \delta$. If $|p| \leq \delta$, then $F_{\max} = \tau - \hat{F}\hat{\alpha} = G_B$. If $p < -\delta$, then $G_B = \tau - \hat{F}\hat{\alpha}$, and using Observation 2 and $A = -p$ we have $F_{\max} = \tau - \hat{F}\hat{\alpha}$.

(iv) $\gamma < \hat{\alpha}$, $p > \delta$. This case leads to $F_{\max} = \tau - \hat{F}(p^2 + \gamma^2)^{1/2} = G_B$. □

LEMMA 2.6. *A function u is a viscosity subsolution for G if and only if u is a viscosity subsolution for $F_{\min}$.*

Proof. We use the notation for $(\hat{x}, \hat{t}, \phi, \tau, p)$ introduced in Definition 2.1. Clearly there is nothing to prove if $\hat{x} \in \Omega$ since G and $F_{\min}$ agree in Ω. Furthermore, without loss of generality we may assume $\hat{x} = L \in \partial\Omega$ so that $\nu = 1$.

If u is a subsolution for G, then

$$\tau \le \hat{F} \max\left\{\hat{\alpha}, \left(([p\nu \mathrm{Sign}\hat{F}]_-)^2 + \gamma^2\right)^{1/2}\right\}$$

so that either $\tau \le \hat{F}\hat{\alpha}$ or $\tau \le \hat{F}(([p\nu\mathrm{Sign}\hat{F}]_-)^2 + \gamma^2)^{1/2}$. If $\hat{F} > 0$, then this implies $\min\{\tau - \hat{F}\hat{\alpha}, \tau - \hat{F}(p^2+\gamma^2)^{1/2}\} \le 0$ and u is a subsolution for $F_{\min}$.

On the other hand if $\hat{F} < 0$, then $\tau \le \hat{F}((p\nu+\delta)(p\nu-\delta)_+ + \gamma^2 + \delta^2)^{1/2}$. If $\gamma \ge \hat{\alpha}$, then either $\tau \le \hat{F}(p^2+\gamma^2)^{1/2}$ or $\tau \le \hat{F}\gamma \le \hat{F}\hat{\alpha}$, which implies u is a subsolution for $F_{\min}$. Whenever $\hat{\alpha} > \gamma$, then either $\tau \le \hat{F}(\gamma^2+\delta^2)^{1/2} = \hat{F}\hat{\alpha}$ or $\tau \le \hat{F}(p^2+\gamma^2)^{1/2}$ and again u is a subsolution for $F_{\min}$.

We may suppose that u is a subsolution for $F_{\min}$ so that

$$\min\left\{\tau - \hat{F}\hat{\alpha}, \tau - \hat{F}(p^2+\gamma^2)^{1/2}\right\} \le 0.$$

It is convenient to make the following observation.

Observation 1. The following device shifts the maximizer into the interior. Let $h \in C^1(0,\infty)$ be a nonincreasing function such that $h(\sigma) = 0$ for all $\sigma \ge 1$ and that $h(\sigma) \to +\infty$ as $\sigma \to 0$. Set $d(x) := L - x$ and $\phi^\varepsilon(x,t) := \phi(x,t) + \varepsilon h(\frac{d(x)}{\varepsilon})$. Let $(x_\varepsilon, t_\varepsilon)$ be a maximum point of $u - \phi^\varepsilon$ on $\hat{Q}$. Since

$$\limsup_{\varepsilon\to 0}{}^*(u - \phi^\varepsilon) = u - \phi$$

on $\hat{Q}$ we see that $(x_\varepsilon, t_\varepsilon) \to (L, \hat{t})$ as $\varepsilon \to 0$. Furthermore, since $h(\sigma) \to \infty$ as $\sigma \to 0$ we have that, for ε sufficiently small, $x_\varepsilon < L$ and $x_\varepsilon \in \Omega$. Because u is a subsolution for $F_{\min}$ this implies that

$$\phi_t^\varepsilon(x_\varepsilon, t_\varepsilon) \le F(x_\varepsilon, t_\varepsilon)\left(\phi_x^\varepsilon(x_\varepsilon, t_\varepsilon)^2 + \gamma^2\right)^{1/2},$$

which yields

$$\phi_t(x_\varepsilon, t_\varepsilon) \le F(x_\varepsilon, t_\varepsilon)\left(\left(\phi_x(x_\varepsilon, t_\varepsilon) - h'\left(\frac{d(x_\varepsilon)}{\varepsilon}\right)\right)^2 + \gamma^2\right)^{1/2}.$$

Observation 2. Set for $A > 0$, $\psi(x,t) := \phi(x,t) + Ad(x)$. Clearly

$$(u-\psi)(x,t) = (u-\phi)(x,t) - Ad(x) \le (u-\phi)(L,\hat{t}) = (u-\psi)(L,\hat{t})$$

for all $(x,t) \in \hat{Q}$. Since u is a subsolution for $F_{\min}$, we have

$$\min\left\{\tau - \hat{F}\hat{\alpha}, \tau - \hat{F}\left((p-A)^2 + \gamma^2\right)^{1/2}\right\} \le 0.$$

We treat the cases $\hat{F} > 0$ and $\hat{F} < 0$ separately.

Case I. $\hat{F} > 0$.

(i) $\gamma \geq \hat{\alpha}$. If $p \leq 0$, then $\tau \leq \hat{F}(p^2+\gamma^2)^{1/2} = \hat{F}\max\{\hat{\alpha}, (([p\nu]_-)^2+\gamma^2)^{1/2}\}$. If $p > 0$, then we use Observation 2, which yields, with $A = p$, $\tau \leq \hat{F}\gamma = \hat{F}\max\{\hat{\alpha}, (([p\nu]_-)^2+\gamma^2)^{1/2}\}$.

(ii) $\gamma < \hat{\alpha}$. If $p \leq -\delta$, then $\tau \leq \hat{F}(p^2+\gamma^2)^{1/2} = \hat{F}((p-\delta)(p+\delta)_- + \gamma^2+\delta^2)^{1/2}$. If $|p| < \delta$, then $\tau \leq \hat{F}\hat{\alpha} = \hat{F}\max\{\hat{\alpha}, (([p\nu]_-)^2+\gamma^2)^{1/2}\}$. If $p > \delta$, then we use Observation 2, which yields, with $A = p$, $\tau \leq \hat{F}\gamma \leq \hat{F}\max\{\hat{\alpha}, (([p\nu]_-)^2+\gamma^2)^{1/2}\}$.

Case II. $\hat{F} < 0$.

(i) $\gamma \geq \hat{\alpha}$ and $p \leq 0$. This is immediately treated by Observation 1. Sending ε to zero in

$$\phi_t(x_\varepsilon, t_\varepsilon) \leq F(x_\varepsilon, t_\varepsilon)(\phi_x^\varepsilon(x_\varepsilon, t_\varepsilon)^2+\gamma^2)^{1/2} \leq F(x_\varepsilon, t_\varepsilon)\gamma$$

yields $\tau \leq \hat{F}\gamma = \hat{F}\max\{\hat{\alpha}, (([-p\nu]_-)^2+\gamma^2)^{1/2}\}$.

(ii) $p\nu - \delta > 0$. Using Observation 1 we get that for small ε

$$\phi_x^\varepsilon(x_\varepsilon, t_\varepsilon) = \phi_x(x_\varepsilon, t_\varepsilon) - h'\left(\frac{d(x_\varepsilon)}{\varepsilon}\right) \geq \phi_x(x_\varepsilon, t_\varepsilon) > 0$$

so that

$$\phi_t(x_\varepsilon, t_\varepsilon) \leq F(x_\varepsilon, t_\varepsilon)\left(\phi_x^\varepsilon(x_\varepsilon, t_\varepsilon)^2+\gamma^2\right)^{1/2} \leq F(x_\varepsilon, t_\varepsilon)\left(\phi_x(x_\varepsilon, t_\varepsilon)^2+\gamma^2\right)^{1/2},$$

and sending $\varepsilon \to 0$,

$$\tau \leq \hat{F}(p^2+\gamma^2)^{1/2} = \hat{F}((p\nu+\delta)(p\nu-\delta)_+ + \gamma^2+\delta^2)^{1/2}.$$

(iii) $p\nu - \delta \leq 0$, $\gamma < \hat{\alpha}$. This is the remaining case. From Observation 2, by choosing A large we find

$$\tau \leq \hat{F}\hat{\alpha} = \hat{F}((p\nu+\delta)(p\nu-\delta)_+ + \gamma^2+\delta^2)^{1/2}. \qquad \square$$

Remark 1. As usual the definition of subsolutions (Definition 2.1) extends to an upper semicontinuous function u on $\hat{Q}$ provided that u is locally bounded on $\overline{Q}$. Similarly, a supersolution is defined for lower semicontinuous functions and not only for continuous functions. Results on equivalence (Lemmas 2.5, 2.6) are still valid for semicontinuous functions.

3. Comparison principle. Let Ω and T be as introduced in section 2 and set $\hat{Q} = \overline{\Omega} \times (0,T)$ and $\overline{Q} = \overline{\Omega} \times [0,T]$. In section 2 we defined a function G by

$$G(x,t,\tau,p) = \begin{cases} \tau - F(x,t)\left(p^2+\gamma^2\right)^{1/2} & \text{if} \quad x \in \Omega, \\ \tau - F(x,t)\max\left\{\alpha(x,t), \left(([p\nu(x)\mathrm{Sign}F(x,t)]_-)^2+\gamma^2\right)^{1/2}\right\} & \text{if} \quad x \in \partial\Omega, \end{cases}$$

where $\gamma \geq 0$ is a constant and $\nu(x)$ denotes the outer unit normal of $\partial\Omega$ (i.e., $\nu(0) = -1$, $\nu(L) = 1$).

THEOREM 3.1. *Assume that* $F \in C(\overline{Q})$, $\alpha \in C(\partial\Omega \times [0,T])$, *and*

$$|F(x,t) - F(y,t)| \leq C|x-y| \quad \textit{for all } (x,t),(y,t) \in \overline{Q} \tag{3.1}$$

holds for some constant $C > 0$ *independent of* t. *Let* u *and* $-v$ *be bounded upper semicontinuous functions on* $\overline{\Omega} \times [0,T)$. *Let* u *be a viscosity subsolution for* $G = 0$ *in*

$\hat{Q}$ and let v be a viscosity supersolution for $G = 0$ in $\hat{Q}$. If $u(\cdot, 0) \le v(\cdot, 0)$ in $\overline{\Omega}$, then $u \le v$ in $\hat{Q}$.

Proof. Suppose that the conclusion is false. Then there would exist a point $(x_1, t_1) \in \overline{\Omega} \times [0, T)$ such that $\mu := u(x_1, t_1) - v(x_1, t_1) > 0$. For positive parameters λ, β, δ, we set

$$\phi(x,t,y,s) = \lambda(x-y)^2 + \beta(t-s)^2 + \frac{\delta}{T-t} + \frac{\delta}{T-s},$$
$$\Phi(x,t,y,s) = u(x,t) - v(y,s) - \phi(x,t,y,s)$$

and, as preparation, study the behavior of a maximum point $(\hat{x}, \hat{t}, \hat{y}, \hat{s})$ of Φ on $\overline{Q} \times \overline{Q}$. We choose a small δ (fixed here) such that $0 < \delta < (T - t_1)\mu/4$. So we have

$$\max_{\overline{Q}\times\overline{Q}} \Phi \ge \mu/2 > 0, \tag{3.2}$$

and then $0 \le \hat{t}, \hat{s} < T$ holds uniformly for λ and β. Let $M > 0$ be an upper bound of both u and $-v$. By using (3.2) we see that

$$2M \ge u(\hat{x}, \hat{t}) - v(\hat{y}, \hat{s}) > \lambda|\hat{x} - \hat{y}|^2 + \beta|\hat{t} - \hat{s}|^2,$$

which leads to

$$\lambda|\hat{x} - \hat{y}|^2,\ \beta|\hat{t} - \hat{s}|^2 \text{ are bounded}, \tag{3.3}$$

and then $|\hat{x}-\hat{y}| \to 0$ (as $\lambda \to \infty$), $|\hat{t}-\hat{s}| \to 0$ (as $\beta \to \infty$), i.e., by taking a subsequence, there exists $(x_0, t_0) \in \hat{Q}$ such that

$$\hat{x}, \hat{y} \to x_0 \ (\text{as } \lambda \to \infty), \quad \hat{t}, \hat{s} \to t_0 \ (\text{as } \beta \to \infty). \tag{3.4}$$

(Because of our assumption $u \le v$ at $t = 0$, the time $t_0 > 0$ so that $\hat{t}$, $\hat{s} > 0$ for sufficiently large λ and β.) From now on, we use the same notation after taking a subsequence. By taking a subsequence, (3.3) implies that there are λ_0 and β_0 such that

$$\lambda|\hat{x} - \hat{y}|^2 \to \lambda_0 \ (\text{as } \lambda \to \infty), \quad \beta|\hat{t} - \hat{s}|^2 \to \beta_0 \ (\text{as } \beta \to \infty).$$

It follows that

$$\limsup_{\lambda\to\infty,\beta\to\infty} \max_{\overline{Q}\times\overline{Q}} \Phi \le u(x_0, t_0) - v(x_0, t_0) - \lambda_0 - \beta_0 - \frac{2\delta}{T - t_0}.$$

Since the left-hand side is equal to or greater than $u(x_0, t_0) - v(x_0, t_0) - 2\delta/(T - t_0)$, we have $\lambda_0 = \beta_0 = 0$, i.e.,

$$\lambda|\hat{x} - \hat{y}|^2 \to 0 \ (\text{as } \lambda \to \infty), \quad \beta|\hat{t} - \hat{s}|^2 \to 0 \ (\text{as } \beta \to \infty). \tag{3.5}$$

Now, let us start the main part of the proof. Note that our classifications given below are not disjoint but cover whole cases.

Case 1. $x_0 \in \Omega$. First, we discuss the case when $\hat{x}$, $\hat{y}$ converge to an interior point x_0 as $\lambda \to \infty$. We may assume that $\hat{x}$, $\hat{y} \in \Omega$. We use an abbreviated notation $\hat{\phi}_t = \phi_t(\hat{x}, \hat{t}, \hat{y}, \hat{s})$, etc. It follows from the definition of viscosity solutions that

$$\hat{\phi}_t - F(\hat{x}, \hat{t})(\hat{\phi}_x^2 + \gamma^2)^{1/2} \le 0 \quad \text{and} \quad (-\hat{\phi}_s) - F(\hat{y}, \hat{s})((-\hat{\phi}_y)^2 + \gamma^2)^{1/2} \ge 0.$$

Subtracting the second inequality from the first one we get

$$\begin{aligned}0 &\geq \hat{\phi}_t - F(\hat{x},\hat{t})(\hat{\phi}_x^2+\gamma^2)^{1/2} - \left((-\hat{\phi}_s) - F(\hat{y},\hat{s})((-\hat{\phi}_y)^2+\gamma^2)^{1/2}\right)\\ &\geq \frac{2\delta}{T^2} + (-F(\hat{x},\hat{t}) + F(\hat{y},\hat{s}))(4\lambda^2|\hat{x}-\hat{y}|^2+\gamma^2)^{1/2}.\end{aligned}$$

We send β to infinity and, after that, we send λ to infinity. Then, by using (3.5) and the Lipschitz continuity of $F(\cdot,t)$ as in (3.1), we see that the second term goes to zero. Since $\delta>0$, we get a contradiction.

Case 2. $x_0\in\partial\Omega$. Next, we discuss the case when $\hat{x}$, $\hat{y}$ go to a boundary point x_0 as $\lambda\to\infty$. If both $\hat{x}$ and $\hat{y}$ are in Ω for any large λ, we get a contradiction similar to that of Case 1. We classify the rest of Case 2 into three cases, Cases 2a, 2b, 2c, depending on the limit of the convergent subsequences. We further classify Cases 2b and 2c into more subcases as follows:

Case 2a	$\hat{x}=\hat{y}=x_0\in\partial\Omega$		
Case 2b	$\hat{x}\in\Omega\to x_0$, $\hat{y}=x_0\in\partial\Omega$	Case 2b(i)	$F(x_0,t_0)>0$
		Case 2b(ii)	$F(x_0,t_0)=0$
		Case 2b(iii)	$F(x_0,t_0)<0$
Case 2c	$\hat{x}=x_0\in\partial\Omega$, $\hat{y}\in\Omega\to x_0$	Case 2c(i)	$F(x_0,t_0)<0$
		Case 2c(ii)	$F(x_0,t_0)=0$
		Case 2c(iii)	$F(x_0,t_0)>0$

Since the proof for Case 2c and its subcases is symmetric to that of Case 2b, we do not present the proof for Case 2c.

Case 2a. When there exists a subsequence $\lambda\to\infty$ such that $\hat{x}=\hat{y}=x_0\in\partial\Omega$, it follows that

$$\begin{aligned}0 &\geq \hat{\phi}_t - F(\hat{x},\hat{t})\max\left\{\alpha(\hat{x},\hat{t}),\left(([\hat{\phi}_x\nu(\hat{x})\mathrm{Sign}F(\hat{x},\hat{t})]_-)^2+\gamma^2\right)^{1/2}\right\}\\ &\quad-\left((-\hat{\phi}_s) - F(\hat{y},\hat{s})\max\left\{\alpha(\hat{y},\hat{s}),\left(([(-\hat{\phi}_y)\nu(\hat{y})\mathrm{Sign}F(\hat{y},\hat{s})]_-)^2+\gamma^2\right)^{1/2}\right\}\right)\\ &\geq \frac{2\delta}{T^2} - F(x_0,\hat{t})\max\{\alpha(x_0,\hat{t}),\gamma\} + F(x_0,\hat{s})\max\{\alpha(x_0,\hat{s}),\gamma\},\end{aligned}$$

since $\hat{\phi}_x=-\hat{\phi}_y=0$. Since the second and third terms are continuous and since the sum of them goes to zero as $\beta\to\infty$ by (3.4), we get a contradiction.

Case 2b. When there exists a subsequence $\lambda\to\infty$ such that $\hat{x}\in\Omega$ and $\hat{y}=x_0\in\partial\Omega$, it follows that

(3.6)
$$\begin{aligned}&\hat{\phi}_t - F(\hat{x},\hat{t})(\hat{\phi}_x^2+\gamma^2)^{1/2}\leq 0,\\ &(-\hat{\phi}_s) - F(x_0,\hat{s})\max\left\{\alpha(x_0,\hat{s}),\left(([(-\hat{\phi}_y)\nu(x_0)\mathrm{Sign}F(x_0,\hat{s})]_-)^2+\gamma^2\right)^{1/2}\right\}\geq 0.\end{aligned}$$

We see that $(-\hat{\phi}_y)\nu(x_0)=2\lambda(\hat{x}-x_0)\nu(x_0)<0$. We shall classify this case into three subcases depending on the sign of F.

Case 2b(i). $F(x_0,t_0)>0$. When $F(x_0,t_0)>0$, we may assume that $F(x_0,\hat{s})>0$ holds for sufficiently large β. The second inequality of (3.6) implies that

$$\begin{aligned}0 &\leq (-\hat{\phi}_s) - F(x_0,\hat{s})\max\left\{\alpha(x_0,\hat{s}),(\hat{\phi}_y^2+\gamma^2)^{1/2}\right\}\\ &\leq (-\hat{\phi}_s) - F(x_0,\hat{s})(\hat{\phi}_y^2+\gamma^2)^{1/2}.\end{aligned}$$

We get a contradiction similar to that of Case 1.

Case 2b(ii). $F(x_0, t_0) = 0$. When $F(x_0, t_0) = 0$, we see that both $F(\hat{x}, \hat{t})$ and $F(x_0, \hat{s})$ go to zero as λ, $\beta \to \infty$. Then it is easy to get a contradiction from (3.6).

Case 2b(iii). $F(x_0, t_0) < 0$. When $F(x_0, t_0) < 0$, we may assume that $F(x_0, \hat{s}) < 0$ holds for any large β. The second inequality of (3.6) implies that

$$(-\hat{\phi}_s) - F(x_0, \hat{s}) \max\{\alpha(x_0, \hat{s}), \gamma\} \geq 0.$$

If $\alpha(x_0, t_0) \leq \gamma$, sending β to infinity, we have

$$0 \geq \frac{2\delta}{T^2} + (-F(\hat{x}, t_0) + F(x_0, t_0))(4\lambda^2|\hat{x} - x_0|^2 + \gamma^2)^{1/2}.$$

By using (3.5) and (3.1) the second term goes to zero as $\lambda \to \infty$. This yields a contradiction since $\delta > 0$.

Case R. We must discuss the remaining case when $\alpha_0 = \alpha(x_0, t_0) > \gamma$ from Case 2b(iii) (similarly from Case 2c(iii)). Let us change ϕ to a new test function ψ as follows:

$$\begin{aligned}\psi(x, t, y, s) &= \lambda \left(x - y + \mathrm{Sign} F(x_0, t_0) \frac{(\alpha_0^2 - \gamma^2)^{1/2} \nu(x_0)}{2\lambda} \right)^2 + \beta(t - s)^2 \\ &\quad + \frac{\delta}{T - t} + \frac{\delta}{T - s} \\ &= \lambda \left(x - y - \frac{(\alpha_0^2 - \gamma^2)^{1/2} \nu(x_0)}{2\lambda} \right)^2 + \beta(t - s)^2 + \frac{\delta}{T - t} + \frac{\delta}{T - s}.\end{aligned}$$

We then consider the maximum point $(\tilde{x}, \tilde{t}, \tilde{y}, \tilde{s})$ of

$$\Psi(x, t, y, s) = u(x, t) - v(y, s) - \psi(x, t, y, s)$$

on $\overline{Q} \times \overline{Q}$. It is easy to see that $0 < \tilde{t}, \tilde{s} < T$ holds uniformly for λ and β, $|\tilde{x} - \tilde{y}| \to 0$ (as $\lambda \to \infty$), and $|\tilde{t} - \tilde{s}| \to 0$ (as $\beta \to \infty$). We claim that

$$\tilde{x}, \tilde{y} \to x_0 \ (\text{as } \lambda \to \infty), \quad \tilde{t}, \tilde{s} \to t_0 \ (\text{as } \beta \to \infty). \tag{3.7}$$

If (3.7) does not hold, we see that, for some closed neighborhood K of (x_0, t_0), there exists $\mu' > 0$ such that

$$\Psi(\tilde{x}, \tilde{t}, \tilde{y}, \tilde{s}) - \max_{K \times K} \Psi \geq \mu'.$$

Since ψ is almost equal to ϕ as $\lambda \to \infty$ and $|x - y| \to 0$, we see that

$$\Phi(\tilde{x}, \tilde{t}, \tilde{y}, \tilde{s}) - \max_{K \times K} \Phi = \Phi(\tilde{x}, \tilde{t}, \tilde{y}, \tilde{s}) - \Phi(\hat{x}, \hat{t}, \hat{y}, \hat{s}) \geq \mu'/2$$

for large λ, which is inconsistent with the property that $(\hat{x}, \hat{t}, \hat{y}, \hat{s})$ is a global maximum point of Φ. Thus (3.7) holds.

We can discuss, similarly to Case 1 and Case 2a, respectively, the case when $\tilde{x}$, $\tilde{y} \in \Omega$ or $\tilde{x}$, $\tilde{y} \in \partial\Omega$ for large λ and obtain a contradiction. We thus study the remaining two cases, Cases Rb and Rc.

Case Rb. When there exists a subsequence $\lambda \to \infty$ such that $\tilde{x} \in \Omega$ and $\tilde{y} = x_0 \in \partial\Omega$, it follows that

(3.8)

$$\begin{aligned}&\tilde{\psi}_t - F(\tilde{x}, \tilde{t})(\tilde{\psi}_x^2 + \gamma^2)^{1/2} \leq 0, \\ &(-\tilde{\psi}_s) - F(x_0, \tilde{s}) \max\left\{ \alpha(x_0, \tilde{s}), \left(([(-\tilde{\psi}_y)\nu(x_0)\mathrm{Sign} F(x_0, \tilde{s})]_-)^2 + \gamma^2 \right)^{1/2} \right\} \geq 0.\end{aligned}$$

By the definition of ψ we see that $(-\tilde{\psi}_y)\nu(x_0) = 2\lambda(\tilde{x}-x_0)\nu(x_0) - (\alpha_0^2-\gamma^2)^{1/2} < 0$. In the remaining case from Case 2b(iii) we see that $F(x_0,t_0) < 0$, and then $F(x_0,\tilde{s}) < 0$ for large β. Thus the second inequality of (3.8) implies that

$$(-\tilde{\psi}_s) - F(x_0,\tilde{s})\max\{\alpha(x_0,\tilde{s}),\gamma\} \geq 0. \tag{3.9}$$

By the definition of ψ we also see that $(\gamma <)\ \alpha_0 \leq (\tilde{\psi}_x^2+\gamma^2)^{1/2}$. Subtracting (3.9) from the first inequality of (3.8) and sending $\beta \to \infty$, we have

$$0 \geq \frac{2\delta}{T^2} + (-F(\tilde{x},t_0) + F(x_0,t_0))\alpha_0$$

since $F(\tilde{x},t_0) < 0$ for large λ. By (3.7) and (3.1) the second term goes to zero as $\lambda \to \infty$. This yields a contradiction since $\delta > 0$.

Case Rc. When there exists a subsequence $\lambda \to \infty$ such that $\tilde{x} = x_0 \in \partial\Omega$ and $\tilde{y} \in \Omega$, it follows that

$$\tilde{\psi}_t - F(x_0,\tilde{t})\max\left\{\alpha(x_0,\tilde{t}), \left(([\tilde{\psi}_x\nu(x_0)\mathrm{Sign}F(x_0,\tilde{t})]_-)^2+\gamma^2\right)^{1/2}\right\} \leq 0,$$

$$(-\tilde{\psi}_s) - F(\tilde{y},\tilde{s})((-\tilde{\psi}_y)^2+\gamma^2)^{1/2} \geq 0.$$

If $\tilde{\psi}_x\nu(x_0) \geq 0$, the first inequality implies

$$\tilde{\psi}_t - F(x_0,\tilde{t})(\tilde{\psi}_x^2+\gamma^2)^{1/2} \leq 0$$

since $F(x_0,\tilde{t}) < 0$ for large β. We thus obtain a contradiction similar to that of Case 1. If $\tilde{\psi}_x\nu(x_0) < 0$, we have

$$0 \leq 2\lambda(x_0-\tilde{y})\nu(x_0) < (\alpha_0-\gamma^2)^{1/2},$$

and then $((-\tilde{\psi}_y)^2+\gamma^2)^{1/2} < \alpha_0$. Since $F(\tilde{y},\tilde{s}) < 0$ for large λ, β, we see that

$$0 \geq \frac{2\delta}{T^2} - F(x_0,\tilde{t})\alpha(x_0,\tilde{t}) + F(\tilde{y},\tilde{s})\alpha(x_0,t_0).$$

We get a contradiction by the continuity of the second and third terms. The proof of Theorem 3.1 is now complete. □

4. Existence theorem. Let Ω and T be introduced in section 2. Our goal is to show the existence of viscosity solutions of the dynamic boundary problem

$$\begin{cases} u_t - F\left(u_x^2+\gamma^2\right)^{1/2} = 0 & \text{in} \quad Q = \Omega\times(0,T), \\ u_t - F\alpha = 0 & \text{on} \quad \partial\Omega\times(0,T), \\ u|_{t=0} = a & \text{on} \quad \Omega. \end{cases} \tag{4.1}$$

THEOREM 4.1. *Assume that $F \in C^1(\overline{Q})$ and $\alpha \in C(\partial\Omega\times[0,T])$. Assume that a is a Lipschitz function over $\overline{\Omega}$. Then there exists a function $u \in C(\overline{Q})$ which is a unique viscosity solution of* (4.1). *Moreover, $|u_x|$ is bounded in $\overline{Q}$.*

Let $\varepsilon > 0$. First, we shall prove a priori estimates for a classical solution u^ε for the approximate problem

$$\begin{cases} u_t^\varepsilon - \varepsilon u_{xx}^\varepsilon = F^\varepsilon\left((u_x^\varepsilon)^2+\gamma^2\right)^{1/2} & \text{in} \quad Q, \\ u_t^\varepsilon + \varepsilon\nu u_x^\varepsilon = F^\varepsilon\max\left\{\alpha^\varepsilon, \left(([\nu u_x^\varepsilon\mathrm{Sign}F^\varepsilon]_-)^2+\gamma^2\right)^{1/2}\right\} & \text{on} \quad \partial\Omega\times(0,T), \\ u^\varepsilon|_{t=0} = a^\varepsilon & \text{on} \quad \Omega, \end{cases} \tag{4.2}$$

where ν denotes the outer unit normal of $\partial\Omega$. The existence of a solution of (4.2) shall be proved in the appendix (Theorem A.1).

PROPOSITION 4.2. *Assume that $F^\varepsilon \in C^1(\overline{Q}) \cap C^\infty(Q)$ and $\alpha^\varepsilon \in C^1(\partial\Omega \times [0,T])$. Assume that a^ε is a C^3 function over $\overline{\Omega}$ and $\varepsilon a^\varepsilon_{xx}$ is bounded on $\overline{\Omega}$ uniformly for ε. Let u^ε be a classical solution of* (4.2). *Then the estimate*

$$\max_{\overline{Q}} (|u^\varepsilon| + |u^\varepsilon_x| + |u^\varepsilon_t|) \le C \tag{4.3}$$

holds with some constant $C > 0$ depending only on T, γ, $|a^\varepsilon|_{C^1(\overline{\Omega})}$, $|\varepsilon a^\varepsilon_{xx}|_{C(\overline{\Omega})}$, $|F^\varepsilon|_{C^1(\overline{Q})}$, and $|\alpha^\varepsilon|_{C(\partial\Omega\times[0,T])}$.

Proof. We shall prove (4.3) by using maximum principles. In the proof we suppress superscripts of F^ε and α^ε to simplify the notation.

(i) *The estimate for u^ε.* We set $w(x,t) = e^{-t}u^\varepsilon(x,t)$. It follows from (4.2) that

$$\begin{cases} w_t + w - \varepsilon w_{xx} = e^{-t}F\left((e^t w_x)^2 + \gamma^2\right)^{1/2} & \text{in} \quad Q, \\ w_t + w + \varepsilon\nu w_x \\ \qquad = e^{-t}F\max\left\{\alpha, \left(([e^t\nu w_x \mathrm{Sign} F]_-)^2 + \gamma^2\right)^{1/2}\right\} & \text{on} \quad \partial\Omega\times(0,T), \\ w(x,0) = a^\varepsilon(x) & \text{for} \quad x \in \Omega. \end{cases} \tag{4.4}$$

Assume that w has a positive maximum in $\overline{Q}$. Let $(\hat{x},\hat{t})$ be the maximum point of w and let λ be its maximum value, i.e., $\max_{\overline{Q}} w = w(\hat{x},\hat{t})$ and $\lambda = w(\hat{x},\hat{t})$. We assume that

$$\lambda > \max_{\overline{\Omega}} |a^\varepsilon| \quad \text{and} \quad \lambda > \max_{\overline{Q}} |F| \max\left\{\max_{\partial\Omega\times[0,T]} |\alpha|, \gamma\right\} \tag{4.5}$$

and shall show that it is inconsistent with (4.4) for w. First, we observe that $\hat{t} > 0$ by the first inequality of (4.5) and obtain $w_t(\hat{x},\hat{t}) \ge 0$. When $\hat{x} \in \partial\Omega$, we also observe that $\nu(\hat{x})w_x(\hat{x},\hat{t}) \ge 0$. If $F(\hat{x},\hat{t}) > 0$, then it follows from the second identity of (4.4) that

$$\lambda \le e^{-\hat{t}}F(\hat{x},\hat{t})\max\{\alpha(\hat{x},\hat{t}),\gamma\},$$

which is a contradiction of the second inequality of (4.5). On the other hand, $F(\hat{x},\hat{t}) \le 0$ implies that $\lambda \le 0$, but it is also a contradiction. When $\hat{x} \in \Omega$, we see that $w_x(\hat{x},\hat{t}) = 0$, $w_{xx}(\hat{x},\hat{t}) \le 0$ to get $\lambda \le e^{-\hat{t}}F(\hat{x},\hat{t})\gamma$ by the first identity of (4.4), which is a contradiction of the second inequality of (4.5). Thus we have an a priori estimate,

$$\max_{\overline{Q}} u^\varepsilon \le e^T \max\left\{\max_{\overline{\Omega}} |a^\varepsilon|, \max_{\overline{Q}} |F| \max\left\{\max_{\partial\Omega\times[0,T]} |\alpha|, \gamma\right\}\right\}.$$

We argue in the same way for a negative minimum to get

$$\max_{\overline{Q}} |u^\varepsilon| \le e^T \max\left\{\max_{\overline{\Omega}} |a^\varepsilon|, \max_{\overline{Q}} |F| \max\left\{\max_{\partial\Omega\times[0,T]} |\alpha|, \gamma\right\}\right\}. \tag{4.6}$$

(ii) *The estimate for u^ε_x.* We set $w(x,t) = e^{-Kt}u^\varepsilon_x$ and $K = 2\max_{\overline{Q}} |F_x|$. It

follows from (4.2) that

(4.7)
$$\begin{cases} w_t + Kw - \varepsilon w_{xx} \\ \qquad = e^{-Kt}F_x\left((e^{Kt}w)^2+\gamma^2\right)^{1/2} + \dfrac{Fe^{Kt}ww_x}{((e^{Kt}w)^2+\gamma^2)^{1/2}} & \text{in} \quad Q, \\ \varepsilon w_x + e^{-Kt}F\left((e^{Kt}w)^2+\gamma^2\right)^{1/2} + \varepsilon\nu w \\ \qquad = e^{-Kt}F\max\left\{\alpha, \left(([e^{Kt}\nu w \mathrm{Sign} F]_-)^2+\gamma^2\right)^{1/2}\right\} & \text{on} \quad \partial\Omega\times(0,T), \\ w(x,0) = a_x^\varepsilon(x) & \text{for} \quad x\in\Omega. \end{cases}$$

As before we take $(\hat{x},\hat{t})$, λ satisfying $\max_{\overline{Q}} w = w(\hat{x},\hat{t})$ and $\lambda = w(\hat{x},\hat{t})$. We assume that

$$\lambda > \max_{\overline{\Omega}} |a_x^\varepsilon|, \quad \lambda > \max_{\partial\Omega\times[0,T]} |\alpha|, \quad \text{and} \quad \lambda > \gamma \tag{4.8}$$

and shall show that it is inconsistent with (4.7) for w. First, we see that $\hat{t} > 0$ by the first inequality of (4.8) and observe $w_t(\hat{x},\hat{t}) \geq 0$. When $\hat{x}\in\partial\Omega$, we also see that $\nu(\hat{x})w_x(\hat{x},\hat{t}) \geq 0$. If $\nu(\hat{x})F(\hat{x},\hat{t}) > 0$, then it follows from the second identity of (4.7) after multiplying $\nu(\hat{x})$ on both sides that

$$\nu(\hat{x})e^{-K\hat{t}}F(\hat{x},\hat{t})\left((e^{K\hat{t}}\lambda)^2+\gamma^2\right)^{1/2} + \varepsilon\lambda \leq \nu(\hat{x})e^{-K\hat{t}}F(\hat{x},\hat{t})\max\{\alpha(\hat{x},\hat{t}),\gamma\}.$$

Dividing both sides by $\nu(\hat{x})e^{-K\hat{t}}F(\hat{x},\hat{t}) > 0$, we obtain

$$\left((e^{K\hat{t}}\lambda)^2+\gamma^2\right)^{1/2} + \frac{\varepsilon\lambda}{\nu(\hat{x})e^{-K\hat{t}}F(\hat{x},\hat{t})} \leq \max\{\alpha(\hat{x},\hat{t}),\gamma\}.$$

The left-hand side is strictly greater than λ, which is a contradiction of the second and third inequalities of (4.8). If $\nu(\hat{x})F(\hat{x},\hat{t}) < 0$, then a similar calculation shows that

$$\begin{aligned} &\nu(\hat{x})e^{-K\hat{t}}F(\hat{x},\hat{t})\left((e^{K\hat{t}}\lambda)^2+\gamma^2\right)^{1/2} + \varepsilon\lambda \\ &\qquad \leq \nu(\hat{x})e^{-K\hat{t}}F(\hat{x},\hat{t})\max\left\{\alpha(\hat{x},\hat{t}), ((e^{K\hat{t}}\lambda)^2+\gamma^2)^{1/2}\right\} \end{aligned}$$

and, since $\nu(\hat{x})e^{-K\hat{t}}F(\hat{x},\hat{t}) < 0$,

$$\left((e^{K\hat{t}}\lambda)^2+\gamma^2\right)^{1/2} + \frac{\varepsilon\lambda}{\nu(\hat{x})e^{-K\hat{t}}F(\hat{x},\hat{t})} \geq \max\left\{\alpha(\hat{x},\hat{t}), ((e^{K\hat{t}}\lambda)^2+\gamma^2)^{1/2}\right\}.$$

Since the second term of the left-hand side is negative, we get a contradiction. The term $\varepsilon\nu u_x$ plays a crucial role in getting a contradiction for the case $\nu(\hat{x})F(\hat{x},\hat{t}) \neq 0$. If $F(\hat{x},\hat{t}) = 0$, then the second identity of (4.7) implies $\lambda \leq 0$, which is also a contradiction. When $\hat{x}\in\Omega$, we see that $w_x(\hat{x},\hat{t}) = 0$, $w_{xx}(\hat{x},\hat{t}) \leq 0$ and then

$$K\lambda \leq e^{-K\hat{t}}F_x(\hat{x},\hat{t})\left((e^{K\hat{t}}\lambda)^2+\gamma^2\right)^{1/2}$$

from the first identity of (4.7). The right-hand side is less than or equal to $K(\lambda^2+\gamma^2)^{1/2}/2$, which is a contradiction of the third inequality of (4.8). Hence, we have the estimate

$$\max_{\overline{Q}} |u_x^\varepsilon| \leq e^{KT}\max\left\{\max_{\overline{\Omega}} |a_x^\varepsilon|, \max_{\partial\Omega\times[0,T]} |\alpha|, \gamma\right\}, \quad K = 2\max_{\overline{Q}} |F_x|. \tag{4.9}$$

(iii) *The estimate for u_t^ε.* We set $w(x,t) = e^{-\mu t} u_t^\varepsilon(x,t)$ ($\mu = 1$). It follows from (4.2) that

$$
\begin{cases}
w_t + \mu w - \varepsilon w_{xx} & \\
\qquad = e^{-\mu t} F_t \left((u_x^\varepsilon)^2 + \gamma^2 \right)^{1/2} + \dfrac{F u_x^\varepsilon w_x}{((u_x^\varepsilon)^2 + \gamma^2)^{1/2}} & \text{in} \quad Q, \\
w + \varepsilon e^{-\mu t} \nu u_x^\varepsilon & \\
\qquad = e^{-\mu t} F \max \left\{ \alpha, \left(([\nu u_x^\varepsilon \mathrm{Sign} F]_-)^2 + \gamma^2 \right)^{1/2} \right\} & \text{on} \quad \partial\Omega \times (0,T), \\
w(x,0) = \varepsilon a_{xx}^\varepsilon(x) + F(x,0) \left(a_x^\varepsilon(x)^2 + \gamma^2 \right)^{1/2} & \text{for} \quad x \in \Omega.
\end{cases} \tag{4.10}
$$

Let $(\hat{x}, \hat{t})$ and λ satisfy $\max_{\overline{Q}} w = w(\hat{x}, \hat{t})$ and $\lambda = w(\hat{x}, \hat{t})$. We assume that

$$
\lambda > \Gamma_0, \quad \lambda > \Gamma_1, \quad \text{and} \quad \lambda > \Gamma_2, \tag{4.11}
$$

with

$$
\begin{aligned}
\Gamma_0 &= \varepsilon \max_{\overline{\Omega}} |a_{xx}^\varepsilon| + \max_{\overline{Q}} |F| \left(\max_{\overline{\Omega}} |a_x^\varepsilon| + \gamma \right), \\
\Gamma_1 &= \max_{\overline{Q}} |F| \max \left\{ \max_{\partial\Omega \times [0,T]} |\alpha|, \max_{\overline{Q}} |u_x^\varepsilon| + \gamma \right\}, \\
\Gamma_2 &= \max_{\overline{Q}} |F_t| \left(\max_{\overline{Q}} |u_x^\varepsilon| + \gamma \right).
\end{aligned}
$$

We shall show that it is inconsistent with (4.10) for w. First, we see that $\hat{t} > 0$ by the first inequality of (4.11) and obtain $w_t(\hat{x}, \hat{t}) \geq 0$. When $\hat{x} \in \partial\Omega$, by the second identity of (4.10) we see that

$$
\lambda + \varepsilon e^{-\mu \hat{t}} \nu(\hat{x}) u_x^\varepsilon(\hat{x}, \hat{t}) \leq e^{-\mu \hat{t}} F(\hat{x}, \hat{t}) \max \left\{ \alpha(\hat{x}, \hat{t}), (u_x^\varepsilon(\hat{x}, \hat{t})^2 + \gamma^2)^{1/2} \right\}.
$$

Since u_x^ε is bounded uniformly for ε, by choosing ε sufficiently small at the second term of the left-hand side, we get a contradiction to the second inequality of (4.11). When $\hat{x} \in \Omega$, we see that $w_x(\hat{x}, \hat{t}) = 0$, $w_{xx}(\hat{x}, \hat{t}) \leq 0$ and then

$$
\mu \lambda \leq e^{-\mu \hat{t}} F_t(\hat{x}, \hat{t}) ((u_x^\varepsilon)^2 + \gamma^2)^{1/2}
$$

from the first identity of (4.10), which is a contradiction of the third inequality of (4.11). Hence, we have the estimate

$$
\max_{\overline{Q}} |u_t^\varepsilon| \leq e^T \max \{ \Gamma_0, \Gamma_1, \Gamma_2 \}. \tag{4.12}
$$

By (4.6), (4.9), (4.12) we get the estimate (4.3) and now complete the proof of Proposition 4.2. □

Remark 2. (1) When $F_x^\varepsilon \equiv 0$, one can choose any $K > 0$ in the proof (ii). So, we have

$$
\max_{\overline{Q}} |u_x^\varepsilon| \leq \max \left\{ \max_{\overline{\Omega}} |a_x^\varepsilon|, \max_{\partial\Omega \times [0,T]} |\alpha|, \gamma \right\}. \tag{4.9$'$}
$$

(2) When $F_t^\varepsilon \equiv 0$, we can choose any $\mu > 0$ in the proof (iii). So, we have

$$
\max_{\overline{Q}} |u_t^\varepsilon| \leq \max \{ \Gamma_0, \Gamma_1, \Gamma_2 \}. \tag{4.12$'$}
$$

(3) To carry out the above proof we implicitly invoke the regularity u^ε, u^ε_x, u^ε_{xx}, $u^\varepsilon_t \in C(\overline{Q})$ together with u^ε_{xt}, u^ε_{xxx}, u^ε_{tt}, $u^\varepsilon_{xxt} \in C(Q)$. In Proposition 4.2 and Corollary 4.3 as a classical solution we require at least this regularity.

In a way similar to the proof of Proposition 4.2 one is able to prove an a priori estimate, which is useful in proving the global existence of solutions of (4.2) (cf. Theorem A.1).

COROLLARY 4.3. *Assume that F^ε and α^ε are in Proposition* 4.2 *and that a is a C^3 function over $\overline{\Omega}$. Let $\sigma \in [0,1]$ and $\varepsilon > 0$. Let v be a classical solution of*

$$\begin{cases} v_t - \varepsilon v_{xx} = \sigma F^\varepsilon \left((v_x)^2 + \gamma^2\right)^{1/2} & \text{in} \quad Q, \\ v_t = \sigma F^\varepsilon \max\left\{\alpha^\varepsilon, \left(([\nu v_x \mathrm{Sign} F^\varepsilon]_-)^2 + \gamma^2\right)^{1/2}\right\} - \sigma\varepsilon\nu v_x & \text{on} \quad \partial\Omega \times (0,T), \\ v|_{t=0} = \sigma a & \text{on} \quad \Omega. \end{cases}$$

Then the estimate

$$\max_{\overline{Q}} (|v| + |v_x|) \le C \tag{4.13}$$

holds with some constant $C > 0$ independent of $\varepsilon \in (0,1)$ and $\sigma \in [0,1]$.

Proof of Theorem 4.1. For a given Lipschitz function a there is a sequence $a^\varepsilon \in C^\infty(\overline{\Omega})$ such that $a^\varepsilon \to a$ uniformly and that $|a^\varepsilon_x|_{C(\overline{\Omega})}$ and $|\varepsilon a^\varepsilon_{xx}|_{C(\overline{\Omega})}$ are bounded. For a given $F \in C^1(\overline{Q})$ and $\alpha \in C(\partial\Omega \times [0,T])$ there is a sequence $\{F^\varepsilon, \alpha^\varepsilon\}$ with $F^\varepsilon \in C^1(\overline{Q}) \cap C^\infty(Q)$, $\alpha^\varepsilon \in C^1(\partial\Omega \times [0,T])$ such that $F^\varepsilon \to F$ uniformly in $\overline{Q}$ and $\alpha^\varepsilon \to \alpha$ uniformly in $\partial\Omega \times [0,T]$ and that $|F^\varepsilon|_{C^1(\overline{Q})}$ and $|\alpha^\varepsilon|_{C(\partial\Omega\times[0,T])}$ are bounded as $\varepsilon \to 0$. By Theorem A.1 there exists a unique classical solution u^ε of (4.2).

By the uniform estimate (4.3) the Arzelà–Ascoli theorem implies that there exists a function u such that

$$u^\varepsilon \to u \quad \text{uniformly on } \overline{Q}.$$

We shall show that u is the viscosity solution of the original dynamic boundary problem (4.1). Since the proof for viscosity supersolutions is symmetric, we only prove that u is a viscosity subsolution for $G = 0$. To do this, let $\phi \in C^2(\overline{Q})$ be a test function and let $(\hat{x}, \hat{t}) \in \hat{Q} = \overline{\Omega} \times (0,T)$ be the maximum point of $u - \phi$. We may assume that $(\hat{x}, \hat{t})$ is a strict maximum of $u - \phi$. Then there exists $(x_\varepsilon, t_\varepsilon)$ such that $(x_\varepsilon, t_\varepsilon) \to (\hat{x}, \hat{t})$ and $\sup_{\hat{Q}}(u^\varepsilon - \phi) = (u^\varepsilon - \phi)(x_\varepsilon, t_\varepsilon)$.

Case 1. When there exists a subsequence $\{(x_\varepsilon, t_\varepsilon) \in Q\}$, we see that $u^\varepsilon_t(x_\varepsilon, t_\varepsilon) = \phi_t(x_\varepsilon, t_\varepsilon)$, $u^\varepsilon_x(x_\varepsilon, t_\varepsilon) = \phi_x(x_\varepsilon, t_\varepsilon)$, and $u^\varepsilon_{xx}(x_\varepsilon, t_\varepsilon) \le \phi_{xx}(x_\varepsilon, t_\varepsilon)$. Since u^ε satisfies the first identity of (4.2) at $(x_\varepsilon, t_\varepsilon)$ as a classical solution, we get

$$\phi_t(x_\varepsilon, t_\varepsilon) - \varepsilon\phi_{xx}(x_\varepsilon, t_\varepsilon) - F^\varepsilon(x_\varepsilon, t_\varepsilon)(\phi_x(x_\varepsilon, t_\varepsilon)^2 + \gamma^2)^{1/2} \le 0.$$

By $\varepsilon \to 0$ we see that u is a viscosity subsolution at $(\hat{x}, \hat{t})$.

Case 2. When $\hat{x} \in \partial\Omega$ and there is a subsequence $\{(x_\varepsilon, t_\varepsilon) \in \partial\Omega \times (0,T)\}$, we see that $u^\varepsilon_t(x_\varepsilon, t_\varepsilon) = \phi_t(x_\varepsilon, t_\varepsilon)$ and $\nu u^\varepsilon_x(x_\varepsilon, t_\varepsilon) \ge \nu\phi_x(x_\varepsilon, t_\varepsilon)$. Since u^ε satisfies the second identity of (4.2) at $(x_\varepsilon, t_\varepsilon)$ as a classical solution, we get

$$\begin{aligned} &\phi_t(x_\varepsilon, t_\varepsilon) + \varepsilon\nu\phi_x(x_\varepsilon, t_\varepsilon) \\ &\quad \le F^\varepsilon(x_\varepsilon, t_\varepsilon) \max\left\{\alpha^\varepsilon(x_\varepsilon, t_\varepsilon), \left(([\nu u^\varepsilon_x(x_\varepsilon, t_\varepsilon)\mathrm{Sign} F^\varepsilon(x_\varepsilon, t_\varepsilon)]_-)^2 + \gamma^2\right)^{1/2}\right\}. \end{aligned} \tag{4.14}$$

If $F(\hat{x},\hat{t}) > 0$, we may assume that $F^\varepsilon(x_\varepsilon,t_\varepsilon) > 0$. We also see that $([\nu u_x^\varepsilon(x_\varepsilon,t_\varepsilon)]_-)^2 \le \phi_x(x_\varepsilon,t_\varepsilon)^2$ and then

$$\phi_t(x_\varepsilon,t_\varepsilon) + \varepsilon\nu\phi_x(x_\varepsilon,t_\varepsilon) \le F^\varepsilon(x_\varepsilon,t_\varepsilon)\max\left\{\alpha^\varepsilon(x_\varepsilon,t_\varepsilon), \left(\phi_x(x_\varepsilon,t_\varepsilon)^2+\gamma^2\right)^{1/2}\right\}.$$

By $\varepsilon \to 0$ it holds that u satisfies either the first or second identity of (4.1) as a viscosity subsolution at $(\hat{x},\hat{t})$. If $F(\hat{x},\hat{t}) < 0$, we may assume that $F^\varepsilon(x_\varepsilon,t_\varepsilon) < 0$. It is easy to see that

$$\phi_t(x_\varepsilon,t_\varepsilon) + \varepsilon\nu\phi_x(x_\varepsilon,t_\varepsilon) \le F^\varepsilon(x_\varepsilon,t_\varepsilon)\alpha^\varepsilon(x_\varepsilon,t_\varepsilon).$$

By $\varepsilon \to 0$ we get the second identity of (4.1) as a viscosity subsolution at $(\hat{x},\hat{t})$. If $F(\hat{x},\hat{t}) = 0$, the right-hand side of (4.14) vanishes as $\varepsilon \to 0$. We get $u_t \le 0$ in the viscosity sense at $(\hat{x},\hat{t})$. Thus u is a viscosity solution of (4.1), and it is unique by the comparison principle (Theorem 3.1).

The Lipschitz continuity of u in x follows from (4.9). □

5. Relation to other boundary conditions. We shall relate an inhomogeneous Neumann boundary value problem for

$$u_t - F(u_x^2+\gamma^2)^{1/2} = 0 \tag{5.1}$$

supplemented with the dynamic boundary

$$u_t - F\alpha = 0. \tag{5.2}$$

Formally, (5.1) and (5.2) yields

$$F(u_x^2+\gamma^2)^{1/2} = F\alpha.$$

If F is not zero, this implies $u_x^2+\gamma^2 = \alpha^2$. Thus we obtain

$$\partial u/\partial\nu = u_x\nu = \pm(\alpha^2-\gamma^2)^{1/2} \tag{5.3}$$

on the boundary. The Neumann data in (5.3) needs more explanation since both its sign and its value for $\alpha^2 < \gamma^2$ are unclear. We shall clarify these points and prove that a solution of (5.1), (5.2) solves an inhomogeneous Neumann problem in the viscosity sense (Theorem 5.1).

When we are asked to solve (5.1) and (5.2), we are tempted to integrate (5.2) in order to obtain the Dirichlet condition:

$$u(x,t) = \int_0^t F(x,\tau)\alpha(x,\tau)d\tau + a(x), \quad x \in \partial\Omega. \tag{5.4}$$

However, (5.1) with the Dirichlet condition (5.4) is not, unfortunately, equivalent to (5.1), (5.2). We shall give a counterexample in the last part of this section.

THEOREM 5.1. *Assume that F and α are continuous on $\overline{Q}$ and $\partial\Omega\times[0,T]$, respectively. Assume that u is a viscosity subsolution (resp., supersolution) for G in $\hat{Q}$. Then u is a viscosity subsolution (resp., supersolution) of the Neumann problem of* (5.1) *in $\hat{Q}$ with*

$$\partial u/\partial\nu = \mathrm{Sign}F\left\{(\alpha-\gamma)_+(\alpha+\gamma)\right\}^{1/2}. \tag{5.5}$$

Here β_+ is the plus part of β defined by $\beta_+ = \max(\beta, 0)$.

Proof. We suppress the word viscosity in the proof. Since the proof for supersolutions is symmetric, we shall present the proof for subsolutions only. We may assume that u is upper semicontinuous in $\hat{Q}$. Assume that u is a subsolution for G in $\hat{Q}$. Assume that $u - \phi$ takes its maximum over $\hat{Q}$ at $(\hat{x}, \hat{t})$ with $\hat{x} \in \overline{\Omega}$, $\hat{t} \in (0, T)$ for $\phi \in C^1(\hat{Q})$. We may assume that $\hat{x} \in \partial\Omega$ since the equation is the same in $\Omega \times (0, T)$. To simplify notation we set

$$\tau = \phi_t(\hat{x}, \hat{t}), \quad p = \phi_x(\hat{x}, \hat{t}), \quad \hat{F} = F(\hat{x}, \hat{t}), \quad \hat{\alpha} = \alpha(\hat{x}, \hat{t}).$$

We have to prove that

$$\min\left\{\tau - \hat{F}(p^2 + \gamma^2)^{1/2}, p\nu - \mathrm{Sign}\hat{F}\left\{(\hat{\alpha} - \gamma)_+(\hat{\alpha} + \gamma)\right\}^{1/2}\right\} \leq 0. \tag{5.6}$$

To prove (5.6) we may assume that

$$\tau - \hat{F}(p^2 + \gamma^2)^{1/2} > 0. \tag{5.7}$$

Case 1 ($\hat{F} < 0$). Since u is a subsolution of $G = 0$, we have

$$\tau - \hat{F}\max\left\{\hat{\alpha}, \left(([p\nu]_+)^2 + \gamma^2\right)^{1/2}\right\} \leq 0. \tag{5.8}$$

From (5.7) and (5.8) it follows that

$$\hat{F}\left(p^2 + \gamma^2\right)^{1/2} < \hat{F}\max\left\{\hat{\alpha}, \left(([p\nu]_+)^2 + \gamma^2\right)^{1/2}\right\}$$

or

$$\begin{aligned}\left(p^2 + \gamma^2\right)^{1/2} &> \max\left\{\hat{\alpha}, \left(([p\nu]_+)^2 + \gamma^2\right)^{1/2}\right\} \\ &\geq \left(([p\nu]_+)^2 + \gamma^2\right)^{1/2}.\end{aligned} \tag{5.9}$$

This implies $p^2 > ([p\nu]_+)^2$, so we obtain

$$p\nu < 0. \tag{5.10}$$

Assume that $\hat{\alpha} > \gamma$. From (5.9) it follows that $(p^2 + \gamma^2)^{1/2} > \hat{\alpha}$. This together with (5.10) implies that

$$p\nu < -(\hat{\alpha}^2 - \gamma^2)^{1/2} \quad \text{for } \hat{\alpha} > \gamma. \tag{5.11}$$

By (5.10) and (5.11) we obtain

$$p\nu < -\left\{(\hat{\alpha} - \gamma)_+(\hat{\alpha} + \gamma)\right\}^{1/2}.$$

We now obtain (5.6) when $\hat{F} < 0$.

Case 2 ($\hat{F} > 0$). We note that $G = 0$ is equivalent to the dynamic boundary value problem (5.1), (5.2). Since (5.7) holds, we have

$$\tau - \hat{F}\hat{\alpha} \leq 0. \tag{5.12}$$

From (5.7) and (5.12) it follows that

$$\hat{F}(p^2 + \gamma^2)^{1/2} < \hat{F}\hat{\alpha}.$$

Since $\hat{F} > 0$, this yields $(p^2 + \gamma^2)^{1/2} < \hat{\alpha}$ and implies

$$p^2 < \hat{\alpha}^2 - \gamma^2 \quad \text{or} \quad |p|^2 \le \hat{\alpha}^2 - \gamma^2 = (\hat{\alpha} - \gamma)_+(\hat{\alpha} + \gamma).$$

We have thus proved (5.6) when $\hat{F} > 0$.

Case 3 ($\hat{F} = 0$). Since $G = 0$ is equivalent to the dynamic boundary value problem (5.1), (5.2), $\tau \le 0$ is always fulfilled if $\hat{F} = 0$. Thus we have proved (5.6). □

We shall give a counterexample to show that the problem (5.1), (5.2) is different from the Dirichlet problem (5.1), (5.4) in the viscosity sense. We suppress the word viscosity.

We shall give two different functions u and v which initially agree with each other, but u solves (5.1), (5.2) while v solves (5.1), (5.4) when $\alpha \equiv 1$, $F \equiv 1$, $\alpha > \gamma$, and $\Omega = (0, \infty)$. Although it is not difficult to give such functions for $\Omega = (0, L)$ with more general α and F, we keep such assumptions to clarify the argument. Let β be a constant strictly greater than $\sigma = (1 - \gamma^2)^{1/2}$ so that $\eta = (\beta^2 + \gamma^2)^{1/2} > 1$. We set

$$w(x,t) = \min\{\beta + \gamma t, \beta x + \eta t, -\sigma x + \sigma + \beta + t\}, \quad x \in \overline{\Omega}. \tag{5.13}$$

This function is nondecreasing in t and

$$w(x,0) = \min\{\beta x, -\sigma x + \sigma + \beta\}$$

so that $w(x,0)$ is linear except at $x = 1$. At time $t_0 = \beta(\eta - \gamma)^{-1}$

$$w(x,t_0) = \min\{\beta + \gamma t_0, -\sigma x + \sigma + \beta + t_0\}.$$

Since $\beta \ge \sigma$, it is easy to see that

$$\phi_t - \left(\phi_x^2 + \gamma^2\right)^{1/2} \le 0 \quad \text{at } (\hat{x}, \hat{t})$$

if $w - \phi$ attains its maximum at $(\hat{x}, \hat{t})$ over $\overline{\Omega} \times (0, t_0]$ even if $\hat{x} \in \partial\Omega$. So w is a subsolution of $\overline{\Omega} \times (0, t_0]$ of (5.1), (5.2) and (5.1), (5.4). It is easy to see that w is a supersolution of (5.1), (5.2) and (5.1), (5.4) in $\overline{\Omega} \times (0, t_0]$ since $w_t \ge 1$, $w \ge t_0$ on the boundary. We now set

$$u(x,t) = v(x,t) = w(x,t) \quad \text{for } t \le t_0, x \in \overline{\Omega} \tag{5.14}$$

and

$$v(x,t) = \min\{\beta + \gamma t, -\sigma x + \sigma + \beta + t\} \quad \text{for } t \ge t_0, x \in \overline{\Omega}, \tag{5.15}$$

$$u(x,t) = \max\{\beta + (\gamma - 1)t_0 + t - \sigma x, v(x,t)\} \quad \text{for } t \ge t_0, x \in \overline{\Omega}. \tag{5.16}$$

As for w it is easy to see that v is a subsolution of both the dynamic (5.1), (5.2) and the Dirichlet problem (5.1), (5.4) in $\overline{\Omega} \times (0, \infty)$. Since $\eta > 1$ so that $t_1 = \beta(1 - \gamma)^{-1} > t_0$, and since $v(0,t) > t$ for $t < t_1$, v is a supersolution of the Dirichlet problem in $\overline{\Omega} \times (0, t_1)$. However, v is not a supersolution in $\overline{\Omega} \times (0, t_1)$ of (5.1), (5.2) since at the boundary $v_t < 1$ with $v_x = 0$.

Since $u_t = 1$ on the boundary and since it is easy to see that u is a solution of (5.1) in $\Omega \times (0, \infty)$, we conclude that u is a solution of (5.1), (5.2) in $\overline{\Omega} \times (0, \infty)$. This is not a subsolution of (5.1), (5.4) in $\overline{\Omega} \times (0, \infty)$ since $u(0,t) > t$ by $\eta > 1$ and

$$\phi_t - \left(\phi_x^2 + \gamma^2\right)^{1/2} > 0 \quad \text{at } (0, \hat{t})$$

if $u-\phi$ attains its maximum on $\overline{\Omega}\times(0,\infty)$ and $\hat{t}>t_0$. (The function u is a supersolution of (5.1), (5.4) since $u(0,t)>t$.) We summarize our results.

PROPOSITION 5.2. *Assume that $\alpha\equiv F\equiv 1$ and $\gamma<1$. Let $\beta>\sigma=(1-\gamma^2)^{1/2}$. For $\Omega=(0,\infty)$, let u and v be functions defined by* (5.13)–(5.16). *Then u is a solution of the dynamic boundary problem* (5.1), (5.2) *in $\overline{\Omega}\times(0,\infty)$ while v is a solution of the Dirichlet problem* (5.1), (5.4) *in $\overline{\Omega}\times(0,t_1)$ with $t_1=\beta(1-\gamma)^{-1}$. However, u is not a subsolution of* (5.1), (5.4) *in $\overline{\Omega}\times(0,T)$, $T>t_0$, while u is a supersolution of* (5.1), (5.4) *in $\overline{\Omega}\times(0,\infty)$. The function v is not a supersolution of* (5.1), (5.2) *while it is a subsolution of* (5.1), (5.2).

Appendix. Existence of solutions of approximate solutions. Our goal is to prove the following theorem.

THEOREM A.1. *For $T>0$ assume that $F\in C^1(\overline{Q})\cap C^\infty(Q)$ and $\alpha\in C^1(\partial\Omega\times[0,T])$ with $Q=\Omega\times(0,T)$, where Ω is a bounded open interval. Assume that $a\in C^3(\overline{\Omega})$ and $\gamma\in\mathbb{R}$. Then for each $\varepsilon>0$ there exists a solution $u\in C^{2,1}(\overline{Q})\cap C^\infty(Q)$ of*

$$\begin{cases} u_t-\varepsilon u_{xx}=F(u_x^2+\gamma^2)^{1/2} & \text{in} \quad Q,\\ u_t+\varepsilon\nu u_x=F\max\left\{\alpha,\left(([\nu u_x\mathrm{Sign}F]_-)^2+\gamma^2\right)^{1/2}\right\} & \text{on} \quad \partial\Omega\times(0,T),\\ u|_{t=0}=a & \text{on} \quad \Omega. \end{cases}$$

The space $C^{2,1}(\overline{Q})$ denotes the space of all $u\in C(\overline{Q})$ satisfying u_x, u_{xx}, $u_t\in C(\overline{Q})$. The space $X=C^{1,0}(\overline{Q})$ denotes the space of all $u\in C(\overline{Q})$ satisfying $u_x\in C(\overline{Q})$. The space X is a Banach space equipped with the norm $\|u\|_X=\max(|u|_{C(\overline{\Omega})},|u_x|_{C(\overline{\Omega})})$.

We shall find a solution in X by a method of continuity which is a version of a fixed point argument [9, Theorem 11.6]. For $\sigma\in[0,1]$ we define a mapping $\mathfrak{F}_\sigma: X\to Y$ by

$$\mathfrak{F}_\sigma(\phi)=\left(\sigma F(\phi_x^2+\gamma^2)^{1/2},\sigma F\max\left\{\alpha,\left(([\nu\phi_x\mathrm{Sign}F]_-)^2+\gamma^2\right)^{1/2}\right\}\Big|_{\partial\Omega}-\sigma\varepsilon\nu\phi_x\Big|_{\partial\Omega}\right),$$

where $Y=C(\overline{Q})\times C(\partial\Omega\times[0,T])$. Let $\mathfrak{H}_\sigma$ denote the solution operator of the problem

$$\begin{cases} u_t-\varepsilon u_{xx}=f & \text{in} \quad Q,\\ u_t=g & \text{on} \quad \partial\Omega\times(0,T),\\ u|_{t=0}=\sigma a & \text{on} \quad \Omega. \end{cases}$$

In other words, it is formally defined by $\mathfrak{H}_\sigma(f,g)=u$ for $(f,g)\in Y$. Let us give a rigorous definition. We replace the boundary condition by the standard Dirichlet condition

$$u(x,t)=\int_0^t g(x,\tau)d\tau+\sigma a(x)=:h(x,t).$$

We extend h linearly in x, i.e.,

$$\tilde{h}(x,t)=\frac{L-x}{L}h(0,t)+\frac{x}{L}h(L,t),\quad x\in\Omega,$$

when $\Omega=(0,L)$. Then $v=u-\tilde{h}$ solves

$$\begin{cases} v_t-\varepsilon v_{xx}=f-\tilde{h}_t & \text{in} \quad Q,\\ v=0 & \text{on} \quad \partial\Omega\times(0,T),\\ v|_{t=0}=\sigma a-\tilde{h}|_{t=0} & \text{on} \quad \Omega. \end{cases}$$

Since $\tilde{h}_t \in C(\overline{Q})$, by the standard L^p theory [11] there is a unique solution v of the above problem, and it belongs to the Sobolev space $W_p^{2,1}(Q)$ for every $p > 1$ if a is sufficiently regular, say $a \in C^2(\overline{\Omega})$. The value $\mathfrak{H}_\sigma(f, g)$ is defined by $v + \tilde{h}$. By the construction the mapping $\mathfrak{H}_\sigma$ is bounded linearly from Y to $W_p^{2,1}(Q)$ for every $p > 1$.

Thus the mapping $\mathfrak{H} : Y \times [0, 1] \to X$ defined by $\mathfrak{H}((f, g), \sigma) = \mathfrak{H}_\sigma(f, g)$ is well-defined and compact by the standard embedding theory [11]. We define $\mathfrak{F} : X \times [0, 1] \to X$ by

$$\mathfrak{F}(\phi, \sigma) = \mathfrak{H}(\mathfrak{F}_\sigma(\phi), \sigma).$$

Evidently, $\mathfrak{F}(\phi, 0) = 0$ for all $\phi \in X$. Moreover $\mathfrak{F}$ is compact since $\mathfrak{H}$ is compact and $\mathfrak{F}$ is continuous. To apply the Leray–Schauder fixed point theorem [9, Theorem 11.6], it remains to prove the a priori estimate

$$\|\phi\|_X < M \quad \text{for } \phi = \mathfrak{F}(\phi, \sigma) \tag{A.1}$$

with M independent of ϕ and σ. We first observe that $\phi \in C^{2,1}(\overline{Q}) \cap C^\infty(Q)$. Since $\phi \in W_p^{2,1}(Q)$ for $p > n + 2$, a standard embedding result [11, Chapter II, Lemma 3.3] implies that $\phi_x \in C^{\mu,\mu/2}(\overline{Q})$ with some $\mu \in (0, 1)$; i.e., ϕ_x is Hölder continuous in $\overline{Q}$. This implies that $\mathfrak{F}_\sigma(\phi) \in C^{\mu,\mu/2}(\overline{Q}) \times C^{\mu/2}(\partial\Omega \times [0, T])$. Since $\mathfrak{F}(\phi, \sigma) = \phi$ and $a \in C^{2+\mu}(\overline{\Omega})$, by the Schauder estimates [11] we conclude that $\phi \in C^{2+\mu,1+\mu/2}(\overline{Q})$. Since $F \in C^\infty(Q)$, then a standard bootstrap argument [11] yields $\phi \in C^\infty(Q)$. Thus the estimate (A.1) is obtained in Corollary 4.3. Note that the term $\varepsilon\nu u_x$ plays a crucial role here. We have thus proved that there exists $u \in X$ such that $\mathfrak{F}(u, 1) = u$, which is the desired solution. So, Theorem A.1 has been proved.

Remark 3. Of course there is another way to prove Theorem A.1. A local-in-time classical solution u can be constructed as in [7]. Once there is a bound for u_x, then the solution can be extended globally in time as in [8]. However, Theorem A.1 is not explicitly included in these references, so we have given a complete proof for the reader's convenience. The solution in Theorem A.1 is actually unique, although we do not use this property.

Acknowledgments. This work was carried out during extremely enjoyable and stimulating visits by C. M. E. to Hokkaido University, whose hospitality he gratefully acknowledges. We are grateful to the referees for their valuable comments.

RECOVERY OF SMALL INHOMOGENEITIES FROM THE SCATTERING AMPLITUDE AT A FIXED FREQUENCY*

HABIB AMMARI†, EKATERINA IAKOVLEVA†, AND SHARI MOSKOW‡

Abstract. We rigorously derive the leading order term in the asymptotic expansion of the scattering amplitude of a collection of a finite number of dielectric inhomogeneities of small diameter. We then apply this asymptotic formula for the purpose of identifying the location and certain properties of the shapes of the small inhomogeneities from scattering amplitude measurements at a fixed frequency. Our main idea is to reduce this reconstruction problem to the calculation of an inverse Fourier transform.

Key words. inverse scattering problem, scattering amplitude, Helmholtz equation, dielectric imperfections, reconstruction

1. Introduction. In this paper, we consider three-dimensional electromagnetic scattering from a collection of small dielectric inhomogeneities. We suppose that there is a finite number of dielectric imperfections in $\mathbf{R}^3$, each of the form $z_j + \alpha B_j$, where $B_j \subset \mathbf{R}^3$ is a bounded, smooth (C^∞) domain containing the origin. This regularity assumption could be considerably weakened. The total collection of imperfections thus takes the form

$$\mathcal{I}_\alpha = \cup_{j=1}^m (z_j + \alpha B_j).$$

The points $z_j \in \mathbf{R}^3$, $j = 1, \ldots, m$, that determine the location of the imperfections are assumed to satisfy

$$0 < d_0 \leq |z_j - z_l| \quad \forall\, j \neq l. \tag{1}$$

We also assume that $\alpha > 0$, the common order of magnitude of the diameters of the imperfections, is small enough such that the imperfections are disjoint.

Our first goal is to provide a rigorous derivation of the asymptotic expansion of the scattering amplitude for such a collection of small dielectric imperfections. Our second goal is to use this expansion for efficiently determining the locations and/or shapes of the small inhomogeneities from scattering amplitude measurements at a fixed frequency by reducing the reconstruction problem of the small inhomogeneities to the calculation of an inverse Fourier transform. We expect that our asymptotic formulas will form the basis for very effective computational identification algorithms, aimed at determining information about the small inhomogeneities from scattering amplitude measurements.

To the best of our knowledge, the present paper is the first attempt to design an effective and accurate method to determine the location and the size of small dielectric inhomogeneities with *both* different electric permittivities and magnetic permeabilities from scattering amplitude measurements. Our method is quite similar to the ideas used by Calderon [5] in his proof of uniqueness of the linearized conductivity problem and later by Sylvester and Uhlmann in their important work [20] on uniqueness of the three-dimensional inverse conductivity problem. Our technique for studying the scattering problem is to reduce the problem to a bounded domain with the aid of integral equation methods. On the bounded domain, the derivation of the asymptotic expansion of the solution relies heavily on the results of [24]. The current work is also a natural extension of the identification procedure that we have presented in [2], where we demonstrated numerically its accuracy and stability. For discussions on other closely related inverse scattering problems, the reader is referred, for example, to [7], [15], [10], [11], [12], [22], [23], [14], [17], [18], [19], and [8].

Let $\mu^0 > 0$ and $\varepsilon^0 > 0$ denote the permeability and the permittivity of the free space; we shall assume that these are positive constants. Let $\mu^j > 0$ and $\varepsilon^j > 0$ denote the permeability and the permittivity of the jth inhomogeneity, $z_j + \alpha B_j$; these are also assumed to be positive constants. Using this notation, we introduce the piecewise constant magnetic permeability

$$\mu_\alpha(x) = \begin{cases} \mu^0, & x \in \mathbf{R}^3 \setminus \bar{\mathcal{I}}_\alpha, \\ \mu^j, & x \in z_j + \alpha B_j,\ j = 1, \dots, m. \end{cases} \tag{2}$$

If we allow the degenerate case $\alpha = 0$, then the function $\mu_0(x)$ equals the constant μ^0. The piecewise constant electric permittivity $\varepsilon_\alpha(x)$ is defined analogously. We need to introduce some additional notation. Let γ^j, $1 \le j \le m$, be a set of positive constants. In effect, $\{\gamma^j\}$ will be either the set $\{\varepsilon^j\}$ or the set $\{\mu^j\}$. For any fixed $1 \le j_0 \le m$, let γ denote the coefficient given by

$$\gamma(x) = \begin{cases} \gamma^0, & x \in \mathbf{R}^3 \setminus \bar{B}_{j_0}, \\ \gamma^{j_0}, & x \in B_{j_0}. \end{cases} \tag{3}$$

By ϕ_l, $1 \le l \le 3$, we denote the solution to

$$\begin{aligned} &\nabla_y \cdot \gamma(y) \nabla_y \phi_l = 0 \quad \text{in } \mathbf{R}^3, \\ &\phi_l - y_l \to 0 \quad \text{as } |y| \to \infty. \end{aligned}$$

This problem may alternatively be written as

$$\begin{cases} \Delta \phi_l = 0 \quad \text{in } B_{j_0}, \text{ and in } \mathbf{R}^3 \setminus \overline{B_{j_0}}, \\ \phi_l \text{ is continuous across } \partial B_{j_0}, \\ \dfrac{\gamma^0}{\gamma^{j_0}} (\partial_\nu \phi_l)^+ - (\partial_\nu \phi_l)^- = 0 \quad \text{on} \quad \partial B_{j_0}, \\ \phi_l(y) - y_l \to 0 \quad \text{as } |y| \to \infty. \end{cases}$$

Here ν denotes the outward unit normal to $\partial(z_j + \alpha B_j)$; superscripts $+$ and $-$ indicate the limiting values as we approach $\partial(z_j + \alpha B_j)$ from outside $z_j + \alpha B_j$ and from inside $z_j + \alpha B_j$. It is obvious that the function ϕ_l depends only on the coefficients γ^0 and γ^{j_0} through the ratio $c = \frac{\gamma^0}{\gamma^{j_0}}$. The existence and uniqueness of this ϕ_l can be established using single layer potentials with suitably chosen densities. It is essential here that

the constant c, by assumption, cannot be 0 or a negative real number. We now define the polarization tensor $M^{j_0}(c)$ of the inhomogeneity B_{j_0} (with aspect ratio c), by

$$M_{kl}^{j_0}(c) = c^{-1} \int_{B_{j_0}} \partial_{y_k} \phi_l \, dy. \tag{4}$$

It is quite easy to see that the tensor $M_{kl}^{j_0}(c)$ is symmetric; since c is a positive real number, it is furthermore positive definite (see [6], [13]).

2. Asymptotic formula for the solution. Consider in this section a homogeneous background medium in all of $\mathbf{R}^3$ with electric permittivity ε^0 and magnetic permeability μ^0, and let ε_α and μ_α be the corresponding dielectric functions in the presence of the small inhomogeneities described above. Let u_α be the solution to the Helmholtz equation

$$\left(\nabla \cdot \frac{1}{\mu_\alpha} \nabla + \omega^2 \varepsilon_\alpha \right) u_\alpha = 0 \quad \text{in} \quad \mathbf{R}^3, \tag{5}$$

with the radiation condition as $r \to \infty$,

$$|\partial_r (u_\alpha - e^{ik\eta \cdot x}) - ik(u_\alpha - e^{ik\eta \cdot x})| = O\left(\frac{1}{r^2} \right), \tag{6}$$

where ω is the frequency, $k^2 = \omega^2 \varepsilon^0 \mu^0$, η is a vector on the unit sphere S^2 in $\mathbf{R}^3$, $\eta \cdot \eta = 1$, and $u_0 = e^{ik\eta \cdot x}$ is an incident plane wave. Note that u_0 satisfies the homogeneous Helmholtz equation

$$\left(\nabla \cdot \frac{1}{\mu^0} \nabla + \omega^2 \varepsilon^0 \right) u_0 = 0 \quad \text{in} \quad \mathbf{R}^3. \tag{7}$$

In this section, we find and prove a formula, asymptotic with respect to the inhomogeneity size α, for u_α in terms of u_0. We begin by defining the outgoing Green function $G(x, y)$ to satisfy

$$\begin{aligned} \left(\Delta_y + k^2 \right) G(x, y) &= -\delta_x(y) \quad \text{in} \quad \mathbf{R}^3, \\ |\partial_r G - ikG| &= O\left(\frac{1}{r^2} \right) \quad \text{as} \quad r \to \infty. \end{aligned} \tag{8}$$

In fact, we know G explicitly:

$$G(x, y) = \frac{e^{ik|x-y|}}{4\pi |x - y|}.$$

Let Ω denote some fixed domain in $\mathbf{R}^3$ that contains the inhomogeneities. Without loss of generality, we can assume that k^2 is not an eigenvalue of $-\Delta$ in Ω corresponding to Dirichlet boundary conditions on $\partial\Omega$. We know that Proposition 1 in [24], which is based on properties of collectively compact operators, guarantees that, for α sufficiently small, the trivial solution is the unique solution to $(\nabla \cdot \frac{1}{\mu_\alpha} \nabla + \omega^2 \varepsilon_\alpha) v_\alpha = 0$ in Ω, with the boundary condition $v_\alpha = 0$ on $\partial\Omega$.

If we consider the equation for u_α in the *exterior* of Ω, multiply G, and integrate by parts, we get that, for $x \in \mathbf{R}^3 \setminus \overline{\Omega}$,

$$u_\alpha(x) = u_0(x) + \int_{\partial\Omega} \partial_{\nu_y} G u_\alpha(y) \, d\sigma_y - \int_{\partial\Omega} G \partial_\nu u_\alpha(y) \, d\sigma_y,$$

where ν is the unit outward normal to $\partial\Omega$. Of course, this equation does not hold up to the boundary of Ω, but if we take the limit as $x \to \partial\Omega$, we get (see, for example, [7] and [16])

$$\frac{1}{2}u_\alpha|_{\partial\Omega} = u_0|_{\partial\Omega} + \int_{\partial\Omega} \partial_{\nu_y} G u_\alpha(y)\, d\sigma_y - \int_{\partial\Omega} G \partial_\nu u_\alpha(y)\, d\sigma_y \tag{9}$$

for $x \in \partial\Omega$. Now define the Dirichlet to Neumann map

$$N_\alpha : H^{1/2}(\partial\Omega) \to H^{-1/2}(\partial\Omega),$$

$$N_\alpha(f) = \partial_\nu v_\alpha,$$

where v_α is the solution to

$$\begin{aligned} \left(\nabla \cdot \frac{1}{\mu_\alpha}\nabla + \omega^2 \varepsilon_\alpha\right) v_\alpha = 0 \quad &\text{in} \quad \Omega, \\ v_\alpha = f \quad &\text{on} \quad \partial\Omega. \end{aligned} \tag{10}$$

Hence

$$N_\alpha(u_\alpha|_{\partial\Omega}) = \partial_\nu u_\alpha|_{\partial\Omega}.$$

Similarly, let

$$N_0 : H^{1/2}(\partial\Omega) \to H^{-1/2}(\partial\Omega)$$

be the Neumann to Dirichlet map for the limiting problem so that

$$N_0(u_0|_{\partial\Omega}) = \partial_\nu u_0|_{\partial\Omega}.$$

We also define the single and double layer potential operators

$$S : H^{-1/2}(\partial\Omega) \to H^{1/2}(\partial\Omega)$$

and

$$D : H^{1/2}(\partial\Omega) \to H^{1/2}(\partial\Omega),$$

where

$$S : g \to \int_{\partial\Omega} G(x,y) g(y)\, d\sigma_y$$

and

$$D : f \to \int_{\partial\Omega} \partial_{\nu_y} G(x,y) f(y)\, d\sigma_y.$$

Using this operator notation, we see that from (9) we have

$$\left(\frac{I}{2} - D + S N_\alpha\right)(u_\alpha|_{\partial\Omega}) = u_0|_{\partial\Omega}.$$

Similarly, u_0 satisfies

$$\left(\frac{I}{2} - D + SN_0\right)(u_0|_{\partial\Omega}) = u_0|_{\partial\Omega}.$$

Define

$$T_\alpha : H^{1/2}(\partial\Omega) \to H^{1/2}(\partial\Omega)$$

by

$$T_\alpha = \frac{I}{2} - D + SN_\alpha, \tag{11}$$

and let

$$T_0 = \frac{I}{2} - D + SN_0. \tag{12}$$

By subtracting the two above equations, we have that

$$T_\alpha(u_\alpha|_{\partial\Omega}) - T_0(u_0|_{\partial\Omega}) = 0,$$

and hence

$$T_\alpha((u_\alpha - u_0)|_{\partial\Omega}) = S(N_0 - N_\alpha)(u_0|_{\partial\Omega}).$$

We will need the following proposition. The reader is referred to the appendix for its proof. In the following proposition and in the remainder of this paper, all asymptotic terms and constants may depend on the separation d_0 of the inhomogeneities.

PROPOSITION 1. *Let T_α be defined by* (11) *and T_0 by* (12). *Then we have the following:*

(a) *T_α converges to T_0 pointwise.*
(b) *$T_\alpha - T_0$ is collectively compact.*
(c) *There exists a constant C that is independent of α and the set of points $\{z_j\}_{j=1}^m$ such that, for any $f \in H^{1/2}(\partial\Omega)$, T_α^{-1} exists and*

$$\|T_\alpha^{-1} f\|_{H^{1/2}(\partial\Omega)} \leq C\|f\|_{H^{1/2}(\partial\Omega)}.$$

(d) *The following asymptotic formula holds:*

$$\begin{aligned}(T_0 - T_\alpha)(u_0|_{\partial\Omega})(x) &= S(N_0 - N_\alpha)(u_0|_{\partial\Omega})(x) \\ &= \alpha^3 \left[\sum_{j=1}^m \left(1 - \frac{\mu^j}{\mu^0}\right) \nabla u_0(z_j) \cdot M^j \left(\frac{\mu^j}{\mu^0}\right) \nabla_y G(x, z_j) \right. \\ &\qquad \left. + k^2 \left(1 - \frac{\varepsilon^j}{\varepsilon^0}\right) u_0(z_j) G(x, z_j)\right] + o(\alpha^3), \end{aligned} \tag{13}$$

where the asymptotic term $o(\alpha^3)$ is independent of $x \in \partial\Omega$ and the set of points $\{z_j\}_{j=1}^m$.

Define the correction

$$u^{(1)}(x) = \sum_{j=1}^m \left(1 - \frac{\mu^j}{\mu^0}\right) \nabla u_0(z_j) \cdot M^j \left(\frac{\mu^j}{\mu^0}\right) \nabla_y G(x, z_j) + k^2 \left(1 - \frac{\varepsilon^j}{\varepsilon^0}\right) u_0(z_j) G(x, z_j) \tag{14}$$

for $x \neq z_j$, $j = 1, \ldots, m$. We have therefore shown that

$$T_\alpha((u_\alpha - u_0)|_{\partial\Omega}) = \alpha^3 u^{(1)}|_{\partial\Omega} + o(\alpha^3) \tag{15}$$

uniformly for $x \in \partial\Omega$. Note that, from the definition of G, $u^{(1)}$ satisfies

$$(\Delta + k^2)u^{(1)} = \sum_{j=1}^{m} \left(1 - \frac{\mu^j}{\mu^0}\right) \nabla u_0(z_j) \cdot M^j \left(\frac{\mu^j}{\mu^0}\right) \nabla \delta_{z_j} + k^2 \left(1 - \frac{\varepsilon^j}{\varepsilon^0}\right) u_0(z_j) \delta_{z_j}, \tag{16}$$

in the sense of distributions, where δ_{z_j} is the Dirac delta function at the point z_j.

LEMMA 1. *Let the correction term $u^{(1)}$ be defined by* (14). *Then we have*

$$T_0(u^{(1)}|_{\partial\Omega}) = u^{(1)}|_{\partial\Omega}.$$

Proof. Multiplying (16) by G, integrating by parts over Ω, and taking the limit as $x \to \partial\Omega$, we get

$$\frac{1}{2} u^{(1)}|_{\partial\Omega} - \int_{\partial\Omega} \partial_{\nu_y} G u^{(1)}(y)\, d\sigma_y + \int_{\partial\Omega} G \partial_\nu u^{(1)}(y)\, d\sigma_y = 0$$

for $x \in \partial\Omega$. Define $v^{(1)}$ as the unique solution to

$$\begin{cases} \Delta v^{(1)} + k^2 v^{(1)} = 0 & \text{in} \quad \Omega, \\ v^{(1)} = u^{(1)} & \text{on} \quad \partial\Omega; \end{cases}$$

that is,

$$\partial_\nu v^{(1)} = N_0(u^{(1)}|_{\partial\Omega}).$$

Green's formula yields, for any $x \in \Omega$ away from the centers of the inhomogeneities,

$$\begin{aligned} \int_{\partial\Omega} G(x,y) \partial_\nu (u^{(1)} - v^{(1)})(y)\, d\sigma_y &= \sum_{j=1}^{m} \left(1 - \frac{\mu^j}{\mu^0}\right) \nabla u_0(z_j) \cdot M^j \left(\frac{\mu^j}{\mu^0}\right) \nabla_y G(x, z_j) \\ &\quad + k^2 \left(1 - \frac{\varepsilon^j}{\varepsilon^0}\right) u_0(z_j) G(x, z_j) - u^{(1)}(x) + v^{(1)}(x) \\ &= v^{(1)}(x). \end{aligned}$$

Hence, for $x \in \partial\Omega$,

$$\int_{\partial\Omega} G(x,y) \partial_\nu (u^{(1)} - v^{(1)})(y)\, d\sigma_y = u^{(1)}(x).$$

Using this, we can rewrite

$$\begin{aligned} \int_{\partial\Omega} G \partial_\nu u^{(1)}(y)\, d\sigma_y &= \int_{\partial\Omega} G N_0(u^{(1)})(y)\, d\sigma_y + \int_{\partial\Omega} G(\partial_\nu u^{(1)}(y) - N_0(u^{(1)})(y))\, d\sigma_y \\ &= \int_{\partial\Omega} G N_0(u^{(1)})(y)\, d\sigma_y + u^{(1)}(x), \end{aligned}$$

from which it follows that

$$\frac{1}{2} u^{(1)}|_{\partial\Omega} - \int_{\partial\Omega} \partial_{\nu_y} G u^{(1)}(y)\, d\sigma_y + \int_{\partial\Omega} G N_0(u^{(1)})(y)\, d\sigma_y = u^{(1)}(x)$$

for $x \in \partial\Omega$. This just says exactly that $T_0(u^{(1)}|_{\partial\Omega}) = u^{(1)}|_{\partial\Omega}$. ∎

LEMMA 2. *The following estimate holds:*

$$\|u_\alpha - u_0 - \alpha^3 u^{(1)}\|_{H^{1/2}(\partial\Omega)} = o(\alpha^3), \tag{17}$$

where the term $o(\alpha^3)$ goes to zero faster than α^3 independent of the set of points $\{z_j\}_{j=1}^m$.

Proof. From (15) it follows that

$$T_\alpha((u_\alpha - u_0 - \alpha^3 u^{(1)})|_{\partial\Omega}) = \alpha^3 u^{(1)}|_{\partial\Omega} - \alpha^3 T_\alpha(u^{(1)}|_{\partial\Omega}) + o(\alpha^3).$$

Lemma 1 yields

$$T_\alpha((u_\alpha - u_0 - \alpha^3 u^{(1)})|_{\partial\Omega}) = \alpha^3 (T_0 - T_\alpha)(u^{(1)}|_{\partial\Omega}) + o(\alpha^3).$$

Therefore, due to the pointwise convergence of T_α to T_0, we obtain

$$T_\alpha((u_\alpha - u_0 - \alpha^3 u^{(1)})|_{\partial\Omega}) = o(\alpha^3),$$

which leads, by using point (c) in Proposition 1, to the desired estimate (17). ∎

From this lemma, we obtain the following theorem.

THEOREM 1. *Let u_α be the solution to* (5)*, and let $M^j(\frac{\mu^j}{\mu^0})$ be the polarization tensors for the shapes B_j defined by* (4)*. Then, for $x \in \mathbf{R}^3 \setminus \overline{\Omega}$ bounded away from $\partial\Omega$, we have the pointwise expansion*

$$\begin{aligned} u_\alpha(x) = {} & e^{ik\eta\cdot x} \\ & + \alpha^3 \sum_{j=1}^m e^{ik\eta\cdot z_j} \left[ik \left(1 - \frac{\mu^j}{\mu^0}\right) \nabla_y G(x, z_j) \cdot M^j \left(\frac{\mu^j}{\mu^0}\right) \eta \right. \\ & \qquad \left. + k^2 \left(1 - \frac{\varepsilon^j}{\varepsilon^0}\right) |B_j| G(x, z_j) \right] \\ & + o(\alpha^3). \end{aligned} \tag{18}$$

Here the remainder term $o(\alpha^3)$ is independent of x and the set of points $\{z_j\}_{j=1}^m$.

Proof. From Lemma 2, it follows that $u_\alpha - u_0$ satisfies in $\mathbf{R}^3 \setminus \overline{\Omega}$

$$\begin{cases} \Delta(u_\alpha - u_0) + k^2(u_\alpha - u_0) = 0 \quad \text{in} \quad \mathbf{R}^3 \setminus \overline{\Omega}, \\ (u_\alpha - u_0) = \alpha^3 u^{(1)} + o(\alpha^3) \quad \text{on} \quad \partial\Omega, \\ |\partial_r(u_\alpha - u_0) - ik(u_\alpha - u_0)| = O(\frac{1}{r^2}). \end{cases}$$

Let $\mathcal{G}$ denote the outgoing Dirichlet Green function that is defined by

$$\begin{cases} \Delta\mathcal{G} + k^2\mathcal{G} = -\delta \quad \text{in} \quad \mathbf{R}^3 \setminus \overline{\Omega}, \\ \mathcal{G} = 0 \quad \text{on} \quad \partial\Omega, \\ |\partial_r\mathcal{G} - ik\mathcal{G}| = O(\frac{1}{r^2}). \end{cases}$$

It is easy to see that $u_\alpha - u_0$ has the following integral representation in $\mathbf{R}^3 \setminus \overline{\Omega}$:

$$(u_\alpha - u_0)(x) = \int_{\partial\Omega} \frac{\partial\mathcal{G}}{\partial\nu_y}(x, y)(u_\alpha - u_0)(y)\, d\sigma(y) \quad \forall\, x \in \mathbf{R}^3 \setminus \overline{\Omega}.$$

Moreover, for any $x \in \mathbf{R}^3 \setminus \overline{\Omega}$ which is bounded away from $\partial\Omega$, we obtain from the asymptotic expansion of the boundary condition in Lemma 2 that

$$(u_\alpha - u_0)(x) = \alpha^3 \int_{\partial\Omega} \frac{\partial \mathcal{G}}{\partial \nu_y}(x,y) u^{(1)}(y)\, d\sigma(y) + o(\alpha^3),$$

where $o(\alpha^3)$ is independent of x and the set of points $\{z_j\}_{j=1}^m$. Since, for any $x \in \mathbf{R}^3 \setminus \overline{\Omega}$ and $z \in \Omega$, we have by standard integration by parts the identities

$$\int_{\partial\Omega} \frac{\partial \mathcal{G}}{\partial \nu}(x,y) G(y,z)\, d\sigma(y) = G(x,z)$$

and

$$\int_{\partial\Omega} \frac{\partial \mathcal{G}}{\partial \nu}(x,y) \nabla_z G(y,z)\, d\sigma(y) = \nabla_z G(x,z),$$

the expression of the correction term $u^{(1)}$ immediately leads to the promised asymptotic expansion. □

We also can obtain the next proposition on the norm convergence of the solutions.

PROPOSITION 2. *There exists a constant C that is independent of α and the set of points $\{z_j\}_{j=1}^m$ such that the following energy estimate holds:*

$$\|u_\alpha - u_0\|_{L^2(\Omega)} + \|\nabla u_\alpha - \nabla u_0\|_{L^2(\Omega)} \le C\alpha^2. \tag{19}$$

Proof. Let $\tilde{u}_\alpha$ be defined as the unique solution to

$$\begin{cases} \Delta \tilde{u}_\alpha + k^2 \tilde{u}_\alpha = 0 & \text{in} \quad \Omega, \\ \tilde{u}_\alpha = u_\alpha & \text{on} \quad \partial\Omega. \end{cases}$$

We have

$$\begin{cases} \Delta(\tilde{u}_\alpha - u_0) + k^2(\tilde{u}_\alpha - u_0) = 0 & \text{in} \quad \Omega, \\ (\tilde{u}_\alpha - u_0) = u_\alpha - u_0 & \text{on} \quad \partial\Omega, \end{cases}$$

which leads to

$$\|\tilde{u}_\alpha - u_0\|_{H^1(\Omega)} \le C \|u_\alpha - u_0\|_{H^{1/2}(\Omega)},$$

where the constant C is independent of α. Using Lemma 2, we get that $\|\tilde{u}_\alpha - u_0\|_{H^1(\Omega)}$ is of order α^3. Now note that the function $(u_\alpha - \tilde{u}_\alpha)$ is in $H_0^1(\Omega)$, and for any $v \in H_0^1(\Omega)$

$$\begin{aligned} \int_\Omega \frac{1}{\mu_\alpha} \nabla(u_\alpha - \tilde{u}_\alpha) \cdot \nabla v - \omega^2 \int_\Omega \varepsilon_\alpha (u_\alpha - \tilde{u}_\alpha) v \quad &= \quad \int_\Omega \frac{1}{\mu_\alpha} \nabla u_\alpha \cdot \nabla v - \omega^2 \int_\Omega \varepsilon_\alpha u_\alpha v \\ &- \quad \int_\Omega \frac{1}{\mu^0} \nabla \tilde{u}_\alpha \cdot \nabla v + \omega^2 \int_\Omega \varepsilon^0 \tilde{u}_\alpha v \\ &+ \quad \sum_{j=1}^m \left(\frac{1}{\mu^0} - \frac{1}{\mu^j} \right) \int_{z_j + \alpha B_j} \nabla \tilde{u}_\alpha \cdot \nabla v \\ &+ \quad k^2 \left(\frac{\varepsilon^j}{\varepsilon^0} - 1 \right) \int_{z_j + \alpha B_j} \tilde{u}_\alpha v. \end{aligned}$$

Next we can bound

$$\left| \int_{z_j + \alpha B_j} \nabla \tilde{u}_\alpha \cdot \nabla v \right| \le \|\nabla \tilde{u}_\alpha\|_{L^2(z_j + \alpha B_j)} \|\nabla v\|_{L^2(\Omega)}$$

and

$$\left| \int_{z_j+\alpha B_j} \tilde{u}_\alpha v \right| \leq \|\tilde{u}_\alpha\|_{L^2(z_j+\alpha B_j)} \|v\|_{L^2(\Omega)}.$$

However, using the triangle inequality,

$$\|\nabla \tilde{u}_\alpha\|_{L^2(z_j+\alpha B_j)} \leq \|\nabla(\tilde{u}_\alpha - u_0)\|_{L^2(\Omega)} + \|\nabla u_0\|_{L^2(z_j+\alpha B_j)},$$

and

$$\|\tilde{u}_\alpha\|_{L^2(z_j+\alpha B_j)} \leq \|(\tilde{u}_\alpha - u_0)\|_{L^2(\Omega)} + \|u_0\|_{L^2(z_j+\alpha B_j)}.$$

Therefore, since

$$\|u_0\|_{H^1(z_j+\alpha B_j)} = O(\alpha^2)$$

and

$$\|(\tilde{u}_\alpha - u_0)\|_{H^1(\Omega)} = O(\alpha^3),$$

we obtain

$$\left| \int_\Omega \frac{1}{\mu_\alpha} \nabla(u_\alpha - \tilde{u}_\alpha) \cdot \nabla v - \omega^2 \int_\Omega \varepsilon_\alpha (u_\alpha - \tilde{u}_\alpha) v \right| \leq C\alpha^2 \|v\|_{H^1(\Omega)}$$

for any $v \in H_0^1(\Omega)$. From Proposition 1 in [24], it then follows that

$$\|(u_\alpha - \tilde{u}_\alpha)\|_{H^1(\Omega)} = O(\alpha^2);$$

hence

$$\|(u_\alpha - u_0)\|_{H^1(\Omega)} \leq \|(u_\alpha - \tilde{u}_\alpha)\|_{H^1(\Omega)} + \|(u_0 - \tilde{u}_\alpha)\|_{H^1(\Omega)} \leq C\alpha^2,$$

exactly as desired. ∎

3. Asymptotic formula for the scattering amplitude. We now use the results derived in the previous section to prove an asymptotic formula for the scattering amplitude. The scattering amplitude, $A_\alpha(\frac{x}{|x|}, \eta, k)$, is defined to be a function which satisfies

$$u_\alpha(x) = e^{ik\eta\cdot x} + A_\alpha\left(\frac{x}{|x|}, \eta, k\right) \frac{e^{ik|x|}}{|x|} + o\left(\frac{1}{|x|}\right) \tag{20}$$

as $|x| \to \infty$. Recall that

$$G(x, z_j) = \frac{e^{ik|x-z_j|}}{4\pi|x-z_j|}.$$

One can show from a simple calculation that, as $|x| \to \infty$,

$$G(x, z_j) = \frac{e^{ik|x|}}{|x|} \frac{e^{-ik\frac{x}{|x|}\cdot z_j}}{4\pi} + o\left(\frac{1}{|x|}\right) \tag{21}$$

and

$$\nabla_y G(x,z_j) = \frac{e^{ik|x|}}{|x|}\frac{ikx}{4\pi|x|}e^{-ik\frac{x}{|x|}\cdot z_j} + o\left(\frac{1}{|x|}\right). \tag{22}$$

The following asymptotic formula for the scattering amplitude holds.

THEOREM 2. *The scattering amplitude*

$$A_\alpha\left(\frac{x}{|x|},\eta,k\right) = \frac{\alpha^3k^2}{4\pi}\sum_{j=1}^{m} e^{ik(\eta-\frac{x}{|x|})\cdot z_j}\left[\left(\frac{\mu^j}{\mu^0}-1\right)\frac{x}{|x|}\cdot M^j\eta - \left(\frac{\varepsilon^j}{\varepsilon^0}-1\right)|B_j|\right] + o(\alpha^3) \tag{23}$$

for any $\frac{x}{|x|}$ *and* $\eta \in S^2$, *where* $o(\alpha^3)$ *is independent of the set of points* $\{z_j\}_{j=1}^m$.

Proof. This follows from (21), (22), and the expansion in Theorem 1.

4. Method for reconstruction of inhomogeneities at a fixed frequency. In this section, we present a linear method to determine the locations and the polarization tensors of the small inhomogeneities from scattering amplitude measurements for a fixed frequency. Based on the asymptotic expansion (23), we reduce the reconstruction of the small dielectric inhomogeneities from the scattering amplitude to the calculation of an inverse Fourier transform. For convenience, we are going to assume that B_j, for $j = 1,\dots,m$, are balls. In this case, the polarization tensors M^j have the following explicit forms (see, for example, [25]):

$$M^j\left(\frac{\mu^j}{\mu^0}\right) = m^j I_3,$$

where I_3 is the 3×3 identity matrix and the scalars m^j are given by

$$m^j = 8\pi|B_j|\frac{\mu^j}{\mu^j+\mu^0}.$$

We assume that we are in possession of the scattering amplitude $A_\alpha(\frac{x_l}{|x_l|},\eta_{l'},k)$ for a collection of pairs $(\frac{x_l}{|x_l|},\eta_{l'})$, where $l = 1,\dots,L$ and $l' = 1,\dots,L'$. Introduce

$$g\left(\frac{x}{|x|},\eta\right) = \sum_{j=1}^{m} e^{ik(\eta-\frac{x}{|x|})\cdot z_j}\left[\left(\frac{\mu^j}{\mu^0}-1\right)m^j\frac{x}{|x|}\cdot\eta - \left(\frac{\varepsilon^j}{\varepsilon^0}-1\right)|B_j|\right], \quad \frac{x}{|x|},\ \eta\in S^2. \tag{24}$$

We first observe that

$$g\left(\frac{x}{|x|},\eta\right) = g\left(-\eta,-\frac{x}{|x|}\right) \quad \forall\ \frac{x}{|x|},\eta\in S^2. \tag{25}$$

Define, for $l = 1,\dots,L$ and $l' = 1,\dots,L'$, the coefficients $a_{l,l'}$ by

$$a_{l,l'} = \frac{4\pi}{k^2\alpha^3}A_\alpha\left(\frac{x_l}{|x_l|},\eta_{l'},k\right).$$

Our reconstruction procedure is divided into three steps.

Step 1. Given that

$$g\left(\frac{x_l}{|x_l|},\eta_{l'}\right) \approx a_{l,l'},$$

we can compute using the fast Fourier transform (FFT) an accurate approximation of $g(\frac{x}{|x|},\eta)$ on $S^2 \times S^2$.

Step 2. Let M denote the following complex variety:

$$M = \{\xi \in C^3,\ \xi \cdot \xi = 1\}.$$

It is easy to see that $g(\frac{x}{|x|},\eta)$ has an analytic continuation to $M \times M$. Let $(Y_{p,q})_{-p\le q\le p,\, p=0,1,\ldots,}$ denote the normalized (in $L^2(S^2)$) spherical harmonics. Denote by $g_{p,q}$ the Fourier coefficients of g:

$$g\left(\frac{x}{|x|},\eta\right) = \sum_{p,q} g_{p,q}\left(\frac{x}{|x|}\right) Y_{p,q}(\eta) \quad \forall\ \frac{x}{|x|},\eta \in S^2. \tag{26}$$

Recall that, from Step 1, we are in fact in possession of an accurate approximation of $g_{p,q}(\frac{x}{|x|})$ on S^2 for $-p \le q \le p$ and $p \le P$. In view of (26), the analytic continuation of the truncated Fourier series

$$\sum_{p,q;\, p\le P} g_{p,q}\left(\frac{x}{|x|}\right) Y_{p,q}(\eta)$$

of $g(\frac{x}{|x|},\eta)$ on $M \times M$ can be obtained by using the standard analytic continuation of the spherical harmonics $(Y_{p,q}(\eta))_{p,q}$ on the complex variety M followed by another analytic continuation of the Fourier expansion in $\frac{x}{|x|}$. We know that the analytic continuation of g from $S^2 \times S^2$ to $M \times M$ is unique.

Step 3. Recall that, given $a_{l,l'}$ for $l = 1,\ldots,L$ and $l' = 1,\ldots,L'$, we have constructed by Steps 1 and 2 an accurate approximation of the function $g(\frac{x}{|x|},\eta)$ that is analytic on $M \times M$ and is such that

$$g\left(\frac{x_l}{|x_l|},\eta_{l'}\right) \approx a_{l,l'} \quad \forall\, l = 1,\ldots,L \text{ and } l' = 1,\ldots,L'.$$

However, for any $\xi \in \mathbf{R}^3$, we know that there exist ξ_1 and ξ_2 in M such that $\xi = k(\xi_1 - \xi_2)$; see, for example, [5] and [20]. Let us now view $(a_{l,l'})$ as a function of $\xi \in \mathbf{R}^3$. We have

$$g(\xi_1,\xi_2) = \sum_{j=1}^{m} e^{-i\xi\cdot z_j}\left[\left(\frac{\mu^j}{\mu^0} - 1\right) m^j \xi_1 \cdot \xi_2 - \left(\frac{\varepsilon^j}{\varepsilon^0} - 1\right)|B_j|\right],$$

and, since

$$\xi_1 \cdot \xi_2 = 1 - \frac{1}{2}k^2|\xi|^2,$$

we can rewrite g as follows:

$$g(\xi_1,\xi_2) = \sum_{j=1}^{m} e^{-i\xi\cdot z_j}\left[\left(\frac{\mu^j}{\mu^0} - 1\right) m^j \left(1 - \frac{1}{2}k^2|\xi|^2\right) - \left(\frac{\varepsilon^j}{\varepsilon^0} - 1\right)|B_j|\right]. \tag{27}$$

Define

$$\tilde{g}(\xi) = g(\xi_1,\xi_2),$$

and note that we are now in possession of an approximation to $\tilde{g}(\xi)$ for any $\xi \in \mathbf{R}^3$. Here we rely on the fact that the analytic continuation is unique.

Recall that $e^{-i\xi\cdot z_j}$ (up to a multiplicative constant) is exactly the Fourier transform of the Dirac function δ_{z_j} (a point mass located at z_j). Multiplication by powers of ξ in Fourier space corresponds to differentiation of the Dirac function. Therefore, using the inverse Fourier transform, we obtain

$$\mathcal{F}^{-1}(\tilde{g}(\xi)) = \sum_{j=1}^{m} L_j(\delta_{z_j}),$$

where L_j are, in view of (27), second order constant coefficient differential operators.

Hence $\tilde{g}(\xi)$ is the inverse Fourier transform of a distribution with its support at the locations of the centers of inhomogeneities z_j. Therefore, we think that a numerical Fourier inversion of a sample of $(\tilde{g}(\xi))$ will efficiently pin down the z_j's. The method of location of the points z_j is then similar to that proposed for the conductivity problem [2] from boundary measurements. The number of data (sampling) points needed for an accurate discrete Fourier inversion of $\tilde{g}(\xi)$ follows from the Shannon theorem [9]. We need (conservatively), of order $(h/\delta)^3$, sampled values of ξ to reconstruct, with resolution δ, a collection of inhomogeneities that lie inside a square of side h. Note, however, that real measurements are taken only in Step 1. It remains to be seen how many such measurements are needed. Once the locations $\{z_j\}_{j=1}^m$ are known, we may calculate $|B_j|$ by solving the appropriate linear system arising from (27). If B_j are general domains, our calculations become more complex, and eventually we have to deal with pseudodifferential operators (independent of the space variable x) applied to the same Dirac functions. Numerical experiments examining the feasibility of this approach will be presented in a forthcoming publication.

Appendix. Proof of Proposition 1. Recall that Ω is some fixed domain in $\mathbf{R}^3$ containing the inhomogeneities. Define $\hat{G}(x,z)$ to be the Dirichlet Green function for Ω,

$$\begin{aligned} &\Delta_z \hat{G}(x,z) + k^2 \hat{G}(x,z) = -\delta_x \quad \text{in} \quad \Omega, \\ &\hat{G}(x,z) = 0 \quad \text{on} \quad \partial\Omega. \end{aligned} \tag{28}$$

Recall that

$$N_\alpha f - N_0 f = \frac{\partial v_\alpha}{\partial \nu} - \frac{\partial v_0}{\partial \nu},$$

where

$$\nabla \cdot \frac{1}{\mu_\alpha} \nabla v_\alpha + \omega^2 \varepsilon_\alpha v_\alpha = 0 \quad \text{in} \quad \Omega, \tag{29}$$

$$v_\alpha = f \quad \text{on} \quad \partial\Omega,$$

and

$$\nabla \cdot \frac{1}{\mu^0} \nabla v_0 + \omega^2 \varepsilon^0 v_0 = 0 \quad \text{in} \quad \Omega, \tag{30}$$

$$v_0 = f \quad \text{on} \quad \partial\Omega.$$

Integration by parts gives

$$\begin{aligned} v_\alpha(x) &= -\int_\Omega v_\alpha(z)(\Delta_z \hat{G} + k^2 \hat{G})\, dz \\ &= \int_{\partial\Omega} f \frac{\partial \hat{G}}{\partial \nu_z}\, d\sigma_z + \int_\Omega \nabla v_\alpha \cdot \nabla_z \hat{G}\, dz - \int_\Omega k^2 v_\alpha \hat{G}\, dz \\ &= v_0(x) + \sum_{j=1}^m \int_{z_j+\alpha B_j} \left[\left(1 - \frac{\mu^0}{\mu^j}\right) \nabla v_\alpha \nabla \hat{G} dz + k^2 \left(1 - \frac{\varepsilon^j}{\varepsilon^0}\right) v_\alpha \hat{G} \right], \end{aligned} \tag{31}$$

since by (29) and (30)

$$\int_\Omega \frac{1}{\mu_\alpha} \nabla v_\alpha \cdot \nabla_z \hat{G}\, dz - \omega^2 \int_\Omega \varepsilon_\alpha v_\alpha \hat{G}\, dz = 0$$

and

$$v_0(x) = \int_{\partial\Omega} f \frac{\partial \hat{G}}{\partial \nu_z}\, d\sigma_z.$$

We first derive a uniform asymptotic expansion for $\frac{\partial v_\alpha}{\partial \nu}$ on $\partial\Omega$. We note that this is similar to Theorem 1 in [24], where the authors derived an expansion when $n = 2$ using the free space Green function. We use the Dirichlet Green function because it is more convenient for our purposes.

LEMMA 3. *Let v_α and v_0 be defined as above. Then we have the pointwise expansion*

$$\begin{aligned} &(N_\alpha - N_0)(f) \\ &\quad = \frac{\partial v_\alpha}{\partial \nu}(x) - \frac{\partial v_0}{\partial \nu}(x) \\ &\quad = \alpha^3 \sum_{j=1}^m \left[\left(\frac{1}{\mu^j} - \frac{1}{\mu^0} \right) \nabla v_0(z_j) \cdot M^j \left(\frac{\mu^j}{\mu^0} \right) \nabla_y \frac{\partial}{\partial \nu_x} \hat{G}(x, z_j) \right. \\ &\qquad \left. + k^2 \left(1 - \frac{\varepsilon^j}{\varepsilon^0}\right) v_0(z_j) \frac{\partial}{\partial \nu_x} \hat{G}(x, z_j) \right] + o(\alpha^3), \end{aligned} \tag{32}$$

where the term $o(\alpha^3)$ is uniform for $x \in \partial\Omega$.

For reasons of brevity, we restrict a significant part of the derivation of the asymptotic expansion (32) to the case of one inhomogeneity ($m = 1$). We suppose that this inhomogeneity is centered at the origin, so it is of the form αB. The general case may be verified by a fairly direct iteration of the argument we will present here, adding one inhomogeneity at a time. We will as usual make the change of variables

$$y = x/\alpha,$$

where

$$\tilde{\Omega} = \frac{1}{\alpha}\Omega$$

and

$$B = \frac{1}{\alpha} B_\alpha.$$

Define the correction $w_\alpha(y)$ to be the unique solution to

$$
\begin{aligned}
&\Delta_y w_\alpha + \alpha^2\omega^2\varepsilon^1\mu^1 w_\alpha = 0 \quad \text{in} \quad B,\\
&\Delta_y w_\alpha + \alpha^2\omega^2\varepsilon^0\mu^0 w_\alpha = 0 \quad \text{in} \quad \tilde{\Omega}\setminus\overline{B},\\
&\frac{1}{\mu^0}\frac{\partial w_\alpha}{\partial \nu_y}^+ - \frac{1}{\mu^1}\frac{\partial w_\alpha}{\partial \nu_y}^- = -\left(\frac{1}{\mu^0}-\frac{1}{\mu^1}\right)\nabla_x v_0(0)\cdot\nu \quad \text{on} \quad \partial B,\\
&w_\alpha = 0 \quad \text{on} \quad \partial\tilde{\Omega},
\end{aligned}
\tag{33}
$$

with

$$w_\alpha \text{ continuous across } \partial B.$$

Also, define $w(y)$, which is independent of α and a sort of limit of w_α, as the unique solution to

$$
\begin{aligned}
&\Delta_y w = 0 \quad \text{in} \quad B,\\
&\Delta_y w = 0 \quad \text{in} \quad \mathbf{R}^n\setminus\overline{B},\\
&\frac{1}{\mu^0}\frac{\partial w}{\partial \nu_y}^+ - \frac{1}{\mu^1}\frac{\partial w}{\partial \nu_y}^- = -\left(\frac{1}{\mu^0}-\frac{1}{\mu^1}\right)\nabla_x v_0(0)\cdot\nu \quad \text{on} \quad \partial B,\\
&\lim_{|y|\to\infty}|w(y)| = 0,
\end{aligned}
\tag{34}
$$

with

$$w \text{ continuous across } \partial B.$$

Recall that $|w(y)| = O(\frac{1}{|y|})$ as $|y|\to+\infty$. We now need to prove two lemmas before we can proceed with the derivation of the asymptotic formula (13).

LEMMA 4. *Let v_α, v_0, and w_α be given by* (29), (30), *and* (33), *respectively. Let*

$$z_\alpha(y) = v_\alpha(\alpha y) - v(\alpha y) - \alpha w_\alpha(y).$$

Then there exists a constant C independent of α such that

$$\|z_\alpha\|_{L^2(\tilde{\Omega})} \le C$$

and

$$\|\nabla_y z_\alpha\|_{L^2(\tilde{\Omega})} \le C\alpha.$$

Proof. Note that $z_\alpha(x/\varepsilon)\in H_0^1(\Omega)$. For any $\phi\in H_0^1(\Omega)$, integration by parts gives us that

$$
\begin{aligned}
&\int_{\tilde{\Omega}}\frac{1}{\mu_\alpha}\nabla_y z_\alpha\cdot\nabla_y\phi(\alpha y)\,dy - \alpha^2\omega^2\int_{\tilde{\Omega}}\varepsilon_\alpha(\alpha y) z_\alpha\phi(\alpha y)\,dy\\
&= \left(\frac{1}{\mu^0}-\frac{1}{\mu^1}\right)\int_{\partial B}\nabla_x(v_0(\alpha y)-v_0(0))\cdot\nu\phi(\alpha y)\,d\sigma_y - \alpha^2\omega^2(\varepsilon^0-\varepsilon^1)\int_B v_0(\alpha y)\phi(\alpha y)\,dy\\
&= \left(\frac{1}{\mu^0}-\frac{1}{\mu^1}\right)\int_B \alpha\Delta_x(v_0(\alpha y)-v_0(0))\phi(\alpha y)\,d\sigma_y - \alpha^2\omega^2(\varepsilon^0-\varepsilon^1)\int_B v_0(\alpha y)\phi(\alpha y)\,dy\\
&\quad + \left(\frac{1}{\mu^0}-\frac{1}{\mu^1}\right)\int_B \nabla_x(v_0(\alpha y)-v_0(0)\cdot\nabla_y\phi(\alpha y)\,d\sigma_y.
\end{aligned}
$$

Next we change variables back to the small domain on the left-hand side and multiply by α to obtain

$$\begin{aligned}&\int_\Omega \frac{1}{\mu_\alpha}\nabla_x z_\alpha \cdot \nabla_x \phi\, dx - \omega^2 \int_\Omega \varepsilon_\alpha z_\alpha \phi\, dx \\ &= \alpha^2 \left(\frac{1}{\mu^0} - \frac{1}{\mu^1}\right) \int_B \Delta_x (v_0(\alpha y) - v_0(0))\phi(\alpha y)\, dy - \alpha^3 \omega^2 (\varepsilon^0 - \varepsilon^1) \int_B v_0(\alpha y)\phi(\alpha y)\, dy \\ &\quad + \alpha \left(\frac{1}{\mu^0} - \frac{1}{\mu^1}\right) \int_B \nabla_x (v_0(\alpha y) - v_0(0)) \cdot \nabla_y \phi(\alpha y)\, dy.\end{aligned}$$

Using a Taylor expansion of v_0, we find that there exists C, depending on v_0 but independent of α, such that

$$\left| \int_\Omega \frac{1}{\mu_\alpha}\nabla_x z_\alpha \cdot \nabla_x \phi\, dx - \omega^2 \int_\Omega \varepsilon_\alpha z_\alpha \phi\, dx \right| \leq C\alpha^3 \|\phi(\alpha y)\|_{L^2(B)} + C\alpha^2 \|\nabla_y \phi(\alpha y)\|_{L^2(B)}.$$

By rescaling, we see that

$$\|\phi(\alpha y)\|_{L^2(B)} = \alpha^{-3/2} \|\phi\|_{L^2(\alpha B)}$$

and

$$\|\nabla_y \phi(\alpha y)\|_{L^2(B)} = \alpha^{-1/2} \|\nabla_x \phi\|_{L^2(\alpha B)}$$

so that

$$\left| \int_\Omega \frac{1}{\mu_\alpha}\nabla_x z_\alpha \cdot \nabla_x \phi\, dx - \omega^2 \int_\Omega \varepsilon_\alpha z_\alpha \phi\, dx \right| \leq C\alpha^{3/2} \|\phi\|_{H^1(\Omega)}.$$

By Proposition 1 of [24], it follows that

$$\|z_\alpha\|_{H^1(\Omega)} \leq C\alpha^{3/2}.$$

The result then follows from another scaling. ∎

LEMMA 5. *Let w_α and w be defined by* (33) *and* (34)*, respectively. Then there exists C independent of α such that*

$$\|\nabla_y (w_\alpha - w)\|_{L^2(\tilde{\Omega})} \leq \frac{C}{\alpha^{1/2}}.$$

Proof. Consider $w_\alpha(x/\alpha) - w(x/\alpha)$. Since w_α and w share the same jump condition on the boundary of the ball, their difference satisfies an equation across this boundary. It is not hard to see that in fact we have

$$\begin{aligned}\nabla_x \cdot \frac{1}{\mu_\alpha}\nabla_x (w_\alpha - w) + \omega^2 \varepsilon_\alpha (w_\alpha - w) &= -\omega^2 \varepsilon_\alpha w \quad \text{in} \quad \Omega, \\ w_\alpha - w &= -w \quad \text{on} \quad \partial\Omega.\end{aligned}$$

By Proposition 1 and Corollary 1 in [24], there exists a constant C independent of α such that

$$\|w_\alpha - w\|_{H^1(\Omega)} \leq C \left(\|w\|_{L^2(\Omega)} + \|w\|_{H^{1/2}(\partial\Omega)} \right).$$

Since Ω is a bounded domain and $w(y)$ is bounded, we clearly have $\|w\|_{L^2(\Omega)}$ bounded. Also, since $w(x/\alpha)$ decays as $\alpha \to 0$, we also have $\|w\|_{H^{1/2}(\partial\Omega)}$ bounded independently of α. Hence

$$\|w_\alpha - w\|_{H^1(\Omega)} \leq C,$$

which by rescaling proves the lemma. □

Now define

$$r_\alpha(y) = v_\alpha(\alpha y) - v_0(\alpha y) - \alpha w - c_\alpha,$$

where the constant c_α is defined so that r_α satisfies

$$\int_{\partial B} r_\alpha \, d\sigma_y = 0.$$

The previous two lemmas together imply that

$$\|\nabla_y r_\alpha\|_{L^2(\tilde{\Omega})} \leq C\alpha^{1/2}.$$

Then, from (31),

$$\begin{aligned}
v_\alpha(x) - v_0(x) &= \int_{\alpha B} \left[\left(1 - \frac{\mu^0}{\mu^1}\right) \nabla_z v_\alpha(z) \nabla_z \hat{G}(x,z) + k^2 \left(1 - \frac{\varepsilon^1}{\varepsilon^0}\right) v_\alpha(z) \hat{G}(x,z) \right] dz \\
&= \alpha^3 \int_B \left[\left(1 - \frac{\mu^0}{\mu^1}\right) \nabla_z v_\alpha(\alpha y) \nabla_z \hat{G}(x, \alpha y) \right. \\
&\quad \left. + k^2 \left(1 - \frac{\varepsilon^1}{\varepsilon^0}\right) v_\alpha(\alpha y) \hat{G}(x, \alpha y) \right] dy \\
&= \alpha^2 \int_B \left(1 - \frac{\mu^0}{\mu^1}\right) \nabla_y (v_0 + \alpha w) \nabla_z \hat{G}(x, \alpha y) \\
&\quad + k^2 \alpha^3 \int_B \left(1 - \frac{\varepsilon^1}{\varepsilon^0}\right) v_\alpha(\alpha y) \hat{G}(x, \alpha y) \, dy \\
&\quad + \alpha^2 \int_B \left(1 - \frac{\mu^0}{\mu^1}\right) \nabla_y (r_\alpha) \nabla_z \hat{G}(x, \alpha y) \, dy. \qquad (35)
\end{aligned}$$

By expanding $\hat{G}$ in a Taylor series and using the above estimate for r_α, we have that

$$\int_B \nabla_y r_\alpha \cdot \nabla_x \hat{G}(x, \alpha y) \, dy = \int_B \nabla_y r_\alpha \cdot \nabla_x \hat{G}(x, 0) \, dy + O(\alpha^{3/2}), \qquad (36)$$

and since we have chosen r_α to have integral zero around the boundary of B, the first term on the right-hand side above is zero by integration by parts. Hence

$$\int_B \nabla_y r_\alpha \cdot \nabla_x \hat{G}(x, \alpha y) \, dy = O(\alpha^{3/2}). \qquad (37)$$

Inserting this into (35), we have shown that

$$\begin{aligned}
v_\alpha(x) - v_0(x) &= \alpha^2 \int_B \left(1 - \frac{\mu^0}{\mu^1}\right) \nabla_y (v_0 + \alpha w) \nabla_z \hat{G}(x, \alpha y) \\
&\quad + \alpha^3 k^2 \int_B \left(1 - \frac{\varepsilon^1}{\varepsilon^0}\right) v_\alpha(\alpha y) \hat{G}(x, \alpha y) \, dy + o(\alpha^3). \qquad (38)
\end{aligned}$$

From this expression, we now derive the formulae with the polarization tensor:

$$\begin{aligned} v_\alpha(x) - v_0(x) &= \alpha^3 \left(1 - \frac{\mu^0}{\mu^1}\right) \left[\int_B \nabla_x v_0(\alpha y) \cdot \nabla_z \hat{G}(x, \alpha y)\, dy \right. \\ &\quad \left. + \int_B \nabla_y w \cdot \nabla_z \hat{G}(x, \alpha y)\, dy\right] \\ &\quad + k^2 \alpha^3 \int_B \left(1 - \frac{\varepsilon^1}{\varepsilon^0}\right) v_\alpha(\alpha y) \hat{G}(x, \alpha y)\, dy + o(\alpha^3) \qquad (39) \\ &= \alpha^3 \left(1 - \frac{\mu^0}{\mu^1}\right) |B| \nabla_x v_0(0) \cdot \nabla_z \hat{G}(x, 0) \\ &\quad + \alpha^3 \left(1 - \frac{\mu^0}{\mu^1}\right) \int_B \nabla_y w \cdot \nabla_z \hat{G}(x, 0)\, dy \qquad (40) \\ &\quad + k^2 \alpha^3 \left(1 - \frac{\varepsilon^1}{\varepsilon^0}\right) |B| v_0(0)\, \hat{G}(x, 0) + o(\alpha^3) \qquad (41) \end{aligned}$$

by Taylor expansions for v_0 and $\hat{G}$. Note that

$$\int_B \nabla_y w\, dy = \int_{\partial B} \frac{\partial w^-}{\partial \nu_y} y\, d\sigma_y$$

and

$$\psi = w + \nabla_x v_0(0) \cdot y = \frac{\partial v_0}{\partial x_l}(0) \phi_l,$$

where the ϕ_l are defined by (4). Hence

$$|B| \nabla_x v_0(0) + \int_B \nabla_y w\, dy = \int_B \nabla_y \psi\, dy,$$

from which we may rewrite (41) as

$$\begin{aligned} v_\alpha(x) - v_0(x) &= \alpha^3 \left(\frac{1}{\mu^1} - \frac{1}{\mu^0}\right) \nabla u_0(0) \cdot M\left(\frac{\mu^1}{\mu^0}\right) \nabla_z \hat{G}(x, 0) \\ &\quad + k^2 \left(1 - \frac{\varepsilon^1}{\varepsilon^0}\right) u_0(0) \hat{G}(x, 0) + o(\alpha^3) \qquad (42) \end{aligned}$$

for M defined by (4). By standard elliptic regularity, we obtain (32), where the term $o(\alpha^3)$ is uniform for $x \in \partial\Omega$.

We are now ready to prove Proposition 1. Integration by parts yields

$$\begin{aligned} &\int_{\partial\Omega} G(x, y) \frac{\partial}{\partial \nu_y} (\nabla_z \hat{G}(y, 0))\, d\sigma_y = \nabla_z G(x, 0) \text{ and} \\ &\int_{\partial\Omega} G(x, y) \frac{\partial}{\partial \nu_y} (\hat{G}(y, 0))\, d\sigma_y = G(x, 0). \qquad (43) \end{aligned}$$

By applying the operator S to (32) and using (43), we arrive at the promised asymptotic expansion (13), which, along with the boundedness of the operator S, implies that T_α converges to T_0 pointwise, which is the claim in point (a). Furthermore,

since the points z_j are away from the boundary $\partial\Omega$, it follows from (13) that the family of operators $T_\alpha - T_0$ is collectively compact, and so point (b) holds. Rewriting $T_\alpha = T_0 + (T_\alpha - T_0)$ and recalling that the operator T_0 is invertible, it follows immediately from [4] that T_α^{-1} is well defined, and point (c) in Proposition 1 holds.

Acknowledgment. The authors express their thanks to M. Vogelius for various beneficial discussions.

ON k-MONOTONE APPROXIMATION BY FREE KNOT SPLINES*

KIRILL KOPOTUN† AND ALEXEI SHADRIN‡

Abstract. Let $\mathbb{S}_{N,r}$ be the (nonlinear) space of free knot splines of degree $r-1$ with at most N pieces in $[a,b]$, and let $\mathcal{M}^k$ be the class of all k-monotone functions on (a,b), i.e., those functions f for which the kth divided difference $[x_0,\dots,x_k]f$ is nonnegative for all choices of $(k+1)$ distinct points $x_0,\dots,x_k$ in (a,b).

In this paper, we solve the problem of *shape preserving* approximation of k-monotone functions by splines from $\mathbb{S}_{N,r}$ in the $\mathbb{L}_p$-metric, i.e., by splines which are constrained to be k-monotone as well. Namely, we prove that the order of such approximation is essentially the same as that by the nonconstrained splines. Precisely, it is shown that, for every $k,r,N\in\mathbb{N}$, $r\ge k$, and any $0<p\le\infty$, there exist constants $c_0=c_0(r,k)$ and $c_1=c_1(r,k,p)$ such that

$$\operatorname{dist}(f,\mathbb{S}_{c_0N,r}\cap M^k)_p\le c_1\operatorname{dist}(f,\mathbb{S}_{N,r})_p\quad\forall f\in M^k.$$

This extends to all $k\in\mathbb{N}$ results obtained earlier by Leviatan and Shadrin and by Petrov for $k\le 3$.

1. Introduction and main results.

In this paper, we solve the problem of *shape preserving* approximation of k-monotone functions by splines with free knots in the $\mathbb{L}_p$-metric, i.e., by splines which are constrained to be k-monotone as well. Namely, we prove that the order of such approximation is essentially the same as that for the nonconstrained splines, thus confirming expectations of some standing.

Given $k\in\mathbb{Z}_+$ and an interval $I=(a,b)$, a function $f:I\mapsto\mathbb{R}$ is said to be k-monotone on I if its kth divided differences $[x_0,\dots,x_k]f$ are nonnegative for all choices of $(k+1)$ distinct points $x_0,\dots,x_k$ in I. We denote the class of all such functions by $\mathcal{M}^k:=\mathcal{M}^k(I)$. Thus $f\in\mathcal{M}^0$ is nonnegative, $f\in\mathcal{M}^1$ is nondecreasing, and $f\in\mathcal{M}^2$ is a convex function. If $f\in\mathbb{C}^k(I)$, then $f\in\mathcal{M}^k$ if and only if $f^{(k)}\ge 0$ on I.

We would like to emphasize that functions from $\mathcal{M}^k$ are not assumed to be defined at the endpoints of the interval (a,b) and hence have to be neither bounded nor integrable on (a,b). For example, if $f(x)=(-1)^kx^{-1-1/p}$, then $f\in\mathcal{M}^k(0,1)$ for $k\in\mathbb{N}$, but $f\notin\mathbb{L}_p(0,1)$, $0<p\le\infty$. (Throughout the paper, $\mathbb{L}_\infty(I)$ denotes the space of all measurable essentially bounded functions equipped with the norm $\|f\|_{\mathbb{L}_\infty(I)}:=\operatorname{ess\,sup}_I|f|$.)

Hence we now define $\mathcal{M}^k_p:=\mathcal{M}^k\cap\mathbb{L}_p$ and also remark that the functions from the cone $\mathcal{M}^k$ are sometimes referred to as "k-convex."

Let $f\in\mathcal{M}^k_p$ and $\mathcal{U}$ be a subset of $\mathbb{L}_p$. The best (nonconstrained) approximation of f from $\mathcal{U}$ is defined by

$$E(f,\mathcal{U})_p:=\inf_{u\in\mathcal{U}}\|f-u\|_p.$$

In contrast, in k-monotone approximation, one is interested in the value

$$E^{(k)}(f,\mathcal{U})_p := \inf_{u\in\mathcal{U}\cap\mathcal{M}^k} \|f-u\|_p.$$

That is, approximants are assumed to preserve the k-monotone shape of f. Clearly, the shape preserving approximation is more restrictive; hence $E^{(k)}(f,\mathcal{U})_p \ge E(f,\mathcal{U})_p$ for all $f\in\mathcal{M}^k$ and $\mathcal{U}\subset\mathbb{L}_p$. Is it much worse? Lorentz and Zeller [10], [11] proved that, for $\mathcal{U}=\Pi_n$, the space of all algebraic polynomials of order n, any $k\in\mathbb{N}$, and any constant $c_0\in\mathbb{N}$, there exists a function $f\in\mathcal{M}^k_p$ such that

$$\frac{E^{(k)}(f,\Pi_{c_0 n})_p}{E(f,\Pi_n)_p}\to\infty \quad \text{as} \quad n\to\infty. \tag{1.1}$$

(The same estimate is true for a sequence of any reasonable linear subspaces $\mathcal{U}_n$ instead of Π_n.) On the other hand, monotone and convex polynomial approximations allow Jackson-type estimates, for example,

$$E^{(k)}(f,\Pi_n)_\infty \le c_k\omega_{k+1}(f,\tfrac{1}{n})_\infty, \quad k=1,2,$$

but they have essential restrictions (as well as gaps) in comparison with the nonconstrained estimates.

Splines with free knots, $s\in\mathcal{S}_{N,r}$, are piecewise polynomials of order r (degree $r-1$), where only the number of pieces, N at most, not their position, is prescribed. (Note that we do not make any assumptions about the smoothness of functions in $\mathcal{S}_{N,r}$.) They are a classical tool of *nonlinear* approximation (along with the rational functions). As that, they achieve a better rate of approximation compared with the linear methods. The simplest example (see, e.g., [4, p. 365]) is that

$$E(f,\mathcal{S}_{N,1})_\infty \le \frac{K}{2N} \quad\Leftrightarrow\quad \operatorname{Var}_{[0,1]}(f)\le K,$$

whereas, for $\mathbb{L}_\infty$-approximation by piecewise constants with N *equidistant* knots, the rate $\mathcal{O}(N^{-1})$ is attained only for $\mathbb{W}^1_\infty$, roughly the class of continuously differentiable functions, which is much narrower than the class of functions of bounded variation.

It was DeVore who had much advocated the studies of the nonlinear methods in k-monotone approximation. Set

$$E_{N,r}(f)_p := E(f,\mathcal{S}_{N,r})_p, \quad E^{(k)}_{N,r}(f)_p := E^{(k)}(f,\mathcal{S}_{N,r})_p.$$

Notice that, since $\mathcal{M}^k(0,1)\subset\mathbb{C}^{k-2}(0,1)$ (see Lemma 3.1), the set $\mathcal{S}_{N,r}\cap\mathcal{M}^k$ contains functions other than k-monotone polynomials of order r only if $r\ge k$. In 1995, Leviatan and Shadrin [9] and Petrov [14] independently proved that, for $k=1,2$, $r\ge k$, and $0<p\le\infty$, there exists a constant $c_0=\mathcal{O}(r)$ such that, for any $f\in\mathcal{M}^k_p$, $k=1,2$,

$$E^{(k)}_{c_0 N,r}(f)_p \le E_{N,r}(f)_p. \tag{1.2}$$

This result showed that the order of monotone and convex approximation by free knot splines is essentially the same as that in the nonconstrained case, which, in view of (1.1), is a striking contrast to the linear approximation methods. Naturally, one would expect that the situation is similar for $k\ge 3$. However, the technique used in [9], [14] was based on some explicit constructions and some properties of monotone

and convex functions which have no straightforward analogues for general k. (Say, for $k = 1, 2$, the maximum of two k-monotone functions is a k-monotone function, while this is no longer true for larger k.) Petrov [15] has managed to adopt this technique for $k = 3$ and $p = \infty$, obtaining an analogue of (1.2), but it became clear that, for general $k \in \mathbb{N}$, new ideas are required.

Here, we prove the following general result.

THEOREM 1.1. *Let $k, r, N \in \mathbb{N}$, $r \geq k$, and $0 < p \leq \infty$. Then there exist constants $c_0 \leq C(k)\max(1, r-k)$ and $c_1 = c_1(r, k, p)$ such that, for all $f \in \mathcal{M}_p^k$,*

$$E^{(k)}_{c_0 N, r}(f)_p \leq c_1 E_{N,r}(f)_p. \tag{1.3}$$

Using [9, Lemma 3], the following result on k-monotone approximation by smooth splines is an immediate corollary of Theorem 1.1.

COROLLARY 1.2. *Let $k, r, N \in \mathbb{N}$, $r \geq k$, and $0 < p \leq \infty$, and denote $\widetilde{E}^{(k)}_{N,r}(f)_p := E^{(k)}(f, \mathcal{S}_{N,r} \cap \mathbb{C}^{(r-2)})_p$. Then there exist constants $c_0 \leq C(k)\max(1, r-k)$ and $c_1 = c_1(r, k, p)$ such that, for all $f \in \mathcal{M}_p^k$,*

$$\widetilde{E}^{(k)}_{c_0 N, r}(f)_p \leq c_1 E_{N,r}(f)_p.$$

For $k = 1$ and 2, Theorem 1.1 is an immediate consequence of (1.2). Because functions in $\mathcal{M}^1(a, b)$ (unlike those in $\mathcal{M}^k(a, b)$ with $k \geq 2$) do not have to be continuous everywhere on (a, b), the case $k = 1$ is somewhat different from $k \geq 2$ (though constructions are much simpler, and some auxiliary statements become trivial if one lets k be equal to 1). Thus, in order to make this paper more readable, we concentrate below only on the more difficult case for $k \geq 2$. At the same time, we mention that some of the statements are valid or can be modified to become valid for $k = 1$ as well.

Now, all direct results for the best (unconstrained) free knot spline approximation are being readily extended for the k-monotone case.

COROLLARY 1.3. *Let $k, r, N \in \mathbb{N}$, $r \geq k$, and let $f \in \mathcal{M}_\infty^k$ be such that $f^{(r-1)}$ is of bounded variation on $[0, 1]$. Then*

$$E^{(k)}_{N,r}(f)_\infty \leq c(r, k) N^{-r} \operatorname{Var}_{[0,1]}(f^{(r-1)}).$$

This corollary is an immediate consequence of Theorem 1.1 and [4, Theorem 12.4.5]. It is related to an earlier result of Hu [5] which was actually the first result in k-monotone approximation by free knot splines: *For $f \in \mathbb{W}_1^r \cap \mathcal{M}_\infty^k$, the order of k-monotone approximation by $S_{N,r}$ in $\mathbb{L}_\infty$ is $\mathcal{O}(N^{-r})$.*

The following corollary follows from Petrushev's estimate of (unconstrained) free knot spline approximation (see [16], [17, Theorem 7.3], and [4, Theorem 12.8.2]).

COROLLARY 1.4. *Let $k, r, N \in \mathbb{N}$, $r \geq k$, $0 < p < \infty$, and $0 < \alpha < r$. Then, if $f \in \mathcal{M}_p^k \cap B^\alpha$,*

$$E^{(k)}_{N,r}(f)_p \leq c(\alpha, p, r) N^{-\alpha} |f|_{B^\alpha},$$

where $B^\alpha := B^\alpha_\gamma(L_\gamma)$, $1/\gamma = \alpha + 1/p$, denotes the Besov space with the seminorm $|f|_{B^\alpha}$ defined by

$$|f|_{B^\alpha} = \left(\int_0^\infty t^{-\alpha\gamma - 1} \omega_r(f, t)_\gamma^\gamma \, dt \right)^{1/\gamma}.$$

Let us comment on the constants c_0, c_1 involved in (1.3), namely, on the question of whether it is possible to have any (or both) of them equal to 1.

Leviatan and Shadrin [9] showed that, in order to retain the same degree of approximation for the k-monotone free knot splines approximation as for the best one, the increase of the knot number is unavoidable if $r \geq k+2$. Precisely, *for any* $r \geq k+2$, $N \in \mathbb{N}$, $0 < p \leq \infty$, *any* $c > 0$, *and* $c_* = 2\lfloor \frac{r-k}{2} \rfloor$, *there exists a function* $f \in \mathcal{M}^k_\infty$ *such that*

$$E^{(k)}_{c_* N,r}(f)_p > cE_{N,r}(f)_p, \quad r \geq k+2.$$

Thus the question about whether or not it is necessary to increase the number of knots remains open only for $r = k$ and $k+1$.

On the other hand, for $r = k$ and $p = \infty$, a part of a theorem by Johnson (see Braess [2, Theorem VIII.3.4, p. 238]) is that *for any* k, *the best free knot spline approximant of order* k *to a* k*-monotone function in the* $\mathbb{L}_\infty$*-norm is* k*-monotone itself*; i.e., in this case, $c_0 = c_1 = 1$, $r = k$, and, for any $f \in \mathcal{M}^k_\infty$,

$$E^{(k)}_{N,k}(f)_\infty = E_{N,k}(f)_\infty. \tag{1.4}$$

It would be interesting to find the exact order of $c_0(r,k)$ as a function of r and k. Estimates (1.2) and (1.4) also suggest another question—namely, whether the value $c_1 = 1$ in (1.3) can be attained with some $c_0' = c_0'(r,k)$.

Notation. We let $I = (a,b)$ if not stated otherwise and set $\mathbb{L}_p := \mathbb{L}_p(I)$, $\|\cdot\|_p := \|\cdot\|_{\mathbb{L}_p(I)}$, $\mathcal{S}_{N,k} := \mathcal{S}_{N,k}(I)$, etc.; i.e., the interval I is omitted if there is no risk of confusion.

Further, $f^{(i)}(x+)$ and $f^{(i)}(x-)$ denote the right and the left ith derivatives of f at x, respectively.

$c_{p,r,k}$ and $c(p,r,k)$ stand for a constant which depends only on the parameters given (p, r, and k in this case), where, for $0 < p \leq \infty$, dependence on p means dependence on $\min(1,p)$.

The "prime" notation k' is going to be reserved for $\lfloor k/2 \rfloor + 1$ throughout this paper:

$$k' := \lfloor k/2 \rfloor + 1.$$

For $f \in \mathbb{L}_p(a,b)$ and a set $\mathcal{U} \subset \mathbb{L}_p(a,b)$, we define

$$\mathcal{P}_\mathcal{U}(f)_p := \mathcal{P}_\mathcal{U}(f)_{\mathbb{L}_p(a,b)} := \{u \in \mathcal{U} : \ \|f-u\|_p = E(f,\mathcal{U})_p\}.$$

In other words, $\mathcal{P}_\mathcal{U}(f)_p$ is the set of all best $\mathbb{L}_p$-approximants to f from $\mathcal{U}$ on (a,b).

2. Outline of the proof. The general direction of the proof is the same as it was for $k = 1, 2$: given a k-monotone function f, one takes $\sigma \in \mathcal{P}_{S_{N,r}}(f)_p$, a best free knot spline approximant to f (which is not necessarily k-monotone), and puts some corrections into it trying to convert it into a k-monotone spline preserving the approximation order. For $k = 1$ and 2, these corrections were done by explicit constructions which, unfortunately, have no straightforward generalizations for $k \geq 3$, and so our basic idea came from the following general considerations.

There is another notion of k-monotone approximation in which a function f which is not in $\mathcal{M}^k$ is approximated by elements from the entire $\mathcal{M}^k$. ($\mathcal{M}^k$ is a convex cone.) There is an extended literature on this subject, where one studies existence

and uniqueness of best k-monotone approximant of this type, its characterization, and its structural properties; see, e.g., [19] and the references therein. When can one have a need to approximate an arbitrary function by a k-monotone one? The only situation we can think of is the necessity to correct the data which must be k-monotone by some a priori assumptions. This is exactly the case of shape preserving approximation, and this is how we correct σ.

Given $f \in \mathcal{M}^k$, we take $\sigma \in \mathcal{P}_{\mathcal{S}_{N,r}}(f)_p$, a best free knot spline approximant to f, and correct σ by $\mathfrak{f}_* \in \mathcal{P}_{\mathcal{M}^k}(\sigma)_p$, a best approximant to σ from $\mathcal{M}^k$.

Here are two observations concerning this idea.

(1) *Approximation property of* $\mathfrak{f}_*$. The function f belongs to $\mathcal{M}^k$, but $\mathfrak{f}_*$ is a best approximant to σ from $\mathcal{M}^k$; hence

$$\|\sigma - \mathfrak{f}_*\|_p \le \|\sigma - f\|_p.$$

Therefore,

$$c_p\|f - \mathfrak{f}_*\|_p \le \|f - \sigma\|_p + \|\sigma - \mathfrak{f}_*\|_p \le 2\|f - \sigma\|_p;$$

i.e., $\mathfrak{f}_*$ approximates f as well as σ.

(2) *Spline structure of* $\mathfrak{f}_*$. A result from the theory of approximation by elements of $\mathcal{M}^k$ reads that (in the "piecewise sense") either $\mathfrak{f}_*$ is identical with σ (which is a spline of order r) or it is a spline of order k (because the functions $g(x) = \sum_\alpha c_\alpha(x - x_\alpha)_+^{k-1}$, $c_\alpha > 0$, are the boundary points of the cone $\mathcal{M}^k$). Thus $\mathfrak{f}_*$ is a spline of order r. If $\mathfrak{f}_*$ had $\mathcal{O}(N)$ knots, then we could stop at this point. The problem is that it may have too many knots (infinitely many, in fact).

The paper is organized as follows.

(1) First, to ease the exposition, we switch to a local version of the idea described above and correct separately each polynomial part of σ by its best approximation $\mathfrak{f}_*$ from $\mathcal{M}^k[f]$, a subclass of k-monotone functions defined locally (see section 3 for precise definition of $\mathcal{M}^k[f]$).

(2) In section 3, we cite some known results concerning existence and structure of the elements $\mathfrak{f}_* \in \mathcal{P}_{\mathcal{M}^k[f]}(\sigma)_p$. As mentioned earlier, $\mathfrak{f}_*$ is a spline of order r, but it may have too many knots to be in $\mathcal{S}_{cN,r}$, in which case we modify it into an appropriate spline s.

(3) Properties of s are formulated as Proposition 4.2 in section 4, where we use them to prove Theorem 1.1.

(4) The proof of Proposition 4.2 takes the rest of the paper. In sections 5–7, we blend $\mathfrak{f}_*$ with the polynomial parts of σ using some results from the theory of moments and consider some general aspects of this procedure. In section 8, we prepare to show that the blending spline s approximates f as well as $\mathfrak{f}_*$, and the final section 9 joins all the parts of the proof together.

Remark 2.1. The number of knots of $\mathfrak{f}_* \in \mathcal{P}_{\mathcal{M}^k[f]}(\sigma)_p$ is approximately the same as the number of distinct zeros of $\sigma - \mathfrak{f}_*$ (see Lemma 3.8). In our proofs, we assume that this number may be arbitrarily large. However, we conjecture that this is not the case; i.e., a best k-monotone approximant to a piecewise polynomial σ (and perhaps to any piecewise k-monotone function) with M pieces has only $\mathcal{O}(M)$ points of intersection with σ. If this is indeed the case, then there is no need for the considerations given in sections 5–9. This conjecture is true for $k = 1, 2$ as one can easily check, and our method gives a simpler proof for these cases than in [9] and [14]. For $k \ge 3$, the problem is open.

Remark 2.2. Actually, the correction of σ made explicitly for $k = 1, 2$ in [9] and [14] is exactly the best k-monotone approximation of σ from $\mathcal{M}^k[f]$ under the additional restriction that this is also a one-sided approximation. This restriction provides the constant $c_1 = 1$ on the right-hand side of (1.2). For $k \geq 3$, we cannot pose such a restriction; hence $c_1 > 1$ in (1.3).

3. Classes $\mathcal{M}^k[f]$ and their properties. The following lemma lists some basic properties of k-monotone functions for $k \geq 2$.

LEMMA 3.1. *The following statements are equivalent for* $k \geq 2$:

(0) $f \in \mathcal{M}^k(0,1)$.

(1) $f^{(k-2)}$ *exists and is convex on* $(0,1)$.

(2) $f^{(k-2)}$ *is absolutely continuous on any closed subinterval of* $(0,1)$ *and has left and right derivatives,* $f^{(k-1)}(\cdot-)$ *and* $f^{(k-1)}(\cdot+)$*, which are, respectively, left- and right-continuous and nondecreasing on* $(0,1)$.

(3) *For each closed subinterval* $[a,b] \subset (0,1)$*, there is a polynomial* $p \in \Pi_k$ *and a bounded nondecreasing function* μ *such that*

$$f(x) = p(x) + \frac{1}{k!}\int_a^b k(x-t)_+^{k-1}\,d\mu(t), \quad x \in [a,b].$$

Proof. See Bullen [3, Theorem 7, Corollary 8]. See also [13], [18] for various properties of k-monotone functions (called "k-convex" there) and their applications. ∎

Lemma 3.1(2) allows us to introduce the following classes of function.

By $\mathcal{M}^k_{a+} := \mathcal{M}^k_{a+}(a,b)$ and $\mathcal{M}^k_{b-} := \mathcal{M}^k_{b-}(a,b)$ we denote the subclasses of those functions $f \in \mathcal{M}^k(a,b)$ for which the values $\{f^{(i)}(a+)\}_{i=0}^{k-1}$ and $\{f^{(i)}(b-)\}_{i=0}^{k-1}$, respectively, are finite, and we set $\mathcal{M}^k_* := \mathcal{M}^k_*(a,b) := \mathcal{M}^k_{a+} \cap \mathcal{M}^k_{b-}$.

For $f \in \mathcal{M}^k_{a+}$ and $g \in \mathcal{M}^k_{b-}$, we define

$$\mathcal{M}^k_{a+}[f] := \{h \in \mathcal{M}^k \mid\ h^{(i)}(a+) = f^{(i)}(a+),\ i = 0,\dots,k-2;\ h^{(k-1)}(a+) \geq f^{(k-1)}(a+)\},$$
$$\mathcal{M}^k_{b-}[g] := \{h \in \mathcal{M}^k \mid\ h^{(i)}(b-) = g^{(i)}(b-),\ i = 0,\dots,k-2;\ h^{(k-1)}(b-) \leq g^{(k-1)}(b-)\}.$$

Finally, let

$$\mathcal{M}^k[f,g] = \mathcal{M}^k_{a+}[f] \cap \mathcal{M}^k_{b-}[g],$$

and, for $f \in \mathcal{M}^k_*$,

$$\mathcal{M}^k[f] = \mathcal{M}^k[f,f].$$

Note that $\mathcal{M}^k[f]$ is always nonempty (it contains f), while $\mathcal{M}^k[f,g]$ can be the empty set. In section 7, we give a sufficient condition on f and g which guarantees that there is a function h from $\mathcal{M}^k[f,g]$.

LEMMA 3.2. *Let* $f, g \in \mathcal{M}^k(0,1)$*, and let* $[a,b] \subset (0,1)$*. Then* $f, g \in \mathcal{M}^k_*(a,b)$*, and, for any* $h \in \mathcal{M}^k[f,g](a,b)$ *(if it exists), the function*

$$\widetilde{h}(x) := \begin{cases} f(x), & x \in (0,a], \\ h(x), & x \in (a,b), \\ g(x), & x \in [b,1), \end{cases}$$

belongs to $\mathcal{M}^k(0,1)$.

Proof. The proof is an immediate consequence of Lemma 3.1(2). ∎

We will use Lemma 3.2 without further reference to build k-monotone functions from k-monotone pieces. For example, if $f \in \mathcal{M}^k_*(0,1)$, $\cup I_\ell = (0,1)$ with $I_\ell \cap I_{\ell'} = \emptyset$ if $\ell \neq \ell'$, and $h_\ell \in \mathcal{M}^k[f](I_\ell)$, then the function h, defined as $h := h_\ell$ on I_ℓ, belongs to $\mathcal{M}^k[f](0,1)$.

Now we consider some properties of approximation from $\mathcal{M}^k[f]$.

LEMMA 3.3. *Let $k \geq 2$, $0 < p \leq \infty$, and $f \in \mathcal{M}^k_*(a,b)$. Then, for any $g \in \mathbb{L}_p$, an element of its best $\mathbb{L}_p$-approximation from $\mathcal{M}^k[f]$ exists; i.e., the set $\mathcal{P}_{\mathcal{M}^k[f]}(g)_p$ is not empty.*

Proof. The proof is based on arguments similar to those used by Zwick [20, Theorem 4] for the case $p = \infty$. We give it here for completeness. Set

$$\alpha_i := f^{(i)}(a+) \quad \text{and} \quad \beta_i := f^{(i)}(b-), \quad i = 0, \dots, k-1,$$

and consider a sequence $(f_j) \subset \mathcal{M}^k[f]$ such that, for $j \in \mathbb{N}$,

$$\|f_j - g\|_p^p \leq E(g, \mathcal{M}^k[f])_p^p + 1/j \quad \text{if} \quad 0 < p < 1$$

and

$$\|f_j - g\|_p \leq E(g, \mathcal{M}^k[f])_p + 1/j \quad \text{if} \quad 1 \leq p \leq \infty.$$

Since $f_j^{(k-2)}(x) = \alpha_{k-2} + \int_a^x f_j^{(k-1)}(t)\,dt$ and $\|f_j^{(k-1)}\|_\infty \leq \max\{|\alpha_{k-1}|, |\beta_{k-1}|\}$, we conclude that $(f_j^{(k-2)})$ is uniformly bounded and equicontinuous on $[a,b]$. Therefore, there exists a subsequence $(f_{j_s}^{(k-2)})$ which converges to a function h_* uniformly on $[a,b]$, and this h_* is necessarily convex and satisfies $h_*'(a+) \geq \alpha_{k-1}$ and $h_*'(b-) \leq \beta_{k-1}$. Now, the function $\mathfrak{f}_*$ such that $\mathfrak{f}_* := h_*$, if $k = 2$, and

$$\mathfrak{f}_*(x) := \sum_{i=0}^{k-3} \frac{\alpha_i}{i!}(x-a)^i + \frac{1}{(k-3)!}\int_a^b (x-t)_+^{k-3} h_*(t)\,dt, \quad k \geq 3,$$

is in $\mathcal{M}^k[f]$ and satisfies $\|g - \mathfrak{f}_*\|_p = E(g, \mathcal{M}^k[f])_p$, i.e., $\mathfrak{f}_* \in \mathcal{P}_{\mathcal{M}^k[f]}(g)_p$. ∎

LEMMA 3.4 (Zwick [21]). *Let $k \in \mathbb{N}$ and $f \in \mathcal{M}^k_*(a,b)$. Then there exist two splines $z_\nu = z_\nu(f,[a,b])$, $\nu = 1,2$, such that*

$$z_1, z_2 \in \mathcal{M}^k[f] \cap \mathcal{S}_{k',k}, \quad k' = \lfloor k/2 \rfloor + 1,$$

and

$$z_1 \leq f \leq z_2 \quad \text{on} \quad [a,b].$$

If f does not belong to $\mathcal{S}_{k',k}$, then the inequalities are strict, respectively, on some nonempty intervals I_1, I_2 in $[a,b]$.

Remark 3.5. In [21], more precise conclusions regarding the number of polynomial pieces k' of the splines z_ν and their boundary values are given. The proof is based on the Markov–Krein theorem from the theory of moments.

Remark 3.6. We emphasize that k' denotes $\lfloor k/2 \rfloor + 1$ throughout this paper.

A simple, yet important, consequence of Lemma 3.4 is the following result on the structural properties of best $\mathbb{L}_p$-approximants from $\mathcal{M}^k[f]$.

LEMMA 3.7. *For $k \geq 2$, $0 < p < \infty$, and $I = (a,b)$, let $g \in \mathbb{C}$, $f \in \mathcal{M}^k_*$, and $\mathfrak{f}_* \in \mathcal{P}_{\mathcal{M}^k[f]}(g)_p$. If the difference $g - \mathfrak{f}_*$ has no zeros inside an interval $(c,d) \subset (a,b)$, then $\mathfrak{f}_* \in \mathcal{S}_{k',k}[c,d]$.*

Proof. The idea of the proof is similar to what was considered by Zwick [21] in the case for $p = 1$. Suppose that $0 < p < \infty$. Without loss of generality, we can assume that $\mathfrak{f}_*(x) > g(x)$, $x \in (c, d)$. Now suppose that $\mathfrak{f}_* \notin \mathcal{S}_{k',k}[c+\epsilon, d-\epsilon]$ for some $\epsilon > 0$. Consider a function $\tilde{f}$ obtained from $\mathfrak{f}_*$ by replacing it on the interval $[c+\epsilon, d-\epsilon]$ by $z_1(\mathfrak{f}_*, [c+\epsilon, d-\epsilon])$ (see Lemma 3.4). Then $\tilde{f} \in \mathcal{M}^k[f]$ and $\mathfrak{f}_* - \tilde{f} \geq 0$ on $[a, b]$ with this inequality being strict on a nonempty interval contained in $(c+\epsilon, d-\epsilon)$.

Since $\mathfrak{f}_* - g$ is a continuous positive function on a closed interval $[c+\epsilon, d-\epsilon]$, there exists $\delta > 0$ such that $\mathfrak{f}_*(x) \geq g(x) + \delta$, $x \in [c+\epsilon, d-\epsilon]$. Therefore, there exists $0 < \mu < 1$ such that $\widehat{f}(x) := \mu\mathfrak{f}_*(x) + (1-\mu)\tilde{f}(x)$ satisfies the inequalities $g(x) < \widehat{f} \leq \mathfrak{f}_*$ on $[c+\epsilon, d-\epsilon]$, and $\|\mathfrak{f}_* - \widehat{f}\|_{\mathbb{L}_p[c+\epsilon, d-\epsilon]} \neq 0$. This implies that $\|\widehat{f} - g\|_p < \|\mathfrak{f}_* - g\|_p$, which contradicts our assumption that $\mathfrak{f}_* \in \mathcal{P}_{\mathcal{M}^k[f]}(g)_p$.

Hence $\mathfrak{f}_* \in \mathcal{S}_{k',k}[c+\epsilon, d-\epsilon]$ for all $\epsilon > 0$, which implies that $\mathfrak{f}_* \in \mathcal{S}_{k',k}[c, d]$. ∎

LEMMA 3.8. *For $k \geq 2$, $0 < p < \infty$, and $I = (a, b)$, let $g \in \mathbb{C}$, $f \in \mathcal{M}^k_*$, and $\mathfrak{f}_* \in \mathcal{P}_{\mathcal{M}^k[f]}(g)_p$. Further, let $\mathfrak{Z}$ be the set of zeros of $g - \mathfrak{f}_*$, i.e.,*

$$\mathfrak{Z} := \{z \in I \mid \ g(z) = \mathfrak{f}_*(z)\},$$

and let $\mathfrak{Z}^*$ be the set of all limit points of $\mathfrak{Z}$. Then the following are true.

(1) *$\mathfrak{f}_* = g$ on $\mathfrak{Z}^*$.*

(2) *If, for a closed interval $[c, d] \subset I \setminus \mathfrak{Z}^*$, the difference $g - \mathfrak{f}_*$ has (necessarily finitely many) $m - 1$ distinct zeros in (c, d), then $\mathfrak{f}_* \in \mathcal{S}_{mk',k}[c, d]$.*

Proof. This lemma is a variation of Zwick [21, Theorem 2]. In a similar form (though with $\mathfrak{Z}^*$ defined differently), it appeared in Damas and Marano [12]. Part 1 immediately follows from the continuity of g and $\mathfrak{f}_*$. Part 2 is a consequence of Lemma 3.7. ∎

For $p = \infty$, Lemma 3.7 is not valid because local changes influence the integral's value but not necessarily the sup-norm; hence there may be best k-monotone $\mathbb{L}_\infty$-approximants with a structure different from that specified in Lemma 3.8. However, for our purposes, it is enough that there is at least one element from $\mathcal{P}_{\mathcal{M}^k[f]}(g)_\infty$ that has the spline structure. The following statement is valid.

LEMMA 3.9. *For $k \geq 2$, $p = \infty$, and $I = (a, b)$, let $g \in \mathbb{C}$ and $f \in \mathcal{M}^k_*$. Then there exists $\mathfrak{f}_* \in \mathcal{P}_{\mathcal{M}^k[f]}(g)_\infty$ such that all the conclusions of Lemma 3.8 hold true.*

Proof. The idea of the proof is to take as $\mathfrak{f}_*$ an element which minimizes, say, the L_2-norm of $g - \mathfrak{f}_*$ over $\mathfrak{f}_* \in \mathcal{P}_{\mathcal{M}^k[f]}(g)_\infty$. We omit the details. ∎

Now the spline structure of the best k-monotone approximant to any spline readily follows.

COROLLARY 3.10. *For $r \geq k \geq 2$, $0 < p \leq \infty$, and $I = (a, b)$, let $g \in \mathcal{S}_{N,r} \cap \mathbb{C}$ and $f \in \mathcal{M}^k_*$. Then there is an $\mathfrak{f}_* \in \mathcal{P}_{\mathcal{M}^k[f]}(g)_p$ which is a piecewise polynomial of order r.*

4. Proof of Theorem 1.1. The following three propositions are the main components of the proof.

PROPOSITION 4.1. *For $k, r \in \mathbb{N}$, $r \geq k \geq 2$, $0 < p \leq \infty$, and $I = (a, b)$, let $f \in \mathcal{M}^k_*$ and $(-\mathfrak{p}) \in (\Pi_r \setminus \Pi_k) \cap \mathcal{M}^k$. Then there exists a spline s such that*

$$s \in \mathcal{S}_{(k+1)k',k} \cap \mathcal{M}^k[f]$$

and

$$\|\mathfrak{p} - s\|_p = E(\mathfrak{p}, \mathcal{M}^k[f])_p.$$

Proof. Let us show that $\mathfrak{f}_*$, a best approximant to $\mathfrak{p}$ from $\mathcal{M}^k[f]$, satisfies all the conclusions of the proposition (hence $s := \mathfrak{f}_*$). Since, by the definition,

$$\mathfrak{f}_* \in \mathcal{M}^k[f], \quad \|\mathfrak{p} - \mathfrak{f}_*\|_p = E(\mathfrak{p}, \mathcal{M}^k[f])_p,$$

only the spline structure needs to be proved. Since $(-\mathfrak{p})$ is a k-monotone polynomial of degree $> k-1$, it is a strictly k-monotone function in the sense that $(-\mathfrak{p})^{(k-2)}$ is strictly convex. Hence the function $(\mathfrak{f}_* - \mathfrak{p})^{(k-2)}$ is strictly convex too; thus it has at most two zeros, and, therefore, $\mathfrak{f}_* - \mathfrak{p}$ has not more than k distinct zeros on I. By Lemma 3.8 (or Lemma 3.9 in the case for $p = \infty$), $\mathfrak{f}_* \in \mathcal{S}_{(k+1)k',k}$, and the proof is complete. □

PROPOSITION 4.2. *Let $k, r \in \mathbb{N}$, $r \geq k \geq 2$, $0 < p \leq \infty$, $I = (a, b)$, $f \in \mathcal{M}^k_*$, and $\mathfrak{p} \in \Pi_r \cap \mathcal{M}^k$. Then there exist a constant $C(k)$ independent of I and a spline $s \in \mathcal{S}_{C(k),r} \cap \mathcal{M}^k[f]$ such that*

$$\|\mathfrak{p} - s\|_p \leq c_2 E(\mathfrak{p}, \mathcal{M}^k[f])_p, \quad c_2 = c_2(p, r, k).$$

Now, $\mathfrak{f}_*$ from $\mathcal{P}_{\mathcal{M}^k[f]}(\mathfrak{p})_p$ is still a piecewise polynomial of order r, but we cannot take $s = \mathfrak{f}_*$ because two k-monotone functions ($\mathfrak{f}_*$ and $\mathfrak{p}$ in our case) may have any number of intersections; hence $\mathfrak{f}_*$ may have any number of knots. We obtain s as a modification of $\mathfrak{f}_*$, which will be done in the following sections with the proof of Proposition 4.2 given in section 9.

PROPOSITION 4.3. *Let $k, r \in \mathbb{N}$, $r \geq k \geq 2$, $0 < p \leq \infty$, $I = (a, b)$, and $f \in \mathcal{M}^k_*$, and let $\mathfrak{p}$ be such that either $\mathfrak{p} \in \Pi_r \cap \mathcal{M}^k$ or $(-\mathfrak{p}) \in (\Pi_r \setminus \Pi_k) \cap \mathcal{M}^k$. Then there exists a spline s such that*

$$s \in \mathcal{S}_{C(k),r} \cap \mathcal{M}^k[f]$$

and

$$\|f - s\|_p \leq c_1 \|f - \mathfrak{p}\|_p, \quad c_1 = c_1(p, r, k). \tag{4.1}$$

Proof. Let s be the spline from either of Propositions 4.1 and 4.2 so that $s \in \mathcal{S}_{C(k),r} \cap \mathcal{M}^k[f]$ and

$$\|\mathfrak{p} - s\|_p \leq c_2 E(\mathfrak{p}, \mathcal{M}^k[f])_p. \tag{4.2}$$

We need only to prove (4.1). Using the triangle inequality and the estimate (4.2), we obtain

$$c_p \|f - s\|_p \leq \|f - \mathfrak{p}\|_p + \|\mathfrak{p} - s\|_p \leq \|f - \mathfrak{p}\|_p + c_2 E(\mathfrak{p}, \mathcal{M}^k[f])_p.$$

Since f belongs to $\mathcal{M}^k[f]$ in a trivial manner, it follows that

$$E(\mathfrak{p}, \mathcal{M}^k[f])_p := \inf_{u \in \mathcal{M}^k[f]} \|\mathfrak{p} - u\|_p \leq \|\mathfrak{p} - f\|_p.$$

Thus

$$c_p \|f - s\|_p \leq (c_2 + 1) \|f - \mathfrak{p}\|_p. \qquad \square$$

Finally, the following lemma shows that, in the proof of Theorem 1.1, instead of an arbitrary $f \in \mathcal{M}^k_p(0, 1)$, we may consider $f \in \mathcal{M}^k_*(0, 1)$; i.e., we may assume that the function f and its derivatives are bounded at the endpoints.

LEMMA 4.4. *Let $k \in \mathbb{N}$, $0 < p \le \infty$, and $f \in \mathcal{M}_p^k(0,1)$. Then, for any $\epsilon > 0$, there exists $f_\epsilon \in \mathcal{M}_*^k(0,1)$ such that*

$$\|f - f_\epsilon\|_p < \epsilon.$$

Proof. For $f \in \mathcal{M}_p^k(0,1)$ and $x_0 \in (0,1)$, let T_{x_0} be the Taylor polynomial of degree $k-1$ at x_0+ (or at x_0-); i.e.,

$$T_{x_0}(x) := \sum_{i=0}^{k-1} \frac{1}{i!} f^{(i)}(x_0+)(x - x_0)^i.$$

Given ϵ, for δ to be prescribed, let

$$f_\epsilon := \begin{cases} T_\delta & \text{on} \quad [0,\delta], \\ f & \text{on} \quad [\delta, 1-\delta], \\ T_{1-\delta} & \text{on} \quad [1-\delta, 1]. \end{cases}$$

Then obviously $f_\epsilon \in \mathcal{M}_*^k(0,1)$ and

$$\|f - f_\epsilon\|_p \le c_p \|f - T_\delta\|_{\mathbb{L}_p[0,\delta]} + c_p \|f - T_{1-\delta}\|_{\mathbb{L}_p[1-\delta,1]}. \tag{4.3}$$

From [6, Theorem 1], it follows that, for $I = (a,b)$, $f \in \mathcal{M}_p^k(I)$, and $x_* := \frac{a+b}{2}$, we have

$$\|f - T_{x_*}\|_{\mathbb{L}_p(I)} \le c_{k,p} \omega_k(f)_{\mathbb{L}_p(I)},$$

where $\omega_k(f)_{\mathbb{L}_p(I)}$ is the kth modulus of smoothness of $f \in \mathbb{L}_p(I)$ (see section 8 for the definition), which, as is well known, has the property that $\omega_k(f)_{\mathbb{L}_p(J)} \to 0$ if $|J| \to 0$, $J \subset I$. Applying this result to the interval $(0, 2\delta) \subset (0,1)$, we obtain

$$\|f - T_\delta\|_{\mathbb{L}_p(0,\delta)} \le \|f - T_\delta\|_{\mathbb{L}_p(0,2\delta)} \le c_{k,p} \omega_k(f)_{\mathbb{L}_p(0,2\delta)} \to 0 \quad \text{as} \quad \delta \to 0.$$

Similarly,

$$\|f - T_{1-\delta}\|_{\mathbb{L}_p(1-\delta,1)} \le c_{k,p} \omega_k(f)_{\mathbb{L}_p(1-2\delta,1)} \to 0 \quad \text{as} \quad \delta \to 0. \qquad \square$$

Proof of Theorem 1.1. By Lemma 4.4, we can assume that $f \in \mathcal{M}_*^k(0,1)$. Let $\sigma \in \mathcal{S}_{N,r}$ be a spline of best $\mathbb{L}_p$-approximation to f on $(0,1)$. We need to prove that there exists a spline s such that

$$s \in \mathcal{S}_{c_0 N, r} \cap \mathcal{M}^k(0,1) \quad \text{and} \quad \|f - s\|_p \le c_1 \|f - \sigma\|_p.$$

Denote by $\{J_m\}$ the set of largest subintervals of $[0,1]$ on which σ is a polynomial of order r, and denote by $\{I_\ell\}$ the set of largest subintervals of J_m's on which $\sigma^{(k)}$ has a constant sign. Since $\sigma \in \mathcal{S}_{N,r}[0,1]$, there are at most N intervals J_m, and, on each J_m, the spline $\sigma^{(k)}$ is a polynomial of degree $r-1-k$; hence there are at most $\max(1, r-k)$ subintervals I_ℓ in each interval J_m. Thus $\{I_\ell\}$ is a partition of $[0,1]$ such that

$$[0,1] = \cup I_\ell, \quad \#\{I_\ell\} \le N \max(1, r-k),$$

and, on each I_ℓ,

$$\text{either} \quad \sigma \in \Pi_r \cap \mathcal{M}^k \qquad \text{or} \quad (-\sigma) \in (\Pi_r \setminus \Pi_k) \cap \mathcal{M}^k.$$

By Proposition 4.3, on each interval I_ℓ, there exists a spline s_ℓ such that

$$s_\ell \in \mathcal{S}_{C(k),r} \cap \mathcal{M}^k[f](I_\ell)$$

and

$$\|f - s_\ell\|_{\mathbb{L}_p(I_\ell)} \le c_1 \|f - \sigma\|_{\mathbb{L}_p(I_\ell)}. \tag{4.4}$$

Now define the spline s so that

$$s := s_\ell \quad \text{on} \quad I_\ell.$$

Relations $s_\ell \in \mathcal{S}_{C(k),r}(I_\ell)$ and $\#\{I_\ell\} \le N \max(1, r-k)$ imply that

$$s \in \mathcal{S}_{c_0 N,r}(0,1), \quad c_0 = C(k)\max(1, r-k),$$

while inclusions $s_\ell \in \mathcal{M}^k[f](I_\ell)$ with $\cup I_\ell = [0,1]$ yield

$$s \in \mathcal{M}^k[f](0,1) \subset \mathcal{M}^k(0,1).$$

Thus

$$s \in \mathcal{S}_{c_0 N,r} \cap \mathcal{M}^k(0,1).$$

Finally, to estimate the degree of approximation of f by s for $0 < p < \infty$ (modifications for $p = \infty$ are obvious), from (4.4) we obtain

$$\|f - s\|^p_{\mathbb{L}_p(0,1)} \le \sum_\ell \|f - s_\ell\|^p_{\mathbb{L}_p(I_\ell)} \le c_1^p \sum_\ell \|f - \sigma\|^p_{\mathbb{L}_p(I_\ell)} = c_1^p \|f - \sigma\|^p_{\mathbb{L}_p(0,1)},$$

i.e.,

$$E^{(k)}_{c_0 N,r}(f)_p \le c_1 E_{N,r}(f)_p. \qquad \square$$

5. k-monotone interpolation. If $\mathfrak{p} - \mathfrak{f}_*$ has many intersections (see Proposition 4.2), then the spline $\mathfrak{f}_* \in \mathcal{P}_{\mathcal{M}^k[f]}(\mathfrak{p})$ has many knots. In this case, we will modify $\mathfrak{f}_*$ into a spline s with a smaller number of knots by blending f_* with $\mathfrak{p}$. This procedure is related to the following general problem.

Problem 5.1. Given two k-monotone functions f, g on J and an interval $(a,b) \subset J$, determine whether or not there exists a k-monotone function h in $\mathcal{M}^k[f,g](a,b)$. Note that the existence of such h implies that there is a function $\widetilde{h}$ such that

$$\widetilde{h} \in \mathcal{M}^k(J) \quad \text{and} \quad \widetilde{h}(x) = \begin{cases} f(x), & x \le a, \\ g(x), & x \ge b. \end{cases}$$

We will refer to this problem as a *blending* of $f, g \in \mathcal{M}^k(J)$ on $[a,b]$. Actually, all we need is a k-monotone interpolation of data $f^{(i)}(a+), g^{(i)}(b-)$, $i = 0, \dots, k-1$, so that we consider this topic more generally.

Let

$$\boldsymbol{x} := (x_i)_{i=1}^{n+k} := \{a = x_1 \le \cdots \le x_{n+k} = b\}$$

be a sequence of interpolation knots such that $x_i < x_{i+k}$, and let

$$\boldsymbol{y} := \boldsymbol{y}(\boldsymbol{x}) := (y_i)_{i=1}^{n+k}.$$

We use the usual convention that, if some of the knots in $\boldsymbol{x}$ are repeated, then interpolation of corresponding derivatives takes place. For each $j = 1, \dots, n+k$, denote by l_j the number of points x_i such that $x_i = x_j$ with $i \le j$; i.e.,

$$l_j := l_j(\boldsymbol{x}) := \#\{i \mid \ 1 \le i \le j,\ x_i = x_j\}.$$

Note that, because of the restriction $x_i \ne x_{i+k}$, the inequality $l_j \le k$ is valid for all j.

DEFINITION 5.2. *A data sequence $(\boldsymbol{x}, \boldsymbol{y}) := (x_i, y_i)_{i=1}^{n+k}$ is called k-monotone if there exists a k-monotone function $f \in \mathcal{M}_*^k(a,b)$ such that*

$$f^{(l_j-1)}(x_j) = y_j, \quad j = 1, \dots, n+k. \tag{5.1}$$

Note that if all the knots in $\boldsymbol{x}$ are distinct, then the sequence $(\boldsymbol{x}, \boldsymbol{y})$ is k-monotone if $f(x_i) = y_i$, $j = 1, \dots, n+k$, for some $f \in \mathcal{M}_*^k(a,b)$. Also, if $l_j = k$ for some j, then $f^{(l_j-1)}(x_j) = f^{(k-1)}(x_j)$ is understood as $f^{(k-1)}(x_j+)$ or $f^{(k-1)}(x_j-)$.

Since

$$f \in \mathcal{M}^k \quad \Leftrightarrow \quad [t_i, \dots, t_{i+k}]f \ge 0 \quad \forall\ (t_i),$$

where not all t_i's are the same, one must necessarily have for a k-monotone sequence $(\boldsymbol{x}, \boldsymbol{y})$

$$[x_i, \dots, x_{i+k}]\boldsymbol{y} \ge 0.$$

If $k = 1$ or 2 (i.e., in the case of monotone or convex interpolation), this condition is sufficient as well. However, it is *not* sufficient if $k \ge 3$, as the following example shows.

Example 5.3. The data set

$\boldsymbol{x}$	$\boldsymbol{y}$	δ^1	δ^2	δ^3
-5	-77			
		25		
-3	-27		-3	
		13		0
-1	-1		-3	
		1		1
1	1		3	
		13		0
3	27		3	
		25		
5	77			

has nonnegative divided differences of order 3, but, at the same time,

$$\begin{aligned}
&[-5,-3,-1,0]\boldsymbol{y} + [0,1,3,5] \\
&\quad = \ -\frac{1}{5}[-5,-3,-1]\boldsymbol{y} - \frac{1}{15}[-3,-1]\boldsymbol{y} - \frac{1}{15}[-1]\boldsymbol{y} + \frac{1}{15}[0]\boldsymbol{y} \\
&\qquad\quad + \frac{1}{5}[1,3,5]\boldsymbol{y} \quad - \frac{1}{15}[1,3]\boldsymbol{y} \quad + \frac{1}{15}[1]\boldsymbol{y} - \frac{1}{15}[0]\boldsymbol{y} \\
&\quad = \ \frac{1}{5}\cdot 6 - \frac{1}{15}\cdot 26 + \frac{1}{15}\cdot 2 = -\frac{6}{15} < 0.
\end{aligned}$$

Hence there is no 3-monotone function passing through $(\boldsymbol{x}, \boldsymbol{y})$.

Denote by

$$\boldsymbol{v} := \boldsymbol{v}(\boldsymbol{x}, \boldsymbol{y}) := (v_i)_1^n, \quad v_i := [x_i, \dots, x_{i+k}]\boldsymbol{y},$$

the sequence of divided differences of $\boldsymbol{y}(\boldsymbol{x})$, and denote by

$$\mathfrak{M} := \mathfrak{M}(\boldsymbol{x}) := \left(\frac{1}{k!}M_i\right), \quad M_i(t) := k[x_i, \dots, x_{i+k}](\cdot - t)_+^{k-1},$$

the sequence of the B-splines of order k with the knot sequence $\boldsymbol{x}$. Recall that $\operatorname{supp} M_i = [x_i, x_{i+k}]$, $M_i \ge 0$, $\int M_i = 1$, and, for any $f \in \mathbb{C}^k(a,b)$ (in fact, the condition $f \in \mathbb{W}_1^k(a,b)$ is sufficient),

$$[x_i, \dots, x_{i+k}]f = \frac{1}{k!}\int_a^b M_i(t) f^{(k)}(t)\, dt.$$

Notice that if a k-monotone function f belongs to $\mathbb{C}^k$, then $f^{(k)} \ge 0$. Thus, to check whether the data sequence (x_i, y_i) is k-monotone, one needs to form the sequence of divided differences (v_i) and check whether there is a nonnegative function λ such that

$$v_i = \frac{1}{k!}\int M_i(t)\lambda(t)\, dt.$$

The last problem is the so-called *Markov moment problem*, which we discuss in the next section.

6. Markov moment problem and k-monotone interpolation. Let $\mathcal{U} := (u_i)_{i=1}^n$ be a sequence of continuous linearly independent real-valued functions on $I = (a,b)$, and let $\boldsymbol{v} := (v_i)_{i=1}^n$ be a sequence of real numbers.

DEFINITION 6.1. *A sequence $\boldsymbol{v} \in \mathbb{R}^n$ is called a moment sequence with respect to $\mathcal{U}$ if, for some bounded nondecreasing function μ, it admits the representation*

$$v_i = \int_a^b u_i(t)\, d\mu(t), \quad 1 \le i \le n.$$

LEMMA 6.2. *A data sequence $(\boldsymbol{x}, \boldsymbol{y})$ is k-monotone if and only if the sequence of divided differences $\boldsymbol{v}(\boldsymbol{x}, \boldsymbol{y})$ is a moment sequence with respect to $\mathfrak{M}(\boldsymbol{x})$, the sequence of B-splines.*

Proof. By Lemma 3.1(3), $f \in \mathcal{M}_*^k(a,b)$ can be represented as

$$f(x) = p(x) + \frac{1}{k!}\int_a^b k(x-t)_+^{k-1}\, d\mu(t), \tag{6.1}$$

where $p \in \Pi_k$ and μ is a bounded nondecreasing function. If $f|_{\boldsymbol{x}} = \boldsymbol{y}$, then

$$v_i := [x_i, \dots, x_{i+k}]\boldsymbol{y} = [x_i, \dots, x_{i+k}]f = \frac{1}{k!}\int_a^b M_i(t)\, d\mu(t),$$

i.e., $\boldsymbol{v}$ is a moment sequence with respect to $\mathfrak{M}$.

Conversely, if for the sequences $\boldsymbol{v}(\boldsymbol{x}, \boldsymbol{y})$ and $\mathfrak{M}(\boldsymbol{x})$ there exists a bounded nondecreasing function μ such that

$$v_i = \frac{1}{k!}\int_a^b M_i(t)\, d\mu(t), \quad i = 1, \dots, n,$$

then, for any $p \in \Pi_k$, the function f defined by (6.1) is in $\mathcal{M}_*^k$ and satisfies

$$[x_i, \dots, x_{i+k}]f = v_i := [x_i, \dots, x_{i+k}]\boldsymbol{y}, \quad i = 1, \dots, n. \tag{6.2}$$

Finally, in (6.1), we can choose $p \in \Pi_k$ so that the equality in (5.1) holds for $j = 1, \dots, k$, and that, together with (6.2), implies successively that it is also true for $j = k+1, \dots, n+k$; hence the sequence (x_i, y_i) is k-monotone. ∎

Now we need a result from the theory of moments which gives a characterization of the moment sequences.

DEFINITION 6.3. *A sequence $\boldsymbol{v} \in \mathbb{R}^n$ of real numbers is called positive with respect to $\mathcal{U} = (u_i)_{i=1}^n$ (recall that $\mathcal{U}$ is a sequence of continuous linearly independent real-valued functions on $[a, b]$) if*

$$\sum_{i=1}^{n} a_i u_i(t) \geq 0, \quad a \leq t \leq b, \qquad \Rightarrow \qquad \sum_{i=1}^{n} a_i v_i \geq 0.$$

THEOREM 6.4 (Krein and Nudelman [7, Theorem 3.1.1, p. 58], [8]). *Let $\mathcal{U} := (u_i)_{i=1}^n$ be a sequence of continuous linearly independent real-valued functions on $I = [a, b]$ with the property that there exists a strictly positive polynomial $p \in \operatorname{span} \mathcal{U}$. A sequence $\boldsymbol{v} \in \mathbb{R}^n$ is a moment sequence with respect to $\mathcal{U}$ if and only if $\boldsymbol{v}$ is positive with respect to $\mathcal{U}$.*

Since $\operatorname{span} \mathfrak{M}(\boldsymbol{x})$ contains constants, we may combine this theorem with Lemma 6.2 to obtain the following criterion for k-monotonicity of data.

COROLLARY 6.5. *A data sequence $(\boldsymbol{x}, \boldsymbol{y})$ is k-monotone if and only if the sequence of divided differences $\boldsymbol{v}(\boldsymbol{x}, \boldsymbol{y})$ is positive with respect to $\mathfrak{M}(\boldsymbol{x})$, i.e., if and only if*

$$\sum_{i=1}^{n} a_i M_i(t) \geq 0 \quad \Rightarrow \quad \sum_{i=1}^{n} a_i v_i \geq 0, \quad v_i = [x_i, \dots, x_{i+k}]\boldsymbol{y}.$$

7. Blending of k-monotone functions. In this section, we will give a partial solution to Problem 5.1. Namely, in Proposition 7.3, we prove that, provided f and g have sufficiently many points of intersection, a function $h \in \mathcal{M}^k[f, g]$ exists.

We need two auxiliary statements.

The following lemma is a particular case of Lemma 3.2 in Beatson [1] concerning the spline blending. Actually, we will use a more detailed statement which is formulated within the proof of Proposition 7.3.

LEMMA 7.1 (Beatson [1]). *Let $k \in \mathbb{N}$, $n = 2k^2$, and let $p \in \Pi_k$ be a nonnegative polynomial on $[a, b]$. Then, for any knot sequence*

$$\mathbf{t} := \{a = t_0 \leq t_1 \leq \cdots \leq t_n < t_{n+1} = b\},$$

there exists a nonnegative spline $s_2 \in \mathcal{S}_{\mathbf{t},k}(\mathbb{R})$ (i.e., s_2 is a spline of order r on the knot sequence $\mathbf{t}$) such that

$$s_2 \equiv 0 \quad \text{on} \quad (-\infty, a], \qquad 0 \leq s_2 \leq p \quad \text{on} \quad [a, b], \qquad s_2 = p \quad \text{on} \quad [b, \infty).$$

The next statement is a well-known property of divided differences.

LEMMA 7.2. *Let $(x_j)_{j=1}^{n+k}$ be any nondecreasing sequence such that $x_j < x_{j+k}$. Then, for any subsequence $(x_{i_0}, \dots, x_{i_k})$ of length $k+1$, there exist coefficients ν_j such that, for any continuous f (which is differentiable at the repeated knots),*

$$[x_{i_0}, \dots, x_{i_k}]f = \sum_{j=1}^{n} \nu_j [x_j, \dots, x_{j+k}]f.$$

PROPOSITION 7.3. *For $k \in \mathbb{N}$ and $n = 2k^2$, let $f, g \in \mathcal{M}_*^k(a,b)$ be such that*

$$f(t_j) = g(t_j) \quad on \quad \{a = t_0 < t_1 < \cdots < t_n < t_{n+1} = b\}.$$

Then there exists a function $h \in \mathcal{M}_*^k(a,b)$ such that

$$h^{(l)}(a+) = f^{(l)}(a+), \quad h^{(l)}(b-) = g^{(l)}(b-), \quad l = 0, \dots, k-1.$$

Note that the condition that all points t_i in the statement of Proposition 7.3 are distinct is not essential and is used here only in order to simplify the exposition.

Proof. Let us introduce two sequences $\boldsymbol{x} = (x_i)_{i=1}^{n+2k}$ and $\boldsymbol{y} = (y_i)_{i=1}^{n+2k}$:

$$x_j := \begin{cases} a, & 1 \le j \le k, \\ t_{j-k}, & k+1 \le j \le n+k, \\ b, & n+k+1 \le j \le n+2k, \end{cases}$$

and

$$y_j := \begin{cases} f^{(j-1)}(a+), & 1 \le j \le k, \\ f(x_j) = g(x_j), & k+1 \le j \le n+k, \\ g^{(j-n-k-1)}(b-), & n+k+1 \le j \le n+2k. \end{cases}$$

It is convenient to arrange this data set $(\boldsymbol{x}, \boldsymbol{y})$ as follows:

$$\begin{array}{cccccccccccc}
\boldsymbol{y}_1 & & & & & & & & & & & \\
\| & & & & & & & & & & & \\
(y_j)_{j=1}^{n+k+1} \to & f(a) & \dots & f^{(k-1)}(a) & f(x_{k+1}) & \dots & f(x_{n+k}) & & f(b) & & & \\
& \uparrow & & \uparrow & \uparrow & & \uparrow & & \uparrow & & & \\
& x_1 = \cdots = x_k & < & x_{k+1} & \le \cdots \le & x_{n+k} & < & b = & x_{n+k+1} = \cdots = & x_{n+2k} & & \\
& \downarrow & & \downarrow & \downarrow & & \downarrow & & \downarrow & & \downarrow & \\
& g(a) & & g(x_{k+1}) & \dots & g(x_{n+k}) & & g(b) & \dots & g^{(k-1)}(b) & \leftarrow (y_j)_{j=k}^{n+2k} & \\
& & & & & & & & & & \| & \\
& & & & & & & & & & \boldsymbol{y}_2 &
\end{array}$$

Set

$$\begin{aligned} \boldsymbol{x}_* &:= (x_1, \dots, x_k, x_{n+k+1}, \dots, x_{n+2k}) := (\overbrace{a, \dots, a}^{k}, \overbrace{b, \dots, b}^{k}), \\ \boldsymbol{y}_* &:= (y_1, \dots, y_k, y_{n+k+1}, \dots, y_{n+2k}) \\ &:= \left(f(a), \dots, f^{(k-1)}(a), g(b), \dots, g^{(k-1)}(b)\right). \end{aligned} \tag{7.1}$$

We need to interpolate $\boldsymbol{y}_*$ on $\boldsymbol{x}_*$ by a k-monotone function h. Denote by

$$\mathfrak{M}(\boldsymbol{x}_*) =: (B_i)_{i=1}^k, \quad \boldsymbol{v}(\boldsymbol{x}_*, \boldsymbol{y}_*) =: (w_i)_{i=1}^k$$

the sequences of the B-splines and of divided differences, respectively, which correspond to $(\boldsymbol{x}_*, \boldsymbol{y}_*)$. By Corollary 6.5, existence of a k-monotone interpolant h to the data (7.1) will follow if we show that

$$\sum_{i=1}^k a_i B_i(t) \ge 0 \quad \Rightarrow \quad \sum_{i=1}^k a_i w_i \ge 0. \tag{7.2}$$

We start with some preliminaries.

(1) Let $(v_j)_{j=1}^{n+k}$ and $(M_j)_{j=1}^{n+k}$ be the sequences of divided differences and B-splines, respectively, constructed with respect to the entire set $(x_j, y_j)_{j=1}^{n+2k}$. Consider two sets of the following subsequences:

$$\begin{array}{llll} \boldsymbol{x}_1 := (x_j)_{j=1}^{n+k+1}, & \boldsymbol{y}_1 := (y_j)_{j=1}^{n+k+1}, & \boldsymbol{v}_1 := (v_j)_{j=1}^{n+1}, & \mathfrak{M}_1 := (M_j)_{j=1}^{n+1}; \\ \boldsymbol{x}_2 := (x_j)_{j=k}^{n+2k}, & \boldsymbol{y}_2 := (y_j)_{j=k}^{n+2k}, & \boldsymbol{v}_2 := (v_j)_{j=k}^{n+k}, & \mathfrak{M}_2 := (M_j)_{j=k}^{n+k}. \end{array} \tag{7.3}$$

By assumption, k-monotone f interpolates $\boldsymbol{y}_1$ on $\boldsymbol{x}_1$, and k-monotone g interpolates $\boldsymbol{y}_2$ on $\boldsymbol{x}_2$; thus both sets of data $(\boldsymbol{x}_\nu, \boldsymbol{y}_\nu)$, $\nu = 1, 2$, are k-monotone. Then Corollary 6.5 implies that

$$\boldsymbol{v}_\nu \text{ is positive with respect to } \mathfrak{M}_\nu, \quad \nu = 1, 2. \tag{7.4}$$

(2) Since (v_j), (M_j) are divided differences of certain functions on $\boldsymbol{x}$, while (w_i), (B_i) are divided differences of the same functions on $\boldsymbol{x}_* \subset \boldsymbol{x}$, by Lemma 7.2 there exist expansions

$$w_i = \sum_{j=1}^{n+k} c_{ij} v_j, \quad B_i(x) = \sum_{j=1}^{n+k} c_{ij} M_j(x)$$

with the same coefficients (c_{ij}) in both of these equations. This implies that, for any $(a_i)_{i=1}^k \subset \mathbb{R}$, the expansions

$$\sum_{i=1}^{k} a_i B_i(x) = \sum_{j=1}^{n+k} c_j M_j(x), \quad \sum_{i=1}^{k} a_i w_i = \sum_{j=1}^{n+k} c_j v_j$$

have the same coefficients $c_j = \sum_{i=1}^k a_i c_{ij}$.

(3) The B-splines $(B_i) \in \mathfrak{M}(\boldsymbol{x}_*)$ have the form

$$\begin{aligned} B_i(t) &:= k[\overbrace{a, \dots, a}^{k+1-i}, \overbrace{b, \dots, b}^{i}](\cdot - t)_+^{k-1} \\ &= \frac{k}{(b-a)^k} \binom{k-1}{i-1} (t-a)^{i-1} (b-t)^{k-i}, \quad i = 1, \dots, k, \end{aligned}$$

i.e., they are Bernstein basis polynomials of order k, so that

$$\sum a_i B_i \in \Pi_k \quad \forall\ (a_i).$$

Now let us prove (7.2). Suppose that, for some sequence (a_i),

$$p_a(x) := \sum_{i=1}^{k} a_i B_i(x) \geq 0.$$

Since p_a is a polynomial of order k,

$$p_a(x) := \sum_{i=1}^{k} a_i B_i(x) = \sum_{j=1}^{n+k} c_j M_j(x) \geq 0, \quad \text{and} \quad n \geq 2k^2,$$

the method of the proof of Beatson's smoothing lemma [1, Lemma 3.2] shows that there is an index l, $k \le l \le n+1$, such that

$$s_1(x) := \sum_{j=1}^{l} c_j M_j(x) \ge 0, \quad s_2(x) := \sum_{j=l+1}^{n+k} c_j M_j(x) \ge 0. \tag{7.5}$$

(We will not repeat Beatson's argument here and mention only that the sign variation diminishing property of B-spline series (see [4, section 5.10], for example) as well as their finite support are used.) From the definitions in (7.3), it follows that $s_\nu \in \mathfrak{M}_\nu$, $\nu = 1, 2$, which allows us to conclude that, since $\boldsymbol{v}_\nu$ are positive with respect to $\mathfrak{M}_\nu$ (see (7.4)), (7.5) implies

$$\sum_{j=1}^{l} c_j v_j \ge 0, \quad \sum_{j=l+1}^{n+k} c_j v_j \ge 0.$$

Finally,

$$\sum_{i=1}^{k} a_i w_i = \sum_{j=1}^{n+k} c_j v_j = \sum_{i=1}^{l} c_j v_j + \sum_{j=l+1}^{n+k} c_j v_j \ge 0.$$

Hence (7.2) is proved, and the proof of the proposition is now complete. □

Now, having proved the existence of a function $h \in \mathcal{M}^k[f, g]$, we may use Lemma 3.4 to derive the existence of a spline $z \in \mathcal{M}^k[f, g]$.

COROLLARY 7.4. *For $k \in \mathbb{N}$, $n = 2k^2$, let $f, g \in \mathcal{M}^k_*(a, b)$ be such that*

$$f(t_j) = g(t_j) \quad \text{on} \quad \{a = t_0 < t_1 < \cdots < t_n < t_{n+1} = b\}.$$

Then there exists a spline z such that

$$z \in \mathcal{S}_{k',k} \cap \mathcal{M}^k[f, g].$$

Note that, for $k = 1$ or 2, that is, for monotone or convex functions f and g, a procedure of k-monotone blending of f and g is quite evident geometrically.

8. Auxiliary Whitney-type estimates. In this section, we give some Whitney-type estimates for approximation of polynomials $\mathfrak{p} \in \Pi_r$ by splines and polynomials of degree k.

As usual, $\omega_k(f, \delta, I)_p$ denotes the kth modulus of smoothness of f with the step δ on the interval I,

$$\omega_k(f, \delta, I)_p := \sup_{0<h\le\delta} \left\| \Delta_h^k(f, \cdot, I) \right\|_{\mathbb{L}_p(I)},$$

where $\Delta_h^k(f, x, I)$ is the kth forward difference,

$$\Delta_h^k(f, x, I) := \begin{cases} \sum_{i=0}^{k} \binom{k}{i} (-1)^{k-i} f(x + ih) & \text{if } [x, x + kh] \subset I, \\ 0 & \text{otherwise.} \end{cases}$$

It is also convenient to denote

$$\omega_k(f)_p := \omega_k(f)_{\mathbb{L}_p(I)} := \omega_k(f, |I|, I)_p.$$

LEMMA 8.1. *Let $k, r \in \mathbb{N}$, $0 < p \le \infty$, $I = (a, b)$, and $\mathfrak{p} \in \Pi_r$, and let s be a spline of order k with at most $C(k)$ pieces in I (i.e., $s \in \mathcal{S}_{C(k),k}$). Then*

$$\|\mathfrak{p} - s\|_p \ge c_{p,r,k}\omega_k(\mathfrak{p})_p.$$

Proof. Let J be a largest subinterval of I between two successive knots of s (and hence $|J|/|I| \ge 1/C(k)$), and let $\mathfrak{q} \in \Pi_k$ be the restriction of s to J. Then, using Whitney's inequality,

$$E(\mathfrak{p}, \Pi_k)_{\mathbb{L}_p(I)} \overset{p,k}{\sim} \omega_k(\mathfrak{p})_{\mathbb{L}_p(I)}, \tag{8.1}$$

and the Markov-type inequality (see [4, (4.2.10) and (4.2.16)])

$$\|\mathfrak{p}\|_{\mathbb{L}_p(I)} \le c_{p,r}(|I|/|J|)^{r-1+1/p}\|\mathfrak{p}\|_{\mathbb{L}_p(J)},$$

we find

$$\begin{aligned}\|\mathfrak{p} - s\|_{\mathbb{L}_p(I)} &\ge \|\mathfrak{p} - \mathfrak{q}\|_{\mathbb{L}_p(J)} \ge c_{p,r}(|J|/|I|)^{r-1+1/p}\|\mathfrak{p} - \mathfrak{q}\|_{\mathbb{L}_p(I)} \\ &\ge c_{p,r,k}E(\mathfrak{p}, \Pi_k)_{\mathbb{L}_p(I)} \ge c'_{p,r,k}\omega_k(\mathfrak{p})_p. \qquad \square\end{aligned}$$

LEMMA 8.2. *Let $k, r \in \mathbb{N}$, $0 < p \le \infty$, $I = (a, b)$, and $\mathfrak{p} \in \Pi_r$, and let $l_k(\mathfrak{p})$ be the Lagrange polynomial of order k interpolating $\mathfrak{p}$ at any k (not necessarily distinct) points inside I. Then*

$$\|\mathfrak{p} - l_k(\mathfrak{p})\|_p \le c_{p,r,k}\omega_k(\mathfrak{p})_p.$$

Proof. Taking into account Lebesgue's inequality

$$\|\mathfrak{p} - l_k(\mathfrak{p})\|_p \le \left(\sup_{\mathfrak{q}\in\Pi_r} \frac{\|l_k(\mathfrak{q})\|_p}{\|\mathfrak{q}\|_p} + 1\right) E(\mathfrak{p}, \Pi_k)_p$$

and Whitney's inequality (8.1), it suffices to prove that

$$\|l_k(\mathfrak{q})\|_p \le c_{p,r,k}\|\mathfrak{q}\|_p \quad \forall\ \mathfrak{q} \in \Pi_r.$$

We make use of Markov's inequality

$$\|\mathfrak{q}^{(k)}\|_\infty \le c_{p,r,k}|I|^{-k-1/p}\|\mathfrak{q}\|_p$$

and the well-known error bound for the Lagrange interpolation

$$\|f - l_k(f)\|_\infty \le c_k|I|^k\|f^{(k)}\|_\infty$$

to obtain

$$\|\mathfrak{q} - l_k(\mathfrak{q})\|_p \le |I|^{1/p}\|\mathfrak{q} - l_k(\mathfrak{q})\|_\infty \le c_k|I|^{1/p}|I|^k\|\mathfrak{q}^{(k)}\|_\infty \le c_{p,r,k}\|\mathfrak{q}\|_p. \qquad \square$$

LEMMA 8.3. *Let $k \in \mathbb{N}$ and $f \in \mathcal{M}^k(a, b)$, and let $l_k(f, x; x_1, \dots, x_k)$ be the Lagrange (Hermite–Taylor) polynomial of degree $\le k-1$ interpolating f at the points x_i, $1 \le i \le k$, where $a =: x_0 < x_1 \le \cdots \le x_k < x_{k+1} := b$. Then*

$$(-1)^{k-i}(f(x) - l_k(f, x; x_1, \dots, x_k)) \ge 0, \quad x \in (x_i, x_{i+1}), \quad i = 0, \dots, k.$$

In other words, $f - l_k$ changes sign at $x_1, \dots, x_k$.

Proof. First, if all the points x_i, $1 \le i \le k$, are distinct, this is Theorem 5 in Bullen [3].

If some of x_i (but not all) coincide, the statement of the lemma is a consequence of the following result which follows from [4, Theorem 4.6.3]: *For a given $f \in \mathbb{C}^{(k-2)}(a,b)$, the Lagrange–Hermite polynomial $l_k(X) = l_k(f,x;x_1,\dots,x_k)$ is a continuous function of $X = (x_1,\dots,x_k)$ at each point $X^* = (x_1^*,\dots,x_k^*) \in (a,b)^k$ such that not all x_i^*, $i = 1,\dots,k$, are the same.*

If all points coincide, i.e., $x_1 = \cdots = x_k = \xi$, the lemma follows from the following statement, which can be proved by induction on k: *Let $k \in \mathbb{N}$, $f \in \mathcal{M}^k(a,b)$, and $\xi \in (a,b)$. If t_k is a Taylor polynomial of degree $\le k-1$ for f at ξ, i.e., $t_k^{(i)}(\xi) = f^{(i)}(\xi\pm)$ for $i = 0,\dots,k-1$ (or, more precisely, $t_k^{(i)}(\xi) = f^{(i)}(\xi)$ for $i = 0,\dots,k-2$ and $t_k^{(k-1)}(\xi)$ is either $f^{(k-1)}(\xi+)$ or $f^{(k-1)}(\xi-)$), then*

$$f(x) - t_k(x) \ge 0,\ x \in (\xi,b), \quad \text{and} \quad (-1)^k(f(x) - p_k(x)) \ge 0,\ x \in (a,\xi). \qquad \square$$

The following is an immediate corollary of Lemma 8.3.

COROLLARY 8.4. *For $k \in \mathbb{N}$, $f \in \mathcal{M}_*^k(a,b)$, and a set of interpolation points $\{a = x_0 \le \cdots \le x_k = b\}$, let*

$$l_k := l_k(f; x_0 \dots, x_{k-1}) \quad \textit{and} \quad \widetilde{l}_k := \widetilde{l}_k(f, x_1 \dots, x_k)$$

be two Lagrange (Hermite–Taylor) interpolants to f on the given sets. Then f lies between l_k and $\widetilde{l}_k$ on $[a,b]$; i.e.,

$$\min\{l_k, \widetilde{l}_k\} \le f \le \max\{l_k, \widetilde{l}_k\}.$$

LEMMA 8.5. *Let $k, r \in \mathbb{N}$, $0 < p \le \infty$, $I = (a,b)$, $\mathfrak{p} \in \Pi_r \cap \mathcal{M}^k$, $0 \le \mu \le k-1$, and let $g \in \mathcal{M}^k$ be a function such that*

$$g^{(i)}(a) = \mathfrak{p}^{(i)}(a), \quad i = 0,\dots,\mu, \tag{8.2}$$

and

$$g^{(i)}(b) = \mathfrak{p}^{(i)}(b), \quad i = 0,\dots,k-\mu-1. \tag{8.3}$$

(Here, in the cases $\mu = 0$ and $\mu = k-1$, $g^{(k-1)}(b)$ and $g^{(k-1)}(a)$ are understood as $g^{(k-1)}(b-)$ and $g^{(k-1)}(a+)$, respectively.) Then

$$\|\mathfrak{p} - g\|_p \le c_{p,r,k}\omega_k(\mathfrak{p})_p.$$

Proof. Consider the following Lagrange (Hermite–Taylor) polynomials of order k on $[a,b]$:

$$l_k := l_k(\mathfrak{p}; \overbrace{a,\dots,a}^{\mu+1}, \overbrace{b,\dots,b}^{k-\mu-1}) \quad \text{and} \quad \widetilde{l}_k := \widetilde{l}_k(\mathfrak{p}; \overbrace{a,\dots,a}^{\mu}, \overbrace{b,\dots,b}^{k-\mu}).$$

By Corollary 8.4, both k-monotone functions $\mathfrak{p}$ and g lie between l_k and $\widetilde{l}_k$ in $[a,b]$, i.e.,

$$\min\{l_k, \widetilde{l}_k\} \le \min\{\mathfrak{p}, g\} \le \max\{\mathfrak{p}, g\} \le \max\{l_k, \widetilde{l}_k\}.$$

Therefore,

$$\|g - \mathfrak{p}\|_p \le \|l_k - \widetilde{l}_k\|_p \le c_p\|l_k - \mathfrak{p}\|_p + c_p\|\mathfrak{p} - \widetilde{l}_k\|_p \le c_{p,r,k}\omega_k(\mathfrak{p})_p,$$

where the last inequality follows from Lemma 8.2. ∎

In our proof, we need a slightly stronger statement in the case for $\mu = 0$.

LEMMA 8.6. *Let $k, r \in \mathbb{N}$, $0 < p \le \infty$, $I = (a, b)$, and $\mathfrak{p} \in \Pi_r \cap \mathcal{M}^k$, and let $h \in \mathcal{M}^k$ be a function such that*

$$h(a) = \mathfrak{p}(a) \quad \text{and} \quad h^{(i)}(b) = \mathfrak{p}^{(i)}(b),\ i = 0, \dots, k-2, \quad h^{(k-1)}(b-) \le \mathfrak{p}^{(k-1)}(b). \tag{8.4}$$

Then

$$\|\mathfrak{p} - h\|_p \le c_{p,r,k}\omega_k(\mathfrak{p})_p. \tag{8.5}$$

Proof. First, assume that there exists $\delta > 0$ such that $\mathfrak{p} \in \mathcal{M}^k(a, b+\delta)$, and set

$$g = \begin{cases} h & \text{on} \quad [a, b), \\ \mathfrak{p} & \text{on} \quad [b, b+\delta]. \end{cases}$$

Then g is k-monotone on $[a, b+\delta]$ and satisfies all other assumptions of Lemma 8.5 (with $\mu = 0$); hence

$$\|g - \mathfrak{p}\|_{\mathbb{L}_p[a,b+\delta]} \le c_{p,r,k}\omega_k(\mathfrak{p})_{\mathbb{L}_p[a,b+\delta]}.$$

Letting $\delta \to 0$, we obtain

$$\|h - \mathfrak{p}\|_{\mathbb{L}_p[a,b]} \le \lim_{\delta\to 0} \|g - \mathfrak{p}\|_{\mathbb{L}_p[a,b+\delta]} \le c_{p,r,k} \lim_{\delta\to 0} \omega_k(\mathfrak{p})_{\mathbb{L}_p[a,b+\delta]} = c_{p,r,k}\omega_k(\mathfrak{p})_{\mathbb{L}_p[a,b]}.$$

If, for any $\delta > 0$, $\mathfrak{p} \notin \mathcal{M}^k(a, b+\delta)$, one can replace $\mathfrak{p}$ by

$$\widetilde{\mathfrak{p}}(x) := \mathfrak{p}(x) + \epsilon(x-a)(x-b)^{k-1}.$$

Then $\widetilde{\mathfrak{p}} \in \Pi_{\max\{r,k+1\}} \cap \mathcal{M}^k(a, b+\Delta)$ for some $\Delta > 0$,

$$\widetilde{\mathfrak{p}}(a) = \mathfrak{p}(a), \quad \widetilde{\mathfrak{p}}^{(i)}(b) = \mathfrak{p}^{(i)}(b),\ 0 \le i \le k-2,$$

and

$$\widetilde{\mathfrak{p}}^{(k-1)}(b) = \mathfrak{p}^{(k-1)}(b) + (k-1)!\,\epsilon(b-a) \ge \mathfrak{p}^{(k-1)}(b) \ge h^{(k-1)}(b-).$$

Now using the same argument as above and letting $\epsilon \to 0$ and $\Delta \to 0$ complete the proof of the lemma. ∎

9. Proof of Proposition 4.2. The following statement summarizes the results of sections 5–8.

PROPOSITION 9.1. *Let $k \in \mathbb{N}$, $n = 2k^2$, $0 < p \le \infty$, $I = (a, b)$, and $\mathfrak{p} \in \Pi_r \cap \mathcal{M}^k$, and let $g_* \in \mathcal{S}_{C(k),k} \cap \mathcal{M}^k_*$ be such that*

$$g_*(t_j) = \mathfrak{p}(t_j) \quad \text{on} \quad \{a = t_0 < t_1 < \cdots < t_n < t_{n+1} = b\}.$$

Then there exists a spline z such that

$$z \in \mathcal{S}_{k',k} \cap \mathcal{M}^k[g_*, \mathfrak{p}]$$

and

$$\|\mathfrak{p} - z\|_p \le c_2\|\mathfrak{p} - g_*\|_p, \quad c_2 = c_2(p, r, k). \tag{9.1}$$

Proof. First, Corollary 7.4 implies that there exists a spline $z \in \mathcal{S}_{k',k} \cap \mathcal{M}^k[g_*, \mathfrak{p}]$. Now, since z satisfies condition (8.4) of Lemma 8.6 (which follows from the definition of the class $\mathcal{M}^k[g_*, \mathfrak{p}]$ and the fact that $g_*(a) = \mathfrak{p}(a)$), we have the estimate

$$\|\mathfrak{p} - z\|_p \le c_{p,r,k}\omega_k(\mathfrak{p})_p.$$

On the other hand, for $g_* \in \mathcal{S}_{C(k),k}$, Lemma 8.1 yields

$$\|\mathfrak{p} - g_*\|_p \ge c_{p,r,k}\omega_k(\mathfrak{p})_p.$$

Combining both estimates, we obtain (9.1). □

Remark 9.2. Applying Proposition 9.1 to $\widetilde{\mathfrak{p}}(t) := (-1)^k\mathfrak{p}(-t)$ and $\widetilde{g}_*(t) := (-1)^k g_*(-t)$, we conclude that there also exists a spline $\widetilde{z} \in \mathcal{S}_{k',k} \cap \mathcal{M}^k[\mathfrak{p}, g_*]$ for which (9.1) is valid.

We also need the following elementary statement.

LEMMA 9.3. *Let $(x_j)_{j=1}^{\infty}$ be such that $x_i \ne x_j$ if $i \ne j$, and $\lim_{j\to\infty} x_j = L$, and let, for some $k \ge 2$, f be $(k-2)$ times continuously differentiable in some ϵ-neighborhood of L and have one-sided $(k-1)$st derivatives at L. If $f(x_j) = 0$ for all j, then $f^{(i)}(L) = 0$ for $i = 0, \dots, k-2$ and either $f^{(k-1)}(L+) = 0$ or $f^{(k-1)}(L-) = 0$.*

Proof of Proposition 4.2. If $0 < p < \infty$, let $\mathfrak{f}_*$ be a best $\mathbb{L}_p$-approximant to $\mathfrak{p} \in \Pi_r \cap \mathcal{M}^k$ from the set $\mathcal{M}^k[f]$ whose existence is guaranteed by Lemma 3.3, and so Lemma 3.8 is valid. If $p = \infty$, we choose $\mathfrak{f}_*$ to be a best $\mathbb{L}_\infty$-approximant to $\mathfrak{p}$ from the set $\mathcal{M}^k[f]$ which satisfies Lemma 3.9.

We need to prove that there exists a spline s such that

$$s \in \mathcal{S}_{C(k),r} \cap \mathcal{M}^k[f] \tag{9.2}$$

and

$$\|\mathfrak{p} - s\|_p \le c_2\|\mathfrak{p} - \mathfrak{f}_*\|_p. \tag{9.3}$$

Lemmas 3.8 and 3.9 imply that, on any interval (c, d) where the difference $\mathfrak{f}_*(x) - \mathfrak{p}(x)$ has exactly $m-1$ distinct zeros, we have

$$\mathfrak{f}_* \in \mathcal{S}_{mk',k}, \quad k' = \lfloor k/2 \rfloor + 1. \tag{9.4}$$

Denote by $\mathfrak{Z}$ the set of all zeros of the function $\mathfrak{f}_* - \mathfrak{p}$, i.e.,

$$\mathfrak{Z} := \{x \in [a, b] \mid \mathfrak{f}_*(x) = \mathfrak{p}(x)\},$$

and let $\mathfrak{Z}^*$ be the set of all limit points of $\mathfrak{Z}$. Also, let $\#\mathfrak{Z}$ denote the cardinality of $\mathfrak{Z}$. (Note that the set $\mathfrak{Z}$ does not take into account multiplicity of zeros. This is not essential and is done only to simplify the exposition.)

The proof is quite transparent. If $\mathfrak{Z}$ consists of only a few (less than $4k^2 + 4$) points, (9.4) implies that $\mathfrak{f}_*$ has to be in $\mathcal{S}_{C(k),k}$, and so there is nothing to prove. If $\#\mathfrak{Z}$ is not less than $4k^2 + 4$ but is finite, we use Proposition 9.1 to blend $\mathfrak{f}_*$ and $\mathfrak{p}$ on intervals containing the first and the last $2k^2 + 2$ points from $\mathfrak{Z}$ (and hence $\mathfrak{f}_*$, which has many "knots" between these intervals, is replaced there by the polynomial $\mathfrak{p}$). Finally, if $\mathfrak{Z}$ is an infinite set, the set $\mathfrak{Z}^*$ is necessarily not empty and connected. Hence $\mathfrak{Z}^*$ is a closed subinterval of (or a point in) $[a, b]$. We will show that $\mathfrak{f}_* \equiv \mathfrak{p}$ on $\mathfrak{Z}^*$, and so it will remain to apply the above-mentioned argument in the case in which $\#\mathfrak{Z} < \infty$ to the set $[a, b] \setminus \mathfrak{Z}^*$ which is a union of at most two intervals.

We now fill in the details and consider the following three cases.

Case 1. $\#\mathfrak{Z} < 4k^2 + 4$. According to (9.4),

$$\mathfrak{f}_* \in \mathcal{S}_{C(k),k}, \quad C(k) \le (4k^2+4)k',$$

so we let $s = \mathfrak{f}_*$.

Case 2. $4k^2+4 \le \#\mathfrak{Z} < \infty$. Denote by $I_\nu := [a_\nu, b_\nu]$, $\nu = 1, 2$, the smallest closed subintervals of $[a, b]$ which contain the first and the last $2k^2+2$ points of $\mathfrak{Z}$, respectively (i.e., $a_1 = \min(\mathfrak{Z})$ and $b_2 = \max(\mathfrak{Z})$). By (9.4), $\mathfrak{f}_* \in \mathcal{S}_{(2k^2+1)k',k}(I_\nu)$, $\nu = 1, 2$, and hence, by Proposition 9.1 and Remark 9.2, we conclude that there exist two splines s_1, s_2 such that

$$s_1 \in S_{k',k} \cap \mathcal{M}^k[\mathfrak{f}_*, \mathfrak{p}](I_1), \quad s_2 \in S_{k',k} \cap \mathcal{M}^k[\mathfrak{p}, \mathfrak{f}_*](I_2),$$

and

$$\|\mathfrak{p} - s_\nu\|_{\mathbb{L}_p(I_\nu)} \le c_2 \|\mathfrak{p} - \mathfrak{f}_*\|_{\mathbb{L}_p(I_\nu)}. \tag{9.5}$$

Also note that $\mathfrak{f}_* \in \mathcal{S}_{k',k}[a, a_1]$ and $\mathfrak{f}_* \in \mathcal{S}_{k',k}[b_2, b]$, and define

$$s(x) = \begin{cases} \mathfrak{f}_*(x), & x \in [a, a_1] \cup [b_2, b], \\ s_1(x), & x \in [a_1, b_1], \\ \mathfrak{p}(x), & x \in [b_1, a_2], \\ s_2(x), & x \in [a_2, b_2]. \end{cases}$$

Then

$$s \in \mathcal{S}_{C(k),r} \cap \mathcal{M}^k[f](a, b), \quad C(k) \le 4k' + 1,$$

and, clearly, (9.3) is satisfied.

Case 3. $\#\mathfrak{Z} = \infty$. Clearly, the set of all limit points $\mathfrak{Z}^*$ is not empty in this case. Also, $\mathfrak{Z}^*$ is closed, and we now show that it has to be connected. This will imply that $\mathfrak{Z}^* = [c, d] \subset [a, b]$ (not excluding the possibility that $c = d$). Taking into account that $\mathfrak{f}_* - \mathfrak{p}$ is $(k-2)$ times continuously differentiable and has one-sided $(k-1)$st derivatives on $[a, b]$ (which is guaranteed by the assumption that $\mathfrak{f}_* \in \mathcal{M}^k[f]$), we apply Lemma 9.3 to conclude that, for every $x \in \mathfrak{Z}^*$, at least one of two relations takes place:

$$\mathfrak{f}_*^{(i)}(x\pm) = \mathfrak{p}^{(i)}(x), \quad i = 0, \dots, k-1.$$

Thus, if $\{c, d\} \subset \mathfrak{Z}^*$, then $\mathfrak{p} \in \mathcal{M}^k[\mathfrak{f}_*](c, d)$ so that the function

$$g_*(x) = \begin{cases} \mathfrak{f}_*(x), & x \in [a, b] \setminus [c, d], \\ \mathfrak{p}(x), & x \in [c, d], \end{cases}$$

is in $\mathcal{M}^k[\mathfrak{f}_*](a, b) \subset \mathcal{M}^k[f](a, b)$. Also, if $\mathfrak{f}_* \not\equiv \mathfrak{p}$ on $[c, d]$, then g_* approximates $\mathfrak{p}$ better (in the $\mathbb{L}_p$-metric) than $\mathfrak{f}_*$ on $[a, b]$ if $0 < p < \infty$ and not worse than $\mathfrak{f}_*$ if $p = \infty$. Therefore, we know (can assume) that $\mathfrak{f}_* \equiv \mathfrak{p}$ on $[c, d]$; hence $[c, d] \subset \mathfrak{Z}^*$.

Thus we can assume that $\mathfrak{Z}^* = [c, d]$ for some $[c, d] \subset [a, b]$. We also assume that $a < c \le d < b$, the cases in which $c = a$ or $d = b$ being analogous (and simpler).

Since $(a, c) \cap \mathfrak{Z}^* = \emptyset$, any closed subinterval of (a, c) contains finitely many points from $\mathfrak{Z}$.

Now, if $\#((a,c)\cap\mathfrak{Z})<2k^2+2$, (9.4) implies that $\mathfrak{f}_*\in\mathcal{S}_{(2k^2+2)k',k}[a,c]$, and we define the spline s_1 to be $\mathfrak{f}_*$ on $[a,c]$.

If, on the other hand, $\#((a,c)\cap\mathfrak{Z})\geq 2k^2+2$, then there exists $c'\in(a,c)$ such that $c'\in\mathfrak{Z}$, and the interval (a,c') contains exactly $2k^2+1$ points from $\mathfrak{Z}$. The same construction as in Case 2 allows us to obtain a k-monotone spline $\tilde{s}_1\in\mathcal{S}_{2k',k}(a,c')\cap\mathcal{M}^k[\mathfrak{f}_*,\mathfrak{p}]$ which "blends" $\mathfrak{f}_*$ with $\mathfrak{p}$ (in a k-monotone fashion) on (a,c') and approximates $\mathfrak{p}$ as well as $\mathfrak{f}_*$. Now we define s_1 by

$$s_1(x)=\begin{cases}\tilde{s}_1(x), & x\in[a,c'],\\ \mathfrak{p}(x), & x\in[c',c].\end{cases}$$

The same argument can now be used "at the right end" to yield a construction of $s_2\in\mathcal{S}_{(2k^2+2)k',k}[d,b]$ satisfying all conditions required.

Finally, we set

$$s(x)=\begin{cases}s_1(x), & x\in[a,c],\\ \mathfrak{p}(x), & x\in[c,d],\\ s_2(x), & x\in[d,b].\end{cases}$$

Then

$$s\in\mathcal{S}_{C(k),k}\cap\mathcal{M}^k[f][a,b],\quad C(k)\leq(4k^2+4)k'+1,$$

which completes the proof of Case 3 and of Proposition 4.2. □

FORMATION OF δ-SHOCKS AND VACUUM STATES IN THE VANISHING PRESSURE LIMIT OF SOLUTIONS TO THE EULER EQUATIONS FOR ISENTROPIC FLUIDS*

GUI-QIANG CHEN† AND HAILIANG LIU‡

Abstract. The phenomena of concentration and cavitation and the formation of δ-shocks and vacuum states in solutions to the Euler equations for isentropic fluids are identified and analyzed as the pressure vanishes. It is shown that, as the pressure vanishes, any two-shock Riemann solution to the Euler equations for isentropic fluids tends to a δ-shock solution to the Euler equations for pressureless fluids, and the intermediate density between the two shocks tends to a weighted δ-measure that forms the δ-shock. By contrast, any two-rarefaction-wave Riemann solution of the Euler equations for isentropic fluids is shown to tend to a two-contact-discontinuity solution to the Euler equations for pressureless fluids, whose intermediate state between the two contact discontinuities is a vacuum state, even when the initial data stays away from the vacuum. Some numerical results exhibiting the formation process of δ-shocks are also presented.

1. Introduction.

We are concerned with the phenomena of concentration and cavitation and the formation of δ-shocks and vacuum states in solutions to the Euler equations for compressible fluids as the pressure vanishes. In this paper, we consider the Euler equations of isentropic gas dynamics in Eulerian coordinates,

$$\partial_t \rho + \partial_x(\rho v) = 0, \tag{1.1}$$

$$\partial_t(\rho v) + \partial_x(\rho v^2 + P) = 0, \tag{1.2}$$

where ρ, P, and $m = \rho v$ represent the density, the scalar pressure, and the momentum, respectively; and ρ and m are in the physical region $\{(\rho, m) \,|\, \rho \geq 0, |m| \leq V_0\rho\}$ for some $V_0 > 0$. For $\rho > 0$, $v = m/\rho$ is the velocity with $|v| \leq V_0$. The scalar pressure P is a function of the density ρ and a small parameter $\epsilon > 0$ satisfying

$$\lim_{\epsilon \to 0} P(\rho, \epsilon) = 0.$$

For concreteness, we focus on the prototypical pressure function for polytropic gases:

$$P(\rho, \epsilon) = \epsilon p(\rho), \qquad p(\rho) = \rho^\gamma/\gamma, \quad \gamma > 1. \tag{1.3}$$

System (1.1)–(1.3) is an example of hyperbolic systems of conservation laws with form

$$\partial_t u + \partial_x f(u, \epsilon) = 0, \tag{1.4}$$

with $u = (\rho, \rho v)$ and $f(u, \epsilon) = (\rho v, \rho v^2 + \epsilon p(\rho))$. Observe that system (1.1)–(1.3) with parameter $\epsilon > 0$ is generic in the sense that such a system can also be obtained under the scaling

$$(x, t) \longrightarrow (\alpha x, \alpha t), \qquad \rho \longrightarrow \alpha \rho,$$

with $\alpha = \epsilon^{-1/(\gamma-1)}$ from system (1.1)–(1.2) with $p = p(\rho)$.

In Chang, Chen, and Yang [4, 5, 6], a phenomenon of concentration in solutions of the two-dimensional Riemann problem was first observed numerically, which led to the occurrence of so-called smoothed δ-shocks for the Euler equations of gas dynamics when the Riemann data produces four initial contact discontinuities with different signs and the initial pressure data is close to zero. One of the main objectives of this paper is to show rigorously that the phenomenon of concentration in solutions, observed numerically in [4, 5, 6], for inviscid compressible fluid flow is fundamental and occurs not only in the multidimensional situations but also naturally in the one-dimensional case.

The limit system as $\epsilon \to 0$ formally becomes the transport equations

$$\partial_t \rho + \partial_x (\rho v) = 0, \tag{1.5}$$

$$\partial_t (\rho v) + \partial_x (\rho v^2) = 0, \tag{1.6}$$

which are also called the one-dimensional system of pressureless Euler equations, modeling the motion of free particles which stick under collision (see [3, 11, 30]).

The transport equations (1.5)–(1.6) have been analyzed extensively since 1994; for example, see [1, 2, 3, 11, 12, 13, 17, 18, 19, 20, 22, 28, 29] and the references cited therein. In particular, the existence of measure solutions of the Riemann problem was first presented in Bouchut [1], and a connection of (1.5)–(1.6) with adhesion particle dynamics and the behavior of global weak solutions with random initial data were discussed in E, Rykov, and Sinai [11]. Also see [14, 15, 16, 21, 26, 27] for related equations and results. It has been shown that, for the transport equations (1.5)–(1.6), δ-shocks and vacuum states do occur in the Riemann solutions. Since the two eigenvalues of the transport equations coincide, the occurrence of δ-shocks and vacuum states as $t > 0$ can be regarded as a result of resonance between the two characteristic fields.

In this paper, we rigorously analyze the phenomena of concentration and cavitation and the formation of δ-shocks and vacuum states in solutions to the Euler equations for isentropic fluids as the pressure vanishes. The vanishing pressure limit can be regarded as a singular flux-function limit for hyperbolic systems of conservation laws (1.4). We show that such phenomena occur naturally in the one-dimensional case as the pressure vanishes: any two-shock Riemann solution to the Euler equations for isentropic fluids tends to a δ-shock solution to the Euler equations for pressureless fluids, and the intermediate density between the two shocks tends to a weighted δ-measure that forms a δ-shock; by contrast, any two-rarefaction-wave Riemann solution to the Euler equations for isentropic fluids tends to a two-contact-discontinuity solution to the Euler equations for pressureless fluids, whose intermediate state between the two contact discontinuities is a vacuum state even when the initial data

stays away from the vacuum. These results show that the δ-shocks for the transport equations result from a phenomenon of concentration, while the vacuum states result from a phenomenon of cavitation in the process of the vanishing pressure limit; both are fundamental and physical in fluid dynamics.

From the point of view of hyperbolic conservation laws, since the limit system loses hyperbolicity, the phenomena of concentration and cavitation in the process of the vanishing pressure limit can be regarded as phenomena of resonance between the two characteristic fields. These phenomena show that the flux-function limit can be very singular: the limit functions of solutions are no longer in the spaces of functions BV or L^∞; and the space of Radon measures, for which the divergences of certain entropy and entropy flux fields are also Radon measures, is a natural space in order to deal with such a limit in general. In this regard, a theory of divergence-measure fields has been established in Chen and Frid [7, 8, 9].

The organization of this paper is as follows. In section 2, we discuss the δ-shocks and vacuum states for the transport equations (1.5)–(1.6) and examine the dependence of the Riemann solutions on the parameter $\epsilon > 0$ for the Euler equations (1.1)–(1.3). In section 3, we analyze the formation of δ-shocks in the Riemann solutions to the Euler equations (1.1)–(1.3) as the pressure vanishes. In section 4, we analyze the formation of vacuum states in the Riemann solutions to (1.1)–(1.3), even when the initial data stays away from the vacuum, as the pressure decreases. In section 5, we present some representative numerical results, produced by using the higher order essentially nonoscillatory (ENO) scheme in [23, 24], to examine the phenomenon of concentration and the formation process of δ-shocks in the level of the Euler dynamics (1.1)–(1.3) as the pressure decreases.

2. δ-shocks, vacuum states, and Riemann solutions. In this section, we first discuss δ-shocks and vacuum states in the Riemann solutions to the transport equations (1.5)–(1.6), and then we examine the dependence of the Riemann solutions on the parameter $\epsilon > 0$ to the Euler equations (1.1)–(1.3).

2.1. δ-shocks and vacuum states for the transport equations. Consider the Riemann problem of the transport equations (1.5)–(1.6) with Riemann initial data

$$(\rho, v)(x, 0) = (\rho_\pm, v_\pm), \qquad \pm x > 0, \tag{2.1}$$

with $\rho_\pm > 0$. Since the equations and the Riemann data are invariant under uniform stretching of coordinates

$$(x, t) \to (\beta x, \beta t), \qquad \beta \text{ constant},$$

we consider the self-similar solutions of (1.5), (1.6), and (2.1):

$$(\rho, v)(x, t) = (\rho, v)(\xi), \quad \xi = x/t.$$

Then the Riemann problem is reduced to a boundary value problem for ordinary differential equations:

$$\begin{aligned} &-\xi\rho_\xi + (\rho v)_\xi = 0,\\ &-\xi(\rho v)_\xi + (\rho v^2)_\xi = 0,\\ &(\rho, v)(\pm\infty) = (\rho_\pm, v_\pm). \end{aligned}$$

As shown in [22], in the case in which $v_- < v_+$, we can obtain a solution $(\rho, v)(\xi)$ that consists of two contact discontinuities and a vacuum state which are uniquely determined by the Riemann data $(\rho_\pm, v_\pm)$. That is,

$$(\rho, v)(\xi) = \begin{cases} (\rho_-, v_-), & -\infty < \xi \le v_-, \\ (0, \xi), & v_- \le \xi \le v_+, \\ (\rho_+, v_+), & v_+ \le \xi < \infty. \end{cases}$$

In the case in which $v_- > v_+$, a key observation in [22] is that the singularity cannot be a jump with finite amplitude; that is, there is no solution which is piecewise smooth and bounded. Hence a solution containing a weighted δ-measure (i.e., δ-shock) supported on a line was constructed in order to establish the existence in a space of measures from the mathematical point of view (see also [26, 27]).

To define the measure solutions, the weighted δ-measure $w(t)\delta_S$ supported on a smooth curve $S = \{(x(s), t(s)) : a < s < b\}$ can be defined by

$$\langle w(\cdot)\delta_S, \psi(\cdot,\cdot)\rangle = \int_a^b w(t(s))\psi(x(s), t(s))\sqrt{x'(s)^2 + t'(s)^2}\, ds$$

for any $\psi \in C_0^\infty((-\infty, \infty) \times [0, \infty))$.

With this definition, a family of δ-measure solutions with parameter σ in the case in which $v_- > v_+$ can be obtained as

$$\rho(x,t) = \rho_0(x,t) + w(t)\delta_S, \qquad v(x,t) = v_0(x,t),$$

where $S = \{(\sigma t, t) : 0 \le t < \infty\}$,

$$\rho_0(x,t) = \rho_- + [\rho]\,\chi(x - \sigma t), \;\; v_0(x,t) = v_- + [v]\,\chi(x - \sigma t), \;\; w(t) = \frac{t}{1+\sigma^2}(\sigma[\rho] - [\rho v]),$$

in which $[h] := h_+ - h_-$ denotes the jump of function h across the discontinuity, and $\chi(x)$ is the characteristic (or indicator) function that is 0 when $x < 0$ and 1 when $x > 0$.

It was shown in [22] that the δ-measure solutions (ρ, v) constructed above satisfy

$$\langle \rho, \phi_t\rangle + \langle \rho v, \phi_x\rangle = 0, \tag{2.2}$$

$$\langle \rho v, \phi_t\rangle + \langle \rho v^2, \phi_x\rangle = 0 \tag{2.3}$$

for any $\phi \in C_0^\infty((-\infty, \infty) \times (0, \infty))$, where

$$\langle \rho, \phi\rangle = \int_0^\infty \int_{-\infty}^\infty \rho_0 \phi \, dx dt + \langle w\delta_S, \phi\rangle$$

and

$$\langle \rho v, \phi\rangle = \int_0^\infty \int_{-\infty}^\infty \rho_0 v_0 \phi \, dx dt + \langle \sigma w \delta_S, \phi\rangle.$$

A unique solution can be singled out by the so-called δ-Rankine–Hugoniot condition

$$\sigma = \frac{\sqrt{\rho_+}v_+ + \sqrt{\rho_-}v_-}{\sqrt{\rho_+} + \sqrt{\rho_-}} \tag{2.4}$$

that satisfies the δ-entropy condition

$$v_+ < \sigma < v_-. \tag{2.5}$$

The entropy condition (2.5) means that, in the (x,t)-plane, all the characteristic lines on either side of a δ-shock run into the line of δ-shock, which implies that a δ-shock is an overcompressive shock.

2.2. Riemann solutions to the Euler equations for isentropic fluids. The eigenvalues of system (1.1)–(1.3) are

$$\lambda_1 = v - c(\rho,\epsilon), \quad \lambda_2 = v + c(\rho,\epsilon) \qquad \text{for } \rho > 0$$

with

$$c(\rho,\epsilon) = \sqrt{\epsilon\, p'(\rho)} = \sqrt{\epsilon}\,\rho^{\theta}, \qquad \theta = \frac{\gamma-1}{2}.$$

The Riemann invariants are

$$w = v + \int_0^{\rho} \frac{\sqrt{\epsilon p'(s)}}{s} ds, \qquad z = v - \int_0^{\rho} \frac{\sqrt{\epsilon p'(s)}}{s} ds.$$

Then the Riemann solutions, which are functions of $\xi = x/t$, are solutions of

$$-\xi\rho_\xi + (\rho v)_\xi = 0, \tag{2.6}$$

$$-\xi(\rho v)_\xi + (\rho v^2 + \epsilon\, p(\rho))_\xi = 0, \tag{2.7}$$

$$(\rho, v)(\pm\infty) = (\rho_\pm, v_\pm). \tag{2.8}$$

Shock curves. The Rankine–Hugoniot conditions for discontinuous solutions of (1.1)–(1.3) are

$$-\sigma[\rho] + [\rho v] = 0, \qquad -\sigma[\rho v] + [\rho v^2 + \epsilon\, p(\rho)] = 0.$$

The Lax entropy inequalities imply

$$\rho_+ > \rho_- \ \text{(one-shock)}, \qquad \rho_+ < \rho_- \ \text{(two-shock)}.$$

Then, given a state $u_- = (\rho_-, \rho_- v_-)$, the shock curves in the phase plane, which are the sets of states that can be connected on the right by a one-shock or a two-shock, are the following.

One-shock curve $S_1(u_-)$:

$$v - v_- = -\sqrt{\frac{\epsilon\,(p(\rho) - p(\rho_-))}{\rho_-\rho(\rho-\rho_-)}}(\rho-\rho_-), \qquad \rho > \rho_-.$$

Two-shock curve $S_2(u_-)$:

$$v - v_- = -\sqrt{\frac{\epsilon\,(p(\rho) - p(\rho_-))}{\rho_-\rho(\rho-\rho_-)}}(\rho-\rho_-), \qquad \rho < \rho_-.$$

Then the shock curves are concave or convex, respectively, with respect to the point $u_- = (\rho_-, \rho_- v_-)$ in the $\rho - m$ plane with $m = \rho v$; that is, the quotient $\frac{m-m_-}{\rho-\rho_-}$ as a function of ρ is monotone.

We now turn to analyzing the Riemann solutions that consist of rarefaction waves and constant states. There are also two families of rarefaction waves, corresponding to characteristic fields λ_1 and λ_2, respectively.

Rarefaction wave curves. A rarefaction wave is a continuous solution of (2.6)–(2.8) of the form $(\rho, \rho v)(\xi)$, $\xi = x/t$, satisfying

$$\xi = v \mp \sqrt{\epsilon\, p'(\rho)}, \qquad -\xi\rho_\xi + (\rho v)_\xi = 0.$$

Then, given a state $u_- = (\rho_-, \rho_- v_-)$, the rarefaction-wave curves in the phase plane, which are the sets of states that can be connected on the right by a one-rarefaction or two-rarefaction wave, are the following.

One-rarefaction wave curve $R_1(u_-)$:

$$v - v_- = -\int_{\rho_-}^{\rho} \frac{\sqrt{\epsilon\, p'(s)}}{s} ds, \qquad \rho < \rho_-.$$

Two-rarefaction wave curve $R_2(u_-)$:

$$v - v_- = \int_{\rho_-}^{\rho} \frac{\sqrt{\epsilon\, p'(s)}}{s} ds, \qquad \rho > \rho_-.$$

The rarefaction wave curves are concave or convex, respectively, in the $\rho - m$ plane.

Given a left state $u_- = (\rho_-, \rho_- v_-)$, the set of states that can be connected on the right by a shock or a rarefaction wave in the phase plane consists of the one-shock curve $S_1(u_-)$, the one-rarefaction curve $R_1(u_-)$, the two-shock curve $S_2(u_-)$, and the two-rarefaction curve $R_2(u_-)$. These curves divide the phase plane into four regions $S_2S_1(u_-)$, $S_2R_1(u_-)$, $R_2S_1(u_-)$, and $R_2R_1(u_-)$; any right state of the Riemann data staying in one of them yields a unique global Riemann solution $R(x/t)$, which contains a one-shock (or a one-rarefaction wave) and/or a two-shock (or a two-rarefaction wave) satisfying

$$w(R(x/t)) \le w(u_+), \;\; z(R(x/t)) \ge z(u_-), \;\; w(R(x/t)) - z(R(x/t)) \ge 0.$$

In particular, when $u_+ \in S_2S_1(u_-)$, $R(x/t)$ contains a one-shock, a two-shock, and a nonvacuum intermediate constant state; and, when $u_+ \in R_2R_1(u_-)$, $R(x/t)$ contains a one-rarefaction wave, a two-rarefaction wave, and an intermediate constant state that may be a vacuum state. Since the other two regions $S_2R_1(u_-)$ and $R_2S_1(u_-)$ have empty interiors when $\epsilon \to 0$, it suffices to analyze the limit process for the two cases $u_+ \in S_2S_1(u_-)$ (in section 3) and $u_+ \in R_2R_1(u_-)$ (in section 4). For more details about Riemann solutions, see [10, 25].

3. Formation of δ-shocks. In this section, we study the formation of δ-shocks in the Riemann solutions to the Euler equations for isentropic fluids in the case $u_+ \in S_2S_1(u_-)$ with $v_- > v_+$ and $\rho_\pm > 0$ as the pressure vanishes.

3.1. Limiting behavior of the Riemann solutions as $\epsilon \to 0$. For fixed $\epsilon > 0$, let $u_*^\epsilon := (\rho_*^\epsilon, \rho_*^\epsilon v_*^\epsilon)$ be the intermediate state in the sense that u_- and u_*^ϵ are connected by one-shock S_1 with speed σ_1^ϵ and that u_*^ϵ and u_+ are connected by two-shock S_2 with speed σ_2^ϵ. Then $(\rho_*^\epsilon, v_*^\epsilon)$ are determined by

$$v_*^\epsilon - v_- = -\sqrt{\frac{\epsilon\,(p(\rho_*^\epsilon) - p(\rho_-))}{\rho_-\rho_*^\epsilon(\rho_*^\epsilon - \rho_-)}}(\rho_*^\epsilon - \rho_-), \qquad \rho_*^\epsilon > \rho_-, \tag{3.1}$$

and

$$v_+ - v_*^\epsilon = -\sqrt{\frac{\epsilon\,(p(\rho_+) - p(\rho_*^\epsilon))}{\rho_+\rho_*^\epsilon(\rho_+ - \rho_*^\epsilon)}}(\rho_+ - \rho_*^\epsilon), \qquad \rho_*^\epsilon > \rho_+. \tag{3.2}$$

Define $g(s,\tau)=\sqrt{(\frac{1}{s}-\frac{1}{\tau})(p(\tau)-p(s))}$ for $s,\tau>0$. Thus a combination of the jump conditions (3.1) and (3.2) gives

$$v_- - v_+ = \sqrt{\epsilon}\,(g(\rho_*^\epsilon,\rho_-)+g(\rho_*^\epsilon,\rho_+))>0. \tag{3.3}$$

Then one must have $\lim_{\epsilon\to 0} g(\rho_*^\epsilon,\rho_\pm)=\infty$, which yields $\lim_{\epsilon\to 0}\rho_*^\epsilon=\infty$. Letting $\epsilon\to 0$ in (3.3) yields

$$\lim_{\epsilon\to 0}\epsilon(\rho_*^\epsilon)^\gamma=\frac{\sqrt{\rho_-\rho_+}}{\sqrt{\rho_-}+\sqrt{\rho_+}}(v_- - v_+).$$

Therefore, we have the following lemma.

LEMMA 3.1. $\lim_{\epsilon\to 0}\epsilon^{1/\gamma}\rho_*^\epsilon=(\frac{\sqrt{\rho_-\rho_+}}{\sqrt{\rho_-}+\sqrt{\rho_+}}(v_- - v_+))^{1/\gamma}$.

LEMMA 3.2. *Set* $\sigma=\frac{\sqrt{\rho_-}v_-+\sqrt{\rho_+}v_+}{\sqrt{\rho_-}+\sqrt{\rho_+}}\in(v_+,v_-)$. *Then*

$$\lim_{\epsilon\to 0} v_*^\epsilon=\lim_{\epsilon\to 0}\sigma_1^\epsilon=\lim_{\epsilon\to 0}\sigma_2^\epsilon=\sigma$$

and

$$\lim_{\epsilon\to 0}\rho_*^\epsilon(\sigma_2^\epsilon-\sigma_1^\epsilon)=\sigma[\rho]-[\rho v].$$

Proof. First, Lemma 3.1 and (3.1)–(3.2) immediately imply that

$$\lim_{\epsilon\to 0} v_*^\epsilon=\sigma.$$

On the other hand, using the Lax entropy inequalities for the shocks, we have

$$v_*^\epsilon-\sqrt{\epsilon}\,(\rho_*^\epsilon)^\theta<\sigma_1^\epsilon<\min(v_*^\epsilon+\sqrt{\epsilon}\,(\rho_*^\epsilon)^\theta, v_- -\sqrt{\epsilon}\,(\rho_-)^\theta) \tag{3.4}$$

and

$$\max(v_*^\epsilon-\sqrt{\epsilon}\,(\rho_*^\epsilon)^\theta, v_+ +\sqrt{\epsilon}\,(\rho_+)^\theta)<\sigma_2^\epsilon<v_*^\epsilon+\sqrt{\epsilon}\,(\rho_*^\epsilon)^\theta. \tag{3.5}$$

Noting that $\sqrt{\epsilon}\,(\rho_*^\epsilon)^\theta=\epsilon^{\frac{1}{2\gamma}}(\epsilon^{1/\gamma}\rho_*^\epsilon)^\theta$, we can see from Lemma 3.1 that, for $\gamma>1$,

$$\lim_{\epsilon\to 0}\sqrt{\epsilon}\,(\rho_*^\epsilon)^\theta=0. \tag{3.6}$$

Then (3.4)–(3.6) yield

$$\lim_{\epsilon\to 0} v_*^\epsilon=\lim_{\epsilon\to 0}\sigma_1^\epsilon=\lim_{\epsilon\to 0}\sigma_2^\epsilon=\sigma. \tag{3.7}$$

The Rankine–Hugoniot conditions for (1.1) on the shocks and the results of (3.7) yield

$$\rho_*^\epsilon(\sigma_2^\epsilon-\sigma_1^\epsilon)=\sigma_2^\epsilon\,\rho_+-\sigma_1^\epsilon\,\rho_--[\rho v]\to\sigma[\rho]-[\rho v]\qquad\text{as}\quad\epsilon\to 0.$$

This completes the proof of Lemma 3.2. ∎

Remark 3.1. The quantity σ that is the limit of v_*^ϵ, σ_1^ϵ, and σ_2^ϵ uniquely determines the δ-shock solution of (1.5)–(1.6) as the limit of the Riemann solutions when $\epsilon\to 0$ and is consistent with the δ-Rankine–Hugoniot condition (2.4) and the δ-entropy condition (2.5), as proposed for the Riemann solutions for pressureless Euler equations.

3.2. Weighted δ-shocks. We now show the following theorem characterizing the vanishing pressure limit in the case in which $v_- > v_+$.

THEOREM 3.1. *Let $v_- > v_+$. For each fixed $\epsilon > 0$, assume that $(\rho^\epsilon, m^\epsilon) = (\rho^\epsilon, \rho^\epsilon v^\epsilon)$ is a two-shock solution of (1.1)–(1.3) with Riemann data $u_\pm = (\rho_\pm, \rho_\pm v_\pm)$, constructed in section 2.2. Then, when $\epsilon \to 0$, ρ^ϵ and m^ϵ converge in the sense of distributions, and the limit functions ρ and m are the sums of a step function and a δ-measure with weights*

$$\frac{t}{\sqrt{1+\sigma^2}}(\sigma[\rho] - [\rho v]) \quad \text{and} \quad \frac{t}{\sqrt{1+\sigma^2}}(\sigma[\rho v] - [\rho v^2]),$$

respectively, which form a δ-shock solution of (1.5)–(1.6) with the same Riemann data $u_\pm$.

Proof. 1. Set $\xi = x/t$. Then, for each fixed $\epsilon > 0$, the Riemann solution can be written as

$$\rho^\epsilon(\xi) = \begin{cases} \rho_- & \text{for } \xi < \sigma_1^\epsilon, \\ \rho_*^\epsilon(\xi) & \text{for } \sigma_1^\epsilon < \xi < \sigma_2^\epsilon, \\ \rho_+ & \text{for } \xi > \sigma_2^\epsilon \end{cases}$$

and

$$v^\epsilon(\xi) = \begin{cases} v_- & \text{for } \xi < \sigma_1^\epsilon, \\ v_*^\epsilon(\xi) & \text{for } \sigma_1^\epsilon < \xi < \sigma_2^\epsilon, \\ v_+ & \text{for } \xi > \sigma_2^\epsilon, \end{cases}$$

satisfying the following weak formulations: For any $\psi \in C_0^1(-\infty, \infty)$,

$$-\int_{-\infty}^{\infty} (v^\epsilon(\xi) - \xi)\rho^\epsilon(\xi)\,\psi'(\xi)d\xi + \int_{-\infty}^{\infty} \rho^\epsilon(\xi)\,\psi(\xi)\,d\xi = 0, \tag{3.8}$$

and

$$\begin{aligned} -\int_{-\infty}^{\infty} (v^\epsilon(\xi) - \xi)\rho^\epsilon(\xi)v^\epsilon(\xi)\,\psi'(\xi)d\xi + \int_{-\infty}^{\infty} \rho^\epsilon(\xi)v^\epsilon(\xi)\,\psi(\xi)d\xi \\ = \epsilon \int_{-\infty}^{\infty} p(\rho^\epsilon(\xi))\,\psi'(\xi)d\xi. \end{aligned} \tag{3.9}$$

2. The first integral in (3.8) can be decomposed into

$$-\left\{\int_{-\infty}^{\sigma_1^\epsilon} + \int_{\sigma_1^\epsilon}^{\sigma_2^\epsilon} + \int_{\sigma_2^\epsilon}^{\infty}\right\} (v^\epsilon(\xi) - \xi)\rho^\epsilon(\xi)\psi'(\xi)d\xi. \tag{3.10}$$

The sum of the first and last term of (3.10) is

$$\begin{aligned} &-\int_{-\infty}^{\sigma_1^\epsilon} (v_- - \xi)\rho_-\psi'(\xi)d\xi - \int_{\sigma_2^\epsilon}^{\infty} (v_+ - \xi)\rho_+\psi'(\xi)d\xi \\ &= -\rho_- v_-\psi(\sigma_1^\epsilon) + \rho_+ v_+\psi(\sigma_2^\epsilon) + \rho_-\sigma_1^\epsilon\psi(\sigma_1^\epsilon) - \rho_+\sigma_2^\epsilon\psi(\sigma_2^\epsilon) \\ &\quad - \int_{-\infty}^{\sigma_1^\epsilon} \rho_-\psi(\xi)d\xi - \int_{\sigma_2^\epsilon}^{\infty} \rho_+\psi(\xi)d\xi, \end{aligned}$$

which converges as $\epsilon \to 0$ to

$$([\rho v] - \sigma[\rho])\,\psi(\sigma) - \int_{-\infty}^{\infty} \rho_0(\xi - \sigma)\,\psi(\xi)d\xi$$

with

$$\rho_0(\xi) = \rho_- + [\rho]\,\chi(\xi),$$

where $\chi(\xi)$ is the characteristic function.

For the second term of (3.10),

$$\begin{aligned}
&\lim_{\epsilon\to 0}\int_{\sigma_1^\epsilon}^{\sigma_2^\epsilon} (v^\epsilon(\xi) - \xi)\rho^\epsilon(\xi)\psi'(\xi)d\xi \\
&\quad = \rho_*^\epsilon(\sigma_2^\epsilon - \sigma_1^\epsilon)\left\{ v_*^\epsilon \frac{\psi(\sigma_2^\epsilon) - \psi(\sigma_1^\epsilon)}{\sigma_2^\epsilon - \sigma_1^\epsilon} - \frac{\sigma_2^\epsilon\psi(\sigma_2^\epsilon) - \sigma_1^\epsilon\psi(\sigma_1^\epsilon)}{\sigma_2^\epsilon - \sigma_1^\epsilon} + \frac{1}{\sigma_2^\epsilon - \sigma_1^\epsilon}\int_{\sigma_1^\epsilon}^{\sigma_2^\epsilon} \psi(\xi)d\xi \right\},
\end{aligned}$$

which converges as $\epsilon \to 0$ to

$$([\rho v] - \sigma[\rho])\{-\sigma\psi'(\sigma) + \sigma\psi'(\sigma) + \psi(\sigma) - \psi(\sigma)\} = 0$$

since $\psi \in C_0^1(-\infty, \infty)$, $\lim_{\epsilon\to 0} v_*^\epsilon = \sigma$, and $\lim_{\epsilon\to 0} \sigma_j^\epsilon = \sigma$ for $j = 1, 2$.

Then the integral identity (3.8) yields

$$\lim_{\epsilon\to 0}\int_{-\infty}^{\infty} (\rho^\epsilon(\xi) - \rho_0(\xi - \sigma))\,\psi(\xi)d\xi = (\sigma[\rho] - [\rho v])\,\psi(\sigma)$$

for any function $\psi \in C_0^\infty(-\infty, \infty)$.

3. We now turn to justifying the limit of momentum $m^\epsilon = \rho^\epsilon v^\epsilon$ using the weak formulation (3.9). As done previously, we can obtain the limit for the first term on the left of (3.9) as

$$\begin{aligned}
&-\lim_{\epsilon\to 0}\int_{-\infty}^{\infty} (v^\epsilon(\xi) - \xi)\,\rho^\epsilon(\xi)v^\epsilon(\xi)\psi'(\xi)d\xi \\
&= \psi(\sigma)\,([\rho v^2] - \sigma[\rho v]) - \int_{-\infty}^{\sigma} \rho_- v_-\,\psi(\xi)d\xi - \int_{\sigma}^{\infty} \rho_+ v_+\,\psi(\xi)d\xi.
\end{aligned}$$

The term on the right of (3.9) equals

$$\epsilon\int_{-\infty}^{\infty} p(\rho^\epsilon)\,\psi'(\xi)d\xi = \epsilon\left\{\int_{-\infty}^{\sigma_1^\epsilon} + \int_{\sigma_1^\epsilon}^{\sigma_2^\epsilon} + \int_{\sigma_2^\epsilon}^{\infty}\right\} p(\rho^\epsilon)\,\psi'(\xi)d\xi,$$

which converges to

$$\begin{aligned}
&\epsilon\,\{p(\rho_-)\psi(\sigma_1^\epsilon) + p(\rho_*^\epsilon)(\psi(\sigma_2^\epsilon) - \psi(\sigma_1^\epsilon)) - p(\rho_+)\psi(\sigma_2^\epsilon)\} \\
&\quad = o(\epsilon) + \epsilon\,p(\rho_*^\epsilon)(\psi(\sigma_2^\epsilon) - \psi(\sigma_1^\epsilon)) \to 0 \qquad \text{as } \epsilon \to 0,
\end{aligned}$$

where we used the fact that $\epsilon p(\rho_*^\epsilon)$ is bounded and $\lim_{\epsilon\to 0} \sigma_j^\epsilon = \sigma$ for $j = 1, 2$.

Returning to the weak formulation (3.9), one has

$$\lim_{\epsilon\to 0}\int_{-\infty}^{\infty} ((\rho^\epsilon v^\epsilon)(\xi) - (\rho_0 v_0)(\xi - \sigma))\,\psi(\xi)d\xi = \psi(\sigma)(\sigma[\rho v] - [\rho v^2]).$$

4. Finally, we are in a position to study the limits of ρ^ϵ and $m^\epsilon = \rho^\epsilon v^\epsilon$ by tracking the time-dependence of the weights of the δ-measures as $\epsilon \to 0$.

Let $\phi(x,t) \in C_0^\infty((-\infty,\infty)\times[0,\infty))$ be a smooth test function, and let $\tilde{\phi}(\xi,t) := \phi(\xi t, t)$. Then we have

$$\lim_{\epsilon\to 0}\int_0^\infty\int_{-\infty}^\infty \rho^\epsilon(x/t)\phi(x,t)dxdt = \lim_{\epsilon\to 0}\int_0^\infty t\left(\int_{-\infty}^\infty \rho^\epsilon(\xi)\tilde{\phi}(\xi,t)d\xi\right)dt.$$

On the other hand, we have

$$\begin{aligned}\lim_{\epsilon\to 0}\int_{-\infty}^\infty \rho^\epsilon(\xi)\tilde{\phi}(\xi,t)d\xi &= \int_{-\infty}^\infty \rho_0(\xi-\sigma)\tilde{\phi}(\xi,t)d\xi + (\sigma[\rho]-[\rho v])\tilde{\phi}(\sigma,t)\\ &= t^{-1}\int_{-\infty}^\infty \rho_0(x-\sigma t)\phi(x,t)dx + (\sigma[\rho]-[\rho v])\phi(\sigma t,t).\end{aligned}$$

Combining the two relations above yields

$$\begin{aligned}&\lim_{\epsilon\to 0}\int_0^\infty\int_{-\infty}^\infty \rho^\epsilon(x/t)\phi(x,t)dxdt\\ &\quad= \int_0^\infty\int_{-\infty}^\infty \rho_0(x-\sigma t)\phi(x,t)dxdt + \int_0^\infty t([\rho v]-\sigma[\rho])\phi(\sigma t,t)dt.\end{aligned}$$

The last term, by the definition, equals

$$\langle w_1(\cdot)\delta_S, \phi(\cdot,\cdot)\rangle$$

with

$$w_1(t) = \frac{t}{\sqrt{1+\sigma^2}}(\sigma[\rho]-[\rho v]).$$

Similarly, we can show that

$$\begin{aligned}&\lim_{\epsilon\to 0}\int_0^\infty\int_{-\infty}^\infty m^\epsilon(x/t)\phi(x,t)dxdt\\ &\quad= \int_0^\infty\int_{-\infty}^\infty (\rho_0 v_0)(x-\sigma t)\phi(x,t)dxdt + \langle w_2(\cdot)\delta_S, \phi(\cdot,\cdot)\rangle\end{aligned}$$

with

$$w_2(t) = \frac{t}{\sqrt{1+\sigma^2}}(\sigma[\rho v]-[\rho v^2]).$$

This completes the proof of Theorem 3.1. □

4. Formation of vacuum states. In this section, we show the formation of vacuum states in the Riemann solutions of (1.1)–(1.3) in the case in which $u_+ \in R_2R_1(u_-)$ with $v_- < v_+$ and $\rho_\pm > 0$ as the pressure decreases.

As stated previously, on the rarefaction waves, the solution satisfies

$$\xi = x/t = v^\epsilon \pm \sqrt{\epsilon\, p'(\rho^\epsilon)} \tag{4.1}$$

for each fixed $\epsilon > 0$. More precisely, we have that, on the one-rarefaction wave,

$$\xi = v^\epsilon - \sqrt{\epsilon\, p'(\rho^\epsilon)}, \qquad v_- - \sqrt{\epsilon\, p'(\rho_-)} < \xi < v_*^\epsilon - \sqrt{\epsilon\, p'(\rho_*^\epsilon)}, \qquad \rho_- > \rho_*^\epsilon,$$

and, on the two-rarefaction wave,

$$\xi = v^\epsilon + \sqrt{\epsilon\, p'(\rho^\epsilon)}, \qquad v_*^\epsilon + \sqrt{\epsilon\, p'(\rho_*^\epsilon)} < \xi < v_+ + \sqrt{\epsilon\, p'(\rho_+)}, \qquad \rho_*^\epsilon < \rho_+,$$

where $(\rho_*^\epsilon, \rho_*^\epsilon v_*^\epsilon)$ is the intermediate state in the Riemann solutions. Since $(\rho_*^\epsilon, \rho_*^\epsilon v_*^\epsilon)$ is on the curve $R_1(u_-)$, we have

$$v_*^\epsilon = v_- - \int_{\rho_-}^{\rho_*^\epsilon} \frac{\sqrt{\epsilon\, p'(s)}}{s} ds \le v_- + \int_0^{\rho_-} \frac{\sqrt{\epsilon\, p'(s)}}{s} ds = v_- + \sqrt{\epsilon}\frac{\rho_-^\theta}{\theta} \equiv A^\epsilon.$$

When $v_- < v_+ < A^\epsilon$, that is,

$$\epsilon > \left(\frac{\theta(v_+ - v_-)}{\rho_-^\theta}\right)^2 \equiv \epsilon_0(u_-, u_+), \tag{4.2}$$

there is no vacuum in the solution. This implies that, for a fluid with strong pressure, no vacuum occurs in the solution generically.

However, when ϵ decreases so that $\epsilon < \epsilon_0(u_-, u_+)$, then $A^\epsilon < v_+$, and the intermediate state $(\rho_*^\epsilon, \rho_*^\epsilon v_*^\epsilon)$ becomes a vacuum state with

$$(\rho_*^\epsilon, v_*^\epsilon)(\xi) = (0, \xi), \qquad v_1^\epsilon \le \xi \le v_2^\epsilon,$$

where

$$v_1^\epsilon = v_- + \int_0^{\rho_-} \frac{\sqrt{\epsilon p'(s)}}{s} ds, \quad v_2^\epsilon = v_+ - \int_0^{\rho_+} \frac{\sqrt{\epsilon p'(s)}}{s} ds.$$

The uniform boundedness of $\rho^\epsilon(\xi)$ with respect to ϵ in this case leads to

$$\lim_{\epsilon\to 0} v_1^\epsilon = v_-, \qquad \lim_{\epsilon\to 0} v_2^\epsilon = v_+,$$

and

$$\lim_{\epsilon\to 0} v^\epsilon(\xi) = \xi \qquad \text{for } \xi \in (v_-, v_+).$$

In summary, the limit function (ρ, v) in this case is

$$(\rho, v)(\xi) = \begin{cases} (\rho_-, v_-), & -\infty < \xi \le v_-, \\ (0, \xi), & v_- \le \xi \le v_+, \\ (\rho_+, v_+), & v_+ \le \xi < \infty, \end{cases}$$

which is a solution to the transport equations (1.5)–(1.6) containing a vacuum state that fills up the region formed by the two contact discontinuities $\xi = x/t = v_\pm$.

We can clearly see from the analysis above that, when ϵ decreases, the left boundary of the one-rarefaction wave and the right boundary of the two-rarefaction wave are fixed, the right boundary of the one-rarefaction wave becomes closer to the left boundary of the one-rarefaction wave, and the left boundary of the two-rarefaction wave becomes closer to the right boundary of the two-rarefaction wave; while the state between the right boundary of the one-rarefaction wave and the left boundary of the two-rarefaction wave in the Riemann solution is a vacuum state; and, in the limit, the left boundary of the one-rarefaction wave and the right boundary of the two-rarefaction wave become two contact discontinuities of the transport equations (1.5)–(1.6), and the vacuum state fills up the region between the two contact discontinuities.

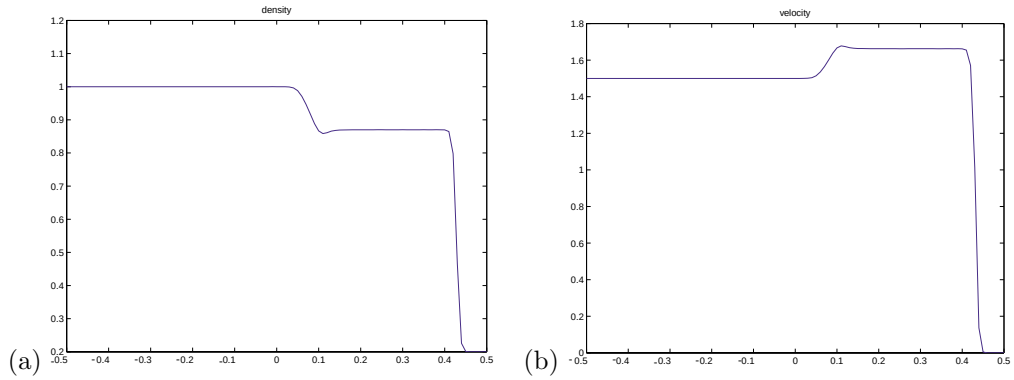

FIG. 5.1. *Density and velocity for* $\epsilon = 1.4$.

5. Formation process of δ-shocks: Numerical simulations. After the cavitation process in the Riemann solutions of (1.1)–(1.3) has been described clearly as the pressure decreases in section 4, understanding the formation process of δ-shocks in the Riemann solutions as the pressure decreases becomes more constructive for comparison. For this purpose, in this section we present a selected group of representative numerical results in the level of Euler dynamics (1.1)–(1.3) starting with Riemann initial data. We have performed many more numerical tests to make sure what we present are not numerical artifacts.

We solve the Riemann problem for (1.1)–(1.3) with $p(\rho) = \rho^\gamma/\gamma$ and $\gamma = 1.4$ for an ideal gas. The Riemann initial data is

$$(\rho, v)(x, 0) = \begin{cases} (1.0, 1.5) & \text{for} \quad x < 0, \\ (0.2, 0.0) & \text{for} \quad x > 0. \end{cases}$$

To discretize the system, we use the higher order ENO scheme to obtain a method-of-line ordinary differential equation in time and then discretize the ordinary differential equation by the classical higher order explicit Runge–Kutta method (see [23, 24]). We calculate by the third-order ENO scheme [24] up to $t = 0.2$ with mesh 100. The numerical simulations with different choices of ϵ are presented in Figures 5.1–5.3. These figures show the formation process of a δ-shock in the two-shock Riemann solutions for the Euler equations (1.1)–(1.3) for isentropic fluids as the pressure decreases. We start with $\epsilon/\gamma = 1.0$ and choose then $\epsilon/\gamma = 0.05$ and finally $\epsilon/\gamma = 0.001$. Figures 5.1a–5.3a show the concentration process of the density yielding a weighted δ-measure in the limit, in which the horizontal axis stands for the space variable x and the vertical axis stands for the density. Figures 5.1b–5.3b show the change of the velocity as ϵ decreases yielding a step function in the limit, in which the horizontal axis stands for the space variable x and the vertical axis stands for the velocity.

We can see clearly from these numerical results that, when ϵ decreases, the locations of the two shocks become closer, and the density of the intermediate state increases dramatically, while the velocity is closer to a step function. In the vanishing pressure limit, the two shocks coincide to form, along with the intermediate state, a δ-shock of the transport equations (1.5)–(1.6), while the velocity is a step function.

We remark that it is delicate to calculate solutions of hyperbolic systems of conservation laws that strict hyperbolicity fails, for which the system of pressureless Euler

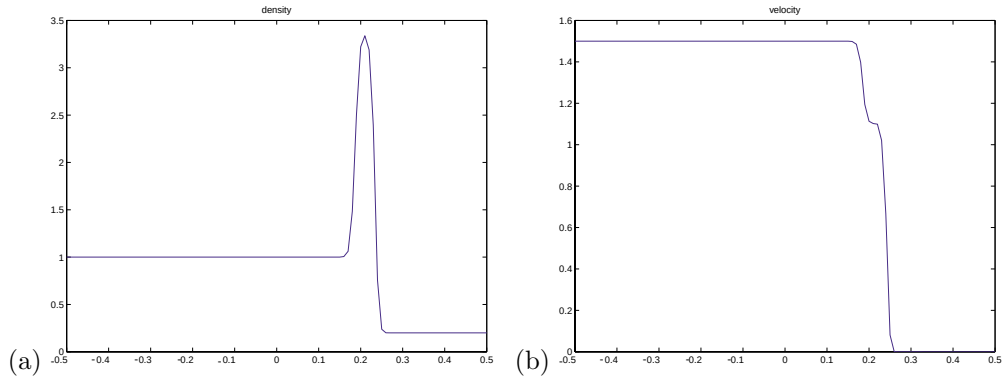

FIG. 5.2. *Density and velocity for* $\epsilon = 0.07$.

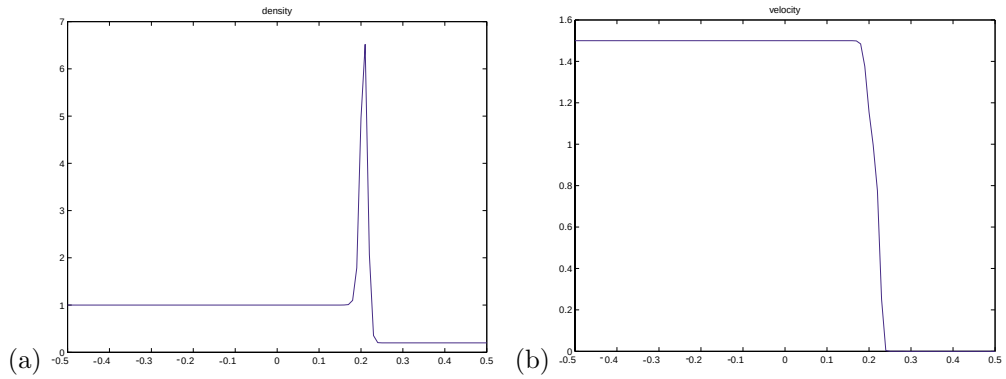

FIG. 5.3. *Density and velocity for* $\epsilon = 0.0014$.

equations for (1.5)–(1.6) is an example. In this section, we have proposed an efficient numerical approach to calculate the solutions containing δ-shocks for (1.5)–(1.6) via the vanishing pressure limit. It would be interesting to apply the approach and ideas set forth here to develop efficient numerical algorithms to calculate solutions for more complex physical models.

THE DECREASE OF BULK-SUPERCONDUCTIVITY CLOSE TO THE SECOND CRITICAL FIELD IN THE GINZBURG–LANDAU MODEL*

ETIENNE SANDIER† AND SYLVIA SERFATY‡

Abstract. We study solutions of the Ginzburg–Landau equations describing superconductors in a magnetic field, just below the "second critical field" H_{c_2}. We thus bridge the gap between the situations described in [E. Sandier and S. Serfaty, *Rev. Math. Phys.*, 12 (2000), pp. 1219–1257] and [X. B. Pan, *Comm. Math. Phys.*, 228 (2002), pp. 327–370]. We prove estimates on the energy, among them one by an algebraic trick inspired by the Bogomoln'yi trick for self-duality. We thus show how, for energy-minimizers, superconductivity decreases in average in the bulk of the sample when the applied field increases to H_{c_2}.

Key words. superconductivity, second critical field, phase transitions, asymptotic analysis

1. Introduction.

Superconductivity is modeled by the two-dimensional Ginzburg–Landau free energy

$$J(u,A)=\frac{1}{2}\int_\Omega |\nabla_A u|^2+|h-h_{\rm ex}|^2+\frac{\kappa^2}{2}(1-|u|^2)^2. \tag{1.1}$$

We are interested in studying critical points of this energy when the applied field $h_{\rm ex}$ gets close (from below) to the "second critical field" H_{c_2}.

Let us first explain the notation. Ω is a smooth, bounded, simply connected domain of $\mathbb{R}^2$, corresponding to the section of an infinite cylindrical body. J is a function of u, the "order parameter," complex-valued function, and of the "vector potential" $A:\Omega\mapsto\mathbb{R}^2$. u indicates the local state of the material, $|u|^2\le 1$ being the local density of superconducting electrons. Roughly speaking, where $|u|\sim 1$ it is the "superconducting phase," while where $|u|\sim 0$ it is the "normal phase." A is the potential associated to the magnetic field $h=\operatorname{curl} A=\partial_1 A_2-\partial_2 A_1$ (real-valued function) that exists in the sample. ∇_A denotes the covariant derivation $\nabla-iA$; it is an abelian gauge theory, and everything is invariant under gauge transformations: $u\to ue^{i\Phi}, A\to A+\nabla\Phi$. A configuration is really an orbit of gauge-equivalent couples (u,A).

The parameter $h_{\rm ex}$ is the intensity of the applied magnetic field (assumed to be uniform, parallel to the cylinder axis). Finally κ is the Ginzburg–Landau parameter; it is the ratio of two characteristic lengths of the material.

The equations associated to this functional are the Ginzburg–Landau equations

$$-\nabla_A^2 u = \kappa^2 u(1-|u|^2) \text{ in } \Omega, \tag{1.2}$$

$$-\nabla^\perp h = \langle iu, \nabla_A u\rangle \text{ in } \Omega, \tag{1.3}$$

$$h = h_{\text{ex}} \text{ on } \partial\Omega, \tag{1.4}$$

$$(\nabla u - iAu)\cdot \nu = 0 \text{ on } \partial\Omega, \tag{1.5}$$

where $\nabla^\perp$ denotes $(-\partial_2, \partial_1)$ and $\langle ., .\rangle$ is the scalar product in $\mathbb{C}$ identified with $\mathbb{R}^2$.

When type-II superconductors are submitted to a magnetic field, they exhibit phase transitions for certain critical fields, denoted H_{c_1}, H_{c_2}, and H_{c_3}. When $h_{\text{ex}} \leq H_{c_1}$, the sample is in the superconducting phase everywhere and repels the magnetic field (called the Meissner effect). At H_{c_1}, there is a phase transition where vortices appear. Vortices are zeros of the order parameter u around which u has a nonzero winding number. (For a mathematical description of vortices in Ginzburg–Landau without magnetic field, see [BBH] and subsequent works.) As h_{ex} increases, vortices get more and more numerous and tend to arrange in a triangular lattice, called an "Abrikosov lattice." When $H_{c_2} \leq h_{\text{ex}} \leq H_{c_3}$, the material is in the normal phase everywhere except on a layer near the boundary where superconductivity persists, while for $h_{\text{ex}} \geq H_{c_3}$ it is normal everywhere ($u \equiv 0$). For a more thorough physical presentation, one may see [DeG, SST, T].

We are interested in the "London limit" $\kappa \to +\infty$. We will also write $\varepsilon = \frac{1}{\kappa}$. ε is the lengthscale of a vortex. Letting $\varepsilon \to 0$ corresponds to having vortices that are small compared to the scale of the sample.

Mathematically, a lot of results have been proved on this functional. Let us start with the situation around the third critical field H_{c_3}. First, observe that there is always a trivial normal solution ($u \equiv 0, h \equiv h_{\text{ex}}$) and that its energy is $\frac{1}{4}|\Omega|\kappa^2$. When the applied field h_{ex} is decreased to H_{c_3}, there is a bifurcation from that normal solution to a branch of solutions with superconductivity on the boundary. This superconductivity actually first appears at H_{c_3} near the point of maximal curvature of the boundary.

The story goes back to Saint-James and de Gennes [SdG] and later Chapman [C], who studied the bifurcation in the half-space based on formal analysis. Rigorously, it was proved by Giorgi and Phillips [GP] that $H_{c_3} = O(\kappa^2)$ and that above H_{c_3} the only solution is the normal one. Then, in the particular case of a disc-domain, Bauman, Phillips, and Tang [BPT] considered radially symmetric solutions bifurcating from eigenfunctions. In a general domain, a formula relating H_{c_3} to the curvature of the boundary, as well as a result showing that eigenfunctions concentrate around the points of maximal curvature of the boundary, was first given by Bernoff and Sternberg in [BS] through a formal analysis, by Del Pino, Felmer, and Sternberg [DFS], and simultaneously by Lu and Pan in [LP3], based on the linear analysis of [LP1, LP2]. Finally, Helffer and Pan, using the analysis of [HM], obtained in [HP] the most accurate result, stating that superconductivity first appears at H_{c_3} near the point of maximum curvature of the boundary and that

$$H_{c_3} \sim_{\kappa\to\infty} \frac{\kappa^2}{\beta_0} + \left(\frac{C_1}{\beta_0^{3/2}} k_{max}\right)\kappa, \tag{1.6}$$

where β_0 is the lowest eigenvalue of a Schrödinger operator with magnetic field in the half-plane, and k_{max} is the maximum of the curvature on the boundary of Ω.

Let us now turn to the situation further below H_{c_3}. Recently, Pan proved in [P1] a very nice result describing global minimizers of the energy between H_{c_2} and H_{c_3}. He showed that H_{c_2} can be defined as the infimum of h_{ex} such that global minimizers of J do not have *bulk-superconductivity* but only surface-superconductivity, and that

$$H_{c_2} \sim_{\kappa\to\infty} \kappa^2. \tag{1.7}$$

Following his notation, we define b by

$$h_{\text{ex}} = (b + o(1))\kappa^2, \tag{1.8}$$

and we will also denote by J_D the Ginzburg–Landau functional restricted to a subdomain D of Ω.

He proved the following.

THEOREM 1.1 (Pan [P1]). *Let (u, A) be a minimizer of J. For $1 < b < \frac{1}{\beta_0}$, there exist positive numbers E_b and κ_b such that for $\kappa > \kappa_b$,*

$$J(u, A) \sim_{\kappa\to\infty} \frac{|\Omega|}{4}\kappa^2 - \kappa E_b|\partial\Omega| + o(\kappa), \tag{1.9}$$

where $|\Omega|$ denotes the volume of Ω and $|\partial\Omega|$ denotes the length of $\partial\Omega$. For any closed subdomain D of $\overline{\Omega}$, for $\kappa > \kappa_D$,

$$J_D(u, A) \sim_{\kappa\to\infty} \frac{|D \cap \Omega|}{4}\kappa^2 - \kappa E_b|D \cap \partial\Omega| + o(\kappa). \tag{1.10}$$

Moreover, $\frac{1}{\kappa}|\nabla_A u|$ and $|u|$ exponentially decay in the interior of Ω in the sense that for all $\alpha > 0$, for $\kappa > \kappa(\alpha)$,

$$\int_\Omega \left(|u|^2 + \frac{1}{\kappa^2}|\nabla_A u|^2\right) \exp(\alpha\kappa dist(x, \partial\Omega))\, dx \le \frac{O(1)}{\kappa}.$$

He also proved results for the case $b = 1$. Let us point out that slightly stronger exponential-decay results have been proved by Almog in [Al1] replacing the large-kappa limit by the large-domain limit.

Thus, when h_{ex} is decreased and crosses H_{c_3}, superconductivity first nucleates at the points of maximal curvature of the boundary, and u is a small perturbation of the normal solution 0. As h_{ex} further decreases, a uniform superconducting sheath of scale $\varepsilon = \frac{1}{\kappa}$ rapidly forms on the entire boundary of the sample, while the bulk remains normal as shown in the previous theorem. Superconductivity increases on the boundary as $b \to 1$.

On the other hand, the situation is also well understood for small applied fields: the superconducting state below H_{c_1} has been studied in [S1, S3, SS1]; the value of H_{c_1} being asymptotic to $C(\Omega)\log\kappa$ was proved in [S1, SS1, SS5]. Above H_{c_1}, we showed vortices appear first near the center of the domain [S1, S2], and a vortex region where the density of vortices is uniform and proportional to h_{ex}, surrounded by a purely superconducting region, forms and inflates (see [SS3]). As soon as $h_{\text{ex}} \gg \log\kappa$, the vortex region covers up the whole sample, and we have proved the following.

THEOREM 1.2 (Sandier and Serfaty [SS2]). *Assume h_{ex} is any function of κ such that $\log\kappa \ll h_{\text{ex}} \ll \kappa^2$ as $\kappa \to \infty$. If (u, A) is a corresponding minimizer of J, then*

$$J(u, A) \sim_{\kappa\to\infty} \frac{1}{2}|\Omega| h_{\text{ex}} \log\frac{\kappa}{\sqrt{h_{\text{ex}}}}, \tag{1.11}$$

where $|\Omega|$ denotes the volume of Ω; and if D is any closed subdomain of $\overline{\Omega}$, then

$$J_D(u,A) \sim_{\kappa\to\infty} \frac{1}{2}|D|h_{\rm ex}\log\frac{\kappa}{\sqrt{h_{\rm ex}}}. \tag{1.12}$$

Moreover, the density of vortices converges in some sense to the uniform density $h_{\rm ex}$.

In this regime $h_{\rm ex}\ll\kappa^2$, the superconducting phase surrounding the vortices still dominates in the sense that, from estimate (1.11), $\int_\Omega(1-|u|^2)^2=o(1)$. Essentially, one can think of the vortices as of degree 1 and placed regularly, for example, on a periodic lattice, one per cell of size $\frac{1}{\sqrt{h_{\rm ex}}}$, which remains much larger than their characteristic size ε (as long as $h_{\rm ex}\ll\kappa^2$).

The question is thus to bridge the gap between the situations of these two theorems (that of $h_{\rm ex}\ll\kappa^2$, i.e., $b=0$, and that above H_{c_2}, i.e., $b>1$) in the only range of applied fields which remained unstudied: $b\in[0,1]$. How do the vortices disappear and how does the bulk superconductivity disappear? Essentially two scenarios could be suggested. One is that as $h_{\rm ex}$ increases, the distance between the vortices decreases, and before it becomes smaller than their size $O(\varepsilon)$, the vortices merge into one "giant vortex" of large degree. The other scenario is that $\max|u|$ decreases in the bulk, while the vortex array structure remains unchanged, until $|u|$ is close to 0 in the bulk, and superconductivity remains only on the boundary, as described by Pan. It is considered by physicists that it is the second scenario rather than the first which occurs, at least in this limit $\kappa\to\infty$, and the results we prove confirm this. However, giant vortices do occur (and are observed) for smaller κ.

We start with a general lower bound result, proved through a very simple argument. Introducing the operator $\mathcal{D}_A=\partial_1+i\partial_2-i(A_1+iA_2)$, we have the identity

$$|\mathcal{D}_A u|^2=|\nabla_A u|^2-\operatorname{curl}(iu,\nabla_A u)-|u|^2h. \tag{1.13}$$

This operator is the one that was used by Bogomoln'yi (see [JT]) to exhibit the self-duality of the Ginzburg–Landau equations for $\kappa=\frac{1}{\sqrt{2}}$. By a purely algebraic manipulation quite similar to the trick of Bogomoln'yi (the same kind of manipulation was also behind the results of [M] and [GP]), we deduce from (1.13) the following *nontrivial* lower bound.

PROPOSITION 1.3. *Let (u,A) be any solution of the Ginzburg–Landau system (1.2)–(1.5) and $B\subset\Omega$ any ball of radius $R\gg\varepsilon=\frac{1}{\kappa}$. Then if $b\geq 1$,*

$$\frac{J_B(u,A)}{|B|}\geq\frac{\kappa^2}{4}+o(\kappa^2), \tag{1.14a}$$

while if $b\leq 1$,

$$\begin{aligned}\frac{J_B(u,A)}{|B|}&=\left(\frac{b}{2}-\frac{b^2}{4}\right)\kappa^2+\frac{1}{2|B|}\int_B|\mathcal{D}_A u|^2+\frac{\kappa^2}{2}(1-b-|u|^2)^2+|h-h_{\rm ex}|^2+o(\kappa^2)\\&\geq\left(\frac{b}{2}-\frac{b^2}{4}\right)\kappa^2+o(\kappa^2).\end{aligned} \tag{1.14b}$$

By this we mean that given a function $R(\kappa)\gg 1/\kappa$, there exists a function $o(\kappa^2)$ such that the above inequalities are verified for any solution of (1.2)–(1.5).

Observe that this estimate is true for *any solution* of the equations, not necessarily minimizing or stable. It is in fact true for any configuration that satisfies the a priori estimates $\|u\|_{L^\infty(\overline{\Omega})}\leq 1$, $\|\nabla_A u\|_{L^\infty(\overline{\Omega})}\leq C\kappa$, $\|h-h_{\rm ex}\|_{L^\infty(\overline{\Omega})}\leq C\kappa$ (see the proof).

Let us now turn to energy-minimizers. We denote by $\min J_{B_R}$ the minimum of the energy-functional on a ball B_R, i.e.,

$$\min J_{B_R} = \min_{(u,A)} \frac{1}{2} \int_{B_R} |\nabla_A u|^2 + |\operatorname{curl} A - h_{\text{ex}}|^2 + \frac{\kappa^2}{2}(1-|u|^2)^2.$$

We also denote by $(\overline{u}, \overline{A})$ a minimizer for this problem.

THEOREM 1.4. *Let $0 \leq b \leq 1$. There exists a continuous increasing function f from $[0,1]$ to $[0, \frac{1}{4}]$ such that, as $\kappa \to \infty$, for (u,A) any minimizer of J, for all $R_\kappa \gg \varepsilon = \frac{1}{\kappa}$, and for all balls B_{R_κ} in Ω,*

$$\frac{J_{B_R}(u,A)}{\kappa^2 |B_R|} \sim \frac{\min J_{B_R}}{\kappa^2 |B_R|} \longrightarrow f(b), \tag{1.15}$$

$$\frac{1}{|B_R|} \int_{B_R} |u|^4 \sim \frac{1}{|B_R|} \int_{B_R} |\overline{u}|^4 \longrightarrow 1 - 4f(b), \tag{1.16}$$

$$|u|^4 \rightharpoonup 1 - 4f(b) \quad \text{in } L^\infty \text{ weak-}*, \tag{1.17}$$

$$\frac{1-4f(b)}{1-b} - o(1) \leq \frac{1}{|B_R|} \int_{B_R} |u|^2 \leq \sqrt{1-4f(b)} + o(1), \tag{1.18}$$

and the following estimates hold: There exists universal constants $0 < \alpha < 1$ and $c > 0$ such that

$$\frac{b}{2} - \frac{b^2}{4} \leq f(b) \leq \min\left(\frac{b}{4}\left(\log \frac{1}{b} + c \right), \frac{1-\alpha(1-b)^2}{4} \right) \leq \frac{1}{4}, \tag{1.19}$$

and hence

$$\alpha(1-b)^2 \leq 1 - 4f(b) \leq (1-b)^2.$$

COROLLARY 1.5. *For all D closed subdomains of $\overline{\Omega}$,*

$$J_D(u,A) \sim_{\kappa \to \infty} |D| f(b) \kappa^2.$$

COROLLARY 1.6. *$f(0) = 0$ and $f(1) = \frac{1}{4}$. Therefore for $b = 0$ and for all $R_\kappa \gg \varepsilon$ we get the following result proved in* [SS2]:

$$\lim_{\kappa \to \infty} \frac{J_{B_R}(u,A)}{\kappa^2 |B_R|} = 0.$$

For $b \geq 1$ and for all $R_\kappa \gg \varepsilon$ we get

$$\lim_{\kappa \to \infty} \frac{J_{B_R}(u,A)}{\kappa^2 |B_R|} = \frac{1}{4},$$

which follows also from [P1] *and Proposition* 1 *in* [SS2].

We thus show that the loss of superconductivity happens through a decrease of the average of $|u|^4$, such as $(1-b)^2$ in Ω, and that the energy-repartition remains uniform. Those two facts go in the direction of the second scenario.

We have given asymptotic estimates of the minimal energy which extend that of (1.11). We have proved that the energy is uniformly spread over Ω and that a minimizer almost minimizes locally the energy at any scale $\gg \varepsilon$ (ε being the characteristic

scale of variation of u). At scales $O(\varepsilon)$ this ceases to be true: minimizers in regions of smaller sizes start to depend greatly on the region-size, as seen in [AD]. We have also shown that for global minimizers, some superconductivity remains in the bulk as long as $b < 1$, since from (1.18) the average of $|u|^2$ remains larger than $\alpha(1-b)$.

This theorem relies on upper and lower bounds for the energy, in the spirit of gamma-convergence. It seems difficult to give a more explicit expression or a finer estimate on $f(b)$. The lower bound is given by Proposition 1.3. The upper bound is obtained by constructing test configurations. They are chosen to be periodic with respect to a square lattice of size $\sqrt{\frac{2\pi}{b}}\varepsilon$, with a vortex of degree 1 in each cell. In view of (1.14), a minimizer (u, A) should almost be a minimizer of $\frac{1}{2}\int_\Omega |\mathcal{D}_A u|^2 + |h - b\kappa^2|^2 + \frac{\kappa^2}{2}(1-b-|u|^2)^2$. We choose our test configuration to satisfy $|u| \leq C\sqrt{1-b}$ and also $\mathcal{D}_A u = 0$ (following somewhat the construction of [JT] of vortex solutions in the self-dual case). This configuration of course has no reason to be optimal (nor does the square-shape) but gives the right order of energy.

We get as a corollary of Proposition 1.3 and Theorem 1.4 that, for energy-minimizers,

$$\begin{aligned}\limsup_{\kappa\to\infty} \frac{1}{2\kappa^2|B_R|}\int_{B_R} |\mathcal{D}_A u|^2 + \frac{\kappa^2}{2}(1-b-|u|^2)^2 + |h-h_{\text{ex}}|^2 \leq\ & f(b) - \frac{b}{2} + \frac{b^2}{4} \\ \leq\ & \frac{1-\alpha}{4}(1-b)^2\end{aligned}$$

and that

$$\frac{1}{R^2}\int_{B_R} (1-b-|u|^2)^2 \leq (1-\alpha)(1-b)^2, \tag{1.20}$$

from which one can deduce (1.18). It is also tempting, in view of (1.14), to think that $|u|^2 \leq C(1-b)$ in the bulk.

There remain many open questions on the behavior of minimizers, which all seem quite delicate.

First of all, we conjecture that, next to an interior point of Ω, a minimizing solution should converge, after blow-up at the scale ε, to a unique limiting profile in $\mathbb{R}^2$. A much more difficult task would be to show that this limiting profile is periodic. For a study of periodic solutions of Ginzburg–Landau, see [Du], [C], and [Al2].

We have not mentioned vortices of the minimizers. It is difficult to describe them and even define them: $|u|$ becomes uniformly small, so one can no longer define the vortices as the regions where $|u|$ is small. Nevertheless, there should be vortices (they appear in our upper bound construction), with a total degree $2\pi h_{\text{ex}}$ on the boundary of Ω. Heuristically, using the second Ginzburg–Landau equation,

$$-\frac{\nabla^\perp h}{\rho^2} + h = \nabla\varphi,$$

where we write $u = \rho e^{i\varphi}$ in polar coordinates. Taking the curl of this equation, we are led to

$$\text{div}\ \left(\frac{\nabla h}{\rho^2}\right) + h = \pi\sum_i d_i\delta_{a_i},$$

where the a_i are the zeros (or vortices) of u, and d_i their degrees or winding number.

Since $h \to h_{\rm ex}$ strongly, we should have, at least formally,

$$2\pi \sum_i d_i \delta_{a_i} \sim h_{\rm ex}$$

(as we had for $h_{\rm ex} \ll \kappa^2$). However, it seems difficult to give a rigorous meaning to this statement. We can prove that on any subdomain D of volume $R^2 \gg \frac{1}{\kappa^2}$ such that $|u| > c > 0$ independently of κ on ∂D, and such that the perimeter of D is less than $O(R)$, the total degree of u on ∂D is equivalent to $h_{\rm ex}|D|$. But the existence of such a D is not proved.

To conclude, it would be very nice, but certainly difficult, to prove a bifurcation at H_{c_2} from the surface-superconductivity solution to one of the known periodic-like vortex solutions.

2. The algebraic trick. From now on, we denote $h = \operatorname{curl} A$ and $u = \rho e^{i\varphi}$ in polar coordinates. Then

$$|\nabla_A u|^2 = |\nabla \rho|^2 + \rho^2 |\nabla \varphi - A|^2.$$

We are interested in this section in studying families of solutions of Ginzburg–Landau, or configurations which satisfy the following a priori estimates.

LEMMA 2.1. *If (u, A) is a solution of Ginzburg–Landau, we have*

$$\|h - h_{\rm ex}\|_{C^1(\overline{\Omega})} \le C\kappa, \qquad \|h - h_{\rm ex}\|_{C^2(\overline{\Omega})} \le C\kappa^2, \tag{2.1}$$

$$\|\nabla_A u\|_{L^\infty(\overline{\Omega})} \le C\kappa, \qquad \|\nabla \rho\|_{L^\infty(\overline{\Omega})} \le C\kappa, \tag{2.2}$$

$$e_\kappa(u, A) := |\nabla_A u|^2 + |h - h_{\rm ex}|^2 + \frac{\kappa^2}{2}(1 - \rho^2)^2 \le C\kappa^2. \tag{2.3}$$

These estimates are proved in [HP, Proposition 4.3]; see also [P1, Lemma 7.1]. They rely on a blow-up at scale $\varepsilon = \frac{1}{\kappa}$, which leads to equations at scale 1, for which all the quantities are uniformly bounded.

Proof of Proposition 1.3. As already mentioned, the proof relies on the Bogomoln'yi identity on the operator $\mathcal{D}_A = \partial_1 + i\partial_2 - i(A_1 + iA_2)$. One can check that, in polar coordinates,

$$|\mathcal{D}_A u|^2 = |\rho(\nabla \varphi - A) - \nabla^\perp \rho|^2. \tag{2.4}$$

Expanding the square on the right-hand side, one gets the crucial identity

$$|\mathcal{D}_A u|^2 = |\nabla_A u|^2 - \operatorname{curl} j - \rho^2 h, \tag{2.5}$$

where j is the superconducting current $\langle iu, \nabla_A u \rangle$. Inserting (2.5) in J, we are led to

$$J_{B_R}(u, A) = \frac{1}{2} \int_{B_R} |\mathcal{D}_A u|^2 + \operatorname{curl} j + \rho^2 h + |h - h_{\rm ex}|^2 + \frac{\kappa^2}{2}(1 - \rho^2)^2. \tag{2.6}$$

Moreover, using the fact that $|j| \le |\nabla_A u| \le C\kappa$ with (2.2), we have

$$\left| \int_{B_R} \operatorname{curl} j \right| = \left| \int_{\partial B_R} j \cdot \tau \right| \le \int_{\partial B_R} |j| \le O(R\kappa). \tag{2.7}$$

Also $h = h_{\rm ex} + O(\kappa) = b\kappa^2 + o(\kappa^2)$ in view of (2.1). Combining these facts with (2.6) yields

(2.8)
$$\begin{aligned} J_{B_R}(u,A) &= \frac{1}{2}\int_{B_R} |\mathcal{D}_A u|^2 + \rho^2 b\kappa^2 + \frac{\kappa^2}{2}(1-\rho^2)^2 + |h-h_{\rm ex}|^2 + O(R\kappa) + o(R^2\kappa^2) \\ &= \frac{1}{2}\int_{B_R} |\mathcal{D}_A u|^2 + \kappa^2\left(\frac{1}{2} + \rho^2(b-1) + \frac{\rho^4}{2}\right) + |h-h_{\rm ex}|^2 + O(R\kappa) + o(R^2\kappa^2). \end{aligned}$$

If $b \geq 1$, this immediately implies that

$$\frac{J_{B_R}(u,A)}{\kappa^2|B_R|} \geq \frac{1}{4} + o(1).$$

(Thus, we see why the value $b = 1$ plays a particular role.)

If $b \leq 1$, we observe that $\rho^2(b-1) + \frac{\rho^4}{2} = \frac{1}{2}(\rho^2 - (1-b))^2 - \frac{1}{2}(1-b)^2$ and obtain

(2.9)
$$\begin{aligned} J_{B_R}(u,A) = |B_R|\frac{\kappa^2}{4}(1-(1-b)^2) + \frac{1}{2}\int_{B_R} |\mathcal{D}_A u|^2 + \frac{\kappa^2}{2}(1-b-\rho^2)^2 + |h-h_{\rm ex}|^2 \\ + O(R\kappa) + o(R^2\kappa^2). \end{aligned}$$

We conclude that (1.14) holds. ∎

3. Energy localization and convergence. We are now interested in families of global minimizers of J. The following lemma allows us to localize all energy comparisons.

LEMMA 3.1. *Let R_κ be such that $R_\kappa \gg \varepsilon$. Then, (u,A) being a minimizer of J, for any ball B_R of radius R_κ in Ω,*

$$\frac{J_{B_R}(u,A)}{\kappa^2|B_R|} = \frac{\min J_{B_R}}{\kappa^2|B_R|} + o(1).$$

Proof. One inequality is obvious:

$$J_{B_R}(u,A) \geq \min J_{B_R}.$$

The converse relies on a comparison argument. Let $(\tilde{u},\tilde{A})$ be a minimizer of J_{B_R}. We construct a test configuration in Ω which coincides with (u,A) in $\Omega\backslash B_R$, and with $(\tilde{u},\tilde{A})$ in $B_{R-3\varepsilon}$.

Let χ be a $C^\infty(\Omega)$ function such that

(3.1)
$$\begin{cases} \chi(x) = 1 & \text{in } \Omega\backslash B_R, \\ \chi(x) = 0 & \text{in } B_{R-\frac{\varepsilon}{2}}\backslash B_{R-\frac{5}{2}\varepsilon}, \\ \chi(x) = 1 & \text{in } B_{R-3\varepsilon}, \\ |\nabla\chi| \leq \dfrac{C}{\varepsilon}, \\ \displaystyle\int_\Omega |\nabla\chi|^2 \leq O\left(\frac{R}{\varepsilon}\right). \end{cases}$$

We define $(\overline{u}, \overline{A})$ by

$$(\overline{u}, \overline{A}) = (\chi u, A) \text{ in } \Omega \backslash B_{R-\varepsilon},$$
$$(\overline{u}, \overline{A}) = (\chi \tilde{u}, \tilde{A}) \text{ in } B_{R-2\varepsilon}.$$

There remains the matter of extending $(\overline{u}, \overline{A})$ in $B_{R-\varepsilon} \backslash B_{R-2\varepsilon}$. We take $\overline{u} = 0$ there and may extend $\overline{A}$ in such a way that

$$\|\operatorname{curl} \overline{A} - h_{\text{ex}}\|_{L^\infty(\Omega)} \leq C\kappa \tag{3.2}$$

(indeed, this is true for A and $\tilde{A}$.) Then, (u, A) being a minimizer of J, we have

$$\begin{aligned} 0 \geq J(u, A) - J(\overline{u}, \overline{A}) &= \int_{B_R} e_\kappa(u, A) - e_\kappa(\overline{u}, \overline{A}) \\ &= \int_{B_R \backslash B_{R-\varepsilon}} + \int_{B_{R-\varepsilon} \backslash B_{R-2\varepsilon}} + \int_{B_{R-2\varepsilon} \backslash B_{R-3\varepsilon}} + \int_{B_{R-3\varepsilon}} e_\kappa(u, A) - e_\kappa(\overline{u}, \overline{A}). \end{aligned} \tag{3.3}$$

Then

$$\begin{aligned} &\left| \int_{B_R \backslash B_{R-\varepsilon}} e_\kappa(u, A) - e_\kappa(\overline{u}, \overline{A}) \right| \\ &\qquad = \frac{1}{2} \left| \int_{B_R \backslash B_{R-\varepsilon}} |\nabla \rho|^2 + \rho^2 |\nabla \varphi - A|^2 + \frac{\kappa^2}{2}(1 - \rho^2)^2 \right. \\ &\qquad\qquad \left. - \int_{B_R \backslash B_{R-\varepsilon}} |\nabla(\chi\rho)|^2 + \chi^2 \rho^2 |\nabla \varphi - A|^2 + \frac{\kappa^2}{2}(1 - \rho^2 \chi^2)^2 \right| \\ &= \frac{1}{2} \left| \int_{B_R \backslash B_{R-\varepsilon}} (1 - \chi^2) |\nabla_A u|^2 + \frac{\kappa^2}{2} \left((1 - \rho^2)^2 - (1 - \rho^2 \chi^2)^2 \right) - \int_{B_R \backslash B_{R-\varepsilon}} \rho^2 |\nabla \chi|^2 \right| \\ &\leq O\left(\frac{R}{\varepsilon} \right), \end{aligned} \tag{3.4}$$

where we have used (2.3) and (3.1). Similarly, exchanging the roles of (u, A) and $(\tilde{u}, \tilde{A})$, we find

$$\left| \int_{B_{R-2\varepsilon} \backslash B_{R-3\varepsilon}} e_\kappa(u, A) - e_\kappa(\overline{u}, \overline{A}) \right| \leq O\left(\frac{R}{\varepsilon} \right). \tag{3.5}$$

In $B_{R-\varepsilon} \backslash B_{R-2\varepsilon}$, $\overline{u} = 0$, so with (2.3) again and (3.2),

$$\left| \int_{B_{R-\varepsilon} \backslash B_{R-2\varepsilon}} e_\kappa(u, A) - e_\kappa(\overline{u}, \overline{A}) \right| \leq O\left(\frac{R}{\varepsilon} \right) + \frac{1}{2} \int_{B_{R-\varepsilon} \backslash B_{R-2\varepsilon}} |\operatorname{curl} \overline{A} - h_{\text{ex}}|^2 \leq O\left(\frac{R}{\varepsilon} \right). \tag{3.6}$$

By (2.3) again, we have

$$\int_{B_{R-3\varepsilon}} e_\kappa(u, A) = \int_{B_R} e_\kappa(u, A) + O\left(\frac{R}{\varepsilon} \right), \tag{3.7}$$

$$\int_{B_{R-3\varepsilon}} e_\kappa(\tilde{u}, \tilde{A}) = \int_{B_R} e_\kappa(\tilde{u}, \tilde{A}) + O\left(\frac{R}{\varepsilon} \right). \tag{3.8}$$

But, since $(\tilde{u}, \tilde{A})$ minimizes J_{B_R}, we have

$$\int_{B_R} e_\kappa(u, A) \geq \int_{B_R} e_\kappa(\tilde{u}, \tilde{A}). \tag{3.9}$$

Combining this with (3.7) and (3.8), and using the fact that $(\overline{u}, \overline{A})$ is equal to $(\tilde{u}, \tilde{A})$ in $B_{R-3\varepsilon}$, we deduce that

$$\int_{B_{R-3\varepsilon}} e_\kappa(u, A) - e_\kappa(\overline{u}, \overline{A}) \geq O\left(\frac{R}{\varepsilon}\right).$$

Combining this with (3.3)–(3.7), we get

$$\left| \int_{B_R} e_\kappa(u, A) - e_\kappa(\overline{u}, \overline{A}) \right| \leq O\left(\frac{R}{\varepsilon}\right),$$

i.e.,

$$J_{B_R}(u, A) = J_{B_R}(\tilde{u}, \tilde{A}) + O(R\kappa),$$

which leads to the result. □

What we did with balls in the previous lemma can be done with squares K_R of size R.

LEMMA 3.2. *For all $b \geq 0$, and for $R_\kappa \geq R'_\kappa \gg \varepsilon$,*

$$\frac{\min J_{K_R}}{\kappa^2 |K_R|} = \frac{\min J_{K_{R'}}}{\kappa^2 |K_{R'}|} + o(1); \tag{3.10}$$

hence $\frac{\min J_{K_R}}{\kappa^2 |K_R|}$ does not depend on $R \gg \varepsilon$ (up to an $o(1)$).

Proof. Let us denote by [.] the integer part of a real number. Assume first that $R' \ll R$. K_R can be split into at least $[R^2/R'^2]$ disjoint squares of size R'. Thus, for (u, A) a minimizer of J_{K_R},

$$\begin{aligned} J_{K_R}(u, A) &\geq \left[\frac{R^2}{(R')^2}\right] J_{K_{R'}}(u, A) \\ &\geq \left[\frac{R^2}{(R')^2}\right] \min J_{K'_R}. \end{aligned}$$

We deduce that

$$\frac{\min J_{K_R}}{\kappa^2 |K_R|} \geq \frac{\min J_{K_{R'}}}{\kappa^2 |K_{R'}|}(1 + o(1)).$$

Conversely, let us split K_R into $[R^2/(R')^2] + o(1)$ squares of size R' with a layer of size 3ε between them. Using the pasting procedure of Lemma 3.1, we can construct a test configuration (u, A) in K_R that agrees with the minimizer of $J_{K_{R'}}$ in each subsquare of size R', and such that

$$J_{K_R}(u, A) \leq ([R^2/(R')^2] + o(1)) \left(\min J_{K_{R'}} + C\frac{R'}{\varepsilon}\right).$$

We can check that the error terms are negligible and deduce that

$$\frac{\min J_{K_R}}{\kappa^2 |K_R|} \leq \frac{\min J_{K_{R'}}}{\kappa^2 |K_{R'}|}(1 + o(1)).$$

Since for all R, $\frac{\min J_{K_R}}{\kappa^2|K_R|} \leq \frac{1}{4} \leq O(1)$ (by comparison with the normal solution), we deduce that (3.10) holds. If R and R' are of the same order, one may introduce R'' such that $R' \gg R'' \gg \varepsilon$. From the above, one deduces that

$$\frac{\min J_{K'_R}}{\kappa^2|K'_R|} = \frac{\min J_{K_{R''}}}{\kappa^2|K_{R''}|} + o(1),$$

and the same with R' replaced by R, from which it follows that

$$\frac{\min J_{K_R}}{\kappa^2|K_R|} = \frac{\min J_{K'_R}}{\kappa^2|K'_R|} + o(1). \qquad \square$$

LEMMA 3.3. *For all $R_\kappa \gg \varepsilon$, $\frac{\min J_{B_R}}{\kappa^2|B_R|}$ has a limit as $\kappa \to \infty$, which depends only on b. We denote it by $f(b)$. f is continuous, increasing in $[0,1]$.*

Proof. Consider $R_\kappa \gg \varepsilon$ and (u, A) as a minimizer of J_{B_R}. We denote for a moment by J_{κ,B_R} the functional for κ defined on B_R (b being fixed, $h_{\text{ex}} = b\kappa^2$). Let $\lambda < 1$, and define in $B_{\frac{R}{\lambda}}$,

$$v(x) = u(\lambda x), \qquad B(x) = \lambda A(\lambda x).$$

Then, by change of variables, we have

(3.11)
$$\min J_{\kappa,B_R} = J_{\kappa,B_R}(u,A) = \frac{1}{2}\int_{B_{R/\lambda}} |\nabla_B v|^2 + \frac{1}{\lambda^2}|\operatorname{curl} B - \kappa^2\lambda^2 b|^2 + \frac{\kappa^2\lambda^2}{2}(1-|v|^2)^2.$$

Since $\frac{1}{\lambda} > 1$, this implies that

$$\begin{aligned}
\frac{\min J_{\kappa,B_R}}{\kappa^2R^2} &\geq \frac{1}{2\kappa^2R^2}\int_{B_{R/\lambda}} |\nabla_B v|^2 + \frac{1}{\lambda^2}|\operatorname{curl} B - \kappa^2\lambda^2 b|^2 + \frac{\kappa^2\lambda^2}{2}(1-|v|^2)^2 \\
&\geq \frac{J_{\kappa\lambda,B_{R/\lambda}}(v,B)}{\kappa^2R^2} + \frac{1}{2\kappa^2R^2}\left(\frac{1}{\lambda^2}-1\right)\int_{B_{R/\lambda}} |\operatorname{curl} B - \kappa^2\lambda^2 b|^2 \\
&\geq \frac{\min J_{\kappa\lambda,B_{R/\lambda}}}{(\kappa\lambda)^2(R/\lambda)^2} + \frac{1}{2\kappa^2R^2}(1-\lambda^2)\int_{B_R} |\operatorname{curl} A - b\kappa^2|^2.
\end{aligned}$$

But from Lemma 3.2, we have

$$\frac{\min J_{\kappa\lambda,B_{R/\lambda}}}{(\kappa\lambda)^2(R/\lambda)^2} = \frac{\min J_{\kappa\lambda,B_R}}{(\kappa\lambda)^2R^2} + o(1).$$

Hence, we deduce that for all $\lambda < 1$,

$$\frac{\min J_{\kappa,B_R}}{\kappa^2R^2} \geq \frac{\min J_{\kappa\lambda,B_R}}{(\kappa\lambda)^2R^2} + o(1) + (1-\lambda^2)\frac{1}{2\kappa^2R^2}\int_{B_R} |\operatorname{curl} A - b\kappa^2|^2. \tag{3.12}$$

Hence $\frac{\min J_{\kappa,B_R}}{\kappa^2R^2}$ is monotonic (up to $o(1)$) with respect to κ and must have a limit as $\kappa \to \infty$, which depends only on b. We denote it by $f(b)$. Then letting κ tend to infinity in (3.12) yields

$$f(b) \geq f(b) + \limsup_{\kappa\to\infty}(1-\lambda^2)\frac{1}{2\kappa^2R^2}\int_{B_R} |\operatorname{curl} A - b\kappa^2|^2;$$

thus we also deduce that

$$\frac{1}{2\kappa^2 R^2}\int_{B_R}|h-h_{\rm ex}|^2=o(1). \tag{3.13}$$

This means that, for energy-minimizers, the term $\int_\Omega |h-h_{\rm ex}|^2$ is negligible in the energy. This will be helpful later.

We now prove that f is monotonic. Let $\lambda<1$ again and let J_{b,B_R} now denote the functional restricted to B_R for the value $b\kappa^2$ of the applied field. Let us consider the same v and B as defined previously. By definition,

$$\begin{aligned}J_{\lambda^2 b,B_{R/\lambda}}(v,B)&=\frac12\int_{B_{R/\lambda}}|\nabla_B v|^2+|\operatorname{curl}B-\lambda^2 b\kappa^2|^2+\frac{\kappa^2}{2}(1-|v|^2)^2\\&=\frac{1}{\lambda^2}J_{b,B_R}(u,A)-\left(\frac{1}{\lambda^2}-1\right)\frac12\int_{B_{R/\lambda}}|\nabla_B v|^2-\left(\frac{1}{\lambda^4}-1\right)\frac12\int_{B_{R/\lambda}}|\operatorname{curl}B-\lambda^2 b\kappa^2|^2,\end{aligned}$$

where we have used (3.11). Thus, using (3.13),

$$J_{\lambda^2 b,B_{R/\lambda}}(v,B)=\frac{1}{\lambda^2}J_{b,B_R}(u,A)-\left(\frac{1}{\lambda^2}-1\right)\frac12\int_{B_R}|\nabla_A u|^2-o(1). \tag{3.14}$$

Therefore,

$$\frac{\min J_{\lambda^2 b,B_{R/\lambda}}}{\kappa^2(R/\lambda)^2}\le\frac{J_{b,B_R}(u,A)}{\lambda^2\kappa^2(R/\lambda)^2}.$$

In view of the previous results, the left-hand side of this inequality converges to $f(\lambda^2 b)$, while the right-hand side converges to $f(b)$. We deduce that for all $\lambda<1$,

$$f(\lambda^2 b)\le f(b);$$

thus f is nondecreasing. One can even deduce from (3.14) that f is increasing, because $\liminf \frac{1}{\kappa^2R^2}\int_{B_R}|\nabla_A u|^2>0$. Now taking $\lambda\ge1$, we get, as in (3.14), that

$$f(\lambda^2 b)\le f(b)-\psi(\lambda),$$

where $\psi(\lambda)\to0$ as $\lambda\to1$. This implies that f is continuous. □

In view of the result of Proposition 1.3, we have, for $b\le1$,

$$\frac{b}{2}-\frac{b^2}{4}\le f(b)\le\frac14. \tag{3.15}$$

We will prove the upper bound on f in the next section. Leaving it aside, let us now complete the proof of the theorem.

End of the proof of Theorem 1.4. Taking the scalar product of the first Ginzburg–Landau equation (1.2) with u yields the standard equation for $\rho=|u|$:

$$-\Delta\rho+\rho|\nabla\varphi-A|^2=\kappa^2\rho(1-\rho^2). \tag{3.16}$$

Then we multiply it by ρ and integrate. We are led, after integration by parts (using (1.5)), to

$$\int_\Omega|\nabla\rho|^2+\rho^2|\nabla\varphi-A|^2=\int_\Omega\kappa^2\rho^2(1-\rho^2).$$

We deduce the following relation, true for any solution of Ginzburg–Landau:

$$J(u,A)=\frac{\kappa^2}{4}\int_\Omega(1-\rho^4)+\frac{1}{2}\int_\Omega|h-h_{\rm ex}|^2. \tag{3.17}$$

In view of (3.13), if (u,A) is an energy-minimizer, this becomes

$$J(u,A)=\frac{\kappa^2}{4}\int_\Omega(1-\rho^4)+o(\kappa^2).$$

If we integrate over B_R instead of Ω and use (2.2) to handle the boundary term, we find, still for minimizers,

$$J_{B_R}(u,A)=\frac{\kappa^2}{4}\int_{B_R}(1-\rho^4)+O(\kappa R)+o(\kappa^2R^2). \tag{3.18}$$

Applying (3.18) to u and $\overline{u}$ successively gives (1.16).

Then

$$\frac{1}{|B_R|}\int_{B_R}|u|^4\to 1-4f(b)$$

for all $R\gg\varepsilon$, which implies the weaker conclusion that $|u|^4\rightharpoonup 1-4f(b)$ in L^∞ weak-*.

We also deduce from (1.14) combined with (1.19) that (1.20) holds. Plugging (1.16) in (1.20), we obtain

$$\begin{aligned}\frac{1}{|B_R|}\int_{B_R}|u|^2&\geq\frac{(1-b)^2+1-8f(b)+2b-b^2}{2(1-b)}\\&\geq\frac{1-4f(b)}{1-b}\geq\alpha(1-b),\end{aligned}$$

while

$$\frac{1}{|B_R|}\int_{B_R}|u|^2\leq\sqrt{\frac{1}{|B_R|}\int_{B_R}|u|^4}$$

comes from the Cauchy–Schwarz inequality.

This completes the proof of the theorem. □

4. Construction of test configurations. The upper bound of Theorem 1.4 relies on the construction of two test configurations, one being more interesting when $b\to 1$, the other one when $b\to 0$. Let us start with the first one, which follows somehow the construction of vortex solutions of [JT] in the self-dual situation.

PROPOSITION 4.1. *With the notation of the previous section, there exists a universal constant* $0<\alpha<1$ *such that*

$$f(b)\leq\frac{1-\alpha(1-b)_+^2}{4}. \tag{4.1}$$

Proof. Assume $b\leq 1$ (otherwise the conclusion is trivial). We construct a test configuration which is periodic with respect to a square lattice of size $\sqrt{\frac{2\pi}{b}}\varepsilon$. Let

$K_{\sqrt{\frac{2\pi}{b}}\varepsilon}$ denote an elementary square of the lattice and let $K_{\sqrt{2\pi}}$ denote the square of size $\sqrt{2\pi}$ centered at the origin. We solve for

$$\begin{cases} \Delta \log \rho_0 + 1 = 2\pi\delta_0 & \text{in } K_{\sqrt{2\pi}}, \\ \dfrac{\partial \log \rho_0}{\partial n} = 0 & \text{on } \partial K_{\sqrt{2\pi}}, \\ \displaystyle\int_{K_{\sqrt{2\pi}}} \log \rho_0 = 0. \end{cases} \tag{4.2}$$

There exists a (unique) solution to this system because the volume of $K_{\sqrt{2\pi}}$ is 2π. Let (r, θ) be the polar coordinates in the plane. We observe that $\log \rho_0 - \log r$ is smooth in $K_{\sqrt{2\pi}}$; hence $\frac{\rho}{r}$ too, and thus $\rho_0(0) = 0$. We then define in $K_{\sqrt{\frac{2\pi}{b}}\varepsilon}$,

$$\rho(x) = C\rho_0\left(\frac{x\sqrt{b}}{\varepsilon}\right),$$

where C minimizes $\int_{K_{\sqrt{\frac{2\pi}{b}}\varepsilon}} (1 - b - C^2\rho_0^2(\frac{x\sqrt{b}}{\varepsilon}))^2$, i.e. (after a little computation),

$$\rho(x) = \sqrt{1-b}\sqrt{\frac{\int_{K_{\sqrt{2\pi}}} \rho_0^2}{\int_{K_{\sqrt{2\pi}}} \rho_0^4}}\,\rho_0\left(\frac{x\sqrt{b}}{\varepsilon}\right). \tag{4.3}$$

One can see that ρ is a solution of

$$\begin{cases} \Delta \log \rho + \frac{b}{\varepsilon^2} = 2\pi\delta_0 & \text{in } K_{\sqrt{\frac{2\pi}{b}}\varepsilon}, \\ \dfrac{\partial \log \rho}{\partial n} = 0 & \text{on } \partial K_{\sqrt{\frac{2\pi}{b}}\varepsilon}. \end{cases} \tag{4.4}$$

ρ_0 is symmetric with respect to the axes of symmetry of the square and $\frac{\partial \rho_0}{\partial n} = 0$ on $\partial K_{\sqrt{2\pi}}$; thus we may extend ρ to any ball B_R ($R \gg \varepsilon$) by periodicity and get a C^1 function, which vanishes on a lattice Λ.

We then pick A to solve

$$\begin{cases} \operatorname{curl} A = b\kappa^2 & \text{in } B_R, \\ \operatorname{div} A = 0 & \text{in } B_R \end{cases}$$

and φ to satisfy

$$\nabla\varphi = \frac{\nabla^\perp \rho}{\rho} + A = \nabla^\perp \log \rho + A. \tag{4.5}$$

To achieve this, we fix a point x_0 of $B_R\backslash\Lambda$ and define

$$\varphi(x) = \int_{x_0}^{x} \partial_n \log \rho + A \cdot \tau.$$

This definition does not depend on the path joining x_0 to x, modulo 2π. Indeed, if $\gamma = \partial\omega$ is a closed path in $B_R\backslash\Lambda$ with positive orientation, using (4.4), we have

$$\int_\gamma \partial_n \log \rho + A \cdot \tau = \int_\omega \Delta \log \rho + \operatorname{curl} A = \int_\omega \Delta \log \rho + b\kappa^2 = 2\pi card(\omega \cap \Lambda) \in 2\pi\mathbb{Z}.$$

Hence $e^{i\varphi(x)}$ is well defined in $B_R\backslash\Lambda$. We then take

$$u(x) = \rho(x)e^{i\varphi(x)},$$

which has a continuous extension in B_R because ρ vanishes on Λ. Once this test configuration (u, A) is constructed, we evaluate its energy. In view of (2.9),

$$J_{B_R}(u, A) = |B_R|\kappa^2\left(\frac{b}{2} - \frac{b^2}{4}\right) + \frac{1}{2}\int_{B_R} |\mathcal{D}_A u|^2 + \frac{\kappa^2}{2}(1 - b - \rho^2)^2 + O(R\kappa^2). \tag{4.6}$$

But $|\mathcal{D}_A u|^2 = |\rho(\nabla\varphi - A) - \nabla^\perp\rho|^2 = 0$ by construction; cf. (4.5). Moreover, from (4.3),

$$\begin{aligned}\int_{K_{\sqrt{\frac{2\pi}{b}}\varepsilon}} (1 - b - \rho^2)^2 &= (1 - b)^2 \int_{K_{\sqrt{\frac{2\pi}{b}}\varepsilon}} \left(1 - \frac{\int_{K_{\sqrt{2\pi}}} \rho_0^2}{\int_{K_{\sqrt{2\pi}}} \rho_0^4}\, \rho_0^2\left(\frac{x\sqrt{b}}{\varepsilon}\right)\right) dx \\ &= (1 - b)^2\left(\frac{2\pi}{b}\varepsilon^2 - \frac{\varepsilon^2}{b}\frac{\left(\int_{K_{\sqrt{2\pi}}} \rho_0^2\right)^2}{\int_{K_{\sqrt{2\pi}}} \rho_0^4}\right). \qquad (4.7)\end{aligned}$$

Let us write

$$\alpha = \frac{\left(\int_{K_{\sqrt{2\pi}}} \rho_0^2\right)^2}{2\pi\int_{K_{\sqrt{2\pi}}} \rho_0^4}.$$

Since ρ_0 is not a constant function (see (4.2)), we have a strict Cauchy–Schwarz inequality

$$\left(\int_{K_{\sqrt{2\pi}}} \rho_0^2\right)^2 < 2\pi\int_{K_{\sqrt{2\pi}}} \rho_0^4,$$

and hence $0 < \alpha < 1$. Then, from (4.7),

$$\int_{B_R} (1 - b - \rho^2)^2 = |B_R|(1 - b)^2(1 - \alpha) + o(R^2). \tag{4.8}$$

Combining (4.6) and (4.8), we are led to

$$J_{B_R}(u, A) = |B_R|\kappa^2\left(\frac{b}{2} - \frac{b^2}{4} + \frac{(1 - b)^2(1 - \alpha)}{4}\right) + o(\kappa^2 R^2).$$

We conclude that

$$f(b) \le \limsup_{\kappa\to\infty} \frac{\min J_{B_R}}{\kappa^2|B_R|} \le \limsup_{\kappa\to\infty} \frac{J_{B_R}(u, A)}{\kappa^2|B_R|} \le \frac{1 - \alpha(1 - b)^2}{4}. \qquad \square$$

PROPOSITION 4.2. *There exists a universal constant c such that for $b \le 1$,*

$$f(b) \le \frac{b}{4}\left(\log\frac{1}{b} + c\right). \tag{4.9}$$

Proof. This estimate is stronger than (4.1) when $b \to 0$ and corresponds to a regime in which the distance between vortices is rather large compared to their core size ε, i.e., is close to the regime described in [SS2]. In order to prove this estimate, we just adjust the construction of a test function that we did in [SS2].

This test function is again periodic with respect to a square lattice of size $\sqrt{\frac{2\pi}{b}}\varepsilon$. Let us consider an elementary square $K_{\sqrt{\frac{2\pi}{b}}\varepsilon}$ centered at the origin, with B_ε the ball of radius ε centered at the origin, which is included in $K_{\sqrt{\frac{2\pi}{b}}\varepsilon}$ for all $b \leq 1$. The centers of the squares of the lattice will be denoted a_i. We take a $\rho \leq 1$, which satisfies

$$\begin{cases} \rho \equiv 1 & \text{in } K_{\sqrt{\frac{2\pi}{b}}\varepsilon} \backslash B_\varepsilon, \\ \rho \equiv 0 & \text{in } B_{\varepsilon/2}, \\ \displaystyle\int_{K_{\sqrt{\frac{2\pi}{b}}\varepsilon}} |\nabla\rho|^2 + \frac{\kappa^2}{2}(1-\rho^2)^2 \leq C. \end{cases} \tag{4.10}$$

Then we take h such that

$$\begin{cases} -\Delta h + h = \frac{8}{\varepsilon^2}\mathbf{1}_{B_{\varepsilon/2}} & \text{in } K_{\sqrt{\frac{2\pi}{b}}\varepsilon}, \\ \dfrac{\partial h}{\partial n} = 0 & \text{on } \partial K_{\sqrt{\frac{2\pi}{b}}\varepsilon}, \end{cases} \tag{4.11}$$

where $\mathbf{1}$ denotes a characteristic function. We extend ρ and h by periodicity to B_R ($R \gg \varepsilon$) and pick A such that $\operatorname{curl} A = h$ and $\operatorname{div} A = 0$. Then we take φ such that

$$\nabla\varphi = -\nabla^\perp h + A, \tag{4.12}$$

i.e., by choosing a point x_0 in $B_R \backslash \cup_i B_{\varepsilon/2}(a_i)$ and setting

$$\varphi(x) = \int_{x_0}^{x} -\frac{\partial h}{\partial n} + A \cdot \tau.$$

This integral does not depend on the path joining x_0 to x in $B_R \backslash \cup_i B_{\varepsilon/2}(a_i)$, modulo 2π. This can be seen from (4.11). Thus $e^{i\varphi}$ is well defined in $B_R \backslash \cup_i B_{\varepsilon/2}(a_i)$, and

$$u(x) = \rho(x) e^{i\varphi(x)}$$

has a meaning on all of B_R (since $\rho \equiv 0$ in $\cup_i B_{\varepsilon/2}(a_i)$). Exactly as in [SS2], one shows that

$$\frac{1}{2}\int_{K_{\sqrt{\frac{2\pi}{b}}\varepsilon}} |\nabla h|^2 + |h - h_{\text{ex}}|^2 \leq \pi \log \frac{\sqrt{\frac{1}{b}}\varepsilon}{b} + C = \frac{\pi}{2}\log\frac{1}{b} + C. \tag{4.13}$$

There remains the matter of evaluating the energy of (u, A) per square. From (4.12), we have $\rho^2|\nabla\varphi - A|^2 \leq |\nabla h|^2$, and hence

$$\begin{aligned} J_K(u,A) &= \int_{K_{\sqrt{\frac{2\pi}{b}}\varepsilon}} |\nabla\rho|^2 + \rho^2|\nabla\varphi - A|^2 + |h - h_{\text{ex}}|^2 + \frac{\kappa^2}{2}(1-\rho^2)^2 \\ &\leq \frac{\pi}{2}\log\frac{1}{b} + c. \end{aligned}$$

Multiplying this estimate by the number of squares in B_R, $\frac{|B_R|b}{2\pi\varepsilon^2}$, we find

$$J_{B_R}(u,A) \leq |B_R|\kappa^2 \left(\frac{b}{4}\log\frac{1}{b} + cb\right).$$

We then conclude, as in the previous proposition, that (4.9) holds. ∎

SUPERCONDUCTING FILMS IN PERPENDICULAR FIELDS AND THE EFFECT OF THE DE GENNES PARAMETER*

XING-BIN PAN†

Abstract. In this paper we study superconductivity of a thin film placed in a perpendicular magnetic field. We discuss the dependence of the upper critical field H_{C_3} on the thickness l of the film and the Ginzburg–Landau parameter κ, and we examine nucleation of superconductivity. We show that a critical change occurs at $l = 2\gamma\kappa^{-2}$. If $l > a\kappa^{-2}$ $(a > 2\gamma)$, the film exhibits type II behaviors: as the applied magnetic field decreases from H_{C_3}, superconductivity nucleates in a strip at the lateral surface and develops a lateral surface superconducting state. If $l \le 2\gamma\kappa^{-2} + C\kappa^{-4}$, the film exhibits type I behaviors.

Key words. superconductivity, Ginzburg–Landau system, critical field, Schrödinger operator with a magnetic field, de Gennes parameter, thin film

1. Introduction.

Motivated by the recent work of Richardson and Rubinstein [RR1, RR2], we study the effect of the de Gennes parameter on superconductivity of thin films.

Mathematical models of superconducting thin films have been studied recently by many authors; see, for instance, Du and Gunzburger [DG], Chapman, Du, and Gunzburger [CDG], Chen, Elliott, and Tang [CET], Berger and Rubinstein [BR1, BR2], Rubinstein and Schatzman [RS], Richardson and Rubinstein [RR1, RR2], Jimbo and Morita [JM], Ding and Du [DD], and references therein.[1] Among other things, it was shown in [CDG] that all superconducting materials, whether type I (with small Ginzburg–Landau parameter κ) or type II (with large κ), behave as type II superconductors when made into sufficiently thin films; and for a very thin film placed in a magnetic field, only the perpendicular component of the applied field has influence on the superconductivity.[2] On the other hand, the recent works of Richardson and Rubinstein [RR1, RR2] show that the de Gennes parameter has an important effect on superconductivity of thin films. It was mentioned in [RR1] that "the effect of the de Gennes boundary condition is to depress the temperature at which superconductivity occurs," and they conjectured that "for sufficiently thin wires or small de Gennes distance,[3] superconductivity may never be favorable." This question motivated us to study nucleation of superconductivity of thin films in a general content.

Let us consider a superconducting film of thickness l and a cross-section Ω:

$$D_l = \{(x, z) : \ x \in \Omega, \ 0 < z < l\},$$

[1] Superconductivity on samples with small size has also been studied by Aftalion and Dancer [ADa] and Aftalion and Du [ADu].

[2] See also [HT, Chapter 8].

[3] A large de Gennes parameter gives a small de Gennes distance.

where $0 < l \ll 1$, and Ω is a bounded, simply-connected, and smooth (C^4) domain in $\mathbb{R}^2$. Throughout this paper, $x = (x_1, x_2)$ denotes a point in $\bar{\Omega}$, (x, z) denotes a point in D_l; ds denotes the measure on $\partial\Omega$, dS denotes the measure on ∂D_l; ν denotes the unit outer-normal vector of $\partial\Omega$, and ν_D denotes the unit outer-normal vector of the boundary of D_l, which is well defined in $\partial^* D_l$, where

$$\partial^* D_l = \partial\Omega \times (0, l) \bigcup \Omega \times \{0, l\}.$$

Let

$$d_{\partial\Omega}(x) = \operatorname{dist}(x, \partial\Omega), \qquad d_l(x, z) = \operatorname{dist}((x, z), \partial D_l).$$

Let κ_r be the curvature of $\partial\Omega$, and set

$$\kappa_{\max} = \max_{x\in\partial\Omega} \kappa_r(x), \qquad \mathcal{N}(\partial\Omega) = \{x \in \partial\Omega : \ \kappa_r(x) = \kappa_{\max}\}.$$

According to the Ginzburg–Landau theory, superconductivity is described by a complex-valued function ψ (order parameter) and a real vector field $\mathcal{A}$ (magnetic potential), and $(\psi, \mathcal{A})$ is a minimizer of the Ginzburg–Landau functional. Let us consider a homogeneous applied magnetic field $\mathcal{H} = \sigma\mathbf{h}$, where $\mathbf{h}$ is a constant unit vector and σ is a positive number. In this paper, as we are concerned with the behavior of a film in a perpendicular field, $\mathbf{h}$ is chosen to be perpendicular to Ω:

$$\mathbf{h} = \mathbf{e}_3 = (0, 0, 1).$$

We shall treat σ as a parameter. So we set $\mathcal{A} = \sigma\mathbf{A}$. With a proper scaling, we may rewrite the Ginzburg–Landau functional as (see [GL, dG, CHO, DGP, R])

$$\begin{aligned}\mathcal{G}[\psi, \mathbf{A}] = \int_{D_l} \left\{ |\nabla_{\kappa\sigma\mathbf{A}}\psi|^2 + \frac{\kappa^2}{2}(|\psi|^2 - 1)^2 \right\} dxdz + \gamma \int_{\partial D_l} |\psi|^2 dS \\ + \kappa^2\sigma^2 \int_{\mathbb{R}^3} |\operatorname{curl} \mathbf{A} - \mathbf{h}|^2 dxdz.\end{aligned}$$

The minimizers $(\psi, \mathbf{A})$ satisfy the following Ginzburg–Landau system:

(1.1)
$$\begin{cases} -\nabla^2_{\kappa\sigma\mathbf{A}}\psi = \kappa^2(1 - |\psi|^2)\psi & \text{in } D_l, \\ \operatorname{curl}^2\mathbf{A} = -\dfrac{i}{2\kappa\sigma}(\bar{\psi}\nabla\psi - \psi\nabla\bar{\psi}) - |\psi|^2\mathbf{A} & \text{in } D_l, \\ \operatorname{curl}^2\mathbf{A} = \mathbf{0} & \text{in } \mathbb{R}^3 \setminus D_l, \\ (\nabla_{\kappa\sigma\mathbf{A}}\psi)\cdot\nu_D + \gamma\psi = 0, \quad [\nu_D \cdot \mathbf{A}] = 0, \quad [\nu_D \times \operatorname{curl}\mathbf{A}] = \mathbf{0} & \text{on } \partial^* D_l, \\ \operatorname{curl}\mathbf{A} \to \mathbf{h} & \text{as } |(x, z)| \to \infty. \end{cases}$$

Here $i = \sqrt{-1}$, κ is the Ginzburg–Landau parameter, and $[\cdot]$ denotes the jump in the enclosed quantity across ∂D_l. The boundary condition for ψ in the fourth equality was posed by de Gennes [dG] for a superconductor adjacent to other material. $\gamma \geq 0$ is the de Gennes parameter.[4] γ is very small for insulators, very large for magnetic

[4] In the literature $d = 1/\gamma$ is called the de Gennes distance.

materials, and lying in between for nonmagnetic materials. In this paper we shall always assume that $\gamma > 0$. Note that in the above system the unit of length is the penetration depth.

We call a minimizer $(\psi, \mathbf{A})$ of the functional $\mathcal{G}$ a *minimal solution* of (1.1). Let $\mathbf{F_h}$ be a smooth vector field defined on $\mathbb{R}^3$ such that

$$\text{curl } \mathbf{F_h} = \mathbf{h} \quad \text{and} \quad \text{div } \mathbf{F_h} = 0 \quad \text{in } \mathbb{R}^3. \tag{1.2}$$

$(0, \mathbf{F_h})$ is a trivial solution of (1.1), and it is the only minimal solution if σ is large. As in [LP4], we define the upper critical field (here emphasizing the dependence of H_{C_3} on the thickness of the film) by

$$H_{C_3}(\mathbf{h}, \kappa, l) = \inf\{\sigma > 0 : (0, \mathbf{F_h}) \text{ is a minimizer of } \mathcal{G}\}.$$

We are interested in the dependence of H_{C_3} on κ, l, γ and on the geometry of the cross-section of the film. Using the methods developed in [LP1, LP2, LP3, LP4, LP5, LP6, HM1, HP], and especially in [P1], we are able to establish an estimate of $H_{C_3}(\mathbf{h}, \kappa, l)$ for small l.

THEOREM 1.1. *Let* $\mathbf{h}$ *be a unit vector perpendicular to* Ω *and let* $\gamma > 0$ *be given. Let* a*,* b*, and* c *be fixed positive constants. For large* κ *we have*

(1.3)
$$H_{C_3}(\mathbf{h}, \kappa, l) = \begin{cases} \frac{\kappa}{\beta_0} + \frac{C_1}{\beta_0^{3/2}}(\kappa_{\max} - 3\gamma) - \frac{2\gamma}{a\beta_0} + o(1) & \text{if } l = a\kappa^{-1},\ a > 0, \\ (1 - \frac{2\gamma}{a})\frac{\kappa}{\beta_0} + \frac{C_1}{\beta_0^{3/2}}(\kappa_{\max} - 3\gamma)(1 - \frac{2\gamma}{a})^{1/2} + o(1) & \text{if } l = a\kappa^{-2},\ a > 2\gamma, \\ \frac{c}{2\gamma\beta_0} + O(\kappa^{-1}) & \text{if } l = 2\gamma\kappa^{-2} + c\kappa^{-3},\ c > 0, \\ O(\kappa^{-1}) & \text{if } l = 2\gamma\kappa^{-2} + b\kappa^{-4},\ b \geq b_0, \\ 0 & \text{if } l = 2\gamma\kappa^{-2} + b\kappa^{-4},\ b < b_0, \end{cases}$$

where C_1 *and* β_0 *are universal constants and* b_0 *depends only on* Ω *and* γ.

The numbers C_1, β_0, and b_0 will be given in section 2. In section 6 we shall give a proof of Theorem 1.1 and also discuss nucleation of superconductivity.

Remark 1. One may expect that a superconducting thin film placed in a perpendicular magnetic field will behave as a two-dimensional superconductor.[5] In fact, this is true if $l > a\kappa^{-2}$ for some $a > 2\gamma$. Recall that for a two-dimensional superconductor Ω placed in an applied magnetic field perpendicular to Ω, we have the following (see [LP4, HP, P2]):

(a) For large κ,

$$H_{C_3}(\kappa) = \frac{\kappa}{\beta_0} + \frac{C_1}{\beta_0^{3/2}}\kappa_{\max} + O(\kappa^{-1/3}). \tag{1.4}$$

(b) As the applied field decreases from $H_{C_3}(\kappa)$, superconductivity nucleates first in the set of the maximum points of the curvature, $\mathcal{N}(\partial\Omega)$, and then develops a *surface superconducting state*.[6]

[5] By a *two-dimensional superconductor* we actually mean a superconducting cylinder with infinite height and a cross-section Ω, and placed in an applied magnetic field perpendicular to Ω. In this case one may reduce the Ginzburg–Landau system to a two-dimensional system on Ω.

[6] See [P2, footnote on p. 328] for the meaning of a "surface superconducting state."

We may call such types of behavior *two-dimensional type* II *behaviors*.[7] For a thin film $D_l = \Omega \times (0, l)$ with $l \geq a\kappa^{-2}$ $(a > 2\gamma)$, we have the following (see Theorem 1.1 above and Theorems 6.2 and 6.3 in section 6):

(a′) $H_{C_3}(\mathbf{h}, \kappa, l)$ has order of κ and depends on the curvature of the cross-section.

(b′) As the applied field decreases from H_{C_3}, superconductivity nucleates first in the strip $\mathcal{N}(\partial\Omega) \times [0, l]$ and then develops a *lateral surface superconducting state*.[8] So we can say that a film with thickness $l \geq a\kappa^{-2}$ $(a > 2\gamma)$ also exhibits two-dimensional type II behaviors when placed in a perpendicular field.

Remark 2. Equation (1.3) also indicates a thin film behavior, which is presented by the quantities involving the de Gennes parameter γ. These quantities become important when l is close to $2\gamma\kappa^{-2}$. In fact, $l = 2\gamma\kappa^{-2}$ is a critical value in the following sense:

(i) When $l \geq a\kappa^{-2}$ $(a > 2\gamma)$, the film exhibits a two-dimensional behavior of type II superconductors.

(ii) When $l \sim 2\gamma\kappa^{-2}$, the film behaves like a type I superconductor.

(iii) The film loses superconductivity if $l < 2\gamma\kappa^{-2} + b_0\kappa^{-4}$.

In order to estimate the value of H_{C_3}, we need an estimate of the lowest eigenvalue $\mu_\gamma(\mathbf{A})$ of the following problem associated with a given vector field $\mathbf{A}$:

$$\begin{cases} -\nabla^2_{\mathbf{A}}\phi = \mu\phi & \text{in } D_l, \\ (\nabla_{\mathbf{A}}\phi)\cdot\nu_D + \gamma\phi = 0 & \text{on } \partial^* D_l. \end{cases} \tag{1.5}$$

We especially need to estimate $\mu_\gamma(b\mathbf{F}_{\mathbf{h}})$ for large b. We shall discuss only a perpendicular field ($\mathbf{h} = (0, 0, 1)$) in this paper and wish to consider applied fields in general directions in the near future. We expect that the parallel components of the applied field play roles in determining the location of nucleation.

The outline of this paper is the following. In section 2 we collect some preliminary results that will be used in later sections. In section 3 we study an eigenvalue problem in a two-dimensional domain and extend the Helffer–Morame estimate [HM1] of the lowest eigenvalue to the problems with de Gennes boundary conditions. In section 4 we give some elliptic estimates for the minimizers of the Ginzburg–Landau functional in the films D_l, with constants independent of l. In section 5 we present estimates of the lowest eigenvalue for eigenvalue problems on the films. In section 6 we study superconductivity of the films in perpendicular magnetic fields, establish an estimate of H_{C_3}, and find the location of nucleation. From the results established in section 6 we get Theorem 1.1.

We should mention that the Ginzburg–Landau system with de Gennes boundary conditions has been studied in Lu and Pan [LP1, LP2, LP3, LP4, LP5, LP6]. In particular, Lu and Pan [LP1] discussed the Ginzburg–Landau system without applied fields and described the asymptotic behavior of the minimal solutions for large value of the de Gennes parameter. Combining the results in this paper and those in [LP1] we see that the effect of the de Gennes parameter is important when its value is large compared with the scale of the samples.

The upper critical field H_{C_3} and surface superconductivity have been studied by many physicists and mathematicians. For early research see Saint-James and de

[7] More precisely, two-dimensional behaviors are those of a cylindrical superconductor of infinite height and a constant cross-section in response to an applied magnetic field perpendicular to the cross-section.

[8] For a film, a *lateral surface superconducting state* is such a state that superconductivity is confined in a thin layer around the lateral surface, and superconductivity in the layer is not weak.

Gennes [SdG], Saint-James and Sarma [SST], and Tinkham [T]; for recent mathematical research on the estimates of H_{C_3} and the study of the surface nucleation phenomenon, see Chapman [C], Bauman, Phillips, and Tang [BPT], Giorgi and Phillips [GP], Bernoff and Sternberg [BS], Lu and Pan [LP1, LP2, LP3, LP4, LP5], del Pino, Felmer, and Sternberg [DFS], Jadallah [J], Pan [P1, P2, P3], Pan and Kwek [PK], Helffer and Morame [HM1, HM2], Helffer and Pan [HP], and Almog [Al].

2. Preliminaries. In this section we give some preliminary results which will be used in later sections. We first recall an eigenvalue variation problem. For every constant z, let $\beta(z)$ denote the lowest eigenvalue of the following problem in $L^2(\mathbb{R}_+)$:

$$-u'' + (z+t)^2 u = \beta(z)u \quad \text{for } t > 0, \qquad u'(0) = 0. \tag{2.1}$$

It was first proved by Dauge and Helffer [DH] (also see Bolley and Helffer [BH]) that[9] there is a unique z_0, $z_0 < 0$ such that

$$\beta_0 \equiv \beta(z_0) = \inf_{z\in\mathbb{R}} \beta(z). \tag{2.2}$$

Moreover, $\beta_0 = z_0^2$ and $0.5 < \beta_0 < 0.76$. Throughout this paper, β_0 always denotes the number given in (2.2), and C_1 always denotes the number defined by

$$C_1 = \frac{u^2(0)}{3\|u\|^2_{L^2(\mathbb{R}_+)}},$$

where $u(t)$ is the positive eigenfunction of (2.1) for $z = z_0$ and $\beta = \beta_0$. β_0 and C_1 appeared in (1.3) and (1.4) and will be used frequently in later sections.

In Lemma 2.1 below we shall give a simple estimate for the lowest eigenvalue $\mu_\gamma(\mathbf{A})$ of (1.5). For this purpose, we need the numbers $\beta_{\gamma,\Omega}$, $\mu_{\gamma,\Omega}$, and $\tau_\gamma(l)$, where

$$\beta_{\gamma,\Omega} = \inf_{\phi\in W^{1,2}(\Omega)} \frac{\int_\Omega |\nabla\phi|^2 dx + \gamma\int_{\partial\Omega}|\phi|^2 ds}{\int_\Omega |\phi|^2 dx},$$
$$\mu_{\gamma,D_l} = \inf_{\phi\in W^{1,2}(D_l)} \frac{\int_{D_l} |\nabla\phi|^2 dxdz + \gamma\int_{\partial D_l}|\phi|^2 dS}{\int_{D_l} |\phi|^2 dxdz},$$

and $\lambda = \tau_\gamma(l)^2$ is the lowest eigenvalue of

$$\begin{cases} -\xi'' = \lambda\xi & \text{for } 0 < t < l, \\ \xi'(0) = \gamma\xi(0), \qquad \xi'(l) = -\gamma\xi(l). \end{cases} \tag{2.3}$$

$\tau_\gamma(l)$ is determined by the smallest positive solution of the algebraic equation

$$\tan(\tau_\gamma(l)l) = \frac{2\gamma\tau_\gamma(l)}{\tau_\gamma(l)^2 - \gamma^2},$$

and the eigenfunctions of (2.3) associated with $\tau_\gamma(l)^2$ are $c\xi_l(t)$, where

$$\xi_l(t) = \tau_\gamma(l)\cos(\tau_\gamma(l)t) + \gamma\sin(\tau_\gamma(l)t). \tag{2.4}$$

[9]It was proved again by Lu and Pan [LP2] (also see [LP4]) without their knowing the results of [DH] and [BH]. The methods are different though.

When $0 < l < \frac{\pi}{2\gamma}$, we have $\tau_\gamma(l) > \gamma$, and $\tau_\gamma(l)l \to 0$ as $l \to 0$. Using Taylor expansion we find

$$\frac{2\gamma}{l} - \frac{\gamma^2}{3} < \tau_\gamma(l)^2 < \frac{2\gamma}{l} - \frac{\gamma^2}{3} + O(\gamma^3 l) \quad \text{as } l \to 0. \tag{2.5}$$

The following equality shows the relation between these numbers:

$$\mu_{\gamma,D_l} = \beta_{\gamma,\Omega} + \tau_\gamma(l)^2, \tag{2.6}$$

which is obtained by solving, using the separable variables method, the eigenvalue problem corresponding with μ_{γ,D_l}.

LEMMA 2.1. (i) *For any vector field* $\mathbf{A}$*, the lowest eigenvalue* $\mu_\gamma(\mathbf{A})$ *of* (1.5) *satisfies*

$$\mu_\gamma(\mathbf{A}) \geq \mu_{\gamma,D_l} > \beta_{\gamma,\Omega} + \frac{2\gamma}{l} - \frac{\gamma^2}{3}.$$

(ii) *For any unit vector* $\mathbf{h}$*,* $H_{C_3}(\mathbf{h}, \kappa, l) > 0$ *if and only if* $\mu_{\gamma,D_l} < \kappa^2$.

Proof. For any vector field $\mathbf{A}$ and any $\phi \in W^{1,2}(D_l)$, from Kato's inequality we have

$$\int_{D_l} |\nabla_{\mathbf{A}}\phi|^2 dxdz \geq \int_{D_l} \big|\nabla|\phi|\big|^2 dxdz.$$

Hence $\mu_\gamma(\mathbf{A}) \geq \mu_{\gamma,D_l}$. We get (i) from this and (2.5), (2.6).

If $H_{C_3}(\mathbf{h}, \kappa, l) > 0$, then for $0 < \sigma < H_{C_3}$, the Ginzburg–Landau functional $\mathcal{G}$ has a nontrivial minimizer $(\psi, \mathbf{A})$ and thus the lowest eigenvalue $\mu_\gamma(\sigma\kappa\mathbf{A}) < \kappa^2$; see [LP4, Lemma 2.1]. From conclusion (i) we must have $\mu_{\gamma,D_l} < \kappa^2$.

On the other hand, if $\mu_{\gamma,D_l} < \kappa^2$, then for the vector field $\mathbf{F_h}$ given in (1.2), $\mu_\gamma(\sigma\kappa\mathbf{F_h}) < \kappa^2$ for all sufficiently small $\sigma > 0$. Hence the functional $\mathcal{G}$ has a nontrivial minimizer; see [LP4, Lemma 2.1]. Thus $H_{C_3}(\mathbf{h}, \kappa, l) > 0$. (ii) is proved. □

Remark 3. (i) As a consequence of Lemma 2.1, if $\kappa^2 + \frac{\gamma^2}{3} - \beta_{\gamma,\Omega} > 0$ and if

$$0 < l < \frac{2\gamma}{\kappa^2 + \frac{\gamma^2}{3} - \beta_{\gamma,\Omega}}, \tag{2.7}$$

then $\mu_{\gamma,D_l} > \kappa^2$, and hence $\mu_\gamma(\mathbf{A}) > \kappa^2$ for any vector field $\mathbf{A}$. Thus (1.1) has no nontrivial solution; see [LP4, Lemma 2.1]. Hence superconductivity is not favorable for a very thin film with its thickness l satisfying (2.7). This verifies the prediction of Richardson and Rubinstein [RR1, RR2].

(ii) Let us define $l = l(\kappa)$ to be the positive root of the equation

$$\mu_{\gamma,D_l} = \kappa^2.$$

Lemma 2.1 indicates that nontrivial minimal solutions $(\psi, \mathbf{A})$ of the Ginzburg–Landau system (1.1) bifurcate from $(0, \mathbf{0})$ when the parameter (κ, l) moves upward in the parameter space $\{(\kappa, l) : \ \kappa > 0, \ l > 0\}$ away from the bifurcation point $(\kappa, l(\kappa))$. From (2.5) we find that for large κ,

$$l(\kappa) = 2\gamma\kappa^{-2} + 2\gamma\left(\beta_{\gamma,\Omega} - \frac{\gamma^2}{3}\right)\kappa^{-4} + O(\kappa^{-6}).$$

(iii) The number b_0 that appeared in (1.3) is defined by

$$b_0 = 2\gamma\left(\beta_{\gamma,\Omega} - \frac{\gamma^2}{3}\right). \tag{2.8}$$

If $l = 2\gamma\kappa^{-2} + b\kappa^{-4}$ with $b < b_0$ and κ is large, the minimizers of the Ginzburg–Landau functional $\mathcal{G}$ are trivial. This verifies the last conclusion in Theorem 1.1.

(iv) Since superconducting states exist on thin films only when $l > l(\kappa)$, we assume in the following that

$$\kappa^2 > \mu_{\gamma,D_l}.$$

It implies that $\kappa \to \infty$ as $l \to 0$. Thus we consider only thin films with large value of κ. We remark that a bulk superconductor is type II if κ is large; however, a thin film with large κ and $l \sim 2\gamma\kappa^{-2}$ may present a type I behavior; see Theorem 6.5 below.

3. A two-dimensional eigenvalue problem. In this section we estimate the lowest eigenvalue $\beta_\gamma(\varepsilon^{-2}\mathbf{A})$, as $\varepsilon \to 0$, of the problem

$$\begin{cases} -\nabla^2_{\varepsilon^{-2}\mathbf{A}}\phi = \beta\phi & \text{in } \Omega, \\ (\nabla_{\varepsilon^{-2}\mathbf{A}}\phi)\cdot\nu + \gamma\phi = 0 & \text{on } \partial\Omega, \end{cases} \tag{3.1}$$

where Ω is a bounded C^4 domain in $\mathbb{R}^2$, γ is a positive constant, and the vector field $\mathbf{A} = (A_1, A_2)$ is given and satisfies

$$\text{curl } \mathbf{A} \equiv \partial_1 A_2 - \partial_2 A_1 = 1 \quad \text{and} \quad \text{div } \mathbf{A} = 0 \quad \text{in } \Omega, \qquad \mathbf{A}\cdot\nu = 0 \quad \text{on } \partial\Omega. \tag{3.2}$$

From the variational characterization, the lowest eigenvalue is given by

$$\beta_\gamma(\varepsilon^{-2}\mathbf{A}) = \inf_{\phi\in W^{1,2}(\Omega)} \frac{\int_\Omega |\nabla_{\varepsilon^{-2}\mathbf{A}}\phi|^2 dx + \gamma\int_{\partial\Omega}|\phi|^2 ds}{\int_\Omega |\phi|^2 dx}.$$

THEOREM 3.1. *Let* $\mathbf{A}$ *satisfy* (3.2) *and let* $\gamma > 0$ *be fixed. We have, as* $\varepsilon \to 0$,

$$\beta_\gamma(\varepsilon^{-2}\mathbf{A}) = \frac{1}{\varepsilon^2}[\beta_0 + C_1(3\gamma - \kappa_{\max})\varepsilon + O(\varepsilon^{4/3})], \tag{3.3}$$

where β_0 *and* C_1 *are the numbers given in section* 2, *and* $\kappa_{\max}$ *is the maximum value of the curvature of* $\partial\Omega$.

Proof. An upper bound of H_{C_3} with different error terms, which can be controlled by careful computations, has been obtained by [LP4, Lemma A.3].[10] When $\gamma = 0$, the lower bound estimate was obtained by Helffer and Morame [HM1]. Note that the key ingredients in Helffer and Morame's arguments are (i) the estimates of various cut-off functions; (ii) the estimate of the lowest eigenvalue of an ordinary differential operator with parameter ε in the half-line $\mathbb{R}_+$, with a homogeneous Neumann boundary condition $u'(0) = 0$. When $\gamma > 0$, (i) is still valid, and (ii) needs a minor modification to fit the de Gennes boundary condition $u'(0) + \varepsilon\gamma u(0) = 0$, and hence we can modify Helffer and Morame's arguments to get the lower bound. The details are omitted. □

[10] The constant C_2 appeared in [LP4] and was given by $\frac{u(0)^2}{\|u\|^2_{L^2}}$, where u is the eigenfunction of (2.1) for $z = z_0$. Hence $C_2 = 3C_1$.

As in [HM1], we can show that the eigenfunctions of (3.1) concentrate at the set of the maximum points of the curvature of $\partial\Omega$, $\mathcal{N}(\partial\Omega)$, as $\varepsilon \to 0$. In a neighborhood of $\partial\Omega$, $\Omega_\delta = \{x : \text{dist}(x, \partial\Omega) < \delta\}$, where $\delta > 0$ is small, $d_{\partial\Omega}(x)$ is a smooth function. Thus we can introduce a local coordinate (s, t), with s measuring the tangential distance and $t = d_{\partial\Omega}(x)$ measuring the normal distance. Any point $x \in \Omega_\delta$ can be represented by a vector-valued function $x(s, t)$, with $|s| \le L = |\partial\Omega|/2$ and $0 \le t < \delta$. Thus a point $x(s, t) \in \Omega_\delta$ corresponds with a unique (s, t), and hence we have functions $s(x)$ and $t(x)$, which are well defined on Ω_δ. After extending these functions onto $\bar\Omega$, every point $x \in \bar\Omega$ can be represented as $x = x(s, t)$.

COROLLARY 3.2. *Let* $\mathbf{A}$ *satisfy* (3.2) *and let* $\gamma > 0$ *be fixed. There exist positive constants* α_j, c_j, *and* M_j *depending only on* Ω *such that for the eigenfunctions* ϕ_ε *of* (3.1) *associated with* $\mu_\gamma(\varepsilon^{-2}\mathbf{A})$, *we have*

(i) $\int_\Omega \exp\big(\alpha_1\varepsilon^{-1}d_{\partial\Omega}(x)\big)|\phi_\varepsilon|^2dx \le M_1 \int_{\Omega\cap\{d_{\partial\Omega}(x)<c_2\varepsilon\}} |\phi_\varepsilon|^2dx$;

(ii) $\int_\Omega \exp\big(\alpha_2\varepsilon^{-1/2}[\kappa_{\max} - \kappa_r(s) - c_1\varepsilon^{1/3}]\big)|\phi_\varepsilon|^2dx \le M_2 \int_{\Omega\cap\{d_{\partial\Omega}(x)<c_2\varepsilon\}} |\phi_\varepsilon|^2dx$.

Proof. Conclusion (i) has been established in [HM1] when $\gamma = 0$, and the proof works when $\gamma > 0$, with a slight modification. In order to prove (ii), we use the method in [HM1] and (3.3) to show that for any $\mathbf{A}$ satisfying (3.2) and $\gamma > 0$, there exists a positive constant C such that for any $\phi \in W^{1,2}(\Omega)$ and small $\varepsilon > 0$,

$$\int_\Omega |\nabla_{\varepsilon^{-2}\mathbf{A}}\phi|^2dx + \gamma\int_{\partial\Omega} |\phi|^2ds \ge \frac{1}{\varepsilon^2}\int_\Omega W_\Omega(x)|\phi|^2dx, \tag{3.4}$$

where

$$W_\Omega(x) = \begin{cases} 1 - C\varepsilon^{4/3} & \text{if } d_{\partial\Omega}(x) \ge 2\varepsilon^{1/3}, \\ \beta_0 + C_1[3\gamma - \kappa_r(s)]\varepsilon - C\varepsilon^{4/3} & \text{if } d_{\partial\Omega}(x) < 2\varepsilon^{1/3}. \end{cases} \tag{3.5}$$

Here β_0 and C_1 are the numbers given in section 2, and $s = s(x)$ is associated with x through the representation $x = x(s, t)$. Then we apply the argument in [HP, proof of Theorem 6.1] and use (3.4) to get (ii). □

4. Elliptic estimates of minimizers. The regularity of the weak solutions of the Ginzburg–Landau system in three-dimensional domains has been discussed in [P4]. In this section we establish the estimates on a film, with constants independent of the thickness of the film. Let

$$D^{1,2}(\mathbb{R}^3) = \{\phi \in L^2_{\text{loc}}(\mathbb{R}^3) : \ \nabla\phi \in L^2(\mathbb{R}^3)\},$$

and on $D^{1,2}(\mathbb{R}^3)$ we define a seminorm $\|\phi\|_{1,2} = \|\nabla\phi\|_{L^2(\mathbb{R}^3)}$. After identifying two functions that differ by a constant, $(D^{1,2}(\mathbb{R}^3), \|\cdot\|_{1,2})$ is a Hilbert space [G, Lemma II.5.1]. Let $\mathbf{D}^{1,2}(\mathbb{R}^3)$ denote the corresponding space of vector fields. It follows from Theorem II.6.2 in [G] that for any $\mathbf{B} \in \mathbf{D}^{1,2}(\mathbb{R}^3)$, there exists a unique constant vector $\mathbf{b}$ such that $\mathbf{B} - \mathbf{b}$ can be approximated in the norm $\|\cdot\|_{1,2}$ by C_0^∞ vector fields. It is well known that for any $\mathbf{B} \in \mathbf{D}^{1,2}(\mathbb{R}^3)$,

$$\|\mathbf{B}\|^2_{1,2} \equiv \int_{\mathbb{R}^3} |\nabla\mathbf{B}|^2dxdz = \int_{\mathbb{R}^3} \{|\text{curl } \mathbf{B}|^2 + |\text{div } \mathbf{B}|^2\}dxdz; \tag{4.1}$$

see [L], as well as [GP, (3.2)]. The following space will also be useful to us:

$$\mathbf{D}^{1,2}(\mathbb{R}^3, \text{div}) = \{\mathbf{B} \in \mathbf{D}^{1,2}(\mathbb{R}^3) : \ \text{div } \mathbf{B} = 0 \ \text{ in } \mathbb{R}^3\}.$$

Let $W^{1,2}(D_l,\mathbb{C})$ be the Sobolev space of all complex-valued functions defined on $\bar{D}_l$. Given a unit vector $\mathbf{h}$, define $\mathbf{F_h}$ by (1.2), and let

$$\mathcal{W}(D_l)=\{(\psi,\mathbf{A}):\ \psi\in W^{1,2}(D_l,\mathbb{C}),\ \mathbf{A}-\mathbf{F_h}\in\mathbf{D}^{1,2}(\mathbb{R}^3)\}. \tag{4.2}$$

We consider the variational problem for the Ginzburg–Landau functional $\mathcal{G}$ on $\mathcal{W}(D_l)$. Define

$$C(\mathbf{h},\kappa,l,\sigma)=\inf_{(\psi,\mathbf{A})\in\mathcal{W}(D_l)}\mathcal{G}[\psi,\mathbf{A}]. \tag{4.3}$$

Due to the gauge invariance of $\mathcal{G}$, we can replace $\mathbf{A}$ by $\hat{\mathbf{A}}$ that satisfies curl $\hat{\mathbf{A}}=$ curl $\mathbf{A}$ and div $\hat{\mathbf{A}}=0$ in $\mathbb{R}^3$; see [GP, Lemma 3.1]. So we can restrict the functional $\mathcal{G}$ on a subspace of $\mathcal{W}(D_l)$:

$$\mathcal{W}(D_l,\mathrm{div})=\{(\psi,\mathbf{A})\in\mathcal{W}(D_l):\ \mathrm{div}\ \mathbf{A}=0\ \text{in}\ \mathbb{R}^3\}. \tag{4.4}$$

It is easy to show that the (global) minimizers exist, and they are the weak solutions of the Euler equations

$$\begin{cases} -\nabla^2_{\kappa\sigma\mathbf{A}}\psi=\kappa^2(1-|\psi|^2)\psi & \text{in } D_l,\\ \mathrm{curl}^2\mathbf{A}=\dfrac{1}{\kappa\sigma}\Im\{\bar{\psi}\nabla_{\kappa\sigma\mathbf{A}}\psi\}\chi_{D_l} & \text{in } \mathbb{R}^3,\\ (\nabla_{\kappa\sigma\mathbf{A}}\psi)\cdot\nu_D+\gamma\psi=0 & \text{on } \partial^*D_l,\\ \mathbf{A}-\mathbf{F_h}\in\mathbf{D}^{1,2}(\mathbb{R}^3,\mathrm{div}), \end{cases} \tag{4.5}$$

where χ_{D_l} is the characteristic function of D_l, namely, χ_{D_l} equals 1 in D_l and equals 0 in $\mathbb{R}^3\setminus D_l$. In the content of weak solutions, (4.5) is equivalent to (1.1); see [L, Chapter 5, section 4].

LEMMA 4.1. *Let $\kappa>0$, $\sigma>0$, and let $(\psi,\mathbf{A})$ be a minimal solution of* (1.1). *Then, for any $0<\alpha<1$,*

$$\begin{aligned} &\psi\in C^{2+\alpha}(D_l\cup\partial\Omega\times[0,l])\bigcup C^{2+\alpha}(D_l\cup\Omega\times\{0,l\}),\\ &\mathbf{A}\in C^{1+\alpha}(\bar{D}_l)\cup C^{2+\alpha}_{loc}(D_l)\cup C^{2+\alpha}_{loc}(\mathbb{R}^3\setminus\bar{D}_l). \end{aligned} \tag{4.6}$$

Moreover, we have the following estimates:

(i) *There exists $C>0$ independent of $\mathbf{h}$, l, κ, and σ such that*

$$\begin{aligned} \|\mathbf{A}-\mathbf{F_h}\|_{L^6(\mathbb{R}^3)}&\le\frac{C}{\sigma}\|\psi\|^2_{L^4(D_l)},\\ \|\mathrm{curl}\ \mathbf{A}-\mathbf{h}\|_{L^2(\mathbb{R}^3)}&\le\frac{C}{\sigma}\|\psi\|^2_{L^4(D_l)}. \end{aligned} \tag{4.7}$$

(ii) *For any $0<\alpha<1$, and for any $R>0$ such that $\bar{D}_l\subset B_R$, there exists $C(\alpha,R)>0$ independent of $\mathbf{h}$, l, κ, and σ such that for $q=3/(1-\alpha)$,*

$$\|\mathbf{A}-\mathbf{F_h}\|_{C^{1+\alpha}(R_R)}\le\ C(\alpha,R)\left\{\frac{1}{\sigma}\|\psi\|^2_{L^4(D_l)}+\frac{1}{\kappa\sigma}\|\Im\{\bar{\psi}\nabla_{\kappa\sigma\mathbf{A}}\psi\}\|_{L^q(D_l)}\right\}. \tag{4.8}$$

(iii) *For any positive numbers $a < b$ and $q > 1$, there exist positive constants $C(a,b)$ and $C(a,b,q)$ independent of $\mathbf{h}$, l, κ, and σ ($a\kappa^{-1} \le \sigma \le b\kappa$) such that*

$$\begin{aligned} &\|\Im\{\bar\psi\nabla_{\kappa\sigma\mathbf{A}}\psi\}\|_{L^\infty(D_l)} \le C(a,b)\sqrt{\kappa\sigma}\|\psi\|^2_{L^\infty(D_l)},\\ &\|\Im\{\bar\psi\nabla_{\kappa\sigma\mathbf{A}}\psi\}\|_{L^q(D_l)} \le C(a,b,q)\sqrt{\kappa\sigma}\|\psi\|_{L^q(D_l)}\|\psi\|_{L^\infty(D_l)}. \end{aligned} \tag{4.9}$$

Proof. Step 1. We prove (4.7). From the first equation in (1.1) we have

$$\int_{D_l} |\nabla_{\kappa\sigma\mathbf{A}}\psi|^2 dxdz = \kappa^2 \int_{D_l} (1-|\psi|^2)|\psi|^2 dxdz.$$

So

$$\mathcal{G}[\psi,\mathbf{A}] = \frac{\kappa^2}{2}|D_l| - \frac{\kappa^2}{2}\int_{D_l}|\psi|^4 dxdz + \kappa^2\sigma^2\int_{\mathbb{R}^3}|\text{curl }\mathbf{A}-\mathbf{h}|^2 dxdz.$$

Since $C(\mathbf{h},\kappa,l,\sigma) \le \mathcal{G}[0,\mathbf{F_h}] = \frac{\kappa^2}{2}|D_l|$, we have

$$\kappa^2\sigma^2\int_{\mathbb{R}^3}|\text{curl }\mathbf{A}-\mathbf{h}|^2 dxdz = C(\mathbf{h},\kappa,l,\sigma) - \frac{\kappa^2}{2}|D_l| + \frac{\kappa^2}{2}\int_{D_l}|\psi|^4 dxdz \le \frac{\kappa^2}{2}\|\psi\|^4_{L^4(\Omega)}.$$

So the second inequality in (4.7) is true. Using the Sobolev imbedding theorem we have

$$\|\mathbf{A}-\mathbf{F_h}\|^2_{L^6(\mathbb{R}^3)} \le C\int_{\mathbb{R}^3}\{|\text{curl}(\mathbf{A}-\mathbf{F_h})|^2 + |\text{div}(\mathbf{A}-\mathbf{F_h})|^2\}dxdz.$$

Since $\text{div}(\mathbf{A}-\mathbf{F_h}) = 0$, the first inequality in (4.7) follows.

Step 2. We prove (4.8). Let

$$\mathbf{f} = \frac{1}{\kappa\sigma}\Im\{\bar\psi\nabla_{\kappa\sigma\mathbf{A}}\psi\}\chi_{D_l}, \qquad \mathbf{U} = \mathbf{A}-\mathbf{F_h}.$$

$\mathbf{f} \in L^2(\mathbb{R}^3)$, and $\mathbf{U}$ is a weak solution of the equation $\text{curl}^2\mathbf{U} = \mathbf{f}$ in $\mathbb{R}^3$. Since $\text{div }\mathbf{U} = 0$, this equation can be written as

$$-\Delta\mathbf{U} = \mathbf{f} \qquad \text{in } \mathbb{R}^3. \tag{4.10}$$

Applying the De Giorge L^∞ estimate [GT, Theorem 8.17] to each component of (4.10), we find that there exists $C > 0$ independent of κ and σ such that for any $0 < r < R$,

$$\|\mathbf{U}\|_{L^\infty(B_r)} \le C\big\{(R-r)^{-3/2}\|\mathbf{U}\|_{L^2(B_R)} + R^{1/2}\|\mathbf{f}\|_{L^2(B_R)}\big\}.$$

Let us choose $\rho > \max_{(x,z)\in D_l}\sqrt{|x|^2+z^2}$ and $\rho < r < R$. We have

$$\|\mathbf{U}\|_{L^\infty(B_r)} \le C(r,R)\big\{\|\mathbf{U}\|_{L^2(B_R)} + \|\mathbf{f}\|_{L^2(B_R)}\big\}.$$

Then, applying the Hölder estimate for weak solutions [GT, Theorem 8.24], we find that for some $0 < \alpha_0 < 1$ and for all $\rho < r < R$,

$$\|\mathbf{U}\|_{C^{\alpha_0}(B_r)} \le C(r,R)\big\{\|\mathbf{U}\|_{L^2(B_R)} + \|\mathbf{f}\|_{L^2(B_R)}\big\}. \tag{4.11}$$

In particular, $\mathbf{A} \in C^{\alpha_0}(\bar D_l)$.

Next, from (1.1) we see that ψ satisfies

$$\begin{cases} -\Delta\psi + 2i\kappa\sigma\mathbf{A}\cdot\nabla\psi + \kappa^2\sigma^2|\mathbf{A}|^2\psi = \kappa^2(1-|\psi|^2)\psi & \text{in } D_l, \\ \dfrac{\partial\psi}{\partial\nu_D} - i\kappa\sigma(\mathbf{A}\cdot\nu_D)\psi + \gamma\psi = 0 & \text{on } \partial^* D_l. \end{cases} \tag{4.12}$$

Since $\mathbf{A} \in C^{\alpha_0}(\bar{D}_l)$, applying the Hölder estimate (see, for instance, [GT, Lemma 6.27]) on $\bar{D}_l$, we find that

$$\psi \in C^{1+\alpha_0}(D_l \cup \partial\Omega \times [0,l]) \bigcup C^{1+\alpha_0}(D_l \cup \Omega \times \{0,l\}).$$

Therefore,

$$\mathbf{f} \in C^{\alpha_0}(D_l \cup \partial\Omega \times [0,l]) \bigcup C^{\alpha_0}(D_l \cup \Omega \times \{0,l\}),$$

and hence $\mathbf{f} \in L^\infty(\mathbb{R}^3)$.

Now we apply the Hölder gradients estimate to (4.10) again and find that for any $0 < \alpha < 1$, $\mathbf{U} \in C^{1+\alpha}_{\text{loc}}(\mathbb{R}^3)$ (hence $\mathbf{A} \in C^{1+\alpha}_{\text{loc}}(\mathbb{R}^3)$), and for $q = 3/(1-\alpha)$,

$$\|\nabla\mathbf{U}\|_{C^\alpha(B_r)} \le C(r,R,\alpha)\big\{\|\mathbf{f}\|_{L^q(B_R)} + \|\nabla\mathbf{U}\|_{L^2(B_R)} + \|\mathbf{U}\|_{L^2(B_R)}\big\}.$$

Since div $\mathbf{A} = 0$, we find that

$$\|\nabla\mathbf{U}\|_{C^\alpha(B_r)} \le C(r,R,\alpha)\big\{\|\mathbf{f}\|_{L^q(B_R)} + \|\text{curl } \mathbf{U}\|_{L^2(B_R)} + \|\mathbf{U}\|_{L^2(B_R)}\big\}.$$

Using this inequality and $\|\mathbf{U}\|_{L^2(B_R)} \le CR\|\mathbf{U}\|_{L^6(B_R)}$, together with (4.11) and (4.7), we get (4.8).

Step 3. For any $0 < \alpha < 1$, since $\mathbf{A} \in C^{1+\alpha}(\bar{D}_l)$, we apply the Hölder estimate to (4.12) again (see [GT, Lemma 6.27]) and find that

$$\psi \in C^{2+\alpha}(D_l \cup \Omega \times [0,l]) \bigcup C^{2+\alpha}(D_l \cup \partial\Omega \times \{0,l\}).$$

Step 4. We prove (4.9). First we assume $l \ge (\kappa\sigma)^{-1/2}$. Without loss of generality we assume $\kappa\sigma \gg 1$. We use a blow-up argument in the scale of $(\kappa\sigma)^{-1/2}$ and get a limiting equation with bounded coefficients and apply the L^∞ estimate to it. Then we return to the original scale and find

$$\|\nabla_{\kappa\sigma\mathbf{A}}\psi\|_{L^\infty(D_l)} \le C\sqrt{\kappa\sigma}\|\psi\|_{L^\infty(D_l)}. \tag{4.13}$$

Equation (4.9) follows from (4.13) immediately. We omit the details but refer to [HP, Proposition 4.2] for a two-dimensional problem.

Next we assume that $l \le (\kappa\sigma)^{-1/2}$. Recall that div $\mathbf{A} = 0$. Let $\chi \in W^{1,2}(D_l)$ be a weak solution of the equation

$$\Delta\chi = 0 \quad \text{in } D_l, \qquad \frac{\partial\chi}{\partial\nu_D} = \mathbf{A}\cdot\nu_D \quad \text{on } \partial^* D_l,$$

and satisfy $\int_{D_l}\chi dxdz = 0$. Note that χ is a piecewise $C^{2+\alpha}$ function, and (see [GT, Lemma 6.27])

$$\begin{aligned} &\|\chi\|_{C^{2+\alpha}(D_l \cup \partial\Omega\times[0,l])} + \|\chi\|_{C^{2+\alpha}(D_l \cup \bar{\Omega}\times\{0,l\})} \\ &\le C\Big\{\|\mathbf{A}\cdot\nu_D\|_{C^{1+\alpha}(D_l \cup \partial\Omega\times[0,l])} + \|\mathbf{A}\cdot\nu_D\|_{C^{1+\alpha}(D_l \cup \bar{\Omega}\times\{0,l\})}\Big\} \le C\|\mathbf{A}\|_{C^{1+\alpha}(B_\rho)}, \end{aligned} \tag{4.14}$$

where $\rho > \max_{(x,z)\in D_l} \sqrt{|x|^2+z^2}$.

Let $\tilde{\psi} = e^{-i\kappa\sigma\chi}\psi$ and $\tilde{\mathbf{A}} = \mathbf{A} - \nabla\chi$. Then $\tilde{\mathbf{A}}\cdot\nu_D = 0$ on $\partial^* D_l$. In particular,

$$\tilde{A}_3(x_1,x_2,0) = \tilde{A}_3(x_1,x_2,l) = 0. \tag{4.15}$$

$\tilde{\psi}$ satisfies

$$\begin{cases} -\Delta\tilde{\psi} + 2i\kappa\sigma\tilde{\mathbf{A}}\cdot\nabla\tilde{\psi} + \kappa^2\sigma^2|\tilde{\mathbf{A}}|^2\tilde{\psi} = \kappa^2(1-|\tilde{\psi}|^2)\tilde{\psi} & \text{in } D_l, \\ \dfrac{\partial\tilde{\psi}}{\partial\nu_D} + \gamma\tilde{\psi} = 0 & \text{on } \partial^* D_l. \end{cases}$$

Let ξ_l be the eigenfunction of (2.3) and $c_l = 1/\|\xi_l\|_{L^\infty([0,l])}$. Using (2.4) and (2.5) we can find $C>0$ such that for all small l,

$$\max_{0\le z\le l}\left|\frac{\xi_l'(z)}{\xi_l(z)}\right| \le C.$$

Let

$$\phi = \frac{\tilde{\psi}}{c_l\xi_l} = \frac{e^{-i\chi}}{c_l\xi_l}\psi.$$

Then ϕ satisfies

$$\begin{cases} -\Delta\phi + 2i\kappa\sigma\tilde{\mathbf{A}}\cdot\nabla\phi + \kappa^2\sigma^2|\tilde{\mathbf{A}}|^2\phi - \dfrac{2\xi_l'}{\xi_l}\partial_z\phi + \Big[\tau_\gamma(l)^2 + 2i\kappa\sigma\tilde{A}_3\dfrac{\xi_l'}{\xi_l}\Big]\phi \\ \qquad = \kappa^2(1-c_l^2\xi_l^2|\phi|^2)\phi & \text{in } D_l, \\ \dfrac{\partial\phi}{\partial z} = 0 & \text{if } z=0, \text{ or } l, \\ \dfrac{\partial\phi}{\partial\nu} + \gamma\phi = 0 & \text{on } \partial\Omega\ \times(0,l). \end{cases} \tag{4.16}$$

Using (4.15), we can extend ϕ and $\tilde{\mathbf{A}}$ in the z direction in the following way: for $0<z<l$,

$$\begin{aligned} &\tilde{A}_j(x_1,x_2,-z) = \tilde{A}_j(x_1,x_2,z) \quad \text{and} \quad \tilde{A}_j(x_1,x_2,l+z) = \tilde{A}_j(x_1,x_2,l-z), \quad j=1,\ 2, \\ &\tilde{A}_3(x_1,x_2,-z) = \tilde{A}_3(x_1,x_2,z) \quad \text{and} \quad \tilde{A}_3(x_1,x_2,l+z) = -\tilde{A}_3(x_1,x_2,l-z), \\ &\phi(x_1,x_2,-z) = \phi(x_1,x_2,z) \qquad \text{and} \quad \phi(x_1,x_2,l+z) = \phi(x_1,x_2,l-z). \end{aligned}$$

Extend ξ_l by letting $\xi_l(-z) = \xi_l(z)$ and $\xi_l(l+z) = \xi_l(l-z)$. Then we get an equation for ϕ on $\Omega\times(-l,2l)$, which is an extension of (4.16):

$$\begin{cases} -\Delta\phi + 2i\kappa\sigma\tilde{\mathbf{A}}\cdot\nabla\phi + \kappa^2\sigma^2|\tilde{\mathbf{A}}|^2\phi - \dfrac{2\xi_l'}{\xi_l}\partial_z\phi + \Big[\tau_\gamma(l)^2 + 2i\kappa\sigma\tilde{A}_3\dfrac{\xi_l'}{\xi_l}\Big]\phi \\ \qquad = \kappa^2(1-c_l^2\xi_l^2|\phi|^2)\phi & \text{in } \Omega\times(-l,2l), \\ \dfrac{\partial\phi}{\partial z} = 0 & \text{if } z=-l, \text{ or } 2l, \\ \dfrac{\partial\phi}{\partial\nu} + \gamma\phi = 0 & \text{on } \partial\Omega\ \times(-l,2l). \end{cases} \tag{4.17}$$

We can verify that $\tilde{\mathbf{A}} \in C^\alpha(\bar{\Omega}\times[-l,2l])$. After the extension ξ_l' is no longer continuous at $z=0$ and l, however, $\xi_l'\partial_z\phi$ and $\tilde{A}_3\xi_l'$ vanish at $z=0$ and l. So we can verify that ϕ is a weak solution of (4.17) on $\Omega\times(-l,2l)$.

We can repeat this process and extend ϕ onto a cylinder $\Omega\times(a,b)$ with $b-a=1$, and ϕ is a weak solution of a new equation similar to (4.17) on the cylinder. Then we apply the elliptic estimate to the new equation and conclude that

$$\|\nabla_{\kappa\sigma\tilde{\mathbf{A}}}\phi\|_{L^\infty(\bar{\Omega}\times[a,b])} \le C\sqrt{\kappa\sigma}\|\phi\|_{L^\infty(\Omega\times[a,b])} = C\sqrt{\kappa\sigma}\|\psi\|_{L^\infty(D_l)}.$$

Returning to D_l we get

$$\|\nabla_{\kappa\sigma\tilde{\mathbf{A}}}\phi\|_{L^\infty(D_l)} \le C\sqrt{\kappa\sigma}\|\psi\|_{L^\infty(D_l)}.$$

Since $\psi = c_l\xi_l\phi e^{i\kappa\sigma\chi}$ and $\mathbf{A} = \tilde{\mathbf{A}} + \nabla\chi$, we have

$$\begin{aligned}
&\bar{\psi}\nabla_{\kappa\sigma\mathbf{A}}\psi = c_l^2\xi_l^2\bar{\phi}\nabla_{\kappa\sigma\tilde{\mathbf{A}}}\phi + c_l^2|\phi|^2\xi_l\nabla\xi_l,\\
&\Im\{\bar{\psi}\nabla_{\kappa\sigma\mathbf{A}}\psi\} = c_l^2\xi_l^2\Im\{\bar{\phi}\nabla_{\kappa\sigma\tilde{\mathbf{A}}}\phi\}.
\end{aligned}$$

Hence

$$\begin{aligned}
&\|\Im\{\bar{\psi}\nabla_{\kappa\sigma\mathbf{A}}\psi\}\|_{L^\infty(D_l)} \le \|\Im\{\bar{\phi}\nabla_{\kappa\sigma\tilde{\mathbf{A}}}\phi\}\|_{L^\infty(D_l)} \le C\sqrt{\kappa\sigma}\|\psi\|^2_{L^\infty(D_l)},\\
&\|\Im\{\bar{\psi}\nabla_{\kappa\sigma\mathbf{A}}\psi\}\|_{L^q(D_l)} \le \|\Im\{\bar{\phi}\nabla_{\kappa\sigma\tilde{\mathbf{A}}}\phi\}\|_{L^q(D_l)} \le C(q)\sqrt{\kappa\sigma}\|\psi\|_{L^q(D_l)}\|\psi\|_{L^\infty(D_l)}.
\end{aligned}$$

Equation (4.9) is proved. □

5. An eigenvalue problem on films. In this section we study the lowest eigenvalue $\mu_\gamma(\varepsilon^{-2}\mathbf{F})$ of

$$\begin{cases} -\nabla^2_{\varepsilon^{-2}\mathbf{F}}\phi = \mu\phi & \text{in } D_l,\\ (\nabla_{\varepsilon^{-2}\mathbf{F}}\phi)\cdot\nu_D + \gamma\phi = 0 & \text{on } \partial^* D_l, \end{cases} \tag{5.1}$$

where curl $\mathbf{F} = \mathbf{e}_3 = (0,0,1)$.

THEOREM 5.1. *Let* curl $\mathbf{F} = (0,0,1)$. *For small* ε *and* l *we have*

$$\mu_\gamma(\varepsilon^{-2}\mathbf{F}) = \tau_\gamma(l)^2 + \beta_0\varepsilon^{-2} + C_1(3\gamma - \kappa_{\max})\varepsilon^{-1} + O(\varepsilon^{-2/3}), \tag{5.2}$$

where $\tau_\gamma(l)^2$ *is the lowest eigenvalue of* (2.3), *and* β_0 *and* C_1 *are the numbers given in section* 2.

Proof. Due to gauge invariance of the operator $-\nabla^2_{\varepsilon^{-2}\mathbf{F}}$, we choose $\mathbf{F} = (-x_2,0,0)$. Then (5.1) is a separable equation. The eigenfunctions have the form $\phi(x,z) = \varphi(x_1,x_2)\xi_l(z)$, and

$$\mu_\gamma(\varepsilon^{-2}\mathbf{F}) = \beta_\gamma(\varepsilon^{-2}\mathbf{E}) + \tau_\gamma(l)^2,$$

where ξ_l is the function given in (2.4), $\mathbf{E} = (-x_2,0)$, and $\beta_\gamma(\varepsilon^{-2}\mathbf{E})$ is the lowest eigenvalue of (3.1) for $\mathbf{A} = \mathbf{E}$. An estimate for $\beta_\gamma(\varepsilon^{-2}\mathbf{E})$ has been obtained in (3.3). So the conclusion follows. □

Next we establish an integral inequality for functions vanishing at the lateral surface of D_l. Let

$$W^{1,2}(D_l,0) = \{\phi\in W^{1,2}(D_l):\ \phi = 0 \ \text{ on } \partial\Omega\times[0,l]\}.$$

LEMMA 5.2. *Let* $\mathbf{A} = (A_1, A_2, A_3) \in C^1(\bar{D}_l)$. *For any* $\phi \in W^{1,2}(D_l, 0)$ *we have*

(5.3)
$$\int_{D_l} |\nabla_{\varepsilon^{-2}\mathbf{A}}\phi|^2 dxdz + \gamma \int_{\partial D_l} |\phi|^2 dS \geq \int_{D_l} \{\varepsilon^{-2}(\partial_1 A_2 - \partial_2 A_1) + \tau_\gamma(l)^2\}|\phi|^2 dxdz.$$

In particular, for any $\phi \in W^{1,2}(D_l, 0)$,

$$\int_{D_l} |\nabla_{\varepsilon^{-2}\mathbf{F}}\phi|^2 dxdz + \gamma \int_{D_l} |\phi|^2 dS \geq \left[\varepsilon^{-2} + \tau_\gamma(l)^2\right] \int_{D_l} |\phi|^2 dxdz. \tag{5.4}$$

Proof. Let $\phi \in W^{1,2}(D_l, 0) \cap C^1(\bar{D}_l)$. For a fixed $z \in [0, l]$, since $\phi(x, z) = 0$ for $x \in \partial\Omega$, using Theorem 4 in [M] we have

$$\int_\Omega \left\{|(\partial_1 - i\varepsilon^{-2}A_1)\phi(x,z)|^2 + |(\partial_2 - i\varepsilon^{-2}A_2)\phi(x,z)|^2\right\} dx \geq \frac{1}{\varepsilon^2} \int_\Omega (\partial_1 A_2 - \partial_2 A_1)|\phi(x,z)|^2 dx.$$

Integrating this inequality in z we get

$$\int_{D_l} \left\{|(\partial_1 - i\varepsilon^{-2}A_1)\phi|^2 + |(\partial_2 - i\varepsilon^{-2}A_2)\phi|^2\right\} dxdz \geq \frac{1}{\varepsilon^2} \int_{D_l} (\partial_1 A_2 - \partial_2 A_1)|\phi|^2 dxdz.$$

On the other hand, for a fixed $x \in \Omega$, using the Kato's inequality we find

$$\begin{aligned} &\int_0^l |(\partial_z - i\varepsilon^{-2}A_3)\phi(x,z)|^2 dz + \gamma\left[|\phi(x,0)|^2 + |\phi(x,l)|^2\right] \\ &\geq \int_0^l \left|\partial_z|\phi(x,z)|\right|^2 dz + \gamma\left[|\phi(x,0)|^2 + |\phi(x,l)|^2\right] \geq \tau_\gamma(l)^2 \int_0^l |\phi(x,z)|^2 dz. \end{aligned}$$

Thus

$$\int_{D_l} |(\partial_z - i\varepsilon^{-2}A_3)\phi|^2 dxdz + \gamma \int_\Omega \left[|\phi(x,0)|^2 + |\phi(x,l)|^2\right] dx \geq \tau_\gamma(l)^2 \int_{D_l} |\phi|^2 dxdz.$$

So we get (5.3). Since $\partial_1 F_2 - \partial_2 F_1 = 1$, (5.4) follows. □

The inequality (5.4) yields an estimate of the lowest eigenvalue of $-\nabla^2_{\varepsilon^{-2}\mathbf{F}}$ in D_l with Dirichlet boundary condition on the lateral surface $\partial\Omega \times [0, l]$ and Robin condition on the top and bottom faces:

$$\begin{cases} -\Delta\phi + 2i\varepsilon^{-2}x_2\partial_1\phi + \varepsilon^{-4}x_2^2\phi = \lambda\phi & \text{in } \Omega \times (0, l), \\ \partial_z\phi = \gamma\phi & \text{on } \Omega \times \{0\}, \\ \partial_z\phi = -\gamma\phi & \text{on } \Omega \times \{l\}, \\ \phi = 0 & \text{on } \partial\Omega \times (0, l). \end{cases}$$

This problem can be solved by the method of separable variables as for (5.1). Hence the lowest eigenvalue is given by $\lambda = \alpha + \tau_\gamma(l)^2$, where α is the lowest eigenvalue of the Dirichlet problem

$$\begin{cases} -\Delta\varphi + 2i\varepsilon^{-2}x_2\partial_1\varphi + \varepsilon^{-4}x_2^2\varphi = \alpha\varphi & \text{in } \Omega, \\ \varphi = 0 & \text{on } \partial\Omega. \end{cases}$$

Using the result in [LP2, Theorem 2] about an eigenvalue problem in the entire plane we find that $\alpha \geq \varepsilon^{-2}$. So $\lambda \geq \varepsilon^{-2} + \tau_\gamma(l)^2$. Hence we get (5.4) again.

Now we can establish an integral inequality on D_l, which can be viewed as a three-dimensional version of (3.4) and is useful in the study of the concentration phenomenon of order parameters on films.

THEOREM 5.3. *For any $\phi \in W^{1,2}(D_l)$ we have*

$$\int_{D_l} |\nabla_{\varepsilon^{-2}\mathbf{F}}\phi|^2 dxdz + \gamma \int_{\partial D_l} |\phi|^2 dS \geq \varepsilon^{-2} \int_{D_l} \mathcal{W}_{D_l}(x,z)|\phi|^2 dxdz. \tag{5.5}$$

$\mathcal{W}_{D_l}$ is defined by

$$\mathcal{W}_{D_l}(x,z) = \begin{cases} 1 + \varepsilon^2\tau_\gamma(l)^2 - C\varepsilon^{4/3} & \text{if } d_{\partial\Omega}(x) \geq 2\varepsilon^{1/3}, \\ \beta_0 + C_1[3\gamma - \kappa_r(s)]\varepsilon + \varepsilon^2\tau_\gamma(l)^2 - C\varepsilon^{4/3} & \text{if } d_{\partial\Omega}(x) < 2\varepsilon^{1/3}, \end{cases} \tag{5.6}$$

where β_0, C_1, and $\tau_\gamma(l)$ are the numbers given in section 2, C depends only on Ω and γ, and $s = s(x)$ is associated with x through the representation $x = x(s,t)$.

Proof. We apply the idea in [HM1]. Let (s,t) be the local coordinates in Ω_δ described in section 3, and (s,t) has been extended onto $\bar{\Omega}$. Then (s,t,z) gives the new coordinates on $\bar{D}_l$. Choose cut-off functions $\eta_0(t)$ and $\eta_1(t)$ depending only on t such that

$$\mathrm{spt}(\eta_0) \subset \left[\frac{\varepsilon^{1/3}}{20}, +\infty\right), \quad \mathrm{spt}(\eta_1) \subset \left(-\infty, \frac{\varepsilon^{1/3}}{10}\right], \quad |\eta_j'(t)| \leq C\varepsilon^{-1/3}, \quad \eta_0^2 + \eta_1^2 = 1.$$

Then

$$\begin{aligned} &\int_{D_l} |\nabla_{\varepsilon^{-2}\mathbf{F}}\phi|^2 dxdz + \gamma \int_{\partial D_l} |\phi|^2 dS \\ &= \sum_{j=0}^{1} \left\{ \int_{D_l} \left[|\nabla_{\varepsilon^{-2}\mathbf{F}}(\eta_j\phi)|^2 - |\nabla\eta_j|^2|\phi|^2 \right] dxdz + \gamma \int_{\partial D_l} |\eta_j\phi|^2 dS \right\}. \end{aligned} \tag{5.7}$$

Note that $\eta_0\phi$ is supported in $\Omega^\varepsilon \times [0,l]$, where

$$\Omega^\varepsilon = \left\{ x \in \Omega : \ d_{\partial\Omega}(x) \geq \frac{\varepsilon^{1/3}}{20} \right\},$$

namely, $\eta_0\phi = 0$ in a thin cylinder around the lateral surface $\partial\Omega \times [0,l]$. $\eta_1\phi$ is supported near the lateral surface.

Step 1. We estimate $\eta_0\phi$. The sum in (5.7) involving $\eta_0\phi$ is

$$S_1 \equiv \int_{D_l} |\nabla_{\varepsilon^{-2}\mathbf{F}}(\eta_0\phi)|^2 dxdz + \gamma \int_{\Omega^\varepsilon} \eta_0^2 \{|\phi(x,0)|^2 + |\phi(x,l)|^2\} dx - \int_{D_l} |\nabla\eta_0|^2|\phi|^2 dxdz.$$

Since $|\nabla\eta_0| \leq C\varepsilon^{-1/3}$, we use (5.4) to get

$$S_1 \geq \left[\varepsilon^{-2} + \tau_\gamma(l)^2\right] \int_{D_l} |\eta_0\phi|^2 dxdz - O(\varepsilon^{-2/3}) \int_{D_l} |\phi|^2 dxdz.$$

Step 2. We estimate $\eta_1\phi$. The sum in (5.7) involving $\eta_1\phi$ is

$$S_2 \equiv \int_{D_l} |\nabla_{\varepsilon^{-2}\mathbf{F}}(\eta_1\phi)|^2 dxdz + \gamma \int_{\partial D_l} |\eta_1\phi|^2 dS - \int_{D_l} |\nabla\eta_1|^2|\phi|^2 dxdz.$$

Choose a family of cut-off functions $\{\chi_i\}_{i\in I}$ such that

$$\sum_{i\in I}\chi_i^2(x)=1 \quad \text{for all } x\in\Omega_{\varepsilon^{1/3}}, \qquad \sum_{i\in I}|\nabla\chi_i(x)|^2\le C\varepsilon^{-2/3}.$$

Then

$$\begin{aligned}S_2=&\sum_{i\in I}\left\{\int_{D_l}|\nabla_{\varepsilon^{-2}\mathbf{F}}(\chi_i\eta_1\phi)|^2dxdz+\gamma\int_{\partial D_l}|\chi_i\eta_1\phi|^2dS\right\}\\&-\int_{D_l}|\nabla\eta_1|^2|\phi|^2dxdz-\sum_{i\in I}\int_{D_l}|\nabla\chi_i|^2|\eta_1\phi|^2dxdz.\end{aligned}$$

For each $i\in I$, let $\phi_i=\chi_i\eta_1\phi$. Note that $\chi_i\eta_1$ depends only on x. $\bar D_l\cap\operatorname{spt}(\phi_i)$ is contained in a set G_i, whose coordinates (s,t,z) satisfy

$$|s-s_i|\le C\varepsilon^{1/3},\quad 0\le t\le\frac{\varepsilon^{1/3}}{10},\quad 0\le z\le l.$$

$\phi_i=0$ on three of the faces of G_i, which correspond with $t=\frac{\varepsilon^{1/3}}{10}$, $s=s_i-C\varepsilon^{1/3}$, and $s=s_i+C\varepsilon^{1/3}$, respectively. Hence, to estimate S_2, we are led to an eigenvalue problem on G_i with Dirichlet conditions on the three faces of G_i and Robin conditions on the other three faces of G_i. As in Theorem 5.1, we find the lowest eigenvalue λ_i of this problem by the method of separable variables:

$$\lambda_i=\frac{1}{\varepsilon^2}[\beta_0+C_1(3\gamma-\kappa_i)\varepsilon+O(\varepsilon^{4/3})]+\tau_\gamma(l)^2, \tag{5.8}$$

where

$$\kappa_i=\max_{x\in\partial\Omega\cap\bar G_i}\kappa_r(x).$$

Note that if $|s-s_i|\le C\varepsilon^{1/3}$, then $|\kappa_r(s)-\kappa_r(s_i)|\le C\varepsilon^{1/3}$. Using this and (5.8) we get

$$\begin{aligned}&\int_{D_l}|\nabla_{\varepsilon^{-2}\mathbf{F}}\phi_i|^2dxdz+\gamma\int_{\partial D_l}|\phi_i|^2dS\ge\lambda_i\int_{D_l}|\phi_i|^2dxdz\\&=\left\{\varepsilon^{-2}\left[\beta_0+C_1(3\gamma-\kappa_i)\varepsilon+O(\varepsilon^{4/3})\right]+\tau_\gamma(l)^2\right\}\int_{D_l}|\phi_i|^2dxdz\\&\ge\varepsilon^{-2}\int_{D_l}\left\{\beta_0+C_1(3\gamma-\kappa_r(s))\varepsilon+O(\varepsilon^{4/3})+\varepsilon^2\tau_\gamma(l)^2\right\}|\phi_i|^2dxdz.\end{aligned}$$

So

$$\begin{aligned}&\sum_{i\in I}\left\{\int_{D_l}|\nabla_{\varepsilon^{-2}\mathbf{F}}(\chi_i\eta_1\phi)|^2dxdz+\gamma\int_{\partial D_l}|\chi_i\eta_1\phi|^2dS\right\}\\&\ge\varepsilon^{-2}\int_{D_l}\left\{\beta_0+C_1(3\gamma-\kappa_r(s))\varepsilon+O(\varepsilon^{4/3})+\varepsilon^2\tau_\gamma(l)^2\right\}|\eta_1\phi|^2dxdz.\end{aligned}$$

From the choice of η_1 and χ_i we have

$$\begin{aligned}\int_{D_l}|\nabla\eta_1|^2|\phi|^2dxdz&\le C\varepsilon^{-2/3}\int_{D_l}|\phi|^2dxdz,\\\sum_{i\in I}\int_{D_l}|\nabla\chi_i|^2|\eta_1\phi|^2dxdz&\le C\varepsilon^{-2/3}\int_{D_l}|\phi|^2dxdz.\end{aligned}$$

Hence we have

$$S_2 \geq \varepsilon^{-2} \int_{D_l} \{\beta_0 + C_1(3\gamma - \kappa_r(s))\varepsilon + \varepsilon^2 \tau_\gamma(l)^2\} |\eta_1 \phi|^2 dxdz - O(\varepsilon^{-2/3}) \int_{D_l} |\phi|^2 dxdz.$$

Step 3. Combining the computations in Steps 1 and 2 we find

$$\begin{aligned}
&\int_{D_l} |\nabla_{\varepsilon^{-2}\mathbf{F}} \phi|^2 dxdz + \gamma \int_{\partial D_l} |\phi|^2 dS = S_1 + S_2 \\
&\geq \varepsilon^{-2} \int_{D_l} \{[1 + \varepsilon^2 \tau_\gamma(l)^2] |\eta_0 \phi|^2 + [\beta_0 + C_1(3\gamma - \kappa_r(s))\varepsilon + \varepsilon^2 \tau_\gamma(l)^2] |\eta_1 \phi|^2\} dxdz \\
&\quad - O(\varepsilon^{-2/3}) \int_{D_l} |\phi|^2 dxdz \\
&\geq \varepsilon^{-2} \int_{D_l} \mathcal{W}_{D_l}(x,z) |\phi|^2 dxdz,
\end{aligned}$$

where $\mathcal{W}_{D_l}(x,z)$ is the function given in (5.6). □

COROLLARY 5.4. *Let* curl $\mathbf{F} = (0,0,1)$ *and let* ϕ_ε *be an eigenfunction associated with* $\mu_\gamma(\varepsilon^{-2}\mathbf{F})$. *Then there exist positive numbers* α_j, b_j, c_j, *and* M_j *independent of* l *such that, for all small* $\varepsilon > 0$,

(i) $\int_{D_l} \exp\big(\alpha_1 \varepsilon^{-1} d_{\partial\Omega}(x)\big) |\phi_\varepsilon|^2 dxdz \leq M_1 \int_{D_l \cap \{d_{\partial\Omega}(x) < c_1\varepsilon\}} |\phi_\varepsilon|^2 dxdz$;

(ii) $\int_{D_l} \exp\big(\alpha_2 \varepsilon^{-1/2} [\kappa_{\max} - \kappa_r(s) - b_2 \varepsilon^{1/3}]\big) |\phi_\varepsilon|^2 dxdz \leq M_2 \int_{D_l \cap \{d_{\partial\Omega}(x) < c_2\varepsilon\}} |\phi_\varepsilon|^2 dxdz$.

Moreover, if $l \gg \varepsilon$,

(iii) $\int_{D_l} \exp\big(\alpha_3 \varepsilon^{-1} d_l(x,z)\big) |\phi_\varepsilon|^2 dxdz \leq M_3 \int_{D_l \cap \{d_l(x,z) < c_3\varepsilon\}} |\phi_\varepsilon|^2 dxdz$.

Remark 4. The above corollary shows that, as $\varepsilon \to 0$, the eigenfunctions of (5.1) associated with the lowest eigenvalue localize in the strip $\mathcal{N}(\partial\Omega) \times [0,l]$. Conclusion (i) gives an exponential decay of the eigenfunctions in the direction normal to the lateral surface, conclusion (ii) shows an exponential decay in tangential direction away from $\mathcal{N}(\partial\Omega) \times [0,l]$, and conclusion (iii) shows an exponential decay away from the total boundary of D_l. These conclusions are proved using the Agmon argument [A], and the details are omitted (see the proof of Theorem 6.2 in section 6 for a related estimate).

6. Films in perpendicular fields. In this section we study a film with small l and large κ (l may vary with κ) that is placed in a perpendicular applied field, namely, $\mathbf{h} \equiv \mathbf{e}_3 = (0,0,1)$. We shall estimate the value of H_{C_3} and study nucleation of superconductivity. Let curl $\mathbf{F} = \mathbf{e}_3$.

First, using Theorem 5.1 and applying the argument in [LP4, Appendix], we obtain a lower bound of H_{C_3}.

LEMMA 6.1. *When* $l - 2\gamma\kappa^{-2} \gg \kappa^{-4}$ *we have*

$$H_{C_3}(\mathbf{e}_3, \kappa, l) \geq \left(1 - \frac{2\gamma}{l\kappa^2}\right) \frac{\kappa}{\beta_0} + \frac{C_1}{\beta_0^{3/2}} (\kappa_{\max} - 3\gamma) \left(1 - \frac{2\gamma}{l\kappa^2}\right)^{1/2} + O(\kappa^{-1/3}).$$

Proof. As observed in [LP4],

$$H_{C_3} \geq \sigma_* \equiv \sigma_*(\kappa) = \max\{\sigma > 0 : \mu_\gamma(\kappa\sigma\mathbf{F}) = \kappa^2\}.$$

Using the equality

$$\kappa^2 = \mu_\gamma(\kappa\sigma_*\mathbf{F}) = \beta_\gamma(\kappa\sigma_*\mathbf{E}) + \tau_\gamma(l)^2,$$

where $\mathbf{E} = (-x_2, 0)$, and the condition $l - 2\gamma\kappa^{-2} \gg \kappa^{-4}$, we find that as $\kappa \to \infty$, $\beta_\gamma(\kappa\sigma_*\mathbf{E}) \to \infty$, and hence $\kappa\sigma_* \to \infty$. Then we use Theorem 5.1 to get

$$\kappa^2 = \beta_0\kappa\sigma_* + C_1(3\gamma - \kappa_{\max})\sqrt{\kappa\sigma_*} + O((\kappa\sigma_*)^{1/3}) + \frac{2\gamma}{l} - \frac{\gamma^2}{3} + O(\gamma^3 l).$$

Thus

$$\sqrt{\kappa\sigma_*} = \frac{1}{2\beta_0}\left\{C_1(\kappa_{\max} - 3\gamma) + \left[4\beta_0\left(\kappa^2 - \frac{2\gamma}{l}\right) + O(\kappa\sigma_*)^{1/3}\right]^{1/2}\right\}.$$

So $\sigma_* = O(\kappa)$, and

$$\sigma_* = \left(1 - \frac{2\gamma}{l\kappa^2}\right)\frac{\kappa}{\beta_0} + \frac{C_1}{\beta_0^{3/2}}(\kappa_{\max} - 3\gamma)\left(1 - \frac{2\gamma}{l\kappa^2}\right)^{1/2} + O(\kappa^{-1/3}).$$

This yields the conclusion. □

The upper bound of H_{C_3} and the nature of nucleation of superconductivity vary according to the scale of l and κ. In Theorem 6.2 we consider the case where l has order of κ^{-1}, namely, there exist positive constants $a < b$ such that

$$a\kappa^{-1} \le l \le b\kappa^{-1}. \tag{6.1}$$

In Theorems 6.3, 6.4, and 6.5, we consider the case where l has order of κ^{-2}.

THEOREM 6.2. *Assume the condition* (6.1).

(i) *Given* $0 < \alpha < 1/3$ *we have, for large* κ,

$$H_{C_3}(\mathbf{e}_3, \kappa, l) = \frac{\kappa}{\beta_0} + \frac{C_1}{\beta_0^{3/2}}(\kappa_{\max} - 3\gamma) - \frac{2\gamma}{\beta_0\kappa l} + o(\kappa^{-\alpha}). \tag{6.2}$$

(ii) *As the applied field decreases from* $H_{C_3}(\mathbf{e}_3, \kappa, l)$, *superconductivity nucleates first in the strip* $\mathcal{N}(\partial\Omega) \times [0, l]$. *More precisely, assume that*

$$\sigma = H_{C_3}(\mathbf{e}_3, \kappa, l) - \rho > 0. \tag{6.3}$$

For any $0 < p < 1/9$, *there exist positive constants* c_1, c_2, *and* C *such that for any minimal solution* $(\psi, \mathbf{A})$ *of* (1.1), *we have*

$$\int_{D_l} \exp\bigl(c_1\sqrt{\kappa}[\kappa_{\max} - \kappa_r(x) - c_2\rho - c_2\kappa^{-p}]\bigr)|\psi|^2 dxdz \le C\kappa^{-2}. \tag{6.4}$$

Proof. Step 1. Lemma 6.1 provides a lower bound of $H_{C_3}(\mathbf{e}_3, \kappa, l)$. To prove (6.2), let us fix $0 < \alpha < 1/3$ and choose σ such that

$$\frac{\kappa}{\beta_0} + \frac{C_1}{\beta_0^{3/2}}(\kappa_{\max} - 3\gamma) - \frac{2\gamma}{\beta_0\kappa l} + O(\kappa^{-1/3}) < \sigma < H_{C_3}(\mathbf{e}_3, \kappa, l). \tag{6.5}$$

For our convenience we introduce $\varepsilon = (\kappa\sigma)^{-1/2}$. From (6.1) and (6.5) we see that l has order of ε. From Lemma 6.1, the Ginzburg–Landau functional has nontrivial minimizers, which will be denoted by $(\psi^\varepsilon, \mathbf{A}^\varepsilon)$. We need some elliptic estimates for $(\psi^\varepsilon, \mathbf{A}^\varepsilon)$. In the following, C denotes a generic constant which may vary from line to line.

CLAIM 1. *Assume* (6.1) *and* (6.5).

(i) *There exists* $C_1(a,b)>0$ *independent of* l *and* ε *such that*

$$\begin{aligned} &\|\psi^\varepsilon\|_{L^\infty(D_l)} = o(1) \quad \text{as } \varepsilon\to 0,\\ &\|\nabla_{\varepsilon^{-2}\mathbf{A}^\varepsilon}\psi^\varepsilon\|_{L^\infty(D_l)} \le \frac{C_1(a,b)}{\varepsilon}\|\psi^\varepsilon\|_{L^\infty(D_l)}. \end{aligned} \tag{6.6}$$

(ii) *For any* $0<\alpha<1$, *there exists* $C_2(a,b,\alpha)>0$ *independent of* l *and* ε, *and* $q=3/(1-\alpha)$ *such that*

$$\|\mathbf{A}^\varepsilon-\mathbf{F}\|_{C^{1+\alpha}(\bar D_l)} \le \varepsilon C_2(a,b,\alpha)\big\{\|\psi^\varepsilon\|^2_{L^4(D_l)} + \|\psi^\varepsilon\|_{L^q(D_l)}\|\psi^\varepsilon\|_{L^\infty(D_l)}\big\}. \tag{6.7}$$

(iii) *For any* $0<\alpha<2\sqrt{1-\beta_0}$, *there exists* $C_3(a,b,\alpha)>0$ *independent of* l *and* ε *such that*

$$\int_{D_l}\exp\big(\alpha\varepsilon^{-1}d_{\partial\Omega}(x)\big)\{|\psi^\varepsilon|^2+\varepsilon^2|\nabla_{\varepsilon^{-2}\mathbf{A}^\varepsilon}\psi^\varepsilon|^2\}dxdz \le C_3(a,b,\alpha)l\varepsilon. \tag{6.8}$$

As in the proof of Lemma 4.1 (Step 4), we use a blow-up argument in the scale ε to prove (6.6). Since l has order of ε, the blow-up process leads to a limiting equation with bounded coefficients in a domain of the form $(-\infty,\infty)\times(0,\infty)\times(0,L)$, where $L>0$. We first apply the L^∞ estimates to this equation and then return to the original scale and obtain the second inequality in (6.6). To prove the first inequality in (6.6), we use the fact that the limiting nonlinear equation has no nontrivial bounded solutions (see [LP4, Proposition 2.5 and Theorem 5.1] for two-dimensional problems).

Equation (6.7) follows from (6.6) and (4.8).

Equation (6.8) can be proved by an Agmon-type argument [A]. For a two-dimensional linear problem, such an estimate has been established by Helffer and Morame [HM1, (6.25), (6.59)]. For a two-dimensional nonlinear problem, a similar estimate was proved in [P2, Lemma 7.2]. Here we sketch an outline of the proof. Let χ be a smooth function which vanishes at $\partial\Omega\times[0,l]$. From the equation for ψ^ε we get

$$\int_{D_l}|\nabla_{\varepsilon^{-2}\mathbf{A}^\varepsilon}(\chi\psi^\varepsilon)|^2dxdz+\gamma\int_{\partial D_l}|\chi\psi^\varepsilon|^2dS = \int_{D_l}\big\{\kappa^2(1-|\psi^\varepsilon|^2)|\chi\psi^\varepsilon|^2+|\nabla\chi|^2|\psi^\varepsilon|^2\big\}dxdz. \tag{6.9}$$

From (6.7) we have $|\mathrm{curl}(\mathbf{A}^\varepsilon-\mathbf{F})|=O(\varepsilon)$. Thus

$$\partial_1 A_2^\varepsilon-\partial_2 A_1^\varepsilon \ge 1+O(\varepsilon).$$

So we use Lemma 5.2 to get

$$\int_{D_l}|\nabla_{\varepsilon^{-2}\mathbf{A}^\varepsilon}(\chi\psi^\varepsilon)|^2dxdz+\gamma\int_{\partial D_l}|\chi\psi^\varepsilon|^2dS \ge \frac{1+O(\varepsilon)+\varepsilon^2\tau_\gamma(l)^2}{\varepsilon^2}\int_{D_l}|\chi\psi^\varepsilon|^2dxdz.$$

From this and (6.9), and using the fact $\varepsilon^2\kappa^2=\frac{\kappa}{\sigma}=\beta_0+o(1)<1$ (see (6.5)), we have

$$\int_{D_l}|\chi\psi^\varepsilon|^2dxdz \le \frac{\varepsilon^2(1+o(1))}{1-\beta_0}\int_{D_l}|\nabla\chi|^2|\psi^\varepsilon|^2dxdz.$$

Now we choose

$$\chi(x,z)=\chi(x)=\eta(x)\exp\Big(\frac{\alpha}{2}\varepsilon^{-1}\zeta(x)\Big),$$

where $0 < \alpha < 2\sqrt{1-\beta_0}$ is a constant, $\zeta(x)$ is a smooth function on $\bar{\Omega}$ such that $\zeta(x) = d_{\partial\Omega}(x)$ on Ω_{δ_0}, $\eta(x)$ is a cut-off function such that $\eta(x) = 0$ if $d_{\partial\Omega}(x) < \varepsilon$, $\eta(x) = 1$ if $d_{\partial\Omega}(x) > 2\varepsilon$, and $|\nabla\eta(x)| \le \frac{4}{\varepsilon}$. Plugging it into the above inequality we find

$$\int_{D_l} \eta^2 \exp\bigl(\alpha\varepsilon^{-1}\zeta\bigr)|\psi^\varepsilon|^2 dxdz \le C\int_{D_l\cap\{\mathrm{dist}(x,\partial\Omega)<2\varepsilon\}} |\psi^\varepsilon|^2 dxdz \le Cl\varepsilon,$$

which implies that for a larger C,

$$\int_{D_l} \exp\bigl(\alpha\varepsilon^{-1}d_{\partial\Omega}(x)\bigr)|\psi^\varepsilon|^2 dxdz \le Cl\varepsilon.$$

Using this and (6.9) we find

$$\int_{D_l} \exp\bigl(\alpha\varepsilon^{-1}d_{\partial\Omega}(x)\bigr)|\nabla_{\varepsilon^{-2}\mathbf{A}^\varepsilon}\psi^\varepsilon|^2 dxdz \le \frac{Cl}{\varepsilon}.$$

Hence (6.8) is true. Now Claim 1 is proved.

As a consequence of (6.8) we have, for any nonnegative integer k,

$$\int_{D_l} d_{\partial\Omega}(x)^k\bigl\{|\psi^\varepsilon|^2 + \varepsilon^2|\nabla_{\varepsilon^{-2}\mathbf{A}^\varepsilon}\psi^\varepsilon|^2\bigr\}dxdz \le C_k l\varepsilon^{k+1}. \tag{6.10}$$

In particular

$$\int_{D_l} |\psi^\varepsilon|^2 dxdz \le Cl\varepsilon. \tag{6.11}$$

We define, for $q > 3$,

$$d(\varepsilon) = \|\psi^\varepsilon\|^2_{L^4(D_l)} + \|\psi^\varepsilon\|_{L^q(D_l)}\|\psi^\varepsilon\|_{L^\infty(D_l)}. \tag{6.12}$$

From (6.11) we find

$$d(\varepsilon) \le C\bigl\{(l\varepsilon)^{1/2}\|\psi^\varepsilon\|_{L^\infty(D_l)} + (l\varepsilon)^{1/q}\|\psi^\varepsilon\|^{2(q-1)/q}_{L^\infty(D_l)}\bigr\}. \tag{6.13}$$

Step 2. Now we establish the weighted L^2 estimates. In the following, let ϕ^ε denote the eigenfunction of the operator $-\nabla^2_{\varepsilon^{-2}\mathbf{A}^\varepsilon}$ associated with the lowest eigenvalue $\mu_\gamma(\varepsilon^{-2}\mathbf{A}^\varepsilon)$. Similar to Corollary 5.4 we have the following.

Claim 2. *Assume* (6.1) *and* (6.5).

(i) *For any* $0 < \alpha < 2\sqrt{1-\beta_0}$, *there exists a positive constant* $C_4(a,b,\alpha)$ *independent of* l *and* ε *such that*

$$\int_{D_l} \exp\bigl(\alpha\varepsilon^{-1}d_{\partial\Omega}(x,z)\bigr)\{|\phi^\varepsilon|^2 + \varepsilon^2|\nabla_{\varepsilon^{-2}\mathbf{A}^\varepsilon}\phi^\varepsilon|^2\}dxdz \le \varepsilon C_4(a,b,\alpha)\int_{D_l}|\phi^\varepsilon|^2 dxdz. \tag{6.14}$$

(ii) *There exists a positive constant* C *independent of* l *and* ε *such that for any smooth function* χ *we have*

$$\begin{aligned}&\int_{D_l} |\nabla_{\varepsilon^{-2}\mathbf{A}^\varepsilon}(\chi\phi^\varepsilon)|^2 dxdz + \gamma\int_{\partial D_l}|\chi\phi^\varepsilon|^2 dS\\ &\quad\ge \varepsilon^{-2}\int_{D_l}\mathcal{W}_{D_l}(x,z)|\chi\phi^\varepsilon|^2 dxdz - C\varepsilon^{-4/3}d(\varepsilon)^{2/3}\int_{D_l}|\chi\phi^\varepsilon|^2 dxdz.\end{aligned} \tag{6.15}$$

Here $\mathcal{W}_{D_l}(x,z)$ is the function given in (5.6).

Equation (6.14) can be proved as for (6.8). Before proving (6.15), we would like to mention that in the two-dimensional case studied in [HP], the magnetic potentials vanish at the boundary. This condition makes it easy to control error terms in various estimates. In the three-dimensional case discussed here, on the contrary, this condition is no longer true, and hence a harder estimate is needed in order to obtain (6.15). We should also mention the difference between (5.5) and (6.15), although they look similar. The inequality (5.5) is regarding a fixed vector field, $\mathbf{F}$, while (6.15) gives a uniform estimate for a family of vector fields $\mathbf{A}^\varepsilon$. When proving (5.5), we divided D_l into subsets in the form of the product $\Omega_j \times [0,l]$, where $\{\Omega_j\}$ is a partition of Ω. In order to prove (6.15), we need a finer partition and have to choose the cut-off functions carefully. If l is small compared with ε (for example, if l has order of ε), we may choose cut-off functions to be independent of z, and hence cut D_l into a finite number of blocks with height l. If l is not very small, the interval $[0,l]$ should also be divided, and hence the cut-off functions must depend on z. In the following we describe the choice of cut-off functions which are valid for a general case, not only for the purpose here.

Let $\{\eta_{0,\tau(\varepsilon)}, \eta_{1,\tau(\varepsilon)}\}$ be the partition of unity on $\mathbb{R}$ introduced in [HM2, (9.22), (9.23)] such that

$$\eta^2_{0,\tau(\varepsilon)}(t) + \eta^2_{1,\tau(\varepsilon)}(t) = 1, \qquad |\eta'_{j,\tau(\varepsilon)}(t)| \le \frac{C}{\tau(\varepsilon)} \quad \text{for } j = 0,1,$$
$$\text{spt } (\eta_{0,\tau(\varepsilon)}) \subset \left[\frac{\tau(\varepsilon)}{20}, +\infty\right), \qquad \text{spt } (\eta_{1,\tau(\varepsilon)}) \subset \left(-\infty, \frac{\tau(\varepsilon)}{10}\right].$$

As in [HM1, (9.10)–(9.14)], let $\{\chi_i(x,z)\}_I$ be a partition of unity of $\mathbb{R}^3$ such that $I = \mathbb{Z}^3$ and

$$\chi_i \in C^\infty(\mathbb{R}^3, \mathbb{R}) \quad \text{and} \quad \text{spt } (\chi_i) \subset i + [-1,1]^3 \quad \text{for any } i \in I,$$
$$\sum_{i\in I} \chi_i^2(x,z) = 1, \qquad \sum_{i\in I} |\nabla \chi_i(x,z)|^2 < C.$$

Let $\delta_0 > 0$ be chosen such that the distance function $d_{\partial\Omega}$ is differentiable in Ω_{δ_0}. Let $\omega(\varepsilon)$ be a function of ε such that $0 < \omega(\varepsilon) < \delta_0$ for all small ε, and set

$$\chi_{i,\omega(\varepsilon)}(x,z) = \chi_i\left(\frac{x}{\omega(\varepsilon)}, \frac{z}{\omega(\varepsilon)}\right), \qquad i \in I.$$

Thus we have a new partition of unity such that

$$\begin{aligned} &\text{spt}(\chi_{i,\omega(\varepsilon)}) \subset \omega(\varepsilon) i + [-\omega(\varepsilon), \omega(\varepsilon)]^3, \\ &\sum_{i\in I} \chi_{i,\omega(\varepsilon)}(x,z)^2 = 1, \qquad \sum_{i\in I} |\nabla \chi_{i,\omega(\varepsilon)}(x,z)|^2 < \frac{C}{\omega(\varepsilon)^2}. \end{aligned} \tag{6.16}$$

In the following, we choose $0 < \tau(\varepsilon) \le \omega(\varepsilon)$. Let us introduce

$$I(\omega(\varepsilon)) = \big\{ i \in I \ : \ \text{spt}(\chi_{i,\omega(\varepsilon)}) \cap D_l \neq \emptyset, \quad \text{dist}\big(\text{spt}(\chi_{i,\omega(\varepsilon)}), \partial\Omega \times [0,l]\big) \le \omega(\varepsilon) \big\}.$$

Note that Ω_{δ_0} can be covered by a finite number of open sets Ω_j such that on each of them we can define a diffeomorphism that straightens a portion of $\partial\Omega$. For simplicity we let f denote any of these maps. Then $\Omega_{\delta_0} \times [0,l]$ is covered by a finite number of

open sets $\Omega_j \times [a_k, b_k]$, and on each of them we can define a diffeomorphism of the form $\mathcal{F}(y,z) = (f(y), z)$. For each $i \in I(\omega(\varepsilon))$, we can choose $x(i) \in \partial\Omega$, $z(i) \in [0,l]$ such that

$$\operatorname{spt}(\chi_{i,\varepsilon}) \subset B^2\left(x(i), \frac{3}{2}\omega(\varepsilon)\right) \times [z(i) - \omega(\varepsilon), z(i) + \omega(\varepsilon)],$$

where $B^2\big(x(i), \frac{3}{2}\omega(\varepsilon)\big)$ denotes a two-dimensional disc with center $x(i)$ and radius $\frac{3}{2}\omega(\varepsilon)$. Choose $y(i) = (y_1(i), 0)$ such that $\mathcal{F}(y(i), z(i)) = (x(i), z(i))$. Let

$$K(i,\varepsilon) = \{\mathcal{F}(y_1, y_2, z) :\ |y_1 - y_1(i)| < 2\omega(\varepsilon),\ 0 \le y_2 \le \tau(\varepsilon),\ |z - z(i)| \le 2\omega(\varepsilon)\}.$$

Then, for small $\varepsilon > 0$, $\operatorname{spt}(\chi_{i,\varepsilon}) \cap \bar{D}_l \subseteq K(i,\varepsilon)$, and $\{K(i,\varepsilon) : i \in I(\omega(\varepsilon))\}$ covers the thin cylinder $\Omega_{\tau(\varepsilon)} \times [0,l]$.

Given a smooth function χ, we write

$$\begin{aligned}
&\phi_\varepsilon(x,z) = \chi\phi^\varepsilon(x,z),\\
&u_\varepsilon(x,z) = \eta_{1,\tau(\varepsilon)}(t(x))\phi_\varepsilon(x,z),\\
&u_{i,\varepsilon}(x,z) = \chi_{i,\omega(\varepsilon)}u_\varepsilon(x,z),
\end{aligned}$$

where $t(x) = d_{\partial\Omega}(x)$. Note that for any smooth functions ϕ and ψ we have

(6.17)
$$\begin{aligned}
&\int_{D_l} |\nabla_{\varepsilon^{-2}\mathbf{A}^\varepsilon}\phi|^2 dxdz + \gamma\int_{\partial D_l} |\phi|^2 dS\\
&= \sum_{j=0}^{1}\left\{\int_{D_l}\big[|\nabla_{\varepsilon^{-2}\mathbf{A}^\varepsilon}(\eta_{j,\tau(\varepsilon)}\phi)|^2 - |\phi\nabla\eta_{j,\tau(\varepsilon)}|^2\big]dxdz + \gamma\int_{\partial D_l}|\eta_j\phi|^2 dS\right\},\\
&\int_{D_l} |\nabla_{\varepsilon^{-2}\mathbf{A}^\varepsilon}\psi|^2 dxdz + \gamma\int_{\partial D_l} |\psi|^2 dS\\
&= \sum_{i\in I(\omega(\varepsilon))}\left\{\int_{D_l}\big[|\nabla_{\varepsilon^{-2}\mathbf{A}^\varepsilon}(\chi_{i,\omega(\varepsilon)}\psi)|^2 - |\psi\nabla\chi_{i,\omega(\varepsilon)}|^2\big]dxdz + \gamma\int_{\partial D_l}|\psi\chi_{i,\omega(\varepsilon)}|^2 dS\right\}.
\end{aligned}$$

Applying the second equality in (6.17) to $\psi = u_\varepsilon$, and using (6.16), we find

(6.18)
$$\begin{aligned}
&\int_{D_l} |\nabla_{\varepsilon^{-2}\mathbf{A}^\varepsilon}u_\varepsilon|^2 dxdz + \gamma\int_{\partial D_l} |u_\varepsilon|^2 dS\\
&= \sum_{i\in I(\omega(\varepsilon))}\left\{\int_{D_l}|\nabla_{\varepsilon^{-2}\mathbf{A}^\varepsilon}u_{i,\varepsilon}|^2 dxdz + \gamma\int_{\partial D_l}|u_{i,\varepsilon}|^2 dS\right\} - \frac{O(1)}{\omega(\varepsilon)^2}\int_{D_l}|u_\varepsilon|^2 dxdz,
\end{aligned}$$

where $O(1)$ remains bounded as $\varepsilon \to 0$.

Now we fix $i \in I(\omega(\varepsilon))$ and estimate the integral of $|\nabla_{\varepsilon^{-2}\mathbf{A}^\varepsilon}u_{i,\varepsilon}|^2$. Note that

$$\int_{D_l}|\nabla_{\varepsilon^{-2}\mathbf{A}^\varepsilon}u_{i,\varepsilon}|^2 dxdz = \int_{K(i,\varepsilon)}|\nabla_{\varepsilon^{-2}\mathbf{A}^\varepsilon}u_{i,\varepsilon}|^2 dxdz.$$

On $K(i,\varepsilon)$ we write

$$\mathbf{A}^\varepsilon(x,z) = \mathbf{F}(x,z) + \mathbf{B}_i(x,z) + \mathbf{b}_i, \qquad u_{i,\varepsilon}(x,z) = v_{i,\varepsilon}(x,z)e^{i\mathbf{b}_i\cdot(x,z)},$$

where $\mathbf{b}_i = \mathbf{A}^\varepsilon(x(i), z(i)) - \mathbf{F}(x(i), z(i))$. From (6.7) we have

$$\|\mathbf{B}_i\|_{C^{1+\alpha}(\bar{D}_l)} = O(\varepsilon)d(\varepsilon), \qquad |\mathbf{b}_i| = O(\varepsilon),$$

where $d(\varepsilon)$ is given in (6.12) with $q = 3/(1-\alpha)$. Since $\mathbf{B}_i(y(i), z(i)) = \mathbf{0}$, we have

$$|\mathbf{B}_i(x,z)| \le C\varepsilon d(\varepsilon)\sqrt{|x-x(i)|^2 + |z-z(i)|^2} \le C\varepsilon d(\varepsilon)\omega(\varepsilon) \qquad \text{on } K(i,\varepsilon). \tag{6.19}$$

We compute

$$\begin{aligned}
&\int_{K(i,\varepsilon)} |\nabla_{\varepsilon^{-2}\mathbf{A}^\varepsilon} u_{i,\varepsilon}|^2 dxdz = \int_{K(i,\varepsilon)} |\nabla_{\varepsilon^{-2}(\mathbf{F}+\mathbf{B}_i)} v_{i,\varepsilon}|^2 dxdz \\
&= \int_{K(i,\varepsilon)} \big\{ |\nabla_{\varepsilon^{-2}\mathbf{F}} v_{i,\varepsilon}|^2 - 2\varepsilon^{-2}\mathbf{B}_i \cdot \Im(\bar{v}_{i,\varepsilon}\nabla_{\varepsilon^{-2}\mathbf{F}} v_{i,\varepsilon}) + \varepsilon^{-4}|\mathbf{B}_i|^2 |v_{i,\varepsilon}|^2 \big\} dxdz \\
&\ge \int_{K(i,\varepsilon)} |\nabla_{\varepsilon^{-2}\mathbf{F}} v_{i,\varepsilon}|^2 dxdz - 2\varepsilon^{-2} \int_{K(i,\varepsilon)} \mathbf{B}_i \cdot \Im(\bar{v}_{i,\varepsilon}\nabla_{\varepsilon^{-2}\mathbf{F}} v_{i,\varepsilon}) dxdz.
\end{aligned}$$

Using (6.19) we have, for a constant $M > 0$,

$$\begin{aligned}
&2\varepsilon^{-2}\Big| \int_{K(i,\varepsilon)} \mathbf{B}_i \cdot \Im(\bar{v}_{i,\varepsilon}\nabla_{\varepsilon^{-2}\mathbf{F}} v_{i,\varepsilon}) dxdz \Big| \\
&\le M\varepsilon^{-4} \int_{K(i,\varepsilon)} |\mathbf{B}_i|^2 |v_{i,\varepsilon}|^2 dxdz + M^{-1} \int_{K(i,\varepsilon)} |\nabla_{\varepsilon^{-2}\mathbf{F}} v_{i,\varepsilon}|^2 dxdz \\
&\le CMd(\varepsilon)^2\omega(\varepsilon)^2\varepsilon^{-2} \int_{K(i,\varepsilon)} |v_{i,\varepsilon}|^2 dxdz + M^{-1} \int_{K(i,\varepsilon)} |\nabla_{\varepsilon^{-2}\mathbf{F}} v_{i,\varepsilon}|^2 dxdz.
\end{aligned}$$

Therefore

$$\begin{aligned}
&\int_{K(i,\varepsilon)} |\nabla_{\varepsilon^{-2}\mathbf{A}^\varepsilon} u_{i,\varepsilon}|^2 dxdz \\
&\ge (1 - M^{-1}) \int_{K(i,\varepsilon)} |\nabla_{\varepsilon^{-2}\mathbf{F}} v_{i,\varepsilon}|^2 dxdz - CMd(\varepsilon)^2\omega(\varepsilon)^2\varepsilon^{-2} \int_{K(i,\varepsilon)} |v_{i,\varepsilon}|^2 dxdz.
\end{aligned}$$

Since $|v_{i,\varepsilon}| = |u_{i,\varepsilon}|$, using Theorem 5.3 and the above inequality we find

$$\begin{aligned}
&\int_{K(i,\varepsilon)} |\nabla_{\varepsilon^{-2}\mathbf{A}^\varepsilon} u_{i,\varepsilon}|^2 dxdz + \gamma \int_{\partial D_l} |u_{i,\varepsilon}|^2 dS \\
&\ge (1 - M^{-1})\varepsilon^{-2} \int_{K(i,\varepsilon)} \mathcal{W}_{D_l} |u_{i,\varepsilon}|^2 dxdz - CMd(\varepsilon)^2\omega(\varepsilon)^2\varepsilon^{-2} \int_{K(i,\varepsilon)} |u_{i,\varepsilon}|^2 dxdz.
\end{aligned} \tag{6.20}$$

From (6.18) and (6.20) we get

$$\begin{aligned}
&\int_{D_l} |\nabla_{\varepsilon^{-2}\mathbf{A}^\varepsilon} u_\varepsilon|^2 dxdz + \gamma \int_{\partial D_l} |u_\varepsilon|^2 dS \\
&\ge (1 - M^{-1})\varepsilon^{-2} \sum_{i \in I(\omega(\varepsilon))} \int_{K(i,\varepsilon)} \mathcal{W}_{D_l} |u_{i,\varepsilon}|^2 dxdz \\
&\quad - CMd(\varepsilon)^2\omega(\varepsilon)^2\varepsilon^{-2} \sum_{i \in I(\omega(\varepsilon))} \int_{K(i,\varepsilon)} |u_{i,\varepsilon}|^2 dxdz - \frac{O(1)}{\omega(\varepsilon)^2} \int_{D_l} |u_\varepsilon|^2 dxdz \\
&\ge (1 - M^{-1})\varepsilon^{-2} \int_{D_l} \mathcal{W}_{D_l} |u_\varepsilon|^2 dxdz - C\left\{ Md(\varepsilon)^2\omega(\varepsilon)^2\varepsilon^{-2} + \frac{1}{\omega(\varepsilon)^2} \right\} \int_{D_l} |u_\varepsilon|^2 dxdz.
\end{aligned}$$

Equation (6.1) implies that $\mathcal{W}_{D_l}$ is uniformly bounded. If we choose

$$\omega(\varepsilon) = \varepsilon^{1/2} d(\varepsilon)^{-1/2} M^{-1/4},$$

then we get

$$\begin{aligned}
&\int_{D_l} |\nabla_{\varepsilon^{-2}\mathbf{A}^\varepsilon} u_\varepsilon|^2 dxdz + \gamma \int_{\partial D_l} |u_\varepsilon|^2 dS \\
&\geq (1 - M^{-1})\varepsilon^{-2} \int_{D_l} \mathcal{W}_{D_l} |u_\varepsilon|^2 dxdz - Cd(\varepsilon) M^{1/2} \varepsilon^{-1} \int_{D_l} |u_\varepsilon|^2 dxdz \\
&\geq \varepsilon^{-2} \int_{D_l} \mathcal{W}_{D_l} |u_\varepsilon|^2 dxdz - C\{M^{-1}\varepsilon^{-2} + d(\varepsilon) M^{1/2} \varepsilon^{-1}\} \int_{D_l} |u_\varepsilon|^2 dxdz.
\end{aligned}$$

Now we let

$$M = [\varepsilon d(\varepsilon)]^{-2/3}.$$

Then

$$\omega(\varepsilon) = \varepsilon^{2/3} d(\varepsilon)^{-1/3},$$

and we obtain

$$\begin{aligned}
&\int_{D_l} |\nabla_{\varepsilon^{-2}\mathbf{A}^\varepsilon} u_\varepsilon|^2 dxdz + \gamma \int_{\partial D_l} |u_\varepsilon|^2 dS \\
&\geq \varepsilon^{-2} \int_{D_l} \mathcal{W}_{D_l} |u_\varepsilon|^2 dxdz - C\varepsilon^{-4/3} d(\varepsilon)^{2/3} \int_{D_l} |u_\varepsilon|^2 dxdz.
\end{aligned} \tag{6.21}$$

Next, we choose $\tau(\varepsilon) = \omega(\varepsilon) = \varepsilon^{2/3} d(\varepsilon)^{-1/3}$ and use (6.21) and the first equality in (6.17) to get

(6.22)

$$\begin{aligned}
&\int_{D_l} |\nabla_{\varepsilon^{-2}\mathbf{A}^\varepsilon} (\chi\phi^\varepsilon)|^2 dxdz + \gamma \int_{\partial D_l} |\chi\phi^\varepsilon|^2 dS \\
&\geq \int_{D_l} |\nabla_{\varepsilon^{-2}\mathbf{A}^\varepsilon} u_\varepsilon|^2 dxdz + \gamma \int_{\partial D_l} |u_\varepsilon|^2 dS - C\varepsilon^{-4/3} d(\varepsilon)^{2/3} \int_{D_l} |\chi\phi^\varepsilon|^2 dxdz \\
&\geq \varepsilon^{-2} \int_{D_l} \mathcal{W}_{D_l} |u_\varepsilon|^2 dxdz - C\varepsilon^{-4/3} d(\varepsilon)^{2/3} \int_{D_l} |u_\varepsilon|^2 dxdz - C\varepsilon^{-4/3} d(\varepsilon)^{2/3} \int_{D_l} |\chi\phi^\varepsilon|^2 dxdz.
\end{aligned}$$

Finally, using (6.14), we find

$$\begin{aligned}
\int_{D_l} \mathcal{W}_{D_l} |u_\varepsilon|^2 dxdz &= \int_{D_l} [\mathcal{W}_{D_l} + O(\varepsilon)] |\chi\phi^\varepsilon|^2 dxdz, \\
\int_{D_l} |u_\varepsilon|^2 dxdz &= \int_{D_l} [1 + O(\varepsilon)] |\chi\phi^\varepsilon|^2 dxdz.
\end{aligned}$$

Using these equalities and (6.22) we get (6.15).

Step 3. We establish a uniform lower bound estimate of the lowest eigenvalue. From (6.15) we have, for all small $\varepsilon > 0$,

$$\mu_\gamma(\varepsilon^{-2}\mathbf{A}^\varepsilon) \geq \frac{1}{\varepsilon^2}\{\beta_0 + C_1(3\gamma - \kappa_{\max})\varepsilon + \varepsilon^2 \tau_\gamma(l)^2 - C\varepsilon^{4/3} - C\varepsilon^{2/3} d(\varepsilon)^{2/3}\}.$$

From (6.6) and (6.13) we have $d(\varepsilon) = o((l\varepsilon)^{1/q})$. Thus

$$\mu_\gamma(\varepsilon^{-2}\mathbf{A}^\varepsilon) \geq \frac{1}{\varepsilon^2}\Big\{\beta_0 + C_1(3\gamma - \kappa_{\max})\varepsilon + \varepsilon^2\tau_\gamma(l)^2 - C\varepsilon^{4/3} - o(l^{\frac{2}{3q}}\varepsilon^{\frac{2(1+q)}{3q}})\Big\}. \tag{6.23}$$

Note that (6.23) holds if we only assume $l \geq c\kappa^{-1}$.

Now we use the condition (6.1) to simplify (6.23) and get

$$\mu_\gamma(\varepsilon^{-2}\mathbf{A}^\varepsilon) \geq \frac{1}{\varepsilon^2}\Big\{\beta_0 + C_1(3\gamma - \kappa_{\max})\varepsilon + \varepsilon^2\tau_\gamma(l)^2 - C\varepsilon^{4/3} - o(\varepsilon^b)\Big\},$$

where $b = \frac{2(2+q)}{3q}$. For any $0 < \alpha < 1/3$ we can choose $3 < q < 4$ such that $b = 1 + \alpha$. So, under the condition (6.1) we have

$$\mu_\gamma(\varepsilon^{-2}\mathbf{A}^\varepsilon) \geq \frac{1}{\varepsilon^2}\Big\{\beta_0 + C_1(3\gamma - \kappa_{\max})\varepsilon + \varepsilon^2\tau_\gamma(l)^2 - o(\varepsilon^{1+\alpha})\Big\}. \tag{6.24}$$

Step 4. We prove an upper bound estimate of $H_{C_3}(\mathbf{e}_3, \kappa, l)$. Recall that in order to have nontrivial minimizers we must have $\mu_\gamma(\varepsilon^{-2}\mathbf{A}^\varepsilon) < \kappa^2$; see [LP4]. Using this and (6.1), (6.24) we find that

$$\sigma \leq \frac{\kappa}{\beta_0} + \frac{C_1}{\beta_0^{3/2}}(\kappa_{\max} - 3\gamma) - \frac{\tau_\gamma(l)^2}{\beta_0\kappa} + o(\kappa^{-\alpha}).$$

From this and (2.5) we get

$$H_{C_3}(\mathbf{e}_3, \kappa, l) \leq \frac{\kappa}{\beta_0} + \frac{C_1}{\beta_0^{3/2}}(\kappa_{\max} - 3\gamma) - \frac{2\gamma}{\beta_0 l\kappa} + o(\kappa^{-\alpha}).$$

Now (6.2) is proved.

Step 5. Using (6.2), the conclusion about the location of nucleation can be proved following the argument in [HP, proof of Theorem 6.1]. In the following we outline the proof. Assume σ satisfies (6.3). Again we let $\varepsilon = (\kappa\sigma)^{-1/2}$, and let $(\psi^\varepsilon, \mathbf{A}^\varepsilon)$ be the minimizer. For any smooth function χ, we have (6.9). As in Step 2 we have (see (6.22))

$$\begin{aligned}&\int_{D_l} |\nabla_{\varepsilon^{-2}\mathbf{A}^\varepsilon}(\chi\psi^\varepsilon)|^2 dxdz + \gamma\int_{\partial D_l} |\chi\psi^\varepsilon|^2 dS\\ &\geq \varepsilon^{-2}\int_{D_l} \mathcal{W}_{D_l}|\chi\psi^\varepsilon|^2 dxdz - C\varepsilon^{-4/3}d(\varepsilon)^{2/3}\int_{D_l} |\chi\psi^\varepsilon|^2 dxdz.\end{aligned}$$

Using this and (6.9) we get

$$\int_{D_l} |\chi\psi^\varepsilon|^2\{\mathcal{W}_{D_l} - \varepsilon^2\kappa^2 - C\varepsilon^{2/3}d(\varepsilon)^{2/3}\}dxdz \leq \varepsilon^2\int_{D_l} |\nabla\chi|^2|\psi^\varepsilon|^2 dxdz. \tag{6.25}$$

From (6.2) and (6.3) we have, for some α with $p < \alpha < 1/3$,

$$\begin{aligned}\varepsilon^2\kappa^2 &= \frac{\kappa}{\sigma} = \beta_0 - \left[\sqrt{\beta_0}C_1(\kappa_{\max} - 3\gamma) - \frac{2\gamma\beta_0}{\kappa l}\right]\kappa^{-1} + \beta_0^2\rho\kappa^{-1} + o(\kappa^{-1-\alpha}),\\ \varepsilon &= \frac{1}{\sqrt{\kappa\sigma}} = \sqrt{\beta_0}\kappa^{-1} + O(\kappa^{-2}).\end{aligned}$$

So we have

$$\varepsilon^2\mu_\gamma(\varepsilon^{-2}\mathbf{F})-\varepsilon^2\kappa^2=\beta_0+C_1(3\gamma-\kappa_{\max})\varepsilon+\varepsilon^2\tau_\gamma(l)^2-\varepsilon^2\kappa^2+O(\varepsilon^{4/3})$$
$$=\frac{2\gamma}{l\kappa}\left(\frac{1}{\sigma}-\sqrt{\beta_0}\varepsilon\right)-\beta_0^{3/2}\varepsilon\rho+O(\varepsilon^{1+\alpha})=-\beta_0^{3/2}\varepsilon\rho+O(\varepsilon^{1+\alpha}).$$

From this and (6.25) we get

$$\varepsilon^2\int_{D_l}|\nabla\chi|^2|\psi^\varepsilon|^2dxdz$$
$$\geq\int_{D_l}|\chi\psi^\varepsilon|^2\{\mathcal{W}_{D_l}-\varepsilon^2\mu_\gamma(\varepsilon^{-2}\mathbf{F})-\beta_0^{3/2}\varepsilon\rho-C\varepsilon^{2/3}d(\varepsilon)^{2/3}+O(\varepsilon^{1+\alpha})\}dxdz.$$

Using Theorems 5.1 and 5.3 we find

$$\int_{D_l}\big\{C_1[k_{\max}-\kappa_r(x)]-\beta_0^{3/2}\rho-C\varepsilon^\alpha-C\varepsilon^{-1/3}d(\varepsilon)^{2/3}\big\}|\chi\psi^\varepsilon|^2dxdz\leq\varepsilon\int_{D_l}|\nabla\chi|^2|\psi^\varepsilon|^2dxdz.$$

Recall that $d(\varepsilon)=o(l\varepsilon)^{1/q}$ for some $q>3$. Thus $\varepsilon^{-1/3}d(\varepsilon)^{2/3}=o(\varepsilon^b)$, where $b=\frac{4}{3q}-\frac{1}{3}$. We can choose q close to 3 such that $b\geq\alpha>p$.

Let $\phi(x)$ be a smooth function such that $\phi(x)=\kappa_{\max}-\kappa_r(x)$ in Ω_{δ_0}. There exists $C_0>0$ such that $|\nabla\phi|^2\leq C_0\phi$. Let $a=\sqrt{\frac{C_1}{2C_0}}$ and

$$\chi=\exp\big(a\varepsilon^{-1/2}\phi(x)\big).$$

Plugging it into the above integral inequality we get

$$\int_{D_l}|\psi^\varepsilon|^2\exp\big(2a\varepsilon^{-1/2}\phi\big)\big\{C_1[k_{\max}-\kappa_r(x)]-2\beta_0^{3/2}\rho-o(\varepsilon^p)\big\}dxdz\leq 0.$$

So there exist positive constants c and M_1 such that

$$\int_{\{\kappa_{\max}-\kappa_r(x)\geq c\rho+c\varepsilon^p,\ 0\leq z\leq l\}}|\psi^\varepsilon|^2\exp\big(2a\varepsilon^{-1/2}(\phi-c\rho-c\varepsilon^p)\big)dxdz$$
$$\leq M_1\int_{\{\kappa_{\max}-\kappa_r(x)\leq c\rho+c\varepsilon^p,\ 0\leq z\leq l\}}|\psi^\varepsilon|^2dxdz,$$

and hence

$$\int_{D_l}|\psi^\varepsilon|^2\exp\big(2a\varepsilon^{-1/2}(\phi-c\rho-c\varepsilon^p)\big)dxdz\leq 2M_1\int_{\{\kappa_{\max}-\kappa_r(x)\leq c\rho+c\varepsilon^p,\ 0\leq z\leq l\}}|\psi^\varepsilon|^2dxdz.$$

Using this and (6.8) we get, for some $M_3>M_2>2M_1$ and $m>0$,

$$\int_{D_l}|\psi^\varepsilon|^2\exp\big(2a\varepsilon^{-1/2}(\phi-c\rho-c\varepsilon^p)\big)dxdz$$
$$\leq M_2\int_{\{\kappa_{\max}-\kappa_r(x)\leq c\varepsilon^p,\ d_{\partial\Omega}(x)<m\varepsilon,\ 0\leq z\leq l\}}|\psi^\varepsilon|^2dxdz\leq M_3l\varepsilon.$$

From this we get (6.4). □

Remark 5. (i) From (6.23) and Lemma 6.1 we find that if $l \geq a\kappa^{-1}$, then for any $q > 3$ fixed, we have

$$H_{C_3}(\mathbf{e}_3, \kappa, l) = \frac{\kappa}{\beta_0} + \frac{C_1}{\beta_0^{3/2}}(\kappa_{\max} - 3\gamma) - \frac{2\gamma}{\beta_0 l\kappa} + o(l^{\frac{2}{3q}}\kappa^{\frac{q-2}{3q}}). \tag{6.26}$$

In particular, if there exists α_0, $1/2 < \alpha_0 < 1$, such that $a\kappa^{-1} \leq l \leq b\kappa^{-\alpha_0}$, then we choose $3 < q < 2 + 2\alpha_0$ in (6.26) and also get (6.2) with $\alpha = \alpha_0$.

(ii) We expect that if $l \gg \kappa^{-1}$, the solutions on D_l behave as the solutions on a bulk domain, say, a cylinder with a finite height,[11] and we expect that superconductivity nucleates at a subset of the top and bottom edges, namely, at the set

$$\mathcal{N}(\partial\Omega) \times \{0\} \bigcup \mathcal{N}(\partial\Omega) \times \{l\}.$$

In the following we consider the films with $l \sim a\kappa^{-2}$. We shall see in Theorems 6.3, 6.4, and 6.5 that $H_{C_3}(\mathbf{e}_3, \kappa, l)$ depends sensitively on the value of a, and $a = 2\gamma$ is a critical value.

THEOREM 6.3. *Assume that*

$$l = a\kappa^{-2} + O(\kappa^{-4}), \qquad a > 2\gamma. \tag{6.27}$$

(i) *Let* $\frac{1}{6} < \alpha < \frac{1}{3}$. *For large* κ *we have*

$$H_{C_3}(\mathbf{e}_3, \kappa, l) = \left(1 - \frac{2\gamma}{a}\right)\frac{\kappa}{\beta_0} + \frac{C_1}{\beta_0^{3/2}}(\kappa_{\max} - 3\gamma)\left(1 - \frac{2\gamma}{a}\right)^{1/2} + o(\kappa^{-\alpha}). \tag{6.28}$$

(ii) *As the applied field decreases from* $H_{C_3}(\mathbf{e}_3, \kappa, l)$, *superconductivity nucleates first in the strip* $\mathcal{N}(\partial\Omega) \times [0, l]$. *More precisely, assume that* σ *satisfies* (6.3), *and let* $(\psi, \mathbf{A})$ *be the minimizer of the Ginzburg–Landau functional* $\mathcal{G}$. *Then for any* $0 < p < 1/3$, *there exist positive constants* c_1, c_2, *and* C *such that* (6.4) *holds.*

Proof. We modify the proof of Theorem 6.2 to get the conclusions.

Step 1. From Lemma 6.1 we get a lower bound of H_{C_3}:

$$H_{C_3}(\mathbf{e}_3, \kappa, l) \geq \left(1 - \frac{2\gamma}{a}\right)\frac{\kappa}{\beta_0} + \frac{C_1}{\beta_0^{3/2}}(\kappa_{\max} - 3\gamma)\left(1 - \frac{2\gamma}{a}\right)^{1/2} + O(\kappa^{-1/3}). \tag{6.29}$$

Now let us choose σ such that

$$\left(1 - \frac{2\gamma}{a}\right)\frac{\kappa}{\beta_0} + \frac{C_1}{\beta_0^{3/2}}(\kappa_{\max} - 3\gamma)\left(1 - \frac{2\gamma}{a}\right)^{1/2} + O(\kappa^{-1/3}) < \sigma < H_{C_3}(\mathbf{e}_3, \kappa, l). \tag{6.30}$$

Again we let $\varepsilon = (\kappa\sigma)^{-1/2}$. Then l has order of ε^2. Let $(\psi^\varepsilon, \mathbf{A}^\varepsilon)$ be a minimizer of the Ginzburg–Landau functional. Then, as in the proof of Theorem 6.2, we have $\|\psi^\varepsilon\|_{L^\infty(D_l)} = o(1)$. Using the second inequality of (4.9) we have, for any $q > 3$,

$$\|\Im\{\bar{\psi}^\varepsilon \nabla_{\varepsilon^{-2}\mathbf{A}^\varepsilon}\psi^\varepsilon\}\|_{L^q(D_l)} \leq \frac{C(q)}{\varepsilon}\|\psi^\varepsilon\|_{L^q(D_l)}\|\psi^\varepsilon\|_{L^\infty(D_l)}. \tag{6.31}$$

[11] Minimal solutions on such domains have been examined in [P1].

We use (4.8) to get

$$\|\mathbf{A}^\varepsilon - \mathbf{F}\|_{C^{1+\alpha}(\bar{D}_l)} \le C(\alpha)\varepsilon\{\|\psi^\varepsilon\|^2_{L^4(D_l)} + \|\psi^\varepsilon\|_{L^q(D_l)}\|\psi^\varepsilon\|_{L^\infty(D_l)}\}.$$

Then we use the argument in the proof of Theorem 6.2 to show that (see (6.11))

$$\|\psi^\varepsilon\|_{L^2(D_l)} = O((l\varepsilon)^{1/2}).$$

Hence for $0 < \alpha_0 < 1$ and $q = 3/(1-\alpha_0)$,

$$\|\mathbf{A}^\varepsilon - \mathbf{F}\|_{C^{1+\alpha_0}(\bar{D}_l)} = o(\varepsilon)d(\varepsilon), \qquad d(\varepsilon) = (l\varepsilon)^{1/2} + (l\varepsilon)^{1/q} = O(\varepsilon^{\frac{3}{q}}),$$

since $l = O(\varepsilon^2)$. Let ϕ^ε be the eigenfunction of $-\nabla^2_{\varepsilon^{-2}\mathbf{A}^\varepsilon}$ associated with the lowest eigenvalue. As in the proof of Theorem 6.2 (Step 2) we can show that for any smooth function χ,

(6.32)
$$\int_{D_l} |\nabla_{\varepsilon^{-2}\mathbf{A}^\varepsilon}(\chi\phi^\varepsilon)|^2 dxdz \ge \int_{D_l} |\nabla_{\varepsilon^{-2}\mathbf{F}}(\chi\phi^\varepsilon)|^2 dxdz - C\varepsilon^{-4/3}d(\varepsilon)^{2/3}\int_{D_l}|\chi\phi^\varepsilon|^2 dxdz.$$

Then, similar to (6.23), now we have

$$\mu_\gamma(\varepsilon^{-2}\mathbf{A}^\varepsilon) \ge \frac{1}{\varepsilon^2}\{\beta_0 + C_1(3\gamma - \kappa_{\max})\varepsilon + \varepsilon^2\tau_\gamma(l)^2 - o(\varepsilon^{\frac{2}{3}+\frac{2}{q}})\}.$$

Since $(\psi^\varepsilon, \mathbf{A}^\varepsilon)$ is nontrivial, we have $\mu_\gamma(\varepsilon^{-2}\mathbf{A}^\varepsilon) < \kappa^2$. If $\frac{1}{6} < \alpha < \frac{1}{3}$, we choose $3 < q < 4$ such that $\frac{2}{q} - \frac{1}{3} = \alpha$. Using this and (6.32) we find

$$H_{C_3}(\mathbf{e}_3, \kappa, l) \le \left(1 - \frac{2\gamma}{a}\right)\frac{\kappa}{\beta_0} + \frac{C_1}{\beta_0^{3/2}}(\kappa_{\max} - 3\gamma)\left(1 - \frac{2\gamma}{a}\right)^{1/2} + o(\kappa^{-\alpha}).$$

Equation (6.28) follows from this and (6.29).

Step 2. Using the argument in the proof of Theorem 6.2 (Step 5) and (6.28), we can show that superconductivity nucleates in the strip $\mathcal{N}(\partial\Omega)\times[0,l]$. In fact, now (6.25) also holds, and $d(\varepsilon) = O(\varepsilon^{3/q})$. From (6.28) and (6.3) we have, for some α with $p < \alpha < 1/3$,

$$\begin{aligned}
\frac{\kappa}{\sigma} &= \beta_0\left(1 - \frac{2\gamma}{a}\right)^{-1} - C_1(\kappa_{\max} - 3\gamma)\frac{\sqrt{\beta_0}}{\kappa}\left(1 - \frac{2\gamma}{a}\right)^{-3/2} \\
&\quad + \frac{\beta_0^2\rho}{\kappa}\left(1 - \frac{2\gamma}{a}\right)^{-2} + o(\kappa^{-1-\alpha}), \\
\varepsilon &= \frac{\sqrt{\beta_0}}{\kappa}\left(1 - \frac{2\gamma}{a}\right)^{-1/2} + O(\kappa^{-2}), \\
\varepsilon^2\mu_\gamma(\varepsilon^{-2}\mathbf{F}) - \varepsilon^2\kappa^2 &= -\beta_0^{3/2}\left(1 - \frac{2\gamma}{a}\right)^{-1/2}\varepsilon\rho + o(\varepsilon^{1+\alpha}).
\end{aligned}$$

Thus we have

$$\begin{aligned}
&\int_{D_l}\left\{[C_1(\kappa_{\max} - \kappa_r(x)] - \beta_0^{3/2}\left(1 - \frac{2\gamma}{a}\right)^{-1/2}\rho - o(\varepsilon^\alpha)\right\}|\chi\psi^\varepsilon|^2 dxdz \\
&\quad \le \varepsilon\int_{D_l}|\nabla\chi|^2|\psi^\varepsilon|^2 dxdz.
\end{aligned}$$

Then we can proceed as in Step 5 of the proof of Theorem 6.2 to obtain (6.4). □

Next we consider the case where

$$l = 2\gamma\kappa^{-2} + c\kappa^{-3} + O(\kappa^{-4}), \qquad c > 0. \tag{6.33}$$

We shall see that $H_{C_3}(\mathbf{e}_3, \kappa, l)$ remains bounded between two positive numbers. The discussion is valid for a more general case $2\gamma\kappa^{-2} + a\kappa^{-3} \le l \le 2\gamma\kappa^{-2} + b\kappa^{-3}$.

THEOREM 6.4. *Assume* (6.33).

(i) *For large* κ *we have*

$$H_{C_3}(\mathbf{e}_3, \kappa, l) = \frac{c}{2\gamma\beta_0} + \frac{C_1}{\beta_0^{3/2}}(\kappa_{\max} - 3\gamma)\sqrt{\frac{c}{2\gamma}}\kappa^{-1/2} + O(\kappa^{-2/3}). \tag{6.34}$$

(ii) *Fix* σ_0 *such that*

$$\frac{c}{2\gamma} < \sigma_0 < \frac{c}{2\gamma\beta_0}, \tag{6.35}$$

and let $(\psi, \mathbf{A})$ *be the minimizer of the Ginzburg–Landau functional* $\mathcal{G}$ *for* $\sigma = \sigma_0$. *Then for any constant* $0 < \alpha < 2\sqrt{\sigma_0 - \frac{c}{2\gamma}}$ *there exists* $C(\alpha) > 0$ *independent of* κ *and* l *such that*

$$\int_{D_l} \exp\bigl(\alpha\sqrt{\kappa}d_{\partial\Omega}(x)\bigr)\{|\psi|^2 + \kappa^{-2}|\nabla_{\sigma_0\kappa\mathbf{A}}\psi|^2\}dxdz \le C\kappa^{-5/2}. \tag{6.36}$$

Proof. Step 1. From (6.33) and (2.5) we have

$$\kappa^2 - \tau_\gamma(l)^2 = \frac{c}{2\gamma}\kappa + O(1). \tag{6.37}$$

Using (6.37) and the proof of Lemma 6.1 we get the lower bound of H_{C_3}. To obtain an upper bound of H_{C_3}, we choose σ such that

$$\sigma_* + O(\kappa^{-1/3}) < \sigma < H_{C_3}(\mathbf{e}_3, \kappa, l).$$

Note that σ is bounded away from 0. Let $\varepsilon = (\kappa\sigma)^{-1/2}$ and let $(\psi^\varepsilon, \mathbf{A}^\varepsilon)$ be the minimizer. From the second inequality in (4.9) we have, for $q > 3$,

$$\|\Im\{\bar{\psi}^\varepsilon\nabla_{\varepsilon^{-2}\mathbf{A}^\varepsilon}\psi^\varepsilon\}\|_{L^q(D_l)} \le \frac{C(q)}{\varepsilon}\|\psi^\varepsilon\|_{L^q(D_l)}\|\psi^\varepsilon\|_{L^\infty(D_l)}.$$

For $q = 3/(1-\alpha)$, where $0 < \alpha < 1$, we get

$$\|\mathbf{A}^\varepsilon - \mathbf{F}\|_{C^{1+\alpha}(\bar{D}_l)} \le C\delta, \qquad \text{where} \qquad \delta = \frac{1}{\sigma}\|\psi^\varepsilon\|_{L^4(D_l)}^2 + \varepsilon\|\psi^\varepsilon\|_{L^q(D_l)}\|\psi^\varepsilon\|_{L^\infty(D_l)}. \tag{6.38}$$

Note that $\|\psi\|_{L^q(D_l)} = O(l^{1/q})$. Hence

$$\delta \le C(l^{1/2} + \varepsilon l^{1/q}).$$

Let ϕ^ε be the eigenfunction of $-\nabla^2_{\varepsilon^{-2}\mathbf{A}^\varepsilon}$ associated with the lowest eigenvalue. As in the proof of Theorem 6.2 (Step 2), we find

$$\int_{D_l} |\nabla_{\varepsilon^{-2}\mathbf{A}^\varepsilon}\phi^\varepsilon|^2 dxdz \ge \int_{D_l} |\nabla_{\varepsilon^{-2}\mathbf{F}}\phi^\varepsilon|^2 dxdz - C\varepsilon^{-2}\delta^{2/3}\int_{D_l} |\phi^\varepsilon|^2 dxdz. \tag{6.39}$$

Therefore

$$\kappa^2 > \mu_\gamma(\varepsilon^{-2}\mathbf{A}^\varepsilon) \geq \tau_\gamma(l)^2 + \frac{1}{\varepsilon^2}\Big\{\beta_0 + C_1(3\gamma - \kappa_{\max})\varepsilon - C\varepsilon^{4/3} - C\delta^{2/3}\Big\}. \tag{6.40}$$

So

$$\kappa^2 - \tau_\gamma(l)^2 > \frac{\beta_0 + o(1)}{\varepsilon^2} = [\beta_0 + o(1)]\kappa\sigma.$$

Using this and (6.37) we find

$$\sigma \leq \frac{c}{2\gamma\beta_0} + o(1).$$

Hence ε has order of $\kappa^{-1/2}$, and l has order of ε^4. We choose $3 < q < 4$ in (6.38) and find

$$\delta \leq C\varepsilon^2.$$

Then we write (6.40) as

$$\kappa^2 > \mu_\gamma(\varepsilon^{-2}\mathbf{A}^\varepsilon) \geq \tau_\gamma(l)^2 + \frac{1}{\varepsilon^2}\{\beta_0 + C_1(3\gamma - \kappa_{\max})\varepsilon - C\varepsilon^{4/3}\}.$$

From this we obtain

$$H_{C_3}(\mathbf{e}_3, \kappa, l) \leq \frac{c}{2\gamma\beta_0} + \frac{C_1}{\beta_0^{3/2}}(\kappa_{\max} - 3\gamma)\sqrt{\frac{c}{2\gamma}}\kappa^{-1/2} + O(\kappa^{-2/3}).$$

Equation (6.34) is proved.

Step 2. Let σ satisfy (6.35), and let $(\psi, \mathbf{A})$ be the minimizer for $\sigma = \sigma_0$. Let χ be a smooth function vanishing at $\partial\Omega \times [0, l]$. From the equation of ψ we get

$$\int_{D_l} |\nabla_{\kappa\sigma_0\mathbf{A}}(\chi\psi)|^2 dxdz + \gamma\int_{\partial D_l} |\chi\psi|^2 dS = \int_{D_l} \{\kappa^2(1 - |\psi|^2)|\chi\psi|^2 + |\nabla\chi|^2|\psi|^2\} dxdz. \tag{6.41}$$

Note that $|\psi| \leq 1$, and (6.38) remains true. We choose $3 < q < 4$ in (6.38) to find

$$\|\mathbf{A} - \mathbf{F}\|_{C^{1+\alpha}(\bar{D}_l)} \leq C\big\{\|\psi\|^2_{L^4(D_l)} + \kappa^{-1/2}\|\psi\|_{L^q(D_l)}\big\} \leq C(l^{1/2} + \kappa^{-1/2}l^{1/q}) \leq C\kappa^{-1}.$$

Thus $\partial_1\mathbf{A}_2 - \partial_2\mathbf{A}_1 = 1 + O(\kappa^{-1})$. Using this and Lemma 5.2 we get

$$\int_{D_l} |\nabla_{\kappa\sigma_0\mathbf{A}}(\chi\psi)|^2 dxdz + \gamma\int_{\partial D_l} |\chi\psi|^2 dS \geq \big[\kappa\sigma_0(1 + O(\kappa^{-1})) + \tau_\gamma(l)^2\big]\int_{D_l} |\chi\psi|^2 dxdz.$$

From this, (6.37), and (6.41) we have

$$\left\{\left(\sigma_0 - \frac{c}{2\gamma}\right)\kappa + O(1)\right\}\int_{D_l} |\chi\psi|^2 dxdz \leq \int_{D_l} |\nabla\chi|^2|\psi|^2 dxdz.$$

Now we choose

$$\chi(x, z) = \chi(x) = \eta(x)\exp\left(\frac{\alpha}{2}\sqrt{\kappa}\zeta\right),$$

where $0 < \alpha < 2\sqrt{\sigma_0 - \frac{c}{2\gamma}}$, $\zeta(x)$ is a smooth function on $\bar{\Omega}$ such that $\zeta(x) = d_{\partial\Omega}(x)$ on Ω_{δ_0}, $\eta(x)$ is a cut-off function such that $\eta(x) = 0$ if $d_{\partial\Omega}(x) < \kappa^{-1/2}$, $\eta(x) = 1$ if $d_{\partial\Omega}(x) > 2\kappa^{-1/2}$, and $|\nabla\eta(x)| \le 4\sqrt{\kappa}$. Plugging it into the above inequality we find

$$\int_{D_l} |\psi|^2 \eta^2 \exp(\alpha\sqrt{\kappa}\zeta) dxdz \le C \int_{D_l \cap \{\mathrm{dist}(x,\partial\Omega) < 2\kappa^{-1/2}\}} |\psi|^2 dxdz \le Cl\kappa^{-1/2},$$

which implies that for a larger C,

$$\int_{D_l} |\psi|^2 \exp\bigl(\alpha\sqrt{\kappa} d_{\partial\Omega}(x)\bigr) dxdz \le Cl\kappa^{-1/2}.$$

Using this and (6.41) we find

$$\int_{D_l} |\nabla_{\kappa\sigma_0\mathbf{A}}\psi|^2 \exp\bigl(\alpha\sqrt{\kappa} d_{\partial\Omega}(x)\bigr) dxdz \le Cl\kappa^{3/2}.$$

From these two inequalities and the condition (6.33) we get (6.36). □

THEOREM 6.5. *Assume that*

$$l(\kappa) < l < 2\gamma\kappa^{-2} + O(\kappa^{-4}), \tag{6.42}$$

where $l(\kappa)$ was defined in section 2. For large κ we have $H_{C_3}(\mathbf{e}_3, \kappa, l) = O(\kappa^{-1})$.

Proof. We show that $\kappa H_{C_3}(\mathbf{e}_3, \kappa, l)$ is bounded as $\kappa \to \infty$. Suppose this is not the case. Then for each κ we can find σ, $0 < \sigma < H_{C_3}(\mathbf{e}_3, \kappa, l)$, such that $\sigma\kappa \to \infty$ as $\kappa \to \infty$. Thus $\varepsilon = (\kappa\sigma)^{-1} \to 0$. Let $(\psi^\varepsilon, \mathbf{A}^\varepsilon)$ be the minimizer of the Ginzburg–Landau functional. As in the proof of Theorem 6.4 we have

$$\|\mathbf{A}^\varepsilon - \mathbf{F}\|_{C^{1+\alpha}(D_l)} \le C\delta, \qquad \text{where we choose} \qquad \delta = \frac{1}{\sigma}\|\psi^\varepsilon\|^2_{L^4(D_l)} + \varepsilon\|\psi^\varepsilon\|_{L^q(D_l)}.$$

Since $\sigma = \frac{1}{\varepsilon^2\kappa}$ and $\|\psi\|_{L^q(D_l)} = O(l^{1/q})$, we have

$$\delta \le C\varepsilon^2\kappa l^{1/2} + C\varepsilon l^{1/q} = O(\varepsilon^2 + \varepsilon l^{1/q}).$$

As in the proof of Theorem 6.4 we get (6.39). Hence, as $\varepsilon \to 0$,

$$\kappa^2 > \mu_\gamma(\varepsilon^{-2}\mathbf{A}^\varepsilon) - C\varepsilon^{-2}\delta^{2/3} = \tau_\gamma(l)^2 + \frac{\beta_0 + o(1)}{\varepsilon^2},$$

so

$$\beta_0 + o(1) \le \varepsilon^2[\kappa^2 - \tau_\gamma(l)^2] = \varepsilon^2\left[\frac{C}{2\gamma} + \frac{\gamma^2}{3} + o(1)\right] \to 0.$$

This contradiction shows that ε is bounded away from 0. Hence $\sigma \le C\kappa^{-1}$. □

Remark 6. Assume that $l = 2\gamma\kappa^{-2} + c\kappa^{-4}$. From Theorem 6.5, $H_{C_3}(\mathbf{e}_3, \kappa, l) \le C\kappa^{-1}$. Now we look for a lower bound. Let $a_0 > 0$ be the smallest positive number such that

$$\mu_\gamma(a_0\mathbf{E}) = \frac{c}{2\gamma} + \frac{\gamma^2}{3}.$$

Then

$$H_{C_3}(\mathbf{e}_3, \kappa, l) \ge \frac{a_0 + o(1)}{\kappa}. \tag{6.43}$$

To prove (6.43), we let $\sigma\kappa = a < a_0$ and choose test functions $(\psi, \mathbf{F})$ with $\psi(x,z) = a_l\xi_l(z)\phi(x)$, where ξ_l is the function given in (2.4), and $a_l = 1/\|\xi_l\|_{L^2([0,l])}$. Recall that $\mathbf{F} = (-x_2, 0, 0)$ and $\mathbf{E} = (-x_2, 0)$. We have

$$\mathcal{G}[\psi, \mathbf{F}] = l\mathcal{J}_\kappa[\phi] + \frac{\kappa^2 l|\Omega|}{2},$$

where

$$\mathcal{J}_\kappa[\phi] = \int_\Omega \left\{ |\nabla_{\kappa\sigma\mathbf{E}}\phi|^2 - (\kappa^2 - \tau_\gamma(l)^2)|\phi|^2 + \frac{\kappa^2 b_l}{2}|\phi|^4 \right\} dx + \gamma \int_{\partial\Omega} |\phi|^2 ds$$

and

$$b_l = \frac{\|\xi_l\|^4_{L^4([0,l])}}{\|\xi_l\|^4_{L^2([0,l])}}.$$

Note that $lb_l \to 1$ and $\kappa^2 b_l \to 2\gamma$ as $l \to 0$. When $\kappa\sigma = a < a_0$, the functional $\mathcal{J}_\kappa$ has a nontrivial minimizer with negative energy. Thus $\mathcal{G}$ has a nontrivial minimizer. So (6.43) is true.

Proof of Theorem 1.1. It follows from Theorems 6.2, 6.3, 6.4, and 6.5, and Remark 3. □

Remark 7. We may further discuss the behavior of thin films subjected to a perpendicular magnetic field far below H_{C_3}. We would like to give some observations.

(i) Consider a film with large κ and $l = 2\gamma\kappa^{-2} + c\kappa^{-3}$ placed in a perpendicular magnetic field $\mathcal{H} = \sigma\mathbf{e}_3$.

If $\frac{c}{2\gamma} < \sigma < \frac{c}{2\gamma\beta_0}$, superconductivity concentrates in a thin cylinder with thickness $O(\kappa^{-1/2})$ around the lateral surface $\partial\Omega \times [0, l]$. In fact, from Theorem 6.4, the order parameters exponentially decay in the direction normal to the lateral surface. Moreover the minimizers have energy

$$\mathcal{G}[\psi, \mathbf{A}] = \frac{\kappa^2 l|\Omega|}{2} + O(\kappa^{3/2} l).$$

If $0 < \sigma < \frac{c}{2\gamma}$, superconductivity occurs in the interior. To see this, let us compute the energy of the minimizers. Using (6.37) we can show that when $0 < \sigma < \frac{c}{2\gamma}$, the functional $\mathcal{J}_\kappa$ has a nontrivial minimizer $w_\kappa(x)$, and there exists a constant $C > 0$ such that for all large κ, $\int_\Omega |w_\kappa|^4 dx \geq C|\Omega|$ (see, for instance, [SS]). Hence

$$\mathcal{J}_\kappa[w_\kappa] = -\frac{\kappa^2 b}{2} \int_\Omega |w_\kappa|^4 dx \leq -\frac{C\kappa^2 l|\Omega|}{2}.$$

Let $\psi_\kappa = \alpha_l\xi_l(z)w_\kappa(x)$, and choose $(\psi_\kappa, \mathbf{F})$ as a test function. As in Remark 6 we find that $\mathcal{G}[\psi, \mathbf{F}] \leq \frac{1}{2}(1 - C)\kappa^2 l|\Omega|$. Thus the minimizers have energy

$$\mathcal{G}[\psi, \mathbf{A}] \leq \frac{1}{2}(1 - C)\kappa^2 l|\Omega|.$$

Hence the local energy of the minimizers in the interior is not negligible.

If we compare these phenomena with the behaviors of the minimizers of the two-dimensional Ginzburg–Landau functional (see [P2]), we may say that a film with thickness $l = 2\gamma\kappa^{-2} + c\kappa^{-3}$ exhibits a lateral surface superconductivity in a perpendicular field with magnitude $\frac{c}{2\gamma} < \sigma < \frac{c}{2\gamma\beta_0}$ and exhibits a bulk superconductivity if $0 < \sigma < \frac{c}{2\gamma\beta_0}$.

(ii) Now consider a film with $l = a\kappa^{-1}$, $a > 2\gamma$. From Theorems 6.2 and 6.3 we know that in a perpendicular magnetic field, superconductivity nucleates in a strip $\mathcal{N}(\partial\Omega) \times [0, l]$. Now consider the applied field far below H_{C_3} and assume $\mathcal{H} = \lambda\kappa\mathbf{e}_3$.

If $1 < \lambda < 1/\beta_0$, we expect that the minimizers concentrate at a thin layer around the lateral surface $\partial\Omega \times [0, l]$. Moreover, the behavior of the minimizers in the thin layer, after rescaling, can be described by the solutions of the limiting equation

$$\begin{cases} -\nabla^2_{\mathbf{F}}\psi = \lambda(1 - |\phi|^2)\psi & \text{in } \mathbb{R}^2_+ \times (0, a), \\ \nabla_{\mathbf{F}}\psi \cdot \nu = 0 & \text{if } x_2 = 0, \text{ or if } z = 0,\ a. \end{cases}$$

Thus we may say that in a perpendicular applied field lying in between κ and H_{C_3}, a film with thickness $l = a\kappa^{-1}$ behaves like a type II superconductor and exhibits a lateral surface superconducting state. We do not present the discussion here since it is similar to what we have done in [P2] for cylindrical domains with infinite height.[12]

If $0 < \lambda < 1$, we can show that superconductivity occurs at interior (see item (i)).

(iii) Similarly we can analyze the films with $l = a\kappa^{-2}$, where $a > 2\gamma$.

From Theorem 1.1 we have

$$H_{C_3}(\mathbf{e}_3, \kappa, l) \sim \begin{cases} \frac{\kappa}{\beta_0} & \text{if } l = a\kappa^{-1}, \quad a > 0, \\ (1 - \frac{2\gamma}{a})\frac{\kappa}{\beta_0} & \text{if } l = a\kappa^{-2}, \quad a > 2\gamma, \\ \frac{c}{2\gamma\beta_0} & \text{if } l = 2\gamma\kappa^{-2} + c\kappa^{-3}, \ \ c > 0. \end{cases}$$

The above observations suggest that

$$H_{C_2}(\mathbf{e}_3, \kappa, l) \sim \begin{cases} \kappa & \text{if } l = a\kappa^{-1}, \quad a > 0, \\ (1 - \frac{2\gamma}{a})\kappa & \text{if } l = a\kappa^{-2}, \quad a > 2\gamma, \\ \frac{c}{2\gamma} & \text{if } l = 2\gamma\kappa^{-2} + c\kappa^{-3}, \ \ c > 0. \end{cases}$$

DROPLET SPREADING UNDER WEAK SLIPPAGE: A BASIC RESULT ON FINITE SPEED OF PROPAGATION*

GÜNTHER GRÜN†

Abstract. We prove a new qualitative result on finite speed of propagation for the thin film equation subjected to Navier slippage or even weaker slip conditions. Our approach works in multiple space dimensions and is based on a novel technique which combines recently established weighted energy estimates with a Hardy-type inequality and with Stampacchia's iteration lemma. It can be adapted to degenerate parabolic equations of order different from four as well.

Key words. fourth order degenerate parabolic equations, finite speed of propagation, thin films

PII. S0036141002403298

1. Introduction. In this paper, we present a new method for the proof of qualitative results on finite speed of propagation for degenerate parabolic equations. It is inspired by the idea developed by Dal Passo, Giacomelli, and Grün in [10] to show the occurrence of a waiting time phenomenon for the thin film equation. We apply the method to establish new results on finite speed of propagation for the thin film equation

$$\begin{aligned} u_t + \operatorname{div}(|u|^n \nabla \Delta u) &= 0 \qquad \text{in } \mathbb{R}^N \times (0,\infty), \\ u(\cdot,0) &= u_0 \qquad \text{on } \mathbb{R}^N \end{aligned} \tag{1.1}$$

in the parameter range $n \in [2,3)$ in space dimensions $N < 4$. For ease of presentation, we confine ourselves to a mobility $m(u) := |u|^n$. However, modifications of (1.1) obtained by replacing the term $|u|^n$ with more general functions $m \in C^2(\mathbb{R};\mathbb{R}_0^+)$, $m(0) = 0$, could be handled as well.

Let us make a few comments on the physical background. In the course of lubrication approximation (see, e.g., Bernis [2] or Oron, Davis, and Bankoff [29]), the equation

$$h_t + \frac{\sigma}{3\eta} \operatorname{div}\left(m(h) \nabla \Delta h\right) = 0 \tag{1.2}$$

is derived to describe the surface tension driven evolution of the thickness h of a thin film of viscous liquid spreading on a horizontal surface. Here, η is the viscosity of the liquid and σ denotes surface tension. The explicit form of the mobility $m(\cdot)$ is determined by the flow condition at the liquid-solid interface. In case of a no-slip condition we get $m(h) = h^3$, whereas a generic slip condition

$$\vec{v}_{\text{hor}}\Big|_{z=0} = \beta h^{n-2} \cdot \frac{\partial \vec{v}_{\text{hor}}}{\partial z}\Big|_{z=0}$$

entails

$$m(h) = h^3 + \beta h^n.$$

Here, $\vec{v}_{\rm hor}$ denotes the horizontal component of the fluid velocity field, β is a positive parameter, and z stands for the vertical coordinate. For $n = 2$, the classical slip condition of Navier is recovered, but in the physical literature (cf., e.g., [15], [16], or [27]) different parameters of $n \in (0, 3)$ were suggested as well to model effects of stronger ($n < 2$) or weaker ($n \in (2, 3)$) slippage.

Analytically, the qualitative behavior of solutions is governed by the smoothness of $m(\cdot)$ in its point of degeneracy, i.e., in $h_0 = 0$. For this reason, in the mathematical literature usually the model problem (1.1) is studied, as it exhibits already all the essential mathematical difficulties. So let us emphasize that the physically important case of surface tension driven thin film flow subjected to Navier's slip condition or to even weaker slip conditions corresponds in the framework of the model problem (1.1) to the choices $n = 2$ or $2 < n < 3$, respectively. Hence, it is covered by the results to be presented in the present paper.

Recall that (1.1) admits globally nonnegative solutions (cf., e.g., Bernis and Friedman [5] or Grün [19]) and that it implicitly defines a free boundary problem where the free boundary at time $T \geq 0$ is given by $\partial[\mathrm{supp}(u(\cdot, T))]$. It is one of the striking features of (1.1) that the qualitative behavior of solutions is sensitive to the mobility growth exponent $n > 0$. Despite the fact that scaling invariances of (1.1) (for details cf. Giacomelli and Otto [14]) suggest the existence of compactly supported self-similar solutions for arbitrary $n > 0$, these solutions only exist for $0 < n < 3$ (cf. Bernis, Peletier, and Williams [6] and Ferreira and Bernis [13]). Moreover, for $n > 4$ the support of arbitrary solutions is constant in time, as was proven by Beretta, Bertsch, and Dal Passo [1]. And asymptotic analysis suggests that this behavior holds true for all $n \geq 3$. This is in good agreement with the spreading paradox observed by Dussan and Davis [12] in the framework of Navier–Stokes equations. It says that a no-slip condition at the liquid-solid interface (which entails $n = 3$) implies infinite energy dissipation at the liquid-solid-gas contact line in the case of moving droplets. On the other hand, it is well known (see Bernis and Friedman [5], Beretta, Bertsch, and Dal Passo [1], and Bertozzi and Pugh [7] in space dimension $N = 1$; Dal Passo, Garcke, and Grün [9] and Grün [18] in the multidimensional case) that for $n \in (0, 3)$ in space dimensions $N < 4$ so called *strong solutions* exist. They exhibit a zero contact angle at the free boundary, and for $t \to \infty$ their support tends to cover the spatial domain entirely.

The existence of compactly supported self-similar solutions indicates that solutions to (1.1) have the property of finite speed of propagation. In Bernis [3], [4] and in Bertsch et al. [8], this could be confirmed rigorously for $n \in (0, 2)$ in space dimensions $N < 4$ and for $n \in [2, 3)$ in space dimension $N = 1$. Surprisingly, the case $n \in [2, 3)$, $N > 1$, remained open for rather a long time. Only recently, the author succeeded in proving in his habilitation thesis [21] a first result on finite speed of propagation in the higher-dimensional setting for that critical parameter regime.

While the result of [21] took advantage of Bernis's technique of higher order differential inequalities, the new approach to be presented here essentially uses an iteration lemma due to Stampacchia, and it seems to be technically less involved. Let us emphasize that this method also applies to degenerate parabolic equations of sixth or even higher order or of second order like the *porous-media equation* or like *doubly degenerate parabolic equations* (cf., e.g., Vazquez [30] or Ivanov [26]).

Before describing the outline of the present paper, let us recall the peculiarities of the regime $n \in [2, 3)$ which seem to exclude an applicability of the techniques used for $n \in (0, 2)$. As (1.1) is fourth order parabolic, comparison principles do not hold and

the argumentation has to be based solely on integral estimates. At this time, there are basically two types of integral estimates known: first the energy estimate

$$\frac{1}{2}\int_{\mathbb{R}^N}|\nabla u(\cdot,T)|^2+\int_0^T\int_{\mathbb{R}^N}u^n|\nabla\Delta u|^2\le\frac{1}{2}\int_{\mathbb{R}^N}|\nabla u_0|^2 \tag{1.3}$$

and second the α-entropy estimate

$$\begin{aligned}\frac{1}{\alpha(\alpha+1)}\int_{\mathbb{R}^N}u^{\alpha+1}(\cdot,T)+C^{-1}\int_0^T\int_{\mathbb{R}^N}\Big\{|\nabla u^{\frac{\alpha+n+1}{4}}|^4+|D^2u^{\frac{\alpha+n+1}{2}}|^2\Big\}\\ \le\frac{1}{\alpha(\alpha+1)}\int_{\mathbb{R}^N}u_0^{\alpha+1},\end{aligned} \tag{1.4}$$

which is valid for

$$\alpha\in\left(\frac{1}{2}-n,2-n\right)\setminus\{-1,0\}. \tag{1.5}$$

Note that for compactly supported initial data, the global version of estimate (1.4) is valid only for $n\in(0,3)$. Observe, moreover, that condition (1.5) does not permit the parameter α to be chosen positive in the parameter regime $n\in[2,3)$. As a consequence, in that regime the entropy $u^{\alpha+1}(T)$ can no longer be controlled in terms of the initial entropy. This is the reason why analytical approaches based on the entropy estimate are restricted to the interval $n\in(0,2)$.

On the other hand, the energy estimate requires additional analytical tools in order to become accessible to Gagliardo–Nirenberg-type arguments. To this end, it would be desirable to estimate the dissipated energy $\int u^n|\nabla\Delta u|^2$ from below by derivatives of certain powers of u. In the multidimensional case, this goal was achieved only recently by virtue of the interpolation inequality

$$\int_\Omega|\nabla u^{\frac{n+2}{6}}|^6+\int_\Omega|\nabla\Delta u^{\frac{n+2}{2}}|^2\le C(n,N)\int_\Omega u^n|\nabla\Delta u|^2, \tag{1.6}$$

which was proven in [21] (see also the recently published paper [20]) and which holds on convex domains Ω for positive functions of class H^2 having zero normal derivatives on the boundary.

This result was the key observation to establish in [21] on bounded convex domains Ω the existence of strong solutions to the thin film equation associated with compactly supported, nonnegative initial data which satisfy, besides an α-entropy estimate, the following energy-type estimate:

$$\int_\Omega|\nabla u(\cdot,T)|^2+C(n,N)\left\{\int_0^T\int_\Omega|\nabla u^{\frac{n+2}{6}}|^6+\int_0^T\int_\Omega|\nabla\Delta u^{\frac{n+2}{2}}|^2\right\}\le\int_\Omega|\nabla u_0|^2. \tag{1.7}$$

By virtue of appropriate weighted versions of that estimate, first existence results for the Cauchy problem in the parameter regime $n\in(2-\sqrt{8/(8+N)},3)$ could be established as well; see [21].

In the present paper, we will prove that these solutions have the property of finite speed of propagation in the following sense.

DEFINITION 1.1. *Let $v:\mathbb{R}^N\times[0,\infty)\to\mathbb{R}$ be a nonnegative function and assume that $v(.,0)$ has compact support in $\mathbb{R}^N$. We say that v* has finite speed of propagation

iff for each ball $\overline{B_{R_0}(x_0)}$, $x_0 \in \mathbb{R}^N$, $R_0 > 0$, *that contains* $\operatorname{supp} v(\cdot,0)$, *a continuous, monotonically increasing function* $R : [0,\infty) \to \mathbb{R}_0^+$, $R(0) = 0$, *exists such that*

$$\operatorname{supp} v(.,t) \subset \overline{B_{R_0+R(t)}(x_0)}\,.$$

In section 2, we will recall the properties of strong solutions to the Cauchy problem as constructed in [21]. Section 3 is devoted to the proof of a Hardy-type inequality on exterior domains. Combining that Hardy-type inequality with the aforementioned weighted version of the energy estimate, we may formulate an integral estimate which will serve as the key ingredient for the subsequent proof of finite speed of propagation which follows in section 4. The idea of proof is to derive via appropriate interpolation arguments a recursive inequality for the function

$$G_T(R) := \int_0^T \left(\int_{\mathbb{R}^N \setminus B_R} u^2 \right)^{\frac{n+2}{2}}$$

which permits an application of Stampacchia's iteration lemma (see Lemma 4.3). This way, we deduce for fixed $T > 0$ the existence of a number $0 < R(T) < \infty$ such that $G_T(R(T)) = 0$. As a consequence, it becomes evident that $\operatorname{supp}(u(\cdot,t)) \subset B_{R(T)}(0)$ for all $0 \le t < T$. Furthermore, $R(T)$ continuously depends on T, which gives the result.

Throughout the paper, we use the usual notation for Sobolev and Lebesgue spaces. We write $\|u\|_p$ for $(\int |u|^p)^{1/p}$ also in the case $0 < p < 1$. Finally, $B_R(x)$ denotes the ball with radius R and center $x \in \mathbb{R}^N$, and $[u > 0]_T$ stands for the set $\{(x,t) \in \mathbb{R}^N \times (0,T) | u(x,t) > 0\}$.

2. Preliminaries. In this section, we will summarize recent results on strong solutions for the Cauchy problem in the multidimensional case. In addition, we will formulate a version of Gagliardo–Nirenberg's inequality to be used in what follows.

THEOREM 2.1. *Let* $n \in (2 - \sqrt{8/(8+N)}, 3)$, $N < 4$, *and assume* $u_0 \in H^1(\mathbb{R}^N)$ *to be nonnegative with compact support in the sense that* $u_0(x) = 0$ *almost everywhere on* $\mathbb{R}^N \setminus B_{R_0}(0)$ *for a positive number* R_0. *Then a nonnegative function* u *exists that has the following properties:*

(i) *Regularity:*

$$(2.1)\quad u_t \in L^2(\mathbb{R}^+; (W^{1,p}(\Omega))') \text{ for } p > \frac{4N}{2N + n(2-N)} \text{ and any } \Omega \subset\subset \mathbb{R}^N,$$

$$(2.2)\quad u \in L^\infty(\mathbb{R}^+; H^1(\mathbb{R}^N)),$$

$$(2.3)\quad D^2 u^{\frac{\alpha+n+1}{2}} \in L^2(\mathbb{R}^N \times \mathbb{R}^+) \text{ for any } \alpha \in (\max\{-1, 1/2-n\}, 2-n),$$

$$(2.4)\quad \nabla u^{\frac{\alpha+n+1}{4}} \in L^4(\mathbb{R}^N \times \mathbb{R}^+) \text{ for any } \alpha \in (\max\{-1, 1/2-n\}, 2-n),$$

$$(2.5)\quad J = \begin{cases} u^n \nabla \Delta u & \text{on } [u>0]_T \\ 0 & \text{on } [u=0]_T \end{cases} \in L^2(\mathbb{R}^+; L^q(\mathbb{R}^N))$$

$$\text{for any } 1 < q < \frac{4N}{2N + n(N-2)}.$$

(ii) u *is a solution to the Cauchy problem in the sense that*

$$(2.6)\qquad \int_0^T \langle u_t, \phi \rangle_{(W^{1,p}(B(0)))' \times W^{1,p}(B(0))} - \int_{[u>0]_T} u^n \nabla \Delta u \nabla \phi = 0$$

for $p > \frac{4N}{2N+n(2-N)}$, *arbitrary* $T > 0$, *and for all test functions* ϕ *contained in* $L^2((0,T);W^{1,\infty}(\mathbb{R}^N))$ *such that* $\bigcup_{t\in(0,T)} \mathrm{supp}(\phi(.,t)) \subset B(0)$, *where* $B(0)$ *is an arbitrary ball centered in the origin* $0 \in \mathbb{R}^N$.

(iii) *The solution* u *attains initial data* u_0 *in the sense that*

$$\lim_{t\searrow 0} u(\cdot,t) = u_0(\cdot) \qquad \text{in } L^\beta_{loc}(\mathbb{R}^N) \tag{2.7}$$

for arbitrary $1 \le \beta < \frac{2N}{N-2}$.

(iv) *The solution* u *is an element of* $L^\infty(\mathbb{R}^+;L^\beta(\mathbb{R}^N))$ *for* $1 < \beta < \frac{2N}{N-2}$. *More precisely, a positive constant* $C = C(\beta,N)$ *exists such that the following estimate holds:*

$$\sup_{t\in\mathbb{R}^+} \int_{\mathbb{R}^N} u^\beta(x,t)dx \le C(\beta,N) \left\{ \left(\int_{\mathbb{R}^N} |\nabla u_0|^2 \right)^{1/2} + \int_{\mathbb{R}^N} u_0 \right\}^\beta . \tag{2.8}$$

(v) u *satisfies for arbitrary* $T > 0$ *the basic energy estimate*

$$\begin{aligned} &\int_{\mathbb{R}^N} |\nabla u(\cdot,T)|^2 + C_0^{-1} \int_0^T \int_{\mathbb{R}^N} \left\{ |\nabla u^{\frac{n+2}{6}}|^6 + |\nabla \Delta u^{\frac{n+2}{2}}|^2 \right\} \\ &\qquad \le \int_{\mathbb{R}^N} |\nabla u_0|^2 . \end{aligned} \tag{2.9}$$

Moreover, for arbitrary $R_0 \ge 0$ *and arbitrary* $T > 0$ *the following weighted version of the energy estimate holds with a positive constant* C_1 *that depends only on* n *and* N*:*

$$\begin{aligned} &\int_{\mathbb{R}^N\setminus B_{R_0}(0)} (|x|-R_0)^6 |\nabla u(\cdot,T)|^2 \, dx \\ &\qquad + C_1^{-1} \int_0^T \int_{\mathbb{R}^N\setminus B_{R_0}(0)} (|x|-R_0)^6 \left\{ |\nabla u^{\frac{n+2}{6}}|^6 + |\nabla \Delta u^{\frac{n+2}{2}}|^2 \right\} \\ &\qquad \le \int_{\mathbb{R}^N\setminus B_{R_0}(0)} (|x|-R_0)^6 \cdot |\nabla u_0|^2 \, dx + C_1 \int_0^T \int_{\mathbb{R}^N\setminus B_{R_0}(0)} u^{n+2}. \end{aligned} \tag{2.10}$$

Remark 1. For $n \in (\frac{1}{8}, 2 - \sqrt{8/(8+N)})$, an existence result for the Cauchy problem can be found in Bertsch et al. [8]. However, the solution concept applied in that paper is technically much more involved since third order derivatives are not controlled.

In the course of proof of the result on finite speed of propagation, we need a homogeneous version of Gagliardo–Nirenberg's inequality valid on the complement of balls in $\mathbb{R}^N$. It reads as follows.

LEMMA 2.2. *Let* $1 \le r < \infty$, $0 < q < p$, $m \in \mathbb{N}_+$ *such that*

$$\frac{1}{r} - \frac{m}{N} < \frac{1}{p}.$$

Assume w *to be contained in* $W^{m,r}(\mathbb{R}^N \setminus \overline{B_R(0)}) \cap L^q(\mathbb{R}^N \setminus \overline{B_R(0)})$. *There is a positive constant* $K_1 = K_1(N,m,p,q,r)$ *such that*

$$\|w\|_{p,\mathbb{R}^N\setminus\overline{B_R(0)}} \le K_1 \cdot \|D^m w\|^a_{r;\mathbb{R}^N\setminus\overline{B_R(0)}} \cdot \|w\|^{1-a}_{q,\mathbb{R}^N\setminus\overline{B_R(0)}} . \tag{2.11}$$

Here, $a = (\frac{1}{q} - \frac{1}{p})/(\frac{1}{q} + \frac{m}{N} - \frac{1}{r})$.

Remark 2. With a slight misuse of notation, we write $\|u\|_p$ for $(\int |u|^p)^{1/p}$ also in the case $0 < p < 1$.

Before giving the proof, let us state Gagliardo–Nirenberg's inequality in the following form (see Dal Passo, Giacomelli, and Shishkov [11]).

LEMMA 2.3. *Let* $1 \le r \le \infty$, $0 < q < p$, $m \in \mathbb{N}_+$ *such that*

$$\frac{1}{r} - \frac{m}{N} < \frac{1}{p}.$$

If $\Omega \subset \mathbb{R}^N$ *is bounded with piecewise smooth boundary, then positive constants* c_1 *and* c_2 *depending only on* $\Omega, r, p, m,$ *and* q *exist such that for any* $u \in L^q(\Omega)$ *satisfying* $D^m u \in L^r(\Omega)$, *the following inequality holds:*

$$\|u\|_p \le c_1 \|D^m u\|_r^a \|u\|_q^{1-a} + c_2 \|u\|_q, \tag{2.12}$$

where $a = (\frac{1}{q} - \frac{1}{p})/(\frac{1}{q} + \frac{m}{N} - \frac{1}{r})$.

Especially, if Ω *is an infinite cone, i.e., for given points* $x_0, y_0 \in \mathbb{R}^N$, $x_0 \notin B_1(y_0)$ *a set*

$$C_{x_0,y_0} := \left\{ z \in \mathbb{R}^N | z = x_0 + \lambda(y - x_0), \quad y \in B_1(y_0), \quad \lambda > 0 \right\},$$

then (2.12) *holds with constants* $c_1 = c(\|x_0 - y_0\|, r, p, m, q)$ *and* $c_2 = 0$.

Proof of Lemma 2.2. Let us prove the result first for the special case $\Omega = \mathbb{R}^N \setminus \overline{B_1(0)}$. To this purpose, we write

$$\Omega = \Omega_+ \cup \Omega_-,$$

where Ω_+ and Ω_- are open sets which are $W^{m,\infty}$-diffeomorphic to the half-space $\mathbb{R}^N_+ := \{x \in \mathbb{R}^N | x_N > 0\}$. In the case $m = 1$, for instance, we may choose Ω_+ and Ω_- as the complements in $\mathbb{R}^N$ of the closed sets

$$A_+ := \overline{B_1(0)} \cup \left\{ x \in \mathbb{R}^N | x_N \ge 0 \right\}$$

and

$$A_- := \overline{B_1(0)} \cup \left\{ x \in \mathbb{R}^N | x_N \le 0 \right\},$$

respectively. For $m > 1$, an appropriate smoothing procedure has to be applied.

By virtue of Lemma 2.3 and a straightforward transformation argument, a Gagliardo–Nirenberg inequality in the spirit of (2.11) holds both on Ω_+ and on Ω_-.

This is sufficient to prove (2.11) for $\Omega = \mathbb{R}^N \setminus \overline{B_1(0)}$. Indeed,

$$\begin{aligned}
\int_\Omega |w|^p &\le \int_{\Omega_+} |w|^p + \int_{\Omega_-} |w|^p \\
&\le C\Bigg\{ \left(\int_{\Omega_+} |D^m w|^r \right)^{\frac{ap}{r}} \cdot \left(\int_{\Omega_+} |w|^q \right)^{\frac{p}{q}(1-a)} \\
&\qquad + \left(\int_{\Omega_-} |D^m w|^r \right)^{\frac{ap}{r}} \cdot \left(\int_{\Omega_-} |w|^q \right)^{\frac{p}{q}(1-a)} \Bigg\} \\
&\le C \left(\int_{\Omega_+} |D^m w|^r + \int_{\Omega_-} |D^m w|^r \right)^{\frac{ap}{r}} \left(\int_{\Omega_+} |w|^q + \int_{\Omega_-} |w|^q \right)^{\frac{p}{q}(1-a)} \\
&\le K_1 \left(\int_\Omega |D^m w|^r \right)^{\frac{ap}{r}} \left(\int_\Omega |w|^q \right)^{\frac{p}{q}(1-a)} .
\end{aligned}$$

In the second step of this estimate, we used the assumption

$$\frac{1}{r} - \frac{m}{N} < \frac{1}{p} < \frac{1}{q}$$

together with the calculus inequality

$$\sum_{i=1}^k a_i^\alpha b_i^\beta \le \left(\sum_{i=1}^k a_i \right)^\alpha \left(\sum_{i=1}^k b_i \right)^\beta ,$$

which holds for numbers α, β and a_i, b_i, $i = 1, \dots, k$, that satisfy

$$a_i, b_i \ge 0, \quad \alpha, \beta > 0, \quad \text{and} \quad \alpha + \beta \ge 1.$$

For a proof, see, for instance, Dal Passo, Giacomelli, and Shishkov [11]. Finally, (2.11) follows for arbitrary $R > 0$ by a straightforward scaling argument. □

3. An application of Hardy's inequality. In this section we will prove a Hardy-type estimate on $\mathbb{R}^N \setminus B_R(0)$, which will be combined with the weighted energy-type estimate (2.10) to yield a key ingredient for the proof of the main result of the paper. The Hardy-type estimate reads as follows.

LEMMA 3.1. *Assume that $w(r) := r^4$ and $v(r) := r^6$ and that $u \in H^1_{loc}(\mathbb{R}^N) \cap C(\mathbb{R}^N)$ satisfies the inequalities*

$$\int_{\mathbb{R}^N} v(|x|) \cdot |\nabla u|^2 \, dx < \infty, \tag{3.1}$$

$$\int_{\partial B_R(0)} u^2 \, d\mathcal{H}^{N-1} \le C_1 \cdot R^{-1} . \tag{3.2}$$

Then a positive constant C_2 exists which is independent of $R > 0$ such that

$$\int_{\mathbb{R}^N \setminus B_R(0)} w(\operatorname{dist}(x, B_R(0))) \cdot u^2 \, dx \le C_2 \int_{\mathbb{R}^N \setminus B_R(0)} v(\operatorname{dist}(x, B_R(0))) |\nabla u|^2 \, dx . \tag{3.3}$$

Let us first recall the following version of Hardy's inequality in one space dimension (see [23], [24], and the monograph [28]).

LEMMA 3.2. *Let a be a real number and assume the weight functions v, w to be nonnegative and measurable on (a, ∞). Consider for $x \in (a, \infty)$ the quantity*

$$F_{Har}(x) := \int_a^x w(s)ds \cdot \int_x^\infty v^{-1}(s)ds.$$

If $\sup_{a<x<\infty} F_{Har}(x) < \infty$, then there exists a positive constant $C = C(a, v, w)$ such that

$$\int_a^\infty w(s) \cdot u^2(s)ds \le C \int_a^\infty v(s) \cdot u_x^2(s)ds \tag{3.4}$$

for all

$$u \in AC_R(a, \infty) := \{u \in W^{1,1}_{loc}(a, \infty) : \lim_{x \nearrow \infty} u(x) = 0\}.$$

Proof of Lemma 3.1. The strategy is to apply the one-dimensional Hardy inequality (3.4) to appropriate integrals over spheres of radius r. Therefore, let us switch to polar coordinates and prove an estimate on the derivative of the L^2-norm of u over such spheres. First we need some notation.

$$\begin{aligned}\int_{\mathbb{R}^N \setminus B_R(0)} w(\operatorname{dist}(x, B_R(0))u^2\, dx &= \int_R^\infty \int_{S^{N-1}} w(r-R)u^2 r^{N-1}\, dS^{N-1}\, dr \\ &= \int_R^\infty w(r-R)U^2(r)r^{N-1}\, dr,\end{aligned} \tag{3.5}$$

where we defined

$$U(r) := \left(\int_{S^{N-1}} u^2(r, \theta)\, dS^{N-1}\right)^{1/2}.$$

Note that we use "u" to denote the function u in both polar and Euclidean coordinates. Here, "θ" is an abbreviation of the angular coordinates and "dS^{N-1}" stands for the surface element on the unit sphere. We have in particular that

$$\frac{\partial}{\partial r}U(r) = \left(\int_{S^{N-1}} u^2(r, \theta)\, dS^{N-1}\right)^{-1/2} \cdot \underbrace{\left(\int_{S^{N-1}} u(r, \theta) \cdot u_r(r, \theta) \cdot dS^{N-1}\right)}_{\le \left(\int_{S^{N-1}} u^2\, dS^{N-1}\right)^{1/2}\left(\int_{S^{N-1}} u_r^2\, dS^{N-1}\right)^{1/2}}, \tag{3.6}$$

which implies that

$$\left|\frac{\partial}{\partial r}U(r)\right|^2 \le \int_{S^{N-1}} u_r^2\, dS^{N-1}. \tag{3.7}$$

On the other hand, (3.2) entails the decay estimate

$$U(r) \le C \cdot r^{-\frac{N}{2}}$$

for $r > 0$. Altogether,

$$U(r) \in AC_R(R, \infty).$$

Now assuming that we may apply Hardy's inequality for the weight functions

$$\tilde{w}(r) := (r-R)^4 \cdot r^{N-1}$$

and

$$\tilde{v}(r) := (r-R)^6 \cdot r^{N-1},$$

we obtain the following result by virtue of Lemma 3.2:

$$\begin{aligned}\int_{\mathbb{R}^N \setminus B_R(0)} w(\mathrm{dist}(x, B_R(0)))u(x)^2\, dx &= \int_R^\infty \tilde{w}(r) \cdot U^2(r) dr \\ &\le C \int_R^\infty \tilde{v}(r) \cdot U_r^2(r) dr \\ &\quad \text{(by (3.7))} \\ &\le \int_{\mathbb{R}^N \setminus B_R(0)} v(\mathrm{dist}(x, B_R(0)))|\nabla u|^2\, dx\,.\end{aligned} \tag{3.8}$$

It remains to verify that we were indeed allowed to use Hardy's inequality. This means we have to convince ourselves that

$$\sup_{R<x<\infty} \left\{ \int_R^x \tilde{w}(s) ds \cdot \int_x^\infty \tilde{v}^{-1}(s) ds \right\} < \infty\,.$$

Indeed, we find for arbitrary $x \in (R, \infty)$ that

$$\begin{aligned}&\int_R^x (r-R)^4 \cdot r^{N-1}\, dr \cdot \int_x^\infty (r-R)^{-6} r^{1-N}\, dr \\ &\le x^{N-1} \cdot \int_R^x (r-R)^4\, dr \cdot x^{1-N} \int_x^\infty (r-R)^{-6}\, dr \\ &\le \int_R^x (r-R)^4\, dr \cdot \int_x^\infty (r-R)^{-6} \\ &= \frac{1}{25}\,,\end{aligned}$$

and the lemma is proved. □

Lemma 3.1 can be combined with Theorem 2.1 to establish the following estimate on solutions to the Cauchy problem.

Lemma 3.3. *Let u be a solution to the Cauchy problem as constructed in Theorem 2.1. Then a positive constant C_2 which is independent of $R_0 \ge 0$ exists such that*

$$\begin{aligned}&\int_{\mathbb{R}^N \setminus B_{R_0}(0)} (|x| - R_0)^4 u(\cdot, T)^2\, dx \\ &\quad + C_2^{-1} \int_0^T \int_{\mathbb{R}^N \setminus B_{R_0}(0)} (|x| - R_0)^6 \left\{ |\nabla u^{\frac{n+2}{6}}|^6 + |\nabla \Delta u^{\frac{n+2}{2}}|^2 \right\} \\ &\quad \le C_2 \left\{ \int_{\mathbb{R}^N \setminus B_{R_0}(0)} (|x| - R_0)^6 \cdot |\nabla u_0|^2\, dx + \int_0^T \int_{\mathbb{R}^N \setminus B_{R_0}(0)} u^{n+2} \right\}.\end{aligned} \tag{3.9}$$

Proof. The proof will be an immediate consequence of Lemma 3.1 and the weighted energy estimate (2.10), provided we can show a decay estimate like (3.2) for $\int_{\partial B_R(0)} u^2 d\mathcal{H}^{N-1}$.

Note that the weighted energy estimate (2.10) and the global energy estimate

$$\int_{\mathbb{R}^N} |\nabla u(\cdot,T)|^2 + C_1 \int_0^T \int_{\mathbb{R}^N} \left\{ |\nabla u^{\frac{n+2}{6}}|^6 + |\nabla \Delta u^{\frac{n+2}{2}}|^2 \right\} \le \int_{\mathbb{R}^N} |\nabla u_0|^2$$

imply that

$$\sup_{0<t<T} \int_{\mathbb{R}^N} |x|^2 |\nabla u(x,t)|^2 < \infty. \tag{3.10}$$

On the other hand, (2.8) entails that

$$\sup_{0<t<T} \int_{\mathbb{R}^N} u^2(x,t) dx < \infty.$$

Then the result follows by application of the following lemma. ∎

LEMMA 3.4. *Assume that a function $v \in H^1(\mathbb{R}^N)$ satisfies*

$$\int_{\mathbb{R}^N} x^2 |\nabla v|^2 \, dx + \int_{\mathbb{R}^N} v^2 \, dx < \infty. \tag{3.11}$$

Then there is a positive constant C_3 such that

$$\int_{\partial B_R(0)} v^2 d\mathcal{H}^{N-1} \le C_2 \cdot R^{-1} \tag{3.12}$$

for arbitrary $R > 0$.

Proof. Let us denote the transformation of v to polar coordinates by $\hat{v}$. Consider the quantity

$$r \cdot \|\hat{v}\|^2_{2,\partial B_r(0)} := r \cdot \int_{S^{N-1}} \hat{v}^2(r,\theta) \cdot r^{N-1} \, dS^{N-1} \,. \tag{3.13}$$

Differentiation with respect to r gives

$$\frac{\partial}{\partial r} \left(r \|\hat{v}\|^2_{2,\partial B_r(0)} \right) = 2r \int_{S^{N-1}} \hat{v} \hat{v}_r r^{N-1} \, dS^{N-1} + N \int_{S^{N-1}} \hat{v}^2 r^{N-1} \, dS^{N-1} \,.$$

Integrating this identity over the interval $(0,R)$ with respect to r implies that

$$\begin{aligned}
R \int_{S^{N-1}} & \hat{v}^2 R^{N-1} \, dS^{N-1} \\
&= 2 \int_0^R \int_{S^{N-1}} r \hat{v} \hat{v}_r r^{N-1} \, dS^{N-1} \, dr + N \int_0^R \int_{S^{N-1}} \hat{v}^2 r^{N-1} \, dS^{N-1} \, dr \\
&\le C \left(\int_0^R \int_{S^{N-1}} r^2 \hat{v}_r^2 r^{N-1} \, dS^{N-1} \, dr + \int_0^R \int_{S^{N-1}} \hat{v}^2 r^{N-1} \, dS^{N-1} \, dr \right) \\
&\le C \left(\int_{B_R} |x|^2 |\nabla v|^2 \, dx + \int_{B_R} v^2 \, dx \right) .
\end{aligned}$$

This proves the assertion of Lemma 3.4. ∎

4. The main result. This section is devoted to the proof of Theorem 4.1.

THEOREM 4.1. *Let $n \in (2 - \sqrt{8/(8+N)}, 3)$, $N < 4$, and assume initial data $u_0 \in H^1(\mathbb{R}^N)$ to be nonnegative with compact support in the sense that $u_0(x) = 0$ almost everywhere on $\mathbb{R}^N \setminus B_{R_0}(0)$ for a positive number R_0. Let u be the strong solution to the Cauchy problem constructed in* Theorem 2.1. *Then u has finite speed of propagation in the sense of Definition* 1.1. *More precisely,* $\mathrm{supp}(u(\cdot,t)) \subset B_{R(t)}(0)$, *where*

$$R(t) = R_0 + C \cdot t^{\frac{1}{\alpha}} \left(\int_0^t \left(\int_{\mathbb{R}^N \setminus B_{R_0}} u^2 \right)^{\frac{n+2}{2}} \right)^{\frac{n}{2\alpha}} \tag{4.1}$$

with a positive constant $C = C(n,N)$ and $\alpha = \frac{(8+Nn)(n+2)}{4}$.

Remark 3. 1. The notion of *finite speed of propagation* formulated in Definition 1.1 is still a rather weak one. However, it is possible to replace balls by general convex sets having sufficiently smooth boundary. With—sometimes rather tedious—technical changes, the results to be proved in this section continue to hold. For further improvements, e.g., the treatment of initial data with nonconvex support, refined versions of Hardy's inequality will be necessary. In the forthcoming paper [17], we will prove a Hardy-type inequality valid on infinite cones. On the basis of the finite speed of propagation result established in the present paper, new weighted energy estimates will be formulated for which the spatial support will be given by an infinite cone. These estimates will be the key ingredient for proving local results both on finite speed of propagation and on the occurrence of a waiting time phenomenon wherever the support of initial data locally satisfies an exterior cone condition.

2. Note that (4.1) can be combined with the global energy estimate (2.9) to yield the estimate

$$R(t) \le R_0 + \hat{C} \cdot t^{\frac{2}{8+nN}}$$

with a constant $\hat{C}$ depending on $n, N, \|\nabla u_0\|_2$, and the initial mass. However, the exponent $\gamma = \frac{2}{8+nN}$ is not optimal as a comparison with self-similar solutions reveals (see Ferreira and Bernis [13]). Nevertheless, the merely qualitative result presented here is the starting point for providing optimal quantitative estimates on the diameter of $\mathrm{supp}(u(\cdot,t))$. This is the subject of the forthcoming paper [22].

Proof of Theorem 4.1. The starting point is the estimate (3.9), which can be simplified for arbitrary $R \ge R_0$ and $T > 0$ in the following way:

$$\begin{aligned} \sup_{t\in(0,T)} \int_{\mathbb{R}^N \setminus B_R} (|x| - R)^4 u(\cdot,t)^2 + C_2^{-1} \int_0^T \int_{\mathbb{R}^N \setminus B_R} (|x| - R)^6 |\nabla u^{\frac{n+2}{6}}|^6 \\ \le C_2 \int_0^T \int_{\mathbb{R}^N \setminus B_R} u^{n+2}. \end{aligned} \tag{4.2}$$

Consider positive numbers $\varrho > R$. Obviously, $|x| - R > \varrho - R$ on $\mathbb{R}^N \setminus B_\varrho$. This implies that

$$\begin{aligned} \sup_{t\in(0,T)} \int_{\mathbb{R}^N \setminus B_\varrho} u(\cdot,t)^2 + (\varrho - R)^2 \int_0^T \int_{\mathbb{R}^N \setminus B_\varrho} |\nabla u^{\frac{n+2}{6}}|^6 \\ \le \frac{C}{(\varrho - R)^4} \int_0^T \int_{\mathbb{R}^N \setminus B_R} u^{n+2} \end{aligned} \tag{4.3}$$

for $\varrho > R \geq R_0$.

By virtue of Lemma 2.2, the term on the right-hand side can be estimated as follows:

(4.4)
$$\int_0^T \int_{\mathbb{R}^N \setminus B_R} u^{n+2} \leq K_1 \left(\int_0^T \int_{\mathbb{R}^N \setminus B_R} |\nabla u^{\frac{n+2}{6}}|^6 \right)^{\frac{nN}{nN+12}} \left(\int_0^T \left(\int_{\mathbb{R}^N \setminus B_R} u^2 \right)^{\frac{n+2}{2}} \right)^{\frac{12}{nN+12}}.$$

Young's inequality yields

(4.5)
$$\begin{aligned} \frac{1}{(\varrho - R)^4} \int_0^T \int_{\mathbb{R}^N \setminus B_R} u^{n+2} &\leq (\varrho - R)^{\frac{2nN}{nN+12}} K_1 \left(\int_0^T \int_{\mathbb{R}^N \setminus B_R} |\nabla u^{\frac{n+2}{6}}|^6 \right)^{\frac{nN}{nN+12}} \\ &\quad \cdot (\varrho - R)^{-4-\frac{2nN}{nN+12}} \left(\int_0^T \left(\int_{\mathbb{R}^N \setminus B_R} u^2 \right)^{\frac{n+2}{2}} \right)^{\frac{12}{nN+12}} \\ &\leq \varepsilon (\varrho - R)^2 \int_0^T \int_{\mathbb{R}^N \setminus B_R} |\nabla u^{\frac{n+2}{6}}|^6 \\ &\quad + C_\varepsilon (\varrho - R)^{-(4+\frac{nN}{2})} \int_0^T \left(\int_{\mathbb{R}^N \setminus B_R} u^2 \right)^{\frac{n+2}{2}}. \end{aligned}$$

Putting everything together gives

(4.6)
$$\begin{aligned} &\sup_{t \in (0,T)} \int_{\mathbb{R}^N \setminus B_\varrho} u^2(\cdot, t) + (\varrho - R)^2 \int_0^T \int_{\mathbb{R}^N \setminus B_\varrho} |\nabla u^{\frac{n+2}{6}}|^6 \\ &\qquad \leq \varepsilon (\varrho - R)^2 \int_0^T \int_{\mathbb{R}^N \setminus B_R} |\nabla u^{\frac{n+2}{6}}|^6 + \frac{C_\varepsilon}{(\varrho - R)^{4+\frac{nN}{2}}} \int_0^T \left(\int_{\mathbb{R}^N \setminus B_R} u^2 \right)^{\frac{n+2}{2}} \end{aligned}$$

for all $\varrho > R > R_0$.

Introducing the quantities

$$V(\varrho) := \sup_{t \in (0,T)} \int_{\mathbb{R}^N \setminus B_\varrho} u^2, \qquad U(\varrho) := \int_0^T \int_{\mathbb{R}^N \setminus B_\varrho} |\nabla u^{\frac{n+2}{6}}|^6,$$
$$F_\varepsilon(\varrho, R) := \frac{C_\varepsilon}{(\varrho - R)^{4+\frac{nN}{2}}} \int_0^T \left(\int_{\mathbb{R}^N \setminus B_R} u^2 \right)^{\frac{n+2}{2}},$$

(4.6) can be written as follows:

$$V(\varrho) + (\varrho - R)^2 U(\varrho) \leq \varepsilon (\varrho - R)^2 U(R) + F_\varepsilon(\varrho, R)$$

for all $\varepsilon > 0$ and all $\varrho > R \geq R_0$. An application of the subsequent iteration result Lemma 4.2 shows that

$$V(\varrho) + \frac{(\varrho - R)^2}{4} U(\varrho) \leq K_\varepsilon F_\varepsilon(\varrho, R)$$

for sufficiently small but fixed $\varepsilon > 0$. Therefore,

$$\sup_{t\in(0,T)} \int_{\mathbb{R}^N\setminus B_\varrho} u^2(\cdot,t) + (\varrho - R)^2 \int_0^T \int_{\mathbb{R}^N\setminus B_\varrho} |\nabla u^{\frac{n+2}{6}}|^6 \leq \frac{K_\varepsilon}{(\varrho-R)^{4+\frac{nN}{2}}} \int_0^T \left(\int_{\mathbb{R}^N\setminus B_R} u^2 \right)^{\frac{n+2}{2}}. \tag{4.7}$$

Using the estimate

$$\int_0^T \left(\int_{\mathbb{R}^N\setminus B_\varrho} u^2 \right)^{\frac{n+2}{2}} \leq T \cdot \sup_{t\in(0,T)} \left(\int_{\mathbb{R}^N\setminus B_\varrho} u^2 \right)^{\frac{n+2}{2}},$$

we find that

$$\int_0^T \left(\int_{\mathbb{R}^N\setminus B_\varrho} u^2 \right)^{\frac{n+2}{2}} \leq \frac{CT}{(\varrho-R)^{(4+\frac{nN}{2})\frac{n+2}{2}}} \cdot \left(\int_0^T \left(\int_{\mathbb{R}^N\setminus B_R} u^2 \right)^{\frac{n+2}{2}} \right)^{\frac{n+2}{2}}. \tag{4.8}$$

Introducing

$$G(\varrho) := \int_0^T \left(\int_{\mathbb{R}^N\setminus B_\varrho} u^2 \right)^{\frac{n+2}{2}},$$

$$\alpha := \left(4 + \frac{nN}{2}\right)\frac{n+2}{2}, \qquad \beta := \frac{n+2}{2} > 1,$$

(4.8) can be rewritten in the form

$$G(\varrho) \leq \frac{CT}{(\varrho-R)^\alpha} \cdot G(R)^\beta$$

for all $\varrho > R \geq R_0$. An application of Stampacchia's iteration lemma (Lemma 4.3) shows that $G(\varrho) = 0$, provided

$$(\varrho - R_0)^\alpha \geq C \cdot T \cdot \left(\int_0^T \left(\int_{\mathbb{R}^N\setminus B_{R_0}} u^2 \right)^{\frac{n+2}{2}} \right)^{\frac{n}{2}}.$$

Hence, we obtain for $R(T)$ the estimate given in equation (4.1). Recalling in addition that $u \in L^\infty(\mathbb{R}^+; L^\beta(\mathbb{R}^N))$ for all $1 < \beta < \frac{2N}{N-2}$, we have proved finite speed of propagation. □

We used the following iteration lemma, which is a slight modification of an argument presented in the proof of Theorem 6.1 of [10] (see also [25]). For the reader's convenience, we sketch the proof.

LEMMA 4.2. *Assume that*

$$V(\varrho') + (\varrho' - R')^2 U(\varrho') \leq \varepsilon(\varrho' - R')^2 U(R') + F_\varepsilon(\varrho', R') \tag{4.9}$$

for $\varepsilon > 0$ sufficiently small and $0 \leq R_0 \leq R < R' < \varrho' < \varrho$. Then there exists a positive constant K_ε such that

$$V(\varrho) + \frac{(\varrho - R)^2}{4} U(\varrho) \leq K_\varepsilon F_\varepsilon(\varrho, R). \tag{4.10}$$

Proof. Introduce for $k \in \mathbb{N}$ points ϱ_k, R_k such that

$$\varrho_k = R + \frac{(\varrho - R)}{2^{k-1}}, \qquad R_k := R + \frac{(\varrho - R)}{2^k}, \tag{4.11}$$

i.e.,

$$R_k = \varrho_{k+1} \qquad \text{and} \qquad \varrho_k - R_k = \frac{(\varrho - R)}{2^k}. \tag{4.12}$$

Along the lines of the corresponding result in [10], we may prove that

$$V(\varrho) + \frac{(\varrho - R)^2}{4} U(\varrho) \le \frac{\varepsilon^M}{4} (\varrho - R)^2 U(R_M) + \sum_{k=1}^{M} (4\varepsilon)^{k-1} F_\varepsilon(\varrho_k, R_k). \tag{4.13}$$

Now estimating

$$F_\varepsilon(\varrho_k, R_k) \le 2^{k(4+\frac{nN}{2})} \frac{C_\varepsilon}{(\varrho - R)^{4+\frac{nN}{2}}} \int_0^T \left(\int_{\mathbb{R}^N \setminus B_R} u^2 \right)^{\frac{n+2}{2}},$$

it becomes evident that for ε sufficiently small, the right-hand side of (4.13) is convergent, which proves the lemma. ∎

For the sake for completeness, we state the following.

LEMMA 4.3 (Stampacchia's iteration lemma). *Assume that a given nonnegative, nonincreasing function $G : (0, \varrho_0) \to \mathbb{R}$ satisfies*

$$G(\xi) \le \frac{c_0}{(\xi - \eta)^\alpha} G(\eta)^\beta$$

for $0 \le \eta < \xi \le \varrho_0$ and positive numbers c_0, α, β with $\beta > 1$. Assume further that

$$\varrho_0^\alpha \ge 2^{\frac{\alpha\beta}{\beta-1}} \cdot c_0 \cdot G(0)^{\beta-1}.$$

Then G has a root in ϱ_0.

ROBUST PERMANENCE FOR ECOLOGICAL DIFFERENTIAL EQUATIONS, MINIMAX, AND DISCRETIZATIONS*

BARNABAS M. GARAY† AND JOSEF HOFBAUER‡

Abstract. We present a sufficient condition for robust permanence of ecological (or Kolmogorov) differential equations based on average Liapunov functions. Via the minimax theorem we rederive Schreiber's sufficient condition [S. Schreiber, *J. Differential Equations*, 162 (2000), pp. 400–426] in terms of Liapunov exponents and give various generalizations. Then we study robustness of permanence criteria against discretizations with fixed and variable stepsizes. Applications to mathematical ecology and evolutionary games are given.

Key words. population dynamics, average Liapunov functions, robust permanence, discretizations of Kolmogorov type, invariant measures, Liapunov exponent, minimax, Conley index, evolutionary games

1. Introduction.

The concept of permanence (also known as uniform persistence) emerged in the late seventies as the appropriate mathematical description of coexistence in deterministic models of interacting species, replacing the previously used, but far too restrictive, global asymptotic stability of an equilibrium. It simply requires that the boundary of the state space, or the set of all extinction states, be a repeller for the dynamics of the ecological system.

In the late eighties it was realized [16], [28] that the proper framework for permanence (for the boundary as a whole) in topological dynamics was already developed by Zubov, Ura, Kimura, and others (see historical remarks in section 2), while Conley's Morse decompositions allow a finer description. New ideas of Schreiber [57] in a C^r setting are the use of invariant measures and ergodic theory, in particular smooth ergodic theory, and lead to characterizations of a robust form of permanence, meaning that nearby systems are still permanent.

In the present paper we derive sufficient conditions for robust permanence along a more classical approach using topological dynamics, in particular "good" average Liapunov functions (GALF), the Zubov–Ura–Kimura theorem, and Morse decompositions. Our key result is to relate the standard average Liapunov functions $P(x) = \prod x_i^{p_i}$ via the minimax theorem to invariant measures. This allows us to rederive and strengthen Schreiber's [57] sufficient conditions stated in terms of "unsaturated" invariant measures. (Our paper does not concern Schreiber's necessary conditions for robust permanence, based on the deep theory of measurable stable manifolds of Pesin.) Our approach leads to sharper robustness results: First, we allow C^0-perturbations; second, we prove uniform separation of the dual attractor from the repelling boundary. Similar sharper results were recently and independently obtained also by Hirsch, Smith, and Zhao [26] by refining the invariant measure ap-

proach of [57]. However, our approach, based on GALF, is suitable to derive explicit estimates; see Remark 2.7. It also leads to exponential repulsivity; see section 3, where we also shed light on the relation between GALF and Liapunov functions.

We work out the details for dynamics on the probability simplex and indicate that similar results hold for ecological (or Kolmogorov) systems in $\mathbb{R}^n_+$ (as in [57]) and also for systems with a compact codimension 1 invariant manifold; see section 11.1.

In the second part of the paper we transfer the previous results to discrete-time systems and then turn our attention to discretization problems. We show that natural discretizations of ecological differential equations respect the invariance of boundary faces. For such discretizations of Kolmogorov type we prove robustness of permanence and discuss also Kloeden–Schmalfuss pullback attractor–repeller pairs with free step-size sequences.

In section 10 we give a short review (including open problems) of the literature on index theorems ensuring that isolated invariant sets on the boundary actually repel trajectories into the interior.

In the final section 11 we illustrate the theory with a number of applications to ecological and game theoretic models, such as Lotka–Volterra equations, replicator equations, and imitation dynamics, as well as their discretized versions. Other applications concern invasion of an ecological system by a new species and explicit characterizations of totally permanent systems which are robustly permanent together with all their subsystems.

We use the terminology of standard textbooks like Conley [12] and Nemytzkii and Stepanov [55] without any further notice. In particular, we use the terms attractor and repeller as in [12]. Index theory and ergodic theory of dynamical systems, used in this paper, are contained in these two monographs. We recommend also [2], [51], and [62].

Notation. The nonnegative orthant in $\mathbb{R}^n$ is denoted by $\mathbb{R}^n_+$ and the positive orthant by $\operatorname{int}\mathbb{R}^n_+$. The boundary, closure, and interior of a subset $S \subset X$ are denoted by ∂S, $\operatorname{cl}(S)$, and $\operatorname{int}(S)$. $\mathcal{B}[A,\varepsilon] = \{x : d(x,A) \le \varepsilon\}$ and $\mathcal{B}(A,\varepsilon) = \{x : d(x,A) < \varepsilon\}$ denote the closed and open ε-neighborhood of a set A.

Capital Greek letters Φ, Ψ denote continuous-time dynamical systems. Discretizations are denoted by the respective lowercase Greek letters. In dynamical concepts like $\gamma^+_\Phi(x)$, $\mathcal{A}_\Psi$, $\omega_{\varphi(h,\cdot)}(x)$, etc., the subscripts refer to the corresponding continuous-time or discrete-time dynamical systems.

2. Robust permanence. We consider an autonomous differential equation of Kolmogorov type,

$$\dot{x}_i = x_i f_i(x), \quad x \in X, \tag{1}$$

where X is the probability simplex $\{x \in \mathbb{R}^n : x_i \ge 0, \sum_i x_i = 1\}$ and $f : X \to \mathbb{R}^n$ is a continuous function satisfying $\sum_i x_i f_i(x) = 0$ for each $x \in X$. The standard interpretation in biology is that x_i represents the proportion of the ith species in a given ecosystem, $i = 1, 2, \dots, n$.

Together with (1), we consider its δ-perturbations of the form

$$\dot{x}_i = x_i g_i(x), \ \ x \in X, \quad \text{such that} \quad |g_i(x) - f_i(x)| < \delta \ \text{ for all } x \in X. \tag{2}$$

It is of course assumed that $g : X \to \mathbb{R}^n$ is a continuous function and $\sum_i x_i g_i(x) = 0$ for each $x \in X$. We assume further that both (1) and (2) have the uniqueness

property. Denote by $\Phi(\cdot, x)$ and $\Psi(\cdot, x)$ the solutions of (1) and (2) starting in $x \in X$. It is immediate that both $\Phi : \mathbb{R} \times X \to X$ and $\Psi : \mathbb{R} \times X \to X$ are dynamical systems on X.

The boundary of X is denoted by Y. Y is invariant under Φ and Ψ. System (1) is called *permanent* (or uniformly persistent) if Y is a repeller. In ecological equations, permanence means the ultimate survival of all species. If (2) is permanent, then $(\mathcal{A}_\Psi, Y)$ forms an attractor–repeller pair, where $\mathcal{A}_\Psi$ denotes the maximal compact Ψ-invariant set in $X \setminus Y$.

The aim of this section is to give a sufficient condition for *robust permanence*, guaranteeing that every system near (1) is permanent.

DEFINITION 2.1. *Let us call a continuous mapping $P : \mathbb{R}^n_+ \to \mathbb{R}$ a* good average Liapunov function *(GALF)* for (1) *if*

(a) *$P(x) = 0$ for all $x \in \partial\mathbb{R}^n_+$, $P(x) > 0$ for all $x \in \operatorname{int}\mathbb{R}^n_+$;*

(b) *P is differentiable on $\operatorname{int}\mathbb{R}^n_+$ and $p_i(x) := \frac{x_i}{P(x)}\frac{\partial P}{\partial x_i}$ can be extended to a continuous function on X for every i;*

(c) *for every $y \in Y$ there is a positive constant T_y with the property that*

$$\int_0^{T_y} \sum_i p_i(\Phi(t,y)) f_i(\Phi(t,y))\, dt > 0.$$

Now we are in a position to present the main result of this section.

THEOREM 2.2. *If there is a GALF for* (1)*, then* (1) *is robustly permanent: There are a $\delta > 0$ and a compact subset S of $X \setminus Y$ such that every δ-perturbation* (2) *of* (1) *is permanent and $\mathcal{A}_\Psi$ is contained in S.*

Remark 2.3. If the inequality in (c) is reversed, then Y can be shown to be a robust attractor for (1).

The concept of an *average Liapunov function* (ALF) *for* (1) (with (a), (c), and a weaker version of (b), namely, the assumption that

$$\text{(3)} \qquad \text{the function} \quad \frac{\dot P}{P} = \sum_{i=1}^n \frac{1}{P(x)}\frac{\partial P}{\partial x_i} x_i f_i(x) \quad \text{is continuous on } X \ )$$

and Theorem 2.2 (without the robustness conclusion) are due to Hofbauer [27], inspired by Schuster, Sigmund, and Wolff [58]. The standard candidate for an ALF satisfying (a) and (b) is $P(x) = \prod_{i=1}^n x_i^{p_i}$ with constants $p_i > 0$.[1] In this case $p_i(x) = p_i$, and Theorem 2.2 reduces to the following.

COROLLARY 2.4. *Suppose there are positive constants p_i, $i = 1, \dots, n$, such that for each $y \in Y$ of* (1) *there is a time $T_y > 0$ such that $\int_0^{T_y} \sum_i p_i f_i(\Phi(t,y))\, dt > 0$. Then* (1) *is robustly permanent.*

The concept of an ALF is—like that of a Liapunov function—a topological one: It can be formulated [37] in metric spaces X to show that a closed invariant subset Y is a repeller. The concept of a GALF, on the other hand, makes use of the smooth structure of X. Besides for the simplex, it applies to X being any manifold with corners (i.e., modeled after $\mathbb{R}^n_+$). Theorem 2.2 continues to hold in this more general

[1] In most practical applications this function has been used. Hutson [37] and Hofbauer [28] use more general ALFs (that are not GALFs, however). But in these instances, the standard form $P(x) = \prod_{i=1}^n x_i^{p_i}$ would be sufficient if used as in Theorem 5.5 below, i.e., taking different choices of the vector p on different Morse sets.

setting as long as X is compact. A simple example, arising in section 11.5, is X being a product of simplices. For another simple example let X be a manifold with smooth boundary, as in section 11.1. In this case, the standard GALF is simply the distance to the boundary manifold Y. This standard GALF is even good enough here to *characterize* robust repulsivity of Y.

If the state space is not compact, then some adjustments have to be made. We describe the most important case of (1) defining an ecological differential equation on $\mathbb{R}^n_+$. We restrict ourselves to systems (1) that generate dissipative (semi)flows. Φ need no longer define a flow on $\mathbb{R}^n_+$ (solutions need not be defined for all negative times, as, e.g., in the logistic equation $\dot{x} = x(1-x)$ on $\mathbb{R}_+$). Let X be a compact absorbing subset for the local flow Φ. Then $Y = X \cap \partial\mathbb{R}^n_+$ is also compact and forward invariant under (1). There are at least two ways to define robustness:

1. Consider δ-perturbations only on X and assume that X remains absorbing for the perturbed flow Ψ, i.e., $\Psi(t, X) \subset X$ holds for all $t \geq 0$. This is done in [26, Cor. 4.6], where X is taken as a cube.
2. Allow perturbations of f in (1) in the strong Whitney topology, an approach taken in [57].

Either way, Theorem 2.2 and Corollary 2.4 remain true as stated.

Corollary 2.4 (again without the robustness conclusion) has been widely used to prove permanence of population dynamical systems; see Hofbauer and Sigmund [35]. The new aspect treated in this paper and the difference between ALF and GALF is illustrated by the following example. For a different kind of robustness, see [38].

Example 2.5. Consider $n = 2$, so that (1) is of the form $\dot{x}_1 = x_1(1-x_1)F(x_1)$, $\dot{x}_2 = -x_2(1-x_2)F(1-x_2)$. Both systems

$$\text{(i)} \begin{cases} \dot{x}_1 = x_1(1-x_1)(1/2-x_1), \\ \dot{x}_2 = -x_2(1-x_2)(x_2-1/2) \end{cases} \quad \text{and} \quad \text{(ii)} \begin{cases} \dot{x}_1 = x_1^2(1-x_1)^2(1/2-x_1), \\ \dot{x}_2 = -x_2^2(1-x_2)^2(x_2-1/2) \end{cases}$$

are permanent, since $Y = \{(0,1)\} \cup \{(1,0)\}$ is a repeller. However, (i) is robustly permanent, whereas (ii) is not. The reason is of course that in (i) both $\{(0,1)\}$ and $\{(1,0)\}$ are hyperbolic, but they are not for (ii). This is captured by the auxiliary function $P(x_1, x_2) = x_1 x_2$ (or $x_1^{p_1} x_2^{p_2}$ for any $p_1, p_2 > 0$): Condition (c) reduces to $\min\{F(0), -F(1)\} > 0$, which holds for (i) but not for (ii). Hence P is a GALF for (i) but not (ii). On the other hand, the new auxiliary function $\tilde{P}(x_1, x_2) = e^{-1/x_1 - 1/x_2}$ satisfies

$$x_1(1-x_1)^2\left(\frac{1}{2}-x_1\right)\tilde{p}_1(x_1,x_2) - x_2(1-x_2)^2\left(x_2-\frac{1}{2}\right)\tilde{p}_2(x_1,x_2) = \frac{(x_1-x_2)^2}{2}$$

for each $(x_1, x_2) \in X \setminus Y$. Taking continuous extensions, we see that (a), (c), and (3) are satisfied for (ii). But (b) is violated since $\tilde{p}_1(x_1, x_2) = 1/x_1$ and $\tilde{p}_2(x_1, x_2) = 1/x_2$ do not have continuous extensions to X. Thus $\tilde{P}$ is not a GALF (but only an ALF) for (ii).

Next we illustrate the method of GALFs by deriving a stability criterion for a heteroclinic cycle. For further examples, see [27] for the planar case and [31] for higher-dimensional examples.

Example 2.6. Consider the replicator dynamics

$$\dot{x}_i = x_i((Ax)_i - xAx), \quad i = 1, 2, \ldots, n, \tag{4}$$

on the simplex $X = \{x \in \mathbb{R}^n : x_i \geq 0, \sum_{i=1}^n x_i = 1\}$, with $n = 3$ for a rock-scissors-paper game with payoff matrix

$$A = \begin{pmatrix} 0 & -a_2 & b_3 \\ b_1 & 0 & -a_3 \\ -a_1 & b_2 & 0 \end{pmatrix}. \tag{5}$$

Then the boundary Y forms a heteroclinic cycle, with "outgoing" eigenvalues $b_i > 0$ and "incoming" eigenvalues $-a_i < 0$ at the ith corner. Consider the standard function $P(x) = \prod_{i=1}^3 x_i^{p_i}$ (with $p_i > 0$ to be suitably chosen), which satisfies (a) and (b). Since every orbit on the boundary Y converges to one of the corners, it is sufficient to check (c) at these three equilibria. Hence (c) leads to a system of three linear inequalities

$$b_1 p_2 > a_1 p_3, \quad b_2 p_3 > a_2 p_1, \quad b_3 p_1 > a_3 p_2, \tag{6}$$

which can be summarized as

$$A^T p > 0 \quad \text{for suitable} \quad p > 0. \tag{7}$$

Obviously (6) has a solution in $p_i > 0$ if and only if

$$b_1 b_2 b_3 > a_1 a_2 a_3. \tag{8}$$

In this case, by Corollary 2.4, (4) is robustly permanent, i.e., the heteroclinic cycle Y is robustly repelling. If the inequalities in (6), (7), or, equivalently, in (8) are reversed, then, by Remark 2.3, the heteroclinic cycle Y is robustly attracting for (4). Note that the result does not depend on the special dynamics (4) but only on the "external eigenvalues" at the three corner equilibria which correspond to the entries of the matrix A. (Note that the above derivation of the stability criterion (8) using GALFs is much easier compared to other methods, such as finding a true Liapunov function near Y or applying Poincaré sections [35].)

Now we turn to the proof of Theorem 2.2. We shall make use of Corollary 6.1.2 of [8], which is a reformulation of Theorem 9 of the 1957 Russian edition[2] of Zubov's monograph [68].

ZUBOV–URA–KIMURA THEOREM. *Let (W, d) be a locally compact separable metric space and let Θ be a dynamical system on W. Finally, let $\emptyset \neq M$ be a compact isolated Θ-invariant set in W. Suppose that M is not a repeller. Then $\emptyset \neq \omega(x) \subset M$ for some $x \notin M$.*

Neither Zubov's work [68] nor the paper by Ura and Kimura [64] had been generally known before the 1970 monograph of Bhatia and Szegö [8]. Had they been known before, they might have led to essential simplifications in establishing such important notions of topological dynamics as the Auslander–Seibert duality between stability

[2]The proof of Theorem 9 in [68] is based on Theorem 7 of that work. Unfortunately, this latter statement is false. As it is remarked in the 1964 English edition [69], the error was pointed out by S. Lefschetz to V. I. Zubov. A corrected version of Theorem 7 was published by Bass [5], an associate of Lefschetz. A corrected version of Theorem 7 appears also in [69] and (although the last sentence on p. 35 of [69] is still false) makes the derivation of Theorem 9 correct, too. From Theorem 8 onward, section 11 of the English edition is a word-for-word translation of the Russian edition and contains several interconnected results on the local behavior of continuous-time dynamical systems near compact isolated invariant sets. More or less the same set of results was obtained by Ura and Kimura [64] independently in 1960. What we call the Zubov–Ura–Kimura theorem is a collection of several technical lemmas of [64, pp. 26–31].

and boundedness, Bhatia's concept of weak attraction, and the Wilson–Yorke hyperbolic Liapunov function in the early sixties.[3] A large number of much later results in persistence theory during the eighties (including the Butler–McGehee lemma in the appendix of [15]) followed easily from those in [68] and [64].

Proof of Theorem 2.2. Suppose P is a GALF for (1). We claim that there are three constants $c, \delta, T > 0$ and a compact subset S of $X \setminus Y$ with the following property. Given $x \in \mathrm{cl}(X \setminus S) \setminus Y$ arbitrarily, there exists a time $T_x \in (0, T]$ such that

$$P(\Psi(T_x, x)) > (1 + c)P(x) \quad \text{for every } \delta\text{-perturbation (2) of (1).} \tag{9}$$

In fact, condition (c) plus an easy compactness argument imply that there are positive constants c, d, and T such that for all $x \in I(d) = \{x \in X : P(x) \le d\}$ (= a small compact neighborhood of Y) there is a time $T_x \in (0, T]$ with

$$\int_0^{T_x} \sum_i p_i(\Phi(t, x)) f_i(\Phi(t, x))\, dt > 3c > 0. \tag{10}$$

Uniform continuity of $p_i f_i$, $i = 1, 2, \ldots, n$, provides an $\varepsilon > 0$ such that

$$|p_i(z)f_i(z) - p_i(w)f_i(w)| < \frac{c}{nT} \quad \text{whenever} \quad z, w \in X \text{ and } |z - w| < \varepsilon.$$

Since the p_i's are bounded and $|g - f| < \delta$, we obtain for δ small enough by the triangle inequality that

$$|p_i(z)g_i(z) - p_i(w)f_i(w)| < \frac{2c}{nT} \quad \text{whenever} \quad z, w \in X \text{ and } |z - w| < \varepsilon.$$

By a standard Arzelà–Ascoli argument, the uniqueness property of (1) implies there is a $\delta > 0$ such that $|\Psi(t, x) - \Phi(t, x)| < \varepsilon$ for $t \in [0, T]$, $x \in X$, and every δ-perturbation (2) of (1). In view of inequality (10), we conclude via condition (b) that

$$\log(P(\Psi(T_x, x)) - \log(P(x)) = \int_0^{T_x} \sum_i p_i(\Psi(t, x)) g_i(\Psi(t, x))\, dt$$

$$\ge - \int_0^{T_x} \left| \sum_i p_i(\Psi(t, x)) g_i(\Psi(t, x)) - \sum_i p_i(\Phi(t, x)) f_i(\Phi(t, x)) \right| dt$$

$$+ \int_0^{T_x} \sum_i p_i(\Phi(t, x)) f_i(\Phi(t, x))\, dt \ge -\frac{2T_x c}{T} + 3c \ge c \qquad \text{for each } x \in I(d) \setminus Y.$$

Set $S = \mathrm{cl}(X \setminus I(d))$ and note that $\mathrm{cl}(X \setminus S) = I(d)$. Since $e^c > 1 + c$, inequality (9) follows.

[3] All proofs of the Zubov–Ura–Kimura theorem work equally well for discrete-time dynamical systems. However, the first discrete-time version of the Zubov–Ura–Kimura theorem was discovered independently of [68] and [64]. It is Lemma 1 in Browder [10] (termed "a crucial one" by Browder himself), stating that a strongly ejective fixed point is repulsive. Establishing his famous existence theorem on nonejective fixed points, Browder worked out a great deal of basic topological dynamics using his own terminology. His crucial lemma is a direct consequence of the (discrete-time semidynamical version of the) Zubov–Ura–Kimura theorem. (Multivalued and various discretization aspects are investigated in [61] and [22], respectively.)

Next we point out that

$$I(d) \setminus \gamma_\Psi^+(x) \neq \emptyset \qquad \text{for each} \quad x \notin Y. \tag{11}$$

In fact, suppose there is a $z \in I(d)$ such that $\gamma_\Psi^+(z) \subset I(d)$. Then P attains its maximum value on $\mathrm{cl}(\gamma_\Psi^+(z))$ at some point w. In particular, if $z \notin Y$, this implies $P(w) > 0$ and the existence of a time sequence $\{\tau_n\} \subset \mathbb{R}_+$ such that $P(\Psi(\tau_n, z)) \to P(w)$ as $n \to \infty$. Applying (9), we obtain that $P(\Psi(T_{\Psi(\tau_n,z)}, \Psi(\tau_n, z))) \geq (1 + c)P(\Psi(\tau_n, z)) \to (1 + c)P(w)$, a contradiction to the choice of w.

As a byproduct of (11), $I(d)$ is an isolating neighborhood of Y and for each $x \in I(d) \setminus Y$, inclusion $\emptyset \neq \omega_\Psi(x) \subset Y$ is impossible. By the Zubov–Ura–Kimura theorem, Y is a repeller for (2) and the dual attractor $\mathcal{A}_\Psi$ is contained in S. □

Remark 2.7. As for any proof using compactness considerations, the proof of Theorem 2.2 is also nonconstructive. However, it is not hard to see that all "intrinsically nonconstructive ingredients" of the proof are contained in assumption (c). To be more precise, assume that the conditions of Theorem 2.2 are all satisfied. In addition, assume that

(H1) there exist positive constants c, T with the property that, given $y \in Y$ arbitrarily, $\int_0^{T_y} \sum_i p_i(\Phi(t, y)) f_i(\Phi(t, y))\, dt > 4c$ for some $T_y \in (0, T]$.

Finally, assume that (no extra assumptions on the g_i's are needed!)

(H2) the functions p_i, f_i, $i = 1, 2, \ldots, n$, are (globally) Lipschitz.

Reconsidering the proof of Theorem 2.2, it is routine to check that all compactness arguments including the Zubov–Ura–Kimura argument can be replaced by Gronwall inequalities. The final conclusion is that the parameters δ and the distance of S from Y are both larger than $\Lambda c \exp(-\lambda T)$, where $\lambda, \Lambda > 0$ are computable constants and do not depend on c, T (provided by (H1)) and on the perturbation g, but only on the various Lipschitz constants (provided by (H2)). Hence the GALF assumption, together with (H1) and (H2), provides a way of estimating the distance between S and Y. Thus we have a feasible approach to the problem of "practical persistence" discussed by Hutson and Mischaikow [39] in two dimensions.

3. Exponential repulsivity. In this section we explore the concept of an average Liapunov function and its relation to exponential repulsion and existence of (ordinary) Liapunov functions.

THEOREM 3.1. (1) *If P is an ALF for* (1)*, then there exist an open neighborhood $\mathcal{N}$ of Y in X and positive constants κ_1, κ_2 such that*

$$P(\Phi(t, x)) \leq \kappa_1 e^{\kappa_2 t} P(x) \quad \text{for each} \quad x \in \mathcal{N} \quad \text{and} \quad t \leq 0. \tag{12}$$

(2) *If P is a GALF for* (1)*, then there exist an open neighborhood $\mathcal{N}$ of Y in X and positive constants $\delta, \kappa_1, \kappa_2$ such that for each δ-perturbation*

$$P(\Psi(t, x)) \leq \kappa_1 e^{\kappa_2 t} P(x) \quad \text{for each} \quad x \in \mathcal{N} \quad \text{and} \quad t \leq 0.$$

(3) *If $P(x) = \prod_{i=1}^n x_i^{p_i}$ is a GALF for* (1) *and letting $\delta > 0$ be the same constant as in Theorem* 2.2*, then there exist an open neighborhood $\mathcal{N}$ of Y in X and positive constants $\kappa_1, \kappa_2, \kappa_3$ such that*

$$d_E(\Psi(t, x), Y) \leq \kappa_1 e^{\kappa_2 t} (d_E(x, Y))^{\kappa_3} \quad \text{for each} \quad x \in \mathcal{N} \quad \text{and} \quad t \leq 0.$$

Here $d_E(x, Y)$ denotes the Euclidean distance between a point $x \in X$ and the set Y.

Proof. The proof of assertion 1 will be omitted since it is the same as that of 2 but ignores the robustness.

(2) The application of the Zubov–Ura–Kimura theorem in the last step of proving Theorem 2.2 will be replaced by an explicit computation, as in the earlier proofs in [27], [37]. Parameters introduced and auxiliary inequalities derived in proving Theorem 2.2 will be used throughout.

Since $\sum |p_i g_i| \leq \kappa$ for some $\kappa > 0$, we obtain via integrating the identity

$$\frac{d}{dt} \log P(\Psi(t,x)) = \sum_{i=1}^{n} p_i(\Psi(t,x)) g_i(\Psi(t,x)) \quad \text{for } t \in \mathbb{R} \text{ and } x \in X \setminus Y, \tag{13}$$

a consequence of assumption (b) that

$$e^{\kappa\tau} P(x) \geq P(\Psi(\tau,x)) \geq e^{-\kappa\tau} P(x) \quad \text{for every} \quad x \in X\,,\ \tau \geq 0 \tag{14}$$

and every δ-perturbation (2) of (1).

Suppose now that $x \in I(d) \setminus Y$. Since $\mathcal{A}_\Psi \subset S = \mathrm{cl}(X \setminus I(d))$, there exists a nonnegative integer $K(x)$ with the properties that $\Psi([0, K(x)T], x) \subset I(d)$ but $\Psi(t,x) \notin I(d)$ for some $t \in (K(x)T, (K(x)+1)T]$. Set $T_{x,0} = 0$ and, recursively, as long as $T_{x,k} \leq K(x)T$, set $T_{x,k+1} = T_{\Psi(T_{x,k},x)}$, $k = 0, 1, \ldots,$ (say) $k(x)$. Inequality (9) can be iterated $k(x)$ times and yields that

$$P(\Psi(T_{x,k}, x)) \geq (1+c)^k P(x) \quad \text{for each} \quad k = 0, 1, \ldots, k(x).$$

Recall that $0 < T_{x,k+1} - T_{x,k} \leq T$. In view of inequality (14), it follows immediately that

$$P(\Psi(t,x)) \geq e^{-\kappa T}(1+c)^k P(x) \quad \text{whenever } \ T_{x,k} \leq t \leq T_{x,k+1}\,,$$

and $k = 0, 1, \ldots, k(x)$. By using $T_{x,k+1} \leq (k+1)T$, we conclude that

$$P(\Psi(t,x)) \geq \frac{e^{-\kappa T}}{1+c} \cdot (1+c)^{t/T} \cdot P(x) \quad \text{whenever} \quad t \in [0, K(x)T]. \tag{15}$$

Choose $T^* > 0$ in such a way that $e^{-\kappa T} \cdot (1+c)^{-1+T^*/T} > 1$ and set $\Delta = e^{-\kappa T^*} d$. We claim that

$$P(\Psi(t, I(\Delta))) \leq d \qquad \text{for each} \quad t \leq 0. \tag{16}$$

Suppose this is not the case. Then there exist a $t^* > 0$ and an $x^* \in X$ with $P(x^*) \leq \Delta$, $P(\Psi(-t^*, x^*)) = d$ but $P(\Psi(t, x^*)) < d$ for each $t \in (-t^*, 0]$. By the construction,

$$e^{-\kappa t^*} d = e^{-\kappa t^*} P(\Psi(-t^*, x^*)) \leq P(\Psi(t^*, \Psi(-t^*, x^*))) = P(x^*) \leq \Delta,$$

and thus $t^* \geq T^*$. A similar application of (14) and the simple inequality $T < T^*$ show that

$$P(\Psi([0,T], x^*)) \leq e^{\kappa T} P(x^*) < e^{\kappa T^*} \Delta = d.$$

We conclude that $K(\Psi(-t^*, x^*))T \geq t^* \geq T^*$, and hence, by using inequality (15) with $t = T^*$ and $x = \Psi(-t^*, x^*)$,

$$P(\Psi(-t^* + T^*, x^*)) \geq e^{-\kappa T} \cdot (1+c)^{-1+T^*/T} \cdot P(\Psi(-t^*, x^*)) > 1 \cdot d = d,$$

a contradiction.

Set $\mathcal{N} = \{x \in X \mid P(x) < \Delta\}$. By virtue of (16), we can pass to negative times and obtain from inequality (15) that

$$P(\Psi(t,x)) \le \frac{1+c}{e^{-\kappa T}} \cdot (1+c)^{t/T} \cdot P(x) \quad \text{whenever} \quad x \in \mathcal{N} \ \text{ and } \ t \le 0. \tag{17}$$

This completes the proof of assertion 2.

(3) The Euclidean distance between a point $x \in X$ and the set Y equals

$$d_E(x,Y) = \left(\min \left\{ \sum_{j=1}^{n} (x_j - y_j)^2 \mid y \in Y \right\} \right)^{1/2} = \min_{1 \le j \le n} x_j.$$

By compactness, there exist continuous, strictly increasing functions $\alpha, \beta : [0, 1/n] \to \mathbb{R}^+$ with the properties that $\alpha(0) = \beta(0) = 0$ and

$$\alpha(d_E(x,Y)) \le P(x) \le \beta(d_E(x,Y)) \quad \text{whenever} \quad x \in X. \tag{18}$$

Combining (16) and (18), the rate of repulsion near Y can be estimated *in terms of the Euclidean distance function.*

For example, the standard GALF $P(x) = \prod_{i=1}^{n} x_i^{p_i}$ satisfies

$$(d_E(x,Y))^{\sum_{i=1}^n p_i} = \prod_{i=1}^{n} \left(\min_{1 \le j \le n} x_j \right)^{p_i} \le P(x) \le \min_{1 \le i \le n} x_i^{p_i} \le (d_E(x,Y))^{\min_{1 \le i \le n} p_i}$$

for each $x \in X$ and leads to the desired exponential rate of repulsion. In fact, given $x \in \mathcal{N}$ arbitrarily, we obtain that

$$(d_E(\Psi(t,x),Y))^{\sum_{i=1}^n p_i} \le \frac{1+c}{e^{-\kappa T}} \cdot (1+c)^{t/T} \cdot (d_E(x,Y))^{\min_{1 \le i \le n} p_i}$$

for each $t \le 0$. This shows how constants $\kappa_1, \kappa_2, \kappa_3$ in assertion 3 must be chosen. □

COROLLARY 3.2. *If P is an ALF for* (1)*, then there exists an exponentially increasing Liapunov function for* (1)*. In other words, there exist a negatively invariant open neighborhood $\mathcal{U}$ of Y in X, a positive constant κ, and a continuous function $V : \mathcal{U} \to \mathbb{R}_+$ such that $V(x) = 0$ if and only if $x \in Y$ and*

$$V(\Phi(t,x)) \le e^{\kappa t} V(x) \quad \textit{for each} \quad x \in \mathcal{U} \ \textit{ and } \ t \le 0. \tag{19}$$

Proof. The standard integration trick [8] is used for eliminating κ_1 from (12). We fix a negatively invariant open neighborhood $\mathcal{U}$ of Y in $\mathcal{N}$ and define

$$V(x) = \int_{-\infty}^{0} e^{-\kappa_2 t/(1+\Delta)} P(\Phi(t,x)) dt \quad \text{for each} \quad x \in \mathcal{U}. \tag{20}$$

Here $\Delta > 0$ is arbitrary and $\kappa = \kappa_2/(1+\Delta)$ in (19). □

LEMMA 3.3. *If P is a GALF for* (1) *and $W = \exp(w)$ is any positive C^1 function, then $\tilde{P} = PW$ is also a GALF for* (1)*.*

Proof. $\tilde{P}$ obviously satisfies condition (a) in Definition 2.1. (b) follows from $\tilde{p}_i := \frac{x_i}{\tilde{P}(x)} \frac{\partial \tilde{P}}{\partial x_i} = p_i + x_i \frac{\partial w}{\partial x_i}$, $i = 1, 2, \ldots, n$. And the identity

$$\frac{1}{T} \int_0^T \sum_i \left(\tilde{p}_i(\Phi(t,y)) - p_i(\Phi(t,y)) \right) f_i(\Phi(t,y)) \, dt = \frac{w(\Phi(T,y)) - w(y)}{T}, \quad y \in Y,$$

together with Lemma 4.2 below, shows (c). □

THEOREM 3.4. *For $P(x) = \prod_{i=1}^n x_i^{p_i}$ (with $p_i > 0$) and $f \in C^1(X, \mathbb{R}^n)$ the following conditions are equivalent:*

(A) *$P(x)$ is a GALF for (1).*

(B) *There exist a negatively invariant open neighborhood $\mathcal{U}$ of Y in X, a positive constant κ, and a C^1 function $W : \mathcal{U} \to (0, \infty)$ such that $V = PW$ is an exponentially increasing Liapunov function for (1):*

$$\dot{V}(x) \geq \kappa V(x) \quad \text{for all} \quad x \in \mathcal{U}. \tag{21}$$

Proof. If (B) holds, then V is a GALF, and hence by Lemma 3.3, with $P, W, \tilde{P}$ replaced by $V, 1/W, P$, also P must be a GALF. Now suppose that $P(x) = \prod_{i=1}^n x_i^{p_i}$ is a GALF for (1). We write $\Phi_i(t,x) = x_i Q_i(t,x)$. By Corollary 6.1, $Q_i(t,x) > 0$ for all $t \in \mathbb{R}$ and $x \in X$. Define $q(t,x) := \sum_i p_i \log Q_i(t,x)$. Then (12) implies

$$P(\Phi(t,x)) = e^{q(t,x)} P(x) \leq \kappa_1 e^{\kappa_2 t} P(x) \quad \text{for } t \leq 0. \tag{22}$$

Furthermore $\frac{\partial q(t,x)}{\partial t} = \sum_i p_i f_i(\Phi(t,x)) =: \tilde{f}(\Phi(t,x))$, and for the partial derivatives

$$\frac{\partial}{\partial t}\frac{\partial q}{\partial x_j}(t,x) = \sum_i \frac{\partial \tilde{f}}{\partial x_i}(\Phi(t,x)) \frac{\partial \Phi_i}{\partial x_j}(t,x). \tag{23}$$

Let L be a Lipschitz constant of (1). Then Gronwall's inequality implies $|\frac{\partial \Phi_i}{\partial x_j}(t,x)| \leq e^{L|t|}$, and hence in (23)

$$\left| \frac{\partial}{\partial t}\frac{\partial q}{\partial x_j}(t,x) \right| \leq C e^{L|t|}. \tag{24}$$

After integration this gives

$$\left| \frac{\partial q}{\partial x_j}(t,x) \right| \leq C' e^{L|t|} \tag{25}$$

for some positive constants C, C'. Now use P^α (for any $\alpha > 0$) instead of P in (20) and consider

$$V_\alpha(x) = \int_{-\infty}^0 e^{-\alpha\kappa_2 t/(1+\Delta)} P(\Phi(t,x))^\alpha dt = P(x)^\alpha W_\alpha(x) \tag{26}$$

with

$$W_\alpha(x) = \int_{-\infty}^0 e^{-\alpha\kappa_2 t/(1+\Delta)} e^{\alpha q(t,x)} dt. \tag{27}$$

Then, by (22), for every $\alpha > 0$ and $\Delta > 0$, the function V_α is continuous on X and satisfies (19) with $\kappa = \alpha\kappa_2/(1+\Delta)$. The function W_α is continuous and positive on X. Formal differentiation of (27) gives

$$\frac{\partial W_\alpha}{\partial x_j}(x) = \int_{-\infty}^0 e^{-\alpha\kappa_2 t/(1+\Delta)} e^{\alpha q(t,x)} \alpha \frac{\partial q}{\partial x_j}(t,x) dt. \tag{28}$$

With (22) and (25) we can estimate the integrand up to a constant factor by $\exp(-\frac{\alpha\kappa_2 t}{1+\Delta} + \alpha\kappa_2 t - Lt)$ (for $t < 0$). Hence for

$$\alpha > \frac{1+\Delta}{\Delta}\frac{L}{\kappa_2} \tag{29}$$

the indefinite integral in (28) converges absolutely and uniformly in $x \in X$. This implies that for all these α large enough, W_α is C^1. Then the claim follows for $V = V_\alpha^{1/\alpha} = PW_\alpha^{1/\alpha} =: PW$. □

Remark 3.5. We note that W (and hence V) can be made as smooth as the vector field (1) by choosing α sufficiently large: This follows easily by further differentiating (28). The relationship between (12) and (21) is in line with the general observation that, under certain conditions, inequalities can be differentiated with respect to parameters [9], [47].

Remark 3.6. Lemma 3.3 shows that to each GALF P there belongs a whole equivalence class of GALFs differing by a smooth positive factor. Theorem 3.4 shows that for a standard GALF, there is a true Liapunov function among these equivalent GALFs. Still, the advantage of the GALF concept is its considerably easier practical applicability, as compared to a true Liapunov function. Finding a standard GALF for (1) is reduced in the next section to the algebraic problem of finding suitable constants $p_i > 0$. In the setting of manifolds with smooth boundary in section 11.1, there is essentially a unique standard GALF, which is simply the distance to the boundary manifold. The GALF conditions for this simple function *characterize* robust repulsivity of the boundary. Finding an explicit true Liapunov function is considerably more difficult.

Remark 3.7. Theorem 3.4 (B) implies another, very simple proof of robust permanence (under the stronger assumption $f \in C^1$): Write $V = Pe^w$. Then along interior solutions of a δ-perturbation (2)

$$\dot{V}/V = \sum_i p_i \frac{\dot{x}_i}{x_i} + \dot{w} = \sum_i \left(p_i + x_i \frac{\partial w}{\partial x_i}\right) g_i(x)$$

$$= \sum_i \left(p_i + x_i \frac{\partial w}{\partial x_i}\right) f_i(x) + \sum_i \left(p_i + x_i \frac{\partial w}{\partial x_i}\right) (g_i(x) - f_i(x)).$$

The first sum is $\geq \kappa > 0$ by (21) and the second term is less than a constant (since w is C^1) times δ. Hence for δ small enough, V is a local Liapunov function near Y also for (2).

4. GALF and minimax. We need the minimax theorem in the following simplified formulation (see, e.g., [59]).

MINIMAX THEOREM. *Let A, B be Hausdorff topological vector spaces and let $\Gamma : A \times B \to \mathbb{R}$ be a continuous bilinear function. Finally, let C and D be nonempty, convex, compact subsets of A and B, respectively. Then*

$$\min_{a\in C}\max_{b\in D}\Gamma(a,b) = \max_{b\in D}\min_{a\in C}\Gamma(a,b).$$

In what follows $\mathcal{M}_\Phi$ denotes the collection of Φ-invariant Borel probability measures on Y. The collection of all Borel probability measures on Y is denoted by $\mathcal{M}$. Recall that both $\mathcal{M}_\Phi$ and $\mathcal{M}$ are nonempty, convex, weakly-$*$ compact subsets of

$C_w^*(Y,R)$, the dual space of $C(Y,R)$ equipped with the weak-$*$ topology. The subset $\mathcal{M}_\Phi^E$ of ergodic Φ-invariant measures is the set of extreme points of $\mathcal{M}_\Phi$. The characteristic function of a Borel set $B \subset Y$ is denoted by χ_B.

LEMMA 4.1.[4] *Let $h : Y \to \mathbb{R}$ be a continuous function. Then*

$$\min_{\mu\in\mathcal{M}_\Phi} \int_Y h\, d\mu = \min_{y\in Y} \left\{ \limsup_{T\to\infty} \frac{1}{T} \int_0^T h(\Phi(t,y))\, dt \right\}. \tag{30}$$

Proof. Replacing "lim" by "lim sup" in the ergodic theorem, we have that

$$\int_Y h\, d\mu = \limsup_{T\to\infty} \frac{1}{T} \int_0^T h(\Phi(t,y))\, dt \quad \text{for } \mu\text{–almost all } y \in Y. \tag{31}$$

Note that the right-hand side of (31) defines a lower semicontinuous function on Y. Since Y is compact and $\mathcal{M}_\Phi$ is weakly-$*$ compact, we can take minima on both sides. This proves the "$\geq$ part" of (30).

To prove the "$\leq$ part," we argue via reductio ad absurdum and suppose there exist a $y_0 \in Y$, an $\varepsilon_0 > 0$, and a time sequence $\{\tau_n\} \subset \mathbb{R}_+$ such that $\tau_n \to \infty$ and

$$\int_Y h\, d\mu > \varepsilon_0 + \frac{1}{\tau_n} \int_0^{\tau_n} h(\Phi(t,y_0))\, dt \quad \text{for each } \mu \in \mathcal{M}_\Phi \text{ and } n = 1,2,\ldots. \tag{32}$$

By letting $\mu_n(B) = \frac{1}{\tau_n}\int_0^{\tau_n} \chi_B(\Phi(t,y_0))\, dt$ for each Borel set $B \subset Y$, a $\mu_n \in \mathcal{M}$ is defined and the inequality in (32) goes over into $\int_Y h\, d\mu > \varepsilon_0 + \int_Y h\, d\mu_n$. We may assume that, in the weak-$*$ topology, $\mu_n \to \mu_0$ for some $\mu \in \mathcal{M}$. The crucial observation is that $|\mu_n(\Phi(\tau,B)) - \mu_n(B)| \leq \frac{2|\tau|}{\tau_n}$ for each Borel set $B \subset Y$, $\tau \in \mathbb{R}$ and $n = 1,2,\ldots$. By letting $n \to \infty$, we conclude that[5] $\mu_0 \in \mathcal{M}_\Phi$. Hence $\int_Y h\, d\mu_0 \geq \varepsilon_0 + \int_Y h\, d\mu_0$, a contradiction. ∎

LEMMA 4.2. *For any continuous function $h : Y \to \mathbb{R}$, the following properties are equivalent:*

(i) $\min_{y\in Y}\{\limsup_{T\to\infty} \frac{1}{T}\int_0^T h(\Phi(t,y))\, dt\} > 0$.

(ii) *For every $y \in Y$ there is a $T(y) > 0$ with $\int_0^{T(y)} h(\Phi(t,y))\, dt > 0$.*

Proof. (i) $\Rightarrow$ (ii) is trivial. Suppose now that (ii) is satisfied. By an easy compactness argument, we see there is no loss of generality in assuming there are positive constants c_0, T_1, T_2 such that

$$T_1 \leq T(y) \leq T_2 \quad \text{and} \quad \int_0^{T(y)} h(\Phi(t,y))\, dt > c_0 \quad \text{for all } y \in Y.$$

Set $\tau_0 = 0$ and, recursively, $\tau_n(y) = \tau_{n-1}(y) + T(\Phi(\tau_{n-1}(y), y))$. By the construction, $nT_1 \leq \tau_n \leq nT_2$ and

$$\frac{1}{\tau_n(y)} \int_0^{\tau_n(y)} h(\Phi(t,y))\, dt \geq \frac{c_0}{T_2} \qquad \text{for each } n = 1,2,\ldots.$$

Even with lim sup replaced by lim inf, (i) follows immediately. ∎

[4] This is Exercise 8.5 on p. 57 in [51] (with "limsup" replaced by "liminf"). Proofs were written in [30] and [56], who derived it from a much more general setting. Other generalizations were given in [3] and [11]. We include a proof for completeness.

[5] The argumentation leading to μ_0 is truly fundamental and plays a vital role in the ergodic theory of dynamical systems from its very beginnings in Krylov and Bogoliubov [46] to (proving the first part of) Theorem 4.3 of Schreiber [57].

Remark 4.3. Note that condition (c) in Definition 2.1 has to be checked only for $y \in MC_\Phi(Y)$, the minimal center of attraction of Y (i.e., by definition, the smallest compact Φ-invariant set containing the support of each invariant measure in $\mathcal{M}_\Phi(Y)$). This follows from a twofold application of Lemmas 4.1 and 4.2 with Y and Y replaced by $MC_\Phi(Y)$; cf. [56]. Note that $MC_\Phi(Y)$ is contained in the closure of the set of all $\Phi|_Y$-recurrent points.

THEOREM 4.4. *The following properties are equivalent:*

(α) *For some* $p_1, p_2, \dots, p_n > 0$ *suitably chosen,* $P(x) = \prod_{i=1}^n x_i^{p_i}$ *is a GALF for* (1).

(β) *For every* $\mu \in \mathcal{M}_\Phi$ *there exists an* $i \in \{1, 2, \dots, n\}$ *with* $\int_Y f_i \, d\mu > 0$.

(γ) *There are* $p_1, p_2, \dots, p_n > 0$ *such that* $\sum_{i=1}^n p_i \int_Y f_i \, d\mu > 0$ *holds for every ergodic* $\mu \in \mathcal{M}_\Phi^E$.

Proof. We may assume by homogeneity that $p = (p_1, p_2, \dots, p_n) \in X$. Applying the lemmas for $h = \sum_i p_i f_i$, we obtain that

$$(\alpha) \Leftrightarrow \max_{p \in X} \min_{\mu \in \mathcal{M}_\Phi} \sum_{i=1}^n p_i \int_Y f_i \, d\mu > 0. \tag{33}$$

On the other hand, it is elementary to check that

$$(\beta) \Leftrightarrow \min_{\mu \in \mathcal{M}_\Phi} \max_{p \in X} \sum_{i=1}^n p_i \int_Y f_i \, d\mu > 0. \tag{34}$$

With $C = \mathcal{M}_\Phi$, $D = X$, $A = C_w^*(Y, R)$, $B = \mathbb{R}^n$, and $\Gamma(p, \mu) = \sum_i p_i \int_Y f_i \, d\mu$, the minimax theorem implies the equivalence of (α) and (β). Since the minimum in (33) is attained at an ergodic measure, the equivalence of (α) and (γ) follows. ∎

Example 4.5. Returning to the rock-scissors-paper game (4)–(5), note that

$$\mathcal{M}_\Phi = \left\{ \sum_{k=1}^3 q_k \delta_k \;\middle|\; q_k \geq 0, \sum_{k=1}^3 q_k = 1 \right\},$$

where δ_k is the Dirac measure at the kth vertex of the two-dimensional simplex, $k = 1, 2, 3$. By using homogeneity, condition (β) then translates into the requirement that

$$\text{for any } \; q > 0 \; \text{ there exists an } \; i \in \{1, 2, 3\} \text{ with } \; (Aq)_i > 0. \tag{35}$$

The equivalence of (7) and (35), for arbitrary $n \times m$ real matrices, is the well-known Farkas lemma on linear inequalities. Note that in an alternative proof of Theorem 4.4, the minimax theorem can be replaced by using an infinite-dimensional version of the Farkas lemma.

The integrals $\int_Y f_i \, d\mu$ are Liapunov exponents of μ. If μ is ergodic, then there exists a unique nonempty supporting subset $I \subset \{1, 2, \dots, n\}$ such that $\mu(X_I) = 1$ for the (relatively) open face $X_I := \{x \in X : x_i > 0 \text{ for } i \in I \text{ and } x_j = 0 \text{ for } j \notin I\}$. According to Lemma 5.1 in [57], $\int_Y f_i \, d\mu = 0$ for $i \in I$ (compare also Remark 5.4). The integrals $\int_Y f_i \, d\mu$ for $i \notin I$ are called *external Liapunov exponents*. Biologically, they describe the invasion rate of the missing species i at μ. For point measures $\delta_{\bar{x}}$, the external Liapunov exponents reduce to the external eigenvalues $f_i(\bar{x})$ at the boundary equilibrium $\bar{x}$; see [35]. For periodic orbits in Y, the external Liapunov exponents coincide with the (normalized) external Floquet exponents; see [57].

Combining Theorems 2.2 and 4.4, we see that (β) is a sufficient condition for robust permanence. This is a version of the main result in [57]. Strengthening condition (β) leads to the following result on "totally permanent systems" due to Mierczyński and Schreiber [52].

COROLLARY 4.6. *If for every $\mu \in \mathcal{M}_\Phi^E$ all external Liapunov exponents $\int_Y f_i d\mu$ are positive, then* (1) *and each of its subsystems are robustly permanent.*

Proof. This follows immediately from Theorems 2.2 and 4.4, together with the aforementioned Lemma 5.1 of [57] or Remark 5.4 below. Note that $P(x) = \prod_{i=1}^n x_i^{p_i}$ is a GALF for (1) for any choice of the exponents $p_i > 0$. ∎

Using Pesin theory, a converse result can also be shown; see [52].

5. Local GALFs and Morse decompositions. Throughout this section, let K be a nonempty Φ-invariant compact subset of Y, and let U be an open neighborhood of K in $\mathbb{R}^n_+$.

DEFINITION 5.1. *A continuous mapping $P_K : U \to \mathbb{R}$ is a GALF* for (1) on K *if*

(a)$_K$ $P_K(x) = 0$ *for all* $x \in U \cap \partial\mathbb{R}^n_+$, $P_K(x) > 0$ *for all* $x \in U \cap \operatorname{int}\mathbb{R}^n_+$;

(b)$_K$ P_K *is differentiable on* $U \cap \operatorname{int}\mathbb{R}^n_+$ *and* $p_i(x) := \frac{x_i}{P_K(x)} \frac{\partial P_K}{\partial x_i}$ *can be extended to a continuous function on* U *for every* i;

(c)$_K$ *for every* $y \in K$ *there is a positive constant* T_y *with the property that* $\int_0^{T_y} \sum_i p_i(\Phi(t,y)) f_i(\Phi(t,y))\, dt > 0$.

THEOREM 5.2. *If P_K is a GALF for* (1) *on K, then there exist an open neighborhood $\mathcal{N}_K$ of K in X and positive constants $\delta, \kappa_1, \kappa_2$ such that for each δ-perturbation*

$$P_K(\Psi(t,x)) \le \kappa_1 e^{\kappa_2 t} P_K(x) \quad \text{whenever} \quad \{\Psi(\tau,x) \mid t \le \tau \le 0\} \subset \mathcal{N}_K.$$

In particular, $\mathcal{N}_K \setminus Y$ does not contain entire trajectories of Ψ and, for each $x \in \mathcal{N}_K \setminus Y$, inclusion $\emptyset \ne \omega_\Psi(x) \subset K$ is impossible.

Proof. Reconsidering the respective proofs in sections 2 and 3, we see that the existence of a local GALF implies that both (17) and (11) remain valid in the local setting. ∎

The collection of Φ-invariant Borel probability measures on K is denoted by $\mathcal{M}_\Phi(K)$. Clearly $\mathcal{M}_\Phi(Y) = \mathcal{M}_\Phi$ and, for a general K, $\mathcal{M}_\Phi(K)$ can be identified with $\{\mu \in \mathcal{M}_\Phi : \mu(K) = 1\}$. The collection of ergodic measures in $\mathcal{M}_\Phi(K)$ is denoted by $\mathcal{M}_\Phi^E(K)$.

THEOREM 5.3. *The following properties are pairwise equivalent:*

$(\alpha)_K$ *There are $p_1, p_2, \dots, p_n > 0$ such that $P(x) = \prod_{i=1}^n x_i^{p_i}$ is a GALF for* (1) *on K.*

$(\beta)_K$ *For every $\mu \in \mathcal{M}_\Phi(K)$ there exists an $i \in \{1, 2, \dots, n\}$ with $\int_K f_i\, d\mu > 0$.*

$(\gamma)_K$ *There are $p_1, p_2, \dots, p_n > 0$ such that $\sum_{i=1}^n p_i \int_K f_i d\mu > 0$ for all $\mu \in \mathcal{M}_\Phi^E(K)$.*

Proof. This is the localized version of Theorem 4.4, replacing Y by K, with the same proof. ∎

Remark 5.4. Assume that $K \subset \{y \in Y : y_n > 0\}$. Then

$$\int_K f_n\, d\mu = 0 \quad \text{for each } \mu \in \mathcal{M}_\Phi(K).$$

In fact, a twofold application of the Φ-invariance of μ implies via Fubini's theorem that

$$\begin{aligned}\int_K f_n\, d\mu &= \int_0^1 \int_K f_n(\Phi(t,\cdot))\, d\mu dt = \int_K \int_0^1 f_n(\Phi(t,\cdot))\, dt d\mu \\ &= \int_K \{\log(\Phi_n(t,\cdot))\}_{t=0}^{t=1}\, d\mu = \int_K \log(\Phi_n(1,\cdot))\, d\mu - \int_K \log(\Phi_n(0,\cdot))\, d\mu = 0.\end{aligned}$$

The property established above (proved differently in [57, Lem. 5.1], using the ergodic theorem and Poincaré's recurrence theorem) helps check whether $(\beta)_K$ is satisfied or not.

Schreiber [57] (working on $\mathbb{R}^n_+$) defines an invariant probability measure $\mu \in \mathcal{M}_\Phi$ to be *unsaturated* if $\max_{1\le i\le n} \int_Y f_i \, d\mu > 0$, i.e., at least one external Liapunov exponent is positive. (For point measures this reduces to the notion of an unsaturated equilibrium from [35].) He calls a compact invariant set $K \subset Y$ unsaturated if every $\mu \in \mathcal{M}_\Phi(K)$ is unsaturated. By our Theorem 5.3, K is unsaturated if and only if there exists a local GALF near K of the standard form $\prod_i x_i^{p_i}$. One of the main results in [57] and [26] says that if Y has a Morse decomposition with all Morse sets being unsaturated, then (1) is robustly permanent. This result is generalized as follows.

THEOREM 5.5. *Let $M_1, M_2, \dots, M_\ell$ be a Morse decomposition on Y for $\Phi|_Y$. Further, for $k = 1, 2, \dots, \ell$, let U_k be an open neighborhood of M_k in Y and let $P_k : U_k \to \mathbb{R}$ be a GALF for* (1) *on M_k. Then* (1) *is robustly permanent.*

Proof. Arguing as in the first paragraph of the proof of Theorem 2.2, we obtain that there are three constants $c, \delta, T > 0$ and, for $k = 1, 2, \dots, \ell$, there is an open neighborhood N_k of M_k in U_k with $\mathrm{cl}(N_j) \cap \mathrm{cl}(N_k) = \emptyset$ for $j \ne k$ and the property as follows. Given $x \in N_k \setminus Y$, $k = 1, 2, \dots, \ell$, arbitrarily, there exists a time $T_x \in (0, T]$ such that

$$P_k(\Psi(T_x, x)) > (1 + c)P_k(x) \quad \text{for every } \delta\text{-perturbation (2) of (1).}$$

We claim that, for δ sufficiently small,

$$\gamma_\Psi(x) \subset \mathcal{B}[Y, \delta] \Rightarrow \alpha_\Psi(x) \cup \omega_\Psi(x) \subset \bigcup_{k=1}^{\ell} N_k. \tag{36}$$

Since $\bigcup_k M_k$ is the intersection of a finite collection of attractor–repeller pairs, there is no loss of generality in assuming that $\ell = 2$ and that (M_1, M_2) is an attractor–repeller pair for $\Phi|_Y$.

Since M_1 is an attractor for $\Phi|_Y$, there exists a compact neighborhood S_1 of M_1 in N_1 satisfying $\Phi(\mathbb{R}_+, Y \cap S_1) \subset N_1$. We point out next that, for δ sufficiently small,

$$\gamma_\Psi(z) \subset \mathcal{B}[Y, \delta] \text{ plus } z \in S_1 \Rightarrow \gamma^+_\Psi(z) \subset N_1. \tag{37}$$

To the contrary, suppose that, for each $j = 1, 2, \dots$, there exists a $\frac{1}{n}$-perturbation (2) of (1), a $z_j \in S_1$, and a time $t_j > 0$ satisfying $\gamma_{\Psi_j}(z_j) \subset \mathcal{B}[Y, \frac{1}{j}]$ but $w_j = \Psi_j(t_j, z_j) \notin N_1$. We may assume that $z_j \in \partial S_1$, $w_j \in \partial N_1$, $\Psi_j((0, t_j), z_j) \subset N_1 \setminus S_1$ and, by compactness, $z_n \to z_0$ and $w_n \to w_0$ for some $z_0 \in Y \cap \partial S_1$ and $w_0 \in Y \cap \partial N_1$. We distinguish two cases according to whether $\{t_j\} \subset \mathbb{R}_+$ is bounded or not. By passing to a subsequence, we may assume that $t_j \to t_0$ for some $t_0 \in \mathbb{R}_+$ or $t_j \to \infty$. If $t_j \to t_0$, then $\Phi(t_0, z_0) = w_0$, a contradiction. If $t_j \to \infty$, we may assume that $q_j = \Psi_j(t_j/2, z_j) \to q$ for some $q \in Y \cap \mathrm{cl}(N_1 \setminus S_1)$. It is readily checked that $\gamma_\Phi(q) \subset Y \cap \mathrm{cl}(N_1 \setminus S_1)$, a contradiction.

By continuity (and passing to a smaller δ if necessary), we see there exist positive times T_1, $T_2 > T_1$ such that

$$\Psi([T_1, T_2], \mathcal{B}[Y \setminus (N_1 \cup N_2), \delta]) \subset S_1 \quad \text{for every } \delta\text{-perturbation (2) of (1).}$$

In view of property (37), this ends the proof (of case $\ell = 2$) of (36).

The rest is easy. For each $k = 1, 2, \dots, \ell$, the Zubov–Ura–Kimura argument we used in the last two paragraphs of the proof of Theorem 2.2 applies in $\mathrm{cl}(N_k)$ individually. ∎

Remark 5.6. The proof of Theorem 5.5 shows that any continuous function $P : X \to \mathbb{R}$ satisfying conditions (a) and $P|_{N_k} = P_k|_{N_k}$, $k = 1, 2, \dots, \ell$, satisfies condition (9), too. Thus, in a technical sense, local GALFs can be joined together to a global "nearly-GALF."

6. Discrete-time analogues. Mutatis mutandis, all the previous results remain valid for discrete-time dynamical systems.

With $F_i : X \to \mathbb{R}$, $i = 1, 2, \dots, n$, continuous, consider a mapping of the form

$$\mathcal{F} : X \to X, \quad x \to (x_1 F_1(x), x_2 F_2(x), \dots, x_n F_n(x)). \tag{38}$$

Throughout this section, it is assumed that $\mathcal{F}$ is a self-homeomorphism of X. Brouwer's open mapping theorem implies that $\mathcal{F}(X \setminus Y) = X \setminus Y$ and $\mathcal{F}(Y) = Y$. In particular, $F_i(x) > 0$ for each $x \in X \setminus Y$, $i = 1, 2, \dots, n$. Throughout this section, we assume further that $F_i(y) > 0$ for each $y \in Y$, $i = 1, 2, \dots, n$.

Our next result implies that this latter assumption is quite natural. It will also be crucial in establishing Lemma 7.2, the starting point of the theory of discretizations of Kolmogorov type in the next chapter, and it was used already in the proof of Theorem 3.4.

Surjectivity theorem. *Let $F_i : X \to \mathbb{R}_+$, $i = 1, 2, \dots, n$, be continuous functions, $\sum_i x_i F_i(x) = 1$ for each $x \in X$, and consider the mapping $\mathcal{F} : X \to X$, $x \to (x_1 F_1(x), x_2 F_2(x), \dots, x_n F_n(x))$. Then $\mathcal{F}(S) = S$ for each subsimplex S of X.*

Proof. By the particular form of our mapping, this is certainly true for the zero-dimensional subsimplices (vertices) of X. For a k-member subset $\{i_1, i_2, \dots, i_k\}$ of $\{1, 2, \dots, n\}$, consider the subsimplex of the form $S = \{x \in X : x_{i_1} = x_{i_2} = \cdots = x_{i_k} = 0\}$. Applying $\mathcal{F}_i(x) = x_i F_i(x)$ for $i = i_1, i_2, \dots, i_k$, we obtain that $\mathcal{F}(S) \subset S$. By induction on the subsimplices, we may assume that $S = X$ and $\mathcal{F}(s) = s$ for each facet s of $S = X$. Consider a point $p_0 \in \mathrm{int}(S)$ arbitrarily chosen. For any $\lambda \in [0, 1]$, any facet s of S, and any point $p \in s$, the convexity of s implies that $(1 - \lambda)p + \lambda\mathcal{F}(p) \in s$. It follows that

$$(1 - \lambda)p + \lambda\mathcal{F}(p) \neq p_0 \quad \text{whenever } p \in \partial S \text{ and } \lambda \in [0, 1].$$

By the homotopy property of Brouwer's degree, it follows that

$$\deg(\mathcal{F}, p_0, \mathrm{int}(S)) = \deg(\mathrm{id}_{R^n}, p_0, \mathrm{int}(S)),$$

where id_{R^n} denotes the identity on $\mathbb{R}^n$. Since $\deg(\mathrm{id}_{R^n}, p_0, \mathrm{int}(S)) = 1$, the existence property of the degree implies that $p_0 \in \mathcal{F}(S)$. ∎

Corollary 6.1. *In addition, assume that F_i, $i = 1, 2, \dots, n$, is of class C^1 (in the sense that F_i admits a C^1 extension $\hat{F}_i : U_i \to \mathbb{R}$ defined on an open neighborhood U_i of X in $\mathbb{R}^n$) and that $\mathcal{F}$ is a C^1 self-diffeomorphism of X. Then $F_i(y) > 0$ for each $y \in Y$, $i = 1, 2, \dots, n$.*

Proof. Pick $y \in Y$ arbitrarily. For index j satisfying $y_j \neq 0$, inequality $F_j(y) > 0$ is a direct consequence of the surjectivity theorem when applied to the X-facet $S_j = \{x \in X : x_j = 0\}$. For j satisfying $y_j = 0$, inequality $F_j(y) > 0$ follows from the diffeomorphism assumption. To the contrary, assume that $F_j(y) = 0$ (and $y_j = 0$). A direct computation shows that the jth row of the Jacobian of $\mathcal{F}$ evaluated at y equals $(0, 0, \dots, 0)$, a contradiction. ∎

The discrete-time version of an ALF for $\mathcal{F}$ [40] is a continuous mapping $R : X \to \mathbb{R}$ with the following properties:

(d) $R(x) = 0$ for all $x \in Y$, $R(x) > 0$ for all $x \in X \setminus Y$.

(e) There exists a continuous function $r : X \to \mathbb{R}$ such that $r(x) = \log(R(\mathcal{F}(x))) - \log(R(x))$ whenever $x \in X \setminus Y$.

(f) For every $y \in Y$ there is a positive integer $N_y > 0$ with the property that $\sum_{k=1}^{N_y} r(\mathcal{F}^{k-1}(y)) > 0$.

In contrast to the continuous-time case, we did not find a reasonable analogue of the notion of GALF for discrete time. Hence for studying robust permanence in discrete-time systems, we restrict ourselves to the standard ALF of the form $R(x) = \prod_{i=1}^{n} x_i^{r_i}$ with $r_i > 0$, $i = 1, 2, \ldots, n$. For this choice of R, condition (e) holds with $r(x) = \sum_i r_i \log F_i(x)$.

Remark 6.2. One can characterize this R by a functional equation. More precisely, if the continuous mappings $r_i, R : X \to \mathbb{R}$ satisfy condition (d) and $\log R(\mathcal{F}(x)) - \log R(x) = \sum_i r_i(x) \log F_i(x)$ for arbitrary $\mathcal{F}$, then $r_i(x) = r_i$ and $R(x) = c_n \prod_{i=1}^{n} x_i^{r_i}$ for some positive constants r_i, $i = 1, 2, \ldots, n$, and c_n. For a proof, see [19].

With $G_i : X \to \mathbb{R}$, $i = 1, 2, \ldots, n$, continuous, consider δ-perturbations of $\mathcal{F}$ of the form $\mathcal{G} : X \to X$, $x \to (x_1 G_1(x), x_2 G_2(x), \ldots, x_n G_n(x))$, where $|G_i(x) - F_i(x)| < \delta$, $i = 1, 2, \ldots, n$. It is of course assumed that $\sum x_i G_i(x) = 1$ for each $x \in X$. We assume further that $\mathcal{G}$ is a self-homeomorphism of X. If $\mathcal{G}$ is permanent, then $(\mathcal{A}_{\mathcal{G}}, Y)$ forms an attractor–repeller pair, where $\mathcal{A}_{\mathcal{G}}$ denotes the maximal compact $\mathcal{G}$-invariant set in $X \setminus Y$. In analogy to the relation between (2) and (1), we say that $\mathcal{G}$ is a δ-perturbation of $\mathcal{F}$ if $|G_i(x) - F_i(x)| < \delta$ for each $x \in X$ and $i = 1, 2, \ldots, n$.

THEOREM 6.3. *If there is an ALF for $\mathcal{F}$, then $\mathcal{F}$ is permanent. Moreover, assume that for some constants $r_i > 0$ suitably chosen, $R(x) = \prod_{i=1}^{n} x_i^{r_i}$ is an ALF for $\mathcal{F}$. Then $\mathcal{F}$ is robustly permanent. There are a $\delta > 0$ and a compact subset S of $X \setminus Y$ with the properties as follows. Every δ-perturbation $\mathcal{G}$ of $\mathcal{F}$ is permanent and $\mathcal{A}_{\mathcal{G}}$ is contained in S.*

Proof. The proof of Theorem 2.2 can be repeated. The computations are based on the formulae

$$\log(R(\mathcal{F}^{N_x}(x))) - \log(R(x)) = \sum_{k=1}^{N_x} r(\mathcal{F}^{k-1}(x))$$

and

$$\log(R(\mathcal{G}^{N_x}(x))) - \log(R(x)) = \sum_{k=1}^{N_x} \sum_{i=1}^{n} r_i \cdot \log(G_i(\mathcal{G}^{k-1}(x))),$$

respectively. The last step is the application of the discrete-time version of the Zubov–Ura–Kimura theorem. ∎

The first statement of Theorem 6.3 is due to [40]; see also [36]. The robustness result is new.

The set of $\mathcal{F}$-invariant Borel probability measures on Y is denoted by $\mathcal{M}_{\mathcal{F}}$. When combined with Theorem 6.3, our next result establishes a sufficient condition for robust permanence of $\mathcal{F}$. Note that inequality $\int_Y \log(F_i)\, d\nu > 0$ is stronger than the (seemingly) "more natural" inequality $\int_Y F_i\, d\nu > 1$. A special case of heteroclinic cycles was treated in [24].

THEOREM 6.4. *The following properties are equivalent:*

$(\alpha)^d$ *For some $r_1, r_2, \ldots, r_n > 0$ suitably chosen, $R(x) = \prod_{i=1}^{n} x_i^{r_i}$ is an ALF for $\mathcal{F}$.*

$(\beta)^d$ *For every* $\nu \in \mathcal{M}_{\mathcal{F}}$ *there exists an* $i \in \{1, 2, \dots, n\}$ *with* $\int_Y \log F_i \, d\nu > 0$.

$(\gamma)^d$ *There are* $r_1, r_2, \dots, r_n > 0$ *such that* $\sum_{i=1}^n r_i \int_Y \log F_i \, d\nu > 0$ *holds for every ergodic* $\nu \in \mathcal{M}_{\mathcal{F}}^E$.

Proof. The proof of Theorem 4.4 can be repeated. Almost no changes are needed. The method of proving Lemma 4.1 yields for each $h \in C(Y, \mathbb{R})$ that

$$\min_{\nu \in \mathcal{M}_{\mathcal{F}}} \int_Y h \, d\nu = \min_{y \in Y} \limsup_{N \to \infty} \frac{1}{N} \sum_{k=1}^{N} h(\mathcal{F}^{k-1}(y)).$$

The compactness argument we used in proving Lemma 4.2 implies that inequality $\min_{\nu \in \mathcal{M}_{\mathcal{F}}} \int_Y h \, d\nu > 0$ is equivalent to the following assertion: For every $y \in Y$ there is a positive integer $N_y > 0$ such that $\sum_{k=1}^{N_y} h(\mathcal{F}^{k-1}(y)) > 0$. We may assume by homogeneity that $r = (r_1, r_2, \dots, r_n) \in X$. With $h = \sum r_i \cdot \log(F_i)$, the minimax theorem applies. □

THEOREM 6.5. *Let* $M_1, M_2, \dots, M_\ell$ *be a Morse decomposition on* Y *for* $\mathcal{F}|_Y$. *Further, for* $k = 1, 2, \dots, \ell$, *let* U_k *be an open neighborhood of* M_k *in* Y *and let* $R_k : U_k \to \mathbb{R}$ *be an ALF for* $\mathcal{F}$ *on* M_k. *Then* $\mathcal{F}$ *is permanent. Moreover, assume that each* R_k *is of the special form* $R_k(x) = \prod_{i=1}^n x_i^{r_i^k}$ *for some positive constants* $r_1^k, r_2^k, \dots, r_n^k$. *Then* $\mathcal{F}$ *is robustly permanent.*

Proof. The method we used in proving Theorem 5.5 applies. □

The formulation of the discrete-time version of Theorems 3.1, 3.4, 5.2, and 5.3 is left to the reader.

7. Discretizations of Kolmogorov type. We discuss definition and basic properties of $\mathcal{P}$th order one-step discretizations of (1).

Let h_0 be a positive constant. Let $\mathcal{P} \geq 1$, $k \geq 0$ be integers with $\mathcal{P} + k \geq 2$. Assume that $f_1, f_2, \dots, f_n$ are $C^{\mathcal{P}+k+1}$ functions. The $C^{\mathcal{P}+k+1}$ property on closed sets like X (or $[0, h_0] \times X$) is understood as the existence of a $C^{\mathcal{P}+k+1}$ extension defined on an open neighborhood of X in $\mathbb{R}^n$ (or of $[0, h_0] \times X$ in $\mathbb{R} \times \mathbb{R}^n$). Consider a $C^{\mathcal{P}+k+1}$ discretization operator $\varphi : [0, h_0] \times X \to \mathbb{R}^n$. We assume that φ is of order $\mathcal{P}$, i.e., there exists a positive constant K (depending only on $\{f_i\}_{i=1}^n$) such that

$$|\Phi(h, x) - \varphi(h, x)| \leq K h^{\mathcal{P}+1} \quad \text{for all } h \in [0, h_0] \text{ and } x \in X.$$

We require also that φ is locally determined by $\{f_i\}_{i=1}^n$; i.e., we assume the existence of a continuous function $\Delta : [0, h_0] \to [0, \infty)$ such that $\Delta(0) = 0$ and, for all $h \in (0, h_0]$ and $x \in X$, $\varphi(h, x)$ is determined solely by the restriction of $\{f_i\}_{i=1}^n$ to $\mathcal{B}(x, \Delta(h))$. All these assumptions are satisfied if φ comes from a (general r-stage explicit or implicit) Runge–Kutta method. The standard theory of discretization operators (see, e.g., Stuart and Humphries [60]) implies that for all h sufficiently small, say $h \in [0, h_0]$, $\varphi(h, \cdot)$ is a $C^{\mathcal{P}+k+1}$ diffeomorphism of X onto $\varphi(h, X)$.

Now we are in a position to define discretizations of Kolmogorov type. Besides the above requirements on differentiability, consistency, and determinacy (these three were grouped together in [7] for the first time), two further conditions on a general discretization operator are imposed.

DEFINITION 7.1. *We say that our discretization operator is* of Kolmogorov type *on* X *for* (1) *if, for each* $i = 1, 2, \dots, n$, *there exists a* $C^{\mathcal{P}+k+1}$ *function* $q_i : [0, h_0] \times X \to \mathbb{R}$ *satisfying*

$$\varphi_i(h, x) = x_i q_i(h, x) \quad \text{whenever } h \in [0, h_0] \text{ and } x \in X \tag{39}$$

and, in addition, $\varphi(h, X) \subset X$ *for each* $h \in [0, h_0]$.

LEMMA 7.2. *Let φ be a discretization operator of Kolmogorov type on X for* (1). *Then, for all h sufficiently small, say $h \in [0, h_0]$, $\varphi(h, \cdot)$ defines a $C^{\mathcal{P}+k+1}$ discrete-time dynamical system on X.*

Proof. We know already that $\varphi(h, \cdot)$ is a $C^{\mathcal{P}+k+1}$ diffeomorphism of X onto $\varphi(h, X) \subset X$. The surjectivity theorem applies. ∎

Remark 7.3. In accordance with (39), the solution operator of (1) satisfies

$$\Phi_i(h, x) = x_i Q_i(h, x) \quad \text{whenever } h \in [0, h_0] \text{ and } x \in X, \tag{40}$$

where $Q : [0, h_0] \times X \to \mathbb{R}^n$ is a $C^{\mathcal{P}+k}$ function defined by

$$Q_i(h, x) = \int_0^1 \frac{d}{dx_i} \Phi_i(h, x_1, \ldots, x_{i-1}, \theta x_i, x_{i+1}, \ldots, x_n)\, d\theta, \quad i = 1, 2, \ldots, n.$$

Actually, Q is of class $C^{\mathcal{P}+k+1}$. Existence and continuity of the last derivative is a consequence of the $C^{\mathcal{P}+k+1}$ parametrized version of the Picard–Lindelöf theorem. In fact, with $x \in X$ as a parameter, let $z(\cdot; x)$ denote the solution of the initial value problem

$$\dot{z}_i = z_i f_i(x_1 z_1, x_2 z_2, \ldots, x_n z_n) \quad \text{and} \quad z_i(0) = 1, \qquad i = 1, 2, \ldots, n.$$

Since $(x_1 z_1(\cdot; x), x_2 z_2(\cdot; x), \ldots, x_n z_n(\cdot; x))$ is a solution to (1), we have by uniqueness that $z(t; x) = Q(t, x)$ for all $t \in R$ and $x \in X$.

Example 7.4. Let $\vartheta : [0, h_0] \times X \to \mathbb{R}^n$ be a discretization operator coming from a (general r-stage explicit or implicit) Runge–Kutta method. It is a straightforward but rather lengthy task to check that, for all h sufficiently small, say $h \in [0, h_0]$, formula

$$\varphi_i(h, x) = \frac{\vartheta_i(h, x)}{\sum_j \vartheta_j(h, x)}\,, \qquad x \in X, \quad i = 1, 2, \ldots, n,$$

makes sense and defines a $\mathcal{P}$th order discretization operator of Kolmogorov type on X for (1). For example, the explicit Euler method leads to

$$\varphi_i^E(h, x) = x_i \frac{1 + h f_i(x)}{1 + h \sum_j x_j f_j(x)}\,, \quad (h, x) \in [0, h_0] \times X, \qquad i = 1, 2, \ldots, n\,,$$

a first order discretization operator of Kolmogorov type.

The difference between exact and discretized solutions of (1) on finite-time intervals can be estimated as follows.

LEMMA 7.5. *Let φ be a $\mathcal{P}$th order discretization operator of Kolmogorov type on X for* (1). *Given $T > 0$ arbitrarily, there exists a positive constant $\kappa(T)$ such that for any $M = 0, 1, 2, \ldots$ with $Mh \le T$, the estimate*

$$|\Phi_i(Mh, x) - \{\varphi^M(h, \cdot)\}_i(x)| \le x_i \cdot \kappa(T) \cdot h^{\mathcal{P}}, \quad (h, x) \in [0, h_0] \times X \tag{41}$$

holds true. (Here of course $\{\varphi^M(h, \cdot)\}_i$ denotes the ith coordinate function of the Mth iterate of the discretization mapping $\varphi(h, \cdot)$, $i = 1, 2, \ldots, n$.)

Proof. Writing out the coordinate functions explicitly, we find that methods of deriving the standard error estimate $|\Phi(Mh, x) - \varphi^M(h, x)| \le \kappa_0(T) h^{\mathcal{P}}$ (e.g., in [60]) apply and κ is an exponential function of T. For details, see [21]. ∎

LEMMA 7.6. *The previous lemma holds true for variable stepsize sequences. More precisely, given $T > 0$ arbitrarily and $\kappa(T)$ denoting the same constant as in* (41)*, the estimate*

$$\left|\Phi_i\left(\sum_{m=1}^{M} h_m, x\right) - \{\varphi(h_M,\cdot)\circ\cdots\circ\varphi(h_1,\cdot)\}_i(x)\right| \le x_i\cdot\kappa(T)\cdot\left(\max_{1\le m\le M} h_m\right)^{\mathcal{P}}$$

holds true whenever $h_m \in (0, h_0]$, $m = 1, 2, \ldots, M$, with $\sum_m h_m < T$, and $x \in X$.

Proof. The proof is almost the same as that for constant stepsizes. ∎

8. Permanence for discretizations. Results in this section fit well in the list of papers in [60] on attraction, Liapunov functions, and discretization. They are particularly closely related to continuity results on exponentially attracting attractors in [4] and on convergence rates of perturbed attracting sets with vanishing perturbation [25]. For the qualitative theory of discretizations in general, see the monograph [60] as well as the fundamental paper [48].

LEMMA 8.1. *Fix $p_i > 0$, $i = 1, 2, \ldots, n$, and consider mapping $P : X \to \mathbb{R}_+$, $P(x) = \prod_{i=1}^n x_i^{p_i}$. Then P is an ALF for* (1) *if and only if P is an ALF for $\mathcal{F} = \Phi(1,\cdot)$.*

Proof. By letting $b = 1$ and $a = k - 1$, $k = 1, 2, \ldots, N$, in the identity $\log(Q_i(b, \Phi(a, y))) = \int_a^{a+b} f_i(\Phi(t, y))\, dt$ (a simple consequence of (40)) and forming the respective linear combinations,

$$\sum_{k=1}^{N}\sum_{i=1}^{n} p_i\cdot\log(Q_i(1,(\mathcal{F}^{k-1}(y)))) = \int_0^N \sum_{i=1}^{n} p_i f_i(\Phi(t,y))\, dt$$

holds for each $y \in Y$ and $N = 1, 2, \ldots$. Consequently, if P is an ALF for $\mathcal{F}$, then P is an ALF for (1) and $T_y = N_y$. Conversely, assume that $\int_0^{T_y}\sum f_i(\Phi(t,y))\, dt > 0$ for some $T_y > 0$. The compactness argument we used in proving Lemma 4.2 implies that $\int_0^{\tau_y}\sum f_i(\Phi(t,y))\, dt > 0$ for some positive integer τ_y. Thus P is an ALF for $\mathcal{F}$ and $N_y = \tau_y$. ∎

Remark 8.2. Together with Lemma 4.1, a similar argument implies that

$$\min_{\nu\in\mathcal{M}_{\Phi(1,\cdot)}}\int_Y \log(Q_i(1,\cdot))\, d\nu = \min_{\mu\in\mathcal{M}_\Phi}\int_Y f_i\, d\mu \qquad \text{for each } \ i = 1, 2, \ldots, n.$$

This is somewhat strange because $\mathcal{M}_\Phi \subset \mathcal{M}_{\Phi(1,\cdot)}$ and the set $\mathcal{M}_{\Phi(1,\cdot)}$ is usually a much larger subset of $\mathcal{M}$ than $\mathcal{M}_\Phi$. It is not hard to establish that the dependence of $\mathcal{M}_{\Phi(t,\cdot)}$ on the parameter $t \in (0,\infty)$ is weakly-$*$ upper semicontinuous. Moreover, if $\mathcal{U}$ is an open neighborhood of $\mathcal{M}_\Phi$ in the weak-$*$ topology of $\mathcal{M}$, then $\mathcal{M}_{\Phi(t,\cdot)} \subset \mathcal{U}$ for $|t|$ sufficiently small. Similarly, if φ is a discretization operator of Kolmogorov type, then there exists a positive constant $h_{\mathcal{U}}$ such that $\mathcal{M}_{\varphi(h,\cdot)} \subset \mathcal{U}$ whenever $0 < h \le h_{\mathcal{U}}$. (A detailed proof of this latter statement is contained in [21].) No upper semicontinuity result holds true for (the closure of the union of) supports of (all) invariant measures. On the general problem of measures and discretization, we recommend [14] and the references therein. Several upper semicontinuity results of numerical dynamics are contained also in [60].

Lemma 8.1 enables us to give a short proof for permanence under discretization.

THEOREM 8.3. *Assume that $P(x) = \prod_{i=1}^n x_i^{p_i}$ is an ALF for* (1)*. Let φ be a $\mathcal{P}$th order discretization operator of Kolmogorov type for* (1)*. Then, for all h sufficiently*

small, say $h \in (0, h_0]$, Y is a repeller for the discrete-time dynamical system induced by $\varphi(h,\cdot)$. In addition, there is a compact subset S of $X \setminus Y$ with the property that the dual attractor $\mathcal{A}_{\varphi(h,\cdot)}$ is contained in S, $h \in (0, h_0]$.

Proof. Assume that $0 < h \le h_0 < 1$ and consider the positive integer M_h satisfying $M_h h < 1 \le (M_h + 1)h$. Since[6] Y is $\varphi(h,\cdot)$-invariant, Y is a repeller for $\varphi(h,\cdot)$ if and only if Y is a repeller for $\varphi^{M_h}(h,\cdot)$. Combining Lemma 8.1 and Theorem 6.3, we see it is enough to point out that $\mathcal{G} = \varphi^{M_h}(h,\cdot)$ is a δ-perturbation of $\mathcal{F} = \Phi(1,\cdot)$.

In fact, for each $x \in X$, $h \in (0, h_0]$ and $i = 1, 2, \ldots, n$, inequality $0 < 1 - M_h h \le h$ implies that

$$|\Phi_i(1,x) - \Phi_i(M_h h, x)| = |\Phi_i(1 - M_h h, \Phi(M_h h, x)) - \Phi_i(M_h h, x)| \le x_i \cdot (e^{Kh} - 1)$$

with $K = \max_{1\le i\le n} \max_{x\in X} |f_i(x)|$. We conclude via (41) that

$$|\Phi_i(1,x) - \{\varphi^{M_h}(h,\cdot)\}_i(x)| \le x_i \left\{(e^{Kh} - 1) + \kappa(1) \cdot h^{\mathcal{P}}\right\}. \tag{42}$$

Note that the coefficient of x_i on the right-hand side of (42) approaches zero as $h \to 0^+$. Thus $\mathcal{G} = \varphi^{M_h}(h,\cdot)$ is a δ-perturbation of $\mathcal{F} = \Phi(1,\cdot)$ for h small enough and Theorem 6.3 applies. ∎

We do not know if Theorem 8.3 is true for a general GALF. The main difficulty is in proving the inequality

$$|P(\Phi(Mh, x)) - P(\varphi^M(h,x))| \le \tilde{\kappa}_1(T) h^{\mathcal{P}} \cdot P(x) \quad \text{if } 0 < T,\ 0 \le Mh \le T, \tag{43}$$

which seems to be a rather delicate matter.

Remark 8.4. Assume that the conditions of Theorem 8.3 are all satisfied. Combining Theorem 4.4 and the discretization result in Remark 8.2, one can establish the existence of positive constants c_*, h_* with the following property: For every stepsize $h \in (0, h_*]$ and $\mu_h \in \mathcal{M}_{\varphi(h,\cdot)}$ there exists an $i \in \{1, 2, \ldots, n\}$ with $\int_Y \log q_i(h,\cdot)\, d\mu_h > c_* h$. An alternative presentation of a great part of sections 8, 9, 10, and 11 can be centered around (the local version of) this inequality.

9. Variable stepsize discretizations. In this section we present a generalization of Theorem 8.3 for variable stepsize discretizations.

The natural framework of handling variable stepsize sequences is that of nonautonomous dynamics. For general considerations, including several attractor definitions in the nonautonomous setting, we refer to [45]. In what follows we restrict ourselves to recalling the concept of cocycle attractors/repellers and to presenting a special case of the key result from Kloeden and Schmalfuss [44].

THEOREM 9.1. *Assume that* (1) *is permanent and let φ be a discretization operator of Kolmogorov type for* (1). *In addition, let $\mathcal{U}_Y$ be an open neighborhood of Y in X, let $\mathcal{U}_{\mathcal{A}_\Phi}$ be an open neighborhood of $\mathcal{A}_\Phi$ in X, and assume that $\mathcal{U}_Y \cap \mathcal{U}_{\mathcal{A}_\Phi} = \emptyset$. Then there are positive constants h_* and τ with the following properties: Given an arbitrary set C with $\mathcal{U}_{\mathcal{A}_\Phi} \subset C \subset X \setminus \mathcal{U}_Y$ and a doubly infinite stepsize sequence $\mathbf{h} = \{h_k\}_{k=-\infty}^{\infty}$ with $\sum_{k=1}^{\infty} h_k = \sum_{k=-\infty}^{0} h_k = \infty$ and $\|\mathbf{h}\| = \sup h_k \le h_*$,*

$$\{\varphi(h_M,\cdot) \circ \cdots \circ \varphi(h_1,\cdot)\}(C)\ ,\ \{\varphi(h_0,\cdot) \circ \cdots \circ \varphi(h_{-M},\cdot)\}(C) \subset \mathcal{U}_{\mathcal{A}_\Phi} \tag{44}$$

[6] Consider $W = [-1, 1] \subset \mathbb{R}$, $\mathcal{F}_0(w) = -w^3$ for $w \in W$. Then $\{1\}$ is a repeller for $\mathcal{F}_0^2$ but not for $\mathcal{F}_0$. The reason is that $\{1\}$ is not $\mathcal{F}_0$-invariant.

whenever $\sum_{k=1}^{M} h_k \geq \tau$ *and* $\sum_{k=-M}^{0} h_k \geq \tau$. *In addition, the set*

$$A(\mathbf{h}) = \bigcap\nolimits_{M\geq 0} \mathrm{cl}\left(\bigcup\nolimits_{m\geq M} \{\varphi(h_0,\cdot)\circ\cdots\circ\varphi(h_{-m},\cdot)\}(C)\right)$$

(45) *is independent of* C *and is contained in* $\mathrm{cl}(\mathcal{U}_{\mathcal{A}_\Phi})$,

(46) $$\mathrm{cl}\left(\bigcup\nolimits_{m\geq M} \{\varphi(h_0,\cdot)\circ\cdots\circ\varphi(h_{-m},\cdot)\}(C)\right) \to A(\mathbf{h})$$

in the Hausdorff metric as $M\to\infty$, *and, with* $\theta^m\mathbf{h}$ *denoting the doubly infinite shifted stepsize sequence defined by* $(\theta^m\mathbf{h})_k = h_{k+m}$,

(47) $$\{\varphi(h_m,\cdot)\circ\cdots\circ\varphi(h_1,\cdot)\}(A(\mathbf{h})) = A(\theta^m\mathbf{h}) \quad \textit{for each} \quad m=1,2,\ldots.$$

Proof. This is a restatement of Theorems 3.1 and 4.5 of [44] within the context of the present paper. Actually, the original results in Kloeden and Schmalfuss [44] are proved under the additional requirement

(48) $$\sup\{h_k/h_\ell \mid k,\ell\in\{0,\pm1,\pm2,\ldots\}\} \leq \text{const.}$$

The starting point of their proof is a classical result in converse Liapunov theory, Theorem 22.5 of Yoshizawa [67] on the existence of Lipschitz continuous Liapunov functions. However, when starting from Conley's C^∞ Liapunov function for the attractor–repeller pair $(\mathcal{A}_\Phi, Y)$, condition (48) turns out to be irrelevant. It is enough to replace Lemma 4.1 of [44] by Lemma 9.2 below and to reconsider the Kloeden–Schmalfuss argumentation. We find that Theorem 9.1 holds true for free stepsize sequences (subject only to the requirements $\sum_{k=1}^{\infty} h_k = \sum_{k=-\infty}^{0} h_k = \infty$ and $\|\mathbf{h}\| = \sup h_k \leq h_*$). ∎

For convenience, recall Lemma 1 of [20], which we "inserted" in the original proof of Theorem 9.1 in [44] above.

LEMMA 9.2. *There exists a* C^∞ *function* $V: X\to[0,1]$ *with the following properties: For every* $x\in X\setminus(\mathcal{A}_\Phi\cup Y)$, *function* $\mathbb{R}\to(0,1)$, $t\to\Phi(t,x)$ *is strictly decreasing, and, in addition,* $V^{-1}(0)=\mathcal{A}_\Phi$, $V^{-1}(1)=Y$. *Finally, for* $c\in(0,1)$ *arbitrarily given, there exists a positive constant* $h^*(c)$ *such that* $V(\varphi(h,x))<c$ *whenever* $h\in(0,h^*(c)]$ *and* $V(x)\leq c$.

Proof. This is a discretization consequence of Theorem 6.12 of Akin [2]. Details can be found in [20]. ∎

Most results in [44], [45] are stated and proved for abstract cocycles with the shift operator θ acting on a compact parameter space. Having applications to stochastic numerics in mind, no attempt is made in these papers to lift/weaken condition (48) in the simplest special case of deterministic discretizations with variable stepsize. The set $A(\mathbf{h})$ is called a *cocycle* or *pull-back attractor*. Properties (44), (45), (46), and (47) are called the *upper semicontinuity, uniqueness, pull-back convergence*, and *equivariance properties*, respectively. Elementary examples show that, together with the stepsize sequence $\mathbf{h}=\{h_k\}_{k=-\infty}^{\infty}$, the accompanying push-forward sequence of sets $\{\varphi(h_M,\cdot)\circ\cdots\circ\varphi(h_1,\cdot)\}(C)$ may also exhibit an oscillating behavior in $\mathcal{U}_{\mathcal{A}_\Phi}$. This explains why cocycle attractors are defined as they are, i.e., by using pull-back convergence. For constant stepsize sequences, Theorem 9.1 reduces to results in [43], the starting point of the theory on numerical attractors.

The dual concept to cocycle attractors is that of a cocycle repeller. Reversing time, Theorem 9.1 establishes the existence of a cocycle repeller $R(\mathbf{h})$. Nevertheless, even

for discretizations of Kolmogorov type, the general theory says only that $R(\mathbf{h}) \to Y$ in an upper semicontinuous way. However, in the case that permanence is granted by the standard GALF assumption, $R(\mathbf{h}) = Y$ for every doubly infinite stepsize sequence with $\|\mathbf{h}\|$ sufficiently small.

Actually, a stronger result—a discretized version of Theorem 3.1—holds true.

THEOREM 9.3. *Assume that $P(x) = \prod_{i=1}^n x_i^{p_i}$ is a GALF and let φ be a $\mathcal{P}$th order discretization operator of Kolmogorov type for (1) on X. Then there exist an open neighborhood $\mathcal{W}$ of Y in X and positive constants $h_0, \lambda_1, \lambda_2, \lambda_3$ with the properties as follows. Given an infinite stepsize sequence $\{h_k\}_{k=1}^\infty$ with $\sum_{k=1}^\infty h_k = \infty$ and $\sup h_k \le h_0$,*

$$d_E\left(\{\varphi^{-1}(h_1,\cdot)\circ\cdots\circ\varphi^{-1}(h_M,\cdot)\}(x), Y\right) \le \lambda_1 e^{-\lambda_2(h_1+\cdots+h_M)}(d_E(x,Y))^{\lambda_3}$$

whenever $x \in \mathcal{W}$, $M = 1, 2, \ldots$. Here of course $\varphi^{-1}(h_k,\cdot)$ denotes the inverse of $\varphi(h_k,\cdot)$, $k = 1, 2, \ldots, M$, established by Lemma 7.2.

Proof. The proof is an expanded version of that of Theorem 3.1. For details, see [21]. □

A similar result holds true for asymptotically autonomous systems. Consider the ordinary differential equation

$$\dot{x}_i = x_i e_i(t,x), \qquad (t,x) \in \mathbb{R}\times X, \tag{49}$$

where $e_i : \mathbb{R}\times X \to X$ is a continuous function satisfying

$$e_i(t,x) \to f_i(x) \qquad \text{uniformly in } \ x \in X \ \text{ as } \ t \to \infty, \quad i = 1, 2, \ldots, n$$

and $\sum_i x_i e_i(t,x) = 0$ for each $(t,x) \in \mathbb{R}\times X$. Assume that system (49) has the uniqueness property and that function f in the limiting autonomous system (1) is Lipschitz. The solution of (49) through $(t_0,x) \in \mathbb{R}\times X$ is denoted by $\Psi(\cdot, t_0, x)$.

If the limiting autonomous system (1) is robustly permanent due to a standard GALF, then (49) is permanent too. More precisely, the following result holds true.

THEOREM 9.4. *Assume that $P(x) = \prod_{i=1}^n x_i^{p_i}$ is a GALF for (1) on X. Let $\mathcal{U}_{\mathcal{A}_\Phi}$ be an open neighborhood of $\mathcal{A}_\Phi$ in X and let C be a compact subset of $X \setminus Y$. Given an initial time t_0 arbitrarily, there exists a time T such that*

$$\Psi(t_0+t, t_0, x) \in \mathcal{U}_{\mathcal{A}_\Phi} \qquad \text{whenever } \ t \ge T \ \text{ and } \ x \in C.$$

Proof. The proof is a simple variation of the proof of Theorem 9.3. Some details are contained in [21]. □

10. Connections to index theories. Let K be a nonempty Φ-invariant compact subset of Y. Following Szymczak, Wojcik, and Zgliczynski [63], we say that K is *of repelling type* if $\{x \in X : \emptyset \ne \omega(x) \subset K\} \subset Y$. In view of Theorem 5.2 above, the existence of a GALF for (1) on K implies that K is of repelling type and, for some $\eta > 0$, $\mathcal{B}(K,\eta) \setminus Y$ does not contain entire trajectories. Starting from property $(\beta)_K$, the very same conclusions are derived in the first part of the proof of Theorem 4.4 of Schreiber [57]. By $(\alpha)_K \Leftrightarrow (\beta)_K$ in Theorem 5.3, property $(\beta)_K$ means that $P_K : X \to \mathbb{R}$, $P_K = \prod_{i=1}^n x_i^{p_i}$ defines a GALF for Φ on K. In particular, the existence of a local GALF plus the isolatedness of K with respect to the boundary flow $\Phi|_Y$ imply that K is isolated (i.e., isolated with respect to the entire flow Φ on X).

From now on, assume that $\emptyset \ne K \subset Y$ is a compact isolated invariant set of repelling type. Assume, in addition, that K is a repeller for $\Phi|_Y$. In view of the

Zubov–Ura–Kimura theorem, K is a repeller for Φ (i.e., an attractor for the backward flow Φ^* defined by $\Phi^*(t,x) = \Phi(-t,x)$ for all $(t,x) \in \mathbb{R} \times X$) and thus $\emptyset \neq \alpha(x) \subset K$ for any $x \in X$ with $d_E(x,K)$ sufficiently small. Alternatively, assume that K is an attractor for $\Phi|_Y$. Applying the Zubov–Ura–Kimura theorem again, we find *there exists an* $x \in X \setminus Y$ *with* $\emptyset \neq \alpha(x) \subset K$. Geometrically, the property italicized above means that K repels a trajectory from Y into $X \setminus Y$. However, if K is neither a repeller nor an attractor for $\Phi|_Y$, then the existence of an $x \in X \setminus Y$ with $\emptyset \neq \alpha(x) \subset K$ is a rather delicate matter and requires methods of algebraic topology.

By using standard degree theory, the same problem in $\mathbb{R}^{n-1} \times [0,\infty)$ (and $K \subset \mathbb{R}^{n-1} \times \{0\}$ being a finite collection of equilibria (and $\mathbb{R}^{n-1} \times \{0\}$ invariant)) was first investigated by Hofbauer [29]. Capietto and Garay [13] used the fixed point index (which is an appropriate version of degree theory) and a more general index theory developed by Conley [12]. Their approach, however, worked only for flows induced by vector fields and some special kinds of isolated invariant sets. Both restrictions were removed and much more Conley-type results proved by Wojcik [65]. Generalizations for discrete-time semidynamical systems were given by Szymczak, Wojcik, and Zgliczynski [63]. For details, in particular for the index theories involved, we refer to the original papers [13], [65], [63] and the references cited therein.

The next theorem is a straightforward consequence of the main results of [63] within the context of the present paper.

THEOREM 10.1. *Let $\emptyset \neq K \subset Y$ be a compact isolated invariant set of repelling type. Assume that the homotopical Conley index $I_C(K, \Phi|_Y, Y)$ of K with respect to the boundary flow $\Phi|_Y$ in Y is nontrivial. Then there exists an $x \in X \setminus Y$ with $\emptyset \neq \alpha(x) \subset K$.*

Proof. If $K = Y$, then the Zubov–Ura–Kimura theorem applies.

If $K \neq Y$, then consider a point $y_0 \in Y \setminus K$ and note that the pair $(X \setminus \{y_0\}, Y \setminus \{y_0\})$ is homeomorphic to the pair $(\mathbb{R}^{n-2} \times [0,\infty), \mathbb{R}^{n-2} \times \{0\})$. Modifying the dynamics in a small vicinity of y_0 in X, we may assume that y_0 is an equilibrium point for Φ. Hence all results in [63] (proved for compact isolated invariant subsets of $\mathbb{R}^{n-2} \times \{0\}$, the boundary of the half-space $(\mathbb{R}^{n-2} \times [0,\infty))$ translate into results on compact Φ-invariant subsets of $Y \setminus \{y_0\}$.

By Theorem 2 of [63], the homotopical Conley index $I_C(K, \Phi(1,\cdot), X)$ of K with respect to the time-one map of Φ in X is trivial. If $x \in X \setminus Y$ with $\emptyset \neq \alpha(x) \subset K$ for no $x \in X \setminus Y$, then K is also of attracting type, and thus, by Theorem 1 of [63], $I_C(K, \Phi(1,\cdot), X) = I_C(K, \Phi(1,\cdot)|_Y, Y)$. Since the index map is homotopic to the identity, we conclude that, together with $I_C(K, \Phi(1,\cdot)|_Y, Y)$, also $I_C(K, \Phi|_Y, Y)$ is trivial, a contradiction. □

Unfortunately, it is in general very difficult to check whether the homotopical Conley index $I_C(K, \Phi|_Y, Y)$ is nontrivial or not. Note, however, that nontriviality of $I_C(K, \Phi|_Y, Y)$ is a consequence of $I_F(K, \Phi|_Y, Y) \neq 0$, nontriviality of the fixed point index, and that this latter condition can be fairly easily checked [1]. Besides, $I_F(K, \Phi^*|_Y, Y) = (-1)^n I_F(K, \Phi|_Y, Y)$. The time-duality problem for the homotopical Conley index, in particular the question of whether nontriviality of $I_C(K, \Phi^*|_Y, Y)$ is equivalent to the nontriviality of $I_C(K, \Phi|_Y, Y)$, seems to be open. The answer is affirmative on the homology–cohomology level of the Conley index [53].

The following result is a discretization analogue of Theorem 10.1.

THEOREM 10.2. *Let $\emptyset \neq K \subset Y$ be a compact isolated invariant set of repelling type. Let U be an open neighborhood of K in $\mathbb{R}^n_+$ and let $P_K : U \to \mathbb{R}$, $x \to \prod_{i=1}^n x_i^{p_i}$ be a GALF for* (1) *on K. In addition, assume that K is the maximal compact $\Phi|_Y$-invariant set in* $\mathrm{cl}(U) \cap Y$ *and that the cohomological Conley index $i_C(K, \Phi|_Y, Y)$ is*

nontrivial. Finally, let $K_h \subset Y$ denote the maximal compact $\varphi(h,\cdot)|_Y$-invariant set in $\mathrm{cl}(U) \cap Y$. Then, for h sufficiently small, $K_h \neq \emptyset$ and, for some $x_h \in X \setminus Y$ suitably chosen, $\emptyset \neq \alpha_{\varphi(h,\cdot)}(x_h) \subset K_h$.

Proof. If $K = Y$ and h is small enough, then $K_h = Y$ is a repeller for $\varphi(h,\cdot)$ by Theorem 8.3, and the discrete-time version of the Zubov–Ura–Kimura theorem applies.

If $K \neq Y$ and h is small enough, then $i_C(K_h, \varphi(h,\cdot)|_Y, Y) = i_C(K, \Phi|_Y, Y)$ by the main result in Mrozek and Rybakowski [54] (when applied to $Y \setminus \{y_0\}$, which is locally Lipschitz homeomorphic to $\mathbb{R}^{n-2}$ for any $y_0 \in Y \setminus K$). Hence $K_h \neq \emptyset$. On the other hand, $K_h \subset U \cap Y$ by the upper semicontinuity result in [22], h sufficiently small. Furthermore, combining the proofs of Theorems 5.2 and 8.3, it is not hard to show that K_h (as a subset of X) is isolated with respect to $\varphi(h,\cdot)$ and, for each $x \in U \setminus Y$, inclusion $\emptyset \neq \omega_{\varphi(h,\cdot)}(x) \subset K_h$ is impossible. Thus $\emptyset \neq K_h \subset Y$ is a compact isolated $\varphi(h,\cdot)$-invariant set of repelling type and (as a weakening of the nontriviality of the cohomological Conley index $i_C(K_h, \varphi(h,\cdot)|_Y, Y)$), the homotopical Conley index $I_C(K_h, \varphi(h,\cdot)|_Y, Y)$ is nontrivial. Using Theorems 1 and 2 of [63], the desired result follows immediately. □

Discretizations have better topological properties than general discrete-time dynamical systems. For example, they preserve orientation. Near transversal sections, discretizations (for h small enough) embed to continuous-time local dynamical systems [17], [23]. A further nontrivial topological property of discretizations is what we called numerical Wazewski property [22], [18]. In certain applications, as it was pointed out by Conley [12] himself, the classical Wazewski principle is stronger than the index.

Conjecture. *We conjecture that the nontriviality of the cohomological Conley index $i_C(K, \Phi|_Y, Y)$ in Theorem* 10.2 *can be replaced by the following requirement: Assume that B^+ is not a retract of B, where $B \subset U$ is an isolating block with respect to the boundary flow $\Phi|_Y$ for K in Y and B^+ denotes the entry set of B.*

Combining Theorems 1 in [13] and C4 in [22], we find that the conjecture holds true under the additional conditions that K is contained in a single face of Y and B is an isolating block with corners. One of the major difficulties in proving the conjecture is constructing C^∞ Liapunov functions for attractor–repeller pairs on manifolds with corners (such as Y).

11. Applications. In all the previous sections we worked with the simplex as the phase space and noted only that analogous results are valid in $\mathbb{R}^n_+$ for dissipative flows. In the present section we give applications to systems on other phase spaces such as compact smooth manifolds, half-spaces, products of a simplex with a ray, and products of simplices.

Subsection 11.1 is devoted to differential equations near compact smooth codimension 1 submanifolds of $\mathbb{R}^n$. Note that a much deeper codimension $k \geq 1$ analysis, based on Oseledec's theory, is given in [3], [11] for diffeomorphisms. It is an open problem to extend the concept of GALF (which is at present a codimension 1 object) to codimension k problems.

In subsections 11.2 and 11.3 we study robust permanence of replicator and Lotka–Volterra equations. The problem of successful invasion is discussed in subsection 11.4. Subsection 11.5 is devoted to discretized game dynamics with variable stepsizes.

11.1. Manifolds with smooth boundary. Let Ω be a bounded open set in $\mathbb{R}^n$ and assume that $Z = \partial\Omega$ is a compact smooth codimension 1 submanifold of $\mathbb{R}^n$. Let U be an open neighborhood of Z in $\mathbb{R}^n$ and let $F : U \to \mathbb{R}^n$ be a C^1 function. Assume

that Z is invariant with respect to the (local) flow Θ of the ordinary differential equation $\dot{x} = F(x)$, $x \in U$. The set of Θ-invariant Borel probability measures on Z is denoted by $\mathcal{M}_\Theta(Z)$. Finally, for $z \in Z$, let $\nu(z) \in \mathbb{R}^n$ denote the outer normal unit vector of Z at z. It is well known that, for some $\varepsilon > 0$, mapping $(-\varepsilon, \varepsilon) \times Z \to U$, $(\lambda, z) \to x = z + \lambda\nu(z)$ is a coordinate transformation. In this new system of normal and tangential coordinates, $\dot{x} = F(x)$, $x \in U$ can be rewritten as the system $\dot{\lambda} = N(\lambda, z)$, $\dot{z} = T(\lambda, z)$, $(\lambda, z) \in (-\varepsilon, \varepsilon) \times Z$. Since $N(0, z) = 0$ for each $z \in Z$, there exists a continuous function $S : (-\varepsilon, \varepsilon) \times Z \to \mathbb{R}$ satisfying $N(\lambda, z) = \lambda S(\lambda, z)$. With $P(x) = \lambda$ (or, equivalently, $P(x) = \lambda^p$ for any $p > 0$) as GALF and applying (the corresponding analogue, with (X, Y) replaced by $(\mathrm{cl}(\Omega), Z)$, of) Theorem 2.2 and Lemmas 4.1 and 4.2, we obtain the following theorem.

THEOREM 11.1. *If the normal Liapunov exponent*

$$\int_Z S(0, z)\, d\mu > 0 \tag{50}$$

for each (ergodic) $\mu \in \mathcal{M}_\Theta(Z)$, then Z is a repeller for Θ.

It is not hard to compute $S(0, z)$ explicitly:

$$S(0, z) = \sum_{i=1}^{n} \sum_{j=1}^{n} \frac{dF_i}{dx_j}(z) \cdot \nu_j(z) \cdot \nu_i(z) = \langle \nu(z), \mathcal{J}(z)\nu(z) \rangle,$$

where $\mathcal{J}(z)$ denotes the Jacobian of F evaluated at z and $\langle \cdot, \cdot \rangle$ denotes the standard scalar product in $\mathbb{R}^n$.

We note that an analogous result holds for abstract manifolds X with smooth collared boundary $\partial X = Z$. Condition (50) implies via Theorem 3.4 the existence of a Liapunov function in a neighborhood of Z of the form $V(x) = \lambda Q(\lambda, z)$ with Q positive and C^1.

Using Pesin's theory, one can show, as in [3] or [57], that the converse of Theorem 11.1 is "almost" true: If F is C^2 and the reverse inequality holds in (50) for at least one invariant measure $\mu \in \mathcal{M}_\Theta(Z)$ (i.e., at least one normal Liapunov exponent is negative), then the invariant manifold Z attracts at least one orbit from $\Omega \setminus Z$. If F is only C^1, then a weaker converse result can be obtained from the ergodic closing lemma, as in [30], [57]: There are arbitrarily small C^1-perturbations of the flow, with Z as invariant manifold, that have a periodic orbit in Z, which has negative normal Floquet exponent and is therefore normally attracting. Other converse results can be derived from index theory, as used in section 10.

We finally remark that Theorem 11.1 can be applied also to study dissipativity in a suitable compactification of the state space and to investigate critical cases of stability by analyzing homogeneous differential equations that arise as the principal part of normal forms, such as Molchanov's theorem [42]; for details see [21].

11.2. Consequences for replicator equations. The replicator equation (4) on the simplex X enjoys an important averaging principle (see [35, Thm. 7.6.4], [41]), which can be stated in terms of time averages or space averages.

LEMMA 11.2. (1) *Suppose that for $x \in X$, $\omega(x)$ is contained in some (relatively open) face of the simplex. Then every limit point of the time average of this solution,*

$$\lim_{T \to \infty} \frac{1}{T} \int_0^T \Phi(t, x) dt, \tag{51}$$

is an equilibrium point $\bar{x}$ on this face.

(2) *Let $\mu \in \mathcal{M}_{\mathcal{F}}^{E}$ be an ergodic invariant measure for* (4). *Then its mean $\bar{x} = \int x d\mu(x)$ is an equilibrium of* (4), *and the external Liapunov exponents of μ coincide with that at $\bar{x}$.*

A consequence of this averaging property is that in applying Theorem 4.4 for replicator equations one can restrict oneself to (convex combinations of) point measures instead of all invariant measures. Hence a finitely computable sufficient condition for robust permanence can be established. In particular, Corollary 2.4 simplifies to the following result from [35] and [41], but now strengthened with robustness.

THEOREM 11.3. *If there are $p_i > 0$ $(i = 1, \dots, n)$ such that for every fixed point $\bar{x}$ of* (4) *in Y,*

$$p \cdot A\bar{x} > \bar{x} \cdot A\bar{x},$$

then $P(x) = \prod_i x_i^{p_i}$ is a GALF, and hence (4) *is robustly permanent.*

Consider now the discrete-time replicator dynamics

$$(\mathcal{F}(x))_i = x_i \frac{1 + h(Ax)_i}{1 + h\ x \cdot Ax}. \tag{52}$$

Here $h > 0$ is such that $1 + ha_{ij} > 0$ for all i, j. Then the map (52) is a diffeomorphism on X [49]. Another discrete-time replicator dynamics is

$$(\mathcal{F}(x))_i = x_i \frac{e^{h(Ax)_i}}{\sum_j x_j\ e^{h(Ax)_j}}, \tag{53}$$

which is a diffeomorphism for h small and, in contrast to (52), enjoys a similar averaging property to that of (4) [35, p. 79, Ex. 7.6.6]. Note that both (52) and (53) are first order discretization operators of Kolmogorov type for (4), but none of them is of the form of those investigated in Example 7.4 (except for zero-sum games, i.e., $A = -A^T$).

The first part of our next result is a simple consequence of Theorem 8.3, whereas the stronger result in the second part follows from Theorem 6.3 and the averaging property. Finding a finitely computable condition for robust permanence for (52) for arbitrary $h > 0$ is an open problem.

THEOREM 11.4. *Let the assumption of Theorem* 11.3 *hold, i.e., there exists a standard ALF $P(x) = \prod_i x_i^{p_i}$ for the continuous-time replicator dynamics* (4). *Then for small $h > 0$, the discrete-time replicator equation* (52) *is robustly permanent. Similarly, for all $h > 0$, P is also an ALF for* (53), *and hence* (53) *is robustly permanent.*

11.3. Consequences for Lotka–Volterra equations. Lotka–Volterra systems

$$\dot{x}_i = x_i\big(r_i + (Ax)_i\big), \quad x \in \mathbb{R}^n_+, \tag{54}$$

enjoy a similar averaging property to that of Lemma 11.2 for replicator equations. This goes essentially back to Volterra; see [35], [41], [57, Lem. 7.1]. Hence for Lotka–Volterra equations (54) it is sufficient to consider point measures at boundary equilibria when applying our permanence results. In particular, our Theorem 4.4 shows that the sufficient condition in Schreiber's [57, Thm. 7.2] for robust permanence of Lotka–Volterra equations is *equivalent* to the sufficient condition for permanence based on a standard GALF due to Jansen [41] (see also [35, Ex. 13.6.3]):

There are $p_i > 0$ $(i = 1, \dots, n)$ such that for every fixed point $\bar{x}$ of (54) *on* $\partial\mathbb{R}^n_+$,

$$p\cdot(r + A\bar{x}) > 0. \tag{55}$$

Now we turn to discrete-time Lotka–Volterra systems such as a higher-dimensional version of the logistic map,

$$(\mathcal{F}(x))_i = x_i(1 + h(r_i + (Ax)_i)), \tag{56}$$

and an exponential version (see [33] and [50]),

$$(\mathcal{F}(x))_i = x_i e^{h(r_i+(Ax)_i)}. \tag{57}$$

The first part of our next result is a simple consequence of Theorem 8.3, whereas the second part follows from Theorem 6.3 and from the averaging principle in [33].

THEOREM 11.5. *Suppose* (56) *and* (57) *are (robustly) dissipative and* (55) *holds true; i.e., there exists a standard ALF $P(x) = \prod_i x_i^{p_i}$ for* (54). *Then for small $h > 0$,* (56) *is (robustly) permanent. Similarly, for all $h > 0$, P is an ALF for* (57), *which is (robustly) permanent.*

Dissipativity of (57) is discussed in [33] and [50].

As a further application we rederive and strengthen a recent result of Mierczyński and Schreiber [52] on totally permanent Lotka–Volterra systems. They established the equivalence (L2) $\Leftrightarrow$ (L4) with their weaker meaning of robust permanence. Note that (L3) and (L4) are computable conditions.

THEOREM 11.6. *The following conditions are equivalent:*

(L1) *Equation* (54) *as well as all its subsystems are permanent.*

(L2) *Equation* (54) *as well as all its subsystems are robustly permanent.*

(L3) *$-A$ is a P-matrix (i.e., all principal minors of $-A$ are positive) and each (relatively open k-dimensional, $k = 1, 2, \dots, n$) face of $\mathbb{R}^n_+$ contains an equilibrium.*

(L4) *Equation* (54) *is dissipative, each face contains a unique equilibrium, and all its external eigenvalues are positive.*

Proof. Every permanent Lotka–Volterra system has a unique interior equilibrium and $\det(-A) > 0$; see [35, Thms. 13.5.1 and 13.5.2]. Applying this to all subsystems we conclude that (L1) implies (L3). The P-matrix property implies the dissipativity of (54) and also uniqueness of saturated equilibrium; see [35, Thms. 15.2.1 and 15.4.5]. Hence no boundary equilibrium can have an external eigenvalue ≤ 0. This shows (L3) $\Rightarrow$ (L4). Finally (L4) implies (L2) by Corollary 4.6, and (L2) $\Rightarrow$ (L1) is trivial. ∎

11.4. Invasion of a permanent system. Consider a permanent n-species community and a further species which is able to invade that resident community. Will the invader be able to survive, i.e., will the population move towards a new stable community consisting of the invader and a certain subset of the resident population? In the biological literature, e.g., in [66], this question is often phrased as, *Does invasion lead to persistence?*

A positive answer to this question is possible only under stringent assumptions. For example, if in the resident system there are several attractors, and the new species invades at one attractor, it could be driven out again by leading the population to the other attractor. This can be avoided only if all normal Liapunov exponents on the global interior attractor are positive.

Even then, one could imagine that the population evolves to a state where the invader as well as some of the resident species are eliminated. A simple example in two dimensions is the system

$$\dot{x} = x\left(x(1-x) - y\right),$$
$$\dot{y} = y(x-y).$$

The density of the invading species y increases near the resident equilibrium $x = 1, y = 0$. But every interior solution converges to the origin: $\frac{y}{x}$ increases monotonically, and for $y > x$, y decreases. However, this dynamics is degenerate, since the origin is not hyperbolic. If the resident system is robustly permanent (thanks to a GALF), this extinction phenomenon cannot occur. This is the essence of the next theorem, which generalizes an analogous result on Lotka–Volterra equations in [32].

THEOREM 11.7. *We consider a system of n resident species on $X = \mathbb{R}^n_+$ and an invader whose density we denote by $y \geq 0$,*

$$\dot{x}_i = x_i f_i(x, y), \tag{58}$$
$$\dot{y} = y g(x, y) \tag{59}$$

on the augmented state space $X' = \mathbb{R}^n_+ \times \mathbb{R}_+$. We identify X with the subsystem $X \times \{0\}$ of X' and assume that (58)–(59) give rise to a dissipative dynamical system $\Theta = (\Phi, \Psi) : \mathbb{R} \times X' \to X' = X \times \mathbb{R}_+$. In addition, assume there exists a GALF for the resident system (58) with $y = 0$ which is therefore robustly permanent. Finally, assume that the global attractor $\mathcal{A} \subset \operatorname{int} X$ of (58) is nonsaturated in the sense that

$$\int_{\mathcal{A}} g(x,0)\, d\mu_x > 0 \qquad \text{for each} \quad \mu_x \in \mathcal{M}_\Theta(\mathcal{A}). \tag{60}$$

Then

$$\limsup_{t\to\infty} \Psi(t, x, y) > 0 \qquad \text{for all } (x, y) \in \operatorname{int} X'.$$

Proof. To the contrary, suppose that $\Psi(t, z, w) \to 0$ for some $(z, w) \in \operatorname{int} X'$. Hence $\emptyset \neq \omega_\Theta(z, w) \subset X$. Actually, since $(\mathcal{A}, \partial X)$ is an attractor–repeller decomposition of the resident system, $\omega_\Theta(z, w) \subset \mathcal{A}$ or $\omega_\Theta(z, w) \subset \partial X = Y$. Combining Theorems 5.3 and 5.2, condition (60) implies that the first inclusion is impossible. Hence $\omega_\Theta(z, w) \subset Y$.

Consider now the GALF $P : X \to \mathbb{R}$ and observe for each $t \in \mathbb{R}$ that

$$\frac{d}{dt}\log(P(\Phi(t, z, w))) = \sum_{i=1}^{n} p_i(\Phi(t, z, w)) f_i(\Phi(t, z, w), \Psi(t, z, w)).$$

Integrating between 0 and T yields

$$\frac{1}{T}\log\left(\frac{P(\Phi(T, z, w))}{P(z)}\right) = \frac{1}{T}\int_0^T \sum_{i=1}^{n} p_i(\Phi(t, z, w)) f_i(\Theta(t, z, w))\, dt. \tag{61}$$

Since $\Phi(t, z, w)$ approaches Y, $P(\Phi(T, z, w)) \to 0$ as $T \to \infty$. Thus each limit point of the left-hand side of (61) is ≤ 0. On the other hand, property $\Psi(T, z, w) \to 0$, the GALF assumption, Lemma 4.2, and the robustness arguments in the proof of

Theorem 2.2 imply that every limit point as $T \to \infty$ on the right-hand side is positive. This is a contradiction. □

An obvious drawback of Theorem 11.7 is that only positivity of the limsup can be guaranteed. However, one cannot do better in general: It is easy to construct examples with $\liminf_{t\to\infty} \Psi(t,x,y) = 0$. Consider (58)–(59) on $X' = \mathbb{R}^4_+$ with three resident species (1,2,3). Suppose, that the invader eliminates resident species 3 and forms together with 1 and 2 a system with an attracting heteroclinic cycle, such as in Example 2.6. Then $\limsup_{t\to\infty} \Psi(t,x,y) > 0$ but $\liminf_{t\to\infty} \Psi(t,x,y) = 0$. Moreover, the invader gets arbitrarily close to 0 for arbitrarily long times. Hence, practically, the invader is not safe from extinction. This example shows that information on the global dynamics of the full system (58)–(59) is needed to guarantee persistence after invasion.

11.5. Discretizations and diminishing stepsizes. Hofbauer and Schlag [34] studied imitation dynamics for two-person (bimatrix) games. These led to recurrence relations of the following form ($k = 0, 1, \dots$):

$$\begin{aligned} p_i^{k+1} &= p_i^k \left(1 + h f_i\left(p^k, q^k\right)\right), \\ q_j^{k+1} &= q_j^k \left(1 + h g_j\left(p^k, q^k\right)\right). \end{aligned} \tag{62}$$

Here the state space X is a product of two simplices, $X = X_n \times X_m \subseteq \mathbb{R}^n_+ \times \mathbb{R}^m_+$, and $f_i, g_j : X_n \times X_m \to \mathbb{R}$ ($1 \le i \le n$, $1 \le j \le m$) are appropriately chosen functions such that $(p^k, q^k) \mapsto (p^{k+1}, q^{k+1})$ defines a map from $X_n \times X_n$ into itself. In the limit $h \to 0$ these discrete-time models tend to the differential equation

$$\begin{aligned} \dot{p}_i &= p_i f_i(p,q), \\ \dot{q}_j &= q_j g_j(p,q). \end{aligned} \tag{63}$$

The functions f_i, g_j are given by

$$\begin{aligned} f_i(p,q) &= (\pi^1(i,q) - \pi^1(p,q))\phi^1(\pi^1(p,q)), \\ g_j(p,q) &= (\pi^2(p,j) - \pi^2(p,q))\phi^2(\pi^2(p,q)), \end{aligned} \tag{64}$$

where π^1, π^2 are the payoff functions for the two players, and ϕ^i are strictly decreasing functions with positive values.

For $n = m = 2$, i.e., each of the two players has two pure strategies, X is simply the square $[0,1]^2$. Of particular interest are games with a cyclic structure: For these games, the boundary of the square, Y, forms a heteroclinic cycle for the dynamics (62) and (63). They have a unique Nash equilibrium E which lies in the interior of X and which has been shown [34, Thm. 1] to be globally asymptotically stable for (63); i.e., E is the dual attractor to the repeller Y. Furthermore, there exists a standard GALF for (63), so that Y is a robust repeller.

For small enough $h \in (0, h_0)$ (h_0 being the minimal slope of the reciprocal of ϕ^i), the map (62) still has a standard GALF, so that Y remains a robust repeller; see [34, Prop. 1]. The dual attractor, $\mathcal{A}_h$, contains E (which is unstable for the maps [34, Prop. 3]) as proper subset.

Combining now Theorem 8.3 and the upper semicontinuity result [20] for the attractor–repeller pair (E, Y) of (63) shows that for small enough $h > 0$, the numerical attractor $\mathcal{A}_h$ arising from E attracts all of the interior of the square X, i.e., is dual to the robust repeller Y. This confirms the conjecture in [34, p. 535, footnote 4].

On the other hand, if instead of a constant stepsize h a decreasing sequence of stepsizes satisfying $h_k \to 0$ and $\sum h_k = \infty$ is chosen in (62), then every orbit starting

in the interior of the square converges to the equilibrium E. This conjecture from [34, p. 539 and footnote 9] follows now from the permanence result in Theorem 9.3 above, Lemma 4 from [20] (or Benaim and Hirsch [6]), and the attractor–repellor decomposition (E, Y) for the limiting differential equation (63).

FINITE-DIMENSIONAL ATTRACTORS AND EXPONENTIAL ATTRACTORS FOR THE NAVIER–STOKES EQUATIONS OF COMPRESSIBLE FLOW*

DAVID HOFF† AND MOHAMMED ZIANE‡

Abstract. We prove that the uniform attractor for the Navier–Stokes equations of compressible flow with quasi-periodic external forces has finite fractal dimension. As a byproduct of our analysis, we also obtain the existence of finite-dimensional *exponential* attractors for the Navier–Stokes system.

Key words. Navier–Stokes equations, compressible flow, exponential attractors

AMS subject classifications. 35Q30, 35B41, 76N10

PII. S0036141002400889

1. Introduction. We prove the finite dimensionality of the compact attractor obtained in [11], as well as the existence of finite-dimensional exponential attractors, for the Navier–Stokes equations of compressible fluid flow in one space dimension,

$$\begin{cases} \rho_t + (\rho u)_x = 0, \\ (\rho u)_t + (\rho u^2)_x + P(\rho)_x = \varepsilon u_{xx} + \rho f, \qquad 0 < x < L, \end{cases} \tag{1.1}$$

with boundary and initial conditions

$$\begin{cases} u(0,t) = u(L,t) = 0, \\ (\rho, u)(\cdot, 0) = (\rho_0, u_0), \\ \displaystyle\int_0^L \rho_0 \, dx = M. \end{cases} \tag{1.2}$$

Here $\rho(x,t)$ and $u(x,t)$ are the density and fluid velocity, $P(\rho) = c^2\rho$ is the isothermal pressure, ε is a viscosity constant, and $f = f(x,t)$ is a time-dependent external force. The attractor, which is determined by the force f, is the smallest closed set in (ρ, u) space which is invariant for the flow and which attracts all trajectories as time goes to infinity. The exponential attractor is a compact, positively invariant subset of (ρ, u) space which contains the attractor, which attracts all trajectories exponentially in time, and which has finite fractal dimension. Precise definitions of the uniform and exponential attractors are given in Definitions 3.1 and 3.2, and the fractal dimension is defined, for example, in [17].

In [10] and [11] we gave a complete global existence, uniqueness, continuous dependence, and regularity theory for solutions of (1.1)–(1.2), obtaining *time-independent* estimates for solutions with large, discontinuous initial data and large external forces. We found, however, that, due to the persistence of singularities in solutions, continuous dependence on initial data would not hold in any reasonable topology which dominates the sup norm of ρ. We therefore constructed the attractor in a reduced

phase space $Y \times X_u$, where $X_u = L^2$ and Y is the set of positive BV densities ρ for which the Lebesgue decomposition of the distribution ρ_x has a singular part consisting of a countable sum of point masses and an absolutely continuous part in L^2. We let $\mathcal{U}_f(t,\tau)$ be the semiprocess on the phase space $Y \times X_u$ defined by taking $\mathcal{U}_f(t,\tau)(\rho_0,u_0)$ to be the solution of (1.1)–(1.2) with force f and initial condition (ρ_0,u_0) imposed at time τ. Then assuming that f belongs to a compact subset Σ of $W^{1,\infty}([0,\infty);\, L^2) \cap L^\infty([0,\infty); W^{1,\infty})$ and that there exists a continuous family of translation operators $\mathcal{T} :\ \Sigma \mapsto \Sigma$, we proved the continuity and asymptotic compactness properties required for the existence of a uniform compact attractor $\mathcal{A}_\Sigma \subset Y \times X_u$, and we showed that $\mathcal{A}_\Sigma$ is a compact subset of $H^1 \times H^1_0$ and is contained in $H^1 \times H^2 \cap H^1_0$. Finally, we proved that the attractor is characterized by a finite number of so-called determining nodes, but the question of finite dimensionality of the attractor was left open.

The purpose of the present paper is therefore to establish that, for quasi-periodic external forces, the uniform attractor $\mathcal{A}_\Sigma$ obtained in [11] does in fact have finite fractal dimension. As a byproduct of our analysis, we will also obtain the existence of finite-dimensional *exponential* attractors for the Navier–Stokes system.

Our specific assumptions on the external force f are as follows: Let $\mathcal{C}^1_b(\mathbb{R}; W^{1,\infty}([0,1]))$ be the set of bounded functions with bounded first derivatives, and assume that

$$
\begin{aligned}
&f \in \mathcal{C}^1_b(\mathbb{R}; W^{1,\infty}([0,1])), \quad f(\cdot,t) = \tilde{f}(\cdot,\alpha_1 t,\dots,\alpha_N t),\\
&\text{where } \alpha_1,\dots,\alpha_N \text{ are rationally independent, and} \qquad (1.3)\\
&\tilde{f}(\cdot,\omega_1,\dots,\omega_N) \text{ is } 2\pi\text{-periodic in each argument } \omega_i,\ i = 1,\dots,N.
\end{aligned}
$$

We fix $\tilde{f}$ and denote by Σ the set of forces f satisfying the above conditions. This set Σ will be fixed throughout the paper and is a particular realization of the more general classes Σ for which global attractors were constructed in [11].

We shall show that the uniform attractor $\mathcal{A}_\Sigma$ has finite fractal dimension with respect to $H^r \times H^r_0$ for a particular $r \in (0,1)$. This means that the balls which are counted in coverings of $\mathcal{A}_\Sigma$ are chosen in the topology of $H^r \times H^r_0$. We also recall a classical result of Mañe [13], who proves that any metric space with fractal dimension less than $m_0/2$ can be embedded in $\mathbb{R}^{m_0}$ with a Lipschitz function whose inverse is Hölder continuous (see [8]). Consequently, the uniform attractor $\mathcal{A}_\Sigma$ for the Navier–Stokes system (1.1)–(1.2) can be embedded in $\mathbb{R}^{m_0}$ for some m_0 depending on the size of the force and the constants appearing in the equations.

The following theorem contains the main results of this paper.

THEOREM 1.1. *The Navier–Stokes system* (1.1)–(1.2) *with external force f satisfying* (1.3) *and with data in the phase space $Y \times X_u$ (of discontinuous functions) has a uniform attractor $\mathcal{A}_\Sigma$ which is compact in $H^1 \times H^1_0$ and which has finite fractal dimension with respect to the $H^r \times H^r_0$-topology for some $r \in (0,1)$. The fractal dimension is bounded above by a constant depending only on N, ε, L, M, and the size of the force. In addition, there exists a compact set $\mathcal{M}_\Sigma$ in $H^1 \times H^1_0$ which is positively invariant under the family of semiprocesses $\mathcal{U}_f(t,\tau)$, contains the attractor $\mathcal{A}_\Sigma$, has finite fractal dimension with respect to the $H^r \times H^r_0$-topology, and has the property that trajectories of solutions starting at initial points in $(Y \times X_u) \cap (H^1 \times H^1_0)$ converge exponentially as time goes to infinity to $\mathcal{M}_\Sigma$ in the topology of $H^r \times H^r_0$.*

We now give a brief outline of the ideas in the proof of Theorem 1.1. First, following [3], we imbed the Navier–Stokes equations (1.1)–(1.2) in a family of equations depending on a parameter σ in the N-dimensional torus $\mathbb{T}^N$, now taking $f(\cdot,t) =$

$\tilde f(\cdot,\omega(t))$, where $\omega(t) = (\alpha t + \sigma)(\mathrm{mod}\ \mathbb{T}^N)$ and $\alpha = (\alpha_1,\dots,\alpha_N)$. The set of such forces is thus parameterized by σ, and the associated processes will now be denoted by $\mathcal{U}_\sigma(t,\tau)$. That is, $\mathcal{U}_\sigma(t,\tau) = \mathcal{U}_f(t,\tau)$ for $f(\cdot,t) = \tilde f(\cdot,\alpha t + \sigma(\mathrm{mod}\mathbb{T}^N))$. To the family $\mathcal{U}_\sigma(t,\tau)$ of semiprocesses we associate the operator $S(t)$ defined by

$$\begin{aligned} &S(t) : (Y\times X_u)\times\mathbb{T}^N \to (Y\times X_u)\times\mathbb{T}^N,\\ &\qquad (\rho,u;\sigma)\mapsto S(t)(\rho,u;\sigma) = (\mathcal{U}_\sigma(t,0)(\rho,u);(\alpha t+\sigma)(\mathrm{mod}\ \mathbb{T}^N)). \end{aligned} \tag{1.4}$$

The set of operators $S(t)$ thus forms a semigroup on $Y\times X_u\times\mathbb{T}^N$. In [11] we showed that this semigroup has a *global* attractor $\mathcal{A}$ (see Definition 3.4 below) which is compact in $H^1\times H^1_0\times\mathbb{T}^N$, and hence compact in $Y\times X_u\times\mathbb{T}^N$. The *uniform* attractor $\mathcal{A}_\Sigma$ referred to in Theorem 1.1 associated with the family $\mathcal{U}_\sigma(t,\tau)$ is then obtained by projecting the global attractor $\mathcal{A}$ onto $Y\times X_u$. Thus if $\mathcal{A}$ has finite fractal dimension, then so does $\mathcal{A}_\Sigma$.

One standard approach to finite dimensionality is through the Kaplan–Yorke trace formula, which requires time-independent bounds for solutions of the system obtained by linearizing about a trajectory in the attractor. As we pointed out in [11], however, such bounds appear to be unavailable for these particular equations. We shall instead prove that $\mathcal{A}_\Sigma$ and $\mathcal{A}$ have finite fractal dimension by applying the following result of Ladyzhenskaya [12].

LEMMA 1.2. *Let M be a subset of a Hilbert space H and assume that M is invariant under a map $S : M\mapsto H$, that is, that $M = S(M)$. Assume also that there is a positive integer n and constants $C>0$ and $\delta\in(0,1)$ such that, for any two points w_1, w_2 in the set M,*

$$||S(w_1)-S(w_2)||_H \le C||w_1-w_2||_H, \tag{1.5}$$

$$||Q_nS(w_1)-Q_nS(w_2)||_H \le \delta||w_1-w_2||_H, \tag{1.6}$$

where Q_n is the projector onto a subspace of H of codimension n. Then the set M has finite fractal dimension bounded by a constant $d(C,\delta)n$, which is proportional to n.

We shall apply this result with $H = H^r\times H^r\times\mathbb{T}^N$ for a particular $r\in(0,1)$, $M=\mathcal{A}$, and $S = S(t^*)$, where t^* is large. To verify the hypotheses (1.5) and (1.6) we apply a decomposition method introduced in [2]. Specifically, we shall show that, for $w_1, w_2\in H$, there is a decomposition $S(t)w_1 - S(t)w_2 = W^I(t) + W^{II}(t)$, with W^I satisfying

$$|W^I(t)|_{H^r\times H^r_0\times\Sigma} \le K_0e^{-\nu_1 t}|w_1-w_2|_{H^r\times H^r_0\times\Sigma} \tag{1.7}$$

for positive constants ν_1 and K_0 depending only on the size of the attractor, and W^{II} satisfying

$$|W^{II}(t)|_{H^1\times H^1_0\times\Sigma} \le K_0e^{\nu_2 t}|w_1-w_2|_{H^r\times H^r_0\times\Sigma}. \tag{1.8}$$

We let V_n be the vector space generated by $\{e^{2k\pi ix/L}\}_{|k|\le n}$ and take Q_n to be the projector onto the orthogonal complement of $V_n\times V_n\times\mathbb{T}^n$ in $H^1\times H^1_0\times\mathbb{T}^N$. Then by (1.8),

$$|Q_nW^{II}(t)|_{H^r\times H^r_0\times\Sigma} \le \frac{C}{n^{1-r}}|W^{II}(t)|_{H^1\times H^1_0\times\Sigma} \le \frac{CK_0}{n^{1-r}}e^{\nu_2 t}|w_1-w_2|_{H^r\times H^r_0\times\Sigma} \tag{1.9}$$

for a constant C. The coefficients on the right-hand sides of (1.7) and (1.9) can then be made arbitrarily small by choosing $t = t^*$ sufficiently large, then n sufficiently large depending on t^*. This proves (1.6), and (1.5) is easy to check; the finite dimensionality of $\mathcal{A}$, and hence of $\mathcal{A}_\Sigma$, then follows.

This same decomposition can also be applied to show that the semigroup $S(t)$ satisfies the so-called squeezing property, and that this squeezing property implies the existence of exponential attractors, as described in the statement of Theorem 1.1. Since the exponential attractor has finite fractal dimension and contains the uniform attractor, its existence affords a second (though not unrelated) proof that the uniform attractor has finite fractal dimension.

The main contribution of the present paper is therefore the construction of the decomposition $S(t)w_1 - S(t)w_2 = W^I(t) + W^{II}(t)$ and the derivation of its essential properties. This decomposition is rather complicated, even for the relatively simple system (1.1)–(1.2) (see the description in section 3.2), and the analysis leading to the required bounds (1.7) and (1.8) is based on a fairly involved sequence of energy estimates for L^2 and H^1 norms, together with a Riesz–Thorin interpolation argument for the intermediate H^r norms.

This paper is organized as follows. First, in section 2 we recall the results of [11] concerning the existence, uniqueness, and continuous dependence of solutions of the system (1.1)–(1.2) (but only for relatively smooth initial data, which is all that is required here), as well as results establishing the existence of the attractor $\mathcal{A}_\Sigma$. We also derive several higher-order regularity estimates which were not given in [11] but which will be needed here. In section 3.1 we describe the abstract framework in which the proof of Theorem 1.1 will be given, including precise definitions of uniform and exponential attractors and statements of known results concerning the squeezing property and the related decomposition of the semigroup. In section 3.2 we construct this decomposition for the particular semigroup associated with the solution operator of (1.1)–(1.2) and then apply the abstract results of section 3.1 to complete the proof of Theorem 1.1. The essential properties of this decomposition are stated and applied in section 3.2, but the derivations, which are rather long and technical, are deferred to section 4.

Existence and regularity of solutions of the Navier–Stokes equations (1.1)–(1.2) in one space dimension have been studied by a great many authors. See the references in [11], for example, for a representative list. The unique feature of the existence theory of [11] is that solutions are constructed satisfying *time-independent* estimates, even with large external forces and large, discontinuous initial data. This, together with the uniqueness and continuous dependence results of [11], makes an attractor theory both possible and interesting. A corresponding well-posedness theory for the case of several space variables is not yet available, however, so that an attractor theory, at least in the sense of the present paper, is not yet feasible. On the other hand, there is a weaker notion of attractor, whose existence does not depend on uniqueness and continuous dependence, and which has been shown to exist for the Navier–Stokes equations in three space dimensions; see Feireisl [7].

The notion of exponential attractor was introduced in [4], and the overall approach of the present paper has also been applied successfully in a number of other contexts. See, for example, [6], [9], [14], and [15].

2. Preliminaries. In this section we recall the results of [10] and [11] concerning the existence and regularity properties of solutions of (1.1)–(1.2) and the existence of the global and uniform attractors. We also derive several additional higher-order regularity estimates required for the analysis in sections 3 and 4.

First we write the Navier–Stokes equations of compressible fluid flow in one space dimension in nondimensional form:

$$\begin{cases} \rho_t + (\rho u)_x = 0, \\ (\rho u)_t + (\rho u^2)_x + A^2 \rho_x = u_{xx} + \rho f \ , \quad 0 < x < 1, \\ u(0,t) = u(1,t) = 0, \\ (\rho, u)(\cdot, 0) = (\rho_0, u_0), \\ \displaystyle\int_0^1 \rho_0 \ dx = 1, \end{cases} \tag{2.1}$$

where A is the dimensionless constant $A = cM/\varepsilon$.

We say that (ρ, u) is a weak solution of (2.1) on $[0,T]$ provided that

$$(\rho, u) \ \in \ C([0,T];\ L^2([0,1])) \text{ with } (\rho, u)(\cdot, 0) = (\rho_0, u_0), \tag{2.2}$$

$$u \ \in \ C((0,T];\ H_0^1([0,1])), \tag{2.3}$$

$$\rho \ \in \ L^\infty([0,1] \times [0,T]) \quad \text{and} \quad \rho > 0 \text{ a.e.;} \tag{2.4}$$

for test functions $\varphi \ \in \ C^1([0,1] \times [0,T])$ and for times $t_1, t_2 \ \in [0,T]$,

$$\int_0^1 (\rho\varphi)(x,\cdot) dx \ \Big|_{t_1}^{t_2} - \int_{t_1}^{t_2} \int_0^1 (\rho\varphi_t + \rho u \varphi_x) dx dt = 0; \tag{2.5}$$

and for $\psi \ \in \ C^1([0,1] \times [0,T])$ with $\psi(0,t) = \psi(1,t) = 0$,

$$\begin{aligned} &\int_0^1 (\rho u \psi)(x,\cdot) dx \ \Big|_{t_1}^{t_2} - \int_{t_1}^{t_2} \int_0^1 (\rho u \psi_t + \rho u^2 \psi_x + A^2 \rho \psi_x) dx dt \\ &\qquad = \int_{t_1}^{t_2} \int_0^1 (-u_x \psi_x + \rho f \psi) dx dt \,. \end{aligned} \tag{2.6}$$

We define

$$G(\rho) = \rho \log \rho - \rho + 1, \tag{2.7}$$

and for weak solutions (ρ, u) of (2.1) with ρ in H^1,

$$H(\rho, u) = \int_0^1 \left[\tfrac{1}{6} \ \rho u^2 + A^2 G(\rho) + \tfrac{1}{16} \ \frac{\rho_x^2}{\rho^3} \right] dx. \tag{2.8}$$

($H(\rho, u)$ is thus a function of t.) We shall denote the usual norm in $L^2([0,1])$ by $|\cdot|$.

The following theorem gives a version of the existence, uniqueness, and regularity theory of [10] and [11] for the special case that the initial density is in H^1.

THEOREM 2.1. (a) *Given positive constants C_0 and C_Σ, arbitrarily large, there is a constant $C = C(C_0, C_\Sigma, A)$ such that if $f \in W^{1,\infty}([0,\infty); L^2)$ with*

$$\sup_{t \geq 0} [|f(\cdot,t)| + |f_t(\cdot,t)|] \ \leq C_\Sigma, \tag{2.9}$$

and if (ρ_0, u_0) satisfies $\rho_0 > 0$ a.e., $\rho_0, \rho_0^{-1} \in L^\infty$, $\int_0^1 \rho_0 \ dx = 1$, and

$$H(\rho_0, u_0) \leq C_0, \tag{2.10}$$

then there is a unique global weak solution of (2.1) *satisfying* (2.2)–(2.6)*, as well as*

$$H(\rho(\cdot,t),u(\cdot,t)) \le C, \quad t \ge 0, \tag{2.11}$$

$$|u(\cdot,t)| + (1\wedge t)^{1/2}|u_x(\cdot,t)| + (1\wedge t)|u_t(\cdot,t)| \le C, \quad t>0, \tag{2.12}$$

(*where* $1\wedge t \equiv \min\{1,t\}$)*, and*

$$\int_t^{t+1}\int_0^1 [u_x^2 + (1\wedge s)u_t^2 + (1\wedge s)^2 u_{xt}^2]dxds \ \le C, \quad t>0. \tag{2.13}$$

(b) *There is a constant* K_f*, depending only on* C_Σ *and on* A*, such that, given constants* C_0 *and* τ*, there is a time* $T = T(C_0, C_\Sigma, \tau, A)$*, so that if* (ρ,u) *is a weak solution of* (2.1) *with force* f*, satisfying* (2.9)–(2.13) *with constants* C_0, C_Σ*, then for* $t \ge T$*,*

$$H(\rho(\cdot,t),u(\cdot,t)) \le K_f. \tag{2.14}$$

(c) *The solution transforms to Lagrangian coordinates: that is, if we define the Lagrangian coordinate*

$$h(x,t) = \int_0^x \rho(s,t)ds,$$

its inverse $\Phi(h,t)$*, given by*

$$\Phi(h(x,t),t) = x,$$

and functions

$$\begin{aligned} v(h,t) &= \rho(\Phi(h,t),t)^{-1},\\ w(h,t) &= u(\Phi(h,t),t), \end{aligned} \tag{2.15}$$

then (v,w) *is a weak solution of the corresponding system*

$$\begin{cases} v_t - w_h = 0\\ w_t + (A^2 v^{-1})_h = \left(\dfrac{w_h}{v}\right)_h + f\circ\Phi\ , \quad 0<h<1,\\ w(0,t) = w(1,t) = 0. \end{cases} \tag{2.16}$$

For the sake of simplicity, in this paper we will use the Lagrangian formulation and assume throughout that u_τ and v_τ are given and satisfy

$$u_\tau \in L^2, \quad v_\tau \in H^1 \quad \text{with} \quad v_\tau > 0,\ v_\tau \in L^\infty, \tag{2.17}$$

and that the force f satisfies $f \in C_b^1(\mathbb{R}^+; L^2)$. Furthermore, we will assume that f is quasi-periodic in time. More precisely

$$f(\cdot,t) = \tilde f(\cdot, \alpha_1 t, \dots, \alpha_N t), \tag{2.18}$$

where $\tilde{f}(\cdot,\omega_1,\dots,\omega_N)$ is 2π-periodic in each argument ω_i and the α_i are rationally independent. We now replace h by x and rewrite the Navier–Stokes equations in Lagrangian coordinates

$$v_t = u_x, \tag{2.19}$$

$$u_t + A^2\big(v^{-1}\big)_x = \Big(\frac{u_x}{v}\Big)_x + f(\Phi(x,t),t), \tag{2.20}$$

with the boundary conditions

$$u(0,t) = u(1,t) = 0, \quad \int_0^1 v(x,t)\,dx = 1 \tag{2.21}$$

and initial data, given at time $t = \tau$,

$$u(x,\tau) = u_\tau, \quad v(x,\tau) = v_\tau. \tag{2.22}$$

We have the following as a consequence of Theorem 2.1.

THEOREM 2.2. *Let C_0 and C_Σ be two positive constants, arbitrarily large. Then there exist positive constants a_0, b_1, α, β depending on C_Σ and A such that if $f \in W^{1,\infty}(\mathbb{R}_+, L^2)$ is given satisfying $\|f\|_{W^{1,\infty}(\mathbb{R}_+,L^2)} \le C_\Sigma$, and if initial data (v_τ, u_τ) is given satisfying $v_\tau > 0$, $\int_0^1 v_\tau(x)dx = 1$, and*

$$|u_\tau| + |(v_\tau)_x| + |{v_\tau}^{-1}|_{L^\infty} \le C_0, \tag{2.23}$$

then there exists a unique global weak solution (v,u) satisfying

$$v \in C([\tau,\infty); H^1), \quad v(\cdot,\tau) = v_\tau, \quad v(\cdot,t) > 0,\ t \ge \tau, \tag{2.24}$$

$$u \in C([\tau,\infty); L^2) \cap C((\tau,\infty); H^2 \cap H_0^1); \quad u(\cdot,\tau) = u_\tau. \tag{2.25}$$

Furthermore, there exists $T_0 = T_0(C_0, C_\Sigma, A)$ such that, for $t - \tau \ge T_0$, we have

$$|u(\cdot,t)|^2 \le a_0^2, \quad \int_t^{t+1} |u_x|^2 ds \le b_1^2, \quad |v_x(\cdot,t)| \le \beta, \quad \frac{1}{\alpha} \le v(x,t) \le \alpha. \tag{2.26}$$

Thus if we define $\mathcal{B} \subset H^1 \times H_0^1$ to be the set of (v,u) satisfying (2.26) *(so that $\mathcal{B}$ is determined solely by C_Σ and A), then given C_0, there is a time T_0 depending only on C_0, C_Σ, and A such that if $(v(\cdot,t),u(\cdot,t))$ is the solution of* (2.19)–(2.22) *with initial data (v_τ,u_τ) satisfying the conditions $v_\tau > 0$, $\int_0^t v_\tau(x)dx = 1$, and* (2.23)*, then $(v(\cdot,t),u(\cdot,t)) \in \mathcal{B}$ for $t \ge T_0(C_0, C_\Sigma, A)$.*

The set $\mathcal{B}$ is called the absorbing ball. It is the first indication of a dissipative mechanism for the compressible Navier–Stokes equations. Its existence, together with the asymptotic compactness property of the solution operator, leads to the existence of the uniform attractor; see [10] and [11] for more details. Theorem 2.2 allows us to define a family of semiprocesses $\{\mathcal{U}_f(t,\tau)\}_{t\ge\tau\ge 0}$ on the set $\mathcal{X} = \{(v,u) \in H^1 \times L^2, v > 0, v^{-1} \in L^\infty\}$ as follows:

$$\begin{aligned} &\mathcal{U}_f(t,\tau)\colon\ \mathcal{X} \to \mathcal{X}, \\ &\qquad (v,u) \mapsto \mathcal{U}_f(t,\tau)(v,u) = (v(\cdot,t), u(\cdot,t)), \end{aligned} \tag{2.27}$$

where $(v(\cdot,t),u(\cdot,t))$ is the solution of (2.19)–(2.22) at time t with initial data (v,u) given at time τ.

We also established in [10, 11], using Theorem 2.2, the existence of the uniform attractor for the family of semiprocesses $\{\mathcal{U}_f(t,\tau)\}$. The precise statement is as follows.

THEOREM 2.3. *Let C_Σ and A be as in Theorem 2.2. Then there is a set $\mathcal{A}$ which is compact in $H^1 \times H_0^1 \times \Sigma$, which is invariant under $S(t)$, and which attracts all trajectories $S(t)w_0$ for $w_0 \in \mathcal{X} \times \Sigma$ in the topology of $H^1 \times H_0^1 \times \Sigma$. The projection of $\mathcal{A}$ onto $H^1 \times H_0^1$ is compact in the topology of $H^1 \times H_0^1$, is positively invariant under the family of semiprocesses $\mathcal{U}_f(t,\tau)$, and is uniformly attracting in the sense that, for all bounded sets $B \subset \mathcal{X}$,*

$$\lim_{t\to\infty} \sup_{f\in\Sigma} \operatorname{dist}_{\mathcal{X}}(\mathcal{U}_f(t,\tau)B, \mathcal{A}_\Sigma) = 0 \qquad \forall\ \tau \geq 0. \tag{2.28}$$

The sets $\mathcal{A}$ and $\mathcal{A}_\Sigma$ are, respectively, the global attractor for the semigroup $S(t)$ and the uniform attractor for the family of semiprocesses $\mathcal{U}$; see section 3 for more formal definitions.

The remainder of this section is devoted to obtaining uniform estimates on some higher derivatives of the solution of (2.19)–(2.22). In deriving these estimates, we will make use of the uniform Gronwall lemma (see [17, page 89]): if $g,\ h$, and y are three positive locally integrable function on (t_0,∞) such that $\frac{dy}{dt} \leq gy + h$ for $t \geq t_0$, and if

$$\int_t^{t+1} g(s)\,ds \leq k_1, \quad \int_t^{t+1} h(s)\,ds \leq k_2, \quad \int_t^{t+1} y(s)\,ds \leq k_3 \quad \text{for } t \geq t_0,$$

where $k_1,\ k_2,\ k_3$ are positive constants, then

$$y(t+1) \leq (k_2 + k_3)\exp(k_1) \quad \text{for } t \geq t_0 + 1.$$

(i) Uniform estimates on $|u_x|$. We multiply (2.20) by u_{xx} and integrate with respect to x to obtain

$$\frac{1}{2}\frac{d}{dt}|u_x|^2 + \int_0^1 \frac{{u_{xx}}^2}{v}\,dx = \int_0^1 \frac{u_x u_{xx} v_x}{v^2}\,dx - A^2\int_0^1 \frac{v_x}{v^2}u_{xx}\,dx - \int_0^1 f u_{xx}\,dx, \tag{2.29}$$

and thanks to (2.26), we obtain

$$\frac{d}{dt}|u_x|^2 + \frac{1}{\alpha}|u_{xx}|^2 \leq C\alpha^{11}\beta^4|u_x|^2 + CA^4\alpha^5\beta^2 + C\alpha C_\Sigma^2, \tag{2.30}$$

where C will denote here and throughout this paper a numerical constant. Therefore, by the uniform Gronwall lemma and (2.13), we obtain

$$|u_x(\cdot,t)|^2 \leq a_1^2 \quad \text{and} \quad \int_t^{t+1} |u_{xx}|^2 ds \leq b_2^2 \quad \text{for } t - \tau \geq T_0 + 1, \tag{2.31}$$

where

$$a_1^2 = \left[b_1^2 + A^4\alpha^5\beta^2 + \alpha C_\Sigma^2\right]\exp(C\alpha^{11}\beta^4), \tag{2.32}$$

$$b_2^2 = C(\alpha^{12}\beta^4 b_1^2 + A^4\alpha^6\beta^2 + \alpha^2 C_\Sigma^2) + 2\alpha a_1^2. \tag{2.33}$$

Furthermore, using (2.20), we have

$$|u_t|^2 \leq 2A^4\alpha^4|v_x|^2 + 2|u_{xx}|^2\alpha^2 + 2\alpha^2|u_x||u_{xx}||v_x|^2 + 2C_\Sigma^2. \tag{2.34}$$

Therefore

$$\int_t^{t+1} |u_t|^2\,ds \le 2(A^4\alpha^4\beta^2 + b_2^2 + \alpha^2 b_2^2 + 2\alpha^4\beta^2 b_1 b_2) + 2C_\Sigma^2 = b_3^2. \tag{2.35}$$

(ii) Estimates on $|u_t|$. Taking the derivative with respect to time in (2.20), multiplying by u_t, and integrating over $(0,1)$, we obtain after a few calculations

$$\begin{aligned}\frac{1}{2}\frac{d}{dt}|u_t|^2 + \int_0^1 \frac{u_{xt}^2}{v^2}\,dx &= -A^2\int_0^1 \frac{u_x u_{xt}}{v^2}\,dx - \int_0^1 \frac{u_x^2 u_{xt}}{v^2}\,dx + \int_0^1 \frac{df}{dt}u_t\,dx \\ &\le A^2\alpha^2 a_1|u_{xt}| + \alpha^2|u_x||u_{xx}||u_{xt}| + \left|\frac{df}{dt}\right||u_{xt}|.\end{aligned}$$

Hence

$$\frac{d}{dt}|u_t|^2 + \frac{1}{\alpha}|u_{xt}|^2 \le CA^4\alpha^5 a_1^2 + 2\alpha^5 a_1^2|u_{xx}|^2 + 2\alpha C_\Sigma^2, \tag{2.36}$$

and since $u_{xx} = vu_t - A^2\frac{v_x}{v} + \frac{u_x v_x}{v} - vf$, we have

$$|u_{xx}|^2 \le 2\alpha^2|u_t|^2 + 2A^4\alpha^2\beta^2 + 2\alpha^2\beta^2|u_x||u_{xx}| + 2\alpha^2 C_\Sigma^2, \tag{2.37}$$

and, using Young's inequality together with (2.31), we obtain

$$|u_{xx}|^2 \le 16\alpha^2|u_t|^2 + 16\alpha^2(A^4\alpha^2\beta^2 + \alpha^2\beta^4 a_1^2 + C_\Sigma^2). \tag{2.38}$$

Hence

$$\frac{d}{dt}|u_t|^2 + \frac{1}{\alpha}|u_{tx}|^2 \le k_1^2|u_t|^2 + k_2^2, \tag{2.39}$$

where

$$k_1^2 = C\alpha^7 a_1^2, \tag{2.40}$$

$$k_2^2 = C\alpha^7 a_1^2(A^4\beta^2 + \alpha^2\beta^4 a_1^2 + C_\Sigma^2) + 2A^4\alpha^5 a_1^2 + 2\alpha C_\Sigma^2. \tag{2.41}$$

Applying the uniform Gronwall lemma, we obtain

$$|u_t(\cdot,t)|^2 \le (k_2^2 + b_3^2)\exp(k_1^2) = a_2 \quad \text{for } t - \tau \ge T_0 + 1, \tag{2.42}$$

$$\int_t^{t+1} |u_{xt}|^2\,ds \le k_1^2 b_3^2 k_2^2 = b_4^2 \quad \text{for } t - \tau \ge T_0 + 1, \tag{2.43}$$

$$|u_{xx}(\cdot,t)|^2 \le C(k_2^2 + b_3^2)\exp(k_1^2) + 16\alpha^2(A^4\beta^2 + \alpha^2\beta^4 a_1^2 + C_\Sigma^2) = a_2^2. \tag{2.44}$$

(iii) Uniform estimates on $|u_{xt}|$. We differentiate (2.20) with respect to time and multiply by u_{tt} to obtain

$$\begin{aligned}\frac{1}{2}\frac{d}{dt}\int_0^1 \frac{u_{xt}^2}{v}\,dx + |u_{tt}|^2 &= -A^2\int_0^1 \left(\frac{1}{v}\right)_{xt} u_{tt}\,dx - \frac{1}{2}\int_0^1 \frac{u_{xt}^2 u_x}{v^2}\,dx \\ &\quad + \int_0^1 \left(\frac{u_x^2}{v^2}\right)_x u_{tt}\,dx + \int_0^1 u_{tt}\frac{df}{dt}\,dx.\end{aligned} \tag{2.45}$$

Now note that

$$\left(\frac{1}{v}\right)_{xt} = -\frac{u_{xx}}{v^2} + 2\frac{u_x v_x}{v^3}.$$

Hence

$$\left|\left(\frac{1}{v}\right)_{xt}\right|^2 \le 2\alpha^4 a_2^2 + 4\alpha^6 |u_x||u_{xx}||v_x| \le 2\alpha^4 a_2^2 + 4\alpha^6 a_1 a_2 \beta,$$

$$\left|\int_0^1 \frac{u_{xt}^2 u_x}{v^2}\,dx\right| \le \alpha^2 |u_x|_{L^\infty} |u_{xt}|^2 \le \alpha^2 (a_1 a_2)^{1/2} |u_{xt}|^2,$$

and

$$\begin{aligned}\left|\int_0^1 \left(\frac{u_x^2}{v^2}\right)_x u_{tt}\,dx\right| &= \left|\int_0^1 \left[\frac{2u_x u_{xx}}{v^2} u_{tt} - \frac{2u_x^2 v_x}{v^3} u_{tt}\right] dx\right| \\ &\le 2\alpha^2 |u_x|_{L^\infty} a_2 |u_{tt}| + 2\alpha^3 |u_x|_{L^\infty}^2 |u_{tt}|.\end{aligned}$$

Therefore

$$\begin{aligned}\frac{1}{2}\frac{d}{dt}\int_0^1 \frac{u_{xt}^2}{v}\,dx + \frac{1}{2}|u_{tt}|^2 &\le C(\alpha^4 a_2^2 + \alpha^6 a_1 a_2 \beta) A^4 + C(a_1 a_2)^{1/2} |u_{xt}|^2 \\ &\quad + C\alpha^4 a_2^3 a_1 + C\alpha^6 a_1^2 a_2^2 + C C_\Sigma^2 \\ &\le k_3^2 + C\alpha^3 (a_1 a_2)^{1/2} \int_0^1 \frac{u_{xt}^2}{v}\,dx.\end{aligned} \tag{2.46}$$

Hence

$$\frac{d}{dt}\int_0^1 \frac{{u_{xt}}^2}{v}\,dx + |u_{tt}|^2 \le k_3^2 + k_4^2 \int_0^1 \frac{u_{xt}^2}{v}\,dx,$$

where

$$\begin{aligned}k_3^2 &= C(\alpha^4 a_2^2 + \alpha^6 a_1 a_2 \beta) A^4 + C\alpha^4 a_2^3 a_1 + C\alpha^6 a_1^2 a_2^2 + C C_\Sigma^2, \\ k_4^2 &= C\alpha^3 (a_1 a_2)^{1/2}.\end{aligned}$$

Finally, using the uniform Gronwall lemma, we obtain

$$|u_{xt}|^2 \le \alpha (k_3^2 + b_4^2) \exp(k_4^2). \tag{2.47}$$

We collect the previous estimates in the following lemma.

LEMMA 2.4. *Let C_0 and C_Σ be positive constants, arbitrarily large, and let (v, u) be the solution described in Theorem 2.2. Then there exists a positive constant M_0 depending only on C_Σ and A, and there exists a time $T_0 = T_0(C_0, C_\Sigma, A)$ such that if $||f||_{W^{1,\infty}} \le C_\Sigma$ and $t - \tau \ge T_0 + 1$, then*

$$|u(\cdot,t)|^2 + |u_x(\cdot,t)|^2 + |u_{xx}(\cdot,t)|^2 + |u_t(\cdot,t)|^2 + |u_{xt}(\cdot,t)|^2 \le M_0^2. \tag{2.48}$$

In particular, this inequality holds for any solution on the uniform attractor $\mathcal{A}_\Sigma$.

We conclude this section with the following lemma, which is a consequence of Lemma 2.4.

LEMMA 2.5. *Let the hypotheses and notation of Lemma 2.4 be in force, and let g be a smooth function. Then there exists a constant $M_0 = M_0(C_\Sigma, A, g)$, independent of C_0, such that*

$$\int_0^1 \left|\frac{\partial^2}{\partial x \partial t} g(v(x,t))\right|^2 dx + \int_0^1 \left|\frac{\partial^2}{\partial t^2} g(v(x,t))\right|^2 dx \le M_0^2 \tag{2.49}$$

for $t-\tau \geq T_0+1$. In particular, if $(v(\cdot,\cdot),u(\cdot,\cdot))$ and $(\bar{v}(\cdot,\cdot),\bar{u}(\cdot,\cdot))$ are two solutions in $\mathcal{A}_\Sigma$ and if G is a smooth real-valued function, then

$$\theta(x,t) \equiv \frac{G(v)-G(\bar{v})}{v-\bar{v}} = \int_0^1 G'(\tau v(x,t)+(1-\tau)\bar{v}(x,t))\,d\tau \tag{2.50}$$

satisfies

$$|\theta_{xt}(\cdot,t)|^2 + |\theta_{tt}(\cdot,t)|^2 \leq M_0^2 \tag{2.51}$$

for all t.

Proof. We write

$$(g(v))_{xt} = (g'(v)u_x)_x = g''(v)u_x^2 + g'(x)u_{xx}. \tag{2.52}$$

Since, by Lemma 2.4, $|u_{xx}(\cdot,t)|_{L^2}$, $|g''(v(\cdot,t))|_{L^\infty}$, and $|u_x^2(\cdot,t)|_{L^2}$ are bounded for $t-\tau \geq T_0+1$, we have that $|g(v)_{xt}(\cdot,t)|$ is bounded for $t-\tau \geq T$. Similarly

$$(g(v))_{tt} = (g'(v)u_x)_t = g''(v)u_x^2 + g'(v)u_{xt}, \tag{2.53}$$

and, thanks to Lemma 2.4, the proof is complete. ∎

3. Construction of the exponential attractor: Proof of Theorem 1.1. In this section we prove Theorem 1.1 by constructing the decomposition discussed in section 1 for the semigroup associated with the semiprocess generated by the solution operator for the Navier–Stokes system (1.1)–(1.2). This decomposition enables us to apply the result of Lemma 1.2 to show that the attractor $\mathcal{A}$ of Theorem 2.3 has finite fractal dimension, and therefore that its projection $\mathcal{A}_\Sigma$ has finite fractal dimension as well. The same decomposition also enables us to apply other known results to show that the semigroup $S(t)$ satisfies the so-called squeezing property and that, as a consequence, it has an exponential attractor of finite fractal dimension, as does the associated process $\mathcal{U}_\sigma$.

We begin in section 3.1 by giving a brief description of the abstract framework in which the proof of Theorem 1.1 will be given, including the general formulation of the required decomposition of the semigroup and statements of standard results concerning the implications of this decomposition for the existence of exponential attractors. Then in section 3.2 we show how to construct the required decomposition for the semigroup associated with the system (1.1)–(1.2) and how the abstract results of section 3.1 can be applied to complete the proof of Theorem 1.1. The properties of the decomposition required for the application of this abstract framework will be seen to follow from certain a priori bounds for solutions of two systems of differential equations derived from (1.1)–(1.2). These estimates are stated in Theorem 3.9, and their proofs are deferred to section 4.

3.1. Exponential attractors. Let $\mathcal{Y}$ be a metric space and consider the equation

$$\begin{cases} \dfrac{du}{dt} = \mathcal{F}(\alpha t, u), \quad t \geq \tau, \quad \tau \in \mathbb{R}, \\ u(\tau) = u_\tau \in \mathcal{Y}, \end{cases} \tag{3.1}$$

where $\alpha = (\alpha_1,\dots,\alpha_N)$. We assume that the α_i's are rationally independent and that $\mathcal{F}(\omega_1,\dots,\omega_N,\cdot)$ is 2π-periodic in each argument ω_i, $i=1,\dots,N$. In the spirit

of the theory developed in [3] for nonautonomous systems, we associate with (3.1) the following family of equations, depending on a parameter $\sigma \in \mathbb{T}^N$:

$$\begin{cases} \dfrac{du}{dt} = \mathcal{F}(\alpha t + \sigma, u), \quad t \geq \tau, \quad \tau \in \mathbb{R}, \\ u(\tau) = u_\tau \in \mathcal{Y}. \end{cases} \tag{3.2}$$

Assuming that (3.2) is well-posed for initial data in $\mathcal{Y}$, we can define a family of semiprocesses $\mathcal{U}_\sigma(t,\tau)$ by taking $\mathcal{U}_\sigma(t,\tau)u_\tau$ to be the solution of (3.2) at time t. Thus

$$\mathcal{U}_\sigma(t,t) = Id \quad \forall\, t \in \mathbb{R}, \quad \forall\, \sigma \in \mathbb{T}^N, \tag{3.3}$$

$$\mathcal{U}_\sigma(t,s) \circ \mathcal{U}_\sigma(s,\tau) = \mathcal{U}_\sigma(t,\tau) \quad \forall\, t \geq s \geq \tau, \quad \forall\, \sigma \in \mathbb{T}^N. \tag{3.4}$$

Uniform attractors and uniform exponential attractors for semiprocesses are then defined as follows (see [16]).

DEFINITION 3.1. *A closed set $\mathcal{A}_\Sigma \subset \mathcal{Y}$ is called the uniform (with respect to σ) attractor for the family of processes $\mathcal{U}_\sigma(t,\tau)$ defined on $\mathcal{Y}$ if*

(a) *$\mathcal{A}_\Sigma$ is a compact subset of $\mathcal{Y}$;*

(b) *for all $B \subset \mathcal{Y}$ bounded,*

$$\lim_{t\to\infty} \sup_{\sigma\in\mathbb{T}^N} dist_{\mathcal{Y}}(\mathcal{U}_\sigma(t,\tau)B, \mathcal{A}_\Sigma) = 0; \tag{3.5}$$

(c) *for all $\mathcal{A}' \subset \mathcal{Y}$ closed and satisfying* (b), *$\mathcal{A}_\Sigma \subset \mathcal{A}'$.*

DEFINITION 3.2. *Let H and V be Hilbert spaces with V compactly imbedded in H, and assume that the family of semiprocesses $\mathcal{U}_\sigma(t,\tau)$ is defined on a closed subset $\mathcal{Y}$ of V. A closed set $\mathcal{M}_\Sigma \subset \mathcal{Y}$ is a uniform $\mathcal{Y}-V$ exponential attractor for the family of processes $\mathcal{U}_\sigma(t,\tau)$ and for initial data in V if*

(a) *$\mathcal{A}_\Sigma \subset \mathcal{M}_\Sigma \subset V$, where $\mathcal{A}_\Sigma$ is the uniform attractor;*

(b) *$\mathcal{M}_\Sigma$ is compact in V and has finite fractal dimension;*

(c) *for all $B \subset \mathcal{Y}$ bounded in V, there exist constants $c_1(B)$ and $c_2(B)$ such that*

$$\sup_{\sigma\in\mathbb{T}^N} dist_H(\mathcal{U}_\sigma(t,\tau)B, \mathcal{M}_\Sigma) \leq c_1 e^{-c_2(t-\tau)}. \tag{3.6}$$

REMARK 3.3. *Note that the exponential convergence in* (3.6) *is in a weaker norm than that in which the set B is assumed to be bounded. For example, as we shall see below for the Navier–Stokes system* (1.1)–(1.2), *the set $\mathcal{Y}$ will be the closed absorbing ball (see Theorem* 2.3*) in the Hilbert space $V = H^1 \times H^1_0$, whereas H will be the Hilbert space $H^r \times H^r_0$ for some $r \in (0,1)$. Thus exponential convergence to $\mathcal{M}_\Sigma$ will occur in the topology of $H = H^r \times H^r_0$ for sets $B \subset \mathcal{Y}$ which are bounded in the stronger topology of $H^1 \times H^1_0$.*

The proof of the existence of uniform exponential attractors for nonautonomous evolution equations follows the theory in [3]: one considers the semigroup $S(t)$ defined on the extended phase space $\mathcal{Y} \times \mathbb{T}^N$ by

$$\begin{aligned} S(t)\colon\ & \mathcal{Y} \times \mathbb{T}^N \longrightarrow \mathcal{Y} \times \mathbb{T}^N, \\ & (u,\sigma) \longmapsto (\mathcal{U}_\sigma(t,0)u, (\alpha t + \sigma)(\mathrm{mod}\mathbb{T}^N)) \end{aligned} \tag{3.7}$$

and then proves that $S(t)$ has an exponential attractor $\mathcal{M}$. The uniform exponential attractor $\mathcal{M}_\Sigma$ for the semiprocess $\mathcal{U}_\sigma$ is then obtained by projecting $\mathcal{M}$ onto $\mathcal{Y}$. We recall the definitions of global attractor and exponential attractor for semigroups.

DEFINITION 3.4. *A closed set $\mathcal{A} \subset \mathcal{Y} \times \mathbb{T}^N$ is called the global attractor for the semigroup $S(t)$ defined on $\mathcal{Y} \times \mathbb{T}^N$ if*

(a) *$\mathcal{A}$ is a compact subset of $\mathcal{Y} \times \mathbb{T}^N$;*

(b) *$\mathcal{A}$ is invariant under $S(t)$, i.e., $S(t)\mathcal{A} = \mathcal{A}$ for all t;*

(c) *for all $B \subset \mathcal{Y} \times \mathbb{T}^N$ bounded,*

$$\lim_{t\to\infty} dist_{\mathcal{Y}\times\mathbb{T}^N}(S(t)B, \mathcal{A}) = 0. \tag{3.8}$$

DEFINITION 3.5. *Let H and V be Hilbert spaces with V compactly imbedded in H, and assume that $S(t)$ is a semigroup defined on $\mathcal{Y} \times \mathbb{T}^N$, where $\mathcal{Y}$ is a closed subset of V. A closed set $\mathcal{M} \subset V \times \mathbb{T}^N$ is a uniform $\mathcal{Y} \times \mathbb{T}^N - V \times \mathbb{T}^N$ exponential attractor for the semigroup $S(t)$ for initial data in $V \times \mathbb{T}^N$ if*

(a) *$\mathcal{A} \subset \mathcal{M} \subset V \times \mathbb{T}^N$, where $\mathcal{A}$ is the global attractor of $S(t)$;*

(b) *$\mathcal{M}$ is compact in $V \times \mathbb{T}^N$ and has finite fractal dimension;*

(c) *for all $B \subset \mathcal{Y} \times \mathbb{T}^N$ bounded in $V \times \mathbb{T}^N$, there exist constants $c_1(B)$ and $c_2(B)$ such that*

$$\sup dist_{H\times\mathbb{T}^N}(S(t)B, \mathcal{M}) \le c_1 e^{-c_2(t-\tau)}. \tag{3.9}$$

As discussed earlier, an effective method for proving the existence of exponential attractors for semigroups arising from systems which are only partially dissipative, and therefore whose solution operators are only asymptotically compact, is based on a decomposition of the semigroup $S(t)$ into the sum of two operators $S(t) = S_1(t) + S_2(t)$, where $S_1(t)$ is compact in a suitable sense, $S_2(t)$ is continuous, and

$$\sup_{w\in C} |S_2(t)w|_{\mathcal{Y}\times\mathbb{T}^N} \to 0 \quad \text{as} \quad t \to \infty \tag{3.10}$$

for every bounded set $C \subset \mathcal{Y} \times \mathbb{T}^N$. The existence of such a decomposition is known to imply a certain "squeezing property," and this in turn is known to imply the existence of an exponential attractor. This squeezing property, its relation to the above decomposition of the semigroup, and its sufficiency for the existence of exponential attractors are described as follows.

DEFINITION 3.6. *We say that the semigroup $S(t)$ satisfies the squeezing property on a positively invariant closed set $X \subset \mathcal{Y} \times \mathbb{T}^N$ if for every $\delta \in (0, 1/4)$ there exist an orthogonal projector $\mathcal{P}$ with finite rank and a time $t^*(\delta) > 0$ such that for all $(w_1, w_2) \in X \times X$, either*

$$|S(t^*)w_1 - S(t^*)w_2|_{\mathcal{Y}\times\mathbb{T}^N} \le \delta |w_1 - w_2|_{\mathcal{Y}\times\mathbb{T}^N} \tag{3.11}$$

or

$$|(I - \mathcal{P})(S(t^*)w_1 - S(t^*)w_2)|_{\mathcal{Y}\times\mathbb{T}^N} \le |\mathcal{P}(S(t^*)w_1 - S(t^*)w_2)|_{\mathcal{Y}\times\mathbb{T}^N}. \tag{3.12}$$

The following result of Eden et al. [4] guarantees the existence of exponential attractors for semigroups satisfying the squeezing property.

THEOREM 3.7. *If the semigroup $S(t)$ defined by* (3.7) *satisfies the squeezing property of Definition* 3.6*, and if the global attractor $\mathcal{A}$ exists in the sense of Definition* 3.4*, then $S(t)$ has a finite-dimensional exponential attractor $\mathcal{M}$, and the semiprocess $\mathcal{U}_\sigma(t, \tau)$ associated with $S(t)$ has a finite-dimensional exponential attractor $\mathcal{M}_\Sigma$.*

We shall verify that the semigroup associated with the Navier–Stokes system (1.1)–(1.2) does indeed satisfy the squeezing property by applying the following sufficient condition of Galusinski, Hind, and Miranville [9].

PROPOSITION 3.8. *Let V and H be Hilbert spaces with V compactly imbedded in H. Assume that $\mathcal{Y}$ is a closed subset of V and that for each $n \in \mathbb{N}$ there exists an orthogonal projector $P_n\colon\ H \to H$ with finite rank such that*

$$\forall\ y \in V, \quad |Q_n y|_H \le C(n)|y|_V, \tag{3.13}$$

where $Q_n = I - P_n$ and $\lim_{n\to\infty} C(n) = 0$. Assume also that there are continuous functions d and h on $[0,\infty)$ such that $\lim_{t\to\infty} d(t) = 0$, and that for all w_1 and w_2 in $\mathcal{Y} \times \mathbb{T}^N$, there exist $W^I(t)$ and $W^{II}(t)$ such that

$$S(t)w_1 - S(t)w_2 = W^I(t) + W^{II}(t), \ \textit{with} \tag{3.14}$$

$$|W^I(t)|^2_{H\times\mathbb{T}^N} \le d(t)|w_1 - w_2|^2_{H\times\mathbb{T}^N}, \tag{3.15}$$

$$|W^{II}(t)|^2_{V\times\mathbb{T}^N} \le h(t)|w_1 - w_2|^2_{H\times\mathbb{T}^N}. \tag{3.16}$$

Then $S(t)$ satisfies the squeezing property of Definition 3.6.

Proof. See [9]. □

3.2. Application to the Navier–Stokes system: Proof of Theorem 1.1. It suffices to prove Theorem 1.1 for the Lagrangian formulation (2.19)–(2.22) of the Navier–Stokes system (1.1)–(1.2). Following [3], we first imbed the system (2.19)–(2.22) in a family of autonomous systems depending on a parameter $\sigma \in \mathbb{T}^N$, taking $f(\Phi(x,t),t) = \tilde{f}(\Phi(x,t), \alpha t + \sigma)$:

$$v_t = u_x, \tag{3.17}$$

$$u_t + (A^2 v^{-1})_x = \left(\frac{u_x}{v}\right)_x + \tilde{f}\left(\int_0^x v(\xi,t)d\xi, \omega\right), \tag{3.18}$$

$$\frac{d\omega(t)}{dt} = \alpha, \tag{3.19}$$

$$u(0,t) = u(1,t) = 0, \quad \int_0^1 v(x,t)dx = 1, \quad t \ge 0, \tag{3.20}$$

$$u(x,0) = u_0, \quad v(x,0) = v_0, \quad \text{and} \quad \omega(0) = \sigma. \tag{3.21}$$

The existence and regularity theory of section 2 applies to the system (3.17)–(3.21), and all the estimates of Lemmas 2.4 and 2.5 hold uniformly for $\sigma \in \mathbb{T}^N$.

To construct the decomposition described in Proposition 3.8, we let $(\bar{v}, \bar{u}, \bar{\omega})$ and (v, u, ω) be solutions of (3.17)–(3.21) with respective initial values $(\bar{v}_0, \bar{u}_0, \bar{\sigma})$ and (v_0, u_0, σ), and we set

$$\varphi = v - \bar{v}, \quad \psi = u - \bar{u}, \quad \eta = \omega - \bar{\omega}, \tag{3.22}$$

$$\Phi(x,t) = \int_0^x v(s,t)\,ds, \quad \bar{\Phi}(x,t) = \int_0^1 \bar{v}(s,t)\,ds, \quad \text{and} \tag{3.23}$$

$$R(x,t) = \Phi(x,t) - \bar{\Phi}(x,t) = \int_0^x \varphi(\xi,t)d\xi. \tag{3.24}$$

Then

$$R(0,t) = R(1,t) = 0 \tag{3.25}$$

and

$$\text{(3.26)}\quad \begin{cases} \varphi_t - \psi_x = 0, \\ \psi_t + (q\varphi)_x = \varepsilon\psi_{xx} + (\zeta\varphi)_{xt} + hR + \bar{h}\eta, \\ \dfrac{d\eta}{dt} = 0, \\ \varphi_0(x,0) = v_0(x) - \bar{v}_0(x), \quad \psi_0(x,0) = u_0(x) - \bar{u}_0(x), \quad \eta(0) = \sigma - \bar{\sigma}, \end{cases}$$

where

$$\text{(3.27)}\quad \Delta\tilde{f} = \tilde{f}(\Phi(x,t), \alpha t + \sigma) - \tilde{f}(\bar{\Phi}(x,t), \alpha t + \bar{\sigma}) = h(x,t)R(x,t) + \bar{h}(x,t)\eta(t),$$

$$\text{(3.28)}\quad p(v) - p(\bar{v}) = q(x,t)\varphi(x,t), \quad \text{with} \quad q(x,t) = -\frac{A^2}{v(x,t)\bar{v}(x,t)},$$

$$\frac{u_x}{v} - \frac{\bar{u}_x}{v} = \varepsilon\psi_x + (\log v - \varepsilon v)_t - (\log\bar{v} - \varepsilon\bar{v})_t = \varepsilon\psi_x + (\zeta\varphi)_t,$$

where

$$\text{(3.29)}\qquad \zeta = \zeta(x,t) = \frac{1}{\tilde{v}(x,t)} - \varepsilon \quad \text{for some} \quad \tilde{v}(x,t) \in [v(x,t), \bar{v}(x,t)],$$

and ε is defined by $\varepsilon = \frac{1}{2}\inf[v(x,t)^{-1}],\ x \in (0,1),\ t \geq T_0 + 1$.

We now let λ be a large positive constant and k a large positive integer, to be chosen later, and introduce the following decomposition of (φ, ψ, η):

$$(\varphi, \psi, \eta) = (\varphi^I, \psi^I, 0) + (\varphi^{II}, \psi^{II}, \eta),$$

where (φ^I, ψ^I) and $(\varphi^{II}, \psi^{II})$ are the solutions of

$$\text{(3.30)}\quad \begin{cases} \varphi^I_t - \psi^I_x = 0, \\ \psi^I_t + (q\varphi^I)_x = \varepsilon\psi^I_{xx} + (\zeta\varphi^I)_{xt} + \lambda\tilde{v}(x,t)(P_k\psi^I_{xx}) + hQ_kR^I, \\ \varphi^I(x,0) = \varphi_0(x,0), \quad \psi^I(x,0) = \psi_0(x), \end{cases}$$

$$\text{(3.31)}\quad \begin{cases} \varphi^{II}_t - \psi^{II}_x = 0, \\ \psi^{II}_t + (q\varphi^{II})_x = \varepsilon\psi^{II}_{xx} + (\zeta\varphi^{II})_{xt} - \lambda\tilde{v}(P_k\psi^I_{xx}) + hP_kR^I + hR^{II} + \bar{h}\eta, \\ \varphi^{II}(x,0) = \psi^{II}(x,0) = 0, \end{cases}$$

where

$$\text{(3.32)}\qquad P_k\psi = \sum_{|j|\leq k} \widehat{\psi}_j e^{2\pi ijx} \quad \text{and} \quad Q_k\psi = \psi - P_k\psi.$$

It is readily verified that the sum of the solutions $(\varphi^I, \psi^I, 0)$ and $(\varphi^{II}, \psi^{II}, \eta)$ of the above systems is indeed the solution (φ, ψ, η) of (3.17)–(3.21).

The proof that this decomposition satisfies the hypotheses of Proposition 3.8 will depend on certain a priori estimates for solutions of the systems (3.30) and (3.31). We state these estimates without proof below in Theorem 3.9, and we then complete the proof of Theorem 1.1 by showing how these a priori estimates can be used to fit the Navier–Stokes system (2.19)–(2.22) into the abstract framework of section 3.1. The proof of Theorem 3.9 will be deferred to section 4.

THEOREM 3.9. *For k, λ, and k/λ sufficiently large, there exist positive constants $r \in (0,1)$, ν, ν_1, ν_2, ν_3, and K_0, all depending only on A and C_Σ (see* (2.1) *and*

Theorem 2.1*), such that if* (v_0, u_0) *and* $(\bar v_0, \bar u_0)$ *are in the uniform attractor* $\mathcal{A}_\Sigma$*, then*

$$|\varphi_x^I(\cdot,t)|^2 + |\psi_x^I(\cdot,t)|^2 \le K_0 e^{-\nu t}\big[|\varphi_{0x}^I| + |\psi_{0x}^I|^2\big], \tag{3.33}$$

$$|\varphi^I(\cdot,t)|^2 + |\psi^I(\cdot,t)|^2 \le K_0 e^{\nu_1 t}\big[|\varphi_0^I|^2 + |\psi_0^I|^2\big], \tag{3.34}$$

$$|\varphi^I(\cdot,t)|_{H^r}^2 + |\psi^I(\cdot,t)|_{H^r}^2 \le K_0 e^{-\nu_2 t}\big[|\varphi_0^I|_{H^r}^2 + |\psi_0^I|_{H^r}^2\big], \tag{3.35}$$

$$|\varphi_x^{II}(\cdot,t)|^2 + |\psi_x^{II}(\cdot,t)|^2 \le K_0 e^{\nu_3 t}\big[|\varphi_0^I|_{H^r}^2 + |\psi_0^I|_{H^r}^2\big]. \tag{3.36}$$

Proof of Theorem 1.1. We first show that the global attractor $\mathcal{A}$ of Theorem 2.3 has finite fractal dimension by applying the result of Lemma 1.2. To do this, we let H be the Hilbert space $H = H^r \times H_0^r \times \mathbb{T}^N$, where r is as above in Theorem 3.9, and we take $M = \mathcal{A}$, which is compact in H. To check the hypotheses (1.5) and (1.6) we let $w_1 = (v_0, u_0, \sigma_0)$ and $w_2 = (\bar v_0, \bar u_0, \bar\sigma_0)$ be two points in $\mathcal{A}$ and write $S(t)w_1 - S(t)w_2 = W^I(t) + W^{II}(t)$, with $W^I(t) = (\varphi^I(t), \psi^I(t), 0)$ and $W^{II}(t) = (\varphi^{II}(t), \psi^{II}(t), \eta(t))$, where $\eta(t) = \alpha t + \sigma - \bar\sigma$, $(\varphi^I(t), \psi^I(t))$ is the solution of (3.30) with initial data $(v_0 - \bar v_0, u_0 - \bar u_0)$, and $(\varphi^{II}(t), \psi^{II}(t))$ is the solution of (3.31) with zero initial data. Then for t^* large,

$$|W^I(t^*)|_{H^r\times H_0^r\times\mathbb{T}^N} \le 2^{-1/2}\delta |w_1 - w_2|_{H^r\times H_0^r\times\mathbb{T}^N} \tag{3.37}$$

with $\delta < 1$, by (3.35). Next, if $\tilde P_n$ is the orthogonal projector onto the span of $\{e^{2k\pi i x}\}_{|k|\le n}$, and if $\tilde Q_n = I - \tilde P_n$, then

$$|\tilde Q_n g|_{H^r} \le n^{1-r}|g|_{H^1}$$

for $g \in H^1([0,1])$. Letting P_n be the projector $P_n = (\tilde P_n, \tilde P_n, Id)$ on $L^2 \times L^2 \times \mathbb{T}^N$ and $Q_n = I - P_n$, we then have from (3.36) that, for a generic constant C,

$$\begin{aligned} |Q_n W^{II}(t^*)|_{H^r\times H_0^r\times\mathbb{T}^N} &\le Cn^{1-r}|(\phi^{II}(t^*), \psi^{II}(t^*), 0)|_{H^1\times H_0^1\times\mathbb{T}^N} \\ &\le Cn^{1-r}e^{\nu_3 t^*}|w_1 - w_2|_{H^r\times H_0^r\times\mathbb{T}^N} \\ &\le 2^{-1/2}\delta |w_1 - w_2|_{H^r\times H_0^r\times\mathbb{T}^N} \end{aligned} \tag{3.38}$$

if n is chosen sufficiently large, depending on t^*. Taking the square root of the sum of the squares of (3.37) and (3.38), we then obtain (1.6) for $S = S(t^*)$. The Lipschitz continuity (1.5) then follows immediately from (3.35) and (3.36). Since $\mathcal{A}$ is compact, by Theorem 2.3, the result of Lemma 1.2 applies to show that $\mathcal{A}$ has finite fractal dimension in $H^r \times H_0^r \times \mathbb{T}^N$, and therefore that its projection $\mathcal{A}_\Sigma$ has finite fractal dimension in $H^r \times H_0^r$, as asserted in Theorem 1.1.

To prove the existence of a finite-dimensional exponential attractor for the semigroup $S(t)$, we apply the results of Theorem 3.7 and Proposition 3.8 as follows. Let H and V be the Hilbert spaces $H = H^r \times H_0^r \times \mathbb{T}^N$, where r is as above in Theorem 3.9, and $V = H^1 \times H_0^1 \times \mathbb{T}^N$, and let $\mathcal{Y}$ be the absorbing ball $\mathcal{B}$ of Theorem 2.3, which is compact in H. Taking P_n, Q_n, W^I, and W^{II} exactly as above, we then obtain (3.15) and (3.16) directly from the conclusions of Theorem 3.9. Proposition 3.8 and Theorem 3.7 then apply to show that the semigroup $S(t)$ satisfies the squeezing property, and that therefore there exists an exponential attractor $\mathcal{M}$ of finite fractal dimension. The uniform exponential attractor $\mathcal{M}_\Sigma$ for the process $\mathcal{U}_\sigma$ is then obtained as the projection of $\mathcal{M}$ onto $H^r \times H_0^r$. This completes the proof of Theorem 1.1. ∎

4. Proof of Theorem 3.9. This section is devoted to the proof of Theorem 3.9. We will concentrate on the proof of the inequalities (3.33) and (3.34) and then obtain the inequality (3.35) (which corresponds to (3.15) in Proposition 3.8) by the Riesz–Thorin interpolation theorem. The last inequality (3.36) (which corresponds to the inequality (3.16) in Proposition 3.8) is straightforward and will be sketched.

We assume throughout this section that all the hypotheses and notation of Theorem 3.9 are in force, and we begin with the following technical lemma.

LEMMA 4.1. *Assume that the initial data* (v_0, u_0), $(\bar v_0, \bar u_0)$ *are in the attractor* $\mathcal{A}_\Sigma$ *and let* $(v(t), u(t))$, $(\bar v(t), \bar u(t))$ *be the corresponding solutions of the Navier–Stokes equations, so that, as a consequence of Lemmas* 2.4 *and* 2.5,

$$0 < -q(x,t) \le M_0, \quad |\zeta(\cdot,t)|_{L^\infty} \le M_0, \quad |\zeta_t(\cdot,t)|_{L^\infty} \le M_0, \tag{4.1}$$

$$|\zeta_x(\cdot,t)|_{L^2} \le M_0, \quad |\zeta_{xt}(\cdot,t)|_{L^\infty} \le M_0, \quad \frac{1}{M_0} \le \tilde v(x,t) \le M_0, \tag{4.2}$$

where M_0 *is a constant depending only on* A *and* C_Σ. *Then there exists a numerical constant* C *such that*

$$|\psi^I_x|^2_{L^\infty} \le C M_0^8 \left[\frac{1}{\lambda^2}|\varphi^I|^2 + |\psi^I_x|^2 + \frac{1}{k}|\psi^I_{xx}|^2 + \frac{1}{\lambda^2}|\psi^I_t|^2 + \frac{1}{\lambda^2}|\varphi^I||\varphi^I_x| \right] \tag{4.3}$$

and

$$|\psi^I_{xx}|^2 \le C M_0^8 \left[|\varphi^I|^2 + M_0^4 |\varphi^I_x|^2 + |\psi^I_x|^2 + |\psi^I_t|^2 \right]. \tag{4.4}$$

Proof. Let $w = \frac{\psi^I_x}{\tilde v} + (\zeta_t - q)\varphi^I + \lambda \tilde v P_k \psi^I_x$. Thanks to Lemmas 2.4 and 2.5

$$|w|^2 \le 2M_0^2(|\psi^I_x|^2 + |\varphi^I|^2 + \lambda^2 |P_k \psi^I_x|^2) \le C M_0^2 \big[\lambda^2 |\psi^I_x|^2 + |\varphi^I|^2 \big], \tag{4.5}$$

where C denotes a generic numerical constant. We note that equations (3.30) imply that $w_x = \psi^I_t + \lambda \tilde v_x P_k \psi^I_x - h Q_k R^I$. Therefore,

$$|w_x| \le |\psi^I_t| + \lambda |\tilde v_x| |P_k \psi^I_x|_{L^\infty} + |h|_{L^\infty} |Q_k R^I|. \tag{4.6}$$

Since $|Q_k R^I| \le |\varphi^I|$, Lemmas 2.4 and 2.5 yield

$$|w_x|^2 \le C M_0^2 \big(|\psi^I_t|^2 + |\varphi^I|^2 + \lambda^2 |P_k \psi_x|^2_{L^\infty} \big). \tag{4.7}$$

Now using Agmon's inequalities

$$|P_k \psi^I_x|^2_{L^\infty} \le |\psi^I_x|^2_{L^\infty} + \frac{1}{k}|\psi^I_{xx}|^2, \tag{4.8}$$

$$|w|^2_{L^\infty} \le |w|^2 + 2|w||w_x|, \tag{4.9}$$

we obtain

$$|w|^2_{L^\infty} \le C M_0^2 \left[\lambda^2 |\psi^I_x|^2 + |\varphi^I|^2 + \frac{\lambda^2}{k}|\psi^I_{xx}|^2 + \big(\lambda |\psi^I_x| + |\varphi^I| \big) \big(|\psi^I_t| + \lambda |\psi^I_x|_{L^\infty} \big) \right]. \tag{4.10}$$

Furthermore, from the definition of w, we can write

$$\psi^I_x = \left(\frac{1}{\tilde v} + \lambda \tilde v \right)^{-1} [w - (\zeta_t - q)\varphi^I + \lambda \tilde v Q_k \psi^I_x], \tag{4.11}$$

which implies that, for $\lambda \geq 1$,

$$|\psi_x^I|_{L^\infty}^2 \leq \frac{CM_0^2}{\lambda^2}\left[|w|_{L^\infty}^2 + |\zeta_t - q|_{L^\infty}^2|\varphi^I|_{L^\infty}^2 + \lambda^2|\tilde{v}|_{L^\infty}^2|Q_k\psi_x^I|_{L^\infty}^2\right], \tag{4.12}$$

and since $|Q_k\psi_x^I|_{L^\infty}^2 \leq \frac{1}{k^2}|\psi_{xx}^I|^2$, we obtain, thanks to Lemmas 2.4 and 2.5,

$$\begin{aligned}|\psi_x^I|_{L^\infty}^2 \leq CM_0^4 &\left[|\psi_x^I|^2 + \frac{1}{\lambda^2}|\varphi^I|^2 + \frac{1}{k}|\psi_{xx}^I|^2 + \left(\frac{1}{\lambda}|\psi_x^I| + \frac{1}{\lambda^2}|\varphi^I|\right)\left(|\psi_t^I| + \lambda|\psi_x^I|_{L^\infty}\right)\right] \\ &+ \frac{CM_0^4}{\lambda^2}|\varphi^I|_{L^\infty}^2 + \frac{CM_0^4}{k^2}|\psi_{xx}^I|^2,\end{aligned} \tag{4.13}$$

and with the inequality

$$CM_0^4\left(|\psi_x^I| + \frac{1}{\lambda}|\varphi|\right)|\psi_x^I|_{L^\infty} \leq \frac{1}{2}|\psi_x^I|_{L^\infty}^2 + CM_0^8|\psi_x^I|^2 + \frac{CM_0^8}{\lambda^2}|\varphi^I|^2, \tag{4.14}$$

we conclude that

$$|\psi_x^I|_{L^\infty}^2 \leq CM_0^8\left(|\psi_x^I|^2 + \frac{1}{\lambda^2}|\varphi^I|^2 + \frac{1}{k}|\psi_{xx}^I|^2 + \frac{1}{\lambda^2}|\psi_t^I|^2\right) + \frac{CM_0^4}{\lambda^2}|\varphi^I||\varphi_x^I|. \tag{4.15}$$

This completes the proof of (4.3).

In order to prove inequality (4.4), we rewrite the equations (3.30) in the form

$$\psi_t^I + q_x\varphi^I + q\varphi_x^I = \frac{1}{\tilde{v}}\psi_{xx}^I + \zeta_x\psi_x^I + \zeta_t\varphi_x^I + \zeta_{tx}\varphi^I + \lambda\tilde{v}P_k\psi_{xx}^I + hQ_kR^I. \tag{4.16}$$

Let $\mathcal{F}$ be defined by

$$\mathcal{F} = \psi_t^I + q_x\varphi^I + q\varphi_x^I - \zeta_x\psi_x^I - \zeta_t\varphi_x^I - \zeta_{tx}\varphi^I - hQ_kR^I. \tag{4.17}$$

We have

$$\frac{1}{\tilde{v}}P_k\psi_{xx}^I + \frac{1}{\tilde{v}}Q_k\psi_{xx}^I + \lambda\tilde{v}P_k\psi_{xx}^I = \mathcal{F}, \tag{4.18}$$

and, with Lemmas 2.4 and 2.5,

$$\begin{aligned}|\mathcal{F}| &\leq |\psi_t^I| + |q_x||\varphi^I|_{L^\infty} + |q|_{L^\infty}|\varphi_x^I| + |\zeta_x||\psi_x^I|_{L^\infty} \\ &\quad + |\zeta_t|_{L^\infty}|\varphi_x^I| + |\zeta_{tx}||\varphi^I|_{L^\infty} + |h|_{L^\infty}|Q_kR^I| \\ &\leq CM_0\left[|\psi_t| + |\varphi_x^I| + |\varphi^I| + |\psi_x^I|_{L^\infty}\right].\end{aligned} \tag{4.19}$$

We multiply (4.18) by $\frac{Q_k\psi_{xx}}{\tilde{v}}$ and integrate with respect to x to obtain

$$\begin{aligned}|\tilde{v}^{-1}Q_k\psi_{xx}^I|^2 &= \int_0^1 \mathcal{F}\tilde{v}^{-1}Q_k\psi_{xx}^I\,dx \\ &\quad - \int_0^1 \tilde{v}^{-2}Q_k\psi_{xx}^IP_k\psi_{xx}^I\,dx \leq \left[|\mathcal{F}| + |\tilde{v}^{-1}P_k\psi_{xx}^I|\right]|\tilde{v}^{-1}Q_k\psi_{xx}^I|,\end{aligned}$$

so that

$$|\tilde{v}^{-1}Q_k\psi_{xx}^I|^2 \leq C|\mathcal{F}|^2 + |\tilde{v}^{-1}P_k\psi_{xx}^I|^2.$$

Hence

$$|Q_k\psi^I_{xx}|^2 \le CM_0^2[|\mathcal{F}|^2 + |P_k\psi^I_{xx}|^2] \le CM_0^4\Big[|\psi_t|^2 + |\varphi^I_x|^2 + |\varphi^I|^2 + |\psi^I_x|^2_{L^\infty}\Big] + |P_k\psi^I_{xx}|^2. \tag{4.20}$$

Now we multiply (4.18) by $\tilde v P_k\psi^I_{xx}$ and obtain

$$\int_0^1 (1+\lambda\tilde v^2)(P_k\psi^I_{xx})^2dx = \int_0^1 \mathcal{F}\tilde v P_k\psi_{xx}\,dx \le M_0|\mathcal{F}||P_k\psi_{xx}| \le CM_0^2|\mathcal{F}|^2 + \frac{1}{2}|P_k\psi_{xx}|^2. \tag{4.21}$$

Therefore

$$|P_k\psi^I_{xx}|^2 \le \frac{CM_0^4}{\lambda}|\mathcal{F}|^2 \le \frac{CM_0^4}{\lambda}\Big[|\psi_t|^2 + |\varphi^I_x|^2 + |\varphi^I|^2 + |\psi^I_x|^2_{L^\infty}\Big]. \tag{4.22}$$

Combining (4.20) and (4.22), we obtain

$$|\psi^I_{xx}|^2 \le CM_0^4\Big[|\psi^I_t|^2 + |\varphi^I|^2 + |\varphi^I_x|^2 + |\psi^I_x|^2_{L^\infty}\Big]. \tag{4.23}$$

Finally, applying Agmon's inequality, we obtain

$$|\psi^I_{xx}|^2 \le CM_0^8\Big[|\psi^I_t|^2 + |\varphi^I|^2 + |\varphi^I_x|^2 + |\psi^I_x|^2\Big]. \tag{4.24}$$

This concludes the proof of Lemma 4.1. □

Proof of Theorem 3.9.

***L*²-estimate for ψ^I.** We rewrite (3.30) in the form

$$\psi^I_t + (q\varphi^I)_x = \left(\frac{\psi^I_x}{\tilde v} + \zeta_t\varphi^I\right)_x + \lambda\tilde v P_k\psi^I_{xx} + hQ_kR^I \tag{4.25}$$

and multiply by $\frac{\psi^I}{\tilde v}$ to obtain

$$\begin{aligned}\frac{1}{2}\frac{d}{dt}\int_0^1 \frac{(\psi^I)^2}{\tilde v}dx - \frac{1}{2}\int_0^1 (\psi^I)^2\zeta_t\,dx &= \int_0^1 q\varphi^I\left(\frac{\psi^I_x}{\tilde v} + \psi^I\zeta_x\right)dx\\ &\quad - \int_0^1\left(\frac{\psi^I_x}{\tilde v} + \zeta_t\varphi^I\right)\left(\frac{\psi^I_x}{\tilde v} + \psi^I\zeta_x\right)dx\\ &\quad - \lambda\int_0^1 (P_k\psi^I_x)^2dx + \int_0^1 \frac{h}{\tilde v}\psi^I Q_kR^I\,dx.\end{aligned} \tag{4.26}$$

Since $|\psi^I| \le |\psi^I_x|$, Lemmas 2.4 and 2.5 yield

$$\frac{1}{2}\frac{d}{dt}\int_0^1 \frac{(\psi^I)^2}{\tilde v}dx + \int_0^1\left(\frac{(\psi^I_x)^2}{\tilde v^2} + \lambda(P_k\psi^I_x)^2\right)dx \le CM_0^2\big[|\varphi^I||\psi^I_x| + |\psi^I_x|^2\big], \tag{4.27}$$

and since

$$\lambda|P_k\psi^I_x|^2 = \lambda|\psi^I_x|^2 - \lambda|Q_k\psi^I_x|^2 \ge \lambda|\psi^I_x|^2 - \frac{\lambda}{k^2}|\psi^I_{xx}|^2 \tag{4.28}$$

we obtain

$$\begin{aligned}\frac{d}{dt}\int_0^1 \frac{(\psi^I)^2}{2\tilde v}dx + \lambda|\psi_x^I|^2 &\le CM_0^2|\varphi^I||\psi_x^I| + CM_0^2|\psi_x^I|^2 + C\frac{\lambda}{k^2}|\psi_{xx}^I|^2\\ &\le \frac{\lambda}{2}|\psi_x^I|^2 + C\frac{M_0^4}{\lambda}|\varphi^I|^2 + CM_0^2|\psi_x^I|^2\\ &\quad + C\frac{\lambda}{k^2}M_0^8\Big[|\varphi^I|^2 + |\varphi_x^I|^2 + |\psi_x^I|^2 + |\psi_t^I|^2\Big].\end{aligned} \tag{4.29}$$

Now assuming that

$$\lambda \ge 4CM_0^2 \quad \text{and} \quad k^2 \ge 4CM_0^8, \tag{4.30}$$

we obtain

$$\frac{d}{dt}\int_0^1 \frac{(\psi^I)^2}{\tilde v}dx + \frac{\lambda}{2}|\psi_x^I|^2 \le CM_0^8\left(\frac{1}{\lambda}+\frac{\lambda}{k^2}\right)|\varphi^I|^2 + CM_0^8\frac{\lambda}{k^2}\big(|\varphi_x^I|^2 + |\psi_t^I|^2\big). \tag{4.31}$$

***H^1*-estimate for ψ^I.** We multiply (4.25) by $\frac{\psi_t^I}{\tilde v}$ and integrate to obtain

$$\begin{aligned}\int_0^1 \frac{(\psi_t^I)^2}{\tilde v}dx + \int_0^1 \frac{\psi_t^I}{\tilde v}(q\varphi^I)_x dx &= -\int_0^1 \left(\frac{\psi_t^I}{\tilde v}\right)_x\left(\frac{\psi_x^I}{\tilde v} + \zeta_t\varphi^I\right)dx\\ &\quad - \frac{\lambda}{2}\frac{d}{dt}\int_0^1 (P_k\psi_x^I)^2dx + \int_0^1 \frac{h}{\tilde v}\psi_t^I Q_k R^I\ dx.\end{aligned}$$

We note that

$$\begin{aligned}\int_0^1 \frac{\psi_t^I}{\tilde v}(q\varphi^I)_x dx &= -\frac{d}{dt}\int_0^1 \frac{q}{\tilde v}\psi_x^I\varphi^I\ dx + \int_0^1 (\psi_x^I)^2\frac{q}{\tilde v}dx + \int_0^1 \frac{q_t}{\tilde v}\varphi^I\psi_x^I\ dx\\ &\quad + \int_0^1 \psi_x^I\varphi^I q\zeta_t\,dx - \int_0^1 \zeta_x\psi_t^I\tilde v_x q\varphi^I\ dx + \int_0^1 \frac{\psi_t^I}{\tilde v}q\varphi_x^I\ dx,\end{aligned} \tag{4.32}$$

which implies

$$\int_0^1 \frac{\psi_t^I}{\tilde v}(q\varphi^I)_x dx = -\frac{d}{dt}\int_0^1 \frac{q}{\tilde v}\psi_x^I\varphi^I\ dx + \mathcal{E}_1, \tag{4.33}$$

with

$$|\mathcal{E}_1| \le CM_0^2\left[|\psi_x^I|^2 + |\psi_x^I||\varphi^I| + |\psi_t^I||\varphi^I| + |\psi_t^I||\varphi^I|\right]. \tag{4.34}$$

Furthermore,

$$\begin{aligned}\int_0^1 \left(\frac{\psi_t^I}{\tilde v}\right)_x\left(\frac{\psi_x^I}{\tilde v} + \zeta_t\varphi^I\right)dx &= \frac{d}{dt}\int_0^1 \left(\frac{(\psi_x^I)^2}{2\tilde v^2} + \frac{\zeta_t}{\tilde v}\psi_x^I\varphi^I\right)dx + \int_0^1 \frac{(\psi_x^I)^2\tilde v_t}{\tilde v^3}dx\\ &\quad - \int_0^1 \frac{\zeta_{tt}}{\tilde v}\psi_x^I\varphi^I\ dx - \int_0^1 \frac{\zeta_t(\psi_x^I)^2}{\tilde v}dx\\ &\quad + \int_0^1 \left[\frac{\zeta_x}{\tilde v}\psi_t^I\psi_x^I + \zeta_x\zeta_t\psi_t^I\varphi^I\right]dx.\end{aligned} \tag{4.35}$$

Hence

$$\int_0^1 \left(\frac{\psi_t^I}{\tilde v}\right)_x \left(\frac{\psi_x^I}{\tilde v} - \zeta_t \varphi^I\right) dx = \frac{d}{dt}\int_0^1 \left[\frac{(\psi_x^I)^2}{2\tilde v^2} + \frac{\zeta_t \psi_x^I \varphi^I}{\tilde v}\right] dx + \mathcal{E}_2, \tag{4.36}$$

with

$$|\mathcal{E}_2| \le CM_0^2\big[|\psi_x^I|^2 + |\varphi^I|^2\big] + CM_0^2\big[|\psi_t^I||\psi_x^I| + |\psi_t^I||\varphi^I|^{1/2}|\varphi_x^I|^{1/2}\big]. \tag{4.37}$$

Therefore

$$\begin{aligned}
&\frac{d}{dt}\int_0^1 \left[\frac{(\psi_x^I)^2}{2\tilde v^2} + \frac{\zeta_t \psi_x^I \varphi^I}{\tilde v} - \frac{q}{\tilde v}\psi_x^I \varphi^I + \frac{\lambda}{2}(P_k \psi_x^I)^2\right] dx + \int_0^1 \frac{(\psi_t^I)^2}{\tilde v} dx \\
&\quad \le CM_0^2\big[|\psi_x^I|^2 + |\varphi^I|^2\big] + CM_0^2|\psi_t^I|\big[|\varphi^I| + |\psi_x^I| + |\varphi_x^I|^{1/2}|\varphi^I|^{1/2}\big] \\
&\quad \le CM_0^2\big[|\psi_x^I|^2 + |\varphi^I|^2\big] + \frac{1}{2M_0}|\psi_t^I|^2 + CM_0^5\big[|\psi_x^I|^2 + |\varphi^I|^2\big] + CM_0^5|\varphi^I||\varphi_x^I|
\end{aligned} \tag{4.38}$$

and

$$\begin{aligned}
\frac{d}{dt}\int_0^1 \left[\frac{(\psi_x^I)^2}{2\tilde v} + \frac{\lambda}{2}(P_k\psi_x^I)^2 + \frac{\zeta_t - q}{\tilde v}\psi_x^I\varphi^I\right] dx + \frac{1}{2M_0}|\psi_t^I|^2 \le CM_0^5\big[|\psi_x^I|^2 + |\varphi^I|^2\big] \\
+ CM_0^5|\varphi^I||\varphi_x^I|.
\end{aligned} \tag{4.39}$$

***L^2*-estimate for φ^I.** We write (3.30) in the form

$$\psi_t^I + (q\varphi^I)_x = \left(\frac{1}{\tilde v}\varphi_t^I + \zeta_t \varphi^I\right)_x + \lambda \tilde v P_k \psi_{xx}^I + hQ_k R^I, \tag{4.40}$$

and noting that

$$R_x^I = \varphi^I \quad \text{and} \quad R_t^I = \psi^I, \tag{4.41}$$

we multiply (4.40) by R^I and integrate to obtain

$$\begin{aligned}
\frac{d}{dt}\int_0^1 R^I\psi^I\,dx - \int_0^1 (\psi^I)^2 dx + \int_0^1 (-q)(\varphi^I)^2\,dx = -\int_0^1 \left[\frac{1}{\tilde v}\varphi^I\varphi_t^I + \zeta_t(\varphi^I)^2\right] dx \\
- \lambda\int_0^1 (\tilde v R^I)_x P_k\psi_x^I\,dx + \int_0^1 hR^I Q_k R^I\,dx.
\end{aligned}$$

Since

$$\frac{d}{dt}\int_0^1 \frac{1}{\tilde v}(\varphi^I)^2 dx = 2\int_0^1 \frac{1}{\tilde v}\varphi^I\varphi_t^I\,dx + \int_0^1 \zeta_t(\varphi^I)^2 dx, \tag{4.42}$$

we can write

$$\begin{aligned}
&\frac{d}{dt}\int_0^1 \left[R^I\psi^I + \frac{(\varphi^I)^2}{\tilde v}\right] dx + \int_0^1 (-q)(\varphi^I)^2 dx = \int_0^1 |\psi^I|^2 dx + \int_0^1 \frac{1}{\tilde v}\varphi^I\psi_x^I\,dx \\
&\qquad - \lambda\int_0^1 (R^I\tilde v)_x P_k\psi_x^I\,dx + \int_0^1 hR^I Q_k R^I\,dx \\
&\qquad \le C|\psi^I|^2 + M_0|\varphi^I||\psi_x^I| + \lambda M_0|\varphi^I||P_k\psi_x^I| + C\frac{M_0}{k}|\varphi^I|^2,
\end{aligned} \tag{4.43}$$

and since $M_0^{-1} \le -q(x,t)$ for $x \in (0,1)$ and $t \ge 0$, and $|\psi^I| \le |\psi_x^I|$, we conclude that for $k \ge 4CM_0^2$,

$$\frac{d}{dt}\int_0^1 \left[R^I\psi^I + \frac{(\varphi^I)^2}{\tilde v}\right] dx + \frac{1}{2M_0}|\varphi^I|^2 \le CM_0^3\lambda^2|\psi_x^I|^2. \tag{4.44}$$

H^1-estimate for φ^I. We write the equation satisfied by ψ^I in the form

$$\psi_t^I + (q_x\varphi^I + q\varphi_x^I) = \left(\frac{\varphi_x^I}{\tilde v}\right)_t + (\zeta_x\varphi^I)_t + \lambda\tilde v P_k\varphi_{xt} + hQ_kR^I \tag{4.45}$$

and multiply by $\frac{\varphi_x}{\tilde v}$ and integrate to obtain

$$\begin{aligned}\int_0^1 \frac{\varphi_x^I}{\tilde v}\psi_t^I\,dx + \int_0^1 \frac{\varphi_x^I}{\tilde v}(q_x\varphi^I + q\varphi_x^I)dx &= \int_0^1 \frac{\varphi_x^I}{\tilde v}\left(\frac{\varphi_x^I}{\tilde v}\right)_t dx \\ &+ \int_0^1 (\zeta_x\varphi)_t\frac{\varphi_x}{\tilde v}\,dx + \lambda\int \frac{\varphi_x^I}{\tilde v}\tilde v P_k\varphi_{xt}^I\,dx + \int_0^1 \frac{\varphi_x^I}{\tilde v}hQ_kR^I\,dx.\end{aligned} \tag{4.46}$$

Therefore, using Lemmas 2.4 and 2.5,

$$\begin{aligned}\frac{d}{dt}\int_0^1 \left(\frac{(\varphi_x^I)^2}{2\tilde v^2} + \frac{\lambda}{2}(P_k\varphi_x^I)^2\right)dx + \frac{1}{M_0^2}|\varphi_x^I|^2dx &\le CM_0|\varphi_x^I||\psi_t^I| + CM_0^2|\varphi^I|^{1/2}|\varphi_x^I|^{3/2} \\ &+ CM_0^2|\varphi_x^I||\varphi^I| + CM_0^2|\psi_x|_{L^\infty}|\varphi_x^I|.\end{aligned} \tag{4.47}$$

Hence, using (4.4),

$$\frac{d}{dt}\int_0^1 \left(\frac{(\varphi_x^I)^2}{2\tilde v^2} + \frac{\lambda}{2}(P_k\varphi_x^I)^2\right)dx + \frac{1}{2M_0^2}|\varphi_x^I|^2 \le CM_0^{20}\big[|\psi_t^I|^2 + |\varphi^I|^2 + |\psi_x^I|^2\big]. \tag{4.48}$$

Let γ_1, γ_2, and γ_3 be large positive numbers, to be determined below, and multiply (4.39) by γ_1, (4.44) by γ_2, and (4.31) by γ_3. The resulting inequalities and inequality (4.48) are

$$\frac{d}{dt}\int_0^1 \left(\frac{(\varphi_x^I)^2}{2\tilde v^2} + \frac{\lambda}{2}(P_k\varphi_x^I)^2\right)dx + \frac{1}{2M_0^2}|\varphi_x^I|^2 \le CM_0^{20}\big[|\psi_t^I|^2 + |\varphi^I|^2 + |\psi_x^I|^2\big], \tag{4.49}$$

$$\gamma_2\frac{d}{dt}\int_0^1 \left[R^I\psi^I + \frac{(\varphi^I)^2}{\tilde v}\right]dx + \frac{\gamma_2}{2M_0}|\varphi^I|^2 \le C\gamma_2\lambda^2M_0^3|\psi_x^I|^2, \tag{4.50}$$

$$\begin{aligned}\gamma_1\frac{d}{dt}\int_0^1 \left[\frac{(\psi_x^I)^2}{2\tilde v} + \frac{\lambda}{2}(P_k\psi_x^I)^2 + \frac{\zeta_t - q}{\tilde v}\psi_x^I\varphi^I\right]dx + \frac{\gamma_1}{2M_0}|\psi_t^I|^2 \\ \le \gamma_1CM_0^5\big[|\psi_x^I|^2 + |\varphi^I|^2\big] + \gamma_1CM_0^5|\varphi^I||\varphi_x^I| \\ \le CM_0^5\big[|\psi_x^I|^2 + |\varphi^I|^2\big] + \frac{1}{2M_0^2}|\varphi_x|^2 + C\gamma_1^2M_0^{12}|\varphi^I|^2,\end{aligned} \tag{4.51}$$

$$\gamma_3\frac{d}{dt}\int_0^1 \frac{(\psi^I)^2}{\tilde v}dx + \gamma_3\frac{\lambda}{2}|\psi_x^I|^2 \le C\gamma_3M_0^8\left(\frac{1}{\lambda} + \frac{\lambda}{k^2}\right)|\varphi^I|^2 + C\gamma_3M_0^8\frac{\lambda}{k^2}\big(|\varphi_x^I|^2 + |\psi_t^I|^2\big). \tag{4.52}$$

We choose γ_1 and γ_2 to be large enough so that

$$\gamma_1 \geq 4CM_0^{21}, \quad \gamma_2 \geq 8CM_0^{21}, \quad \gamma_1 \leq C\frac{\gamma_2}{M_0^6}, \quad \gamma_1^2 \leq C\frac{\gamma_2}{M_0^{13}}. \tag{4.53}$$

Then choose γ_3 large enough so that $\gamma_3\lambda/2 > 2C\gamma_2\Lambda^2 M_0^3$, and finally choose λ and k large enough so that

$$\lambda \geq 4CM_0^{20}, \quad \lambda \geq 4CM_0^3\gamma_2, \quad C\gamma_3 M_0^8\left(\frac{1}{\lambda}+\frac{\lambda}{k^2}\right) \leq \min\left\{\frac{\gamma_2}{8M_0}, \frac{1}{4M_0^2}, \frac{\gamma_1}{8M_0}\right\}. \tag{4.54}$$

From now on, λ and k are fixed. Let

$$\begin{aligned}\mathcal{H}(t) = \int_0^1 \left(\frac{(\varphi_x^I)^2}{2\tilde{v}^2} + \frac{\lambda}{2}(P_k\varphi_x^I)^2\right)dx + \gamma_2\int_0^1\left[R^I\psi^I + \frac{(\varphi^I)^2}{\tilde{v}}\right]dx \\ + \gamma_1\int_0^1\left[\frac{(\psi_x^I)^2}{2\tilde{v}} + \frac{\lambda}{2}(P_k\psi_x^I)^2 + \frac{\zeta_t - q}{\tilde{v}}\psi_x^I\varphi^I\right]dx + \gamma_3\int_0^1\frac{(\psi^I)^2}{\tilde{v}}dx\end{aligned} \tag{4.55}$$

and

$$\mathcal{D}(t) = \frac{1}{4M_0^2}|\varphi_x^I|^2 + \frac{\gamma_2}{4M_0}|\varphi^I|^2 + \frac{\gamma_1}{4M_0}|\psi_t^I|^2 + \frac{\lambda\gamma_3}{4}|\psi_x^I|^2. \tag{4.56}$$

We have, thanks to (4.53) and (4.54),

$$\frac{d}{dt}\mathcal{H}(t) + \mathcal{D}(t) \leq 0. \tag{4.57}$$

It is clear that there exists a constant ν depending only on M_0 such that $\mathcal{H} \leq \frac{1}{\nu}\mathcal{D}$. Therefore

$$\frac{d}{dt}\mathcal{H}(t) + \nu\mathcal{H}(t) \leq 0, \tag{4.58}$$

and $\mathcal{H}(t) \leq \mathcal{H}(0)\mathrm{e}^{-\nu t}$. Thus there exists a constant K_0 depending only on M_0 such that

$$|\varphi_x^I(\cdot,t)|^2 + |\psi_x^I(\cdot,t)|^2 \leq K_0\mathrm{e}^{-\nu t}\big(|\varphi_x^I(\cdot,0)|^2 + |\psi_x^I(\cdot,0)|^2\big). \tag{4.59}$$

(Note that φ^I and ψ^I satisfy the Poincaré inequality.) Finally, since φ^I and ψ^I satisfy linear equations, we can apply (3.34), which is proved below, and the Riesz–Thorin interpolation theorem to obtain (3.35).

***L^2*-continuous dependence for φ^I and ψ^I.** At this point λ and k are fixed. We multiply the equations satisfied by ψ^I, φ^I, and η by ψ^I, φ^I, and η, respectively, and obtain using $|P_k\psi_{xx}^I| \leq k^2|\psi^I|$ that

$$\frac{d}{dt}\big[|\psi^I|^2 + |\varphi^I|^2 + |\eta|^2\big] \leq CM_0^2[|\psi^I|^2 + |\varphi^I|^2] + CM_0^2k^2|\psi^I|^2 + C|\eta|^2, \tag{4.60}$$

from which (3.34) follows immediately.

***H^1*-estimates for φ^{II} and ψ^{II}.** We multiply the equation satisfied by ψ^{II} by $\frac{\psi_t^{II}}{\tilde{v}}$, the equation satisfied by φ^{II} by φ_{xx}^{II}, and the equation satisfied by η by η. Then we apply

$$|\psi_{xx}^{II}|^2 \leq M_0^2\left|\left(\frac{\psi^{II}}{\tilde{v}}\right)_x\right|^2 + CM_0^2|\psi_x^{II}|^2 \tag{4.61}$$

and

$$\left|\left(\frac{\psi^{II}}{\tilde{v}}\right)_x\right| \le |\psi_t^{II}| + M_0|\varphi_x^{II}| + \lambda k^2|\psi^I| + M_0|\varphi^I| + M_0|\varphi^{II}| + M_0|\eta| \tag{4.62}$$

to obtain (3.36). The details are straightforward.

ON ANALYSIS OF STEADY FLOWS OF FLUIDS WITH SHEAR-DEPENDENT VISCOSITY BASED ON THE LIPSCHITZ TRUNCATION METHOD*

JENS FREHSE†, JOSEF MÁLEK‡, AND MARK STEINHAUER§

Abstract. We deal with a system of partial differential equations describing a steady motion of an incompressible fluid with shear-dependent viscosity and present a new global existence result for $p > \frac{2d}{d+2}$. Here p is the coercivity parameter of the nonlinear elliptic operator related to the stress tensor and d is the dimension of the space. Lipschitz test functions, a subtle splitting of the level sets of the maximal functions for the velocity gradients, and a decomposition of the pressure are incorporated to obtain almost everywhere convergence of the velocity gradients.

Key words. incompressible fluid, power-law fluid, shear-dependent viscosity, existence, weak solution, Lipschitz approximation of $W^{1,p}$-functions

1. Introduction.

Let Ω be an open bounded set in $\mathbb{R}^d$ with boundary $\partial\Omega$. We study the following problem: For given $\mathbf{f} = (f^1, \dots, f^d) : \Omega \to \mathbb{R}^d$ and $\mathbf{T} : \Omega \times \mathbb{R}^{d\times d} \to \mathbb{R}^{d\times d}$ we find $\mathbf{v} = (v^1, \dots, v^d) : \Omega \to \mathbb{R}^d$ and $P : \Omega \to \mathbb{R}$ solving

$$-\operatorname{div} \mathbf{T}(\cdot, \mathbf{D}(\mathbf{v})) + \operatorname{div}(\mathbf{v} \otimes \mathbf{v}) + \nabla P = \mathbf{f} \quad \text{in } \Omega, \tag{1.1}$$

$$\operatorname{div} \mathbf{v} = 0 \quad \text{in } \Omega, \tag{1.2}$$

$$\mathbf{v} = \mathbf{0} \quad \text{on } \partial\Omega, \tag{1.3}$$

where $\mathbf{D}(\mathbf{v})$ denotes the symmetric part of the velocity gradient $\nabla\mathbf{v}$, i.e.,

$$\mathbf{D}(\mathbf{v}) \equiv \frac{1}{2}(\nabla\mathbf{v} + \nabla\mathbf{v}^T) \quad \text{with } D_{ij}(\mathbf{v}) = \frac{1}{2}(\partial_i v^j + \partial_j v^i).$$

The main aim of this paper is to present new existence results to (1.1)–(1.3).

Before specifying the main result precisely we fix our notation and give the assumptions on the form of $\mathbf{T}$. The formulation of the main theorem is then completed by comments on earlier results and methods related to the problem (1.1)–(1.3). The last part of this introductory section is devoted to a physical background of the problem and its significance. We also give examples of functions $\mathbf{T}$ and show that they satisfy the assumptions of the main theorem.

1.1. Notation. Let $\mathbb{M}$ denote the space of all real $(d \times d)$ matrices $\mathbf{F} = (F_{ij})$, and let $\mathbb{S}$ be its subspace consisting of all symmetric $(d \times d)$ matrices. Using the usual summation convention on repeated indices we set $\mathbf{a} \cdot \mathbf{b} \equiv a^i b^i$ and $(\mathbf{a} \otimes \mathbf{b})_{ij} = a^i b^j$ for $\mathbf{a}$, $\mathbf{b} \in \mathbb{R}^d$ and $\mathbf{F} : \mathbf{H} \equiv F_{ij} H_{ij}$ for $\mathbf{F}$, $\mathbf{H} \in \mathbb{M}$. Also we set $|\mathbf{a}| \equiv (\mathbf{a} \cdot \mathbf{a})^{1/2}$ and $|\mathbf{F}| \equiv (\mathbf{F} : \mathbf{F})^{1/2}$.

We use the standard notation of function spaces. If $1 \le q \le +\infty$, then $L^q(\Omega)$ and $W^{k,q}(\Omega)$ ($\mathring{W}^{k,q}(\Omega)$) denote the usual Lebesgue and Sobolev spaces of scalar-, vector-, and tensor-valued functions (with zero traces at the boundary $\partial\Omega$). The norm of $u \in W^{k,q}(\Omega)$ is defined as $\|u\|^q_{k,q;\Omega} \equiv \sum_{|\alpha| \le k} \int_\Omega |D^\alpha u|^q \, dx$.

By $W^{-1,p'}(\Omega)$ we mean the dual space $(\mathring{W}^{1,p}(\Omega))'$ to $\mathring{W}^{1,p}(\Omega)$ with corresponding duality pairing $\langle ., . \rangle_{1,p,\Omega}$.

As usual, $C_0^\infty(\Omega)$ denotes the set of all C^∞-functions with compact support in Ω, while the space $C^\infty_{0,\sigma}(\Omega)$ consists of $\mathbf{\Phi} \in C_0^\infty(\Omega)$ such that $\operatorname{div} \mathbf{\Phi} = 0$. For $p, q \ge 1$ we set

$$
\begin{aligned}
H_q &\equiv \overline{C^\infty_{0,\sigma}(\Omega)}^{\|\cdot\|_{0,q}} = \{\mathbf{v} \in L^q(\Omega) \, : \operatorname{div} \mathbf{v} = 0, \mathbf{v} \cdot \mathbf{n} = 0 \text{ at } \partial\Omega\}, \\
V_p &\equiv \overline{C^\infty_{0,\sigma}(\Omega)}^{\|\nabla\cdot\|_{0,p}} = \{\mathbf{v} \in \mathring{W}^{1,p}(\Omega) \, : \operatorname{div} \mathbf{v} = 0\}, \\
V_p^{'} &\equiv \text{ dual of } V_p.
\end{aligned}
$$

The brackets $\langle ., . \rangle_{V_p}$ represent the duality pairing between V_p and $V_p^{'}$.

If $\mathbf{g}, \mathbf{h}$ are vector-valued functions and $g_i h_i \in L^1(\Omega)$, then $(\mathbf{g}, \mathbf{h}) \equiv \int_\Omega \mathbf{g} \cdot \mathbf{h} \, dx$. Analogously, for tensor-valued functions $\boldsymbol{\eta}, \boldsymbol{\xi}$ satisfying $\eta_{ij} \xi_{ij} \in L^1(\Omega)$ we set $(\boldsymbol{\eta}, \boldsymbol{\xi}) \equiv \int_\Omega \boldsymbol{\eta} : \boldsymbol{\xi} \, dx$.

We will also use the Korn inequality (see [29] for a proof), saying that for $1 < p < +\infty$ there exists a constant $K_p = K_p(\Omega)$ such that

$$
\|\nabla \mathbf{v}\|_{0,p} \le K_p \, \|\mathbf{D}(\mathbf{v})\|_{0,p} \quad \text{for all } \mathbf{v} \in \mathring{W}^{1,p}(\Omega). \tag{1.4}
$$

1.2. Assumptions and main theorem. We start with the formulation of the assumptions on $\mathbf{T} = (T_{ij}) \in \mathbb{S}$.

We assume that $\mathbf{T}$ is a Carathéodory function (i.e., for each fixed $\mathbf{F} \in \mathbb{S}$ the function $x \mapsto \mathbf{T}(x, \mathbf{F})$ is (Lebesgue-) measurable in Ω and the function $\mathbf{F} \mapsto \mathbf{T}(x, \mathbf{F})$ is continuous in $\mathbb{S}$ for almost every $x \in \Omega$) and satisfies for some $p > 1$ the following conditions:

- p-coercivity: there are $c_1 > 0$ and $\varphi_1 \in L^1(\Omega)$ such that

$$
\mathbf{T}(x, \boldsymbol{\eta}) : \boldsymbol{\eta} \ge c_1 |\boldsymbol{\eta}|^p - \varphi_1(x) \tag{1.5}
$$

  for almost all $x \in \Omega$ and for all $\boldsymbol{\eta} \in \mathbb{S}$;
- polynomial growth of order $p - 1$: there are $c_2 > 0$ and $\varphi_2 \in L^{\frac{p}{p-1}}(\Omega)$ such that

$$
|\mathbf{T}(x, \boldsymbol{\eta})| \le c_2 |\boldsymbol{\eta}|^{p-1} + \varphi_2(x) \tag{1.6}
$$

  for almost all $x \in \Omega$ and for all $\boldsymbol{\eta} \in \mathbb{S}$;
- strict monotonicity:

$$
(\mathbf{T}(x, \boldsymbol{\eta}) - \mathbf{T}(x, \boldsymbol{\xi})) : (\boldsymbol{\eta} - \boldsymbol{\xi}) > 0 \tag{1.7}
$$

  for almost all $x \in \Omega$ and for all $\boldsymbol{\eta}, \boldsymbol{\xi} \in \mathbb{S}$ such that $\boldsymbol{\eta} \ne \boldsymbol{\xi}$.

Next, assume that $\mathbf{f} \in W^{-1,p'}(\Omega)$ and (1.5)–(1.7) hold. We say that $\mathbf{v} \in V_p$ is a weak solution to problem (1.1)–(1.3) if

$$\int_\Omega \mathbf{T}(x, \mathbf{D}(\mathbf{v})) : \mathbf{D}(\mathbf{\Phi})\, dx = \langle \mathbf{f}, \mathbf{\Phi} \rangle_{1,p} + \int_\Omega (\mathbf{v} \otimes \mathbf{v}) : \mathbf{D}(\mathbf{\Phi})\, dx \quad \text{for all } \mathbf{\Phi} \in C^\infty_{0,\sigma}(\Omega). \tag{1.8}$$

Note that $(\mathbf{v} \otimes \mathbf{v})_{ij} \equiv v^i v^j \in L^1(\Omega)$ for $p \geq \frac{2d}{d+2}$ due to Sobolev's embedding theorem.

Now we are ready to formulate our existence theorem.

THEOREM 1.1. *Let $p > \frac{2d}{d+2}$, $d \geq 2$. Let $\Omega \subset \mathbb{R}^d$ be an open, bounded set with $\partial\Omega$ of the class $C^{1,1}$. Assume that $\mathbf{f} \in W^{-1,p'}(\Omega)$ and* (1.5)–(1.7) *hold. Then there exists $\mathbf{v} \in V_p$, being a weak solution to* (1.1)–(1.3).

The proof of Theorem 1.1 is split into three parts, each presented in a separate section. In section 2, we introduce suitable approximations to (1.1) and study their basic properties (energy estimates and their consequences, existence of the pressure). Then, in section 3, we present a subtle decomposition of the pressure suitable to our analysis. Finally, in section 4, we present the passage from the solutions of the approximative problems to the solution of (1.1)–(1.3), thus completing the proof.

1.3. Historical comments. Let us first remark that if the convective term $\operatorname{div}(\mathbf{v} \otimes \mathbf{v})$ is neglected in (1.1) and the tensor $\mathbf{T} = (T_{ij})_{i,j=1}^d$ has a potential, i.e., $T_{ij} = \frac{\partial \Phi}{\partial D_{ij}}$, a variational approach can be used. Then the existence of a weak solution can be easily established for all $p > 1$. We refer to the recent works of Fuchs and Seregin [14], [15], where in particular regularity questions for these kinds of problems are discussed.

For proving existence of a weak solution to (1.1)–(1.3) two different methods have been developed. The first one combines the arguments of the standard monotone operator theory with the compactness for $\mathbf{v}$, which turns out to be applicable to (1.1)–(1.3) if $p \geq \frac{3d}{d+2}$. It was performed by Lions [22] and Ladyzhenskaya [18], [19], [20] in the late sixties. The second method, which we call the L^∞-truncation method, yields existence of a weak solution if $p \geq \frac{2d}{d+1}$. It is based on the construction of a special (bounded) test function, a precise characterization of the pressure, and also relies strongly on the strict monotonicity of $\mathbf{T}$. This method was successfully applied to the steady problem in [12] and [32] (in [32] the limiting case $p = \frac{2d}{d+1}$ is not included).

In the present paper we introduce yet another approach, which we call the Lipschitz truncation method, in order to prove the existence of a weak solution for $p > \frac{2d}{d+2}$. We construct a Lipschitz test function to show that for conveniently introduced approximations $\mathbf{v}^n$ we can find a subsequence $\{\mathbf{v}^k\} \subset \{\mathbf{v}^n\}$ such that $\mathbf{D}(\mathbf{v}^k)$ converge almost everywhere to their weak limit $\mathbf{D}(\mathbf{v})$, which is the crucial point in proving that $\mathbf{v}$ is a weak solution to (1.1)–(1.3). *Note that because of earlier results mentioned above we can restrict ourselves within the proof to the case $p \in (\frac{2d}{d+2}, \frac{2d}{d+1}]$.*

Lipschitz truncations of Sobolev functions were already successfully used in different contexts; see [1], [2], [8], [9], [21], [28], [39], [40], [41], and [42]. The novelty of our application of the Lipschitz approximations of Sobolev functions consists of discovering the mechanism of obtaining almost everywhere convergence of gradients for weakly convergent sequences.

Finally we mention that the corresponding time-dependent system is treated in [4], [13], [18], [19], [20], [22], [23], [24], [25], [26], and [30]. We are not going to discuss the dependence of the known existence results on p. We wish to emphasize, however, that we believe that a convenient, probably not straightforward, modification

of the techniques presented in this paper can also improve the existence results for the evolutionary model.

1.4. Continuum mechanical background. Consider isothermal steady flows of an incompressible fluid with a constant density $\rho > 0$. Such flows in a fixed domain Ω are described by the system of equations

$$\operatorname{div} \mathbf{v} = 0, \tag{1.9}$$

$$\rho v^k \frac{\partial \mathbf{v}}{\partial x_k} = \rho \mathbf{f} + \operatorname{div} \mathbf{S}, \tag{1.10}$$

where $\mathbf{v} = (v^1, \dots, v^d)$ is the velocity, $\mathbf{f} = (f^1, \dots, f^d)$ is the density of the volume forces acting on the fluid, and $\mathbf{S}$ is the Cauchy stress.

Equation (1.9) expresses the fact that the fluid is incompressible. Note that due to (1.9) and the fact that the density is constant, the balance of mass is fulfilled.

Equation (1.10) represents the balance of linear momentum. Setting

$$P \equiv -\frac{1}{d} \operatorname{tr} \mathbf{S}, \tag{1.11}$$

we see that the tensor

$$\mathbf{S}_D \equiv \mathbf{S} + P\mathbf{I} \tag{1.12}$$

satisfies

$$\operatorname{tr} \mathbf{S}_D = 0. \tag{1.13}$$

Assuming that $\mathbf{S}_D$ is a tensorial function of the velocity gradient and the fluid is isotropic, the principle of material frame indifference then implies that it happens only through its symmetric part $\mathbf{D}(\mathbf{v})$. Thus,

$$\mathbf{S}_D = \mathbf{T}(\mathbf{D}(\mathbf{v})), \tag{1.14}$$

and one observes that if we put (1.12) with (1.14) into (1.10) and divide the result by ρ, one obtains (1.1). (In fact, the form of $\mathbf{T}$ in (1.1) is more general, as it also permits the dependence of $\mathbf{T}$ on the spatial variable.) Clearly, $v^k \frac{\partial \mathbf{V}}{\partial x_k} = \operatorname{div}(\mathbf{v} \otimes \mathbf{v})$ due to (1.9).

Consider a subclass of (1.14) defined through

$$\mathbf{T}(\mathbf{D}(\mathbf{v})) = \nu(|\mathbf{D}(\mathbf{v})|^2)\mathbf{D}(\mathbf{v}), \tag{1.15}$$

where ν, being a function of the second invariant[1] of the tensor $\mathbf{D}(\mathbf{v})$, is called the generalized viscosity. Materials with the constitutive equation (1.15) are called *fluids with shear-dependent viscosity*. Note that models (1.14)–(1.15) satisfy the requirement (1.13) thanks to (1.9).

Fluids with shear-dependent viscosity represent an important subclass of non-Newtonian fluids, consisting of fluids that have the ability to shear thin (the generalized viscosity decreases as the shear rate in a simple flow increases) or shear thicken (the viscosity increases with the increasing shear rate). In [31], the interested reader

[1]The second invariant II of $\mathbf{D}(\mathbf{v})$ is defined through $II = 1/2[(\operatorname{tr} \mathbf{D}(\mathbf{v}))^2 - \operatorname{tr} \mathbf{D}^2(\mathbf{v})]$. Since in our case $\operatorname{div} \mathbf{v} = \operatorname{tr} \mathbf{D}(\mathbf{v}) = 0$ we conclude that $II = -1/2 \operatorname{tr} \mathbf{D}^2(\mathbf{v}) = -1/2|\mathbf{D}(\mathbf{v})|^2$.

can find a detailed description of these phenomena that were experimentally observed in various areas of engineering such as blood and food rheology, glaciology, geology, and koloid mechanics. We refer to [26] (see also [25]), where a representative list of references to experimental works confirming the presence of nonconstant viscosities in fluids is provided. The power-law fluids, which enjoy significant attention among engineers and physicists, fall into this category; their constitutive equation takes the form (1.15) with

$$\nu(|\mathbf{D}(\mathbf{v})|^2) = \nu_0 |\mathbf{D}(\mathbf{v})|^{p-2}, \tag{1.16}$$

where $p > 1$ is the so-called power-law exponent and $\nu_0 > 0$. Note that if $p = 2$ in (1.16), then the (generalized) viscosity is constant, the dependence of $\mathbf{T}$ on $\mathbf{D}(\mathbf{v})$ in (1.15) is then linear (i.e., the fluid is by definition Newtonian), and the system (1.9)–(1.10) with $\mathbf{S}$ given by (1.12) reduces to the well-known Navier–Stokes equations. For $1 \le p < 2$, the generalized viscosity in (1.16) decreases with increasing $|\mathbf{D}(\mathbf{v})|^2$ and (1.14)–(1.16) then represent shear thinning fluids, while for $p > 2$ (1.14)–(1.16) represent shear thickening fluids. Typical values of the power-law exponent p used in many areas are of the form $\frac{3}{2}$, $\frac{4}{3}$, $\frac{6}{5}$, etc. This recalls a need to have an existence theory for $p \in [1, 2)$, and this also motivates our interest in this direction.

Other examples of models that are widely used in various areas of engineering are given by

$$\mathbf{T}_1(\mathbf{D}(\mathbf{v})) \equiv \nu_0 |\mathbf{D}(\mathbf{v})|^{p-2}\mathbf{D}(\mathbf{v}) + \mu_\infty \mathbf{D}(\mathbf{v}), \tag{1.17}$$

$$\mathbf{T}_2(\mathbf{D}(\mathbf{v})) \equiv \nu_0 (\mu_0 + |\mathbf{D}(\mathbf{v})|^2)^{\frac{p-2}{2}}\mathbf{D}(\mathbf{v}) + \mu_\infty \mathbf{D}(\mathbf{v}), \tag{1.18}$$

$$\mathbf{T}_3(\mathbf{D}(\mathbf{v})) \equiv \mu_\infty \mathbf{D}(\mathbf{v}) + \mu_1 \operatorname{arcsinh}(|\mathbf{D}(\mathbf{v})|)\frac{\mathbf{D}(\mathbf{v})}{|\mathbf{D}(\mathbf{v})|}, \tag{1.19}$$

where μ_0, μ_1, μ_∞, and ν_0 are (at least) nonnegative constants and $p \ge 1$.

Another interesting issue consists of boundary conditions. Here we suppose that the fluid adheres to the boundary, meaning that (no-slip) boundary conditions

$$\mathbf{v} = \mathbf{0} \quad \text{on} \quad \partial\Omega \tag{1.20}$$

are considered.

One could require another type of requirement on the boundary, as for example Navier's, slip, free, or nonhomogeneous Dirichlet boundary conditions, or consider the problem without boundaries in the whole space or in the spatial periodic setting.

We restrict ourselves in what follows to the Dirichlet boundary condition (1.20) for two reasons:

- If one considers another type of boundary condition, the statements of Theorem 1.1 and its proof do not change essentially if one has at one's disposal the basic energy estimates. Thus, the energy estimates are more important than the type of the chosen boundary conditions.
- Boundary conditions (1.20) seem to be reasonable in many applications.

Nevertheless, the reader might find it worthwhile to look at [11] and [17] for further discussion and the treatment of other boundary conditions.

Let us finish this section by showing that the tensors given by formulas (1.17) and (1.18) satisfy the hypotheses (1.5)–(1.7) of Theorem 1.1 if $\nu_0 > 0$ and μ_0, $\mu_\infty \ge 0$. The third example (1.19) satisfies the assumption $p > \frac{2d}{d+2}$ only if $\mu_\infty > 0$.

Example (1.17). Consider $\mathbf{T}_1(\mathbf{F}) = \nu_0|\mathbf{F}|^{p-2}\mathbf{F} + \mu_\infty\mathbf{F}$ with constants $\nu_0 > 0$ and $\mu_\infty \geq 0$ and $\mathbf{F} \in \mathbb{S}$ (corresponding to $\mathbf{D}(\mathbf{v})$). Obviously $\mathbf{T}_1$ is continuous and satisfies both the growth condition

$$|\mathbf{T}(\mathbf{F})| \leq \nu_0|\mathbf{F}|^{p-1} + \mu_\infty|\mathbf{F}|$$

and the coercivity condition

$$\mathbf{T}(\mathbf{F}) : \mathbf{F} = \nu_0|\mathbf{F}|^p + \mu_\infty|\mathbf{F}|^2 \geq \nu_0|\mathbf{F}|^p.$$

For monotonicity we consider two cases.

Case 1. $p \geq 2$. Then we have

$$(\mathbf{T}_1(\mathbf{F}_1) - \mathbf{T}_1(\mathbf{F}_2)) : (\mathbf{F}_1 - \mathbf{F}_2) \geq \nu_0\gamma_0(p,d)|\mathbf{F}_1 - \mathbf{F}_2|^p + \mu_\infty|\mathbf{F}_1 - \mathbf{F}_2|^2,$$

where we use Lemma 4.4 of [7, p. 13]. This inequality shows not only that $\mathbf{T}_1$ is strictly monotone but also that $\mathbf{T}_1$ is uniformly monotone (see [37, p. 500ff., Def. 25.2]).

Case 2. $1 < p < 2$. We are going to verify that

$$(\mathbf{T}_1(\mathbf{F}_1) - \mathbf{T}_1(\mathbf{F}_2)) : (\mathbf{F}_1 - \mathbf{F}_2) \geq \nu_0\gamma_1(p,d)\frac{|\mathbf{F}_1 - \mathbf{F}_2|^2}{(|\mathbf{F}_1| + |\mathbf{F}_2|)^{2-p}} + \mu_\infty|\mathbf{F}_1 - \mathbf{F}_2|^2.$$

To prove it, it is enough to show that

$$(|\mathbf{a}|^{p-2}\mathbf{a} - |\mathbf{b}|^{p-2}\mathbf{b}) \cdot (\mathbf{a} - \mathbf{b}) \geq \gamma_1(p,d)\frac{|\mathbf{a} - \mathbf{b}|^2}{(|\mathbf{a}| + |\mathbf{b}|)^{2-p}} \quad \text{for } \mathbf{a}, \mathbf{b} \in \mathbb{R}^k,$$

which is due to the computations

$$\begin{aligned}
&(|\mathbf{a}|^{p-2}\mathbf{a} - |\mathbf{b}|^{p-2}\mathbf{b}) \cdot (\mathbf{a} - \mathbf{b}) \\
&= \left(\int_0^1 \tfrac{d}{ds}|s\mathbf{a} + (1-s)\mathbf{b}|^{p-2}(s\mathbf{a} + (1-s)\mathbf{b})\, ds\right) \cdot (\mathbf{a} - \mathbf{b}) \\
&= \int_0^1 |s\mathbf{a} + (1-s)\mathbf{b}|^{p-2}|\mathbf{a} - \mathbf{b}|^2\, ds \\
&\qquad + \int_0^1 (p-2)|s\mathbf{a} + (1-s)\mathbf{b}|^{p-2}\left((\mathbf{a} - \mathbf{b}) \cdot \frac{s\mathbf{a} + (1-s)\mathbf{b}}{|s\mathbf{a} + (1-s)\mathbf{b}|}\right)^2 ds \\
&\geq (1 + \min(0, p-2)) \int_0^1 |s\mathbf{a} + (1-s)\mathbf{b}|^{p-2}\, ds\, |\mathbf{a} - \mathbf{b}|^2 \\
&\geq (p-1)\, \frac{|\mathbf{a} - \mathbf{b}|^2}{(|\mathbf{a}| + |\mathbf{b}|)^{2-p}},
\end{aligned}$$

where we use the fact that $1 < p < 2$ and $|s\mathbf{a} + (1-s)\mathbf{b}| \leq |\mathbf{a}| + |\mathbf{b}|$ for all $s \in [0,1]$. Thus, we conclude that $\mathbf{T}_1$ is strictly monotone but in general not uniformly monotone.

Example (1.18). Consider $\mathbf{T}_2(\mathbf{F}) = \nu_0(\mu_0 + |\mathbf{F}|^2)^{\frac{p-2}{2}}\mathbf{F} + \mu_\infty\mathbf{F}$ with constants $\nu_0 > 0$ and $\mu_0, \mu_\infty \geq 0$. Computations similar to the previous example show that all hypotheses of Theorem 1.1 are satisfied (see [25, Chap. 5, pp. 193–196, 198ff., Lem. 1.19]).

2. Approximations and their properties. We define approximations to our problem in the following way: For $m = 1, 2, 3, \dots, p > 1$ and $q \geq \frac{2p}{p-1} = 2p'$ we look for $(\mathbf{v}^m, P^m)$ solving in Ω

$$\begin{aligned} -\operatorname{div} \mathbf{T}(\cdot, \mathbf{D}(\mathbf{v}^m)) + \operatorname{div}(\mathbf{v}^m \otimes \mathbf{v}^m) + \frac{1}{m}|\mathbf{v}^m|^{q-2}\mathbf{v}^m &= \mathbf{f} - \nabla P^m, \\ \operatorname{div} \mathbf{v}^m &= 0, \end{aligned} \tag{2.1}$$

complemented by the boundary conditions

$$\mathbf{v}^m = \mathbf{0} \quad \text{on } \partial\Omega. \tag{2.2}$$

The following lemma can be proved by standard arguments of the monotone operator theory and via the compact embedding $\mathring{W}^{1,p}(\Omega) \hookrightarrow\hookrightarrow L^2(\Omega)$ valid for $p > \frac{2d}{d+2}$.

LEMMA 2.1. *Let $p > \frac{2d}{d+2}$ and $q \geq \frac{2p}{p-1} = 2p'$. Suppose $\mathbf{f} \in W^{-1,p'}(\Omega)$. Then there exists $\mathbf{v}^m \in V_p \cap H_q$ satisfying*

$$\begin{aligned} \int_\Omega \mathbf{T}(\cdot, \mathbf{D}(\mathbf{v}^m)) : \mathbf{D}(\mathbf{\Phi})\, dx + \frac{1}{m}\int_\Omega |\mathbf{v}^m|^{q-2}\mathbf{v}^m \cdot \mathbf{\Phi}\, dx &= \langle \mathbf{f}, \mathbf{\Phi} \rangle_{1,p} \\ + \int_\Omega (\mathbf{v}^m \otimes \mathbf{v}^m) : \mathbf{D}(\mathbf{\Phi})\, dx \quad &\text{for all } \mathbf{\Phi} \in C^\infty_{0,\sigma}(\Omega). \end{aligned} \tag{2.3}$$

Moreover, all $\mathbf{v}^m$ satisfy the uniform estimate

$$\|\mathbf{D}(\mathbf{v}^m)\|^p_{0,p} + \|\nabla \mathbf{v}^m\|^p_{0,p} + \frac{1}{m}\|\mathbf{v}^m\|^q_{0,q} \leq K \tag{2.4}$$

and consequently, due to the growth condition (1.6) *and Sobolev's embedding theorem (considered in the interesting case $p < d$),*

$$\|\mathbf{T}(\cdot, \mathbf{D}(\mathbf{v}^m))\|_{0,p'} \leq K, \tag{2.5}$$

$$\|\mathbf{v}^m\|_{0,\frac{dp}{d-p}} \leq K, \tag{2.6}$$

$$\|\mathbf{v}^m \otimes \mathbf{v}^m\|_{0,\frac{dp}{2(d-p)}} \leq K. \tag{2.7}$$

Let us emphasize that due to earlier existence results mentioned in the introduction, it is enough to deal with the case

$$p \in \Big(\frac{2d}{d+2}, \frac{2d}{d+1}\Big].$$

Next, we introduce the (approximative) pressures P^m, observing that in (2.3) we can use test functions $\mathbf{\Phi}$ from $V_p \cap V_r = V_r$, where $\frac{1}{r} = 1 + \frac{2}{d} - \frac{2}{p} = \frac{(d+2)p-2d}{dp}$ because of $V_p \hookrightarrow L^{\frac{dp}{d-p}}$. Let us note that for all $s \in [1, \infty)$, $V_r \hookrightarrow\hookrightarrow L^s$ for $\frac{2d}{d+2} < p \leq \frac{2d}{d+1}$. Defining the functional $\mathbf{F}^m$ as

$$\begin{aligned} \langle \mathbf{F}^m, \mathbf{\Phi} \rangle_{1,r,\Omega} \equiv \int_\Omega \mathbf{T}(\cdot, \mathbf{D}(\mathbf{v}^m)) : \mathbf{D}(\mathbf{\Phi})\, dx + \frac{1}{m}\int_\Omega |\mathbf{v}^m|^{q-2}\mathbf{v}^m \cdot \mathbf{\Phi}\, dx \\ - \int_\Omega (\mathbf{v}^m \otimes \mathbf{v}^m) : \mathbf{D}(\mathbf{\Phi})\, dx - \langle \mathbf{f}, \mathbf{\Phi} \rangle_{1,p,\Omega} \end{aligned} \tag{2.8}$$

we see that $\langle \mathbf{F}^m, \mathbf{\Phi}\rangle_{1,r,\Omega} = 0$ for all $\mathbf{\Phi} \in C^\infty_{0,\sigma}(\Omega)$ due to (2.3). Moreover $\mathbf{F}^m \in W^{-1,r'}(\Omega)$ and

$$\|\mathbf{F}^m\|_{-1,r'} \le K \quad \text{with } r' = \frac{r}{r-1} = \frac{dp}{dp-(d+2)p+2d} = \frac{dp}{2(d-p)}\,.$$

By a version of De Rham's theorem (see, for example, [3, Thm. 2.8, p. 116ff.]) there exists $P^m \in L^{r'}(\Omega)$ with zero mean value over each connected component of Ω such that

$$\langle \mathbf{F}^m, \mathbf{\Phi}\rangle_{1,r,\Omega} \equiv \langle -\nabla P^m, \mathbf{\Phi}\rangle_{1,r,\Omega} = \int_\Omega P^m \operatorname{div} \mathbf{\Phi}\, dx \tag{2.9}$$

and

$$\|P^m\|_{0,r'} \le C\, \|\nabla P^m\|_{-1,r'} \le C\, \|F^m\|_{-1,r'} \le K. \tag{2.10}$$

As a consequence of these observations we obtain the equivalent weak formulation to (2.3),

$$\begin{aligned}\int_\Omega \mathbf{T}(\cdot, \mathbf{D}(\mathbf{v}^m)) : \mathbf{D}(\mathbf{\Phi})\, dx + \frac{1}{m}\int_\Omega |\mathbf{v}^m|^{q-2}\mathbf{v}^m \cdot \mathbf{\Phi}\, dx \\ = \langle \mathbf{f}, \mathbf{\Phi}\rangle_{1,p} + \int_\Omega (\mathbf{v}^m \otimes \mathbf{v}^m) : \mathbf{D}(\mathbf{\Phi})\, dx + \int_\Omega P^m \operatorname{div} \mathbf{\Phi}\, dx,\end{aligned} \tag{2.11}$$

valid for all $m = 1, 2, 3, \dots$ and all $\mathbf{\Phi} \in \mathring{W}^{1,r}(\Omega)$ with $r = \frac{dp}{(d+2)p-2d}$. Note that if $p \in (\frac{2d}{d+2}, \frac{2d}{d+1}]$, then $r \ge d$.

The uniform estimates (2.4)–(2.7) and (2.10) imply the existence of a subsequence $\{(\mathbf{v}^k, P^k)\}_{k\in\mathbb{N}} = \{(\mathbf{v}^{m_k}, P^{m_k})\}_{k\in\mathbb{N}}$ of $\{(\mathbf{v}^m, P^m)\}_{m\in\mathbb{N}}$ and $(\mathbf{v}, P) \in V_p \times L^{r'}(\Omega)$ such that $(k \to \infty)$

$$\mathbf{D}(\mathbf{v}^k) \rightharpoonup \mathbf{D}(\mathbf{v}) \qquad \text{weakly in } L^p(\Omega), \tag{2.12}$$

$$\nabla \mathbf{v}^k \rightharpoonup \nabla \mathbf{v} \qquad \text{weakly in } L^p(\Omega), \tag{2.13}$$

$$\mathbf{v}^k \to \mathbf{v} \qquad \text{strongly in } L^s(\Omega) \text{ for all } s \in [1, 2r'), \tag{2.14}$$

$$\mathbf{v}^k \to \mathbf{v} \qquad \text{almost everywhere in } \Omega, \tag{2.15}$$

$$\mathbf{T}(\cdot, \mathbf{D}(\mathbf{v}^k)) \rightharpoonup \boldsymbol{\chi} \qquad \text{weakly in } L^{p'}(\Omega), \tag{2.16}$$

$$P^k \rightharpoonup P \qquad \text{weakly in } L^{r'}(\Omega). \tag{2.17}$$

Now we want to pass to the limit in (2.11) as $k \to \infty$. In order to do so we first observe that (2.4) implies for every $\mathbf{\Phi} \in C^\infty_0(\Omega)$ and $k \to \infty$

$$\left|\frac{1}{k}\int_\Omega |\mathbf{v}^k|^{q-2}\mathbf{v}^k \cdot \mathbf{\Phi}\, dx\right| \le \frac{1}{k^{1/q}}\left(\frac{1}{k}\|\mathbf{v}^k\|_q^q\right)^{\frac{q-1}{q}} \|\mathbf{\Phi}\|_q \ \to 0. \tag{2.18}$$

The convective term is treated with help from the compact embedding $\mathring{W}^{1,p} \hookrightarrow\hookrightarrow L^2$, $p > \frac{2d}{d+2}$. Writing $\mathbf{v}^k = \mathbf{v} + \mathbf{v}^k - \mathbf{v}$ we have for every $\mathbf{\Phi} \in C^\infty_0(\Omega)$ and $k \to \infty$

$$\begin{aligned}\int_\Omega (\mathbf{v}^k \otimes \mathbf{v}^k) : \mathbf{D}(\mathbf{\Phi})\, dx &= \int_\Omega [(\mathbf{v}^k - \mathbf{v}) \otimes \mathbf{v}^k] : \mathbf{D}(\mathbf{\Phi})\, dx \\ &\quad + \int_\Omega [\mathbf{v} \otimes (\mathbf{v}^k - \mathbf{v})] : \mathbf{D}(\mathbf{\Phi})\, dx + \int_\Omega (\mathbf{v} \otimes \mathbf{v}) : \mathbf{D}(\mathbf{\Phi})\, dx \\ &\to \int_\Omega (\mathbf{v} \otimes \mathbf{v}) : \mathbf{D}(\mathbf{\Phi})\, dx.\end{aligned} \tag{2.19}$$

Owing to (2.17) we also observe that for $\boldsymbol{\Phi} \in C_0^\infty(\Omega)$ and $k \to \infty$

$$\int_\Omega P^k \mathrm{div}\, \boldsymbol{\Phi}\, dx \quad \to \quad \int_\Omega P \mathrm{div}\, \boldsymbol{\Phi}\, dx. \tag{2.20}$$

Collecting our results we find that $\mathbf{v} \in V_p$ satisfies

$$\int_\Omega \boldsymbol{\chi} : \mathbf{D}(\boldsymbol{\Phi})\, dx = \langle \mathbf{f}, \boldsymbol{\Phi} \rangle_{1,p} + \int_\Omega (\mathbf{v} \otimes \mathbf{v}) : \mathbf{D}(\boldsymbol{\Phi})\, dx + \int_\Omega P \mathrm{div}\, \boldsymbol{\Phi}\, dx \tag{2.21}$$

for all $\boldsymbol{\Phi} \in C_0^\infty(\Omega)$, respectively, $\boldsymbol{\Phi} \in \mathring{W}^{1,r}(\Omega)$.

Our aim now is to demonstrate that $\boldsymbol{\chi} = \mathbf{T}(\cdot, \mathbf{D}(\mathbf{v}))$. For this purpose it suffices to show that

$$\mathbf{D}(\mathbf{v}^k) \to \mathbf{D}(\mathbf{v}) \qquad \text{in measure on } \Omega$$

or almost everywhere convergence on compact subsets of Ω. If this were true, then we could find a further subsequence by a diagonal procedure (for simplicity we do not change notation) such that

$$\mathbf{D}(\mathbf{v}^k) \to \mathbf{D}(\mathbf{v}) \qquad \text{almost everywhere in } \Omega. \tag{2.22}$$

Then, by Vitali's theorem (with help from the growth condition (1.6)) we obtain

$$\int_\Omega \mathbf{T}(\cdot, \mathbf{D}(\mathbf{v}^k)) : \mathbf{D}(\boldsymbol{\Phi})\, dx \quad \to \quad \int_\Omega \mathbf{T}(\cdot, \mathbf{D}(\mathbf{v})) : \mathbf{D}(\boldsymbol{\Phi})\, dx \tag{2.23}$$

and we can finish the proof of Theorem 1.1.

Note also that once we have (2.22) then we easily conclude from (2.4), respectively, (2.12), using Vitali's theorem that

$$\mathbf{D}(\mathbf{v}^k) \to \mathbf{D}(\mathbf{v}) \qquad \text{strongly in } L^s(\Omega) \qquad \text{for all } s \in [1, p),$$

which is due to (1.4) tantamount to

$$\mathbf{v}^k \to \mathbf{v} \qquad \text{strongly in } \mathring{W}^{1,s}(\Omega) \qquad \text{for all } s \in [1, p).$$

The missing proof of (2.22) will be given in section 4, while the next section is devoted to a decomposition of the pressure P^k.

3. Decomposition of the pressure. Consider four auxiliary Stokes problems, $I = 1, 2, 3, 4$,

$$\begin{aligned} -\Delta \mathbf{u}^{I_k} + \nabla P^{I_k} &= \mathbf{H}^{I_k} && \text{in } \Omega, \\ \mathrm{div}\, \mathbf{u}^{I_k} &= 0 && \text{in } \Omega, \\ \mathbf{u}^{I_k} &= \mathbf{0} && \text{on } \partial\Omega, \end{aligned} \tag{3.1}$$

where

$$\begin{aligned} \mathbf{H}^{1_k} &= -\mathrm{div}\, \mathbf{T}(\cdot, \mathbf{D}(\mathbf{v}^k)) \in (\mathring{W}^{1,p}(\Omega))^*, \\ \mathbf{H}^{2_k} &= \mathrm{div}\, (\mathbf{v}^k \otimes (\mathbf{v}^k - \mathbf{v})) \in (\mathring{W}^{1,r}(\Omega))^*, \\ \mathbf{H}^{3_k} &= \mathrm{div}\, ((\mathbf{v}^k - \mathbf{v}) \otimes \mathbf{v}) \in (\mathring{W}^{1,r}(\Omega))^*, \\ \mathbf{H}^{4_k} &= \frac{1}{k} |\mathbf{v}^k|^{q-2} \mathbf{v}^k \in (L^q(\Omega))^*. \end{aligned} \tag{3.2}$$

The classical theory for the Stokes system (cf. [3], for example) implies the existence of solutions $(\mathbf{u}^{I_k}, P^{I_k})$, $I = 1,2,3,4$, with the following estimates on the pressures P^{I_k} having zero mean value over each connected component of Ω:

$$\|P^{1_k}\|_{0,p';\Omega} \le C\|\mathbf{H}^{1_k}\|_{(\mathring{W}^{1,p}(\Omega))^*} \le C\|\mathbf{T}(\cdot,\mathbf{D}(\mathbf{v}^k))\|_{0,p';\Omega}, \tag{3.3}$$

$$\begin{aligned}\|P^{2_k}\|_{0,r';\Omega} &\le C\|\mathbf{H}^{2_k}\|_{(\mathring{W}^{1,r}(\Omega))^*} \le C\|\mathbf{v}^k\otimes(\mathbf{v}^k-\mathbf{v})\|_{0,r';\Omega}\\ &\le C\|\mathbf{v}^k\|_{0,2r';\Omega}\|\mathbf{v}^k-\mathbf{v}\|_{0,2r';\Omega},\end{aligned} \tag{3.4}$$

$$\|P^{3_k}\|_{0,r';\Omega} \le C\|\mathbf{H}^{3_k}\|_{(\mathring{W}^{1,r}(\Omega))^*} \le C\|\mathbf{v}^k-\mathbf{v}\|_{0,2r';\Omega}\|\mathbf{v}^k\|_{0,2r';\Omega}, \tag{3.5}$$

$$\begin{aligned}\|\nabla P^{4_k}\|_{0,q';\Omega} &\le C\|\mathbf{H}^{4_k}\|_{(L^q(\Omega))^*} \le \frac{C}{k}\||\mathbf{v}^k|^{q-1}\|_{0,q';\Omega}\\ &\le \frac{C}{k^{1/q}}\left(\frac{1}{k^{1/q}}\|\mathbf{v}^k\|_{0,q;\Omega}\right)^{q-1}.\end{aligned} \tag{3.6}$$

As $2r' = \frac{dp}{d-p}$, it follows from (3.4), (3.5), and (2.14) that for $k\to\infty$ we have

$$P^{2_k}\to 0 \text{ and } P^{3_k}\to 0 \quad \text{strongly in } L^s(\Omega) \quad \text{for all } s\in[1,r'). \tag{3.7}$$

Also, due to (2.4) we observe that for $k\to\infty$

$$\nabla P^{4_k}\to 0 \quad \text{strongly in } L^{q'}(\Omega). \tag{3.8}$$

Of course, one has analogous estimates for $\mathbf{u}^{I_k}$. For our purpose, it is enough to know that

$$\mathbf{U}^k \equiv \mathbf{u}^{1_k}+\mathbf{u}^{2_k}+\mathbf{u}^{3_k}+\mathbf{u}^{4_k} \quad \text{with} \quad \operatorname{div}\mathbf{U}^k = 0$$

satisfy

$$\|\mathbf{U}^k\|_{1,r';\Omega} \le K. \tag{3.9}$$

Next, summing up the weak forms of the problems $(3.1)_I$ over $I = 1,2,3,4$ and using (2.11) we obtain

$$\begin{aligned}\int_\Omega \nabla\mathbf{U}^k : \nabla\boldsymbol{\Phi}\,dx - \sum_{I=1}^4 \int P^{I_k}\operatorname{div}\boldsymbol{\Phi}\,dx &= \langle\mathbf{f},\boldsymbol{\Phi}\rangle_{1,p} + \int P^k\operatorname{div}\boldsymbol{\Phi}\,dx\\ &\quad + \int_\Omega(\mathbf{v}\otimes\mathbf{v}) : \mathbf{D}(\boldsymbol{\Phi})\,dx \qquad \text{for all } \boldsymbol{\Phi}\in\mathring{W}^{1,r}(\Omega).\end{aligned} \tag{3.10}$$

Taking $\boldsymbol{\Phi}$ from V_r in (3.10) (i.e., $\operatorname{div}\boldsymbol{\Phi} = 0$) we conclude that

$$\int_\Omega \nabla\mathbf{U}^k : \nabla\boldsymbol{\Phi}\,dx = \langle\mathbf{f},\boldsymbol{\Phi}\rangle_{1,p} + \int_\Omega(\mathbf{v}\otimes\mathbf{v}) : \mathbf{D}(\boldsymbol{\Phi})\,dx \qquad \text{for all } \boldsymbol{\Phi}\in V_r. \tag{3.11}$$

This and (3.9) then imply

$$\mathbf{U}^k = \mathbf{U}\in\mathring{W}^{1,r'}(\Omega) \qquad \text{for all } k\in\mathbb{N}. \tag{3.12}$$

Indeed, it follows from (3.11) that for $k,\ell\in\mathbb{N}$

$$\int_\Omega \nabla(\mathbf{U}^k-\mathbf{U}^\ell) : \nabla\boldsymbol{\Phi}\,dx = 0 \qquad \text{for all } \boldsymbol{\Phi}\in V_r.$$

Choosing $\mathbf{\Phi}$ to be the solution of

$$\begin{aligned} -\Delta\mathbf{\Phi} + \nabla Q &= \frac{\mathbf{U}^k - \mathbf{U}^\ell}{|\mathbf{U}^k - \mathbf{U}^\ell|} && \text{in } \Omega, \\ \operatorname{div}\mathbf{\Phi} &= 0 && \text{in } \Omega, \\ \mathbf{\Phi} &= \mathbf{0} && \text{on } \partial\Omega \end{aligned}$$

leads to (3.12).

Finally, taking (2.11) into account again and replacing $\int_\Omega P^k \operatorname{div}\mathbf{\Phi}\,dx$ with help from (3.10) and (3.12) we obtain

$$\begin{aligned} &\int_\Omega \mathbf{T}(\cdot,\mathbf{D}(\mathbf{v}^k)) : \mathbf{D}(\mathbf{\Phi})\,dx + \frac{1}{k}\int_\Omega |\mathbf{v}^k|^{q-2}\mathbf{v}^k \cdot \mathbf{\Phi}\,dx \\ &\quad = \int_\Omega (\mathbf{v}^k \otimes \mathbf{v}^k) : \mathbf{D}(\mathbf{\Phi})\,dx - \sum_{I=1}^{4}\int_\Omega P^{I_k}\operatorname{div}\mathbf{\Phi}\,dx \\ &\qquad + \int_\Omega \nabla\mathbf{U} : \nabla\mathbf{\Phi}\,dx - \int_\Omega (\mathbf{v}\otimes\mathbf{v}) : \mathbf{D}(\mathbf{\Phi})\,dx \quad \text{for all } \mathbf{\Phi} \in \mathring{W}^{1,r}(\Omega). \end{aligned} \tag{3.13}$$

The advantage of this formulation stems from more precise control of the particular pressures P^{1_k}, P^{2_k}, P^{3_k}, and P^{4_k} owing to (3.3)–(3.8).

4. Almost everywhere convergence of $\mathbf{D}(\mathbf{v}^k)$ to $\mathbf{D}(\mathbf{v})$. The desired convergence of $\mathbf{D}(\mathbf{v}^k)$ to $\mathbf{D}(\mathbf{v})$ almost everywhere in Ω will certainly hold if one shows that for a given but arbitrary $\eta > 0$ there is a subsequence $\{\mathbf{v}^\ell\}_{\ell\in\mathbb{N}} \subset \{\mathbf{v}^k\}_{k\in\mathbb{N}}$ such that (for some $\theta \in (0,1)$, say, $\theta = \frac{1}{2}$)

$$\lim_{\ell\to\infty}\int_\Omega \Big[(\mathbf{T}(\cdot,\mathbf{D}(\mathbf{v}^\ell)) - \mathbf{T}(\cdot,\mathbf{D}(\mathbf{v}))) : \mathbf{D}(\mathbf{v}^\ell - \mathbf{v})\Big]^\theta\,dx \le \eta. \tag{4.1}$$

To reach this goal it seems natural to consider

$$\mathbf{v}^k - \mathbf{v} \tag{4.2}$$

as a test function in (2.3), rewrite the left-hand side of the obtained equality as in (4.1) with $\theta = 1$, and show that the remaining terms are small as $k \to \infty$. Unfortunately, this idea works only for $p \ge \frac{3d}{d+2}$.

In [12], the L^∞-truncation of (4.2), namely,

$$(\mathbf{v}^k - \mathbf{v})\left(1 - \min\left(\frac{|\mathbf{v}^k - \mathbf{v}|}{L}, 1\right)\right) \quad \text{with} \quad L > 0 \quad \text{small}, \tag{4.3}$$

has been successfully applied to deduce (4.1). The main difficulty is showing the smallness of the integral

$$\int_{\Omega_L^k} \mathbf{T}(\cdot,\mathbf{D}(\mathbf{v}^k)) : \mathbf{D}\left((\mathbf{v}^k - \mathbf{v})\left(1 - \min\left(\frac{|\mathbf{v}^k - \mathbf{v}|}{L}, 1\right)\right)\right)\,dx,$$

where $\Omega_L^k \equiv \{x \in \Omega; |\mathbf{v}^k(x) - \mathbf{v}(x)| < L\}$. The L^∞-truncation method works for $p \ge \frac{2d}{d+1}$; the bound is due to the required L^1-integrability of the convective term $(\mathbf{v}\cdot\nabla)\mathbf{v}$.

Following the goal to prove Theorem 1.1 we have observed that it is enough to restrict ourselves to the case $p \in (\frac{2d}{d+2}, \frac{2d}{d+1}]$, and it is necessary to use a smoother test function than in (4.3) in order to control the convective term; yet the test function should not differ from (4.2) too much.

For this purpose, we test (3.13) by

$$(\mathbf{v}^k - \mathbf{v})_\lambda \quad \text{with } \lambda > 0 \quad \text{large enough,} \tag{4.4}$$

using the notation z^k_λ to denote such a Lipschitz (i.e., $\mathring{W}^{1,\infty}$-) truncation of z^k so that z^k_λ coincides with z^k except for a small set A^k_λ.

Let us remark that the idea to approximate a $\mathring{W}^{1,p}$-function $\mathbf{w}$ by a Lipschitz-continuous function which agrees with $\mathbf{w}$ on a "large" set was developed earlier; see [2], [10], [16], [21], [8], and [9], among others.

The proof of (4.1), and consequently of Theorem 1.1, is split into three steps. First, in Proposition 4.1, we study properties of $(\mathbf{v}^k - \mathbf{v})_\lambda$ for general λ. Then we cover the exceptional sets of noncoincidence A^k_λ by two sets F^k_λ and G^k_λ and show (see Propositions 4.1 and 4.3) by fixing λ and taking a convenient subsequence $\{\mathbf{v}^\ell\}_{\ell\in\mathbb{N}}$ that certain quantities are small on these sets. Finally, we prove (4.1) in Proposition 4.4.

PROPOSITION 4.1. *There is a constant $C = C(\Omega, d)$ such that whenever $\mathbf{w}^m \rightharpoonup 0$ weakly in $\mathring{W}^{1,p}(\Omega)$, then for all $\lambda > 0$ there is a sequence $\{\mathbf{w}^m_\lambda\}_{m\in\mathbb{N}} \subset \mathring{W}^{1,\infty}(\Omega)$ such that*

$$\|\mathbf{w}^m_\lambda\|_{1,\infty;\,\Omega} \le C\lambda. \tag{4.5}$$

Moreover, denoting $A^m_\lambda \equiv \{x \in \Omega; \mathbf{w}^m_\lambda(x) \neq \mathbf{w}^m(x)\}$, we then obtain

$$|A^m_\lambda| \le \frac{C}{\lambda^p}\|\nabla \mathbf{w}^m\|^p_{0,p;\,\Omega}. \tag{4.6}$$

Consequently,

$$\|\nabla \mathbf{w}^m_\lambda\|^p_{0,p;\,\Omega} \le C\|\nabla \mathbf{w}^m\|^p_{0,p;\,\Omega} \le K \tag{4.7}$$

and (as $m \to \infty$)

$$\begin{aligned} &\mathbf{w}^m_\lambda \to 0 \quad \textit{strongly in } L^s(\Omega) \qquad \textit{for all } s \in [1,\infty), \\ &\mathbf{w}^m_\lambda \rightharpoonup 0 \quad \textit{weakly in } \mathring{W}^{1,s}(\Omega) \qquad \textit{for all } s \in [1,\infty). \end{aligned} \tag{4.8}$$

In addition, we construct sets F^m_λ and G^m_λ such that

$$|A^m_\lambda| \le |F^m_\lambda| + |G^m_\lambda|, \tag{4.9}$$

$$|F^m_\lambda| \le \frac{C}{\lambda^p}\|\nabla \mathbf{w}^m\|^p_{0,p;\,\Omega}, \tag{4.10}$$

$$|G^m_\lambda| \le \frac{C}{\lambda^{2p}}\|\nabla \mathbf{w}^m\|^p_{0,p;\,\Omega}. \tag{4.11}$$

Before providing a proof of this proposition we recall Kirszbraun's extension theorem (see [21, Prop. 2.1, p. 708]).

LEMMA 4.2. *Let $\mathcal{M}$ be a metric space and let $\mathcal{K}$ be a subset of $\mathcal{M}$ such that $u : \mathcal{K} \to \mathbb{R}$ is Lipschitz-continuous with Lipschitz constant L. Then there exists a*

continuation $\hat{u} : \mathcal{M} \to \mathbb{R}$ of u such that $\hat{u}$ is Lipschitz-continuous with the same Lipschitz bound L and

$$\sup_{x\in\mathcal{M}} |\hat{u}(x)| \le \sup_{x\in\mathcal{K}} |u(x)|.$$

Proof of Proposition 4.1. The proof is based on ideas from [21, Prop. 2.2, p. 709] and [9, Lem. 4.1, pp. 21–22]. Extending $\mathbf{w}^m$ by zero we obtain $\tilde{\mathbf{w}}^m \in \tilde{W}^{1,p}(\mathbb{R}^d) = W^{1,p}(\mathbb{R}^d)$ with $\tilde{\mathbf{w}}^m \rightharpoonup 0$ weakly in $W^{1,p} = W^{1,p}(\mathbb{R}^d)$.

Recalling the definition of the Hardy–Littlewood maximal function of $\nabla\tilde{\mathbf{w}}^m$,

$$M(\nabla\tilde{\mathbf{w}}^m)(x) \equiv \sup_{r>0} \frac{1}{|B_r(x)|} \int_{B_r(x)} |\nabla\tilde{\mathbf{w}}^m(y)|\, dy,$$

we define for $\lambda > 1$

$$R^m_\lambda \equiv F^m_\lambda \cup G^m_\lambda \cup \left\{x \in \mathbb{R}^d : x \text{ is not a Lebesgue point of } \nabla\tilde{\mathbf{w}}^m\right\}, \tag{4.12}$$

where

$$\begin{aligned} F^m_\lambda &\equiv \left\{x \in \mathbb{R}^d : \lambda < M(\nabla\tilde{\mathbf{w}}^m)(x) \le \lambda^2\right\}, \\ G^m_\lambda &\equiv \left\{x \in \mathbb{R}^d : M(\nabla\tilde{\mathbf{w}}^m)(x) > \lambda^2\right\}. \end{aligned} \tag{4.13}$$

Note that the Lebesgue measure of the last set in the definition of R^m_λ is zero.

Since $M : L^p \to L^p$ is a "bounded" operator (see, for example, [34, pp. 4–12] or [38, Thm. 2.8.2, p. 84ff.]) we obtain

$$\begin{aligned} \lambda|R^m_\lambda| &\le \int_{R^m_\lambda} M(\nabla\tilde{\mathbf{w}}^m(x))\, dx \le \|M(\nabla\tilde{\mathbf{w}}^m)\|_{0,p} |R^m_\lambda|^{1-\frac{1}{p}} \\ &\le C\|\nabla\tilde{\mathbf{w}}^m\|_{0,p} |R^m_\lambda|^{1-\frac{1}{p}}, \end{aligned}$$

which implies

$$|R^m_\lambda| \le \frac{C}{\lambda^p} \|\nabla\tilde{\mathbf{w}}^m\|^p_{0,p} \quad \text{and} \quad |F^m_\lambda| \le \frac{C}{\lambda^p} \|\nabla\tilde{\mathbf{w}}^m\|^p_{0,p}. \tag{4.14}$$

Analogously, one obtains

$$|G^m_\lambda| \le \frac{C}{\lambda^{2p}} \|\nabla\tilde{\mathbf{w}}^m\|^p_{0,p}. \tag{4.15}$$

Next, from Lemma 1 in [2] it follows that there is a constant $C(d)$ such that

$$|\tilde{\mathbf{w}}^m(x) - \tilde{\mathbf{w}}^m(y)| \le C(d)\, \lambda\, |x - y| \quad \text{on } \mathbb{R}^d \setminus R^\lambda_m \tag{4.16}$$

and

$$|\tilde{\mathbf{w}}^m(x) - (\tilde{\mathbf{w}}^m)_{x,r}| \le C(d)\, r\, \lambda \quad \text{on } \mathbb{R}^d \setminus R^\lambda_m,$$

where $(\tilde{\mathbf{w}}^m)_{x,r}$ is the mean value of $\tilde{\mathbf{w}}^m$ over $B_r(x)$. Choosing $x \in \Omega \setminus R^\lambda_m$ and $r = 2\,\mathrm{dist}(x, \Omega^C)$, the smoothness of the boundary[2] implies the existence of A (independent of x) such that

$$|B_r(x) \cap \Omega^C| \ge A\, r^d.$$

[2] In fact, it would be sufficient for this part of the proof to assume that the boundary of Ω satisfies the cone property.

Hence Poincaré's inequality yields

$$|(\tilde{\mathbf{w}}^m)_{x,r}| \le C\, r \sup_{r>0} \frac{1}{|B_r(x)|} \int_{B_r(x)} |\nabla \tilde{\mathbf{w}}^m(y)|\, dy \le C \operatorname{dist}(x, \Omega^C)\, \lambda.$$

Thus

$$|\tilde{\mathbf{w}}^m(x)| \le C \operatorname{dist}(x, \Omega^C)\, \lambda \quad \text{on } \mathbb{R}^d \setminus R^\lambda_m.$$

This implies that

$$\tilde{\mathbf{w}}^m_\lambda(x) \equiv \begin{cases} \mathbf{w}^m(x) & \text{on } \Omega \setminus (R^\lambda_m), \\ 0 & \text{on } \mathbb{R}^d \setminus \Omega \end{cases}$$

is bounded and Lipschitz-continuous on its domain of definition. Thus by Lemma 4.2 there exists an extension $\mathbf{w}^m_\lambda$ to $\mathbb{R}^d$ with Lipschitz constant $C(d)\,\lambda$ and L^∞-bound $C\rho\lambda$, where ρ denotes the diameter of Ω. The assertion (4.5) is proved.

Moreover, the set $A^m_\lambda = \{x \in \Omega; \mathbf{w}^m_\lambda(x) \ne \mathbf{w}^m(x)\}$ is a subset of R^m_λ and $|A^m_\lambda| \le |R^m_\lambda|$. This together with (4.12)–(4.15) yields (4.6) and (4.9)–(4.11). Further, by (4.14) we have

$$\begin{aligned} \|\nabla \mathbf{w}^m_\lambda\|_{0,p;\,\Omega} &= \|\nabla \mathbf{w}^m_\lambda\|_{0,p;\,\Omega\setminus R^m_\lambda} + \|\nabla \mathbf{w}^m_\lambda\|_{0,p;\,R^m_\lambda} \\ &\le \|\nabla \mathbf{w}^m\|_{0,p;\,\Omega\setminus R^m_\lambda} + C\lambda |R^m_\lambda|^{1/p} \\ &\le \|\nabla \mathbf{w}^m\|_{0,p;\,\Omega\setminus R^m_\lambda} + C\|\nabla \mathbf{w}^m\|_{0,p;\,\Omega} \le (C+1)\|\nabla \mathbf{w}^m\|_{0,p;\,\Omega}, \end{aligned}$$

which is (4.7). Since we also have (with the help of $\|\mathbf{w}^m_\lambda\|_\infty \le C\rho\lambda$)

$$\|\mathbf{w}^m_\lambda\|_{0,p;\,\Omega} \le C\|\mathbf{w}^m\|_{0,p;\,\Omega}$$

and $\mathbf{w}^m \rightharpoonup 0$ weakly in $\mathring{W}^{1,p}(\Omega)$ we use compact embedding and interpolation to conclude $(4.8)_1$. From this and (4.5), equation $(4.8)_2$ follows easily. ∎

Next, we consider $\{(\mathbf{v}^k, P^{I_k})\}^{I=1,2,3,4}_{k\in\mathbb{N}}$ and $(\mathbf{v}, P) \in V_p \times L^{r'}(\Omega)$ satisfying (2.4)–(2.7), (2.10), (2.12)–(2.17), (3.3)–(3.8), and (3.13) and set

$$g^k \equiv C\left(|\mathbf{D}(\mathbf{v}^k)|^p + |\mathbf{D}(\mathbf{v})|^p + |\varphi_2|^{\frac{p}{p-1}} + |P^{1_k}|^{\frac{p}{p-1}}\right), \tag{4.17}$$

where φ_2 comes from (1.6).

Due to a priori estimates we see that g^k satisfy the uniform bound

$$\int_\Omega g^k\, dx \le K. \tag{4.18}$$

PROPOSITION 4.3. *For a given $\varepsilon > 0$ there are a subsequence $\{\mathbf{v}^\ell\}_{\ell\in\mathbb{N}} \subset \{\mathbf{v}^k\}_{k\in\mathbb{N}}$ and $\lambda \ge \frac{1}{\varepsilon}$ independent of ℓ such that*

$$\int_{F^\ell_\lambda} g^\ell\, dx \le \varepsilon, \tag{4.19}$$

where

$$F^\ell_\lambda \equiv \{x \in \Omega; \lambda < M(\nabla(\mathbf{v}^\ell - \mathbf{v}))(x) \le \lambda^2\}. \tag{4.20}$$

Proof of Proposition 4.3. For a given $\varepsilon \in (0,1)$ we find $N \in \mathbb{N}$ such that

$$N\varepsilon > K \qquad (K \text{ from (4.18)}) \tag{4.21}$$

and set

$$\lambda_0 = \frac{1}{\varepsilon}. \tag{4.22}$$

For each $k \in \mathbb{N}$ we introduce sets F_i^k, $i = 0, 1, \dots, N-1$,

$$F_i^k \equiv \{x \in \Omega; \lambda_0^{2^i} < M(\nabla(\mathbf{v}^k - \mathbf{v}))(x) \le \lambda_0^{2^{i+1}}\},$$

which are for fixed k mutually disjoint. Thus, due to (4.18),

$$\sum_{i=0}^{N-1} \int_{F_i^k} g^k \, dx \le K.$$

Due to (4.21), however, for each k there is an index $i(k)$ such that

$$\int_{F_{i(k)}^k} g^k \, dx \le \varepsilon.$$

As $i(k)$'s take values from the finite set $\{0, 1, \dots, N-1\}$ there exists certainly a subsequence $\{\mathbf{v}^\ell\}_{\ell \in \mathbb{N}}$ of $\{\mathbf{v}^k\}_{k \in \mathbb{N}}$ and an index $i_0 \in \{0, 1, \dots, N-1\}$ so that $i(\ell) = i_0$ for all $\ell \in \mathbb{N}$. Then setting $\lambda = \lambda_0^{2^{i_0}}$ and defining F_λ^ℓ as in (4.20) we observe that Proposition 4.3 is proved. □

PROPOSITION 4.4. *Let $\theta \in (0,1)$ be chosen and $\eta > 0$ be arbitrary. Then the sequence $\{\mathbf{v}^\ell\}_{\ell \in \mathbb{N}}$ determined in Proposition* 4.3 *satisfies* (4.1).

Proof of Proposition 4.4. We fix $p \in (\frac{2d}{d+2}, \frac{2d}{d+1}]$ and recall that $\frac{1}{r} = \frac{(d+2)p - 2d}{dp}$. Then we take $\varepsilon > 0$ so small that condition (4.32) specified at the end of the proof is fulfilled. To this ε, find $\{\mathbf{v}^\ell\}_{\ell \in \mathbb{N}} \subset \{\mathbf{v}^k\}_{k \in \mathbb{N}}$ and $\lambda \ge \frac{1}{\varepsilon}$ such that Proposition 4.3 holds. Now, we apply Proposition 4.1 to $(\mathbf{v}^\ell - \mathbf{v})$ and use the Lipschitz truncation $(\mathbf{v}^\ell - \mathbf{v})_\lambda$ as a test function in (3.13). We also subtract from both sides of the obtained equality the term

$$\int_\Omega \mathbf{T}(\cdot, \mathbf{D}(\mathbf{v})) : \mathbf{D}((\mathbf{v}^\ell - \mathbf{v})_\lambda) \, dx.$$

Then we use the facts that $\mathbf{v}^\ell - \mathbf{v} = (\mathbf{v}^\ell - \mathbf{v})_\lambda$ on $\Omega \setminus A_\lambda^\ell$. Thus, $\operatorname{div}(\mathbf{v}^\ell - \mathbf{v})_\lambda = 0$ almost everywhere on $\Omega \setminus A_\lambda^\ell$.

As a result of this consideration we obtain

$$
\begin{aligned}
J^\ell &\equiv \int_{\Omega\setminus A^\ell_\lambda} \Big[\mathbf{T}(\cdot,\mathbf{D}(\mathbf{v}^\ell)) - \mathbf{T}(\cdot,\mathbf{D}(\mathbf{v}))\Big] : \mathbf{D}(\mathbf{v}^\ell - \mathbf{v})\,dx \\
&= \int_{A^\ell_\lambda} \Big[\mathbf{T}(\cdot,\mathbf{D}(\mathbf{v})) - \mathbf{T}(\cdot,\mathbf{D}(\mathbf{v}^\ell))\Big] : \mathbf{D}((\mathbf{v}^\ell - \mathbf{v})_\lambda)\,dx \\
&\quad - \int_{A^\ell_\lambda} P^{1\ell}\mathrm{div}\,((\mathbf{v}^\ell - \mathbf{v})_\lambda)\,dx \\
&\quad - \int_{A^\ell_\lambda} (P^{2\ell} + P^{3\ell})\mathrm{div}\,((\mathbf{v}^\ell - \mathbf{v})_\lambda)\,dx \\
&\quad + \int_\Omega \Big(\mathbf{v}^\ell \otimes (\mathbf{v}^\ell - \mathbf{v}) + (\mathbf{v}^\ell - \mathbf{v}) \otimes \mathbf{v}\Big) : \mathbf{D}((\mathbf{v}^\ell - \mathbf{v})_\lambda)\,dx \\
&\quad + \int_\Omega \Big(\nabla P^{4\ell} - \frac{1}{\ell}|\mathbf{v}^\ell|^{q-2}\mathbf{v}^\ell\Big)\cdot(\mathbf{v}^\ell - \mathbf{v})_\lambda\,dx \\
&\quad + \int_\Omega (\nabla\mathbf{U} - \mathbf{T}(\cdot,\mathbf{D}(\mathbf{v}))) : \nabla(\mathbf{v}^\ell - \mathbf{v})_\lambda\,dx \\
&\equiv I^\ell_1 + I^\ell_2 + I^\ell_3 + I^\ell_4 + I^\ell_5 + I^\ell_6.
\end{aligned}
\tag{4.23}
$$

We evaluate terms on the right-hand side of (4.23) one after another. Note that λ is fixed and

$$
\|\nabla(\mathbf{v}^\ell - \mathbf{v})_\lambda\|_{0,\infty;\,\Omega} \le C\lambda. \tag{4.24}
$$

We are interested in showing that all terms I^ℓ_k, $k = 1,2,3,4,5,6$, are small for $\ell \to \infty$. First, using the compactness (2.14) and (3.7) together with (4.24) we observe that

$$
\lim_{\ell\to\infty} I^\ell_3 + I^\ell_4 = 0. \tag{4.25}
$$

But the same is true for I^ℓ_5 due to (3.8), (2.18), and (4.24). Thus

$$
\lim_{\ell\to\infty} I^\ell_5 = 0. \tag{4.26}
$$

When dealing with I^ℓ_1 and I^ℓ_2 we use Propositions 4.1 and 4.3 and the Hölder inequality

$$
\begin{aligned}
|I^\ell_1 + I^\ell_2| &= \Big|\int_{F^\ell_\lambda\cup G^\ell_\lambda} \Big[\mathbf{T}(\cdot,\mathbf{D}(\mathbf{v})) - \mathbf{T}(\cdot,\mathbf{D}(\mathbf{v}^\ell)) - P^{1\ell}\mathbf{I}\Big] : \nabla(\mathbf{v}^\ell - \mathbf{v})_\lambda\,dx\Big| \\
&\le \int_{F^\ell_\lambda} |\,\ldots\ldots\,|\,dx + \int_{G^\ell_\lambda} |\,\ldots\ldots\,|\,dx \\
&\le \Big(\int_{F^\ell_\lambda} g^\ell\,dx\Big)^{\frac{p-1}{p}} \|\nabla(\mathbf{v}^\ell - \mathbf{v})_\lambda\|_{0,p,F^\ell_\lambda} + C\lambda\Big(\int_{G^\ell_\lambda} g^\ell\,dx\Big)^{\frac{p-1}{p}} |G^\ell_\lambda|^{\frac{1}{p}} \\
&\le K\left(\varepsilon^{1-\frac{1}{p}} + \frac{C}{\lambda}\right) \le K\,C(\varepsilon^{1-\frac{1}{p}} + \varepsilon).
\end{aligned}
\tag{4.27}
$$

Further, from (4.8) applied to $(\mathbf{v}^\ell - \mathbf{v})_\lambda$ we know particularly that

$$
(\mathbf{v}^\ell - \mathbf{v})_\lambda \rightharpoonup 0 \qquad \text{weakly in } \mathring{W}^{1,r}(\Omega). \tag{4.28}
$$

Since $\nabla \mathbf{U} \in L^{r'}(\Omega)$ and $\mathbf{T}(\cdot, \mathbf{D}(\mathbf{v})) \in L^{p'}(\Omega)$ we have

$$\lim_{\ell \to \infty} I_6^\ell = 0. \tag{4.29}$$

To summarize, we have observed that

$$\lim_{\ell \to \infty} J^\ell = KC(\varepsilon^{1-\frac{1}{p}} + \varepsilon). \tag{4.30}$$

Finally, fix $\theta \in (0,1)$ and denote the integral in (4.1) by Y^ℓ. Then we have

$$\begin{aligned} Y^\ell \le & \int_{\Omega \setminus A_\lambda^\ell} \Big[(\mathbf{T}(\cdot, \mathbf{D}(\mathbf{v}^\ell)) - \mathbf{T}(\cdot, \mathbf{D}(\mathbf{v}))) : \mathbf{D}(\mathbf{v}^\ell - \mathbf{v}) \Big]^\theta \, dx \\ & + \int_{A_\lambda^\ell} \Big[(\mathbf{T}(\cdot, \mathbf{D}(\mathbf{v}^\ell)) - \mathbf{T}(\cdot, \mathbf{D}(\mathbf{v}))) : \mathbf{D}(\mathbf{v}^\ell - \mathbf{v}) \Big]^\theta \, dx. \end{aligned} \tag{4.31}$$

With help from the Hölder inequality and a priori estimates we obtain

$$Y^\ell \le (J^\ell)^\theta |\Omega \setminus A_\lambda^\ell|^{1-\theta} + K |A_\lambda^\ell|^{1-\theta}.$$

Using (4.31) and (4.9)–(4.11) we finally conclude

$$\begin{aligned} \lim_{\ell \to \infty} Y^\ell & \le |\Omega|^{1-\theta} (K\,C)^\theta (\varepsilon^{1-\frac{1}{p}} + \varepsilon)^\theta + K \left(\frac{C}{\lambda^p} \right)^{1-\theta} \\ & \le |\Omega|^{1-\theta} (K\,C)^\theta (\varepsilon^{1-\frac{1}{p}} + \varepsilon)^\theta + K\,(K\,C)^{1-\theta} \varepsilon^{p(1-\theta)}. \end{aligned}$$

If ε is so small that

$$|\Omega|^{1-\theta} (K\,C)^\theta (\varepsilon^{1-\frac{1}{p}} + \varepsilon)^\theta + K\,(K\,C)^{1-\theta} \varepsilon^{p(1-\theta)} < \eta, \tag{4.32}$$

then Proposition 4.4 and consequently Theorem 1.1 are proved. □

5. Final remarks. (1) The proof of Theorem 1.1 offers also another argument for the existence result in the case $p = \frac{2d}{d+1}$. This limiting case (for this p the convective term is "a priori" only in L^1) was included in our previous existence result in [12] where we used the fact that the convective term $(\mathbf{v} \cdot \nabla)\mathbf{v}$ belongs locally to the Hardy space $\mathcal{H}^1$ (due to $\operatorname{div} \mathbf{v} = 0$) and the duality of $\mathcal{H}^1$ and BMO (= the John–Nirenberg space of functions with bounded mean oscillation). The above given proof of Theorem 1.1 also works (of course) in this case, and therefore we do not need to use the above-mentioned facts (in this case).

(2) On the other hand one can give an alternative proof of Theorem 1.1 by using the following compensated integrability result: For $\frac{1}{r} = \frac{2}{p} - \frac{1}{d} = \frac{2d-p}{dp}$ and $\mathbf{w} \in V_p$ it holds that

$$(\mathbf{w} \cdot \nabla)\mathbf{w} \in h^r(\Omega),$$

where $h^r(\Omega)$ denotes the local Hardy space. Observe that $\frac{d}{d+1} < r < 1$ is equivalent to $\frac{2d}{d+2} < p < \frac{2d}{d+1}$ (see [5], [27]).

Taking [35, section 2.11.3, pp. 180–182; section 2.5.7, pp. 89–91; and section 2.5.12, pp. 109–114] into account we can dispose of

$$h^r(\Omega) \equiv F^0_{r,2}(\Omega) \equiv \text{Triebel–Lizorkin space for } 0 < r \le 1$$

and

$$(h^r(\Omega))' \equiv (F^0_{r,2}(\Omega))' \equiv B^{d(\frac{1}{r}-1)}_{\infty,\infty}(\Omega) \equiv B^{\frac{2d-(d+1)p}{p}}_{\infty,\infty}(\Omega) \equiv C^{0,\alpha}(\overline{\Omega}),$$

where $\alpha = \frac{2d-(d+1)p}{p} \in (0,1)$ if and only if $\frac{2d}{d+2} < p < \frac{2d}{d+1}$. Noticing that our test function $\mathbf{\Phi}^k_\lambda = (\mathbf{v}^k - \mathbf{v})_\lambda$ belongs to $\mathring{W}^{1,\beta}(\Omega)$ for all finite β we certainly have $\mathbf{\Phi}^k_\lambda \in C^{0,\alpha}(\overline{\Omega})$. The only difference to the above given proof appears now in dealing with the convective term: Instead of integrating by parts we keep it in the form

$$\int_\Omega (\mathbf{v}^k \cdot \nabla)\mathbf{v}^k \cdot \mathbf{\Phi}^k_\lambda \, dx \equiv \langle (\mathbf{v}^k \cdot \nabla)\mathbf{v}^k, \mathbf{\Phi}^k_\lambda \rangle,$$

where the brackets now denote the duality between h^r and $C^{0,\alpha}$, use the uniform boundedness of $(\mathbf{v}^k \cdot \nabla)\mathbf{v}^k$ in h^r, and have to ensure that it converges to zero for $k \to \infty$. This can be achieved by observing that

$$\mathbf{\Phi}^k_\lambda \to 0 \quad \text{strongly in } C^{0,\alpha} \qquad \text{for some } \alpha \in (0,1).$$

This follows, however, from $(4.8)_1$ and the interpolation inequalities

$$\begin{aligned}\|\mathbf{\Phi}^k_\lambda\|_{C^{0,\alpha}} &\le C\,\|\mathbf{\Phi}^k_\lambda\|^\theta_\infty\,\|\mathbf{\Phi}^k_\lambda\|^{1-\theta}_{C^{0,\beta}} \\ &\le C\|\mathbf{\Phi}^k_\lambda\|^{\frac{\theta}{2}}_{0,2d}\|\mathbf{\Phi}^k_\lambda\|^{\frac{\theta}{2}}_{1,2d}\,\|\mathbf{\Phi}^k_\lambda\|^{1-\theta}_{C^{0,\beta}} \le C\|\mathbf{\Phi}^k_\lambda\|^{\frac{\theta}{2}}_{0,2d}\|\mathbf{\Phi}^k_\lambda\|^{1-\frac{\theta}{2}}_{1,s},\end{aligned}$$

valid for $0 < \alpha < \beta < 1$, $\theta = 1 - \frac{\alpha}{\beta}$, $1-\theta = \frac{\alpha}{\beta}$, and $s \ge 2d$ so that $W^{1,s} \hookrightarrow C^{0,\beta}$.

The rest of the proof coincides with the original proof.

(3) Using the method of proof of our main theorem we can also generalize the result of Dal Maso and Murat [6] to include "some" nonlinear terms on the right-hand side satisfying "suitable" growth conditions, but we will not follow these possibilities here.

(4) Another possible use of our scheme of proof developed here would be in the theory of electrorheological fluids with shear-dependent viscosities (steady flows), but this will be a future project. The interested reader is referred to [33].

(5) The $C^{1,1}$-regularity of boundary is required in Theorem 1.1 and its proof due to the applications of the L^q-theory for the Stokes system in various places. However, the result of Theorem 1.1 holds for the Lipschitz domains. ($C^{0,1}$-regularity of the boundary seems to be needed to have the global estimates on the pressure.) Considering Lipschitz domains within the proof would certainly reduce the readability of the paper. This is why we finally prefer to deal with domains of the $C^{1,1}$-class.

(6) It follows from the proof that the pressure P corresponding to the weak solution $\mathbf{v} \in V_p$ belongs to $L^{r'}$ where $r' = \frac{dp}{2(d-p)}$.

MINIMIZATION PROBLEMS AND ASSOCIATED FLOWS RELATED TO WEIGHTED p ENERGY AND TOTAL VARIATION*

YUNMEI CHEN† AND MURALI RAO†

Abstract. Motivated by the problem of edge preserving regularization in image restoration, in this paper we investigate the relations between weighted p energy based and total variation based minimization problems and their associated flows. We prove that the weighted total variation based minimization and its associated flow in a weakened formulation can be approximated by the weighted p energy based minimization and its associated flows, respectively.

Moreover, we show that the flow of the weighted total variation based minimization converges weakly in BV and strongly in L^2 to the minimizer as $t \to \infty$.

Key words. BV-space, pseudosolutions, trace, minimization, degenerate parabolic equations

1. Introduction.

In this paper, we investigate the relation of two variational models and their associated flows applied in image recovery. One of them is weighted total variation based minimization, and the other one is based on minimizing the weighted L^p-norm of image gradients.

The image recovery problem we consider here is a problem of recovering an unknown data u from an observed noisy data I, which is related to u by $I = u + noise$. The challenging aspect of solving this problem is to selectively filter the noise without losing significant features. Standard regularization methods, for instance, Gaussian filters corresponding to minimizing L^2-norm of image gradients, cannot solve this problem since they are isotropical smoothing and do not allow discontinuous solutions. One approach for solving this problem is to use total variation based regularization—that is, to minimize the total variation norm of u subject to the constraint $\|u - I\|_{L^2}^2 = \sigma^2$ (see [15], [16]), or to solve the related unconstrained minimization problem

$$\min_u \int_\Omega |\nabla u| + \frac{\lambda}{2}|u - I|^2$$

(see [1], [4], [24], and the references therein). To smooth images more selectively, spatially adaptive total variation models were proposed (see, e.g., [17], [18], [19], [3]), where the adaptivity is realized by using a weighted total variation norm. These models can be represented in the following framework:

$$\min_u E(u) =: \min_u \int_\Omega \alpha(x)|\nabla u| + \int_\Omega \frac{1}{2}|u - I|^2 dx,$$

where $\alpha(x)$ is chosen to be inversely proportional to the likelihood of the presence of an edge. Certain choices of $\alpha(x)$ based on image features or noise levels or both were given in [17], [18], and [19]. Their numerical results showed the effectiveness of the model in removing noise and sharpening image features.

On the other hand, minimizing L^p-norms $(1 < p < 2)$ of the gradient has been employed as one of the approximation methods for image denoising and has been considered as an alternate way between a total variation based approach and one which minimizes the L^2-norm of the gradient depending on the needs of a particular image [2]. More applications of minimizing L^p-norms $(1 < p < 2)$ of the gradient in image processing can be found in [23].

Motivated by these works, we are interested in the mathematical theories on the relations of the solutions to the following two minimization problems and their associated flows:

$$\min_v E(v) =: \min_{v \in BV_g \cap L^2} \int_\Omega \alpha(x)|\nabla v| + \frac{1}{2}\int_\Omega |v - I|^2 dx \tag{1.1}$$

and

$$\min_v E_p(v) =: \min_{v \in W_g^{1,p} \cap L^2} \frac{1}{p}\int_\Omega \alpha(x)|\nabla v|^p + \frac{1}{2}|v - I|^2 dx, \tag{1.2}$$

where

$$BV_g = \{v \in BV(\Omega) | v = g \text{ on } \partial\Omega\}, \qquad W_g^{1,p} = \{v \in W^{1,p}(\Omega) | v = g \text{ on } \partial\Omega\}.$$

Here the boundary conditions are in the sense of trace. The purpose of this paper is to investigate if the solution of (1.1) and its associated flow can be approximated by a sequence of solutions to (1.2) and their associated flows. This study is of more than theoretical interest because it will provide an alternate approximation scheme for solving total variation based minimization problems and their associated flows that have many applications.

The existence of a Lipschitz continuous solution to the problem $\min_{u \in BV_g} \int_\Omega |\nabla u|$ has been obtained under certain conditions on Ω and g (see [12], [13], [14], [20], [21], and [26]). However, it seems difficult to apply their arguments to the problem (1.1) due to the presence of $\alpha(x)$ and the term $|v - I|^2$ in $E(v)$.

Although much attention to the existence and regularity for the solutions to the problem $\min \int_\Omega |\nabla u|^p dx$ with fixed boundary data has been given (see [7], [8], [9], and references therein), we found, after careful checking, that the Lipschitz continuous solutions obtained in pioneering works have their Lipschitz constants depending on p and tending to infinity as $p \to 1$.

The existence and uniqueness for the solution of (1.1) in bounded variation (BV-) space for constant α has been proved in [1] and [4]. Results for more general cases were obtained by Vese in [25] for the functional

$$F(u) = \int_\Omega (Ku - u_0)^2 dx + \alpha \int_\Omega \phi(|\nabla u|)$$

and its associated flow. Here $\alpha \geq 0$ is constant, $\phi : \mathbf{R} \to \mathbf{R}^+$ is a convex, even function nondecreasing in $\mathbf{R}^+$ with linear growth, and $K : L^p(\Omega) \to L^2(\Omega)$ is a linear, continuous, and injective operator. The existence result for the flow associated with this minimization problem is only in dimensions one and two because the methods employed there use general results on maximal monotone operators and evolution operators in Hilbert spaces.

The existence, uniqueness, and large time asymptotic behavior for the flow associated with the minimization problem

$$\min_{u \in BV_g} \int_\Omega \phi(Du),$$

i.e.,

$$\frac{\partial u}{\partial t} = \mathrm{div}_x(\phi_p(\nabla u)) \quad \text{in } \Omega \times R_+,$$

$$u = g \ \text{ on } \ \partial\Omega \times R_+,$$

$$u = u_0 \ \text{ on } \Omega \times \{0\},$$

has been proved in [10], provided that ϕ is a convex linear-growth function. A typical example of ϕ is

$$\phi(q) =: 1/2|q|^2 \text{ if } |q| \le 1, \text{ and } \phi(q) =: |q| - 1/2 \text{ if } |q| \ge 1;$$

the same results have been shown in [26]. The key idea of their work is to approximate the solution to the equation $\frac{\partial u}{\partial t} = \mathrm{div}_x(\phi_p(\nabla u))$ by the solutions to the equations $\frac{\partial u}{\partial t} = \mathrm{div}_x(\phi_p^\epsilon(\nabla u))$ with the same initial and boundary conditions, where $\phi_\epsilon(q) = \eta_\epsilon * \phi(q)$ and η_ϵ is the standard molifier.

In this paper, we will use the so-called *relaxed energy* (see [10], [22], and [26]) to define a pseudosolution u of (1.1) as a solution to the problem

$$\min_{v \in BV(\Omega) \cap L^2} E^g(v),$$

where

$$E^g(v) =: \int_\Omega \alpha(x)|\nabla v| + \frac{1}{2}|v - I|^2 dx + \int_{\partial\Omega} \alpha(x)|v - g| dH^{n-1}.$$

We will show that the pseudosolution of (1.1) can be approximated weakly as $p \downarrow 1$ either by the solutions to (1.2) or by a sequence of functions that minimize the functional

$$E_p^g(v) =: \frac{1}{p}\int_\Omega \alpha(x)|\nabla v|^p + \frac{1}{2}|v - I|^2 dx + \int_{\partial\Omega} \alpha(x)|v - g| dH^{n-1}$$

over $v \in W^{1,p}(\Omega) \cap L^2$.

Moreover, we will show the existence and uniqueness of a pseudosolution $u(x,t)$ to the flow associated with (1.1):

$$\partial_t u - \mathrm{div}(\alpha(x)\nabla u/|\nabla u|) + (u - I) = 0, \quad x \in \Omega, \ t > 0, \tag{1.3}$$

$$u(x,0) = I(x), \quad x \in \Omega, \tag{1.4}$$

$$u(x,t) = g(x), \quad x \in \partial\Omega, \ t \ge 0. \tag{1.5}$$

This will be done by proving that the weak solutions to the flow associated with (1.2) converge weakly in $BV \cap L^2$ as $p \to 1$ to a pseudosolution of (1.3)–(1.5).

Finally, we prove that as $t \to \infty$ the solution $u(\cdot, t)$ of (1.3)–(1.5) converges strongly in L^2 and weakly in BV to the solution of the relaxed problem associated with (1.1).

We would like to point out that all the proofs presented in this paper can easily be carried over to the problem of minimizing the energy function in (1.1) over $BV(\Omega) \cap L^2$ and the flow (1.3)–(1.4) with a free Neumann boundary condition by just dropping the boundary term.

2. Preliminaries. From now on we always assume the following:
(H.1) Ω is a bounded open subset of $\mathbf{R}^n$ with Lipschitz boundary.
(H.2) $\alpha(x)$ is a positive valued continuous function on R^n.
In practical image restoration problems, $\alpha(x)$ may be chosen as

$$\alpha(x) = \frac{\alpha_1}{1 + k|\nabla G_\sigma * I|^2}, \tag{2.1}$$

where $G_\sigma(x) = \frac{1}{\sigma}\exp(-|x|^2/4\sigma^2)$ and $\alpha_1 > 0$, $k > 0$, and $\sigma > 0$ are parameters. With this choice, $\alpha(x)$ satisfies assumption (H.2) and takes much smaller values near likely edges than on homogeneous regions so that edges are much less smoothed and, hence, preserved. Moreover, if $I \in L^\infty(\Omega)$, then

$$0 < \alpha_0 \le \alpha(x) \le \alpha_1, \quad x \in \Omega, \tag{2.2}$$

with $\alpha_0 = \alpha_1/(1 + C(k,\sigma)|I|_{L^\infty(\Omega)})$.

Now we define the weighted total variation norm with weight function α satisfying (H.2).

DEFINITION 2.1. *A function $f \in L^1(\Omega)$ has bounded α-total variation in Ω if*

$$\sup_{\phi \in \Phi(\alpha,\Omega)} \int_\Omega f \mathrm{div}\phi dx < \infty,$$

where

$$\Phi(\alpha,\Omega) =: \{\phi \in C_0^1(\Omega, R^n)|\ |\phi| \le \alpha\}. \tag{2.3}$$

We can see that if $f \in L^1(\Omega)$ has bounded α-total variation in Ω, there is a Radon vector measure ∇f on Ω such that

$$\int_\Omega \alpha|\nabla f| =: \sup_{\phi \in \Phi_\alpha} \int_\Omega f \mathrm{div}\phi dx. \tag{2.4}$$

Under assumption (H.2), $f \in L^1(\Omega)$ having bounded α-total variation in Ω implies that $f \in BV(\Omega)$.

We further assume the following:
(H.3) $I \in L^2(\Omega)$, and g is the trace of a function $G \in H^1(\Omega)$.
Under assumptions (H.1)–(H.3), for $v \in BV(\Omega) \cap L^2$, we define

$$E^g(v) =: \int_\Omega \alpha(x)|\nabla v| + \frac{1}{2}|v - I|^2 dx + \int_{\partial\Omega} \alpha(x)|v - g| dH^{n-1}, \tag{2.5}$$

and, for $v \in W^{1,p}(\Omega) \cap L^2$, we define

$$E_p^g(v) =: \frac{1}{p}\int_\Omega \alpha(x)|\nabla v|^p + \frac{1}{2}|v - I|^2 dx + \int_{\partial\Omega} \alpha(x)|v - g| dH^{n-1}. \tag{2.6}$$

PROPOSITION 2.2. *Let* (H.1)–(H.2) *hold. Assume that $f_1 \in BV(\Omega)$ and $f_2 \in BV(R^n - \bar{\Omega})$. Define*

$$\bar{f} = \begin{cases} f_1 & \text{if } x \in \Omega, \\ f_2 & \text{if } x \in R^n - \bar{\Omega}. \end{cases}$$

Then $\bar{f} \in BV(R^n)$, and

$$\int_{R^n} \alpha(x)|\nabla \bar{f}| = \int_\Omega \alpha(x)|\nabla f_1| + \int_{R^n-\bar{\Omega}} \alpha(x)|\nabla f_2| + \int_{\partial\Omega} \alpha(x)|Tf_1 - Tf_2| dH^{n-1}, \tag{2.7}$$

where Tf denotes the trace of $f \in BV(\Omega)$ on $\partial\Omega$.

Proof. For each $\phi \in C_0^1(R^n; R^n)$, $|\phi(x)| \le \alpha(x)$ on Ω, denoting μ to be the unit outward normal to Ω, we have

$$\int_{R^n} \bar{f} \mathrm{div}\phi dx = \int_\Omega f_1 \mathrm{div}\phi dx + \int_{R^n-\bar{\Omega}} f_2 \mathrm{div}\phi dx$$

$$= -\int_\Omega \phi \cdot \nabla f_1 - \int_{R^n-\bar{\Omega}} \phi \cdot \nabla f_2 + \int_{\partial\Omega} (Tf_1 - Tf_2)(\phi \cdot \mu) dH^{n-1}$$

$$\le \int_\Omega \alpha|\nabla f_1| + \int_{R^n-\bar{\Omega}} \alpha|\nabla f_2| + \int_{\partial\Omega} \alpha|Tf_1 - Tf_2| dH^{n-1}.$$

Therefore, $\int_{R^n} \alpha|\nabla \bar{f}| < \infty$, and then $\bar{f} \in BV(R^n)$. Moreover, for each $\phi \in C_0^1(R^n; R^n)$,

$$\int_{R^n} \phi \cdot \nabla \bar{f} = \int_\Omega \phi \cdot \nabla f_1 + \int_{R^n-\bar{\Omega}} \phi \cdot \nabla f_2 - \int_{\partial\Omega} (Tf_1 - Tf_2)(\phi \cdot \mu) dH^{n-1}.$$

Therefore,

$$\nabla \bar{f} = \begin{cases} \nabla f_1 & \text{on } \Omega, \\ \nabla f_2 & \text{on } R^n - \bar{\Omega}. \end{cases}$$

This implies

$$-\int_{\partial\Omega} \phi \cdot \nabla \bar{f} = \int_{\partial\Omega} (Tf_1 - Tf_2)(\phi \cdot \mu) dH^{n-1}.$$

Then

$$\int_{\partial\Omega} \alpha|\nabla \bar{f}| = \int_{\partial\Omega} \alpha|Tf_1 - Tf_2| dH^{n-1}. \tag{2.8}$$

Now (2.7) follows from (2.8). □

THEOREM 2.3. *Let* (H.1)–(H.3) *hold. Assume that $\{f_k\}_{k=1}^\infty \subset BV(\Omega)$ and $f_k \to f$ in $L^1(\Omega)$. Then $f \in BV(\Omega)$, and*

$$\int_\Omega \alpha|\nabla f| + \int_{\partial\Omega} \alpha|f - g| dH^{n-1} \le \liminf_{k\to\infty} \left\{ \int_\Omega \alpha|\nabla f_k| + \int_{\partial\Omega} \alpha|f_k - g| dH^{n-1} \right\}. \tag{2.9}$$

Proof. Let EG be the extension of G such that $EG \in H^1(R^n)$,

$$EG = G \text{ on } \Omega, \quad T(EG) = TG = g \text{ on } \partial\Omega, \quad \text{and} \quad \|EG\|_{H^1(R^n)} \le C\|G\|_{H^1(\Omega)}.$$

Define

$$\bar{f}_k = \begin{cases} f_k & \text{on } \Omega, \\ EG & \text{on } R^n - \bar{\Omega} \end{cases}$$

and

$$\bar{f} = \begin{cases} f & \text{on } \Omega, \\ EG & \text{on } R^n - \bar{\Omega}. \end{cases}$$

Then $\bar{f}_k \to \bar{f}$ in $L^1(R^n)$, and, for each $\phi \in \Phi(\alpha, R^n)$ (see (2.3)),

$$\int_{R^n} \bar{f} \mathrm{div}\phi = \lim_{k\to\infty} \int_{R^n} \bar{f}_k \mathrm{div}\phi \le \liminf_{k\to\infty} \int_{R^n} \alpha |\nabla \bar{f}_k|.$$

Taking the supremum with respect to ϕ over $\Phi(\alpha, R^n)$ yields that

$$\int_{R^n} \alpha |\nabla \bar{f}| \le \liminf_{k\to\infty} \int_{R^n} \alpha |\nabla \bar{f}_k|. \tag{2.10}$$

Moreover, by Proposition 2.2, $\bar{f}_k \in BV(R^n)$ $(k = 1, 2, \ldots)$, and $\bar{f} \in BV(R^n)$, we get

$$\int_{R^n} \alpha |\nabla \bar{f}_k| = \int_{\Omega} \alpha |\nabla f_k| + \int_{R^n - \bar{\Omega}} \alpha |\nabla G| + \int_{\partial\Omega} \alpha |f_k - g| dH^{n-1}, \tag{2.11}$$

$$\int_{R^n} \alpha |\nabla \bar{f}| = \int_{\Omega} \alpha |\nabla f| + \int_{R^n - \bar{\Omega}} \alpha |\nabla G| + \int_{\partial\Omega} \alpha |f - g| dH^{n-1}. \tag{2.12}$$

Passing to the limit $k \to \infty$ in (2.11) and using (2.10) and (2.12), we get (2.9). □

THEOREM 2.4. *Let* (H.1)–(H.3) *hold and* $u \in BV(\Omega) \cap L^2$. *Then, for each* $\epsilon > 0$, *there exists a function* $u_\epsilon \in C^\infty(\bar{\Omega})$ *such that*

$$E^g(u_\epsilon) \le E^g(u) + \epsilon. \tag{2.13}$$

Proof. (1) By a minor modification of the proof of Theorem 1.17 and Remark 1.18 in [11], we can find a sequence $u_j \in C^\infty(\Omega) \cap W^{1,1} \cap L^2$ such that

$$T_r u_j = T_r u \quad \text{in } L^1(\partial\Omega), \tag{2.14}$$

and, as $j \to \infty$,

$$\|u_j - u\|_{L^2(\Omega)} \to 0, \tag{2.15}$$

and

$$\int_{\Omega} |\nabla u_j| \to \int_{\Omega} |\nabla u|. \tag{2.16}$$

Moreover, from (2.16) we have

$$\int_{\Omega} \alpha |\nabla u_j| \to \int_{\Omega} \alpha |\nabla u|. \tag{2.17}$$

The combination of (2.14), (2.15), and (2.17) leads to

$$\lim_{j\to\infty} E^g(u_j) = E^g(u). \tag{2.18}$$

Therefore, for each given $\epsilon > 0$, there exists a function $v_\epsilon \in C^\infty(\Omega) \cap W^{1,1} \cap L^2$ such that

$$E^g(v_\epsilon) \le E^g(u) + \epsilon/2. \tag{2.19}$$

(2) Since $C^\infty(\bar\Omega)$ is dense in $W^{1,1}(\Omega)\cap L^2$, for v_ϵ obtained above, there is a function $u_\epsilon\in C^\infty(\bar\Omega)$ such that

$$\|v_\epsilon-u_\epsilon\|_{W^{1,1}(\Omega)}+\|v_\epsilon-u_\epsilon\|^2_{L^2(\Omega)}$$

$$+\|T_rv_\epsilon-T_ru_\epsilon\|_{L^1(\partial\Omega)}\le\frac{\epsilon}{4\max_{\bar\Omega}\alpha(x)};\tag{2.20}$$

here we have used the trace theorem for the third term in (2.20). By using (H.2), we get from (2.20) that

$$E^g(u_\epsilon)\le E^g(v_\epsilon)+\epsilon/2.\tag{2.21}$$

Now (2.13) follows from (2.19) and (2.21). □

THEOREM 2.5. *Let* (H.1)–(H.3) *hold. Assume that* $u\in BV(\Omega)\cap L^2$, *with* $T_ru=g$ *on* $\partial\Omega$, *where* g *is the trace of a function* $G\in H^1(\Omega)$ *(see* (A.3)*). Then, for each* $\epsilon>0$, *there exists a function* $u_\epsilon\in H^1(\Omega)$ *such that*

$$u_\epsilon=g \text{ on } \partial\Omega \text{ in the sense of trace},\tag{2.22}$$

$$\|u_\epsilon-u\|_{L^2(\Omega)}\le\epsilon,\tag{2.23}$$

$$\int_\Omega\alpha|\nabla u_\epsilon|\le\int_\Omega\alpha|\nabla u|+\epsilon.\tag{2.24}$$

Proof. To see this, we need only to modify the second part of the proof of the above theorem. Let v_ϵ be the function obtained in the proof of the first step. Then v_ϵ verifies (2.14)–(2.16), and $v_\epsilon-G\in W_0^{1,1}(\Omega)\cap L^2$. Therefore, there exists a function $h_\epsilon\in C_0^\infty(\Omega)$ such that

$$\int_\Omega\alpha|\nabla(v_\epsilon-G-h_\epsilon)|+\|v_\epsilon-G-h_\epsilon\|_{L^2(\Omega)}\le\epsilon.$$

Let $u_\epsilon=G+h_\epsilon$. Then $u_\epsilon\in H^1(\Omega)$ satisfies (2.22)–(2.24). □

3. Minimization problems (1.1) and (1.2). In this section, we shall show the existence of the solution to the relaxed problem associated with (1.1) and the convergence of the solutions to the problem (1.2) or to the problem (3.2) below to the pseudosolution of (1.1), as $p\to1$.

Note that the weak limit in $BV(\Omega)$ of a minimizing sequence of (1.1) may fail to have the same boundary data g; hence it may not be in BV_g. As in [10], [22], and [26], we will incorporate the boundary condition into the functional by using the so-called *relaxed energy* and define a pseudosolution of (1.1) as follows.

DEFINITION 3.1. *A function* $u\in BV(\Omega)\cap L^2$ *is a pseudosolution of* (1.1) *if it is a solution to the minimization problem*

$$\min_{v\in BV(\Omega)\cap L^2}E^g(v),\tag{3.1}$$

where $E^g(v)$ *is as defined in* (2.5).

In the appendix, we shall show (see Theorem A.3)

$$\inf_{v\in BV(\Omega)\cap L^2} E^g(v) = \inf_{v\in BV_g\cap L^2} E(v).$$

This is why the solution of (3.1) is called a pseudosolution of (1.1).

Now we prove the existence and uniqueness results for (3.1).

THEOREM 3.2 (existence for (3.1)). *Let* (H.1)–(H.3) *hold. Then there is a unique solution to the problem* (3.1).

Proof. Let $u_n \subset BV(\Omega)\cap L^2$ be a minimizing sequence for E^g; i.e.,

$$E^g(u_n) \to \inf_{v\in BV(\Omega)\cap L^2} E^g(v).$$

By (H.2), α has a lower bound $\alpha_0 > 0$; hence the $u_n's$ are bounded in $BV(\Omega)$ and $L^2(\Omega)$. By the compactness result (see [11] or [5]), there exist a subsequence u_{n_j} of u_n and a function $u \in BV(\Omega)\cap L^2$ such that, as $j\to\infty$,

$$u_{n_j} \to u \text{ strongly in } L^1(\Omega), \quad \text{weakly in } L^2(\Omega).$$

By Theorem 2.3 and the weak lower semicontinuity of the L^2-norm, we get

$$E^g(u) \le \liminf_{j\to\infty} E^g(u_{n_j}) = \inf_{v\in BV(\Omega)\cap L^2} E^g(v).$$

The uniqueness of the minimizer follows from the strict convexity of E^g. ∎

Similarly, we can prove the following theorem.

THEOREM 3.3. *Let* (H.1)–(H.3) *hold. Then there is a unique solution to the problem*

$$\min_{v\in W^{1,p}\cap L^2} E_p^g(v), \tag{3.2}$$

where $E_p^g(v)$ *is as defined in* (2.6).

We also have the following theorem.

THEOREM 3.4 (existence for (1.2)). *Let* (H.1)–(H.3) *hold. Then there is a unique solution to the problem* (1.2).

Proof. Let $u_n \subset W_g^{1,p}\cap L^2$ be a minimizing sequence for E_p. Then the $u_n^{'}s$ are bounded in $W^{1,p}(\Omega)$ and $L^2(\Omega)$ since α is bounded below. Therefore, there exist a subsequence u_{n_j} of u_n and a function $u \in W^{1,p}(\Omega)\cap L^2$ such that, as $j\to\infty$,

$$u_{n_j} \to u \text{ weakly in } W^{1,p}(\Omega) \text{ and } L^2(\Omega), \tag{3.3}$$

and

$$Tu_{n_j} \to Tu \text{ weakly in } L^p(\partial\Omega).$$

Since $Tu_{n_j} = g$ for all j, $Tu = g$ on $\partial\Omega$. Hence $u \in W_g^{1,p}\cap L^2$. From (3.3) and the weak lower semicontinuity of the norms, we get

$$E_p(u) \le \liminf_{j\to\infty} E_p(u_{n_j}) = \inf_{v\in W_g^{1,p}\cap L^2} E_p(v).$$

This shows that u is a solution of (1.2). The uniqueness of the minimizer follows from the strict convexity of E_p. ∎

Next we shall show that the solution of (3.1) can be approximated by both the solutions of (3.2) and (1.2), respectively.

THEOREM 3.5. *Let* (H.1)–(H.3) *hold. Assume* u *is a solution of* (3.1) *and* u_p *are the solutions of* (3.2) *for* $1 < p < 2$. *Then there exists a sequence* u_{p_j} *from* u_p *such that, as* $p_j \to 1$,

$$u_{p_j} \to u \quad \textit{weakly in } BV(\Omega) \textit{ and } L^2(\Omega),$$

and

$$E^g_{p_j}(u_{p_j}) \to E^g(u). \tag{3.4}$$

Proof. Since u_p are solutions of (3.2) for $1 < p < 2$ and α is bounded below by a positive constant, the u_p are bounded in $W^{1,1}(\Omega) \cap L^2$. Therefore, there exist a sequence u_{p_j} from u_p and a function $u_1 \in BV(\Omega) \cap L^2$ such that, as $p_j \to 1$,

$$u_{p_j} \to u_1 \ \text{ strongly in } L^1(\Omega) \text{ and weakly in } L^2(\Omega), \tag{3.5}$$

and ∇u_{p_j} converges to ∇u_1 in the sense of measure. By Theorem 2.4, for u_1, any $\epsilon > 0$, and any fixed $p > 1$, there is a function $u_\epsilon \in W^{1,p}(\Omega) \cap L^2$ such that

$$E^g(u_\epsilon) \le E^g(u_1) + \epsilon. \tag{3.6}$$

Note that

$$E^g_{p_j}(u_{p_j}) = \min_{v \in W^{1,p_j} \cap L^2} E^g_{p_j}(v).$$

From (3.6), we have that

$$\liminf_{p_j \to 1} E^g_{p_j}(u_{p_j}) \le \lim_{p_j \to 1} E^g_{p_j}(u_\epsilon) = E^g(u_\epsilon) \le E^g(u_1) + \epsilon.$$

Letting $\epsilon \to 0$ in the above inequality yields that

$$\lim_{p_j \to 1} E^g_{p_j}(u_{p_j}) \le E^g(u_1). \tag{3.7}$$

On the other hand, by Theorem 2.3 and (3.5),

$$E^g(u_1) \le \liminf_{p_j \to 1} E^g(u_{p_j}) \le \lim_{p_j \to 1} \left\{ \left(\int_\Omega \alpha |\nabla u_{p_j}|^{p_j} dx \right)^{\frac{1}{p_j}} \left(\int_\Omega \alpha dx \right)^{1 - \frac{1}{p_j}} \right.$$

$$\left. + 1/2 \int_\Omega |u_{p_j} - I|^2 dx + \int_{\partial\Omega} \alpha |u_{p_j} - g| dH^{n-1} \right\} = \liminf_{p_j \to 1} E^g_{p_j}(u_{p_j}). \tag{3.8}$$

The combination of (3.7) and (3.8) leads to

$$E^g(u_1) = \lim_{p_j \to 1} E^g_{p_j}(u_{p_j}). \tag{3.9}$$

Next we shall show that u_1 solves (3.1), and hence $u_1 = u$. To see this, let $v \in BV(\Omega) \cap L^2$, and apply Theorem 2.4 to v. Then, for each $\epsilon > 0$, we have a function $v_\epsilon \in W^{1,p}(\Omega) \cap L^2$ such that

$$E^g(v_\epsilon) \le E^g(v) + \epsilon. \tag{3.10}$$

On the other hand, by (3.9) and (3.6),

$$E^g(u_1) = \lim_{p_j \to 1} E^g_{p_j}(u_{p_j}) \le \lim_{p_j \to 1} E^g_{p_j}(v_\epsilon) = E^g(v_\epsilon).$$

Then, from (3.10), we get

$$E^g(u_1) \le E^g(v) + \epsilon. \tag{3.11}$$

Letting $\epsilon \to 0$ in (3.11), we get

$$E^g(u_1) \le E^g(v)$$

for any $v \in BV(\Omega) \cap L^2$. Thus u_1 solves (3.1). By the uniqueness of the solution to (3.1), $u = u_1$, and then, from (3.9),

$$E^g(u) = \lim_{p_j \to 1} E^g_{p_j}(u_{p_j}). \qquad \square$$

THEOREM 3.6. *Let* (H.1)–(H.3) *hold. Assume* u *is a solution of* (3.1) *and* u_p *are the solutions of* (1.2) *for* $1 < p < 2$. *Then there exists a sequence* u_{p_j} *from* u_p *such that, as* $p_j \to 1$,

$$u_{p_j} \to u \quad \textit{weakly in } BV(\Omega) \textit{ and } L^2(\Omega),$$

and

$$E_{p_j}(u_{p_j}) \to E^g(u). \tag{3.12}$$

Proof. Since u_p are solutions of (1.2) for $1 < p < 2$ and α is bounded below by a positive constant, the u_p are bounded in $W^{1,1}(\Omega) \cap L^2$. Therefore, there exist a sequence u_{p_j} from u_p and a function $u_1 \in BV(\Omega) \cap L^2$ such that, as $p_j \to 1$,

$$u_{p_j} \to u_1 \ \text{ strongly in } L^1(\Omega) \text{ and weakly in } L^2(\Omega).$$

Using Theorem 2.3 and noticing the fact that $u_{p_j} = g$ a.e. on $\partial\Omega$, we have

$$E^g(u_1) \le \liminf_{p_j \to 1} E^g_{p_j}(u_{p_j}) = \liminf_{p_j \to 1} E_{p_j}(u_{p_j}). \tag{3.13}$$

Since u_{p_j} is the solution of (1.2) with $p = p_j$, $E^g_{p_j}(u_{p_j}) = \min_{v \in W_g^{1,p_j} \cap L^2} E^g_{p_j}(v)$. By Proposition A.2 and Theorem A.3, we get

$$\liminf_{p_j \to 1} E_{p_j}(u_{p_j}) = \inf_{v \in BV_g \cap L^2} E(v)$$

$$= \inf_{v \in BV(\Omega) \cap L^2} E^g(v) = E^g(u). \tag{3.14}$$

The combination of (3.13)–(3.14) shows that

$$E^g(u_1) \le E^g(u).$$

Therefore, $u_1 = u$, and (3.12) follows from (3.14). $\square$

4. Evolution problems. In this section, we shall show that the flow associated with the minimization problem (1.1), i.e., (1.3)–(1.5), in a weakened formulation can be approximated by a sequence of the solutions to the flows associated with the minimization problem (1.2). We shall also discuss the large time behavior of the solution to (1.3)–(1.5) by an approach different from the subdifferential theory used in both [10] and [25].

Denote $\Omega^T = \Omega \times [0,T)$ and $\partial\Omega^T = \partial\Omega \times [0,T)$, $0 < T \le \infty$.

4.1. Definition of a pseudosolution to (1.3)–(1.5). As mentioned in the previous section, the weak limit (as $p \to 1$) in $BV(\Omega)$ of a sequence in W_g^{1,p_j} may fail to have the same boundary data g. Hence we consider a weakened formulation for the solution to (1.3)–(1.5).

Assume that the solution $u(x,t)$ of (1.3)–(1.5) is sufficiently smooth to justify the following calculations. For arbitrary $v \in L^2(0,T;H^1(\Omega))$, we multiply (1.3) by $v-u$. After integrating by parts and using the convexity of the functions $p \to |p|$ and $u \to |u-I|^2$ and the inequality $\frac{\nabla u}{|\nabla u|} \cdot \mu \le 1$, where μ denotes the exterior unit normal vector to Ω, we get that, for any $t \in [0,T]$,

$$\int_\Omega (\partial_t u)(v-u)dx + E^g(v) \ge E^g(u). \tag{4.1}$$

Then we integrate with respect to t to get that, for any $s \in [0,T]$,

$$\int_0^s \int_\Omega (\partial_t u)(v-u)dxdt + \int_0^s E^g(v)dt \ge \int_0^s E^g(u). \tag{4.2}$$

Conversely, choosing $v = v_\epsilon = u + \epsilon w$, where $w \in C_0^\infty(\Omega)$, in (4.2), and noticing that the left-hand side (LHS) of (4.2) has a minimum at $\epsilon = 0$, we can show that u is a solution of (1.3) in the sense of distribution by computing $\frac{d}{d\epsilon}\int_\Omega (\partial_t(u\epsilon w))dx + E^g(u+\epsilon w)$ at $\epsilon = 0$.

Prompted by these facts, we give the following definition for a pseudosolution of (1.3)–(1.5).

DEFINITION 4.1. *A function $u \in L^2(0,T;BV(\Omega)\cap L^2)$ $(0 < T \le \infty)$ is called a pseudosolution of* (1.3)–(1.5) *if $\partial_t u \in L^2(\Omega^T)$, $u(x,0) = u_0(x)$ on Ω, and u satisfies* (4.2) *for every $v \in L^2([0,T];BV(\Omega)\cap L^2)$, and $s \in [0,T]$.*

Let (H.1)–(H.3) hold. Assume $g \in L^\infty(\partial\Omega)$ and $I \in BV(\Omega)\cap L^\infty$ with $I|_{\partial\Omega} = g$.

We first consider the *approximating* problem

$$\frac{\partial u_{p,\delta}}{\partial t} - \operatorname{div}(\alpha|\nabla u_{p,\delta}|^{p-2}\nabla u_{p,\delta} + (u_{p,\delta} - I_\delta)) = 0 \ \text{ in } \Omega \times \mathbf{R}_+, \tag{4.3}$$

$$u_{p,\delta} = g \ \text{ on } \ \partial\Omega \times \mathbf{R}_+, \tag{4.4}$$

$$u_{p,\delta}(x,0) = I_\delta \ \text{ on } \ \Omega, \tag{4.5}$$

where $1 < p \le 2$ and $I_\delta \in H^1(\Omega)$ such that, as $\delta \to 0$,

$$I_\delta \to I \text{ in } L^2(\Omega), \quad \int_\Omega \alpha|\nabla I_\delta| \to \int_\Omega \alpha|\nabla I|, \tag{4.6}$$

and

$$\|I_\delta\|_{L^\infty(\Omega)} \le \|I\|_{L^\infty}(\Omega), \quad I_\delta|_{\partial\Omega} = I|_{\partial\Omega} = g. \tag{4.7}$$

The existence of I_δ is concluded from Theorem 2.5.

We have the following existence and uniqueness result for the problem (4.3)–(4.5).

LEMMA 4.2. *The problem* (4.3)–(4.5) *admits a unique pseudosolution* $u_{p,\delta} \in L^\infty(0,\infty;W^{1,p}(\Omega)\cap L^2)$, *with* $\partial_t u_{p,\delta} \in L^2(0,\infty;L^2(\Omega))$ *and, for any* $T>0$,

$$\int_0^T\int_\Omega |\partial_t u_{p,\delta}|^2 dxdt + \sup_{t\in[0,T]}\left\{\frac{1}{p}\int_\Omega \alpha|\nabla u_{p,\delta}|^p dx + \frac{1}{2}\int_\Omega |u_{p,\delta}-I_\delta|^2 dx\right\} \le \frac{1}{p}\int_\Omega \alpha|\nabla I_\delta|^p dx. \tag{4.8}$$

This result can be obtained by using the fact that the p-Laplacian operator is a maximal monotone operator.

We can also have the following $L^\infty(\Omega)$ bound for the solution to (4.3)–(4.5).

LEMMA 4.3. *Suppose* $I \in BV(\Omega)\cap L^\infty$, $g \in L^\infty(\partial\Omega)$, *and* $u_{p,\delta}$ *is a weak solution to* (4.3)–(4.5). *Then we have, for any* $T>0$,

$$\|u_{p,\delta}\|_{L^\infty(\Omega^T)} \le \max(\|I\|_{L^\infty(\Omega)}, \|g\|_{L^\infty(\partial\Omega)}). \tag{4.9}$$

Proof. Denote $M = \max(\|I_\delta\|_{L^\infty(\Omega)}, \|g\|_{L^\infty(\partial\Omega)})$. From (4.7),

$$M \le \max(\|I\|_{L^\infty(\Omega)}, \|g\|_{L^\infty(\partial\Omega)}). \tag{4.10}$$

Multiply both sides of (4.3) by $(u_{p,\delta}-M)_+$, where $(u_{p,\delta}-M)_+ = u_{p,\delta}-M$ if $u_{p,\delta}-M\ge 0$ and, otherwise, $(u_{p,\delta}-M)_+ = 0$. Then integrate over Ω to get

$$\int_\Omega \partial_t u_{p,\delta}(u_{p,\delta}-M)_+ dx + \int_{\{u_{p,\delta}\ge M\}} \alpha|\nabla u_{p,\delta}|^p dx$$

$$+\int_\Omega (u_{p,\delta}-M)_+(u_{p,\delta}-I_\delta)dx = 0.$$

Since the last two integrals are nonnegative, we have

$$\int_\Omega \partial_t u_{p,\delta}(u_{p,\delta}-M)_+ dx \le 0. \tag{4.11}$$

Let

$$I(t) = \frac{1}{2}\int_\Omega |(u_{p,\delta}-M)_+|^2 dx.$$

Then $I(0)=0$, and from (4.11)

$$I'(t) = \int_\Omega (u_{p,\delta}-M)_+(\partial_t u_{p,\delta})dx \le 0.$$

Hence $I(t)\le 0$ for all $t\ge 0$, which implies

$$u_{p,\delta}(t) \le M,\ \mathcal{L} \text{ a.e. on } \Omega, \text{ and } \forall t>0.$$

We obtain $u_{p,\delta}(t)\le M$. Similarly, multiplying (4.3) by $(-M-u_{p,\delta})_+$, we can have $u_{p,\delta}(t)\ge -M$. Thus $\|u_{p,\delta}\|_{L^\infty(\Omega^T)}\le M$ for any $T\ge 0$. Then (4.9) follows from (4.10). ∎

Next we shall prove the main theorem regarding the existence, uniqueness, and large time behavior for the solution to (1.3)–(1.5).

THEOREM 4.4. *Let* (H.1)–(H.3) *hold. Assume* $g \in L^\infty(\partial\Omega)$ *and* $I \in BV(\Omega)\cap L^\infty$ *with* $I|_{\partial\Omega} = g$. *Then there exists a unique pseudosolution* $u \in L^\infty(0,\infty; BV(\Omega)\cap L^\infty)$ *to* (1.3)–(1.5). *Moreover, as* $t \to \infty$, *the functions* $u(\cdot,t)$ *converge strongly in* $L^2(\Omega)$ *to a function* $\tilde{u}$, *which minimizes* E^g; *i.e.,* $\tilde{u}$ *is a pseudosolution of* (1.1).

Proof. Let $u_{p,\delta}$ be the weak solution of (4.3)–(4.5). From (4.8)–(4.9), we know that, for fixed $\delta > 0$,

$$u_{p,\delta} \text{ is uniformly bounded in } L^\infty(0,\infty; W^{1,p}(\Omega)\cap L^\infty), \tag{4.12}$$

$$\partial_t u_{p,\delta} \text{ is uniformly bounded in } L^2(\Omega^\infty). \tag{4.12$'$}$$

Now we claim that there exist a sequence of functions $u_{p_j,\delta}$ and a function $u_\delta \in L^\infty(0,\infty; BV(\Omega)\cap L^\infty)$ such that, as $j \to \infty$, $p_j \to 1$,

$$\partial_t u_{p_j,\delta} \to \partial_t u_\delta \text{ weakly in } L^2(\Omega^\infty), \tag{4.13}$$

$$u_{p_j,\delta} \to u_\delta \text{ weakly}^* \text{ in } L^\infty(\Omega^\infty), \tag{4.14}$$

and

$$u_{p_j,\delta} \to u_\delta \text{ in } L^2(\Omega) \text{ uniformly in } t. \tag{4.15}$$

In fact, from (4.12)–(4.12$'$), there is a sequence $u_{p_j,\delta}$ and a function $u_\delta \in L^\infty(\Omega^\infty)$ with $\partial_t u_\delta \in L^2(\Omega^\infty)$ such that (4.13) and (4.14) hold. To see (4.15), note that, for any $f \in L^2(\Omega)$, as $j \to \infty$,

$$\int_\Omega (u_{p_j,\delta}(x,t) - I_\delta(x))f(x)dx = \int_{\Omega^\infty} \partial_s u_{p_j,\delta}(x,s)1_{[0,t]}(s)f(x)dxds$$

$$\to \int_{\Omega^\infty} \partial_s u_\delta(x,s)1_{[0,t]}(s)f(x)dxds = \int_\Omega (u_\delta(x,t) - I_\delta(x))f(x)dx,$$

where $1_{[0,t]}$ is the characteristic function of the set $[0,t] \subset [0,\infty)$. This shows that, for each t,

$$u_{p_j,\delta} \to u_\delta \text{ weakly in } L^2(\Omega). \tag{4.15$'$}$$

By (4.8), for each $t \in [0,\infty)$, $u_{p_j,\delta}(\cdot,t)$ is a bounded sequence in $W^{1,1}(\Omega)$. Hence there is a subsequence of $u_{p_j,\delta}(\cdot,t)$ converging a.e. in Ω and strongly in $L^1(\Omega)$ to u_δ (here we used (4.15$'$)). Since every convergent subsequence of $u_{p_j,\delta}(\cdot,t)$ converges to the same limit, we get that, for each t as $p_j \to 1$,

$$u_{p_j,\delta}(\cdot,t) \to u_\delta(\cdot,t) \text{ in } L^1(\Omega). \tag{4.15$''$}$$

Combining this with (4.9), we get for each t

$$u_{p_j,\delta}(\cdot,t) \to u_\delta(\cdot,t) \text{ in } L^2(\Omega).$$

Furthermore, $t \to u_{p_j,\delta}(\cdot,t) \in L^2(\Omega)$ is equicontinuous since

$$\|u_{p_j,\delta}(\cdot,t) - u_{p_j,\delta}(\cdot,t')\|^2_{L^2(\Omega)} \le |t-t'| \int_{\Omega^\infty} (\partial_t u_{p_j,\delta})^2 dxdt.$$

Then, by a standard argument, we can have the convergence of $u_{p_j,\delta}(\cdot,t)$ to $u_\delta(\cdot,t)$ in $L^2(\Omega)$ uniform in t; this is (4.15). The claim is proved.

Now from (4.8) and (4.15″) we have that

$$\{u_\delta(\cdot,t),\ t\in[0,\infty),\ 1<p\le 2\} \text{ is a bounded set in } BV(\Omega).$$

Moreover, from (4.14),

$$u_\delta \in\ L^\infty(0,\infty;BV(\Omega)\cap L^\infty).$$

Next we show that, for all $v\in L^\infty(0,\infty;H^1(\Omega))$ and each $s\in[0,\infty)$,

$$\int_0^s\int_\Omega \partial_t u_\delta(v-u_\delta)dxdt+\int_0^s\int_\Omega \alpha|\nabla v|dt+1/2\int_0^s\int_\Omega |v-I_\delta|^2dxdt+\int_0^s\int_{\partial\Omega}\alpha|v-g|dH^{n-1}dt$$

$$\ge \int_0^s\int_\Omega \alpha|\nabla u_\delta|dt+1/2\int_0^s\int_\Omega |u_\delta-I_\delta|^2dxdt+\int_0^s\int_{\partial\Omega}|u_\delta-g|dH^{n-1}dt. \tag{4.16}$$

To show this, we first assume further that $v=g$ on $\partial\Omega^\infty$. Multiply (4.3) by $v-u_{p_j,\delta}$, and integrate over Ω^s:

$$\int_0^s\int_\Omega \partial_t u_{p,\delta}(v-u_{p,\delta})dxdt+\int_0^s\int_\Omega \alpha|\nabla u_{p,\delta}|^{p-2}\nabla u_{p,\delta}\cdot\nabla(v-u_{p,\delta})dxdt$$

$$+\int_0^s\int_\Omega (u_{p,\delta}-I_\delta)(v-u_{p,\delta})dxdt=0. \tag{4.17}$$

Write $v-u_{p,\delta}=(v-I_\delta)-(u_{p,\delta}-I_\delta)$, and use the convexity of $|\cdot|^p$ $(p\ge 1)$ to get from (4.17)

$$\int_0^s\int_\Omega \partial_t u_{p,\delta}(v-u_{p,\delta})dxdt+1/p\int_0^s\int_\Omega\alpha|\nabla v|^pdxdt+1/2\int_0^s\int_\Omega|v-I_\delta|^2dxdt$$

$$+\int_0^s\int_{\partial\Omega}|v-g|dH^{n-1}dt\ge 1/p\int_0^s\int_\Omega\alpha|\nabla u_{p,\delta}|^pdxdt+1/2\int_0^s\int_\Omega|u_{p,\delta}-I_\delta|^2dxdt. \tag{4.18}$$

Notice that, using Theorem 2.3, we have

$$\int_\Omega\alpha|\nabla u_\delta|+\int_{\partial\Omega}\alpha|u_\delta-g|dH^{n-1}\le\liminf_{j\to\infty}\int_\Omega\alpha|\nabla u_{p,\delta}|+\int_{\partial\Omega}\alpha|u_{p,\delta}-g|dH^{n-1}$$

$$\le\liminf_{j\to\infty}\left(\int_\Omega\alpha|\nabla u_{p,\delta}|^p\right)^{1/p}\left(\int_\Omega\alpha\right)^{1-\frac{1}{p}}+\int_{\partial\Omega}\alpha|u_{p,\delta}-g|dH^{n-1}$$

$$=\liminf_{j\to\infty}\frac{1}{p}\left(\int_\Omega\alpha|\nabla u_{p,\delta}|^p\right)^{1/p}+\int_{\partial\Omega}\alpha|u_{p,\delta}-g|dH^{n-1}. \tag{4.19}$$

Letting p tend to 1 along p_j in (4.18), using (4.13), (4.15), and (4.19), we get (4.16) for $v\in L^\infty(0,\infty;H^1(\Omega))$ with $v=g$ on $\partial\Omega^\infty$.

To get (4.16) for all $v \in L^\infty(0,\infty;H^1(\Omega))$ (i.e., the condition that $v = g$ on $\partial\Omega^\infty$ is not necessarily satisfied), we let for $\beta > 0$

$$d_\beta(x) = \min(d(x)/\beta, 1),$$

where $d(x)$ is the distance of the point x to the boundary of Ω. Since $|d(x) - d(y)| \le |x - y|$, $d \in W^{1,\infty}$, with $|\nabla d| = 1$. It follows that

$$|\nabla d_\beta| = 1/\beta \text{ if } d(x) < \beta, \text{ and } |\nabla d_\beta| = 0 \text{ if } d(x) \ge \beta.$$

Let

$$v_\beta = d_\beta v + (1 - d_\beta)G \quad \text{for } (x,t) \in \Omega^T.$$

Then

$$v_\beta \in L^\infty(0,\infty;H^1(\Omega)), \text{ and } v_\beta = g \text{ on } \partial\Omega^\infty. \tag{4.20}$$

Therefore, (4.16) holds with v replaced by v_β. It is clear that

$$v_\beta \to v \text{ in } L^2(\Omega^\infty). \tag{4.21}$$

Moreover,

$$\nabla v_\beta = \nabla v_\beta (v - G) + d_\beta \nabla v + (1 - d_\beta)\nabla G.$$

By using Theorem A.1 in the appendix and the fact that $d_\beta \to 1$ as $\beta \to 0$, we get

$$\lim_{\beta\to 0} \int_\Omega \alpha |\nabla v_\beta| = \int_\Omega \alpha |\nabla v| + \int_{\partial\Omega} \alpha |v - g| dH^{n-1}. \tag{4.22}$$

Replacing v by v_β in (4.16), letting $\beta \to 0$, and using (4.20)–(4.22) we get that (4.16) holds for all $v \in L^\infty(0,\infty;H^1(\Omega))$ and each $s \in [0,T]$. Furthermore, by Theorem 2.4, (4.16) also holds for all $v \in L^2(0,\infty;BV(\Omega)\cap L^2)$.

Moreover, replacing u_p by u_{p_j} in (4.8), letting $j \to \infty$ ($p_j \to 1$), and using (4.13), (4.15), (4.19), (4.4), and (4.6), we get

$$\int_0^\infty \int_\Omega |\partial_t u_\delta|^2 dx dt + \sup_{t\in[0,\infty)} \left\{ \int_\Omega \alpha |\nabla u_\delta| + \int_{\partial\Omega} \alpha |u_\delta - g| dH^{n-1} + \frac{1}{2}\int_\Omega |u_\delta - I_\delta|^2 dx \right\}$$

$$\le \int_\Omega \alpha |\nabla I|. \tag{4.23}$$

Next we shall pass to the limit as $\delta \to 0$. Recall from (4.9) and (4.23) that

$$u_\delta \text{ is uniformly bounded in } L^\infty(0,\infty;BV(\Omega)\cap L^\infty), \tag{4.24}$$

$$\partial_t u_\delta \text{ is uniformly bounded in } L^2(\Omega^\infty). \tag{4.25}$$

Then, by an argument similar to the one for getting (4.13)–(4.15), we can find a sequence of functions u_{δ_j} and a function $u \in L^\infty(0,\infty;BV(\Omega)\cap L^\infty)$ such that, as $j \to \infty$, $\delta_j \to 0$,

$$\partial_t u_{\delta_j} \to \partial_t u \text{ weakly in } L^2(\Omega^\infty), \tag{4.26}$$

$$u_{\delta_j} \to u \text{ weakly}^* \text{ in } L^\infty(\Omega^\infty), \tag{4.27}$$

and

$$u_{\delta_j} \to u \text{ in } L^2(\Omega) \text{ uniformly in } t \in [0,\infty). \tag{4.28}$$

Replacing u_δ by u_{δ_j}, letting $j \to \infty$ in (4.16), and using Theorem 2.3, we can have from (4.6), (4.26), and (4.28) that, for all $v \in L^2(0,\infty; BV(\Omega) \cap L^2)$ and each $s \in [0,\infty)$,

$$\int_0^s \int_\Omega \partial_t u(v-u)dxdt + \int_0^s \int_\Omega \alpha|\nabla v|dt + 1/2 \int_0^s \int_\Omega |v-I|^2 dxdt + \int_0^s \int_{\partial\Omega} \alpha|v-g|dH^{n-1}dt$$

$$\geq \int_0^s \int_\Omega \alpha|\nabla u|dt + 1/2 \int_0^s \int_\Omega |u-I|^2 dxdt + \int_0^s \int_{\partial\Omega} |u-g|dH^{n-1}dt. \tag{4.29}$$

We proved the existence of a pseudosolution of (1.3)–(1.5) (see Definition 4.1).

Furthermore, replacing u_δ by u_{δ_j} and letting $j \to \infty$ in (4.23), we get by using (4.26), (4.28), and Theorem 2.3 that the solution u obtained above satisfies the following estimate:

$$\int_0^\infty \int_\Omega |\partial_t u|^2 dxdt + \sup_{t\in[0,\infty)} \left\{ \int_\Omega \alpha|\nabla u| + \int_{\partial\Omega} \alpha|u-g|dH^{n-1} + \frac{1}{2}\int_\Omega |u-I|^2 dx \right\}$$

$$\leq \int_\Omega \alpha|\nabla I|. \tag{4.30}$$

The uniqueness result for (1.3)–(1.5) follows as in [10] and [26]: If u_1 and u_2 are two solutions, one writes the definition of the pseudosolution using each as the function v in (4.2). Adding the resulting inequalities, one finds

$$\int_0^s \int_\Omega \partial_t (u_1 - u_2)^2 \leq 0$$

for all $s > 0$.

At last, we shall show the asymptotic limit of the solution $u(\cdot,t)$ as $t \to \infty$.

Take a function $v \in BV(\Omega) \cap L^2$ in (4.29):

$$\int_\Omega (u(x,s) - u(x,0))v(x)dx - 1/2 \int_\Omega (u^2(x,s) - u^2(x,0))dx + s\int_\Omega \alpha|\nabla v|$$

$$+ s/2 \int_\Omega |v-I|^2 dx + s\int_{\partial\Omega} \alpha|v-g|dH^{n-1} \geq \int_0^s \int_\Omega \alpha|\nabla u|dxdt + 1/2 \int_0^s \int_\Omega |u-I|^2 dxdt$$

$$+ \int_0^s \int_{\partial\Omega} |u-g|dH^{n-1}dt. \tag{4.31}$$

Let

$$w(x,s) = \frac{1}{s}\int_0^s u(x,t)dt.$$

Then, from (4.27) and (4.30), for each s, $w(\cdot,s) \in BV(\Omega) \cap L^\infty$ with uniformly bounded BV and L^∞-norms. Thus there is a sequence $w(\cdot,s_i)$ converging strongly in

$L^1(\Omega)$ and weakly in $BV(\Omega)$ and $L^\infty(\Omega)$ to a function $\hat{w} \in BV(\Omega) \cap L^\infty$ as $s_i \to \infty$. In fact, since $w(\cdot, s_i)$ have uniformly bounded L^∞-norms, the convergence of $w(\cdot, s_i)$ to $\hat{w}$ is strong in $L^2(\Omega)$.

By dividing s in (4.31) and then taking the limit along $s_i \to \infty$, we get that, for any $v \in BV(\Omega) \cap L^2$,

$$\int_\Omega \alpha|\nabla v| + 1/2 \int_\Omega |v - I|^2 dx + \int_{\partial\Omega} \alpha|v - g| dH^{n-1}$$

$$\geq \int_\Omega \alpha|\nabla \hat{w}| + 1/2 \int_\Omega |\hat{w} - I|^2 dx + \int_{\partial\Omega} \alpha|\hat{w} - g| dH^{n-1}.$$

This shows that $\hat{w}$ is the pseudosolution of (1.1). □

Appendix. For $\beta > 0$, let

$$d_\beta(x) = \min(d(x)/\beta, 1),$$

where $d(x)$ is the distance of the point x to the boundary of Ω.

THEOREM A.1. *For each $v \in BV(\Omega) \cap L^\infty$, the vector measures $v\nabla d_\beta$ converge weakly to $-v\gamma dH^{n-1}$ as $\beta \to 0$, where γ is the outward normal to $\partial\Omega$, and*

$$\lim_{\beta\to 0} \int_\Omega |v||\nabla d_\beta| = \int_{\partial\Omega} |v| dH^{n-1}. \tag{A.1}$$

Proof. Without loss of generality, assume $\|v\|_{L^\infty} \leq 1$. By Theorem 3.2.39 in [6], we see that

$$\int_\Omega |v||\nabla d_\beta| \leq \int_\Omega |\nabla d_\beta|$$

is bounded, and as $\beta \to 0$, $\int_\Omega |\nabla d_\beta|$ tends to $H^{n-1}(\partial\Omega)$. Therefore, the family of the vector measures $v\nabla d_\beta$ is uniformly bounded in β as $\beta \to 0$. Let

$$w_\beta = (1 - d_\beta)v.$$

Then $w_\beta \in BV(\Omega)$, and, for each $\phi \in C^1(R^n, R^n)$, by the divergence theorem,

$$\int_\Omega w_\beta \mathrm{div}\phi = -\int_\Omega \phi\nabla w_\beta + \int_{\partial\Omega} (\phi \cdot \gamma) v dH^{n-1}. \tag{A.2}$$

Since $|w_\beta| \leq |v|$ and $w_\beta \to 0$ as $\beta \to 0$, the LHS of (A.2) tends to zero as $\beta \to 0$. Therefore, from (A.2),

$$\lim_{\beta\to 0} \int_\Omega \phi\nabla w_\beta = \int_{\partial\Omega} (\phi \cdot \gamma) v dH^{n-1}. \tag{A.3}$$

Furthermore,

$$\nabla w_\beta = -v\nabla d_\beta + (1 - d_\beta)\nabla v.$$

Since $(1-d_\beta)|\nabla v|$ tends to zero as $\beta \to 0$, and the vector measures $v\nabla d_\beta$ are uniformly bounded in β, we conclude from (A.3) that $v\nabla d_\beta$ converges weakly to $-v\gamma dH^{n-1}$ as $\beta \to 0$.

Using the weak lower semicontinuity of total variation, we get

$$\liminf \int_\Omega |v||\nabla d_\beta| \geq \int_{\partial\Omega} |v| dH^{n-1}. \tag{A.4}$$

Using (A.4) with $1-|v|$ replacing $|v|$, we get

$$\int_{\partial\Omega} dH^{n-1} = \int_{\partial\Omega} |v| dH^{n-1} + \int_{\partial\Omega} (1-|v|) dH^{n-1}$$

$$\leq \liminf \left\{ \int_\Omega |v||\nabla d_\beta| + \int_\Omega (1-|v|)|\nabla d_\beta| \right\}$$

$$\leq \liminf \int_\Omega |\nabla d_\beta| = \int_{\partial\Omega} dH^{n-1}. \tag{A.5}$$

Therefore, each inequality in (A.5) should be an equality. Furthermore, noticing that $\int_{\partial\Omega} |v| dH^{n-1} \leq \liminf \int_\Omega |v||\nabla d_\beta|$ and $\int_{\partial\Omega}(1-|v|)dH^{n-1} \leq \liminf \int_\Omega (1-|v|)|\nabla d_\beta|$, we obtain (A.1). □

Let

$$a_p = \inf_{v \in W^{1,p}(\Omega)\cap L^2} E_p^g(v) \text{ for } p>1, \text{ and } a_1 = \inf_{v\in BV(\Omega)\cap L^2} E^g(v),$$

$$A_p = \inf_{v \in W_g^{1,p}\cap L^2} E_p(v) \text{ for } p>1, \text{ and } A_1 = \inf_{v\in BV_g\cap L^2} E(v),$$

where $E(v)$, $E^g(v)$, $E_p(v)$, and $E_p^g(v)$ are as defined in (1.1)–(1.2) and (2.5)–(2.6), respectively. If $p>1$, both infima a_p and A_p are attained. For $p=1$, a_1 is attained. We will show below that $a_1 = A_1$. This will justify the definition of the pseudosolution for (1.1). We will use the following simple inequality:

For $b>0$ and $1 \leq q \leq p < \infty$,

$$\frac{b^q}{q} \leq \frac{b^p}{p} + \frac{p-q}{pq}. \tag{A.6}$$

This can be proved by using the Hölder inequality

$$b^q \leq \frac{qb^p}{p} + \frac{p-q}{pq}.$$

Proposition A.2. *For $p \geq 1$, both a_p and A_p are right continuous in p. We also have for $1 \leq q \leq p < \infty$*

$$a_q \leq \frac{p-q}{pq}|\Omega| + a_p, \tag{A.7}$$

$$A_q \leq \frac{p-q}{pq}|\Omega| + A_p, \tag{A.7$'$}$$

Proof. (1) Let $1 \leq q \leq p < \infty$ and $v_p \in W^{1,p}(\Omega)\cap L^2$ if $p>1$, and $v_p \in v \in BV(\Omega)\cap L^2$ if $p=1$. Then, using (A.6),

$$a_q \leq E_q^g(v_p) = 1/q \int_\Omega \alpha |\nabla v_p|^q + 1/2 \int_\Omega |v_p - I|^2 dx + \int_{\partial\Omega} \alpha |v_p - g| dH^{n-1}$$

$$\leq \frac{p-q}{pq}|\Omega| + E_p^g(v_p).$$

Since this is valid for all $v_p \in W^{1,p}(\Omega) \cap L^2$ if $p > 1$ and $v_p \in BV(\Omega) \cap L^2$ if $p = 1$, we get (A.7). (A.7′) can be proved by the same argument.

(2) Now we prove the right continuity of a_p, i.e.,

$$\lim_{p \downarrow q} a_p = a_q, \quad q \geq 1.$$

For $\epsilon > 0$, assume $u \in W^{1,\infty}(\Omega) \cap L^2$ such that

$$E_q^g(u) \leq a_q + \epsilon.$$

Then

$$\limsup_{p \downarrow q} a_p \leq \limsup_{p \downarrow q} E_p^g(u) = E_q^g(u) \leq a_q + \epsilon.$$

Let $\epsilon \to 0$, and we get

$$\limsup_{p \downarrow q} a_p \leq a_q. \tag{A.8}$$

On the other hand, by taking liminf as $p \downarrow q$ on both sides of (A.7),

$$a_q \leq \liminf_{p \downarrow q} a_p.$$

Combining this with (A.8) proves the right continuity of a_p for $p \geq 1$.

(3) To prove the right continuity of A_p, we need some modification for the argument applied above for a_p since the inequality similar to (A.9) is not valid for $q = 1$ due to the fact that $W_g^{1,\infty}$ is not dense in BV_g, while $W^{1,\infty}$ is weakly dense in BV. However, in this case, we can use Theorem 2.5 to get a similar result as follows: Let $\epsilon > 0$, and assume that $u \in BV_g \cap L^2$ such that

$$E(u) \leq A_1 + \epsilon. \tag{A.9}$$

By using (A.9) and Theorem 2.5, there is $v \in W_g^{1,2} \cap L^2$ such that

$$E(v) \leq E(u) + \epsilon \leq A_1 + 2\epsilon. \tag{A.10}$$

For $q > 1$, it is clear that there is a function $v \in W_g^{1,\infty} \cap L^2$ such that

$$E_q(v) \leq a_q + \epsilon. \tag{A.11}$$

Now repeating the argument in the second step and using (A.10)–(A.11) give the right continuity of A_p for $p \geq 1$. □

THEOREM A.3. *Let* (H.1)–(H.3) *hold. Then*

$$\inf_{v \in BV(\Omega) \cap L^2} E^g(v) = \inf_{v \in BV_g \cap L^2} E(v). \tag{A.12}$$

Proof. Since $BV_g \subset BV(\Omega)$,

$$\inf_{v \in BV(\Omega) \cap L^2} E^g(v) \leq \inf_{v \in BV_g \cap L^2} E(v).$$

Next we shall prove

$$\inf_{v \in BV(\Omega) \cap L^2} E^g(v) \geq \inf_{v \in BV_g \cap L^2} E(v). \tag{A.13}$$

to get (A.12).

From Theorem 3.2, we know that there exists a unique $u \in BV(\Omega) \cap L^2$ such that $E^g(u) = \inf_{v \in BV(\Omega) \cap L^2} E^g(v)$. Let $d_\beta(x)$ be the function defined in (4.20). Define

$$u_\beta = d_\beta u + (1 - d_\beta)G.$$

Then $u_\beta \in BV_g$ so that

$$\inf_{v \in BV_g \cap L^2} E(v) \leq E(u_\beta). \tag{A.14}$$

Furthermore, noticing that $u_\beta = u$ on $\{d(x) \geq \beta\}$, we have

$$E(u_\beta) \leq \int_{\Omega \cap \{d(x) \geq \beta\}} \alpha |\nabla u| + \int_{\Omega \cap \{d(x) < \beta\}} \alpha |u - G| |\nabla d_\beta|$$

$$+ \int_{\Omega \cap \{d(x) < \beta\}} \alpha |\nabla (u - G)| |d_\beta| + \int_{\Omega \cap \{d(x) < \beta\}} \alpha |\nabla G| + \int_\Omega |u_\beta - I|^2. \tag{A.15}$$

As $\beta \to 0$, $u_\beta \to u$ in $L^2(\Omega)$, and $|\{\Omega \cap \{d(x) \leq \beta\}\}| \to 0$. Using these facts and (A.1) with $v = u - G$, we get from (A.15) that

$$\lim_{\beta \to 0} E(u_\beta) \leq \int_\Omega \alpha |\nabla u| + \int_{\partial \Omega} \alpha |u - g| dH^{n-1} + \int_\Omega |u - I|^2.$$

The combination of this with (A.14) leads to (A.13) and hence to (A.12). □

VORTICES IN p-WAVE SUPERCONDUCTIVITY*

FANGHUA LIN† AND TAI-CHIA LIN‡

Abstract. In the theory of p-wave superconductivity, the Ginzburg–Landau energy functionals with multicomponent order parameters were employed. Here we find a minimizer of a reduced form of the p-wave Ginzburg–Landau free energy with two-component order parameters. The minimizer has distinct degree-one (or minus one) vortices in each component. We also derive a system of ordinary differential equations as the motion equations of vortices in the approximated gradient flow for p-wave superconductivity.

Key words. vortices, dynamics, p-wave superconductivity, Ginzburg–Landau

1. Introduction.

It is well known that many of the heavy-fermion superconductors are thought to represent a novel form of superconductivity. Remarkable evidence in support of an unconventional superconducting state in the heavy-fermion superconductors has accumulated from specific heat, upper critical field, and various transport measurements, all of which show anomalous properties compared with those of conventional superconductors (cf. [2], [7], [22], [23], [25]). Conventional superconductors refer to those with the pairing symmetry of the s-wave and the spin singlet. However, it is widely accepted that an anisotropic p-wave spin-triplet pairing may be realized in heavy-fermion superconductors.

The possibility of the p-wave spin-triplet pairing has been investigated since the 1970's for superfluid ^3He, a heavy-fermion system UPt_3, or, most recently, an oxide Sr_2RuO_4 (cf. [12], [19], [28], [29]). The strongest evidence for unconventional superconductivity comes from the multiple superconducting phases of UPt_3. There are two superconducting phases in the zero field (cf. [7]).

To describe p-wave superconductors, we consider a simple situation with two-component order parameters η_i, $i = 1, 2$. In the absence of a magnetic field, the Ginzburg–Landau free energy is given by

$$F(\eta_1,\eta_2)=\int_{\mathbb{R}^2} \begin{aligned} &K_1(|\partial_x\eta_1|^2+|\partial_y\eta_2|^2)+K_2(|\partial_x\eta_2|^2+|\partial_y\eta_1|^2)+f_{pot}(\eta_1,\eta_2)\\ &+K_3\left(\partial_x\eta_1^*\partial_y\eta_2+\text{c.c.}\right)+K_4\left(\partial_x\eta_2^*\partial_y\eta_1+\text{c.c.}\right)dx\,dy, \end{aligned} \tag{1.1}$$

for η_1 and η_2 are complex-valued order parameters, where $K_j, j = 1, \dots, 4$, are material constants and the asterisk denotes the complex conjugate. Hereafter,

$$f_{pot}(\eta_1,\eta_2)=-\alpha_0\left(|\eta_1|^2+|\eta_2|^2\right)+\alpha_1\left(|\eta_1|^2+|\eta_2|^2\right)^2+\alpha_2\left(\eta_1^*\eta_2-\eta_1\eta_2^*\right)^2, \tag{1.2}$$

where $\alpha_j, j = 0, 1, 2$, are constants. Zhu et al. [30] derived (1.1) from reasonable microscopic models describing Sr_2RuO_4. The expression of the Ginzburg–Landau free energy (1.1) agrees quite well with that constructed from the group-theoretical argument (cf. [24]) for the Γ_5^- superconducting state in the tetragonal D_{4h} (except one coefficient) and hexagonal symmetry D_{6h}.

In this paper, we assume that $K_1 = K_2 = K > 0$ and $K_3 = K_4 = 0$ to avoid various complications which come from additional derivative terms. Then (1.1) becomes

$$F(\eta_1, \eta_2) = \int_{\mathbb{R}^2} K(|\nabla \eta_1|^2 + |\nabla \eta_2|^2) + f_{pot}(\eta_1, \eta_2)\, dx\, dy. \tag{1.3}$$

Moreover, it is easy to check that

$$f_{pot}(\eta_1, \eta_2) = -\alpha_0 (|\eta_1|^2 + |\eta_2|^2) + \beta_1 (|\eta_1|^2 + |\eta_2|^2)^2 + \beta_2 |\eta_1^2 + \eta_2^2|^2, \tag{1.4}$$

where $\beta_1 = \alpha_1 - \alpha_2, \beta_2 = \alpha_2$. From [11], we use the following convenient parametrization of the order parameter:

$$(\eta_1, \eta_2)(x, y) = f(x, y)\, (N\, \cos\phi + i\, M\, \sin\phi), \tag{1.5}$$

where $f = f(x, y), \phi = \phi(x, y)$ are real-valued functions and $N = N(x, y) = (N_1, N_2)$, $M = M(x, y) = (M_1, M_2)$ are S^1-valued functions. Then (1.4) becomes

$$f_{pot} = -\alpha_0\, f^2 + \beta_1\, f^4 + \beta_2\, f^4\, [\cos^2 2\phi + (M \cdot N)^2 \sin^2 2\phi], \tag{1.6}$$

which can be easily minimized to give the two phases as follows:

(i) *Phase* I. As $\beta_2 > 0, (\eta_1, \eta_2) = f\, \frac{N + i\, M}{\sqrt{2}}\, , N \perp M\, , \phi = \pi/4$.

(ii) *Phase* II. As $\beta_2 < 0, (\eta_1, \eta_2) = f\, e^{i\, \phi}\, N\, , N = M$.

In phase I, we set $M = \pm(-N_2, N_1)$ and $\psi = f\, (N_1 + i\, N_2)$. Then (1.3) becomes

$$F(\psi) = \int_{\mathbb{R}^2} K\, |\nabla\, \psi|^2 - \alpha_0\, |\psi|^2 + \beta_1\, |\psi|^4\, dx\, dy, \tag{1.7}$$

for ψ is a complex-valued function, where K, α_0, and β_1 are positive constants. We may rescale ψ and spatial variables suitably and then transform (1.7) into (up to some constants) the s-wave Ginzburg–Landau free energy (cf. [8]) given by

$$\int_{\mathbb{R}^2} \frac{1}{2}|\nabla\psi|^2 + \frac{1}{4}(1 - |\psi|^2)^2\, .$$

Moreover, we may approximate the s-wave Ginzburg–Landau free energy by

$$\int_{\frac{1}{\epsilon}\Omega} \frac{1}{2}|\nabla\psi|^2 + \frac{1}{4}(1 - |\psi|^2)^2\, ,$$

where $0 < \epsilon \ll 1$ is a small parameter and Ω is a bounded smooth domain in $\mathbb{R}^2$. Then we rescale the spatial variables by ϵ and obtain the energy functional as follows:

$$E_\epsilon(\psi) = \int_\Omega \frac{1}{2}\, |\nabla\, \psi|^2 + \frac{1}{4\, \epsilon^2}\, (1 - |\psi|^2)^2. \tag{1.8}$$

The Euler–Lagrange equation and the gradient flow of (1.8) with the Dirichlet boundary condition have been investigated as the fundamental equations for understanding

s-wave superconductors; see Bethuel, Brezis, and Helein [1], Struwe [26], [27], Lin [14], Lin and Lin [17], Pacard and Riviére [20], and many others.

In phase II, we set $\psi = f\, e^{i\,\phi}$. Then (1.3) becomes

$$F(\psi, N) = \int_{\mathbb{R}^2} K\,(|\nabla\,\psi|^2 + |\psi|^2\,|\nabla N|^2) - \alpha_0\,|\psi|^2 + (\beta_1 + \beta_2)\,|\psi|^4\,dx\,dy, \tag{1.9}$$

for ψ is a complex-valued function and N is an S^1-valued function. Hereafter, we assume that $\beta_1+\beta_2 > 0$ in order to ensure the stability of the phase II superconductivity. As for (1.8), we may, after proper normalization, put (1.9) in the form

$$G_\epsilon(\psi, N) = \int_\Omega \frac{1}{2}\,(|\nabla\,\psi|^2 + |\psi|^2\,|\nabla N|^2) + \frac{1}{4\,\epsilon^2}\,(1 - |\psi|^2)^2\,dx\,dy. \tag{1.10}$$

Note that when ψ is real-valued, (1.10) can be regarded as a model of nematic liquid crystals (cf. [6]). Let $u = |\psi|\,Z \in \mathbb{C}$, where $Z = (N_1 + i\,N_2) \in S^1$ in $\mathbb{C}$ and $N = (N_1, N_2) \in S^1$ in $\mathbb{R}^2$. Then we may rewrite (1.10) as

$$E_\epsilon(\psi, u) = \int_\Omega \frac{1}{2}\,(|\nabla\,\psi|^2 + |\nabla\,u|^2 - |\nabla\,|\psi||^2) + \frac{1}{4\,\epsilon^2}\,(1 - |\psi|^2)^2\,, \tag{1.11}$$

for ψ and u are complex-valued functions satisfying $|\psi| = |u|$.

Vortex configurations and vortex dynamics in superconductivity are physically meaningful problems. One way to create vortices of the energy minimizers and the solutions of gradient flows without external fields is to impose the Dirichlet boundary condition of ψ and u; see also [15] for the Neumann boundary condition. In this paper, we study the asymptotic behavior of the energy minimizer of (1.11) with a given Dirichlet boundary condition as $\epsilon \to 0+$. Using the idea introduced by the first author in studying the dynamics of Ginzburg–Landau vortices (see, e.g., [14]), we also derive the corresponding dynamical law of vortices for p-wave superconductivity with two-component order parameters.

Let $(\psi_\epsilon, u_\epsilon)$ be the energy minimizer of (1.11) for $\psi \in H^1_\eta(\Omega;\mathbb{C})$, $u \in H^1_g(\Omega;\mathbb{C})$, and $|\psi| = |u|$ in Ω. Hereafter, $H^1_\eta(\Omega;\mathbb{C}) = \{v \in H^1(\Omega;\mathbb{C}) : v = \eta \text{ on } \partial\Omega\}$, and $H^1_g(\Omega;\mathbb{C}) = \{w \in H^1(\Omega;\mathbb{C}) : w = g \text{ on } \partial\Omega\}$, where η and g are given smooth maps from $\partial\Omega$ into S^1 with degrees d_1 and d_2, respectively. We shall assume, by simply taking the complex conjugate if it is needed, that $d_1, d_2 \geq 0$. The case in which either d_1 or d_2 vanishes will be seen to be very easy. Essentially, all the statements in this case follow from earlier works (cf. [1], [14]). In the case that both d_1 and d_2 are positive, the general picture will be as follows: ψ_ϵ has d_1 degree-one vortices and u_ϵ has d_2 degree-one vortices in Ω. We shall denote essential zeros (see Proposition 2.2) as degree-one vortices. Moreover, there is an integer $0 \leq N_0 \leq \min(d_1, d_2)$, N_0 distinct points $a_1, \ldots, a_{N_0} \in \Omega$, $d_1 - N_0$ distinct points $b_1, \ldots, b_{d_1-N_0} \in \Omega$, and $d_2 - N_0$ distinct points $c_1, \ldots, c_{d_2-N_0} \in \Omega$ such that the essential zeros of ψ_ϵ converge (as $\epsilon \to 0+$) to $a_1, \ldots, a_{N_0}, b_1, \ldots, b_{d_1-N_0}$, and the essential zeros of u_ϵ converges (as $\epsilon \to 0+$) to $a_1, \ldots, a_{N_0}, c_1, \ldots, c_{d_2-N_0}$. Due to the constraint $|\psi_\epsilon| = |u_\epsilon|$, ψ_ϵ has nonessential (i.e., degree-zero) zeros near $c_1, \ldots, c_{d_2-N_0}$, and u_ϵ has nonessential zeros near $b_1, \ldots, b_{d_1-N_0}$. The number N_0 may depend on the domain Ω and the boundary conditions η and g. The reader may find various situations in which the number N_0 may be zero or may be equal to d_1 or d_2. Some such cases may be found in Remark 3.1. The dynamical law that governs motions of vortices will be a system of ordinary differential equations for those corresponding point vortices $a_1(t), \ldots, a_{N_0}(t), b_1(t), \ldots, b_{d_1-N_0}(t), c_1(t), \ldots, c_{d_2-N_0}(t)$ for time $t > 0$. In our forthcoming paper, we shall address the multicomponent p-wave superconductivity.

2. Basic energy estimates. We start with the following proposition (see [16]).

PROPOSITION 2.1. *Suppose* $v_\epsilon \in H^1_z(\Omega;\mathbb{C}) \equiv \{v \in H^1(\Omega;\mathbb{C}) : v = z \text{ on } \partial\Omega\}$ *such that*

$$E_\epsilon(v_\epsilon) \le \pi\, d \log \frac{1}{\epsilon} + C_0 \qquad \text{as } \epsilon \to 0+, \tag{2.1}$$

where C_0 *is a positive constant independent of* ϵ *and* $z : \partial\Omega \to S^1$ *is a smooth map with degree* $d > 0$. *Here*

$$E_\epsilon(v_\epsilon) = \int_\Omega e_\epsilon(v_\epsilon)\,,$$
$$e_\epsilon(v_\epsilon) = \frac{1}{2}\left[|\nabla v_\epsilon|^2 + \frac{1}{2\,\epsilon^2}\,(1-|v_\epsilon|^2)^2\right].$$

Then there are exactly d *distinct points* $a^\epsilon_j \in \Omega, j = 1,\dots,d$, *of* v_ϵ *such that* $a^\epsilon_j \to a_j \in \Omega$ *(up to a subsequence) as* $\epsilon \to 0+$,

$$\epsilon^{\alpha_j} \int_{\partial B_j} e_\epsilon(v_\epsilon) \le C_1 \qquad \text{and} \qquad \deg\left(\frac{v_\epsilon}{|v_\epsilon|}, \partial B_j\right) = 1, \tag{2.2}$$

where $B_j = B_{\epsilon^{\alpha_j}}(a^\epsilon_j)$ *for* $j = 1,\dots,d$, $0 < \alpha_j < 1$, *and* $C_1 > 0$ *is a universal constant. Furthermore,*

$$\min\{|a_i - a_j|,\, dist(a_i, \partial\Omega) : i, j = 1,\dots,d, i \ne j\} \ge \delta_0(z,\Omega,C_0) > 0,$$

and v_ϵ *converges (up to a subsequence) to a map of the form*

$$\prod_{j=1}^{d} \frac{x - a_j}{|x - a_j|}\, e^{i\,h(x)}$$

strongly in $L^2(\Omega)$ *and weakly in* $H^1_{loc}(\bar\Omega\backslash\{a_1,\dots,a_d\})$ *as* $\epsilon \to 0+$. *Moreover,*

$$\|h\|_{H^1(\Omega)} \le C(C_0, z, \Omega).$$

We shall call these a^ϵ_j's essential zeros of v_ϵ. It is obvious that these essential zeros are well defined (up to a possible error of ϵ to a fixed positive power; see [14]).

To study (1.11), we may decompose it as

$$E_\epsilon(\psi, u) = \tilde E_\epsilon(\psi) + \tilde E_\epsilon(u) + \frac{1}{6}\int_\Omega |\nabla\,|u||^2, \tag{2.3}$$

where

$$\tilde E_\epsilon(u) = \int_\Omega \frac{1}{2}\left(|\nabla u|^2 - \frac{2}{3}\,|\nabla\,|u||^2\right) + \frac{1}{8\,\epsilon^2}\,(1-|u|^2)^2, \tag{2.4}$$

for ψ and u are complex-valued functions with $|\psi| = |u|$.

The following lower bound for $\tilde E_\epsilon$ is crucial as in [1].

PROPOSITION 2.2. *Suppose* v_ϵ *is a minimizer of* $\tilde E_\epsilon$ *over* $H^1_z(\Omega;\mathbb{C}) \equiv \{v \in H^1(\Omega;\mathbb{C}) : v = z \text{ on } \partial\Omega\}$, *where* $z : \partial\Omega \to S^1$ *is a smooth map with degree* $d > 0$. *Then* v_ϵ *has exactly* d *essential zeros* $a^\epsilon_j, j = 1,\dots,d$, *in* Ω; *i.e., there are exactly* d *balls, say,* $B_j = B_{\epsilon^{\alpha_j}}(a^\epsilon_j)$, $\alpha_j \in (0,1), j = 1,\dots,d$, *such that* $\deg(\frac{v_\epsilon}{|v_\epsilon|}, \partial B_j) = 1$

and $\epsilon^{\alpha_j} \int_{\partial B_j} \tilde{e}_\epsilon(v_\epsilon) \le K_j$ *for* $j = 1, \dots, d$, *where* $K_j = K_j(\alpha_j) > 0$ *are constants. Hereafter,* $\tilde{e}_\epsilon$ *is the energy density of* $\tilde{E}_\epsilon$ *defined by*

$$\tilde{e}_\epsilon(u) = \frac{1}{2}\left(|\nabla u|^2 - \frac{2}{3}|\nabla |u||^2\right) + \frac{1}{8\,\epsilon^2}(1-|u|^2)^2\,. \tag{2.5}$$

Moreover,

$$\tilde{E}_\epsilon(v_\epsilon) = \pi\, d\, \log\frac{1}{\epsilon} + O(1) \quad \text{as } \epsilon \to 0+\,, \tag{2.6}$$

where $O(1)$ *is independent of* ϵ.

From (2.3), Proposition 2.2, and Lecture 1 of [14], we have the following corollary.

COROLLARY 2.3. *Let* $\psi_\epsilon \in H^1_\eta(\Omega;\mathbb{C})$ *and* $u_\epsilon \in H^1_g(\Omega;\mathbb{C})$. *Then*

$$E_\epsilon(\psi_\epsilon, u_\epsilon) \le \pi\,(d_1+d_2)\,\log\frac{1}{\epsilon} + O(1) \tag{2.7}$$

if and only if

$$E_\epsilon(\psi_\epsilon) \le \pi\, d_1\, \log\frac{1}{\epsilon} + O(1), \quad E_\epsilon(u_\epsilon) \le \pi\, d_2\, \log\frac{1}{\epsilon} + O(1).$$

By Proposition 2.2, (2.3), and (2.7), it is also easy to check that

$$\int_\Omega |\nabla\,|\psi_\epsilon||^2 = \int_\Omega |\nabla\,|u_\epsilon||^2 \le M_5, \tag{2.8}$$

where M_5 is a positive constant independent of ϵ. Moreover, by (2.7), (2.8), and Lecture 1 of [14], we can write

$$E_\epsilon(\psi_\epsilon) \le \pi\, d_1\, \log\frac{1}{\epsilon} + M_6\,, \quad E_\epsilon(u_\epsilon) \le \pi\, d_2\, \log\frac{1}{\epsilon} + M_6, \tag{2.9}$$

where M_6 is a positive constant independent of ϵ.

The proof of Proposition 2.2 is based on Lemma 2.2 of [16], Theorem 3.1, and the structure theorem of [14]. One may find another proof using techniques of Theorems 2 and 3 in [21]. For the sake of completeness, we give the proof of Proposition 2.2.

Proof of Proposition 2.2. From [13], $\tilde{E}_\epsilon$ has a minimizer v_ϵ over the space $H^1_z(\Omega;\mathbb{C})$. Moreover, v_ϵ is Lipschitz continuous on Ω. Let U_ϵ be the minimizer of E_ϵ (defined in (1.8)) over $H^1_z(\Omega;\mathbb{C})$. Then it is well known (see [1]) that $E_\epsilon(U_\epsilon) \le \pi\, d \log\frac{1}{\epsilon} + M_0$, where M_0 is a positive constant. Hence it is obvious that

$$\tilde{E}_\epsilon(v_\epsilon) \le \tilde{E}_\epsilon(U_\epsilon) \le E_\epsilon(U_\epsilon) \le \pi\, d\, \log\frac{1}{\epsilon} + M_0. \tag{2.10}$$

By the energy comparison, it is easy to show that

$$|v_\epsilon| \le 1 \quad \text{in } \Omega. \tag{2.11}$$

To obtain d essential zeros of v_ϵ, we need the following lemma.

LEMMA 2.4. *Suppose* $|v_\epsilon(a_1)| < \frac{1}{2}$, *where* $a_1 \in \Omega$. *Then there exists* $\alpha_1 \in (0,1)$ *independent of* $\epsilon \le \epsilon_o$ *for some small but fixed positive* ϵ_o *such that* $\deg(\frac{v_\epsilon}{|v_\epsilon|}, \partial B_1) \ne 0$ *and* $\epsilon^{\alpha_1} \int_{\partial B_1} \tilde{e}_\epsilon(v_\epsilon) \le K_1$, *where* $B_1 = B_{\epsilon^{\alpha_1}}(a_1)$ *and* $K_1 = K_1(\alpha_1) > 0$ *is a universal constant.*

Assume Lemma 2.4 for the moment; we continue the proof of Proposition 2.2 as follows. By (2.10), (2.11), Lemma 2.4, and the proof of the structure theorem in [14], v_ϵ has only d essential zeros a_j^ϵ's in Ω, and $\deg(\frac{v_\epsilon}{|v_\epsilon|}, \partial B_j) = 1$ for $j = 1, \dots, d$, where $B_j = B_{\epsilon^{\alpha_j}}(a_j^\epsilon)$ and $\alpha_j \in (0,1)$. Moreover, by the same argument of Lemma 2.2 in [16], we obtain

$$\int_{\Omega \setminus \cup_{j=1}^d B_j} \tilde{e}_\epsilon(v_\epsilon) \geq \pi \sum_{j=1}^d \alpha_j \log \frac{1}{\epsilon} - M_1, \tag{2.12}$$

and hence

$$\int_{B_j} \tilde{e}_\epsilon(v_\epsilon) \leq \pi (1-\alpha_j) \log \frac{1}{\epsilon} + M_1 \quad \text{for } j = 1, \dots, d, \tag{2.13}$$

where M_1 is a positive constant independent of ϵ.

Now we claim that

$$\int_{B_j} \tilde{e}_\epsilon(v_\epsilon) \geq \pi (1-\alpha_j) \log \frac{1}{\epsilon} - K \quad \text{for } j = 1, \dots, d, \tag{2.14}$$

where K is a positive constant independent of ϵ. Without loss of generality, we may assume that $B_j = B_{\theta_0}(0), \theta_0 = \epsilon^{\alpha_j}$. Then (2.13) implies that

$$\int_{B_{\theta_0}(0)} \tilde{e}_\epsilon(v_\epsilon) \leq \pi \log \frac{\theta_0}{\epsilon} + M_1. \tag{2.15}$$

Moreover, we may rescale the spatial variable and rewrite (2.13) as

$$\int_{B_1(0)} \tilde{e}_{\epsilon_1}(v_\epsilon) \leq \pi (1-\alpha_j) \log \frac{1}{\epsilon} + M_1, \tag{2.16}$$

where $\epsilon_1 = \epsilon^{1-\alpha_j}$. By (2.16) and the Fubini theorem (cf. [15]), there exists $\theta_1 \in (\epsilon^{2\alpha_j}, \epsilon^{\alpha_j})$ such that

$$\theta_0 \theta_1 \int_{\partial B_{\theta_0 \theta_1}(0)} \tilde{e}_\epsilon (v_\epsilon) \leq C(\alpha_j, M_1)$$

and that

$$\deg\left(\frac{v_\epsilon}{|v_\epsilon|}, \partial B_{\theta_0 \theta_1}(0)\right) = 1.$$

Hence, by the same argument of Lemma 2.2 in [16], we have

$$\int_{B_{\theta_0}(0) \setminus B_{\theta_0\, \theta_1}(0)} \tilde{e}_\epsilon(v_\epsilon) \geq \pi \log \frac{1}{\theta_1} - M_2 \tag{2.17}$$

and

$$\int_{B_{\theta_0\, \theta_1}(0)} \tilde{e}_\epsilon(v_\epsilon) \leq \pi \log \frac{\theta_0\, \theta_1}{\epsilon} + M_1 + M_2, \tag{2.18}$$

where M_2 is a positive constant satisfying $M_2 \le C_0\,\theta_0$. Here C_0 is a positive constant independent of ϵ. Thus, by induction, we may obtain $\theta_1, \dots, \theta_m \in (\epsilon^{2\alpha_j}, \epsilon^{\alpha_j})$ such that $\epsilon = \theta_0\theta_1\cdots\theta_m$ and

$$\int_{B_{\theta_0\cdots\theta_{k-1}}(0)\setminus B_{\theta_0\cdots\theta_k}(0)} \tilde{e}_\epsilon(v_\epsilon) \ge \pi \log\frac{1}{\theta_k} - M_{k+1} \tag{2.19}$$

and

$$\int_{B_{\theta_0\cdots\theta_k}(0)} \tilde{e}_\epsilon(v_\epsilon) \le \pi \log\frac{\theta_0\cdots\theta_k}{\epsilon} + \sum_{j=1}^{k+1} M_j \tag{2.20}$$

for $k = 1, \dots, m$, where the M_j's are positive constants satisfying $M_{k+1} \le C_0\,\theta_0^k$ for $k \ge 0$. Note that $\sum_{j=1}^{k+1} M_j \le M_1 + C_0 \sum_{j=1}^{\infty} \theta_0^j \le C_1$, where C_1 is a positive constant independent of ϵ and k. Therefore, by (2.19), we may obtain (2.14), and we complete the proof of Proposition 2.2.

2.1. Proof of Lemma 2.4. By the Fubini theorem, there exists a constant $\alpha_1 \in (0,1)$ such that

$$\epsilon^{\alpha_1} \int_{\partial B_1} \tilde{e}_\epsilon\,(v_\epsilon) \le K_1, \tag{2.21}$$

where $K_1 = K_1(\alpha_1) > 0$ is a universal constant and $B_1 = B_{\epsilon^{\alpha_1}}(a_1)$. Then $\deg(\frac{v_\epsilon}{|v_\epsilon|}, \partial B_1)$ is well defined. We claim that $\deg(\frac{v_\epsilon}{|v_\epsilon|}, \partial B_1) \ne 0$. By contradiction, suppose that $\deg(\frac{v_\epsilon}{|v_\epsilon|}, \partial B_1) = 0$. We introduce the notation $\tilde{E}_\epsilon(u; B)$ as follows:

$$\tilde{E}_\epsilon(u; B) = \int_B \tilde{e}_\epsilon\,(u) \tag{2.22}$$

for B a bounded smooth domain in Ω and for $u \in H^1(B; \mathbb{C})$. Let $\tilde{v}_\epsilon(x) = v_\epsilon(\epsilon^{\alpha_1}\,x + a_1)$ for $x \in \tilde{B}_1$, where $\tilde{B}_1$ is the unit disk in $\mathbb{R}^2$ with its center at the origin. Then $\deg(\frac{\tilde{v}_\epsilon}{|\tilde{v}_\epsilon|}, \partial\tilde{B}_1) = 0$, and $\tilde{v}_\epsilon$ is a minimizer of $\tilde{E}_{\tilde{\epsilon}}(v; \tilde{B}_1)$ for $v \in H^1(\tilde{B}_1; \mathbb{C})$ and $v = \tilde{v}_\epsilon$ on $\partial\tilde{B}_1$, where $\tilde{\epsilon} = \epsilon^{1-\alpha_1}$. Hence, by Theorem 1 of [14],

$$\tilde{E}_{\tilde{\epsilon}}(\tilde{v}_\epsilon; \tilde{B}_1) \le M_3, \tag{2.23}$$

where M_3 is a positive constant independent of ϵ. Moreover, by (2.23), we obtain

$$\tilde{v}_\epsilon \to n_h \quad \text{weakly in} \quad H^1(\tilde{B}_1; \mathbb{C}), \tag{2.24}$$

where $n_h \in H^1(\tilde{B}_1; S^1)$ with zero degree and finite energy.

Now we want to prove that

$$|\nabla\tilde{v}_\epsilon(x)| \le \frac{M_4}{\tilde{\epsilon}} \quad \text{for } |x| \le \tilde{\epsilon}, \tag{2.25}$$

where M_4 is a positive constant independent of ϵ. From (2.23), we have

$$\int_{B_{\tilde{\epsilon}}} \tilde{e}_{\tilde{\epsilon}}\,(\tilde{v}_\epsilon) \le M_3, \tag{2.26}$$

where $B_{\tilde\epsilon}$ is a disk in $\mathbb{R}^2$ with radius $\tilde\epsilon$ and center at the origin. Let $\hat v_\epsilon(x) = \tilde v_\epsilon(\tilde\epsilon\, x)$ for $x \in \tilde B_1$. Then (2.26) implies that

$$\int_{\tilde B_1} \tilde e_1\,(\hat v_\epsilon) \,\le\, M_3. \tag{2.27}$$

Moreover, $\hat v_\epsilon$ is a minimizer of $\tilde E_1(w;\tilde B_1)$ for $w \in H^1(\tilde B_1;\mathbb{C})$ and $w = \hat v_\epsilon$ on $\partial\tilde B_1$. Hence, by [13], we obtain

$$|\nabla \hat v_\epsilon(x)| \,\le\, M_4 \quad \text{ for } x \in \tilde B_1, \tag{2.28}$$

where M_4 is a positive constant independent of ϵ. Thus, by (2.28), we have (2.25).

Since $|v_\epsilon(a_1)| \le \frac12$,

$$|\tilde v_\epsilon(0)| \le \frac12\,. \tag{2.29}$$

Hence, by (2.25) and (2.29), we have

$$\int_{\tilde B_1} \frac{1}{\tilde\epsilon^2}\,(1-|\tilde v_\epsilon|^2)^2 \,\ge c_0, \tag{2.30}$$

where c_0 is a positive constant independent of ϵ. By (2.24), (2.30), and Fatou's lemma, we obtain

$$\liminf_{\tilde\epsilon\to 0+} \tilde E_{\tilde\epsilon}(\tilde v_\epsilon;\tilde B_1) \,\ge\, E(n_h) + c_0, \tag{2.31}$$

where $E(n_h) = \int_{\tilde B_1} \frac12\,|\nabla n_h|^2$ and n_h is of unit length. On the other hand, since $\tilde v_\epsilon$ is a minimizer of $\tilde E_{\tilde\epsilon}(v;\tilde B_1)$ among all $v \in H^1(\tilde B_1;\mathbb{C})$ and $v = \tilde v_\epsilon$ on $\partial\tilde B_1$, a simple comparison yields

$$\begin{aligned} \tilde E_{\tilde\epsilon}(\tilde v_\epsilon;\tilde B_1) &\le \tilde E_{\tilde\epsilon}(n_h;\tilde B_1) + o_\epsilon(1) \\ &= E(n_h) + o_\epsilon(1), \end{aligned} \tag{2.32}$$

as $\epsilon \to 0+$, where $o_\epsilon(1)$ is a small quantity which tends to zero as $\epsilon \to 0+$. Therefore, by (2.31) and (2.32), we obtain a contradiction and complete the proof of Lemma 2.4.

3. Minimization of (1.11). In this section, we prove the following result.

THEOREM 3.1. *Assume $(\psi_\epsilon, u_\epsilon)$ is a minimizer of (1.11) for $\psi \in H^1_\eta(\Omega;\mathbb{C})$, $u \in H^1_g(\Omega;\mathbb{C})$, and $|\psi| = |u|$ in Ω. Then there exist an integer $0 \le N_0 \le \min(d_1, d_2)$, N_0 distinct points $a_1, \dots, a_{N_0}$, $d_1 - N_0$ distinct points $b_1, \dots, b_{d_1-N_0}$, and $d_2 - N_0$ distinct points $c_1, \dots, c_{d_2-N_0}$ in Ω such that*

$$\psi_\epsilon \to \Psi_{a,b} \quad \textit{weakly in } H^1_{loc}(\bar\Omega\backslash\{a_1, \dots, a_{N_0}, b_1, \dots, b_{d_1-N_0}\})$$

and

$$u_\epsilon \to U_{a,c} \quad \textit{weakly in } H^1_{loc}(\bar\Omega\backslash\{a_1, \dots, a_{N_0}, c_1, \dots, c_{d_2-N_0}\}),$$

where

$$\Psi_{a,b}(x) = \prod_{j=1}^{N_0} \frac{x-a_j}{|x-a_j|} \prod_{k=1}^{d_1-N_0} \frac{x-b_k}{|x-b_k|}\, e^{i\,h_{a,b}(x)},$$

$$U_{a,c}(x) = \prod_{j=1}^{N_0} \frac{x-a_j}{|x-a_j|} \prod_{k=1}^{d_2-N_0} \frac{x-c_k}{|x-c_k|}\, e^{i\,h_{a,c}(x)},$$

and $h_{a,b}$ and $h_{a,c}$ are harmonic functions on Ω such that the value of $h_{a,b}$ and $h_{a,c}$ on $\partial\Omega$ is uniquely determined (mod·2π) *by the requirements $\Psi_{a,b} = \eta$ and $U_{a,c} = g$ on $\partial\Omega$, respectively. Note that a_j's, b_k's, and c_l's are all distinct. Moreover,*

(3.1)
$$\begin{aligned} E_\epsilon(\psi_\epsilon, u_\epsilon) \quad &= \pi\,(d_1+d_2)\,\log\tfrac{1}{\epsilon} + W_\eta(a_1,\dots,a_{N_0},b_1,\dots,b_{d_1-N_0}) \\ &\quad + W_g(a_1,\dots,a_{N_0},c_1,\dots,c_{d_2-N_0}) + (d_1+d_2)\,\gamma - 2N_0\,\tilde\gamma + o_\epsilon(1), \end{aligned}$$

where W_η and W_g are renormalized energies (cf. [1]*), and γ and $\tilde\gamma$ are two universal constants.*

Proof of Theorem 3.1. To study the energy minimization and the dynamics of vortices, we consider the cone $\mathbb{C}_0 \equiv \{(s,\psi,u) \in \mathbb{R}^{4,1} : |s| = |\psi| = |u|\}$ in the Minkowski-space $\mathbb{R}^{4,1}$. Note that $\mathbb{C}$ is identified with $\mathbb{R}^2$. Here $\mathbb{R}^{4,1} \simeq \mathbb{R}^5$ is endowed with the Minkowski metric $dx_1^2 + \cdots + dx_4^2 - ds^2$ for $(s,x) \in \mathbb{R}^{4,1}$. We shall denote the upper half cone $\{(s,x) \in \mathbb{C}_0 : s \ge 0\}$ by $\mathbb{C}_0^+$. The metric h on $\mathbb{C}_0$ which is induced from the metric of $\mathbb{R}^{4,1}$ is Riemannian. In fact, one may view $\mathbb{C}_0^+$ as a graph over $\mathbb{R}^4$. Then h in the coordinate system $x \in \mathbb{R}^4$ can be expressed as

$$\begin{aligned} h \quad &= h_{i\,j}(x)\,dx^i \otimes dx^j, \\ h_{i\,j}(x) \quad &= \delta_{ij} - \frac{1}{2}\frac{x_i\,x_j}{|x|^2} \qquad \text{for } i,j \in \{1,2\} \text{ or } \{3,4\}, \\ h_{i\,j}(x) \quad &= 0 \qquad\qquad\qquad\quad \text{otherwise.} \end{aligned} \tag{3.2}$$

We introduce the notation $\|\nabla\,(s,\psi,u)\|^2 = |\nabla\,\psi|^2 + |\nabla\,u|^2 - |\nabla\,s|^2$ and $\|(s,\psi,u)\|^2 = |\psi|^2 + |u|^2 - |s|^2$. Then (1.11) is equivalent to

$$\int_\Omega \frac{1}{2}\,\|\nabla\,(s,\psi,u)\|^2 + \frac{1}{4\,\epsilon^2}\,(1-s^2)^2. \tag{3.3}$$

Let $H^1_*(\Omega;\mathbb{C}_0)$ be the set of all maps $(s,\psi,u) : \Omega \to \mathbb{C}_0$ such that $\int_\Omega \|\nabla\,(s,\psi,u)\|^2 < \infty$ and $\psi = \eta, u = g$ on $\partial\Omega$, where $\eta, g : \partial\Omega \to S^1$ are smooth maps with degrees d_1, d_2, respectively. It is then easy to check that $(s,\psi,u) \in H^1_*(\Omega;\mathbb{C}_0)$ if and only if $(s,\psi,u) : \Omega \to \mathbb{C}_0$, $\psi \in H^1_\eta(\Omega;\mathbb{C}), u \in H^1_g(\Omega;\mathbb{C}), |s| = |\psi| = |u|$ in Ω, and $\int_\Omega |\nabla s|^2 + |\nabla\psi|^2 + |\nabla u|^2 < \infty$. That is, $H^1_*(\Omega;\mathbb{C}_0)$ coincides with the usual H^1-maps from Ω to $\mathbb{C}_0$ when we view $\mathbb{C}_0$ as embedded in $\mathbb{R}^5$. Since the energy functional $\int_\Omega \|\nabla\,(s,\psi,u)\|^2$ is a lower semicontinuous functional, by the direct method of calculus of variations, (3.3) has a minimizer over $H^1_*(\Omega;\mathbb{C}_0)$. Therefore, there is a minimizer $(\psi_\epsilon, u_\epsilon)$ of (1.11) such that $\psi_\epsilon \in H^1_\eta(\Omega;\mathbb{C}), u_\epsilon \in H^1_g(\Omega;\mathbb{C})$, and $|\psi_\epsilon| = |u_\epsilon|$ in Ω.

Now we want to show the energy estimate (3.1). To describe more precisely our results, we let Ω be a bounded smooth domain in $\mathbb{R}^2$ and let $\eta : \partial\Omega \to S^1, g : \partial\Omega \to S^1$ be smooth maps of degrees d_1, d_2, respectively. Note that d_1, d_2 are positive integers. From [1] and [14], it is easy to obtain a pair of maps $w_\epsilon \in H^1_\eta(\Omega,\mathbb{C})$ and $\hat w_\epsilon \in H^1_g(\Omega,\mathbb{C})$ such that $|w_\epsilon| = |\hat w_\epsilon|$ in Ω and

$$E_\epsilon(w_\epsilon, \hat w_\epsilon) \le \pi\,(d_1+d_2)\,\log\frac{1}{\epsilon} + K,$$

where K is a positive constant independent of ϵ. Then we have

$$E_\epsilon(\psi_\epsilon, u_\epsilon) \le E_\epsilon(w_\epsilon, \hat w_\epsilon) \le \pi\,(d_1+d_2)\,\log\frac{1}{\epsilon} + K. \tag{3.4}$$

Hence, by (3.4), Corollary 2.3, and Proposition 2.1, there exist a nonnegative integer $0 \le N_0 \le \min(d_1,d_2)$, N_0 distinct points $a_j, j = 1,\dots,N_0$, $d_1 - N_0$ distinct points

$b_k, k = 1, \dots, d_1 - N_0$, and $d_2 - N_0$ distinct points $c_l, l = 1, \dots, d_2 - N_0$, such that $b_k \neq c_l \ \forall k, l$,

$$\psi_\epsilon \to \Psi_{a,b} \quad \text{weakly in } H^1_{loc}(\bar{\Omega}\backslash\{a_1, \dots, a_{N_0}, b_1, \dots, b_{d_1-N_0}\}), \tag{3.5}$$

and

$$u_\epsilon \to U_{a,c} \quad \text{weakly in } H^1_{loc}(\bar{\Omega}\backslash\{a_1, \dots, a_{N_0}, c_1, \dots, c_{d_2-N_0}\}), \tag{3.6}$$

where $\Psi_{a,b}$ and $U_{a,c}$ are defined by

$$\Psi_{a,b}(x) = \prod_{j=1}^{N_0} \frac{x - a_j}{|x - a_j|} \prod_{k=1}^{d_1-N_0} \frac{x - b_k}{|x - b_k|} e^{i\, h_{a,b}(x)} \tag{3.7}$$

and

$$U_{a,c}(x) = \prod_{j=1}^{N_0} \frac{x - a_j}{|x - a_j|} \prod_{k=1}^{d_2-N_0} \frac{x - c_k}{|x - c_k|} e^{i\, h_{a,c}(x)}. \tag{3.8}$$

Here $h_{a,b}$ and $h_{a,c}$ are H^1-functions on Ω such that the value of $h_{a,b}$ and $h_{a,c}$ on $\partial\Omega$ is uniquely determined (mod$\cdot 2\pi$) by the requirements $\Psi_{a,b} = \eta$ and $U_{a,c} = g$ on $\partial\Omega$, respectively. Note that a_j's, b_k's, and c_l's are all distinct. Moreover, ψ_ϵ has d_1 essential zeros, and u_ϵ has d_2 essential zeros. By the Euler–Lagrange equation of $(\psi_\epsilon, u_\epsilon)$ and the same argument of Proposition 3.3 in [26], we obtain that $h_{a,b}$ and $h_{a,c}$ are harmonic functions on Ω.

A simple computation shows that

$$\begin{aligned} &\tfrac{1}{2} \int_{\Omega\backslash[\cup_{j=1}^{N_0} B_\rho(a_j) \cup_{k=1}^{d_1-N_0} B_\rho(b_k)]} |\nabla\, \Psi_{a,b}|^2(x)\, dx \\ &= \pi\, d_1\, \log \frac{1}{\rho} + W_\eta(a_1, \dots, a_{N_0}, b_1, \dots, b_{d_1-N_0}) + O(\rho) \end{aligned} \tag{3.9}$$

and

$$\begin{aligned} &\tfrac{1}{2} \int_{\Omega\backslash[\cup_{j=1}^{N_0} B_\rho(a_j) \cup_{k=1}^{d_2-N_0} B_\rho(c_k)]} |\nabla\, U_{a,c}|^2(x)\, dx \\ &= \pi\, d_2\, \log \frac{1}{\rho} + W_g(a_1, \dots, a_{N_0}, c_1, \dots, c_{d_2-N_0}) + O(\rho)\,, \end{aligned} \tag{3.10}$$

as $\rho \to 0+$, where W_η and W_g are called the renormalized energies associated with the boundary conditions η and g, respectively (cf. [1]). Hereafter, we set $0 < \epsilon \ll \rho \ll 1$.

Next we want to give a more precise upper bound of $E_\epsilon(\psi_\epsilon, u_\epsilon)$, where E_ϵ is defined in (1.11) and $(\psi_\epsilon, u_\epsilon)$ is the associated minimizer. We will construct a pair of comparison maps $\psi^\epsilon_{a,b} \in H^1_\eta(\Omega; \mathbb{C})$, $u^\epsilon_{a,c} \in H^1_g(\Omega; \mathbb{C})$, and $|\psi^\epsilon_{a,b}| = |u^\epsilon_{a,c}|$ in Ω such that

$$\begin{aligned} E_\epsilon(\psi^\epsilon_{a,b}, u^\epsilon_{a,c}) &= \pi\,(d_1 + d_2)\, \log \frac{1}{\epsilon} + W_\eta(a_1, \dots, a_{N_0}, b_1, \dots, b_{d_1-N_0}) \\ &\quad + W_g(a_1, \dots, a_{N_0}, c_1, \dots, c_{d_2-N_0}) + (d_1 + d_2)\,\gamma \\ &\quad - 2N_0\,\tilde{\gamma} + O(\rho) + o_\epsilon(1), \end{aligned} \tag{3.11}$$

where $\gamma, \tilde{\gamma} > 0$ are universal constants, $O(\rho) \to 0$ as $\rho \to 0$, and $o_\epsilon(1)$ is a small quantity which tends to zero as $\epsilon \to 0$. We may choose ρ sufficiently small such that

$B_\rho(a_j)$'s, $B_\rho(b_k)$'s, and $B_\rho(c_l)$'s are disjoint disks in $\mathbb{R}^2$. The map $\psi^\epsilon_{a,b}$ can be chosen so that

$$\psi^\epsilon_{a,b}(x) = \begin{cases} \Psi_{a,b}(x) & \text{for } |x-a_j|, |x-b_k|, |x-c_l| \geq \rho\,, \\ \psi_0(x-a_j) & \text{for } |x-a_j| \leq \rho/2\,, \\ v_0(x-b_k) & \text{for } |x-b_k| \leq \rho/2\,, \\ |v_0(x-c_l)|\,\Psi_{a,b}(x) & \text{for } |x-c_l| \leq \rho/2\,, \\ \omega_{a,b}(x) & \text{elsewhere,} \end{cases} \tag{3.12}$$

and $u^\epsilon_{a,c}$ can be chosen by

$$u^\epsilon_{a,c}(x) = \begin{cases} U_{a,c}(x) & \text{for } |x-a_j|, |x-b_k|, |x-c_l| \geq \rho\,, \\ u_0(x-a_j) & \text{for } |x-a_j| \leq \rho/2\,, \\ |v_0(x-b_k)|\,U_{a,c}(x) & \text{for } |x-b_k| \leq \rho/2\,, \\ v_0(x-c_l) & \text{for } |x-c_l| \leq \rho/2\,, \\ \omega_{a,c}(x) & \text{elsewhere,} \end{cases} \tag{3.13}$$

where v_0 is the minimizer of $\int_{B_{\rho/2}(0)} e_\epsilon(u)$ with the boundary condition $\frac{x}{|x|}$ on $\partial B_{\rho/2}(0)$, $\omega_{a,b}$ and $\omega_{a,c}$ are the canonical harmonic maps with admissible boundary conditions (cf. [1]), and (ψ_0, u_0) is the minimizer of $\int_{B_{\rho/2}(0)} e_\epsilon(\psi,u)$ for $|\psi| = |u|$ in $B_{\rho/2}(0)$ and $\psi = u = \frac{x}{|x|}$ on $\partial B_{\rho/2}(0)$. Hereafter, $e_\epsilon(u) \equiv \frac{1}{2}\,|\nabla\, u|^2 + \frac{1}{4\,\epsilon^2}\,(1-|u|^2)^2$ and $e_\epsilon(\psi,u) \equiv \frac{1}{2}\,(|\nabla\,\psi|^2 + |\nabla\, u|^2 - |\nabla\,|\psi||^2) + \frac{1}{4\,\epsilon^2}\,(1-|\psi|^2)^2$. By Lemma IX.1 in [1],

$$\int_{B_{\rho/2}(0)} e_\epsilon(v_0) = \pi\,\log\,\frac{\rho}{2\,\epsilon} + \gamma + o_\epsilon(1), \tag{3.14}$$

where γ is a positive universal constant defined by

$$\gamma = \lim_{t\to 0+} I(t) + \pi \log t. \tag{3.15}$$

Here $I(t)$ is defined by

$$I(\epsilon, R) = \min_{v\in V} \int_{B_R(0)} e_\epsilon(v), \text{ and } \quad I(t) = I(t,1) \quad \text{for } \epsilon, R, t > 0, \tag{3.16}$$

where

$$V = \left\{ v : v \in H^1(B_R(0))\,, v = \frac{x}{|x|} \text{ on } \partial B_R(0) \right\}.$$

Now we want to prove

$$\int_{B_{\rho/2}(0)} e_\epsilon(\psi_0, u_0) = 2\,\pi\,\log\,\frac{\rho}{2\,\epsilon} + 2(\gamma - \tilde{\gamma}) + o_\epsilon(1), \tag{3.17}$$

where γ and $\tilde{\gamma}$ are positive universal constants. By the energy comparison, Corollary 2.3, and Proposition 2.1, it is easy to obtain

$$\int_{B_{\rho/2}(0)} e_\epsilon(\psi_0, u_0) = 2\,\pi\,\log\,\frac{\rho}{2\,\epsilon} + O(1). \tag{3.18}$$

To get the delicate estimate of $O(1)$ in (3.18), we define

$$J(\epsilon, R) = \min_{(\psi\,,u)\in W} \int_{B_R(0)} e_\epsilon(\psi, u) \quad \text{and} \quad J(t) = J(t,1) \quad \text{for } \epsilon, R, t > 0\,, \tag{3.19}$$

where

$$W = \left\{ (\psi, u) : \psi\,, u \in H^1(B_R(0))\,, |\psi| = |u| \text{ in } B_R(0)\,, \psi = u = \frac{x}{|x|} \text{ on } \partial B_R(0) \right\}.$$

By scaling, it is obvious that

$$J(\epsilon, R) = J(\epsilon/R) = J(1, R/\epsilon)\,. \tag{3.20}$$

As for the proof of Lemma III.1 in [1], we have

$$J(t_1) \le J(t_2) + 2\pi \log(t_2/t_1) \quad \forall t_1 \le t_2; \tag{3.21}$$

i.e., the function $J(t) + 2\pi \log t$ is nondecreasing. Let $\gamma_1 = \lim_{t\to 0+} J(t) + 2\pi \log t$. Then it is easy to check that $\gamma_1 < 2\gamma$, and we may set $\gamma_1 = 2(\gamma - \tilde{\gamma})$, where $\tilde{\gamma}$ is a positive universal constant. Here we have used the fact that

$$\begin{aligned} \int_{B_{\rho/2}(0)} e_\epsilon(\psi_0, u_0) &\le \int_{B_{\rho/2}(0)} e_\epsilon(v_0, v_0) \\ &= 2 \int_{B_{\rho/2}(0)} e_\epsilon(v_0) - \int_{B_{\rho/2}(0)} \frac{1}{2} |\nabla\, |v_0||^2 + \frac{1}{4\,\epsilon^2} \left(1 - |v_0|^2\right)^2 dx \\ &= 2\,\pi\, \log \frac{\rho}{2\,\epsilon} + 2(\gamma - \gamma_2) + o_\epsilon(1), \end{aligned}$$

where

$$\gamma_2 = \lim_{\epsilon \longrightarrow 0} \frac{1}{2} \int_{B_{\rho/2}(0)} \frac{1}{2} |\nabla\, |v_0||^2 + \frac{1}{4\,\epsilon^2} \left(1 - |v_0|^2\right)^2 dx.$$

By Theorem 11.1 of [20], $v_0 = f_\epsilon(r)\, e^{i\,\theta}$ is the radial solution of the Ginzburg–Landau equation, where f_ϵ satisfies an ordinary differential equation. The quantitative properties of f_ϵ can be found in [3], [9], and [10]. Hence γ_2 is a universal positive constant, and we may complete the proof of (3.17).

By (3.12) and (3.13), we have

$$\int_{B_{\rho/2}(a_j)} e_\epsilon(\psi^\epsilon_{a,b}, u^\epsilon_{a,c}) = \int_{B_{\rho/2}(0)} e_\epsilon(\psi_0, u_0), \tag{3.22}$$

$$\int_{B_{\rho/2}(b_k)} e_\epsilon(\psi^\epsilon_{a,b}, u^\epsilon_{a,c}) = \int_{B_{\rho/2}(0)} e_\epsilon(v_0) + \int_{B_{\rho/2}(0)} |v_0|^2\, |\nabla\, U_{a,c}(x + b_k)|^2\,, \tag{3.23}$$

and

$$\int_{B_{\rho/2}(c_l)} e_\epsilon(\psi^\epsilon_{a,b}, u^\epsilon_{a,c}) = \int_{B_{\rho/2}(0)} e_\epsilon(v_0) + \int_{B_{\rho/2}(0)} |v_0|^2\, |\nabla\, \Psi_{a,b}(x + c_l)|^2\,. \tag{3.24}$$

Hence by (3.9), (3.10), (3.14), (3.17), (3.22)–(3.24), and the results of [1], we may obtain (3.11) and

$$\begin{aligned} E_\epsilon(\psi_\epsilon, u_\epsilon) \le{}& \pi\,(d_1+d_2)\,\log\frac{1}{\epsilon} + W_\eta(a_1,\dots,a_{N_0},b_1,\dots,b_{d_1-N_0}) \\ &+ W_g(a_1,\dots,a_{N_0},c_1,\dots,c_{d_2-N_0}) + (d_1+d_2)\,\gamma - 2N_0\,\tilde\gamma + O(\rho) \\ &+ o_\epsilon(1). \end{aligned} \tag{3.25}$$

By (3.5), (3.6), (3.9), (3.10), (3.14), (3.17), and Fatou's lemma, we can derive that

$$\begin{aligned} E_\epsilon(\psi_\epsilon, u_\epsilon) \ge{}& \pi\,(d_1+d_2)\,\log\frac{1}{\epsilon} + W_\eta(a_1,\dots,a_{N_0},b_1,\dots,b_{d_1-N_0}) \\ &+ W_g(a_1,\dots,a_{N_0},c_1,\dots,c_{d_2-N_0}) + (d_1+d_2)\,\gamma - 2N_0\,\tilde\gamma + O(\rho) \\ &+ o_\epsilon(1). \end{aligned} \tag{3.26}$$

Therefore, by (3.25), (3.26), and suitable choice of ρ, we obtain (3.1), and we complete the proof of Theorem 3.1.

Remark 3.1. From (3.1), N_0, a_k's, b_j's, and c_l's are determined by the minimization of

$$W_\eta(a_1,\dots,a_{N_0},b_1,\dots,b_{d_1-N_0}) + W_g(a_1,\dots,a_{N_0},c_1,\dots,c_{d_2-N_0}) + (d_1+d_2)\,\gamma - 2N_0\,\tilde\gamma$$

for $N_0 \ge 0$, and $a_1,\dots,a_{N_0},b_1,\dots,b_{d_1-N_0},c_1,\dots,c_{d_2-N_0}$ are distinct points in Ω. Hence they may depend on η, g, and Ω. Now we divide our discussion of N_0 into two cases as follows.

Case (a). Suppose $\eta = g$ and $d_1 = d_2$. Then it is obvious that $N_0 = d_1 = d_2$ and $(a_1,\dots,a_{N_0})$ is the global minimal point of W_η.

Case (b). Suppose η is quite different from g. Then N_0 may become zero. We may give an example for the case that $N_0 = 0 < \min\{d_1, d_2\}$. Assume $d_1 = d_2 = 1$ and Ω is a smooth dumbbell-shaped domain defined by $\Omega = B_1((-\xi,0)) \cup B_1((\xi,0)) \cup D_{r_0}$, where $\xi \ge 3$ is a constant, $D_{r_0} \subset [-\xi+\frac{1}{2}, \xi+\frac{1}{2}] \times [-r_0, r_0]$ is the neck region joining $B_1((-\xi,0))$ and $B_1((\xi,0))$, and r_0 is a positive constant. Let

$$g(x) = \begin{cases} e^{i\,\arg(x-(-\xi,0))} & \text{for } x \in \partial B_1((-\xi,0))\backslash\partial D_{r_0}\,, \\ e^{i\,\tilde g(x)} & \text{for } x \in \partial[B_1((\xi,0)) \cup D_{r_0}]\backslash\partial B_1((-\xi,0))\,, \end{cases}$$

and

$$\eta(x) = \begin{cases} e^{i\,\arg(x-(\xi,0))} & \text{for } x \in \partial B_1((\xi,0))\backslash\partial D_{r_0}\,, \\ e^{i\,\tilde\eta(x)} & \text{for } x \in \partial[B_1((-\xi,0)) \cup D_{r_0}]\backslash\partial B_1((\xi,0))\,, \end{cases}$$

where both $\tilde g$ and $\tilde\eta$ are smooth and monotone functions such that $\deg(g, \partial\Omega) = \deg(\eta, \partial\Omega) = 1$, respectively. From the definition of the renormalized energy (see [1]), it is easy to check that, as $0 < r_0 \ll 1$,

$$W_g(a) + W_\eta(b) \ll \min_{c\in\Omega} W_g(c) + W_\eta(c),$$

for a is close to $(-\xi, 0)$ and b is close to $(\xi, 0)$. Hence N_0 must be zero.

4. Vortex dynamics in *p*-wave superconductivity. In this section, we consider the dynamics of vortices in the gradient flow of (1.11). There are basically two methods for deriving these dynamical laws. The first one that applies to our problem is somewhat restrictive in the range of parameters for regularization, though it is less restrictive on the initial data. This first method was used by the first author in the heat flow of Ginzburg–Landau vortices (see Lecture 3 in [14] and the references therein). The second method was used by Colliander–Jerrard [4] and by Lin and Xin [18] in the study of dynamics of Ginzburg–Landau–Schrödinger vortices; see also [16]. We shall first sketch a proof of Theorem 4.1 by using the first method and then give a more detailed proof by using the second method.

The gradient flow of (1.11) is given by

(4.1)
$$\begin{cases} \partial_t w = -\text{ grad } \tilde{E}_\epsilon(w), & w(x,t) = (s,\psi,u)(x,t) \in \mathbb{C}_0^+ & \text{for } x \in \Omega, t > 0\,, \\ s = 1\,, \psi = \eta\,, & u = g & \text{for } x \in \partial\Omega\,, t > 0\,, \\ s = |\psi_0|\,, \psi = \psi_0\,, & u = u_0 & \text{for } x \in \Omega\,, t = 0\,, \end{cases}$$

where $\tilde{E}_\epsilon(w) \equiv \int_\Omega \frac{1}{2}\|\nabla w\|^2 + \frac{1}{4\,\epsilon^2}\,(1-s^2)^2$. Note that $\tilde{E}_\epsilon$ is equivalent to (1.11) for w is a $\mathbb{C}_0^+$-valued map. Hereafter, ψ_0 and u_0 are smooth maps from Ω to $\mathbb{C}$, ψ_0 has d_1 essential zeros (degree ± 1 vortices) in Ω, and u_0 has d_2 essential zeros (degree ± 1 vortices) in Ω such that $|\psi_0| = |u_0|$ in Ω, and

$$E_\epsilon(\psi_0, u_0) \le \pi\,(d_1 + d_2)\,\log\frac{1}{\epsilon} + \chi_1, \quad \int_\Omega |\nabla |u_0||^2\,dx \le \chi_1, \tag{4.2}$$

where χ_1 is a positive constant independent of ϵ. It is not obvious that (4.1) has a unique weak solution. The main difficulties are that the target manifold $\mathbb{C}_0^+$ may have positive intrinsic curvature somewhere and the metric h on $\mathbb{C}_0^+$ is singular at the vertex $(0,0)$. To overcome this, we approximate $\mathbb{C}_0^+$ by a family of smooth graphs $\{\mathbb{C}_\delta\}$ over $\mathbb{R}^4$ in $\mathbb{R}^{4,1}$. Due to the smoothness of $\mathbb{C}_\delta$, we obtain the regular solution of the gradient flow (4.1) on the target manifold $\mathbb{C}_\delta$. Such a regular solution can be regarded as an approximated solution of the gradient flow (4.1) on the target manifold $\mathbb{C}_0^+$. Hereafter, $\mathbb{C}_\delta$ is one of the sheets of $s^2 = |\psi|^2 + \frac{1}{2}\,\delta^2 = |u|^2 + \frac{1}{2}\,\delta^2$ which lies in $\{s > 0\}$, where $\delta > 0$ is a small parameter. The induced metric on $\mathbb{C}_\delta$ in $\mathbb{R}^{4,1}$ is given by

$$\begin{aligned} h_\delta &= \text{diag } (h_\delta^1, h_\delta^2), \\ h_\delta^1 &= \left(1 - \frac{1}{2}\,\frac{r^2}{r^2+\delta^2}\right) dr^2 + r^2\,d\theta_1^2, \\ h_\delta^2 &= \left(1 - \frac{1}{2}\,\frac{r^2}{r^2+\delta^2}\right) dr^2 + r^2\,d\theta_2^2, \end{aligned} \tag{4.3}$$

where (r,θ_1) is the polar coordinate of $\psi \in \mathbb{R}^2$ and (r,θ_2) is the polar coordinate of $u \in \mathbb{R}^2$.

In our first approach, we shall set $\delta = \epsilon$ and use $\mathbb{C}_\epsilon$ to approximate $\mathbb{C}_0$. Then we consider the gradient flow (4.1) on the target manifold $\mathbb{C}_\epsilon$ as the approximated gradient flow given by

(4.4)
$$\begin{cases} \partial_t w = -\text{ grad } \tilde{E}_\epsilon(w), & w(x,t) = (s,\psi,u)(x,t) \in \mathbb{C}_\epsilon & \text{for } x \in \Omega, t > 0, \\ s = 1 + \frac{1}{2}\epsilon^2, \psi = \eta\,, & u = g & \text{for } x \in \partial\Omega, t > 0, \\ s = s_0, \psi = \psi_0, & u = u_0 & \text{for } x \in \Omega, t = 0, \end{cases}$$

where $s_0 = (|\psi_0|^2 + \frac{1}{2}\epsilon^2)^{\frac{1}{2}}$. Note that $(s_0, \psi_0, u_0)(x) \in \mathbb{C}_\epsilon$ for $x \in \Omega$. To study the dynamics of vortices in (4.4), we may rescale the time variable by $\lambda_\epsilon = \log(1/\epsilon)$. Then (4.4) becomes

(4.5)
$$\begin{cases} \lambda_\epsilon^{-1}\,\partial_t\, w = -\text{ grad }\tilde{E}_\epsilon(w), & w(x,t) = (s,\psi,u)(x,t) \in \mathbb{C}_\epsilon & \text{for } x \in \Omega, t > 0, \\ s = 1 + \frac{1}{2}\epsilon^2\,, \psi = \eta\,, & u = g & \text{for } x \in \partial\Omega\,, t > 0, \\ s = s_0\,, \psi = \psi_0\,, & u = u_0 & \text{for } x \in \Omega\,, t = 0. \end{cases}$$

From [5], (4.5) has a regular solution w_ϵ with $\|\nabla w_\epsilon(\cdot,t)\|_{L^\infty} \le C/\epsilon$ for almost all $t > 0$, where C is a positive constant.

By (4.5), it is easy to check that

$$\frac{d}{d\,t}\,\tilde{E}_\epsilon(w_\epsilon) = -\left(\log\frac{1}{\epsilon}\right)^{-1}\int_\Omega \|\partial_t\, w_\epsilon\|^2\,dx \tag{4.6}$$

for $t > 0$, where $\|\cdot\|$ is the norm of $\mathbb{R}^{4,1}$ defined in section 3. Then by (4.2), (4.6), and $|\psi_0| = |u_0|$ in Ω, we have

$$\tilde{E}_\epsilon(w_\epsilon)(t) \le \tilde{E}_\epsilon(s_0,\psi_0,u_0) \le \pi\,(d_1+d_2)\,\log\frac{1}{\epsilon} + 2\chi_1 \tag{4.7}$$

for $t > 0$. Hence we have

$$E_\epsilon(\psi_\epsilon, u_\epsilon)(t) \le (d_1+d_2)\,\log\frac{1}{\epsilon} + 3\chi_1 \tag{4.8}$$

for $t > 0$. Note that we have used the fact that

$$\|\nabla\, w_\epsilon\|^2 \ge \|\nabla\,(|u_\epsilon|,\psi_\epsilon,u_\epsilon)\|^2\,,\quad \frac{1}{\epsilon^2}\,(1-s_\epsilon^2)^2 \ge \frac{1}{\epsilon^2}\,(1-|u_\epsilon|^2)^2 - 1, \tag{4.9}$$

where $w_\epsilon = (s_\epsilon, \psi_\epsilon, u_\epsilon), |\psi_\epsilon| = |u_\epsilon|$, and $s_\epsilon = (|u_\epsilon|^2 + \frac{1}{2}\epsilon^2)^{\frac{1}{2}}$. Thus, by (4.8) and Corollary 2.3,

$$E_\epsilon(\psi_\epsilon)(t) \le \pi\,d_1\,\log\frac{1}{\epsilon} + O(1)\,,\quad E_\epsilon(u_\epsilon)(t) \le \pi\,d_2\,\log\frac{1}{\epsilon} + O(1) \tag{4.10}$$

for $t > 0$, where $O(1)$ is a bounded quantity depending only on χ_1. Therefore, by Proposition 2.1 and arguments in Lecture 3 of [14], there exist an integer N_0, $0 \le N_0 \le \min(d_1, d_2)$, N_0 distinct points $a_j(t)$, $j = 1,\dots,N_0$, $d_1 - N_0$ distinct points $b_k(t)$, $k = 1,\dots,d_1 - N_0$, and $d_2 - N_0$ distinct points $c_l(t)$, $l = 1,\dots,d_2 - N_0$, such that, for a subsequence of $\epsilon \to 0$, the essential zeros of ψ_ϵ tend to a_j's and b_k's; the essential zeros of u_ϵ tend to a_j's and c_l's. Moreover, for this subsequence of $\epsilon \to 0$, one has

$$\begin{aligned} &\psi_\epsilon(\cdot,t) \to \Psi_{a,b}(\cdot,t) \quad \text{weakly in } H^1_{loc}(\bar{\Omega}\backslash\{a_1,\dots,a_{N_0},b_1,\dots,b_{d_1-N_0}\}), \\ &u_\epsilon(\cdot,t) \to U_{a,c}(\cdot,t) \quad \text{weakly in } H^1_{loc}(\bar{\Omega}\backslash\{a_1,\dots,a_{N_0},c_1,\dots,c_{d_2-N_0}\}) \end{aligned} \tag{4.11}$$

for $0 \le t \le T$, where $T > 0$ is chosen so that all a_j's, b_k's, and c_l's stay inside Ω and for $0 \le t \le T$, no collision occurs on a_j's, b_k's, and c_l's. Here

$$\Psi_{a,b}(x,t) \equiv \prod_{j=1}^{N_0}\frac{x-a_j(t)}{|x-a_j(t)|}\prod_{k=1}^{d_1-N_0}\frac{x-b_k(t)}{|x-b_k(t)|}\,e^{i\,h_{a,b}(x,t)}$$

and

$$U_{a,c}(x,t) \equiv \prod_{j=1}^{N_0} \frac{x-a_j(t)}{|x-a_j(t)|} \prod_{l=1}^{d_2-N_0} \frac{x-c_l(t)}{|x-c_l(t)|}\, e^{i\, h_{a,c}(x,t)},$$

where $h_{a,b}$ and $h_{a,c}$ are H^1-functions with bounded H^1-norms independent of ϵ and t.

We remark that the existence of a subsequence of $\epsilon \to 0$ so that (4.11) is valid for all $0 \le t \le T$ (not just for one t that will be an easy consequence of Proposition 2.1) is probably the key point in this step. It follows in a manner identical to that in Lecture 3 of [14]. Note, however, that N_0 may depend on t in this stage. Indeed, we let μ_ϵ be a Radon measure defined by

$$\mu_\epsilon(t) = \left(\log\frac{1}{\epsilon}\right)^{-1} \left[\frac{1}{2}\,\|\nabla w_\epsilon\|^2 + \frac{1}{4\,\epsilon^2}\,(1-s_\epsilon^2)^2\right] dx. \tag{4.12}$$

For $\phi \in C_0^1(\mathbb{R}^2)$, we obtain

(4.13)

$$\begin{aligned}
\frac{d}{d\,t}\int_\Omega \phi^2(x)\,\mu_\epsilon(t) &= -\left(\log\frac{1}{\epsilon}\right)^{-2}\int_\Omega \phi^2\,\|\partial_t w_\epsilon\|^2 - \left(\log\frac{1}{\epsilon}\right)^{-1}\int_\Omega 2\phi\,\nabla\phi\,\nabla w_\epsilon\,\cdot\,\partial_t w_\epsilon \\
&\le \int_\Omega \phi^2\cdot\mu_\epsilon(t) + \left(\log\frac{1}{\epsilon}\right)^{-1} C(\phi)\int_\Omega \|\partial_t w_\epsilon\|^2 \\
&\le C(\phi)\,[\|\mu_\epsilon(0)\| + K_\epsilon'(t)],
\end{aligned}$$

where $C(\phi)$ is a positive constant depending on the C^1-norm of ϕ,

$$K_\epsilon(t) = \left(\log\frac{1}{\epsilon}\right)^{-1}\int_0^t\int_\Omega \|\partial_t w_\epsilon\|^2,$$

and $\|\mu_\epsilon(0)\|$ denotes the total measures of $\mu_\epsilon(0)$. Here we have used (4.5), (4.6), and integration by parts. Hence by Lecture 3 of [14] or the argument of [15] (Proof of Theorem 2.1(iii)), we may obtain such a subsequence so that (4.11) is valid and $a_j(t)$'s, $b_k(t)$'s, and $c_l(t)$'s are continuous in t.

For the dynamics of vortices, we have the equations of a_j's, b_k's, and c_l's as follows.

THEOREM 4.1. *Assume a_j's, b_k's, and c_l's are as above. Then they satisfy a system of ordinary differential equations given by*

(4.14)

$$\begin{cases}
-2\,\dot a_j &= \nabla_{a_j} W_\eta(a_1,\dots,a_{N_0},b_1,\dots,b_{d_1-N_0}) + \nabla_{a_j} W_g(a_1,\dots,a_{N_0},c_1,\dots,c_{d_2-N_0}),\\
-\dot b_k &= \nabla_{b_k} W_\eta(a_1,\dots,a_{N_0},b_1,\dots,b_{d_1-N_0}),\\
-\dot c_l &= \nabla_{c_l} W_g(a_1,\dots,a_{N_0},c_1,\dots,c_{d_2-N_0})
\end{cases}$$

for $j = 1,\dots,N_0, k = 1,\dots,d_1-N_0$, and $l = 1,\dots,d_2-N_0$, where W_η and W_g are the renormalized energies (cf. [1]*). Here $\nabla_{a_j}, \nabla_{b_k}$, and ∇_{c_l} are to take the gradient only on a_j, b_k, and c_l, respectively.*

Hereafter, we regard N_0 as a fixed constant with respect to time t, $0 \le t \le T$. Actually, such an assumption is reasonable. For instance, suppose the energy of the initial data (s_0,ψ_0,u_0) satisfies that $\tilde E_\epsilon(s_0,\psi_0,u_0)$ is equal to the right side of (3.1).

Since the energy is dissipative with time t, then it is impossible to decrease N_0 as time t increases. Moreover, we may claim that N_0 may not increase with time t, generically. From (4.14) and the standard theorem of ordinary differential equations, the map from

$$\Gamma(0) \equiv (a_1(0), \dots, a_{N_0}(0), b_1(0), \dots, b_{d_1-N_0}(0), c_1(0), \dots, c_{d_2-N_0}(0)) \in \mathbb{R}^{2(d_1+d_2)}$$

to

$$\Gamma(t) \equiv (a_1(t), \dots, a_{N_0}(t), b_1(t), \dots, b_{d_1-N_0}(t), c_1(t), \dots, c_{d_2-N_0}(t)) \in \mathbb{R}^{2(d_1+d_2)}$$

is a diffeomorphism for $t > 0$. Hence the collision manifold $\Lambda_{j,k}(t) \equiv \{\Gamma(0) : b_j(t) = c_k(t)\}$ has codimension two for $t > 0$. Thus $\cup_{j,k,t>0} \Lambda_{j,k}(t)$ has measure zero in $\mathbb{R}^{2(d_1+d_2)}$. Therefore, the trajectories of b_j's and c_k's may not come together, and N_0 may not increase with time t, generically.

Proof of Theorem 4.1 (sketch).

By (4.2), (4.6), (4.9), and Theorem 3.1, we have

$$\begin{aligned} \left(\log \frac{1}{\epsilon}\right)^{-1} \int_0^T \int_\Omega \|\partial_t w_\epsilon\|^2 &= -\int_0^T \frac{d}{d\,t}\, \tilde{E}_\epsilon(w_\epsilon)\, dt \\ &= \tilde{E}_\epsilon(s_0, \psi_0, u_0) - \tilde{E}_\epsilon(w_\epsilon) \\ &\le C(\eta, g, \chi_1, \Omega). \end{aligned} \tag{4.15}$$

Since a_j's, b_k's, and c_l's are distinct, we may choose a small constant $\delta_* > 0$ such that $B_R(a_j)$'s, $B_R(b_k)$'s, and $B_R(c_l)$'s are disjoint for $R \in [\delta_*/2, \delta_*]$. We multiply (4.5) by ∇w_ϵ and then integrate on $B_R(\beta)$, where β is one of a_j's, b_k's, and c_l's. Using integration by parts, we have

$$\begin{aligned} &\frac{-1}{\log \frac{1}{\epsilon}} \int_{B_R(\beta)} \langle \partial_t w_\epsilon\,, \nabla w_\epsilon \rangle \\ &= \frac{1}{4\,\epsilon^2} \int_{\partial B_R(\beta)} (1 - s_\epsilon^2)^2\, \nu + \frac{1}{2} \int_{\partial B_R(\beta)} \|\nabla w_\epsilon\|^2\, \nu - \int_{\partial B_R(\beta)} \left\langle \frac{\partial w_\epsilon}{\partial \nu}\,, \nabla w_\epsilon \right\rangle, \end{aligned} \tag{4.16}$$

where $\langle \cdot, \cdot \rangle$ is the standard inner product in the hyperbolic space $\mathbb{R}^{4,1}$. On the other hand, we calculate with $e_\epsilon \equiv \frac{1}{2}\, \|\nabla\, w_\epsilon\|^2 + \frac{1}{4\,\epsilon^2}\, (1 - s_\epsilon^2)^2$ that

$$\begin{aligned} &\frac{1}{\log \frac{1}{\epsilon}}\, \frac{d}{d\,t} \int_{B_R(\beta)} x \cdot e_\epsilon(w_\epsilon)\, dx \\ &= -\frac{1}{(\log \frac{1}{\epsilon})^2} \int_{B_R(\beta)} x\, \|\partial_t w_\epsilon\|^2\, dx - \frac{1}{\log \frac{1}{\epsilon}} \int_{B_R(\beta)} \langle \partial_t w_\epsilon\,, \nabla w_\epsilon \rangle\, dx \\ &\quad + \frac{1}{\log \frac{1}{\epsilon}} \int_{\partial B_R(\beta)} x \left\langle \frac{\partial w_\epsilon}{\partial \nu}\,, \partial_t w_\epsilon \right\rangle. \end{aligned} \tag{4.17}$$

For (4.16) and (4.17), we may consider the isometric embedding from $\mathbb{C}_\epsilon$ to $\mathbb{R}^k$, where k is a positive integer, and we transform (4.5) into a standard nonlinear parabolic system. Then using such a nonlinear parabolic system and integration by parts, we may obtain (4.16) and (4.17), respectively.

In order to derive dynamical equations for vortices from (4.17), we have to establish the strong convergence in H^1 of maps away from vortices. For the strong

convergence theorems in section 5 of [15], it is crucial to get Pohozaev's identity for the steady state equation of (4.5) given by

$$-\text{ grad }\tilde{E}_\epsilon(w)=0 \quad \text{ for } x\in\Omega\,, \tag{4.18}$$

with boundary conditions $s=1+\frac{1}{2}\epsilon^2, \psi=\eta, u=g$ on $\partial\Omega$. By the isometric embedding from $\mathbb{C}_\epsilon$ into $\mathbb{R}^k$, where k is a positive integer, we may transform (4.18) into a semilinear elliptic system. Hence it is easy to obtain the associated Pohozaev identity given by

$$\begin{aligned}&\int_{B_r(0)}\frac{1}{4\,\epsilon^2}\,(1-s_\epsilon^2)^2+\frac{r}{2}\int_{\partial B_r(0)}\left\|\frac{\partial w_\epsilon}{\partial\nu}\right\|^2\\&=\frac{r}{4\,\epsilon^2}\int_{\partial B_r(0)}(1-s_\epsilon^2)^2+\frac{r}{2}\int_{\partial B_r(0)}\left\|\frac{\partial w_\epsilon}{\partial\tau}\right\|^2\end{aligned} \tag{4.19}$$

for $0<r<1$, where $\frac{\partial}{\partial\nu}$ and $\frac{\partial}{\partial\tau}$ denote normal and tangential gradients, respectively. Hence by the same argument of Lemma 5.4 in [15], we may have the associated strong convergence theorems for (4.5). Therefore, by (4.15)–(4.17) and the associated strong convergence theorems for (4.5), we follow the argument of Theorem 2.1(iii) in [15], and we may complete the proof of Theorem 4.1.

Next we shall give an alternate approach to the vortex dynamics. We set $\delta=\delta(\epsilon)$ such that $0<\delta\ll\epsilon\ll 1$, and we use $\mathbb{C}_\delta$ to approximate $\mathbb{C}_0$. This is more accurate than using $\mathbb{C}_\epsilon$ to approximate $\mathbb{C}_0$. Then we consider the gradient flow (4.1) on the target manifold $\mathbb{C}_\delta$ as the approximated gradient flow given by

$$\begin{cases}\partial_t\, w=-\text{ grad }\tilde{E}_\epsilon(w), & w(x,t)=(s,\psi,u)(x,t)\in\mathbb{C}_\delta & \text{for } x\in\Omega, t>0\,,\\ s=1+\frac{1}{2}\delta^2\,,\psi=\eta\,, & u=g & \text{for } x\in\partial\Omega\,, t>0\,,\\ s=s_0\,,\psi=\psi_0\,, & u=u_0 & \text{for } x\in\Omega\,, t=0\,,\end{cases} \tag{4.20}$$

where $s_0=(|\psi_0|^2+\frac{1}{2}\delta^2)^{\frac{1}{2}}$. Hereafter, ψ_0 and u_0 are smooth maps from Ω to $\mathbb{C}$, ψ_0 has d_1 essential zeros (vortices) at a_j^0's and b_k^0's in Ω, and u_0 has d_2 essential zeros (vortices) at a_j^0's and c_l^0's in Ω for $j=1,\dots,N_0, k=1,\dots,d_1-N_0, l=1,\dots,d_2-N_0$, such that $|\psi_0|=|u_0|$ in Ω, and

$$\begin{aligned}\tilde{E}_\epsilon(s_0,\psi_0,u_0)=\pi\,(d_1+d_2)\,\log\frac{1}{\epsilon}+W_\eta(a_1^0,\dots,a_{N_0}^0,b_1^0,\dots,b_{d_1-N_0}^0)\\+W_g(a_1^0,\dots,a_{N_0}^0,c_1^0,\dots,c_{d_2-N_0}^0)+(d_1+d_2)\,\gamma-2N_0\,\tilde{\gamma}+o_\epsilon(1),\end{aligned} \tag{4.21}$$

where γ and $\tilde{\gamma}$ are two universal constants defined in Theorem 3.1. Note that $(s_0,\psi_0,u_0)(x)\in\mathbb{C}_\delta$ for $x\in\Omega$. To study the dynamics of vortices in (4.20), we may rescale the time variable by $\lambda_\epsilon=\log(1/\epsilon)$. Then (4.20) becomes

$$\begin{cases}\lambda_\epsilon^{-1}\,\partial_t\, w=-\text{ grad }\tilde{E}_\epsilon(w), & w(x,t)=(s,\psi,u)(x,t)\in\mathbb{C}_\delta & \text{for } x\in\Omega, t>0\,,\\ s=1+\frac{1}{2}\delta^2\,,\psi=\eta\,, & u=g & \text{for } x\in\partial\Omega\,, t>0\,,\\ s=s_0\,,\psi=\psi_0\,, & u=u_0 & \text{for } x\in\Omega\,, t=0\,.\end{cases} \tag{4.22}$$

From [5], (4.22) has a regular solution $w_{\epsilon,\delta}$ satisfying

$$\|\nabla w_{\epsilon,\delta}(\cdot,t)\|_{L^\infty}\le C/\delta. \tag{4.23}$$

Since $0 < \delta = \delta(\epsilon) \ll \epsilon \ll 1$, the inequality (4.23) cannot ensure $\|\nabla w_\epsilon(\cdot,t)\|_{L^\infty} \le C/\epsilon$ for all $t > 0$, where C is a positive constant. Hereafter, we denote $w_{\epsilon,\delta}$ as w_ϵ for notation convenience. Hence the strong convergence theorem may not be true for (4.22), and we cannot follow the argument of Theorem 4.1 to derive the dynamics of vortices. To overcome such a difficulty, we may follow the idea of energy concentration (cf. [15] and [16]) and obtain (4.24). Then we use the energy comparison and the Gronwall inequality (cf. [16, pp. 746–754]) to prove Theorem 4.2. Such an idea can also be found in [4] and [18].

THEOREM 4.2. *Suppose the initial condition* (s_0, ψ_0, u_0) *satisfies* (4.21) *and* $(s_0, \psi_0, u_0)(x) \in \mathbb{C}_\delta$ *for* $x \in \Omega$. *Moreover,* a_j^0*'s and* b_k^0*'s are distinct essential zeros of* ψ_0*, and* a_j^0*'s and* c_l^0*'s are distinct essential zeros of* u_0*, respectively. Let* $w_\epsilon = (s_\epsilon, \psi_\epsilon, u_\epsilon)$ *be the solution of* (4.22). *Then* (4.11) *holds for* ψ_ϵ *and* u_ϵ*, and* (4.14) *is also valid.*

The target manifold of Theorem 4.1 is $\mathbb{C}_\epsilon$, and the target manifold of Theorem 4.2 is $\mathbb{C}_\delta\,, 0 < \delta \ll \epsilon$. This is the main difference between Theorems 4.1 and 4.2. Moreover, the target manifold $\mathbb{C}_\delta$ of Theorem 4.2 is closer to $\mathbb{C}_0$ than the target manifold $\mathbb{C}_\epsilon$ of Theorem 4.1. However, the dynamics of vortices in Theorem 4.1 is same as the dynamics of vortices in Theorem 4.2. Thus it is reasonable to say that (4.14) is the motion equation of vortices in the gradient flow (4.1) on the target manifold $\mathbb{C}_0$.

Proof of Theorem 4.2. As for the proof of Theorem 4.1, we may obtain (4.11) for the solution w_ϵ of (4.22). In addition, $\psi_\epsilon(\cdot,t)$ has distinct essential zeros near $a_j(t)$'s and $b_k(t)$'s, and $u_\epsilon(\cdot,t)$ has distinct essential zeros near $a_j(t)$'s and $c_l(t)$'s for $j = 1,\dots,N_0\,, k = 1,\dots,d_1 - N_0\,, l = 1,\dots,d_2 - N_0$. Furthermore, (4.15)–(4.17) also hold for the solution w_ϵ of (4.22). We want to derive the system of ordinary differential equations for $a_j(t)$'s, $b_k(t)$'s, and $c_l(t)$'s. For notation convenience, we set

$$\begin{aligned}\vec{a} &= (a_1,\dots,a_{N_0},b_1,\dots,b_{d_1-N_0},c_1,\dots,c_{d_2-N_0})\,,\\ W(\vec{a}) &= W_\eta(a_1,\dots,a_{N_0},b_1,\dots,b_{d_1-N_0}) + W_g(a_1,\dots,a_{N_0},c_1,\dots,c_{d_2-N_0}).\end{aligned}$$

Let $a(t)$ be any one component of $\vec{a}(t)$. For any $t_0 \ge 0$, we let $R > 0$ be a suitable constant so that, for t close to t_0, $a(t) \in B_{R/2}(a(t_0))$ by the continuity of $a(t)$ in t. From [15] and [16], we have

$$\int_{B_R(a(t_0))} \frac{1}{\log\frac{1}{\epsilon}}\, x \cdot e_\epsilon(w_\epsilon)\,dx \to \xi(a)\,a(t) \quad \text{as } \epsilon = \epsilon_n \to 0+\,, \tag{4.24}$$

where

$$\xi(a) = \begin{cases} 2 & \text{if} \quad a \in \{a_1,\dots,a_{N_0}\}\,,\\ 1 & \text{if} \quad a \in \{b_1,\dots,b_{d_1-N_0},c_1,\dots,c_{d_2-N_0}\}\,.\end{cases}$$

As for [16, pp. 747], we may use a family of approximation of the identity to convolute both sides of (4.17). Then, by (4.11), (4.15), (4.16), and (4.24), $\dot{a}(t)$ is bounded in t. Moreover, by (2.28) of [16], we may obtain

$$\begin{aligned}\xi(a)^2\,|\dot{a}(t)|^2 &= \left|\frac{1}{\pi\,\log\frac{1}{\epsilon}}\int_{B_R(a(t_0))} \langle \partial_t w_\epsilon\,, \nabla w_\epsilon\rangle\right|^2 + o_\epsilon(1)\\ &\le \frac{1}{\pi\,\log\frac{1}{\epsilon}}\int_{B_R(a(t_0))} \|\partial_t\, w_\epsilon\|^2 + o_\epsilon(1)\,.\end{aligned} \tag{4.25}$$

Hence, by (4.15) and (4.25), we have

(4.26)
$$\int_0^T \sum_{j=1}^{N_0} 2|\dot{a}_j|^2 + \sum_{k=1}^{d_1-N_0} |\dot{b}_k|^2 + \sum_{l=1}^{d_2-N_0} |\dot{c}_l|^2 \;\le \left(\log\frac{1}{\epsilon}\right)^{-1} \int_0^T \int_\Omega \|\partial_t w_\epsilon\|^2 + o_\epsilon(1)$$
$$= \tilde{E}_\epsilon(s_0,\psi_0,u_0) - \tilde{E}_\epsilon(w_\epsilon)(T)$$

for $T > 0$. By (4.11) and [15, pp. 427–437], we may obtain

$$\tilde{E}_\epsilon(w_\epsilon)(T) = \pi\,(d_1+d_2)\,\log\frac{1}{\epsilon} + W(\vec{a}(T)) + (d_1+d_2)\,\gamma - 2N_0\,\tilde{\gamma} + \rho(T) \tag{4.27}$$

for $T > 0$, where $\rho(T)$ comes from the weak convergence in H^1 of $w_\epsilon(\cdot,T)$. Note that $\rho(T) = 0$ if $w_\epsilon(\cdot,T)$ has strong convergence. By (4.21), we have

$$\tilde{E}_\epsilon(w_\epsilon)(0) = \pi\,(d_1+d_2)\,\log\frac{1}{\epsilon} + W(\vec{a}(0)) + (d_1+d_2)\,\gamma - 2N_0\,\tilde{\gamma} + o_\epsilon(1)\,. \tag{4.28}$$

Hereafter, $\vec{a}(0) = (a_1^0,\dots,a_{N_0}^0,b_1^0,\dots,b_{d_1-N_0}^0,c_1^0,\dots,c_{d_2-N_0}^0)$. Thus by (4.26)–(4.28), we obtain

$$\rho(T) \le W(\vec{a}(0)) - W(\vec{a}(T)) - \int_0^T \sum_{j=1}^{N_0} 2|\dot{a}_j|^2 + \sum_{k=1}^{d_1-N_0} |\dot{b}_k|^2 + \sum_{l=1}^{d_2-N_0} |\dot{c}_l|^2\,. \tag{4.29}$$

Since we do not know the strong convergence theorem for w_ϵ, the argument of Theorem 2.1(iii) in [15] can only ensure $\vec{a}(t)$ satisfying

$$M_0\,\frac{d}{d\,t}\,\vec{a}(t) = -\nabla W(\vec{a}(t)) + \zeta(t)\,, \tag{4.30}$$

where ζ is from the defect measure of weak convergence and $M_0 = \text{ diag }(M_0^i | i = 1,\dots,d_1+d_2)$ is a diagonal matrix such that $M_0^i = 2$ if $i = 1,\dots,N_0$ and $M_0^i = 1$ otherwise. By a simple energy comparison (cf. [16]), it is easy to check that

$$|\zeta(T)| \le C\,\rho(T) \quad \text{ for } T > 0\,, \tag{4.31}$$

where C is a positive constant independent of ϵ and T. Now we want to claim $\zeta \equiv 0$ and (4.14) is valid. Let $\vec{b}(t)$ be the solution of

$$M_0\,\frac{d}{d\,t}\,\vec{b}(t) = -\nabla W(\vec{b}(t))\,, \tag{4.32}$$

with initial data $\vec{b}(0) = \vec{a}(0)$. Then it is obvious that

$$W(\vec{a}(0)) = W(\vec{b}(T)) + \int_0^T \frac{d}{d\,t}\vec{b}(t)\cdot\left(M_0\,\frac{d}{d\,t}\vec{b}(t)\right)\,dt\,. \tag{4.33}$$

Hence, by (4.29) and (4.33), we have

$$\rho(T) \le C_0\,|\vec{a}(T) - \vec{b}(T)| + C_1\int_0^T \left|\frac{d}{d\,t}\,(\vec{a}-\vec{b})\right|(t)\,dt \tag{4.34}$$

for $T > 0$. Hereafter we set C_j's as positive constants independent of ϵ and T. From (4.30) and (4.32),

$$\left|\frac{d}{dt}(\vec{a}-\vec{b})\right|(T) \le C_2|\vec{a}-\vec{b}|(T) + |\zeta(T)|\,. \tag{4.35}$$

Thus, by (4.31), (4.34), and (4.35), we obtain

$$\left|\frac{d}{dt}(\vec{a}-\vec{b})\right|(T) \le C_3|\vec{a}-\vec{b}|(T) + C_4\int_0^T \left|\frac{d}{dt}(\vec{a}-\vec{b})\right|(t)\,dt \tag{4.36}$$

for $T > 0$. Therefore, by the Gronwall's inequality, we obtain $\vec{a} \equiv \vec{b}$; i.e., $\zeta \equiv 0$, and we complete the proof of Theorem 4.2.

Final remark. For the approximated gradient flow with the Neumann boundary condition, we may consider

(4.37)
$$\begin{cases} \partial_t w = -\text{ grad }\tilde{E}_\epsilon(w), & w(x,t) = (s,\psi,u)(x,t) \in \mathbb{C}_\delta & \text{for } x \in \Omega, t > 0, \\ \frac{\partial}{\partial \nu}(s,\psi,u)(x,t) = 0 & & \text{for } x \in \partial\Omega\,, t > 0, \\ s = s_0\,, \psi = \psi_0\,, & u = u_0 & \text{for } x \in \Omega\,, t = 0, \end{cases}$$

where $s_0 = (|\psi_0|^2 + \frac{1}{2}\delta^2)^{\frac{1}{2}}$ and $\frac{\partial}{\partial \nu}$ is the normal derivative on $\partial\Omega$. Here $(s_0,\psi_0,u_0)(x) \in \mathbb{C}_\delta$ for $x \in \Omega$ and

$$\begin{aligned}\tilde{E}_\epsilon(s_0,\psi_0,u_0) = \pi\,(d_1+d_2)\,\log\frac{1}{\epsilon} + W_1(a_1^0,\dots,a_{N_0}^0,b_1^0,\dots,b_{d_1-N_0}^0) \\ + W_2(a_1^0,\dots,a_{N_0}^0,c_1^0,\dots,c_{d_2-N_0}^0) + (d_1+d_2)\,\gamma - 2N_0\,\tilde{\gamma} + o_\epsilon(1),\end{aligned} \tag{4.38}$$

where a_j^0's and b_k^0's are distinct essential zeros of ψ_0, and a_j^0's and c_l^0's are distinct essential zeros of u_0, respectively. Hereafter, W_i's are defined by

$$\begin{aligned} &W_1(a_1,\dots,a_{N_0},b_1,\dots,b_{d_1-N_0}) \\ &\quad = \lim_{r\to 0+}\left\{\frac{1}{2}\int_{\Omega\setminus[\cup_{j=1}^{N_0} B_r(a_j)\ \cup_{k=1}^{d_1-N_0}\ B_r(b_k)]} |\nabla\Psi_{a,b}|^2\,dx - \pi\,d_1\,\log\frac{1}{r}\right\}, \\ &W_2(a_1,\dots,a_{N_0},c_1,\dots,c_{d_2-N_0}) \\ &\quad = \lim_{r\to 0+}\left\{\frac{1}{2}\int_{\Omega\setminus[\cup_{j=1}^{N_0} B_r(a_j)\ \cup_{k=1}^{d_2-N_0}\ B_r(c_l)]} |\nabla U_{a,c}|^2\,dx - \pi\,d_2\,\log\frac{1}{r}\right\}, \end{aligned}$$

where

$$\begin{aligned}\Psi_{a,b}(x) &= \prod_{j=1}^{N_0}\frac{x-a_j}{|x-a_j|}\prod_{k=1}^{d_1-N_0}\frac{x-b_k}{|x-b_k|}\,e^{i\,h_{a,b}(x)}\,, \\ U_{a,c}(x) &= \prod_{j=1}^{N_0}\frac{x-a_j}{|x-a_j|}\prod_{k=1}^{d_2-N_0}\frac{x-c_k}{|x-c_k|}\,e^{i\,h_{a,c}(x)}\,,\end{aligned}$$

and $h_{a,b}$ and $h_{a,c}$ are harmonic functions on Ω such that the value of $h_{a,b}$ and $h_{a,c}$ on $\partial\Omega$ is determined by the requirement $\frac{\partial}{\partial\nu}\Psi_{a,b} = \frac{\partial}{\partial\nu}U_{a,c} = 0$ on $\partial\Omega$. Then, by the

argument of Theorem 2.1 in [15] and the proof of Theorem 4.2, we may derive the dynamics of vortices as follows:

$$\begin{cases} -2\,\dot{a}_j &= \nabla_{a_j} W_1(a_1,\dots,a_{N_0},b_1,\dots,b_{d_1-N_0}) + \nabla_{a_j} W_2(a_1,\dots,a_{N_0},c_1,\dots,c_{d_2-N_0}),\\ -\dot{b}_k &= \nabla_{b_k} W_1(a_1,\dots,a_{N_0},b_1,\dots,b_{d_1-N_0}),\\ -\dot{c}_l &= \nabla_{c_l} W_2(a_1,\dots,a_{N_0},c_1,\dots,c_{d_2-N_0}). \end{cases}$$

for $j = 1,\dots,N_0, k = 1,\dots,d_1 - N_0$, and $l = 1,\dots,d_2 - N_0$.

Acknowledgment. The second author wishes to express his sincere thanks to B. Rosenstein for helpful discussions.

STUDY OF THE BUCKLING OF A TAPERED ROD WITH THE GENUS OF A SET*

GRÉGORY VUILLAUME†

Abstract. This paper, which can be considered a continuation of the papers [C. A. Stuart, *J. Math. Pures Appl.*, 80 (2001), pp. 281–337] and [C. A. Stuart, *Proc. Roy. Soc. Edinburgh Sect. A*, 132 (2002), pp. 729–764], is concerned with the study of the buckling of a tapered rod. This physical phenomenon leads to the nonlinear eigenvalue problem

$$\{A(s)u'(s)\}' + \mu \sin u(s) = 0 \quad \text{for all } s \in (0,1),$$
$$u(1) = \lim_{s\to 0} A(s)u'(s) = 0,$$
$$\int_0^1 A(s)u'(s)^2 ds < \infty,$$

where $A(s) \in C([0,1])$ is such that $A(s) > 0$ for all $s > 0$ and $\lim_{s\to 0} A(s)/s^p = L$ for some constants $p \geq 0$ and $L \in (0,\infty)$. We study the set of all solutions of the problem and, in particular, find the points $\mu \in \mathbb{R}_+$ such that bifurcation occurs at $(\mu, 0)$.

As was shown by Stuart in [*J. Math. Pures Appl.*, 80 (2001), pp. 281–337], there is a number $\Lambda(A) \geq 0$ such that, for $\mu \leq \Lambda(A)$, $u \equiv 0$ is the only solution of the problem, and it minimizes the energy in the space of all admissible configurations. For $\mu > \Lambda(A)$, the energy is minimized by a nontrivial solution. For $0 \leq p < 2$, bifurcation occurs at a discrete set of eigenvalues μ_i, $i \in \mathbb{N}^* = \{1, 2, \dots\}$, which satisfy $\mu_1 = \Lambda(A)$, $\mu_i < \mu_{i+1}$ for all $i \in \mathbb{N}^*$ and $\lim_{i\to\infty} \mu_i = \infty$. At $p = 2$, changes occur. For $0 \leq p \leq 2$, $\Lambda(A) > 0$, whereas $\Lambda(A) = 0$ for $p > 2$. For $p = 2$, there is a number $\Lambda_e(A) \in [\Lambda(A), \infty)$ such that bifurcation occurs at every value $\mu \in [\Lambda_e(A), \infty)$. In this paper, we show the following points:

- For $p = 2$, if $\Lambda(A) < \Lambda_e(A)$, bifurcation from the solution $u \equiv 0$ also occurs at a finite or countable set of eigenvalues $\mu_i \in I \subset \mathbb{N}^*$, where $\mu_1 = \Lambda(A)$ and $\mu_i < \Lambda_e(A)$ for all $i \in I$.
- For $2 < p < 3$, bifurcation occurs at every value $\mu \geq 0$.

1. Introduction.

We begin by recalling the definition of the problem we consider in this paper. For this, the following definition is crucial.

DEFINITION 1.1. *A profile for a column with tapering of order $p \geq 0$ is a function $A \in C([0,1])$ such that $A(s) > 0$ for $0 < s \leq 1$, and there exists $L \in (0,\infty)$ such that* $\lim_{s\to 0} \frac{A(s)}{s^p} = L$.

For such a profile there exist constants $K_1 \geq K_2 > 0$ such that

$$K_2 s^p \leq A(s) \leq K_1 s^p \quad \text{for all } s \in [0,1]. \tag{1}$$

We now give the formal statement of the mathematical problem to be considered. We recall that this problem represents one of the simplest models for the planar buckling of a tapered column. For more details, see [8]. Consider a profile A with tapering of order $p \geq 0$ and a constant $\mu \geq 0$.

DEFINITION 1.2. *A solution of problem P is a function* $u \in C^1((0,1])$ *such that* $Au' \in C^1((0,1])$,

$$\{A(s)u'(s)\}' + \mu \sin u(s) = 0 \quad \text{for all } s \in (0,1], \tag{2}$$

$$u(1) = \lim_{s \to 0} A(s)u'(s) = 0, \tag{3}$$

$$\int_0^1 A(s)u'(s)^2 ds < \infty. \tag{4}$$

In fact, for a given profile, we would like to find the parameters μ where bifurcation from the trivial solution $u \equiv 0$ occurs. Clearly problem P is a nonlinear eigenvalue problem of Sturm–Liouville type, but it becomes increasingly singular at $s = 0$ as the order of tapering p gets bigger. For the cases $p \geq 2$, which we deal with here, the singularity is so severe that the problem cannot be treated by standard tools from bifurcation theory such as the Crandall–Rabinowitz theorem. Indeed, for $p > 2$, the problem does not have a rigorous linearization about the trivial solution $u \equiv 0$.

Stuart (see [8], [9]) showed that in several respects (the shape of the buckled configurations, the nature of the bifurcation diagrams) tapering of order 2 plays a critical role, in the sense that the situation when $p < 2$ is very different from what happens when $p \geq 2$. He proved that there is a number $\Lambda(A) \geq 0$ such that, for $\mu \leq \Lambda(A)$, $u \equiv 0$ is the only solution of the problem, and it minimizes the energy in the space of all admissible configurations that will be denoted by H_A. For $\mu > \Lambda(A)$, the energy is minimized by a nontrivial solution. For $0 \leq p < 2$, bifurcation occurs at a discrete set of eigenvalues μ_i, $i \in \mathbb{N}^* = \{1, 2, \dots\}$, which satisfy $\mu_1 = \Lambda(A)$, $\mu_i < \mu_{i+1}$ for all $i \in \mathbb{N}^*$, and $\lim_{i \to \infty} \mu_i = \infty$. At $p = 2$, changes occur. For $0 \leq p \leq 2$, $\Lambda(A) > 0$, whereas $\Lambda(A) = 0$ for $p > 2$. For $p = 2$, there is a number $\Lambda_e(A) \in [\Lambda(A), \infty)$ such that bifurcation occurs at every value $\mu \in [\Lambda_e(A), \infty)$. In this paper, we show the following points:

- For $p = 2$, if $\Lambda(A) < \Lambda_e(A)$, bifurcation from the solution $u \equiv 0$ occurs also at a finite or countable set of eigenvalues $\mu_i \in I \subset \mathbb{N}^*$, where $\mu_1 = \Lambda(A)$ and $\mu_i < \Lambda_e(A)$ for all $i \in I$.
- For $2 < p < 3$, bifurcation occurs at every value $\mu \geq 0$.

Now we introduce the Hilbert space of all admissible configurations.

1.1. The energy space H_A. Consider $p \in [0, \infty)$. If an element $u \in L^1_{loc}((0,1])$ admits a generalized derivative u' on $(0,1)$ such that $\int_0^1 s^p u'(s)^2 ds < \infty$, it follows that $u \in W^{1,1}((\epsilon, 1))$ for all $\epsilon \in (0,1)$ and hence, from Theorem VIII.2 of [1], that (after a modification on a set of measure zero) $u \in C((0,1])$. For $p \geq 0$, let

$$H_p = \left\{ u \in L^1_{loc}((0,1]) : \int_0^1 s^p u'(s)^2 ds < \infty \text{ and } u(1) = 0 \right\}.$$

The next proposition recalls some important properties concerning the space H_p (for the proof; see [8]).

PROPOSITION 1.3.

1. *For* $p \in [0, \infty)$, H_p *with the scalar product*

$$\langle u, v \rangle_p = \int_0^1 s^p u'(s) v'(s) ds$$

is a Hilbert space.

2. *For any bounded sequence* $\{u_n\}$ *in* H_p *there exist a function* $u \in C((0,1])$ *and a subsequence* $\{u_{n_k}\}$ *such that* $u_{n_k} \to u$ *uniformly on* $[\epsilon, 1]$ *for every* $\epsilon \in (0,1)$.
3. $H_p \cap L^\infty(0,1)$ *is dense in* H_p.
4. *If* $u \in H_p$, *then so does* $|u|$, *and* $|u|'(s)^2 = u'(s)^2$ *almost everywhere (a.e.) on* $(0,1)$.

Remark. If A is a profile for a column with tapering of order p, then

$$\langle u, v\rangle_A = \int_0^1 A(s)u'(s)v'(s)ds$$

is a scalar product on $H_A = H_p$ whose norm is equivalent to $\|.\|_p$. Indeed, we have

$$\sqrt{K_2}\|u\|_p \le \|u\|_A \le \sqrt{K_1}\|u\|_p \quad \text{for all } u \in H_A, \tag{5}$$

with the constants given in (1). The Hilbert space $(H_A, \langle .,.\rangle_A)$ will be referred to as the *energy space for the profile A*. If the sequence $\{u_n\}$ converges weakly to u in H_A, then $u_n \to u$ uniformly on $[\epsilon, 1]$ for every $\epsilon \in (0,1)$.

Now we are able to state our first main result.

THEOREM 1.4. *Let A be a profile with tapering of order* $2 < p < 3$ *and consider* $\mu > 0$. *For this value of* μ, *there are infinitely many solutions* $\{u_k\}$ *of problem P with the property that* $|u_k(s)| < \pi$ *for all* $s \in (0,1]$. *Furthermore,* $\|u_k\|_A \to 0$ *as* $k \to 0$ *and the number of zeros of* u_k *tends to infinity as* $k \to \infty$.

A proof of this result is given in section 4, after we give some preliminaries in the rest of this section and in sections 2 and 3.

1.2. The linearized problem. To understand our next main results, we need to introduce the "linearization" of problem P.

DEFINITION 1.5. *A solution of problem PL is a function* $u \in C^1((0,1])$ *such that* $Au' \in C^1((0,1])$,

$$\{A(s)u'(s)\}' + \mu u(s) = 0 \quad \text{for all } s \in (0,1], \tag{6}$$

and (3) *and* (4) *are satisfied. If* $u \neq 0$, *it is called an eigenfunction associated with the eigenvalue* μ.

Now we consider profiles with tapering of order $p \in [0,2]$ and summarize the results obtained by Stuart in [9] concerning problem PL. We first introduce a bounded linear operator $T : H_A \to H_A$ associated with this problem. All proofs of these results can be found in [9].

PROPOSITION 1.6. *Let A be a profile with tapering of order* $p \in [0,2]$. *There is a unique bounded linear operator* $T : H_A \to H_A$ *such that*

$$\langle Tu, v\rangle_A = \int_0^1 u(s)v(s)ds \quad \text{for all } u, v \in H_A. \tag{7}$$

Furthermore T is a positive self-adjoint operator in H_A *and* 0 *is not an eigenvalue of T. For* $p < 2$, $T : H_A \to H_A$ *is also compact.*

The spectrum of T, the discrete spectrum of T, and the essential spectrum of T are the sets defined, respectively, by

$$\begin{aligned}
\sigma(T) &= \{\lambda \in \mathbb{R} : T - \lambda I : H_A \to H_A \text{ is not an isomorphism}\},\\
\sigma_d(T) &= \{\lambda \in \sigma(T) : T - \lambda I : H_A \to H_A \text{ is a Fredholm operator}\},\\
\sigma_e(T) &= \sigma(T) \setminus \sigma_d(T).
\end{aligned}$$

Note that $\sigma_d(T)$ is formed by the isolated eigenvalues of T which have finite multiplicity (see Theorem 1.6 in Chapter IX of [3]). Since T is positive and self-adjoint, we know that $\sigma(T) \subset [0, \infty)$ and

$$\begin{aligned}\|T\| = \max \sigma(T) &= \sup \Big\{ \langle Tu, u\rangle_A : u \in H_A \text{ with } \|u\|_A = 1 \Big\} \\ &= \sup \left\{ \frac{\langle Tu, u\rangle_A}{\langle u, u\rangle_A} : u \in H_A \setminus \{0\} \right\}.\end{aligned}$$

We can express this by defining the Rayleigh quotient,

$$Q_A(u) = \frac{\int_0^1 A(s)u'(s)^2 ds}{\int_0^1 u(s)^2 ds} \tag{8}$$

(we set $Q_A(u) = 0$ if $\int_0^1 u(s)^2 ds = \infty$) and its infimum

$$\Lambda(A) = \inf \big\{ Q_A(u) : u \in H_A \setminus \{0\} \big\}. \tag{9}$$

For $p > 2$, using the functions u_α defined below in (16) with $(1-p)/2 < \alpha < -1/2$, we have that

$$0 < \int_0^1 A(s)u'_\alpha(s)^2 ds < \infty \quad \text{and} \quad \int_0^1 u_\alpha(s)^2 ds = \infty.$$

This implies that

$$\Lambda(A) = 0 \quad \text{if } p > 2. \tag{10}$$

Now if $p \in [0, 2]$, it follows from Lemma 2.1 and (5) that

$$\Lambda(A) \geq \frac{K_2}{4} > 0. \tag{11}$$

In this case, we have

$$\|T\| = \max \sigma(T) = 1/\Lambda(A), \tag{12}$$

and $\Lambda(A)$ is the infimum of the spectrum of problem PL since the eigenfunctions of problem PL are precisely the eigenfunctions of the operator T, as is shown by the next proposition.

PROPOSITION 1.7. *Let A be a profile with tapering of order $p \in [0, 2]$. Then u is an eigenfunction of problem PL if and only if $u \in H_A \setminus \{0\}$ and $u = \mu Tu$. Furthermore, all eigenvalues of T are simple.*

THEOREM 1.8. *Let A be a profile with tapering of order $0 \leq p < 2$. Then*

$$\sigma_d(T) = \big\{ \lambda_i : i \in \mathbb{N}^* \big\} \quad \textit{and} \quad \sigma_e(T) = \{0\},$$

where $\lambda_{i+1} < \lambda_i$, $\lambda_1 = \Lambda(A)^{-1}$, $\lim_{i\to\infty} \lambda_i = 0$, and each λ_i is a simple eigenvalue of T.

The preceding theorem shows that in the case $0 \leq p < 2$ problem PL behaves like a regular Sturm–Liouville problem, in particular $\sigma_e(T) = \{0\}$. For $p = 2$, the situation changes. We always have $\max \sigma_e(T) > 0$, and we may have $\sigma_d(T) = \emptyset$. That is what proves the following results.

THEOREM 1.9. *Let A be a profile with tapering of order $p = 2$. Then $\max \sigma_e(T) = 4/L$, where $L = \lim_{s\to 0} A(s)/s^2$ and $T : H_A \to H_A$ is not compact.*

Note that $\sigma(A) = \{\mu = 1/\lambda : \lambda \in \sigma(T) \setminus \{0\}\}$, so $\Lambda(A) = \inf \sigma(A)$ is the infimum of the spectrum of problem PL. We introduce the following notation for the infimum of the essential spectrum of problem PL:

$$\Lambda_e(A) = \inf \sigma_e(A),$$

where $\sigma_e(A) = \{\mu = 1/\lambda : \lambda \in \sigma_e(T) \setminus \{0\}\}$.

THEOREM 1.10. *Let A be a profile with tapering of order $p = 2$. Then*

$$0 < \frac{K_2}{4} \le \Lambda(A) \le \frac{L}{4} = \Lambda_e(A),$$

where $L = \lim_{s\to 0} A(s)/s^2$ and $K_2 = \inf_{0<s\le 1} A(s)/s^2$.

In particular, $\Lambda(A) = \Lambda_e(A) = L/4$, provided that

$$A(s) \ge Ls^2 \quad \textit{for all } s \in (0, 1].$$

Remark 1.1. To show that $\Lambda(A) < \Lambda_e(A)$ it is sufficient to find one function $u \in H_2$ such that $Q_A(u) < L/4$. As is shown in [9], this can be done, provided that

$$\frac{\pi^2 \max_{s\in I} A(s)}{|I|\{2\delta + |I|\}} < L$$

for some interval $I = [\delta, \gamma] \subset (0, 1]$.

Remark 1.2. In some cases, there may be no eigenfunctions at all. For example, if $A(s) = Ls^2$ for all $s \in [0, 1]$, then T has no eigenvalues and $u \equiv 0$ is the only solution of problem PL.

Remark 1.3. We have been able to prove that for each $N \in \mathbb{N}^*$, there exists a profile $A(s)$ with tapering of order 2 such that $T : H_A \to H_A$ has at least N simple characteristic values $\lambda_1 = \Lambda(A) < \lambda_2 < \cdots < \lambda_N < \Lambda_e(A)$.

We now are able to express our next main results. We make the following assumption:

$$\text{(H)} \qquad \begin{cases} A(s) \text{ is a profile with tapering of order 2 such that} \\ \\ \qquad\qquad \Lambda(A) < \Lambda_e(A). \end{cases}$$

Notation. Under the assumption (H), the operator $T : H_A \to H_A$ defined by (7) has at least one simple eigenvalue $\Lambda(A)^{-1}$. In fact, T has a finite or countable number of simple eigenvalues $\{\mu_i^{-1} : i \in I \subset \mathbb{N}^*\}$ such that $\mu_i^{-1} > \mu_{i+1}^{-1} > \max \sigma_e(T)$ for all $i \in I$ and $\sigma_d(T) \cap (\Lambda_e(A)^{-1}, \Lambda(A)^{-1}] = \{\mu_i^{-1} : i \in I\}$. We have $\mu_1 = \Lambda(A)$ and $\mu_i < \Lambda_e(A)$ for each $i \in I$. For $i \in I$, we note $\varphi_i \in H_A$, the eigenvector associated to μ_i such that $\|\varphi_i\|_A = 1$. We then have $\varphi_i = \mu_i T\varphi_i$ for all $i \in I$.

For each $i \in I$, we note μ_i^+ for $\min\{\mu \in \sigma(A) : \mu > \mu_i\}$. In our context, we have that $\mu_i^+ = \mu_{i+1}$ if T has at least $(i+1)$ eigenvalues above $\max \sigma_e(T)$ and $\mu_i^+ = \Lambda_e(A)$ if T has exactly i eigenvalues above $\max \sigma_e(T)$.

THEOREM 1.11. *Under assumption* (H)*, and with the corresponding notation, choose $i \in I$. Consider $\mu > \mu_i$. For this value μ, problem P has at least i nontrivial solutions $\{u_k\}$, $k = 1, \ldots, i$, with the property that $|u_k(s)| < \pi$ and $u_k'(1) < 0$ for all $s \in (0, 1]$ and for all $k = 1, \ldots, i$.*

Remark. In fact, in the context of Theorem 1.11, we could show that problem P admits at least $2i$ solutions, since if u is a solution, then $-u$ is another solution.

Moreover, we have the following bifurcation result.

THEOREM 1.12. *Under assumption* (H), *and with the corresponding notation, choose* $i \in I$. *Then bifurcation from the trivial solution* $u \equiv 0$ *occurs at* $(\mu_i, 0) \in \mathbb{R} \times H_A$ *in the sense that there exists a sequence* $\{(\mu^n, u_n)\}_{n\geq 1} \in \mathbb{R} \times H_A \setminus \{0\}$ *such that* (μ^n, u_n) *is a solution of problem P for all* $n \geq 1$, $\lim_{n\to\infty} \mu^n = \mu_i$, *and* $\lim_{n\to\infty} \|u_n\|_A = 0$.

To have a better comprehension of the way we prove these results, we now give some explanations of the tools used by Stuart to prove his results in [8]. After that, we will explain the main differences between this work and that of Stuart.

For a profile with tapering of any order $p \geq 0$ and a constant $\mu > 0$, Stuart defined in [8] the following energy functional:

$$J_\mu(u) = \frac{1}{2}\|u\|_A^2 - \mu \int_0^1 \{1 - \cos u(s)\} ds. \tag{13}$$

For $p > 2$, J_μ may not be Fréchet differentiable. However, for all $p \geq 0$ and $u \in H_A$, we have that

$$\frac{d}{dt} J_\mu(u + tv)|_{t=0} = \int_0^1 A(s)u'(s)v'(s)ds - \mu \int_0^1 v(s) \sin u(s) ds$$

for all $v \in H_A \cap L^1(0,1)$. We recall from Proposition 1.3 that $H_A \cap L^\infty(0,1)$ is dense in H_A. Thus J_μ has directional derivatives at u for all directions in a dense subspace of H_A. The solutions of problem P are related to stationary points of J_μ in the following way (a proof of all these facts can be found in [8]).

THEOREM 1.13. *Let* A *be a profile with tapering of order* $p \geq 0$.

(i) *A function* u *is a solution of problem P if and only if* $u \in H_A$ *and*

$$\int_0^1 A(s)u'(s)v'(s)ds = \mu \int_0^1 v(s) \sin u(s) ds$$

for all $v \in H_A \cap L^1(0,1)$.

(ii) *For* $p \in [0,2]$, $J_\mu \in C^1(H_A)$ *and a function* u *is a solution of problem P if and only if* $u \in H_A$ *and* $J'_\mu(u) = 0$. *Moreover, there exists a completely continuous function* $G_A : H_A \to H_A$ *such that*

$$J'_\mu(u)v = \langle u - \mu G_A(u), v\rangle_A \quad \text{for all } u, v \in H_A.$$

If A is a profile with tapering of order $p \in [0,2]$ and if $F : \mathbb{R} \times H_A \to H_A$ is defined by

$$F(\mu, u) = u - \mu G_A(u),$$

we have by Theorem 1.13 that (μ, u) is a solution of problem P if and only if $u \in H_A$ and $F(\mu, u) = 0$.

In the case $0 \leq p < 2$, F is continuously Fréchet differentiable with $DF(\mu, 0) = I - \mu T$, where I denotes the identity mapping in H_A and T is the positive self-adjoint and compact operator on H_A defined by (7). In this case, Theorem 1.8 tells us that $\sigma(T) = \sigma_d(T) \cup \sigma_e(T)$, where $\sigma_e(T) = \{0\}$ and $\sigma_d(T) = \{\mu_i^{-1} : i \in \mathbb{N}^*\}$ with $\mu_{i+1}^{-1} < \mu_i^{-1}$, $\mu_1^{-1} = \Lambda(A)^{-1}$, $\lim_{i\to\infty} \mu_i^{-1} = 0$ and each μ_i^{-1} is a simple eigenvalue of

T. Using standard results like the theorem of Crandall and Rabinowitz concerning bifurcation from simple eigenvalues or the theorem of Rabinowitz concerning global bifurcation (it is possible to use these results since F is Fréchet differentiable), it is proved in [8] that global bifurcation from the trivial solution $u \equiv 0$ occurs at the discrete set of characteristic values $\{\mu_i : i \in \mathbb{N}^*\}$ of T.

For $p = 2$, the situation is different. The function F is not Fréchet differentiable at $(\mu, 0)$ anymore, but only Gâteaux differentiable, and the Gâteaux derivative of F at $(\mu, 0)$ is still of the form $I - \mu T$, but now T is self-adjoint and not compact. Moreover, $\max \sigma_e(T) = \Lambda_e(A)^{-1} > 0$ (see Theorems 1.9 and 1.10). In this case, the results in [8] show that bifurcation occurs at $\mu = \Lambda(A)$ and also at every $\mu \in [\Lambda_e(A), \infty)$. For $p = 2$, the operator T may or may not have eigenvalues depending on the form of the profile A (see Remarks 1.1, 1.2, 1.3 following Theorem 1.10).

Remark. To see that F is not Fréchet differentiable at $(\mu, 0)$ for $p = 2$, we only have to show that G_A is not Fréchet differentiable at $u = 0$. To see this, suppose that G_A is Fréchet differentiable at $u = 0$. Since T is the Gâteaux derivative of G_A at 0, we have that $G'_A(0) = T$. But then T would be compact by Lemma 4.1 of [5, p. 135] and part (ii) of Theorem 1.13, which implies that G_A is compact. But this is a contradiction of Theorem 1.9.

In the present work, we suppose that A is a profile with tapering of order $2 \leq p < 3$. Since F is not Fréchet differentiable for $p = 2$ and is not even defined for $2 < p < 3$, we cannot use standard results like the ones mentioned above for the case $0 \leq p < 2$. However, for a profile A with tapering of order $p = 2$, introducing a modified version of the energy functional $J_\mu : H_A \to \mathbb{R}$, denoted by $j_\mu : H_A \to \mathbb{R}$, Stuart was able to show the following points (see [8] for the proofs):

(1) $j_\mu \in C^1(H_A)$ for all $\mu > 0$.
(2) If $\nabla j_\mu(u) = 0$ for some $\mu > 0$ and $u \in H_A$, then u is a solution of problem P and $|u(s)| < \pi$ for all $s \in (0, 1]$.
(3) j_μ satisfies the hypotheses of Theorem 2.5.

Then, applying Theorem 2.5 to the functional j_μ with $\mu > \Lambda_e(A)$, he obtained, for this value of μ, that there are infinitely many solutions $\{u_k\}$ of problem P and that $\|u_k\|_A \to \infty$ as $k \to \infty$. Then every $\mu \in [\Lambda_e(A), \infty)$ is a bifurcation point (see Theorem 5.8 of [8]).

We first consider profiles with tapering of order $2 < p < 3$. For such a profile, the functional j_μ can also be defined, and we are able to show that j_μ satisfies the hypotheses of Theorem 2.5 for all $\mu > 0$ (recall that in this case we have $\Lambda(A) = 0$). This is done in section 3, after some preliminaries are given in section 2. Section 4 is devoted to proving Theorem 1.4. Section 4 begins with the crucial Lemma 4.1 that will allow us to estimate the quantities $b_k(j_\mu)$ given in Theorem 2.5. For $p = 2$, Stuart obtained such estimates by using properties of the operator T. In our case, T is not defined and the main idea to prove Lemma 4.1 is to transform our profile A with tapering of order $2 < p < 3$ to a profile A_δ with tapering of order 2. Then, using Lemma 4.1, Theorem 1.4 can be proved in a similar way to Theorem 5.8 of [8].

In section 5, the approach is similar (that is, we apply Theorem 2.5 to the functional j_μ), but the situation and the conclusion are rather different. Here we consider a profile with tapering of order 2 satisfying assumption (H) with the corresponding notation. Stuart proved that for every $\mu > \Lambda_e(A)$, there are infinitely many solutions of problem P. Now, if we suppose that $\mu \in (\Lambda(A), \Lambda_e(A))$ and that $\mu_i < \mu$, then j_μ has at least i critical points, for in this case we are not able to prove that $b_k(j_\mu) < 0$ for infinitely many k, as it was the case for $\mu > \Lambda_e(A)$, or for $\mu > 0$ in the case of a

profile A with tapering of order $2 < p < 3$. In this case, we are able to prove only that $b_k(j_\mu) < 0$ for $k = 1, \dots, i$ (see the proof of Theorem 1.11). To prove that bifurcation occurs at μ_i (that is, to prove Theorem 1.12), we need the important Proposition 5.7, which states that $\lim_{\mu \to \mu_i} b_i(j_\mu) = 0$. See section 5.

After proving these results, a natural question arises. In the case of a profile with tapering of order 2 satisfying assumption (H), we have by Theorem 1.12 that bifurcation from the trivial solution occurs at each $(\mu, 0) \in \mathbb{R} \times H_A$, where μ is any characteristic value of T such that $\mu \in (\Lambda(A), \Lambda_e(A))$. Moreover, we know by Theorem 5.8 of [8] that bifurcation occurs at each $\mu \in [\Lambda_e(A), \infty)$. The question is, Do we have all bifurcation points, or is it possible that bifurcation occurs at a point $\mu \in (\Lambda(A), \Lambda_e(A))$ such that μ^{-1} does not belong to $\sigma(T)$ (recall that for $\mu < \Lambda(A)$, there is no nontrivial solution)? In fact, this is not a standard result because our problem, which can be written under the form $u = \mu G_A(u)$, is such that G_A is not Fréchet differentiable in 0. So we cannot conclude that every bifurcation value belongs to the spectrum of T^{-1} using standard results.

At first sight, this conclusion seems rather routine for a nonlinear eigenvalue like problem P. But we point out that we have an example of the following situation. H is a real Hilbert space and $G : H \to H$ is a Lipschitz continuous function such that $G(0) = 0$. Furthermore, G is Gâteaux differentiable at zero and $G'(0) : H \to H$ is a bounded self-adjoint operator. Nonetheless, the equation $u = \mu G(u)$ has bifurcation points $(\mu, 0)$ such that $\mu^{-1} \notin \sigma(G'(0))$. Of course G is not Fréchet differentiable at 0 since it is well known that $\mu^{-1} \in \sigma(G'(0))$ for all bifurcation points $(\mu, 0)$ in that case. Nevertheless, in our case, despite the lack of Fréchet differentiability, and making an additional assumption on the profile A, we have been able to prove that bifurcation cannot occur at a point $\mu \in (\Lambda(A), \Lambda_e(A))$ that is not a characteristic value of T. This is the subject of a forthcoming paper.

2. Preliminaries. In this part, we introduce the tools that we will need to prove our main results.

2.1. Some properties on H_A. We begin by recalling some properties of the Hilbert space H_A obtained by Stuart [8]. By Proposition 1.3, we have that

$$\|u\|_p = \left\{ \int_0^1 s^p u'(s)^2 ds \right\}^{1/2}$$

is a norm on the linear space H_p and we have the following estimation: For $u \in H_p$ and $s \in (0, 1]$,

$$|u(s)| \le \|u\|_p \left\{ \frac{1 - s^{1-p}}{1-p} \right\}^{1/2} \quad \text{if } p \neq 1, \tag{14}$$

whereas

$$|u(s)| \le \|u\|_p \left\{ \ln \frac{1}{s} \right\}^{1/2} \quad \text{if } p = 1. \tag{15}$$

Remark. Setting

$$u_\alpha(s) = s^\alpha (1 - s) \quad \text{for } 0 < s \le 1, \tag{16}$$

we see that $u_\alpha \in H_p \Leftrightarrow \alpha > (1-p)/2$. The following result shows that $H_p \subset L^2(0,1)$ for $0 \le p \le 2$. For $p > 2$ and $\alpha \in ((1-p)/2, -1/2]$, the function u_α defined by (16) belongs to H_p but not to $L^2(0,1)$.

Notation. In this work, the norm on $L^p(0,1)$ for $1 \le p \le \infty$ will be denoted by $\|.\|_{L^p}$ and the usual scalar product on $L^2(0,1)$ will be denoted by $\langle ., . \rangle_{L^2}$.

LEMMA 2.1. *Let $0 \le p \le 2$. Then $H_p \subset L^2(0,1)$ and*

$$\left\{ \int_0^1 u(s)^2 ds \right\}^{1/2} \le 2\|u\|_p \quad \textit{for all } u \in H_p. \tag{17}$$

Now, in particular, consider a profile A with tapering of order $2 < p < 3$. We recall that $\Lambda(A) = 0$. Using estimate (14) and inequality (5), we have that

$$\begin{aligned} \int_0^1 |u(s)| ds &\le \|u\|_p \int_0^1 \left\{ \frac{s^{1-p} - 1}{p-1} \right\}^{1/2} ds \\ &\le \frac{\|u\|_A}{\sqrt{K_2(p-1)}} \int_0^1 s^{(1-p)/2} ds < \infty \quad \text{for all } u \in H_A, \end{aligned}$$

since $s^{(1-p)/2}$ is integrable on $(0,1)$. Thus there exists a constant $C_1 > 0$ such that

$$\|u\|_{L^1} \le C_1 \|u\|_A \quad \text{for all } u \in H_A. \tag{18}$$

This implies that $H_A \subset L^1(0,1)$. In fact, we have a little bit more. That is what the next lemma shows.

LEMMA 2.2. *Let A be a profile with tapering of order $2 < p < 3$. Then there exist a number $\alpha(p) \in (1,2)$ and a constant $C > 0$ such that*

$$\|u\|_{L^{\alpha(p)}} \le C \|u\|_A \quad \textit{for all } u \in H_A.$$

In particular, $H_A \subset L^{\alpha(p)}(0,1)$.

Recall that in the case of profiles with tapering of order $p \le 2$, we have that $H_A \subset L^2(0,1)$.

Proof. For $2 < p < 3$, we use estimates (14) and (5). For all $u \in H_p$ and for all $s \in (0,1]$, we have

$$|u(s)| \le \|u\|_p \left\{ \frac{1 - s^{1-p}}{1-p} \right\}^{1/2} \le \frac{1}{\sqrt{K_2}} \|u\|_A \left\{ \frac{s^{1-p}}{p-1} \right\}^{1/2}.$$

For all $u \in H_A$, for all $\alpha > 1$, and if $(1-p)\frac{\alpha}{2} > -1$, we have

$$\begin{aligned} \int_0^1 |u(s)|^\alpha ds &\le \frac{\|u\|_A^\alpha}{(K_2(p-1))^{\alpha/2}} \int_0^1 s^{(1-p)\alpha/2} ds \\ &= \frac{\|u\|_A^\alpha}{(K_2(p-1))^{\alpha/2}} \cdot \left. \frac{s^{1+(1-p)\frac{\alpha}{2}}}{1 + (1-p)\frac{\alpha}{2}} \right|_0^1 \\ &= \tilde{C} \|u\|_A^\alpha < \infty. \end{aligned}$$

Now $1 + (1-p)\frac{\alpha}{2} > 0 \Longleftrightarrow \alpha < \frac{2}{p-1}$. But since $p < 3$, $\frac{2}{p-1} > 1$ and there exists $\alpha(p) \in (1, \frac{2}{p-1})$. With this $\alpha(p)$ we have

$$\|u\|_{L^{\alpha(p)}} = \left\{ \int_0^1 |u(s)|^{\alpha(p)} ds \right\}^{1/\alpha(p)} \le \tilde{C}^{1/\alpha(p)} \|u\|_A = C \|u\|_A.$$

Note that $p > 2$ implies that $\alpha(p) < \frac{2}{p-1} < 2$. □

Later on, we will need the following lemma, which is not difficult to check.

LEMMA 2.3. *For all $\theta \in \mathbb{R}$ and for all $\alpha \in [1, 2]$, we have*

$$|1 - \cos\theta| \le 2|\theta|^{\alpha},$$
$$|\theta - \sin\theta| \le 2|\theta|^{\alpha}.$$

2.2. Genus of a set. In this part, we recall a result due to Clark [2] concerning the existence of a finite or infinite number of critical points of a C^1-functional on a real Hilbert space $(H, \langle ., . \rangle)$. (See also [4] and [7].) It is based on the notion of the genus of a set. Let $M > 0$ and let

$$\Sigma = \big\{\Omega \subset H : \Omega \text{ is closed and } \Omega = -\Omega\big\},$$
$$\Sigma_M = \big\{\Omega \in \Sigma : \|u\| \le M \text{ for all } u \in \Omega\big\},$$

and define the genus $g : \Sigma \to \mathbb{N} \cup \{0, \infty\}$ as follows:

- $g(\emptyset) = 0$,
- $g(\Omega) = k$ if there is an odd mapping $h \in C(\Omega, \mathbb{R}^k \setminus \{0\})$ and k is the smallest integer with this property, and
- $g(\Omega) = \infty$ if there is no integer k with the above property.

Set

$$G_k = \Big\{\Omega \in \Sigma : g(\Omega) \ge k\Big\}.$$

We recall that if there is an odd homeomorphism from Ω onto the unit sphere on $\mathbb{R}^k$, we have $g(\Omega) = k$. Then we have that $G_k \neq \emptyset$ for all $k \in \mathbb{N}$ when $\dim H = \infty$. We will need the following result.

LEMMA 2.4. *Let $(H, \langle ., . \rangle)$ be a real Hilbert space and let $\Omega \in G_{i+1}$ for some $i \in \mathbb{N}^*$. If $P : H \to H_1$ is a continuous linear projection onto an i-dimensional subspace H_1 of H, then $\Omega \cap (I - P)(H) \neq \emptyset$.*

Proof. See Corollary 44.12 of [10]. □

Now we recall the definition of the condition of Palais and Smale (PS). A functional $f \in C^1(H, \mathbb{R})$ is said to satisfy the condition (PS) on H provided that every sequence $\{w_n\} \subset H$ which has the properties

(i) $\{f(w_n)\}$ is a bounded sequence,

(ii) $\|\nabla f(w_n)\| \to 0$

has a convergent subsequence in H.

We now define the following quantities. For $k \le \dim H$ and for $f \in C^1(H, \mathbb{R})$, let

$$b_k(f) = \inf_{\Omega \in G_k} \sup_{x \in \Omega} f(x). \tag{19}$$

Clearly $-\infty \le b_1(f) \le b_2(f) \le \cdots \le b_k(f) \le \cdots$.

The result of Clark is then the following.

THEOREM 2.5. *Let $f \in C^1(H, \mathbb{R})$ be an even functional with $f(0) = 0$, which is bounded below and satisfies the condition* (PS). *Suppose that* $\dim H = \infty$ *and that $-\infty < b_k(f) < 0$ for some $k \in \mathbb{N}^*$. Setting $K_b = \{w \in H : f(w) = b \text{ and } \nabla f(w) = 0\}$, we have that $K_{b_k(f)}$ is nonempty and compact. Moreover, if $-\infty < b_k(f) = b_{k+1}(f) = \cdots = b_{k+j-1}(f) < 0$, then $g(K_{b_k(f)}) \ge j$.*

In particular, if $-\infty < b_k(f) < 0$ for all $k \in \mathbb{N}^*$, we have that $K_{b_k(f)} \neq \emptyset$ for all $k \in \mathbb{N}^*$ and that f has an infinite number of critical points. Furthermore, $\lim_{k \to \infty} b_k(f) = 0$.

This theorem is due to Clark [2], except for the conclusion that $b_k(f) \to 0$ if $k \to \infty$, which is due to Heinz [4].

As was done by Stuart in [8], we are going to introduce a functional $j_\mu : H_A \to \mathbb{R}$. This functional will satisfy the hypotheses of Theorem 2.5. Applying this theorem to this functional, we obtain critical points which are solutions of problem P and satisfy the additional condition that $|u(s)| < \pi$ for all $s \in (0, 1]$. Stuart introduced this functional in the case of a profile with tapering of order $p = 2$, but it is possible to extend this to the case $2 < p < 3$. We do that in the next part.

3. A useful functional. In this part, we introduce a functional in order to apply Theorem 2.5, as was done by Stuart [8] to show that bifurcation from the solution $u \equiv 0$ occurs at every $\mu \geq \Lambda_e(A)$ in the case of profiles with tapering of order $p = 2$. Our goal is to extend this result to the case of profiles with tapering of order $2 < p < 3$ by showing that every $\mu \geq 0$ is a bifurcation value (recall that we are in the case $\Lambda(A) = 0$; see (10)). All the results of this part, which we prove in the case of profiles with tapering of order $2 < p < 3$, are also true in the case of order $p = 2$. For this order, the reader can find the proofs in [8, Lemmas 5.4 and 5.6 and Corollary 5.5], so we omit them in this case.

Let A be a profile with tapering of order $2 \leq p < 3$. Set

$$h(\theta) = \begin{cases} \sin\theta & \text{for } \theta \in [-\pi, \pi], \\ 0 & \text{for } \theta \notin [-\pi, \pi] \end{cases}$$

and let

$$H(\theta) = \int_0^\theta h(\sigma)d\sigma \quad \text{for all } \theta \in \mathbb{R}.$$

Clearly h is Lipschitz continuous on $\mathbb{R}$ with Lipschitz constant 1, and $H(\theta) = 1 - \cos\theta$ for $\theta \in [-\pi, \pi]$ and $H(\theta) = 2$ for $\theta \notin [-\pi, \pi]$, implying that $H \in C^1(\mathbb{R})$ is even. We define the functionals φ and $j_\mu(u) : H_A \to \mathbb{R}$ by

$$\varphi(u) = \int_0^1 H(u(s))ds \quad \text{and} \quad j_\mu(u) = \frac{1}{2}\|u\|_A^2 - \mu\varphi(u).$$

For u, $v \in H_A$,

$$\left| \int_0^1 v(s)h(u(s))ds \right| \leq \int_0^1 |v(s)|ds \leq C_1\|v\|_A,$$

where C_1 is the constant defined in (18), and so, by the Riesz representation theorem, there is a unique element $D_A(u) \in H_A$ such that

$$\langle D_A(u), v\rangle_A = \int_0^1 v(s)h(u(s))ds$$

for all $v \in H_A$.

LEMMA 3.1. *Let A be a profile with tapering of order $2 \leq p < 3$. The functional $\varphi : H_A \to \mathbb{R}$ has the following properties:*

(i) $0 \leq \varphi(u) = \varphi(-u) \leq 2$ *for all* $u \in H_A$.

(ii) $\varphi \in C^1(H_A)$ *and* $\nabla\varphi = D_A$.

(iii) $\varphi : H_A \to \mathbb{R}$ *is weakly sequentially continuous and* $D_A : H_A \to H_A$ *is completely continuous.*

Proof. (i) The proof of (i) is clear.
(ii) For all $\theta, \eta \in \mathbb{R}$, we have

$$\begin{aligned} H(\theta+\eta) - H(\theta) - h(\theta)\eta &= \int_0^1 \frac{d}{dt} H(\theta + t\eta)dt - h(\theta)\eta \\ &= \int_0^1 \{h(\theta + t\eta) - h(\theta)\}\eta dt. \end{aligned}$$

On one hand, since h is Lipschitz continuous with constant 1, we have

$$|h(\theta + t\eta) - h(\theta)| \le |\theta + t\eta - \theta| \le t|\eta|,$$

which implies

$$|H(\theta+\eta) - H(\theta) - h(\theta)\eta| \le \int_0^1 t\eta^2 dt = \frac{\eta^2}{2} \quad \text{for all } \theta, \eta \in \mathbb{R}.$$

On the other hand, we have

$$|h(\theta + t\eta) - h(\theta)| \le 2,$$

which implies

$$|H(\theta+\eta) - H(\theta) - h(\theta)\eta| \le 2\int_0^1 |\eta| dt = 2|\eta| \quad \text{for all } \theta, \eta \in \mathbb{R}.$$

Combining these two inequalities, we have, for all $\alpha \in [1, 2]$,

$$|H(\theta+\eta) - H(\theta) - h(\theta)\eta| \le 2|\eta|^\alpha \quad \text{for all } \theta, \eta \in \mathbb{R}.$$

Now for all $u, v \in H_A$, and using $\alpha(p)$ given by Lemma 2.2, we have

$$\begin{aligned} &|\varphi(u+v) - \varphi(u) - \langle D_A(u), v\rangle_A| \\ &= \left| \int_0^1 H(u(s) + v(s)) - H(u(s)) - h(u(s))v(s)ds \right| \\ &\le \int_0^1 |H(u(s) + v(s)) - H(u(s)) - h(u(s))v(s)|ds \\ &\le 2\int_0^1 |v(s)|^{\alpha(p)} ds \\ &\le 2C^{\alpha(p)} \|v\|_A^{\alpha(p)}, \end{aligned}$$

where C is the constant given by Lemma 2.2 and then

$$\lim_{\|v\|_A \to 0} \frac{|\varphi(u+v) - \varphi(u) - \langle D_A(u), v\rangle_A|}{\|v\|_A} \le \lim_{\|v\|_A \to 0} 2C^{\alpha(p)} \|v\|_A^{\alpha(p)-1} = 0,$$

showing that φ is Fréchet differentiable at u and $\varphi'(u)v = \langle D_A(u), v\rangle_A$ for all $u, v \in H_A$.

Now we shall show that $D_A : H_A \to H_A$ is completely continuous, which implies that φ' is continuous. Consider a sequence $\{u_n\}$ such that u_n converges weakly to

u in H_A. We must show that $\{D_A(u_n)\}$ converges strongly to $D_A(u)$ in H_A. For $v \in H_A$ and for $\varepsilon \in (0,1)$, we have

$$\begin{aligned}
|\langle D_A(u_n) - D_A(u), v\rangle_A| &= \left| \int_0^1 v(s)\{h(u_n(s)) - h(u(s))\}ds \right| \\
&\le 2\int_0^\varepsilon |v(s)|ds + \int_\varepsilon^1 |v(s)| \cdot |u_n(s) - u(s)|ds \\
&\le 2\|v\|_p \int_0^\varepsilon \left\{ \frac{s^{1-p}-1}{p-1} \right\}^{1/2} ds + \int_\varepsilon^1 |v(s)| \cdot |u_n(s) - u(s)|ds \\
&\le 2\frac{\|v\|_A}{\sqrt{K_2}} S(\varepsilon) + \int_\varepsilon^1 |v(s)| \cdot |u_n(s) - u(s)|ds,
\end{aligned}$$

where we used estimates (14) and (5) and we set

$$S(\varepsilon) = \int_0^\varepsilon \left\{ \frac{s^{1-p}-1}{p-1} \right\}^{1/2} ds.$$

Now since $u_n \to u$ uniformly on $[\varepsilon, 1]$, for $\eta > 0$, there exists $N(\eta) \in \mathbb{N}$ such that $n \ge N(\eta)$ implies $|u_n(s) - u(s)| < \eta$ for all $s \in [\varepsilon, 1]$. Thus, for $n \ge N(\eta)$, $|u_n - u|$ belongs to $L^\beta(0,1)$ for every $\beta \ge 1$. Choose β such that $1/\beta + 1/\alpha(p) = 1$, where $\alpha(p)$ is given by Lemma 2.2. We then have, for $n \ge N(\eta)$,

$$\begin{aligned}
&\int_\varepsilon^1 |v(s)| \cdot |u_n(s) - u(s)|ds \\
&\le \left\{ \int_\varepsilon^1 |v(s)|^{\alpha(p)} ds \right\}^{1/\alpha(p)} \left\{ \int_\varepsilon^1 |u_n(s) - u(s)|^\beta ds \right\}^{1/\beta} \\
&\le C\|v\|_A \cdot \eta,
\end{aligned}$$

where we have used the constant C given by Lemma 2.2. Thus we have

$$\limsup_{n\to\infty} \|D_A(u_n) - D_A(u)\|_A \le \frac{2}{\sqrt{K_2}} S(\varepsilon) \quad \text{for all } \varepsilon \in (0,1).$$

Furthermore, we have

$$0 \le \lim_{\varepsilon\to 0} S(\varepsilon) \le \frac{1}{\sqrt{p-1}} \lim_{\varepsilon\to 0} \int_0^\varepsilon s^{\frac{1-p}{2}} ds = 0$$

since we are in the case $2 < p < 3$. Then $\lim_{\varepsilon\to 0} S(\varepsilon) = 0$ and D_A is completely continuous.

(iii) We only have to prove that φ is weakly sequentially continuous. Consider a sequence $\{u_n\}$ which is weakly convergent to $u \in H_A$. For any $\varepsilon \in (0,1)$, we have

$$\begin{aligned}
|\varphi(u_n) - \varphi(u)| &= \left| \int_0^1 H(u_n(s)) - H(u(s))ds \right| \\
&\le 4\varepsilon + \int_\varepsilon^1 |H(u_n(s)) - H(u(s))|ds.
\end{aligned}$$

Since u_n converges uniformly to u on $[\varepsilon, 1]$, it follows that

$$\limsup_{n\to\infty} |\varphi(u_n) - \varphi(u)| \le 4\varepsilon \quad \text{for all } \varepsilon \in (0,1).$$

Then $\varphi(u_n)$ converges to $\varphi(u)$ and φ is weakly sequentially continuous. □

COROLLARY 3.2. *Let A be a profile with tapering of order $2 \le p < 3$. For all $\mu > 0$, the functional $j_\mu : H_A \to \mathbb{R}$ has the following properties:*

(i) *$j_\mu \in C^1(H_A)$ and $\nabla j_\mu = I - \mu D_A$.*

(ii) *j_μ is bounded below and satisfies the condition* (PS).

Proof. By Lemma 3.1, $j_\mu \in C^1(H_A)$ and $\nabla j_\mu(u) = I - \mu D_A$. Moreover, $j_\mu(u) \ge -2\mu$ for all $u \in H_A$. Consider a sequence $\{w_n\} \subset H_A$ such that

(i) $\{j_\mu(w_n)\}$ is bounded,

(ii) $\|\nabla j_\mu(w_n)\|_A \to 0$ as $n \to \infty$.

Since $j_\mu(u) = \frac{1}{2}\|u\|_A - \mu\varphi(u)$ and $0 \le \varphi(u) \le 2$ for all $u \in H_A$, it follows immediately from (i) that $\{w_n\}$ is a bounded sequence in H_A. Passing to a subsequence we can suppose that $w_n \rightharpoonup w$ weakly in H_A, and hence $\|D_A(w_n) - D_A(w)\|_A \to 0$ by Lemma 3.1(iii). But then

$$w_n = \nabla j_\mu(w_n) + \mu D_A(w_n) \to \mu D_A(w),$$

proving that the condition (PS) is satisfied. □

LEMMA 3.3. *Let A be a profile with tapering of order $2 \le p < 3$, and suppose that $\nabla j_\mu(u) = 0$ for some $\mu > 0$ and $u \in H_A$. Then u is a solution of problem P and $|u(s)| < \pi$ for all $s \in (0, 1]$.*

Proof. Suppose that $u \in H_A$ and $\nabla j_\mu(u) = 0$. Thus we have $u = \mu D_A(u)$, and then $\langle u, v\rangle_A = \mu\langle D_A(u), v\rangle_A$ for all $v \in H_A$. Then

$$\int_0^1 A(s)u'(s)v'(s)ds = \mu \int_0^1 v(s)h(u(s))ds \quad \text{for all } v \in H_A.$$

It follows that $A(s)u'(s)$ admits a generalized derivative on $(0, 1)$ and that

$$\{A(s)u'(s)\}' = -\mu h(u(s)) \quad \text{a.e. on } (0, 1).$$

However, since $u \in H_A$, we know that $u \in C((0, 1])$ and hence $Au' \in C^1((0, 1])$. From the properties of A, this implies that $u \in C^1((0, 1])$. Moreover, $u \in H_A$ implies $u(1) = 0$. Let $v \in C^1([0, 1])$ be such that $v(1) = 0$ and $v(s) = 1$ for all $s \le 1/2$. Clearly $v \in H_A \cap L^1(0, 1)$ and, for any $\varepsilon \in (0, 1/2)$,

$$\begin{aligned} A(\varepsilon)u'(\varepsilon) &= -\int_\varepsilon^1 A(s)u'(s)v'(s)ds - \int_\varepsilon^1 \{A(s)u'(s)\}'v(s)ds \\ &= -\int_0^1 A(s)u'(s)v'(s)ds + \mu\int_\varepsilon^1 v(s)h(u(s))ds \\ &= -\mu\int_0^\varepsilon h(u(s))ds \end{aligned}$$

since $v' \equiv 0$ on $(0, 1/2)$ and $\{A(s)u'(s)\}' = -\mu h(u(s))$ on $(0, 1)$. Then

$$|A(\varepsilon)u'(\varepsilon)| \le \mu\varepsilon \quad \text{for } \varepsilon \in (0, 1/2)$$

and, in particular,

$$\lim_{s\to 0} A(s)u'(s) = 0.$$

We have shown that $u \in C^1((0, 1])$, $Au' \in C^1((0, 1])$, and

$$\{A(s)u'(s)\}' + \mu h(u(s)) = 0 \quad \text{for all } s \in (0, 1] \tag{20}$$

with $\lim_{s\to 0} A(s)u'(s) = 0$ and $u(1) = 0$.

Let us now show that $|u(s)| < \pi$ for all $s \in (0,1]$. Then we will have that $h(u(s)) = \sin u(s)$ for all $s \in (0,1]$ and u will be a solution of problem P.

Suppose that there is a point $s_0 \in (0,1)$ such that $u(s_0) > \pi$ and let (a,b) be a maximal interval on which $u > \pi$. Then $h(u(s)) = 0$ on (a,b) and so there is a constant c such that $A(s)u'(s) = c$ on (a,b). Since $u(1) = 0$ we must have $c < 0$. Indeed, if $c \geq 0$ and since $A(s) \geq 0$ for all $s \in [0,1]$, we would have that u is increasing on (a,b). We would then have $b = 1$ and $u(1) \geq \pi$, which is in contradiction to $u(1) = 0$. But $c < 0$ implies that u is strictly decreasing on (a,b) and hence that $a = 0$.

But then $\lim_{s\to 0} A(s)u'(s) = c \neq 0$, which contradicts an earlier assertion. Hence $u \leq \pi$ on $(0,1]$. Now if there is a point $s \in (0,1)$ such that $u(s) = \pi$, $u'(s) = 0$ and, consequently, $u \equiv \pi$ on $(0,1]$ by the uniqueness of the Cauchy problem for (20). This is in contradiction to $u(1) = 0$, so we can conclude $u(s) < \pi$ on $(0,1]$. Replacing u by $-u$, we see that $|u(s)| < \pi$ for all $s \in (0,1]$. This concludes the proof. □

4. Bifurcation for profiles A with tapering of order $2 < p < 3$. In this section we consider profiles A with tapering of order $2 < p < 3$. We want to prove Theorem 1.4. To do that we use arguments similar to those used by Stuart [8] to show that for a profile with tapering of order $p = 2$, every $\mu \geq \Lambda_e(A)$ is a bifurcation value.

In order to apply Theorem 2.5 to our problem we still need to estimate quantities $b_k(j_\mu)$ for the functional j_μ introduced in section 3, and for this the following result is crucial.

LEMMA 4.1. *Let A be a profile with tapering of order $2 < p < 3$. Given any $k \in \mathbb{N}^*$ and any $\varepsilon > 0$, there is a subspace E of $H_A \cap L^\infty(0,1)$ such that* $\dim E = k$ *and*

$$\int_0^1 A(s)u'(s)^2 ds \leq \varepsilon \int_0^1 u(s)^2 ds$$

for all $u \in E$.

Proof. Let $k \in \mathbb{N}^*$ and $\varepsilon > 0$. First of all, we note that the space $H_2 \subset H_p$ for all $p \geq 2$. Now consider $0 < \delta < 1$ and set

$$A_\delta(s) = \begin{cases} A(s) & \text{if } \delta \leq s \leq 1, \\ \frac{A(\delta)s^2}{\delta^2} & \text{if } 0 \leq s < \delta. \end{cases}$$

It is clear that $A_\delta \in C([0,1])$ and there exists $L_\delta \in (0,\infty)$ such that

$$\lim_{s\to 0} \frac{A_\delta(s)}{s^2} = \frac{A(\delta)}{\delta^2} = L_\delta.$$

Then A_δ is a profile with tapering of order 2. By Proposition 1.6, there exists $T_\delta : H_2 \to H_2$ such that

$$\langle T_\delta u, v\rangle_{A_\delta} = \langle u, v\rangle_{L^2} \quad \text{for all } u, v \in H_2.$$

Furthermore, by Theorems 1.9 and 1.10, we have

$$\max \sigma_e(T_\delta) = \frac{4}{L_\delta} = \frac{1}{\Lambda_e(A_\delta)}.$$

Now, since

$$\lim_{\delta\to 0} L_\delta = \lim_{\delta\to 0} \frac{A(\delta)}{\delta^2} = \lim_{\delta\to 0} \frac{A(\delta)}{\delta^p} \cdot \frac{\delta^p}{\delta^2} = 0,$$

we have $\lim_{\delta\to 0}\max\sigma_e(T_\delta)=+\infty$ and $\lim_{\delta\to 0}\Lambda_e(A_\delta)=0$.

Then there exists $\delta_0>0$ such that $0<\delta<\delta_0$ implies

$$\Lambda_e(A_\delta)<\frac{K_2\varepsilon}{2K_1},$$

where the constants K_1 and K_2 are defined in (1). Choose $0<\delta<\delta_0$. Applying Lemma 5.7 of [8], we know that there is a subspace E of $H_2\cap L^\infty(0,1)$ such that dim $E=k$ and

$$\begin{aligned}\int_0^1 A_\delta(s)u'(s)^2ds &\le \Big\{\Lambda_e(A_\delta)+\frac{K_2\varepsilon}{2K_1}\Big\}\int_0^1 u(s)^2ds\\ &\le \Big\{\frac{K_2\varepsilon}{2K_1}+\frac{K_2\varepsilon}{2K_1}\Big\}\int_0^1 u(s)^2ds=\frac{K_2}{K_1}\varepsilon\int_0^1 u(s)^2ds\end{aligned}$$

for all $u\in E\subset H_2\cap L^\infty(0,1)$. Now since $H_2\subset H_p$, we have that $E\subset H_p\cap L^\infty(0,1)$. Then we only need to verify that

$$\int_0^1 A(s)u'(s)^2ds\le\varepsilon\int_0^1 u(s)^2ds\quad\text{for all } u\in E.$$

On one hand, for $0\le s<\delta$, we have

$$\begin{aligned}&A(s)\le K_1s^p\\ &=K_1\Big(\frac{s}{\delta}\Big)^{p-2}\cdot\frac{s^2}{\delta^2}\delta^p\le K_1\frac{s^2}{\delta^2}\delta^p\\ &\le\frac{K_1A(\delta)s^2}{K_2\delta^2}=\frac{K_1}{K_2}A_\delta(s).\end{aligned}$$

On the other hand, for $\delta\le s\le 1$, since $K_1/K_2\ge 1$ we have

$$A(s)=A_\delta(s)\le\frac{K_1}{K_2}A_\delta(s).$$

Finally we have shown that

$$A(s)\le\frac{K_1}{K_2}A_\delta(s)\quad\text{for all } s\in[0,1].$$

Then, for all $u\in E$, we have

$$\begin{aligned}&\int_0^1 A(s)u'(s)^2ds\le\frac{K_1}{K_2}\int_0^1 A_\delta(s)u'(s)^2ds\\ &\le\frac{K_1}{K_2}\cdot\frac{K_2}{K_1}\varepsilon\int_0^1 u(s)^2ds\\ &=\varepsilon\int_0^1 u(s)^2ds.\qquad\square\end{aligned}$$

LEMMA 4.2. *Let A be a profile with tapering of order $2<p<3$ and consider $\xi>0$. Let $v\in C^1((0,1])$ such that $Av'\in C^1((0,1])$. Suppose that v is any nontrivial solution of the linearized equation*

$$\big\{A(s)v'(s)\big\}'+\xi v(s)=0\quad\text{on } (0,1).\tag{21}$$

For any $n \in \mathbb{N}$, there exists $\delta > 0$ such that v has at least $n+1$ zeros in the interval $(\delta, 1]$.

Proof. Choose $\varepsilon > 0$ such that $\xi/\varepsilon > 1/4$. Since there exists $L \in (0, \infty)$ such that $\lim_{s\to 0} A(s)/s^p = L$, we have

$$\lim_{s\to 0} \frac{A(s)}{s^2} = \lim_{s\to 0} \frac{A(s)}{s^p} \cdot \frac{s^p}{s^2} = 0.$$

Then there exists $\eta > 0$ such that $s \in (0, \eta)$ implies $|A(s)/s^2| < \varepsilon$, that is, $A(s) < \varepsilon s^2$. Consider $w \neq 0$ a solution of the equation

$$\{\varepsilon s^2 w'(s)\}' + \xi w(s) = 0 \quad \text{on } (0,1).$$

Since $\xi/\varepsilon > 1/4$, as was shown by Stuart (see the proof of Corollary 5.2 of [9]), w has a sequence of zeros converging to 0. Now, by the Sturm comparison theorem (see Theorem 3.1 in Chapter II of [6]), every solution of (21) has at least one zero between successive zeros of w in $(0, \eta)$. Then there exists $0 < \delta < \eta$ such that v has at least $n+1$ zeros on (δ, η) and hence on $(\delta, 1]$. □

We now are able to prove Theorem 1.4.

Proof of Theorem 1.4. Consider $\mu > 0$. We apply Theorem 2.5 to the functional $j_\mu : H_A \to \mathbb{R}$. By Corollary 3.2 and Lemma 3.3, it is sufficient to show that $b_k(j_\mu) < 0$ for each $k \in \mathbb{N}^*$. To do that, consider $k \in \mathbb{N}^*$ and $\varepsilon > 0$ such that $\varepsilon < \mu$. Let E be the subspace given by Lemma 4.1 and, for $t > 0$, consider

$$\Omega_t = \Big\{ u \in E : \|u\|_{L^\infty} = t \Big\}.$$

Then the genus of Ω_t is equal to $k = \dim E$, and since $\|.\|_{L^\infty}$ and $\|.\|_A$ are equivalent on E, there exists $C > 0$ such that $\|u\|_A \geq Ct$ for all $u \in \Omega_t$. Fix $\delta \in (0, 1 - \varepsilon/\mu)$ and fix $t \in (0, \pi)$ such that

$$1 - \cos\theta \geq \frac{1-\delta}{2}\theta^2 \quad \text{for all } |\theta| \leq t.$$

Using this and Lemma 4.1, we have that for $u \in \Omega_t$,

$$\begin{aligned} j_\mu(u) &= \frac{1}{2}\|u\|_A^2 - \mu \int_0^1 \{1 - \cos u(s)\} ds \\ &\leq \frac{1}{2}\left\{ \|u\|_A^2 - \mu(1-\delta) \int_0^1 u(s)^2 ds \right\} \\ &\leq \frac{1}{2}\|u\|_A^2 \left\{ 1 - \mu(1-\delta)\frac{1}{\varepsilon} \right\} \\ &\leq \frac{(Ct)^2}{2}\left\{ 1 - \frac{(1-\delta)\mu}{\varepsilon} \right\} < 0 \end{aligned}$$

and thus

$$0 > \sup_{u\in\Omega_t} j_\mu(u) \geq \inf_{\Omega\in G_k} \sup_{u\in\Omega} j_\mu(u) = b_k(j_\mu).$$

The existence of a sequence $\{u_k\}$ of solutions of problem P with $j_\mu(u_k) = b_k(j_\mu)$ now follows from Theorem 2.5 and Lemma 3.3. Furthermore, since $\lim_{k\to\infty} b_k(j_\mu) = 0$,

we have $j_\mu(u_k) \to 0$ and $\nabla j_\mu(u_k) = 0$, so the condition (PS) implies that $\{u_k\}$ has a subsequence $\{u_{k_i}\}$ which converges to an element u in H_A. Then $j_\mu(u) = 0$, $\nabla j_\mu(u) = 0$, and $|u(s)| \le \pi$ for all $s \in (0,1]$ since $\{u_{k_i}\}$ converges to u uniformly on compact subsets of $(0,1]$. By Lemma 3.3 we can conclude that $|u(s)| < \pi$ for all $s \in (0,1]$. However,

$$\begin{aligned} 0 &= 2j_\mu(u) - \langle \nabla j_\mu(u), u\rangle_A \\ &= \|u\|_A^2 - \mu \int_0^1 \{2 - 2\cos u(s)\} ds - \{\langle u - \mu D_A(u), u\rangle_A\} \\ &= \mu \int_0^1 \{u(s)\sin u(s) - 2 + 2\cos u(s)\} ds \end{aligned}$$

and $\theta \sin\theta - 2\{1 - \cos\theta\} < 0$ for $0 < |\theta| < \pi$. This implies that $u \equiv 0$ on $(0,1]$. Since this argument applies to every subsequence of $\{u_k\}$, we can conclude that the whole sequence $\{u_k\}$ converges to 0 in H_A. Indeed, if $\{u_k\}$ does not converge in H_A, there exists a constant $\eta > 0$ and a subsequence $\{u_{k_i}\}$ such that $\|u_{k_i}\|_A \ge \eta$ for all i. But this subsequence satisfies $j_\mu(u_{k_i}) \to 0$ if $i \to \infty$ and $\nabla j_\mu(u_{k_i}) = 0$ for all i. Thus, by the condition (PS) and repeating the argument used above, $\{u_{k_i}\}$ has a convergent subsequence to 0 in H_A. Now this is a contradiction.

Now fix $n \in \mathbb{N}$. We show that there exists $K \in \mathbb{N}$ such that u_k has at least n zeros in $(0,1]$ for all $k \ge K$. First choose $\xi \in (0,\mu)$ and any nontrivial solution v of the linearized equation

$$\big\{A(s)v'(s)\big\}' + \xi v(s) = 0 \quad \text{on } (0,1).$$

By Lemma 4.2, there exists $\delta > 0$ such that v has at least $n+1$ zeros in the interval $(\delta, 1]$. Since the sequence $\{u_k\}$ tends to 0 in H_A, it converges to 0 uniformly on $[\delta, 1]$, and so there is a constant $K \in \mathbb{N}$ such that

$$q_k(s) = \mu \frac{\sin u_k(s)}{u_k(s)} > \xi \quad \text{for all } s \in [\delta,1] \text{ and all } k \ge K.$$

But $\{u_k\}$ satisfies the linear equation

$$\big\{A(s)v'(s)\big\}' + q_k(s)v(s) = 0 \quad \text{on } (0,1)$$

and so, by the Sturm comparison theorem (see Theorem 3.1 in Chapter II of [6]), u_k vanishes at least once between successive zeros of v in $(\delta,1]$. Hence u_k has at least n zeros in $(\delta,1]$ for all $k \ge K$. □

5. Profile of order $p = 2$: Bifurcation at simple eigenvalues. The goal of this part is to prove Theorems 1.11 and 1.12. We use arguments similar to those of the previous section. We first need some lemmas.

LEMMA 5.1. *Let $(X, \|.\|)$ be a normed space. If $\{v_1, \dots, v_k\}$ are linearly independent, there is an $\varepsilon > 0$ with the following property: If $\{w_1, \dots, w_k\} \subset X$ is such that $\|v_i - w_i\| \le \varepsilon$ for all $i = 1, \dots, k$, then $\{w_1, \dots, w_k\}$ is linearly independent.*

Proof. Suppose that there is no such $\varepsilon > 0$. Then, for each $n \in \mathbb{N}^*$, there exists a set $\{u_1^n, \dots, u_k^n\}$ which is linearly dependent and such that $\|u_i^n - v_i\| \le 1/n$ for all $i = 1, \dots, k$. Then we can find $\lambda_1^n, \dots, \lambda_k^n$ such that

$$\sum_{i=1}^k \lambda_i^n u_i^n = 0$$

and

$$\lambda^n = \left\{ \sum_{i=1}^{k} (\lambda_i^n)^2 \right\}^{1/2} > 0.$$

Then we have

$$\sum_{i=1}^{k} \frac{\lambda_i^n}{\lambda^n} u_i^n = 0.$$

Now, for $i = 1, \dots, k$ and since $|\lambda_i^n|/\lambda^n \leq 1$ for all $n \in \mathbb{N}^*$, passing to a subsequence, there exists γ_i such that $\lambda_i^n/\lambda^n \to \gamma_i$ as $n \to \infty$. We then have

$$\sum_{i=1}^{k} \gamma_i v_i = 0.$$

Since $\{v_1, \dots, v_k\}$ is linearly independent, we have $\gamma_i = 0$ for all $i = 1, \dots, k$. But, since for all $n \in \mathbb{N}^*$,

$$\sum_{i=1}^{k} \left\{ \frac{\lambda_i^n}{\lambda^n} \right\}^2 = \frac{\sum_{i=1}^{k} (\lambda_i^n)^2}{(\lambda^n)^2} = 1,$$

and since

$$\lim_{n \to \infty} \sum_{i=1}^{k} \left\{ \frac{\lambda_i^n}{\lambda^n} \right\}^2 = \sum_{i=1}^{k} \gamma_i^2,$$

we have $\sum_{i=1}^{k} \gamma_i^2 = 1$. Now this is a contradiction. □

LEMMA 5.2. *Let H be a Hilbert space and let $S : D(S) \to H$, with $D(S) \subset H$, be self-adjoint and bounded below. We suppose that all eigenvalues of S are simple. We set $\lambda_e := \inf\{\lambda : \lambda \in \sigma_e(S)\}$, where $\sigma_e(S)$ denotes the essential spectrum of S, and let $\lambda_1 < \lambda_2 < \cdots < \lambda_k < \lambda_e$ be eigenvalues of S arranged in increasing order with corresponding orthonormal eigenvectors $e_1, e_2, \dots, e_k$. Then we have*

$$\begin{aligned} \inf \big\{ (S\psi, \psi) : \|\psi\| = 1, \psi \in D(S) \cap [e_1, \dots, e_k]^\perp \big\} \\ = \inf \big\{ \lambda : \lambda \in \sigma(S) \setminus \{\lambda_1, \dots, \lambda_k\} \big\}, \end{aligned}$$

where $\sigma(S)$ denotes the spectrum of S.

Proof. See Lemma 1.1 in Chapter XI of [3]. □

As a consequence of this lemma, we have the following.

LEMMA 5.3. *Under assumption* (H)*, and with the corresponding notation, choose $i \in I$. Then we have*

$$\|\psi\|_A^2 - \mu_i^+ \|\psi\|_{L^2}^2 \geq 0 \quad \textit{for all } \psi \in [\varphi_1, \dots, \varphi_i]^\perp.$$

Proof. We apply Lemma 5.2 to the operator $S = -T : H_A \to H_A$. Since T is self-adjoint, it is clear that S is self-adjoint. Moreover, using Lemma 2.1 and (5),

$$\langle Tu, u \rangle_A = \|u\|_{L^2}^2 \leq \frac{4}{K_2} \|u\|_A^2 \quad \text{for all } u \in H_A.$$

Then

$$\langle Su,u\rangle_A = -\langle Tu,u\rangle_A \geq -\frac{4}{K_2}\|u\|_A^2 \quad \text{for all } u \in H_A,$$

implying that S is bounded below. The spectrum of S is given by $\sigma(S) = -\sigma(T)$. Applying Lemma 5.2, we have

$$\begin{aligned}&\inf\big\{(S\psi,\psi) : \|\psi\| = 1, \psi \in H_A \cap [\varphi_1,\dots,\varphi_i]^\perp\big\}\\ &= \inf\big\{\lambda : \lambda \in \sigma(S) \setminus \{-\mu_1^{-1},\dots,-\mu_i^{-1}\}\big\} = -\frac{1}{\mu_i^+}.\end{aligned}$$

We then have

$$\begin{aligned}&\left\langle -T\Big(\frac{\psi}{\|\psi\|_A}\Big), \frac{\psi}{\|\psi\|_A}\right\rangle_A \geq -\frac{1}{\mu_i^+} \quad \text{for all } \psi \in [\varphi_1,\dots,\varphi_i]^\perp \setminus \{0\}\\ \Rightarrow\ &-\langle T\psi,\psi\rangle_A \geq -\frac{1}{\mu_i^+}\|\psi\|_A^2 \quad \text{for all } \psi \in [\varphi_1,\dots,\varphi_i]^\perp,\end{aligned}$$

which implies

$$\|\psi\|_A^2 - \mu_i^+\|\psi\|_{L^2}^2 \geq 0 \quad \text{for all } \psi \in [\varphi_1,\dots,\varphi_i]^\perp. \qquad \square$$

LEMMA 5.4. *Under assumption* (H)*, and with the corresponding notation, choose* $i \in I$*. Given any* $\varepsilon > 0$*, there is a subspace* E *of* $H_A \cap L^\infty(0,1)$ *such that* $\dim E = i$ *and*

$$\int_0^1 A(s)u'(s)^2 ds \leq (\mu_i + \varepsilon)\int_0^1 u(s)^2 ds$$

for all $u \in E$.

Proof. Let $\varepsilon > 0$. Set $F = span\{\varphi_1,\dots,\varphi_i\}$. Then for $j = 1,\dots,i$, we have

$$\begin{aligned}\int_0^1 A(s)\varphi_j'(s)^2 ds &= \langle \varphi_j,\varphi_j\rangle_A = \mu_j\langle T\varphi_j,\varphi_j\rangle_A\\ &= \mu_j\int_0^1 \varphi_j(s)^2 ds \leq \mu_i\int_0^1 \varphi_j(s)^2 ds.\end{aligned}$$

Then, for all $u = \sum_{j=1}^i \alpha_j\varphi_j \in F$, we have

$$\begin{aligned}&\int_0^1 A(s)\left(\sum_{j=1}^i \alpha_j\varphi_j\right)'(s)^2 ds = \left\langle \sum_{j=1}^i \alpha_j\varphi_j, \sum_{j=1}^i \alpha_j\varphi_j\right\rangle_A\\ &= \sum_{j=1}^i \langle \alpha_j\varphi_j,\alpha_j\varphi_j\rangle_A = \sum_{j=1}^i \mu_j\langle T\alpha_j\varphi_j,\alpha_j\varphi_j\rangle_A\\ &\leq \mu_i\sum_{j=1}^i \langle T\alpha_j\varphi_j,\alpha_j\varphi_j\rangle_A = \mu_i\left\langle T\left(\sum_{j=1}^i \alpha_j\varphi_j\right), \sum_{j=1}^i \alpha_j\varphi_j\right\rangle_A\\ &= \mu_i\int_0^1 u(s)^2 ds.\end{aligned}$$

We then have

$$\int_0^1 A(s)u'(s)^2 ds \le \mu_i \int_0^1 u(s)^2 ds \quad \text{for all } u \in F.$$

Now, since $H_A \cap L^\infty(0,1)$ is dense in H_A and T is continuous, there exist $v_1, \dots, v_i \in H_A \cap L^\infty(0,1)$ (which are linearly independent by Lemma 5.1) such that if $E = span\{v_1, \dots, v_i\}$, then $E \subset H_A \cap L^\infty(0,1)$, dim $E = i$, and

$$\int_0^1 A(s)v'(s)^2 ds \le (\mu_i + \varepsilon) \int_0^1 v(s)^2 ds \quad \text{for all } v \in E. \qquad \square$$

Now we are able to give the proof of Theorem 1.11.

Proof of Theorem 1.11. We apply Theorem 2.5 to the functional $j_\mu : H_A \to \mathbb{R}$. In light of Corollary 3.2 and Lemma 3.3, we only need to show that $b_i(j_\mu) < 0$ (recall that $b_k(j_\mu) \le b_i(j_\mu)$ for $k = 1, \dots, i$). To this end choose $\varepsilon > 0$ such that $\mu_i + \varepsilon < \mu$. Let E be the subspace given by Lemma 5.4 and, for $t > 0$, let

$$\Omega_t = \Big\{ u \in E : \|u\|_{L^\infty} = t \Big\}.$$

Then the genus of Ω_t is equal to $i = \dim E$, and since $\|.\|_{L^\infty}$ and $\|.\|_A$ are equivalent on E, there exists $C > 0$ such that $\|u\|_A \ge Ct$ for all $u \in \Omega_t$. Fix $\delta \in (0, 1 - (\mu_i + \varepsilon)/\mu)$ and fix $t \in (0, \pi)$ such that

$$1 - \cos\theta \ge \frac{1-\delta}{2}\theta^2 \quad \text{for all } |\theta| \le t.$$

Using this and Lemma 5.4, we have that for $u \in \Omega_t$,

$$\begin{aligned} j_\mu(u) &= \frac{1}{2}\|u\|_A^2 - \mu \int_0^1 \{1 - \cos u(s)\} ds \\ &\le \frac{1}{2}\Big\{ \|u\|_A^2 - \mu(1-\delta) \int_0^1 u(s)^2 ds \Big\} \\ &\le \frac{1}{2}\|u\|_A^2 \Big\{ 1 - \mu(1-\delta)\frac{1}{\mu_i + \varepsilon} \Big\} \\ &\le \frac{(Ct)^2}{2} \Big\{ 1 - \frac{(1-\delta)\mu}{\mu_i + \varepsilon} \Big\} < 0 \end{aligned}$$

and thus

$$0 > \sup_{u \in \Omega_t} j_\mu(u) \ge \inf_{\Omega \in G_i} \sup_{u \in \Omega} j_\mu(u) = b_i(j_\mu).$$

The existence of a set $\{u_k\}$, $k = 1, \dots, i$, of solutions of problem P with $j_\mu(u_k) = b_i(j_\mu)$ now follows from Theorem 2.5 and Lemma 3.3. $\square$

Using the notation of section 2.2, we have the following.

LEMMA 5.5. *Under assumption* (H)*, and with the corresponding notation, choose* $i \in I$. *Let* $\mu_i < \mu < \mu_i^+$ *and consider* $b_i(j_\mu)$. *Then there exists* $M = \sqrt{2 + 4\Lambda_e(A)} > 0$ *(independent of* μ*) with the following property: For each* $0 < \varepsilon \le 1$, *there exists* $\Omega_\varepsilon \in \Sigma_M$ *such that*

(i) $g(\Omega_\varepsilon) \ge i$,

(ii) $b_i(j_\mu) \le \sup_{u \in \Omega_\varepsilon} j_\mu(u) < b_i(j_\mu) + \varepsilon$.

Remark. Lemma 5.5 means that to construct $b_i(j_\mu)$ for $\mu \in (\mu_i, \mu_i^+)$, it is sufficient to consider the sets $\Omega \in G_i$ such that $\Omega \in \Sigma_M$, instead of all sets $\Omega \in G_i$ such that $\Omega \in \Sigma$.

Proof. Let $0 < \varepsilon \leq 1$. By definition of the infimum, there is $\Omega \in G_i$ such that

$$b_i(j_\mu) \leq \sup_{u\in\Omega} j_\mu(u) < b_i(j_\mu) + \varepsilon.$$

Then, for each $u \in \Omega$,

$$\frac{1}{2}\|u\|_A^2 - \mu\varphi(u) < b_i(j_\mu) + \varepsilon,$$

which implies, since $0 \leq \varphi(u) \leq 2$ for all $u \in H_A$,

$$\|u\|_A^2 < 2(b_i(j_\mu) + 1) + 4\mu < 2 + 4\Lambda_e(A),$$

where we used the fact proved by Theorem 1.11 that $b_i(j_\mu) < 0$. Setting $M = \sqrt{2 + 4\Lambda_e(A)}$, we have that $\Omega \in \Sigma_M$. □

LEMMA 5.6. *Under assumption* (H)*, and with the corresponding notation, choose* $i \in I$. *Let* $\mu_i < \mu < \mu_i^+$. *Then we have* $b_{i+1}(j_\mu) \geq 0$.

Proof. For each $\varepsilon > 0$, there is $\Omega \in G_{i+1}$ such that

$$b_{i+1}(j_\mu) \leq \sup_{u\in\Omega} j_\mu(u) < b_{i+1}(j_\mu) + \varepsilon.$$

By Lemma 2.4, there exists $\psi \in \Omega \cap [\varphi_1, \ldots, \varphi_i]^\perp$. By Lemma 5.3, we have

$$\|\psi\|_A^2 - \mu_i^+\|\psi\|_{L^2}^2 \geq 0.$$

We then have

$$\begin{aligned} j_\mu(\psi) &= \frac{1}{2}\|\psi\|_A^2 - \mu\varphi(\psi) \\ &\geq \frac{1}{2}\|\psi\|_A^2 - \mu\frac{1}{2}\int_0^1 \psi(s)^2 ds \\ &\geq \frac{1}{2}\{\|\psi\|_A^2 - \mu_i^+\|\psi\|_{L^2}^2\} \geq 0. \end{aligned}$$

Then $\sup_{u\in\Omega} j_\mu(u) \geq 0$ and $b_{i+1}(j_\mu) \geq 0$. □

PROPOSITION 5.7. *Under assumption* (H)*, and with the corresponding notation, choose* $i \in I$. *We have*

$$\lim_{\mu\to\mu_{i+}} b_i(j_\mu) = 0.$$

Proof. By definition, and using Lemma 5.5, we have

$$b_i(j_\mu) = \inf_{\Omega\in G_i}\sup_{u\in\Omega} j_\mu(u) = \inf_{\Omega\in G_i\cap\Sigma_M}\sup_{u\in\Omega} j_\mu(u).$$

Let $\Omega \in G_i \cap \Sigma_M$, and let $u \in \Omega$. Then

$$\begin{aligned} j_\mu(u) &= \frac{1}{2}\|u\|_A^2 - \mu\varphi(u) \\ &\geq \frac{1}{2}\{\|u\|_A^2 - \mu\|u\|_{L^2}^2\} \\ &= \frac{1}{2}\{\|u\|_A^2 - \mu_i\|u\|_{L^2}^2 + (\mu_i - \mu)\|u\|_{L^2}^2\}. \end{aligned}$$

Since $g(\Omega) \geq i$, by Lemma 2.4, there exists $\psi \in \Omega \cap [\varphi_1, \ldots, \varphi_{i-1}]^{\perp}$. By Lemma 5.3, we have

$$\|\psi\|_A^2 - \mu_i \|\psi\|_{L^2}^2 \geq 0.$$

Using Lemma 2.1 and (5), we then have (recalling that $\psi \in \Sigma_M$),

$$j_\mu(\psi) \geq \frac{1}{2}(\mu_i - \mu)\|\psi\|_{L^2}^2 \geq \frac{2}{K_2} M^2(\mu_i - \mu).$$

Thus we have shown that for each $\Omega \in G_i \cap \Sigma_M$, there is a $\psi \in \Omega$ such that

$$j_\mu(\psi) \geq \frac{2}{K_2} M^2(\mu_i - \mu).$$

Then, for all $\mu \in (\mu_i, \mu_i^+)$, we have

$$0 > b_i(j_\mu) \geq \frac{2}{K_2} M^2(\mu_i - \mu) \to 0 \quad \text{if } \mu \to \mu_{i+}.$$

Then $\lim_{\mu \to \mu_{i+}} b_i(j_\mu) = 0$. □

LEMMA 5.8. *Let there be a sequence $\{\mu_k\} \subset \mathbb{R}_+$ which converges to $\mu \in \mathbb{R}$. Consider a sequence $\{u_k\} \subset H_A$ such that*

(i) *$\{j_{\mu_k}(u_k)\}$ is bounded;*

(ii) *$\|\nabla j_{\mu_k}(u_k)\|_A \to 0$ if $k \to \infty$.*

Then $\{u_k\}$ has a convergent subsequence.

Proof. Since $j_\mu(u) = \frac{1}{2}\|u\|_A^2 - \mu\varphi(u)$ with $0 \leq \varphi(u) \leq 2$, and since $\{j_{\mu_k}(\mu_k)\}$ is bounded, we have that $\{u_k\}$ is a bounded sequence in H_A. Then there is a subsequence $\{u_{k_i}\}$, and $u \in H_A$ such that u_{k_i} converges weakly to u in H_A. But since D_A is completely continuous, we have $\|D_A(u_{k_i}) - D_A(u)\|_A \to 0$ if $i \to \infty$.

Now, since $\nabla j_\mu = I - \mu D_A$, we have

$$u_{k_i} = \nabla j_{\mu_{k_i}}(u_{k_i}) + \mu_{k_i} D_A(u_{k_i}) \to 0 + \mu D_A(u) \quad \text{if } i \to \infty.$$

Finally $\{u_{k_i}\}$ converges in H_A. □

We now prove our second bifurcation result.

Proof of Theorem 1.12. For $\mu > \mu_i$, by Theorem 1.11 there is $u_\mu \in H_A \setminus \{0\}$ such that u_μ is a solution of problem P, $|u_\mu(s)| < \pi$ for all $s \in (0, 1]$, $\nabla j_\mu(u_\mu) = 0$, and $j_\mu(u_\mu) = b_i(j_\mu)$. Now choose a sequence $\{\alpha_k\}$ such that $\alpha_k > \mu_i$ for all $k \geq 1$ and such that $\alpha_k \to \mu_i$ as $k \to \infty$. Then, for each $k \geq 1$, there exists $u_k \in H_A \setminus \{0\}$ such that $j_{\alpha_k}(u_k) = b_i(j_{\alpha_k})$ and u_k is a solution of problem P. Furthermore, $\nabla j_{\alpha_k}(u_k) = 0$ for all $k \geq 1$. Now Proposition 5.7 implies

$$\lim_{k \to \infty} j_{\alpha_k}(u_k) = \lim_{k \to \infty} b_i(j_{\alpha_k}) = 0.$$

Thus $\{j_{\alpha_k}(u_k)\}$ is bounded. By Lemma 5.8, there is a subsequence $\{u_{k_i}\}$ which converges to $u \in H_A$. We then have $j_{\mu_i}(u) = 0$, $\nabla j_{\mu_i}(u) = 0$, and $|u(s)| \leq \pi$ for all $s \in (0, 1]$ since $\{u_{k_i}\}$ converges to u uniformly on compact subsets of $(0, 1]$. By Lemma 3.3, we have $|u(s)| < \pi$ for all $s \in (0, 1]$. But we have

$$\begin{aligned}
0 &= 2j_{\mu_i}(u) - \langle \nabla j_{\mu_i}(u), u \rangle_A \\
&= 2j_{\mu_i}(u) - \langle u - \mu_i D_A(u), u \rangle_A \\
&= \|u\|_A^2 - \mu_i \int_0^1 \{2 - 2\cos u(s)\} ds - \langle u, u \rangle_A + \mu_i \langle D_A(u), u \rangle_A \\
&= \mu_i \int_0^1 \{u(s) \sin u(s) - 2 + 2\cos u(s)\} ds
\end{aligned}$$

and $\theta \sin\theta - 2\{1 - \cos\theta\} < 0$ for all $0 < |\theta| < \pi$. This implies that $u \equiv 0$ on $(0, 1]$. Since this argument applies to every subsequence of $\{u_k\}$, we can conclude that the whole sequence $\{u_k\}$ converges to 0 in H_A. □

Acknowledgment. I would like to thank Professor C. A. Stuart for his precious advice that helped me to do this work.

HIGH-ORDER TERMS IN THE ASYMPTOTIC EXPANSIONS OF THE STEADY-STATE VOLTAGE POTENTIALS IN THE PRESENCE OF CONDUCTIVITY INHOMOGENEITIES OF SMALL DIAMETER*

HABIB AMMARI† AND HYEONBAE KANG‡

Abstract. We derive high-order terms in the asymptotic expansions of the steady-state voltage potentials in the presence of a finite number of diametrically small inhomogeneities with conductivities different from the background conductivity. Our derivation is rigorous and based on layer potential techniques. The asymptotic expansions in this paper are valid for inhomogeneities with Lipschitz boundaries and those with extreme conductivities.

Key words. small conductivity inhomogeneities, asymptotic expansions, generalized polarization tensors

1. Introduction.

Let Ω be a bounded domain in $\mathbb{R}^d$, $d \geq 2$, with a connected Lipschitz boundary $\partial\Omega$. Let ν denote the unit outward normal to $\partial\Omega$. Suppose that Ω contains a finite number m of small inhomogeneities $(D_l)_{l=1}^m$, each of the form $D_l = z_l + \epsilon B_l$, where B_l, $l = 1, \ldots, m$, is a bounded Lipschitz domain in $\mathbb{R}^d$ containing the origin. We assume that the domains $(D_l)_{l=1}^m$ are separated from each other and from the boundary. More precisely, we assume that there exists a constant $c_0 > 0$ such that

$$|z_l - z_{l'}| \geq 2c_0 > 0 \quad \forall\, l \neq l' \quad \text{and} \quad \operatorname{dist}(z_l, \partial\Omega) \geq 2c_0 > 0 \quad \forall\, l, \tag{1.1}$$

that ϵ, the common order of magnitude of the diameters of the inhomogeneities, is sufficiently small, that these inhomogeneities are disjoint, and that their distance to $\mathbb{R}^d \setminus \overline{\Omega}$ is larger than c_0. We also assume that the "background" is homogeneous with conductivity 1 and the inhomogeneities D_l have conductivities k_l, $k_l \neq 1$, $1 \leq l \leq m$.

Let u_ϵ denote the steady-state voltage potential in the presence of the conductivity inhomogeneities, i.e., the solution to

$$\begin{cases} \nabla \cdot \left(\chi\left(\Omega \setminus \bigcup_{l=1}^m \overline{D_l} \right) + \sum_{l=1}^m k_l \chi(D_l) \right) \nabla u_\epsilon = 0 \quad \text{in } \Omega, \\ \dfrac{\partial u_\epsilon}{\partial \nu}\Big|_{\partial\Omega} = g. \end{cases} \tag{1.2}$$

Let U denote the "background" potential, that is, the solution to

$$\begin{cases} \Delta U = 0 \quad \text{in } \Omega, \\ \dfrac{\partial U}{\partial \nu}\big|_{\partial\Omega} = g. \end{cases} \tag{1.3}$$

The function g represents the applied boundary current; it belongs to $L^2_0(\partial\Omega) = \{g \in L^2(\partial\Omega), \int_{\partial\Omega} g = 0\}$. The potentials, u_ϵ and U, are normalized by $\int_{\partial\Omega} u_\epsilon = \int_{\partial\Omega} U = 0$.

The main achievement of this paper is a rigorous derivation, based on layer potential techniques, of high-order terms in the asymptotic expansion of $u_\epsilon|_{\partial\Omega}$ as $\epsilon \to 0$. The leading order term in this asymptotic formula has been derived by Cedio-Fengya, Moskow, and Vogelius [7]; see also the prior work of Friedman and Vogelius [14] for the case of perfectly conducting or insulating inhomogeneities. The main result of this paper is the following full asymptotic expansion of the solution for the case $m = 1$.

THEOREM 1.1. *Suppose that the inhomogeneity consists of a single component and let u_ε be the solution of* (1.2). *The following pointwise asymptotic expansion on $\partial\Omega$ holds for $d = 2, 3$:*

$$\begin{aligned} u_\varepsilon(x) = U(x) &- \epsilon^{d-2} \sum_{|i|=1}^{n} \sum_{|j|=1}^{n-|i|+1} \frac{1}{j!} \epsilon^{|i|+|j|} \\ &\times \left[\left(\left(I + \sum_{p=1}^{n+2-|i|-|j|-d} \epsilon^{d+p-1} \mathcal{Q}_p \right) (\partial^l U(z)) \right)_i M_{ij} \partial_z^j N(x,z) \right] \\ &+ O(\epsilon^{d+n}), \end{aligned} \tag{1.4}$$

where the remainder $O(\epsilon^{d+n})$ is dominated by $C\epsilon^{d+n}\|g\|_{L^2(\partial\Omega)}$ for some C independent of $x \in \partial\Omega$. Here $N(x,z)$ is the Neumann function, that is, the solution to (2.12)–(2.13), *M_{ij}, $i, j \in \mathbb{N}^d$, are the generalized polarization tensors defined in* (3.2), *and the matrix $\mathcal{Q}_p$ is defined in* (4.12).

We have a similar expansion for the solutions of the Dirichlet problem (Theorem 4.2).

The derivation of the asymptotic expansions for any fixed number m of well-separated inhomogeneities (these are a fixed distance apart) follows by iteration of the arguments that we will present for the case $m = 1$. In other words, we may develop asymptotic formulas involving the difference between the fields u_ϵ and U on $\partial\Omega$ with l inhomogeneities and those with $l - 1$ inhomogeneities, $l = m, \ldots, 1$, and then at the end essentially form the sum of these m formulas (the reference fields change, but that may easily be remedied). The derivation of each of the m formulas is virtually identical.

We also note that the asymptotic expansion (1.4) is valid for inhomogeneities with zero or infinity conductivity (cavity or perfect conductor). Precise definitions of generalized polarization tensors (GPTs) associated with the domains B_l and the conductivities k_l will be given at the end of section 3. These GPTs seem to be natural generalizations of the tensors that have been introduced by Schiffer and Szegö [23] and thoroughly studied by many other authors [22], [18], [14], [7]. (See section 3.)

The higher-order terms are essential when $\nabla U(z_l) = 0$, for then the leading order term in the asymptotic expansion of $u_\epsilon|_{\partial\Omega}$, given in [7], vanishes. We remind the reader that, for general current inputs g, ∇U vanishes at some "critical points" inside Ω.

The proof of our asymptotic expansion is radically different from the ones in [14], [7], and [26]. It is based on layer potential techniques and a decomposition formula of the steady-state voltage potential into a harmonic part and a refraction part. This formula is due to Kang and Seo [15]. What makes our proof particularly original and elegant is that the rigorous derivation of high-order terms follows almost immediately. The extension of the techniques used in [14], [7], and [26] to construct higher-order terms in the expansion of $u_\epsilon|_{\partial\Omega}$ as $\epsilon \to 0$ seems to be laborious. Furthermore, the general approach developed in this paper could be carried out to obtain more precise asymptotic formulas for the full Maxwell equations and for the equations of linear elasticity than those derived in [3] and [1]. The method of this paper also enables us to extend the asymptotic expansions to the cases of inhomogeneities with Lipschitz boundaries. Previously, the leading order term was derived under the assumption that inhomogeneities are $C^{1,\alpha}$ smooth [14], [7]. We note that our method works as well even when the inhomogeneities have extreme conductivities ($k = 0$ or $k = \infty$).

Let us now explain what makes this asymptotic formula interesting in electrical impedance tomography (EIT). It is well known that the ultimate objective of EIT is to recover, most efficiently and accurately, the conductivity distribution inside a body from measurements of current flows and voltages on the body's surface. The vast and growing literature reflects the many possible applications of EIT, e.g., for medical diagnosis or nondestructive evaluation of materials [6]. In its most general form EIT is severely ill-posed and nonlinear. Taking advantage of the smallness of the inhomogeneities, Cedio-Fengya, Moskow, and Vogelius [7] used the leading order term in the asymptotic expansion of $u_\epsilon|_{\partial\Omega}$ to find the locations z_l, $l = 1, \dots, m$, of the inhomogeneities and certain properties of the domains B_l, $l = 1, \dots, m$ (relative size, orientation). The algorithm proposed in [7] is based on a least-squares algorithm. Ammari, Moskow, and Vogelius [2] also utilized this leading order term to design a variationally based direct reconstruction method. The new idea in [2] is to form the integral of the "measured boundary data" against harmonic test functions and choose the input current g so as to obtain an expression involving the inverse Fourier transform of distributions supported at the locations z_l, $l = 1, \dots, m$. Applying a direct Fourier transform to this data then pins down the locations. This approach is similar to the ideas used by Calderón [5] in his proof of uniqueness of the linearized conductivity problem and later by Sylvester and Uhlmann in their important work [24] on uniqueness of the three-dimensional inverse conductivity problem. Another algorithm that makes use of an asymptotic expansion of the voltage potentials was derived by Brühl, Hanke, and Vogelius [4]. This algorithm is in the spirit of the linear sampling method of Colton and Kirsch [9].

In all of these algorithms, the locations z_l, $l = 1, \dots, m$, of the inhomogeneities are found with an error $O(\epsilon)$, and little about the domains B_l can be reconstructed. Making use of higher-order terms in the asymptotic expansion of $u_\epsilon|_{\partial\Omega}$, we certainly would be able to reconstruct the small inhomogeneities with higher resolution from boundary information about specific solutions to (1.2). Perhaps, more importantly, this would allow us to identify quite general conductivity inhomogeneities without restrictions on their sizes.

The use of higher-order terms in the asymptotic expansion of $u_\epsilon|_{\partial\Omega}$ may also be decisive in dramatically improving the algorithm of Kwon, Seo, and Yoon [19], which is based on the observation of the pattern of a simple weighted combination of an input current g of the form $g = a \cdot \nu$ for some constant vector a and the corresponding output voltage. We also believe that the use of such higher-order terms would improve

the algorithm of Mast, Nachman, and Waag [20], which uses eigenfunctions of the scattering operator.

This paper is organized as follows. In section 2, we collect some notation and preliminary results regarding layer potentials. In section 3, we introduce the GPTs associated with the domains D_l and the conductivities k_l. In section 4, we provide a rigorous derivation of high-order terms in the asymptotic expansion of the output voltage potentials. For reasons of brevity we restrict a significant part of this derivation to the case of a single inhomogeneity ($m = 1$). The proof in the case of multiple well-separated inhomogeneities may be derived by a fairly straightforward iteration of the arguments we present; however, we leave the details to the reader.

2. Layer potentials for the Laplacian. Let us first review some well-known properties of the layer potentials for the Laplacian and prove some useful identities.

The theory of layer potentials has been developed in relation to the boundary value problems. Let D be a bounded domain in $\mathbb{R}^d, d \geq 2$. We assume that ∂D is Lipschitz. Let $\Gamma(x)$ be the fundamental solution of the Laplacian Δ,

$$\Gamma(x) = \begin{cases} \dfrac{1}{2\pi} \ln |x|, & d = 2, \\ \dfrac{1}{(2-d)\omega_d} |x|^{2-d}, & d \geq 3, \end{cases} \tag{2.1}$$

where ω_d is the area of $(d-1)$-dimensional unit sphere. The single and double layer potentials of the density function ϕ on D are defined by

$$\mathcal{S}_D\phi(x) := \int_{\partial D} \Gamma(x-y)\phi(y)d\sigma(y), \quad x \in \mathbb{R}^d, \tag{2.2}$$

$$\mathcal{D}_D\phi(x) := \int_{\partial D} \frac{\partial}{\partial \nu_y}\Gamma(x-y)\phi(y)d\sigma(y), \quad x \in \mathbb{R}^d \setminus \partial D. \tag{2.3}$$

For a function u defined on $\mathbb{R}^d \setminus \partial D$, we denote

$$\frac{\partial}{\partial \nu^{\pm}} u(x) := \lim_{t \to 0^+} \langle \nabla u(x \pm t\nu_x), \nu_x \rangle, \quad x \in \partial D,$$

if the limit exists. Here ν_x is the outward unit normal to ∂D at x.

The proof of the following trace formula can be found in [11], [13], [21] (for Lipschitz domains, see [25]):

$$\frac{\partial}{\partial \nu^{\pm}} \mathcal{S}_D\phi(x) = \left(\pm\frac{1}{2}I + \mathcal{K}_D^*\right)\phi(x), \tag{2.4}$$

$$(\mathcal{D}_D\phi)|_{\pm} = \left(\mp\frac{1}{2}I + \mathcal{K}_D\right)\phi(x), \quad x \in \partial D, \tag{2.5}$$

where

$$\mathcal{K}_D\phi(x) = \frac{1}{\omega_d} \text{p.v.} \int_{\partial D} \frac{\langle x-y, \nu_y \rangle}{|x-y|^d}\phi(y)d\sigma(y)$$

and $\mathcal{K}_D^*$ is the L^2-adjoint of $\mathcal{K}_D$. When ∂D is Lipschitz, $\mathcal{K}_D$ is a singular integral operator and known to be bounded on $L^2(\partial\Omega)$ [8]. Let $L_0^2(\partial D) := \{f \in L^2(\partial D) :$

$\int_{\partial D} f d\sigma = 0\}$. The following results are due to Verchota [25] and Escauriaza, Fabes, and Verchota [10].

THEOREM 2.1 (see [10], [25]). *$\lambda I - \mathcal{K}_D^*$ is invertible on $L_0^2(\partial D)$ if $|\lambda| \geq \frac{1}{2}$, and for $\lambda \in (-\infty, -\frac{1}{2}] \cup (\frac{1}{2}, \infty)$, $\lambda I - \mathcal{K}_D^*$ is invertible on $L^2(\partial D)$.*

For proofs when ∂D is smooth, see [11], [13].

The following theorem was proved in [15], [16], [17].

THEOREM 2.2. *Suppose that D is a domain compactly contained in Ω with a connected Lipschitz boundary and conductivity k. Then the solution u of the problem*

$$\begin{cases} \nabla \cdot ((1 + (k-1)\chi(D))\nabla u) = 0 \quad \text{in } \Omega, \\ \dfrac{\partial u}{\partial \nu}\Big|_{\partial\Omega} = g \end{cases} \tag{2.6}$$

is represented as

$$u(x) = H(x) + \mathcal{S}_D\phi(x), \quad x \in \Omega, \tag{2.7}$$

where the harmonic function H is given by

$$H(x) = -\mathcal{S}_\Omega(g)(x) + \mathcal{D}_\Omega(f)(x), \quad x \in \Omega, \quad f := u|_{\partial\Omega}, \tag{2.8}$$

and $\phi \in L_0^2(\partial D)$ satisfies the integral equation

$$\left(\frac{k+1}{2(k-1)} I - \mathcal{K}_D^*\right)\phi = \frac{\partial H}{\partial \nu}\Big|_{\partial D} \quad \text{on } \partial D. \tag{2.9}$$

Moreover, $\forall\, n \in \mathbb{N}$, there exists a constant $C_n = C(n, \Omega, dist(D, \partial\Omega))$ independent of $|D|$ and k such that

$$\|H\|_{\mathcal{C}^n(\overline{D})} \leq C_n \|g\|_{L^2(\partial\Omega)}. \tag{2.10}$$

Proof. The representation formula (2.7) was proved in [15], [17]. Equation (2.10) was proved in [16] for $d = 2$, and it is easily seen that the same proof works for $d = 3$. We only need to check carefully whether the constant C_n in the estimate (2.10) is independent of $|D|$. Before doing this, let us point out that the harmonic function H can be computed explicitly from the boundary measurements $(\frac{\partial u}{\partial \nu}\big|_{\partial\Omega}, u\big|_{\partial\Omega})$, and the density ϕ is uniquely and explicitly determined by the domain D and the harmonic function H. The decomposition of the function u into a harmonic part H and a refraction part $\mathcal{S}_D\phi$ is unique [15], [17]. The representation formula (2.7) seems to inherit geometric properties of D.

Suppose that $\text{dist}(D, \partial\Omega) > 2c_0$ for some constant $c_0 > 0$. From the definition of H in (2.8) it is easy to see that

$$\|H\|_{\mathcal{C}^n(\overline{D})} \leq C_n\Big(\|g\|_{L^2(\partial\Omega)} + \|u|_{\partial\Omega}\|_{L^2(\partial\Omega)}\Big), \tag{2.11}$$

where C_n depends only on n, $\partial\Omega$, and c_0. Let $\vec{\alpha}$ be a vector field supported in the set $\text{dist}(x, \partial\Omega) < 2c_0$ such that $\vec{\alpha} \cdot \nu(x) \geq \delta$ for some $\delta > 0\ \forall\ x \in \partial\Omega$. Using the Rellich identity with this $\vec{\alpha}$, we can show that

$$\left\|\frac{\partial u}{\partial T}\right\|_{L^2(\partial\Omega)} \leq C\Big(\|g\|_{L^2(\partial\Omega)} + \|\nabla u\|_{L^2(\Omega\setminus\overline{D})}\Big),$$

where C depends only on $\partial\Omega$ and c_0 and $T(x)$ is the tangent vector to $\partial\Omega$ at x. (See the proof of Lemma 2.1 of [12] for details of the proof.) Observe that

$$\begin{aligned}\|\nabla u\|^2_{L^2(\Omega\setminus\overline{D})} &\le C\int_\Omega (1+(k-1)\chi(D))\nabla u\cdot\nabla u\,dx\\ &= C\int_{\partial\Omega} gu\,d\sigma\\ &\le C\|g\|_{L^2(\partial\Omega)}\|u|_{\partial\Omega}\|_{L^2(\partial\Omega)}.\end{aligned}$$

Since $\int_{\partial\Omega} u\,d\sigma = 0$, it follows from the Poincaré inequality that

$$\|u|_{\partial\Omega}\|_{L^2(\partial\Omega)} \le C\left\|\frac{\partial u}{\partial T}\right\|_{L^2(\partial\Omega)}.$$

Thus we obtain

$$\|u|_{\partial\Omega}\|^2_{L^2(\partial\Omega)} \le C\Big(\|g\|^2_{L^2(\partial\Omega)} + \|g\|_{L^2(\partial\Omega)}\|u|_{\partial\Omega}\|_{L^2(\partial\Omega)}\Big),$$

and hence

$$\|u|_{\partial\Omega}\|_{L^2(\partial\Omega)} \le C\|g\|_{L^2(\partial\Omega)}.$$

From (2.11) we finally obtain (2.10). □

Using the above representation we can derive a formula similar to (1.4) which is potentially useful in detecting the inhomogeneities (see the remark at the end of this paper). However, it uses the function H, which depends on D and hence on ϵ. Thus in order to derive (1.4) we will transform it to representations using only background potentials.

Let $N(x,z)$ be the Neumann function for Δ in Ω corresponding to a Dirac mass at z. That is, N is the solution to

$$\begin{cases}\Delta_x N(x,z) = -\delta_z & \text{in } \Omega,\\ \dfrac{\partial N}{\partial\nu}\Big|_{\partial\Omega} = -\dfrac{1}{|\partial\Omega|}.\end{cases} \tag{2.12}$$

In addition, we assume that

$$\int_{\partial\Omega} N(x,y)d\sigma(x) = 0 \quad \text{for } y\in\Omega. \tag{2.13}$$

Let us fix one more notation: For D, a subset of Ω, let

$$N_D f(x) := \int_{\partial D} N(x,y)f(y)d\sigma(y).$$

The following lemma relates the fundamental solution with the Neumann function.

LEMMA 2.3. *For $z\in\Omega$ and $x\in\partial\Omega$, let $\Gamma_z(x) := \Gamma(x-z)$ and $N_z(x) := N(x,z)$. Then*

$$\left(-\frac{1}{2}I + \mathcal{K}_\Omega\right)(N_z)(x) = \Gamma_z(x) \quad \textit{modulo constants}, \quad x\in\partial\Omega, \tag{2.14}$$

or, to be more precise, for any simply connected Lipschitz domain D compactly contained in Ω and for any $g \in L^2_0(\partial D)$, we have

$$\int_{\partial D}\left(-\frac{1}{2}I+\mathcal{K}_\Omega\right)(N_z)(x)g(z)d\sigma(z)=\int_{\partial D}\Gamma_z(x)g(z)d\sigma(z)\quad\forall x\in\partial\Omega. \tag{2.15}$$

Proof. Let $f \in L^2_0(\partial\Omega)$ and define

$$u(z):=\left\langle\left(-\frac{1}{2}I+\mathcal{K}_\Omega\right)(N_z),f\right\rangle_{\partial\Omega},\quad z\in\Omega.$$

Then

$$u(z)=\int_{\partial\Omega}N(x,z)\left(-\frac{1}{2}I+\mathcal{K}^*_\Omega\right)f(x)d\sigma(x).$$

Therefore, $\Delta u = 0$ in Ω and $\frac{\partial u}{\partial\nu}|_{\partial\Omega} = (-\frac{1}{2}I+\mathcal{K}^*_\Omega)f$. Thus by (2.4) we have

$$u(z)-\mathcal{S}_\Omega f(z)=\text{constant},\quad z\in\Omega.$$

Thus if $g \in L^2_0(\partial\Omega)$, then we obtain

$$\begin{aligned}&\int_{\partial\Omega}\int_{\partial D}\left(-\frac{1}{2}I+\mathcal{K}_\Omega\right)(N_z)(x)g(z)d\sigma(z)f(x)d\sigma(x)\\&=\int_{\partial\Omega}\int_{\partial D}\Gamma_z(x)g(z)d\sigma(z)f(x)d\sigma(x).\end{aligned}$$

Since f is arbitrary, we have equation (2.14) or, equivalently, (2.15). This completes the proof. ∎

Let $g \in L^2_0(\partial\Omega)$. Let $U(y) := \int_{\partial\Omega} N(x,y)g(x)d\sigma(x)$. Then U satisfies

$$\begin{cases}\Delta U=0\quad\text{in }\Omega,\\ \dfrac{\partial U}{\partial\nu}|_{\partial\Omega}=g\in L^2_0(\partial\Omega),\\ \displaystyle\int_{\partial\Omega}U(x)d\sigma(x)=0.\end{cases} \tag{2.16}$$

THEOREM 2.4. *The solution u of* (2.6) *can be represented as*

$$u(x)=U(x)-N_D\phi(x),\quad x\in\partial\Omega, \tag{2.17}$$

where ϕ is defined in (2.9).

Proof. By substituting (2.7) into (2.8), we obtain

$$H(x)=-\mathcal{S}_\Omega(g)(x)+\mathcal{D}_\Omega(H|_{\partial\Omega}+(\mathcal{S}_D\phi)|_{\partial\Omega})(x),\quad x\in\Omega.$$

It then follows from (2.5) that

$$\left(\frac{1}{2}I-\mathcal{K}_\Omega\right)(H|_{\partial\Omega})=-(\mathcal{S}_\Omega g)|_{\partial\Omega}+\left(\frac{1}{2}I+\mathcal{K}_\Omega\right)((\mathcal{S}_D\phi)|_{\partial\Omega})\quad\text{on }\partial\Omega. \tag{2.18}$$

Since by Green's theorem $U = -\mathcal{S}_\Omega(g) + \mathcal{D}_\Omega(U|_{\partial\Omega})$ in Ω, we have

$$\left(\frac{1}{2}I - \mathcal{K}_\Omega\right)(U|_{\partial\Omega}) = -(\mathcal{S}_\Omega g)|_{\partial\Omega}. \tag{2.19}$$

Since $\phi \in L_0^2(\partial D)$, it follows from (2.14) that

$$-\left(\frac{1}{2}I - \mathcal{K}_\Omega\right)((N_D\phi)|_{\partial\Omega}) = (\mathcal{S}_D\phi)|_{\partial\Omega}. \tag{2.20}$$

From (2.18), (2.19), and (2.20), we conclude that

$$\left(\frac{1}{2}I - \mathcal{K}_\Omega\right)\left(H|_{\partial\Omega} - U|_{\partial\Omega} + \left(\frac{1}{2}I + \mathcal{K}_\Omega\right)((N_D\phi)|_{\partial\Omega})\right) = 0.$$

Therefore, we have

$$H|_{\partial\Omega} - U|_{\partial\Omega} + \left(\frac{1}{2}I + \mathcal{K}_\Omega\right)((N_D\phi)|_{\partial\Omega}) = C \text{ (constant)}. \tag{2.21}$$

Note that $(\frac{1}{2}I+\mathcal{K}_\Omega)((N_D\phi)|_{\partial\Omega}) = (N_D\phi)|_{\partial\Omega}+(\mathcal{S}_D\phi)|_{\partial\Omega}$. Thus we get from (2.7) and (2.21)

$$u|_{\partial\Omega} = U|_{\partial\Omega} - (N_D\phi)|_{\partial\Omega} + C. \tag{2.22}$$

Since all the functions entering (2.22) belong to $L_0^2(\partial\Omega)$, we conclude that $C = 0$, and the theorem is proved. □

We have a similar representation for solutions of the Dirichlet problem. Let $G(x, y)$ be the Green function for the Dirichlet problem; i.e., the function V defined by $V(x) := \int_{\partial\Omega} \frac{\partial G}{\partial\nu(y)}(x, y)f(y)d\sigma(y)$ is the solution of the problem $\Delta V = 0$ in Ω and $V|_{\partial\Omega} = f$ for any $f \in L^2(\partial\Omega)$. Then we have the following representation theorem.

THEOREM 2.5.

$$\left(\frac{1}{2}I + \mathcal{K}_\Omega^*\right)^{-1}\left(\frac{\partial\Gamma_z(y)}{\partial\nu(y)}\right)(x) = \frac{\partial G_z}{\partial\nu(x)}(x), \quad x \in \partial\Omega,\ z \in \Omega. \tag{2.23}$$

Let u be the solution of (2.6) *with the Neumann condition replaced by the Dirichlet condition $u|_{\partial\Omega} = f$. Then u can be represented as*

$$\frac{\partial u}{\partial\nu}(x) = \frac{\partial V}{\partial\nu}(x) - G_D\phi(x), \quad x \in \partial\Omega, \tag{2.24}$$

where ϕ is defined in (2.9) *and $G_D\phi(x) := \int_{\partial D} \frac{\partial G}{\partial\nu(y)}(x, y)\phi(y)d\sigma(y)$.*

Theorem 2.5 can be proved in the same way as Theorem 2.4. In fact, it is simpler because of the solvability of the Dirichlet problem or, equivalently, the invertibility of $(\frac{1}{2}I + \mathcal{K}_\Omega^*)$. So we omit the proof.

3. Generalized polarization tensors. In this section we introduce the generalized polarization tensors (GPTs) associated with a domain B and a conductivity k. These GPTs are the basic building block for the asymptotic expansions in this paper.

Let B be a Lipschitz bounded domain in $\mathbb{R}^d$ and let the conductivity of B be k $(k \neq 1)$. The polarization tensor $M = (m_{ij})$, $1 \leq i, j \leq d$, is defined by

$$m_{ij} := \left(1 - \frac{1}{k}\right)\left[\delta_{ij}|B| + (k-1)\int_{\partial B} y_i \frac{\partial}{\partial\nu^+}\psi_j(y)d\sigma(y)\right],$$

where ψ_j is the unique solution of the following transmission problem:

$$\begin{cases} \Delta\psi_j(x) = 0, \quad x \in B \cup \mathbb{R}^d \setminus \overline{B}, \\ \psi_j|_+ - \psi_j|_- = 0 \quad \text{on } \partial B, \\ \dfrac{\partial}{\partial \nu^+}\psi_j - k\dfrac{\partial}{\partial \nu^-}\psi_j = \nu_j \quad \text{on } \partial B, \\ \psi_j(x) \to 0 \text{ as } |x| \to \infty. \end{cases}$$

See [23], [7], and [14]. One can easily check, using (2.4), that

$$(k-1)\psi_j = \mathcal{S}_B(\lambda I - \mathcal{K}_B^*)^{-1}(\nu_j).$$

Using (2.4) again, we have

$$\begin{aligned} (k-1)\int_{\partial B} y_i \frac{\partial}{\partial \nu^+}\psi_j(y)d\sigma(y) &= \int_{\partial B} y_i\left(\frac{1}{2}I + \mathcal{K}_B^*\right)(\lambda I - \mathcal{K}_B^*)^{-1}(\nu_j)(y)d\sigma(y) \\ &= -\int_{\partial B} y_i\nu_j d\sigma(y) + \left(\lambda + \frac{1}{2}\right)\int_{\partial B} y_i(\lambda I - \mathcal{K}_B^*)^{-1}(\nu_j)(y)d\sigma(y) \\ &= -\delta_{ij}|B| + \frac{k}{k-1}\int_{\partial B} y_i(\lambda I - \mathcal{K}_B^*)^{-1}(\nu_j)(y)d\sigma(y). \end{aligned}$$

Therefore we prove that the polarization tensor M associated with B and k is given by

$$m_{ij} = \int_{\partial B} y_i(\lambda I - \mathcal{K}_B^*)^{-1}(\nu_j)(y)d\sigma(y). \tag{3.1}$$

Recall $\lambda := \frac{k+1}{2(k-1)}$.

For a multi-index $i = (i_1, \dots, i_d) \in \mathbb{N}^d$, let $\partial^i f = \partial_1^{i_1} \cdots \partial_d^{i_d} f$ and $x^i := x_1^{i_1} \cdots x_d^{i_d}$. For $i, j \in \mathbb{N}^d$, we define the *GPT* M_{ij} by

$$M_{ij} := \int_{\partial B} y^j \phi_i(y)d\sigma(y), \tag{3.2}$$

where ϕ_i is defined by

$$\phi_i(x) := (\lambda I - \mathcal{K}_B^*)^{-1}\left(\frac{1}{i!}\nu_y \cdot \nabla y^i\right)(x), \quad x \in \partial B.$$

4. Derivation of the full asymptotic formula. In this section we derive our asymptotic formula (1.4). As stated in the introduction, we restrict our derivation to the case of a single inhomogeneity ($m = 1$). We only give the details when considering the difference between the fields corresponding to one and zero inhomogeneities. In order to further simplify notation we assume that the single inhomogeneity D has the form $D = \epsilon B + z$, where $z \in \Omega$ and B is a bounded Lipschitz domain in $\mathbb{R}^d$ containing the origin. Suppose that the conductivity of D is k. Let $\lambda := \frac{k+1}{2(k-1)}$. Then by (2.7) and (2.9), the solution u of (2.6) takes the form

$$u(x) = U(x) - N_D(\lambda I - \mathcal{K}_D^*)^{-1}\left(\frac{\partial H}{\partial \nu}|_{\partial D}\right)(x), \quad x \in \partial\Omega,$$

where U is the background potential given in (2.16).

Define

$$H_n(x) := \sum_{|i|=0}^{n} \frac{1}{i!}(\partial^i H)(z)(x-z)^i.$$

Here we use the multi-index notation $i = (i_1, \dots, i_d) \in \mathbb{N}^d$. Then we have from (2.10) that

$$\begin{aligned}\left\| \frac{\partial H}{\partial \nu} - \frac{\partial H_n}{\partial \nu} \right\|_{L^2(\partial D)} &\le \sup_{x \in \partial D} |\nabla H(x) - \nabla H_n(x)| |\partial D|^{1/2} \\ &\le \|H\|_{\mathcal{C}^{n+1}(\overline{D})} |x-z|^n |\partial D|^{1/2} \\ &\le C \|g\|_{L^2(\partial\Omega)} \epsilon^n |\partial D|^{1/2}.\end{aligned}$$

Note that

$$\text{if } \int_{\partial D} h d\sigma = 0, \text{ then } \int_{\partial D} (\lambda I - \mathcal{K}_D^*)^{-1} h d\sigma = 0. \tag{4.1}$$

If $\int_{\partial D} h d\sigma = 0$, then we have for $x \in \partial\Omega$ that

$$\begin{aligned}\left| N_D(\lambda I - \mathcal{K}_D^*)^{-1} h(x) \right| &= \left| \int_{\partial D} [N(x-y) - N(x-z)](\lambda I - \mathcal{K}_D^*)^{-1} h(y) d\sigma(y) \right| \\ &\le C\epsilon |\partial D|^{1/2} \|h\|_{L^2(\partial D)}.\end{aligned}$$

It then follows that

$$\begin{aligned}\sup_{x \in \partial D} \left| N_D(\lambda I - \mathcal{K}_D^*)^{-1} \left(\frac{\partial H}{\partial \nu}|_{\partial D} - \frac{\partial H_n}{\partial \nu}|_{\partial D} \right)(x) \right| &\le C\epsilon |\partial D|^{1/2} \left\| \frac{\partial H}{\partial \nu} - \frac{\partial H_n}{\partial \nu} \right\|_{L^2(\partial D)} \\ &\le C \|g\|_{L^2(\partial\Omega)} \epsilon^{d+n}.\end{aligned}$$

Therefore, we have

$$u(x) = U(x) - N_D(\lambda I - \mathcal{K}_D^*)^{-1} \left(\frac{\partial H_n}{\partial \nu}|_{\partial D} \right)(x) + O(\epsilon^{d+n}), \quad x \in \partial\Omega, \tag{4.2}$$

where the $O(\epsilon^{d+n})$ term is dominated by $C\|g\|_{L^2(\partial\Omega)}\epsilon^{d+n}$ for some C depending only on c_0. Note that

$$(\lambda I - \mathcal{K}_D^*)^{-1} \left(\frac{\partial H_n}{\partial \nu}|_{\partial D} \right)(x) = \sum_{|i|=1}^{n} (\partial^i H)(z) (\lambda I - \mathcal{K}_D^*)^{-1} \left(\frac{1}{i!} \nu_x \cdot \nabla (x-z)^i \right)(x).$$

Since $D = \epsilon B + z$, one can prove by using the change of variables $y = \frac{x-z}{\epsilon}$ and the expression of $\mathcal{K}_D^*$ defined as the L^2-adjoint of $\mathcal{K}_D$ that

$$(\lambda I - \mathcal{K}_D^*)^{-1} \left(\frac{1}{i!} \nu_x \cdot \nabla (x-z)^i \right)(x) = \epsilon^{|i|-1} (\lambda I - \mathcal{K}_B^*)^{-1} \left(\frac{1}{i!} \nu_y \cdot \nabla y^i \right) \left(\frac{1}{\epsilon}(x-z) \right).$$

Put

$$\phi_i(x) := (\lambda I - \mathcal{K}_B^*)^{-1} \left(\frac{1}{i!} \nu_y \cdot \nabla y^i \right)(x), \quad x \in \partial B. \tag{4.3}$$

Then we get

$$
\begin{aligned}
(4.4)\qquad & N_D(\lambda I - \mathcal{K}_D^*)^{-1}\left(\frac{\partial H_n}{\partial \nu}|_{\partial D}\right)(x) \\
&= \sum_{|i|=1}^{n} (\partial^i H)(z)\epsilon^{|i|-1} \int_{\partial D} N(x,y)\phi_i(\epsilon^{-1}(y-z))d\sigma(y) \\
&= \sum_{|i|=1}^{n} (\partial^i H)(z)\epsilon^{|i|+d-2} \int_{\partial B} N(x,\epsilon y+z)\phi_i(y)d\sigma(y).
\end{aligned}
$$

We now expand $N(x,\epsilon y+z)$ asymptotically as $\epsilon \to 0$. By (2.14) we have the following relation:

$$
\left(-\frac{1}{2}I + \mathcal{K}_\Omega\right)[N(\cdot,\epsilon y+z)](x) = \Gamma(x-z-\epsilon y) \quad \text{modulo constants}, \quad x \in \partial\Omega.
$$

Using the Taylor expansion

$$
\Gamma(x-\epsilon y) = \sum_{|j|=0}^{+\infty} \frac{(-1)^j}{j!}\epsilon^{|j|}\partial^j(\Gamma(x))y^j,
$$

we obtain

$$
\begin{aligned}
\left(-\frac{1}{2}I + \mathcal{K}_\Omega\right)[N(\cdot,\epsilon y+z)](x) &= \sum_{|j|=0}^{+\infty} \frac{(-1)^j}{j!}\epsilon^{|j|}\partial^j(\Gamma(x-z))y^j \\
&= \sum_{|j|=0}^{+\infty} \frac{(-1)^j}{j!}\epsilon^{|j|}\partial_x^j\left(\left(-\frac{1}{2}I + \mathcal{K}_\Omega\right)N(\cdot,z)(x)\right)y^j \\
&= \sum_{|j|=0}^{+\infty} \frac{1}{j!}\epsilon^{|j|}\left(\left(-\frac{1}{2}I + \mathcal{K}_\Omega\right)\partial_z^j N(\cdot,z)(x)\right)y^j \\
&= \left(-\frac{1}{2}I + \mathcal{K}_\Omega\right)\left[\sum_{|j|=0}^{+\infty} \frac{1}{j!}\epsilon^{|j|}\partial_z^j N(\cdot,z)y^j\right](x).
\end{aligned}
$$

Since $\int_{\partial\Omega} N(x,w)d\sigma(x) = 0 \ \forall\ w \in \Omega$, we have the following asymptotic expansion of the Neumann function, which is of independent interest.

LEMMA 4.1. *For $x \in \partial\Omega$, $z \in \Omega$, and $y \in \partial B$, and as $\epsilon \to 0$,*

$$
(4.5)\qquad N(x,\epsilon y+z) = \sum_{|j|=0}^{+\infty} \frac{1}{j!}\epsilon^{|j|}\partial_z^j N(x,z)y^j.
$$

We now have from (4.4)

$$
\begin{aligned}
& N_D(\lambda I - \mathcal{K}_D^*)^{-1}\left(\frac{\partial H_n}{\partial \nu}|_{\partial D}\right)(x) \\
&= \sum_{|i|=1}^{n} (\partial^i H)(z)\epsilon^{|i|+d-2} \sum_{|j|=0}^{+\infty} \frac{1}{j!}\epsilon^{|j|}\partial_z^j N(x,z) \int_{\partial B} y^j \phi_i(y)d\sigma(y).
\end{aligned}
$$

Observe that since H is a harmonic function in Ω we may compute

$$\sum_{|i|=l} \frac{1}{i!}(\partial^i H)(z)\Delta(y^i) = \Delta_y \left(\sum_{|i|=l} \frac{1}{i!}(\partial^i H)(z) y^i \right) = 0,$$

and therefore, by Green's theorem, it follows that

$$\int_{\partial B} \sum_{|i|=l} \frac{1}{i!}(\partial^i H)(z)\nabla(y^i)\cdot \nu(y)\, d\sigma(y) = 0.$$

Thus, in view of (4.3), the following identity holds by using observation (4.1):

$$\sum_{|i|=l} (\partial^i H)(z) \int_{\partial B} \phi_i(y) d\sigma(y) = 0 \quad \forall\, l \geq 1. \tag{4.6}$$

In fact, this follows immediately from (4.1). Recall now that

$$\epsilon^{d-2} N(x, \epsilon y + z) = \epsilon^{d-2} \sum_{|j|=0}^{n-|i|+1} \frac{1}{j!} \epsilon^{|j|} \partial_z^j N(x,z) y^j + O(\epsilon^{d+n-|i|}) \quad \forall\, i, 1 \leq |i| \leq n,$$

and on the other hand $M_{ij} = \int_{\partial B} y^j \phi_i(y) d\sigma(y)$ is the GPT associated with the domain B and the conductivity k to obtain the following pointwise asymptotic formula: For $x \in \partial\Omega$,

$$u(x) = U(x) - \epsilon^{d-2} \sum_{|i|=1}^{n} \sum_{|j|=1}^{n-|i|+1} \frac{1}{j!} \epsilon^{|i|+|j|} (\partial^i H)(z) M_{ij} \partial_z^j N(x,z) + O(\epsilon^{d+n}). \tag{4.7}$$

Observing that the formula (4.7) still contains $\partial^i H$ factors, we see that the remaining task is to convert (4.7) to a formula given solely by U and its derivatives.

As a simplest case, let us now take $n = 1$ to find the leading order term in the asymptotic expansion of $u|_{\partial\Omega}$ as $\epsilon \to 0$. From (2.7) and (2.17), we get

$$\|H - U\|_{L^\infty(\partial\Omega)} \leq C\epsilon^{\frac{d}{2}} \|\phi\|_{L^2(\partial D)} \leq C\epsilon^{\frac{d}{2}} \|g\|_{L^2(\partial\Omega)}$$

for some C depending only on Ω and c_0. It then follows from the maximum principle that

$$\|H - U\|_{L^\infty(\Omega)} \leq C\epsilon^{\frac{d}{2}} \|g\|_{L^2(\partial\Omega)}.$$

Then, from the mean value property of harmonic functions, we obtain

$$|\nabla H(z) - \nabla U(z)| \leq C\epsilon^{\frac{d}{2}} \|g\|_{L^2(\partial\Omega)}.$$

It thus follows from (4.7) that

$$u(x) = U(x) - \epsilon^d \sum_{|i|=1,|j|=1} (\partial^i U)(z) M_{ij} \partial^j N(x,z) + O(\epsilon^{d+1}), \quad x \in \partial\Omega, \tag{4.8}$$

which is, in view of (3.1), exactly the formula derived in [14] and [7] when D has $C^{1,\alpha}$ boundary.

We now return to (4.7). Recalling that by Green's theorem $U = -\mathcal{S}_\Omega(g) + \mathcal{D}_\Omega(U|_{\partial\Omega})$ in Ω, substitution of (4.7) into (2.8) immediately yields that, for any $x \in \Omega$,

(4.9)
$$H(x) = U(x) - \epsilon^{d-2} \sum_{|i|=1}^{n} \sum_{|j|=1}^{n-|i|+1} \frac{1}{j!} \epsilon^{|i|+|j|} (\partial^i H)(z) M_{ij} \mathcal{D}_\Omega(\partial_z^j N(\cdot, z))(x) + O(\epsilon^{d+n}).$$

In (4.9) the remainder $O(\epsilon^{d+n})$ is uniform in the $\mathcal{C}^n$ norm on any compact subset of Ω for any n, and therefore

$$(\partial^l H)(z) + \sum_{|i|=1}^{n} \epsilon^{d-2} \sum_{|j|=1}^{n-|i|+1} \epsilon^{|i|+|j|} (\partial^i H)(z) P_{ijl} = (\partial^l U)(z) + O(\epsilon^{d+n}) \tag{4.10}$$

$\forall\, l \in \mathbb{N}^d$ with $|l| \le n$, where

$$P_{ijl} = \frac{1}{j!} M_{ij} \partial_x^l \mathcal{D}_\Omega(\partial_z^j N(\cdot, z))|_{x=z}. \tag{4.11}$$

Define the operator

$$\mathcal{P}_\epsilon : (v_l)_{l \in \mathbb{N}^d, |l| \le n} \mapsto \left(v_l + \epsilon^{d-2} \sum_{|i|=1}^{n} \sum_{|j|=1}^{n-|i|+1} \epsilon^{|i|+|j|} v_i P_{ijl} \right)_{l \in \mathbb{N}^d, |l| \le n}.$$

Observe that

$$\mathcal{P}_\epsilon = I + \epsilon^d \mathcal{R}_1 + \cdots + \epsilon^{n+d-1} \mathcal{R}_{n-1}.$$

Defining the matrices $\mathcal{Q}_p, p = 1, \ldots, n-1$, by

(4.12)
$$(I + \epsilon^d \mathcal{R}_1 + \cdots + \epsilon^{n+d-1} \mathcal{R}_{n-1})^{-1} = I + \epsilon^d \mathcal{Q}_1 + \cdots + \epsilon^{n+d-1} \mathcal{Q}_{n-1} + O(\epsilon^{n+d})$$

for small ϵ, we finally obtain that

$$((\partial^i H)(z))_{i \in \mathbb{N}^d, |i| \le n} = \left(I + \sum_{p=1}^{n} \epsilon^{d+p-1} \mathcal{Q}_p \right) ((\partial^i U)(z))_{i \in \mathbb{N}^d, |i| \le n} + O(\epsilon^{d+n}), \tag{4.13}$$

which yields the main result of this paper stated in Theorem 1.1.

We also have a complete asymptotic expansion of the solutions of the Dirichlet problem.

THEOREM 4.2. *Suppose that the inhomogeneity consists of a single component, and let u be the solution of* (1.2) *with the Neumann condition replaced by the Dirichlet condition $u|_{\partial\Omega} = f$. Let V be the solution of $\Delta V = 0$ in Ω with $V|_{\partial\Omega} = f$. The following pointwise asymptotic expansion on $\partial\Omega$ holds for $d = 2, 3$:*

$$\begin{aligned} \frac{\partial u}{\partial \nu}(x) = {} & \frac{\partial V}{\partial \nu}(x) - \epsilon^{d-2} \sum_{|i|=1}^{n} \sum_{|j|=1}^{n-|i|+1} \frac{1}{j!} \epsilon^{|i|+|j|} \\ & \times \left[\left(\left(I + \sum_{p=1}^{n+2-|i|-|j|-d} \epsilon^{d+p-1} \mathcal{Q}_p \right) (\partial^l V(z)) \right)_i M_{ij} \partial_z^j \frac{\partial}{\partial \nu_x} G(x, z) \right] \\ & + O(\epsilon^{d+n}), \end{aligned} \tag{4.14}$$

where the remainders $O(\epsilon^{d+n})$ *are dominated by* $C\epsilon^{d+n}\|f\|_{H^{1/2}(\partial\Omega)}$ *for some* C *independent of* $x \in \partial\Omega$. *Here* $G(x,z)$ *is the Dirichlet Green function,* M_{ij}, $i,j \in \mathbb{N}^d$, *are the GPTs, and* $\mathcal{Q}_p$ *is the operator defined in* (4.12), *where* $\mathcal{P}_{ijk}$ *is defined, in this case, by*

$$P_{ijl} = \frac{1}{j!} M_{ij} \partial_x^l \mathcal{S}_\Omega \left(\partial_z^j \left(\frac{\partial}{\partial \nu_x} G \right)(\cdot, z) \right)|_{x=z}. \tag{4.15}$$

Theorem 4.2 can be proved in the exactly same manner as Theorem 1.1. We begin with Theorem 2.5. Then the same arguments give us

$$u(x) = V(x) - \epsilon^{d-2} \sum_{|i|=1}^{n} \sum_{|j|=1}^{n-|i|+1} \frac{1}{j!} \epsilon^{|i|+|j|} (\partial^i H)(z) M_{ij} \partial_z^j G(x,z) + O(\epsilon^{d+n}).$$

From this we can get (4.14) as before.

We conclude this paper by making a remark. The following formula is not exactly an asymptotic formula. However, since the formula is simple and has some potential applicability in solving the inverse conductivity problem, we make a record of it as a theorem.

THEOREM 4.3. *We have*

$$u(x) = H(x) + \epsilon^{d-2} \sum_{|i|=1}^{n} \sum_{|j|=1}^{n-|i|+1} \frac{1}{j!} \epsilon^{|i|+|j|} \partial^i H(z) M_{ij} \partial^j \Gamma(x-z) + O(\epsilon^{d+n}), \tag{4.16}$$

where $x \in \Omega_0$ *and the* $O(\epsilon^{d+n})$ *term is dominated by* $C\|g\|_{L^2(\partial\Omega)}\epsilon^{d+n}$ *for some* C *depending only on* c_0, *and* H *is given in* (2.8).

BROWNIAN TRAJECTORY IS A REGULAR LATERAL BOUNDARY FOR THE HEAT EQUATION*

N. V. KRYLOV†

Abstract. The one-dimensional heat equation in the domain $x > w_t$, $t > 0$, is considered. Here w_t is a trajectory of Brownian motion. For almost any trajectory, it is proved that if the boundary data are continuous, then the solution is continuous in the closure of the domain. The proof is based on Davis's law of square root for Brownian motion or on its weaker version, which is obtained by using the theory of stochastic partial differential equations.

1. Introduction and main results.

Let $w_t, t \geq 0$, be a one-dimensional Wiener process on a complete probability space $(\Omega, \mathcal{F}, P)$ and constants $T, \nu \in (0, \infty)$. Define

$$Q = Q(w.) = \{(t, x) : t \in (0, T), x > w_t\}.$$

This is a region depending on ω. For each fixed ω we consider the following boundary value problem:

$$u_t(t,x) + \frac{1}{2}\nu^2 u_{xx}(t,x) = 0, \quad (t,x) \in Q(w.), \tag{1.1}$$

$$u(t, w_t) = g(t, w_t) \quad \text{for} \quad t \in [0, T), \qquad u(T, x) = g(T, x) \quad \text{for} \quad x \geq w_T. \tag{1.2}$$

We assume that g is a bounded continuous function, and by solution u of (1.1)–(1.2) we mean Perron's or probabilistic solution. One of the main goals of this article is to prove the following result, saying that, with probability one, any point of the parabolic boundary of $Q(w.)$ is regular.

THEOREM 1.1. *There is a measurable set $\Omega' \subset \Omega$ such that $P(\Omega') = 1$ and for each $\omega \in \Omega'$, any continuous bounded g, and any $t_0 \in [0, T]$, we have*

$$\lim_{\substack{(t,x) \to (t_0, w_{t_0}) \\ (t,x) \in Q(w.)}} u(t,x) = g(t_0, w_{t_0}). \tag{1.3}$$

Parabolic equations in noncylindrical domains have been considered for quite some time, and many important results are known for them. We refer the interested reader to [1] and the very extensive bibliography in this book. Most of the literature treats the case of boundary which is Hölder (1/2+), and in this case it is possible to get Hölder estimates up to the boundary if g is Hölder continuous. However, a typical Wiener trajectory is only (1/2−) Hölder continuous. Therefore, in this article we only deal with regularity and not with Hölder estimates up to the boundary.

The best tractable conditions for the caloric regularity of a point on the lateral boundary are expressed in terms of Khinchin's law of the iterated logarithm or, more generally, Kolmogorov–Petrovskii criteria. However, Lévy's theorem says that (a.s.)

$$\varliminf_{\substack{h=t-s\downarrow 0\\ t,s\leq T}} \frac{w_t-w_s}{\sqrt{2h|\ln h|}}=-1,$$

so that, in particular, $w_{t+h}-w_t\leq -\sqrt{h|\ln h|}$ for appropriate t's in $[0,T]$ and as small $h>0$ as we like. Such functions are way off the range of applicability of Kolmogorov–Petrovskii criteria, and actually only chaotic behavior of Brownian trajectories saves the regularity. In section 2 we give the proof of Theorem 1.1 based on Theorem 1.5, which is a weak version of Davis's law of square root (see [2]).

THEOREM 1.2. *With probability one*

$$\inf_{t\in[0,T]} \varlimsup_{h\downarrow 0} \frac{w_{t+h}-w_t}{\sqrt{h}}=-1. \tag{1.4}$$

The author's interest in Theorem 1.1 arose from the theory of stochastic partial differential equations (SPDEs). To understand how it happened, consider the following situation. Take a number $\sigma\geq 0$ satisfying $\sigma^2<2$ and a nonnegative function $\zeta\in C_0^\infty(0,\infty)$ such that $\zeta(x)=1$ for $x\in[1,2]$. Let $f(t,x)$ be a solution of

$$df(t,x)=f_{xx}(t,x)\,dt+\sigma f_x(t,x)\,dw_t \tag{1.5}$$

for $t\in(0,T)$ and $x>0$ with zero lateral condition and with $f(0,x)=\zeta(x)$ for $x>0$. Here the lateral condition is understood in a certain generalized sense (we say more about it in section 3). Interestingly enough, the general theory of SPDEs developed in [11] implies that the solution f exists for any $\sigma^2<2$, but (a.s.) it is continuous up to the boundary, thus assuming the boundary data, only if $\sigma^2<1$. The author's numerous attempts failed to use the L_p-theory of SPDEs and get *any* information about the usual continuity of f up to the boundary if $1\leq\sigma^2<2$. One may attribute this failure to the fact that in the theory of SPDEs the moments of Hölder constants are estimated and, probably, for $1\leq\sigma^2<2$ the moments are infinite. Anyhow, Theorem 1.1 allows us to prove in section 3 (see Theorem 3.2) the continuity of f in $[0,T]\times[0,\infty)$ assuming that $\sigma^2<2$ and observing that the function $u(t,x):=f(t,\sigma(x-w_t))$ satisfies the equation

$$u_t=\frac{1}{2}\nu^2u_{xx}\quad\text{for}\quad x>w_t, t\in(0,T), \tag{1.6}$$

where $\nu^2=(2-\sigma^2)/\sigma^2$, which is not very different from (1.1).

Due to Theorems 1.1 and 3.2 it is natural to ask with which rate the boundary values are taken if the boundary data are smooth. We show some rather strong restrictions on the rate in section 5, the results of which are based on Theorem 1.2 and the properties of an explicit barrier function introduced in section 4. Actually again we need not Theorem 1.2 but only the fact that the left-hand side of (1.4) is strictly negative. In section 5 we show that the modulus of continuity of solutions to (1.1) even with smooth g can be as bad as we wish if ν is sufficiently small, and the same happens to (1.5) if σ^2 is below but sufficiently close to 2. In this way we get natural restrictions showing what cannot be proved.

The properties of the barrier function from section 4 also allow us to give a proof of the following deterministic result saying that the Hölder boundary regularity of

solutions to $u_t + (1/2)\nu^2 u_{xx} = 0$ for a ν implies the regularity for all ν. By C we denote the set of all real-valued continuous functions $x.$ given on $[0,\infty)$.

THEOREM 1.3. *Let a deterministic function $w.$ belong to C, let $\nu, \nu_0 \in (0,\infty)$, and let v be a Perron's or probabilistic solution of*

$$v_t(t,x) + \frac{1}{2}\nu_0^2 v_{xx}(t,x) = 0, \quad (t,x) \in Q(w.),$$

$$v(t,w_t) = g_0(t,w_t) \quad \text{for} \quad t \in [0,T), \quad u(T,x) = g_0(T,x) \quad \text{for} \quad x \geq w_T,$$

where g_0 is a nonnegative bounded continuous function such that $g_0(T,x) > 0$ for an $x > w_T$. Assume that for a $\lambda \in (0,1]$ and all $t \in [0,T]$ and $x \in (0,1]$, we have

$$v(t, x + w_t) \leq x^\lambda. \tag{1.7}$$

Finally, let u be a Perron's or probabilistic solution of (1.1)–(1.2) *with a bounded continuous function g. Then* (1.3) *holds for any $t_0 \in [0,T]$.*

Notice that if instead of (1.7) we just assume that (1.3) holds with v in place of u for any $t_0 \in [0,T]$, then the conclusion of Theorem 1.3 becomes false. This is easily shown by referring to Khinchin's law of the iterated logarithm.

The proof of Theorem 1.3, which we present in section 6, is based on two components. The first one is just a standard fact (see Lemma 2.1) that the solution of (1.1)–(1.2) is continuous at a point (t_0, w_{t_0}) on the lateral boundary if there is a parabola $t \geq t_0 + a^2(x - w_{t_0})^2$ with the pole at this point such that the boundary has common points with the (interior of the) parabola in any small neighborhood of the pole. This fact is quite similar to the exterior cone condition for elliptic equations, and, actually, it also holds in the situation when ν^2 is any Borel bounded function of (t,x) bounded away from zero. Although the proof of this generalization follows the same lines and is not much longer than that in the case of constant ν^2, we chose not to give it for the sake of brevity and because of the particular applications of our results to SPDEs. The referee of this paper kindly communicated to us how the continuity of solutions on the boundary for constant ν^2 can also be derived from the general necessary and sufficient condition of regularity proved in [4].

The second component is provided by the following result.

THEOREM 1.4. *Under the assumptions of Theorem* 1.3 *there exists a constant $c_0 \in (0,\infty)$ depending only on ν_0 and λ (see Remark* 6.1*) such that for all $t \in [0,T)$,*

$$\varlimsup_{h \downarrow 0} \frac{w_{t+h} - w_t}{\sqrt{h}} \geq -c_0. \tag{1.8}$$

We prove this theorem in section 6. Observe that if the left-hand side of (1.8) were too big negative at a point $t_0 \in [0,T)$, then there would exist a parabola $t \geq t_0 + a^2(x - w_{t_0})^2$ with large a such that its sufficiently small piece near the pole was inside of Q. Then the barrier from section 4 would imply that an opposite inequality holds in (1.7) for small $x > 0$ with $\lambda > 0$ tending to zero as $a \to \infty$.

Also in section 6, general existence and embedding theorems from the theory of SPDEs and the above discussed relation between (1.5) and (1.6) allow us to get Hölder continuity for solutions of the latter equation, which after combining with Theorem 1.4 allows us to give a proof of a relaxed version of the law of square root (of course, without using this law). This proof does a poor job in what concerns specifying the constant c_0, but the fact that $c_0 < \infty$ is explained qualitatively without computations.

By the "relaxed version" we mean the following fact in which $w_\cdot$ is the one-dimensional Wiener process from the beginning of the article.

THEOREM 1.5. (i) *There exists a constant $c_0 < \infty$ such that for any constant $T \in (0,\infty)$, we have (a.s.)*

$$\sup_{t\in(0,T]} \varliminf_{h\downarrow 0} \frac{w_t - w_{t-h}}{\sqrt{h}} \le c_0. \tag{1.9}$$

(ii) *One can take $c_0 = 2\sqrt{\pi}$. (Theorem 1.2 says that one can take $c_0 = 1$ and replace $\le$ with $=$ in (1.9).)*

2. Proof of Theorem 1.1. We start with the standard result we alluded to before Theorem 1.4.

LEMMA 2.1. *Take a deterministic function $w_\cdot \in C$ and assume that for any $t \in [0,T)$,*

$$\varliminf_{h\downarrow 0} \frac{w_{t+h} - w_t}{\sqrt{h}} =: -c(t) > -\infty. \tag{2.1}$$

Let g be a bounded continuous function. Then the probabilistic solution u of (1.1)–(1.2) satisfies (1.1) and assumes the boundary data (1.2). In particular, for any $t_0 \in [0,T]$, (1.3) holds.

Proof. Let B_t be a one-dimensional Wiener process (remember that here $w_\cdot$ is a fixed element of C). For $t, x \in \mathbb{R}$ also define

$$\tau(t,x) = \inf\{s > 0 : (t+s, x + \nu B_s) \notin Q\},$$

$$u(t,x) = Eg(t + \tau(t,x), x + \nu B_{\tau(t,x)}),$$

so that u is the probabilistic solution of (1.1)–(1.2).

Since B_t is a strong Markov process, for any box $P := (a,b) \times (c,d) \subset Q$ and $(t,x) \in P$, we have

$$u(t,x) = Eu(t + \gamma(t,x), x + \nu B_{\gamma(t,x)}),$$

where $\gamma(t,x) = \inf\{s > 0 : (t+s, x + \nu B_s) \notin P\}$. Therefore, it follows from [5] that u is infinitely differentiable in P and satisfies (1.1) there. Since $P \subset Q$ is arbitrary, u satisfies (1.1) in Q.

Now the only issue is that of the boundary values. Of course, as $t \uparrow T$ we have $T - t \ge \tau(t,x) \to 0$ and $u(t,x) \to g(t,x)$ for $x \ge w_T$ due to the continuity of g. However, the issue of the lateral boundary values is more delicate.

Observe that obviously $\tau(t,x)$ is a decreasing function of x, in particular, $\tau(t,x) \ge \tau(t,w_t)$ for $x \ge w_t$, and

$$u(t,x) \to Eg(t + \tau(t,w_t+), w_t + \nu B_{\tau(t,w_t+)})$$

as $x \downarrow w_t$, where

$$\tau(t,w_t+) \ge \tau(t,w_t).$$

Notice that by Blumenthal's 0-1 law, for any (t,x), we have that $P(\tau(t,x) = 0)$ equals 0 or 1. Furthermore, obviously, for $t \in [0,T)$, for $x = w_t$, and for any $h \in (0, T-t)$, we have

$$P(x + \nu B_h \le w_{t+h}) \le P(\tau(t,x) \le h).$$

Owing to (2.1), we can choose $h \in (0, T-t)$ as small as we like so that $w_{t+h} \geq x - 2c(t)\sqrt{h}$, and then

$$P(\nu B_h \leq -2c(t)\sqrt{h}) = P(x + \nu B_h \leq x - 2c(t)\sqrt{h}) \\ \leq P(x + \nu B_h \leq w_{t+h}) \leq P(\tau(t,x) \leq h).$$

Here the first expression is independent of h and is strictly positive. Hence

$$P(\tau(t, w_t) = 0) = \lim_{h \downarrow 0} P(\tau(t, w_t) \leq h) > 0,$$

which implies that $P(\tau(t, w_t) = 0) = 1$ by Blumenthal's 0-1 law.

The proof of the lemma would have stopped here if we knew a reference showing that the well-known boundary regularity results (see, for instance, [3], [6]) were true not only for strong Feller processes but also for processes with strong Feller resolvent. The author could not find such a reference in the literature and this is why, to show that for any $t \in [0, T)$, not only $\tau(t, w_t) = 0$ (a.s.) but also $\tau(t, w_t+) = 0$ (a.s.), we just repeat a standard argument from the theory of Markov processes (see, for instance, [3]). Define

$$v(t,x) = E\tau(t,x)$$

and notice that, for $s > 0, t \in [0, T)$, and $t + s \leq T$, by Markov property

$$Ev(t + s, x + \nu B_s) = E\tau_s(t,x) - s,$$

where

$$\tau_s(t,x) = \inf\{r > s : (t + r, x + \nu B_r) \notin Q\}.$$

Hence

$$E\tau_s(t,x) = s + \frac{1}{\sqrt{2\pi\nu^2 s}} \int_{\mathbb{R}} v(t+s, y) e^{-(y-x)^2/(2\nu^2 s)}\, dy,$$

which shows that $E\tau_s(t,x)$ is continuous in x. Furthermore, obviously $\tau_s(t,x) \downarrow \tau(t,x)$ as $s \downarrow 0$, and by the dominated convergence theorem (remember that $\tau_s(t,x) \leq T - t$) we have $E\tau_s(t,x) \downarrow E\tau(t,x)$. Since $E\tau_s(t,x)$ is continuous in x, we conclude that $E\tau(t,x)$ is upper semicontinuous in x for any $t \in [0, T)$. In particular,

$$E\tau(t, w_t+) = \overline{\lim_{x \downarrow w_t}} E\tau(t,x) \leq E\tau(t, w_t).$$

Here the right-hand side is zero by the above. Thus,

$$v(t, w_t+) = E\tau(t, w_t+) = 0$$

indeed. We assumed that $t < T$, but since $\tau(T, x) \equiv 0$, our conclusion holds for all $t \in [0, T]$

Now, observe that by Itô's formula, for $h(t,x) = t$, we have

$$h(t,x) = -v(t,x) + Eh(t + \tau(t,x), x + \nu B_{\tau(t,x)}),$$

so that the argument in the beginning of the proof shows that $v(t,x)$ is a continuous function in $Q \cup \{(0,x) : x > 0\}$. It is also continuous in $Q \cup \{(T,x) : x \geq w_T\}$

because $v(t,x) \le T - t \to 0$ as $t \uparrow T$. Finally, the functions $v(t, x + w_t)$ are continuous in $t \in [0,T]$ if $x > 0$ and for each t decrease to zero as $x \downarrow 0$. By Dini's theorem $v(t, x + w_t) \to 0$ as $x \downarrow 0$ uniformly in $t \in [0,T]$. In particular, $\tau(t,x) \to 0$ in probability as $Q \ni (t,x) \to (t_0, w_{t_0})$. After that, (1.3) follows from the definition of u and the continuity of g. The lemma is proved.

Remark 2.2. One can show that for each particular $t_0 \in [0,T)$, (1.3) holds if (2.1) holds only for $t = t_0$.

Now, Theorem 1.2 says that the conditions of Lemma 2.1 hold with $c(t) = 1$ for almost any trajectory $w.$ of the Wiener process. Hence, for almost any trajectory $w.$, the conclusion of this lemma holds no matter which continuous and bounded g we take. This is exactly the assertion of Theorem 1.1.

In the same way we get Theorem 1.1 from Theorem 1.5 after noticing that since $w_T - w_{T-t}$ is a Wiener process on $[0,T]$, (1.9) is equivalent to saying that (a.s.)

$$\inf_{t \in [0,T)} \varlimsup_{h \downarrow 0} \frac{w_{t+h} - w_t}{\sqrt{h}} \ge -c_0.$$

3. An application to SPDEs. Let $\sigma \ge 0$ be a number such that $\sigma^2 < 2$, and let ζ be a nonnegative function satisfying $\zeta \in C_0^\infty(0,\infty)$ and $\zeta(x) = 1$ for $x \in [1,2]$. Consider equation (1.5) for $t \in (0,T)$ and $x > 0$ with zero lateral condition and with $f(0,x) = \zeta(x)$ for $x > 0$.

Of course, by solution f we mean an appropriately measurable and integrable function $f = f(\omega, t, x)$ such that for any test function $\psi \in C_0^\infty(0,\infty)$,

$$(f(t,\cdot),\psi) = (\zeta,\psi) + \int_0^t (f(s,\cdot),\psi_{xx})\,ds - \sigma \int_0^t (f(s,\cdot),\psi_x)\,dw_s \tag{3.1}$$

(a.s.) for all $t \in [0,T]$, and where $(\cdot,\cdot)$ is the scalar product in L_2. This shows how the equation and the initial condition are understood. The condition that $f = 0$ on $x = 0$ is reflected in the requirement that f belong to an appropriate Banach space. To be a little bit more specific, if $r \ge 2$ and $\theta \in \mathbb{R}$ satisfy

$$1 - \frac{2}{(r-1)\sigma^2 + 2} < \frac{\theta}{r} < 1, \tag{3.2}$$

then by Theorem 3.3 of [11] equation (1.5) with given initial data admits a (unique) solution belonging to the class $\mathfrak{H}^\gamma_{r,\theta}(T)$ for all $\gamma \in \mathbb{R}$. Here γ is the number of derivatives of f in x, r is the power of summability in (ω,t,x), and θ is "responsible" for the rate with which the derivatives of f in x are allowed to blow up near $x = 0$. The precise definition of $\mathfrak{H}^\gamma_{r,\theta}(T)$, which we do not need in the present article, is given in [10] and [11]. The following fact is a direct consequence of the results in [12], [7], and [9].

LEMMA 3.1. *For almost any ω, the function $f(t,x)$ is infinitely differentiable in x, any of its derivatives with respect to x are continuous in (t,x) in the region $t \in [0,T], x > 0$, and, for any $x > 0$, (1.5) holds for $t \in (0,T)$.*

It may be worth noting that, of course, the assertions of the lemma refer to an appropriate modification of the solution rather than to the solution itself. Here is the main result of this section also stated for the modification.

THEOREM 3.2. *For almost any ω, we have*

$$\sup_{t \in [0,T]} |f(t,x)| \to 0 \quad \text{as} \quad x \downarrow 0.$$

What follows below in this section is aimed at proving this theorem. On the space C with Wiener measure W, introduce the coordinate process $x_t(x.) := x_t$, which is a Wiener process. For $t \geq 0$, $x \in \mathbb{R}$, and $x., y. \in C$, define

$$\tau(t, x, x., y.) = t \wedge \inf\{s \geq 0 : x + \nu x_s \leq y_{t-s}\},$$

where $y_r := 0$ for $r \leq 0$ and $\nu = \sigma^{-1}\sqrt{2 - \sigma^2}$. Then the probabilistic solution of (1.6) with zero lateral condition and with initial condition $\eta(x) := \zeta(\sigma x)$ is given by

$$u(t, x) = u(\omega, t, x) := v(w.(\omega), t, x),$$

where

$$v(y., t, x) := \int_C I_{\tau(t,x,x.,y.)=t}\, \eta(x + \nu x_t)\, W(dx.).$$

From Theorem 1.1, upon noticing that $u(T - t, x + w_T)$ solves (1.1)–(1.2) with $w_{T-t} - w_T$ in place of w_t and with $g = 0$ on the lateral boundary, we immediately get that $u(t, x/\sigma + w_t) \to 0$ as $x \downarrow 0$ uniformly in $t \in [0, T]$. Therefore, to prove the present theorem it suffices to show that $f = \bar{f}$ (a.s.), where

$$\bar{f}(t, x) := u(t, x/\sigma + w_t).$$

Observe that $\tau(t, x, x., y.)$ is a lower semicontinuous function of $\nu x. - y_{t-.}$ for each (t, x). Therefore by Fubini's theorem $v(y., t, x)$ is a Borel function of $y.$ and $u(t, x)$ is a random variable. Furthermore, $v(y., t, x)$ will not change if we change y_r for $r > t$. Therefore, $v(y., t, x)$ is $\sigma(y_r : r \leq t)$-measurable and $u(t, x)$ is $\mathcal{F}_t^w$-adapted, where $\mathcal{F}_t^w = \sigma(w_r : r \leq t)$. In addition u satisfies (1.6) and hence is infinitely differentiable in $[0, T] \times (0, \infty)$ and, in particular, continuous in (t, x) for any ω. Hence $\bar{f}$ satisfies the measurability properties required for solutions of (1.5). By using (1.6) and the fact that u is infinitely differentiable in (t, x) and by using the Itô–Wentzell formula, we get that with probability one, for all $t \in [0, T]$ and $x > 0$,

$$\bar{f}(t, x) = \zeta(x) + \int_0^t \bar{f}_{xx}(s, x)\, ds + \sigma \int_0^t \bar{f}_x(s, x)\, dw_s. \tag{3.3}$$

Next we want to pass from this pointwise equation to (3.1). For $\varepsilon > 0$ denote by $\Gamma(\varepsilon, w.)$ the two-dimensional ε-neighborhood of the graph of $w_t, t \in [0, T]$. Obviously $0 \leq u \leq 1$ and for such solutions of the heat equation it is known that, given $\varepsilon > 0$, any derivative of u with respect to (t, x) is bounded in

$$(t, x) \notin \Gamma(\varepsilon, w.), \quad x > w_t, \quad t \in [0, T],$$

by a constant depending only on ε and the order of the derivative. Therefore, if we take a $\psi \in C_0^\infty(0, \infty)$, then with probability one any derivative in x of $\bar{f}(t, x)$ is bounded and continuous in (t, x) whenever $x \in \operatorname{supp} \psi$ and $t \in [0, T]$. This allows us to use the stochastic Fubini's theorem and obtain (3.1) for $\bar{f}$ after multiplying (3.3) by $\psi(x)$ and integrating with respect to x.

Since f also satisfies (3.1) and there is uniqueness, to show that $f = \bar{f}$ we prove that $\bar{f}$ belongs to $\mathfrak{H}_{r,\theta}^\gamma(T)$.

LEMMA 3.3. *For $r \geq 1$ and $\theta \in (r - 1, r)$, we have $\bar{f} \in \mathbb{L}_{r,\theta-r}(T)$, that is,*

$$E \int_0^T \int_0^\infty x^{\theta-r-1} |\bar{f}(t, x)|^r\, dx dt < \infty.$$

Proof. Fix $t \in (0,T)$ and $x > 0$. By Hölder's inequality

$$E|\bar{f}(t,x)|^r \leq \int_\Omega \int_C I_{\gamma(t,x)=t}\, \zeta^r(x + \sigma\nu x_t + \sigma w_t)\, W(dx.)P(d\omega), \tag{3.4}$$

where

$$\begin{aligned}\gamma(t,x) &= \tau(t, x/\sigma + w_t, x., w.)\\ &= t \wedge \inf\{s \geq 0 : x/\sigma + w_t + \nu x_s \leq w_{t-s}\}\\ &= t \wedge \inf\{s \geq 0 : x + \sigma m_t + \sqrt{2-\sigma^2}\, x_s \leq 0\},\end{aligned}$$

and $m_s := w_t - w_{t-s}$ is a Wiener process with respect to $s \in [0,t]$. Denote

$$\sqrt{2}B_s = \sigma m_t + \sqrt{2-\sigma^2}\, x_s$$

and notice that B_t is a Wiener process on $\Omega \times C$,

$$\gamma(t,x) = t \wedge \inf\{s \geq 0 : x + \sqrt{2}B_s \leq 0\}.$$

Now, in a common abuse of notation we write E for the expectation sign on $\Omega \times C$ and rewrite (3.4) as

$$E|\bar{f}(t,x)|^r \leq E I_{\gamma(t,x)=t}\zeta^r(x + \sqrt{2}\, B_t) =: h(t,x).$$

We recognize h as the probabilistic solution of the heat equation $h_t = h_{xx}$, $t \in (0,T), x > 0$, with zero boundary condition and with initial condition ζ^r. From well-known estimates for solutions of such problems, we get that

$$|h(t,x)| \leq Nx \quad \text{for} \quad x \leq 1, \qquad |h(t,x)| \leq Ne^{-x} \quad \text{for} \quad x \geq 1,$$

where the constant N is independent of $t \in [0,T], x > 0$. The reader preferring probabilistic proofs can get the same estimates after noticing that the event $\gamma(t,x) = t$ coincides (a.s.) with $\inf_{s \leq t} B_s > -x/\sqrt{2}$ and the distribution of $(B_t, \inf_{s\leq t} B_s)$ is well known.

The above estimate of $E|\bar{f}(t,x)|^r$ immediately implies the assertion of the lemma. The lemma is proved.

From [10], [11] we know what the differentiating does to functions from $\mathbb{H}^\gamma_{r,\theta}(T)$ and obtain the following.

COROLLARY 3.4. *We have $\bar{f}_x \in \mathbb{H}^{-1}_{r,\theta}(T)$, $\bar{f}_{xx} \in \mathbb{H}^{-2}_{r,\theta+r}(T)$, so that $\bar{f}$ is an $\mathfrak{H}^0_{r,\theta}(T)$-solution of (1.5) if $\theta \in (r-1, r)$ and $r \geq 2$.*

Now since the initial data is smooth, the results of [10] show that $\bar{f} \in \mathfrak{H}^\gamma_{r,\theta}(T)$ for any γ if $\theta \in (r-1,r)$ and $r \geq 2$. Finally, uniqueness theorems (see, for instance, Lemma 4.3 of [10]) prove that no matter to which space $\mathfrak{H}^\gamma_{p,\tau}(T)$ the function f belongs, we have $f = \bar{f}$ for almost all $(\omega,t,x) \in \Omega \times [0,T] \times (0,\infty)$. Since both functions are continuous in (t,x), we conclude that (a.s.) $f(t,x) = \bar{f}(t,x)$ for all $t \in [0,T], x > 0$, and this brings the proof of Theorem 3.2 to an end.

4. A barrier function. For $c \geq 0$ consider the domain

$$D_c = \{(t,x) : t \in (0,1), x > -c\sqrt{1-t}\}$$

with the lateral boundary being the parabola

$$\Gamma_c := \{(t,x) : t \in [0,1], x = -c\sqrt{1-t}\}.$$

We will be interested in finding a nonnegative nontrivial solution of the heat equation

$$u_t = \frac{1}{2}u_{xx} \quad \text{in} \quad D_c \tag{4.1}$$

which is continuous in $\bar{D}_c$ and vanishes on Γ_c. If we look for u in the form $u(t,x) = f(t)\phi(y)$, where $y = x/\sqrt{1-t}$, then, by noticing that

$$u_t = f'\phi + \frac{y}{2(1-t)}f\phi', \quad u_x = \frac{1}{\sqrt{1-t}}f\phi', \quad u_{xx} = \frac{1}{1-t}f\phi'',$$

we find that u satisfies (4.1) if

$$f'\phi = \frac{f}{2(1-t)}\,(\phi'' - y\phi'),$$

that is, if there is a number λ such that

$$\frac{f'}{f} = -\frac{\lambda}{2(1-t)}, \quad t \in (0,1), \qquad \phi'' - y\phi' = -\lambda\phi, \quad y > -c.$$

The following argument is based on the results of [14]. According to [14] the function

$$\psi_0(\lambda,x) := \int_0^\infty p(x,r)r^{-\lambda-1}\,dr, \qquad p(x,r) := \exp(-rx - r^2/2),$$

satisfies $\phi'' - y\phi' = -\lambda\phi$ for all $x \in \mathbb{R}$ if $\lambda < 0$. By repeatedly integrating by parts, we see that for those λ and any $n = 0,1,2,\ldots$, we have $\psi_0(\lambda,x) = N(\lambda)\psi_n(\lambda,x)$, where

$$\psi_n(\lambda,x) := \int_0^\infty r^{n-\lambda-1}\frac{\partial^n}{(\partial r)^n}\,p(x,r)\,dr,$$

and $N(\lambda) \neq 0$. Hence $\psi_n(\lambda,x)$ also satisfies $\psi_n'' - y\psi_n' = -\lambda\psi_n$ for all $x \in \mathbb{R}$ if $\lambda < 0$. However, since both parts of the equation are obviously analytic in λ if $\Re\lambda < n$, the equation holds whenever $\lambda < n$. (Actually, this can be checked out by directly integrating back by parts and noticing that by Leibniz's formula

$$p_r^{(n+1)}(x,r) = -((x+r)p(r,x))_r^{(n-1)} = -(x+r)p_r^{(n)}(x,r) - np_r^{(n-1)}(x,r).\ )$$

We will be interested in $n = 1$ and $0 < \lambda < 1$ when

$$\psi_1(\lambda,x) = \int_0^\infty r^{-\lambda}\frac{\partial}{\partial r}\,[p(x,r) - 1]\,dr = -\lambda\phi(\lambda,x),$$

where

$$\phi(\lambda,x) := \int_0^\infty [1 - e^{-xr-r^2/2}]r^{-\lambda-1}\,dr. \tag{4.2}$$

It is seen that $\phi(\lambda,x)$ is a strictly increasing function of x, $\phi(\lambda,x) \geq \phi(\lambda,0) > 0$ for $x \geq 0$, $\phi(\lambda,x) \to \pm\infty$ as $x \to \pm\infty$. Hence, for any $\lambda \in (0,1)$, there exists a unique point $c(\lambda) > 0$ such that $\phi(\lambda,-c(\lambda)) = 0$. In addition,

$$\phi_x(\lambda,x) = \int_0^\infty e^{-xr-r^2/2}r^{-\lambda}\,dr > 0, \tag{4.3}$$

and, for $c = c(\lambda)$,

$$\phi_\lambda(\lambda, -c) = -\int_0^\infty [1 - e^{cr - r^2/2}] r^{-\lambda - 1} \ln(r/2c)\, dr < 0.$$

(Notice that the last integrand is nonnegative. The author learned this observation from M. Safonov.) It follows that $c(\lambda)$ is continuously differentiable and strictly decreasing for $\lambda \in (0,1)$. Therefore, the function $\lambda \to c(\lambda)$ is invertible. In this way we obtain part of the results in [14] where the properties of Sturm–Liouville problems are used. The remaining part of the following result is taken directly from [14]. At this point it is also worth noting that similar results for equation $\phi'' - x\phi' = -\lambda\phi$ not on half lines but on finite intervals are given in [13].

LEMMA 4.1. *For any $c > 0$ there exists a unique $\lambda = \lambda(c) \in (0,1)$ such that*

$$\int_0^\infty [1 - e^{cr - r^2/2}] r^{-\lambda - 1}\, dr = 0. \tag{4.4}$$

The function $\lambda(c)$ is differentiable and strictly decreasing on $(0,\infty)$. Finally ($a \sim b$ means $a/b \to 1$), we have $1 - \lambda(c) \sim c\sqrt{2/\pi}$ as $c \downarrow 0$ and $\lambda(c) \sim (2\pi)^{-1/2} ce^{-c^2/2}$ as $c \to \infty$.

Remark 4.2. There is a very indirect argument showing that (4.4) for $\lambda \in (0,1)$, $c > 0$ is equivalent to the equation

$$\int_0^1 \left[\frac{1}{\sqrt{1 - r^2}} e^{c^2 r/(1+r)} - 1 \right] r^{-\lambda - 1}\, dr = \frac{1}{\lambda}\,.$$

The author does not know any elementary proof of the equivalence.

Now we are ready to introduce a barrier function.

LEMMA 4.3. *Take $c \in (0,\infty)$, define $\lambda \in (0,1)$ as the unique solution of (4.4), and let*

$$v(t,x) := \int_0^\infty [1 - e^{-rx - (1-t)r^2/2}] r^{-\lambda - 1}\, dr, \quad (t,x) \in \bar{D}_c.$$

Then

(i) *v is infinitely differentiable in D_c, $v_x > 0$, $v_{xx} < 0$, and $v_t < 0$ in D_c, and v satisfies (4.1);*

(ii) *v is continuous in $\bar{D}_c$, increases and is concave in x, decreases in t, $v > 0$ in D_c, $v = 0$ on Γ_c;*

(iii) *$v(1,x) = Nx^\lambda$ for $x \geq 0$, where $N = \lambda^{-1}\Gamma(1-\lambda)$, and $v(t,0) = N_1(1-t)^{\lambda/2}$ for $t \in [0,1]$, where the constant $N_1 \in (0,\infty)$.*

Proof. Take the function $\phi(\lambda, x)$ according to (4.2). Then the substitution $r \to r\sqrt{1-t}$ shows that $(1-t)^{\lambda/2}\phi(\lambda, x/\sqrt{1-t}) = v(t,x)$ if $(t,x) \in \bar{D}_c$ and $t \neq 1$. This, together with what has been said before in this section, immediately implies all assertions in (i), perhaps apart from the ones concerning the signs of derivatives. However, the signs of (all) derivatives in x are obtained from (4.3), and then we get $v_t = (1/2)v_{xx} < 0$.

We also see that to prove (ii) we need only prove that v is continuous at the top of D_c. The continuity at points $t = 1, x > 0$ follows from the dominated convergence theorem. To consider the point $(1,0)$, observe that for any $\alpha > 0$,

$$\int_0^\infty [1 - e^{-\alpha r}] r^{-\lambda - 1}\, dr = \alpha^\lambda \int_0^\infty [1 - e^{-r}] r^{-\lambda - 1}\, dr = N\alpha^\lambda. \tag{4.5}$$

Then, for $(t,x) \in \bar{D}_c$, $t \neq 1$, we find

$$\begin{aligned} v(t,x) - v(1,0) = v(t,x) &= v(t,x) - \int_0^\infty [1 - e^{cr\sqrt{1-t} - r^2(1-t)/2}] r^{-\lambda-1}\, dr \\ &= \int_0^\infty e^{cr\sqrt{1-t} - r^2(1-t)/2} [1 - e^{-r(x+c\sqrt{1-t})}] r^{-\lambda-1}\, dr \\ &\le e^{c^2/2} \int_0^\infty [1 - e^{-r(x+c\sqrt{1-t})}] r^{-\lambda-1}\, dr = N(x + c\sqrt{1-t})^\lambda \to 0 \end{aligned}$$

as $(t,x) \to (1,0)$. This finishes the proof of (ii).

Obviously, assertion (iii) follows immediately from (4.5). The lemma is proved.

Now comes the main result of this section. It says that the modulus of continuity of solutions to the heat equation in a domain bounded by half parabola *is* affected by the slope of the parabola. Of course, we consider parabolas only with axes parallel to the t-axis and directed down with respect to the t-axis. This, together with Lemma 4.1, shows that if we have a nonnegative solution which is, say, λ-Hölder continuous in a domain, then the domain cannot contain parabolas that are too "wide" with poles on the boundary and the critical "width" is determined by λ.

LEMMA 4.4. *Let $c \in (0,\infty)$, $t_0 \in (0,\infty)$, and $x_0 \in \mathbb{R}$. Take an $a \in (0, t_0]$ and denote*

$$G_{c,a}(t_0,x_0) = \{(t,x) : t_0 - a < t < t_0, -c\sqrt{(t_0 - t)} < x - x_0 < 2\sqrt{a}\}.$$

Let $u(t,x)$ be a bounded continuous function given in $\bar{G}_{c,a}(t_0,x_0)$ and satisfying

$$\frac{1}{2} u_{xx} - u_t \le 0 \tag{4.6}$$

in $G_{c,a}(t_0,x_0)$ in the classical sense. Assume that $u \ge 0$ and $u \not\equiv 0$ in $G_{c,a}(t_0,x_0)$. Then there exists a constant $\delta > 0$ such that

$$u(t_0,x) \ge \delta (x - x_0)^{\lambda(c)}$$

for $0 \le x - x_0 \le \sqrt{a}$, where $\lambda(c)$ is introduced in Lemma 4.1.

Proof. Notice that the function

$$u(a(t-1) + t_0, x\sqrt{a} + x_0)$$

satisfies the assumption of the lemma with $t_0 = a = 1$ and $x_0 = 0$. Furthermore, the assertion of the lemma is also easily rewritten in terms of this new function. Therefore, without losing generality we assume that $t_0 = a = 1$ and $x_0 = 0$, so that u satisfies (4.6) in

$$G_c := G_{c,1}(1,0).$$

By the Harnack inequality, we have $u(t,1) > 0$ in a closed left neighborhood of 1. Then simple barriers show that for any $s_0 \in (0,1)$ sufficiently close to 1, there exists an $\varepsilon > 0$ such that

$$u(s_0,x) \ge \varepsilon (x + c\sqrt{(1 - s_0)})$$

for all $x \in [-c\sqrt{(1-s_0)}, 1]$ and $u(t,1) \ge \varepsilon$ for $t \in [s_0, 1]$. We fix appropriate $s_0 \in [3/4, 1)$ and $\varepsilon > 0$ and take $\lambda = \lambda(c) \in (0,1)$.

We also take the functions v from Lemma 4.3 and observe that $v(s_0,x)$ is a smooth function vanishing at $x=-c\sqrt{(1-s_0)}$. Therefore, there is a constant $\gamma>0$ such that

$$\gamma v(s_0,x)\leq\varepsilon(x+c\sqrt{(1-s_0)})\leq u(s_0,x).$$

By reducing $\gamma>0$ if necessary we can achieve the inequality $\gamma v(t,1)\leq u(t,1)$ for all $t\in[s_0,1]$. Then the inequality $v\leq u$ holds on the parabolic boundary of G_c, and by virtue of (4.6) and the maximum principle we have $\gamma v\leq u$ everywhere in $\bar{G}_c$. In particular, $u(1,x)\geq\gamma v(1,x)$ for $0\leq x\leq 1$, which, owing to Lemma 4.3(iii), yields our assertion. The lemma is proved.

Remark 4.5. One can get estimates for $u(t_0,x)$ from above as well. Let $c\in(0,\infty)$, $t_0\in(0,\infty)$, $a\in(0,t_0]$, and $x_0\in\mathbb{R}$. Let $u(t,x)$ be a bounded continuous function given in $\bar{G}_{c,a}(t_0,x_0)$ and satisfying

$$\frac{1}{2}u_{xx}-u_t\geq 0$$

in $G_{c,a}(t_0,x_0)$ in the classical sense. Also assume that $u\leq 0$ for $x-x_0=-c\sqrt{(t_0-t)}$ if $t_0-a\leq t\leq t_0$. Then by using the maximum principle, one easily obtains that there exists a constant $K>0$ such that $u(a(t-1)+t_0,x\sqrt{a}+x_0)\leq Kv(t,x)$ in the intersection of $\bar{G}_c$ with a neighborhood of $(1,0)$. It follows that there exists a constant N such that $u(t_0,x)\leq N(x-x_0)^{\lambda(c)}$ for $0\leq x-x_0\leq\sqrt{a}$, where $\lambda(c)$ is introduced in Lemma 4.1.

5. Lower estimates on the modulus of continuity of u and f on the boundary. In view of Lemma 4.1 the following theorem shows that the Hölder exponent of solutions to (1.1)–(1.2) can be extremely small if ν is small.

THEOREM 5.1. *Let $c>0$ be a constant, and let $0<\nu c<1$. Then there exists a measurable set $\Omega'\subset\Omega$ such that $P(\Omega')=1$ and for each $\omega\in\Omega'$, there exists an everywhere dense subset S of $[0,T]$ such that for any $t_0\in S$ and nonnegative continuous bounded g, satisfying $g(T,x)\not\equiv 0$ for $x>w_T$ (and, say, equal to zero whenever $x=w_t$ and $t\in[0,T]$), we have*

$$\lim_{x\downarrow w_{t_0}}\frac{u(t_0,x)}{(x-w_{t_0})^{\lambda(c)}}=\infty, \tag{5.1}$$

where u is the probabilistic solution of problem (1.1)–(1.2).

Proof. Obviously, it suffices to show that (a.s.) on each dyadic subinterval $[Tk2^{-n},T(k+1)2^{-n}]$ of $[0,T]$ there is a point t_0 such that (5.1) holds for any solution of (1.1) on $[Tk^{-n},T(k+1)2^{-n})$ in place of $[0,T)$ satisfying $u(T(k+1)2^{-n},x)\geq 0$ and $u(T(k+1)2^{-n},x)\not\equiv 0$. Due to self similarity of the heat equation and the Wiener process, the problem for each subinterval reduces to the one for $[0,1]$, and since there are only countably many dyadic subintervals, it suffices to prove the existence of S which is not everywhere dense but rather just nonempty.

Notice that

$$I:=\lim_{n\to\infty}\inf_{t\in[0,T/2]}\sup_{h\in(0,1/n]}\frac{w_{t+h}-w_t}{\sqrt{h}}=\inf_{n\geq 1}\inf_{t\in[0,T/2]}\sup_{h\in(0,1/n]}\frac{w_{t+h}-w_t}{\sqrt{h}}$$

$$=\inf_{t\in[0,T/2]}\inf_{n\geq 1}\sup_{h\in(0,1/n]}\frac{w_{t+h}-w_t}{\sqrt{h}}=\inf_{t\in[0,T/2]}\overline{\lim_{h\downarrow 0}}\frac{w_{t+h}-w_t}{\sqrt{h}}:=J.$$

Owing to (1.4), we have $J=-1$ (a.s.). Hence, there is a set Ω' of full probability on which $I=-1$. We take any $\omega\in\Omega'$ and a $c'\in(c,\nu^{-1})$. Then there exists $n\geq 1$ and $t_0\in[0,T/2]$ such that for $w_\cdot=w_\cdot(\omega)$,

$$\sup_{h\in(0,1/n]}\frac{w_{t_0+h}-w_{t_0}}{\sqrt{h}}\leq -c'\nu$$

or, equivalently, $w_{t_0+h}\leq x_0-c'\nu\sqrt{h}$ for $h\in(0,1/n)$, where $x_0=w_{t_0}$. It follows that the function $v(t,x)=u(t/\nu^2,x)$ satisfies the equation $v_t+(1/2)v_{xx}=0$ for

$$x>x_0-c'\sqrt{t-t_0}$$

and $0<t-t_0<a$, where $a=\nu^2/n$. After changing variables $t\to T-t$ we transform the equation $v_t+(1/2)v_{xx}=0$ into $v_t=(1/2)v_{xx}$ and get the possibility to apply Lemma 4.4, which leads to $u(t_0,x)\geq\delta(x-x_0)^{\lambda(c')}$ for small $x-x_0>0$ and to

$$\lim_{x\downarrow x_0}\frac{u(t_0,x)}{(x-x_0)^{\lambda(c)}}=\lim_{x\downarrow x_0}\frac{u(t_0,x)}{(x-x_0)^{\lambda(c')}}\frac{1}{(x-x_0)^{\lambda(c)-\lambda(c')}}=\infty,$$

where the last conclusion follows from the inequality $\lambda(c)>\lambda(c')$, which holds because λ is a strictly decreasing function. The theorem is proved.

Remark 5.2. The results of [13] show that actually (a.s.) S has a nonzero Hausdorff dimension, which is independent of ω.

Our last result shows that there are some nontrivial restrictions on the modulus of continuity on the boundary of solutions of SPDEs.

THEOREM 5.3. *Let f be the function introduced in section* 3 *as a solution of* (1.5)*, and let a constant c satisfy*

$$0<c\sqrt{2-\sigma^2}<\sigma.$$

Then with probability one there exists a dense subset $S\in[0,T]$, which is unrelated with f and is such that for any $t_0\in S$, we have

$$\lim_{x\downarrow 0}\frac{f(t_0,x)}{x^{\lambda(c)}}=\infty.$$

Proof. Notice that as we have seen in the proof of Theorem 3.2 the function $u(t,x):=f(t,\sigma(x-w_t))$ satisfies $u_t=(1/2)\nu^2u_{xx}$ for $x>w_t$, $t\in[0,T]$, where $\nu^2=(2-\sigma^2)/\sigma^2$. After that it only remains to either reverse time and refer to Theorem 5.1 or just repeat the proof of this theorem again using Lemma 4.4 and avoid any time change, since the lemma is stated for the "usual" heat equation. The theorem is proved.

6. Proofs of Theorems 1.3, 1.4, and 1.5.

Proofs of Theorems 1.3 *and* 1.4. First we deal with Theorem 1.4. Take a $t_0\in[0,T)$ and observe that the function $u(t,x)=v(T-t,\nu_0x)$ satisfies $u_t=(1/2)u_{xx}$ in

$$R:=\{(t,x):t\in(0,T),x>\nu_0^{-1}w_{T-t}\}.$$

Then take any $c\in(0,\infty)$ such that

$$\lambda(c)<\lambda. \tag{6.1}$$

We notice that the point $(T-t_0,\nu_0^{-1}w_{t_0})$ is on the parabolic boundary of R and claim that no matter how small $a>0$ is,

$$G_{c,a}(T-t_0,\nu_0^{-1}w_{t_0})\notin R.$$

Indeed, otherwise there would exist $a>0$ such that for any $c'\in(0,c)$, the function u would be continuous in $\bar{G}_{c',a}(T-t_0,\nu_0^{-1}w_{t_0})$ and satisfy $u_t=(1/2)u_{xx}$ in $G_{c',a}(T-t_0,\nu_0^{-1}w_{t_0})$. Then by Lemma 4.4 we would have

$$0<\varliminf_{x\downarrow0}\frac{u(T-t_0,x+\nu_0^{-1}w_{t_0})}{x^{\lambda(c')}}=\varliminf_{x\downarrow0}\frac{v(t_0,\nu x+w_{t_0})}{x^{\lambda(c')}}=:I.$$

However, if $\lambda(c')<\lambda$, then $I=0$ due to condition (1.7). We get a contradiction since $\lambda(c)<\lambda$ and, owing to the continuity of $\lambda(c)$, one can indeed choose $c'\in(0,c)$ so that $\lambda(c')<\lambda$.

Our claim just proved is equivalent to saying that for any $a\in(0,T-t_0)$, there exists $h\in(0,a)$ such that

$$\nu_0^{-1}w_{t_0}-c\sqrt{h}\le\nu_0^{-1}w_{t_0+h}.$$

It follows that

$$\overline{\varlimsup_{h\downarrow0}}\ \frac{w_{t_0+h}-w_{t_0}}{\sqrt{h}}\ge-c\nu_0. \tag{6.2}$$

This finishes the proof of Theorem 1.4.

Theorem 1.3 follows immediately from Theorem 1.4 and Lemma 2.1.

Remark 6.1. Equation (6.2) holds whenever $c>0$ and condition (6.1) is satisfied. The latter can be rewritten as $c>c(\lambda)$, where we define $c(1)=c(1-)=0$ and, for other $\lambda\in(0,1)$, by $c(\lambda)$ we mean the function introduced in section 4 before Lemma 4.1.

It follows that (1.8) holds with $c_0=\nu_0c(\lambda)$. By the way, Lemma 4.3 shows that this value of c_0 is sharp as long as all possible boundaries are allowed.

Proof of Theorem 1.5. We will be using some properties of the solution f to (1.5) introduced in section 3 for the parameters $r\ge2$ and θ satisfying (3.2). Again the exact definition of the spaces $\mathfrak{H}^\gamma_{r,\theta}(T)$ is not at issue here. What is important for us is that by Theorem 4.1 of [9] or by Theorem 2.7 of [12], if $2/r<\eta\le1$ and $\gamma\in\mathbb{R}$, then

$$E\sup_{t\le T}||M^{\eta-1}f(t,\cdot)||^r_{H^\gamma_{r,\theta}}<\infty$$

and, finally, by Lemma 2.2 of [9] or by Theorem 3.1 of [7] that

$$E\sup_{t\le T}\sup_{x>0}|x^{\eta-1+\theta/r}f(t,x)|^r<\infty.$$

Due to the arbitrariness in the choice of η and θ, we get that

$$E\sup_{t\le T,x>0}(x^{\varepsilon-\beta}|f(t,x)|)^r<\infty,\qquad\beta=\frac{2}{(r-1)\sigma^2+2}-\frac{2}{r},$$

where $\varepsilon>0$ is as small as we like. Important at this moment is that there are $\sigma\in(0,1)$, $r>2$, and $\varepsilon\in(0,\beta)$ such that $\beta>0$ and the event

$$B(\beta-\varepsilon):=\left\{\omega:\overline{\varlimsup_{x\downarrow0}}\sup_{t\in[0,T]}\frac{|f(t,x)|}{x^{\beta-\varepsilon}}<\infty\right\}$$

has full probability. We fix some $\sigma \in (0,1)$, $r > 2$, and $\varepsilon \in (0, \beta)$ such that $\beta > 0$. By the way, if $\sigma \geq 1$, then $\beta < 0$ for any $r > 0$.

Next, we remember that according to section 3, for $\omega \in \Omega'$ with $P(\Omega') = 1$, the function $u(t,x) := f(t, \sigma(x - w_t))$ satisfies $u_t = (1/2)\nu^2 u_{xx}$ for $x > w_t$, $t \in (0,T)$, where $\nu = \sigma^{-1}\sqrt{2-\sigma^2}$. Hence, for $\omega \in \Omega'$, the function $v(t,x) := u(T-t,x)$ satisfies $v_t + (1/2)\nu^2 v_{xx} = 0$ for $x > w_{T-t}$, $t \in (0,T)$.

Furthermore, if $\omega \in \Omega' \cap B(\beta - \varepsilon)$, then there is a constant $K = K(\omega)$ such that (1.7) is satisfied with v/K in place of v and $\beta - \varepsilon$ in place of λ. Therefore, by Theorem 1.4 and Remark 6.1 we have

$$\overline{\lim_{h \downarrow 0}} \frac{w_{T-(t+h)} - w_{T-t}}{\sqrt{h}} \geq -\nu c(\beta - \varepsilon)$$

whenever $\omega \in \Omega' \cap B(\beta - \varepsilon)$ and $t \in [0,T)$. This proves assertion (i) of Theorem 1.5 with $c_0 = \nu c(\beta - \varepsilon)$.

To prove assertion (ii) notice that, due to the above, one can take

$$c_0 = c_1 := \inf\{\nu c(\beta - \varepsilon) : \sigma \in (0,1), r \geq 2, \beta > 0, \varepsilon \in (0, \beta)\}.$$

Since $c(\lambda)$ is a continuous decreasing function, we have

$$c_1 = \inf\{\nu c(\beta) : \sigma \in (0,1), r \geq 2, \beta > 0\}.$$

Next, if $0 < \sigma < 1$, then the largest value of β is

$$\beta_0 = 2\,\frac{(1-\sigma)^2}{2-\sigma^2},$$

which occurs for $r = (2-\sigma^2)(\sigma - \sigma^2)^{-1}$. Notice that in similar computations in Remark 3.7 of [8] there is a misprint in the expression of β_0, which contains $1 - \sigma^2$ in the numerator in [8] instead of $(1-\sigma)^2$. Thus,

$$c_1 = \inf_{\sigma \in (0,1)} c\left(2\,\frac{(1-\sigma)^2}{2-\sigma^2}\right)\sigma^{-1}\sqrt{2-\sigma^2}.$$

We give an estimate for this inf by using Lemma 4.1 and letting $\sigma \downarrow 0$. Then we see that (a.s.)

$$c_1 \leq \lim_{\sigma \downarrow 0} c\left(2\,\frac{(1-\sigma)^2}{2-\sigma^2}\right)\sigma^{-1}\sqrt{2-\sigma^2} = \sqrt{\pi}\lim_{\sigma \downarrow 0}\sigma^{-1}\left(1 - 2\,\frac{(1-\sigma)^2}{2-\sigma^2}\right) = 2\sqrt{\pi}.$$

This proves assertion (ii) and the theorem.

Remark 6.2. It turns out that taking $\sigma = 0.31$ yields a slightly better approximation of c_1, but still very far from the sharp value of c_0, which is 1.

Acknowledgments. The author is sincerely grateful to D. Aronson, N. Jain, W. Littman, E. Perkins, M. Safonov, H. Weinberger, and O. Zeitouni for fruitful discussions. This article took its almost final form after the author gave a talk at the conference on Stochastic Partial Differential Equations, Levico Terme (Trento), 2002, and the author uses this opportunity to thank the organizers of the conference for the invitation. Finally, he wishes to thank the referee for several very useful comments.

CALIBRATION OF THE LOCAL VOLATILITY IN A GENERALIZED BLACK–SCHOLES MODEL USING TIKHONOV REGULARIZATION*

S. CRÉPEY†

Abstract. Following an approach introduced by Lagnado and Osher [*J. Comput. Finance*, 1 (1) (1997), pp. 13–25], we study Tikhonov regularization applied to an inverse problem important in mathematical finance, that of calibrating, in a generalized Black–Scholes model, a local volatility function from observed vanilla option prices.

We first establish $W_p^{1,2}$ estimates for the Black–Scholes and Dupire equations with measurable ingredients. Applying general results available in the theory of Tikhonov regularization for ill-posed nonlinear inverse problems, we then prove the stability of this approach, its convergence towards a minimum norm solution of the calibration problem (which we assume to exist), and discuss convergence rates issues.

Key words. options, calibration, ill-posed nonlinear inverse problem, Tikhonov regularization, parameter estimation, $W_p^{1,2}$ estimates

1. Introduction.

A quantity of fundamental importance to the trading of options on a stock S is the stochastic component in the evolution of the stock price, the so-called *volatility*. Obtaining estimates for the volatility is a major challenge for market finance. Unlike historical estimates of the volatility, based upon observations of the time-series of the stock price, calibration estimates rely upon the anticipation of the trading agents reflected in the prices of the traded option products derived from S. We consider in this article Tikhonov regularization applied to a widely studied inverse problem in mathematical finance, that of calibrating a local volatility function from a given set of option prices in a generalized Black–Scholes model.

This calibration problem has received intensive study in the last ten years; see, for instance, [19, 17, 18, 35, 1, 11, 8, 34, 2, 29, 24, 7, 14, 15, 4] and references therein. Notable approaches include entropy regularization (Avellaneda et al. [2]) or parametrix expansion (Bouchouev and Isakov [8]). In this paper, we shall focus upon the Tikhonov regularization method, following an approach introduced by Lagnado and Osher [29]. Jackson, Süli, and Howison [24] devised an implementation of this method with splines. Bodurtha and Jermakyan used linearization [7]. However, while most previous approaches adopted a numerical and empirical point of view, our aim is to establish a rigorous theoretical ground for this inverse problem in a partial differential equation framework.

Work corresponding to a first stage of this research has been published in my Ph.D. thesis [14, Part IV] (in French), while a preliminary version of this article has been published as a CMAP Internal Research Report [15]. A further article addresses an implementation of the method in a trinomial tree (explicit finite differences) setting and reports numerical experiments illustrating the stability of the local volatility function thus calibrated [16].

2. Preliminaries. In this section, we will give an informal presentation of the calibration problem and of the Tikhonov regularization method, provide an overview of the paper, and define the main notation and general assumptions.

2.1. Generalized Black–Scholes model. In market finance, a European *call* (respectively, *put*) option with maturity date T and strike K, on an underlying asset S, denotes a right to buy (respectively, sell), at price K, a unit of S at time T. Let us then consider a theoretical financial market, with two traded assets: cash, with constant interest rate r, and a risky stock, with diffusion price process

$$dS_t = S_t(\rho(t,S_t)dt + \sigma(t,S_t)dW_t)\ , \quad t > t_0\ ; \quad S_{t_0} = S_0\ .$$

Here W means a standard Brownian motion. Moreover, the stock is assumed to yield a continuously compounded dividend at constant rate q. Suppose finally that the market is liquid, nonarbitrable, and perfect. These assumptions mean, respectively, that first, there are always buyers and sellers; second, there can be no opportunity that a riskless investment can earn more than the interest rate of the economy r; and third, there are no restrictions of any kind on the sales and no transaction costs. Under these assumptions the market is complete. This means that any option can be duplicated by a portfolio of cash and stock. Moreover, a European call/put on S has a theoretical fair price within the model, which we will denote by $\Pi^{+/-}_{T,K}(t_0,S_0;r,q,a)$, where $a \equiv \sigma^2/2$, and

$$\Pi^{+/-}_{T,K}(t_0,S_0;r,q,a) = e^{-r(T-t_0)}\mathrm{E}_P^{t_0,S_0}(S_T-K)^{+/-}\ . \tag{2.1}$$

Here P denotes the so-called *risk-neutral* probability, under which

$$dS_t = S_t((r-q)dt + \sigma(t,S_t)dW_t)\ , \quad t > t_0\ ; \quad S_{t_0} = S_0\ . \tag{2.2}$$

Alternatively to the probabilistic representation (2.1), the prices $\Pi^{+/-}$ can be given as the solution to a differential equation. One can use either the *Black–Scholes* backward parabolic equation in the variables (t_0,S_0), which is

$$\left\{\begin{array}{l} -\partial_t\Pi - (r-q)S\partial_S\Pi - a(t,S)S^2\partial^2_{S^2}\Pi + r\Pi \ = \ 0, \quad t<T, \\ \Pi|_T \ \equiv \ (S-K)^{+/-}\ , \end{array}\right. \tag{2.3}$$

or the *Dupire* forward parabolic equation, in the variables (T,K), given by

$$\left\{\begin{array}{l} \partial_T\Pi - (q-r)K\partial_K\Pi - a(T,K)K^2\partial^2_{K^2}\Pi + q\Pi \ = \ 0, \quad T>t_0, \\ \Pi|_{t_0} \ \equiv \ (S_0-K)^{+/-}\ . \end{array}\right. \tag{2.4}$$

We will show in Lemma 4.1 and Theorem 4.3 that (2.1) or (2.3)–(2.4) hold for an arbitrary measurable, positively bounded local volatility function a. However, let us give a less formal insight by recalling the Black–Scholes seminal analysis [6], valid in the special case where the volatility depends on time alone. We consider a self-financing portfolio, short one option and long $\partial_S\Pi$ shares of the underlying stock. The value V of the risky component of the portfolio then evolves as

$$\begin{aligned} dV_t &= -d\Pi(t,S_t) + \partial_S\Pi(dS_t + qS_tdt) \\ &= -(\partial_t\Pi - qS\partial_S\Pi + aS^2\partial^2_{S^2}\Pi)dt \end{aligned}$$

from Itô's lemma. Since V has a deterministic rate of return, absence of opportunity of arbitrage implies that this rate equals the riskless interest rate r. Otherwise said,

$$-\partial_t\Pi + qS\partial_S\Pi - aS^2\partial^2_{S^2}\Pi = r(-\Pi + S\partial_S\Pi)\ ,$$

whence (2.3). As for (2.1), it can be viewed as the Feynman–Kac representation for the solution of (2.3). Notice that this analysis does not rely on the specific character of the payoff of the call or put option. However, the opposite is true for (2.4). It is indeed, as noticed by Dupire [19], a Fokker–Planck equation integrated twice with respect to the space variable K, using moreover the formal identity

$$\partial^2_{K^2}(S_0 - K)^{+/-} \equiv \delta_{S_0}(K) \ ,$$

where δ_{S_0} denotes the Dirac mass at S_0.

2.2. Direct and inverse problems. In the special case where the volatility, $a \equiv \sigma^2/2$, is a constant, or a function of time alone, explicit formulas for the prices $\Pi^{+/-}$ are known (see Black and Scholes [6] or Merton [31]). But in the case of a general local volatility function $a(t, S)$, one must turn to finite differences or a Monte Carlo procedure based upon (2.3)–(2.4) or (2.1). Moreover, observation teaches that no constant or merely time-dependent local volatility function is consistent with most sets of market quotes. This phenomenon is known by market practitioners as the *smile of implied volatility*.

However, in practice it is not the local volatility that is known but the prices themselves. In fact the local volatility is the only quantity in (2.1) or (2.3)–(2.4) which cannot be obtained from the market. Indeed r and q, as well as, to some extent, Π, can all be retrieved from market-quoted quantities. Consequently, one usually wishes to solve the inverse problem: finding $a(t, S)$ such that the theoretical prices given by (2.1) or (2.3)–(2.4) match the observed option prices. We thus use liquid quotations of actively traded options, which are usually referred to as *vanilla* options, as a way to extract information about the future behavior of the underlying asset. The calibrated local volatility function is then used by risk managers or traders to value risk exposure, or price *exotic* (nonvanilla) options and calculate hedge ratios consistently with the market.

This is the problem we will be concerned with here. In particular, there are two cases which are commonly considered in the literature, and we will treat both in parallel. In the first one, this matching is required to occur on the actual, hence finite, set of pairs (T, K) with observed prices. In the second case, the matching is required to occur over all (T, K) such that $T \geq t_0, \ K > 0$. This makes sense, for example, if the actual set of observed prices has been interpolated. To distinguish between these two cases, we will refer to the first as the *discrete* calibration problem and the second as the *continuous* calibration problem.

2.3. The Tikhonov regularization method. Both the discrete and continuous calibration problems are ill-posed. This is the case in the continuous calibration problem because the solution depends upon the data in an unstable manner, and in the discrete calibration problem because the full surface $a(t, S)$ is simply underdetermined by the discrete data. It is then necessary to introduce stabilizing procedures in the reconstruction method for the local volatility function. One of these is known as the Tikhonov regularization method [38, 21]. The idea is to tackle the calibration problem as a minimization problem, where the cost criterion to be minimized is

$$J_\alpha(a) \equiv d(\Pi(a), \pi)^2 + \alpha\rho(a, a_0)^2 \ .$$

Here $d(\Pi(a), \pi)$ denotes a distance between the model prices $\Pi(a)$ and the observed prices π, α is the regularization parameter, and ρ is a penalty designed to keep a

close to the so-called *prior* a_0, which reflects a priori information about a. Following Lagnado and Osher [29], we shall choose $\rho(a, a_0)^2 \equiv \|a - a_0\|^2_{H^1}$, where

$$\|u\|^2_{H^1} \equiv \int\int u^2 + \|\nabla u\|^2,$$

which is the H^1-(squared) norm of u with logarithmic variables $t, y = \ln(S)$.

2.4. Overview. We first study, in an appropriate functional analysis setting, Black–Scholes and Dupire linear parabolic equations with measurable ingredients (sections 3 and 4). These are linear one-dimensional equations in nondivergence form, with positively bounded dominant coefficients. We thus extend well-known results when the dominant coefficient a is a regular function. Mixing the probabilistic pointwise and L_p estimates of Krylov [26] with the analytic $W^{1,2}_p$ estimates of Fabes [23] and Stroock and Varadhan [37], we obtain $W^{1,2}_p$ estimates for the equations with source terms. Using the theory of L_p-viscosity solutions [10, 13], we then show that our equations admit unique solutions, for which we provide a probabilistic representation (Theorems 4.2 and 4.3).

Proposition 5.1 sums up the main properties of the pricing functional Π useful for the study of the calibration problems, namely, compactness, twice Gâteaux differentiability and stability with respect to perturbations of parameters. We can then apply the general theory of Tikhonov regularization for ill-posed nonlinear inverse problems [21, 22, 27, 32, 33] to both the continuous and discrete calibration problems. We thus prove the stability of the method for arbitrary values of the regularization parameter (section 5). Assuming the existence of a solution of the calibration problem, we prove the convergence of the method towards an a_0-minimum norm solution when the regularization parameter tends to 0, and we exhibit conditions sufficient to ensure convergence rates in $\mathrm{O}(\sqrt{\delta})$, where δ is the data noise (section 6).

2.5. Main notation and general assumptions. To avoid much repetition, we define now a set of notation and related general assumptions that will be assumed to hold throughout the paper. When stronger assumptions are required, they will be stated explicitly in the body of the paper.

General notation.

- $x \wedge y$, $x \vee y$: $\min(x, y)$, $\max(x, y)$.
- x^+, x^-: $\max(x, 0)$, $\max(-x, 0)$.
- $C, C', \ldots, C \equiv C_\rho(\rho_1, \ldots, \rho_n)$: Constants $C, C', \ldots$ depending upon nothing but the parameters $\rho, \rho_1, \ldots, \rho_n$.

One should be aware that these constants may vary with the context. We will also use the notation "$\equiv$" for "denotes" or "equals identically" (that is, equality between functions), according to the context.

Mathematical finance.

- S, $y = \ln(S)$: Lognormal underlying diffusion in financial and logarithmic variables.
- $q, r \in [0, R]$: Dividend yield attached to S, short rate of the economy.
- $a \equiv \sigma^2/2$, a_0: Local volatility function, prior a_0 on a.
- $\underline{a}$, $\overline{a}$, $\hat{a}$: Bounds on a_0 and a such that $0 < \underline{a} < \overline{a}$, $\hat{a} \equiv (\underline{a} + \overline{a})/2$.
- $\overline{p} \equiv \overline{p}(\underline{a}, \overline{a})$: A real in $]2, 3[$ depending upon $\underline{a}$ and $\overline{a}$; see Theorem 4.2.
- W: Standard Brownian motion.
- $Q =]\underline{t}, \overline{T}[\times \mathbb{R}$: A plane strip on which a is defined, in logarithmic variables.

- $(t_0, y_0), (T, k)$: Points in $\overline{Q}$, with $t_0 \leq T$.
- $\overline{y}_0, \overline{k}$: Bounds on $|y_0|$, $|k|$.
- Q_{t_0}, Q^T: $Q \cap \{t > t_0\}$, $Q \cap \{t < T\}$.
- $\overline{Q}_{t_0}$, $\overline{Q}^T$: Closures of Q_{t_0}, Q^T.
- $\Pi^{+/-}_{T,K}(t_0, S_0; r, q, a)$, $\Pi^{+/-}_{T,k}(t_0, y_0; r, q, a)$: The price, in a generalized Black–Scholes model, for a European call/put option with maturity T and strike $K = e^k$, at the current phase $t_0, S_0 = e^{y_0}$, in financial and logarithmic variables.
- $\gamma_{t_0,y_0}(t, y; r, q, a)$: Transition probability density discounted at rate r (that is, $e^{-r(t-t_0)}\times$ the density), for the underlying diffusion in logarithmic variable y.
- $BS^{+/-}_{Q^T}(k; r, q, a)$, $BS'_{Q^T}(r, q, a; \Gamma)$, $DUP^{+/-}_{Q_{t_0}}(y_0; r, q, a)$: Black–Scholes call/put equation on Q^T, Black–Scholes derived equation with source term Γ, Dupire call/put equation on Q_{t_0}; see section 3.2.

To alleviate notation, r, q, a will sometimes be abbreviated to a; $\Pi^{+/-}_{T,K}(t_0, S_0; a)$ or $\Pi^{+/-}_{T,k}(t_0, y_0; a)$ to $\Pi^{+/-}$; $BS^{+/-}_{Q^T}(k; a)$, $BS'_{Q^T}(a; \Gamma)$, $DUP^{+/-}_{Q_{t_0}}(y_0; a)$, and $\gamma_{t_0,y_0}(t, y; a)$ to $BS^{+/-}$, BS', $DUP^{+/-}$, and γ, respectively.

In the case of the call option, we will sometimes drop the $^+$ superscript. For instance, by default, Π will refer to Π^+.

Functional analysis.

- Ω: Regular by parts, open plane area.
- p, θ: Real $p \in]2, +\infty[$, $\theta \equiv 1 - 2/p > 0$.
- $L_p(\Omega)$, $L_{p,loc}(\Omega)$, $H^1(\Omega)$, $H^2(\Omega)$, $W^1_p(\Omega)$, $W^{1,2}_p(\Omega)$, $W^{1,2}_{p,loc}(\Omega)$, $\mathcal{C}^0_\theta(\overline{\Omega})$, $\mathcal{D}(\overline{\Omega})$: Sobolev spaces on Ω; see section 3.1.
- Γ: Element of $L_p(Q)$.
- $\mathcal{M}_Q(\underline{a}, \overline{a})$: Set of real measurable functions on Q with bounds $\underline{a}$ and $\overline{a}$.
- $a_0 + H^1_Q(\underline{a}, \overline{a})$: Set of functions in $a_0 + H^1(Q)$ with bounds $\underline{a}$ and $\overline{a}$.
- h, h': Elements of $H^1(Q)$.
- $\mathcal{E} \rightarrow$: Convergence in the topology of the space $\mathcal{E}$.
- $\|X\|$, $\|X\|_{\mathcal{E}}$: Euclidean norm of X, norm of X in the surrounding normed space $\mathcal{E}$.
- $\langle X, Y\rangle$, $\langle X, Y\rangle_{\mathcal{E}}$: Inner product of X and Y in the surrounding Euclidean space, Hilbert space $\mathcal{E}$.
- $d\Pi(a).h$: Derivative in the direction h of the functional Π at the local volatility function a.
- $d\Pi(a)^\star$: Adjoint operator of $h \mapsto d\Pi(a).h$; see section 6.2.
- $\nabla J(a)$: Gâteaux derivative of the cost criterion J at the local volatility function a.

For instance, if J denotes a cost criterion on a Hilbert space $\mathcal{E}$, then in our notation

$$\langle \nabla J(a)\ , h\rangle_{\mathcal{E}} \ = \ dJ(a).h\ , \quad h \in \mathcal{E}\ .$$

In the same way, the general assumptions we have made above on a and a_0 can be stated as

$$a_0, a \in \mathcal{M}_Q(\underline{a}, \overline{a})\ .$$

Finally, we will refer to the statements in Remark 3.5 and Lemma 4.1(3) as *symmetry* and *parity*, respectively.

3. Strong solutions of parabolic problems.

3.1. Functional spaces and Sobolev embeddings. Let us first introduce some Hilbert and Banach spaces, which we will use as spaces of local volatility functions and solutions of Black–Scholes and Dupire equations.

Given the open plane area Ω, we will denote by $\mathcal{D}(\overline{\Omega})$ the space of traces on Ω of regular functions with compact support in the plane. We will use the usual Hilbert spaces $H^2(\Omega) \subset H^1(\Omega) \subset L_2(\Omega)$ and the Banach spaces $\mathcal{C}^0_\theta(\overline{\Omega})$, $L_p(\Omega)$, $W^1_p(\Omega)$, $W^{1,2}_p(\Omega)$, where

$$\begin{aligned}
\|u\|_{\mathcal{C}^0_\theta(\overline{\Omega})} &= \sup_{(t,y)\in\overline{\Omega}} |u| \;+\; \sup_{(t,y)\neq(t',y')\in\overline{\Omega}} \frac{|u(t,y)-u(t',y')|}{|t-t'|^\theta + |y-y'|^\theta};\\
\|u\|_{W^1_p(\Omega)} &= \|u\|_{L_p(\Omega)} \;+\; \|\partial_t u\|_{L_p(\Omega)} \;+\; \|\partial_y u\|_{L_p(\Omega)};\\
\|u\|_{W^{1,2}_p(\Omega)} &= \|u\|_{L_p(\Omega)} \;+\; \|\partial_t u\|_{L_p(\Omega)} \;+\; \|\partial_y u\|_{L_p(\Omega)} \;+\; \|\partial^2_{y^2} u\|_{L_p(\Omega)}\,.
\end{aligned}$$

Finally, we will denote by $W^{1,2}_{p,loc}(\Omega)$ the localized Fréchet space of functions which belong to $W^{1,2}_p(\Omega')$ for every regular open bounded subset Ω' with $\overline{\Omega}' \subset \Omega$.

Now we have the following Sobolev embeddings, for which the reader is referred, for instance, to Larrouturou and Lions [30]:

1. For Ω bounded or half-plane,

$$W^1_p(\Omega) \hookrightarrow \mathcal{C}^0_\theta(\overline{\Omega})\,. \tag{3.1}$$

This embedding notably implies the existence of a unique continuous extension up to the boundary for the strong solutions introduced by item 1 of Definition 3.1 below.

2. For Ω bounded,

$$H^1(\Omega) \hookrightarrow L_p(\Omega)\,. \tag{3.2}$$

This embedding, called the Rellich–Kondrakov embedding, is *compact*, which means that it maps weakly convergent sequences into strongly convergent ones.

Let us now present the definitions of a solution of a partial differential equation that we will need. For more about these definitions, the reader is referred to Ladyzhenskaya, Solonnikov, and Ural'tseva [28], Crandall, Kocan, and Swiech [13], Wang [39], Caffarelli et al. [10], and Crandall, Ishii, and Lions [12].

DEFINITION 3.1. *Let there be a linear parabolic equation on $\overline{\Omega}$, with measurable ingredients and a continuous boundary condition on $\partial_p\Omega$, the parabolic boundary of Ω.*

1. *We call a function a* strong solution in $L_p(\Omega)$*, or an* $L_p(\Omega)$-solution*, if it is a function in $W^{1,2}_p(\Omega)$, which satisfies the boundary condition, and solves the equation almost everywhere. We also use this definition with $W^{1,2}_{p,loc}(\Omega)$ to define a* strong solution in $L_{p,loc}(\Omega)$*, or an* $L_{p,loc}(\Omega)$-solution.

2. *We call a function an* $L_{p,loc}(\Omega)$-viscosity solution *if it is a continuous function on $\overline{\Omega}$, which satisfies the boundary condition, and solves the equation in the viscosity meaning for test functions in $W^{1,2}_{p,loc}(\Omega)$.*

The relations between these definitions of a solution are as follows (see Crandall, Kocan, and Swiech [13]):

1. An $L_{p,loc}(\Omega)$-solution is an $L_{p,loc}(\Omega)$-viscosity solution.

2. Conversely, an $L_{p,loc}(\Omega)$-viscosity solution that belongs to $W^{1,2}_{p,loc}(\Omega)$ is an $L_{p,loc}(\Omega)$-solution.

The following theorem gathers the main properties of the Sobolev spaces on plane strips that we will need.

THEOREM 3.2.

1. *$H^1(Q)$ is continuously embedded in $L_p(Q)$.*
2. *$\mathcal{D}(\overline{Q})$ is dense in $L_p(Q)$, $H^1(Q)$, $H^2(Q)$.*
3. *The application*

$$\mathcal{D}(\overline{Q}) \times \mathcal{D}(\overline{Q}) \ni (u, v) \mapsto (u|_{\partial Q}, \partial_n v) \in L_2(\partial Q)^2 \ ,$$

where $\partial_n v$ denotes the normal derivative, admits a unique linear continuous extension, called trace*, from $H^1(Q) \times H^2(Q)$ to $L_2(\partial Q)^2$.*

4. *The set of traces on ∂Q of functions of $H^1(Q) \times H^2(Q)$ forms a dense subset of $L^2(\partial Q)^2$, and we have the so-called* generalized Green formula *for every $(u, v) \in H^1(Q) \times H^2(Q)$:*

$$-\int\int_Q u\ (\Delta v) \ = \ \int\int_Q \langle \nabla u, \nabla v \rangle \ - \ \int_{\partial Q} u\ \partial_n v \ .$$

Proof. These properties result from the analogous properties well known on open half-planes (see, for instance, Larrouturou and P. L. Lions [30], Bensoussan and J.-L. Lions [3]). For details, the reader is referred to Crépey [14, Theorem F.1] and the proof given therein. □

In the upcoming proofs, we will often be able to proceed by density thanks to the following lemma.

LEMMA 3.3. *There exist Lipschitzian functions $a_n \in \mathcal{M}_Q(\underline{a}, \overline{a})$ ($n \in \mathbb{N}^\star$) such that a_n converges to a in $L_{p,loc}(Q)$ when $n \to +\infty$.*

Proof. This follows from standard mollification with compact support, applied to a extended by zero outside Q (see, for instance, Brézis [9]). □

3.2. Black–Scholes, Dupire, and derived equations. Let us now introduce the main equations in this work.

DEFINITION 3.4.

1. *We define the Black–Scholes call/put equation, $BS^{+/-}_{Q^T}(k; r, q, a)$, with backward logarithmic variables $(t, y) \in \overline{Q}^T$, parameterized by (T, k), as*

$$\left\{ \begin{array}{l} -\partial_t \Pi - (r - q - a(t,y))\, \partial_y \Pi - a(t,y) \partial^2_{y^2} \Pi + r\Pi \ = \ 0 \quad \text{on } Q_T \ , \\ \Pi|_T = (e^y - e^k)^{+/-} \ . \end{array} \right.$$

We also define the Black–Scholes derived equation with source term Γ, $BS'_{Q^T}(r, q, a; \Gamma)$, as

$$\left\{ \begin{array}{l} -\partial_t (\delta\Pi) - (r - q - a(t,y))\, \partial_y (\delta\Pi) - a(t,y) \partial^2_{y^2} (\delta\Pi) + r(\delta\Pi) \ = \ \Gamma \quad \text{on } Q_T \ , \\ \delta\Pi|_T \ \equiv \ 0 \ . \end{array} \right.$$

2. *We define the Dupire call/put equation, $DUP^{+/-}_{Q_{t_0}}(y_0; r, q, a)$, with forward logarithmic variables (T, k), at the current phase (t_0, y_0), as*

$$\left\{ \begin{array}{l} \partial_T \Pi_{T,k} - (q - r - a(T,k)) \partial_k \Pi_{T,k} - a(T,k) \partial^2_{k^2} \Pi_{T,k} + q \Pi_{T,k} \ = \ 0 \quad \text{on } Q_{t_0} \ , \\ \Pi|_{t_0} \ \equiv \ (e^{y_0} - e^k)^{+/-} \ . \end{array} \right.$$

3. *Finally, we define the diffusion underlying the previous problems, with logarithmic variables, as*

$$dy_t \;=\; \left(r-q-\frac{\sigma(t,y_t)^2}{2}\right)\,dt+\sigma(t,y_t)\;dW_t\;,\qquad y_{t_0}\;=\;y_0\;. \tag{3.3}$$

Remark 3.5 (symmetry). Changing, moreover, the direction of time T, via $\tau\equiv\overline{T}+t_0-T$, $\check{\phi}(\tau,k)\equiv\phi(T,k)$ for any function ϕ, then $DUP^{+/-}_{Q_{t_0}}(y_0;r,q,a)$ becomes $BS^{-/+}_{Q_{t_0}}(y_0;q,r,\check{a})$.

LEMMA 3.6.

1. *(Black–Scholes and Dupire equations.) Equations $BS^{+/-}$ have at most one $L_{p,loc}(Q^T)$-solution Π such that $|\Pi|\le K\vee S$.*

2. *(Derived equations.) For any $L_p(Q^T)$-solution $\delta\Pi$ of BS', we have*

$$\|\delta\Pi\|_{\mathcal{C}^0_\theta(\overline{Q}^T)}\;\le\;C'\;\|\delta\Pi\|_{W^{1,2}_p(Q^T)}\;, \tag{3.4}$$

where $C'\equiv C'_p$. Moreover, $\delta\Pi$ is also the unique $L_{p,loc}(Q^T)$-solution of BS' which converges to 0 when $|y|\to+\infty$, uniformly with t.

Proof. 1. Given two such solutions Π and Π', let us define $\delta\Pi\equiv e^{-2y+\rho t}(\Pi-\Pi')$, where $\rho=r+2\overline{a}$. By linearity, $\delta\Pi$ is an $L_{p,loc}(Q^T)$-solution of

$$\left\{\begin{array}{l}-\partial_t\delta\Pi-(r-q+3a)\,\partial_y\delta\Pi-a\partial^2_{y^2}\delta\Pi+(2q+2\overline{a}-2a)\delta\Pi=0,\\ \delta\Pi|_T\;\equiv\;0\;.\end{array}\right. \tag{3.5}$$

Moreover, let us fix $\varepsilon>0$. One can choose $Y_\varepsilon\ge1/\varepsilon$ such that for $|y|\ge Y_\varepsilon$, we have $|\delta\Pi(t,y)|\le 2e^{-2y+\rho t}(K\vee e^y)\le\varepsilon$, uniformly with $t\in[\underline{t},T]$. Then $|\delta\Pi|\le\varepsilon$ on $Q^T\cap\{|y|\le Y_\varepsilon\}$, by the maximum principle in Crandall, Kocan, and Swiech [13, Proposition 2.6]. So $\delta\Pi\equiv0$ on Q^T by passage to the limit when $\varepsilon\to0$.

2. By the same maximum principle as above, we have uniqueness in the class of $L_{p,loc}(Q^T)$-solutions of BS' which converge to 0 when $|y|\to+\infty$, uniformly with t. Now, let us be given an $L_p(Q^T)$-solution $\delta\Pi$ of BS'. Since the solution $\delta\Pi$ is continuous on $\overline{Q}^T$ and vanishes at T, it may be identified with an element of $W^1_p(\Omega)$, where $\Omega\equiv\,]\underline{t},+\infty[\times\mathbb{R}$, by extension with 0 on the right of T. Estimate (3.4) then follows from the Sobolev embedding (3.1) on the half-plane Ω. Finally, $\delta\Pi\in\mathcal{C}^0_\theta(\overline{Q}^T)\cap L_p(Q^T)$ converges to 0 when $|y|\to+\infty$, uniformly with t. ∎

4. Existence, uniqueness, and probabilistic representation of solutions.

4.1. Diffusion. The following lemma links the price of a European call/put with the discounted expectation of the corresponding payoff in a generalized Black–Scholes model.

LEMMA 4.1.

1. *The diffusion equation (2.2) has a unique weak solution on $]t_0,\overline{T}[$:*

$$S_t\;=\;S_0\;e^{(r-q)(t-t_0)}\;\exp\left(\int_{t_0}^t\sigma(s,S_s)dW_s-\frac{1}{2}\int_{t_0}^t\sigma^2(s,S_s)ds\right)\;,\quad t\in\,]t_0,\overline{T}[,$$

where the last exponential is a martingale, under the risk-neutral probability P. In particular,

$$E_P^{t_0,S_0}S_t=S_0e^{(r-q)(t-t_0)}\;,\quad t\in\,]t_0,\overline{T}[\;. \tag{4.1}$$

2. *The price* $\Pi^{+/-}$ *equals the payoff expectation of the call/put at* T*, discounted at rate* r*:*

$$\Pi^{+/-} = e^{-r(T-t_0)} E_P^{t_0,S_0} \left(S_T - K\right)^{+/-}$$

under the risk-neutral probability P*. In particular,* $0 \le \Pi \le S_0$*.*

3. *Denoting* $\Pi^+ - \Pi^-$ *by* $\delta\Pi$*, we have*

$$\delta\Pi \equiv S_0 e^{-q(T-t_0)} - K e^{-r(T-t_0)} \ .$$

This relation, known as call/put parity*, notably implies that* $\partial^2_{S^2}\delta\Pi$*,* $\partial^2_{K^2}\delta\Pi$*,* $(\partial^2_{y^2} - \partial_y)\delta\Pi$*, and* $(\partial^2_{k^2} - \partial_k)\delta\Pi$ *all vanish identically.*

Proof. 1. For the proof, see, for instance, Stroock and Varadhan [37, Exercise 7.3.3] and Karatzas and Shreve [25, Problem 5.6.15 and Corollary 3.5.13].

2. and 3. The expression for $\Pi^{+/-}$ then follows from Karatzas and Shreve [25, section 5.8.A]. Using this expression, the bounds on Π and the call/put parity proceed from (4.1). ∎

4.2. Derived hedge equations with source terms. The following theorem and the estimate (4.3) therein are the cornerstones of this article. The difficulty comes from the lack of regularity of the local volatility function a, which is merely required to be measurable and positively bounded. But this turns out to be sufficient in the present one-dimensional linear framework. Recall that Γ denotes an element of $L_p(Q)$.

THEOREM 4.2. *There exists* $\overline{p} \equiv \overline{p}(\underline{a}, \overline{a}) \in \,]2,3[$ *such that if* $p \in \,]2, \overline{p}[$*, then, when* (t,y) *varies within* $\overline{Q}^T$*,*

$$\delta\Pi(t,y) \ = \ E_P^{t,y} \int_{s=t}^{T} e^{-r(s-t)} \Gamma(s, y_s)\ ds \tag{4.2}$$

is the only $L_p(Q^T)$*-solution, or* $L_{p,loc}(Q^T)$*-solution converging to* 0 *when* $|y| \to +\infty$*, uniformly with* t*, of* $BS'_{Q^T}(a;\Gamma)$*.*

Moreover,

$$\|\delta\Pi\|_{\mathcal{C}^0_\theta(\overline{Q}^T)} \ \le \ C' \ \|\delta\Pi\|_{W_p^{1,2}(Q^T)} \ \le \ C'C \ \|\Gamma\|_{L_p(Q^T)} \ , \tag{4.3}$$

where $C' \equiv C'_p$ *is as in* (3.4)*, and* $C \equiv C_p(\underline{t}, \overline{T}; R, \underline{a}, \overline{a})$*.*

Proof. For the moment, $p \in \,]2, +\infty[$. We first show that for $\varphi \in W_p^{1,2}(Q^T)$,

$$\|\varphi\|_{W_p^{0,1}(Q^T)} \ \le \ C_p \ \|\varphi\|^{1/2}_{W_p^{0,2}(Q^T)} \ \|\varphi\|^{1/2}_{L_p(Q^T)} \ . \tag{4.4}$$

Inequality (4.4) can be more readily seen on the following equivalent norms:

$$\|\varphi\|^p_{\widetilde{W}_p^{0,j}(Q^T)} \ \equiv \ \sum_{k \le j} \|\partial^k_{y^k}\varphi\|^p_{L_p(Q^T)} \ , \quad 0 \le j \le 2 \ .$$

Indeed, by integration over time of a classic Sobolev inequality (see, for instance, Bensoussan and J.-L. Lions [3, Chapter 2, equation (5.8)]):

$$\|\varphi\|^p_{\widetilde{W}_p^{0,1}(Q^T)} = \int_{t=\underline{t}}^{T} \|\varphi(t,\cdot)\|^p_{\widetilde{W}_p^1(\mathbb{R})} \ dt$$

$$\begin{aligned}
&\le C_p^p \int_{t=\underline{t}}^T \|\varphi(t,\cdot)\|^{p/2}_{\widetilde{W}^2_p(\mathbb{R})} \, \|\varphi(t,\cdot)\|^{p/2}_{L_p(\mathbb{R})} \, dt \\
&\le C_p^p \left(\int_{t=\underline{t}}^T \|\varphi(t,\cdot)\|^{p}_{\widetilde{W}^2_p(\mathbb{R})} \, dt \right)^{1/2} \left(\int_{t=\underline{t}}^T \|\varphi(t,\cdot)\|^{p}_{L_p(\mathbb{R})} \, dt \right)^{1/2} \\
&= C_p^p \, \|\varphi\|^{p/2}_{\widetilde{W}^{0,2}_p(Q^T)} \, \|\varphi\|^{p/2}_{L_p(Q^T)}
\end{aligned}$$

by the Cauchy–Schwarz inequality. This shows (4.4), which in turn implies

$$\|\varphi\|_{W^{0,1}_p(Q^T)} \;\le\; rC_p \|\varphi\|_{W^{0,2}_p(Q^T)} + C_p(r) \|\varphi\|_{L_p(Q^T)} \tag{4.5}$$

for every fixed $r > 0$, provided $C_p(r) \le C_p/4r$.

On the other hand, since (3.3) admits a unique weak solution (see item 1 of Lemma 4.1), then from Krylov [26, Theorem 2.4.5.a (proof) and Theorem 2.4.1]

$$E_P^{t,y} \int_t^T e^{-r(s-t)} |\Gamma(s, y_s)| \, ds \le C \, \|\Gamma\|_{L_p(Q^T)} \, , \tag{4.6}$$

where $C \equiv C_p(\underline{t}, T, R, \underline{a}, \overline{a})$.

We now assume that φ is an $L_p(Q^T)$-solution of $BS'_{Q^T}(a; \Gamma)$. For $\varepsilon > 0$, let τ_ε denote the exit time of $Q^T \cap \{|y| \le 1/\varepsilon\}$ for the y-process (3.3). It can be shown that (4.6) implies the following probabilistic representation:

$$E_P^{t,y} e^{-r(\tau_\varepsilon - t)} \varphi(\tau_\varepsilon, y_{\tau_\varepsilon}) - \varphi(t,y) \;=\; - E_P^{t,y} \int_{s=t}^{\tau_\varepsilon} e^{-r(s-t)} \Gamma(s, y_s) \, ds \, . \tag{4.7}$$

This has been shown by Bensoussan and J.-L. Lions [3, Chapter 2, section 8.3] in a variational context. We do not reproduce the proof here, though it proceeds in a similar fashion, using regularization and Itô's classic formula.

When $\varepsilon \to 0$, τ_ε almost surely converges to T. Moreover, φ is bounded and continuous. Estimate (4.6) then implies, through dominated convergence on the left- and right-hand sides of (4.7),

$$\varphi(t,y) = E_P^{t,y} \int_{s=t}^T e^{-r(s-t)} \Gamma(s, y_s) \, ds. \tag{4.8}$$

Then, from Krylov [26, Theorem 2.4.5.a],

$$\|\varphi\|_{L_p(Q^T)} \;\le\; C \, \|\Gamma\|_{L_p(Q^T)} \, , \tag{4.9}$$

where $C \equiv C_p(\underline{t}, T, R, \underline{a}, \overline{a})$. The probabilistic representation (4.8), for any a priori $L_p(Q^T)$-solution φ of $BS'_{Q^T}(a; \Gamma)$, also shows the consistency of such a priori solutions across various values of $p > 2$.

Moreover, by linearity, such an a priori solution φ is the $L_p(Q^T)$-solution of the equation $-\partial_t \varphi - \hat{a} \partial^2_{y^2} \varphi \;=\; \hat{\Gamma}$, where

$$\hat{\Gamma} \;=\; \Gamma - r\varphi + (r - q - a(t,y)) \partial_y \varphi + (a - \hat{a}) \partial^2_{y^2} \varphi \, ,$$

with homogeneous terminal condition. Therefore, following Stroock and Varadhan [37, Exercise 7.3.3, p. 211], we have the following estimate:

$$\begin{aligned}
&\|\partial^2_{y^2} \varphi\|_{L_p(Q^T)} \;\le\; C_p(\hat{a}) \\
&\times \left(\|\Gamma\|_{L_p(Q^T)} + R \|\varphi\|_{L_p(Q^T)} + (R + \overline{a}) \|\partial_y \varphi\|_{L_p(Q^T)} + \frac{1}{2} (\overline{a} - \underline{a}) \|\partial^2_{y^2} \varphi\|_{L_p(Q^T)} \right),
\end{aligned} \tag{4.10}$$

where $C_p(\hat{a})$ is a log-convex, hence continuous, function of $1/p$, also defined at $p = 2$, such that

$$C_{p=2}(\hat{a}) = \frac{1}{\hat{a}} < \frac{2}{\underline{a}}.$$

Therefore one can choose $\overline{p} \equiv \overline{p}(\underline{a}, \overline{a}) \in]2, 3[$ such that $C_p(\hat{a}) \leq \frac{2}{\underline{a}}$ if $p \in]2, \overline{p}[$. Estimate (4.3), at least with T instead of $\overline{T}$ in C, then results from (4.10), (4.5), (4.9), and (3.4). We will refer to the estimate (4.3) with T instead of $\overline{T}$ in C as *the temporary version* of estimate (4.3).

We now show the existence of an $L_p(Q^T)$-solution φ of $BS'_{Q^T}(a; \Gamma)$ in the special case where $\Gamma \in \mathcal{D}(\overline{Q}^T)$ by density using Lemma 3.3: Define $p' \equiv (2 + p)/2$. Following Fabes [23], $BS'_{Q^T}(a_n; \Gamma)$ admits an $L_p(Q^T) \cap L_{p'}(Q^T)$-solution φ_n. By the temporary version of estimate (4.3) and by successive extractions, one can find a subsequence $\varphi_{n'}$ that converges to a limit φ, weakly in $W_p^{1,2}(Q^T)$ or $W_{p'}^{1,2}(Q^T)$ and locally uniformly on $\overline{Q}^T$. By $W_p^{1,2}(Q^T)$-weak passage to the limit, φ inherits the temporary version of estimate (4.3). Then φ is an $L_p(Q^T)$-solution of $BS'_{Q^T}(a; \Gamma)$ by Lemma A.1. The general case where $\Gamma \in L_p(Q^T)$ follows straightaway by density using item 2 of Theorem 3.2.

Let us now consider the $L_p(Q)$-solution $\tilde{\varphi}$ of $BS'_Q(a; \widetilde{\Gamma})$, where $\widetilde{\Gamma} \equiv \Gamma/0$ on the left/right of T. By linearity and uniqueness of solutions of BS', $\tilde{\varphi}$ vanishes on Q_T, and $\tilde{\varphi}$ is equal to φ on Q^T. Therefore, the estimate (4.3) for φ on Q^T results from the temporary version of estimate (4.3) for $\tilde{\varphi}$ on Q. □

4.3. Homogeneous valuation equations. The following theorem is formally well known. When the local volatility function a is Hölderian (with logarithmic variables), it has indeed been justified by many authors. For instance, Dupire [19] and Bouchouev and Isakov [8] used partial differential equation arguments involving fundamental solutions. Alternatively, El Karoui [20] and Crépey [14, section 4.1, Part IV] used probabilistic arguments involving local time. We also refer the reader to Crépey [14, section 4.1, Part IV] and Berestycki, Busca, and Florent [4] for results in the case where a is uniformly continuous. Here, we prove the more general case where $a \in \mathcal{M}_Q(\underline{a}, \overline{a})$. This is indeed the case that will be relevant for the study of the calibration problems.

THEOREM 4.3. *Assume $p \in]2, \overline{p}[$. Then the following hold:*

1. *The call price*

$$\overline{Q}^T \ni (t, y) \mapsto \Pi_{T,k}(t, y; a)$$

is the unique $L_{p,loc}(Q^T)$-solution between 0 and S of $BS_{Q^T}(k; a)$. Moreover, it is convex and nondecreasing with respect to S, nondecreasing with the local volatility, and converges to 0 when $S \to 0$, uniformly with t.

2. *The call price*

$$\overline{Q}_{t_0} \ni (T, k) \mapsto \Pi_{T,k}(t_0, y_0; a)$$

is the unique $L_{p,loc}(Q_{t_0})$-solution between 0 and S_0 of $DUP_{Q_{t_0}}(y_0; a)$. Moreover, it is convex and nonincreasing with respect to K, nondecreasing with the local volatility, and converges to 0 when $K \to +\infty$, uniformly with T. Finally, for almost every $t > t_0$, the y-process (3.3) admits a transition probability density between t_0 and t. Discounting this density at rate r, it becomes

$$\gamma_{t_0,y_0}(t, y; a) \equiv e^{-y}(\partial_{y^2}^2 - \partial_y)\Pi_{t,y}(t_0, y_0; a) \ . \tag{4.11}$$

Proof. We proceed by density from the known case of a Lipschitzian function a_n approximating a as in Lemma 3.3. Denoting $(p+\overline{p})/2$ by p', let $\hat{\Pi}$, respectively, Π_n, be the strong solution in $L_{p,loc}(Q^T) \cap L_{p',loc}(Q^T)$ between 0 and S of $BS_{Q^T}(k;\hat{a})$, respectively, $BS_{Q^T}(k;a_n)$.

Since $2 < p < p' < \overline{p} < 3$, it is well known that

$$(\partial^2_{y^2} - \partial_y)\hat{\Pi} \in L_p(Q^T) \cap L_{p'}(Q^T)$$

(see, for instance, Crépey [14, Remark 4.1, Part IV]). Therefore, using Theorem 4.2, there exists an $L_p(Q^T) \cap L_{p'}(Q^T)$-solution $\delta\Pi$ of $BS'_{Q^T}(a;\Gamma)$, where $\Gamma \equiv (a-\hat{a})(\partial^2_{y^2} - \partial_y)\hat{\Pi}$. By linearity, $\Pi \equiv \hat{\Pi} + \delta\Pi$ is then a strong solution in $L_{p,loc}(Q^T) \cap L_{p',loc}(Q^T)$ of $BS_{Q^T}(k;a)$. Moreover,

$$(\partial^2_{y^2} - \partial_y)\Pi \equiv (\partial^2_{y^2} - \partial_y)\hat{\Pi} + (\partial^2_{y^2} - \partial_y)\delta\Pi \in L_p(Q^T) \cap L_{p'}(Q^T)\ .$$

Denote $\Pi_n - \hat{\Pi}$ by $\delta_n\Pi$. By linearity, symmetry, parity, and the results of the theorem in the Lipschitzian case, $\delta_n\Pi$ converges to 0 when $|y| \to +\infty$, uniformly with t, and $\delta_n\Pi$ is a strong solution in $L_{p,loc}(Q^T) \cap L_{p',loc}(Q^T)$ of $BS'_{Q^T}(a_n;\Gamma_n)$, where $\Gamma_n \equiv (a_n - \hat{a})(\partial^2_{y^2} - \partial_y)\hat{\Pi}$. Therefore, by Theorem 4.2, $\delta_n\Pi$ is the strong solution in $L_p(Q^T) \cap L_{p'}(Q^T)$ of $BS'_{Q^T}(a_n;\Gamma_n)$. So $\Pi_n - \Pi = \delta_n\Pi - \delta\Pi$ is the strong solution in $L_p(Q^T) \cap L_{p'}(Q^T)$ of $BS'_{Q^T}(a_n;\Gamma'_n)$, where

$$\Gamma'_n \equiv \Gamma_n - \Gamma + (a_n - a)(\partial^2_{y^2} - \partial_y)\delta\Pi = (a_n - a)(\partial^2_{y^2} - \partial_y)\Pi.$$

Furthermore, Γ'_n converges to 0 in $L_p(Q^T)$ when $n \to +\infty$. Indeed, having fixed $\varepsilon > 0$, let us choose a subset $Q_\varepsilon \equiv Q^T \cap \{|y| \le Y_\varepsilon\}$ such that $\|(\partial^2_{y^2} - \partial_y)\Pi\|_{L_p(Q^c_\varepsilon)} \le \varepsilon$, where $Q^c_\varepsilon \equiv Q^T \setminus Q_\varepsilon$. By Hölder's inequality, it follows, thanks to Lemma 3.3, that

$$\|\Gamma'_n\|^p_{L_p(Q^T)} \le (\|(\partial^2_{y^2} - \partial_y)\Pi\|^p_{L_{p'}(Q^T)} + (\overline{a} - \underline{a})^p)\varepsilon^p$$

for n large enough.

Using estimate (4.3) applied to $\Pi_n - \Pi$, Π then inherits the bounds on Π_n. So $BS^+_{Q^T}(k;a)$ admits an $L_{p,loc}(Q^T)$-solution $\Pi^+ \equiv \Pi$ between 0 and S. Similarly, $BS^-_{Q^T}(k;a)$ admits an $L_{p,loc}(Q^T)$-solution Π^- between 0 and K. We also have symmetric solutions $\Pi^{+/-}_{T,k}$ for $DUP^{+/-}_{Q_{t_0}}(y_0;a)$. Moreover, $\Pi^{+/-} \equiv \Pi^{+/-}_{T,k}$ by passage to the limits in the analogous identities at fixed n. Furthermore, by item 1 of Lemma 3.6, the solutions $\Pi^{+/-}$ and $\Pi^{+/-}_{T,k}$ are the only ones between the required bounds.

The probabilistic representation for Π^- then results from a generalized integrated Itô formula, as in the proof of Theorem 4.2. Since $\Pi^{+/-}$ is the limit of the $\Pi^{+/-}_n$, the probabilistic representation for Π^+ then follows from those for Π^- and $\Pi^{+/-}_n$, using also the call/put parity at a and a_n.

$\Pi^{+/-}$ and $\Pi^{+/-}_{T,k}$ then inherit the monotonicity and convexity properties valid at fixed n by passage to the limit locally uniform over (t,y) and (T,k), respectively. The asymptotic results follow from those, already known, at constant volatility $\underline{a}$ or $\overline{a}$ and from the monotonicity with respect to a.

Finally, by standard arguments developed, for instance, in Stroock and Varadhan [37, proof of Theorem 9.1.9, p. 224], estimate (4.3), or merely (4.6), valid for all $\Gamma \in L_p(Q^T)$, enforces the existence of a transition probability density between t_0 and t for the process y for almost every $t > t_0$.

Then, by general arguments set out, for instance, in Crépey [14, section 4.1, Part IV], independent of the Lipschitzian assumption on a therein, the discounted density for the process S is $\partial^2_{S^2}\Pi_{t,S}(t_0, S_0; a)$, whence, after a change of variables, we obtain the expression for γ. ∎

The following proposition gathers a few consequences of the previous results that will be useful in the following study of the calibration problems. The proposition is stated for $\Pi \equiv \Pi^+$. The analogous statements for $\Pi \equiv \Pi^-$ follow by parity. We then also have the symmetric statements in the variables (T, k). Recall that h and h' denote elements of $H^1(Q)$.

PROPOSITION 4.4. *Assume $p \in]2, \overline{p}[$.*

1. *Then*

$$\|(\partial^2_{y^2} - \partial_y)\Pi\|_{L_p(Q^T)} \;\leq\; C_p \;, \tag{4.12}$$

where $C_p \equiv C_p(\underline{t}, \overline{T}, \overline{k}; R, \underline{a}, \overline{a})$.

2. *The price Π is locally θ-Hölderian, jointly with respect to $(t_0, y_0), (T, k)$, uniformly with $q, r \in [0, R]$, $a \in \mathcal{M}_Q(\underline{a}, \overline{a})$.*

3. *Further define $p' = (2 + p)/2$, $p'' = (2 + p')/2$, and $\Gamma \equiv h(\partial^2_{y^2} - \partial_y)\Pi$. Then*

$$\|\Gamma\|_{L_{p'}(Q^T)} \;\leq\; C'_{p'}\; \|h\|_{H^1(Q)} \;,$$

where $C'_{p'} \equiv C'_{p'}(\underline{t}, \overline{T}, \overline{k}; R, \underline{a}, \overline{a})$. Then let $d\Pi$, or $d\Pi_{T,k}(\cdot; a).h$, be the $L_{p'}(Q^T)$-solution of $BS'_{Q^T}(a;\, \Gamma)$. Furthermore, let Γ' and $d\Pi'$ be defined as Γ and $d\Pi$ with h' instead of h, and

$$d\Gamma \;\equiv\; h'(\partial^2_{y^2} - \partial_y)d\Pi \;+\; h(\partial^2_{y^2} - \partial_y)d\Pi' \;.$$

Then

$$\|d\Gamma\|_{L_{p''}(Q^T)} \;\leq\; C''_{p''}\; \|h\|_{H^1(Q)}\; \|h'\|_{H^1(Q)} \;,$$

where $C''_{p''} \equiv C''_{p''}(\underline{t}, \overline{T}, \overline{k}; R, \underline{a}, \overline{a})$. We shall then denote by $d^2\Pi$, or $d^2\Pi_{T,k}(\cdot; a).(h, h')$, the $L_{p''}(Q^T)$-solution of $BS'_{Q^T}(a; d\Gamma)$.

4. *We have*

$$\begin{aligned}
\|d\Pi\|_{\mathcal{C}^0_\theta(\overline{Q}^T)} &\leq C'\; \|d\Pi\|_{W^{1,2}_p(Q^T)} \leq\; C'C\; \|h\|_{H^1(Q)},\\
\|d^2\Pi\|_{\mathcal{C}^0_\theta(\overline{Q}^T)} &\leq C'\; \|d^2\Pi\|_{W^{1,2}_p(Q^T)} \leq C'C\; \|h\|_{H^1(Q)}\|h'\|_{H^1(Q)} \;,
\end{aligned}$$

where $C' \equiv C'_p$ is as in (3.4), and $C \equiv C_p(\underline{t}, \overline{T}, \overline{k}; R, \underline{a}, \overline{a})$. Moreover, if $a + h \in \mathcal{M}_Q(\underline{a}, \overline{a})$, let us define, for $\varepsilon \in]0, 1[$,

$$\begin{aligned}
\varepsilon^{-1}\delta_\varepsilon\Pi &\equiv \varepsilon^{-1}[\Pi_{T,k}(\cdot; a + \varepsilon h) - \Pi_{T,k}(\cdot; a)],\\
\varepsilon^{-1}\delta_\varepsilon d\Pi &\equiv \varepsilon^{-1}[d\Pi_{T,k}(\cdot; a + \varepsilon h).h' - d\Pi_{T,k}(\cdot; a).h'] \;.
\end{aligned}$$

When $\varepsilon \to 0$, $\varepsilon^{-1}\delta_\varepsilon\Pi$ and $\varepsilon^{-1}\delta_\varepsilon d\Pi$ converge in $\mathcal{C}^0_\theta(\overline{Q}^T) \cap W^{1,2}_p(Q^T)$, respectively, to $d\Pi$ and $d^2\Pi$.

5. *Assume furthermore that a and, for $n \in \mathbb{N}^\star$, a_n, belong to $a_0 + H^1_Q(\underline{a}, \overline{a})$, where $a_n - a$ converges to 0 weakly in $H^1(Q)$ when $n \to +\infty$. Then $\Pi_n \equiv \Pi_{T,k}(\cdot; a_n)$ converges to $\Pi \equiv \Pi_{T,k}(\cdot; a)$ in $\mathcal{C}^0_\theta(\overline{Q}^T) \cap W^{1,2}_p(Q^T)$.*

Notice that $d\Pi$ and $d^2\Pi$ in this proposition are well defined by Theorem 4.2.

Proof. The proof is deferred to Appendix B. ∎

5. Stability.

5.1. The ill-posed calibration problems. Let us now give a rigorous statement of the calibration problems. From now on, we assume $p \in]2, \overline{p}[$, and we will denote by $\overset{\circ}{W}{}_p^{1,2}(Q_{t_0})$ the set of functions in $W_p^{1,2}(Q_{t_0})$ that vanish at time t_0. We also fix a finite subset $\mathcal{F} \subset Q_{t_0}$ with $|\mathcal{F}| = M \in \mathbb{N}^\star$. Then we define the following nonlinear *pricing functional*:

$$a_0 + H_Q^1(\underline{a}, \overline{a}) \ni a \overset{\Pi}{\longmapsto} \Pi(a) \in \Pi_0 + \overset{\circ}{W}{}_p^{1,2}(Q_{t_0}) ,$$

where Π_0, respectively, $\Pi(a)$, denotes the $L_{p,loc}(Q_{t_0})$-solution between 0 and S_0 of $DUP_{Q_{t_0}}(y_0; a_0)$, respectively, $DUP_{Q_{t_0}}(y_0; a)$. Recall that $a_0 \in \mathcal{M}_Q(\underline{a}, \overline{a})$ denotes the *prior* of the calibration problem (see section 2.3).

PROPOSITION 5.1. *The pricing functional* Π *and the restriction* $\Pi_{|\mathcal{F}}$ *are well defined on the closed convex subset* $a_0 + H_Q^1(\underline{a}, \overline{a})$ *of* $a_0 + H^1(Q)$. *Moreover, we have the following:*

1. *(Compactness.)* Π *and* $\Pi_{|\mathcal{F}}$ *map weakly convergent sequences into strongly convergent ones.*

2. *(Differentiability.)* Π *and* $\Pi_{|\mathcal{F}}$ *are twice Gâteaux differentiable.*

3. *(Perturbations of the operator.)* $\Pi_{|\mathcal{F}}$ *has* θ*-Hölderian dependence with respect to* (t_0, y_0) *and* $\mathcal{F}$.

Proof. By Theorems 4.2 and 4.3, Π and $\Pi_{|\mathcal{F}}$ are well defined. Now, points 1, 2, and 3, respectively, follow from the results symmetric to Proposition 4.4(5), 4.4(4), and 4.4(2) in the variables (T, k). □

DEFINITION 5.2. *By* the continuous calibration problem *with data*

$$\widetilde{\Pi} \in \Pi_0 + \overset{\circ}{W}{}_p^{1,2}(Q_{t_0}) ,$$

respectively, the discrete calibration problem *with data* $\pi \in \mathbb{R}^M$, *we will mean, finding an* $a \in a_0 + H_Q^1(\underline{a}, \overline{a})$ *such that*

$$\widetilde{\Pi}_{T,k} = \Pi_{T,k}(t_0, y_0; a) , \quad (T, k) \in Q_{t_0},$$

respectively,

$$\pi_{T,k} = \Pi_{T,k}(t_0, y_0; a) , \quad (T, k) \in \mathcal{F} .$$

Data for which this is possible will be said to be calibrateable.

Remark 5.3. To fix notation, we thus consider the calibration problems with European call option prices. However, by symmetry and parity, all the results below extend straightaway to the following situations:

1. (Continuous problem.) Calibration from European put option prices.
2. (Discrete problem.) Calibration from European call and put option prices.

A nonlinear inverse problem is said to be *ill-posed* at any data set around which the direct operator (here, the pricing functional Π or $\Pi_{|\mathcal{F}}$) is not continuously invertible.

THEOREM 5.4. *For every continuous function* $a \in a_0 + H_Q^1(\underline{a}, \overline{a})$, *the continuous calibration problem is ill-posed at* $\widetilde{\Pi} \equiv \Pi(a)$, *and the discrete calibration problem is ill-posed at* $\pi \equiv \Pi_{|\mathcal{F}}(a)$.

Proof. See Appendix C for the proof. □

5.2. Stabilization by Tikhonov regularization. The best-known stabilization method for ill-posed nonlinear inverse problems is Tikhonov regularization [38, 21], which we now consider. The properties of the nonlinear pricing functional Π, summed up in Proposition 5.1, will allow us to apply the general theory surveyed, for instance, in Engl, Hanke, and Neubauer [21, Chapter 10].

In practice, market prices π are defined as bid-ask spreads. Moreover, $\widetilde{\Pi}$ depends on an interpolation procedure. Therefore, the actual set of observed prices, or input data, for the calibration, π^δ or $\widetilde{\Pi}^\delta$, is only known up to some noise δ. Moreover, any numerical procedure used to tackle the discrete calibration problem entails some computational burden η. Furthermore, the local volatility function is calibrated at the current phase (t_0, y_0) and set $\mathcal{F}$, and used later at the perturbed phase (t_0^μ, y_0^μ) and set $\mathcal{F}_\mu$. The Tikhonov regularization method allows one to overcome such data noise, computational burden, and perturbations of the operator.

DEFINITION 5.5. (Continuous problem.) *By an* α-solution *of the continuous calibration problem with prior* a_0 *and noisy data*

$$\widetilde{\Pi}^\delta \in \Pi_0 + \overset{\circ}{W}{}_p^{1,2}(Q_{t_0}) \,,$$

we will mean, in $a_0 + H_Q^1(\underline{a}, \overline{a})$*, any* a_α^δ *such that for every* a*,*

$$J_\alpha^\delta \left(a_\alpha^\delta\right) \leq J_\alpha^\delta \left(a\right),$$

where

$$2J_\alpha^\delta (a) \equiv \left\| \Pi \left(t_0, y_0, a\right) - \widetilde{\Pi}^\delta \right\|^2_{W_p^{1,2}(Q_{t_0})} + \alpha \left\| a - a_0 \right\|^2_{H^1(Q)} \,.$$

(Discrete problem.) *By an* α-solution *of the discrete calibration problem with prior* a_0*, noisy data* $\pi^\delta \in \mathbb{R}^M$*, perturbed parameters* $(t_0^\mu, y_0^\mu) \in Q$*,* $\mathcal{F}_\mu \subset Q_{t_0^\mu}$ *(*$|\mathcal{F}_\mu| = M$*), and computational burden* $\eta \geq 0$*, we will mean, in* $a_0 + H_Q^1(\underline{a}, \overline{a})$*, any* $a_\alpha^{\delta,\mu,\eta}$ *such that for every* a*,*

$$J_\alpha^{\delta,\mu} \left(a_\alpha^{\delta,\mu,\eta}\right) \leq J_\alpha^{\delta,\mu} \left(a\right) + \eta,$$

where

$$2J_\alpha^{\delta,\mu} (a) \equiv \left\| \Pi_{|\mathcal{F}_\mu} \left(t_0^\mu, y_0^\mu, a\right) - \pi^\delta \right\|^2_{\mathbb{R}^M} + \alpha \left\| a - a_0 \right\|^2_{H^1(Q)} \,.$$

Such α-solutions do exist because of Proposition 5.1(1). We shall not address in this paper the problem of the uniqueness of the unregularized calibration problems, or of the regularized problems for arbitrary values of the regularization parameter α. However, at least for the discrete problem, one has the following result when α tends to $+\infty$. The intuition behind this result is that when α tends to $+\infty$, the regularization term becomes dominant and enforces the convexity of the cost criterion as a whole.

THEOREM 5.6. *There exists* $C \equiv (1 + \overline{\pi}^\delta) MC_p(\underline{t}, \overline{y}_0, \overline{T}; R, \underline{a}, \overline{a})$ *such that the cost criterion* $J \equiv J_\alpha^{\delta,\mu}$ *is* C*-strongly convex on* $a_0 + H_Q^1(\underline{a}, \overline{a})$ *for every* $\alpha \geq 2C$*. Here,* $\overline{y}_0$ *and* $\overline{\pi}^\delta$ *denote bounds on* $|y_0^\mu|$ *and* $\pi_{T,k}^\delta$ *for* $(T, k) \in \mathcal{F}_\mu$*.*

$J_\alpha^{\delta,\mu}$ then admits a unique minimum, which depends continuously upon (t_0^μ, y_0^μ), $\mathcal{F}_\mu$, and π^δ. Otherwise said, the minimization problem of $J_\alpha^{\delta,\mu}$ is well-posed in the sense of Hadamard.

Proof. By the chain rule, we have

$$\begin{aligned} d^2J(a).(h,h') \;\equiv\; & \alpha\langle h,h'\rangle_{H^1(Q)} \\ & + \sum_{(T,k)\in\mathcal{F}_\mu} d\Pi_{T,k}(t_0^\mu,y_0^\mu;a).h \; d\Pi_{T,k}(t_0^\mu,y_0^\mu;a).h' \\ & + \sum_{(T,k)\in\mathcal{F}_\mu} \left(\Pi_{T,k}(t_0^\mu,y_0^\mu;a)-\pi^\delta_{T,k}\right)\; d^2\Pi_{T,k}(t_0^\mu,y_0^\mu;a).(h,h') \;. \end{aligned}$$

For $a,b\in a_0+H^1_Q(\underline{a},\overline{a})$ and $\varepsilon\in\,]0,1[$, let us define $a_\varepsilon\equiv(1-\varepsilon)a+\varepsilon b$, $J_\varepsilon\equiv J(a_\varepsilon)$. Using Proposition 5.1(2) and the bound $e^{y_0^\mu}$ on $|\Pi|$, it follows, denoting by $'$ the derivative with respect to ε, that

$$\begin{aligned} \langle\nabla J(b)-\nabla J(a),b-a\rangle_{H^1(Q)} = J_1'-J_0' \;=\; & \int_0^1 J_\varepsilon''d\varepsilon \\ = \int_0^1 d^2J(a_\varepsilon).(b-a,b-a) \geq (\alpha-(1+e^{y_0^\mu}+\overline{\pi}^\delta)MC)\;\|b-a\|^2_{H^1(Q)}\;, & \end{aligned}$$

where $C\equiv C_p(\underline{t},\overline{y}_0,\overline{T};R,\underline{a},\overline{a})$. ∎

Moreover, Tikhonov regularized solutions of the calibration problems at arbitrary level $\alpha>0$ are *stable* in the following meaning.

THEOREM 5.7. (Stability, continuous problem.) *Assume* $\widetilde{\Pi}^{\delta_n}\to\widetilde{\Pi}^\delta$ *when* $n\to+\infty$. *Then any sequence of* α*-solutions* $a_\alpha^{\delta_n}$ *admits a subsequence which converges towards an* α*-solution* a_α^δ.

(Stability, discrete problem.) *Assume*

$$\pi^{\delta_n},\quad (t_0^{\mu_n},y_0^{\mu_n}),\quad \mathcal{F}_{\mu_n},\quad \eta_n\longrightarrow\pi^\delta,\quad (t_0^\mu,y_0^\mu),\quad \mathcal{F}_\mu,\quad \eta\equiv 0,$$

when $n\to+\infty$. *Then any sequence of* α*-solutions* $a_\alpha^{\delta_n,\mu_n,\eta_n}$ *admits a subsequence which converges towards an* α*-solution* $a_\alpha^{\delta,\mu,\eta\equiv0}$.

Notice that this convergence is strong in $H^1(Q)$.

Proof. Using Proposition 5.1(1), this results directly from Theorem 2.1 in Engl, Kunisch, and Neubauer [22], supplemented by Remark 3.4 in Binder et al. [5], for the continuous problem. For the discrete problem, the proof is an immediate adaptation of the one in [22, Theorem 2.1], using items 1 and 3 of Proposition 5.1. ∎

6. Convergence and convergence rates.

6.1. Convergence. We are going to see that the Tikhonov regularization method behaves as an approximating scheme for the pseudoinverse of Π or $\Pi_{|\mathcal{F}}$. By *pseudoinverse*, we mean the operator that maps calibrateable data $\widetilde{\Pi}$ or π to an element a which minimizes $\|a-a_0\|$ over the set of all preimages of $\widetilde{\Pi}$ or π through Π or $\Pi_{|\mathcal{F}}$.

DEFINITION 6.1 (a_0-MNS). *Given calibrateable data, we shall call an* a_0-minimum norm solution *(a_0-MNS) of the calibration problem any solution a that minimizes $\|a-a_0\|$ over the set of all solutions.*

Such an a_0-MNS a exists for all calibrateable data. But it may be nonunique, since the pricing functional Π is nonlinear.

THEOREM 6.2. (Convergence, continuous problem.) *Given calibrateable data* $\widetilde{\Pi}$, *suppose that*

$$\begin{aligned} \left\|\widetilde{\Pi}-\widetilde{\Pi}^{\delta_n}\right\|_{W_p^{1,2}(Q_{t_0})} \leq \delta_n \quad & \textit{for} \quad n\in\mathbb{N}, \\ \alpha_n,\;\delta_n^2/\alpha_n \quad \longrightarrow 0 \quad & \textit{when} \quad \to+\infty. \end{aligned}$$

Then any sequence $a^{\delta_n}_{\alpha_n}$ admits a subsequence which converges towards an a_0-MNS a. Moreover, $a^{\delta_n}_{\alpha_n} \to a$ if a is the unique a_0-MNS of the calibration problem at $\widetilde{\Pi}$.

(Convergence, discrete problem.) *Given calibrateable data π, suppose that*

$$\left\|\pi - \pi^{\delta_n}\right\|_{\mathbb{R}^M} \leq \delta_n, \quad |t_0 - t_0^{\mu_n}| \vee |y_0 - y_0^{\mu_n}| \vee \|\mathcal{F} - \mathcal{F}_{\mu_n}\| \leq \mu_n \ \text{ for } \ n \in \mathbb{N},$$
$$\alpha_n, \quad \delta_n^2/\alpha_n, \quad \mu_n^{2\theta}/\alpha_n, \quad \eta_n/\alpha_n \longrightarrow 0 \ \text{ when } \ n \to +\infty.$$

Then any sequence $a^{\delta_n,\mu_n,\eta_n}_{\alpha_n}$ admits a subsequence which converges towards an a_0-MNS a. Moreover, $a^{\delta_n,\mu_n,\eta_n}_{\alpha_n} \to a$ if a is the unique a_0-MNS of the calibration problem at π.

Proof. Using Proposition 5.1(1), this follows directly from Theorem 2.3 in Engl, Kunisch, and Neubauer [22], supplemented by Remark 3.4 in Binder et al. [5], for the continuous problem. For the discrete problem, it results, for instance, from Kunisch and Geymayer [27, Proposition 1], using items 1 and 3 of Proposition 5.1. □

Following Engl, Hanke, and Neubauer [21, Proposition 3.11 and Remark 3.12], there can be, for the convergence of such regularized schemes towards solutions of ill-posed inverse problems, no uniform rate over all calibrateable data. In fact, this presents a generic character for any method of resolution, Tikhonov or otherwise. It is therefore important to be able to specialize subsets of $a_0 + H^1_Q(\underline{a}, \overline{a})$ on which such uniform rates may be exhibited.

6.2. Convergence rates. We first have the following abstract statement. Let $d\Pi_{|\mathcal{F}}(a)^\star$ and $d\Pi(a)^\star$ denote the adjoints of the operators $d\Pi_{|\mathcal{F}}(a)$ and $d\Pi(a)$, respectively. That is to say, by definition,

$$\langle h\ , d\Pi_{|\mathcal{F}}(a)^\star \lambda \rangle_{H^1(Q)} \ = \sum_{(T,k)\in\mathcal{F}} \lambda_{T,k} d\Pi_{T,k}(a).h\ ; \quad (h,\lambda) \in H^1(Q) \times \mathbb{R}^M,$$

respectively,

$$\langle h\ , d\Pi(a)^\star \lambda \rangle_{H^1(Q)} \ = \ \langle d\Pi(a).h\ , \lambda \rangle_{W^{1,2}_p(Q_{t_0}), W^{1,2}_\rho(Q_{t_0})}\ ; \quad (h,\lambda) \in H^1(Q) \times W^{1,2}_\rho(Q_{t_0}),$$

where $p^{-1} + \rho^{-1} = 1$, and where the last bracket denotes the *duality bracket* between λ and $d\Pi(a).h$.

THEOREM 6.3. (Convergence rates, continuous problem.) *There exists $C_p \equiv C_p(\underline{t}, \overline{y}_0, \overline{T}; R, \underline{a}, \overline{a})$ such that for every a_0-MNS a of the calibration problem at $\widetilde{\Pi}$ with*

$$a - a_0 = d\Pi(a)^\star \lambda \tag{6.1}$$

for some $\|\lambda\|_{W^{1,2}_\rho(Q_{t_0})} \leq C_p$, then

$$\|a^\delta_\alpha - a\|_{H^1(Q)} = \mathrm{O}(\delta^{\frac{1}{2}}),$$

whenever

$$\left\|\widetilde{\Pi} - \widetilde{\Pi}^\delta\right\|_{W^{1,2}_p(Q_{t_0})} \leq \delta, \quad \alpha \ \sim \ \delta\ .$$

(Convergence rates, discrete problem.) *There exists $C_p \equiv C_p(\underline{t}, \overline{y}_0, \overline{T}; R, \underline{a}, \overline{a})$ such that for every a_0-MNS a of the calibration problem at π with*

$$a - a_0 = d\Pi_{|\mathcal{F}}(t_0, y_0; a)^\star \lambda \tag{6.2}$$

for some $\|\lambda\|_{\mathbb{R}^M} \leq C_p/\sqrt{M}$*, then*

$$\|a_\alpha^{\delta,\mu,\eta} - a\|_{H^1(Q)} = \mathrm{O}(\delta^{\frac{1}{2}} + \mu^{\frac{\theta}{2}}),$$

whenever

$$\left\|\pi - \pi^\delta\right\|_{\mathbb{R}^M} \leq \delta\,, \quad |t_0 - t_0^\mu| \vee |y_0 - y_0^\mu| \vee \|\mathcal{F} - \mathcal{F}_\mu\| \leq \mu\,, \quad \alpha \;\sim\; \delta \vee \mu^\theta\,, \quad \eta = \mathrm{O}\left(\delta^2\right).$$

Therefore a is the only a_0-MNS satisfying condition (6.1) or (6.2).

Proof. (Continuous problem.) Using items 1 and 2 of Proposition 5.1, this follows from Engl, Hanke, and Neubauer [21, Theorem 10.4 and Remark 10.5] by noticing that the proof therein readily extends from their Hilbert → Hilbert to our Hilbert → reflexive Banach setting, by reading duality brackets instead of inner products.

(Discrete problem.) Using Proposition 5.1, this follows from Kunisch and Geymayer [27, Theorem 2 and Remark iv, p. 86]. □

Remark 6.4. Kunisch and Geymayer [27, Theorem 2] assume that a belongs to the interior of $a_0 + H_Q^1(\underline{a}, \overline{a})$. However, this cannot be realized in our case. Indeed, $a_0 + H_Q^1(\underline{a}, \overline{a})$ has an empty interior. But this assumption is not used as long as discretization of the source space is not dealt with.

Except in the trivial case where $a \equiv a_0$, conditions (6.1)–(6.2) may seem rather abstract. Whether there is a neighborhood around a_0 such that they are satisfied is an open question. However, in the case where a is uniformly continuous with respect to its space variable y, one can derive a more explicit formulation of (6.2). In the following, let $\widetilde{\nabla}\Pi_{T,k}$, not to be mistaken with the Gâteaux derivative of Π in $H^1(Q)$, denote the following function on Q, parameterized by (t_0, y_0, T, k) and a:

$$\widetilde{\nabla}\Pi_{T,k}(t,y) \;\equiv\; \mathbf{1}_{\{t_0<t<T\}} e^{-y}(\partial_{y^2}^2 - \partial_y)\Pi_{t,y}(t_0, y_0; a)(\partial_{y^2}^2 - \partial_y)\Pi_{T,k}(t, y; a)\,.$$

Lemma 6.5. *For* $(T,k) \in \mathcal{F}$*,*

$$d\Pi_{T,k}(t_0, y_0; a)\,.\,h \;=\; \int\!\!\int_Q \widetilde{\nabla}\Pi_{T,k}\; h\,.$$

Proof. Indeed, this is just the probabilistic representation (4.2) for $d\Pi$, given the expression for γ in Theorem 4.3(2) and the L_p estimate on Γ in Proposition 4.4(3). □

Theorem 6.6. *Let* $a \in a_0 + H_Q^1(\underline{a}, \overline{a})$ *be uniformly continuous with respect to its space variable* y*. Then the following hold:*

1. $\widetilde{\nabla}\Pi_{T,k} \in L_2(Q)$ *for* $(T,k) \in \mathcal{F}$*.*
2. $\Lambda \equiv d\Pi_{|\mathcal{F}}(a)^\star\lambda$ *is the unique solution in* $H^2(Q)$ *of the following problem:*

$$\left\{\begin{array}{l} \Lambda - \Delta\Lambda = \sum_{(T,k)\in\mathcal{F}} \lambda_{T,k}\widetilde{\nabla}\Pi_{T,k}\,, \quad Q\text{-a.e.},\\ \partial_n\Lambda \;=\; 0\,, \quad \partial Q\text{-a.e.} \end{array}\right. \tag{6.3}$$

3. *Condition* (6.2) *means that* (6.3) *holds with* $\Lambda \equiv a - a_0$ *for some*

$$\|\lambda\|_{\mathbb{R}^M} \;\leq\; C_p(\underline{t}, \overline{y}_0, \overline{T}; R, \underline{a}, \overline{a})/\sqrt{M}.$$

Notice that by Theorem 3.2(3), the normal derivative $\partial_n\Lambda \in L_2(\partial Q)$ is well defined for $\Lambda \in H^2(Q)$.

Proof. 1. According to Proposition 4.4(3),

$$(\partial_{y^2}^2 - \partial_y)\Pi_{T,k}(t,y;a) \in L_p\left(\left]\frac{t_0+T}{2}, T\right[\times \mathbb{R}\right).$$

On the other hand, we have by Stroock and Varadhan [37, Theorem 9.1.9, equation (1.35)],

$$e^{-y}(\partial_{y^2}^2 - \partial_y)\Pi_{t,y}(t_0,y_0;a) = \gamma_{t_0,y_0}(t,y;a) \in L_q\left(\left]\frac{t_0+T}{2}, T\right[\times \mathbb{R}\right)$$

for every $1 \leq q < +\infty$. More precisely,

$$\|\gamma_{t_0,y_0}(\cdot;a)\|_{L_q(]\frac{t_0+T}{2},T[\times\mathbb{R})} \leq C_q^\omega(\underline{t}, \overline{T}, R, \underline{a}, \overline{a}) \,,$$

where ω denotes a modulus of continuity of a with respect to y. Hence $\widetilde{\nabla}\Pi_{T,k} \in L_2(]\frac{t_0+T}{2}, T[\times\mathbb{R})$ by Hölder's inequality. By symmetry and parity, we can conclude that $\widetilde{\nabla}\Pi_{T,k} \in L_2(Q)$.

2. Therefore, using Lemma 6.5, the adjunction relations for Λ can be written as

$$\langle \Lambda\ , h\rangle_{H^1(Q)} \ = \sum_{(T,k)\in\mathcal{F}} \lambda_{T,k}\ \langle \widetilde{\nabla}\Pi_{T,k}, h\rangle_{L_2(Q)}\ , \quad h \in H^1(Q)\ . \tag{6.4}$$

It is then known that the adjoint $\Lambda \in H^1(Q)$ belongs in fact to $H^2(Q)$—see, for instance, Bensoussan and J.-L. Lions [3, Theorem 5.10, Chapter 2, and the footnote on p. 96]. We can then apply the generalized Green formula to identity (6.4) and conclude in a classic way, using Theorem 3.2(4); see, for example, Larrouturou and P. L. Lions [30, p. 150, step 6, Interpretation of the variational formulation].

3. Item 3 follows immediately from 2. □

Remark 6.7.

1. The condition in Theorem 6.6(3), which ensures a convergence rate in $\mathrm{O}(\delta^{\frac{1}{2}} + \mu^{\frac{\theta}{2}})$, is very severe, since its implies that $(\mathrm{Id} - \Delta).(a - a_0)$ belongs to the $\leq M$-dimensional subspace of $L_2(Q)$ spanned by the $\widetilde{\nabla}\Pi_{T,k}$, $(T,k) \in \mathcal{F}$ for sufficiently small coefficients $\lambda_{T,k}$.

2. This condition is both a closedness and smoothness condition of a with respect to a_0, which says that, as already noted elsewhere, "Tikhonov regularization can only resolve smooth details fast" [36, p. 611]. Indeed, one then has the following $H^2(Q)$ estimate from regularity theory for elliptic equations (method of tangential translations; see, for instance, Brézis [9, pp. 181 and 184]):

$$\|a - a_0\|_{H^2(Q)} \ \leq\ \sqrt{M}\ C_p^\omega(\underline{t}, \overline{y}_0, \overline{T}; R, \underline{a}, \overline{a})\ \|\lambda\|_{\mathbb{R}^M},$$

where ω denotes a modulus of continuity of a with respect to y.

3. At least in the Hilbert → Hilbert setting of the discrete problem, there exist conditions stronger than (6.2) ensuring better convergence rates, typically in $\mathrm{O}(\delta^{\frac{2}{3}})$; see, for instance, [32, 33, 21]. But these conditions require that a be interior to the domain of definition of the direct operator—see, for instance, Neubauer [32, equation (2.5)]. As already observed above, this cannot be realized in our case. Indeed, $H_Q^1(\underline{a}, \overline{a})$ has an empty interior. Nonetheless, the reader is referred to Neubauer and Scherzer [33, section 3] for a special case in which an $\mathrm{O}(\delta^{\frac{2}{3}})$ convergence rate is proved, although the domain of definition of the direct operator has empty interior.

7. Conclusion. Having established $W_p^{1,2}$ estimates for Black–Scholes and Dupire equations with measurable ingredients, we have shown that the problem of inverting observed vanilla option prices into a local volatility function, in a generalized Black–Scholes model, fits into the frame of the Tikhonov regularization method. Moreover, this holds true both when the option prices form a continuum and when they consist of a finite set. We were then able to derive results for stability, convergence, and convergence rates for this method. Discretization and effective implementation, as well as numerical results, can be found in [16]. This work also deals with an extension of the numerical implementation to the problem of calibration from American option prices. With respect to this, an open problem is whether the theoretical results obtained in the present article relating to calibration from European option prices, in a generalized Black–Scholes model, may be extended to calibration from American option prices. Another more incidental open problem is whether the continuity assumption is necessary in Theorem 6.6.

Appendix A. A technical lemma. The following lemma justifies the passage to the limit at the end of the proof of Theorem 4.2. Although it is an adaptation of Theorem 3.8 in Caffarelli et al. [10], using also Theorem 2.8 in Crandall, Kocan, and Swiech [13], we give the proof in detail for completeness. The notation is the same as above.

LEMMA A.1. *Let us be given $\Gamma \in \mathcal{D}(\overline{Q}^T)$, and $2 < p' < p$. For $n \in \mathbb{N}$, let φ_n be an $L_{p',loc}(Q^T)$-solution of $BS'_{Q^T}(a_n;\Gamma)$, where a_n is a Lipschitzian approximation of a as in Lemma 3.3. Assume the existence of a function $\varphi \in W^{1,2}_{p,loc}(Q^T)$ such that $\varphi_n \to \varphi$ when $n \to +\infty$, locally uniformly on $\overline{Q}^T$. Then φ is an $L_{p,loc}(Q^T)$-solution of $BS'_{Q^T}(a;\Gamma)$.*

Proof. The proof proceeds by contradiction. Assume that φ is, say, no $L_{p,loc}(Q^T)$-viscosity subsolution of $BS'_{Q^T}(a;\Gamma)$. Therefore, there exist open nonempty bounded intervals I and J, a rectangle $Q' = I \times J \subseteq Q^T$ centered at a point $(t_0, y_0) \in Q^T$, and a test function $\psi \in W_p^{1,2}(Q')$ such that

$$-\partial_t\psi - (r - q - a(t,y))\,\partial_y\psi - a(t,y)\partial^2_{y^2}\psi + r\varphi \;>\; \Gamma + \varepsilon \quad \text{on} \quad Q', \tag{A.1}$$

$$(\varphi - \psi)(t_0, y_0) = 0,\ \varphi - \psi < -\delta \quad \text{on} \quad \partial_p Q'\ . \tag{A.2}$$

Moreover, due to the Hölderian character of φ and ψ through the Sobolev embedding (3.1) on Q', one can assume

$$\varphi - \psi < -\frac{\delta}{2} \quad \text{on } \partial_p Q'' \tag{A.3}$$

for some subrectangle Q'' with the same properties as Q' and $\overline{Q}'' \subset Q'$.

We are going to construct a sequence of functions ψ_n (hence, $\psi+\psi_n) \in W^{1,2}_{p',loc}(Q')$ such that

$$\psi_n \;\to\; 0 \quad \text{in } L_\infty(Q'') \quad \text{as } n \to \infty \tag{A.4}$$

and for n large enough

$$\begin{aligned} &-\partial_t(\psi+\psi_n) - (r - q - a_n(t,y))\,\partial_y(\psi+\psi_n) - a_n(t,y)\partial^2_{y^2}(\psi+\psi_n) + r\varphi_n \\ &\qquad \geq \Gamma + \varepsilon \text{ on } Q''. \end{aligned} \tag{A.5}$$

Then by (A.2), (A.3), (A.4), and the assumed local uniform convergence of φ_n to φ, $\varphi_n - (\psi+\psi_n)$ will be larger at (t_0, y_0) than anywhere else on $\partial_p Q''$ for n large enough.

In view of (A.5), this contradicts the assumption that φ_n is an $L_{p',loc}(Q^T)$-viscosity solution of $BS'_{Q^T}(a_n;\Gamma)$.

To construct ψ_n, notice that by (A.1), we have on Q', for ψ_n arbitrary in $W^{1,2}_{p',loc}(Q')$,

$$\begin{aligned}
&-\partial_t(\psi+\psi_n)-(r-q-a_n(t,y))\,\partial_y(\psi+\psi_n)-a_n(t,y)\partial^2_{y^2}(\psi+\psi_n)+r\varphi_n-\Gamma\\
&\geq \varepsilon+(a-a_n)(\partial^2_{y^2}-\partial_y)\psi-r(\varphi-\varphi_n)\\
&\quad-\partial_t\psi_n-(r-q-a_n(t,y))\,\partial_y\psi_n-a_n(t,y)\partial^2_{y^2}\psi_n\\
&\geq \varepsilon+\Gamma_n-\partial_t\psi_n-(R+\overline{a})\,|\partial_y\psi_n|-\overline{a}\big(\partial^2_{y^2}\psi_n\big)^+-\underline{a}\big(\partial^2_{y^2}\psi_n\big)^-,
\end{aligned}$$

where

$$\Gamma_n\equiv(a-a_n)(\partial^2_{y^2}-\partial_y)\psi-r(\varphi-\varphi_n)\;\to\;0\quad\text{in } L_{p'}(Q')\quad\text{as } n\to\infty.$$

Now, choose ψ_n to be, by Theorem 2.8 in Crandall, Kocan, and Swiech [13], the $L_{p',loc}(Q')$-solution of the following problem:

$$\begin{cases}\partial_t\psi_n+(R+\overline{a})\,|\partial_y\psi_n|+\overline{a}\,\big(\partial^2_{y^2}\psi_n\big)^+-\underline{a}\,\big(\partial^2_{y^2}\psi_n\big)^- \;=\;\Gamma_n\quad\text{on } Q',\\ \psi_n\;=\;0\quad\text{on } \partial_pQ',\end{cases}$$

with estimate

$$\|\psi_n\|_{W^{1,2}_{p'}(Q'')}\;\leq\;C\;\|\Gamma_n\|_{L_{p'}(Q')},$$

$C\equiv C_{p'}(R,\underline{a},\overline{a},Q',Q'')$ independent of n. Considering the Sobolev embedding (3.1) on Q'', this furnishes the desired sequence ψ_n. ∎

Appendix B. Proof of Proposition 4.4.

1. By Theorem 4.3(1), let us consider Π, respectively, $\hat{\Pi}$, the $L_{p,loc}(Q^T)$-solution between 0 and S of $BS_{Q^T}(k;a)$, respectively, $BS_{Q^T}(k;\hat{a})$. Then by linearity, symmetry, parity, and the asymptotic results in Theorem 4.3(1), $\delta\Pi\equiv\Pi-\hat{\Pi}$ converges to 0 when $|y|\to+\infty$, uniformly with t, and $\delta\Pi$ is an $L_{p,loc}(Q^T)$-solution of $BS'_{Q^T}(a;\Gamma)$, where $\Gamma\equiv(a-\hat{a})(\partial^2_{y^2}-\partial_y)\hat{\Pi}$. Now, it is well known that

$$\|(\partial^2_{y^2}-\partial_y)\hat{\Pi}\|_{L_p(Q^T)}\;\leq\;C_p(\underline{t},\overline{T},\overline{k},R,\underline{a},\overline{a})$$

(see, for instance, Crépey [14, Remark 4.1, Part IV]). Using also (4.3), this gives (4.12).

2. Let us be given $(t_0,y_0),(t'_0,y'_0),(T,k),(T',k')\in\overline{Q}$, where $t_0\leq t'_0$; $|y_0|,|y'_0|\leq\overline{y}_0$; $|k|,|k'|\leq\overline{k}$; $0<\varepsilon\leq T-t_0,T'-t'_0$. Define Π, $\hat{\Pi}$, $\delta\Pi$ as above. Then using the estimates (4.3), (4.12), and the results symmetric in the variables (T,k), and using also well-known results related to $\hat{\Pi}$, which is explicitly given by the Black–Scholes formula, it follows that

$$\begin{aligned}
&|\Pi_{T,k}(t_0,y_0)-\Pi_{T',k'}(t'_0,y'_0)|\\
&\leq|\Pi_{T,k}(t_0,y_0)-\Pi_{T',k'}(t_0,y_0)|+|\Pi_{T',k'}(t_0,y_0)-\Pi_{T',k'}(t'_0,y'_0)|\\
&\leq|\delta\Pi_{T,k}(t_0,y_0)-\delta\Pi_{T',k'}(t_0,y_0)|+|\hat{\Pi}_{T,k}(t_0,y_0)-\hat{\Pi}_{T',k'}(t_0,y_0)|\\
&+|\delta\Pi_{T',k'}(t_0,y_0)-\delta\Pi_{T',k'}(t'_0,y'_0)|+|\hat{\Pi}_{T',k'}(t_0,y_0)-\hat{\Pi}_{T',k'}(t'_0,y'_0)|\\
&\leq\|\delta\Pi_{\cdot}(t_0,y_0)\|_{\mathcal{C}^0_\theta(\overline{Q}_{t_0})}\big(|T-T'|^\theta+|k-k'|^\theta\big)+C^\varepsilon_p(\underline{t},\overline{y}_0,\overline{T},\overline{k};R,\underline{a},\overline{a})(|T-T'|+|k-k'|)\\
&+\|\delta\Pi_{T',k'}(\cdot)\|_{\mathcal{C}^0_\theta(\overline{Q}^{T'})}\big(|t_0-t'_0|^\theta+|y_0-y'_0|^\theta\big)+C^\varepsilon_p(\underline{t},\overline{y}_0,\overline{T},\overline{k};R,\underline{a},\overline{a})(|t_0-t'_0|+|y_0-y'_0|)\\
&\leq C'_p(C_p(\underline{t},\overline{y}_0,\overline{T};R,\underline{a},\overline{a})\vee C_p(\underline{t},\overline{T},\overline{k};R,\underline{a},\overline{a}))\\
&\times\big(|T-T'|^\theta+|k-k'|^\theta+|t_0-t'_0|^\theta+|y_0-y'_0|^\theta\big)\\
&+C^\varepsilon_p(\underline{t},\overline{y}_0,\overline{T},\overline{k};R,\underline{a},\overline{a})\,(|T-T'|+|k-k'|+|t_0-t'_0|+|y_0-y'_0|)\;.
\end{aligned}$$

3. Using (4.12), if ${p'}^{-1} = p^{-1} + \rho^{-1}$, by Hölder's inequality we obtain

$$\begin{aligned}\|h(\partial^2_{y^2} - \partial_y)\Pi\|_{L_{p'}(Q^T)} &\leq \|h\|_{L_\rho(Q^T)}\ \|(\partial^2_{y^2} - \partial_y)\Pi\|_{L_p(Q^T)}\\ &\leq C'_{p'}\ \|h\|_{H^1(Q)}\end{aligned}$$

through the Sobolev embedding in Theorem 3.2(1). Using estimates (4.12) for Π and (4.3) for $d\Pi$ and $d\Pi'$, we obtain similarly

$$\begin{aligned}\|d\Gamma\|_{L_{p''}(Q^T)} &\leq \|h'(\partial^2_{y^2} - \partial_y)d\Pi\|_{L_{p''}(Q^T)}\ +\ \|h(\partial^2_{y^2} - \partial_y)d\Pi'\|_{L_{p''}(Q^T)}\\ &\leq \|h'\|_{L_\nu(Q^T)}\ \|(\partial^2_{y^2} - \partial_y)d\Pi\|_{L_{p'}(Q^T)}\\ &\quad +\ \|h\|_{L_\nu(Q^T)}\ \|(\partial^2_{y^2} - \partial_y)d\Pi'\|_{L_{p'}(Q^T)}\\ &\leq C''_{p''}\ \|h\|_{H^1(Q)}\ \|h'\|_{H^1(Q)}\ .\end{aligned}$$

4. The estimates for $d\Pi$ and $d^2\Pi$ result from point 3 and Theorem 4.2. Let us additionally suppose that $a + h \in \mathcal{M}_Q(\underline{a}, \overline{a})$. By linearity as above, $\varepsilon^{-1}\delta_\varepsilon\Pi$ is the $L_p(Q^T)$-solution of $BS'_{Q^T}(a + \varepsilon h; \Gamma)$, and $\varepsilon^{-1}\delta_\varepsilon\Pi$ converges in $\mathcal{C}^0_\theta(\overline{Q}^T) \cap W^{1,2}_p(Q^T)$, when $\varepsilon \to 0$, towards the solution $d\Pi$ of $BS'_{Q^T}(a; \Gamma)$. Similarly, $\varepsilon^{-1}\delta_\varepsilon d\Pi$ is the $L_p(Q^T)$-solution of $BS'_{Q^T}(a + \varepsilon h; d\Gamma_\varepsilon)$, where

$$\begin{aligned}d\Gamma_\varepsilon \equiv\ & h(\partial^2_{y^2} - \partial_y)d\Pi_{T,k}(\cdot; a).h'\\ &+\ h'(\partial^2_{y^2} - \partial_y)\left[\varepsilon^{-1}(\Pi_{T,k}(\cdot; a + \varepsilon h) - \Pi_{T,k}(\cdot; a))\right]\ .\end{aligned}$$

Moreover, $d\Gamma_\varepsilon$ converges in $L_p(Q^T)$ to $d\Gamma$ when $\varepsilon \to 0$. Therefore, $\varepsilon^{-1}\delta_\varepsilon d\Pi$ converges in $\mathcal{C}^0_\theta(\overline{Q}^T) \cap W^{1,2}_p(Q^T)$ to $d^2\Pi$ when $\varepsilon \to 0$.

5. Having fixed $\varepsilon > 0$, and $2 < p < p' < \overline{p}$, define ρ such that $p^{-1} = {p'}^{-1} + \rho^{-1}$. By (4.12), we can choose a subset $Q_\varepsilon \equiv Q^T \cap \{|y| \leq Y_\varepsilon\}$ such that $\|(\partial^2_{y^2} - \partial_y)\Pi\|_{L_p(Q^c_\varepsilon)} \leq \varepsilon$, where $Q^c_\varepsilon \equiv Q^T \setminus Q_\varepsilon$. By the assumed weak convergence of $a_n - a$ to 0, and by the Sobolev compact embedding (3.2), $a_n - a$ converges to 0 in $L_\rho(Q_\varepsilon)$. Denoting ${\Gamma'}_n \equiv (a_n - a)(\partial^2_{y^2} - \partial_y)\Pi$, it follows, in the same manner as in the proof of Theorem 4.3, that ${\Gamma'}_n$ converges to 0 in $L_p(Q^T)$. The $L_p(Q^T)$-solution $\Pi_n - \Pi$ of $BS'_{Q^T}(a_n; {\Gamma'}_n)$ then converges to 0 in $\mathcal{C}^0_\theta(\overline{Q}^T) \cap W^{1,2}_p(Q^T)$ when $n \to +\infty$ by Theorem 4.2.

Appendix C. Proof of Theorem 5.4. We are going to construct, for $n \in \mathbb{N}^\star$, $a_n \in a_0 + H^1_Q(\underline{a}, \overline{a})$, which takes values in the vicinity of a, such that when $n \to +\infty$, $a_n - a$ converges to 0 weakly in $H^1(Q)$. Hence, by Proposition 5.1(1), $\Pi_\cdot(t_0, y_0; a_n) - \Pi_\cdot(t_0, y_0; a)$ converges to 0 in $\mathcal{C}^0_\theta(\overline{Q}_{t_0}) \cap W^{1,2}_p(Q_{t_0})$. But no subsequence of $a_n - a$ will converge to 0 strongly in $H^1(Q_{t_0})$. Therefore Π or $\Pi_{|\mathcal{F}}$ cannot be continuously invertible around $\widetilde{\Pi} = \Pi(a)$ or $\pi = \Pi_{|\mathcal{F}}(a)$.

Since $\underline{a} < \overline{a}$, and because a is continuous, there exists an open subset $\mathcal{R} \subset Q_{t_0}$ on which $\underline{a} + \varepsilon \leq a$ or $a + \varepsilon \leq \overline{a}$ for some well-chosen $\varepsilon > 0$. Let us assume, for instance, that $a + \varepsilon \leq \overline{a}$ on a rectangle $\mathcal{R} =]t_1, t_2[\times]0, \varepsilon[$, as well as on the union $\mathcal{T}$ of the two equilateral triangles adjacent to the time boundaries of $\mathcal{R}$, with $\mathcal{R} \cup \mathcal{T} \subset Q_{t_0}$. Let us define $a_n - a = u_n$ to be the continuous function on Q such that the following hold:

1. On $\mathcal{R}$, u_n is a continuous function of the space variable y alone, which vanishes at both sides of the space interval $]0, \varepsilon[$ and oscillates between the values 0 and $1/2n$. More precisely, $\partial_y u_n = -1$ or $+1$ on $]0, \varepsilon[$ according to whether $E\{2ny/\varepsilon\}$ is odd or even.

2. On the left and right of $\mathcal{R}$, u_n decreases to 0 at unit speed with respect to the time variable, then vanishes identically.

3. Outside $\mathcal{R} \cup \mathcal{T}$, u_n vanishes identically.

Therefore, u_n vanishes identically outside $\mathcal{R}$, except on a set of measure tending to 0 as $n \to \infty$. Moreover, for every n, we have on Q

$$0 \leq u_n \leq \varepsilon/2n \leq \varepsilon \ , \quad |\partial_t u_n| \leq 1 \ , \quad |\partial_y u_n| \leq 1 \ .$$

So, by construction, $u_n = a_n - a \in H^1(Q)$ and

$$a_n = (a_n - a) + (a - a_0) + a_0 \in a_0 + H^1_Q(\underline{a}, \overline{a}) \ .$$

Moreover, for $n \in \mathbb{N}^\star$, $|\partial_y u_n| \equiv 1$ on $\mathcal{R}$, so that no subsequence of u_n can converge to 0 strongly in $H^1(Q_{t_0})$. But u_n converges to 0 weakly in $H^1(Q)$. Indeed, for any regular test function $\psi(t, y)$, let us define $\phi(y) = \int_{t=t_1}^{t_2} \partial_y \psi \ dt$. Then

$$\int \int_{\mathcal{R}} (\partial_y u_n)\, (\partial_y \psi) \ dydt = \int_{y=0}^{\varepsilon} (\partial_y u_n)\, \phi(y) \ dy = - \int_{y=0}^{\varepsilon} u_n \phi'(y) \ dy$$

by integration by parts. Since $|u_n| \leq \varepsilon/2n$, this converges to 0 when $n \to \infty$. The rest of the verification is straightforward.

Acknowledgments. I am greatly indebted to Henri Berestycki for his enlightening direction of the first stage of this research during a "Stage industriel pour doctorant INRIA" at CAR (Caisse Autonome de Refinancement, Groupe Caisse des Dépôts, Paris; see Crépey [14, Part IV]). Thanks also to Jerôme Busca for kind advice and encouragement throughout the work.

NEIGHBORHOODS OF PARALLEL WELLS IN TWO DIMENSIONS THAT SEPARATE GRADIENT YOUNG MEASURES*

KEWEI ZHANG†

Abstract. We give estimates for the closed ϵ-neighborhood K_ϵ of the set $K = \cup_{i=1}^k \lambda_i SO(2) \subset M^{2\times 2}$ of multiple parallel elastic wells such that $\text{dist}(Du_j, K_\epsilon) \to 0$ in $L^1(\Omega)$ implies, up to a subsequence, $\text{dist}(Du_j, (\lambda_{i_0} SO(2))_\epsilon) \to 0$ in $L^1(\Omega)$ for some $1 \le i_0 \le k$, where $\Omega \subset \mathbb{R}^2$ is an arcwise connected domain. In other words, K_ϵ separates gradient Young measures.

Key words. two-dimensional parallel wells, separation of gradient Young measures, Laplacian operator, BMO estimate, quasi-convex functions, density argument

1. Introduction.

The study of weak convergent sequences of gradients approaching a compact set of matrices and their corresponding gradient Young measures [15] is the central theme for the variational approach to material microstructure [8, 9, 21, 5]. An important mathematical question in this approach is the following [5]: Given a compact set $K \subset M^{N\times n}$ of real matrices and a bounded sequence of vector-valued mappings $u_j : \Omega \subset \mathbb{R}^n \to \mathbb{R}^N$ such that the sequence of gradients (Du_j) satisfies $\text{dist}(Du_j, K) \to 0$ in $L^1(\Omega)$ as $j \to \infty$, what can we say about the possible oscillation of (Du_j) (mathematically, the gradient Young measure generated by (Du_j))? In particular, in the multiwell model of material microstructure, by using nonlinear elasticity, we see that the set $K \subset M^{n\times n}$ with $n = 2$ or 3 consists of finitely many copies of $SO(n)$ in the form $K = \cup_{i=1}^k SO(n)H_i$, where H_i's are positive definite matrices. Each $SO(n)H_i$ is called an elastic well.

In practice, one uses the algebraic properties of the set K. If there are rank-one connections in K, one can construct microstructures by using laminates [9, 10, 21] or laminates within laminates [5]. This construction does not give all (mathematically) possible microstructures, as shown by an example due to Šverák [21]. For certain sets K without rank-one connections, one seeks to show that the set prevents the formation of microstructure by using partial differential equation methods [25, 26, 19] or the minors relations [5]. The question we address in this paper, loosely speaking, lies between the two situations above; that is, we give conditions for certain disconnected sets in the multiwell model in two dimensions which prevent "large" scale oscillations among different wells, while microstructures can be formed "locally" near each individual well.

In their study of metastability and local minimizers, Ball and James [9] addressed this problem. They established by a contradiction argument that for a disjoint set $K = K_1 \cup K_2 \subset M^{N\times n}$ with $K_1 \cap K_2 = \emptyset$, which separates gradient Young measures, there is some $\epsilon > 0$ such that the closed ϵ-neighborhood $K_\epsilon = (K_1)_\epsilon \cup (K_1)_\epsilon$ still separates gradient Young measures.

In this paper we give estimates of closed ϵ-neighborhoods K_ϵ of the set of parallel

multielastic wells $K = \cup_{i=1}^k \lambda_i SO(2) \subset M^{2\times 2}$, $0 < \lambda_1 < \cdots < \lambda_k$ in two dimensions. This is a continuation of the earlier work [32] for finite sets in a subspace of $M^{N\times n}$ without rank-one matrices. The main feature of the present case is that the set K has nontrivial topology, while it is the simplest model among the multielastic well structure $\cup_{i=1}^k SO(2)H_i$ in two dimensions [8, 28, 9, 5, 21]. We have the following theorem.

THEOREM 1. *Let $k \geq 1$, and let $K = \cup_{i=1}^k \lambda_i SO(2) \subset M^{2\times 2}$ be given as above. Suppose $\Omega \subset \mathbb{R}^2$ is a bounded arcwise connected Lipschitz domain. Then there is some $\epsilon_1 > 0$ depending on $r_K = \min_{1\leq i\leq k-1}(\lambda_{i+1}^2 - \lambda_i^2)$, $g_K = \min_{1\leq i\leq k-1}(\lambda_{i+1} - \lambda_i)$, and $d_K = 2\lambda_k$ such that for every $0 < \epsilon \leq \epsilon_1$ and every bounded sequence $(u_j) \subset \mathbb{W}^{1,1}(\Omega, \mathbb{R}^2)$ satisfying*

$$\lim_{j\to\infty} \int_\Omega \operatorname{dist}(Du_j,\, K_\epsilon)dx = 0, \tag{1.1}$$

there is a weak convergent subsequence $u_{j_s} \rightharpoonup u$ in $W^{1,1}(\Omega,\, \mathbb{R}^2)$ and some $1 \leq i_0 \leq k$ such that

$$\lim_{s\to\infty} \int_\Omega \operatorname{dist}(Du_{j_s},\, [\lambda_{i_0} SO(2)]_\epsilon)dx = 0 \quad \textit{and} \quad Du(x) \in [\lambda_{i_0} SO(2)]_\epsilon \ \textit{ a.e. in } \ \Omega. \tag{1.2}$$

Remark 1. Theorem 1 can be stated by using gradient Young measures. Suppose (u_j) satisfies (1.1) and let $\{\nu_x\}_{x\in\Omega}$ be the family of gradient Young measures [15] corresponding to a subsequence of (Du_j). Clearly, the support of ν_x satisfies $\operatorname{supp}\nu_x \subset K_\epsilon$ a.e. Then for some $\epsilon_1 > 0$ depending on the parameters above, we claim that $\operatorname{supp}\nu_x \subset (\lambda_{i_0} SO(2))_\epsilon$ a.e. for some $1 \leq i_0 \leq k$ and the weak limit $Du(x) = \bar\nu_x \in (\lambda_{i_0} SO(2))_\epsilon$ when $0 < \epsilon < \epsilon_1$, where $\bar\nu_x = \int_{K_\epsilon} \lambda d\nu_x$ is the integral average of ν_x.

A disjoint compact set $K = K_1 \cup K_2 \subset M^{N\times n}$ with $K_1 \cap K_2 = \emptyset$ is said to separate gradient Young measures if, for any family of Young measures $\{\nu_x\}_{x\in\Omega}$ supported in K, either $\operatorname{supp}\nu_x \subset K_1$ a.e. or $\operatorname{supp}\nu_x \subset K_2$ a.e. [10]. Our contribution for the present case is a direct estimate of the neighborhood K_ϵ of K that still separates gradient Young measures.

Our approach is based on Schauder's estimates in BMO and Campanato spaces for the Laplacian operator [14], the weak continuity of Jacobians [20, 3, 11], and a recent approximation result due to Müller [22], improving upon an earlier result of the author [30] for sequences of gradients approaching a compact set $K \subset M^{N\times n}$.

Let E_∂ and $E_{\bar\partial}$ be the subspaces of conformal and anticonformal matrices in $M^{2\times 2}$. Note that E_∂ and $E_{\bar\partial}$ are orthogonal complements to each other. We denote by P_{E_∂} and $P_{E_{\bar\partial}}$ the orthogonal projections to these subspaces, respectively. Let $Q\operatorname{dist}^2(A, K)$ be the quasi-convex relaxation of $\operatorname{dist}^2(A, K)$.

Since in our case we can calculate explicitly the quasi-convex relaxation $Q\operatorname{dist}^2(A, K)$, we are able to locate the weak limit Du of Du_j by showing that $Du \in K_\epsilon$ a.e. The use of the homogeneous Young measure [15] makes it possible for us to localize our problem first by considering sequences with fixed affine boundary values. Due to the fact that our set K is contained in E_∂, the projection $P_{E_{\bar\partial}} Du_j$ of the gradient Du_j to its orthogonal complement $E_{\bar\partial}$ is elliptic [5] and the operator $2\operatorname{div} P_{E_{\bar\partial}} Du_j = \Delta u_j$ is exactly the Laplacian. The local Schauder estimate on the approximate solutions v_j obtained in [22] shows that the BMO seminorm of Dv_j is small, so we can use the special geometric and analytic features of the Jacobian, together with a density argument, to establish Theorem 1.

We conclude this section by examining the geometry of the quasi-convex relaxation of the squared distance function to K in Theorem 1. One of the implications of our calculations is that for $0 < \epsilon \le g_K\sqrt{2}/2$, if $\lim_{j\to\infty}\int_\Omega \operatorname{dist}^2(Du_j,\, K_\epsilon)dx = 0$ and u_j converges weakly to u in $W^{1,2}$, then $Du(x) \in K_\epsilon$ a.e. We have the following theorem.

THEOREM 2. *Suppose K is given as in Theorem* 1. *Then the quasi-convex relaxation $Q\operatorname{dist}^2(A, K)$ is given by $Q\operatorname{dist}^2(A, K) = C_{E_\partial}[\operatorname{dist}^2(P_{E_\partial}(A),\, K) + |P_{E_{\bar\partial}}(A)|^2] + [|P_{E_{\bar\partial}}(A)|^2 - |P_{E_\partial}(A)|^2]$, where $C_{E_\partial}[\operatorname{dist}^2(P_{E_\partial}(A),\, K) + |P_{E_\partial}(A)|^2]$ is the convexification of $\operatorname{dist}^2(P_{E_\partial}(A),\, K) + |P_{E_\partial}(A)|^2$ in E_∂. Furthermore,*

(i) *the relaxation is bounded below by the function itself:*

$$Q\operatorname{dist}^2(A,\, K) \ge \frac{1}{2}\operatorname{dist}^2(A,\, K),\ A \in M^{2\times 2};$$

(ii) *whenever* $\operatorname{dist}(A,\, K) \le g_K\sqrt{2}/2$ *with* g_K *given by Theorem* 1, *that is,* $A \in K_{\sqrt{2}g_K/2}$,

$$Q\operatorname{dist}^2(A,\, K) = \operatorname{dist}^2(A,\, K);$$

(iii) *let* $F_\epsilon(X) = \max\{Q\operatorname{dist}^2(A,\, K) - \epsilon^2,\ 0\}$ *for* $0 < \epsilon \le g_K\sqrt{2}/2$; *then* $F_\epsilon \ge 0$ *is a quasi-convex function with quadratic growth and* $F_\epsilon^{-1}(0) = K_\epsilon$.

Theorem 2 shows that at least the quasi-convex relaxation $Q\operatorname{dist}^2(A,\, K)$ does not have any effect on $\operatorname{dist}^2(A,\, K)$ as long as A is in the closed neighborhood $K_{\sqrt{2}g_K/2}$. If a bounded sequence (u_j) in $W^{1,2}(\Omega,\, \mathbb{R}^N)$ converges weakly to u and $\lim_{j\to\infty}\int_\Omega \operatorname{dist}^2(Du_j,\, K_\epsilon)dx = 0$, then $\lim_{j\to\infty}\int_\Omega F_\epsilon(Du_j)dx = 0$, and hence by [2] $\int_\Omega F_\epsilon(Du)dx = 0$, which implies $Du(x) \in K_\epsilon$.

In section 2, notation and preliminaries are given that are needed for proving our main theorem. We establish Theorem 1 in section 3 through two lemmas by assuming Theorem 2. Finally, we prove Theorem 2 in section 4.

2. Preliminaries. Throughout this paper, Ω denotes a bounded arcwise connected open subset of $\mathbb{R}^n$ with Lipschitz boundary. By an arcwise connected domain Ω we mean that for any $x_1, x_2 \in \Omega$, there is a piecewise affine curve $\gamma : [0, 1] \to \Omega$ such that $\gamma(0) = x_1$, $\gamma(1) = x_2$ and each affine piece of γ is parallel to one of the coordinate axes. We denote by $M^{N\times n}$ the space of real $N \times n$ matrices ($N,\, n \ge 2$) with inner product $A \cdot B = \operatorname{tr}(A^TB)$ and norm $|A| = (\operatorname{tr} A^TA)^{1/2}$, where A^T and tr are the transpose of A and the trace operator, respectively. We denote the Lebesgue spaces $L^p(\Omega, \mathbb{R}^N)$ and Sobolev spaces $W^{1,p}(\Omega,\, \mathbb{R}^N)$ and $W_0^{1,p}(\Omega, \mathbb{R}^N)$ for vector-valued functions $u : \Omega \to \mathbb{R}^N$ as usual [1]. The Lebesgue measure of a measurable set S in $\mathbb{R}^n$ is denoted by $\operatorname{meas}(S)$, and we use $\rightharpoonup$ and $\overset{*}{\rightharpoonup}$ to denote weak convergence and weak-$*$ convergence, respectively. The integral average of a (matrix-valued) function f over a measurable set S is written as

$$\fint_S f(x)\,dx = \frac{1}{\operatorname{meas}(S)}\int_S f(x)dx := [f]_S.$$

We define the p-distant function from $Y \in M^{N\times n}$ to a set $K \subset M^{N\times n}$ by $\operatorname{dist}^p(Y, K) := \inf_{A\in K}|Y - A|^p$. The subspaces of conformal and anticonformal matrices are given by

$$E_\partial = \left\{\begin{pmatrix} a & b \\ -b & a\end{pmatrix},\ a,\, b \in \mathbb{R}\right\}, \quad E_{\bar\partial} = \left\{\begin{pmatrix} a & b \\ b & -a\end{pmatrix},\ a,\, b \in \mathbb{R}\right\},$$

respectively. Note that E_∂ and $E_{\bar\partial}$ are orthogonal to each other and

$$SO(2) = \{A \in M^{2\times 2},\ A^T A = I,\ \det A = 1\} \subset E_\partial.$$

A continuous function $f : M^{N\times n} \to \mathbb{R}$ is quasi-convex (see [20, 3]) if

$$\int_U f(A + D\phi(x))\,dx \geq f(A)\,\mathrm{meas}(U)$$

for every $A \in M^{N\times n}$, $\phi \in C_0^\infty(U;\mathbb{R}^N)$, and every open bounded subset $U \subset \mathbb{R}^n$. Also, f is called rank-one convex if, for any A, $B \in M^{N\times n}$ with $\mathrm{rank}(A-B) = 1$ and any $0 \leq \lambda < 1$, $f(\lambda A + (1-\lambda)B) \leq \lambda f(A) + (1-\lambda) f(B)$. It is well known that quasi convexity implies rank-one convexity [20, 3, 11]. However, the converse is not true [27]. It is also well known that the Jacobian $A \to \det(A)$ is quasi-convex.

For a continuous function $f : M^{N\times n} \to \mathbb{R}$ bounded below, the quasi-convex relaxation Qf and rank-one convex relaxation Rf of f are defined, respectively, by $Qf = \sup\{g \leq f,\ g \,\text{quasiconvex}\}$ and $Rf = \sup\{g \leq f,\ g \,\text{rank-one convex}\}$. It is well known that in general $Qf \leq Rf$ (see [11]).

There is an iterative construction of Rf for a given continuous function f due to Kohn and Strang [16, 17, 18], namely,

$$\begin{cases} R_0 f = f, \\ R_{k+1} f(A) = \inf\{\lambda R_k f(A_1) + (1-\lambda) R_k f(A_2), \\ \lambda A_1 + (1-\lambda) A_2 = A, \quad \mathrm{rank}(A_1 - A_2) \leq 1\}. \end{cases} \tag{2.1}$$

It was proved in [16, 17, 18] that $Rf = \lim_{k\to\infty} R_k f$. We call this construction the Kohn–Strang scheme, which will be used to establish Theorem 2. Similarly, we see that the convex envelope Cf can also be calculated by dropping the rank-one restriction in (2.1):

$$\begin{cases} C_0 f = f, \\ C_{k+1} f(A) = \inf\{\lambda C_k f(A_1) + (1-\lambda) R_k f(A_2), \quad \lambda A_1 + (1-\lambda) A_2 = A\}, \\ Cf = \lim_{k\to\infty} C_k f. \end{cases} \tag{2.2}$$

We use the following theorem concerning the existence and properties of Young measures [29, 4, 15] and the homogeneous Young measures [15].

PROPOSITION 1. *Let (z_j) be a bounded sequence in $L^1(\Omega;\mathbb{R}^s)$. Then there exist a subsequence (z_{j_k}) of $(z^{(j)})$ and a family $(\nu_x)_{x\in\Omega}$ of probability measures on $\mathbb{R}^s$, depending measurably on $x \in \Omega$, such that*

$$f(z_{j_k}) \rightharpoonup \int_{\mathbb{R}^s} f(\lambda) d\nu_x(\lambda) \qquad \text{in } L^1(\Omega) \text{ as } k \to \infty$$

for every continuous function $f : \mathbb{R}^s \to \mathbb{R}$ such that $(f(z_{j_k}))$ is sequentially weakly relatively compact in $L^1(\Omega)$.

If the sequence z_j is in the form $z_j = Du_j$, where $\Omega \subset \mathbb{R}^n$ is open and bounded, and (u_j) is a bounded sequence in $W^{1,p}(\Omega, \mathbb{R}^N)$ for some $1 < p \leq \infty$, then the corresponding family of Young measures (ν_x) is called p-gradient Young measures (see [15, 5]). A family of (gradient) Young measures is *trivial* if ν_x is a Dirac measure for almost every x. In this case there exists a function u such that ν_x is the Dirac measure at $Du(x)$, and, up to a subsequence, $Du_k \to Du$ a.e.

The following result on homogeneous Young measures was obtained in [15].

PROPOSITION 2. *Let $\{\nu_x\}_{x\in\Omega}$ be a family of p-gradient Young measures with*

$$\int_{M^{N\times n}} \lambda d\nu_x(\lambda) = Du(x)$$

and $\operatorname{supp}\nu_x \subset K$ *for almost every* $x \in \Omega$ *for a compact set* $K \subset M^{N\times n}$. *Then for almost every* $x_0 \in \Omega$, *there exists a bounded sequence* (ϕ_k) *in* $W_0^{1,\infty}(D,\mathbb{R}^N)$ *such that the corresponding gradient Young measures* $\{\hat\nu_y\}$ *of the sequence* $(Du(x_0)+D\phi_k)$ *satisfy* $\hat\nu_y = \nu_{x_0}$ *for almost every* $y \in D$, *where* D *is the unit open cube in* $\mathbb{R}^n$. *We call* $\nu := \hat\nu_y$ *a homogeneous Young measure.*

Now we recall some definitions and results for linear elliptic systems with constant coefficients [14]. The Campanato spaces $\mathcal{L}^{p,\lambda}(\Omega)$ for $p \ge 1$, $\lambda \ge 1$ on a Lipschitz domain are defined by

$$\mathcal{L}^{p,\lambda}(\Omega) = \left\{ u \in L^p(\Omega),\ \sup_{x_0\in\Omega,\,0<\rho\le\operatorname{diam}(\Omega)} \rho^{-\lambda}\int_{\Omega(x_0,\rho)} |u-[u]_{x_0,\rho}|^p dx = [u]^p_{\mathcal{L}^{p,\lambda}(\Omega)} < \infty \right\},$$

where $\Omega(x_0,\rho) = \Omega\cap B_\rho(x_0)$ and $[u]_{x_0,\rho} = \fint_{\Omega(x_0,\rho)} u dx$.

We also have the local version of the space $BMO(\Omega)$ as L^1 functions on Ω with seminorm

$$\|u\|_{BMO(\Omega)} = \sup\left\{ \left(\fint_Q |u-[u]_Q|^p dx\right)^{1/p},\quad Q\subset\Omega \right\} < +\infty,$$

where $1 \le p < \infty$, $Q \subset \Omega$ are closed cubes with edges parallel to the coordinate axes, and $[u]_Q = \fint_Q u dx$. In this paper we mainly consider BMO on a cube or a ball.

It is well known [14] from John–Nirenberg's inequality that for all $1 \le p < \infty$, the BMO seminorms are equivalent, and one can replace cubes $Q \subset \Omega$ by balls and the resulting seminorm is still equivalent. It is also known that $\mathcal{L}^{p,n}(\Omega)$ is equivalent to $BMO(\Omega)$.

PROPOSITION 3 (see [14, Chap. 3–4]). *Let* $\Omega \subset \mathbb{R}^n$ *be open. Suppose* $u \in W^{1,2}_{loc}(\Omega)$ *is a weak solution of the Poisson equation* $\Delta u = \operatorname{div} f$ *in* Ω *with* $f \in L^\infty(\Omega,\mathbb{R}^n)$; *then for any* $x_0 \in \Omega$ *and* $0 < \rho < R$ *such that* $B_\rho(x_0) \subset B_R(x_0) \subset \bar B_R(x_0) \subset \Omega$, *we have that*

$$\fint_{B_\rho(x_0)} |Du-[Du]_{x_0,\rho}|^2 dx \le C\left[\left(\frac{\rho}{R}\right)^\tau \fint_{B_R(x_0)} |Du-[Du]_{x_0,R}|^2 dx + [f]^2_{\mathcal{L}^{2,2}(\Omega)}\right],$$

where $C > 0$ *and* $0 < \tau < 2$ *are constants.*

Next we state the approximation result of Müller [22], which we will need later.

PROPOSITION 4. *Let* $\Omega \subset \mathbb{R}^n$ *be an open set and let* $K \subset M^{N\times n}$ *be compact and convex. Suppose* $(u_j) \subset W^{1,p}(\Omega,\mathbb{R}^N)$, $1 \le p < \infty$, *and* $\lim_{j\to\infty}\int_\Omega \operatorname{dist}^p(Du_j,K)dx \to 0$. *Then there exists a sequence* (v_j) *of Lipschitz mappings such that*

$$\|\operatorname{dist}(Dv_j,K)\|_{L^\infty} \to 0,\quad \operatorname{meas}\{x\in\Omega,\ u_j \ne v_j\} \to 0 \qquad \text{as } j\to\infty.$$

We conclude this section by briefly recalling the notion of density for a measurable subset V of $\mathbb{R}^n$. A point $x \in \mathbb{R}^n$ is a point of density 1 of V if $\lim_{r\to 0}\operatorname{meas}(B_r(x)\cap$

$V)/\operatorname{meas}(B_r(x) = 1$ and a point of density 0 of V if $\lim_{r\to 0}\operatorname{meas}(B_r(x)\cap V)/\operatorname{meas}(B_r(x)) = 0$ [24, 12]. It is well known [24, 12] that

$$\lim_{r\to 0}\frac{\operatorname{meas}(B_r(x)\cap V)}{\operatorname{meas}(B_r(x))} = 1 \text{ for almost every } x\in V$$

and

$$\lim_{r\to 0}\frac{\operatorname{meas}(B_r(x)\cap V)}{\operatorname{meas}(B_r(x))} = 0 \text{ for almost every } x\in \mathbb{R}^n\setminus V;$$

that is, almost every $x\in V$ is a point of density 1 of V and almost every $x\notin V$ is a point of density 0 of V. It is also known that the balls $B_r(x)$ in the definition can be replaced by cubes $Q_r(x)$ centered at x with edges parallel to one of the coordinate axes and with radius $r>0$ [24].

3. Proof of Theorem 1. We decompose the proof of Theorem 1 into two lemmas. By using homogeneous gradient Young measures [15] in Lemma 1, we localize our problem to a simpler one. We show that if a sequence of gradients Dv_j corresponds to a homogeneous Young measure ν satisfying $\operatorname{supp}\nu\subset K_\epsilon$, then $\operatorname{supp}\nu\subset(\lambda_{i_0}SO(2))_\epsilon$ for some $1\le i_0\le k$. Then in Lemma 2 we deal with the regularity problem that $Du\in K_\epsilon$ a.e. implies that $Du\in(\lambda_{i_0}SO(2))_\epsilon$ for some i_0 a.e. Let $D\subset\mathbb{R}^2$ be the unit closed square $[0,\,1]^2$.

LEMMA 1. *Let $K=\cup_{i=1}^k\lambda_i SO(2)$ with $0<\lambda_1<\cdots<\lambda_k$. Then there is some $\epsilon_2>0$ depending on r_K, g_K, and d_K in Theorem 1 such that for $0<\epsilon\le\epsilon_2$, $A\in(\lambda_{i_0}SO(2))_\epsilon$ with a fixed $1\le i_0\le k$, and $\phi_j\in W_0^{1,\infty}(D,\mathbb{R}^2)$ satisfying $\phi_j\overset{*}{\rightharpoonup}0$ in $W^{1,\infty}(D,\mathbb{R}^2)$ such that $(A+D\phi_j)$ generates the homogeneous gradient Young measure ν with $\operatorname{supp}\nu\subset K_\epsilon$; then $\operatorname{supp}\nu\subset(\lambda_{i_0}SO(2))_\epsilon$.*

The assumption that A is in one of the wells is guaranteed by Theorem 2.

LEMMA 2. *Let K be as in Lemma 1 and let $\Omega\subset\mathbb{R}^n$ be a bounded arcwise connected Lipschitz domain. Then there are some $\epsilon_3>0$ depending on r_K, g_K, and d_K as above such that $u\in W^{1,\infty}(\Omega,\mathbb{R}^N)$, $Du(x)\in K_\epsilon$ for almost every $x\in\Omega$, and $0<\epsilon\le\epsilon_3$ imply $Du(x)\in(\lambda_{i_0}SO(2))_\epsilon$ a.e. in Ω for some $1\le i_0\le k$.*

We prove Lemma 1 first, followed by the proof of Lemma 2. Then the proof of Theorem 1 will follow easily from them.

Before we establish Lemma 1, let me explain the main idea and steps of the proof.

By using induction, Theorem 2, and Proposition 4, we may find another sequence v_j bounded in $W^{1,\infty}$ such that $A+Dv_j$ is in a small neighborhood of $C(K)$, while A is near $\lambda_{i_0}SO(2)$ for some $1\le i_0\le k$. By using BMO seminorm locally on a fixed small square Q_0, we can show that $\|Dv_j\|_{BMO(Q_0)}$ is small.

To deal with the geometry of the set K, we consider $\|\det(A+Dv_j)\|_{BMO(Q_0)}$, which is also small, while the values of $\det(A+Dv_j)$ will be close to the ordered set $\{\lambda_i^2\}$, that is,

$$\det(A+Dv_j)=\sum_{i=1}^k\lambda_i^2\chi_{U_j^i}+\det(A+Dv_j)\chi_{W_j}+O(\epsilon),$$

with U_j^i the subset in Q_0, and where $\det(A+Dv_j)$ is close to λ_i^2, while W_j is the transition part whose measure tends to zero as $j\to\infty$.

Then we consider two cases, either (a) $\lambda_k^2 - \lambda_{i_0}^2 \geq \lambda_{i_0}^2 - \lambda_1^2$, or (b) $\lambda_{i_0}^2 - \lambda_1^2 \geq \lambda_k^2 - \lambda_1^2$. For case (a), we show that $\operatorname{meas}(U_j^k) \to 0$ to finish the proof by the induction assumption. If (b) happens, we can prove that $\operatorname{meas}(U_j^1) \to 0$, and again the proof will be finished.

Under assumption (a), if we let $\alpha_j^k = \operatorname{meas}(U_j^k \cap Q)/\operatorname{meas}(Q)$ for $Q \subset Q_0$, we use the smallness of the *BMO* seminorm of the Jacobian to show that (see (3.8))

$$\alpha_j^k(1-\alpha_j^k) \leq C\left(\epsilon + \fint_Q (\lambda_k^2 + |\det(A+Dv_j)|)\chi_{W_j}dx\right).$$

On the other hand, on Q_0, we will see that $\alpha_j^k < 3/4$ for large j, while at each point $x \in Q_0$ of density 1 for U_j^k, we can find a small square $Q \subset Q_0$ containing x such that $\alpha_j^k > 3/4$. By a continuous deformation of squares, we can find a square Q_x lying between Q and Q_0 over which $\alpha_j^k = 3/4$. The idea here is to "maximize" the left-hand side of the above inequality.

If we substitute this square in the above inequality (i.e., (3.8) below) and assume $\epsilon > 0$ small, we can bound $\operatorname{meas}(Q_x)$ by $\int_{Q_x \cap W_j}(\lambda_k^2 + |\det(A+Dv_j)|)dx$. We then apply Besicovitch's lemma to show that $\operatorname{meas}(U_j^k)$ is bounded by $\int_{W_j}(\lambda_k^2 + |\det(A+Dv_j)|)dx$, which goes to zero; hence $\operatorname{meas}(U_j^k) \to 0$.

Proof of Lemma 1. We use induction. When $k = 1$, there is nothing to prove except that the weak limit satisfies $Du(x) \in (\lambda_{i_0} SO(2))_\epsilon$, which can be checked by using the estimates in Theorem 2 and the weak lower semicontinuity theorem of Acerbi and Fusco [2].

Suppose Lemma 1 is true for $k-1 \geq 1$ and that we seek to prove that it is still true for k. Let $A \in (\lambda_{i_0} SO(2))_\epsilon$. We apply Proposition 4 to $u_j = \phi_j$ and the compact set $C(K_\epsilon) - A$ to obtain a sequence $v_j \in W^{1,\infty}$ such that $Dv_j(x) \in (C(K_\epsilon) - A)_\epsilon$ and $\operatorname{meas}(\{x \in D,\, \phi_j \neq v_j\}) \to 0$. Thus $\int_D |D\phi_j - Dv_j|dx \to 0$ as $j \to \infty$. Letting $h_j = P_{E_{\bar\partial}} Dv_j$, we have $\|h_j\|_{L^\infty} \leq 3\epsilon$ and v_j satisfies $\operatorname{div} P_{E_{\bar\partial}} Dv_j = \operatorname{div} h_j$ in the weak sense. However, we see that $2\operatorname{div} P_{E_{\bar\partial}} Dv_j = \Delta v_j$ (see [6, 7]). Thus in the weak sense, $\Delta v_j = 2\operatorname{div} h_j$ in Ω.

From Schauder estimates for the Laplacian operator (Proposition 3), for a fixed $x_0 \in D$, $0 < \rho < R$ such that $B_\rho(x_0) \subset B_R(x_0) \subset \bar B_R(x_0) \subset B_{2R}(x_0) \subset D$, we have

$$\fint_{B_\rho(x_0)} |Dv_j - [Dv_j]_{x_0,\rho}|^2 dx \leq C\left[\left(\frac{\rho}{R}\right)^\tau \fint_{B_R(x_0)} |Dv_j - [Dv_j]_{x_0,R}|^2 dx + [h_j]^2_{\mathcal{L}^{2,2}(D)}\right],$$

where $C > 0$ and $0 < \tau < 2$ are constants. Hence we have

$$\begin{aligned}\|Dv_j\|^2_{BMO(Q_0)} &\leq C\left[\left(\frac{\rho}{2R}\right)^\tau \fint_{B_{2R}(x_0)} |Dv_j - [Dv_j]_{x_0,2R}|^2 dx + [h_j]^2_{\mathcal{L}^{2,2}(D)}\right] \\ &\leq C\left[\left(\frac{\rho}{2R}\right)^\tau 4(\lambda_k + 3\epsilon)^2 + \epsilon^2\right],\end{aligned}$$

where Q_0 is a cube centered at x_0 with side length ρ. Here we have used the fact that

$\|Dv_j\|_{L^\infty} \le 2\lambda_k+6\epsilon$. Now we choose $\rho>0$ small enough such that $(\frac{\rho}{2R})^\tau 4(\lambda_k+3\epsilon)^2 \le \epsilon^2$. Thus we have, for small $\rho>0$, $\|Dv_j\|^2_{BMO(Q_0)} \le C\epsilon^2$ for all $j>0$. Now we write $A+Dv_j(x)$ as

$$A+Dv_j(x)=\sum_{i=1}^{k} R_j(x)(\lambda_i I+f_j^i(x))\chi_{U_j^i}+(A+Dv_j(x))\chi_{W_j}, \tag{3.1}$$

where $U_j^i=\{x\in Q_0,\, A+Dv_j(x)\in(\lambda_i SO(2))_{2\epsilon}\}$, $i=1,\dots,k$, $W_j=Q_0\setminus(\cup_{i=1}^k U_j^i)$, and $\chi_{U_j^i}$ and χ_{W_j} are the characteristic functions of these sets, respectively. Also $R_j: Q_0\to SO(2)$ is a measurable mapping and f_j^i a small matrix-valued mapping for $i=1,2,\dots,k$, $j=1,2,\dots$. Note that $\mathrm{meas}(W_j)\to 0$ as $j\to\infty$. Let $w_j=\sum_{i=1}^k f_j^i\chi_{U_j^i}$; then w_j is a matrix-valued function with $\|w_j\|_{L^\infty}\le 2\epsilon$. Since A is a constant matrix, we have $\|A+Dv_j\|_{BMO(Q_0,M^{2\times 2})}\le C\epsilon$, and for each cube $Q\subset Q_0$,

$$⨍_Q |A+Dv_j-[A+Dv_j]_Q|dx\le C_1\epsilon, \tag{3.2}$$

where $C_1>0$ is an absolute constant independent of λ_k. We then have, from (3.2) and Taylor's expansion of the Jacobian, that

$$\begin{aligned}
&⨍_Q |\det(A+Dv_j)-[\det(A+Dv_j)]_Q|dx\\
&=⨍_Q\left|\int_0^1 \{\mathrm{adj}(t(A+Dv_j))+(1-t)[(A+Dv_j)]_Q\}\,dt((A+Dv_j)-[(A+Dv_j)]_Q)\right.\\
&\left.-\left[\int_0^1 \{\mathrm{adj}(t(A+Dv_j))+(1-t)[(A+Dv_j)]_Q\}\,dt((A+Dv_j)-[(A+Dv_j)]_Q)\right]_Q\right|dx\\
&\le 4(\lambda_k+3\epsilon)⨍_Q |A+Dv_j-[A+Dv_j]_Q|dx\le 32\lambda_k C_1\epsilon\le C_2\epsilon,
\end{aligned} \tag{3.3}$$

where $\mathrm{adj}(A)$ is the adjoint of A. Note that $C_2>0$ depends on the diameter $2\lambda_k$ of K. Also (3.1) implies

$$\begin{aligned}
\det(A+Dv_j(x))&=\sum_{i=1}^k(\det(R_j(x)\lambda_i I+f_j^i(x)))\chi_{U_j^i}+\det(A+Dv_j(x))\chi_{W_j}\\
&=\sum_{i=1}^k\lambda_i^2\chi_{U_j^i}+\det(A+Dv_j(x))\chi_{W_j}+H_j(x),
\end{aligned}$$

where $|H_j(x)|\le C\epsilon$. Now we substitute this decomposition into (3.3). For each fixed $Q\subset Q_0$,

$$\begin{aligned}
⨍_Q\Bigg|&\sum_{i=1}^k\lambda_i^2\chi_{U_j^i}+\det(A+Dv_j(x))\chi_{W_j}+H_j(x)\\
&-\left[\sum_{i=1}^k\lambda_i^2\chi_{U_j^i}+\det(A+Dv_j)\chi_{W_j}+H_j\right]_Q\Bigg|dx\le C_2\epsilon.
\end{aligned} \tag{3.4}$$

The left-hand side of (3.4) gives

$$
\begin{aligned}
(3.5)\quad & \fint_Q \left| \sum_{i=1}^{k} (\lambda_i^2 \chi_{U_j^i}) + \det(A + Dv_j(x)) \chi_{W_j} + H_j(x) \right. \\
& \qquad \left. - \left[\sum_{i=1}^{k} (\lambda_i^2 \chi_{U_j^i}) + \det(A + Dv_j) \chi_{W_j} + H_j \right]_Q \right| dx \\
& \geq \fint_Q \left| \sum_{i=1}^{k} ((\lambda_i^2 - \lambda_{i_0}^2) \chi_{U_j^i}) - \left[\sum_{i=1}^{k} ((\lambda_i^2 - \lambda_{i_0}^2) \chi_{U_j^i}) \right]_Q \right| dx - 2C\epsilon \\
& \quad - \fint_Q \left| \det(A + Dv_j(x)) \chi_{W_j} - \lambda_{i_0}^2 \chi_{U_j^{i_0}} - \left[\det(A + Dv_j(x)) \chi_{W_j} - \lambda_{i_0}^2 \chi_{U_j^{i_0}} \right]_Q \right| dx.
\end{aligned}
$$

Let $\alpha_j^i = \operatorname{meas}(U_j^i \cap Q)/\operatorname{meas}(Q)$ and $\beta_j = \operatorname{meas}(W_j \cap Q)/\operatorname{meas}(Q)$ so that $(\sum_{i=1}^{k} \alpha_j^i) + \beta_j = 1$ and $\alpha_j^i \geq 0$, $\beta_j \geq 0$, $i = 1, \ldots, k$.

We may assume that either (a) $\lambda_k^2 - \lambda_{i_0}^2 \geq \lambda_{i_0}^2 - \lambda_1^2$, or (b) $\lambda_{i_0}^2 - \lambda_1^2 \geq \lambda_k^2 - \lambda_1^2$.

If (a) holds, from (3.5) we have first that

$$
\begin{aligned}
& \fint_Q \left| \sum_{i=1}^{k} ((\lambda_i^2 - \lambda_{i_0}^2) \chi_{U_j^i}) - \left[\sum_{i=1}^{k} ((\lambda_i^2 - \lambda_{i_0}^2) \chi_{U_j^i}) \right]_Q \right| dx \\
& = \fint_Q \sum_{i=1}^{k} \left| (\lambda_i^2 - \lambda_{i_0}^2) - \left[\sum_{i=1}^{k} ((\lambda_i^2 - \lambda_{i_0}^2) \chi_{U_j^i}) \right]_Q \right| \chi_{U_j^i} dx \\
& \geq \fint_Q \left| (\lambda_k^2 - \lambda_{i_0}^2) - \left[\sum_{i=1}^{k} ((\lambda_i^2 - \lambda_{i_0}^2) \chi_{U_j^i}) \right]_Q \right| \chi_{U_j^k} dx \\
& \geq \fint_Q \left| \lambda_k^2 - \sum_{i=1}^{k} \lambda_i^2 \alpha_j^i \right| \chi_{U_j^k} dx - \beta_j \lambda_{i_0}^2 \\
& \geq \fint_Q \left| \lambda_k^2 - \sum_{i=1}^{k} \lambda_i^2 \alpha_j^i \right| \chi_{U_j^k} dx - \epsilon
\end{aligned}
$$

for large j as $\beta_j \to 0$. Thus,

$$
\begin{aligned}
& \frac{1}{\operatorname{meas}(Q)} \int_{U_j^k} \left| \lambda_k^2 - \sum_{i=1}^{k} \lambda_i^2 \alpha_j^i \right| dx = \alpha_j^k \left(\left| \lambda_k^2 - \sum_{i=1}^{k} \lambda_i^2 \alpha_j^i \right| \right) \\
(3.6)\qquad & \leq C_3 \epsilon + 2 \fint_Q (\lambda_k^2 + |\det(A + Dv_j(x))|) \chi_{W_j} dx \\
& \leq C_3 \epsilon + 2 \fint_Q (\lambda_k^2 + |\det(A + Dv_j(x))|) \chi_{W_j} dx.
\end{aligned}
$$

On the other hand, we have from (3.6) that

(3.7)
$$\alpha_j^k\left(\left|\lambda_k^2-\sum_{i=1}^k\lambda_i^2\alpha_j^i\right|\right)=\alpha_j^k\left(\left(\sum_{i=1}^k(\lambda_k^2-\lambda_i^2)\alpha_j^i\right)+\beta_j\lambda_k^2\right)$$
$$\geq\alpha_j^k\left(\sum_{i=1}^{k-1}(\lambda_k^2-\lambda_{k-1}^2)\alpha_j^i\right)+\alpha_j^k\beta_j\lambda_k^2=\alpha_j^k\left[(\lambda_k^2-\lambda_{k-1}^2)(1-\alpha_j^k-\beta_j)+\beta_j\lambda_k^2\right]$$
$$=(\lambda_k^2-\lambda_{k-1}^2)\alpha_j^k(1-\alpha_j^k)+\alpha_j^k\beta_j\lambda_{k-1}^2\geq(\lambda_k^2-\lambda_{k-1}^2)\alpha_j^k(1-\alpha_j^k)\geq r_K\alpha_j^k(1-\alpha_j^k).$$

Combining (3.6) and (3.7) we obtain

(3.8)
$$\frac{\operatorname{meas}(U_j^k\cap Q)}{\operatorname{meas}(Q)}\left(1-\frac{\operatorname{meas}(U_j^k\cap Q)}{\operatorname{meas}(Q)}\right)\leq C_4\epsilon+\frac{2}{r_K}⨍_Q(\lambda_k^2+|\det(A+Dv_j(x))|)\chi_{W_j}dx.$$

Here $C_4>0$ depends on λ_k^2 and r_K.

We also have $A=R_0(\lambda_{i_0}I+A_0)$ with A_0 a symmetric matrix, $|A_0|\leq\epsilon$, and $R_0\in SO(2)$; hence

$$|\det(A)-\lambda_{i_0}^2|\leq C(\lambda_k\epsilon+\epsilon^2),$$

where $C>0$ is an absolute constant. Now since $\det(A+Dv_j)\rightharpoonup\det(A)$ in $L^p(\Omega)$, $1\leq p<\infty$, we have for large j that

$$\left|⨍_{Q_0}(\det(A+Dv_j)-\det(A))dx\right|\leq\epsilon,$$

so that

$$\left|⨍_{Q_0}(\det(A+Dv_j)-\det(A)+(\lambda_{i_0}^2-\lambda_1^2)dx\right|\leq\epsilon+(\lambda_{i_0}^2-\lambda_1^2). \tag{3.9}$$

Therefore

$$\begin{aligned}&\left|⨍_{Q_0}\left(\sum_{i=1}^k(\lambda_i^2-\lambda_{i_0}^2)\chi_{U_j^i}+(\lambda_{i_0}^2-\lambda_1^2)\right)dx\right|\\&\leq C_2(\epsilon+\epsilon^2)+(\lambda_{i_0}^2-\lambda_1^2)+2⨍_{Q_0}(\lambda_k^2+|\det(A+Dv_j)|)\chi_{W_j}dx,\end{aligned} \tag{3.10}$$

while

$$\begin{aligned}&\left|⨍_{Q_0}\left(\sum_{i=1}^k(\lambda_i^2-\lambda_{i_0}^2)\chi_{U_j^i}+(\lambda_{i_0}^2-\lambda_1^2)\right)dx\right|\\&=\left|⨍_{Q_0}\left(\sum_{i=1}^k(\lambda_i^2-\lambda_1^2)\chi_{U_j^i}\right)+(\lambda_{i_0}^2-\lambda_1^2)\chi_{W_j}dx\right|\\&\geq(\lambda_k^2-\lambda_1^2)⨍_{Q_0}\chi_{U_j^k}dx=(\lambda_k^2-\lambda_1^2)\frac{\operatorname{meas}(U_j^k\cap Q_0)}{\operatorname{meas}(Q_0)}.\end{aligned} \tag{3.11}$$

Consequently,

$$\frac{\operatorname{meas}(U_j^k \cap Q_0)}{\operatorname{meas}(Q_0)} \le C_5\epsilon + \frac{\lambda_{i_0}^2 - \lambda_1^2}{\lambda_k^2 - \lambda_1^2} + \frac{2}{\lambda_k^2 - \lambda_1^2} \fint_{Q_0} (\lambda_k^2 + |\det(A + Dv_j)|)\chi_{W_j} dx$$
$$\le C_5\epsilon + \frac{1}{2} + \frac{2}{\lambda_k^2 - \lambda_1^2} \fint_{Q_0} (\lambda_k^2 + |\det(A + Dv_j)|)\chi_{W_j} dx,$$

where $C_5 > 0$ is a constant depending on r_K and d_K. Here we have used assumption (a), which gives $(\lambda_{i_0}^2 - \lambda_1^2)/(\lambda_k^2 - \lambda_1^2) \le 1/2$. Since $\fint_{Q_0} (\lambda_k^2 + |\det(A+Dv_j)|)\chi_{W_j} dx \to 0$ as $j \to \infty$, we have

$$\frac{\operatorname{meas}(U_j^k \cap Q_0)}{\operatorname{meas}(Q_0)} < \frac{3}{4} \qquad \text{if we require } \; C_5\epsilon < \frac{1}{4} \tag{3.12}$$

for large $j > 0$.

If (b) holds, we may obtain estimates similar to those above by replacing $\lambda_{i_0}^2 - \lambda_1^2$ by $\lambda_{i_0}^2 - \lambda_k^2$ in (3.10).

Now for any $x \in U_j^k$ with density 1, it is easy to see that x is an interior point of Q_0. We define a function on squares Q_x containing x with $Q_x \subset Q_0$ (by a square we always mean an open square in $\mathbb{R}^2$ with its edges parallel to the coordinate axes):

$$G(Q_x) = \frac{\operatorname{meas}(U_j^k \cap Q_x)}{\operatorname{meas}(Q_x)}.$$

Then the function $G(Q_x)$ is continuous with respect to continuous deformations of $Q_x \subset Q_0$ when $\operatorname{meas}(Q_x) > 0$. If we take $Q_x = Q_0$, then $G(Q_0) < 3/4$. We can also find some $Q_x^* \subset Q_0$ strictly inside Q_0 such that $G(Q_x^*) > 3/4$. Therefore, starting from Q_0 we may find a family of decreasing squares $Q(t) \subset Q_0$, $0 \le t \le 1$, such that $Q(t) \subset Q(s)$ if $t > s$, $\operatorname{meas}(Q(s) \setminus Q(t)) \to 0$ as $t \to s$ or $s \to t$, and $Q(0) = Q_0$, $Q(1) = Q_x^*$. Since $G(Q(t))$ is a continuous function of t, the intermediate value theorem implies that we may find some $Q(t_0) := Q_x$ containing x and inside Q_0 such that $G(Q_x) = 3/4$. Substituting this Q_x in (3.8), we obtain

$$G(Q_x)(1 - G(Q_x)) \le C_4\epsilon + \frac{2}{r_K} \fint_{Q_x} \left(\lambda_k^2 + |\det(A + Dv_j(y))|\right) \chi_{W_j} dy.$$

Substituting $G(Q_x) = 3/4$ in the last inequality, we obtain

$$\frac{3}{16} \le C_4\epsilon + \frac{2}{r_K} \fint_{Q_x} \left(\lambda_k^2 + |\det(A + Dv_j(y))|\right) \chi_{W_j} dy,$$

so that

$$\left(\frac{3}{16} - C_4\epsilon\right) \operatorname{meas}(Q_x) \le \frac{2}{r_K} \int_{Q_x} \left(\lambda_k^2 + |\det(A + Dv_j(y))|\right) \chi_{W_j} dy. \tag{3.13}$$

Here we need the left-hand side of (3.13) to be positive, so we require $\epsilon < 3/(16C_4)$. For each $x \in U_j^k$ with density 1, there is some $Q_x \subset Q_0$ containing x with the side-length less than 1 because $Q_0 \subset D$. Hence $\{Q_x\}$ covers U_j^k except for a subset of measure zero. From Besicovitch's covering lemma (see, for example, [12, 24, 14]), there is a countable subcollection $\{Q_s\}_{s=1}^{\infty}$ of $\{Q_x\}$ which still covers the subset of U_j^k

of points with density 1, with Q_s's overlapping at most 4 times (in two-dimensional Euclidean spaces), or $\sum_s^\infty \chi_{Q_s} \le 4$. Now we replace Q_x by Q_s and sum up the inequality over all Q_s's to obtain

$$\begin{aligned}\left(\frac{3}{16} - C_4\epsilon\right)\operatorname{meas}(U_j^k) &\le \sum_{s=1}^{\infty} \frac{2}{r_K}\int_{Q_s\cap W_j} \left(\lambda_k^2 + |\det(A+Dv_j(y))|\right) dy \\ &\le 8\frac{1}{r_K}\int_{W_j}\left(\lambda_k^2 + |\det(A+Dv_j(y))|\right) dy.\end{aligned} \tag{3.14}$$

So there is a $\gamma > 0$ such that for large $j > 0$,

$$\operatorname{meas}(U_j^k) \le \gamma \int_{W_j} \left(\lambda_k^2 + |\det(A+Dv_j(y))|\right)\chi_{W_j} dy.$$

We see that $\operatorname{meas}(U_j^k) \to 0$ as $j \to \infty$ if (a) holds, because

$$\lim_{j\to\infty}\int_{W_j}\left(\lambda_k^2 + |\det(A+Dv_j(y))|\right) dy = 0.$$

Hence $\operatorname{dist}^2(A+Dv_j, \cup_{i=1}^{k-1}(\lambda_k SO(2))_\epsilon) \to 0$ in $L^p(Q_0)$ as $j\to\infty$ for each fixed $1 \le p < \infty$. Therefore the gradient Young measure $\{\nu_x\}_{x\in D}$ corresponding to $A+Dv_j$ satisfies $\operatorname{supp}\nu_x \subset \cup_{i=1}^{k-1}(\lambda_i SO(2))_\epsilon$ a.e., at least for $x \in Q_0$. However, since $|Dv_j - D\phi_j| \to 0$ in $L^2(D)$, $A+Dv_j$ and $A+D\phi_j$ correspond to the same Young measures, while the Young measure generated by $A+D\phi_j$ is ν—a homogeneous Young measure. Thus $\nu = \nu_x$ for almost every $x \in D$, which implies that $\operatorname{supp}\nu \subset \cup_{i=1}^{k-1}(\lambda_i SO(2))_\epsilon$. From the induction assumption, $\operatorname{supp}\nu \subset (\lambda_{i_0} SO(2))_\epsilon$.

If (b) happens, we can show that $\operatorname{meas}(U_j^1) \to 0$ so that $\operatorname{supp}\nu \subset \cup_{i=2}^{k}(\lambda_i SO(2))_\epsilon$. In either case, the proof of Lemma 1 is finished. □

Next we prove Lemma 2. The idea is similar to that of Lemma 1, with a few exceptions. We write $Du(x) = \sum_{i=1}^k R(x)(\lambda_1 I + f^i(x))\chi_U^i(x)$ and assume that x_0 is a point of density 1 for some U^{i_0} and show that there is no point of density 1 for U^k if $i_0 \ne k$.

Let $D_s(x_0)$ be a small square on which $\det Du$ has small *BMO* seminorm, while $\alpha^{i_0} = \operatorname{meas}(U^{i_0}\cap D_s(x_0))/\operatorname{meas}(D_s(x_0)) > 3/4$, so that $\alpha^k \le 1/4$ on $D_s(x_0)$. Since in general we can show that $\alpha^k(1-\alpha^k) \le C\epsilon$ on small squares inside Ω (see (3.18)) due to the *BMO* estimate, we may separate the values of α_k on small squares as either $\alpha^k \ge 1/2 + \mu_0$ or $\alpha_k \le 1/2 - \mu_0$ for some small $\mu_0 > 0$. Instead of "maximizing" the left-hand side of the above inequality (see (3.18) below), as in the proof of Lemma 1, we claim that there is no point of density 1 for U^k in $D_s(x_0)$. Otherwise, a continuous deformation of squares in $D_s(x_0)$ and the intermediate value theorem will lead to a square with $\alpha^k = 1/2$, which contradicts the estimates for α^k. Then a continuation argument will finish the induction process.

Proof of Lemma 2. We use the notation in the proof of Lemma 1 except for the subscript j. If $k = 1$, we have nothing to prove. If for $k-1 \ge 1$ the statement is true, we consider the case k. Suppose $Du(x) \in K_\epsilon$; we also have $|P_{E_{\bar\partial}}(Du(x)| \le \epsilon$ a.e. in Ω. Let $F(x) = P_{E_{\bar\partial}}(Du(x))$ for $x \in \Omega$; then u is a weak solution of

$$\Delta u = 2\operatorname{div}(P_{E_{\bar\partial}}(Du(x))) = 2\operatorname{div} F(x).$$

From Proposition 3, we have, for each $x_0 \in \Omega$, $0 < \rho < R$ such that $\bar B_\rho(x_0) \subset$

$\bar{B}_R(x_0) \subset \Omega$, and there is some $0 < \gamma < 2$ such that

(3.15)
$$\int_{B_\rho(x_0)} |Du - [Du]_{B_\rho(x_0)}|^2 dx \le C_1 \left(\frac{\rho}{R}\right)^{\gamma+2} \int_{B_R(x_0)} |Du - [Du]_{B_R(x_0)}|^2 dx + C_1 \epsilon^2 \rho^2,$$

where $C_1 > 0$ is a constant. If we choose $R > 0$ such that $\bar{B}_{2R}(x_0) \subset \Omega$, then for any $0 < \rho < R$ in (3.15),

(3.16)
$$\begin{aligned} &⨍_{B_\rho(x_0)} |Du - [Du]_{B_\rho(x_0)}|^2 dx \le C_2 \left(\frac{\rho}{R}\right)^{\gamma} ⨍_{B_R(x_0)} |Du - [Du]_{B_R(x_0)}|^2 dx + C_2 \epsilon^2 \\ &\le 16 C_2 \lambda_k^2 \left(\frac{\rho}{R}\right)^{\gamma} + C_2 \epsilon^2. \end{aligned}$$

Here we have used the fact that $\|Du\|_{L^\infty(\Omega, M^{2\times 2})} \le 2(\lambda_k + \epsilon) \le 4\lambda_k$ if we require $\epsilon < \lambda_k$. Thus if we choose $0 < \rho < R$ such that $\rho^\gamma < R^\gamma \epsilon^2 / C_2 (4\lambda_k)^2$, then $\|Du\|_{BMO(D_\rho(x_0))} \le C_3 \epsilon$ for squares centered at x_0 with side-length ρ, where $C_3 > 0$ is a constant depending on λ_k. Thus for every $x_0 \in \Omega$, there is $r = r(x_0, \Omega) > 0$ such that

$$\|Du\|_{BMO(D_r(x))} \le C_3 \epsilon. \tag{3.17}$$

Now since $Du(x) \in K_\epsilon$ in Ω, we write

$$Du(x) = \sum_{i=1}^{k} R(x)(\lambda_i I + f^i(x)) \chi_U^i(x), \tag{3.18}$$

where $\chi_{U^i}(x)$ is the characteristic function of $U^i = \{x \in \Omega,\, Du(x) \in (\lambda_i SO(2))_\epsilon\}$, while

$$\left\| \sum_{i=1}^{k} f^i \chi_{U^i} \right\|_{L^\infty(\Omega, M^{2\times 2})} \le \epsilon.$$

Since $\mathrm{meas}(\Omega \setminus (\cup_{i=1}^k (U_i)_\epsilon) = 0$ and U^i's are disjoint, without loss of generality, we may assume that $x_0 \in U^{i_0} \subset \Omega$ is a point of density 1. By definition of the density, there is a square $D_s(x_0) \subset D_r(x_0)$ with $s = s(x_0, \Omega)$ such that

$$\frac{\mathrm{meas}(U^{i_0} \cap D_s(x_0))}{\mathrm{meas}(D_s(x_0))} > \frac{3}{4}; \quad \text{hence} \quad \frac{\mathrm{meas}((\cup_{i\neq i_0}^k U^i) \cap D_s(x_0))}{\mathrm{meas}(D_s(x_0))} < \frac{1}{4}. \tag{3.19}$$

Notice that λ_1 and λ_k are two end points of the set $\{\lambda_i,\, 1 \le i \le k\}$. Now we claim that (i) if $\lambda_{i_0} \neq \lambda_k$, $\mathrm{meas}(U^k \cap D_s(x_0)) = 0$; (ii) if $\lambda_{i_0} \neq \lambda_1$, $\mathrm{meas}(U^1 \cap D_s(x_0)) = 0$. Supposing the assumption of (i) is satisfied, we use the Jacobian again as in the proof of Lemma 1. Since (3.17) and the boundedness of Du in L^∞ imply

$$⨍_Q |\det(Du) - [\det(Du)]_Q| dx \le C\epsilon \tag{3.20}$$

for every square $Q \subset D_r(x_0)$, where $C > 0$ depends on λ_k, we substitute (3.18) into (3.20) to obtain

$$⨍_Q \left| \sum_{i=1}^{k} \lambda_i^2 \chi_{U^i} - \left[\sum_{j=1}^{k} \lambda_j^2 \chi_{U^j} \right]_Q \right| dx \le C_4 \epsilon,$$

where $C_4 > 0$ depends on λ_k. Letting $\alpha^i = \operatorname{meas}(Q \cap U^i)/\operatorname{meas}(Q)$, $i = 1, \dots, k$, we have $\sum_{i=1}^k \alpha^i = 1$, $\alpha_i \geq 0$, and

$$\fint_Q \left| \sum_{i=1}^k \lambda_i^2 \chi_{U^i} - \left[\sum_{j=1}^k \lambda_j^2 \chi_{U^j} \right]_Q \right| dx \geq \fint_Q \left| \lambda_k^2 \chi_{U^k} - \left[\sum_{j=1}^k \lambda_j^2 \chi_{U^j} \right]_Q \right| \chi_{U^k} dx$$

$$= \alpha_k \left| \sum_{i=1}^k (\lambda_k^2 - \lambda_i^2)\alpha^i \right| \geq \alpha_k \sum_{i=1}^{k-1} (\lambda_k^2 - \lambda_{k-1}^2)\alpha^i = (\lambda_k^2 - \lambda_{k-1}^2)\alpha_k(1-\alpha_k) \geq r_K \alpha_k(1-\alpha_k).$$

Combining the last two sets of inequalities, we have

$$\alpha_k(1-\alpha_k) \leq C_4 \epsilon / r_K$$

on any square $Q \subset D_r(x_0)$. Note that the inequality above holds for any square $Q \subset D_r(y)$, $y \in \Omega$ and $r = r(y, \Omega)$. Now we require that $\epsilon < r_K/(4C_4)$. Then

$$\frac{\operatorname{meas}(U^k \cap Q)}{\operatorname{meas}(Q)} \left(1 - \frac{\operatorname{meas}(U^k \cap Q)}{\operatorname{meas}(Q)} \right) \leq \frac{1}{4} - \mu_0 \tag{3.21}$$

for some $0 < \mu_0 < 1/4$. Solving inequality (3.21), we have either

$$\text{(a)} \quad \frac{\operatorname{meas}(U^k \cap Q)}{\operatorname{meas}(Q)} \leq \frac{1}{2} - \sqrt{\mu_0}, \quad \text{or} \quad \text{(b)} \quad \frac{\operatorname{meas}(U^k \cap Q)}{\operatorname{meas}(Q)} \geq \frac{1}{2} + \sqrt{\mu_0} \tag{3.22}$$

for all squares $Q \subset D_r(x_0)$. We claim that (3.22(b)) cannot happen if $Q \subset D_s(x_0)$. If the claim is not true, there is some $Q_0 \subset D_s(x_0)$ such that (3.22(b)) holds. Since on $Q = D_s(x_0)$, (3.19) holds, and hence (3.22(a)) must hold, we may find a continuous family of squares $Q(t) \subset D_s(x_0)$, $0 \leq t \leq 1$, with $Q(0) = D_s(x_0)$ and $Q(1) = Q_0$, and show that there is some $Q(t_0) \subset D_s(x_0)$, $0 < t_0 < 1$, such that

$$\frac{\operatorname{meas}(U^k \cap Q(t_0))}{\operatorname{meas}(Q(t_0))} = \frac{1}{2}.$$

However, such a $Q(t_0)$ satisfies neither (3.22(a)) nor (3.22(b)), a contradiction.

Since (3.22(a)) holds for every nondegenerate square in $D_s(x_0)$, we may conclude that the points of density 1 for U^k in $D_s(x_0)$ are an empty set, and hence $\operatorname{meas}(U^k \cap D_s(x_0)) = 0$. Consequently, $Du(x) \in \cup_{i=1}^{k-1} (\lambda_i SO(2))_\epsilon$ a.e. in $D_s(x_0)$.

Now we show that $Du(x) \in \cup_{i=1}^{k-1} (\lambda_i SO(2))_\epsilon$ a.e. in Ω. Since Ω is arcwise connected, for any $x_1 \in \Omega$, there is a piecewise affine curve $\gamma : [0,1] \to \Omega$ connecting x_0 and x_1, with each piece of affine subcurve parallel to one of the coordinate axes such that $\operatorname{dist}(\gamma, \partial\Omega) = R_0 > 0$. So we may assume that there is some $0 < r_0 < R$ such that (3.17) holds on $D_{r_0}(x)$ for every $x \in \gamma$ and either (3.22(a)) or (3.22(b)) holds (note that (3.22(a)) and (3.22(b)) are independent of Q_0). Starting from $x_0 = \gamma(0)$ for sufficiently small $s > 0$, we consider a family of squares $Q(t) = D_s(\gamma(t))$ and a continuous function

$$f_s(t) = \frac{\operatorname{meas}(U^k \cap Q(t))}{\operatorname{meas}(Q(t))}.$$

Since $f_s(0) = 0$ as we proved earlier and either $f_s(t) \leq 1/2 - \sqrt{\mu_0}$ or $f_s(t) \geq 1/2 + \sqrt{\mu_0}$, we see that $f_s(t) \leq 1/2 - \sqrt{\mu_0}$ for all $t \in [0, 1]$. Hence $f_s(1) \leq 1/2 - \sqrt{\mu_0}$. Equivalently, we have

$$\frac{\operatorname{meas}(U^k \cap D_s(x_1))}{\operatorname{meas}(D_s(x_1))} \leq \frac{1}{2} - \sqrt{\mu_0}$$

for sufficiently small $s > 0$. Thus x_1 and, in general, every point in Ω are not points of density 1 for U^k; hence $\text{meas}(U^k) = 0$. Therefore $Du(x) \in \cup_{i=1}^{k-1}(\lambda_i SO(2))_\epsilon$ a.e. in Ω. The conclusion then follows from the induction assumption.

If the assumption of (ii) is satisfied, that is, $\lambda_{i_0} \neq \lambda_1$, a similar argument will lead to the conclusion that $\text{meas}(U^1) = 0$. Again by induction assumption, $Du(x) \in (\lambda_{i_0} SO(2))_\epsilon$ a.e. in Ω. □

Proof of Theorem 1. Let $\epsilon > 0$ satisfy the requirements of Theorem 2 and Lemmas 1 and 2. Since $\lim_{j\to 0} \int_\Omega \text{dist}(Du_j\, K_\epsilon)dx = 0$, there is a subsequence $u_{j_s} \rightharpoonup u$ in $W^{1,1}(\Omega, \mathbb{R}^2)$ with $\{\nu_x\}_{x\in\Omega}$ the corresponding gradient Young measures. This is because K_ϵ is compact, and hence $|Du_j|$ is equi-integrable in Ω. Therefore,

$$\lim_{s\to\infty} \int_\Omega \text{dist}(Du_{j_s}\, K_\epsilon)dx = \int_\Omega \int_{K_\epsilon} \text{dist}(\tau,\, K_\epsilon)d\nu_x(\tau)\, dx = 0,$$

which implies that $\text{supp}\,\nu_x \subset K_\epsilon$ a.e. Then for almost every $x_0 \in \Omega$, we see, from Proposition 2, that there is a homogeneous Young measure $\mu_x = \nu = \nu_{x_0}$, $x \in D$ a.e., supported in K_ϵ with the generating sequence $Du(x_0) + D\phi_{j_s}$ (up to yet another subsequence; see Proposition 4) with $\phi_{j_s} \in W_0^{1,\infty}(D, \mathbb{R}^2)$, and ϕ_{j_s} converges in the weak-$*$ sense to 0 in $W_0^{1,\infty}(D, \mathbb{R}^2)$, where D is the unit square in $\mathbb{R}^2$. Let $A = Du(x_0)$. Since $\lim_{k\to\infty} \int_D \text{dist}^p(A + D\phi_{j_s}(x), K_\epsilon)dx = 0$ for all $1 \leq p < \infty$, we may apply Theorem 2 to the quasi-convex function $F_\epsilon(\cdot)$ given by Theorem 2 to conclude that $Du(x_0) = A \in K_\epsilon$, and hence $Du(x_0) \in (\lambda_{i_0} SO(2))_\epsilon$ for some $1 \leq i_0 \leq k$. Lemma 1 then implies that

$$\lim_{k\to\infty} \int_D \text{dist}^p(A + D\phi_{j_k}(x),\, (\lambda_{i_0} SO(2))_\epsilon)dx = 0.$$

Thus $\text{supp}\,\nu_{x_0} = \text{supp}\,\nu \subset (\lambda_{i_0} SO(2))_\epsilon$ and $Du(x_0) \in (\lambda_{i_0} SO(2))_\epsilon$. Since this is true for almost every $x_0 \in \Omega$, we may claim that $\text{supp}\,\nu_x \subset (\lambda_{i_x} SO(2))_\epsilon$ if $Du(x) \in (\lambda_{i_x} SO(2))_\epsilon$ for some $1 \leq i_x \leq k$.

Since in any case we have $Du(x) \in K_\epsilon$ a.e., from Lemma 2 we see that $Du(x) \in (\lambda_{i_0} SO(2))_\epsilon$ a.e. in Ω for some fixed $1 \leq i_0 \leq k$. Combining this with the last paragraph, we see that $\text{supp}\,\nu_x \subset (\lambda_{i_0} SO(2))_\epsilon$ a.e. in Ω, that is,

$$\lim_{k\to\infty} \int_D \text{dist}(Du_{j_s}(x),\, (\lambda_{i_0} SO(2))_\epsilon)dx = 0. \qquad \square$$

4. Proof of Theorem 2. The quasi-convex relaxation for $Q\,\text{dist}^2(A,\, SO(2)H)$ was obtained in [13]. We first show that

(4.1)
$$Q\,\text{dist}^2(A, K) = C_{E_\partial}[\text{dist}^2(P_{E_\partial}(A), K) + |P_{E_\partial}(A)|^2] + [|P_{E_{\bar\partial}}(A)|^2 - |P_{E_\partial}(A)|^2].$$

Clearly

$$\begin{aligned} F(A) &:= \text{dist}^2(A, K) \\ &= [\text{dist}^2(P_{E_\partial}(A), K) + |P_{E_\partial}(A)|^2] + [|P_{E_{\bar\partial}}(A)|^2 - |P_{E_\partial}(A)|^2] \\ &= V(A) + H(A) \qquad (4.2) \\ &\geq C_{E_\partial}[\text{dist}^2(P_{E_\partial}(A), K) + |P_{E_\partial}(A)|^2] + [|P_{E_{\bar\partial}}(A)|^2 - |P_{E_\partial}(A)|^2] \\ &= G(A) + H(A), \end{aligned}$$

where $G(A) = C_{E_\partial} V(A)$, and the right-hand side of (4.2) is quasi-convex because G is convex and $2H(A) = -\det A$ is quasi-convex. Thus

$$Q\,\mathrm{dist}^2(A, K) \geq G(A) + H(A). \tag{4.3}$$

Next we show that $R\,\mathrm{dist}^2(A, K) \leq G(A) + H(A)$. To see this we use the Kohn–Strang scheme (2.1). Let $\Lambda = \{a \otimes b \in M^{2\times 2},\, a,\, b \in \mathbb{R}^2\}$ be the set of all rank-one matrices in $M^{2\times 2}$. It is easy to check that the mapping $P_{E_\partial} : \Lambda \to E_\partial$ is an onto map. Also $H(a \otimes b) = 0$ for every $a \otimes b \in \Lambda$. We let $P_{E_\partial}(A) = X$, Y_1, Y_2 be arbitrary matrices in E_∂ satisfying $\lambda Y_1 + (1-\lambda)Y_2 = X$, and we let $Z = (Y_1 - Y_2)$. Since $P_{E_\partial} : \Lambda \to E_\partial$ is onto, there is a rank-one matrix $B \in \Lambda$ such that $P_{E_\partial}(B) = Z$. Now we estimate $R_1 F(A)$ by lifting the matrices in E_∂ to $M^{2\times 2}$. We have $Y_1 = X + (1-\lambda)Z$, $Y_2 = X - \lambda Z$. We let $A_1 = A + (1-\lambda)B$, $A_2 = A - \lambda B$; then

$$\lambda A_1 + (1-\lambda)A_2 = A, \quad A_1 - A_2 = B \in \Lambda, \quad P_{E_\partial}(A_1) = Y_1, \quad P_{E_\partial}(A_2) = Y_2.$$

Thus

$$\begin{aligned} R_1 F(A) &\leq \lambda F(A_1) + (1-\lambda) F(A_2) \\ &= [\lambda V(P_{E_\partial}(A_1)) + (1-\lambda) G(P_{E_\partial}(A_2))] + [\lambda H(A_1) + (1-\lambda) H(A_2)] \\ &= I_1 + I_2. \end{aligned}$$

We have

$$\begin{aligned} I_1 &= \lambda V(P_{E_\partial}(A_1)) + (1-\lambda) V(P_{E_\partial}(A_2)) = \lambda V(Y_1) + (1-\lambda) V(Y_2), \\ I_2 &= \lambda H(A_1) + (1-\lambda) H(A_2) = \lambda H(A + (1-\lambda)B) + (1-\lambda) H(A - \lambda B). \end{aligned}$$

Since for a quadratic form, we have $H(A + P) = H(A) + H(B) + DH(A)B$, where $DH(A)$ is the gradient of H at A, which is linear in A, then

$$\begin{aligned} &\lambda H(A + (1-\lambda)B) = \lambda H(A) + \lambda H((1-\lambda)B) + \lambda(1-\lambda) DH(A)B \\ &= \lambda H(A) + \lambda(1-\lambda) DH(A)B. \end{aligned}$$

Here we have used the fact $H(B) = 0$. Similarly, we have

$$(1-\lambda) H(A - \lambda B) = (1-\lambda) H(A) - (1-\lambda)\lambda DH(A)B.$$

Hence $I_2 = \lambda H(A) + \lambda(1-\lambda) DH(A)B + (1-\lambda) H(A) - (1-\lambda)\lambda DH(A)B = H(A)$. Consequently, we obtain $R_1 F(A) \leq [\lambda V(Y_1) + (1-\lambda) V(Y_2)] + H(A)$. Taking infimum on Y_1, Y_2 with $\lambda Y_1 + (1-\lambda)Y_2 = X$ (cf. (2.2)), we obtain

$$R_1 F(A) \leq C_1 V(A) + H(A). \tag{4.4}$$

Repeating the previous step by using (4.4), we see that $R_k F(A) \leq C_k V(A) + H(A)$. Passing to the limit $k \to \infty$, we have $RF(A) \leq [C_{E_\partial} V(P_{E_\partial}(A))] + H(A)$. So the reversed inequality of (4.3) is reached. Since we also have $RF(A) \geq QF(A) \geq C_{E_\partial} V(P_{E_\partial}(A)) + H(A)$, the proof of $Q\,\mathrm{dist}^2(A, K) = G(A) + H(A)$ is complete.

The estimates in (i) can be easily deduced from the following lemma, which was established in [31] by taking $\lambda = 1$.

LEMMA 3. *Let $K \subset \mathbb{R}^n$ be a closed set with $K \neq \mathbb{R}^n$. Then*

$$C[\mathrm{dist}^2(x, K) + \lambda|x|^2] - \lambda|x|^2 \geq \frac{\lambda}{1+\lambda}\,\mathrm{dist}^2(x, K)$$

for $x \in \mathbb{R}^n$, where $\lambda > 0$ is a constant.

Notice that if $K = \mathbb{R}^n$, the above inequality is trivially true.

Now we prove (ii). Note that (iii) is a direct consequence of (ii). We may view the problem in (ii) as a problem in the Euclidean space $\mathbb{R}^2$: Suppose $K \subset \mathbb{R}^2$ consists of finitely many circles, in our case, $K = \cup_{i=1}^k S_{\sqrt{2}\lambda_i} \subset \mathbb{R}$, where $S_\lambda = \{x \in \mathbb{R}^2,\ |x| = \lambda\}$. Let $\hat{K} = \{\sqrt{2}\lambda_i\}_{i=1}^k$. Then squared distance function can be written as $\operatorname{dist}^2(x, K) = \operatorname{dist}^2(|x|, \hat{K})$. We may view the function $[\operatorname{dist}^2(|x|, \hat{K}) + \lambda|x|^2]$ as an even function of one variable $\operatorname{dist}^2(t, \hat{K} \cup -\hat{K}) + \lambda t^2 := h(t)$, where $-\hat{K} = \{-\sqrt{2}\lambda_i\}_{i=1}^k$. We show that when t is close to $\hat{K} \cup -\hat{K}$, $C[h(t)] = h(t)$.

We give an estimate for the general case when $L \subset \mathbb{R}$ is any finite set and $f(x) = \operatorname{dist}^2(x, L) + \lambda|x|^2$ for $x \in \mathbb{R}$. Since for a function f defined on $\mathbb{R}$, we have (see [23])

$$Cf(x) = \sup\{l(x),\ l(y) \le f(y),\ y \in \mathbb{R},\ l \text{ affine}\}.$$

It suffices if we can show for y_0 near L and $\operatorname{dist}(y_0, L) = |y_0 - x_0| < \epsilon$ for some $\epsilon > 0$ to be determined, $x_0 \in L$, that the tangent line of the graph of f at $(y_0, f(y_0))$ stays underneath the graph of f. The tangent line at y_0 is given by

$$l(y) = (y_0 - x_0)^2 + \lambda y_0^2 + 2(y - x_0)(y - y_0) + 2\lambda y_0(y - y_0).$$

Let us estimate $f(y)$. If $\operatorname{dist}(y, L) = |y - x_0|$, then $f(y) \ge l(y)$ because of the convexity of f near x_0. Let $d = \min\{|x - y|,\ x \ne y,\ x,\ y \in L\} > 0$. If $\operatorname{dist}(y, L) = |y - x_1| < |y - x_0|$ for some $x_1 \in L$, we have

$$\begin{aligned} f(y) &= (y - x_1)^2 + \lambda y^2 = (y - x_0)^2 + \lambda y^2 + 2(y - x_0)(x_0 - x_1) + (x_0 - x_1)^2 \\ &= G(y) + H(y), \end{aligned}$$

where $G(y) = (y - x_0)^2 + \lambda y^2$ and $H(y) = 2(y - x_0)(x_0 - x_1) + (x_0 - x_1)^2$. We then have, by Taylor's expansion of G at y_0, that $G(y) = l(y) + (1 + \lambda)(y - y_0)^2$, and hence

$$\begin{aligned} &f(y) - l(y) = (1 + \lambda)(y - y_0)^2 + H(y) \\ &\ge (1 + \lambda)(y - y_0)^2 - 2|y - x_0||x_1 - x_0| + (x_0 - x_1)^2 \\ &\ge [(1 + \lambda)(y - y_0)^2 - 2|y - y_0||x_1 - x_0| + (x_0 - x_1)^2] - 2|x_0 - y_0||x_1 - x_0| \\ &\ge \frac{\lambda}{1 + \lambda}(x_0 - x_1)^2 - 2|x_0 - y_0||x_1 - x_0| \\ &\ge |x_0 - x_1| \left(\frac{\lambda}{1 + \lambda} d - |x_0 - y_0| \right) \ge 0 \end{aligned}$$

whenever $|y_0 - x_0| \le \lambda d/(1 + \lambda)$. Therefore we have $Cf(y_0) = f(y_0)$ when $\operatorname{dist}(y_0, L) \le \lambda d/(1 + \lambda)$. Hence we conclude that $R \operatorname{dist}^2(A, K) = Q \operatorname{dist}^2(A, K) = \operatorname{dist}^2(A, K)$ whenever $\operatorname{dist}(A, K) \le \lambda d/(1 + \lambda)$. Setting $\lambda = 1$ in our case and calculating

$$\begin{aligned} d &= \min\{|X - Y|,\ X, Y \in P_{E\partial}(K),\ X \ne Y\} \\ &= \sqrt{2} \min\{\lambda_{i+1} - \lambda_i,\ i = 1, \dots, k - 1\} = \sqrt{2} g_K, \end{aligned}$$

thus $R \operatorname{dist}^2(A, K) = Q \operatorname{dist}^2(A, K) = \operatorname{dist}^2(A, K)$ whenever $\operatorname{dist}^2(A, K) \le \frac{\sqrt{2}}{2} g_K$.

Acknowledgment. I wish to thank the referees for their helpful suggestions.

L^1 STABILITY FOR SYSTEMS OF HYPERBOLIC CONSERVATION LAWS WITH A RESONANT MOVING SOURCE*

SEUNG-YEAL HA† AND TONG YANG‡

Abstract. In this paper, we study the L^1 stability for the system $u_t + f(u)_x = g(x-ct,u)$ when one of the characteristic fields has resonance with the moving source. The nonlinear resonance occurs when the speed of the source can coincide with one of the characteristic speeds of the hyperbolic conservation laws. In this situation, a wave pattern can be either stable or unstable. By employing a nonlinear functional approach, we prove the L^1 stability of a transonic shock wave under the stability conditions introduced in [W.-C. Lien, *Comm. Pure Appl. Math.,* 52 (1999), pp. 1075–1098; T.-P. Liu, *Comm. Math. Phys.,* 83 (1982), pp. 243–260].

Key words. L^1 nonlinear functional, hyperbolic conservation laws, resonant source

1. Introduction.

The purpose of this paper is to study the L^1 stability for systems of hyperbolic conservation laws with a resonant moving source:

$$\begin{cases} u_t + f(u)_x = g(x-ct,u), & (x,t) \in \mathbb{R} \times \mathbb{R}_+, \\ u(x,0) = u_0(x), & x \in \mathbb{R}, \end{cases} \tag{1.1}$$

where $u \in \mathcal{N} \subset \mathbb{R}^n$, $f : \mathcal{N} \to \mathbb{R}^n$, and $g : \mathbb{R} \times \mathcal{N} \to \mathbb{R}^n$ denote the conserved quantities, the C^3 flux function, and the source, respectively. Here $\mathcal{N}$ is a small neighborhood of some reference state u_0 in $\mathbb{R}^n$. This system is assumed to be strictly hyperbolic with the ith characteristic field being resonant with the source, i.e., $\lambda_i(u) \approx c$. It is well known [13] that in general, the system (1.1) does not admit a classical solution even for the smooth initial data because of the nonlinearity of the flux function. Therefore, one needs to consider weak solutions.

DEFINITION 1.1. *A bounded measurable function $u(x,t)$ is a weak solution of the system* (1.1) *with given initial data $u_0(x)$ if and only if*

$$\int_0^\infty \int_{-\infty}^\infty [u\phi_t + f(u)\phi_x + g(x-ct,u)\phi](x,t)dxdt + \int_{-\infty}^\infty u_0(x)\phi(x,0)dx = 0$$

$$\textit{for any } \phi \in C_c^1(\mathbb{R}^2).$$

Hyperbolic systems of conservation laws with sources appear in many physical situations, such as three-dimensional compressible Euler equations with symmetries

[6], a flow through a duct of variable cross section [6, 14, 19, 18, 17, 16, 24], and a moving magnetic field for magneto-hydrodynamics (MHD) [12]. A prototype of these systems is a quasi-one-dimensional nozzle flow model:

$$\begin{cases} \dfrac{\partial \rho}{\partial t} + \dfrac{\partial(\rho u)}{\partial x} = -\dfrac{A'(x)}{A(x)}(\rho u), \quad (x,t) \in \mathbb{R} \times \mathbb{R}_+, \\ \dfrac{\partial(\rho u)}{\partial t} + \dfrac{\partial(\rho u^2 + P)}{\partial x} = -\dfrac{A'(x)}{A(x)}(\rho u^2), \\ \dfrac{\partial(\rho E)}{\partial t} + \dfrac{\partial(\rho u E + P u)}{\partial x} = -\dfrac{A'(x)}{A(x)}(\rho u E + P u), \\ P = P(e, \rho), \end{cases}$$

where $A(x)$ is the cross sectional area of a nozzle, ρ is the density, u is the velocity, P is the pressure, e is the internal energy, and $E = e + \frac{u^2}{2}$ is the total energy of a gas.

The global existence and time-asymptotic stability of (1.1) were studied in [14, 19, 18, 17, 16]. Recently in [2, 11], the L^1 stability of small initial data was studied for systems with a nonresonant moving source, i.e., in the case in which the characteristic speeds are strictly different from that of the source. In contrast, for the system with a resonant moving source, the global existence of weak solutions with bounded total variation (BV) has been studied only for special initial data such as a small perturbation of one transonic shock wave moving with speed c in [14, 18, 17], and its time-asymptotic stability and instability were shown to be strongly dependent on the source. Moreover, the time-asymptotic stability of a steady transonic shock wave under the stability condition (1.3) or (1.4) was analyzed in [14, 18]. Under the condition (1.3), a simple wave pattern consisting of one steady transonic shock wave in a nozzle is stable time-asymptotically so that the perturbed transonic shock wave is still observed in the nozzle. However, under the condition (1.4), the perturbed transonic shock wave is unstable time-asymptotically so that it is not observed in a nozzle after a finite time [9, 19, 18, 17]. Let $u_0 \in \mathcal{N}$ be a fixed reference state, and assume that the right (left) eigenvectors $r_i(u_0)$, $l_j(u_0)$ form dual bases such that

$$l_i(u_0) \cdot r_j(u_0) = \delta_{ij}, \quad 1 \le i,\ j \le n.$$

And by using a moving coordinate with speed c, we may assume that c equals zero; i.e.,

$$u_t + f(u)_x = g(x,u). \tag{1.2}$$

Set

$$u = \sum u^i r_i(u_0), \quad f(u) = \sum f^i(u) r_i(u_0), \quad g(x,u) = \sum g^i(x,u) r_i(u_0).$$

Then it follows from (1.2) that

$$\begin{cases} u^i = l_i(u_0) \cdot u, \quad f^i(u) = l_i(u_0) \cdot f(u), \quad g^i(x,u) = l_i(u_0) \cdot g(x,u), \\ u^i_t + f^i(u)_x = g^i(x,u), \quad 1 \le i \le n. \end{cases}$$

In the following, we assume that the source $g(x,u)$ has support $[0,1]$ in x and define a function $G(x)$ as follows.

$$g(x,u)=0, \quad x\notin(0,1), \quad G(x)\equiv \sup_{p\in\mathcal{N}}\left\{|g(x,p)|+\left\|\frac{\partial g(x,p)}{\partial p}\right\|\right\}.$$

For the resonant ith characteristic field, the following time-asymptotic stability and instability conditions were introduced in [14, 18]:

$$G_{ii}(x,u)\doteq l_i(u_0)\frac{\partial g(x,u)}{\partial u}r_i(u_0)<0 \quad \text{(stability)}, \tag{1.3}$$

$$G_{ii}(x,u)\doteq l_i(u_0)\frac{\partial g(x,u)}{\partial u}r_i(u_0)>0 \quad \text{(instability)}, \tag{1.4}$$

where we have used the notation $G_{ij}(x,u)\doteq l_i(u_0)\frac{\partial g(x,u)}{\partial u}r_j(u_0)$. In this paper, for the sake of definiteness, we assume the first characteristic field is resonant with the source. In the study of L^1 stability for the system (1.1), in order to have a uniform L^1 stability in time, one needs to control the error caused by the source, in addition to the analysis of the homogeneous hyperbolic conservation laws. In [2, 11], when the source has no resonance with any of the characteristic fields, a quadratic functional $Q_{so}(t)$ was introduced to control these errors in L^1 analysis:

$$\begin{aligned}
&Q_{so}(t)=\sum_{j=1}^{n}Q_{so}^j(t),\\
&Q_{so}^j(t)\equiv\begin{cases}\int_{-\infty}^{\infty}|q_j(x,t)|\left(\int_{x(q_j)}^{\infty}G(x)dx\right) & \text{if } \lambda(q_j)>0,\\ \int_{-\infty}^{\infty}|q_j(x,t)|\left(\int_{-\infty}^{x(q_j)}G(x)dx\right) & \text{if } \lambda(q_j)<0.\end{cases}
\end{aligned}$$

As long as the characteristic speeds of the system (1.2) are strictly away from zero, $Q_{so}(t)$ gives a good decay term with respect to time which is enough to control the errors caused by the source. However, for the resonant field $(\lambda_1(u),r_1(u))$, since $\lambda_1(u)$ has a definite sign depending on the relative location compared to the relatively strong shock wave, we need to modify the $Q_{so}^1(t)$, defined as in [2, 11], so that it gives the decay estimate:

$$\begin{aligned}
Q_{so}^1(t)=&\int_{-\infty}^{x_f(t)}|q_1(x,t)|\left(\int_{x(q_1)}^{\infty}G(\xi)d\xi\right)dx\\
&+\int_{x_f(t)}^{\infty}|q_1(x,t)|\left(\int_{x_f(t)}^{x(q_1)}G(\xi)d\xi+\int_{x_f(t)}^{\infty}G(\xi)d\xi\right)dx,
\end{aligned}$$

where $x_f(t)$ is the location of the relatively strong shock at time t. In Lemma 3.3, we estimate the error of time variation of L^1 distance due to the source which is in the following form:

$$\begin{aligned}
\Gamma_{so}&\equiv\sum_{j}\sum_{\alpha^i\in J}\{\lambda(q_j^-(\alpha^i))|q_j^-(\alpha^i)|-\lambda(q_j^+(\alpha^i))|q_j^+(\alpha^i)|\}\\
&=\sum_{j=1}^{n}\mathcal{O}(1)\int_{-\infty}^{\infty}G(x)|q_j(x,t)|dx.
\end{aligned}$$

As shown in [2, 11], the quadratic functional $Q_{so}(t)$,

$$
\begin{aligned}
Q_{so}(t) &\equiv \sum_{j=1}^{n} Q_{so}^{j}(t),\\
Q_{so}^{1}(t) &= \int_{-\infty}^{x_f(t)} |q_1(x,t)| \left(\int_{x(q_1)}^{\infty} G(\xi) d\xi \right) dx\\
&\quad + \int_{x_f(t)}^{\infty} |q_1(x,t)| \left(\int_{x_f(t)}^{x(q_1)} G(\xi) d\xi + \int_{x_f(t)}^{\infty} G(\xi) d\xi \right) dx,\\
Q_{so}^{j}(t) &= \int_{-\infty}^{\infty} |q_j(x,t)| \left(\int_{x(q_j)}^{\infty} G(\xi) d\xi \right) dx, \quad j \geq 2,
\end{aligned}
$$

can compensate the Γ_{so} effectively, and a uniform L^1 stability follows. The main assumptions of this paper are as follows.

Main Assumptions.

1. The system (1.1) is strictly hyperbolic. Let $\lambda_i(u), (i \in \{1, \dots, n\})$ be distinct real eigenvalues of $f'(u)$, and let $r_i(u)$ ($l_i(u)$) be the corresponding right (left) eigenvectors of $f'(u)$; i.e.,

$$
\begin{aligned}
&f'(u) r_i(u) = \lambda_i(u) r_i(u), \qquad && \lambda_1(u) < \cdots < \lambda_n(u),\\
&l_i(u) f'(u) = \lambda_i(u) l_i(u), && l_i(u) \cdot r_j(u) = \delta_{ij}.
\end{aligned}
$$

2. Each characteristic field $(\lambda_j(u), r_j(u))$ is either genuinely nonlinear (g.n.l.) or linearly degenerate (l.d.g.) in the sense of Lax [13]:

$$
\begin{aligned}
&(\lambda_j(u), r_j(u)) \quad \text{is g.n.l.} \iff \nabla \lambda_j(u) \cdot r_j(u) \neq 0 \quad \text{for all } u \in \mathcal{N},\\
&(\lambda_j(u), r_j(u)) \quad \text{is l.d.g.} \iff \nabla \lambda_j(u) \cdot r_j(u) \equiv 0.
\end{aligned}
$$

3. The first characteristic field is g.n.l. and resonant with the source; that is,

$$
\nabla \lambda_1(u) \cdot r_1(u) \neq 0, \quad \lambda_1(u) \approx 0 \text{ for } u \in \mathcal{N}.
$$

4. $g(x,p)$ is piecewise differentiable in x, is continuously differentiable in p, has compact support in x, and is sufficiently weak in the following sense:

$$
\begin{cases}
g(x,p) = 0 \ \text{ if } \ x \notin [0,1],\\
G(x) \equiv \sup\limits_{p \in \mathcal{N}} \left\{ |g(x,p)| + \left\| \dfrac{\partial g(x,p)}{\partial p} \right\| \right\}, \quad G_1 \equiv \|G(\cdot)\|_{L^1(\mathbb{R})},\\
G_0 \equiv \|G(\cdot)\|_{L^\infty(\mathbb{R})}, \quad G_0 + G_1 \ll 1.
\end{cases}
$$

We notice that the case in which the source is not of compact support but has the above smallness properties can be treated similarly.

Without any smallness assumption on the source, we can expect only a local L^1 stability in time. That is, there exist a finite time T and constants $C, \bar{c} > 0$ such that

$$
||u(\cdot,t) - v(\cdot,t)||_{L^1(\mathbb{R})} \leq C e^{\bar{c}t} ||u(\cdot,0) - v(\cdot,0)||_{L^1(\mathbb{R})} \quad \text{when} \quad 0 < t < T.
$$

This local L^1 stability was first proved in [8]. For a "diagonally dominant dissipative

system," L^1 stability based on a nonlinear functional approach through the front tracking algorithm was studied in [1].

The main result of this paper is as follows. Let $u(x)$ be a stationary solution consisting of a transonic 1-shock wave connecting to a supersonic stationary wave $u_1(x)$ for $x < x_*$ and a subsonic stationary wave $u_2(x)$ for $x > x_*$ as follows:

$$u(x) = \begin{cases} u(-\infty), & x < 0, \\ u_1(x), & 0 \le x < x_*, \\ u_2(x), & x_* < x \le 1, \\ u(+\infty), & x > 1, \end{cases}$$

and $\lambda_1(u_2(x)) < 0 < \lambda_1(u_1(x))$, $|\lambda_1(u(x))| \ge \lambda_* > 0$, $\sigma(u_1(x_*-), u_2(x_*+)) = 0$. Here λ_* is a positive constant.

THEOREM 1.2. *Let $v(x,t)$ be a weak solution obtained by the Glimm scheme corresponding to initial data v_0, which is a small perturbation of $u(x)$ in* [14, 18]. *Assume that the condition* (1.3) *holds. Then the steady transonic* 1*-shock wave solution is uniformly L^1 stable, i.e.,*

$$||v(\cdot,t) - u(\cdot)||_{L^1(\mathbb{R})} \le G||v_0(\cdot) - u(\cdot)||_{L^1(\mathbb{R})},$$

where G is a generic constant independent of t,

Remark 1.1. Under the instability condition (1.4), it is well known [14, 18] that there exists a perturbation which can be arbitrarily small so that the perturbed big shock wave moves away from the nozzle and goes to infinity as time goes to infinity. Therefore, the L_1 distance between the stationary solution and the perturbed solution grows in time and can reach any given constant in finite time. The detailed analysis will show that the L_1 distance between these two solutions grows at least linearly in time in the general setting.

The rest of the paper is organized as follows. In section 2, we will first define a modified Glimm-type functional which is slightly different from the one in [14]. Then we will review the basic theory of the nonlinear functional approach for L^1 stability. In section 3, we will derive basic estimates on the shock strength and on how the source affects the L^1 distance. Finally, in section 4, by using the nonlinear functional defined in section 2, we will prove L^1 stability of a steady transonic 1-shock wave solution under the condition (1.3).

2. Preliminaries. In this section, we are going to define a modified Glimm-type functional, which is slightly different from the one in [14], and briefly present the simplified wave patterns given in [3, 11, 21, 22]. And then, we will define a nonlinear functional which is equivalent to the L^1 distance of two approximate weak solutions.

We first review the basics of the theory for the system of hyperbolic conservation laws:

$$\begin{aligned} &u_t + f(u)_x = 0, \quad (x,t) \in \mathbb{R} \times \mathbb{R}_+, \\ &u(x,0) = u_0(x), \quad x \in \mathbb{R}. \end{aligned} \tag{2.1}$$

A discontinuity (u_-, u_+) is called an i-shock wave for (2.1) with speed σ if it satisfies the Rankine–Hugoniot and entropy conditions

$$\begin{cases} f(u_+) - f(u_-) = \sigma(u_+ - u_-) \ \text{(R–H condition)}, \\ \lambda_i(u_+) < \sigma < \lambda_i(u_-) \ \text{(entropy condition)}. \end{cases}$$

The Riemann problem for (2.1) is the initial value problem with simple jump initial data

$$u(x,0) = \begin{cases} u_l, & x < 0, \\ u_r, & x > 0. \end{cases}$$

It is well known [13] that the Riemann solution is a function of $\frac{x}{t}$ and consists of $n+1$ constant states $\{u_l = u_0, u_1, u_2, \dots, u_n = u_r\}$, which are connected by shock waves, rarefaction waves, or contact discontinuities.

In the following, we define an ith rarefaction curve $R_i(u_0)$ and an ith shock curve $H_i(u_0)$.

$$\begin{aligned} R_i(u_0) \equiv & \text{ the integral curve of a vector field } r_i(u) \cdot \nabla_u \text{ passing through } u_0, \\ H_i(u_0) \equiv & \{u \in \mathbb{R}^n : \lambda_i(u_0,u)(u-u_0) = f(u) - f(u_0) \text{ for some scalar } \lambda_i(u_0,u), \\ & \max_u \lambda_{i-1}(u) < \lambda_i(u_0,u) < \min_u \lambda_{i+1}(u)\}. \end{aligned}$$

For an l.d.g. characteristic field $(\lambda_i(u), r_i(u))$, it is well known [13] that $H_i(u_0) = R_i(u_0)$. We parameterize these curves by the arc length ξ, and we divide the ith shock curve $H_i(u_0)$ and the ith rarefaction curve $R_i(u_0)$ as follows:

$$\begin{aligned} H_i^+(u_0) &\equiv \{u \in H_i(u_0) : \lambda_i(u) > \lambda_i(u_0,u) > \lambda_i(u_0)\}, \\ H_i^-(u_0) &\equiv \{u \in H_i(u_0) : \lambda_i(u) < \lambda_i(u_0,u) < \lambda_i(u_0)\}, \\ R_i^+(u_0) &\equiv \{u \in R_i(u_0) : \lambda_i(u) \geq \lambda_i(u_0)\}, \\ R_i^-(u_0) &\equiv \{u \in R_i(u_0) : \lambda_i(u) \leq \lambda_i(u_0)\}. \end{aligned}$$

Moreover, we define an ith wave curve as follows:

$$W_i(u_0) \equiv \begin{cases} H_i^-(u_0) \cup R_i^+(u_0) \text{ if } i\text{th characteristic field is g.n.l.}, \\ H_i(u_0) = R_i(u_0) \text{ if } i\text{th characteristic field is l.d.g.} \end{cases}$$

Then by the second order contact of the ith shock curve and the ith rarefaction curve at u_0, the ith wave curve $W_i(u_0)$ is a C^2-curve [13].

We consider a small perturbation of a steady transonic shock wave under the condition (1.3). In this case, the Glimm-type functional is defined as follows [10, 14]. Let $r = \Delta x$ and $s = \Delta t$ in the Glimm scheme. Let J be a space like curve in $x - t$ plane. We use x_J to denote the location of the big shock wave on J and x_α to denote the location of any other small wave α.

$$\begin{aligned} F(J) &\equiv |\sigma_J| + \sum_{j>1} \bar{L}_j(J) + M_1 \bar{L}_1(J) + M_2 Q(J), \\ \bar{L}_j(J) &\equiv \sum \{|\alpha| : \alpha \text{ is a small } j\text{-wave which crosses } J\}, \\ \sigma_J, |\beta_J| &\equiv \text{ the speed and strength of the strong shock crossing } J, \text{ respectively}, \\ Q(J) &\equiv Q_0(J) + Q_1(J) + Q_2(J), \end{aligned}$$

$$Q_0(J) \equiv \sum \{|\alpha\beta| : \alpha \text{ and } \beta \text{ are strengths of small waves which are approaching and cross } J\},$$

$$Q_1(J) \equiv \sum \left\{ \frac{|\alpha|}{\lambda_*^2} \int_{x_\alpha}^{\infty} G(x)dx : \alpha \text{ is the strength of 1-wave which crosses } J \text{ with } x_\alpha < x_J \right\},$$

$$+ \sum \left\{ \frac{|\alpha|}{\lambda_*^2} \int_{x_J}^{x_\alpha} G(x)dx + \frac{|\alpha|}{\lambda_*^2} \int_{x_J}^{\infty} G(x)dx : \alpha \text{ is the strength of 1-wave which crosses } J \text{ with } x_\alpha > x_J \right\},$$

$$Q_2(J) \equiv \sum_{i>1} \sum \left\{ \frac{|\alpha|}{\lambda_*^2} \int_{x_\alpha}^{\infty} G(x)dx : \alpha \text{ is the strength of } i\text{-wave which crosses for } J \text{ for } i \neq 1 \right\},$$

where $1 \ll M_1 \ll M_2$ are positive constants which will be determined later. Here λ_* is the lower bound on $|\lambda_1(u)|$ defined before Theorem 1.2.

Remark 2.1. It is noted in [14] that the linear part of the Glimm-type functional is $L(J) = |\sigma_J| + \bar{L}(J)$. However, here we use $L(J) = |\sigma_J| + \sum_{j\neq 1} \bar{L}_j(J) + M_1\bar{L}_1(J)$. The reason for this is as follows. Near the relatively strong shock, small 1-waves from the perturbation will be combined with the relatively strong shock so that $L_1(J)$ decreases by the amount of the total strengths of these small 1-waves up to the order of the interaction potential. On the other hand, the interaction of the small 1-wave α with the relatively strong shock changes the speed of the relatively strong shock by the amount of $|\alpha|$. Therefore, by choosing $M_1 \ll M_2$ large enough to compensate for the contribution to the change of the speed of the relatively strong shock and the new created waves, $F(J)$ can be shown to be decreasing in time by the usual argument (cf. [14]).

Next, for the convenience of the readers, we will briefly explain the simplified wave pattern given in [11, 21, 22]. Let $\epsilon > 0$ be small, and let time $T > 0$ be given. Set $N = \frac{1}{\epsilon}$, and choose M such that

$$(M-1)Ns < T \leq MNs.$$

Without loss of generality, we may assume that N and M are integers; then it is easy to see that, for a fixed N,

$$\lim_{s\to 0} M = \infty.$$

Let δ be the error from the randomness of an equidistributed sequence $\{a_j\}$. Then we have

$$\delta \to 0, \quad \text{as} \quad M \to \infty, \quad \text{for any } \epsilon.$$

In the following, we define a time zone Λ_p, an interaction measure $Q(\Lambda_p)$, and a cancellation measure $C(\Lambda_p)$. For $i = 1, \ldots, M$,

$$\Lambda_p \equiv \{(x,t) \in \mathbb{R} \times \mathbb{R}_+ : (p-1)Ns \le t < pNs\},$$
$$Q(\Lambda_p) = \sum_{\Delta_{mn} \in \Lambda_p} Q(\Delta_{mn}), \quad C(\Lambda_p) = \sum_{\Delta_{mn} \in \Lambda_p} C(\Delta_{mn}),$$

where a local interaction measure $Q(\Lambda_{mn})$ and a local cancellation measure $C(\Lambda_{mn})$ are defined as follows. Let Δ_{mn} be a diamond whose vertices are $((m-1)r + a_j r, ns), (mr + a_j r, ns), (mr, (n+\frac{1}{2})s)$, and $(mr, (n-\frac{1}{2})s)$.

$$Q(\Delta_{mn}) \equiv \sum_{(\alpha_i,\beta_j):opp} \{|\alpha_i||\beta_j| : \ \alpha_i \text{ and } \beta_j \text{ pass through } \Delta_{mn} \ \},$$
$$C(\Delta_{mn}) \equiv \sum_{(\alpha_i,\beta_j):opp} \left\{ \frac{|\alpha_i| + |\beta_i| - |\alpha_i + \beta_j|}{2} : \ \alpha_i \text{ and } \beta_i \text{ pass through } \Delta_{mn} \right\},$$

where $(\alpha_i, \beta_j) : opp$ denotes the approaching pair defined in section 3.1 in [11].

In Λ_p, we can partition all waves at time $t = (p-1)Ns$ into surviving waves and cancelled waves as in [11, 21, 22]. Based on this wave partition, we can define a simplified wave pattern which consists only of surviving nonlinear waves with fixed speeds in each small time zone Λ_p. That is, in Λ_p all nonlinear waves are linearly superimposed. More precisely, since $u_r(x,t)$ is of bounded variation, for a given small number ϵ, we can find E such that $T.V\{u_r(x,t) : |x| > E\} < \epsilon$ for $(p-1)Ns \le t \le pNs$. Then we replace the $u_r(x,t)$ on $x < -E$ or $x > E$ by the values of $\lim_{x\to-\infty} u(x,t)$ or $\lim_{x\to\infty} u(x,t)$, respectively, in Λ_p. Therefore, we have a finite number of surviving waves in Λ_p. Let us denote surviving i-waves in Λ_p by $v_i^1, \dots, v_i^N$. For each i-wave v_i^k, its location in the Glimm scheme is randomly chosen by the sequence $\{a_j\}$. However, in the simplified wave pattern, it is replaced by the line connecting its locations at time $t = (p-1)Ns$ and $t = pNs$. As in the approximate solutions of the Glimm scheme, the hyperbolic waves in the simplified wave pattern are connected by stationary waves. Notice also that i-waves do not cross each other in Λ_p.

For the secondary waves such as nonsurviving waves in $u_r(x,t)$ and generated waves from the nonlinear interactions in Λ_p, we do not keep track of them in Λ_p but put them back at $t = pNs+$. This generates an error in the L^1-norm which vanishes eventually as $s \to 0$. Therefore, we can assume that waves in the simplified wave pattern $\bar{u}_r(x,t)$ move in a deterministic way, but their end states evolve according to a stationary solution. For details, please refer to [11, 21, 22].

Let $u(x,t)$ and $v(x,t)$ be two Glimm solutions of (1.1) such that

$$\lim_{r\to 0} u_r(x,t) = u(x,t), \quad \lim_{r\to 0} v_r(x,t) = v(x,t) \quad \text{in } L^1_{loc}(\mathbb{R} \times \mathbb{R}_+),$$

and let $\bar{u}_r(x,t)$ and $\bar{v}_r(x,t)$ be the corresponding simplified wave patterns, respectively. For the time being, we will fix r, and, without any confusion, we denote $\bar{u}_r(x,t)$ and $\bar{v}_r(x,t)$ by $u(x,t)$ and $v(x,t)$, respectively. For given $(x,t) \in \mathbb{R} \times \mathbb{R}_+$, we resolve a discontinuity $(u(x,t), v(x,t))$ by the n Hugoniot curves; i.e.,

$$\omega_0(x,t) = u(x,t), \quad \omega_n(x,t) = v(x,t), \quad \omega_i(x,t) \in H_i(\omega_{i-1}(x,t)), \ i = 0, 1, \dots, n.$$

Here, $H_i(\omega_{i-1}(x,t))$ is an ith Hugoniot curve passing through $\omega_{i-1}(x,t)$ in the state space. We define the strength $q_i(x,t)$ of $(\omega_{i-1}(x,t), \omega_i(x,t))$ as follows:

$$q_i(x,t) \equiv l_i(u_0) \cdot (\omega_i(x,t) - \omega_{i-1}(x,t)), \quad i = 1, \dots, n.$$

The strict hyperbolicity implies

$$\frac{1}{C_1}|u(x,t)-v(x,t)| \le \sum_{i=1}^{n}|q_i(x,t)| \le C_1|u(x,t)-v(x,t)| \tag{2.2}$$

for some positive constant C_1 independent of t.

In what follows, we will use the following simplified notation:

$$\begin{aligned}\mathcal{J}(u),\ \mathcal{J}(v):&\ \text{the set of all discontinuities in } u(x,t), v(x,t),\ \text{respectively,}\\ &\ \text{and } \mathcal{J}=\mathcal{J}(u)\cup\mathcal{J}(v).\end{aligned}$$

For an i-wave $\alpha^i \in \mathcal{J}$, we define the location of α^i and the virtual waves $q_j^{\pm}(\alpha^i)$ generated by the difference of u and v at both sides of α^i as follows:

$$\begin{aligned}x(\alpha^i) &\equiv \ \text{the location of an } i\text{-wave } \alpha^i,\\ q_j^{\pm}(\alpha^i) &\equiv q_j(x(\alpha^i)\pm,t),\quad \lambda_j^{\pm}(\alpha^i)\equiv\lambda_j(\omega_{j-1}(x(\alpha^i)\pm,t),\omega_j(x(\alpha^i)\pm,t)).\end{aligned}$$

In the following, we state three lemmas which are direct consequences of the smoothness of the Hugoniot curves which are proved in [5] and [22].

LEMMA 2.1. *Let $\bar{u}\in\mathcal{N}$ and $k\in\{1,2,\dots,n\}$. Let us define the states and wave speeds as follows:*

$$\begin{aligned}&u=H_k(\xi)(\bar{u}),\quad u'=H_k(\xi')(u),\quad u''=H_k(\xi+\xi')(\bar{u}),\\ &\lambda=\lambda_k(\bar{u},u),\quad \lambda'=\lambda_k(u,u'),\quad \lambda''=\lambda_k(\bar{u},u'').\end{aligned}$$

Then we have

$$|(\xi+\xi')\lambda''-(\xi\lambda+\xi'\lambda')| = \mathcal{O}(1)|\xi||\xi'||\xi+\xi'|.$$

LEMMA 2.2. *Suppose that ξ_j,ξ_j', and ξ_j'' satisfy*

$$H_n(\xi_n)\circ\cdots\circ H_1(\xi_1)(u)=H_n(\xi_n')\circ\cdots\circ H_1(\xi_1')\circ H_n(\xi_n'')\circ\cdots\circ H_1(\xi_1'')(u).$$

Then

$$\sum_{i=1}^{n}|\xi_i-\xi_i'-\xi_i''| = \mathcal{O}(1)\left\{\sum_{j=1}^{n}|\xi_j'||\xi_j''||\xi_j'+\xi_j''|+\sum_{j>i}|\xi_j''||\xi_i'|\right\}.$$

If the values ξ_i' and ξ are related by

$$R_i(\xi)(u^*)=H_n(\xi_n')\circ\cdots\circ H_1(\xi_1')(u^*),$$

then

$$|\xi-\xi_i'|+\sum_{j\neq i}|\xi_j'| = \mathcal{O}(1)\left\{|\xi||\xi_i'||\xi+\xi_i'|+\sum_{j\neq i}|\xi_j'||\xi|\right\}.$$

Suppose $\alpha^i=(v_-,v_+)\in\mathcal{J}$ is an i-wave in either v or u and the other solution is continuous at $x=x(\alpha^i)$.

Denote

$$\begin{aligned} e(\Lambda_p) &\equiv (Q(\Lambda_p) + C(\Lambda_p) + \delta + \epsilon + NsG_0), \\ \Gamma_s(\alpha^i) &\equiv |\alpha^i||q_i^-(\alpha^i)||q_i^+(\alpha^i)|, \\ \Gamma_d(\alpha^i) &\equiv |\alpha^i| \sum_{j>i} |q_j^-(\alpha^i)| + |\alpha^i| \sum_{j<i} |q_j^+(\alpha^i)|. \end{aligned}$$

The following lemma gives the variation of $q_j(x,t)$ across the wave α^i.

LEMMA 2.3. *Let $\alpha^i = (v_-, v_+) \in \mathcal{J}$ be an i-wave in the time zone Λ_p. Then we have*

$$q_j^+(\alpha^i) = \begin{cases} q_i^-(\alpha^i) + [\alpha^i] + \mathcal{O}(1)(\Gamma_s + \Gamma_d)(\alpha^i) + \mathcal{O}(1)|\alpha^i|e(\Lambda_p), & j = i, \\ q_j^-(\alpha^i) + \mathcal{O}(1)(\Gamma_s + \Gamma_d)(\alpha^i) + \mathcal{O}(1)|\alpha^i|e(\Lambda_p), & j \neq i, \end{cases}$$

where $[\alpha^i] \equiv l_i(u_0) \cdot (v_+ - v_-)$.

Finally, we define a nonlinear functional $H(t)$, which is the weighted sum of four component functionals: First, we define a linear part $L(t)$ by

$$L(t) = \sum_{j=1}^{n} L^j(t), \;\; L^j(t) \equiv \int_{-\infty}^{\infty} |q_j(x,t)| dx.$$

Then it follows from (2.2) that $L(t)$ is equivalent to $||u(\cdot,t) - v(\cdot,t)||_{L^1(\mathbb{R})}$. As shown in [5], [22], $L(t)$ may increase in time t. So, in order to compensate for the possible increase of $L(t)$, we need to consider functionals with a good decay property in time t. They are $Q_d(t)$ measuring nonlinear couplings between waves of different characteristic families, $E(t)$ capturing the nonlinearity of the characteristic field due to the bifurcation of a shock curve and a rarefaction curve, and $Q_{so}(t)$ measuring the source effect on the L^1 distance. Both $Q_d(t)$ and $E(t)$ are used in the study of homogeneous hyperbolic conservation laws (cf. [5, 20, 21, 22]). We now explain $Q_{so}(t)$ briefly. This functional is defined to capture the effect of the source on the L^1 distance. For this, we need to consider the potential interactions between the virtual waves $q_i(x,t)$ and stationary waves. For definiteness, we consider a virtual wave $q_j(x_0,t)$, $j \geq 2$, located at $x = x_0$. Since this wave has a positive speed, it will interact with the stationary waves lying $x \geq x_0$ with the interaction potential of the order

$$\sum_{j \geq 2} |q_j(x_0,t)| \left(\int_{x(q_j)}^{\infty} G(\xi) d\xi \right).$$

For the resonant field $(r_1(u), \lambda_1(u))$, the left states and right states of a relatively strong shock are supersonic and subsonic, respectively. Next we consider the potential interactions with an imaginary wave $q_1(x_0,t)$ and stationary waves. If $x_0 < x_f(t)$ (= location of the relatively strong shock at time t), then the imaginary wave $q_1(x_0,t)$ has a positive speed, so before it interacts with a relatively strong shock, it will interact with stationary waves, and after it interacts with a relatively strong shock, as part of a relatively strong wave, it will interact with the stationary wave lying on $[0,1]$, so the potential interactions with $q_1(x_0,t)$ and stationary waves are

$$|q_1(x_0,t)| \int_{x(q_1(x_0,t))}^{\infty} G(\xi) d\xi.$$

In contrast, if $x_0 > x_f(t)$, then the imaginary wave $q_1(x_0,t)$ has a negative speed and will interact with stationary waves before it is combined with a relatively strong shock wave, and after it is absorbed into a relatively strong shock wave, as part of a relatively strong shock, it will interact with stationary waves. So potential interactions are

$$|q_1(x_0,t)|\left(\int_{x(q_1(x_0,t))}^{x_f(t)} G(\xi)d\xi + \int_{x_f(t)}^{\infty} G(\xi)d\xi\right).$$

Based on this observation, we define a nonlinear functional $H(t)$ for two simplified wave patterns as follows:

$$\begin{aligned}
&L(t) = \sum_{j=1}^{n} L^j(t), \quad L^j(t) \equiv \int_{-\infty}^{\infty} |q_j(x,t)|dx,\\
&Q_d(t) = \sum_{\alpha^i \in \mathcal{J}} Q_d(\alpha^i(t)),\\
&Q_d(\alpha^i(t)) \equiv |\alpha^i(t)|\left\{\sum_{j>i}\int_{-\infty}^{x(\alpha^i)} |q_j(x,t)|dx + \sum_{j<i}\int_{x(\alpha^i)}^{\infty} |q_j(x,t)|dx\right\},\\
&E(t) = \sum_{\alpha^i \in \mathcal{J}} E(\alpha^i(t)),\\
&E(\alpha^i(t)) \equiv |\alpha^i(t)| \cdot \begin{cases} \int_{-\infty}^{x(\alpha^i)} q_i(x,t)_+dx + \int_{x(\alpha^i)}^{\infty} q_i(x,t)_-dx, \ \alpha^i \in J(u),\\ \int_{x(\alpha^i)}^{\infty} q_i(x,t)_+dx + \int_{-\infty}^{x(\alpha^i)} q_i(x,t)_-dx, \ \alpha^i \in J(v), \end{cases}\\
&Q_{so}(t) = \sum_{j\geq 1} Q_{so}^j(t),\\
&Q_{so}^j(t) \equiv \int_{-\infty}^{\infty} |q_j(x,t)|\left(\int_{x(q_j)}^{\infty} G(\xi)d\xi\right)dx, \ j \geq 2,\\
&Q_{so}^1(t) \equiv \int_{-\infty}^{x_f(t)} |q_1(x,t)|\left(\int_{x(q_1)}^{\infty} G(\xi)d\xi\right)dx\\
&\qquad + \int_{x_f(t)}^{\infty} |q_1(x,t)|\left(\int_{x_f(t)}^{x(q_1)} G(\xi)d\xi + \int_{x_f(t)}^{\infty} G(\xi)d\xi\right)dx,\\
&H(t) \equiv [1 + K_1F((p-1)Ns)]L(t) + K_2[Q_d(t) + E(t) + Q_{so}(t)], \ t \in [(p-1)Ns, pNs),\\
&\quad 1 \leq p \leq M,
\end{aligned}$$

where K_1 and K_2 are positive constants to be determined later and $F(t) = F(u(x,t)) + F(v(x,t))$ is sum of the Glimm functionals for the solutions $u(x,t)$ and $v(x,t)$. In the following sections, we will study the time-evolutional property of this nonlinear functional $H(t)$ under the condition (1.3).

3. Basic estimates. In this section, we study some basic estimates which are necessary for the decay analysis of the nonlinear functional $H(t)$. First, we estimate the time variation of a shock strength through a stationary background.

LEMMA 3.1. *Let $\alpha^i(t) = (u_-(t), u_+(t))$, $t \in [(p-1)Ns, pNs)$ be an i-wave issued from $(hr, (p-1)Ns)$ in the simplified wave pattern $u(x,t)$. Then*

$$\frac{d|\alpha^i(t)|}{dt} = \mathcal{O}(1)G(x(\alpha^i))|\alpha^i(t)|,$$

where $\mathcal{O}(1)$ depends only on (1.1).

Proof. Let $(x(t), t)$ be the locus of the shock in x-t plane. Denote the states at both sides of the shock as follows:

$$u_-(t) \equiv u(x(t)-, t), \quad u_+(t) \equiv u(x(t)+, t).$$

Since $u(x,t)$ is a local steady state solution, we have

$$u_x = (f'(u))^{-1} g(x,u) \equiv \tilde{g}(x,u). \tag{3.1}$$

From this, we have

$$u_+(t+h) = u_+(t) + \int_{x(t)}^{x(t+h)} \tilde{g}(\xi, u_+(\xi))d\xi, \tag{3.2}$$

$$u_-(t+h) = u_-(t) + \int_{x(t)}^{x(t+h)} \tilde{g}(\xi, u_-(\xi))d\xi. \tag{3.3}$$

It follows from (3.2) and (3.3) that

$$u_+(t+h) - u_-(t+h) = u_+(t) - u_-(t) + \mathcal{O}(1) \int_{x(t)}^{x(t+h)} G(\xi)|\alpha^i(t)|d\xi,$$

where we have used the fact that $|u_+(\xi) - u_-(\xi)| = \mathcal{O}(1)|\alpha^i(t)|$. Hence we have

$$(u_-(t+h), u_+(t+h))_i = (u_-(t), u_+(t))_i + \mathcal{O}(1) \int_{x(t)}^{x(t+h)} G(\xi)|\alpha^i(t)|d\xi.$$

This implies that

$$\frac{d|\alpha^i(t)|}{dt} = \mathcal{O}(1) G(x(\alpha^i))|\alpha^i(t)|,$$

which completes the proof. ∎

Assume now at time t that there is no wave interaction. Let $\mathcal{J} = \{\alpha_j\}_{j=1}^{N_t}$ be the set of all waves in u and v at this time with locations

$$-\infty < x(\alpha_1) < \cdots < 0 \le x(\alpha_k) < x(\alpha_{k+1}) < \cdots < 1 \le x(\alpha_l) < \cdots < x(\alpha_{N_t}) < \infty.$$

Without loss of generality, we may assume that $x(\alpha_k(t)) = 0$ and $x(\alpha_l(t)) = 1$. As shown in [11], the term

$$II^j \equiv \sum_{\alpha \in J} \{\lambda(q_j^-(\alpha))|q_j^-(\alpha)| - \lambda(q_j^+(\alpha))|q_j^+(\alpha)|\}$$

denotes the effect of the source on the time evolution of $L^j(t)$. In the following lemma, we estimate this quantity.

LEMMA 3.2. *For each $j, k \in \{1, \ldots, n\}$, we have the following estimates.*

$$f^j(\omega_k(x,t))_x - g^j(x, \omega_k(x,t)) = \mathcal{O}(1) G(x) \max\left(\sum_{i=1}^{k} |q_i(x,t)|, \sum_{i=k+1}^{n} |q_i(x,t)| \right).$$

Proof. For given smooth functions $p(x,t)$ and $q(x,t)$, we set

$$h^j(x,p,q) \equiv \nabla_p f^j(p)q - g^j(x,p).$$

Then, since $u(x,t) = \omega_0(x,t)$ and $v(x,t) = \omega_n$ are local steady state solutions,

$$h^j(x,\omega_0,\partial_x\omega_0) = h^j(x,\omega_n,\partial_x\omega_n) = 0. \tag{3.4}$$

By the mean value theorem and (3.4), we have

$$\begin{aligned} h^j(x,\omega_k,\partial_x\omega_k) &= h^j(x,\omega_k,\partial_x\omega_k) - h^j(x,\omega_0,\partial_x\omega_0) \\ &= h^j(x,\omega_k,\partial_x\omega_k) - h^j(x,\omega_0,\partial_x\omega_k) + h^j(x,\omega_0,\partial_x\omega_k) - h^j(x,\omega_0,\partial_x\omega_0) \\ &= \nabla_p h^j(x,\theta_k^1,\partial_x\omega_k)\cdot(\omega_k-\omega_0) + \nabla_q h^j(x,\omega_0,\theta_k^2)\partial_x(\omega_k-\omega_0), \end{aligned} \tag{3.5}$$

where θ_k^1 is a point on the line segment connecting ω_0 and ω_k and θ_k^2 is a point on the line segment connecting $\partial_x\omega_0$ and $\partial_x\omega_k$, respectively. Next, we claim the following:

1. $\nabla_p h^j(x,\theta_k^1,\partial_x\omega_k) = \mathcal{O}(1)G(x)$.
2. $\nabla_q h^j(x,\omega_0,\theta_k^2) = \mathcal{O}(1)$, $\partial_x(\omega_k-\omega_0) = \mathcal{O}(1)G(x)\max(\sum_{i=1}^k |q_i(x,t)|, \sum_{i=k+1}^n |q_i(x,t)|)$.

Proof of 1. Since $\omega_k(x,t)$ is determined by connecting two end states $u(x,t)$ and $v(x,t)$ by Hugoniot curves, we can write

$$\omega_k(x,t) = \Phi^k(u(x,t),v(x,t)) \quad \text{for some } C^2 \text{ function } \Phi^k.$$

It follows from (3.1) that

$$\partial_x(\omega_k(x,t)) = \Phi_u^k u_x + \Phi_v^k v_x = \mathcal{O}(1)G(x), \tag{3.6}$$

where we have used the fact that all states are not sonic, i.e., $\lambda_i(u) \neq 0$ for all i and $u \in \mathcal{N}$. On the other hand, (3.6) implies

$$\begin{aligned} \nabla_p h^j(x,\theta_k^1,\partial_x\omega_k) &= \nabla_p^2 f^j(\theta_k^1)\partial_x\omega_k - \nabla_p g^j(x,\theta_k^1) \\ &= \mathcal{O}(1)G(x). \end{aligned}$$

Proof of 2. By definition of h^j, it is easy to see

$$\nabla_q h^j(x,\omega_0,\theta_k^2) = \mathcal{O}(1).$$

Next we show

$$\partial_x(\omega_k-\omega_0) = \mathcal{O}(1)G(x)\max\left(\sum_{i=1}^k |q_i(x,t)|, \sum_{i=k+1}^n |q_i(x,t)|\right).$$

For given t, we define $\omega_k^*(y,t)$ by a local steady state solution such that

$$f(\omega_k^*(x,t))_x = g(x,\omega_k^*(x,t)), \quad \omega_k^*(x,t) = \omega_k(x,t).$$

Notice that when $\sum_{i=k+1}^n |q_i(x,t)| = 0$, since $v(x,t) = \omega_k(x,t)$, by the local uniqueness of the ODE solution we have

$$\omega_k^*(x,t) = v(x,t).$$

In this case, the difference between $\omega_k(x+\Delta x,t)$ and $\omega_k^*(x+\Delta x,t)=v(x+\Delta x,t)$ is due to the interaction between the imaginary waves $q_i(x,t), i=1,\dots,k$, and stationary waves. Therefore, the difference is the order of the interaction errors between imaginary waves $q_i(x,t),\ i=1,\dots,k$, and stationary waves, i.e.,

$$\omega_k(x+\Delta x,t)-\omega_k^*(x+\Delta x,t)=\mathcal{O}(1)\max\sum_{i=1}^{k}|q_i(x,t)|\int_x^{x+\Delta x}G(\eta)d\eta. \tag{3.7}$$

By the same argument as above, when $\sum_{i=1}^{k}|q_i(x,t)|=0$, we have

$$\omega_k(x+\Delta x,t)-\omega_k^*(x+\Delta x,t)=\mathcal{O}(1)\max\sum_{i=1}^{k}|q_i(x,t)|\int_x^{x+\Delta x}G(\eta)d\eta. \tag{3.8}$$

By (3.7), (3.8), and the continuity argument, we obtain

$$\begin{aligned}&\omega_k(x+\Delta x,t)-\omega_k^*(x+\Delta x,t)\\ &\quad=\mathcal{O}(1)\max\left(\sum_{i=1}^{k}|q_i(x,t)|,\sum_{i=k+1}^{n}|q_i(x,t)|\right)\int_x^{x+\Delta x}G(\eta)d\eta.\end{aligned} \tag{3.9}$$

On the other hand, we can rewrite

$$\partial_x[\omega_k(x,t)-\omega_0(x,t)]=\partial_x[\omega_k(x,t)-\omega_k^*(x,t)]+\partial_x[\omega_k^*(x,t)-\omega_0(x,t)]=\Gamma_1+\Gamma_2.$$

Then, by the same argument as in [14], we have

$$\Gamma_2=\mathcal{O}(1)\sum_{i=1}^{k}|q_i(x,t)|G(x).$$

Now, we estimate Γ_1 using (3.9). Since $\omega_k(x,t)-\omega_k^*(x,t)=0$, we have

$$\begin{aligned}&[\omega_k(x+\Delta x,t)-\omega_k^*(x+\Delta x,t)]-[\omega_k(x,t)-\omega_k^*(x,t)]\\ &=\mathcal{O}(1)\max\left(\sum_{i=1}^{k}|q_i(x,t)|,\sum_{i=k+1}^{n}|q_k(x,t)|\right)\int_x^{x+\Delta x}G(\eta)d\eta.\end{aligned}$$

Now, dividing by Δx and letting $\Delta x\to 0$, we obtain

$$\partial_x[\omega_k(x,t)-\omega_k^*(x,t)]=\mathcal{O}(1)\max\left(\sum_{i=1}^{k}|q_i(x,t)|,\sum_{i=k+1}^{n}|q_i(x,t)|\right)G(x).$$

Combining the estimates for Γ_1 and Γ_2, we have

$$\partial_x(\omega_k(x,t)-\omega_0(x,t))=\mathcal{O}(1)\max\left(\sum_{i=1}^{k}|q_i(x,t)|,\sum_{i=k+1}^{n}|q_i(x,t)|\right)G(x).$$

In (3.5), using the above claim, we obtain

$$f^j(\omega_k(x,t))_x-g^j(x,\omega_k(x,t))=\mathcal{O}(1)G(x)\max\left(\sum_{i=1}^{k}|q_i(x,t)|,\sum_{i=k+1}^{n}|q_i(x,t)|\right).$$

This completes the proof. □

LEMMA 3.3. *Suppose that* $G_{11}(x,u) \le -\lambda$ $(\lambda > 0)$. *Then we have*

$$\sum_{j=1}^{n} II^j \le \mathcal{O}(1)\sum_{k=1}^{n}\int_{-\infty}^{\infty} G(x)|q_k(x,t)|dx - |\mathcal{O}(1)|\lambda\int_{-\infty}^{\infty}\mathbf{1}_{G(x)>0}|q_1(x,t)|dx.$$

Proof. Let us set

$$II^j \equiv \sum_{i=1}^{N_t-1} II^j(\alpha_i,\alpha_{i+1}), \quad II^j(\alpha_i,\alpha_{i+1}) \equiv \lambda(q_j^-(\alpha_{i+1}))|q_j^-(\alpha_{i+1})| - \lambda(q_j^+(\alpha_i))|q_j^+(\alpha_i)|.$$

We first estimate $II^j(\alpha_i,\alpha_{i+1})$. Since $\lambda(q_j(x))|q_j(x)|$ is continuous on $(x(\alpha_i),x(\alpha_{i+1}))$, we have

$$\lambda(q_j^+(x,t))|q_j^+(x,t)| = \lambda(q_j^-(x,t))|q_j^-(x,t)|, \quad x \in (x(\alpha_i),x(\alpha_{i+1})).$$

So, if necessary, by inserting

$$\lambda(q_j^+(x,t))|q_j^+(x,t)| - \lambda(q_j^-(x,t))|q_j^-(x,t)|, x \in (x(\alpha_i),x(\alpha_{i+1})),$$

it suffices to consider only two cases, i.e., either $q_j(x,t) \ge 0$ or $q_j(x,t) < 0$, on the whole interval $(x(\alpha_i),x(\alpha_{i+1}))$.

In the following, we consider only the case in which $q_j(x,t) \ge 0$ on $(x(\alpha_i),x(\alpha_{i+1}))$. The other case can be discussed similarly. By a direct calculation, we have

$$\begin{aligned} II^j(\alpha_i,\alpha_{i+1}) &= f^j(\omega_j(x(\alpha_{i+1}))) - f^j(\omega_j(x(\alpha_i))) \\ &\quad - [f^j(\omega_{j-1}(x(\alpha_{i+1}))) - f^j(\omega_{j-1}(x(\alpha_i)))] \\ &= \int_{x(\alpha_i)}^{x(\alpha_{i+1})} \left[f^j(\omega_j(x,t))_x - f^j(\omega_{j-1}(x,t))_x\right] dx. \end{aligned} \tag{3.10}$$

And now we can prove the estimates in the lemma as follows.

Case 1. $j = 1$. By Lemma 3.2, we have

$$\begin{aligned} &f^1(\omega_1(x,t))_x = g^1(x,\omega_1(x,t)) + \mathcal{O}(1)G(x)\max\left(|q_1(x,t)|, \sum_{k=2}^{n}|q_k(x,t)|\right), \\ &f^1(\omega_0(x,t))_x = g^1(x,\omega_0(x,t)). \end{aligned}$$

From (3.10), we have

$$\begin{aligned} II^1(\alpha_i,\alpha_{i+1}) &= \int_{x(\alpha_i)}^{x(\alpha_{i+1})} \left[g^1(x,\omega_1(x,t)) - g^1(x,\omega_0(x,t))\right] dx \\ &\quad + \mathcal{O}(1)\int_{x(\alpha_i)}^{x(\alpha_{i+1})} G(x)\left(\sum_{k=1}^{n}|q_k(x,t)|\right) dx. \end{aligned} \tag{3.11}$$

Moreover, we have

$$\begin{aligned} g^1(x,\omega_1(x,t)) - g^1(x,\omega_0(x,t)) &= \nabla_u g^1(x,\bar{\theta}_1(x,t))\cdot(\omega_1(x,t) - \omega_0(x,t)) \\ &= \nabla_u g^1(x,\bar{\theta}_1(x,t))\cdot\sum_{i=1}^{n}(l_i(u_0)\cdot(\omega_1(x,t) - \omega_0(x,t)))r_i(u_0) \end{aligned}$$

$$= \left(l_1(u_0) \frac{\partial g(x, \bar{\theta}_1)}{\partial u} r_1(u_0) \right) |q_1(x,t)| + \nabla_u g^1(x, \bar{\theta}_1(x,t)) \cdot \sum_{i=2}^{n} [l_i(u_0) \cdot (\omega_1(x,t) - \omega_0(x,t))] r_i(u_0),$$

where $\bar{\theta}_1(x,t)$ is a point on the line segment connecting $\omega_0(x,t)$ and $\omega_1(x,t)$. On the other hand, we assume that d ($\equiv$ the diameter of $\mathcal{N}$) is small. Since

$$\omega_1 = \omega_0 + q_1(x,t) r_1(u_0) + \mathcal{O}(1) d |q_1(x,t)|,$$

we therefore have, for $i \neq 1$,

$$\begin{aligned} l_i(u_0) \cdot ((\omega_1(x,t) - \omega_0(x,t))) &= q_1(x,t)[l_i(u_0) \cdot r_1(u_0)] + \mathcal{O}(1) d |q_1(x,t)| \\ &= \mathcal{O}(1) d |q_1(x,t)| \ll |q_1(x,t)|, \end{aligned}$$

where we have used that $l_i(u_0) \cdot r_1(u_0) = 0,\ i \neq 1$. Hence we have

$$g^1(x, \omega_1(x,t)) - g^1(x, \omega_0(x,t)) \leq |\mathcal{O}(1)| \left(l_1(u_0) \frac{\partial g(x, \bar{\theta}_1)}{\partial u} r_1(u_0) \right) |q_1(x,t)|. \tag{3.12}$$

Since $G_{11}(x,u) \leq -\lambda$ for some $\lambda > 0$, it follows from (3.11) and (3.12) that

$$\begin{aligned} II^1(\alpha_i, \alpha_{i+1}) \leq\ & \mathcal{O}(1) \int_{x(\alpha_i)}^{x(\alpha_{i+1})} G(x) \left(\sum_{k=1}^{n} |q_k(x,t)| \right) dx \\ & - |\mathcal{O}(1)| \lambda \int_{x(\alpha_i)}^{x(\alpha_{i+1})} \mathbf{1}_{G(x)>0} |q_1(x,t)| dx, \end{aligned}$$

where $\mathbf{1}_{G(x)>0}$ denotes the characteristic function of the set $\{G(x) > 0\}$. By summing up all $II^1(\alpha_i, \alpha_{i+1})$ over all $i = 1, \ldots, N_t - 1$, we have

$$II^1 \leq \mathcal{O}(1) \int_{-\infty}^{\infty} G(x) \left(\sum_{k=1}^{n} |q_k(x,t)| \right) dx - |\mathcal{O}(1)| \lambda \int_{-\infty}^{\infty} \mathbf{1}_{G(x)>0} |q_1(x,t)| dx.$$

Case 2. By Lemma 3.2, we have

$$\sum_{j=2}^{n} II^j = \mathcal{O}(1) \int_{-\infty}^{\infty} G(x) \left(\sum_{k=1}^{n} |q_k(x,t)| \right) dx.$$

Combining Cases 1 and 2, we have

$$\sum_{j=1}^{n} II^j \leq \mathcal{O}(1) \int_{-\infty}^{\infty} G(x) \left(\sum_{k=1}^{n} |q_k(x,t)| \right) dx - |\mathcal{O}(1)| \lambda \int_{-\infty}^{\infty} \mathbf{1}_{G(x)>0} |q_1(x,t)| dx.$$

This completes the proof. ∎

Remark 3.1. In the resonant scalar case, the dissipation condition $G_{11}(x,u) \leq -\lambda$ gives an estimate

$$II^1 \leq -\lambda \int_{-\infty}^{\infty} \mathbf{1}_{G(x)>0} |q_1(x,t)| dx.$$

4. Stability analysis. In this section, we study the L^1 stability of a steady transonic shock wave solution under the condition (1.3). First, we study time decay rates for each component functional. Recall that an open interval $I_p = ((p-1)Ns, pNs), p \in \{1, \dots, M\}$, is the union of two disjoint sets, $I_p = I_p^1 \cup I_p^2$, where I_p^1 is the set of all countable interaction times such that $H(t)$ is simply continuous, and I_p^2 is the set of all differentiable points of $H(t)$. For notational convenience, we set

$$\Gamma_s \equiv \sum_{\alpha\in\mathcal{J}} \Gamma_s(\alpha), \quad \Gamma_d \equiv \sum_{\alpha\in\mathcal{J}} \Gamma_d(\alpha),$$
$$\Gamma_{so} \equiv \sum_{j=1}^{n} \int_0^1 G(x)|q_j(x,t)|dx, \quad \Gamma \equiv \Gamma_s + \Gamma_d + \Gamma_{so}.$$

Let $v_0(x)$ be a small perturbation of $u(x)$ such that

$$T.V_x(v_0(x) - u(x)) \ll 1.$$

In the following, we briefly sketch the time-evolution estimates of the Glimm functional defined in section 2. For the details, we refer to [14].

LEMMA 4.1 (see [14, 18]). *Assume that the condition* (1.3) *holds. Then we have the following estimates on the Glimm functional defined in section* 2*:*

$$F(J) \le F(0) - \frac{1}{2}Q(\Lambda_J) - \frac{c_0}{2}\sum_{k=1}^{k_J}\left|\int_{x_f((k-1)s)}^{x_f(ks)} G(x)dx\right|,$$

where c_0 is a positive constant.

Proof. Let J_1 and J_2 be space-like curves such that J_2 is an immediate successor of J_1 and $\Delta \equiv \Delta(J_1, J_2)$ is the diamond spanned by J_1 and J_2. Based on the estimates obtained in [14], we consider the following two cases.

Case 1. $\Delta(J_1, J_2)$ contains the relatively strong shock. In this case, we have

$$\begin{aligned}
|\sigma_{J_2}| - |\sigma_{J_1}| &\le -|\mathcal{O}(1)|\left|\int_{x_f(J_1)}^{x_f(J_2)} G(x)dx\right| + \mathcal{O}(1)\Big(Q(\Delta)\\
&\quad + \sum\{|\alpha_1| : \alpha_1 \text{ is a 1-wave passing through } J_1 \text{ in } \Delta\}\Big),\\
\bar{L}_1(J_2) - \bar{L}_1(J_1) &\le -\sum\{|\alpha_1| : \alpha_1 \text{ is a 1-wave passing through } J_1 \text{ in } \Delta\}\\
&\quad + \mathcal{O}(1)Q(\Delta),\\
\sum_{j\neq 1} L_j(J_2) - \sum_{j\neq 1} L_j(J_1) &\le \mathcal{O}(1)Q(\Delta),\\
Q(J_2) - Q(J_2) &\le -Q(\Delta) + \mathcal{O}(1)(\bar{L}(J_1) + G_1)\\
&\quad \cdot\left(Q(\Delta) + |\beta_{J_1}|\left|\int_{x_f(J_1)}^{x_f(J_2)} G(x)dx\right|\right).
\end{aligned}$$

By definition of $F(J)$, we have

$$\begin{aligned}
F(J_2) - F(J_1) &\le [-|\mathcal{O}(1)| + \mathcal{O}(1)M_2(\bar{L}(J_1) + G_1)|\beta_{J_1}|]\left|\int_{x_f(J_1)}^{x_f(J_2)} G(x)dx\right|\\
&\quad + (\mathcal{O}(1) + M_1\mathcal{O}(1) - M_2)Q(\Delta)
\end{aligned}$$

$$+ (\mathcal{O}(1) - M_1) \sum \{|\alpha_1| : \alpha_1 \text{ is a 1-wave } \in \Delta \cap J_1\}.$$

Since $1 \ll M_1 \ll M_2$ (see section 2), we have

$$-|\mathcal{O}(1)| + \mathcal{O}(1)M_2(\bar{L}(J_1) + G_1)|\beta_{J_1}| \le -c_0 \quad \text{for some positive constant } c_0,$$
$$\mathcal{O}(1) + M_1\mathcal{O}(1) - M_2 \le -\frac{1}{2}, \quad \mathcal{O}(1) - M_1 < 0.$$

Then we have

$$F(J_2) - F(J_1) \le -\frac{1}{2}Q(\Delta) - \frac{c_0}{2}\left|\int_{x_f(J_1)}^{x_f(J_2)} G(x)dx\right|.$$

Case 2. $\Delta(J_1, J_2)$ does not contain the relatively strong shock. We have

$$\begin{aligned} |\sigma_{J_2}| - |\sigma_{J_1}| &= 0, \\ \bar{L}_1(J_2) - \bar{L}_1(J_1) &\le \mathcal{O}(1)Q(\Delta), \\ \sum_{j\neq 1} L_j(J_2) - \sum_{j\neq 1} L_j(J_1) &\le \mathcal{O}(1)Q(\Delta), \\ Q(J_2) - Q(J_2) &\le -Q(\Delta) + \mathcal{O}(1)(\bar{L}(J_1) + G_1)Q(\Delta). \end{aligned}$$

Thus

$$F(J_2) - F(J_1) \le (\mathcal{O}(1) + M_1\mathcal{O}(1) - M_2)Q(\Delta).$$

Since $1 \ll M_1 \ll M_2$ in section 2, we have

$$\mathcal{O}(1) + M_1\mathcal{O}(1) - M_2 \le -\frac{1}{2},$$

which implies

$$F(J_2) - F(J_1) \le -\frac{1}{2}Q(\Delta).$$

By telescoping the above estimates from every space-like curve between J and 0, we obtain

$$F(J) \le F(0) - \frac{1}{2}Q(\Lambda_J) - \frac{c_0}{2}\sum_{k=1}^{k_J}\left|\int_{x_f((k-1)s)}^{x_f(ks)} G(x)dx\right|. \qquad \square$$

Remark 4.1. Because of the dissipation condition on $G_{11}(x, u)$, the speed of the relatively strong shock is decreasing in time when the relatively strong shock only interacts with stationary waves (see Lemma 3.1 in [14]), and this gives a good term,

$$-\sum_{k=1}^{k_J}\left|\int_{x_f((k-1)s)}^{x_f(ks)} G(x)dx\right|,$$

in Glimm functional $F(J)$. This good term will be used in Lemma 4.3 in order to control the bad term in $\frac{dQ^1_{so}(t)}{dt}$.

Next we estimate the time-evolution of $Q^1_{so}(t)$, which is different from $Q^1_{so}(t)$ in [11]. But the estimates for the $Q^i_{so}(t)$, $i \ge 2$, will be the same as in [11].

LEMMA 4.2. *Suppose that the main assumptions in section* 1 *hold. Then we have the following estimate:*

$$\frac{dQ^1_{so}(t)}{dt} \le -\lambda_* \int_{-\infty}^{\infty} G(x)|q_1(x,t)|dx + 2\left(\frac{d}{dt}\int_{x_f(t)}^{\infty} G(\xi)d\xi\right)\int_{x_f(t)}^{\infty}|q_1(x,t)|dx + \mathcal{O}(1)G_1\left\{\Gamma + (T.V + G_1)e(\Lambda_p)\right\},$$

where λ_* is a positive constant which is a lower bound on $|\lambda_1(u)|$.

Proof. For a given noninteraction time $t \in \Lambda_p$, we have three cases, depending on the location of a relatively strong shock wave:

$$x_f(t) < 0, \quad 0 \le x_f(t) \le 1, \quad x_f(t) > 1.$$

Case 1 ($x_f(t) < 0$). In this case, $Q^1_{so}(t)$ becomes

$$Q^1_{so}(t) = G_1\int_{-\infty}^{\infty}|q_1(x,t)|dx + \int_{x_f(t)}^{\infty}|q_1(x,t)|\left(\int_{x_f(t)}^{x(q_1)} G(\xi)d\xi\right)dx \equiv I_1 + I_2.$$

We denote the locations of waves as follows.

$$\begin{aligned}-\infty < x(\alpha_1) < \cdots < x(\alpha_e) = x_f(t) < x(\alpha_{e+1}) < \cdots < x(\alpha_k)\\ = 0 < x(\alpha_{k+1}) < \cdots < x(\alpha_l) = 1 < x(\alpha_{l+1}) < \cdots < x(\alpha_m) < \infty.\end{aligned}$$

For notational convenience, let us denote $x(\alpha_0) \equiv -\infty$ and $x(\alpha_{m+1}) \equiv \infty$.

Now, we take the derivative of $Q^1_{so}(t)$, and then we have

$$\frac{dQ^1_{so}(t)}{dt} = G_1\frac{d}{dt}\int_{-\infty}^{\infty}|q_1(x,t)|dx + \frac{d}{dt}\int_{x_f(t)}^{\infty}|q_1(x,t)|\left(\int_{x_f(t)}^{x(q_1)} G(\xi)d\xi\right)dx \equiv \frac{dI_1}{dt} + \frac{dI_2}{dt}. \tag{4.1}$$

By the same estimates in [14], the first term of (4.1) can be estimated as follows:

$$\frac{dI_1}{dt} = \mathcal{O}(1)G_1[\Gamma + (T.V + G_1)e(\Lambda_p)]. \tag{4.2}$$

Now, we consider the second term of (4.1). Using $\int_{x_f(t)}^{x} G(\xi)d\xi = 0,\ x \le 0$, we have

$$\frac{dI_2}{dt} = \sum_{i=k+1}^{l}\frac{d}{dt}\int_{x(\alpha_{i-1})}^{x(\alpha_i)}|q_1(x,t)|\left(\int_{x_f(t)}^{x(q_1)} G(\xi)d\xi\right)dx + G_1\sum_{i=l+1}^{m+1}\frac{d}{dt}\int_{x(\alpha_{i-1})}^{x(\alpha_i)}|q_1(x,t)|dx.$$

Then, by a direct calculation, we have

$$\begin{aligned}\frac{dI_2}{dt} &\le \sum_{i=k}^{l}\left(\int_{x_f(t)}^{x(\alpha_i))} G(\xi)d\xi\right)\dot{x}(\alpha_i)(|q_1^-(\alpha_i)| - |q_1^+(\alpha_i)|)\\ &\quad + G_1\sum_{i=l+1}^{m}\dot{x}(\alpha_i)(|q_1^-(\alpha_i)| - |q_1^+(\alpha_i)|) + \int_0^1|q_1(x,t)|\dot{x}(q_1)G(x)dx\\ &\le \mathcal{O}(1)G_1\left\{\sum_{i=k}^{m}(\Gamma_s + \Gamma_d)(\alpha_i) + \Gamma_{so} + (T.V + G_1)e(\Lambda_p)\right\}\\ &\quad - \lambda_*\int_0^1 G(x)|q_1(x,t)|dx,\end{aligned} \tag{4.3}$$

where we have used the fact that

$$G(x_f(t)) = 0, \quad \dot{x}(q_1) \le -\lambda_* \quad \text{if } x(q_1) > x_f(t).$$

Combining (4.2) and (4.3), we have

$$\frac{dQ^1_{so}(t)}{dt} \le \mathcal{O}(1)G_1(\Gamma + (T.V + G_1)e(\Lambda_p)) - \lambda_* \int_0^1 G(x)|q_1(x,t)|dx. \tag{4.4}$$

Case 2 ($0 \le x_f(t) \le 1$). We consider only the case for $0 < x_f(t) < 1$. The cases for $x_f(t) = 0$ and $x_f(t) = 1$ can be treated similarly. We denote the locations of waves as follows:

$$\begin{aligned} -\infty < x(\alpha_1) < \cdots < x(\alpha_k) = 0 < x(\alpha_{k+1}) < \cdots < x(\alpha_e) = x_f(t) \\ < x(\alpha_{e+1}) < \cdots < x(\alpha_l) = 1 < x(\alpha_{l+1}) < \cdots < x(\alpha_m) < \infty. \end{aligned}$$

For notational convenience, let us denote $x(\alpha_0) \equiv -\infty$ and $x(\alpha_{m+1}) \equiv \infty$.

Using $\int_x^\infty G(\xi)d\xi = G_1,\ x \le 0$, we have

$$\begin{aligned} \frac{dQ^1_{so}(t)}{dt} &= G_1 \sum_{i=1}^{k} \frac{d}{dt} \int_{x(\alpha_{i-1})}^{x(\alpha_i)} |q_1(x,t)|dx + \sum_{i=k+1}^{e} \frac{d}{dt} \int_{x(\alpha_{i-1})}^{x(\alpha_i)} |q_1(x,t)| \\ &\quad \cdot \left(\int_{x(q_1)}^{\infty} G(\xi)d\xi \right) dx \\ &\quad + \sum_{i=e+1}^{m+1} \frac{d}{dt} \int_{x(\alpha_{i-1})}^{x(\alpha_i)} |q_1(x,t)| \left(\int_{x_f(t)}^{x(q_1)} G(\xi)d\xi + \int_{x_f(t)}^{\infty} G(\xi)d\xi \right) dx. \end{aligned}$$

Then, by a direct calculation, we have

$$\begin{aligned} \frac{dQ^1_{so}(t)}{dt} &= G_1 \sum_{i=1}^{k} \dot{x}(\alpha_i)(|q_1^-(\alpha_i)| - |q_1^+(\alpha_i)|) \\ &\quad + \sum_{i=k+1}^{e} \left(\int_{x(\alpha_i)}^{\infty} G(\xi)d\xi \right) \dot{x}(\alpha_i)(|q_1^-(\alpha_i)| - |q_1^+(\alpha_i)|) \\ &\quad + \sum_{i=e+1}^{m} \left(\int_{x_f(t)}^{x(\alpha_i)} G(\xi)d\xi + \int_{x_f(t)}^{\infty} G(\xi)d\xi \right) \dot{x}(\alpha_i)(|q_1^-(\alpha_i)| - |q_1^+(\alpha_i)|) \\ &\quad + \sum_{i=k+1}^{e} \int_{x(\alpha_{i-1})}^{x(\alpha_i)} |q_1(x,t)|(-\dot{x}(q_1))G(x)dx \\ &\quad + \sum_{i=e+1}^{m+1} \int_{x(\alpha_{i-1})}^{x(\alpha_i)} |q_1(x,t)|(\dot{x}(q_1))G(x)dx \\ &\quad - 2\dot{x}_f(t)G(x_f(t)) \left(\int_{x_f(t)}^{\infty} |q_1(x,t)|dx \right) \\ &\le \mathcal{O}(1)G_1 \{\Gamma + (T.V + G_1)e(\Lambda_p)\} - \lambda_* \int_0^1 G(x)|q_1(x,t)|dx \\ &\quad + 2 \left(\frac{d}{dt} \int_{x_f(t)}^{\infty} G(\xi)d\xi \right) \int_{x_f(t)}^{\infty} |q_1(x,t)|dx, \end{aligned} \tag{4.5}$$

where we have used the fact that

$$\text{if} \quad x(q_1) < x_f(t), \quad \dot{x}(q_1) > \lambda_*, \quad \text{and if} \quad x(q_1) > x_f(t), \quad \dot{x}(q_1) < -\lambda_*.$$

Case 3 ($x_f(t) > 1$). In this case, $Q^1_{so}(t)$ becomes

$$Q^1_{so}(t) = \int_{-\infty}^{x_f(t)} |q_1(x,t)| \left(\int_{x(q_1)}^{\infty} G(\xi) d\xi \right) dx.$$

We denote the locations of waves as follows:

$$\begin{aligned} &-\infty = x(\alpha_0) < x(\alpha_1) < \cdots < x(\alpha_k) = 0 < x(\alpha_{k+1}) < \cdots < x(\alpha_l) = 1 \\ &< x(\alpha_{l+1}) < \cdots < x(\alpha_e) = x_f(t) < x(\alpha_{e+1}) < \cdots < x(\alpha_m) < x(\alpha_{m+1}) = \infty. \end{aligned}$$

Using the fact that $\int_x^\infty G(\xi) d\xi = 0, \ x \geq 1$, we have

$$\begin{aligned} \frac{dQ^1_{so}(t)}{dt} &= G_1 \sum_{i=1}^{k} \frac{d}{dt} \int_{x(\alpha_{i-1})}^{x(\alpha_i)} |q_1(x,t)| dx + \sum_{i=k+1}^{l} \frac{d}{dt} \int_{x(\alpha_{i-1})}^{x(\alpha_i)} |q_1(x,t)| \\ &\quad \cdot \left(\int_{x(q_1)}^{\infty} G(\xi) d\xi \right) dx \\ &= G_1 \sum_{i=1}^{k} \dot{x}(\alpha_i)(|q_j^-(\alpha_i)| - |q_j^+(\alpha_i)|) \\ &\quad + \sum_{i=k+1}^{l} \left(\int_{x(\alpha_i)}^{\infty} G(\xi) d\xi \right) \dot{x}(\alpha_i)(|q_1^-(\alpha_i)| - |q_1^+(\alpha_i)|) \\ &\quad + \sum_{i=k+1}^{l} \int_{x(\alpha_{i-1})}^{x(\alpha_i)} |q_1(x,t)|(-\dot{x}(q_1)) G(x) dx \end{aligned} \tag{4.6}$$

$$\leq \mathcal{O}(1) G_1 \left\{ \Gamma + (T.V + G_1) e(\Lambda_p) \right\} - \lambda_* \int_0^1 G(x) |q_1(x,t)| dx. \tag{4.7}$$

Combining all estimates (4.4)–(4.7), we have

$$\begin{aligned} \frac{dQ^1_{so}(t)}{dt} \leq & -\lambda_* \int_{-\infty}^{\infty} G(x) |q_1(x,t)| dx + 2 \left(\frac{d}{dt} \int_{x_f(t)}^{\infty} G(\xi) d\xi \right) \int_{x_f(t)}^{\infty} |q_1(x,t)| dx \\ & + \mathcal{O}(1) G_1 \left\{ \Gamma + (T.V + G_1) e(\Lambda_p) \right\}. \end{aligned}$$

This completes the proof. □

Using the lemmas in sections 2 and 3, we can obtain the following time-evolution estimates of functionals defined in section 2. Since the proof of the decay rates of the functionals in $H(t)$ given in the following lemma was given in [11, 22], we omit this proof here.

LEMMA 4.3. *Under the same assumption as in Lemma* 4.1, *we have the following time-decay estimates on the component functionals. For* $t \in I_p^2$,

1. $\frac{dL(t)}{dt} \leq \mathcal{O}(1)\Gamma + \mathcal{O}(1)(T.V + G_1) e(\Lambda_p)$,
2. $\frac{dQ_d(t)}{dt} \leq -\tilde{c}\Gamma_d + \mathcal{O}(1)(\sum_{\alpha \in \mathcal{J}} G(x(\alpha))|\alpha|) L(t) + \mathcal{O}(1)(T.V + G_1)(\Gamma + e(\Lambda_p))$,
3. $\frac{dE(t)}{dt} \leq -\tilde{c}\Gamma_s + \mathcal{O}(1)(\sum_{\alpha \in \mathcal{J}} G(x(\alpha))|\alpha|) L(t) + \mathcal{O}(1)(T.V + G_1)(\Gamma + e(\Lambda_p))$,

4. $\frac{dQ_{so}(t)}{dt} \le -\tilde{c}\Gamma_{so} + 2(\frac{d}{dt}\int_{x_f(t)}^{\infty} G(\xi)d\xi)L^1(t) + \mathcal{O}(1)G_1\{\Gamma + (T.V + G_1)e(\Lambda_p)\}$, *where* $e(\Lambda_p) = Q(\Lambda_p)+C(\Lambda_p)+(\epsilon+\delta+NsG_0)$ *and* $\tilde{c}$ *is a positive constant independent of time* t.

The following lemma gives the change of the nonlinear functional $H(t)$ after time $t = Ns$.

LEMMA 4.4. *Under the same assumption as in Lemma* 4.1*, we have*

$$H(pNs+) \le H((p-1)Ns+) + \mathcal{O}(1)\left(e(\Lambda_p) + \int_{x_f((p-1)Ns)}^{x_f(pNs)} G(\xi)d\xi\right)Ns.$$

Proof. From the definition of $H(t)$ and Lemma 4.1, for $t \in I_p^2$, we have

$$\begin{aligned}
\frac{dH(t)}{dt} &= (1 + K_1F((p-1)Ns))\frac{dL(t)}{dt} + K_2\left(\frac{dQ_d(t)}{dt} + \frac{dE(t)}{dt} + \frac{dQ_{so}(t)}{dt}\right)\\
&\le [\mathcal{O}(1)\{1 + K_1F((p-1)Ns))\} + \mathcal{O}(1)K_2(T.V + G_1) + \mathcal{O}(1)K_2G_1 - \tilde{c}K_2]\Gamma\\
&\quad + \Bigg[\mathcal{O}(1)(T.V + G_1)(1 + K_1F((p-1)Ns)) + \mathcal{O}(1)K_2(T.V + G_1)\\
&\quad + \mathcal{O}(1)K_2\left[\sum G(x(\alpha))|\alpha| + \frac{d}{dt}\int_{x_f(t)}^{\infty} G(\xi)d\xi\right]L(t)\\
&\quad + \mathcal{O}(1)K_2G_1(T.V + G_1)\Bigg]e(\Lambda_p). \qquad (4.8)
\end{aligned}$$

Since $L(t)$ is Lipschitz continuous on $((p-1)Ns, pNs)$, we have

$$L(t) \le \mathcal{O}(1)Ns + L(pNs-). \qquad (4.9)$$

By definition of $H(t)$, there is a jump across $t = pNs, p \in \{1, \dots, M\}$. Next we estimate the size of this jump.

$$\begin{aligned}
H(pNs+) - H(pNs-) &= [(1 + K_1F(pNs+))L(pNs+) + K_2(Q_d(pNs+) + E(pNs+)\\
&\quad + Q_{so}(pNs+))] - [(1 + K_1F((p-1)Ns+)))L(pNs-)\\
&\quad + K_2(Q_d(pNs-) + E(pNs-) + Q_{so}(pNs-))] = \sum_{i=1}^{5} I_i,
\end{aligned}$$

where

$$\begin{aligned}
I_1 &\equiv K_1(F(pNs+) - F((p-1)Ns+))L(pNs-),\\
I_2 &\equiv (1 + K_1F(pNs+))(L(pNs+) - L(pNs-)),\\
I_3 &\equiv K_2(Q_d(pNs+) - Q_d(pNs-)),\\
I_4 &\equiv K_2(E(pNs+) - E(pNs-)),\\
I_5 &\equiv K_2(Q_{so}(pNs+) - Q_{so}(pNs-)).
\end{aligned}$$

Since $G_{11}(x, u) \le -\lambda$, it follows from Lemma 4.1 that

$$F(pNs+) - F((p-1)Ns+) \le -\frac{1}{2}(Q(\Lambda_p) + C(\Lambda_p)) - \frac{c_0}{2}\sum_{k=(p-1)N}^{pN-1}\left|\int_{x_f(ks)}^{x_f((k+1)s)} G(x)dx\right|.$$

Therefore,

$$I_1 \le -\frac{K_1}{2}\left(Q(\Lambda_p)+C(\Lambda_p)+\frac{c_0}{2}\sum_{k=(p-1)N}^{pN-1}\left|\int_{x_f(ks)}^{x_f((k+1)s)}G(x)dx\right|\right)L(pNs-). \tag{4.10}$$

On the other hand, the difference of a wave pattern at time $t = pNs+$ and $t = pNs-$ comes from interaction, cancellation, and randomness, so we have

$$L(pNs+) - L(pNs-) \le \mathcal{O}(1)e(\Lambda_p)Ns.$$

Hence

$$I_2 \le \mathcal{O}(1)(1 + K_1F(pNs+))e(\Lambda_p)Ns. \tag{4.11}$$

By definition of $Q_d(t)$, I_3 can be estimated by considering the following two terms: one term is the product of the change of the wave strengths and the L^1 norm at $t = pNs-$, and the other term is the product of the change of the L_1 norm times the wave strengths. Therefore, for some $C_2 > 0$, we have

$$I_3 \le C_2K_2(T.V + G_1)e(\Lambda_p)Ns + C_2K_2(Q(\Lambda_p) + C(\Lambda_p))L(pNs-). \tag{4.12}$$

Similarly, we have

$$I_4 \le C_2K_2(T.V + G_1)e(\Lambda_p)Ns + C_2K_2(Q(\Lambda_p) + C(\Lambda_p))L(pNs-). \tag{4.13}$$

$$I_5 \le C_2K_2G_1e(\Lambda_p)Ns. \tag{4.14}$$

Summing up all I_k's (4.10)–(4.14), we have

$$\begin{aligned} H(pNs+) - H(pNs-) \le{}& \left(2C_2K_2 - \frac{K_1}{2}\right)(Q(\Lambda_p) + C(\Lambda_p))L(pNs-) \\ &- \frac{K_1c_0}{2}\left(\sum_{k=(p-1)N}^{pN-1}\left|\int_{x_f(ks)}^{x_f((k+1)s)}G(x)dx\right|\right)L(pNs-) \\ &+ [\mathcal{O}(1)(1 + K_1F(pNs+)) + \mathcal{O}(1)K_2(T.V + G_1) \\ &+ \mathcal{O}(1)K_2G_1]e(\Lambda_p)Ns. \end{aligned} \tag{4.15}$$

If we integrate (4.8) from $(p-1)Ns$ to pNs, then, using (4.9), we have

$$\begin{aligned} &H(pNs-) - H((p-1)Ns+) \\ &\le [\mathcal{O}(1)(1 + K_1F((p-1)Ns)) + \mathcal{O}(1)K_2(T.V + G_1) \\ &+ \mathcal{O}(1)K_2G_1 - \tilde{c}K_2]\int_{(p-1)Ns}^{pNs}\Gamma(t)dt + \mathcal{O}(1)K_2\left(\int_{x_f((p-1)Ns)}^{x_f(pNs)}G(\xi)d\xi\right)Ns \\ &+ [\mathcal{O}(1)(T.V + G_1)(1 + K_1F((p-1)Ns)) + \mathcal{O}(1)K_2(T.V + G_1) \\ &+ \mathcal{O}(1)K_2G_1(T.V + G_1)]e(\Lambda_p)Ns + \mathcal{O}(1)K_2(Q_1(\Lambda_p) + Q_2(\Lambda_p))Ns \\ &+ \mathcal{O}(1)K_2(Q_1(\Lambda_p) + Q_2(\Lambda_p))L(pNs-) \\ &+ \mathcal{O}(1)K_2\left(\int_{x_f((p-1)Ns)}^{x_f(pNs)}G(\xi)d\xi\right)L(pNs-), \end{aligned} \tag{4.16}$$

where the integral is over $((p-1)Ns, pNs)$, and we have used the fact that $\int_{(p-1)Ns}^{pNs} \sum_{\alpha\in\mathcal{J}} G(x(\alpha))|\alpha|dt = \mathcal{O}(1)(Q_1(\Lambda_p) + Q_2(\Lambda_p))$. From (4.15) and (4.16), we have

$$
\begin{aligned}
&H(pNs+) - H((p-1)Ns+)\\
&\le [\mathcal{O}(1)(1 + K_1F((p-1)Ns)) + \mathcal{O}(1)K_2(T.V + G_1)\\
&+ \mathcal{O}(1)K_2G_1 - \tilde{c}K_2] \int \Gamma(t)dt\\
&+ [\mathcal{O}(1)(T.V + G_1)(1 + K_1F((p-1)Ns)) + \mathcal{O}(1)K_2(T.V + G_1)\\
&+ \mathcal{O}(1)K_2G_1(T.V + G_1) + \mathcal{O}(1)(1 + K_1F(pNs+))\\
&+ \mathcal{O}(1)K_2G_1 + \mathcal{O}(1)K_2]e(\Lambda_p)Ns + \mathcal{O}(1)K_2 \left(\int_{x_f((p-1)Ns)}^{x_f(pNs)} G(\xi)d\xi \right) Ns\\
&+ \left[2C_2K_2 + \mathcal{O}(1)K_2 - \frac{K_1}{2} \right] (Q(\Lambda_p) + C(\Lambda_p))L(pNs-)\\
&+ \left(\mathcal{O}(1)K_2 \int_{x_f((p-1)Ns)}^{x_f(pNs)} G(\xi)d\xi - \frac{K_1c_0}{2} \sum_{k=(p-1)N}^{pN-1} \left| \int_{x_f(ks)}^{x_f((k+1)s)} G(x)dx \right| \right) L(pNs-).
\end{aligned}
$$

Since $F(t), G_0, G_1$, and $T.V$ are sufficiently small, we can choose positive constants K_1 and K_2 so that

$$
\begin{aligned}
&\mathcal{O}(1)(1 + K_1F((p-1)Ns)) + \mathcal{O}(1)K_2(T.V + G_1) + \mathcal{O}(1)K_2G_1 - \tilde{c}K_2 < 0,\\
&2C_2K_2 + \mathcal{O}(1)K_2 - \frac{K_1}{2} < 0, \quad \mathcal{O}(1)K_2 - \frac{K_1c_0}{2} < 0.
\end{aligned}
$$

Then, for such K_1 and K_2, we have

$$
H(pNs+) \le H((p-1)Ns+) + \mathcal{O}(1) \left(e(\Lambda_p) + \mathcal{O}(1) \int_{x_f((p-1)Ns)}^{x_f(pNs)} G(\xi)d\xi \right) Ns.
$$

This completes the proof. ∎

Using Lemma 4.4 successively, we obtain the following estimates.

LEMMA 4.5. *Let $v(x,t)$ be a Glimm solution corresponding to the small perturbation $v_0(x)$ of $u(x)$. Suppose the condition* (1.3) *holds. Then we have*

$$
H(T) \le H(0) + \mathcal{O}(1) \left(Q(\Lambda_T) + C(\Lambda_T) + \int_{x_f(0)}^{x_f(T)} G(\xi)d\xi \right) Ns + \mathcal{O}(1)(\epsilon + \delta + NsG_0)T.
$$

Proof. Let $v_r(x,t)$ and $u_r(x)$ be the simplified wave patterns and $T = MNs$. By Lemma 4.4, we have

$$
H(MNs+) \le H((M-1)Ns+) + \mathcal{O}(1) \left(e(\Lambda_M) + \int_{x_f((M-1)Ns)}^{x_f(MNs)} G(\xi)d\xi \right) Ns.
$$

If we use Lemma 4.4 successively in p, we obtain

$$
H(T) \le H(0) + \mathcal{O}(1) \left(Q(\Lambda_T) + C(\Lambda_T) + \int_{x_f(0)}^{x_f(T)} G(\xi)d\xi \right) Ns + \mathcal{O}(1)(\epsilon + \delta + NsG_0)T.
$$

Now we can complete the proof of Theorem 1.2 as follows. ∎

Proof of Theorem 1.2. Let $v_r(x,t)$ and $u_r(x)$ be two simplified wave patterns such that

$$\lim_{r,\epsilon,\delta\to 0} v_r(x,t) = v(x,t), \qquad \lim_{r,\epsilon,\delta\to 0} u_r(x) = u(x) \quad \text{in } L^1_{loc}(\mathbb{R}\times\mathbb{R}_+).$$

Since $H[v(\cdot,t),u(\cdot)] = \lim_{r,\epsilon,\delta\to 0} H[v_r,u_r]$, it follows from Lemma 4.4 that

$$H(t) \le H(0).$$

Since $H[v(\cdot,t),u(\cdot)]$ is equivalent to $\|v(\cdot,t)-u(\cdot)\|_{L^1(\mathbb{R})}$, i.e.,

$$\frac{1}{C_3}\|v(\cdot,t)-u(\cdot)\|_{L^1(\mathbb{R})} \le H(t) \le C_3\|v(\cdot,t)-u(\cdot)\|_{L^1(\mathbb{R})} \quad \text{for some positive constant } C_3,$$

we therefore have

$$\|v(\cdot,t)-u(\cdot)\|_{L^1(\mathbb{R})} \le C_3H(t) \le C_3H(0) \le C_3^2\|v(\cdot,0)-u(\cdot)\|_{L^1(\mathbb{R})}.$$

This completes the proof. □

ON THE DISCRETE SPECTRUM OF SYSTEMS IN THE PLANE AND THE DAVEY–STEWARTSON II EQUATION*

JAVIER VILLARROEL† AND MARK J. ABLOWITZ‡

Abstract. The discrete spectrum of first order systems in the plane and localized solutions of the Davey–Stewartson II equation are studied via the inverse scattering transform. Localized nonsingular algebraically decaying potentials are found which correspond to a discrete spectrum whose related eigenfunctions have, in general, multiple poles and are associated to kernels with dimension ≥ 2. There is an associated index, or winding number, which is used to classify these potentials. With suitable assumptions the mass of the corresponding Davey–Stewartson solution is found to be proportional to the index.

1. Introduction.

In this paper we study the classification and properties of the discrete spectrum associated with the linear differential operator in the plane (the Dirac system)

$$L\psi \equiv (\partial_x + iJ\partial_y - A)\,\psi = 0, \tag{1}$$

where J is a real constant diagonal $n \times n$ matrix, $J = \text{Diag}(J_1, \dots, J_n)$, $J_1 \neq J_2 \neq \cdots \neq J_n$, and $A(x, y)$ is an off-diagonal $n \times n$ matrix of decaying potentials.

The above problem, often referred to as the Dirac system, has attracted significant interest by itself. The Dirac system, along with the nonstationary Schrödinger (NS) equation, is one of the most relevant linear operators in two space dimensions. The importance of this problem is highlighted by noting that the solution to the Cauchy problem, corresponding to decaying data, to some of the most interesting two space, one time $(2+1)$ dimensional integrable nonlinear equations can be obtained via the inverse scattering transform (IST) and associated spectral analysis of the operator (1). Foremost among them is the Davey–Stewartson II (DSII) equation

$$iq_t + \frac{1}{2}(q_{yy} - q_{xx}) + q\,(R_{yy} - R_{xx}) = 0, \tag{2.1}$$

$$\left(\partial_y^2 + \partial_x^2\right) R(x, y) = -\sigma|q|^2, \tag{2.2}$$

which corresponds to $n = 2$ and certain reductions (see formula (18) below). Here $\sigma^2 = 1$.

Equations (2.1) and (2.2) describe, upon scaling of the physical parameters, two-dimensional quasi-monochromatic wave packets in dispersive media; here $q(x, y, t)$ is

the complex amplitude of the wave. Applications include both fluid dynamics [1, 2] and plasma physics [3]. Interesting solutions of this and other integrable equations are the lumps: localized wave configurations decaying rationally at infinity that asymptotically move with uniform velocities. (We call this an N-lump solution if the result consists of N of these objects. A class of such solutions was constructed in [4].) After these waves interact they asymptotically recover their velocity and size. This kind of behavior is usually expected for localized solutions of integrable equations. From a spectral perspective, the N-lump solution is associated with wave functions that have simple poles and hence correspond to the discrete spectrum of the spectral problem (1).

IST has been employed to solve (formally) other initial value problems for a number of important nonlinear evolution equations appearing in physics ([5, 6]; see also [7]). The relevant ideas in multidimensions regarding the continuous spectrum of the operator (1) were developed in [8], where the continuous spectrum is related to a $\bar{\partial}$ (DBAR) problem, a nontrivial generalization of the Riemann problems that appear in the one-dimensional case. We note that the IST has also been used to obtain the Hamiltonian structure and the action angle variables of (2.1), (2.2) [9, 10]. Another major difference with regard to one dimension stems from the fact that in multidimensions "small" norm assumptions are required, rendering the analysis incomplete; in particular homogeneous solutions, which make up the discrete spectrum and are intimately related to the lumps of the associated integrable equation, are beyond the scope of the theory. In terms of the rigorous theory this situation is quite unsatisfactory, as it fails to explain the most physically interesting solutions.

Recently, new localized solutions possessing nontrivial dynamics have been found for several integrable equations [11, 12, 13, 14, 15]. The connection with the discrete spectrum of the relevant spectral problem has been described in the case of the NS operator and the Kadomtsev–Petviashvili I equation (KPI) [11, 12]. This new class of solutions is found to correspond to wave functions that have higher order poles in the spectral variable. As it happened with the continuous part, the description of the discrete spectrum in multidimensions was found to involve novel features not present in one-dimensional problems.

The present work continues the development of discrete spectral theory in multidimensions, first set forth in [12] in connection with the NS operator. We find a class of rationally decaying, regular, localized potentials of the Dirac system (1) that yield meromorphic wave functions with simple or multiple poles in the spectral variable. We also consider the general case when both continuous and discrete spectrums are present. In this regard we note the following facts: (i) Different potentials exist (apparently infinitely many) that correspond to the same analytic structure (i.e., simple, double ... poles) of the wave function; this degeneracy of the discrete spectrum is explained in terms of a new topological number or index Q. (ii) The corresponding DSII solution describes the interaction of lumps with nontrivial dynamics; both (i) and (ii) hold even for eigenfunctions with simple poles and no continuous spectrum (see section 4 below). These remarkable facts have so far not been observed for any other integrable equation including the KPI equation. (iii) The results of [4] correspond to simple poles with $Q = 1$. Different values of Q and/or higher order pole multiplicities yield new DSII solutions. (iv) We obtain several different representations of the index and show that it is a winding number. (v) We prove that the mass of the lump is proportional to the index, namely (see (33)), $(4\pi)^{-1}\|q\|_2^2 = Q$, and hence it is "quantized" (can only take integer values).

Remark. 1. Ample classes of localized solutions of integrable equations can be derived using direct Darboux methods (see [13] in the context of DSII, and also [16, 17, 18] in connection with KPI equation). Despite the latter fact, direct methods cannot be used to solve the corresponding initial value problem, to study the interaction of radiation and localized solutions, or to obtain the Hamiltonian structure with the action angle variables and constants of the motion. Neither do they provide information regarding the associated and interesting linear problem; spectral analysis, in contrast, does, thus giving important and much deeper insight into the study.

2. We also find remarkable differences between the Dirac operator (DO) and the other natural spectral operator in the plane, NS. The most obvious is that the latter is a scalar operator while the former is a matrix operator. Hence so is the index Q, with several complications arising from this fact. Another important difference regards the fact that at eigenvalues the dimension d of the null space of homogeneous solutions of the DO is not restricted to be one (as happens in NS) and typically is found to be two (at least); we note that the appearance of lumps of DSII is intimately related with this possibility. Equally significant is the fact that even for the case of simple pole eigenfunctions an infinite degeneracy regarding the index (independent of that of the null space) is found, with every integer value of the index permitted; hence there exist different localized potentials associated to wave functions having simple poles. This extra freedom is inherited by the associated integrable equations. Corresponding to pure simple pole eigenfunctions the NS operator requires $Q = 1$, and hence there is only one such function. The corresponding lump of KPI decays as $\frac{1}{r^2}$ and has trivial dynamics. In contrast, for the DO the degeneracy in the dimension of the null space opens the possibility of having localized solutions with stronger decay (as $\frac{1}{r^3}, \dots$). Besides, the infinite degeneracy of the index implies that there exist localized solutions of DSII that decay as $|q|^2 = -\sigma(\partial_y^2 + \partial_x^2)\log(r^{2Q} + \dots)$ for any integer Q. Generically these solutions have a nontrivial dynamics. Another remarkable fact, not found for KPI, is the following. Given a localized solution q of DSII, the physically related state $\tilde{q}(x, y, t) \equiv \bar{q}(x, y, -t)$, obtained by backwards evolution and conjugation of phase, can correspond to a totally different spectral description and singularity structure.

The table below summarizes the differences for the case of (only) simple poles.

Operator	Type	d	Q	Equation	Dynamics of associated lumps	Decay	Number of lumps
Dirac	$n \times n$ matrix	1, 2	any integer	DSII	nontrivial	$\frac{Q}{r^2}$, any Q, or $\frac{1}{r^3}, \dots$	Q
NS	scalar	1	1	KPI	trivial	$\frac{1}{r^2}$	1

1.1. A review of known results on the spectrum of the DO. We consider here the spectral theory for the general DO where ψ is an $n \times n$ matrix. It is convenient to introduce a related function μ_{lj}, $\mu_{lj} = \psi_{lj} e^{-k(iJ_j x - y)}$ and find that μ satisfies

$$(\partial_x + iJ_l\partial_y + ik(J_j - J_l))\,\mu_{lj} - (A\mu)_{lj} = 0, \qquad l, j = 1, \dots, n. \tag{3}$$

If the potential is suitably decaying as $x^2 + y^2 \to \infty$, we can convert the above equation normalized to $\mu \to I$ as $x^2 + y^2 \to \infty$ and $|k| \to \infty$ into an integral equation

$$\mu_{lj}(\tilde{x}, k) = \delta_{lj} + \int\int G_{lj}(\tilde{x} - \tilde{x}', k)(A\mu)_{lj}(\tilde{x}', k)d\tilde{x}' \tag{4}$$

(integration is over the plane). Here $\tilde{x}$ stands for the coordinate pair (x, y) and we denote $d\tilde{x} \equiv dxdy$. Green's function is given by

$$G_{lj}(\tilde{x}, k) = \frac{\text{sign } J_l}{2\pi(J_l x + iy)} e^{i\theta_{lj}}, \tag{5}$$

where

$$\theta_{lj}(k) \equiv c_{-lj}(J_l k_R x + k_I y), \qquad c_{\pm lj} \equiv \frac{J_l \pm J_j}{J_l} \tag{6}$$

(c_{+lj} will be used later). We find it convenient also to consider these equations in columnwise form. Thus the jth column $\vec{\mu}_j, (\vec{\mu}_j)_i = \mu_{ij}$ satisfies

$$\vec{\mu}_j(\tilde{x}, k) = \vec{I}_j + \int\int \vec{G}_j(\tilde{x} - \tilde{x}', k)(A\vec{\mu})_j(\tilde{x}', k) d\tilde{x}'. \tag{7}$$

We next define the operator $\mathcal{G}_j(k)$ acting on column vectors by

$$\mathcal{G}_j(k)\vec{\mu}(\tilde{x}, k) \equiv \vec{\mu}(\tilde{x}, k) - \int\int \vec{G}_j(\tilde{x} - \tilde{x}', k)(A\vec{\mu})_j(\tilde{x}', k) d\tilde{x}' \tag{8}$$

in terms of which (7) reads $\mathcal{G}_j(k)\vec{\mu}_j = \vec{I}_j$. Note that $(\vec{I}_j)_i = \delta_{ij}$ and $(\vec{G}_j)_i = G_{ij}$.

Equation (7) implies that generically its solution $\vec{\mu}_j(\tilde{x}, k)$ is nowhere holomorphic as a function of $k \equiv k_R + ik_I$. This departure from holomorphicity defines the continuous spectrum of the problem. We recall the basic results in this regard. Define the $n \times n$ matrix Ω^{lj} by $\{\Omega^{lj}\}_{\alpha\beta} = e^{i\theta_{lj}} T_{lj} \delta_{l\alpha} \delta_{j\beta}$, where

$$T_{lj}(k) = \frac{ic_{-lj}\text{sign}J_l}{4\pi} \int e^{-i\theta_{lj}} (A\mu)_{lj} d\tilde{x} \tag{9}$$

are the "continuous" scattering data. Then one finds that

$$\frac{\partial \mu}{\partial \bar{k}} = \sum_{j,l=1}^{n} \mu \left(k_R + i\frac{J_j}{J_l} k_I \right) \Omega^{lj}(k). \tag{10}$$

Using that $\mu \to I$ as $|k| \to \infty$, the generalized Cauchy formula yields

$$\mu(k) = I + \frac{1}{2\pi i} \int_C \frac{\frac{\partial \mu}{\partial \bar{z}}}{z - k} dz \wedge d\bar{z}. \tag{11}$$

The departure from holomorphicity (10) and (11) are the basic inverse problem equations. They define a so-called $\bar{\partial}$ (DBAR) problem.

We also recall the inverse formula to reconstruct the potential:

$$A_{lj} = i(J_j - J_l)\xi_{lj}, \qquad \text{where } \mu_{lj} = \delta_{lj} + \frac{\xi_{lj}}{k} + O(1/k^2), \qquad k \to \infty. \tag{12}$$

The study of the continuous spectrum of the integral equation (4) was carried out formally in [8] evaluating the above DBAR derivative. Rigorous properties of solutions to (4) were obtained in [19] (see also [20, 21, 22]). Existence and uniqueness for the direct problem (4) are guaranteed if the potentials are in $L_\infty \cap L_1$ and "small" enough (see (24) below).

If the small norm condition is not satisfied, solutions $\vec{\omega}$ to the homogeneous equation $\mathcal{G}_j(k_1)\vec{\omega} = \vec{0}$ may exist at some points $k = k_1$ (the eigenvalues). The span (vector space) of all such functions is denoted Ker $\mathcal{G}_j(k_1)$. By the discrete spectrum of the operator (1) we mean the set $\mathcal{E}$ of all eigenvalues; we say that a potential corresponds (purely) to this part of the spectrum when there exist solutions $\vec{\omega}$ to the homogeneous equation $\mathcal{G}_j(k_1)\vec{\omega} = \vec{0}$ at some points $k = k_1 \in \mathcal{E}$ and the continuous data (9) vanishes. Note that in general $\mathcal{E} \neq \emptyset$ if the norms $\|q\|_\infty, \|q\|_1$ are only bounded. The study of the analytic properties of eigenfunctions corresponding to the latter potentials is beyond the theory developed in [19, 20, 21, 22] and has so far not been considered in detail. In this case the above description of the inverse problem is not complete; one can expect that generically $\mu(k)$ will have singularities. Indeed, suppose that the jth column $\vec{\mu}_j(k)$ of μ has a pole k_1 with multiplicity m and tends to I_j as $k \to \infty$. Around this pole $\vec{\mu}_j(k)$ has the Laurent expansion

$$\vec{\mu}_j(k) = \vec{\mu}_{j\text{sing.}}(k) + \vec{\mu}_{j\text{reg.}}(k),$$

$$\vec{\mu}_{j\text{sing.}}(k) \equiv \sum_{r=1}^{m} \frac{\vec{\Psi}_j^r}{(k-k_1)^r}, \qquad \vec{\mu}_{j\text{reg.}}(k) \equiv \sum_{r=0}^{\infty} \vec{\nu}_j^r (k-k_1)^r + \sum_{r=1}^{\infty} \vec{\zeta}_j^r (\bar{k}-\bar{k}_1)^r, \tag{13}$$

where $\vec{\mu}_{j,reg}(k)$ is regular (but in general not analytic) in the neighborhood of k_1 and tends to $\vec{I}_j$ as $k \to \infty$. Coefficients corresponding to $r = 0$ and the principal part or residue with $r = 1$ deserve particular interest, and we shall use special notation for them. Accordingly we denote

$$\vec{\Psi}_j^1 = \text{ Residue of } \vec{\mu}_j(k) \text{ at } k_1 \equiv \vec{\Phi}_j,$$

$$\vec{\nu}_j^0 = \lim_{k \to k_1} [\text{Regular part of } \vec{\mu}_j(k) \text{ at } k_1] \equiv \vec{\nu}_j. \tag{14}$$

Letting $k \to k_1$ shows that $\vec{\Psi}_j^m$ satisfies $\mathcal{G}_j(k_1)\vec{\Psi}_j^m = \vec{0}$, which means that k_1 must be an eigenvalue and $\vec{\Psi}_j^m \in$ Ker $\mathcal{G}_j$. Thus the existence of wave functions with pole singularities (singular eigenfunctions, for short) requires that $\mathcal{E} \neq \emptyset$, and hence they are naturally associated with the discrete spectrum.

In general we expect that the only singularities of $\vec{\mu}_j(k)$ are poles of any order in k. This can be substantiated as follows; first, we note that $\mathcal{L}_j \equiv \mathcal{G}_j - I$ is a Fredholm operator [20]. The case with compactly supported potentials is particularly easy to understand, as polar operators (i.e., with the kernel having only weak singularities and vanishing away a bounded set) are well known to be Fredholm. Potentials supported on the entire plane can be viewed as having compact support on the compactified plane; the result then follows, noting that $\sup_{\mu, \|\mu\|_\infty \leq 1} \mathcal{L}_j(k)\vec{\mu}(\tilde{x}, k)$ goes to zero uniformly as $r^2 \equiv x^2 + y^2 \to \infty$ on a bounded set of functions μ. Hence Fredholm theory (and the results of [6, 8]) indicates that generically the solutions $\mu(k)$ to (4) are not holomorphic anywhere and that they may have a denumerable set of poles of any order in $k, \bar{k}$ as singularities in the finite plane. Note also that, in principle, pole singularities in the variable $\bar{k}$ are not allowed, as can be seen by expanding $\mu(k)$ for large values of $|k|$ and using (3) (we detail this in the appendix). A class of special solutions exists, however, that are analytic everywhere except at (isolated) poles; i.e., they are meromorphic. This class corresponds purely to the discrete spectrum and has localized associated potentials.

Another critical property involving the distribution of eigenvalues is the following.

Result 0. Assume that $\vec{\omega}_l$ solves the lth homogeneous equation at a point $k_l \equiv a_l + ib_l$: $\mathcal{G}_l(k_l)\vec{\omega}_l = \vec{0}$. Then $\vec{\pi}_j$ defined as $\vec{\pi}_j = e^{-i\theta_{jl}(k_l)}\vec{\omega}_l$ solves the jth homogeneous equation at the point $k_{jl} \equiv a_l + i\frac{J_l}{J_j}b_l$. Note also that $\theta_{jl}(k_l) = -\theta_{lj}(k_{jl})$.

For a proof of this remarkable fact, note that [8]

$$\omega_{il}(\tilde{x}) = \int\int G_{il}(\tilde{x} - \tilde{x}', k_l)(A\omega)_{il}(\tilde{x}')d\tilde{x}',$$

and hence

$$\pi_{ij}(\tilde{x}) = \int\int \left(e^{-i\theta_{jl}}G_{il}\right)(\tilde{x} - \tilde{x}', k_l)(A\pi)_{ij}(\tilde{x}')d\tilde{x}'.$$

The proof is finished by noting that the Green's function (equation (5)) satisfies the following symmetric relationship:

$$G_{ij}(k_{jl}) = e^{-i\theta_{jl}(k_l)}G_{il}(k_l). \tag{15}$$

In particular, taking $l = 1, j = 2, J_1 = -J_2 = 1$ we obtain that if there exists a solution $\vec{\omega}_1$ to the first homogeneous equation at a point $k_1 \equiv a + ib$, then $\vec{\pi}_2 \equiv e^{-2i(by-ax)}\vec{\omega}_1$ solves the second homogeneous equation at $\bar{k}_1$; i.e.,

$$\vec{\pi}_2 \in \text{ Ker } \mathcal{G}_2(\bar{k}_1) : \ \mathcal{G}_2(\bar{k}_1)\vec{\pi}_2 = \vec{0}. \tag{16}$$

1.2. The DSII reduction. The physical DSII problem (2.1), (2.2) is obtained with $n = 2$ and

$$J = \begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix}, \quad A = \begin{pmatrix} 0 & q \\ r & 0 \end{pmatrix}, \quad r(\tilde{x}) = \sigma\bar{q}(\tilde{x}), \quad \tilde{x} \equiv (x, y), \quad \sigma = \pm 1, \tag{17}$$

and $\bar{q}$ stands for the complex conjugate of q. This entails a number of restrictions or symmetry relations on the wave function that we now discuss. One finds that

$$\begin{pmatrix} \mu_{12}(k) \\ \mu_{22}(k) \end{pmatrix} = \begin{pmatrix} \sigma\bar{\mu}_{21}(\bar{k}) \\ \bar{\mu}_{11}(\bar{k}) \end{pmatrix}, \tag{18}$$

and this implies in particular that the position, number, and multiplicities of the poles of different columns are related. One has the following:

(i) Singular functions μ have the structure (13) and (18), where the location of the poles of $\vec{\mu}_2$ are the complex conjugates of those of $\vec{\mu}_1$ and have the same order m. Hence the discrete spectrum is an even-dimensional set $\{k_j, \bar{k}_j\}_{j=1,\dots,N}$.

(ii) The Laurent coefficients of the first and second columns of μ,

$$\vec{\Psi}_1^r = \begin{pmatrix} \Psi_{11}^r \\ \Psi_{21}^r \end{pmatrix}, \quad \vec{\Psi}_2^r = \begin{pmatrix} \Psi_{12}^r \\ \Psi_{22}^r \end{pmatrix}, \quad r = 1, \dots, m,$$

are related as follows:

$$\Psi_{12}^r = \sigma\bar{\Psi}_{21}^r, \qquad \Psi_{22}^r = \bar{\Psi}_{11}^r. \tag{19}$$

We can thus drop the subscripts $1, 2$ of the Laurent coefficients and simply write $\vec{\Psi}_1^r \equiv \vec{\Psi}^r, \vec{\Psi}_2^r = \tau\vec{\Psi}^r$ where we define the following involution:

$$\vec{\Psi} \equiv \begin{pmatrix} \Psi_1 \\ \Psi_2 \end{pmatrix} \Rightarrow \tau\vec{\Psi} \equiv \begin{pmatrix} \sigma\bar{\Psi}_2 \\ \bar{\Psi}_1 \end{pmatrix}. \tag{20}$$

Besides, $\vec{\mu}_{2reg}(k) = \tau\vec{\mu}_{1reg}(\bar{k})$.

(iii) At each eigenvalue $k_1 \equiv a + ib, \bar{k}_1$, there are two eigenfunctions, and hence the null space is (at least) two-dimensional. One has that

$$\{\vec{\Psi}^m, e^{2i(by-ax)}\tau\vec{\Psi}^m\} \subset \text{ Ker } \mathcal{G}_1(k_1), \qquad \{\tau\vec{\Psi}^m, e^{-2i(by-ax)}\vec{\Psi}^m\} \subset \text{Ker } \mathcal{G}_2(\bar{k}_1). \tag{21}$$

(We use the notation $\{f, g\}$ to symbolize the vector span of the two function f, g.)

Indeed, according to the comments under equation (14) $\vec{\Psi}^m \in$ Ker $\mathcal{G}_1(k_1)$, $\tau\vec{\Psi}^m \in$ Ker $\mathcal{G}_2(\bar{k}_1)$. With $\omega_1 \equiv \vec{\Psi}^m$ (16) yields that $\vec{\pi}_2 = e^{-2i(by-ax)}\vec{\Psi}^m \in$ Ker $\mathcal{G}_2(\bar{k}_1)$, whereby one has that $\{\tau\vec{\Psi}^m, e^{-2i(by-ax)}\vec{\Psi}^m\} \subset$ Ker $\mathcal{G}_2(\bar{k}_1)$. Likewise we obtain ($l = 2, j = 1, \omega_2 \equiv \tau\vec{\Psi}^m$) that $\pi_1 \equiv e^{2i(by-ax)}\tau\vec{\Psi}^m \in$ Ker $\mathcal{G}_1(k_1)$.

(iv) For wave functions with simple poles $k_1, \bar{k}_1$ and residue $\vec{\Phi}$ at k_1,

$$\vec{\mu}_1(k) = \vec{\mu}_{1,reg}(k) + \frac{\vec{\Phi}}{(k - k_1)}, \tag{22}$$

the following relationship for the Laurent coefficients $\vec{\nu} \equiv \vec{\nu}^0$ and $\vec{\Phi}$ can be derived:

$$\vec{\nu} = (z + \gamma)\vec{\Phi} + \rho_1 e^{2i(by-ax)}\tau\vec{\Phi} \tag{23}$$

(where $z \equiv y - iJ_1x \equiv y - ix$, and γ and ρ_1 are constants). Corresponding to $\rho_1 = 0$, (23) was first derived in [8], noticing that $\vec{\nu} - z\vec{\Phi} \in$ Ker $\mathcal{G}_1(k_1)$, and was employed to obtain a class of solutions to DSII which decay weakly (as $1/r$, $r \equiv (x^2 + y^2)^{\frac{1}{2}}$) but are singular. The general formula (23) with $\rho_1 \neq 0$ was first derived in [4] and used to find nonsingular rational solutions that decay as $1/r^2$ at infinity (in [23] the stability of these configurations is discussed). These solutions are usually referred to as the lumps of DSII. We recover them in section 4 below.

(v) Corresponding to the focusing case ($\sigma = -1$) of DSII, convergence via iteration requires that $q(x, y)$ satisfies the condition $\|q\|_\infty\|q\|_1 < \frac{\pi}{2}$ [19]. If in addition q satisfies

$$\frac{2}{\pi}\|q\|_\infty\|q\|_1 \leq \frac{1}{(1-\tau)^2}\|\hat{q}\|_\infty\|\hat{q}\|_1 < 1, \qquad \tau^2 \equiv \frac{1}{(2\pi)^3}\|q\|_1\|\hat{q}\|_1, \tag{24}$$

where $\hat{q}$ is the Fourier transform, then it is proven that the inverse problem also has a unique solution, and hence so does the Cauchy problem for (2.1), (2.2).

(vi) The inverse formula to reconstruct the potential (12) yields in this case that

$$q \equiv A_{12} = -2i\xi_{12}, \qquad \text{where } \xi_{lj} = \lim_{k\to\infty} k\mu_{lj}, \tag{25.1}$$

$$|q|^2 = -4\sigma\frac{\partial}{\partial\bar{z}}\xi_{11}, \qquad R = \partial_z^{-1}\xi_{11}, \qquad \text{where } z \equiv y - ix. \tag{25.2}$$

2. New results for the discrete spectrum of the DO. We now elaborate on our results for the discrete spectrum of the operator (1). As has been remarked, the appearance of lumps of DSII is intimately related to the possibility of having a higher-dimensional null space Ker $\mathcal{G}_1(k_1)$, i.e., with (21). We shall see that there is also additional freedom in both (i) the order of the poles and (ii) the value of an integer-valued quantity that we call indices or charges (as we shall see they are winding numbers), which we now introduce.

At any pole $k_1 \equiv a + ib$, of the jth column $\vec{\mu}_j(k)$ we define the index of the pole as the matrix functional $Q_{lj}[\Phi, k_1] \equiv Q_{lj},\ l, j = 1, \dots, n$,

$$Q_{jj} = \frac{\text{sign } J_j}{2\pi i} \int\int (A\Phi)_{jj}(\tilde{x}')d\tilde{x}',$$

$$Q_{lj} \equiv \frac{c_{+lj}}{4\pi i} \text{ sign } J_j \int\int e^{-i\theta_{lj}(k_1)}(A\Phi)_{lj}(\tilde{x}')d\tilde{x}', \tag{26}$$

where $\vec{\Phi}_j(k)$ is the residue of $\vec{\mu}_j(k)$ at the pole k_1, the quantities c_{lj+}, θ_{lj} are defined in (6), and we recall our notation $(\vec{\mu}_j)_i = \mu_{ij}$. We shall see that meromorphic wave functions with simple or multiple poles yield a new class of rationally decaying, regular and localized potentials of (1) and (2). We find that different potentials exist that correspond to the same analytic structure of the wave function, in particular to simple poles. The degeneracy of the spectrum is classified in terms of the index. These potentials—even in the case of simple poles in the wave function—are found to correspond to values of the index that satisfy $Q_{lj} = (Q\delta_{lj})$, with Q being a positive integer. We note that both in [8] and [4] the relationship (23) and the lump potentials correspond to assuming $Q = 1$. (This has been checked a posteriori by direct evaluation of the integral (26) in [23].) In this regard, a natural problem is to determine the most general values the index may take. We can state the following.

Result 1. (i) The index can be represented as

$$Q_{lj} = \frac{c_{+lj}}{4\pi i} \text{ sign } J_j \oint_\Gamma \tilde{\Phi}_{lj}(\tilde{x})dz, \tag{27}$$

where Γ is a closed contour at infinity that winds the origin once in the positive (counterclockwise) direction and $z \equiv y - iJ_l x$, and we write $e^{-i\theta_{lj}(k_1)}\Phi_{lj} \equiv \tilde{\Phi}_{lj}$.

(ii) If $\tilde{\Phi}_{lj}$ is nonsingular, decaying with a power series expansion in $z, \bar{z}$ at infinity (see below), one has for the index matrix

$$Q_{lj} = \begin{cases} \lambda^{\frac{c_{+lj}}{2}} \text{ sign } J_j & \text{if } \tilde{\Phi}_{lj} = \frac{\lambda}{z} \text{ as } r^2 \equiv x^2 + y^2 \to \infty, \\ 0 \text{ otherwise.} \end{cases} \tag{28}$$

It will turn out that Q_{jj} are integers.

(iii) The index matrix must be diagonal:

$$Q_{lj} = 0, \qquad l \neq j. \tag{29}$$

(iv) For the Dirac system corresponding to the DSII reduction, $Q_{22} = \bar{Q}_{11}$.

(v) If for some positive integer Q is $\Phi_{jj} = \frac{d}{dz} \ln H(z, \bar{z})$ with $H(z, \bar{z}) > 0$ and $H \sim (z\bar{z})^Q$ as $r^2 \to \infty$, then

$$Q_{jj} \text{sign } J_j = Q = \text{winding number of } H. \tag{30}$$

Proof. (i) Considering (3) for Φ_{lj} and using Green's theorem, we obtain

$$\begin{aligned} \int\int e^{-i\theta_{lj}(k_1)}(A\Phi)_{lj}(\tilde{x}')d\tilde{x}' &= \int\int (\partial_x + iJ_l\partial_y)\left(e^{-i\theta_{lj}(k_1)}\Phi_{lj}\right)d\tilde{x}' \\ &= \oint_\Gamma e^{-i\theta_{lj}(k_1)}\Phi_{lj}(z, \bar{z})dz. \end{aligned}$$

(ii) Assume that at infinity $\tilde{\Phi}_{lj}(z,\bar{z})$ has the power series expansion

$$\tilde{\Phi}_{lj}(z,\bar{z}) = \sum_{n,m=0}^{\infty} \frac{\lambda_{n,m}}{z^n \bar{z}^m}, \qquad n+m \geq 1.$$

Recalling that for a large contour Γ at infinity

$$\oint_\Gamma \frac{1}{2\pi i z^n \bar{z}^m} dz = \begin{cases} 1, & n = 1-m = 1, \\ 0 & \text{otherwise}, \end{cases}$$

(27) yields that

$$Q_{lj} = \frac{c_{+lj}}{4\pi i} \text{ sign } J_j \oint_\Gamma \tilde{\Phi}_{lj}(z,\bar{z}) dz = \frac{c_{+lj}}{2} (\text{ sign } J_j) \lambda_{1,0}.$$

(iii) We skip the proof here.
(iv) This follows directly from (19): $\Phi_{22} = \bar{\Phi}_{11}$ and (27).
(v)

$$Q_j = \frac{\text{sign } J_j}{2\pi i} \oint_\Gamma \Phi_{jj}(z,\bar{z}) dz = \frac{\text{sign } J_j}{2\pi i} \oint_\Gamma \frac{d \ln H}{dz} dz = Q.$$

Note. By (ii) $Q_{lj} \neq 0$ iff at infinity $\tilde{\Phi}_{lj}$ decays like $\frac{1}{z}$. According to (iii) this holds only for the diagonal elements of the index matrix. It follows that we can simply write $Q_j \equiv Q_{jj}$ for the diagonal elements.

Conjecture. For any potential of the DSII reduction for which μ is singular, the index matrix must be an integer multiple of the identity matrix:

$$Q_{lj} = Q\delta_{lj} \text{ or } Q_{11} = Q_{22} \equiv Q \text{ a positive integer}, \qquad Q_{12} = Q_{21} = 0, \tag{31}$$

and in addition $\Phi_{11} = \frac{d}{dz} \ln H(z,\bar{z})$ with $H \sim (z\bar{z})^Q$ as $r^2 \to \infty$.

We note that in all the examples of lump-type solutions considered, this turns out to be the case; we also note that the proofs corresponding to section 4 below apply for generic singular eigenfunctions, irrespective of whether a continuous spectrum is present or not.

Index and L_2 norms. The index has been originally defined (cf. (26) and (27)) as an integral of certain functions that are inherent to the spectral space: the residues Φ_j. A natural question arises as to whether Q is directly related to the potential $q(x,y)$ itself. We see next that under certain conditions the answer is affirmative. Let

$$\|q\|_2^2 \equiv \int\int |q(x,y)|^2 dxdy$$

be the (square of the) L_2 norm. With time present (e.g., Davey–Stewartson) physically it represents the mass of the wave $q(x,y,t)$ and it is conserved in time (i.e., it is an integral of the motion). We can state the following.

Result 2. (i) Assume that $R(x,y) = \ln \Delta(x,y)$, where $\Delta(x,y) > 0$ satisfies $\Delta = (z\bar{z})^s + O((z\bar{z})^{s-1})$ as $r^2 \to \infty$ for some positive integer s and $z \equiv y - ix$ with $J_1 = 1 = -J_2 = -\sigma$. Then

$$\|q\|_2^2 = 4\pi s. \tag{32}$$

(ii) Assume $\vec{\mu}_1$ is purely meromorphic with just one pole and residue Φ_{11} satisfying $\Phi_{11} = \frac{d}{dz} \ln H(z, \bar{z})$ with $H > 0$ and $H \sim (z\bar{z})^Q$ as $r^2 \to \infty$. Then

$$4\pi Q = \|q\|_2^2. \tag{33}$$

Proof. (i) Using (2.2) with $\sigma = -1$ and Green's theorem, one has that

$$\begin{aligned}\int\int |q(x,y,t)|^2 dxdy &= \int\int \left(\partial_y^2 + \partial_x^2\right) R dxdy = \oint_\Gamma \left(dy\partial_x - dx\partial_y\right) R(\tilde{x}) \\ &= \frac{2}{i} \oint_\Gamma \frac{d}{dz} R(z,\bar{z}) dz = \frac{2}{i} \oint_\Gamma \frac{d}{dz} \ln \Delta(z,\bar{z}) dz,\end{aligned}$$

where Γ is a closed contour at infinity that winds the origin once in the positive direction. We have $R = \ln \Delta$, where we write $\Delta = \Delta_1.\Delta_2.\Delta_3$, $\Delta_1 \equiv z^s, \Delta_2 \equiv \bar{z}^s$, and $\Delta_3 \equiv 1 + O(1/(z\bar{z}))$. The remainder decays, and it is zero when integrated out along Γ. It follows by the argument principle that

$$\frac{1}{4\pi} \int\int |q(x,y,t)|^2 dxdy = \frac{1}{2\pi i} \oint_\Gamma \frac{d}{dz} \log \Delta_1(z) dz = s.$$

(ii) In this case in (25.1) $\xi_{11} = \Phi_{11}$ and by (25.2) $R(x,y) = \ln H(z,\bar{z})$; hence by (30) Q equals the index. The result follows by (i) with $\Delta(x,y) = H$ and $s = Q$.

Remarks. 1. This formula extends to the case in which μ is purely meromorphic with N simple poles $k_1, \dots, k_N$, residues $\Phi^{j)}, j = 1, \dots, N$, and different indices $Q[\Phi^{j)}, k_j], j = 1, \dots, N$. In this case $s = \sum_{j=1}^N Q[\Phi^{j)}, k_j] = \frac{1}{4\pi}\|q\|_2^2$.

2. By means of Green's theorem as well as the argument principle, we have given three different representations, (26), (27), and (33), of the index. We have also shown that it is a winding number (the reader may consult [24] in connection with the above ideas). The mass of the wave is proportional to the index for basic lump solutions of DSII, and to the sum of indices for N-lump solution. For generic potentials (solutions of DSII) we do not expect that the mass of the wave be finite.

3. Determination of the wave functions of the discrete spectrum. We shall see that the determination of singular eigenfunctions associated with the discrete spectrum requires the following integers: the number of poles N, and at every pole $m \equiv$ multiplicity of the pole, $Q \equiv$ index matrix, and $d \equiv \text{Dim Ker } \mathcal{G}_1(k_1)$. Note: we find that certain constants determine Ker $\mathcal{G}_1(k_1)$. If $\tilde{d}$ of these constants vanish, we consider that the effective dimension of the null space is $\geq d - \tilde{d}$. Given this information we find a linear relationship between a subset of the Laurent coefficients $\{\vec{\Psi}_j^r, \vec{\nu}_j^r, r = 0, 1, \dots\}$ of $\mu(k)$, which fixes the function μ. We consider here the DSII reduction. The general case is taken up later.

Simple poles. We consider first the case of simple poles. In this case we show that the formula (23) is not the only possible one corresponding to this pole structure; this implies that there exist different localized potentials of DSII that correspond to wave functions having simple poles.

Result 3. Assume that there exists a solution to (7) such that its columns $\vec{\mu}_1(k), \vec{\mu}_2(k)$ have simple poles $k_1 \equiv a + ib, \bar{k}_1$ and residues Φ_1, Φ_2, respectively. Define

$$F_{j;1} \equiv (z_j + \gamma_j), \qquad F_{j;2} \equiv \frac{1}{2}(F_{j;1}^2 + \delta_j), \qquad j = 1, 2, \tag{34}$$

where γ_j, δ_j are certain constants (under evolution γ_j, δ_j are functions of time), and we recall that $z_j \equiv y - ixJ_j$ and that (see (16), (21) for the DSII reduction) we have as homogeneous solutions

$$\vec{\Phi}_1; \pi_1 \equiv e^{2i(by-ax)}\tau\vec{\Phi}_1 \qquad \text{and} \qquad \vec{\Phi}_2 = \tau\vec{\Phi}_1, \vec{\pi}_2 = e^{-2i(by-ax)}\vec{\Phi}. \tag{35}$$

We also introduce $f_{j;r} \equiv F_{j;r}(\gamma = \delta = 0)$. The conditions (18), (19) require that $\gamma_2 = \bar{\gamma}_1, \delta_2 = \bar{\delta}_1$, which implies $F_{2;1} = \bar{F}_{1;1}, F_{2;2} = \bar{F}_{1;2}$. It follows that we can drop the column indices of these functions and write $F_{1;n} \equiv F_n, \gamma_1 \equiv \gamma, \delta_1 \equiv \delta$. Define also $\theta \equiv \theta_{21} = 2(by - ax)$. The following hold:

(i) The index matrix must be diagonal: $(Q)_{lj} = \text{ Diag } (Q_1, \bar{Q}_1)$.

(ii) If $Q_1 = 1$, then the Laurent coefficients $\vec{\nu}_j, \vec{\Phi}_j$ satisfy $\vec{\nu}_j = F_j\vec{\Phi}_j + \rho_j\vec{\pi}_j$, where ρ_j are certain constants (we take here $\rho_1 \equiv \bar{\rho}, \rho_2 \equiv \sigma\bar{\rho}_1$), or

$$\vec{\nu}_1 = F_1\vec{\Phi}_1 + \bar{\rho}e^{i\theta}\vec{\Phi}_2, \tag{36.1.1}$$

$$\vec{\nu}_2 = \bar{F}_1\vec{\Phi}_2 + \sigma\rho e^{-i\theta}\vec{\Phi}_1. \tag{36.1.2}$$

(iii) If $Q_1 = 2$, then the Laurent coefficients $\vec{\nu}_j^1, \vec{\nu}_j, \vec{\Phi}_j$ satisfy

$$\vec{\nu}_1^1 = F_1\vec{\nu}_1 + \bar{\rho}e^{i\theta}\vec{\nu}_2 - F_2\vec{\Phi}_1 + e^{i\theta}\bar{H}\vec{\Phi}_2, \tag{36.2.1}$$

$$\vec{\nu}_2^1 = \bar{F}_1\vec{\nu}_2 + \sigma\rho e^{-i\theta}\vec{\nu}_1 - \bar{F}_2\vec{\Phi}_2 + \sigma e^{-i\theta}H\vec{\Phi}_1, \tag{36.2.2}$$

where $H \equiv \rho' - \rho\tilde{F}_1$, $\tilde{F}_1 \equiv (z_1 + \gamma_1')$, and where γ_1', ρ' are certain constants (which become functions of time under evolution).

(iv) If Q_1 is any positive integer, then the Laurent coefficients $\vec{\nu}_j^{Q-1}, \dots, \vec{\nu}_j, \vec{\Phi}_j$ satisfy

$$\vec{\nu}_1^{Q-1} = \sum_{l=-1}^{Q-2}(-1)^{l+1}F_{Q-l-1}\vec{\nu}_1^l + e^{i\theta}\sum_{l=-1}^{Q-2}(-1)^{l+1}\tilde{F}_{Q-l-2}\vec{\nu}_2^l, \tag{36.Q.1}$$

$$\vec{\nu}_2^{Q-1} = \sum_{l=-1}^{Q-2}(-1)^{l+1}\bar{F}_{Q-l-1}\vec{\nu}_2^l + \sigma e^{-i\theta}\sum_{l=-1}^{Q-2}(-1)^{l+1}\tilde{F}_{Q-l-2}^*\vec{\nu}_1^l, \tag{36.Q.2}$$

where we define $F_l, \tilde{F}_l$ recursively via $\partial_{z_1}F_l + F_{l-1} = 0, F_1 = z_1$, $\partial_{z_1}\tilde{F}_l + \tilde{F}_{l-1} = 0$, $\tilde{F}_0 = \bar{\rho}$, and $\vec{\nu}_1^{-1} \equiv \vec{\Phi}_1, \vec{\nu}_2^{-1} \equiv \vec{\Phi}_2$. In addition, by obvious reasons we use $F^* \equiv \bar{F}$.

We skip here the rather technical proof.

Double poles. We briefly mention how the above theory generalizes to deal with higher order singular wave functions, in particular those for the case of poles of order 2. Assume that around $k = k_j$, $\vec{\mu}_j(k)$ has the singular representation (13) with $m = 2$, i.e.,

$$\vec{\mu}_{j\text{sing.}}(k) = \frac{\vec{\Psi}_j}{(k-k_j)^2} + \frac{\vec{\Phi}_j}{k-k_j}, \qquad j = 1, 2, \tag{37}$$

and $k_2 = \bar{k}_1$.

Note that in this case (19) implies the following relationship for the principal Laurent coefficients of the first and second columns of μ:

$$\vec{\Psi}_1 \equiv \vec{\Psi}, \quad \vec{\Psi}_2 = \tau\vec{\Psi}; \qquad \vec{\Phi}_1 \equiv \vec{\Phi}, \quad \vec{\Phi}_2 = \tau\vec{\Phi}.$$

In addition, if $\vec{\pi}_1 \equiv e^{2i(by-ax)}\vec{\Psi}_2, \vec{\pi}_2 = e^{-2i(by-ax)}\vec{\Psi}_1$, then (21) implies

$$\{\vec{\Psi}_1, \vec{\pi}_1\} \subset \text{ Ker } \mathcal{G}_1(k_1), \qquad \{\vec{\Psi}_2, \vec{\pi}_2\} \subset \text{ Ker } \mathcal{G}_2(\bar{k}_1).$$

Define also (similar to the case of simple poles) the functions (see (34))

$$F_{j;1} \equiv (z_j + \gamma_j); \quad F_{j;2} \equiv \frac{1}{2}(F_{j;1}^2 + \delta_j), \quad H_j \equiv \rho_j' - \rho_j\tilde{F}_j; \quad \tilde{F}_j \equiv (z_j + \gamma_j'), \tag{38}$$

where $\gamma_j, \delta_j, \rho_j, \gamma_j', \rho_j'$ are constants (functions of time under evolution).

Result 4. Assume that there exists a solution to (7) such that its columns $\vec{\mu}_1(k), \vec{\mu}_2(k)$ have double poles. Then the charge $Q_j(\Phi, k_1)$ takes integer values with $Q_j \geq 2$. If $Q_j(\Phi, k_1) = 2, Q_j(\Psi, k_1) = 0$, then the Laurent coefficients $\vec{\nu}_j, \vec{\Phi}_j, \vec{\Psi}_j$ are linearly related as follows:

$$\vec{\Phi}_j = F_{j;1}\vec{\Psi}_j + \rho_j\pi_j, \tag{39.1}$$

$$\vec{\nu}_j = F_{j;2}\vec{\Psi}_j - H_j\vec{\pi}_j. \tag{39.2}$$

4. DSII potentials. The former development has a direct bearing on the construction of localized, nonsingular rationally decaying solutions of the DSII equation. Upon considering particular analytic structures for the wave functions and relevant indices, using the inverse formula (25) we can reconstruct the potential, with the appropriate temporal dependence of the scattering data (the constants $(\gamma, \delta, \dots)$) inserted.

Recall that the DSII equations (2.1), (2.2) arise from the compatibility $[L, M] = 0$, with L given by (1) and with $M = -\partial_t + A_1 - A\partial_y + iJ\partial_{yy}$. Here A_1 is given by

$$A_1 = \begin{pmatrix} A_{11} & A_{12} \\ A_{21} & A_{22} \end{pmatrix} \tag{40}$$

with elements satisfying

$$(\partial_x + i\partial_y)A_{11} = i\frac{\sigma}{2}(\partial_x - i\partial_y)|q|^2, \qquad (\partial_x - i\partial_y)A_{22} = -i\frac{\sigma}{2}(\partial_x + i\partial_y)|q|^2,$$

$$A_{12} = -\frac{i}{2}(\partial_x - i\partial_y)q, \qquad a_{21} = \frac{\sigma}{2}(i\partial_x - \partial_y)\bar{q}. \tag{41}$$

The temporal evolution of the scattering data follows in the standard way by substituting the relevant eigenfunctions in the time operator evolution M. The constants $\gamma_j, \delta_j, \dots$ of section 3 are found to satisfy the following:

Simple poles.

$$\partial_t\gamma_j = -2iJ_jk_j, \quad \partial_t\delta_j = 2iJ_j, \quad \partial_t\rho = 2i(a^2 - b^2)\rho, \quad j = 1, 2, \tag{42}$$

and hence the temporal evolution is given by

$$\gamma_j(t) = \gamma_j(0) - 2iJ_jk_jt, \quad \delta_j(t) = \delta_j(0) + 2iJ_jt, \quad \rho(t) = \rho(0)\exp 2i(a^2 - b^2)t \tag{43}$$

both for quantities with or without primes.

Double poles. In this case one has that the temporal evolution is given by

$$\gamma_j(t) = \gamma_j(0) - 2iJ_jk_jt, \qquad \rho(t) = \rho_0 e^{2i(a^2-b^2)t} \tag{44.1}$$

both for quantities with or without primes, and (notice the change in sign)

$$\delta_j(t) = \delta_j(0) - 2iJ_jt. \tag{44.2}$$

We consider here the simplest examples of DSII solutions that correspond to pure discrete spectrums; in this case the wave function is purely meromorphic.

Simple poles. Assume that the column components of wave functions $\vec{\mu}_1(k), \vec{\mu}_2(k)$ have simple poles $k_1 \equiv a + ib$ and $\bar{k}_1$, residues $\vec{\Phi}_1, \vec{\Phi}_2$, respectively, and $\vec{\mu}_{1,2reg} = \vec{I}_{1,2}$; i.e., take $N = m = 1$ and

$$\vec{\mu}_1(k) = \vec{I}_1 + \frac{\vec{\Phi}}{(k-k_1)}, \qquad \vec{\mu}_2(k) = \vec{I}_2 + \frac{\vec{\Phi}_2}{(k-\bar{k}_1)}. \tag{45}$$

We obtain the following:

(i) $Q = 1$. Then the relevant system is (36.1) with $\vec{\nu}_j(k) = \vec{I}_j$. Upon solution and use of (25) we find that the eigenfunctions and potentials are given by [4]

$$\vec{\Phi}_2 = \tau\vec{\Phi}_1 = \frac{1}{\Delta}\begin{pmatrix} \sigma\rho e^{-i\theta} \\ F_1 \end{pmatrix}, \tag{46}$$

$$q(x,y,t) = -2i\rho\sigma\frac{e^{-i\theta}}{\Delta}, \qquad R = \ln\Delta, \tag{47}$$

$$\Delta \equiv |F_1|^2 - \sigma|\rho|^2 \equiv (x - \gamma_I + 2at)^2 + (y + \gamma_R + 2bt)^2 - \sigma|\rho|^2, \tag{48}$$

where $\theta \equiv 2(by - ax + (b^2 - a^2)t)$. This solution is characterized by the integers $m = N = Q = 1$ and $d = 2$.

The potential takes a simpler form upon transformation to a frame moving with the wave with coordinates

$$\hat{x} = x - \gamma_I + 2at, \qquad \hat{y} = y + \gamma_R + 2bt. \tag{49}$$

Indeed, relative to this coordinate frame

$$q = -2i\sigma\rho\frac{e^{2i(a\hat{x}-b\hat{y}+(b^2-a^2)t+a\gamma_I+b\gamma_R)}}{\hat{y}^2 + \hat{x}^2 - \sigma|\rho|^2}. \tag{50}$$

Note that upon transformation of the Galilean frame, the field $q(x,y,t)$ is not invariant but picks a phase factor $4(b^2 - a^2)t + 2a\gamma_I + 2b\gamma_R$.

Corresponding to $\sigma = -1$ and taking $\rho \neq 0$ the solution is nonsingular and decays rationally as $1/(x^2+y^2)$ at infinity. Hence it has all the $L_p, p > 1$ norms finite. Indeed by direct calculation one finds

$$\|q\|_1 = \infty, \quad \|q\|_p \equiv \left(\int\int |q(x,y,t)|^p dxdy\right)^{\frac{1}{p}} = 2\left(\frac{\rho^{2-p}\pi}{p-1}\right)^{\frac{1}{p}}, \quad p > 1. \tag{51}$$

This implies that all the constants of the motion (see [9]) are finite. The opposite situation arises in the defocusing case ($\sigma = 1$), where the solution is singular and hence the $L_p, p > 1$ norms are all infinite (unlike what was claimed in [4]).

From a physical perspective the solution for $\sigma = -1$ describes a wave (lump) traveling with constant velocity $v_x = -2a, v_y = -2b$, and amplitude $|q| = \frac{2}{|\rho|}$ modulated by the phase $\theta(x, y, t)$. However, this wave is unstable against perturbations [23].

(ii) If $\mu(k)$ has the structure (45) and $Q = 2$, then the Laurent coefficients satisfy (36.2) with $\vec{\nu}_j^1 = 0$:

$$F_1\vec{I}_1 + \bar{\rho}e^{i\theta}\vec{I}_2 - F_2\vec{\Phi}_1 + e^{i\theta}\bar{H}\vec{\Phi}_2 = 0,$$

$$\bar{F}_1\vec{I}_2 + \sigma\rho e^{-i\theta}\vec{I}_1 - \bar{F}_2\vec{\Phi}_2 + \sigma e^{-i\theta}H\vec{\Phi}_1 = 0, \tag{52}$$

where we recall that $F_1 \equiv z_1 + \gamma$, $\tilde{F}_1 \equiv (z_1 + \gamma')$, $F_2 \equiv \frac{1}{2}(F_1^2 + \delta)$, $H \equiv \rho' - \rho\tilde{F}_1 = -\rho(F_1 + \eta)$, and $\eta \equiv \gamma' - \gamma - \frac{\rho'}{\rho}$. We first analyze the case corresponding to $\rho = 0$. Solving this system we obtain the corresponding residue and DSII solution as

$$\vec{\Phi}_2 = \frac{1}{\Delta}\begin{pmatrix}\sigma F_1\rho' e^{-i\theta}\\ F_2\bar{F}_1\end{pmatrix}, \qquad q(x,y) = -\frac{2i\sigma\rho'}{\Delta}\ F_1 e^{-i\theta} \tag{53}$$

with $\Delta \equiv |F_2|^2 + |G|^2$. Finally Δ is now

$$\Delta \equiv |F_2|^2 + |H|^2 = \frac{1}{4}(\hat{y}^2 - \hat{x}^2 + \delta_R)^2 + (\hat{x}\hat{y} - \frac{\delta_I}{2} - t)^2 - \sigma|\rho'|^2. \tag{54}$$

In the moving frame with coordinates (49) we have

$$q(x,y) = -8i\sigma\rho'\frac{e^{2i(a\hat{x} - b\hat{y} + (b^2 - a^2)t + a\gamma_I + b\gamma_R)}(\hat{y} - i\hat{x})}{(\hat{y}^2 - \hat{x}^2 + \delta_R)^2 + 4(\hat{x}\hat{y} - \frac{\delta_I}{2} - t)^2 - 4\sigma|\rho'|^2}. \tag{55}$$

From a spectral point of view, and since ρ equals 0 this solution could be interpreted as arising from a one-dimensional homogeneous space of solutions and hence to correspond to the integers $m = N = d = 1$ and $Q = 2$. Note that, as has been commented, $\Phi_{11} = \frac{d}{dz}\log\Delta$ with $\Delta = (z\bar{z})^2, r^2 \to \infty$ (see (30), (33)). This solution for particular choice of the parameters was also obtained in [13] by use of Darboux formalism.

We consider next the general case corresponding to $\rho \neq 0$. Solving (52) we obtain the corresponding residue and DSII solution as

$$\vec{\Phi}_2 = \frac{1}{\Delta}\begin{pmatrix}\sigma(F_2\rho + F_1 H)e^{-i\theta}\\ F_2\bar{F}_1 + \sigma\bar{\rho}H\end{pmatrix}, \quad q(x,y) = -i\rho\sigma e^{-i\theta}\frac{(F_1^2 + 2\eta F_1 - \delta)}{\Delta}, \quad R = \ln\Delta, \tag{56}$$

and $\Delta \equiv |F_2|^2 - \sigma|H|^2$. In the moving frame with coordinates (49) we obtain

$$\Delta = \frac{1}{4}(\hat{y}^2 - \hat{x}^2 + \delta_R)^2 + \left(\hat{x}\hat{y} - \frac{\delta_I}{2} - t\right)^2 - \sigma|\rho|^2((\hat{x} - \eta_I)^2 + (\hat{y} + \eta_R)^2, \tag{57}$$

$$q(x,y,t) = -4i\sigma\rho e^{2i(a\hat{x}-b\hat{y}+(b^2-a^2)t+a\gamma_I+b\gamma_R)}$$

$$\cdot\frac{(\hat{y}^2-\hat{x}^2+2(\eta_R\hat{y}+\eta_I\hat{x})-\delta_R-2i(\hat{x}\hat{y}+\eta_R\hat{x}-\eta_I\hat{y}+\frac{\delta_I}{2}+t))}{(\hat{y}^2-\hat{x}^2+\delta_R)^2+4(\hat{x}\hat{y}-\frac{\delta_I}{2}-t)^2-4\sigma|\rho|^2((\hat{x}-\eta_I)^2+(\hat{y}+\eta_R)^2)}. \tag{58}$$

Spectrally this solution corresponds to the integers $m = N = 1$ and $d = Q = 2$.

Next we describe the main physical features of the above solution corresponding to $\sigma = -1$. The solution depends on 5 complex (or 10 real) parameters: $k_1, \gamma, \delta, \eta$, and ρ. It is nonsingular and at infinity it decays like $O(\frac{1}{r^2})$. The lump positions are asymptotically expected to be found at the locations at which the denominator has smallest order. Inspection of (54) shows that this occurs when the highest polynomials vanish at leading order. Hence we require $\hat{y}^2 - \hat{x}^2 = \hat{x}\hat{y} - t = 0$ and obtain for the lump positions

$$(\hat{x}_\pm, \hat{y}_\pm) \sim \pm\sqrt{|t|}(-1,1), \qquad t \to -\infty, \tag{59$-$}$$

and

$$(\hat{x}_\pm, \hat{y}_\pm) \sim \pm\sqrt{|t|}(1,1), \qquad t \to \infty, \tag{59$+$}$$

where $(\hat{x}_+, \hat{y}_+)$ and $(\hat{x}_-, \hat{y}_-)$ are the coordinates of the front and rear lumps. It follows that asymptotically the solution decomposes into two separate lumps, which, as seen in the Galilean frame (49), are moving with respect to the origin along the straight line $y = -x$ with velocities $\pm\frac{1}{2\sqrt{t}}(1,-1)$. Eventually they will collide and scatter off at an angle of $\frac{\pi}{2}$. This is unlike KPI, where the scattering angle takes on any possible value between 0 and 2π depending on the value of parameters [12]. The amplitude of both humps is maintained constant through the interaction process and given by $\frac{2}{|\rho|}$; this follows noting that at lump locations (59$\pm$) one has $\Delta = O(t)$, $F_1^2 + 2\eta F_1 = O(t)$, and hence their ratio is bounded with limit $\frac{2}{|\rho|}$. With respect to a frame at rest, the asymptotic motion of the lumps is more complicated. As $t \to \infty$ the trajectories follow a hyperbola given by $2(bx - ay)^2 + (a-b)(x-y) = 0$.

Lump scattering and motion can be thought of as the motion due to an attractive force $f(r) \approx \frac{1}{r^3}$ between the lumps. Define $x_{i,j} \equiv x_i - x_j, y_{i,j} \equiv y_i - y_j, i,j = +,-$, $\vec{r}_i \equiv (x_i, y_i), \vec{r}_{i,j} \equiv (x_{i,j}, y_{i,j}), r_{i,j} \equiv |\vec{r}_{i,j}|$. The above trajectories as $t \to \pm\infty$ of the humps solve the following system:

$$\frac{d^2\vec{r}_i}{dt^2} = \sum_{j,j\neq i}\frac{\vec{r}_{i,j}}{r_{i,j}}f(r_{i,j}).$$

We see that humps attract each other, but they do not form a bound state since the attractive interaction is not strong enough to bind them together. Figures 1, 2, and 3 show a plot of this configuration before, during, and after interaction.

We next study the regularity properties of the solution corresponding to $\sigma = -1$. The possible singularities of the solution appear at points at which the denominator vanishes. The denominator attains a minimum value $\mathcal{S}^2$ at $\hat{x} = \eta_I; \hat{y} = -\eta_R$ at a time $2t = -2\eta_I\eta_R - \delta_I \equiv 2\tilde{t}$, where $\mathcal{S} \equiv \eta_R^2 - \eta_I^2 + \delta_R$. At this point

$$|q|(\eta_I, -\eta_R, \tilde{t}) = \frac{4\rho}{|\mathcal{S}|}. \tag{60}$$

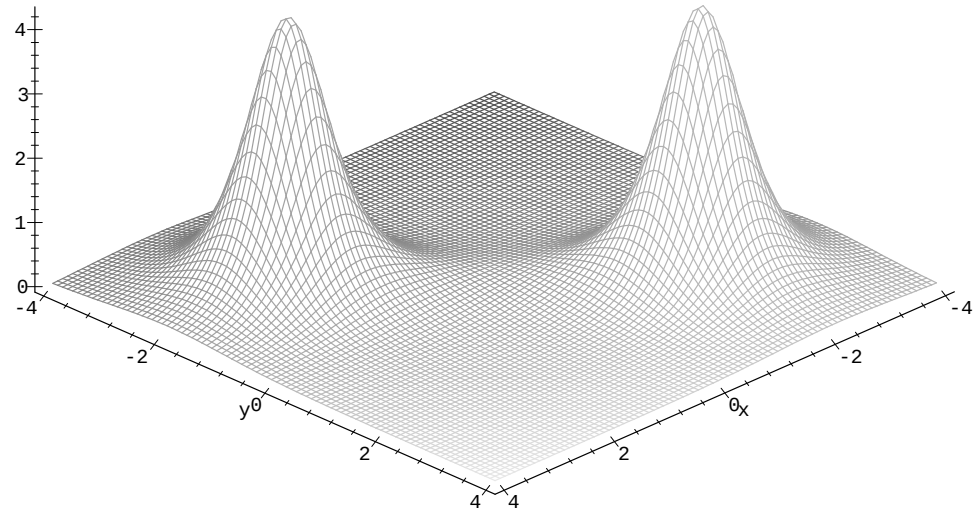

FIG. 1.

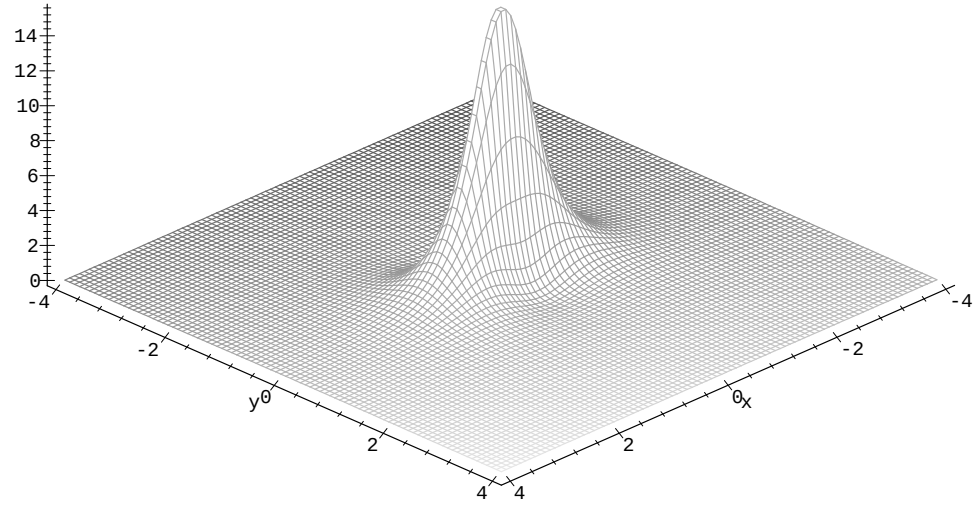

FIG. 2.

Thus the condition $\mathcal{S} \neq 0$ on the free parameters guarantees that the solution is never singular. However, one should not be misled into thinking that the amplitude grows unboundedly if the parameters satisfy $\mathcal{S} = 0$. The difficulty stems from letting first $\hat{x} = \eta_I$, $\hat{y} = -\eta_R$, $t = \tilde{t}$ and then $\mathcal{S} = 0$ (instead of doing these manipulations in the opposite order). Setting $t = \tilde{t}$, $\mathcal{S} = 0$ we find that (58) yields

$$|q|(\hat{x}, \hat{y}, \tilde{t}) = \frac{4\rho}{(\hat{x} + \eta_I)^2 + (\hat{y} - \eta_R)^2 + 4\rho^2}, \tag{60'}$$

and hence

$$|q|(\eta_I, -\eta_R, \tilde{t}) = \frac{\rho}{\eta_I^2 + \eta_R^2 + \rho^2} \leq |q|(-\eta_I, \eta_R, \tilde{t}) \equiv \frac{1}{\rho}.$$

This means that at time $t = \tilde{t}$ the two lumps have merged into one single rotationally

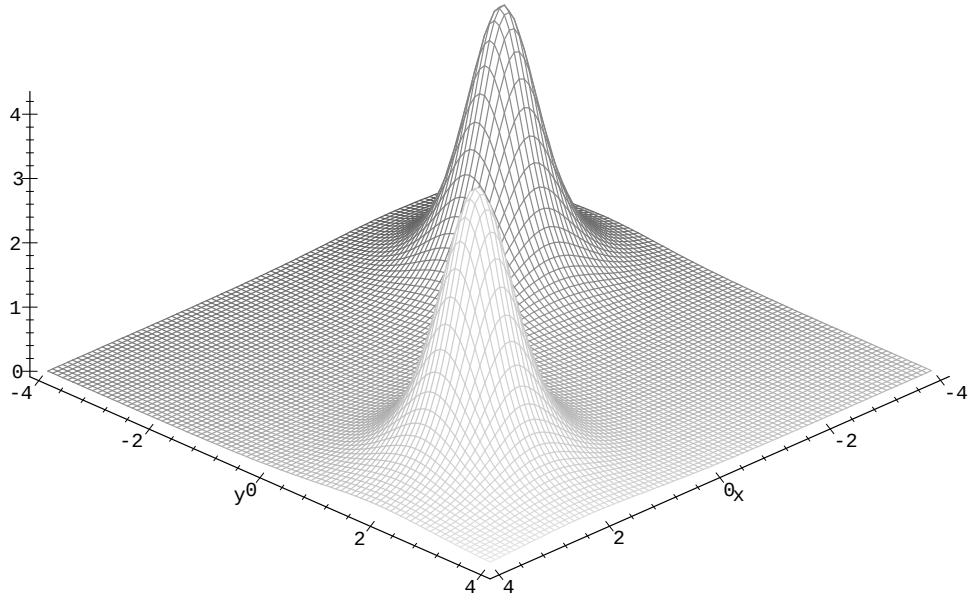

FIG. 3.

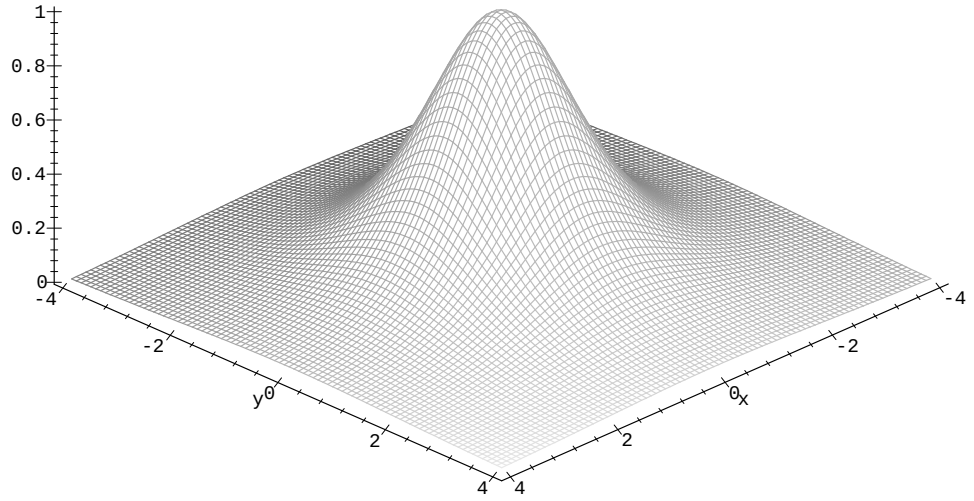

FIG. 4.

invariant structure and with an amplitude that is the sum of that of the individual lumps. This is interesting; it implies that all constants of motion of (58) depending only on the amplitude take the same value as those of (50) upon setting $\rho \to 2\rho$. In Figure 4 we show a plot of configuration during interaction $t = \tilde{t}$ displaying its rotational invariance.

The interaction process is similar to the solution (55). There exist several differences, however, between (55) and (58). We note that the DSII potential (55) decays as $\frac{1}{r^3}$ at infinity. Hence it has all the $L_p, p \geq 1$ norms finite. However, it depends only on 8 real parameters, and furthermore the lump's amplitude is not bounded but grows with time as $\sqrt{|t|}$ (recall that at the lump locations (55) one has $\Delta = O(1)$

and $F_1 = O(\sqrt{|t|}))$. Hence only for moderate periods of time can (55) be physically meaningful. On the other hand, (58) depends on 10 real parameters and decays at infinity (away from lump locations (55)) as $\frac{1}{r^2}$. The $L_p, p > 1$ norms are therefore finite—and hence there are all constants of the motion—but the L_1 norm is infinite. Unlike (55), the lump's amplitude of the lump (58) is bounded by $\frac{2}{|\rho|}$, and hence it can be physically meaningful for all times.

(iii) If $\mu(k)$ has the structure (45) and Q is any positive integer, then the Laurent coefficients satisfy (36.Q) with $\vec{\nu}_j^l = 0, l \geq 1, j = 1, 2$. Obtaining the corresponding DSII potential is a matter of linear algebra and is left for the reader.

Double poles. Next we briefly describe the simplest example of potentials corresponding to a double pole in the wave function. Assume that $\mu_1(k)$ has the representation

$$\vec{\mu}_1(k) = \frac{\vec{\Psi}_1}{(k-k_1)^2} + \frac{\vec{\Phi}_1}{k-k_1} + \vec{I}_1.$$

From Result 4 in such a case (39.1), (39.2) apply with $\vec{\nu}_1(k) = \vec{I}_1$. The resulting system can be solved to give the DSII potential (for convenience we take $\sigma = -1$)

$$q(x,y,t) = -2i\bar{\rho}e^{-i\theta}\frac{(\bar{F}_1^2 + 2\eta\bar{F}_1 - \delta)}{\Delta}$$

$$= -4i\bar{\rho}e^{i\theta}\frac{(\hat{y}^2 - \hat{x}^2 + 2(\eta_R\hat{y} + \eta_I\hat{x}) - \delta_R + 2i(\hat{x}\hat{y} + \eta_R\hat{x} - \eta_I\hat{y} + \frac{\delta_I}{2} - t))}{(\hat{y}^2 - \hat{x}^2 + \delta_R)^2 + 4(\hat{x}\hat{y} - \frac{\delta_I}{2} + t)^2 + 4|\rho|^2((\hat{x}-\eta_I)^2 + (\hat{y}+\eta_R)^2)}. \tag{61}$$

Spectrally this solution corresponds to the integers $N = 1$ and $m = d = Q = 2$. Note that this solution can be obtained from (58) upon letting $t \to -t$ and taking a complex conjugation. This is remarkable: it means that if $q(x,y)$ is a potential on the discrete spectrum of the DO corresponding to a wave function with simple poles and $Q = 2$, then $\bar{q}(x,y)$ is also related to the discrete spectrum of the DO corresponding to a wave function with double poles! Thus the transformation $q \to \tilde{q} \equiv \bar{q}(x,y,-t)$ preserves the index but not the pole structure. From a physical perspective this means that $q(x,y,t)$ and the physically related state $\tilde{q}(x,y,t) \equiv \bar{q}(x,y,-t)$, obtained by backwards evolution and conjugation of phase, have quite a different spectral classification in the case $Q = 2$. This stems from the following reason: the integers $N = 1$ and $m = d = Q = 2$ define an entire (equivalence) class of potentials, those $q_{k_1,\gamma,\delta,\eta,\rho}(x,y,t)$ members of the 10-parameter family (61). However, $\tilde{q}$ is not a member of the latter family, unlike what happens for $Q = 1$, where $\tilde{q}_{k_1,\gamma,\rho}(x,y,t) = q_{-k_1,\gamma,-\rho}(x,y,t)$. It follows that for $Q = 2$, $\tilde{q}$ cannot correspond to the same spectral numbers that q does.

Potentials corresponding to superposition of simple poles. More complicated solutions are found by taking a simple linear combination of N poles located at $k_l \equiv a_l + ib_l, l = 1, \ldots, N$. Assume that

$$\vec{\mu}_1(k) = \vec{I}_1 + \sum_{l=1}^{N}\frac{\vec{\Phi}^{l)}}{(k-k_l)}, \qquad \vec{\mu}_2(k) = \vec{I}_2 + \sum_{l=1}^{N}\frac{\tau\vec{\Phi}^{l)}}{(k-\bar{k}_l)}. \tag{62}$$

In this case one has that at every pole k_j

$$\vec{\nu}_1(k_j) = \vec{I}_1 + \sum_{l\neq j}^{N} \frac{\vec{\Phi}^{l)}}{a_{jl}}, \qquad \vec{\nu}_1^1(k_j) = -\sum_{l\neq j}^{N} \frac{\vec{\Phi}^{l)}}{a_{jl}^2}, \tag{63.1}$$

$$\vec{\nu}_2(\bar{k}_j) = \vec{I}_2 + \sum_{l\neq j}^{N} \frac{\tau\vec{\Phi}^{l)}}{\bar{a}_{jl}}, \qquad \vec{\nu}_2^1(\bar{k}_j) = -\sum_{l\neq j}^{N} \frac{\tau\vec{\Phi}^{l)}}{\bar{a}_{jl}^2}, \tag{63.2}$$

where $a_{jl} \equiv k_j - k_l$. We obtain the following:

(i) Assume that $Q^{j)} = 1, j = 1, \dots, N$. Then the solution satisfies

$$|q|^2 = -\sigma(\partial_{xx} + \partial_{yy})R, \qquad R(x,y) = \log\Delta. \tag{64}$$

Here $\Delta \equiv \det B$ is real, B is the $2N \times 2N$ matrix with the block decomposition

$$B = \begin{pmatrix} m & n \\ \sigma\bar{n} & \bar{m} \end{pmatrix}, \tag{65}$$

and we have defined

$$m_{jl} = F_1^{j)}\delta_{jl} - (1-\delta_{jl})\frac{e^{-a_{jl}z}}{a_{jl}}, \qquad n_{jl} = \bar{\rho}^{j)}\delta_{jl}, \qquad j,l = 1,2,\dots,N, \tag{66}$$

$$F_1^{j)} = z_1 + \gamma^{j)}, \quad z_1 \equiv z \equiv y - ix, \quad \theta^{j)} \equiv \theta_{21}^{j)} = 2(b^{j)}y - a^{j)}x + ({b^{j)}}^2 - {a^{j)}}^2)t).$$

(Note that we use superscripts to label functions corresponding to different poles.)

The solution is a rational function with coefficients modulated by the difference of phases $\theta^{j)} - \theta^{k)}, j,k = 1,\dots,N$; for long times it is a superposition of N lumps like (50), each of them traveling with a speed that for the $^{j)}$th lump is given by $(-2a^{j)}, -2b^{j)})$. These lumps asymptotically do not suffer interaction effects among themselves. Finally

$$\|q\|_2^2 = 4\pi N. \tag{67}$$

(ii) All the $Q^{j)} = 2$. In this case let

$$B = \begin{pmatrix} m & n \\ \sigma\bar{n} & \bar{m} \end{pmatrix}, \qquad \Delta = \det B, \tag{68}$$

where we define the $N \times N$ matrices m and n by

$$m_{jl} \equiv F_2^{j)}\delta_{jl} - \left[\frac{F^{j)}}{a_{jl}} + \frac{1}{a_{jl}^2}\right] e^{-a_{jl}z}(1-\delta_{jl}), \quad n_{jl} \equiv -\bar{H}^{j)}\delta_{jl} - \bar{\rho}^{j)}\frac{e^{-\bar{a}_{jl}\bar{z}}}{\bar{a}_{jl}}(1-\delta_{jl}). \tag{69}$$

Then

$$|q|^2 = -\sigma(\partial_y^2 + \partial_x^2)\log\Delta, \qquad R(x,y) = \log\Delta, \tag{70}$$

where Δ is real and

$$\|q\|_2^2 = 8\pi N. \tag{71}$$

The solution is a rational function with coefficients depending on the difference of phases $e^{i(\theta^{j)}-\theta^{k)})}, j,k=1,\dots,N$. For long time, the solution is composed of a sum of $2N$ lumps like (58); the trajectory for the $^{j)}$th lump is given by (59) with the relevant parameters. Only pairs of lumps corresponding to the same pole interact, and in a similar way to that described above with scattering in an angle of $\frac{\pi}{2}$. Otherwise, lumps corresponding to different poles do not interact.

Proof. We first prove that Δ is real (note that the proof is valid for both case (i) and case (ii)). We note the following:

$$\Delta = \det\begin{pmatrix} m & n \\ \sigma\bar{n} & \bar{m}\end{pmatrix} = (1)^N \det\begin{pmatrix} \sigma\bar{n} & \bar{m} \\ m & n\end{pmatrix} = \det\begin{pmatrix} \bar{m} & \sigma\bar{n} \\ n & m\end{pmatrix}$$
$$= \det\begin{pmatrix} \bar{m} & \bar{n} \\ \sigma n & m\end{pmatrix} = \overline{\Delta}.$$

We next prove formula (64). If all the $Q^{j)}=1$, then equations (36.1) apply and for $j=1,\dots,N$ we obtain the system

$$F_1^{j)}\Phi^{j)} - \sum_{l\neq j}^{N} \frac{\vec{\Phi}^{l)}}{a_{jl}} + \bar{\rho}^{j)} e^{i\theta^{j)}} \tau\vec{\Phi}^{j)} = \vec{I}_1,$$

$$\bar{F}_1^{j)}\tau\Phi^{j)} - \sum_{l\neq j}^{N} \frac{\tau\vec{\Phi}^{l)}}{\bar{a}_{jl}} + \sigma\rho^{j)} e^{-i\theta^{j)}} \vec{\Phi}^{j)} = \vec{I}_2. \tag{72}$$

For convenience we introduce the column vector $\vec{p}$ with entries $p^{j)} \equiv e^{-k^{j)}z}$ and

$$\vec{\pi}^{j)} = \vec{\Phi}^{j)} p^{j)}, \quad \zeta^{j)} \equiv \vec{\pi}_1^{j)}, \quad \omega^{j)} \equiv \sigma\bar{\pi}_2^{j)},$$

in terms of which (72) reads

$$\sum_{l\neq j}^{N} m_{jl}\zeta^{l)} + \bar{\rho}^{j)}\omega^{j)} = e^{-k^{j)}z}, \qquad \sum_{l\neq j}^{N} \bar{m}_{jl}\omega^{l)} + \sigma\rho^{j)}\zeta^{j)} = 0.$$

If B is the $2N\times 2N$ matrix defined in (65) and for $j=1,\dots,n$, $B^{j)}$ is the $2N\times 2N$ matrix obtained substituting the $^{j)}$th column of B by the column vector $\left(\begin{smallmatrix}\vec{p}\\ \vec{0}\end{smallmatrix}\right)$, the above system can be written as

$$B\begin{pmatrix}\zeta^{j)}\\ \omega^{j)}\end{pmatrix} = \begin{pmatrix}\vec{p}\\ \vec{0}\end{pmatrix}.$$

Therefore

$$\zeta^{j)} = \frac{B^{j)}}{B}, \qquad \sum_{j=1}^{N}\Phi_{j1} = \frac{1}{B}\sum_{j=1}^{N}\frac{B^{j)}}{p^{j)}} = \frac{\partial}{\partial z}\log\Delta,$$

where the last equality is obtained using the expression for the derivative of a determinant along with the fact

$$\frac{\partial}{\partial z}m_{jl}(z) = \frac{p^{l)}}{p^{j)}}, \qquad \frac{\partial}{\partial z}\bar{m}_{jl}(z) = \frac{\partial}{\partial z}\sigma\bar{n}_{jl}(z) = \frac{\partial}{\partial z}n_{jl}(z) = 0$$

and on account of (25.2)

$$|q|^2 = -4\sigma \frac{\partial}{\partial \bar{z}} \frac{\partial}{\partial z} \log \Delta.$$

This solution was obtained in [4]. Unlike what (64)–(66) suggests (and as was claimed in [4]), for $N > 1$, Δ does not increase exponentially; to see this note that $\Delta = \det B'$, where B' is the $2N \times 2N$ matrix with the block decomposition

$$B' = \begin{pmatrix} m' & n' \\ \sigma \bar{n}' & \bar{m}' \end{pmatrix},$$

and we have defined

$$m'_{jl} = F_1^{j)} \delta_{jl} - (1 - \delta_{jl}) \frac{1}{a_{jl}}, \quad n'_{jl} = \bar{\rho}^{j)} e^{i\theta^{j)}} \delta_{jl}, \quad j, l = 1, 2, \dots, N.$$

From this expression it can be proven that Δ is a polynomial with coefficients depending on $e^{i(\theta^{j)} - \theta^{k)})}, j, k = 1, \dots, N$. It also follows that for long values of either z or t, $\Delta = \prod_{j=1}^{N} F_1^{j)} \bar{F}_1^{j)} + O(z\bar{z})^{N-2}$; i.e., the relevant determinant factorizes as a product of determinants corresponding to one lumps, with relevant parameters, and hence that the solution is a superposition of N lumps like (50). In addition, (32) and $\Delta = (z\bar{z})^N + O(z\bar{z})^{N-2}$ imply that $\|q\|_2^2 = 4\pi N$, i.e., (67).

The case corresponding to all the $Q^{j)} = 2$ can be proven along similar lines using equations (36).

Summary of potentials. Below we summarize the above discussion on the spectral classification of potentials on the discrete spectrum and DSII solutions. Recall that the integers N, m, Q, d are defined at the beginning of section 3. Finally s represents the number of fundamental lumps the solution is composed of.

Spectral classification.

Solution	N	m	Q	d	s
(50)	1	1	1	2	1
(55)	1	1	2	1	2
(58)	1	1	2	2	2
(61)	1	2	2	2	2
(66)	N	1	1	2	N
(69)	N	1	2	2	$2N$

Physical properties. The following table gives a summary of the physical properties of the main localized DSII solutions (we take $\sigma = -1$). Recall that $\|q\|_2^2 = 4\pi s$ is the (square of the) L_2 norm, which physically represents the mass of the wave.

Solution	s	Smooth	Scattering	Angle	Amplitude	Decay	Parameters	Mass
(50)	1	Yes			$\frac{2}{\rho}$	$1/r^2$	5	4π
(55)	2	Yes	Yes	$\frac{\pi}{2}$	$\sqrt{t} \to \infty$	$1/r^3$	8	8π
(58)	2	Yes	Yes	$\frac{\pi}{2}$	$\frac{2}{\rho}$	$1/r^2$	10	8π
(61)	2	Yes	Yes	$\frac{\pi}{2}$	$\frac{2}{\rho}$	$1/r^2$	10	8π
(66)	N	Yes	No	0	$\frac{2}{\rho}$	$1/r^2$	$5N$	$4\pi N$
(69)	$2N$	Yes	Yes (by pairs)	$\frac{\pi}{2}$	$\frac{2}{\rho}$	$1/r^2$	$10N$	$8\pi N$

Remarks. We have presented the simplest examples of potentials associated with the discrete spectrum and localized solutions to DSII. While we shall not elaborate any further on this, we remark that one could also consider a mixture of poles of different types. Also, following the methods described one can in principle derive equations corresponding to higher order charges and/or poles.

Potentials corresponding to general spectrum. Next we consider potentials corresponding to the general case when both continuous and discrete spectrums are present. For simplicity we assume that the discrete spectrum corresponds to having just one simple pole; more general cases can be handled via the theory exposed before and linear algebra. One has the following:

Assume that there exists a solution to (7) such that its columns $\vec{\mu}_1(k), \vec{\mu}_2(k)$ have simple poles $k_1 \equiv a + ib, \bar{k}_1$ and residues $\vec{\Phi}, \tau\vec{\Phi}$, respectively,

$$\vec{\mu}_1(k) = \vec{\mu}_{1\mathrm{reg}}(k) + \frac{\vec{\Phi}}{(k-k_1)}, \qquad \vec{\mu}_2(k) = \tau\vec{\mu}_{1\mathrm{reg}}(k) + \frac{\tau\vec{\Phi}}{(k-\bar{k}_1)}, \tag{73}$$

where $\vec{\mu}_{1\mathrm{reg}}(k) \neq \vec{I}_1$ and $\vec{\mu}_{1\mathrm{reg}}(k) \to \vec{I}_1$ as $k \to \infty$. Then, in terms of the definitions given above, $\vec{\mu}_1(k)$ solves the linear equation of the inverse problem

$$\vec{\mu}_1(k) = \vec{I}_1 + \frac{1}{2\pi i}\int_C \frac{e^{i\theta_{12}}T_{12}(z)}{z-k}\tau\vec{\mu}_1(\bar{z})dz\wedge d\bar{z} + \frac{\vec{\Phi}}{(k-k_1)}, \tag{74}$$

and also, if $Q = 1$,

$$\vec{I}_1 + \frac{1}{2\pi i}\int_C \frac{e^{i\theta_{12}}T_{12}(z)}{z-k_1}\tau\vec{\mu}_1(\bar{z})dz\wedge d\bar{z} = F_1\vec{\Phi} + \bar{\rho}e^{i\theta}\tau\vec{\Phi} \tag{75.1}$$

or, if $Q = 2$,

$$\frac{\partial}{\partial k_1}\int_C \frac{e^{i\theta_{12}}T_{12}(z)}{z-k_1}\tau\vec{\mu}_1(\bar{z})dz\wedge d\bar{z} = F_1\left[2\pi i\vec{I}_1 + \int_C \frac{e^{i\theta_{12}}T_{12}(z)}{z-k_1}\tau\vec{\mu}_1(\bar{z})dz\wedge d\bar{z}\right]$$

$$+\bar{\rho}e^{i\theta}\left[2\pi i\vec{I}_2 + \sigma\int_C \frac{e^{-i\theta_{12}}\bar{T}_{12}(z)}{\bar{z}-\bar{k}_1}\vec{\mu}_1(z)dz\wedge d\bar{z}\right] - 2\pi i F_2\vec{\Phi} + 2\pi i e^{i\theta}\bar{H}\tau\vec{\Phi}. \tag{75.2.}$$

Finally the potential is obtained from (25) with

$$\xi_{12} = \frac{\sigma}{2\pi i}\int_C e^{-i\theta_{12}}\bar{T}_{12}(z)\mu_{11}(\bar{z})dz\wedge d\bar{z} + \sigma\bar{\Phi}_2. \tag{76}$$

Proof. If $\mu(k)$ has the structure (73), it follows that there exists a solution $\vec{\Phi}$ to the homogeneous equation $\mathcal{G}_1(k_1)\vec{\Phi} = \vec{0}$ at $k = k_1$. In this case one finds that (10) is to be modified as follows:

$$\frac{\partial\mu}{\partial\bar{k}} = \sum_{j,l=1}^{n}\mu\left(k_R + i\frac{J_j}{J_l}k_I\right)\Omega^{lj}(k) + A\Phi\delta(k-k_j), \tag{10$'$}$$

where A is an arbitrary constant. Direct derivation of (73) and use of the relationship $\frac{\partial}{\partial\bar{k}}\frac{1}{(k-k_j)} = \pi\delta(k-k_j)$ shows that $A = \pi$. Equation (74) follows substituting (10′) in (11). To obtain (75) use (36)—which is valid for general wave functions that have

only simple poles—the symmetry relationship (18), (19), and also the fact that (74) implies that

$$\vec{\nu}_1(k_1) = \vec{I}_1 + \frac{1}{2\pi i}\int_C \frac{e^{i\theta_{12}}T_{12}(z)}{z-k_1}\tau\vec{\mu}_1(\bar{z})dz\wedge d\bar{z},$$

$$\vec{\nu}_1^1 = \frac{1}{2\pi i}\frac{\partial}{\partial k_1}\int_C \frac{e^{i\theta_{12}}T_{12}(z)}{z-k_1}\tau\vec{\mu}_1(\bar{z})dz\wedge d\bar{z}.$$

Equation (76) also follows from (73).

Remark. We leave it to the reader to derive the linear equation of the inverse problem that $\vec{\mu}_1(k)$ satisfies when it has the structure (73) and Q is any positive integer. One only needs to determine $\vec{\nu}_j^l, l \geq 1, j = 1, 2$, and note that in this case the Laurent coefficients satisfy (36.Q).

5. The general case. Most of the former theory can be generalized to the general case corresponding to $J = \text{ Diag}(J_1, \dots, J_n)$, $J_1 \neq J_2 \neq \cdots \neq J_n$, and $A(x, y)$ an off-diagonal matrix. We mention the relevant generalizations.

Consequence of Result 0. For any fixed column j, let $k_j \equiv a_j + ib_j$ be an eigenvalue for that column: i.e., there exists a solution $\vec{\omega}_j$ to the jth homogeneous equation at the point k_j and let $\mathcal{L}_j$ be the set of indices

$$\mathcal{L}_j = \left\{ l| \text{ exists } \vec{\omega}_l \text{ that solves the } l\text{th homogeneous equation at } a_j + i\frac{J_j b_j}{J_l} \equiv k_{lj} \right\}.$$

Let $\pi_{lj} \equiv e^{-i\theta_{jl}(k_{lj})}\vec{\omega}_l$. Note that $j \in \mathcal{L}_j \subset \{1, \dots, n\}$ and hence in particular (if $l = j$) $\pi_{jj} = \vec{\omega}_j$. Then the null space of the jth homogeneous equation at $k = k_j$ contains the span of the functions π_{lj} when l ranges in $\mathcal{L}$:

$$\{\pi_{lj}\}_{l\in\mathcal{L}} \subset \text{ Ker } \mathcal{G}_j(k_j) =; \quad \text{Dim Ker } \mathcal{G}_j(k_j) \equiv |\mathcal{L}| \geq 1.$$

Result 3 is generalized as follows.

Let $\vec{\mu}_j(k)$ have the Laurent expansion (13) around any simple pole k_1. Then the following hold:

(i) The index matrix must be diagonal: $(Q)_{lj} = \text{ Diag } (Q_1, \dots, Q_n)$.

(ii) If $Q_j = 1$, then the Laurent coefficients satisfy

$$\vec{\nu}_j = F_{j;1}\vec{\Phi}_j + \sum_{l\in\mathcal{L}} \rho_{jl}e^{-i\theta_{jl}(k_l)}\vec{\Phi}_l, \tag{77.1}$$

where $F_{j;1} \equiv (z_j + \gamma_j), F_{j;2} \equiv \frac{1}{2}(F_{j;1}^2 + \delta_j)$, and $\gamma, \delta, \rho_{jl}, \dots$ are arbitrary constants.

(iii) If $Q_j = 2$, then the Laurent coefficients satisfy

$$\vec{\nu}_j^1 = F_{j;1}\vec{\nu}_j - F_{j;2}\vec{\Phi}_j + \sum_{l\in\mathcal{L}} e^{-i\theta_{jl}(k_l)}\left(\rho_{jl}\vec{\nu}_l + (\rho'_{jl} - \rho_{jl}\tilde{F}_{l;1})\vec{\Phi}_l\right), \tag{77.2}$$

where $\tilde{F}_{j;1} \equiv (z_j + g'_j)$ and g'_j, ρ'_{jl} are new constants.

Temporal evolution. In the general case the relevant evolution equation is the compatibility of (1) and

$$\left[\partial_t - iJ_l\partial_{yy} + 2ik_jJ_l\partial_y + ik_j^2(J_j - J_l)\right]\mu_{lj} + \sum_r A_{lr}\partial_y\mu_{rj} - A_{1lr}\mu_{rj} + k_jA_{lr}\mu_{rj} = 0,$$
$$l, j = 1, \dots, n,$$

where A_{1lr} is a certain matrix. One finds that the discrete scattering data corresponding to an eigenvalue $k_j \equiv a_j + ib_j$ evolves as the following.

Simple poles.

$$\partial_t \gamma_j = -2iJ_j k_j, \quad \partial_t \delta_j = 2iJ_j, \quad \partial_t \rho_{lj} = iJ_{lj}\left(a_l^2 + i\frac{J_l}{J_j}b_l^2\right)\rho_{lj},$$

$J_{lj} \equiv J_l - J_j$ and hence that $\gamma_j(t) = \gamma_j(0) - 2iJ_j k_j t$, $\delta_j(t) = \delta_j(0) + 2iJ_j t$,

$$\rho_{lj}(t) = \rho_{lj}(0)\exp iJ_{lj}\left(a_l^2 + i\frac{J_l}{J_j}b_l^2\right). \tag{78}$$

Double poles.

$$\gamma_j(t) = \gamma_j(0) - 2iJ_j k_j t, \qquad \delta_j(t) = \delta_j(0) - 2iJ_j t, \tag{79}$$

$$\rho_{lj}(t) = \rho_{lj}(0)\exp iJ_{lj}\left(a_l^2 + i\frac{J_l}{J_j}b_l^2\right). \tag{80}$$

Appendix. Here we prove that for DSII, no poles in $\bar{k}$ may exist.

Assume the eigenfunction has canonical normalization and the following expansion as $|k| \to \infty$:

$$\mu(k) = I + \frac{\Phi}{k} + \frac{\varphi}{\bar{k}} + o(1/k). \tag{A.1}$$

Inserting this expansion into (3) one obtains that (we consider $n = 2$, i.e., DSII)

$$\bullet O(k): \quad (J_j - J_l)\delta_{lj} = 0,$$

which is identically satisfied.

$$\bullet O(1): \quad A_{lj} = i(J_j - J_l)\Phi_{lj}, \tag{A.2}$$

which implies

$$A_{ii} = 0, \tag{A.3}$$

$$\bullet O(k/\bar{k}): \quad (J_j - J_l)\varphi_{lj} = 0. \tag{A.4}$$

It follows that

$$\varphi_{ij} = 0, \qquad i \neq j, \tag{A.5}$$

$$\bullet O(1/\bar{k}): \quad (\partial_x + iJ_l\partial_y)\,\varphi_{lj} = \sum_r A_{lr}\varphi_{rj} = A_{lj}\varphi_{jj}.$$

With $l \neq j$ we have that the left-hand side is zero: $(\partial_x + iJ_l\partial_y)\,\varphi_{lj} = 0$ (using (A.5)); since for off-diagonal elements $A_{lj} \neq 0, l \neq j$, we conclude that

$$\varphi_{jj} = 0 \qquad \text{and} \qquad \varphi_{lj} = 0 \text{ for all } l, j. \tag{A.6}$$

Assume a wave function with canonical normalization and pure simple poles at $k_1, \bar{k}_1$ in both variables $k, \bar{k}$ exists, i.e., that

$$\vec{\mu}_1(k) = \vec{I}_1 + \frac{\vec{\Phi}_1}{(k-k_1)} + \frac{\vec{\varphi}_1}{(\bar{k}-\bar{k}_1)} \tag{A.7}$$

and (recalling that we consider DSII)

$$\vec{\mu}_2(k) = \vec{I}_2 + \frac{\tau\vec{\Phi}_1}{(k-\bar{k}_1)} + \frac{\tau\vec{\varphi}_1}{(\bar{k}-k_1)}. \tag{A.8}$$

It follows that this eigenfunction has, as $|k| \to \infty$, the expansion (A.1) with

$$\varphi = \begin{pmatrix} \vec{\varphi}_1 & \tau\vec{\varphi}_1 \end{pmatrix} = \begin{pmatrix} \varphi_{11} & \sigma\bar{\varphi}_{21} \\ \varphi_{21} & \bar{\varphi}_{11} \end{pmatrix}.$$

It follows that $\vec{\varphi}_1 = \vec{0}$.

Therefore, no "pure" poles eigenfunctions of the type (A.7) exist; we expect that neither will do more complicated pole states.

This argument must still apply when a continuous spectrum is added; indeed, in the scattering theory the discrete spectrum separates from the continuous spectrum—so it seems unnecessary to consider the latter. This is substantiated using a formal expansion of the continuous spectrum in formula (74), which does not contain terms in $1/\bar{k}$.

EXISTENCE OF WEAK SOLUTIONS TO SOME VORTEX DENSITY MODELS*

QIANG DU† AND PING ZHANG‡

Abstract. We study the weak solutions to equations arising in the modeling of vortex motions in superfluids such as superconductors. The global existence of measure-valued solutions is established with a bounded Radon measure as initial data. Moreover, we get a local space-time L^q estimate for the continuous part of the solution, and we prove the global existence of a distributional weak solution for a particular case. We also consider a modification to the model in order to physically account for the different signs of vortices, and we present, in one space dimension, the global existence of weak solutions with the initial data in BV for the modified model.

Key words. quantized vortices, vortex density, hydrodynamics, vortex sheets, weak convergence, measure-valued solutions

1. Introduction.

In this paper, we study the concentration phenomenon of the approximate solution sequences to the equations

$$\begin{cases} \partial_t \rho + \operatorname{div}(u\rho) = 0, \quad (t,x) \in (0,\infty) \times \mathbb{R}^2, \\ u = M\nabla \triangle^{-1} \rho, \\ \rho|_{t=0} = \rho_0, \end{cases} \tag{1.1}$$

with ρ_0 being a bounded Radon measure and M being a constant orthogonal matrix of the form

$$M(\theta) = \begin{pmatrix} \cos\theta & -\sin\theta \\ \sin\theta & \cos\theta \end{pmatrix}.$$

Our investigation yields the global existence of a measure-valued solution to (1.1) and the classical weak solution to (1.1) if ρ_0 is a bounded positive (resp., negative) Radon measure when $\cos\theta > 0$ (resp., $\cos\theta < 0$). For the case $\cos\theta = 1$, our results here extend those available in the literature (see, for instance, [21]). In the more general case, our study is related to the mathematical study of incompressible fluids as well as the vortex state in superfluids.

Indeed, when $\cos\theta = 0$, (1.1) is the classical two-dimensional incompressible Euler equations, which can be rewritten in the velocity formulation

$$\begin{cases} \partial_t u + \operatorname{div}(u \otimes u) = -\nabla P, \quad (t,x) \in (0,\infty) \times \mathbb{R}^2, \\ \operatorname{div} u = 0, \\ u|_{t=0} = u_0. \end{cases} \tag{1.2}$$

The initial value problem to (1.2) with $u_0 = (u_0^1, u_0^2) \in L^2_{loc}(\mathbb{R}^2)$ and $\omega_0 = \partial_2 u_0^1 - \partial_1 u_0^2 \in \mathcal{M}(\mathbb{R}^2)$ is an outstanding open problem, known as the vortex sheets problem, in incompressible fluid mechanics (see [25]). In 1991, Delort [7] proved the global existence of weak solutions to this problem when ω_0 is a bounded Radon measure without negative singular part. Later, Majda [26] obtained the same result by the vanishing viscosity limit to the two-dimensional incompressible Navier–Stokes equations. When ω_0 is a general Radon measure, only a measure-valued solution seems possible for this problem; see [8, 9, 27, 28] for more details.

In recent years, studies of the stability, dynamics, and interactions of the vortices in both classical fluids and superfluids have received a lot of attention. For example, in the mezoscale Ginzburg–Landau models of superconductors [14], the individual vortices are resolved and their interactions and dynamics are studied in great detail. On a macroscopic level, when the number of vortices becomes exceedingly large, it is advantageous to model the vortex state using a vortex density function [4, 16]. When $\cos\theta = 1$, (1.1) has been obtained as the hydrodynamic limit of Ginzburg–Landau vortices governing by gradient dynamics. A formal derivation was given in [16], and a rigorous justification was given in [21]. Studies in this direction also include [2, 4, 15] on model derivation, [19, 29, 30] on mathematical analysis, and [5, 12, 13, 18] on numerical simulations (see [3] for additional references). The general case of $\theta \neq 0$ corresponds to a complex time relaxation in the gradient dynamics. In [21], the global existence of weak solutions to (1.1) with $\cos(\theta) = 1$ and ρ_0 being a positive bounded Radon measure was established. In the case of ρ_0 taking on different signs, the notion of weak solutions to (1.1) with $\cos(\theta) \neq 0$ requires further study, as additional difficulties do arise.

A similar but somewhat modified version of (1.1) was studied in [2, 4] when the vortices are of different signs. Taking the London approximation to the induced magnetic field into account, a system of equations similar to (1.1) with $\cos(\theta) = 1$ was derived in [4]:

$$\begin{cases} \partial_t \rho + \operatorname{div}(u|\rho|) = 0, \quad (t,x) \in (0,\infty) \times \mathbb{R}^2, \\ u = \nabla(\lambda^2 \triangle - I)^{-1} \rho, \\ \rho|_{t=0} = \rho_0. \end{cases} \tag{1.3}$$

Here, λ denotes the penetration depth. The density function ρ is allowed to change sign in order to represent vortices of different signs. The general case of $\theta \neq 0$ can also be easily derived when the time relaxation parameter becomes complex valued [17]. In [11], such an approach was taken to account for the Hall effect. A vector-valued version of (1.3) was also available [4] to account for the three-dimensional effect. The existence and uniqueness of a viscosity solution to an equation similar to (1.3) was proved in [19] by the viscosity solution method in [6] for an $\mathbb{R}^2$-valued function ρ, since a scalar stream function ψ can be found in that case such that $\rho = \nabla^\perp \psi$. Such a technique obviously is not applicable here. To our knowledge, the general existence to (1.3) is still open except for the stationary solutions studied in [4].

To draw an analogy with (1.1), we consider a modification of the above equation:

$$\begin{cases} \partial_t \rho + \operatorname{div}(u|\rho|) = 0, \quad (t,x) \in (0,\infty) \times \mathbb{R}^2, \\ u = \nabla \triangle^{-1} \rho, \\ \rho|_{t=0} = \rho_0. \end{cases} \tag{1.4}$$

Notice that when $\rho_0 \geq 0$, (1.4) is the same as (1.1).

This paper consists of two main parts. In the first part, we study the global existence of weak solutions to (1.1) with general Radon measure as initial data under the condition that $\cos\theta \neq 0$ and obtain more general results than those given in [21]. Without loss of generality, we restrict ourselves to the case $\cos\theta > 0$; the results for $\cos\theta < 0$ can be similarly obtained. In the second part of the paper, we present an existence result to (1.4) in one space dimension.

To introduce our main results, let us examine the general procedure on proving the global existence of weak solutions. As in [9], the first step is to construct the approximate solution sequences. For simplicity, let us define the following cut-off function:

$$T_\epsilon(\xi) := \begin{cases} \xi, & \xi \geq -1/\epsilon, \\ -1/\epsilon, & \xi \leq -1/\epsilon. \end{cases} \tag{1.5}$$

We study the approximate solution sequence to (1.1) constructed by the equations

$$\begin{cases} \partial_t \rho_\epsilon + u_\epsilon \nabla \rho_\epsilon = -\cos\theta T_\epsilon(\rho_\epsilon)\rho_\epsilon, \quad (t,x) \in \mathbb{R}^+ \times \mathbb{R}^2, \\ u_\epsilon = M(\theta)\nabla \triangle^{-1}\rho_\epsilon, \\ \rho_\epsilon|_{t=0} = \rho_{0,\epsilon}, \end{cases} \tag{1.6}$$

where $\rho_{0,\epsilon} = (\rho_0 \chi_\epsilon) * j_\epsilon$, $\chi_\epsilon(x) = \chi(\frac{x}{\epsilon})$, $\chi \in C_c^\infty(\mathbb{R}^2)$, $\chi(x) = \begin{cases} 1, & |x| \leq 1, \\ 0, & |x| \geq 2, \end{cases}$ and $j_\epsilon(x)$ is the standard Friedrich's mollifier with $\mathrm{supp} j_\epsilon \subset B_\epsilon(0)$.

Let $S_\epsilon(\xi) = |\xi| * j_\epsilon$. The approximate solution sequence to (1.4) may be defined by the following equation:

$$\begin{cases} \partial_t \rho_\epsilon + \mathrm{div}(u_\epsilon S_\epsilon(\rho_\epsilon)) = \epsilon \triangle \rho_\epsilon, \quad (t,x) \in \mathbb{R}^+ \times \mathbb{R}^2, \\ u_\epsilon = \nabla \triangle^{-1}\rho_\epsilon, \\ \rho_\epsilon|_{t=0} = (\rho_0 \chi_\epsilon) * j_\epsilon. \end{cases} \tag{1.7}$$

Now, a main result of this paper can be stated in the following theorem.

THEOREM 1.1. *Let $\rho_0 \in \mathcal{M}(\mathbb{R}^2)$ and $\cos\theta > 0$. Then there exist a subsequence of $\{\rho_\epsilon, u_\epsilon\}$ constructed by (1.6) (still denoted by $\{\rho_\epsilon, u_\epsilon\}$ for convenience), functions $\rho \in L^q_{loc}(\mathbb{R}^+ \times \mathbb{R}^2) \cap L^\infty(\mathbb{R}^+, L^1(\mathbb{R}^2))$ and $u \in L^q_{loc}(\mathbb{R}^+, W^{1,q}_{loc}(\mathbb{R}^2))$ for any $q < 2$, and a positive Radon measure $\mu \in \mathcal{M}^+(\mathbb{R}^+ \times \mathbb{R}^2)$ such that the following hold:*

1. *The following convergence properties and estimates hold:*

$$\rho_\epsilon \rightharpoonup \rho \quad \text{weakly in} \quad L^q_{loc}(\mathbb{R}^+ \times \mathbb{R}^2), \tag{1.8}$$

$$u_\epsilon \rightharpoonup u \quad \text{weakly in} \quad L^q_{loc}(\mathbb{R}^+, W^{1,q}_{loc}(\mathbb{R}^2)), \tag{1.9}$$

$$\left(\rho_\epsilon + \frac{1}{\epsilon}\right)\rho_\epsilon 1_{\rho_\epsilon \leq -\frac{1}{\epsilon}} \rightharpoonup \mu \quad \text{in the sense of} \quad \mathcal{M}(\mathbb{R}^+ \times \mathbb{R}^2), \tag{1.10}$$

$$\int_0^\infty \int_{\mathbb{R}^2} d\mu \leq \int_{\mathbb{R}^2} |\, d\rho_0(x)|. \tag{1.11}$$

2. *The following decay estimates hold:*

$$\rho(t,x) \leq \frac{\cos\theta}{t} \quad \text{for a.e.} \quad (t,x) \in \mathbb{R}^+ \times \mathbb{R}^2. \tag{1.12}$$

3. *For all test functions $\varphi \in C_c^\infty([0,\infty) \times \mathbb{R}^2)$, there holds*

$$\int_0^\infty \int_{\mathbb{R}^2} (\rho \partial_t \varphi + \rho u \nabla \varphi + \mu \varphi)\, dx\, dt + \int_{\mathbb{R}^2} \varphi(0,x)\rho_0\, dx = 0 \tag{1.13}$$

and

$$u = M(\theta)\nabla\triangle^{-1}\rho. \tag{1.14}$$

DEFINITION 1.1. *We call* (ρ, u, μ) *the measure-valued solution to* (1.1) *if* (ρ, u, μ) *satisfies* (1.13) *and* (1.14).

A similar definition was used by Alexandre and Villani in the study of the Boltzmann equation without Grad's angular assumption to the cross section [1]. There, $f(t, x, v)$ was defined as a renormalized solution to the Boltzmann equation with a defect measure $\mu(t, x, v)$ if, for all nonlinearity $\beta \in C^2(\mathbb{R}^+, \mathbb{R}^+)$ satisfying $\beta(0) = 0$, $0 < \beta'(f) \le \frac{C}{1+f}$, $\beta''(f) < 0$, there holds

$$\partial_t \beta(f) + v \cdot \nabla\beta(f) = \beta'(f)Q(f, f) + \mu$$

in the sense of distributions. One may check [1] for more details.

When $\rho_0 \in \mathcal{M}^+(\mathbb{R}^2)$, we have the following improvement of Theorem 1.1.

COROLLARY 1.1. *Let* $0 < \cos\theta < 1$ *and* $\rho_0 \in \mathcal{M}^+(\mathbb{R}^2)$. *Then* $\mu = 0$ *in* (1.13), *and* $\rho \in L^2((0, \infty) \times \mathbb{R}^2)$. *Moreover,*

$$\|\rho\|_{L^2((0,\infty)\times\mathbb{R}^2)} \le C\rho_0(\mathbb{R}^2). \tag{1.15}$$

If $0 \le \rho_0 \in L^p(\mathbb{R}^2)$ *for* $1 < p < \infty$, *we have the following better estimate for* ρ*:*

$$\int_{\mathbb{R}^2} \rho^p(T, x)\,dx + (p-1)\cos\theta \int_0^T \int_{\mathbb{R}^2} \rho^{p+1}(t, x)\,dx\,dt \le \int_{\mathbb{R}^2} \rho_0^p(x)\,dx \quad \text{for a.e. } T \in \mathbb{R}^+. \tag{1.16}$$

Remark 1.1. In comparison with the measure-valued solutions to (1.2) in [8] and that of the one-dimensional two-component Vlasov–Poisson equations in [27, 28], the measure-valued solution to (1.1) here is much more explicit and closer to the distributional weak solution of (1.1). By (1.10), if ρ_0 is a sign-changing Radon measure, μ may not be 0 even if $\{\rho_\epsilon\}$ strongly converges to ρ in $L^q_{\text{loc}}(\mathbb{R}^+ \times \mathbb{R}^2)$ for any $q < 2$. Moreover, from the corollary, we can see that if $\cos\theta > 0$ and ρ_0 is a positive Radon measure, then the approximate solutions satisfy $\rho_\epsilon(t, x) \ge 0$ for all $(t, x) \in \mathbb{R}^+ \times \mathbb{R}^2$, which in turn implies, by the definition of μ, that $\mu = 0$. Thus, (ρ, u) is the classical distributional weak solution to (1.1).

Remark 1.2. If $\cos\theta > 0$ and $0 \le \rho_0(x) \in L^\infty_{\text{comp}}(\mathbb{R}^2)$, following exactly the same procedure as that in [21] and [33], we can prove the uniqueness of the weak solution in the above corollary.

Remark 1.3. We can replace the second equation in (1.1) by $u = -M(\theta)\nabla(-\lambda^2\triangle + 1)^{-1}\rho$ in correspondence to the equations derived in [4]. Step-by-step modifications of the proofs given here will yield similar results for such equations as those in Theorem 1.1.

In one space dimension, (1.4) takes on the following form:

$$\begin{cases} \partial_t \rho + \partial_x(u|\rho|) = 0, \quad (t, x) \in (0, \infty) \times \mathbb{R}, \\ u = \int_{-\infty}^x \rho(t, y)\,dy, \\ \rho|_{t=0} = \rho_0. \end{cases} \tag{1.17}$$

Then we have the following existence result to (1.17).

THEOREM 1.2. *Let* $\rho_0 \in BV(\mathbb{R})$. *Then the weak limit* (ρ, u) *obtained by the vanishing viscosity of* (1.7) *satisfies* (1.17) *in the sense of distributions, and*

$\rho \in C([0,T], L^p(K)) \cap L^\infty([0,T], BV(\mathbb{R}))$, $u \in L^\infty([0,T], W^{1,p}(\mathbb{R}))$ *for any* $T < \infty$, $2 < p < \infty$, *and any compact subset* K *of* $\mathbb{R}$. *Furthermore,*

$$\int_{\mathbb{R}} |\rho(t,x)|\,dx \le \int_{\mathbb{R}} |\rho_0|\,dx, \quad \int_{\mathbb{R}} |\,d\rho(t,x)| \le \int_{\mathbb{R}} |\,d\rho_0|, \tag{1.18}$$

where $\int_{\mathbb{R}} |\,d\rho|$ *denotes the total variation of* ρ, *if* $\operatorname{supp}\rho_0 \subset B_r(0)$, $\operatorname{supp}\rho(t,\cdot) \subset \{x : |x| \le r + Mt\}$ *with* M *the* L^∞ *bound of* u.

Remark 1.4. (1) An explicit solution to (1.17) may be constructed: let ρ_0 be defined by $\rho_0(x) = 1$ in $(0,1)$, $\rho_0(x) = -1$ in $(1,2)$, and $\rho_0(x) = 0$ elsewhere; then a global weak solution to (1.17) may be defined by

$$\rho(t,x) = \begin{cases} \frac{1}{1+t}, & x \in (0,1), \\ \frac{-1}{1+t}, & x \in (1,2), \\ 0 & \text{otherwise.} \end{cases}$$

Here, $x = 1$ is the shock line of this solution. Naturally, this leads to a conjecture that shocks will be formed for $d = 2$ when ρ_0 changes sign. In general we cannot prove $|\rho_\epsilon| \rightharpoonup m = |\rho|$. Nevertheless, we can prove that

$$\partial_t \rho + \operatorname{div}(um) = 0, \quad u = \nabla \triangle^{-1} \rho$$

holds in the sense of distributions and $m = |\rho|$ for almost all (t,x) in a subset of $\mathbb{R}^+ \times \mathbb{R}^2$; see Proposition 3.1 for more details.

(2) With $d = 2$, to get the uniform $L^\infty([0,T], L^1(\mathbb{R}^2))$ estimate for $\{\partial_x \rho_\epsilon\}$, the solution sequence to (1.7), we need the uniform L^∞ estimate for ∇u_ϵ (see the proof of Lemma 3.2 for details). But with ρ_ϵ being uniformly bounded, we cannot get the desired estimate for $\nabla \otimes u_\epsilon = \nabla \otimes \nabla \triangle^{-1} \rho_\epsilon$ by the singular integral operator theory [31]. However, in the case of $d = 1$, by the second equation of (1.17), we find $\partial_x u_\epsilon = \rho_\epsilon$, which gives the desired estimate for $\partial_x u_\epsilon$.

Remark 1.5. Again, one may replace the second equation of (1.17) by $u = -\partial_x(-\lambda^2 \partial_{xx} + 1)^{-1} \rho$ and, using the same type of arguments as those in Theorem 1.2, prove similar results.

We now introduce some notation that will be used throughout the paper. We let $B_r(0) = \{x : |x| \le r\}$ and denote by $\mathcal{M}(\Omega)$ the bounded Radon measure space on Ω, by $\mathcal{M}^+(\Omega)$ the bounded positive Radon measure space on Ω, and $BV(\mathbb{R}) = \{f : f \in L^1(\mathbb{R}), \partial_x f \in \mathcal{M}(\mathbb{R})\}$. We use $C(a,b,\ldots)$ as a uniform constant which only depends on the listed variables and may change from line to line.

The proofs of the above theorems are given in later sections.

2. Proof of Theorem 1.1. Now let us first prove the global existence of solutions to (1.6). For convenience, we omit the subscript ϵ in the approximate solution sequence $\{(\rho_\epsilon, u_\epsilon)\}$ in the following lemma.

LEMMA 2.1 (solution of (1.6) with smooth data). *For* $\rho_0 \in C_c^\infty(\mathbb{R}^2)$, (1.6) *has a global strong solution* (ρ, u) *such that* $\rho \in L^\infty([0,T], W^{1,p}(\mathbb{R}^2))$, $\nabla u \in L^\infty([0,T], W^{1,p}(\mathbb{R}^2))$ *for any* $p > 1$, $T < \infty$, *and*

$$\|\rho(t,\cdot)\|_{L^1} \le \|\rho_0\|_{L^1} \quad \textit{and} \quad \rho(t,x) \le \frac{\cos\theta}{t}, \qquad t > 0. \tag{2.1}$$

Proof. 1. (Blow-up principle.) Following the standard argument for a nonlinear hyperbolic equation, we can prove the local existence of solution (ρ, u) to (1.6) with

smooth data such that $\rho, \nabla u \in L^\infty([0,T], W^{1,p}(\mathbb{R}^2))$ for some positive constant T and any $p < \infty$. Now, let T^* be the lifespan of the solution (ρ, u) to (1.6). We are going to show that if $T^* < \infty$,

$$\lim_{t \to T^*} \|\rho(t,\cdot)\|_{L^\infty} = \infty. \tag{2.2}$$

In fact, for any even positive number p, it follows from (1.6) that

$$\begin{aligned} \partial_t(\partial_{x_i}\rho)^p + u\nabla(\partial_{x_i}\rho)^p + p\partial_{x_i}u\nabla\rho(\partial_{x_i}\rho)^{p-1} \\ = -p\cos\theta\partial_{x_i}(T_\epsilon(\rho)\rho)(\partial_{x_i}\rho)^{p-1}. \end{aligned} \tag{2.3}$$

Noticing that $\mathrm{div} u = \cos\theta\rho$, $|\partial_{x_i}(T_\epsilon(\rho)\rho)| \le 2|\rho||\partial_{x_i}\rho|$, integrating the above equation over $\mathbb{R}^2$, and using integration by parts, we get

$$\frac{d}{dt}\int_{\mathbb{R}^2} |\partial_{x_i}\rho|^p\,dx \le ((2p+1)\cos\theta\|\rho\|_{L^\infty} + p\|\partial_{x_i}u\|_{L^\infty})\int_{\mathbb{R}^2}|\nabla\rho|^p\,dx. \tag{2.4}$$

Let us take $\chi(\xi) \in C_c^\infty(\mathbb{R}^2), \chi(D)$ the corresponding pseudodifferential operator with symbol $\chi(\xi)$; then by singular integrals theory [31, 32], we have

$$\|\chi(D)\nabla\otimes\nabla\triangle^{-1}\rho\|_{L^\infty} \le C\|\nabla\otimes\nabla\triangle^{-1}\rho\|_{L^p} \le C\|\rho\|_{L^p}. \tag{2.5}$$

While by Lemma B.1.C of [32], for all $p > 2$, we find

$$\|(1-\chi(D))\nabla\otimes\nabla\triangle^{-1}\rho\|_{L^\infty} \le C\|\rho\|_{L^\infty}\left(1 + \log\frac{\|\rho\|_{W^{1,p}}}{\|\rho\|_{L^\infty}}\right). \tag{2.6}$$

Summing up the second equation of (1.6) and inequalities (2.5) and (2.6), we find

$$\|\nabla u\|_{L^\infty} \le C\left\{\|\rho\|_{L^\infty}\left(1 + \log\frac{\|\rho\|_{W^{1,p}}}{\|\rho\|_{L^\infty}}\right) + \|\rho\|_{L^p}\right\}. \tag{2.7}$$

A simple interpolation result gives us

$$\|\rho\|_{L^p} \le \|\rho\|_{L^\infty}^{\frac{p-1}{p}}\|\rho\|_{L^1}^{\frac{1}{p}}. \tag{2.8}$$

Summing up (2.4) and (2.7)–(2.8) we obtain

$$\frac{1}{2}\frac{d}{dt}\|\nabla\rho(t,\cdot)\|_{L^p}^p \le C\left\{\|\rho\|_{L^\infty}\left(1 + \log\frac{\|\nabla\rho\|_{L^p}}{\|\rho\|_{L^\infty}}\right) + \|\rho\|_{L^1}\right\}\|\nabla\rho\|_{L^p}^p. \tag{2.9}$$

Then the Gronwall inequality yields that

$$\|\nabla\rho(t,\cdot)\|_{L^p} \le C(T, \|\rho\|_{L^1}, \|\rho\|_{L^\infty})\|\nabla\rho_0\|_{L^p}. \tag{2.10}$$

On the other hand, by multiplying $\mathrm{sign}\rho$ on both sides of (1.6), we find by (1.5) that

$$\partial_t|\rho| + \mathrm{div}(u|\rho|) = \cos\theta(\rho - T_\epsilon(\rho))|\rho| \le 0. \tag{2.11}$$

Integrating (2.11) over $\mathbb{R}^2$, we get the first inequality of (2.1). Summing up (2.1) and (2.10), we complete the proof of the claim (2.2).

2. (Estimate of $\|\rho\|_{L^\infty}$.) By (2.7) and the classical theory on ordinary differential equations, the equation

$$\begin{cases} \frac{d\Phi_t(x)}{dt} = u(t, \Phi_t(x)), \\ \Phi_t(x)|_{t=0} = x \end{cases} \tag{2.12}$$

has a unique solution $\Phi_t(x) \in C([0,T^*)\times\mathbb{R}^2)$, and $\partial_x\Phi_t(x) \in L^\infty([0,T]\times\mathbb{R}^2)$ for any $T<T^*$. Then, by the first equation of (1.6), we have

$$\frac{d\rho(t,\Phi_t(x))}{dt} \le 0,$$

which implies that

$$\rho(t,\cdot) \le \|\rho_0\|_{L^\infty}. \tag{2.13}$$

This together with (1.5) shows that

$$\|T_\epsilon(\rho)\|_{L^\infty} \le \max\left\{\frac{1}{\epsilon}, \|\rho_0\|_{L^\infty}\right\}. \tag{2.14}$$

Thus by the first equation of (1.6) and by (2.12), we have

$$\frac{d|\rho|(t,\Phi_t(x))}{dt} \le \cos\theta \max\left\{\frac{1}{\epsilon}, \|\rho_0\|_{L^\infty}\right\} |\rho|(t,\Phi_t(x)),$$

which together with the Gronwall inequality yields that

$$\|\rho\|_{L^\infty} \le \exp\left(\cos\theta \max\left\{\frac{1}{\epsilon}, \|\rho_0\|_{L^\infty}\right\} t\right) \|\rho_0\|_{L^\infty}. \tag{2.15}$$

Summing up (2.2) and (2.15), we get the global existence of strong solutions to (1.6) with smooth initial data.

3. (Decay estimate.) By the first equation of (1.6) and by (2.12), we have

$$\frac{d\rho(t,\Phi_t(x))}{dt} = -\cos\theta (T_\epsilon(\rho)\rho)(t,\Phi_t(x)), \tag{2.16}$$

which implies that if $\rho_0(x) \le 0$, then $\rho(t,\Phi_t(x)) \le 0$, and if $\rho_0(x) \ge 0$, then $\rho(t,\Phi_t(x)) \ge 0$. So to prove the one-sided decay estimate (2.1), we need to consider only the points where $\rho_0(x) > 0$. By (1.5), $T_\epsilon(\rho(t,\Phi_t(x)) = \rho(t,\Phi_t(x))$. Solving (2.16), we get

$$\rho(t,\Phi_t(x)) = \frac{\cos\theta\rho_0(x)}{1+t\rho_0(x)} < \frac{\cos\theta}{t}, \quad t>0. \tag{2.17}$$

Summing up the above, we get the second inequality of (2.1). This completes the proof of the lemma. □

Next let us get the key uniform space-time estimate for the approximate solution sequence $\{\rho_\epsilon\}$ constructed in Lemma 2.1.

LEMMA 2.2 ($L^{1+\alpha}$ estimate). *Let $\rho_{0,\epsilon} \in L^1(\mathbb{R}^2), \alpha \in (0,1), T, R > 0$. Then for the solutions $(\rho_\epsilon, u_\epsilon)_{\epsilon>0}$ of (1.6), there holds the estimate*

$$\int_0^T \int_{|x|\le R} |\rho_\epsilon|^{1+\alpha}\, dx\, dt \le C_{\alpha,T,R}, \tag{2.18}$$

where the constant $C_{\alpha,T,R}$ depends only on the L^1 norm of $\rho_{0,\epsilon}$ and the listed variables.

Proof. 1. (Elementary estimate.) We first assume $\alpha = d_2/d_1 \in (0,1/2)$, where d_1 and d_2 are odd positive integers. Let $\chi \in C_c^\infty(\mathbb{R}^2), \chi \ge 0$ and $\chi = 1$ on $\{x||x| \le R\}$,

with $\operatorname{supp}\chi \subset \{x||x| \le R+1\}$. Set $\eta(\xi) = \alpha\int_0^\xi \max(1,|s|)^{\alpha-1}\,ds$ for $\xi \in \mathbb{R}^1$ such that $\eta'(\xi) = \alpha\max(1,|\xi|)^{\alpha-1}$. Multiplying (1.6) by $\chi\eta'(\rho_\epsilon)$, integrating the resulting identity over $[0,T]\times\mathbb{R}^2$, and performing integration by parts several times, we obtain

$$\begin{aligned}(2.19)\quad \cos\theta\int_0^T\int_{\mathbb{R}^2}\chi(\rho_\epsilon\eta(\rho_\epsilon)-\rho_\epsilon T_\epsilon(\rho_\epsilon)\eta'(\rho_\epsilon))\,dx\,dt\\ =\int_{\mathbb{R}^2}\chi\eta(\rho_\epsilon)\,dx|_0^T-\int_0^T\int_{\mathbb{R}^2}\nabla\chi u_\epsilon\eta(\rho_\epsilon)\,dx\,ds.\end{aligned}$$

First, by the second equation of (1.6), for all test functions $\phi(x),\psi(x)\in C_c^\infty(\mathbb{R}^2)$, we have

$$\begin{aligned}\phi(x)\psi(x)u_\epsilon(t,x) &= M(\theta)\phi(x)\int_{\mathbb{R}^2}(\psi(x)-\psi(y))\frac{x-y}{|x-y|^2}\rho_\epsilon(t,y)\,dy\\ &\quad + M(\theta)\int_{\mathbb{R}^2}\phi(x)\psi(y)\frac{x-y}{|x-y|^2}\rho_\epsilon(t,y)\,dy.\end{aligned}\tag{2.20}$$

Notice that $\phi(x)\psi(y)\frac{x-y}{|x-y|^2} = \phi(x)\psi(y)\zeta(|x-y|)\frac{x-y}{|x-y|^2}$, where $\zeta(z)\in C_c^\infty(\mathbb{R})$ with $\zeta(z)=1$ for $z\in\operatorname{supp}\phi+\operatorname{supp}\psi$. And trivially $\zeta(z)\frac{z}{|z|^2}\in L^p(\mathbb{R}^2)$ for all $p<2$, by the Hausdorff–Young inequality to the second term of (2.20), we get

$$\|\phi\psi u_\epsilon(t,\cdot)\|_{L^p} \le (\sup|\nabla\psi|\|\phi\|_{L^p}+c_{\phi,\psi})\|\rho_\epsilon(t,\cdot)\|_{L^1}\quad\text{for all } 1\le p<2.$$

In particular, by taking $\phi(x)=\psi(x)=1$ for $|x|\le R+1$, we get

$$\left(\int_{|x|\le R+1}|u_\epsilon(t,x)|^p\,dx\right)^{\frac{1}{p}} \le C_R\|\rho_{0,\epsilon}\|_{L^1}\quad\text{for all } 1<p<2.\tag{2.21}$$

Note that $\alpha<\frac12$, and thus by (2.1) and (2.21), we have

$$\begin{aligned}\left|\int_0^T\int_{\mathbb{R}^2}\nabla\chi u_\epsilon\eta(\rho_\epsilon)\,dx\,ds\right| &\le \int_0^T\left(\int_{|x|\le R+1}|u_\epsilon|^{\frac{1}{1-\alpha}}\,dx\right)^{1-\alpha}\left(\int_{|x|\le R+1}|\rho_\epsilon|\,dx\right)^{\alpha}dt\\ &\le C_1(R,\|\rho_{0,\epsilon}\|_{L^1})\,.\end{aligned}\tag{2.22}$$

By (2.1) and the definition of η, we have

$$\begin{aligned}&\left|\int_{\mathbb{R}^2}\chi\eta(\rho_\epsilon)(T,x)\,dx\right|\\ &\le\int_{|\rho_\epsilon|\ge1}\chi(\alpha+|\rho_\epsilon|^\alpha)(T,x)\,dx+\alpha\int_{|\rho_\epsilon|\le1}\chi(x)|\rho_\epsilon|\,dx\\ &\le 2\pi\alpha(R+1)^2+\left(\int_{|x|\le R+1}|\rho_\epsilon|(T,x)\,dx\right)^{\alpha}(2\pi(R+1)^2)^{1-\alpha}+\alpha2\pi(R+1)^2\\ &\le C_2(\alpha,R,\|\rho_{0,\epsilon}\|_{L^1}).\end{aligned}\tag{2.23}$$

Finally it follows from the definition of α and η that

$$\begin{aligned}&\int_0^T\int_{\mathbb{R}^2}\chi(x)(\rho_\epsilon\eta(\rho_\epsilon)-\rho_\epsilon T_\epsilon(\rho_\epsilon)\eta'(\rho_\epsilon))\,dx\,dt\\ &=\int_0^T\int_{\mathbb{R}^2}1_{|\rho_\epsilon|\ge1}\chi\left((1-\alpha)\rho_\epsilon^{1+\alpha}+\alpha(\rho_\epsilon^{1+\alpha}-T_\epsilon(\rho_\epsilon)\rho_\epsilon^\alpha)+\alpha\rho_\epsilon\right)dx\\ &\ge\int_0^T\int_{\mathbb{R}^2}1_{|\rho_\epsilon|\ge1}\chi((1-\alpha)\rho_\epsilon^{1+\alpha}+\alpha\rho_\epsilon)\,dx,\end{aligned}\tag{2.24}$$

where $1_{|\rho_\epsilon|\geq 1}$ is the characteristic function on the set $\{(t,x) : |\rho_\epsilon(t,x)| \geq 1\}$.

Summing up (2.19)–(2.24), we find

$$\int_0^T \int_{|\rho_\epsilon|\geq 1} \chi \rho_\epsilon^{1+\alpha}\, dx\, dt \leq \frac{1}{1-\alpha}\left(\alpha \int_{\mathbb{R}^2} \chi|\rho_\epsilon|\, dx + C_1 + C_2\right) \tag{2.25}$$

for all $\alpha = d_2/d_1 \in (0, 1/2)$.

2. (Inductive step 1.) Next, we are going to show by the bootstrap method that (2.25) holds for all $\alpha \in (0,1)$. First, let us take $\alpha = d_2/d_1 \in (0, 5/6)$ with d_1, d_2 positive odd integers. In particular, due to the arbitrariness of R, by interpolation, and by (2.25), we have

$$\int_0^T \int_{|x|\leq R+1} |\rho_\epsilon|^{p_1}\, dx\, dt \leq C(R, T, \|\rho_{0,\epsilon}) \quad \text{for all } p_1 < \frac{3}{2}. \tag{2.26}$$

On the other hand, again by (2.20) and the Hausdorff–Young inequality, we have

$$\begin{aligned} &\int_0^T \left(\int_{\mathbb{R}^2} |\phi\psi u_\epsilon(t,\cdot)|^{q_1}\, dx\right)^{p_1/q_1} dt \\ &\leq (\sup|\nabla\psi| \|\rho_\epsilon(t,\cdot)\|_{L^1} \|\phi\|_{L^{q_1}})^{p_1}\, T + C_{\phi,\psi} \int_0^T \|\psi\rho_\epsilon(t,\cdot)\|_{L^{p_1}}^{p_1}\, dt, \end{aligned} \tag{2.27}$$

with $\frac{1}{q_1} = \frac{1}{p_1} + \frac{1}{p} - 1$ for any $p < 2$. This implies that

$$\int_0^T \left(\int_{|x|\leq R+1} |u_\epsilon(t,x)|^{q_1}\, dx\right)^{\frac{p_1}{q_1}} dt \leq C(R, T, \|\rho_{0,\epsilon}\|_{L^1}), \tag{2.28}$$

with the same p_1 and q_1. Thus by the Hölder inequality, we have

$$\begin{aligned} \left|\int_0^T \int_{\mathbb{R}^2} \nabla\chi u_\epsilon \eta(\rho_\epsilon)\, dx\, ds\right| &\leq \int_0^T \left(\int_{|x|\leq R+1} |u_\epsilon|^{\frac{1}{1-\alpha}}\, dx\right)^{1-\alpha} \left(\int_{|x|\leq R+1} |\rho_\epsilon|\, dx\right)^{\alpha} dt \\ &\leq \|\rho_{0,\epsilon}\|_{L^1}^{\alpha} \int_0^T \left(\int_{|x|\leq R+1} |u_\epsilon|^{\frac{1}{1-\alpha}}\, dx\right)^{1-\alpha} dt \\ &\leq C_3(\chi, T, \|\rho_{0,\epsilon}\|_{L^1}), \end{aligned} \tag{2.29}$$

with $1 - \alpha \geq \frac{1}{p_1} + \frac{1}{p} - 1$. As $p_1 < \frac{3}{2}, p < 2$, we can always take $\alpha = \frac{d_2}{d_1} \in (0, \frac{5}{6})$ such that $1 - \alpha \geq \frac{1}{p_1} + \frac{1}{p} - 1$.

Summing up (2.19), (2.23), (2.24), and (2.29), we then find

$$\int_0^T \int_{|\rho_\epsilon|\geq 1} \chi \rho_\epsilon^{1+\alpha}\, dx\, dt \leq \frac{1}{1-\alpha}\left(\int_{\mathbb{R}^2} \chi|\rho_\epsilon|\, dx + C_2 + C_3\right). \tag{2.30}$$

This together with interpolation theory implies

$$\int_0^T \int_{|x\leq R+1} |\rho_\epsilon|^{p_2}\, dx\, dt \leq C(\alpha, R, T, \|\rho_{0,\epsilon}\|_{L^1}) \quad \text{for all } p_2 < \frac{11}{6}. \tag{2.31}$$

3. (Induction.) Inductively, let us assume $\alpha \in (0, \alpha_n)$, with $\frac{1}{2} < \alpha_n < 1$, and set $\bar{p}_n = 1 + \alpha_n$; there holds the estimate (2.18). Then by (2.27) and the similar proof of (2.28), we have

$$\int_0^T \left(\int_{|x| \le R+1} |\chi u_\epsilon|^{q_{n+1}} \, dx \right)^{\frac{p_n}{q_{n+1}}} dt \le C(\chi, T, \|\rho_{0,\epsilon}\|_{L^1}), \tag{2.32}$$

with $\frac{1}{q_{n+1}} = \frac{1}{p_n} - \frac{1}{2}$ and $p_n < \bar{p}_n$. Thus by the similar proof of (2.28), we have

$$\begin{aligned} \left| \int_0^T \int_{\mathbb{R}^2} \nabla \chi u_\epsilon \eta(\rho_\epsilon) \, dx \, dt \right| &\le \|\rho_{0,\epsilon}\|_{L^1}^{\alpha} \int_0^T \left(\int_{|x| \le R+1} |u_\epsilon|^{\frac{1}{1-\alpha}} \, dx \right)^{1-\alpha} dt \\ &\le C(\chi, T, \|\rho_{0,\epsilon}\|_{L^1}), \end{aligned} \tag{2.33}$$

with $1 - \alpha \ge \frac{1}{p_n} - \frac{1}{2}$. As $p_n < 1 + \alpha_n$, we can always take $\alpha = \frac{d_2}{d_1} \in (0, \alpha_{n+1})$ with d_1, d_2 being positive odd integers, and $\alpha_{n+1} = \frac{1+3\alpha_n}{2(1+\alpha_n)}$ such that $1 - \alpha \ge \frac{1}{p_n} - \frac{1}{2}$. Then, summing up (2.19), (2.23), (2.24), and (2.33), we find there holds (2.29) with $\alpha \in (0, \alpha_{n+1})$, which implies that

$$\int_0^T \int_{|x| \le R+1} |\rho_\epsilon|^{p_{n+1}} \, dx \, dt \le C(\alpha, R, T, \|\rho_{0,\epsilon}\|_{L^1}) \quad \text{for all } p_{n+1} < 1 + \alpha_{n+1}. \tag{2.34}$$

Notice by the definition of α_n we have $\alpha_{n+1} > \alpha_n$ if $1/2 < \alpha_n < 1$. Thus, the limit $\lim_{n\to\infty} \alpha_n$ exists. Moreover, by the inductive formula $\alpha_{n+1} = \frac{1+3\alpha_n}{2(1+\alpha_n)}$, we have

$$\lim_{n \to \infty} \alpha_n = 1. \tag{2.35}$$

Summing up (2.34) and (2.35), we complete the proof of Lemma 2.2. □

When $\rho_{0,\epsilon} \ge 0$ and $0 < \cos\theta < 1$, we can have the following improved estimates for the approximate solution sequence $\{\rho_\epsilon\}$.

LEMMA 2.3 (L^{p+1} estimate). *Let $\rho_{0,\epsilon} \ge 0$ and $0 < \cos\theta < 1$. The solution sequence $\{\rho_\epsilon\}$ then satisfies*

$$\int_0^T \int_{\mathbb{R}^2} \rho_\epsilon^2 \, dx \, dt \le C \|\rho_{0,\epsilon}\|_{L^1}, \tag{2.36}$$

$$\int_{\mathbb{R}^2} \rho_\epsilon^p(T, x) \, dx + (p-1)\cos\theta \int_0^T \int_{\mathbb{R}^2} \rho_\epsilon^{p+1} \, dx \, dt = \int_{\mathbb{R}^2} \rho_{0,\epsilon}^p \, dx \tag{2.37}$$

for $1 < p < \infty$.

Proof. First, by the first equation of (1.6), we know that if $\rho_{0,\epsilon} \ge 0$, then $\rho_\epsilon(t, x) \ge 0$ for $(t, x) \in \mathbb{R}^+ \times \mathbb{R}^2$. Then, by the definition of $T_\epsilon(\xi)$ in (1.5), we have $T_\epsilon(\rho_\epsilon) = \rho_\epsilon$ and

$$\partial_t \rho_\epsilon + u_\epsilon \nabla \rho_\epsilon = -\cos\theta \rho_\epsilon^2. \tag{2.38}$$

Thus by (2.12) and (2.17), we have

$$\begin{aligned} \det\left(\frac{\partial \Phi_t^\epsilon(x)}{\partial x} \right) &= \exp\left(\int_0^t \mathrm{div} u_\epsilon(s, \Phi_s^\epsilon(x)) \, ds \right) \\ &= \exp\left(\cos\theta \int_0^t \rho_\epsilon(s, \Phi_s^\epsilon(x)) \, ds \right) \\ &= \exp\left(\cos\theta \int_0^t \frac{\rho_{0,\epsilon}(x)}{1 + s\rho_{0,\epsilon}(x)} \, ds \right) \\ &= (1 + t\rho_{0,\epsilon})^{\cos\theta}. \end{aligned} \tag{2.39}$$

Moreover, by (2.12) and (2.17), we can write the solution to (1.6) in the following form:

$$\rho_\epsilon(t,y)=\frac{\cos\theta\rho_{0,\epsilon}((\Phi_s^\epsilon)^{-1}(y))}{1+t\rho_{0,\epsilon}((\Phi_s^\epsilon)^{-1}(y))}. \tag{2.40}$$

Thus, summing up (2.39) and (2.40), we have for any $T<\infty$ and $0<\cos\theta<1$ that

$$\begin{aligned}\int_0^T\int_{\mathbb{R}^2}\rho_\epsilon^2\,dy\,dt&=\int_0^T\int_{\mathbb{R}^2}\left(\frac{\cos\theta\rho_{0,\epsilon}((\Phi_s^\epsilon)^{-1}(y))}{1+t\rho_{0,\epsilon}((\Phi_s^\epsilon)^{-1}(y))}\right)^2dy\,dt\\&=\int_0^T\int_{\mathbb{R}^2}\frac{\cos^2\theta\rho_{0,\epsilon}^2}{(1+t\rho_{0,\epsilon}(x))^{2-\cos\theta}}\,dx\,dt\\&=\frac{\cos^2\theta}{\cos\theta-1}\int_{\mathbb{R}^2}\rho_{0,\epsilon}(1+t\rho_{0,\epsilon})^{\cos\theta-1}|_0^T\,dx\\&\le\frac{1}{1-\cos\theta}\int_{\mathbb{R}^2}\rho_{0,\epsilon}\,dx\le C\|\rho_{0,\epsilon}\|_{L^1},\end{aligned} \tag{2.41}$$

which proves (2.36).

On the other hand, multiplying $p\rho_\epsilon^{p-1}$ with (2.38), we find

$$\partial_t\rho_\epsilon^p+\operatorname{div}(u_\epsilon\rho_\epsilon^p)=\cos\theta(1-p)\rho_\epsilon^{p+1}. \tag{2.42}$$

Integrating (2.42) over $[0,T]\times\mathbb{R}^2$, we get (2.37). This proves the lemma. □

Now, we are in a position to complete the proof of Theorem 1.1.

Proof of Theorem 1.1. First by (2.18), there is a subsequence of $\{\rho_\epsilon\}$, which is still denoted by $\{\rho_\epsilon\}$ for convenience, and some $\rho\in L^q_{\rm loc}(\mathbb{R}^+\times\mathbb{R}^2)$ such that

$$\{\rho_\epsilon\}\rightharpoonup\rho\quad\text{weakly in}\quad L^q([0,T],L^q_{\rm loc}(\mathbb{R}^2))\quad\text{for all } q<2 \tag{2.43}$$

as $\epsilon\to0$. Thus by (2.43) and the first equation of (2.1), for all $\varphi\in C_c^\infty(\mathbb{R}^+\times\mathbb{R}^2)$, there holds

$$\begin{aligned}\left|\int_{\mathbb{R}^+}\int_{\mathbb{R}^2}\varphi\rho\,dx\,dt\right|&=\left|\lim_{\epsilon\to0}\int_{\mathbb{R}^+}\int_{\mathbb{R}^2}\varphi\rho_\epsilon\,dx\,dt\right|\\&\le\sup_{t\in\mathbb{R}^+}\|\rho_\epsilon(t,\cdot)\|_{L^1}\int_0^\infty\|\varphi(t,\cdot)\|_{L^\infty}\,dt\\&\le C\int_0^\infty\|\varphi(t,\cdot)\|_{L^\infty}\,dt,\end{aligned} \tag{2.44}$$

which implies that $\rho\in L^\infty(\mathbb{R}^+,L^1(\mathbb{R}^2))$.

Notice that the first equation of (1.6) can be rewritten as

$$\begin{aligned}\partial_t\rho_\epsilon+\operatorname{div}(u_\epsilon\rho_\epsilon)&=\cos\theta(\rho_\epsilon^2-T_\epsilon(\rho_\epsilon)\rho_\epsilon)\\&=\cos\theta\left(\rho_\epsilon+\frac{1}{\epsilon}\right)1_{\rho_\epsilon\le-\frac{1}{\epsilon}}\rho_\epsilon.\end{aligned} \tag{2.45}$$

By integrating the above equation over $[0,T]\times\mathbb{R}^2$ and using (2.1), we find

$$\begin{aligned}\cos\theta\int_0^T\int_{\mathbb{R}^2}\left(\rho_\epsilon+\frac{1}{\epsilon}\right)\rho_\epsilon1_{\rho_\epsilon\le-\frac{1}{\epsilon}}\,dx\,dt&=\int_{\mathbb{R}^2}\rho_\epsilon(T,x)\,dx-\int_{\mathbb{R}^2}\rho_{0,\epsilon}\,dx\\&\le2\int_{\mathbb{R}^2}|\rho_{0,\epsilon}|\,dx.\end{aligned} \tag{2.46}$$

Thus by [20], up to a subsequence, which we still denote by $\{(\rho_\epsilon + \frac{1}{\epsilon})\rho_\epsilon 1_{\rho_\epsilon \le -\frac{1}{\epsilon}}\}$ for convenience, there exists a positive Radon measure μ on $R \times \mathbb{R}^2$ such that

$$\left(\rho_\epsilon + \frac{1}{\epsilon}\right)\rho_\epsilon 1_{\rho_\epsilon \le -\frac{1}{\epsilon}} \rightharpoonup \mu \quad \text{in the sense of measure as} \quad \epsilon \to 0. \tag{2.47}$$

On the other hand, by (2.1), (2.18), and interpolation theory,

$$\{\rho_\epsilon\} \quad \text{is uniformly bounded in} \quad L^{p_1}([0,T], L^{p_2}_{\text{loc}}(\mathbb{R}^2)), \tag{2.48}$$

with $\frac{1}{p_1} = \frac{\beta}{\infty} + \frac{1-\beta}{q}$, $\frac{1}{p_2} = \frac{\beta}{1} + \frac{1-\beta}{q}$ for any $0 < \beta < 1, 1 < q < 2$. Since $u_\epsilon = M(\theta)\nabla\triangle^{-1}\rho_\epsilon$, by Bessel potential theory [31], we have

$$\{u_\epsilon\} \quad \text{is uniformly bounded in} \quad L^{p_1}([0,T], L^{p_3}_{\text{loc}}(\mathbb{R}^2)), \tag{2.49}$$

with $\frac{1}{p_3} = \frac{1}{p_2} - \frac{1}{2}$. If we take $\beta = 2 - q$ for $\frac{3}{2} < q < 2$, then $\frac{1}{p_1} + \frac{1}{q} = 1$ and $\frac{1}{q} + \frac{1}{p_3} = \frac{1}{2} + \beta < 1$. With these particular choices, and with (2.45), (2.46), we find

$$\{\partial_t \rho_\epsilon\} \quad \text{is uniformly bounded in} \quad L^1\left([0,T], W^{-1,\frac{2}{5-2q}}_{\text{loc}}(\mathbb{R}^2) + L^1(\mathbb{R}^2)\right). \tag{2.50}$$

Moreover by the definition of u_ϵ, (2.48), and Riesz transform theory [31], we have

$$\{\nabla_x u_\epsilon\} \quad \text{is uniformly bounded in} \quad L^{p_1}([0,T], L^{p_2}_{\text{loc}}(\mathbb{R}^2)), \tag{2.51}$$

so that

$$\|u_\epsilon(t,\cdot) - u_\epsilon(t, x+\xi)\|_{L^{p_1}([0,T], L^p(B_R))} \to 0 \quad \text{as} \quad |\xi| \to 0 \tag{2.52}$$

for all $p < p_3$ but close to p_3, so that $\frac{1}{q} + \frac{1}{p} \le 1$.

Thus if we denote u to be the weak limits of $\{u_\epsilon\}$ in $L^{p_1}([0,T], L^{p_3}_{\text{loc}}(\mathbb{R}^2))$, summing up (2.50), (2.52) and using Lemma 5.1 of [23], we find

$$\rho_\epsilon u_\epsilon \rightharpoonup \rho u \quad \text{in the sense of distributions as} \quad \epsilon \to 0. \tag{2.53}$$

While by (2.45) and integration by parts, for any test function $\varphi \in C^\infty_c([0,T] \times \mathbb{R}^2)$, we obviously have

$$\begin{aligned} \int_0^T \int_{\mathbb{R}^2} (\partial_t \varphi \rho_\epsilon + \rho_\epsilon u_\epsilon \nabla \varphi)\, dx\, dt + \cos\theta \int_0^T \int_{\mathbb{R}^2} \varphi \left(\rho_\epsilon + \frac{1}{\epsilon}\right)\rho_\epsilon 1_{\rho_\epsilon \le -\frac{1}{\epsilon}}\, dx\, dt \\ + \int_{\mathbb{R}^2} \varphi \rho_{0,\epsilon}\, dx = 0. \end{aligned} \tag{2.54}$$

Summing up (2.43), (2.47), and (2.53), and taking ϵ to 0 in (2.54), we get (1.13). Moreover, by the second equation of (1.6), it is trivial to get (1.14). By summing up (2.1) and (2.43), we get (1.12). This completes the proof of Theorem 1.1. □

Now let us turn to the proof of Corollary 1.1.

Proof of Corollary 1.1. First by the proof of Lemma 2.1, if ρ_0 is a positive Radon measure, then $\rho_\epsilon(t,x) \ge 0$ for all $(t,x) \in \mathbb{R}^+ \times \mathbb{R}^2$, and thus by (2.47), $\mu(t,x) = 0$. Moreover, by (2.36) and [20], we have

$$\|\rho(t,x)\|_{L^2([0,T]\times\mathbb{R}^2)} \le \underline{\lim}_{\epsilon\to 0}\|\rho_\epsilon(t,x)\|_{L^2([0,T]\times\mathbb{R}^2)} \le C\rho_0(\mathbb{R}^2) \tag{2.55}$$

for all $0 < \cos\theta < 1$. Then (2.55) and Fatou's lemma imply (1.15). For $p > 1$, again by [20] and (2.37), we have

$$\begin{aligned}\int_{\mathbb{R}^2} \rho^p(T,x)\,dx + (p-1)\cos\theta \int_0^T \int_{\mathbb{R}^2} \rho^{p+1}\,dx\,dt \\ \le \underline{\lim}_{\epsilon\to 0}\left(\int_{\mathbb{R}^2} \rho_\epsilon^p(T,x)\,dx + (p-1)\cos\theta \int_0^T \int_{\mathbb{R}^2} \rho_\epsilon^{p+1}\,dx\,dt\right) \\ \le \underline{\lim}_{\epsilon\to 0}\int_{\mathbb{R}^2} \rho_{0,\epsilon}^p(x)\,dx = \int_{\mathbb{R}^2} \rho_0^p\,dx. \qquad (2.56)\end{aligned}$$

Then, by summing (2.55) and (2.56), we complete the proof of Corollary 1.1. ∎

3. Proof of Theorem 1.2 and the remarks. Again the first step in the proof of Theorem 1.2 is to construct the approximate solution sequence $\{(\rho_\epsilon, u_\epsilon)\}$. By Theorem A.1, we immediately have the following lemma.

LEMMA 3.1 (solution of (1.7) with smooth data). *Let $d = 1, 2$, $\rho_0 \in L^\infty(\mathbb{R}^d)$. Then (1.7) has a global smooth solution $(\rho_\epsilon, u_\epsilon)$ such that $\rho_\epsilon, \nabla u_\epsilon \in L^\infty([0,T], H^s(\mathbb{R}^d)) \cap L^2([0,T], H^{s+1}(\mathbb{R}^d))$ for any $s > \frac{d}{2} + 1, T < \infty$, and*

$$\|\rho_\epsilon(t,\cdot)\|_{L^1} \le \|\rho_0\|_{L^1}, \quad \|\rho_\epsilon(t,\cdot)\|_{L^\infty} \le \|\rho_0\|_{L^\infty} + \epsilon, \qquad (3.1)$$

$$\int_{\mathbb{R}^d} \rho_\epsilon^2(t,x)\,dx + 2\epsilon \int_0^t \int_{\mathbb{R}^d} |\nabla \rho_\epsilon|^2\,dx\,ds \le \int_{\mathbb{R}^d} \rho_0^2\,dx + \epsilon^2 t \int_{\mathbb{R}^d} |\rho_0|\,dx. \qquad (3.2)$$

Furthermore, if $\operatorname{supp}\rho_0 \subset B_r(0)$, we denote $M = (\|\rho_0\|_{L^\infty} + 1)^{\frac{1}{d}} \|\rho_0\|_{L^1}^{1-\frac{1}{d}}$; then for $r > \epsilon$ and $(t,x) \in \Omega^o =: \{(t,x) : |x| \ge r + Mt, t \ge 0\}$, there holds

$$|\rho_\epsilon(t,x)| \le \|\rho_0\|_{L^\infty} \exp[\epsilon^{-1}(r + Mt - |x|) + t\|\rho\|_{L^\infty}] \equiv Q_\epsilon(t,x). \qquad (3.3)$$

Proof. First by the third equation of (1.7), the global existence and uniqueness of solution to (1.7) is a direct consequence of Theorem A.1. Moreover, (A.2) and (A.3) imply (3.1) and (3.2), respectively. Consequently, (A.15) implies that

$$\|u_\epsilon\|_{L^\infty} \le M.$$

Next, we rewrite the first equation of (1.7) as

$$\partial_t \rho_\epsilon + u_\epsilon S_\epsilon'(\rho_\epsilon)\nabla\rho_\epsilon + S_\epsilon(\rho_\epsilon)\rho_\epsilon = \epsilon\triangle\rho_\epsilon. \qquad (3.4)$$

Let us denote $\mathcal{L} = \partial_t + u_\epsilon S_\epsilon'(\rho_\epsilon)\nabla + S_\epsilon(\rho_\epsilon) - \epsilon\triangle$. Notice by the definition of $S_\epsilon(\xi)$ that $|S_\epsilon'(\rho_\epsilon)| \le 1$ and $\|S_\epsilon(\rho_\epsilon)\|_{L^\infty} \le \|\rho_\epsilon\|_{L^\infty}$. We find

$$\mathcal{L}Q_\epsilon \ge 0 \quad \text{on} \quad \Omega^o, \qquad (3.5)$$

$$Q_\epsilon|_{|x|=r+Mt} \ge \|\rho_0\|_{L^\infty}, \quad Q_\epsilon|_{t=0,|x|\ge r} \ge 0. \qquad (3.6)$$

Hence by the maximum principle, we have

$$\rho_\epsilon(t,x) \le Q_\epsilon(t,x) \quad \text{for all } (t,x) \in \Omega^o. \qquad (3.7)$$

Similarly, we can prove

$$-\rho_\epsilon(t,x) \le Q_\epsilon(t,x) \quad \text{for all } (t,x) \in \Omega^o. \qquad (3.8)$$

Combining (3.7) with (3.8), we get (3.3). This completes the proof of the lemma. ∎

With this lemma, by (1.7), (3.1), (3.2), and [31], we have that

$$\partial_t u_\epsilon = \partial_t \nabla \triangle^{-1} \rho_\epsilon = -\nabla \triangle^{-1} \mathrm{div}(u_\epsilon S_\epsilon(\rho_\epsilon)) + \epsilon \nabla \rho_\epsilon \tag{3.9}$$

is uniformly bounded in $L^\infty([0,T], L^2(\mathbb{R}^d))$.

While again by (1.7), (3.1), and [31], we have

$$u_\epsilon \quad \text{is uniformly bounded in} \quad L^\infty([0,T], W^{1,p}(\mathbb{R}^d)) \tag{3.10}$$

for any $2 < p < \infty$. Thus by combining (3.9), (3.10), the Lions–Aubin lemma, and the similar proof of Lemma 3 in [34], we obtain that there exists a subsequence of $\{u_\epsilon\}$, which we still denote by $\{u_\epsilon\}$, and some $u \in L^\infty([0,T], W^{1,p}(\mathbb{R}^d))$ such that

$$u_\epsilon \to u \quad \text{uniformly on any compact subset of} \quad [0,T] \times \mathbb{R}^d. \tag{3.11}$$

Trivially by (3.1), there exist $\rho, m \in L^\infty([0,T] \times \mathbb{R}^d)$ such that

$$\rho_\epsilon \rightharpoonup \rho \quad \text{weakly} \quad * \quad \text{in} \quad L^\infty([0,T] \times \mathbb{R}^d), \tag{3.12}$$

$$|\rho_\epsilon| \rightharpoonup m \quad \text{weakly} \quad * \quad \text{in} \quad L^\infty([0,T] \times \mathbb{R}^d). \tag{3.13}$$

While by the definition of $S_\epsilon(\xi)$, for any compact subset K of $[0,T] \times \mathbb{R}^2$, we have

$$\|S_\epsilon(\rho_\epsilon) - |\rho_\epsilon|\|_{L^1(K)} \to 0 \quad \text{as} \quad \epsilon \to 0. \tag{3.14}$$

Thus by combining the first equation of (1.7) with (3.11)–(3.14), we have that

$$\partial_t \rho + \mathrm{div}(um) = 0 \tag{3.15}$$

holds in the sense of distributions.

Summing up the second equation of (1.7) and (3.11) and (3.12), we get

$$u = \nabla \triangle^{-1} \rho\,. \tag{3.16}$$

Thus, in order to prove that (ρ, u) is indeed a global weak solution to (1.4), we only need to prove that $m = |\rho|$. However, only in one space dimension, and $\rho_0 \in BV(\mathbb{R})$, we can prove that $d(t,x) = |\rho|(t,x)$ for almost all $(t,x) \in \mathbb{R}^+ \times \mathbb{R}$. In order to do so, let us first present the following lemma.

LEMMA 3.2. *Let $\rho_0 \in BV(\mathbb{R})$. Then*

$$\int_{\mathbb{R}} |\partial_x \rho_\epsilon(T,x)|\,dx \le e^{3\epsilon T} \int_{\mathbb{R}} |\,d\rho_0|, \tag{3.17}$$

where $\int_{\mathbb{R}} |\,d\rho_0|$ is the total variation of ρ_0.

Proof. Let g be the solution of the adjoint equation

$$\partial_t g + u_\epsilon S_\epsilon'(\rho_\epsilon)\partial_x g - (S_\epsilon(\rho_\epsilon) + \rho_\epsilon S_\epsilon'(\rho_\epsilon))g + \epsilon \partial_{xx} g = 0, \tag{3.18}$$

with the Cauchy data $g(T,\cdot) = \gamma \in C_0^\infty(\{x : |x| < R\})$, and $\|\gamma\|_{L^\infty} \le 1$. Let $\tau = T - t$, $h = e^{-3\epsilon\tau} g$; then by (3.18), we have

$$\partial_\tau h - u_\epsilon S_\epsilon'(\rho_\epsilon)\partial_x h + (S_\epsilon(\rho_\epsilon) + \rho_\epsilon S_\epsilon'(\rho_\epsilon) + 3\epsilon)h - \epsilon \partial_{xx} h = 0. \tag{3.19}$$

We assume that h reaches its minimum value at (τ_0, x_0). Then we claim that

$$\text{either} \quad h(\tau_0, x_0) \geq 0 \qquad \text{or} \quad \tau_0 = 0. \tag{3.20}$$

Otherwise, if $h(\tau_0, x_0) < 0$ and $\tau_0 > 0$, we have by the definition of (τ_0, x_0) that

$$\partial_t h(\tau_0, x_0) = 0, \quad \partial_x h(\tau_0, x_0) = 0, \quad \partial_{xx} h(\tau_0, x_0) \geq 0, \tag{3.21}$$

which implies that

$$\{\partial_\tau h - u_\epsilon S'_\epsilon(\rho_\epsilon)\partial_x h + (S_\epsilon(\rho_\epsilon) + \rho_\epsilon S'_\epsilon(\rho_\epsilon) + 3\epsilon)h - \epsilon\partial_{xx} h\}\,(t_0, x_0) < 0$$

as $S_\epsilon(\rho_\epsilon) \geq 0, \rho_\epsilon S'_\epsilon(\rho_\epsilon) + 3\epsilon > 0$. This contradicts (3.19), which proves the claim (3.20). Hence

$$h(\tau, x) \geq \min\,(0, \min(h(0, x))) = -1,$$

which implies that

$$g(t, x) \geq -e^{3\epsilon(T-t)} \quad \text{for all } (t, x) \in [0, T] \times \mathbb{R}. \tag{3.22}$$

Exactly as in the proof of (3.22), we can also prove that

$$g(t, x) \leq e^{3\epsilon(T-t)} \quad \text{for all } (t, x) \in [0, T] \times \mathbb{R}. \tag{3.23}$$

Combining (3.22) with (3.23), we get

$$\|g(t, \cdot)\|_{L^\infty} \leq e^{3\epsilon(T-t)}, \quad 0 \leq t \leq T. \tag{3.24}$$

With (3.24) and the similar proof to (3.3), we get

$$|g(t, x)| \leq \exp[\epsilon^{-1}(R + M(T-t) - |x|) + 4(T-t)\|\rho_\epsilon\|_{L^\infty}] \tag{3.25}$$

for all $(t, x) \in \{(t, x) : |x| \geq R + M(T-t), 0 \leq t \leq T\}$.

On the other hand, taking ∂_x to the first equation of (1.7), we have

$$\partial_t(\partial_x \rho_\epsilon) + \partial_x(u_\epsilon S'_\epsilon(\rho_\epsilon)\partial_x \rho_\epsilon) + (S_\epsilon(\rho_\epsilon) + \rho_\epsilon S'_\epsilon(\rho_\epsilon))\partial_x \rho_\epsilon - \epsilon\partial_{xx}\partial_x \rho_\epsilon = 0. \tag{3.26}$$

Combining (3.18), (3.25), and (3.26), we get

$$\begin{aligned} &\int_{\mathbb{R}} \partial_x \rho_\epsilon(T, x)\gamma(x)\,dx - \int_{\mathbb{R}} \partial_x \rho_{0,\epsilon} g(0, x)\,dx \\ &= \int_0^T \int_{\mathbb{R}} (\partial_t(\partial_x \rho_\epsilon)g + \partial_x \rho_\epsilon \partial_t g)\,dx\,dt = 0. \end{aligned} \tag{3.27}$$

It follows from (3.24) that

$$\begin{aligned} \left|\int_{\mathbb{R}} \partial_x \rho_\epsilon(T, x)\gamma(x)\,dx\right| &\leq e^{3\epsilon T} \int_{\mathbb{R}^2} \int_{\mathbb{R}} |\partial_x \rho_{0,\epsilon}|\,dx \\ &\leq e^{3\epsilon T} \int_{\mathbb{R}} |d\rho_0|, \end{aligned} \tag{3.28}$$

which implies (3.17). This completes the proof of the lemma. □

We now complete the proof of Theorem 1.2.

Proof of Theorem 1.2. First by (3.17), we find that $\{\rho_\epsilon(t,x)\}$ is uniformly bounded in $L^\infty([0,T],BV(\mathbb{R}))$. While by (3.1), (3.2), and the first equation in (1.7), we find that $\{\partial_t\rho_\epsilon\}$ is uniformly bounded in $L^\infty([0,T],W^{-1,\infty}(\mathbb{R}))+L^2([0,T],H^{-1}(\mathbb{R}))$. Notice by the compact embedding theorem that $BV(\mathbb{R})\hookrightarrow\hookrightarrow L^p(\mathbb{R})$ for any $p<\infty$. Thus by the Lions–Aubin lemma and a proof similar to that of Lemma 3 in [34], we find that there exists a $\rho\in L^\infty([0,T],BV(\mathbb{R}))$ for any $T<\infty$ such that

$$\rho_\epsilon\to\rho \quad \text{in} \quad C([0,T],L^p(K)) \quad \text{for all} \quad T<\infty \tag{3.29}$$

and all compact subset K of $\mathbb{R}$. In particular, this implies that $m=|\rho|$. Thus by combining (3.15) and (3.16), we prove that (ρ,u) satisfies (1.17) in the sense of distributions. Moreover, if $\operatorname{supp}\rho_0\subset B_r(0)$, (3.3) implies that

$$\sup_{(t,x)\in\Omega^o}|\rho_\epsilon|\to 0 \quad \text{as} \quad \epsilon\to 0, \tag{3.30}$$

where Ω^o is the set defined by Lemma 3.1. Thus $\operatorname{supp}\rho(t,\cdot)\subset\{x:|x|\le r+Mt\}$. This completes the proof of the theorem. □

For $d=2$, in general, we cannot prove that $m=|\rho|$. Instead, the following proposition can be proved.

PROPOSITION 3.1. *Let $\rho_0\in L^\infty(\mathbb{R}^2)$ with $\operatorname{supp}\rho_0\subset B_r(0)$, and let us use the notation $\operatorname{supp}\rho_0^+=:\{x,\rho_0(x)>0\}$ and $\operatorname{supp}\rho_0^-=:\{x,\rho_0(x)<0\}$. Then $m=|\rho|$ for almost all $(t,x)\in D=D^+\cup D^-$, where*

$$D^+=\{(t,\Phi_t^+(x))\ :\ x\in\operatorname{supp}\rho_0^-\},\quad D^-=\{(t,\Phi_t^-(x))\ :\ x\in\operatorname{supp}\rho_0^+\},$$

with $\Phi_t^\pm(x)$ being defined by

$$\begin{cases}\frac{d\Phi_t^\pm(x)}{dt}=\pm u(t,\Phi_t^\pm(x)),\\ \Phi_t^\pm(x)|_{t=0}=x.\end{cases} \tag{3.31}$$

Proof. First by multiplying $\operatorname{sign}\rho_\epsilon$ on both sides of (1.7), we find

$$\partial_t|\rho_\epsilon|+\operatorname{div}(u_\epsilon\operatorname{sign}(\rho_\epsilon)(S_\epsilon(\rho_\epsilon)-S_\epsilon(0)))\le-|\rho_\epsilon|S_\epsilon(0)+\epsilon\triangle|\rho_\epsilon|. \tag{3.32}$$

Then by (3.1), it is trivial to prove that

$$\|\operatorname{sign}(\rho_\epsilon)(S_\epsilon(\rho_\epsilon)-S_\epsilon(0))-\rho_\epsilon\|_{L^1(K)}\to 0,\quad \|S_\epsilon(0)\rho_\epsilon\|_{L^1(K)}\to 0 \tag{3.33}$$

as $\epsilon\to 0$. Hence by summing up (3.11), (3.32), (3.33), and taking $\epsilon\to 0$ in (3.32), we find

$$\partial_t m+\operatorname{div}(u\rho)\le 0. \tag{3.34}$$

Now let $w=\rho+m$. By summing up (3.15) and (3.34), we find

$$\partial_t w+\operatorname{div}(uw)\le 0. \tag{3.35}$$

Denote $w^\epsilon(t,x)=\int_{\mathbb{R}^2}j_\epsilon(y)w(t,x-y)\,dy$, and by [22, Lemma 2.3], we find that w^ϵ satisfies

$$\partial_t w^\epsilon+\operatorname{div}(uw^\epsilon)\le R_\epsilon(t,x), \tag{3.36}$$

where $R_\epsilon(t,x) = \mathrm{div}(uw^\epsilon) - j_\epsilon * \mathrm{div}(uw)$, and $R_\epsilon \to 0$ in $L^1_{\mathrm{loc}}(\mathbb{R}^+ \times \mathbb{R}^2)$. Equation (3.36) directly implies that

$$\frac{dw^\epsilon(t,\Phi_t^+(x))}{dt} \le (\rho w^\epsilon)(t,\Phi_t^+(x)) + R_\epsilon(t,\Phi_t^+(x)). \tag{3.37}$$

On the other hand, by (3.3), we find that

$$\mathrm{supp}\rho \subset \{(t,x) : |x| \le r + Mt\} =: B.$$

Thus by [21, Lemma 1] or [33], we find that (3.31) has a unique global solution such that

$$C(T)^{-1}|x_1 - x_2|^{e^{4\pi t}} \le |\Phi_t^+(x_1) - \Phi_t^+(x_2)| \le C(T)|x_1 - x_2|^{e^{-4\pi t}}, \tag{3.38}$$

and because $\mathrm{div}u = \rho$, by [10, equation (74)], we have

$$\|R_\epsilon(t,\Phi_t^+(x))\|_{L^1(K)} \le e^{\|\rho\|_{L^\infty} t}\|R_\epsilon\|_{L^1(B_T)} \to 0 \tag{3.39}$$

as $\epsilon \to 0$, where $B_T = B \cap \{(t,x) : t \le T\}$. By summing up (3.37), (3.39), and letting $\epsilon \to 0$ in (3.37), we get for almost all $x \in \mathbb{R}^2$ that there holds

$$\begin{cases} \frac{dw(t,\Phi_t^+(x))}{dt} \le (\rho w)(t,\Phi_t^+(x)), \\ w(t,\Phi_t^+(x))|_{t=0} = 0, \quad x \in \mathrm{supp}\,\rho_0^-. \end{cases} \tag{3.40}$$

Then the Gronwall inequality implies that

$$w(t,\Phi_t^+(x)) = 0, \quad x \in \mathrm{supp}\,\rho_0^-, \quad t \in \mathbb{R}^+. \tag{3.41}$$

By (3.38) and (3.41), we get

$$d(t,x) = -\rho(t,x) \quad \text{for a.e.} \quad (t,x) \in D^+. \tag{3.42}$$

Similarly, by subtracting (3.15) from (3.34) and letting $q = m - \rho$, we have

$$\partial_t q - \mathrm{div}(uq) \le 0. \tag{3.43}$$

By the proof of (3.42), we have

$$m(t,x) = \rho(t,x) \quad \text{for a.e.} \quad (t,x) \in D^-. \tag{3.44}$$

Combining (3.42) and (3.44), we complete the proof of the proposition. □

Appendix. The construction of the approximate solutions. Let $S_\epsilon(\xi) = |\xi| * j_\epsilon(\xi)$, where $j_\epsilon(\xi)$ is the standard Friedrich mollifier with $\mathrm{supp}\, j_\epsilon(\cdot) \subset B_\epsilon(0)$. In the following, we are going to prove the global existence of smooth solutions to the following equations:

$$\begin{cases} \partial_t\rho + \mathrm{div}(uS_\epsilon(\rho)) = \epsilon\triangle\rho, \quad (t,x) \in (0,\infty)\times\mathbb{R}^d, \quad d = 1,2,3, \\ u = \nabla\triangle^{-1}\rho \quad \text{for} \quad d = 2,3, \qquad u = \int_{-\infty}^x \rho\, dy \quad \text{for} \quad d = 1, \\ \rho|_{t=0} = \rho_0. \end{cases} \tag{A.1}$$

THEOREM A.1. *Let $s > d/2+1, \rho_0 \in H^s_0(\mathbb{R}^d)$. Equation* (A.1) *has a unique global solution (ρ, u) such that $\rho, \nabla u \in L^\infty([0,T], H^s(\mathbb{R}^d)) \cap L^2([0,T], H^{s+1}(\mathbb{R}^d))$ for any $T < \infty$. Furthermore,*

$$\|\rho(t,\cdot)\|_{L^1} \le \|\rho_0\|_{L^1}, \quad \|\rho(t,\cdot)\|_{L^\infty} \le \|\rho_0\|_{L^\infty} + \epsilon. \tag{A.2}$$

$$\int_{\mathbb{R}^d} \rho^2(t,x)\,dx + 2\epsilon \int_0^t \int_{\mathbb{R}^d} |\nabla\rho|^2\,dx\,ds \le \int_{\mathbb{R}^d} \rho_0^2\,dx + \epsilon^2 t \int_{\mathbb{R}^d} |\rho_0|\,dx. \tag{A.3}$$

Proof. Following the standard argument for a nonlinear parabolic equation, we can prove the local existence and uniqueness of solution (ρ, u) to (A.1) such that $\rho, \nabla u \in L^\infty([0,T], H^s(\mathbb{R}^d)) \cap L^2([0,T], H^{s+1}(\mathbb{R}^d))$ for some positive constant T. Now let T^* be the lifespan of the solution (ρ, u) to (A.1). Then for $t < T^*$, notice the classical convex inequality: $\mathrm{sign}\rho\triangle\rho \le \triangle|\rho|$. By multiplying $\mathrm{sign}\rho$ on both sides of (A.1), we find

$$\partial_t|\rho| + \mathrm{div}(u\,\mathrm{sign}\rho(S_\epsilon(\rho) - S_\epsilon(0))) \le -|\rho|S_\epsilon(0) + \epsilon\triangle|\rho|. \tag{A.4}$$

Integrating the above inequality over $\mathbb{R}^d$, we get the first inequality of (A.2) for $t < T^*$.

Next, multiplying $p\rho^{p-1}$ on both sides of the first equation of (A.1) with p an even integer, we get

$$\partial_t\rho^p + \mathrm{div}(uF_\epsilon(\rho)) = G_\epsilon(\rho) + \epsilon p\rho^{p-1}\triangle\rho, \tag{A.5}$$

with $F_\epsilon(\rho) = \int_0^\rho pS'_\epsilon(\xi)\xi^{p-1}\,d\xi$ and $G_\epsilon(\rho) = \rho F_\epsilon(\rho) - p\rho^p S_\epsilon(\rho)$.

By the definition of $S_\epsilon(\rho)$, we have

$$G_\epsilon(\rho) = \begin{cases} p\rho\int_0^\epsilon S'_\epsilon(\xi)\xi^{p-1}\,d\xi - (p-1)\rho^{p+1} - \epsilon^p\rho + p\rho^p\int_{\mathbb{R}^d}\xi j_\epsilon(\xi)\,d\xi, & \rho \ge \epsilon, \\ p\rho\int_0^\rho S'_\epsilon(\xi)\xi^{p-1}\,d\xi - p\rho^p S_\epsilon(\rho), & |\rho| \le \epsilon \\ p\rho\int_0^{-\epsilon} S'_\epsilon(\xi)\xi^{p-1}\,d\xi + (p-1)\rho^{p+1} + \epsilon^p\rho - p\rho^p\int_{\mathbb{R}^d}\xi j_\epsilon(\xi)\,d\xi, & \rho \le -\epsilon, \end{cases}$$

which together with the simple inequalities that

$$p|\rho|^p \le (p-1)|\rho|^{p+1} + |\rho|, \quad p\left|\int_0^\epsilon S'_\epsilon(\xi)\xi^{p-1}\,d\xi\right| \le \epsilon^p, \quad S_\epsilon(\rho) \ge 0$$

gives us

$$G_\epsilon(\rho) \le \epsilon^p|\rho|. \tag{A.6}$$

Combining (A.2) with (A.6), and integrating (A.5) over $\mathbb{R}^d$, we find

$$\begin{aligned} &\int_{\mathbb{R}^d} \rho^p\,dx + p(p-1)\epsilon\int_0^t\int_{\mathbb{R}^d} \rho^{p-2}|\nabla\rho|^2\,dx\,ds \\ &\le \int_{\mathbb{R}^d}\rho_0^p\,dx + \epsilon^p\int_0^t\int_{\mathbb{R}^d}|\rho|\,dx\,ds \le \int_{\mathbb{R}^d}\rho_0^p\,dx + \epsilon^p t\int_{\mathbb{R}^d}|\rho_0|\,dx. \end{aligned} \tag{A.7}$$

In particular, by taking $p = 2$ in the above, we get (A.3). Moreover, for any compact subset K of $\mathbb{R}^d$, (A.7) implies that

$$\left(\int_K \rho^p(t,x)\,dx\right)^{\frac{1}{p}} \le \|\rho(t,\cdot)\|_{L^p} \le \|\rho_0\|_{L^p} + \epsilon t^{\frac{1}{p}}\|\rho_0\|_{L^1}^{\frac{1}{p}}. \tag{A.8}$$

Letting $p \to \infty$ in (A.8), we prove the second inequality of (A.2) for $t < T^*$.

Now let $E(t,x)$ be the fundamental solution of the heat operator $(\partial_t - \epsilon\triangle)$; then

$$E(t,x) = (4\pi\epsilon t)^{-\frac{d}{2}} e^{-\frac{|x|^2}{4\epsilon t}}, \quad t > 0, \tag{A.9}$$

by (A.1), and ρ can also be written by the following form:

$$\rho(t,x) = -\int_0^t \int_{\mathbb{R}^d} E(t-s, x-y)\mathrm{div}(uS_\epsilon(\rho))(s,y)\,dy\,ds + \int_{\mathbb{R}^d} E(t,x-y)\rho_0(y)\,dy$$

for $t < T^*$. By integrating by parts in the above formula, we find

$$\rho(t,x) = -\int_0^t \int_{\mathbb{R}^d} \nabla_x E(t-s,x-y)(uS_\epsilon(\rho))(s,y)\,dy\,ds + \rho_0(t,x), \tag{A.10}$$

and consequently,

$$\begin{aligned}\partial_x\rho(t,x) = -\int_0^t \int_{\mathbb{R}^d} &\nabla_x E(t-s,x-y)(\partial_x u S_\epsilon(\rho)\\ &+ uS'_\epsilon(\rho)\partial_x\rho)(s,y)\,dy\,ds + \partial_x\rho_0(t,x).\end{aligned} \tag{A.11}$$

Thus by the Hausdorff–Young inequality and the fact that $|S'_\epsilon(\xi)| \le 1$, we get

$$\begin{aligned}\|\partial_x\rho(t,\cdot)\|_{L^1} \le C(\sup_{t>0}\|\rho(t,\cdot)\|_{L^1} + \|u\|_{L^\infty}) \int_0^t (t-s)^{-\frac{1}{2}} &(\|\partial_x u(s,\cdot)\|_{L^\infty}\\ + \|\partial_x\rho(s,\cdot)\|_{L^1})\,ds + \|\partial_x\rho_0\|_{L^1},\end{aligned} \tag{A.12}$$

$$\begin{aligned}\|\partial_x\rho(t,\cdot)\|_{L^\infty} \le C(\|\rho(t,\cdot)\|_{L^\infty} + \|u\|_{L^\infty}) \int_0^t (t-s)^{-\frac{1}{2}} &(\|\partial_x u(s,\cdot)\|_{L^\infty}\\ + \|\partial_x\rho(s,\cdot)\|_{L^\infty})\,ds + \|\partial_x\rho_0\|_{L^\infty}.\end{aligned} \tag{A.13}$$

On the other hand, for $d = 2$ and 3, by the second equation of (A.1), we have

$$\begin{aligned}|u(t,x)| &= \left|\int_{\mathbb{R}^d} \frac{x-y}{|x-y|^d}\rho(t,y)\,dy\right|\\ &\le \|\rho(t,\cdot)\|_{L^\infty}\int_{|x-y|\le R}\frac{1}{|x-y|^{d-1}}\,dy + \frac{\|\rho(t,\cdot)\|_{L^1}}{R^{d-1}}\\ &\le CR\|\rho(t,\cdot)\|_{L^\infty} + \frac{\|\rho(t,\cdot)\|_{L^1}}{R^{d-1}}.\end{aligned} \tag{A.14}$$

Taking $R = (\frac{\|\rho(t,\cdot)\|_{L^1}}{\|\rho(t,\cdot)\|_{L^\infty}})^{\frac{1}{d}}$ in (A.14), we find

$$\|u(t,\cdot)\|_{L^\infty} \le C\|\rho(t,\cdot)\|_{L^1}^{\frac{1}{d}}\|\rho(t,\cdot)\|_{L^\infty}^{1-\frac{1}{d}} \le C\left(\|\rho(t,\cdot)\|_{L^1} + \|\rho(t,\cdot)\|_{L^\infty}\right), \tag{A.15}$$

while for $d = 1$, the second equation of (A.1) directly implies that

$$\|u(t,\cdot)\|_{L^\infty} \le \|\rho(t,\cdot)\|_{L^1}. \tag{A.16}$$

Similar to the proof of (A.15) and (A.16), we have

$$\|\partial_x u(t,\cdot)\|_{L^\infty} \le C\left(\|\partial_x\rho(t,\cdot)\|_{L^1} + \|\partial_x\rho(t,\cdot)\|_{L^\infty}\right). \tag{A.17}$$

Now let us set $y(t) = \|\partial_x \rho(t,\cdot)\|_{L^1} + \|\partial_x \rho(t,\cdot)\|_{L^\infty}$. By combining (A.2) with (A.12)–(A.17), we find

$$y(t) \le C \int_0^t (t-s)^{-\frac{1}{2}} y(s)\, ds + y_0, \quad t < T^*.$$

The Gronwall inequality yields that

$$y(t) \le y_0 e^{C\sqrt{t}}, \quad t < T^*. \tag{A.18}$$

On the other hand, standard energy estimates (see [24]) show that if $T^* < \infty$, then

$$\lim_{t \to T^*} (\|\partial_x u(t,\cdot)\|_{L^\infty} + \|\partial_x \rho(t,\cdot)\|_{L^\infty}) = \infty. \tag{A.19}$$

This contradicts (A.17) and (A.18). Thus $T^* = \infty$. This completes the proof of the theorem. □

OPTIMAL RATE OF CONVERGENCE FOR ANISOTROPIC VANISHING VISCOSITY LIMIT OF A SCALAR BALANCE LAW*

CHARALAMBOS MAKRIDAKIS† AND BENOÎT PERTHAME‡

Abstract. An open question in numerical analysis of multidimensional scalar conservation laws discretized on nonstructured grids is the optimal rate of convergence. The main difficulty lies on a priori BV bounds which cannot be derived by opposition to the case of structured (Cartesian) grids. In this paper we consider a related question for a corresponding continuous model, namely, the vanishing viscosity method for a multidimensional scalar conservation law with a general diffusion matrix which is only bounded. Then BV estimates are not available here; nevertheless we prove the $h^{1/2}$ convergence rate. Our strategy of proof differs from the classical method of Kuznetsov. It consists in using in an accurate way the entropy dissipation due to the parabolic terms. The dissipation of the conservation law is not strong enough, and we thus consider an auxiliary parabolic problem to compensate that. Using the kinetic formulation and the related uniqueness method also helps to avoid unessential technicalities.

Key words. rate of convergence, vanishing viscosity method, kinetic formulation, scalar conservation laws

1. Introduction.

We consider the entropy solution

$$u \in C(\mathbb{R}^+; L^1(\mathbb{R}^d)) \cap L^\infty(\mathbb{R}^+; BV(\mathbb{R}^d))$$

to a multidimensional scalar conservation law

$$\begin{aligned} &\frac{\partial}{\partial t} u(t,x) + \operatorname{div} A(u) = 0, \qquad t > 0,\ x \in \mathbb{R}^d, \\ &\frac{\partial}{\partial t} S(u(t,x)) + \operatorname{div} \eta^S(u) \le 0 \qquad \text{for all } S \text{ convex}, \\ &u(t=0,x) = u^0(x) \in BV \cap L^\infty(\mathbb{R}^d), \end{aligned} \tag{1.1}$$

with the notation $\eta^S(u) = \int_0^u S'(\cdot) a(\cdot)$ and $a = A' : \mathbb{R} \to \mathbb{R}^d$.

A classical open question in the numerical analysis of this equation discretized on nonstructured grids is the optimal rate of convergence. Indeed, in such situations BV bounds on the numerical approximation are not available, and thus Kuznetsov's classical approach [13] does not apply and only a reduced convergence rate in $h^{1/4}$ can be established (see [5], [19] and also [7] , [11], [10], [15], [9]). This multidimensional situation is in opposition with the one-dimensional case, where such BV bounds are derived [18] and optimal rate of convergence $h^{1/2}$ follows. The result of Sanders [18] can be generalized in more than one dimension only for Cartesian grids. Recently, Cockburn and Gremaud [6], as a means of proving the optimal rate, proposed a variant

of Kuznetsov's approach aiming to show the expected rates by bypassing the stability estimates of the approximate problem. This approach was, however, restricted to strong conditions on the mesh and the discrete fluxes.

It is usual to relate numerical methods to the vanishing viscosity method (below we always use the convention of summation upon the repeated index),

$$\begin{aligned} &\frac{\partial}{\partial t}v(t,x)+\mathrm{div}A(v)=\frac{\partial}{\partial x_i}\left(a_{ij}(x)\frac{\partial}{\partial x_j}v\right), \qquad t>0,\ x\in\mathbb{R}^d,\\ &v(t=0,x)=v^0(x)\in L^1\cap L^\infty(\mathbb{R}^d), \end{aligned} \tag{1.2}$$

where the anisotropic matrix a_{ij} *reflects the unstructured character of the grid*, and thus it is only natural to assume that for some constant $K>0$,

$$a_{ij} \text{ is a positive definite symmetric matrix,} \quad \| a_{ij} \|_{L^\infty(\mathbb{R}^d)} = K. \tag{1.3}$$

Then the same difficulty appears that the standard method for error estimates does not apply.

Indeed, we recall that, as stated in a compact form in [1], Kuznetsov's result requires us to control entropies in a weak form. Namely, error terms E^S in the hyperbolic entropy inequalities, for convex S,

$$\frac{\partial}{\partial t}S(v)+\mathrm{div}\eta^S(v)\le \mathrm{div}E^S(t,x), \tag{1.4}$$

imply error estimates

$$\|u(t)-v(t)\|_{L^1(\mathbb{R}^d)}\le \|u^0-v^0\|_{L^1(\mathbb{R}^d)}+C(t)\big(\|u^0\|_{TV(\mathbb{R}^d)}\big)^{1/2}|||E|||^{1/2}, \tag{1.5}$$

with

$$|||E|||=\int_0^t\int_{\mathbb{R}^d}\sup_{|S'|\le 1,S''\ge 0}|E^S(s,x)|dx\ ds.$$

For the vanishing viscosity method (1.2), we have, for S convex,

$$\frac{\partial}{\partial t}S(v)+\mathrm{div}\eta^S(v)\le \frac{\partial}{\partial x_i}\left(a_{ij}(x)\frac{\partial}{\partial x_j}S(v)\right). \tag{1.6}$$

Therefore the inequality (1.5) applies with

$$E^S(t,x)=\nabla S(v(t,x))=S'(v)\nabla v,$$

and we directly deduce the standard result

$$\begin{aligned} \|u(t)-v(t)\|_{L^1(\mathbb{R}^d)}\le{}& \|u^0-v^0\|_{L^1(\mathbb{R}^d)}\\ &+C(t)\big(\|u^0\|_{TV(\mathbb{R}^d)}\ \|v\|_{L^\infty((0,t);TV(\mathbb{R}^d))}\big)^{1/2}\big(\|a_{ij}\|_{L^\infty(\mathbb{R}^d)}\big)^{1/2}. \end{aligned}$$

With only the L^∞ assumption (1.3), we do not have a priori BV bound for the function v (except in one dimension). Therefore the general estimate (1.5) does not apply here.

The present paper develops new ideas to prove the following.

THEOREM 1.1. *For a smooth matrix a_{ij} satisfying* (1.3) *and the smooth bounded solution $v \in C(\mathbb{R}^+; L^1(\mathbb{R}^d))$ to* (1.2)*, we have*

$$\begin{aligned} \|u(t) - v(t)\|_{L^1(\mathbb{R}^d)} \le \|u^0 - v^0\|_{L^1(\mathbb{R}^d)} \\ + C(d)\|u^0\|_{TV(\mathbb{R}^d)} \left(t \,\|\, a_{ij} \,\|_{L^\infty(\mathbb{R}^d)}\right)^{1/2}. \end{aligned} \tag{1.7}$$

One of the ingredients of the proof relies on the precise entropy equality for (1.2), namely,

$$\frac{\partial}{\partial t} S(v) + \mathrm{div}\eta^S(v) = \frac{\partial}{\partial x_i}\left(a_{ij}(x)\frac{\partial}{\partial x_j}S(v)\right) - S''(v)a_{ij}(x)\frac{\partial v}{\partial x_i}\frac{\partial v}{\partial x_j}. \tag{1.8}$$

In particular we have included the precise parabolic entropy dissipation term $S''(v)a_{ij}(x)\frac{\partial v}{\partial x_i}\frac{\partial v}{\partial x_j}$, which is essential in our analysis. This term has already been used in the proof of uniqueness for various hyperbolic/parabolic problems with the anisotropic nonlinear diffusions [4], and also by Chen and DiBenedetto [3] (but it can be recovered from a weaker entropy inequality for isotropic diffusions [2], [8]). Another idea developed here is that this entropy dissipation is not enough and a direct comparison with the hyperbolic solution u is not possible. In order to obtain such entropy dissipation we can only compare v with a solution to a parabolic equation with a constant diffusion term.

The proof also covers the case

$$\frac{\partial}{\partial t} v(t,x) + \mathrm{div}A(v) = \frac{\partial}{\partial x_i}\left(a_{ij}(x,v)\frac{\partial v}{\partial x_j}\right), \qquad t > 0,\ x \in \mathbb{R}^d,$$

under appropriate smoothness assumptions on v and, provided that matrix a_{ij} still is bounded, (1.3). Note that estimates of the viscosity approximation

$$\frac{\partial}{\partial t} v(t,x) + \mathrm{div}A(v) = \frac{\partial}{\partial x_i}\left(B_{ij}(v)\frac{\partial v}{\partial x_j}\right), \qquad t > 0,\ x \in \mathbb{R}^d,$$

without using the TV stability of v, were first proved in [6] in one dimension and extended to many dimensions in [1]. These proofs do not cover our case (1.3) since when applied to (1.2) they require a_{ij} to be differentiable.

Remark 1.1. The method does not use the smoothness of the function v, neither the positivity nor smoothness of the matrix a_{ij}, and it could be extended to a purely $C(\mathbb{R}^+; L^1(\mathbb{R}^d))$ setting using kinetic solutions along the lines of [17]. We have chosen, for simplicity, to use this framework on v in order to avoid unessential technicalities.

2. Proof of Theorem 1.1.

2.1. More entropy dissipation. In fact we are going to prove a variant of Theorem 1.1, comparing v with the solution $w \in C(\mathbb{R}^+; L^1(\mathbb{R}^d)) \cap L^\infty(\mathbb{R}^+; BV(\mathbb{R}^d))$ to the parabolic equation (recall the definition of K in (1.3))

$$\begin{aligned} \frac{\partial}{\partial t} w + \mathrm{div}A(w) = K\Delta w, \\ w(t=0,x) = u^0(x). \end{aligned} \tag{2.1}$$

THEOREM 2.1. *With the assumptions of Theorem* 1.1*, we have*

$$\begin{aligned} \|w(t) - v(t)\|_{L^1(\mathbb{R}^d)} \le \|u^0 - v^0\|_{L^1(\mathbb{R}^d)} \\ + C(d)\ \|u^0\|_{TV(\mathbb{R}^d)}\ (K\,t)^{1/2}. \end{aligned} \tag{2.2}$$

Theorem 1.1 follows directly from this because we can apply (1.5) to compare u and w. Since we have, for all $t \geq 0$,

$$\|w(t)\|_{TV(\mathbb{R}^d)} \leq \|u^0\|_{TV(\mathbb{R}^d)},$$

we indeed deduce from (1.5) that

$$\|w(t) - u(t)\|_{L^1(\mathbb{R}^d)} \leq C(t)\|u^0\|_{TV(\mathbb{R}^d)}\ K^{1/2}.$$

The proof is therefore reduced to proving Theorem 2.1. This will be shown in what follows; a main point here is the fact that (2.1) contains more entropy dissipation than (1.1).

2.2. Kinetic formulations. We use the kinetic framework [14], [16], [17], which simplifies very much uniqueness arguments compared to the initial Kruzhkov approach [12]. This needs some notation. We define after [14] the "equilibrium" function of density w by $\boldsymbol{\chi}(t,x,\xi) := \boldsymbol{\chi}(\xi; w(t,x))$ by

$$\boldsymbol{\chi}(\xi;w) = \begin{cases} +1 & \text{for } \ 0 < \xi < w(t,x), \\ -1 & \text{for } \ w(t,x) < \xi < 0, \\ 0 & \text{otherwise.} \end{cases} \tag{2.3}$$

The theory of kinetic formulations states that (2.1) is equivalent to writing the kinetic equation on $\boldsymbol{\chi}$,

$$\partial_t \boldsymbol{\chi} + a(\xi)\cdot\nabla_x \boldsymbol{\chi} = K\ \Delta \boldsymbol{\chi} + \frac{\partial}{\partial_\xi} m(t,x,\xi), \tag{2.4}$$

for some nonnegative bounded measure m given by

$$m(t,x,\xi) = K\ \delta(\xi - w(t,x))\ |\nabla w|^2. \tag{2.5}$$

The derivation of this equation from (2.1) shows that the measure m expresses the entropy dissipation. Indeed, after multiplying (2.4) by $S'(\xi)$ and ξ integration, we obtain

$$\frac{\partial}{\partial t} S(w) + \mathrm{div}\eta^S(w) = K\Delta S(w) - S''(w)\ K\ |\nabla w|^2, \tag{2.6}$$

which is the entropy equality for (2.1). Indeed, the function $\boldsymbol{\chi}$ is chosen because it provides the equalities

$$S(w) = \int_{\mathbb{R}} S'(\xi)\,\boldsymbol{\chi}(t,x,\xi)\,d\xi, \quad \eta^S(w) = \int_{\mathbb{R}} S'(\xi)\,a(\xi)\,\boldsymbol{\chi}(t,x,\xi)\,d\xi.$$

Similarly, we can perform the same construction for the function v and define, still using the notation in (2.3), $\bar{\boldsymbol{\chi}}(t,x,\xi) := \boldsymbol{\chi}(\xi; v(t,x))$. It solves

$$\partial_t \bar{\boldsymbol{\chi}} + a(\xi)\cdot\nabla_x \bar{\boldsymbol{\chi}} = \frac{\partial}{\partial x_i}\left(a_{ij}(x)\frac{\partial}{\partial x_j}\bar{\boldsymbol{\chi}}\right) + \frac{\partial}{\partial_\xi}\bar{m}(t,x,\xi), \tag{2.7}$$

$$\bar{m}(t,x,\xi) = \delta(\xi - v(t,x))\ a_{ij}\frac{\partial}{\partial x_i} v \frac{\partial}{\partial x_j} v. \tag{2.8}$$

2.3. Regularization. We shall need more regularity than is available on the function $\boldsymbol{\chi}(\xi; w(t,x))$. We set $\varepsilon = (\varepsilon_1, \varepsilon_2)$, ε_1 for the forward time regularization and ε_2 for the space regularization, and we define

$$\varphi_\varepsilon(t,x) = \frac{1}{\varepsilon_1}\varphi_1\left(\frac{t}{\varepsilon_1}\right)\ \frac{1}{\varepsilon_2^d}\varphi_2\left(\frac{x}{\varepsilon_2}\right),$$

where $\varphi_j \geq 0, j = 1,2$, denote the normalized regularizing kernels with $\int \varphi_j = 1$, $\mathrm{supp}(\varphi_1) \subset (-1,0)$ in order to allow the time regularization. Next we set

$$\boldsymbol{\chi}_\varepsilon(t,x,\xi) = \boldsymbol{\chi}(\xi; w(t,x)) \star_{(t,x)} \varphi_\varepsilon. \tag{2.9}$$

The regularity of the kinetic formulation leads to an equation on $\boldsymbol{\chi}_\varepsilon$,

$$\partial_t \boldsymbol{\chi}_\varepsilon + a(\xi)\cdot\nabla_x \boldsymbol{\chi}_\varepsilon = K\Delta\boldsymbol{\chi}_\varepsilon + \frac{\partial}{\partial_\xi} m_\varepsilon(t,x,\xi), \tag{2.10}$$

$$m_\varepsilon(t,x,\xi) = m(t,x,\xi) \star_{(t,x)} \varphi_\varepsilon. \tag{2.11}$$

2.4. Decay functional. Following [16], we introduce the decay functional

$$Q_\varepsilon(t) = \int_{\mathbb{R}\times\mathbb{R}^d} [|\boldsymbol{\chi}_\varepsilon(t,x,\xi)| + |\bar{\boldsymbol{\chi}}(t,x,\xi)| - 2\boldsymbol{\chi}_\varepsilon(t,x,\xi)\ \bar{\boldsymbol{\chi}}(t,x,\xi)]\, d\xi\, dx \geq 0. \tag{2.12}$$

Since $|\boldsymbol{\chi}_\varepsilon| = sgn(\xi)\boldsymbol{\chi}_\varepsilon$, and using the L^1 assumption, which allows us to integrate by parts, we have

$$\begin{aligned}
\frac{d}{dt}Q_\varepsilon(t) &= -2\int_{\mathbb{R}\times\mathbb{R}^d} [m_\varepsilon(t,x,\xi=0) + \bar{m}(t,x,\xi=0)]\, d\xi\, dx \\
&+2\int_{\mathbb{R}^d} a_{ij}\frac{\partial}{\partial x_i}\bar{\boldsymbol{\chi}}\ \frac{\partial}{\partial x_j}\boldsymbol{\chi}_\varepsilon\ dx + 2\int_{\mathbb{R}\times\mathbb{R}^d} \bar{m}(t,x,\xi)\ \frac{\partial}{\partial_\xi}\boldsymbol{\chi}_\varepsilon\, d\xi\, dx \\
&-2\int_{\mathbb{R}\times\mathbb{R}^d} K\bar{\boldsymbol{\chi}}\ \Delta\boldsymbol{\chi}_\varepsilon\, d\xi\, dx + 2\int_{\mathbb{R}\times\mathbb{R}^d} m_\varepsilon(t,x,\xi)\ \frac{\partial}{\partial_\xi}\bar{\boldsymbol{\chi}}\, d\xi\, dx \\
&= -2\int_{\mathbb{R}^+\times\mathbb{R}^{2d}} \bar{m}(t,x,\xi=w(s,y))\ \varphi_\varepsilon(t-s,x-y)dsdydx - 2\int_{\mathbb{R}^d} m_\varepsilon(t,x,\xi=v(t,x))\ dx \\
&+2\int_{\mathbb{R}\times\mathbb{R}^d} a_{ij}\frac{\partial}{\partial x_i}\bar{\boldsymbol{\chi}}\ \frac{\partial}{\partial x_j}\boldsymbol{\chi}_\varepsilon\, d\xi\, dx - 2\int_{\mathbb{R}\times\mathbb{R}^d} K\bar{\boldsymbol{\chi}}\ \Delta\boldsymbol{\chi}_\varepsilon\, d\xi\, dx.
\end{aligned}$$

We refer to [16], [17] for justification of the significance of all these terms. Here the two negative terms containing m are favorable to proving the decay of Q_ε, and the two other terms have to be controlled, which we do now.

We begin with the worse, containing a_{ij}, which is treated in an original way here.

$$\int_{\mathbb{R}\times\mathbb{R}^d} a_{ij}\frac{\partial}{\partial x_i}\bar{\boldsymbol{\chi}}\ \frac{\partial}{\partial x_j}\boldsymbol{\chi}_\varepsilon\, d\xi\, dx$$

$$= \int_{\mathbb{R}^+\times\mathbb{R}^{2d+1}} \delta(\xi - v(t,x))\delta(\xi - w(s,y))\ a_{ij}(x)\frac{\partial}{\partial x_i}v(t,x)\ \frac{\partial}{\partial x_j}w(s,y)\ \varphi_\varepsilon(t-s,x-y)$$

$$\le \frac{1}{2}\int_{\mathbb{R}^+\times\mathbb{R}^{2d+1}} \delta(\xi - v(t,x))\delta(\xi - w(s,y))\ a_{ij}(x)\left[\frac{\partial}{\partial x_i}v(t,x)\ \frac{\partial}{\partial x_j}v(t,x)\right.$$

$$\left. + \frac{\partial}{\partial x_i}w(s,y)\ \frac{\partial}{\partial x_j}w(s,y)\right]\ \varphi_\varepsilon(t-s,x-y)\, d\xi\, dx\, dy\, ds$$

$$\le \frac{1}{2}\int_{\mathbb{R}^+\times\mathbb{R}^{2d}} \bar{m}(t,x,\xi = w(s,y))\ \varphi_\varepsilon(t-s,x-y) + \frac{1}{2}\int_{\mathbb{R}^d} m_\varepsilon(t,x,\xi = v(t,x))\ dx,$$

where we have used the definitions of m_ε and $\bar{m}$ and the bound in (1.3). Hence we conclude that

$$\frac{d}{dt}Q_\varepsilon(t) \le -2\int_{\mathbb{R}\times\mathbb{R}^d} K\bar{\boldsymbol{\chi}}\ \Delta\boldsymbol{\chi}_\varepsilon\, d\xi\, dx \le 2K\int_{\mathbb{R}\times\mathbb{R}^d} |\Delta\boldsymbol{\chi}_\varepsilon|\, d\xi\, dx. \tag{2.13}$$

To proceed further, we upper bound the right-hand side of (2.13) by

$$|\Delta\boldsymbol{\chi}_\varepsilon| = \left|\int_{\mathbb{R}^+\times\mathbb{R}^d} \Delta\boldsymbol{\chi}(s,y,\xi)\varphi_\varepsilon(t-s,x-y)ds\, dy\right|$$

$$= \left|\int_{\mathbb{R}^+\times\mathbb{R}^d} \nabla\boldsymbol{\chi}(s,y,\xi)\cdot\nabla\varphi_\varepsilon(t-s,x-y)ds\, dy\right|$$

$$= \left|\int_{\mathbb{R}^+\times\mathbb{R}^d} \delta(\xi - w(s,y))\,\nabla w(s,y)\cdot\nabla\varphi_\varepsilon(t-s,x-y)ds\, dy\right|,$$

and we conclude that

$$\int_{\mathbb{R}\times\mathbb{R}^d} |\Delta\boldsymbol{\chi}_\varepsilon|\, d\xi\, dx \le \frac{C}{\varepsilon_2}\|u^0\|_{TV(\mathbb{R}^d)},$$

$$\frac{d}{dt}Q_\varepsilon(t) \le \frac{C\,K}{\varepsilon_2}\,\|u^0\|_{TV(\mathbb{R}^d)}. \tag{2.14}$$

2.5. Conclusion of the proof. We can now conclude the proof. We deduce from (2.14) that

$$Q_\varepsilon(t) \le Q_\varepsilon(0) + \frac{C\,K\,t}{\varepsilon_2}\,\|u^0\|_{TV(\mathbb{R}^d)}.$$

On the other hand, we can upper bound the initial error by

$$Q_\varepsilon(0) = \int_{\mathbb{R}^{2d}} [|w(s,y)| + |v^0(x)| - 2\min(|w(s,y)|, |v^0(x)|)_{sgn(w(s,y)v^0(x))\ge 0}]$$

$$\varphi_\varepsilon(-s,x-y)\, dx\ dy\ ds$$

$$= \int_{\mathbb{R}^{2d}} |u^0(s,y) - v^0(x)|\ \varphi_\varepsilon(-s,x-y)\, dx\ dy\ ds.$$

At this level we may pass to limit as ε_1 vanishes, and we find (with the obvious modification on the definition of Q_{ε_2})

$$Q_{\varepsilon_2}(t) \le \|u^0 - v^0\|_{L^1(\mathbb{R}^d)} + C\varepsilon_2 \|u^0\|_{TV(\mathbb{R}^d)} + \frac{C\,K\,t}{\varepsilon_2}\,\|u^0\|_{TV(\mathbb{R}^d)}. \tag{2.15}$$

Finally, following the above lines, we lower bound $Q_{\varepsilon_2}(t)$ by

$$Q_{\varepsilon_2}(t) = \int_{\mathbb{R}^{2d}} |w(t,y) - v(t,x)| \varphi_{\varepsilon_2}(x-y)\,dx\,dy$$

$$\ge \|w(t) - v(t)\|_{L^1(\mathbb{R}^d)} - C\varepsilon_2 \|u^0\|_{TV(\mathbb{R}^d)}.$$

Together with (2.15) we find

$$\|w(t) - v(t)\|_{L^1(\mathbb{R}^d)} \le \|u^0 - v^0\|_{L^1(\mathbb{R}^d)} + C\varepsilon_2 \|u^0\|_{TV(\mathbb{R}^d)} + \frac{C\,K\,t}{\varepsilon_2}\,\|u^0\|_{TV(\mathbb{R}^d)},$$

and optimizing the parameter ε_2, we conclude the proof of Theorem 2.1.

ASYMPTOTIC DECAY TOWARD THE RAREFACTION WAVES OF SOLUTIONS FOR VISCOUS CONSERVATION LAWS IN A ONE-DIMENSIONAL HALF SPACE*

TOHRU NAKAMURA†

Abstract. This paper is concerned with convergence rates toward the rarefaction waves of the solutions for scalar viscous conservation laws in a half space. We show that the convergence rate is $(1+t)^{-1/4}\log(2+t)$ in L^2-norm if the initial perturbation from the corresponding rarefaction waves is located in $H^1 \cap L^1$. This rate is equal to the well-known rate obtained for viscous conservation laws in the whole space. The proof is given by the combination of the standard L^2-energy method and L^1-estimate.

Key words. rarefaction wave, decay estimate, conservation laws, half space

1. Introduction.

We consider the initial-boundary value problem for scalar viscous conservation laws in the one-dimensional half space $\mathbb{R}_+ := (0,\infty)$:

$$\begin{cases} u_t + f(u)_x = u_{xx}, \quad x \in \mathbb{R}_+,\ t > 0, \\ u(0,t) = u_-, \quad t > 0, \\ u(x,0) = u_0(x) = \begin{cases} u_-, & x = 0, \\ \to u_+, & x \to \infty, \end{cases} \end{cases} \tag{1.1}$$

where f is a smooth function and $u_\pm$ are constants. We assume that f is strictly convex, i.e., for a certain positive constant α,

$$f''(u) \geq \alpha > 0, \tag{1.2}$$

and that the characteristic speeds $f'(u_\pm)$ satisfy

$$0 \leq f'(u_-) < f'(u_+). \tag{1.3}$$

We have from (1.2) and (1.3) that $u_- < u_+$. Under the conditions (1.2) and (1.3), it was already shown in [9] that the solutions of (1.1) converge to the corresponding rarefaction waves as $t \to \infty$. The rarefaction wave $r(x,t)$ is given as a weak solution of the Riemann problem for the corresponding hyperbolic conservation laws on the whole space:

$$\begin{cases} r_t + f(r)_x = 0, \quad x \in \mathbb{R},\ t > -1, \\ r(x,-1) = r_0^{\mathrm{R}}(x) := \begin{cases} u_-, & x < 0, \\ u_+, & x > 0. \end{cases} \end{cases} \tag{1.4}$$

†Department of Mathematical and Computing Sciences, Tokyo Institute of Technology, Tokyo 152-8552, Japan (tooru@is.titech.ac.jp).

Note here that $r(x,t)$ is a continuous function for $t \geq 0$. $r(x,t)$ is expressed explicitly for $t > -1$ by

$$r(x,t) = \begin{cases} u_-, & x \leq f'(u_-)(t+1), \\ (f')^{-1}\big(\dfrac{x}{t+1}\big), & f'(u_-)(t+1) \leq x \leq f'(u_+)(t+1), \\ u_+, & f'(u_+)(t+1) \leq x. \end{cases}$$

In the case of a one-dimensional whole space, Il'in and Oleinik [3] studied the stability of rarefaction waves. The convergence rate toward the rarefaction waves was first investigated by Harabetian [1] and has been considered by many authors [2, 10, 11]. This problem was also considered for the multidimensional conservation laws in [4, 12].

For the half space, it is shown by Liu, Matsumura, and Nishihara [9] that the asymptotic states of the solutions of (1.1) are classified into the following three cases according to the signatures of $f'(u_\pm)$: (a) $f'(u_-) < f'(u_+) \leq 0$, (b) $f'(u_-) < 0 < f'(u_+)$, and (c) $0 \leq f'(u_-) < f'(u_+)$. In case (a), the solutions of (1.1) converge to stationary waves. In case (b), the asymptotic states are superpositions of stationary waves and rarefaction waves. And case (c) yields rarefaction waves. Recently, the large time behaviors of the solutions for multidimensional conservation laws were studied by Kawashima, Nishibata, and Nishikawa [6, 7]. Their results will be published.

The main purpose of the present paper is to obtain the convergence rate for case (c). Note that the convergence rate for case (a) was also considered in [9] and that case (b) should be considered. The main theorem of the present paper is stated as follows.

THEOREM 1.1. *Suppose that* (1.2) *and* (1.3) *hold. Let* $u_0 - u_+ \in (H^1 \cap L^1)(\mathbb{R}_+)$ *and* $u_0(0) = u_-$. *Then the initial-boundary value problem* (1.1) *has a unique global solution* $u(x,t)$. *Moreover,* $u(x,t)$ *satisfies the following estimates:*

$$|u(t) - r(t)|_2 \leq C(1+t)^{-\frac{1}{4}} \log(2+t),$$
$$|u(t) - r(t)|_\infty \leq C(1+t)^{-\frac{1}{2}} \log^3(2+t),$$

where C *is a positive constant depending only on* u_0.

Notation. L^p denotes the usual Lebesgue space with the norm $|\cdot|_p$ for $1 \leq p \leq \infty$. For $m = 0, 1, \ldots$, H^m denotes the mth order Sobolev space with the norm $\|\cdot\|_m$. $C^k(I; H^m)$ denotes the space of k-times continuously differentiable functions from the interval I into H^m. We also denote generic positive constants by c and C.

The paper is outlined as follows. In section 2, we construct the "smooth approximation $w(x,t)$" of the rarefaction wave $r(x,t)$ in the same way as in [2]. Such an approximation is necessary because $r(x,t)$ is not smooth. The difficulty of the present problem comes from the boundary effects, which result from the fact that $w(0,t) \neq u_-$. Here u_- is the boundary data in (1.1). To avoid this difficulty, we construct the "modified smooth approximation $W(x,t)$" which is given by modifying $w(x,t)$ around the boundary to satisfy $W(0,t) = u_-$. This modification enables us to obtain the L^1-estimate of the perturbation in section 4. In section 3, we get the a priori estimates of the perturbation by using the standard energy method. Finally, in section 4, we show the decay estimates of the perturbation by combining the L^1-estimate with the L^2-estimate.

2. Smooth approximation and reformulation of the problem. First, we derive the smooth approximation of the rarefaction wave $r(x,t)$ by employing the idea of Hattori and Nishihara [2]. We define $\tilde{w}(x,t)$ as a solution of the Cauchy problem

$$\begin{cases} \tilde{w}_t + \tilde{w}\tilde{w}_x = \tilde{w}_{xx}, & x \in \mathbb{R},\ t > -1, \\ \tilde{w}(x,-1) = w_0^{\mathrm{R}}(x), & x \in \mathbb{R}, \end{cases} \tag{2.1}$$

where the initial data $w_0^{\mathrm{R}}(x)$ is defined by

$$w_0^{\mathrm{R}}(x) := \begin{cases} f'(u_-), & x < 0, \\ f'(u_+), & x > 0, \end{cases}$$

for the case $f'(u_-) > 0$. When $f'(u_-) = 0$, $\tilde{w}(x,t)$ defined above does not converge to the corresponding rarefaction wave fast enough around the boundary $x = 0$. Therefore, when $f'(u_-) = 0$, we need to modify $w_0^{\mathrm{R}}(x)$ as

$$w_0^{\mathrm{R}}(x) := \begin{cases} -f'(u_+), & x < 0, \\ f'(u_+), & x > 0, \end{cases}$$

for which the solution $\tilde{w}(x,t)$ of (2.1) satisfies $\tilde{w}(0,t) = 0$. Because (2.1) is the Burgers equation, we can get the explicit formula of $\tilde{w}(x,t)$ by using the Hopf–Cole transformation. Then, using this formula, we can get the optimal estimates of $\tilde{w}(x,t)$ [2]. Successively, we define a smooth approximation $w(x,t)$ of the rarefaction wave $r(x,t)$ as

$$w(x,t) := (f')^{-1}(\tilde{w}(x,t)). \tag{2.2}$$

$w(x,t)$ is well-defined since f is strictly convex. Substituting (2.2) for (2.1), we have the equation of $w(x,t)$:

$$\begin{cases} w_t + f(w)_x = w_{xx} + \dfrac{f'''(w)}{f''(w)} w_x^2, & x \in \mathbb{R},\ t > 0, \\ w(x,0) = w_0(x) := (f')^{-1}(\tilde{w}(x,0)), & x \in \mathbb{R}. \end{cases} \tag{2.3}$$

Here we summarize the well-known results for the smooth approximation $w(x,t)$ in Lemma 2.1. This lemma is proved by the direct computations of the explicit formula of $\tilde{w}(x,t)$. For details, readers are referred to [2, 8].

LEMMA 2.1. *For $1 \le p \le \infty$ and $t \ge 0$, $w(x,t)$ satisfies the following:*

(i) $0 \le w(0,t) - u_- \le Ce^{-c(1+t)}$ *for* $f'(u_-) > 0$ *and* $w(0,t) = u_-$ *for* $f'(u_-) = 0$.

(ii) $|w_x(0,t)| \le Ce^{-c(1+t)}$, $\quad |w_{xx}(0,t)| \le Ce^{-c(1+t)}$.

(iii) $|w(t) - r(t)|_p \le C(1+t)^{-\frac{1}{2}+\frac{1}{2p}}$.

(iv) $|w_x(t)|_p \le C(1+t)^{-1+\frac{1}{p}}$, $\quad |w_{xx}(t)|_p \le C(1+t)^{-\frac{3}{2}+\frac{1}{2p}}$.

(v) $w_x(x,t) > 0$ *for* $x \in \mathbb{R}$.

If the characteristic speed satisfies $f'(u_-) > 0$, $w(x,t)$ does not satisfy the boundary condition in (1.1), i.e., $w(0,t) \neq u_-$. So we need to modify $w(x,t)$ around the boundary. Our modified smooth approximation $W(x,t)$ is defined as

$$W(x,t) := w(x,t) - \psi(x,t), \tag{2.4}$$

where

$$\psi(x,t) := (w(0,t) - u_-)e^{-x}. \tag{2.5}$$

By virtue of this modification, $W(x,t)$ satisfies the boundary condition $W(0,t)=u_-$. Note that $\psi(x,t)\equiv 0$ if $f'(u_-)=0$. Substituting (2.4) for (2.3), we get the equation of $W(x,t)$:

$$\begin{cases} W_t + f(W)_x = W_{xx} - R(x,t), & x\in\mathbb{R}_+,\ t>0,\\ W(0,t)=u_-, & t>0,\\ W(x,0)=W_0(x):=w_0(x)-\psi(x,0), & x\in\mathbb{R}_+, \end{cases} \tag{2.6}$$

where $R(x,t)$ is defined as

$$R(x,t):=-\frac{f'''(w)}{f''(w)}w_x^2+\psi_t+(f(W+\psi)-f(W))_x-\psi_{xx}. \tag{2.7}$$

By using Lemma 2.1, the direct computations give the estimates of $W(x,t)$ and $R(x,t)$, as follows.

LEMMA 2.2. *For $1\le p\le\infty$ and $t\ge 0$, $W(x,t)$ and $R(x,t)$ satisfy*

(i) $|W(t)-r(t)|_p\le C(1+t)^{-\frac{1}{2}+\frac{1}{2p}}$,

(ii) $|W_x(t)|_p\le C(1+t)^{-1+\frac{1}{p}}$, $|W_{xx}(t)|_p\le C(1+t)^{-\frac{3}{2}+\frac{1}{2p}}$,

(iii) $W_x(x,t)>0$ *for* $x\in\mathbb{R}_+$,

(iv) $|R(t)|_p\le C(1+t)^{-2+\frac{1}{p}}$.

Define the perturbation $v(x,t)$ from the modified smooth approximation $W(x,t)$ as

$$v(x,t):=u(x,t)-W(x,t).$$

Since $W(x,t)$ converges to the rarefaction wave $r(x,t)$ fast enough, it suffices to obtain the decay estimates of $v(x,t)$. From (1.1) and (2.6), we have the equation of $v(x,t)$:

$$\begin{cases} v_t + (f(W+v)-f(W))_x = v_{xx}+R(x,t), & x\in\mathbb{R}_+,\ t>0,\\ v(0,t)=0, & t>0,\\ v(x,0)=v_0(x):=u_0(x)-W_0(x), & x\in\mathbb{R}_+. \end{cases} \tag{2.8}$$

Here we state an existence result for the solution $v(x,t)$ of (2.8). To this end, we define the solution space as

$$X_M(0,T)=\Big\{v\in C^0([0,T];H^1(\mathbb{R}_+))\ \Big|\ v_x\in L^2(0,T;H^1(\mathbb{R}_+))\ \text{ and } \sup_{0\le t\le T}\|v(t)\|_1\le M\Big\}$$

for positive constants T and M. Equation (2.8) is rewritten as an integral equation

$$v(x,t)=G_t*v_0+\int_0^t G_{t-\tau}*N(v(\tau))\,d\tau,$$

where $N(v)$ and G_t* are given by

$$N(v):=-(f(W+v)-f(W))_x+R,$$

$$G_t*v:=\frac{1}{\sqrt{4\pi t}}\int_0^\infty\left(e^{-(x-y)^2/4t}-e^{-(x+y)^2/4t}\right)v(y)\,dy.$$

By making use of a standard iteration method, it is shown that (2.8) has a unique solution locally in time.

PROPOSITION 2.3 (local existence). *Suppose that $v_0\in H^1(\mathbb{R}_+)$ and $v_0(0)=0$. For any $M>0$ with $\|v_0\|_1\le M$, there exists a positive time T depending on M such that* (2.8) *has a unique solution $v\in X_{2M}(0,T)$.*

3. A priori estimate. In this section, we show the a priori estimate of $v(x,t)$. The outline of the proof is similar to [4, 12], which consider the full space problems, but we also need to pay attention to the boundary effects.

PROPOSITION 3.1 (a priori estimate). *Suppose that $v \in X_M(0,T)$ is a solution of (2.8) for some positive constants T and M. Then there exists a positive constant C independent of T such that $v(x,t)$ satisfies the estimate*

$$\|v(t)\|_1^2 + \int_0^t |\sqrt{W_x(\tau)}v(\tau)|_2^2 + \|v_x(\tau)\|_1^2\,d\tau \le C(\|v_0\|_1^2 + 1). \tag{3.1}$$

Proof. First, we obtain the L^2-estimate of the perturbation $v(x,t)$. Multiplying (2.8) by v, we have

$$\Big(\frac{1}{2}v^2\Big)_t + (f(W+v) - f(W) - f'(W)v)\cdot W_x + v_x^2 + \{B(x,t)\}_x = Rv, \tag{3.2}$$

where $B(x,t)$ are boundary terms represented as

$$B(x,t) = (f(W+v) - f(W))v - \int_W^{W+v} f(s)ds + f(W)v - vv_x.$$

Note that the integration of $\{B(x,t)\}_x$ over $\mathbb{R}_+$ is equal to 0 since $v(0,t) = 0$. The second term of (3.2) is estimated below by using (1.2) and Lemma 2.2(iii) as

$$(f(W+v) - f(W) - f'(W)v)\cdot W_x \ge \frac{\alpha}{2}W_x v^2 \ge 0. \tag{3.3}$$

Here we have used the maximum principle of the parabolic equations. Integrating the right-hand side of (3.2) over $\mathbb{R}_+ \times (0,t)$ and using the Schwarz inequality and Lemma 2.2(iv), we have

$$\begin{aligned}\int_0^t\int_0^\infty |Rv|\,dxd\tau &\le \int_0^t |R(\tau)|_2|v(\tau)|_2\,d\tau \\ &\le \int_0^t \frac{1}{2}|R(\tau)|_2 + \frac{1}{2}|R(\tau)|_2|v(\tau)|_2^2\,d\tau \\ &\le C + \frac{1}{2}\int_0^t |R(\tau)|_2|v(\tau)|_2^2\,d\tau. \end{aligned}\tag{3.4}$$

Therefore, integrating (3.2) over $\mathbb{R}_+ \times (0,t)$ and using the estimates (3.3) and (3.4) yield

$$|v(t)|_2^2 + \int_0^t |\sqrt{W_x}v|_2^2 + |v_x|_2^2\,d\tau \le |v_0|_2^2 + C + \int_0^t |R|_2|v|_2^2\,d\tau. \tag{3.5}$$

Especially, we have

$$|v(t)|_2^2 \le |v_0|_2^2 + C + \int_0^t |R|_2|v|_2^2\,d\tau. \tag{3.6}$$

Applying the Gronwall inequality to (3.6), we obtain

$$|v(t)|_2^2 \le (|v_0|_2^2 + C)\exp\Big(\int_0^t |R|_2\,d\tau\Big) \le C(|v_0|_2^2 + 1),$$

where we have used Lemma 2.2(iv). Applying the above inequality to the last term of (3.5), we get the basic energy estimate

$$|v(t)|_2^2 + \int_0^t |\sqrt{W_x}v(\tau)|_2^2 + |v_x(\tau)|_2^2\,d\tau \le C(|v_0|_2^2 + 1). \tag{3.7}$$

Next, we estimate the spatial derivative of v. Multiplying (2.8) by $-v_{xx}$, we have

$$\Big(\frac{1}{2}v_x^2\Big)_t - (f(W+v) - f(W))_x v_{xx} + v_{xx}^2 - (v_t v_x)_x = -Rv_{xx}. \tag{3.8}$$

Note that the fourth term of (3.8) disappears after integrating over $\mathbb{R}_+$. By using the maximum principle of v and boundedness of W_x, the second term of (3.8) is estimated as

$$\begin{aligned} |(f(W+v) - f(W))_x v_{xx}| &\le \frac{1}{4}v_{xx}^2 + \{f'(W+v)v_x + (f'(W+v) - f'(W))W_x\}^2 \\ &\le \frac{1}{4}v_{xx}^2 + C(W_x v^2 + v_x^2). \end{aligned} \tag{3.9}$$

The right-hand side of (3.8) is estimated by the Schwarz inequality as

$$|Rv_{xx}| \le \frac{1}{4}v_{xx}^2 + R^2. \tag{3.10}$$

Apply the inequalities (3.9) and (3.10) to (3.8) and integrate the resultant inequality over $\mathbb{R}_+ \times (0,t)$. Then we obtain the estimate of v_x:

$$\begin{aligned} |v_x(t)|_2^2 + \int_0^t |v_{xx}|_2^2\,d\tau &\le |v_{0x}|_2^2 + C\int_0^t |\sqrt{W_x}v|_2^2 + |v_x|_2^2 + |R|_2^2\,d\tau \\ &\le C(\|v_0\|_1^2 + 1). \end{aligned} \tag{3.11}$$

Here the last inequality in (3.11) is given by using (3.7). Finally, adding (3.7) to (3.11) gives the desired estimate (3.1). □

The combination of Propositions 2.3 and 3.1 proves the global existence theorem.

THEOREM 3.2 (global existence). *Suppose that $v_0 \in H^1(\mathbb{R}_+)$ and $v_0(0) = 0$. Then there exists a unique global solution $v(x,t)$ of* (2.8) *satisfying*

$$v \in C^0([0,\infty); H^1(\mathbb{R}_+)), \quad v_x \in L^2(0,\infty; H^1(\mathbb{R}_+))$$

and the estimate (3.1).

4. Decay estimate. In order to derive the decay rate, we employ the L^1-estimate of v. This method is adopted from [4, 5, 12]. To this end, we define $a_\delta(v)$ and $A_\delta(v)$ as follows:

$$a_\delta(v) := (\operatorname{sgn} * \rho_\delta)(v) = \int_{-\infty}^{\infty} \operatorname{sgn}(y)\rho_\delta(v-y)dy,$$
$$A_\delta(v) := \int_0^v a_\delta(\eta)d\eta,$$

where sgn is a usual signature function defined as

$$\operatorname{sgn}(v) := \begin{cases} -1 & \text{for } v < 0, \\ 0 & \text{for } v = 0, \\ 1 & \text{for } v > 0. \end{cases}$$

ρ_δ denotes the Friedrichs mollifier defined as

$$\rho_\delta(v) := \frac{1}{\delta}\rho\left(\frac{v}{\delta}\right),$$

where ρ is a smooth function which has a compact support and satisfies $\int_{-\infty}^{\infty}\rho(x)dx = 1$. The time global solution $v(x,t)$ obtained in Theorem 3.2 satisfies the following L^1-estimate.

PROPOSITION 4.1 (L^1-estimate). *Suppose that $v_0 \in (H^1 \cap L^1)(\mathbb{R}_+)$. Then the solution $v(x,t)$ of (2.8) satisfies the estimate*

$$|v(t)|_1 \le |v_0|_1 + C\log(1+t). \tag{4.1}$$

Proof. Multiplying $a_\delta(v)$ on (2.8), we obtain

$$A_\delta(v)_t + (f(W+v) - f(W))_x a_\delta(v) - v_{xx}a_\delta(v) = R(x,t)a_\delta(v). \tag{4.2}$$

The second and third terms on the left-hand side of (4.2) are computed as

$$\begin{aligned}(f(W+v) - f(W))_x a_\delta(v) - v_{xx}a_\delta(v) &= \left\{(f(W+v) - f(W))a_\delta(v) - \int_0^v (f(W+s) - f(W))a_\delta'(s)\,ds - v_x a_\delta(v)\right\}_x \\ &\quad + \int_0^v (f'(W+s) - f'(W))a_\delta'(s)W_x\,ds + v_x^2 a_\delta'(v).\end{aligned} \tag{4.3}$$

Note that the integration of the first term on the right-hand side of (4.3) over $\mathbb{R}_+$ is equal to 0 since $v(0,t) = 0$ and $a_\delta(0) = 0$. The second and third terms on the right-hand side of (4.3) are positive since $a_\delta' \ge 0$ and $W_x \ge 0$. The right-hand side of (4.2) is estimated by Lemma 2.2(iv) as

$$\left|\int_0^t\int_0^\infty Ra_\delta(v)\,dxd\tau\right| \le \int_0^t |R(\tau)|_1\,d\tau \le C\log(1+t). \tag{4.4}$$

Integrate (4.2) over $\mathbb{R}_+\times(0,t)$ by using the above estimates and make $\delta \to 0$ afterward. This yields the desired estimate (4.1). □

Finally, we obtain the decay estimate of v. The combination of Lemma 2.2 and the following theorem immediately proves Theorem 1.1. The following theorem is proved by the same idea as that in [4, 12].

THEOREM 4.2 (decay estimate). *Suppose that $v_0 \in (H^1 \cap L^1)(\mathbb{R}_+)$. Then the solution $v(x,t)$ of (2.8) satisfies*

$$\begin{aligned}(1+t)^{\frac{1}{2}+\varepsilon}|v(t)|_2^2 + \int_0^t (1+\tau)^{\frac{1}{2}+\varepsilon}\left\{|\sqrt{W_x}v(\tau)|_2^2 + |v_x(\tau)|_2^2\right\}d\tau \\ \le C(1+t)^\varepsilon\log^2(2+t),\end{aligned} \tag{4.5}$$

$$\begin{aligned}(1+t)^{\frac{3}{2}+\varepsilon}|v_x(t)|_2^2 + \int_0^t (1+\tau)^{\frac{3}{2}+\varepsilon}\Big\{|\sqrt{W_x}v_x(\tau)|_2^2 + |v_{xx}(\tau)|_2^2 \\ + f'(u_-)v_x(0,\tau)^2\Big\}d\tau \le C(1+t)^\varepsilon\log^{10}(2+t)\end{aligned} \tag{4.6}$$

for arbitrary constant $\varepsilon \in (0, \frac{1}{2})$.

Proof. First, we obtain the decay estimate of v. Integrating (3.2) over $\mathbb{R}_+$ and using Lemma 2.2(iv), we have

$$\frac{1}{2}\frac{d}{dt}|v(t)|_2^2 + \frac{\alpha}{2}|\sqrt{W_x}v(t)|_2^2 + |v_x(t)|_2^2 \le \int_0^\infty |Rv|\,dx \le C(1+t)^{-1}|v(t)|_\infty. \tag{4.7}$$

From the Gagliardo–Nirenberg inequality, it follows that

$$|v|_2^2 + |v|_\infty \le |v|_\infty(|v|_1 + 1) \le |v_x|_2^{\frac{2}{3}}(|v|_1+1)^{\frac{4}{3}}.$$

Using this inequality, multiplying $(1+t)^{\frac{1}{2}+\varepsilon}$ by (4.7) yields

$$\begin{aligned}
&\frac{d}{dt}\Big\{(1+t)^{\frac{1}{2}+\varepsilon}|v(t)|_2^2\Big\} + (1+t)^{\frac{1}{2}+\varepsilon}\Big\{|\sqrt{W_x}v(t)|_2^2 + |v_x(t)|_2^2\Big\} \\
&\qquad \le C(1+t)^{-\frac{1}{2}+\varepsilon}(|v(t)|_2^2 + |v(t)|_\infty) \\
&\qquad \le C(1+t)^{\frac{1}{6}+\frac{1}{3}\varepsilon}|v_x(t)|_2^{\frac{2}{3}} \cdot (1+t)^{-\frac{2}{3}+\frac{2}{3}\varepsilon}(|v(t)|_1+1)^{\frac{4}{3}} \\
&\qquad \le \frac{1}{2}(1+t)^{\frac{1}{2}+\varepsilon}|v_x(t)|_2^2 + C(1+t)^{-1+\varepsilon}(|v(t)|_1+1)^2,
\end{aligned} \tag{4.8}$$

where the last inequality is obtained by using the Young inequality. Applying Proposition 4.1, (4.8) is rewritten as

$$\begin{aligned}
&\frac{d}{dt}\Big\{(1+t)^{\frac{1}{2}+\varepsilon}|v(t)|_2^2\Big\} + (1+t)^{\frac{1}{2}+\varepsilon}\Big\{|\sqrt{W_x}v(t)|_2^2 + |v_x(t)|_2^2\Big\} \\
&\qquad \le C(1+t)^{-1+\varepsilon}(|v(t)|_1+1)^2 \\
&\qquad \le C(|v_0|_1+1)^2(1+t)^{-1+\varepsilon}\log^2(2+t).
\end{aligned} \tag{4.9}$$

Integrating (4.9) over $(0,t)$, we get the estimate (4.5). In particular, we have

$$|v(t)|_2 \le C(1+t)^{-\frac{1}{4}}\log(2+t). \tag{4.10}$$

Next, we obtain the decay estimate of v_x. Integrating (3.8) over $\mathbb{R}_+$ yields

$$\begin{aligned}
&\frac{1}{2}\frac{d}{dt}|v_x(t)|_2^2 - \int_0^\infty (f(W+v)-f(W))_x v_{xx}\,dx + \frac{1}{2}|v_{xx}(t)|_2^2 \le C|R(t)|_2^2 \\
&\qquad\qquad \le C(1+t)^{-3}.
\end{aligned} \tag{4.11}$$

The second term on the left-hand side of (4.11) is computed by using integration by parts as

$$\begin{aligned}
&-\int_0^\infty (f(W+v)-f(W))_x v_{xx}\,dx \\
&= -\int_0^\infty (f'(W+v)-f'(W))W_x v_{xx}\,dx - \int_0^\infty f'(W+v)\Big(\frac{1}{2}v_x^2\Big)_x\,dx \\
&= -\int_0^\infty (f'(W+v)-f'(W))W_x v_{xx}\,dx + \frac{1}{2}\int_0^\infty f''(W+v)v_x^3\,dx \\
&\qquad + \frac{1}{2}\int_0^\infty f''(W+v)W_x v_x^2\,dx + \frac{f'(u_-)}{2}v_x(0,t)^2.
\end{aligned} \tag{4.12}$$

Note that the third and fourth terms on the right-hand side of (4.12) are positive. The first term on the right-hand side of (4.12) is estimated by using the Schwarz inequality and Lemma 2.2(ii) as

$$\begin{aligned}\Big|\int_0^\infty (f'(W+v)-f'(W))W_x v_{xx}\,dx\Big| &\le C\int_0^\infty |W_x v v_{xx}|\,dx\\ &\le \frac{1}{4}|v_{xx}|_2^2 + C(1+t)^{-1}|\sqrt{W_x}v|_2^2.\end{aligned}\tag{4.13}$$

By using the Gagliardo–Nirenberg inequality and the Young inequality, the second term on the right-hand side of (4.12) is estimated as

$$\Big|\int_0^\infty f''(W+v)v_x^3\,dx\Big| \le C|v_x|_3^3 \le C|v_{xx}|_2^{\frac{7}{4}}|v|_2^{\frac{5}{4}} \le \frac{1}{4}|v_{xx}|_2^2 + C|v|_2^{10}.\tag{4.14}$$

Therefore, by using (4.12)–(4.14), (4.11) is rewritten as

$$\begin{aligned}&\frac{d}{dt}|v_x(t)|_2^2 + |\sqrt{W_x}v_x(t)|_2^2 + |v_{xx}(t)|_2^2 + f'(u_-)v_x(0,t)^2\\ &\qquad\le C\left\{(1+t)^{-3} + (1+t)^{-1}|\sqrt{W_x}v(t)|_2^2 + |v(t)|_2^{10}\right\}.\end{aligned}\tag{4.15}$$

Multiply (4.15) by $(1+t)^{\frac{3}{2}+\varepsilon}$ and integrate the resultant inequality over $(0,t)$. Then by applying (4.5) and (4.10) we have that

$$\begin{aligned}&(1+t)^{\frac{3}{2}+\varepsilon}|v_x(t)|_2^2 + \int_0^t (1+\tau)^{\frac{3}{2}+\varepsilon}\left\{|\sqrt{W_x}v_x|_2^2 + |v_{xx}|_2^2 + f'(u_-)v_x(0,\tau)^2\right\}d\tau\\ &\quad\le |v_{0x}|_2^2 + C + C\int_0^t (1+\tau)^{\frac{1}{2}+\varepsilon}\left\{|\sqrt{W_x}v|_2^2 + |v_x|_2^2\right\} + (1+\tau)^{\frac{3}{2}+\varepsilon}|v|_2^{10}\,d\tau\\ &\quad\le |v_{0x}|_2^2 + C + C(1+t)^{\varepsilon}\log^2(2+t) + C\int_0^t (1+\tau)^{-1+\varepsilon}\log^{10}(2+\tau)\,d\tau\\ &\quad\le C(1+t)^{\varepsilon}\log^{10}(2+t).\end{aligned}$$

This completes the proof. □

Acknowledgments. The author would like to express his deepest gratitude to his supervisor, Professor Shinya Nishibata, for his support. He is also very grateful to Professors Shuichi Kawashima, Kenji Nishihara, and Seiji Ukai for their helpful advice.

SHARP SOBOLEV INEQUALITY OF LOGARITHMIC TYPE AND THE LIMITING REGULARITY CONDITION TO THE HARMONIC HEAT FLOW*

TAKAYOSHI OGAWA†

Dedicated to Professor Takaaki Nishida on the occasion of his sixtieth birthday.

Abstract. We show a sharp version of the Sobolev inequality of the Beale–Kato–Majda and the Kozono–Taniuchi type in Lizorkin–Triebel space. As an application of this inequality, the regularity problem under the critical condition to the gradient flow of the harmonic map into a sphere is considered in the class $L^2(0,T;BMO(\mathbb{R}^n;\mathbb{S}^m))$, where BMO is the class of functions of bounded mean oscillations.

Key words. critical Sobolev inequalities, Lizorkin–Triebel space, interpolation inequality, harmonic heat flow, regularity criterion, bounded mean oscillation

1. Introduction. In this paper, we discuss the regularity problem of smooth solutions to the time dependent harmonic heat flow from $\mathbb{R}^n$ into a unit sphere $\mathbb{S}^m$,

$$\begin{cases} \partial_t u - \Delta u = u(\nabla u, \nabla u), & t > 0, x \in \mathbb{R}^n, \\ u(t,x) : \mathbb{R}_+ \times \mathbb{R}^n \to \mathbb{S}^m, & t > 0, x \in \mathbb{R}^n, \\ u(0,x) = u_0(x), \end{cases} \tag{1.1}$$

where $u(\nabla u, \nabla u) = u_i \sum_{1 \le l,j \le n} |\nabla_l u_j|^2$ denotes the second fundamental form on the sphere. This equation is first considered by Eells and Sampson [13] for the sake of constructing the stationary harmonic map from $\mathbb{R}^n$ into a sphere. By a simple observation, the following type of energy inequality is immediately obtained:

$$\|\nabla u(t)\|_2^2 + 2\int_0^t \|\partial_t u(\tau)\|_2^2 d\tau \le \|\nabla u_0\|_2^2, \quad t \in [0,T]. \tag{1.2}$$

Based on the above energy inequality, a weak solution is constructed in the space $L^\infty(0,T;\dot{H}^1(\mathbb{R}^n;\mathbb{S}^m))$ with $\partial_t u \in L^2(0,T;L^2(\mathbb{R}^n;\mathbb{S}^m))$. By an elegant penalizing method, the existence of a weak solution on the general compact Riemannian manifold was established by Chen and Struwe [10]. On the other hand, if the initial data is smooth, it is implicitly known that a smooth solution exists in time locally by using the Bochner-type formula (see, for example, Eells and Sampson [13] and Struwe [31]). This time the local smooth solution belongs to $u \in W^{1,\infty}(\mathbb{R}^n;\mathbb{S}^m)$, and the maximal existence time is characterized by $\|\nabla u_0\|_\infty$.

The regularity of the weak solution fails in general because of the existence of a blowing-up weak solution for large initial data. The example for the map from $\mathbb{R}^n$ to a sphere was shown by Coron and Ghidaglia [12] for $n \geq 3$ and by Chang, Ding, and Ye [9] for $n = 2$. However, some smallness assumption on the initial data or integrability condition on the solution itself may be possible to give the regularity.

This situation is related to the theory of a weak solution to the incompressible fluid mechanics. For the viscous incompressible fluid governed by the Navier–Stokes equation,

$$\begin{cases} \partial_t u - \Delta u + u \cdot \nabla u + \nabla p = 0, & t > 0, x \in \mathbb{R}^n, \\ \text{div } u = 0, & t > 0, x \in \mathbb{R}^n, \\ u(0, x) = u_0(x), \end{cases} \tag{1.3}$$

it is well known that there exists a global weak solution u based on an analogous energy inequality to (1.1) due to Leray [23]:

$$\|u(t)\|_2^2 + 2 \int_0^t \|\nabla u(\tau)\|_2^2 d\tau \leq \|u_0\|_2^2. \tag{1.4}$$

Although the full regularity of the weak solution to (1.3) remains open, there is some sufficient condition for the regularity in terms of a seminorm invariant under the scaling that maintains the equations. For the Navier–Stokes case, the equation is invariant under the scaling $u_\lambda(t, x) = \lambda u(\lambda^2 t, \lambda x)$, $p_\lambda(t, x) = \lambda^2 p(\lambda^2 t, \lambda x)$ $(\lambda > 0)$. Hence a criterion by the space-time norms such as

$$\int_0^T \||\nabla|^\alpha u(t)\|_p^\theta dt < \infty, \quad \frac{2}{\theta} + \frac{n}{p} = 1 + \alpha, \quad 2 \leq \theta < \infty,$$

gives the regularity of a weak solution. This is known as the Serrin condition (Ohyama [24], Serrin [28], Giga [17], Beirão da Veiga [2]). By observing the analogous scaling $u \to u_\lambda = u(\lambda^2 t, \lambda x)$ to (1.1) that preserves the equation, it is expected that there is a regularity criterion for (1.1) under the conditions

$$\nabla u \in L^\theta(0, T; L^p(\mathbb{R}^n)), \qquad \frac{2}{\theta} + \frac{n}{p} = 1, \quad n < p \leq \infty.$$

These conditions correspond to the Serrin criterion and are enough to show the regularity of the strong solution to (1.1).

In Kozono, Ogawa, and Taniuchi [21], the above observation is extended to an even weaker regularity criterion to the harmonic heat flow (1.1) by terms of the Besov spaces: Let $\phi_j(x)$ be the Littlewood–Paley dyadic decomposition of unity. Then the homogeneous Besov space $\dot{B}^s_{p,\rho}$ is defined by

$$\dot{B}^s_{p,\rho} = \{f \in \mathcal{Z}'(\mathbb{R}^n) : \|f\|_{\dot{B}^s_{p,\rho}} < \infty\},$$

where $\|f\|_{\dot{B}^s_{p,\rho}} = \left(\sum_{j=-\infty}^{\infty} 2^{js\rho} \|\phi_j * f\|_p^\rho\right)^{1/\rho}$ and $\mathcal{Z}'(\mathbb{R}^n)$ denotes the coefficient space of $\mathcal{S}'$ by the polynomials $\mathcal{P}$. The regularity criterion in the Besov space obtained in [21] is as follows.

PROPOSITION 1.1 (Kozono, Ogawa, and Taniuchi [21]). *Let u be a smooth solution to (1.1) in $C([0,T);W^{1,\infty}(\mathbb{R}^n;\mathbb{S}^m))\cap C^1((0,T);W^{2,\infty}(\mathbb{R}^n;\mathbb{S}^m))$ with initial data $u_0\in W^{1,\infty}(\mathbb{R}^n;\mathbb{S}^m)$. Suppose that the solution u satisfies either*

(i) *for any pair of (p,θ) with $\frac{2}{\theta}+\frac{n}{p}=1$ and $n<p<\infty$ and for any $\sigma\le 2p/n$,*

$$\int_0^T \|\nabla u(\tau)\|_{\dot B^0_{p,\sigma}}^{\theta} d\tau<\infty \tag{1.5}$$

or

(ii)

$$\int_0^T \|\nabla u(\tau)\|_{\dot B^0_{\infty,2}}^{2} d\tau<\infty. \tag{1.6}$$

Then the solution can be extended after $t=T$, namely, for some $T<\tilde T$, $u\in C([0,\tilde T);W^{1,\infty}(\mathbb{R}^n;\mathbb{S}^m))\cap C^1((0,\tilde T);W^{2,\infty}(\mathbb{R}^n;\mathbb{S}^m))$. In other words, if the solution blows up at $t=T$, then

$$\int_0^T \|\nabla u(\tau)\|_{\dot B^0_{p,\sigma}}^{\theta} d\tau=\infty$$

for any pair of (p,θ) satisfying $2/\theta+n/p=1$ with $\sigma\le 2p/n$ if $p<\infty$ and $\sigma=2$ if $p=\infty$.

The analogous regularity criterion to the Navier–Stokes equations is established in the scale where the equation remains invariant under the scaling [20], [27]. Among others, the corresponding condition involving bounded mean oscillation (BMO) is considered [21] (cf. for the Euler equations [22]). More precisely, the Leray weak solution is regular up to $t=T$ under the condition

$$\int_0^T \|\mathrm{rot}\ u(t)\|_{BMO}dt<\infty.$$

Here BMO is the space of the *bounded mean oscillation* defined by

$$f\in L^1_{loc}(\mathbb{R}^n)\quad \sup_{x,R}\frac{1}{|B_R|}\int_{B_R(x)}|f(y)-\bar f_{B_R(x)}|dy<\infty,$$

where $\bar f_{B_R}$ is the average of f over $B_R(x)=\{y\in\mathbb{R}^n;|x-y|<R\}$. We see that there is a gap comparing the result for the Navier–Stokes equations with the one to the harmonic heat flow, namely, the criterion at the limiting case $p=\infty$, $\theta=2$. By the strict inclusion $\dot B^0_{\infty,2}\subsetneq BMO$ (cf. Strichartz [30], Bergh and Löfström [3]), the result for (1.1) in [21] is slightly weaker than the one for the Navier–Stokes equations in view of $\dot B^0_{\infty,2}\subsetneq BMO$. This gap appears between the two cases because of the balance between the order of the nonlinearity and the order of the interpolation inequalities. To see this, we recall the basic argument found in [1] and [22]. In both results, the critical Sobolev embedding inequality of logarithmic type plays the crucial role of the regularity criterion.

Namely, the inequality originally due to Brezis and Gallouet [4], Beale, Kato, and Majda [1], and Kozono and Taniuchi [22] is suitable only for the quadratic order of nonlinearity like in the Navier–Stokes equations (1.3).

In the result of Beale, Kato, and Majda [1] (see also Kato and Ponce [20]), they showed that, for $f \in \{W^{s,p}(\mathbb{R}^n)\}^n$ $(s > n/p + 1)$ with div $f = 0$,

$$\|\nabla f\|_\infty \le C\left\{1 + \|\nabla f\|_2 + \|\omega\|_\infty \log(e + \|f\|_{W^{s+1,p}})\right\}, \quad \omega = \operatorname{rot} f. \tag{1.7}$$

An even more improved version of the inequality due to Kozono and Taniuchi [22] states that, for $f \in \{W^{s,p}(\mathbb{R}^n)\}^n$ $(s > n/p + 1)$ with div $f = 0$, there holds

$$\|f\|_\infty \le C\left\{1 + \|f\|_{BMO} \log(e + \|f\|_{W^{s,p}})\right\}. \tag{1.8}$$

However, for the regularity problem (1.1) under the condition

$$\int_0^t \|\nabla u(t)\|_{BMO}^2 dt < \infty,$$

inequalities (1.7) and (1.8) are not sufficient.

One way to fill this gap is to improve the Sobolev inequality (1.8). We first introduce a generalized version of the critical Sobolev inequality in the Lizorkin–Triebel space that includes the above inequalities. It then turns out that the second exponent of those spaces gives an explicit dependence of the logarithmic order of higher regularity, which reflects hypotheses on the integral exponent in the time direction of those criteria. In the following section, we show a refined version of the Beale–Kato–Majda- and Kozono–Taniuchi-type inequalities and give some discussion. Then, in section 3, we show our new regularity criterion for each of the problems of (1.1). The statement reads as follows.

THEOREM 1.2 (limiting regularity criterion). *Let u be a smooth solution to (1.1) in $C([0,T); W^{1,\infty}(\mathbb{R}^n;\mathbb{S}^m)) \cap C^1((0,T); W^{2,\infty}(\mathbb{R}^n;\mathbb{S}^m))$ with initial data $u_0 \in W^{1,\infty}(\mathbb{R}^n;\mathbb{S}^m)$. Suppose that the solution u satisfies*

$$\int_0^T \|\nabla u(\tau)\|_{BMO}^2 d\tau < \infty. \tag{1.9}$$

Then the solution can be extended after $t = T$, namely, for some $T < \tilde{T}$, $u \in C([0,\tilde{T}); W^{1,\infty}(\mathbb{R}^n;\mathbb{S}^m)) \cap C^1((0,T); W^{2,\infty}(\mathbb{R}^n;\mathbb{S}^m))$. In other words, if the solution blows up at $t = T$, then

$$\int_0^T \|\nabla u(\tau)\|_{BMO}^2 d\tau = \infty$$

for any pair of (p,θ) satisfying $2/\theta + n/p = 1$ and $\sigma \le 2p/n$ and $\sigma = 2$ if $p = \infty$.

It is important to compare the results of the existence of blowing-up solutions for (1.1) to the above criterion. There are several results for constructing the finite time blow-up of the solution. Coron and Ghidaglia [12] and Chen and Ding [8] showed that there exists a finite time blowing-up solution to (1.1) for $n \ge 3$. For $n = 2$, Chang, Ding, and Ye [9] constructed a blowing-up solution from a smooth data (cf. for the regularity of the stationary harmonic maps Hélein [19], Evans [15], and Coifman et al. [11], and see also Feldman [16] for the time dependent case). The solution satisfies

$$\int_0^T \|\nabla u(t)\|_\infty^r dt = \infty \quad (r > 1),$$

where $T > 0$ is the expected blow-up time. We simply remark that, for the two dimensional case, if we make the stronger regularity assumption that

$$\int_0^T \|\Delta u(t)\|_2^2 dt < \infty, \tag{1.10}$$

then, by the embedding,

$$\int_0^T \|\nabla u(t)\|_{BMO}^2 dt < \infty,$$

and our criterion gives the regularity. Because the weak solution satisfies the energy inequality, we have

$$\int_0^T \|\partial_t u(t)\|_2^2 dt < \infty.$$

Hence, if the nonlinearity has the integrability condition

$$\int_0^T \|\nabla u(t)\|_4^4 dt < \infty,$$

then the condition (1.10) is fulfilled, and the solution has to be smooth near $t = T$. This is nothing but the case of the criterion from the scaling invariant norm

$$\int_0^T \|\nabla u(t)\|_p^\theta dt < \infty, \quad \frac{2}{\theta} + \frac{n}{p} = 1.$$

Our criterion Theorem 1.2 is a stronger result and is outside of this kind of regularity criterion. We should also remark on the related results for the Euler equation. Chemin [7] considered the Euler equation in the Zygmund and log-Lipschitz class. His argument also includes the logarithmic type functional inequality in terms of the log-Lipschitz seminorm and Bony's para-product formula. Vishik [33] also develops this direction in the two dimensional case. Some related uniqueness result was shown by Yudovich [34] and Ogawa and Taniuchi [26] for the two dimensional unbounded vorticity solution.

Before closing this section, we introduce some notation. $\mathcal{F}f$ and $\hat{f}$ denote the Fourier transform of f. $\langle x \rangle = (1+|x|^2)^{1/2}$. We define a saturated logarithmic function $\log^+ t = \log(e + t)$. The usual Sobolev space $W^{s,p}(\mathbb{R}^n)$ is abbreviated as $W^{s,p}$ with the norm

$$\|f\|_{W^{s,p}} \equiv \|\mathcal{F}^{-1}\langle\cdot\rangle^s \hat{f}(\cdot)\|_p$$

for $1 < p < \infty$ and $s \geq 0$.

We recall the Paley–Littlewood dyadic decomposition (cf. Stein [29] and Bergh and Löfström [3]). Let $\phi_j(x)$ be the inverse Fourier transform of the jth component of the dyadic decomposition, i.e., $\sum_{j=-\infty}^{\infty} \hat{\phi}(2^{-j}\xi) = 1$ except $\xi = 0$, where the support

of $\hat{\phi}(\xi)$ is located on $2^{-1} < |\xi| < 2$. We denote $\psi(x) = \mathcal{F}^{-1}[\hat{\psi}(\xi)](x)$, where

$$\hat{\psi} = \begin{cases} 1, & |\xi| < 1, \\ \text{smooth}, & |\xi| < 2, \\ 0, & |\xi| > 2. \end{cases}$$

Set $\psi_j = \mathcal{F}^{-1}[\hat{\psi}(2^j\xi)](x)$. For a smooth function f, we set $\Phi_j f = \phi_j * f$ and $\Psi(x)f = \psi * f$. The homogeneous Besov space $\dot{B}^s_{p,\rho}$ is defined through the full dyadic decomposition by

$$\dot{B}^s_{p,\rho} = \{f \in \mathcal{Z}'(\mathbb{R}^n) : \|f\|_{\dot{B}^s_{p,\rho}} < \infty\},$$

where $\|f\|_{\dot{B}^s_{p,\rho}} = \left(\sum_{j=-\infty}^{\infty} 2^{js\rho}\|\phi_j * f\|_p^\rho\right)^{1/\rho}$ and $\mathcal{Z}'(\mathbb{R}^n)$ denotes the dual space of $\mathcal{Z}(\mathbb{R}^n) = \{f \in \mathcal{S}; D^\alpha \hat{f}(0) = 0 \,\forall \alpha \in \mathbb{N}^n \text{ multiindex}\}$ and can be identified by the coefficient space of $\mathcal{S}'/\mathcal{P}$ with the polynomial space $\mathcal{P}$. The homogeneous Lizorkin–Triebel space $\dot{F}^s_{p,\rho}$ is similarly defined by

$$\dot{F}^s_{p,\rho} = \{f \in \mathcal{Z}'(\mathbb{R}^n) : \|f\|_{\dot{F}^s_{p,\rho}} < \infty\},$$

where $\|f\|_{\dot{F}^s_{p,\rho}} = \|\left(\sum_{j=-\infty}^{\infty} 2^{js\rho}|\phi_j * f|^\rho\right)^{1/\rho}\|_p$ and $1 \le p < \infty$, $1 \le \rho \le \infty$ ($1 \le \rho < \infty$ if $p = \infty$). We refer to Triebel [32] for more detailed properties of those spaces.

2. Sharp version of logarithmic inequality. In this section, we give a sharp version of the logarithmic Sobolev inequality. The original type of Sobolev inequality was found by Brezis and Gallouet [4] and Brezis and Wainger [5] (see also Engler [14]). And the similar type of inequality we shall discuss here was first established by Beale, Kato, and Majda [1] and was improved by Kozono and Taniuchi [22] and Kozono, Ogawa, and Taniuchi [21]. We show the sharp version of the Kozono–Taniuchi inequality.

THEOREM 2.1 (sharp version of logarithmic inequality). (1) *For any $p, \rho, \sigma \in [1, \infty]$, $q \in [1, \infty)$, $\nu \le \sigma_1, \sigma_2$, $\nu < \rho$, and $\gamma > 0$, there exists a constant C which depends only on n, p such that, for $f \in \dot{F}^{\gamma}_{p,\sigma_1} \cap \dot{F}^{-\gamma}_{p,\sigma_2}$, we have*

$$\|f\|_{\dot{F}^0_{p,\nu}} \le C\|f\|_{\dot{F}^0_{p,\rho}} \left(1 + \left(\frac{1}{\gamma}\log^+ \frac{\|f_+\|_{\dot{F}^{\gamma}_{p,\sigma_1}} + \|f_-\|_{\dot{F}^{-\gamma}_{p,\sigma_2}}}{\|f\|_{\dot{F}^0_{p,\rho}}}\right)^{1/\nu - 1/\rho}\right), \tag{2.1}$$

where $f_+ = \sum_{j>0} \phi_j * f$ and $f_- = \sum_{j<0} \phi_j * f$.

Remark 2.1. In the theorem, the assumption $\gamma > 0$ is essential. The analogous version of the inequality (2.1) in the Besov space was proved in Ogawa and Taniuchi [25].

Proof of Theorem 2.1. To show Theorem 2.1, we recall the definition of the Lizorkin–Triebel (semi)norm. We decompose f into the following three parts: Noting that $\nu < \rho, \sigma_1, \sigma_2$, we have

(2.2)

$$
\begin{aligned}
\|f\|_{\dot{F}^0_{p,\nu}} &\le \left\| \left(\sum_{j>N} |\phi_j * f|^\nu \right)^{1/\nu} \right\|_p + \left\| \left(\sum_{|j|\le N} |\phi_j * f|^\nu \right)^{1/\nu} \right\|_p + \left\| \left(\sum_{j<-N} |\phi_j * f|^\nu \right)^{1/\nu} \right\|_p \\
&\le \left\| \left(\sum_{j>N} 2^{-j\gamma(1/\nu-1/\sigma_1)} \right)^{1/\nu-1/\sigma_1} \left(\sum_{j>N} 2^{j\gamma\sigma_1} |\phi_j * f|^{\sigma_1} \right)^{1/\sigma_1} \right\|_p \\
&\quad + (2N+1)^{1/\nu-1/\rho} \left\| \left(\sum_{|j|\le N} |\phi_j * f|^\rho \right)^{1/\rho} \right\|_p \\
&\quad + \left\| \left(\sum_{j<-N} 2^{j\gamma(1/\nu-\sigma_2)} \right)^{1/\nu-1/\sigma_2} \left(\sum_{j<-N} 2^{-j\gamma\sigma_2} |\phi_j * f|^{\sigma} \right)^{1/\sigma_2} \right\|_p \\
&\le 2^{-\gamma N} \left\{ \left\| \left(\sum_{j>N} 2^{j\gamma\sigma_1} |\phi_j * f|^{\sigma_1} \right)^{1/\sigma_1} \right\|_p + \left\| \left(\sum_{j<-N} 2^{-j\gamma\sigma_2} |\phi_j * f|^{\sigma_2} \right)^{1/\sigma_2} \right\|_p \right\} \\
&\quad + (2N+1)^{1/\nu-1/\rho} \left\| \left(\sum_{|j|\le N} |\phi_j * f|^\rho \right)^{1/\rho} \right\|_p \\
&\le 2^{-\gamma N} \left\{ \|f_+\|_{\dot{F}^{\gamma}_{p,\sigma_1}} + \|f_-\|_{\dot{F}^{-\gamma}_{p,\sigma_2}} \right\} + (2N+1)^{1/\nu-1/\rho} \|f\|_{\dot{F}^0_{p,\rho}}.
\end{aligned}
$$

Now we optimize (2.2) for each f by setting $N = 1$ if

$$\|f_+\|_{\dot{F}^{\gamma}_{p,\sigma}} + \|f_-\|_{\dot{F}^{\gamma}_{p,\sigma}} \le \|f\|_{\dot{F}^0_{p,\rho}}$$

and

$$N \simeq \left[\log_{2^\gamma} \left(\frac{\|f_+\|_{\dot{F}^{\gamma}_{p,\sigma_1}} + \|f_-\|_{\dot{F}^{-\gamma}_{p,\sigma_2}}}{\|f\|_{\dot{F}^0_{p,\rho}}} \right) \right] + 1$$

otherwise. □

Some minor modification shows that the exponents of the higher regularity for f can be chosen arbitrarily under the following form.

COROLLARY 2.2. *There exists a constant C which depends only on n, p such that, for $f \in \dot{F}^{n/p+\gamma}_{p,\sigma_1} \cap \dot{F}^{n/p-\gamma}_{p,\sigma_2}$, we have for $\gamma < \gamma'$*

$$\|f\|_{\dot{F}^0_{\infty,\nu}} \le C \|f\|_{\dot{F}^0_{\infty,\rho}} \left(1 + \left(\frac{1}{\gamma} \log^+ \frac{\|f_+\|_{\dot{F}^{n/p+\gamma'}_{p,\sigma_1}} + \|f_-\|_{\dot{F}^{n/p-\gamma'}_{p,\sigma_2}}}{\|f\|_{\dot{F}^0_{\infty,\rho}}} \right)^{1/\nu-1/\rho} \right), \tag{2.3}$$

where $f_+ = \sum_{j\ge 0} \phi_j * f$ and $f_- = \sum_{j\le 0} \phi_j * f$.

The relation between the Lizorkin–Triebel spaces and the BMO is well understood. The following result is due to Peetre and Triebel (see also Qui [6]).

PROPOSITION 2.3 (Triebel [32]). *$\dot{F}^0_{\infty,2} \simeq BMO$. Namely, there exists a constant C such that*

$$C^{-1}\|f\|_{\dot{F}^0_{\infty,2}} \le \|f\|_{BMO} \le C\|f\|_{\dot{F}^0_{\infty,2}}.$$

From (2.3) and the equivalence between $\dot{F}^0_{\infty,2} \simeq BMO$ and $\dot{F}^0_{\infty,\infty} \simeq \dot{B}^0_{\infty,\infty}$, it is explicitly shown that the difference between L^∞, BMO, and the Besov space $\dot{B}^0_{\infty,\infty}$ is as follows. This is a version of the sharp form of the Kozono–Taniuchi inequality (1.8).

COROLLARY 2.4. *We have the following: For $\gamma' > 0$,*

$$\|f\|_{BMO} \le C\left(1 + \|f\|_{\dot{B}^0_{\infty,\infty}}\left(\frac{1}{\kappa}\log^+(\|f_+\|_{\dot{F}^\kappa_{\infty,\sigma_1}} + \|f_-\|_{\dot{F}^{-\kappa}_{\infty,\sigma_2}})\right)^{1/2}\right), \tag{2.4}$$

and if $\hat{f}(0) = 0$,

$$\|f\|_\infty \le C\left(1 + \|f\|_{BMO}\left(\frac{1}{\kappa}\log^+(\|f_+\|_{\dot{F}^\kappa_{\infty,2}} + \|f_-\|_{\dot{F}^{-\kappa}_{\infty,2}})\right)^{1/2}\right). \tag{2.5}$$

In particular, if $\nabla f \in W^{1,q}(\mathbb{R}^n) \cap L^2(\mathbb{R}^n)$ for $n < q$, we have

$$\|\nabla f\|_\infty \le C(q)\left(1 + \|\nabla f\|_{BMO}\left(\log^+(\|\nabla f\|_{W^{1,q}} + \|f\|_\infty)\right)^{1/2}\right). \tag{2.6}$$

Remark 2.2. The last inequality (2.5) improves the related logarithmic inequalities (1.7) and (1.8) due to Beale, Kato, and Majda and Kozono and Taniuchi. Recalling the Brezis–Gallouet inequality,

$$\|f\|_\infty \le C(1 + \|f\|_2 + \|\nabla f\|_2(\log^+\|\Delta f\|_2)^{1/2}), \quad f \in H^2(\mathbb{R}^2),$$

one may notice that inequality (2.6) has the same order of the higher regular term despite the dimension independence, although it is substituted by the Dirichlet norm instead of the BMO seminorm.

Proof of Corollary 2.4. Noting the inequality

$$x\left(\log\left(e + \frac{y}{x}\right)\right)^{1/2} \le \begin{cases} C(1 + x(\log(e+y))^{1/2}) & \text{for } 0 < x \le 1, \\ Cx\,(\log(e+y))^{1/2} & \text{for } 1 < x, \end{cases}$$

the first inequality (2.4) is an immediate consequence of (2.1) with $\nu = 2$ and $\rho = \infty$ and Proposition 2.3. Similarly, the second inequality (2.4) follows from (2.1) with $\nu = 1$ and $\rho = 2$, observing that

$$\|f\|_\infty = \left\|\sum_{i=-\infty}^{\infty} \phi_j * f\right\|_\infty \le \|f\|_{\dot{F}^0_{\infty,1}}$$

when $\hat{f}(0) = 0$.

To obtain the last modification (2.6), we first notice

$$\lim_{M\to\infty}\left\|\nabla f - \left(\sum_{j\ge -M}\phi_j * f\right)\right\|_\infty = 0.$$

To see this, we define a smooth function $\psi(x)$ such that

$$\hat{\psi}(\xi) = \begin{cases} 1, & |\xi| \le 1/2, \\ 0, & |\xi| \ge 1, \end{cases}$$

and we set $\widehat{\psi}_j(\xi) = \widehat{\psi}(\xi/2^j)$. Then we have by the L^1-L^∞ bound of the Fourier inverse transform

$$\begin{aligned} \|\psi_{-M} * \nabla f\|_\infty &\le C_n \|\widehat{\psi}_{-M} \xi \hat{f}\|_1 \\ &\le C_n \int_{B_{2^{-M}}} |\xi \hat{f}(\xi)| d\xi \\ &\le C_n |B_{2^{-M}}|^{1/2} \left(\int_{B_{2^{-M}}} |\xi|^2 |\hat{f}(\xi)|^2 d\xi \right)^{1/2} \\ &\le C_n 2^{-Mn/2} \|\nabla f\|_2 \to 0, \end{aligned} \tag{2.7}$$

as $M \to \infty$. Hence, for sufficiently large M such that $\|\psi_{-M} * \nabla f\|_\infty \le 1$, it suffices to estimate $\sum_{j \ge -M} \phi_j * f$. We apply inequality (2.4) with small κ specified below. For small $\kappa > 0$ and $\alpha > 0$ with $\kappa < \alpha < 1 - n/q$,

$$\begin{aligned} \|\nabla f_+\|_{\dot{F}^\kappa_{\infty,2}} &= \left\| \left(\sum_{j=1}^\infty 2^{2j\kappa} |\phi_j * \nabla f|^2 \right)^{1/2} \right\|_\infty \\ &\le \left(\sum_{j=1}^\infty 2^{2j(\kappa-\alpha)} \right)^{1/2} \left\| \sup_j 2^{\alpha j} |\phi_j * \nabla f| \right\|_\infty \\ &\le C \|\nabla f\|_{\dot{B}^\alpha_{\infty,\infty}} \le C \|\nabla f\|_{\dot{B}^{\alpha+n/q}_{q,\infty}} \\ &\le C \|\nabla f\|_{\dot{W}^{1,q}}, \end{aligned} \tag{2.8}$$

where $\|\cdot\|_{\dot{W}^{1,q}}$ stands for the homogeneous Sobolev seminorm. This is possible under the condition $n < q$. On the other hand, using the L^∞ boundedness of the Hardy–Littlewood maximal function (cf. Stein [29, p. 62–63]), we have for small $0 < \kappa < 1$

$$\begin{aligned} \|\nabla f_-\|_{\dot{F}^{-\kappa}_{\infty,2}} &= \left\| \left(\sum_{j=-1}^{-\infty} 2^{-2j\kappa} |\phi_j * \nabla f|^2 \right)^{1/2} \right\|_\infty \\ &\le \left\| \left(\sum_{j=-1}^{-\infty} 2^{2j(1-\kappa)} |(\nabla \phi)_j * f|^2 \right)^{1/2} \right\|_\infty \\ &\le \left(\sum_{j=-1}^{-\infty} 2^{2j(1-\kappa)} \right)^{1/2} \left\| \sup_j |(\nabla \phi)_j * f| \right\|_\infty \\ &\le C \|M[f]\|_\infty \le C \|f\|_\infty, \end{aligned} \tag{2.9}$$

where $(\nabla\phi)_j(x) = 2^{nj} \nabla\phi(2^j x)$. From (2.8) and (2.9), we obtain the last inequality (2.6). □

3. The harmonic heat flow. In this section, we give the proof of the regularity criterion to the weak solution of the harmonic heat flow equation onto a sphere:

$$\begin{cases} \partial_t u - \Delta u = u(\nabla u, \nabla u), & t > 0, x \in \mathbb{R}^n, \\ u(t,x) : \mathbb{R}_+ \times \mathbb{R}^n \to \mathbb{S}^m, & t > 0, x \in \mathbb{R}^n, \\ u(0,x) = u_0(x), \end{cases} \tag{3.1}$$

where $u(\nabla u, \nabla u) = u_i \sum_{1 \le l,j \le n} |\nabla_l u_j|^2$ denotes the second fundamental form on the sphere, and in the following we express this form as $u|\nabla u|^2$ except when it may cause confusion.

The proof is in fact a simple application to the argument in the previous section.

Proof of Theorem 1.2. We first give a proof for $n < p < \infty$. Let u be a smooth solution to (3.1) on $[0, T)$. By operating the Laplacian to the equation and then taking an L^2 inner product of the equation with $|\Delta u|^{q-2}\Delta u$, we have

$$\begin{aligned} \frac{1}{q}\frac{d}{dt}\|\Delta u(t)\|_q^q &+ \int_{\mathbb{R}^n} \nabla_k \Delta u(t) \cdot \nabla_k (|\Delta u|^{q-2}\Delta u(t))dx \\ &= \int_{\mathbb{R}^n} |\nabla u(t)|^2 \Delta u(t) \cdot |\Delta u(t)|^{q-2}\Delta u(t)dx \\ &\quad + \int_{\mathbb{R}^n} \nabla_k u(t) \cdot \nabla_k |\nabla u(t)|^2 |\Delta u(t)|^{q-2}\Delta u(t)dx \\ &\quad - \int_{\mathbb{R}^n} u(t)\nabla_k |\nabla_l u(t)|^2 \cdot \nabla_k (|\Delta u(t)|^{q-2}\Delta u(t))dx \\ &= (|\nabla u(t)|^2, |\Delta u(t)|^q) \\ &\quad + 2(\nabla_k u(t)(\nabla_l u(t) \cdot \nabla_k \nabla_l u(t)), |\Delta u(t)|^{q-2}\Delta u(t)) \\ &\quad - 2(u(t)(\nabla_l u(t) \cdot \nabla_k \nabla_l u(t)), |\Delta u(t)|^{q-2}\nabla_k \Delta u(t)) \\ &\quad - 2(u(t)(\nabla_l u(t) \cdot \nabla_k \nabla_l u(t)), \Delta u(t)\nabla_k (|\Delta u(t)|^{q-2})) \\ &\equiv I_1 + I_2 + I_3 + I_4. \end{aligned} \tag{3.2}$$

The first and second terms I_1, I_2 in (3.2) are dominated by the elliptic estimate in L^q (cf. [18]),

$$I_1 + I_2 \le \|\nabla u\|_\infty^2 \|\Delta u\|_q^q. \tag{3.3}$$

For the third term I_3, we again use the elliptic estimate to get

$$\begin{aligned} I_3 &\le \|u\|_\infty \int_{\mathbb{R}^n} |\nabla u||\nabla_k \nabla_l u| \cdot |\Delta u|^{q-2}|\nabla_k \Delta u|dx \\ &\le \|u\|_\infty \left(\int_{\mathbb{R}^n} |\nabla u|^2 |\Delta u|^{q-2} |\nabla_k \nabla_l u|^2 dx \right)^{1/2} \left(\int_{\mathbb{R}^n} |\Delta u|^{q-2} |\nabla_k \Delta u|^2 dx \right)^{1/2} \\ &\le C \int_{\mathbb{R}^n} |\nabla u|^2 |\Delta u|^{q-2} |\nabla_k \nabla_l u|^2 dx + \varepsilon \int_{\mathbb{R}^n} |\Delta u|^{q-2} |\nabla_k \Delta u|^2 dx \\ &\le C\|\nabla u\|_\infty^2 \|\Delta u\|_q^q + \frac{1}{2} \int_{\mathbb{R}^n} |\Delta u|^{q-2} |\nabla_k \Delta u|^2 dx. \end{aligned} \tag{3.4}$$

The last term I_4 can be dealt with in a similar manner:

$$
\begin{aligned}
I_4 &= \int_{\mathbb{R}^n} u_i \nabla_l u_j \nabla_k \nabla_l u_j \Delta u_i \nabla_k (|\Delta u|^2)^{(q-2)/2} dx \\
&= \frac{q-2}{2} \int_{\mathbb{R}^n} u_i \nabla_l u_j \nabla_k \nabla_l u_j \Delta u_i |\Delta u|^{q-4} \nabla_k (|\Delta u|^2) dx \\
&= (q-2) \int_{\mathbb{R}^n} u_i \nabla_l u_j \nabla_k \nabla_l u_j \Delta u_i |\Delta u|^{q-4} (\Delta u \cdot \nabla_k \Delta u) dx \\
&\le (q-2) \|u\|_\infty \left(\int_{\mathbb{R}^n} |\nabla u|^2 |\Delta u|^{q-2} |\nabla_k \nabla_l u|^2 dx \right)^{1/2} \left(\int_{\mathbb{R}^n} |\Delta u|^{q-2} |\nabla_k \Delta u|^2 dx \right)^{1/2} \\
&\le C \|\nabla u\|_\infty^2 \|\Delta u\|_q^q + \frac{1}{2} \int_{\mathbb{R}^n} |\Delta u|^{q-2} |\nabla_k \Delta u|^2 dx.
\end{aligned} \tag{3.5}
$$

On the other hand, the second term in the left-hand side of (3.2) is

$$
\begin{aligned}
&\int_{\mathbb{R}^n} \nabla_k \Delta u \cdot \nabla_k (|\Delta u|^{q-2} \Delta u) dx \\
&\quad = \int_{\mathbb{R}^n} |\Delta u|^{q-2} |\nabla_k \Delta u|^2 dx + \frac{1}{2} \int_{\mathbb{R}^n} \nabla_k |\Delta u|^2 \cdot \nabla_k |\Delta u|^{q-2} dx \\
&\quad = \int_{\mathbb{R}^n} |\Delta u|^{q-2} |\nabla_k \Delta u|^2 dx + \frac{q-2}{4} \int_{\mathbb{R}^n} |(|\Delta u|^2)^{(q-4)/4} \nabla_k |\Delta u|^2|^2 dx \\
&\quad = \int_{\mathbb{R}^n} |\Delta u|^{q-2} |\nabla_k \Delta u|^2 dx + \frac{4(q-2)}{q^2} \int_{\mathbb{R}^n} |\nabla (|\Delta u|^2)^{q/4}|^2 dx.
\end{aligned} \tag{3.6}
$$

Hence, by gathering estimates (3.3)–(3.5) and (3.6) and plugging them into (3.2), it follows that

$$
\begin{aligned}
&\frac{1}{q} \frac{d}{dt} \|\Delta u(t)\|_q^q + \frac{4(q-2)}{q^2} \|\nabla |\Delta u|^{q/2}\|_2^2 \\
&\qquad \le C \|\nabla u\|_\infty^2 \|\Delta u\|_q^q.
\end{aligned} \tag{3.7}
$$

Integration (3) over $[0, T]$ and the Young inequality imply

$$
\|\Delta u(t)\|_q^q \le \|\Delta u(0)\|_q^q + C(\varepsilon) \int_0^T \|\nabla u\|_\infty^2 \|\Delta u(\tau)\|_q^q d\tau. \tag{3.8}
$$

Noting the energy inequality (1.2), the logarithmic inequality (2.6) in Corollary 2.4 yields that, for $\gamma > n/q$ and $q > n$,

$$
\begin{aligned}
\|\nabla u\|_\infty &\le C(1 + \|\nabla u\|_{BMO} (\log^+ (\|\nabla u_+\|_{W^{1,q}} + \|u\|_\infty))^{1/2}) \\
&\le C(1 + \|\nabla u\|_{BMO} (\log^+ (\|\nabla u\|_{W^{1,q}} + 1))^{1/2}).
\end{aligned} \tag{3.9}
$$

Hence it follows from (3.8) and (3.9) that

$$
\begin{aligned}
\|\Delta u(t)\|_q^q &\le \|\Delta u_0\|_q^q + C \int_0^T \|\nabla u(\tau)\|_\infty^2 \|\Delta u(\tau)\|_q^q d\tau \\
&\le \|\Delta u_0\|_q^q + C \int_0^T \|\nabla u\|_{BMO}^2 (1 + \log^+ (\|\nabla u(\tau)\|_{W^{1,q}} + 1)^{\frac{1}{2}})^2 \|\Delta u(\tau)\|_q^q d\tau.
\end{aligned} \tag{3.10}
$$

Combining the energy inequality

$$\|\nabla u(t)\|_2^2 + 2\int_0^t \|\partial_t u(\tau)\|_2^2 d\tau \le \|\nabla u_0\|_2^2$$

with $\|u\|_\infty = 1$, we conclude by the Gronwall argument that

$$\|\nabla u(t)\|_{W^{1,q}}^q \le C\|\nabla u_0\|_{W^{1,q}}^q \exp\left\{C\exp\left(C\int_0^T (1+\|\nabla u\|_{BMO}^2)d\tau\right)\right\}.$$

This estimate ensures that the solution has regularity in $C((0,T];\dot{W}^{2,q})$ under the assumption (1.9). Since we have chosen that $q > n$, the Sobolev embedding implies that $\nabla u(t)$ is a continuous function in (x,t). A general argument for the harmonic heat flow gives the higher regularity. This completes the proof of Theorem 1.2. □

Acknowledgments. The author would like to thank Professor Masashi Misawa, Professor George Weiss, and Dr. Tôru Nakajima for stimulating discussion.

A GAS-SOLID FREE BOUNDARY PROBLEM FOR A COMPRESSIBLE VISCOUS GAS*

FEIMIN HUANG†‡, AKITAKA MATSUMURA†, AND XIAODING SHI†§

Abstract. In this paper we propose a gas-solid free boundary problem for a one-dimensional model system of a compressible viscous gas associated with the inflow problem, where the solid constantly changes into the gas and produces the inflow of the gas on the free boundary. We first show the existence of the traveling wave solution and its asymptotic stability. We further discuss the case in which the asymptotic state of the solution is given by a combination of the traveling wave solution and rarefaction wave.

Key words. gas-solid free boundary, compressible viscous gas, traveling wave, rarefaction wave

AMS subject classification. 35L65

1. Introduction. We consider the one-dimensional barotropic motion of compressible viscous gas and study the situation where the gas is adjacent to the solid by the free boundary $\tilde{x} = X(t)$. In what follows we use the *Eulerian* coordinates $(\tilde{x}, t)$ to represent the spatial and time variables. We assume that the part $\tilde{x} < X(t)$ is filled by the solid whose density $\bar{\rho}$ is a given positive constant and whose velocity $\bar{u}$ is zero, and that the part $\tilde{x} > X(t)$ is filled by the gas with the density $\tilde{\rho}(\tilde{x}, t)$ and velocity $\tilde{u}(\tilde{x}, t)$ satisfying the conservation of mass

$$\tilde{\rho}_t + (\tilde{\rho}\tilde{u})_{\tilde{x}} = 0 \tag{1.1}$$

and the conservation of momentum

$$(\tilde{\rho}\tilde{u})_t + (\tilde{\rho}\tilde{u}^2 + \tilde{p} - \mu\tilde{u}_{\tilde{x}})_{\tilde{x}} = 0, \tag{1.2}$$

where the pressure $\tilde{p}$ is a given function of $\tilde{\rho}$, and the viscosity coefficient μ is a given positive constant. Here we should note that in the solid part, $\tilde{\rho} = \bar{\rho}$ and $\tilde{u} = \bar{u} = 0$ also satisfy (1.1) and (1.2). On the free boundary, so that the conservation of mass holds, we assume the Rankine–Hugoniot condition

$$-\frac{dX(t)}{dt}(\tilde{\rho} - \bar{\rho}) + (\tilde{\rho}\tilde{u} - \bar{\rho}\bar{u}) = 0 \quad \text{on } \tilde{x} = X(t),$$

which implies

$$\frac{dX(t)}{dt} = \frac{\tilde{\rho}\tilde{u}}{\tilde{\rho} - \bar{\rho}}. \tag{1.3}$$

Depending on the sign of $X'(t)$ and also on whether $\tilde{\rho}$ is more or less than $\bar{\rho}$, we can consider various situations. Among them we study here the situation

$$\tilde{\rho} < \bar{\rho}, \qquad \frac{dX(t)}{dt} < 0. \tag{1.4}$$

It is noted that the first condition is physically natural because the density of the gas changed in phase from the solid is usually much less than that of the solid, and the second condition makes us focus on the phase transition process from the solid to the gas. In this situation, since the density in front of the free boundary is more than that in back of the boundary, the discontinuity of the solution at the boundary is not a classical shock but a *detonation*-type discontinuity. By (1.3) we also know the velocity $\tilde{u}$ on the boundary is positive, which means the gas constantly flows in from the free boundary, so this situation is closely related to the inflow problem on the half space for (1.1), (1.2) (cf. [5, 19]). We discuss this matter more later. Since we need another boundary condition on the density in this inflow situation, we assume

$$\tilde{\rho} = \rho_b \quad \text{on } \tilde{x} = X(t), \qquad \tilde{p}(\rho_b) = \bar{p} := \tilde{p}(\bar{\rho}), \tag{1.5}$$

where $\rho_b\,(< \bar{\rho})$ is a given positive constant, and the second assumption means the pressure is continuous across the interface. We also assume

$$\tilde{p}(\tilde{\rho}) > 0, \quad \tilde{p}'(\tilde{\rho}) > 0, \quad \tilde{p}''(\tilde{\rho}) \geq 0 \qquad \text{in a neighborhood of } \tilde{\rho} = \rho_b, \tag{1.6}$$

which means that once the solid changes to the gas it follows the standard property of pressure-density relation as barotropic gas. Since we need another boundary condition to determine the movement of the free boundary, the data of the density, and momentum on the boundary, we also assume another Rankine–Hugoniot condition for the conservation of momentum

$$-\frac{dX}{dt}\tilde{\rho}\tilde{u} + \tilde{\rho}\tilde{u}^2 + \tilde{p} - \mu\tilde{u}_{\tilde{x}} - \bar{p} = 0 \quad \text{on } \tilde{x} = X(t). \tag{1.7}$$

By (1.3), (1.5), and (1.7), we have a nonlinear Neumann condition for the velocity

$$\mu\tilde{u}_{\tilde{x}} = \frac{\bar{\rho}\rho_b}{\bar{\rho} - \rho_b}\tilde{u}^2. \tag{1.8}$$

We know that to be more physical, especially to unify the arguments of fluid dynamical aspects and that of Stephan problems, we should further take into account the conservation of energy and its Rankine–Hugoniot condition with a jump of energy structure. However, even for 2×2 systems like (1.1), (1.2) there have been no mathematical results under the free boundary condition like (1.3) because of various difficulties. In all previous works (e.g., Kazhikhov [10], Nagasawa [20]) they assume

$$\frac{dX(t)}{dt} = \tilde{u}, \tag{1.9}$$

which means the particles on the free boundary always stay on the boundary. In this case, if we introduce the Lagrangian mass coordinates, we can reformulate the problem to that with the fixed boundary. On the other hand, in our case (1.3) we cannot do it, which gives us serious difficulty. We believe that to investigate a simple mathematical model as (1.1), (1.2) under the conditions (1.3), (1.8) is a quite meaningful one-step to overcoming mathematical difficulties and proceeding to more general problems. We

should note that Kaliev and Kazhikhov [7] showed the existence and uniqueness of the local solution for a free boundary value problem which does not satisfy (1.9). But in their case they assumed that there is no discontinuity of the density. That is, $\tilde{\rho} = \rho_b$ on the boundary. Thus we propose and concentrate on the following system in the *Eulerian* coordinates:

$$
\begin{cases}
\tilde{\rho}_t + (\tilde{\rho}\tilde{u})_{\tilde{x}} = 0 & \text{in } \tilde{x} > X(t), \\
(\tilde{\rho}\tilde{u})_t + (\tilde{\rho}\tilde{u}^2 + \tilde{p})_{\tilde{x}} = \mu \tilde{u}_{\tilde{x}\tilde{x}} & \text{in } \tilde{x} > X(t), \\
\tilde{\rho}(X(t), t) = \rho_b, & \\
\mu \tilde{u}_{\tilde{x}}(X(t), t) = \dfrac{\rho_b \bar{\rho}}{\bar{\rho} - \rho_b} \tilde{u}^2(X(t), t), & \\
\dfrac{dX(t)}{dt} = \dfrac{\rho_b}{\rho_b - \bar{\rho}} \tilde{u}(X(t), t) & X(0) = 0, \\
(\tilde{\rho}, \tilde{u})|_{(+\infty, t)} = (\rho_+, u_+), & \\
(\tilde{\rho}, \tilde{u})|_{t=0} = (\rho_0, u_0). &
\end{cases}
\tag{1.10}
$$

It is worthwhile to point out that in (1.10) the density $\tilde{\rho}$ must be imposed on the boundary because the boundary is moving to the left, while the fluid particles on the boundary are moving to the right, so that characteristics for the $\tilde{\rho}$ equation come *out* of the boundary in forward time.

In this paper we first investigate the existence of the traveling wave solution of (1.10) and establish its asymptotic stability. We further discuss the case in which the asymptotic state of the solution is expected to consist of the traveling wave solution and rarefaction wave.

We now state the relations of (1.10) to the inflow problem with the fixed boundary and recall the results on it. We consider the case $X(t) = \bar{s}t (\bar{s} < 0)$. Let $y = \tilde{x} - \bar{s}t$, $z(y, t) = \tilde{u}(\tilde{x}, t) - \bar{s}$, $\rho(y, t) = \tilde{\rho}(\tilde{x}, t)$; then (1.3) and (1.5) yield the following boundary condition:

$$
\rho|_{y=0} = \rho_b > 0, \quad z|_{y=0} = -\frac{\bar{\rho}\bar{s}}{\rho_b} =: u_b > 0.
$$

Thus the system (1.10) is changed into

$$
\begin{cases}
\rho_t + (\rho z)_y = 0 & \text{in } y > 0, \\
(\rho z)_t + (\rho z^2 + p)_y = \mu z_{yy} & \text{in } y > 0, \\
\rho(0, t) = \rho_b > 0, & \\
z(0, t) = u_b > 0, & \\
(\rho, z)|_{(+\infty, t)} = (\rho_+, u_+ - \bar{s}), & \\
(\rho, z)|_{t=0} = (\rho_0, u_0 - \bar{s}), &
\end{cases}
\tag{1.11}
$$

where $p = \tilde{p}(\rho(y, t))$.

The problem (1.11) is called the inflow problem with the fixed boundary. In this situation, a new wave, denoted by the boundary layer solution, or BL-solution, appears in the solutions due to the presence of a boundary. Matsumura [13] classified all possible large time behaviors of the solutions in terms of the boundary values. Matsumura and Nishihara [19] and we [5] have proved that if the boundary values are in the subsonic region, the solution tends to the superposition of a BL-solution and

a rarefaction wave, and the superposition of a BL-solution and a viscous shock wave under some smallness conditions. Shi [23] studied the rarefaction wave case when the boundary values are in the supersonic region. We refer the readers to [5, 13, 19, 23].

We now concentrate on the free boundary problem (1.10). We here transform (1.10) to the problem in the Lagrangian coordinate:

$$
\begin{cases}
v_t - u_x = 0, & x > x(t), \quad t > 0,\\
u_t + p(v)_x = \mu\left(\dfrac{u_x}{v}\right)_x, & x > x(t), \quad t > 0,\\
v(x(t),t) = v_b,\\
\mu u_x(x(t),t) = \dfrac{v_b}{v_b - \bar{v}} u^2(x(t),t),\\
\dfrac{dx(t)}{dt} = \dfrac{1}{\bar{v} - v_b} u(x(t),t), \quad x(0) = 0,\\
(v,u)|_{(+\infty,t)} = (v_+, u_+) = \left(\dfrac{1}{\rho_+}, u_+\right),\\
(v,u)|_{t=0} = (v_0, u_0), \quad v_0(0) = v_b,
\end{cases}
\tag{1.12}
$$

where $v = 1/\rho$. The transformation $(\tilde{x}, t) \to (x, t)$ is given by

$$
\begin{cases}
\dfrac{\partial \tilde{x}(x,t)}{\partial t} = \tilde{u}(\tilde{x}(x,t),t), \quad t > 0, \quad x > 0\\
\tilde{x}(x,0) = \tilde{x}_0(x),
\end{cases}
$$

with

$$
\int_0^{\tilde{x}_0(x)} \tilde{\rho}(r,0)dr = x,
$$

where $(\tilde{x}, t) \in \sum_1 = \{(\tilde{x}, t); \tilde{x} > \tilde{x}(0, t)\}$, and by

$$
\begin{cases}
\dfrac{\partial \tilde{x}(x,t)}{\partial t} = \tilde{u}(\tilde{x}(x,t),t), \quad t > t_0(x), \quad x > 0\\
\tilde{x}(x, t_0(x)) = X(t_0(x)),
\end{cases}
$$

with

$$
x = \int_0^{X(t_0(x))} \rho_b dr - \int_0^{t_0(x)} \rho_b \tilde{u}(X(t),t)dt = \bar{\rho} X(t_0(x)),
$$

where $(\tilde{x}, t) \in \sum_2 = \{(\tilde{x}, t); X(t) < \tilde{x} < \tilde{x}(0, t)\}$. From the definition, we have

$$
x \geq x(t) = \bar{\rho} X(t)
$$

and

$$
\int_{\tilde{x}(0,t)}^{\tilde{x}(x,t)} \tilde{\rho}(r,t)dr = x
$$

for $(\tilde{x}, t) \in \sum_i (i = 1, 2)$. Hence, for $f(x, t) = \tilde{f}(\tilde{x}(x, t), t)$,

$$
\frac{\partial}{\partial t} f(x,t) = \left(\frac{\partial}{\partial t} + u\frac{\partial}{\partial \tilde{x}}\right)\tilde{f}(\tilde{x}(x,t),t), \quad \frac{\partial}{\partial x} f(x,t) = v\frac{\partial}{\partial \tilde{x}}\tilde{f}(\tilde{x}(x,t),t),
$$

which gives (1.12).

We now seek a traveling wave solution of (1.12). The argument of section 2 shows that for any given $0 < \bar{v} < v_b < v_+$, if

$$u_+ = (v_+ - \bar{v})^{\frac{1}{2}}(p(v_b) - p(v_+))^{\frac{1}{2}}, \quad u_b = \frac{\bar{v} - v_b}{\bar{v} - v_+}u_+, \quad \bar{s} = \frac{u_b}{\bar{v} - v_b}, \tag{1.13}$$

there exists a unique traveling wave solution $(V, U)(\xi)$, $\xi = x - \bar{s}t$, satisfying

$$\begin{cases} -\bar{s}V' - U' = 0, \\ -\bar{s}U' + p(V)' = \mu\left(\dfrac{U'}{V}\right)', \end{cases} \tag{1.14}$$

with

$$\begin{cases} V(0) = v_b, \quad U(0) = u_b, \quad \mu U'(0) = v_b(v_b - \bar{v})\bar{s}^2, \\ V(+\infty) = v_+, \quad U(+\infty) = u_+, \end{cases} \tag{1.15}$$

provided that $u_+^2 < (v_+ - \bar{v})^2|p'(v_+)|$. We call (V, U) the traveling wave solution. Therefore for any $0 < \bar{v} < v_b < +\infty$, the traveling wave solution curve with the parameter $\bar{v}$ through the point $(v_b, 0)$ in the phase plane is defined by

$$\begin{aligned} &TW_{\bar{v}}(v_b, 0) \\ &= \left\{(v, u); u = (v - \bar{v})^{\frac{1}{2}}(p(v_b) - p(v))^{\frac{1}{2}}, u^2 < (v - \bar{v})^2|p'(v)|, v > v_b\right\}. \end{aligned} \tag{1.16}$$

When $(v_+, u_+) \in TW_{\bar{v}}(v_b, 0)$, the solution of (1.12) is expected to tend to the traveling wave solution satisfying (1.13)–(1.15) as t tends to infinity.

On the other hand, it is known that the 2-rarefaction curve $R_2(v_b, 0)$ through the point $(v_b, 0)$ is

$$R_2(v_b, 0) = \left\{(v, u); u = -\int_{v_b}^{v} \lambda_2(s)ds, v < v_b\right\} \tag{1.17}$$

and $R_2(v_p, u_p)$ through the point (v_p, u_p) is

$$R_2(v_p, u_p) = \left\{(v, u); u = u_p - \int_{v_p}^{v} \lambda_2(s)ds, v < v_p\right\}, \tag{1.18}$$

where $\lambda_2 = \sqrt{-p'(v)}$ is the second characteristic speed of the corresponding hyperbolic system without viscosity and

$$u_p = (v_p - \bar{v})^{\frac{1}{2}}(p(v_b) - p(v_p))^{\frac{1}{2}}, \quad u_p^2 = (v_p - \bar{v})^2|p'(v_p)|.$$

Then let us define $R_2TW_{\bar{v}}(v_b, 0)$ as the domain surrounded by curves $TW_{\bar{v}}(v_b, 0)$, $R_2(v_b, 0)$, $R_2(v_p, u_p)$, and the u-axis. When (v_+, u_+) is in $R_2TW_{\bar{v}}(v_b, 0)$, the solution of (1.12) is expected to tend to the superposition of a traveling wave solution and a 2-rarefaction wave as t tends to infinity.

Our aim in this present paper is to investigate the stability of the traveling wave solution and of a superposition of the traveling wave solution and the 2-rarefaction wave. Our results are, roughly speaking, as follows.

(I) If $(v_+, u_+) \in TW_{\bar{v}}(v_b, 0)$, then the traveling wave solution is stable, provided that $|v_+ - v_b|$ is small. The precise statement is given in Theorem 4.1 below.

(II) If $(v_+, u_+) \in R_2TW_{\bar{v}}(v_b, 0)$, then there exists $(v_*, u_*) \in TW_{\bar{v}}(v_b, 0)$ such that $(v_+, u_+) \in R_2(v_*, u_*)$, and the superposition of the traveling wave solution connecting (v_b, u_b) with (v_*, u_*) and the 2-rarefaction wave connecting (v_*, u_*) with (v_+, u_+) is stable provided that $|v_* - v_b|$ is small. That is, the traveling wave solution is necessary to be weak; however, the 2-rarefaction wave is not necessarily weak. The precise statement is given in Theorem 5.3 below.

Remark. Although we only study the case (1.4) in this paper, the case $\tilde{\rho} > \bar{\rho}$, $\frac{dX(t)}{dt} < 0$ could be treated by the same method. We note that in this case both the boundary and the fluid are moving to the left. However, the fluid speed is faster than that of the boundary. Therefore, similar to the case (1.4), the characteristics for the $\tilde{\rho}$ equation still come *out* of the boundary in forward time and the density $\tilde{\rho}$ must be imposed on the boundary.

It is interesting to compare our results with those of the traveling wave with shock profile. For the stability of the viscous shock wave, it is known that the scalar equation has been extensively investigated (cf. [6, 21, 22]). Studies on systems began with the independent works of Goodman [3] and Matsumura and Nishihara [15] with zero mass. The generic initial perturbations were investigated by Liu [11] and Szepessy and Xin [24]. Unlike the viscous shock wave, since the traveling wave is unique here, it is not necessary to locate which of its translates the perturbed solution converges to. Therefore we do not need any hypothesis that states that the perturbations in Theorems 4.1 and 5.3 have zero mass.

Our method is based on the energy estimates and a new approximation to the rarefaction wave. It is noted that the new approximation could be applied to extend the results of [19]—where a stability theorem for the superposition of a BL-solution and a weak rarefaction wave with the fixed boundary was obtained by Matsumura and Nishihara—to the strong rarefaction wave.

Our paper is organized as follows. In sections 2–4, we focus on case I. Precisely speaking, in section 2, we study the existence of the traveling wave solution. In section 3, we reformulate the original problem to a new initial boundary value problem and prove the local existence of the solution. In section 4, we establish the a priori estimates and then prove the stability of the traveling wave solution. In section 5, case II is treated.

Notation. Throughout this paper, several positive generic constants are denoted by c, C without confusion. For function spaces, $L^p(\Omega), 1 \le p \le \infty$, denotes a usual Lebesgue space on $\Omega \subset R = (-\infty, \infty)$ with its norm

$$\|f\|_{L^p(\Omega)} = \left(\int_\Omega |f(x)|^p dx \right)^{\frac{1}{p}}, \quad 1 \le p < \infty, \quad \|f\|_{L^\infty(\Omega)} = \sup_\Omega |f(x)|. \tag{1.19}$$

$H^l(\Omega)$ denotes the lth order Sobolev space with its norm

$$\|f\|_l = \left(\sum_{j=0}^{l} \|\partial_x^j f\|^2 \right)^{\frac{1}{2}}, \quad \text{when } \|\cdot\| := \|\cdot\|_{L^2(\Omega)}. \tag{1.20}$$

The domain Ω will often be abbreviated to avoid confusion.

2. Existence of the traveling wave solution. In this section we investigate the existence of the traveling wave solution $(V,U)(\xi)$, $\xi = x - \bar{s}t$, satisfying

$$\begin{cases} -\bar{s}V' - U' = 0, \qquad ' = d/d\xi, \quad \xi = x - \bar{s}t, \\ -\bar{s}U' + p(V)' = \mu\left(\dfrac{U'}{V}\right)', \\ V(0) = v_b, \quad U(0) = u_b, \\ \mu U'(0) = v_b(v_b - \bar{v})\bar{s}^2, \\ V(+\infty) = v_+, \quad U(+\infty) = u_+, \end{cases} \tag{2.1}$$

where

$$\bar{s} = \frac{u_b}{\bar{v} - v_b} < 0. \tag{2.2}$$

We have the following existence result.

LEMMA 2.1. *For any given $\bar{v}, v_b$, and v_+ with $0 < \bar{v} < v_b < v_+$, when*

$$u_b = \frac{\bar{v} - v_b}{\bar{v} - v_+}u_+, \quad u_+ = (v_+ - \bar{v})^{\frac{1}{2}}(p(v_b) - p(v_+))^{\frac{1}{2}}, \tag{2.3}$$

there exists a unique solution $(V,U)(\xi)$ to (2.1) and (2.2) satisfying $0 < v_b < V(\xi) < v_+, V' > 0$, provided that $u_+^2 < (v_+ - \bar{v})^2|p'(v_+)|$. Furthermore, fix $\bar{v}$ and v_b, and let $v_+ - v_b = \delta$; then there exists a positive constant $\delta_0 > 0$ such that, for any $\delta \le \delta_0$,

$$|V(\xi) - v_+| = O(\delta)e^{-\frac{c}{\sqrt{\delta}}\xi} \tag{2.4}$$

and

$$u_+, \bar{s}, u_b = O(\delta^{\frac{1}{2}}), \quad V' = O(\delta^{\frac{1}{2}})e^{-\frac{c}{\sqrt{\delta}}\xi}. \tag{2.5}$$

Proof. When (V,U) exists, the integration of (2.1) with respect to ξ yields

$$\begin{cases} \bar{s}V + U = \bar{s}v_b + u_b = \bar{s}v_+ + u_+, \\ \mu\dfrac{U'}{V} = p(V) + \bar{s}^2(V - v_+) - p(v_+). \end{cases} \tag{2.6}$$

Let $\xi = 0$; then (2.3) holds. By (2.6) we have the ordinary equation

$$\begin{cases} -\bar{s}\mu\dfrac{V'}{V} = \mathcal{F}(V) := p(V) + \bar{s}^2(V - v_+) - p(v_+), \\ V(0) = v_b, \quad V(+\infty) = v_+. \end{cases} \tag{2.7}$$

To the contrary, since

$$u_+^2 < (v_+ - \bar{v})^2|p'(v_+)| \tag{2.8}$$

implies $\mathcal{F}(V) > 0$ for $v_b < V < v_+$, it is easy to see there exists a unique solution (V,U) of (2.1). Furthermore, (2.3) and (2.7) imply that the solution satisfies (2.4) and (2.5) if $v_+ - v_b$ is suitably small. Thus Lemma 2.1 is proved.

3. Local existence of the solution. In this section, we first reformulate (1.12) to a new initial-boundary value problem and then prove the local existence of the solution.

Assume that $(v_+, u_+) \in TW_{\bar{v}}(v_b, 0)$. Then Lemma 2.1 gives a unique solution $(V, U)(\xi), \xi = x - \bar{s}t \geq 0$, satisfying

$$\begin{cases} -\bar{s}V' - U' = 0, \\ -\bar{s}U' + p(V)' = \mu\left(\dfrac{U'}{V}\right)', \\ V(0) = v_b, U(0) = u_b, \\ \mu U'(0) = v_b(v_b - \bar{v})\bar{s}^2, \\ (V, U)|_{(+\infty)} = (v_+, u_+), \end{cases} \tag{3.1}$$

where $\bar{s} = \frac{u_b}{\bar{v} - v_b} < 0$ and u_b, u_+ satisfies (2.3). To investigate the free boundary problem (1.12), we consider the coordinate transformation

$$t = t, \quad y = x - x(t), \tag{3.2}$$

where $x(t) = \bar{s}t + \gamma(t)$. By (3.2), we rewrite (1.12) as

$$\begin{cases} v_t - (\bar{s} + \gamma'(t))v_y - u_y = 0, & y > 0, \quad t > 0, \\ u_t - (\bar{s} + \gamma'(t))u_y + p(v)_y = \mu\left(\dfrac{u_y}{v}\right)_y, & y > 0, \quad t > 0, \\ v(0, t) = v_b, \\ \mu u_y(0, t) = \dfrac{v_b}{v_b - \bar{v}}u^2(0, t), \\ \dfrac{d\gamma(t)}{dt} = \dfrac{1}{\bar{v} - v_b}u(0, t) - \bar{s}, \quad \gamma(0) = 0, \\ (v, u)|_{(+\infty, t)} = (v_+, u_+), \\ (v, u)(y, 0) = (v_0, u_0)(y), \quad y > 0. \end{cases} \tag{3.3}$$

On the other hand, we take the traveling wave solution as the form $(V, U)(y)$. Thus, by (3.1) (V, U) satisfies

$$\begin{cases} -\bar{s}V_y - U_y = 0, & y > 0, \\ -\bar{s}U_y + p(V)_y = \mu\left(\dfrac{U_y}{V}\right)_y, & y > 0, \\ V(0) = v_b, U(0) = u_b, \\ \mu U_y(0) = v_b(v_b - \bar{v})\bar{s}^2, \\ (V, U)|_{(+\infty)} = (v_+, u_+). \end{cases} \tag{3.4}$$

We now put the perturbation $(\phi, \psi)(y, t)$ by

$$(v, u)(y, t) = (V, U)(y) + (\phi, \psi)(y, t), \tag{3.5}$$

so that the reformulated problem is

$$
\begin{cases}
\phi_t - (\bar{s}+\gamma'(t))\phi_y - \psi_y = \gamma'(t)V'(y), & y>0, \quad t>0,\\
\psi_t - (\bar{s}+\gamma'(t))\psi_y + (p(V+\phi)-p(V))_y & \\
-\mu\left(\dfrac{\psi_y}{V+\phi} + \dfrac{\bar{s}V'(y)\phi}{V(V+\phi)}\right)_y = -\bar{s}\gamma'(t)V'(y), & y>0, \quad t>0,\\
\phi(0,t)=0, & \\
\mu\psi_y(0,t) = \dfrac{2v_bu_b}{v_b-\bar{v}}\psi(0,t) + \dfrac{v_b}{v_b-\bar{v}}\psi^2(0,t), & \\
\gamma'(t) = \dfrac{1}{\bar{v}-v_b}\psi(0,t), \quad \gamma(0)=0, & \\
(\phi,\psi)|_{(+\infty,t)} = (0,0), & \\
(\phi,\psi)(y,0) = (\phi_0,\psi_0) = (v_0-V, u_0-U)(y). &
\end{cases} \tag{3.6}
$$

We shall combine the local existence and the a priori estimates to investigate the stability of the traveling wave solution. The a priori estimates will be treated in the next section. Here we only study the problem of local existence.

The solution space is

$$
\begin{aligned}
X_{m,M}(0,T) = \Big\{ & \phi \in C(0,T;H_0^1), \psi \in C(0,T;H^1) | \phi_y \in L^2(0,T;L^2),\\
& \psi_y \in L^2(0,T;H^1), \text{with } \sup_{[0,T]} \|(\phi,\psi)(t)\|_1 \le M,\\
& \inf_{R_+\times[0,T]} (V+\phi)(y,t) \ge m \Big\}
\end{aligned} \tag{3.7}
$$

for some positive constants m, M.

PROPOSITION 3.1 (local existence). *For any given $0<\bar{v}<v_b<+\infty$, there exist positive constants δ_0 and M_0 such that if $v_+ - v_b = \delta \le \delta_0$, $\phi_0 \in H_0^1$, $\psi_0 \in H^1$, $\|(\phi_0,\psi_0)\|_1 \le M(\le \frac{M_0}{b})$, and $\inf_{\mathbb{R}_+}(V+\phi_0) \ge m$, then there exists a positive constant $T_0 = T(m,M_0)$ such that there exists a unique solution $(\phi(y,t),\psi(y,t),\gamma(t))$ to (3.6) satisfying*

$$
\phi(y,t), \psi(y,t) \in X_{\frac{m}{2},bM}(0,T_0), \quad \gamma(t) \in C^1([0,T_0]),
$$

where $b = 3(1+2\sqrt{\frac{v_b}{\mu}} + \sqrt{\frac{2v_b}{v_b-\bar{v}}})$.

Proof. We first consider the characteristic equation of $(3.6)_1$. When $y \ge -x(t)$ ($x(t) = \bar{s}t + \gamma(t)$), the characteristic starts from the y-axis. That is, for any $\bar{x}_0 \ge 0$, the characteristic $y(\bar{x}_0,t)$ from $(\bar{x}_0,0)$ satisfies

$$
\begin{cases}
\dfrac{dy(\bar{x}_0,t)}{dt} = -\bar{s} - \gamma'(t),\\
y(\bar{x}_0,0) = \bar{x}_0,
\end{cases} \tag{3.8}
$$

which yields

$$
y(\bar{x}_0,t) = -x(t) + \bar{x}_0. \tag{3.9}
$$

Thus, ϕ has the explicit form

$$\phi(y,t)=\phi_0(\bar{x}_0)+\int_0^t \psi_y(\bar{x}_0-x(\tau),\tau)d\tau + \int_0^t \gamma'(\tau)V'(\bar{x}_0-x(\tau))d\tau, \quad \bar{x}_0=y+x(t). \tag{3.10}$$

In the same way, when $0\le y\le -x(t)$, the characteristic starts from the t-axis. It is noted that the inverse function of $x(t)$ exists if $|\gamma'(t)|=|\frac{1}{\bar{v}-v_b}\psi(0,t)|\le c\|\psi(t)\|_1$ is small. Thus, by $(3.6)_1$ and the boundary condition $\phi(0,t)=0$, we have

$$\phi(y,t)=\int_{\bar{t}_0}^t \psi_y(x(\bar{t}_0)-x(\tau),\tau)d\tau + \int_{\bar{t}_0}^t \gamma'(\tau)V'(x(\bar{t}_0)-x(\tau))d\tau, \quad \bar{t}_0=x^{-1}(y+x(t)). \tag{3.11}$$

On the other hand, $(3.6)_2$ is regarded as the initial-boundary value problem for the parabolic equation of ψ:

$$\begin{cases} \psi_t-\mu(\dfrac{\psi_y}{V+\phi})_y=g:=g(\phi,\phi_y,\psi(0,t),\psi_y) \\ \mu\psi_y(0,t)=\dfrac{2v_bu_b}{v_b-\bar{v}}\psi(0,t)+\dfrac{v_b}{v_b-\bar{v}}\psi^2(0,t), \\ \psi|_{t=0}=\psi_0, \end{cases} \tag{3.12}$$

where

$$\begin{aligned} & g(\phi,\phi_y,\psi(0,t),\psi_y) \\ = & -(p(V+\phi)-p(V))_y+\left(\bar{s}+\frac{1}{\bar{v}-v_b}\psi(0,t)\right)\psi_y \\ & +\mu\left(\frac{U_y}{V+\phi}-\frac{U_y}{V}\right)_y-\frac{\bar{s}}{\bar{v}-v_b}\psi(0,t)V'(y). \end{aligned}$$

By virtue of the boundary condition of (3.6), $\gamma(t)$ has the explicit form

$$\gamma(t)=\int_0^t \frac{1}{\bar{v}-v_b}\psi(0,\tau)d\tau. \tag{3.13}$$

We now approximate $\phi_0\in H^1_0, \psi_0\in H^1$ by $\phi_{0k}\in H^3\cap H^1_0, \psi_{0k}\in H^3$ such that

$$(\phi_{0k},\psi_{0k})\to(\phi_0,\psi_0) \quad \text{strongly} \quad \text{in} \quad H^1 \tag{3.14}$$

as $k\to\infty$ and $\|(\phi_{0k},\psi_{0k})\|_1\le\frac{3}{2}M$, $\inf_{R_+}(V+\phi_{0k})\ge\frac{2}{3}m$ hold for any k.

We will use the iteration method to prove Proposition 3.1. We define the sequence $\{(\phi_k^{(n)}(y,t),\psi_k^{(n)}(y,t),\gamma_k^{(n)}(t))\}$ for each k so that

$$(\phi_k^{(0)},\psi_k^{(0)})(y,t)=(\phi_{0k},\psi_{0k})(y), \quad \gamma_k^{(0)}(t)=\int_0^t \frac{1}{\bar{v}-v_b}\psi_{0k}(0)d\tau \tag{3.15}$$

and for a given $((\phi_k^{(n-1)}, \psi_k^{(n-1)})(y,t), \gamma_k^{(n-1)}(t))$, $\psi_k^{(n)}$ is a solution to

(3.16)
$$\begin{cases} \psi_{kt}^{(n)} - \mu\left(\dfrac{\psi_{ky}^{(n)}}{V+\phi_k^{(n-1)}}\right)_y = g^{(n-1)} = g\left(\phi_k^{(n-1)}, \phi_{ky}^{(n-1)}, \psi_k^{(n-1)}(0,t), \psi_{ky}^{(n-1)}\right), \\ \mu\psi_{ky}^{(n)}(0,t) = \dfrac{2v_b u_b}{v_b-\bar v}\psi_k^{(n)}(0,t) + \dfrac{v_b}{v_b-\bar v}[\psi_k^{(n)}(0,t)]^2, \\ \psi_k^{(n)}|_{t=0} = \psi_{0k}, \end{cases}$$

$$\gamma_k^{(n)}(t) = \int_0^t \frac{1}{\bar v - v_b}\psi_k^{(n)}(0,\tau)d\tau, \tag{3.17}$$

and

$$\phi_k^{(n)}(y,t) = \begin{cases} \displaystyle\int_{\bar t_k^{(n-1)}}^t \psi_{ky}^{(n)}(x_k^{(n-1)}(\bar t_k^{(n-1)}) - x_k^{(n-1)}(\tau), \tau)d\tau \\ \displaystyle + \int_{\bar t_k^{(n-1)}}^t [\gamma_k^{(n-1)}(\tau)]' V'(x_k^{(n-1)}(\bar t_k^{(n-1)}) - x_k^{(n-1)}(\tau))d\tau \\ \qquad \text{if} \quad 0 \le y \le -x_k^{(n-1)}(t), \\ \phi_{0k}(\bar x_k^{(n-1)}) + \displaystyle\int_0^t \psi_{ky}^{(n)}(\bar x_k^{(n-1)} - x_k^{(n-1)}(\tau), \tau)d\tau \\ \displaystyle + \int_0^t [\gamma_k^{(n-1)}(\tau)]' V'(\bar x_k^{(n-1)} - x_k^{(n-1)}(\tau))d\tau, \\ \qquad \text{if} \quad y \ge -x_k^{(n-1)}(t), \end{cases} \tag{3.18}$$

where

$$x_k^{(n-1)}(t) = \bar s t + \gamma_k^{(n-1)}(t),$$

$$\bar t_k^{(n-1)} = (x_k^{(n-1)})^{-1}(y + x_k^{(n-1)}(t)),$$

$$\bar x_k^{(n-1)} = y + x_k^{(n-1)}(t).$$

We now assume M_0 is small. By the principle of contraction mapping, it is easy to prove there exists a positive time $t_0(m, M_0) \ll 1$ such that if $g^{(n-1)} \in C(0, t_0; H^2)$ and $\psi_{0k} \in H^3$, there exists a unique local solution $\psi_k^{(n)}$ to (3.16) satisfying

$$\psi_k^{(n)} \in C(0,t_0;H^3) \cap C^1(0,t_0;H^1) \cap L^2(0,t_0;H^4)$$

and $|\psi_k^{(n)}(y,t)| \le CM_0$.

Thus, if $(\phi_k^{(n-1)}, \psi_k^{(n-1)}) \in X_{\frac{1}{2}m,bM}$, multiplying (3.16) by $\psi_k^{(n)}$ and integrating it over R_+, we have

$$\begin{aligned} &\|\psi_k^{(n)}(t)\|_t^2 + \frac{\mu}{v_+}\|\psi_{ky}^{(n)}\|^2 + \frac{4v_bu_b}{v_b-\bar v}[\psi_k^{(n)}(0,t)]^2 \\ \le\ & 2\int_0^\infty |g^{(n-1)}\psi_k^{(n)}|dy + C|\psi_k^{(n)}(0,t)|^3 \\ \le\ & C(m,M_0)(1+\|\psi_k^{(n)}(t)\|^2) + \frac{2v_bu_b}{v_b-\bar v}[\psi_k^{(n)}(0,t)]^2. \end{aligned} \tag{3.19}$$

Thus, we have $\|\psi_k^{(n)}(t)\|^2 \le (2M)^2$ due to $t_0 = t_0(m, M_0) \ll 1$ and

$$\int_0^{t_0} \|\psi_{ky}^{(n)}\|^2 dt \le \frac{v_+}{\mu}(2M)^2. \tag{3.20}$$

Multiplying (3.16) by $-\psi_{kyy}^{(n)}$ and integrating it over $\mathbb{R}_+$, one has, if δ_0 is suitably small,

$$\begin{aligned} &\left(\|\psi_{ky}^{(n)}\|^2 + \frac{2v_bu_b}{v_b-\bar v}[\psi_k^{(n)}(0,t)]^2 + \frac{2v_b}{3(v_b-\bar v)}[\psi_k^{(n)}(0,t)]^3\right)_t \\ &+\frac{\mu}{2v_+}\|\psi_{kyy}^{(n)}(t)\|^2 \le C(m,M_0) + \|\psi_{ky}^{(n)}\|^2. \end{aligned} \tag{3.21}$$

The integration of (3.21) over $(0,t)$ gives

$$\begin{aligned} &\|\psi_{ky}^{(n)}\|^2 + \frac{2v_bu_b}{v_b-\bar v}[\psi_k^{(n)}(0,t)]^2 + \frac{2v_b}{3(v_b-\bar v)}[\psi_k^{(n)}(0,t)]^3 \\ &+ \frac{\mu}{2v_+}\int_0^t \|\psi_{kyy}^{(n)}(\tau)\|^2 d\tau \\ \le\ & \|\psi_{0k}\|_1^2 + \frac{2v_bu_b}{v_b-\bar v}[\psi_{0k}(0)]^2 + \frac{2v_b}{3(v_b-\bar v)}|\psi_{0k}(0)|^3 \\ &+ C(m,M_0)t + \int_0^t \|\psi_{ky}^{(n)}\|^2 d\tau \\ \le\ & (2M)^2\left(1+\frac{2v_+}{\mu}+\frac{2v_bu_b}{v_b-\bar v}\right) \le (2M)^2\left(1+\frac{4v_b}{\mu}+\frac{2v_b}{v_b-\bar v}\right). \end{aligned} \tag{3.22}$$

Thus, we have

$$\|\psi_{ky}^{(n)}\|^2 \le \left(3\left(1+2\sqrt{\frac{v_b}{\mu}}+\sqrt{\frac{2v_b}{v_b-\bar v}}\right)M\right)^2 = (bM)^2 \tag{3.23}$$

and

$$\int_0^{t_0} \|\psi_{kyy}^{(n)}\|^2 dt \le \frac{2v_+}{\mu}(bM)^2. \tag{3.24}$$

On the other hand, a direct estimate on (3.18) together with (3.20), (3.23), and (3.24) gives

$$\|\phi_k^{(n)}(t)\|_1^2 \le (3M)^2 \tag{3.25}$$

and $\inf_{R_+\times[0,T]}(V+\phi_k^{(n)})(y,t) \geq \frac{1}{2}m$.

Therefore, $(\phi_k^{(n)}, \psi_k^{(n)}) \in X_{\frac{1}{2}m,bM}(0,t_0)$. From (3.17), it is easy to see $\gamma_k^{(n)}(t) \in C^1([0,t_0])$. By a standard way, $(\phi_k^{(n)}, \psi_k^{(n)})$ is a Cauchy sequence in $C(0,t_0;H^2)$. Thus we have a solution $(\phi_k(y,t), \psi_k(y,t), \gamma_k(t))$ by letting n tend to infinity, where $\gamma_k(t) = \int_0^t \frac{1}{\bar{v}-v_b}\psi_k(0,\tau)d\tau$. In the same way, letting $k \to \infty$, we obtain the desired unique-local solution $(\phi(y,t), \psi(y,t), \gamma(t))$ to (3.6), which satisfies $(\phi,\psi) \in X_{\frac{1}{2}m,bM}(0,T_0)$ and $\gamma(t) \in C^1([0,T_0])$ (taking T_0 smaller than t_0 if necessary).

4. Stability of the traveling wave solution. This section is devoted to the stability of the traveling wave solution. Our stability theorem is as follows.

THEOREM 4.1. *For any given $0 < \bar{v} < v_b < +\infty$, there exist positive constants δ_1 and C_1. If $(v_+,u_+) \in TW_{\bar{v}}(v_b,0)$, $v_+ - v_b = \delta \leq \delta_1$, $v_0 - V \in H_0^1$, $u_0 - U \in H^1$, and $\|v_0 - V, u_0 - U\|_1 \leq C_1\delta$, then there exists a global solution $(v(x,t), u(x,t), x(t))$ to* (1.12) *satisfying*

$$(v-V, u-U)(x,t) \in C(0,+\infty; H^1(x(t),+\infty)),$$

$$(v-V)_x(x,t) \in L^2(0,+\infty; L^2(x(t),+\infty)),$$

$$(u-U)_x(x,t) \in L^2(0,+\infty; H^1(x(t),+\infty)), \quad x(t) \in C^1([0,+\infty)),$$

$$x'(t) - \bar{s} \in L^2(0,+\infty),$$

and

$$\sup_{x\geq x(t)} |(v,u)(x,t) - (V,U)(x-x(t))| \to 0 \quad \textit{as} \quad t \to +\infty.$$

Theorem 4.1 is derived directly from local existence (Proposition 3.1) and the following a priori estimates.

PROPOSITION 4.2. *For any given $\bar{v}$ and v_b, there exist positive constants δ_1 and C_0. If $v_+ - v_b = \delta \leq \delta_1 (\leq \delta_0)$, $(\phi,\psi) \in X_{\frac{1}{4}v_b,bM}(0,T)$ with $M \leq \frac{C_0}{b}\delta$ is a solution to* (3.6) *for some positive constant T, then*

$$\begin{aligned} &\|(\phi,\psi)(t)\|_1^2 + \delta^{\frac{1}{2}}\int_0^t \psi^2(0,\tau)d\tau + \delta^{\frac{1}{2}}\int_0^t\int_0^\infty \phi^2 V'(y)dyd\tau \\ &+ \int_0^t \|\phi_y(\tau)\|^2 d\tau + \int_0^t \|\psi_y(\tau)\|_1^2 d\tau \leq C\|(\phi_0,\psi_0)\|_1^2, \end{aligned} \tag{4.1}$$

where $C > 1$ is a constant.

Proof. By virtue of the previous section, (ϕ,ψ) satisfies

$$
\begin{cases}
\phi_t-(\bar{s}+\gamma'(t))\phi_y-\psi_y=\gamma'(t)V'(y), & y>0,\quad t>0,\\
\psi_t-(\bar{s}+\gamma'(t))\psi_y+(p(V+\phi)-p(V))_y,\\
-\mu\big(\dfrac{\psi_y}{V+\phi}+\dfrac{\bar{s}V'(y)\phi}{V(V+\phi)}\big)_y=-\bar{s}\gamma'(t)V'(y), & y>0,\quad t>0,\\
\phi(0,t)=0,\\
\mu\psi_y(0,t)=\dfrac{2v_bu_b}{v_b-\bar{v}}\psi(0,t)+\dfrac{v_b}{v_b-\bar{v}}\psi^2(0,t),\\
\gamma'(t)=\dfrac{1}{\bar{v}-v_b}\psi(0,t),\quad \gamma(0)=0,\\
(\phi,\psi)|_{(+\infty,t)}=(0,0),\\
(\phi,\psi)(y,0)=(\phi_0,\psi_0)=(v_0-V,u_0-U)(y).
\end{cases}
\tag{4.2}
$$

Let

$$
\Phi(v,V)=p(V)\phi-\int_V^{V+\phi}p(s)ds.
$$

Multiplying the first equation of (4.2) by $(p(V)-p(V+\phi))$ and the second one by ψ, we have

$$
\begin{aligned}
&\left\{\left[\frac{1}{2}\psi^2+\Phi(v,V)\right]\right\}_t-(\bar{s}+\gamma')\Delta\phi V_y\\
&+\left\{(p(V+\phi)-p(V))\psi-(\bar{s}+\gamma')\left(\Phi(v,V)+\frac{1}{2}\psi^2\right)\right.\\
&\left.-\mu\left(\frac{\psi_y}{V+\phi}+\frac{\bar{s}V_y\phi}{V(V+\phi)}\right)\psi\right\}_y+\mu\frac{\psi_y^2}{V+\phi}\\
&+\frac{\mu\bar{s}V_y\psi_y\phi}{V(V+\phi)}+(p(V+\phi)-p(V))\gamma'V_y+\bar{s}\gamma'V_y\psi=0,
\end{aligned}
\tag{4.3}
$$

where $\Delta\phi=p(V+\phi)-p(V)-p'(V)\phi$ satisfies $c\phi^2\le\Delta\phi\le C\phi^2$.

Let $E=\int_0^\infty\frac{1}{2}\psi^2+\Phi(v,V)dy$. The integration of (4.3) over $R_+\times[0,T]$ gives

$$
\begin{aligned}
&E(t)-E(0)+\mu\int_0^t\int_0^\infty\frac{\psi_y^2}{V+\phi}dyd\tau-\int_0^t\int_0^\infty(\bar{s}+\gamma')\Delta\phi V_ydyd\tau\\
&+\int_0^t\left[\frac{1}{2}(\bar{s}+\gamma')\psi(0,\tau)+\mu\frac{\psi_y(0,\tau)}{v_b}\right]\psi(0,\tau)d\tau+\int_0^t\int_0^\infty\frac{\mu\bar{s}V_y\psi_y\phi}{V(V+\phi)}dyd\tau\\
&+\int_0^t\int_0^\infty(p(V+\phi)-p(V))\gamma'V_ydyd\tau+\int_0^t\int_0^\infty\bar{s}\gamma'V_y\psi dyd\tau=0.
\end{aligned}
\tag{4.4}
$$

Since $\bar{s}=O(\delta^{\frac{1}{2}})$ is negative and $|\gamma'|=O(\delta)$, we have

$$
-(\bar{s}+\gamma')\Delta\phi V_y\ge c\delta^{\frac{1}{2}}\phi^2V_y.
\tag{4.5}
$$

On the other hand, the boundary conditions of (4.2) give

$$\mu\frac{\psi_y(0,\tau)}{v_b}\psi(0,\tau)=\frac{2u_b}{v_b-\bar v}\psi^2(0,\tau)+\frac{1}{v_b-\bar v}\psi^3(0,\tau)\ge-\frac{3}{2}\bar s\psi^2(0,\tau), \tag{4.6}$$

which implies

$$\left[\frac{1}{2}(\bar s+\gamma')\psi(0,\tau)+\mu\frac{\psi_y(0,\tau)}{v_b}\right]\psi(0,\tau)\ge-\frac{1}{2}\bar s\psi^2(0,\tau)\ge c\delta^{\frac12}\psi^2(0,\tau). \tag{4.7}$$

Thus, from (4.4)–(4.7), we have

$$\begin{aligned}&E(t)-E(0)+\mu\int_0^t\int_0^\infty\frac{\psi_y^2}{V+\phi}dyd\tau+c\delta^{\frac12}\int_0^t\int_0^\infty\phi^2V_ydyd\tau\\&+c\delta^{\frac12}\int_0^t\psi^2(0,\tau)d\tau=-\int_0^t\int_0^\infty\frac{\mu\bar sV_y\psi_y\phi}{V(V+\phi)}dyd\tau\\&-\int_0^t\int_0^\infty(p(V+\phi)-p(V))\gamma'V_ydyd\tau-\int_0^t\int_0^\infty\bar s\gamma'V_y\psi dyd\tau.\end{aligned} \tag{4.8}$$

We now estimate each term on the right-hand side of (4.8). From Lemma 2.1 and

$$c\phi^2\le\Phi(v,V)\le C\phi^2, \tag{4.9}$$

we have

$$\frac{\mu\bar sV_y\psi_y\phi}{V(V+\phi)}\le\lambda\psi_y^2+C\bar s^2\phi^2V_y^2\le\lambda\psi_y^2+C\delta^{\frac32}\phi^2V_y, \tag{4.10}$$

$$\begin{aligned}&\int_0^\infty|(p(V+\phi)-p(V))\gamma'V_y|dy\\&\le C\int_0^\infty|\gamma'V_y\phi|dy\le C|\gamma'|\|\phi_y\|\int_0^\infty y^{\frac12}V_ydy\\&\le C\delta^{\frac54}|\gamma'|\|\phi_y\|\le\lambda\delta^{\frac12}|\gamma'|^2+C\delta^2\|\phi_y\|^2,\end{aligned} \tag{4.11}$$

and

$$\begin{aligned}\int_0^\infty\bar s\gamma'V_y\psi dy&=-\bar s\gamma'\int_0^\infty(V-v_+)\psi_ydy-\bar s(v_b-v_+)\gamma'\psi(0,\tau)\\&\le\lambda\|\psi_y\|^2+C\delta^{\frac32}\psi^2(0,\tau),\end{aligned} \tag{4.12}$$

where we have used the fact that

$$|\phi(y,\tau)|=\left|\int_0^y\phi_ydy\right|\le y^{\frac12}\|\phi_y\|,$$

due to [8] and λ is a suitably small positive constant.

Combining (4.8)–(4.12), we get the basic lemma.

LEMMA 4.3. *Let the conditions of Proposition* 4.2 *hold. Then*

$$\begin{aligned}&\|(\phi,\psi)(t)\|^2+\int_0^t\|\psi_y(\tau)\|^2d\tau+\delta^{\frac12}\int_0^t\psi^2(0,\tau)d\tau+\delta^{\frac12}\int_0^t\int_0^{+\infty}V_y\phi^2dyd\tau\\&\le C\|(\phi,\psi)(0)\|^2+C\delta^2\int_0^t\|\phi_y(\tau)\|^2d\tau.\end{aligned}\tag{4.13}$$

Following [17], we adapt a new variable,

$$\tilde v=\frac{v}{V},\tag{4.14}$$

to estimate $\|\phi_y\|$. Then $(4.2)_2$ is rewritten as

$$\begin{aligned}&\left(\mu\frac{\tilde v_y}{\tilde v}-\psi\right)_t-(\bar s+\gamma'(t))\left(\mu\frac{\tilde v_y}{\tilde v}-\psi\right)_y-p'(v)V\tilde v_y+(p'(V)-p'(v)\tilde v)V_y\\&=\mu\left(\frac{V_y}{V}\right)_y\gamma'(t)-\bar s\gamma'(t)V_y.\end{aligned}\tag{4.15}$$

Thus, we have the following lemma.

LEMMA 4.4. *It holds that*

$$\begin{aligned}&\|\frac{\tilde v_y}{\tilde v}(t)\|^2+\int_0^t\int_0^{+\infty}\frac{\tilde v_y^2}{\tilde v^{\gamma+2}}dyd\tau\\&\le C(\|\phi_0\|_1^2+\|\psi_0\|^2).\end{aligned}\tag{4.16}$$

Proof. Multiplying (4.15) by $\frac{\tilde v_y}{\tilde v}$, one gets

$$\begin{aligned}&\left\{\frac{\mu}{2}\left(\frac{\tilde v_y}{\tilde v}\right)^2-\psi\left(\frac{\tilde v_y}{\tilde v}\right)\right\}_t-p'(v)V\frac{\tilde v_y^2}{\tilde v}\\&+\left\{\psi\frac{\tilde v_t}{\tilde v}-\frac{\mu(\bar s+\gamma'(t))}{2}\left(\frac{\tilde v_y}{\tilde v}\right)^2\right\}_y\\&=\frac{\psi_y^2}{v}+\frac{\bar s\phi\psi_yV_y}{vV}+(p'(V)-p'(v)\tilde v)V_y\frac{\tilde v_y}{\tilde v}\\&+\left(\mu\left(\frac{V_y}{V}\right)_y\gamma'-\bar s\gamma'(t)V_y\right)\frac{\tilde v_y}{\tilde v}+\gamma'(t)\psi_y\frac{V_y}{V}.\end{aligned}\tag{4.17}$$

We compute

$$\left|\left(\frac{\tilde v_y}{\tilde v}\right)(0,t)\right|=\left|\frac{\phi_y(0,t)}{v_b}\right|=\left|\frac{\gamma'(t)V'(0)+\psi_y(0,t)}{v_b(\bar s+\gamma'(t))}\right|\le C|\psi(0,t)|,\tag{4.18}$$

$$\left|(p'(V)-p'(v)\tilde v)V_y\frac{\tilde v_y}{\tilde v}\right|\le\lambda\tilde v_y^2+CV_y^2\phi^2,\tag{4.19}$$

and

$$\begin{aligned}
&\int_0^\infty \left| \left(\frac{V_y}{V}\right)_y \gamma'(\tau)\frac{\tilde{v}_y}{\tilde{v}} \right| \\
&\le \int_0^\infty \lambda \tilde{v}_y^2 dy + C\int_0^\infty \left| \left(\frac{V_y}{V}\right)_y \right|^2 dy|\gamma'(\tau)|^2 \\
&\le \int_0^\infty \lambda \tilde{v}_y^2 dy + C\delta^{\frac{1}{2}}|\gamma'(\tau)|^2,
\end{aligned} \tag{4.20}$$

where we have used $V'(0) = O(\delta^{\frac{1}{2}})$ and $\psi_y(0,t) = O(\delta^{\frac{1}{2}})|\psi(0,t)|$. It is noted that

$$c_1\phi_y^2 - c_2V_y^2\phi^2 \le \left|\frac{\tilde{v}_y}{\tilde{v}}\right|^2 \le C_1\phi_y^2 + C_2V_y^2\phi^2,$$

where $c_i, C_i, i = 1, 2$, are positive constants which only depend on $\bar{v}$ and v_b. Integrating (4.17) over $(0, +\infty) \times (0, t)$ and using Lemma 4.3, we get Lemma 4.4.

LEMMA 4.5. *It holds that*

$$\|\psi_y(t)\|^2 + \int_0^t \|\psi_{yy}(\tau)\|^2 d\tau \le C\|\phi_0, \psi_0\|_1^2. \tag{4.21}$$

Proof. Multiplying $(4.2)_2$ by $-\psi_{yy}$, we have

$$\begin{aligned}
&\left(\frac{\psi_y}{2}\right)_t^2 + \left(-\psi_t\psi_y + \frac{\bar{s}+\gamma'(t)}{2}\psi_y^2\right)_y + \mu\frac{\psi_{yy}^2}{v} \\
&= \left\{-\mu\tfrac{\psi_y(V_y+\phi_y)}{(V+\phi)^2} + \mu\left(\tfrac{\bar{s}V_y\phi}{(V+\phi)V}\right)_y - (p(V+\phi)-p(V))_y\right\}(-\psi_{yy}) \\
&\quad + \bar{s}\gamma'(t)V_y\psi_{yy}.
\end{aligned} \tag{4.22}$$

Integrating (4.22) over $(0, +\infty) \times (0, t)$, one has

$$\begin{aligned}
&\frac{1}{2}\|\psi_y(t)\|^2 + \int_0^t \psi_t(0,\tau)\psi_y(0,\tau)d\tau - \int_0^t \frac{\bar{s}+\gamma'(t)}{2}\psi_y^2(0,\tau)d\tau \\
&\quad + \frac{\mu}{2v_+}\int_0^t \|\psi_{yy}(\tau)\|^2 d\tau \\
&\le C(\|\phi_0\|_1^2 + \|\psi_0\|_1^2) + C\int_0^t \|\phi_y(\tau)\|^2 + \|\psi_y(\tau)\|^2 d\tau \\
&\quad + C\int_0^t\int_0^\infty \bar{s}^2V_{yy}^2\phi^2 dyd\tau.
\end{aligned} \tag{4.23}$$

By the boundary conditions of (4.2), we have

$$\psi_t(0,t)\psi_y(0,t) = \frac{v_b}{v_b - \bar{v}}\left\{u_b\psi^2(0,t) + \frac{1}{3}\psi^3(0,t)\right\}_t. \tag{4.24}$$

On the other hand,

$$\int_0^t\int_0^\infty \bar{s}^2V_{yy}^2\phi^2 dyd\tau \le C\delta\int_0^t\int_0^\infty |V_{yy}|ydy \cdot \|\phi_y\|^2 d\tau \le C\delta^2\int_0^t \|\phi_y\|^2 d\tau.$$

Thus, combining (4.22)–(4.24) and the fact that $\bar{s} < 0$, we get Lemma 4.5.

Proposition 4.2 is obtained at once from Lemmas 4.3–4.5.

Proof of Theorem 4.1. Let δ_1, C_0, C, and M_0 be the constants in Propositions 3.1 and 4.2. We assume $C_0\delta_1 \le M_0$. This is possible because we can choose δ_1 smaller if necessary. We now let $v_+ - v_b = \delta \le \delta_1$ and the initial data $\|(\phi_0, \psi_0)\|_1 \le M \le \frac{C_0\delta}{\sqrt{C}b} \le M_0/b$. Then by Proposition 3.1 there exists a positive time $t_0 = t_0(v_b, M_0)$ such that there is a unique local solution (ϕ, ψ, γ) to (3.6) satisfying

$$\phi(y,t), \psi(y,t) \in X_{\frac{v_b}{4}, bM}(0, t_0), \quad \gamma(t) \in C^1([0, t_0]).$$

It is noted that $bM \le C_0\delta$. Thus, by virtue of Proposition 4.2, we have

$$\|(\phi, \psi)(t_0)\|_1 \le \sqrt{C}\|(\phi_0, \psi_0)\|_1 \le C_0\delta/b \le M_0/b,$$

which satisfies the conditions of Proposition 3.1. Hence, from the time $t = t_0$, again using Propositions 3.1 and 4.2, we know there exists a solution (ϕ, ψ, γ) to (3.6) in the interval $[t_0, 2t_0]$ and

$$\|(\phi, \psi)(2t_0)\|_1 \le \sqrt{C}\|\phi_0, \psi_0\|_1 \le C_0\delta/b \le M_0/b.$$

Repeating the above procedure, we obtain the asymptotic stability theorem, Theorem 4.1.

5. Superposition of a traveling wave solution and a rarefaction wave. This section is devoted to the superposition of a traveling wave solution and a rarefaction wave. Assume that

$$(v_+, u_+) \in R_2 TW_{\bar{v}}(v_b, 0), \tag{5.1}$$

where $0 < \bar{v} < v_b$.

In this case, there exists $(v_*, u_*) \in TW_{\bar{v}}(v_b, 0)$ such that $(v_+, u_+) \in R_2(v_*, u_*)$, and the superposition of the traveling wave solution connecting (v_b, u_b) with (v_*, u_*) and the 2-rarefaction wave connecting (v_*, u_*) with (v_+, u_+).

We now consider the 2-rarefaction wave $(v^R, u^R)(\frac{x}{t})$ connecting (v_*, u_*) with (v_+, u_+), which is the weak solution of the *Riemann* problem

$$\begin{cases} v_t - u_x = 0, \quad (x,t) \in \Re \times (0, +\infty), \\ v_t + p(v)_x = 0, \\ (v,u)\big|_{t=0} = (v_0^R, u_0^R)(x) = \begin{cases} (v_*, u_*), & x < 0, \\ (v_+, u_+), & x > 0. \end{cases} \end{cases} \tag{5.2}$$

It is known that $(v^R, u^R)(\frac{x}{t})$ has the explicit form

$$\begin{aligned} &(v^R, u^R)\left(\frac{x}{t}\right) \\ &= \begin{cases} (v_*, u_*), & -\infty \le \dfrac{x}{t} \le \lambda_2(v_*), \\ \left(\lambda_2^{-1}\left(\dfrac{x}{t}\right), u_* - \displaystyle\int_{v_*}^{\lambda_2^{-1}(\frac{x}{t})} \lambda_2(s)ds\right), & \lambda_2(v_*) \le \dfrac{x}{t} \le \lambda_2(v_+), \\ (v_+, u_+), & \lambda_2(v_+) \le \dfrac{x}{t} \le +\infty, \end{cases} \end{aligned} \tag{5.3}$$

where $\lambda_2(v) = \sqrt{-p'(v)}$.

To study the large time behavior of solutions to (1.12), it is necessary to construct a smooth approximate rarefaction wave $(\tilde{V}, \tilde{U})(x,t)$ of $(v^R, u^R)(\frac{x}{t})$ in $\Re \times (0, +\infty)$ and its restriction $(V^R, U^R)(x,t) := (\tilde{V}, \tilde{U})(x,t)\big|_{x \geq x(t)}$. For this reason, we investigate the *Riemann* problem on $\Re \times (0, +\infty)$ of the *Burgers* equation

$$\begin{cases} w_t^R + w^R w_x^R = 0, \quad (x,t) \in \Re \times \Re_+, \\ w^R(x,0) = w_0^R(x) = \begin{cases} w_- = \lambda_2(v_*), & x < 0, \\ w_+ = \lambda_2(v_+), & x > 0. \end{cases} \end{cases} \tag{5.4}$$

Here $0 < w_- < w_+$. The weak solution of (5.4) with the entropy condition is a rarefaction wave $w^R(\frac{x}{t})$ connecting w_- and w_+,

$$w^R\left(\frac{x}{t}\right) = \begin{cases} w_-, & x \leq w_- t, \\ \dfrac{x}{t}, & w_- t < x < w_+ t, \\ w_+. & w_+ t \leq x. \end{cases} \tag{5.5}$$

We now approximate $w^R(\frac{x}{t})$ by

$$\begin{cases} w_t + w w_x = 0, \quad (x,t) \in \Re \times (0, +\infty), \\ w\big|_{t=0} = w_0(x) \\ \qquad = \begin{cases} w_-, & x < 0, \\ w_- + \tilde{w}\kappa_q \displaystyle\int_0^{\varepsilon x} z^q e^{-z} dz, & x \geq 0. \end{cases} \end{cases} \tag{5.6}$$

Here $\tilde{w} = w_+ - w_-$, κ_q is a constant such that $\kappa_q \int_0^{+\infty} z^q e^{-z} dz = 1$ for large constant $q \geq 8$, and ε is a positive constant determined later. We have the following lemma.

LEMMA 5.1. *Let $0 < w_- < w_+$. Then the problem* (5.6) *has a unique smooth solution $w(x,t)$ satisfying the following:*

(i) $w_- \leq w(x,t) < w_+, w_x \geq 0$ *for* $x \geq 0, t \geq 0$.

(ii) *For any $p (1 \leq p \leq +\infty)$, there exists a constant $C_{p,q}$ such that for $t \geq 0$,*

$$\|w_x(\cdot,t)\|_{L^p} \leq C_{p,q} \min\left(\tilde{w}\varepsilon^{1-\frac{1}{p}}, \tilde{w}^{\frac{1}{p}} t^{-1+\frac{1}{p}}\right),$$
$$\|w_{xx}(\cdot,t)\|_{L^p} \leq C_{p,q} \min\left(\tilde{w}\varepsilon^{2-\frac{1}{p}}, \tilde{w}^{\frac{1}{q}}\varepsilon^{1-\frac{1}{p}+\frac{1}{q}} t^{-1+\frac{1}{q}}\right).$$

(iii) *When* $x \leq 0$, $w(x,t) - w_- = w_x(x,t) = w_{xx}(x,t) = 0$.

(iv) $\limsup_{t \to +\infty, x \in \Re} \left|w(x,t) - w^R(x,t)\right| = 0$.

Proof. Since the solution $w(x,t)$ of (5.6) has the explicit form

$$w(x,t) = w_0(x_0(x,t)), x = x_0(x,t) + w_0(x_0(x,t))t,$$

and

$$w_0'(x_0) = \begin{cases} 0, & x_0 \leq 0, \\ \tilde{w} k_q \varepsilon (\varepsilon x_0)^q e^{-\varepsilon x_0}, & x_0 > 0, \end{cases}$$

$$|w_0''(x_0)| \leq C \tilde{w}^{\frac{1}{q}} \varepsilon^{1+\frac{1}{q}} |w_0'(x_0)|^{1-\frac{1}{q}} e^{-\frac{\varepsilon x_0}{2q}},$$

it is not difficult to get Lemma 5.1 by virtue of the method of [17]. We omit the details here.

Now we define the approximate solution $(\tilde{V},\tilde{U})(x,t)$ as follows:

$$(\tilde{V},\tilde{U})(x,t)=\left(\lambda_2^{-1}\big(w(x,t)\big),u_*-\int_{v_*}^{\lambda_2^{-1}\left(w(x,t)\right)}\lambda_2(s)ds\right). \tag{5.7}$$

Setting

$$(V^R,U^R)(y,t):=(\tilde{V},\tilde{U})\big|_{x\geq x(t)},\quad y=x-x(t). \tag{5.8}$$

Since $w(x,t)$ is the smooth solution of the problem (5.6), it is easy to see

$$\begin{cases} V_t^R-(\bar{s}+\gamma'(t))V_y^R-U_y^R=0,\\ U_t^R-(\bar{s}+\gamma'(t))U_y^R+p(V^R)_y=0,\quad (y,t)\in R_+\times(0,+\infty),\\ (V^R,U^R)\big|_{y=0}=(v_*,u_*),\\ (V^R,U^R)\big|_{t=0}=\left(\lambda_2^{-1}(w_0(y)),u_*-\displaystyle\int_{v_*}^{\lambda_2^{-1}(w_0(y))}\lambda_2(s)ds\right). \end{cases} \tag{5.9}$$

Note that $|V_{yy}^R|\leq C(|w_{xx}|+|w_x|^2)$, and one has the following from Lemma 5.1.

LEMMA 5.2. *Let $\delta_2=|v_+-v_*|+|u_+-u_*|$. Then $(V^R,U^R)(y,t)$ satisfies the following if $q\geq p$:*

(i) *$U_y^R(y,t)\geq 0, |U_y^R|\leq C\varepsilon\delta_2$ for $t\geq 0, y\geq 0$.*

(ii) *For any $p(1\leq p\leq+\infty)$, there exists a constant $C_{p,q}$ such that*

$$\|V_y^R(\cdot,t)\|_{L^p(\{y\geq 0\})}\leq C_{p,q}\min\left\{\delta_2\varepsilon^{1-\frac{1}{p}},\delta_2^{\frac{1}{p}}(1+t)^{-1+\frac{1}{p}}\right\},$$
$$\|V_{yy}^R(\cdot,t)\|_{L^p(\{y\geq 0\})}\leq C_{p,q}\min\left\{\delta_2\varepsilon^{2-\frac{1}{p}},\delta_2^{\frac{1}{q}}(1+t)^{-1+\frac{1}{q}}\right\},\quad t\geq 0.$$

(iii) $(V^R,U^R)|_{y\leq -x(t)}=(v_*,u_*),\quad (V_y^R,U_y^R,V_{yy}^R,U_{yy}^R)|_{y\leq -x(t)}=0.$

(iv) $\limsup_{t\to+\infty,y\in\{y\geq 0\}}|(V^R,U^R)(y,t)-(v^R,u^R)(\frac{y+x(t)}{t})|=0.$

On the other hand, the traveling wave solution $(V_B,U_B)(y)$ connecting (v_b,u_b) with (v_*,u_*) satisfies, from Lemma 2.1,

$$\begin{cases} -\bar{s}V_y-U_y=0, & y>0,\\ -\bar{s}U_y+p(V)_y=\mu\left(\dfrac{U_y}{V}\right)_y, & y>0,\\ V(0)=v_b,U(0)=u_b,\\ \mu U_y(0)=v_b(v_b-\bar{v})\bar{s}^2,\\ (V,U)|_{(+\infty)}=(v_*,u_*), \end{cases} \tag{5.10}$$

where

$$\bar{s}=\frac{u_b}{\bar{v}-v_b}<0,\quad u_b=\frac{\bar{v}-v_b}{\bar{v}-v_*}u_*,\quad u_*=(v_*-\bar{v})^{\frac{1}{2}}(p(v_b)-p(v_*))^{\frac{1}{2}}. \tag{5.11}$$

Let

$$V(y,t) = V_B(y) + V^R(y,t) - v_*, \quad U(y,t) = U_B(y) + U^R(y,t) - u_*; \tag{5.12}$$

we set the perturbation $(\phi,\psi)(y,t)$ by $(v,u)(y,t) = (V+\phi, U+\psi)(y,t)$. Then the reformulated equation is, from (1.12), (5.9), and (5.10),

$$\begin{cases} \phi_t - (\bar{s}+\gamma'(t))\phi_y - \psi_y = \gamma'(t)V_{By}, & y>0, \quad t>0, \\ \psi_t - (\bar{s}+\gamma'(t))\psi_y + (p(V+\phi)-p(V))_y \\ -\mu\left(\dfrac{\psi_y}{V+\phi} - \dfrac{U_y\phi}{V(V+\phi)}\right)_y = -\bar{s}\gamma'(t)V_{By} + G(y), & y>0, \quad t>0, \\ \phi(0,t) = 0, \\ \mu\psi_y(0,t) = \dfrac{2v_bu_b}{v_b-\bar{v}}\psi(0,t) + \dfrac{v_b}{v_b-\bar{v}}\psi^2(0,t), \\ \gamma'(t) = \dfrac{1}{\bar{v}-v_b}\psi(0,t), \quad \gamma(0) = 0, \\ (\phi,\psi)|_{(+\infty,t)} = (0,0), \\ (\phi,\psi)(y,0) = (\phi_0,\psi_0) = (v_0-V_0, u_0-U_0)(y), \end{cases} \tag{5.13}$$

where

$$G = -(p(V)-p(V_B)-p(V^R)+p(v_*)) + \mu\left(\frac{U_y}{V} - \frac{U_{By}}{V_B}\right) = -G_1 + G_2. \tag{5.14}$$

We now derive the a priori estimates like Proposition 4.2. First we fix $\bar{v}$ and v_b. Then we choose a suitably small constant δ_0 which will be given later. We assume that $v_* - v_b = \delta \le \delta_0$ and $(\psi,\psi) \in X_{\frac{1}{4}v_b,M}(0,T)$ is a solution to (5.13) with $M \le C_0\delta^{\frac{3}{5}}$ for some positive constants T and C_0.

Multiplying $(5.13)_1$ by $p(V)-p(V+\phi)$ and $(5.13)_2$ by ψ, we have

$$\begin{aligned} &\left\{\left[\frac{1}{2}\psi^2 + \Phi(v,V)\right]\right\}_t + \Delta\phi U_y^R - (\bar{s}+\gamma')\Delta\phi V_{By} \\ &+ \left\{(p(V+\phi)-p(V))\psi - (\bar{s}+\gamma')\left(\Phi(v,V) + \frac{1}{2}\psi^2\right)\right. \\ &\left. - \mu\left(\frac{\psi_y}{V+\phi} - \frac{U_y\phi}{V(V+\phi)}\right)\psi\right\}_y + \mu\frac{\psi_y^2}{V+\phi} \\ &- \frac{\mu(U_y^R+U_{By})\psi_y\phi}{V(V+\phi)} + (p(V+\phi)-p(V))\gamma'V_{By} \\ &+ \bar{s}\gamma'V_{By}\psi - G_y\psi = 0. \end{aligned} \tag{5.15}$$

Since $p''(V) > 0$, one has

$$\Delta\phi = p(V+\phi) - p(V) - p'(V)\phi = f(v,V)\phi^2 \ge 0. \tag{5.16}$$

We regard

$$Q = \Delta\phi U_y^R - \frac{\mu U_y^R\psi_y\phi}{V(V+\phi)} + \mu\frac{\psi_y^2}{v} \tag{5.17}$$

as the quadratic equation:

$$\left(\sqrt{\mu}\frac{\psi_y}{\sqrt{v}}\right)^2 - \frac{\sqrt{\mu U_y^R}}{V\sqrt{vf(v,V)}}\cdot\sqrt{\mu}\frac{\psi_y}{\sqrt{v}}\cdot\sqrt{U_y^R f(v,V)}\phi + \left(\sqrt{U_y^R f(v,V)}\phi\right)^2. \tag{5.18}$$

By Lemma 5.2, if ε is suitably small, the discriminate of (5.18) satisfies

$$D = \frac{\mu U_y^R}{V^2 v f(v,V)} - 4 < 0. \tag{5.19}$$

It is noted that all terms including $V_B(y)$ could be treated by the same methods of the previous section; thus if δ_0 is suitably small, then we have

$$\begin{aligned}
&\|(\phi,\psi)(t)\|^2 + \int_0^t \|\psi_y(\tau)\|^2 d\tau + \delta^{\frac{1}{2}}\int_0^t \psi^2(0,\tau)d\tau \\
&+ \delta^{\frac{1}{2}}\int_0^t\int_0^{+\infty} V_{By}\phi^2 dyd\tau + \int_0^t\int_0^{+\infty} U_y^R\phi^2 dyd\tau \\
&\le C\|(\phi,\psi)(0)\|^2 + C\delta^2\int_0^t\|\phi_y(\tau)\|^2 d\tau + \int_0^t\int_0^{+\infty}|G_y||\psi|dyd\tau.
\end{aligned} \tag{5.20}$$

We now estimate the last term of (5.20). We compute

$$\begin{aligned}
|G_{1y}| &= |p'(V)(V_{By}+V_y^R) - p'(V_B)V_{By} - p'(V^R)V_y^R| \\
&\le |V_{By}||V^R - v_*| + |V_y^R||V_B - v_*|.
\end{aligned} \tag{5.21}$$

It is observed that $(V^R - v_*, V_y^R)|_{y\le -\bar{s}t-\gamma(t)} = 0$; thus we have, from Lemma 2.1,

$$\begin{aligned}
\|G_{1y}\|^2 &= \int_{-\left(\bar{s}t+\gamma(t)\right)}^{+\infty}|G_{1y}|^2(y,t)dy \\
&\le C\sup_{y\ge-\left(\bar{s}t+\gamma(t)\right)}\{|V^R(y,t)-v_*|^2|V_{By}|\}\int_{-\left(\bar{s}t+\gamma(t)\right)}^{+\infty}|V_{By}|dy \\
&\quad + C\sup_{y\ge-\left(\bar{s}t+\gamma(t)\right)}\{|V_y^R(y,t)|^2|v_*-V_B|\}\int_{-\left(\bar{s}t+\gamma(t)\right)}^{+\infty}|v_*-V_B|dy \\
&\le C\delta^{\frac{3}{2}}\delta_2^2 e^{-ct}.
\end{aligned} \tag{5.22}$$

This implies, by $\|\psi\| \le C_0\delta^{\frac{3}{5}}$,

$$\begin{aligned}
&\int_0^t\int_0^{\infty}|G_{1y}||\psi|dyd\tau \\
&\le C\int_0^t\|G_{1y}\|\|\psi\|d\tau \le C\delta^{\frac{27}{20}}.
\end{aligned} \tag{5.23}$$

On the other hand, we calculate

$$G_2 = \mu\left(\frac{U_y}{V} - \frac{U_{By}}{V_B}\right) = \mu\left(\frac{U_y^R}{V} - \frac{U_{By}(V^R - v_*)}{VV_B}\right) \tag{5.24}$$

and

$$|G_{2y}| \le C(|V^R_{yy}| + |V^R_y|^2 + |V^R_y||V_{By}| + |U_{Byy}||V^R - v_*| + |U_{By}||V^R - v_*||V_{By}|). \tag{5.25}$$

From Lemma 5.2 and (5.25), we have

$$\int_0^\infty |G_{2y}|dy \le C(\|V^R_{yy}\|_{L^1} + \delta e^{-ct} + \varepsilon^{\frac{1}{6}}(1+t)^{-\frac{5}{6}}). \tag{5.26}$$

Thus,

$$\begin{aligned}
&\int_0^t \int_0^\infty |G_{2y}||\psi|dyd\tau \\
&\le C\int_0^t \|\psi\|^{\frac{1}{2}}\|\psi_y\|^{\frac{1}{2}}(\|V^R_{yy}\|_{L^1} + \delta e^{-ct} + \varepsilon^{\frac{1}{6}}(1+t)^{-\frac{5}{6}})d\tau \\
&\le \lambda\int_0^t \|\psi_y\|^2 + C\left(\int_0^t \delta^{\frac{2}{5}}\|V^R_{yy}\|^{\frac{4}{3}}_{L^1} + \delta^{\frac{26}{15}}e^{-ct} + \varepsilon^{\frac{2}{9}}\delta^{\frac{2}{5}}(1+\tau)^{-\frac{10}{9}}d\tau\right) \\
&\le \lambda\int_0^t \|\psi_y\|^2 d\tau + C\varepsilon^{\frac{1}{6}}\delta^{\frac{2}{5}} + C\delta^{\frac{26}{15}} \\
&\le \lambda\int_0^t \|\psi_y\|^2 d\tau + C\delta^{\frac{7}{5}}
\end{aligned} \tag{5.27}$$

if $\varepsilon = O(\delta^6)$, where λ is a small positive constant. Therefore, we have the following estimate:

$$\begin{aligned}
&\|(\phi,\psi)(t)\|^2 + \int_0^t \|\psi_y(\tau)\|^2 d\tau + \delta^{\frac{1}{2}}\int_0^t \psi^2(0,\tau)d\tau \\
&+\delta^{\frac{1}{2}}\int_0^t\int_0^{+\infty} V_{By}\phi^2 dyd\tau + \int_0^t\int_0^{+\infty} U^R_y\phi^2 dyd\tau \\
&\le C\|(\phi,\psi)(0)\|^2 + C\delta^2\int_0^t \|\phi_y(\tau)\|^2 d\tau + C\delta^{\frac{27}{20}}.
\end{aligned} \tag{5.28}$$

Remark 5.1. If we choose the approximate waves (V^R, U^R) defined by (5.8) instead of the waves in [19], and let ε be suitably small, then it is not difficult to extend the stability theorem of [19] to the strong rarefaction wave by the same method.

The estimates of higher order derivatives are also obtained, though the calculations are rather tedious. Thus, we have the following theorem.

THEOREM 5.3 (the case $(v_+, u_+) \in R_2TW_{\bar v}(v_b, 0)$). *For any given $0 < \bar v < v_b < +\infty$, assume that $(v_+, u_+) \in R_2TW_{\bar v}(v_b, 0)$. Define $(V, U)(y,t)$ by* (5.12). *Then there exist positive constants δ_0 and C_0. If $v_* - v_b = \delta \le \delta_0$, $v_0(y) - V(y,0) \in H^1_0$, $u_0(y) - U(y,0) \in H^1$, and $\|v_0 - V(y,0), u_0 - U(y,0)\|_1 \le C_0\delta^{\frac{3}{5}}$, then there exists a global solution $(v(x,t), u(x,t), x(t))$ to* (1.12) *satisfying*

$$(v - V, u - U)(x,t) \in C(0,+\infty; H^1(x(t),+\infty)),$$

$$(v - V)_x(x,t) \in L^2(0,+\infty; L^2(x(t),+\infty)),$$

$$(u - U)_x(x,t) \in L^2(0,+\infty; H^1(x(t),+\infty)), \quad x(t) \in C^1([0,+\infty)),$$

$$x'(t) - \bar{s} \in L^2(0, +\infty),$$

and

$$\sup_{x \geq x(t)} |(v, u)(x, t) - (V, U)(x - x(t))| \to 0 \quad as \quad t \to +\infty.$$

Remark 5.2. Theorem 5.3 implies that it is not necessary for the 2-rarefaction wave to be weak, though the traveling wave solution is necessarily weak.

Acknowledgments. We would like to thank the referees, whose comments led to considerable improvement in this paper.

ANALYSIS OF A SEMILINEAR PDE FOR MODELING STATIC SOLUTIONS OF JOSEPHSON JUNCTIONS*

J.-G. CAPUTO†, N. FLYTZANIS‡, A. TERSENOV§, AND E. VAVALIS§

Abstract. A semilinear elliptic partial differential equation problem that models the static (zero voltage) behavior of a Josephson window junction is considered. A priori estimates and differential properties of the solution are obtained. The existence of the solutions is shown and iterative methods for solving this problem are analyzed. Experimental numerical data that couple with the theoretical results are presented. Useful physical information is extracted from our analysis

Key words. semilinear elliptic equations, a priori estimates, Josephson window junction

1. Introduction.

A Josephson junction is a weak link between two superconducting films separated by a thin oxide layer enabling the tunneling of Cooper pairs of electrons. The steady state operation under the action of an external magnetic field and bias with a constant external current is described by a semilinear elliptic partial differential equation (PDE) with a sinusoidal nonlinearity which arises from the Josephson tunneling current. The quantity that completely describes the electromagnetic properties of such a device is the difference $\phi(x, y)$ of the phases of the superconducting order parameters in the two films. The response of the junction to an external current and magnetic field depends crucially on the ratio of the junction dimensions $\mathcal{L}$ (length) and $\mathcal{W}$ (width) to the characteristic length of the problem, the Josephson penetration depth λ_j. Short junctions for which $\mathcal{L}, \mathcal{W} < \lambda_j$ are widely used in the static case (zero voltage) for magnetic field detection. When ϕ becomes time dependent the governing equation is of hyperbolic type, and such small junctions are used for voltage standard, while long junctions ($\mathcal{L} > \lambda_j > \mathcal{W}$) are very high frequency oscillators (> 100 GHz) used in astrophysical measurements. An in-depth presentation of the physics and the technological applications of Josephson junctions can be found in [2].

The main difficulty of the resonant fluxon operation of a long junction is its low energy output compounded by a strong impedance mismatch at the boundaries. The coupling of the Josephson junction to a cavity in the so-called window design allows a better impedance matching [6, 4]. It is also interesting for tailoring the static or zero voltage behavior of the device for specific purposes [10] like increasing the maximum allowed bias current in the absence of magnetic field. An extension of this model to inhomogeneous critical current density can be relevant for high T_c superconducting materials with grain boundaries [7]. Finally static solutions can be considered as fixed points and play an important role in computing the solutions of the associated

hyperbolic time-dependent problem. In [4] we proposed a semilinear PDE problem which accurately and effectively modeled the static behavior of a window Josephson junction. This model enabled us to predict specific effects depending on the size of the cavity, such as the rescaling of λ_j and the increase of the maximum current for zero magnetic field [5].

If an annular geometry is considered, the periodic boundary conditions are appropriate and in this case an exhaustive classification and stability analysis of the solutions has already been carried out in one and two space dimensions including time [8]. For this geometry one is limited only to solutions with integer number of fluxons. Note, however, that this eliminates many of the interesting physical solutions that arise due to the finite size and the possibility of continuously introducing flux from the boundaries as we vary the magnetic field H.

The static two-dimensional Josephson junction problem was solved numerically by Barone et al. [1] only in the homogeneous junction case by introducing a damping term. This transforms the equation into a semilinear diffusion equation which can be discretized using explicit finite differences. A careful choice of the initial condition can lead to stable static solutions, but this cannot be guaranteed in general. In particular the junction with inhomogeneous properties requires special care. In all cases the multiplicity of solutions makes the choice of initial conditions very important, so that we need to address the static problem directly. Notice also that both the proof of the existence of a solution and some regularity estimates can be obtained easily in this time-dependent case but that these results cannot be extended to the static limit, which turns out to be a more difficult problem.

The derivation of this PDE model together with preliminary numerical experiments was presented in [4] and is briefly discussed in section 2, where comments on several mathematical peculiarities inherent in our problem are also included. In particular the periodic nonlinear right-hand side and the Neumann boundary conditions lead to an obvious nonuniqueness of the solution. Note also that the coefficients of the operator are nonsmooth. Using the *additional variable method* proposed in [11] and [17, 18], we first obtain a priori estimates on the gradient of the solution that are of physical interest. We then prove, under certain assumptions, the existence and uniqueness of the solution and the convergence of a fixed point linearization method. The study of the stability of the solutions is under way and will not be considered here. In particular we obtain in section 3 a priori estimates of the gradient of the solution of ϕ and show that the gradients are Hölder continuous functions. Based on these estimates we prove in section 4 the existence of the solution and show that a generalized second derivative exists in L_2. Assuming that the domain is narrow enough, we show, in the case of zero Neumann boundary conditions in one direction, that the solution does not depend on the associated variable. In section 5 we obtain additional estimates for the solution and its first derivatives only in terms of the external current and the magnetic field applied to it. Furthermore, assuming that the solution is in a given interval, we improve our a priori estimates. In section 6 we prove the convergence of an iterative method for linearizing the semilinear PDE problem. Numerical results that couple with our theoretical results are presented in section 7, which also discusses their physical relevance. Our conclusions are given in section 8.

2. The mathematical Josephson window junction model. Figure 2.1 shows a window junction for the case where the window Ω_j is a rectangle of size $\ell \times w$ centered in Ω. The spatial variation of the difference ϕ of the superconducting phases in both superconductors is modeled accurately in the case where the surface inductances

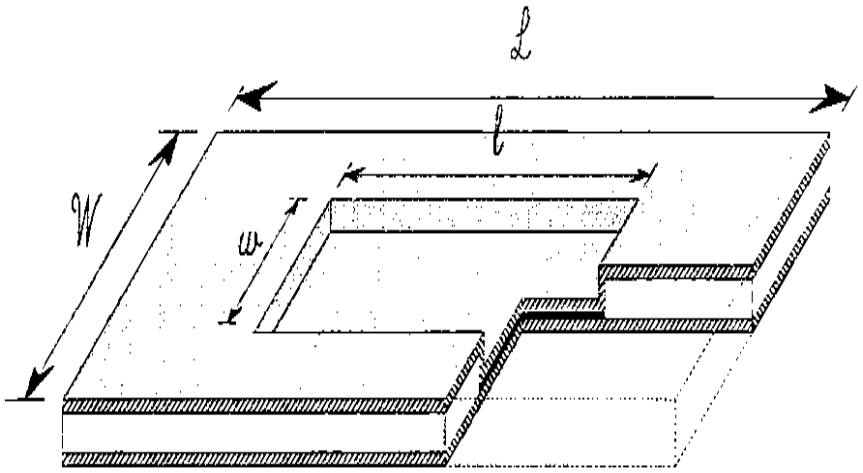

FIG. 2.1. *A window Josephson junction.*

are equal in the junction and the idle region by the equation

$$\frac{\partial^2\phi}{\partial x^2}+\frac{\partial^2\phi}{\partial y^2}=\mathcal{I}_j(x,y)\sin(\phi) \quad \text{in} \quad \Omega\equiv\left(-\frac{\mathcal{L}}{2},\frac{\mathcal{L}}{2}\right)\times\left(-\frac{\mathcal{W}}{2},\frac{\mathcal{W}}{2}\right), \tag{2.1}$$

coupled with the boundary conditions

$$\frac{\partial\phi}{\partial x}\bigg|_{x=-\frac{\mathcal{L}}{2}}=H-\alpha_1,\quad \frac{\partial\phi}{\partial x}\bigg|_{x=\frac{\mathcal{L}}{2}}=H+\alpha_2,\quad \frac{\partial\phi}{\partial y}\bigg|_{y=-\frac{\mathcal{W}}{2}}=-\delta_1,\quad \frac{\partial\phi}{\partial y}\bigg|_{y=\frac{\mathcal{W}}{2}}=\delta_2, \tag{2.2}$$

where all lengths have been normalized by λ_j. Physically $\mathcal{I}_j$ in (2.1) is the indicator function of the domain Ω_j and is discontinuous. Although in the derivation of the results that will follow we have assumed that $\mathcal{I}_j$ is continuous, we will see that all our results are independent of the smoothness of $\mathcal{I}_j$.

The model given in (2.1) can be made more realistic by including the difference in the surface inductances in the superconducting and junction regions, which leads to the equation

$$\frac{\partial}{\partial x}\left(\frac{1}{\tilde{L}(x,y)}\frac{\partial\phi}{\partial x}\right)+\frac{\partial}{\partial y}\left(\frac{1}{\tilde{L}(x,y)}\frac{\partial\phi}{\partial y}\right)=\mathcal{I}_j(x,y)\sin(\phi),$$

where $\tilde{L}$ is the normalized surface inductance. We believe that the analysis presented below can be extended to cover the case where $\tilde{L}(x,y)$ is strictly positive and differentiable.

The boundness of the right-hand side of (2.1) determines the maximum allowed values for α_1, α_2, δ_1, and δ_2. To see this, integrate both sides of (2.1) and use Green's theorem to obtain

$$\int_{\Omega_j}\sin\phi dxdy=\int_{\Omega}\nabla(\nabla\phi)dxdy=\int_{\partial\Omega}\frac{\partial\phi}{\partial n}ds=(\alpha_1+\alpha_2)\mathcal{W}+(\delta_1+\delta_2)\mathcal{L},$$

from which we have that

$$|(\alpha_1+\alpha_2)\mathcal{W}+(\delta_1+\delta_2)\mathcal{L}|\le\mu(\Omega_j), \tag{2.3}$$

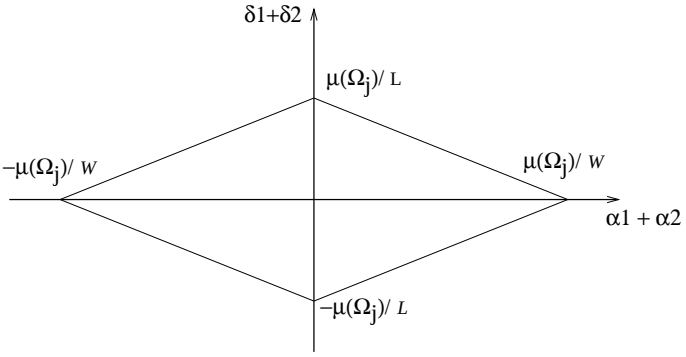

FIG. 2.2. *Allowed values for α's and δ's.*

where $\mu(\Omega_j)$ is the measure of the window domain Ω_j. From (2.3) we easily see that our PDE problem has no solutions if the α's and δ's are outside the rhombus shown in Figure 2.2.

Physically H corresponds to an external magnetic field applied in the y-direction which induces a gradient of ϕ along the x-direction. α's and δ's are current densities flowing through the device along the x- and y-directions, respectively. They can be assumed to be positive and constant. As can be seen in Figure 2.2 the sum of these currents cannot exceed the maximum critical current of the junction, which is the measure of Ω_j.

Notice also that if ϕ is a solution of the problem, then $\phi + 2k\pi, k \in Z$, is also a solution. This defines an equivalence class, so that solutions can be classified in terms of their fluxon content $n_{f\ell}$ defined by

$$n_{f\ell} \equiv \left(\sup_{\Omega} \phi - \inf_{\Omega} \phi \right) / (2\pi).$$

We also define the oscillation of $\phi(x, y)$ with respect to the variable x (and similarly for the variable y) as

$$osc_x \phi \equiv \sup_y \left(\sup_x \phi - \inf_x \phi \right). \tag{2.4}$$

Depending on the boundary conditions we can have (see [4]) a one-fluxon solution where the oscillation is between 0 and 2π, a two-fluxon solution where the oscillation is between 0 and 4π, and so on. These different solutions will have different regions of existence and different stability properties with respect to a perturbation of the boundary conditions, and as the current is increased only one will subsist. This solution gives the maximum current at zero voltage of the junction, which can be observed experimentally to indicate the quality of the junction. In the inline configuration $\alpha_1 = \alpha_2 = \alpha$, $\delta_1 = \delta_2 = 0$, in the absence of an idle region ($\Omega_j = \Omega$), Owen and Scalapino showed that the maximum current for $H = 0$ is $4\mathcal{W}$ [15]. For that they reduced the problem to one dimension and wrote the solution in terms of elliptic functions. In the same geometry but with the overlap design for which $\alpha_1 = \alpha_2 = 0$ $\delta_1 = \delta_2 = \delta$, the problem can be reduced to a one-dimensional equation only for $\mathcal{W} < 2$ [3], yielding a maximum current for $H = 0$ of $\mathcal{L} \times \mathcal{W}$. When $\mathcal{W} > 2$ the current for $H = 0$ saturates, as expected, to $4 \times \mathcal{L}$, and transverse modes are needed

for the description [3]. The presence of an idle region ($\Omega_j \neq \Omega$) has important effects on the behavior of the junction. In particular the characteristic length is larger than $\lambda_J \equiv 1$, which leads to an increase of the maximum current for $H = 0$.

An important case is when the device is symmetric with respect to the center. Then if $\delta_1 = \delta_2$, one can assume the solution to be symmetric with respect to the horizontal middle line, and if the x boundary conditions are antisymmetric, i.e., $\alpha_1 = \alpha_2$ and $H = 0$, the solution will be symmetric with respect to the vertical middle line, so that just a quarter of the device might be considered. A priori estimates have been derived for these cases also.

Notice also that the solution of the PDE problem is a minimum of the free energy functional

$$\begin{aligned} F = &\int_\Omega \left[\frac{1}{2}\left(\frac{\partial\phi}{\partial x}\right)^2 + \frac{1}{2}\left(\frac{\partial\phi}{\partial y}\right)^2 + \mathcal{I}_j\left(1-\cos\phi\right)\right] dxdy \\ &- \int_{-\frac{\mathcal{W}}{2}}^{\frac{\mathcal{W}}{2}} \left[(H-\alpha_1)\phi\left(-\frac{\mathcal{L}}{2}, y\right) - (H+\alpha_2)\phi\left(\frac{\mathcal{L}}{2}, y\right)\right] dy \\ &- \int_{-\frac{\mathcal{L}}{2}}^{\frac{\mathcal{L}}{2}} \left[-\delta_2\phi\left(x, \frac{\mathcal{W}}{2}\right) - \delta_1\phi\left(x, -\frac{\mathcal{W}}{2}\right)\right] dx. \end{aligned}$$

Due to the multiplicity of solutions there are several minima. In the simple case where the boundary conditions are nonzero only in x or y and $\Omega \equiv \Omega_j$, the y or x dependence can be neglected and the last term of the free energy can be significantly simplified.

3. A priori estimates of the gradient. The main objective of this section is to obtain estimates of the gradient of the solution that are of practical interest in either proving the existence of the solution or measuring the gradient in terms of physical quantities. Estimates of the gradient in terms of the maximum of the solution are easily obtained from well-known results [13, 9]. In this section we obtain a priori estimates for the gradient of a classical solution of the proposed PDE model only in terms of the size of the domain and the physical parameters of the problem. Note that the estimates obtained below are independent of the solution and cannot be obtained from classical results [13, 9].

We start by homogenizing the problem (2.1)–(2.2) by setting $u \equiv \phi - f$ with

$$f \equiv Hx + \frac{\alpha_1}{2\mathcal{L}}\left(x - \frac{\mathcal{L}}{2}\right)^2 + \frac{\alpha_2}{2\mathcal{L}}\left(x + \frac{\mathcal{L}}{2}\right)^2 + \frac{\delta_1}{2\mathcal{W}}\left(y - \frac{\mathcal{W}}{2}\right)^2 + \frac{\delta_2}{2\mathcal{W}}\left(y + \frac{\mathcal{W}}{2}\right)^2$$

to get from (2.1) and (2.2) that

$$\frac{\partial^2 u}{\partial x^2} + \frac{\partial^2 u}{\partial y^2} = \mathcal{I}_j \sin(u+f) - \frac{\alpha_1+\alpha_2}{\mathcal{L}} - \frac{\delta_1+\delta_2}{\mathcal{W}} \quad \text{in } \Omega \tag{3.1}$$

and

$$\left.\frac{\partial u}{\partial x}\right|_{x=\pm\frac{\mathcal{L}}{2}} = \left.\frac{\partial u}{\partial y}\right|_{y=\pm\frac{\mathcal{W}}{2}} = 0. \tag{3.2}$$

In what follows, without explicitly stating, we assume that the indicator function $\mathcal{I}_j$ is smooth. This assumption is set only to guarantee the existence of a classical solution of the problem and does not affect the result of the lemmas since we do

not have any smoothness requirements. In practice these indicator functions are discontinuous (i.e., $\mathcal{I}_j(x,y)$ is 1 if $(x,y) \in \overline{\Omega}_j$ and 0 otherwise). To treat such $\mathcal{I}_j$ we can consider a continuously differentiable function $\mathcal{I}_j^\delta \in C^1\left(\overline{\Omega}\right)$, $0 \le \mathcal{I}_j^\delta \le 1$, such that $\mathcal{I}_j^\delta \to \mathcal{I}_j$ *weak in L_∞ for which the analysis that will follow is valid. Therefore in what follows and for simplicity in the notation we will use the symbol $\mathcal{I}_j$ instead of $\mathcal{I}_j^\delta$.

LEMMA 3.1. *For any classical solution $u(x,y)$ of the problem* (3.1)–(3.2) *we have that*

$$|u_x| \le \mathcal{L}, \qquad |u_y| \le \mathcal{W}. \tag{3.3}$$

Proof. We start by writing (3.1) at a point $(\xi, y) \in \Omega$ with $\xi \neq x$ as

$$\frac{\partial^2 u(\xi,y)}{\partial \xi^2} + \frac{\partial^2 u(\xi,y)}{\partial y^2} = \mathcal{I}_j(\xi,y)\sin\left(u(\xi,y)+f(\xi,y)\right) - \frac{\alpha_1+\alpha_2}{\mathcal{L}} - \frac{\delta_1+\delta_2}{\mathcal{W}}. \tag{3.4}$$

Now define the function $v(x,y,\xi) \equiv u(x,y) - u(\xi,y)$, for which, by subtracting (3.4) from (3.1), we have

$$\frac{\partial^2 v}{\partial x^2} + \frac{\partial^2 v}{\partial y^2} + \frac{\partial^2 v}{\partial \xi^2} = \mathcal{I}_j(x,y)\sin\left(u(x,y)+f(x,y)\right) - \mathcal{I}_j(\xi,y)\sin\left(u(\xi,y)+f(\xi,y)\right),$$

and thus

$$\frac{\partial^2 v}{\partial x^2} + \frac{\partial^2 v}{\partial y^2} + \frac{\partial^2 v}{\partial \xi^2} \ge -2. \tag{3.5}$$

Now consider the prism

$$P_1 = \left\{(x,\xi,y) : |x| < \frac{\mathcal{L}}{2}, |\xi| < \frac{\mathcal{L}}{2}, |y| < \frac{\mathcal{W}}{2}, x-\xi > 0\right\}$$

and the ordinary differential equation problem

$$h''(\tau) = -1, \quad \text{with} \quad h(0) = 0 \quad \text{and} \quad h'(\mathcal{L}) = \epsilon, \tag{3.6}$$

where ϵ is a positive constant. The solution of (3.6) is given by $h(\tau) = -\frac{\tau^2}{2} + \tau(\mathcal{L}+\epsilon)$. Define the function $\omega(x,y,\xi) \equiv v(x,y,\xi) - h(x-\xi)$ and take into account (3.5) to get that

$$\frac{\partial^2 \omega}{\partial x^2} + \frac{\partial^2 \omega}{\partial y^2} + \frac{\partial^2 \omega}{\partial \xi^2} \ge 0, \tag{3.7}$$

from which, using the strong maximum principle (see Lemma 3.5 in [9]), we conclude that ω does not achieve its maximum value in P_1 unless it is a constant function. On the boundary sector defined by $x = \frac{\mathcal{L}}{2}$, $|y| \le \frac{\mathcal{W}}{2}$, and $-\frac{\mathcal{L}}{2} \le \xi < \frac{\mathcal{L}}{2}$ we have that

$$\frac{\partial \omega(\frac{\mathcal{L}}{2},y,\xi)}{\partial x} = \frac{\partial u(\frac{\mathcal{L}}{2},y)}{\partial x} - h'\left(\frac{\mathcal{L}}{2}-\xi\right) = -h'\left(\frac{\mathcal{L}}{2}-\xi\right) < 0.$$

Since x is the outward normal to the domain, ω does not achieve its maximum on this part of the boundary. On the boundary sector defined by $\xi = -\frac{\mathcal{L}}{2}$, $|y| \le \frac{\mathcal{W}}{2}$, and $-\frac{\mathcal{L}}{2} < x \le \frac{\mathcal{L}}{2}$ we have that

$$\frac{\partial \omega(x,y,-\frac{\mathcal{L}}{2})}{\partial \xi} = -\frac{\partial u(-\frac{\mathcal{L}}{2},y)}{\partial \xi} + h'\left(x+\frac{\mathcal{L}}{2}\right) = h'\left(x+\frac{\mathcal{L}}{2}\right) > 0,$$

and since ξ is the inward normal we conclude that the maximum of ω is not achieved on this part of the boundary either. On the planes $y = \pm\frac{\mathcal{W}}{2}$, $|x| < \frac{\mathcal{L}}{2}$, and $|\xi| < \frac{\mathcal{L}}{2}$ we have that

$$\frac{\partial\omega(x,\pm\frac{\mathcal{W}}{2},\xi)}{\partial y} = \frac{\partial u(x,\pm\frac{\mathcal{W}}{2})}{\partial y} - \frac{\partial u(\xi,\pm\frac{\mathcal{W}}{2})}{\partial y} = 0,$$

and assuming that ω is not a constant function we have, from Lemma 3.4 in [9], that ω does not achieve its maximum on these boundary planes either. Therefore, the maximum is achieved at $x = \xi$, and since $\omega(x,y,\xi)|_{x=\xi} = 0$ we have that the inequality

$$u(x,y) - u(\xi,y) \le h(x-\xi)$$

holds in Ω, which, as can be easily seen, becomes an equality if ω is a constant function.

Subtracting relation (3.1) from (3.4) and applying the above analysis we obtain that

$$u(\xi,y) - u(x,y) \le h(x-\xi),$$

and hence

$$|u(x,y) - u(\xi,y)| \le h(x-\xi) \quad \text{for} \quad x > \xi.$$

Working in a similar way (or directly obtained by symmetry) for $x < \xi$ we easily see that

$$|u(x,y) - u(\xi,y)| \le h(|x-\xi|) - h(0).$$

By dividing the last relation by $|x-\xi|$ and taking the limit, we have that $\left|\frac{\partial u}{\partial x}\right| \le h'(0)$ and finally obtain the first of the following inequalities (when $\epsilon \to 0$), while the second can be obtained similarly.

$$\sup_{(x,y)\in\Omega}\left|\frac{\partial u(x,y)}{\partial x}\right| \le \mathcal{L}, \qquad \sup_{(x,y)\in\Omega}\left|\frac{\partial u(x,y)}{\partial y}\right| \le \mathcal{W}. \qquad \square$$

Remark 3.1. As a direct consequence of the above lemma, we easily get the following estimates for the gradient of the solution of the problem (2.1)–(2.2):

$$-\mathcal{L} + H + \frac{\alpha_1+\alpha_2}{\mathcal{L}}x + \frac{\alpha_2-\alpha_1}{2} \le \frac{\partial\phi}{\partial x} \le \mathcal{L} + H + \frac{\alpha_1+\alpha_2}{\mathcal{L}}x + \frac{\alpha_2-\alpha_1}{2} \tag{3.8}$$

and

$$-\mathcal{W} + \frac{\delta_1+\delta_2}{\mathcal{W}}y + \frac{\delta_2-\delta_1}{2} \le \frac{\partial\phi}{\partial y} \le \mathcal{W} + \frac{\delta_1+\delta_2}{\mathcal{W}}y + \frac{\delta_2-\delta_1}{2}. \tag{3.9}$$

It is worth noting here that as it follows from (3.8) $\phi_x > 0$ in the case of large magnetic field H. This is consistent with the physical properties of Josephson junctions [2].

Next we obtain sharper estimates by making certain assumptions, on typical junction's size, on the domain.

LEMMA 3.2. (a) *Suppose that $\mathcal{I}_j$ depends only on the variable y. If $\mathcal{L} < 2$, then for any classical solution $u(x,y)$ of the problem* (2.1)–(2.2) *we have*

$$|u_x| \le \frac{\mathcal{L}^2 f_1}{4-\mathcal{L}^2}, \tag{3.10}$$

where $f_1 = \max|f_x(x,y)|$.

(b) *Suppose that $\mathcal{I}_j$ depends only on the variable x. If $\mathcal{W} < 2$, then for any classical solution $u(x,y)$ of the problem* (2.1)–(2.2) *we have*

$$|u_y| \le \frac{\mathcal{W}^2 f_2}{4-\mathcal{W}^2}, \tag{3.11}$$

where $f_2 = \max|f_y(x,y)|$.

Proof. Arguing in the same manner as in the proof of Lemma 3.1, for $v(x,y,\xi) = u(x,y) - u(\xi,y)$ we obtain

$$\frac{\partial^2 v}{\partial x^2} + \frac{\partial^2 v}{\partial y^2} + \frac{\partial^2 v}{\partial \xi^2} = \mathcal{I}_j(y)\left(\sin\left(u(x,y)+f(x,y)\right) - \sin\left(u(\xi,y)+f(\xi,y)\right)\right), \tag{3.12}$$

and thus (from Lemma 3.1 we already have that $|u_x| \le \mathcal{L}$)

$$\frac{\partial^2 v}{\partial x^2} + \frac{\partial^2 v}{\partial y^2} + \frac{\partial^2 v}{\partial \xi^2} \ge -\mathcal{L}(x-\xi) \quad \text{for} \quad x > \xi. \tag{3.13}$$

Consider the prism

$$P_1 = \left\{(x,\xi,y) : |x| < \frac{\mathcal{L}}{2}, |\xi| < \frac{\mathcal{L}}{2}, |y| < \frac{\mathcal{W}}{2}, x-\xi > 0\right\},$$

and let $h_1(\tau)$ be a solution of the problem

$$h_1''(\tau) = -\frac{\mathcal{L}+f_1}{2}\tau, \quad h_1(0) = 0, \quad \text{and} \quad h_1'(\mathcal{L}) = \epsilon > 0. \tag{3.14}$$

Obviously for $h_1 = h_1(x-\xi)$ we have

$$\frac{\partial^2 h_1}{\partial x^2} + \frac{\partial^2 h_1}{\partial y^2} + \frac{\partial^2 h_1}{\partial \xi^2} = -(\mathcal{L}+f_1)(x-\xi). \tag{3.15}$$

Subtracting (3.15) from (3.13) for $\omega(x,y,\xi) \equiv v(x,y,\xi) - h_1(x-\xi)$ we obtain that

$$\frac{\partial^2 \omega}{\partial x^2} + \frac{\partial^2 \omega}{\partial y^2} + \frac{\partial^2 \omega}{\partial \xi^2} \ge 0. \tag{3.16}$$

Arguing analogously to the proof of Lemma 3.1 we have

$$|u_x(x,y)| \le h_1'(0) = \frac{\mathcal{L}+f_1}{4}\mathcal{L}^2 + \epsilon,$$

and passing to the limit when $\epsilon \to 0$,

$$|u_x(x,y)| \le \frac{\mathcal{L}+f_1}{4}\mathcal{L}^2 \equiv \mathcal{L}_1.$$

Returning back to (3.12) and taking into account that now $|u_x| \le \mathcal{L}_1$ we obtain

$$\frac{\partial^2 v}{\partial x^2} + \frac{\partial^2 v}{\partial y^2} + \frac{\partial^2 v}{\partial \xi^2} \ge -(\mathcal{L}_1 + f_1)(x-\xi) \quad \text{for} \quad x > \xi. \tag{3.17}$$

Construct the function

$$h_2''(\tau) = -\frac{\mathcal{L}_1 + f_1}{2}\tau, \quad h_2(0) = 0, \quad \text{and} \quad h_2'(\mathcal{L}) = \epsilon. \tag{3.18}$$

In a similar manner as above we conclude that

$$|u_x(x,y)| \le h_2'(0) = \frac{\mathcal{L}_1 + f_1}{4}\mathcal{L}^2 + \epsilon,$$

and letting $\epsilon \to 0$ we have

$$|u_x(x,y)| \le \frac{\mathcal{L}_1 + f_1}{4}\mathcal{L}^2 = \left(\frac{\mathcal{L}}{2}\right)^4 (\mathcal{L} + f_1) + \left(\frac{\mathcal{L}}{2}\right)^2 f_1 \equiv \mathcal{L}_2.$$

Continuing this procedure we obtain the sequence of the bounds for $|u_x|$,

$$\mathcal{L}_n = \left(\frac{\mathcal{L}}{2}\right)^{2n} \mathcal{L} + f_1 \left[\left(\frac{\mathcal{L}}{2}\right)^{2n} + \left(\frac{\mathcal{L}}{2}\right)^{2(n-1)} + \cdots + \left(\frac{\mathcal{L}}{2}\right)^4 + \left(\frac{\mathcal{L}}{2}\right)^2\right].$$

If $\mathcal{L} < 2$, then $\left(\frac{\mathcal{L}}{2}\right)^{2n} \mathcal{L} \to 0$ when $n \to \infty$, and the second term

$$f_1 \left[\left(\frac{\mathcal{L}}{2}\right)^{2n} + \cdots + \left(\frac{\mathcal{L}}{2}\right)^2\right] \to f_1 \frac{\mathcal{L}^2}{4 - \mathcal{L}^2}.$$

This concludes the proof of part (a); the proof of part (b) is similar. □

Remark 3.2. Recall that $u \equiv \phi - f$ and use the above lemma to obtain the following estimates in terms of ϕ:

$$-\frac{\mathcal{L}^2 f_1}{4-\mathcal{L}^2} + H + \frac{\alpha_1 + \alpha_2}{\mathcal{L}}x + \frac{\alpha_2 - \alpha_1}{2} \le \frac{\partial \phi}{\partial x} \le \frac{\mathcal{L}^2 f_1}{4-\mathcal{L}^2} + H + \frac{\alpha_1 + \alpha_2}{\mathcal{L}}x + \frac{\alpha_2 - \alpha_1}{2}. \tag{3.19}$$

In particular, if $f_1 = H = \alpha_1 = \alpha_2 \equiv 0$, then $\frac{\partial \phi}{\partial x} \equiv 0$.

$$-\frac{\mathcal{W}^2 f_2}{4-\mathcal{W}^2} + \frac{\delta_1 + \delta_2}{\mathcal{W}}y + \frac{\delta_2 - \delta_1}{2} \le \frac{\partial \phi}{\partial y} \le \frac{\mathcal{W}^2 f_2}{4-\mathcal{W}^2} + \frac{\delta_1 + \delta_2}{\mathcal{W}}y + \frac{\delta_2 - \delta_1}{2}. \tag{3.20}$$

In particular, if $f_2 = \delta_1 = \delta_2 \equiv 0$, then $\frac{\partial \phi}{\partial y} \equiv 0$.

Remark 3.3. If $\delta_1 = \delta_2 = 0$, $\mathcal{I}_j = \mathcal{I}_j(x)$, and $\mathcal{W} < 2$, then our problem becomes one-dimensional: $\phi(x,y) = \phi(x)$ and (2.1)–(2.2) take the form

$$\phi''(x) = \mathcal{I}_j(x)\sin\phi(x), \qquad \phi'\left(-\frac{\mathcal{L}}{2}\right) = H - \alpha_1, \qquad \phi'\left(\frac{\mathcal{L}}{2}\right) = H + \alpha_2. \tag{3.21}$$

LEMMA 3.3. *The first order derivatives of the classical solution of problem* (2.1)–(2.2) *are Hölder continuous with the Hölder coefficient and exponent depending only on* $||\frac{\partial \phi}{\partial x}||_{L^2(\Omega)}$, $||\frac{\partial \phi}{\partial y}||_{L^2(\Omega)}$, *and* $\alpha_1, \alpha_2, \delta_1, \delta_2, \mathcal{L}$, *and* $\mathcal{W}$.

The bounds on the Hölder norm of the gradient follow from Theorem 9.11 in [9].

4. Existence and uniqueness. In this section we show, under certain conditions, the existence and the uniqueness of a solution of the PDE problem (3.1)–(3.2) (and therefore of the problem (2.1)–(2.2)). We start by giving the definition of the generalized solution.

DEFINITION 4.1. *We call a function* $u(x,y) \in C^{1,\alpha}(\overline{\Omega}) \cap W_2^2(\Omega)$ *a generalized solution of the PDE problem* (3.1)–(3.2) *if it satisfies the integral identity*

$$\int_\Omega (u_{xx} + u_{yy} - \mathcal{I}_j \sin(u+f) - g)\,\psi dxdy = 0 \quad \forall \psi \in L^2(\Omega) \tag{4.1}$$

and the boundary conditions (3.2), *where* $g \equiv -\frac{\alpha_1+\alpha_2}{\mathcal{L}} - \frac{\delta_1+\delta_2}{\mathcal{W}}$.

4.1. Existence. We start by assuming that $\mathcal{I}_j$ is smooth and consider the auxiliary problem

$$\Delta v = \kappa \mathcal{I}_j \left(\sin(v+f) - \frac{1}{\mu(\Omega_j)} \int_{\Omega_j} \sin(v+f) dxdy \right) \text{ in } \Omega, \tag{4.2}$$

$$\frac{\partial v}{\partial n} = 0 \quad \text{on } \partial\Omega, \tag{4.3}$$

and

$$\frac{1}{\mu(\Omega)} \int_\Omega v dxdy = \zeta, \tag{4.4}$$

where $\kappa \in [0,1]$ and ζ is an arbitrary fixed real number. Recall that by $\mu(\Omega)$ we denote the measure of Ω. We will show that a solution $v \in C^{1,\gamma}(\bar{\Omega}) \cap C^3(\Omega)$ of the auxiliary problem (4.2)–(4.4) exists. For this we define $\psi \equiv v - \zeta$ and write the above problem in the following equivalent form:

$$\Delta \psi = \kappa \mathcal{I}_j \left[\sin(\psi + \zeta + f) - \frac{1}{\mu(\Omega_j)} \int_{\Omega_j} \sin(\psi + \zeta + f) dxdy \right] \text{ in } \Omega, \tag{4.5}$$

$$\frac{\partial \psi}{\partial n} = 0 \quad \text{on } \partial\Omega, \tag{4.6}$$

and

$$\int_\Omega \psi dxdy = 0. \tag{4.7}$$

As we easily see, the only difference between (3.1) and (4.5) is a bounded constant term on the right-hand side. Hence the estimates obtained in the lemmas in the previous section hold for (4.5)–(4.6) too. We can also observe that ψ becomes zero at least at one point in Ω so that using the estimate of the gradient (which are independent of the $\max|\psi|$) we can obtain a bound for the maximum of $|\psi|$ in the domain $\bar{\Omega}$. We are in the position now to use the Leray–Schauder theorem [9, Theorem 11.3] (see the appendix) to prove the existence of the generalized solution of problem (4.2)–(4.4).

LERAY–SCHAUDER THEOREM. *Let* T *be a compact mapping from a Banach space* $\mathcal{B}$ *to itself, and suppose there exists a constant* M *such that* $||u||_{\mathcal{B}} < M$ *for all* $u \in \mathcal{B}$ *and* $\kappa \in [0,1]$ *satisfying* $u = \kappa T u$. *Then* T *has a fixed point.*

We now address the case of a nonsmooth function $\mathcal{I}_j$.

LEMMA 4.2. *For the classical solution of the PDE problem* (4.2)–(4.4) *for* $\zeta = 1$ *the following inequality holds:*

$$\int_\Omega \left[\left(\frac{\partial^2 v}{\partial x^2} \right)^2 + 2 \left(\frac{\partial^2 v}{\partial x \partial y} \right)^2 + \left(\frac{\partial^2 v}{\partial y^2} \right)^2 \right] dxdy \le 4\mu(\Omega_j). \tag{4.8}$$

Proof. We square both sides of (4.2), integrate them two times (using integration by parts for the second term on the left-hand side). Then the use of the boundary conditions easily gives the above bound. ∎

Obviously the classical solution v satisfies the integral identity (4.1), i.e.,

$$\int_\Omega \left(\frac{\partial^2 v}{\partial x^2} + \frac{\partial^2 v}{\partial y^2} - \mathcal{I}_j^\delta \sin(v+f) + \frac{1}{\mu(\Omega)} \int_{\Omega_j} \sin(v+f) dxdy \right) \psi dxdy = 0 \ \forall \psi \in L^2(\Omega). \tag{4.9}$$

Taking the limit, as $\delta \to 0$ we readily obtain the existence of the generalized solution.

Let us fix arbitrarily $\zeta = \zeta_0$. For this ζ_0 we find the generalized solution of the problem (4.2)–(4.4) for $\kappa = 1$. In order to obtain the existence of the original problem we need to find boundary conditions such that

$$R(c) = c, \tag{4.10}$$

where

$$c \equiv \mu(\Omega_j) \left(\frac{\alpha_1 + \alpha_2}{\mathcal{L}} + \frac{\delta_1 + \delta_2}{\mathcal{W}} \right)$$

and

$$R(c) \equiv \int_{\Omega_j} \sin(v+f) dxdy.$$

Note that R satisfies the inequality $|R| < \mu(\Omega_j)$, and observe, assuming that R continuously depends on c, that it is impossible to have $R < c$ for c varying from $\mu(\Omega_j)$ to $-\mu(\Omega_j)$. Hence there exists such c_0 that verifies (4.10). For this c_0 the solution of the auxiliary problem (4.2)–(4.4) coincides with the solution of the original one (2.1)–(2.2). Mark that the assumption on the continuity of R is satisfied in the cases of the uniqueness of the solution of the auxiliary problem. Such uniqueness can be proved following an analysis similar to the one presented in Theorem 4.4. From the above we readily obtain the following theorem.

THEOREM 4.3. *If the solution of the problem* (4.2)–(4.4) *is unique, then for any* $\zeta \in \mathbb{R}$ *we can find values for* $H, \alpha_1, \alpha_2, \delta_1,$ *and* δ_2 *for which there exists a generalized solution* ϕ *of the problem* (2.1)–(2.2) *such that*

$$\frac{1}{\mu(\Omega)} \int_\Omega (\phi - f) dxdy = \zeta. \tag{4.11}$$

Let us note that Theorem 4.3 also holds if condition (4.11) is replaced by

$$(\phi - f)|_{(x_0, y_0)} = \zeta, \quad (x_0, y_0) \in \Omega.$$

To prove this, one has to carry out an analysis similar to the above, which is lengthy and tedious and so will not be presented here.

4.2. Uniqueness. It has been observed both numerically and experimentally [2, 3, 4] and it is intuitively expected that our PDE problem might have more than one nontrivial solution. In the case when $\mathcal{L} < 2$ and $\mathcal{W} < 2$ we can easily see from Lemma 3.2 that the only solution is $n\pi$, $n = 0, \pm 1, \pm 2, \ldots$. An extensive theoretical and experimental bifurcation analysis is under way and will be presented elsewhere. Nevertheless, as we show below, under certain conditions only one solution exists.

THEOREM 4.4. *Assume that either*

(a) $\mathcal{L} < 2$, $w < \sqrt{2}$, $\mathcal{I}_j = \mathcal{I}_j(y)$, *and* $H = \alpha_1 = \alpha_2 = 0$, *or*

(b) $\mathcal{W} < 2$, $\ell < \sqrt{2}$, $\mathcal{I}_j = \mathcal{I}_j(x)$, *and* $\delta_1 = \delta_2 = 0$.

Then the generalized solution u *of* (3.1)–(3.2) *satisfying the condition*

$$\frac{1}{\mu(\Omega)} \int_\Omega u dx dy = \zeta, \tag{4.12}$$

where ζ *is an arbitrarily given constant, is unique.*

Proof. From Lemma 3.2 it follows that $u_x \equiv 0$. Thus we have

$$u_{yy} = \mathcal{I}_j(y) \sin(u + f) - \frac{\delta_1 + \delta_2}{\mathcal{W}} \quad \text{in} \quad \Omega, \tag{4.13}$$

$$u_y \left(\pm \frac{\mathcal{W}}{2} \right) = 0, \tag{4.14}$$

and

$$\int_{-\frac{\mathcal{W}}{2}}^{\frac{\mathcal{W}}{2}} u dy = \zeta. \tag{4.15}$$

Suppose now that there exist two different solutions u and v, both satisfying condition (4.15), i.e.,

$$\int_{-\frac{\mathcal{W}}{2}}^{\frac{\mathcal{W}}{2}} u dy = \int_{-\frac{\mathcal{W}}{2}}^{\frac{\mathcal{W}}{2}} v dy. \tag{4.16}$$

This implies that u and v cross each other. Now let $\sigma \equiv u - v$ and observe that

$$\sigma_{yy} = \mathcal{I}_j(y) \left(\sin(u(y) + f(y)) - \sin(v(y) + f(y)) \right) = \mathcal{I}_j(y) \sigma \cos\theta. \tag{4.17}$$

Suppose that u and v intersect at a point y_0. Consider the two cases

$$(\alpha) \quad y_0 \notin \left[-\frac{w}{2}, \frac{w}{2} \right], \qquad (\beta) \quad y_0 \in \left[-\frac{w}{2}, \frac{w}{2} \right]. \tag{4.18}$$

In (α) consider the case $y_0 \in \left(-\frac{\mathcal{W}}{2}, \frac{w}{2}\right]$. In the interval $\left(-\frac{\mathcal{W}}{2}, y_0\right)$ we have $\sigma_{yy} = 0$ and $\sigma_y(-\frac{\mathcal{W}}{2}) = \sigma(y_0) = 0$. Hence $\sigma \equiv 0 \in \left(-\frac{\mathcal{W}}{2}, y_0\right)$. Therefore, due to the analyticity of σ in $\left(-\frac{\mathcal{W}}{2}, \frac{w}{2}\right]$ we have $\sigma \equiv 0 \in \left(-\frac{\mathcal{W}}{2}, \frac{w}{2}\right]$. Similarly we can consider the case $y_0 \in \left[\frac{w}{2}, \frac{\mathcal{W}}{2}\right)$.

Consider now the (β) case. Multiplying (4.17) by σ and integrating by parts we get

$$\int_{y_0}^{\frac{\mathcal{W}}{2}} \sigma_y^2 dy \le \int_{y_0}^{\frac{\mathcal{W}}{2}} \mathcal{I}_j \sigma^2 dy = \int_{y_0}^{\frac{w}{2}} \sigma^2 dy. \tag{4.19}$$

Applying the Poincaré inequality we obtain

$$\int_{y_0}^{\frac{w}{2}} \sigma_y^2 dy \le \int_{y_0}^{\frac{\mathcal{W}}{2}} \sigma_y^2 dy \le \int_{y_0}^{\frac{w}{2}} \sigma^2 dy \le \frac{w^2}{2} \int_{y_0}^{\frac{w}{2}} \sigma_y^2 dy. \tag{4.20}$$

Due to the assumption $w < \sqrt{2}$ we have $\int_{y_0}^{\frac{w}{2}} \sigma_y^2 dy = 0$, and therefore $\sigma_y \equiv 0$. Since $\sigma(y_0) = 0$ we have $\sigma \equiv 0$ and $u \equiv v$. □

We note that there are other cases where one might be able to show this uniqueness. For example, we have shown that if we assume that the window is such that $\ell < \sqrt{2}$ and $w < \sqrt{2}$, then the generalized solution u of (3.1)–(3.2) satisfying the condition

$$\frac{1}{\mu(\Omega)} \int_\Omega u dx dy = \zeta, \tag{4.21}$$

where ζ is an arbitrarily given constant, is unique. The proof of this statement is similar to the proof of the previous theorem. Since it is rather technical, tedious, and lengthy it is not included here.

In a manner similar to the above theorem it can be shown that there exist cases where the solution of the auxiliary problem is unique.

5. Additional estimates. In this section we obtain estimates of the gradient of the solution of the problem in some special cases that are of physical interest. As discussed in section 2 it is useful [3, 4, 5] to characterize the solutions of (2.1)–(2.2) by their oscillations, defined by (2.4). In what follows we derive estimates of the gradient of the solution as a function of its oscillations in the x- and y-directions.

LEMMA 5.1. *For any classical solution $\phi(x, y)$ of the problem* (2.1)–(2.2) *we have that*

$$\left|\frac{\partial \phi}{\partial x}\right| \le \sqrt{2 osc_x \phi + (H + \alpha_2)^2} \tag{5.1}$$

and

$$\left|\frac{\partial \phi}{\partial y}\right| \le \sqrt{2 osc_y \phi + \delta_2^2}. \tag{5.2}$$

Proof. We follow the analysis of Lemma 3.1, with the main difference being in the construction of the barrier h. Specifically we set $v(x, y, \xi) \equiv \phi(x, y) - \phi(\xi, y)$ and define $h(\tau)$ as the solution of the problem

$$h''(\tau) = -1, \quad h(0) = 0, \quad h(\tau^*) = osc_x \phi,$$

where τ^* will be defined later. We need to compare the functions v and $h(x - \xi)$ in the prism $P_2 \cap \{x - \xi < \mathcal{L}\}$, where

$$P_2 = \left\{(x, \xi, y) : |x| < \frac{\mathcal{L}}{2}, |\xi| < \frac{\mathcal{L}}{2}, |y| < \frac{\mathcal{W}}{2}, \tau^* > x - \xi > 0\right\},$$

whose cross-section along the y-axis is given in Figure 5.1. Obviously (see (3.7)) we have $\Delta(v - h) \ge 0$ in $P_2 \cap \{x - \xi < \mathcal{L}\}$, and hence the maximum is not achieved in the interior of $P_2 \cap \{x - \xi < \mathcal{L}\}$. We need to check the boundary. When $x = \xi$ and $y \in [-\frac{\mathcal{W}}{2}, \frac{\mathcal{W}}{2}]$ we have $v - h = 0$.

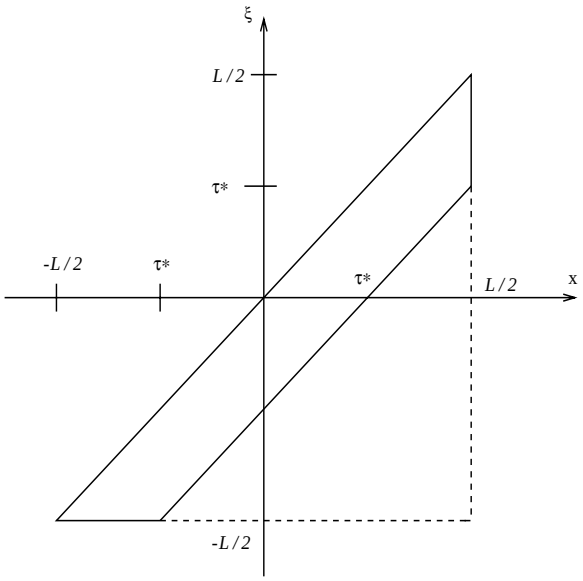

FIG. 5.1. *A cross-section of domain P_2 along a plane in the y-direction.*

For $x - \xi = \tau^*$ we obtain $v - osc_x\phi \leq 0$ for $y \in [-\frac{\mathcal{W}}{2}, \frac{\mathcal{W}}{2}]$. For $x = \frac{\mathcal{L}}{2}$, $\xi \in (-\tau^* + \frac{\mathcal{L}}{2}, \frac{\mathcal{L}}{2})$, and $y \in [-\frac{\mathcal{W}}{2}, \frac{\mathcal{W}}{2}]$ we have that

$$\frac{\partial(v-h)}{\partial x}\bigg|_{x=\frac{\mathcal{L}}{2}} = H + \alpha_2 - h'\left(\frac{\mathcal{L}}{2} - \xi\right).$$

Similarly if $\xi = -\frac{\mathcal{L}}{2}$, $x \in (-\frac{\mathcal{L}}{2}, -\frac{\mathcal{L}}{2} + \tau^*)$, and $y \in [-\frac{\mathcal{W}}{2}, \frac{\mathcal{W}}{2}]$, then

$$\frac{\partial(v-h)}{\partial \xi}\bigg|_{\xi=-\frac{\mathcal{L}}{2}} = -(H - \alpha_1) + h'\left(x + \frac{\mathcal{L}}{2}\right).$$

Therefore if $h' > H + \alpha_2$ (note that $H, \alpha_1, \alpha_2, \delta_1, \delta_2$ are positive constants), then

$$\frac{\partial(v-h)}{\partial x}\bigg|_{x=\frac{\mathcal{L}}{2}} < 0, \qquad \frac{\partial(v-h)}{\partial \xi}\bigg|_{\xi=-\frac{\mathcal{L}}{2}} > 0,$$

and hence we do not have a maximum on these parts of the boundary of P_2. Furthermore, since for $y = \pm\frac{\mathcal{L}}{2}$, $x \in (-\frac{\mathcal{L}}{2}, \frac{\mathcal{L}}{2})$, and for $\xi \in (-\frac{\mathcal{L}}{2}, \frac{\mathcal{L}}{2})$ and $\xi \in (-\frac{\mathcal{L}}{2}, \frac{\mathcal{L}}{2})$ and $0 < x - \xi < \tau^*$ we have $\frac{\partial(v-h)}{\partial y} = 0$, we conclude (see Lemma 3.4 in [8]) that we do not have a maximum here either. It remains to choose τ^* such that $h'(\tau) > H + \alpha_2$ for $\tau \in [0, \tau^*]$. For this we get

$$\tau^* < -(H + \alpha_2) + \sqrt{(H + \alpha_2)^2 + 2osc_x\phi}.$$

As previously we have that

$$|\phi_x(x, y)| \leq h'(0) = \frac{osc_x\phi}{\tau^*} + \frac{\tau^*}{2}.$$

It can be seen that the minimum of $h'(0)$ with respect to τ^* is achieved when $\tau^* = -(H + \alpha_2) + \sqrt{(H + \alpha_2)^2 + 2osc_x\phi}$, from which we obtain relation (5.1).

For $\tau^* \geq \mathcal{L}$ the only difference is the absence of the boundary $x - \xi = \tau^*$, and the boundaries $x = \frac{\mathcal{L}}{2}$, $\xi \in (-\tau^* + \frac{\mathcal{L}}{2}), \frac{\mathcal{L}}{2}$, $y \in [-\frac{\mathcal{W}}{2}, \frac{\mathcal{W}}{2}]$ become $x = \frac{\mathcal{L}}{2}$, $\xi \in (-\frac{\mathcal{L}}{2}, \frac{\mathcal{L}}{2}$, $y \in [-\frac{\mathcal{W}}{2}, \frac{\mathcal{W}}{2}]$, and $\xi = -\frac{\mathcal{L}}{2}$, $x \in (-\frac{\mathcal{L}}{2}, -\frac{\mathcal{L}}{2} + \tau^*)$, $y \in [-\frac{\mathcal{W}}{2}, \frac{\mathcal{W}}{2}]$ become $\xi = -\frac{\mathcal{L}}{2}$, $x \in (-\frac{\mathcal{L}}{2}, \frac{\mathcal{L}}{2})$, $y \in [-\frac{\mathcal{W}}{2}, \frac{\mathcal{W}}{2}]$. We work similarly for the case $\tau^* < \mathcal{L}$

One can obtain relation (5.2) working similarly for the y variable. □

Remark. We conclude the discussion in this section by observing that in the case where $\alpha_1 = \alpha_2 = \alpha$ and $\delta_1 = \delta_2 = \delta$ the numerical experiments that we have conducted, shown in section 7, indicate that a solution of the PDE problem (2.1)–(2.2) is symmetric along the axis $y = 0$. To obtain this solution one can reduce the PDE problem (2.1) to the domain defined by $(-\frac{\mathcal{L}}{2}, \frac{\mathcal{L}}{2}) \times (-\frac{\mathcal{W}}{2}, 0)$ together with the boundary conditions $\frac{\partial \phi(x,y)}{\partial x} = H \pm \alpha$ on $x = \pm\mathcal{L}/2$, $\frac{\partial \phi(x,y)}{\partial y} = \delta$ on $y = -\mathcal{W}/2$, and $\frac{\partial \phi(x,y)}{\partial y} = 0$ on $y = 0$. The solution to the original problem is obtained by applying symmetry across the y-axis. For the reduced problem the estimates (3.9) and (4.8) obtained above can be improved to become

$$-\frac{\mathcal{W}}{2} - \frac{2\delta}{\mathcal{W}} y \leq \frac{\partial \phi(x,y)}{\partial y} \leq \frac{\mathcal{W}}{2} - \frac{2\delta}{\mathcal{W}} y \tag{5.3}$$

and

$$\begin{aligned} &\int_{-\frac{\mathcal{L}}{2}}^{\frac{\mathcal{L}}{2}} \int_{-\frac{\mathcal{W}}{2}}^{0} \left[\left(\frac{\partial^2 \phi}{\partial x^2} \right)^2 + 2 \left(\frac{\partial^2 \phi}{\partial x \partial y} \right)^2 + \left(\frac{\partial^2 \phi}{\partial y^2} \right)^2 \right] dxdy \\ &\leq \frac{1}{2} \mu(\Omega_j) \left[1 + 4 \left(\frac{\alpha}{\mathcal{L}} + \frac{\delta}{\mathcal{W}} \right) \right] + 2\alpha \frac{H\mathcal{W}}{\mathcal{L}} + 5\delta^2 \frac{\mathcal{L}}{\mathcal{W}} + 2\alpha\delta, \end{aligned} \tag{5.4}$$

respectively.

In the particular case when $H = \delta = 0$ and the junction is placed symmetrically inside Ω, we have observed the existence of a solution for which the phase is equal to a constant along the line $x = 0$ (see the top of Figure 7.2). Although we are unable to prove their existence, such solutions have been observed in practice, and their physical justification is well established in the case where no extra fluxons have entered the interior of the window [4, 5]. For this type of solution we are able to obtain the following estimations of its size.

LEMMA 5.2. *For any classical solution $\phi(x, y)$ of the problem (2.1)–(2.2) with $H, \delta = 0$ and $\alpha_i = a$, for which $\phi = k$, k is a constant, at $x = 0$, we have that*

$$k + \frac{x^2}{2} + \left(\frac{\mathcal{L}}{2} - \alpha \right) x \leq \phi \leq k - \frac{x^2}{2} - \left(\alpha + \frac{\mathcal{L}}{2} \right) x \quad \text{for} \quad -\frac{\mathcal{L}}{2} \leq x \leq 0, \tag{5.5}$$

$$k + \frac{x^2}{2} - \left(\frac{\mathcal{L}}{2} - \alpha \right) x \leq \phi \leq k - \frac{x^2}{2} + \left(\frac{\mathcal{L}}{2} + \alpha \right) x \quad \text{for} \quad 0 \leq x \leq \frac{\mathcal{L}}{2}. \tag{5.6}$$

Proof. To obtain relation (5.5) we consider the domain $\Omega_1 \equiv (-\frac{\mathcal{L}}{2}, 0) \times (-\frac{\mathcal{W}}{2}, \frac{\mathcal{W}}{2})$, and from (3.1) we have

$$-\beta - 1 \leq \frac{\partial^2 u(x,y)}{\partial x^2} + \frac{\partial^2 u(x,y)}{\partial y^2} \leq -\beta + 1,$$

where $\beta = \frac{2\alpha}{\mathcal{L}}$. We define now the function $g(x) \equiv \frac{1-\beta}{2}(x + \frac{\mathcal{L}}{2})^2 + \epsilon x$, where $\epsilon > 0$ and $v \equiv u - g$. Obviously we have that

$$\frac{\partial^2 v(x,y)}{\partial x^2} + \frac{\partial^2 v(x,y)}{\partial y^2} \leq 0;$$

thus v does not achieve its minimum in Ω_1 (unless it is a constant). It does not achieve it on the boundary lines $x = -\frac{\mathcal{L}}{2}$, $y \in [-\frac{\mathcal{W}}{2}, \frac{\mathcal{W}}{2}]$ (since the derivative in the x-direction is negative) and $y = \pm\frac{\mathcal{W}}{2}$ for $x \in (-\frac{\mathcal{L}}{2}, 0)$ (see Lemma 3.4, p. 34 in [9]) either. So, we conclude that the minimum of v occurs at $x = 0$, and we have that

$$v \geq \min\,(u-g)|_{x=0} = k - \frac{\mathcal{L}^2}{8},$$

and therefore

$$u \geq k + \frac{1-\beta}{2}x^2 + (1-\beta)\frac{\mathcal{L}}{2}x - \frac{\beta}{8}\mathcal{L}^2 + \epsilon x.$$

We now set $\hat{v} \equiv u - \hat{g}$, where $\hat{g}(x) \equiv -\frac{\beta+1}{2}(x + \frac{\mathcal{L}}{2})^2 - \epsilon x$, where $\epsilon > 0$, from which we have that

$$\frac{\partial^2 \hat{v}(x,y)}{\partial x^2} + \frac{\partial^2 \hat{v}(x,y)}{\partial y^2} \geq 0.$$

Using arguments similar to those above we can show that $\hat{v} \leq \max \hat{v}|_{x=0}$ to obtain

$$u \leq k - \frac{\beta+1}{2}x^2 - (\beta+1)\frac{\mathcal{L}}{2}x - \frac{\beta}{8}\mathcal{L}^2 - \epsilon x.$$

To conclude the proof of relation (5.5) we simply repeat the above analysis for the domain $(0, \frac{\mathcal{L}}{2}) \times (-\frac{\mathcal{W}}{2}, \frac{\mathcal{W}}{2})$, use the fact that ϵ is an arbitrary positive constant, and simply go from the function u to the function ϕ. □

6. Linearization. For the numerical solution of the semilinear elliptic PDE problem (2.1)–(2.2) one can linearize the PDE equation by means of the following fixed point iteration scheme:

$$L\phi^{(i)} \equiv \Delta\phi^{(i)} - \mathcal{I}_j r\phi^{(i)} = \mathcal{I}_j\left(\sin(\phi^{(i-1)}) - r\phi^{(i-1)}\right), \quad i = 1, 2, \ldots, \tag{6.1}$$

where $r \equiv r(x,y)$ is a relaxation function to accelerate the convergence, and it can be any nonzero function. We start these iterations using an initial guess $u^{(0)}$ of the solution u obtained using one of the approaches described in [4], and we terminate them when the `max`-norm of the difference of two successive approximations of the solution vector ($||\phi^{(i)} - \phi^{(i-1)}||_\infty$) or the `max`-norm of the residual of the problem ($||\Delta\phi^{(i)} - \mathcal{I}\sin\phi^{(i)}||_\infty$) is less than a given tolerance. Two obvious choices for that parameter are $r(x,y) = c$ (constant function) and $r(x,y) = \cos(\phi^{(i-1)}(x,y))$. With the latter one, the iteration scheme (6.1) reduces to the well-known Newton iterative method [14]. The implementation and the performance of this quadratically converging method is given in [4], and its convergence analysis is under way and will be presented elsewhere. For the convergence of (6.1) when r is a positive constant we have the following theorem.

THEOREM 6.1. *If $c \equiv c(r)$ is the measure of the smallest eigenvalue of the operator L, then the iterative method* (6.1) *converges, from any initial guess $\phi^{(0)}$, to the solution of* (3.1)–(3.2) *if*

$$\frac{1}{c}\left(\frac{1}{2} + r\right) < 1. \tag{6.2}$$

Proof. If we denote by $e^{(i)} \equiv \phi - \phi^{(i)}$ the error at the ith iteration, we see that for $i = 1, 2, \ldots$ we have

$$Le^{(i)} = \mathcal{I}_j \left[\cos\left(\frac{e^{(i-1)}}{2} + \phi \right) \sin\left(\frac{e^{(i-1)}}{2} \right) - re^{(i-1)} \right],$$

from which we obtain

$$||Le^{(i)}|| \leq \left\| \cos\left(\frac{e^{(i-1)}}{2} + \phi \right) \sin\left(\frac{e^{(i-1)}}{2} \right) \right\| + r||e^{(i-1)}||.$$

By expanding the sine term and dropping the cosine term in the above relation we have for $i = 1, 2, \ldots$ that

$$||Le^{(i)}|| \leq \left(\frac{1}{2} + r \right) ||e^{(i-1)}||,$$

from which relation (6.2) can be easily obtained by requiring the amplification factor to be less than 1. □

It is worth pointing out here that the lack of convergence, as one increases the current, of the Newton iterative scheme defined above reflects the dynamical instability of the static solution in the time-dependent sine-Gordon system.

7. Numerical experiments and physical relevance. Using the proposed PDE model we have built a powerful simulation tool that accurately and effectively models window Josephson junctions. Our implementation, described in detail in [4], is based on the ELLPACK infrastructure [16], and its basic components are as follows: a uniform discretization of the domain Ω using a tensor product of $n \times n$ grid lines, the Newton linearization scheme, and the discretization of the PDE problem (3.1)–(3.2) using the standard 5-point-star finite difference method. For all experiments we have used a junction $\Omega = [0, 12] \times [0, 3]$, and unless otherwise stated the window Ω_j has sizes $\ell = 10$ and $w = 1$ in the x- and y-direction, respectively, and is placed in the center of Ω. The boundary conditions were selected such that $\alpha_1 = \alpha_2 \equiv \alpha$ and $\delta_1 = \delta_2 \equiv \delta$.

In Figure 7.1 we present the properties of the Newton linearization scheme with which we obtained all the numerical data reported here. On the left we see the history of convergence during the first four iterations. Specifically we plot, in log–log scale, the quantity $||\phi^{(i)} - \phi^{(i-1)}||_\infty$ versus the iteration number i for $i = 1, 2, 3, 4$ with $n = 20, 40$, and 60, and we easily see the quadratic rate of convergence. To measure the accuracy obtained in the fourth iteration, we plot in the middle panel the infinity and the L_2 norms of the residual $(\Delta\phi - \mathcal{I}_j \sin\phi)$ versus n in semilog scale. The theoretically expected [16] second order convergence, with respect to discretization stepsize, of the 5-point-star discretization scheme used to solve the linear problems at every step in (6.1) can be easily verified. The time complexity of the Newton iterative algorithm is presented in the right panel, where we plot the per-iteration CPU time required versus n. As is easily seen this is approximately n^3.

To understand the structure of the solutions for various boundary conditions and confirm the obtained barrier functions, we give in Figures 7.2 and 7.3 a series of contour and three-dimensional plots of the computed solutions and their gradients for three different boundary conditions. Figure 7.2 corresponds to a situation where $H = 0$, $\delta \equiv 0$, and $\alpha \equiv 0$ in the top plate and bottom plate, respectively. In this case the solution has an oscillation in x smaller than 2π.

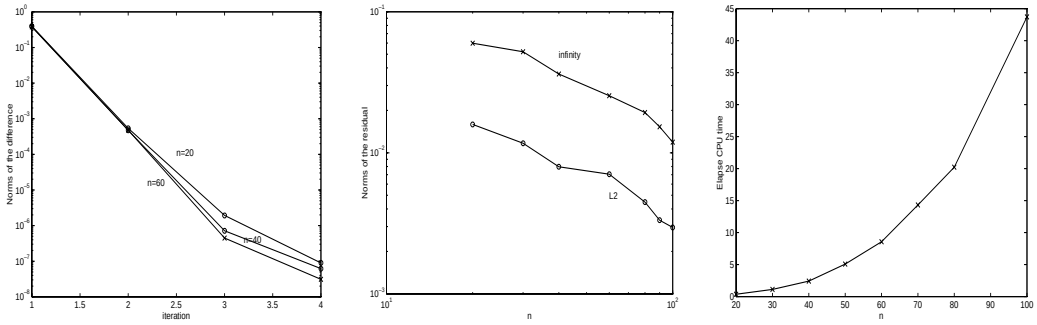

FIG. 7.1. *Log–log plot of the infinity norm of the difference of two successive iterants of Newton method for discretization parameter $n = 20, 40, 60$ versus the iteration number (left), semilog plot of the infinity and L_2 norms of the residual versus the discretization parameter n (middle), and plot of the per-iteration CPU time versus the discretization parameter n (right).*

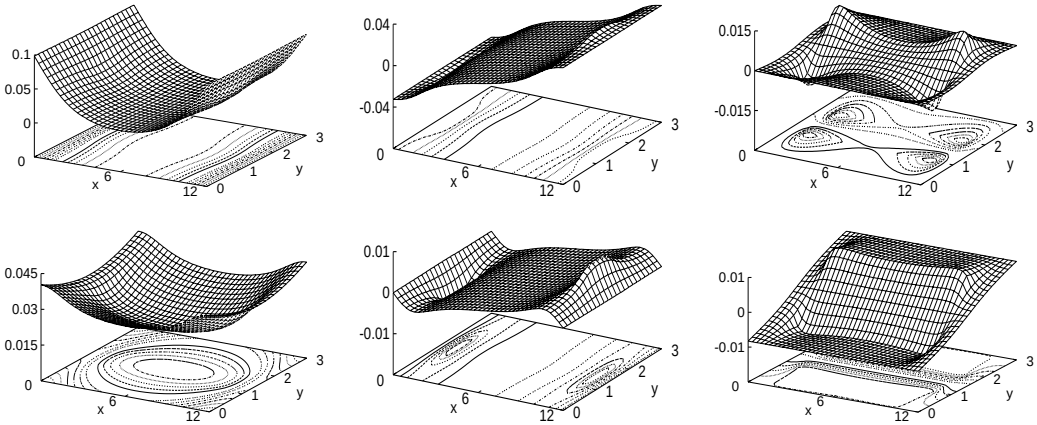

FIG. 7.2. *Plots of the solution (left column) and the derivatives in the x- (middle column) and the y- (right column) directions for $H = 0$ and $\alpha = .033$, $\delta = 0$ (top) and $\alpha = 0$, $\delta = .0083$ (bottom).*

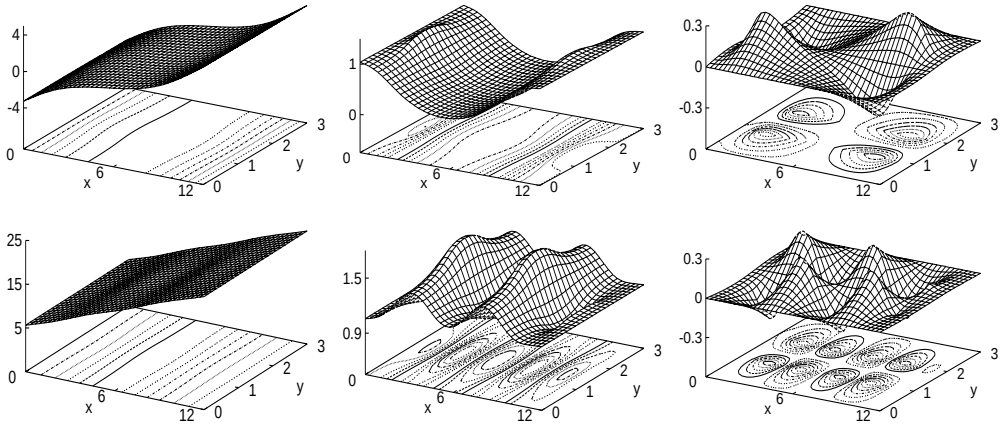

FIG. 7.3. *Plots of the solution (left column) and the derivatives in the x- (middle column) and the y- (right column) directions for $H = 1.1$ $\alpha = .05$ and $\delta = 0$ for one-fluxon (top) and three-fluxon (bottom) solutions.*

TABLE 7.1
A priori bounds for the gradients of the solution associated with the PDE problems considered in Figures 7.2 *and* 7.3.

Figures	Lemma 3.1	Lemma 5.1
7.2 top	$\frac{\partial\phi}{\partial x} \le 12 + 0.055(x-6)$ $\frac{\partial\phi}{\partial y} \le 3$	$\frac{\partial\phi}{\partial x} \le 0.448$ $\frac{\partial\phi}{\partial y} \le 0.14$
7.2 bottom	$\frac{\partial\phi}{\partial x} \le 12$ $\frac{\partial\phi}{\partial y} \le 3 + 0.00553y$	$\frac{\partial\phi}{\partial x} \le 0.223$ $\frac{\partial\phi}{\partial y} \le 0.173$
7.3 top	$\frac{\partial\phi}{\partial x} \le 13.1 + 0.00833(x-6)$ $\frac{\partial\phi}{\partial y} \le 3$	$\frac{\partial\phi}{\partial x} \le 3.72$ $\frac{\partial\phi}{\partial y} \le 0.447$
7.3 bottom	$\frac{\partial\phi}{\partial x} \le 13.1 + 0.055(x-6)$ $\frac{\partial\phi}{\partial y} \le 3$	$\frac{\partial\phi}{\partial x} \le 6.43$ $\frac{\partial\phi}{\partial y} \le 0.447$

For a larger value of the magnetic field $H = 1.1$, shown in Figure 7.3, the oscillation in x of the solution increases. The existence of more than one solution for certain values of the boundary conditions is confirmed here. The first solution presented in the top plate has an oscillation of less than 2π (one-fluxon solution) while the oscillation of the second one is between 4π and 6π (three-fluxon solution).

For the PDE problems considered in Figures 7.2 and 7.3 we present in Table 7.1 the a priori estimates for the gradients of the solution theoretically obtained using Lemmas 3.1 and 5.1, respectively. The confirmation of these lemmas can be readily obtained by comparing the entries of the table with the associated plots in the figures. We also easily see the improvement of the estimates in the x-direction obtained in section 5. To confirm the theoretically obtained estimates in Lemma 5.2 of the solution (in the special case where it has a constant value on the line $x = 0$) we have computed using this lemma the upper and lower bounds of ϕ for the problems considered in the top of Figure 7.2,

$$5.967(x-6) + 0.5(x-6)^2 \le \phi \le -6.033(x-6) - 0.5(x-6)^2 \quad \text{for } 0 \le x \le 6$$

and

$$-5.967(x-6) + 0.5(x-6)^2 \le \phi \le 6.033(x-6) - 0.5(x-6)^2 \quad \text{for } 6 \le x \le 12,$$

and in the top of Figure 7.3,

$$5.95(x-6) + 0.5(x-6)^2 \le \phi \le -6.05(x-6) - 0.5(x-6)^2 \quad \text{for } 0 \le x \le 6$$

and

$$-5.95(x-6) + 0.5(x-6)^2 \le \phi \le 6.05(x-6) - 0.5(x-6)^2 \quad \text{for } 6 \le x \le 12.$$

As is easily seen these estimates agree with the numerical data presented in the associated figures.

As mentioned in section 2 an important question from both a theoretical and a practical point of view is, For what values of H, α, and δ does the solution to our PDE problem exist? Or, equivalently, Which is the maximum current $I_t = 2(\alpha\mathcal{W} + \delta\mathcal{L})$ that the device can carry for a given magnetic field? We have numerically determined

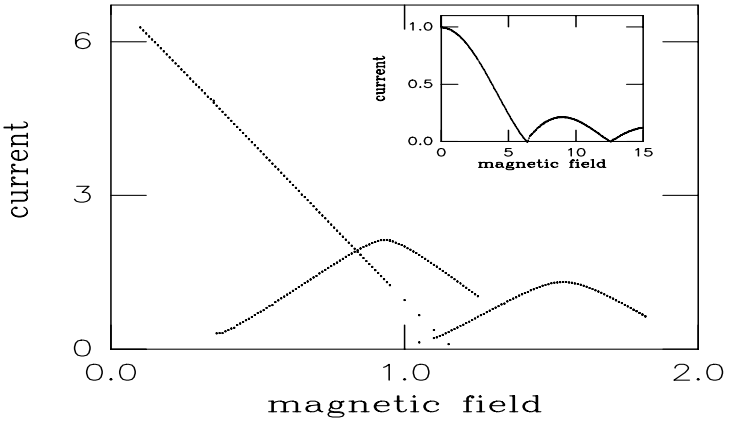

FIG. 7.4. *Allowed values for magnetic field and current for the inline geometry ($\delta \equiv 0$).*

the relation between the magnetic field and the maximum current for the case where $\delta = 0$, and we present it graphically in Figure 7.4. It is important to note that for pairs of currents and magnetic fields below each (starting from the leftmost) of the three "maximum lines" shown, there exist one-fluxon, two-fluxon, and three-fluxon solutions, respectively. Above them no solutions exist. The overlap of the branches corresponding to one fluxon and three fluxons is consistent with the observation made from Figure 7.3 on the coexistence of a one-fluxon solution and three-fluxon solution for $H = 1.1$. Notice also that in this case the maximum current which is obtained for $H = 0$ is significantly lower than the bound given by (2.3), which is $l \times w = 10$.

We have calculated the oscillations in the x- and y-directions for the solutions corresponding to the maximum current for several values of the magnetic field and reported them in Table 7.2. An initial observation is that the oscillations in the y-direction are small and do not vary significantly as a function of H for the values considered. This indicates that a one-dimensional description of this problem could be possible; such a heuristic approach based on an appropriate rescaling of a one-dimensional sine-Gordon equation is currently under way. In turn the oscillations in the x-direction vary from π to 6π and correspond to the different fluxon branches described in the introduction. Notice, however, that the oscillation for the solution at the right-hand tip of the first branch is larger than 2π, contrary to what happens for the pure one-dimensional sine-Gordon equation. This is due to the fact that the

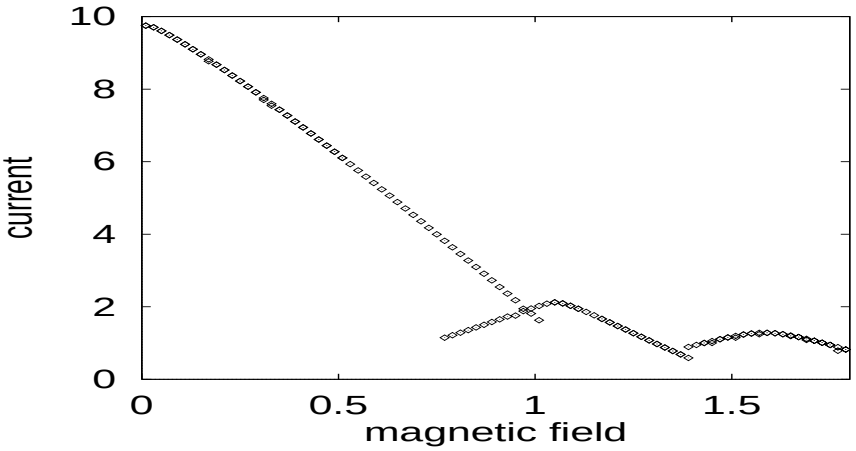

FIG. 7.5. *Allowed values for magnetic field and current for the overlap geometry ($\alpha \equiv 0$).*

TABLE 7.3
Oscillations for the solutions corresponding to the branches of Figure 7.5 *for several values of the magnetic field H.*

junction domain is smaller than Ω. The case of a very small domain $\Omega = [0,3] \times [0,3]$ and a window $\Omega_j = [1,2] \times [1,2]$ is presented in the inset of Figure 7.4. Another interesting feature is that the branches do not overlap and that their graph is very well approximated by $\left|\frac{\sin \frac{H}{2}}{\frac{H}{2}}\right|$, a feature that is well known for small Josephson junctions [2]. In this situation, the maximum current for $H = 0$ is $l \times w = 1$, corresponding to a solution equal to $\frac{\pi}{2}$ inside the junction.

Returning to the long junction, we have calculated the maximum current when the distribution is of the overlap type ($\alpha = 0$) and present it in Figure 7.5. In this case the maximum current for $H = 0$ is very close to the theoretical bound $l \times w = 10$, indicating that the solution inside the junction is very close to $\frac{\pi}{2}$. As in the inline case the branches overlap, indicating a multiplicity of solutions. The oscillations are reported in Table 7.3. Contrary to the inline case discussed above the oscillation in the y-direction varies significantly, indicating a stronger two-dimensional variation of the solution. As expected the values of the magnetic field corresponding to the zeros of the current coincide in Figures 7.4 and 7.5.

It is possible to use the bounds obtained on $\frac{\partial \phi}{\partial x}$ and $\frac{\partial \phi}{\partial y}$ in section 5 to obtain an estimate of the total current I_t. To do this notice by integrating the PDE (2.1)–(2.2)

over the domains Ω_j and Ω that

$$I_t = 2(\alpha\mathcal{W} + \delta\mathcal{L}) = \int_{\Omega_j} \sin\phi dxdy = \int_{\partial\Omega_j} \nabla\phi \mathbf{n} ds = \int_{\partial\Omega_j} \left(\frac{\partial\phi}{\partial x}\mathrm{n_x} + \frac{\partial\phi}{\partial y}\mathrm{n_y}\right) ds, \tag{7.1}$$

where the last integral is a flux integral taken on the boundary of the junction $\partial\Omega_j$, and $\mathbf{n} = \binom{\mathrm{n_x}}{\mathrm{n_y}}$ is the normal vector associated to this boundary. This integral can be bounded in the case of a junction with arbitrary shape and perimeter P,

$$\left| \int_{\partial\Omega_j} \left(\frac{\partial\phi}{\partial x}\mathrm{n_x} + \frac{\partial\phi}{\partial y}\mathrm{n_y}\right) ds \right| \leq \left(\max\left|\frac{\partial\phi}{\partial x}\right| + \max\left|\frac{\partial\phi}{\partial y}\right| \right) P,$$

so that using Lemma 5.2 one obtains the following inequality for α and δ assumed positive:

$$\frac{I_t}{2} = \alpha\mathcal{W} + \delta\mathcal{L} \leq \frac{P}{2}\left(\sqrt{2osc_x + (H+\alpha)^2} + \sqrt{2osc_y + \delta^2}\right). \tag{7.2}$$

In the case of a rectangular junction centered in the domain Ω, this estimate can be improved by separating the integrals on the parts of the boundary $\partial\Omega_j$ parallel to the x- and y-directions to obtain

$$\begin{aligned}\int_{\partial\Omega_j} \left(\frac{\partial\phi}{\partial x}\mathrm{n_x} + \frac{\partial\phi}{\partial y}\mathrm{n_y}\right) ds = &\int_{-\frac{l}{2}}^{\frac{l}{2}} \left[\frac{\partial\phi}{\partial y}\left(x, \frac{w}{2}\right) - \frac{\partial\phi}{\partial y}\left(x, -\frac{w}{2}\right)\right] dx \\ &+ \int_{-\frac{w}{2}}^{\frac{w}{2}} \left[\frac{\partial\phi}{\partial x}\left(\frac{l}{2}, y\right) - \frac{\partial\phi}{\partial x}\left(-\frac{l}{2}, y\right)\right] dy.\end{aligned}$$

Recall that l and w are the length and width of the junction domain Ω_j, respectively. One can then bound the absolute values of the above integrals using Lemma 5.2 and obtain

$$\frac{I_t}{2} = \alpha\mathcal{W} + \delta\mathcal{L} \leq \sqrt{2osc_x + (H+\alpha)^2}\, w + \sqrt{2osc_y + \delta^2}\, l. \tag{7.3}$$

This upper bound for the current is not as sharp as (2.3). For example, for the case of Figure 7.4 for $H = 0.41$ we find $I_t = 4.37$ corresponding to $\alpha = 0.728$. Using the values of the oscillations given by Table 7.2 we obtain for the right-hand side of the inequality (7.3) 9.62, which corresponds to a total current of 19.24, while the maximum current allowed is $l \times w = 10$.

8. Conclusions and future work. Josephson junctions have already proved themselves to be technologically useful, and it is our belief that their importance will increase significantly in the near future. Many recent reports and books have been dedicated to the analysis of the one-dimensional case, where one can usually give the solution of the associated boundary value problem analytically in terms of elliptic functions. Our report is, to the best of our knowledge, the first to try to theoretically analyze the semilinear PDE problem that effectively and accurately models two-dimensional window Josephson junctions. Specifically we established the existence of solutions and obtained regularity and a priori estimates for the derivatives of the solution. We had to use a specific method to establish these estimates instead of the well-known theory for elliptic PDEs [9] because the solution is defined modulo a

multiple of 2π due to the periodicity of the nonlinearity and the Neumann boundary conditions, and therefore its norm cannot be bounded.

From the practical point of view this study validates the practical observation that for a pure junction ($\Omega_j \equiv \Omega$) of small dimensions $\mathcal{L} < 2$, $\mathcal{W} < 2$ and zero boundary conditions the only solutions are the constants $n\pi$, where n is an integer. Another important practical result is that if I_j depends only on x and $\delta \equiv 0$ and if $\mathcal{W} < 2$, then $\frac{\partial \phi}{\partial y} \equiv 0$. It is interesting to notice that in both results, the value 2 comes up. The same value appears in the one-dimensional reductions of the problem, where it corresponds to the maximum of $\frac{\partial \phi}{\partial x}$ for the separatrix of the pendulum phase space.

The theoretical analysis of two-dimensional window Josephson junctions is by no means complete. Below are some of the issues that are of practical interest (and as such some experimental analysis has already been carried out), and their theoretical analysis will be mathematically challenging.

Notice that all a priori estimates obtained are independent of the window Ω_j. This is due to the fact that we bound $|\sin(\phi)|$ by 1 very early in our analysis. Therefore, although these estimates seem to be very generous for the PDE problems considered in Table 7.1, they are sharp for large windows. Nevertheless, since many important physical properties of Josephson junctions depend on the size and the geometry of the window [4, 5] new a priori estimates which sense the geometrical parameters of the window would be of importance.

The maximum current that a Josephson junction can carry for a given configuration of α's and δ's and for a given H is another point of interest, and its theoretical estimation is a challenging and difficult problem. One approach for that is carrying out a three-parameter stability analysis. These parameters are the values at the boundary conditions and the size of the window. Such stability analysis to determine the turning and bifurcation points and eigenvalues corresponding to the different solutions is under way.

The method of Newton proved to be a very reliable and efficient linearization tool. We believe that the proof of its quadratic convergence at continuum level (PDE analysis) or discrete level (numerical analysis) is another interesting mathematical problem. This problem does not have a unique solution and is therefore ill-posed in the Hadamard sense.

Appendix. Proof of existence of the generalized solution for the auxiliary problem. To apply the Leray–Schauder theorem we consider the Banach space $\mathcal{B}$,

$$\mathcal{B} = \left\{ u \in C^1(\bar{\Omega}) \ \text{ and } \ \int_\Omega u dx dy = 0 \right\},$$

and construct the mapping

$$\kappa T : \forall u \in \mathcal{B} \longrightarrow w,$$

where w is the solution of the problem

$$\Delta w = \kappa \left[\mathcal{I}_j \sin(u + \zeta + f) - \frac{1}{\mu(\Omega)} \int_{\Omega_j} \sin(u + \zeta + f) dx dy \right] \equiv \mathcal{F}(x, y) \quad \text{in } \Omega,$$

$$\frac{\partial w}{\partial n} = 0 \quad \text{on } \partial\Omega.$$

Note that we have formed the right-hand side $\mathcal{F}$ so that the solution of the above linear PDE problem exists up to a constant and, as it can be easily seen using the a priori estimates obtained in section 3, it belongs to $C^{1,\gamma}(\bar{\Omega})$. From this class of infinitely many solutions, we can select (by choosing the appropriate constant) the one that satisfies relation (4.7). Therefore we have constructed a mapping from $\mathcal{B}$ to $\mathcal{B}^\gamma$, where $\mathcal{B}^\gamma = \left\{u \in C^{1,\gamma}(\bar{\Omega}) \text{ and } \int_\Omega u dx dy = 0\right\}$. The mapping $T : \mathcal{B} \longrightarrow \mathcal{B}^\gamma$ is bounded and hence $T : \mathcal{B} \longrightarrow \mathcal{B}$ is compact. To apply the Leray–Schauder theorem, and therefore to prove the existence of a fixed point of T, we need only show that for every solution of $w = \kappa T w$, $\kappa \in [0, 1]$ we have that $||w||_{C^1(\overline{\Omega})}$ is bounded. This is a direct consequence of the a priori estimates we have already obtained. Note that from Schauder estimates we also have that the above-mentioned solution belongs to $C^3(\Omega)$.

YOUNG MEASURE SOLUTIONS FOR NONCONVEX ELASTODYNAMICS*

MARC OLIVER RIEGER†

Abstract. We study the nonlinear equation of elastodynamics where the free energy functional is allowed to be nonconvex. We define the notion of Young measure solutions for this problem and prove an existence theorem in this class. This can be used as a model for the evolution of microstructures in crystals. We furthermore introduce an optional coupling with a parabolic equation and prove the existence of a Young measure solution for this system.

Key words. nonlinear elasticity, hyperbolic-parabolic systems, Young measures, nonconvex variational problems

1. Introduction.

A crucial assumption to obtaining the existence of weak solutions for nonlinear elasticity equations in the static case is the quasi convexity of the underlying free energy potential (see [2]). However, in many cases the quasi convexity of the potential is not appropriate to reflect the physical situation. Therefore a weaker concept for solutions has been introduced, the so-called Young measure solutions (YM-solutions). This concept can be applied to crystals where nonconvex elasticity equations can be used to describe the development of microstructures (which are important especially for shape-memory alloys), as has been pointed out in the fundamental paper [3]. (For further information and references consider, e.g., [16], [15].)

The equation of elastodynamics,

$$u_{tt}(x,t) - \operatorname{div} S(\nabla u(x,t)) = 0,$$

is even more difficult to handle. Global existence results for weak solutions have been found only in one space dimension in [10], [19]. Under certain convexity assumptions Dafermos and Hrusa [5] proved the local existence of smooth solutions.

The concept of YM-solutions has been applied to dynamic problems in [20], [12], and [6] (in the context of the forward-backward heat equation) and was applied to the wave equation by [14] and [7].

An approach to the dynamic elasticity equation (with some additional assumptions on the free energy, valid in particular for antiplane shear, and with an *optional* coupling to a parabolic partial differential equation) was presented in [17] using the method of discretization in time. (For a numerical implementation of this construction, see [18] and [4].) A similar result was obtained in [9], where (in a different context) existence was proved in arbitrary space dimensions for the *polyconvex* case under some growth conditions.

In the first part of this article we prove the existence (globally in time for large initial data) of YM-solutions for nonconvex elasticity equations in arbitrary space

dimensions under some growth conditions on the free energy. In contrast to [9] we have to assume that the Andrews–Ball condition (see below) is satisfied, but we do *not* need polyconvexity.

In the second part we study a model problem where we couple a nonconvex elasticity equation with a parabolic equation (possibly of forward-backward type). The physical motivation is to study crystals consisting of different types of atoms, where solid state diffusion occurs and influences the elastic properties of the material. The mathematical structure is also similar to thermoelastic problems (cf. [24]). We extend the concept of YM-solutions to this hyperbolic-parabolic system and prove existence.

We remark that the coupling is not crucial for the proof, so the system studied in section 2 is a special case of the system in section 3, but we need stronger bounds for the energy density in the coupled case. This is probably only due to technical reasons, but we decided to discuss both cases separately.

2. YM-solutions for an elasticity equation. In this section we prove the existence of YM-solutions for nonconvex elasticity equations. Let $p \geq 2$ be a fixed constant. (Later p will denote the growth rate of the free energy at infinity.) By p' we denote its conjugate, i.e., $\frac{1}{p} + \frac{1}{p'} = 1$.

Throughout this article we denote by M a positive generic constant depending only on the initial data. By $||\cdot||$ we denote the $L^2(\Omega)$-norm.

For an open bounded set $\Omega \subset \mathbb{R}^n$ with Lipschitz boundary, $T > 0$, $g \in W^{1,p}(\Omega, \mathbb{R}^m)$ and a function $u : \Omega \to \mathbb{R}^m$ we study the initial boundary value problem

$$\begin{aligned} u_{tt}(x,t) - \operatorname{div} S(\nabla u(x,t)) &= 0, \quad (x,t) \in \Omega \times [0,T), \\ u(\cdot,0) &= u_0, \\ u_t(\cdot,0) &= z_0, \\ u &= g \quad \text{on } \partial\Omega, \end{aligned} \tag{2.1}$$

with $S = \nabla\phi$ and $\phi \in \mathcal{C}^2(\mathbb{R}^{m\times n}, \mathbb{R}_+)$ satisfying the growth conditions (for positive constants M_1, M_2)

$$\begin{aligned} |S(A)| &\leq M_2(|A|^{p-1} + 1), \\ M_1(|A|^p - 1) \leq \phi(A) &\leq M_2(|A|^p + 1) \end{aligned} \tag{2.2}$$

and S satisfying the Andrews–Ball condition (introduced in [1] and generalized in [11]) for some $R > 0$:

$$(S(F_1) - S(F_2))\,(F_1 - F_2) \geq 0 \tag{2.3}$$

for all $F_1 \in \mathbb{R}^{m\times n}$, $F_2 \in \mathbb{R}^{m\times n}$, and $|F_1|, |F_2| \geq R$. An interpretation of this condition is that for "large" values the potential ϕ is assumed to be convex. The condition is not very restrictive since every sufficiently smooth function ϕ on an arbitrarily large ball $\mathcal{B}(0,R)$ can be extended to a function $\tilde{\phi}$ such that $\tilde{S} := \nabla\tilde{\phi}$ satisfies the Andrews–Ball condition.

We can even relax this condition slightly (see [11]): It is sufficient to assume that there exists a constant $M > 0$ such that for all F_1, $F_2 \in \mathbb{R}^{m\times n}$,

$$(S(F_1) - S(F_2))\,(F_1 - F_2) \geq -M|F_1 - F_2|^2. \tag{2.4}$$

We now want to define a YM-solution. Therefore we introduce a measure ν expressing the probability distribution of the deformation gradient at a certain point $(x,t) \in$

$\Omega \times (0,T)$. For "classical" solutions this measure will be a Dirac measure concentrated in ∇u.

DEFINITION 2.1 (YM-solutions for elasticity). *A pair* (u,ν) *is a* YM-solution *of the system* (2.1) *if for fixed* $T>0$,

$$\begin{aligned} u \in W^{1,\infty}((0,T),L^2(\Omega)), \quad u-g \in L^\infty((0,T),W_0^{1,p}(\Omega)),\\ \nu=(\nu_{x,t})_{x,t} \text{ is a probability measure,}\\ \int_0^T \int_\Omega \langle \nu, S(\cdot)\rangle \nabla\zeta - u_t\zeta_t \,dx\,dt = 0 \quad \forall \zeta \in \mathcal{C}_0^\infty((0,T)\times\Omega),\\ \nabla u(x,t) = \langle \nu_{x,t}, Id\rangle \quad a.e. \end{aligned}$$

Here $\langle \nu, S(\cdot)\rangle$ *is defined as a dual pairing of* S *with the measure* ν, *i.e.,* $\langle \nu, S(\cdot)\rangle := \int S(A)\,d\nu(A)$.

In this section we prove the following existence theorem.

THEOREM 2.1 (existence of YM-solutions). *Assume* $\phi \in \mathcal{C}^2$, *that the growth conditions* (2.2) *are satisfied, and that one of the conditions* (2.3) *or* (2.4) *is valid. Furthermore let* $u_0 - g \in W_0^{1,p}(\Omega)$, $z_0 \in H_0^1(\Omega)$. *Then there exists a YM-solution* (u,ν) *of problem* (2.1).

To prove this we use a viscosity regularization, based on an idea of [21]. Under the assumptions stated above the following viscoelastic equation (together with the standard initial and boundary conditions) has a weak solution (see [11], or consider [8] for more general viscosity terms):

$$u_{tt}^\varepsilon(x,t) - \operatorname{div} S(\nabla u^\varepsilon(x,t)) - \varepsilon \Delta u_t^\varepsilon(x,t) = 0.$$

More precisely there exists

$$\begin{aligned} u^\varepsilon \in W^{2,2}((0,T),W^{-1,p'}(\Omega)) \cap W^{1,2}((0,T),W^{1,2}(\Omega)) \cap W^{1,\infty}((0,T),L^2(\Omega)),\\ u^\varepsilon - g \in L^\infty((0,T),W_0^{1,p}(\Omega)) \end{aligned}$$

such that for all $T>0$ and for all $\zeta \in \mathcal{C}_0^\infty((0,T)\times\Omega))$,

$$\int_0^T \int_\Omega (S(\nabla u^\varepsilon) + \varepsilon \nabla u_t^\varepsilon)\nabla\zeta - u_t^\varepsilon \zeta_t \,dx\,dt = 0. \tag{2.5}$$

Furthermore we have the inequality

$$\frac{1}{2}||u_t^\varepsilon||^2 + ||\nabla u^\varepsilon||_{L^p(\Omega)}^p + \int_0^T ||\sqrt{\varepsilon}\nabla u_t^\varepsilon||^2\,dt \le M,$$

where $M>0$ is independent of ε and t. To get this estimate we can follow [11], where we simply add an ε to the viscosity term. Additionally we use the growth condition on ϕ.

These bounds on u^ε imply that there exists a subsequence, again denoted by u^ε, with

$$u^\varepsilon \overset{\star}{\rightharpoonup} u \quad \text{in } L^\infty((0,T),W^{1,p}(\Omega)) \cap W^{1,\infty}((0,T),L^2(\Omega)),$$

and $(\nabla u^\varepsilon(\cdot,t))_\varepsilon$ generates for every fixed $t\in(0,T)$ a Young measure $\nu_{\cdot,t}$.

Now we claim that (u,ν) is a YM-solution of the elasticity equation. To prove this we consider the convergence of the terms in the viscoelastic equation (taking

subsequences if necessary). First we observe that by the convergence proved above and the Hölder inequality,

$$u_t^\varepsilon \overset{\star}{\rightharpoonup} u_t \quad \text{in} \quad L^2((0,T),L^2(\Omega)).$$

Thus $\int_0^T \int_\Omega u_t^\varepsilon \zeta_t \, dx\, dt$ (the third term in the weak equation (2.5)) converges to $\int_0^T \int_\Omega u_t \zeta_t \, dx\, dt$. On the other hand $\int_0^T \int_\Omega \varepsilon \nabla u_t^\varepsilon \nabla \zeta \, dx\, dt$ converges for $\varepsilon \to 0$ to zero as the following calculation (using the Cauchy–Schwarz inequality) proves:

$$\int_0^T \int_\Omega \varepsilon \nabla u_t^\varepsilon \nabla \zeta \, dx\, dt \le \Bigg(\varepsilon \underbrace{\int_0^T ||\sqrt{\varepsilon} \nabla u_t^\varepsilon||^2 \, dt}_{\le M} \Bigg)^{1/2} \Bigg(\underbrace{\int_0^T ||\nabla \zeta||^2 \, dt}_{=const.} \Bigg)^{1/2} \to 0.$$

It remains to consider the term $\int_0^T \int_\Omega S(\nabla u^\varepsilon) \nabla \zeta \, dx\, dt$. If we define $\nu_{\cdot,t}$ for all $t \in (0,T)$ as the gradient Young measure generated by the sequence $\nabla u^\varepsilon(\cdot,t)$ (for a definition and an existence proof, consider, e.g., [13], [15], or [16]), we can see that $S(\nabla u^\varepsilon(\cdot,t))$ converges for all $t \in (0,T)$ weakly in $L^{p-1}(\Omega)$ to $\langle \nu_{\cdot,t}, S \rangle$.

On the other hand a subsequence of $S(\nabla u^\varepsilon)$ converges weakly-$\star$ in $L^\infty((0,T), L^{p'}(\Omega))$, since the bounds from the energy estimate together with the growth condition imply

$$\begin{aligned} \sup_t ||S(\nabla u^\varepsilon)||^{p'}_{L^{p'}(\Omega)} &\le M \sup_t \int_\Omega (1 + |\nabla u^\varepsilon|^{p-1})^{p'} \, dx \\ &\le M \sup_t \left(1 + \int_\Omega |\nabla u^\varepsilon|^{(p-1)p'} \right) dx \\ &= M \sup_t \left(1 + ||\nabla u^\varepsilon||^p_{L^p(\Omega)} \right) dx \\ &\le M. \end{aligned}$$

Hence the term $S(\nabla u^\varepsilon)$ converges weakly-$\star$ in $L^\infty((0,T), L^{p'}(\Omega))$ to $\langle \nu, S \rangle$, and since $\nabla \zeta \in \mathcal{C}_0^\infty((0,T) \times \Omega) \subset L^1((0,T), L^p(\Omega))$ we have derived that (u, ν) is a YM-solution of the elasticity equation, proving Theorem 2.1. ∎

We notice that the Andrews–Ball condition was used only to find a solution to the viscous system.

3. Hyperbolic-parabolic systems. If we want to consider a coupling between elasticity and diffusion, or if we want to study thermoelastic problems, we have to couple a parabolic equation (possibly of forward-backward type) to the elasticity equation. For this purpose we study the following model problem, where $\Omega \subset \mathbb{R}^n$ is a domain with Lipschitz boundary, $T > 0$, $(x,t) \in \Omega \times [0,T)$, $g \in H^1(\Omega, \mathbb{R}^m)$, $u : \Omega \times [0,T) \to \mathbb{R}^m$, and $c : \Omega \times [0,T) \to \mathbb{R}^d$:

$$\begin{aligned} u_{tt}(x,t) - \operatorname{div} S(\nabla u(x,t), c(x,t)) &= 0, \\ c_t(x,t) - \operatorname{div} K(\nabla c(x,t), u(x,t)) &= 0, \\ u(\cdot,0) &= u_0, \\ u_t(\cdot,0) &= z_0, \\ c(\cdot,0) &= c_0, \\ u &= g \quad \text{on } \partial\Omega, \\ \vec{n} K(\nabla c, u) &= 0 \quad \text{on } \partial\Omega, \end{aligned} \tag{3.1}$$

with $S = \nabla_1 \phi$ and $K = \nabla_1 \psi$ (∇_1 denoting the derivative with respect to the first variable). By $\vec{n}$ we denote the outward normal on $\partial\Omega$.

Here we consider only the case $p = 2$; i.e., we assume that S and K are of linear growth in the first variable and ϕ, $\psi \in \mathcal{C}^2$ are positive and of quadratic growth in the first variable. More precisely there are constants M_1, $M_2 > 0$ such that for all $A \in \mathbb{R}^{m\times n}$, $B \in \mathbb{R}^{n\times d}$, $b \in \mathbb{R}^d$, and $a \in \mathbb{R}^m$ the following estimates hold:

$$\begin{aligned} M_1(|A|^2 - 1) \le \phi(A,b) &\le M_2(|A|^2 + |b|^2 + 1),\\ M_1(|B|^2 - 1) \le \psi(B,a) &\le M_2(|B|^2 + |a|^2 + 1),\\ S(A,b) &\le M_2(|A| + |b| + 1),\\ K(B,a) &\le M_2(|B| + |a| + 1). \end{aligned} \tag{3.2}$$

Furthermore we assume that S and K are globally Lipschitz continuous.

We want to remark that (3.1) is only a model problem for studying some typical mathematical difficulties. A realistic model for diffusion phenomena should include at least a ∇u-dependence of the diffusion tensor K rather than a u-dependence.

We extend the notion of YM-solutions to the coupled system, where the measure ν describes the probability distribution of the gradient of u (in the same way as in the last section) and the measure μ describes the probability distribution of the gradient of c.

Definition 3.1 (YM-solutions for an hyperbolic-parabolic system). *We call the quadruple (u, ν, c, μ) a* YM-solution *of the system* (3.1) *if for $T > 0$,*

$$\begin{aligned} u \in W^{1,\infty}((0,T), L^2(\Omega)), \quad u - g \in L^\infty((0,T), H_0^1(\Omega)),\\ c \in W^{1,2}((0,T), L^2(\Omega)) \cap L^\infty((0,T), H^1(\Omega)),\\ \nu = (\nu_{x,t})_{x,t},\ \mu = (\mu_{x,t})_{x,t},\ \textit{probability measures,} \end{aligned}$$

$$\int_0^T \int_\Omega \langle \nu, S(\cdot, c)\rangle \nabla\zeta - u_t\zeta_t \, dx\, dt = 0 \quad \forall \zeta \in H^1((0,T)\times\Omega),\ \zeta|_{\partial\Omega} = 0, \tag{3.3}$$

$$\int_0^T \int_\Omega \langle \mu, K(\cdot, u)\rangle \nabla\zeta + c_t\zeta \, dx\, dt = 0 \quad \forall \zeta \in H^1((0,T)\times\Omega), \tag{3.4}$$

$$\begin{aligned} \nabla u(x,t) &= \langle \nu_{x,t}, Id\rangle \quad a.e.,\\ \nabla c(x,t) &= \langle \mu_{x,t}, Id\rangle \quad a.e. \end{aligned}$$

In the rest of this section we prove the following existence theorem.

Theorem 3.1 (existence of YM-solutions). *Let S, K, ϕ, ψ satisfy the conditions in* (3.2)*, and assume that S and K are globally Lipschitz continuous. Then for $u_0 - g \in H_0^1$, $z_0 \in H_0^1$, $c_0 \in H^1$, $\vec{n}K(\nabla c_0, 0) = 0$ there exists a YM-solution (u, ν, c, μ) of the problem stated above.*

To prove this theorem we apply the same methods as in the previous section: We first prove the existence of a weak solution for our system equipped with additional dissipation terms; i.e., we study (for $\varepsilon > 0$)

$$\begin{aligned} u^\varepsilon_{tt}(x,t) - \operatorname{div} S(\nabla u^\varepsilon(x,t), c^\varepsilon(x,t)) - \varepsilon\Delta u^\varepsilon_t(x,t) = 0,\\ c^\varepsilon_t(x,t) - \operatorname{div} K(\nabla c^\varepsilon(x,t), u^\varepsilon(x,t)) - \varepsilon\Delta c^\varepsilon_t(x,t) = 0,\\ u^\varepsilon(\cdot,0) = u_0,\\ u^\varepsilon_t(\cdot,0) = z_0,\\ c^\varepsilon(\cdot,0) = c_0, \end{aligned}$$

$$u^\varepsilon = g \quad \text{on } \partial\Omega,$$
$$\vec{n}(K(\nabla c^\varepsilon, u^\varepsilon) + \varepsilon \nabla c_t^\varepsilon) = 0 \quad \text{on } \partial\Omega. \tag{3.5}$$

For this system we can prove the following theorem.

THEOREM 3.2. *For every $T > 0$ and $u_0 - g \in H_0^1$, $z_0 \in H_0^1$, $c_0 \in H^1$, $\vec{n}K(\nabla c_0, 0) = 0$ there exists a weak solution $(u^\varepsilon, c^\varepsilon)$ of the system (3.5); i.e.,*

$$u^\varepsilon \in L^\infty((0,T), H_0^1(\Omega)) \cap W^{1,\infty}((0,T), L^2(\Omega)) \cap W^{1,2}((0,T), H^1(\Omega)) \cap W^{2,2}((0,T), H^{-1}(\Omega)),$$
$$c^\varepsilon \in W^{1,2}(\mathbb{R}^+, L^2(\Omega)) \cap L^\infty(\mathbb{R}^+, H^1(\Omega)),$$

and

$$\int_0^T \int_\Omega S(\nabla u^\varepsilon, c^\varepsilon)\nabla\zeta + \varepsilon \nabla u_t^\varepsilon \nabla\zeta - u_t^\varepsilon \zeta_t \, dx\, dt = 0 \quad \forall \zeta \in H_0^1((0,T)\times\Omega), \tag{3.6}$$

$$\int_0^T \int_\Omega K(\nabla c^\varepsilon, u^\varepsilon)\nabla\zeta + \varepsilon \nabla c_t^\varepsilon \nabla\zeta + c_t^\varepsilon \zeta \, dx\, dt = 0 \quad \forall \zeta \in H^1((0,T)\times\Omega). \tag{3.7}$$

Furthermore we have the following inequality:

$$\frac{1}{2}||u_t^\varepsilon||^2 + ||u^\varepsilon||_{H^1}^2 + ||c^\varepsilon||_{H^1}^2 + \int_0^T ||\sqrt{\varepsilon}\nabla u_t^\varepsilon||^2 \, dt + \int_0^T ||\sqrt{\varepsilon}\nabla c_t^\varepsilon||^2 \, dt \le M. \tag{3.8}$$

For the proof of this theorem we apply the methods introduced by [12] for the heat equation and [7] for the wave equation. These methods were used for viscoelasticity by [8] and [11]. For a different coupled system describing thermoviscoelastic materials, Zimmer proved the existence of weak-renormalized solutions [24].

First we discretize with respect to time. To make life easier we drop the ε in the notation of u^ε and c^ε and use u and c instead. We denote the discretized variables by $(u^{h,j})_{h,j}, (c^{h,j})_{h,j}$. (Often we will drop the h.) For $j = 0, 1, \ldots$ we will construct (weak) solutions $u^{h,j} \in H_0^1(\Omega)$, $c^{h,j} \in H^1(\Omega)$ of these discretized equations (together with the standard boundary conditions), valid in $H^{-1}(\Omega)$:

$$\frac{u^{h,j} - 2u^{h,j-1} + u^{h,j-2}}{h^2} - \operatorname{div} S(\nabla u^{h,j}, c^{h,j-1}) - \varepsilon \frac{\Delta u^{h,j} - \Delta u^{h,j-1}}{h} = 0,$$
$$\frac{c^{h,j} - c^{h,j-1}}{h} - \operatorname{div} K(\nabla c^{h,j}, u^{h,j-1}) - \varepsilon \frac{\Delta c^{h,j} - \Delta c^{h,j-1}}{h} = 0,$$
$$u^{h,0} = u_0, \quad u^{h,-1} = u_0 - hz_0, \quad c^{h,0} = c_0.$$

More precisely we consider the integral form of these equations; i.e., for $\zeta \in H_0^1(\Omega)$, $\xi \in H_0^1(\Omega)$ we have

$$\int_\Omega \frac{u^{h,j} - 2u^{h,j-1} + u^{h,j-2}}{h^2}\zeta + S(\nabla u^{h,j}, c^{h,j-1})\nabla\zeta + \varepsilon \frac{\nabla u^{h,j} - \nabla u^{h,j-1}}{h}\nabla\zeta = 0, \tag{3.9}$$

$$\int_\Omega \frac{c^{h,j} - c^{h,j-1}}{h}\xi + K(\nabla c^{h,j}, u^{h,j-1})\nabla\xi + \varepsilon \frac{\Delta c^{h,j} - \Delta c^{h,j-1}}{h}\nabla\xi = 0. \tag{3.10}$$

It is convenient to define the "discretized velocity":

$$v^{h,j} := \frac{u^{h,j} - u^{h,j-1}}{h}.$$

We now want to derive an a priori estimate for the discrete energy:

$$E_j := E^{h,j} := \int_\Omega \phi(\nabla u^{h,j}, c^{h,j-1}) + \eta\psi(\nabla c^{h,j}, u^{h,j-1}) + \frac{1}{2}|v^{h,j}|^2\,dx,$$

where $\eta > 0$ will be chosen later.

We formulate the following lemma.

LEMMA 3.3 (discrete energy). *Let $T > 0$, $jh < T$, and $\delta \in (0, \varepsilon)$. Then for every positive $h < h_0(\delta)$ the following inequality holds:*

$$E_j + \sum_{j=1}^{\infty} \frac{h}{2} \int_\Omega (\varepsilon - \delta)|\nabla v^{h,j}|^2 dx + \sum_{j=1}^{\infty} \frac{h}{2} \int_\Omega (\varepsilon - \delta) \left| \frac{\nabla c^{h,j} - \nabla c^{h,j-1}}{h} \right|^2 dx \le M.$$

To prove this we exploit the fact that the nonconvex energy densities ϕ and ψ are "convexified" by the viscosity term. We start by considering the energy difference in one time step:

$$\begin{aligned}
\Delta E_j &:= E_{j+1} - E_j \\
&= \int_\Omega \left(\phi(\nabla u^{j+1}, c^j) + \frac{1}{2}|v^{j+1}|^2 + \eta\psi(\nabla c^{j+1}, u^j) \right) \\
&\quad - \left(\phi(\nabla u^j, c^{j-1}) + \frac{1}{2}|v^j|^2 + \eta\psi(\nabla c^j, u^{j-1}) \right) dx \\
&= \int_\Omega \Bigg(\phi(\nabla u^{j+1}, c^j) - \phi(\nabla u^j, c^{j-1}) \\
&\qquad + \frac{\delta}{h}|\nabla u^{j+1} - \nabla u^j|^2 - \frac{\delta}{h}|\nabla u^{j+1} - \nabla u^j|^2 - \frac{\delta}{h}\underbrace{|\nabla u^j - \nabla u^j|^2}_{=0} \\
&\qquad + \eta\psi(\nabla c^{j+1}, u^j) - \eta\psi(\nabla c^j, u^{j-1}) \\
&\qquad + \eta\frac{\delta}{h}|\nabla c^{j+1} - \nabla c^j|^2 - \eta\frac{\delta}{h}|\nabla c^{j+1} - \nabla c^j|^2 - \eta\frac{\delta}{h}\underbrace{|\nabla c^j - \nabla c^j|^2}_{=0} \\
&\qquad + \frac{1}{2}|v^{j+1}|^2 - \frac{1}{2}|v^j|^2 \Bigg) dx.
\end{aligned}$$

Before we proceed by estimating this expression, we first state the following auxiliary lemma.

LEMMA 3.4. *Let $r, s \ge 1$ and $\omega \in \mathcal{C}^2(\mathbb{R}^{r\times s}, \mathbb{R}_+)$. Assume that either ω satisfies, for every F_1, $F_2 \in \mathbb{R}^{r\times s}$, the inequality*

$$(\nabla\omega(F_1) - \nabla\omega(F_2))(F_1 - F_2) \ge -M|F_1 - F_2|^2, \tag{3.11}$$

where $M > 0$ is a constant, or that $\nabla\omega$ satisfies the Andrews–Ball condition; see (2.3).

Then for every $A \in \mathbb{R}^{r\times s}$ the function

$$g : F \longmapsto \omega(F) + \frac{\delta}{h}|F - A|^2$$

is convex for every $h \le h_0(\delta)$.

Furthermore for every F_1, $F_2 \in \mathbb{R}^{r\times s}$ and $h \le h_0(\delta)$ the following estimate holds:

$$\begin{aligned}&\left(\omega(F_1)+\frac{\delta}{h}|F_1-A|^2\right)-\left(\omega(F_2)+\frac{\delta}{h}|F_2-A|^2\right)\\ &\le\left(\nabla\omega(F_1)+\frac{2\delta}{h}(F_1-A)\right)(F_1-F_2).\end{aligned}\tag{3.12}$$

To prove the convexity of g we apply (3.11), which itself is a consequence of the Andrews–Ball condition (for a proof see, e.g., [11]). By the convexity of g we get $g(F_1)-g(F_2)\le \nabla g(F_1)(F_1-F_2)$, and this gives (3.12). ∎

We apply this lemma twice: once with $F_1 := \nabla u^{j+1}$, $F_2 := \nabla u^j$, $A := \nabla u^j$, and $\omega(X) := \phi(X, c^j)$ and once with $F_1 := \nabla c^{j+1}$, $F_2 := \nabla c^j$, $A := \nabla c^j$, and $\omega(X) := \psi(X, u^j)$. Furthermore we use the global Lipschitz continuity of S and K in the second variable (with Lipschitz constant L) to derive

$$\begin{aligned}\Delta E_j \le{}&\int_\Omega\left(\nabla_1\phi(\nabla u^{j+1},c^j)+\frac{2\delta}{h}(\nabla u^{j+1}-\nabla u^j)\right)(\nabla u^{j+1}-\nabla u^j)\\ &-\frac{\delta}{h}|\nabla u^{j+1}-\nabla u^j|^2+L|c^j-c^{j-1}|^2\\ &+\eta\left(\nabla_1\psi(\nabla c^{j+1},u^j)+\frac{2\delta}{h}(\nabla c^{j+1}-\nabla c^j)\right)(\nabla c^{j+1}-\nabla c^j)\\ &-\frac{\delta\eta}{h}|\nabla c^{j+1}-\nabla c^j|^2+L\eta|u^j-u^{j-1}|^2\\ &+\frac{1}{2}\left(|v^{j+1}|^2-|v^j|^2\right)dx.\end{aligned}$$

By rearranging the terms we get

$$\begin{aligned}\Delta E_j \le{}&\int_\Omega\left(\nabla_1\phi(\nabla u^{j+1},c^j)+\frac{\varepsilon}{h}(\nabla u^{j+1}-\nabla u^j)\right)(\nabla u^{j+1}-\nabla u^j)\\ &-\frac{\varepsilon-\delta}{h}|\nabla u^{j+1}-\nabla u^j|^2+L|c^j-c^{j-1}|^2\\ &+\eta\left(\nabla_1\psi(\nabla c^{j+1},u^j)+\frac{\varepsilon}{h}(\nabla c^{j+1}-\nabla c^j)\right)(\nabla c^{j+1}-\nabla c^j)\\ &-\eta\frac{\varepsilon-\delta}{h}|\nabla c^{j+1}-\nabla c^j|^2+L\eta|u^j-u^{j-1}|^2\\ &+\frac{1}{2}\left(|v^{j+1}|^2-|v^j|^2\right)dx.\end{aligned}\tag{3.13}$$

Before we continue with our estimate we now consider (3.9) with $\zeta := u^{j+1}-u^j$ (or to be precise a smooth sequence ζ_k converging to $u^{j+1}-u^j$ and considering the limit $k\to\infty$), which gives us the following expression:

$$\begin{aligned}&\int_\Omega S(\nabla u^{j+1},c^j)(\nabla u^{j+1}-\nabla u^j)\,dx\\ &=\int_\Omega -(v^{j+1}-v^j)v^{j+1}-\frac{\varepsilon}{h}|\nabla u^{j+1}-\nabla u^j|^2\,dx.\end{aligned}$$

Using the same ideas for (3.10) we get

$$\begin{aligned}&\int_\Omega K(\nabla c^{j+1},u^j)(\nabla c^{j+1}-\nabla c^j)\,dx\\ &=\int_\Omega -\frac{1}{h}|c^{j+1}-c^j|^2-\frac{\varepsilon}{h}|\nabla c^{j+1}-\nabla c^j|^2\,dx.\end{aligned}$$

We insert these equations into (3.13) and use the Poincaré inequality for $u^{j+1}-u^j$, i.e.,

$$-\int_\Omega \frac{\varepsilon-\delta}{2h}|\nabla u^{j+1}-\nabla u^j|^2 \le -M_P\int_\Omega \frac{\varepsilon-\delta}{2h}|u^{j+1}-u^j|^2,$$

to get the following estimate:

$$\begin{aligned}
E_{j+1}-E_j \le \int_\Omega & -(v^{j+1}-v^j)v^{j+1}+\frac{1}{2}\left(|v^{j+1}|^2-|v^j|^2\right)\\
&-\frac{\varepsilon-\delta}{h}|\nabla u^{j+1}-\nabla u^j|^2-\frac{\varepsilon}{h}|\nabla u^{j+1}-\nabla u^j|^2+\frac{\varepsilon}{h}|\nabla u^{j+1}-\nabla u^j|^2\\
&-\frac{\varepsilon-\delta}{h}|\nabla c^{j+1}-\nabla c^j|^2-\frac{\varepsilon\eta}{h}|\nabla c^{j+1}-\nabla c^j|^2+\frac{\varepsilon\eta}{h}|\nabla c^{j+1}-\nabla c^j|^2\\
&+L\eta|u^j-u^{j-1}|^2-\frac{\eta}{h}|c^{j+1}-c^j|^2+L|c^j-c^{j-1}|^2\,dx\\
\le \int_\Omega & -\frac{1}{2}|v^{j+1}+v^j|^2-\frac{\varepsilon-\delta}{2h}|\nabla u^{j+1}-\nabla u^j|^2-\eta\frac{\varepsilon-\delta}{h}|\nabla c^{j+1}-\nabla c^j|^2\\
&-\left(\frac{\varepsilon-\delta}{2h}M_P-L\eta\right)|u^{j+1}-u^j|^2+L\eta\left(|u^j-u^{j-1}|^2-|u^{j+1}-u^j|^2\right)\\
&-\frac{\eta}{h}|c^{j+1}-c^j|^2+L|c^j-c^{j-1}|^2\,dx.
\end{aligned}$$

If we choose $\eta \le \frac{\varepsilon-\delta}{2}\frac{M_P}{L}$, $h<\min\left(\frac{\eta}{L},1\right)$ and sum over all $j\ge 1$, then we get

$$E_j-E_0 \le -\sum_{i=1}^{j}(\varepsilon-\delta)\frac{h}{2}||\nabla v^i||^2-\sum_{i=1}^{j}(\varepsilon-\delta)\frac{h}{2}\left|\left|\frac{\nabla c^i-\nabla c^{i-1}}{h}\right|\right|^2+M(c_0,z_0).$$

This gives the statement of the lemma. □

The following inequality is an easy corollary of Lemma 3.3.

COROLLARY 3.5. *For every $T=kh>0$ and $h\le h_0(\varepsilon)$ there exists a constant $M>0$ such that*

$$\sup_j\left(||\nabla u^{h,j}||^2+||\nabla c^{h,j}||^2+||v^{h,j}||^2\right)+\varepsilon\sum_{j=1}^{\frac{T}{h}}h||\nabla v^{h,j}||^2+\varepsilon\sum_{j=1}^{\frac{T}{h}}h\left|\left|\frac{\nabla c^i-\nabla c^{i-1}}{h}\right|\right|^2 \le M<\infty.$$

To obtain the proof one simply applies the growth conditions for ϕ and ψ and Lemma 3.3. □

We are now able to prove the existence of solutions $(u^{h,j},c^{h,j})$ of our time-discretized system.

We first solve the time-step problem with the help of a variational ansatz; i.e., we consider for $u\in H_0^1(\Omega)$, $c\in H^1(\Omega)$ the functional

$$\begin{aligned}
W^{h,j}(u,c) := \int_\Omega & \phi(\nabla u,c^{h,j-1})+\psi(\nabla c,u^{h,j-1})\\
&+\frac{\varepsilon}{2h}|\nabla u-\nabla u^{h,j-1}|^2+\frac{1}{2h^2}|u-2u^{h,j-1}+u^{h,j-2}|^2\\
&+\frac{\varepsilon}{2h}|\nabla c-\nabla c^{h,j-1}|^2+\frac{1}{2h}|c-c^{h,j-1}|^2\,dx.
\end{aligned}$$

The functional $W^{h,j}$ is weakly lower semicontinuous since its integrand is convex in $(\nabla u, \nabla c)$, which is true since the "critical" terms $\phi(\nabla u, c^{h,j-1}) + \frac{1}{2h}|\nabla u|^2$ and $\psi(\nabla c, u^{h,j-1}) + \frac{1}{2h}|\nabla c|^2$ are convex for sufficiently small $h > 0$.

Since $W^{h,j}$ is also bounded from below by zero, there exists a (not necessarily unique) minimizer (u, c). By a standard calculation one can show that (u, c) solves the time-step problem. We define $(u^{h,j}, c^{h,j}) := (u, c)$. By induction we get the existence of a time-discretized solution to the discrete problem.

In the next step we interpolate this discrete approximation $(u^{h,j}, c^{h,j})$ in time. Here it is convenient to use two different approximation schemes, i.e., the piecewise constant and the piecewise affine interpolation.

We define for $h > 0$, $0 \le j < \frac{T}{h}$, and the characteristic function $\chi^{h,j} := \chi_{[hj,h(j+1)]}$:

- $w^h(t) := \sum_j \chi^{h,j}(t) \frac{v^{h,j+1} - v^{h,j}}{h}$ (step function appr. of u_{tt}),
  $\tilde{v}^h(t) := \sum_j \chi^{h,j}(t) \left(v^{h,j} + \frac{v^{h,j+1} - v^{h,j}}{h}(t - hj) \right)$ (its primitive),
- $v^h(t) := \sum_j \chi^{h,j}(t) v^{h,j+1}$ (step function appr. of u_t),
  $\tilde{u}^h(t) := \sum_j \chi^{h,j}(t) \left(u^{h,j} + v^{h,j+1}(t - hj) \right)$ (its primitive),
- $u^h(t) := \sum_j \chi^{h,j}(t) u^{h,j+1}$ (step function appr. of u),
- $d^h(t) := \sum_j \chi^{h,j}(t) \frac{c^{h,j+1} - c^{h,j}}{h}$ (step function appr. of c_t),
  $\tilde{c}^h(t) := \sum_j \chi^{h,j}(t) \left(c^{h,j} + \frac{c^{h,j+1} - c^{h,j}}{h}(t - hj) \right)$ (its primitive),
- $c^h(t) := \sum_j \chi^{h,j}(t) c^{h,j+1}$ (step function appr. of c).

We have chosen the notation in such a way that the step functions are each labeled with different characters (w, v, u, resp., d and c) depending on the order of derivative they are approximating. Their primitives are denoted by the character of the corresponding lower order terms with a tilde; e.g., the primitive of w^h is denoted as $\tilde{v}^h$. Later we will show that the interpolations of the same character with or without a tilde (i.e., terms of the same order) coincide in the limit $h \to 0$ and converge to our solution or its derivatives.

To prove convergence for these sequences we use Corollary 3.5, and we use the growth conditions (in the cases where the H^{-1}-norm is involved we also use the discretized partial differential equations) to prove the following bounds (uniformly in h) for fixed $T > 0$:

$$\begin{aligned}
\sup_{0 \le t \le T} ||u^h(t)||^2_{H^1_0} &\le M(u_0, z_0, c_0), \\
\sup_{0 \le t \le T} ||\tilde{u}^h(t)||^2_{H^1_0} &\le M(u_0, z_0, c_0), \\
\sup_{0 \le t \le T} ||v^h(t)||^2 &\le M(u_0, z_0, c_0), \\
\varepsilon \int_0^T ||v^h(t)||^2_{H^1_0} \, dt &\le M(u_0, z_0, c_0), \\
\sup_{0 \le t \le T} ||\tilde{v}^h(t)||^2 &\le M(u_0, z_0, c_0),
\end{aligned}$$

$$\begin{aligned}
\varepsilon \int_0^T ||\tilde{v}^h(t)||^2_{H^1_0}\,dt &\le M(u_0,z_0,c_0),\\
\sup_{0\le t\le T} ||w^h(t)||^2_{H^{-1}} &\le M(u_0,z_0,c_0),\\
\sup_{0\le t\le T} ||c^h(t)||^2_{H^1} &\le M(u_0,z_0,c_0),\\
\sup_{0\le t\le T} \left(||\tilde{c}^h(t)||^2 + ||d^h(t)||^2_{H^{-1}}\right) &\le M(u_0,z_0,c_0),\\
\varepsilon \int_0^T ||d^h(t)||^2_{H^1}\,dt &\le M(u_0,z_0,c_0).
\end{aligned}$$

From these bounds we get the following weak convergence results (again choosing subsequences) for $h \to 0$:

$$\begin{aligned}
&u^h \overset{\star}{\rightharpoonup} u \quad \text{in } L^\infty\left((0,T),H^1(\Omega)\right),\\
&\tilde{u}^h \overset{\star}{\rightharpoonup} \tilde{u} \quad \text{in } L^\infty\left((0,T),H^1(\Omega)\right)\cap W^{1,\infty}\left((0,T),L^2(\Omega)\right)\cap W^{1,2}\left((0,T),H^1(\Omega)\right),\\
&v^h \overset{\star}{\rightharpoonup} v \quad \text{in } L^\infty\left((0,T),L^2(\Omega)\right)\cap L^2\left((0,T),H^1(\Omega)\right),\\
&\tilde{v}^h \overset{\star}{\rightharpoonup} \tilde{v} \quad \text{in } L^\infty\left((0,T),L^2(\Omega)\right)\cap L^2\left((0,T),H^1(\Omega)\right)\cap W^{1,\infty}\left((0,T),H^{-1}(\Omega)\right),\\
&w^h \overset{\star}{\rightharpoonup} w \quad \text{in } L^2\left((0,T),H^{-1}(\Omega)\right),\\
&c^h \overset{\star}{\rightharpoonup} c \quad \text{in } L^\infty\left((0,T),H^1(\Omega)\right),\\
&\tilde{c}^h \overset{\star}{\rightharpoonup} \tilde{c} \quad \text{in } W^{1,\infty}\left((0,T),H^{-1}(\Omega)\right),\\
&d^h \overset{\star}{\rightharpoonup} d \quad \text{in } L^2\left((0,T),H^1(\Omega)\right).
\end{aligned}$$

Additionally we deduce by applying Corollary 3.5 and the growth conditions on S and K that there exists $\tilde{S}$ and $\tilde{K}$ such that for $\hat{c} \in L^\infty((0,T),L^2(\Omega,\mathbb{R}^d))$, $\hat{u} \in L^\infty((0,T),L^2(\Omega,\mathbb{R}^m))$,

$$\begin{aligned}
\sup_{0\le t\le T}\int_\Omega |S(\nabla u^h,\hat{c})|^2 &\le M \sup_{0\le t\le T}(||\nabla u^h||^2 + ||\hat{c}||^2 + 1) \;\le\; M(\hat{c}),\\
\sup_{0\le t\le T}\int_\Omega |K(\nabla c^h,\hat{u})|^2 &\le M \sup_{0\le t\le T}(||\nabla c^h||^2 + ||\hat{u}||^2 + 1) \;\le\; M(\hat{u}),
\end{aligned}$$

and hence (for subsequences)

$$\begin{aligned}
S(\nabla u^h,\hat{c}) &\overset{\star}{\rightharpoonup} \tilde{S}_c \quad \text{in } L^\infty\left((0,T),L^2(\Omega)\right),\\
K(\nabla c^h,\hat{u}) &\overset{\star}{\rightharpoonup} \tilde{K}_u \quad \text{in } L^\infty\left((0,T),L^2(\Omega)\right).
\end{aligned}$$

We now have to make sure that the different interpolations we have chosen converge to the same limit. For this we use a standard lemma (see, e.g., [12]).

LEMMA 3.6. *Suppose that $(f^{h,j})_{h,j}$ is bounded in $L^2(\Omega)$, that $f^h(t)$ is its step function interpolation, and that $g^h(t)$ is its continuous and piecewise affine interpolation. Assume furthermore that $f^h \rightharpoonup f$ and $g^h \rightharpoonup g$ in $L^2_{loc}(\Omega\times\mathbb{R}^+)$. Then we have $f = g$.*

Sketch of the proof. We show the equivalence after testing with a smooth function. Therefore we need only consider test functions of the "separated" form $w(x)z(t)$. Let $\xi^h(t)$ be the step function approximation of $z(t)$ and let $\zeta^h(t)$ be the piecewise affine

approximation of $z(t)$. Then $w(x)\xi^h(t)$ and $w(x)\zeta^h(t)$ converge strongly to $w(x)z(t)$. If we now test $f^h(t)$ with $w(x)\xi^h(t)$ and $g^h(t)$ with $w(x)\zeta^h(t)$, we get the same result, and this equation holds also for $h \to 0$. (See [12] for the complete proof.) ∎

We can apply this lemma to deduce $u = \tilde{u}$, $v = \tilde{v}$, and $c = \tilde{c}$. This is nearly enough to consider the limit $h \to 0$ in our equation, but the nonlinearities S and K cannot be handled in this way, since weak convergence of ∇u^h to ∇u is not enough to get weak convergence of $S(\nabla u^h, c)$ to $S(\nabla u, c)$. (And the analogous statement holds for K.) Fortunately we can prove strong convergence of ∇u^h, $\nabla \tilde{u}^h$, ∇c^h, and $\nabla \tilde{c}^h$ in $L^2\left((0,T), L^2(\Omega)\right)$ as $h \to 0$.

We first need some lemmas, where we state only simplified counterparts of the corresponding lemmas in [11]. The proofs can also be found there.

LEMMA 3.7 (Aubin-type result). *Let $X_s := W^{1,2}(\Omega)$, $X := L^2(\Omega)$, and $X_w := W^{-1,2}(\Omega)$. Then the imbedding of $L^2((0,T), X_s) \cap W^{1,2}((0,T), X_w)$ equipped with the natural norm $||\cdot||_{L^2(X_s)} + ||\partial_t \cdot||_{L^2(X_w)}$ into $L^2((0,T), X)$ is compact.*

The next lemma gives a closer connection between the two kinds of interpolations we have used.

LEMMA 3.8. *Let X be a Banach space and $\{f^{h,j}\}_{j\geq 1, h>0}$ a collection of elements in X. Let f^h be the piecewise constant and let $\tilde{f}^h$ be the piecewise linear interpolation of $\{f^{h,j}\}$ defined (as usual) by*

$$f^h(t) := \sum_j \chi_j(t) f^{h,j},$$

$$\tilde{f}^h(t) := \sum_j \chi_j(t) \left(\left(j - \frac{t}{h} \right) f^{h,j-1} + \left(\frac{t}{h} - (j-1) \right) f^{h,j} \right),$$

where χ_j is the characteristic function of $(jh, (j+1)h)$.

Assume that $\sup_j ||f^{h,j}||^2 \leq M_1$ and for some $\alpha > 0$,

$$\sum_{j=1}^{\frac{T}{h}} h \left|\left| \frac{f^{h,j} - f^{h,j-1}}{h^\alpha} \right|\right|^2 \leq M_2.$$

Then for all $f \in L^2((0,T), X)$ with $\sup_t ||f(t)||^2 \leq M_1$ we have the following estimate:

$$\int_0^T ||f^h - f||^2 \, dt \leq 2 \int_0^T ||\tilde{f}^h - f||^2 \, dt + 4hM_1 + \frac{2}{3} h^{2\alpha} M_2.$$

We also use the following fact following from the definition of weak convergence and compactness.

LEMMA 3.9. *Let $G \subset \mathbb{R}^N$ be open, let $\{f^h\}_h \subset L^2(\Omega)$, let $f^h \rightharpoonup 0$ in $L^2(\Omega)$ as $h \to 0$, and let K be a compact subset of $L^2(\Omega)$; then*

$$\sup_{\xi \in K} \left| \int_G f^h \xi \, dx \right| \to 0 \quad \text{as } h \to 0.$$

Now we have collected all ingredients for the proof of the strong convergence of ∇u^h, $\nabla \tilde{u}^h$, ∇c^h, and $\nabla \tilde{c}^h$. First we consider ∇u^h and $\nabla \tilde{u}^h$, and later we will apply the methods introduced there to prove the strong convergence of ∇c^h and $\nabla \tilde{c}^h$.

We start with the following time-integrated version of our elasticity equation, which does not require that the test function ζ be differentiable in time; i.e., for

$\zeta \in L^2((0,T), H_0^1(\Omega))$,

$$\int_0^T \int_\Omega \left(S(\nabla u^h, c^h(\cdot - h)) + \varepsilon \nabla v^h\right) \nabla \zeta - v^h \frac{\zeta(\cdot + h) - \zeta}{h} \, dx \, dt$$
$$+ \frac{1}{h} \int_{T-h}^T \int_\Omega v^h \zeta(\cdot + h) \, dx \, dt - \frac{1}{h} \int_{-h}^0 \int_\Omega v_0 \zeta(\cdot + h) \, dx \, dt = 0. \tag{3.14}$$

We consider the limit $h \to 0$ in equation (3.14), where we use that $c^h(\cdot - h) \to c$ in $L^\infty((0,T), L^2(\Omega))$. Using the definition of $\tilde{S}_c$ we get

$$\int_0^T \int_\Omega \tilde{S}_c \nabla \zeta + \varepsilon \nabla u_t \nabla \zeta - u_t \zeta_t \, dx \, dt$$
$$+ \int_\Omega \underbrace{v(T)\zeta(T) + v_0 \zeta(0)}_{=0} \, dx = 0. \tag{3.15}$$

We insert $\zeta := u^h - u$ in (3.14) and $\zeta := \tilde{u}^h - u$ in (3.15) and substract the resulting equations. (To be exact we have to approximate $u^h - u^h(\cdot - h)$ and $\tilde{u}^h - u$ by sequences of smooth functions.) This gives, for $t \in (0,T)$,

$$0 = \underbrace{\int_0^t \int_\Omega S(\nabla u^h, c^h(\cdot - h))(\nabla u^h - \nabla u) - \tilde{S}_c(\nabla \tilde{u}^h - \nabla u) \, dx \, dt}_{=:T_1}$$
$$+ \varepsilon \underbrace{\int_0^t \int_\Omega \nabla v^h (\nabla u^h - \nabla u) - \nabla u_t (\nabla \tilde{u}^h - \nabla u) \, dx \, dt}_{=:T_2}$$
$$\underbrace{- \int_0^t \int_\Omega v^h \left(v^h(\cdot + h) - \frac{\tilde{u}(\cdot + h) - u}{h} \right) - u_t \left((\tilde{u}^h)_t - u_t \right) \, dx \, dt}_{=:T_3}$$
$$\underbrace{+ \int_\Omega \int_{t-h}^t v^h (u^h(\cdot + h) - u(\cdot + h)) - u_t \left(\tilde{u}^h - u \right) \, dt \, dx}_{=:T_4}$$
$$\underbrace{- \int_\Omega v_0 \frac{1}{h} \int_{-h}^0 u^h(\cdot + h) - u(\cdot + h) \, dt \, dx}_{=:T_5},$$

where we have defined the terms $T_1, \ldots, T_5$, which we will estimate in the following calculation. To simplify notation we denote all terms converging to zero as $h \to 0$ (uniformly in t) by $\alpha(h)$.

We start by estimating T_1, where we use the global Lipschitz continuity of S, giving us for a certain $M > 0$ and every $F_1, F_2 \in \mathbb{R}^{m \times n}$ and $\hat{c} \in \mathbb{R}^d$ the inequality

$$(S(F_1, \hat{c}) - S(F_2, \hat{c})(F_1 - F_2)) \geq -M |F_1 - F_2|^2.$$

(This corresponds to condition (2.4) in the last section.)

$$T_1 = \int_0^t \int_\Omega \left(S(\nabla u^h, c^h(\cdot - h)) - S(\nabla u, c^h(\cdot - h)) \right) (\nabla u^h - \nabla u)$$

$$+ S(\nabla u, c^h(\cdot - h))(\nabla u^h - \nabla u) - \tilde{S}_c(\nabla \tilde{u}^h - \nabla u)\,dx\,dt$$
$$\geq -M \int_0^t \int_\Omega |\nabla u^h - \nabla u|^2\,dx\,dt - \sup_{t\in(0,T)} \left| \int_0^T \int_\Omega \left(\chi_{\Omega\times(0,t)} \tilde{S}_c\right)(\nabla \tilde{u}^h - \nabla u)\,dx\,dt \right|^2.$$

Applying Lemma 3.9 we can show that the last three terms converge to zero for $h \to 0$, i.e.,

$$T_1 \geq -M \int_0^t \int_\Omega |\nabla u^h - \nabla u|^2 + \alpha(h).$$

Applying Lemma 3.8 we finally get

$$T_1 \geq -2M \int_0^t \int_\Omega |\nabla \tilde{u}^h - \nabla u|^2 + \alpha(h).$$

We can use the same calculations as in the purely viscoelastic case (see [11][1]) to derive

$$-T_2 = -\frac{1}{2} \int_\Omega |\nabla \tilde{u}^h(t) - \nabla u(t)|^2\,dx + \frac{1}{2} \int_\Omega \underbrace{|\nabla \tilde{u}^h(0) - \nabla u(0)|^2}_{=0}\,dx + \alpha(h),$$

where the discrete energy estimate proved above is used. This (together with the estimate for T_1) is the key step to the desired strong convergence result, since at the end we want to apply the Gronwall lemma to the inequality we get by estimating these terms. Therefore we need the terms T_3–T_5 to be "well behaved," i.e., that they are simply $\alpha(h)$.

In fact by applying Lemma 3.7 combined with Lemma 3.8 we can prove this:

$$T_3 = \alpha(h), \quad T_4 = \alpha(h), \quad T_5 = \alpha(h).$$

Taking everything together we have the inequality

$$\partial_t \int_0^t \int_\Omega |\nabla \tilde{u}^h - \nabla u|^2\,dx\,dt \leq \frac{4M}{\varepsilon} \int_0^t \int_\Omega |\nabla \tilde{u}^h - \nabla u|^2\,dx\,dt + \alpha(h).$$

Now we can apply the Gronwall lemma to get

$$\int_0^T \int_\Omega |\nabla \tilde{u}^h - \nabla u|^2\,dx\,dt \leq \alpha(h) \frac{\varepsilon}{4M} e^{\frac{4MT}{\varepsilon}},$$

and this converges to zero for $h \to 0$. Hence

$$\nabla \tilde{u}^h \to \nabla u \quad \text{in } L^2\left((0,T), L^2(\Omega)\right).$$

Due to Lemma 3.8 the same convergence result holds for ∇u^h. This ensures that $\tilde{S}_{\hat{c}} = S(\nabla u, \hat{c})$.

Now we are ready to apply the same methods to prove $\tilde{K}_{\hat{u}} = K(\nabla c, \hat{u})$. First we consider the following weak formulation of (3.10):

$$\int_0^T \int_\Omega K(\nabla c^h, u^h(\cdot - h))\nabla\zeta + \varepsilon \frac{\nabla c^h - \nabla c^h(\cdot - h)}{h} \nabla\zeta + \frac{c^h - c^h(\cdot - h)}{h} \zeta\,dx\,dt = 0. \tag{3.16}$$

[1]Recall the slightly different notation in their article.

Then we consider the limit $h \to 0$ in (3.16) to get

$$\int_0^T \int_\Omega \tilde{K}_u \nabla\zeta + \varepsilon \nabla c_t \nabla\zeta + c_t \zeta \, dx \, dt = 0. \tag{3.17}$$

We insert $\zeta := c^h - c$ in (3.16) and $\zeta := \tilde{c}^h - c$ in (3.17) and substract the resulting equations. (To be exact we have to approximate $c^h - c^h(\cdot - h)$ and $\tilde{c}^h - c$ by sequences of smooth functions.) This gives

$$\begin{aligned} 0 = \int_0^T \int_\Omega & K(\nabla c^h, u^h(\cdot - h)) \nabla(c^h - c) - \tilde{K}_u \nabla(\tilde{c}^h - c) \\ & + \varepsilon \frac{\nabla c^h - \nabla c^h(\cdot - h)}{h} \nabla(c^h - c) - \varepsilon \nabla c_t \nabla(\tilde{c}^h - c) \\ & + \frac{c^h - c^h(\cdot - h)}{h} (c^h - c) - c_t(\tilde{c}^h - c) \, dx \, dt. \end{aligned} \tag{3.18}$$

Now we consider the three terms in (3.18). We start with the third one. We want to prove that

$$\int_0^T \int_\Omega \frac{c^h - c^h(\cdot - h)}{h} (c^h - c) - c_t(\tilde{c}^h - c) \, dx \, dt \to 0 \quad \text{as } h \to 0.$$

But this is true for the first part, since $\left(\tilde{c}^h\right)_t$ is bounded in $L^\infty((0,T), H^{-1}(\Omega))$ and $c^h \overset{\star}{\rightharpoonup} c$ in $L^\infty((0,T), H^1(\Omega))$, and it is true for the second part, since $c_t \in L^2((0,T), H^1(\Omega))$ and $\tilde{c}^h \overset{\star}{\rightharpoonup} c$ in $W^{1,\infty}(H^{-1}(\Omega))$.

We now rewrite the first term in (3.18), denote it by T_6, and estimate it as follows:

$$\begin{aligned} T_6 := \int_0^t \int_\Omega & \left(K(\nabla c^h, u^h(\cdot - h)) - K(\nabla c, u^h(\cdot - h))\right) \nabla(c^h - c) \\ & + K(\nabla c, u^h(\cdot - h)) \nabla(c^h - c) \\ & - \tilde{K}_{u^h(\cdot - h)} \nabla(\tilde{c}^h - c) + \left(\tilde{K}_{u^h(\cdot - h)} - \tilde{K}_u\right) \nabla(\tilde{c}^h - c) \, dx \, dt \\ \geq & -M \int_0^t \int_\Omega |\nabla \tilde{c}^h - \nabla c|^2 \, dx \, dt + \alpha(h). \end{aligned}$$

So we get

$$T_6 \geq -M \int_0^t \int_\Omega |\nabla \tilde{c}^h - \nabla c|^2 \, dx \, dt + \alpha(h). \tag{3.19}$$

It remains to estimate the second term in (3.18). Here we apply the methods we had used to estimate T_2. This gives the following inequality:

$$\begin{aligned} & -\varepsilon \int_0^T \int_\Omega \frac{\nabla c^h - \nabla c^h(\cdot - h)}{h} (\nabla c^h - \nabla c) - \nabla c_t (\nabla \tilde{c}^h - \nabla c) \\ & \geq -\frac{\varepsilon}{2} \int_0^T \int_\Omega |\nabla \tilde{c}^h(t) - \nabla u(t)|^2 \, dx \, dt + \alpha(h). \end{aligned} \tag{3.20}$$

If we insert (3.19) and (3.20) into (3.18) and apply the Gronwall lemma in the same way as before, we derive

$$\int_0^T \int_\Omega |\nabla \tilde{c}^h - \nabla c|^2 \, dx \, dt \leq \alpha(h) \frac{\varepsilon}{4M} e^{\frac{4MT}{\varepsilon}},$$

and this is converging to zero for $h \to 0$. Therefore $\nabla \tilde{c}^h$ is converging to ∇c strongly in $L^2((0,T), L^2(\Omega))$. And due to Lemma 3.8 this also holds for ∇c^h. Hence for $h \to 0$ the nonlinear term $K(\nabla c^h, u^h)$ converges to $K(\nabla c, u)$.

Taking everything together we have proved that the solutions of the time-discretized equations converge to solutions of the hyperbolic-parabolic system (3.5).

To prove Theorem 3.2 it remains only to prove the energy inequality,

$$E(t) \le M(u_0, v_0, c_0) - \varepsilon \int_0^t \int_\Omega |\nabla u_t|^2 + |\nabla c_t|^2 \, dx \, dt,$$

where $E(t) := \int_\Omega \phi(\nabla u(t), c(t)) + \psi(\nabla c(t), u(t)) + \frac{1}{2}|u_t(t)|^2 \, dx$ and $M(u_0, v_0, c_0)$ is a constant depending only on the initial values u_0, v_0, c_0.

To prove this we start from the discrete energy inequality (Lemma 3.3), telling us that for $\eta > 0$ sufficiently small, $h < \min\left(1, \frac{\eta}{L}\right)$, and $\delta \in (0,1)$ the following inequality holds for every $t \in (0,T)$:

$$\begin{aligned} &\int_\Omega \phi(\nabla u^h, c^h(\cdot - h)) \, dx + \eta \int_\Omega \psi(\nabla c^h, u^h(\cdot - h)) \, dx \\ &+ \frac{1}{2} \int_\Omega |v^h|^2 \, dx + (\varepsilon - \delta) \int_0^t \int_\Omega |\nabla v^h|^2 + |\nabla d^h|^2 \, dx \, dt \le M(u_0, v_0, c_0). \end{aligned}$$

Now we notice that we can apply these convergence results:

$$\begin{aligned} v^h(t) &\to u_t(t) \quad \text{in } L^2(\Omega) \text{ for almost every } t \in (0,T), \\ \nabla v^h &\rightharpoonup \nabla u_t \quad \text{in } L^2((0,T) \times \Omega), \\ \nabla d^h &\rightharpoonup \nabla c_t \quad \text{in } L^2((0,T) \times \Omega). \end{aligned}$$

By the weakly lower semicontinuity of the $L^2((0,T)\times\Omega)$-norm we get for almost every $t \in (0,T)$

$$\begin{aligned} &\limsup_{h \to 0} \int_\Omega \phi(\nabla u^h, c^h(\cdot - h)) \, dx + \eta \limsup_{h \to 0} \int_\Omega \psi(\nabla c^h, u^h(\cdot - h)) \, dx \\ &+ \frac{1}{2} \int_\Omega |u_t|^2 \, dx + (\varepsilon - \delta) \int_0^t \int_\Omega |\nabla u_t|^2 + |\nabla c_t|^2 \, dx \, dt \le M(u_0, v_0, c_0). \end{aligned} \tag{3.21}$$

Now we apply the strong convergence of $\nabla u^h(t)$ to estimate

$$\begin{aligned} \int_\Omega \phi(\nabla u, c) \, dx &= \int_\Omega \left(\phi(\nabla u, c) + \frac{M}{2} |\nabla u|^2 \right) dx - \int_\Omega \frac{M}{2} |\nabla u|^2 \, dx \\ &\le \limsup_{h \to 0} \int_\Omega \left(\phi(\nabla u^h, c^h(\cdot - h)) + \frac{M}{2} |\nabla u^h|^2 \right) dx \\ &\quad - \int_\Omega \frac{M}{2} |\nabla u|^2 \, dx \\ &\le \limsup_{h \to 0} \int_\Omega \phi(\nabla u^h, c^h(\cdot - h)) \, dx + \limsup_{h \to 0} \int_\Omega \frac{M}{2} |\nabla u^h|^2 \, dx \\ &\quad - \int_\Omega \frac{M}{2} |\nabla u|^2 \, dx \\ &= \limsup_{h \to 0} \int_\Omega \phi(\nabla u^h, c^h(\cdot - h)) \, dx. \end{aligned}$$

Similarly, applying the strong convergence of $\nabla c^h(t)$ we get

$$\int_\Omega \psi(\nabla c, u)\,dx = \limsup_{h\to 0} \int_\Omega \psi(\nabla c^h, u^h(\cdot - h))\,dx.$$

If we insert these estimates into (3.21) and take the limit $\delta \to 0$, then we get

$$\int_\Omega \phi(\nabla u, c)\,dx + \eta \int_\Omega \psi(\nabla c, u)\,dx + \frac{1}{2}\int_\Omega |u_t|^2\,dx \\ + \varepsilon \int_0^t \int_\Omega |\nabla u_t|^2 + |\nabla c_t|^2\,dx\,dt \le M(u_0, v_0, c_0)$$

for almost every $t \in (0,T)$.

By adjusting the constant M we get the desired estimate (3.8). This completes the proof of Theorem 3.2. □

Now we apply this to prove Theorem 3.1 by considering $\varepsilon \to 0$ in the same spirit as in the previous section: First the energy inequality (3.8) gives the following weak convergence results (for subsequences) as $\varepsilon \to 0$:

$$u^\varepsilon \overset{\star}{\rightharpoonup} u \quad \text{in } L^\infty((0,T), H_0^1(\Omega)),$$
$$c^\varepsilon \overset{\star}{\rightharpoonup} c \quad \text{in } L^\infty((0,T), H_0^1(\Omega)),$$
$$u^\varepsilon \overset{\star}{\rightharpoonup} u \quad \text{in } W^{1,\infty}((0,T), L^2(\Omega)).$$

Furthermore for almost every $t \in (0,T)$ the sequence $\nabla u^\varepsilon(t)$ generates the Young measure $\nu_{\cdot,t}$ and $\nabla c^\varepsilon(t)$ generates the Young measure $\mu_{\cdot,t}$, since $||\nabla u^\varepsilon(t)||$ and $||\nabla c^\varepsilon(t)||$ are bounded (uniformly in t).

In particular we get that for any $\zeta \in H_0^1(\Omega)$

$$\int_\Omega S(\nabla u^\varepsilon(\cdot,t), c^\varepsilon(\cdot,t))\nabla\zeta \to \int_\Omega \langle \nu_{\cdot,t}, S(\cdot, c(\cdot,t))\rangle \nabla\zeta.$$

For a subsequence we can consider the limit of the viscoelastic equations for $\varepsilon \to 0$ by using the growth conditions on S and K and the strong convergence of u^ε and c^ε in L^2: Since for all $\varepsilon > 0$

$$||S(\nabla u^\varepsilon, c^\varepsilon)||_{L^\infty((0,T),L^2(\Omega))} \le M,$$

we obtain the existence of a function $\tilde{S} \in L^\infty((0,T), L^2(\Omega))$ with

$$\int_0^T \int_\Omega S(\nabla u^\varepsilon, c^\varepsilon)\nabla\zeta \to \int_0^T \int_\Omega \tilde{S}\nabla\zeta.$$

Taking both together and repeating the calculations from section 2 to estimate the other terms, we obtain (3.3) and (3.4). The Neumann boundary condition on c^ε is converging to the Neumann boundary condition on c. This calculation concludes the proof of existence for Theorem 3.1. □

An easy consequence of this theorem is the following corollary.

COROLLARY 3.10 (vector-valued parabolic equations). *Under the assumptions on ψ, K, and c_0 stated above there exists a YM-solution, defined in an analogous way to YM-solutions for hyperbolic-parabolic systems, for the parabolic system*

$$c_t(x,t) - \operatorname{div} K(\nabla c(x,t)) = 0,$$
$$c(\cdot,0) = c_0,$$
$$\vec{n} K(\nabla c, u) = 0 \quad \text{on } \partial\Omega,$$

where $c\colon \Omega \to \mathbb{R}^m$.

Proof. To prove this we only have to study the uncoupled case in Theorem 3.1, which is not excluded by the growth conditions. □

This result is an extension of a scalar version that can be found in [6].

4. Concluding remarks. The regularity of the YM-solutions as constructed in the last sections is still a widely open problem. Although there are easy examples for YM-solutions which are no weak solutions even in the one-dimensional parabolic case (see, e.g., [18]), to the author's knowledge, there is no example where *every* YM-solution to a given data fails to be a weak solution. It would be very interesting to find an example where a smooth initial data develops a microstructure in finite time. For some related results, see [22], [23].

Acknowledgments. I am grateful to Stefan Müller for his steady and valuable help, and to Sophia Demoulini and Johannes Zimmer for very stimulating discussions.

ON THE OORT–HULST–SAFRONOV COAGULATION EQUATION AND ITS RELATION TO THE SMOLUCHOWSKI EQUATION*

MIROSŁAW LACHOWICZ†, PHILIPPE LAURENÇOT‡, AND DARIUSZ WRZOSEK†

Abstract. A connection is established between the classical Smoluchowski continuous coagulation equation and the Oort–Hulst–Safronov coagulation equation via generalized coagulation equations. Existence of solutions to the Oort–Hulst–Safronov coagulation equation is shown, and the large time behavior and the occurrence of gelation are studied as well. It is also shown that a compactly supported initial distribution propagates with finite speed.

Key words. coagulation, Smoluchowski equation, Oort–Hulst–Safronov equation, existence, gelation, finite speed of propagation

1. Introduction.

Coagulation processes are found in a wide variety of physical situations where clusters (or particles, droplets, etc.) merge by coalescence to form larger ones. Such a phenomenon takes place in, e.g., colloidal chemistry [18, 19], aerosol science (evolution of a system of solid or liquid particles suspended in a gas [6]), astrophysics [3], or hematology (red blood cell formation [16]). Assuming that each cluster is fully identified by its size (or volume), mean-field models have been developed and used to predict the time evolution of the size distribution function of the clusters. Various levels of description are also available within these models according to the range of the size parameter, which is either $\mathbb{N}\backslash\{0\}$ (discrete models) or $\mathbb{R}_+ = (0, +\infty)$ (continuous models). Among these models, the most widely used is the classical coagulation equation introduced by Smoluchowski (in its discrete version) to describe the aggregation of colloidal particles moving according to Brownian motion [18]. Since then, the Smoluchowski coagulation equation has been the subject of several physical and mathematical studies. In a different context, another coagulation model was proposed by Oort and van de Hulst thirty years later to describe the process of aggregation of protoplanetary bodies in astrophysics [15]. It was then written under a more tractable form by Safronov [17], to which we refer for a more detailed account on coagulation processes in astrophysics. Though the Smoluchowski and Oort–Hulst–Safronov (OHS) coagulation models were derived in different ways, it is natural to wonder whether there is some relationship between them. The main purpose of this work is actually to establish a connection between these two different coagulation equations. As a byproduct, we also obtain the existence of a solution to the OHS equation and study qualitative properties of this model.

Let us now state both models more precisely. If $f(u,t)$ denotes the density of clusters of size $u \in \mathbb{R}_+$ at time $t \geq 0$, then the classical continuous coagulation equation reads [6]

$$\partial_t f = Q_1(f)\,, \quad (u,t) \in \mathbb{R}_+^2\,, \tag{1.1}$$

$$f(0) = f_0\,, \quad u \in \mathbb{R}_+\,, \tag{1.2}$$

where

$$Q_1(f)(u) = \frac{1}{2}\int_0^u a(u-v,v)\ f(u-v)\ f(v)\ dv - f(u)\ \int_0^\infty a(u,v)\ f(v)\ dv\,, \quad u \in \mathbb{R}_+\,, \tag{1.3}$$

and ∂_t denotes the partial derivative with respect to time. The reaction rate a in $Q_1(f)$ is a nonnegative function usually called the coagulation kernel and satisfies the following symmetry property:

$$0 \le a(u,v) = a(v,u)\,, \quad (u\,,v)\ \in \mathbb{R}_+^2\,. \tag{1.4}$$

The first term in $Q_1(f)$ is a gain term which describes the rate of formation of clusters of size u due to the merging of smaller clusters as a result of binary collisions. The second term in $Q_1(f)$ is a loss term accounting for the depletion of clusters of size u resulting from their coalescence with other clusters.

With the same notation, we may formulate the OHS model as follows [17]:

$$\partial_t f = Q_0(f)\,, \quad (u,t) \in \mathbb{R}_+^2\,, \tag{1.5}$$

along with the initial condition (1.2), where

$$Q_0(f)(u) = -\partial_u\left(f(u)\ \int_0^u v\ a(u,v)\ f(v)\ dv\right) - f(u)\ \int_u^\infty a(u,v)\ f(v)\ dv\,, \quad u \in \mathbb{R}_+\,. \tag{1.6}$$

Here ∂_u denotes the partial derivative with respect to u. Notice that if we omit the second term of $Q_0(f)$ in (1.5), the remaining part is a continuity equation which describes the increase of clusters of size u with velocity

$$\frac{du}{dt} = \int_0^u v\ a(u,v)\ f(v,t)\ dv$$

depending on the density of smaller clusters. Thus, in this model, the rate of formation of clusters of size u from smaller clusters does not depend on the sizes of the clusters involved in the coagulation event but on some averaged quantity, and this is a fundamental difference with (1.1). The second term of $Q_0(f)$ corresponds to the depletion of clusters of size u, which is here possible only as a result of their "sedimentation" on larger clusters. Another qualitative difference between both models is related to the speed with which an initial perturbation propagates. It is well known that the Smoluchowski equation (1.1) enjoys the property of infinite speed of propagation. (That is, if f_0 is compactly supported, the solution $f(t)$ to (1.1), (1.2) is not compactly supported for any positive time $t > 0$. We refer to [2] for a proof in the case of the discrete Smoluchowski equations.) This is in contrast with the OHS equation, where the propagation velocity is finite, as already observed in [7, 8] (see also section 5 below).

Nevertheless, our main goal is to show rigorously that it is possible to connect (1.1) to (1.5). Let us first mention that a relationship between these models has already

been observed by Dubovski [7] at a formal level. More precisely, Dubovski introduces a family of generalized discrete coagulation equations which includes the discrete Smoluchowski equations on the one hand and a discrete version of the OHS equation on the other hand. The connection is then completed by showing formally that the discrete version of the OHS equation leads to the OHS equation after a suitable rescaling, since it follows from [13] that (1.1) can be obtained as a limit of suitably rescaled discrete Smoluchowski equations. Our approach is completely different and directly connects (1.1) to (1.5) without using discrete models. We actually introduce an ε-dependent family of generalized coagulation equations for $\varepsilon \in (0\,,1]$. While $\varepsilon = 1$ corresponds to the Smoluchowski equation (1.1), letting $\varepsilon \to 0$ leads us to the OHS equation (1.5). Heuristically our approach is based on the following observation. Given a test function $\phi \in \mathcal{D}([0,+\infty))$, it follows from (1.3) and the Fubini theorem that

$$\int_0^\infty Q_1(f)\ \phi\ du = \int_0^\infty \int_0^v \left[\phi(v+w) - \phi(w) - \phi(v)\right] a(v,w) f(v) f(w)\ dwdv\,. \tag{1.7}$$

Similarly, (1.6) yields

$$\int_0^\infty Q_0(f)\ \phi\ du = \int_0^\infty \int_0^v \left[w\ \phi'(v) - \phi(w)\right]\ a(v,w)\ f(v)\ f(w)\ dwdv\,. \tag{1.8}$$

Observe now that for $v \gg w$, we have

$$\left[\phi(v+w) - \phi(w) - \phi(v)\right] \sim \left[w\ \phi'(v) - \phi(w)\right]\,, \tag{1.9}$$

so that we expect to recover (1.5) from (1.1) when the dominating reactions are the coalescence of clusters with very different sizes. Providing the rigorous justification of this observation is the first aim of our work and will be achieved with the help of the so-called generalized Boltzmann equations [1]. In order to see both equations in a common frame, we introduce the following generalized coagulation equation:

$$\partial_t f = Q_{GC}(f)\,, \quad (u,t) \in \mathbb{R}^2_+\,, \tag{1.10}$$

where

$$\begin{aligned} Q_{GC}(f)(u) = \frac{1}{2}\ &\int_0^\infty \int_0^\infty A(u;v,w)\ a(v,w)\ f(v)\ f(w)\ dwdv \\ &- f(u)\ \int_0^\infty a(u,v)\ f(v)\ dv\,. \end{aligned} \tag{1.11}$$

Here, A is the weighted probability that the collision of a cluster of size v and a cluster of size w generates a cluster of size u and is a nonnegative function satisfying

$$A(u;v,w) = A(u;w,v)\,, \quad (u,v,w) \in \mathbb{R}^3_+\,, \tag{1.12}$$

$$\int_0^\infty A(u;v,w)\ u\ du = v + w\,, \quad (v,w) \in \mathbb{R}^2_+\,. \tag{1.13}$$

It is worth mentioning here that many bilinear equations and systems in applied mathematics fit into this general structure after specifying appropriately A and a (cf. [11]). Observe also that the condition (1.13) ensures that the total volume is

preserved during the coagulation reactions. Indeed, we have

$$\int_0^\infty Q_{GC}(f)\ \phi\ du = \int_0^\infty \int_0^v \left\{ \left(\int_0^\infty A(u;v,w)\ \phi(u)\ du \right) - \phi(v) - \phi(w) \right\} a(v,w)\ f(v)\ f(w)\ dwdv \tag{1.14}$$

for any test function $\phi \in \mathcal{D}([0,+\infty))$. Setting now $\phi(u) = u$ in (1.14) and using (1.13), we obtain (at least formally)

$$\int_0^\infty Q_{GC}(f)\ u\ du = 0\,.$$

We thus formally deduce from (1.10) that, for $t > 0$,

$$\int_0^\infty u\ f(u,t)\ du = \int_0^\infty u\ f_0(u)\ du\,, \tag{1.15}$$

which is nothing but the conservation of the total mass throughout time evolution.

We are now in a position to introduce a family of generalized coagulation equations connecting the Smoluchowski and the OHS equations. For $\varepsilon \in (0\,,1)$ and $(v,w) \in \mathbb{R}_+^2$, we define

$$\begin{aligned} A_\varepsilon(u;v,w) = {} & \delta\left(u - \max\{v,w\} - \varepsilon\ \min\{v,w\}\right) \\ & + (1-\varepsilon)\ \delta(u - \min\{v,w\})\,, \end{aligned} \tag{1.16}$$

$$a_\varepsilon(v,w) = \frac{a(v,w)}{\varepsilon}\,, \tag{1.17}$$

where $\delta(u)$ is the Dirac mass. We next put A_ε instead of A and a_ε instead of a in (1.14) and set $Q_{GC} = Q_\varepsilon$. With this notation, (1.14) yields

$$\begin{aligned} & \int_0^\infty Q_\varepsilon(f)\ \phi\ du \\ & \quad = \int_0^\infty \int_0^v \left\{ \frac{\phi(v+\varepsilon w) - \phi(v)}{\varepsilon} - \phi(w) \right\} a(v,w)\ f(v)\ f(w)\ dwdv \end{aligned} \tag{1.18}$$

for any test function $\phi \in \mathcal{D}([0,+\infty))$. It is then straightforward to see that the choice $\varepsilon = 1$ in (1.18) yields (1.7), while letting $\varepsilon \to 0$ in (1.18) leads to (1.8). We have thus obtained the announced connection between (1.1) and (1.5). In fact, $Q_\varepsilon(f)$ may be written in a more explicit form, namely,

$$\begin{aligned} Q_\varepsilon(f)(u) = {} & \frac{1}{\varepsilon} \int_0^{u/(1+\varepsilon)} a(u-\varepsilon v, v)\ f(u-\varepsilon v)\ f(v)\ dv \\ & - f(u) \left[\left(\frac{1}{\varepsilon} - 1 \right) \int_0^u a(u,v)\ f(v)\ dv + \int_0^\infty a(u,v)\ f(v)\ dv \right] \end{aligned} \tag{1.19}$$

for $u \in \mathbb{R}_+$. We will actually prove the convergence of the solution f_ε to

$$\partial_t f_\varepsilon = Q_\varepsilon(f_\varepsilon)\,, \quad (u,t) \in \mathbb{R}_+^2\,, \tag{1.20}$$

with $f_\varepsilon(0) = f_0$ toward a solution to (1.5), (1.2) as $\varepsilon \to 0$.

Another issue we consider in this paper is the validity of the total mass conservation (1.15) which is derived formally from (1.14). It is well known that it is not always true for the classical Smoluchowski coagulation equation (1.1) and that the total mass may decrease after some time, a phenomenon known as gelation (see [5, 9, 10] and the references therein). The occurrence of gelation depends heavily on the growth of the coagulation kernel a, and the situation is quite clear for (1.1). We obtain here a similar result for the OHS equation by the arguments of [9] and investigate the connection between gelation and the propagation of the support for compactly supported initial data. We thereby extend results from [7, section 5] to a wider class of coagulation kernels.

We now describe the contents of this paper: The next section is devoted to a precise statement of our results, including convergence of solutions to (1.20) toward a solution to (1.5), occurrence of gelation, and behavior of the support for compactly supported initial data. The convergence proof is performed in section 3, and the occurrence of gelation is studied in section 4. Compactly supported initial data are the subject of the final section.

2. Main results. We first introduce the basic assumptions on the data a and f_0 that we shall use in what follows. Besides the nonnegativity and symmetry condition (1.4), we assume that the coagulation kernel a satisfies

$$a \in W^{1,\infty}_{\rm loc}([0,+\infty)^2) \quad \text{and} \quad \partial_u a(u,v) \ge -\alpha\,, \quad (u,v) \in \mathbb{R}^2_+\,, \tag{2.1}$$

for some constant $\alpha \ge 0$. We also need to prescribe the behavior of a for large values of u and v. A natural growth condition is to say that the rate of cluster interactions is limited by the product of their sizes or volumes, that is,

$$a(u,v) \le K\ (1+u)\ (1+v)\,, \quad (u,v) \in \mathbb{R}^2_+\,, \tag{2.2}$$

which includes most of the cases considered in the physical literature. However, under the sole growth condition (2.2), the existence of a solution is still an open problem even for (1.1), so that additional growth conditions have to be specified. Two different sets of growth assumptions will actually be used in what follows. Namely, in addition to (2.2), we will require that either a is *strictly subquadratic*, that is,

$$\omega_R(v) = \sup_{u\in[0,R]} \frac{a(u,v)}{v} \longrightarrow 0 \quad \text{as} \quad v \to +\infty \tag{2.3}$$

for each $R \ge 1$, or a is *subadditive*, that is, there is $K_1 > 0$ such that

$$a(u,v) \le K_1\ (1+u+v)\,, \quad (u,v) \in \mathbb{R}^2_+\,. \tag{2.4}$$

We turn next to the initial datum f_0 and notice that physically relevant requirements on f_0 are nonnegativity and finite total mass. We thus assume that the initial datum f_0 satisfies

$$f_0 \in X^+\,, \tag{2.5}$$

where X^+ denotes the positive cone of the Banach space

$$X = L^1(0,+\infty;(1+u)du)\,,$$

endowed with the norm

$$\|f\|_X = \int_0^\infty |f(u)|\ (1+u)\ du\,.$$

Notice that the last term in the norm $\|.\|_X$ corresponds to the total mass of clusters.

We now give the definition of a weak solution we use in this paper.

DEFINITION 2.1. *Let $T \in (0\,,+\infty]$ and $f_0 \in X^+$. A weak solution to* (1.5), (1.2) *on $[0,T)$ is a nonnegative function*

$$f \in \mathcal{C}([0\,,T); weak - L^1(\mathbb{R}_+)) \cap L^\infty(0,T;X^+), \tag{2.6}$$

which satisfies

$$\begin{aligned}\int_0^\infty f(u,t)\ \phi(u)\ du &= \int_0^\infty f_0(u)\ \phi(u)\ du \\ &+ \int_0^t \int_0^\infty \int_0^v [w\ \phi'(v) - \phi(w)]\ a(v,w)\ f(v,s)\ f(w,s)\ dwdvds\end{aligned} \tag{2.7}$$

for any $\phi \in W^{1,\infty}(\mathbb{R}_+)$ with compactly supported first derivative and $t \in [0,T)$.

Similarly, for $\varepsilon \in (0\,,1]$, a weak solution to (1.20), (1.2) *on $[0,T)$ is a nonnegative function*

$$f_\varepsilon \in \mathcal{C}([0\,,T); weak - L^1(\mathbb{R}_+)) \cap L^\infty(0,T;X^+)$$

satisfying

$$\begin{aligned}\int_0^\infty f_\varepsilon(u,t)\ \phi(u)\ du &= \int_0^\infty f_0(u)\ \phi(u)\ du \\ &+ \int_0^t \int_0^\infty \int_0^v \left\{ \frac{\phi(v+\varepsilon w) - \phi(v)}{\varepsilon} - \phi(w) \right\} a(v,w) f_\varepsilon(v,s) f_\varepsilon(w,s)\ dwdvds\end{aligned} \tag{2.8}$$

for any $\phi \in L^\infty(\mathbb{R}_+)$ and $t \in [0,T)$.

Our first result then reads as follows.

THEOREM 2.2. *Assume that the coagulation kernel a satisfies* (1.4), (2.1), *and either* (2.3) *or* (2.4). *Then, for $\varepsilon \in (0,1]$ and $f_0 \in X^+$, there exists at least one weak solution f_ε to* (1.20), (1.2) *on $[0,+\infty)$ which satisfies*

$$\int_0^\infty u\ f_\varepsilon(u,t)\ du \le \int_0^\infty u\ f_0(u)\ du\,, \quad t \ge 0\,, \tag{2.9}$$

if (2.3) *holds and*

$$\int_0^\infty u\ f_\varepsilon(u,t)\ du = \int_0^\infty u\ f_0(u)\ du\,, \quad t \ge 0\,, \tag{2.10}$$

if (2.4) *holds.*

Furthermore, there is a subsequence $\varepsilon_k \to 0$ and a weak solution f to (1.5), (1.2) *on $[0,+\infty)$ such that*

$$f_{\varepsilon_k} \longrightarrow f \quad in \quad \mathcal{C}([0\,,T]; weak - L^1(\mathbb{R}_+)) \tag{2.11}$$

for each $T > 0$ and f satisfies (2.9) *if* (2.3) *holds and* (2.10) *if* (2.4) *holds.*

Here and below, if B is a Banach space and $T \in (0,+\infty)$, $\mathcal{C}([0\,,T];weak-B)$ denotes the space of weakly continuous functions from $[0,T]$ in B.

For the classical Smoluchowski coagulation equation (1.1) ($\varepsilon = 1$), the existence results stated in Theorem 2.2 are already known; see [20, 13] and the references therein.

Remark 2.3. Under the assumption (2.4), the convergence (2.11) can actually be improved to

$$f_{\varepsilon_k} \longrightarrow f \quad \text{in} \quad \mathcal{C}([0\,,T];weak-X). \tag{2.12}$$

If f_0 is bounded, the solution constructed in Theorem 2.2 is also bounded, as we state now.

PROPOSITION 2.4. *Assume that the assumptions of Theorem* 2.2 *are fulfilled and also that* $f_0 \in L^\infty(\mathbb{R}_+)$. *Then the solution* f_ε *to* (1.20), (1.2) *for* $\varepsilon \in (0,1]$ *and the solution* f *to* (1.5), (1.2) *constructed in Theorem* 2.2 *satisfy*

$$\|f_\varepsilon(t)\|_{L^\infty}\,,\ \|f(t)\|_{L^\infty} \le \|f_0\|_{L^\infty}\ \exp\left(\alpha\ t\ \int_0^\infty u\ f_0(u)\ du\right) \tag{2.13}$$

for $t \ge 0$.

Next we turn to the occurrence of gelation and define the gelation time $T_{gel} \in [0,+\infty]$ of a solution f to the OHS equation (1.5), (1.2) by

$$T_{gel} = \inf\left\{t \ge 0\,,\quad \int_0^\infty u\ f(u,t)\ du < \int_0^\infty u\ f_0(u)\ du\right\}. \tag{2.14}$$

The occurrence of gelation then corresponds to $T_{gel} < +\infty$. Clearly, Theorem 2.2 ensures that there are mass-conserving solutions to the OHS equation (1.5) for subadditive coagulation kernels, the same result being true for the classical Smoluchowski coagulation equation. We now show that gelation takes place for (1.5) for the same class of coagulation kernels as for (1.1).

THEOREM 2.5. *Assume that a satisfies* (1.4), (2.2) *and*

$$a(u,v) \ge K_0\ (uv)^{\lambda/2}\,,\quad (u,v) \in \mathbb{R}_+^2, \tag{2.15}$$

for some $\lambda \in (1,2]$ *and* $K_0 > 0$. *Consider* $f_0 \in X^+$, $f_0 \not\equiv 0$, *and denote by* f *a weak solution to* (1.5), (1.2). *Then* $T_{gel} < +\infty$.

The proof of Theorem 2.5 is similar to that of [9, Theorem 1.1] for (1.1). It is worth mentioning that the method developed in [9] provides actually much more information on (1.1) than the mere occurrence of gelation (temporal decay estimates, behavior of higher moments near the gelation time, etc.). It is likely that similar results are valid for (1.5) with the same proofs, and we refer to [9] for a more detailed description of available results.

We finally consider compactly supported initial data. As already mentioned, a striking difference between (1.1) and (1.5) is that solutions to the latter enjoy the property of finite speed of propagation. More precisely, we have the following result.

THEOREM 2.6. *Assume that a satisfies* (1.4), (2.2) *and is continuous on* $[0,+\infty)^2$. *We consider* $f_0 \in X^+ \cap L^\infty(\mathbb{R}_+)$ *such that*

$$\text{supp}\ \ f_0 \subset [0,R_0] \tag{2.16}$$

for some $R_0 > 0$ *and denote by* f *a weak solution to* (1.5), (1.2) *such that* $f \in L^\infty((0,T)\times\mathbb{R}_+)$ *for each* $T \ge 0$. *Then there are* $T_\star \in (0,+\infty]$ *and* $R \in \mathcal{C}^1([0,T_\star))$ *such that*

(a) $R(0) = R_0$ *and* R *satisfies*

$$R'(t) = \int_0^{R(t)} u\ a(R(t),u)\ f(u,t)\ du\,, \quad t \in [0,T_\star)\,. \tag{2.17}$$

In addition, R *is a nondecreasing function on* $[0,T_\star)$ *and either* $T_\star = +\infty$ *or*

$$T_\star < +\infty \quad \text{and} \quad \lim_{t\to T_\star} R(t) = +\infty\,. \tag{2.18}$$

(b) supp $f(t) \subset [0,R(t)]$ *for* $t \in [0,T_\star)$.

In particular, when $f_0 \in L^\infty(\mathbb{R}_+)$, Theorem 2.6 applies to the solution f to (1.5), (1.2) constructed in Theorem 2.2 by Proposition 2.4. Next, some information on the time behavior of the total mass readily follows from Theorem 2.6 and is gathered below.

COROLLARY 2.7. *Under the assumptions and notation of Theorem* 2.6, *we have*

$$\int_0^\infty u\ f(u,t)\ du = \int_0^\infty u\ f_0(u)\ du \quad \text{for} \quad t \in [0,T_\star)\,, \tag{2.19}$$

and thus $T_\star \le T_{gel}$.

Since we already know that gelation takes place for coagulation kernels satisfying (2.15), we conclude that $T_\star < +\infty$ in that case, thereby extending [7, section 5]. Let us also mention that a natural conjecture is of course that $T_\star = T_{gel}$, but we have not been able to prove it.

3. Existence of weak solutions. The existence proof relies on the construction of an approximating sequence of solutions to some regularized problems combined with weak compactness arguments in $L^1(\mathbb{R}_+)$. Such an approach was introduced in [20] for the classical coagulation equation (1.1) and further developed in [13]. We will adapt arguments from both papers to prove Theorem 2.2.

We first derive the following a priori estimates.

LEMMA 3.1. *Let* $f_0 \in X^+$ *and* $\varepsilon \in (0,1]$. *Assume that there is a nonnegative and convex piecewise* $\mathcal{C}^2$*-function* $\Phi \in \mathcal{C}^1([0\,,+\infty))$ *such that* $\Phi(0) = 0$, $\Phi'(0) = 1$, Φ' *is concave, and*

$$C_0 = \int_0^\infty \Phi(f_0)(u)\ du < \infty\,. \tag{3.1}$$

Let $T > 0$ *and* $f_\varepsilon \in \mathcal{C}^1([0,T);L^1(\mathbb{R}_+))$ *be a weak solution to* (1.20), (1.2) *on* $[0,T)$. *There is a positive constant* C_1 *depending only on* C_0, T, α *in* (2.1) *and* $\|f_\varepsilon\|_{L^\infty(0,T;X)}$ *such that*

$$\sup_{t\in[0\,,T)} \int_0^\infty \Phi(f_\varepsilon(u,t))\ du \le C_1\,. \tag{3.2}$$

Proof. We first recall (cf. [12, Lemma A.1]) that the properties of Φ imply

$$x\ \Phi'(x) \le 2\ \Phi(x) \quad \text{for} \quad x \ge 0\,. \tag{3.3}$$

Next we introduce

$$\Phi_R(x) = \begin{cases} \Phi(x) & \text{if} \quad x \in [0\,,R]\,, \\ \Phi'(R)(x-R) + \Phi(R) & \text{if} \quad x \in [R\,,+\infty) \end{cases} \tag{3.4}$$

for $R \ge 2$ and notice that Φ_R has a bounded first derivative, $\Phi_R \le \Phi$, and also Φ_R enjoys the same properties as Φ and in particular (3.3).

We multiply (1.20) by $\Phi_R'(f_\varepsilon)$, integrate on $\mathbb{R}_+$, and use (1.18) with $\phi = \Phi_R'(f_\varepsilon)$ to obtain

$$\begin{aligned}
&\frac{d}{dt}\int_0^\infty \Phi_R(f_\varepsilon)\ du \\
&\le \int_0^\infty \int_0^v \left\{ \frac{\Phi_R'(f_\varepsilon(v+\varepsilon w)) - \Phi_R'(f_\varepsilon(v))}{\varepsilon} \right\}\ a(v,w)\ f_\varepsilon(v)\ f_\varepsilon(w)\ dwdv\,,
\end{aligned}$$

since the monotonicity of Φ_R ensures that the last term of the right-hand side of (1.18) gives a nonpositive contribution. The convexity of Φ_R next entails that for $x,\ y \ge 0$,

$$x\ (\Phi_R'(y) - \Phi_R'(x)) \le y\ \Phi_R'(y) + \Phi_R(x) - \Phi_R(y) - x\ \Phi_R'(x) = \Psi_R(y) - \Psi_R(x)\,,$$

where $\Psi_R(x) = x\ \Phi_R'(x) - \Phi_R(x)$, $x \ge 0$, is a nonnegative function since Φ_R is convex with $\Phi_R(0) = 0$. Consequently,

$$\begin{aligned}
&\frac{d}{dt}\int_0^\infty \Phi_R(f_\varepsilon)\ du \\
&\le \frac{1}{\varepsilon}\ \int_0^\infty \int_0^v (\Psi_R(f_\varepsilon(v+\varepsilon w)) - \Psi_R(f_\varepsilon(v)))\ a(v,w)\ f_\varepsilon(w)\ dwdv \\
&\le \frac{1}{\varepsilon}\ \int_0^\infty f_\varepsilon(w) \int_w^\infty (\Psi_R(f_\varepsilon(v+\varepsilon w)) - \Psi_R(f^\varepsilon(v)))\ a(v,w)\ dvdw \\
&\le \frac{1}{\varepsilon}\ \int_0^\infty \int_{(1+\varepsilon)w}^\infty a(v-\varepsilon w, w)\ \Psi_R(f_\varepsilon(v))\ f_\varepsilon(w)\ dvdw \\
&\quad - \frac{1}{\varepsilon}\ \int_0^\infty \int_w^\infty a(v,w)\ \Psi_R(f_\varepsilon(v))\ f_\varepsilon(w)\ dvdw \\
&\le \int_0^\infty \int_w^\infty \left\{ \frac{a(v-\varepsilon w, w) - a(v,w)}{\varepsilon} \right\}\ \Psi_R(f_\varepsilon(v))\ f_\varepsilon(w)\ dvdw\,.
\end{aligned}$$

Next we use (2.1) and (3.3) to deduce that

$$\begin{aligned}
\frac{d}{dt}\int_0^\infty \Phi_R(f_\varepsilon)\ du &\le \alpha \int_0^\infty \int_0^\infty w\ \Psi_R(f_\varepsilon(v))\ f_\varepsilon(w)\ dwdv \\
&\le \alpha\ \|f_\varepsilon\|_{L^\infty(0,T;X)}\ \int_0^\infty \Phi_R(f_\varepsilon(v))\ dv\,.
\end{aligned}$$

We now apply the Gronwall lemma and let $R \to +\infty$ with the help of (3.1) to complete the proof. □

We next prove that for subadditive coagulation kernels, moments propagate throughout time evolution.

LEMMA 3.2. *Let $f_0 \in X^+$ and $\varepsilon \in (0,1]$. Assume that there is a nonnegative and convex piecewise $\mathcal{C}^2$-function $\varphi \in \mathcal{C}^1([0\,,+\infty))$ such that $\varphi(0) = 0$, $\varphi'(0) = 1$, φ' is concave, and*

$$C_2 = \int_0^\infty \varphi(u)\ f_0(u)\ du < \infty\,. \tag{3.5}$$

Assume further that the coagulation kernel a satisfies (2.4), and let $T > 0$ and $f_\varepsilon \in \mathcal{C}^1([0,T); L^1(\mathbb{R}_+))$ be a weak solution to (1.20), (1.2) on $[0,T)$. There is a positive

constant C_3 depending only on C_2, T, K_1 in (2.4), $\|\varphi\|_{L^\infty(0,2)}$, and $\|f_\varepsilon\|_{L^\infty(0,T;X)}$ such that

$$\sup_{t\in[0\,,T)} \int_0^\infty \varphi(u)\ f_\varepsilon(u,t)\ du \le C_3\,. \tag{3.6}$$

Proof. We first recall (cf. [12, Lemma A.2]) that the properties of φ imply

$$(x+y)\ (\varphi(x+y)-\varphi(x)-\varphi(y)) \le 2\ (x\ \varphi(y)+y\ \varphi(x))\ , \quad x,y\ge 0\,. \tag{3.7}$$

Owing to the convexity of φ, we have

$$\begin{aligned}\varphi(v+\varepsilon w)-\varphi(v) &\le \varepsilon\ \varphi(v+w)+(1-\varepsilon)\ \varphi(v)-\varphi(v)\\ &\le \varepsilon\ (\varphi(v+w)-\varphi(v))\end{aligned}$$

for $(v,w)\in\mathbb{R}^2_+$, and it follows from (1.18) with $\phi=\varphi$, (2.4), and (3.7) that

$$\begin{aligned}&\frac{d}{dt}\int_0^\infty \varphi(u)\ f_\varepsilon\ du\\ &\le \int_0^\infty\int_0^v (\varphi(v+w)-\varphi(v)-\varphi(w))\ a(v,w)\ f_\varepsilon(v)\ f_\varepsilon(w)\ dwdv\\ &\le 3\ K_1\ \|\varphi\|_{L^\infty(0,2)}\ \int_0^1\int_0^v f_\varepsilon(v)\ f_\varepsilon(w)\ dwdv\\ &\quad +\ 2\ K_1\ \int_1^\infty\int_0^v (v+w)\ (\varphi(v+w)-\varphi(v)-\varphi(w))\ f_\varepsilon(v)\ f_\varepsilon(w)\ dwdv\\ &\le C_3\ \|f_\varepsilon\|^2_{L^\infty(0,T;X)}+4\ K_1\ \int_0^\infty\int_0^\infty (v\ \varphi(w)+w\ \varphi(v))\ f_\varepsilon(v)\ f_\varepsilon(w)\ dwdv\\ &\le C_3+8\ K_1\ \|f_\varepsilon\|_{L^\infty(0,T;X)}\ \int_0^\infty \varphi(v)\ f_\varepsilon(v)\ dv\,.\end{aligned}$$

Recalling (3.5), we conclude by the Gronwall lemma that (3.6) holds true. The above computation is actually mostly formal as f_ε might not be integrable against the weight φ. A rigorous justification can be performed by approximating φ by Lipschitz continuous functions, as in the proof of Lemma 3.1. □

Before turning to the proof of Theorem 2.2, let us recall the following lemma.

LEMMA 3.3. *Let $p>0$, $(\psi_n)_{n\ge1}$, $\psi\in L^\infty((0\,,p)\times(0\,,p))$, and $(g_n)_{n\ge1}$, $g\in L^1(0\,,p)$. Suppose that*

$$\sup_{n\ge1}\|\psi_n\|_{L^\infty((0\,,p)\times(0\,,p))}<+\infty$$

and

$$\begin{aligned}\psi_n &\longrightarrow \psi \quad \text{a.e. in} \quad (0\,,p)\times(0\,,p)\,,\\ g_n &\rightharpoonup g \quad \text{weakly in } L^1(0\,,p)\,.\end{aligned}$$

Then

$$\lim_{n\to+\infty}\int_0^p\int_0^p \psi_n(x,y)\ g_n(x)\ g_n(y)\ dxdy=\int_0^p\int_0^p \psi(x,y)\ g(x)\ g(y)\ dxdy\,.$$

The proof of Lemma 3.3 relies on the Dunford–Pettis and Egorov theorems and is contained implicitly in [20, Lemma 4.1], to which we refer.

Proof of Theorem 2.2. Throughout the proof, we denote by C any positive constant which depends only on α in (2.1), K in (2.2), and f_0. The dependence of C upon additional parameters will be indicated explicitly.

We fix $\varepsilon \in (0\,,1]$ and $\varrho \ge 1$. We first consider a regularized problem obtained by substituting a in (1.19) for a_ϱ defined by

$$a_\varrho(v,w) = \min\{a(v,w),\varrho\}\,, \quad (v,w) \in \mathbb{R}_+^2\,, \tag{3.8}$$

denoting by $Q_{\varepsilon,\varrho}$ the coagulation operator thus obtained. Introducing

$$Q^1_{\varepsilon,\varrho}(f)(u) = \frac{1}{\varepsilon} \int_0^{u/(1+\varepsilon)} a_\varrho(u-\varepsilon v, v)\ f(u-\varepsilon v)\ f(v)\ dv\,, \quad u \in \mathbb{R}_+\,,$$

and $Q^2_{\varepsilon,\varrho}(f) = Q_{\varepsilon,\varrho}(f) - Q^1_{\varepsilon,\varrho}(f)$, it is easy to check that the boundedness of a_ϱ ensures that $Q^i_{\varepsilon,\varrho}$, $i = 1,2$, are locally Lipschitz continuous functions from $L^1(\mathbb{R}_+)$ in $L^1(\mathbb{R}_+)$. Using the Banach fixed point theorem, one proves that there exist $T_{\varepsilon,\varrho} \in (0,+\infty]$ and a unique solution $f_{\varepsilon,\varrho} \in \mathcal{C}^1([0,T_{\varepsilon,\varrho}); L^1(\mathbb{R}_+))$ to

$$\partial_t f_{\varepsilon,\varrho} = \left(Q^1_{\varepsilon,\varrho}(f_{\varepsilon,\varrho})\right)_+ + Q^2_{\varepsilon,\varrho}(f_{\varepsilon,\varrho})\,, \quad (u,t) \in \mathbb{R}_+ \times [0,T_{\varepsilon,\varrho})\,, \tag{3.9}$$

with $f_{\varepsilon,\varrho}(0) = f_0$. Here and below, we denote by $x_+ = \max\{x,0\}$ the positive part of the real number x. Since f_0 and the first term of the right-hand side of (3.9) are nonnegative, we deduce from (3.9) that

$$f_{\varepsilon,\varrho}(t) \ge 0 \quad \text{a.e. in} \quad \mathbb{R}_+$$

for every $t \in [0,T_{\varepsilon,\varrho})$. Consequently, $\left(Q^1_{\varepsilon,\varrho}(f_{\varepsilon,\varrho})\right)_+ = Q^1_{\varepsilon,\varrho}(f_{\varepsilon,\varrho})$ and $f_{\varepsilon,\varrho}$ solves

$$\partial_t f_{\varepsilon,\varrho} = Q_{\varepsilon,\varrho}(f_{\varepsilon,\varrho})\,, \quad (u,t) \in \mathbb{R}_+ \times [0,T_{\varepsilon,\varrho})\,, \tag{3.10}$$

with $f_{\varepsilon,\varrho}(0) = f_0$. In addition, it follows at once from (1.18) with $\phi(v) = 1$ and (3.10) that

$$\int_0^\infty f_{\varepsilon,\varrho}(u,t)\ du \le \int_0^\infty f_0(u)\ du\,, \quad t \in [0\,,T_{\varepsilon,\varrho})\,, \tag{3.11}$$

whence $T_{\varepsilon,\varrho} = +\infty$. Next, let $t > 0$ and $R \ge 1$. It follows from (3.10) that

$$\begin{aligned}\int_0^\infty \min\{u,R\}\ f_{\varepsilon,\varrho}(u,t)\ du = &\int_0^\infty \min\{u,R\}\ f_0(u)\ du \\ &+ \int_0^t \int_0^\infty Q_{\varepsilon,\varrho}(f_{\varepsilon,\varrho}(u,s))\ \min\{u,R\}\ du ds\,.\end{aligned} \tag{3.12}$$

Since

$$\frac{\min\{v+\varepsilon w,R\} - \min\{v,R\}}{\varepsilon} - \min\{w,R\} \le 0\,, \quad 0 \le w \le v\,,$$

we infer from (1.18) with $\phi(v) = \min\{v,R\}$, $v \in \mathbb{R}_+$, that the last term on the right-hand side of (3.12) is nonpositive, and we conclude that

$$\int_0^\infty \min\{u,R\}\ f_{\varepsilon,\varrho}(u,t)\ du \le \int_0^\infty \min\{u,R\}\ f_0(u)\ du \le \int_0^\infty u\ f_0(u)\ du\,.$$

Consequently, $f_{\varepsilon,\varrho} \in L^\infty(0,+\infty;X)$ by the Fatou lemma, which, together with the boundedness of a_ϱ, entails that

$$\lim_{R\to+\infty} \int_0^t \int_0^\infty Q_{\varepsilon,\varrho}(f_{\varepsilon,\varrho}(u,s))\ \min\{u,R\}\ du ds = 0\,.$$

We may then let $R \to +\infty$ in (3.12) and obtain

$$\int_0^\infty u\ f_{\varepsilon,\varrho}(u,t)\ du = \int_0^\infty u\ f_0(u)\ du\,, \quad t \ge 0\,. \tag{3.13}$$

Gathering (3.11) and (3.13), we thus have shown that

$$\sup_{t\ge 0}\ \|f_{\varepsilon,\varrho}(t)\|_X \le \|f_0\|_X\,, \quad \varrho \ge 1\,. \tag{3.14}$$

Step 1. Compactness in $\mathcal{C}([0,T];weak - L^1(\mathbb{R}_+))$.

In this part of the proof, we require only the coagulation kernel a to fulfill (1.4), (2.1), and (2.2). Recall that, since $f_0 \in L^1(\mathbb{R}_+)$, it follows from a refined version of the de la Vallée–Poussin theorem [4, 14] that there exists a function Φ fulfilling the assumptions of Lemma 3.1 and such that

$$\frac{\Phi(x)}{x} \to +\infty \quad \text{as } x \to +\infty \quad \text{and} \quad \int_0^\infty \Phi(f_0(u))\ du < +\infty\,. \tag{3.15}$$

Also, we infer from (2.1) that

$$\partial_u a_\varrho(u,v) = \left(\frac{1 - \ \text{sign}\ (a(u,v)-\varrho)}{2}\right)\ \partial_u a(u,v) \ge -\alpha\,, \quad (u,v) \in \mathbb{R}_+^2\,. \tag{3.16}$$

Owing to (3.14), (3.15), and (3.16), we are in a position to apply Lemma 3.1 and conclude that for each $T > 0$,

$$\sup_{t\in[0,T]} \int_0^\infty \Phi(f_{\varepsilon,\varrho}(u,t))\ du \le C(T)\,, \tag{3.17}$$

uniformly with respect to $\varepsilon \in (0,1]$ and $\varrho \ge 1$. Thanks to (3.14), the superlinearity (3.15) of Φ, and (3.17), we infer from the Dunford–Pettis theorem that for each $T > 0$, there is a weakly compact subset $\mathcal{K}_T$ of $L^1(\mathbb{R}_+)$ such that

$$f_{\varepsilon,\varrho}(t) \in \mathcal{K}_T\,, \quad (t,\varepsilon,\varrho) \in [0,T] \times (0,1] \times [1,+\infty)\,. \tag{3.18}$$

We next show the time equicontinuity of the sequence $(f_{\varepsilon,\varrho})$ in the weak topology of $L^1(\mathbb{R}_+)$. We first consider $\phi \in \mathcal{D}(\mathbb{R}_+)$ and let $r_0 > 0$ be such that supp $\phi \subset [0,r_0]$. For $h > 0$ and $t \in [0,T-h]$, it follows from (1.18), (2.2), and (3.14) that

$$\begin{aligned}
&\left| \int (f_{\varepsilon,\varrho}(t+h) - f_{\varepsilon,\varrho}(t))\ \phi\ du \right| \\
&\le \int_t^{t+h} \int_0^{r_0} \int_0^v a(v,w)\ \left| \frac{\phi(v+\varepsilon\ w) - \phi(v)}{\varepsilon} \right|\ f_{\varepsilon,\varrho}(v)\ f_{\varepsilon,\varrho}(w)\ dw dv ds \\
&\quad + \int_t^{t+h} \int_0^\infty \int_0^\infty a(v,w)\ |\phi(w)|\ f_{\varepsilon,\varrho}(v)\ f_{\varepsilon,\varrho}(w)\ dv dw ds
\end{aligned}$$

$$
\begin{aligned}
&\le \|\partial_v \phi\|_{L^\infty} \int_t^{t+h} \int_0^{r_0} \int_0^v a(v,w)\ w\ f_{\varepsilon,\varrho}(v)\ f_{\varepsilon,\varrho}(w)\ dwdvds \\
&\quad + \|\phi\|_{L^\infty} \int_t^{t+h} \int_0^{\infty} \int_0^{\infty} a(v,w)\ f_{\varepsilon,\varrho}(v)\ f_{\varepsilon,\varrho}(w)\ dvdwds \\
&\le K\ (1+r_0)\ \|\phi\|_{W^{1,\infty}} \int_t^{t+h} \int_0^{\infty} \int_0^{\infty} (1+v)\ (1+w)\ f_{\varepsilon,\varrho}(v)\ f_{\varepsilon,\varrho}(w)\ dvdwds \\
&\le K\ (1+r_0)\ \|\phi\|_{W^{1,\infty}}\ \|f_{\varepsilon,\varrho}\|^2_{L^\infty(0,T;X)}\ |h| \\
&\le C(\phi)\ |h|\,.
\end{aligned}
$$

This proves the time equicontinuity for test functions ϕ in $\mathcal{D}(\mathbb{R}_+)$. For a general function in $L^\infty(\mathbb{R}_+)$, we use the following approximation argument: for a given $\phi \in L^\infty(0,+\infty)$, there is a sequence of functions (ϕ_k) in $\mathcal{D}(\mathbb{R}_+)$ such that $\|\phi_k\|_{L^\infty} \le 2\ \|\phi\|_{L^\infty}$ and

$$
\phi_k \longrightarrow \phi \quad \text{a.e. in} \quad \mathbb{R}_+.
$$

It then follows from the Egorov theorem that for each $R > 0$ and $\delta \in (0,1)$, there is a measurable subset $Z_{\delta,R}$ of $(0,R)$ with $|Z_{\delta,R}| \le \delta$ and such that

$$
\lim_{k\to+\infty} \sup_{v\in(0,R)\setminus Z_{\delta,R}} |\phi_k(v) - \phi(v)| = 0.
$$

Now, we have

$$
\begin{aligned}
&\left| \int_0^{\infty} (f_{\varepsilon,\varrho}(t+h) - f_{\varepsilon,\varrho}(t))\ \phi\ du \right| \\
&\le \left| \int_0^{\infty} (f_{\varepsilon,\varrho}(t+h) - f_{\varepsilon,\varrho}(t))\ \phi_k\ du \right| + \left| \int_0^{\infty} (f_{\varepsilon,\varrho}(t+h) - f_{\varepsilon,\varrho}(t))\ (\phi - \phi_k)\ du \right| \\
&\le C(\phi_k)\ |h| + \int_{(0,R)\setminus Z_{\delta,R}} (f_{\varepsilon,\varrho}(t+h) + f_{\varepsilon,\varrho}(t))\ |\phi_k - \phi|\ du \\
&\quad + 3\ \|\phi\|_{L^\infty} \sup_{t\in[0,T]} \int_R^{\infty} f_{\varepsilon,\varrho}(t)\ du + 3\ \|\phi\|_{L^\infty} \sup_{t\in[0,T]} \int_{Z_{\delta,R}} f_{\varepsilon,\varrho}(t)\ du \\
&\le C(\phi_k)\ |h| + 2\ \|f_{\varepsilon,\varrho}\|_{L^\infty(0,T;X)} \sup_{v\in(0,R)\setminus Z_{\delta,R}} |\phi_k(v) - \phi(v)| \\
&\quad + 3\ \|\phi\|_{L^\infty} \sup_{t\in[0,T]} \int_R^{\infty} f_{\varepsilon,\varrho}(t)\ du + 3\ \|\phi\|_{L^\infty} \sup_{t\in[0,T]} \int_{Z_{\delta,R}} f_{\varepsilon,\varrho}(t)\ du\,.
\end{aligned}
$$

We first let $h \to 0$ and use (3.14) to obtain

$$
\begin{aligned}
\limsup_{h\to 0} \left| \int_0^{\infty} (f_{\varepsilon,\varrho}(t+h) - f_{\varepsilon,\varrho}(t))\ \phi\ du \right| &\le 2\ \|f_0\|_X \sup_{v\in(0,R)\setminus Z_{\delta,R}} |\phi_k(v) - \phi(v)| \\
&\quad + \frac{3}{R}\ \|\phi\|_{L^\infty}\ \|f_0\|_X \\
&\quad + 3\ \|\phi\|_{L^\infty} \sup_{t\in[0,T]} \int_{Z_{\delta,R}} f_{\varepsilon,\varrho}(t)\ du
\end{aligned}
$$

for every k, R, and δ. We then let $k \to +\infty$, and next $\delta \to 0$ and $R \to +\infty$, to conclude that

$$
\lim_{h\to 0} \left| \int_0^{\infty} (f_{\varepsilon,\varrho}(t+h) - f_{\varepsilon,\varrho}(t))\ \phi\ du \right| = 0\,,
$$

this limit being uniform with respect to $\varepsilon \in (0\,,1]$, $\varrho > 1$, and $t \in [0\,,T]$. Notice that in order to pass to the limit as $\delta \to 0$ in the last term of the above inequality, we used (3.18) and the Dunford–Pettis theorem.

We are now in a position to apply a variant of the Ascoli theorem (see, e.g., [21, Theorem 1.3.2]) to deduce that $(f_{\varepsilon,\varrho})$ lies in a relatively compact subset of $\mathcal{C}([0\,,T];weak-L^1(\mathbb{R}_+))$. There are thus sequences $\varrho \to +\infty$ and $\varepsilon \to 0$ (not relabeled) and nonnegative functions f_ε, $f \in \mathcal{C}([0\,,T];weak-L^1(\mathbb{R}_+))$ such that

$$f_{\varepsilon,\varrho} \longrightarrow f_\varepsilon \quad \text{in} \quad \mathcal{C}([0\,,T];weak-L^1(\mathbb{R}_+)) \tag{3.19}$$

for each $T > 0$ and $\varepsilon \in (0,1]$, and

$$f_\varepsilon \longrightarrow f \quad \text{in} \quad \mathcal{C}([0\,,T];weak-L^1(\mathbb{R}_+)) \tag{3.20}$$

for each $T > 0$. As a first consequence of (3.19) and (3.20), it follows from (3.14) and the weak lower semicontinuity of $\|.\|_X$ that

$$\sup_{t\ge 0} \|f_\varepsilon(t)\|_X \le \|f_0\|_X \quad \text{and} \quad \sup_{t\ge 0} \|f(t)\|_X \le \|f_0\|_X \tag{3.21}$$

for $\varepsilon \in (0\,,1]$.

We next identify the equations satisfied by f_ε for $\varepsilon \in (0\,,1]$ and f. We recall that for $\varepsilon \in (0\,,1]$ and $\varrho > 1$, the function $(f_{\varepsilon,\varrho})$ satisfies the weak form (2.8) of (3.10), that is,

$$\int_0^\infty f_{\varepsilon,\varrho}(u,t)\ \phi(u)\ du = \int f_0(u)\ \phi(u)\ du + \mathcal{R}^1_{\varepsilon,\varrho}(\phi,t) - \mathcal{R}^2_{\varepsilon,\varrho}(\phi,t) \tag{3.22}$$

for every $\phi \in \mathcal{D}([0\,,+\infty))$ and $t \ge 0$, where

$$\mathcal{R}^1_{\varepsilon,\varrho}(\phi,t) = \int_0^t \int_0^\infty \int_0^v \left(\frac{\phi(v+\varepsilon w) - \phi(v)}{\varepsilon} \right)\ a_\varrho(v,w)\ f_{\varepsilon,\varrho}(v,s)\ f_{\varepsilon,\varrho}(w,s)\ dwdvds\,,$$

$$\mathcal{R}^2_{\varepsilon,\varrho}(\phi,t) = \int_0^t \int_0^\infty \int_0^v \phi(w)\ a_\varrho(v,w)\ f_{\varepsilon,\varrho}(v,s)\ f_{\varepsilon,\varrho}(w,s)\ dwdvds\,.$$

We now fix $\phi \in \mathcal{D}([0\,,+\infty))$ and $t > 0$ in the above formulae and pass to the limit in (3.22) first as $\varrho \to +\infty$ and then as $\varepsilon \to 0$. Let R_0 be such that $\operatorname{supp}\phi \subset [0, R_0]$. On the one hand, notice that (3.19) and (3.20) readily imply that

$$\lim_{\varrho\to+\infty} \int_0^\infty f_{\varepsilon,\varrho}(u,t)\ \phi(u)\ du = \int_0^\infty f_\varepsilon(u,t)\ \phi(u)\ du \tag{3.23}$$

for $\varepsilon \in (0,1]$ and

$$\lim_{\varepsilon\to 0} \int_0^\infty f_\varepsilon(u,t)\ \phi(u)\ du = \int_0^\infty f(u,t)\ \phi(u)\ du\,. \tag{3.24}$$

On the other hand,

$$\phi(v+\varepsilon w) - \phi(v) = 0 \quad \text{if} \quad (v,w) \notin (0,R_0)^2 \quad \text{and} \quad 0 \le w \le v\,,$$

so that $\mathcal{R}^1_{\varepsilon,\varrho}(\phi,t)$ reduces to an integral over $(0,t)\times(0,R_0)^2$. Owing to (2.2), (3.19), and the definition of a_ϱ, we are in a position to apply Lemma 3.3 and conclude that

$$\lim_{\varrho\to+\infty} \mathcal{R}^1_{\varepsilon,\varrho}(\phi,t) = \mathcal{R}^1_\varepsilon(\phi,t)\,, \tag{3.25}$$

where

$$\mathcal{R}^1_\varepsilon(\phi,t) = \int_0^t \int_0^\infty \int_0^v \left(\frac{\phi(v+\varepsilon w)-\phi(v)}{\varepsilon} \right) \, a(v,w) \, f_\varepsilon(v,s) \, f_\varepsilon(w,s) \, dwdvds \, .$$

Similarly, we deduce from (2.2), (3.20), and Lemma 3.3 that

$$\lim_{\varepsilon\to 0} \mathcal{R}^1_\varepsilon(\phi,t) = \int_0^t \int_0^\infty \int_0^v w \, \phi'(v) \, a(v,w) \, f(v,s) \, f(w,s) \, dwdvds \, . \tag{3.26}$$

It remains to pass to the limit in $\mathcal{R}^2_{\varepsilon,\varrho}(\phi,t)$. Observe that this term involves values of $f_{\varepsilon,\varrho}(v,s)$ for large values of v so that more precise information on the behavior of a for large values of v is needed. We thus now split the proof according to the assumed growth of a.

Step 2. Convergence for strictly subquadratic kernels.

In this step, we complete the proof of Theorem 2.2 when the coagulation kernel a satisfies (2.3) in addition to (2.1) and (2.2). On the one hand, we observe that, given $R > 1$, it follows as above from (2.2), (3.19), and Lemma 3.3 that

$$\begin{aligned} &\lim_{\varrho\to+\infty} \int_0^t \int_0^R \int_0^v \phi(w) \, a_\varrho(v,w) \, f_{\varepsilon,\varrho}(v,s) \, f_{\varepsilon,\varrho}(w,s) \, dwdvds \\ &= \int_0^t \int_0^R \int_0^v \phi(w) \, a(v,w) \, f_\varepsilon(v,s) \, f_\varepsilon(w,s) \, dwdvds \, . \end{aligned}$$

On the other hand, we infer from (2.3) and (3.14) that

$$\begin{aligned} &\int_0^t \int_R^\infty \int_0^v \phi(w) \, a_\varrho(v,w) \, f_{\varepsilon,\varrho}(v,s) \, f_{\varepsilon,\varrho}(w,s) \, dwdvds \\ &\le \|\phi\|_{L^\infty} \int_0^t \int_R^\infty \int_0^{R_0} a(w,v) \, f_{\varepsilon,\varrho}(v,s) \, f_{\varepsilon,\varrho}(w,s) \, dwdvds \\ &\le \|\phi\|_{L^\infty} \int_0^t \int_R^\infty \int_0^{R_0} v \, \omega_{R_0}(v) \, f_{\varepsilon,\varrho}(v,s) \, f_{\varepsilon,\varrho}(w,s) \, dwdvds \\ &\le C(\phi) \, \|\omega_{R_0}\|_{L^\infty(R,+\infty)} \, , \end{aligned}$$

whence

$$\lim_{R\to+\infty} \int_0^t \int_R^\infty \int_0^v \phi(w) \, a_\varrho(v,w) \, f_{\varepsilon,\varrho}(v,s) \, f_{\varepsilon,\varrho}(w,s) \, dwdvds = 0$$

by (2.3), uniformly with respect to $\varepsilon \in (0,1]$ and $\varrho \ge 1$. Similarly, we deduce from (2.3) and (3.21) that

$$\lim_{R\to+\infty} \int_0^t \int_R^\infty \int_0^v \phi(w) \, a(v,w) \, f_\varepsilon(v,s) \, f_\varepsilon(w,s) \, dwdvds = 0 \, .$$

The above analysis then yields that

$$\lim_{\varrho\to+\infty} \mathcal{R}^2_{\varepsilon,\varrho}(\phi,t) = \mathcal{R}^2_\varepsilon(\phi,t) \, , \tag{3.27}$$

where

$$\mathcal{R}^2_\varepsilon(\phi,t) = \int_0^t \int_0^\infty \int_0^v \phi(w) \, a(v,w) \, f_\varepsilon(v,s) \, f_\varepsilon(w,s) \, dwdvds \, .$$

Proceeding analogously, we next obtain that

$$\lim_{\varepsilon\to 0} \mathcal{R}^2_\varepsilon(\phi,t) = \int_0^t \int_0^\infty \int_0^v \phi(w)\ a(v,w)\ f(v,s)\ f(w,s)\ dwdvds\,. \tag{3.28}$$

Gathering (3.23), (3.25), and (3.27) ensures that f_ε satisfies (2.8) for any $\phi \in \mathcal{D}([0\,,+\infty))$, and (3.21) together with classical approximation arguments entails that f_ε actually satisfies (2.8) for any $\phi \in L^\infty(0\,,+\infty)$. Also, (3.13) and (3.19) warrant that (2.9) holds true. Next, gathering (3.24), (3.26), and (3.28) implies that f satisfies (2.7) for any $\phi \in \mathcal{D}([0\,,+\infty))$. Using again classical approximation arguments along with (3.21) then yields that f satisfies (2.7) for any $\phi \in W^{1,\infty}(0\,,+\infty)$ with compactly supported first derivative. Finally, the inequality (2.9) for f_ε and (3.20) yield (2.9) for f. Recalling the convergence (3.20), we have proved Theorem 2.2 for strictly subquadratic coagulation kernels a.

Step 3. Convergence for subadditive kernels.

This final step is devoted to the proof of Theorem 2.2 for a subadditive coagulation kernel a satisfying (2.4) besides (2.1) and (2.2). As in the previous step, the main issue is to pass to the limit in $\mathcal{R}^2_{\varepsilon,\varrho}(\phi,t)$. For that purpose, we will employ Lemma 3.2 and use once more a refined version of the de la Vallée–Poussin theorem [4, 14] to find a function φ enjoying the requirements of Lemma 3.2 and

$$\frac{\varphi(x)}{x} \to +\infty \quad \text{as } x \to +\infty \quad \text{and} \quad \int_0^\infty \varphi(u)\ f_0(u)\ du < +\infty\,. \tag{3.29}$$

Since a_ϱ fulfills (2.4) with the same constant K_1 as a, we infer from Lemma 3.2 that

$$\sup_{t\in[0,T]} \int_0^\infty \varphi(u)\ f_{\varepsilon,\varrho}(u,t)\ du \le C(T)$$

for every $T > 0$, $\varepsilon \in (0,1]$, and $\varrho \ge 1$. As a straightforward consequence of the superlinearity (3.29) of φ and the above inequality, we realize that

$$\lim_{R\to+\infty} \sup_{t\in[0,T]} \int_R^\infty u\ f_{\varepsilon,\varrho}(u,t)\ du = 0 \tag{3.30}$$

for every $T > 0$, uniformly with respect to $\varepsilon \in (0,1]$ and $\varrho \ge 1$. One then employs (3.30) to proceed as in Step 2 and conclude that (3.27) and (3.28) hold true. We next argue as in Step 2 to show that f and f_ε satisfy (2.7) and (2.8), respectively. In addition, it readily follows from (3.13), (3.19), (3.20), and (3.30) that f_ε and f satisfy (2.10) and that the convergence (3.20) can be improved to the one claimed in (2.12). □

Proof of Proposition 2.4. We proceed along the same lines as those of Lemma 3.1. We put $P(x) = x_+$ for $x \in \mathbb{R}$ and

$$\sigma(t) = \|f_0\|_{L^\infty}\ \exp\left(\alpha\ t\ \int_0^\infty u\ f_0(u)\ du\right)$$

for $t \ge 0$. For $\varepsilon \in (0,1]$ and $\varrho \ge 1$, it follows from (1.18) and (3.10) that

$$\begin{aligned}
&\frac{d}{dt}\int_0^\infty P(f_{\varepsilon,\varrho}-\sigma)\ du \\
&\le \int_0^\infty \int_0^v \left\{ \frac{P'(f_{\varepsilon,\varrho}(v+\varepsilon w)-\sigma) - P'(f_{\varepsilon,\varrho}(v)-\sigma)}{\varepsilon} \right\} a_\varrho(v,w)\ f_{\varepsilon,\varrho}(v)\ f_{\varepsilon,\varrho}(w)\ dwdv \\
&\quad - \int_0^\infty P'(f_{\varepsilon,\varrho}-\sigma)\ \sigma'\ du\,.
\end{aligned}$$

Owing to the convexity of P, we have for $x,\ y \ge 0$,

$$\begin{aligned} x\ (P'(y-\sigma) - P'(x-\sigma)) &\le y\ P'(y-\sigma) + P(x-\sigma) - P(y-\sigma) - x\ P'(x-\sigma) \\ &\le \sigma\ (P'(y-\sigma) - P'(x-\sigma))\ . \end{aligned}$$

Consequently, since $P' \ge 0$,

$$\begin{aligned} &\int_0^\infty \int_0^v \left\{ \frac{P'(f_{\varepsilon,\varrho}(v+\varepsilon w)-\sigma) - P'(f_{\varepsilon,\varrho}(v)-\sigma)}{\varepsilon} \right\}\ a_\varrho(v,w)\ f_{\varepsilon,\varrho}(v)\ f_{\varepsilon,\varrho}(w)\ dwdv \\ &\le \sigma\ \int_0^\infty \int_0^v \left\{ \frac{P'(f_{\varepsilon,\varrho}(v+\varepsilon w)-\sigma) - P'(f_{\varepsilon,\varrho}(v)-\sigma)}{\varepsilon} \right\}\ a_\varrho(v,w)\ f_{\varepsilon,\varrho}(w)\ dwdv \\ &\le \sigma\ \int_0^\infty \int_w^\infty \left\{ \frac{a_\varrho(v-\varepsilon w,w) - a_\varrho(v,w)}{\varepsilon} \right\}\ P'(f_{\varepsilon,\varrho}(v)-\sigma)\ f_{\varepsilon,\varrho}(w)\ dvdw \\ &\le \alpha\ \sigma\ \int_0^\infty u\ f_0(u)\ du\ \int_0^\infty P'(f_{\varepsilon,\varrho}(v)-\sigma)\ dv\,, \end{aligned}$$

where we have used (2.1) and (3.13) to obtain the last inequality. Thanks to the choice of σ, combining the previous two inequalities yields that

$$\frac{d}{dt} \int_0^\infty P(f_{\varepsilon,\varrho} - \sigma)\ du \le 0\,,$$

whence

$$\|f_{\varepsilon,\varrho}(t)\|_{L^\infty} \le \sigma(t)\,, \quad t \ge 0\,.$$

Proposition 2.4 then follows from the above inequality by (3.19) and (3.20). ∎

4. Large time behavior and gelation. Throughout this section, we consider $f_0 \in X^+$, $f_0 \not\equiv 0$ and denote by f a weak solution to (1.5), (1.2) on $[0,+\infty)$. We also denote the total mass of f at time t by $M_1(t)$, that is,

$$M_1(t) = \int_0^\infty u\ f(u,t)\ du\,. \tag{4.1}$$

Since the OHS equation (1.5) accounts for only coagulation reactions, the total number of particles (which is nothing but the L^1-norm of f) is expected to decrease to zero as time increases to infinity. More precisely, we have the following result.

PROPOSITION 4.1. *For $k \in [0,1]$ and $t_2 \ge t_1 \ge 0$, we have*

$$\int_0^\infty u^k\ f(u,t_2)\ du \le \int_0^\infty u^k\ f(u,t_1)\ du\,. \tag{4.2}$$

Assume further that for each $\eta > 0$, there is $\delta_\eta > 0$ such that

$$a(u,v) \ge \delta_\eta \quad \text{for} \quad (u,v) \in (\eta,+\infty) \times (\eta,+\infty)\,. \tag{4.3}$$

Then

$$\lim_{t \to +\infty} \int_0^\infty f(u,t)\ du = 0\,.$$

Proof. Let $R \ge 1$ and take $\phi(v) = \min\{v^k, R^k\}$, $v \in \mathbb{R}_+$, in (2.7) with $t = t_1$ and $t = t_2$. Substracting the resulting identities yields

$$\int_0^\infty f(u,t_2)\ \phi(u)\ du = \int_0^\infty f(u,t_1)\ \phi(u)\ du + \int_{t_1}^{t_2}\int_0^\infty\int_0^v [w\ \phi'(v) - \phi(w)]\ a(v,w)\ f(v,s)\ f(w,s)\ dwdvds\,.$$

Since $k \in [0,1]$, we have $[w\ \phi'(v) - \phi(w)] \le 0$ for $0 \le w \le v$, from which we conclude that

$$\int_0^\infty f(u,t_2)\ \min\{u^k, R^k\}\ du \le \int_0^\infty f(u,t_1)\ \min\{u^k, R^k\}\ du$$

for every $R \ge 1$. Owing to Definition 2.1, we may let $R \to +\infty$ and deduce (4.2).

We next prove the second assertion of Proposition 4.1. For $U > 0$ and $t \ge 0$, we put

$$L(U,t) = \int_0^U f(u,t)\ du\,.$$

We fix $U > 0$ and put $\phi_\nu(v) = \min\{1, (U+\nu-v)_+/\nu\}$ for $v \in \mathbb{R}_+$ and $\nu \in (0,1)$. Then $\phi_\nu \in W^{1,\infty}(\mathbb{R}_+)$ and $\phi_\nu' \le 0$. We then infer from (2.7) with $\phi = \phi_\nu$ that for $t_2 \ge t_1 \ge 0$,

$$\begin{aligned}&\int_0^\infty (f(u,t_2) - f(u,t_1))\ \phi_\nu(u)\ du\\ &\le -\int_{t_1}^{t_2}\int_0^\infty\int_0^v \phi_\nu(w)\ a(v,w)\ f(v,s)\ f(w,s)\ dwdvds\\ &\le -\frac{1}{2}\int_{t_1}^{t_2}\int_0^U\int_0^U a(v,w)\ f(v,s)\ f(w,s)\ dwdvds\,.\end{aligned}$$

We may then let $\nu \to 0$ and deduce that

$$L(U,t_2) - L(U,t_1) \le -\frac{1}{2}\int_{t_1}^{t_2}\int_0^U\int_0^U a(v,w)\ f(v,s)\ f(w,s)\ dwdvds\,. \tag{4.4}$$

A first consequence of (4.4) is that $L(U,.)$ is a nondecreasing and nonnegative function of time, and there exists $L(U) \ge 0$ such that

$$\lim_{t\to+\infty} L(U,t) = L(U)\,. \tag{4.5}$$

As a second consequence of (4.4), we realize that (4.3) yields, for $\eta \in (0,U)$, that

$$\begin{aligned}\int_0^t \left(\int_\eta^U f(v,s)\ dv\right)^2 ds &\le \frac{1}{\delta_\eta}\int_0^t\int_0^U\int_0^U a(v,w)\ f(v,s)\ f(w,s)\ dwdvds\\ &\le \frac{2}{\delta_\eta}\ L(U,0)\,,\end{aligned}$$

and thus

$$t \mapsto L(U,t) - L(\eta,t) \in L^2(0,+\infty)\,. \tag{4.6}$$

It then readily follows from (4.5), (4.6), and the time monotonicity of $L(\eta,.)$ that

$$0 \le L(U) = L(\eta) \le L(\eta,0)\,, \quad \eta \in (0,U)\,.$$

Since $f_0 \in L^1(\mathbb{R}_+)$, we pass to the limit as $\eta \to 0$ in the above identity to conclude that $L(U) = 0$ for each $U > 0$. We next observe that (4.2) entails that

$$\|f(t)\|_{L^1} \le L(U,t) + \frac{1}{U} \int_U^\infty u\ f(u,t)\ du \le L(U,t) + \frac{1}{U} \int_0^\infty u\ f_0(u)\ du\,,$$

from which the second assertion of Proposition 4.1 readily follows by first letting $t \to +\infty$ and then $U \to +\infty$. □

We now turn to the proof of Theorem 2.5, beginning with the following lemma.

LEMMA 4.2. *For $t_2 \ge t_1 \ge 0$, we have*

$$\int_{t_1}^{t_2} \int_0^\infty \int_0^\infty a(v,w)\ f(v,s)\ f(w,s)\ dvdwds \le 2 \int_0^\infty f(v,t_1)\ dv \tag{4.7}$$

and

$$\int_{t_1}^{t_2} \int_R^\infty \int_R^\infty a(v,w)\ f(v,s)\ f(w,s)\ dvdwds \le \frac{2}{R} \int_0^\infty v\ f(v,t_1)\ dv \tag{4.8}$$

for $R > 0$.

Proof. We first take $\phi = 1$ in (2.7) to obtain (4.7). We next take $\phi(v) = \min\{v, R\}$ in (2.7) and notice that

$$\begin{aligned} &w\ \phi'(v) - \phi(w) = -R \quad \text{if} \quad v \ge w \ge R\,, \\ &w\ \phi'(v) - \phi(w) \le 0 \quad \text{if} \quad v \ge w \ge 0 \quad \text{and} \quad w \le R \end{aligned}$$

to conclude that (4.8) holds true. □

We now argue as in [9, Theorem 1.1] to complete the proof of Theorem 2.5.

Proof of Theorem 2.5. Assume first that $\lambda \in (1,2)$. We put $\zeta(v) = \left(v^{1-\lambda/2} - 1\right)_+$, $v \in \mathbb{R}_+$, and notice that

$$\mathcal{J} = \int_0^\infty \zeta'(v)\ v^{-1/2}\ dv < +\infty\,,$$

since $\lambda + 1 > 2$ and ζ vanishes in a neighborhood of $v = 0$. For $t_2 \ge t_1 \ge 0$, it follows from the Hölder inequality, (2.15), and (4.8) that

$$\begin{aligned} &\int_{t_1}^{t_2} \left(\int_0^\infty \zeta'(R) \int_R^\infty u^{\lambda/2}\ f(u,s)\ dudR \right)^2 ds \\ &\le \mathcal{J} \int_{t_1}^{t_2} \int_0^\infty \zeta'(R)\ R^{1/2} \left(\int_R^\infty u^{\lambda/2}\ f(u,s)\ du \right)^2 dRds \\ &\le \frac{\mathcal{J}}{K_0} \int_0^\infty \zeta'(R)\ R^{1/2} \int_{t_1}^{t_2} \int_R^\infty \int_R^\infty a(u,v)\ f(u,s)\ f(v,s)\ dvdudsdR \\ &\le \frac{2\,\mathcal{J}^2}{K_0}\ M_1(t_1)\,. \end{aligned}$$

However,

$$\int_0^\infty \zeta'(R) \int_R^\infty u^{\lambda/2}\ f(u,s)\ du dR = \int_0^\infty u^{\lambda/2}\ \zeta(u)\ f(u,s)\ du \\ \ge C(\lambda)\ \int_2^\infty u\ f(u,s)\ du\,.$$

Combining the previous inequalities yields

$$\int_{t_1}^{t_2} \left(\int_2^\infty u\ f(u,s)\ du \right)^2\ ds \le C\ M_1(t_1) \tag{4.9}$$

for some constant C depending only on λ and K_0. Next it follows from (2.15) and (4.7) that

$$\int_{t_1}^{t_2} \left(\int_0^2 u\ f(u,s)\ du \right)^2\ ds \le C\ \int_0^\infty\ f(v,t_1)\ dv\,. \tag{4.10}$$

We then infer from (4.2), (4.9), (4.10), and the Young inequality that

$$\int_0^\infty M_1(s)^2\ ds \le C\ \|f_0\|_X\,. \tag{4.11}$$

Recalling (4.2), we realize that the total mass M_1 is a nondecreasing and nonnegative function which also belongs to $L^2(0,+\infty)$. Therefore,

$$\lim_{t\to+\infty} M_1(t) = 0\,,$$

which readily implies that $T_{gel} < +\infty$ since $M_1(0) > 0$.

We next consider the case $\lambda = 2$. It then readily follows from (2.15) and (4.7) that (4.11) holds true, and we argue as above to complete the proof. ∎

5. Compactly supported initial data. Throughout this section, we consider $f_0 \in X^+$ and denote by f a weak solution to (1.5), (1.2) on $[0,+\infty)$. As in the previous section, we denote the total mass of f at time t by $M_1(t)$; see (4.1).

Proof of Theorem 2.6. Since

$$(u,t) \mapsto \int_0^u v\ a(u,v)\ f(v,t)\ dv$$

belongs to $\mathcal{C}([0,+\infty)\times[0,+\infty))$, the first assertion of Theorem 2.6 follows at once from the Cauchy–Péano theorem. The monotonicity of R is then a consequence of the nonnegativity of f and a. We next put

$$F(u,t) = \int_u^\infty f(v,t)\ dv\,, \quad F_0(u) = F(u,0)\,,$$
$$\lambda(u,t) = \int_0^u v\ a(u,v)\ f(v,t)\ dv\,, \quad \mu(u,t) = \int_u^\infty a(u,v)\ f(v,t)\ dv$$

for $(u,t) \in \mathbb{R}^2_+$. Then (2.2) and (4.2) ensure that $F \in L^\infty(0,+\infty;W^{1,1}(\mathbb{R}_+))$ and λ and μ belong to $L^\infty_{\rm loc}([0,+\infty)^2)$. Moreover, the boundedness of f, (2.1), and (4.2) imply that

$$\partial_u\lambda(u,t) = u\ a(u,u)\ f(u,t) + \int_0^u v\ \partial_u a(u,v)\ f(v,t)\ dv \in L^\infty_{\rm loc}([0,+\infty)^2)\,,$$

and we infer from (2.7) that F satisfies

$$\partial_t F(u,t) + \partial_u \left(\lambda(u,t)\ F(u,t)\right) = \partial_u \lambda(u,t)\ F(u,t) - \int_u^\infty \mu(v,t)\ f(v,t)\ dv$$

a.e. in $\mathbb{R}_+$ for each $t \ge 0$ with $F(0) = F_0$. The regularity of f and a then implies that $F \in W^{1,\infty}_{loc}([0,+\infty) \times \mathbb{R}_+)$. Since μ and f are nonnegative, it follows from (2.17) and the above equation that for $t_0 \in (0, T_\star)$ and $t \in [0, t_0]$, we have

$$\begin{aligned}
\frac{d}{dt} \int_{R(t)}^{R(t_0)} F(u,t)\ du &= \int_{R(t)}^{R(t_0)} \partial_t F(u,t)\ du - F(R(t),t)\ R'(t) \\
&\le -\lambda(R(t_0),t)\ F(R(t_0),t) + \lambda(R(t),t)\ F(R(t),t) \\
&\quad + \int_{R(t)}^{R(t_0)} F(u,t)\ \partial_u \lambda(u,t)\ du - F(R(t),t)\ R'(t) \\
&\le \|\partial_u \lambda\|_{L^\infty((0,R(t_0))\times(0,t_0))} \int_{R(t)}^{R(t_0)} F(u,t)\ du\,.
\end{aligned}$$

We now apply the Gronwall lemma and use (2.16) to conclude that

$$\int_{R(t)}^{R(t_0)} F(u,t)\ du \le \int_{R_0}^{R(t_0)} F_0(u)\ du\ \exp\left(t_0\ \|\partial_u \lambda\|_{L^\infty((0,R(t_0))\times(0,t_0))}\right) = 0$$

for each $t \in [0, t_0]$. Consequently,

$$F(R(t),t) = \int_{R(t)}^\infty f(u,t)\ du = 0$$

for each $t \in [0, t_0]$, whence the second assertion of Theorem 2.6 since t_0 is arbitrary in $[0, T_\star)$. ∎

Proof of Corollary 2.7. Let $t \in (0, T_\star)$. Since $f(t)$ is compactly supported, (2.19) follows at once from (2.7) with $\phi(u) = u$, $u \in \mathbb{R}_+$. ∎

We next show that $T_\star = +\infty$ for subadditive coagulation kernels.

LEMMA 5.1. *Assume that $a \in \mathcal{C}([0,+\infty)^2)$ satisfies* (2.4). *Then $T_\star = +\infty$.*

Proof. The subadditivity (2.4) of the coagulation kernel, (2.17), and (4.2) entail that for $t \in [0, T_\star)$,

$$\begin{aligned}
R'(t) &\le K_1 \int_0^{R(t)} u\ (1 + R(t) + u)\ f(u,t)\ du \\
&\le K_1\ (1 + 2\ R(t)) \int_0^\infty u\ f(u,t)\ du \\
&\le K_1\ (1 + 2\ R(t)) \int_0^\infty u\ f_0(u)\ du\,,
\end{aligned}$$

and the Gronwall lemma ensures that (2.18) cannot occur, whence $T_\star = +\infty$. ∎

We next give some bounds from above and below for R for additive and product coagulation kernels. We first consider additive coagulation kernels.

LEMMA 5.2. *Assume that*

$$a(u,v) = u^\lambda + v^\lambda\,, \quad (u,v) \in \mathbb{R}_+^2\,,$$

with $\lambda \in [0,1]$. Then $T_\star = +\infty$ and, for $t \ge 0$,

$$\left(R(0)^{1-\lambda} + (1-\lambda)\ M_1(0)\ t\right)^{1/(1-\lambda)} \le R(t) \le \left(R(0)^{1-\lambda} + 2\ (1-\lambda)\ M_1(0)\ t\right)^{1/(1-\lambda)}$$

if $\lambda \in [0,1)$ *and*

$$R(0)\ e^{M_1(0)t} \le R(t) \le R(0)\ e^{2M_1(0)t}$$

if $\lambda = 1$.

Proof. By Lemma 5.1, we have $T_\star = +\infty$, and we infer from (2.17) that

$$R'(t) = \int_0^{R(t)} u\ \left(R(t)^\lambda + u^\lambda\right)\ f(u,t)\ du\,.$$

Owing to (2.19), the above identity yields that

$$R'(t) \le 2\ R(t)^\lambda\ \int_0^\infty u\ f(u,t)\ du \le 2\ M_1(0)\ R(t)^\lambda\,,$$

whence the upper bound by the Gronwall lemma. Similarly,

$$R'(t) \ge R(t)^\lambda\ \int_0^\infty u\ f(u,t)\ du \ge M_1(0)\ R(t)^\lambda\,,$$

and the expected lower bound follows again from the Gronwall lemma. ∎

Remark 5.3. Of course, similar upper or lower bounds are also available for coagulation kernels being bounded from below or above by an additive coagulation kernel.

We next turn to product kernels, that is, $a(u,v) = (u\ v)^{\lambda/2}$, $(u,v) \in \mathbb{R}_+^2$, for some $\lambda \in [0,2]$. Observe that by Lemma 5.1, $T_\star = +\infty$ if $\lambda \in [0,1]$, while Theorem 2.5 entails that $T_\star < +\infty$ if $\lambda \in (1,2]$. The estimates we obtain for product kernels will therefore be of a different nature according to whether $\lambda \in [0,1]$ or $\lambda \in (1,2]$.

LEMMA 5.4. *Assume that*

$$a(u,v) = (u\ v)^{\lambda/2}\,, \quad (u,v) \in \mathbb{R}_+^2\,,$$

with $\lambda \in [0,2]$.

1. *If* $\lambda \in [0,1]$, *then* $T_\star = +\infty$ *and*

$$R(t) \le \left(R(0)^{1-\lambda} + (1-\lambda)\ M_1(0)\ t\right)^{1/(1-\lambda)}$$

if $\lambda \in [0,1)$ *and*

$$R(t) \le R(0)\ e^{M_1(0)t}$$

if $\lambda = 1$.

2. *If* $\lambda \in (1,2]$, *then* $T_\star < +\infty$ *and*

$$T_\star \ge \frac{1}{(\lambda-1)\ M_1(0)\ R(0)^{\lambda-1}}\,.$$

Proof. By (2.17) and (4.2), we have

$$R'(t) = R(t)^{\lambda/2}\ \int_0^{R(t)} u^{1+\lambda/2}\ f(u,t)\ du \le M_1(0)\ R(t)^\lambda$$

for $t \in [0,T_\star)$. Lemma 5.4 then readily follows by direct integration of the previous inequality. ∎

An interesting question is whether it is possible to obtain similar estimates from below for R when $\lambda \in [0,1]$ and from above for $T_\star$ when $\lambda \in (1,2]$, but this seems to be less obvious.

Acknowledgments. Part of this work was performed while the second author enjoyed the hospitality and support of the Institute of Applied Mathematics and Mechanics, Warsaw University.

FIRST BOUNDARY VALUE PROBLEM FOR THE DIFFUSION EQUATION I. ITERATED LOGARITHM TEST FOR THE BOUNDARY REGULARITY AND SOLVABILITY*

UGUR G. ABDULLA†

Abstract. This paper establishes a precise sufficient condition for the regularity of a boundary point of an arbitrary open subset of $\mathbb{R}^{N+1}$ $(N \geq 2)$ and for the solvability of the first boundary value problem for the diffusion (or heat) equation in general domains.

Key words. first boundary value problem, diffusion (or heat) equation, boundary regularity, iterated logarithm test

1. Introduction. Let $\Omega \subset \mathbb{R}^{N+1}$ $(N \geq 2)$ denote any bounded open subset and $\partial\Omega$ its topological boundary. We write a typical point as $z = (x,t) = (x_1, \overline{x}, t), x = (x_1, \overline{x}) \in \mathbb{R}^N, \overline{x} = (x_2, \dots, x_N) \in \mathbb{R}^{N-1}, t \in \mathbb{R}$. For a given point $z_0 = (x^0, t_0)$ and a positive number ϵ define the cylinder

$$Q(z_0, \epsilon) = \{z : |x - x_0| < \epsilon, t_0 - \epsilon < t < t_0\}.$$

We split $\partial\Omega$ as $\partial\Omega = \mathcal{P}\Omega \bigcup \mathcal{D}\Omega$, where $\mathcal{P}\Omega$ is the set of all points $z_0 \in \partial\Omega$ such that for any $\epsilon > 0$, the cylinder $Q(z_0, \epsilon)$ contains points not in Ω. The set $\mathcal{P}\Omega$ is called the parabolic boundary of Ω. The set $\mathcal{D}\Omega$ is naturally called the top boundary of Ω. We split also $\mathcal{P}\Omega$ as $\mathcal{P}\Omega = \mathcal{S}\Omega \bigcup \mathcal{B}\Omega$, where $\mathcal{B}\Omega$ is the set of all points $z_0 \in \mathcal{P}\Omega$ such that for some $\epsilon > 0$, the cylinder $Q(z_0, \epsilon)$ lies outside Ω. The set $\mathcal{B}\Omega$ is naturally called the bottom boundary of Ω, while $\mathcal{S}\Omega$ will be called the lateral boundary of Ω.

For $u \in C^{2,1}_{x,t}(\Omega)$, we define the diffusion (or heat) operator

$$\mathbf{D}u = u_t - \Delta u = u_t - \sum_{i=1}^{N} u_{x_i x_i}, \qquad z \in \Omega.$$

A function $u \in C^{2,1}_{x,t}(\Omega)$ is called parabolic in Ω if $\mathbf{D}u = 0$ for $z \in \Omega$. Let $f : \mathcal{P}\Omega \to \mathbb{R}$ be a bounded function. The first boundary value problem (FBVP) may be formulated as follows:

Find a function u which is parabolic in Ω and satisfies the conditions

$$f_* \leq u_* \leq u^* \leq f^* \qquad \text{for } z \in \mathcal{P}\Omega, \tag{1.1}$$

where f_*, u_* (or f^*, u^*) are lower (or upper) limit functions of f and u, respectively.

In particular, if $f \in C(\mathcal{P}\Omega; \mathbb{R})$, from (1.1) it follows that u takes continuously the given values of f on $\mathcal{P}\Omega$. The strategy for solving the FBVP may be well expressed by the citation from the classical paper [W] on the Dirichlet problem (DP) for the

Laplace equation. As pointed out by Lebesgue and independently by Wiener [W], "the DP divides itself into two parts, the first of which is the determination of a harmonic function corresponding to certain boundary conditions, while the second is the investigation of the behaviour of this function in the neighbourhood of the boundary." The same strategy, obviously replacing harmonic function with parabolic function and boundary with the parabolic boundary, is applicable to the FBVP for the diffusion equation. As in the case of the Laplace equation, a generalized solution to the FBVP for the diffusion equation may be constructed by Perron's super- or subsolutions method (see section 2). However, in general the generalized solution doesn't satisfy (1.1).

We say that a point $z_0 \in \mathcal{P}\Omega$ is regular if for any bounded function $f : \mathcal{P}\Omega \to \mathbb{R}$, the generalized solution of the FBVP constructed by Perron's method satisfies (1.1) at the point z_0. It is well known that the boundary points $z_0 \in \mathcal{B}\Omega$ are always regular.

The principal result of this paper is the characterization of the regularity of the boundary points $z_0 \in \mathcal{S}\Omega$ via local geometry of the lateral boundary near this point.

Consider the following domains:

$$\mathcal{G}_\rho^1 = \{z : x_1^2 < 4\xi \log \rho(\xi), (\overline{x}, t) \in P(\delta)\},$$

$$\mathcal{G}_\rho^2 = \{z : -2(\xi \log \rho(\xi))^{\frac{1}{2}} < x_1 < 2(-\delta \log \rho(-\delta))^{\frac{1}{2}}, (\overline{x}, t) \in P(\delta)\},$$

$$P(\delta) = \{(\overline{x}, t) : -\delta < \xi < 0, -\delta < \alpha t < 0\},$$

where $\delta > 0$ is a sufficiently small positive number, $\xi = \alpha t - \beta|\overline{x}|^2$, and α and β are given positive numbers. Throughout this paper we assume that $\rho = \rho(\xi), -\delta \le \xi < 0$ is a positive and continuously differentiable function satisfying the following condition:

$$\rho(\xi) \downarrow 0, \quad \xi\rho^{-1}(\xi)\rho'(\xi) \to 0 \qquad \text{as } \xi \uparrow 0. \tag{1.2}$$

Applying l'Hôpital's rule to (1.2), it follows that $\xi \log \rho(\xi) \to 0$ as $\xi \uparrow 0$. In Figures 1 and 2 the domains $\mathcal{G}_\rho^1$ and $\mathcal{G}_\rho^2$ are described when $N = 2$. The parabolic boundary $\mathcal{P}\mathcal{G}_\rho^1$ consists of two manifolds

$$\mathcal{L}_\pm = \{z \in \overline{\mathcal{G}_\rho^1} : x_1 = \pm 2(\xi \log \rho(\xi))^{\frac{1}{2}}, t > -\delta\alpha^{-1}\}$$

and the cylindrical hypersurface

$$\{z \in \overline{\mathcal{G}_\rho^1} : \xi = -\delta, t > -\delta\alpha^{-1}\}.$$

The bottom boundary $\mathcal{B}\mathcal{G}_\rho^1$ consists of a line segment $\{z : x_1^2 < -4\delta \log \rho(-\delta), |\overline{x}| = 0, t = -\delta\alpha^{-1}\}$. The parabolic boundary $\mathcal{P}\mathcal{G}_\rho^2$ differs from $\mathcal{P}\mathcal{G}_\rho^1$ by replacing the manifold $\mathcal{L}_+$ with

$$\{z \in \overline{\mathcal{G}_\rho^2} : x_1 = 2(-\delta \log \rho(-\delta))^{\frac{1}{2}}, (\overline{x}, t) \in \overline{P(\delta)}\}.$$

Our main theorem reads as follows.

THEOREM 1.1. *Let* $\alpha + 2(N-1)\beta \le 1$ *and*

$$\lim_{\epsilon \uparrow 0} \int_{-\delta}^{\epsilon} \frac{\rho(\eta)}{\eta} d\eta = -\infty. \tag{1.3}$$

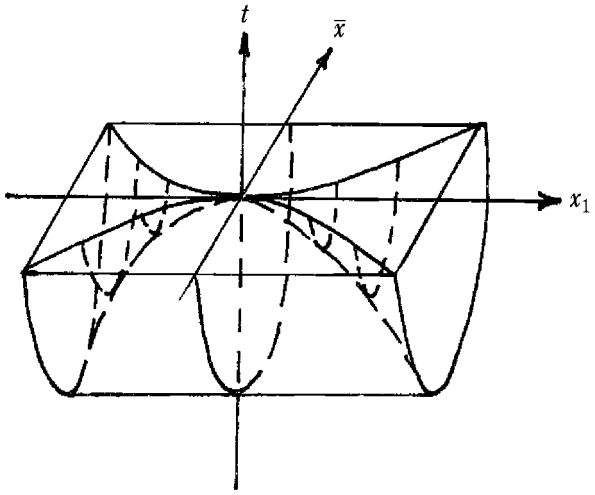

FIG. 1. *The domain* $\mathcal{G}_\rho^1$ *when* $N = 2$.

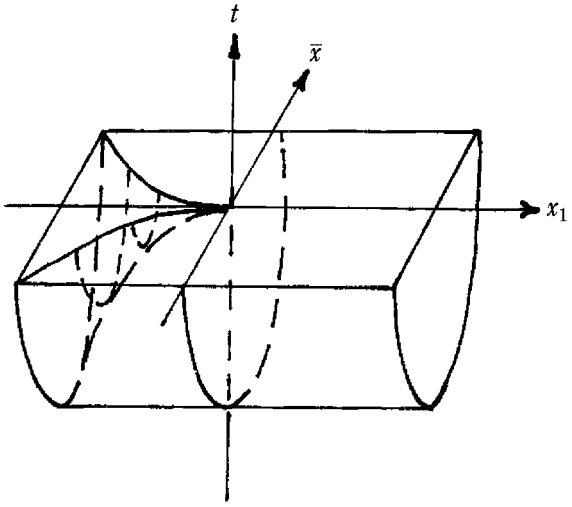

FIG. 2. *The domain* $\mathcal{G}_\rho^2$ *when* $N = 2$.

Then the origin ($\mathcal{O}$) *is a regular point for* $\mathcal{G}_\rho^1$ *(or* $\mathcal{G}_\rho^2$*) and the FBVP is solvable in* $\mathcal{G}_\rho^1$ *(or* $\mathcal{G}_\rho^2$*).*

Some examples of functions ρ that satisfy (1.2), (1.3) are

$$\rho(\xi) = |\log|\xi||^{-1}, \quad \rho(\xi) = \left\{ |\log|\xi|| \prod_{k=2}^{n} \log_k|\xi| \right\}^{-1}, \qquad n = 2, 3, \ldots, \tag{1.4}$$

where we use the following notation:

$$\log_2|\xi| = \log|\log|\xi||, \quad \log_n|\xi| = \log\log_{n-1}|\xi|, \qquad n \geq 3.$$

Theorem 1.1 provides a general sufficient condition for the regularity of the boundary points $z_0 \in \mathcal{S}\Omega$ and for the solvability of the FBVP in Ω.

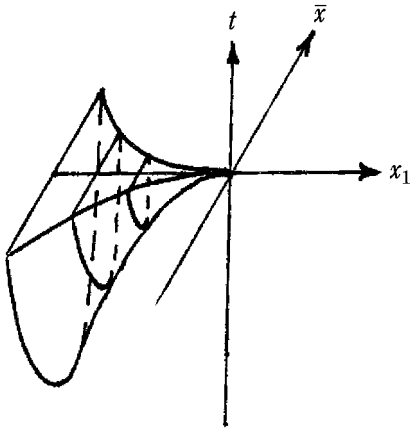

FIG. 3. *The domain $\mathcal{A}_\rho$ when $N = 2$.*

Let $\mathcal{A}_\rho = \mathcal{G}\backslash\overline{\mathcal{G}_\rho^2}$, where

$$\mathcal{G} = \{z : x_1^2 < -4\delta \log \rho(-\delta), (\overline{x}, t) \in P(\delta)\}.$$

In Figure 3 the domain $\mathcal{A}_\rho$ is described when $N = 2$. We call the origin the vertex of $\mathcal{A}_\rho$. Consider the rigid body displacements of $\mathcal{A}_\rho$ composed of translations and (or) rotations in x-space and shift along the t-axis.

DEFINITION 1.2. *We shall say that Ω satisfies the exterior $\mathcal{A}_\rho$-condition at the point $z_0 \in \mathcal{S}\Omega$ if after the above-mentioned displacement the vertex of $\mathcal{A}_\rho$ coincides with z_0 and for all sufficiently small δ, $\mathcal{A}_\rho$ lies in the exterior of Ω.*

Theorem 1.1 implies the following more general result.

THEOREM 1.3. *The boundary point $z_0 \in \mathcal{S}\Omega$ is regular if Ω satisfies the exterior $\mathcal{A}_\rho$-condition at this point. The FBVP is solvable in a region Ω which satisfies the exterior $\mathcal{A}_\rho$-condition at every point $z_0 \in \mathcal{S}\Omega$.*

In the case when the lateral boundary is locally a continuous graph, the exterior $\mathcal{A}_\rho$-condition may be expressed in terms of modulus of lower semicontinuity of the lateral boundary manifold. To make this precise, assume that for $z_0 = (x^0, t_0) \in \mathcal{S}\Omega$ there exists $\epsilon > 0$ and a continuous function ϕ such that, after a suitable rotation of x-axes, we have

$$\overline{\mathcal{S}\Omega} \cap Q(z_0, \epsilon) = \{z \in Q(z_0, \epsilon) : x_1 = \phi(\overline{x}, t)\}, \tag{1.5}$$

$$\text{sign } (x_1 - \phi(\overline{x}, t)) = 1 \qquad \text{for } z \in Q(z_0, \epsilon) \cap \Omega. \tag{1.6}$$

The exterior $\mathcal{A}_\rho$-condition is equivalent to the following one-side inequality for the function ϕ:

$$\phi(\overline{x}^0, t_0) - \phi(\overline{x}, t) \le 2(\xi' \log \rho(\xi'))^{\frac{1}{2}} \qquad \text{for } (\overline{x}, t) \in \overline{P'(\delta)}, \tag{1.7}$$

where $\delta > 0$ is a sufficiently small number, $\xi' = \alpha(t - t_0) - \beta|\overline{x} - \overline{x}^0|^2$; the domain $P'(\delta)$ coincides with $P(\delta)$ by replacing ξ with ξ' and t with $t - t_0$; the numbers $\alpha > 0, \beta > 0$ and the function ρ satisfy the conditions of Theorem 1.1. The equivalence easily follows from the fact that after the displacement according to the exterior $\mathcal{A}_\rho$-condition,

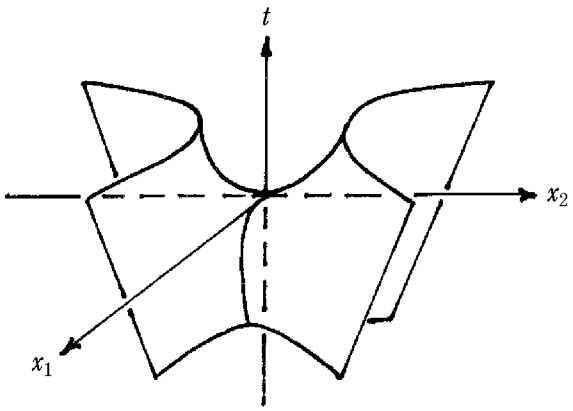

FIG. 4. *Hyperbolic paraboloid* $x_1^2 = M(-t + x_2^2)$.

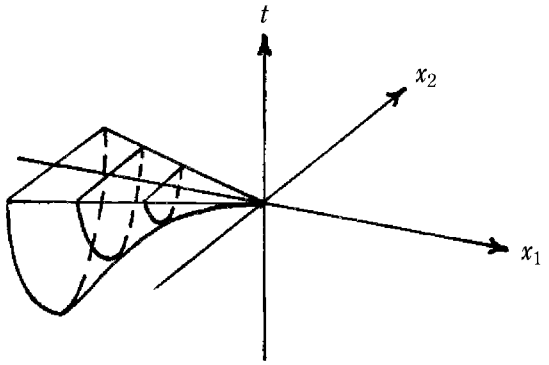

FIG. 5. *The domain* $\mathcal{M}_\delta$.

the boundary manifold which is a common boundary of the translated domains $\mathcal{A}_\rho$ and $\mathcal{G}_\rho^1$ has a representation $x_1 = \phi(\overline{x}, t), (\overline{x}, t) \in P'(\delta)$, where ϕ satisfies (1.7) with "=" instead of "$\leq$". Inequality (1.7) means that at the point $z_0 = (x^0, t_0) \in \mathcal{S}\Omega$, the lateral boundary manifold is allowed to be "slightly worse" than lower Lipschitz in the x-direction and "slightly worse" than lower $\frac{1}{2}$-Hölder in $-t$-direction. "Slightly worse" means that the related Lipschitz (or, respectively, Hölder) coefficient may converge to infinity as $(\overline{x}, t) \to (\overline{x}^0, t_0)$ but not faster than $2(-\beta \log \rho(-\beta|\overline{x} - \overline{x}^0|^2))^{\frac{1}{2}}$ (or, respectively, $2(-\alpha \log \rho(\alpha(t - t_0)))^{\frac{1}{2}}$). In the particular case when both coefficients are constant, we get the parabolic analogue of the well-known exterior cone condition for the Laplace equation. Let us formulate this condition geometrically in the spirit of our exterior $\mathcal{A}_\rho$-condition. For simplicity take $N = 2$ and consider the hyperbolic paraboloid (Figure 4)

$$x_1^2 = M(-t + x_2^2), \qquad M > 0.$$

Let $\delta > 0$ be given and consider the subsurface of the hyperbolic paraboloid which is situated in the half space $\{t \leq 0\}$ between two planes $\{x_1 = 0\}$ and $\{x_1 = -\delta^{\frac{1}{2}}\}$ (Figure 5). Consider the open domain $\mathcal{M}_\delta$ which is bounded by this subsurface and by the planes $\{t = 0\}$ and $\{x_1 = -\delta^{\frac{1}{2}}\}$ (Figure 5). We call the origin the vertex

of $\mathcal{M}_\delta$. Consider the rigid body displacements of $\mathcal{M}_\delta$ composed of translations and (or) rotations in x-space and shift along the t-axis. If after such a displacement the vertex of $\mathcal{M}_\delta$ coincides with the point $z_0 \in \mathcal{S}\Omega$, and for all sufficiently small δ, $\mathcal{M}_\delta$ lies in the exterior of Ω, then z_0 is a regular point. This fact is an easy consequence of Theorem 1.3. A similar condition is obviously true when $N > 2$ just by replacing x_2^2 with $|\overline{x}|^2$. This is exactly the parabolic analogue of the exterior cone condition for the Laplace equation, and it is natural to call it an "exterior hyperbolic paraboloid condition."

It should be mentioned that the boundary regularity result of Theorem 1.1 has a probabilistic meaning in the context of the short-time behavior of the Brownian motion trajectories for the high-dimensional diffusion processes. Without going into details, let us just formulate the probabilistic analogue of this result taking the simplest example $\rho(\xi) = |\log|\xi||^{-1}$. Consider the standard N-dimensional Brownian motion in which the coordinates of the sample path are standard one-dimensional Brownian motions. The intuitive meaning of Theorem 1.1 is that the Brownian path that starts at the origin (assuming that the process goes in the $-t$-direction) with probability 1 will reach the exterior of $\mathcal{G}_\rho^1$ within arbitrarily short time. From the classical iterated logarithm law it easily follows that with probability 1 the same trajectory will remain in the domain $\mathcal{G}_\rho^1$ within some positive time if $\alpha > 1, \beta > 0$. We explain this fact below in section 4 (see five lines after (4.1)). An important open problem is whether the same is true if $0 < \alpha \leq 1$ but $\alpha + 2(N-1)\beta > 1$. The related open problem in the context of the FBVP consists in the derivation of the precise sufficient condition for the irregularity of the boundary points. We address this issue in the next paper.

We prove the main theorems in section 3, after some preliminaries in section 2. Section 4 contains some final remarks.

Historical comments. In 1935, Petrovsky [P] presented complete results on the FBVP for the one-dimensional diffusion equation $u_t = u_{xx}$ in a plane domain whose lateral boundary is given by two continuous curves $x = \phi_1(t)$ and $x = \phi_2(t)$. Petrovsky's paper was motivated by the proof of the so-called Kolmogorov test for the distinction between the upper and the lower functions of the one-dimensional space-time Brownian motion trajectories (see [IM]). If we take $N = 1$, then our Theorem 1.1 coincides with the regularity result from [P, section 2]. Moreover, the analogue of our domain $\mathcal{G}_\rho^1$ is a plane domain between the curve $x_1^2 = 4t \log \rho(t)$ and the line $t = -\delta < 0$. We get a similar domain intersecting $\mathcal{G}_\rho^1$ with the hyperplane $\{\overline{x} = 0\}$. As was proved in [P, section 3], even for the particular example $\rho(t) = |\log|t||^{-1}$ the result is close to being an optimal in the sense that the origin is an irregular point if we replace the boundary curve with $x_1^2 = -4\alpha t \log_2|t|, \alpha > 1$. In the context of the one-dimensional Brownian motion this result repeats Khinchin's iterated logarithm law. As a direct implication of the one-dimensional results, in [P, section 4] the case $N = 2$ was also briefly considered. It was shown that the origin is an irregular point for the bounded domain lying beneath the plane $\{t = 0\}$ and bounded on its sides by the surface of revolution

$$x^2 + y^2 = -4(1+\epsilon)t \log_2|t|,$$

where $\epsilon > 0$ is an arbitrary small number. From another side, from the regularity condition formulated in [P, section 4], it follows that the origin is a regular point for the same domain if we replace the surface of revolution with the following one:

$$x^2 + y^2 = 4t \log \rho(t),$$

where $\rho(t)$ satisfies the conditions of [P, section 4] (or our Theorem 1.1). Both results are true for the case $N \geq 3$ as well. The meaning of these results is that the conditions for the regularity or irregularity of the boundary point on the top of the radially symmetric domain formed with the rotation of the plane curve $x_1^2 = 4t \log \rho(t)$ around the t-axis are the same as in the one-dimensional case. Probabilistic interpretation of this fact may be given in the context of the multidimensional Brownian motion.

Starting from 1954–1955, Wiener's ideas [W] concerning the regularity of the boundary points for the Laplace equation were adapted to the case of the diffusion equation. In [L], Wiener-type necessary and sufficient conditions for the regularity of the boundary points in the FBVP for the diffusion equation were published. The analogue of Wiener's condition, namely, a necessary and sufficient condition which is a quasi-geometric characterization for a boundary point of an arbitrary bounded open subset of $\mathbb{R}^{N+1}$ to be regular for the diffusion equation, was established in [EG]. However, it should be mentioned that Wiener's criterion does not resolve the natural geometric and analytic question which we impose in this paper. Despite its generality, it seems impossible to derive even Petrovsky's one-dimensional results from Wiener's condition.

Another sufficient condition for the regularity of the boundary points in the FBVP for the diffusion equation, the so-called exterior tusk condition which is an analogue of the exterior cone condition for the Laplace equation, was established in [EK]. It should be pointed out that the origin does not satisfy the exterior tusk condition from [EK] as a boundary point of $\mathcal{G}_\rho^1$ (or $\mathcal{G}_\rho^2$). The exterior tusk condition is satisfied for the singularities in the $-t$-direction which are not "more flat" than a branch of parabola near its vertex. Otherwise speaking, the lower Hölder condition with Hölder exponent $\frac{1}{2}$ should be satisfied, provided that (1.5), (1.6) are valid. Similarly, under the assumptions (1.5), (1.6), the exterior tusk condition may be satisfied for the singularities in the x-direction which satisfy the exterior cone condition (or lower Lipschitz condition). For example, the exterior tusk condition is not satisfied for the origin as a boundary point of the cylindrical domain whose projection to the hyperplane $t = 0$ coincides with $\overline{\mathcal{G}_\rho^2} \cap \{t = 0\}$. Hence, the exterior tusk condition is similar to the exterior hyperbolic paraboloid condition.

2. Preliminary results. In this section we present some facts about Perron's solution of the FBVP. Lemma 2.1 is standard and demonstrates the role of barriers for the regularity of the origin for $\mathcal{G}_\rho^1$ or $\mathcal{G}_\rho^2$. Lemma 2.2 proves the equivalence of the regularity (or irregularity) of the origin for $\mathcal{G}_\rho^1$ and $\mathcal{G}_\rho^2$, which allows us to prove Theorem 1.1 only for $\mathcal{G}_\rho^1$.

It should be mentioned that the results of this section are general, and we do not need to assume that the conditions of Theorem 1.1 and the second condition from (1.2) are satisfied. However, we need to assume that $\xi \log \rho(\xi) \to 0$ as $\xi \uparrow 0$.

A bounded open subset $U \in \mathbb{R}^{N+1}$ is called regular if for each continuous function $\phi \in C(\partial U; \mathbb{R})$ there exists one (and only one) function H_ϕ^U, which is parabolic in U, and

$$\lim_{z \to z_0, z \in U} H_\phi^U = \phi(z_0) \qquad \text{for all } z_0 \in \partial U.$$

A function $u \in C(\Omega)$ is called superparabolic in Ω if the following conditions are satisfied:

(a) u is lower semicontinuous; $-\infty < u \leq +\infty$, $u < +\infty$ on a dense subset of Ω;
(b) if $U \subset \overline{U} \subset \Omega$ is a regular open set, $\phi \in C(\partial U; \mathbb{R})$, and $\phi \leq u$ on ∂U, then $H_\phi^U \leq u$ in U.

A function v is called a subparabolic if $-v$ is a superparabolic. For example, any function $u \in C^{2,1}_{x,t}(\Omega)$ satisfying $\mathbf{D}u \geq 0$ (or $\mathbf{D}u \leq 0$) for $z \in \Omega$ is superparabolic (or subparabolic). The classical theory defines Perron's solution of the FBVP to be, for each $z \in \Omega$,

$$H_f^\Omega = \inf\{u(z)\},$$

where the infimum is taken over all superparabolic functions u in Ω such that

$$u_*(z_0) \geq f^*(z_0) \qquad \text{for all } z_0 \in \mathcal{P}\Omega.$$

According to the classical theory (see, for example, [D, B] for the most general framework) H_f^Ω is parabolic in Ω. However, in general it does not satisfy (1.1). A boundary point $z_0 \in \mathcal{P}\Omega$ is called regular if for arbitrary bounded boundary function f, H_f^Ω satisfies (1.1) at this point. It is well known that bottom boundary points $z_0 \in \mathcal{B}\Omega$ are always regular (see, for example, [P]). It is a standard fact in the classical theory that the boundary point $z_0 \in \mathcal{S}\Omega$ is regular if there exists a so-called regularity barrier $\overline{u}$ with the following properties:

(a) $\overline{u}$ is superparabolic in $U = Q(z_0, \epsilon) \cap \Omega$ for some $\epsilon > 0$;

(b) $\overline{u}$ is continuous and nonnegative in $\overline{U}$, vanishing only at z_0.

In particular, concerning the regularity of the origin for $\mathcal{G}_\rho^1$ or $\mathcal{G}_\rho^2$ we have the following.

LEMMA 2.1. *The origin ($\mathcal{O}$) is regular for $\mathcal{G}_\rho^1$ (or $\mathcal{G}_\rho^2$) if and only if there exists a regularity barrier $\overline{u}$ for $\mathcal{O}$ regarded as a boundary point of $\mathcal{G}_\rho^1$ (or $\mathcal{G}_\rho^2$) for sufficiently small δ.*

Proof. The proof of the "if" part is standard. To prove the "only if" part, take $f = -t + |x|^2$ and let $\overline{u} = H_f^{\mathcal{G}_\rho^1}$ be Perron's solution. Since $\rho(\xi)$ is C^1 for $\xi < 0$, from the classical theory it follows that all the boundary points $z_0 \in \mathcal{P}\mathcal{G}_\rho^1, z_0 \neq \mathcal{O}$, are regular points. But $\mathcal{O}$ is regular by our assumption. Therefore, $\overline{u} \in C(\overline{\mathcal{G}_\rho^1})$. From the strong maximum principle it follows that $\overline{u}$ is nonnegative in $\overline{\mathcal{G}_\rho^1}$ and vanishes only at $\mathcal{O}$. Thus $\overline{u}$ is a regularity barrier for $\mathcal{O}$. The proof for the domain $\mathcal{G}_\rho^2$ is similar. The lemma is proved.

The next lemma is the high-dimensional analogue of Theorem III from [P, p. 389].

LEMMA 2.2. *The origin is simultaneously regular or irregular for $\mathcal{G}_\rho^1$ and $\mathcal{G}_\rho^2$.*

Proof. Assume that $\mathcal{O}$ is regular for $\mathcal{G}_\rho^2$. Then by Lemma 2.1 there exists a regularity barrier for $\mathcal{O}$ regarded as a boundary point of $\mathcal{G}_\rho^2$. Obviously, it will also be a regularity barrier for $\mathcal{O}$ regarded as a boundary point of $\mathcal{G}_\rho^1$. From Lemma 2.1 it follows that $\mathcal{O}$ is regular for $\mathcal{G}_\rho^1$.

Conversely, assume now that $\mathcal{O}$ is regular for $\mathcal{G}_\rho^1$. Let $u = H_f^{\mathcal{G}_\rho^2}$, where $f = -t + |x|^2$. Since $\rho(\xi)$ is C^1 for $\xi < 0$, all the boundary points $z_0 \in \mathcal{P}\mathcal{G}_\rho^2, z_0 \neq \mathcal{O}$, are regular points. Accordingly, $u \in C(\overline{\mathcal{G}_\rho^2} \backslash \{\mathcal{O}\})$. Denote

$$L = \limsup_{z \to \mathcal{O}, x_1 = \phi(\overline{x}, t)} u,$$

where $\phi(\overline{x}, t) = 4\xi \log \rho(\xi)$. Obviously, we have $0 \leq L < +\infty$. Let f_1 be an arbitrary function which is defined and continuous in $\mathcal{P}\mathcal{G}_\rho^1 \backslash \{\mathcal{O}\}$, satisfying

$$f_1(x_1, \overline{x}, t) = -f_1(-x_1, \overline{x}, t) \tag{2.1}$$

and

$$\lim_{z \to \mathcal{O}, x_1 = \phi(\overline{x}, t)} f_1 = \frac{L}{2}, \qquad \lim_{z \to \mathcal{O}, x_1 = -\phi(\overline{x}, t)} f_1 = -\frac{L}{2}.$$

Choose a function f_2 in such a way that

$$f_1 + f_2 = u \qquad \text{for } z \in \mathcal{P}\mathcal{G}_\rho^1 \cap \mathcal{G}_\rho^2,$$

$$f_1 + f_2 = f \qquad \text{on the rest of } \mathcal{P}\mathcal{G}_\rho^1.$$

Since all the points $z_0 \in \mathcal{P}\mathcal{G}_\rho^1$ are regular points, Perron's solutions $u_1 = H_{f_1}^{\mathcal{G}_\rho^1}$, $u_2 = H_{f_2}^{\mathcal{G}_\rho^1}$, and $H_{f_1+f_2}^{\mathcal{G}_\rho^1}$ are continuous functions in $\overline{\mathcal{G}_\rho^1}\backslash\{\mathcal{O}\}$. Applying the maximum principle in $\mathcal{G}_\rho^1 \cap \{z : t \le -\epsilon\}$ for arbitrary sufficiently small $\epsilon > 0$ and passing to the limit as $\epsilon \downarrow 0$, we easily derive that

$$u = H_{f_1+f_2}^{\mathcal{G}_\rho^1} = H_{f_1}^{\mathcal{G}_\rho^1} + H_{f_2}^{\mathcal{G}_\rho^1} = u_1 + u_2. \tag{2.2}$$

Applying the same arguments, from (2.1) we deduce that

$$u_1(x_1, \overline{x}, t) = -u_1(-x_1, \overline{x}, t),$$

and hence

$$u_1(0, \overline{x}, t) = 0. \tag{2.3}$$

We have

$$\limsup_{z \to \mathcal{O}, x_1 = \pm\phi(\overline{x}, t)} f_2 \le \frac{L}{2}.$$

Since $\mathcal{O}$ is a regular point for $\mathcal{G}_\rho^1$, it follows that

$$\limsup_{\xi \to 0} u_2(0, \overline{x}, t) \le \frac{L}{2}. \tag{2.4}$$

From (2.2)–(2.4) we have

$$\limsup_{\xi \to 0} u(0, \overline{x}, t) \le \frac{L}{2}.$$

Since $\mathcal{O}$ is a regular point regarded as a boundary point of $\mathcal{G}_3 = \{z \in \mathcal{G}_\rho^2 : x_1 > 0\}$, we have $L \le L/2$, which implies that $L = 0$. Thus u is continuous in $\overline{\mathcal{G}_\rho^2}$ and by the strong maximum principle vanishes only at $\mathcal{O}$. Hence, u is a regularity barrier for $\mathcal{O}$ regarded as a boundary point of $\mathcal{G}_\rho^2$. From Lemma 2.1 it follows that $\mathcal{O}$ is a regular point for $\mathcal{G}_\rho^2$ as well. The lemma is proved.

COROLLARY 2.3. *Let $\mathcal{G}_0$ be a given open set in $\mathbb{R}^{N+1}$ and $\mathcal{O} \in \partial\mathcal{G}_0$, $\mathcal{G}_0^- \ne \emptyset$, where $\mathcal{G}_0^- = \{z \in \mathcal{G}_0 : t < 0\}$. If $\mathcal{G}_0^- \subset \mathcal{G}_\rho^2$, then from the regularity of $\mathcal{O}$ for $\mathcal{G}_\rho^1$ or $\mathcal{G}_\rho^2$ it follows that $\mathcal{O}$ is regular for $\mathcal{G}_0$. Otherwise speaking, from the irregularity of $\mathcal{O}$ for $\mathcal{G}_0$ or $\mathcal{G}_0^-$ it follows that $\mathcal{O}$ is irregular for $\mathcal{G}_\rho^1$ and $\mathcal{G}_\rho^2$.*

Since bottom boundary points are always regular, the assertion of Corollary 2.3 easily follow from Lemmas 2.1 and 2.2 and from the fact that the regularity barrier for $\mathcal{O}$ regarded as a boundary point of $\mathcal{G}_\rho^2$ is at the same time a regularity barrier for $\mathcal{O}$ regarded as a boundary point of $\mathcal{G}_0^-$.

Obviously, the assertion of Corollary 2.3 is true if we take an arbitrary boundary point $z_0 = (x^0, t_0) \in \partial\mathcal{G}_0$, assuming that $\mathcal{G}_0^- = \{z \in \mathcal{G}_0 : t < t_0\} \ne \emptyset$. In this case we need to replace $\mathcal{G}_\rho^1$ and $\mathcal{G}_\rho^2$ with their translations after rigid body displacement composed of a translation in x-space and shift along the t-axis, in such a way that $\mathcal{O}$ coincides with z_0 after this displacement.

3. Proofs of the main results.

Proof of Theorem 1.1. The proof is based on the construction of the regularity barrier for $\mathcal{O}$ regarded as a boundary point of $\mathcal{G}^1_\rho$. We construct the regularity barrier assuming that $\delta > 0$ is sufficiently small. This produces no loss of generality, since boundary regularity is a local property. Without loss of generality we also assume that the positive numbers α and β satisfy

$$\alpha + 2(N-1)\beta = 1. \tag{3.1}$$

Indeed, if $\alpha + 2(N-1)\beta < 1$, then we can take $\tilde\beta > \beta$ such that $\alpha + 2(N-1)\tilde\beta = 1$ and consider the domain $\tilde{\mathcal{G}}^1_\rho$ by replacing β with $\tilde\beta$ in $\mathcal{G}^1_\rho$. It may be easily seen that $\tilde{\mathcal{G}}^1_\rho$ contains $\mathcal{G}^1_\rho$ if we replace δ in $\mathcal{G}^1_\rho$ with $\beta\tilde\beta^{-1}\delta$. Therefore, if we construct a regularity barrier for $\tilde{\mathcal{G}}^1_\rho$ for all $\delta \le \delta_1$, the latter will be a regularity barrier for $\mathcal{G}^1_\rho$ for all $\delta \le \beta\tilde\beta^{-1}\delta_1$.

Without loss of generality we may also assume that $\rho(\xi)$ is twice continuously differentiable for $\xi < 0$ and satisfies

$$\xi^2\rho^{-1}(\xi)\rho''(\xi) \to 0 \qquad \text{as } \xi \uparrow 0. \tag{3.2}$$

Indeed, otherwise we can choose a monotonically decreasing and twice continuously differentiable function $\rho_1(\xi), -\delta \le \xi < 0$, which satisfies the following conditions:

$$\frac{1}{2}\rho(\xi) < \rho_1(\xi) < \rho(\xi), \tag{3.3}$$

$$\min(\rho'(\xi); -\rho(\xi)) < \rho_1'(\xi) < \frac{1}{2}\rho'(\xi). \tag{3.4}$$

From (3.4) and (1.2) it follows that

$$0 < \xi\rho_1^{-1}(\xi)\rho_1'(\xi) < 2\max(\xi\rho^{-1}(\xi)\rho'(\xi); -\xi) \to 0 \qquad \text{as } \xi \uparrow 0. \tag{3.5}$$

Hence, from (3.3)–(3.5) it follows that ρ_1 satisfies (1.2) and (1.3). Applying l'Hôpital's rule from (3.5) and (3.4), we have

$$\frac{\xi\rho_1''(\xi)}{\rho_1'(\xi)} \to -1 \qquad \text{as } \xi \uparrow 0. \tag{3.6}$$

From (3.4)–(3.6) it easily follows that ρ_1 satisfies (3.2). Hence, ρ_1 satisfies all the required conditions, and in view of (3.3) we have $\mathcal{G}^1_\rho \subset \mathcal{G}^1_{\rho_1}$. Accordingly, the regularity barrier for $\mathcal{O}$ regarded as a boundary point of $\mathcal{G}^1_{\rho_1}$ will be a regularity barrier for $\mathcal{O}$ regarded as a boundary point of $\mathcal{G}^1_\rho$.

Thus it is enough to construct a regularity barrier for $\mathcal{O}$ regarded as a boundary point of $\mathcal{G}^1_\rho$, assuming additionally that ρ is C^2 for $\xi < 0$ and satisfies (3.2). By the way, all the examples of ρ from (1.4) satisfy these conditions as well.

We prove that the following function is the required regularity barrier:

$$u(x,t) = g(\xi)\exp\Big(-\frac{x_1^2}{4\xi}\Big) + \phi(\xi),$$

where ϕ is defined via

$$9\log\phi = \int_{\xi_0}^{\xi} \frac{\rho(\eta)}{\eta}d\eta, \qquad \xi_0 < \xi < 0,$$

with ξ_0 being a fixed negative number with sufficiently small $|\xi_0|$, and

$$g(\xi) = -\frac{1}{2}\rho(\xi)\phi(\xi).$$

From (1.2) and (1.3) it follows that

$$\phi(\xi) > 0, \quad 9\phi'(\xi) = \xi^{-1}\rho(\xi)\phi(\xi) < 0; \qquad \phi(\xi) \downarrow 0 \qquad \text{as } \xi \uparrow 0, \tag{3.7}$$

$$g(\xi) < 0, \quad g'(\xi) > 0; \qquad g(\xi) \uparrow 0 \qquad \text{as } \xi \uparrow 0. \tag{3.8}$$

The equation of the level hypersurface $u(x,t) = 0$ is given by

$$x_1^2 = 4\xi[\log\rho(\xi) - \log 2].$$

Moreover, we have

$$u > 0 \text{ in} \qquad \mathcal{G}' = \{z : x_1^2 < 4\xi[\log\rho(\xi) - \log 2], (\overline{x}, t) \in P(2\delta)\}.$$

Since $\mathcal{G}_\rho^1 \subset \mathcal{G}'$, we derive that u is positive and continuous in $\overline{\mathcal{G}_\rho^1}\backslash\{\mathcal{O}\}$. The function u is symmetric with respect to the x_1-variable, and for arbitrary fixed $(\overline{x}, t) \in \overline{P(\delta)}$, $(\overline{x}, t) \neq (0,0)$, u attains its maximum at $x_1 = 0$. Hence, we have

$$0 < u(x_1, \overline{x}, t) \le u(0, \overline{x}, t) = \phi(\xi)\Big(1 - \frac{1}{2}\rho(\xi)\Big) \to 0 \qquad \text{as } \xi \uparrow 0.$$

Thus u has a removable singularity at the point $\mathcal{O}$, and prescribing $u = 0$ at $\mathcal{O}$, we have $u \in C(\overline{\mathcal{G}_\rho^1})$. To complete the proof, we need to show that u is superparabolic in $\mathcal{G}_\rho^1$. Taking into account (3.1), we derive

$$\mathbf{D}u = \exp\Big(-\frac{x_1^2}{4\xi}\Big)\mathbf{S}, \tag{3.9}$$

where

$$\mathbf{S} = \frac{g(\xi)}{\xi}\Big[\frac{1}{2} + 2\beta^2|\overline{x}|^2 x_1^2\xi^{-2} - \frac{1}{4}\beta^2|\overline{x}|^2 x_1^4\xi^{-3}\Big] + g'(\xi)\Big[1 - 2\beta^2|\overline{x}|^2 x_1^2\xi^{-2}\Big]$$

$$+ \phi'(\xi)\exp\Big(\frac{x_1^2}{4\xi}\Big) - 4\beta^2|\overline{x}|^2\Big[g''(\xi) + \phi''(\xi)\exp\Big(\frac{x_1^2}{4\xi}\Big)\Big]. \tag{3.10}$$

Assuming that $|\xi|$ is sufficiently small, from (1.2) and (3.7) it follows that

$$\frac{g(\xi)}{\xi} - g'(\xi) > \frac{1}{2}\phi(\xi)\Big[\rho'(\xi) - \frac{1}{2}\frac{\rho(\xi)}{\xi}\Big] > 0. \tag{3.11}$$

Therefore, from (3.8), (3.10), and (3.11) we derive that

$$\mathbf{S} > \frac{1}{4}\frac{g(\xi)}{\xi} + \phi'(\xi)\exp\Big(\frac{x_1^2}{4\xi}\Big) + \frac{1}{4}\frac{g(\xi)}{\xi} - 4\beta^2|\overline{x}|^2\Big[g''(\xi) + \phi''(\xi)\exp\Big(\frac{x_1^2}{4\xi}\Big)\Big]. \tag{3.12}$$

Using (3.7), we estimate the first two terms on the right-hand side of (3.12) as follows:

$$\frac{1}{4}\frac{g(\xi)}{\xi} + \phi'(\xi)\exp\Big(\frac{x_1^2}{4\xi}\Big) \ge \frac{1}{4}\frac{g(\xi)}{\xi} + \phi'(\xi) = -\frac{\rho(\xi)\phi(\xi)}{72\xi} > 0.$$

Therefore, from (3.12) it follows that

$$\mathbf{S} > \frac{1}{4}\frac{g(\xi)}{\xi} - 4\beta^2|\overline{x}|^2\Big[g''(\xi) + \phi''(\xi)\exp\Big(\frac{x_1^2}{4\xi}\Big)\Big]. \tag{3.13}$$

Using (3.7) and (3.11) we easily derive that

$$9\phi'' = \frac{2}{\xi}\Big[\frac{g(\xi)}{\xi} - g'(\xi)\Big] < 0. \tag{3.14}$$

Since $\mathcal{G}_\rho^1 \subset \mathcal{G}'$, from (3.13), (3.14), and (3.7) we have

$$\mathbf{S} > \frac{1}{4}\frac{g(\xi)}{\xi} - 4\beta^2|\overline{x}|^2\Big[g''(\xi) + \frac{1}{2}\rho(\xi)\phi''(\xi)\Big] = \frac{1}{4}\frac{g(\xi)}{\xi}$$

$$+ 4\beta^2|\overline{x}|^2\Big[\frac{1}{2}\phi(\xi)\rho''(\xi) + \rho'(\xi)\phi'(\xi)\Big] > \frac{1}{4}\frac{g(\xi)}{\xi} + 2\beta^2|\overline{x}|^2\phi(\xi)\rho''(\xi). \tag{3.15}$$

If $|\overline{x}| = 0$, then from (3.15) and (3.8) it follows that $\mathbf{S} > 0$. Otherwise, from (3.15) we derive that

$$\mathbf{S} > 2\beta^2|\overline{x}|^2\phi(\xi)\Big[\frac{1}{16\beta}\frac{\rho(\xi)}{\xi^2} + \rho''(\xi)\Big]. \tag{3.16}$$

Assuming that $|\xi|$ is sufficiently small, from (3.2) and (3.16) we have $\mathbf{S} > 0$. Hence, from (3.9) it follows that u is superparabolic in $\mathcal{G}_\rho^1$ with sufficiently small δ. Accordingly, u is a required regularity barrier. The regularity of $\mathcal{O}$ for $\mathcal{G}_\rho^2$ is a consequence of Lemma 2.2. The theorem is proved.

The first assertion of Theorem 1.3 easily follows from Theorem 1.1 and Lemma 2.1. Indeed, since the space-time transformations due to rigid body displacements in the exterior $\mathcal{A}_\rho$-condition preserve the diffusion equation, the regularity barrier for $\mathcal{G}_\rho^2$ after the transformations according to exterior $\mathcal{A}_\rho$-condition will be a regularity barrier for $z_0 \in \mathcal{S}\Omega$. The second assertion of Theorem 1.3 is a consequence of the classical theory (see section 2).

4. Conclusions. The following natural question arises for each example of ρ from (1.4):

How sharp is the condition $\alpha + 2(N-1)\beta \le 1$ for the regularity of $\mathcal{O}$ for $\mathcal{G}_\rho^1$ or $\mathcal{G}_\rho^2$?

Let

$$\rho(\xi) = |\log|\xi||^{-1}. \tag{4.1}$$

In [P] it was proved that $\mathcal{O}$ is an irregular point for the bounded domain $\mathcal{G}_0$ lying in the strip $\{z : -\delta_1 < t < 0\}$ and bounded on its sides by the hypersurface of revolution

$$|x|^2 = -4\alpha_1 t\log_2|t|, \qquad \alpha_1 > 1.$$

It is easy to see that for sufficiently small δ_1, $\mathcal{G}_0 \subset \mathcal{G}_\rho^1$ if $1 < \alpha_1 < \alpha$. Therefore, from Corollary 2.3 it follows that $\mathcal{O}$ is irregular for $\mathcal{G}_\rho^1$ and $\mathcal{G}_\rho^2$ if $\alpha > 1, \beta > 0$. Obviously, the same result is true if we take any other particular example of ρ from (1.4).

Hence, the following natural question arises:

Is $\mathcal{O}$ regular or irregular for $\mathcal{G}_\rho^1$ and $\mathcal{G}_\rho^2$ if $\rho(\xi) = |\log|\xi||^{-1}$, $0 < \alpha \le 1$, $\beta > 0$, and $\alpha + 2(N-1)\beta > 1$?

The probabilistic analogue of this question was formulated at the end of section 1. This issue is addressed in a subsequent paper.

Another important conclusion says that $\mathcal{O}$ may be regular for

$$u_t = \Delta u \tag{4.2}$$

and at the same time irregular for

$$u_t = a\Delta u, \qquad 0 < a < 1, \tag{4.3}$$

regarded as a boundary point of $\mathcal{G}_\rho^1$ or $\mathcal{G}_\rho^2$. Let us check this fact by considering again the simplest case (4.1). Consider $\mathcal{G}_\rho^1$ and $\mathcal{G}_\rho^2$ with $\alpha = 1 - \frac{\varepsilon}{2}$, $\beta = \frac{\varepsilon}{4(N-1)}$, where ε is an arbitrary number satisfying $0 < \varepsilon \le 1 - a$. From Theorem 1.1 it follows that $\mathcal{O}$ is regular for (4.2) regarded as a boundary point of $\mathcal{G}_\rho^1$ or $\mathcal{G}_\rho^2$. If $u(x,t)$ solves (4.3) in $\mathcal{G}_\rho^1$, then after the transformation $x = x, \tau = at$, the function $\tilde{u}(x,\tau) = u(x,t)$ satisfies

$$\tilde{u}_\tau = \Delta \tilde{u}, \tag{4.4}$$

while the domain $\mathcal{G}_\rho^1$ is transformed to the domain

$$\tilde{\mathcal{G}}_\rho^1 = \{z = (x,\tau) : x_1^2 < 4\xi_1 \log \rho(\xi_1),\ -\delta < \xi_1 < 0,\ -\delta < \alpha a^{-1}\tau < 0\},$$

where $\xi_1 = \alpha a^{-1}\tau - \beta|\overline{x}|^2$. We have

$$\alpha a^{-1} > (1-\varepsilon)a^{-1} \ge 1.$$

Hence, $\mathcal{O}$ is irregular for (4.4) regarded as a boundary point of $\tilde{\mathcal{G}}_\rho^1$. Accordingly, $\mathcal{O}$ is irregular for (4.3) regarded as a boundary point of $\mathcal{G}_\rho^1$ or $\mathcal{G}_\rho^2$.

VORTEX MOTION LAW FOR THE SCHRÖDINGER–GINZBURG–LANDAU EQUATIONS*

DANIEL SPIRN†

Abstract. In the Ginzburg–Landau model for superconductivity a large Ginzburg–Landau parameter κ corresponds to the formation of tight, stable vortices. These vortices are located where an applied magnetic field pierces the superconducting bulk, and each vortex induces a quantized supercurrent about the vortex. The energy of large-κ solutions blows up near each vortex, which brings about difficulties in analysis. Rigorous asymptotic static theory has previously established the existence of a finite number of the vortices, and these vortices are located precisely at the critical points of a renormalized energy. We consider the motion of such vortices in a dynamic model for superconductivity that couples a $U(1)$ gauge-invariant Schrödinger-type Ginzburg–Landau equation to a Maxwell-type equation under the limit of large Ginzburg–Landau parameter κ. It is shown that under an almost-energy-minimizing condition each vortex moves in the direction of the net supercurrent located at the vortex position, and these vortices behave like point vortices in the classical two-dimensional Euler equations.

1. Introduction: Concentration phenomena and the Ginzburg–Landau equations.

Superconductivity has two important regimes, the Meissner state, where a superconductor completely repels a magnetic field, and the mixed-vortex, Shubnikov state, where the bulk is pierced by a magnetic field in small tubular regions called *vortices* or *filaments*. These normal-electron filaments are surrounded by large regions of superconducting Cooper-pairs, and each filament contains a quantized magnetic field inducing a circle of superconducting current around the filament. Both states of superconductivity can be effectively modeled with phase transition equations, called Ginzburg–Landau (GL) equations; see [15, 35].

Static GL equations were first proposed by V. L. Ginzburg and L. D. Landau [15] for a complex ordering parameter u and a magnetic field potential A. These equations allow for macroscopic deviations of the density $|u|^2$ of superconducting Cooper-pairs in the bulk, and the equations are derived from a free energy. Two length scales naturally arise out of the GL equations. The first is the *penetration depth* λ, which describes how far a magnetic field can penetrate the skin of the superconductor, and the second is the *coherence length* ξ, which measures the characteristic variation of the phase in the bulk. The important length scale is the *GL parameter* $\kappa = \lambda/\xi$. Although λ and ξ are temperature dependent, κ is mostly temperature independent and accurately describes the bifurcation between the Meissner state and the mixed-vortex state. After a suitable nondimensionalization the GL energy functional becomes

$$G(u,A) = \frac{1}{2}\int_\Omega |\nabla u - iAu|^2 + |\operatorname{curl} A - H_0|^2 + \frac{\kappa^2}{2}\left(1-|u|^2\right)^2 dx \tag{1.1}$$

and the corresponding GL equations are

$$0 = (\nabla - iA)^2 u + \kappa^2 u \left(1 - |u|^2\right),$$
$$0 = -\operatorname{curl} B + (iu, (\nabla - iA) u),$$

where $B = \operatorname{curl} A$ is the induced magnetic field. Here $(a, b) = \frac{1}{2}\left(a\bar{b} + \bar{a}b\right)$ denotes the complex inner product. When $\kappa < 1/\sqrt{2}$ then the superconductor is in the Meissner state, and when $\kappa > 1/\sqrt{2}$ the superconductor is in the mixed-vortex state. To capture coarse behavior of the GL equations with moderately large κ, as found in high T_C superconductors, it is important to understand the $\kappa \to \infty$ limit, and large κ solutions have tight, particle-like vortices as shown numerically in [23, 25].

1.1. Dynamic GL equations. We now introduce two separate dynamic models of superconductivity, each with a natural energy of the form (1.1). We will be interested in the first model.

Our model for a dynamic theory of superconductivity uses Schrödinger-type dynamics for the order parameter coupled to a Maxwell-type equation for the magnetic field potential. This Schrödinger–Ginzburg–Landau (SGL) model was first proposed in [29] based on arguments of Feynman [14]. The SGL equations retain gauge-invariance and can be viewed as a model for charged superfluids and other Bose–Einstein condensates which are coupled to Maxwell-type equations, such as in neutron stars. In addition to u and A there is an electric field potential Φ such that $E = \partial_t A + \nabla\Phi$ for the induced electric field E. The SGL system consists of [29]

$$\begin{aligned} \frac{1}{i}\left(\hbar\partial_t u + ie\Phi u\right) &= D\left(\hbar\nabla - ieA\right)^2 u + u\left(\beta|u|^2 + \alpha\right), \\ \beta^2\partial_t\left(\partial_t A + \nabla\Phi\right) + \delta\left(\partial_t A + \nabla\Phi\right) &= -\nu \operatorname{curl} B + 2\tau\left(iu, \left(\frac{\hbar}{2e}\nabla - iA\right)\right), \end{aligned} \tag{1.2}$$

where τ and D are microscopic parameters and ν^{-1} measures the conductivity of normal electrons. δ measures the normal conductivity of the medium, and superconducting alloys have δ of the order 10^{-3}, and β^2 measures relativistic effects and is of the order $10^{-9} \sim 10^{-11}$; see [29]. Since it would take an extremely long time to feel the effects of the β^2 term (far beyond the time frame of the asymptotics that follow), we set $\beta^2 = 0$. Suitably nondimensionalizing the SGL equations, we have

$$\begin{aligned} \frac{1}{i}\left(\partial_t u + i\Phi u\right) &= \left(\nabla - iA\right)^2 u + \kappa^2 u\left(1 - |u|^2\right), \\ \delta\left(\partial_t A + \nabla\Phi\right) &= -\operatorname{curl} B + (iu, (\nabla - iA) u) \end{aligned} \tag{1.3}$$

for δ small. The unusual coupling of a nonlinear Schrödinger equation to a parabolic equation for the magnetic field potential results in rather nontrivial behavior. When the electromagnetic field is not present, the equations become a nonlinear Schrödinger equation

$$\frac{1}{i}\partial_t u = \Delta u + \kappa^2 u\left(1 - |u|^2\right),$$

sometimes referred to as the Gross–Pitaevskii equation, especially in the context of the theory of superfluids.

A more widely studied dynamic model of superconductivity, called the time-dependent Ginzburg–Landau (TDGL) equations, can be formally derived from microscopic quantum theory [4, 5] and is sometimes referred to as the Gorkov–Eliashburg equations. The TDGL equations [29, 35] are

$$\begin{aligned}\hbar\partial_t u + ie\Phi u &= D\left(\hbar\nabla - ieA\right)^2 u + u\left(\beta|u|^2 + \alpha\right),\\ \partial_t A + \nabla\Phi &= -\nu \operatorname{curl} B + 2\tau\left(iu, \left(\frac{\hbar}{2e}\nabla - iA\right)u\right),\end{aligned}$$

where τ and D are microscopic parameters and ν^{-1} measures the conductivity of normal electrons. The TDGL equations are essentially a gradient flow of the GL functional (1.1) that preserves a *gauge* symmetry. After a suitable nondimensionalization we have the equations

$$\begin{aligned}\partial_t u + i\Phi u &= \left(\nabla - iA\right)^2 u + \kappa^2 u\left(1 - |u|^2\right),\\ \partial_t A + \nabla\Phi &= -\operatorname{curl} B + \left(iu, \left(\nabla - iA\right)u\right).\end{aligned}$$

We will use results on the asymptotic analysis of the TDGL equations [33] in section 3.

1.2. Vortices and quantization. We are interested in two-dimensional solutions to the SGL equations. A fundamental feature of GL model equations is the formation of vortices, which are locations where superconducting Cooper-pairs are locally absent, i.e., $|u|^2 = 0$. These normal-electron regions allow for quantized magnetic fields to penetrate through, and the quantized magnetic field induces a quantized supercurrent about it. Quantization phenomena have been observed experimentally; see [10, 11, 36]. Mathematically, a quantized supercurrent can be induced by defining the order parameter u over $\mathbb{C}$ and introducing a topological obstruction such that $|u| = 1$ and

$$\oint_{\partial B_r(x_0)} (iu, \partial_\tau u)\, d\omega = \deg\left(u, \partial B_r(x_0)\right) = d$$

with $d \in \mathbb{Z}$, $d \neq 0$. By a simple application of the Brouwer fixed point theorem there exists an $x \in B_r(x_0)$ such that $|u|^2(x) = 0$. Scaling arguments show that the radius of a vortex depends inversely on κ, and as κ becomes very large, a vortex can be described by the limiting point location and its winding number with an energy of order $\log\kappa$. We will be interested in understanding how these vortices move in the SGL equations, and we will look for simple equations of motion that describe the limiting point vortices as $\kappa \to \infty$. Such point vortex equations have been extensively studied in the context of the Euler equations; see [7].

1.3. Renormalized energy. As we will see, our vortex motion law relies on a quantity that depends on the vortex configuration and not the energy associated with an actual vortex. This free energy quantity $W(x_1, \ldots, x_d)$ is called the *renormalized energy* and is the total free energy minus the vortex self-induction energy. For the situation where there is no magnetic field potential A (see [1, 21]), we define the class

$$\mathcal{H}^1(x_j, \rho) = \begin{cases} u \in H^1\left(\Omega \setminus \bigcup_{j=1}^d B_\rho(x_j) : \mathbb{S}^1\right), \\ u = \frac{x - x_j}{|x - x_j|} \text{ on } \partial B_\rho(x_j) \text{ and } \partial_\nu u = 0 \text{ on } \partial\Omega, \end{cases}$$

then

$$W(\{x_j\}) = \lim_{\rho\to 0}\left\{\min_{u\in\mathcal{H}^1(x_j,\rho)}\frac{1}{2}\int_{\Omega\setminus\bigcup_{j=1}^d B_\rho(x_j)}|\nabla u|^2\,dx - \pi d\log\frac{1}{\rho}\right\} + \gamma d,$$

where γ is a universal constant described in [1]. This quantity depends solely on the location of the x_j's and Ω. A quick analysis of the renormalized energy shows that $W(x_j)\to\infty$ as $|x_k - x_l|\to 0$. A detailed analysis of the renormalized energy is performed in the appendix for the full GL energy functional (1.1) with Neumann boundary conditions.

1.4. Asymptotics and vortex motion laws. In the mathematical literature we replace κ^2 with $\frac{1}{\varepsilon^2}$ and study the $\varepsilon\to 0$ limit. It should be expected that the SGL equations would exhibit simple dynamic behavior in the $\varepsilon\to 0$ limit. Formal asymptotics [13, 28, 29] have reduced the equations to simple ODEs of the form

$$\frac{d}{dt}a_j = -\mathcal{J}\nabla_{a_j}\widetilde{W}(a_1,\dots,a_d), \tag{1.4}$$

where a_j is the location of the jth vortex and $\widetilde{W}(a_1,\dots,a_d)$ is a renormalized energy that depends on the precise asymptotic limit. Here

$$\mathcal{J} = \begin{pmatrix} 0 & -1\\ 1 & 0\end{pmatrix}.$$

So far, most efforts to make the $\varepsilon\to 0$ asymptotic limit of the SGL equations rigorous have revolved around the Gross–Pitaevskii equation of the form

$$\frac{1}{i}\partial_t u_\varepsilon = \Delta u_\varepsilon + \frac{1}{\varepsilon^2}u_\varepsilon\left(1-|u_\varepsilon|^2\right). \tag{1.5}$$

Equation (1.5) has been studied rigorously in the $\varepsilon\to 0$ limit in a series of papers [8, 24], where the vortex motion law (1.4) was rigorously derived for the limit of the simplified model equation (1.5) with both Neumann and Dirichlet boundary conditions.

Our aim is to study the $\varepsilon\to 0$ limit of the SGL equations with physically realistic boundary conditions and rigorously derive a vortex motion law. A crucial piece of information that strongly affects whether or not vortices follow this vortex motion law pertains to the precise amount of initial energy of the system. The SGL equations require a rigid bound, as excess energy will destroy the sensitive comparison arguments. This precise bound differs greatly from the TDGL equations, which require a much less stringent control on the initial data; see [33].

THEOREM 1.1. *Let $\{u_\varepsilon, A_\varepsilon\}$ solve the SGL equations*

$$\begin{aligned}\frac{1}{i}\left(\partial_t + i\Phi_\varepsilon\right)u_\varepsilon &= \left(\nabla - iA_\varepsilon\right)^2 u_\varepsilon + \frac{1}{\varepsilon^2}u_\varepsilon\left(1-|u_\varepsilon|^2\right),\\ \delta_\varepsilon\left(\partial_t A_\varepsilon + \nabla\Phi_\varepsilon\right) &= -\operatorname{curl} B_\varepsilon + \left(iu_\varepsilon, \left(\nabla - iA_\varepsilon\right)u_\varepsilon\right)\end{aligned}$$

under the Coulomb gauge in Ω such that $\partial_\nu u_\varepsilon = 0$, $\nu\cdot A_\varepsilon = 0$, and $B_\varepsilon = H_0$ on $\partial\Omega$. Let $\delta_\varepsilon\to 0$ and

$$\frac{\varepsilon^2|\log\varepsilon|}{\delta_\varepsilon}\to 0$$

as $\varepsilon \to 0$. *If the initial data* $\{u_\varepsilon(0), A_\varepsilon(0)\}$ *is chosen so that* d *vortices concentrate at* $\{a_k(0)\}$ *as* $\varepsilon \to 0$ *and satisfy the almost-energy-minimizing condition*

$$G_\varepsilon(u_\varepsilon, A_\varepsilon)(0) \le \pi d |\log \varepsilon| + W(\{a_k(0)\}) + o_\varepsilon(1),$$

then there will be d *vortices at* $\{a_k(t)\}$ *such that*

$$\frac{d}{dt} a_j = -\mathcal{J} \nabla_{a_j} W(\{a_k(t)\}),$$

where

$$\mathcal{J} = \begin{pmatrix} 0 & -1 \\ 1 & 0 \end{pmatrix},$$

and the renormalized energy $W(\{a_k\})$ *is defined by* (*A*.1).

1.5. Outline of paper. The following three sections of this paper can be loosely organized as variational theory, dynamic theory, and the proof of the vortex motion law.

In section 2 we review and generalize a few results on the GL energy functional. The SGL equations satisfy a set of conservation laws, shown in section 3, for the mass $|u_\varepsilon|^2$, the supercurrent or momentum j_ε, and the energy density g_ε. Since energy is slowly dissipative (and is conserved in the $\varepsilon \to 0$ limit), we are naturally led to use variational techniques for the GL energy functional (2.1). These techniques have been applied with great success to various dynamic GL equations; see [8, 19, 20, 24, 33]. We define structures, called essential zeros, where energy will concentrate. Outside of these essential zeros there is a uniform energy bound, and the scaled energy density will converge in measure to a sum of delta functions.

In section 3 we turn to the SGL equations and begin to study the dynamics. We start by showing that essential zeros move continuously in the $O(1)$ time scale. Outside of the essential zeros our uniform bound, along with the asymptotic scaling, yields the limiting expression for both the order parameter and the magnetic field potential. Next we establish a Γ-convergence result similar to results derived for the Gross–Pitaevskii equation; see [8, 24]. This convergence result controls the error of strong convergence by the amount of excess initial energy. At this point we have identified the asymptotic limit, modulo vortex position.

In section 4 we complete the vortex motion law proof by examining the conservation of momentum equation (3.11) in detail. We show that in the $\varepsilon \to 0$ limit

$$\frac{d}{dt} a_j(t) = -\mathcal{J} \nabla_{a_j} W(\{a_k(t)\}) + \nu,$$

where the defect measure ν results from the failure of strong convergence. We compare this limiting ODE to a solution of our desired ODE

$$\frac{d}{dt} b_j(t) = -\mathcal{J} \nabla_{b_j} W(\{b_k(t)\})$$

with $b_j(0) = a_j(0)$. If $\eta = \sum_{j=1}^d |a_j - b_j| \equiv 0$, then our task would be finished. To do so, we need to control the size of the defect measure, and this is accomplished with the Γ-convergence result, a careful restriction δ_ε of (1.3), and a Gronwall inequality.

In the appendix we derive the representations of the renormalized energy and its gradient. These proofs closely follow the methods of [2] for the renormalized

energy and [1] for the gradient of the renormalized energy. Finally, we compute the renormalized energy for a disk domain with d vortices.

Remark 1.2. A vortex motion law can also be rigorously derived for the Maxwell–Higgs equations, which are comprised of a gauge-invariant wave equation coupled to Maxwell's equations. It has the form

$$\begin{aligned}(\partial_t + i\Phi_\varepsilon)^2 u_\varepsilon &= (\nabla - iA_\varepsilon)^2 u_\varepsilon + \frac{1}{\varepsilon^2} u_\varepsilon \left(1 - |u_\varepsilon|^2\right),\\ \partial_t \left(\partial_t A_\varepsilon + \nabla \Phi_\varepsilon\right) &= -\operatorname{curl} B_\varepsilon + \left(iu_\varepsilon, (\nabla - iA_\varepsilon) u_\varepsilon\right).\end{aligned}$$

When time is rescaled $t \mapsto \sqrt{|\log \varepsilon|}t$, a motion law of the form

$$\frac{d^2}{dt^2} a_j = -\nabla_{a_j} W(\{a_k(t)\})$$

can be derived, and this result is communicated in [16].

2. Energy bounds and local regularity. We are interested in two-dimensional asymptotics; therefore $u : \mathbb{R}^2 \to \mathbb{C}$, $\Phi : \mathbb{R}^2 \to \mathbb{R}$, and $A : \mathbb{R}^2 \to \mathbb{R}^2$. We use interchangeably for $a \in \mathbb{R}$, $\operatorname{curl} a = (\partial_2 a, -\partial_1 a)$ and for $A \in \mathbb{R}^2$, $\operatorname{curl} A = \partial_1 A_2 - \partial_2 A_1$. Furthermore, we will take our domain $\Omega \subset \mathbb{R}^2$ to be a compact, simply connected set with smooth boundary. We define the covariant derivatives

$$\begin{aligned}\nabla_A &= \nabla - iA,\\ \partial_\Phi &= \partial_t + i\Phi\end{aligned}$$

for connections $\{A, \Phi\}$. These definitions will simplify notation and calculation. We will try to show as much as possible without fixing the gauge in an effort to increase the generality of our discussion.

2.1. $U(1)$ gauge. A solution $\{u, A, \Phi\}$ to a GL model equation is $U(1)$ gauge invariant if

$$\begin{aligned}u_\chi &= ue^{i\chi},\\ A_\chi &= A + \nabla\chi,\\ \Phi_\chi &= \Phi - \partial_t \chi\end{aligned}$$

is a solution to the same GL model equation. Although there is freedom to choose the gauge, physically relevant quantities are $U(1)$ gauge invariant. They are defined as follows.

DEFINITION 2.1. *We define the* mass $|u|^2$*, the* electric field $E = \partial_t A + \nabla\Phi$*, the* magnetic field $B = \operatorname{curl} A$*, the* supercurrent *or* momentum $j = j(u, A) = (iu, \nabla_A u)$*, the* charge $q = (iu, \partial_t u + iu\Phi)$*, and the* energy density

$$g_\varepsilon(u, A) = \frac{1}{2}\left[|\nabla_A u|^2 + |\operatorname{curl} A - H_0|^2 + \frac{1}{2\varepsilon^2}\left(1 - |u|^2\right)\right].$$

H_0 is a positive, finite constant.

We are given freedom to fix the gauge χ, and the various dynamic GL model equations are ill-posed if the gauge is not fixed; see [12]. In the dynamic setting of section 3 we will fix the *Coulomb gauge*, which makes $\operatorname{div} A = 0$ in Ω and $\nu \cdot A = 0$ on $\partial\Omega$.

PROPOSITION 2.2. *There exists a gauge choice such that* $\operatorname{div} A_\varepsilon = 0$ *for all* ε *with* $\nu \cdot A_\varepsilon = 0$ *on* $\partial\Omega$. *Furthermore,* $\partial_\nu u_\varepsilon = \partial_\nu \Phi_\varepsilon = 0$ *on* $\partial\Omega$.

Proof. Let χ be the $U(1)$ gauge, and let χ solve

$$\begin{aligned} \Delta\chi &= -\operatorname{div} A_\varepsilon \text{ in } \Omega, \\ \partial_\nu \chi &= -\nu \cdot A_\varepsilon \text{ on } \partial\Omega. \end{aligned}$$

Such a χ exists; see [2]. ∎

Unlike other gauges such as the temporal gauge ($\Phi \equiv 0$) or the Lorentz gauge (both $\partial_t \Phi + \operatorname{div} A = 0$ and $\Phi + \operatorname{div} A = 0$), the Coulomb gauge requires us to study and control the electric field potential Φ. However, the Coulomb gauge simplifies both the equation for the magnetic field potential and the representations of $W(\{a_k\})$ and $\nabla_{a_j} W(\{a_k\})$, both of which can be explicitly calculated for disk domains; see subsection A.3. See [12] for a more detailed discussion of the effect of gauge fixing on GL equations.

2.2. GL energy functional. In this subsection we examine the GL energy functional and establish various upper and lower bounds. Since we will be using energy comparison techniques, it is crucial to have estimates on energy minimizers. Energy minimizers $\{u_\varepsilon, A_\varepsilon\}$ of the GL energy functional

$$G_\varepsilon(u, A) = \frac{1}{2} \int_\Omega |\nabla_A u|^2 + |\operatorname{curl} A - H_0|^2 + \frac{1}{2\varepsilon^2} \left(1 - |u|^2\right)^2 dx \tag{2.1}$$

satisfy the static GL equations

$$\begin{aligned} 0 &= \nabla_{A_\varepsilon}^2 u_\varepsilon + \frac{1}{\varepsilon^2} u_\varepsilon \left(1 - |u_\varepsilon|^2\right)^2, \\ 0 &= -\operatorname{curl} B_\varepsilon + j_\varepsilon, \end{aligned}$$

which are the Euler–Lagrange equations of the energy functional. A rigorous treatment of the minimizing sequence with no electromagnetic field subject to Dirichlet boundary conditions was studied in [1], where the singular limit was completely characterized. The minimizing sequence with an applied magnetic field subject to Dirichlet boundary conditions was studied in [2], subject to Neumann boundary conditions with finite H_0 in [23] and with an asymptotically large H_ε in a series of papers [30, 31, 32]. We recall two important results on the full GL energy functional (2.1).

THEOREM 2.3 (Bethuel and Riviere [2]). *Let* $\{u_\varepsilon, A_\varepsilon\}$ *be a sequence of minimizers of the GL energy functional* (2.1) *on* $B_\rho(x_0)$ *such that* $|u_\varepsilon| = 1$ *on* $\partial B_\rho(x_0)$ *and*

$$\deg\left(u_\varepsilon, \partial B_\rho(x_0)\right) = \pm 1;$$

then

$$\pi |\log \varepsilon| - C(g, \rho) \le \int_{B_\rho(x_0)} g_\varepsilon(u_\varepsilon, A_\varepsilon) dx \le \pi |\log \varepsilon| + C(g, \rho).$$

Aside from this energy bound, [2] also characterized the limiting order parameter $u_\star$ and limiting magnetic field potential $A_\star$. $u_\star$ satisfies a harmonic map equation with a finite number of unit-valued positive vortices at $\{a_j\}_{j=1}^d$ equal to the winding number on the boundary, i.e., $d = \deg(u_\varepsilon, \partial\Omega)$. $A_\star$ satisfies a forced London equation $0 = \Delta B_\star - B_\star + 2\pi \sum_{j=1}^d \delta_{a_j}$, and the vortex positions minimize a renormalized energy;

see the appendix. A generalization of this result for any topologically constrained functions was established in [17].

THEOREM 2.4 (Jerrard). *Suppose $u_\varepsilon \in H^1_g(B_\rho, \mathbb{C})$ and $A_\varepsilon \in H^1(B_\rho, \mathbb{R}^2)$ such that $u_\varepsilon = g$ on ∂B_ρ. If $|g| = 1$, $\deg(g, \partial B_\rho) \neq 0$, and*

$$\int_{B_\rho} g_\varepsilon(u_\varepsilon, A_\varepsilon)dx \leq \pi |\log \varepsilon| + C,$$

then

$$\int_{B_\rho} g_\varepsilon(u_\varepsilon, A_\varepsilon)dx \geq \pi |\log \varepsilon| - C$$

and

$$\int_{B_\rho} B_\varepsilon^2 dx \leq C.$$

In order to study concentrations in dynamic GL equations, it is necessary to identify where a vortex will concentrate in the $\varepsilon \to 0$ limit, and to that end we define a structure that will ensure the formation of vortices.

DEFINITION 2.5. *A point $a_j \in \Omega$ is an* essential zero *for $\{u_\varepsilon, A_\varepsilon\}$ if there exists ε_0, α_j such that $\alpha_j \in [\alpha_0, 2\alpha_0]$ for $2\alpha_0 < 1$ and for all $\varepsilon < \varepsilon_0$*

$$\deg\left(\frac{u_\varepsilon}{|u_\varepsilon|}, \partial B_{\varepsilon^{\alpha_j}}(a_j)\right) = \pm 1, \tag{Es 1}$$

$$\varepsilon^{\alpha_j} \int_{\partial B_{\varepsilon^{\alpha_j}}(a_j)} g_\varepsilon(u_\varepsilon, A_\varepsilon)d\omega \leq \frac{\pi\left(d + \frac{1}{2}\right)}{\alpha_0}. \tag{Es 2}$$

Essential zeros were introduced in [34] and used in the context of TDGL equations in [20, 33] and the Gross–Pitaevskii equations in [24]. An essential zero is a natural tool, as it ensures the formation of a unit-valence vortex in the $\varepsilon \to 0$ limit and establishes the position of the vortex up to an ε^α error, in agreement with energy-minimizing sequences; see [9]. Furthermore, the structure theorem of [20] allows us to identify essential zeros with only energy bounds and control of $|\nabla u_\varepsilon|$. Note (Es 2) implies that on $\partial B_{\varepsilon^{\alpha_j}}(a_j)$ the degree is well-defined and $2 \geq |u_\varepsilon| \geq \frac{1}{2}$ for all ε small enough.

We now establish a global energy lower bound away from the essential zeros. Our aim is to identify the location of energy concentration with the location of the essential zeros. Set $\Omega_\varepsilon = \Omega \setminus \bigcup_{j=1}^d B_{\varepsilon^{\alpha_j}}(a_j)$.

LEMMA 2.6. *Let $\{u_\varepsilon, A_\varepsilon\}$, where $u_\varepsilon = \rho_\varepsilon e^{i\Theta_a + i\psi_\varepsilon}$, have essential zeros at $a_j \in \Omega$ with*

$$\min\left(\operatorname{dist}(a_j, a_k), \operatorname{dist}(a_j, \partial\Omega)\right) \geq \sigma > 0.$$

Let $G_\varepsilon(u_\varepsilon, A_\varepsilon) \leq \pi d |\log \varepsilon| + C_1$; then

$$\int_{\Omega_\varepsilon} g_\varepsilon(u_\varepsilon, A_\varepsilon)dx \geq \pi |\log \varepsilon| \sum_{j=1}^d \alpha_j - C_{12}, \tag{2.2}$$

$$\int_{\Omega_\varepsilon} |\nabla \rho_\varepsilon|^2 + \rho_\varepsilon^2 |\nabla \psi_\varepsilon - A_\varepsilon|^2 + |B_\varepsilon - H_0|^2 + \frac{1}{2\varepsilon^2}\left(1 - |u_\varepsilon|^2\right)^2 dx \leq C_{13}, \tag{2.3}$$

where C_{12} and C_{13} are functions of σ, Ω, and d.

Proof. Lemma 2.6 has been established in various forms, including [23, 16], and it is proved here. We prove the lower bound (2.2) by finding a lower bound for a minimizer, and to prove the lower bound for the minimizer, we first determine an upper bound for an energy minimizer $\{u, A\}$ on Ω_ε subject to the constraint that $\{u, A\} = \{u_\varepsilon, A_\varepsilon\}$ on each $\partial B_{\varepsilon^{\alpha_j}}(a_j)$.

1. Define the domains $\Omega_{2\varepsilon} = \Omega \backslash \bigcup_{j=1}^d B_{2\varepsilon^{\alpha_j}}(a_j)$ and $\Omega_{3\varepsilon} = \Omega \backslash \bigcup_{j=1}^d B_{3\varepsilon^{\alpha_j}}(a_j)$ and the comparison functions $\{u_{com}, A_{com}\}$, where

$$u_{com} = \begin{cases} u_{com}^1 & \text{in } \Omega_\varepsilon \backslash \Omega_{2\varepsilon}, \\ u_{com}^2 & \text{in } \Omega_{2\varepsilon} \backslash \Omega_{3\varepsilon}, \\ u_{com}^3 & \text{in } \Omega_{3\varepsilon}, \end{cases}$$

$$A_{com} = \begin{cases} A_{com}^1 & \text{in } \Omega_\varepsilon \backslash \Omega_{2\varepsilon}, \\ A_{com}^2 & \text{in } \Omega_{2\varepsilon} \backslash \Omega_{3\varepsilon}, \\ A_{com}^3 & \text{in } \Omega_{3\varepsilon}. \end{cases}$$

First set

$$u_{com}^3 = \prod_{j=1}^d \frac{x - a_j}{|x - a_j|} e^{i\overline{\psi}_\varepsilon^j} = e^{i\Theta_a} \prod_{j=1}^d e^{i\overline{\psi}_\varepsilon^j},$$
$$A_{com}^3 = \widetilde{A} = -\operatorname{curl} \widetilde{\xi}$$

on $\Omega_{3\varepsilon}$. Here $\overline{\psi}_\varepsilon^j$ is a constant to be set later, and $\widetilde{\xi}$ solves

$$-\Delta^2 \widetilde{\xi} + \Delta \widetilde{\xi} = 0$$

on Ω and $\widetilde{\xi} = 0$ and $\Delta \widetilde{\xi} = H_0$ on $\partial\Omega$. Direct calculation yields

$$\int_{\Omega_{3\varepsilon}} g_\varepsilon(u_{com}^3, A_{com}^3) dx \le \pi |\log \varepsilon| \sum_{j=1}^d \alpha_j + C_2(\Omega, \sigma, d). \tag{2.4}$$

2. We now want to show that $\int_{\Omega_{3\varepsilon} \backslash \Omega_\varepsilon} g_\varepsilon(u_{com}, A_{com}) dx \le C$. Without loss of generality we can compute the energy about one annulus centered at the origin. Start by defining $\{u_{com}^1, A_{com}^1\}$ as

$$A_{com}^1(r, \theta) = A_\varepsilon(\varepsilon^{\alpha_j}, \theta),$$
$$u_{com}^1(r, \theta) = \rho_{int} e^{i\Theta_a + i\psi_\varepsilon(\varepsilon^{\alpha_j}, \theta)},$$

where

$$\rho_{int}^2(r, \theta) = \left(\frac{2\varepsilon^{\alpha_j} - r}{\varepsilon^{\alpha_j}} \right) \rho_\varepsilon^2(\varepsilon^{\alpha_j}, \theta) + \left(\frac{r - \varepsilon^{\alpha_j}}{\varepsilon^{\alpha_j}} \right).$$

It follows that

$$\frac{1}{\varepsilon^2} \left(1 - \rho_{int}^2\right)^2 = \frac{1}{\varepsilon^2} \left(1 - \rho_\varepsilon^2\right)^2 \left(\frac{2\varepsilon^{\alpha_j} - r}{\varepsilon^{\alpha_j}} \right)^2 \le \frac{1}{\varepsilon^2} \left(1 - \rho_\varepsilon^2\right)^2 \tag{2.5}$$

for $r \in [\varepsilon^{\alpha_j}, 2\varepsilon^{\alpha_j}]$. Since (Es 2) implies $2 \geq \rho_\varepsilon \geq \frac{1}{2}$ for ε small enough, then

$$\begin{aligned} |\nabla \rho_{int}|^2 &= \frac{1}{4} \frac{\left|\nabla \rho_{int}^2\right|^2}{\rho_{int}^2} \\ &\leq \frac{1}{4} \frac{4\rho_\varepsilon^2 |\nabla \rho_\varepsilon|^2 + \varepsilon^{2-2\alpha_j} \frac{\left(1-\rho_\varepsilon^2\right)^2}{\varepsilon^2}}{\rho_\varepsilon^2 \left(\frac{2\varepsilon^{\alpha_j}-r}{\varepsilon^{\alpha_j}}\right) + \left(\frac{r-\varepsilon^{\alpha_j}}{\varepsilon^{\alpha_j}}\right)} \\ &\leq 4 \left[|\nabla \rho_\varepsilon|^2 + \varepsilon^{2-2\alpha_j} \frac{\left(1-\rho_\varepsilon^2\right)^2}{\varepsilon^2} \right]. \end{aligned} \tag{2.6}$$

Finally, since $1 \leq 4\rho_\varepsilon^2$ then

$$\rho_{int}^2 |\nabla \Theta_a + \nabla \psi_\varepsilon - A_\varepsilon|^2 \leq 4\rho_\varepsilon^2 |\nabla \Theta_a + \nabla \psi_\varepsilon - A_\varepsilon|^2. \tag{2.7}$$

Combining (2.5)–(2.7) yields

$$\begin{aligned} &\int_{B_{2\varepsilon^{\alpha_j}} \setminus B_{\varepsilon^{\alpha_j}}} g_\varepsilon(u_{com}^1, A_{com}^1) dx \\ &\quad \leq \int_{\varepsilon^{\alpha_j}}^{2\varepsilon^{\alpha_j}} \int_{\partial B_r} 4 \left[|\nabla \rho_\varepsilon|^2 + \varepsilon^{2-2\alpha_j} \frac{\left(1-\rho_\varepsilon^2\right)^2}{\varepsilon^2} \right] + 4\rho_\varepsilon^2 |\nabla \Theta_a + \nabla \psi_\varepsilon - A_\varepsilon|^2 \\ &\qquad + |B_\varepsilon - H_0|^2 + \frac{1}{2\varepsilon^2} \left(1-\rho_\varepsilon^2\right)^2 dw dr \\ &\quad \leq 4 \int_{\varepsilon^{\alpha_j}}^{2\varepsilon^{\alpha_j}} \int_{\partial B_r} g_\varepsilon(u_\varepsilon, A_\varepsilon) d\omega dr \\ &\quad \leq C_3(\Omega, \sigma, d). \end{aligned} \tag{2.8}$$

3. We now bound our comparison function in the next annulus. Define $\{u_{com}^2, A_{com}^2\}$ in $B_{3\varepsilon^{\alpha_j}} \setminus B_{2\varepsilon^{\alpha_j}}$ to be

$$\begin{aligned} A_{com}^2(r,\theta) = A_{int} &= \left(\frac{3\varepsilon^{\alpha_j} - r}{\varepsilon^{\alpha_j}}\right) A_\varepsilon(\varepsilon^{\alpha_j}, \theta) + \left(\frac{r - 2\varepsilon^{\alpha_j}}{\varepsilon^{\alpha_j}}\right) \widetilde{A}(3\varepsilon^{\alpha_j}, \theta), \\ u_{com}^2(r,\theta) &= e^{i\Theta_a + i\psi_{int}}, \end{aligned}$$

where

$$\psi_{int} = \left(\frac{3\varepsilon^{\alpha_j} - r}{\varepsilon^{\alpha_j}}\right) \psi_\varepsilon + \left(\frac{r - 2\varepsilon^{\alpha_j}}{\varepsilon^{\alpha_j}}\right) \overline{\psi}_\varepsilon^j$$

and $\overline{\psi}_\varepsilon^j = \fint_{\partial B_{\varepsilon^{\alpha_j}}} \psi_\varepsilon ds$. Then

$$\begin{aligned} |\nabla \Theta_a + \nabla \psi_{int} - A_{int}|^2 &\leq \left| \left(\frac{3\varepsilon^{\alpha_j} - r}{\varepsilon^{\alpha_j}}\right) (\nabla \Theta_a + \nabla \psi_\varepsilon - A_\varepsilon) + \left(\frac{r - 2\varepsilon^{\alpha_j}}{\varepsilon^{\alpha_j}}\right) \nabla \Theta_a \right. \\ &\qquad \left. + \nabla \left(\frac{r}{\varepsilon^{\alpha_j}}\right) \left(\psi_\varepsilon - \overline{\psi}_\varepsilon^j\right) - \left(\frac{r - 2\varepsilon^{\alpha_j}}{\varepsilon^{\alpha_j}}\right) \widetilde{A} \right|^2 \\ &\leq |\nabla \Theta_a + \nabla \psi_\varepsilon - A_\varepsilon|^2 + |\nabla \Theta_a|^2 + \varepsilon^{-2\alpha_j} \left|\psi_\varepsilon - \overline{\psi}_\varepsilon^j\right|^2 + \left|\widetilde{A}\right|^2 \\ &\leq 4 |\nabla_{A_\varepsilon} u_\varepsilon|^2 + |\nabla \Theta_a|^2 + \varepsilon^{-2\alpha_j} \left|\psi_\varepsilon - \overline{\psi}_\varepsilon^j\right|^2 + \left|\widetilde{A}\right|^2 \end{aligned}$$

and

$$|\operatorname{curl} A_{int} - H_0|^2 = \left|(B_\varepsilon - H_0)\left(\frac{3\varepsilon^{\alpha_j} - r}{\varepsilon^{\alpha_j}}\right) + \left(\frac{3\varepsilon^{\alpha_j} - r}{\varepsilon^{\alpha_j}}\right) H_0 + \left(\widetilde{A} - A_\varepsilon\right) \times \nabla\left(\frac{r}{\varepsilon^{\alpha_j}}\right) + \operatorname{curl} \widetilde{A}\left(\frac{r - 2\varepsilon^{\alpha_j}}{\varepsilon^{\alpha_j}}\right)\right|^2$$
$$\leq |B_\varepsilon - H_0|^2 + H_0^2 + \varepsilon^{-2\alpha_j} |A_\varepsilon|^2 + \varepsilon^{-2\alpha_j} \left|\widetilde{A}\right|^2 + \left|\operatorname{curl} \widetilde{A}\right|^2$$

for $r \in [2\varepsilon^{\alpha_j}, 3\varepsilon^{\alpha_j}]$. By Poincaré's inequality

$$\varepsilon^{-2\alpha_j} \int_{\partial B_{\varepsilon^{\alpha_j}}} |\psi_\varepsilon - \overline{\psi}_\varepsilon^j|^2 d\omega \leq C \int_{\partial B_{\varepsilon^{\alpha_j}}} |\nabla \psi_\varepsilon|^2 d\omega$$
$$\leq C \int_{\partial B_{\varepsilon^{\alpha_j}}} |\nabla \Theta_a + \nabla \psi_\varepsilon - A_\varepsilon|^2 + |\nabla \Theta_a| + |A_\varepsilon|^2 d\omega.$$

Then

$$\begin{aligned}
&\int_{B_{3\varepsilon^{\alpha_j}} \setminus B_{2\varepsilon^{\alpha_j}}} g_\varepsilon(u_{com}^2, A_{com}^2) dx \\
&\quad = \frac{1}{2} \int_{B_{3\varepsilon^{\alpha_j}} \setminus B_{2\varepsilon^{\alpha_j}}} |\nabla \Theta_a + \nabla \psi_{int} - A_{int}|^2 + |\operatorname{curl} A_{int} - H_0|^2 \, dx \\
&\quad \leq C \int_{\varepsilon^{\alpha_j}}^{2\varepsilon^{\alpha_j}} \int_{\partial B_r} |\nabla_{A_\varepsilon} u_\varepsilon|^2 + |B_\varepsilon - H_0|^2 + |\nabla \Theta_a|^2 \\
&\qquad + \varepsilon^{-2\alpha_j} \left[A_\varepsilon^2 + \widetilde{A}^2\right] + \left|\operatorname{curl} \widetilde{A}\right|^2 + H_0^2 \, d\omega dr \\
&\quad \leq C_4(\Omega, \sigma, d),
\end{aligned} \tag{2.9}$$

where we use the smoothness of $\widetilde{A}$ and Sobolev embedding for A_ε. Thus (2.4), (2.8), and (2.9) yield the upper bound

$$\int_{\Omega_\varepsilon} g_\varepsilon(u, A) dx \leq \int_{\Omega_\varepsilon} g_\varepsilon(u_{com}, A_{com}) dx \leq \pi |\log \varepsilon| \sum_{j=1}^{d} \alpha_j + C_5(\Omega, \sigma, d) \tag{2.10}$$

for our minimizer $\{u, A\}$. Note that our minimizer $\{u, A\}$ satisfies Neumann boundary conditions $\nu \cdot \nabla_A u = 0$ and $\operatorname{curl} A = H_0$ on $\partial\Omega$.

4. Next we show that a minimizer $\{u, A\}$ on $\overline{\Omega}_\varepsilon$ satisfies $|u| \geq \frac{1}{2}$. To do so we follow an argument in Lemma 2.2 of [21]. Suppose there exists $x_0 \in \Omega_\varepsilon$ such that $|u| < \frac{1}{2}$; then there are two cases. Suppose first that $\operatorname{dist}(x_0, \partial\Omega) \geq \varepsilon^{2\alpha_0}$; then $(B_{\varepsilon^{2\alpha_0}}(x_0) \cap \overline{\Omega}_\varepsilon) \cap \partial\Omega = \emptyset$. We choose $B_{\varepsilon^\beta}(x_0)$, where $\beta \in [2\alpha_0, 4\alpha_0]$ such that

$$\varepsilon^\beta \int_{\partial\left(B_{\varepsilon^\beta}(x_0) \cap \Omega_\varepsilon\right)} g_\varepsilon(u, A) d\omega \leq C$$

and such that $B_{\varepsilon^\beta}(x_0) \cap \Omega_\varepsilon$ does not intersect $\partial\Omega$. However, since $\{u, A\}$ is a minimizer with $\deg(u/|u|, \partial B_{\varepsilon^\beta}(x_0)) = 0$, then if there is a point x_0 such that $|u(x_0)| < 1/2$, then

$$\int_{B_{\varepsilon^\beta}(x_0)} g_\varepsilon(u, A) dx \geq (1 - \beta)\, \pi |\log \varepsilon| - C$$

for ε small enough; see [20, 21]. This contradicts (2.10) when α_0 is small.

If $\operatorname{dist}(x_0, \partial\Omega) \leq \varepsilon^{2\alpha_0}$, then choose $x_0^\star$ such that $|x_0 - x_0^\star| = \operatorname{dist}(x_0, \partial\Omega)$; then choose $\beta \in (\alpha_0, 2\alpha_0)$ such that $\varepsilon^\beta \int_{\partial B_{\varepsilon^\beta}(x_0^\star)} g_\varepsilon(u, A) dx \leq C$. Let $y = \Psi(x) = (\Psi_1(x), \Psi_2(x))$ be a conformal change of variables that maps $B_{\varepsilon^\beta}(x_0) \cap \Omega$ to B_1^+ such that $\partial\left(B_{\varepsilon^\beta}(x_0^\star) \cap \Omega\right) \cap B_{\varepsilon^\beta}(x_0^\star)$ is mapped to $\{y_2 = 0\}$. Then $u(x) = u'(\Psi(x)) = u'(y)$ and $A_k(x) = \left(\partial_{x_k} \Psi_j(x)\right) A_j'(\Psi(x)) = \left(\partial_{x_k} \Psi_j(x)\right) A_j'(y)$ satisfies

$$\begin{aligned} 0 &= \left(\nabla - iA'\right)^2 u' + \frac{c(y)}{\varepsilon^{2(1-\beta)}} u'(1 - |u'|^2), \\ 0 &= -\operatorname{curl} B' + c(y)\left(iu', \nabla u' - iA'u'\right) \end{aligned}$$

on B_1^+, where

$$c(y)^{-1} = \left(\left(\partial_{x_1}\Psi_1\right)^2 + \left(\partial_{x_1}\Psi_2\right)^2\right)$$

and $\partial_\nu u'(y) = 0$ on $\{y_2 = 0\}$. Our conformal map Ψ maps x_0 to a point y_0 in the interior of B_1^+. By constructing a suitable energy flow, we can show that $|u'| \to 0$ as $\varepsilon \to 0$ uniformly in B_1^+ by following [6], contradicting $|u'| < 1/2$ for all ε.

5. We can now complete the lower bound estimate for the minimizer $\{u, A\}$. Set $u = \rho e^{i(\Theta_a + \psi)}$; then by (2.10)

$$\pi |\log\varepsilon| \sum_{j=1}^d \alpha_j + C_5 \geq \frac{1}{2} \int_{\Omega_\varepsilon} |\nabla\rho|^2 + \rho^2 |\nabla\Theta_a + \nabla\psi - A|^2 + |B - H_0|^2 + \frac{1}{2\varepsilon^2}\left(1 - \rho^2\right)^2 dx.$$

We have the following crude estimates:

$$\begin{aligned} \frac{1}{2}\int_{\Omega_\varepsilon} \rho^2 |\nabla\Theta_a|^2 dx &= \frac{1}{2}\int_{\Omega_\varepsilon} \left(\rho^2 - 1\right)^2 |\nabla\Theta_a|^2 dx + \frac{1}{2}\int_{\Omega_\varepsilon} |\nabla\Theta_a|^2 dx \\ &\leq \left[\frac{|\Omega|}{4}\varepsilon\left(\varepsilon^{-2\alpha_0} + \frac{d-1}{\sigma^2}\right)\left(\int_{\Omega_\varepsilon}\left(1 - \rho^2\right)^2 dx\right)^{1/2}\right] \\ &\quad + \left[\pi |\log\varepsilon| \sum_{j=1}^d \alpha_j + C_6(\Omega, \sigma, d)\right] \\ &\leq \pi |\log\varepsilon| \sum_{j=1}^d \alpha_j + C_7(\Omega, \sigma, d) \end{aligned} \tag{2.11}$$

and

$$\begin{aligned} &\int_{\Omega_\varepsilon} \left|1 - \rho^2\right| |\nabla\Theta_a| \, |\nabla\psi - A| \, dx \\ &\qquad \leq \frac{1}{8}\int_{\Omega_\varepsilon} |\nabla\psi - A|^2 dx + 2\int_{\Omega_\varepsilon} \left(1 - \rho^2\right)^2 |\nabla\Theta_a|^2 dx \\ &\qquad \leq \frac{1}{8}\int_{\Omega_\varepsilon} |\nabla\psi - A|^2 dx + 2C_7(\Omega, \sigma, d). \end{aligned} \tag{2.12}$$

Combining (2.11)–(2.12) yields

$$\begin{aligned} C_7 \geq &\int_{\Omega_\varepsilon} |\nabla\rho|^2 + \rho^2 |\nabla\psi - A|^2 + 2\nabla\Theta_a \cdot (\nabla\psi - A) \, dx \\ &+ \int_{\Omega_\varepsilon} |B - H_0|^2 + \frac{1}{2\varepsilon^2}\left(1 - \rho^2\right)^2 dx. \end{aligned} \tag{2.13}$$

To complete the lower bound it is necessary to control the term

$$\int_{\Omega_\varepsilon} \nabla\Theta_a \cdot (\nabla\psi - A)\, dx.$$

We fix the Coulomb gauge for the minimizer so that $\operatorname{div} A = 0$ in Ω and $\nu \cdot A = 0$ on $\partial\Omega$. Therefore, there exists a scalar function ξ such that $A = -\operatorname{curl}\xi$ in Ω and $\xi = 0$ on $\partial\Omega$. If $e^{i\Theta_a} = \prod_{j=1}^{d} e^{i\theta_{a_j}} = \prod_{j=1}^{d} \frac{x-a_j}{|x-a_j|}$ is the canonical harmonic map, then

$$\int_{\partial B_r(a_j)} \partial_\nu \Theta_a d\omega = \int_{\partial B_r(a_j)} \partial_\nu \theta_{a_j} d\omega = 0$$

and

$$\int_{\partial\Omega} \partial_\nu \Theta_a d\omega = -\sum_{j=1}^{d} \int_{\partial B_r(a_j)} \partial_\nu \theta_{a_j} d\omega = 0,$$

which, by the boundary conditions, implies

$$\int_{\partial\Omega} \partial_\nu \psi \, d\omega = 0.$$

Therefore,

$$\begin{aligned} \int_{\Omega_\varepsilon} \nabla\Theta_a \cdot (\nabla\psi + \operatorname{curl}\xi)\, dx &= \int_{\partial\Omega} \partial_\nu \Theta_a \left(\psi - \bar{\psi}\right) d\omega \\ &\quad + \sum_{j=1}^{d} \int_{\partial B_{\varepsilon^{\alpha_j}}(a_j)} \partial_\nu \Theta_a \left(\psi - \bar{\psi}_j\right) d\omega \\ &\quad + \sum_{j=1}^{d} \int_{\partial B_{\varepsilon^{\alpha_j}}(a_j)} \xi\, \partial_\tau \Theta_a d\omega \\ &\leq \frac{1}{8} \int_{\Omega_\varepsilon} |\nabla\psi|^2 + C_9 + C_{10}, \end{aligned} \tag{2.14}$$

where

$$\bar{\psi}_j = \fint_{B_{\varepsilon^{\alpha_j}}(a_j)} \psi \, d\omega$$

and

$$\bar{\psi} = \fint_{\partial\Omega} \psi \, d\omega,$$

which follows by using (Es 1) and (Es 2). Since $\rho > 1/2$ for the minimizer, then using (2.13) and (2.14) we find

$$\int_{\Omega_\varepsilon} |\nabla\psi + \operatorname{curl}\xi|^2 + |\Delta\xi - H_0|^2 \, dx \leq C_{11}(\Omega, \sigma, d),$$

which implies

$$\begin{aligned}\int_{\Omega_\varepsilon} g_\varepsilon(u_\varepsilon, A_\varepsilon)dx &\geq \int_{\Omega_\varepsilon} g_\varepsilon(u, A)dx \\ &\geq \frac{1}{2}\int_{\Omega_\varepsilon} \rho^2 \left|\nabla \Theta_a\right|^2 dx - \frac{1}{2}\int_{\Omega_\varepsilon} \rho^2 \left|\nabla\psi + \operatorname{curl}\xi\right|^2 dx \\ &\geq \pi|\log\varepsilon| \sum_{j=1}^{d} \alpha_j - C_7 - C_{11},\end{aligned}$$

which proves (2.2).

6. To prove (2.3) we use an argument in the proof of Lemma 4.3 of [23], along with (2.2), (Es 1), and (Es 2), to show

$$\int_{B_{\varepsilon^{\alpha_j}}(a_j)} g_\varepsilon(u_\varepsilon, A_\varepsilon)dx \geq \pi|\log\varepsilon|\,(1-\alpha_j) + C$$

for each essential zero. Equation (2.3) follows directly. ∎

LEMMA 2.7. *Let $\{u_\varepsilon, A_\varepsilon\}$ have d essential zeros at a_j such that*

$$\min\left(\operatorname{dist}(a_j, a_k), \operatorname{dist}(a_j, \partial\Omega)\right) \geq \sigma > 0$$

and let $G_\varepsilon(u_\varepsilon, A_\varepsilon) \leq \pi d|\log\varepsilon| + C_1$; then for any $\varepsilon^{\alpha_j} < r < \frac{\sigma}{4}$

$$\pi\log\frac{r}{\varepsilon} - C_{14} \leq \int_{B_r(a_j)} g_\varepsilon(u_\varepsilon, A_\varepsilon)dx \leq \pi\log\frac{r}{\varepsilon} + C_{14},$$

where C_{14} depends on Ω, σ, and d.

Proof.

$$\begin{aligned}&\int_{B_r(a_j)} g_\varepsilon(u_\varepsilon, A_\varepsilon)dx \\ &\quad= \int_{B_r\setminus B_{\varepsilon^{\alpha_j}}(a_j)} g_\varepsilon(u_\varepsilon, A_\varepsilon)dx + \int_{B_{\varepsilon^{\alpha_j}}(a_j)} g_\varepsilon(u_\varepsilon, A_\varepsilon)dx \\ &\quad\geq \frac{1}{2}\int_{B_r\setminus B_{\varepsilon^{\alpha_j}}(a_j)} \rho_\varepsilon^2 \left|\nabla\Theta_a\right|^2 dx - \frac{1}{2}\int_{B_r\setminus B_{\varepsilon^{\alpha_j}}(a_j)} \rho_\varepsilon^2 \left|\nabla\psi_\varepsilon - A_\varepsilon\right|^2 dx \\ &\qquad+ \int_{B_{\varepsilon^{\alpha_j}}(a_j)} g_\varepsilon(u_\varepsilon, A_\varepsilon)dx \\ &\quad\geq \frac{1}{2}\int_{B_r\setminus B_{\varepsilon^{\alpha_j}}(a_j)} \left|\nabla\Theta_a\right|^2 dx - C_7 - C_{13} + \pi|\log\varepsilon|\,(1-\alpha_j) - C_1 \\ &\quad= \pi|\log\varepsilon| - C_{14},\end{aligned}$$

where we used (2.11), Lemma 2.6, and Lemma 4.3 of [23]. The upper bound can be derived in the same way. ∎

If the essential zeros are well spaced, Lemma 2.7 yields a uniform global bound on the energy.

$$\int_{\Omega\setminus\bigcup_{j=1}^{d} B_r(a_j)} g_\varepsilon(u_\varepsilon, A_\varepsilon)dx \leq C_{14}(\Omega, \sigma, d, r). \tag{2.15}$$

Therefore, establishing the location of essential zeros affords global energy bounds away from vortex concentrations. We also find by a simple calculation that

$$\int_{\Omega\setminus\bigcup_{j=1}^{d} B_r(a_j)} |\nabla\psi_\star - A_\star|^2 + |B_\star - H_0|^2\, dx \le C_{15}(\Omega,\sigma,d,r), \tag{2.16}$$

where $\psi_\star$, $A_\star$, and $B_\star$ are the weak limits of ψ_ε, A_ε, and B_ε, respectively.

3. Asymptotic behavior of the SGL equations. We are interested in the vortex dynamics of the SGL equations under the Coulomb gauge. Many of the techniques in this section are based on the methods found in [8, 24]; however, there are a few difficulties with the SGL equations that do not appear in the Gross–Pitaevskii equation (1.5). The SGL equations are defined as

$$\begin{aligned} \frac{1}{i}\partial_{\Phi_\varepsilon} u_\varepsilon &= \nabla_{A_\varepsilon}^2 u_\varepsilon + \frac{1}{\varepsilon^2} u_\varepsilon \left(1 - |u_\varepsilon|^2\right), \\ \delta_\varepsilon E_\varepsilon &= -\operatorname{curl} B_\varepsilon + j_\varepsilon, \end{aligned}$$

where $E_\varepsilon = \partial_t A_\varepsilon + \nabla\Phi_\varepsilon$. We take $\delta_\varepsilon \to 0$ such that

$$\frac{\varepsilon^2 |\log\varepsilon|}{\delta_\varepsilon} \to 0. \tag{3.1}$$

We have natural boundary conditions

$$\begin{aligned} &\nu\cdot\nabla_{A_\varepsilon} u_\varepsilon = 0, \\ &B_\varepsilon = H_0, \\ &\nu\cdot E_\varepsilon = 0. \end{aligned}$$

Fixing the Coulomb gauge, the SGL equations become

$$\frac{1}{i}\partial_{\Phi_\varepsilon} u_\varepsilon = \nabla_{A_\varepsilon}^2 u_\varepsilon + \frac{1}{\varepsilon^2} u_\varepsilon \left(1 - |u_\varepsilon|^2\right), \tag{3.2}$$

$$\delta_\varepsilon E_\varepsilon = \Delta A_\varepsilon + j_\varepsilon \tag{3.3}$$

with new boundary conditions

$$\partial_\nu u_\varepsilon = 0, \tag{3.4}$$

$$B_\varepsilon = H_0, \tag{3.5}$$

$$\nu\cdot A_\varepsilon = 0, \tag{3.6}$$

$$\partial_\nu \Phi_\varepsilon = 0. \tag{3.7}$$

The Coulomb gauge simplifies our analysis of the magnetic field potential equation (3.3). We should note that global-in-time existence of $C(\mathbb{R}^+, H^2\otimes H^3)\cap C^1(\mathbb{R}^+, L^2\otimes H^1)$ solutions to (3.2)–(3.7) for a fixed ε can be shown by a long, but straightforward, modification of the proofs found in [3].

Since we are dealing extensively with covariant derivatives it is helpful to calculate the following commutator relationships.

PROPOSITION 3.1. *Covariant derivatives satisfy*

$$(\partial_\Phi\nabla_A - \nabla_A\partial_\Phi) = -iE, \tag{3.8}$$

$$\left(\nabla_A u, \nabla_A^2 u\right) = \operatorname{div}\left(\nabla_A u\otimes\nabla_A u\right) - \frac{1}{2}\nabla\left|\nabla_A u\right|^2 - B\left(j\times e_3\right), \tag{3.9}$$

where $\otimes$ is the usual fluid tensor

$$\operatorname{div}(v \otimes v) = \sum_{j=1} \partial_{x_j}(v_i, v_j)$$

for $v_k \in \mathbb{C}$.

Proof. The proof of (3.8) is a direct calculation. We now turn to (3.9).

$$\begin{aligned}
\left(\nabla_A u, \nabla_A^2 u\right) &= (\nabla_A u, \nabla \cdot \nabla_A u) - (\nabla_A u, iA \cdot \nabla_A u) \\
&= \operatorname{div}(\nabla_A u \otimes \nabla_A u) - (\nabla_A u, iA \cdot \nabla_A u) \\
&\quad - \sum_{j=1}^{2} (\partial_j \partial_k u - i \partial_j A_k u - i A_k \partial_j u, \partial_j u - i A_j u) \\
&= \operatorname{div}(\nabla_A u \otimes \nabla_A u) - \frac{1}{2} \nabla |\nabla_A u|^2 \\
&\quad - \sum_{j=1}^{2} (\partial_k A_j - \partial_j A_k)(iu, \partial_j u - i A_j u) \\
&\quad - \sum_{j=1}^{2} (i A_j \partial_k u - i A_k \partial_j u, \partial_j u - i A_j u) \\
&\quad - \sum_{j=1}^{2} \left(\partial_k u - i A_k u, i A_j \partial_j u + A_j^2 u\right) \\
&= \operatorname{div}(\nabla_A u \otimes \nabla_A u) - \frac{1}{2} \nabla |\nabla_A u|^2 - \operatorname{curl} A (j \times e_3). \qquad \square
\end{aligned}$$

3.1. Conservation laws. The SGL equations can be transformed into a series of conservation laws by using a variation of the Madelung transformation [26], used extensively in the study of the nonlinear Schrödinger equation. Recall the mass $|u|^2$, the momentum $j = (iu, \nabla_A u)$, and the energy density

$$g_\varepsilon(u, A) = \frac{1}{2} \left[|\nabla_A u|^2 + |\operatorname{curl} A - H_0|^2 + \frac{1}{2\varepsilon^2} \left(1 - |u|^2\right)^2 \right].$$

Then we have the following proposition.

PROPOSITION 3.2. *A solution $\{u_\varepsilon, A_\varepsilon, \Phi_\varepsilon\}$ to the SGL equations satisfies the conservation laws*

$$\frac{1}{2} \partial_t |u_\varepsilon|^2 = - \operatorname{div} j_\varepsilon = -\delta_\varepsilon \operatorname{div} E_\varepsilon, \tag{3.10}$$

$$\frac{1}{2} \partial_t j_\varepsilon = - \operatorname{div}(\nabla_{A_\varepsilon} u_\varepsilon \otimes \nabla_{A_\varepsilon} u_\varepsilon) + \nabla P_\varepsilon + \delta_\varepsilon B_\varepsilon (E_\varepsilon \times e_3) - \frac{1}{2} |u_\varepsilon|^2 E_\varepsilon, \tag{3.11}$$

$$\partial_t g_\varepsilon = -\delta_\varepsilon E_\varepsilon^2 + \operatorname{div}(\nabla_{A_\varepsilon} u_\varepsilon, \partial_{\Phi_\varepsilon} u_\varepsilon) + \operatorname{curl}(E_\varepsilon (B_\varepsilon - H_0)), \tag{3.12}$$

where

$$\operatorname{div}(\nabla_A u \otimes \nabla_A u) = \partial_j (\partial_k u - i A_k u, \partial_j u - i A_j u)$$

is the usual fluid tensor product and

$$P_\varepsilon = \frac{1}{2} \left[|\nabla_{A_\varepsilon} u_\varepsilon|^2 - B_\varepsilon^2 + \left(u_\varepsilon, \nabla_{A_\varepsilon}^2 u_\varepsilon\right) + \frac{1}{2\varepsilon^2} \left(1 - |u_\varepsilon|^4\right) \right] \tag{3.13}$$

is the pressure.

Proof. Mass conservation (3.10) and energy conservation (3.12) are direct calculations. We prove momentum conservation (3.11). By direct calculation we find

$$\partial_t j_\varepsilon = 2\left(i\partial_{\Phi_\varepsilon} u_\varepsilon, \nabla_{A_\varepsilon} u_\varepsilon\right) + \nabla q_\varepsilon - E_\varepsilon \left|u_\varepsilon\right|^2. \tag{3.14}$$

Plugging the SGL equations into (3.14) yields

$$\begin{aligned}
\partial_t j_\varepsilon &= -2\left(\nabla_{A_\varepsilon} u_\varepsilon, \nabla_{A_\varepsilon}^2 u_\varepsilon\right) + \frac{1}{2\varepsilon^2}\nabla\left(1-\left|u_\varepsilon\right|^2\right)^2 \\
&\quad + \nabla\left[\left(u_\varepsilon, \nabla_{A_\varepsilon}^2 u_\varepsilon\right) + \frac{1}{\varepsilon^2}\left|u_\varepsilon\right|^2\left(1-\left|u_\varepsilon\right|^2\right)\right] - E_\varepsilon\left|u_\varepsilon\right|^2 \\
&= -2\left[\operatorname{div}\left(\nabla_{A_\varepsilon} u_\varepsilon \otimes \nabla_{A_\varepsilon} u_\varepsilon\right) - \frac{1}{2}\nabla\left|\nabla_{A_\varepsilon} u_\varepsilon\right|^2 - B_\varepsilon\left(j_\varepsilon \times e_3\right)\right] \\
&\quad + \nabla\left(\frac{1}{2\varepsilon^2}\left(1-\left|u_\varepsilon\right|^4\right) + \left(u_\varepsilon, \nabla_{A_\varepsilon}^2 u_\varepsilon\right)\right) - E_\varepsilon\left|u_\varepsilon\right|^2,
\end{aligned}$$

where we used (3.9) in the first term. Finally we use

$$B_\varepsilon\left(j_\varepsilon \times e_3\right) = B_\varepsilon\left(\delta_\varepsilon E_\varepsilon + \operatorname{curl} B_\varepsilon\right) \times e_3$$

to complete the proof. □

Let $G_\varepsilon(u, A) = \int_\Omega g_\varepsilon(u, A)dx$; then (3.12) implies

$$G_\varepsilon(u_\varepsilon, A_\varepsilon)(t) + \delta_\varepsilon \int_0^t \int_\Omega E_\varepsilon^2 \, dxdt = G_\varepsilon(u_\varepsilon, A_\varepsilon)(0)$$

for all times. We require the initial data to satisfy the initial conditions

$$\left\{|u_\varepsilon(0)| \le 1/2\right\} \subseteq \bigcup_{j=1}^{d} B_{\delta_0}(a_j(0)) \subseteq \left\{\operatorname{dist}(x, \partial\Omega) \ge \delta_0\right\}, \tag{3.15}$$

$$G_\varepsilon(u_\varepsilon, A_\varepsilon)(0) \le \pi d|\log\varepsilon| + W(\{a_j(0)\}) + o_\varepsilon(1), \tag{3.16}$$

$$\{u_\varepsilon(0), A_\varepsilon(0)\} \text{ has } d \text{ essential zeros at } \{a_j(0)\} \tag{3.17}$$

so that

$$u_\varepsilon(0) \rightharpoonup \prod_{j=1}^{d}\left(\frac{x-a_j(0)}{|x-a_j(0)|}\right)^{d_j} e^{i\psi_0(x)}, \quad \text{where } d_j = \pm 1$$

weakly in $H^1_{loc}(\Omega\backslash\{a_1(0), \ldots, a_d(0)\})$ and $\psi_0 \in H^1(\Omega)$. These initial conditions are chosen to ensure the convergence of the initial data to the form (3.17) with vortices well spaced away from the boundary. The initial conditions (3.15)–(3.17) imply, for all $t > 0$,

$$G_\varepsilon(u_\varepsilon, A_\varepsilon)(t) \le G_\varepsilon(u_\varepsilon, A_\varepsilon)(0) \le \pi d|\log\varepsilon| + W(\{a_j(0)\}) + o_\varepsilon(1). \tag{3.18}$$

3.2. Energy concentration and weak compactness. We now wish to identify the weak limits of u_ε and A_ε, modulo vortex position, for any $t \in [0,T]$. To do so, we need to show that essential zeros move continuously in time. Then we use the asymptotic scaling, along with our uniform energy bounds, to identify the limiting functions.

LEMMA 3.3. *Suppose $\{u_\varepsilon, A_\varepsilon\}$ is a sequence of $H^1 \otimes H^1$ maps from $\Omega \subset \mathbb{R}^2$ into $\mathbb{C} \otimes \mathbb{R}^2$. Suppose*

$$G_\varepsilon(u_\varepsilon, A_\varepsilon) \leq \pi d |\log \varepsilon| + C$$

and suppose there are d essential zeros located at $\{a_j\}_1^d$ that satisfy

$$\min\{\operatorname{dist}(a_i, a_j), \operatorname{dist}(a_i, \partial\Omega)\} \geq \sigma > 0.$$

Then

$$\frac{g_\varepsilon(u_\varepsilon, A_\varepsilon)}{\pi |\log \varepsilon|} \rightharpoonup \sum_{j=1}^d \delta_{a_j}$$

in a Radon measure. Furthermore,

$$u_\varepsilon \rightharpoonup e^{i\Theta_a + i\psi_\star} = \prod_{j=1}^d \frac{x - a_j}{|x - a_j|} e^{i\psi_\star}$$

weakly in $H^1_{loc}(\Omega_a)$.

Proof. The proof follows from Lemma 2.7. ∎

We first establish the vortex motion law for the almost-energy-minimizing assumption. To do so, it will be necessary to trace the location of vortices as time progresses. Let $\Omega_a = \Omega \backslash \{a_j\}$; then we have the following.

PROPOSITION 3.4. *Under the assumptions, the linear momentum j_ε is uniformly bounded in $L^1_{loc}(\Omega)$ and up to subsequence*

$$j_\varepsilon \rightharpoonup v = \nabla\Theta_a + \nabla\psi_\star - A_\star$$

in $L^1_{loc}(\Omega_a)$, where $\operatorname{div} v = 0$ and $\Theta_a = \sum_{j=1}^d \operatorname{Arg} \frac{x-a_j}{|x-a_j|}$.

Proof. This follows directly from Lemma 3.3 and the gauge choice. ∎

LEMMA 3.5. *The linear momentum $j_\varepsilon \in L^1(\Omega)$ uniformly in ε. Let $\varphi \in C_0^\infty(\Omega)$, $\varphi = x_1$ for $x \in B_{R/2}(a_j)$, and $\varphi = 0$ for $x \notin B_R(a_j)$, where $R \in (0, \delta_0)$. Then for $a_j = (a_j^x, a_j^y)$,*

$$\int_{B_R(a_j)} \nabla^\perp \varphi \cdot j_\varepsilon dx \to 2\pi a_j^x.$$

Proof. We first note that $|u_\varepsilon| \in H^1(\Omega)$ uniformly in ε. Therefore, $|u_\varepsilon| \in L^p(\Omega)$ uniformly in ε for all $1 \leq p < \infty$. We wish to establish that $\nabla_{A_\varepsilon} u_\varepsilon \in L^q(\Omega)$ for $1 \leq q < 2$. Then $j_\varepsilon \in L^r(\Omega)$ for all $1 \leq r < 2$. Therefore, for $\phi \in C_0^\infty(\Omega)$

$$\begin{aligned}
\int_{B_R} \nabla^\perp \phi \cdot j_\varepsilon \, dx &\to \int_{B_R} \nabla^\perp \phi \cdot (\nabla\Theta_a + \nabla\psi_\star - A_\star) \, dx \\
&= \int_{B_R} \nabla^\perp \phi \cdot (\nabla\theta_j + A_\star) \, dx \\
&= \int_{B_\varepsilon(a_j)} \nabla^\perp \phi \cdot \nabla\theta_j dx + \int_{\partial B_R} x_1 \partial_\tau \theta_j dx - \int_{B_R} \nabla^\perp \phi \cdot A_\star dx.
\end{aligned}$$

To show L^p control of j_ε, we need to establish an energy bound. In order to do so we assume there is an essential zero at some point x_0. Then using arguments in Lemma 2.6 we can establish

$$\int_{B_r(x_0)} g_\varepsilon(u_\varepsilon, A_\varepsilon)dx \geq \pi \log \frac{r}{\varepsilon} - C.$$

Furthermore, a simple energy upper bound gives

$$\int_{B_{r'}(x_0)} g_\varepsilon(u_\varepsilon, A_\varepsilon)dx \leq \pi \log \frac{r'}{\varepsilon} - C.$$

Therefore, for $r > 2\varepsilon^\alpha$

$$\int_{B_{2r}(x_0)\setminus B_r(x_0)} g_\varepsilon(u_\varepsilon, A_\varepsilon)dx \leq C.$$

Then for $p \in [1, 2)$ we have

$$\begin{aligned}
\int_{B_1(x_0)} |\nabla_{A_\varepsilon} u_\varepsilon|^p \, dx &\leq \int_{B_{2\varepsilon^\alpha}} |\nabla_{A_\varepsilon} u_\varepsilon|^p \, dx + \sum_{j=1}^{d} \int_{B_{2^{j+1}\varepsilon^\alpha}\setminus B_{2^j\varepsilon^\alpha}} |\nabla_{A_\varepsilon} u_\varepsilon|^p \, dx \\
&\leq \left(2 \int_{B_{2\varepsilon^\alpha}} g_\varepsilon(u_\varepsilon, A_\varepsilon)dx\right)^{p/2} \varepsilon^{(2-p)/2} \\
&\quad + \sum_{j=1}^{d} |B_{2^{j+1}\varepsilon^\alpha}\setminus B_{2^j\varepsilon^\alpha}|^{(2-p)/2} \\
&= o_\varepsilon(1) + C \sum_{j=1}^{d} \left(2^j \varepsilon^\alpha\right)^{2-p} \leq C. \qquad \square
\end{aligned}$$

We now wish to show the continuous motion of essential zeros in the SGL equations on the order 1 time scale.

LEMMA 3.6. *The essential zeros do not move on any slower time scale $t \sim o(1)$ as $\varepsilon \to 0$. On the time scale $t \sim O(1)$, the vortex locations $a_j^\varepsilon(t)$ are uniformly continuous in t as $\varepsilon \to 0$.*

Proof. We know

$$u_\varepsilon \rightharpoonup \prod_{j=1}^{d} \frac{x - a_j}{|x - a_j|} e^{i\psi_0(x)}$$

in $H^1_{loc}(\Omega_{a_0})$ with $\|\psi_0\|_{H^1(\Omega)} \leq C_0$. Let $R > 0$ be a small number, $R < \frac{\sigma}{4}$, where

$$\sigma = \min\{|a_l - a_j|, \operatorname{dist}(a_l, \partial\Omega), l, j = 1, \ldots, n, l \neq k\}.$$

If the essential zeros move continuously, then there exists $t_\star > 0$ such that for a fixed $R > 0$ small ($R < \frac{\sigma}{4}$) there exists an essential zero in each $B_{R/2}(a_k(0))$. Suppose the essential zeros are not continuous in time; then let λ_ε be the maximum time such that all essential zeros still lie in $B_{R/2}(a_j(0))$. Therefore, for some essential zero, $a_k(\lambda_\varepsilon) \notin B_{R/2}(a_k(0))$. Our aim is to show

$$\liminf_{\varepsilon \to 0^+} \lambda_\varepsilon > 0.$$

Rescale the time $t \mapsto \lambda_\varepsilon t$ and set

$$\begin{aligned}\widetilde{u}_\varepsilon(t) &= u_\varepsilon(\lambda_\varepsilon t),\\ \widetilde{A}_\varepsilon(t) &= A_\varepsilon(\lambda_\varepsilon t),\\ \widetilde{\Phi}_\varepsilon(t) &= \Phi_\varepsilon(\lambda_\varepsilon t).\end{aligned}$$

Then for all $t \in [0,1)$ the essential zeros lie within $B_{R/4}(a_j(0))$, so the SGL equations become

$$\begin{aligned}\frac{1}{i}\left(\partial_t \widetilde{u}_\varepsilon + i\lambda_\varepsilon \widetilde{\Phi}_\varepsilon \widetilde{u}_\varepsilon\right) &= \lambda_\varepsilon \nabla^2_{\widetilde{A}_\varepsilon}\widetilde{u}_\varepsilon + \frac{\lambda_\varepsilon}{\varepsilon^2}\widetilde{u}_\varepsilon\left(1-|\widetilde{u}_\varepsilon|^2\right),\\ \delta_\varepsilon\left(\partial_t \widetilde{A}_\varepsilon + \lambda_\varepsilon \nabla\widetilde{\Phi}_\varepsilon\right) &= \lambda_\varepsilon \Delta \widetilde{A}_\varepsilon + \lambda_\varepsilon \widetilde{j}_\varepsilon.\end{aligned}$$

Let $\widetilde{E}_\varepsilon = \partial_t \widetilde{A}_\varepsilon + \lambda_\varepsilon \nabla\widetilde{\Phi}_\varepsilon$ and $\partial_{\widetilde{\Phi}_\varepsilon}\widetilde{u}_\varepsilon = \partial_t\widetilde{u}_\varepsilon + i\lambda_\varepsilon\widetilde{\Phi}_\varepsilon\widetilde{u}_\varepsilon$ The momentum equation becomes

$$\begin{aligned}\frac{1}{2}\frac{d}{dt}\widetilde{j}_\varepsilon = &-\lambda_\varepsilon \operatorname{div}\left(\nabla_{\widetilde{A}_\varepsilon}\widetilde{u}_\varepsilon \otimes \nabla_{\widetilde{A}_\varepsilon}\widetilde{u}_\varepsilon\right) - \nabla\left(\lambda_\varepsilon \widetilde{P}_\varepsilon\right)\\ &+ \lambda_\varepsilon\delta_\varepsilon \widetilde{B}_\varepsilon\left(\widetilde{E}_\varepsilon \times e_3\right) - \frac{\lambda_\varepsilon}{2}|\widetilde{u}_\varepsilon|^2\widetilde{E}_\varepsilon\end{aligned} \tag{3.19}$$

and the energy equation becomes

$$\frac{d}{dt}g_\varepsilon(\widetilde{u}_\varepsilon,\widetilde{A}_\varepsilon) = -\frac{\delta_\varepsilon}{\lambda_\varepsilon}\widetilde{E}_\varepsilon^2 + \operatorname{div}\left(\nabla_{\widetilde{A}_\varepsilon}\widetilde{u}_\varepsilon, \partial_{\widetilde{\Phi}_\varepsilon}\widetilde{u}_\varepsilon\right) + \operatorname{curl}\left(\widetilde{E}_\varepsilon\left(\widetilde{B}_\varepsilon - H_0\right)\right). \tag{3.20}$$

Choose $\phi \in C_0^\infty(B_R(a_k(0)))$ such that

$$\phi^2 = \begin{cases} 1 & \text{in } B_{\frac{R}{2}-\delta}(a_k(0)),\\ 0 & \text{in } B_R \backslash B_{\frac{3R}{4}}(a_k(0)),\end{cases}$$

and linear in between, where δ is chosen so that each essential zero $a_j^\varepsilon \in B_{\frac{R}{2}-\delta}(a_j(0))$ for all $j \neq k$ for all $t \in [0,1]$. Multiplying equation (3.19) by $\nabla^\perp\phi$ and integrating over $B_{\frac{R}{2}}(a_k(0)) \times [0,1]$ yields

$$\begin{aligned}\int_{B_{\frac{R}{2}}(a_k(0))} \nabla^\perp\phi \cdot \widetilde{j}_\varepsilon\Big|_0^1 dx = &2\lambda_\varepsilon \int_0^1 \int_{B_{\frac{R}{2}}(a_k(0))}\left(\nabla_{\widetilde{A}_\varepsilon}\widetilde{u}_\varepsilon \otimes \nabla_{\widetilde{A}_\varepsilon}\widetilde{u}_\varepsilon\right) : \nabla\nabla^\perp\phi\, dxdt\\ &+ 2\lambda_\varepsilon \int_0^1 \int_{B_{\frac{R}{2}}(a_k(0))} \delta_\varepsilon \widetilde{B}_\varepsilon\left(\widetilde{E}_\varepsilon \times e_3\right) - \frac{|\widetilde{u}_\varepsilon|^2}{2}\widetilde{E}_\varepsilon\, dxdt.\end{aligned}$$

The left side converges to $a_k^x(1) - a_k^x(0)$ and the right side converges to 0. Likewise $a_k^y(1) - a_k^y(0) = 0$ implies $a_k(1) = a_k(0)$, and $\deg\left(\frac{\widetilde{u}_\varepsilon(1)}{|\widetilde{u}_\varepsilon(1)|}, \partial B_{\frac{R}{2}}(a_k(0))\right) = 1$. From (3.20) we get

$$\int_{B_{\frac{R}{2}}(a_k(0))} g_\varepsilon(u_\varepsilon, A_\varepsilon)dx \leq \pi|\log\varepsilon| + C_{14}.$$

By Proposition 3.7 below, we find a single essential zero within the ball $B_{\frac{R}{2}}(a_k(0))$, which contradicts our assumption. Therefore, $\liminf_{\varepsilon\to 0}\lambda_\varepsilon > 0$ implies that the essential zeros move continuously. ∎

To complete the proof of Lemma 3.6, we need to establish an essential zero with only an energy bound and control on the degree. There are a few results in this direction, and we point out [21], which establishes essential zeros for the simplified GL functional, and [17], which computes precise lower bounds for simplified and full GL functionals. We will follow the spirit of the former, which has less precise bounds but allows for identification of vortices up to order ε^α diameter.

PROPOSITION 3.7. *Set $B_R = B_R(x_0)$; then if $\{\widetilde{u}, \widetilde{A}\}$ satisfies $\int_{\overline{B}_R} g_\varepsilon(\widetilde{u}, \widetilde{A})dx \leq \pi|\log\varepsilon| + C$ and $\deg(\frac{\widetilde{u}}{|\widetilde{u}|}, \partial B_R) = 1$, there exists exactly one essential zero in B_R.*

Proof. In order to isolate the essential zero in B_R, we would like to use the structure theorem of [20]. A sufficient condition to use this theorem is the bound $|\nabla_{\widetilde{A}}\widetilde{u}|_{L^\infty(B_R)} \leq \frac{C}{\varepsilon}$, which we lack. To compensate we employ a short-time gradient flow, i.e., the TDGL equations

$$\begin{aligned} \partial_\Phi u &= \nabla_A^2 u + \frac{1}{\varepsilon^2} u\left(1 - |u|^2\right), \\ E &= -\operatorname{curl} B + (iu, \nabla_A u) \end{aligned}$$

in B_R with initial data $u(x,0) = \widetilde{u}$ if $|\widetilde{u}| \leq 1$ and $u(x,0) = \frac{\widetilde{u}}{|\widetilde{u}|}$ if $|\widetilde{u}| > 1$ and $A(x,0) = \widetilde{A}$, subject to boundary conditions

$$\begin{aligned} (iu, \nabla_A u)(x,t) &= \left(i\widetilde{u}, \nabla_{\widetilde{A}}\widetilde{u}\right), \\ \operatorname{curl} A(x,t) &= \widetilde{B} \end{aligned}$$

on ∂B_R for all $t \geq 0$. These boundary conditions are reasonable given the assumption $\int_{\partial B_R} g_\varepsilon(u, A)d\omega \leq C$. For a more detailed account of asymptotics of the TDGL equations, see [33]. The TDGL equations use a modified potential energy

$$\tilde{g}_\varepsilon(u, A) = \frac{1}{2}\left[|\nabla_A u|^2 + \left|\operatorname{curl} A - \widetilde{B}\right|^2 + \frac{1}{2\varepsilon^2}\left(1 - |u|^2\right)^2\right].$$

Since the gradient flow regularizes data sufficiently to use the structure theorem, we can find an essential zero at a short ε^2 time later. Furthermore, the TDGL equations pin essential zeros to their initial location for any time scale $o(|\log\varepsilon|)$ (see [20, 33]), which allows us to identify the essential zero at time $t = 0$. This method was used in Proposition 1.1 of [22] to study concentrations in the nonlinear wave equation. Let $t = \varepsilon^2$; then parabolic estimates imply $|\nabla_A u|_{L^\infty(B_R)}(\varepsilon^2) \leq \frac{C}{\varepsilon}$ (see Proposition 2.8 of [33]), and we can find an essential zero $a^\varepsilon \in B_R$ for $\left\{u(\varepsilon^2), A(\varepsilon^2)\right\}$ (see Claim 4.3 of [33]).

Next we show that at $t = 0$ an essential zero is located at the same point. From our parabolic energy bound $\int_{B_R} \widetilde{g}_\varepsilon(u, A)(t)dx \leq \pi|\log\varepsilon| + C$, we find

$$\begin{aligned} \int_{B_R}\left[\widetilde{g}_\varepsilon(u,A)(0) + \widetilde{g}_\varepsilon(u,A)(\varepsilon^2) + \int_0^{\varepsilon^2}|\partial_\Phi u|^2 + E^2 dt + \frac{1}{\varepsilon^2}\int_0^{\varepsilon^2}\widetilde{g}_\varepsilon(u,A)dt\right]dx \\ \leq 3\pi|\log\varepsilon| + C. \end{aligned}$$

Then at a^ε

$$\begin{aligned} \varepsilon^\alpha \int_{\partial B_{\varepsilon^\alpha}(a^\varepsilon)}\left[\tilde{g}_\varepsilon(u,A)(0) + \tilde{g}_\varepsilon(u,A)(\varepsilon^2) + \int_0^{\varepsilon^2}|\partial_\Phi u|^2 + E^2 dt + \frac{1}{\varepsilon^2}\int_0^{\varepsilon^2}\tilde{g}_\varepsilon(u,A)dt\right]d\omega \\ \leq C. \end{aligned}$$

We now rescale

$$\left\{\widehat{u}, \widehat{A}, \widehat{\Phi}\right\}(x,t) = \left\{u, \varepsilon^{\alpha} A, \varepsilon^2 \Phi\right\}(\varepsilon^{\alpha} x + a^{\varepsilon}, \varepsilon^2 t).$$

Then

$$\int_0^1 \int_{\partial B_1(0)} \widetilde{g}_{\tilde{\varepsilon}}(\widehat{u}, \widehat{A}) + \varepsilon^{2(\alpha-1)} \left|\partial_{\widehat{\Phi}} \widehat{u}\right|^2 + \varepsilon^{-2} \widehat{E}^2 d\omega dt \leq C, \tag{3.21}$$

where $\tilde{\varepsilon} = \varepsilon^{1-\alpha}$. Inequality (3.21) implies the degree is well-defined. Next, we get

$$\int_{\partial B_1(0)} \widetilde{g}_{\tilde{\varepsilon}}(\widehat{u}, \widehat{A})(0) + \widetilde{g}_{\tilde{\varepsilon}}(\widehat{u}, \widehat{A})(1) d\omega \leq C,$$

which implies

$$\deg\left(\frac{\widetilde{u}}{|\widetilde{u}|}, \partial B_{\varepsilon^{\alpha}}(a^{\varepsilon})\right) = \deg\left(\frac{\widehat{u}(0)}{|\widehat{u}(0)|}, \partial B_1(0)\right) = \deg\left(\frac{\widehat{u}(1)}{|\widehat{u}(1)|}, \partial B_1(0)\right).$$

Therefore, there is an essential zero. ∎

This implies, for all $t \in (0, t_\delta)$ such that $t_\delta = t_\delta(\sigma, d, \Omega)$,

$$\frac{g_\varepsilon(u_\varepsilon, A_\varepsilon)(t)}{\pi |\log \varepsilon|} \rightharpoonup \sum_{j=1}^{d} \delta_{a_j(t)}.$$

Since there are uniform bounds on the energy outside of the concentrations, we can identify the limiting $u_\star$ and $A_\star$.

PROPOSITION 3.8. *The function $\psi_\star(x,t)$ satisfies in the weak limit of Proposition* 3.4

$$\Delta \psi_\star = 0$$

in Ω and $\partial_\nu \psi_\star = -\partial_\nu \Theta_a$ on $\partial\Omega$.

Proof. First, we let $\phi(x) \in C_0^\infty(\Omega)$ and $\varphi(t) \in C_0^\infty(0,T)$; then

$$\lim_{\varepsilon \to 0} \int_0^T \varphi(t) dt \int_{\Omega_a} j_\varepsilon \, \phi(x) dx = \int_0^T \varphi(t) dt \int_{\Omega_a} \left(\nabla \Theta_a + \nabla \psi_\star - A_\star\right) \phi dx, \tag{3.22}$$

and using (3.10)

$$\begin{aligned} \int_0^T \varphi(t) dt \int_{\Omega_a} j_\varepsilon \cdot \nabla \phi(x) dx &= \int_0^T \partial_t \varphi(t) dt \int_{\Omega_a} \frac{|u_\varepsilon|^2}{2} dx \\ &\to 0. \end{aligned}$$

Therefore, j_ε's weak limit is divergence free for a.e. $t \in [0,T]$. Combining with (3.22) implies

$$\Delta \psi_\star = 0$$

in Ω_a since $\operatorname{div} A_\varepsilon = 0$ for all ε. From Lemma 2.6 we find that $\psi_\star$ has removable singularities at the vortices. Therefore, $\psi_\star$ is harmonic throughout Ω.

To establish the Neumann boundary conditions we rely on a method of [24]. Near the boundary $\partial\Omega$ there are no essential zeros by Lemma 3.6. Choose $\phi \in C^\infty(B_r(x))$ such that $B_r(x) \cap \partial\Omega \neq \emptyset$ and $r \leq \frac{\sigma}{4}$. Since $u_\varepsilon = \rho_\varepsilon e^{i(\Theta_a+\psi_\varepsilon)}$, then the boundary conditions under the Coulomb gauge reduce to $\nu\cdot(\nabla\rho_\varepsilon + i\rho_\varepsilon\nabla(\Theta_a+\psi_\varepsilon))e^{i(\Theta_a+\psi_\varepsilon)} = 0$, $\nu\cdot A_\varepsilon = 0$, and $B_\varepsilon = H_0$. This implies, for each $\varepsilon > 0$,

$$\partial_\nu\rho_\varepsilon = \partial_\nu(\Theta_a + \psi_\varepsilon)) = 0$$

for $x \in \partial\Omega$. Now using $\operatorname{div} j_\varepsilon = 0$ on $x \in \partial\Omega$, then

$$\begin{aligned}\int_{\partial\Omega} \phi\,\nu\cdot v\,d\omega &= \int_\Omega v\cdot\nabla\phi\,dx = \lim_{\varepsilon\to 0}\int_\Omega j_\varepsilon\cdot\nabla\phi\,dx \\ &= \lim_{\varepsilon\to 0}\int_{\partial\Omega}\phi\,\nu\cdot j_\varepsilon\,d\omega + \lim_{\varepsilon\to 0}\int_\Omega \phi\,\partial_t\frac{|u_\varepsilon|^2}{2}dx,\end{aligned}$$

where $v = \nabla\Theta_a + \nabla\psi_\star - A_\star$. Integrating over $[0,t]$ yields

$$\int_0^t\int_{\partial\Omega}\phi\,\nu\cdot v\,dx = \lim_{\varepsilon\to 0}\frac{1}{2}\int_0^t\int_{\Omega_a}|u_\varepsilon|^2\partial_t\phi\,dx = 0.$$

Then we get $v\cdot\nu = 0$ on $\partial\Omega$. □

PROPOSITION 3.9. *Let $\{u_\varepsilon, A_\varepsilon\}$ be a solution to the SGL equations with scaling $\delta_\varepsilon \to 0$; then $A_\star = -\operatorname{curl}\xi_\star$ satisfies in the weak limit of Proposition* 3.4

$$\Delta^2\xi_\star - \Delta\xi_\star + 2\pi\sum_{j=1}^d \delta_{a_j(t)} = 0 \tag{3.23}$$

in Ω and $\xi = 0$ and $\Delta\xi = H_0$ on $\partial\Omega$.

Proof. From the lower bound Lemma 2.6 and the initial condition, (3.18) implies

$$\delta_\varepsilon\int_0^T\int_\Omega E_\varepsilon^2\,dxdt \leq C. \tag{3.24}$$

Therefore, we find that

$$\int_0^T\int_\Omega |-\operatorname{curl} B_\varepsilon + j_\varepsilon|^2\,dxdt \to 0$$

in $L^2(\Omega)$. Multiply (3.3) by $\nabla^\perp\phi$, where $\phi \in C_0^\infty(\Omega_a)$; then

$$\Delta B_\star - B_\star = 0$$

in distribution. Next, let $\phi \in C_0^\infty(B_\delta(a_j))$ for some a_j, and

$$\begin{aligned}0 &= \int_{B_\delta(a_j)}\nabla^\perp\phi\cdot E_\varepsilon + \int_{B_\delta(a_j)}\nabla^\perp\phi\,(-\operatorname{curl} B_\varepsilon + j_\varepsilon)\,dx \\ &\to \int_{B_\delta(a_j)}\phi\,(\Delta B_\star - B_\star)\,dx + 2\pi\phi(a_j),\end{aligned}$$

and so

$$\Delta B_\star - B_\star + 2\pi\delta_{a_j(t)} = 0$$

in distribution. Therefore, $B_\varepsilon \rightharpoonup B_\star$ in $H^1_{loc}(\Omega_a)$ and $B_\star$ satisfies

$$\Delta B_\star - B_\star + 2\pi \sum_{j=1}^{d} \delta_{a_j(t)} = 0$$

in distribution.

We now establish the boundary value of $B_\star$. Let $\phi = (\phi_1, \phi_2)$, where $\phi_j \in C^\infty(B_r(x))$, where $B_r \cap \partial\Omega \neq \emptyset$ and $r \leq \frac{\sigma}{4}$. Therefore, ϕ intersects part of the boundary and is supported away from any essential zero. Therefore,

$$\begin{aligned}
\int_{\partial\Omega} (B_\star - H_0)\, \phi \cdot \tau ds &= \int_{\partial\Omega} (B_\star - H_0)\, \phi \cdot dl \\
&= \int_\Omega \operatorname{curl} (\phi\, (B_\star - H_0))\, dx \\
&= \int_\Omega (B_\star - H_0) \operatorname{curl} \phi dx + \int_\Omega \phi \cdot \operatorname{curl} B_\star dx \\
&= \int_\Omega (B_\star - H_0) \operatorname{curl} \phi dx + \int_\Omega \phi \cdot j_\star dx \\
&= \lim_{\varepsilon\to 0} \int_\Omega (B_\varepsilon - H_0) \operatorname{curl} \phi + \phi \cdot j_\varepsilon dx \\
&= \lim_{\varepsilon\to 0} \int_\Omega \operatorname{curl} (\phi\, (B_\varepsilon - H_0)) + \delta_\varepsilon\, \phi \cdot E_\varepsilon dx \\
&= \lim_{\varepsilon\to 0} \int_{\partial\Omega} (B_\varepsilon - H_0)\, \phi \cdot dl + \lim_{\varepsilon\to 0} \delta_\varepsilon \int_\Omega \phi \cdot E_\varepsilon dx \\
&= 0
\end{aligned}$$

for a.e. $t \in [0, T]$. ∎

3.3. Γ-convergence. Unlike the TDGL equations, to establish strong convergence of the SGL equations we need a Γ-convergence-type result in the spirit of [8] and [24]. This result will help us twofold. First, the Γ-convergence will ensure strong convergence along the chosen subsequence, away from essential zeros, to the canonical harmonic map. Second, the Γ-convergence will be used to close a Gronwall inequality, critical in the proof of the vortex motion law.

LEMMA 3.10. *Let $\{u_\varepsilon, A_\varepsilon\}$ have essential zeros at vortex locations $\{a_1, \dots, a_d\}$. If, for some $\mu > 0$,*

$$\limsup_{\varepsilon\to 0} [G_\varepsilon(u_\varepsilon, A_\varepsilon) - \pi d |\log \varepsilon|] \leq \pi W(\{a_j\}) + \mu,$$

then for any $r > 0$, there is a constant C independent of ε and r such that for any $t > 0$

$$\limsup_{\varepsilon\to 0} \left\| \frac{j_\varepsilon}{|u_\varepsilon|} - v \right\|^2_{L^2(\Omega_r)} \leq C\mu, \tag{3.25}$$

$$\limsup_{\varepsilon\to 0} \|B_\varepsilon - B_a\|^2_{L^2(\Omega_r)} \leq C\mu, \tag{3.26}$$

$$\limsup_{\varepsilon\to 0} \|\nabla |u_\varepsilon|\|^2_{L^2(\Omega_r)} \leq C\mu, \tag{3.27}$$

where $\Omega_r = \Omega \backslash \bigcup_{j=1}^d B_r(a_j)$. *Here* $v = \nabla\Theta_a + \nabla\psi_a - A_a$ *such that* $\Delta\psi_a = 0$ *in* Ω, $\partial_\nu\psi_a = -\partial_\nu\Theta_a$ *on* $\partial\Omega$. *Furthermore,* $B_a = \Delta\xi_a$ *and* $A_a = -\operatorname{curl}\xi_a$ *such that* $\Delta^2\xi_a - \Delta\xi_a + 2\pi\sum_{j=1}^d \delta_{a_j} = 0$ *in* Ω, $\xi_a = 0$, $\Delta\xi_a = H_0$ *on* $\partial\Omega$.

Proof. The idea is to cut out small balls of radius ρ that contain d essential zeros. Inside of each of these balls, we replace $\{u_\varepsilon, A_\varepsilon\}$ with a minimizer on a slightly smaller ball subject to canonical boundary conditions on the boundary of the smaller ball and a simple interpolation in the annulus between the two balls. We can then use knowledge of energy minimizers from [2] and the renormalized energy of the appendix to control the strong convergence error.

1. By Lemma 2.6 we have that $u_\varepsilon \rightharpoonup e^{i(\Theta_a+\psi_\star)} = \prod_{j=1}^d \frac{x-a_j}{|x-a_j|} e^{i\psi_\star}$ weakly in $H^1(\Omega_a)$ for some $\nabla\psi_\star \in L^2_{loc}(\Omega_a)$, $A_\varepsilon \rightharpoonup A_\star$ weakly in $H^1(\Omega)$, and $B_\varepsilon \rightharpoonup B_\star$ weakly in $L^2(\Omega)$. Therefore,

$$\frac{j_\varepsilon}{|u_\varepsilon|} \rightharpoonup \nabla\Theta_a + \nabla\psi_\star - A_\star$$

weakly in $L^2(\Omega_a)$, and for any $\rho > 0$ and all $\varepsilon \le \varepsilon_0(\rho)$ small enough

(3.28)
$$\begin{aligned}\int_{\Omega_\rho} g_\varepsilon(u_\varepsilon, A_\varepsilon)dx &= \frac{1}{2}\int_{\Omega_\rho}\left[|\nabla|u_\varepsilon||^2 + \left|\frac{j_\varepsilon}{|u_\varepsilon|}\right|^2 + |B_\varepsilon - H_0|^2 + \frac{1}{2\varepsilon^2}\left(1-|u_\varepsilon|^2\right)^2\right]dx \\ &\ge \frac{1}{2}\int_{\Omega_\rho} |\nabla|u_\varepsilon||^2 + \left|\frac{j_\varepsilon}{|u_\varepsilon|} - (\nabla\Theta_a + \nabla\psi_\star - A_\star)\right|^2 + |B_\varepsilon - B_\star|^2\,dx \\ &\quad + \frac{1}{2}\int_{\Omega_\rho} |\nabla\Theta_a + \nabla\psi_\star - A_\star|^2\,dx + |B_\star - H_0|^2 + o_\varepsilon(1),\end{aligned}$$

where $\Omega_\rho = \Omega \backslash \bigcup_{j=1}^d B_\rho(a_j)$.

2. We now choose $\rho \in (\frac{r}{2}, r)$ such that $\int_{\partial B_\rho} g_\varepsilon(u_\varepsilon, A_\varepsilon)d\omega \le C$; then

$$\begin{aligned} u_\varepsilon &\rightharpoonup e^{i\Theta_a + i\psi_\star}, \\ A_\varepsilon &\rightharpoonup A_\star \end{aligned}$$

weakly in $H^1(\partial B_\rho(a_j))$. We want to show that the $\{u_\varepsilon, A_\varepsilon\}$ is close to a canonical harmonic map inside of $B_\rho(a_j)$. In particular we want to define a comparison map $\{u_\varepsilon^\rho, A_\varepsilon^\rho\}$ that satisfies

$$\int_{B_\rho(a_j)} g_\varepsilon(u_\varepsilon, A_\varepsilon)dx \ge \int_{B_\rho(a_j)} g_\varepsilon(u_\varepsilon^\rho, A_\varepsilon^\rho)dx + o(\rho,\varepsilon), \tag{3.29}$$

$$\int_{B_\rho(a_j)} g_\varepsilon(u_\varepsilon^\rho, A_\varepsilon^\rho)dx \ge \log\frac{\rho}{\varepsilon} + \gamma + o(\rho,\varepsilon). \tag{3.30}$$

We let

$$\{u_\varepsilon^\rho, A_\varepsilon^\rho\} = \begin{cases} \{u_\varepsilon, A_\varepsilon\} & \text{on } \Omega_\rho = \Omega\backslash\bigcup_{j=1}^d B_\rho(a_j), \\ \{u_{int}, A_{int}\} & \text{on each } B_\rho\backslash B_{\tilde\rho}, \\ \{u_{min}, A_{min}\} & \text{on each } B_{\tilde\rho} \end{cases}$$

such that

$$\{u_{min}, A_{min}\} = \min\left\{(u,A) \in H^1_{\psi_j}\left(B_{\tilde\rho}(a_j)\right) \otimes H^1_{\overline{B}_j}\left(B_{\tilde\rho}(a_j)\right)\right\},$$

where

$$H^1_{\overline{\psi}_j}(B_{\widetilde{\rho}}(a_j)) = \left\{ u \in H^1 : B_{\widetilde{\rho}} \to \mathbb{C} \text{ such that } u = \frac{x-a_j}{|x-a_j|} e^{i\overline{\psi}_j} \text{ on } \partial B_{\widetilde{\rho}}(a_j) \right\},$$
$$H^1_{\overline{B}_j}(B_{\widetilde{\rho}}(a_j)) = \left\{ A \in H^1 : B_{\widetilde{\rho}} \to \mathbb{R}^2 \text{ such that } \operatorname{curl} A = \overline{B}_j \text{ on } \partial B_{\widetilde{\rho}}(a_j) \right\}$$

for constants $\overline{\psi}_j$ and $\overline{B}_j$. Minimizers $\{u_{min}, A_{min}\}$ have been treated in [2] and [23]. We choose $\widetilde{\rho} = \rho - C\varepsilon^{\alpha_0}$, and the interpolation functions $\{u_{int}, A_{int}\}$ can be chosen as in the proof of Lemma 2.6. A long but straightforward calculation shows both (3.29) and (3.30).

3. By the definition of the renormalized energy and (3.28),

$$\begin{aligned} &\pi W(\{a_j\}) + o_\varepsilon(1) \\ &\quad \le G_\varepsilon(u^\rho_\varepsilon, A^\rho_\varepsilon) - \pi d |\log \varepsilon| \\ &\quad \le G_\varepsilon(u_\varepsilon, A_\varepsilon) - \pi d |\log \varepsilon| + o_\varepsilon(1) \\ &\qquad - \frac{1}{2}\int_{\Omega_\rho} |\nabla |u_\varepsilon||^2 + \left| \frac{j_\varepsilon}{|u_\varepsilon|} - (\nabla \Theta_a + \nabla \psi_\star - A_\star) \right|^2 + |B_\varepsilon - B_\star|^2 \, dx. \end{aligned} \tag{3.31}$$

Our assumption $G_\varepsilon(u_\varepsilon, A_\varepsilon) - \pi d |\log \varepsilon| \le \pi W(\{a_j\}) + \mu$ and (3.31) yield

$$\lim_{\varepsilon \to 0} \int_{\Omega_\rho} |\nabla |u_\varepsilon||^2 \, dx \le 2\mu + o(\varepsilon, \rho), \tag{3.32}$$

$$\lim_{\varepsilon \to 0} \int_{\Omega_\rho} \left| \frac{j_\varepsilon}{|u_\varepsilon|} - (\nabla \Theta_a + \nabla \psi_\star - A_\star) \right|^2 dx \le 2\mu + o(\varepsilon, \rho), \tag{3.33}$$

$$\lim_{\varepsilon \to 0} \int_{\Omega_\rho} |B_\varepsilon - B_\star|^2 \, dx \le 2\mu + o(\varepsilon, \rho). \tag{3.34}$$

So (3.33) and (3.34) imply

$$\limsup_{\varepsilon \to 0} \int_{\Omega_\rho} \left| \frac{j_\varepsilon}{|u_\varepsilon|} - v \right|^2 dx \le 4\mu + 2\int_{\Omega_\rho} |\nabla \psi_\star - \nabla \psi_a + A_\star - A_a|^2 \, dx + o(\varepsilon, \rho),$$
$$\limsup_{\varepsilon \to 0} \int_{\Omega_\rho} |B_\varepsilon - B_a|^2 \, dx \le 4\mu + 2\int_{\Omega_\rho} |B_\star - B_a|^2 \, dx + o(\varepsilon, \rho).$$

Adding these two together yields

$$\begin{aligned} &\limsup_{\varepsilon \to 0} \int_{\Omega_\rho} \left| \frac{j_\varepsilon}{|u_\varepsilon|} - v \right|^2 + |B_\varepsilon - B_a|^2 \, dx \\ &\qquad \le 8\mu + 2\int_{\Omega_\rho} |\nabla \psi_\star - \nabla \psi_a + A_\star - A_a|^2 + |B_\star - B_a|^2 \, dx + o(\varepsilon, \rho). \end{aligned}$$

4. We now show that

$$\int_{\Omega_\rho} |\nabla \psi_\star - \nabla \psi_a + A_\star - A_a|^2 + |B_\star - B_a|^2 \, dx \le \mu + o(\varepsilon, \rho).$$

By the definition of the renormalized energy in the appendix,

$$\frac{1}{2}\int_{\Omega_\rho} |\nabla \Theta_a + \nabla \psi_a - A_a|^2 + |B_a - H_0|^2 \, dx = \pi d \log \frac{1}{\rho} + \pi W(\{a_j\}) - \gamma d + o(\rho). \tag{3.35}$$

Using our initial energy bound, along with an energy bound inside each $B_\rho(a_j)$, we find that our comparison function satisfies

$$\begin{aligned}\int_{\Omega_\rho} g_\varepsilon(u_\varepsilon, A_\varepsilon)dx &= \int_{\Omega_\rho} g_\varepsilon(u_\varepsilon^\rho, A_\varepsilon^\rho)dx \\ &\le \pi W(\{a_j\}) - \gamma d + \mu + o(\rho,\varepsilon) + \pi d \log\frac{1}{\rho},\end{aligned} \tag{3.36}$$

where we used (3.30). Finally,

$$\begin{aligned}\int_{\Omega_\rho} |\nabla\Theta_a + \nabla\psi_\star - A_\star|^2 &= \int_{\Omega_\rho} |\nabla\Theta_a|^2 + |\psi_\star - A_\star|^2\,dx - 2\int_{\partial\Omega} \psi_\star \partial_\nu \Theta_a d\omega \\ &\quad + 2\sum_{j=1}^d \int_{\partial B_\rho(a_j)} \left(\psi_\star - \overline{\psi}_\star^j\right)\partial_\nu\Theta_a + \xi_\star \partial_\tau \Theta_a d\omega.\end{aligned} \tag{3.37}$$

The second line of (3.37) is $o(\rho,\varepsilon)$. Combining (3.35)–(3.37) we get

$$\int_\Omega |\nabla\psi_\star - A_\star|^2 + |B_\star - H_0|^2\,dx \le \int_\Omega |\nabla\psi_a - A_a|^2 + |B_a - H_0|^2\,dx + \mu + o(\varepsilon,\rho).$$

Since ψ_a is harmonic and $\partial_\nu\psi_a = \partial_\nu\psi_\star$ on $\partial\Omega$ along with $\Delta^2\xi_a - \Delta\xi_a + 2\pi\sum_{j=1}^d \delta_{a_j} = 0$ and $\xi_a = \xi_\star = 0$, $\Delta\xi_a = \Delta\xi_\star = H_0$ on $\partial\Omega$, then

$$\begin{aligned}&\int_\Omega |\nabla\psi_\star - \nabla\psi_a + A_\star - A_a|^2 + |B_\star - B_a|^2\,dx \\ &\qquad \le 2\int_\Omega |\nabla\psi_a - A_a|^2 + |B_a - H_0|^2 + \mu + o(\varepsilon,\rho) \\ &\qquad \le \mu + o(\varepsilon,\rho). \qquad \square\end{aligned}$$

4. Vortex motion law for almost-energy-minimizing bounds. We are now in the position to prove the vortex motion law for almost-energy-minimizing bounds. In particular we prove the following.

THEOREM 4.1. *If $\{u_\varepsilon, A_\varepsilon\}$ satisfies the SGL equations* (3.2)–(3.7) *and initial conditions* (3.15)–(3.17)*, then*

$$\frac{d}{dt}a_j(t) = \left(\nabla\psi_j - A_\star\right)(a_j(t)) = -\mathcal{J}\nabla_{a_j} W(\{a_k(t)\}), \tag{4.1}$$

where

$$\mathcal{J} = \begin{pmatrix} 0 & -1 \\ 1 & 0 \end{pmatrix}$$

and $W(\{a_j\})$ is defined by (A.1)*. $A_\star = -\operatorname{curl}\xi_\star$ satisfies the London equation* (3.23) *and $e^{i\Theta_a + i\psi_\star} = \prod_{j=1}^d \frac{x-a_j}{|x-a_j|}e^{i\psi_\star} = \frac{x-a_j}{|x-a_j|}e^{i\psi_j}$ such that $\Delta\psi_\star = 0$ in Ω and $\partial_\nu\psi_\star = -\partial_\nu\Theta_a$ on $\partial\Omega$.*

We use the momentum equation (3.11) to establish (4.1). Let $m = 1, 2$; then

$$\begin{aligned}\frac{1}{2}\partial_t j_{\varepsilon m} &= -\left(u_{\varepsilon x_m} - iA_{\varepsilon m}u_\varepsilon, u_{\varepsilon x_j} - iA_{\varepsilon j}u_\varepsilon\right)_{x_j} + P_{\varepsilon x_m} \\ &\quad - \frac{|u_\varepsilon|^2}{2}E_\varepsilon + \delta_\varepsilon B_\varepsilon\left(E_\varepsilon \times e_3\right).\end{aligned}$$

Then if $|u_\varepsilon| > 0$,

$$u_{\varepsilon x_m} - iA_{\varepsilon m} = \frac{j_{\varepsilon m}}{|u_\varepsilon|}\frac{iu_\varepsilon}{|u_\varepsilon|} + |u_\varepsilon|_{x_m}\frac{u_\varepsilon}{|u_\varepsilon|}$$

and

$$\begin{aligned}\left(\nabla_{A_{\varepsilon m}} u_\varepsilon, \nabla_{A_{\varepsilon j}} u_\varepsilon\right) &= \frac{\left(j_{\varepsilon m}, j_{\varepsilon j}\right)}{|u_\varepsilon|^2} + |u_\varepsilon|_{x_m}|u_\varepsilon|_{x_j} \\ &= v_m \frac{j_{\varepsilon j}}{|u_\varepsilon|} + v_j \frac{j_{\varepsilon m}}{|u_\varepsilon|} - v_m v_j \\ &\quad + \left(\frac{j_{\varepsilon m}}{|u_\varepsilon|} - v_m\right)\left(\frac{j_{\varepsilon j}}{|u_\varepsilon|} - v_j\right) \\ &\quad + |u_\varepsilon|_{x_m}|u_\varepsilon|_{x_j}.\end{aligned}$$

Since $\|\frac{j_\varepsilon}{|u_\varepsilon|}\|_{L^2_{loc}(\Omega_a)} \leq C$, then there is a weak limit in $L^2[0,T;L^2(\Omega_a)]$, which we denote v. Since $|u_\varepsilon| \to 1$ in $L^2(\Omega_a)$ for a.e. t, then $j_\varepsilon \rightharpoonup v = \nabla\Theta_a + \nabla\psi_\star - A_\star$ and

$$v_j \frac{j_{\varepsilon m}}{|u_\varepsilon|} \rightharpoonup v_j v_m.$$

Therefore,

$$\left(\nabla_{A_\varepsilon} u_\varepsilon \otimes \nabla_{A_\varepsilon} u_\varepsilon\right) \rightharpoonup (v \otimes v) + \nu_j, \tag{4.2}$$

where

$$\left(\frac{j_{\varepsilon j}}{|u_\varepsilon|} - v_j\right)\left(\frac{j_{\varepsilon m}}{|u_\varepsilon|} - v_m\right) + |u_\varepsilon|_j |u_\varepsilon|_m \rightharpoonup \nu_j$$

for a finite, symmetric defect measure, $\nu_j \in \mathcal{M}_+(\Omega_a)$. The failure of strong convergence of $|\frac{j_\varepsilon}{|u_\varepsilon|} - v|_{L^2}$ and $|\nabla|u_\varepsilon||_{L^2}$ accounts for this defect measure. ν is finite on Ω due to Lemma 3.10.

We set $\phi \in C_0^\infty(B_{R_0/2})$ such that $\phi = x$ in B_R. Then the conservation of momentum equation (3.11) yields

$$\begin{aligned}&\int_{B_{R_0/2}} \nabla^\perp\phi \cdot j_\varepsilon\big|_t^{t+k}\, dx \\ &\quad = 2\int_t^{t+k} ds \int_{B_{R_0/2}\setminus B_R} \left(\nabla_{A_\varepsilon} u_\varepsilon \otimes \nabla_{A_\varepsilon} u_\varepsilon\right) : \nabla\nabla^\perp\phi\, dx \\ &\qquad + 2\int_t^{t+k} ds \int_{B_{R_0/2}} \left(\frac{|u_\varepsilon|^2}{2} E_\varepsilon - \delta_\varepsilon B_\varepsilon \left(E_\varepsilon \times e_3\right)\right) \cdot \nabla^\perp\phi\, dx,\end{aligned} \tag{4.3}$$

and using (4.2) we get

$$\begin{aligned}&2\int_t^{t+k} ds \int_{B_{R_0/2}\setminus B_R} \left(\nabla_{A_\varepsilon} u_\varepsilon \otimes \nabla_{A_\varepsilon} u_\varepsilon\right) : \nabla\nabla^\perp\phi\, dx \\ &\qquad \to 2\int_t^{t+k} ds \int_{B_{R_0/2}\setminus B_R} (\mu + v \otimes v) : \nabla\nabla^\perp\phi\, dx,\end{aligned} \tag{4.4}$$

where $\mu \in \mathcal{M}_+(\Omega)$ and $v \otimes v \notin L^1(\Omega)$. We can then examine the second term of (4.4) following [24],

$$\begin{aligned}
&\int_t^{t+k} ds \int_{B_{R_0/2}(a_j(s))\setminus B_R(a_j(s))} (v\otimes v) : \nabla\nabla^\perp \phi \, dx \\
&\quad = \int_t^{t+k} ds \int_{B_{R_0/2}(a_j(s))\setminus B_R(a_j(s))} -v\cdot\nabla v\cdot\nabla^\perp \phi \, dx \\
&\qquad + \int_t^{t+k} ds \int_{\partial B_R(a_j(s))} (v\otimes v) : \left(v\otimes n^\perp\right) \, d\omega \\
&\quad = \int_t^{t+k} ds \int_{\partial B_R(a_j(s))} -\left(v\cdot \nabla v \cdot \nu^\perp\right)(n\cdot x) \, d\omega \\
&\qquad + \int_t^{t+k} ds \int_{\partial B_R(a_j(s))} (v\otimes v) : \left(\nu\otimes n^\perp\right) \, d\omega,
\end{aligned}$$

where $n = (1,0)$ and ν is the normal direction at $\partial B_R(a_j(s))$. Let $(I, II) = (\nabla\psi_j - A_\star)$; then the first integral of the right side becomes

$$\begin{aligned}
&\int_0^{2\pi} \left(a_j^x(t)R + R^2\cos\theta\right)\left[v\cdot\nabla v_1(-\sin\theta) + v\cdot\nabla v_2\cos\theta\right] d\theta \\
&\quad = \int_0^{2\pi} \left(a_j^x(t)R + R^2\cos\theta\right)\left[(I - R^{-1}\sin\theta)(I_x + 2R^{-2}\sin\theta\cos\theta)(-\sin\theta)\right. \\
&\qquad \left. +(II + R^{-1}\cos\theta)(I_y - R^{-2}\cos 2\theta)(-\sin\theta)\right] d\theta \\
&\qquad + \int_0^{2\pi} \left(a_j^x(t)R + R^2\cos\theta\right)\left[(I - R^{-1}\sin\theta)(II_x - R^{-2}\cos 2\theta)\cos\theta\right. \\
&\qquad \left. +(II + R^{-1}\cos\theta)(II_y - 2R^{-2}\sin\theta\cos\theta)(\cos\theta)\right] d\theta \\
&\quad = -I\int_0^{2\pi} 2\left(\sin\theta\cos\theta\right)^2 d\theta - I\int_0^{2\pi}\cos^2\theta\cos 2\theta d\theta + O(R) \\
&\quad = -I\int_0^{2\pi}\cos^2\theta = -\pi I.
\end{aligned}$$

If we let $n = (0,1)$, then the integral yields $-\pi II$. Therefore,

$$\frac{d}{dt}a_j = 2\left(\nabla\psi_j - A_\star(a_j)\right) + f_j(\nu),$$

and by (A.10)

$$\frac{d}{dt}a_j = -\mathcal{J}\nabla_{a_j} W(\{a_k(t)\}) + f_j(\nu), \tag{4.5}$$

where

$$\mathcal{J} = \begin{pmatrix} 0 & -1 \\ 1 & 0 \end{pmatrix}.$$

Unfortunately, we have little control over how the defect measure affects the vortex motion. In fact the interaction of vortices with any excess energy can be very nontrivial [18].

To finish the proof of Theorem 4.1, we compare the true vortex motion $a_j(t)$ with a solution of the ODE

$$\frac{d}{dt}b_j(t) = -\mathcal{J}\nabla_{b_j}W(\{b_k(t)\})$$

such that $b_j(0) = a_j(0)$. Set

$$\zeta(t) = \sum_{j=1}^{d} |a_j(t) - b_j(t)|;$$

hence $\zeta(0) = 0$. We wish to show $\zeta(t) \equiv 0$ for all $t \in [0,T]$. Take a small time interval so that $\zeta(t) \le t_\delta$. Then

(4.6)
$$\begin{aligned}
\frac{d}{dt}\zeta(t) &\le \sum_{j=1}^{d}\left|\frac{d}{dt}a_j(t) - \frac{d}{dt}b_j(t)\right| \\
&= \sum_{j=1}^{d}\left|\frac{d}{dt}a_j(t) + \mathcal{J}\nabla_{a_j}W(\{a_k\}) - \mathcal{J}\nabla_{a_j}W(\{a_k\}) + \mathcal{J}\nabla_{b_j}W(\{b_k\})\right| \\
&\le \sum_{j=1}^{d}\left|\frac{d}{dt}a_j(t) + \mathcal{J}\nabla_{a_j}W(\{a_k\})\right| + \sum_{j=1}^{d}\left|\mathcal{J}\nabla_{b_j}W(\{b_k\}) - \mathcal{J}\nabla_{a_j}W(\{a_k\})\right| \\
&\le \sum_{j=1}^{d}\left|\frac{d}{dt}a_j(t) + \mathcal{J}\nabla_{a_j}W(\{a_k\})\right| + C\zeta(t).
\end{aligned}$$

As before, consider the time interval $[t, t+k]$, with k small, and the ball $B_R = B_R(a_j(t))$ inside $B_{R_0/2}$. Then set $\phi \in C_0^\infty(B_{R_0/2})$ such that $\phi = x$ in B_R:

(4.7)
$$\begin{aligned}
&\int_{B_{R_0/2}} \nabla^\perp\phi\cdot j_\varepsilon\big|_t^{t+k}\,dx \\
&\quad= 2\int_t^{t+k} ds\int_{B_{R_0/2}\setminus B_R} (\nabla_{A_\varepsilon}u_\varepsilon\otimes\nabla_{A_\varepsilon}u_\varepsilon) : \nabla\nabla^\perp\phi\,dx \\
&\qquad+ 2\int_t^{t+k} ds\int_{B_{R_0/2}}\left(\frac{|u_\varepsilon|^2}{2}E_\varepsilon - B_\varepsilon\,(E_\varepsilon\times e_3)\right)\cdot\nabla^\perp\phi\,dx \\
&\quad= 2\int_t^{t+k} ds\int_{B_{R_0/2}\setminus B_R}\left[\left(v\otimes\frac{j_\varepsilon}{|u_\varepsilon|} + \frac{j_\varepsilon}{|u_\varepsilon|}\otimes v - v\otimes v\right) : \nabla\nabla^\perp\phi\right]dx \\
&\qquad+ 2\int_t^{t+k} ds\int_{B_{R_0/2}\setminus B_R}\left[\left(\frac{j_\varepsilon}{|u_\varepsilon|} - v\right)\otimes\left(\frac{j_\varepsilon}{|u_\varepsilon|} - v\right) : \nabla\nabla^\perp\phi\right]dx \\
&\qquad+ 2\int_t^{t+k} ds\int_{B_{R_0/2}\setminus B_R}\left[\nabla|u_\varepsilon|\otimes\nabla|u_\varepsilon| : \nabla\nabla^\perp\phi\right]dx \\
&\qquad+ 2\int_t^{t+k} ds\int_{B_{R_0/2}}\left(\frac{|u_\varepsilon|^2}{2}E_\varepsilon - \delta_\varepsilon B_\varepsilon\,(E_\varepsilon\times e_3)\right)\cdot\nabla^\perp\phi\,dx \\
&\quad= (A)+(B)+(C)+(D).
\end{aligned}$$

We showed that as $\varepsilon \to 0$, (A) will yield $-2\pi\mathcal{J}\nabla_{a_j^x(t)}W(\{a_k(t)\})$. We will control terms (B) and (C) with the Γ-convergence result of section 2. We first show that $(D) \le C\zeta(t)+o_\varepsilon(1)+o_{R_0}(1)$. If we start with an almost-energy-minimizing sequence, then

$$\begin{aligned} G_\varepsilon(u_\varepsilon, A_\varepsilon)(0) &\le \pi d|\log\varepsilon| + W(\{a_j(0)\}) + o_\varepsilon(1) \\ &= \pi d|\log\varepsilon| + W(\{b_j(t)\}) + o_\varepsilon(1) \\ &\le \pi d|\log\varepsilon| + W(\{a_j(t)\}) + C\zeta(t) + o_\varepsilon(1) \end{aligned} \tag{4.8}$$

by the Lipschitz continuity of $W(x)$, $|W(a)-W(b)| \le C|a-b| = C\zeta$. Therefore,

$$\begin{aligned} \delta_\varepsilon \int_0^t \int_\Omega E_\varepsilon^2 \, dxdt &\le G_\varepsilon(u_\varepsilon, A_\varepsilon)(0) - G_\varepsilon(u_\varepsilon, A_\varepsilon)(t) \\ &\le W(\{a_j(0)\}) - W(\{a_j(t)\}) + o_\varepsilon(1) \\ &\le W(\{b_j(t)\}) - W(\{a_j(t)\}) + o_\varepsilon(1) \\ &\le C\zeta(t) + o_\varepsilon(1). \end{aligned} \tag{4.9}$$

Noting that $|\nabla\phi| \le R_0^{-1}$, then

$$\begin{aligned} &-\int_t^{t+k}\int_{B_{R_0}} |u_\varepsilon|^2 \, E_\varepsilon \cdot \nabla^\perp\phi \, dxds \\ &\quad= \int_t^{t+k}\int_{B_{R_0}} \left(1-|u_\varepsilon|^2\right) E_\varepsilon \cdot \nabla^\perp\phi \, dxds + \int_t^{t+k}\int_{B_{R_0}} E_\varepsilon \cdot \nabla^\perp\phi \, dxds \\ &\quad= \frac{1}{R_0^2}\int_t^{t+k}\int_{B_{R_0}} \frac{1}{\delta_\varepsilon}\left(1-|u_\varepsilon|^2\right)^2 dxds + \delta_\varepsilon \int_t^{t+k}\int_{B_{R_0}} E_\varepsilon^2 \, dxds \\ &\qquad+ \int_t^{t+k}\int_{B_{R_0}} \phi \operatorname{curl} E_\varepsilon \, dxds \\ &\quad\le \frac{\varepsilon^2|\log\varepsilon|}{\delta_\varepsilon}\frac{C}{R_0^2} + C\zeta(t) + \int_t^{t+k}\int_{B_{R_0}} \partial_t\left(\phi B_\varepsilon\right) dxds, \end{aligned} \tag{4.10}$$

where we control the second term of (4.10) by (4.9). To control the third term, note that $\|B_\varepsilon\|_{W^{1,r}} \le C$ uniformly for all $r \in [1,2)$ and $t \in [0, t_\delta]$. Then

$$\begin{aligned} &\int_t^{t+k}\int_{B_{R_0}} \partial_t\left(\phi B_\varepsilon\right) dxds \\ &\quad= \int_{B_{R_0}} \phi B_\varepsilon\big|_t^{t+k} \, dx \\ &\quad\le C|\phi|_{C_0(\Omega)}\left(\|B_\varepsilon(t+k)\|_{W^{1,r}}^{1/p} + \|B_\varepsilon(t)\|_{W^{1,r}}^{1/p}\right) R_0^{2/q}. \end{aligned} \tag{4.11}$$

Combining (4.10) and (4.11) along with (3.1) yields

$$\int_t^{t+k}\int_{B_{R_0}} |u_\varepsilon|^2 \, E_\varepsilon \cdot \nabla^\perp\phi \, dxds = C\zeta(t) + o_\varepsilon(1) + o_{R_0}(1), \tag{4.12}$$

which controls the first term of (D). It should be noted that we first let $\varepsilon \to 0$ and

then let $R \to 0$. The second term of (D) is much simpler:

$$\begin{aligned}&\int_t^{t+k}\int_{B_{R_0}} \delta_\varepsilon B_\varepsilon \left(E_\varepsilon \times e_3\right)\cdot \nabla^\perp \phi \, dxds\\ &= \delta_\varepsilon \int_t^{t+k}\int_{B_{R_0}} E_\varepsilon^2 \, dxds + \delta_\varepsilon \int_t^{t+k}\int_{B_{R_0}} B_\varepsilon^2 \, dxds\\ &\leq C\zeta(t) + o_\varepsilon(1),\end{aligned} \tag{4.13}$$

which finishes control of (D).

Next, we bound terms (B) and (C). From (4.8) and Lemma 3.10

$$\limsup_{\varepsilon\to 0}\left[G_\varepsilon(u_\varepsilon, A_\varepsilon) - \pi d|\log\varepsilon|\right] \leq \pi W(\{a_j\}) + C\zeta(t) + o(\varepsilon,\rho)$$

for $\zeta(t) > 0$; then for any $r > 0$, there is a constant C independent of ε and R such that

$$\begin{aligned}&\limsup_{\varepsilon\to 0}\left\|\frac{j_\varepsilon}{|u_\varepsilon|} - v\right\|^2_{L^2\left(\Omega\setminus\bigcup_{j=1}^d B_R(a_j)\right)} \leq C\zeta(t),\\ &\limsup_{\varepsilon\to 0}\|B_\varepsilon - B_\star\|^2_{L^2\left(\Omega\setminus\bigcup_{j=1}^d B_R(a_j)\right)} \leq C\zeta(t),\\ &\limsup_{\varepsilon\to 0}\|\nabla|u_\varepsilon|\|^2_{L^2\left(\Omega\setminus\bigcup_{j=1}^d B_R(a_j)\right)} \leq C\zeta(t).\end{aligned}$$

Choosing $t_\delta C \leq \zeta(t) \in (0,1)$, then for all $t \in (0, t_\delta)$

$$\begin{aligned}&\limsup_{\varepsilon\to 0}\left\|\frac{j_\varepsilon}{|u_\varepsilon|} - v\right\|_{L^2(B_{R_0/2}\setminus B_R)} \leq C_1\zeta(t),\\ &\limsup_{\varepsilon\to 0}\|B_\varepsilon - B_\star\|_{L^2(B_{R_0/2}\setminus B_R)} \leq C_1\zeta(t),\\ &\limsup_{\varepsilon\to 0}\|\nabla|u_\varepsilon|\|_{L^2(B_{R_0/2}\setminus B_R)} \leq C_1\zeta(t).\end{aligned}$$

This controls $(B)+(C)$. Then sending $\varepsilon \to 0$ yields, for $a = (a^x, a^y)$,

$$LHS \to 2\pi \frac{d}{dt} a_j^x(t)$$

and

$$(I) \to -2\pi \mathcal{J}\nabla_{a_j^x} W(\{a_k(t)\}).$$

Therefore, we find

$$\left|\frac{d}{dt}a_j^x(t) + \mathcal{J}\nabla_{a_j^x} W(\{a_k\})\right| \leq C\zeta(t),$$

and performing a similar estimate for $a_j^y(t)$, we get

$$\left|\frac{d}{dt}a_j(t) + \mathcal{J}\nabla_{a_j} W(\{a_k\})\right| \leq C\zeta(t)$$

and the inequality

$$\frac{d}{dt}\zeta(t) \le C\zeta(t)$$

with $\zeta(0) = 0$, which implies $\zeta \equiv 0$ and the vortex motion law. This finishes Theorem 4.1.

Remark 4.2. Although the SGL equations are dissipative for fixed ε, in the $\varepsilon \to 0$ limit, energy is conserved. This asymptotic behavior strongly depends on the choice of δ_ε in (3.3). For a different rate of $\delta_\varepsilon \to 0$, the system will not conserve energy, as dissipation will dominate.

4.1. Incompressible Euler equations. In [24] the authors were able to show the convergence of the supercurrent to a set of incompressible Euler equations for the Gross–Pitaevskii equation (1.5). To do so they found that the defect measure ν, arising from the limit of the convective term

$$(\nabla u_\varepsilon \otimes \nabla u_\varepsilon) \rightharpoonup (v \otimes v + \nu),$$

is curl-free, and that allowed $\operatorname{div} \nu$ to be written as the gradient of a distribution, and hence pushed into the pressure term. It is reasonable to ask whether the supercurrent equation (3.11) converges weakly to a set of Euler equations. Although $j_\varepsilon \rightharpoonup v$ is divergence-free, there are a number of difficulties controlling (3.11), including the lack of a curl-free supercurrent ($\operatorname{curl} v = -B_\star \neq 0$) and the loss of control over the term $\frac{1}{2}|u_\varepsilon|^2 E_\varepsilon$ in $\Omega \backslash \bigcup_{j=1}^d B_r(a_j)$. In the end it may be possible to study only the vorticity equation

$$\frac{1}{2}\operatorname{curl}\left(\partial_t j_\varepsilon + |u_\varepsilon|^2 E_\varepsilon\right) = -\operatorname{curl}\operatorname{div}\left(\nabla_{A_\varepsilon} u_\varepsilon \otimes \nabla_{A_\varepsilon} u_\varepsilon\right) - \left(\delta_\varepsilon \operatorname{div} E_\varepsilon\right) B_\varepsilon,$$

which has better control on both sides of the equation.

Appendix. Renormalized energy. For completeness we include a discussion of the renormalized energy for the full GL energy functional, which we need to verify the dynamic law SGL equations. We note the analysis is similar to [1, 2, 23]. We aim to prove two theorems that characterize both the renormalized energy and the gradient of the renormalized energy.

A.1. Renormalized energy.

THEOREM A.1. *The renormalized energy* $W\left(\{a_j\}_1^d\right)$ *obeys the system*

$$\begin{aligned} W(a_1, \dots, a_d) = &-\pi \sum_{i \neq j} \log|a_i - a_j| - \pi \sum_{j=1}^d R(a_j) + \pi \sum_{j=1}^d \xi(a_j) \\ &+ \frac{H_0^2}{2}|\Omega| - \frac{1}{2} H_0 \int_{\partial\Omega} \partial_\nu \xi \, d\omega. \end{aligned} \tag{A.1}$$

Here ξ *satisfies* $A = -\operatorname{curl}\xi$ *and*

$$\begin{aligned} -\Delta^2 \xi + \Delta \xi &= 2\pi \sum_{j=1}^d \delta_{a_j} \text{ in } \Omega, \\ \xi &= 0 \text{ on } \partial\Omega, \\ \Delta \xi &= H_0 \text{ on } \partial\Omega, \end{aligned} \tag{A.2}$$

and

$$R(x) = P(x) - \sum_{j=1}^{d} \log|x - a_j|, \tag{A.3}$$

where

$$\begin{aligned} \Delta P &= 2\pi \sum_{j=1}^{d} \delta_{a_j} \ \textit{in } \Omega, \\ P &= 0 \ \textit{on } \partial\Omega. \end{aligned} \tag{A.4}$$

We will first prove Theorem A.1 by using a combination of arguments found in [1, 2, 23]. We first note that $u_\star \in \mathbb{S}^1$ can be written as $u_\star = e^{i\Theta_a + i\psi_\star} = \prod_{j=1}^{d} \frac{x-a_j}{|x-a_j|} e^{i\psi_\star}$ for harmonic function $\psi_\star$. $\psi_\star$ is difficult to study, as it is a multivalued function. Since $\partial_\nu u = 0$ on $\partial\Omega$, we can find the conjugate harmonic function P such that

$$u_\star \times \nabla u_\star = \begin{pmatrix} -\partial_2 P \\ \partial_1 P \end{pmatrix} = -\operatorname{curl} P.$$

Then the boundary condition implies $0 = \nu \cdot \nabla^\perp P = \partial_\tau P$ or P is constant on $\partial\Omega$. We choose $P = 0$ to simplify the discussion below. Therefore, the equation for the congugate harmonic equation becomes

$$\begin{aligned} \Delta P_a &= 2\pi\delta_a \text{ in } \Omega, \\ P_a &= 0 \text{ on } \partial\Omega. \end{aligned} \tag{A.5}$$

In two dimensions the singularity at a is $O(\log)$ so we can define

$$P_a(x) = \log|x - a| + S_a(x), \tag{A.6}$$

which is no longer a multivalued function (unlike Θ_a). Furthermore, $S_a(x)$ is harmonic and defined everywhere in Ω. We now outline the proof of the theorem by first defining the class on which we define the renormalized energy. To calculate $W(\{a_j\})$ we subtract the self-induction energy from a canonical harmonic map, and what is left is a function of the d vortex locations. We set $\Omega_\rho = \Omega \setminus \bigcup_{j=1}^{d} B_\rho(a_j)$ and

$$\mathcal{H}^1(a_j, \rho) = \begin{cases} u \in H^1\left(\Omega_\rho, \mathbb{S}^1\right), \ A \in H^1\left(\Omega, \mathbb{R}^2\right) \text{ such that} \\ u = \dfrac{x - a_j}{|x - a_j|} \text{ on } \partial B_\rho(a_j) \quad \text{and} \quad \partial_\nu u = 0 \text{ on } \partial\Omega, \\ \operatorname{div} A = 0 \text{ in } \Omega \quad \text{and} \quad \nu \cdot A = 0 \quad \text{and} \quad \operatorname{curl} A = H_0 \text{ on } \partial\Omega. \end{cases}$$

We set

$$E_\delta(u, A) = \frac{1}{2} \int_{\Omega_\delta} |\nabla_A u|^2 \, dx + \frac{1}{2} \int_{\Omega} |\operatorname{curl} A - H_0|^2 \, dx \tag{A.7}$$

and

$$\mu_\delta = \inf_{(u,A) \in \mathcal{H}^1(a_j, \rho)} E_\delta(u, A). \tag{A.8}$$

Claim A.2. *We have that μ_δ is achieved, and for $\delta < \delta_0$ we have $\mu_\delta \le \pi d \log \frac{1}{\delta} + C$, where $C = C(\{a_j\}, \delta_0)$.*

Proof. This is proved by creating suitable comparison functions $(v_\varepsilon, B_\varepsilon)$, following [2], such that $G_\varepsilon(v_\varepsilon, B_\varepsilon) \le \pi d|\log\varepsilon| + C$. We fix d distinct points $a_1, \dots, a_d$ and R small enough such that $B_R(a_j) \subset \Omega$ and $B_R(a_i) \cap B_R(a_j) = \emptyset$. To construct our comparison functions we start with

$$w_0 = v_\varepsilon = e^{i\theta_a} = \frac{x - a_j}{|x - a_j|} \quad \text{on } \partial B_R(a_j),$$
$$B_0 = B_\varepsilon = (iw_0, \nabla w_0)$$

outside the $B_R(a_j)$'s. We define a mollifier ζ such that $\zeta = 1$ for $r \ge 1$ and $\zeta = 0$ for $\zeta \le 1/2$. We can now define the comparison functions inside the $B_R(a_j)$'s.

$$v_\varepsilon = \frac{x - a_j}{|x - a_j|}\zeta\left(\frac{x - a_j}{\varepsilon}\right),$$
$$B_\varepsilon = B_\varepsilon\left(\frac{x - a_j}{|x - a_j|}R\right)\zeta\left(\frac{x - a_j}{R}\right).$$

A simple computation shows that $\int_{B_R} g_\varepsilon(v_\varepsilon, B_\varepsilon)dx \le C$ and

$$\int_{B_R(a_j)} g_\varepsilon(v_\varepsilon, B_\varepsilon)dx \le \pi|\log\varepsilon| + C.$$

Then we can use the direct method of calculus of variations to establish the existence of μ_δ. ∎

Claim A.3. *We have for $\delta < \delta_0$ and for a minimizer (v_δ, B_δ) of (A.7)*

$$\int_\Omega |\mathrm{curl} B_\delta - H_0|^2\, dx \le C$$

and

$$\int_{\Omega_\delta} |\nabla_{B_\delta} v_\delta|^2\, dx \ge \pi d \log\frac{1}{\delta} - C$$

for $C = C(\{a_j\}, \delta_0)$.

Proof. We again look to [2] for guidance. Let (v_δ, B_δ) be a minimizer of (A.7) such that $\operatorname{div} B_\delta = 0$ with $\nu \cdot B_\delta = 0$ on $\partial\Omega$. Then there exists a ξ_δ such that $B_\delta = \operatorname{curl}\xi_\delta$, where $\Delta\xi_\delta = h_\delta = \operatorname{curl} B_\delta$, where $\xi_\delta = 0$ on $\partial\Omega$. Then

$$\int_{\Omega_\delta} |\nabla_{B_\delta} v_\delta|^2\, dx = \int_{\Omega_\delta} |\nabla v_\delta|^2 + |\nabla\xi_\delta|^2 + 2\,[\xi_\delta, v_\delta]\, dx,$$

where we have $[\xi_\delta, v_\delta] = (iv_\delta, \nabla v_\delta) \times \nabla\xi_\delta$. Then

$$\int_{\Omega_\delta} (iv_\delta, \nabla v_\delta) \times \nabla\xi_\delta\, dx = \int_{\Omega_\delta} \xi_\delta\, \mathrm{curl}(iv_\delta, \nabla v_\delta)dx + \sum_{j=1}^{d} \int_{\partial B_\delta(b_j)} \xi_\delta(iv_\delta, \partial_\tau v_\delta)d\omega$$
$$= \sum_{j=1}^{d} \int_{\partial B_\delta(b_j)} \xi_\delta(iv_\delta, \partial_\tau v_\delta)d\omega,$$

where τ is tangential vector to $\partial B_\delta(b_j)$ since $v_\delta \in \mathbb{S}^1$. We show that

$$\int_{\Omega_\delta} |\nabla_{B_\delta} v_\delta|^2\, dx \ge \pi d \log\frac{1}{\delta} - C.$$

Then the top follows. ∎

CLAIM A.4. *Let ξ be a solution to*

$$-\Delta^2\xi + \Delta\xi = 2\pi\sum_{j=1}^{d}\delta_{a_j} \text{ in } \Omega,$$

$$\xi = 0 \text{ on } \partial\Omega,$$

$$\Delta\xi = H_0 \text{ on } \partial\Omega.$$

Then $\xi_\delta \to \xi$ in $W^{2,2}(\Omega)$ as $\delta \to 0$, where $B_\delta = -\operatorname{curl}\xi_\delta = -\nabla^\perp\xi_\delta$.

Proof. By the minimality in the class,

$$-\Delta^2\xi_\delta + \Delta\xi_\delta = 0 \text{ in } \Omega,$$
$$\Delta\xi = 0 \text{ on } \partial\Omega.$$

Following an argument similar to [2] we establish the above. ∎

CLAIM A.5. *Let*

$$\overline{\mu}_\delta = \min\left\{\frac{1}{2}\int_{\Omega_\delta}|\nabla u|^2 dx, u \in H^1(\Omega_\delta, \mathbb{S}^1), \deg(u, \partial B_\delta(a_i)) = 1, \partial_\nu u = 0 \text{ on } \partial\Omega\right\}.$$

Then

$$\left|\frac{1}{2}\int_{\Omega_\delta}|\nabla v_\delta|^2\,dx - \overline{\mu}_\delta\right|^2 \to 0 \tag{A.9}$$

as $\delta \to 0$.

Proof. By standard elliptic estimates we find

$$\frac{1}{2}\int_{\Omega_\delta}|\nabla v_\delta|^2\,dx \geq \overline{\mu}_\delta + o(\delta),$$

and using $R(\delta) \to 0$ we decouple the phase terms from the magnetic field such that

$$E_\delta(v_\delta, B_\delta) = \frac{1}{2}\int_{\Omega_\delta}|\nabla v_\delta|^2 dx + \frac{1}{2}\int_\Omega |\nabla\xi|^2 + |\Delta\xi - H_0|^2 dx + 2\pi\sum_{j=1}^{d}\xi(a_j) + o(1);$$

see [2]. ∎

We can now use the analysis in [1] to characterize the form of the phase terms.

CLAIM A.6. *Let $1 < p < 2$; then the map v_δ remains bounded in $W^{1,p}$ and $v_\delta \to v$ in $W^{1,p}$ to $v = e^{i\Theta_a + ik} = \prod_{j=1}^{d}\frac{x-a_j}{|x-a_j|}e^{i\psi_\star}$, where $\psi_\star$ is harmonic and*

$$\partial_\nu\psi_\star = -\left(\prod_{j=1}^{d}\frac{x-a_j}{|x-a_j|}, \partial_\nu\prod_{j=1}^{d}\frac{x-a_j}{|x-a_j|}\right) \quad \text{on } \partial\Omega.$$

Proof. Note that v_δ takes values in $\mathbb{S}^1$, and therefore

$$\operatorname{curl}(iv_\delta, \nabla v_\delta) = 0 \in \Omega_\delta.$$

Let P be a solution to

$$\Delta P = 2\pi \sum_{j=1}^{d} \delta_{a_j} \text{ in } \Omega_\delta,$$
$$P = 0 \text{ in } \partial\Omega_\delta.$$

Then

$$\operatorname{curl}((iv_\delta, \nabla v_\delta) + \nabla P) = 0.$$

Therefore, there exists H_δ such that

$$(iv_\delta, \nabla v_\delta) + \nabla P = \operatorname{curl} H_\delta.$$

Following the analysis in [1] we get the claim. □

Proof of Theorem A.1. We show, for any configuration $\{a_j\} = \{a_1, \dots, a_d\}$,

$$\mu_\delta(a_j) = W(\{a_j\}) + \pi d \log \frac{1}{\delta} + o(1),$$

where $W(\{a_j\})$ is defined by (A.1)–(A.4).

From (A.9)

$$\mu_\delta(b_j) = \frac{1}{2}\int_{\Omega_\delta} |\nabla v_\delta|^2 dx + \frac{1}{2}\int_\Omega |\nabla\xi|^2 + |\Delta\xi - H_0|^2 dx + 2\pi \sum_{j=1}^{d} \xi(a_j) + o(1).$$

But (A.2) gives

$$\frac{1}{2}\int_\Omega |\nabla\xi|^2 + |\Delta\xi|^2 dx = -\pi \sum_{j=1}^{d} \xi(a_j) + \frac{H_0}{2}\int_{\partial\Omega} \partial_\nu \xi \, d\omega.$$

Then

$$\mu_\delta(a_j) = \frac{1}{2}\int_{\Omega_\delta} |\nabla v_\delta|^2 dx + \pi \sum_{j=1}^{d} \xi(a_j) - \frac{H_0}{2}\int_{\partial\Omega} \partial_\nu \xi d\omega + \frac{H_0^2}{2}|\Omega| + O(\delta) + o(1),$$

but from [1, 2]

$$\frac{1}{2}\int_{\Omega_\delta} |\nabla v_\delta|^2 dx = \pi d \log \frac{1}{\delta} + \omega(\{a_j\}, d, H_0) + O(\delta).$$

Then

$$W(\{a_j\}) = \omega(\{a_j\}, d, H_0) + \pi \sum_{j=1}^{d} \xi(a_j) - \frac{H_0}{2}\int_{\partial\Omega} \partial_\nu \xi \, d\omega + \frac{H_0^2}{2}|\Omega|.$$

We now use the canonical form of the phase, (A.6).

$$\omega(\{a_j\}, d, H_0) = -\pi \sum_{j=1}^{d} \log|a_i - a_j| - \pi \sum_{j=1}^{d} R(a_j) + \frac{1}{2}\int_{\partial\Omega} P \partial_\nu P \, d\omega,$$

where $R(x) = P(x) - \sum_{j=1}^{d} \log|x - a_j|$, and by previous discussion we know that $P = 0$ on $\partial\Omega$. Therefore, we get (A.1). □

A.2. Renormalized energy gradient. We now establish the form of the gradient of the renormalized energy. In this subsection we derive two forms of the gradient. Theorem A.7 is used in section 4.

THEOREM A.7. *Let* $u_\star = e^{i\Theta_a + i\psi_\star} = \sum_{j=1}^d \frac{x-a_j}{|x-a_j|} e^{i\psi_\star}$ *satisfy* $\Delta\psi_\star = 0$ *in* Ω *and* $\partial_\nu \psi_\star = -\partial_\nu \Theta_a$*; then* $e^{i\Theta_a + i\psi_\star} = \frac{x-a_j}{|x-a_j|} e^{i\psi_j}$ *defines* ψ_j*. Let* ξ *satisfy* $\Delta^2\xi - \Delta\xi + 2\pi \sum_{j=1}^d \delta_{a_j}$ *in* Ω *and* $\xi = 0$, $\Delta\xi = H_0$ *on* $\partial\Omega$*. If* $W(\{a_j\})$ *is as defined by* (A.1)–(A.4)*, then*

$$
\begin{aligned}
DW(\{a_j\}) &= 2\pi \left[\left(-\frac{\partial \psi_1}{\partial x_2}(a_1) + \frac{\partial \xi}{\partial x_1}(a_1), \frac{\partial \psi_1}{\partial x_1}(a_1) + \frac{\partial \xi}{\partial x_2}(a_1) \right), \dots, \right. \\
&\qquad \left. \left(-\frac{\partial \psi_d}{\partial x_2}(a_d) + \frac{\partial \xi}{\partial x_1}(a_d), \frac{\partial \psi_d}{\partial x_1}(a_d) + \frac{\partial \xi}{\partial x_2}(a_d) \right) \right] \\
&= 2\pi \left[\left(-\frac{\partial \psi_1}{\partial x_2}(a_1) + A_2(a_1), \frac{\partial \psi_1}{\partial x_1}(a_1) - A_1(a_1) \right), \dots, \right. \\
&\qquad \left. \left(-\frac{\partial \psi_d}{\partial x_2}(a_d) + A_2(a_d), \frac{\partial \psi_d}{\partial x_1}(a_d) - A_1(a_d) \right) \right].
\end{aligned} \tag{A.10}
$$

Proof. We will use [1] for inspiration. Fix all vortices except vortex a_j, which we call y. Therefore, we have

$$
\begin{aligned}
\Delta P &= 2\pi \sum_{i \neq j} \delta_{a_i} + 2\pi \delta_y \text{ in } \Omega, \\
P &= 0 \text{ on } \partial\Omega,
\end{aligned}
$$

and

$$
\begin{aligned}
-\Delta^2 \xi + \Delta \xi &= 2\pi \sum_{i \neq j} \delta_{a_i} + 2\pi \delta_y \text{ in } \Omega, \\
\Delta \xi &= H_0 \text{ on } \partial\Omega, \\
\xi &= 0 \text{ on } \partial\Omega.
\end{aligned} \tag{A.11}
$$

Set

$$
\begin{aligned}
\Psi(x,y) &= P(x,y) - \sum_{i \neq j} \log|x - a_i|, \\
R(x,y) &= \Psi(x,y) - \log|x-y|.
\end{aligned}
$$

Then the following equations hold:

$$
\begin{aligned}
\Delta \Psi &= 2\pi \delta_y \text{ in } \Omega, \\
\Psi &= -\sum_{i \neq j} \log|x - a_i| = h(x) \text{ on } \partial\Omega.
\end{aligned}
$$

Then for $a, \tilde{a} \in \Omega$

$$
\begin{aligned}
2\pi \left(\Psi(a,\tilde{a}) - \Psi(\tilde{a},a) \right) &= \int_{\partial\Omega} \Psi(\sigma,\tilde{a}) \partial_\nu \Psi(\sigma,a) - \Psi(\sigma,a) \partial_\nu \Psi(\sigma,\tilde{a}) d\sigma \\
&= \int_{\partial\Omega} h(\sigma) \left(\partial_\nu \Psi(\sigma,a) - \partial_\nu \Psi(\sigma,\tilde{a}) \right) d\sigma.
\end{aligned}
$$

Therefore, by the symmetry of the $\log|x-y|$

$$2\pi\left(R(a,\tilde{a})-R(\tilde{a},a)\right)=\int_{\partial\Omega}h(\sigma)\left(\partial_\nu P(\sigma,a)-\partial_\nu P(\sigma,\tilde{a})\right)d\sigma.$$

Now set

$$\zeta(x)=P(x,\tilde{a})-P(x,a)=R(x,\tilde{a})-R(x,a)+\log\frac{|x-\tilde{a}|}{|x-a|}.$$

Then

$$\begin{aligned}\Delta\zeta&=2\pi\left(\delta_{\tilde{a}}-\delta_a\right)\text{ in }\Omega,\\ \zeta&=0\text{ on }\partial\Omega.\end{aligned}$$

Multiplying by $\sum_{i\neq j}\log|x-a_i|$ and integrating yields

$$2\pi\sum_{i\neq j}\zeta(a_i)+\int_{\partial\Omega}\partial_\nu\zeta(\sigma)\sum_{i\neq j}\log|\sigma-a_i|\,d\sigma=2\pi\sum_{i\neq j}\log\frac{|\tilde{a}-a_i|}{|a-a_i|},$$

which gives

$$\begin{aligned}2\pi\left(R(a,\tilde{a})-R(\tilde{a},a)\right)&=-\int_{\partial\Omega}\left(\sum_{i\neq j}\log|\sigma-a_i|\right)\partial_\nu\zeta(\sigma)d\sigma\\&=2\pi\sum_{i\neq j}\zeta(a_i)+2\pi\sum_{i\neq j}\log\frac{|\tilde{a}-a_i|}{|a-a_i|}.\end{aligned}$$

Thus for $\tilde{a}$ fixed and varying a we get $2\pi\left(R_x(a,\tilde{a})-R_y(\tilde{a},a)\right)=2\pi\sum_{i\neq j}R_y(a_i,a)$ or

$$2\pi\left(R_x(a,a)-R_y(a,a)\right)=2\pi\sum_{i\neq j}R_y(a_i,a). \tag{A.12}$$

We now concern ourselves with (A.11). If we let $y=\tilde{a}$, then multiplying by $\xi(\sigma,a)$ and integrating over Ω yields

$$\begin{aligned}&2\pi\xi(a,\tilde{a})+2\pi\sum_{i\neq j}\xi(a_i,a)\\&\quad=H_0\int_{\partial\Omega}\partial_\nu\xi(\sigma,a)d\sigma-\int_\Omega\Delta\xi(\sigma,a)\Delta\xi(\sigma,\tilde{a})+\nabla\xi(\sigma,a)\nabla\xi(\sigma,\tilde{a})d\sigma,\end{aligned}$$

which implies

$$\begin{aligned}&2\pi\left(\xi(a,\tilde{a})-\xi(\tilde{a},a)\right)+2\pi\sum_{i\neq j}\left(\xi(a_i,a)-\xi(a_i,\tilde{a})\right)\\&\qquad=H_0\int_{\partial\Omega}\left(\partial_\nu\xi(\sigma,a)-\partial_\nu\xi(\sigma,\tilde{a})\right)d\sigma.\end{aligned}$$

Then for $\tilde{a}$ fixed and varying a we get

$$2\pi\left(\xi_x(a,a)-\xi_y(a,a)\right)+2\pi\sum_{i\neq j}\xi_y(a_i,a)=H_0\int_{\partial\Omega}\partial_\nu\xi_y(\sigma,a)d\sigma. \tag{A.13}$$

Therefore, noting that we can write the renormalized energy as

$$W(a) = -\pi \sum_{i\neq j} \log|a-a_i| - \pi \sum_{k\neq l\neq j} \log|a_k - a_l| - \pi \sum_{i\neq j} R(a_i,a) - \pi R(a,a) + \pi \sum_{i\neq j} \xi(a_i,a) + \pi\xi(a,a) + \frac{H_0^2}{2}|\Omega| - \frac{H_0}{2}\int_{\partial\Omega} \partial_\nu \xi(\sigma,a)d\sigma,$$

then

$$W_a(a) = -\pi \sum_{i\neq j} \frac{a-a_i}{|a-a_i|^2} - \pi \sum_{i\neq j} R_y(a_i,a) - \pi R_x(a,a) - \pi R_y(a,a) + \pi \sum_{i\neq j} \xi_y(a_i,a) + \xi_x(a,a) + \xi_y(a,a) - \frac{H_0}{2}\int_{\partial\Omega} \partial_\nu \xi_y(\sigma,a)d\sigma. \tag{A.14}$$

Using (A.12) and (A.13) in (A.14) gives

$$W_a(a) = -\pi \sum_{i\neq j} \frac{a-a_i}{|a-a_i|^2} - 2\pi R_x(a,a) + 2\pi\xi_x(a,a). \tag{A.15}$$

So if

$$\begin{aligned} -S_j(x) + \xi(x,a) &= -P(x,a) + \log|x-a| + \xi(x,a) \\ &= -R(x,a) - \pi \sum_{i\neq j} \log|x-a_i| + \xi(x,a), \end{aligned}$$

and since $\nabla\psi_j = -\nabla^\perp S_j$, then (A.15) becomes

$$W_a(a) = -2\pi\nabla S_j(a) + 2\pi\nabla\xi(a_j) = \begin{pmatrix} -\partial_2\psi_j(a) + A_2(a) \\ \partial_1\psi_j(a) - A_1(a) \end{pmatrix}.$$

Since ψ_j is the harmonic conjugate to $R(x,a)$, we establish Theorem A.7. ∎

A.3. Solution in the disk $B_R(0)$. We start with a configuration of d vortices at $a_j(0)$. Let us redefine ξ as our $\xi \longmapsto \xi + \chi$ such that

$$-\Delta^2\xi + \Delta\xi = 2\pi \sum_{j=1}^{d} \delta_{a_j(t)}$$

in $B_R(0)$, $\Delta\xi = \xi = 0$ on $\partial B_R(0)$,

$$-\Delta^2\chi + \Delta\chi = 0$$

in $B_R(0)$, $\Delta\chi = H_0$ and $\chi = 0$ on $\partial B_R(0)$,

$$\Delta P = 2\pi \sum_{j=1}^{d} \delta_{a_j(t)}$$

in $B_R(0)$, and $P = 0$ on $\partial B_R(0)$. For the solid disk, $B_R(0)$, we can solve ξ, χ, and P. Let $a_j = \rho_j e^{i\psi_j}$; then, if we use a general method for calculating Green's functions

[27], the associated Green's functions are

$$\begin{aligned}
\xi(r,\phi) &= -\sum_{j=1}^{d} \log \sqrt{\frac{R^2 - 2r\rho_j\cos(\phi-\psi_j) + \left(\frac{r\rho_j}{R}\right)^2}{r^2 - 2r\rho_j\cos(\phi-\psi_j)+\rho_j^2}} \\
&\quad + \sum_{j=1}^{d} K_0\left(\sqrt{r^2 - 2r\rho_j\cos(\phi-\psi_j)+\rho_j^2}\right) - \frac{I_0(\rho_j)I_0(r)K_0(R)}{I_0(R)} \\
&\quad - 2\sum_{j=1}^{d}\sum_{n=1}^{\infty} \frac{I_n(\rho_j)I_n(r)K_n(R)}{I_n(R)}\cos(n(\phi-\psi_j)), \\
\chi(r,\phi) &= H_0\left(\frac{I_0(r)}{I_0(R)} - 1\right), \\
\Phi(r,\phi) &= \sum_{j=1}^{d} \log \sqrt{\frac{r^2 - 2r\rho_j\cos(\phi-\psi_j)+\rho_j^2}{R^2 - 2r\rho_j\cos(\phi-\psi_j) + \left(\frac{r\rho_j}{R}\right)^2}},
\end{aligned}$$

where $I_n(r)$ and $K_n(r)$ are the modified Bessel functions of the first and second kinds.

Acknowledgments. This research was completed as part of a dissertation at the Courant Institute. The author would like to thank his advisor F.-H. Lin, who suggested this problem and provided valuable guidance. The author would also like to thank R.V. Kohn, J. Shatah, S. Gustafson, F. Han, and R. Jerrard for many interesting and helpful discussions. Finally, the author appreciates the comments of an anonymous referee that greatly improved the final draft.

DIFFRACTIVE NONLINEAR GEOMETRIC OPTICS FOR SHORT PULSES*

DEBORAH ALTERMAN† AND JEFFREY RAUCH‡

Abstract. This paper considers the behavior of pulse-like solutions of length $\varepsilon \ll 1$ to semilinear systems of hyperbolic partial differential equations on the time scale $t = O(1/\varepsilon)$ of diffractive geometric optics. The amplitude is chosen so that nonlinear effects influence the leading term in the asymptotics.

For pulses of larger amplitude so that the nonlinear effects are pertinent for times $t = O(1)$, accurate asymptotic solutions lead to transport equations similar to those valid in the case of wave trains (see [D. Alterman and J. Rauch, *J. Differential Equations*, 178 (2002), pp. 437–465]). The opposite is true here. The profile equation for pulses for $t = O(1/\varepsilon)$ is different from the corresponding equation for wave trains.

Formal asymptotics leads to equations for a leading term in the expansion and for correctors. The equations for the correctors are in general not solvable, being plagued by small divisor problems in the continuous spectrum. This makes the construction of accurate approximations subtle. We use low-frequency cutoffs depending on ε to avoid the small divisors.

1. Introduction.

The simplest pulse-like solutions arise as plane wave solutions of constant coefficient homogeneous hyperbolic equations.

1.1. Linear plane waves.

Assumption 1.1 (symmetric hyperbolicity).

$$L(\partial_y) = \partial_t + \sum_{j=1}^{d} A_j \partial_{x_j}, \tag{1.1}$$

where the coefficients A_j are constant $N \times N$ hermitian symmetric matrices.

The space-time variable is

$$y = (t, x) \in \mathbb{R}^{1+d} \qquad \text{with dual variables} \qquad (\tau, \xi).$$

If $f : \mathbb{R} \to \mathbb{C}^N$ is smooth and $\beta = (\tau, \xi)$, then the chain rule yields

$$L\, f(y.\beta) = L(\beta) f'(y.\beta).$$

Thus $L(f(y.\beta)) = 0$ when f' takes values in the nullspace of $L(\beta)$.

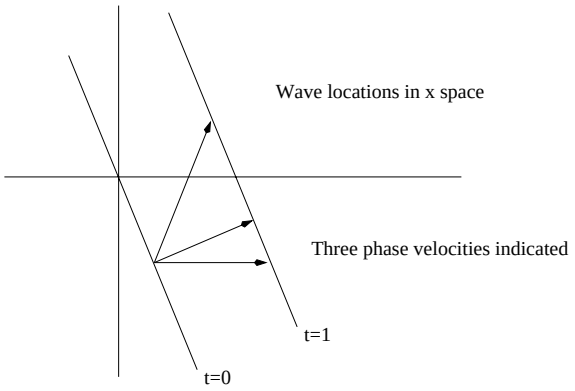

FIG. 1.1. *Planar fronts and phase velocities.*

Recall that the *characteristic variety*, $Char\, L$, is the set of $(\tau, \xi) \in \mathbb{R}^{1+d} \setminus 0$ satisfying the *dispersion relation* $\det L(\tau, \xi) = 0$. The characteristic variety is a real conic algebraic variety. For $\beta \in Char\, L$ one has the orthogonal decomposition

$$\mathbb{C}^N \;=\; \ker L(\beta) \;\oplus_\perp\; \text{range}\, L(\beta).$$

DEFINITION 1.2. *For $\beta \in Char\, L$, $\pi = \pi(\beta)$ is the orthogonal projection of $\mathbb{C}^N$ onto $\ker L(\beta)$. Define the partial inverse $Q(\beta)$ by*

$$Q\pi = 0, \qquad QL(\beta) = (I - \pi).$$

Then $u = f(y.\beta)$ is a *plane wave solution* of $L\,u = 0$ when $\beta \in Char\, L$ and f satisfies the polarization $\pi(\beta)\, f = f$.

1.2. Plane pulses and group velocity. If, in addition,

$$f(s) \to 0 \qquad \text{as} \qquad s \to \pm\infty,$$

then the family of plane wave solutions

$$u^\varepsilon \;:=\; f\Big(\frac{y.\beta}{\varepsilon}\Big)$$

describes pulses with planar wave fronts. If f has compact support, then the pulse u^ε is supported in an $O(\varepsilon)$ neighborhood of the hyperplane $y.\beta = 0$. The pulse cross section is given by the function $f^\varepsilon(s) := f(s/\varepsilon)$. The function f is called the *profile* of this pulse family. For profiles which tend to zero as $s \to \pm\infty$, the conditions $\pi(\beta) f = f$ and $\pi(\beta) f' = f'$ are equivalent.

At $t = 0$ (resp., $t = 1$) the pulse is supported near the planes $x.\xi = 0$ (resp., $x.\xi = -\tau$). This is indicated in Figure 1.1.

The phase is given by

$$y.\beta = t\tau + x.\xi = (x - \mathbf{v}t).\xi$$

for any velocity vector $\mathbf{v}$ satisfying

$$\mathbf{v}.\xi = -\tau.$$

For any such $\mathbf{v}$, the pulse family is given by

$$h^\varepsilon(x - \mathbf{v}t), \qquad \text{where} \qquad h^\varepsilon(x) := f^\varepsilon(x.\xi) = f(x.\xi/\varepsilon).$$

The pulse family can be viewed as moving with any one of these *phase velocities*. Three such velocities are sketched in Figure 1.1. In dimension $d > 1$, the phase velocity is not uniquely determined.

In contrast Definition 1.4 below shows that the *group velocity* is well defined at smooth points β of the characteristic variety.

For $\xi \neq 0$ the points $(\tau, \xi) \in Char\, L$ which project to ξ are those points such that $-\tau$ is a real eigenvalue of $\sum \xi_j A_j$. Thanks to the hyperbolicity assumption this is a finite and nonempty set of points for each ξ, and so the variety has codimension 1. As such its singular points form a variety of codimension at least 2 so that most points of the variety are smooth in the sense of the next assumption.

Assumption 1.3 (smooth point of the characteristic variety). $\beta = (\tau_0, \xi_0)$ belongs to the characteristic variety, and there is a conic neighborhood of ξ_0 and a real analytic function $\tau(\xi)$ on that neighborhood so that on a conic neighborhood of β the variety is given by the equation $\tau = \tau(\xi)$.

DEFINITION 1.4. *For β a smooth point of the characteristic variety, the* group velocity *is defined by*

$$\textit{group velocity} \;:=\; \mathbf{v} \;:=\; -\nabla_\xi \tau(\xi_0).$$

Since τ is homogeneous of degree 1 in ξ, the Euler homogeneity relation implies that

$$\xi.\nabla_\xi \tau(\xi) = \tau(\xi).$$

This implies that the group velocity satisfies $\mathbf{v}.\xi = -\tau$, the equation defining phase velocities. *The group velocity is the correct choice from among the possible phase velocities.*

1.3. Wave trains versus pulses. The geometric optics approximations which are most familiar concern the short wavelength limit of wave trains (see [24]). Wave trains and pulses are contrasted in Figure 1.2. Standard geometric optics yields equations for the envelope of wave trains. The methods go under the name of the slowly varying envelope approximation (SVEA) in science journals. A rule of thumb is that to use the SVEA the amplitude should not change more than 10% per wavelength. The wave train in Figure 1.2 is a borderline case for this rule. The rule of thumb suggests that one must have about ten to twenty wavelengths per pulse length before the SVEA is a reliable approximation.

For much shorter pulses like the one on the right in Figure 1.2 the SVEA is clearly inappropriate. Interest in short-pulse phenomena, which violate this slowly varying envelope assumption, has increased with the development of ultrafast lasers which produce few-cycle pulses. Rothenberg [25] clearly described the problems arising from treating short pulses as wave trains. Short-pulse solutions have been studied via full numerical simulation as in [28], [15], [16], [17], and [14]. A variety of asymptotic attacks are proposed and pursued in [13], [10], [21], [20], and [22]. In this paper the equation defining the leading order asymptotics is simple, and the approximation is proved to be accurate in the limit of small wavelength. Thus, from the above list only those which are consistent with our approximation can also be accurate. Only those whose equations are as simple can be competitive. It is our evaluation that with

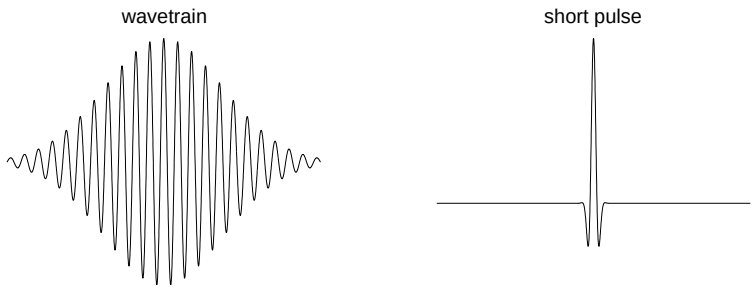

FIG. 1.2. *Example of a wave train and a short pulse.*

these two criteria in mind, a strong case can be made for our approach, but out of politeness we leave detailed comparison to the interested reader.

A difficulty in the study of pulses and wave trains is that the terms in the hyperbolic equation are of radically different magnitudes. Simply dropping the smaller ones and keeping the large ones usually leads to completely incorrect results. This is apparent in the simplest families of short pulses in $\mathbb{R}^{1+1}$,

$$u^\varepsilon := e^{-t} f((x-t)/\varepsilon), \qquad \partial_t u^\varepsilon + \partial_x u^\varepsilon + u^\varepsilon = 0.$$

The three terms of the equation are of sizes $O(1/\varepsilon)$, $O(1/\varepsilon)$, and $O(1)$. Dropping the relatively small $O(1)$ term yields the approximate solution $f((x-t)/\varepsilon)$, which is completely inaccurate.

A second difficulty in short-pulse asymptotics is that formally imitating the expansions of geometric optics generates equations for a leading term and correctors in an asymptotic expansion. Generically, the equations for the correctors cannot be solved. For the time scale $t = O(1)$, before the onset of diffractive effects, Yoshikawa [26], [27] showed that if one imposes physically unnatural assumptions guaranteeing that the corrector equations can be solved, then one does get an accurate description. In [5] we showed that the leading term is accurate without the unnatural assumption and extended the construction to the case of curved wavefronts. In a sequence of articles Carles and Rauch [7], [8], [9] studied the passage of spherical pulse solutions of semilinear wave equations across focal points.

For pulses on the scale of diffractive geometric optics, [1] includes some of the results of the present paper but notably does not prove a rate of convergence of the error as $\varepsilon \to 0$. There is also a study of pulses from Lannes' perspective of waves of broad spectrum (spectre large) in Barrailh and Lannes [6]. It is likely that the present analysis can be extended to nearly planar wavefronts as in the work of Dumas [12] for the diffractive wave train case. The present article contains the proofs of results described and used in [2] and [3].

Typical analytic expressions for the wave forms in Figure 1.2 are

$$\text{wave train :} \qquad a(x)\, e^{ix_1/\varepsilon} \qquad \text{with Fourier transform} \qquad \hat{a}(\xi - (1/\varepsilon), 0);$$

$$\text{pulse :} \qquad a(x_1/\varepsilon) b(x') \qquad \text{with Fourier transform} \qquad \varepsilon \hat{a}(\varepsilon\xi_1)\, \hat{b}(\xi').$$

The Fourier transform of the wave train is localized near $(1/\varepsilon, 0)$, which is called the carrier frequency in applications.

The Fourier transform of the pulse is spread over a box of dimensions $1/\varepsilon \times 1$ in (ξ_1, ξ') space. There is no carrier frequency. There is no exponential prefactor which

renders the quotient slowly varying. Some of the asymptotic approaches cited above are flawed because they insist on identifying a carrier frequency.

The approximations take the form

$$\begin{array}{lllll} \text{wave train :} & U(y\,,\, y.\beta/\varepsilon) & \text{with} & U(y\,,\,\theta) \ \text{ periodic in } \theta; \\ \text{pulse :} & U(y\,,\, y.\beta/\varepsilon) & \text{with} & U(y\,,\, z) \to 0 \ \text{ as } z \to \infty. \end{array}$$

In both cases $\beta \in Char\, L$.

In the latter case the function $U(y, \cdot)$ represents the profile of the pulse. In the former case it gives the envelope of the wave train. The pulse approximation can be called the *slowly varying profile approximation* since the profiles vary on the scale $O(1)$, which is much longer than the pulse length $O(\varepsilon)$.

1.4. The basic problem. Consider the behavior for $t \sim 1/\varepsilon$ of solutions to a system of equations

$$L(\partial_y)u^\varepsilon + \Phi(u^\varepsilon) = 0, \qquad u^\varepsilon(0,x) = \varepsilon^p f\left(x, \frac{x.\xi_0}{\varepsilon}\right), \tag{1.2}$$

where $\beta = (\tau_0, \xi_0)$ is a smooth point of the characteristic variety.

Assumption 1.5 (short pulse initial data). The function $f(x,z)$ satisfies

$$\forall\, N, \quad \langle \xi, \zeta\rangle^N \hat{f}(\xi,\zeta) \ \in \ L^\infty(\mathbb{R}^{d+1}). \tag{1.3}$$

This assumption is slightly stronger than the assumption $f(x,z) \in H^s(\mathbb{R}^{d+1}_{x,z})$ for all $s > 0$, used in [1] and [2], but is weaker than the Schwartz class. We will see that if one starts with f in the Schwartz class, then generically the pulse profile will not be Schwartz class for $t > 0$.

Assumption 1.6 (order J nonlinearity). The nonlinear function $\Phi(u)$ is of order $J \geq 2$ in the sense that for all $|\alpha| \leq J-1$, $\partial^\alpha \Phi(0) = 0$. Denote by $\Phi_J(u)$ the homogeneous Taylor polynomial of degree J approximating $\Phi(u)$ near $u = 0$.

Assumption 1.7 (magnitude of the solution). The exponent p is chosen so that $p = 1/(J-1)$. This insures that nonlinear effects become important on the time scale $t = O(1/\varepsilon)$.

To see that for waves of this amplitude it is reasonable that the nonlinear term is pertinent for times $t = O(1/\varepsilon)$ and not before, make the following back-of-an-envelope estimate. The nonlinear term is of size $\varepsilon^{pJ} = \varepsilon^{p+1}$. The accumulated effect of the nonlinear term for times $t = O(1/\varepsilon)$ is crudely estimated as

$$\frac{1}{\varepsilon}\, \varepsilon^{p+1} \ = \ \varepsilon^p.$$

Since ε^p is the size of our solution it is reasonable to expect the accumulated nonlinear effects to be important on these time scales.

Assumption 1.8 (polarization). The initial data f satisfy the polarization condition $\pi(\beta) f(x,z) = f(x,z)$.

Definition 1.9. *Define the scalar real second order homogeneous differential operator $P(\partial_x)$ by*

$$P(\partial_x) := -\frac{1}{2} \sum_{l,m=1}^{d} \left.\frac{\partial^2 \tau}{\partial \xi_l \partial \xi_m}\right|_{\xi=\xi_0} \frac{\partial^2}{\partial x_l \partial x_m}. \tag{1.4}$$

With these assumptions and definitions, the approximate pulse-like solutions have the form

$$u^{\varepsilon}_{\text{approx}} = \varepsilon^p U_0\Big(\varepsilon t, t, x, \frac{\tau_0 t + \xi_0.x}{\varepsilon}\Big), \qquad \lim_{|z|\to\infty} U_0(T,t,x,z) = 0. \tag{1.5}$$

The slowly varying profile U_0 is polarized as usual, $\pi(\beta)U_0 = U_0$, and is determined from its initial data by the pair of evolution equations

$$(\partial_t + \mathbf{v}.\partial_x)\, U_0 = 0, \qquad \partial_{Tz} U_0 + P(\partial_x)U_0 + \pi(\beta)\partial_z \Phi_J(U_0) = 0.$$

The second equation, for which $T = 0$ is characteristic, is the pulse version of the nonlinear Schrödinger equation.

As these are the key equations that need to be solved in order to understand the behavior of solutions to (1.2), we pause briefly to discuss them. The first equation is handled by writing

$$U_0(T,t,x,z) \;=\; \mathrm{U}_0(T, x - \mathbf{v}t, z). \tag{1.6}$$

The second equation is then equivalent to

$$\partial_{Tz}\mathrm{U}_0 + P(\partial_x)\mathrm{U}_0 + \pi(\beta)\partial_z\Phi_J(\mathrm{U}_0) = 0. \tag{1.7}$$

On the face of it, this is a differential equation in the $d+2$ variables T, x, z. In Proposition 4.1, it is shown that τ'' has rank $\le d-1$, so the differential operator has derivatives in at most $d+1$ independent directions.

To see that (1.7) gives rise to a well-defined evolution, write it formally as

$$\partial_T \mathrm{U}_0 + \partial_z^{-1} P(\partial_x)\mathrm{U}_0 + \pi(\beta)\Phi_J(\mathrm{U}_0) = 0.$$

The operator $\partial_z^{-1}P(\partial_x)$ is antisymmetric on the H^s, which for s large are invariant under Φ_J. Corollary 4.12 implies that for f as above, there is a $T_* \in\,]0,\infty]$ and a unique

$$\mathrm{U}_0 \;\in\; C\big([0,T_*[\,; \cap_s H^s(\mathbb{R}^{d+1}_{x,z})\big)$$

satisfying (1.7) and the initial condition $\mathrm{U}_0|_{T=0} = f$. If $T_* < \infty$, then for all $s > (d+1)/2$,

$$\lim_{T\to T_*} \big\|\mathrm{U}_0(T)\big\|_{H^s(\mathbb{R}^{d+1}_{x,z})} \;=\; \infty.$$

Having constructed U_0, define an approximate solution by (1.6) and (1.5). Our main theorem asserts that the error in this approximation tends to zero as $\varepsilon \to 0$. To motivate a class of natural norms to measure this error, note that $u^{\varepsilon}_{\text{approx}} = O(\varepsilon^p)$. Differentiating u^{ε} costs a power of $1/\varepsilon$ but no worse, so one has

$$\big(\varepsilon\partial\big)^{\alpha} u^{\varepsilon}_{\text{approx}} \;=\; O(\varepsilon^p). \tag{1.8}$$

Denote by $\mathbb{V}$ the $(d+1)$-dimensional space of constant coefficient vector fields. Choose a basis $V_1, \dots, V_d$ of the d-dimensional subspace of fields which are tangent to the hyperplane $\{y.\beta = 0\}$. Choose the basis so that $V_1, \dots, V_{d-1}$ are tangent to $\{t = 0\}$. Then these $d-1$ vectors are a basis for the constant fields on $\mathbb{R}^d_x$ which are

tangent to $\{x.\xi_0 = 0\}$. Differentiating in the d directions $V_1, \dots, V_d$ does not bring out a factor of $1/\varepsilon$, and one has

$$\big(V_1, \dots, V_d\big)^\alpha u^\varepsilon_{\text{approx}} \;=\; O(\varepsilon^p). \tag{1.9}$$

Choose a $(d+1)$st field W, which completes the $V_1, \dots, V_d$ to a basis of $\mathbb{V}$. Since $\xi \neq 0$, this vector field can be chosen tangent to $\{t = 0\}$. Define

$$V_{d+1} \;= \arctan(y.\beta)\, W. \tag{1.10}$$

This vector field vanishes on $\{y.\beta = 0\}$ and so is tangent to that hyperplane. Any smooth vector field tangent to this hyperplane is a linear combination of the V_j with smooth coefficients. Any smooth vector field on $\mathbb{R}^d_x$ tangent to $\{x.\xi_0 = 0\}$ is a combination of $V_1, \dots, V_{d-1}, V_{d+1}|_{\{t=0\}}$ with smooth coefficients. One also has $V_{d+1} u^\varepsilon_{\text{approx}} = O(\varepsilon^p)$. Summarizing, one has for all $\alpha \in \mathbb{N}^{2(d+1)}$

$$\big(\varepsilon\partial_y, V_1, \dots, V_d, V_{d+1}\big)^\alpha u^\varepsilon_{\text{approx}} = O(\varepsilon^p)\,. \tag{1.11}$$

The next result is a straightforward consequence of our main result, Theorem 8.1. Note the technical point that the derivation V_d is not permitted in the error estimate.

THEOREM 1.10. *With the notation of the previous paragraphs, for any $\underline{T} < T_*$ there is an $\varepsilon_0 > 0$ so that for $0 < \varepsilon < \varepsilon_0$ problem (1.2) has a smooth solution $u^\varepsilon \in C^\infty\big(\{0 \le T \le \underline{T}/\varepsilon\} \times \mathbb{R}^d\big)$. The solution is well approximated by $u^\varepsilon_{\text{approx}}$ in the sense that for all $\alpha \in \mathbb{N}^{2(d+1)}$ there is a $C = C(\alpha)$ so that*

$$\big\|\big(\varepsilon\partial_y, V_1, \dots, V_{d-1}, V_{d+1}\big)^\alpha \big(u^\varepsilon - u^\varepsilon_{\text{approx}}\big)\big\|_{L^\infty([0,\underline{T}/\varepsilon]\times\mathbb{R}^d)} \le C\varepsilon^{p+\min(1/5,p)}. \tag{1.12}$$

Remark. Using the techniques of [5], one can show that there is a different family of exact solutions $u^\varepsilon_{\text{ex}}$ with error estimate including V_d, that is,

$$\big\|\big(\varepsilon\partial_y, V_1, \dots, V_{d-1}, V_d, V_{d+1}\big)^\alpha \big(u^\varepsilon_{\text{ex}} - u^\varepsilon_{\text{approx}}\big)\big\|_{L^\infty([0,\underline{T}/\varepsilon]\times\mathbb{R}^d)} \le C\varepsilon^{p+\min(1/5,p)}. \tag{1.13}$$

The initial data of the new family are small perturbations of the initial data for the family u^ε.

2. Formal asymptotics. Seek approximate solutions to the initial value problems with short-pulse initial data,

$$L\,u^\varepsilon + \Phi(u^\varepsilon) = 0, \qquad u^\varepsilon(0,x) = \varepsilon^p\, f\left(x, \frac{x.\xi_0}{\varepsilon}\right), \qquad p = \frac{1}{J-1}. \tag{2.1}$$

The initial function f is assumed to satisfy Assumptions 1.5 and 1.8 for a β satisfying Assumption 1.3. J is the order of the nonlinearity as in Assumption 1.6.

Motivated by its success in the analogous situation of wave train solutions for which f is periodic in z, a first attempt is to try to find a profile

$$U(\varepsilon, T, y, z) \;\sim\; \sum_{j=0}^{\infty} \varepsilon^j\, U_j(T, y, z) \;=\; \sum_{j=0}^{\infty} \varepsilon^j\, U_j(T, t, x, z), \tag{2.2}$$

where $U_j \to 0$ as $|z| \to \infty$, and

$$u^\varepsilon \;\sim\; \varepsilon^p U\left(\varepsilon, \varepsilon t, y, \frac{y.\beta}{\varepsilon}\right). \tag{2.3}$$

The chain rule implies that a sufficient condition guaranteeing that u^ε defined by $u^\varepsilon = U(\varepsilon, \varepsilon t, y, y.\beta/\varepsilon)$ satisfies the differential equation $Lu^\varepsilon + \Phi(u^\varepsilon) = 0$ is that U satisfy

$$L\Big((\varepsilon\partial_T, 0) + \partial_y + \frac{\beta}{\varepsilon}\,\partial_z\Big)\,\varepsilon^p U(\varepsilon, T, y, z) + \Phi(\varepsilon^p U(\varepsilon, T, y, z)) = 0. \tag{2.4}$$

We pursue the less ambitious strategy, which is to satisfy

$$L\Big((\varepsilon\partial_T, 0) + \partial_y + \frac{\beta}{\varepsilon}\partial_z\Big)\,\varepsilon^p U(\varepsilon, T, y, z) + \Phi(\varepsilon^p U(\varepsilon, T, y, z)) \sim 0 \quad \text{as} \quad \varepsilon \to 0, \tag{2.5}$$

in which case

$$Lu^\varepsilon + \Phi(u^\varepsilon) \;\sim\; 0 \qquad \text{as} \quad \varepsilon \to 0. \tag{2.6}$$

We take U to be a sum of only three terms, in which case the equivalence in (2.5) can be no smaller than $O(\varepsilon^{2p+1})$. Two crucial facts affect our implementation of this strategy:

1. A trio of equations, derived in section 3, determine U_0 from its initial data at $t = T = 0$, namely,

$$\begin{aligned} &\pi(\beta)\, U_0 = U_0, \\ &\partial_t U_0 + \mathbf{v}.\partial_x U_0 = 0, \\ &\partial_T \partial_z U_0 + P(\partial_x) U_0 + \pi(\beta)\,\partial_z \Phi_J(U_0) = 0. \end{aligned} \tag{2.7}$$

The middle transport equation of (2.7) is solved by defining $\mathrm{U}_0(T, x, z)$ as in (1.6) so that

$$\mathrm{U}_0(T, x - \mathbf{v}t, z) = U_0(T, t, x, z). \tag{2.8}$$

2. The equations that one finds for the correctors $U_1, U_2, \ldots$ *are not in general solvable*. These equations involve the operator ∂_z^{-1}, which does not act well on a function whose Fourier transform with respect to z does not vanish at the origin, or equivalently, whose integral with respect to z is nonzero. For most choices of initial data, including those for which the transform vanishes on a neighborhood of zero at time $t = 0$, $\int U_0\, dz$ does not vanish at later times, and hence the equations for the correctors are not solvable.

The second fact is the main difficulty this paper overcomes. In our study [5] of geometric optics before the onset of diffractive effects, a similar problem was encountered. In that case we were able to construct correctors which had a different form than the leading term. In the present case of diffractive geometric optics, we do not know how to find such modified correctors.

A crucial ingredient in the analysis is the representation of the exact solution u^ε in terms of an "exact profile" $\mathcal{V}(\varepsilon, t, x, \phi)$ as in [18] and [19] by setting

$$u^\varepsilon = \varepsilon^p\, \mathcal{V}\Big(\varepsilon, t, x, \frac{x.\xi_0}{\varepsilon}\Big). \tag{2.9}$$

A key difference between $\mathcal{V}$ and U is that in the phase variable slot $x.\xi_0/\varepsilon$ replaces $\beta.y/\varepsilon$ for U. To maintain this distinction, the profile variable for which one inserts $x.\xi_0/\varepsilon$ is called ϕ and the profile variable associated with $\beta.y/\varepsilon$ is z. The chain rule shows that u^ε defined by (2.9) satisfies $Lu^\varepsilon + \Phi(u^\varepsilon) = 0$ when

$$L\Big(\partial_t, \partial_x + \frac{\xi_0}{\varepsilon}\partial_\phi\Big)\,\varepsilon^p \mathcal{V} + \Phi(\varepsilon^p \mathcal{V}) = 0. \tag{2.10}$$

The exact profile $\mathcal{V}(\varepsilon, t, x, \phi)$ is then determined from (2.10) and the initial condition

$$\mathcal{V}(\varepsilon, 0, x, \phi) = f(x, \phi). \tag{2.11}$$

The existence and uniqueness of solutions to the initial value problem formed by (2.10) and (2.11) are examined in section 4. Our error estimates proceed by proving that

$$U_0\Big(\varepsilon, \varepsilon t, t, x, \frac{t\tau_0}{\varepsilon} + \phi\Big) - \mathcal{V}(\varepsilon, t, x, \phi) \to 0 \qquad \text{as } \varepsilon \to 0. \tag{2.12}$$

To establish (2.12), first note that the chain rule implies that if (2.5) holds, then as $\varepsilon \to 0$,

$$L\Big(\partial_t, \partial_x + \frac{\xi_0}{\varepsilon}\partial_\phi\Big)\varepsilon^p U\Big(\varepsilon, \varepsilon t, t, x, \frac{t\tau_0}{\varepsilon} + \phi\Big) + \Phi\Big(\varepsilon^p U\Big(\varepsilon, \varepsilon t, t, x, \frac{t\tau_0}{\varepsilon} + \phi\Big)\Big) \sim 0. \tag{2.13}$$

Thus, if one has correctors $U_1, U_2, \ldots$ to the leading profile, then $U(\varepsilon, \varepsilon t, t, x, \frac{t\tau_0}{\varepsilon} + \phi)$ defines an accurate approximate solution of the equation for $\mathcal{V}$, and (2.12) would follow.

The difficulty is the absence of correctors—equivalently, the fact that we do not get (2.5). To circumvent this problem, we solve nearby problems with low-frequency cutoffs applied to the nonlinear term and the initial data. The cutoff problems propagate the property of having a Fourier transform with respect to z, which vanishes on a neighborhood of the origin.

Choose a cutoff function $\chi(\zeta) \in C^\infty(\mathbb{R})$ which vanishes for $|\zeta| < 1$ and is identically equal to 1 for $|\zeta| \geq 3/2$. Define

$$\chi^\delta := \chi^\delta(D_z) = \mathcal{F}_z^{-1}\chi(\zeta/\delta)\mathcal{F}_z,$$

where $\mathcal{F}_z$ denotes the Fourier transform in z. Seek

$$U^\delta(\varepsilon, T, y, z) = U_0^\delta(T, y, z) + \varepsilon U_1^\delta(T, y, z) + \varepsilon^2 U_2^\delta(T, y, z) \tag{2.14}$$

as an approximate solution of the cutoff equation

$$\begin{aligned} L\Big((\varepsilon\partial_T, 0) + \partial_y + \frac{\beta}{\varepsilon}\partial_z\Big)\varepsilon^p U^\delta(\varepsilon, T, y, z) + \chi^\delta(D_z)\,\Phi(\varepsilon^p U^\delta(\varepsilon, T, y, z)) \\ = O(\varepsilon^{2p+1}) \end{aligned} \tag{2.15}$$

with initial data

$$U^\delta(0, 0, x, z) = \chi^\delta(D_z) f(x, z). \tag{2.16}$$

Then the main result is proved by showing that

$$U_0^\delta(T, t, x, z) - U_0(T, t, x, z) = O(\delta), \tag{2.17}$$

and that for $\delta = \varepsilon^{0.4}$,

$$U^\delta\Big(\varepsilon, \varepsilon t, t, x, \frac{t\tau_0}{\varepsilon} + \phi\Big) - \mathcal{V}(\varepsilon, t, x, \phi) \;=\; O\big(\varepsilon^{\min\{p\,,\,1/5\}}\big). \tag{2.18}$$

The proof has three main steps. First the approximate solution U^δ satisfying (2.15) and (2.16) is constructed in Proposition 4.3 and Corollary 4.12. Proposition 5.1 proves the convergence of U_0^δ to U_0 as in (2.17). Then Proposition 7.1 proves the error estimate (2.18). Propositions 5.1 and 7.1 combine to yield (2.12).

3. Derivation of the profile equations for U_j^δ. In this section we analyze (2.15). The construction of the correctors U_1^δ and U_2^δ works for $\delta > 0$. For $\delta = 0$ the analysis shows that the construction of such an approximate solution is in general not possible.

Define U^δ by (2.14). By convention set $U_{-1}^\delta = U_{-2}^\delta = U_3^\delta = U_4^\delta = 0$. Then computing the left-hand side of (2.15) yields

$$\varepsilon^p\Big(\frac{1}{\varepsilon}L(\beta)\partial_z + L(\partial_y) + \varepsilon\partial_T\Big)(U_0^\delta + \varepsilon U_1^\delta + \varepsilon^2 U_2^\delta) + \chi^\delta(D_z)\Phi(\varepsilon^p U^\delta).$$

Grouping by powers of ε yields

$$\sum_{j=-1}^{j=3} \varepsilon^{p+j}\ \left\{\partial_T U_{j-1}^\delta + L(\partial_y)\,U_j^\delta + L(\beta)\,\partial_z U_{j+1}^\delta\right\} + \varepsilon^{p+1}\chi^\delta\Phi_J(U_0^\delta)$$
$$+\chi^\delta\left\{\Phi(\varepsilon^p U^\delta) - \Phi_J(\varepsilon^p U_0^\delta)\right\}. \tag{3.1}$$

We use formula (2.14) for times $t = O(1/\varepsilon)$. Thus if $U_1^\delta(T,t,x,z)$ grew linearly as $t \to \infty$, the term εU_1 would become as large as the U_0 term and would no longer be a small corrector. In order to represent a small correction it is necessary that U_1^δ grow sublinearly as $t \to \infty$. In fact, the correctors will be uniformly bounded in t, x. Sublinearity will play a crucial role in the derivation of the equations satisfied by the U_j.

3.1. Annihilating the ε^{p-1} term. This term is equal to

$$\varepsilon^{p-1}\,L(\beta)\partial_z U_0^\delta. \tag{3.2}$$

It is annihilated by imposing the polarization

$$U_0^\delta = \pi(\beta)U_0^\delta \tag{3.3}$$

from Definition 1.2. This is consistent with the polarization imposed on the initial data $f(x,z)$ in Assumption 1.8.

3.2. Annihilating the ε^p term. This term is equal to

$$\varepsilon^p\ \left\{L(\partial_y)\,U_0^\delta + L(\beta)\,\partial_z U_1^\delta\right\}. \tag{3.4}$$

To annihilate (3.4), one annihilates in turn its image under $\pi(\beta)$ and then its image under $Q(\beta)$.

Multiplying (3.4) by $\pi(\beta)$ eliminates the U_1^δ term since $\pi(\beta)L(\beta) = 0$. Using the polarization of U_0^δ from (3.3), one finds

$$\pi(\beta)L(\partial_y)\pi(\beta)\,U_0^\delta = 0.$$

As shown in [11], whenever β is a smooth point of the characteristic variety,

$$\pi(\beta)L(\partial_y)\pi(\beta) = \big(\partial_t + \mathbf{v}.\partial_x\big)\pi(\beta).$$

This identity yields the transport equation

$$\partial_t U_0^\delta + \mathbf{v}.\partial_x U_0^\delta = 0. \tag{3.5}$$

Setting $Q(\beta)$ times the ε^p term equal to zero yields

$$(I-\pi(\beta))\,\partial_z U_1^\delta = -Q(\beta)L(\partial_y)U_0^\delta. \tag{3.6}$$

This is the key troublesome equation for the correctors. In order for the equation to be solvable in $H^s(\mathbb{R}^{d+1}_{x,z})$, one needs

$$\frac{1}{\zeta}\,\mathcal{F}_z\Big(Q(\beta)\,L(\partial_y)U_0^\delta\Big)$$

to be square integrable near $\zeta = 0$. There is no reason to expect that this condition will be satisfied when $\delta = 0$.

However, (3.11) below defining U_0^δ for $\delta > 0$ implies that the Fourier transform of U_0^δ with respect to z vanishes on a neighborhood of $\zeta = 0$ as soon as it does so at $T = 0$. Thus we can solve (3.6) to find

$$(I-\pi(\beta))\,U_1^\delta = -(\partial_z)^{-1}Q(\beta)L(\partial_y)U_0^\delta \qquad \text{when} \quad \delta > 0. \tag{3.7}$$

3.3. Annihilating the ε^{p+1} term. This term is equal to

$$\varepsilon^{p+1}\Big(\partial_T U_0^\delta + L(\partial_y)\,U_1^\delta + L(\beta)\,\partial_z U_2^\delta + \chi^\delta \Phi_J(U_0^\delta)\Big). \tag{3.8}$$

When $\delta > 0$, use (3.7) to write

$$U_1^\delta = \pi(\beta)U_1^\delta + (I-\pi(\beta))U_1^\delta = \pi(\beta)U_1^\delta - (\partial_z)^{-1}Q(\beta)L(\partial_y)U_0^\delta.$$

Then setting $\pi(\beta)$ times (3.8) equal to zero yields

$$\begin{aligned}\Big(\partial_t + \mathbf{v}.\partial_x\Big)\pi(\beta)U_1^\delta &= \pi\,L(\partial_y)\pi U_1^\delta \\ &= -\Big(\partial_T U_0^\delta - \partial_z^{-1}\pi L(\partial_y)QL(\partial_y)U_0^\delta + \pi\,\chi^\delta\Phi_J(U_0^\delta)\Big).\end{aligned} \tag{3.9}$$

Thanks to (3.5) and (3.7), the right-hand side is constant along the integral curves of $\partial_t + \mathbf{v}.\partial_x$. Therefore (3.9) implies that U_1^δ grows linearly along these straight lines unless the constant value is zero. As pointed out in the paragraph before section 3.1, such growth is unacceptable. Thus we must have

$$(\partial_t + \mathbf{v}.\partial_x)\,\pi(\beta)U_1^\delta = 0 \tag{3.10}$$

and

$$\partial_T\partial_z U_0^\delta - \pi L(\partial_y)QL(\partial_y)U_0^\delta + \pi\,\chi^\delta\partial_z\Phi_J(U_0^\delta) = 0. \tag{3.11}$$

As shown in [11], at smooth points of the characteristic variety of $L(\partial_y)$,

$$\pi(\beta)\,L(\partial_y)\,Q\,(\beta)\,L(\partial_y)\,\pi(\beta) \;=\; -P(\partial_x)\,\pi(\beta), \tag{3.12}$$

where the second order differential operator $P(\partial_x)$ is defined in (1.4). Using (3.12) in (3.11), one gets the fundamental equation

$$\partial_T\partial_z U_0^\delta + \,P(\partial_x)U_0^\delta + \pi\,\chi^\delta\partial_z\Phi_J(U_0^\delta) = 0. \tag{3.13}$$

Note in passing that formulas (3.5), (3.7), and (3.10) imply that U_1^δ satisfies the transport equation

$$\partial_t U_1^\delta + \mathbf{v}.\partial_x U_1^\delta = 0. \tag{3.14}$$

It remains to annihilate the product of $Q(\beta)$ with the ε^{p+1} term. This yields

$$(I-\pi(\beta))\partial_z U_2^\delta = -Q(\beta)\Big(\partial_T U_0^\delta + L(\partial_y)\,U_1^\delta + \chi^\delta \Phi_J(U_0^\delta)\Big). \tag{3.15}$$

Thanks to the polarization (3.3), $Q(\beta)\partial_T U_0^\delta = 0$. When $\delta > 0$, (3.15) is solvable and yields

$$(I-\pi(\beta))\,U_2^\delta = -Q(\beta)\,\partial_z^{-1}\Big(L(\partial_y)\,U_1^\delta + \chi^\delta \Phi_J(U_0^\delta)\Big). \tag{3.16}$$

The above calculations pose no constraints on $\pi(\beta)U_2^\delta$ and $\pi(\beta)U_1^\delta|_{t=0}$. For simplicity we set them equal to zero, and using (3.14) we find that

$$\pi(\beta)U_1^\delta = \pi(\beta)U_2^\delta = 0. \tag{3.17}$$

With these choices, (3.16) implies that

$$(\partial_t + \mathbf{v}.\partial_x)\; U_j^\delta = 0 \qquad \text{for} \quad j = 0,1,2. \tag{3.18}$$

Corrector summary. Once U_0^δ is known with the Fourier transform vanishing on a neighborhood of $\zeta = 0$, the correctors are defined by

$$U_1^\delta = -\partial_z^{-1}\,Q(\beta)\,L(\partial_y)\,U_0^\delta, \tag{3.19}$$

$$U_2^\delta = -\partial_z^{-1}\,Q(\beta)\,\Big(L(\partial_y)\,U_1^\delta + \chi^\delta \Phi_J(U_0^\delta)\Big). \tag{3.20}$$

Residual summary. With the profiles defined in this way,

$$\begin{aligned} &L\Big((\varepsilon\partial_T,0)+\partial_y+\frac{\beta}{\varepsilon}\partial_z\Big)\varepsilon^p U^\delta + \chi^\delta(D_z)\,\Phi(\varepsilon^p U^\delta) \\ &\qquad = \varepsilon^{p+2}\Big(\varepsilon\partial_T U_2^\delta + L(\partial_y)U_2^\delta + \partial_T U_1^\delta\Big) + \chi^\delta(D_z)\Big[\Phi(\varepsilon^p U^\delta) - \Phi_J(\varepsilon^p U_0^\delta)\Big]. \end{aligned} \tag{3.21}$$

4. Solvability of the profile equations for $\mathbf{U_0}(\boldsymbol{T},\boldsymbol{x},\boldsymbol{z})$. U_0^δ must be constructed satisfying the equations

$$\begin{aligned} &\pi(\beta)\,U_0^\delta = U_0^\delta, \\ &\partial_t U_0^\delta + \mathbf{v}.\partial_x U_0^\delta = 0, \\ &\partial_T\partial_z U_0^\delta + P(\partial_x)U_0^\delta + \pi(\beta)\,\chi^\delta(D_z)\,\partial_z\Phi_J(U_0^\delta) = 0. \end{aligned} \tag{4.1}$$

Equations (2.7) satisfied by U_0 are obtained by setting $\delta = 0$. Taking advantage of the middle equations of (2.7) and (4.1), define $\mathrm{U}_0(T,x,z)$ and $\mathrm{U}_j^\delta(T,x,z)$ by

$$U_0(T,t,x,z) := \mathrm{U}_0(T,x-\mathbf{v}t,z), \qquad U_j^\delta(T,t,x,z) := \mathrm{U}_j^\delta(T,x-\mathbf{v}t,z).$$

The last equation in (2.7) is then equivalent to

$$\partial_T\,\partial_z \mathrm{U}_0 + P(\partial_x)\,\mathrm{U}_0 + \pi(\beta)\,\partial_z\Phi_J(\mathrm{U}_0) = 0. \tag{4.2}$$

The *nonlinear diffractive pulse equation* (4.2) has $T = 0$ as a characteristic surface. In the wave train case one would have found an equation of nonlinear Schrödinger type at this stage. It too has $T = 0$ characteristic. In both cases the equation gives rise to a well-defined time evolution, at least locally in T.

Before proving this, we first prove that while the diffractive pulse equation appears to have $d+2$ independent variables (t,x,z), it actually involves one less direction of differentiation.

PROPOSITION 4.1. *The matrix $\partial^2\tau/\partial\xi_j\partial\xi_k$ has rank at most $d-1$. In fact $\xi_0 \in \ker \partial^2\tau(\xi_0)/\partial\xi_j\partial\xi_k$.*

Proof. Since $\tau(\xi)$ is homogeneous of degree 1, it follows that for all j, $\partial\tau(\xi)/\partial\xi_j$ is homogeneous of degree zero. Therefore

$$\frac{d}{d\lambda}\frac{\partial\tau(\lambda\xi)}{\partial\xi_j} \;=\; 0.$$

Expanding the left-hand side using the chain rule yields

$$\sum_i \xi_i \,\frac{\partial^2\tau(\lambda\xi)}{\partial\xi_i\partial\xi_j} \;=\; 0.$$

Setting $\lambda = 1$ yields the desired result. ∎

In coordinates so that $\xi_0 = (1,0,\ldots,0)$ this implies that $\tau_{1,j} = \tau_{j,1} = 0$ so that

$$P(\partial_x) = -\frac{1}{2}\sum_{j,k=\mathbf{2}}^{d} \frac{\partial^2\tau(1,0,\ldots,0)}{\partial\xi_j\partial\xi_k}\,\frac{\partial^2}{\partial x_j\partial x_k}.$$

This decrease in the number of spatial dimensions decreases the complexity of the numerical implementation of the results of this paper.

The local solvability of the nonlinear diffractive pulse equation can be proved in the Sobolev spaces $H^s(\mathbb{R}^{1+d})$ with $s > (d+1)/2$ by standard methods. The results would apply for general nonlinearities. A weakness is that for the Fourier transform of $\mathrm{U}_0(T,x,z)$ with respect to the x,z variables one has only L^2 control locally.

The nonlinear term in the profile equation is always a polynomial. Because of this, we have the luxury of working in spaces related to the Wiener algebra which give us L^1 control of the Fourier transform. That in turn permits us to get L^∞ control of $\mathcal{F}_z U_0$ by estimates entirely on the Fourier side. These L^∞ estimates imply that $(I-\chi^\delta)\mathrm{U}_0 = O(\delta)$ as $\delta \to 0$. The usual strategy to obtain sup norm estimates for Fourier transforms is to prove decay rates as $x, z \to \infty$. The argument completely on the Fourier side circumvents that avenue. We do not prove any decay rates beyond those implied by being in $\cap_s H^s(\mathbb{R}^{d+1}_{x,z})$.

DEFINITION 4.2. *The* Wiener algebra $\mathbb{A}(\mathbb{R}^M)$ *is the Banach space of tempered distributions on $\mathbb{R}^M$ with the property that their Fourier transform belongs to $L^1(\mathbb{R}^M)$. The norm is the L^1 norm of the Fourier transform.*

Recall that for any $1 \le p \le \infty$ the map

$$L^1 \times L^p \ni f, g \quad\to\quad f * g \in L^p$$

is a continuous bilinear map from $L^1 \times L^p$ to L^p and

$$\|f * g\|_{L^p} \le \|f\|_{L^1}\,\|g\|_{L^p}. \tag{4.3}$$

The inequality (4.3) with $p = 1$ shows that the map $\mathrm{U} \to \Phi_J(\mathrm{U})$ maps bounded sets of $\mathbb{A}$ to bounded sets of $\mathbb{A}$. To study the continuity of the map note that the difference $\Phi_J(\mathrm{U}) - \Phi_J(\mathrm{V})$ can be expressed as

$$\Phi_J(\mathrm{U}) - \Phi_J(\mathrm{V}) = \sum_i^d P_i(\mathrm{U},\mathrm{V})\left(\mathrm{U}_i - \mathrm{V}_i\right)$$

with polynomials P_i of degree less than J. Then inequality (4.3) shows that the map $\mathrm{U} \to \Phi_J(\mathrm{U})$ is uniformly Lipschitzian on bounded subsets of $\mathbb{A}$ to $\mathbb{A}$.

The initial value problem for the profile equation (4.2) with initial value

$$\mathrm{U}|_{T=0} = G(x,z)$$

is equivalent to the integral identities

$$\widehat{\mathrm{U}}(T) = e^{-iP(\xi)T/\zeta}\,\widehat{G} + \int_0^T e^{-iP(\xi)(T-\sigma)/\zeta}\;\pi(\beta)\,\mathcal{F}\big(\Phi_J(\mathrm{U}(\sigma))\big)\;d\sigma \tag{4.4}$$

for $0 \le T \le \underline{T}$.

The multipliers $e^{iP(\xi)t/\zeta}$ have modulus one so they define isometries on $\mathbb{A}(\mathbb{R}^{d+1}_{x,z})$. This, together with the uniform Lipschitzian property, is enough to make Picard's classical existence proof work, yielding the following result.

PROPOSITION 4.3. *For each $G \in \mathbb{A}$ there is a $T_* = T_*(G) \in \,]0,\infty]$ and a unique maximal solution $\mathrm{U} \in C\big([0,T_*[\,;\mathbb{A}\big)$ to the profile equation (4.2), which in addition satisfies the initial condition $\mathrm{U}|_{T=0} = G$. The time T_* is uniformly strictly positive on bounded subsets of $\mathbb{A}$, and if $T_* < \infty$, then*

$$\lim_{T\to T_*} \|\mathrm{U}(T)\|_{\mathbb{A}} \;=\; \infty. \tag{4.5}$$

The next result is a regularity theorem which asserts that if the initial data lies in a smaller Banach space $\mathbb{B}$, then the maximal solution is a continuous function with values in $\mathbb{B}$.

DEFINITION 4.4. *A Banach space $\mathbb{B} \subset \mathbb{A}$ is* admissible *if it has the following three properties:*

1. *The inclusion map $\mathbb{B} \to \mathbb{A}$ is continuous.*
2. *The map $\mathrm{U} \to \Phi_J(\mathrm{U})$ maps $\mathbb{B}$ to itself and is uniformly Lipschitzian on subsets of $\mathbb{B}$ which are bounded in $\mathbb{A}$.*
3. *For $T \neq 0$, the Fourier multipliers $e^{iTP(\xi)/\zeta}$ are isometries from $\mathbb{B}$ to itself.*

The following are examples of admissible Banach spaces.

Example 4.5. If $1 < p \le \infty$, then $\mathbb{B} := \{\mathrm{U} \in \mathbb{A} : \widehat{\mathrm{U}} \in L^p\}$ is admissible.

Example 4.6. If $s > (d+1)/2$, then $H^s(\mathbb{R}^{d+1})$ is admissible.

Example 4.7. If $\mathbb{B}_1$ and $\mathbb{B}_2$ are admissible, then so is the intersection $\mathbb{B}_1 \cap \mathbb{B}_2$.

Proof for Example 4.5. Only property 2 in the definition is not immediate. One needs to prove that for every $R > 0$ there is a constant C so that if $\|\mathrm{U}\|_{\mathbb{A}} \le R$ and $\|\mathrm{V}\|_{\mathbb{A}} \le R$, then

$$\big\|\Phi_J(\mathrm{U}) - \Phi_J(\mathrm{V})\big\|_{\mathbb{B}} \le C\,\big\|\mathrm{U}-\mathrm{V}\big\|_{\mathbb{B}}. \tag{4.6}$$

Taylor's theorem implies that

$$\Phi_J(\mathrm{U}) - \Phi_J(\mathrm{V}) = \Psi(\mathrm{U},\mathrm{V})(\mathrm{U}-\mathrm{V}),$$

where Ψ is a matrix-valued homogeneous polynomial of degree $J-1$.

To estimate the L^p norm of the Fourier transform use Young's inequality

$$\begin{aligned}\big\|\mathcal{F}\Big(\Phi_J(\mathrm{U}) - \Phi_J(\mathrm{V})\Big)\big\|_{L^p} &\le \big\|\mathcal{F}\Big(\Psi(\mathrm{U},\mathrm{V})\Big)\big\|_{L^1}\big\|\mathcal{F}(\mathrm{U}-\mathrm{V})\big\|_{L^p}\\ &\le C(R)\,\|\mathrm{U}-\mathrm{V}\|_{\mathbb{B}}. \qquad \square\end{aligned}$$

PROPOSITION 4.8. *If $\mathbb{B}$ is admissible and $G \in \mathbb{B}$, then the maximal solution found in Proposition* 4.3 *satisfies*

$$\mathrm{U} \in C([0, T_*[\,; \mathbb{B}). \tag{4.7}$$

Proof. From the admissibility properties one easily demonstrates using Picard's method that the integral equation (4.4) has a maximal solution

$$\mathrm{U} \in C([0, T^*(G)[\,; \mathbb{B}),$$

and if $T^* < \infty$, then

$$\lim_{T \to T^*} \|\mathrm{U}(T)\|_{\mathbb{B}} \;=\; \infty. \tag{4.8}$$

Since this solution is continuous with values in $\mathbb{A}$ it follows that $T^*(G) \le T_*(G)$. The result of the proposition follows from establishing the inequality $T^*(G) \ge T_*(G)$.

The proof is indirect. We suppose on the contrary that $T^*(G) < T_*(G)$ and derive a contradiction.

If $T^*(G) < T_*(G)$, then U is continuous on $[0, T^*]$ with values in $\mathbb{A}$, and so there is an $R < \infty$ so that

$$\|\mathrm{U}(T)\|_{\mathbb{A}} \le R \qquad \text{for} \quad 0 \le T \le T^*.$$

Taking the $\mathbb{B}$ norm of (4.4) and using the last two properties from the definition of admissibility yields

$$\|\mathrm{U}(T)\|_B \le \|G\|_B + \int_0^T C\,\|\mathrm{U}(\sigma)\|_{\mathbb{B}}\, d\sigma \qquad \text{for} \quad 0 \le T < T^*.$$

Gronwall's inequality implies that

$$\|\mathrm{U}(T)\|_B \le \|G\|_B\; e^{CT} \qquad \text{for} \quad 0 \le T < T^*.$$

In particular, (4.8) is violated. This contradiction proves the proposition. ∎

Our main existence result is a corollary of Propositions 4.9 and 4.10 below.

PROPOSITION 4.9. *Define $\mathbb{B}$ to be the closed subspace of $\mathbb{A}(\mathbb{R}^{d+1}_{x,z})$ consisting of functions* U *such that* (i) $\widehat{\mathrm{U}} \in L^\infty(\mathbb{R}^{d+1}_{\xi,\zeta})$, *and* (ii) *for all $\mu > 0$, $\widehat{\mathrm{U}}$ is uniformly continuous on $\{|\zeta| \ge \mu\}$. Then $\mathbb{B}$ is admissible.*

Proof. $\mathbb{B}$ is a closed subspace of Example 4.5 with $p = \infty$. Thus to prove that $\mathbb{B}$ is admissible it suffices to show that Φ_J maps $\mathbb{B}$ to itself. In fact, more is true. If $\widehat{\mathrm{U}} \in L^1 \cap L^\infty$ (which is true if $\mathrm{U} \in \mathbb{B}$), then $\mathcal{F}_{x,z}\big(\Phi_J(\mathrm{U})\big)$ is bounded and uniformly continuous, which implies that $\Phi_J(\mathrm{U}) \in \mathbb{B}$.

To prove the stronger assertion of the last sentence, write Φ_J as a sum of terms each of which is a product of a monomial of order $J-1$ and a monomial of order 1. The Fourier transform of the first factor belongs to L^1 and the Fourier transform of the second belongs to L^∞. The desired result follows from the fact that the convolution of an element of L^1 with an element of L^∞ is uniformly continuous. ∎

PROPOSITION 4.10. *If $0 \le m \in \mathbb{Z}$ and $1 \le p \le \infty$, then the subspace*

$$\mathbb{B}^{m,p} \;:=\; \Big\{ \mathrm{U} \in \mathbb{A} \,:\, \langle \eta \rangle^m\, \widehat{\mathrm{U}}(\eta) \,\in L^p(\mathbb{R}^N_\eta) \Big\}$$

is admissible.

Proof. This proof follows [23]. The only sticky point is estimate (4.6). Toward that end one must show that for K-fold products one has

$$\text{(4.9)}\quad \left\|\mathrm{U}_j\right\|_{\mathbb{A}} \;\le\; R \quad\Rightarrow\quad \left\|\langle\eta\rangle^m\,\widehat{\mathrm{U}}_1 * \widehat{\mathrm{U}}_2 * \cdots * \widehat{\mathrm{U}}_K\right\|_{L^p} \;\le\; C(K,R)\sum_j \left\|\langle\eta\rangle^m\,\widehat{\mathrm{U}}_j\right\|_{L^p}.$$

Written out, this becomes

$$\text{(4.10)}\quad \begin{aligned}&\Big\|\int \langle\eta\rangle^m\,\widehat{\mathrm{U}}_1(\eta-\eta_1)\,\widehat{\mathrm{U}}_2(\eta_1-\eta_2)\cdots\widehat{\mathrm{U}}_K(\eta_K)\;\,d\eta_1\,d\eta_2\cdots d\eta_{K-1}\,d\eta_K\Big\|_{L^p}\\ &\qquad\le\; C(K,R)\sum_j\left\|\langle\eta\rangle^m\widehat{\mathrm{U}}_j\right\|_{L^p}.\end{aligned}$$

Note that

$$\eta = (\eta-\eta_1)+(\eta_1-\eta_2)+\cdots+(\eta_{K-1}-\eta_K)+\eta_K,$$

so

$$|\eta| \le |\eta-\eta_1|+|\eta_1-\eta_2|+\cdots+|\eta_{K-1}-\eta_K|+|\eta_K|.$$

Define $\eta_0 := \eta, \eta_{K+1} := 0$, so the summands on the right are equal to $|\eta_{j-1}-\eta_j|$ for $1\le j\le K+1$. The integral in (4.10) is split into $K+1$ pieces, the integrals over sets

$$E(j) \;:=\; \Big\{(\eta,\eta_1,\ldots,\eta_K)\;:\;|\eta_{j-1}-\eta_j| = \max_{1\le k\le K}\big\{|\eta_{k-1}-\eta_k|\big\}\Big\}.$$

The sets E_j overlap in measure zero sets, so it suffices to show that

$$\begin{aligned}&\Big\|\int_{E(j)}\langle\eta\rangle^m\,\widehat{\mathrm{U}}_1(\eta-\eta_1)\,\widehat{\mathrm{U}}_2(\eta_1-\eta_2)\cdots\widehat{\mathrm{U}}_K(\eta_K)\;\,d\eta_1\,d\eta_2\cdots d\eta_{K-1}\,d\eta_K\Big\|_{L^P}\\ &\qquad\le\; C(K,R)\sum_j\left\|\langle\eta\rangle^m\widehat{\mathrm{U}}_j\right\|_{L^p}.\end{aligned}$$

On $E(j)$, $|\eta|\le K|\eta_{j-1}-\eta_j|$ so

$$\begin{aligned}&\int_{E(j)}\langle\eta\rangle^m\,|\widehat{\mathrm{U}}_1(\eta-\eta_1)|\cdot|\widehat{\mathrm{U}}_2(\eta_1-\eta_2)|\cdots|\widehat{\mathrm{U}}_K(\eta_K)|\;d\eta_1 d\eta_2\cdots d\eta_{K-1}d\eta_K\\ &\quad\le C(K)\int_{E(j)}\langle\eta_{j-1}-\eta_j\rangle^m\,|\widehat{\mathrm{U}}_1(\eta-\eta_1)|\cdot|\widehat{\mathrm{U}}_2(\eta_1-\eta_2)|\\ &\qquad\qquad\cdots|\widehat{\mathrm{U}}_K(\eta_K)|\;d\eta_1 d\eta_2\cdots d\eta_{K-1}d\eta_K.\end{aligned}$$

Young's inequality bounds the L^p norm of the integral on the right by

$$\left\|\langle\eta\rangle^m\widehat{\mathrm{U}}_j\right\|_{L^p}\prod_{k\ne j}\left\|\widehat{\mathrm{U}}_k\right\|_{L^1} \;=\; C(R)\left\|\langle\eta\rangle^m\widehat{\mathrm{U}}_j\right\|_{L^p}.$$

This completes the proof. ∎

DEFINITION 4.11. *$\mathcal{B}$ is the Fréchet space of tempered distributions $\mathrm{V}(x,z)$ so that*

1. *$\widehat{\mathrm{V}}(\xi,\zeta)\in L^\infty(\mathbb{R}^{d+1})$ and for every $\mu>0$ is uniformly continuous on the set $\{(\xi,\zeta)\;:\;|\zeta|\ge\mu\}$.*

2. *For every nonnegative integer* m

$$\langle \xi, \zeta \rangle^m \, \widehat{\mathrm{V}}(\xi, \zeta) \in L^\infty(\mathbb{R}^{d+1}).$$

Combining Propositions 4.9 and 4.10 shows that $\mathcal{B}$ is the intersection of admissible spaces. By Example 4.7, this implies the following corollary.

COROLLARY 4.12. *Suppose that* $\mathrm{U} \in C\big([0, T_*[\,; \mathbb{A})\big)$ *is a maximal solution of the profile equation* (4.2) *and that* $\mathrm{U}\big|_{T=0} \in \mathcal{B}$. *Then*

$$\mathrm{U} \in C\big([0, T_*[\,; \mathcal{B}\big). \tag{4.11}$$

This corollary gives us more than enough control on the leading profile to carry out our analysis. The most interesting aspect is the sup norm control near $\zeta = 0$ *without* continuity.

5. Construction of $\mathbf{U_0^\delta}$. A perturbation argument is the key to solving the $\delta > 0$ equations (4.1). The third equation in (4.1) is equivalent to

$$\partial_T \partial_z \mathrm{U}_0^\delta + P(\partial_x)\mathrm{U}_0^\delta + \pi(\beta)\, \chi^\delta(D_z)\, \partial_z \Phi_J(\mathrm{U}_0^\delta) = 0. \tag{5.1}$$

Multiplying (4.2) by $\chi^\delta(D_z)$ yields

$$\partial_T\, \partial_z \chi^\delta(D_z)\, \mathrm{U}_0 + P(\partial_x)\, \chi^\delta(D_z)\, \mathrm{U}_0 + \pi(\beta)\, \chi^\delta(D_z)\, \partial_z \Phi_J(\mathrm{U}_0) = 0. \tag{5.2}$$

This equation resembles (5.1), as demonstrated in the next proposition, which shows that the solution of (5.1) can be obtained as a small perturbation of $\chi^\delta(D_z)\, \mathrm{U}_0$.

PROPOSITION 5.1. *Suppose that* $\mathrm{U}_0 = \pi(\beta)\mathrm{U}_0 \in C\big([0, \underline{T}]\,; \cap_m \mathbb{B}^{m,\infty}\big)$ *satisfies* (4.2). *Then there is a* $\delta_0 > 0$ *so that for* $0 < \delta < \delta_0$ *the initial value problem defined by* (5.2) *with initial condition*

$$\mathrm{U}_0^\delta\big|_{T=0} = \chi^\delta(D_z)\mathrm{U}_0\big|_{T=0} \tag{5.3}$$

has a unique solution $\mathrm{U}_0^\delta \in C([0, \underline{T}]\,; \cap_m \mathbb{B}^{m,\infty})$, *and for all* $1 \le q < \infty$ *and* $0 \le m < \infty$,

$$\sup_{0 \le T \le \underline{T}} \big\| \mathrm{U}_0^\delta(T) - \chi^\delta\, \mathrm{U}_0(T) \big\|_{\mathbb{B}^{m,q}(\mathbb{R}^{d+1}_{x,z})} \;=\; O(\delta^{1/q}).$$

Furthermore the Fourier transform $\mathcal{F}_z\big(\mathrm{U}_0^\delta\big)$ *vanishes identically on* $|\zeta| \le \delta$.

Proof of Proposition 5.1. Begin with the proof that U_0^δ has a Fourier transform with respect to z vanishing on $|\zeta| \le \delta$. For any $\gamma(\zeta) \in C_0^\infty(\mathbb{R})$ supported on $|\zeta| \le 1$ define $\gamma^\delta(\zeta) := \gamma(\zeta/\delta)$. It suffices to show that $\mathcal{F}_z \gamma^\delta(D_z)\mathrm{U}_0^\delta(T) = 0$.

The choice of γ implies that $\gamma^\delta \chi^\delta = 0$. Thus multiplying (5.1) by $\gamma^\delta(D_z)$ annihilates the nonlinear term. This implies that $\gamma^\delta(D_z)\mathrm{U}_0^\delta \in C\big([0, T_*[\,; \cap_s H^s\big)$ satisfies

$$\Big(\partial_T \partial_z + P(\partial_x)\Big)\, \gamma^\delta(D_z)\mathrm{U}_0^\delta \;=\; 0. \tag{5.4}$$

In addition $\gamma^\delta(D_z)\mathrm{U}_0^\delta$ vanishes when $T = 0$.

It follows from the basic H^s conservation law for the linear diffractive pulse equation [4] that for all s and all $T \in [0, T_*[$,

$$\|\gamma^\delta(D_z)\, \mathrm{U}_0^\delta(T)\|_{H^s(\mathbb{R}^{d+1}_{x,z})} = \|\gamma^\delta(D_z)\, \mathrm{U}_0^\delta(0)\|_{H^s(\mathbb{R}^{d+1}_{x,z})} = 0. \tag{5.5}$$

Identity (5.5) implies the second assertion of the proposition.

The strategy for proving the $O(\delta^{1/q})$ estimate in the proposition is to construct U_0^δ as a perturbation of $\chi^\delta(D_z)\,\mathrm{U}_0$. Define the perturbation W^δ by

$$\mathrm{W}^\delta := \mathrm{U}_0^\delta - \chi^\delta(D_z)\mathrm{U}_0\,. \tag{5.6}$$

Subtract (5.1) from (5.2) to show that U_0^δ is a solution if and only if W^δ satisfies the initial value problem

$$\begin{aligned} &\partial_T\,\partial_z \mathrm{W}^\delta + P(\partial_x)\,\mathrm{W}^\delta + \pi(\beta)\,\chi^\delta(D_z)\,\partial_z\left(\Phi_J(\mathrm{U}_0^\delta) - \Phi_J(\mathrm{U}_0)\right) = 0,\\ &\mathrm{W}^\delta\big|_{T=0} = 0. \end{aligned} \tag{5.7}$$

Note that

$$\Phi_J(\mathrm{U}_0^\delta) - \Phi_J(\mathrm{U}_0) = \Phi_J(\chi^\delta\mathrm{U}_0 + \mathrm{W}^\delta) - \Phi_J(\chi^\delta\mathrm{U}_0 + (I-\chi^\delta)\mathrm{U}_0).$$

Since $\chi^\delta\mathrm{U}_0(T)$ is bounded in the admissible subspace $\mathbb{B}^{m,\infty}$ uniformly for all $0 < \delta \le 1$ and $0 \le t \le \underline{T}$, the second condition in the definition of admissibility implies that as long as $\|\mathrm{W}^\delta\|_{\mathbb{B}^{m,\infty}} \le 1$,

$$\begin{aligned} \left\|\Phi_J(\mathrm{U}_0^\delta) - \Phi_J(\mathrm{U}_0)\right\|_{\mathbb{B}^{m,q}(\mathbb{R}^{d+1})} \le C(m,q)\,\Big(&\left\|\mathrm{W}^\delta(T)\right\|_{\mathbb{B}^{m,q}(\mathbb{R}^{d+1})}\\ &+ \left\|(I-\chi^\delta)\mathrm{U}_0(T)\right\|_{\mathbb{B}^{m,q}(\mathbb{R}^{d+1})}\Big)\,. \end{aligned} \tag{5.8}$$

Fix $m \ge 0$ and $1 \le q \le \infty$. If $\|\mathrm{W}^\delta(T)\|_{\mathbb{B}^{m,q}} \le 1$ for $0 \le T \le \underline{T}$, define $T_* = T_*(m,q,\delta) = \underline{T}$. Otherwise define

$$T_*(m,q,\delta) \;:=\; \inf\{T \in [0,\underline{T}] \;:\; \|\mathrm{W}^\delta(T)\|_{\mathbb{B}^{m,q}} = 1\}.$$

The homogeneous linear diffractive pulse equation generates a unitary group on each $\mathbb{B}^{m,q}$. The inhomogeneous version of this estimate implies that for $T \in [0, T_*]$,

$$\begin{aligned} \|\mathrm{W}^\delta(T)\|_{\mathbb{B}^{m,q}} \le \int_0^T C(m)\,\Big(&\left\|\mathrm{W}^\delta(\sigma)\right\|_{\mathbb{B}^{m,q}(\mathbb{R}^{d+1})}\\ &+ \left\|(I-\chi^\delta)\mathrm{U}_0(\sigma)\right\|_{\mathbb{B}^{m,q}(\mathbb{R}^{d+1})}\Big)\,d\sigma. \end{aligned} \tag{5.9}$$

Gronwall's inequality then shows that

$$\|\mathrm{W}^\delta(T)\|_{\mathbb{B}^{m,q}} \le C(m)\int_0^T \left\|(I-\chi^\delta)\mathrm{U}_0(T)\right\|_{\mathbb{B}^{m,q}(\mathbb{R}^{d+1})}\,dt\;e^{C(m)T}. \tag{5.10}$$

To proceed we need the following lemma.

LEMMA 5.2. *For any $m \ge 0$, $1 \le q < \infty$, and $M > q + (d+1)/q$ there is a constant $C = C(m,q,M)$ so that for all $\delta > 0$ and all $W \in \mathbb{B}^{M,\infty}$,*

$$\left\|(I-\chi^\delta)W\right\|_{\mathbb{B}^{m,q}(\mathbb{R}^{d+1})} \;\le\; C\,\delta^{1/q}\,\|W\|_{\mathbb{B}^{M,\infty}}.$$

Remark. In contrast note that for $W \in \cap_s H^s$, $||(I-\chi^\delta)W\|_{H^s} = o(1)$ as $\delta \to 0$, but there is no rate of convergence.

Proof of Lemma. By definition

$$\left\|(I-\chi^\delta)W\right\|^q_{\mathbb{B}^{m,q}(\mathbb{R}^{d+1})} \;=\; \int \left|1-\chi(\zeta/\delta)\right|^q\,\left|\widehat{W}(\xi,\zeta)\right|^q\,\langle\xi,\zeta\rangle^{mq}\,d\xi\,d\zeta.$$

Use the estimate

$$|\widehat{W}(\xi,\zeta)| \le \langle \xi,\zeta\rangle^{-M}\, \|\widehat{W}\|_{\mathbb{B}^{M,\infty}}$$

to find

$$\big\|(I-\chi^\delta)W\big\|^q_{\mathbb{B}^{m,q}} \le \|\widehat{W}\|^q_{\mathbb{B}^{M,\infty}} \int \big|1-\chi(\zeta/\delta)\big|^q\ \langle \xi,\zeta\rangle^{-Mq}\ \langle \xi,\zeta\rangle^{mq}\ d\xi\, d\zeta.$$

The integral on the right is over $|\zeta| \le \delta$, so for $Mq > mq + d + 1$, the integral is $O(\delta)$, which proves the lemma. □

This lemma implies that

$$\int_0^{\underline{T}} \big\|(I-\chi^\delta)\mathrm{U}_0(T)\big\|_{\mathbb{B}^{m,q}(\mathbb{R}^{d+1})}\ dt\ =\ O(\delta^{1/q}).$$

Thus, one can choose $\delta_0(m,q)$ so that for $0 < \delta < \delta_0$,

$$C(m)\int_0^{\underline{T}} \big\|(I-\chi^\delta)\mathrm{U}_0(T)\big\|_{\mathbb{B}^{m,q}(\mathbb{R}^{d+1})}\ dt\ e^{C(m)\underline{T}} < \frac{1}{2}.$$

Then (5.10) shows that if $T_* < \underline{T}$, then

$$\|\mathrm{W}^\delta(T)\|_{\mathbb{B}^{m,q}} \le \frac{1}{2}$$

for $0 < t < T_*$. Since this contradicts the definition of T_* we conclude that $T_* = \underline{T}$ and that (5.10) holds for $0 < T < \underline{T}$. In particular, the evolution equation for U_0^δ is solvable up to $\underline{T}$.

In addition, estimate (5.10) implies the $O(\delta^{1/q})$ convergence rate for the value m, q fixed at the start. Since m, q is arbitrary, the proof of Proposition 5.1 is complete. □

Combining the convergence results of Proposition 5.1 and Lemma 5.2 yields

$$\sup_{0\le t\le T} \|\mathrm{U}_0(T) - \mathrm{U}_0^\delta(T)\|_{\mathbb{B}^{m,q}(\mathbb{R}^{d+1}_{x,z})}\ =\ O(\delta^{1/q}). \tag{5.11}$$

Note that the smallest upper bound occurs for the case $q = 1$ corresponding to the Wiener algebra.

6. Estimate for the residual. Suppose that $\underline{T}$ is smaller than the maximal existence time for U_0 in the sense that a solution of (4.2) is known in the space $C\big([0,\underline{T}]\,;\cap_m \mathbb{B}^{m,\infty}(\mathbb{R}^{d+1}_{x,z})\big)$. Then Proposition 5.1 shows that for $0 < \delta < \delta_0$, $U_0^\delta(T,t,x,z) = \mathrm{U}_0^\delta(T, x-\mathbf{v}t, z)$ exists on $[0,\underline{T}]$ and $\mathcal{F}_z U_0^\delta$ vanishes on a neighborhood of $\zeta = 0$. For $\delta > 0$, the equations for the correctors U_1^δ, U_2^δ are solvable, so

$$U^\delta(\varepsilon,T,t,x,z) := U_0^\delta + \varepsilon U_1^\delta + \varepsilon^2 U_2^\delta$$

is well defined for $0 \le t \le \underline{T}/\varepsilon$. The residual equation (3.21) is then

$$\begin{aligned} R^\delta(\varepsilon,T,t,x,z) &:= L\Big((\varepsilon\partial_T,0) + \partial_y + \frac{\beta}{\varepsilon}\partial_z\Big)\,\varepsilon^p U^\delta + \chi^\delta(D_z)\,\Phi(\varepsilon^p U^\delta) \\ &= \varepsilon^{p+1}\Big(\varepsilon^2\partial_T U_2^\delta + \varepsilon L(\partial_y)U_2^\delta + \varepsilon\partial_T U_1^\delta\Big) + \chi^\delta(D_z)\Big[\Phi(\varepsilon^p U^\delta) - \Phi_J(\varepsilon^p U_0^\delta)\Big]. \end{aligned} \tag{6.1}$$

This section is devoted to estimates for the right-hand side of (6.1). There are at least two subtle points. The first is that though the residual is formally $O(\varepsilon^{2p+1})$ it involves correctors which blow up as $\delta \to 0$. Care must be taken about small values of δ. The second point is that the residual involves the smooth function Φ, which need not be polynomial. Therefore, the Wiener algebra need not be invariant. The estimates are therefore done in the scale of Sobolev spaces.

PROPOSITION 6.1. *Suppose that U^δ and $\underline{T}$ are as above, δ_0 is as in Proposition 5.1, and $s > (d+1)/2$. Then there is a constant $C = C(s)$ so that for all*

$$0 \le t < \infty \quad \cap \quad 0 \le T \le \underline{T} \quad \cap \quad 0 < \delta \le \delta_0 \quad \cap \quad 0 \le \varepsilon \le \delta, \tag{6.2}$$

one has

$$\|R^\delta(\varepsilon, T, t, x, z)\|_{H^s(\mathbb{R}^{d+1}_{x,z})} \;\le\; C\,\varepsilon^{p+1}\Big(\frac{\varepsilon}{\delta^2} + \varepsilon^p\Big). \tag{6.3}$$

Proof. The first step is to estimate the size of the correctors U_1^δ, U_2^δ. The formulas for these functions involve U_0^δ and, most importantly, the operator ∂_z^{-1}. The formula for U_1^δ involves ∂_z^{-1}, while the formula for U_2^δ involves ∂_z^{-2} since it has a term with ∂_z^{-1} applied to U_1^δ. The application of the operator ∂_z^{-1} introduces a factor $1/\delta$ in estimates since the support of U_j^δ is in $|\zeta| > \delta$. The boundedness of the family U_0^δ in $\mathbb{B}^{m,\infty}$ yields the following estimates for the correctors for $0 < \delta \le \delta_0$:

$$\forall m\,, \forall\, 0 \le t < \infty, \quad \sup_{0 \le T \le \underline{T}} \; \big\|U_j^\delta(T, t, x, z)\big\|_{\mathbb{B}^{m,\infty}(\mathbb{R}^{d+1}_{x,z})} \le \frac{C(m)}{\delta j}. \tag{6.4}$$

Inserted in the definition of U^δ, this estimate proves that for $t \in \mathbb{R}$ and $0 \le T \le \underline{T}$,

$$\big\|U^\delta(T,t)\big\|_{\mathbb{B}^{m,\infty}(\mathbb{R}^{d+1}_{x,z})} \le C(m)\Big(1 + \frac{\varepsilon}{\delta} + \frac{\varepsilon^2}{\delta^2}\Big).$$

Thus $U^\delta(T,t)$ is uniformly bounded in $\mathbb{B}^{m,\infty}$ for the parameter range (6.2). This is a key element in the estimate of the second term on the right-hand side of (6.1).

For the right-hand side of (6.1) we also need an estimate for $\varepsilon\partial_T U_1^\delta$ and $\varepsilon^2\partial_T U_2^\delta$. Start with an estimate for the T derivative of U_0^δ. The evolution equation (5.1) yields

$$\partial_T \mathrm{U}_0^\delta \;=\; -\partial_z^{-1} P(\partial_x)\mathrm{U}_0^\delta - \pi(\beta)\,\chi^\delta(D_z)\,\Phi_J(\mathrm{U}_0^\delta).$$

Together with the uniform boundedness of U_0^δ this yields

$$\|\partial_T U_0^\delta\|_{\mathbb{B}^{m,\infty}} \;\le\; \frac{C(m)}{\delta}. \tag{6.5}$$

The factor $1/\delta$ comes from the norm of ∂_z^{-1} acting on functions with spectrum in $|\zeta| \ge \delta$. Differentiating (3.19) and (3.20) with respect to T yields

$$\partial_T U_1^\delta = -\partial_z^{-1} Q(\beta) L(\partial_y)\partial_T U_0^\delta$$

and

$$\partial_T U_2^\delta = -\partial_z^{-1} Q(\beta)\Big(L(\partial_y)\partial_T U_1^\delta + \chi^\delta(D_z)\pi(\beta)\Phi_J'(U_0^\delta)\partial_T U_0^\delta\Big).$$

Using estimate (6.5) in the equations above yields in turn

$$\|\partial_T U_1^\delta\|_{\mathbb{B}^{m,\infty}} \;\le\; \frac{C(m)}{\delta^2} \qquad \text{and} \qquad \|\partial_T U_2^\delta\|_{\mathbb{B}^{m,\infty}} \;\le\; \frac{C(m)}{\delta^3}.$$

Inserting these estimates into the first term on the right-hand side of (6.1) and using $\varepsilon \le \delta$ yields

$$\left\|\varepsilon^2\partial_T U_2^\delta + \varepsilon L(\partial_y)U_2^\delta + \varepsilon\partial_T U_1^\delta\right\|_{\mathbb{B}^{m,\infty}} \le C(m)\Big(\frac{\varepsilon^2}{\delta^3} + \frac{\varepsilon}{\delta^2} + \frac{\varepsilon}{\delta^2}\Big) \;\le\; \frac{C(m)\,\varepsilon}{\delta^2}. \tag{6.6}$$

Next turn to the second term on the right of (6.1). Taylor's theorem with remainder implies that there are smooth functions G_α so that

$$\Phi(u) \;=\; \sum_{|\alpha|=J} u^\alpha\, G_\alpha(u). \tag{6.7}$$

It follows that

$$\Phi(\lambda u) = \lambda^J \Psi(\lambda, u), \tag{6.8}$$

with smooth Ψ satisfying $\Psi(\lambda, 0) = 0$. An entirely analogous argument shows that there is a $\Xi(\lambda, u)$ vanishing when $u = 0$ so that

$$\Phi(\lambda u) - \Phi_J(\lambda u) = \lambda^{J+1}\,\Xi(\lambda, u). \tag{6.9}$$

Split the nonlinearity on the right-hand side of (6.1),

$$\Phi(\varepsilon^p U^\delta) - \Phi_J(\varepsilon^p U_0^\delta) \;=\; \big[\Phi(\varepsilon^p U^\delta) - \Phi(\varepsilon^p U_0^\delta)\big] + \big[\Phi(\varepsilon^p U_0^\delta) - \Phi_J(\varepsilon^p U_0^\delta)\big].$$

Using (6.8), (6.9), and the fact that $\varepsilon^{pJ} = \varepsilon^{p+1}$ yields

$$\Phi(\varepsilon^p U^\delta) - \Phi_J(\varepsilon^p U_0^\delta) \;=\; \varepsilon^{p+1}\big[\Psi(\varepsilon^p, U^\delta) - \Psi(\varepsilon^p, U_0^\delta)\big] + \varepsilon^{2p+1}\,\Xi(\varepsilon^p, U_0^\delta). \tag{6.10}$$

Since both U^δ and U_0^δ are H^s uniformly bounded, (6.10) and Schauder's lemma imply that for $s > (d+1)/2$,

$$\big\|\Phi(\varepsilon^p U^\delta) - \Phi_J(\varepsilon^p U_0^\delta)\big\|_{H^s(\mathbb{R}^{d+1}_{x,z})} \;\le\; C(s)\,\varepsilon^{p+1}\Big(\|U^\delta - U_0^\delta\|_{H^s(\mathbb{R}^{d+1}_{x,z})} + \varepsilon^p\Big). \tag{6.11}$$

Using (6.4) and $\varepsilon \le \delta$ yields

$$\|U^\delta - U_0^\delta\|_{H^s(\mathbb{R}^{d+1}_{x,z})} \;\le\; C(s)\Big(\frac{\varepsilon}{\delta} + \frac{\varepsilon^2}{\delta^2}\Big) \;\le\; \frac{C(s)\,\varepsilon}{\delta}. \tag{6.12}$$

Combining (6.6), (6.11), and (6.12) yields the estimate (6.3). ∎

7. Proof of (2.12). In the next proposition we prove the third and last convergence result needed to establish our main result.

PROPOSITION 7.1. *Suppose that $\underline{T}$ is smaller than the maximal existence time for U_0 and that U^δ, U^δ are as in the first paragraph of section* 6*, and hence in the space satisfying* (1.3)*. Then there is a positive ε_1 so that for $0 < \varepsilon < \varepsilon_1$, the differential equation* (2.10) *has a unique solution $\mathcal{V}(\varepsilon, t, x, \phi) \in C\big([0, \underline{T}/\varepsilon\,]\,; \cap_s H^s(\mathbb{R}^{d+1})\big)$ satisfying the initial condition*

$$\mathcal{V}(\varepsilon, 0, x, \phi) = U_0(0, 0, x, \phi).$$

In addition, for all s, for $\delta = \varepsilon^{2/5}$, and for $0 < \varepsilon < \varepsilon_1$,

$$\sup_{0\le t\le \underline{T}/\varepsilon} \left\|U^\delta\Big(\varepsilon, \varepsilon t, t, x, \frac{t\tau_0}{\varepsilon} + \phi\Big) - \mathcal{V}(\varepsilon, t, x, \phi)\right\|_{H^s(\mathbb{R}^d_x \times \mathbb{R}_\phi)} \le C(s)\varepsilon^{\max\{1/5\,,\,p\}}. \tag{7.1}$$

Proof. The construction of U^δ guarantees that $U^\delta(\varepsilon, \varepsilon t, t, x, \frac{t\tau_0}{\varepsilon} + \phi)$ satisfies

$$L\Big(\partial_t, \partial_x + \frac{\xi_0}{\varepsilon}\partial_\phi\Big)\varepsilon^p U^\delta + \Phi(\varepsilon^p U^\delta) = R^\delta\Big(\varepsilon, \varepsilon t, x, \frac{t\tau_0}{\varepsilon} + \phi\Big) + \big(I - \chi^\delta(D_z)\big)\,\Phi(\varepsilon^p U^\delta). \tag{7.2}$$

The strategy is to construct $\mathcal{V}$ as a perturbation, $\mathcal{E}^\delta$, of U^δ. Define

$$\mathcal{E}^\delta(\varepsilon, t, x, \phi) \;:=\; \mathcal{V}(\varepsilon, t, x, \phi) - U^\delta\Big(\varepsilon, \varepsilon t, t, x, \frac{t\tau_0}{\varepsilon} + \phi\Big). \tag{7.3}$$

The equation for $\mathcal{V}$ is rewritten as an equation for $\mathcal{E}^\delta$. The equation for $\mathcal{E}^\delta$ is then analyzed to show that the perturbation remains small for $0 \le t \le \underline{T}/\varepsilon$.

Subtracting (2.10) from (7.2) yields

$$\begin{aligned} L\Big(\partial_t, \partial_x + \frac{\xi_0}{\varepsilon}\partial_\phi\Big)\varepsilon^p \mathcal{E}^\delta = &-R^\delta\Big(\varepsilon, \varepsilon t, t, x, \frac{t\tau_0}{\varepsilon} + \phi\Big) \\ &- \big(I - \chi^\delta(D_z)\big)\Phi\Big(\varepsilon^p U^\delta\Big(\varepsilon, \varepsilon t, t, x, \frac{t\tau_0}{\varepsilon} + \phi\Big)\Big) \\ &+ \Big[\Phi\Big(\varepsilon^p U^\delta\Big(\varepsilon, \varepsilon t, t, x, \frac{t\tau_0}{\varepsilon} + \phi\Big)\Big) - \Phi(\varepsilon^p \mathcal{V})\Big]. \end{aligned} \tag{7.4}$$

The operator L is a symmetric hyperbolic operator with constant coefficients and coefficient of ∂_t equal to I. It follows that L generates a unitary evolution on the spaces $H^s(\mathbb{R}^{d+1}_{x,\phi})$. Thus for all s and for all t smaller than the maximal time of existence,

$$\begin{aligned} \big\|\varepsilon^p \mathcal{E}^\delta(t)\big\|_{H^s(\mathbb{R}^{d+1}_{x,\phi})} \;\le\; &\big\|\varepsilon^p \mathcal{E}^\delta(0)\big\|_{H^s(\mathbb{R}^{d+1}_{x,\phi})} \\ &+ \int_0^t \Big\|L\Big(\partial_t, \partial_x + \frac{\xi_0}{\varepsilon}\partial_\phi\Big)\varepsilon^p \mathcal{E}^\delta(\sigma)\Big\|_{H^s(\mathbb{R}^{d+1}_{x,\phi})}\, d\sigma. \end{aligned} \tag{7.5}$$

The key is to estimate the integral on the right-hand side of (7.5) using the expression (7.4).

7.1. Estimate for the R^δ term in (7.4). Estimate (6.3) implies that

$$\begin{aligned} \Big\|R^\delta\Big(\varepsilon, \varepsilon t, t, x, \frac{t\tau_0}{\varepsilon} + \phi\Big)\Big\|_{H^s(\mathbb{R}^{d+1}_{x,\phi})} &= \big\|\mathrm{R}^\delta(\varepsilon, \varepsilon t, x, z)\big\|_{H^s(\mathbb{R}^{d+1}_{x,z})} \\ &\le C\,\varepsilon^{p+1}\Big(\frac{\varepsilon}{\delta^2} + \varepsilon^p\Big). \end{aligned} \tag{7.6}$$

7.2. Estimate for the $(I - \chi^\delta(D_z))\,\Phi(\varepsilon^p U^\delta(\varepsilon t, t, x, \frac{t\tau_0}{\varepsilon} + \phi))$ term in (7.4). As in the derivation of (7.6), the translation invariance of the H^s norm yields

$$\begin{aligned} &\Big\|\big(I - \chi^\delta(D_z)\big)\Phi\Big(\varepsilon^p U^\delta\Big(\varepsilon t, t, x, \frac{t\tau_0}{\varepsilon} + \phi\Big)\Big)\Big\|_{H^s(\mathbb{R}^{d+1}_{x,\phi})} \\ &\qquad = \big\|\big(I - \chi^\delta(D_z)\big)\Phi(\varepsilon^p \mathrm{U}^\delta(\varepsilon t, x, z))\big\|_{H^s(\mathbb{R}^{d+1}_{x,z})}. \end{aligned}$$

Express $\Phi(\varepsilon^p \mathrm{U}^\delta)$ as the sum of two terms,

$$\Phi(\varepsilon^p \mathrm{U}^\delta) = \Phi_J(\varepsilon^p \mathrm{U}^\delta) + \big(\Phi - \Phi_J\big)(\varepsilon^p \mathrm{U}^\delta) = \varepsilon^{p+1}\Phi_J(\mathrm{U}^\delta) + \varepsilon^{2p+1}\Xi(\varepsilon^p, \mathrm{U}^\delta), \tag{7.7}$$

where we have used (6.9) to derive the second equality.

Since $\Xi(\varepsilon^p, \mathrm{U}^\delta(\varepsilon t, x, z)$ is uniformly bounded in $H^s(\mathbb{R}^{d+1}_{x,z})$ it follows that

$$\big\|(I-\chi^\delta(D_z))\varepsilon^{2p+1}\Xi(\varepsilon^p,\mathrm{U}^\delta)\big\|_{H^s(\mathbb{R}^{d+1}_{x,z})} \;\le\; C\,\varepsilon^{2p+1}. \tag{7.8}$$

Since $\Phi_J(\mathrm{U}^\delta(\varepsilon t, t, x, \frac{t\tau}{\varepsilon}+\phi))$ are uniformly bounded in $\mathbb{B}^{m,\infty}$, Lemma 5.2 implies that

$$\big\|(I-\chi^\delta(D_z))\varepsilon^{p+1}\Phi_J(U^\delta)\big\|_{H^s(\mathbb{R}^{d+1}_{x,z})} \le C\,\sqrt{\delta}\,\varepsilon^{p+1}. \tag{7.9}$$

Adding (7.8) and (7.9) shows that

$$\Big\|\big(I-\chi^\delta(D_z)\big)\,\Phi\Big(\varepsilon^p U^\delta\Big(\varepsilon t, t, x, \frac{t\tau_0}{\varepsilon}+\phi\Big)\Big)\Big\|_{H^s(\mathbb{R}^{d+1}_{x,\phi})} \le C\,\varepsilon^{p+1}(\sqrt{\delta}+\varepsilon^p). \tag{7.10}$$

7.3. Estimate for the $\Phi(\varepsilon^p U^\delta)-\Phi(\varepsilon^p\mathcal{V})$ term in (7.4). Using (6.8) yields

$$\Phi(\varepsilon^p U^\delta)-\Phi(\varepsilon^p\mathcal{V}) = \varepsilon^{p+1}\big[\Psi(\varepsilon^p,U^\delta)-\Psi(\varepsilon^p,\mathcal{V})\big] = \varepsilon^{p+1}\big[\Psi(\varepsilon^p,U^\delta)-\Psi(\varepsilon^p,U^\delta+\mathcal{E}^\delta)\big].$$

The proof of Proposition 5.1 shows that

$$\sup_{0\le t\le T/\varepsilon,\ 0<\varepsilon<\delta\le\delta_0}\ \Big\|U^\delta\Big(\varepsilon,\varepsilon t,t,x,\frac{t\tau_0}{\varepsilon}+\phi\Big)\Big\|_{H^s(\mathbb{R}^{d+1}_{x,\phi})}<\infty.$$

Schauder's lemma then implies that *as long as* $\|\mathcal{E}^\delta\|_{H^s}\le 1$,

$$\varepsilon^{p+1}\big\|\Psi(\varepsilon^p,U^\delta+\mathcal{E}^\delta)-\Psi(\varepsilon^p,U^\delta)\big\|_{H^s(\mathbb{R}^{d+1}_{x,\phi})} \le C\,\varepsilon^{p+1}\,\|\mathcal{E}^\delta(t)\|_{H^s(\mathbb{R}^{d+1}_{x,\phi})}. \tag{7.11}$$

Combining estimates (7.6), (7.10), and (7.11) yields the following estimate, valid *as long as* $\|\mathcal{E}^\delta\|_{H^s}\le 1$:

$$\Big\|L\Big(\partial_t,\partial_x+\frac{\xi_0}{\varepsilon}\partial_\phi\Big)\,\varepsilon^p\mathcal{E}^\delta\Big\|_{H^s(\mathbb{R}^{d+1}_{x,\phi})} \;\le\; C\,\varepsilon^{p+1}\,\Big(\frac{\varepsilon}{\delta^2}+\varepsilon^p+\sqrt{\delta}+\|\mathcal{E}^\delta(t)\|_{H^s(\mathbb{R}^{d+1}_{x,\phi})}\Big). \tag{7.12}$$

7.4. Estimate for $\mathcal{E}^\delta(0)$. The initial value of $\mathcal{E}^\delta(0)$ comes from the correctors in U^δ,

$$\mathcal{E}^\delta(0) = f(x,\phi)-\mathrm{U}^\delta(0,x,\phi) = \varepsilon\mathrm{U}_1^\delta(0,x,\phi)+\varepsilon^2\mathrm{U}_2^\delta(0,x,\phi).$$

Using (6.4) and the fact that $\varepsilon\le\delta$ yields

$$\|\mathcal{E}^\delta(0)\|_{H^s(\mathbb{R}^{d+1})} \;\le\; C\Big(\frac{\varepsilon}{\delta}+\frac{\varepsilon^2}{\delta^2}\Big) \;\le\; \frac{C\varepsilon}{\delta}. \tag{7.13}$$

8. End of proof. We now use the previous results to bound the error $\mathcal{E}^\delta$ between the exact solution $\mathcal{V}$ and the approximate solution defined in terms of U^δ.

Fix $s>(d+1)/2$. Then as long as $\|\mathcal{E}^\delta\|_{H^s}\le 1$, inserting (7.12) and (7.13) into (7.5) yields

$$\big\|\,\varepsilon^p\,\mathcal{E}^\delta(t)\,\big\|_{H^s(\mathbb{R}^{d+1}_{x,\phi})} \;\le\; \frac{C\varepsilon^{p+1}}{\delta}+C\int_0^t\varepsilon^{p+1}\,\Big(\frac{\varepsilon}{\delta^2}+\varepsilon^p+\sqrt{\delta}+\|\mathcal{E}^\delta(\sigma)\|_{H^s(\mathbb{R}^{d+1}_{x,\phi})}\Big)\,d\sigma.$$

Estimate the integral of the constant term using $t \le \underline{T}/\varepsilon$ to find

$$\int_0^t \varepsilon^{p+1}\left(\frac{\varepsilon}{\delta^2}+\varepsilon^p+\sqrt{\delta}\right)\,d\sigma \le \frac{\underline{T}\,\varepsilon^{p+1}}{\varepsilon}\left(\frac{\varepsilon}{\delta^2}+\varepsilon^p+\sqrt{\delta}\right) \;\le\; C\,\varepsilon^p\Big(\frac{\varepsilon}{\delta^2}+\varepsilon^p+\sqrt{\delta}\Big).$$

Combine the last two estimates using $\frac{\varepsilon}{\delta^2} \ge \frac{\varepsilon}{\delta}$ and divide by ε^p to find

$$\big\|\,\mathcal{E}^\delta(t)\,\big\|_{H^s(\mathbb{R}^{d+1}_{x,\phi})} \le C\left(\frac{\varepsilon}{\delta^2}+\varepsilon^p+\sqrt{\delta}\right)+C\,\varepsilon\int_0^t \|\mathcal{E}^\delta(\sigma)\|_{H^s(\mathbb{R}^{d+1}_{x,\phi})}\,d\sigma. \tag{8.1}$$

We need to show that $\mathcal{E}^\delta$ exists for $0 \le T \le \underline{T}/\varepsilon$ and that $\sup_{t\in[0,\underline{T}/\varepsilon]} \|\mathcal{E}^\delta(t)\|_{H^s}$ converges to zero as $\delta \to 0$. The integral inequality (8.1) leads to both of these goals by the "as long as" argument.

For any $0 < \varepsilon < \delta < \delta_0$, define $T_* = T_*(\varepsilon, s, \delta)$ by $T_* = \underline{T}/\varepsilon$ if $U^\delta(\varepsilon, T, t, x, z)$ exists for $0 \le t \le \underline{T}/\varepsilon$ and $\sup_{0\le t\le \underline{T}/\varepsilon} \|\mathcal{E}^\delta(t)\|_{H^s} < 1$. Otherwise define

$$T_* \;:=\; \inf\big\{t \,:\, \|\mathcal{E}^\delta(t)\|_{H^s} = 1\big\}.$$

Gronwall's inequality applied to (8.1) implies that for $0 \le t \le T_*$,

$$\|\mathcal{E}^\delta(t)\|_{H^s(\mathbb{R}^{d+1}_{x,\phi})} \le C(s)\left(\frac{\varepsilon}{\delta^2}+\varepsilon^p+\sqrt{\delta}\right)e^{C(s)\varepsilon t} \le C(s)\left(\frac{\varepsilon}{\delta^2}+\varepsilon^p+\sqrt{\delta}\right). \tag{8.2}$$

Now we can chose δ as a function of ε. Balancing the ε/δ^2 and $\sqrt{\delta}$ terms in (8.2) yields

$$\delta = \varepsilon^{0.4} \qquad \text{and} \qquad \frac{\varepsilon}{\delta^2} = \sqrt{\delta} = \varepsilon^{1/5}.$$

Then (8.2) yields for $\delta = \varepsilon^{0.4}$

$$\|\mathcal{E}^\delta(t)\|_{H^s(\mathbb{R}^{d+1}_{x,\phi})} \;\le\; C(s)\,\varepsilon^{\min\{p\,,\,1/5\}}. \tag{8.3}$$

Choose $\varepsilon(s) > 0$ so that

$$C(s)\,\varepsilon(s)^{\min\{p\,,\,1/5\}} \;<\; \frac{1}{2}. \tag{8.4}$$

Combining (8.3) and (8.4) shows that for $0 \le t \le T_*$, $0 < \varepsilon < \varepsilon(s)$, and $\delta = \varepsilon^{0.4}$

$$\|\mathcal{E}^\delta(t)\|_{H^s(\mathbb{R}^{d+1}_{x,\phi})} < \frac{1}{2}. \tag{8.5}$$

If $T_* < \underline{T}$, setting $t = T_*$ violates the definition of T_*. It follows that for $0 < \varepsilon < \varepsilon(s)$, $\mathcal{E}^{e^{0.4}}(t)$ has H^s norm less than $1/2$ for $0 \le t \le \underline{T}/\varepsilon$.

This proves the solvability for $0 \le t \le \underline{T}/\varepsilon$ of the initial value problem defining $\mathcal{V} \in C([0,T]\,;\,H^s)$. That the solution belongs to $C([0,\underline{T}/\varepsilon]\,;\,\cap_s H^s)$ is then a consequence of standard semilinear hyperbolic theory and the regularity of the initial data for $\mathcal{V}$.

In addition, since (8.5) holds, the "as long as" argument works, and it follows that inequality (8.3) is valid for $0 \le t \le \underline{T}/\varepsilon$, provided that $\varepsilon < \varepsilon(s)$. Since s is arbitrary this proves the convergence asserted in Proposition 7.1. ∎

8.1. The main theorems. Combining Propositions 4.3, 5.1, and 7.1 and Corollary 4.12 proves the following result.

THEOREM 8.1 (main theorem). *Assume that the initial data in* (2.1) *satisfy Assumptions* 1.5 *and* 1.8. *Let* $\mathrm{U}_0 = \pi(\beta)\mathrm{U}_0 \in C([0,T_*[\,;\mathbb{A}(\mathbb{R}^{1+d})$ *be the maximal solution of the principal profile equation* (4.2) *with initial value* f. *Let* $\mathcal{V}(\varepsilon,t,x,\phi) \in \cap_s C([0,T'_*[\,;H^s(\mathbb{R}^{d+1}))$ *denote the maximal solution of the initial value problem* (2.10), (2.11) *defining the exact profile.*

Then, for any $\underline{T} < T_*$ *there is an* $\varepsilon(\underline{T}) > 0$ *so that for* $0 < \varepsilon < \varepsilon(\underline{T})$ *the solution* u^ε *of the initial value problem* (2.1) *exists for* $0 \le t \le \underline{T}/\varepsilon$, $T'_* \ge \underline{T}/\varepsilon$, *and* u^ε *is given by*

$$u^\varepsilon \;=\; \varepsilon^p \mathcal{V}\Big(\varepsilon,t,x,\frac{x.\xi_0}{\varepsilon}\Big).$$

In addition the asymptotic behavior as $\varepsilon \to 0$ *is given by*

$$u^\varepsilon \;\sim\; \varepsilon^p \mathrm{U}_0\Big(\varepsilon,\varepsilon t,x-\mathbf{v}t,\frac{t\tau_0+x.\xi_0}{\varepsilon}\Big)$$

in the sense that for all s, *as* $\varepsilon \to 0$

$$\sup_{0\le t\le \underline{T}/\varepsilon}\Big\|\mathcal{V}(\varepsilon,t,x,\phi)-\mathrm{U}_0\Big(\varepsilon t,x-\mathbf{v}t,\frac{t\tau_0}{\varepsilon}+\phi\Big)\Big\|_{H^s(\mathbb{R}^{1+d}_{x,\phi})} \;\le C(s)\,\varepsilon^{\min\{p,1/5\}}. \tag{8.6}$$

Proof of Theorem 1.10. Theorem 1.10 is an immediate consequence of this result. Simply write

$$u^\varepsilon - u^\varepsilon_{\mathrm{approx}} \;=\; \varepsilon^p \mathcal{V}\Big(\varepsilon,t,x,\frac{x.\xi_0}{\varepsilon}\Big) - \varepsilon^p \mathrm{U}_0\Big(\varepsilon t,x-\mathbf{v}t,\frac{t\tau_0+x.\xi_0}{\varepsilon}\Big).$$

Then the estimate (1.12) follows from (8.6). ∎

Note that the constant field V_d has a nonzero ∂_t component. It acts differently on the two terms in the expression for the error. That is why we have a reduced set of derivatives in the error estimate of Theorem 1.10.
