ON THE SPECTRA OF THREE-DIMENSIONAL LAMELLAR SOLUTIONS OF THE DIBLOCK COPOLYMER PROBLEM*

XIAOFENG REN† AND JUNCHENG WEI‡

Abstract. One-dimensional free energy local minimizers are viewed as three-dimensional lamellar-type critical points in a box. To determine whether they model the lamellar phase of diblock copolymers in the strong segregation region, we analyze their spectra. We obtain the asymptotic expansions of their eigenvalues and eigenfunctions. Consequently we find that they are stable, i.e., are local minimizers in space, only if they have sufficiently many interfaces. Interestingly the one-dimensional global minimizer is near the borderline of three-dimensional stability.

Key words. spectrum, three-dimensional stability, lamellar solution, diblock copolymer

1. Introduction.

In a diblock copolymer melt a molecule is a linear chain consisting of two subchains grafted covalently to each other. The first subchain has N_A type A monomer units, and the second subchain has N_B type B monomer units. In polymer systems even a weak repulsion between unlike monomers A and B induces a strong repulsion between subchains. With many chain molecules in a polymer melt the different type subchains tend to segregate below some critical temperature, but as they are chemically bonded in chain molecules, even a complete segregation of subchains cannot lead to a macroscopic phase separation. Only a local microphase separation occurs: microdomains rich in A and B are formed. These microdomains form morphological patterns/phases in a larger scale. The commonly observed phases include the spherical, cylindrical, and lamellar, depicted in Figure 1.

We consider a scenario in which a diblock copolymer melt is placed in a domain D and maintained at fixed temperature. D is scaled to have unit volume in space. Let $a = N_A/(N_A + N_B) \in (0,1)$ be the relative number of the A monomers in a chain molecule. Similarly $b = N_B/(N_A+N_B)$, so $a+b = 1$. The relative A monomer density field u is an order parameter. $u \approx 1$ stands for high concentration of A monomers. The melt is incompressible so the relative B monomer density is $1-u$, and $u \approx 0$ stands for high concentration of B monomers.

Ohta and Kawasaki [10] introduced an equilibrium theory in which the free energy of the system is a functional of the relative A monomer density:

$$I(u) = \int_D \left\{ \frac{\epsilon^2}{2}|\nabla u|^2 + \frac{\sigma}{2}|(-\Delta)^{-1/2}(u-a)|^2 + W(u) \right\}, \tag{1.1}$$

defined in $X_a = \{u \in W^{1,2}(D) : \overline{u} = a\}$, where $\overline{u} := \frac{1}{|D|}\int_D u$ is the average of u on D. The original formula in [10] is given for the whole space. The expression here on a bounded domain D first appeared in Nishiura and Ohnishi [8].

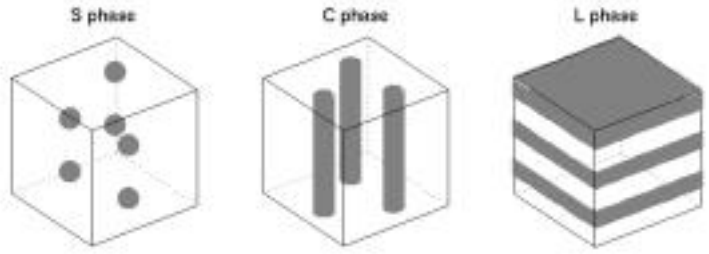

FIG. 1. *The spherical, cylindrical, and lamellar morphology phases commonly observed in diblock copolymer melts. The dark color indicates the concentration of type A monomer, and the white color indicates the concentration of type B monomer.*

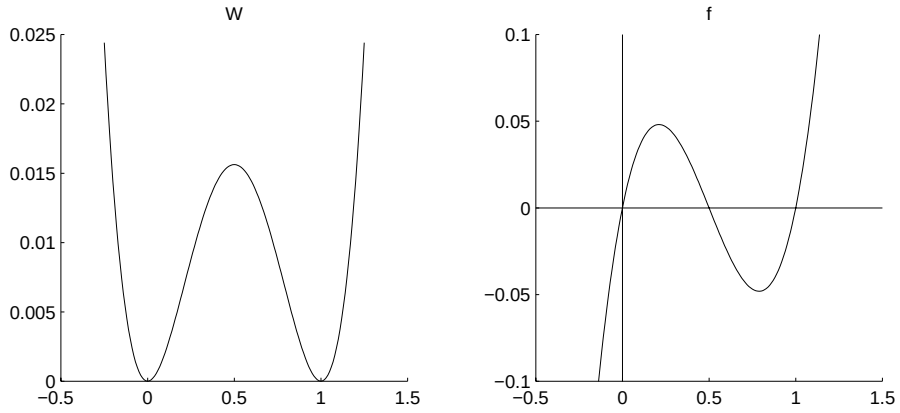

FIG. 2. *The graphs of W and $f = W'$.*

ϵ and σ are positive dimensionless parameters that depend on various physical quantities such as N_A, N_B, the average distance between two adjacent monomers in a chain, the interaction between monomers, the temperature, and the size of the sample. In the strong segregation region where morphology patterns form, ϵ is very small. The size of σ in this paper is chosen to be of order ϵ; i.e., there is a fixed positive constant γ so that $\sigma = \epsilon\gamma$. This particular parameter range is realized if we take the sample size to be of the $(N_A + N_B)^{2/3}$ order.[1]

The local function W is smooth and has the shape of a double well, as depicted in Figure 2. It has the global minimum value 0 at two numbers: 0 and 1. To avoid unnecessary technical difficulties we assume that $W(p) = W(1-p)$. The two global minimum points are nondegenerate, i.e., $W''(0) = W''(1) \neq 0$. A simple example is $W(u) = \frac{1}{4}((u - \frac{1}{2})^2 - \frac{1}{4})^2$.

The most mathematically interesting part in equation (1.1) is the nonlocal term $(-\Delta)^{-1/2}(u-a)$ in the integrand. Let $(-\Delta)^{-1}(u-a)$ be the solution v of

$$-\Delta v = u - a \text{ in } D, \quad \partial_\nu v = 0 \text{ on } \partial D, \quad \overline{v} = 0,$$

where $\partial_\nu v$ is the outward normal derivative of v. $(-\Delta)^{-1/2}$ in I is the square root of the positive operator $(-\Delta)^{-1}$ from $\{w \in L^2(D) : \overline{w} = 0\}$ to itself. If we let

[1] See Choksi and Ren [3] for more on these parameters.

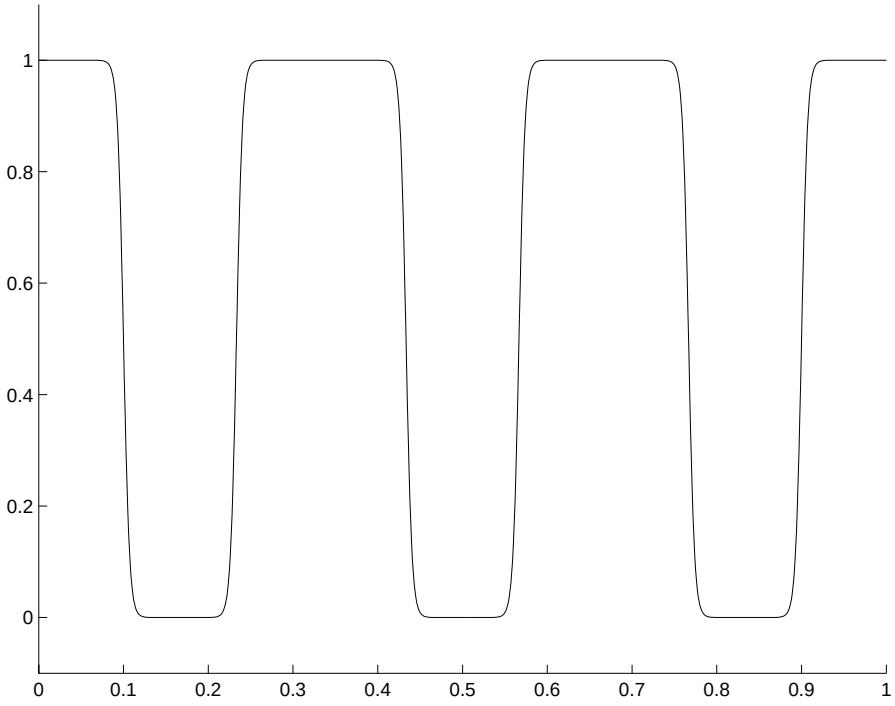

FIG. 3. *A one-dimensional local minimizer u with $K = 6$. The regions where u is close to 1 are microdomains with high concentration of A monomers, and the regions where u is close to 0 are microdomains with high concentration of B monomers.*

$v = (-\Delta)^{-1}(u - a)$, then an often more useful formula is

$$I(u) = \int_D \left\{ \frac{\epsilon^2}{2}|\nabla u|^2 + \frac{\epsilon\gamma}{2}|\nabla v|^2 + W(u) \right\}.$$

Let $f(u) = W'(u)$ as in Figure 2. For the particular $W(u) = \frac{1}{4}((u - \frac{1}{2})^2 - \frac{1}{4})^2$, $f(u) = u(u - \frac{1}{2})(u - 1)$. The Euler–Lagrange equation of I is

$$-\epsilon^2\Delta u + \epsilon\gamma(-\Delta)^{-1}(u - a) + f(u) - \overline{f(u)} = 0, \quad \partial_\nu u = 0 \text{ on } \partial D. \tag{1.2}$$

The term $\overline{f(u)}$ is equal to the Lagrange multiplier corresponding to the constraint $\overline{u} = a$.

It is proved in Ren and Wei [13] using the Γ-limit theory that when $D = (0, 1)$ for any positive integer K there exists a local minimizer u with K interfaces and $K + 1$ microdomains if ϵ is small enough.[2] An example of u with $K = 6$ is shown in Figure 3. u is close to 0 in three regions and close to 1 in four regions. These regions are separated by sharp interfaces. That such u is energetically favored is not too difficult to explain. Note that the W term in I likes to have $u \approx 0$ or $u \approx 1$. The gradient term penalizes oscillation of u, but since it has a small coefficient it tolerates a number of sharp interfaces. The best profile for the nonlocal term is $u \approx a$. But this is impossible due to the presence of the W term and the fact $0 < a < 1$. The second

[2] See Theorem 2.1.

best profile for the nonlocal term is for u to have wild oscillation about a. When all the three terms are present in I, a compromise must be reached, and u as in Figure 3 emerges as a local minimizer.

Now we place such a one-dimensional (1-D) local minimizer in a three-dimensional (3-D) box through trivial extension. The extended u becomes a 3-D critical point of I, i.e., a solution of (1.2). We ask whether this u is a good model of the lamellar phase depicted in plot 3 of Figure 1. In general a morphology phase must be at least *metastable* in the sense that it is described by a local minimizer of I in space. Such a 3-D local minimizer is also called a stable solution of (1.2). We take $D = (0,1)\times(0,1)\times(0,1)$ and study the spectrum of u, i.e., the second variation of I at u. The linearized operator at u is

$$\begin{aligned} &L(\phi) := -\epsilon^2\Delta\phi + \epsilon\gamma(-\Delta)^{-1}\phi + f'(u)\phi - \overline{f'(u)\phi}, \\ &\partial_\nu\phi = 0 \text{ on } \partial D, \quad \phi \in W^{2,2}(D), \quad \overline{\phi} = 0. \end{aligned} \tag{1.3}$$

This is an unbounded self-adjoint operator defined densely on $\{\phi \in L^2(D) : \overline{\phi} = 0\}$ whose spectrum consists of eigenvalues only.

We will obtain detailed information on the spectrum of u when ϵ is small. In particular we will find the asymptotic expansions of the important eigenvalues of small absolute values in terms of ϵ. We will also derive asymptotic expansions of the corresponding eigenfunctions. The analysis in this paper culminates in the following theorem.

THEOREM 1.1. *The eigenvalues λ of L are classified into λ_m by $m = (m_1, m_2)$, which is a pair of nonnegative integers. The following three statements hold when ϵ is sufficiently small:*

1. *There exists $M(K)$, depending on K but not ϵ, so that when $|m| := \sqrt{m_1^2 + m_2^2}$ $\geq M(K)$, $\lambda_m \geq C\epsilon^2$ for some $C > 0$ independent of ϵ.*
2. *When $m = (0,0)$, there are K small positive $\lambda_{(0,0)}$'s. One of them is of order ϵ whose only eigenfunction is approximately $\sum_j (h_j(x) - \overline{h_j})$. The other $K-1$ $\lambda_{(0,0)}$'s are of order ϵ^2. Their only eigenfunctions are approximately $\sum_j c_j^0 h_j(x)$ for some vectors c^0 satisfying $\sum_j c_j^0 = 0$. The remaining $\lambda_{(0,0)}$'s are positive and bounded below by a positive constant independent of ϵ.*
3. *When $m \neq (0,0)$ and $|m| < M(K)$, there are K λ_m's of order ϵ^2, which are not necessarily positive, whose only eigenfunctions are approximately $\sum_j c_j^0 h_j(x)\cos(m_1\pi y_1)\cos(m_2\pi y_2)$. The remaining λ_m's are positive and bounded below by a positive constant independent of ϵ. Only when K is sufficiently large or γ is sufficiently small are all the eigenvalues of L positive and u stable.*

Here a point in D is denoted by (x, y_1, y_2), where x is in the direction perpendicular to the interfaces of a lamellar phase, the up direction in plot 3, Figure 1. The functions h_j are defined in (3.5), and the c^0 vectors are given in sections 5 and 7. The $\lambda_{(0,0)}$ eigenvalues are just the eigenvalues in the 1-D problem. That they are positive, as noted in statement 2, is consistent with the fact that u is a 1-D local minimizer.

The most exciting discovery is apparently statement 3. The presence of the λ_m's there is a 3-D phenomenon. A 1-D local minimizer is *not necessarily* a local minimizer in three dimensions. Not all 1-D local minimizers may be used to model the lamellar phase of diblock copolymers. Only the ones with sufficiently many interfaces, or in other words with sufficiently thin microdomains, are suitable candidates.

Of particular interest is the 1-D global minimizer, which is one of the 1-D local minimizers with $K \approx (\frac{a^2b^2\gamma}{3\tau})^{1/3}$, where τ is a positive number specified in (2.7). Since

its energy is lower than that of any other 1-D local minimizer, it is thermodynamically more preferred. But if it were unstable in three dimensions, then the lamellar phase would only be a transient metastable phase. Thermal fluctuation would eventually destroy any metastable lamellar phase. It turns out that the 1-D global minimizer has a delicate spectral property. It actually lies near the *borderline* of the stability of lamellar solutions.[3]

The stability of a solution of (1.2) may also be defined by a dynamic problem. As observed in [8] one may consider negative gradient flows of I in various function spaces. The simplest one is probably

$$u_t = \epsilon^2 \Delta u - \epsilon\gamma(-\Delta)^{-1}(u-a) - f(u) + \overline{f(u)}, \quad \partial_\nu u = 0 \text{ on } \partial D \times (0,\infty). \tag{1.4}$$

A physically more realistic dynamic model is the Cahn–Hilliard-like [1] fourth order problem:

$$u_t = \Delta(-\epsilon^2\Delta u + \epsilon\gamma(-\Delta)^{-1}(u-a) + f(u)), \quad \partial_\nu \Delta u = \partial_\nu u = 0 \text{ on } \partial D \times (0,\infty). \tag{1.5}$$

The stability of steady states of (1.4) or (1.5) agrees with our static stability definition that a stable solution of (1.2) is a local minimizer of I.

Some preliminary work is done in section 2. We derive inner and outer asymptotic expansions of the lamellar solution u in a rigorous way. The first statement of the theorem is proved in section 3, the second in sections 4 and 5, and the third in sections 6 and 7. In the last section we discuss the spectrum of the 1-D global minimizer.

To avoid clumsy notation a quantity's dependence on ϵ is usually suppressed. For example, we write u, the lamellar solution, instead of u_ϵ. On the other hand we often emphasize a quantity's independence of ϵ with a superscript 0. For example, the limit of a lamellar solution u as $\epsilon \to 0$ is denoted by u^0. In estimates, C is always a positive constant independent of ϵ. Its value may vary from line to line. The shorthand *e.s.* stands for a quantity that is exponentially small, i.e., equals $O(e^{-C/\epsilon})$. The L^2 inner product is denoted by $\langle \cdot, \cdot \rangle$ and the L^p norm by $\| \cdot \|_p$.

References on the mathematical aspects of the block copolymer theory include, in addition to the ones cited already, Ohnishi et al. [9], Choksi [2], Fife and Hilhorst [4], Henry [6], and Ren and Wei [11, 14] on diblock copolymers. On triblock copolymers we refer to Ren and Wei [15, 16].

2. The lamellar solution u. The lamellar solutions we consider in this paper were constructed in [13] by the Γ-limit theory.

THEOREM 2.1 (Ren and Wei [13]). *In* 1-D *for each positive integer K the functional*

$$I_1(u) := \int_0^1 \left\{ \frac{\epsilon^2}{2} \left(\frac{du}{dx}\right)^2 + \frac{\epsilon\gamma}{2} \left| \left(-\frac{d^2}{dx^2}\right)^{-1/2} (u-a) \right|^2 + W(u) \right\} dx \tag{2.1}$$

in $\{u \in W^{1,2}(0,1) : \overline{u} = a\}$ has a local minimizer u near u^0, under the L^2 norm, when ϵ is sufficiently small. It satisfies the Euler–Lagrange equation

$$-\epsilon^2 u'' + f(u) - \overline{f(u)} + \epsilon\gamma G_0[u-a] = 0, \quad u'(0) = u'(1) = 0$$

[3] This phenomenon compares well with the *marginal* stability, observed in Muratov [7], of the corresponding 1-D global minimizer in the Γ-limit.

and the properties

$$\lim_{\epsilon\to 0}\|u-u^0\|_2=0 \quad \textit{and} \quad \lim_{\epsilon\to 0}\epsilon^{-1}I_1(u)=\tau K+\frac{\gamma}{2}\int_0^1|(v^0)'|\,dx.$$

Here u^0 is a step function defined to be

$$u^0(x)=1 \text{ on } (0,x_1^0),\quad 0 \text{ on } (x_1^0,x_2^0),\quad 1 \text{ on } (x_2^0,x_3^0),\quad 0 \text{ on } (x_3^0,x_4^0),\quad 1 \text{ on } (x_4^0,x_5^0),\dots$$

with (recall $b=1-a$)

$$x_1^0=\frac{a}{K},\quad x_2^0=\frac{1+b}{K},\quad x_3^0=\frac{2+a}{K},\quad x_4^0=\frac{3+b}{K},\quad x_5^0=\frac{4+a}{K},\dots,$$

$v^0=G_0[u^0-a]$. G_0 is the solution operator of $-v''=g$, $v'(0)=v'(1)=0$, $\overline{v}=0$. The constant τ is positive and defined in (2.7).

There is another K-interface lamellar solution whose limiting value as $\epsilon\to 0$ is 0 instead of 1 on the first interval $(0,b/K)$. This solution has the same properties as u does, so we focus on u, the solution of the first type, only.

Remark 2.2. This second solution is just $1-\tilde{u}$, where $\tilde{u}$ is a solution of the first type, but with $\overline{\tilde{u}}=1-a$.

In this section we learn more about u. In particular u is periodic.

THEOREM 2.3. *When ϵ is small, for every $x\in(0,1/K)$,*

$$\begin{aligned}u(x)&=u\left(\frac{2}{K}-x\right)=u\left(x+\frac{2}{K}\right)=u\left(\frac{4}{K}-x\right)=u\left(x+\frac{4}{K}\right)=\cdots\\&=\begin{cases}u(1-x) & \textit{if } K \textit{ is even,}\\ u(x+\frac{K-1}{K}) & \textit{if } K \textit{ is odd.}\end{cases}\end{aligned}$$

Moreover when ϵ is small, u is the unique local minimizer of I_1 in an L^2 neighborhood of u^0. If u on $((j-1)/K,j/K)$ for some $j=1,2,\dots,K$ is scaled to a function on $(0,1)$, then it is exactly a one-layer local minimizer of (2.1) *with ϵ and γ replaced by $\tilde{\epsilon}=\epsilon K$ and $\tilde{\gamma}=\gamma/K^3$.*

The nuts and bolts needed to prove this theorem are available in [11]. We give the proof in Appendix A, so the reader may skip it first in order to focus on the spectral properties of u in the following sections.

For that purpose we need asymptotic expansions of u in terms of ϵ. By Lemma A.1 in Appendix A there exist exactly K points x_j, $j=1,2,\dots,K$, in $(0,1)$ so that $u(x_j)=1/2$. These K points identify the interfaces of u. Theorem 2.3 implies that $x_2=\frac{2}{K}-x_1$, $x_3=\frac{4}{K}-x_2$, $x_4=\frac{6}{K}-x_3$, etc. The first approximation of u is

$$\begin{aligned}w(x)&=H\left(-\frac{x-x_1}{\epsilon}\right)+H\left(\frac{x-x_2}{\epsilon}\right)+H\left(-\frac{x-x_3}{\epsilon}\right)-1+\cdots\\&\quad+\begin{cases}H(\frac{x-x_K}{\epsilon}) & \text{if } K \text{ is even,}\\ H(-\frac{x-x_K}{\epsilon})-1 & \text{if } K \text{ is odd.}\end{cases}\end{aligned}\tag{2.2}$$

Here H is the heteroclinic solution of

$$-H''+f(H)=0,\quad H(-\infty)=0,\quad H(\infty)=1,\quad H(0)=1/2.$$

In the case $W(u)=\frac{1}{4}((u-\frac{1}{2})^2-\frac{1}{4})^2$, it is explicitly known that $H(t)=(1/2)(\tanh\frac{t}{2\sqrt{2}}+1)$. $H(t)$ converges to 1 as $t\to\infty$ (and to 0 as $t\to-\infty$) exponentially fast. Also $H'(t)$ and $H''(t)$ decay to 0 exponentially fast as $t\to\pm\infty$. H,

or $H(-\cdot)$, gives the profile of interfaces between the microdomains of u. At every $x \neq x_j^0$, $j = 1, 2, \ldots, K$, $\lim_{\epsilon\to 0} w(x) = u^0(x)$.

Next we define

$$z^0(x) = -\frac{\gamma(v^0(x) - v^0(x_j^0))}{f'(0)}. \tag{2.3}$$

Let us compute

$$(v^0)'(x) = \begin{cases} (a-1)x & \text{on } (0, x_1^0), \\ a(x - \frac{1}{K}) & \text{on } (x_1^0, x_2^0), \\ (a-1)(x - \frac{2}{K}) & \text{on } (x_2^0, x_3^0), \\ a(x - \frac{3}{K}) & \text{on } (x_3^0, x_4^0), \\ (a-1)(x - \frac{4}{K}) & \text{on } (x_4^0, x_5^0), \\ \cdots. \end{cases} \tag{2.4}$$

If we integrate $(v^0)'$ over an interval (x_{j-1}^0, x_j^0), we get 0. So $v^0(x_j^0)$ is independent of j, and the definition of z^0 makes sense. Note that z^0 is independent of ϵ.

LEMMA 2.4. *Let z be defined by $u = w + \epsilon z$. Then $\|z - z^0\|_\infty = O(\epsilon)$.*

Proof. Combine Lemma A.3 in Appendix A and Theorem 2.3. □

LEMMA 2.5. *There exists a constant $C > 0$ independent of ϵ so that $|\epsilon^{-1} z(x_j + \epsilon t)| \le C(1 + |t|)$ for all $t \in (-\frac{x_j}{\epsilon}, \frac{1-x_j}{\epsilon})$. $\epsilon^{-1} z(x_j + \epsilon\cdot)$ converges to P in $C^2_{loc}(-\infty, \infty)$, where $P(t)$ is the solution of*

$$-P'' + f'(H)P = -\gamma(v^0)'(x_j^0)t, \quad P \perp H'$$

in $(-\infty, \infty)$.

There are two different P's depending on whether j is odd or even. But they just differ by a sign, and it is always easy to tell from the context which one is referred to. Once j is given, there exists a unique P since the right side of its equation is perpendicular to the kernel H'.

Proof. Without the loss of generality we assume that j is even. Define $Z(t) = z(x_j + \epsilon t)$. Lemma 2.4 implies $Z = O(1)$ and hence, with the help of Lemma A.4, $\overline{f(u)} = O(\epsilon)$. From the 1-D Euler–Lagrange equation in Theorem 2.1, which u satisfies, we find the equation for Z:

$$-Z'' + f'(H)Z + O(\epsilon)Z^2 + \gamma G_0[u - a] - \epsilon^{-1}\overline{f(u)} = 0.$$

From this equation we also have $Z'' = O(1)$ and $Z' = O(1)$. Multiply the equation by H' and integrate. Set $v(x) = G_0[u - a](x)$. Then

$$\begin{aligned} \text{e.s.} &= \int_{-x_j/\epsilon}^{(1-x_j)/\epsilon} (-Z''H' + f'(H)ZH')\, dt \\ &= \int_{-x_j/\epsilon}^{(1-x_j)/\epsilon} (-O(\epsilon)Z^2 - \gamma v(x_j + \epsilon t) + \epsilon^{-1}\overline{f(u)})H'\, dt \\ &= -\gamma v(x_j) + \epsilon^{-1}\overline{f(u)} + O(\epsilon). \end{aligned}$$

Hence $\gamma v(x_j) - \epsilon^{-1}\overline{f(u)} = O(\epsilon)$ and $\gamma v(x) - \epsilon^{-1}\overline{f(u)} = O(\epsilon) + O(\epsilon)t$. The equation for Z is now simplified to

$$-Z'' + f'(H)Z + O(\epsilon) + O(\epsilon)t = 0.$$

As $\epsilon \to 0$, $Z \to cH'$ in $C^2_{loc}(-\infty,\infty)$ for some c. But $Z(0) = $e.s. implies $c = 0$ since $H'(0) \neq 0$. Therefore $Z \to 0$ in $C^2_{loc}(-\infty,\infty)$.

Next we study $\epsilon^{-1}Z$, whose equation is written as

$$-(\epsilon^{-1}Z)'' + f'(H)(\epsilon^{-1}Z) + O(1)Z^2 + \gamma\epsilon^{-1}v - \epsilon^{-2}\overline{f(u)} = 0.$$

We again multiply by H' and integrate:

$$\begin{aligned}
\text{e.s.} &= \int_{-x_j/\epsilon}^{(1-x_j)/\epsilon} (-\epsilon^{-1}Z''H' + f'(H)\epsilon^{-1}ZH')\,dt \\
&= \int_{-x_j/\epsilon}^{(1-x_j)/\epsilon} (-O(1)Z^2 - \gamma\epsilon^{-1}v(x_j+\epsilon t) + \epsilon^{-2}\overline{f(u)})H'\,dt \\
&= \int_{-x_j/\epsilon}^{(1-x_j)/\epsilon} (-O(1)Z^2 - \gamma\epsilon^{-1}v(x_j) - \gamma v'(x_j)t + O(\epsilon)t^2 + \epsilon^{-2}\overline{f(u)})H'\,dt \\
&= -\gamma\epsilon^{-1}v(x_j) + \epsilon^{-2}\overline{f(u)} + o(1),
\end{aligned}$$

where we have used the facts that $Z \to 0$ locally and $\int_{-x_j/\epsilon}^{(1-x_j)/\epsilon} tH'\,dt = $e.s. Hence $\gamma\epsilon^{-1}v(x_j) - \epsilon^{-2}\overline{f(u)} = o(1)$, which simplifies the equation for $\epsilon^{-1}Z$ to

$$-(\epsilon^{-1}Z)'' + f'(H)(\epsilon^{-1}Z) + O(1)Z^2 + \gamma v'(x_j)t + O(\epsilon)t^2 + o(1) = 0. \tag{2.5}$$

Next we show that $|\epsilon^{-1}Z(t)| \le C(1+|t|)$. Without the loss of generality we consider $t > 0$. Let $\epsilon^{-1}Z(t) = (1+t)R(t)$, where R satisfies

$$-R'' - \frac{2R'}{1+t} + f'(H)R + O(1) = 0 \ \text{ in } \left(0, \frac{1-x_j}{\epsilon}\right), \quad R(0) = \text{e.s.}, \quad R\left(\frac{1-x_j}{\epsilon}\right) = O(1).$$

Suppose that $R = O(1)$ is invalid. We let $\hat{R} = R/\|R\|_{L^\infty}$, which satisfies

$$-\hat{R}'' - \frac{2\hat{R}'}{1+t} + f'(H)\hat{R} + o(1) = 0, \quad \hat{R}(0) = \text{e.s.}, \quad \hat{R}\left(\frac{1-x_j}{\epsilon}\right) = o(1).$$

From this equation we see that $|\hat{R}|$ must attain its maximum value 1 in a bounded region around 0. In the limit $\hat{R}$ approaches in $C^2_{loc}[0,\infty)$ to a nonzero, bounded solution of

$$-\hat{R}_\infty'' - \frac{2\hat{R}_\infty}{1+t} + f'(H)\hat{R}_\infty = 0 \ \text{ in } (0,\infty), \quad \hat{R}_\infty(0) = 0.$$

Then $(1+t)\hat{R}_\infty$ satisfies

$$-((1+t)\hat{R}_\infty)'' + f'(H)(1+t)\hat{R}_\infty = 0 \ \text{ in } (0,\infty).$$

Thus, $(1+t)\hat{R}_\infty(t) = cH'(t)$ for some c. This is because $|(1+t)\hat{R}_\infty(t)|$ grows at most like t, and any other solution, independent of H', of the last equation grows exponentially fast. Since $(1+0)\hat{R}_\infty(0) = 0$ and $H'(0) \neq 0$, we derive $c = 0$ and $\hat{R}_\infty = 0$, a contradiction.

Since $|\epsilon^{-1}Z(t)| \le C(1+|t|)$, we may send $\epsilon \to 0$ in (2.5) and find that $\epsilon^{-1}Z$ approaches in $C^2_{loc}(-\infty,\infty)$ to a solution of

$$-P'' + f'(H)P = -\gamma(v^0)'(x_j^0)t \ \text{ in } (-\infty,\infty).$$

We write the solution family as $P + cH'$ with $P \perp H'$. Here $P(0) = 0$, and $P(0) + cH'(0) = cH'(0)$, where $H'(0) \neq 0$. Since $\epsilon^{-1}Z(0) =$ e.s., we must have $c = 0$, and $\epsilon^{-1}Z \to P$ in $C^2_{loc}(-\infty, \infty)$. □

In the language of singular perturbation theory, the last two lemmas assert that the outer expansion of u is $u^0 + \epsilon z^0 + \cdots$ and the inner expansion at x_j (when j is even) is $H + \epsilon^2 P + \cdots$. The fact that $z^0(x_j^0) = 0$ matches the absence of the ϵ order term in the inner expansion. The function w defined in (2.2) is the 0th order uniform approximation of u.

We close this section by defining two frequently used constants. The first one is

$$s := \int_{-\infty}^{\infty} f''(H(t))(H'(t))^2 P(t)\, dt = -\frac{\gamma ab}{K}. \tag{2.6}$$

Here P is associated with an even j. When P is associated with an odd j in this paper, $f''(H(t))$ will always be changed to $f''(H(-t)) = -f''(H(t))$, so s remains the same. To verify the equality in (2.6) we differentiate the equation for P, multiply by H', and integrate. The right side becomes $-\gamma(v^0)'(x_2^0)$. The left side becomes

$$\int_{-\infty}^{\infty} (-P'''H' + f'(H)P'H' + f''(H)(H')^2 P)\, dt = \int_{-\infty}^{\infty} f''(H)(H')^2 P\, dt,$$

where the first two terms on the left side cancel after integration by parts and using $-H''' + f'(H)H' = 0$, which follows after differentiating the equation for H. From (2.4) we find $(v^0)'(x_2^0) = ab/K$ and $s = -\gamma ab/K$.

The second constant is

$$\tau := \int_{-\infty}^{\infty} (H'(t))^2\, dt > 0. \tag{2.7}$$

Because the equation for H has a first integral $-\frac{(H')^2}{2} + W(H) = 0$, then $\tau = \int_{-\infty}^{\infty} \sqrt{2W(H(t))} H'(t)\, dt = \int_0^1 \sqrt{2W(p)}\, dp$.[4] In the special case $W(u) = \frac{1}{4}((u - \frac{1}{2})^2 - \frac{1}{4})^2$, $\tau = \frac{\sqrt{2}}{12}$.

3. Linearization at u. The 1-D local minimizer u of I_1 is now viewed as a function on D through extension to the second and third dimensions trivially, so $u(x, y_1, y_2) = u(x)$. It is a solution of (1.2) and $I_1(u) = I(u)$.

For an eigenpair (λ, ϕ) of (1.3) we separate variables so that

$$\phi(x, y_1, y_2) = \sum_{m_1, m_2 = 0}^{\infty} \phi_m(x) \cos(m_1 \pi y_1) \cos(m_2 \pi y_2). \tag{3.1}$$

We set $m = (m_1, m_2)$ and let $m^2 = m_1^2 + m_2^2$. Note that

$$(-\Delta)^{-1}\{\phi_m(x) \cos(m_1 \pi y_1) \cos(m_2 \pi y_2)\} = X(x) \cos(m_1 \pi y_1) \cos(m_2 \pi y_2),$$

where X is the solution of

$$-X'' = \phi_{(0,0)}, \quad X'(0) = X'(1) = 0, \quad \overline{X} = 0 \quad \text{if } m = (0, 0)$$

or

$$-X'' + m^2 \pi^2 X = \phi_m, \quad X'(0) = X'(1) = 0 \quad \text{if } m \neq (0, 0).$$

[4] In [13, 14, 16] this constant is defined by the last integral.

The solution operator of the first equation is G_0, already defined. Let $G_m[\cdot]$ be the solution operator of the second equation. They are identified with the Green functions $G_m(\cdot,\cdot)$ in this paper. Therefore $X = G_m[\phi_m]$. The eigenvalue problem $L\phi = \lambda\phi$ now becomes

$$\sum_m \{-\epsilon^2(\phi_m'' - m^2\pi^2\phi_m) + \epsilon\gamma G_m[\phi_m] + f'(u)\phi_m\}\cos(m_1\pi y_1)\cos(m_2\pi y_2) - \overline{f'(u)\phi_0}$$
$$= \lambda\sum_m \phi_m(x)\cos(m_1\pi y_1)\cos(m_2\pi y_2).$$

Here we have used the fact that $\overline{f'(u)\phi_m(x)\cos(m_1\pi y_1)\cos(m_2\pi y_2)} = 0$ if $m \neq (0,0)$.

Multiplying the equation by $\cos(m_1\pi y_1)\cos(m_2\pi y_2)$ and integrating with respect to y_1 and y_2, we find two cases:

1. When $m = (0,0)$,

$$-\epsilon^2\phi_{(0,0)}'' + \epsilon\gamma G_0[\phi_{(0,0)}] + f'(u)\phi_{(0,0)} - \overline{f'(u)\phi_{(0,0)}} = \lambda\phi_{(0,0)},$$
$$\phi_{(0,0)}'(0) = \phi_{(0,0)}'(1) = \overline{\phi_{(0,0)}} = 0. \tag{3.2}$$

2. When $m \neq (0,0)$,

$$-\epsilon^2(\phi_m'' - m^2\pi^2\phi_m) + \epsilon\gamma G_m[\phi_m] + f'(u)\phi_m = \lambda\phi_m,$$
$$\phi_m'(0) = \phi_m'(1) = 0. \tag{3.3}$$

Because the λ's are classified by m, we use λ_m to denote an eigenvalue that is associated with m. The corresponding eigenfunction is $\phi_m(x)\cos(m_1\pi y_1)\cos(m_2\pi y_2)$.

Proof of Theorem 1.1, *statement* 1. We first consider the local eigenvalue problem

$$E(\phi) := -\epsilon^2\phi'' + f'(u)\phi = \nu\phi, \quad \phi'(0) = \phi'(1) = 0. \tag{3.4}$$

In this proof an eigenpair of (3.4) is denoted by (ν,ϕ). We will prove that $\nu \geq -C\epsilon^2$ for some $C > 0$.

Claim 1. If $\nu \to \nu^0$ as $\epsilon \to 0$, then $\nu^0 \geq 0$.

Suppose on the contrary that $\nu^0 < 0$. Let $y \in [0,1]$ so that $\phi(y) = \max|\phi| = 1$. Then $y - x_j = O(\epsilon)$ for some j. Otherwise $-\epsilon^2\phi''(y) \geq 0$, $f'(u(y))\phi(y) > 0$, $\nu\phi(y) < 0$, and hence (3.4) is not satisfied. Then we consider $\Phi(t) = \phi(x_j + \epsilon t)$, which satisfies $-\Phi'' + f'(u)\Phi = \nu\Phi$ in $(-x_j/\epsilon, (1-x_j)/\epsilon)$. As $\epsilon \to 0$, Φ approaches $\Phi_\infty \not\equiv 0$ in $C^2_{loc}(-\infty,\infty)$, which satisfies $-\Phi_\infty'' + f'(H)\Phi_\infty = \nu^0\Phi$ in $(-\infty,\infty)$. But this is impossible since the last equation has no negative eigenvalues. This proves the claim.

The case $\nu^0 > 0$ does not concern us, so we assume $\nu \to 0$. We introduce, for $j = 1, 2, \ldots, K$,

$$h_j(x) = H'\left(\frac{x - x_j}{\epsilon}\right) + \text{e.s.} \tag{3.5}$$

Here e.s. is an exponentially small correction term. It is chosen so that $h_j(0) = h_j(1) = h_j'(0) = h_j'(1) = 0$, $\|h_j' - \epsilon^{-1}H''(\frac{\cdot - x_j}{\epsilon})\|_\infty = \text{e.s.}$, and $\|h_j'' - \epsilon^{-2}H'''(\frac{\cdot - x_j}{\epsilon})\|_\infty = \text{e.s.}$

Remark 3.1. Should we weaken the condition $W(p) = W(1-p)$, H' would no longer be even and we would set

$$h_j(x) = \begin{cases} H'(\frac{x-x_j}{\epsilon}) + \text{e.s.} & \text{if } j \text{ is even,} \\ H'(-\frac{x-x_j}{\epsilon}) + \text{e.s.} & \text{if } j \text{ is odd.} \end{cases}$$

Consider the subspace of $L^2(0,1)$ generated by h_j. Decompose $\phi = \sum_j c_j h_j + \psi$, so that $h_j \perp \psi$ for each $j = 1, 2, \ldots, K$. Note that

$$E(h_j) = (f'(u) - f'(H))h_j + \text{e.s.},$$

and by Lemma 2.5,

$$\begin{aligned} |(f'(u) - f'(H))h_j| &= |(f'(w(x_j + \epsilon t) + \epsilon z(x_j + \epsilon t)) - f'(H(t)))H'(t)| + \text{e.s.} \\ &= |f''(H(t))\epsilon z(x_j + \epsilon t)H'(t)| + O(\epsilon^4) \ = \ O(\epsilon^2). \end{aligned} \tag{3.6}$$

Hence we deduce

$$E(h_j) = O(\epsilon^2). \tag{3.7}$$

We write (3.4) as

$$\sum_{j=1}^{K} c_j E(h_j) + E(\psi) = \nu \sum_j c_j h_j + \nu\psi. \tag{3.8}$$

Claim 2. $\langle E(\psi), \psi\rangle \geq C\|\psi\|_2^2$ for some $C > 0$ independent of ϵ.

When we minimize the quotient $\frac{\langle E(\tilde\psi), \tilde\psi\rangle}{\|\tilde\psi\|_2^2}$ among nonzero $\tilde\psi$ subject to $\tilde\psi \perp h_j$ for every j, the minimizer, denoted by $\tilde\psi$ in this paragraph, satisfies

$$-\epsilon^2\tilde\psi'' + f'(u)\tilde\psi = \iota\tilde\psi + \sum_j d_j h_j. \tag{3.9}$$

The constant $\iota = \frac{\langle E(\tilde\psi), \tilde\psi\rangle}{\|\tilde\psi\|_2^2}$. Suppose that Claim 2 is false. Then $\lim_{\epsilon\to 0} \iota = \iota^0 \leq 0$. We multiply $\tilde\psi$ by a proper constant so there exists $y \in [0,1]$ such that $\tilde\psi(y) = \max|\tilde\psi| = 1$. Now we multiply (3.9) by h_k and integrate.

$$\langle E(h_k), \tilde\psi\rangle = \sum_j d_j \langle h_j, h_k\rangle.$$

The left side is $O(\epsilon^2)$ by (3.7). The right side is

$$\int_0^1 \sum_j d_j h_j h_k = \sum_j \epsilon d_j \tau \delta_{jk} + \text{e.s.}|d| = \epsilon\tau d_k + \text{e.s.}|d|,$$

where $\delta_{jk} = 1$ if $j = k$ and 0 otherwise, and $|d| = \sqrt{d_1^2 + d_2^2 + \cdots + d_K^2}$ is the norm of the vector d. Therefore $d_k = O(\epsilon)$. As in the proof of Claim 1, $y - x_j = O(\epsilon)$ for some j. Moreover we consider $\Psi(t) = \tilde\psi(x_j + \epsilon t)$, which satisfies $-\Psi'' + f'(u)\Psi = \iota\Psi + o(1)$. Passing to the limit we find a nonzero Ψ_∞ which satisfies $-\Psi_\infty'' + f'(H)\Psi_\infty = \iota^0\Psi_\infty$ in $(-\infty, \infty)$. Therefore $\iota^0 = 0$ and Ψ_∞ is proportional to H'. But on the other hand $\tilde\psi \perp h_j$ implies $\Psi_\infty \perp H'$. Hence $\Psi_\infty = 0$, contradicting the fact that Ψ_∞ is nonzero. This proves Claim 2.

We now return to (3.8). Multiply it by ψ and integrate. Use (3.7) to deduce

$$|c|O(\epsilon^2)\|\psi\|_2 + \langle E(\psi), \psi\rangle = \nu \int_0^1 \psi^2.$$

Then Claim 2 implies

$$\|\psi\|_2 = O(\epsilon^2)|c|. \tag{3.10}$$

Next we multiply (3.8) by h_k and integrate. The left side is

$$\begin{aligned}&\int_0^1 \left\{ E(h_k)\psi + \sum_j c_j E(h_j)h_k \right\} \\ &= \int_0^1 \left\{ (f'(u) - f'(H))h_k\psi + \text{e.s.}\psi + \sum_j c_j((f'(u) - f'(H))h_j h_k + \text{e.s.}) \right\},\end{aligned} \tag{3.11}$$

in which

$$\left| \int_0^1 (f'(u) - f'(H))h_k\psi \right| \le \|(f'(u) - f'(H))h_k\|_\infty \|\psi\|_2 = O(\epsilon^4)|c|$$

by (3.6) and (3.10), and

$$\begin{aligned}&\int_0^1 (f'(u) - f'(H))h_j h_k \\ &= \epsilon \int_{-x_j/\epsilon}^{(1-x_j)/\epsilon} \{f'(w(x_j + \epsilon t) + \epsilon z(x_j + \epsilon t)) - f'(H(t))\} H'(t)H'(t + (x_j - x_k)/\epsilon)\, dt + \text{e.s.} \\ &= \epsilon \int_{-x_j/\epsilon}^{(1-x_j)/\epsilon} \{f''(H(t))\epsilon z(x_j + \epsilon t) + O(\epsilon^2)z^2(x_j + \epsilon t)\} H'(t)H'(t + (x_j - x_k)/\epsilon)\, dt + \text{e.s.} \\ &= \epsilon^3 \int_{-x_j/\epsilon}^{(1-x_j)/\epsilon} f''(H(t))P(t)H'(t)H'(t + (x_j - x_k)/\epsilon)\, dt + o(\epsilon^3) \\ &= \epsilon^3 s\delta_{jk} + o(\epsilon^3)\end{aligned} \tag{3.12}$$

by Lemma 2.5. The above argument applies to the case when j is even. When j is odd, $f''(H(t))$ becomes $f''(H(-t)) = -f''(H(t))$ and $P(t)$ has a different sign, but the final result remains unchanged. Hence (3.11) becomes $\epsilon^3 s c_k + o(\epsilon^3)|c|$. The right side of (3.8) multiplied by h_k and integrated is $\nu\epsilon\tau c_k + \text{e.s.}|c|$. Equating the last two quantities, we find that for every k

$$sc_k + o(1)|c| = \frac{\nu\tau}{\epsilon^2} c_k.$$

Therefore $\nu \ge -C\epsilon^2$ for some $C > 0$ independent of ϵ.

Since G_m is a bounded, positive operator in the eigenvalue problem

$$-\epsilon^2\phi'' + \epsilon\gamma G_m[\phi] + f'(u)\phi = \nu\phi, \quad \phi'(0) = \phi'(1) = 0, \tag{3.13}$$

we again have $\nu \ge -C\epsilon^2$ for some $C > 0$ independent of ϵ. This can be seen easily by comparing the variational characterization of the principle eigenvalue of (3.13),

$$\inf \left\{ \int_0^1 \{\epsilon^2(\phi')^2 + \epsilon\gamma G_m[\phi]\phi + f'(u)\phi^2\}\, dx : \phi \in W^{1,2}(0,1),\ \|\phi\|_2 = 1 \right\},$$

to a similar one without the $\epsilon\gamma G_m[\phi]\phi$ term for (3.4). Finally, in (3.3), by setting m^2 large enough, we find $\lambda_m \ge C\epsilon^2$. □

4. $m = (0,0)$ eigenvalues. Here we study the $m_1 = m_2 = 0$ problem (3.2). Denote the linear operator there by L_0. An eigenpair of (3.2) is denoted by (λ, ϕ) in this section. Since (3.2) is precisely the linearized operator of the 1-D problem I_1 defined in (2.1) at a 1-D local minimizer u, we have $\lambda \geq 0$. The case $\lambda \to \lambda^0 > 0$ as $\epsilon \to 0$ does not concern us. So we assume $\lambda \to 0$ along a subsequence throughout the rest of this section.

We decompose $\phi = \sum_j c_j(h_j - \overline{h_j}) + \psi$, where $\psi \perp h_j - \overline{h_j}$ for every j. Note that

$$L_0(h_j - \overline{h_j}) = (f'(u) - f'(H))h_j + \epsilon\gamma G_0[h_j - \overline{h_j}] + (\overline{f'(u)} - f'(u))\overline{h_j} - \overline{f'(u)h_j} + \text{e.s.}$$

A few terms on the right side are estimated once and for all.

$$\epsilon\gamma G_0[h_j - \overline{h_j}](x) = \gamma\epsilon^2 G_0[(h_j - \overline{h_j})/\epsilon](x) = \gamma\epsilon^2 G_0(x, x_j) + O(\epsilon^3). \tag{4.1}$$

$$\begin{aligned}
\overline{f'(u)h_j} &= \epsilon \int_{-x_j/\epsilon}^{(1-x_j)/\epsilon} f'(w(x_j + \epsilon t) + \epsilon z(x_j + \epsilon t))H'(t)\, dt + \text{e.s.} \\
&= \epsilon \int_{-x_j/\epsilon}^{(1-x_j)/\epsilon} (f'(H(t)) + f''(H(t))\epsilon z(x_j + t) + O(\epsilon^4))H'(t)\, dt + \text{e.s.} \\
&= \epsilon^2 \int_{-\infty}^{\infty} f''(H(t))z(x_j + \epsilon t)H'(t)\, dt + O(\epsilon^5) \;=\; O(\epsilon^3),
\end{aligned} \tag{4.2}$$

where the last line follows from Lemma 2.5. The next estimate is not the sharpest.

$$|(\overline{f'(u)} - f'(u))\overline{h_j}| = |(\overline{f'(u)} - f'(u))|(\epsilon + \text{e.s.}) = O(\epsilon). \tag{4.3}$$

So based on the last three estimates and (3.6) we find

$$L_0(h_j - \overline{h_j}) = O(\epsilon). \tag{4.4}$$

We also need an L^1 version of (4.3):

$$\|(\overline{f'(u)} - f'(u))\overline{h_j}\|_1 = O(\epsilon)\|\overline{f'(u)} - f'(u)\|_1 = O(\epsilon)\|\overline{f'(w)} - f'(w) + O(\epsilon)\|_1 = O(\epsilon^2),$$

so we obtain

$$\|L_0(h_j - \overline{h_j})\|_1 = O(\epsilon^2). \tag{4.5}$$

Rewrite (3.2) as

$$\sum_j c_j L_0(h_j - \overline{h_j}) + L_0\psi = \lambda \sum_j c_j(h_j - \overline{h_j}) + \lambda\psi. \tag{4.6}$$

LEMMA 4.1. *$\langle L_0(\psi), \psi\rangle \geq C\|\psi\|_2^2$ for some $C > 0$ independent of ϵ.*

Proof. When we minimize the quotient $\frac{\langle L_0(\tilde\psi), \tilde\psi\rangle}{\|\tilde\psi\|_2^2}$ among nonzero $\tilde\psi$ of zero average subject to $\tilde\psi \perp h_j - \overline{h_j}$ for every j, the minimizer, denoted by $\tilde\psi$ in this proof, satisfies

$$-\epsilon^2\tilde\psi'' + \epsilon\gamma G_0[\tilde\psi] + f'(u)\tilde\psi - \overline{f'(u)\tilde\psi} = \iota\tilde\psi + \sum_j d_j(h_j - \overline{h_j}).$$

The constant $\iota = \frac{\langle L_0(\tilde\psi), \tilde\psi\rangle}{\|\tilde\psi\|_2^2}$. Suppose the lemma is false. Then $\lim_{\epsilon\to 0} \iota = \iota^0 \leq 0$. We multiply $\tilde\psi$ by a proper constant so there exists $y \in [0,1]$ such that $\tilde\psi(y) = \max|\tilde\psi| = 1$.

Now we multiply the last equation by $h_k - \overline{h_k}$ and integrate: $\langle L_0(h_k - \overline{h_k}), \tilde{\psi}\rangle = \sum_j d_j \langle h_j - \overline{h_j}, h_k - \overline{h_k}\rangle$. The left side is $O(\epsilon^2)$ by (4.5). The right side is

$$\int_0^1 \sum_j d_j (h_j - \overline{h_j})(h_k - \overline{h_k}) = \epsilon\tau d_k + O(\epsilon^2)|d|.$$

Therefore $d_k = O(\epsilon)$. The rest of the proof is the same as that of Claim 2 in section 3, since the additional terms in the equation satisfy

$$\epsilon\gamma G_0[\tilde{\psi}] = O(\epsilon),$$
$$\overline{f'(u)\tilde{\psi}} = \overline{(f'(u) - f'(0))\tilde{\psi}} \ = \ O(1)\|f'(u) - f'(0)\|_1 \ = \ O(\epsilon).$$

A minor difference is that $\tilde{\psi} \perp h_j$ here is a consequence of $\tilde{\psi} \perp h_j - \overline{h_j}$ and $\overline{\tilde{\psi}} = 0$. □

Multiply (4.6) by ψ and integrate. Using (4.4) we find

$$|c|O(\epsilon)\|\psi\|_2 + \langle L_0(\psi), \psi\rangle = \lambda\|\psi\|_2^2.$$

Lemma 4.1 implies that

$$\|\psi\|_2 = O(\epsilon)|c|. \tag{4.7}$$

Remark 4.2. As a comparison we compute

$$\left\|\sum_j c_j(h_j - \overline{h_j})\right\|_2 = \left\{\sum_j c_j^2 \int_0^1 h_j^2 + O(\epsilon^2)|c|^2\right\}^{1/2} = \{\epsilon\tau|c|^2 + O(\epsilon^2)|c|^2\}^{1/2} \sim \epsilon^{1/2}|c|.$$

So in the decomposition of ϕ, $\sum_j c_j(h_j - \overline{h_j})$ is more prominent than ψ.

Multiply (4.6) by $h_k - \overline{h_k}$ and integrate:

$$\int_0^1 L_0\psi(h_k - \overline{h_k}) + \sum_j c_j \int_0^1 L_0(h_j - \overline{h_j})(h_k - \overline{h_k}) = \lambda \sum_j c_j \int_0^1 (h_j - \overline{h_j})(h_k - \overline{h_k}). \tag{4.8}$$

The first term on the left side is written as

$$\int_0^1 L_0(\psi)(h_k - \overline{h_k}) \ = \ \int_0^1 L_0(h_k - \overline{h_k})\psi$$
$$= \int_0^1 \{(f'(u) - f'(H))h_k\psi + \epsilon\gamma G_0[h_k - \overline{h_k}]\psi + (\overline{f'(u)} - f'(u))\overline{h_k}\psi - \overline{f'(u)h_k}\psi + \text{e.s. } \psi\}$$
$$= \int_0^1 \{(f'(u) - f'(H))h_k\psi + \epsilon\gamma G_0[\psi]h_k + (f'(0) - f'(u))\overline{h_k}\psi + \text{e.s. } \psi\}. \tag{4.9}$$

The four terms are estimated as follows:

$$\left|\int_0^1 (f'(u) - f'(H))h_k\psi\right| \le \|(f'(u) - f'(H))h_k\|_\infty\|\psi\|_2 \ = \ O(\epsilon^2)\|\psi\|_2 \ = \ O(\epsilon^3)|c|,$$
$$\int_0^1 \epsilon\gamma G_0[\psi]h_k = O(\epsilon)\|G_0[\psi]\|_\infty\|h_k\|_1 \ = \ O(\epsilon^2)\|\psi\|_2 \ = \ O(\epsilon^3)|c|,$$
$$\int_0^1 (f'(0) - f'(u))\overline{h_k}\psi = \|f'(u) - f'(0)\|_2 O(\epsilon)\|\psi\|_2 \ = \ O(\epsilon^{2.5})|c|,$$
$$\int_0^1 \text{e.s. } \psi = \text{e.s.}\|\psi\|_2 \ = \ \text{e.s.}|c|.$$

Note that the first estimate follows from (3.6). The second term on the left of (4.8) is, for each j, by (4.1) and (4.2),

$$\begin{aligned}
&\int_0^1 L_0(h_j-\overline{h_j})(h_k-\overline{h_k}) \;=\; \int_0^1 L_0(h_j-\overline{h_j})h_k \\
&= \int_0^1 \{(f'(u)-f'(H))h_jh_k + \epsilon\gamma G_0[h_j-\overline{h_j}]h_k + (\overline{f'(u)}-f'(u))\overline{h_j}h_k - \overline{f'(u)h_j}h_k + \text{e.s.}\} \\
&= \epsilon^3 s\delta_{jk} + \gamma\epsilon^3 G_0(x_j,x_k) + \epsilon^2\overline{f'(u)} + o(\epsilon^3).
\end{aligned} \tag{4.10}$$

The last line follows from the estimates (3.12), (4.1), (4.2), and

$$\begin{aligned}
\int_0^1 (\overline{f'(u)}-f'(u))\overline{h_j}h_k &= (\epsilon+\text{e.s.})\left\{\overline{f'(u)}(\epsilon+\text{e.s.}) - \int_0^1 f'(u)h_k\right\} \\
&= \epsilon^2\overline{f'(u)} - \epsilon\int_0^1 f'(u)h_k + \text{e.s.} \\
&= \epsilon^2\overline{f'(u)} - \epsilon^2\int_{-x_k/\epsilon}^{(1-x_k)/\epsilon} (f'(H)+O(\epsilon^2))H'(t)\,dt + \text{e.s.} = \epsilon^2\overline{f'(u)} + O(\epsilon^4).
\end{aligned}$$

The right side of (4.8) is

$$\lambda\sum_j c_j\int_0^1 (h_j-\overline{h_j})(h_k-\overline{h_k}) = \lambda(\epsilon\tau c_k + O(\epsilon^2)|c|). \tag{4.11}$$

In summary, for every k

$$\epsilon^3 sc_k + \sum_j \{\gamma\epsilon^3 G(x_j,x_k) + \epsilon^2\overline{f'(u)} + o(\epsilon^3)\}c_j + O(\epsilon^{2.5})|c| = \lambda(\tau\epsilon c_k + O(\epsilon^2)|c|). \tag{4.12}$$

If we consider the c_k of the largest absolute value, since $\epsilon^2\overline{f'(u)} \sim \epsilon^2$, $\lambda = O(\epsilon)$. On the left side of (4.12), $\epsilon^2\overline{f'(u)}$ is the largest term. Because $\epsilon^2\overline{f'(u)}$ is multiplied by $\sum_j c_j$, a dichotomy appears at this point, unless $K = 1$.

Case 1. $\frac{\sum_k c_k}{|c|} \not\to 0$. Note that when $K = 1$, this is the only case. We rewrite (4.12) as

$$\overline{f'(u)}\sum_j c_j + O(\epsilon^{1/2})|c| = \frac{\lambda\tau}{\epsilon}c_k. \tag{4.13}$$

In the limit we have

$$f'(0)\sum_j c_j^0 = \eta\tau c_k^0, \qquad \sum_j c_j^0 \neq 0, \tag{4.14}$$

since $\lim_{\epsilon\to 0}\overline{f'(u)} = f'(0)$. Here $\eta = \lim_{\epsilon\to 0}\lambda/\epsilon$ and $\lim_{\epsilon\to 0} c_j = c_j^0$. Solving (4.14) we find

$$\eta = \frac{f'(0)K}{\tau}, \quad c_1^0 = c_2^0 = \cdots = c_K^0. \tag{4.15}$$

Thus we obtain the asymptotic expansions for one eigenpair $\lambda_{(0,0)} = \lambda$ and $\phi_{(0,0)} = \phi$ of (3.2):

$$\lambda_{(0,0)} = \frac{\epsilon f'(0)K}{\tau} + o(\epsilon), \quad \phi_{(0,0)} \approx \sum_j (h_j - \overline{h_j}). \tag{4.16}$$

Note that this $\lambda_{(0,0)}$ is positive.

Case 2. $\frac{\sum_k c_k}{|c|} \to 0$. This occurs when $K \geq 2$. To study this case, we rewrite $L_0(\phi) = \lambda\phi$ as

$$L_0(\psi) = -\sum_j c_j L_0(h_j - \overline{h_j}) + \lambda \sum_j c_j (h_j - \overline{h_j}) + \lambda\psi.$$

Note that

$$\sum_j c_j L_0(h_j - \overline{h_j}) = O(\epsilon^2)|c| + \sum_j c_j (\overline{f'(u)} - f'(u))\overline{h_j} = O(\epsilon^2)|c| + \left(\sum_j c_j\right) O(\epsilon) = o(\epsilon)|c|$$

by the assumption and by (4.1), (4.2), (3.6), and (4.3). Hence

$$L_0(\psi) = o(\epsilon)|c| + |\lambda| O(1)|c| + \lambda\psi. \tag{4.17}$$

LEMMA 4.3. $\|\psi\|_\infty = o(\epsilon)|c| + |\lambda| O(1)|c|$.

Proof. Suppose that the lemma is false. Replacing ψ by $\pm\frac{\psi}{\|\psi\|_\infty}$ in (4.17) we obtain $L_0(\psi) = o(1) + \lambda\psi$, where at some $y \in [0,1]$, $\psi(y) = \|\psi\|_\infty = 1$. We show that $y - x_j = O(\epsilon)$ for some j. Otherwise $-\epsilon^2\psi''(y) \geq 0$, $\epsilon\gamma G_0[\psi] = O(\epsilon)$, $f'(u)\psi(y) \to f'(0) > 0$, $-\overline{f'(u)\psi} = O(\epsilon)$, and $\lambda\psi(y) = O(\epsilon)$. Hence the equation $L_0(\psi) = o(1) + \lambda\psi$ is not satisfied. Then we set $\Psi(t) = \psi(x_j + \epsilon t)$, which satisfies $-\Psi'' + f'(u)\Psi = o(1)$ in $(-x_j/\epsilon, (1 - x_j)/\epsilon)$. As $\epsilon \to 0$, $\Psi \to \Psi_\infty \not\equiv 0$ in $C^2_{loc}(-\infty, \infty)$ and Ψ_∞ satisfies $-\Psi''_\infty + f'(H)\Psi_\infty = 0$. Hence Ψ_∞ is proportional to H'. On the other hand $\psi \perp h_j$ implies $\int_{-\infty}^{\infty} \Psi_\infty H' = 0$. Thus $\Psi_\infty = 0$, contradicting the fact that $\Psi_\infty \not\equiv 0$. □

With this lemma we return to (4.8) and recall

$$\int_0^1 (f'(u) - f'(H))h_k\psi = O(\epsilon^2)\|\psi\|_2, \quad \int_0^1 \epsilon\gamma G_0[\psi]h_k = O(\epsilon^2)\|\psi\|_2.$$

Rederive

$$\int_0^1 (f'(0) - f'(u))\overline{h_k}\psi = \|f'(u) - f'(0)\|_1 O(\epsilon)\|\psi\|_\infty \ = \ O(\epsilon^2)\|\psi\|_\infty.$$

Therefore

$$\int_0^1 L_0(\psi)(h_k - \overline{h_k}) = o(\epsilon^3)|c| + |\lambda| O(\epsilon^2)|c|, \tag{4.18}$$

and from (4.10)

$$\begin{aligned}\sum_j c_j \int_0^1 L_0(h_j - \overline{h_j})(h_k - \overline{h_k}) &= \epsilon^3 s c_k + \sum_j (\gamma\epsilon^3 G_0(x_j, x_k) + \epsilon^2\overline{f'(u)})c_j + o(\epsilon^3)|c| \\ &= O(\epsilon^3)|c| + \epsilon^2\overline{f'(u)}\left(\sum_j c_j\right) \ = \ o(\epsilon^2)|c|.\end{aligned}$$

This estimate and (4.18), (4.11) turn (4.8) into

$$|\lambda|O(\epsilon^2)|c| + o(\epsilon^2)|c| = \lambda(\epsilon\tau c_k + O(\epsilon^2)|c|).$$

From the c_k of the largest absolute value, we find, with the help of Lemma 4.3,

$$\lambda = o(\epsilon), \quad \|\psi\|_\infty = o(\epsilon)|c|. \tag{4.19}$$

So (4.18) is improved to $o(\epsilon^3)|c|$ and (4.8) reads

$$\epsilon^3 s c_k + \sum_j (\gamma\epsilon^3 G_0(x_j, x_k) + \epsilon^2\overline{f'(u)})c_j + o(\epsilon^3)|c| = \lambda\epsilon\tau c_k. \tag{4.20}$$

We sum over k. $\sum_k G_0(x_j^0, x_k^0)$ is independent of j, an issue further addressed in the next section, so we denote it by g. Then after dividing by $\epsilon^2|c|$ we obtain, using (4.19),

$$\frac{\sum_j c_j}{|c|}(\epsilon s + \gamma\epsilon g + \overline{f'(u)}K) + o(\epsilon) = o(1)\frac{\sum_j c_j}{|c|}.$$

Since $\overline{f'(u)} \sim 1$, $\frac{\sum_j c_j}{|c|} = o(\epsilon)$. Return to (4.20). Divide by ϵ^3. Since $\overline{f'(u)}\sum_j c_j = o(\epsilon)|c|$,

$$s c_k + \gamma \sum_j G_0(x_j, x_k)c_j + o(1)|c| = \frac{\lambda}{\epsilon^2}\tau c_k \tag{4.21}$$

for all k. In the limit we have

$$s c_k^0 + \gamma \sum_j G_0(x_j^0, x_k^0)c_j^0 = \eta\tau c_k^0, \quad \sum_j c_j^0 = 0. \tag{4.22}$$

Here $\eta = \lim_{\epsilon\to 0}\lambda/\epsilon^2$ and $c_j^0 = \lim_{\epsilon\to 0} c_j$. In the next section we will solve (4.22) to find $K-1$ pairs of η and c^0. Once they are determined we obtain the asymptotic expansions of $K-1$ eigenpairs $\lambda_{(0,0)} = \lambda$ and $\phi_{(0,0)} = \phi$ of (3.2):

$$\lambda_{(0,0)} = \epsilon^2\eta + o(\epsilon^2), \quad \phi_{(0,0)} \approx \sum_j c_j^0 h_j. \tag{4.23}$$

Here the $\overline{h_j}$ terms drop out in $\phi_{(0,0)}$ since $\sum_j c_j^0\overline{h_j} = \sum_j(1 + \text{e.s.})c_j^0 = \text{e.s.}|c|$ is negligible.

5. The spectrum of $[G_0(x_j^0, x_k^0)]$. To understand (4.22) we must find the spectrum of the K by K matrix $G_0(x_j^0, x_k^0)$. Suppose for every k that

$$\sum_j G_0(x_j^0, x_k^0)b_j = \Lambda b_k.$$

Note that from (4.22) $s + \gamma\Lambda = \tau\eta$. From the formula

$$G_0(x,y) = \begin{cases} \frac{x^2}{2} + \frac{(1-y)^2}{2} - \frac{1}{6} & \text{if } x < y, \\ \frac{(1-x)^2}{2} + \frac{y^2}{2} - \frac{1}{6} & \text{if } x > y \end{cases}$$

we see by straight computation that $\sum_k G_0(x_j^0, x_k^0)$ is independent of j. This number is an eigenvalue whose associated eigenvector is $(1, 1, \dots, 1)^T$, where the superscript ^{T} denotes the transpose of a vector. However, this eigenpair is discarded since by (4.22) we require that $\sum_j b_j = 0$.

To find other eigenpairs we let $\zeta = \sum_j G_0(x_j^0, \cdot) b_j$. Then ζ satisfies $-\zeta'' = \sum_j (\delta(\cdot - x_j^0) - 1) b_j = \sum_j \delta(\cdot - x_j^0)$, $\zeta'(0) = \zeta'(1) = 0$. Moreover $\zeta(x_k) = \Lambda b_k$ and $[-\zeta']_{x_j^0} = b_j$. Then for every k, $[-\zeta']_{x_j^0} = (1/\Lambda)\zeta(x_k^0)$. We need to express $[-\zeta']_{x_j^0}$ in terms of $\zeta(x_k^0)$. In other words we find a K by K matrix T so that $(T\vec{\zeta})_j = [-\zeta']_{x_j^0}$, where $\vec{\zeta} = (\zeta(x_1^0), \zeta(x_2^0), \dots, \zeta(x_K^0))^T$. This way the original eigenvalue problem is converted to

$$T\vec{\zeta} = \frac{1}{\Lambda}\vec{\zeta} \quad \text{with } b = \frac{1}{\Lambda}\vec{\zeta}. \tag{5.1}$$

To find T note that $-\zeta$ is affine between the x_j^0's. From $(0, x_1^0)$ we deduce

$$-\zeta'(x_1^0-) = \frac{-\zeta(x_1^0) + \zeta(x_0^0)}{a/K} = 0$$

since $\zeta'(0) = 0$. From (x_1^0, x_2^0) we obtain

$$-\zeta'(x_1^0+) = \frac{-\zeta(x_2^0) + \zeta(x_1^0)}{2b/K}.$$

Hence

$$[-\zeta']_{x_1^0} = \frac{K}{2b}\zeta(x_1^0) - \frac{K}{2b}\zeta(x_2^0).$$

On the other intervals we find

$$[-\zeta']_{x_j^0} = \left(\frac{K}{2a} + \frac{K}{2b}\right)\zeta(x_j^0) - \begin{cases} \dfrac{K}{2b}\zeta(x_{j-1}^0) - \dfrac{K}{2a}\zeta(x_{j+1}^0) & \text{if } j \text{ is even,} \\ \dfrac{K}{2a}\zeta(x_{j-1}^0) - \dfrac{K}{2b}\zeta(x_{j+1}^0) & \text{if } j \text{ is odd.} \end{cases}$$

When $K = 2$ we have

$$T = \begin{bmatrix} K/(2b) & -K/(2b) \\ -K/(2b) & K/(2b) \end{bmatrix}.$$

Therefore after discarding the 0 eigenvalue of the matrix, we find $\Lambda = \frac{b}{K}$. And for (4.22)

$$\eta = \frac{1}{\tau}\left(-\frac{\gamma a b}{K} + \frac{\gamma b}{K}\right), \quad c^0 = \begin{bmatrix} 1 \\ -1 \end{bmatrix}. \tag{5.2}$$

Note that $\eta > 0$. When $K \geq 3$ we have $T = (\alpha + \beta) I_{K\times K} - Q$, where $I_{K\times K}$ is the K by K identity matrix, $\alpha = K/(2a)$, $\beta = K/(2b)$, and

$$Q = \begin{bmatrix} \alpha & \beta & & & \\ \beta & 0 & \alpha & & \\ & \alpha & 0 & \beta & \\ & & \beta & 0 & \alpha \\ & & & \cdots & \end{bmatrix}.$$

The K distinct eigenvalues of Q are found in (B.5) of Appendix B. One of them, $\alpha+\beta$, is discarded, for its eigenvector is $(1,1,\dots,1)^T$. If we denote the rest of them by q_1, $q_2,\dots,q_{K-1}$, we have $K-1$ Λ's:

$$\Lambda = \frac{1}{\alpha+\beta-q_j}, \quad j=1,2,\dots,K-1.$$

Therefore $K-1$ pairs of

$$\eta = \frac{1}{\tau}\left(-\frac{\gamma ab}{K} + \frac{\gamma}{\alpha+\beta-q_j}\right), \quad c^0 = \vec{\zeta} \tag{5.3}$$

for (4.22) are found.

When concerned with the positivity of η, we consider the smallest Λ, which is associated with the smallest q_j. According to equation (B.5), the smallest q_j is $-\sqrt{\alpha^2+\beta^2+2\alpha\beta\cos\theta}$, where $\theta = 2\pi/K$. Hence the smallest Λ is

$$\Lambda = \frac{1}{\alpha+\beta+\sqrt{\alpha^2+\beta^2+2\alpha\beta\cos\theta}} > \frac{1}{2(\alpha+\beta)} = \frac{ab}{K}.$$

Therefore the smallest η of (4.22) is

$$\eta = \frac{s+\gamma\Lambda}{\tau} > \frac{1}{\tau}\left(-\frac{\gamma ab}{K} + \frac{\gamma ab}{K}\right) = 0.$$

Thus the η's in both (5.2) and (5.3) are positive.

Finally, we show that L_0 has exactly K simple eigenpairs with the asymptotic expansions (4.16) and (4.23). Let F be the linear subspace generated by small eigenvalues. It is defined nonambiguously by $F = \mathrm{span}\{\phi \in L^2(0,1) : \overline{\phi} = 0,\ L_0(\phi) = \lambda\phi,\ |\lambda| < \epsilon^{1/2}\}$. Since the small eigenvalues of L_0 are of order ϵ^2 or ϵ, F addresses all the small eigenvalues when ϵ is small enough.

First dim F, the dimensional of F, is at most K. Suppose that this is not the case. There exist two distinct eigenpairs (λ,ϕ) and (λ',ϕ') with the same asymptotic behavior. That is,

$$\lambda = \epsilon^2\eta + o(\epsilon^2), \quad \lambda' = \epsilon^2\eta + o(\epsilon^2), \qquad \text{or} \qquad \lambda = \epsilon\eta + o(\epsilon), \quad \lambda' = \epsilon\eta + o(\epsilon),$$

$$\phi = \sum_j c_j(h_j - \overline{h_i}) + \psi, \quad \phi = \sum_j c'_j(h_j - \overline{h_i}) + \psi', \quad \lim_{\epsilon\to 0} c_j = \lim_{\epsilon\to 0} c'_j = c^0_j.$$

However, the two eigenfunctions must be orthogonal, so

$$\begin{aligned} 0 &= \langle\phi,\phi'\rangle \\ &= \sum_{j,k} c_j c_k \langle h_j - \overline{h_i}, h_k - \overline{h_k}\rangle + O(|c|)\|\psi\|_2\|h_j\|_2 + O(|c|)\|\psi'\|_2\|h_j\|_2 + \|\psi\|_2\|\psi'\|_2 \\ &= \sum_j c_j^2 \int_0^1 h_j^2\,dx + o(\epsilon)|c|^2 \ = \ \epsilon|c^0|^2 \int_{-\infty}^{\infty} (H'(t))^2\,dt + o(\epsilon)|c^0|^2 \end{aligned}$$

by Remark 4.2. This is obviously impossible when ϵ is sufficiently small.

Next dim F is at least K. Suppose instead that dim $F < K$. Define a subspace of $\{\phi \in L^2(0,1) : \overline{\phi} = 0\}$: $S = \mathrm{span}\{\sum_j c_j^0(h_j - \overline{h_j}) : \text{all } c^0 \text{ found in (5.3)}\}$. We use

a perturbation argument. The asymmetric distance between the closed subspaces S and F is

$$d(S,F)=\sup\{d(\varphi,F):\varphi\in S,\|\varphi\|_2=1\},$$

where $d(x,F)=\inf\{\|x-y\|_2:y\in F\}$. Since $\dim F<\dim S$, there exists $\sum_j c_j^0(h_j-\overline{h_j})\in S$ such that for every eigenvector in F which may be written as $\sum_j c_j'(h_j-\overline{h_j})+\psi$ with $\|\psi\|_2=O(\epsilon)|c'|$ according to (4.7), $\sum_j \frac{c_j'}{|c'|}\frac{c_j^0}{|c^0|}=o(1)$. Then a straight computation shows

$$\left\langle \frac{\sum_j c_j'(h_j-\overline{h_j})+\psi}{\|\sum_j c_j'(h_j-\overline{h_j})+\psi\|_2}, \frac{\sum_j c_j^0(h_j-\overline{h_j})}{\|\sum_j c_j^0(h_j-\overline{h_j})\|_2}\right\rangle=o(1).$$

So if we use

$$\varphi=\frac{\sum_j c_j^0(h_j-\overline{h_j})}{\|\sum_j c_j^0(h_j-\overline{h_j})\|_2},$$

$d(\varphi,F)=1-o(1)$ and $d(S,F)=1-o(1)$. The following lemma due to Helffer and Sjöstrand [5] will give us a contradiction.

LEMMA 5.1. *Let L be a self-adjoint operator on a Hilbert space H, let R be a compact interval in $(-\infty,\infty)$, and let $e_1,e_2,\dots,e_K$ be normalized linearly independent elements in the domain of L. Assume that the following are true:*

1. *$L(e_k)=p_ke_k+r_k$, $\|r_j\|\le\epsilon'$, and $p_j\in R$, $k=1,2,\dots,K$.*
2. *There is $\omega>0$ so that R is ω-isolated in the spectrum of L, i.e., $(\sigma(L)\backslash R)\cap(R+(-\omega,\omega))=\emptyset$.*

Then $d(S,F)\le\frac{K^{1/2}\epsilon'}{\omega\kappa^{1/2}}$, where $S=span\{e_1,\dots,e_K\}$, $F=$ the closed subspace associated with $\sigma(L)\cap R$, and κ equals the smallest eigenvalue of the matrix $[\langle e_j,e_k\rangle]$.

Here we take $L=L_0$, each $e_k\propto\sum_j c_j^0(h_j-\overline{h_j})$ for each one of the K vectors c^0, and S, F as before. ω and κ are positive and bounded away from 0 as $\epsilon\to0$. Set $p_k=\eta\epsilon^2$ or $\eta\epsilon$ depending on c^0 and $R=[-\epsilon^{1/2},\epsilon^{1/2}]$. From (4.4) we find

$$L_0\left(\sum_j c_j^0(h_j-\overline{h_j})\right)-p_k\sum_j c_j^0(h_j-\overline{h_j})=O(\epsilon)|c^0|,$$

and on the other hand $\|\sum_j c_j^0(h_j-\overline{h_j})\|_2\sim\epsilon^{1/2}|c^0|$, as discussed in Remark 4.2. Therefore $\|r_k\|_2=O(\epsilon^{1/2})$. Consequently $d(S,F)=o(1)$, a contradiction. Statement 2 of Theorem 1.1 is proved.

6. $m\neq(0,0)$ eigenvalues. Rewrite (3.3) as

$$L_m(\phi):=-\epsilon^2\phi''+\epsilon\gamma G_m[\phi]+f'(u)\phi=\mu\phi, \tag{6.1}$$

where $\mu=\lambda_m-\epsilon^2m^2\pi^2$. In this section an eigenpair of (6.1) is denoted by (μ,ϕ).

LEMMA 6.1. *If $\mu\to\mu^0$ as $\epsilon\to0$, then $\mu^0\ge0$.*

The proof of this lemma is almost identical to that of Claim 1 in section 3, and we skip it, because the extra term $\epsilon\gamma G_m[\phi]$ is of order $O(\epsilon)$. The case $\mu^0>0$ does not concern us, so we assume $\mu\to0$. Decompose $\phi=\sum_j c_jh_j+\psi$, where $\psi\perp h_j$, $j=1,2,\dots,K$. Note that

$$L_m(h_j)=(f'(u)-f'(H))h_j+\epsilon\gamma G_m[h_j]+\text{e.s.}$$

Because of (3.6) and

$$\epsilon\gamma G_m[h_j](x) = \gamma\epsilon^2 G_m\left[\frac{h_j}{\epsilon}\right](x) = \gamma\epsilon^2 G_m(x, x_j) + O(\epsilon^3),$$

we deduce

$$L_m(h_j) = O(\epsilon^2). \tag{6.2}$$

We write (6.1) as

$$\sum_{j=1}^{K} c_j L_m(h_j) + L_m(\psi) = \mu \sum_j c_j h_j + \mu\psi. \tag{6.3}$$

LEMMA 6.2. *$\langle L_m(\psi), \psi\rangle \geq C\|\psi\|_2^2$ for some $C > 0$ independent of ϵ.*

We skip the proof of this lemma since it is similar to that of Claim 2 in section 3. Multiply (6.3) by ψ and integrate. Use (6.2) to deduce

$$|c|O(\epsilon^2)\|\psi\|_2 + \langle L_m(\psi), \psi\rangle = \mu\|\psi\|_2^2.$$

Then Lemma 6.2 implies

$$\|\psi\|_2 = O(\epsilon^2)|c|. \tag{6.4}$$

Next we multiply (6.3) by h_k and integrate. The left side is

$$\int_0^1 \left\{ L_m(\psi)h_k + \sum_j c_j L_m(h_j)h_k \right\} = \int_0^1 \left\{ L_m(h_k)\psi + \sum_j c_j L_m(h_j)h_k \right\}$$

$$= \int_0^1 \{(f'(u) - f'(H))h_k\psi + \epsilon\gamma G_m[h_k]\psi + \text{e.s.}\,\psi\}$$

$$+ \sum_j c_j \int_0^1 \{(f'(u) - f'(H))h_j h_k + G_m[h_j]h_k + \text{e.s.}\,h_k\}. \tag{6.5}$$

All terms in (6.5) are estimated.

$$\left|\int_0^1 (f'(u) - f'(H))h_k\psi\right| \leq \|(f'(u) - f'(H))h_k\|_\infty\|\psi\|_2 = O(\epsilon^4)|c|$$

by (3.6) and (6.4).

$$\int_0^1 \epsilon\gamma G_m[h_k]\psi = O(\epsilon)\int_0^1 G_m[\psi]h_k = O(\epsilon)\|G_m[\psi]\|_\infty\|h_k\|_1 = O(\epsilon^2)\|\psi\|_2 = O(\epsilon^4)|c|$$

by (6.4). The rest of (6.5) are estimated as in section 4:

$$\int_0^1 (f'(u) - f'(H))h_j h_k = \epsilon^3 s\delta_{jk} + O(\epsilon^4), \quad \int_0^1 \epsilon\gamma G_m[h_j]h_k = \gamma\epsilon^3 G_m(x_j, x_k) + o(\epsilon^3).$$

Hence (6.5) becomes

$$\epsilon^3 s c_k + \sum_j c_j \gamma\epsilon^3 G_m(x_j, x_k) + o(\epsilon^3)|c|.$$

The right side of (6.3) multiplied by h_k and integrated is

$$\int_0^1 \mu \sum_j c_j h_j h_k = \sum_j \mu\epsilon c_j \tau \delta_{jk} + \text{e.s.}|c| = \mu\epsilon\tau c_k + \text{e.s.}|c|.$$

Equating the last two quantities, we find that $\mu = O(\epsilon^2)$ and, for every k,

$$sc_k + \gamma \sum_j G_m(x_j, x_k) c_j + o(1)|c| = \frac{\mu\tau}{\epsilon^2} c_k. \tag{6.6}$$

So in the limit

$$sc_k^0 + \gamma \sum_j G_m(x_j^0, x_k^0) c_j^0 = \eta\tau c_k^0. \tag{6.7}$$

Here $\eta = \lim_{\epsilon\to 0} \mu/\epsilon^2 =$ and $c_j^0 = \lim_{\epsilon\to 0} c_j$. In the next section we will solve (6.7) to determine η and c^0. Once they are found we obtain the asymptotic expansions for the eigenpair $\lambda_m = \mu + \epsilon^2 m^2\pi^2$ and $\phi_m = \phi$:

$$\lambda_m = \epsilon^2(\eta + m^2\pi^2) + o(\epsilon^2), \quad \phi_m \approx \sum_j c_j^0 h_j. \tag{6.8}$$

7. The spectrum of $[G_m(x_j^0, x_k^0)]$. When dealing with

$$\sum_j G_m(x_j^0, x_k^0) b_j = \Lambda b_k,$$

we first consider the simplest case $K = 1$. Then $\Lambda = G_m(x_1^0, x_1^0)$. On $(0, x_1^0)$

$$G_m(x, x_1^0) = \frac{G_m(x_1^0, x_1^0)}{\cosh \tilde{m} x_1^0} \cosh \tilde{m} x,$$

where $\tilde{m} = \pi\sqrt{m_1^2 + m_2^2}$, and on $(x_1^0, 1)$

$$G_m(x, x_1^0) = \frac{G_m(x_1^0, x_1^0)}{\cosh \tilde{m}(1 - x_1^0)} \cosh \tilde{m}(1 - x).$$

Then

$$1 = [-G_m'(\cdot, x_1^0)]_{x_1^0} = \left\{ \frac{\tilde{m} \sinh \tilde{m} x_1^0}{\cosh \tilde{m} x_1^0} + \frac{\tilde{m} \sinh \tilde{m}(1 - x_1^0)}{\cosh \tilde{m}(1 - x_1^0)} \right\} G_m(x_1^0, x_1^0).$$

Therefore

$$\Lambda = \frac{1}{\tilde{m}(\tanh \tilde{m} a + \tanh \tilde{m} b)},$$

and in (6.7)

$$\eta = \frac{1}{\tau} \left(-\gamma ab + \frac{\gamma}{\tilde{m}(\tanh \tilde{m} a + \tanh \tilde{m} b)} \right), \quad c^0 = 1. \tag{7.1}$$

To see the sign of λ_m, we recall

$$\lim_{\epsilon\to 0} \frac{\lambda_m}{\epsilon^2} = \eta + m^2\pi^2 = \frac{1}{\tau} \left(-\gamma ab + \frac{\gamma}{\tilde{m}(\tanh \tilde{m} a + \tanh \tilde{m} b)} \right) + m^2\pi^2.$$

The right side is positive for all $m \neq (0,0)$ if γ is small enough, because $m^2\pi^2$ dominates the negative term. However, when γ is sufficiently large, we may find some large $\tilde{m}$ that makes the right side negative. To see this we first take $\tilde{m}$ large enough so that sum of the two terms in the parentheses is negative. Then we take γ large enough so the entire right side is negative.

When $K \geq 2$, $\sum_j G_m(x_j^0, x_k^0) b_j = \Lambda b_k$ is a more complex problem. Let ζ be the solution of $-\zeta'' + m^2\pi^2\zeta = \sum_j \delta(\cdot - x_j^0) b_j$, $\zeta'(0) = \zeta'(1) = 0$. Hence $[-\zeta']_{x_k^0} = b_k$ and $\zeta(x_k^0) = \Lambda b_k$. Then for every k, $[-\zeta']_{x_k^0} = \frac{1}{\Lambda}\zeta(x_k^0)$. As in section 5 we express $[-\zeta']_{x_k^0} = (T\vec{\zeta})_k$ in order to convert to the new eigenvalue problem $T\vec{\zeta} = (1/\Lambda)\vec{\zeta}$. Away from x_j^0, $\zeta = g_1 \cosh \tilde{m}x + g_2 \sinh \tilde{m}x$. From here we write, in the matrix notation,

$$\begin{bmatrix} \zeta(x_{j-1}^0) \\ \zeta(x_j^0) \end{bmatrix} = \begin{bmatrix} \cosh \tilde{m}x_{j-1}^0 & \sinh \tilde{m}x_{j-1}^0 \\ \cosh \tilde{m}x_j^0 & \sinh \tilde{m}x_j^0 \end{bmatrix} \begin{bmatrix} g_1 \\ g_2 \end{bmatrix}.$$

We denote the 2 by 2 matrix by A_L for the left of x_j^0. To the right we have similarly

$$\begin{bmatrix} \zeta(x_j^0) \\ \zeta(x_{j+1}^0) \end{bmatrix} = \begin{bmatrix} \cosh \tilde{m}x_j^0 & \sinh \tilde{m}x_j^0 \\ \cosh \tilde{m}x_{j+1}^0 & \sinh \tilde{m}x_{j+1}^0 \end{bmatrix} \begin{bmatrix} g_1 \\ g_2 \end{bmatrix},$$

with the 2 by 2 matrix denoted by A_R. Hence

$$\begin{bmatrix} g_1 \\ g_2 \end{bmatrix} = A_L^{-1} \begin{bmatrix} \zeta(x_{j-1}^0) \\ \zeta(x_j^0) \end{bmatrix} \text{ on } (x_{j-1}^0, x_j^0), \quad \begin{bmatrix} g_1 \\ g_2 \end{bmatrix} = A_R^{-1} \begin{bmatrix} \zeta(x_j^0) \\ \zeta(x_{j+1}^0) \end{bmatrix} \text{ on } (x_j^0, x_{j+1}^0).$$

Then

$$-\zeta'(x_j^0-) = -\tilde{m}[\sinh \tilde{m}x_j^0, \cosh \tilde{m}x_j^0] A_L^{-1} \begin{bmatrix} \zeta(x_{j-1}^0) \\ \zeta(x_j^0) \end{bmatrix},$$

$$-\zeta'(x_j^0+) = -\tilde{m}[\sinh \tilde{m}x_j^0, \cosh \tilde{m}x_j^0] A_R^{-1} \begin{bmatrix} \zeta(x_j^0) \\ \zeta(x_{j+1}^0) \end{bmatrix},$$

and

$$[-\zeta']_{x_j^0} = \tilde{m}[\sinh \tilde{m}x_j^0, \cosh \tilde{m}x_j^0] \left\{ A_L^{-1} \begin{bmatrix} \zeta(x_{j-1}^0) \\ \zeta(x_j^0) \end{bmatrix} - A_R^{-1} \begin{bmatrix} \zeta(x_j^0) \\ \zeta(x_{j+1}^0) \end{bmatrix} \right\}.$$

We also compute

$$A_L^{-1} = \frac{1}{\sinh \tilde{m}(x_j^0 - x_{j-1}^0)} \begin{bmatrix} \sinh \tilde{m}x_j^0 & -\sinh \tilde{m}x_{j-1}^0 \\ -\cosh \tilde{m}x_j^0 & \cosh \tilde{m}x_{j-1}^0 \end{bmatrix},$$

$$A_R^{-1} = \frac{1}{\sinh \tilde{m}(x_{j+1}^0 - x_j^0)} \begin{bmatrix} \sinh \tilde{m}x_{j+1}^0 & -\sinh \tilde{m}x_j^0 \\ -\cosh \tilde{m}x_{j+1}^0 & \cosh \tilde{m}x_j^0 \end{bmatrix}.$$

Thus T is a triagonal matrix. The three entries of the jth row where $j \neq 1, K$ are

$$-\tilde{m}\operatorname{csch} \tilde{m}(x_j^0 - x_{j-1}^0), \quad \tilde{m} \coth \tilde{m}(x_j^0 - x_{j-1}^0) + \tilde{m} \coth \tilde{m}(x_{j+1}^0 - x_j^0),$$

$$-\tilde{m}\operatorname{csch} \tilde{m}(x_{j+1}^0 - x_j^0).$$

For the first row,

$$\zeta(x) = \frac{\zeta(x_1^0)}{\cosh \tilde{m} x_1^0} \cosh \tilde{m} x$$

and

$$[-\zeta']_{x_1^0} = \tilde{m}(\tanh \tilde{m} x_1^0 + \coth \tilde{m}(x_2^0 - x_1^0))\zeta(x_1^0) - \tilde{m}\mathrm{csch}\, \tilde{m}(x_2^0 - x_1^0)\zeta(x_2^0).$$

When $K = 2$ the matrix T is

$$\tilde{m} \begin{bmatrix} \tanh \tilde{m}a/2 + \coth \tilde{m}b & -\mathrm{csch}\, \tilde{m}b \\ -\mathrm{csch}\, \tilde{m}b & \tanh \tilde{m}b/2 + \coth \tilde{m}a \end{bmatrix}$$

$$= \tilde{m}(\coth \tilde{m}a + \coth \tilde{m}b) I_{K\times K} - \tilde{m} \begin{bmatrix} \mathrm{csch}\, \tilde{m}a & \mathrm{csch}\, \tilde{m}b \\ \mathrm{csch}\, \tilde{m}b & \mathrm{csch}\, \tilde{m}a \end{bmatrix}.$$

The two $(1/\Lambda)$'s are

$$\tilde{m}(\coth \tilde{m}a + \coth \tilde{m}b - \mathrm{csch}\, \tilde{m}a - \mathrm{csch}\, \tilde{m}b),$$
$$\tilde{m}(\coth \tilde{m}a + \coth \tilde{m}b - \mathrm{csch}\, \tilde{m}a + \mathrm{csch}\, \tilde{m}b),$$

which again lead to η for (6.7). To see the sign of λ_m, we take the smaller Λ so that the smaller λ_m satisfies

$$\lim_{\epsilon\to 0} \frac{\lambda_m}{\epsilon^2} = \eta + m^2\pi^2 = \frac{1}{\tau}\left(-\frac{\gamma ab}{2} + \frac{\gamma}{\tilde{m}(\coth \tilde{m}a + \coth \tilde{m}b - \mathrm{csch}\, \tilde{m}a + \mathrm{csch}\, \tilde{m}b)}\right) + m^2\pi^2.$$

As in the $K = 1$ case the right side is positive for all $m \neq (0, 0)$ if γ is small, and is negative for some m if γ is large.

When $K \geq 3$ we write $T = d\, I_{K\times K} - Q$ with

$$Q = \begin{bmatrix} \alpha & \beta & & & \\ \beta & 0 & \alpha & & \\ & \alpha & 0 & \beta & \\ & & \beta & 0 & \alpha \\ & & & \cdots & \end{bmatrix},$$

where

$$\alpha = \tilde{m}\mathrm{csch}\, \frac{2\tilde{m}a}{K}, \quad \beta = \tilde{m}\mathrm{csch}\, \frac{2\tilde{m}b}{K}, \quad d = \tilde{m} \coth \frac{2\tilde{m}a}{K} + \tilde{m} \coth \frac{2\tilde{m}b}{K}.$$

Because of diagonal domination the matrix $d\, I_{K\times K} - Q$ is positive definite. The K eigenvalues of Q are found in (B.5) of Appendix B. We again denote them by q_j, $j = 1, 2, \ldots, K$. Then $\Lambda = \frac{1}{d - q_j}$, and for (6.7), K eigenpairs

$$\eta = \frac{1}{\tau}\left(-\frac{\gamma ab}{K} + \frac{\gamma}{d - q_j}\right), \quad c^0 = \vec{\zeta} \tag{7.2}$$

are found. To see the sign of λ_m, we focus on the smallest η, which is associated with $q_j = -\sqrt{\alpha^2 + \beta^2 + 2\alpha\beta\cos\theta}$, where $\theta = 2\pi/K$. For this q_j

$$\lim_{\epsilon\to 0} \frac{\lambda_m}{\epsilon^2} = \eta + m^2\pi^2 = \frac{1}{\tau}\left(-\frac{\gamma ab}{K} + \frac{\gamma}{d - q_j}\right) + m^2\pi^2$$
$$= \frac{1}{\tau}\left(-\frac{\gamma ab}{K} + \frac{\gamma}{d + \sqrt{\alpha^2 + \beta^2 + 2\alpha\beta\cos\theta}}\right) + m^2\pi^2.$$

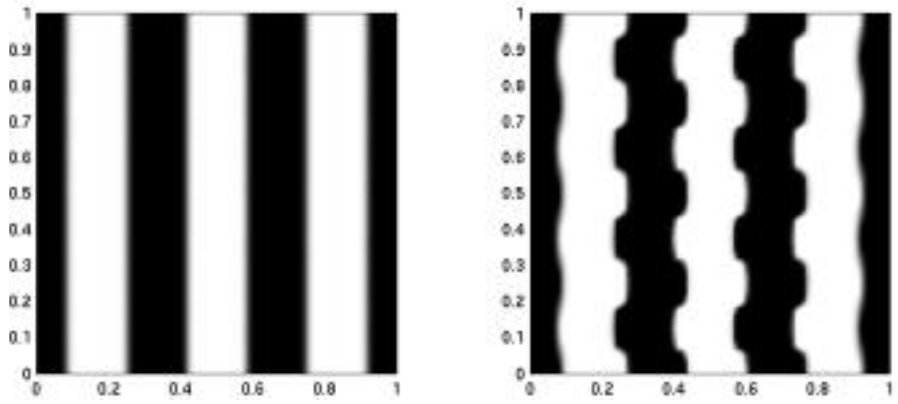

FIG. 4. *A lamellar solution u and its deformation in a cross section perpendicular to y_2.*

The dependence of the positivity of the right side on γ is still the same; i.e., the right side is positive for all m if γ is small and negative for some m if γ is large. The dependence of the positivity on K is also clear. When K is large, $m^2\pi^2$ dominates the negative term, so the whole quantity is positive for all m.

Remark 7.1. If γ and K are held fixed, then the last line is positive if $|m|$ is sufficiently large. This is consistent with statement 1 of Theorem 1.1.

We omit the proof that L_m has exactly K simple eigenpairs with small eigenvalues, because it is similar to that for L_0. This concludes the proof of statement 3, Theorem 1.1.

To visualize statement 3, Theorem 1.1, consider the example $a = 0.4$ and $K = 6$. We study $m = (8, 0)$ and find the c^0 associated with the smallest $\lambda_{(8,0)}$ by numerically diagonalizing Q:

$$c^0 = (0.0424,\ -0.4774,\ 0.5199,\ -0.5199,\ 0.4774,\ -0.0424)^T.$$

The eigenfunction of L associated with this $\lambda_{(8,0)}$ and with c^0 is approximately $\sum_j c_j^0 h_j(x)\cos(8\pi y_1)$. When γ is sufficiently large, we have $\lambda_{(8,0)} < 0$. Then the unstable lamellar solution u may easily be deformed in the direction of this eigenfunction. In Figure 4 we make a cross section of D, perpendicular to the y_2 direction. The first plot shows u on this cross section, where the black color indicates $u \approx 1$ and the white color indicates $u \approx 0$. The second plot shows u deformed by the eigenfunction. Note that under this deformation the straight interfaces in u become wriggled curves. See [7] for a heuristic argument for this change of shape.

8. The 1-D global minimizer. The integral $\int_0^1 |(v^0)'|^2\,dx$ in the conclusion of Theorem 2.1 may be calculated as

$$\begin{aligned}\int_0^1 |(v^0)'|^2\,dx &= K\int_0^{a/K} |(v^0)'|^2\,dx + K\int_{a/K}^{1/K} |(v^0)'|^2\,dx \\ &= K\int_0^{a/K} (1-a)^2x^2\,dx + K\int_{a/K}^{1/K} a^2\left(x-\frac{1}{K}\right)^2\,dx \\ &= \frac{a^3b^2}{3K^2} + \frac{a^2b^3}{3K^2} \;=\; \frac{a^2b^2}{3K^2}.\end{aligned}$$

Hence

$$\lim_{e\to 0}\epsilon^{-1}I_1(u)=\tau K+\frac{\gamma a^2b^2}{6K^2}. \tag{8.1}$$

It was shown in [13] that the 1-D global minimizer is a 1-D local minimizer whose number of interfaces K_* minimizes the right side of (8.1). Note that in some less likely cases two integers K_* and K_*+1 may both minimize the right side of (8.1). Then we may have two global minimizers with K_* and K_*+1 interfaces, respectively.[5] If we pretend that K is a positive real number and minimize the right side with respect to K, then the minimum is achieved at

$$K_*=\left(\frac{a^2b^2\gamma}{3\tau}\right)^{1/3}. \tag{8.2}$$

We set $t=\tilde{m}/K$. Consider the eigenvalue λ_m that is associated with the smallest η of section 7.

$$\lim_{\epsilon\to 0}\frac{\lambda_m}{\epsilon^2}\frac{\tau\tilde{m}}{\gamma}=\frac{\tau\tilde{m}(\eta+m^2\pi^2)}{\gamma}$$

$$=-abt+\frac{1}{\coth 2at+\coth 2bt+\sqrt{(\operatorname{csch}2at)^2+(\operatorname{csch}2bt)^2+2\operatorname{csch}2at\operatorname{csch}2bt\cos\theta}}+\frac{\tau K^3t^3}{\gamma}.$$

For the 1-D global minimizer, we use K_* in (8.2) for K to find

$$\lim_{\epsilon\to 0}\frac{\lambda_m}{\epsilon^2}\frac{\tau\tilde{m}}{\gamma}=\frac{\tau\tilde{m}(\eta+m^2\pi^2)}{\gamma}$$

$$=-abt+\frac{1}{\coth 2at+\coth 2bt+\sqrt{(\operatorname{csch}2at)^2+(\operatorname{csch}2bt)^2+2\operatorname{csch}2at\operatorname{csch}2bt\cos\theta}}+\frac{a^2b^2t^3}{3}. \tag{8.3}$$

Note that a natural lower bound for the second term in (8.3) is

$$\frac{1}{\coth 2at+\coth 2bt+\operatorname{csch}2at+\operatorname{csch}2bt}$$
$$=\frac{\sinh at\sinh bt}{\sinh t}=abt-\frac{a^2b^2t^3}{3}+\frac{(a^2b^2+2a^3b^3)t^5}{45}+\cdots$$

by replacing $\cos\theta$ by 1. This lower bound is sharp if K_* is large, i.e., γ is large. The first three terms of the Taylor expansion are given. We observe that the first two terms in the Taylor expansion are *exactly* canceled by the first and third terms in (8.3). This is certainly no coincidence. The fifth order term is positive. Our numerical tests confirm that all of (8.3) remains positive. The particular K_* of (8.2) is barely large enough to overcome the negative third order term in $\frac{\sinh at\sinh bt}{\sinh t}$.

To contemplate the physical significance of the shaky stability property of the 1-D global minimizer, we first note that the value (8.2) for K_* is only approximate. But the 1-D global minimizer is very close to the borderline of 3-D stability. 1-D local minimizers with larger K are likely to be stable in three dimensions, and 1-D local minimizers with smaller K are likely to be unstable in three dimensions. In the real

[5] Actually there are four global minimizers because of Remark 2.2 if we include solutions of both types.

physical system only the 3-D global minimizer, which is unlikely to be lamellar, is the thermal equilibrium. Other stable solutions of (1.2) are only transient, metastable states. In general lamellar phases, including the 1-D global minimizer, are transient. They are vulnerable to perturbations of the form $\sum_j c_j^0 h_j(x)\cos(m_1\pi y_1)\cos(m_2\pi y_2)$ found in statement 3 of Theorem 1.1, which push the straight interfaces in a lamellar state to a wriggled shape; see Figure 4. In a forthcoming paper [12] we will actually prove, using bifurcation analysis, that (1.2) admits wriggled solutions for some values of γ.

Appendix A. Proof of Theorem 2.3.

LEMMA A.1. *u has exactly K transition layers in the sense that there are exactly K points, $x_1, x_2, \ldots, x_K$, in $(0,1)$, so that $u(x_j) = 1/2$, $j = 1, 2, \ldots, K$, and $\lim_{\epsilon\to 0} x_j = x_j^0$.*

The proof of this lemma is similar to that of [11, Proposition 8.2].

LEMMA A.2. *The derivative of $v = G_0[u-a]$ has exactly $K-1$ zeros, denoted by $y_1, y_2, \ldots, y_{K-1}$, in $(0,1)$, such that $\lim_{\epsilon\to 0} y_j = j/K$.*

Proof. The derivative of $v^0 = G_0[u^0 - a]$ has zeros at $1/K$, $2/K$, ..., $(K-1)/K$. The convergence of v' to $(v^0)'$ implies that v' has exactly $K-1$ zeros y_j with the property $\lim_{\epsilon\to 0} y_j = j/K$. ∎

We set $y_0 = 0$ and $y_K = 1$. Let $l_i = y_i - y_{i-1}, i = 1, \ldots, K$. Between two zeros of v' we integrate the equation $-v'' = u - a$ and find $\frac{1}{l_i}\int_{y_{i-1}}^{y_i} u\,dx = a$. This allows us to localize the energy of u on (y_{i-1}, y_i). If we set $l_i\xi + y_{i-1} = x$, $\mathcal{U}_i(\xi) = u(x)$, and $\mathcal{V}_i(\xi) = l_i^{-2}v(x) = l_i^{-2}G_0[u-a](x)$, then $\int_0^1 \mathcal{U}_i\,dz = a$, $-\mathcal{V}_i'' = \mathcal{U}_i - a$, $\mathcal{V}_i'(0) = \mathcal{V}_i'(1) = 0$. More importantly,

$$\begin{aligned} I_1(u) &= \sum_{i=1}^K \int_{y_{i-1}}^{y_i} \left\{ \frac{\epsilon^2}{2}|u|^2 + \frac{\gamma\epsilon}{2}|v'|^2 + W(u) \right\} dx \\ &= \sum_{i=1}^K l_i \int_0^1 \left\{ \frac{\epsilon^2}{2l_i^2}|\mathcal{U}_i'|^2 + \frac{l_i^2\gamma\epsilon}{2}|\mathcal{V}_i'|^2 + W(\mathcal{U}_i) \right\} d\xi \;=\; \sum_{i=1}^K l_i J_{l_i}(\mathcal{U}_i) \end{aligned} \tag{A.1}$$

if we define a new variational problem:

$$J_l(\mathcal{U}) = \int_0^1 \left\{ \frac{\epsilon^2}{2l^2}|\mathcal{U}'|^2 + \frac{l^3\gamma}{2}\frac{\epsilon}{l}\left| \left(-\frac{d^2}{d\xi^2}\right)^{-1/2}(\mathcal{U}-a) \right|^2 + W(\mathcal{U}) \right\} d\xi, \quad \mathcal{U} \in X_a. \tag{A.2}$$

This new J_l is similar to the original I_1. l lies in a compact subinterval of $(0,1)$, so we take $l \sim 1$. We consider a one-layer local minimizer $\mathcal{U}$ that is close to $\mathcal{U}^0$, which is 0 on $(0, 1-a)$ and 1 on $(1-a, 0)$. The dependence of $\mathcal{U}$ on l and ϵ is suppressed in the notation. It is proved in Proposition 9.2 of [11] that this local minimizer is unique in an L^2 ball centered at $\mathcal{U}^0$ of radius δ. δ is small but independent of ϵ. Denote the transition point of $\mathcal{U}$ by χ, i.e., $\mathcal{U}(\chi) = 1/2$. This one-layer local minimizer has the following asymptotic expansion.

LEMMA A.3. *Let $\tilde\epsilon = \frac{\epsilon}{l}$ and $\tilde\gamma = l^3\gamma$. Then $\mathcal{U} = H(\frac{\cdot-\chi}{\tilde\epsilon}) + \tilde\epsilon\mathcal{Z}$ with $\|\mathcal{Z} - \mathcal{Z}^0\|_\infty = O(\tilde\epsilon)$. Here $\mathcal{Z}^0 = -\frac{\tilde\gamma(\mathcal{V}^0 - \mathcal{V}^0(1-a))}{f'(0)}$, $\mathcal{V}^0 = G_0[\mathcal{U}^0 - a]$. Note that $\mathcal{Z}^0(1-a) = 0$.*

Proof. See Proposition 8.3 in [11]. ∎

LEMMA A.4. *Let $F \in C^2(-\infty, \infty)$ be such that $F(0) = F(1) = 0$. Then*

$$\int_0^1 F(\mathcal{U})\,d\xi = \tilde\epsilon\int_{-\infty}^{\infty} F(H)\,dt + \tilde\epsilon\int_0^{1-a} F'(0)\mathcal{Z}^0\,d\xi + \tilde\epsilon\int_{1-a}^1 F'(1)\mathcal{Z}^0\,d\xi + O(\tilde\epsilon^2).$$

Proof. See Lemma 8.4 in [11]. □

LEMMA A.5. *Let* $\mathcal{W} = \frac{\partial \mathcal{U}}{\partial l}$. *Then*

$$\mathcal{W}(\xi) = H'\left(\frac{l(\xi-\chi)}{\epsilon}\right)\frac{\xi-\chi}{\epsilon} - \overline{H'\left(\frac{l(\xi-\chi)}{\epsilon}\right)\frac{\xi-\chi}{\epsilon}} + \varphi,$$

with $\|\varphi\|_2 = O(1)$. *And* $\varphi = c(h-\overline{h}) + \psi$, *with* $h = H'(\frac{l(\xi-\chi)}{\epsilon})$, $h - \overline{h} \perp \psi$, $c = O(\epsilon^{-1/2})$, *and* $\|\psi\|_2 = O(\epsilon)$.

Proof. The brief argument here summarizes the more elaborate proof of the similar Proposition 9.3 in [11]. Differentiate the Euler–Lagrange equation of (A.2) with respect to l to obtain

$$-\left(\frac{\epsilon}{l}\right)^2 \mathcal{W}'' + \gamma\epsilon l^2 G_0[\mathcal{W}] + f'(\mathcal{U})\mathcal{W} + 4\gamma\epsilon l G_0[u-a] + \frac{2}{l}f(\mathcal{U}) - \frac{2}{l}\overline{f(\mathcal{U})} = \frac{d\overline{f(\mathcal{U})}}{dl} \tag{A.3}$$

for $\mathcal{W}$. Define $g(\xi) = H'(\frac{l(\xi-\chi)}{\epsilon})\frac{\xi-\chi}{\epsilon}$ + e.s. so that g and its derivative vanish at 0 and 1, and $\varphi = \mathcal{W} - (g - \overline{g})$. Here g satisfies the equation

$$-\left(\frac{\epsilon}{l}\right)^2 g'' + f'(H)g + \frac{2}{l}f(H) = \text{e.s.}$$

Subtract this from (A.3) and use the facts $\|g\|_2 = O(\epsilon^{1/2})$, $\overline{g} = O(\epsilon)$, and $(f'(\mathcal{U}) - f'(H))(g - \overline{g}) = O(\epsilon^2)$, where the last one follows from Lemma A.3, to deduce the equation for φ:

$$-\left(\frac{\epsilon}{l}\right)^2 \varphi'' + \epsilon\gamma l^2 G_0[\varphi] + f'(\mathcal{U})\varphi + O(\epsilon) = \text{Const.}, \tag{A.4}$$

where we simply write Const. for a constant since its exact value is not needed in this proof. We multiply this equation by φ and integrate:

$$\int_0^1 \left\{\left(\frac{\epsilon}{l}\right)^2 |\varphi'|^2 + \epsilon\gamma l^2 G_0[\varphi]\varphi + f'(\mathcal{U})\varphi^2\right\} dz = O(\epsilon)\|\varphi\|_2.$$

By Proposition 9.1 in [11] we find $\|\varphi\|_2 = O(1)$.

Decompose $\varphi = c(h-\overline{h}) + \psi$, where $h = H'(\frac{l(\xi-\chi)}{\epsilon})$ + e.s. and $h - \overline{h} \perp \psi$. The exponentially small correction term e.s. is added so that h and h' vanish at 0 and 1. Then

$$c = \frac{\int_0^1 \varphi(h-\overline{h})\,dz}{\|h-\overline{h}\|_2^2} \le \frac{\|\varphi\|_2}{\|h-\overline{h}\|_2} = O(\epsilon^{-1/2}).$$

The equation satisfied by ψ is

$$-\left(\frac{\epsilon}{l}\right)^2 \psi'' + f'(\mathcal{U})\psi + O(\epsilon) = \text{Const.},$$

where we have used the fact $(f(\mathcal{U}) - f'(H))h = O(\epsilon^2)$, again a consequence of Lemma A.3. Argue as in Lemma 4.1 to deduce $\int_0^1 \{-(\frac{\epsilon}{l})^2\psi'' + f'(\mathcal{U})\psi\}\psi\,d\xi \ge C\|\psi\|_2^2$, which implies $\|\psi\|_2 = O(\epsilon)$. □

LEMMA A.6. *Let* $E(l) = lJ_l(\mathcal{U})$. *Then* $E(l)$ *is strictly convex in* l *in any compact subset of* $(0,1)$.

Proof. This lemma is similar to Proposition 10.1 in [11]. Differentiating E with respect to l yields

$$\frac{\partial E}{\partial l} = \int_0^1 \left\{ -\frac{\epsilon^2}{2l^2}|\mathcal{U}'|^2 + W(\mathcal{U}) + \frac{3\epsilon\gamma l^2}{2}|\mathcal{V}'|^2 \right\} d\xi, \tag{A.5}$$

where $\mathcal{V} = G_0[\mathcal{U} - a]$. We have used the fact that $\mathcal{U}$ is a critical point of J_l. Differentiate (A.5) with respect to l:

$$\frac{\partial^2 E}{\partial l^2} = \int_0^1 \left\{ \frac{\epsilon^2}{l^3}|\mathcal{U}'|^2 + 3\epsilon\gamma l|\mathcal{V}'|^2 \right\} d\xi + \int_0^1 \{2f(\mathcal{U})\mathcal{W} + 4\epsilon\gamma l^2 \mathcal{V}\mathcal{W}\}\, d\xi.$$

Call the first integral on the right side T_1 and the second integral T_2. Multiplying the Euler–Lagrange equation of $\mathcal{U}$ by $\mathcal{U} - a$ and integrating by parts, we find the useful integral identity

$$\int_0^1 \left\{ \left(\frac{\epsilon}{l}\right)^2 |\mathcal{U}'|^2 + f(\mathcal{U})(\mathcal{U} - a) + \epsilon\gamma l^2 |\mathcal{V}'|^2 \right\} d\xi = 0.$$

Using this identity and Lemma A.4, we obtain

$$\begin{aligned} T_1 &= \frac{1}{l}\int_0^1 \{-f(\mathcal{U})(\mathcal{U} - a) + 2\epsilon\gamma l^2 |\mathcal{V}'|^2\}\, d\xi \\ &= \frac{\epsilon}{l^2}\int_{-\infty}^{\infty} -f(H)(H - a)\, dt + \frac{\epsilon\gamma l a^2 b^2}{3} + \frac{2\epsilon\gamma l a^2 b^2}{3} + O(\epsilon^2) \\ &= \frac{\epsilon}{l^2}\int_{-\infty}^{\infty} -f(H)H\, dt + \epsilon\gamma l a^2 b^2 + O(\epsilon^2). \end{aligned}$$

Here we have used

$$\int_0^1 |\mathcal{V}'|^2\, d\xi = \int_0^1 |\mathcal{V}_0'|^2\, d\xi + O(\epsilon) = \frac{a^2 b^2}{3} + O(\epsilon),$$

which follows from (8.17) in [11]. By Lemmas A.3 and A.5

$$\begin{aligned} T_2 &= \int_0^1 (2f(H) + O(\epsilon)) \left(\frac{\xi - \chi}{\epsilon} H' + + cH' - c\overline{H'} + \psi \right) d\xi \\ &= \frac{\epsilon}{l^2}\int_{-l\chi/\epsilon}^{l(1-\chi)/\epsilon} 2f(H(t))H'(t)t\, dt + O(\epsilon^{1.5}) \;=\; \frac{\epsilon}{l^2}\int_{-\infty}^{\infty} -2W(H)\, dt + O(\epsilon^{1.5}). \end{aligned}$$

We have used the estimates

$$\begin{aligned} \int_0^1 \left| \frac{\xi - \chi}{\epsilon} H' \right| d\xi &= \frac{\epsilon}{l^2}\int_{-l\chi/\epsilon}^{l(1-\chi)/\epsilon} |H'(t)t|\, dt = O(\epsilon), \\ \int_0^1 |f(H)|\, d\xi &= \frac{\epsilon}{l}\int_{-l\chi/\epsilon}^{l(1-\chi)/\epsilon} |f(H(t))|\, dt = O(\epsilon), \\ \|2f(H) + O(\epsilon)\|_2 &= O(\epsilon^{1/2}), \\ \int_0^1 f(H)H'\, d\xi &= \text{e.s.} \end{aligned}$$

Adding T_1 and T_2, since $\int_{-\infty}^{\infty}(f(H)H+2W(H))\,dt=0$ (a consequence of the integral identity $\int_{-\infty}^{\infty}\{(H')^2+f(H)H\}\,dt=0$ and the first integral of H), we arrive at

$$\frac{\partial^2 E}{\partial l^2}=\epsilon l\gamma a^2b^2+O(\epsilon^{1.5}), \tag{A.6}$$

proving the lemma. □

Proof of Theorem 2.3. We construct a particular periodic solution u_* with K transition layers and show that $u=u_*$. Let $\mathcal{U}$ be the unique minimum of J_l in a δ neighborhood of $\mathcal{U}^0$, with $l=1/K$, and let $\mathcal{U}^R=\mathcal{U}(1-\cdot)$ be its reversal. Set $u_*(x)=\mathcal{U}^R(Kx)$ for $x\in(0,1/K)$. Extend u_* antiperiodically to $(0,1)$, i.e., $u_*(x)=\mathcal{U}(Kx-1)$ for $x\in(1/K,2/K)$, $u_*(x)=\mathcal{U}^R(Kx-2)$ for $x\in(2/K,3/K),\dots$. Clearly u_* is periodic with $K/2$ periods.

For small ϵ, u and u_* belong to the same small L^2 neighborhood in which u is a minimizer. Using the strict convexity of E in Lemma A.6 and (A.1), we find

$$I(u_*)\ge I(u)=\sum_{i=1}^{K}l_iJ_{l_i}(u(l_i\cdot+y_{i-1}))\ge\sum_{i=1}^{K}E(l_i)\ge KE\left(\frac{1}{K}\right)=I(u_*).$$

All the inequalities above must be equalities. Therefore $l_i=1/K$, $y_i=i/K$ for all i, and $l_iJ_{l_i}(u(l_i\cdot+y_{i-1}))=E(l_i)$. Moreover $u((1/K)\cdot+y_{i-1})=\mathcal{U}$ when i is even or $=\mathcal{U}^R$ when i is odd by the local uniqueness of $\mathcal{U}$ and $\mathcal{U}^R$ [11, Proposition 9.2]. Thus $u=u_*$. □

Appendix B. The matrix Q. Consider a matrix Q like those in sections 5 and 7 with $\alpha,\beta>0$. In this appendix Q, whose size is at least 3 by 3, acts on the complex vector space $\mathbf{C}^K$. Let $\vec{q}=(z,tz^2,z^3,tz^4,\dots)^T$, where $z,t\in\mathbf{C}$ and $|z|=1$. Suppose the eigenvalue problem $Q\vec{q}=q\vec{q}$ holds for the second through the next-to-last equations, excluding the first and the last. In these $K-2$ equations

$$\begin{array}{ll}\alpha tz^{l-1}+\beta tz^{l+1}=qz^l & \text{if } l \text{ is odd,}\\ \beta z^{l-1}+\alpha z^{l+1}=qtz^l & \text{if } l \text{ is even.}\end{array} \tag{B.1}$$

They imply

$$t=\pm\frac{\alpha z+\beta\overline{z}}{|\alpha z+\beta\overline{z}|}. \tag{B.2}$$

In particular $|t|=1$. In order to have the first and the last equations satisfied, we let $\vec{h}=A\vec{q}+B\bar{\vec{q}}$ and study $Q\vec{h}=q\vec{h}$.

If the vector $\vec{q}$ is extended by t as the 0th entry and by tz^{K+1} as the $(K+1)$th entry if K is odd, or by z^{K+1} as the $(K+1)$th entry if K is even, then the first and the last equations of $Q\vec{h}=q\vec{h}$ are satisfied if the 0th entry is equal to the first entry and the Kth entry is equal to the $(K+1)$th entry. That is,

$$\begin{cases} Az+B\overline{z}=At+B\bar{t}\\ Az^K+B\overline{z}^K=Atz^{K+1}+B\bar{t}\overline{z}^{K+1}\end{cases}\quad\text{if } K \text{ is odd;} \tag{B.3}$$

$$\begin{cases} Az+B\overline{z}=At+B\bar{t}\\ Atz^K+B\bar{t}\overline{z}^K=Az^{K+1}+B\overline{z}^{K+}\end{cases}\quad\text{if } K \text{ is even.} \tag{B.4}$$

They should have nontrivial solutions for A and B. In the case of (B.3) this means

$$(z-t)(1-\overline{t}\overline{z})\overline{z}^K = (\overline{z}-\overline{t})(1-tz)z^K$$

or, since $|z| = |t| = 1$, $z^{2K} = 1$. The case (B.4) gives the same condition. Define $\theta = \frac{2\pi(j-1)}{K}$, $j = 1, 2, \ldots, 2K$. Then $z = e^{i\theta/2}$. From (B.1) we find

$$q = \alpha t\overline{z} + \beta tz = \pm\sqrt{\alpha^2+\beta^2+2\alpha\beta\cos\theta}.$$

Here θ ranges from 0 to $4\pi - (2\pi/K)$, which is too wide a range. We restrict j to $1, 2, \ldots, (K+1)/2$ if K is odd and $j = 1, 2, \ldots, K/2+1$ if K is even. Even then we have some extra values. When $z = 1$ and $t = -1$, which occur if $\theta = 0$ and $q = -(\alpha+\beta)$, we find $A + B = 0$ and $\vec{h} = \vec{0}$, which is not an eigenvector. Also when K is even, $z = i$, and $t = -i$, which occur if $\theta = \pi$, and $q = \beta - \alpha$, we find $A - B = 0$ and again $\vec{h} = \vec{0}$. In summary the K distinct eigenvalues of Q are

$$\alpha+\beta,\ \pm\sqrt{\alpha^2+\beta^2+2\alpha\beta\cos\theta}\quad\left(\theta = \frac{2\pi(j-1)}{K},\ j = 2, 3, \ldots, \frac{K+1}{2}\right)\quad \text{if } K \text{ is odd;}$$

(B.5)

$$\alpha+\beta,\ \pm\sqrt{\alpha^2+\beta^2+2\alpha\beta\cos\theta}\quad\left(\theta = \frac{2\pi(j-1)}{K},\ j = 2, 3, \ldots, \frac{K}{2}\right),\ \alpha-\beta\ \text{ if } K \text{ is even.}$$

Acknowledgments. We thank Professors R. Kohn and C. Muratov for several stimulating conversations on the subject of block copolymers during the SIAM 50th Anniversary and 2002 Meeting in Philadelphia.

HOMOGENIZATION OF HIGH-CONDUCTIVITY PERIODIC PROBLEMS: APPLICATION TO A GENERAL DISTRIBUTION OF ONE-DIRECTIONAL FIBERS*

MARC BRIANE†

Abstract. This article is devoted to the asymptotic study, as $\varepsilon \to 0$, of the Dirichlet problem

$$\begin{cases} -\operatorname{div}\left(A_\varepsilon(\frac{x}{\varepsilon})\nabla u_\varepsilon\right) = f & \text{in } \Omega, \\ u_\varepsilon = 0 & \text{on } \partial\Omega, \end{cases}$$

where Ω is an x_3-axis bounded open cylinder of $\mathbb{R}^3$, and A_ε is a positive measurable function which does not depend on the variable x_3, periodic with respect to the two-dimensional torus Y_2. The conductivity A_ε is not uniformly bounded in an open set of small measure $Q_\varepsilon \subset Y_2$ and is equal to 1 elsewhere.

We propose a new approach to solving this high-conductivity homogenization problem. It is based on the study of the asymptotic behavior of the periodic spectral problem weighted by the conductivity function A_ε:

$$-\operatorname{div}\left(A_\varepsilon \nabla V_{k,\varepsilon}\right) = \Lambda_k(\varepsilon)\, A_\varepsilon\, V_{k,\varepsilon} \quad \text{in } Y_2, \quad k \in \mathbb{N},$$

where the eigenfunctions $V_{k,\varepsilon}$ are Y_2-periodic.

On the one hand, under suitable conditions on Q_ε we prove that nonlocal effects appear through a coupling in the limit problem if and only if the sequence $(\frac{\Lambda_1(\varepsilon)}{\varepsilon^2})_{\varepsilon>0}$ is bounded, where $\Lambda_1(\varepsilon)$ is the first nonzero eigenvalue of the previous spectral problem.

On the other hand, when Q_ε is composed of N smooth connected open subsets of small diameter, we prove that the limit problem is a coupled system of second order linear PDEs whose size is $n \leq N+1$. The number n is equal to the smallest integer such that the sequence $(\frac{\Lambda_n(\varepsilon)}{\varepsilon^2})_{\varepsilon>0}$ tends to $+\infty$ as ε tends to 0. We illustrate this result by studying the case of $N = 2$ highly conducting cylinders in the period cell of the same radius $r_\varepsilon \ll 1$ and separated by distance $d_\varepsilon > 0$.

1. Introduction.

In this paper we study the asymptotic behavior of a class of conduction problems with nonuniformly bounded coefficients. This class is defined as follows:

Let Ω_2 be a bounded domain of $\mathbb{R}^2$ and let Ω be the open cylinder of $\mathbb{R}^3$ defined by $\Omega := \Omega_2 \times\,]0,1[$ along the x_3-axis. We consider the conduction problem in Ω:

$$\begin{cases} -\operatorname{div}\left(a_\varepsilon \nabla u_\varepsilon\right) = f & \text{in } \Omega, \\ u_\varepsilon = 0 & \text{on } \partial\Omega, \end{cases} \tag{1.1}$$

where f is a given function in $L^2(\Omega)$. The conductivity a_ε is independent of x_3 and is assumed to be a highly oscillating function defined by

$$a_\varepsilon(x) := A_\varepsilon\left(\frac{x}{\varepsilon}\right) \quad \text{for almost every } x \in \Omega, \tag{1.2}$$

where A_ε is a Y_2-periodic ($Y_2 := \mathbb{R}^2/\mathbb{Z}^2$ is the two-dimensional torus) measurable positive function in $L^\infty(\mathbb{R}^2)$. We assume that there exists an open subset Q_ε of Y_2, of small measure such that

(1.3)
$$A_\varepsilon := 1 \text{ a.e. in } Y_2 \setminus Q_\varepsilon, \quad A_\varepsilon \geq 1 \text{ a.e. in } Q_\varepsilon, \quad \text{and} \quad \int_{Q_\varepsilon} A_\varepsilon \underset{\varepsilon\to 0}{\longrightarrow} \kappa \in]0,+\infty[.$$

Therefore A_ε is uniformly bounded from below by a positive constant but nonuniformly bounded from above.

Problem (1.1) is a conduction problem in an ε-periodic medium composed of a moderately conducting material and a highly conducting one. The model composite medium is a matrix periodically reinforced by highly conducting one-directional fibers. We study the asymptotic behavior of problem (1.1) when the period ε tends to zero. Our aim is to determine the homogenized problem satisfied by the limit u of the solution u_ε of (1.1). In general the limit problem is not a conduction problem like (1.1). It may be a coupled system of linear second order PDEs, which expresses nonlocal effects in the homogenization process. Such nonlocal effects are induced by the interaction between the conduction in the matrix and the conduction in the highly conducting fibers.

Fenchenko and Khruslov [11] (see also [12]) studied similar conduction problems with more general nonuniformly bounded coefficients but for Neumann boundary conditions. Under rather complicated assumptions satisfied by the coefficients, they show that the limit of the conduction problem is a coupled system of linear second order PDEs of size 2 satisfied by the limit u of u_ε in $H^1(\Omega)$ and the limit of the rescaled potential in the small size region of high conductivity.

In terms of the strongly local energy

$$E_\varepsilon(u) := \int_\Omega a_\varepsilon \left|\nabla u\right|^2, \tag{1.4}$$

this coupled system corresponds to the appearance of a nonlocal term in the limit energy. From a theoretical point of view Mosco [13] showed, thanks to the Beurling–Deny [2] representation formula of the Dirichlet forms, that the Γ-limit E_0 of strongly local forms of type (1.4) can always be written, for any $u \in C_0^1(\Omega)$,

$$E_0(u) = \int_\Omega a(dx)\nabla u \cdot \nabla u + \int_\Omega u^2\, k(dx) + \int_{\Omega\times\Omega\setminus\mathrm{diag}} (u(x)-u(y))^2\, j(dx,dy), \tag{1.5}$$

where a, k are Radon measures on Ω and the so-called *jumping measure* j is a Radon measure on $\Omega\times\Omega\setminus\mathrm{diag}$ which represents the nonlocal term. The work of Fenchenko and Khruslov [11] thus gives sufficient conditions in order to obtain nonlocal effects. More recently Camar-Eddine and Seppecher [8] proved that a large class of measures k, j can be attained from the convergence of strongly local energies (1.4). An explicit construction is given by Tchou and the author [5] in order to obtain the product Lebesgue measure $dx \otimes dy$ as a jumping measure j in (1.5)

Revisiting the work of Fenchenko and Khruslov, Bellieud and Bouchitté [1] studied in a complete way (for a nonlinear conduction problem with mixed boundary conditions) an example from [11] by using the Γ-convergence of functionals. This example corresponds to the case where the highly conducting set Q_ε is a disk of radius $r_\varepsilon \ll 1$. They prove that nonlocal effects arise if and only if the limit of $\varepsilon^2 \left|\ln r_\varepsilon\right|$

is positive. Moreover they extend the example of [11] by considering an overlapping of $(n-1)$ highly conducting cylinders of different radius and conductivity. For this geometry they obtain a limit coupled system of size n satisfied by the limit u of u_ε and the limit of the rescaled potentials associated with each cylinder.

In this article we propose a completely different approach to the homogenization in periodic media which are reinforced by highly conducting one-directional fibers. This work extends the results of [11] since we obtain limit problems of arbitrary large size, as well as that of [1] since the distribution of the fibers is quite general. Our approach is based on the asymptotic behavior of the "cross-sectional" period cell spectral problem

$$-\operatorname{div}(A_\varepsilon \nabla V_{k,\varepsilon}) = \Lambda_k(\varepsilon)\, A_\varepsilon\, V_{k,\varepsilon} \quad \text{in } Y_2. \tag{1.6}$$

The solutions of (1.6) make an orthonormal basis $(V_{k,\varepsilon})_{k\geq 0}$ of $L^2_\#(Y_2)$ provided with the weighted Hilbert norm

$$\|V\|_\varepsilon := \left(\int_{Y_2} A_\varepsilon\, V^2\right)^{\frac{1}{2}}, \quad V \in L^2_\#(Y_2), \tag{1.7}$$

and are associated with the sequence of eigenvalues

$$\Lambda_0(\varepsilon) = 0 < \Lambda_1(\varepsilon) \leq \cdots \leq \Lambda_k(\varepsilon) \leq \Lambda_{k+1}(\varepsilon) \leq \cdots. \tag{1.8}$$

In the first section of the paper we prove the following result (see Theorem 2.1 for precise statements).

THEOREM 1.1. *Assume that the eigenfunction $V_{1,\varepsilon}$ is not concentrated in the set Q_ε defined by* (1.3)*, that the capacity of Q_ε tends to zero, and that there exists, for any $\mu \in \mathbb{R}^2$, a smooth Y_2-periodic function whose gradient is equal to μ in Q_ε. Then if the eigenvalues $\Lambda_1(\varepsilon), \Lambda_2(\varepsilon)$ of* (1.6) *satisfy*

$$\lim_{\varepsilon\to 0} \frac{\Lambda_1(\varepsilon)}{\varepsilon^2} \in]0, +\infty[\quad \textit{and} \quad \lim_{\varepsilon\to 0} \frac{\Lambda_2(\varepsilon)}{\varepsilon^2} = +\infty, \tag{1.9}$$

the limit problem of (1.1) *is a coupled system of size* 2.

More precisely the limit coupled system is satisfied by the averaged potential u in the matrix and the averaged (rescaled) potential v in the fibers. Following [1] the function v can be expressed in an integral form of u. The coupled system is thus equivalent to a nonlocal equation satisfied by the limit u (see Remark 2.2).

In [3] we studied the case where $\frac{\Lambda_1(\varepsilon)}{\varepsilon^2}$ tends to $+\infty$ in a more general framework. We then obtain a classical conduction problem without coupling or, equivalently, a strongly local limit energy. Therefore (1.9) can be considered as a necessary and sufficient condition of appearance of nonlocal effects under suitable assumptions on Q_ε.

In the second section of the paper we prove a more general result from the point of view of the asymptotic behavior of the spectrum but more restrictive at the level of the geometry of the highly conducting set Q_ε (see Theorem 2.4 and Figure 1).

THEOREM 1.2. *Assume that Q_ε is composed of an arbitrary number N of two-by-two disjoint open subsets $Q_{i,\varepsilon}$ with small diameter and which satisfy a uniform (with respect to ε) Poincaré–Wirtinger inequality. Then there exists a smallest integer n with $1 \leq n \leq N+1$ such that the sequence $(\frac{\Lambda_n(\varepsilon)}{\varepsilon^2})_{\varepsilon>0}$ is not bounded. Moreover if we assume that, for this particular integer n, the eigenvalues of problem* (1.6) *satisfy*

$$\forall\, k = 1, \ldots, n-1, \ \lim_{\varepsilon\to 0} \frac{\Lambda_k(\varepsilon)}{\varepsilon^2} \in]0, +\infty[\quad \textit{and} \quad \lim_{\varepsilon\to 0} \frac{\Lambda_n(\varepsilon)}{\varepsilon^2} = +\infty, \tag{1.10}$$

the limit problem of (1.1) *is then a coupled system of size n.*

Contrary to Theorem 1.1 the averaged potential in the fibers has several $(n-1)$ components which depend on the number N of fibers by period cell. In general the number of components is not equal to N, but it is equal to the number of eigenvalues of order ε^2 of the spectral problem (1.6) according to (1.10). In fact the spectrum connected with (1.6) contains the geometrical information of the distribution of the fibers, which controls the degree of coupling of the limit problem (see Remark 2.5).

In Example 2.6 we illustrate the previous result by considering the case of $N=2$ disks $Q_{1,\varepsilon}, Q_{2,\varepsilon}$ of the same radius r_ε and separated by distance $d_\varepsilon \in]0,1[$. According to the asymptotic behavior of $\varepsilon^2 \left|\ln r_\varepsilon\right|$ and $\frac{\ln d_\varepsilon}{\ln r_\varepsilon}$, we obtain a limit system of size $n = 1, 2,$ or 3 (see Proposition 2.7).

Theorem 1.2 extends the result of [1] to a general periodic distribution of highly conducting one-directional fibers whose sections are the sets $Q_{i,\varepsilon}$ in the period cell. This result shows that the limit problem and in particular its size are completely determined by the asymptotic behavior of the spectrum (1.6) and not by the number of fibers by period cell.

We have already used a similar spectral approach in [4] for low-conductivity problems with isolating regions. In the present context the geometrical assumptions are quite different, and contrary to [4] the reference spectral problem (1.6) is weighted by the conductivity function A_ε. However the conclusion concerning the spectral approach is the same. In the periodic framework the asymptotic behavior of the spectrum (1.6) is a good tool to measure the nonlocal effects arising in fiber-reinforced media.

2. Statement of the results.

2.1. Appearance of nonlocal effects. We denote by (e_1, e_2, e_3) the canonic basis of $\mathbb{R}^3$ and by $|E|$ the Lebesgue measure of any measurable subset E of $\mathbb{R}^2$ or $\mathbb{R}^3$.

Let Ω_2 be a smooth bounded open subset of $\mathbb{R}^2$ and let $\Omega := \Omega \times]0,1[$ be the cylinder of $\mathbb{R}^2$, parallel to e_3, of bottom Ω and height 1.

Let Y_2 be the two-dimensional torus identified as $[0,1[^2$. We denote by $L^2_\#(Y_2)$, resp., $H^1_\#(Y_2)$, the set of the Y_2-periodic functions which are locally in $L^2(\mathbb{R}^2)$, resp., $H^1(\mathbb{R}^2)$.

For any $\varepsilon > 0$ let $A_\varepsilon : \mathbb{R}^2 \longrightarrow \mathbb{R}^*_+$ be a positive measurable function Y_2-periodic, i.e.,

$$A_\varepsilon(y_1+1, y_2) = A_\varepsilon(y_1, y_2+1) = A_\varepsilon(y) \quad \text{for almost every } y = (y_1, y_2) \in \mathbb{R}^2, \tag{2.1}$$

and bounded from above and below by positive constants

$$\operatorname*{infess}_{\mathbb{R}^2} A_\varepsilon = 1 \quad \text{and} \quad \operatorname*{supess}_{\mathbb{R}^2} A_\varepsilon = \beta_\varepsilon < +\infty. \tag{2.2}$$

We assume that there exists an open subset Q_ε of Y_2 such that

$$A_\varepsilon := 1 \text{ a.e. in } Y_2 \setminus Q_\varepsilon, \quad \lim_{\varepsilon\to 0} |Q_\varepsilon| = 0, \quad \text{and} \quad \lim_{\varepsilon\to 0} \int_{Q_\varepsilon} A_\varepsilon = \kappa \in]0, +\infty[. \tag{2.3}$$

We extend A_ε to $\mathbb{R}^3$ by setting $A_\varepsilon(y_1, y_2, y_3) := A_\varepsilon(y_1, y_2)$, and we define the rescaled function

$$a_\varepsilon(x) := A_\varepsilon\left(\frac{x}{\varepsilon}\right) \quad \text{for almost every } x \in \Omega. \tag{2.4}$$

Our aim is to study the asymptotic behavior of the high-conductivity problem

$$\begin{cases} -\operatorname{div}(a_\varepsilon \nabla u_\varepsilon) = f & \text{in } \Omega, \\ u_\varepsilon = 0 & \text{on } \partial\Omega, \end{cases} \tag{2.5}$$

where f is a given function in $L^2(\Omega)$.

We will prove that the asymptotic behavior of the Dirichlet problem (2.5) is completely determined by the asymptotic behavior of the spectrum

$$\Lambda_0(\varepsilon) = 0 < \Lambda_1(\varepsilon) \le \Lambda_2(\varepsilon) \le \cdots \tag{2.6}$$

associated with the periodic eigenfunctions $V_{k,\varepsilon} \in H^1_\#(Y_2)$, $k \in \mathbb{N}$, solutions of

$$-\operatorname{div}(A_\varepsilon \nabla V_{k,\varepsilon}) = \Lambda_k(\varepsilon)\, A_\varepsilon\, V_{k,\varepsilon} \text{ in } Y_2 \quad \text{and} \quad \int_{Y_2} A_\varepsilon\, V^2_{k,\varepsilon} = 1. \tag{2.7}$$

In this section we are only interested in the appearance of nonlocal effects. In [3] we proved, in a more general way, that the limit of $\frac{\Lambda_1(\varepsilon)}{\varepsilon^2}$ is a critical barrier for nonlocal effects. In the present context we will prove that nonlocal effects appear if and only if this limit is finite.

The main result of the section is the following.

THEOREM 2.1. *Assume that*

$$\lim_{\varepsilon\to 0} \frac{\Lambda_1(\varepsilon)}{\varepsilon^2} = \lambda_1 \in]0, +\infty[\quad \textit{and} \quad \lim_{\varepsilon\to 0} \frac{\Lambda_2(\varepsilon)}{\varepsilon^2} = +\infty, \tag{2.8}$$

and that the eigenfunction $V_{1,\varepsilon}$ associated with $\Lambda_1(\varepsilon)$ by (2.7) satisfies

$$\lim_{\varepsilon\to 0} \int_{Y_2} V^2_{1,\varepsilon} > 0. \tag{2.9}$$

Assume that the function A_ε and the set Q_ε satisfy conditions (2.1) to (2.3). Also assume that Q_ε has a vanishing capacity in the torus, i.e.,

$$\operatorname{cap}(Q_\varepsilon) := \inf\left\{ \int_{Y_2} |\nabla\Phi|^2 \;\Big|\; \Phi \in H^1_\#(Y_2),\ \Phi = 0 \text{ in } Q_\varepsilon,\ \textit{and} \int_{Y_2} \Phi = 1 \right\} \underset{\varepsilon\to 0}{\longrightarrow} 0, \tag{2.10}$$

and that there exists, for any $\mu \in \mathbb{R}^2$, a periodic function Ψ_μ such that

$$\Psi_\mu \in C^1_\#(Y_2) \quad \textit{and} \quad \nabla\Psi_\mu = \mu \text{ in } Q_\varepsilon. \tag{2.11}$$

Then the solution u_ε of problem (2.5) weakly converges in $H^1(\Omega)$ to the solution u of the coupled system

$$\begin{cases} -\Delta u - a\dfrac{\partial^2 u}{\partial x_3^2} + \gamma(u - v) = f & \text{in } \Omega, \\ -b\dfrac{\partial^2 v}{\partial x_3^2} + \gamma(v - u) = 0 & \text{in } \Omega, \\ u = 0 & \text{on } \partial\Omega, \\ v(x_1, x_2, 0) = v(x_1, x_2, 1) = 0 & \text{in } \Omega_2, \end{cases} \tag{2.12}$$

where

$$c_1 := \lim_{\varepsilon\to 0} \int_{Y_2} V_{1,\varepsilon}, \tag{2.13}$$

$$a := \frac{\kappa - (1+\kappa)\, c_1^2}{1 + (1+\kappa)\, c_1^2}, \quad b := \frac{(1+\kappa)^2\, c_1^2}{1 + (1+\kappa)\, c_1^2}, \quad \gamma := \lambda_1 \left(\frac{(1+\kappa)\, c_1}{1 + (1+\kappa)\, c_1^2} \right)^2 . \tag{2.14}$$

Remark 2.2. In the homogenized system (2.12) the function u represents the averaged potential in the matrix and v the averaged (rescaled) potential in the fibers. The two potentials are coupled by the second equation of (2.12) thanks to the capacitary parameter γ. If $\gamma < +\infty$, by following Bellieud and Bouchitté [1] this equation also reads as

$$v(x_1, x_2, x_3) = \int_0^1 G(x_3, t)\, u(x_1, x_2, t)\, dt, \tag{2.15}$$

where the kernel G can be explicitly computed. By substituting v by (2.15) in the first equation of (2.12) one obtains the nonlocal limit equation satisfied by u:

$$-\Delta u - a\, \frac{\partial^2 u}{\partial x_3^2} + \gamma \left(u - \int_0^1 G(x_3, t)\, u(x_1, x_2, t)\, dt \right) = f. \tag{2.16}$$

We proved in [3] that if $\gamma = +\infty$, the averaged potentials u and v are equal. The limit equation then reads as

$$-\Delta u - (a+b)\, \frac{\partial^2 u}{\partial x_3^2} = f, \tag{2.17}$$

in which only the residual conductivity $(a+b)$ attests to the reinforcement by fibers.

For example (see [11], [1], or [3]), when Q_ε is a disk of small radius r_ε the coupling and thus the nonlocal effect appears if and only if r_ε is sufficiently small, namely, $|\ln r_\varepsilon| \geq c\, \varepsilon^{-2}$, where c is a positive constant.

In a more general framework we proved in [3] that there is no coupling and hence no nonlocal effect if the limit of $\frac{\Lambda_1(\varepsilon)}{\varepsilon^2}$ is infinite. Under assumptions (2.10) and (2.11) we can thus claim that a nonlocal effect appears if and only if the sequence $\frac{\Lambda_1(\varepsilon)}{\varepsilon^2}$ is bounded.

Under assumption (2.8) we obtain a coupled system of two equations. In the next section we will obtain a coupled system of arbitrary size under a more general assumption on the spectrum.

2.2. A general distribution of one-directional fibers. In this section we consider a general distribution of $N \geq 1$ highly conducting x_3-directional fibers in the period cell. More precisely the fibers' cross sections are represented in the two-dimensional torus Y_2 by the set

$$Q_\varepsilon := \bigcup_{i=1}^{N} Q_{i,\varepsilon}, \tag{2.18}$$

where $Q_{i,\varepsilon}$ are disjoint regular connected open subsets of Y_2. The closures of two sets $Q_{i,\varepsilon}, Q_{j,\varepsilon}$ may have a nonempty intersection as shown in Figure 1.

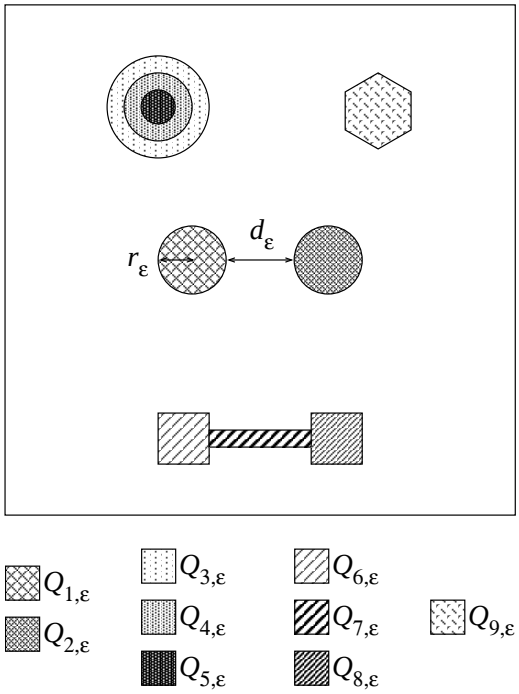

FIG. 1. *The cross section of the period cell with $N = 9$ fibers.*

Moreover we assume that, for any $i = 1, \dots, N$,

$$\lim_{\varepsilon \to 0} \operatorname{diam}(Q_{i,\varepsilon}) = 0, \tag{2.19}$$

and that there exists a positive constant C_i such that the following uniform Poincaré–Wirtinger inequality holds true:

$$\forall\, V \in H^1_{\#}(Q_{i,\varepsilon}), \quad \left\| V - \fint_{Q_{i,\varepsilon}} V \right\|_{L^2(Q_{i,\varepsilon})} \leq C_i \, \|\nabla V\|_{L^2(Q_{i,\varepsilon})}. \tag{2.20}$$

The conductivity of the fiber-reinforced medium is defined by

$$A_\varepsilon := \begin{cases} 1 & \text{in } Y_2 \setminus Q_\varepsilon, \\ \alpha_{i,\varepsilon} & \text{in } Q_{i,\varepsilon}, \end{cases} \qquad \text{where} \quad \lim_{\varepsilon \to 0} \alpha_{i,\varepsilon} \, |Q_{i,\varepsilon}| = \kappa_i \in \,]0, +\infty[. \tag{2.21}$$

We also set

$$\kappa := \kappa_1 + \cdots + \kappa_N, \quad \text{where} \quad \kappa_i := \lim_{\varepsilon \to 0} \alpha_{i,\varepsilon} \, |Q_{i,\varepsilon}|. \tag{2.22}$$

This geometry is more restrictive than in the first section, but we will consider a more general assumption for the asymptotic behavior of the spectrum (2.7).

Before stating the result we need some notation.

Notation 2.3. Let us define the following weighted scalar product and norm in $L^2_\#(Y_2)$:

$$\forall\, V, W \in L^2_\#(Y_2), \quad \langle V, W\rangle_\varepsilon := \int_{Y_2} A_\varepsilon\, V\, W \quad \text{and} \quad \|V\|_\varepsilon := \sqrt{\langle V, V\rangle_\varepsilon}. \tag{2.23}$$

We extend in $L^2(\Omega)$ by

$$\forall\, v, w \in L^2(\Omega), \quad \langle v, w\rangle_\varepsilon := \int_\Omega a_\varepsilon\, v\, w \quad \text{and} \quad \|v\|_\varepsilon := \sqrt{\langle v, v\rangle_\varepsilon}. \tag{2.24}$$

Let us denote by $\approx_\varepsilon$ the following approximation in $L^2_\#(Y_2)$:

$$\forall\, V_\varepsilon, W_\varepsilon \in L^2_\#(Y_2), \quad V_\varepsilon \approx_\varepsilon W_\varepsilon \ \text{ if } \ \lim_{\varepsilon\to 0} \|V_\varepsilon - W_\varepsilon\|_\varepsilon = 0. \tag{2.25}$$

We extend in $L^2(\Omega)$ by

$$\forall\, v_\varepsilon, w_\varepsilon \in L^2(\Omega), \quad v_\varepsilon \approx_\varepsilon w_\varepsilon \ \text{ if } \ \lim_{\varepsilon\to 0} \int_\Omega a_\varepsilon\, (v_\varepsilon - w_\varepsilon)^2 = 0. \tag{2.26}$$

Let $T_{0,1}$ be the truncature defined by

$$T_{0,1}(t) := \frac{1}{2}\,(1 + |t| - |t-1|) = \begin{cases} t & \text{if } t \in [0,1], \\ 0 & \text{if } t < 0, \\ 1 & \text{if } t > 1. \end{cases} \tag{2.27}$$

In what follows we will denote in the same way any function v defined on $\mathbb{R}^2$ and its extension to $\mathbb{R}^3$, i.e., $v(x_1, x_2, x_3) = v(x_1, x_2)$.

Let us now state the main result of this section.

THEOREM 2.4. *Let Q_ε be the set defined by* (2.18) *and conditions* (2.19), (2.20), *and let A_ε be the conductivity defined by* (2.21).

(i) *Then there exists a smallest integer n with*

$$1 \le n \le N+1 \tag{2.28}$$

such that the sequence $(\frac{\Lambda_n(\varepsilon)}{\varepsilon^2})_{\varepsilon>0}$ is not bounded.

We assume that, for this particular integer n, the eigenvalues of problem (2.7) *satisfy*

$$\forall\, k = 1, \dots, n-1, \ \lim_{\varepsilon\to 0} \frac{\Lambda_k(\varepsilon)}{\varepsilon^2} = \lambda_k \in\,]0, +\infty[\quad \textit{and} \quad \lim_{\varepsilon\to 0} \frac{\Lambda_n(\varepsilon)}{\varepsilon^2} = +\infty. \tag{2.29}$$

Let $(V_{0,\varepsilon}, \dots, V_{n-1,\varepsilon})$ ($V_{0,\varepsilon} := \|1\|_\varepsilon^{-1}$) be a family of associated eigenfunctions which is orthonormal with respect to the scalar product $\langle\cdot,\cdot\rangle_\varepsilon$ defined by (2.23).

Then there exists an "asymptotic" partition of the unity $(\hat V_{1,\varepsilon}, \dots, \hat V_{n,\varepsilon})$ composed by n functions in $H^1_\#(Y_2)$ which satisfy the following properties:

$$\forall\, k := 1, \dots, n, \ \ \hat V_{k,\varepsilon} \rightharpoonup \delta_{k,1} \ \textit{ weakly in } H^1_\#(Y_2) \quad \textit{and} \quad \hat V_{1,\varepsilon} + \cdots + \hat V_{n,\varepsilon} \ \approx_\varepsilon \ 1, \tag{2.30}$$

where $\delta_{k,1}$ *is the Kronecker symbol and* $\approx_\varepsilon$ *is defined by* (2.25),

$$\forall\, h \neq k,\ \lim_{\varepsilon\to 0} \langle \hat{V}_{h,\varepsilon}, \hat{V}_{k,\varepsilon}\rangle_\varepsilon = 0 \quad \textit{and} \quad \lim_{\varepsilon\to 0} \|\hat{V}_{k,\varepsilon}\|_\varepsilon > 0, \tag{2.31}$$

$$\forall\, k = 1,\dots,n, \quad T_{0,1}(\hat{V}_{k,\varepsilon}) \approx_\varepsilon \hat{V}_{k,\varepsilon}, \tag{2.32}$$

where $T_{0,1}$ *is defined by* (2.27), *and*

$$\forall\, i = 0,\dots,n-1, \quad V_{i,\varepsilon} = \sum_{k=1}^{n} \hat{c}_{i,k}\hat{V}_{k,\varepsilon}, \quad \textit{where } \hat{c}_{i,k} \in \mathbb{R}. \tag{2.33}$$

(ii) *The solution* u_ε *of the Dirichlet problem* (2.5), *defined with the conductivity* A_ε *of* (2.21), *weakly converges in* $H^1(\Omega)$ *to the solution* u *of the coupled system of size* n*:*

(2.34)
$$\begin{cases} -\Delta u - (\hat{\kappa}_1 - 1)\,\dfrac{\partial^2 u}{\partial x_3^2} + \displaystyle\sum_{i=1}^{n-1} \hat{\kappa}_1\hat{c}_{i,1}\lambda_i \left(\hat{\kappa}_1\hat{c}_{i,1}\,u + \sum_{h=2}^{n} \hat{\kappa}_h\hat{c}_{i,h}\,v_h\right) = f & \textit{in } \Omega, \\ -\hat{\kappa}_k\,\dfrac{\partial^2 v_k}{\partial x_3^2} + \displaystyle\sum_{i=1}^{n-1} \hat{\kappa}_k\hat{c}_{i,k}\lambda_i \left(\hat{\kappa}_k\hat{c}_{i,k}\,u + \sum_{h=2}^{n} \hat{\kappa}_h\hat{c}_{i,h}\,v_h\right) = 0 & \textit{in } \Omega, \\ u = 0 & \textit{on } \Omega, \\ v_k(x_1,x_2,0) = v_k(x_1,x_2,1) = 0 & \textit{in } \Omega_2, \end{cases}$$

$$\textit{where} \quad \forall\, k = 1,\dots,n, \ \ \hat{\kappa}_k := \lim_{\varepsilon\to 0} \langle \hat{V}_{k,\varepsilon}, 1\rangle_\varepsilon = \lim_{\varepsilon\to 0} \|\hat{V}_{k,\varepsilon}\|_\varepsilon^2. \tag{2.35}$$

Remark 2.5. In the homogenized system (2.34) and contrary to the case of Theorem 2.1, the averaged potential in the fibers is divided into several potentials $v_2,\dots,v_{n-1}$. Each function v_k corresponds to the averaged contribution of a group of fibers among the N fibers in the period cell. The number $(n-1)$ of groups is not necessarily equal to the number N of fibers by cell, but it is controlled by the rescaled spectrum $(\frac{\Lambda_k(\varepsilon)}{\varepsilon^2})_{k\in\mathbb{N}}$ of problem (2.7) according to condition (2.29). Of course the spectrum (2.7) strongly depends on the geometry of the distribution of the fibers but, inversely, it contains implicitly the information of geometrical nature. That is the main interest of this spectral approach.

For instance, Example 2.6 below shows that the degree of coupling in the limit problem depends in particular on the closeness of the fibers in the period cell. So two fibers in the period cell ($N = 2$) will induce the same averaged potential in the fibers ($n = 1$) if they are sufficiently neighboring, and two different averaged potentials ($n = 2$) elsewhere.

Example 2.6. The case of $N = 2$ neighboring fibers.

We consider the case where the set Q_ε is composed of two disjoint open disks $Q_{1,\varepsilon}, Q_{2,\varepsilon}$ of the same radius $r_\varepsilon \ll 1$ and separated by distance $d_\varepsilon \in\,]0,1[$, as shown in Figure 1. Then the size n of the limit system is determined by the following result.

Proposition 2.7. (i) *Assume that*

$$\lim_{\varepsilon\to 0} \left(\frac{2\,\pi}{\varepsilon^2\,|\ln r_\varepsilon|}\right) = \delta \in\,]0,+\infty] \quad \textit{and} \quad \lim_{\varepsilon\to 0} \left|\frac{\ln d_\varepsilon}{\ln r_\varepsilon}\right| = \gamma \in [0,+\infty]. \tag{2.36}$$

Then we have

$$\begin{cases} \delta = +\infty & \Leftrightarrow \quad n = 1, \\ \delta < +\infty \text{ and } \gamma \geq 1 & \Rightarrow \quad n = 2, \\ \delta < +\infty \text{ and } \gamma < 1 & \Rightarrow \quad n = 3. \end{cases} \tag{2.37}$$

(ii) *In particular assume that* $\delta < +\infty$, $\gamma = 0$, *and* $\kappa_1 = \kappa_2$ *defined in* (2.22). *Then the asymptotic behavior of the eigenvalues* $\Lambda_1(\varepsilon), \Lambda_2(\varepsilon)$ *of problem* (2.7) *is given by*

$$\lambda_1 = \lim_{\varepsilon \to 0} \frac{\Lambda_1(\varepsilon)}{\varepsilon^2} = \frac{\delta}{\kappa_1} \quad \text{and} \quad \lambda_2 = \lim_{\varepsilon \to 0} \frac{\Lambda_2(\varepsilon)}{\varepsilon^2} = \frac{\delta}{\kappa_1}\,(1 + 2\,\kappa_1), \tag{2.38}$$

and the limit system (2.34) *reads as*

$$\begin{cases} -\,\Delta u + 2\,\delta\,u - \delta\,v_2 - \delta\,v_3 \;= f & \text{in } \Omega, \\ -\,\kappa_1\,\dfrac{\partial^2 v_2}{\partial x_3^2} - \delta\,u + \delta\,v_2 \;= 0 & \text{in } \Omega, \\ -\,\kappa_1\,\dfrac{\partial^2 v_3}{\partial x_3^2} - \delta\,u + \delta\,v_3 \;= 0 & \text{in } \Omega. \end{cases} \tag{2.39}$$

3. Proof of the results.

3.1. Proof of Theorem 2.1. The proof of Theorem 2.1 is divided into three steps. In the first step we build an asymptotic partition of the unity in $H^1_\#(Y_2)$, $(\hat{V}_{1,\varepsilon}, 1 - \hat{V}_{1,\varepsilon})$, which is characterized by Lemma 3.1 below. This partition is the key ingredient of the proof and induces the coupling (2.12). It is also related to the spectral problem (2.7) since both functions $\hat{V}_{1,\varepsilon}$ and $1-\hat{V}_{1,\varepsilon}$ span the same space as the first eigenfunctions 1 and $V_{1,\varepsilon}$ associated with the eigenvalues $\Lambda_0(\varepsilon) = 0$ and $\Lambda_1(\varepsilon)$. We then define the rescaled functions

$$\hat{v}_{1,\varepsilon}(x) := \hat{V}_{1,\varepsilon}\left(\frac{x}{\varepsilon}\right) \quad \text{and} \quad \hat{v}_{2,\varepsilon}(x) := 1 - \hat{V}_{1,\varepsilon}\left(\frac{x}{\varepsilon}\right) \quad \text{for almost every } x \in \Omega. \tag{3.1}$$

In the second step we give the weak $*$ limits of $a_\varepsilon\,\hat{v}_{i,\varepsilon}\,u_\varepsilon$ and $a_\varepsilon\,\hat{v}_{i,\varepsilon}\,\nabla u_\varepsilon$, $i = 1, 2$, in terms of the solutions u and v of (2.12). In the third step we determine the limit problem (2.12) using $\hat{v}_{1,\varepsilon}$ (3.1) as a test function in problem (2.5). In particular we prove in Lemma 3.2 below that $a_\varepsilon\,\nabla\hat{v}_{1,\varepsilon}\,u_\varepsilon$ weakly $*$ tends to 0 in the distributions sense thanks to the assumptions (2.10) and (2.11) satisfied by the set Q_ε.

In the following all the limits hold true up to a subsequence of ε still denoted ε for the sake of simplicity. We will also denote by c an arbitrary positive constant.

First step. Partition of the unity $(\hat{V}_{1,\varepsilon}, 1-\hat{V}_{1,\varepsilon})$. This step is contained in the following result.

LEMMA 3.1. *Let* $\hat{V}_{1,\varepsilon}$ *be the function defined by*

$$\hat{V}_{1,\varepsilon} := \alpha + \beta\,V_{1,\varepsilon} \quad \textit{with} \quad \alpha := \frac{1}{1 + (1+\kappa)\,c_1^2} \quad \textit{and} \quad \beta := \frac{(1+\kappa)\,c_1}{1 + (1+\kappa)\,c_1^2}, \tag{3.2}$$

where $V_{1,\varepsilon}$ *is defined by* (2.7), κ *by* (2.3), *and* c_1 *by* (2.13). *Then the function* $\hat{V}_{1,\varepsilon}$ *satisfies the following properties (see Notation* 2.3.*):*

$$\hat{V}_{1,\varepsilon} \rightharpoonup 1 \;\; H^1_\#(Y_2) \textit{ weak } *, \quad \hat{V}_{1,\varepsilon} \not\approx_\varepsilon 1, \quad T_{0,1}(\hat{V}_{1,\varepsilon}) \approx_\varepsilon \hat{V}_{1,\varepsilon}, \quad \langle \hat{V}_{1,\varepsilon}, 1-\hat{V}_{1,\varepsilon} \rangle_\varepsilon \to 0. \tag{3.3}$$

Proof of Lemma 3.1. By assumption (2.8) the eigenfunction $V_{1,\varepsilon}$ associated with the eigenvalue $\Lambda_1(\varepsilon)$ by (2.7) satisfies

$$\int_{Y_2} |\nabla V_{1,\varepsilon}|^2 \le \int_{Y_2} A_\varepsilon \, |\nabla V_{1,\varepsilon}|^2 = \Lambda_1(\varepsilon) = O(\varepsilon^2) \ \underset{\varepsilon\to 0}{\longrightarrow}\ 0.$$

Then by the Poincaré–Wirtinger inequality in Y_2, the sequence $V_{1,\varepsilon}$ strongly converges in $H^1_\#(Y_2)$ to a constant which is equal to the limit of its averaged value, i.e., c_1 by (2.13). Since $V^2_{1,\varepsilon}$ strongly converges to c_1^2 in $L^1(Y_2)$, assumption (2.9) implies that $c_1 \neq 0$. We can assume that $c_1 > 0$ even if it means replacing $V_{1,\varepsilon}$ by $-V_{1,\varepsilon}$. This choice uniquely determines the eigenfunction $V_{1,\varepsilon}$ since its multiplicity is equal to 1 by (2.8). Therefore we obtain the following by the definitions of (3.2) and the orthogonality of the eigenfunctions 1, $V_{1,\varepsilon}$ with respect to the scalar product $\langle\cdot,\cdot\rangle_\varepsilon$ of (2.23):

$$\hat V_{1,\varepsilon} \rightharpoonup \alpha + \beta\, c_1 = 1 \ \text{ weakly in } H^1_\#(Y_2),$$

$$\|\hat V_{1,\varepsilon} - 1\|_\varepsilon = (\alpha-1)^2 \int_{Y_2} A_\varepsilon + \beta^2 \ \underset{\varepsilon\to 0}{\longrightarrow}\ (1{+}\kappa)\,(\alpha-1)^2 + \beta^2 > 0,$$

$$\langle \hat V_{1,\varepsilon}, 1{-}\hat V_{1,\varepsilon}\rangle_\varepsilon = \alpha\,(1-\alpha) \int_{Y_2} A_\varepsilon - \beta^2 \ \underset{\varepsilon\to 0}{\longrightarrow}\ (1{+}\kappa)\,(\alpha-\alpha^2) - \beta^2 = 0.$$

It remains to prove that $T_{0,1}(\hat V_{1,\varepsilon}) \approx_\varepsilon \hat V_{1,\varepsilon}$. Let $V \in H^1_\#(Y_2)$. By the Courant–Fisher formulas we have

$$\left\| V - \frac{\langle V,1\rangle_\varepsilon}{\langle 1,1\rangle_\varepsilon}\, 1 - \langle V, V_{1,\varepsilon}\rangle_\varepsilon\, V_{1,\varepsilon} \right\|^2_\varepsilon \le \frac{1}{\Lambda_2(\varepsilon)}\ \|\nabla V - \langle V, V_{1,\varepsilon}\rangle_\varepsilon\, \nabla V_{1,\varepsilon}\|^2_\varepsilon . \tag{3.4}$$

Then for any Lipschitz function $T:\mathbb{R}\longrightarrow\mathbb{R}$ and for any function $V_\varepsilon \in \mathrm{Span}\,(1, V_{1,\varepsilon})$ we have $|\nabla T(V_\varepsilon)| \le c_T\,|\nabla V_\varepsilon|$ and $\|\nabla V_{1,\varepsilon}\|^2_\varepsilon \le \Lambda_1(\varepsilon)$, whence by (2.8)

$$\left\| T(V_\varepsilon) - \frac{\langle T(V_\varepsilon),1\rangle_\varepsilon}{\langle 1,1\rangle_\varepsilon}\, 1 - \langle T(V_\varepsilon), V_{1,\varepsilon}\rangle_\varepsilon\, V_{1,\varepsilon} \right\|^2_\varepsilon \le c\,\frac{\Lambda_1(\varepsilon)}{\Lambda_2(\varepsilon)} \ \underset{\varepsilon\to 0}{\longrightarrow}\ 0.$$

Therefore we obtain (up to a subsequence)

$$T(V_\varepsilon) \approx_\varepsilon a + b\, V_{1,\varepsilon}, \quad \text{where} \quad a := \lim_{\varepsilon\to 0} \frac{\langle T(V_\varepsilon),1\rangle_\varepsilon}{\langle 1,1\rangle_\varepsilon} \ \text{ and } \ b := \lim_{\varepsilon\to 0} \langle T(V_\varepsilon), V_{1,\varepsilon}\rangle_\varepsilon. \tag{3.5}$$

In particular there exist two constants $a_1, b_1 \in \mathbb{R}$ such that $|\hat V_{1,\varepsilon}| \approx_\varepsilon a_1 + b_1\, V_{1,\varepsilon}$. Since $\hat V_{1,\varepsilon}$ strongly converges to 1 in $L^2_\#(Y_2)$ we have

$$1 = a_1 + b_1\, c_1 = \alpha + \beta\, c_1.$$

Moreover the equality $|\hat V_{1,\varepsilon}|^2 = \hat V^2_{1,\varepsilon}$ yields

$$\int_{Y_2} A_\varepsilon\,(a_1 + b_1\, V_{1,\varepsilon})^2 + o(1) = \int_{Y_2} A_\varepsilon\,(\alpha + \beta\, V_{1,\varepsilon})^2;$$

then by passing to the limit we obtain

$$(1{+}\kappa)\, a_1^2 + b_1^2 = (1{+}\kappa)\,\alpha^2 + \beta^2 = \frac{1{+}\kappa}{1 + (1{+}\kappa)\, c_1^2}.$$

We deduce from both previous equalities that b_1 is a solution of

$$\big(1+(1+\kappa)\,c_1^2\big)\,b_1^2-2\,(1+\kappa)\,c_1\,b_1+\frac{(1+\kappa)^2\,c_1^2}{1+(1+\kappa)\,c_1^2}=0,$$

which has a unique solution β, whence $b_1=\beta$ and $a_1=\alpha$. We thus obtain $|\hat V_{1,\varepsilon}|\approx_\varepsilon \hat V_{1,\varepsilon}$.

Similarly there exist two constants $a_2,b_2\in\mathbb{R}$ such that $|1-\hat V_{1,\varepsilon}|\approx_\varepsilon a_2+b_2\,V_{1,\varepsilon}$ with

$$a_2+b_2\,c_1=0\quad\text{and}\quad(1+\kappa)\,a_2^2+b_2^2=(1+\kappa)\,(\alpha-1)^2+\beta^2=\frac{(1+\kappa)^2\,c_1^2}{1+(1+\kappa)\,c_1^2},$$

whence $b_2=\pm\beta$. Moreover by applying (3.5) with $V_\varepsilon:=|1-\hat V_{1,\varepsilon}|$, we obtain $a_2\geq 0$ and thus $b_2\leq 0$, whence $b_2=-\beta$ and $a_2=c_1\,\beta=1-\alpha$. Therefore we have $|1-\hat V_{1,\varepsilon}|\approx_\varepsilon 1-\hat V_{1,\varepsilon}$ and $|\hat V_{1,\varepsilon}|\approx_\varepsilon \hat V_{1,\varepsilon}$, which imply $T_{0,1}(\hat V_{1,\varepsilon})\approx_\varepsilon \hat V_{1,\varepsilon}$ and (3.3). This concludes the proof of Lemma 3.1 and the first step.

Second step. Limits of $a_\varepsilon\,\hat v_{i,\varepsilon}\,u_\varepsilon$ and $a_\varepsilon\,\hat v_{i,\varepsilon}\,\nabla u_\varepsilon$, $i=1,2$.

Since the function a_ε defined by (2.4) does not depend on the variable x_3 and u_ε is equal to 0 on $\Omega_2\times\{0,1\}$ the following estimate holds:

$$\int_\Omega a_\varepsilon\,u_\varepsilon^2\leq c\int_\Omega a_\varepsilon\left(\frac{\partial u_\varepsilon}{\partial x_3}\right)^2\leq c\int_\Omega a_\varepsilon\,|\nabla u_\varepsilon|^2.$$

By the Poincaré inequality

$$\int_\Omega a_\varepsilon\,|\nabla u_\varepsilon|^2=\int_\Omega f\,u_\varepsilon\leq\|f\|_{L^2(\Omega)}\,\|u_\varepsilon\|_{L^2(\Omega)}\leq c\,\|\nabla u_\varepsilon\|_{L^2(\Omega)}\leq c\left(\int_\Omega a_\varepsilon\,|\nabla u_\varepsilon|^2\right)^{\frac12},$$

whence the following a priori estimate:

$$\int_\Omega a_\varepsilon\,u_\varepsilon^2+\int_\Omega a_\varepsilon\,|\nabla u_\varepsilon|^2\leq c. \tag{3.6}$$

By definitions (3.1), (2.26) and by the third property of (3.3) we have $T_{0,1}(\hat v_{i,\varepsilon})\approx_\varepsilon \hat v_{i,\varepsilon}$ for $i=1,2$, which combined with estimate (3.6) and assumption (2.3) implies that the sequence $a_\varepsilon\,\hat v_{i,\varepsilon}\,u_\varepsilon$ is bounded in $L^1(\Omega)$. In the beginning of the proof of Lemma 3.1 we showed that the constant c_1 of (2.13) is not equal to 0, whence the constant b in (2.14) is positive. We can then define a Radon measure v by the weak convergence

$$a_\varepsilon\,\hat v_{2,\varepsilon}\,u_\varepsilon\rightharpoonup b\,v\quad\text{weakly in }\mathcal{M}(\overline\Omega). \tag{3.7}$$

In the following we will prove that the weak limits u of u_ε in $H^1(\Omega)$ and v satisfy

$$v\in H_0^1(0,1;L^2(\Omega_2)), \tag{3.8}$$

$$a_\varepsilon\,\hat v_{1,\varepsilon}\,u_\varepsilon\rightharpoonup(1+\kappa)\,\alpha\,u\quad\text{weakly in }\mathcal{D}'(\Omega), \tag{3.9}$$

$$a_\varepsilon\,\hat v_{1,\varepsilon}\,\nabla u_\varepsilon\rightharpoonup\nabla u+a\,\frac{\partial u}{\partial x_3}\,e_3\quad\text{weakly in }\mathcal{D}'(\Omega;\mathbb{R}^3), \tag{3.10}$$

$$a_\varepsilon\,\hat v_{2,\varepsilon}\,\nabla u_\varepsilon\rightharpoonup b\,\frac{\partial v}{\partial x_3}\,e_3\quad\text{weakly in }\mathcal{D}'(\Omega;\mathbb{R}^3), \tag{3.11}$$

where a,b are defined by (2.14) and α by (3.2).

Proof of (3.8). Let $\varphi \in C^0(\overline{\Omega})$. By the Cauchy–Schwarz inequality and estimate (3.6) we have

$$\left| \int_\Omega a_\varepsilon \, T_{0,1}(\hat{v}_{2,\varepsilon}) \, u_\varepsilon \, \varphi \right| \leq c \left(\int_\Omega a_\varepsilon \, \varphi^2 \right)^{\frac{1}{2}},$$

and since $T_{0,1}(\hat{v}_{2,\varepsilon}) \approx_\varepsilon \hat{v}_{2,\varepsilon}$,

$$\left| \int_\Omega a_\varepsilon \, \hat{v}_{2,\varepsilon} \, u_\varepsilon \, \varphi + o(1) \right| \leq c \left(\int_\Omega a_\varepsilon \, \varphi^2 \right)^{\frac{1}{2}}.$$

Moreover the periodicity of A_ε combined with the second limit of (2.3) implies that a_ε weakly $*$ converges to $1+\kappa$ in $\mathcal{M}(\overline{\Omega})$. Then passing to the limit in the previous inequality, thanks to (3.7), yields

$$\left| \int_\Omega v \, \varphi \right| \leq c \, \|\varphi\|_{L^2(\Omega)} \quad \text{for any } \varphi \in C^0(\overline{\Omega}),$$

which implies that $v \in L^2(\Omega)$. Similarly, since $a_\varepsilon \, \hat{v}_{2,\varepsilon}$ does not depend on x_3 and $u_\varepsilon = 0$ on $\partial\Omega$, we obtain, thanks to an integration by parts, for any $\varphi \in C^1(\overline{\Omega})$,

$$\left| \int_\Omega a_\varepsilon \, T_{0,1}(\hat{v}_{2,\varepsilon}) \, u_\varepsilon \, \frac{\partial \varphi}{\partial x_3} \right| = \left| \int_\Omega a_\varepsilon \, T_{0,1}(\hat{v}_{2,\varepsilon}) \, \frac{\partial u_\varepsilon}{\partial x_3} \, \varphi \right| \leq c \left(\int_\Omega a_\varepsilon \, \varphi^2 \right)^{\frac{1}{2}} \quad \text{by (3.6)},$$

whence by passing to the limit

$$\left| \int_\Omega v \, \frac{\partial \varphi}{\partial x_3} \right| \leq c \, \|\varphi\|_{L^2(\Omega)} \quad \text{for any } \varphi \in C^1(\overline{\Omega}),$$

which implies that $\frac{\partial v}{\partial x_3} \in L^2(\Omega)$ and $v = 0$ on $\Omega_2 \times \{0,1\}$. Therefore (3.8) holds.

Proof of (3.9). By estimate (3.4) we have for any $V \in H^1_\#(Y_2)$

$$\left\| V - \frac{\langle V, 1 \rangle_\varepsilon}{\langle 1, 1 \rangle_\varepsilon} \, 1 - \langle V, V_{1,\varepsilon} \rangle_\varepsilon \, V_{1,\varepsilon} \right\|_\varepsilon \leq c \left(\frac{\Lambda_1(\varepsilon)}{\Lambda_2(\varepsilon)} \right)^{\frac{1}{2}} \|V\|_\varepsilon + \Lambda_2(\varepsilon)^{-\frac{1}{2}} \, \|\nabla V\|_\varepsilon,$$

which implies the estimate

$$\left| \langle \hat{V}_{1,\varepsilon}, V \rangle_\varepsilon - \langle \hat{V}_{1,\varepsilon}, 1 \rangle_\varepsilon \int_{Y_2} V \right| \leq c \, \eta_\varepsilon \, \|V\|_\varepsilon + c \, \Lambda_2(\varepsilon)^{-\frac{1}{2}} \, \|\nabla V\|_\varepsilon, \tag{3.12}$$

where by (3.2) and (2.8)

$$\eta_\varepsilon := \left| \langle \hat{V}_{1,\varepsilon}, V_{1,\varepsilon} \rangle_\varepsilon - \langle \hat{V}_{1,\varepsilon}, 1 \rangle_\varepsilon \int_{Y_2} V_{1,\varepsilon} \right| + \left(\frac{\Lambda_1(\varepsilon)}{\Lambda_2(\varepsilon)} \right)^{\frac{1}{2}} \underset{\varepsilon \to 0}{\longrightarrow} |\beta - (1+\kappa) \, \alpha \, c_1| = 0. \tag{3.13}$$

On the other hand, since $A_\varepsilon \, \hat{V}_{1,\varepsilon} - \langle \hat{V}_{1,\varepsilon}, 1 \rangle_\varepsilon$ has a zero Y_2-averaged value, by the Lax–Milgram theorem there exists $W_\varepsilon \in H^1_\#(Y_2)$, defined up to an additive constant, solution of the problem

$$-\operatorname{div}(A_\varepsilon \nabla W_\varepsilon) = A_\varepsilon \, \hat{V}_{1,\varepsilon} - \langle \hat{V}_{1,\varepsilon}, 1 \rangle_\varepsilon \quad \text{in } Y_2, \tag{3.14}$$

whose variational formulation is

$$\forall\, V \in H^1_\#(Y_2), \quad \langle W_\varepsilon, V\rangle_\varepsilon = \langle \hat V_{1,\varepsilon}, V\rangle_\varepsilon - \langle \hat V_{1,\varepsilon}, 1\rangle_\varepsilon \int_{Y_2} V. \tag{3.15}$$

We choose W_ε such that $\langle W_\varepsilon, 1\rangle_\varepsilon = 0$, which implies $\|W_\varepsilon\|^2_\varepsilon \le \Lambda_1(\varepsilon)^{-1}\,\|\nabla W_\varepsilon\|^2_\varepsilon$ by the definition of the eigenvalue $\Lambda_1(\varepsilon)$. Then by putting W_ε in (3.15) we obtain, thanks to estimate (3.12),

$$\|\nabla W_\varepsilon\|_\varepsilon \le c\left(\eta_\varepsilon\,\Lambda_1(\varepsilon)^{-\frac12} + \Lambda_2(\varepsilon)^{-\frac12}\right). \tag{3.16}$$

Let $\varphi \in \mathcal{D}(\Omega)$. Putting φu_ε in the rescaled equation (3.14) yields

$$\varepsilon \int_\Omega a_\varepsilon \nabla_y W_\varepsilon(\tfrac{x}{\varepsilon}) \cdot \nabla(\varphi u_\varepsilon) = \int_\Omega a_\varepsilon\,\hat v_{1,\varepsilon}\,\varphi\,u_\varepsilon - \langle \hat V_{1,\varepsilon}, 1\rangle_\varepsilon \int_\Omega \varphi\,u_\varepsilon. \tag{3.17}$$

Moreover, by estimates (3.6) and (3.16) the left-hand side of (3.17) is bounded by the sequence $\eta_\varepsilon\,\varepsilon\,\Lambda_1(\varepsilon)^{-\frac12} + \varepsilon\,\Lambda_2(\varepsilon)^{-\frac12}$, which tends to zero by (3.13) and (2.8). Therefore, passing to the limit in (3.17) yields

$$\int_\Omega a_\varepsilon\,\hat v_{1,\varepsilon}\,\varphi\,u_\varepsilon \;\underset{\varepsilon\to0}{\longrightarrow}\; (1+\kappa)\,\alpha \int_\Omega \varphi\,u \quad \text{for any } \varphi \in \mathcal{D}(\Omega),$$

whence (3.9).

Proof of (3.10). Let ω_ε be the set of high conductivity whose period is $\varepsilon\,Q_\varepsilon$. Since u_ε is bounded in $H^1(\Omega)$, $\hat v_{1,\varepsilon}$ strongly converges to 1 in $L^2(\Omega)$, and $|\omega_\varepsilon| \to 0$, we have

$$\mathbf{1}_{\Omega\setminus\omega_\varepsilon} a_\varepsilon\,T_{0,1}(\hat v_{1,\varepsilon})\,\nabla u_\varepsilon \rightharpoonup \nabla u \quad \text{weakly in } L^2(\Omega;\mathbb{R}^3),$$

and since $T_{0,1}(\hat v_{1,\varepsilon}) \approx_\varepsilon \hat v_{1,\varepsilon}$ in the sense of definition (2.26) we also have

$$\mathbf{1}_{\Omega\setminus\omega_\varepsilon} a_\varepsilon\,\hat v_{1,\varepsilon}\,\nabla u_\varepsilon - \mathbf{1}_{\Omega\setminus\omega_\varepsilon} a_\varepsilon\,T_{0,1}(\hat v_{1,\varepsilon})\,\nabla u_\varepsilon \longrightarrow \nabla u \quad \text{strongly in } L^2(\Omega;\mathbb{R}^3),$$

whence the weak convergence

$$\mathbf{1}_{\Omega\setminus\omega_\varepsilon} a_\varepsilon\,\hat v_{1,\varepsilon}\,\nabla u_\varepsilon \rightharpoonup \nabla u \quad \text{weakly in } \mathcal{D}'(\Omega;\mathbb{R}^3).$$

It thus remains to prove the following convergence:

$$\mathbf{1}_{\omega_\varepsilon} a_\varepsilon\,\hat v_{1,\varepsilon}\,\nabla u_\varepsilon \rightharpoonup a\,\frac{\partial u}{\partial x_3}\,e_3 \quad \text{weakly in } \mathcal{D}'(\Omega;\mathbb{R}^3). \tag{3.18}$$

Consider $\mu \in (e_3)^\perp$ to be a vector of $\mathbb{R}^2$. By combining assumptions (2.10) and (2.11) the function $\Psi_{\mu,\varepsilon} := (1-\Phi_\varepsilon)\,\Psi_\mu$, where $\mathrm{cap}\,(Q_\varepsilon) = \|\nabla\Phi_\varepsilon\|^2_{L^2(Y_2)}$, satisfies

$$\Psi_{\mu,\varepsilon} \longrightarrow 0 \ \text{ strongly in } H^1_\#(Y_2) \quad \text{and} \quad \nabla\Psi_{\mu,\varepsilon} = \mu \text{ in } Q_\varepsilon. \tag{3.19}$$

We can also assume that $\Psi_{\mu,\varepsilon}$ is uniformly bounded by using a truncature of Φ_ε. By the definition of problem (2.5) we have

$$\varepsilon\,a_\varepsilon \nabla u_\varepsilon \cdot \nabla\left(T_{0,1}(\hat v_{1,\varepsilon})\,\Psi_{\mu,\varepsilon}(\tfrac{x}{\varepsilon})\right) \rightharpoonup 0 \quad \text{weakly in } \mathcal{D}'(\Omega),$$

and since $a_\varepsilon\nabla u_\varepsilon \cdot \nabla T_{0,1}(\hat v_{1,\varepsilon})$ is bounded in $L^1(\Omega)$ by (3.6) and by (2.8) (which implies $\|\nabla \hat V_{1,\varepsilon}\|_\varepsilon = O(\varepsilon)$), we also have

$$\varepsilon\,a_\varepsilon \nabla u_\varepsilon \cdot \nabla T_{0,1}(\hat v_{1,\varepsilon})\,\Psi_{\mu,\varepsilon}(\tfrac{x}{\varepsilon}) \longrightarrow 0 \quad \text{strongly in } L^1(\Omega),$$

whence the convergence

$$a_\varepsilon \nabla u_\varepsilon \cdot \nabla_y \Psi_{\mu,\varepsilon}(\tfrac{x}{\varepsilon})\, T_{0,1}(\hat{v}_{1,\varepsilon}) \rightharpoonup 0 \quad \text{weakly in } \mathcal{D}'(\Omega). \tag{3.20}$$

However, by the strong convergence of (3.19) we have

$$\mathbf{1}_{\Omega\setminus\omega_\varepsilon} a_\varepsilon \nabla u_\varepsilon \cdot \nabla_y \Psi_{\mu,\varepsilon}(\tfrac{x}{\varepsilon})\, T_{0,1}(\hat{v}_{1,\varepsilon}) = \mathbf{1}_{\Omega\setminus\omega_\varepsilon} \nabla u_\varepsilon \cdot \nabla_y \Psi_{\mu,\varepsilon}(\tfrac{x}{\varepsilon})\, T_{0,1}(\hat{v}_{1,\varepsilon}) \longrightarrow 0 \quad \text{in } L^1(\Omega).$$

This, combined with convergence (3.20) and the equality of (3.19), yields

$$\mathbf{1}_{\omega_\varepsilon} a_\varepsilon \nabla u_\varepsilon \cdot \nabla_y \Psi_{\mu,\varepsilon}(\tfrac{x}{\varepsilon})\, T_{0,1}(\hat{v}_{1,\varepsilon}) = \mathbf{1}_{\omega_\varepsilon} a_\varepsilon\, T_{0,1}(\hat{v}_{1,\varepsilon})\, \nabla u_\varepsilon \cdot \mu \rightharpoonup 0 \quad \text{weakly in } \mathcal{D}'(\Omega),$$

and since $T_{0,1}(\hat{v}_{1,\varepsilon}) \approx_\varepsilon \hat{v}_{1,\varepsilon}$ in the sense of (2.26), we obtain

$$\mathbf{1}_{\omega_\varepsilon} a_\varepsilon\, \hat{v}_{1,\varepsilon}\, \nabla u_\varepsilon \cdot \mu \rightharpoonup 0 \quad \text{weakly in } \mathcal{D}'(\Omega). \tag{3.21}$$

On the other hand, since a_ε and $\hat{v}_{1,\varepsilon}$ are independent of x_3 we have

$$\mathbf{1}_{\omega_\varepsilon} a_\varepsilon\, \hat{v}_{1,\varepsilon}\, \frac{\partial u_\varepsilon}{\partial x_3} = \frac{\partial}{\partial x_3}\left(\mathbf{1}_{\omega_\varepsilon} a_\varepsilon\, \hat{v}_{1,\varepsilon}\, u_\varepsilon\right),$$

and by (3.9), (3.3) we have

$$\mathbf{1}_{\omega_\varepsilon} a_\varepsilon\, \hat{v}_{1,\varepsilon}\, u_\varepsilon = a_\varepsilon\, \hat{v}_{1,\varepsilon}\, u_\varepsilon - \mathbf{1}_{\Omega\setminus\omega_\varepsilon} \hat{v}_{1,\varepsilon}\, u_\varepsilon \rightharpoonup (1+\kappa)\, \alpha\, u - u = a\, u \quad \text{weakly in } \mathcal{D}'(\Omega),$$

whence the convergence

$$\mathbf{1}_{\omega_\varepsilon} a_\varepsilon\, \hat{v}_{1,\varepsilon}\, \frac{\partial u_\varepsilon}{\partial x_3} \rightharpoonup a\, \frac{\partial u}{\partial x_3} \quad \text{weakly in } \mathcal{D}'(\Omega).$$

This, combined with (3.21), yields the desired convergence (3.18) and thus (3.10).

Proof of (3.11). It is quite similar to the proof of (3.10) by using the definition (3.7) of the function v.

Third step. Determination of the limit problem.

Let $\varphi \in \mathcal{D}(\Omega)$. We put the function $\varphi\, \hat{v}_{1,\varepsilon}$ defined by (3.1) as a test function in problem (2.5), whence

$$\int_\Omega a_\varepsilon \nabla u_\varepsilon \cdot \nabla \hat{v}_{1,\varepsilon}\, \varphi + \int_\Omega a_\varepsilon \nabla u_\varepsilon \cdot \nabla \varphi\, \hat{v}_{1,\varepsilon} = \int_\Omega f\, \varphi\, \hat{v}_{1,\varepsilon}.$$

Then by the convergence (3.10) of the second step we obtain

$$\int_\Omega a_\varepsilon \nabla u_\varepsilon \cdot \nabla \hat{v}_{1,\varepsilon}\, \varphi \;\underset{\varepsilon\to 0}{\longrightarrow}\; \int_\Omega f\, \varphi - \int_\Omega \nabla u \cdot \nabla \varphi - \int_\Omega a\, \frac{\partial u}{\partial x_3}\, \frac{\partial \varphi}{\partial x_3}. \tag{3.22}$$

For the limit of the left-hand side of (3.22) we need the following result.

LEMMA 3.2. *Let v_ε be a function in $H^1_0(\Omega)$ such that the sequence $\|v_\varepsilon\|_\varepsilon + \|\nabla v_\varepsilon\|_\varepsilon$ (see notation* (2.24)*) is bounded. Then the rescaled function $v_{1,\varepsilon}(x) := V_{1,\varepsilon}(\frac{x}{\varepsilon})$, where $V_{1,\varepsilon}$ is the eigenfunction of* (2.7)*, satisfies*

$$\int_\Omega a_\varepsilon \nabla v_{1,\varepsilon}\, v_\varepsilon \;\underset{\varepsilon\to 0}{\longrightarrow}\; 0. \tag{3.23}$$

By the definition (3.2) of $\hat{V}_{1,\varepsilon}$ and by rescaling the spectral problem (2.7) we have

$$\int_\Omega a_\varepsilon \nabla u_\varepsilon \cdot \nabla \hat{v}_{1,\varepsilon}\, \varphi = \beta \int_\Omega a_\varepsilon \nabla v_{1,\varepsilon} \cdot \nabla(\varphi\, u_\varepsilon) - \beta \int_\Omega a_\varepsilon \nabla v_{1,\varepsilon} \cdot \nabla \varphi\, u_\varepsilon$$
$$= \frac{\Lambda_1(\varepsilon)}{\varepsilon^2} \int_\Omega a_\varepsilon\, u_\varepsilon\, (\hat{v}_{1,\varepsilon} - \alpha)\, \varphi - \beta \int_\Omega a_\varepsilon \nabla v_{1,\varepsilon} \cdot \nabla \varphi\, u_\varepsilon,$$

which, combined with the limit (3.23) of Lemma 3.2, yields

$$\int_\Omega a_\varepsilon \nabla u_\varepsilon \cdot \nabla \hat{v}_{1,\varepsilon}\, \varphi - \frac{\Lambda_1(\varepsilon)}{\varepsilon^2} \int_\Omega a_\varepsilon\, u_\varepsilon\, (\hat{v}_{1,\varepsilon} - \alpha)\, \varphi \ \underset{\varepsilon\to 0}{\longrightarrow}\ 0.$$

Moreover by assumption (2.8), by the convergences (3.9), (3.7) combined with the estimate $\hat{v}_{1,\varepsilon} + \hat{v}_{2,\varepsilon} \approx_\varepsilon 1$, and by the definitions (2.14) we have

$$\frac{\Lambda_1(\varepsilon)}{\varepsilon^2}\, a_\varepsilon\, u_\varepsilon\, (\hat{v}_{1,\varepsilon} - \alpha) \ \underset{\varepsilon\to 0}{\longrightarrow}\ \lambda_1\, (1+\kappa)\, (\alpha - \alpha^2)\, u - \lambda_1\, \alpha\, b\, v = \gamma\, (u - v) \quad \text{weakly in } \mathcal{D}'(\Omega).$$

From both previous limits we deduce that

$$\int_\Omega a_\varepsilon \nabla u_\varepsilon \cdot \nabla \hat{v}_{1,\varepsilon}\, \varphi \ \underset{\varepsilon\to 0}{\longrightarrow}\ \int_\Omega \gamma\, (u - v), \tag{3.24}$$

which, combined with (3.22), yields

$$\int_\Omega \nabla u \cdot \nabla \varphi + \int_\Omega a\, \frac{\partial u}{\partial x_3}\, \frac{\partial \varphi}{\partial x_3} + \int_\Omega \gamma\, (u - v)\, \varphi = \int_\Omega f\, \varphi.$$

This equality is the variational formulation of the first equation of (2.12).

Similarly by using the test function $(1 - \hat{v}_{1,\varepsilon})\, \varphi$ and convergences (3.11), (3.24) we obtain

$$\int_\Omega a\, \frac{\partial v}{\partial x_3}\, \frac{\partial \varphi}{\partial x_3} + \int_\Omega \gamma\, (v - u) = 0,$$

which is the variational formulation of the second equation of problem (2.12). Theorem 2.1 is thus proved.

Proof of Lemma 3.2. Let $(1, V_{1,\varepsilon})^{\perp_\varepsilon}$ be the space of the functions in $L^2_\#(Y_2)$ which are orthogonal to the functions $1, V_{1,\varepsilon}$ in the sense of the scalar product $\langle \cdot, \cdot \rangle_\varepsilon$ of (2.23). The idea is to consider, for $\mu \in \mathbb{R}^2$, the orthogonal projection of $\nabla V_{1,\varepsilon} \cdot \mu$ on the space $(1, V_{1,\varepsilon})^{\perp_\varepsilon}$. So for $\mu \in \mathbb{R}^2$, let us define the function Σ_ε by

$$\varepsilon\, \Sigma_\varepsilon = \nabla V_{1,\varepsilon} \cdot \mu - \frac{\langle \nabla V_{1,\varepsilon} \cdot \mu, 1 \rangle_\varepsilon}{\langle 1, 1 \rangle_\varepsilon} - \langle \nabla V_{1,\varepsilon} \cdot \mu, V_{1,\varepsilon} \rangle_\varepsilon\, V_{1,\varepsilon}. \tag{3.25}$$

By the Lax–Milgram theorem there exists a unique solution X_ε in $H^1_\#(Y_2) \cap (1, V_{1,\varepsilon})^{\perp_\varepsilon}$ of the problem

$$\forall\, V \in H^1_\#(Y_2) \cap (1, V_{1,\varepsilon})^{\perp_\varepsilon}, \quad \langle \nabla X_\varepsilon, \nabla V \rangle_\varepsilon = \langle \Sigma_\varepsilon, V \rangle_\varepsilon. \tag{3.26}$$

Since $X_\varepsilon, \Sigma_\varepsilon \in (1, V_{1,\varepsilon})^{\perp_\varepsilon}$, we have $\langle \nabla X_\varepsilon, \nabla V_{1,\varepsilon} \rangle_\varepsilon = \Lambda_1(\varepsilon)\, \langle X_\varepsilon, V_{1,\varepsilon} \rangle_\varepsilon = 0$ and

$$\forall\, V \in H^1_\#(Y_2), \quad \langle \Sigma_\varepsilon, V \rangle_\varepsilon = \langle \nabla X_\varepsilon, \nabla V \rangle_\varepsilon - \langle \nabla X_\varepsilon, \nabla V_{1,\varepsilon} \rangle_\varepsilon\, \langle V_{1,\varepsilon}, V \rangle_\varepsilon = \langle \nabla X_\varepsilon, \nabla V \rangle_\varepsilon,$$
$$\text{whence} \quad A_\varepsilon\, \Sigma_\varepsilon = -\operatorname{div}(A_\varepsilon \nabla X_\varepsilon) \quad \text{in } Y_2.$$

Set $\sigma_\varepsilon := \Sigma_\varepsilon(\frac{x}{\varepsilon})$ and $\chi_\varepsilon(x) := X_\varepsilon(\frac{x}{\varepsilon})$. Then by rescaling the previous equation we obtain

$$a_\varepsilon\,\sigma_\varepsilon = -\,\varepsilon^2\,\mathrm{div}\,(a_\varepsilon \nabla\chi_\varepsilon) \quad \text{in } \mathcal{D}'(\Omega). \tag{3.27}$$

Moreover, by putting the function X_ε in problem (3.26) and applying estimate (3.4) with $V := X_\varepsilon \in (1, V_{1,\varepsilon})^{\perp_\varepsilon}$ we have

$$\|\nabla X_\varepsilon\|_\varepsilon^2 \le \|\Sigma_\varepsilon\|_\varepsilon\,\|X_\varepsilon\|_\varepsilon \le \frac{1}{\Lambda_2(\varepsilon)}\,\|\Sigma_\varepsilon\|_\varepsilon\,\|\nabla X_\varepsilon\|_\varepsilon,$$

whence by the definitions (3.25) of Σ_ε and (2.7) of $V_{1,\varepsilon}$ the following estimate:

$$\|\nabla X_\varepsilon\|_\varepsilon \le \frac{c}{\varepsilon\,\Lambda_2(\varepsilon)}\,\|\nabla V_{1,\varepsilon}\|_\varepsilon \le \frac{c}{\Lambda_2(\varepsilon)^{\frac{1}{2}}}. \tag{3.28}$$

Now let v_ε be a function such that the sequence $\|v_\varepsilon\|_\varepsilon + \|\nabla v_\varepsilon\|_\varepsilon$ is bounded. We have, by using successively the Cauchy–Schwarz inequality, estimate (3.28), and assumption (2.8),

$$\left|\,\varepsilon^2 \int_\Omega a_\varepsilon \nabla\chi_\varepsilon \cdot \nabla v_\varepsilon\,\right| \le \varepsilon^2\,\|\nabla\chi_\varepsilon\|_\varepsilon\,\|\nabla v_\varepsilon\|_\varepsilon \le c\,\varepsilon\,\|\nabla X_\varepsilon\|_\varepsilon \le \frac{c\,\varepsilon}{\Lambda_2(\varepsilon)^{\frac{1}{2}}} \underset{\varepsilon\to 0}{\longrightarrow} 0.$$

By putting v_ε as a test function in (3.27) we deduce from both previous limits that

$$\int_\Omega a_\varepsilon\,\sigma_\varepsilon\,v_\varepsilon \underset{\varepsilon\to 0}{\longrightarrow} 0. \tag{3.29}$$

Finally by the definition (3.25) of Σ_ε we have

$$a_\varepsilon\,\nabla v_{1,\varepsilon}\cdot\mu\,v_\varepsilon = a_\varepsilon\,\sigma_\varepsilon\,v_\varepsilon + \frac{1}{\varepsilon}\,\frac{\langle \nabla V_{1,\varepsilon}\cdot\mu, 1\rangle_\varepsilon}{\langle 1,1\rangle_\varepsilon}\,a_\varepsilon\,v_\varepsilon + \frac{1}{\varepsilon}\,\langle \nabla V_{1,\varepsilon}\cdot\mu, V_{1,\varepsilon}\rangle_\varepsilon\,a_\varepsilon\,v_{1,\varepsilon}\,v_\varepsilon.$$

Then by taking into account limit (3.29) it remains to prove that

$$\lim_{\varepsilon\to 0}\,\frac{1}{\varepsilon}\,\langle \nabla V_{1,\varepsilon}\cdot\mu, 1\rangle_\varepsilon = \lim_{\varepsilon\to 0}\,\frac{1}{\varepsilon}\,\langle \nabla V_{1,\varepsilon}\cdot\mu, V_{1,\varepsilon}\rangle_\varepsilon = 0 \tag{3.30}$$

in order to establish Lemma 3.2.

Set $W_{1,\varepsilon} := \frac{1}{\varepsilon}(V_{1,\varepsilon} - \int_{Y_2} V_{1,\varepsilon})$. The sequence $W_{1,\varepsilon}$ is bounded in $H^1_\#(Y_2)$ thanks to the Poincaré–Wirtinger inequality combined with assumption (2.8). Therefore $W_{1,\varepsilon}$ weakly converges to some W_1 in $H^1_\#(Y_2)$ up to a subsequence. By assumption (2.10) there exists a function Φ_ε in $H^1_\#(Y_2)$ which strongly converges to 1 in $H^1_\#(Y_2)$ and which is equal to zero in the set Q_ε. Let $V \in C^1_\#(Y_2)$. We have, by the definition (2.7) of the eigenfunction $V_{1,\varepsilon}$ and by assumption (2.8),

$$\frac{1}{\varepsilon}\,\langle \nabla V_{1,\varepsilon}, \nabla(\Phi_\varepsilon\,V)\rangle_\varepsilon = \frac{\Lambda_1(\varepsilon)}{\varepsilon}\,\langle V_{1,\varepsilon}, \Phi_\varepsilon\,V\rangle_\varepsilon = O(\varepsilon) \underset{\varepsilon\to 0}{\longrightarrow} 0,$$

and we also have

$$\begin{aligned}\frac{1}{\varepsilon}\,\langle \nabla V_{1,\varepsilon}, \nabla(\Phi_\varepsilon\,V)\rangle_\varepsilon &= \int_{Y_2} \nabla W_{1,\varepsilon}\cdot\nabla V\,\Phi_\varepsilon + \int_{Y_2} \nabla W_{1,\varepsilon}\cdot\nabla\Phi_\varepsilon\,V \\ &= \int_{Y_2} \nabla W_{1,\varepsilon}\cdot\nabla V + o(1),\end{aligned}$$

$$\text{whence} \quad \int_{Y_2} \nabla W_1\cdot\nabla V = 0 \quad \text{for any } V \in H^1_\#(Y_2).$$

Therefore $W_1 = 0$ and $W_{1,\varepsilon}$ weakly converges to 0 in $H^1_\#(Y_2)$. On the other hand we have by assumption (2.11) and for any $\mu \in \mathbb{R}^2$,

$$\begin{aligned}\frac{1}{\varepsilon}\,\langle \nabla V_{1,\varepsilon}, \nabla \Psi_\mu \rangle_\varepsilon &= \int_{Y\setminus Q_\varepsilon} \nabla W_{1,\varepsilon}\cdot\nabla\Psi_\mu + \frac{1}{\varepsilon}\int_{Q_\varepsilon} A_\varepsilon \nabla V_{1,\varepsilon}\cdot\mu \\ &= \frac{\Lambda_1(\varepsilon)}{\varepsilon}\,\langle V_{1,\varepsilon}, \Psi_\mu\, V\rangle_\varepsilon = O(\varepsilon) \underset{\varepsilon\to 0}{\longrightarrow} 0,\end{aligned}$$

whence $\displaystyle\frac{1}{\varepsilon}\int_{Q_\varepsilon} A_\varepsilon\nabla V_{1,\varepsilon}\cdot\mu = -\int_{Y\setminus Q_\varepsilon}\nabla W_{1,\varepsilon}\cdot\nabla\Psi_\mu + o(1) \underset{\varepsilon\to 0}{\longrightarrow} -\int_{Y_2}\nabla W_1\cdot\nabla\Psi_\mu = 0.$

Finally we obtain

$$\frac{1}{\varepsilon}\,\langle \nabla V_{1,\varepsilon}\cdot\mu, 1\rangle_\varepsilon = \int_{Y\setminus Q_\varepsilon}\nabla W_{1,\varepsilon}\cdot\mu + \frac{1}{\varepsilon}\int_{Q_\varepsilon} A_\varepsilon\nabla V_{1,\varepsilon}\cdot\mu \underset{\varepsilon\to 0}{\longrightarrow} \int_{Y_2}\nabla W_1\cdot\mu = 0,$$

which yields the first limit of (3.30).

Similarly we obtain the second limit of (3.30) by starting from the equality

$$\frac{1}{\varepsilon}\,\langle \nabla V_{1,\varepsilon}, \nabla(V_{1,\varepsilon}\,\Psi_\mu)\rangle_\varepsilon = \frac{\Lambda_1(\varepsilon)}{\varepsilon}\,\langle V_{1,\varepsilon}, V_{1,\varepsilon}\,\Psi_\mu\rangle_\varepsilon = O(\varepsilon)$$

and by using the strong convergence of $V_{1,\varepsilon}$ to c_1 in $L^2_\#(Y_2)$. Lemma 3.2 is proved, which also concludes the proof of Theorem 2.1.

3.2. Proof of Theorem 2.4.

Proof of part (i) *of Theorem* 2.4. Let $n \geq 1$ be an integer such that the eigenvalues $\Lambda_1(\varepsilon), \ldots, \Lambda_{n-1}(\varepsilon)$ of problem (2.7) are $O(\varepsilon^2)$. Let $i = 0, \ldots, n-1$. Since the eigenfunction $V_{i,\varepsilon}$ of (2.7) satisfies $\|V_{i,\varepsilon}\|_\varepsilon = 1$ and $\|\nabla V_{i,\varepsilon}\|^2_\varepsilon = \Lambda_i(\varepsilon) = O(\varepsilon^2)$ by assumption, there exists a constant c_i such that (up to a subsequence)

$$V_{i,\varepsilon} \rightharpoonup c_i \quad \text{weakly in } H^1_\#(Y_2). \tag{3.31}$$

Moreover, for any $j = 1, \ldots, N$, since the conductivity $\alpha_{j,\varepsilon}$ in $Q_{j,\varepsilon}$ satisfies the limit $\alpha_{j,\varepsilon}\,|Q_{j,\varepsilon}| \to \kappa_j > 0$, we have by the Cauchy–Schwarz inequality

$$\left| \fint_{Q_{j,\varepsilon}} V_{i,\varepsilon} \right| \leq \frac{1}{|Q_{j,\varepsilon}|^{\frac{1}{2}}}\,\|V_{i,\varepsilon}\|_{L^2(Q_{j,\varepsilon})} \leq c\,\|V_{i,\varepsilon}\|_\varepsilon = c.$$

Then we have (up to a subsequence)

$$\fint_{Q_{j,\varepsilon}} V_{i,\varepsilon} \underset{\varepsilon\to 0}{\longrightarrow} c_{i,j} \quad \text{for } j = 1, \ldots, N. \tag{3.32}$$

The limit of $V_{i,\varepsilon}$ is thus characterized by the sequence of $\mathbb{R}^{N+1}$:

$$\dot{c}_i := (c_i, c_{i,1}, \ldots, c_{i,N}) \quad \text{for } i = 0, \ldots, n-1. \tag{3.33}$$

Moreover by the orthonormality of the family $(V_{0,\varepsilon}, \ldots, V_{n-1,\varepsilon})$ with respect to the scalar product $\langle\cdot,\cdot\rangle_\varepsilon$ of (2.23), the limit family $(\dot{c}_0, \ldots, \dot{c}_{n-1})$ is also orthonormal with respect to the following scalar product of $\mathbb{R}^{N+1}$:

$$\langle \dot{a}, \dot{b}\rangle := a_0\,b_0 + \sum_{j=1}^N \kappa_j\,a_j\,b_j, \quad \dot{a}, \dot{b} \in \mathbb{R}^{N+1}, \tag{3.34}$$

which implies $n \le N+1$. Hence there exists a largest integer n satisfying (2.28) such that all the eigenvalues $\Lambda_1(\varepsilon), \dots, \Lambda_{n-1}(\varepsilon)$ are $O(\varepsilon^2)$; n is thus the smallest integer such that the sequence $\frac{\Lambda_n(\varepsilon)}{\varepsilon^2}$ is not bounded.

Now we can assume that condition (2.29) is satisfied with this integer n.

We will use as in [3] an argument based on truncatures of the orthonormal family of eigenfunctions $(V_{0,\varepsilon}, \dots, V_{n-1,\varepsilon})$ of (2.7), where $V_{0,\varepsilon} := \|1\|_\varepsilon^{-1}$, in order to build the desired asymptotic partition.

Let $i = 0, \dots, n-1$ and let T be a Lipschitz function in $C^1(\mathbb{R};\mathbb{R})$. By the Courant–Fisher formula applied to the eigenvalue $\Lambda_n(\varepsilon)$ we have by assumption (2.29)

$$\begin{aligned}
&\left\| T(V_{i,\varepsilon}) - \sum_{h=0}^{n-1} \langle T(V_{i,\varepsilon}), V_{h,\varepsilon}\rangle_\varepsilon \, V_{h,\varepsilon} \right\|_\varepsilon \\
&\le \Lambda_n(\varepsilon)^{-\frac12} \left\| \nabla T(V_{i,\varepsilon}) - \sum_{h=1}^{n-1} \langle T(V_{i,\varepsilon}), V_{h,\varepsilon}\rangle_\varepsilon \, \nabla V_{h,\varepsilon} \right\|_\varepsilon \le c\,\varepsilon\,\Lambda_n(\varepsilon)^{-\frac12} \underset{\varepsilon\to 0}{\longrightarrow} 0,
\end{aligned}$$

whence the existence of constants $a_{i,h}$ such that we have according to notation (2.25)

$$T(V_{i,\varepsilon}) \approx_\varepsilon \sum_{h=0}^{n-1} a_{i,h}\, V_{h,\varepsilon} \quad \text{for } i = 0, \dots, n-1. \tag{3.35}$$

On the other hand by using successively the Jensen inequality, the Cauchy–Schwarz inequality, the Poincaré–Wirtinger inequality (2.20), the assumption $\alpha_{j,\varepsilon}\,|Q_{j,\varepsilon}| \to \kappa_j > 0$, and estimate (2.29) we have for any $j = 1, \dots, N$

$$\begin{aligned}
\left| T\left(\fint_{Q_{j,\varepsilon}} V_{i,\varepsilon} \right) - \fint_{Q_{j,\varepsilon}} T(V_{i,\varepsilon}) \right| &\le \fint_{Q_{j,\varepsilon}} \left| T\left(\fint_{Q_{j,\varepsilon}} V_{i,\varepsilon} \right) - T(V_{i,\varepsilon}) \right| \\
&\le |Q_{j,\varepsilon}|^{-\frac12} \left\| T\left(\fint_{Q_{j,\varepsilon}} V_{i,\varepsilon} \right) - T(V_{i,\varepsilon}) \right\|_{L^2(Q_{j,\varepsilon})} \\
&\le \|T'\|_\infty\, |Q_{j,\varepsilon}|^{-\frac12} \left\| V_{i,\varepsilon} - \fint_{Q_{j,\varepsilon}} V_{i,\varepsilon} \right\|_{L^2(Q_{j,\varepsilon})} \\
&\le c\,\|\nabla V_{i,\varepsilon}\|_\varepsilon \le c\,\Lambda_i(\varepsilon)^{\frac12} \underset{\varepsilon\to 0}{\longrightarrow} 0,
\end{aligned}$$

whence by convergence (3.32)

$$\fint_{Q_{j,\varepsilon}} T(V_{i,\varepsilon}) \underset{\varepsilon\to 0}{\longrightarrow} T(c_{i,j}) \quad \text{for } j = 1, \dots, N.$$

Moreover by convergence (3.31) $T(V_{i,\varepsilon})$ weakly converges to $T(c_i)$ in $H^1_\#(Y_2)$. These convergences combined with estimate (3.35) and definition (3.33) yield

$$T(\dot c_i) := (T(c_i), \dots, T(c_{i,N})) = \sum_{h=0}^{n-1} a_{i,h}\, \dot c_h \quad \text{for } i = 0, \dots, n-1.$$

Therefore the subspace $F := \operatorname{Span}(\dot c_0, \dots, \dot c_{n-1})$ of $\mathbb{R}^{N+1}$ satisfies the following truncature property:

$$\text{for any Lipschitz function } T \in C^1(\mathbb{R},\mathbb{R}), \quad T(F) \subset F. \tag{3.36}$$

Moreover the family $(\dot c_0,\dots,\dot c_{n-1})$ is an orthonormal basis of the space F provided with the scalar product (3.34) and the vector $(1,\dots,1)=\frac{1}{\sqrt{1+\kappa}}\,\dot c_0$ belongs to F.

Then, by virtue of Lemma 3.1 of [4], the properties of the space F imply the existence of a partition $(\hat I_1,\dots,\hat I_n)$ of the set $\{0,\dots,N\}$ composed of n nonempty sets such that $0\in\hat I_1$ and for any $i=0,\dots,n-1$,

$$\begin{cases}\forall\, j\in\hat I_1\setminus\{0\}, & \hat c_{i,1}:=c_i=c_{i,j},\\ \forall\, j_1,j_2\in\hat I_k, & \hat c_{i,k}:=c_{i,j_1}=c_{i,j_2}\quad\text{for } k=2,\dots,n.\end{cases}\tag{3.37}$$

This means that for any $i=0,\dots,n-1$, the limits $c_{i,j}$ of (3.32) are equal in a given set $\hat I_k$. We also set from definition (2.22)

$$\begin{cases}\hat\kappa_1:=1+\displaystyle\sum_{h\in\hat I_1\setminus\{0\}}\kappa_h,\\ \hat\kappa_k:=\displaystyle\sum_{h\in\hat I_k}\kappa_h & \text{for } k=2,\dots,n.\end{cases}\tag{3.38}$$

On the first side the existence of such a partition implies inequality (2.28): $n\le N+1$. On the other side we will prove that the functions

$$\hat V_{k,\varepsilon}:=\sum_{i=0}^{n-1}\hat\kappa_k\,\hat c_{i,k}\,V_{i,\varepsilon}\quad\text{for } k=1,\dots,n\tag{3.39}$$

define the desired asymptotic partition of the unity.

Since the family $(V_{0,\varepsilon},\dots,V_{n-1,\varepsilon})$ is orthonormal with respect to the scalar product $\langle\cdot,\cdot\rangle_\varepsilon$ of (2.23) we have for any $i,j=0,\dots,n-1$

$$\delta_{i,j}=\langle V_{i,\varepsilon},V_{j,\varepsilon}\rangle_\varepsilon\ \underset{\varepsilon\to0}{\longrightarrow}\ c_i\,c_j+\sum_{h=1}^{N}\kappa_h\,c_{i,h}\,c_{j,h}=\delta_{i,j},\tag{3.40}$$

where $\delta_{i,j}$ denotes the Kronecker symbol, whence by definition (3.37)

$$\sum_{k=1}^{n}\hat\kappa_k\,\hat c_{i,k}\,\hat c_{j,k}=\delta_{i,j}\quad\text{for any } i,j=0,\dots,n-1;\tag{3.41}$$

i.e., the $(n\times n)$ matrix $\hat C:=\big[\sqrt{\hat\kappa_k}\,c_{i,k}\big]_{0\le i\le n-1,1\le k\le n}$ is orthogonal. From the orthonormality of the columns of $\hat C$ we deduce that

$$\sum_{i=0}^{n-1}\sqrt{\hat\kappa_h\,\hat\kappa_k}\,\hat c_{i,h}\,\hat c_{i,k}=\delta_{h,k}=\sum_{i=0}^{n-1}\hat\kappa_k\,\hat c_{i,h}\,\hat c_{i,k}\quad\text{for any } h,k=1,\dots,n.\tag{3.42}$$

On the other hand, thanks to the Poincaré–Wirtinger inequalities in Y_2 and (2.20) in $Q_{j,\varepsilon}$, any sequence V_ε in $H^1_\#(Y_2)$ such that the sequence $\|V\|_\varepsilon$ is bounded and $\|\nabla V_\varepsilon\|_\varepsilon\to0$ (according to notation (2.23)) can be replaced by its averaged values in Y_2 and in any set $Q_{j,\varepsilon}$ in such a way that (according to notation (2.25))

$$V_\varepsilon\approx_\varepsilon\left(\int_{Y_2}V_\varepsilon\right)\mathbf{1}_{Y_2\setminus Q_\varepsilon}+\sum_{j=1}^{N}\left(\fint_{Q_{j,\varepsilon}}V_\varepsilon\right)\mathbf{1}_{Q_{j,\varepsilon}}.\tag{3.43}$$

Let us now prove the properties (2.30) to (2.33) which define the asymptotic partition of the unity.

Proof of (2.30). By definitions (3.37), (3.39) and by equalities (3.42) we have for any $h,k=1,\dots,n$

$$\text{(3.44)}\qquad \begin{cases} \displaystyle\int_{Y_2} \hat{V}_{k,\varepsilon} \;\underset{\varepsilon\to 0}{\longrightarrow}\; \sum_{i=0}^{n-1} \hat{\kappa}_k\,\hat{c}_{i,k}\,\hat{c}_{i,1} = \delta_{k,1}, \\ \displaystyle\fint_{Q_{j,\varepsilon}} \hat{V}_{k,\varepsilon} \;\underset{\varepsilon\to 0}{\longrightarrow}\; \sum_{i=0}^{n-1} \hat{\kappa}_k\,\hat{c}_{i,k}\,\hat{c}_{i,h} = \delta_{k,h} \quad \text{for any } j\in\hat{I}_h. \end{cases}$$

Then by applying estimate (3.43) with $V_\varepsilon := V_{k,\varepsilon}$ and by taking into account limits (3.44) we obtain estimate (2.30).

Proof of (2.31). By applying again estimate (3.43) with the functions $\hat{V}_{k,\varepsilon}, \hat{V}_{h,\varepsilon}$ we obtain for any $h,k\in\{1,\dots,n\}$

$$\langle \hat{V}_{h,\varepsilon}, \hat{V}_{k,\varepsilon}\rangle_\varepsilon = \left(\int_{Y_2} \hat{V}_{h,\varepsilon}\right)\left(\int_{Y_2} \hat{V}_{k,\varepsilon}\right) + \sum_{j=1}^{N} \alpha_{j,\varepsilon}\,|Q_{j,\varepsilon}| \left(\fint_{Q_{j,\varepsilon}} \hat{V}_{h,\varepsilon}\right)\left(\fint_{Q_{j,\varepsilon}} \hat{V}_{k,\varepsilon}\right) + o(1),$$

which, combined with limits (3.44), (2.21) and definitions (3.38), yields

$$\langle \hat{V}_{h,\varepsilon}, \hat{V}_{k,\varepsilon}\rangle_\varepsilon \;\underset{\varepsilon\to 0}{\longrightarrow}\; \delta_{1,k}\,\delta_{1,h} + \sum_{j\in\hat{I}_k\cap\hat{I}_h\setminus\{0\}} \kappa_j = \delta_{k,h}\hat{\kappa}_k,$$

whence (2.31) and (2.35).

Proof of (2.32). Let $k=1,\dots,n$. Since $\hat{V}_{k,\varepsilon}$ weakly converges to 0 or 1 in $H^1_\#(Y_2)$ we have by the definition of the truncature (2.27)

$$\lim_{\varepsilon\to 0}\left(\int_{Y_2} T_{0,1}(\hat{V}_{k,\varepsilon})\right) = \lim_{\varepsilon\to 0}\left(\int_{Y_2} \hat{V}_{k,\varepsilon}\right),$$

and by the Poincaré–Wirtinger inequality (2.20) combined with $\|\nabla\hat{V}_{k,\varepsilon}\|_\varepsilon\to 0$ we also have for any $j=1,\dots,N$

$$\lim_{\varepsilon\to 0}\left(\fint_{Q_{j,\varepsilon}} T_{0,1}(\hat{V}_{k,\varepsilon})\right) = \lim_{\varepsilon\to 0}\; T_{0,1}\left(\fint_{Q_{j,\varepsilon}} \hat{V}_{k,\varepsilon}\right) = \lim_{\varepsilon\to 0}\left(\fint_{Q_{j,\varepsilon}} \hat{V}_{k,\varepsilon}\right)$$

since the last limit is equal to 0 or 1 by (3.44). We then deduce (2.32) from the previous equalities and from the estimate (3.43) with $V_\varepsilon := T_{0,1}(\hat{V}_{k,\varepsilon}) - \hat{V}_{k,\varepsilon}$.

Proof of (2.33). Let $i=0,\dots,n-1$. We have by the definition (3.39) of $\hat{V}_{k,\varepsilon}$ and by equalities (3.41)

$$\sum_{k=1}^{n} \hat{c}_{i,k}\,\hat{V}_{k,\varepsilon} = \sum_{k=1}^{n} \hat{c}_{i,k}\left(\sum_{j=0}^{n-1} \hat{\kappa}_k\,\hat{c}_{j,k}\,V_{j,\varepsilon}\right) = \sum_{j=0}^{n-1}\left(\sum_{k=1}^{n} \hat{\kappa}_k\,\hat{c}_{i,k}\,\hat{c}_{j,k}\right) V_{j,\varepsilon} = V_{i,\varepsilon},$$

which implies (2.33) and concludes the proof of part (i) of Theorem 2.4.

Proof of part (ii) *of Theorem* 2.4. The proof is quite similar to the second and third steps of the proof of Theorem 2.1 in that it uses the asymptotic partition $(\hat{V}_{1,\varepsilon},\dots,\hat{V}_{n,\varepsilon})$ defined in part (i). Therefore we recall only the main steps of the proof without details.

First we define the rescaled test functions

$$\hat{v}_{k,\varepsilon}(x) := \hat{V}_{k,\varepsilon}\left(\frac{x}{\varepsilon}\right) \quad \text{for almost every } x \in \Omega, \quad k = 1, \dots, n. \tag{3.45}$$

From the conditions (2.30) and (2.32) satisfied by the partition $(\hat{V}_{1,\varepsilon}, \dots, \hat{V}_{n,\varepsilon})$ we easily deduce the following strong convergences:

$$\hat{v}_{1,\varepsilon} \to 1 \text{ strongly in } L^2(\Omega) \quad \text{and} \quad \hat{v}_{k,\varepsilon} \to 0 \text{ strongly in } L^2(\Omega) \quad \text{for } k = 2, \dots, n. \tag{3.46}$$

Moreover by the truncature property (2.32) and the positivity of $\hat{\kappa}_k$ in (3.38) there exists, for any $k = 2, \dots, n$, a Radon measure v_k such that

$$a_\varepsilon \, \hat{v}_{k,\varepsilon} \, u_\varepsilon \rightharpoonup \hat{\kappa}_k \, v_k \quad \text{weakly} * \text{ in } \mathcal{M}(\overline{\Omega}). \tag{3.47}$$

Proceeding as in the second step of the proof of (2.1) we obtain that $v_k \in H^1_0(0,1; L^2(\Omega_2))$.

Then the following convergences hold true:

$$\begin{cases} a_\varepsilon \, \hat{v}_{1,\varepsilon} \, u_\varepsilon \rightharpoonup \hat{\kappa}_1 \, u & \text{weakly in } \mathcal{D}'(\Omega), \\ a_\varepsilon \, \hat{v}_{1,\varepsilon} \, \nabla u_\varepsilon \rightharpoonup \nabla u + (\hat{\kappa}_1 - 1) \, \dfrac{\partial u}{\partial x_3} & \text{weakly in } \mathcal{D}'(\Omega; \mathbb{R}^3), \\ a_\varepsilon \, \hat{v}_{k,\varepsilon} \, \nabla u_\varepsilon \rightharpoonup \hat{\kappa}_k \, \dfrac{\partial v_k}{\partial x_3} & \text{weakly in } \mathcal{D}'(\Omega; \mathbb{R}^3) \quad \text{for } k = 2, \dots, n, \end{cases} \tag{3.48}$$

where u is the weak limit of u_ε in $H^1_0(\Omega)$. The proof of (3.48) is quite similar to the second step of Theorem 2.1 in that it takes into account the following result, the proof of which is given at the end of the section.

LEMMA 3.3. *Under the geometrical assumptions* (2.18) *and* (2.19) *of the distribution of the fibers, the conditions* (2.10) *and* (2.11) *of* Theorem 2.1 *are satisfied.*

Finally for any $k = 1, \dots, n$ and $\varphi \in \mathcal{D}(\Omega)$, we put $\varphi \, \hat{v}_{k,\varepsilon}$ as test function in the conduction problem (2.5) in order to obtain the desired limit system (2.34) of size n. The proof is quite similar to the third step of Theorem 2.1 in that it uses the strong convergences (3.46), the expression (3.39) of the function $\hat{v}_{k,\varepsilon}$ (3.45) in terms of the rescaled eigenfunctions $v_{i,\varepsilon}(x) := V_{i,\varepsilon}(\frac{x}{\varepsilon})$, the assumption (2.29) on the eigenvalues, as well as the weak convergences

$$a_\varepsilon \, \nabla v_{i,\varepsilon} \, u_\varepsilon \rightharpoonup 0 \quad \text{weakly in } \mathcal{D}'(\Omega; \mathbb{R}^3) \quad \text{for } i = 0, \dots, n-1. \tag{3.49}$$

The proof of convergences (3.49) is quite similar to the proof of Lemma 3.2. Indeed by considering the orthogonal projection of $\frac{1}{\varepsilon} \, A_\varepsilon \nabla V_{i,\varepsilon}$ in the space $(V_{0,\varepsilon}, \dots, V_{n-1,\varepsilon})^{\perp_\varepsilon}$ (where $\perp_\varepsilon$ is the orthogonality according to (2.23)) we obtain for any $i = 0, \dots, n-1$ the following convergence:

$$a_\varepsilon \, \nabla v_{i,\varepsilon} \, u_\varepsilon - \sum_{j=0}^{n-1} \frac{1}{\varepsilon} \, \langle \nabla V_{i,\varepsilon}, V_{j,\varepsilon} \rangle_\varepsilon \, a_\varepsilon \, v_{j,\varepsilon} \, u_\varepsilon \rightharpoonup 0 \quad \text{weakly in } \mathcal{D}'(\Omega; \mathbb{R}^3). \tag{3.50}$$

We then deduce (3.49) from (3.50) combined with the limits

$$\frac{1}{\varepsilon} \, \langle \nabla V_{i,\varepsilon}, V_{j,\varepsilon} \rangle_\varepsilon \underset{\varepsilon \to 0}{\longrightarrow} 0 \quad \text{for } i, j = 0, \dots, n-1. \tag{3.51}$$

Proceeding as in the proof of Lemma 3.2, we see that the limits (3.51) are a consequence of conditions (2.10) and (2.11), which are given by Lemma 3.3. It thus remains to prove this lemma in order to conclude the proof of Theorem 2.4.

Proof of Lemma 3.3.

Proof of (2.10). We can regroup the neighboring sets $Q_{i,\varepsilon}$ of (2.18), $i = 1, \dots, N$, in such a way that the distance between two sets $Q_{i,\varepsilon}, Q_{j,\varepsilon}$ of the same group tends to zero and the distance between two different groups is greater than a positive constant. Let us denote by $\widehat{Q}_{1,\varepsilon}, \dots, \widehat{Q}_{p,\varepsilon}$ the p groups defined in this way. By construction for any $k = 1, \dots, p$, $\widehat{Q}_{k,\varepsilon}$ is contained in an open ball $B(y_{k,\varepsilon}, r_{k,\varepsilon})$ in the torus Y_2, of center $y_{k,\varepsilon}$ and of radius $r_{k,\varepsilon} \to 0$. Let Φ_ε be the function of $H^1_\#(Y_2)$ defined by

(3.52)
$$\begin{cases} \Phi_\varepsilon(y) := 0 & \text{if } y \in \displaystyle\bigcup_{k=1}^{p} B(y_{k,\varepsilon}, r_{k,\varepsilon}), \\ \Phi_\varepsilon(y) := 1 & \text{if } y \notin \displaystyle\bigcup_{k=1}^{p} B(y_{k,\varepsilon}, \sqrt{r_{k,\varepsilon}}), \\ \Phi_\varepsilon(y) := \dfrac{\ln|y - y_{k,\varepsilon}| - \ln r_{k,\varepsilon}}{\ln\sqrt{r_{k,\varepsilon}} - \ln r_{k,\varepsilon}} & \text{if } r_{k,\varepsilon} \le |y - y_{k,\varepsilon}| < \sqrt{r_{k,\varepsilon}}, \quad k = 1, \dots, p. \end{cases}$$

We have $\Phi_\varepsilon = 0$ in Q_ε since by definition

$$Q_\varepsilon \subset \bigcup_{k=1}^{p} \widehat{Q}_{k,\varepsilon} \subset \bigcup_{k=1}^{p} B(y_{k,\varepsilon}, r_{k,\varepsilon}).$$

The sequence Φ_ε strongly converges to 1 in $L^2_\#(Y_2)$ since

$$0 \le \Phi_\varepsilon \le 1 \quad \text{and} \quad \left| \bigcup_{k=1}^{p} B(y_{k,\varepsilon}, \sqrt{r_{k,\varepsilon}}) \right| \underset{\varepsilon \to 0}{\longrightarrow} 0.$$

We also have

$$\int_{Y_2} |\nabla \Phi_\varepsilon|^2 = \sum_{k=1}^{p} \frac{4\pi}{|\ln r_{k,\varepsilon}|} \underset{\varepsilon \to 0}{\longrightarrow} 0,$$

whence $\nabla \Phi_\varepsilon$ strongly converges to 0 in $L^2_\#(Y_2)$. Therefore the capacity condition (2.10) is satisfied with the sequence $\frac{1}{\int_{Y_2} \Phi_\varepsilon} \Phi_\varepsilon$.

Proof of (2.11). Let $\mu \in \mathbb{R}^2$. Since the distance between two sets $\widehat{Q}_{h,\varepsilon}, \widehat{Q}_{k,\varepsilon}$ is greater than a positive constant and the diameter of $\widehat{Q}_{k,\varepsilon}$ tends to zero, there exist fixed open balls $B(y_k, r_k), B(y_k, r'_k)$ in the torus Y_2, with radius $r_k < r'_k < \frac{1}{2}$, such that $\widehat{Q}_{k,\varepsilon} \subset B(y_k, r_k)$ for any $k = 1, \dots, p$ and the balls $B(y_k, r'_k)$ are two-by-two disjoint. We then define a smooth Y_2-periodic function Ψ_μ by

$$\begin{cases} \Psi_\mu(y) := \mu \cdot (y - \tau) & \text{if } y \in \tau + B(y_k, r_k) \quad \text{for any } \tau \in \mathbb{Z}^2 \text{ and } k := 1, \dots, p, \\ \Psi_\mu(y) := 0 & \text{if } y \notin \displaystyle\bigcup_{\tau \in \mathbb{Z}^2} \bigcup_{k=1}^{p} (\tau + B(y_k, r'_k)). \end{cases}$$

This definition is consistent since all the balls $\tau + B(y_k, r_k)$ are two-by-two disjoint closures in $\mathbb{R}^2$ by construction. Therefore condition (2.11) is also satisfied, which concludes the proof of Lemma 3.3.

3.3. Proof of Proposition 2.7. *Proof of part* (i) *of Proposition* 2.7.
Case $n=1$. Let $A_{i,\varepsilon}$, $i=1,2$, be the function defined by

$$A_{i,\varepsilon} := \begin{cases} 1 & \text{in } Y_2 \setminus Q_{i,\varepsilon}, \\ \alpha_{i,\varepsilon} & \text{in } Q_{i,\varepsilon}. \end{cases} \tag{3.53}$$

By the definitions (3.31) and (3.32), the eigenfunction $V_{1,\varepsilon}$ satisfies for $i=1,2$

$$\begin{aligned} &\int_{Y_2} A_{i,\varepsilon} \left(V_{1,\varepsilon} - \frac{\int_{Y_2} A_{i,\varepsilon} V_{1,\varepsilon}}{\int_{Y_2} A_{i,\varepsilon}} \right)^2 \\ &\underset{\varepsilon\to 0}{\longrightarrow} \left(c_1 - \frac{c_1 + \kappa_i c_{1,i}}{1+\kappa_i} \right)^2 + \kappa_i \left(c_{1,i} - \frac{c_1 + \kappa_i c_{1,i}}{1+\kappa_i} \right)^2 = d\,(c_1 - c_{1,i})^2, \end{aligned}$$

where d is a positive constant. We cannot have $c_1 = c_{1,1} = c_{1,2}$ since the orthonormality equalities (3.40) for $N=2$ are the following:

$$c_i + \kappa_1\, c_{i,1} + \kappa_2\, c_{i,2} = 0 \quad \text{and} \quad c_i^2 + \kappa_1\, c_{i,1}^2 + \kappa_2\, c_{i,2}^2 = 1 \quad \text{for } i=1,2. \tag{3.54}$$

Hence there exist $i=1,2$ and a positive constant c such that

$$I_{i,\varepsilon} := \int_{Y_2} A_{i,\varepsilon} \left(V_{1,\varepsilon} - \frac{\int_{Y_2} A_{i,\varepsilon} V_{1,\varepsilon}}{\int_{Y_2} A_{i,\varepsilon}} \right)^2 > c.$$

Then the first nonzero eigenvalue $\Lambda_{1,i}(\varepsilon)$ of the problem (2.7) defined with the function $A_{i,\varepsilon}$ satisfies the estimate

$$\Lambda_1(\varepsilon) = \int_{Y_2} A_\varepsilon\, |\nabla V_{1,\varepsilon}|^2 \geq \int_{Y_2} A_{i,\varepsilon}\, |\nabla V_{1,\varepsilon}|^2 = I_{i,\varepsilon}\, \frac{\int_{Y_2} A_{i,\varepsilon}\, |\nabla V_{1,\varepsilon}|^2}{I_{i,\varepsilon}} \geq c\, \Lambda_{1,i}(\varepsilon). \tag{3.55}$$

Now assume that $\delta = +\infty$, i.e., $\varepsilon^2\, |\ln r_\varepsilon| \to 0$. Proposition 2.4 of [3] for one fiber by cell implies that $\frac{\Lambda_{1,i}(\varepsilon)}{\varepsilon^2} \to +\infty$, whence by (3.55) $\frac{\Lambda_1(\varepsilon)}{\varepsilon^2} \to +\infty$. Therefore $n=1$ by the definition of n in part (i) of Theorem 2.4.

Inversely assume that $\delta < +\infty$, i.e., $\lim\limits_{\varepsilon\to 0} \varepsilon^2\, |\ln r_\varepsilon| > 0$. Let $\hat{W}_{i,\varepsilon}$, $i=1,2$, be the Y_2-periodic function defined for $y \in Y_2$ by

$$\hat{W}_{i,\varepsilon}(y) := \begin{cases} 0 & \text{if } r < r_\varepsilon \text{ or equivalently } y \in Q_{i,\varepsilon}, \\ 1 & \text{if } r > \rho_\varepsilon \text{ where } |\ln \rho_\varepsilon| \ll |\ln r_\varepsilon|, \\ \dfrac{\ln r - \ln r_\varepsilon}{\ln \rho_\varepsilon - \ln r_\varepsilon} & \text{if } r_\varepsilon \leq r \leq \rho_\varepsilon, \end{cases} \tag{3.56}$$

where r represents the distance between y and the center of the disk $Q_{i,\varepsilon}$.

It is easy to check that

$$\|\nabla(\hat{W}_{1,\varepsilon}\hat{W}_{2,\varepsilon})\|_\varepsilon^2 \leq \frac{c}{|\ln r_\varepsilon|} = O(\varepsilon^2),$$

and since $\hat{W}_{1,\varepsilon}\hat{W}_{2,\varepsilon} = 0$ in Q_ε we also have, in the sense of definition (2.25),

$$\hat{W}_{1,\varepsilon}\hat{W}_{2,\varepsilon} \not\approx_\varepsilon \frac{\langle \hat{W}_{1,\varepsilon}\hat{W}_{2,\varepsilon}, 1\rangle_\varepsilon}{\langle 1,1\rangle_\varepsilon} \underset{\varepsilon\to 0}{\longrightarrow} \frac{1}{1+\kappa_1+\kappa_2} > 0.$$

From both previous estimates we deduce that

$$\Lambda_1(\varepsilon) \le \frac{\|\nabla(\hat{W}_{1,\varepsilon}\hat{W}_{2,\varepsilon})\|_\varepsilon^2}{\left\|\hat{W}_{1,\varepsilon}\hat{W}_{2,\varepsilon} - \frac{\langle \hat{W}_{1,\varepsilon}\hat{W}_{2,\varepsilon},1\rangle_\varepsilon}{\langle 1,1\rangle_\varepsilon}\right\|_\varepsilon^2} = O(\varepsilon^2). \tag{3.57}$$

Moreover by (3.55) we have $\Lambda_1(\varepsilon) \ge c\,\Lambda_{1,1}(\varepsilon)$. By comparing the result of [1] to Theorem 2.1 (see also the proof of part (ii) of Proposition 2.7) we also have $\frac{\Lambda_{1,1}(\varepsilon)}{\varepsilon^2} \to \delta$. From these results we deduce the estimate $\Lambda_1(\varepsilon) \ge c\,\varepsilon^2$, which, combined with (3.57), implies that (up to a subsequence) $\frac{\Lambda_1(\varepsilon)}{\varepsilon^2} \to \lambda_1 \in]0,+\infty[$. We then obtain $n \ge 2$ thanks to part (i) of Theorem 2.4. Therefore the first equivalence of (2.37) has been proved.

Case $n = 2$. Assume that the left-hand side of the second implication of (2.37) holds true. By the first equivalence of (2.37) and part (i) of Theorem 2.4 the integer n is equal to 2 or 3. Then assume by contradiction that $n = 3$.

We will use the following result.

LEMMA 3.4. *There exists a positive constant* c *such that*

$$\forall\, V \in H^1_\#(Y_2), \quad \left| \fint_{Q_{1,\varepsilon}} V - \fint_{Q_{2,\varepsilon}} V \right| \le c\left(\sqrt{\ln(d_\varepsilon + r_\varepsilon) - \ln r_\varepsilon} + 1\right) \|\nabla V\|_{L^2(Y_2)}. \tag{3.58}$$

By studying the cases where the limit of $\frac{d_\varepsilon}{r_\varepsilon}$ is finite or is not, it is easy to prove the implication

$$\lim_{\varepsilon\to 0}\left|\frac{\ln d_\varepsilon}{\ln r_\varepsilon}\right| = \gamma \ge 1 \quad\Rightarrow\quad \lim_{\varepsilon\to 0}\left|\frac{\ln(d_\varepsilon + r_\varepsilon)}{\ln r_\varepsilon}\right| = 1,$$

and since the first limit is satisfied by assumption, the second one thus holds true. Then, thanks to estimate (3.58) applied to the eigenfunction $V_{j,\varepsilon}$, $j = 1, 2$, we obtain

$$\left| \fint_{Q_{1,\varepsilon}} V_{j,\varepsilon} - \fint_{Q_{2,\varepsilon}} V_{j,\varepsilon} \right| = o\left(\sqrt{|\ln r_\varepsilon|}\right) \|\nabla V_{j,\varepsilon}\|_{L^2(Y_2)} = o\left(\varepsilon\sqrt{|\ln r_\varepsilon|}\right) \underset{\varepsilon\to 0}{\longrightarrow} 0,$$

whence $c_{j,1} = c_{j,1}$ for $j = 1, 2$. These equalities, combined with the orthonormality equalities (3.54), yield

$$c_1 + (\kappa_1 + \kappa_2)\,c_{1,1} = c_2 + (\kappa_1 + \kappa_2)\,c_{2,1} = c_1\,c_2 + (\kappa_1 + \kappa_2)\,c_{1,1}\,c_{2,1} = 0,$$

which implies $c_{1,1}\,c_{2,1} = 0$. For instance, $c_{1,1} = 0$, whence $c_1 = c_{1,1} = c_{1,2} = 0$, which contradicts the second equality of (3.54). The second implication of (2.37) has thus been proved.

Case $n = 3$. Assume that the left-hand side of the third implication of (2.37) holds true. The integer n is still equal to 2 or 3. Assume by contradiction that $n = 2$, whence by Theorem 2.4 we have $\frac{\Lambda_2(\varepsilon)}{\varepsilon^2} \to +\infty$. Let $i = 1, 2$. Since by definition (3.56) we have $\|\nabla\hat{W}_{i,\varepsilon}\|_\varepsilon = O(\varepsilon)$, the Courant–Fisher formula for $\Lambda_2(\varepsilon)$ yields

$$\left\| \hat{W}_{i,\varepsilon} - \frac{\langle \hat{W}_{i,\varepsilon},1\rangle_\varepsilon}{\langle 1,1\rangle_\varepsilon} - \langle \hat{W}_{i,\varepsilon}, V_{1,\varepsilon}\rangle_\varepsilon\, V_{1,\varepsilon} \right\|_\varepsilon \le c\,\Lambda_2(\varepsilon)^{-\frac{1}{2}} \underset{\varepsilon\to 0}{\longrightarrow} 0,$$

which implies (according to notation (2.25)) that

$$\hat{W}_{i,\varepsilon} \approx_\varepsilon a_i + b_i\, V_{1,\varepsilon}, \quad \text{where } a_i, b_i \text{ are two constants.}$$

Since by hypothesis $d_\varepsilon \gg r_\varepsilon$ we also have for $i \neq j$

$$\fint_{Q_{j,\varepsilon}} \hat{W}_{i,\varepsilon} = \frac{\ln(d_\varepsilon + r_\varepsilon) - \ln r_\varepsilon}{\ln \rho_\varepsilon - \ln r_\varepsilon} + o(1) \underset{\varepsilon\to 0}{\longrightarrow} 1 - \gamma.$$

Therefore, for $j \neq i$, a_i, b_i satisfy

$$\begin{cases} 1 = a_i + b_i\, c_1 & \text{by the limit in } Y_2 \setminus Q_\varepsilon, \\ 0 = a_i + b_i\, c_{1,i} & \text{by the limit in } Q_{i,\varepsilon}, \\ 1-\gamma = a_i + b_i\, c_{1,j} & \text{by the limit in } Q_{j,\varepsilon}, \end{cases}$$

whence $c_{1,j} = \gamma\, c_{1,i} + (1-\gamma)\, c_1$. Similarly with $\hat{W}_{j,\varepsilon}$ we obtain $c_{1,i} = \gamma\, c_{1,j} + (1-\gamma)\, c_1$. Since $\gamma \neq 1$ we then deduce from both previous equalities $c_{1,i} = c_{1,j}$ and $c_1 = c_{1,1} = c_{1,2} = 0$, which again contradicts the second equality of (3.54).

Proof of Lemma 3.4. Let $R_{i,\varepsilon}$, $i = 1, 2$, be the disk of radius $d_\varepsilon + r_\varepsilon$ and of the same center as $Q_{i,\varepsilon}$. On the first side by using polar coordinates it is easy to check that for any $V \in H^1_\#(Y_2)$ we have

$$\left| \fint_{\partial Q_{i,\varepsilon}} V - \fint_{\partial R_{i,\varepsilon}} V \right| \leq c \sqrt{\ln(d_\varepsilon + r_\varepsilon) - \ln r_\varepsilon}\, \|\nabla V\|_{L^2(R_{i,\varepsilon})}.$$

We also have

$$\left| \fint_{Q_{i,\varepsilon}} V - \fint_{\partial Q_{i,\varepsilon}} V \right| \leq c\, \|\nabla V\|_{L^2(Q_{i,\varepsilon})},$$

and the same estimate for the disk $R_{i,\varepsilon}$. From these estimates we easily deduce the new estimate,

$$\left| \fint_{Q_{i,\varepsilon}} V - \fint_{R_{i,\varepsilon}} V \right| \leq c \left(\sqrt{\ln(d_\varepsilon + r_\varepsilon) - \ln r_\varepsilon} + 1 \right) \|\nabla V\|_{L^2(R_{i,\varepsilon})}. \tag{3.59}$$

On the other side let R_ε be the disk of radius $3\,(d_\varepsilon + r_\varepsilon)$ whose center is the middle of both centers of $Q_{1,\varepsilon}, Q_{2,\varepsilon}$. In particular we have $R_{1,\varepsilon} \cup R_{2,\varepsilon} \subset R_\varepsilon$. By rescaling with the scale $(d_\varepsilon + r_\varepsilon)$ we obtain that there exists a positive constant c such that

$$\left| \fint_{R_{1,\varepsilon}} V - \fint_{R_{2,\varepsilon}} V \right| \leq c\, \|\nabla V\|_{L^2(R_\varepsilon)}.$$

This, combined with (3.59), implies the desired estimate (3.58), which concludes the proof of Lemma 3.4.

Proof of part (ii) *of Proposition* 2.7. We will use the result of Lemma 1 in [5], which consists of the following estimate satisfied by the function $\hat{W}_{i,\varepsilon}$, $i = 1, 2$, defined by (3.56): for any $V \in H^1_\#(Y_2)$,

$$\begin{aligned} &\left| \int_{Y_2} \nabla \hat{W}_{i,\varepsilon} \cdot \nabla V - \frac{2\,\pi}{|\ln r_\varepsilon|} \left(\fint_{Y_2 \setminus Q_{i,\varepsilon}} V - \fint_{Q_{i,\varepsilon}} V \right) \right| \\ &\leq \frac{C}{|\ln r_\varepsilon|} \left(\sqrt{|\ln \rho_\varepsilon|}\, \|\nabla V\|_{L^2(Y_2)} + \frac{1}{r_\varepsilon}\, \|\nabla V\|_{L^2(Q_{i,\varepsilon})} \right). \end{aligned} \tag{3.60}$$

Since $\gamma = 0$ in (2.36) we can choose ρ_ε in (3.56) such that $\rho_\varepsilon \ll d_\varepsilon$. By this choice we have $\nabla \hat{W}_{i,\varepsilon} = 0$, $i = 1, 2$, in Q_ε, whence by the definition (2.7) of the eigenfunctions $V_{j,\varepsilon}$, $j = 1, 2$, we have

$$\int_{Y_2} \nabla \hat{W}_{i,\varepsilon} \cdot \nabla V_{j,\varepsilon} = \langle \nabla \hat{W}_{i,\varepsilon}, \nabla V_{j,\varepsilon} \rangle_\varepsilon = \Lambda_j(\varepsilon) \, \langle \hat{W}_{i,\varepsilon}, V_{j,\varepsilon} \rangle_\varepsilon.$$

Then by taking $V := V_{j,\varepsilon}$ in estimate (3.60) the condition $\delta < +\infty$, combined with the assumption of (2.21) $\alpha_{i,\varepsilon} \, \pi r_\varepsilon^2 \to \kappa_i > 0$ and the assumption (2.29) satisfied by the eigenvalues, implies that for any $i, j = 1, 2$,

$$\begin{aligned} &\frac{\Lambda_j(\varepsilon)}{\varepsilon^2} \, \langle \hat{W}_{i,\varepsilon}, V_{j,\varepsilon} \rangle_\varepsilon - \frac{2\,\pi}{\varepsilon^2 \, |\ln r_\varepsilon|} \left(\fint_{Y_2 \setminus Q_{i,\varepsilon}} V_{j,\varepsilon} - \fint_{Q_{i,\varepsilon}} V_{j,\varepsilon} \right) \\ &= O\left(\varepsilon \sqrt{|\ln \rho_\varepsilon|} + \varepsilon \right) \underset{\varepsilon \to 0}{\longrightarrow} 0. \end{aligned} \tag{3.61}$$

Since $\hat{W}_{i,\varepsilon} = 0$ in $Q_{i,\varepsilon}$ and $\hat{W}_{3-i,\varepsilon} = 1$ in $Q_{3-i,\varepsilon}$ by the choice of ρ_ε, by passing to the limit in (3.61) with definitions (3.31), (3.32) we thus have

$$\lambda_j \, (c_j + \kappa_{3-i} \, c_{j,3-i}) - \delta \, (c_j - c_{j,i}) = 0,$$

which, combined with the first equality of (3.54), yields

$$\lambda_j \, \kappa_i \, c_{j,i} = \delta \, (c_{j,i} - c_j) \quad \text{for } i, j = 1, 2. \tag{3.62}$$

We have $c_{j,i} \neq 0$. Otherwise (3.62), combined with the first equality of (3.54), leads to a contradiction. Then equalities (3.62) for $i = 1, 2$ and $\kappa_1 = \kappa_2$ imply that $c_j = 0$ or $c_{j,1} = c_{j,2}$. Since $\lambda_1 \leq \lambda_2$ we thus obtain with (3.54)

$$c_1 = 0, \; c_{1,1} = -c_{1,2} = \frac{\pm 1}{\sqrt{2\kappa_1}} \;\text{ and }\; c_2 = - \pm \sqrt{\frac{2\kappa_1}{1+2\kappa_1}}, \; c_{2,1} = -c_{2,2} = \frac{\pm 1}{\sqrt{2\kappa_1 + 4\kappa_1^2}},$$

as well as the values (2.38) for λ_1, λ_2. Finally by the definitions (2.35) of the constant $\hat{\kappa}_k$ with respect to κ_i and the definitions (3.37) of the constant $\hat{c}_{k,i}$ with respect to $c_{i,j}$, we easily deduce the desired limit system (2.39) from the general one, (2.34) of Theorem 2.4. Proposition 2.7 has thus been proved.

MINIMIZING FLOWS FOR THE MONGE–KANTOROVICH PROBLEM*

SIGURD ANGENENT†, STEVEN HAKER‡, AND ALLEN TANNENBAUM§

Abstract. In this work, we formulate a new minimizing flow for the optimal mass transport (Monge–Kantorovich) problem. We study certain properties of the flow, including weak solutions as well as short- and long-term existence. Optimal transport has found a number of applications, including econometrics, fluid dynamics, cosmology, image processing, automatic control, transportation, statistical physics, shape optimization, expert systems, and meteorology.

Key words. optimal transport, gradient flows, weak solutions, image registration, medical imaging

1. Introduction. In this paper, we derive a novel gradient descent flow for the computation of the optimal transport map (when it exists) in the Monge–Kantorovich framework. Besides being quite useful for the efficient computation of the transport map, we believe that the flow presented here is quite interesting from a theoretical point of view as well. In the present work, we undertake a study of some of its key properties.

The *mass transport problem* was first formulated by Monge in 1781 and concerned finding the optimal way, in the sense of minimal transportation cost, of moving a pile of soil from one site to another. This problem was given a modern formulation in the work of Kantorovich [13] and so is now known as the *Monge–Kantorovich problem.* We recall the formulation of the Monge–Kantorovich problem for smooth densities and domains in Euclidean space. For more general measures, see [1]. Let Ω_0 and Ω_1 be two diffeomorphic connected subdomains of $\mathbb{R}^d$, with smooth boundaries, and let μ_0, μ_1 be Borel measures on Ω_0 and Ω_1, each with a positive density function μ_0 and μ_1, respectively. We assume

$$\mu_0(\Omega_0) = \mu_1(\Omega_1),$$

i.e.,

$$\int_{\Omega_0} \mu_0(x)dx = \int_{\Omega_0} \mu_1(x)dx,$$

so that the same total mass is associated with Ω_0 and Ω_1, and we consider diffeomorphisms $u : \Omega_0 \to \Omega_1$ which map one density to the other in the sense that

$$\mu_0 = \det(\nabla u)\, \mu_1 \circ u, \tag{1}$$

where $\det \nabla u$ denotes the determinant of the Jacobian map ∇u. This is the well-known *Jacobian equation*, which constrains the mapping u to be mass preserving with respect to μ_0 and μ_1.

There may be many such mappings, and we want to pick out an optimal one in some sense. Accordingly, we define a generalized Monge–Kantorovich functional as

$$M(u) = \int \Phi(x, u(x))\, \mathrm{d}\mu_0(x),$$

where $\Phi : \bar{\Omega}_0 \times \bar{\Omega}_1 \to \mathbb{R}$ is a positive C^1 cost function. A Φ-*optimal mass preserving map*, when it exists, is a diffeomorphism which satisfies (1) and minimizes this integral.

In particular, the L^2 Monge–Kantorovich problem, corresponding to the cost function $\Phi(x, \xi) = \frac{1}{2}|x-\xi|^2$, has been studied in statistics, functional analysis, atmospheric sciences, automatic control, computer vision, statistical physics, and expert systems. See [3, 5, 8, 15, 16] and the references therein. This functional is seen to place a quadratic penalty on the distance the map u moves each bit of material, weighted by the material's mass. A fundamental theoretical result for the L^2 case [14, 4, 9] is that there is a unique optimal mass preserving u, and that this u is characterized as the gradient of a convex function p, i.e., $u = \nabla p$.

1.1. Reallocation measures. It turns out to be very convenient to use Kantorovich's generalization of the notion of a measure preserving map $u : (\Omega_0, \mu_0) \to (\Omega_1, \mu_1)$. Instead of considering a map u we introduce its graph

$$\{(x, u(x)) \mid x \in \Omega_0\} \subset \Omega_0 \times \Omega_1$$

and, more importantly, the measure

$$\gamma_u = (\mathrm{id} \times u)_{\#}\mu_0 \tag{2}$$

on $\Omega_0 \times \Omega_1$ supported on this graph.

The measures γ that arise in this way all satisfy[1]

$$\big(p_0\big)_{\#}\gamma = \mu_0 \quad \text{and} \quad \big(p_1\big)_{\#}\gamma = \mu_1. \tag{3}$$

We define $\mathfrak{X}$ to be the space of nonnegative Borel measures on $\bar{\Omega}_0 \times \bar{\Omega}_1$ which satisfy (3).

The Monge–Kantorovich cost functional extends in a natural way to the space of measures $\mathfrak{X}$ by

$$M(\gamma) = \int_{\Omega_0 \times \Omega_1} \Phi(x, y)\ \mathrm{d}\gamma(x, y).$$

We may think of a measure $\gamma \in \mathfrak{X}$ as a "multivalued map," which, rather than sending a point $x \in \Omega_0$ to *one* other point $u(x)$, assigns a probability measure P_x on the range space Ω_1 and "smears the point x out over Ω_1 according to the probability measure P_x." The measure γ is reconstructed from the family of probability measures $\{P_x\}$ by specifying

$$\int_{\Omega_0 \times \Omega_1} \phi(x, y)\ \mathrm{d}\gamma(x, y) = \int_{\Omega_0} \left\{ \int_{\Omega_1} \phi(x, y)\ \mathrm{d}P_x(y) \right\}\ \mathrm{d}\mu_0(x). \tag{4}$$

[1] If X and Y are sets with σ-algebras $\mathcal{M}$ and $\mathcal{N}$, and if $f : X \to Y$ is a measurable map, then we write $f_{\#}\mu$ for the pushforward of any measure μ on $(X, \mathcal{M})$, i.e., for any measurable $E \subset Y$ we define $f_{\#}\mu(E) = \mu\big(f^{-1}(E)\big)$.

See [1] for a rigorous measure-theoretic account of this way of decomposing γ. In this paper we will write for any bounded Borel measurable function $\phi : \Omega_0 \times \Omega_1 \to \mathbb{R}$

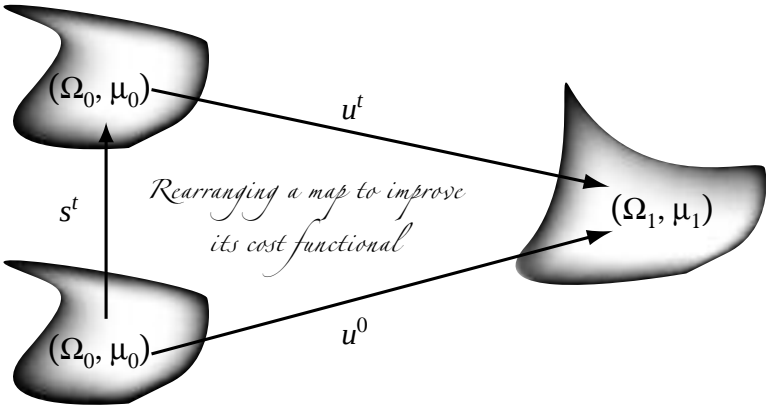
$$\mathbb{E}_\gamma(\phi(x,y) \mid x) = \int_{\Omega_1} \phi(x,y)\, \mathrm{d}P_x(y)$$

for the expectation of $\phi(x,\cdot)$ with respect to the probability measure P_x. See Lemma 3.1, where we define this expectation directly without using the probability measures P_x. The principal role of the expectation $\mathbb{E}_\gamma(\phi(x,y) \mid x)$ is as generalization of the expression $\phi(x,u(x))$. Indeed, when $\gamma = (\mathrm{id} \times u)_\# \mu_0$, then both expressions coincide.

1.2. The gradient flow. To reduce the Monge–Kantorovich cost $M(u)$ of a map $u^0 : \Omega_0 \to \Omega_1$ we "rearrange the points in the domain of the map"; i.e., we replace the map u^0 by a family of maps u^t for which one has $u^t \circ s^t = u^0$ for some family of diffeomorphisms $s^t : \Omega_0 \to \Omega_0$ (see figure below). If the initial map u^0 sends the measure μ_0 to μ_1 (if it satisfies (1)), and if the diffeomorphisms s^t preserve the measure μ_0, then the maps $u^t = u^0 \circ \left(s^t\right)^{-1}$ will also send μ_0 to μ_1. Thus the group $\mathrm{Diff}^1_{\mu_0}(\Omega_0)$ of C^1, μ_0 preserving diffeomorphisms acts on the space of measure preserving maps $u : (\Omega_0, \mu_0) \to (\Omega_1, \mu_1)$. The group action of $\mathrm{Diff}^1_{\mu_0}(\Omega_0)$ can be extended to an action on $\mathfrak{X}$ by

$$s \cdot \gamma = \left(s \times \mathrm{id}_{\Omega_1}\right)_\# \gamma.$$

Any sufficiently smooth family of diffeomorphism $s^t : \Omega_0 \to \Omega_0$ is determined by its velocity field, defined by $\partial_t s^t = v^t \circ s^t$.



In section 3 we compute the change in $M(\gamma^t)$ for measures $\gamma^t = s^t \cdot \gamma^0 \in \mathfrak{X}$ obtained by letting a family of diffeomorphisms $s^t \in \mathrm{Diff}^1_{\mu_0}(\Omega_0)$ act on an initial measure $\gamma^0 \in \mathfrak{X}$. We find that steepest descent is achieved by a family $s^t \in \mathrm{Diff}^1_{\mu_0}(\Omega_0)$, whose velocity is given by

$$v^t = -\frac{1}{\mu_0(x)} \mathcal{P}\left(\mathbb{E}_{\gamma^t}(\Phi_x \mid x)\right). \tag{5}$$

Here $\mathcal{P}$ is the Helmholtz projection, which extracts the divergence-free part of vector fields on Ω_0 (see section 7).

In the special case where the measures γ^t are given by graph measures $\gamma^t = \gamma_{u^t}$ as in (2) we get the following equations for the evolution of the map u^t. From $u^0 = u^t \circ s^t$ we get the transport equation

$$\frac{\partial u^t}{\partial t} + v^t \cdot \nabla u^t = 0. \tag{6}$$

The velocity field is still given by (5) above, but this now simplifies to

$$v^t = \frac{-1}{\mu_0(x)} \mathcal{P}\big\{\Phi_x(x, u^t(x))\big\}.$$

This equation, together with the transport equation (6), determines an initial value problem for the map u^t.

We will show the following.

THEOREM 1.1. *Let $0 < \alpha < 1$. For any $C^{1,\alpha}$, measure preserving initial map u^0 a smooth ($C^{1,\alpha}$) family of maps $\{u^t \mid 0 \le t < T\}$ exists such that the maps s^t generated by the vector field v^t given by* (5) *satisfy $u^0 = u^t \circ s^t$.*

The existence time T of the smooth solution depends on the $C^{1,\alpha}$ norm of the initial map u^0.

See Lemma 11.1 for more detail.

It is not clear if these smooth solutions exist for *all* $t > 0$ (we make no geometric assumptions on Ω_0 or the cost function Φ at all). To construct global solutions we modify the equation by introducing a smoothing operator $\mathcal{A}$. This operator acts on the space $\mathfrak{H}$ of all L^2 vector fields on Ω_0. We choose $\mathcal{A}$ to be an operator which approximates the identity and for which $\mathcal{A}w$ will always be smooth for all $w \in \mathfrak{H}$. The operators $\mathcal{A}$ we use are versions of a parabolic operator $\mathcal{A} = e^{\varepsilon\Delta}$. See section 8 for more detail.

Instead of considering the gradient flow generated by the velocity field (5), we smooth out v^t and consider

$$v^t = -\frac{1}{\mu_0(x)} \mathcal{P}\mathcal{A}^2\mathcal{P}(W^t) = -\frac{1}{\mu_0(x)} \mathcal{P}\mathcal{A}^2\mathcal{P}\left(\mathbb{E}_{\gamma^t}(\Phi_x \mid x)\right). \tag{7}$$

We refer to the corresponding initial value problem as *the regularized problem.* Since the velocity field here is smooth for any possible $\gamma^t \in \mathfrak{X}$, no singularities can occur, and we can prove the following.

THEOREM 1.2. *Under appropriate assumptions on the smoothing operator A solutions to the initial value problem exist for all time $t \ge 0$ and for any initial measure $\gamma^0 \in \mathfrak{X}$.*

See Theorem 9.1 for a more precise statement.

In fact, assuming the smoothing operator is injective, it follows that the initial value problem corresponding to the velocity field (7) generates a continuous semiflow on $\mathfrak{X}$ and that the Monge–Kantorovich functional $M(\gamma)$ acts as a Lyapunov function for this flow. Thus all orbits exist for all $t > 0$, and all orbits have ω-limit sets consisting of critical points only. Here a critical point of the flow is measure $\gamma \in \mathfrak{X}$ whose velocity field defined in (7) vanishes. Injectivity of $\mathcal{A}$ implies that critical points can be characterized independently of the smoothing operator $\mathcal{A}$: *A critical point is a measure $\gamma \in \mathfrak{X}$ for which*

$$\mathbb{E}_\gamma\big(\Phi_x \mid x\big) = \nabla p$$

for some Lipschitz continuous function $p : \Omega_0 \to \mathbb{R}$. These are precisely the measures $\gamma \in \mathfrak{X}$ whose Monge–Kantorovich cost $M(\gamma)$ cannot be reduced by the action of some $s \in \mathrm{Diff}^1_{\mu_0}(\Omega_0)$ infinitesimally close to the identity.

If the measure γ is given by $\gamma = (\mathrm{id} \times u)_{\#}\mu_0$ for some measure preserving $u : \Omega_0 \to \Omega_1$, then $\gamma = \gamma_u$ is a critical point exactly when the map u satisfies

$$\Phi_x(x, u(x)) = \nabla p(x) \quad \text{a.e. on } \Omega_0$$

for some Lipschitz function $p : \Omega_0 \to \mathbb{R}$. This is very important since it motivates our approach for finding a flow which in a certain sense kills the curl of a vector field (see our discussion in section 3.2). In particular, if the cost function is quadratic, $\Phi(x, y) = \frac{1}{2}|x - y|^2$, then a measure preserving map $u : \Omega_0 \to \Omega_1$ whose reallocation measure $\gamma_u \in \mathfrak{X}$ is a critical point also satisfies

$$u(x) = x - \nabla p(x)$$

for some Lipschitz function p.

Our gradient flows (both regularized and unregularized) move measures $\gamma \in \mathfrak{X}$ around on orbits of the group action $\mathrm{Diff}^1_{\mu_0}(\Omega_0) \times \mathfrak{X} \to \mathfrak{X}$.

A pertinent example is the group orbit of a C^1 diffeomorphism $\hat{u} : \bar{\Omega}_0 \to \bar{\Omega}_1$, or, rather, the measure γ_u associated to such a map. This orbit consists of all measures of the form $s \cdot \gamma_u = \gamma_{u \circ s^{-1}}$. Since any other diffeomorphism $\tilde{u} : \bar{\Omega}_0 \to \bar{\Omega}_1$ is of the form $\tilde{u} = \hat{u} \circ s^{-1}$ for some $s \in \mathrm{Diff}^1_{\mu_0}(\Omega_0)$ we see that the set

$$\big\{\gamma_u \mid u : \bar{\Omega}_0 \to \bar{\Omega}_1 \text{ is a } C^1 \text{ measure preserving diffeomorphism}\big\}$$

is exactly one orbit of the group action. So, if we have an initial measure $\gamma = \gamma_u$ which is generated by some map u and solve the initial value problem, then the solution we get will again consist of measures of the form $\gamma^t = \gamma_{u^t}$.

Unfortunately, such group orbits are not always closed, so if $\{\gamma^t = s^t \cdot \gamma^0 \mid t \geq 0\}$ is a trajectory of one of our gradient flows, then its ω-limit set might not be contained in the same orbit of the group action; i.e., if $\hat{\gamma}$ belongs to the ω-limit set, then it is possible that $\hat{\gamma}$ is not of the form $s \cdot \gamma^0$ for any $s \in \mathrm{Diff}^1_{\mu_0}(\Omega_0)$. In particular, if we start with $\gamma^0 = \gamma_{u^0}$, then the corresponding solution γ^t to the regularized flow will be of the form $\gamma^t = \gamma_{u^t}$ for a family of maps $u^t = u^0 \circ (s^t)^{-1}$, but, as $t \nearrow \infty$, the γ^t might converge to a measure $\tilde{\gamma} \in \mathfrak{X}$, which does not correspond to any map. (For example, if $\Omega_0 = \Omega_1$ is the unit disc, $\mu_0 = \mu_1$ is Lebesgue measure, $u^0 = \mathrm{id}_{\Omega_0}$, and s^t is defined by $s^t(z) = e^{it|z|}z$ in complex notation, then the measures γ_{u^t} converge weakly to $\bar{\gamma} \in \mathfrak{X}$. The limiting measure $\bar{\gamma}$ is described as in (4) with P_x the uniform distribution on the circle of radius $|x|$. In other words, instead of corresponding to a map, the limiting measure $\bar{\gamma}$ takes each point $x \in \Omega_0$ and spreads it out uniformly over the circle through x, centered at the origin. See Figure 1.)

We must therefore study the gradient flow(s) on all of $\mathfrak{X}$.

It turns out that there is always one stationary measure, namely,

$$\gamma_\times = \mu_0 \times \mu_1. \tag{8}$$

This measure takes each point in Ω_0 and spreads it out evenly (with a probability measure proportional to μ_1) over Ω_1. This measure must be a critical measure, for it is a fixed point for the group action; i.e., for all $s \in \mathrm{Diff}^1_{\mu_0}$ one has

$$s \cdot \gamma_\times = \big(s \times \mathrm{id}_{\Omega_1}\big)_{\#}\gamma_\times = (s_{\#}\mu_0) \times \mu_1 = \mu_0 \times \mu_1 = \gamma_\infty.$$

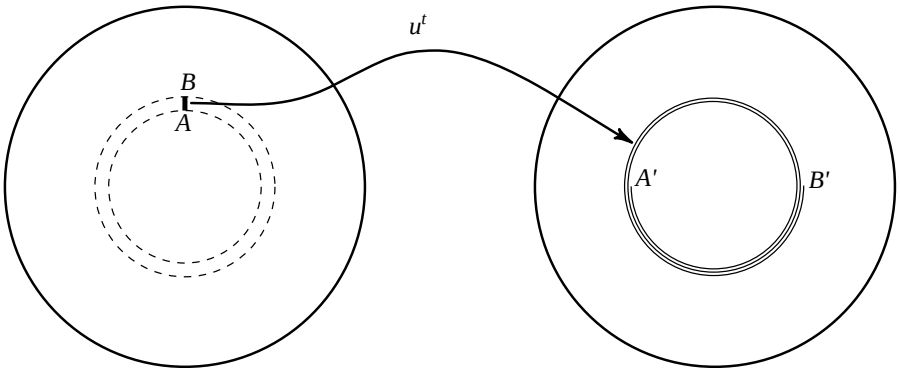


FIG. 1. *The map u^t spreads the short line segment AB out over the spiral $A'B'$.*

Therefore any of the gradient flows $\gamma \mapsto s^t \cdot \gamma$ we construct here act trivially on $\gamma_\times$.

Although we have no global existence result for the unregularized flow, we can choose a family of smoothing operators $\mathcal{A}_\varepsilon = e^{\varepsilon\Delta}$ which approximate the identity operator as $\varepsilon \searrow 0$ and consider the solutions $\{\gamma_\varepsilon^t \mid t \geq 0\}$ of the regularized flows whose existence we have already proved. We then show in section 10.2 that the γ_ε^t converge weakly to a family of measures $\tilde{\gamma}^t$ whose Monge–Kantorovich cost is decreasing and whose ω-limit set consists of critical measures (Proposition 10.1.)

1.3. Computations. Our interest in Monge–Kantorovich arose because of certain problems in computer vision and image processing, including image registration and image warping [2, 11, 12]. Image registration is the process of establishing a common geometric reference frame between two or more data sets possibly taken at different times. In [11, 12], we present a method for computing elastic registration maps based on the Monge–Kantorovich problem of optimal mass transport.

For image registration, it is natural to take $\Phi(x, y) = \frac{1}{2}|x - y|^2$ and $\Omega_0 = \Omega_1$ to be a rectangle. Extensive numerical computations show that the solution to the unregularized flow converges to a limiting map for a large choice of measures and initial maps. Indeed, in this case, we can write the minimizing flow in the following "nonlocal" form:

$$\frac{\partial u^t}{\partial t} = -\frac{1}{\mu_0}\left(u^t - \nabla\Delta^{-1}\operatorname{div}(u^t)\right) \cdot \nabla u^t. \tag{9}$$

In section 12, we give some details on our numerical methods as well as some illustrative examples.

2. Reallocation measures. The search for minimizers of $M(u)$ simplifies greatly if one suitably generalizes the notion of "mapping from Ω_0 to Ω_1." The standard way to do this in the present context is to identify the measure preserving map $u : (\Omega_0, \mu_0) \to (\Omega_1, \mu_1)$ with its graph, or, rather, with the Borel measure γ_u on $\Omega_0 \times \Omega_1$ defined by

$$\gamma_u(E) = \mu_0\big(\{x \in \Omega_0 : (x, u(x)) \in E\}\big).$$

This measure is supported on the graph of the map u; it is the pushforward of μ_0 under the map $\mathrm{id} \times u$, so $\gamma_u = (\mathrm{id} \times u)_\#(\mu_0)$.

The map u is measure preserving if and only if the measure γ_u satisfies $(p_0)_\#(\gamma_u) = \mu_0$ and $(p_1)_\#(\gamma_u) = \mu_1$, where $p_j : \Omega_0 \times \Omega_1 \to \Omega_j$ is the canonical projection. This prompts us to consider the space

$$\mathfrak{X} = \{\text{Borel measures } \gamma \geq 0 \text{ on } \Omega_0 \times \Omega_1 \ \mid (p_j)_\#\gamma = \mu_j \text{ for } j = 0, 1\}.$$

If the measure γ has a density, so that $d\gamma(x, y) = \mu(x, y)\mathrm{d}x\mathrm{d}y$, then $\gamma \in \mathfrak{X}$ exactly when

$$\int_{\Omega_0} \mu(x, y)\mathrm{d}x = \mu_1(y) \quad \text{for } \mu_1 \text{ almost all } y \in \Omega_1 \tag{10}$$

and

$$\int_{\Omega_1} \mu(x, y)\mathrm{d}y = \mu_0(x) \quad \text{for } \mu_0 \text{ almost all } x \in \Omega_0. \tag{11}$$

All measures $\gamma \in \mathfrak{X}$ have total mass

$$\gamma(\Omega_0 \times \Omega_1) = \mu_0(\Omega_0) = \mu_1(\Omega_1). \tag{12}$$

The space $\mathfrak{X}$ with the weak* topology is a compact metrizable space. (It is a closed and convex subset of the dual of $C^0(\Omega_0 \times \Omega_1)$.) The Monge–Kantorovich cost functional is linear on $\mathfrak{X}$. It is simply given by

$$M(\gamma) = \langle \gamma, \Phi \rangle = \int_{\Omega_0 \times \Omega_1} \Phi(x, y) d\gamma(x, y).$$

As such, there is always a minimizer for the cost functional (although in general it is only known to be a measure $\gamma \in \mathfrak{X}$, and it does not follow from general principles that γ is of the form γ_u for some measure preserving map).

3. Steepest descent. The group $\mathcal{G}$ of μ_0 measure preserving transformations on $s : \Omega_0 \to \Omega_0$ acts on $\mathfrak{X}$ by $s \cdot \gamma \mapsto (s \times \mathrm{id}_{\Omega_1})\gamma$. We propose to study a cost reducing flow on $\mathfrak{X}$ which is defined by the group action $\mathcal{G} \times \mathfrak{X} \to \mathfrak{X}$. Rather than applying arbitrary measurable maps $s \in \mathcal{G}$, we restrict ourselves to smooth (C^1) orientation preserving diffeomorphisms $s : \Omega_0 \to \Omega_0$.

3.1. The first variation. If we have a one-parameter family of μ_0 preserving C^1 diffeomorphisms $s^t : \Omega_0 \to \Omega_0$ with velocity field v^t, and we write $\gamma^t = s^t \cdot \gamma$ for some $\gamma \in \mathfrak{X}$, then the first variation of the Monge–Kantorovich cost functional is

$$\begin{aligned} \frac{dM(\gamma^t)}{dt} &= \frac{d}{dt} \int_{\Omega_0 \times \Omega_1} \Phi(x, y)\mathrm{d}(s^t \times \mathrm{id})_\#\gamma(x, y) \\ &= \frac{d}{dt} \int_{\Omega_0 \times \Omega_1} \Phi(s^t(x), y)\mathrm{d}\gamma(x, y) \\ &= \int_{\Omega_0 \times \Omega_1} v^t(s^t(x)) \cdot \Phi_x(s^t(x), y)\mathrm{d}\gamma(x, y) \\ &= \int_{\Omega_0 \times \Omega_1} v^t(x) \cdot \Phi_x(x, y)\mathrm{d}\gamma^t(x, y). \end{aligned} \tag{13}$$

LEMMA 3.1. *For any bounded measurable function $F : \Omega_0 \times \Omega_1 \to \mathbb{R}$ there exists a bounded measurable function $\tilde{F} : \Omega_0 \to \mathbb{R}$ for which*

$$\int_{\Omega_0 \times \Omega_1} \phi(x)F(x, y)\mathrm{d}\gamma(x, y) = \int_{\Omega_0} \phi(x)\tilde{F}(x)\mathrm{d}\mu_0(x)$$

holds for all $\phi \in L^1(\Omega_0; \mathrm{d}\mu_0)$.

Proof. The left-hand side defines a bounded linear functional on $L^1(\Omega_0, \mathrm{d}\mu_0)$, so the existence and uniqueness of $\tilde{F}$ is guaranteed. □

We will denote the function $\tilde{F}$ by

$$\tilde{F}(x) = \mathbb{E}_\gamma(F \mid x) \quad \text{or} \quad \tilde{F}(x) = \mathbb{E}_\gamma(F(x,y) \mid x). \tag{14}$$

If the measure γ has a density $\mu(x,y)$, then $\tilde{F}(x)$ is given by

$$\mathbb{E}_\gamma(F \mid x) = \int_{\Omega_1} F(x,y) \frac{\mu(x,y)}{\mu_0(x)} \mathrm{d}y. \tag{15}$$

Fubini's theorem implies that this integral exists for μ_0 almost all $x \in \Omega_0$. The condition $\mu(x,y)\mathrm{d}x\mathrm{d}y \in \mathfrak{X}$ implies that $\frac{\mu(x,y)}{\mu_0(x)}\mathrm{d}y$ is a probability measure on Ω_1 for every $x \in \Omega_0$, and $\tilde{F}(x)$ is just the expectation of $F(x,y)$ for this probability measure. This justifies the notation in (14).

If the measure is of the form $\gamma = \gamma_u$ for some measure preserving map $u : \Omega_0 \to \Omega_1$, then $\tilde{F}$ is given by

$$\mathbb{E}_\gamma(F \mid x) = F(x, u(x)). \tag{16}$$

One may think of (16) as a special case of (15) in which the "density" $\mu(x,y)$ is given by $\mu(x,y) = \mu_0(x)\delta(y - u(x))$ (δ being the Dirac delta-function). Here the probability measure $\frac{\mu(x,y)}{\mu_0(x)}\mathrm{d}y$ puts probability one at $y = u(x)$, and thus the expectation of $F(x,y)$ for this measure is just $F(x,u(x))$.

With this notation we now complete our computation (13) of the first variation:

$$\frac{dM(\gamma^t)}{dt} = \int_{\Omega_0} v^t(x) \cdot W^t(x) \mathrm{d}\mu_0(x), \tag{17}$$

where

$$W^t(x) = \mathbb{E}_{\gamma^t}(\Phi_x(x,y) \mid x). \tag{18}$$

When the measure $\gamma \in \mathfrak{X}$ is of the form $\gamma = \gamma_u$ for some map $u : \Omega_0 \to \Omega_1$, one has $\gamma^t = \gamma_{u^t}$ with $u^t \circ s^t = u$, and thus (18) reduces to

$$W^t(x) = \Phi_x(x, u^t(x)).$$

In the case of a quadratic cost function $\Phi(x,y) = \frac{1}{2}|x-y|^2$ but general measure $\gamma^t \in \mathfrak{X}$, one has

$$W^t(x) = \mathbb{E}_{\gamma^t}(x - y \mid x) = x - Y^t(x),$$

where

$$Y^t(x) = \mathbb{E}_{\gamma^t}(y|x)$$

is the expected y value to which the measure γ^t reallocates the point x.

If the cost function is quadratic, *and* if the measure γ^t is of the form γ_{u^t}, then we get $Y^t(x) = u^t(x)$, and hence

$$W^t(x) = x - u^t(x).$$

3.2. Steepest descent. To reduce the cost functional we choose the velocity field v^t so as to minimize $\int v^t \cdot W^t \mathrm{d}\mu_0$ subject to a constraint on $\|v^t\|_{L^2}$ (or some similar quadratic norm) and subject to the constraint that v^t preserve the measure μ_0, i.e., $\operatorname{div} \mu_0 v^t = 0$.

To this end we use the Helmholtz projection to split W^t into a gradient and its divergence-free part,

$$W^t = \nabla p^t + \mathcal{P}(W^t),$$

where

$$\operatorname{div} \mathcal{P}(W^t) = 0,$$

and where $\mathcal{P}(W^t)\,|_{\partial\Omega_0}$ is tangential to the boundary of Ω_0. Such a decomposition is always possible, and $\mathcal{P}$ can be interpreted as orthogonal projection in $L^2(\Omega_0) \otimes \mathbb{R}^d$. See section 7, where we discuss $\mathcal{P}$ in more detail.

If the velocity field satisfies $\operatorname{div} \mu_0 v^t = 0$, then we get

$$\begin{aligned} \frac{dM(\gamma^t)}{dt} &= \int_{\Omega_0} \mu_0(x) v^t(x) \cdot W^t \mathrm{d}x \\ &= \int_{\Omega_0} \mu_0(x) v^t(x) \cdot \{\nabla p^t + \mathcal{P}(W^t)\} \mathrm{d}x \\ &= \int_{\Omega_0} \{-p^t \nabla \cdot (\mu_0 v^t) + \mu_0 v^t \cdot \mathcal{P}(W^t)\} \mathrm{d}x \\ &= \int_{\Omega_0} \mu_0(x) v^t(x) \cdot \mathcal{P}(W^t) \mathrm{d}x. \end{aligned} \tag{19}$$

We choose the following velocity field:

$$v^t = -\frac{1}{\mu_0(x)} \mathcal{P}\mathcal{A}^2\mathcal{P}(W^t) = -\frac{1}{\mu_0(x)} \mathcal{P}\mathcal{A}^2\mathcal{P}\left(\mathbb{E}_{\gamma^t}(\Phi_x \mid x)\right). \tag{20}$$

Here $\mathcal{A}$ is an operator on the Hilbert space

$$\mathfrak{H} \stackrel{\text{def}}{=} L^2(\Omega_0) \otimes \mathbb{R}^d.$$

Throughout this paper we will assume that $\mathcal{A}$ satisfies

$$\mathcal{A} \text{ is a } \textit{bounded, symmetric, and injective} \text{ operator on } \mathfrak{H}. \tag{21}$$

Thus $\mathcal{A}^2$ is positive definite, and $\mathcal{P}\mathcal{A}^2\mathcal{P}$ is positive definite on divergence-free vector fields on Ω_0.

The most natural choice for $\mathcal{A}$ would be $\mathcal{A} = I_{\mathfrak{H}}$, the identity operator on $\mathfrak{H}$. In that case $\mathcal{P}\mathcal{A}^2\mathcal{P} = \mathcal{P}$, so that

$$v^t = -\frac{1}{\mu_0(x)} \mathcal{P}\mathbb{E}_{\gamma^t}(\Phi_x \mid x).$$

In what follows we are also interested in the case where the operator $\mathcal{A}$ is an approximate identity, e.g., $\mathcal{A}$ could be defined by running a heat equation for a short time, $\mathcal{A}f = e^{\varepsilon\Delta} f$. In section 8 we specify a class of operators $\mathcal{A}$ to which the theory in this paper is applicable.

3.3. Evolution equation for the measure γ^t. Let $\gamma^t = (s^t \times \mathrm{id})_\# \gamma^0$ for some initial measure $\gamma^0 \in \mathfrak{X}$. Here we compute the distributional time derivative of the γ^t assuming the diffeomorphisms s^t have velocity field v^t given by (20).

Let $\varphi \in C^1(\bar{\Omega}_0 \times \bar{\Omega}_1)$ be a test function. Then $\langle \gamma^t, \varphi \rangle = \big\langle \gamma^0, \varphi \circ (s^t \times \mathrm{id}) \big\rangle$, so that one has

$$\begin{aligned} \frac{d}{dt} \big\langle \gamma^t, \varphi \big\rangle &= \big\langle \gamma^0, (v^t \cdot \nabla_x \varphi) \circ (s^t \times \mathrm{id}) \big\rangle \\ &= \big\langle \gamma^t, v^t \cdot \nabla_x \varphi \big\rangle \\ &= \big\langle -\nabla \cdot (v^t \gamma^t), \varphi \big\rangle \,, \end{aligned} \tag{22}$$

where $\nabla_x f(x,y)$ represents the gradient in the $x \in \Omega_0$ variable for any function $f : \Omega_0 \times \Omega_1 \to \mathbb{R}$.

Thus we have found that the family of measures γ^t satisfies

$$\frac{\partial \gamma^t}{\partial t} + \nabla_x \cdot \big(v^t(x) \gamma^t \big) = 0 \tag{23}$$

in the sense of distributions. This equation, combined with (20), which prescribes v^t in terms of γ^t, gives an initial value problem for γ^t,

$$\boxed{\frac{\partial \gamma^t}{\partial t} = \nabla_x \cdot \left(\frac{1}{\mu_0(x)} \mathcal{P}\mathcal{A}^2\mathcal{P}\big(\mathbb{E}_{\gamma^t}(\Phi_x \mid x)\big)\gamma^t \right).} \tag{24}$$

3.4. A PDE for the map u^t. If the measure γ^t is given by $\gamma^t = \gamma_{u^t}$ for some family of measure preserving maps $u^t : (\Omega_0, \mu_0) \to (\Omega_1, \mu_1)$, then we have $u^0 = u^t \circ s^t$, so that the u^t satisfy the transport equation

$$\frac{\partial u^t}{\partial t} + v^t \cdot \nabla u^t = 0. \tag{25}$$

Since for $\gamma^t = \gamma_{u^t}$ one has

$$\mathbb{E}_{\gamma^t}(\Phi_x \mid x) = \Phi_x(x, u^t(x)),$$

the velocity field is given by

$$v^t = \frac{-1}{\mu_0(x)} \mathcal{P}\mathcal{A}^2\mathcal{P}\big\{\Phi_x(x, u^t(x))\big\}. \tag{26}$$

Together, (25) and (26) determine an evolution equation for the map u^t.

3.5. Evolution of the rearrangement s^t. We return to the case where γ^t is a general measure in $\mathfrak{X}$. Let us assume that the operator $\mathcal{P}\mathcal{A}^2\mathcal{P}$ can be represented as an integral operator with kernel $K(x,\xi)$, so that for any vector field $W \in L^2(\Omega_0; \mathbb{R}^n)$ one has

$$(\mathcal{P}\mathcal{A}^2\mathcal{P}W)(x) = \int_{\Omega_0} K(x,\xi) \cdot W(\xi) \mathrm{d}\xi. \tag{27}$$

Here $\mathrm{d}y$ is the Lebesgue measure, $K(x,y)$ is an $n \times n$ matrix-valued function, and $K(x,y) \cdot W(y)$ is pointwise matrix multiplication.

Self-adjointness of the operator $\mathcal{P}\mathcal{A}^2\mathcal{P}$ implies

$$K(x,\xi) = K(\xi,x)^T. \tag{28}$$

When $\mathcal{A}$ is the identity operator on $\mathfrak{H}$, the kernel $K(x,\xi)$ is a singular integral kernel. When $\mathcal{A}$ is given by solving a heat equation, $\mathcal{A}f = e^{\varepsilon\Delta}f$, then the kernel $K(x,\xi)$ is a $C^{1,\alpha}$ function on $\bar{\Omega}_0 \times \bar{\Omega}_1$. (See section 8 for more details.)

The velocity field is given by

$$\begin{aligned} v^t(x) &= \frac{-1}{\mu_0(x)} \int_{\Omega_0} K(x,\xi)\mathbb{E}_{\gamma^t}(\Phi_x(\xi,\eta) \mid \xi)\,\mathrm{d}\xi \\ &= \frac{-1}{\mu_0(x)} \int_{\Omega_0\times\Omega_1} K(x,\xi)\cdot\Phi_x(\xi,\eta)\,\frac{\mathrm{d}\gamma^t(\xi,\eta)}{\mu_0(\xi)} \\ &= -\int_{\Omega_0\times\Omega_1} \frac{K(x,\xi)}{\mu_0(x)\mu_0(\xi)}\cdot\Phi_x(\xi,\eta)\,\mathrm{d}\gamma^t(\xi,\eta). \end{aligned} \tag{29}$$

Since the rearrangement maps $s^t : \Omega_0 \to \Omega_0$ are related to the velocity field v^t by $\partial_t s^t = v^t \circ s^t$, we find the following integral-differential equation for s^t:

$$\begin{aligned} \frac{\partial s^t}{\partial t} &= -\int_{\Omega_0\times\Omega_1} \frac{K(s^t(x),\xi)}{\mu_0(s^t(x))\mu_0(\xi)}\cdot\Phi_x(\xi,\eta)\,\mathrm{d}\gamma^t(\xi,\eta) \\ &= -\int_{\Omega_0\times\Omega_1} \frac{K(s^t(x),s^t(\xi))}{\mu_0(s^t(x))\mu_0(s^t(\xi))}\cdot\Phi_x(s^t(\xi),\eta)\,\mathrm{d}\gamma^0(\xi,\eta), \end{aligned} \tag{30}$$

where we have used $\gamma^t = (s^t \times \mathrm{id})_{\#}\gamma^0$, with γ^0 the initial measure.

3.6. An alternative steepest descent flow. We can also derive a related flow in the following manner. Instead of using the Helmholtz projection to get a divergence-free vector field out of W^t, as we did in section 3.2, we set

$$\mu_0 v^t = \nabla \mathrm{div} W^t - \Delta W^t. \tag{31}$$

It is straightforward to check that in this case $\mathrm{div}(\mu_0 v^t) = 0$ and

$$\begin{aligned} M_t &= -\int_{\Omega_0} W^t \cdot \mu_0 v^t \,\mathrm{d}x \\ &= -\int_{\Omega_0} W^t \cdot \left(\nabla(\nabla\cdot W^t) - \Delta W^t\right)\,\mathrm{d}x \\ &= -\int_{\Omega_0} (W^t)^k((W^t)^l_{lk} - (W^t)^k_{ll})\,\mathrm{d}x, \end{aligned}$$

where we've used superscripts to denote vector components and subscripts for spatial derivatives, with the standard convention of summation over repeated indices. Integrating by parts, and ignoring the boundary for the sake of exposition, gives

$$\begin{aligned} M_t &= -\int_{\Omega_0} -(W^t)^k_l((W^t)^l_k - (W^t)^k_l)\,\mathrm{d}x \\ &= -\frac{1}{2}\int_{\Omega_0} ((W^t)^l_k - (W^t)^k_l)^2\,\mathrm{d}x \\ &= -\frac{1}{2}\int_{\Omega_0} |\operatorname{curl} W^t|^2\,\mathrm{d}x \\ &\le 0. \end{aligned} \tag{32}$$

If the measures γ^t are of the form $\gamma^t = (\mathrm{id}\times u^t)_\#(\mu_0)$, then we have $W^t = \Phi_x(x, u^t(x))$, resulting in the evolution equation

$$\frac{\partial u^t}{\partial t} = -\frac{1}{\mu_0(x)}\big(\nabla \mathrm{div}\Phi_x(x,u^t) - \Delta\Phi_x(x,u^t)\big)\cdot\nabla u^t \tag{33}$$

for u^t corresponding to (31), and (32) shows that at optimality we must again have curl $W^t = 0$, so $W^t = \nabla p$ for some function p.

For the quadratic cost function $\Phi(x,\xi) = \frac{1}{2}|x-\xi|^2$ we have $\Phi_x(x,\xi) = x - \xi$, so we get the following PDE:

$$\frac{\partial u^t}{\partial t} = \frac{1}{\mu_0(x)}\big(\nabla(\nabla\cdot u^t) - \Delta u^t\big)\cdot\nabla u^t.$$

We plan to study this equation in future work.

4. Weak solutions. Let $\gamma^t = (s^t\times\mathrm{id})_\#\gamma^0$ for some smooth family of diffeomorphisms $s^t : \bar\Omega_0 \to \bar\Omega_0$, whose velocity field satisfies (20).

In section 3.3 we observed that for any test function $\varphi \in C^1(\bar\Omega_0\times\bar\Omega_1)$ one has

$$\frac{d}{dt}\left\langle \gamma^t, \varphi\right\rangle = \left\langle \gamma^t, v^t\cdot\nabla_x\varphi\right\rangle.$$

Using (20) we get

$$\frac{d}{dt}\left\langle \gamma^t, \varphi\right\rangle = \left\langle \gamma^t, \frac{-1}{\mu_0(x)}\varphi_x\cdot\mathcal{P}\mathcal{A}^2\mathcal{P}\big(\mathbb{E}_{\gamma^t}(\Phi_x\mid x)\big)\right\rangle,$$

which implies

$$\begin{aligned}\frac{d}{dt}\left\langle \gamma^t, \varphi\right\rangle &= \big(\mathbb{E}_{\gamma^t}(\varphi_x\mid x), \mathcal{P}\mathcal{A}^2\mathcal{P}\mathbb{E}_{\gamma^t}(\Phi_x\mid x)\big)_{\mathfrak{H}}\\ &= \big(\mathcal{A}\mathcal{P}\mathbb{E}_{\gamma^t}(\varphi_x\mid x), \mathcal{A}\mathcal{P}\mathbb{E}_{\gamma^t}(\Phi_x\mid x)\big)_{\mathfrak{H}}.\end{aligned} \tag{34}$$

Integrate this in time, and you get

$$\int_{t_0}^{t_1}\big(\mathcal{A}\mathcal{P}\mathbb{E}_{\gamma^t}(\varphi_x\mid x), \mathcal{A}\mathcal{P}\mathbb{E}_{\gamma^t}(\Phi_x\mid x)\big)_{\mathfrak{H}}\,\mathrm{d}t = \left\langle\gamma^{t_0},\varphi\right\rangle - \left\langle\gamma^{t_1},\varphi\right\rangle. \tag{35}$$

For any measure $\gamma\in\mathfrak{X}$ and any $\varphi\in C^1(\bar\Omega_0\times\bar\Omega_1)$ the functions $\mathbb{E}_\gamma(\varphi_x\mid x)$ are bounded and measurable, and hence $\mathbb{E}_{\gamma^t}(\varphi_x\mid x)\in\mathfrak{H} = L^2(\Omega_0;\mathbb{R}^d)$ will always hold. Since $\mathcal{P}$ and $\mathcal{A}$ are bounded operators on $\mathfrak{H}$, both sides of the equation in (35) are defined for any weak* continuous family of measures $\gamma^t\in\mathfrak{X}$.

Definition 4.1 (weak solution). *A* weak solution *to the initial value problem* (24) *is a map* $t\in[0,T)\mapsto\gamma^t\in\mathfrak{X}$ *which is weak* continuous, and which satisfies* (35) *for all test functions* $\varphi\in C^1(\bar\Omega_0\times\bar\Omega_1)$ *and for all* $0\le t_0<t_1<T$.

If $\{\gamma^t, 0\le t<T\}$ is a weak solution, then (35) implies that $\langle\gamma^t,\varphi\rangle$ is an absolutely continuous function of t and that (34) holds for almost all t.

We could also introduce the notion of *classical solution* by requiring a classical solution to be a family of measures $\{\gamma^t, t\in[0,T)\}$ which is of the form $\gamma^t = (s^t\times\mathrm{id})_\#\gamma^0$ for some family of C^1 diffeomorphisms $s^t:\Omega_0\to\Omega_0$ whose velocity field $v^t = (\partial_t s^t)\circ(s^t)^{-1}$ satisfies $\mu_0 v^t = -\mathcal{P}\mathcal{A}^2\mathcal{P}\{\mathbb{E}_{\gamma^t}(\Phi_x\mid x)\}$.

LEMMA 4.2. *If the kernel $K(x,\xi)$ of the operator $\mathcal{P}\mathcal{A}^2\mathcal{P}$ is C^1, and if $\{\gamma^t, 0 \le t < T\}$ is a weak solution, then there is a C^1 family of diffeomorphisms $s^t : \bar\Omega_0 \to \bar\Omega_0$ such that $\gamma^t = (s^t \times \mathrm{id})_\# \gamma^0$; i.e., $\{\gamma^t\}$ is a classical solution.*

Proof. The velocity field v^t defined by the first line in (30), i.e.,

$$v^t(s) = -\int_{\Omega_0\times\Omega_1} \frac{K(s,\xi)}{\mu_0(s)\mu_0(\xi)} \cdot \Phi_x(\xi,\eta)\,\mathrm{d}\gamma^t(\xi,\eta),$$

is C^1 in $s \in \bar\Omega_0$. Therefore the ODE $\dot s = v^t(s)$ defines a unique family of diffeomorphisms s^t, $0 \le t < T$, with $s^0(x) \equiv x$. We now verify that $\gamma^t = (s^t \times \mathrm{id})_\# \gamma^0$.

Consider the measure $\lambda^t = \big((s^t)^{-1} \times \mathrm{id}\big)_\# \gamma^0$. We have $\gamma^t = (s^t \times \mathrm{id})_\# \lambda^t$, and $\lambda^0 = \gamma^0$. We will show that λ^t is constant.

For any test function $\varphi \in C^1(\bar\Omega_0 \times \bar\Omega_1)$ we differentiate

$$\frac{d}{dt}\left\langle \lambda^t, \varphi \circ (s^t \times \mathrm{id})\right\rangle = \frac{d}{dt}\left\langle \gamma^t, \varphi\right\rangle$$

(using the fact that γ^t is a weak solution)

$$\begin{aligned}
&= \left\langle \gamma^t, \varphi_x(x,y)\cdot v^t(x)\right\rangle \\
&= \left\langle \gamma^t, \frac{\partial \varphi \circ (s^t \times \mathrm{id})}{\partial t} \circ ((s^t)^{-1} \times \mathrm{id})\right\rangle \\
&= \left\langle \lambda^t, \frac{\partial}{\partial t}\big(\varphi \circ (s^t \times \mathrm{id})\big)\right\rangle.
\end{aligned}$$

On the other hand we also have

$$\frac{d}{dt}\left\langle \lambda^t, \varphi \circ (s^t \times \mathrm{id})\right\rangle = \left\langle \frac{\partial \lambda^t}{\partial t}, \varphi \circ (s^t \times \mathrm{id})\right\rangle + \left\langle \lambda^t, \frac{\partial}{\partial t}\big(\varphi \circ (s^t \times \mathrm{id})\big)\right\rangle.$$

We see that $\langle \partial_t \lambda^t, \varphi \circ (s^t \times \mathrm{id})\rangle$ vanishes for arbitrary test functions φ. Since s^t is C^1, this implies that $\tilde\varphi = \varphi \circ (s^t \times \mathrm{id})$ can also be any C^1 test function, and we conclude that $\partial_t \lambda^t = 0$.

Since $\lambda^0 = \gamma^0$, we get $\lambda^t = \gamma^0$ for all t, and finally, $\gamma^t = (s^t \times \mathrm{id})_\# \lambda^t = (s^t \times \mathrm{id})_\# \gamma^0$, as claimed. ∎

5. General energy bounds. By setting $\varphi = \Phi$ in (35) we get the following.

LEMMA 5.1 (energy identity). *For any weak solution $\{\gamma^t, t \in [0,T)\}$ and any $0 \le t_0 < t_1 < T$ one has*

$$M(\gamma^{t_1}) + \int_{t_0}^{t_1} \|\mathcal{A}\mathcal{P}\mathbb{E}_{\gamma^t}(\Phi_x \mid x)\|_{\mathfrak{H}}^2 \,\mathrm{d}t = M(\gamma^{t_0}).$$

This immediately leads to the following lemma.

LEMMA 5.2. *For any weak solution $\{\gamma^t, t \in [0,T)\}$ the Monge–Kantorovich cost functional is nonincreasing. It remains constant if and only if $\mathcal{P}\mathbb{E}_{\gamma^t}(\Phi_x \mid x) = 0$ for almost all $t \in [0,T)$, i.e., if and only if*

$$\mathbb{E}_{\gamma^t}(\Phi_x \mid x) = \nabla p^t$$

for some function $p^t : \Omega_0 \to \mathbb{R}$ and almost all $t \in [0,T)$.

Proof. It is clear that $M(\gamma^t)$ cannot increase. If $M(\gamma^{t_1}) = M(\gamma^{t_0})$ for certain $t_0 < t_1$, then (35) implies that $\mathcal{AP}\left(\mathbb{E}_{\gamma^t}(\Phi_x \mid x)\right) = 0$ for almost all $t_0 < t < t_1$. Since we assume the smoothing operator $\mathcal{A}$ is injective, this forces $\mathcal{P}\left(\mathbb{E}_{\gamma^t}(\Phi_x \mid x)\right) = 0$. ∎

LEMMA 5.3 (uniform Lipschitz bound). *If $\{\gamma^t, 0 \le t < T\}$ is a weak solution to (24), then for any test function $\varphi \in C^1(\bar{\Omega}_0 \times \bar{\Omega}_1)$ the function $t \mapsto \langle \gamma^t, \varphi \rangle$ is Lipschitz continuous, with*

$$\left| \frac{d\,\langle \mu_n^t, \varphi \rangle}{dt} \right| \le \|\mathcal{A}\|^2_{L(\mathfrak{H})} \left\| \frac{\partial \varphi}{\partial x} \right\|_{L^\infty} \left\| \frac{\partial \Phi}{\partial x} \right\|_{L^\infty}. \tag{36}$$

One could formulate this lemma as follows: weak solutions γ^t are uniformly Lipschitz continuous functions of t with values in $\left(C^1(\bar{\Omega}_0 \times \bar{\Omega}_1)\right)^*$ (the dual of C^1 functions on $\bar{\Omega}_0 \times \bar{\Omega}_1$), with Lipschitz constant depending only on the smoothing operator $\|\mathcal{A}\|$ and the cost function Φ.

Proof. This follows directly from (34) and the fact that for almost all $x \in \Omega_0$

$$|\mathbb{E}_\gamma(f(x,y) \mid x)| \le \operatorname*{ess\,sup}_{y \in \Omega_1} |f(x,y)|$$

for any $f \in L^\infty(\Omega_0 \times \Omega_1)$. ∎

LEMMA 5.4 (equicontinuity). *For any $\varphi \in C^0(\bar{\Omega}_0 \times \bar{\Omega}_1)$ there is a modulus of continuity $\sigma : \mathbb{R}_+ \to \mathbb{R}_+$ which depends only on φ, $\|\mathcal{A}\|_{L(\mathfrak{H})}$, $\|\Phi_x\|_{L^\infty}$, and the total mass $\mu_0(\Omega_0)$ such that*

$$\left| \langle \gamma^{t_1}, \varphi \rangle - \langle \gamma^{t_0}, \varphi \rangle \right| \le \sigma(|t_1 - t_0|).$$

Proof. For test functions $\tilde{\varphi} \in C^1(\bar{\Omega}_0 \times \bar{\Omega}_1)$ the previous lemma gives us a uniform Lipschitz bound. We now approximate our given $\varphi \in C^0$ by a $\tilde{\varphi} \in C^1$ and compute

$$\begin{aligned} \left| \langle \gamma^{t_1}, \varphi \rangle - \langle \gamma^{t_0}, \varphi \rangle \right| &= \left| \langle \gamma^{t_1} - \gamma^{t_0}, \varphi \rangle \right| \\ &\le \left| \langle \gamma^{t_1} - \gamma^{t_0}, \tilde{\varphi} \rangle \right| + \left| \langle \gamma^{t_1} - \gamma^{t_0}, \tilde{\varphi} - \varphi \rangle \right| \\ &\le C \|\tilde{\varphi}_x\|_\infty \delta + 2\mu_0(\Omega_0) \|\varphi - \tilde{\varphi}\|_\infty, \end{aligned}$$

where $C = \|\mathcal{A}\|^2 \|\Phi_x\|_\infty$, and where we have used the fact that all measures γ^t have the same total mass $\gamma^t(\Omega_0 \times \Omega_1) = \mu_0(\Omega_0)$ (see (12)) to estimate the second term.

Thus we see that the modulus of continuity σ is given by

$$\sigma(\delta) = \inf_{\tilde{\varphi} \in C^1} \left\{ \|\mathcal{A}\|^2 \|\Phi_x\|_\infty \|\tilde{\varphi}_x\|_\infty \delta + 2\mu_0(\Omega_0) \|\varphi - \tilde{\varphi}\|_\infty \right\}.$$

Clearly $\sigma(\delta)$ is monotone in $\delta > 0$, and $\lim_{\delta \to 0} \sigma(\delta) = 0$, which makes σ a modulus of continuity. ∎

We note that the modulus of continuity $\sigma(\delta)$ is actually bounded by

$$\sigma(\delta) \le C \sup_{|x - x'| + |y - y'| < \delta} |\varphi(x,y) - \varphi(x',y')|,$$

where C depends only on $\|A\|_{L(\mathfrak{H})}$ and $\|\Phi_x\|_\infty$.

6. Weak compactness. In this section, we study limits of sequences of weak solutions.

LEMMA 6.1. *Let $\mathcal{A}_n$ be a sequence of operators satisfying (21) and let $\Phi_n \in C^1(\bar{\Omega}_0 \times \bar{\Omega}_1)$ be a sequence of cost functions. Assume the $\mathcal{A}_n$ are uniformly bounded in $L(\mathfrak{H})$ and the Φ_n are uniformly bounded in $C^1(\bar{\Omega}_0 \times \bar{\Omega}_1)$.*

Given a family of weak solutions $\{\gamma_n^t, t \in [0,T)\}$*, to* (24) *with* $\mathcal{A} = \mathcal{A}_n$*,* $\Phi = \Phi_n$*, there is a subsequence such that* $\gamma_{n_k}^t \rightharpoonup \gamma_\infty^t$ *for some weak* continuous family of measures* $\{\gamma_\infty^t, t \in [0,T)\}$*.*

Proof. Given any $t \in [0,T)$ weak* compactness of $\mathfrak{X}$ enables us to find a subsequence of $\{\gamma_n^t\}$ which weak* converges. Given a finite subset $\{t_1, \dots, t_m\} \subset [0,T)$ we can repeat this argument m times and obtain a subsequence $n_k \in \mathbb{N}$ such that $\mu_{n_k}^t$ weak* converges for $t = t_1, t_2, \dots, t_m$. A diagonalization trick then gives us a further subsequence $n_k \in \mathbb{N}$ such that $\mu_{n_k}^t$ weak* converges for all rational $t \in [0,T)$.

We now argue that this subsequence $\gamma_{n_k}^t$ actually weak* converges for *all* $t \in [0,T)$ rather than just for all rational t.

Let $\varphi \in C^0(\bar{\Omega}_0 \times \bar{\Omega}_1)$ and some $t \in [0,T)$ be given. By Lemma 5.4 the functions $t \mapsto \langle \gamma_{n_k}^t, \varphi \rangle$ are equicontinuous. By Ascoli–Arzelà they form a precompact subset of $C^0([0,T))$. Since they converge pointwise on a dense subset of the interval $[0,T)$ they must converge uniformly for $0 \le t < T$.

It follows that $\langle \gamma_{n_k}^t, \varphi \rangle$ converges for all $t \in [0,T)$, as claimed.

To complete the proof we check weak* continuity in time of the limit measures γ^t. But this is immediate since the μ_n^t all share the same modulus of continuity from Lemma 5.4. Passing to the limit we find that γ^t also has this modulus of continuity. ∎

PROPOSITION 6.2. *Let* γ_n^t*,* $\mathcal{A}_n$*, and* Φ_n *be as in the previous lemma.*

Assume that the operators $\mathcal{A}_n$ *converge strongly to some operator* $\mathcal{A}_\infty$*. Assume also that the cost functions* Φ_n *converge in* C^1 *to some* $\Phi_\infty \in C^1$*.*

Then $W_n^t \stackrel{\text{def}}{=} \mathbb{E}_{\gamma_n^t}(\Phi_{n,x} \mid x)$ *weak* converges in* $L^\infty(\Omega_0; \mathbb{R}^d) = L^1(\Omega_0; \mathbb{R}^d)^*$ *to* $W_\infty^t \stackrel{\text{def}}{=} \mathbb{E}_{\gamma_\infty^t}(\Phi_{\infty,x} \mid x)$*.*

The limiting family γ_∞^t *satisfies the energy inequality*

$$M(\gamma^{t_1}) + \int_{t_0}^{t_1} \left\| \mathcal{A}_\infty \mathcal{P} W_\infty^t \right\|_{L^2}^2 \, \mathrm{d}t \le M(\gamma^{t_0}) \tag{37}$$

for all $0 \le t_0 < t_1 < T$*.*

Proof. For any $\zeta \in L^1(\Omega_0)$ we have

$$\begin{aligned} \int W_n^t(x) \cdot \zeta(x) \mathrm{d}\mu_0(x) &= \iint_{\Omega_0 \times \Omega_1} \zeta(x) \cdot \frac{\partial \Phi_n(x,y)}{\partial x} \mathrm{d}\mu_n^t(x,y) \\ &\to \iint_{\Omega_0 \times \Omega_1} \zeta(x) \cdot \frac{\partial \Phi_\infty(x,y)}{\partial x} \mathrm{d}\mu_\infty^t(x,y) \qquad \text{as } n \to \infty \\ &= \int W_\infty^t(x) \cdot \zeta(x) \mathrm{d}\mu_0(x), \end{aligned}$$

which establishes the weak* convergence of the W_n^t.

Since $M(\gamma_n^t) = \langle \gamma_n^t, \Phi_n \rangle$ weak* convergence of the measures γ_n^t directly implies convergence of the corresponding costs,

$$\lim_{n \to \infty} M(\gamma_n^t) = M(\gamma_\infty^t),$$

for all $t \in [0,T)$.

To prove the energy inequality (37) we need the following.

LEMMA 6.3. $\mathcal{A}_n \mathcal{P} W_n^t$ *converges weakly to* $\mathcal{A}_\infty \mathcal{P} W_\infty^t$ *in* $\mathfrak{H}$*, and hence*

$$\| \mathcal{A}_\infty \mathcal{P} W_\infty^t \| \le \liminf_{n \to \infty} \| \mathcal{A}_n \mathcal{P} W_n^t \|.$$

Given this lemma, we use Fatou's lemma to get

$$\int_{t_0}^{t_1} \left\|\mathcal{A}\mathcal{P}W_\infty^t\right\|_{L^2}^2 \,\mathrm{d}t \le \liminf_{k\to\infty} \int_{t_0}^{t_1} \left\|\mathcal{A}\mathcal{P}W_k^t\right\|_{L^2}^2 \,\mathrm{d}t.$$

The energy identity in Lemma 5.1 then directly leads to the energy inequality (37).

It therefore remains only to verify Lemma 6.3. To this end we recall that the W_n^t converge in the weak* topology on $L^\infty(\Omega_0)\otimes\mathbb{R}^d$ and hence converge weakly in $L^2(\Omega_0)\otimes\mathbb{R}^d = \mathfrak{H}$.

The Helmholtz projection $\mathcal{P}$ is bounded on $\mathfrak{H}$, so $\mathcal{P}W_n^t$ converges weakly to $\mathcal{P}W_\infty^t$.

The operators $\mathcal{A}_n$ converge strongly to $\mathcal{A}_\infty$, so for an arbitrary $f\in\mathfrak{H}$ we have $\|\mathcal{A}_n f - \mathcal{A}_\infty f\|_{\mathfrak{H}} \to 0$.

Altogether this gives us

$$(f, \mathcal{A}_n\mathcal{P}W_n^t)_{\mathfrak{H}} = (\mathcal{A}_n f, \mathcal{P}W_n^t)_{\mathfrak{H}} \to (\mathcal{A}_\infty f, \mathcal{P}W_\infty^t)_{\mathfrak{H}} = (f, \mathcal{A}_\infty\mathcal{P}W_\infty^t)_{\mathfrak{H}}$$

as $n\to\infty$ and for arbitrary $f\in\mathfrak{H}$; i.e., we find that $\mathcal{A}_n\mathcal{P}W_n^t$ converges weakly to $\mathcal{A}_\infty\mathcal{P}W_\infty^t$, and we are done. ∎

At this point it is not clear whether the limiting family $\{\gamma_\infty^t, t\in[0,T)\}$ is a weak solution.

LEMMA 6.4. *Assume that the integral kernel $K(x,\xi)$ of the operator $\mathcal{P}\mathcal{A}^2\mathcal{P}$ is a continuous function on $\bar\Omega_0\times\bar\Omega_1$.*

Then any weak* limit $\{\gamma_\infty^t\}$ of weak solutions $\{\gamma_k^t\}$ is again a weak solution.

Proof. Since the γ_k^t weak* converge to γ_∞^t, the product measures $\gamma_k^t\times\gamma_k^t$ also weak* converge[2] to $\gamma_\infty^t\times\gamma_\infty^t$.

The measures γ_n^t are uniformly bounded (their total mass is fixed by (12)), so, using the dominated convergence theorem, one easily shows that the Borel measures $\mathrm{d}\gamma_n^t\times\mathrm{d}\gamma_n^t\times\mathrm{d}t$ on $\bar\Omega_0\times\bar\Omega_0\times[0,T)$ converge weakly to $\mathrm{d}\gamma_\infty^t\times\mathrm{d}\gamma_\infty^t\times\mathrm{d}t$.

To prove that γ_∞^t is a weak solution to (24) we must show that γ_∞^t satisfies (35) for all test functions φ. Using the integral kernel $K(x,\xi)$ we rewrite (35) as

$$\int_{t_0}^{t_1}\int_{\Omega_0} \mathbb{E}_{\gamma^t}(\varphi_x \mid x)\cdot\mathcal{P}\mathcal{A}^2\mathcal{P}\{\mathbb{E}_{\gamma^t}(\Phi_x\mid x)\}\,\mathrm{d}x\,\mathrm{d}t = \left\langle\gamma^{t_0},\varphi\right\rangle - \left\langle\gamma^{t_1},\varphi\right\rangle,$$

i.e.,

$$\int_{t_0}^{t_1}\iint_{\Omega_0\times\Omega_0} \mathbb{E}_{\gamma^t}(\varphi_x\mid x)\cdot K(x,\xi)\cdot\mathbb{E}_{\gamma^t}(\Phi_x\mid\xi)\,\mathrm{d}x\mathrm{d}\xi\,\mathrm{d}t = \left\langle\gamma^{t_0},\varphi\right\rangle - \left\langle\gamma^{t_1},\varphi\right\rangle.$$

Using the definition of $\mathbb{E}_{\gamma^t}(\cdot\mid\cdot)$ we see that (35) is equivalent to

$$\int_{t_0}^{t_1}\iint_{(\Omega_0\times\Omega_1)^2} \frac{\varphi_x(x,y)\cdot K(x,\xi)\cdot\Phi_x(\xi,\eta)}{\mu_0(x)\mu_0(\xi)}\,\mathrm{d}\gamma^t(x,y)\mathrm{d}\gamma^t(\xi,\eta)\,\mathrm{d}t = \left\langle\gamma^{t_0},\varphi\right\rangle - \left\langle\gamma^{t_1},\varphi\right\rangle. \tag{38}$$

[2]If Borel measures μ_n and ν_n on compact Hausdorff spaces X and Y, respectively, converge weakly to measures γ and ν, then the product measures $\mu_n\times\nu_n$ converge weakly to $\gamma\times\nu$. Indeed, the $\mu_n\times\nu_n$ are uniformly bounded so one only has to check $\langle\mu_n\times\nu_n, f\rangle\to\langle\gamma\times\nu, f\rangle$ for a dense set of $f\in C^0(X\times Y)$. By the Stone–Weierstraß theorem we may therefore assume that $f(x,y) = g_1(x)h_1(y)+\cdots+g_k(x)h_k(y)$ for continuous functions g_i and h_i. By linearity we may assume that $k=1$. But if $f(x,y)=g_1(x)h_1(y)$, then $\langle\mu_n\times\nu_n,f\rangle = \langle\mu_n,g_1\rangle\langle\nu_n,h_1\rangle$, which converges to $\langle\gamma,g_1\rangle\langle\nu,h_1\rangle = \langle\gamma\times\nu,f\rangle$.

All measures γ_n^t satisfy (38) since they are weak solutions. Our hypotheses are such that the integrand in the triple integral in (38) is a continuous function for any choice of the test function φ. Weak* convergence of the measures $\mathrm{d}\gamma_n^t \times \mathrm{d}\gamma_n^t \times \mathrm{d}t$ then allows us to complete the proof by passing to the limit in (35). □

7. The Helmholtz decomposition. Any vector field $w : \Omega_0 \to \mathbb{R}^d$ can be decomposed into a divergence-free part and a gradient; i.e., one can find a vector field $\mathcal{P}w$ and a function $p = p_w$ such that

$$w = \mathcal{P}w + \nabla p, \qquad \operatorname{div} \mathcal{P}w = 0 \tag{39}$$

holds. We call $\mathcal{P}w$ the *Helmholtz projection* of w, and by analogy with fluid dynamics we will call p_w the corresponding pressure. The pressure p_w is determined by (39) up to an additive constant, at best. We can remove this freedom by imposing some normalization on p_w, such as

$$\int_{\Omega_0} p_w(x)\, \mathrm{d}x = 0.$$

To uniquely specify $\mathcal{P}w$ and p_w we must impose boundary conditions: we will always require $\mathcal{P}w$ to be tangential to the boundary. Thus if ν denotes the outward unit normal to $\partial\Omega_0$, then we require

$$\nu \cdot \nabla(\mathcal{P}w) = 0, \quad \text{or, equivalently,} \quad \nu \cdot \nabla p_w = \nu \cdot w \quad \text{on } \partial\Omega_0. \tag{40}$$

A brief construction of $\mathcal{P}w$ uses Hilbert space theory. Indeed, let $\mathfrak{H}_{\mathrm{div}}$ be the closed subspace of $\mathfrak{H} = L^2(\Omega; \mathbb{R}^d)$ determined by

$$\mathfrak{H}_{\mathrm{div}} = \{w \in \mathfrak{H} \mid (w, \nabla\varphi)_{\mathfrak{H}} = 0 \text{ for all } \varphi \in C^1(\bar{\Omega})\}.$$

Then the Helmholtz projection $\mathcal{P}$ is simply the orthogonal projection of $\mathfrak{H}$ onto $\mathfrak{H}_{\mathrm{div}}$. This implies the following.

LEMMA 7.1. *The operator $\mathcal{P}$ is bounded on $\mathfrak{H}$, with $\|\mathcal{P}\|_{L(\mathfrak{H})} = 1$.*

This construction does not show how $\mathcal{P}$ preserves smoothness of the vector field w. Therefore we now recall a different description of the Helmholtz decomposition.

7.1. Smooth domains. The defining equations (39) and (40) imply

$$\begin{cases} \Delta p_w = \operatorname{div} w \ \text{ on } \Omega_0, \\ \nu \cdot \nabla p_w = \nu \cdot w \text{ on } \partial\Omega_0. \end{cases} \tag{41}$$

Standard elliptic theory tells us that under minimal smoothness assumptions on $\partial\Omega_0$ and w a solution in the weak sense exists for this boundary value problem. Moreover, the vector field $\mathcal{P}w$ defined by

$$\mathcal{P}w := w - \nabla p_w$$

is divergence free and tangential to the boundary.

LEMMA 7.2. *Assume the boundary $\partial\Omega_0$ is $C^{1,\alpha}$ smooth. Then the Helmholtz projection is a bounded operator on $C^{1,\alpha}(\Omega_0; \mathbb{R}^d)$; i.e., for any vector field $w \in C^{1,\alpha}(\Omega_0; \mathbb{R}^d)$ one has $\mathcal{P}w \in C^{1,\alpha}(\Omega_0; \mathbb{R}^d)$ and $\|\mathcal{P}w\|_{C^{1,\alpha}} \le C\|w\|_{C^{1,\alpha}}$.*

Proof. If $w \in C^{1,\alpha}$, then $w \in C^{0,\alpha}$, while $\nu \cdot w \in C^{1,\alpha}$. Furthermore the data satisfy

$$\int_{\partial\Omega_0} \nu \cdot w = \int_{\Omega_0} \operatorname{div} w,$$

so the boundary value problem (41) has a unique solution $p_w \in C^{2,\alpha}(\Omega_0)$ with $\int_{\Omega_0} p_w \, \mathrm{d}x = 0$ (see [10]). One has

$$\begin{aligned}\|p_w\|_{C^{2,\alpha}} &\leq C_{\alpha,\Omega}\left\{\|\nu \cdot \nabla p_w\|_{C^{1,\alpha}} + \|\Delta p_w\|_{C^\alpha}\right\} \\ &= C_{\alpha,\Omega}\left\{\|\nu \cdot w\|_{C^{1,\alpha}(\partial\Omega_0)} + \|\operatorname{div} w\|_{C^\alpha(\Omega_0)}\right\}\end{aligned}$$

for some constant C_{α,Ω_0}. The representation $\mathcal{P}w = w - \nabla p_w$ then implies the lemma. ∎

7.2. Helmholtz decomposition on rectangles. In the case that Ω_0 is a rectangle, i.e., $\Omega_0 = [0, L_1] \times \cdots \times [0, L_d]$, we can give a more explicit representation of the Helmholtz projection by using Fourier series.

Assume for simplicity of notation that all sides of Ω_0 have length π, i.e., $L_j = \pi$. Then one can write any $w \in \mathfrak{H}$ as a series,

$$w(x) = \sum_{j=1}^{d} \sum_{\ell_1,\ldots,\ell_d \geq 0} \hat{w}_{j,\ell_1,\ldots,\ell_d} \cos(\ell_1 x_1) \cdots \sin(\ell_j x_j) \cdots \cos(\ell_d x_d) \mathbf{e}_j. \tag{42}$$

Observe that due to the presence of the factor $\sin \ell_j x_j$ the term with $\ell = 0$, i.e., with $\ell_1 = \cdots = \ell_d = 0$, is absent from the sum. We will not try to incorporate this fact into our notation, but it will allow us to divide by $|\ell|$ in what follows.

The $L^2(\Omega_0; \mathbb{R}^d) = \mathfrak{H}$-norm of such a vector field is

$$\|w\|^2_{\mathfrak{H}} = \left(\frac{\pi}{2}\right)^d \sum_{j=1}^{d} \sum_{\ell_1,\ldots,\ell_d \geq 0} 2^{\mathsf{C}_\ell} \left|\hat{w}_{j,\ell_1,\ldots,\ell_d}\right|^2, \tag{43}$$

where C_ℓ denotes the number of components of $\ell = (\ell_1, \ldots, \ell_d)$ which vanish.

Any L^2 vector field given by (42) extends to a vector field on all of $\mathbb{R}^d$ which is 2π periodic in each of the variables $x_1, \ldots, x_d$. Moreover, any w given by (42) has the symmetry

$$w(R_j x) = R_j\big(w(x)\big) \quad \text{for } j = 1, \ldots, d, \tag{44}$$

in which R_j is the reflection $R_j(x_1, \ldots, x_d) = (x_1, \ldots, x_{j-1}, -x_j, x_{j+1}, \ldots, x_d)$. See Figure 2. Conversely, any vector field $w \in L^2\big([-\pi, \pi]^d; \mathbb{R}^d\big)$ which has the symmetries (44) can be written as a Fourier series of the form (42).

The Helmholtz projection of w is then given by

$$\mathcal{P}w(x) = \sum_{j=1}^{d} \sum_{\ell_1,\ldots,\ell_d \geq 0} \widehat{(\mathcal{P}w)}_{j,\ell_1,\ldots,\ell_d} \cos(\ell_1 x_1) \cdots \sin(\ell_j x_j) \cdots \cos(\ell_d x_d) \mathbf{e}_j, \tag{45}$$

with

$$\widehat{(\mathcal{P}w)}_{j,\ell} = \sum_{k=1}^{d} \left(\delta_{jk} - \frac{\ell_j \ell_k}{|\ell|^2}\right) \hat{w}_{j,\ell}$$

and where $|\ell|^2 = \ell_1^2 + \cdots + \ell_d^2$. The corresponding "pressure" is given by

$$p_w = \sum_{|\ell|>0} \widehat{(p_w)}_\ell \cos(\ell_1 x_1) \cdots \cos(\ell_d x_d),$$

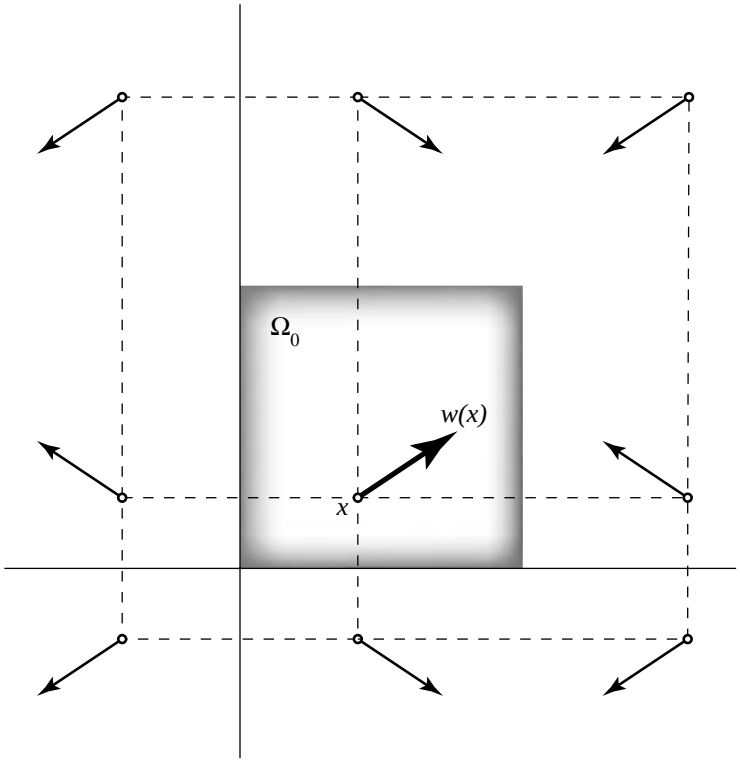

FIG. 2. *The symmetry* (44).

with

$$\widehat{(p_w)}_\ell = \frac{\ell_1 \hat{w}_{1,\ell} + \cdots + \ell_d \hat{w}_{d,\ell}}{|\ell|^2}.$$

Let $C^{1,\alpha}(\mathbb{T}^d;\mathbb{R}^d)$ be the space of all $C^{1,\alpha}$ vector fields on $\mathbb{R}^d$ which are 2π periodic in all variables $x_1, \ldots, x_d$, and let $\mathfrak{C}^{1,\alpha}$ be the closed subspace of $C^{1,\alpha}(\mathbb{T}^d;\mathbb{R}^d)$ consisting of all vector fields which have the symmetry (44).

LEMMA 7.3. *The Helmholtz projection is a bounded operator on* $C^{1,\alpha}(\mathbb{T}^d;\mathbb{R}^d)$ *which leaves the subspace* $\mathfrak{C}^{1,\alpha}$ *invariant.*

Proof. We can write $\mathcal{P}$ on $C^{1,\alpha}(\mathbb{T}^d;\mathbb{R}^d)$ as $\mathcal{P} = \mathrm{I} - \mathrm{grad} \circ (\Delta)^{-1} \circ \mathrm{div}$, where for any f with $\int_{[-\pi,\pi]^d} f \mathrm{d}x = 0$ we define $u = (\Delta)^{-1} f$ to be the unique solution of $\Delta u = f$ with $\int_{[-\pi,\pi]^d} u \mathrm{d}x = 0$. Classical Schauder estimates imply that $(\Delta)^{-1}$ is bounded from $C^{0,\alpha}$ to $C^{2,\alpha}$. This implies that $\mathcal{P} = \mathrm{I} - \mathrm{grad} \circ (\Delta)^{-1} \circ \mathrm{div}$ is bounded on $C^{1,\alpha}$ vector fields.

The Helmholtz decomposition is easily seen to commute with the symmetries (44), so that $\mathfrak{C}^{1,\alpha}$ is an invariant subspace. ∎

8. The smoothing operator $\mathcal{A}$. In this section, we exhibit smoothing operators $\mathcal{A}$ which satisfy all assumptions made so far.

8.1. Smoothing vector fields on $C^{1,\alpha}$ domains. Many different smoothing operators can be constructed. The following is one choice.

LEMMA 8.1. *Let Ω_0 be a domain with $C^{1,\alpha}$ boundary, and let $\mathcal{A}_\varepsilon$ be the operator*

$$\mathcal{A}_\varepsilon = e^{\varepsilon\Delta_N},\ \textit{i.e.,}\ \mathcal{A}_\varepsilon w = \big(e^{\varepsilon\Delta_N} w_1, \dots, e^{\varepsilon\Delta_N} w_d\big),$$

where Δ_N is the Neumann–Laplacian on Ω_0.

Then $\mathcal{A}_\varepsilon$ is a bounded, injective, self-adjoint operator on $\mathfrak{H}$, with $\|A_\varepsilon\|_{L(\mathfrak{H})} \le 1$ for any $\varepsilon > 0$.

The operator $\mathcal{A}_\varepsilon$ is also bounded from $C^{1,\alpha}$ to $C^{1,\alpha}$, with $\|\mathcal{A}_\varepsilon\|_{L(C^{1,\alpha})} \le C$ for some C that does not depend on $\varepsilon > 0$.

Proof. The operator $\mathcal{A}_\varepsilon$ acts on each individual component w_i of a vector field w in the same way. The fact that $e^{\varepsilon\Delta_N}$ is a contraction of L^2 and uniformly bounded on $C^{1,\alpha}$ respectively follows from linear parabolic theory.

The Neumann Laplacian is well known to be a self-adjoint operator on $L^2(\Omega_0)$, so that $\mathcal{A}_\varepsilon$ is self-adjoint. Self-adjointness of Δ_N implies via the spectral theorem for self-adjoint operators that $e^{\varepsilon\Delta_N}$ is injective for all $\varepsilon > 0$. □

LEMMA 8.2. *Let $\mathcal{A}$ be as above.*

The operator $\mathcal{P}\mathcal{A}^2\mathcal{P}$ is bounded from $\mathfrak{H}$ to $C^{1,\alpha}(\Omega;\mathbb{R}^d)$ for any $0 < \alpha < 1$.

The operator $\mathcal{P}\mathcal{A}^2\mathcal{P}$ has an integral kernel $K \in C^{1,\alpha}(\bar\Omega_0 \times \bar\Omega_0)$.

Proof. Boundedness of $\mathcal{A} : \mathfrak{H} \to C^{1,\alpha}$ follows from the smoothing property of the heat equation. (But the operator norm $\|\mathcal{A}\|_{L(\mathfrak{H},C^{1,\alpha})}$ blows up as $\varepsilon \searrow 0$.) Since $\mathcal{P}$ is bounded on both $\mathfrak{H}$ and $C^{1,\alpha}$ it follows that $\mathcal{P}\mathcal{A}^2\mathcal{P}$ is bounded from $\mathfrak{H}$ to $C^{1,\alpha}$.

To study the kernel of the operator $\mathcal{P}\mathcal{A}^2\mathcal{P}$ we write $\mathcal{P}\mathcal{A}^2\mathcal{P}$ as $T \circ T^*$, where $T = \mathcal{P}\mathcal{A}$, and show that T has an integral kernel.

Let $\Gamma_\varepsilon^y(x)$ be the heat kernel for Δ_N; i.e., for any function $\phi \in L^1(\Omega_0)$ one has

$$e^{\varepsilon\Delta_N} f(x) = \int_{\Omega_0} \phi(y)\Gamma_\varepsilon^y(x)\,\mathrm{d}y. \tag{46}$$

Then $(x,y) \mapsto \Gamma^y(x)$ is a $C^{1,\alpha}$ function.

We expand the vector-valued function f into its components, $f(x) = f_1(x)\mathbf{e}_1 + \cdots + f_d(x)\mathbf{e}_d$, $f_1, \dots, f_d$ being scalar L^2 functions. From (46) we then get the following representation for $\mathcal{P}\mathcal{A}f$:

$$\mathcal{P}\mathcal{A}f = \sum_{j=1}^{d} \int_{\Omega_0} f_j(y)\mathcal{P}(\Gamma_\varepsilon^y \otimes \mathbf{e}_j)\,\mathrm{d}y.$$

Let $N_j^y(x)$ be the function $N_j^y = \mathcal{P}(\Gamma_\varepsilon^y \otimes \mathbf{e}_j)$. We get

$$\mathcal{P}\mathcal{A}f(x) = \int_{\Omega_0} \sum_{j=1}^{d} N_j^y(x) f_j(y)\,\mathrm{d}y,$$

which means that $\mathcal{P}\mathcal{A}$ is an integral operator with matrix-valued kernel

$$\mathsf{N}(x,y) = \big[N_1^y(x), \dots, N_d^y(x)\big];$$

i.e., the jth column of the matrix $\mathsf{N}(x,y)$ is $N_j^y(x)$.

For each $y \in \Omega_0$ we have $\Gamma_\varepsilon^y \in C^{1,\alpha}(\bar\Omega_0)$, so by Lemma 7.2 we get $\mathcal{P}\Gamma_\varepsilon^y \in C^{1,\alpha}(\bar\Omega_0;\mathbb{R}^d)$. Moreover, $\Gamma_\varepsilon^y \in C^{1,\alpha}(\bar\Omega_0;\mathbb{R}^d)$ depends $C^{1,\alpha}$ smoothly on y, so we see that the kernel N is a $C^{1,\alpha}$ function on $\bar\Omega_0 \times \bar\Omega_0$.

The operator $\mathcal{P}\mathcal{A}^2\mathcal{P} = (\mathcal{P}\mathcal{A})(\mathcal{P}\mathcal{A})^*$ must now also be an integral operator, and its kernel must be

$$K(x,\xi) = \int_{\Omega_0} \mathsf{N}(x,y)\mathsf{N}(\xi,y)^T \, \mathrm{d}y.$$

This is clearly again a $C^{1,\alpha}$ function on $\bar{\Omega}_0 \times \bar{\Omega}_0$. ∎

The operators $\mathcal{A}_\varepsilon$ do not preserve the boundary condition $n \cdot w = 0$, so they will not commute with the Helmholtz projection $\mathcal{P}$.

8.2. Smoothing operator on a rectangle. In the case that Ω_0 is a rectangle, i.e., $\Omega_0 = [0,\pi]^d$, we can construct a different smoothing operator by using the Fourier series (42).

We define the smoothing operator $\mathcal{A}_\varepsilon$ by

$$\mathcal{A}_\varepsilon w = \big(e^{\varepsilon\Delta_1} w_1, \ldots, e^{\varepsilon\Delta_d} w_d\big),$$

in which Δ_j is the Laplacian with Neumann boundary conditions on the sides $x_j = 0$ and $x_j = \pi$, and Dirichlet boundary conditions on all other sides of the rectangle Ω_0.

An equivalent description of $\mathcal{A}_\varepsilon$ goes like this: to compute $\mathcal{A}_\varepsilon w$ for some vector field w on $\Omega_0 = [0,\pi]^d$ extend w to a vector field $\tilde{w}$ on all of $\mathbb{R}^d$ by imposing the symmetries (44) and by requiring the extension to be 2π periodic in all variables. We then set $\mathcal{A}_\varepsilon = e^{\varepsilon\Delta}\tilde{w}$, in which $e^{\varepsilon\Delta}$ is the standard heat semigroup on $\mathbb{R}^d$; i.e., we have

$$\mathcal{A}_\varepsilon w(x) = \big(4\pi\varepsilon\big)^{-d/2} \int_{\mathbb{R}^d} e^{-|x-\xi|^2/4\varepsilon} \tilde{w}(\xi) \, \mathrm{d}\xi. \tag{47}$$

If w is given by the Fourier series (42), then $\mathcal{A}_\varepsilon w$ is given by

$$\mathcal{A}_\varepsilon w(x) = \sum_{j=1}^{d} \sum_{\ell_1,\ldots,\ell_d \geq 0} \widehat{(\mathcal{A}_\varepsilon w)}_{j,\ell_1,\ldots,\ell_d} \cos(\ell_1 x_1) \cdots \sin(\ell_j x_j) \cdots \cos(\ell_d x_d) \mathbf{e}_j,$$

with

$$\widehat{(\mathcal{A}_\varepsilon w)}_{j,\ell} = e^{-\varepsilon|\ell|^2} \hat{w}_{j,\ell}. \tag{48}$$

LEMMA 8.3. *The smoothing operators $\mathcal{A}_\varepsilon$ are uniformly bounded on $\mathfrak{H}$ and $\mathfrak{C}^{1,\alpha}$. They are self-adjoint and injective, and they commute with the Helmholtz projection.*

Proof. The statements concerning the behavior of the operators on the Hilbert space $\mathfrak{H}$ follow directly from the series expansion (42), the Fourier multiplier descriptions (45) and (47) of $\mathcal{P}$ and $\mathcal{A}_\varepsilon$, respectively, and the Plancherel identity (43).

The $C^{1,\alpha}$ bounds follow from the representation (47). ∎

LEMMA 8.4. *Let $\mathcal{A} = \mathcal{A}_\varepsilon$ be as above.*

The operator $\mathcal{P}\mathcal{A}^2\mathcal{P}$ is bounded from $\mathfrak{H}$ to $\mathfrak{C}^{1,\alpha}(\Omega;\mathbb{R}^d)$ for any $0 < \alpha < 1$.

The operator $\mathcal{P}\mathcal{A}^2\mathcal{P}$ has an integral kernel $K \in C^{1,\alpha}(\bar{\Omega}_0 \times \bar{\Omega}_0)$.

The kernel $K(x,\xi)$ satisfies

$$K(R_j x, \xi) = R_j K(x,\xi), \qquad j = 1,\ldots,d. \tag{49}$$

Proof. This lemma is analogous to Lemma 8.2, and its proof proceeds along the same lines.

Boundedness from $\mathfrak{H}$ to $\mathfrak{C}^{1,\alpha}$ again follows from the smoothing property of the heat equation, i.e., of $e^{\varepsilon\Delta}$. The integral kernel is constructed in the same way, starting from the explicit representation (47) of $e^{\varepsilon\Delta}w$.

For any vector field $f \in \mathfrak{H}$ the smoothed-out projection $w = \mathcal{P}\mathcal{A}^2\mathcal{P}f$ belongs to $\mathfrak{C}^{1,\alpha}$. We therefore may conclude from $w(R_jx) \equiv R_jw(x)$ that

$$\int_{\Omega_0} K(R_jx,\xi)f(\xi)\,\mathrm{d}\xi = R_j\int_{\Omega_0} K(x,\xi)f(\xi)\,\mathrm{d}\xi$$

for all $x \in \mathbb{R}^d$, $j = 1, \ldots, d$, and all $f \in \mathfrak{H}$. This implies (49). □

9. Existence and well-posedness for the regularized flow. In this section, we construct classical solutions γ^t of the initial value problem (24) by writing them as $\gamma^t = (s^t \times \mathrm{id})_\#(\gamma^0)$ and solving the initial value problem (30)

$$\left.\begin{aligned} &\frac{\partial s^t}{\partial t} = -\int_{\Omega_0\times\Omega_1} \frac{K(s^t(x),s^t(\xi))}{\mu_0(s^t(x))\mu_0(s^t(\xi))}\cdot\Phi_x(s^t(\xi),\eta)\,\mathrm{d}\gamma^0(\xi,\eta), && (50)\\ &s^0(x) = x \quad (x\in\Omega) && (51)\end{aligned}\right\}$$

for s^t.

THEOREM 9.1. *Let the cost function Φ be C^1. Assume also that the smoothing operator $\mathcal{A}$ is such that the kernel K is $C^{1,\alpha}$. Then for any initial measure $\gamma^0 \in \mathfrak{X}$ the initial value problem* (50) *has a solution $\{s^t \in C^{1,\alpha}(\bar\Omega_0;\bar\Omega_0) : 0 \le t < \infty\}$.*

If the cost function Φ is C^2, then the solution $\{s^t : t \ge 0\}$ is unique.

We begin the proof by observing that (50) is of the form

$$\frac{\partial s^t}{\partial t} = \int_{\Omega_0\times\Omega_1} F(s^t(x),s^t(\xi);\xi,\eta)\,\mathrm{d}\gamma^0(\xi,\eta), \tag{52}$$

where the map $F : \Omega_0\times\Omega_0\times\Omega_0\times\Omega_1 \to \mathbb{R}^d$ is given by

$$F(s,\sigma;\xi,\eta) = \frac{K(s,\sigma)\cdot\Phi_x(\sigma,\eta)}{\mu_0(s)\mu_0(\sigma)}. \tag{53}$$

If $\Omega_0 = [0,\pi]^d$ is a rectangle, then $K(s,\sigma)$ is defined for all $s \in \mathbb{R}^d$. We agree to extend $\mu_0(x)$ to be 2π periodic and even in each variable so that $F(s,\sigma;\xi,\eta)$ is also defined for $s \in \mathbb{R}^d$.

LEMMA 9.2.

(A) *The map $(s,\sigma;\xi,\eta) \mapsto F(s,\sigma;\xi,\eta)$ is continuous.*

(B) *$F(s,\sigma;\xi,\eta)$ is also C^1 in $s \in \Omega_0$, and the partial derivative $\frac{\partial F}{\partial s}$ is uniformly bounded:*

$$\left|\frac{\partial F}{\partial s}(s,\sigma;\xi,\eta)\right| \le C, \tag{54}$$

with $C < \infty$ independent of s, σ, ξ, and η.

(C1) *If $\partial\Omega_0$ is $C^{1,\alpha}$ smooth, and if $s \in \partial\Omega_0$, then $s\cdot F(s,\sigma,\xi,\eta) = 0$ for all $\sigma,\xi \in \Omega_0$ and $\eta \in \Omega_1$.*

(C2) *If $\Omega_0 = [0,\pi]^d$, then $F(s,\sigma;\xi,\eta)$ is 2π periodic in each component of $s = (s_1,\ldots,s_d)$, and $s \mapsto F(s,\sigma;\xi,\eta)$ satisfies the symmetries* (44), *i.e.,*

$$F(R_js,\sigma;\xi,\eta) = R_jF(s,\sigma;\xi,\eta).$$

Proof. (A) and (B) are immediate from the representation (53), the known continuity and smoothness properties of the kernel K, and the cost function Φ.

(C1). The kernel $K(x,\xi)$ satisfies $x \cdot K(x,\xi) = 0$, since for any vector field $w \in L^2(\Omega;\mathbb{R}^d)$ the vector field $\mathcal{P}\mathcal{A}^2\mathcal{P}w(x) = \int_{\Omega_0} K(x,\xi)w(\xi)d\xi$ is everywhere tangent to $\partial\Omega$. This implies

$$x \cdot \mathcal{P}\mathcal{A}^2\mathcal{P}w(x) = \int_{\Omega_0} x \cdot K(x,\xi) \cdot w(\xi)d\xi = 0$$

for arbitrary w, which can happen only if $x \cdot K(x,\xi) \equiv 0$. Equation (53) then implies (C1).

The kernel $K(s,\sigma)$ and the density $\mu_0(s)$ are periodic and have the appropriate symmetries, so (C2) follows immediately from (53). □

9.1. Construction of a solution to (50). We regard the initial value problem (50) as a fixed point problem for the map $\mathcal{F} : \sigma \mapsto s$, where $s = \mathcal{F}(\sigma)$ is the solution of the ODE

$$\frac{\partial s^t(x)}{\partial t} = \int_{\Omega_0} F(s^t(x), \sigma^t(\xi), \xi, \eta)\ \mathrm{d}\gamma^0(\xi,\eta),$$

with initial data $s^0 = \mathrm{id}$, i.e., $s^0(x) \equiv x$.

To set up a fixed point argument (and, in particular, to use the Brouwer–Leray–Schauder fixed point theorem) we must overcome a technical difficulty, namely, the space of maps $\{s^t : \Omega_0 \to \Omega_0, 0 \le t \le T\}$ is not a linear space, since the target Ω_0 is not a vector space. To deal with this we extend the domain of the definition of the nonlinear map $F(s,\sigma;\xi,\eta)$ to include all $(s,\sigma,\xi,\eta) \in \mathbb{R}^d \times \mathbb{R}^d \times \Omega_0 \times \Omega_1$; in other words, we lift the restriction $s,\sigma \in \Omega_0$. Then we can regard maps $s^t : \Omega_0 \to \Omega_0$ as maps $s^t : \Omega_0 \to \mathbb{R}^d$, and the space of such maps (defined below as $\mathcal{C}_T$) is a vector space.

We only have to go through this extension process in the case where Ω_0 is a smoothly bounded domain. When Ω_0 is a rectangle the function $F(s,\sigma;\xi,\eta)$ is already defined for all $s,\sigma \in \mathbb{R}^d$.

9.1.1. Extending *F*. We choose a defining function $\varrho \in C^{1,\alpha}(\mathbb{R}^d)$ for Ω_0. This means that $\Omega_0 = \{x \in \mathbb{R}^d : \varrho(x) > 0\}$ and $\nabla\varrho \neq 0$ on $\partial\Omega_0$. We can choose ϱ so that $\nabla\varrho(x) \neq 0$ if $-1 \le \varrho(x) \le 1$, while $\varrho(x) = -2$ outside some compact set $K \supset \bar{\Omega}_0$.

Let $U = \{x \in \mathbb{R}^d : \varrho(x) \ge -1\}$, and choose a retraction $\pi : U \to \bar{\Omega}_0$. One possible choice is $\pi(x_0) = x_0$ for $x_0 \in \bar{\Omega}_0$, and

$$\pi(x_0) = \left\{ \begin{matrix} \text{the first point in } \bar{\Omega}_0 \text{ on the orbit } x(t) \text{ of} \\ \text{the gradient flow } \dot{x} = \nabla\varrho(x) \text{ which starts} \\ \text{at } x(0) = x_0 \in U \setminus \bar{\Omega}_0 \end{matrix} \right\}$$

for all $x_0 \in U \setminus \bar{\Omega}_0$. The retraction π is Lipschitz continuous on U and even C^1 on $U \setminus \partial\Omega_0$.

The extension F_* of F will now be defined in several stages. First we introduce a map $F_1 : U \times U \times \Omega_0 \times \Omega_1 \to \mathbb{R}^d$ given by

$$F_1(s,\sigma,\xi,\eta) = F(\pi(s),\pi(\sigma),\xi,\eta).$$

Next, let $\chi : \mathbb{R} \to \mathbb{R}$ be a Lipschitz cutoff function, e.g., $\chi(t) = 1$ for $t \ge 0$, $1 + t$ for $-1 \le t \le 0$, and 0 for $t \ge -1$. Put

$$F_2(s,\sigma,\xi,\eta) = \chi(\varrho(s))\chi(\varrho(\sigma))F_1(s,\sigma,\xi,\eta)$$

when $(s,\sigma) \in U \times U$, and $F_2(s,\sigma,\xi,\eta) = 0$ otherwise. Then $F_2 : \mathbb{R}^d \times \mathbb{R}^d \times \Omega_0 \times \Omega_1 \to \mathbb{R}^d$ is an extension of F which is uniformly Lipschitz continuous in $(s,\sigma) \in \mathbb{R}^d \times \mathbb{R}^d$ and continuous in $\xi \in \Omega_0$, $\eta \in \Omega_1$.

Finally, we define $F_* : \mathbb{R}^d \times \mathbb{R}^d \times \Omega_0 \times \Omega_1 \to \mathbb{R}^d$ by setting

$$F_*(s,\sigma,\xi,\eta) = \begin{cases} F_2 & \text{for } s \in \bar{\Omega}_0, \\ F_2 - \dfrac{\nabla\varrho(s)\cdot F_2}{|\nabla\varrho(s)|^2}\nabla\varrho(s) & \text{for } s \in U \setminus \bar{\Omega}_0, \\ 0 & \text{for } s \in \mathbb{R}^d \setminus U, \end{cases} \tag{55}$$

where $F_2 = F_2(s,\sigma,\xi,\eta)$.

LEMMA 9.3. *The extension $F_* : \mathbb{R}^d \times \mathbb{R}^d \times \Omega_0 \times \Omega_1 \to \mathbb{R}^d$ of F is continuous in (s,σ) and uniformly Lipschitz in $s \in \mathbb{R}^d$; i.e., for all $\sigma \in \mathbb{R}^d$ and $\xi \in \Omega_0$, $\eta \in \Omega_1$ one has*

$$|F_*(s,\sigma,\xi,\eta) - F_*(s',\sigma,\xi,\eta)| \le M|s-s'| \tag{56}$$

for some $M < \infty$. Furthermore, F_* is uniformly bounded,

$$|F_*(s,\sigma,\xi,\eta)| \le M' \tag{57}$$

for some constant $M' < \infty$ and for all $s,\sigma \in \mathbb{R}^d$ and $\xi \in \Omega_0$, $\eta \in \Omega_1$.

If the cost function Φ is C^2, then $F_*(s,\sigma,\xi,\eta)$ is uniformly Lipschitz in $(s,\sigma) \in \mathbb{R}^d$; i.e., for some finite M'' one has

$$|F_*(s,\sigma,\xi,\eta) - F_*(s',\sigma',\xi,\eta)| \le M''\{|s-s'| + |\sigma-\sigma'|\} \tag{58}$$

for all $s,s',\sigma,\sigma' \in \mathbb{R}^d$ and $\xi \in \Omega_0$, $\eta \in \Omega_1$.

Finally, F_* satisfies

$$\nabla\varrho(s)\cdot F_*(s,\sigma,\xi,\eta) = 0 \quad \textit{when} \quad \varrho(s) \le 0. \tag{59}$$

9.1.2. The fixed point argument. We prove existence and uniqueness of solutions for the case where $\partial\Omega_0$ is $C^{1,\alpha}$ smooth. The same arguments with minor modifications apply to the case $\Omega_0 = [0,\pi]^d$.

With the extended F in hand we can set up the fixed point problem. Let $\mathcal{C}_T$ be the Banach space

$$\mathcal{C}_T = C^0([0,T]\times\Omega_0;\mathbb{R}^d).$$

LEMMA 9.4 (definition of $\mathcal{F}$). *Let $\sigma \in \mathcal{C}_T$ be given. Define $s = \mathcal{F}(\sigma)$ to be the solution of*

$$\frac{\partial s^t}{\partial t} = \int_{\Omega_0} F_*(s^t(x),\sigma^t(\xi);\xi,\eta)\,\mathrm{d}\gamma^0(\xi,\eta), \qquad s^0(x) = x. \tag{60}$$

Then

$$\left|\frac{\partial s^t}{\partial t}\right| \le M'|\Omega_0| \tag{61}$$

and

$$|s^t(x) - s^t(x')| \le e^{M|\Omega_0|t}|x-x'|. \tag{62}$$

Proof. Equation (60) is an ODE for $s^t(x)$ of the form $\partial_t s^t = v^t(s^t)$, where

$$v^t(s) = \int_{\Omega_0} F_*(s, \sigma^t(\xi); \xi, \eta)\, \mathrm{d}\gamma^0(\xi, \eta).$$

The estimates (56) and (57) for F_* imply that $|v^t(s)| \le M'|\Omega_0|$ and $|v^t(s) - v^t(s')| \le M|\Omega_0||s - s'|$. Standard theorems for ODEs then imply (61), (62). ∎

LEMMA 9.5. *Let s^t, $0 \le t \le T$, be the solution of (60) for some $\sigma \in \mathcal{C}_T$. Then the s^t are C^1 diffeomorphisms of $\bar\Omega_0$.*

Proof. The s^t are the flow of a vector field v^t, so we only have to show that $s^t(\bar\Omega_0) = \bar\Omega_0$. But our construction of F_* is such that $v^t(s) \cdot \nabla\varrho(s) = 0$ whenever $\varrho(s) \le 0$. Indeed, one has

$$v^t(s) \cdot \nabla\varrho(s) = \int_{\Omega_0} \nabla\varrho(s) \cdot F_*(s, \sigma^t(\xi); \xi, \eta)\, \mathrm{d}\gamma^0(\xi, \eta) = 0$$

by (59). Therefore ϱ is a conserved quantity outside of Ω_0, and in particular $\partial\Omega_0$ is invariant under the flow of v^t. So $s^t(\bar\Omega_0) = \bar\Omega_0$.

Since the vector field v^t is C^1 on $\bar\Omega$ the flow s^t is also C^1. ∎

Existence. The estimates (61) and (62) imply that $\mathcal{F}$ maps all of $\mathcal{C}_T$ into a compact subset of $\mathcal{C}_T$. Hence the Brouwer–Leray–Schauder fixed point theorem applies, and we can conclude the existence of a fixed point $s_T \in \mathcal{C}_T$ for $\mathcal{F}$. The initial value problem for the rearrangement map s^t therefore has a solution on any finite time interval $0 \le t \le T$. Since we have not established uniqueness of the solution, the solutions s_T might actually depend on T. However, they all satisfy the a priori estimates (61), (62) so, as $T \nearrow \infty$, one can extract a subsequence which converges uniformly on any finite time interval. The limit of this subsequence is then a global solution $\{s^t\}_{t\ge0}$.

Uniqueness. If the cost function Φ is C^2, then there is only one solution. To see this let $s, \bar s \in \mathcal{C}_T$ be any two solutions and consider their difference $w^t(x) = s^t(x) - \bar s^t(x)$.

Both s and $\bar s$ are solutions to (52), so subtracting the two equations we get

$$|\partial_t w^t(x)| \le M''|\Omega_0| \sup_{\xi\in\Omega_0} |w^t(\xi)|,$$

where we have used that $F_*(s, \sigma, \xi, \eta)$ is uniformly Lipschitz in $(s, \sigma) \in \mathbb{R}^d \times \mathbb{R}^d$ (by (58)).

This implies that $\sup|w^t| \le e^{M''|\Omega_0|t} \sup|w^0|$. Since $w^0 = s^0 - \bar s^0 = 0$ we find that $w^t \equiv 0$.

9.2. The regularized flow on $\mathfrak{X}$. If the cost function Φ is C^2, then there is another way of proving existence and uniqueness of solutions to (50). Namely, we observe that (50) is an ODE on a Banach space. One can write (50) as

$$\frac{\partial s^t}{\partial t} = \mathrm{V}(s),$$

where V is given by

$$\mathrm{V}(s)(x) = \iint_{\Omega_0\times\Omega_1} F_*(s^t(x), s^t(\xi); \xi, \eta)\, \mathrm{d}\gamma^0(\xi, \eta).$$

Here F_* is the extension of F constructed in section 9.1.1.

The properties of F_* derived in Lemma 9.3 imply that V is a globally Lipschitz vector field on the Banach space $\mathfrak{Z} = C^0(\bar{\Omega}_0; \mathbb{R}^d)$. It follows immediately that $\partial_t s^t = \mathrm{V}(s^t)$ generates a global flow on $\mathfrak{Z}$, since $t \mapsto s^t(x)$ is a solution of the ODE

$$\frac{ds}{dt} = v^t(s),$$

where

$$v^t(\sigma) = \iint_{\Omega_0 \times \Omega_1} F_*(\sigma, s^t(\xi); \xi, \eta)\, \mathrm{d}\gamma^0(\xi, \eta).$$

Thus $s^t = S^t \circ s^0$, where S^t is the flow of the vector field v^t.

9.3. ω-limit sets of the regularized flow. Let $\gamma^0 \in \mathfrak{X}$ be any initial measure, and let $\{\gamma^t, t \geq 0\}$ be a solution of (24) starting at γ^0. In dynamical systems one defines the ω-limit set of the solution $\{\gamma^t\}$ to be

$$\omega(\{\gamma^t\}) = \big\{\lambda \in \mathfrak{X} \mid \exists t_k \nearrow \infty : \gamma^{t_k} \rightharpoonup \lambda\big\} = \bigcap_{s \geq 0} \overline{\{\gamma^t \mid t \geq s\}}.$$

The second description shows that $\omega(\{\gamma^t\})$ is a closed (hence compact) and connected subset of $\mathfrak{X}$.

PROPOSITION 9.6. *$\omega(\{\gamma^t\})$ consists of critical points for* (24).

Proof. For given $\lambda \in \omega(\{\gamma^t\})$ we choose a sequence $t_k \nearrow \infty$ with $\gamma^{t_k} \rightharpoonup \lambda$ and consider the weak solutions $\lambda_k^t = \gamma^{t_k + t}$. By Lemma 6.4 we can find a subsequence t_{k_j} for which the λ_k^t weak* converge to a new weak solution $\lambda_\dagger^t$. The $\lambda_\dagger^t$, being weak solutions, satisfy the energy identity from Lemma 5.1. Furthermore,

$$M(\lambda_\dagger^t) = \lim_{j \to \infty} M(\lambda_{k_j}^t) = \lim_{j \to \infty} M(\gamma^{t_{k_j} + t}) = \lim_{t \to \infty} M(\gamma^t),$$

where the latter limit must exist since $M(\gamma^t)$ is a nonincreasing and bounded quantity.

The energy identity for $\lambda_\dagger^t$ together with constancy of $M(\lambda_\dagger^t)$ imply that the $\lambda_\dagger^t$ are critical points. In particular, $\lambda_\dagger^0 = \lim_{j \to \infty} \gamma^{t_{k_j}} = \lambda$ must be a critical point, as claimed. ∎

10. The unregularized flow. In the unregularized case, where one takes $\mathcal{A} = I_{\mathfrak{H}}$, one can try to construct weak solutions of (35) by solving the equation for a sequence of smoothing operators $\mathcal{A}$ which approximate the identity, and extract a weak limit of the solutions of the regularized equations. In this section, we study the limits of weak solutions which arise in this way. Although we do not show they are weak solutions, these limits still have many of the properties of weak solutions.

10.1. Choice of $\mathcal{A}_\varepsilon$. We let $\mathcal{A}_\varepsilon$ be given by the heat equation with Neumann boundary conditions, $\mathcal{A}_\varepsilon = e^{\varepsilon \Delta_N}$. It is classical that the heat equation defines a strongly continuous semigroup on $L^2(\Omega_0; \mathbb{R}^d)$, so that the $\mathcal{A}_\varepsilon$ converge strongly to the identity operator on $\mathfrak{H}$ as $\varepsilon \searrow 0$.

If Ω_0 is a rectangle, then we choose $\mathcal{A}_\varepsilon$ as in (47), (48).

10.2. Construction of a generalized solution. Let $\gamma^0 \in \mathfrak{X}$ be a given initial measure, and denote by $\{\gamma_\varepsilon^t, t \geq 0\}$ the global solutions to (35) with $\mathcal{A} = \mathcal{A}_\varepsilon$ which exist by Theorem 9.1.

Lemma 6.1 provides us with a convergent sequence $\gamma_{\varepsilon_k}^t$: write $\gamma_\dagger^t$ for the weak limit. We declare this family of measures to be a generalized solution of (24).

By Proposition 6.2 any generalized solution we construct in this way satisfies the energy inequality (37). Thus a generalized solution decreases the cost functional at least as fast as a smooth solution would, i.e.,

$$\frac{d}{dt}M(\gamma_\dagger^t) \le -\left\|\mathcal{P}\mathbb{E}_{\gamma_\dagger^t}(\Phi_x \mid x)\right\|_{\mathfrak{H}}^2.$$

10.3. ω-limit sets of generalized solutions. We define

$$\omega(\{\gamma_\dagger^t, t \ge 0\}) = \left\{\lambda \in \mathfrak{X} \mid \exists t_j \nearrow \infty : \gamma_\dagger^{t_j} \rightharpoonup \lambda\right\} = \bigcap_{s\ge 0} \overline{\{\gamma_\dagger^t \mid t \ge s\}}.$$

PROPOSITION 10.1. *The ω-limit set of a generalized solution is a closed and connected subset of $\mathfrak{X}$ which consists of critical points for the Monge–Kantorovich functional.*

Proof. Connectedness and closedness follow through entirely conventional arguments from the second description of $\omega(\{\gamma_\dagger^t\})$ given above.

Let $\nu \in \omega(\{\gamma_\dagger^t\})$ be given. Choose a sequence of times $t_k \nearrow \infty$ from which $\gamma_\dagger^{t_k} \rightharpoonup \nu$, and consider the families of measures $\nu_k^t = \gamma_\dagger^{t_k+t}$, $t \in \mathbb{R}$. The arguments in the proof of Proposition 6.2 imply that we can select a subsequence $\nu_{k_j}^t$ which weak* converges for all t. The limit $\nu_\dagger^t$ of this subsequence again satisfies the energy inequality. Moreover, the cost functional is constant on $\nu_\dagger^t$, since

$$M(\nu_\dagger^t) = \lim_{k\to\infty} M(\gamma_\dagger^{t_k+t}) = \lim_{t\to\infty} M(\gamma_\dagger^t).$$

The last limit must exist because $M(\gamma_\dagger^t)$ is a nonincreasing bounded quantity.

The energy inequality for $\nu_\dagger^t$ states that

$$\int_{t_0}^{t_1} \|\mathcal{P}\mathbb{E}_{\nu_\dagger^t}(\Phi_x \mid x)\|_{\mathfrak{H}}^2 \,\mathrm{d}t \le M(\nu_\dagger^{t_0}) - M(\nu_\dagger^{t_1}) = 0$$

so that $\mathcal{P}\mathbb{E}_{\nu_\dagger^t}(\Phi_x \mid x) = 0$ for almost all t. Weak* continuity of ν^t with respect to t strengthens this to $\mathcal{P}\mathbb{E}_{\nu_\dagger^t}(\Phi_x \mid x) = 0$ for all t.

Recalling that $\nu = \nu_\dagger^0$, we conclude that $\mathcal{P}\mathbb{E}_\nu(\Phi_x \mid x) = 0$; i.e., $\nu \in \omega(\{\gamma_\dagger^t\})$ is a critical point. ∎

11. The unregularized flow—smooth solutions. If we omit the smoothing operator, i.e., if we set $\mathcal{A} = I_{\mathfrak{H}}$, then (30) for the rearrangement map s^t,

$$\frac{\partial s^t(x)}{\partial t} = -\int_{\Omega_0\times\Omega_1} \frac{K(s^t(x), s^t(\xi))}{\mu_0(s^t(x))\mu_0(s^t(\xi))} \cdot \Phi_x(s^t(\xi), \eta)\,\mathrm{d}\gamma^0(\xi,\eta),$$

is highly singular, since the kernel K now is the kernel of the Helmholtz projection. The fixed point arguments of section 9 no longer work. Nonetheless, it turns out that a short time existence theorem for solutions of this equation *does* hold if one assumes the initial data are sufficiently regular. In this section we prove such a theorem.

We will assume in this section that the measures γ^t are all defined by measure preserving maps $u^t : \Omega_0 \to \Omega_1$, i.e., $\gamma^t = (\mathrm{id} \times u^t)_\#(\mu_0)$.

Our strategy will be to consider the regularized equation in which $\mathcal{A} = \mathcal{A}_\varepsilon$ is given by a heat operator, as in section 10.1. For each positive ε we have already shown that a global solution exists. The heart of this section is an estimate for how fast the $C^{1,\alpha}$

norm of the map u_ε^t grows with time. The estimate is independent of the mollifying parameter ε if the initial data is smooth. Letting $\varepsilon \searrow 0$ then gives an estimate and short time existence result in $C^{1,\alpha}$ for the unregularized equation.

LEMMA 11.1. *Let $s^t : \Omega_0 \to \Omega_0$ be a solution of the regularized equation* (30) *with $s^0 = \mathrm{id}$. If the initial map $u^0 : \Omega_0 \to \Omega_1$ is $C^{1,\alpha}$, then s^t remains $C^{1,\alpha}$ for a short time $T_* > 0$, and one has $\|\mathrm{d}s^t\|_{0,\alpha} \le C_*$ for $0 \le t \le T_*$, where C_* and T_* depend on the initial data but not on $\varepsilon > 0$.*

11.1. Notation for Hölder norms. For any map $f : \Omega_0 \to \mathbb{R}^N$, we write

$$\begin{aligned}
[f]_\alpha &= \sup_{x,x' \in \Omega_0} \frac{|f(x) - f(x')|}{|x - x'|^\alpha}, \\
\|f\|_{0,\alpha} &= \|f\|_\infty + [f]_\alpha, \\
\|f\|_{1,\alpha} &= \|f\|_\infty + \|\mathrm{d}f\|_\infty + [f]_\alpha.
\end{aligned}$$

The Hölder seminorm $[\cdot]_\alpha$ satisfies the "product-rule estimate,"

$$[f \cdot g]_\alpha \le \|f\|_\infty [g]_\alpha + \|g\|_\infty [f]_\alpha,$$

which one easily derives from $f(x)g(x) - f(y)g(y) = f(x)g(x) - f(x)g(y) + f(x)g(y) - f(y)g(y)$. One then also finds

$$\|f \cdot g\|_{0,\alpha} \le \|f\|_{0,\alpha}\, \|g\|_{0,\alpha}.$$

11.2. Estimates of inverses and compositions. The following proposition shows that we will never have to bother with the case of small $\|s\|_\infty$.

PROPOSITION 11.2. *If $s : \bar\Omega_0 \to \bar\Omega_0$ is a C^1 diffeomorphism, then $\|\mathrm{d}s\|_\infty \ge 1$.*

Consequently we also have $\|s\|_{1,\alpha} \ge \|\mathrm{d}s\|_\infty \ge 1$.

Proof. Since $s(\partial\Omega_0) = \partial\Omega_0$, s cannot be a contraction on all of $\partial\Omega_0$, so somewhere on $\partial\Omega_0$ one has $|\mathrm{d}s| \ge 1$. □

Let $s : \Omega_0 \to \Omega_0$ be a C^1 diffeomorphism which preserves μ_0, i.e., for which

$$\mu_0(s(x)) \det \mathrm{d}s(x) = \mu_0(x) \tag{63}$$

holds.

LEMMA 11.3. *Assume the diffeomorphism $s : \Omega_0 \to \Omega_0$ satisfies* (63). *If*

$$K = \max_{x,x' \in \Omega_0} \frac{\mu_0(x)}{\mu_0(x')},$$

then

$$\sup_{\Omega_0} |(\mathrm{d}s(x))^{-1}| \le C_d \left(K \sup_{\Omega_0} |\mathrm{d}s(x)| \right)^{d-1}$$

for some constant C_d which only depends on the dimension d. In particular, if s is Lipschitz continuous with Lipschitz constant L, then s^{-1} is Lipschitz continuous with constant at most $C_d(KL)^{d-1}$.

Proof. We represent $\mathrm{d}s(x)$ as a $d \times d$ matrix. Then

$$(\mathrm{d}s(x))^{-1} = \frac{1}{\det \mathrm{d}s(x)} (\mathrm{d}s(x))^\# = \frac{\mu_0(x)}{\mu_1(s(x))} (\mathrm{d}s(x))^\#, \tag{64}$$

where $\mathrm{d}s^t(x)^\#$ is the cofactor matrix. This matrix is a polynomial of degree $d-1$ in the entries of the matrix $\mathrm{d}s^t$, hence the lemma. ∎

LEMMA 11.4. *Assume the diffeomorphism $s:\Omega_0\to\Omega_0$ satisfies* (63). *If $s\in C^{1,\alpha}$, then $s^{-1}\in C^{1,\alpha}$, and*

$$\|s^{-1}\|_{1,\alpha}\le C\|s\|_{1,\alpha}^{(d-1)(2+\alpha)+1}, \tag{65}$$

where the constant C only depends on μ_0 and the dimension d.

Proof. We will henceforth write $\mathrm{d}s(x)=\mathrm{d}s_x$ if it seems to improve the notation.

We get an estimate for the supremum norm of $\mathrm{d}(s^{-1})$ from the inverse function theorem, which says $\mathrm{d}(s^{-1})=(\mathrm{d}s)^{-1}\circ s^{-1}$, so that $\|\mathrm{d}(s^{-1})\|_\infty=\|(\mathrm{d}s)^{-1}\|_\infty\le C\|\mathrm{d}s\|_\infty^{d-1}$.

To estimate the Hölder seminorm $[\mathrm{d}s^{-1}]_\alpha$ we compute for $x,y\in\Omega_0$

$$\begin{aligned}
|\mathrm{d}(s^{-1})(x)-\mathrm{d}(s^{-1})(y)| &= \left|(\mathrm{d}s)^{-1}_{s^{-1}(x)}-(\mathrm{d}s)^{-1}_{s^{-1}(y)}\right|\\
&= \left|(\mathrm{d}s)^{-1}_{s^{-1}(y)}\left\{\mathrm{d}s_{s^{-1}(x)}-\mathrm{d}s_{s^{-1}(y)}\right\}\mathrm{d}(s^{-1})_{s^{-1}(x)}\right|\\
&\le \|(\mathrm{d}s)^{-1}\|_\infty^2\left\|\mathrm{d}s_{s^{-1}(x)}-\mathrm{d}s_{s^{-1}(y)}\right\|\\
&\le \|(\mathrm{d}s)^{-1}\|_\infty^2[\mathrm{d}s]_\alpha\left|s^{-1}(x)-s^{-1}(y)\right|^\alpha\\
&\le \|(\mathrm{d}s)^{-1}\|_\infty^{2+\alpha}[\mathrm{d}s]_\alpha|x-y|^\alpha\\
&\le C\|\mathrm{d}s\|_\infty^{(d-1)(2+\alpha)}[\mathrm{d}s]_\alpha|x-y|^\alpha.
\end{aligned}$$

Hence we get

$$[d(s^{-1})]_\alpha\le C\|\mathrm{d}s\|_\infty^{(d-1)(2+\alpha)}[\mathrm{d}s]_\alpha\le C\|s\|_{1,\alpha}^{(d-1)(2+\alpha)+1}.$$

To estimate the full $C^{1,\alpha}$ norm of s^{-1} we add the lower order terms,

$$\begin{aligned}
\|s^{-1}\|_{1,\alpha} &= \|s^{-1}\|_\infty+\|\mathrm{d}s^{-1}\|_\infty+[d(s^{-1})]_\alpha\\
&\le C+C\|\mathrm{d}s\|_\infty^{d-1}+C\|s\|_{1,\alpha}^{(d-1)(2+\alpha)+1}\\
&\le C+C\|s\|_{1,\alpha}^{(d-1)(2+\alpha)+1}.
\end{aligned}$$

Finally we use $\|s\|_{1,\alpha}\ge 1$ to get (65). ∎

We will occasionally use the following crude estimate for the $C^{1,\alpha}$ norm of the composition of two maps.

LEMMA 11.5. *For two $C^{1,\alpha}$ maps f,g one has*

$$\begin{aligned}
[f\circ g]_\alpha &\le \|\mathrm{d}g\|_\infty\cdot[f]_\alpha,\\
\|f\circ g\|_{0,\alpha} &\le \left(1+\|\mathrm{d}g\|_\infty^\alpha\right)\|f\|_{0,\alpha},\\
\|f\circ g\|_{1,\alpha} &\le 3\big(1+\|g\|_{1,\alpha}^{1+\alpha}\big)\|f\|_{1,\alpha}.
\end{aligned}$$

Proof. The first inequality follows directly from

$$|f(g(x))-f(g(y))|\le[f]_\alpha|g(x)-g(y)|^\alpha\le[f]_\alpha\|\mathrm{d}g\|_\infty^\alpha\,|x-y|^\alpha.$$

The second inequality follows from

$$\begin{aligned}
\|f\circ g\|_{0,\alpha} &= \|f\circ g\|_\infty+[f\circ g]_\alpha\\
&\le \|f\|_\infty+\|\mathrm{d}g\|_\infty^\alpha\cdot[f]_\alpha\\
&\le \|f\|_{0,\alpha}+\|\mathrm{d}g\|_\infty^\alpha\|f\|_{0,\alpha}.
\end{aligned}$$

To prove the third inequality, we compute

$$\begin{aligned}\|f\circ g\|_{1,\alpha} &= \|f\circ g\|_\infty + \|(\mathrm{d}f\circ g)\cdot \mathrm{d}g\|_{0,\alpha}\\ &\le \|f\|_\infty + \|\mathrm{d}f\circ g\|_{0,\alpha}\|\mathrm{d}g\|_{0,\alpha}\\ &\le \|f\|_\infty + \bigl(1+\|\mathrm{d}g\|_\infty^\alpha\bigr)\|\mathrm{d}f\|_{0,\alpha}\|\mathrm{d}g\|_{0,\alpha}\\ &\le \bigl(1+\|\mathrm{d}g\|_{0,\alpha}+\|\mathrm{d}g\|_{0,\alpha}^{1+\alpha}\bigr)\|f\|_{1,\alpha}\\ &\le 3\bigl(1+\|\mathrm{d}g\|_{0,\alpha}^{1+\alpha}\bigr)\|f\|_{1,\alpha}\end{aligned}$$

since $1+x+x^{1+\alpha}\le 3(1+x^{1+\alpha})$ for all $x\ge 0$. □

11.3. Proof of Lemma 11.1. We summarize the relations that define the maps u^t.

First, u^t and the initial map u^0 are related by

$$u^t = u^0\circ (s^t)^{-1}. \tag{66}$$

The rearrangement maps s^t move with velocity field v^t. This gives two equations, one for s^t and one for its space derivative:

$$\frac{\partial s^t}{\partial t} = v^t\circ s^t, \qquad \frac{\partial \mathrm{d}s^t}{\partial t} = (\mathrm{d}v^t\circ s^t)\cdot \mathrm{d}s^t. \tag{67}$$

The velocity field v^t is determined by the map u^t via

$$v^t(x) = \frac{-1}{\mu_0(x)}\mathcal{P}\mathcal{A}_\varepsilon^2\mathcal{P}W^t, \tag{68}$$

while W^t is given by $W^t = \mathbb{E}_{\gamma^t}(\Phi_x \mid x)$, i.e., by

$$W^t(x) = \Phi_x(x,u^t(x)). \tag{69}$$

We begin our estimate of $\|\partial_t s^t\|_{1,\alpha}$ as follows:

$$\begin{aligned}\left\|\frac{\partial}{\partial t}s^t\right\|_{1,\alpha} &= \|\partial_t s^t\|_\infty + \left\|\frac{\partial}{\partial t}\mathrm{d}s^t\right\|_{0,\alpha}\\ &= \|v^t\|_\infty + \|(\mathrm{d}v^t\circ s^t)\cdot \mathrm{d}s^t\|_{0,\alpha}\\ &\le \|v^t\|_\infty + \|\mathrm{d}v^t\circ s^t\|_{0,\alpha}\cdot\|\mathrm{d}s^t\|_{0,\alpha}\\ &\le \|v^t\|_\infty + \|\mathrm{d}v^t\|_{0,\alpha}\bigl(1+\|\mathrm{d}s^t\|_\infty^\alpha\bigr)\|\mathrm{d}s^t\|_{0,\alpha}\\ &\le \|v^t\|_\infty + 2\|\mathrm{d}v^t\|_{0,\alpha}\|\mathrm{d}s^t\|_{0,\alpha}^{1+\alpha}\\ &\le \|v^t\|_\infty + 2\|v^t\|_{1,\alpha}\|s^t\|_{1,\alpha}^{1+\alpha}\\ &\le 3\|v^t\|_{1,\alpha}\|s^t\|_{1,\alpha}^{1+\alpha},\end{aligned} \tag{70}$$

where we have used $\|\mathrm{d}s^t\|_\infty\ge 1$ again.

Next, we estimate the $C^{1,\alpha}$ norm of the velocity field:

$$\begin{aligned}\|v^t\|_{1,\alpha} &= \left\|\frac{-1}{\mu_0(x)}\mathcal{P}\mathcal{A}^2\mathcal{P}\bigl(\Phi_x(x,u^t(x))\bigr)\right\|_{1,\alpha}\\ &\le C\|\Phi_x(x,u^t(x))\|_{1,\alpha}\\ &\le 3C\|\Phi\|_{2,\alpha}\bigl(1+\|u^t\|_{1,\alpha}^{1+\alpha}\bigr)\\ &\le C\bigl(1+\|u^t\|_{1,\alpha}^{1+\alpha}\bigr).\end{aligned} \tag{71}$$

Here we have used the facts that $\mu_0 \in C^{1,\alpha}$, that the smoothing operators $\mathcal{A}$ are uniformly bounded from $C^{1,\alpha}$ to $C^{1,\alpha}$, and that the Helmholtz decomposition is also bounded on $C^{1,\alpha}$.

Finally we estimate $\|u^t\|_{1,\alpha}$ in terms of $\|s^t\|_{1,\alpha}$. We have

$$\begin{aligned} \|u^t\|_{1,\alpha} &= \|u^0 \circ \big(s^t\big)^{-1}\|_{1,\alpha} \\ &\le 3\big(1 + \|(s^t)^{-1}\|_{1,\alpha}^{1+\alpha}\big)\ \|u^0\|_{1,\alpha} \\ &\le C\ \|(s^t)^{-1}\|_{1,\alpha}^{1+\alpha}\ \|u^0\|_{1,\alpha} \\ &\le C\ \|s^t\|_{1,\alpha}^{(d-1)(2+\alpha)(1+\alpha)+1+\alpha}. \end{aligned} \tag{72}$$

Combining (70), (71), and (72), we arrive at

$$\frac{d}{dt}\|s^t\|_{1,\alpha} \le \|\partial_t s^t\|_{1,\alpha} \le C\left(\|s^t\|_{1,\alpha}\right)^{\kappa}, \tag{73}$$

where

$$\begin{aligned} \kappa &= \{(d-1)(2+\alpha)(1+\alpha) + 1 + \alpha\}(1+\alpha) + 1 + \alpha \\ &= \big((d-1)\alpha^2 + 3(d-1)\alpha + 2d\big)(1+\alpha). \end{aligned}$$

Integrate this ODE, using the initial data $\|s^0\|_{1,\alpha} = 1$ which derives from $s^0 = \mathrm{id}$, and you get

$$\|s^t\|_{1,\alpha} \le \big(1 - Ct\big)^{-\frac{1}{\kappa-1}}.$$

The constant C depends on the initial map u^0 but not on the smoothing parameter $\varepsilon > 0$, as claimed in Lemma 11.1.

12. Numerical methods and examples. In this section, we describe some of the techniques we use to numerically solve (9), as well as how we compute the initial mapping. Briefly, we have employed an upwinding scheme when computing ∇u^t and the FFT when inverting the Laplacian on a rectangular grid. Standard centered differences were used for the other spatial derivatives. In practice, we iterate until the mean absolute curl is sufficiently small. More details of the numerical implementation for solving (9) are given below. See also [11, 12].

12.1. Finding an initial mapping. In this section, we describe our procedure for finding the initial mass preserving mapping u for (9). We work here on the unit square. An initial mapping for general domains can also be obtained using a method of Moser [6].

So we work in $\mathbb{R}^2$ and assume $\Omega_0 = \Omega_1 = [0,1]^2$, the generalization to higher dimensions being straightforward. The idea of this construction is that we solve a family of one-dimensional mass transport problems. In one dimension, the optimal transport map can be found by simple quadrature. We first transport mass along lines parallel to the x-axis, and then afterward transport mass along lines parallel to the y-axis. Accordingly, we define a function $a = a(x)$ by the equation

$$\int_0^{a(x)} \int_0^1 \mu_1(\eta, y)\ dy\ d\eta = \int_0^x \int_0^1 \mu_0(\eta, y)\ dy\ d\eta, \tag{74}$$

which gives by differentiation with respect to x

$$a'(x)\int_0^1 \mu_1(a(x),y)\,dy = \int_0^1 \mu_0(x,y)\,dy. \tag{75}$$

We may now define a function $b = b(x,y)$ by the equation

$$a'(x)\int_0^{b(x,y)} \mu_1(a(x),\rho)\,d\rho = \int_0^y \mu_0(x,\rho)\,d\rho \tag{76}$$

and set $u(x,y) = (a(x), b(x,y))$. Since $a_y = 0$, $|Du| = a_x b_y$, and differentiating (76) with respect to y we find

$$\begin{aligned} a'(x)\; b_y(x,y)\; \mu_1(a(x),b(x,y)) &= \mu_0(x,y), \\ |Du|\; \mu_1 \circ u &= \mu_0, \end{aligned}$$

which is the mass preserving property we need. In practice, a and b can be found with simple numerical integration techniques.

12.2. Defining the warping map. Typically in elastic registration, one wants to see an explicit warping which smoothly deforms one image into the other [11]. This can easily be done using the solution of the Monge–Kantorovich problem. Thus, we assume now that we have applied our gradient descent process as described above and that it has converged to the optimal L^2 Monge–Kantorovich mapping u_{MK}.

Following the work of Benamou and Brenier [3] (see also [9]), we consider the related problem

$$\inf \int\int_0^1 \mu(t,x)|v(t,x)|^2\,dt\,dx \tag{77}$$

over all time varying densities μ and velocity fields v satisfying

$$\frac{\partial \mu}{\partial t} + \operatorname{div}(\mu v) = 0, \tag{78}$$

$$\mu(0,\cdot) = \mu_0, \quad \mu(1,\cdot) = \mu_1. \tag{79}$$

It is shown in [3] that this infimum is attained for some μ_{min} and v_{min}, and that it is equal to the L^2 Kantorovich–Wasserstein distance between μ_0 and μ_1. Recall that this distance is defined by

$$d_2(\mu_0,\mu_1)^2 := \inf_u \int_{\Omega_0} |u(x) - x|^2\,dx,$$

the infimum taken over all diffeomorphisms which satisfy the Jacobian condition (1). Further, the flow $X = X(x,t)$ corresponding to the minimizing velocity field v_{min} via

$$X(x,0) = x, \quad X_t = v_{min} \circ X \tag{80}$$

is given simply as

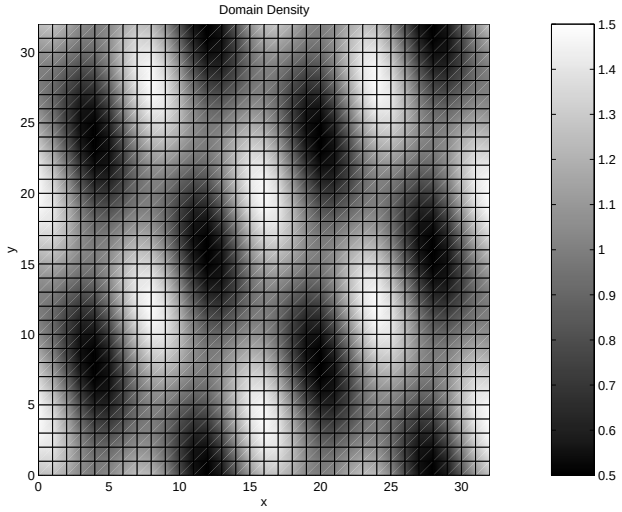

FIG. 3. *Density* μ_1 *on* Ω_0.

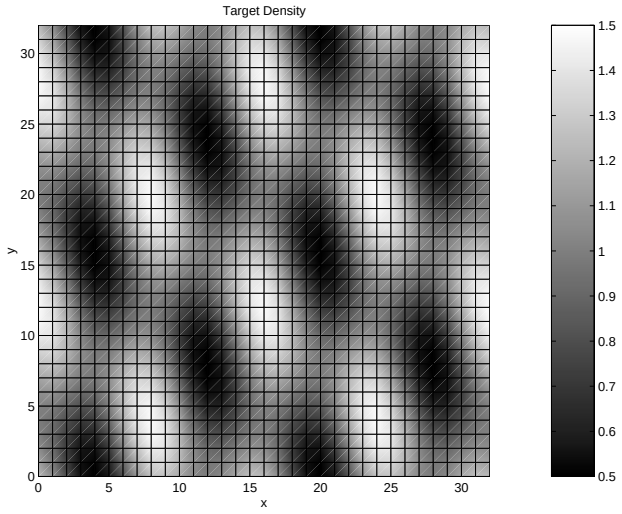

FIG. 4. *Density* μ_1 *on* Ω_1.

$$X(x,t) = x + t\ (u_{MK}(x) - x). \tag{81}$$

Note that when $t = 0$, X is the identity map, and when $t = 1$, it is the solution u_{MK} to the Monge–Kantorovich problem. This analysis provides appropriate justification for using (81) to *define* our continuous warping map X between the densities μ_0 and μ_1.

13. Implementation and examples. We illustrate our methods with the following examples. The first is the mapping of one synthetic density onto another. Figure 3 shows a mass distribution μ_0 on Ω_0, with dark regions representing little mass, lighter regions representing more. Similarly, Figure 4 indicates the density μ_1 on Ω_1. Figure 5 represents the initial mapping u, which was obtained by the method described above. The shading in this figure represents the Jacobian of u. Figure 6

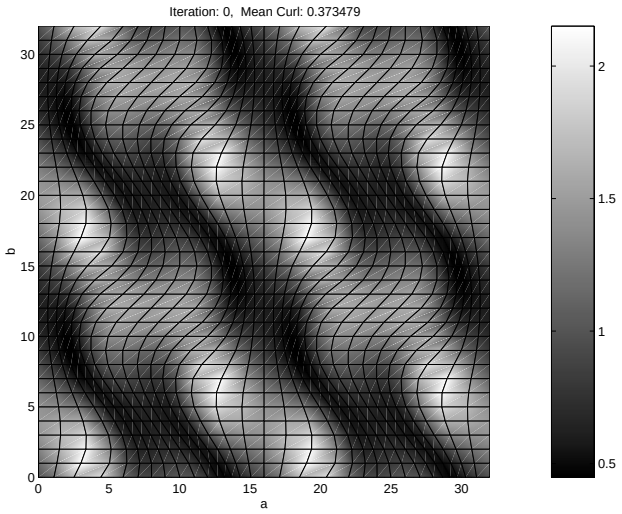

FIG. 5. *Initial mapping from* Ω_0 *to* Ω_1.

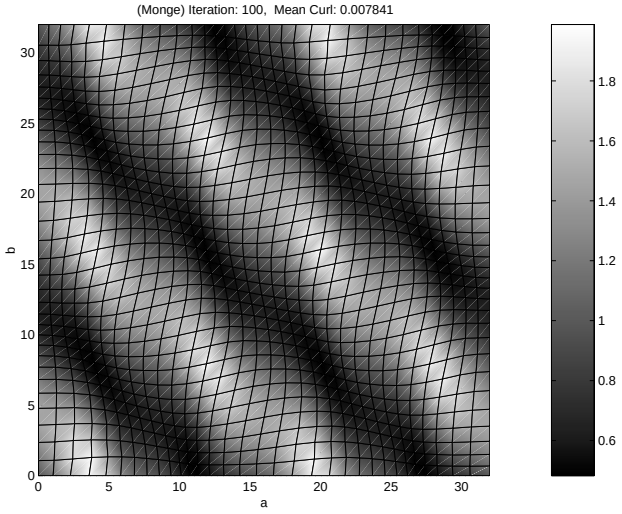

FIG. 6. *Final Monge–Kantorovich mapping from* Ω_0 *to* Ω_1.

shows the nearly optimal Monge–Kantorovich mapping obtained using the nonlocal first order equation (9). One can see that the effect of removing the curl is to straighten out the grid lines somewhat. On a Sun Ultra10, this process took just a few seconds.

In Figures 7 through 10 we show a brain deformation sequence obtained with MRI. The first and last images were given, and the intermediate two were found using our process. This type of elastic brain deformation occurs during surgery, after the skull is opened. These two-dimensional slices were extracted from an original three-dimensional data set ($256 \times 256 \times 124$) to which the registration algorithm was applied. We should note that in contrast to other elastic approaches based on fluid and continuum mechanics ideas (see [17], especially Chapters 1 and 18 for a general discussion) in which the computations may take hours, in our case the three-dimensional set was processed in about half an hour with very reasonable results.

FIG. 7. *Brain warping:* $t = 0.00$.

FIG. 8. *Brain warping:* $t = 0.33$.

In general, the target domain Ω_1 need not be rectangular when using the nonlocal method. However, we note that if the periodic boundary conditions are used on the displacement, as in section 7.1, then the Laplacian in (9) can be inverted using the FFT alone, without the need to solve a subsequent matrix system. For the brain warp, this reduced the processing time by about 1/3.

Acknowledgment. We would like to thank Robert McCann of the University of Toronto for some very useful discussions about the Monge–Kantorovich problem.

FIG. 9. *Brain warping:* $t = 0.66$.

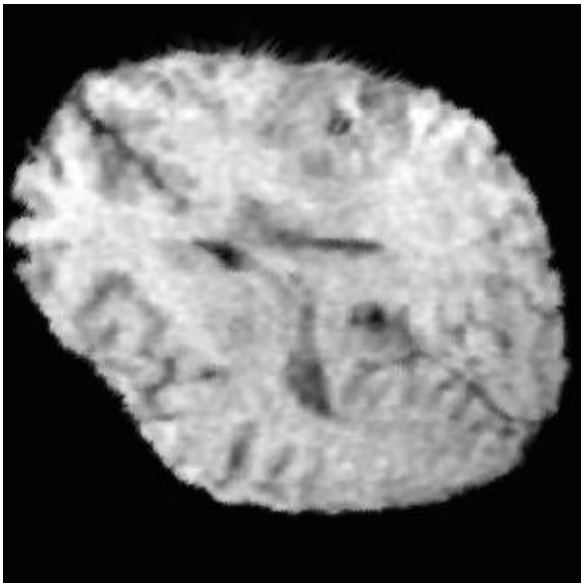

FIG. 10. *Brain warping:* $t = 1.00$.

FRACTIONAL RATE OF CONVERGENCE FOR VISCOUS APPROXIMATION TO NONCONVEX CONSERVATION LAWS*

TAO TANG†, ZHEN-HUAN TENG‡, AND ZHOUPING XIN§

Abstract. This paper considers the viscous approximations to conservation laws with nonconvex flux function. It is shown that if the entropy solutions are piecewise smooth, then the rate of L^1-convergence is a *fractional* number in $(0.5, 1]$. This is in contrast to the corresponding result for the convex conservation laws. Numerical experiments indicate that the theoretical prediction for the convergence rate is optimal.

Key words. rate of convergence, error estimate, viscous approximation, conservation law, nonconvex flux

1. Introduction.

In this paper, we consider the initial value problem for *nonconvex* conservation laws

$$\partial_t u + \partial_x f(u) = 0, \qquad t > 0\,, \quad x \in \mathbf{R}, \tag{1.1}$$

which is subject to the initial condition prescribed at $t = 0$,

$$u(x, 0) = u_0(x), \tag{1.2}$$

where $f \in C^2$. We shall investigate viscous approximations to the entropy solution of (1.1):

$$\partial_t u^\epsilon + \partial_x f(u^\epsilon) = \epsilon \partial_{xx} u^\epsilon \tag{1.3}$$

subject to the initial data

$$u^\epsilon(x, 0) = u_0(x). \tag{1.4}$$

In this work, we assume that $f''(u)$ vanishes at a *finite number* of points. It is also assumed that the entropy solution to (1.1) and (1.2) is *piecewise smooth* with finitely many shock discontinuities. The existence and uniqueness of the solutions to (1.1) in the class of piecewise smooth weak solutions were studied by Ballou [1].

When the flux f is convex, the solution structure for (1.1) and (1.2) has been obtained; see, e.g., Lax [10] and Dafermos [2]. If f has inflection points, then the

situation is more complicated. In this case, some analysis for the solution structure and asymptotic behavior has been done; see, e.g., Dafermos [3], Liu [11], and Zumbrun [32]. However, we are still far from having a complete understanding of this general case, since the geometric structure of the solution, when f changes convexity, is much more complicated due to the presence of contact discontinuities, and there is a large variety of asymptotic states.

The asymptotic convergence of solutions to the viscous problem (1.3) and (1.4) to the corresponding discontinuous solutions of the inviscid problem (1.1) and (1.2) has been the main driving force for the mathematical theory of shock waves from both theoretical and numerical points of view. Substantial progress has been made in the past in this regard (see [29, 20] and the references therein), pioneered by Hopf, Lax [10], Oleinik [18], and Krushkov [7], to name a few. For BV entropy solutions, Kuznetsov [8] was the first to establish the half-order rate of L^1-convergence for viscosity approximation and monotone schemes. It was proved by Tang and Teng [25] that this half-order rate of convergence is optimal in the BV solution class; see also Sabac [19]. However, for convex conservation laws with piecewise smooth solutions the L^1-convergence rate can be improved to first-order; see, e.g., Teng and Zhang [27] for the monotone scheme, Tang and Teng [24] for viscosity approximation, and Teng [26] for the relaxation method. The basic method in obtaining the first-order rate of convergence is the matching asymptotic method developed by Goodman and Xin [5] and Liu and Xin [14]. One of the key ingredients in this method is the nonlinear large asymptotic stability of viscous shock profiles. For systems of viscous conservation laws, this stability theory has been extensively studied in the past decade. Important progress has been made by Goodman [4], Matsumura and Nishihara [16], Liu [12], and Szepessy and Xin [21]; see also some recent new approaches by Howard and Zumbrun [6], Liu [13], and Kreiss and Kreiss [9]. In particular, convergence with a rate to viscous shock profiles was obtained by Liu [13] by using a pointwise estimate for the approximate Green's function. Even in the case of nonconvex fluxes, the nonlinear large time asymptotic stability has been established for some special systems; see, e.g., [15] and [17]. The convergence of viscous solutions to piecewise smooth solutions for general systems was established by Goodman and Xin [5]; see also [31] for a recent improvement. For the convergence of viscous solutions in the presence of physical boundaries, we refer to [30] and the references therein. We also point out that there are some first-order *pointwise* convergence results for viscous approximations to convex conservation laws; see, e.g., Tadmor and Tang [22, 23], who used the energy method with some bootstrap extrapolation technique. It is proved in [24] that, for convex conservation laws whose entropy solution consists of finitely many discontinuities, the L^1-error between the viscosity solution u^ϵ and its inviscid limit u is bounded by $\mathcal{O}(\epsilon|\ln\epsilon|)$. If neither central rarefaction waves nor spontaneous shocks occur, the error bound is improved to $\mathcal{O}(\epsilon)$; see also [28]. In this work, we will show that for *nonconvex* conservation laws, the L^1-error between the viscosity solution and its inviscid limit is bounded by $\mathcal{O}(\epsilon^\alpha|\ln\epsilon|)$, where $\frac{1}{2} < \alpha \le 1$, even in the piecewise smooth solution class. The constant α is determined by the index numbers of shock curves to be defined in the next section. Based on the form of the flux function, the rate α can be any number between $\frac{1}{2}$ and 1. This result suggests that for the viscous approximations the L^1-convergence rate of the nonconvex conservation laws is substantially different from that of the convex ones.

We close the introduction by outlining the rest of the paper. In the next section, we give some preliminaries, define an index number for a shock discontinuity, and list

some properties of the index number. In section 3, we state our main convergence theorem, whose proof occupies section 4 to section 8. Finally, in section 9 numerical experiments are performed to verify the theoretical estimates.

2. Piecewise smooth solution. Throughout this paper, we assume that the entropy solution of (1.1) and (1.2) is *piecewise smooth*, with finitely many shock discontinuities. More precisely, we can divide the given time interval $[0, T]$ into finite intervals $\{[t_{m-1}, t_m]\}_{m=1}^{M}$ such that in each interval $[t_{m-1}, t_m]$ the entropy solution is a finite combination of the cases plotted in Figures 1 and 2 (demonstrated in the case with three inflection points for $f(u)$). Thus, if we denote by $S(t)$ the set of the discontinuous curve of $u(\cdot, t)$ in the time interval $[t_{m-1}, t_m]$, then it consists of finitely many shocks:

$$S(t) := \{(x,t) \,|\, x = X_k(t),\ 1 \le k \le K;\ t_{m-1} \le t \le t_m\},$$

where $X_k(t) < X_{k+1}(t)$ for $t \in (t_{m-1}, t_m)$. It is understood that u is smooth with bounded limits $u(X_k(t) \pm 0, t)$ (denote by $u_k^{\pm}(t)$) and $u_x(X_k(t) \pm 0, t)$. For simplicity, we will not consider the newly formed shock wave here, although this case was investigated extensively in [24]. As a consequence, we always have $u_k^+(t) - u_k^-(t) \neq 0$. For ease of notation we omit the dependence of $S(t)$, $X_k(t)$, and K on m. Each of the *noncontact* shocks $X_k(t)$, plotted in Figure 1, satisfies the Rankine–Hugoniot and the Lax conditions

$$X_k'(t) = \sigma(u_k^+(t), u_k^-(t)) := \frac{f(u_k^+(t)) - f(u_k^-(t))}{u_k^+(t) - u_k^-(t)}, \tag{2.1}$$

$$a(u_k^-(t)) > X_k'(t) > a(u_k^+(t)), \quad \text{where} \quad a(v) := f'(v). \tag{2.2}$$

Each of the *contact shocks* $X_k(t)$, plotted in Figure 2, satisfies the Rankine–Hugoniot and the contact conditions

$$X_k'(t) = \sigma(u_k^+(t), u_k^-(t)), \tag{2.3}$$

$$a(u_k^-(t)) > X_k'(t) = a(u_k^+(t)), \quad \text{and/or} \tag{2.4}$$

$$a(u_k^-(t)) = X_k'(t) > a(u_k^+(t)). \tag{2.5}$$

We now define *index numbers* $\beta_k^{\pm}$ for a shock curve $x = X_k(t)$:

1. If $X_k'(t) > a(u_k^+)$, then the index number $\beta_k^+ = 0$.
2. If $X_k'(t) = a(u_k^+)$ and there exists a positive number $\beta > 0$ such that

$$|a(u_k^+) - a(u)| \sim |u_k^+ - u|^{\beta} \quad \text{as} \quad u \to u_k^+, \tag{2.6}$$

   then the index number $\beta_k^+ = \beta$. In (2.6), the notation " $\sim$ " means equivalence. More precisely, $g(u) \sim h(u)$ as $u \to c$ means that there exists a constant $D > 0$ such that $D^{-1}h \le g \le Dh$ as $u \to c$.
3. Similarly, we can define β_k^- for the shock curve $x = X_k(t)$.

The following result gives a rule for calculating the index number.

THEOREM 2.1. *If $f(u) \in C^r(\mathbf{R})$, $\sigma(u_k^+, u_k^-) = a(u_k^+)$, the derivative of $a(u)$ is zero at $u = u_k^+$ up to $(r-1)$th order but $a^{(r)}(u_k^+) \neq 0$, then $\beta_k^+ = r$.*

Proof. Applying Taylor's theorem to $a(u)$ gives

$$a(u) - a(u_k^+) = \frac{1}{r!} a^{(r)}(u_k^+)(u - u_k^+)^r + o(|u - u_k^+|^r).$$

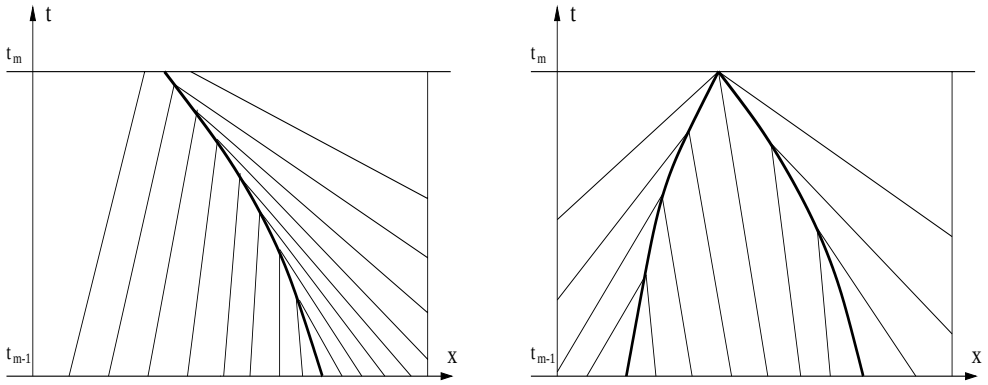

FIG. 1. *Illustration of noncontact shocks: Thin lines are characteristics, and thick ones are* noncontact *shock curves. Here characteristics come into shocks from both sides.*

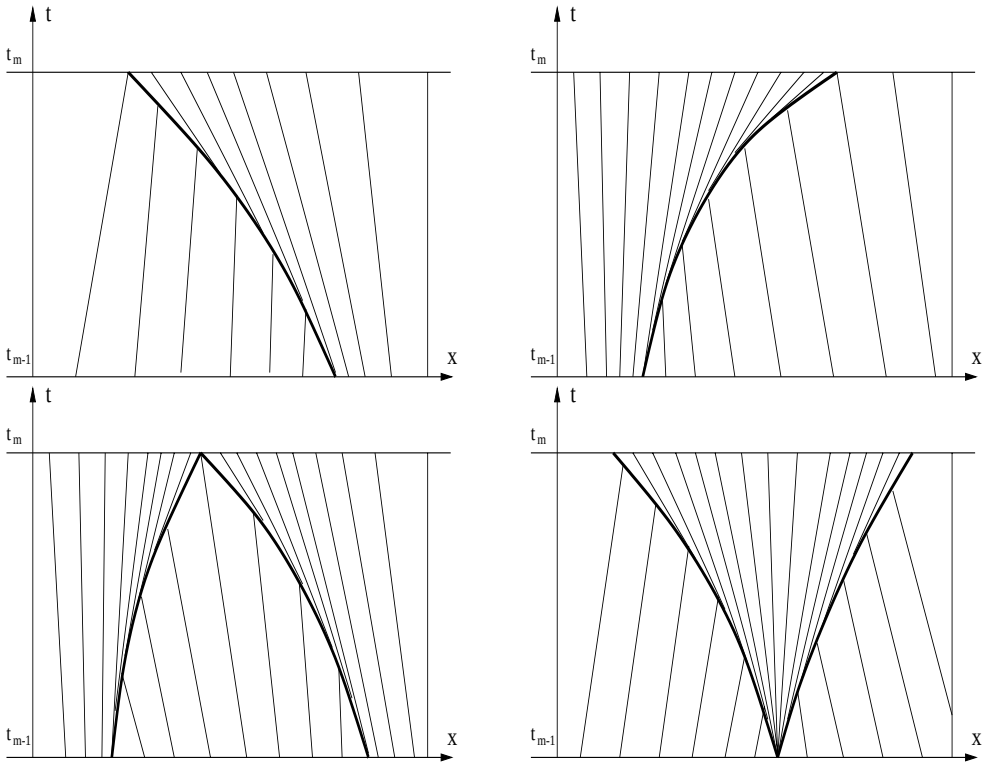

FIG. 2. *Illustration of contact shocks: Thin lines are characteristics, and thick ones are* contact *shock curves. Here characteristics are tangent to shocks at least in one side.*

This means that $|a(u) - a(u_k^+)| \sim |u - u_k^+|^r$ as $u \to u_k^+$. Therefore, it follows from the definition (2.6) that $\beta_k^+ = r$. □

The following result is an immediate consequence of the above theorem.

COROLLARY 2.1. *If $f''(u)$ has only a finite number of zero points, then the index number can take only a finite number of values.*

Example 2.1. Let $f(u) = u^{2m+1}$. Assume the entropy solution is of the form

$$u(x,t) = \begin{cases} u_- & \text{for } x < \sigma(u_+, u_-)t, \\ u_+ & \text{for } x \geq \sigma(u_+, u_-)t, \end{cases} \tag{2.7}$$

where $u_- > 0$ is a given number, and $u_+ < 0$ is the solution of the equation $\sigma(u_+, u_-) = a(u_+)$. In other words, u_+ is determined by

$$\sum_{s=0}^{2m} (u_+)^{2m-s}(u_-)^s = (2m+1)(u_+)^{2m}.$$

It is easy to show that $a(u_-) > \sigma(u_+, u_-) = a(u_+)$, and hence $\beta^- = 0$. Since $a'(u_+) > 0$, it follows from Theorem 2.1 that $\beta^+ = 1$.

Example 2.2. If $f(u) = (1-u)^p(1+u)^q$ with $p \geq 1$, $q \geq 1$, and $p+q > 2$ and an entropy solution is given by

$$u(x,t) = \begin{cases} -1, & x < 0, \\ +1, & x \geq 0, \end{cases} \tag{2.8}$$

then the curve $x = X(t) = 0$ is a contact shock with $\sigma(1,-1) = a(1) = a(-1)$, and the index numbers are $\beta^+ = p - 1$ and $\beta^- = q - 1$.

3. Main theorem. In this section, the main result of this paper presented; its proof will be given in the next few sections.

THEOREM 3.1. *Let $f \in C^2$ and assume that f'' may change its sign at most at a finite number of points. Let u be the piecewise smooth entropy solution of* (1.1)–(1.2) *with finitely many shock discontinuities, and let u^ϵ be the viscosity solution of* (1.3)–(1.4). *Then the following error estimates hold for any $0 < t \leq T$:*

$$\|u^\epsilon(\cdot,t) - u(\cdot,t)\|_{L^1(\mathbf{R})} \leq \begin{cases} C(T)\epsilon|\ln\epsilon| & \text{for } \bar\beta < 1, \\ C(T)\epsilon^{(1+1/\bar\beta)/2}|\ln\epsilon| & \text{for } \bar\beta \geq 1, \end{cases} \tag{3.1}$$

where $\bar\beta = \max_{0\leq t\leq T}\beta(t)$, $\beta = \max\{\beta^+, \beta^-\}$, $\beta^\pm = \max_k\{\beta_k^\pm\}$, and $\beta_k^\pm$ are index numbers defined by (2.6).

The above theorem will be established by using a matched asymptotic analysis, a stability lemma, and some detailed analysis for the traveling wave solution. The stability lemma to be used is valid only for the scalar conservation laws, which makes the present analysis much simpler than the system case. For the hyperbolic system, Goodman and Xin [5] constructed high-order approximations in obtaining a local first-order rate of convergence for the viscous approximations.

In the analysis of this work, we have to deal with the L^1 estimate of piecewisely continuous functions, some of which involve derivatives of some other piecewisely continuous functions; see, e.g., (7.10). In order to avoid confusion, we define the L^1-norm for a piecewisely smooth function q by

$$\|q(\cdot)\|_{\mathrm{pis}(\mathbf{R})} = \sum_{i=1}^{I+1} \|q(\cdot)\|_{L^1(Y_{i-1}, Y_i)},$$

where Y_i, with $Y_0 := -\infty$ and $Y_{I+1} := \infty$, are all the possible discontinuous points of $q(x)$. The proof of the following stability lemma can be found in [24].

LEMMA 3.1. *Let u^ϵ be the viscous solution of* (1.3)–(1.4). *Let $v^\epsilon \in C(\mathbf{R}\times[0,T])$ be a piecewisely smooth function with jumps in the derivative in the set $\mathcal{A} = \{(x,t) \mid x = Y_i(t),\ 1 \le i \le I\}$. If v^ϵ satisfies*

$$\partial_t v^\epsilon + \partial_x f(v^\epsilon) = \epsilon \partial_{xx} v^\epsilon + g(x,t) \tag{3.2}$$

everywhere except on the set $\mathcal{A}$, then for any $0 \le \tau < t \le T$

$$\begin{aligned}\|u^\epsilon(\cdot,t) - v^\epsilon(\cdot,t)\|_{L^1(\mathbf{R})} &\le \|u^\epsilon(\cdot,\tau) - v^\epsilon(\cdot,\tau)\|_{L^1(\mathbf{R})} \\ &+ \epsilon \sum_{i=1}^{I} \int_\tau^t \Big| \left[\partial_x v^\epsilon(x,t)\right] |_{x=Y_i(t)} \Big| dt + \int_\tau^t \|g(\cdot,t)\|_{\mathrm{pis}(\mathbf{R})} dt,\end{aligned}$$

where the jumps are defined by

$$[w(x,t)]|_{x=Y(t)} := w(Y(t)+0,t) - w(Y(t)-0,t).$$

Remark 3.1. It will be seen in sections 7 and 8 that $g(x,t)$ in (3.2) may involve some derivatives of a discontinuous function, so we use the norm $\| \bullet \|_{\mathrm{pis}(\mathbf{R})}$ to define its L^1-norm.

It follows from Theorem 3.1 that both first-order and fractional-order rates of convergence may occur for nonconvex conservation laws, which is in contrast with that for the convex conservation laws. We will demonstrate this fact with the following examples.

Example 3.1. Let $f(u) = u^{2m+1}$. If the entropy solution $u(x,t)$ is defined by (2.7), then it follows from Example 2.1 and Theorem 3.1 that

$$\|u^\epsilon(\cdot,t) - u(\cdot,t)\|_{L^1(\mathbf{R})} \le C(T)\epsilon|\ln\epsilon|. \tag{3.3}$$

Example 3.2. Let $f(u) = (1-u)^p(1+u)^q$, with $s := \max(p,q) \ge 1$. If the entropy solution $u(x,t)$ is defined by (2.8), then it follows from Example 2.2 and Theorem 3.1 that

$$\|u^\epsilon(\cdot,t) - u(\cdot,t)\|_{L^1(\mathbf{R})} \le \begin{cases} C(T)\epsilon|\ln\epsilon| & \text{for} \quad 1 \le s \le 2, \\ C(T)\epsilon^{\frac{s}{2(s-1)}}|\ln\epsilon| & \text{for} \quad s > 2. \end{cases} \tag{3.4}$$

4. Traveling wave solution of viscous equation. Our construction of an approximation solution is based on some detailed properties of viscous shock profiles for (1.3), whose nonlinear asymptotic stability was studied by Matsumura and Nishihara [15]. We will summarize some of their results in this section, which will be used in our error analysis. Some results not obtained in [15] can be derived by using the techniques developed in [24]. Let

$$u^\epsilon(x,t) = V^\epsilon(x - \sigma t; u_+, u_-), \tag{4.1}$$

which is subject to the boundary conditions

$$V^\epsilon(\xi; u_+, u_-) \to u_\pm \quad \text{as} \quad \xi \to \pm\infty.$$

If $V^\epsilon(x-\sigma t; u_+, u_-)$ satisfies (1.3), then it is called a *traveling wave solution* of (1.3). Applying the solution from (4.1) to (1.3) gives

$$\epsilon V^\epsilon_{\xi\xi} = -\sigma V^\epsilon_\xi + f(V^\epsilon)_\xi. \tag{4.2}$$

Integrating the above equation over $(-\infty, \xi)$ gives

$$\epsilon V^\epsilon_\xi = -\sigma(V^\epsilon - u_-) + f(V^\epsilon) - f(u_-). \tag{4.3}$$

It is easy to show by rescaling $\eta = \xi/\epsilon$ that $V^\epsilon(\xi; u_+, u_-) = V^1(\xi/\epsilon; u_+, u_-)$. In the following we will use the notation $V(\eta; u_+, u_-)$ to denote $V^1(\eta; u_+, u_-)$. We also denote by $V(\eta; a, b)_a$ and $V(\eta; a, b)_b$ the partial derivatives of V with respect to a and b, respectively. Note that $V^\epsilon(\xi; u_+, u_-) = V(\xi/\epsilon; u_+, u_-)$, which satisfies

$$V' = -\sigma(V - u_-) + f(V) - f(u_-). \tag{4.4}$$

It is well known that a necessary and sufficient condition for the existence of a traveling wave solution is that the constants $u_\pm$ and σ satisfy the Rankine–Hugoniot condition

$$-\sigma(u_+ - u_-) + f(u_+) - f(u_-) = 0 \tag{4.5}$$

and the entropy condition

$$\Phi(u; u_+, u_-) =: -\sigma(u - u_\pm) + f(u) - f(u_\pm) \begin{cases} < 0 & \text{if } u_+ < u < u_-, \\ > 0 & \text{if } u_- < u < u_+. \end{cases} \tag{4.6}$$

LEMMA 4.1. *Let $u_\pm$ and σ satisfy* (4.5)–(4.6) *and*

$$|\Phi(u; u_+, u_-)| \sim |u - u_\pm|^{1+\beta_\pm} \quad \text{as} \quad u \to u_\pm \tag{4.7}$$

with $\beta_\pm \geq 0$. Then there exists $V(\eta; u_+, u_-)$, unique up to a shift, which is determined by the ordinary differential equation (4.4). *Moreover, for $k = 1, 2$*

1. *if $\beta_\pm = 0$, then $f'(u_+) < \sigma < f'(u_-)$ and for $\eta \to \pm\infty$*

$$\begin{aligned} &|V(\eta; u_+, u_-) - H(\eta; u_+, u_-)| \sim \exp(-c|\eta|), \\ &|V^{(k)}(\eta; u_+, u_-)| \sim \exp(-c|\eta|), \\ &|V(\eta; u_+, u_-)_{u_\pm} - 1| \sim \exp(-c|\eta|), \end{aligned} \tag{4.8}$$

   where $H(\eta; u_+, u_-)$ is the Heaviside function satisfying $H = u_+$ for $\eta > 0$ and $H = u_-$ for $\eta < 0$;

2. *if $\beta_+ > 0$, then $\sigma = f'(u_+)$ and for $\eta \to +\infty$*

$$\begin{aligned} &|V(\eta; u_+, u_-) - u_+| \sim |\eta|^{-1/\beta_+}, \\ &|V^{(k)}(\eta; u_+, u_-)| \sim |\eta|^{-1/\beta_+ - k}, \\ &|V(\eta; u_+, u_-)_{u_+} - 1| \sim |\eta|^{-1/\beta_+}; \end{aligned} \tag{4.9}$$

3. *if $\beta_- > 0$, then $\sigma = f'(u_-)$ and for $\eta \to -\infty$*

$$\begin{aligned} &|V(\eta; u_+, u_-) - u_-| \sim |\eta|^{-1/\beta_-}, \\ &|V^{(k)}(\eta; u_+, u_-)| \sim |\eta|^{-1/\beta_- - k}, \\ &|V(\eta; u_+, u_-)_{u_-} - 1| \sim |\eta|^{-1/\beta_-}. \end{aligned} \tag{4.10}$$

Proof. For completeness, we briefly outline the proof for this lemma. It follows from (4.4) that $V(\eta; u_+, u_-)$ can be defined implicitly by

$$\eta = \int_{(u_+ + u_-)/2}^{V} \Phi(v; u_+, u_-)^{-1} dv. \tag{4.11}$$

The proof of this lemma is mainly based on the above definition and the assumption (4.7). Here we show only some of the estimates in (4.9); other estimates can be obtained similarly. The assumption (4.7) implies

$$D^{-1}|v-u_-|^{1+\beta_-}|v-u_+|^{1+\beta_+} \le |\Phi(v;u_+,u_-)| \le D|v-u_-|^{1+\beta_-}|v-u_+|^{1+\beta_+},$$

where $D>0$ is a constant. It follows from the above inequalities and (4.11) that, for $\eta>0$,

$$\begin{aligned} D^{-1}2^{-(1+\beta_-)}\left|\frac{2}{u_- - u_+}\right|^{(1+\beta_-)}\left|\int_{(u_++u_-)/2}^{V}(v-u_+)^{-1-\beta_+}dv\right| \\ \le \eta \le D\left|\frac{2}{u_- - u_+}\right|^{(1+\beta_-)}\left|\int_{(u_++u_-)/2}^{V}(v-u_+)^{-1-\beta_+}dv\right|. \end{aligned}$$

Solving the above inequalities for V gives

$$\begin{aligned} &\left|\frac{u_+-u_-}{2}\right|\left(1+D2^{(1+\beta_-)}\left|\frac{u_+-u_-}{2}\right|^{1+\beta_++\beta_-}\beta_+\eta\right)^{-1/\beta_+} \\ &\quad \le |V-u_+| \le \left|\frac{u_+-u_-}{2}\right|\left(1+D^{-1}\left|\frac{u_+-u_-}{2}\right|^{1+\beta_++\beta_-}\beta_+\eta\right)^{-1/\beta_+}. \end{aligned}$$

This proves the first estimate in (4.9). It is easy to show that as $\eta\to+\infty$

$$\begin{aligned} |V'(\eta;u_+,u_-)| = |\Phi(V;u_+,u_-)| &\sim |V-u_+|^{1+\beta_+} \\ &\sim |\eta|^{-1/\beta_+(1+\beta_+)} = |\eta|^{-1/\beta_+-1}. \end{aligned}$$

Thus the second estimate in (4.9) follows. □

COROLLARY 4.1. *If* (4.7) *holds and* $\beta_\pm>0$, *then*

$$|a(u)-a(u_\pm)| \sim |u-u_\pm|^{\beta_\pm} \quad as \quad u\to u_\pm. \tag{4.12}$$

COROLLARY 4.2. *Under the same assumptions as in Lemma* 4.1, *the following results hold:*

1. *If* $\beta_\pm=0$, *then* $\forall\eta\in\mathbf{R}$ *and* $k=1,2$

$$\begin{aligned} &|V(\eta;u_+,u_-)-H(\eta;u_+,u_-)| \le C\exp(-c|\eta|), \\ &|V^{(k)}(\eta;u_+,u_-)| \le C\exp(-c|\eta|). \end{aligned} \tag{4.13}$$

2. *If* $\beta_+>0$, *then* $\forall\eta\in\mathbf{R}^+$ *and* $k=1,2$

$$\begin{aligned} &|V(\eta;u_+,u_-)-u_+| \le C(1+|\eta|)^{-1/\beta_+}, \\ &|V^{(k)}(\eta;u_+,u_-)| \le C(1+|\eta|)^{-1/\beta_+-k}. \end{aligned} \tag{4.14}$$

3. *If* $\beta_->0$, *then* $\forall\eta\in\mathbf{R}^-$ *and* $k=1,2$

$$\begin{aligned} &|V(\eta;u_+,u_-)-u_-| \le C(1+|\eta|)^{-1/\beta_-}, \\ &|V^{(k)}(\eta;u_+,u_-)| \le C(1+|\eta|)^{-1/\beta_--k}. \end{aligned} \tag{4.15}$$

4. *If* $\beta_\pm > 0$, *then* $\forall \eta \in \mathbf{R}$

$$\begin{aligned} &\left|V(\eta; u_+, u_-)_{u_+}\dot{u}_+ + V(\eta; u_+, u_-)_{u_-}\dot{u}_- - H(\eta; \dot{u}_+, \dot{u}_-)\right| \\ &\le C(1+|\eta|)^{-1/\beta}, \end{aligned} \tag{4.16}$$

where $\beta = \max\{\beta_-, \beta_+\}$ *and* $\dot{w} = w'(t)$.

Remark 4.1. It is noted that the constant C in the above inequalities depends on $|u_+ - u_-|^{-1}$. Since it is assumed that $u_k^+(t) - u_k^-(t) \neq 0$ on all $[t_{m-1}, t_m]$, C can be regarded as a constant uniform with respect to both $t \in [0, T]$ and $k = 1, \ldots, K$.

5. Construction of an approximate solution. In this section, we construct an approximate solution $\widehat{u}^\epsilon$ to u and u^ϵ by using the method of matching asymptotic expansions. As in [5] and [24], the main idea of constructing $\widehat{u}^\epsilon$ is that $\widehat{u}^\epsilon$ is a small perturbation of u in the smooth region that posseses a viscous shock profile in places of discontinuities. We begin with the simpler case of one single shock.

5.1. An approximation to u and u^ϵ with one shock. Assume that there is only one shock curve $x = X_1(t)$ in the entropy solution $u(x,t)$ in the time interval $[t_{m-1}, t_m]$. We construct a *continuous* approximate solution $\widehat{u}^\epsilon$ to u and u^ϵ in $[t_{m-1}, t_m]$,

$$\widehat{u}^\epsilon(x,t) = m\left(\frac{x - X_1(t)}{\epsilon^\gamma}\right) I(x,t) + \left(1 - m\left(\frac{x - X_1(t)}{\epsilon^\gamma}\right)\right) O(x,t), \tag{5.1}$$

where

$$\begin{aligned} I(x,t) = u(x,t) &+ V\left(\frac{x - X_1(t)}{\epsilon}; u_+(t), u_-(t)\right) \\ &- H\left(\frac{x - X_1(t)}{\epsilon}; u_+(t), u_-(t)\right), \end{aligned} \tag{5.2}$$

$$O(x,t) = u(x,t) \tag{5.3}$$

are called first-order *inner* and *outer* solutions, respectively, $u_\pm(t) = u(X_1(t) \pm 0, t)$, $H(\xi; u_+, u_-)$ is the Heaviside function, $0 < \gamma < 1$ is a constant to be determined later, $m(\xi) \in C^\infty(\mathbf{R})$ satisfying $0 \le m(\xi) \le 1$, and

$$m(\xi) = \begin{cases} 1, & |\xi| \le 1, \\ 0, & |\xi| \ge 2. \end{cases} \tag{5.4}$$

The approximate solution can also be written in an equivalent form:

$$\widehat{u}^\epsilon(x,t) = u(x,t) + m\left(\frac{x - X_1(t)}{\epsilon^\gamma}\right)(V - H)\left(\frac{x - X_1(t)}{\epsilon}; u_+(t), u_-(t)\right). \tag{5.5}$$

The following lemma shows that $\widehat{u}^\epsilon$ is a good approximation to u in the L^1 space.

LEMMA 5.1. *Assume that there is only one shock curve* $x = X_1(t)$ *for the entropy solution* $u(x,t)$ *in the time interval* $[t_{m-1}, t_m]$. *Then, for any* $t \in [t_{m-1}, t_m]$,

$$\|\widehat{u}^\epsilon(\cdot,t) - u(\cdot,t)\|_{L^1(\mathbf{R})} \le \begin{cases} C\epsilon, & \bar{\beta} < 1, \\ C\epsilon^{\gamma + (1-\gamma)/\bar{\beta}}\,|\ln \epsilon|, & \bar{\beta} \ge 1, \end{cases} \tag{5.6}$$

where $\bar{\beta} = \max_t \beta(t)$ *and* $\beta = \max\{\beta_1^+, \beta_1^-\}$.

Proof. It follows from (5.5) and (5.4) that

$$\begin{aligned}
&\|\widehat{u}^\epsilon(\cdot,t)-u(\cdot,t)\|_{L^1(\mathbf{R})}\\
&=\int_{-2\epsilon^\gamma}^{0}+\int_0^{2\epsilon^\gamma} m\left(\frac{x}{\epsilon^\gamma};u_+(t),u_-(t)\right)\left|(V-H)\left(\frac{x}{\epsilon};u_+(t),u_-(t)\right)\right|dx\\
&=: I_-+I_+.
\end{aligned}$$

Using the change of variables $\xi = x/\epsilon$ and the estimate (4.14), we have for $0<\beta_1^+\le 1$ that

$$\begin{aligned}
I_+ &= \epsilon\int_0^{2\epsilon^{-1+\gamma}} m(\epsilon^{1-\gamma}\xi)|V(\xi;u_+,u_-)-H(\xi;u_+,u_-)|d\xi \qquad (5.7)\\
&= C\epsilon\int_0^{2\epsilon^{-1+\gamma}}(1+|\xi|)^{-1/\beta_1^+}d\xi \le \begin{cases} C\epsilon, & 0<\beta_1^+<1,\\ C\epsilon|\ln\epsilon|, & \beta_1^+=1.\end{cases}
\end{aligned}$$

On the other hand, for $\beta_1^+>1$ using the change of variables $\xi^{\beta_1^+}=x/\epsilon$ gives

$$\begin{aligned}
I_+ &= \beta_1^+\epsilon\int_0^{2^{1/\beta_1^+}\epsilon^{-(1-\gamma)/\beta_1^+}} m\Big(\epsilon^{1-\gamma}\xi^{\beta_1^+}\Big)\Big|(V-H)\Big(\xi^{\beta_1^+};u_+,u_-\Big)\Big|\xi^{\beta_1^+-1}d\xi\\
&\le C\epsilon^{1-(1-\gamma)(\beta_1^+-1)/\beta_1^+}\int_0^{2^{1/\beta_1^+}\epsilon^{-(1-\gamma)/\beta_1^+}}(1+|\xi|^{\beta_1^+})^{-1/\beta_1^+}d\xi\\
&\le C\epsilon^{1-(1-\gamma)(\beta_1^+-1)/\beta_1^+}|\ln\epsilon|. \qquad (5.8)
\end{aligned}$$

It follows from the above results that

$$I_+\le\begin{cases} C\epsilon, & 0<\beta_1^+<1,\\ C\epsilon|\ln\epsilon|, & \beta_1^+=1,\\ C\epsilon^{1-(1-\gamma)(\beta_1^+-1)/\beta_1^+}|\ln\epsilon|, & 1<\beta_1^+.\end{cases} \qquad (5.9)$$

Similarly, we can obtain the estimates for I_-:

$$I_-\le\begin{cases} C\epsilon, & 0<\beta_1^-<1,\\ C\epsilon|\ln\epsilon|, & \beta_1^-=1,\\ C\epsilon^{1-(1-\gamma)(\beta_1^--1)/\beta_1^-}|\ln\epsilon|, & 1<\beta_1^-.\end{cases} \qquad (5.10)$$

Combining the estimates for I_+ and I_- gives the desired result (5.6). ∎

We can also estimate the difference between $\widehat{u}^\epsilon$ and u^ϵ. The result will be given below, but its proof will be deferred to section 7.

LEMMA 5.2. *Assume that there is only one shock curve $x=X_1(t)$ for the entropy solution $u(x,t)$ in the time interval $[t_{m-1},t_m]$. Then, for any $t\in[t_{m-1},t_m]$,*

$$\begin{aligned}
&\|\widehat{u}^\epsilon(\cdot,t)-u^\epsilon(\cdot,t)\|_{L^1(\mathbf{R})} \qquad (5.11)\\
&\le \|\widehat{u}^\epsilon(\cdot,t_{m-1})-u^\epsilon(\cdot,t_{m-1})\|_{L^1(\mathbf{R})}+C\epsilon^{(1-\gamma)(\bar\beta+1)/\bar\beta}+C\epsilon^{\gamma+(1-\gamma)/\bar\beta}.
\end{aligned}$$

5.2. An approximation to u and u^ϵ with two shocks. Assume that in the time interval $[t_{m-1},t_m]$ there exist two shock curves $x=X_1(t)$ and $x=X_2(t)$ for the entropy solution $u(x,t)$ which either collide at $t=t_m$, i.e., $X_1(t_m)=X_2(t_m)$, or at $t=t_{m-1}$, i.e., $X_1(t_{m-1})=X_2(t_{m-1})$. We construct a *continuous* approximate

solution $\widehat{u}^\epsilon$ to u and u^ϵ in $[t_{m-1}, t_m]$ by using the method of matching asymptotic expansions:

$$\widehat{u}^\epsilon(x,t) = m\left(\frac{x-X_1(t)}{\epsilon^\gamma}\right) I_1(x,t) + \left(1 - m\left(\frac{x-X_1(t)}{\epsilon^\gamma}\right)\right) O_1(x,t) + m\left(\frac{x-X_2(t)}{\epsilon^\gamma}\right) I_2(x,t) + \left(1 - m\left(\frac{x-X_2(t)}{\epsilon^\gamma}\right)\right) O_2(x,t), \tag{5.12}$$

where

$$I_i(x,t) = u(x,t) + (V-H)\left(\frac{x-X_i(t)}{\epsilon}; u_{i+}(t), u_{i-}(t)\right), \qquad i = 1,2, \tag{5.13}$$

$$O_i(x,t) = u(x,t), \qquad i = 1,2, \tag{5.14}$$

are the first-order inner and outer solutions, respectively. Here, $u_{i\pm}(t) = u(X_i(t) \pm 0, t)$, $H(\xi; u_+, u_-)$ is the Heaviside function, γ is a constant to be determined later. This approximation can be also written in an equivalent form:

$$\begin{aligned}\widehat{u}^\epsilon(x,t) = u(x,t) &+ m\left(\frac{x-X_1(t)}{\epsilon^\gamma}\right)(V-H)\left(\frac{x-X_1(t)}{\epsilon}; u_{1+}(t), u_{1-}(t)\right) \\ &+ m\left(\frac{x-X_2(t)}{\epsilon^\gamma}\right)(V-H)\left(\frac{x-X_2(t)}{\epsilon}; u_{2+}(t), u_{2-}(t)\right).\end{aligned} \tag{5.15}$$

LEMMA 5.3. *Assume that in the time interval $[t_{m-1}, t_m]$ there exist two shock curves $x = X_1(t)$ and $x = X_2(t)$ for the entropy solution $u(x,t)$ which either collide at $t = t_m$ or at $t = t_{m-1}$. Then, for any $t \in [t_{m-1}, t_m]$,*

$$\|\widehat{u}^\epsilon(\cdot,t) - u(\cdot,t)\|_{L^1(\mathbf{R})} \le \begin{cases} C\epsilon, & \bar\beta < 1, \\ C\epsilon^{\gamma+(1-\gamma)/\bar\beta}\,|\ln\epsilon|, & \bar\beta \ge 1, \end{cases} \tag{5.16}$$

where $\bar\beta = \max_t \beta(t)$ and $\beta = \max\{\beta_1^+, \beta_1^-, \beta_2^+, \beta_2^-\}$.

LEMMA 5.4. *Assume that in the time interval $[t_{m-1}, t_m]$ there exist two shock curves $x = X_1(t)$ and $x = X_2(t)$ for the entropy solution $u(x,t)$ which either collide at $t = t_m$ or at $t = t_{m-1}$. Then, for any $t \in [t_{m-1}, t_m]$,*

$$\begin{aligned}&\|\widehat{u}^\epsilon(\cdot,t) - u^\epsilon(\cdot,t)\|_{L^1(\mathbf{R})} \\ &\le \|\widehat{u}^\epsilon(\cdot,t_{m-1}) - u^\epsilon(\cdot,t_{m-1})\|_{L^1(\mathbf{R})} + C\epsilon^{(1-\gamma)(\bar\beta+1)/\bar\beta} + C\epsilon^{\gamma+(1-\gamma)/\bar\beta} + C\epsilon^{2\gamma}.\end{aligned} \tag{5.17}$$

The proof of Lemma 5.3 is similar to that of Lemma 5.1 and will be omitted here. We defer the proof of Lemma 5.4 to section 8.

6. Proof of main theorem. We will prove Theorem 3.1 by considering only the case $\bar\beta \ge 1$, i.e., the nonconvex case; the convex result was obtained in [24]. Recall that it is assumed in each time interval $[t_{m-1}, t_m]$ the entropy solution u is a finite combination of some noncontact shocks, contact shocks, etc. Theorem 3.1 will be established by induction on m. Namely, we will prove

$$\|u(\cdot,t_m) - u^\epsilon(\cdot,t_m)\|_{L^1(\mathbf{R})} \le \begin{cases} C(T)\epsilon|\ln\epsilon| & \text{for } \bar\beta < 1, \\ C(T)\epsilon^{(1+1/\bar\beta)/2}|\ln\epsilon| & \text{for } \bar\beta \ge 1 \end{cases} \tag{6.1}$$

under the induction assumption

$$\|u(\cdot,t_{m-1}) - u^\epsilon(\cdot,t_{m-1})\|_{L^1(\mathbf{R})} \le \begin{cases} C(T)\epsilon|\ln\epsilon| & \text{for } \bar\beta < 1, \\ C(T)\epsilon^{(1+1/\bar\beta)/2}|\ln\epsilon| & \text{for } \bar\beta \ge 1. \end{cases} \tag{6.2}$$

The induction assumption holds for $m = 1$ due to the fact $u(x,0) = u^\epsilon(x,t)$. Observe that

$$\begin{aligned}(6.3)\qquad &\|u(\cdot,t_m) - u^\epsilon(\cdot,t_m)\|_{L^1(\mathbf{R})}\\ &\le \|u(\cdot,t_m) - \hat{v}^\epsilon(\cdot,t_m)\|_{L^1(\mathbf{R})} + \|\hat{v}^\epsilon(\cdot,t_m) - u^\epsilon(\cdot,t_m)\|_{L^1(\mathbf{R})}.\end{aligned}$$

It follows from Lemmas 5.1 and 5.3 that

$$(6.4)\qquad \|u(\cdot,t_m) - \hat{v}^\epsilon(\cdot,t_m)\|_{L^1(\mathbf{R})} \le C\epsilon^{\gamma+(1-\gamma)/\bar{\beta}}|\ln\epsilon|.$$

On the other hand, Lemmas 5.2 and 5.4 imply that

$$\begin{aligned}(6.5)\qquad &\|\hat{v}^\epsilon(\cdot,t_m) - u^\epsilon(\cdot,t_m)\|_{L^1(\mathbf{R})}\\ &\le \|\hat{v}^\epsilon(\cdot,t_{m-1}) - u^\epsilon(\cdot,t_{m-1})\|_{L^1(\mathbf{R})} + C\epsilon^{(1-\gamma)(\bar{\beta}+1)/\bar{\beta}} + C\epsilon^{\gamma+(1-\gamma)/\bar{\beta}} + C\epsilon^{2\gamma}.\end{aligned}$$

Using the induction assumption (6.2) and (6.3)–(6.5) gives

$$\begin{aligned}&\|u(\cdot,t_m) - u^\epsilon(\cdot,t_m)\|_{L^1(\mathbf{R})}\\ &\le C\epsilon^{\gamma+(1-\gamma)/\bar{\beta}}|\ln\epsilon| + C\epsilon^{(1+1/\bar{\beta})/2}|\ln\epsilon| + C\epsilon^{(1-\gamma)(\bar{\beta}+1)/\bar{\beta}} + C\epsilon^{\gamma+(1-\gamma)/\bar{\beta}} + C\epsilon^{2\gamma}.\end{aligned}$$

Setting $\gamma = 1/2$ in the above estimate leads to (6.1), which completes the induction proof.

7. Proof of Lemma 5.2. The main tool for establishing Lemma 5.2 is the stability lemma, Lemma 3.1. Let $v^\epsilon = \widehat{u}^\epsilon$ as defined by (5.1). Then v^ϵ satisfies (3.2) on its smooth region $\{(x,t) : x \ne X_1(t)\}$, with

$$\begin{aligned}g(x,t) &= u_t + (m(V-H))_t + f(u + m(V-H))_x - \epsilon(u_{xx} + (m(V-H))_{xx})\\ &= -a(u)u_x + m_t(V-H) - mV'\frac{\dot{X}_1(t)}{\epsilon} + m(V-H)_{u_+}\dot{u}_+ + m(V-H)_{u_-}\dot{u}_-\\ &\quad + (a(u+m(V-H))\left(u_x + m_x(V-H) + mV'\frac{1}{\epsilon}\right)\\ &\quad - \epsilon\left(u_{xx} + m_{xx}(V-H) + 2m_xV'\frac{1}{\epsilon} + mV''\frac{1}{\epsilon^2}\right).\end{aligned}$$

It follows from Lemma 3.1 that, for any $t \in [t_{m-1}, t_m]$,

$$\begin{aligned}(7.1)\qquad &\|\widehat{u}^\epsilon(\cdot,t) - u^\epsilon(\cdot,t)\|_{L^1(\mathbf{R})}\\ &\le \|\widehat{u}^\epsilon(\cdot,t_{m-1}) - u^\epsilon(\cdot,t_{m-1})\|_{L^1(\mathbf{R})}\\ &\quad + \epsilon\int_{t_{m-1}}^t \Big|\left[\partial_x\widehat{u}^\epsilon(x,t)\right]|_{x=X_1(t)}\Big|dt + \int_{t_{m-1}}^t \|g(\cdot,t)\|_{\mathrm{pis}(\mathbf{R})}dt\\ &\le \|\widehat{u}^\epsilon(\cdot,t_{m-1}) - u^\epsilon(\cdot,t_{m-1})\|_{L^1(\mathbf{R})} + C\epsilon + \int_{t_{m-1}}^t \|g(\cdot,t)\|_{\mathrm{pis}(\mathbf{R})}dt,\end{aligned}$$

where we have used the facts that $[\partial_x\widehat{u}^\epsilon(x,t)]\,|_{x=X_1(t)} = [u_x(x,t)]\,|_{x=X_1(t)}$ and the limits of $u_x(X(t)\pm 0,t)$ are uniformly bounded on $[t_{m-1},t_m]$. We now claim that g is

sufficiently small such that $\widehat{u}^\epsilon$ satisfies (1.3) approximately. To this end, we rewrite g as follows:

$$\begin{aligned} g(x,t) &= m\left(\big(a(u+m(V-H))-\dot{X}_1(t)\big)V'-V''\right)\epsilon^{-1} \\ &\quad + \big(a(u+m(V-H))-a(u)\big)u_x \\ &\quad + \left(\big(a(u+m(V-H))-\dot{X}_1(t)\big)m'-m''\epsilon^{1-\gamma}\right)\epsilon^{-\gamma}(V-H) \\ &\quad - 2m'\epsilon^{-\gamma}V'-\epsilon u_{xx}+m(V-H)_{u_+}\dot{u}_+ + m(V-H)_{u_-}\dot{u}_- \\ &= \big(a(u+m(V-H))-\dot{X}_1(t)\big)\left(mV'\epsilon^{-1}+u_x+m'(V-H)\epsilon^{-\gamma}\right) \\ &\quad - mV''\epsilon^{-1}+(\dot{X}_1(t)-a(u))u_x - m''(V-H)\epsilon^{1-2\gamma}-2m'\epsilon^{-\gamma}V'-\epsilon u_{xx} \\ &\quad + m\left(V_{u_+}\dot{u}_+ + V_{u_-}\dot{u}_- - H\big(x-X_1(t);\dot{u}_+(t),\dot{u}_-(t)\big)\right). \end{aligned}$$

Using the traveling wave equation $V''=(a(V)-\dot{X}_1(t))V'$ gives

$$\begin{aligned} g(x,t) &= \big(a(u+m(V-H))-a(V)\big)mV'\epsilon^{-1} \\ &\quad + \big(a(u+m(V-H))-\dot{X}_1(t)\big)\left(u_x+m'(V-H)\epsilon^{-\gamma}\right) \\ &\quad + (\dot{X}_1(t)-a(u))u_x - m''(V-H)\epsilon^{1-2\gamma}-2m'\epsilon^{-\gamma}V'-\epsilon u_{xx} \\ &\quad + m\left(V_{u_+}\dot{u}_+ + V_{u_-}\dot{u}_- - H\big(x-X_1(t);\dot{u}_+(t),\dot{u}_-(t)\big)\right). \end{aligned} \tag{7.2}$$

Without loss of generality, we will consider only contact shock curves, i.e., $\beta_1^\pm \geq 1$. The assumption $\beta_1^\pm \geq 1$ implies that $\dot{X}_1(t)=a(u_\pm)$, which leads to

$$\begin{aligned} g(x,t) &= \big(a(u+m(V-H))-a(V)\big)mV'\epsilon^{-1} \\ &\quad + \big(a(u+m(V-H))-a(u_\pm)\big)\left(u_x+m'(V-H)\epsilon^{-\gamma}\right) \\ &\quad + (a(u_\pm)-a(u))u_x - m''(V-H)\epsilon^{1-2\gamma}-2m'\epsilon^{-\gamma}V'-\epsilon u_{xx} \\ &\quad + m\left(V_{u_+}\dot{u}_+ + V_{u_-}\dot{u}_- - H\big(x-X_1(t);\dot{u}_+(t),\dot{u}_-(t)\big)\right). \end{aligned} \tag{7.3}$$

We now split $\|g(\cdot,t)\|_{\mathrm{pis}(\mathbf{R})}$ into the following three parts:

$$\begin{aligned} \|g(\cdot,t)\|_{\mathrm{pis}(\mathbf{R})} &= \int_{0<|x-X_1(t)|\leq\epsilon^\gamma} + \int_{\epsilon^\gamma\leq|x-X_1(t)|\leq 2\epsilon^\gamma} + \int_{|x-X_1(t)|\geq 2\epsilon^\gamma} |g(x,t)|dt \\ &= I + II + III. \end{aligned} \tag{7.4}$$

7.1. Piecewise constant solution. In order to estimate I, II, and III above we first consider a simple but important case: the piecewise constant solution, i.e.,

$$u(x,t)=\begin{cases} u_+, & x>X_1(t), \\ u_-, & x\leq X_1(t), \end{cases} \tag{7.5}$$

where u_+ and u_- are constants and $\dot{X}_1(t)=(f(u_-)-f(u_+))/(u_--u_+)$. It is easy to show that $g(x,t)=0$ for $0<|x-X_1(t)|\leq\epsilon^\gamma$ and $|x-X_1(t)|>2\epsilon^\gamma$. Therefore $I=III=0$, and what we need to estimate is the term II. Let

$$II = II_+ + II_-, \tag{7.6}$$

where

$$
\begin{aligned}
II_\pm =: \pm \int_{X_1(t)\pm\epsilon^\gamma}^{X_1(t)\pm 2\epsilon^\gamma} \Big| & \big(a(u_\pm + m(V-u_\pm)) - a(V)\big) mV'\epsilon^{-1} \\
& + \big(a(u_\pm + m(V-u_\pm)) - a(u_\pm)\big) m'(V-u_\pm)\epsilon^{-\gamma} \\
& - m''(V-u_\pm)\epsilon^{1-2\gamma} - 2m'\epsilon^{-\gamma}V' \Big| dx \qquad (7.7)\\
= \pm \int_{X_1(t)\pm\epsilon^\gamma}^{X_1(t)\pm 2\epsilon^\gamma} \Big| & \big(a(u_\pm + m(V-u_\pm)) - a(u_\pm)\big)\big(mV'\epsilon^{-1} + m'(V-u_\pm)\epsilon^{-\gamma}\big) \\
& - (a(V) - a(u_\pm))mV'\epsilon^{-1} - m''(V-u_\pm)\epsilon^{1-2\gamma} - 2m'\epsilon^{-\gamma}V' \Big| dx.
\end{aligned}
$$

Using the change of variables $\xi = (x - X_1(t))/\epsilon^\gamma$ gives

$$
\begin{aligned}
II_\pm = \pm \int_{\pm 1}^{\pm 2} \Big| & \big(a(u_\pm + m(V-u_\pm)) - a(u_\pm)\big)\big(mV'\epsilon^{-1+\gamma} + m'(V-u_\pm)\big) \\
& - (a(V) - a(u_\pm))mV'\epsilon^{-1+\gamma} - m''(V-u_\pm)\epsilon^{1-\gamma} - 2m'V' \Big| d\xi, \qquad (7.8)
\end{aligned}
$$

where $m = m(\xi)$ and $V = V(\xi/\epsilon^{1-\gamma})$. The following estimates can be obtained from Lemma 4.1 and Corollary 4.1:

$$
\begin{aligned}
& |V - u_\pm| \le C\epsilon^{(1-\gamma)/\beta_1^\pm}, \qquad |V'| \le C\epsilon^{(1-\gamma)(1+1/\beta_1^\pm)}, \\
& |a(u_\pm + m(V-u_\pm)) - a(u_\pm)| \le C|V-u_\pm|^{\beta_1^\pm} \le C\epsilon^{1-\gamma}, \\
& |a(V) - a(u_\pm)| \le C|V-u_\pm|^{\beta_1^\pm} \le C\epsilon^{1-\gamma},
\end{aligned}
$$

provided ϵ is sufficiently small. It follows from (7.8) and the above estimates that

$$
II_\pm \le C\epsilon^{(1-\gamma)(1+1/\beta_1^\pm)}. \qquad (7.9)
$$

The above results, together with the facts $I = III = 0$, give the desired upper bound for $\|g(\cdot,t)\|_{\mathrm{pis}(\mathbf{R})}$. Therefore, Lemma 5.2 is established in the case of the piecewise constant solution.

7.2. Piecewise smooth solution. We now consider a more general case, i.e., u is piecewise smooth. It follows from (7.3) that $g(x,t) = -\epsilon u_{xx}$ for $|x - X_1(t)| > 2\epsilon^\gamma$, and

$$
\begin{aligned}
g(x,t) = & \big(a(u + (V-H)) - a(V)\big)V'\epsilon^{-1} \\
& + \big(a(u + (V-H)) - a(u)\big)u_x - \epsilon u_{xx} \\
& + V_{u_+}\dot{u}_+ + V_{u_-}\dot{u}_- - H(x - X_1(t); \dot{u}_+, \dot{u}_-)
\end{aligned} \qquad (7.10)
$$

for $0 < |x - X_1(t)| \le \epsilon^\gamma$. It is easy to see from (7.4) that

$$
III = \epsilon \int_{|x-X_1(t)|\ge 2\epsilon^\gamma} |u_{xx}| dx \le C\epsilon, \qquad (7.11)
$$

where $u_{xx}(\cdot,t)$ is assumed piecewisely in L^1. It follows from (7.10) that

$$
I \le I_1 + I_2 + I_3 + I_4, \qquad (7.12)
$$

where

$$
\begin{aligned}
I_1 &= \int_{0<|x-X_1(t)|\le\epsilon^\gamma} -|a(u+(V-H))-a(V)|V'\epsilon^{-1}dx,\\
I_2 &= \int_{0<|x-X_1(t)|\le\epsilon^\gamma} \big|\big(a(u+(V-H))-a(u)\big)u_x\big|dx,\\
I_3 &= \int_{0<|x-X_1(t)|\le\epsilon^\gamma} \epsilon|u_{xx}|dx,\\
I_4 &= \int_{0<|x-X_1(t)|\le\epsilon^\gamma} \big|V_{u_+}\dot u_+ + V_{u_-}\dot u_- - H(x-X_1(t);\dot u_+,\dot u_-)\big|dx.
\end{aligned}
$$

We now estimate $I_i, 1\le i\le 4$. Since u is piecewise smooth and $u-H\to 0$ as $x\to X_1(t)\pm 0$, we have

$$
\begin{aligned}
|a(u+(V-H))-a(V)| &= |a'(V+\theta(u-H))(u-H)|\\
&\le C|x-X_1(t)|.
\end{aligned}
$$

Therefore, we can find a positive function $A(\xi)$ such that $\forall x\in(-\infty,\infty)$

- $|a(u+(V-H))-a(V)|\le A\left(x-X_1(t)\right)$;
- $A(\xi)\le C|\xi|$;
- $|A'(\xi)|\le M$,

where M is a constant. It follows from the above auxiliary function A and the estimates (4.9) and (4.10) that

$$
\begin{aligned}
I_1 &\le \int_{|x-X_1(t)|\le\epsilon^\gamma} -A(x-X_1(t))V'((x-X_1(t))/\epsilon)\epsilon^{-1}dx\\
&= \int_{-\epsilon^{\gamma-1}}^{\epsilon^{\gamma-1}} -A(\epsilon\xi)V'(\xi)d\xi\\
&= \int_{-\epsilon^{\gamma-1}}^{\epsilon^{\gamma-1}} -A(\epsilon\xi)\big(V(\xi)-H(\xi)\big)'d\xi \qquad \text{(using the fact } A(0)=0)\\
&\le A(\epsilon^\gamma)|V(\epsilon^{\gamma-1})-H(\epsilon^{\gamma-1})| + A(-\epsilon^\gamma)|V(-\epsilon^{\gamma-1})-H(-\epsilon^{\gamma-1})|\\
&\qquad +M\epsilon\int_{-\epsilon^{\gamma-1}}^{\epsilon^{\gamma-1}}|V(\xi)-H(\xi)|d\xi \qquad \text{(using integration by parts)}\\
&\le C\epsilon^{\gamma+(1-\gamma)/\beta} + C\epsilon^{1-(1-\gamma)(1-1/\beta)} \le \epsilon^{\gamma+(1-\gamma)/\beta}.
\end{aligned}
\tag{7.13}
$$

Observe that $|a(u+(V-H))-a(u)|\le C|V-H|$, which, if applied to I_2, gives

$$
\begin{aligned}
I_2 &\le C\int_{|x-X_1(t)|\le\epsilon^\gamma}|V-H|dx\\
&\le C\epsilon\int_{-\epsilon^{\gamma-1}}^{\epsilon^{\gamma-1}}|V(\xi)-H(\xi)|d\xi\\
&\le C\epsilon\int_{-\epsilon^{\gamma-1}}^{\epsilon^{\gamma-1}}(1+|\xi|)^{-1/\beta}d\xi\\
&\le C\epsilon^{1-(1-\gamma)(1-1/\beta)} = C\epsilon^{\gamma+(1-\gamma)/\beta}.
\end{aligned}
\tag{7.14}
$$

Moreover, by the definition of I_3 we can easily obtain $I_3 \le C\epsilon^{1+\gamma}$. Using the change of variables $\xi = (x - X_1(t))/\epsilon$ and the estimate (4.16) gives

$$I_4 \le C\epsilon \int_{-\epsilon^{\gamma-1}}^{\epsilon^{\gamma-1}} (1+|\xi|)^{-1/\beta} d\xi \le C\epsilon^{1-(1-\gamma)(1-1/\beta)} = C\epsilon^{\gamma+(1-\gamma)/\beta}. \tag{7.15}$$

Combining the above estimates yields

$$I \le C\left(\epsilon^{\gamma+(1-\gamma)/\beta} + \epsilon^{\gamma(1+\beta)} + \epsilon|\ln\epsilon| + \epsilon^{(1+\gamma)}\right). \tag{7.16}$$

It remains to estimate II. It follows from (7.3) that

$$II \le II_+ + II_- + \sum_{i=1}^{5} II_+^{(i)} + \sum_{i=1}^{5} II_-^{(i)},$$

where $II_\pm$ is defined by (7.7) and

$$\begin{aligned}
II_\pm^{(1)} &= \pm \int_{X_1(t)\pm\epsilon^\gamma}^{X_1(t)\pm 2\epsilon^\gamma} |(a(u + m(V-H)) - a(u_\pm + m(V-H)))mV'|\epsilon^{-1} dx,\\
II_\pm^{(2)} &= \pm \int_{X_1(t)\pm\epsilon^\gamma}^{X_1(t)\pm 2\epsilon^\gamma} |(a(u + m(V-H)) - a(u))u_x| dx,\\
II_\pm^{(3)} &= \pm \int_{X_1(t)\pm\epsilon^\gamma}^{X_1(t)\pm 2\epsilon^\gamma} |(a(u + m(V-H)) - a(u_\pm + m(V-H)))m'(V-H)|\epsilon^{-\gamma} dx,\\
II_\pm^{(4)} &= \pm \int_{X_1(t)\pm\epsilon^\gamma}^{X_1(t)\pm 2\epsilon^\gamma} \epsilon|u_{xx}| dx,\\
II_\pm^{(5)} &= \pm \int_{X_1(t)\pm\epsilon^\gamma}^{X_1(t)\pm 2\epsilon^\gamma} m\big|V_{u_+}\dot{u}_+ + V_{u_-}\dot{u}_- - H(x - X_1(t); \dot{u}_+, \dot{u}_-)\big| dx.
\end{aligned}$$

It follows from (7.9) that

$$II_\pm \le C\epsilon^{(1-\gamma)(1+1/\beta_1^\pm)}. \tag{7.17}$$

The estimate for $II_\pm^{(1)}$ is similar to that for I_1, with the same error bound as (7.13), namely,

$$II_\pm^{(1)} \le C\epsilon^{\gamma+(1-\gamma)/\beta}. \tag{7.18}$$

The estimate for $II_\pm^{(2)}$ is similar to that for I_2, with the same error bound as (7.14), namely,

$$II_\pm^{(2)} \le C\left(\epsilon^{\gamma(1+\beta)} + \epsilon|\ln\epsilon|\right). \tag{7.19}$$

The estimate for $II_\pm^{(5)}$ is similar to that for I_4, with the same error bound as (7.15), namely,

$$II_\pm^{(5)} \le C\epsilon^{1-(1-\gamma)(1-1/\beta)} = C\epsilon^{\gamma+(1-\gamma)/\beta}. \tag{7.20}$$

Using the facts that $a(u+m(V-H))-a(u_\pm+m(V-H))=a'(\bullet)(u-u_\pm)$, and $|u-u_\pm|\le C|x-X_1(t)|$ for $\pm(x-X_1(t))>0$, we obtain

$$I\!I_\pm^{(3)} \le \pm C\epsilon^\gamma \int_{X_1(t)\pm\epsilon^\gamma}^{X_1(t)\pm 2\epsilon^\gamma} |(V-H)|\epsilon^{-\gamma}dx.$$

Applying the change of variables $(x-X_1(t))/\epsilon=\xi$ to the above integration gives

$$I\!I_\pm^{(3)} \le \pm C\epsilon \int_{\pm\epsilon^{\gamma-1}}^{\pm 2\epsilon^{\gamma-1}} |V(\xi)-H(\xi)|d\xi.$$

It then follows from (4.14) and (4.15) that

$$\begin{aligned} I\!I_\pm^{(3)} &\le \pm C\epsilon \int_{\pm\epsilon^{\gamma-1}}^{\pm 2\epsilon^{\gamma-1}} (1+|\xi|)^{-1/\beta_1^\pm} d\xi \le C\epsilon^{1-(1-\gamma)(1-1/\beta_1^\pm)} \\ &= C\epsilon^{\gamma+(1-\gamma)/\beta_1^\pm}. \end{aligned} \tag{7.21}$$

Moreover, using the definition of $I\!I_\pm^{(4)}$ gives

$$I\!I_\pm^{(4)} \le \pm C \int_{X_1(t)\pm\epsilon^\gamma}^{X_1(t)\pm 2\epsilon^\gamma} \epsilon|u_{xx}|dx \le C\epsilon^{1+\gamma}. \tag{7.22}$$

Combining the estimates (7.17)–(7.22) leads to

$$\begin{aligned} I\!I &\le C\Big(\epsilon^{(1-\gamma)(1+1/\beta)} + \epsilon^{\gamma+(1-\gamma)/\beta)} + \epsilon^{\gamma(1+\beta)} + \epsilon|\ln\epsilon| + \epsilon^{1+\gamma}\Big) \\ &\le C\Big(\epsilon^{(1-\gamma)(1+1/\beta)} + \epsilon^{\gamma+(1-\gamma)/\beta)}\Big). \end{aligned} \tag{7.23}$$

Adding the estimates for I, $I\!I$, and $I\!I\!I$ gives

$$\begin{aligned} \|g(\cdot,t)\|_{\mathrm{pis}(\mathbf{R})} &\le C\left(\epsilon^{\gamma+(1-\gamma)/\beta} + \epsilon^{(1-\gamma)(1+1/\beta)}\right) \\ &\le C\left(\epsilon^{\gamma+(1-\gamma)/\bar\beta} + \epsilon^{(1-\gamma)(1+1/\bar\beta)}\right). \end{aligned} \tag{7.24}$$

This completes the proof for Lemma 5.2.

8. Proof of Lemma 5.4. The main difference between Lemmas 5.2 and 5.4 is that Lemma 5.2 deals with only one shock, while the latter deals with two interacting shocks. The main tool for the proof of Lemma 5.4 is still the stability lemma, Lemma 3.1. Let $v^\epsilon=\widehat{u}^\epsilon$, which is defined by (5.15). Then v^ϵ satisfies (3.2) on its smooth region $\{(x,t): x\ne X_i(t),\ i=1,2\}$, with

$$\begin{aligned} g(x,t) \;=\; & \left(a(u+m_1(V_1-H_1)+m_2(V_2-H_2))-a(u)\right)u_x \\ & + m_1'\left(a(u+m_1(V_1-H_1)+m_2(V_2-H_2))-a(H_1)\right)(V_1-H_1)\epsilon^{-\gamma} \\ & + m_2'(a(u+m_1(V_1-H_1)+m_2(V_2-H_2))-a(H_2))(V_2-H_2)\epsilon^{-\gamma} \\ & + m_1(a(u+m_1(V_1-H_1)+m_2(V_2-H_2))-a(V_1))V_1'\epsilon^{-1} \\ & + m_2(a(u+m_1(V_1-H_1)+m_2(V_2-H_2))-a(V_2))V_2'\epsilon^{-1} \\ & - \epsilon u_{xx} - \left(m_1''(V_1-H_1)+m_2''(V_2-H_2)\right)\epsilon^{1-2\gamma} - 2\left(m_1'V_1'+m_2'V_2'\right)\epsilon^{-\gamma} \\ & + m_1(V_{1u_+}\dot u_{1+}+V_{1u_-}\dot u_{1-}-\dot H_1)+m_2(V_{2u_+}\dot u_{2+}+V_{2u_-}\dot u_{2-}-\dot H_2) \\ :=\; & g_1+g_2+g_3+g_4+g_5+g_6+g_7, \end{aligned}$$

where for $i = 1, 2$

$$m_i = m((x - X_i(t))/\epsilon^\gamma), \qquad u_{i\pm}(t) = \lim_{x \to X_i \pm 0} u(x,t),$$
$$\dot{u}_{i\pm}(t) = \frac{d}{dt} u_{i\pm}(t), \qquad V_i = V((x - X_i(t))/\epsilon; u_{i+}, u_{i-}),$$
$$H_i = H((x - X_i(t))/\epsilon; u_{i+}, u_{i-}), \qquad \dot{H}_i = H((x - X_i(t))/\epsilon; \dot{u}_{i+}, \dot{u}_{i-}).$$

Similarly, it follows from Lemma 3.1 that, for any $t \in [t_{m-1}, t_m]$,

$$\begin{aligned} &\|\widehat{u}^\epsilon(\cdot,t) - u^\epsilon(\cdot,t)\|_{L^1(\mathbf{R})} \\ &\le \|\widehat{u}^\epsilon(\cdot,t_{m-1}) - u^\epsilon(\cdot,t_{m-1})\|_{L^1(\mathbf{R})} \\ &\quad + \epsilon \sum_{i=1}^{2} \int_{t_{m-1}}^{t} \Big| \left[\partial_x \widehat{u}^\epsilon(x,t)\right] |_{x=X_i(t)} \Big| dt + \int_{t_{m-1}}^{t} \|g(\cdot,t)\|_{\mathrm{pis}(\mathbf{R})} dt \\ &\le \|\widehat{u}^\epsilon(\cdot,t_{m-1}) - u^\epsilon(\cdot,t_{m-1})\|_{L^1(\mathbf{R})} + C\epsilon + \int_{t_{m-1}}^{t} \|g(\cdot,t)\|_{\mathrm{pis}(\mathbf{R})} dt. \end{aligned} \tag{8.1}$$

In order to estimate the last term above we need to estimate $\int_{t_{m-1}}^{t} \|g_i(\cdot,t)\|_{\mathrm{pis}(\mathbf{R})} dt$, $1 \le i \le 7$. It is noticed that the estimates for $\|g_6\|_{\mathrm{pis}(\mathbf{R})}$ and $\|g_7\|_{\mathrm{pis}(\mathbf{R})}$ are similar to those in one shock case, so they can be bounded above by the right-hand side of (7.24). Therefore, we just need to estimate $\|g_i\|_{\mathrm{pis}(\mathbf{R})}$ for $1 \le i \le 5$.

In what follows we assume that the two shock curves start at a same point, i.e.,

$$X_1(t_{m-1} + 0) = X_2(t_{m-1} + 0), \tag{8.2}$$

but do not become tangent to each other at this point:

$$\dot{X}_1(t_{m-1} + 0) < \dot{X}_2(t_{m-1} + 0). \tag{8.3}$$

This implies that there is a constant $c > 0$ such that

$$\delta(t) := X_2(t) - X_1(t) \ge c(t - t_{m-1}) \quad \text{for} \quad t \in [t_{m-1}, t_m]. \tag{8.4}$$

Note that the support of $m((\cdot - X_i(t))/\epsilon^\gamma)$ is $[X_i(t) - 2\epsilon^\gamma, X_i(t) + 2\epsilon^\gamma]$. Hence, if $X_2(t) - X_1(t) \ge 4\epsilon^\gamma$, then for each $x \in \mathbf{R}$ only one of m_1 and m_2 appears in $g(x,t)$. Therefore, when $X_2(t) - X_1(t) \ge 4\epsilon^\gamma$, the estimates for $\|g_i\|_{L^1}$, $1 \le i \le 5$, are similar to those for the one shock case. Let $\tau \in (t_{m-1}, t_m)$ such that

$$X_2(\tau) - X_1(\tau) = 4\epsilon^\gamma \quad \text{and} \quad X_2(t) - X_1(t) > 4\epsilon^\gamma \quad \text{for} \quad t \in (\tau, t_m]. \tag{8.5}$$

The above analysis implies that we only need to estimate $\|g_i\|_{L^1}$, $1 \le i \le 5$, for $t \in [t_{m-1}, \tau]$.

We first estimate $\|g_1\|_{L^1}$ for $t \in [t_{m-1}, \tau]$. Observe that

$$\begin{aligned} \|g_1(\cdot,t)\|_{\mathrm{pis}(\mathbf{R})} &= \int_{\{x \le X_1(t) - 2\epsilon^\gamma\} \cup \{x \ge X_2(t) + 2\epsilon^\gamma\}} |g_1| dx \\ &\quad + \int_{X_1(t) - 2\epsilon^\gamma < x < X_2(t) + 2\epsilon^\gamma} |g_1| dx \\ &:= G_{11} + G_{12}. \end{aligned} \tag{8.6}$$

Since only one of m_1 and m_2 appears in G_{11}, the estimate of G_{11} is similar to that of $II_{\pm}^{(2)}$ in the one shock case, and it follows from (7.19) that

$$G_{11} \le C\Big(\epsilon^{\gamma(1+\beta)} + \epsilon|\ln\epsilon|\Big), \tag{8.7}$$

where $\beta = \max\{\beta_1, \beta_2\}$. The integrand of G_{12} is bounded, and therefore

$$G_{12} \le C\Big(X_2(t) - X_1(t) + \epsilon^{\gamma}\Big).$$

It follows from (8.5), (8.4), and (8.2) that $\tau - t_{m-1} \le C\epsilon^{\gamma}$ and $X_2(t) - X_1(t) \le C(t - t_{m-1})$ as $t \to t_{m-1} + 0$. Therefore,

$$\int_{t_{m-1}}^{\tau} G_{12}dt \le C\epsilon^{2\gamma},$$

which, together with (8.7), gives

$$\int_{t_{m-1}}^{\tau} \|g_1(\cdot,t)\|_{\mathrm{pis}(\mathbf{R})}dt \le C\Big(\epsilon^{2\gamma} + \epsilon^{\gamma(2+\beta)} + \epsilon^{1+\gamma}|\ln\epsilon|\Big). \tag{8.8}$$

Next we estimate $\|g_2\|_{\mathrm{pis}(\mathbf{R})}$. Observe that

$$\begin{aligned}\|g_2\|_{\mathrm{pis}(\mathbf{R})} &= \int_{2\epsilon^{\gamma}>|x-X_1(t)|\ge\epsilon^{\gamma}} |g_2(x,t)|dx \le C\int_{2\epsilon^{\gamma}>|x-X_1(t)|\ge\epsilon^{\gamma}} |V_1 - H_1|\epsilon^{-\gamma}dx \\ &= \int_{2>|\xi|>1} |V_1(\xi/\epsilon^{1-\gamma}) - H_1(\xi/\epsilon^{1-\gamma})|d\xi \le C\epsilon^{(1-\gamma)/\beta_1}.\end{aligned}$$

Therefore,

$$\int_{t_{m-1}}^{\tau} \|g_2(\cdot,t)\|_{\mathrm{pis}(\mathbf{R})}dt \le C\epsilon^{(1-\gamma)/\beta_1+\gamma}. \tag{8.9}$$

Similarly, it can be shown that

$$\int_{t_{m-1}}^{\tau} \|g_3(\cdot,t)\|_{\mathrm{pis}(\mathbf{R})}dt \le C\epsilon^{(1-\gamma)/\beta_2+\gamma}. \tag{8.10}$$

We now estimate $\|g_4\|_{\mathrm{pis}(\mathbf{R})}$. Note that

$$\begin{aligned}\|g_4(\cdot,t)\|_{\mathrm{pis}(\mathbf{R})} &= \int_{0<|x-X_1(t)|<\epsilon^{\gamma}} + \int_{|x-X_1(t)|\ge\epsilon^{\gamma}} |g_4(x,t)|dx \\ &:= G_{41} + G_{42}.\end{aligned} \tag{8.11}$$

The integrand in G_{41} satisfies the following inequality:

$$\begin{aligned}|g_4| \text{ in } G_{41} &= |a(u + (V_1 - H_1) + m_2(V_2 - H_2)) - a(V_1)|(-V_1')\epsilon^{-1} \\ &\le |a(u + (V_1 - H_1) + m_2(V_2 - H_2)) - a(V_1 + m_2(V_2 - H_2))|(-V_1')\epsilon^{-1} \\ &\quad + |a(V_1 + m_2(V_2 - H_2)) - a(V_1)|(-V_1')\epsilon^{-1} \\ &:= |g_{41}| + |g_{42}|.\end{aligned}$$

The integration of $|g_{41}|$ is similar to that of (7.13), so it follows from (7.13) that

$$\int_{\{0<|x-X_1|\le\epsilon^\gamma\}} |g_{41}|dx \le C\epsilon^{\gamma+(1-\gamma)/\beta_1}. \tag{8.12}$$

We estimate the integral of g_{42} by observing

$$\begin{aligned}
&\int_{\{0<|x-X_1|\le\epsilon^\gamma\}} |g_{42}|dx \\
&= \int_{\{|x-X_1|\le\epsilon^\gamma\}\cap\{|x-X_2|\le\delta(t)/2\}} |g_{42}|dx + \int_{\{|x-X_1|\le\epsilon^\gamma\}\cap\{|x-X_2|>\delta(t)/2\}} |g_{42}|dx \\
&:= G_{411} + G_{412},
\end{aligned}$$

where $\delta(t) := X_2(t) - X_1(t)$. Since $|g_{42}| \le -CV_1'\epsilon^{-1}$, we have

$$\begin{aligned}
G_{411} &\le C\epsilon^{-1}\int_{|x-X_2(t)|\le\delta(t)/2} -V_1'((x-X_1(t))/\epsilon)dx \\
&\le C\epsilon^{-1}\left(\frac{2\epsilon}{\delta(t)}\right)^{1/\beta_1+1}\delta(t) \le C\left(\frac{\epsilon}{\delta(t)}\right)^{1/\beta_1},
\end{aligned}$$

which leads to

$$\begin{aligned}
\int_{t_{m-1}}^{\tau} G_{411}dt &\le C\epsilon^{1/\max_t\beta_1}(t-t_{m-1})^{1-1/\max_t\beta_1}\Big|_{t_{m-1}}^{\tau} \\
&= C\epsilon^{1/\max_t\beta_1}(\tau-t_{m-1})^{1-1/\max_t\beta_1},
\end{aligned}$$

where we have applied the inequality (8.4) to the above integration. Since $\tau - t_{m-1} \le C\epsilon^\gamma$ we have

$$\int_{t_{m-1}}^{\tau} G_{411}dt \le C\epsilon^{\gamma+(1-\gamma)/\max_t\beta_1}. \tag{8.13}$$

On the other hand,

$$|g_{42}| \le C|V_2 - H_2|(-V_1')\epsilon^{-1}$$

by the mean value theorem. Substituting this inequality into G_{412} yields

$$\begin{aligned}
G_{412} &= \int_{\{|x-X_1|\le\epsilon^\gamma\}\cap\{|x-X_2|>\delta(t)/2\}} |g_{42}|dx \\
&\le C\left|V_2\left(\frac{\delta(t)}{2\epsilon}\right) - H_2\left(\frac{\delta(t)}{2\epsilon}\right)\right|\int_{-\infty}^{\infty}(-V_1'((x-X_1)/\epsilon))\epsilon^{-1}dx \\
&\le C\left(\frac{2\epsilon}{\delta(t)}\right)^{1/\beta_2}\int_{-\infty}^{\infty} -V_1'(\xi)d\xi \le C\left(\frac{2\epsilon}{\delta(t)}\right)^{1/\beta_2}.
\end{aligned}$$

Therefore, on account of $\delta(t) \ge c(t-t_{m-1})$ and $\tau - t_{m-1} \le C\epsilon^\gamma$, we obtain

$$\int_{t_{m-1}}^{\tau} G_{412}dt \le C\epsilon^{1/\max_t\beta_2}\epsilon^{\gamma(1-1/\max_t\beta_2)} = C\epsilon^{\gamma+(1-\gamma)/\max_t\beta_2}. \tag{8.14}$$

This result, together with (8.13) and (8.12), yields

$$\int_{t_{m-1}}^{\tau} G_{41}dt \le C\epsilon^{\gamma+(1-\gamma)/\bar{\beta}}, \tag{8.15}$$

where $\bar{\beta} = \max\{\max_t \beta_1, \max_t \beta_2\}$. In order to estimate G_{42} in (8.11), we first split it into two parts:

$$\begin{aligned} G_{42} &= \int_{\{\epsilon^\gamma<|x-X_1|\le 2\epsilon^\gamma\}\cap\{|x-X_2|\le\delta(t)/2\}} \\ &\qquad + \int_{\{\epsilon^\gamma<|x-X_1|\le 2\epsilon^\gamma\}\cap\{|x-X_2|>\delta(t)/2\}} |g_4|dx \\ &:= G_{421} + G_{422}. \end{aligned} \tag{8.16}$$

The integrand $|g_4|$ in G_{422} can be estimated as

$$\begin{aligned} |g_4| \text{ in } G_{422} &= m_1|a(u + m_1(V_1 - H_1) + m_2(V_2 - H_2)) - a(V_1)|(-V_1')\epsilon^{-1} \\ &\le m_1|a(u + m_1(V_1 - H_1) + m_2(V_2 - H_2)) \\ &\qquad - a(H_1 + m_1(V_1 - H_1) + m_2(V_2 - H_2))|(-V_1')\epsilon^{-1} \\ &\quad + m_1\big(|a(H_1 + m_1(V_1 - H_1) + m_2(V_2 - H_2)) - a(H_1)| \\ &\qquad + |a(H_1) - a(H_1 + V_1 - H_1)|\big)(-V_1')\epsilon^{-1} \\ &\le C\Big(|u - H_1| + |V_1 - H_1|^{\beta_1} + |V_2 - H_2|^{\beta_1}\Big)(-V_1')\epsilon^{-1}, \end{aligned}$$

where we have used the facts that $|V_1 - H_1| \to 0$ and $|V_2 - H_2| \to 0$ as $\epsilon \to 0$ for $\{\epsilon^\gamma < |x - X_1| \le 2\epsilon^\gamma\} \cap \{|x - X_2| > \delta(t)/2\}$. Therefore,

$$\begin{aligned} G_{422} &\le C\int_{\{\epsilon^\gamma<|x-X_1|\le 2\epsilon^\gamma\}\cap\{|x-X_2|>\delta(t)/2\}} |u - H_1|(-V_1')\epsilon^{-1}dx \\ &\quad + C\int_{\{\epsilon^\gamma<|x-X_1|\le 2\epsilon^\gamma\}\cap\{|x-X_2|>\delta(t)/2\}} |V_1 - H_1|^{\beta_1}(-V_1')\epsilon^{-1}dx \\ &\quad + C\int_{\{\epsilon^\gamma<|x-X_1|\le 2\epsilon^\gamma\}\cap\{|x-X_2|>\delta(t)/2\}} |V_2 - H_2|^{\beta_1}(-V_1')\epsilon^{-1}dx \\ &=: J_1 + J_2 + J_3. \end{aligned}$$

The estimate for J_1 is similar to that of I_1, with an upper bound the same as (7.13), namely,

$$J_1 \le C\epsilon^{\gamma+(1-\gamma)/\beta_1}. \tag{8.17}$$

It follows from (4.9) and (4.10) that

$$J_2 \le C\epsilon^{1-\gamma}\epsilon^{(1-\gamma)(1+1/\beta_1)}\epsilon^{-1}\epsilon^{\gamma} \le C\epsilon^{(1-\gamma)(1+1/\beta_1)}. \tag{8.18}$$

Observe that

$$\begin{aligned} J_3 &= C\int_{\{|x-X_1|\le 2\epsilon^\gamma\}\cap\{|x-X_2|>\delta(t)/2\}} |V_2-H_2|^{\beta_1}(-V_1')\epsilon^{-1}dx \\ &\le C\left|V_2\left(\frac{\delta(t)}{2\epsilon}\right)-H_2\left(\frac{\delta(t)}{2\epsilon}\right)\right|^{\beta_1}\int_{-\infty}^{\infty}(-V_1'((x-X_1)/\epsilon))\epsilon^{-1}dx \\ &\le C\left(\frac{2\epsilon}{\delta(t)}\right)^{\beta_1/\beta_2}\int_{-\infty}^{\infty}-V_1'(\xi)d\xi \\ &\le C\left(\frac{2\epsilon}{\delta(t)}\right)^{\beta_1/\beta_2}\le C\left(\frac{2\epsilon}{\delta(t)}\right)^{1/\beta_2}. \end{aligned}$$

Therefore, on account of $\delta(t)\ge c(t-t_{m-1})$ and $\tau-t_{m-1}\le C\epsilon^\gamma$, we have

$$\int_{t_{m-1}}^{\tau} J_3dt \le C\epsilon^{1/\max_t\beta_2}\epsilon^{\gamma(1-1/\max_t\beta_2)} = C\epsilon^{\gamma+(1-\gamma)/\max_t\beta_2}. \tag{8.19}$$

This, together with (8.17) and (8.18), yields

$$\int_{t_{m-1}}^{\tau} G_{422}dt \le C\Big(\epsilon^{\gamma+(1-\gamma)/\bar\beta}+\epsilon^{(1-\gamma)(1+1/\bar\beta)}\Big), \tag{8.20}$$

where $\bar\beta=\max\{\max_t\beta_1,\max_t\beta_2\}$. Since $|g_4|\le -CV_1'\epsilon^{-1}$, we have

$$\begin{aligned} G_{421} &\le C\epsilon^{-1}\int_{|x-X_2(t)|\le\delta(t)/2}-V_1'((x-X_1(t))/\epsilon)dx \\ &\le C\epsilon^{-1}\left(\frac{2\epsilon}{\delta(t)}\right)^{1/\beta_1+1}\delta(t)\le C\left(\frac{\epsilon}{\delta(t)}\right)^{1/\beta_1}. \end{aligned}$$

Thus

$$\begin{aligned} \int_{t_{m-1}}^{\tau} G_{421}dt &\le C\epsilon^{1/\max_t\beta_1}(t-t_{m-1})^{1-1/\max_t\beta_1}\Big|_{t_{m-1}}^{\tau} \\ &= C\epsilon^{1/\max_t\beta_1}(\tau-t_{m-1})^{1-1/\max_t\beta_1}, \end{aligned}$$

where we have used the inequality (8.4). Since $\tau-t_{m-1}\le C\epsilon^\gamma$, we have

$$\int_{t_{m-1}}^{\tau} G_{421}dt \le C\epsilon^{\gamma+(1-\gamma)/\max_t\beta_1}.$$

This result, together with (8.20), gives

$$\int_{t_{m-1}}^{\tau} G_{42}dt \le C\Big(\epsilon^{\gamma+(1-\gamma)/\bar\beta}+\epsilon^{(1-\gamma)(1+1/\bar\beta)}\Big).$$

Combining the above result and (8.15) gives

$$\int_{t_{m-1}}^{\tau}\|g_4(\cdot,t)\|_{\mathrm{pis}(\mathbf{R})}dt \le C\Big(\epsilon^{\gamma+(1-\gamma)/\bar\beta}+\epsilon^{(1-\gamma)(1+1/\bar\beta)}\Big). \tag{8.21}$$

Similarly, it can be shown that

$$\int_{t_{m-1}}^{\tau}\|g_5(\cdot,t)\|_{\mathrm{pis}(\mathbf{R})}dt \le C\Big(\epsilon^{\gamma+(1-\gamma)/\bar\beta}+\epsilon^{(1-\gamma)(1+1/\bar\beta)}\Big). \tag{8.22}$$

Therefore, we have proved that

$$\int_{t_{m-1}}^{\tau} \|g(\cdot,t)\|_{\mathrm{pis}(\mathbf{R})} dt \le C\Big(\epsilon^{\gamma+(1-\gamma)/\bar{\beta}} + \epsilon^{(1-\gamma)(1+1/\bar{\beta})}\Big). \tag{8.23}$$

This result and (8.1) yield Lemma 5.4.

9. Numerical experiments. To verify the theoretical results obtained in this work, we shall carry out a computational study in this section. The main purpose is to demonstrate the existence of the fractional rate of convergence. It is generally believed that monotone schemes have the same rate of convergence as that for the viscosity approximation. Therefore, to make the numerical verification available, we consider the (generalized) Lax–Friedrichs scheme

$$u_j^{n+1} = u_j^n - \frac{\lambda}{2}\left(f(u_{j+1}^n) - f(u_{j-1}^n)\right) + \frac{\mu}{2}\left(u_{j+1}^n - 2u_j^n + u_{j-1}^n\right) \tag{9.1}$$

to approximate the conservation law (1.1), where u_j^n is an approximation of $u(x_j, t_n)$, and $x_j = j\Delta x$, and $t_n = n\Delta t$, with Δx and Δt being the spatial and temporal grid sizes, respectively; μ is a constant satisfying $0 < \mu < 1$, and the temporal and spatial grid ratio $\lambda = \Delta t/\Delta x$ satisfies a Courant–Friedrichs–Levy condition,

$$\lambda \sup_{|u|\le\|u_0\|_\infty} |f'(u)| \le \mu.$$

The theoretical properties of the scheme (9.1) were investigated by Liu and Xin [14].

Example 9.1. In the first example, we approximate

$$\partial_t u + \partial_x f(u) = 0, \qquad f(u) = (1-u^2)^3,$$

with the initial data $u_0(x) = \mathrm{sgn}(x)$, by using the Lax–Friedrichs scheme (9.1).

The entropy solution for the above Riemann problem is $u(x,t) = u_0(x)$. It can be verified that $\max_{|u|\le 1} |f'(u)| \le 6/\sqrt{5}$. We then choose $\mu = 0.5$, $T = 1$, and $\lambda = \sqrt{5}\mu/6$. It follows from Theorem 3.1 that the rate of convergence should be $(1+\frac{1}{2})/2 = \frac{3}{4}$. It is observed from Table 1 that the numerical rate of convergence agrees very well with the theoretical prediction.

TABLE 1
The L^1-error and the convergence order for Example 9.1.

Mesh Δx	$\frac{1}{8}$	$\frac{1}{16}$	$\frac{1}{32}$	$\frac{1}{64}$	$\frac{1}{128}$
L^1-error	3.22×10^{-1}	2.01×10^{-1}	1.23×10^{-1}	7.44×10^{-2}	4.46×10^{-2}
Order		0.680	0.709	0.725	0.738

Example 9.2. In the second example, we approximate

$$\partial_t u + \partial_x f(u) = 0, \qquad f(u) = (1-u)^3(1+u)^4,$$

with the initial data $u_0(x) = \mathrm{sgn}(x)$, by using the Lax–Friedrichs scheme (9.1).

The entropy solution for the above Riemann problem is again $u(x,t) = u_0(x)$. It can be verified that $\max_{|u|\le 1} |f'(u)| \le 2$. We then choose $\mu = 0.5$, $T = 1$, and $\lambda = \mu/2$. It follows from Theorem 3.1 that the rate of convergence should be $(1+\frac{1}{3})/2 = \frac{2}{3}$. It is observed from Table 2 that the numerical result is again in excellent agreement with the theoretical prediction.

LONG TIME BEHAVIOR OF SOLUTIONS TO P-LAPLACIAN EQUATION WITH ABSORPTION*

XINFU CHEN†, Y. W. QI‡, AND MINGXIN WANG§

Abstract. In this paper, we study the long time behavior of solutions to the Cauchy problem of $u_t = \mathrm{div}(|\nabla u|^{p-2}\nabla u) - u^q$ in $R^n \times (0,\infty)$, with nonnegative initial value $u(x,0) = \phi(x)$ in R^n, where $(2n)/(n+1) < p < 2$ and $q > 1$. For initial data of various decay rates, especially the critical decay $\phi = O(|x|^{-\mu})$ with $\mu = p/(q+1-p)$, we show that the solution converges as $t \to \infty$ to a self-similar solution. This extends the recent result of Escobedo, Kavian, and Matano for the semilinear case of $p = 2$. Here an essential role is played by singular and very singular self-similar solutions established in our previous works [X. Chen, Y. Qi, and M. Wang, *J. Differential Equations*, 190 (2003), pp. 1–15; X. Chen, Y. Qi, and M. Wang, preprint, Department of Mathematics, HKUST, Hong Kong, 1998].

1. Introduction.

In this paper, we study the long time behavior of solutions to the Cauchy problem

$$\text{(I)} \qquad \begin{cases} \mathcal{L}u := u_t - \mathrm{div}(|\nabla u|^{p-2}\nabla u) = -u^q & \text{in } R^n \times (0,\infty), \\ u(x,0) = \phi(x) & \text{in } R^n, \end{cases}$$

where $2n/(n+1) < p < 2$, $q > 1$, and ϕ is a nonnegative continuous function which decays to 0 as $|x| \to \infty$. The existence, uniqueness, and Hölder continuity of nonnegative weak solutions of (I) are well established by Chen and DiBenedetto [1, 2] and DiBenedetto and Herrero [7] under much weaker conditions, say, if $\phi \in L^1_{loc}(R^n)$. Therefore, our continuity assumption on ϕ is more than necessary and is used only for the convenience of stating our results.

Our major concern is the behavior of $u(\cdot,t)$ as $t \to \infty$ and how it is influenced by

(a) the decay rate of $\phi(x)$ as $|x| \to \infty$, and

(b) the competition between the diffusion $\mathrm{div}(|\nabla u|^{p-2}\nabla u)$ and the absorption u^q.

It turns out that a critical decay rate for ϕ is $O(|x|^{-\mu})$, and a critical exponent of absorption is q^*, where μ and q^* are defined by

$$q^* := p - 1 + \frac{p}{n}, \qquad \mu := \frac{p}{q+1-p} = \frac{n}{1 + n(q-q^*)/p}. \tag{1.1}$$

The exponents μ and q^* arise naturally from finding radially symmetric and scaling invariant solutions, i.e., self-similar solutions of the form $t^{-\beta}w(|x|t^{-\gamma})$. For later

references, we cite several relevant results on self-similar solutions [3, 5, 6, 8, 9, 14, 15, 17, 20, 21, 22].

PROPOSITION 1.1. *Let $p > 2n/(n+1)$ and $\mathcal{L}u = u_t - (|\nabla u|^{p-2}\nabla u)$.*

(1) *A self-similar solution to $\mathcal{L}u = 0$ has the form $t^{\gamma\nu}w(xt^{\gamma})$ with $\gamma = -1/[p + (p-2)\nu]$ and some $\nu \in \mathbb{R}$. Self-similar solutions to $\mathcal{L}u = -u^q$ have the form $t^{\gamma\mu}w(xt^{\gamma})$ with $\gamma = -1/[p + (p-2)\mu]$.*

(2) *For every $\nu \in (0, n)$ and $B \geq 0$, the solution G_B^{ν} to $\mathcal{L}u = 0$ with initial value $B|x|^{-\nu}$ is self-similar of the form $t^{-\gamma\nu}w(|x|t^{-\gamma})$ with $\gamma = 1/[p + (p-2)\nu]$.*

For each $c > 0$, there is a unique fundamental solution E_c of $\mathcal{L}u = 0$ with initial mass c. It is self-similar of the form $t^{-\gamma n}w(|x|t^{-\gamma})$ with $\gamma = 1/[p + (p-2)n]$.

(3) *For each $A > 0$, there is a unique radially symmetric self-similar solution W_A to $\mathcal{L}u = -u^q$ such that $W(x, 0+) = A|x|^{-\mu}$ for all $x \neq 0$.*

When $1 < q < q^*$ (i.e., $\mu > n$), W_A is monotonic in A, and $W_0 := \lim_{A \searrow 0} W_A$ is the unique very singular solution (VSS) of $\mathcal{L}u = -u^q$ in the sense that

$$\lim_{t \searrow 0} \sup_{|x| > \varepsilon} W_0(x,t) = 0 \quad \text{and} \quad \lim_{t \searrow 0} \int_{|x| \leq \varepsilon} W_0 dx = \infty \qquad \forall\, \varepsilon > 0.$$

Also, for every $c > 0$, $\mathcal{L}u = -u^q$ admits a unique fundamental solution u^c with initial mass c. Fundamental solutions are not self-similar, but $\lim_{c \to \infty} u^c = W_0$ is the self-similar VSS.

When $q = q^*$ (i.e., $\mu = n$), W_A is monotonic in A and $\lim_{A \searrow 0} W_A = 0$ in $\mathbb{R}^n \times (0, \infty)$. There are neither fundamental solutions nor VSSs to $\mathcal{L}u = -u^{q^*}$.

When $q > q^*$ (i.e., $\mu < n$), W_A is the solution with the initial data $A|x|^{-\mu} \in L^1_{loc}(\mathbb{R}^n)$. There are neither fundamental solutions nor VSSs to $\mathcal{L}u = -u^q$.

In what follows, $W_0 \equiv 0$ when $q \geq q^*$, and W_0 is the VSS when $1 < q < q^*$.

To study the long time behavior of solutions of (I), it is convenient to divide the decay rates of ϕ ($\phi \not\equiv 0$) as follows:

(A1) $\lim_{|x| \to \infty} |x|^{\mu}\phi(x) = \infty$;

(A2) $\lim_{|x| \to \infty} |x|^{\mu}\phi(x) = A \in [0, \infty)$;

(B1) $q > q^*$ and $\lim_{|x| \to \infty} |x|^{\nu}\phi(x) = B \in [0, \infty)$ for some $\nu \in (\mu, n)$;

(B2) $q > q^*$ and $\phi \in L^1(\mathbb{R}^n)$.

(B3) $q = q^*$ and $\lim_{x \to \infty} |x|^{\alpha}\phi(x) = A > 0$ for some $\alpha > n$.

Note that the analogues of (B1), (B2) are not needed for $1 < q < q^*$ since $\mu > n$ then.

For $p = 2$, questions (a) and (b) have been discussed by Gmira and Veron [12], Kamin and Peletier [14, 15], Escobedo and Kavian [9], and recently by Escobedo, Kavian, and Matano [10] and Herraiz [13].

PROPOSITION 1.2. *Let $p = 2, q > 1$, and u solve* (I). *Set $q^* = 1 + 2/n$, $\mu = 2/(q-1)$, and $\gamma = 1/2$.*

(1) (See [12].) *If* (A1) *holds, then*

$$\lim_{t \to \infty} \sup_{|x| \leq at^{\gamma}} |t^{1/(q-1)}u(x,t) - (q-1)^{-1/(1-q)}| = 0 \quad \forall\, a > 0. \tag{1.2}$$

(2) (See [10].) *If $1 < q < q^*$ and* (A2) *holds, then*

$$\lim_{t \to \infty} \sup_{|x| < at^{\gamma}} t^{1/(q-1)}|u(x,t) - W_A(x,t)| = 0 \quad \forall\, a > 0. \tag{1.3}$$

(3) (See [15].) *If* (B1) *holds, then*

$$\lim_{t \to \infty} \sup_{|x| \leq at^{\gamma}} t^{\gamma\nu}|u(x,t) - G_B^{\nu}(x,t)| = 0 \quad \forall\, a > 0. \tag{1.4}$$

(4) (See [12].) *If* (B2) *holds, then for some* $c \in [0, \infty)$

$$\lim_{t\to\infty} \sup_{|x|<at^\gamma} t^{\gamma n}|u(x,t) - E_c(x,t)| = 0 \quad \forall\, a > 0. \tag{1.5}$$

(5) (See [13].) *If* $q > q^*$ *and* $\lim_{|x|\to\infty} |x|^n \phi(x) = B > 0$, *then*

$$\lim_{t\to\infty} \sup_{|x|<at^\gamma} t^{\gamma n}|u/\log t - E_c(x,t)| = 0 \quad \forall\, a > 0, \tag{1.6}$$

where $c = \omega_n B/2$ *with* ω_n *the area of unit sphere* S^{n-1}.

(6) (See [13].) *If* (B3) *holds, then*

$$\lim_{t\to\infty} \sup_{|x|<at^\gamma} t^{n/2}|u(x,t)(\log t)^{n/2} - E_{C_n}(x,t)| = 0 \quad \forall\, a > 0 \tag{1.7}$$

for a unique constant $C_n > 0$.

Remark. It is of great interest to know whether the results in Propositions 1.1 and 1.2 are still valid if the precise pointwise assumptions on initial values are replaced by more general integral estimates. However, we do not have a clear idea of how to approach a situation like that. One possible difficulty is the loss of scaling laws.

For $p \neq 2$, similar but not as complete results were obtained by Zhao [23].

PROPOSITION 1.3. *Let* $p > 2n/(n+1)$, $q > 1$, *and* u *solve* (I).

(1) *If* $\lim_{|x|\to\infty} |x|^{\mu-\varepsilon}\phi(x) = \infty$ *for some* $\varepsilon > 0$, *then* (1.2) *holds with* $\gamma = 1/[p + (p-2)\mu]$.

(2) *If* $1 < q < q^*$ *and* $\lim_{|x|\to\infty} |x|^{\mu+\varepsilon}\phi(x) = 0$ *for some* $\varepsilon > 0$, *then* (1.3) *holds with* $A = 0$ *and* $\gamma = 1/[p + (p-2)\mu]$. *(The result for when* $p > 2$ *and* ϕ *has compact support was obtained by Kamin and Vasquez* [17].*)*

(3) *If* (B1) *holds, so does* (1.4) *with* $\gamma = 1/[p + (p-2)\nu]$.

(4) *If* $\lim_{|x|\to\infty} |x|^{n+\varepsilon}\phi(x) = 0$ *for some* $\varepsilon > 0$, *then* (1.5) *holds with* $\gamma = 1/[p + (p-2)n]$ *and some* $c \in [0, \infty)$.

There are also analogous results for the porous medium equation

$$\text{(II)} \qquad \begin{cases} u_t = \triangle u^m - u^q & \text{in } R^n \times (0,\infty), \\ u(x,0) = \phi(x) & \text{in } R^n. \end{cases}$$

In this case, the critical exponents should be defined as $\mu = 2/(q-m)$ and $q^* = m + 2/n$. For radially symmetric self-similar solutions and for $m > (1-2/n)_+$ and $q > \max\{1, m\}$, Proposition 1.1 holds with $\mathcal{L}$ defined as $\mathcal{L}u = u_t - \Delta u^m$; see [4, 12, 16, 17, 19, 21]. The results on noncritical decay rates were obtained by Kamin and Peletier [16] for $m > 1$ and Peletier and Zhao [21] for $(1-2/n)_+ < m < 1$, and the result on the critical decay rate was obtained by Kwak [18].

PROPOSITION 1.4. *Let* $m > (1-2/n)_+$, $q > \max\{1, m\}$, *and* u *be a solution to* (II).

(1) *If* (A1) *holds, so does* (1.2) *with* $\gamma = 1/[2 + (m-1)\mu]$.

(2) *Suppose* $1 < q < q^*$. *If* (A2) *holds with* $A > 0$ *or* $A = 0$ *and in addition* $\lim_{|x|\to\infty} |x|^{\mu+\varepsilon}\phi(x) = 0$ *for some* $\varepsilon > 0$, *then* (1.3) *holds with* $\gamma = 1/[2 + (m-1)\mu]$.

(3) *The condition* (B1) *implies* (1.4) *with* $\gamma = 1/[2 + (m-1)\nu]$.

(4) *The condition* (B2) *implies* (1.5) *with* $\gamma = 1/[2 + (m-1)n]$.

(5) *If* $q > q^*$ *and* $\lim_{|x|\to\infty} |x|^n \phi(x) = A > 0$, *then*

$$\lim_{t\to\infty} \sup_{|x|<at^\gamma} \tau^{\gamma n}|u(x,t)/\log\tau - E_c(x,\tau)| = 0 \quad \forall\, a > 0, \tag{1.8}$$

where $c = c(m, n, a) > 0$, $t = c^{1-m}\tau(\log\tau)^{1-m}$, *and* $\gamma = 1/[2 + (m-1)n]$.

One may notice that the recent results of Escobedo, Kavian, and Matano [10] listed in Proposition 1.2 (2) and that of Kwak [18] in Proposition 1.4 (2) address the critical decay of ϕ with sharp results for semilinear and porous media cases, respectively. We would like to mention that though some ideas of Escobedo, Kavian, and Matano [10] and Kwak [18] can be adopted to study (I), their approach cannot be extended easily to the present case.

In this paper, we shall extend the results of Propositions 1.2, 1.3, and 1.4 to the case in which $p \in (2n/(n+1), 2)$. Our main results are the following.

Assume that $2n/(n+1) < p < 2$ *and* $q > 1$. *Let* μ *and* q^* *be defined as in* (1.1), *and let* u *be a solution to* (I). *Let* E_c, G_B^ν, *and* W_A *be defined as in Proposition* 1.1. *Denote* $L^\infty = L^\infty(\mathbb{R}^n)$.

THEOREM 1.5. *Assume* (A1). *Then* (1.2) *holds with* $\gamma = 1/[p + (p-2)\mu]$.

THEOREM 1.6. *Assume* (A2). *Then* (1.3) *holds with* $\gamma = 1/[p + (2-p)\mu]$; *more precisely,*

$$\lim_{t\to\infty} t^{\gamma\mu}\|u(\cdot,t) - W_A(\cdot,t)\|_{L^\infty} = \lim_{t\to\infty} \|t^{\gamma\mu}u(yt^\gamma,t) - W_A(y,1)\|_{L^\infty} = 0. \tag{1.9}$$

In particular, when $A = 0$ *and* $q = q^*$,

$$\lim_{t\to\infty} t^{1/(q^*-1)}\|u(\cdot,t)\|_{L^\infty} = 0 \quad \textit{and} \quad \lim_{t\to\infty} t^{1/(q^*-1-\varepsilon)}u(0,t) = \infty \quad \forall \varepsilon > 0. \tag{1.10}$$

THEOREM 1.7. *Assume* (B1). *Then* (1.4) *holds with* $\gamma = 1/[p + (p-2)\nu]$; *more precisely,*

$$\lim_{t\to\infty} t^{\gamma\nu}\|u(\cdot,t) - G_B^\nu(\cdot,t)\|_{L^\infty} = \lim_{t\to\infty} \|t^{\gamma\nu}u(yt^\gamma,t) - G_B^\nu(y,1)\|_{L^\infty} = 0. \tag{1.11}$$

THEOREM 1.8. *Assume* (B2). *Then for* $\gamma = 1/[p + (p-2)n]$ *and some constant* $c > 0$,

$$\lim_{t\to\infty} t^{\gamma n}\|u(\cdot,t) - E_c(\cdot,t)\|_{L^\infty} = \lim_{t\to\infty} \|t^{\gamma n}u(yt^\gamma,t) - E_c(y,1)\|_{L^\infty} = 0. \tag{1.12}$$

Remark. We make some interesting observations.

1. Theorem 1.5 says that when ϕ decays too slowly, absorption dominates diffusion.

2. When $1 < q < q^*$, $W_0 = VSS > 0$, so Theorem 1.6 indicates that the absorption is still strong, but diffusion plays a role to balance it.

When $q \geq q^*$, $W_0 \equiv 0$, so the conclusion of Theorem 1.6 for $A = 0$ is insufficient. Theorems 1.7 and 1.8 exactly compensate for this insufficiency for the case in which $q > q^*$ but not for $q = q^*$.

3. Here we show explicitly that the constant c in Theorem 1.8 is positive, which is not mentioned in [12, 16, 21]. With this improvement, we can conclude that when ϕ decays quickly enough (say, of compact support), then in large time, the solution approaches the VSS when $q \in (1, q^*)$ or the fundamental solution E_c of the pure diffusion equation when $q > q^*$.

4. For the case in which $q = q^*$ and ϕ decays quickly (say, of compact support or L^1), except the two limits in (1.10), we do not have a more precise description. Here, different scaling is needed. For the case in which $p = 2$, we refer interested readers to the work of Herraiz [13] and some insightful observation of Galaktionov, Kurdyumov, and Samarskii [11].

5. The most striking fact, of course, is that in each and every case being discussed, the limiting behavior of $u(x,t)$ as $t \to \infty$ is characterized by a self-similar solution of the same equation or the corresponding equation without absorption.

6. We intend to answer questions (a) and (b) as follows: The absorption dynamics ($u_t = -u^{-q}$) decreases the solution (in time) with a $O(t^{-1/(q-1)})$ rate. The diffusion process ($u_t = \operatorname{div}(|\nabla u|^{p-2}\nabla u)$) makes mass diffuse, thereby decreasing u at a maximum rate of $O(t^{-n/(p+[p-2]n)}) = O(t^{-1/(q^*-1)})$, as can be seen from the fundamental solutions. Hence, when $1 < q < q^*$, the diffusion-related decay is slower than that of the absorption, so absorption is strong and will dominate, or at least not subordinate to, the diffusion. When $q > q^*$, as diffusion can diminish u at a rate ranging from $O(1)$ (for constant initial data) to $O(t^{-1/(q^*-1)})$ (for L^1 initial data), the relative strengths of absorption and diffusion then heavily depend on the decay rate of the initial data. For fast decay, diffusion dominates; for slow decay, absorption prevails; the critical decay rate is $O(|x|^{-\mu})$.

We shall first prove Theorem 1.8 in the next section since, with the results we established in [3, 5], the proof becomes very easy. Although Theorem 1.7 had already been proven by Zhao [23] (cf. Proposition 1.3 (3)), we provide a different proof in section 2 for completeness. In section 3, we first prove Theorem 1.6 for the case in which $A \in (0,\infty)$. Then the cases in which $A = \infty$ and $A = 0$ can be handled by taking appropriate limits.

2. Proof of Theorems 1.7 and 1.8. For each $\nu \in [\mu, p/(2-p))$ and $\lambda \geq 1$, we define

$$\gamma = 1/[p + (p-2)\nu], \quad \sigma = \gamma(q+1-p)[\nu-\mu], \quad u_\lambda = \lambda^{\gamma\nu} u(\lambda^\gamma x, \lambda t). \tag{2.1}$$

Then

$$\begin{cases} \mathcal{L}u_\lambda = -\lambda^{-\sigma} u^q & \text{in } \mathbb{R}^n \times (0,\infty), \\ u_\lambda(x,0) = \phi_\lambda(x) := \lambda^{\gamma\nu}\phi(\lambda^\gamma x) & \text{on } \mathbb{R}^n \times \{0\}. \end{cases} \tag{2.2}$$

Proof of Theorem 1.8. Set $\nu = n$. Let ψ_λ be the solution to $\mathcal{L}\psi_\lambda = 0$ with initial value ϕ_λ. Define $c_0 = \int_{\mathbb{R}^n} \phi$. Then $\int_{R^n} \phi_\lambda(x)\, dx = c_0$ for every $\lambda > 1$, and $\lim_{\lambda\to\infty} \int_{|x|>\varepsilon} \phi_\lambda(x)\, dx = 0$ for all $\varepsilon > 0$. Hence $\{\frac{1}{c_0}\phi_\lambda\}$ is a δ-sequence (i.e., a sequence approaching the δ function). It then follows from Theorem 3.1 of [5] that

$$\lim_{\lambda\to\infty} \psi_\lambda = E_{c_0} \qquad \text{in} \quad L^\infty((\varepsilon,\varepsilon^{-1});\ L^1(R^n) \cap C(\mathbb{R}^n)) \qquad \forall\ \varepsilon > 0.$$

Now we consider $\{u_\lambda\}_{\lambda>1}$. First by applying an L^∞ estimate (cf. [6, p. 127] or [7]) for ψ_λ and then by comparison, we obtain $u_\lambda \leq \psi_\lambda \leq M(p,n,c_0)t^{-\gamma n}$ for all $\lambda > 0$ and $t > 0$. By the regularity results in [1, 2, 7], $\{u_\lambda\}_{\lambda>1}$ is an equicontinuous family in any compact subset of $\mathbb{R}^n \times (0,\infty)$. Hence there exist a function U and a sequence $\{\lambda_j\}$ with $\lim_{j\to\infty} \lambda_j = \infty$ such that $\lim_{j\to\infty} u_{\lambda_j} = U(x,t)$ uniformly in any compact subset of $R^n \times (0,\infty)$. As σ is positive, (2.2) implies $\mathcal{L}U = 0$ in $\mathbb{R}^n \times (0,\infty)$. In addition, from $u_\lambda \leq \psi_\lambda$, there holds $U \leq E_{c_0}$ in $R^n \times (0,\infty)$ so that $\lim_{t\searrow 0} \sup_{|x|>\varepsilon} U(x,t) = 0$ for all $\varepsilon > 0$. Furthermore, for every fixed $\tau > 0$,

$$\begin{aligned} \limsup_{j\to\infty} \int_{\mathbb{R}^n} |U - u_{\lambda_j}|(x,\tau)dx &= \lim_{M\to\infty} \limsup_{j\to\infty} \int_{|x|>M} |U - u_{\lambda_j}|(x,\tau)|dx \\ &\leq \lim_{M\to\infty} \limsup_{j\to\infty} \int_{|x|\geq M} (E_c + \psi_{\lambda_j})(x,\tau)dx = 0. \end{aligned} \tag{2.3}$$

Note that $\int_{\mathbb{R}^n} u(x,t)dx$ is a nonincreasing function of t, so $c := \lim_{t\to\infty}\int_{\mathbb{R}^n} u(x,t)dx$ exists. Consequently, for every $\tau > 0$,

$$\int_{\mathbb{R}^n} U(x,\tau)dx = \lim_{j\to\infty}\int_{\mathbb{R}^n} u_{\lambda_j}(x,\tau)dx = \lim_{j\to\infty}\int_{\mathbb{R}^n} u(y,\lambda_j\tau)dy$$
$$= \lim_{t\to\infty}\int_{\mathbb{R}^n} u(x,t)dx = c.$$

Thus U is a fundamental solution with mass c; i.e., $U = E_c$. As c is independent of $\{\lambda_j\}$, the whole sequence $\{u_\lambda\}$ must converge to E_c in any compact subset of $\mathbb{R}^n \times (0,\infty)$. A similar argument to that in (2.3) yields $u_\lambda(\cdot,\tau) \to E_c(\cdot,\tau)$ in $L^1(\mathbb{R}^n)$ for every $\tau > 0$. Local regularity estimates then imply that $u_\lambda(\cdot,1) \to E_c(\cdot,1)$ in $L^\infty(\mathbb{R}^n)$. The assertion (1.12) thus follows from the definition of u_λ and the scaling invariance of E_c.

It remains to show $c > 0$. As $u \le \psi_1 \le Mt^{-\gamma n}$ for all $t > 0$,

$$-\frac{d}{dt}\int_{R^n} u(x,t)\ dx = \int_{R^n} u^q(x,t)\ dx \le Mt^{-(q-1)\gamma n}\int_{R^n} u(x,t)\ dx.$$

An integration over $[1,t]$ then gives

$$\log\int_{R^n} u(x,t)\ dx \ge \log\int_{R^n} u(\cdot,1)\ dx + \frac{M(1-t^{1-(q-1)\gamma n})}{1-(q-1)\gamma n} \qquad \forall\ t > 1.$$

Simple calculation shows $1-(q-1)\gamma n = \gamma n[q^*-q] < 0$. Thus $\lim_{t\to\infty}\log\int_{R^n} u(\cdot,t) > -\infty$; i.e., $c > 0$. This completes the proof. □

Proof of Theorem 1.7. Let $\nu \in (\mu, n)$ be as in the statement of the theorem, and let γ, σ, u_λ, and ϕ_λ be as in (2.1). Let G_B^ν be the solution to $\mathcal{L}G = 0$ with initial data $B|x|^{-\nu}$. Fix an arbitrary $\delta \in (0, (n/\nu - 1)/q)$ (so that $\nu(1+q\delta) < n$). To prove the theorem, it suffices to show

$$\lim_{\lambda\to\infty}\sup_{0<t<2, x_0\in\mathbb{R}^n}\int_{|x-x_0|<1}|u_\lambda(x,t) - G_B^\nu(x,t)|^{1+\delta}dx = 0. \tag{2.4}$$

Indeed, by local regularities of solutions, the above limit implies that $\|u_\lambda(\cdot,1) - G_B^\nu(\cdot,1)\|_{L^\infty(\mathbb{R}^n)} \to 0$ as $\lambda\to\infty$, and therefore (1.11) follows from the definition of u_λ and the scaling invariance of G_B^ν. We now prove (2.4).

Let $x_0 \in \mathbb{R}^n$ and $R > 2$ be arbitrarily given. We can find a smooth cut-off function $\zeta(x)$ satisfying $0 \le \zeta \le 1$ in $\mathbb{R}^n$, $\zeta = 1$ when $|x-x_0| < 1$, $\zeta = 0$ when $|x-x_0| > R$, and $|\nabla\zeta| \le 3/R$ in $\mathbb{R}^n$. Let $s = (1+q\delta)p/(2-p)$. In what follows, all positive constants depending only on p, n, q, δ, and ν will be denoted by the same letter C.

Integrating the identity $0 = (1+q\delta)u_\lambda^{q\delta}\zeta^s(\mathcal{L}u_\lambda + \lambda^{-\sigma}u_\lambda^q)$ over $\mathbb{R}^n$ and using integration by parts, the assumption $|\nabla\zeta| \le 3/R$, and the Cauchy inequality

$$su^{q\delta}\zeta^{s-1}|\nabla u_\lambda|^{p-2}\nabla u_\lambda\cdot\nabla\zeta \le mu_\lambda^{q\delta-1}|\nabla u_\lambda|^p\zeta^s + \frac{1}{q\delta+1}u_\lambda^{q\delta+1}\zeta^s$$
$$+ C|\nabla\zeta|^{(q\delta+1)p/(2-p)},$$

we obtain

$$\frac{d}{dt}\int_{R^n} u_\lambda^{1+q\delta}\zeta^s dx + \int_{R^n}\{(1+q\delta)\lambda^{-\sigma}u_\lambda^{q+q\delta}\zeta^s - u_\lambda^{1+q\delta}\zeta^s\}dx \tag{2.5}$$
$$\le CR^{n-(q\delta+1)p/(2-p)}.$$

Before proceeding further, we first establish an elementary algebraic inequality. Since $p \in (1,2)$, there are positive constants $C(p,n)$ and $c(p,n)$ such that for every $\mathbf{a}, \mathbf{b} \in \mathbb{R}^n$,

$$\begin{aligned} |\ |\mathbf{a}|^{p-2}\mathbf{a} - |\mathbf{b}|^{p-2}\mathbf{b}\ | &\le C(p,n)\{|\mathbf{a}-\mathbf{b}|^2(|\mathbf{a}|+|\mathbf{b}|)^{p-2}\}^{1-1/p}, \\ (|\mathbf{a}|^{p-2}\mathbf{a} - |\mathbf{b}|^{p-2}\mathbf{b})\cdot(\mathbf{a}-\mathbf{b}) &\ge c(p,n)|\mathbf{a}-\mathbf{b}|^2(|\mathbf{a}|+|\mathbf{b}|)^{p-2}. \end{aligned}$$

(They can be proven first for $1 = |\mathbf{a}| \ge |\mathbf{b}|$, and then for the general case by scaling.) It then follows that for any $\mathbf{a}, \mathbf{b}, \mathbf{c} \in \mathbb{R}^n$,

$$(|\mathbf{a}|^{p-2}\mathbf{a} - |\mathbf{b}|^{p-2}\mathbf{b})\cdot((\mathbf{a}-\mathbf{b})+\mathbf{c}) \ge -\hat{C}(p,n)|\mathbf{c}|^p. \tag{2.6}$$

Denote $v = u_\lambda - G_B^\nu$. Multiplying the difference of the equations for u_λ and G_B^ν by $|v|^{\delta-1}v\zeta^s$, integrating the resulting equation over $\mathbb{R}^n$, and using integration by parts and the inequality (2.6) with $\mathbf{a} = \nabla u_\lambda, \mathbf{b} = \nabla G_B^\nu$, and $\mathbf{c} = sv\delta^{-1}\zeta^{-1}\nabla\zeta$, we then obtain

$$\frac{d}{dt}\int_{R^n}|v|^{1+\delta}\zeta^s dx \le \int_{R^n}\{(1+\delta)\lambda^{-\sigma}|v|^\delta u_\lambda^q\zeta^s dx + C|v|^{\delta-1+p}\zeta^{s-p}|\nabla\zeta|^p\}.$$

Cauchy's inequality and the assumptions $|\nabla\zeta| < 3/R$ and $s = (1+q\delta)p/(2-p)$ then yield

$$\frac{d}{dt}\int_{R^n}|v|^{1+\delta}\zeta^s dx - \int_{R^n}\{|v|^{1+\delta}\zeta^s + C\lambda^{-\sigma-\sigma\delta}u_\lambda^{q+q\delta}\zeta^s\}dx \le CR^{n-(1+\delta)p/(2-p)}.$$

Now adding to it a $C\lambda^{-\sigma\delta}$ multiple of (2.6), we obtain

$$\begin{aligned} \frac{d}{dt}\int_{\mathbb{R}^n}\{|v|^{1+\delta} + C\lambda^{-\sigma\delta}u_\lambda^{1+q\delta}\}\zeta^s dx - \int_{\mathbb{R}^n}\{|v|^{1+\delta} + C\lambda^{-\sigma\delta}u_\lambda^{1+q\delta}\}\zeta^s dx \\ \le CR^{n-(1+\delta)p/(2-p)} \end{aligned}$$

for all $\lambda > 1$. Gronwall's inequality then yields

$$\sup_{0<t<2} e^{-t}\int_{\mathbb{R}^n}|v|^{1+\delta}\zeta^s dx \le CR^{n-(1+\delta)p/(2-p)} + \int_{\mathbb{R}^n}\zeta^s\{|v(\cdot,0)|^{1+\delta} + C\lambda^{-\sigma\delta}\phi_\lambda^{1+q\delta}\}dx.$$

Denote by $B_r(x_0)$ the ball of radius r and center x_0. That ζ is a cut-off function then gives, after replacing v by $u_\lambda - G_B^\nu$,

$$\begin{aligned} &\sup_{x_0\in\mathbb{R}^n}\sup_{0<t<2}\int_{B_1(x_0)}|u_\lambda - G_B^\nu|^{1+\delta}dx \le CR^{n-(1+\delta)p/(2-p)} \\ &+ C\sup_{x_0\in\mathbb{R}^n}\int_{B_R(x_0)}|\phi_\lambda - B|x|^{-\nu}|^{1+\delta}dx + C\sup_{x_0\in\mathbb{R}^n}\lambda^{-\sigma\delta}\int_{B_R(x_0)}\phi_\lambda^{1+q\delta}dx. \end{aligned} \tag{2.7}$$

Set $M = \sup_{x\in\mathbb{R}^n}|x|^\nu\phi(x)$. Then the definition of ϕ_λ implies $\phi_\lambda(x) \le M|x|^{-\nu}$. Consequently, the last term in (2.7) converges to zero as $\lambda \to \infty$.

To estimate the first integral in (2.7), one notices that $\phi_\lambda(x) \to B|x|^{-\nu}$ uniformly in $\mathbb{R}^n \setminus B_\varepsilon(0)$ for any $\varepsilon > 0$. As $\int_{B_\varepsilon(0)}|x|^{-\nu(1+\delta)}dx = O(\varepsilon^{n-(1+\delta)\nu})$, we see also that, as $\lambda \to \infty$, the first term in (2.7) converges to zero. Hence, sending $\lambda \to \infty$, we obtain from (2.7) that

$$\limsup_{\lambda\to\infty}\sup_{x_0\in\mathbb{R}^n,0<t<2}\int_{B_1(x_0)}|u_\lambda - G_B^\nu|^{1+\delta}dx \le CR^{n-(1+\delta)p/(2-p)}.$$

Sending $R \to \infty$, we then obtain (2.4), thereby completing the proof. □

3. Proof of Theorems 1.5 and 1.6. Set $\gamma = 1/[p+(p-2)\mu]$. Then $(q-1)\gamma\mu = 1$. For some $\delta > 0$ to be chosen later, we make a self-similar transformation:

$$u(x,t) = [(t+\delta)/\gamma\mu]^{-\gamma\mu} w(y,\tau), \quad y = [(t+\delta)/\gamma\mu]^{-\gamma} x, \quad \tau = \gamma\mu \, \log[(t+\delta)/\delta]. \tag{3.1}$$

Then w satisfies

$$\begin{cases} w_\tau = \operatorname{div}(|\nabla w|^{p-2}\nabla w) + \mu^{-1} y \cdot \nabla w + w - w^q, & y \in R^n, \quad \tau > 0, \\ w(y,0) = [\delta/\gamma\mu]^{\gamma\mu} \phi([\delta/\gamma\mu]^\gamma y), & y \in \mathbb{R}^n. \end{cases} \tag{3.2}$$

Now we fix $\delta = \gamma\mu \|\phi\|^{-1/\gamma\mu}_{L^\infty(\mathbb{R}^n)}$. Then

(1) $0 \le w(y,0) \le 1$ in R^n;

(2) $\lim_{|y|\to\infty} |y|^\mu w(y,0) = \lim_{|x|\to\infty} |x|^\mu \phi(x) = A$.

To prove Theorem 1.6 for $A \in (0,\infty)$, we need only to show that

$$\lim_{\tau\to\infty} w(y,\tau) = W_A(y,1) = w_A(|y|) \quad \text{uniformly in } y \in \mathbb{R}^n; \tag{3.3}$$

here $w_A(r)$, $r \in [0,\infty)$, is the unique solution to the following boundary value problem:

$$\begin{cases} \mathcal{L}_r w := |w'|^{p-2}[(p-1)w'' + (n-1)r^{-1}w'] + w + \mu^{-1} r w' - w^q = 0, \quad r > 0, \\ w_A'(0) = 0, \quad w(r) > 0 \quad \text{on } [0,\infty), \quad \text{and} \quad \lim_{r\to\infty} r^\mu w(r) = A. \end{cases} \tag{3.4}$$

We prove (3.3) by using sub- and supersolutions. To ease the computation, it is convenient to introduce new dependent and independent variables

$$w(r) = r^{-\mu} J(\theta), \qquad r = Re^\theta, \tag{3.5}$$

where R is a parameter of our choice. Then $\mathcal{L}_r w = r^{-\mu q}\mathcal{L}_\theta J$, where, denoting $\dot{} = d/d\theta$,

$$\mathcal{L}_\theta J := |\dot J - \mu J|^{p-2}\{a(\ddot J - \mu \dot J) + b(\dot J - \mu J)\} + \mu^{-1} R^l e^{l\theta} \dot J - J^q,$$
$$a = (p-1), \quad b = (n-1) - (\mu+1)a, \quad l = \mu(q-1).$$

LEMMA 3.1. *For every $A \in (0,\infty)$, there exists $R_0(A) > 0$ such that for every $R > R_0$, there are two functions $w^+_{A,R}(r)$ and $w^-_{A,R}(r)$ with the following properties:*

(a) $w^+_{A,R}(r) = 1$ *in* $[0,R]$, $Ar^{-\mu} \le w^+_{A,R}(r) \le 1$ *in* $[R,\infty)$;

(b) $w^-_{A,R}(r) = 0$ *in* $[0,R]$, $0 \le w^-_{A,R}(r) \le Ar^{-\mu}$ *in* $[R,\infty)$;

(c) $\mathcal{L}_r w^+_{A,R} \le 0$ *and* $\mathcal{L}_r w^-_{A,R} \ge 0$ *in* $(0,\infty)$ *in the distributional sense;*

(d) $\lim_{r\to\infty} r^\mu w^+_{A,R}(r) = \lim_{r\to\infty} r^\mu w^-_{A,R}(r) = A$.

Proof. (I) Construction of $w^+_{A,R}(r)$. We define $w^+_{A,R} = 1$ in $[0,R]$ and $w^+_{A,R} = r^{-\mu}[A + (R^\mu - A)(R/r)^l]$ in $[R,\infty)$. Then $w^+_{A,R}$ satisfies (a) and (d). In addition, $(w^+_{A,R})'' \le 0$ at $r = R$ in the distributional sense. It remains to check $\mathcal{L}_r w^+_{A,R} \le 0$ in (R,∞) or, equivalently, $\mathcal{L}_\theta J \le 0$ in $(0,\infty)$, where

$$J = A + (R^\mu - A)e^{-l\theta}.$$

Note that $\mu J - \dot J = \mu A + (R^\mu - A)(l+\mu)e^{-l\theta} > \mu A$ in $(0,\infty)$. Also, assuming $R > 2A$, then $R^\mu - A > R^\mu/2$. Hence, using $p - 2 < 0$, we can calculate, for all $\theta \in (0,\infty)$,

$$\mathcal{L}_\theta J = |rJ' - \mu J|^{p-2}\{(l+\mu)(al-b)(R^\mu - A)e^{-l\theta} - \mu b A\}$$
$$-l\mu^{-1}(R^\mu - A)R^l - J^q \le (\mu A)^{p-2}(l+\mu)(al+|b|)R^\mu - lR^\mu R^l/(2\mu) \le 0$$

if R is sufficiently large (depending on A). The construction of $w^+_{A,R}(r)$ is now complete.

(II) Construction of $w^-_{A,R}(r)$. We need only construct $J(\theta) := r^\mu w^-_{A,R}(r)|_{r=Re^\theta}$. Let $m \geq 1$ be the smallest integer such that $(p-1)(2m+1) \geq 1$. Define

$$\Theta(J) = \begin{cases} \mu[J - (J-\varepsilon)^{2m+1}], & 0 < J < 2\varepsilon, \\ (A-J)D, & 2\varepsilon \leq J < A, \end{cases}$$
$$D = \mu[2\varepsilon - \varepsilon^{2m+1}]/[A - 2\varepsilon],$$
$$\varepsilon = \min\{1/(2m+1),\ 1/(4A),\ l/(4\mu A)\}.$$

Clearly Θ is Lipschitz continuous and positive in $[0, A)$. In addition, $0 < D \leq l$.

Let $J(\theta), \theta \in [0, \infty)$, be the solution to

$$\dot{J} = \Theta(J) \quad \text{in } (0,\infty), \qquad J(0) = 0.$$

Since $\Theta > 0$ in $[0, A)$ and $\Theta(A) = 0$, J is strictly increasing, and $\lim_{\theta\to\infty} J(\theta) = A$.

Now we define $w^-_{A,R} = 0$ for $r \leq R$ and $w^-_{A,R} = r^{-\mu} J(\theta)|_{\theta=\log(r/R)}$ for $r > R$. Then $w^-_{A,R}$ satisfies conditions (b) and (d) in the lemma. In addition, $(w^-_{A,R})'' \geq 0$ at $r = R$ in the distributional sense. It remains to check that $\mathcal{L}_r w^-_{A,R} \geq 0$ in (R, ∞), which is equivalent to checking that $\mathcal{L}_\theta J(\theta) \geq 0$ for all $\theta > 0$.

Let $\theta_1 := \int_0^{2\varepsilon} dJ/\Theta(J)$ be the unique point such that $J = 2\varepsilon$. We consider two cases: (i) $\theta \in (\theta_1, \infty)$ and (ii) $\theta \in (0, \theta_1]$.

Case (i). $\theta \in (\theta_1, \infty)$. Then $J = A - (A-2\varepsilon)e^{D(\theta_1-\theta)}$ and $\dot{J} = D(A-2\varepsilon)e^{D(\theta_1-\theta)}$. Also, $\mu J - \dot{J} = (\mu + D)J - DA \geq 2\varepsilon(\mu + D) - AD = \mu\varepsilon^{2m+1}$. Thus, as $p < 2$ and $D \leq l$,

$$\mathcal{L}_\theta J \geq -(\mu\varepsilon^{2m+1})^{p-2} C(A) + \mu^{-1} R^l D(A - 2\varepsilon) e^{D\theta_1 + (l-D)\theta} - A^q \geq 0$$

provided that R is large enough.

Case (ii). $\theta \in (0, \theta_1]$. Then $J \in (0, 2\varepsilon]$ and $\dot{J} - \mu J = -\mu(J-\varepsilon)^{2m+1}$ so that

$$\begin{aligned} &|\dot{J} - \mu J|^{p-2}\{a(\ddot{J} - \mu\dot{J}) + b(\dot{J} - \mu J)\} \\ &= -\mu^{p-1}|J-\varepsilon|^{(p-2)(2m+1)+2m}\{(2m+1)a\dot{J} + b(J-\varepsilon)\} \geq -C(A) \end{aligned}$$

since $(p-2)(2m+1) + 2m \geq 0$. Noting that $\dot{J} = \mu[J - (J-\varepsilon)^{2m+1}] \geq \mu\varepsilon^{2m+1}$, we have

$$\mathcal{L}_\theta J \geq -C(A) + R^l e^{l\theta} \varepsilon^{2m+1} - (2\varepsilon)^q \geq 0$$

if R is large enough. This completes the proof of the lemma. □

LEMMA 3.2. *For every $A \in (0, \infty)$, $R > R_0(A)$, let $W^\pm_{A,R}(y, \tau)$ be the solution to the PDE in* (3.2) *with initial value $w^\pm_{A,R}(|y|)$. Then*

$$\lim_{\tau\to\infty} \|W^\pm_{A,R}(\cdot, \tau) - w_A(|\cdot|)\|_{L^\infty(R^n)} = 0.$$

Proof. Since $w^+_{A,R}(|y|)$, as a function of (y, τ), is a supersolution to the PDE in (3.2), by comparison, $W^+_{A,R}(\cdot, \tau) \leq w^+_{A,R}(|\cdot|)$ for all $\tau > 0$. In turn, this implies that $W^+_{A,R}(\cdot, \tau + \tau_1) \leq W^+_{A,R}(\cdot, \tau_1)$ for all $\tau > 0$ and $\tau_1 \geq 0$. It then follows that $W^+_{A,R}(\cdot, \tau)$

is monotone decreasing in τ. Similarly, $W^-_{A,R}(\cdot,\tau)$ is monotone increasing in τ. Hence there exist $w^{\infty,\pm}_{A,R}$ such that

$$W^{\pm}_{A,R}(\cdot,\tau) \to w^{\infty,\pm}_{A,R}(\cdot) \qquad \text{as } \tau\to\infty \text{ pointwise in } R^n. \tag{3.6}$$

It is clear that $w^{\infty,\pm}_{A,R}$ solve $\mathcal{L}_r w^{\infty,\pm}_{A,R}=0$ and are radially symmetric and that

$$w^-_{A,R}(|y|) \le w^{\infty,-}_{A,R}(y) \le w^{\infty,+}_{A,R}(y) \le w^+_{A,R}(|y|).$$

It follows that $\lim_{|y|\to\infty}|y|^\mu w^{\infty,\pm}_{A,R} = A$. By the uniqueness of solution to (3.4) (cf. [3]), $w^{\infty,\pm}_{A,R}(y) = w_A(|y|)$. Hence $\lim_{\tau\to\infty} W^{\pm}_{A,R}(\cdot,\tau) = w_A(|\cdot|)$. Since $W^{\pm}_{A,R}(y,\tau) \le w^+_{A,R}(|y|)$, by local regularity, the convergence is uniform in any compact subset of $\mathbb{R}^n$. Further, as $w^+_{A,R}(|y|) = O(|y|^{-\mu})$, the convergence is also in L^∞. This completes the proof. □

Proof of Theorems 1.5 *and* 1.6.

Case 1. $0<A<\infty$. Let $w(y,\tau)$ be the solution to (3.2). We need to prove (3.3). Since we have the limit $\lim_{|y|\to\infty}|y|^\mu w_0(y) = A$, for every $\varepsilon>0$, there exists $R_\varepsilon>0$ such that

$$A-\varepsilon < |y|^\mu w(y,0) < A+\varepsilon \qquad \forall\ |y|\ge R_\varepsilon.$$

It follows from Lemma 3.1 (a), (b) and $0\le w(y,0)\le 1$ that

$$w^-_{A-\varepsilon,R_\varepsilon}(|\cdot|) \le w(\cdot,0) \le w^+_{A+\varepsilon,R_\varepsilon}(|\cdot|).$$

Consequently, by the comparison principle,

$$W^-_{A-\varepsilon,R_\varepsilon}(y,\tau) \le w(y,\tau) \le W^+_{A+\varepsilon,R_\varepsilon}(y,\tau).$$

Thus, by Lemma 3.2,

$$\limsup_{\tau\to\infty} \|w(y,\tau) - w_A(|y|)\|_{L^\infty} \le \|w_{A+\varepsilon} - w_A\|_{L^\infty} + \|w_{A-\varepsilon} - w_A\|_{L^\infty}.$$

However, since $\varepsilon>0$ is arbitrary, we obtain (3.3).

Case 2. $\lim_{|x|\to\infty}|x|^{-\nu}\phi(x) = A = \infty$. By comparison,

$$\liminf_{\tau\to\infty} w(y,\tau) \ge \lim_{A\to\infty} w_A(|y|) = 1$$

uniformly in any compact subset of $y\in\mathbb{R}^n$. Since $w\le 1$ for all y and $\tau\ge 0$, we conclude that as $\tau\to\infty$, $w(y,\tau)\to 1$ uniformly in any compact subset of $\mathbb{R}^n$. Using the definition of $w(y,\tau)$ in (3.1) and the fact that $\gamma\mu = 1/(q-1)$, the assertion of Theorem 1.5 thus follows.

Case 3. $A=0$. If $1<q<q^*$, then

$$\limsup_{\tau\to\infty} w(y,\tau) \le \lim_{A\to 0} w_A(|y|) = w_0(|y|) = W_0(y,1),$$

where w_0 is the unique positive solution of (3.4) with $A=0$ and W_0 is the unique VSS. It remains to show that

$$\liminf_{\tau\to\infty} w(y,\tau) \ge w_0(|y|). \tag{3.7}$$

To do this, we go back to the PDE (I). Set $\nu = \mu$, and define γ and u_λ as in (2.1). Then (2.2) holds with $\sigma = 0$. In addition,

$$\lim_{\lambda\to\infty}\int_{|x|\le\varepsilon}\phi_\lambda(x)dx = \lim_{\lambda\to\infty}\int_{|x|\le\varepsilon\lambda^\gamma}\lambda^{\gamma(\mu-n)}\phi(x)dx = \infty \quad \forall\,\varepsilon > 0.$$

Hence, for each $c > 0$, there exists a sequence $\{\psi^c_\lambda\}_{\lambda\ge1}$ such that $0 \le \psi_\lambda \le \phi_\lambda$ for all $\lambda \ge 1$ and $\{\frac{1}{c}\psi_\lambda\}_{\lambda>1}$ is a δ-sequence. Consequently, the solution u^c_λ of $\mathcal{L}u_\lambda = -u^q_\lambda$ with initial value $u^c_\lambda(x,0) = \psi^c_\lambda$ tends to the fundamental solution u^c of $\mathcal{L}u_\lambda = -u^q_\lambda$ with initial mass c as $\lambda \to \infty$; see [5]. Since $u_\lambda \ge u^c_\lambda$, we have

$$\liminf_{\lambda\to\infty} u_\lambda \ge \lim_{\lambda\to\infty} u^c_\lambda = u^c.$$

It follows that

$$\liminf_{\lambda\to\infty} u_\lambda(x,t) \ge \lim_{c\to\infty} u^c(x,t) = W_0(x,t).$$

A direct translation of the above relation in terms of $w(y,\tau)$ is exactly (3.7). Thus

$$\lim_{\tau\to\infty} w(y,\tau) = w_0(|y|) = W_0(y,1)$$

uniformly in any compact subset of $\mathbb{R}^n$. Since for $A = 1$ and some large R, $w(y,\tau) \le w^+_{A,R}(|y|)$ for all $\tau > 0$ and $w^+_{1,R}$ decays to zero as $|y| \to \infty$, the above limit is uniform in $\mathbb{R}^n$. This completes the proof of Theorem 1.6 for the case in which $A = 0$ and $1 < q < q^*$.

If $q \ge q^*$, then

$$\limsup_{\tau\to\infty} \|w(y,\tau)\|_{L^\infty(\mathbb{R}^n)} \le \lim_{A\to0+} \|w_A(|y|)\|_{L^\infty(\mathbb{R}^n)} = 0.$$

Finally, we prove the second limit in (1.10), where $q = q^*$. By taking smaller ϕ if necessary, we can assume that $\phi \le 1$ and has compact support. Then $u \le 1$ in $\mathbb{R}^n \times (0,\infty)$. Consequently, $\mathcal{L}u = -u^{q^*} \ge -u^{q^*-\varepsilon}$. Now let u^ε be the solution to $\mathcal{L}u^\varepsilon = -u^{q^*-\varepsilon}$ and initial data $u^\varepsilon(x,0) = \phi$. Then, from what we just proved, we have $\lim_{t\to\infty} t^{1/(q-\varepsilon-1)}u^\varepsilon(0,t) = W_0^{q^*-\varepsilon}(0,1)$, where $W_0^{q^*-\varepsilon}$ is the VSS for $q = q^* - \varepsilon$. Thus $\liminf_{t\to\infty} t^{1/(q^*-\varepsilon-1)}u(0,t) > 0$. As ε is arbitrary, the second limit in (1.10) follows. This completes the proof of Theorem 1.6. □

PERTURBATION THEORY FOR VISCOSITY SOLUTIONS OF HAMILTON–JACOBI EQUATIONS AND STABILITY OF AUBRY–MATHER SETS*

DIOGO AGUIAR GOMES†

Abstract. In this paper we study the stability of integrable Hamiltonian systems under small perturbations, proving a weak form of the KAM/Nekhoroshev theory for viscosity solutions of Hamilton–Jacobi equations. The main advantage of our approach is that only a finite number of terms in an asymptotic expansion are needed in order to obtain uniform control. Therefore there are no convergence issues involved. An application of these results is to show that Diophantine invariant tori and Aubry–Mather sets are stable under small perturbations.

Key words. Hamiltonian dynamics, KAM theory, Aubry–Mather sets, viscosity solutions

AMS subject classifications. 37J40, 49L25, 35C20

1. Introduction.

We consider Hamiltonians of the form

$$H_\epsilon(p,x) = H_0(p) + \epsilon H_1(p,x), \tag{1}$$

with H_0, H_1 smooth, $H_0(p)$ strictly convex and $H_1(p,x)$ bounded with bounded derivatives, and $\mathbb{Z}^n$ periodic in x. The objective of this paper is to understand the dependence on ϵ of periodic viscosity solutions (for the definition of viscosity solution, see section 3) of

$$H_\epsilon(P + D_x u^\epsilon, x) = \overline{H}_\epsilon(P), \tag{2}$$

and prove stability of Aubry–Mather sets [Mat89a], [Mat89b], [Mat91], [Mn92], [Mn96] under small perturbations. Equation (2) has two unknowns, the function u^ϵ and the value of the effective Hamiltonian $\overline{H}_\epsilon(P)$. Given a viscosity solution of (2), the Mather set is a set invariant under the Hamiltonian dynamics

$$\dot{x} = -D_p H_\epsilon(p,x), \qquad \dot{p} = D_x H_\epsilon(p,x)$$

that is contained on the graph $(x,p) = (x, P + D_x u^\epsilon(x))$. For smooth solutions of (2) it corresponds to KAM tori.

We are given a reference value $P = P_0$, and we assume that for $\epsilon = 0$ the rotation vector $\omega_0 = D_P \overline{H}_0(P_0)$ satisfies Diophantine nonresonance conditions

$$|\omega_0 \cdot k| \geq \frac{C}{|k|^s} \tag{3}$$

for some positive constant C and some real $s > 0$. Is well known that the KAM theory applies to all nonresonant vectors ω_0. In particular it implies that for sufficiently

small perturbations the solution to (2) is smooth. However, our results hold even if the solution to (2) fails to be smooth.

In general, if one keeps the momentum P_0 fixed, for $\epsilon > 0$ the new rotation vector $D_P\overline{H}_\epsilon(P_0)$ may fail to be Diophantine. In particular an ergodic flow for $\epsilon = 0$ may give rise to periodic orbits when $\epsilon > 0$. Therefore it is convenient to let the momentum P change with ϵ while keeping the rotation vector fixed. To that effect, given $N > 0$ we construct an approximate solution $\tilde{u}^\epsilon_N(x, P)$ of (2); that is, $\tilde{u}^\epsilon_N(x, P)$ solves

$$H_\epsilon(P + D_x\tilde{u}^\epsilon, x) = \tilde{H}^N_\epsilon(P) + O(\epsilon^N + |P - P_0|^N)$$

for all P close to P_0. Using the implicit function theorem, we can prove that there exists a new momentum $P_\epsilon = P_0 + O(\epsilon)$ such that $D_P\tilde{H}^N_\epsilon(P_\epsilon) = D_P\overline{H}_0(P_0)$. Therefore we are able to keep the rotation vector fixed (up to order N) under small perturbations.

The two main results of this paper are stated in Theorems 3 and 4. In Theorem 3, we show that for any $M > 0$ there exists $N(M)$ such that

$$|u^\epsilon(x, P_\epsilon) - \tilde{u}^\epsilon_N(x, P_\epsilon)| = O(\epsilon^M).$$

To show this, we first prove estimates along trajectories of the Hamiltonian flow. Then we extend these estimates to nearby points using a priori Lipschitz continuity of viscosity solutions. To that effect, we use the fact that the rotation vector is kept unchanged so that we can take advantage of the Diophantine properties. These properties imply that the Hamiltonian flow takes at most time $O\left(\frac{1}{\epsilon^{Ms}}\right)$ to visit an arbitrary ϵ^M neighborhood of any point of the torus [BGW98] (similar estimates were proved originally in [Dum91], [DDG96]). From this we can extend the estimates along trajectories to ϵ^M neighborhoods, using the Lipschitz continuity of viscosity solutions, and therefore obtain uniform control. The technique of the proof would break down if we choose $P_\epsilon = P_0$ because we do not have any control over the number of theoretical properties of $D_P\overline{H}_\epsilon(P_0)$.

Finally, in Theorem 4, we prove estimates for the derivatives of viscosity solutions, showing that

$$\operatorname{esssup} |D_x u^\epsilon - D_x\tilde{u}^\epsilon_N| = O(\epsilon^{M/2}).$$

Note that these estimates do not imply that u^ϵ is differentiable; therefore they apply even when the invariant tori that exist when $\epsilon = 0$ cease to exist and are replaced by Mather sets. Therefore this result implies the stability of Mather sets under small perturbations.

Our results should be compared with previous results. One result is KAM theory, which states that, for all Diophantine rotation vectors, u^ϵ is smooth and can be computed by summing a convergent series for ϵ small enough. A result that is somewhat close to ours is the following (see [BGGM98], [MG95]): Suppose P_0 is such that the corresponding frequency is Diophantine. Then there exists a canonical transformation T_ϵ, defined in the domain $|P - P_0| \leq C\epsilon$, such that in the new coordinates, the new Hamiltonian can be written as

$$H_0(P) + \tilde{H}_\epsilon(P) + e^{-C/\epsilon 1/n}R(x, P);$$

that is, the system is very close to integrable in an appropriate coordinate system. At the other extreme one has that the viscosity solution u^ϵ, which is Lipschitz, converges uniformly to a constant, provided the rotation number is nonresonant ($\omega_0 \cdot k \neq 0$ for all

$k \in \mathbb{Z}^n$) [Gom02]. The results in this paper apply to all Diophantine rotation vectors, provided the Hamiltonian is smooth enough so that one can construct $\tilde{u}_N^\epsilon$ to all orders, and yields an asymptotic representation, for small ϵ, of u^ϵ and its derivatives, even when there is not smoothness or no convergence of the approximations.

This paper is organized as follows: In section 2 we review the classical Lindstedt series expansion for perturbations of nonresonant integrable Hamiltonians. In section 3 we recall the necessary background from the theory of viscosity solutions and its relation to Aubry–Mather theory. In section 4 we study the expansions for $\overline{H}_\epsilon$. Uniform estimates for viscosity solutions are discussed in section 5. In the last section we present some applications to the stability of viscosity solutions and Aubry–Mather sets, bootstrapping from L^∞ estimates for viscosity solutions to $W^{1,\infty}$ estimates.

Other examples of asymptotic expansions for Hamilton–Jacobi equations in the case in which the perturbation is a second order elliptic operator can be found in [FS86a], [FS86b], and [Bes].

2. Classical perturbation theory. In this section we review the classical perturbation theory for Hamiltonian systems using a construction equivalent to the Poincaré normal form near an invariant torus. Somewhat incorrectly, but following [AKN97], we call it the Lindstedt series method. Although these results are fairly standard (see [AKN97], for instance), we present them in a more convenient form for our purposes.

Consider the Hamiltonian dynamics

$$\begin{cases} \dot{\mathbf{x}} = -D_p H_\epsilon(\mathbf{p}, \mathbf{x}), \\ \dot{\mathbf{p}} = D_x H_\epsilon(\mathbf{p}, \mathbf{x}). \end{cases} \tag{4}$$

We use the convention that boldface $(\mathbf{x}, \mathbf{p})$ are trajectories of the Hamiltonian flow and not the coordinates (x, p). The Hamilton–Jacobi integrability theory suggests that we should look for functions $\overline{H}_\epsilon(P)$ and $u^\epsilon(x, P)$, periodic in x, solving the Hamilton–Jacobi equation

$$H_\epsilon(P + D_x u^\epsilon, x) = \overline{H}_\epsilon(P). \tag{5}$$

Then, by performing the change of coordinates $(x, p) \leftrightarrow (X, P)$ determined by

$$\begin{cases} X = x + D_P u^\epsilon, \\ p = P + D_x u^\epsilon, \end{cases} \tag{6}$$

the dynamics (4) is simplified to

$$\begin{cases} \dot{\mathbf{X}} = -D_P \overline{H}(\mathbf{P}), \\ \dot{\mathbf{P}} = 0. \end{cases}$$

We again use the convention that boldface $(\mathbf{X}, \mathbf{P})$ are trajectories of the Hamiltonian flow and not the new coordinates (X, P).

If $\tilde{u}$ is an approximate solution to (5) satisfying

$$H_\epsilon(P + D_x \tilde{u}, x) = \overline{H}_\epsilon(P) + f(x, P), \tag{7}$$

then the change of coordinates (6) transforms (4) into

$$\begin{cases} \dot{\mathbf{X}} = -D_P \overline{H}_\epsilon(\mathbf{P}) - D_P f(\mathbf{X}, \mathbf{P}), \\ \dot{\mathbf{P}} = D_X f(\mathbf{X}, \mathbf{P}), \end{cases} \tag{8}$$

with the convention that $f(X,P) = f(x(X,P),P)$.

The KAM theory deals with constructing solutions of (5) by using an iterative procedure, a modified Newton's method, that yields an expansion

$$u^\epsilon = u_0 + \epsilon v_1 + \epsilon^2 v_2 \cdots .$$

The main technical point in KAM theory is to prove the convergence of these expansions. An alternate method that yields such an expansion is the Lindstedt series [AKN97]. However, we should point out that whereas the KAM expansion is a convergent one, the Lindstedt series may fail to converge. Nevertheless, since we will need only finitely many terms, we will use a variation of the Lindstedt series that we describe next.

We say that a vector $\omega \in \mathbb{R}^n$ is Diophantine if for all $k \in \mathbb{Z}^n \backslash \{0\}$, $|\omega \cdot k| \geq \frac{C}{|k|^s}$ for some $C, s > 0$. Let P_0 be such that $\omega_0 = D_P \overline{H}_0(P_0)$ is Diophantine. We look for an approximate solution of

$$H_\epsilon(P + D_x u^\epsilon(x,P), x) = \overline{H}_\epsilon(P),$$

valid for $P = P_0 + O(\epsilon)$. When $\epsilon = 0$, $\overline{H}_0(P) = H_0(P)$ and the solution u^0 is constant; for instance, we may take $u^0 \equiv 0$. For $\epsilon > 0$ we have, formally, $u^\epsilon = O(\epsilon)$, and so we suggest the following approximation $\tilde{u}^\epsilon_N$ to u^ϵ:

$$\begin{aligned} \tilde{u}^\epsilon_N = {} & \epsilon v_1(x,P_0) + \epsilon (P-P_0) D_P v_1(x,P_0) + \epsilon^2 v_2(x,P_0) \\ & + \frac{1}{2}\epsilon (P-P_0)^2 D^2_{PP} v_1(x,P_0) + \epsilon^2 (P-P_0) D_P v_2(x,P_0) \\ & + \epsilon^3 v_3(x,P_0) + \cdots . \end{aligned} \tag{9}$$

This expansion is carried out up to order $N-1$ in such a way that, formally, $u^\epsilon - \tilde{u}^\epsilon_N = O(\epsilon^N)$. For example,

$$\tilde{u}^\epsilon_1 = 0, \quad \tilde{u}^\epsilon_2 = \epsilon v_1, \quad \tilde{u}^\epsilon_3 = \epsilon v_1 + \epsilon^2 v_2 + \epsilon (P-P_0) D_P v_1.$$

The functions v_i and $D^k_{P^k} v_i$ satisfy transport equations

$$D_p H_0(P_0) D_x w = f(\cdots)$$

for some suitable f and can be solved inductively. For instance,

$$\overline{H}_1(P_0) = D_p H_0(P_0) D_x v_1 + H_1(P_0, x),$$

$$D_P \overline{H}_1(P_0) = D_p H_0(P_0) D_x (D_P v_1) + D^2_{pp} H_0(P_0) D_x v_1 + D_p H_1(P_0, x),$$

and

$$\overline{H}_2(P_0) = D_p H_0(P_0) D_x v_2 + \frac{1}{2} D^2_{pp} H_0(P_0) D_x v_1 D_x v_1 + D_p H_1(P_0, x) D_x v_1.$$

Note that the derivatives of v_i with respect to P and $D^k_{P^k} v_i$ are computed by solving appropriate transport equations, as illustrated above for $D_P v_1$, and not by differentiating v_i. In fact v_i may not be defined for $P \neq P_0$. However, if its derivative exists, it satisfies a transport equation.

The constants $\overline{H}_1(P_0), D_P\overline{H}_1(P_0), \overline{H}_2(P_0), \dots$ are uniquely determined by integral compatibility conditions; for example,

$$\overline{H}_1(P_0) = \int H_1(P_0, x)dx,$$

$$D_P\overline{H}(P_0) = \int D_p H_1(P_0, x)dx,$$

and

$$\overline{H}_2(P_0) = \int \frac{1}{2} D^2_{pp} H_0(P_0) D_x v_1 D_x v_1 + D_p H_1(P_0, x) D_x v_1 dx.$$

If H is sufficiently smooth and ω_0 is nonresonant, then these equations have smooth solutions that are unique up to constants. Finally one can check that

$$H_\epsilon(P + D_x\tilde{u}^\epsilon_N, x) = \tilde{H}^N_\epsilon(P) + O(\epsilon^N + |P - P_0|^N), \tag{10}$$

with

$$\tilde{H}^N_\epsilon(P) = \overline{H}_0(P_0) + \epsilon\overline{H}_1(P_0) + (P - P_0)D_P\overline{H}_0(P_0) + \epsilon^2\overline{H}_2(P_0) + \cdots,$$

and this expansion is carried up to order $N - 1$ in such a way that, formally,

$$\overline{H}_\epsilon(P) = \tilde{H}^N_\epsilon(P) + O(\epsilon^N + |P - P_0|^N).$$

Consider the change of coordinates

$$\begin{cases} p = P + D_x\tilde{u}^\epsilon_N(x, P), \\ X = x + D_P\tilde{u}^\epsilon_N(x, P). \end{cases}$$

Then, by (7) and (8), (4) is transformed into

$$\begin{cases} \dot{\mathbf{X}} = -D_P\overline{H}_\epsilon(\mathbf{P}) + O(\epsilon^N + |\mathbf{P} - P_0|^{N-1}), \\ \dot{\mathbf{P}} = O(\epsilon^N + |\mathbf{P} - P_0|^N). \end{cases}$$

3. Viscosity solutions, optimal control, and Mather measures. In general (5) does not admit smooth classical solutions. However, (5) has viscosity solutions which are known to be the appropriate notion of weak solution for Hamilton–Jacobi equations. In this section we review the necessary background, and in the rest of the paper we extend rigorously the classical perturbation procedure from the previous section to viscosity solutions.

For our purposes, a convenient definition of viscosity solution is the following: We say that a function u is a viscosity solution of (5), provided that it satisfies the fixed point identity

$$u(x) = \inf \int_0^t L(\mathbf{x}, \dot{\mathbf{x}}) + P\dot{\mathbf{x}} + \overline{H}(P)dt + u(\mathbf{x}(t)), \tag{11}$$

in which the infimum is taken over Lipschitz trajectories $\mathbf{x}(\cdot)$, with initial condition $\mathbf{x}(0) = x$, and $\overline{H}$ is the unique number for which (11) holds with $u(x)$ bounded. The Lagrangian L is the Legendre transform of the Hamiltonian

$$L(x, v) = \sup_p -vp - H(p, x).$$

This definition of viscosity solution is equivalent to the standard one [FS93], [BCD97], as long as the Hamiltonian and Lagrangian L are strictly convex. Note that viscosity solutions do not have to be smooth. However, they are semiconcave and therefore twice differentiable almost everywhere. Furthermore they are differentiable along the optimal trajectory $\mathbf{x}(t)$. In fact, the optimal trajectory $\mathbf{x}(t)$ in (11) and the momentum $\mathbf{p}(t) = P + D_x u(\mathbf{x}(t))$ are solutions of (4) for all $t > 0$.

First, let us quote an existence result [LPV88].

THEOREM 1 (Lions, Papanicolao, and Varadhan [LPV88]). *For each P there exists a number $\overline{H}(P)$ and a function $u(x, P)$, periodic in x, that solves* (5) *in the viscosity sense. Furthermore $\overline{H}(P)$ is convex in P, and $u(x, P)$ is Lipschitz in x.*

This theorem does not assert anything about uniqueness of the viscosity solution u. Indeed, such viscosity solutions are not unique even up to constants; see, for instance, [Con95]. However, as it was shown in [Gom02], under certain hypotheses one can prove uniqueness and even continuity of the viscosity solution u with respect to parameters. These hypotheses can be formulated in terms of the ergodic properties of certain measures—Mather measures (see Theorem 2)—that are invariant under the Hamiltonian dynamics.

The connection between classical mechanics and viscosity solutions is well known and was explored by several authors, for instance, [Fat97a], [Fat97b], [Fat98a], [Fat98b], [E99], [EG01], [EG02], and [Gom00b]. One of the most basic results is the following.

THEOREM 2 (A. Fathi, W. E). *Let u be a viscosity solution of* (5).

- *For each P there exists a set invariant under the dynamics* (4) *contained in the graph $(x, P + D_x u)$.*
- *There exists a probability measure $\mu(x, p)$ (Mather measure) invariant under* (4) *supported on this invariant set.*
- *This measure minimizes*

$$\int L(x, v) + Pv d\mu, \tag{12}$$

with $v = -D_p H(p, x)$, over all probability measures that are invariant under (4).

Conversely, any probability measure invariant under (4) *that minimizes* (12) *is supported on the graph $(x, P + D_x u)$ for any viscosity solution u of* (5).

One of the main advantages of the previous theorem is that one can translate properties of viscosity solutions into properties of Mather sets or measures and vice versa. Some properties of viscosity solutions are described in the following proposition.

PROPOSITION 1. *Suppose (x, p) is a point in the graph*

$$\mathcal{G} = \{(x, P + D_x u(x)) : \ u \text{ is differentiable at } x\}.$$

Then for all $t > 0$ the solution $(\mathbf{x}(t), \mathbf{p}(t))$ of (4) *with initial conditions (x, p) belongs to $\mathcal{G}$.*

Proof. The invariance of the graph for $t > 0$ is a consequence of the optimal control interpretation of viscosity solutions [FS93], and the reader may find a proof, for instance, in [Gom00b] or [Gom00a]. □

Finally, the following is an important identity [CIPP98].

PROPOSITION 2 (Contreras et al. [CIPP98]).

$$\overline{H}(P) = \inf_{\phi} \sup_{x} H(P + D_x \phi, x), \tag{13}$$

in which the infimum is taken over C^1 periodic functions ϕ.

This formula can be used to compute $\overline{H}(P)$ effectively [GO02a] and, in conjunction with properties of viscosity solutions, to detect nonintegrability of Hamiltonian systems [GO02b].

4. Estimates for the effective Hamiltonian. We start this section by proving that $\tilde{H}^N_\epsilon$ is an asymptotic expansion to $\overline{H}_\epsilon$. Then we will use convexity techniques to prove estimates for the derivatives of viscosity solutions that we will use in the subsequent sections.

PROPOSITION 3. *Suppose we can construct an approximate solution as in* (9). *Then*

$$\overline{H}_\epsilon(P) \le \tilde{H}^N_\epsilon(P) + O(\epsilon^N + |P - P_0|^N). \tag{14}$$

Remark. Note that the error term is a function of x, but, by periodicity, it can be estimated uniformly by $O(\epsilon^N + |P - P_0|^N)$.

Proof. The inf sup formula (13) implies

$$\overline{H}_\epsilon(P) \le \sup_x H_\epsilon(P + D_x\tilde{u}^\epsilon_N, x).$$

By expanding this expression in Taylor series and taking the supremum, we obtain the result. □

A converse inequality is also true.

PROPOSITION 4. *At any point at which $D_x u^\epsilon$ exists we have*

$$\begin{aligned}\overline{H}_\epsilon(P) \ge{}& H_\epsilon(P + D_x\tilde{u}^\epsilon_N, x) + D_p H_\epsilon(P + D_x\tilde{u}^\epsilon_N, x)(D_x\tilde{u}^\epsilon_N - D_x u^\epsilon)\\ &+ \frac{\gamma}{2}|D_x\tilde{u}^\epsilon_N - D_x u^\epsilon|^2\end{aligned} \tag{15}$$

for some positive constant $\gamma > 0$.

Proof. Since $H_\epsilon(p, x)$ is strictly convex, there exists a constant $\gamma > 0$ such that

$$\begin{aligned}\overline{H}_\epsilon(P) &\ge H_\epsilon(P + D_x u^\epsilon, x)\\ &\ge H_\epsilon(P + D_x\tilde{u}^\epsilon_N, x) + D_p H_\epsilon(P + D_x\tilde{u}^\epsilon_N, x)(D_x\tilde{u}^\epsilon_N - D_x u^\epsilon)\\ &\quad + \frac{\gamma}{2}|D_x\tilde{u}^\epsilon_N - D_x u^\epsilon|^2. \qquad \square\end{aligned}$$

The following corollary is going to be used in the next section.

COROLLARY 1. *If there exists an approximate solution as in Proposition* 3, *then there exists a point x_0 for which*

$$|D_x\tilde{u}^\epsilon(x_0) - D_x u^\epsilon(x_0)| \le C\epsilon^{N/2}.$$

Proof. Since u^ϵ is semiconcave, $\tilde{u}^\epsilon - u^\epsilon$ is semiconvex. Therefore at the maximum x_0, $D_x(\tilde{u}^\epsilon - u^\epsilon) = 0$; that is, the derivative exists and is zero. Then the two previous propositions yield the desired result. □

COROLLARY 2. *If there exists an approximate solution as in Proposition* 3, *then*

$$\overline{H}_\epsilon = \tilde{H}^N_\epsilon + O(\epsilon^N).$$

Proof. It suffices to combine Propositions 3 and 4 at the point x_0 given by the previous corollary. □

5. Uniform estimates. In this section we prove uniform estimates

$$\sup_x |u^\epsilon - \tilde{u}_N^\epsilon| = O(\epsilon^M)$$

under Diophantine conditions on the rotation vector ω_0 of the unperturbed problem. These results should be compared with the ones in [Gom02], which show that unique ergodicity of the Mather measure implies uniform continuity of the viscosity solution with respect to the parameters.

First we construct an approximate solution $\tilde{u}_N^\epsilon$ for a sufficiently large but finite N using the Lindstedt series expansion described in section 2. Then, by changing coordinates, we show that for long times there are uniform estimates along trajectories. Finally, by using Lipschitz estimates for u^ϵ and $\tilde{u}_N^\epsilon$ and the results by [Dum91] on ergodization times, we extend them to whole space.

THEOREM 3. *Suppose the rotation vector*

$$\omega_0 = D_P \overline{H}_0(P_0)$$

satisfies the Diophantine property (3). *Furthermore suppose that for every N there exists $P_\epsilon = P + O(\epsilon)$,*

$$D_P \tilde{H}_\epsilon^N(P_\epsilon) = \omega_0;$$

that is, the approximate rotation vector corresponding to P_ϵ is the original rotation vector ω_0. Let u^ϵ be a solution of

$$H_\epsilon(P_\epsilon + D_x u^\epsilon, x) = \overline{H}_\epsilon(P_\epsilon),$$

and let $\tilde{u}_N^\epsilon$ be the corresponding approximate solution using a Lindstedt series expansion up to order N.

Then for every M there exists $N(M)$ such that

$$\sup_x |u^\epsilon - \tilde{u}_N^\epsilon| = O(\epsilon^M).$$

Proof. Define P_ϵ by solving the equation

$$\omega_0 = D_P \tilde{H}_\epsilon^N(P_\epsilon),$$

that is,

$$\omega_0 = D_P \overline{H}_0(P_0) + \epsilon D_P \overline{H}_1(P_0) + (P_\epsilon - P_0) D_{PP}^2 \overline{H}_0(P_0) + \cdots,$$

with expansion taken up to order $N-1$. Under the nondegeneracy condition $\det D_{pp}^2 \overline{H}_0 \neq 0$ (which holds because $\overline{H}_0(P) = H_0(P)$ is strictly convex), the implicit function theorem yields a unique solution of the form

$$P_\epsilon = P_0 + \epsilon P_1 + \cdots$$

with $P_1 = -\left[D_{PP}^2 \overline{H}_0(P_0)\right]^{-1} D_P \overline{H}_1(P_0)$.

Define the new coordinates (P, X) by

$$\begin{cases} p = P + D_x \tilde{u}_N^\epsilon(x, P), \\ X = x + D_P \tilde{u}_N^\epsilon(x, P). \end{cases}$$

To simplify notation we denote $X = \phi_\epsilon(x)$.

Let x_0 be the point given by Corollary 1. Set

$$(\mathbf{x}(0), \mathbf{p}(0)) = (x_0, P_\epsilon + D_x u^\epsilon(x_0))$$

as the initial conditions for a trajectory $(\mathbf{x}(t), \mathbf{p}(t))$ of (4). Since $|D_x \tilde{u}^\epsilon(x_0) - D_x u^\epsilon(x_0)| \leq C\epsilon^{N/2}$, in the new coordinates we have

$$\mathbf{P}(0) = P_\epsilon + O(\epsilon^{N/2}).$$

Consider the Hamiltonian dynamics in the new coordinates (X, P), with initial condition $(\mathbf{X}(0), \mathbf{P}(0))$ (the value $\mathbf{X}(0)$ is not important):

$$\begin{cases} \dot{\mathbf{X}} = -D_P \tilde{H}_\epsilon(\mathbf{P}) + O(\epsilon^N + |\mathbf{P} - P_0|^{N-1}), \\ \dot{\mathbf{P}} = O(\epsilon^N + |\mathbf{P} - P_0|^N). \end{cases}$$

From this equation it follows that the momentum P in the new coordinates is conserved for long times.

Proposition 5.

$$\sup_{0 \leq t \leq \frac{1}{\epsilon^{N/2}}} |\mathbf{P}(t) - P_\epsilon| \leq O(\epsilon^{N/4}).$$

Proof. Note that

$$\begin{aligned} \frac{d}{dt}|\mathbf{P} - P_\epsilon|^2 &\leq C|\mathbf{P} - P_\epsilon|(\epsilon^N + |\mathbf{P} - P_\epsilon|^N) \\ &\leq C\epsilon^N |\mathbf{P} - P_\epsilon|^2 + C\epsilon^N \end{aligned}$$

as long as $|\mathbf{P} - P_\epsilon|^{N-1} \leq C\epsilon^N$. Note that for $N > 3$—and we are always assuming N large enough—we have $|\mathbf{P}(0) - P_\epsilon|^{N-1} \leq C\epsilon^N$. Thus the Gronwall inequality implies

$$|\mathbf{P}(T) - P_\epsilon|^2 \leq e^{C\epsilon^N T} \left(|\mathbf{P}(0) - P_\epsilon|^2 + C\epsilon^N T \right).$$

Therefore, up to $T = \frac{1}{\epsilon^{N/2}}$ we have

$$|\mathbf{P}(t) - P_\epsilon|^2 \leq C\epsilon^{N/2}$$

for ϵ sufficiently small. □

Observe that $\phi_\epsilon(x) = X$ is a diffeomorphism for small ϵ. Let

$$U(X) = u^\epsilon(\phi_\epsilon^{-1}(X)) - \tilde{u}_N^\epsilon(\phi_\epsilon^{-1}(X)),$$

in particular

$$U(\mathbf{X}(t)) = u^\epsilon(\mathbf{x}(t)) - \epsilon v_1(\mathbf{x}(t)) - \epsilon(P_\epsilon - P_0) D_P v_1(\mathbf{x}(t)) - \cdots.$$

Recall that $D_x u^\epsilon(\mathbf{x}(t)) = \mathbf{p}(t) - P_\epsilon$. Thus

$$\begin{aligned} \frac{d}{dt} U(\mathbf{X}(t)) &= (\mathbf{p}(t) - P_\epsilon) D_p H_\epsilon(\mathbf{p}(t), \mathbf{x}(t)) \\ &\quad - \epsilon D_x v_1(\mathbf{x}(t)) D_p H_\epsilon(\mathbf{p}(t), \mathbf{x}(t)) - \cdots \\ &= (\mathbf{p}(t) - P_\epsilon - \epsilon D_x v_1 - \cdots) D_p H_\epsilon \\ &= (\mathbf{P}(t) - P_\epsilon) D_p H_\epsilon(\mathbf{p}(t), \mathbf{x}(t)), \end{aligned}$$

since $\mathbf{p}(t) = \mathbf{P}(t) + \epsilon D_x v_1(\mathbf{x}(t)) + \cdots$. Therefore

$$\frac{d}{dt} U(\mathbf{X}(t)) = O(\epsilon^{N/4})$$

for $0 \leq t \leq \frac{1}{\epsilon^{N/2}}$.

We may also add a convenient constant to u^ϵ in such a way that $U(\mathbf{X}(0)) = 0$, and so we obtain

$$\sup_{0 \leq t \leq \frac{1}{\epsilon^{N/8}}} U(\mathbf{X}(t)) = O(\epsilon^{N/8})$$

along the trajectory.

Since, for small ϵ, ϕ_ϵ is a diffeomorphism, U is a Lipschitz function. The Diophantine property implies that the flow

$$\dot{\mathbf{X}} = D_P \overline{H}_0(P_0) + O(\epsilon^{N/2})$$

takes at most time $T = O\left(\frac{1}{\epsilon^{Ms}}\right)$ to get within distance ϵ^M of any point (see [BGW98], and also [Dum91], [DDG96]). Thus, if $M < \frac{N}{8s}$, we get for some $0 \leq t \leq \frac{1}{\epsilon^{N/8}}$ that

$$|X - \mathbf{X}(t)| \leq C\epsilon^M,$$

and so

$$|U(X)| \leq |U(X) - U(\mathbf{X}(t))| + |U(\mathbf{X}(t))| \leq C\epsilon^M.$$

Because ϕ_ϵ is a diffeomorphism, the same estimate carries over for the difference $u^\epsilon - \tilde{u}^\epsilon_N$. □

A final comment is that since $\tilde{u}^\epsilon_N - \tilde{u}^\epsilon_M = O(\epsilon^M)$, we also have

$$\sup_x |u^\epsilon - \tilde{u}^\epsilon_M| = O(\epsilon^M),$$

although we need the existence of $\tilde{u}^\epsilon_N$ to prove this estimate.

6. Applications: Stability of Mather sets and regularity. This last section is dedicated to proving estimates on the derivatives $D_x u^\epsilon - D_x \tilde{u}^\epsilon$. Such estimates rely on the uniform estimates from the previous section. Since the Mather sets are supported on the graph $(x, P + D_x u)$, estimates on the derivatives show the stability of Mather sets.

PROPOSITION 6. *Suppose $\omega_0 = D_P H_0(P_0)$ is Diophantine and (2) admits an approximate solution $\tilde{u}^\epsilon_N$. Then*

$$\begin{aligned} \frac{1}{T} \int_0^T \frac{\gamma}{2} |D_x u^\epsilon(\mathbf{x}(t)) - D_x \tilde{u}^\epsilon_N(\mathbf{x}(t))|^2 dt \\ \leq C\epsilon^N + \frac{2}{T} \sup_x |u^\epsilon - \tilde{u}^\epsilon_N|, \end{aligned}$$

in which the integral is taken along a trajectory $\mathbf{x}(\cdot)$ of

$$\dot{\mathbf{x}}(t) = -D_p H_\epsilon(P_\epsilon + D_x u^\epsilon(\mathbf{x}(t)), \mathbf{x}(t)).$$

Proof. The strict convexity of H_ϵ together with Corollary 2 implies

$$O(\epsilon^N) \geq D_p H_\epsilon(P_0 + D_x u^\epsilon(\mathbf{x}(t)), \mathbf{x}(t))(D_x \tilde{u}_N^\epsilon(\mathbf{x}(t)) - D_x u^\epsilon(\mathbf{x}(t))) + \frac{\gamma}{2}|D_x \tilde{u}_N^\epsilon(\mathbf{x}(t)) - D_x u^\epsilon(\mathbf{x}(t))|^2.$$

Integrating with respect to t and observing that

$$\begin{aligned}&\int_0^T D_p H_\epsilon(P_0 + D_x u^\epsilon(\mathbf{x}(t)), \mathbf{x}(t))(D_x \tilde{u}_N^\epsilon(\mathbf{x}(t)) - D_x u^\epsilon(\mathbf{x}(t)))dt \\ &= -\int_0^T \dot{\mathbf{x}}(t)(D_x \tilde{u}_N^\epsilon(\mathbf{x}(t)) - D_x\ u^\epsilon(\mathbf{x}(t)))dt \\ &= -u^\epsilon(\mathbf{x}(0)) + \tilde{u}_N^\epsilon(\mathbf{x}(0)) + u^\epsilon(\mathbf{x}(T)) - \tilde{u}_N^\epsilon(\mathbf{x}(T)),\end{aligned}$$

we obtain the result. □

This proposition is the key to proving the main result of this paper, which is discussed in the next theorem—pointwise estimates for first derivatives of viscosity solutions.

THEOREM 4. *Let $M > 0$. Suppose $\omega_0 = D_P H_0(P_0)$ is Diophantine such that the cell problem* (2) *admits an approximate solution $\tilde{u}_N^\epsilon$ for N sufficiently large such that Theorem* 3 *holds. Then*

$$\operatorname*{esssup}_x |D_x u^\epsilon - D_x \tilde{u}_N^\epsilon| \leq C\epsilon^{M/2}.$$

Proof. Since $\sup_x |\tilde{u}_N^\epsilon - u^\epsilon| = O(\epsilon^M)$ we have

$$\int_0^1 \frac{\gamma}{2}|D_x u^\epsilon(\mathbf{x}(t)) - D_x \tilde{u}_N^\epsilon(\mathbf{x}(t))|^2 dt \leq C\epsilon^M, \tag{16}$$

with $\mathbf{x}(t)$ as in the previous theorem and for any initial condition $\mathbf{x}(0) = x$.

Let G be the set of the points at which $D_x u^\epsilon$ exists and such that

$$|D_x u^\epsilon - D_x \tilde{u}_N^\epsilon| \leq C\epsilon^{M/2}$$

for some fixed constant C, and set

$$B = \{x \in G^c | u^\epsilon \text{ is differentiable at } x\}.$$

Since u^ϵ is Lipschitz, then $(B \cup G)^c$, which is the set of points of nondifferentiability of u^ϵ, is of zero Lebesgue measure.

Let x be a point for which $D_x u^\epsilon$ exists and $|D_x \tilde{u}_N^\epsilon - D_x u^\epsilon| > C\epsilon^{M/2}$. Define $p_x = P_\epsilon + D_x u^\epsilon(x)$. Let $(\mathbf{x}(t), \mathbf{p}(t))$ be the solution of (4) with initial conditions (x, p_x).

The estimate (16) implies that we may assume that there exists $0 < T < 1$ such that $\mathbf{x}(T) \in G$. Let $y = \mathbf{x}(T)$ and

$$\tilde{p}_y = P_\epsilon + D_x \tilde{u}_N^\epsilon(\mathbf{x}(T)), \quad p_y = P_\epsilon + D_x u^\epsilon(\mathbf{x}(T)).$$

Since $y \in G$ we have

$$|\tilde{p}_y - p_y| \leq C\epsilon^{M/2}.$$

Let $(\mathbf{x}(t), \tilde{\mathbf{p}}(t))$ be the solution of (4) with initial conditions $(y, \tilde{p}_y)$. Define $\tilde{x} = \mathbf{x}(-T)$, $p_{\tilde{x}} = \tilde{\mathbf{p}}(-T)$.

By standard ODE theory

$$|p_x - p_{\tilde{x}}| \leq C\epsilon^{M/2}, \qquad |x - \tilde{x}| \leq C\epsilon^{M/2}.$$

Note that

$$\begin{aligned}|D_x u^\epsilon(x) - D_x \tilde{u}_N^\epsilon(x)| \leq |P_\epsilon + D_x u^\epsilon(x) - p_{\tilde{x}}| + |p_{\tilde{x}} - P_\epsilon - D_x \tilde{u}_N^\epsilon(\tilde{x})| \\ + |D_x \tilde{u}_N^\epsilon(\tilde{x}) - D_x \tilde{u}_N^\epsilon(x)|.\end{aligned}$$

The first term is controlled by

$$|P_\epsilon + D_x u^\epsilon(x) - p_{\tilde{x}}| = |p_x - p_{\tilde{x}}| \leq C\epsilon^{M/2}.$$

The last term is controlled by the Lipschitz constant of $\tilde{u}_N^\epsilon$,

$$|D_x \tilde{u}_N^\epsilon(\tilde{x}) - D_x \tilde{u}_N^\epsilon(x)| \leq C|x - \tilde{x}| \leq C\epsilon^{M/2}.$$

Therefore it suffices to estimate $|p_{\tilde{x}} - P_\epsilon - D_x \tilde{u}_N^\epsilon(\tilde{x})|$. To that effect observe that from differentiating (10) with respect to x it follows that

$$D_p H(P_\epsilon + D_x \tilde{u}_N^\epsilon, x) D_{xx}^2 \tilde{u}_N^\epsilon + D_x H(P_\epsilon + D_x \tilde{u}_N^\epsilon, x) = O(\epsilon^N). \tag{17}$$

Then by combining

$$\begin{aligned}&\frac{d}{dt}\frac{|\tilde{\mathbf{p}}(t) - P_\epsilon - D_x \tilde{u}_N^\epsilon(\tilde{\mathbf{x}}(t)|^2}{2} \\ &\quad = (\tilde{\mathbf{p}}(t) - P_\epsilon - D_x \tilde{u}_N^\epsilon(\tilde{\mathbf{x}}(t)) \left[D_x H(\tilde{\mathbf{p}}(t), \tilde{\mathbf{x}}(t)) + D_{xx}^2 \tilde{u}_N^\epsilon(\tilde{\mathbf{x}}(t))\right] D_p H(\tilde{\mathbf{p}}(t), \tilde{\mathbf{x}}(t)))\end{aligned}$$

with (17), we obtain

$$\frac{d}{dt}\frac{|\tilde{\mathbf{p}}(t) - P_\epsilon - D_x \tilde{u}_N^\epsilon(\tilde{\mathbf{x}}(t)|^2}{2} \leq C|\tilde{\mathbf{p}}(t) - P_\epsilon - D_x \tilde{u}_N^\epsilon(\tilde{\mathbf{x}}(t))|^2 + O(\epsilon^N).$$

Then the Gronwall inequality yields

$$|p_{\tilde{x}} - P_\epsilon - D_x \tilde{u}_N^\epsilon(\tilde{x})|^2 \leq C\epsilon^N. \qquad \square$$

Acknowledgments. I would like to thank the referees, L. C. Evans, R. de la Llave, and C. Valls for many suggestions and comments on the original version of this paper.

UNIQUENESS IN IDENTIFICATION OF THE SUPPORT OF A SOURCE TERM IN AN ELLIPTIC EQUATION*

SUNGWHAN KIM† AND MASAHIRO YAMAMOTO†

Abstract. We consider an inverse problem of identifying the support D of a source term in an elliptic equation

$$-\Delta u(x) + q(x)\chi_D(x)u(x) = 0, \quad x \in \Omega, \qquad \text{and} \qquad u(x) = f(x), \quad x \in \partial\Omega.$$

Here q is a given positive function and χ_D is the characteristic function of a subdomain D such that $\overline{D} \subset \Omega$. In this paper, we prove the global uniqueness in this inverse problem within convex hulls of polygons D.

Key words. inverse problem, uniqueness, determination of supports

1. Introduction. We consider an inverse problem of recovering the shape and location of an unknown stationary heat source F. Let $\Omega \subset \mathbb{R}^2$ be a bounded domain with smooth boundary and D a subdomain of Ω with Lipschitz boundary.

In this paper, we assume that the source F at $x = (x_1, x_2)$ is limited to D and proportional to the temperature u at x, that is, $F(x,t,u) = q(x)\chi_D(x)u(x,t)$. Here and henceforth, χ_D is the characteristic function of the subdomain $D \subset \Omega$, and $q \in C^2(\overline{\Omega})$, $q > 0$, on $\overline{\Omega}$.

If we apply a potential f to the boundary $\partial\Omega$ of Ω, then the resulting temperature u satisfies the Dirichlet problem

$$\begin{cases} -\Delta u + q\chi_D u = 0 & \text{in} \quad \Omega, \\ u = f & \text{on} \quad \partial\Omega. \end{cases} \tag{1.1}$$

It is well known that for a given domain D and $f \in H^{\frac{1}{2}}(\partial\Omega)$, there exists a unique solution $u \in H^1(\Omega)$ to (1.1). Thus we can define the Dirichlet-to-Neumann map $\Lambda_D : H^{\frac{1}{2}}(\partial\Omega) \to H^{-\frac{1}{2}}(\partial\Omega)$ by

$$\Lambda_D(f) := \frac{\partial u}{\partial \nu}|_{\partial\Omega}, \tag{1.2}$$

where ν is the unit outward normal vector to $\partial\Omega$.

Restricting D to a polygon such that $\overline{D} \subset \Omega$, we discuss an inverse problem of determining D by a single boundary measurement $(f, \Lambda_D(f))$.

There has been research related to our inverse problem, which is motivated by determination of transistor contact resistivity and contact window location in the equation $-\Delta u + \chi_D u = 0$ in Ω. See [3], [8], [12], [15]. In particular, a uniqueness result within a one-parameter monotone family from a one-point boundary measurement of the potential was obtained in [3]. Moreover [12] provides a global uniqueness result

†Graduate School of Mathematical Sciences, The University of Tokyo, 3-8-1 Komaba, Meguro, Tokyo 153-8914, Japan (sungwhan@ms.u-tokyo.ac.jp, myama@ms.u-tokyo.ac.jp).

and a reconstruction scheme within the class of two- or three-dimensional balls from a single boundary measurement. In [15], the first author proved global uniqueness within some classes which can contain balls or ellipses. As for a general convex D, the uniqueness is still open (see, e.g., Problem 4.7.2 (p. 104) in [11]).

As for related inverse problems of determining piecewise continuous $\gamma = \gamma(x)$ in $\nabla \cdot (\gamma \nabla u) = 0$ in Ω, we can refer to [4], [5], [9], [13], [14], [17]. The case where $\gamma(x) = 1 + k\chi_D(x)$ and k is constant, in particular, has been studied by many researchers. The papers [5] and [17] dealt with the global uniqueness problem for polygons by one (or two) boundary measurement(s) under extra conditions. Our inverse problem is concerned with the determination of shapes of domains and is of a character similar to the classical inverse source problem or the inverse gravimetry where we are required to determine a domain D in $-\Delta u = q\chi_D$ by a single measurement of an exterior potential. As for the inverse source problem, we refer to the books [2], [10], [11] and the references therein. However, the methods for the inverse source problem are difficult to apply to the case where q depends on the whole components of x. Our method is applicable also to the inverse source problem.

The main purpose of this paper is to prove global uniqueness results within polygons under extra conditions. We always assume that the boundary of a polygon under consideration is a simply closed curve, and by a polygon we mean its interior. Moreover, throughout this paper, we assume

$$f \geq 0, \quad \not\equiv 0 \quad \text{on } \partial\Omega \quad \text{and} \quad q \in C^2(\overline{\Omega}), \quad q > 0, \quad \text{on } \overline{\Omega}. \tag{1.3}$$

We state our first main theorem. For $D \subset \mathbb{R}^2$, we denote the convex hull (i.e., the smallest convex set containing D) by $\mathrm{co}\,(D)$.

THEOREM 1.1. *If D_1 and D_2 are polygons such that $\overline{D_1}, \overline{D_2} \subset \Omega$ and $\Lambda_{D_1}(f) = \Lambda_{D_2}(f)$, then $co\,(D_1) = co\,(D_2)$.*

From Theorem 1.1, we can readily derive the following.

COROLLARY 1.2. *If D_1 and D_2 are convex polygons such that $\overline{D_1}, \overline{D_2} \subset \Omega$ and $\Lambda_{D_1}(f) = \Lambda_{D_2}(f)$, then $D_1 = D_2$.*

In Theorem 1.1, we cannot conclude that $D_1 = D_2$ without convexity. In the case of Figure 1, our argument does not work, and we do not know the uniqueness.

Next we show some uniqueness results for nonconvex polygons. First we show the uniqueness in a case where D_1 and D_2 have a common contact edge. For any domains D, E compactly contained in Ω, we denote the outer most boundary of $D \cup E$ by $\partial_{\mathrm{out}}(D \cup E)$, i.e.,

$$\partial_{\mathrm{out}}(D \cup E) = \{x \in \partial(D \cup E) |\, \text{there exists a continuous curve in } \Omega \setminus \overline{(D \cup E)} \text{ joining } x \text{ with some point of } \partial\Omega\}.$$

Here and henceforth, by a curve, we exclude the end points.

THEOREM 1.3. *Assume that D_1 and D_2 are polygons and that a line segment $\overline{A_0B_0} \subset \partial D_1 \cap \partial D_2$ lies on $\partial_{out}(D_1 \cup D_2)$. Then $\Lambda_{D_1}(f) = \Lambda_{D_2}(f)$ yields $D_1 = D_2$.*

Second we show the uniqueness in a case where all edges of D_1 and D_2 are parallel to two independent vectors.

THEOREM 1.4. *Assume that D_1 and D_2 are polygons such that there exist two independent vectors $\vec{a}$ and $\vec{b}$ such that all the edges of D_1 and D_2 are parallel to $\vec{a}$ or $\vec{b}$. Then $\Lambda_{D_1}(f) = \Lambda_{D_2}(f)$ yields $D_1 = D_2$.*

In particular, if polygons D_1 and D_2 are composed of rectangles in the forms of $\{(x_1, x_2) |\, a_1 < x_1 < b_1, a_2 < x_2 < b_2\}$, then Theorem 1.4 is applicable. Our

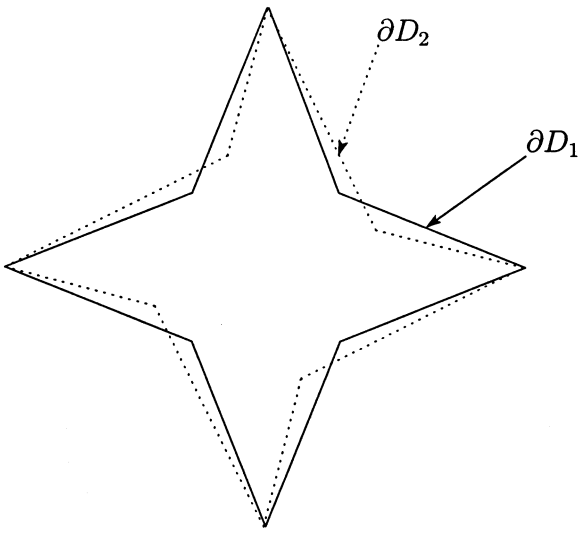

FIG. 1. *An example for $D_1 \neq D_2$ in the nonconvex case.*

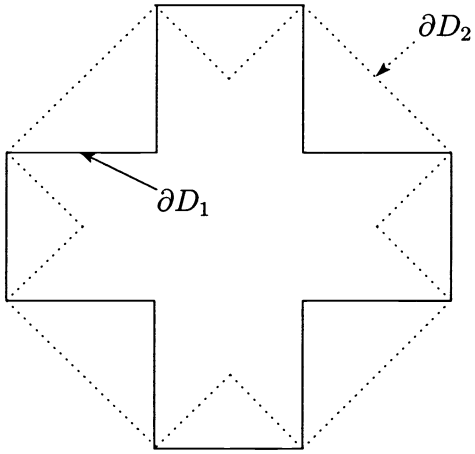

FIG. 2. *An example for $D_1 \neq D_2$ in the case where all the angles are right and all the edges are not parallel to the two fixed vectors.*

argument does not work even if all the vertex angles are right angles but all the edges are not parallel to one of the two fixed directions. See Figure 2. We think that the uniqueness results for nonconvex cases obtained so far are not comprehensive and should be improved.

Let u_j, $j = 1, 2$, be the solution to (1.1) corresponding to the domain D_j. We can prove (see, e.g., [7], [16]) that for any subdomain Ω' compactly contained in Ω, the solutions u_j, $j = 1, 2$, satisfy

$$u_j \in H^2(\Omega') \cap C^1(\Omega'). \tag{1.4}$$

Moreover, the maximum principle applied to u_j shows that

$$u_j > 0 \qquad \text{in} \quad \Omega, \quad j = 1, 2. \tag{1.5}$$

In the next section, we show a proposition on nonexistence of solutions to a Cauchy problem from which our main theorem is derived.

2. Nonexistence of an H^2-solution to a Cauchy problem for the Laplace equation. For the proof of the next nonexistence proposition, we need the following lemma about regularity of an H^1-solution to an elliptic equation. The proof of our lemma is essentially based on [6]. For completeness, we will give the proof.

LEMMA 2.1. *Let $\triangle P_1P_2P_3$ be the interior of a triangle which has three vertices $P_j \in \mathbb{R}^2$, $j = 1, 2, 3$. Assume that $f \in L^\mu(\triangle P_1P_2P_3)$ for some $\mu > 2$. If $v \in H^1(\triangle P_1P_2P_3)$ is the solution to a Dirichlet problem for the Laplace equation*

$$\begin{cases} \Delta v = f & \text{in} \quad \triangle P_1P_2P_3, \\ v = 0 & \text{on} \quad \overline{P_1P_2} \cup \overline{P_2P_3} \cup \overline{P_3P_1}, \end{cases} \tag{2.1}$$

then there exists a real number $p > 2$ such that

$$v \in W^{2,p}(\triangle P_1P_2P_3). \tag{2.2}$$

Proof. Let θ_1, θ_2, and θ_3 be the angles $\measuredangle P_3P_1P_2$, $\measuredangle P_1P_2P_3$, and $\measuredangle P_2P_3P_1$, respectively. Since $0 < \theta_j < \pi$ for any $j = 1, 2, 3$, we can take a real number $q_0 \in (1, 2)$ so that

$$\frac{2}{q_0} < \min\left\{\frac{\pi}{\theta_1}, \frac{\pi}{\theta_2}, \frac{\pi}{\theta_3}\right\}. \tag{2.3}$$

Let $p := \min\{\frac{q_0}{q_0 - 1}, \mu\}$. Clearly the number p is greater than 2. We claim that

$$v \in W^{2,p}(\triangle P_1P_2P_3). \tag{2.4}$$

Let $q := \frac{p}{p-1}$. Then by (2.3) we have

$$\frac{2}{q} = \frac{2(p-1)}{p} \le \frac{2}{q_0} < \min\left\{\frac{\pi}{\theta_1}, \frac{\pi}{\theta_2}, \frac{\pi}{\theta_3}\right\},$$

which implies that the number $\frac{2\theta_j}{q\pi}$ is not an integer for any $j = 1, 2, 3$. Since $p \le \mu$ and $f \in L^\mu(\triangle P_1P_2P_3)$, $f \in L^p(\triangle P_1P_2P_3)$. Therefore, it follows from Theorem 4.4.4.13 in [6] that there exist real numbers $c_{j,m}$ and a function w such that

$$w - \sum_{\substack{1 \le j \le 3 \\ -\frac{2}{q} < \lambda_{j,m} < 0 \\ \lambda_{j,m} \ne -1}} c_{j,m} S_{j,m} \in W^{2,p}(\triangle P_1P_2P_3)$$

and

$$\begin{cases} \Delta w = f & \text{in} \quad \triangle P_1P_2P_3, \\ w = 0 & \text{on} \quad \overline{P_1P_2} \cup \overline{P_2P_3} \cup \overline{P_3P_1}, \end{cases}$$

where m is a negative integer, $\lambda_{j,m} = \frac{m\pi}{\theta_j}$, and the functions $S_{j,m}$ are defined in equation $(4,4,3,7)$ in [6]. We note that $S_{j,m}$ does not necessarily belong to $W^{2,p}(\triangle P_1P_2P_3)$. The uniqueness of the Dirichlet problem yields

$$w = v.$$

Furthermore, our choice of constants p, q implies that there is no negative integer m such that

$$-\frac{2}{q} < \lambda_{j,m} = \frac{m\pi}{\theta_j} < 0.$$

Hence we can conclude that

$$v \in W^{2,p}(\triangle P_1P_2P_3). \qquad \square$$

Applying Lemma 2.1, we can show a proposition about the nonexistence of an H^2-solution to a Cauchy problem of the Laplace equation. This proposition plays the essential role in proving our theorems.

PROPOSITION 2.2. *Let $\triangle P_1P_2P_3$ be the interior of a triangle which has three vertices $P_j \in \mathbb{R}^2$, $j = 1, 2, 3$. Let $G \in W^{1,\infty}(\triangle P_1P_2P_3)$ be strictly positive in $\triangle P_1P_2P_3$. Then there exists no solution $y \in H^2(\triangle P_1P_2P_3)$ to*

$$\begin{cases} \Delta y = G & \text{in} \quad \triangle P_1P_2P_3, \\ y = |\nabla y| = 0 & \text{on} \quad \overline{P_1P_2} \cup \overline{P_1P_3}. \end{cases} \tag{2.5}$$

Proof. Let $\vec{a} = \overrightarrow{OP_2} - \overrightarrow{OP_1} := (a_1, a_2)$, $\vec{b} = \overrightarrow{OP_3} - \overrightarrow{OP_1} := (b_1, b_2)$, and $D = \triangle P_1P_2P_3$. We can take a rotation and a translation, if necessary, so that we may assume that the point P_1 is the origin O, $b_2 = 0$, and $a_2 > 0$. Let $\epsilon = \frac{1}{8}\text{dist}(O, \overline{P_2P_3})$, and for any real number $s > 0$ let us take a cut-off function χ_s satisfying $0 \le \chi_s \le 1$, $\chi_s \in C^\infty(\mathbb{R}^2)$, and

$$\chi_s(x) = \begin{cases} 1 & \text{if} \quad |x| < s\epsilon, \\ 0 & \text{if} \quad |x| > (s+1)\epsilon. \end{cases}$$

Suppose that $y \in H^2(D)$ satisfies (2.5). By $y \in H^2(D)$, the Sobolev imbedding theorem yields that for any $\ell \ge 2$

$$y\chi_6 \in W^{1,\ell}(D). \tag{2.6}$$

Since $y \in H^2(D)$ and $y = |\nabla y| = 0$ on $\overline{OP_2} \cup \overline{OP_3}$, the function $y\chi_4$ belongs to $H^1(D)$ and is the solution to

$$\begin{cases} \Delta(y\chi_4) = G\chi_4 + 2\nabla y \cdot \nabla\chi_4 + y(\Delta\chi_4) & \text{in} \quad D, \\ y\chi_4 = 0 & \text{on} \quad \partial D. \end{cases}$$

Relation (2.6) implies that $G\chi_4 + 2\nabla y \cdot \nabla\chi_4 + y(\Delta\chi_4) \in L^\ell(D)$ for any $\ell > 2$. It follows from Lemma 2.1 that there exists a real number $\mu > 2$ such that

$$y\chi_4 \in W^{2,\mu}(D), \tag{2.7}$$

and hence

$$y \in W^{2,\mu}(D \cap B(O, 4\epsilon)), \tag{2.8}$$

where $B(O, 4\epsilon) = \{z \in \mathbb{R}^2 \mid |z| < 4\epsilon\}$. Next from (2.8) we can see that $\partial_{x_j}(y\chi_2)$, $j = 1, 2$, belongs to $H^1(D)$ and is the solution to

$$\begin{cases} \Delta(\partial_{x_j}(y\chi_2)) = \partial_{x_j}[G\chi_2 + 2\nabla y \cdot \nabla\chi_2 + y(\Delta\chi_2)] & \text{in} \quad D, \\ \partial_{x_j}(y\chi_2) = 0 & \text{on} \quad \partial D. \end{cases}$$

Relation (2.8) implies that

$$\partial_{x_j}[G\chi_2 + 2\nabla y \cdot \nabla\chi_2 + y(\Delta\chi_2)] \in L^{\mu}(D).$$

Since $\mu > 2$, by Lemma 2.1, there exists a real number $p > 2$ such that

$$\partial_{x_j}(y\chi_2) \in W^{2,p}(D). \tag{2.9}$$

Therefore, we have

$$y \in W^{3,p}(D \cap B(O, 2\epsilon)). \tag{2.10}$$

The imbedding theorem (see, e.g., [1]) implies that

$$y \in C^2(\overline{D \cap B(O, \epsilon)}). \tag{2.11}$$

Then $y(b_1 t, 0) = \partial_{x_2} y(b_1 t, 0) = 0$ and $y(a_1 t, a_2 t) = 0$ for $0 \le t \le \delta$, where $\delta > 0$ is sufficiently small. Therefore,

$$(\partial_{x_1}\partial_{x_2} y)(b_1 t, 0) = (\partial_{x_1}^2 y)(b_1 t, 0) = 0$$

and

$$0 = \frac{d^2 y(a_1 t, a_2 t)}{dt^2} = a_1^2(\partial_{x_1}^2 y)(a_1 t, a_2 t) + 2a_1 a_2(\partial_{x_1}\partial_{x_2} y)(a_1 t, a_2 t) + a_2^2(\partial_{x_2}^2 y)(a_1 t, a_2 t)$$

for $0 \le t \le \delta$. Hence, by $y \in C^2(\overline{D \cap B(O, \epsilon)})$, we have

$$\partial_{x_1}^2 y(0, 0) = \partial_{x_2}^2 y(0, 0) = \partial_{x_1}\partial_{x_2} y(0, 0) = 0,$$

so that $\Delta y(0, 0) = G(0, 0) = 0$, which contradicts that $G > 0$ in D. □

REMARK 2.3. *In Proposition* 2.2, *it is essential that* $\overline{P_1P_2}$ *and* $\overline{P_1P_3}$ *intersect at* P_1 *transversally. In fact, if a curve joining* P_1, P_2 *and a curve joining* P_1, P_3 *intersect smoothly at* P_1, *there may exist a solution* $y \in H^2(D)$ *for some positive* $G \in H^1(D)$ *with* $\partial_{x_2} G \in L^{\infty}(D)$.

Example for existence for a smooth curve passing P_1, P_2, P_3. Let

$$D = \left\{(x_1, x_2) \middle| \, 0 \le x_1 < \frac{1}{2},\ 0 < x_2 < -\frac{1}{8}\left(x_1 - \frac{1}{2}\right)\right\}$$
$$\cup \left\{(x_1, x_2) \middle| \, -\frac{1}{2} < x_1 < 0,\ x_1^3 < x_2 < -\frac{1}{8}\left(x_1 - \frac{1}{2}\right)\right\}$$

and

$$y(x_1,x_2)=\begin{cases} x_2^2, & x_1\geq 0,\\ (x_1^3-x_2)^2, & x_1<0,\end{cases}$$

$$G(x_1,x_2)=\begin{cases} 2, & x_1\geq 0,\\ 2-12x_1x_2+30x_1^4, & x_1<0.\end{cases}$$

We regard $\{(x_1,0)|0\leq x_1<\frac{1}{2}\}\cup\{(x_1,x_1^3)|-\frac{1}{2}<x_1<0\}$ as the curve $P_2P_1P_3$. Then the two parts of the curve $P_2P_1P_3$ connect smoothly at $P_1\equiv O$. Moreover, we can directly verify that $y\in C^2(\overline{D})$, $G\in H^1(D)$ and $\partial_{x_2}G\in L^\infty(D)$, $y=|\nabla y|=0$ on the curve $P_2P_1P_3$ and $\Delta y=G>0$ in D.

3. Proof of Theorem 1.1. Let us define $y:=u_1-u_2$ in Ω. Then by (1.1) and (1.5), the function y satisfies

$$\Delta y=0 \quad \text{in} \quad \Omega\setminus(\overline{D_1\cup D_2}), \tag{3.1}$$

$$\Delta y=qu_1>0 \quad \text{in} \quad D_1\setminus\overline{D_2}, \tag{3.2}$$

$$\Delta y=-qu_2<0 \quad \text{in} \quad D_2\setminus\overline{D_1}, \tag{3.3}$$

$$\Delta y=qy \quad \text{in} \quad D_1\cap D_2, \tag{3.4}$$

$$y=|\nabla y|=0 \quad \text{on} \quad \partial\Omega. \tag{3.5}$$

Henceforth F is the component of $\Omega\setminus(\overline{D_1\cup D_2})$ which is connected with $\partial\Omega$. Since y is harmonic in $\Omega\setminus(\overline{D_1\cup D_2})$ and $y=\frac{\partial y}{\partial\nu}=0$ on $\partial\Omega$, the unique continuation (see, e.g., [10]) implies that

$$y\equiv 0 \quad \text{on} \quad \overline{F}. \tag{3.6}$$

Then we can see the following two facts:

If $D,E\subset\Omega$ are convex polygons and $D\neq E$, then there exists

a vertex O of D such that $O\in\Omega\setminus\overline{E}$

or a vertex O of E such that $O\in\Omega\setminus\overline{D}$. (3.7)

(3.8) If $D,E\subset\Omega$ are convex polygons, then $\Omega\setminus\overline{(D\cup E)}$ is connected.

Now we will complete the proof of Theorem 1.1. Assume contrarily that $\operatorname{co}(D_1)\neq\operatorname{co}(D_2)$. Then, by (3.7), there exists a vertex O of $\operatorname{co}(D_1)$ such that $O\in\Omega\setminus\overline{\operatorname{co}(D_2)}$ or a vertex O of $\operatorname{co}(D_2)$ such that $O\in\Omega\setminus\overline{\operatorname{co}(D_1)}$. Without loss of generality, we may assume the former case. Then, since $O\in\Omega\setminus\overline{\operatorname{co}(D_2)}$, we can take a sufficiently small triangle $\triangle OAB$ such that

$$\overline{OA}\cup\overline{OB}\subset\partial(\operatorname{co}(D_1)) \qquad \text{and} \qquad \triangle OAB\subset\operatorname{co}(D_1)\setminus\overline{\operatorname{co}(D_2)}.$$

By (3.8), we have

$$\overline{OA}\cup\overline{OB}\subset\Omega\setminus(\operatorname{co}(D_1)\cup\operatorname{co}(D_2))\subset\overline{F}. \tag{3.9}$$

Any vertex of $\mathrm{co}\,(D_1)$ is a convex vertex of D_1; that is, in a neighborhood of that vertex, D_1 is convex. Therefore O is a convex vertex of D_1. By $\mathrm{co}\,(D_1) \supset D_1$, we can take $\triangle OA'B'$ such that

$$\overline{OA'} \cup \overline{OB'} \subset \partial D_1 \qquad \text{and} \qquad \triangle OA'B' \subset \triangle OAB.$$

Hence it follows from $\triangle OAB \subset \mathrm{co}\,(D_1) \setminus \overline{\mathrm{co}\,(D_2)}$ that $\triangle OA'B' \subset \mathrm{co}\,(D_1) \setminus \overline{\mathrm{co}\,(D_2)}$. Moreover, by (3.9), we see that $\overline{OA'} \cup \overline{OB'}$ is included in $\overline{F}$. Therefore, by (3.2) and (3.6), we have $\Delta y = qu_1 > 0$ in $\triangle OA'B'$ and $y = |\nabla y| = 0$ on $\overline{OA'} \cup \overline{OB'}$. Again by (1.4), we see that $qu_1 \in H^1(\triangle OA'B')$ and $|\nabla(qu_1)|$ is bounded in $\overline{\triangle OA'B'}$, and so we apply Proposition 2.2, which yields a contradiction. Hence $\mathrm{co}\,(D_1) = \mathrm{co}\,(D_2)$ follows. Thus the proof of Theorem 1.1 is complete.

4. Proof of Theorem 1.3. Let E be the connected component of $D_1 \cap D_2$ such that $\overline{A_0B_0} \subset \partial E$. Since $\overline{A_0B_0} \subset \partial_{\mathrm{out}}(D_1 \cup D_2)$ and $\Delta y - qy = 0$ in E, the unique continuation implies that

$$y = 0 \quad \text{in } E. \tag{4.1}$$

We represent the boundary ∂D_j, $j = 1, 2$, by a continuous curve $\alpha_j : [0, 1] \to \partial D_j$ such that α_j is injective in $[0, 1)$, $\alpha_j(0) = A_0$, $\alpha_j(\frac{1}{2}) = B_0$, and $\alpha_j(1) = \alpha_j(0)$. Exchanging A_0 with B_0 if necessary, we may assume that the curves α_j are oriented in the positive direction; that is, the outward normal vector to ∂D_j and the oriented tangential vector of ∂D_j form a right-handed system at any point of ∂D_j.

Let

$$a = \inf\{t \in [0, 1] |\, \alpha_1(t) \neq \alpha_2(t)\}.$$

Then we note that $\alpha_1(t) = \alpha_2(t)$ if $0 \leq t \leq a$.

We will prove the theorem by reduction to absurdity. That is, assume that $D_1 \neq D_2$. Then, by $\alpha_1(1/2) = \alpha_2(1/2)$ and $\alpha_1(1) = \alpha_2(1)$, we can take a number $\frac{1}{2} \leq a < b \leq 1$ such that $\alpha_1(t) \neq \alpha_2(t)$ for $t \in (a, b)$ and $\alpha_1(b) = \alpha_2(b)$.

Since $\alpha_1(t) = \alpha_2(t)$ for $0 \leq t \leq a$ and $\alpha_1(t) \neq \alpha_2(t)$ for $t \in (a, b)$, the point $\alpha_1(a)$ is a vertex of D_1 or a vertex of D_2. Therefore we see that $\alpha_1(a, b)$ is outside $\overline{D_2}$ or $\alpha_2(a, b)$ is outside $\overline{D_1}$. Therefore either $\alpha_1[a, b]$ or $\alpha_2[a, b]$ is on $\partial_{\mathrm{out}}(D_1 \cup D_2)$.

In fact, let $\alpha_1(a, b)$ be outside $\overline{D_2}$. For any $x \in \alpha_1[a, b]$, there exists a continuous curve γ_1 connecting x and some $y \in \alpha_1[0, \frac{1}{2}]$ such that $\gamma_1 \setminus \{x, y\} \subset \Omega \setminus \overline{(D_1 \cup D_2)}$. Since $\alpha_1[0, \frac{1}{2}] \subset \partial_{\mathrm{out}}(D_1 \cup D_2)$, we can take a continuous curve γ_2 connecting y and some $x_0 \in \partial\Omega$ such that $\gamma_2 \setminus \{y\} \subset \Omega \setminus \overline{(D_1 \cup D_2)}$. Hence we can choose a continuous curve γ such that γ is sufficiently close to $\gamma_1 \cup \gamma_2$, $\gamma \subset \Omega \setminus \overline{(D_1 \cup D_2)}$, and γ connects x and x_0. Thus $\alpha_1[a, b] \subset \partial_{\mathrm{out}}(D_1 \cup D_2)$.

Without loss of generality, we may assume that

$$\alpha_1[a, b] \text{ is contained in } \partial_{\mathrm{out}}(D_1 \cup D_2). \tag{4.2}$$

Let $a < t_1^j < \cdots < t_{k_j}^j < b$, $j = 1, 2$, be a partition of $[a, b]$ such that $\alpha_j(t_1^j), \ldots, \alpha_j(t_{k_j}^j)$ are all the vertices of D_j on $\alpha_j(a, b)$.

We will claim that

$$\alpha_1(a) \text{ is a vertex of both } D_1 \text{ and } D_2. \tag{4.3}$$

In fact, since $\alpha_1(t) = \alpha_2(t)$ for $t \in [0, a]$ and $\alpha_1(t) \neq \alpha_2(t)$ for $t \in (a, b)$, the point $\alpha_1(a)$ cannot be simultaneously on an edge of D_1 and on an edge of D_2. Here and henceforth, by an edge, we mean that it does not contain any vertices.

Moreover, if $\alpha_1(a)$ is on an edge of one domain and is a vertex of the other, then, in terms of (4.2), we can take a triangle $\triangle\alpha_2(t_1^2)\alpha_1(a)\alpha_1(t_1^1)$, so that

$$\begin{cases} \overline{\alpha_1(a)\alpha_2(t_1^2)} \subset \partial E, \quad \overline{\alpha_1(a)\alpha_1(t_1^1)} \subset \partial_{\text{out}}(D_1 \cup D_2), \\ \text{and the interior of this triangle is contained in} \quad D_1 \setminus \overline{D_2}. \end{cases} \tag{4.4}$$

By (4.1) and (3.6), we apply Proposition 2.2 to be led to a contradiction. Thus we have proved (4.3).

We choose small $\varepsilon > 0$, so that $\alpha_1(t) = \alpha_2(t)$ is on an edge of D_j, $j = 1, 2$, for $t \in [a - \varepsilon, a]$. Furthermore we can take a suitable rotation, if necessary, so that $\alpha_1(t)$ is on the x_1-axis for $t \in [a - \varepsilon, a]$ and the x_1-component of $\alpha_1(a - \varepsilon)$ is smaller than the one of $\alpha_1(a)$. Then, by the orientation of α_1 and α_2, the domains D_1 and D_2 are located in the upper half plane $\mathbb{R}^2_+ := \{(x_1, x_2) | x_2 > 0\}$ locally near the edge $\overline{\alpha_1(a - \varepsilon)\alpha_1(a)}$.

Furthermore

$$\text{the edge } \overline{\alpha_1(a)\alpha_1(t_1^1)} \text{ lies in the lower half plane } \mathbb{R}^2_-$$

$$:= \{(x_1, x_2) | x_2 < 0\} \text{ and the edge } \overline{\alpha_1(a)\alpha_2(t_1^2)} \text{ in } \mathbb{R}^2_+. \tag{4.5}$$

In fact, assume contrarily. Then, by (4.3), we alternatively have two cases:

(i) $\overline{\alpha_1(a)\alpha_1(t_1^1)} \subset \mathbb{R}^2_+$, $\overline{\alpha_1(a)\alpha_2(t_1^2)} \subset \mathbb{R}^2_-$.

(ii) $\overline{\alpha_1(a)\alpha_1(t_1^1)} \cup \overline{\alpha_1(a)\alpha_2(t_1^2)} \subset \mathbb{R}^2_+$ or $\mathbb{R}^2_-$.

Case (i) is impossible, because the domains D_1 and D_2 are located in $\mathbb{R}^2_+$ locally near $\overline{\alpha_1(a - \varepsilon)\alpha_1(a)}$, and so, if (i) occurs, then $\overline{\alpha_1(a)\alpha_1(t_1^1)} \subset \partial_{\text{out}}(D_1 \cup D_2)$ does not hold. This contradicts (4.2). Case (ii) is impossible also. In fact, assume that case (ii) occurs. Then, by (4.2), we can take a triangle $\triangle\alpha_2(t_1^2)\alpha_1(a)\alpha_1(t_1^1)$ satisfying (4.4). This is again a contradiction of Proposition 2.2. Hence we have proved (4.5).

By (4.2), we have $\alpha_2[a, b] \subset \partial E$, so that Proposition 2.2 implies that

$$\alpha_1(t_i^1) \notin \text{CV}(D_1), \quad i = 1, \ldots, k_1, \tag{4.6}$$

and

$$\alpha_2(t_i^2) \in \text{CV}(E), \quad i = 1, \ldots, k_2. \tag{4.7}$$

Here $\text{CV}(D)$ denotes the set of all convex vertices of a polygon D.

We will prove (4.6) and (4.7). In fact, otherwise, there is a vertex $\alpha_1(t_{i_0}^1) \in CV(D_1)$ or $\alpha_2(t_{j_0}^2) \notin CV(E)$. First let $\alpha_1(t_{i_0}^1) \in CV(D_1)$ for some i_0. Then, by (4.2), we can take a triangle $\triangle P_1\alpha_1(t_{i_0}^1)Q_1 \subset D_1 \setminus \overline{D_2}$ such that $y = |\nabla y| = 0$ on the parts $\overline{P_1\alpha_1(t_{i_0}^1)}$ and $\overline{\alpha_1(t_{i_0}^1)Q_1}$ of the edges of D_1. This is a contradiction by Proposition 2.2. Therefore (4.6) must hold. Second let $\alpha_2(t_{j_0}^2) \notin CV(E)$ for some j_0. By (4.1), $y = |\nabla y| = 0$ on the parts $\overline{P_2\alpha_2(t_{j_0}^2)}$ and $\overline{\alpha_2(t_{j_0}^2)Q_2}$ of the edges of D_2. Moreover, by (4.2), we see that $\triangle P_2\alpha_2(t_{j_0}^2)Q_2 \subset D_1 \setminus \overline{D_2}$. This is a contradiction again by Proposition 2.2. Thus the proof of (4.7) is complete.

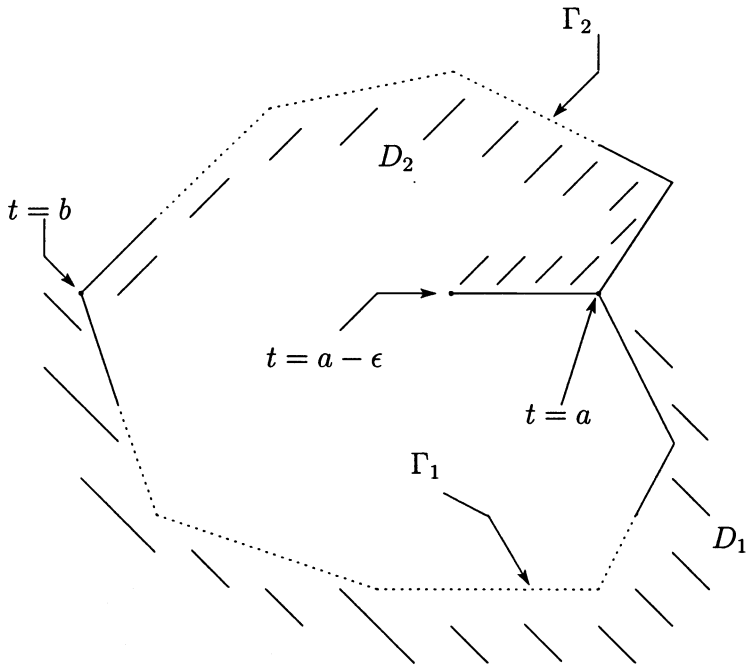

FIG. 3. *The figure for the proof of Theorem* 1.3.

Let us trace the curves $\Gamma_1 := \alpha_1[a-\varepsilon, b]$ and $\Gamma_2 := \alpha_2[a-\varepsilon, b]$. Both curves coincide from $t = a-\varepsilon$ to $t = a$. By (4.6) and (4.7), the former is oriented clockwise, while the latter is oriented counterclockwise. By $\alpha_1(b) = \alpha_2(b)$, the curves $(-\Gamma_1) \cup \Gamma_2 \setminus \alpha_1[a-\varepsilon, a]$ is a closed curve and surrounds a polygon $\widetilde{D}$. Here we regard $-\Gamma_1$ as a curve oriented from $\alpha_1(b)$ to $\alpha_1(a-\varepsilon)$. Moreover, the intersection of $\widetilde{D}$ and some neighborhood of Γ_2 is in D_2, while the intersection of $\Omega \setminus \overline{\widetilde{D}}$ and some neighborhood of $-\Gamma_1$ is in D_1 (Figure 3).

Therefore Γ_1 cannot be connected to $\partial\Omega$ by any continuous curve in $\partial_{\text{out}}(D_1 \cup D_2)$. In fact, for any $x \in \partial\Omega$ and $\widetilde{x} \in \Gamma_1$, let γ be an arbitrary continuous curve connecting x and $\widetilde{x}$. Then γ must intersect Γ_1 or Γ_2 transversally. If γ intersects Γ_1 transversally, then γ must pass in D_1. If γ intersects Γ_2 transversally, then γ must pass in D_2. Therefore $\gamma \not\subset \Omega \setminus \overline{(D_1 \cup D_2)}$. This contradicts (4.2). Thus, by reduction to absurdity, the proof of Theorem 1.3 is complete.

5. Proof of Theorem 1.4. Without loss of generality, we may assume that $\vec{b} = (1, 0)$. Since $a_2 \neq 0$ by the linear independence of $\vec{a}$ and $\vec{b}$, we can choose $a_2 = 1$. Let us set $\vec{\mu} = (1, -a_2)$. We set $x = (x_1, x_2) \in \mathbb{R}^2$, and

$$t_0 = \min\{x \cdot \vec{\mu} | x \in \overline{D_1}\} \quad \text{and} \quad s_0 = \min\{x \cdot \vec{\mu} | x \in \overline{D_2}\}. \tag{5.1}$$

Here and henceforth, $x \cdot \vec{\mu}$ denotes the scalar product of $x, \vec{\mu} \in \mathbb{R}^2$. Then

$$t_0 = s_0. \tag{5.2}$$

In fact, otherwise, we may assume that $t_0 < s_0$. Then

$$\{x \in D_1 | t_0 < x \cdot \vec{\mu} < s_0\} \subset \Omega \setminus \overline{D_2},$$

and there exists a vertex O of D_1 with $O \cdot \vec{\mu} = t_0$. Therefore, we can take a small triangle such that

$$\overline{OA} \cup \overline{OB} \subset \partial D_1 \quad \text{and} \quad \triangle OAB \subset \{x \in D_1 | t_0 < x \cdot \vec{\mu} < s_0\}.$$

We recall that F is the connected component of $\Omega \setminus \overline{(D_1 \cup D_2)}$ with $\partial\Omega$. Then we see that $\overline{OA} \cup \overline{OB} \subset \overline{F}$. Hence, by (3.6), we have $y = |\nabla y| = 0$ on $\overline{OA} \cup \overline{OB}$. In terms of (3.2), we apply Proposition 2.2, so that nonexistence of y is shown, which is a contradiction. Thus (5.2) has been proved.

Next for $j = 1, 2$, let $q_j = \sup\{x_2 | x = (x_1, x_2) \in \partial D_j \text{ and } x \cdot \vec{\mu} = t_0\}$ and let $P_j = (p_j, q_j)$ be the intersection point of $x_2 = q_j$ and $x \cdot \vec{\mu} = t_0$. If $q_1 \neq q_2$, then we may assume that $q_1 > q_2$. Then we can take a small triangle $\triangle P_1 Q R$ such that

$$\overline{P_1 Q} \cup \overline{P_1 R} \subset \partial D_1 \quad \text{and} \quad \triangle P_1 Q R \subset D_1 \setminus \overline{D_2}.$$

Then $\overline{P_1 Q} \cup \overline{P_1 R} \subset \overline{F}$, by (3.2) and (3.6), we apply Proposition 2.2, so that nonexistence of y is shown, which is a contradiction. Therefore,

$$q_1 = q_2. \tag{5.3}$$

Relations (5.2) and (5.3) imply that $\partial D_1 \cap \partial D_2 \cap \{x \mid x \cdot \vec{\mu} = t_0\}$ must contain a common line segment in $\partial_{\text{out}}(D_1 \cup D_2)$. By Theorem 1.3, we can conclude that $D_1 = D_2$.

Acknowledgments. The authors thank Professor Victor Isakov (Wichita State University) for helpful comments. Moreover, they are grateful to the referees for their invaluable comments. In particular, they highly appreciate the proposal by one referee for simplification of the proof of Proposition 2.2. In fact, the authors can simplify the proof, although their proof is slightly different from the proposal for the sake of more safety.

TRAVELING WAVES IN A SUSPENSION BRIDGE SYSTEM*

ZHONGHAI DING†

Abstract. In this paper, we study traveling waves in a suspension bridge system governed by the coupled nonlinear wave and beam equations describing oscillations in the supporting cable and roadbed. By applying the variational method, it is proved that the suspension bridge system has at least one nontrivial traveling wave.

Key words. suspension bridge system, traveling wave, mountain pass lemma

1. Introduction.

The suspension bridge is a common type of civil engineering structure. It is well known that suspension bridges may display certain oscillations under external aerodynamic forces. Under the action of a strong wind, for example, a narrow and very flexible suspension bridge can undergo dangerous oscillations [2]. Therefore, it is imperative to investigate dynamic oscillations in suspension bridges, especially the destructive large-amplitude oscillations, and to develop design techniques to prevent such destructive oscillations. In the last decade, Lazer and McKenna [13], [14] proposed new mathematical models describing oscillations in suspension bridges, which are based upon the observation of the fundamental nonlinearity in suspension bridges that the stays connecting the supporting cables and the roadbed resist expansion but do not resist compression. These new models are described by systems of coupled nonlinear partial differential equations.

The new study of suspension bridges initiated by Lazer and McKenna has obtained many important and interesting results. Multiple large-amplitude periodic oscillations have been found theoretically and numerically in the single Lazer–McKenna suspension bridge equation (see [3], [4], [10], [11], [12], [13], [14], [16], [17], and the references therein). Recently, we studied the Lazer–McKenna suspension bridge system governed by coupled nonlinear beam and wave equations and obtained multiple periodic nonlinear oscillations [6], [7], [8], [9] by applying the variational critical point theory.

In this paper, we are interested in traveling waves in suspension bridge systems. Consider a simplified suspension bridge configuration: the roadbed of length L is modeled by a horizontal vibrating beam with both ends being simply supported; the supporting cable of length L is modeled by a horizontal vibrating string with both ends being fixed; and the vertical stays connecting the roadbed to the supporting cable are modeled by one-sided springs which resist expansion but do not resist compression. Let $u(x,t)$ and $w(x,t)$ denote the downward deflections of the cable and the roadbed, respectively. The following suspension bridge model was proposed by Lazer

*Received by the editors August 6, 2002; accepted for publication (in revised form) January 15, 2003; published electronically June 25, 2003. Part of this work was completed during the author's sabbatical leave (Fall, 2002).

and McKenna [13]:

$$\text{(1.1)}\qquad \begin{cases} m_c u_{tt} - Q u_{xx} - K(w-u)^+ = m_c g + f_1(x,t), \quad 0 < x < L, \\ m_b w_{tt} + EI w_{xxxx} + K(w-u)^+ = m_b g + f_2(x,t), \quad 0 < x < L, \\ u(0,t) = u(L,t) = 0, \\ w(0,t) = w(L,t) = 0, \quad w_{xx}(0,t) = w_{xx}(L,t) = 0, \end{cases}$$

where $(w-u)^+ = \max\{w-u,\ 0\}$; m_c and m_b are the mass densities of the cable and the roadbed, respectively; Q is the coefficient of cable tensile strength; EI is the roadbed flexural rigidity; K is Hooke's constant of the stays; and f_1 and f_2 represent the external aerodynamic forces. If L is sufficiently large and $f_1 = f_2 = 0$, then (1.1) can be replaced approximately by the following model:

$$\text{(1.2)}\qquad \begin{cases} m_c u_{tt} - Q u_{xx} - K(w-u)^+ = m_c g, \quad x \in R,\ t \in R, \\ m_b w_{tt} + EI w_{xxxx} + K(w-u)^+ = m_b g, \quad x \in R,\ t \in R. \end{cases}$$

By letting $u = 0$, the second equation in (1.2) is the single Lazer–McKenna suspension bridge equation. The traveling waves in the single Lazer–McKenna suspension bridge equation were studied by McKenna and Walter [17] and Chen and McKenna [4] numerically and analytically. However, there has been little discussion of traveling waves in suspension bridge systems such as system (1.2). By applying the variational method and the mountain pass lemma, we show in this paper that (1.2) admits at least one nontrivial traveling wave.

The organization of this paper is as follows. In section 2, we formulate an equivalent system of (1.2). In section 3, we formulate the corresponding variational problem and follow the same idea presented in [4] by Chen and McKenna to prove that the system (1.2) admits at least one nontrivial traveling wave.

2. An equivalent system of (1.2). In order to investigate traveling waves in the suspension bridge system (1.2), we assume $u(x,t) = u_e(x) + y(x-ct)$ and $w(x,t) = w_e(x) + z(x-ct)$, where c is the wave speed and (u_e, w_e) are given by

$$\begin{cases} u_e(x) = -\dfrac{(m_c+m_b)g}{2Q} x^2, \\ w_e(x) = -\dfrac{(m_c+m_b)g}{2Q} x^2 + \dfrac{m_b g}{K}, \end{cases}$$

which satisfy the steady state equations of (1.2),

$$\begin{cases} -Q u_{xx} - K(w-u)^+ = m_c g, & x \in R, \\ EI w_{xxxx} + K(w-u)^+ = m_b g, & x \in R. \end{cases}$$

Thus $(y(s), z(s))$, where $s = x - ct$, satisfies

$$\text{(2.1)}\qquad \begin{cases} (c^2 m_c - Q) y'' - K\left[\left(z - y + \dfrac{m_b g}{K}\right)^+ - \dfrac{m_b g}{K}\right] = 0, & s \in R, \\ \\ c^2 m_b z'' + EI z^{(4)} + K\left[\left(z - y + \dfrac{m_b g}{K}\right)^+ - \dfrac{m_b g}{K}\right] = 0, & s \in R. \end{cases}$$

Let $H^r(R)$ denote the usual Sobolev space on R of order r. We are interested in those solutions (y,z) of (2.1) such that $(y,z) \in H^2(R) \times H^4(R)$.

Assume

$$0 < c^2 < \frac{Q}{m_c + m_b}. \tag{2.2}$$

By adding the two equations in (2.1) together and by integrating the resulting equation twice, we obtain

$$y = \frac{1}{Q - c^2 m_c}\left[EIz'' + c^2 m_b z\right] \stackrel{def}{=} L_1 z. \tag{2.3}$$

Thus L_1 is a bounded linear operator from $H^{r+2}(R)$ to $H^r(R)$. By substituting (2.3) into the second equation of (2.1), we obtain

$$c^2 m_b z'' + EIz^{(4)} + K\left[\left(\frac{1}{Q-c^2 m_c}\left(-EIz'' + (Q - c^2(m_c + m_b))z\right) + \frac{m_b g}{K}\right)^+ - \frac{m_b g}{K}\right] = 0. \tag{2.4}$$

Define operators L_2 and L_3 by

$$L_2 z = \frac{1}{Q - c^2 m_c}\left[-EIz'' + (Q - c^2(m_c + m_b))z\right],$$

$$L_3 z = EIz^{(4)} + c^2 m_b z''.$$

Thus L_2 is a bounded linear operator from $H^{r+2}(R)$ to $H^r(R)$, and L_3 is a bounded linear operator from $H^{r+4}(R)$ to $H^r(R)$. Then (2.4) can be written as

$$L_3 z + K\left[\left(L_2 z + \frac{m_b g}{K}\right)^+ - \frac{m_b g}{K}\right] = 0. \tag{2.5}$$

Under condition (2.2), one can verify easily that L_2 is invertible from $H^r(R)$ to $H^{r+2}(R)$. Let $\widetilde{z} = L_2 z$; then (2.5) can be written as

$$L_3 L_2^{-1}\widetilde{z} + K\left[\left(\widetilde{z} + \frac{m_b g}{K}\right)^+ - \frac{m_b g}{K}\right] = 0. \tag{2.6}$$

Define

$$\mathcal{A}\widetilde{z} = L_3 L_2^{-1}\widetilde{z}.$$

Then $\mathcal{A}$ is a bounded linear operator from $H^{r+2}(R)$ to $H^r(R)$. Let $v = \frac{K}{m_b g}\widetilde{z}$. Then (2.6) becomes

$$\mathcal{A}v + K[(v+1)^+ - 1] = 0. \tag{2.7}$$

Therefore we have the following theorem.

THEOREM 2.1. *Let condition* (2.2) *be satisfied. If* (2.7) *admits a nontrivial solution* $v \in H^2(R)$*, then the suspension bridge system* (2.1) *admits a nontrivial solution* $(y,\ z) \in H^2(R) \times H^4(R)$*. The relations between* (y, z) *and* v *are given by*

$$y = \frac{m_b g}{K} L_1 L_2^{-1} v, \qquad z = \frac{m_b g}{K} L_2^{-1} v.$$

Thus studying the existence of traveling waves in (1.2) becomes a matter of proving the existence of nontrivial solutions of (2.7).

3. Nonlinear traveling waves. To study nontrivial solutions of (2.7), we define a functional $I(v) : H^1(R) \longrightarrow R$ by

$$I(v) = \frac{1}{2}\int_R \mathcal{A}v \cdot v ds + \frac{K}{2}\int_R [((v+1)^+)^2 - 1] ds - K\int_R v ds. \tag{3.1}$$

$I(v)$ can also be rewritten as

$$I(v) = \frac{1}{2}\int_R \mathcal{A}v \cdot v ds + \frac{K}{2}\int_{v>-1} v^2 ds - K\int_{v\le -1}\left(v + \frac{1}{2}\right) ds.$$

It is easy to show the following lemma.

LEMMA 3.1. *Assume condition* (2.2) *is satisfied. Then* $I(v)$ *is continuously Fréchet differentiable with*

$$I'(v)\varphi = \int_R \mathcal{A}v \cdot \varphi ds + K\int_{v>-1} v\varphi ds - K\int_{v\le -1}\varphi ds$$

for any $v,\ \varphi \in H^1(R)$. *Consequently, the solutions of* (2.7) *in* $H^1(R)$ *correspond to critical points of* $I(v)$ *in* $H^1(R)$.

For any $v \in H^1(R)$, let $\|v\|_{H^1}$ denote the usual H^1-norm given by

$$\|v\|_{H^1}^2 = \int_R \left(|v'|^2 + |v|^2\right) ds.$$

For any $v \in H^1(R)$, define

$$\|v\|_*^2 = \int_R \mathcal{A}v \cdot v ds + K\int_R |v|^2 ds. \tag{3.2}$$

Assume throughout this paper that

$$\begin{cases} \dfrac{m_b}{m_c} < \dfrac{\sqrt{KEI}}{Q - \sqrt{KEI}} & \text{if } \ 0 < K < \dfrac{Q^2}{EI}; \\ \text{no condition on } m_b \text{ and } m_c & \text{if } \ K \ge \dfrac{Q^2}{EI}. \end{cases} \tag{3.3}$$

Under condition (3.3), one can verify easily

$$\max\left\{0,\ \frac{Q - \sqrt{KEI}}{m_c}\right\} < \frac{Q}{m_c + m_b}.$$

Assume throughout this paper that

$$\max\left\{0,\ \frac{Q - \sqrt{KEI}}{m_c}\right\} < c^2 < \frac{Q}{m_c + m_b}, \tag{3.4}$$

which is exactly condition (2.2) if $K \ge Q^2/EI$ and is stronger than condition (2.2) if $0 < K < Q^2/EI$. We have the following useful lemma.

LEMMA 3.2. *Assume conditions* (3.3) *and* (3.4) *are satisfied. Then*

$$C_1\|v\|_{H^1}^2 \le \|v\|_*^2 \le C_2\|v\|_{H^1}^2 \qquad \forall v \in H^1(R),$$

where

$$C_1 = \min\left\{Q - c^2 m_c,\ K - \frac{(Q - c^2 m_c)^2}{EI}\right\} > 0 \quad \textit{and} \quad C_2 = \max\left\{K,\ Q - c^2 m_c\right\} > 0.$$

Proof. For any $v \in H^1(R)$, denote by $\widehat{v}$ the Fourier transform of v, which is defined by

$$\widehat{v}(\xi) = \mathcal{F}(v)(\xi) = \frac{1}{\sqrt{2\pi}} \int_R e^{-i\xi s} v(s) ds.$$

By Plancherel's theorem, we have

$$\|v\|_{H^1}^2 = \int_R \left(1 + \xi^2\right) |\widehat{v}(\xi)|^2 d\xi.$$

Note that

$$\begin{aligned} \|v\|_*^2 &= \int_R \mathcal{A}v \cdot v ds + K \int_R v^2 ds \\ &= \int_R \widehat{v}(\xi) \overline{\widehat{\mathcal{A}v}(\xi)} d\xi + K \int_R |\widehat{v}(\xi)|^2 d\xi \\ &= \int_R (H(\xi) + K) |\widehat{v}(\xi)|^2 d\xi, \end{aligned}$$

where

$$H(\xi) = \frac{(Q - c^2 m_c)(EI\xi^4 - c^2 m_b \xi^2)}{EI\xi^2 + Q - c^2(m_c + m_b)}. \tag{3.5}$$

Under condition (3.4), we have

$$H(\xi) + K \le (Q - c^2 m_c)\xi^2 + K \le C_2(1 + \xi^2),$$

where $C_2 = \max\left\{K,\ Q - c^2 m_c\right\} > 0$. Note that

$$\begin{aligned} H(\xi) + K &= (Q - c^2 m_c)\xi^2 - (Q - c^2 m_c)^2 \frac{\xi^2}{EI\xi^2 + Q - c^2(m_c + m_b)} + K \\ &\ge (Q - c^2 m_c)\xi^2 - \frac{(Q - c^2 m_c)^2}{EI} + K. \end{aligned}$$

Under conditions (3.3) and (3.4), we have $K - \dfrac{(Q - c^2 m_c)^2}{EI} > 0$. Let

$$C_1 = \min\left\{Q - c^2 m_c,\ K - \frac{(Q - c^2 m_c)^2}{EI}\right\} > 0;$$

then

$$H(\xi) + K \ge C_1(\xi^2 + 1).$$

Thus upon applying Plancherel's theorem, we have

$$C_1 \|v\|_{H^1}^2 \le \|v\|_*^2 \le C_2 \|v\|_{H^1}^2 \qquad \forall v \in H^1(R). \qquad \square$$

LEMMA 3.3. *For any* $v \in H^1(R)$,

$$\|v\|_\infty \le \sqrt{2}\|v\|_{H^1},$$

where $\|v\|_\infty = \sup_{s\in R}|v(s)|$.

The proof of this lemma can be found in [4, Lemma 2.3].

To prove the existence of nontrivial critical points of $I(v)$ in $H^1(R)$, we use the mountain pass lemma and the concentration-compactness principle of P. L. Lions [18].

THEOREM 3.4 (mountain pass lemma [15]). *Let* X *be a real Banach space,* $B_\rho = \{v \in X \,|\, \|v\|_X < \rho\}$, *and* $\partial B_\rho = \{v \in E \,|\, \|v\|_X = \rho\}$. *Assume that* $J \in C^1(X, R)$ *satisfies the following conditions:*

(a) *for some* $v_0 \in X$, *there are constants* ρ, $\alpha > 0$ *such that* $J|_{v_0+\partial B_\rho} \ge J(v_0)+\alpha$;

(b) *there is an* $e \in X\backslash\overline{v_0 + B_\rho}$ *such that* $J(e) \le J(v_0)$.

Then there exists a sequence $\{v_n\}$ *in* X *such that* $J(v_n) \to \beta$ *and* $J'(v_n) \to 0$ *as* $n \to \infty$, *where* β *can be characterized by*

$$\beta = \inf_{\gamma\in\Gamma}\max_{v\in\gamma([0,1])} J(v),$$

where $\Gamma = \{\gamma \in C([0,1], X) \mid \gamma(0) = v_0,\ \gamma(1) = e\}$.

We are going to show that the functional $I(v)$ given by (3.1) satisfies the ingredients in the mountain pass lemma. Note that $I(0) = 0$ and $I \in C^1(H^1(R), R)$ by Lemma 3.1.

LEMMA 3.5. *Assume conditions* (3.3) *and* (3.4) *are satisfied. Then there exist constants* ρ, $\alpha > 0$ *such that*

$$I(v) \ge \alpha \qquad \forall v \in \partial B_\rho,$$

where $B_\rho = \{v \in H^1(R) \,|\, \|v\|_{H^1} < \rho\}$.

Proof. By Lemma 3.3, $\|v\|_\infty \le \sqrt{2}\|v\|_{H^1}$ for any $v \in H^1(R)$.

Let $\rho = \frac{\sqrt{2}}{2}$. Thus for any $v \in B_\rho$, $\|v\|_\infty < 1$; hence $v(s)+1 > 0$ on R. Therefore, by Lemma 3.2,

$$\begin{aligned} I(v) &= \frac{1}{2}\int_R \mathcal{A}v\cdot v ds + \frac{K}{2}\int_R [(v+1)^2 - 1]ds - K\int_R v ds \\ &= \frac{1}{2}\left[\int_R \mathcal{A}v\cdot v ds + K\int_R v^2 ds\right] = \frac{1}{2}\|v\|_*^2 \ge \frac{C_1}{2}\|v\|_{H^1}^2. \end{aligned}$$

Thus 0 is a local minimum of $I(v)$ in $H^1(R)$. Let $\alpha = \frac{\sqrt{2}C_1}{4}$. Then

$$I(v) \ge \alpha \qquad \forall v \in \partial B_\rho. \qquad \square$$

LEMMA 3.6. *Assume conditions* (3.3) *and* (3.4) *are satisfied. Then there exists an* $e \in H^1(R)$ *such that* $I(e) \le I(0) = 0$.

Proof. Let $\varphi \in H^1(R)$ be given such that $\varphi \le 0$ on R and

$$\overline{\text{supp}(\varphi)} = \overline{\{s \in R \mid \varphi(s) \ne 0\}}$$

is compact. Note that

$$\int_R \xi^2|\widehat{\varphi}(\xi)|^2 d\xi \le \int_R (1+\xi^2)|\widehat{\varphi}(\xi)|^2 d\xi = \|\varphi\|_{H^1}^2.$$

Let ε be a given very small positive number; then there exists an $M > 0$ such that

$$\int_{|\xi|\geq M} \xi^2 |\widehat{\varphi}(\xi)|^2 d\xi \leq \varepsilon$$

and

$$\int_R \xi^2 |\widehat{\varphi}(\xi)|^2 d\xi - \varepsilon \leq \int_{|\xi|<M} \xi^2 |\widehat{\varphi}(\xi)|^2 d\xi \leq \int_R \xi^2 |\widehat{\varphi}(\xi)|^2 d\xi + \varepsilon.$$

Let $\psi_\lambda(s) = \varphi(\lambda s)$ for some $\lambda > 0$.

Then

$$\int_R \mathcal{A}\psi_\lambda \cdot \psi_\lambda ds = \int_R \widehat{\psi}_\lambda(\xi) \overline{\widehat{\mathcal{A}\psi}_\lambda(\xi)} d\xi = \frac{1}{\lambda} \int_R H(\lambda\xi) |\widehat{\varphi}(\xi)|^2 d\xi,$$

where $H(\xi)$ is defined by (3.5). Thus

$$\begin{aligned}
&\int_R \mathcal{A}\psi_\lambda \cdot \psi_\lambda ds \\
&= \lambda(Q - c^2 m_c) \int_R \left(1 - \frac{Q - c^2 m_c}{EI\lambda^2\xi^2 + Q - c^2(m_c + m_b)}\right) \xi^2 |\widehat{\varphi}(\xi)|^2 d\xi \\
&\leq \lambda(Q - c^2 m_c) \left[\varepsilon + \int_{|\xi|<M} \left(1 - \frac{Q - c^2 m_c}{EI\lambda^2\xi^2 + Q - c^2(m_c + m_b)}\right) \xi^2 |\widehat{\varphi}(\xi)|^2 d\xi\right] \\
&\leq \lambda(Q - c^2 m_c) \left[\varepsilon + \int_{|\xi|<M} \left(1 - \frac{Q - c^2 m_c}{EI\lambda^2 M^2 + Q - c^2(m_c + m_b)}\right) \xi^2 |\widehat{\varphi}(\xi)|^2 d\xi\right] \\
&= \lambda(Q - c^2 m_c) \left[\varepsilon - \frac{c^2 m_b - EI\lambda^2 M^2}{EI\lambda^2 M^2 + Q - c^2(m_c + m_b)} \int_{|\xi|<M} \xi^2 |\widehat{\varphi}(\xi)|^2 d\xi\right].
\end{aligned}$$

Under conditions (3.3) and (3.4), we can choose λ to be a very small positive number such that

$$\int_R \mathcal{A}\psi_\lambda \cdot \psi_\lambda ds \leq \lambda(Q - c^2 m_c) \left[\varepsilon - \frac{c^2 m_c - EI\lambda^2 M^2}{EI\lambda^2 M^2 + Q - c^2(m_c + m_b)} \left(\int_R \xi^2 |\widehat{\varphi}(\xi)|^2 d\xi - \varepsilon\right)\right] < 0.$$

Let $\psi_0(s) = \psi_{\lambda_0}(s)$ for some $\lambda_0 > 0$ such that

$$\int_R \mathcal{A}\psi_{\lambda_0} \cdot \psi_{\lambda_0} ds = -\delta < 0. \tag{3.6}$$

Then, for any $B > 0$,

$$\begin{aligned}
\frac{1}{B} I(B\psi_0) = \frac{B}{2} \int_R \mathcal{A}\psi_0 \cdot \psi_0 ds + \frac{KB}{2} \int_{0>\psi_0>-1/B} \psi_0^2 ds \\
- K \int_{\psi_0 \leq -1/B} \left(\psi_0 + \frac{1}{2B}\right) ds.
\end{aligned} \tag{3.7}$$

Since φ has a compact support, $\psi_0(s) = \varphi(\lambda_0 s)$ also has a compact support. Let $\mu = |\operatorname{supp}(\psi_0)| < \infty$. Then we have

$$0 \leq \lim_{B\to\infty} \frac{KB}{2} \int_{0>\psi_0>-1/B} \psi_0^2 ds \leq \lim_{B\to\infty} \frac{K\mu}{2B} = 0 \tag{3.8}$$

and

$$0 \le \lim_{B\to\infty} \int_{\psi_0 \le -1/B} \frac{1}{2B} ds \le \lim_{B\to\infty} \frac{\mu}{2B} = 0. \tag{3.9}$$

By Lemma 3.3, we have

$$0 \le \lim_{B\to\infty} \int_{\psi_0 \le -1/B} |\psi_0| ds \le \|\psi_0\|_\infty \mu \le \sqrt{2}\|\psi_0\|_{H^1}\mu < \infty. \tag{3.10}$$

Thus it follows from (3.6)–(3.10) that

$$\lim_{B\to\infty} \frac{1}{B} I(B\psi_0) \le -\lim_{B\to\infty} \frac{B\delta}{2} + \sqrt{2}\|\psi_0\|_{H^1}\mu = -\infty.$$

Therefore, there exists a $B_0 > 0$ such that $I(B_0\psi_0) < 0$. Then we can choose $e = B_0\psi_0 \in H^1(R)$, which satisfies $I(e) < 0$. □

By Lemmas 3.1, 3.5, and 3.6, $I(v)$ satisfies conditions in the mountain pass lemma. Thus, by applying the mountain pass lemma, we have the following lemma.

LEMMA 3.7. *Assume conditions* (3.3) *and* (3.4) *are satisfied. Then there exists a sequence* $\{v_n\}$ *in* $H^1(R)$ *such that* $I(v_n) \to \beta$ *and* $I'(v_n) \to 0$ *as* $n \to \infty$, *where* β *can be characterized by*

$$\beta = \inf_{\gamma\in\Gamma} \max_{v\in\gamma([0,1])} I(v),$$

where $\Gamma = \{\gamma \in C([0,1], H^1(R)) \mid \gamma(0) = 0,\ \gamma(1) = e\}$.

Note that $0 < \alpha < \beta < \infty$ and, if $v \in H^1(R)$ is a solution of (2.7), then any translation of $v(s)$ is also a solution of (2.7). Thus the sequence $\{v_n\}$ given in Lemma 3.7 does not necessarily have a convergent subsequence. By using the concentration-compactness principle of P. L. Lions [18], we show that $I(v)$ has a nontrivial critical point in $H^1(R)$.

LEMMA 3.8. *Assume conditions* (3.3) *and* (3.4) *are satisfied. Then the sequence* $\{v_n\}$ *defined in Lemma* 3.7 *is bounded in* $H^1(R)$.

Proof. Suppose $\{v_n\}$ is unbounded in $H^1(R)$. Then $\{v_n\}$ has a subsequence, denoted also by $\{v_n\}$, such that $\|v_n\|_* \to \infty$ as $n \to \infty$. Since $I(v_n) \to \beta < \infty$ and $I'(v_n) \to 0$, we have $\frac{I(v_n)}{\|v\|_*} \to 0$ and $\frac{I'(v_n)v_n}{\|v_n\|_*} \to 0$. By Lemmas 3.2 and 3.3, we have $\|v_n\|_\infty \le \sqrt{2/C_1}\|v_n\|_*$. By Lemma 3.1, we have

$$2I(v_n) = \|v_n\|_*^2 + K\int_{v_n\le -1} (-v_n^2 - 2v_n - 1)ds$$

and

$$I'(v_n)v_n = \|v_n\|_*^2 + K\int_{v_n\le -1} (-v_n^2 - v_n)ds.$$

Thus

$$\begin{aligned}
0 &= \lim_{n\to\infty} \frac{I'(v_n)v_n}{\|v_n\|_*^2} \\
&= 1 + K \lim_{n\to\infty} \int_{v_n\le -1} \frac{-v_n^2 - v_n}{\|v_n\|_*^2} ds \\
&= 1 - K \lim_{n\to\infty} \int_{v_n\le -1} \frac{|v_n|(|v_n|-1)}{\|v_n\|_*^2} ds \\
&\ge 1 - K \lim_{n\to\infty} \frac{\|v_n\|_\infty}{\|v_n\|_*} \int_{v_n\le -1} \frac{|v_n|-1}{\|v_n\|_*} ds \\
&\ge 1 - K \frac{\sqrt{2}}{\sqrt{C_1}} \lim_{n\to\infty} \int_{v_n\le -1} \frac{|v_n|-1}{\|v_n\|_*} ds \\
&= 1 - \frac{\sqrt{2}}{\sqrt{C_1}} \lim_{n\to\infty} \frac{2I(v_n) - I'(v_n)v_n}{\|v_n\|_*} \\
&= 1,
\end{aligned}$$

which is a contradiction. Therefore $\{v_n\}$ is bounded. □

LEMMA 3.9. *Assume conditions* (3.3) *and* (3.4) *are satisfied. Then there is a* $\tilde{v} \in H^1(R)$, $\tilde{v} \neq 0$, *such that* $I'(\tilde{v}) = 0$.

Proof. By Lemma 3.8, $\{v_n\}$ defined in Lemma 3.7 is bounded. Let $M > 0$ such that $\|v_n\|_* \le M$ for any n. Note that

$$2\beta = \lim_{n\to\infty} (2I(v_n) - I'(v_n)v_n) = \lim_{n\to\infty} \int_{v_n\le -1} (-v_n - 1) ds$$

and

$$\int_{v_n\le -1} (-v_n - 1) ds \le \int_{v_n\le -1} |v_n|^3 ds \le \int_R |v_n|^3 ds \le \|v_n\|_\infty \|v_n\|_{H^1}^2.$$

Thus there exists $n_0 > 0$ such that, for $n \ge n_0$, we have

$$0 < \beta < \|v_n\|_\infty \|v_n\|_{H^1}^2 \le \frac{1}{C_1} \|v_n\|_\infty \|v_n\|_*^2 \le \frac{M^2}{C_1} \|v_n\|_\infty.$$

Thus

$$\|v_n\|_\infty = \sup_{s\in R} |v_n(s)| \ge \frac{C_1\beta}{M^2} = C_0 > 0 \qquad \forall n \ge n_0.$$

Let $n \ge n_0$. For each $v_n \in H^1(R)$, let $s_n \in R$ such that $v_n(s_n) = \|v_n\|_\infty$. Let $\tilde{v}_n(s) = v_n(s_n + s)$. Then $\{\tilde{v}_n\} \subset H^1(R)$ is bounded and $\{\tilde{v}_n\}$ has a weakly convergent subsequence which converges to $\tilde{v} \in H^1(R)$ [18]. Since $\tilde{v}_n(0) \ge C_0$, we have $\tilde{v}(0) \ge C_0$. Thus $\tilde{v} \neq 0$. Note that $I(\tilde{v}_n) \to \beta$ and $I'(\tilde{v}_n) \to 0$ as $n \to \infty$. We will show $I'(\tilde{v}) = 0$.

For any $\varphi \in H^1(R)$, by Lemma 3.2 and the definition of weak convergence, we have

$$\lim_{n\to\infty} \int_R (\mathcal{A}\tilde{v}_n \cdot \varphi + K\tilde{v}_n\varphi)\, ds = \int_R (\mathcal{A}\tilde{v} \cdot \varphi + K\tilde{v}\varphi)\, ds. \tag{3.11}$$

For any given $\varepsilon > 0$, we can choose a compact set $K \subset R$ such that

$$\|\varphi\|_{L^2(R\setminus K)} < \frac{\varepsilon}{2N_1},$$

where N_1 is a constant such that $\|\tilde{v}_n\|_2 + \|\tilde{v}\|_2 \le N$ for any n. Then

$$\begin{aligned}
&\left| \int_{R\setminus K} \left[(\tilde{v}_n + 1)^- - (\tilde{v} + 1)^- \right] \varphi ds \right| \\
&\le \int_{R\setminus K} \left| (\tilde{v}_n + 1)^- - (\tilde{v} + 1)^- \right| |\varphi| ds \\
&\le \int_{R\setminus K} |\tilde{v}_n - \tilde{v}| \, |\varphi| ds \\
&\le \|\tilde{v}_n - \tilde{v}\|_{L^2(R\setminus K)} \|\varphi\|_{L^2(R\setminus K)} \\
&\le \frac{\varepsilon}{2}.
\end{aligned}$$

By the Sobolev imbedding theorem [1], the weak convergence of $\{\tilde{v}_n\}$ in $H^1(R)$ implies the uniform convergence of $\{\tilde{v}_n\}$ in $C(K)$. Thus there exists an $n_1 > 0$ such that for any $n \ge n_1$,

$$\sup_{s\in K} |\tilde{v}_n(s) - \tilde{v}(s)| < \frac{\varepsilon}{2N_2},$$

where N_2 is a constant such that $\displaystyle\int_K |\varphi| ds \le N_2$. Thus

$$\begin{aligned}
&\left| \int_K \left[(\tilde{v}_n + 1)^- - (\tilde{v} + 1)^- \right] \varphi ds \right| \\
&\le \int_K \left| (\tilde{v}_n + 1)^- - (\tilde{v} + 1)^- \right| |\varphi| ds \\
&\le \int_K |\tilde{v}_n - \tilde{v}| \, |\varphi| ds \\
&\le \frac{\varepsilon}{2}.
\end{aligned}$$

Therefore for any $\varphi \in H^1(R)$

$$\lim_{n\to\infty} \int_R (\tilde{v}_n + 1)^- \varphi ds = \int_R (\tilde{v} + 1)^- \varphi ds. \tag{3.12}$$

By Lemma 3.1, (3.11), and (3.12), we have

$$0 = \lim_{n\to\infty} I'(\tilde{v}_n)\varphi = I'(\tilde{v})\varphi \qquad \forall \varphi \in H^1(R).$$

Thus $\tilde{v}$ is a nontrivial critical point of $I(v)$ on $H^1(R)$. □

By Lemmas 3.1 and 3.9, we have the following theorem.

THEOREM 3.10. *Let conditions* (3.3) *and* (3.4) *be satisfied. Then* (2.7) *admits at least one nontrivial solution in* $H^1(R)$.

By Theorems 2.1 and 3.10, and by using the bootstrapping technique, we obtain the main theorem in this paper.

THEOREM 3.11. *Let conditions* (3.3) *and* (3.4) *be satisfied. Then* (2.1) *admits at least one nontrivial solution* $(y, z) \in H^2(R) \times H^4(R)$. *Consequently, the suspension bridge system* (1.2) *admits at least one nontrivial traveling wave.*

It should be pointed out that Lemmas 3.5–3.7 may shed light on computing solutions of (2.7) by using the numerical mountain pass algorithm [5]. This algorithm has been applied successfully to the single Lazer–McKenna suspension bridge equation (the second equation of (1.2) with $u = 0$) to obtain traveling waves numerically [4]. Due to the facts that $\mathcal{A}$ is a pseudodifferential operator and that the domain is the real line R, the implementation of the numerical mountain pass algorithm to $I(v)$ defined by (3.1) is not trivial. Since the finite difference method or the finite element method cannot be used directly to handle the pseudodifferential operator $\mathcal{A}$, some different approximation methods would be needed to overcome this difficulty. By devising a wavelet-type approximation method, we are able to implement the numerical mountain pass algorithm to $I(v)$ and obtain numerically some traveling waves in the suspension bridge system (1.2). The detailed description and numerical examples will be reported in a separate paper.

Acknowledgment. The author thanks the University of Nevada Las Vegas for its support.

THE CALDERON PROBLEM FOR TWO-DIMENSIONAL MANIFOLDS BY THE BC-METHOD*

M. I. BELISHEV†

Dedicated to the jubilee of O. A. Ladyzhenskaya

Abstract. As was shown by Lassas and Uhlmann [*Ann. Sci. École Norm. Sup.* (4), 34 (2001), pp. 771–787], the smooth two-dimensional compact orientable Riemann manifold with the boundary is uniquely determined by its Dirichlet-to-Neumann map (DN-map) up to conformal equivalence. We give a new proof of this fact based on relations between the Calderon problem and function algebras: the manifold is identified with the spectrum of the algebra of holomorphic functions determined by the DN-map up to isometry; as such, the manifold is recovered from the DN-map by the use of the Gelfand transform. A simple formula linking the DN-map to the Euler characteristic of the manifold is derived.

Key words. Riemann manifolds, Dirichlet-to-Neumann map, reconstruction problem, function algebras, BC-method

Introduction.

0.1. General statement. Let (Ω, g) be a smooth[1] n-dimensional Riemann manifold with the boundary Γ; let g be the metric tensor; and let Δ_g be the Beltrami–Laplace operator. Consider the Dirichlet problem

$$\Delta_g u = 0 \quad \text{in } \operatorname{int}\Omega, \tag{0.1}$$

$$u = f \quad \text{on } \Gamma; \tag{0.2}$$

let $u = u^f(x)$ be the solution for a smooth f. With the problem (0.1), (0.2) one associates the Dirichlet-to-Neumann map (DN-map) $\Lambda_g : f \to \frac{\partial u^f}{\partial \nu}|_\Gamma$ (ν is the outward normal).

Assume that the boundary Γ is given and the operator $\Lambda_g : C^\infty(\Gamma) \mapsto C^\infty(\Gamma)$ is known; the *Calderon problem* is to recover (Ω, g). In another formulation, one needs to construct a manifold with a prescribed DN-map.

0.2. The case of $n = 2$. The results. The well-known peculiarity of the 2-dimensional case is the following. If g' and g'' are two metrics on Ω such that $g'' = \rho g'$ with a positive function ρ (i.e., g'' is a conformal deformation of g'), then the DN-maps of the manifolds (Ω, g') and (Ω, g'') are connected through the relation $\Lambda_{g''} = \frac{1}{\sqrt{\rho}}\Lambda_{g'}$, whereas the additional condition $\rho|_\Gamma = 1$ implies $\Lambda_{g''} = \Lambda_{g'}$. This motivates the following definition.

[1]Everywhere in the paper "smooth" means C^∞-smooth.

Let (Ω', g') and (Ω'', g'') be two smooth manifolds with the common boundary $\partial\Omega' = \partial\Omega'' = \Gamma$; we call them *conformally equivalent* if there exist a diffeomorphism $\beta : \Omega' \mapsto \Omega'', \quad \beta(\Omega') = \Omega'', \quad \beta|_\Gamma = \mathrm{id}$ and a positive function $\rho \in C^\infty(\Omega'), \quad \rho|_\Gamma = 1$ such that β is an isometry of $(\Omega', \rho g')$ onto (Ω'', g'').

The conformal equivalence of manifolds implies the coincidence of their DN-maps. The remarkable fact is that the converse is also true.

THEOREM 1. *Two 2-dimensional compact orientable manifolds with the common boundary are conformally equivalent iff their DN-maps coincide.*

In other words, in dimension 2 the class of conformally equivalent manifolds is determined by its DN-map. This fact was first established by Lassas and Uhlmann in [7] by means of a technique based on the analytic continuation.

This paper is a corrected and extended version of the preprint [3]. Our results are the following:

- we show a relationship between the Calderon problem and function algebras and give a new proof of Theorem 1 exploiting this relationship;
- a simple formula (see (1.6)) linking the DN-map to the Euler characteristic of the manifold is derived.

The paper is addressed to the specialists in inverse problems. Perhaps it is of some interest as an application of the commutative Banach algebras.

0.3. A bit of philosophy. Setting the goal to construct the manifold with a prescribed DN-map, one encounters the naive question: What type of "material" can it be constructed from?

A traditional situation in the boundary value inverse problems is the following: a domain $\Omega \subset \mathbf{R}^n$ *is given* whereas a function $c(x)$ on Ω (density, conductivity, etc.) has to be found through inverse data. Thus, we possess an initial reserve of points Ω, can mark an $x_0 \in \Omega$, and then discuss a possibility to determine $c(x_0)$.

Another situation occurs in the Calderon problem for manifolds: Ω is unknown in itself and has to be recovered, so that the question of "material" turns out to be a fundamental one. In similar dynamic inverse problem this role is played by a subset of the space-time cylinder $\Gamma \times [0, T]$ (the so-called pattern; see [1]). In [7] the manifold is constructed as a Riemann surface (set of germs) of a real analytic function found by the classical procedure of analytic continuation along paths from the boundary.

We propose to identify Ω to the spectrum (the set of multiplicative functionals or, the same, the space of maximal ideals) of some function algebra determined by inverse data. Roughly speaking, the "material" proposed is the set of the Dirac measures $\{\delta_{x_0} \,|\, x_0 \in \Omega\}$. As we show, it is the set which may be recovered through the DN-map.

0.4. The plan. The following basic facts are in use:

(i) (Ω, g) has the complex structure of a Riemann surface; this structure determines the class of metrics conformally equivalent to g;

(ii) the algebra $\mathcal{A}(\Omega)$ of functions continuous in Ω and holomorphic in $\operatorname{int}\Omega$ is nontrivial; functions $w \in \mathcal{A}(\Omega)$ (as local homeomorphisms $\Omega \mapsto \mathbf{C}$) determine the complex structure;

(iii) algebra $\mathcal{A}(\Omega)$ is generic: its (topologized) spectrum is homeomorphic to the manifold, $\operatorname{sp}\mathcal{A}(\Omega) \asymp \Omega$, whereas the algebra itself is identical to its Gelfand transform, $\hat{\mathcal{A}}(\Omega) \equiv \mathcal{A}(\Omega)$;

(iv) the algebra of traces $\mathcal{A}(\Gamma) := \{w|_\Gamma \,|\, w \in \mathcal{A}(\Omega)\}$ is isometrically isomorphic to $\mathcal{A}(\Omega)$ (through the map $\mathrm{tr} : w \mapsto w|_\Gamma$); the isometry yields $\operatorname{sp}\mathcal{A}(\Gamma) \asymp \operatorname{sp}\mathcal{A}(\Omega)$, $\hat{\mathcal{A}}(\Gamma) \equiv \hat{\mathcal{A}}(\Omega)$ that leads to $\operatorname{sp}\mathcal{A}(\Gamma) \asymp \Omega$ and $\hat{\mathcal{A}}(\Gamma) \equiv \mathcal{A}(\Omega)$;

(v) the algebra $\mathcal{A}(\Gamma)$ is determined by the DN-map Λ_g.

To solve the Calderon problem we use these facts in reverse order:

(α) from the operator Λ_g one recovers the trace algebra $\mathcal{A}(\Gamma)$;

(β) finding its spectrum and Gelfand transform we get $\Omega \asymp \operatorname{sp}\mathcal{A}(\Gamma)$ and $\mathcal{A}(\Omega) \equiv \hat{\mathcal{A}}(\Gamma)$;

(γ) using functions of algebra $\mathcal{A}(\Omega)$ we endow Ω with the complex structure;

(δ) introducing a metric g on Ω conformal to the complex structure we get the manifold (Ω, g) whose DN-map coincides with Λ_g by construction.

The procedure (α)$-$(δ) gives a canonical representative of the class of conformally equivalent manifolds which has the given DN-map. The assertion of Theorem 1 is a simple corollary of determinacy of this procedure.

0.5. A little more philosophy. Let us explain why we look at our approach as a variant of the BC-method. In dynamic problems the BC-method

(i) constructs a model (isometric copy) of the initial system through inverse data;

(ii) proposes a mechanism (the amplitude formulas of geometric optics) recovering the initial system through the model.

(See [1], [2].) The same is done in this paper: DN-map determines trace algebra $\mathcal{A}(\Gamma)$, which is a model of algebra $\mathcal{A}(\Omega)$; the Gelfand transform recovers $\mathcal{A}(\Omega)$ (together with manifold Ω). Moreover, there are some reasons to believe that the mechanism based on geometric optics formulas is in fact a kind of the Gelfand transform.

1. Harmonic functions and fields.

1.1. Harmonic functions. So, we have a 2-dimensional smooth orientable compact (Ω, g) with the boundary Γ. Just for simplicity we assume that Γ is homeomorphic to the circle (consists of one connected component).

Let $\operatorname{Harm}_g\Omega := \{u \,|\, \Delta_g\, u = 0 \quad \text{in } \operatorname{int}\Omega\}$ be the set of functions harmonic in Ω; in local coordinates one has

$$\frac{\partial}{\partial x^i}\det{}^{\frac{1}{2}} g(x)\, g^{ij}(x)\frac{\partial u(x)}{\partial x^j} = 0. \tag{1.1}$$

Solutions of the problem (0.1), (0.2) are said to be *potentials*; the family of potentials $\mathcal{U} := \{u^f \,|\, f \in C^\infty(\Gamma)\}$ coincides with $\operatorname{Harm}_g\Omega \bigcap C^\infty(\Omega)$.

1.2. Rotation operator. Introduce near Γ the semigeodesic coordinates γ, τ such that $ds^2 = Ed\gamma^2 + d\tau^2$ and $E|_\Gamma = 1$, so that γ is the natural parameter on Γ and $\tau(x) = \operatorname{dist}(x, \Gamma)$. The field $\frac{\partial}{\partial\gamma}$ fixes an orientation of Γ and an orientation of Ω; note that $\frac{\partial}{\partial\tau} = -\frac{\partial}{\partial\nu}$.

The orientation determines the continuous family of rotations $\Phi(x) \in \operatorname{End} T_x\Omega$ such that $\langle\Phi(x)\, a, \Phi(x)\, b\rangle = \langle a, b\rangle$, $\langle\Phi(x)\, a, a\rangle = 0$ for $a, b \in T_x\Omega$ and $\Phi(\gamma)\frac{\partial}{\partial\nu} = \frac{\partial}{\partial\gamma}$ on Γ. Note that $\Phi^2(x) = -\mathrm{id}$, $x \in \Omega$.

Let $\vec{\mathcal{L}}$ be the (real) space of the square integrable vector fields on (Ω, g) with the inner product $(a, b) = \int_\Omega d\Omega_x\, \langle a(x), b(x)\rangle$. The *rotation operator* $\Phi : \vec{\mathcal{L}} \mapsto \vec{\mathcal{L}}$, $(\Phi y)(x) := \Phi(x)y(x)$, $x \in \Omega$, is a unitary operator in $\vec{\mathcal{L}}$.

1.3. Harmonic fields. Let $\vec{\mathcal{H}} := \{h \in \vec{\mathcal{L}} \,|\, \operatorname{div} h = \operatorname{div}\Phi h = 0 \quad \text{in } \operatorname{int}\Omega\}$ be the (sub)space of *harmonic fields*. Harmonic fields are smooth in $\operatorname{int}\Omega$; the set $\vec{\mathcal{H}}^\infty := \vec{\mathcal{H}} \bigcap \vec{C}^\infty(\Omega)$ is dense in $\vec{\mathcal{H}}$.

The space $\vec{\mathcal{H}}$ contains the subspace of *potential fields* $\vec{\mathcal{E}} := \{\nabla u \in \vec{\mathcal{H}} \,|\, u \in \mathrm{Harm}_g\,\Omega \bigcap H^1(\Omega)\}$ ($H^1(\Omega)$ is the Sobolev class). The set $\vec{\mathcal{E}}^\infty := \vec{\mathcal{E}} \bigcap \vec{C}^\infty(\Omega) = \nabla\mathcal{U}$ is dense in $\vec{\mathcal{E}}$.

Recall in addition that every $h \in \vec{\mathcal{H}}$ is locally potential: for any $x_0 \in \Omega$ there exist a neighborhood U_{x_0} and a function $v \in \mathrm{Harm}_g\,U_{x_0}$ such that $h = \nabla v$ in U_{x_0}.

In what follows we denote by the common symbol "tr" the reduction of fields and functions given in Ω on the boundary Γ. The important fact is that the harmonic field is determined by its trace: $h \in \vec{\mathcal{H}}$ and $\mathrm{tr}\,h = 0$ implies $h = 0$ in Ω. Indeed, fixing an $x_0 \in \Gamma$, in U_{x_0} we have $h = \nabla v$ that leads to $\Delta_g v = 0$ and $\mathrm{tr}\,\nabla v = 0$, yielding $v = \mathrm{const}$ and $h = 0$ in U_{x_0} due to the uniqueness of the solution to the Cauchy problem for the second order elliptic equation. Covering the manifold with neighborhoods and applying the same uniqueness theorem, one easily obtains $h = 0$ everywhere in Ω.

Introduce the subspace $\vec{\mathcal{D}} := \vec{\mathcal{H}} \ominus \vec{\mathcal{E}}$ and list some of its known properties (see, e.g., [10]). This subspace has a finite dimension determined by topology of Ω:

$$\dim\vec{\mathcal{D}} \;=\; \dim\vec{\mathcal{H}}/\vec{\mathcal{E}} \;=\; \beta_1(\Omega) \;=\; 1-\chi(\Omega), \tag{1.2}$$

where β_1 is the first Betti number (dimension of the first homology group of the manifold) and χ is its Euler characteristic. Elements of the subspace are smooth: $\vec{\mathcal{D}} \subset \vec{C}^\infty(\Omega)$. The fields $b \in \vec{\mathcal{D}}$ are tangent on Γ; indeed, for any $f \in C^\infty(\Gamma)$ we have

$$0 = \int_\Omega d\Omega\,\langle \nabla u^f, b\rangle = \int_\Gamma d\gamma\, f\,\left\langle b, \frac{\partial}{\partial\nu}\right\rangle,$$

yielding $\langle b, \frac{\partial}{\partial\nu}\rangle = 0$ or, equivalently, $\mathrm{tr}\,b = \kappa\frac{\partial}{\partial\gamma}$ with a smooth $\kappa = \langle b, \frac{\partial}{\partial\gamma}\rangle$.

1.4. Topology from DN-map. Let $\dot{C}^\infty(\Gamma) := \{f \in C^\infty(\Gamma) \,|\, \int_\Gamma d\gamma\, f(\gamma) = 0\}$ be the subset of smooth functions with zero mean value. For $f \in \dot{C}^\infty(\Gamma)$ we denote by Jf the primitive function with zero mean value: $Jf \in \dot{C}^\infty(\Gamma)$, $\frac{d}{d\gamma}Jf = f$.

Recall the well-known properties of the DN-map: $\mathrm{Ker}\,\Lambda_g = \{\mathrm{const}\}$, $\mathrm{Ran}\,\Lambda_g \subset \dot{C}^\infty(\Gamma)$. Note also that by standard elliptic theory the operator $\Lambda_g J : L_2(\Gamma) \mapsto L_2(\Gamma)$, $\mathrm{Dom}\,\Lambda_g J = \dot{C}^\infty(\Gamma)$ is continuous.

Fix $f \in C^\infty(\Gamma)$; in accordance with the decomposition $\vec{\mathcal{H}} = \vec{\mathcal{E}} \oplus \vec{\mathcal{D}}$ the field $\Phi\nabla u^f \in \vec{\mathcal{H}}$ may be represented in the form

$$\Phi\nabla u^f = \nabla u^p + b^f \tag{1.3}$$

with $\nabla u^p \in \vec{\mathcal{E}}^\infty$ (p being determined by f) and $b^f \in \vec{\mathcal{D}}$; let $\mathrm{tr}\,b^f = \kappa^f\frac{\partial}{\partial\gamma}$.

LEMMA 1. (i) *The equality*

$$[\mathbf{1} + (\mathbf{\Lambda_g J})^\mathbf{2}]\frac{\mathbf{df}}{\mathbf{d}\gamma} = \mathbf{\Lambda_g J}\kappa^\mathbf{f} \tag{1.4}$$

holds.

(ii) *The inclusion $\Phi\nabla u^f \in \vec{\mathcal{E}}^\infty$ is equivalent to the relation*

$$[\mathbf{1} + (\mathbf{\Lambda_g J})^\mathbf{2}]\frac{\mathbf{df}}{\mathbf{d}\gamma} = \mathbf{0}. \tag{1.5}$$

(iii) *The equality*

$$\dim\,[\mathbf{1} + (\mathbf{\Lambda_g J})^\mathbf{2}]\,\dot{\mathbf{C}}^\infty(\mathbf{\Gamma}) = \mathbf{1} - \chi(\mathbf{\Omega}) \tag{1.6}$$

is valid.

Proof. (i) The traces of the left- and right-hand sides of (1.3) may be written as follows:

$$\operatorname{tr}\Phi\nabla u^f = \Phi\operatorname{tr}\nabla u^f = \Phi\left[\frac{df}{d\gamma}\frac{\partial}{\partial\gamma} + \Lambda_g f\frac{\partial}{\partial\nu}\right]$$

$$= \frac{df}{d\gamma}\Phi\frac{\partial}{\partial\gamma} + \Lambda_g f\,\Phi\frac{\partial}{\partial\nu} = \Lambda_g f\,\frac{\partial}{\partial\gamma} - \frac{df}{d\gamma}\frac{\partial}{\partial\nu} \tag{1.7}$$

and

$$\operatorname{tr}\left[\nabla u^p + b^f\right] = \left(\frac{dp}{d\gamma} + \kappa^f\right)\,\frac{\partial}{\partial\gamma} + \Lambda_g p\,\frac{\partial}{\partial\nu}. \tag{1.8}$$

Using (1.7) and (1.8) we get

$$\Lambda_g f = \frac{dp}{d\gamma} + \kappa^f, \qquad -\frac{df}{d\gamma} = \Lambda_g J\,\frac{dp}{d\gamma}$$

(note that the first equality yields $\kappa^f \in \dot{C}^\infty(\Gamma)$). Eliminating $\frac{dp}{d\gamma}$ one easily gets (1.4).

(ii) In accordance with (1.3) the inclusion $\Phi\nabla u^f \in \vec{\mathcal{E}}^\infty$ is equivalent to $b^f = 0$, which is equivalent to $\kappa^f = 0$ leading to (1.5).

(iii) Let P be the (orthogonal) projection in $\vec{\mathcal{H}}$ onto $\vec{\mathcal{D}}$; we will show that

$$P\Phi\vec{\mathcal{E}}^\infty = \vec{\mathcal{D}}. \tag{1.9}$$

Indeed, if $b \in \vec{\mathcal{D}},\ b \perp P\Phi\vec{\mathcal{E}}^\infty$, then for any smooth f one has

$$0 = \int_\Omega d\Omega\,\langle\Phi\nabla u^f, b\rangle = \int_\Omega d\Omega\,\langle\nabla u^f, \Phi^* b\rangle$$

$$= \int_\Gamma d\gamma\,u^f\,\left\langle\frac{\partial}{\partial\nu}, \Phi^* b\right\rangle = \int_\Gamma d\gamma\,f\,\left\langle\Phi\frac{\partial}{\partial\nu}, b\right\rangle = \int_\Gamma d\gamma\,f\,\left\langle\frac{\partial}{\partial\gamma}, b\right\rangle.$$

This leads to $\langle\frac{\partial}{\partial\gamma}, b\rangle = 0$, then $\operatorname{tr} b = \langle b, \frac{\partial}{\partial\gamma}\rangle\frac{\partial}{\partial\gamma} = 0$ (recall that b's are tangent to Γ), and, finally, to $b = 0$. Thus, the set $P\Phi\vec{\mathcal{E}}^\infty$ is dense in $\vec{\mathcal{D}}$, which implies (1.9) in view of $\dim\vec{\mathcal{D}} < \infty$.

Let f in (1.3) run over $C^\infty(\Gamma)$; due to (1.9) the corresponding projections b^f cover $\vec{\mathcal{D}}$. Since the map $b^f \mapsto \kappa^f$ is injective, one has $\dim\{\kappa^f \mid f \in C^\infty(\Gamma)\} = \dim\vec{\mathcal{D}}$. As is easy to see, the operator $\Lambda_g J$ is injective on $\dot{C}^\infty(\Gamma)$; therefore

$$\dim\vec{\mathcal{D}} = \dim\{\kappa^f \mid f \in C^\infty(\Gamma)\} = \dim\{\Lambda_g J\kappa^f \mid f \in C^\infty(\Gamma)\}.$$

Taking into account (1.2), the last equality, and (1.4) we get

$$1 - \chi(\Omega) = \dim\vec{\mathcal{D}} = \dim\left[\mathbf{1} + (\mathbf{\Lambda_g J})^{\mathbf{2}}\right]\frac{\mathbf{d}}{\mathbf{d}\boldsymbol{\gamma}}\mathbf{C}^\infty(\boldsymbol{\Gamma}),$$

which is equivalent to (1.6). The lemma is proved.

In the situation of the Calderon problem, Lemma 1 may be exploited as follows. Assume that Ω is a fortiori known to be homeomorphic to the sphere with handles and one removed disk. In this case $\chi(\Omega) = 1 - 2m$, where m is the number of handles, and one can find m by the formula

$$m = \frac{1}{2} \dim \left[\mathbf{1} + (\mathbf{\Lambda_g J})^{\mathbf{2}}\right] \dot{\mathbf{C}}^{\infty}(\mathbf{\Gamma}).$$

In particular, Ω is homeomorphic to the disk (so that $m = 0$) iff $(\Lambda_g J)^2 = -\mathbf{1}$ on $\dot{C}^{\infty}(\Gamma)$.

Given the DN-map and checking (1.5) one can select a subset of f's in $C^{\infty}(\Gamma)$ such that the "conjugate" fields $\Phi \nabla u^f$ are also potential. Later we'll use this opportunity.

2. Algebras.

2.1. CBA dictionary. We begin with minimal information concerning the commutative Banach algebras (CBAs); for details, see [6], [9].

A. The CBA is a (complex or real) Banach space $\mathcal{A}$ equipped with the multiplication operation ab satisfying $ab = ba$; $||ab|| \leq ||a||\,||b||$, $a, b \in \mathcal{A}$. Example: the algebra $C(X)$ of functions continuous on a (topological) compact X with the norm $||a|| = \max_{\Omega} |a(\cdot)|$; the subalgebras of $C(X)$ are called *function algebras*.

CBA is said to be *uniform* if it has the unit $e : ea = a$ and the relation $||a^2|| = ||a||^2$ holds. All the function algebras are uniform.

B. A subspace $I \neq \mathcal{A}$ is called *ideal* if $ja \in I$ for any $j \in I$, $a \in \mathcal{A}$. Ideal I is *maximal* if for any ideal $\tilde{I} \subset \mathcal{A}$ the relation $I \subset \tilde{I}$ implies $I = \tilde{I}$.

Let $\mathcal{I}$ be the set of maximal ideals of algebra $\mathcal{A}$. Every $I \in \mathcal{I}$ is closed; $\operatorname{codim} I = 1$; the quotient space $\mathcal{A}/I$ is isometrically isomorphic to the field of complex numbers $\mathbf{C}$.

C. Let $\mathcal{A}'$ be the space of continuous functionals on $\mathcal{A}$. A functional $\delta \in \mathcal{A}'$ is called *multiplicative* if $\delta(ab) = \delta(a)\delta(b)$. Example: the Dirac measure $\delta_{x_0} \in C'(X)$: $\delta_{x_0}(a) = a(x_0)$. The set of multiplicative functionals is denoted by $\mathcal{M}$.

D. There exists a canonical bijection between the sets $\mathcal{M}$ and $\mathcal{I}$: if $\delta \in \mathcal{M}$, then $I_\delta := \operatorname{Ker} \delta \in \mathcal{I}$; if $I \in \mathcal{I}$, then the projection $\delta_I : \mathcal{A} \mapsto \mathcal{A}/I = \mathbf{C}$ is an element of $\mathcal{M}$. In what follows we identify $\mathcal{M}$ to $\mathcal{I}$ through this bijection.

E. The *Gelfand transform* maps element $a \in \mathcal{A}$ into function $\hat{a}$ on $\mathcal{M}$ by the rule $\hat{a}(\delta) := \delta(a)$, $\delta \in \mathcal{M}$. The *Gelfand topology* is defined as the weakest topology on $\mathcal{M}$ in which all of $\hat{a}$ are continuous. The set $\mathcal{M}$ equipped with this topology is a compact; this compact is called the *spectrum* (or the maximal ideal space) of the algebra $\mathcal{A}$ and denoted by $\operatorname{sp} \mathcal{A}$.

The Gelfand transform $\hat{\mathcal{A}} := \{\hat{a} \,|\, a \in \mathcal{A}\}$ of algebra $\mathcal{A}$ is a subalgebra of the algebra $C(\operatorname{sp} \mathcal{A})$. If $\mathcal{A}$ is uniform, the map $a \mapsto \hat{a}$ turns out to be an isometric isomorphism (on its image): $(\alpha a + \beta b + cd)^{\wedge} = \alpha\hat{a} + \beta\hat{b} + \hat{c}\hat{d}$, $||\hat{a}|| = ||a||$ for all $\alpha, \beta \in \mathbf{C}$ and $a, b, c, d, \in \mathcal{A}$; in this case $\hat{\mathcal{A}}$ is a canonical realization of $\mathcal{A}$ in the form of function algebra.

F. An isomorphism $t : A(X) \mapsto B(Y)$ of two function algebras is called *spatial* if there exists a bijection $\beta : X \mapsto Y$ such that $tw = w \circ \beta^{-1}$. For a function algebra $\mathcal{A} \subset C(X)$, to each point $x_0 \in X$ one associates the Dirac measure $\delta_{x_0} \in \operatorname{sp} \mathcal{A}$, and because of this the natural embedding $\varepsilon : X \mapsto \operatorname{sp} \mathcal{A}$, $\varepsilon(x_0) = \delta_{x_0}$ occurs.

A function algebra $\mathcal{A} \subset C(X)$ is said to be *generic* if ε is a homeomorphism from X onto $\operatorname{sp} \mathcal{A}$. Generic algebra is spatially isomorphic to its Gelfand transform $\hat{\mathcal{A}}$: $\hat{w} = w \circ \varepsilon^{-1}$.

2.2. Algebra $\mathcal{A}(\Omega)$. The functions $u, u^* \in \mathrm{Harm}_g\,\Omega$ are said to be *conjugate* if they satisfy the Cauchy–Riemann conditions $\nabla u^*(x) = \Phi(x)\nabla u(x)$, $x \in \mathrm{int}\,\Omega$. Note the relation $(u^*)^* = -u$ (mod const). If Ω is homeomorphic to the disk, each harmonic u possesses the conjugate u^*; it is not the case if topology of Ω is non-trivial [5].

We assign a harmonic u to the set $\mathcal{P}$ if it has the conjugate u^* and $u, u^* \in \mathrm{Harm}_g\,\Omega \bigcap C(\Omega)$.

Let us define the family of complex functions $\mathcal{A}(\Omega) := \{w = u + iu^* \,|\, u \in \mathcal{P}\}$ and mention some of its properties [5]:

(i) in proper (isothermal) local coordinates x^1, x^2 each $w \in \mathcal{A}(\Omega)$ is a holomorphic function of $z = x^1 + ix^2$; functions of $\mathcal{A}(\Omega)$, as local homeomorphisms from Ω into $\mathbf{C}$, determine on Ω a complex structure of the Riemann surface;

(ii) for each $w \in \mathcal{A}(\Omega)$ $|w|$ attains maximum on Γ;

(iii) $\mathcal{A}(\Omega)$ is a closed subalgebra of the (complex) algebra $C(\Omega)$;

LEMMA 2. *The algebra $\mathcal{A}(\Omega)$ is generic.*

Proof. (1) The embedding $\varepsilon(\Omega) \subset \mathrm{sp}\,\mathcal{A}(\Omega)$ is a general fact (see section 2.1, item F) and one needs to prove the converse embedding only.

(2) Choose an $I \in \mathrm{sp}\,\mathcal{A}(\Omega)$; we are going to show that there exists a point $x_I \in \Omega$ such that $j(x_I) = 0$ for all $j \in I$. Assume the opposite: for any $x \in \Omega$ one can find $j_x \in I$ such that $j_x(x) \neq 0$. Due to continuity of j_x there exists a neighborhood $U_x \ni x$ such that j_x doesn't vanish in U_x. Since $\bigcup_x U_x$ covers Ω, we can select a finite subcovering $U_{x_1}, \ldots, U_{x_p}$; in this case the corresponding $j_{x_1}, \ldots, j_{x_p}$ have no common zeros in Ω.

(3) Due to smoothness of the boundary Γ the manifold (Ω, g) may be embedded into a larger manifold $(\Omega', g') : \Omega \subset \Omega', \mathrm{dist}_{g'}(\partial\Omega', \Omega) = r_0 > 0, g'|_\Omega = g$. One way to realize such an embedding is to use the semigeodesic coordinates, extending E on $\tau < 0$.

Denote $\Omega_r := \{x \in \Omega' \,|\, \mathrm{dist}_{g'}(x, \Omega) < r\}$, $0 < r < r_0$. Assign a function $w \in \mathcal{A}(\Omega)$ to the family $\mathcal{O}(\Omega)$ if it has a holomorphic continuation in Ω_r (with r depending on w). The family $\mathcal{O}(\Omega)$ is dense in $\mathcal{A}(\Omega)$ (see [4, p. 48, Corollary 2]).

(4) Since $\mathrm{codim}\, I = 1$, the set $I \bigcap \mathcal{O}(\Omega)$ is dense in I. Due to this one can approximate $j_{x_1}, \ldots, j_{x_p}$ by functions $\tilde{j}_{x_1}, \ldots, \tilde{j}_{x_p} \in I \bigcap \mathcal{O}(\Omega)$ so that $\tilde{j}_{x_k} \neq 0$ in U_{x_k} and $\tilde{j}_{x_1}, \ldots, \tilde{j}_{x_p}$ have no common zeros in Ω.

Since the set $\{\tilde{j}_{x_k}\}$ is finite, there exists $\Omega_r \supset \Omega$ such that $\tilde{j}_{x_1}, \ldots, \tilde{j}_{x_p}$ are defined and have no common zeros in Ω_r. Considering Ω_r as a noncompact Riemann surface one can find functions $g_1, \ldots, g_p$ holomorphic in Ω_r and satisfying the condition $g_1\tilde{j}_{x_1} + \cdots + g_p\tilde{j}_{x_p} = 1$ everywhere in Ω_r (see [5, p. 205]). Reducing functions on Ω we get $\tilde{g}_1\tilde{j}_{x_1} + \cdots + \tilde{g}_p\tilde{j}_{x_p} = 1$ in Ω for $\tilde{g}_k := g_k|_\Omega \in \mathcal{A}(\Omega)$ and $\tilde{j}_{x_k} \in I$, which yields the inclusion $1 \in I$. The last leads evidently to $I = \mathcal{A}(\Omega)$, which contradicts I to be a proper ideal.

Thus, all the functions belonging to I vanish in a point $x_I \in \Omega$ and the embedding $\varepsilon(\Omega) \supset \mathrm{sp}\,\mathcal{A}(\Omega)$ is established. So, $\varepsilon(\Omega) = \mathrm{sp}\,\mathcal{A}(\Omega)$, and it remains to show that ε is a homeomorphism.

(5) Identifying maximal ideals of $\mathcal{A}(\Omega)$ to multiplicative functionals we set $I_{x_0} \equiv \delta_{x_0}$, where δ_{x_0} is the Dirac measure. In terms of the bijection $\varepsilon : \Omega \mapsto \mathrm{sp}\,\mathcal{A}(\Omega)$, existence of which has been proved above, the Gelfand transform takes the form $\hat{w}(\delta) := \delta(w) = w(x_\delta) = (w \circ \varepsilon^{-1})(\delta)$ (i.e., is a spatial isomorphism).

Topologizing $\mathrm{sp}\,\mathcal{A}(\Omega)$ by Gelfand, we endow it with the weakest topology in which all $\hat{w} \in \hat{\mathcal{A}}(\Omega)$ are continuous. Since the corresponding topology on Ω determined by

functions $w \in \mathcal{A}(\Omega)$ coincides with the initial (metric) topology of (Ω, g), the bijection ε turns out to be a homeomorphism. The lemma is proved.

The density of $\mathcal{O}(\Omega)$ in $\mathcal{A}(\Omega)$ used in the proof provides one more important property of the algebra $\mathcal{A}(\Omega)$:

(iv) the smooth subalgebra $\mathcal{A}^\infty(\Omega) := \mathcal{A}(\Omega) \bigcap C^\infty(\Omega)$ is dense in $\mathcal{A}(\Omega)$.

2.3. Conforming metrics. The algebra $\mathcal{A}(\Omega)$ as well as the corresponding complex structure on Ω (see (i), section 2.2) are determined by the metric g, the structures corresponding to metrics g and ρg being identical since these metrics define one and the same reserve of harmonic functions.[2]

The converse is true in the following sense. We call a metric g *conforming* to the complex structure determined by the algebra $\mathcal{A}(\Omega)$ if $\mathrm{Re}\mathcal{A}(\Omega) \subset \mathrm{Harm}_g\,\Omega$. It can be shown that any two metrics conforming to the given structure are distinguished by a functional multiplier.

To construct a metric conforming to a given structure one can use the following standard trick. Let us choose an atlas $\{U_k, \varphi_k\} : \bigcup_k U_k \supset \Omega$; $\varphi_k : U_k \mapsto \mathbf{R}^2$, $\varphi_k(x) = \{\mathrm{Re}\, w_k(x), \mathrm{Im}\, w_k(x)\}, w_k \in \mathcal{A}(\Omega)$; let η_k be a subordinated partition of unity: $\eta_k \geq 0$, $\mathrm{supp}\,\eta_k \subset U_k$, $\sum_k \eta_k = 1$. Define on Ω the tensors $g_{ij}^{(k)} := \eta_k \delta_{ij}$. The tensor $g := \sum_k g^{(k)}$ defines a required metric.

Another way to find a conforming metric is to solve (1.1) with respect to the entries $\det{}^{\frac{1}{2}} g\, g^{ij}$ for sufficiently many $u \in \mathrm{Re}\,\mathcal{A}(\Omega)$, i.e., to recover the metric g up to a function multiplier.

2.4. Algebra $\mathcal{A}(\Gamma)$. The set of traces $\mathcal{A}(\Gamma) := \mathrm{tr}\,\mathcal{A}(\Omega) = \{\mathrm{tr}\, w \,|\, w \in \mathcal{A}(\Omega)\}$ is a closed subalgebra of the (complex) algebra $C(\Gamma)$. We list some of its properties.

(i) Since $\max_\Omega |w|$ for $w \in \mathcal{A}(\Omega)$ is attained at Γ, the equality $||w||_{\mathcal{A}(\Omega)} = ||\mathrm{tr}\, w||_{\mathcal{A}(\Gamma)}$ holds. Therefore, the mapping tr is an isometric isomorphism of algebras.

(ii) Since $\mathcal{A}(\Omega)$ is generic, whereas $\mathcal{A}(\Gamma)$ is isometrically isomorphic to $\mathcal{A}(\Omega)$, the Gelfand transform $\hat{\mathcal{A}}(\Gamma) \subset C(\mathrm{sp}\,\mathcal{A}(\Gamma))$ turns out to be spatially isomorphic to $\mathcal{A}(\Omega)$. The corresponding spatial isomorphism from $\mathcal{A}(\Omega)$ onto $\hat{\mathcal{A}}(\Gamma)$ is $\wedge\,\mathrm{tr}$,[3] whereas the corresponding space bijection is $\beta : \Omega \mapsto \mathrm{sp}\,\mathcal{A}(\Gamma)$, $\beta(x_0) = \mathrm{tr}\, I_{x_0}$.

(iii) Define the smooth subalgebra $\mathcal{A}^\infty(\Gamma) := \mathcal{A}(\Gamma) \bigcap C^\infty(\Gamma) = \mathrm{tr}\,\mathcal{A}^\infty(\Omega)$. Since $\mathcal{A}^\infty(\Omega)$ is dense in $\mathcal{A}(\Omega)$ (see (iv), section 2.2) $\mathcal{A}^\infty(\Gamma)$ turns out to be dense in $\mathcal{A}(\Gamma)$.

The following lemma plays a key role: it shows that the trace algebra $\mathcal{A}(\Gamma)$ is determined by the DN-map. Introduce the set

$$\mathcal{F} := \left\{ f \in C^\infty(\Gamma) \,|\, [\mathbf{1} + (\mathbf{\Lambda_g J})^\mathbf{2}] \frac{\mathbf{df}}{\mathbf{d\gamma}} = \mathbf{0} \right\}$$

of (real) functions satisfying (1.5). To each $f \in \mathcal{F}$ we associate the *conjugate function* f^* such that $\frac{df^*}{d\gamma} = \Lambda_g J \frac{df}{d\gamma}$ holds. As is easy to see, f^* is determined by f up to constant, $f^* \in \mathcal{F}$, and $f^{**} = -f \pmod{\mathrm{const}}$.

LEMMA 3. *The representation*

$$\mathcal{A}(\Gamma) = \mathrm{clos}_{C(\Gamma)}\, \{f + if^* \,|\, f \in \mathcal{F}\} \tag{2.1}$$

is valid.

[2] In dimension 2 the equalities $\Delta_g\, u = 0$ and $\Delta_{\rho g}\, u = 0$ are equivalent.

[3] Here and below (section 3.2) $\wedge$ denotes the Gelfand transform $\wedge\mathcal{A} := \hat{\mathcal{A}}$.

Proof. If $w = u + iu^* \in \mathcal{A}^\infty(\Omega)$, then $u = u^f$ with $f = \operatorname{tr} u$, $u^* = u^p$ with $p = \operatorname{tr} u^*$, and $\Phi\nabla u^f = \nabla u^p$. According to (ii) of Lemma 1 the last equality implies that $f, p \in \mathcal{F}$. Taking the traces in the same equality one easily gets $\frac{dp}{d\gamma} = \Lambda_g f = \Lambda_g J \frac{df}{d\gamma}$, so $p = f^*$. Hence $\operatorname{tr} w = f + ip = f + if^* \in \mathcal{A}^\infty(\Gamma)$, which establishes the inclusion $\mathcal{A}^\infty(\Gamma) \subset \{f + if^* \,|\, f \in \mathcal{F}\}$.

Take $f \in \mathcal{F}$ and its conjugate $f^* \in \mathcal{F}$. By virtue of Lemma 1(ii) the fields ∇u^f and ∇u^{f^*} are potential and satisfy

$$\operatorname{tr} \Phi\nabla u^f = \Lambda_g f \frac{\partial}{\partial\gamma} - \frac{df}{d\gamma}\frac{\partial}{\partial\nu} = \frac{df^*}{d\gamma}\frac{\partial}{\partial\gamma} + \Lambda_g f^* \frac{\partial}{\partial\nu} = \operatorname{tr} \nabla u^{f^*}.$$

Equality of the traces leads to equality of the fields: $\Phi\nabla u^f = \nabla u^{f^*}$ in Ω. Hence, the function $w = u^f + iu^{f^*}$ belongs to $\mathcal{A}^\infty(\Omega)$, whereas its trace $f + if^*$ belongs to $\mathcal{A}^\infty(\Gamma)$. Thus, we have $\{f + if^* \,|\, f \in \mathcal{F}\} \subset \mathcal{A}^\infty(\Gamma)$, which establishes the equality $\mathcal{A}^\infty(\Gamma) = \{f + if^* \,|\, f \in \mathcal{F}\}$.

Since $\mathcal{A}^\infty(\Gamma)$ is dense in $\mathcal{A}(\Gamma)$ one gets (2.1). The lemma is proved.

3. Solving the problem.

3.1. Construction of the manifold. So, let an operator Λ_g acting in (real) $C^\infty(\Gamma)$ be given and known to be the DN-map of a manifold. By results of Lee and Uhlmann [8] Λ_g determines the metric tensor at the boundary $g|_\Gamma$; therefore one can also assume the length element $d\gamma$ to be known. Due to the latter the class $\dot{C}^\infty(\Gamma)$ as well as the integration operator J acting in this class are at our disposal.

The following procedure gives a canonical representative of the class of manifolds whose DN-maps coincide with Λ_g.

Step 1. Select the set $\mathcal{F}$ in $C^\infty(\Gamma)$. Through $\mathcal{F}$ recover the algebra $\mathcal{A}(\Gamma)$ by the representation (2.1).

Step 2. Find $\operatorname{sp}\mathcal{A}(\Gamma) =: \Omega$ (see (ii), section 2.4). Identify the subset of ideals $\{I_{\gamma_0} \,|\, \gamma_0 \in \Gamma\} \subset \Omega$ to Γ by the rule $I_{\gamma_0} \equiv \gamma_0$.

Step 3. Find the Gelfand transform $\hat{\mathcal{A}}(\Gamma) =: \mathcal{A}(\Omega)$. Note that the "boundary" $\{I_{\gamma_0} \,|\, \gamma_0 \in \Gamma\}$ constructed in the previous step may also be identified as the Shilov boundary of $\mathcal{A}(\Omega)$ (see, e.g., [9]).

Step 4. Using functions $w \in \mathcal{A}(\Omega)$ as local homeomorphisms $\Omega \mapsto \mathbf{C}$ recover on Ω the complex structure. Its realifying determines on Ω a structure of the smooth 2-dimensional manifold with the boundary Γ.

Step 5. Equip Ω with a metric $\tilde{g}$ conforming to the complex structure (see section 2.3). Choose a positive function $\rho \in C^\infty(\Omega)$ such that the metric $g := \rho\tilde{g}$ satisfies $(\rho\tilde{g})_\Gamma = g|_\Gamma$.

The manifold (Ω, g) solves the Calderon problem: its DN-map coincides with Λ_g by construction.

3.2. Proof of Theorem 1. We recall that $\wedge$ denotes the Gelfand transform $\wedge\mathcal{A} = \hat{\mathcal{A}}$. The statement of the theorem is just a consequence of the well-determinacy of the procedure described above.[4] Indeed,

(1) if (Ω', g') and (Ω'', g'') have the common DN-map, the corresponding sets $\mathcal{F}$ determined by Λ_g coincide: $\mathcal{F}' = \mathcal{F}''$. Whence, by Lemma 3 the trace algebras coincide: $\mathcal{A}'(\Gamma) = \mathcal{A}''(\Gamma)$;

[4]Such a situation is quite usual for the BC-method.

(2) by the property (ii), section 2.4, the algebras $\mathcal{A}(\Omega')$ and $\mathcal{A}(\Omega'')$ are spatially isomorphic to the Gelfand transform of the common trace algebra:

$$\wedge' [\mathrm{tr}' \mathcal{A}(\Omega')] = \hat{\mathcal{A}}'(\Gamma) = \hat{\mathcal{A}}''(\Gamma) = \wedge'' [\mathrm{tr}'' \mathcal{A}(\Omega'')];$$

for the corresponding space bijections one has

$$\beta'(\Omega') = \mathrm{sp}\, \mathcal{A}'(\Gamma) = \mathrm{sp}\, \mathcal{A}''(\Gamma) = \beta''(\Omega''). \tag{3.1}$$

Therefore the algebras $\mathcal{A}(\Omega')$ and $\mathcal{A}(\Omega'')$ are spatially isomorphic (through the map $(\mathrm{tr}'')^{-1}\,(\wedge'')^{-1}\,\wedge'\,\mathrm{tr}'$), whereas the manifolds Ω' and Ω'' are connected through the bijection $\beta : \Omega' \mapsto \Omega''$, $\beta = {\beta''}^{-1}\beta'$;

(3) since the differentiable structures on Ω' and Ω'' are determined by the algebras $\mathcal{A}(\Omega')$ and $\mathcal{A}(\Omega'')$, the bijection β is a diffeomorphism. Due to (3.1) one has $\beta'(\gamma_0) = I'_{\gamma_0} = I''_{\gamma_0} = \beta''(\gamma_0)$, $\gamma_0 \in \Gamma$, which follows to $\beta(\gamma_0) = {\beta''}^{-1}(\beta'(\gamma_0)) = \gamma_0$, i.e., $\beta|_\Gamma = \mathrm{id}$;

(4) introduce on Ω' the (induced) metric $\tilde{g}''$ providing β to be isometry from $(\Omega', \tilde{g}'')$ onto (Ω'', g''). Since $\mathcal{A}(\Omega')$ and $\mathcal{A}(\Omega'')$ are isomorphic, the metric $\tilde{g}''$ (as well as g') turns out to be conforming to the structure determined by $\mathcal{A}(\Omega')$. Due to the last, one has $\tilde{g}'' = \rho g'$ with a $\rho \in C^\infty(\Omega')$. By $\beta|_\Gamma = \mathrm{id}$ one has $\tilde{g}''|_\Gamma = g''|_\Gamma$; taking into account $g'|_\Gamma = g''|_\Gamma = g|_\Gamma$ we obtain $\tilde{g}''|_\Gamma = g'|_\Gamma$, implying $\rho|_\Gamma = 1$.

So, β is an isometry from $(\Omega', \rho g')$ onto (Ω'', g''); i.e., (Ω', g') and (Ω'', g'') belong to one and the same conformal class. The theorem is proved.

Comments and acknowledgments. The first variant of this paper [3], published as a preprint in June 2002, doesn't contain references to the results of Lassas and Uhlmann: unfortunately, we hadn't known of their work [7]. We would like to apologize for this confusion and to thank G. Alessandrini and V. Isakov for informing us about this paper.

To the best of our knowledge, the relation $\mathrm{sp}\, \mathcal{A}(\Omega) \asymp \Omega$ was first established by J. Wermer [11] in the case of the Riemann surface with analytic Γ homeomorphic to the circle. If $\Omega \subset \mathbf{C}$, the algebra $\mathcal{A}(\Omega)$ is generic in a much more general situation (without assumptions on smoothness and connectedness of Γ, see, e.g., [6]). Perhaps, the same is valid for Riemann surfaces, so that, most probably, Lemma 2 is well known for specialists in function algebras. However, we didn't succeed in finding exact references.

Some relations between topology of Ω and the number of generators of the algebra $\mathcal{A}(\Omega)$ (and, hence, of $\mathcal{A}(\Gamma)$) are mentioned in [3]. This is also a way to extract topological properties from DN-map.

If $\Omega \subset \mathbf{C}$ is the unit disk, the operator $\Lambda_g J$ in fact coincides with the Hilbert transform on the unit circle. Perhaps this operator has an abstract analogue in a class of the uniform algebras with nontrivial Shilov boundary.

This paper was written during my stay at the University of Nantes in May 2002. I'm grateful to this university for the kind invitation and the support of my visit.

I'm much obliged to R. Novikov for hospitality, friendly help, and fruitful discussions. I'm deeply indebted to G. M. Henkin for valuable discussions; his consultations helped me to avoid a lot of mistakes. I would like to thank S. Belisheva for help in preparing the manuscript.

SOLVING TIME-HARMONIC SCATTERING PROBLEMS BASED ON THE POLE CONDITION I: THEORY*

THORSTEN HOHAGE†, FRANK SCHMIDT‡, AND LIN ZSCHIEDRICH‡

Abstract. The pole condition is a general concept for the theoretical analysis and the numerical solution of a variety of wave propagation problems. It says that the Laplace transform of the physical solution in radial direction has no poles in the lower complex half-plane. In the present paper we show that for the Helmholtz equation with a radially symmetric potential the pole condition is equivalent to Sommerfeld's radiation condition. Moreover, a new representation formula based on the pole condition is derived and used to prove existence, uniqueness, and asymptotic properties of solutions. This makes it possible to compute the far field of the solution without a Green function, which may not be known explicitly.

Key words. transparent boundary conditions, Laplace transform, Sommerfeld radiation condition

1. Introduction.

Differential equations of Helmholtz type describe a large variety of time-harmonic wave propagation problems in acoustics, electromagnetics, and quantum mechanics. To formulate such problems properly on unbounded domains, a so-called radiation condition has to be imposed at infinity. Physically this condition implies that asymptotically no energy is transported towards the origin. The standard condition for bounded obstacles is *Sommerfeld's radiation condition* (cf. [19]). For scattering at rough surfaces or for inhomogeneous exterior domains containing wave guides, Sommerfeld's radiation condition is not valid, and it is often not obvious how to formulate an appropriate radiation condition. In some simple cases a radiation condition can be formulated by a *series representation* of the solution. For general rough surface scattering problems the so-called *upward propagating radiation condition* based on an integral representation of the solution is commonly used (cf. [22]). In this paper we propose a new radiation condition called the pole condition, which seems to be valid for a wide range of problems. Roughly speaking, a function satisfies the *pole condition* if its Laplace transform in the propagation direction has a holomorphic extension to the lower part of the complex plane. Here we show that for bounded obstacles and radially symmetric potentials the pole condition is equivalent to Sommerfeld's radiation condition.

The aim of this paper is not only to give a new proof of existence, uniqueness, and asymptotic properties of solutions to scattering problems based on the pole condition but also to lay the foundations of a new class of efficient numerical algorithm. We derive a set of equations, which can be solved numerically. A detailed discussion of numerical algorithms based on the pole condition will be published elsewhere [10].

For a preliminary report on numerical results we refer to [11]. For an analysis of the PML method based on the pole condition we refer to [9].

In many applications, one is interested in the behavior of the solution far away from the obstacle. Using a representation formula derived in this paper the solution can be evaluated at any given point in a cheap and stable manner. For problems for which neither a fundamental solution nor a series representation of the solution is known explicitly, this distinguishes our method from the standard methods (cf. [1, 2, 3, 7, 8, 12]).

The potential range of applications of our method is not restricted to the class of problems considered in this paper. A basic requirement is that the Laplace transform of the differential equation along a family of rays connecting the artificial boundary to infinity can be carried out analytically. The original motivation of this work was problems in integrated optics involving waveguides. For a numerical solution of such problems by methods based on the pole condition we refer to [11, 16].

The pole condition was first considered by the second author for problems with one space-like and one time-like variable. In [15, 17] the time-discretized Schrödinger equation is interpreted as a sequence of inhomogeneous Helmholtz problems. One-way wide-angle Helmholtz equations, ranging between the Schrödinger and the Helmholtz equations, were studied in [18]. With the results below, we hope to be able to carry over the analysis of these papers to time-dependent problems in arbitrary space dimensions.

2. Main results and outline of the paper. We consider partial differential equations of the form

$$\Delta u + (1 + p(|x|))\,\kappa^2 u = 0 \tag{2.1}$$

with a real-valued functions p in some exterior domain $\Omega \supset \{x \in \mathbb{R}^d : |x| > a_*\}$, $a_* > 0$. p is assumed to be analytic of the form $p(r) = \sum_{j=2}^{\infty} p_j r^{-j}$ and describes either a radially symmetric potential or a variation of the refractive index.

Let us motivate the pole condition by the simplest case $d = 1$, $p = 0$, and $a_* = 1$. Here (2.1) reduces to the ordinary differential equation $u'' + \kappa^2 u = 0$ with the general solution

$$u(1 + r) = C_1 e^{i\kappa r} + C_2 e^{-i\kappa r}, \qquad r > 0.$$

The term $C_1 e^{i\kappa r}$ corresponds to an outgoing wave, and $C_2 e^{-i\kappa r}$ to an incoming wave. The Laplace transform $\hat{u}_1(s) := \int_0^\infty e^{-sr} u(1 + r)\,\mathrm{d}r$ of $u(1 + \cdot)$, $\operatorname{Re} s > 0$, is given by

$$\hat{u}_1(s) = \frac{C_1}{s - i\kappa} + \frac{C_2}{s + i\kappa}.$$

This function, which has a holomorphic extension to $\mathbb{C} \setminus \{i\kappa, -i\kappa\}$, satisfies $\operatorname{res}_{i\kappa} \hat{u}_1 = C_1$ and $\operatorname{res}_{-i\kappa} \hat{u}_1 = C_2$. u is outgoing if and only if $\hat{u}_1$ has no pole at $-i\kappa$, i.e., if and only if $\operatorname{res}_{-i\kappa} \hat{u}_1 = 0$.

To avoid notational difficulties we assume that $d \geq 2$ from now on. Let us introduce the function

$$U(\rho, \hat{x}) := \rho^{\frac{d-1}{2}} u(\rho \hat{x}) \tag{2.2}$$

for $\rho > a_*$, $\hat{x} \in S^{d-1} := \{x \in \mathbb{R}^d : |x| = 1\}$, and its (shifted) Laplace transform

$$\hat{U}_a(s, \hat{x}) := \int_0^\infty e^{-sr} U(r + a, \hat{x})\,\mathrm{d}r \tag{2.3}$$

for $\operatorname{Re} s > 0$, $\hat{x} \in S^{d-1}$, and $a \geq a_*$. Note that the scaling factor in the definition of U is chosen such that $\|U(\rho, \cdot)\|_{L^2(S^{d-1})} = \|u\|_{L^2(\rho S^{d-1})}$ for all $\rho > a_*$.

DEFINITION 2.1 (pole condition). *A bounded function $u : \{x \in \mathbb{R}^d : |x| > a_*\} \to \mathbb{C}$ satisfies the pole condition if for some $a \geq a_*$ the function $\hat{U}_a(\cdot, \hat{x})$ defined by (2.2) and (2.3) has a holomorphic extension to the lower complex half-plane $\mathbb{C}^- := \{s \in \mathbb{C} : \operatorname{Im} s < 0\}$ for all $\hat{x} \in S^{d-1}$ such that the function $s \mapsto \int_{S^{d-1}} |\frac{\partial \hat{U}_a}{\partial s}(s, \hat{x})|^2 \, \mathrm{d}s(\hat{x})$ is bounded on compact subsets of $\mathbb{C}^-$.*

Remark 2.2. If the pole condition is satisfied for one $a \geq a_*$, it is satisfied for all $a \geq a_*$. This follows from the identity

$$\int_0^\infty e^{-sr} U(a + r, \hat{x}) \, \mathrm{d}r = \int_0^{b-a} e^{-sr} U(a + r, \hat{x}) \, \mathrm{d}r + e^{-s(b-a)} \int_0^\infty e^{-sr} U(b + r, \hat{x}) \, \mathrm{d}r \tag{2.4}$$

and the fact that both $s \mapsto \int_0^{b-a} e^{-sr} U(a + r, \hat{x}) \, \mathrm{d}r$ and $s \mapsto e^{-s(b-a)}$ are entire functions. Hence, the pole condition is a condition concerning the behavior of u at infinity but not the behavior of u on any compact set.

A similar condition without the scaling (2.2) was considered in [14]. We will show that a solution u to the differential equation (2.1) satisfies the pole condition if and only if it satisfies the Sommerfeld radiation condition

$$\lim_{\rho \to \infty} \rho^{\frac{d-1}{2}} \left(\frac{\partial u}{\partial \rho} - i\kappa u \right) = 0, \qquad \rho = |x|, \tag{2.5}$$

uniformly for all directions $\frac{x}{|x|}$.

The structure of the singularity is more complicated in general than in the simple example above. If a solution to (2.1) satisfies the pole condition, then $\hat{U}(\cdot, \hat{x})$ has an analytic extension not only to $\mathbb{C}_-$ but even to $\mathbb{C} \backslash \{i\kappa - t : t \geq 0\}$; i.e., we do not have an isolated singularity, but a singularity with a branch cut. For a holomorphic function $f : V \to \mathbb{C}$ defined on a domain $V \subset \mathbb{C}$ and $\sigma \in \overline{V}$ we define $\operatorname{Res}_\sigma f := \lim_{s \to \sigma, s \in V} (s - \sigma) f(s)$ if this limit exists. If f has an isolated pole of order 1 at σ, then $\operatorname{Res}_\sigma f = \operatorname{res}_\sigma f$. The functions

$$u_\infty(\hat{x}) = e^{-i\kappa a} \operatorname{Res}_{i\kappa} \hat{U}_a(\cdot, \hat{x}), \tag{2.6a}$$

$$\Psi_a(t, \hat{x}) = \frac{e^{-i\kappa a}}{2\pi i} \lim_{\epsilon \to 0} \left(\hat{U}_a(i\kappa - t - i\epsilon, \hat{x}) - \hat{U}_a(i\kappa - t + i\epsilon) \right) \tag{2.6b}$$

are well defined for $\hat{x} \in S^{d-1}$, $t > 0$, and a sufficiently large; i.e., u_∞ is independent of a and the limit in (2.6b) exists. It is a crucial result of our analysis that these functions determine the solution U completely via the representation formula

$$U(a + r, \hat{x}) = e^{i\kappa(a+r)} \left(u_\infty(\hat{x}) + \int_0^\infty e^{-tr} \Psi_a(t, \hat{x}) \, \mathrm{d}t \right), \qquad r \geq 0. \tag{2.7}$$

Let $\Delta_{S^{d-1}}$ denote the Laplace–Beltrami operator on S^{d-1} and define

$$\tilde{\Delta}_{\hat{x}} \varphi := \Delta_{S^{d-1}} \varphi + \left(\frac{(d-1)(3-d)}{4} \right) \varphi \tag{2.8}$$

for $\varphi \in C^2(S^{d-1})$. Then u_∞ and Ψ_a satisfy the Volterra integrodifferential equation

$$\left\{\check{p}_a(t) + te^{-at}\tilde{\Delta}_{\hat{x}}\right\} u_\infty(\hat{x}) + t(t-2i\kappa)\Psi_a(t,\hat{x}) + \int_0^t \left\{\check{p}_a(t-t_1) + (t-t_1)e^{-a(t-t_1)}\tilde{\Delta}_{\hat{x}}\right\} \Psi_a(t_1,\hat{x})\,\mathrm{d}t_1 = 0. \tag{2.9}$$

Here $\check{p}_a$ is the inverse Laplace transform of $p_a := p(a+\cdot)$ (cf. Lemma 4.1). If $p = 0$, then (2.9) can be converted to a differential equation by multiplying by e^{at} and differentiating twice with respect to t.

Given boundary data $f(\hat{x}) = U(a,\hat{x})$, (2.7) implies

$$u_\infty(\hat{x}) + \int_0^\infty \Psi_a(t,\hat{x})\,\mathrm{d}t = e^{-i\kappa a} f(\hat{x}). \tag{2.10}$$

We show that the system (2.9), (2.10) has a unique solution (u_∞, Ψ_a) if the radius a of the artificial boundary $\Gamma_a := \{x : |x| = a\}$ is chosen sufficiently large. Other boundary conditions can easily be taken care of by differentiating (2.7). It suffices to compute $\Psi_a(t,\hat{x})$ on a small interval $t \in [0,T]$ since $\Psi_a(t,\hat{x})$ decays exponentially as $t \to \infty$. Once u_∞ and Ψ_a are known, $U(\rho,\hat{x})$ can be evaluated for $\rho \geq a$ using (2.7).

The plan of this paper is as follows: In section 3 we introduce the Dirichlet-to-Neumann map on Γ_a and prove an existence and uniqueness theorem based on properties of this operator. In section 4 we derive an ordinary differential equation for the Fourier coefficients of $U(r,\cdot)$ and a corresponding Volterra integral equation for the Laplace transform of these functions. Existence and uniqueness of solutions to these integral equations is established in section 5. In the following section the main results of this paper are proved for single Fourier modes. As a simple consequence of a representation formula corresponding to (2.7) we derive asymptotic formulas for (generalized) Hankel functions for large arguments. In section 8 we construct the Dirichlet-to-Neumann map using Fourier series and show that it satisfies the assumptions of the existence and uniqueness theorem in section 3. Then, in section 9, we establish the formulas (2.7) and (2.9) and show the equivalence of the pole condition and Sommerfeld's radiation condition.

3. The Dirichlet-to-Neumann map on the artificial boundary. For simplicity, we assume that Ω is the complement of some sufficiently smooth compact set K contained in $\{x : |x| < a_*\}$ such that $p(|x|)$ is well defined and finite for $x \in \Omega$. Moreover, we assume that u satisfies the Neumann boundary conditions $\frac{\partial u}{\partial \nu} = f$ on the boundary ∂K. We could easily accommodate for more complicated situations, e.g., different boundary conditions or inhomogeneities in the interior of Γ_a.

From now on we assume without loss of generality (w.l.o.g.) that $\kappa = 1$. Since a and p are arbitrary, this can be achieved by the following rescaling: $\tilde{x} = \kappa x$, $\tilde{\rho} = \kappa\rho$, $\tilde{a} = \kappa a$, $\tilde{t} = \kappa^{-1}t$, $\tilde{s} = \kappa^{-1}s$, $\tilde{p}(\tilde{\rho}) = p(\rho)$, $\tilde{\check{p}}(\tilde{t}) = \kappa\check{p}(t)$, $\tilde{u}(\tilde{x}) = u(x)$, $\tilde{U}(\tilde{\rho},\hat{x}) = \kappa^{\frac{d-1}{2}} U(\rho,\hat{x})$, $\tilde{\hat{U}}(\tilde{s},\hat{x}) = \kappa^{\frac{d+1}{2}}\hat{U}(s,\hat{x})$, $\tilde{u}_\infty(\hat{x}) = \kappa^{\frac{d-1}{2}} u_\infty(\hat{x})$, $\tilde{\Psi}(\tilde{t},\hat{x}) = \kappa^{\frac{d+1}{2}}\Psi(t,\hat{x})$. For notational convenience we will drop the tildes in the following.

To arrive at a weak formulation, we multiply (2.1) by a function $-\overline{v}$ and integrate over $\Omega_a := \{x \in \Omega : |x| < a\}$. Formally applying Green's theorem yields

$$\int_{\Omega_a} \left(\nabla u \nabla \overline{v} - (1 + p(|x|))\, u\overline{v}\right)\,\mathrm{d}x - \int_{\Gamma_a \cup \partial K} \frac{\partial u}{\partial \nu}\overline{v}\,\mathrm{d}s = 0,$$

where the unit normal vector ν points to the exterior of Ω_a. Now we introduce a so-called *Dirichlet-to-Neumann map* $\mathrm{DtN} : H^{1/2}(\Gamma_a) \to H^{-1/2}(\Gamma_a)$ which maps the

Dirichlet data $u|_{\Gamma_a}$ of a solution u satisfying (2.1) and (2.5) to its Neumann data $\frac{\partial u}{\partial \nu}|_{\Gamma_a}$. Existence and uniqueness of such solutions in $\{x : |x| > a\}$ will be proved later. With the sesquilinear form $a : H^1(\Omega_a) \times H^1(\Omega_a) \to \mathbb{C}$,

$$a(u,v) := \int_{\Omega_a} \left(\nabla u \nabla \overline{v} - (1 + p(|x|))\, u\overline{v}\right) \mathrm{d}x - \int_{\Gamma_a} \mathrm{DtN} u \overline{v}\, \mathrm{d}s,$$

and the continuous antilinear functional $F : H^1(\Omega_a) \to \mathbb{C}$,

$$F(v) := \int_{\partial K} f \overline{v}\, \mathrm{d}s,$$

the variational problem reads

$$a(u,v) = F(v) \qquad \text{for all } v \in H^1(\Omega_a). \tag{3.1}$$

PROPOSITION 3.1. *Let* DtN *be an operator with the following properties:*

1. $\mathrm{DtN} : H^{1/2}(\Gamma_a) \to H^{-1/2}(\Gamma_a)$ *is linear and bounded.*
2. *There exists a compact operator* $L : H^{1/2}(\Gamma_a) \to H^{-1/2}(\Gamma_a)$ *such that the inequality* $\mathrm{Re} \int_{\Gamma_a} (-\mathrm{DtN} + L)\varphi\, \overline{\varphi}\, \mathrm{d}s \geq 0$ *holds for all* $\varphi \in H^{1/2}(\Gamma_a)$.
3. $\mathrm{Im} \int_{\Gamma_a} \mathrm{DtN}\varphi\, \overline{\varphi}\, \mathrm{d}s > 0$ *for all* $\varphi \in H^{1/2}(\Gamma_a)$, $\varphi \neq 0$.

Then the variational problem (3.1) *has a unique solution* u *for all right-hand sides* F, *and* u *depends continuously on* F.

Proof. As the proof is rather standard (cf., e.g., [2, Thm. 5.7] for a similar proof), we give only a brief sketch. Condition 1 ensures that the sesquilinear form a is well defined. Condition 2 is used to establish the Gårding inequality

$$\mathrm{Re}\, a(u,u) + c_2 \|u\|^2_{L^2(\Omega_a)} + \mathrm{Re}\, \langle L \,\mathrm{Tr}\, u, \mathrm{Tr}\, u\rangle_{L^2(\Gamma_a)} \geq c_1 \|u\|^2_{H^1(\Omega_a)}$$

for all $u \in H^1(\Omega_a)$ with constants $c_1, c_2 > 0$ and the trace operator $\mathrm{Tr} : H^1(\Omega_a) \to H^{1/2}(\Gamma_a)$. Since the embedding operator $H^1(\Omega_a) \hookrightarrow (H^1(\Omega_a))'$ and the operator $\mathrm{Tr}'\, L\, \mathrm{Tr} : H^1(\Omega_a) \to H^1(\Omega_1)$ are compact, it can be shown by the Lax–Milgram lemma and Riesz theory that the operator induced by the sesquilinear form a is Fredholm with index 0; i.e., uniqueness implies existence and stability. Let $u \in H^1(\Omega_a)$ satisfy $a(u,v) = 0$ for all $v \in H^1(\Omega_a)$. Taking the imaginary part of this equation and using condition 3, it follows that u has vanishing Cauchy data on Γ_a. Hence, by virtue of the Cauchy–Kovalevskaya theorem and elliptic regularity results, u must vanish everywhere. ∎

Usually the properties of DtN required in the previous proposition are proved using special properties of the Hankel functions (cf. [2, 12]). In the following we present a more systematic approach which also works for $p \neq 0$.

4. The Laplace transform of the separated differential equation. Let $\{(\varphi_j, \lambda_j) : j \in \mathbb{N}\}$ be a complete orthonormal system of eigenfunctions and eigenvalues of the operator $\tilde{\Delta}_{\hat{x}}$ defined in (2.8). φ_j may be chosen as trigonometric monomials for $d = 2$ and spherical harmonics for $d = 3$. Let $U_j(r) := \int_{S^1} U(r,\cdot)\, \overline{\varphi_j}\, \mathrm{d}s$ denote the Fourier coefficients of U. Using the formula

$$\Delta = \frac{\partial^2}{\partial \rho^2} + \frac{d-1}{\rho}\frac{\partial}{\partial \rho} + \frac{1}{\rho^2}\Delta_{S^{d-1}}$$

it follows after some simple computations that the Fourier coefficients $U_j(r)$ satisfy the differential equations

$$U_j''(\rho) + \left(1 + p(\rho) + \lambda_j \rho^{-2}\right) U_j(\rho) = 0. \tag{4.1}$$

Note that there is no term involving U_j' due to the scaling factor $\rho^{(d-1)/2}$.

Let $(\mathcal{L}f)(s) := \int_0^\infty e^{-s\rho} f(\rho)\,\mathrm{d}\rho$, $\operatorname{Re} s > 0$, denote the Laplace transform of a function f. In order to derive an equation for $\hat{U}_{j,a} := \mathcal{L}U_j(\cdot + a)$ we need the following lemma.

LEMMA 4.1. *Assume that the convergence radius of* $p(t^{-1}) = \sum_{m=1}^\infty p_m t^m$ *is greater than* $\frac{1}{a_p}$, $a_p \in (0,\infty)$, *and let* $a > a_p$. *Let*

$$\check{p}_a(s) := e^{-as} \sum_{m=1}^\infty \frac{p_m}{(m-1)!} s^{m-1} \tag{4.2}$$

be the inverse Laplace transform of $p(\cdot + a)$ *(i.e.,* $(\mathcal{L}\check{p}_a)(r) = p(r + a)$*), and let* $u \in C([0,\infty))$ *be a bounded function. Then*

$$\mathcal{L}\left(p(\cdot + a)u\right)(s) = \int_s^\infty \check{p}_a(s_1 - s)(\mathcal{L}u)(s_1)\,\mathrm{d}s_1 \tag{4.3}$$

for $\operatorname{Re} s > 0$. *Here* $\int_s^\infty f(s_1)\,\mathrm{d}s_1 := \int_0^\infty f(s + t)\,\mathrm{d}t$. *For all* $k = 0, 1, \ldots$ *there exists a constant* $C > 0$ *such that*

$$|\check{p}_a^{(k)}(s)| \le Ce^{-a\operatorname{Re} s + a_p|s|} \tag{4.4a}$$

for all $s \in \mathbb{C}$. *If* $p_1 = 0$, *then also*

$$|\check{p}_a(s)| \le C|s|e^{-a\operatorname{Re} s + a_p|s|}. \tag{4.4b}$$

Proof. We first prove by induction in $m \in \mathbb{N}$ that (4.3) is true for $p(t^{-1}) = t^m$. To show this for $m = 1$ we consider the function $f(t) := (t + a)^{-1}u(t)$. A simple computation shows that $\lim_{s\to\infty} \mathcal{L}f(s) = 0$ and

$$(\mathcal{L}u)(s) = \left(\mathcal{L}\left((\cdot + a)f\right)\right)(s) = a(\mathcal{L}f)(s) - (\mathcal{L}f)'(s).$$

On the other hand, the right-hand side of (4.3) with $\check{p}_a(s) = e^{-as}$ is the unique solution of this differential equation vanishing at ∞. Now assume that (4.3) holds true for $p(t^{-1}) = t^m$ with $m \le j$, $j \in \mathbb{N}$. Then

$$\begin{aligned}
\mathcal{L}\left(\frac{u}{(\cdot + a)^{j+1}}\right)(s) &= \int_s^\infty \frac{e^{a(s-s_1)}(s_1 - s)^{j-1}}{(j-1)!} \left(\mathcal{L}\left(\frac{u}{\cdot + a}\right)\right)(s_1)\,\mathrm{d}s_1 \\
&= \int_s^\infty \frac{e^{a(s-s_1)}(s_1 - s)^{j-1}}{(j-1)!} \int_{s_1}^\infty e^{a(s_1-s_2)}(\mathcal{L}u)(s_2)\,\mathrm{d}s_2\,\mathrm{d}s_1 \\
&= \int_s^\infty e^{a(s-s_2)}(\mathcal{L}u)(s_2) \int_s^{s_2} \frac{(s_1 - s)^{j-1}}{(j-1)!}\,\mathrm{d}s_1\,\mathrm{d}s_2 \\
&= \int_s^\infty \frac{e^{a(s-s_2)}(s_2 - s)^j}{j!}(\mathcal{L}u)(s_2)\,\mathrm{d}s_2.
\end{aligned}$$

So far we have proved (4.3) if $t \mapsto p(t^{-1})$ is a polynomial. It remains to consider the case that p is given by an infinite series. It follows from the definition of a_p that $C := \sup_{m\ge 0} |p_{m+1}|a_p^{-m} < \infty$. Hence,

$$\begin{aligned}
|\check{p}_a(s)| &\le e^{-a\operatorname{Re} s} \sum_{m=0}^\infty \frac{|p_{m+1}||s|^m}{m!} \le Ce^{-a\operatorname{Re} s} \sum_{m=0}^\infty \frac{a_p^m|s|^m}{m!} \\
&\le Ce^{-a\operatorname{Re} s + a_p|s|}.
\end{aligned}$$

The other estimates in (4.4) are derived in a similar manner. Since all partial sums in the definition of $\check{p}_a$ are bounded by the right-hand side of the previous inequality and since the series $p(t)$ converges uniformly for $|t| \geq a$, it can be shown by Lebesgue's dominated convergence theorem that

$$\begin{aligned}\int_0^\infty e^{-sr} p(r+a)u(r)\,\mathrm{d}r &= \lim_{M\to\infty} \int_0^\infty e^{-sr} \sum_{m=1}^{M} \frac{p_m}{(r+a)^m} u(r)\,\mathrm{d}r \\ &= \lim_{M\to\infty} \int_s^\infty e^{a(s-s_1)} \sum_{m=1}^{M} \frac{p_m (s-s_1)^{m-1}}{(m-1)!} (\mathcal{L}u)(s_1)\,\mathrm{d}s_1 \\ &= \int_s^\infty \check{p}_a(s_1-s)(\mathcal{L}u)(s_1)\,\mathrm{d}s_1. \qquad \square\end{aligned}$$

It follows from (4.1) and Lemma 4.1 that

$$\begin{aligned}&\int_s^\infty \left(\check{p}_a(s_1-s) + e^{-a(s_1-s)}(s_1-s)\lambda_j\right) \hat{U}_{j,a}(s_1)\,\mathrm{d}s_1 \\ &\qquad + (s^2+1)\hat{U}_{j,a}(s) = s\,U_j(a) + U_j'(a), \qquad \operatorname{Re} s > 0.\end{aligned} \tag{4.5}$$

5. The integral equation in the Laplace domain. In this and the following two sections we consider differential equations of the form

$$U''(a+r) + (1 + (\mathcal{L}P_a)(r))\,U(a+r) = 0, \qquad r > 0, \tag{5.1}$$

with an analytic function P_a of the form (4.2) with $p_1 = 0$ which satisfies the estimates (4.4) with $a > a_p$. Equations (4.1) are of this form. The dependence of the solution on λ_j will be discussed later. For studying the integral equation in the Laplace domain, it is useful to factor out the singularities of $\hat{U}_a$ at $\pm i$, i.e., to look at the function

$$w_a(s) = \hat{U}_a(s)(s^2+1). \tag{5.2}$$

In the following we often omit the index a in $\hat{U}_a$, w_a, and P_a. Due to Lemma 4.1 the function w satisfies the Volterra integral equation

$$w(s) + Jw(s) = sU(a) + U'(a) \tag{5.3}$$

with

$$(Jw)(s) := \int_s^\infty P(s_1-s)\frac{w(s_1)}{s_1^2+1}\,\mathrm{d}s_1. \tag{5.4}$$

Let us introduce the cuts $S_{\pm i} := \{\pm i + t : t < 0\}$ and $V := \mathbb{C}\backslash(S_i \cup S_{-i})$ (cf. Figure 5.1(a)). We define the metric on V by $d(s_1,s_2) := |s_1-s_2| + |\varphi(s_1)-\varphi(s_2)|$ with the function $\varphi : V \to \mathbb{R}$ given by $\varphi(s) := -\operatorname{Re} s$ if $\operatorname{Re} s \leq 0$ and $|\operatorname{Im} s| < 1$, $\varphi(s) := 0$ else. This metric is defined such that points on opposite sides of the cuts are far away from each other. Let $(\overline{V}, \overline{d})$ denote the completion of the metric space (V,d). Then $\overline{V}$ is the union of V and the set of points $s_\pm := \lim_{\epsilon\to 0,\epsilon>0} s \pm i\epsilon$ with $s \in S_i \cup S_{-i}$. For a continuous function $v : \overline{V} \to \mathbb{C}$ we can define a "jump function" $[v] : S_i \cup S_{-i} \to \mathbb{C}$ by

$$[v](s) := v(s_-) - v(s_+), \qquad s \in S_i \cup S_{-i}. \tag{5.5}$$

Note that $[v]$ is continuous on $S_i \cup S_{-i}$ with respect to the topology induced by the usual norm of $\mathbb{C}$.

We introduce the norm

$$\|w\|_X := \sup_{s\in\overline{V}} \frac{|w(s)|}{|s|^2+1}$$

and denote by X the space of all $w \in C(\overline{V})$ which are holomorphic in V and satisfy $w(s) = \mathrm{o}\big(|s|^2\big)$ uniformly for $|s| \to \infty$. X is equipped with the norm $\|\cdot\|_X$.

In the following we use the notation $|s|_1 := |\operatorname{Re} s| + |\operatorname{Im} s|$ for $s \in \mathbb{C}$. Moreover, we define the diamond-shaped domains $D_\pm := \{s \in \overline{V} : |s \mp i|_1 < \frac{1}{2}\}$.

LEMMA 5.1. *Let $0 < \alpha < 1$. Then there exists a constant c such that for all $w \in X$*

$$|(Jw)(s)| \le c \left(\sup_{\operatorname{Re} s_1 \ge \operatorname{Re} s} \frac{|w(s_1)|}{|s_1|^2+1} \right), \qquad s \in \overline{V}\backslash(D_+ \cup D_-), \tag{5.6a}$$

$$|(Jw)'(s)| \le c \left(\sup_{\operatorname{Re} s_1 \ge \operatorname{Re} s} \frac{|w(s_1)|}{|s_1|^2+1} \right), \qquad s \in \overline{V}\backslash(D_+ \cup D_-), \tag{5.6b}$$

$$|(Jw)(s) - (Jw)(\sigma)| \le c\|w\|_X\, d(s,\sigma)^\alpha, \qquad s, \sigma \in D_\pm, \tag{5.6c}$$

$$|(Jw)(s)| \le c\|w\|_X, \qquad s \in \overline{V}. \tag{5.6d}$$

Proof. Part (a). Since the operator J is defined by an integral over a holomorphic function (cf. (5.4)), we may deform the integration path in order to facilitate the proof. We choose the path $\gamma_s(t) := s + t$, $t \ge 0$, if it does not intersect with $D_+ \cup D_-$. Otherwise we set

$$\gamma_s(t) := s + t + i\psi_s(t), \qquad t \ge 0, \tag{5.7}$$

with a real-valued function ψ_s as shown in Figure 5.1(a). ψ_s is chosen such that γ_s does not intersect $D_+ \cup D_- \cup S_i \cup S_{-i}$, $\psi_s(0) = 0$, $|\psi_s| \le \frac{1}{2}$, $|\psi_s'| \le 1$, $\operatorname{meas}(\operatorname{supp}\psi_s) \le 1$, and $\lim_{t\to\infty} \psi(t) = 0$. We have

$$(Jw)(s) = \int_0^\infty P(t + i\psi_s(t)) \frac{|\gamma_s(t)|^2+1}{\gamma_s(t)^2+1} \frac{w(\gamma_s(t))}{|\gamma_s(t)|^2+1} \gamma_s'(t)\,\mathrm{d}t. \tag{5.8}$$

Due to (4.4a) there exists a constant $c > 0$ such that for all $t \ge 0$

$$\sup_{|\tau|\le \min(t,1/2)} |P(t+i\tau)|\,\mathrm{d}t \le ce^{-(a-a_p)t/2}. \tag{5.9}$$

To see this, choose T such that $-at + a_p|t + i/2| \le -(a-a_p)t/2$ for $t \ge T$. Then (5.9) holds true for $t \ge T$. By a compactness argument it is also true that $0 \le t \le T$. Here and in the following, c is a generic constant. Moreover, $\sup_{s\in\mathbb{C}\backslash(D_+\cup D_-)} \frac{|s|^2+1}{|s^2+1|} < \infty$. Hence,

$$\begin{aligned} |(Jw)(s)| &\le c \left(\int_0^\infty e^{-(a-a_p)t/2}\,\mathrm{d}t \right) \left(\sup_{\operatorname{Re} s_1 \ge \operatorname{Re} s} \frac{|w(s_1)|}{|s_1|^2+1} \right) \\ &= \frac{2c}{a-a_p} \left(\sup_{\operatorname{Re} s_1 \ge \operatorname{Re} s} \frac{|w(s_1)|}{|s_1|^2+1} \right). \end{aligned}$$

This implies (5.6a).

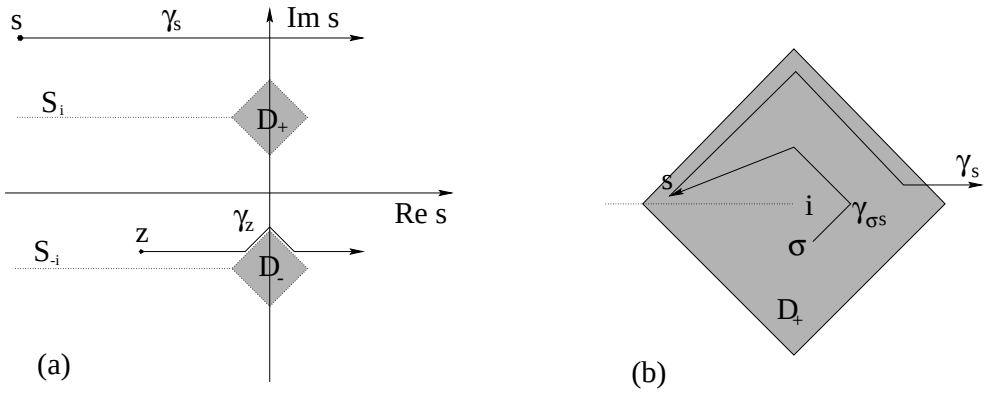

FIG. 5.1. *Integration paths in the proof of Lemma* 5.1.

Part (b). Differentiating (5.4) yields

$$(Jw)'(s) = -\int_s^\infty P'(s_1 - s)\frac{w(s_1)}{s_1^2+1}\,\mathrm{d}s_1 \tag{5.10}$$

since $P(0) = 0$. Now (5.6b) follows as above.

Part (c). W.l.o.g. we may assume that $s, \sigma \in D_+$ and that $|s-i|_1 \geq |\sigma - i|_1$. In this proof we say that s and σ are *on opposite sides of* S_i if $\operatorname{Re} s, \operatorname{Re}\sigma < 0$ and $\operatorname{Im}(s-i)\operatorname{Im}(\sigma-i) < 0$ or if s and σ are the limit of a sequence of such points. We first assume that s and σ are not on opposite sides of S_i. Let $\gamma_{\sigma s}$ be the shortest path from σ to s in D_+ such that $|s_1 - i|_1 \geq |\sigma - i|_1$ for all $s_1 \in \gamma_{\sigma s}$ (cf. Figure 5.1(b)). The length of this path can be estimated by $l(\gamma_{\sigma s}) \leq 3\delta$, where $\delta := |s - \sigma|$. Moreover, we choose the path γ_s from s to ∞ such that $|s_1 - i|_1 \geq |s - i|_1$ for all $s \in \gamma_s$ (cf. Figure 5.1(b)). We have

$$\begin{aligned}(Jw)(\sigma) - (Jw)(s) = &\int_{\gamma_{\sigma s}} \frac{P(s_1-\sigma)}{s_1^2+1} w(s_1)\,\mathrm{d}s_1 \\ &+ \int_{\gamma_s} \left(P(s_1-\sigma) - P(s_1 - s)\right)\frac{w(s_1)}{s_1^2+1}\,\mathrm{d}s_1.\end{aligned}$$

To estimate the integral over $\gamma_{\sigma s}$, we use the inequalities $|s| \leq |s|_1 \leq \sqrt{2}|s|$ and (4.4b):

$$\left|\frac{P(s_1 - s)}{(s_1+i)(s_1-i)}\right| \leq \sqrt{2}\left|\frac{1}{s_1+i}\right| \cdot \left|\frac{P(s-s_1)}{s-s_1}\right| \leq c.$$

Together with the bound on $l(\gamma_{\sigma s})$ this yields $\left|\int_{\gamma_{\sigma s}} \ldots\right| \leq c\delta\|w\|_X$.

The integral over γ_s is estimated by the mean value theorem:

$$\begin{aligned}&\left|\int_{\gamma_s} \left(P(s_1-\sigma) - P(s_1-s)\right)\frac{w(s_1)\,\mathrm{d}s_1}{s_1^2+1}\right| \\ &\leq \delta \int_{\gamma_s} \sup_{\lambda\in[0,1]} |P'(s_1 - \lambda s - (1-\lambda)\sigma)| \frac{|w(s_1)|\,|\,\mathrm{d}s_1|}{|s_1^2+1|}.\end{aligned}$$

To bound the integrand for $s_1 \in D_+ \cap \gamma_s$ we note that

$$\begin{aligned}|s_1 - i|_1 &\geq |s_1 - s|_1 - |s-i|_1 \geq |s_1 - s|_1 - |s_1 - i|_1, \\ 2|s_1 - i|_1 &\geq 2|s-i|_1 \geq |s-i|_1 + |\sigma - i|_1 \geq |s-\sigma|_1 \geq \delta\end{aligned}$$

due to the choice of γ_s. Adding these inequalities yields $4|s_1 - i|_1 \geq |s_1 - s|_1 + \delta$. Together with the estimates $|s_1 - s|_1 \geq \operatorname{Re}(s_1 - s)$ and $|s_1 + i|_1 \geq 1$ we obtain $|s_1^2 + 1| \geq \frac{1}{2}|s_1 + i|_1 |s_1 - i|_1 \geq \frac{1}{8}(\operatorname{Re}(s_1 - s) + \delta)$. Outside of D_+ the bound $\left|\frac{w(s_1)}{s_1^2+1}\right| \leq c\|w\|_X$ holds true. With (4.4a) and $t^* := \sup\{t \geq 0 : s + t \in D_+\}$ we obtain

$$\begin{aligned}\left|\int_{\gamma_s} \dots\right| &\leq c\delta\|w\|_X \left(\int_0^{t^*} \frac{\mathrm{d}t}{t+\delta} + \int_{t^*}^{\infty} e^{-(a-a_p)t/2}\,\mathrm{d}t\right) \\ &\leq c\delta\|w\|_X \left(\ln\delta + \frac{a-a_p}{2}\right) \leq c\delta^\alpha \|w\|_X.\end{aligned}$$

Since $\delta \leq d(s,\sigma)$, we have proved (5.6c) if s and σ are not on opposite sides of S_i. Otherwise, we obtain from our previous estimates that

$$\begin{aligned}|(Jw)(\sigma) - (Jw)(s)| &\leq |(Jw)(\sigma) - (Jw)(i)| + |(Jw)(i) - Jw(s)| \\ &\leq c(|\sigma - i|^\alpha + |i - s|^\alpha).\end{aligned}$$

We may assume w.l.o.g. that $\operatorname{Im}(\sigma - i) \leq 0$ and $\operatorname{Im}(s - i) \geq 0$. Then $d(\sigma, s) = |\operatorname{Re}\sigma| + |\sigma - s|$ and

$$\begin{aligned}&|\operatorname{Im}(\sigma - i)| + |\operatorname{Im}(i - s)| = |\operatorname{Im}(\sigma - s)| \leq d(\sigma, s), \\ &|\operatorname{Re}(s - i)| = |\operatorname{Re} s| \leq |\operatorname{Re}\sigma| + |\operatorname{Re}(s - \sigma)| \leq d(s, \sigma), \\ &|\operatorname{Re}(\sigma - i)| = |\operatorname{Re}\sigma| \leq d(s, \sigma).\end{aligned}$$

Inserting these inequalities in the previous inequality yields (5.6c).

Part (d). Inequality (5.6d) follows easily from (5.6a) and (5.6c). ∎

LEMMA 5.2. *The operator J is compact from X to X.*

Proof. It follows from (5.4) that Jw is holomorphic in V for $w \in X$ and from Lemma 5.1 that Jw is continuous in $\overline{V}$. Together with the estimate (5.6d) this shows that J maps X into X. To prove compactness, let $(w_n)_{n\in\mathbb{N}}$ be a sequence in X with $\|w_n\|_X \leq 1$ for all $n \in \mathbb{N}$. We have to show that the sequence $v_n := Jw_n$, $n \in \mathbb{N}$, has a convergent subsequence in X. Let us first consider the restrictions of v_n on some compact subset $K \subset \overline{V}$. Due to (5.6b) and (5.6c), the sequence $(v_n|_K)_{n\in\mathbb{N}}$ is equicontinuous on K with respect to the metric d. Hence, by the Arzelà–Ascoli theorem, there exists a subsequence of $(v_n)_{n\in\mathbb{N}}$ which converges with respect to the norm $\|\varphi\|_{\infty,K} := \sup_{s\in K} |\varphi(s)|$. In order to construct a subsequence which converges globally, we introduce the sets $K_j := \{s \in \overline{V} : |s| \leq j\}$ for $j \in \mathbb{N}$. It is easy to show that these sets are compact with respect to the metric d. By the argument above, there exists a subsequence $(v_{n_1(l)})_l$ which converges with respect to $\|\cdot\|_{\infty,K_1}$. Applying the same argument again, we get a subsequence $(v_{n_2(l)})_l$ which converges with respect to $\|\cdot\|_{\infty,K_2}$. Repeating this process of selecting subsequences, we arrive at an array $v_{n_j(l)}$ with the property that each row is a subsequence of the previous row. The diagonal subsequence $v_{n(l)} := v_{n_l(l)}$ converges to some function v with respect to the supremum norm on each K_j. In particular, $\lim_{l\to\infty} v_{n(l)}(s) = v(s)$ for all $s \in \overline{V}$. It remains to show that $\|v_{n(l)} - v\|_X \to 0$. Let $\epsilon > 0$. By virtue of (5.6d) there exists a constant $C > 0$ such that $|v_{n(l)}(s)| \leq C$ for all $s \in \overline{V}$ and $l \in \mathbb{N}$. Therefore,

$$\frac{|v(s) - v_{n(l)}(s)|}{1 + |s|^2} \leq \epsilon \qquad \text{for all } l \in \mathbb{N} \text{ and } |s| \geq \sqrt{\frac{2C}{\epsilon}}. \tag{5.11}$$

Let $J \geq \sqrt{2C/\epsilon}$, $J \in \mathbb{N}$. Since $v_{n(l)}$ converges to v with respect to $\|\cdot\|_{\infty,K_J}$, there exists $L \in \mathbb{N}$ such that

$$\sup_{s\in K_J} \frac{\big|v(s) - v_{n(l)}(s)\big|}{|s^2|+1} \leq \|v(s) - v_{n(l)}\|_{\infty,K_J} \leq \epsilon \tag{5.12}$$

for $l \geq L$. Putting (5.11) and (5.12) together yields $\|v - v_{n(l)}\|_X \leq \epsilon$ for $l \geq L$. ∎

PROPOSITION 5.3. *The integral equation* (5.3) *has a unique solution in* X *for all* $U(a), U'(a) \in \mathbb{C}$.

Proof. Let $w \in X$ satisfy the homogeneous equation $w + Jw = 0$. If we can show that $w = 0$, then the assertion follows from Riesz theory and Lemma 5.2. Inequality (5.6d) implies that $\|w\|_\infty < \infty$. Hence, there exists $s^* \in \mathbb{C}$ with $|\operatorname{Re} s^*| \geq \sigma := 2\sqrt{c/a^2}$ such that $|w(s)| \leq 2|w(s^*)|$ for all $s \in \mathbb{C}$ with $|\operatorname{Re} s| \geq \sigma$. It follows from (5.6a) that

$$\begin{aligned} |w(s^*)| = |(Jw)(s^*)| &\leq \sup_{\operatorname{Re} s_1 \geq \sigma} \frac{c}{|s_1^2|+1}|w(s_1)| \\ &< \frac{1}{4} \sup_{\operatorname{Re} s_1 \geq \sigma} |w(s_1)| \leq \frac{1}{2}|w(s^*)|, \end{aligned}$$

i.e., $w(s^*) = 0$. This, however, implies that $w(s) = 0$ for all $s \in \mathbb{C}$ with $\operatorname{Re} s \geq \sigma$, and since w is holomorphic in V and continuous in $\overline{V}$, $w(s) = 0$ for all $s \in \overline{V}$. ∎

6. The cut functions. In this section we study the cut functions

$$\psi_{a,\pm}(t) := \frac{[\hat{U}_a](\pm i - t)}{2\pi i \operatorname{Res}_{\pm i} \hat{U}_a}, \qquad t > 0 \tag{6.1}$$

(cf. (5.5)). Note that $\pm 2i \operatorname{Res}_{\pm i} \hat{U}_a = w(\pm i)$. In the next lemma we derive Volterra integral equations for $\psi_{a,\pm}$, which are uniquely solvable. This shows that $\psi_{a,\pm}$ can be defined without the assumption $\operatorname{Res}_i \hat{U}_a \neq 0$ and that, in fact, $\psi_{a,\pm}$ depends only on P_a but not on U.

LEMMA 6.1. *If* $\operatorname{Res}_{\pm i} \hat{U}_a \neq 0$, *the cut functions* $\psi_{a,\pm}(t)$ *defined by* (6.1) *for* $t > 0$ *satisfy the integral equations*

$$\psi_{a,+}(t) + \int_0^t \frac{P_a(t-t_1)}{t(t-2i)} \psi_{a,+}(t_1)\,\mathrm{d}t_1 = -\frac{P_a(t)}{t(t-2i)}, \tag{6.2a}$$

$$\psi_{a,-}(t) + \int_0^t \frac{P_a(t-t_1)}{t(t+2i)} \psi_{a,-}(t_1)\,\mathrm{d}t_1 = -\frac{P_a(t)}{t(t+2i)}. \tag{6.2b}$$

Proof. We will only prove (6.2a) since the proof of (6.2b) is analogous. Due to (5.3) and (5.2) we have

$$(s_\pm^2 + 1)\hat{U}(s_\pm) + \int_{\gamma_\pm^\epsilon} P(s_1 - s_\pm)\hat{U}(s_1)\,\mathrm{d}s_1 = s_\pm U(a) + U'(a)$$

for $s = i - t \in S_i$ and $\epsilon > 0$. The paths γ_+^ϵ and γ_-^ϵ are shown in Figure 6.1. Subtracting the equation with the $+$ sign from the equation with the $-$ sign yields

$$\begin{aligned} &t(t-2i)[\hat{U}](i-t) + \int_{-t}^{-\epsilon} P(t+t_1)[\hat{U}](i+t_1)\,\mathrm{d}t_1 \\ &+ \int_0^{2\pi} P(t - \epsilon e^{-i\varphi}) \frac{w(i - \epsilon e^{i\varphi})}{(-\epsilon e^{i\varphi})(2i - \epsilon e^{i\varphi})} (-i\epsilon) e^{i\varphi}\,\mathrm{d}\varphi = 0. \end{aligned}$$

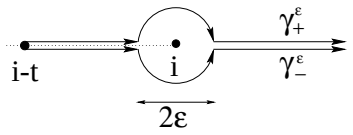

FIG. 6.1. *Integration path in the proof of Lemma* 6.1.

Since w is continuous at i, the last integral converges to $\pi P(t)w(i) = 2\pi i P(t)\operatorname{Res}_i \hat{U}$ as $\epsilon \to 0$. Dividing by $2\pi i(\operatorname{Res}_i \hat{U})t(t-2i)$ establishes (6.2a). ∎

Since both the kernel of the integral operators and the right-hand sides are bounded due to our assumptions on P, the Volterra integral equations (6.2) are uniquely solvable (cf., e.g., [13, Thm. 10.15]). From these integral equations we can deduce the following two lemmas concerning the behavior of $\psi_\pm$ near 0 and near ∞. Since

$$\psi_-(t) = \overline{\psi_+(t)} \tag{6.3}$$

the first lemma is only formulated for ψ_+.

LEMMA 6.2. *The function ψ_+ defined in* (6.1) *belongs to $C^\infty([0,\infty))$, and the derivatives of ψ_+ at* 0 *can be computed recursively as follows:*

$$\psi_+(0) = -\lim_{t\to 0} \frac{P(t)}{t(t-2i)}, \tag{6.4a}$$

$$\psi_+^{(k+1)}(0) = -\lim_{t\to 0} \frac{d^{k+1}}{dt^{k+1}} \left\{ \frac{P(t)}{t(t-2i)} \right\} + \frac{(k+1)!}{2i} \sum_{j=1}^{k+1} \frac{1}{(2i)^{k+1-j}(j+1)!} \sum_{n=1}^{j} P^{(n)}(0)\psi_+^{(j-n)}(0). \tag{6.4b}$$

Proof. Introducing $(Kv)(t) := \int_0^t \frac{P(t-t_1)}{t(t-2i)} v(t_1)\,\mathrm{d}t_1$, (6.2a) can be written as

$$\psi_+(t) + (K\psi_+)(t) = -\frac{P(t)}{t(t-2i)}, \qquad t > 0. \tag{6.5}$$

By repeated partial integration we obtain

$$\int_0^t P(t-t_1)\frac{t_1^j}{j!}\,\mathrm{d}t_1 = \sum_{l=1}^{\infty} P^{(l)}(0) \int_0^t \frac{(t-t_1)^l}{l!}\frac{t_1^j}{j!}\,\mathrm{d}t_1 = \sum_{l=1}^{\infty} \frac{P^{(l)}(0)t^{l+j+1}}{(l+j+1)!}.$$

Changing the order of integration and summation in the first equality is justified because the Taylor series of P converges uniformly. The right-hand side of the last equation is an analytic function in t. If $v(t) = \sum_{j=0}^{\infty} \frac{v^{(j)}(0)}{j!}t^j$ is a polynomial, then

$$\begin{aligned}(Kv)(t) &= \frac{1}{t(t-2i)} \int_0^t P(t-t_1) \sum_{j=0}^{\infty} \frac{v^{(j)}(0)}{j!} t_1^j\,\mathrm{d}t_1 \\ &= \frac{1}{t-2i} \sum_{l=1}^{\infty}\sum_{j=0}^{\infty} P^{(l)}(0)v^{(j)}(0)\frac{t^{l+j}}{(l+j+1)!}.\end{aligned}$$

Expanding $(t-2i)^{-1}$ in a power series and using the Cauchy product twice yields

$$(Kv)(t) = \frac{1}{-2i}\sum_{r=0}^{\infty}\left(\frac{t}{2i}\right)^r \sum_{m=1}^{\infty}\frac{t^m}{(m+1)!}\sum_{n=1}^{m}P^{(n)}(0)v^{(m-n)}(0) \tag{6.6}$$
$$= \frac{1}{-2i}\sum_{l=1}^{\infty}t^l\sum_{j=1}^{l}\left(\frac{1}{2i}\right)^{l-j}\frac{1}{(j+1)!}\sum_{n=1}^{j}P^{(n)}(0)v^{(j-n)}(0).$$

In particular, it can be seen that Kv is analytic at $t=0$.

We prove by induction that $\psi_+ \in C^n([0,\infty))$ for $n \in \mathbb{N}$. Note that the right-hand side of (6.5) is analytic at $t=0$ due to our assumptions on P. The case $n=0$ follows from the continuity and boundedness of the kernel of the integral operator K for $0 \le t_1 < t$. Equation (6.4a) is a consequence of $(K\psi_+)(0)=0$. Assume now that $\psi_+ \in C^k([0,\infty))$, $k \ge 0$. Then there exists a function R_k such that $\psi_+(t) = \sum_{j=0}^{k}\frac{\psi_+^{(j)}(0)}{j!}t^j + R_k(t)$ and $R_k(t) = \mathrm{o}\big(t^k\big)$ as $t \to 0$. We have

$$|(KR_k)(t)| \le \frac{1}{t|t-2i|}\int_0^t |P(t-t_1)|\,\mathrm{d}t_1 \sup_{0\le t_1\le t}|R_k(t_1)| = \mathrm{o}\big(t^{k+1}\big)$$

since $P(t) = \mathcal{O}(t)$ as $t \to 0$. Therefore, $KR_k \in C^{k+1}([0,\infty))$ and $(KR_k)^{(k+1)}(0)=0$. Now it follows from (6.5) and (6.6) that $\psi_+ \in C^{k+1}([0,\infty))$ and that $\psi_+^{(k+1)}(0)$ satisfies (6.4b). ∎

Since the first term on the right-hand side of (the analogue of) (2.4) does not contribute to $\operatorname{Res}_{\pm i}\hat{U}_a$ and $\psi_{a,\pm}$, the quantities

$$U_\infty^\pm := e^{\pm ia}\operatorname{Res}_{\pm i}\hat{U}_a \tag{6.7}$$

are independent of a, and

$$e^{at}\psi_{a,\pm}(t) = e^{bt}\psi_{b,\pm}(t) \tag{6.8}$$

for $b \ge a$. Alternatively, (6.8) follows from (6.2) using $e^{at}P_a(t) = e^{bt}P_b(t)$ (cf. (4.2)). Note that $\psi_{b,\pm}$ can be defined for all $b \in \mathbb{R}$ as a solution to (6.2) even if $\hat{U}_b$ does not exist.

LEMMA 6.3. *For all $a \in \mathbb{R}$ and $\epsilon > 0$ the cut functions satisfy*

$$|\psi_{a,\pm}(t)| = \mathcal{O}\Big(e^{-(a-a_p-\epsilon)t}\Big), \qquad t \to \infty. \tag{6.9}$$

Proof. Due to (6.8) it suffices to prove the lemma for $a = a_p$. It follows from (4.4a) with $k=0$ and (6.2) that

$$|\psi_{a_p,\pm}(t)| \le \frac{C}{|t(t-2i)|}\left(1 + \int_0^t |\psi_{a_p,\pm}(t_1)|\,\mathrm{d}t_1\right)$$

for all $t > 0$. Choosing t_* such that $\frac{C}{|t_*(t_*-2i)|} \le \epsilon$, it follows that

$$|\psi_{a_p,\pm}(t)| \le \Gamma + \int_{t_*}^t \epsilon|\psi_{a_p,\pm}(t_1)|\,\mathrm{d}t_1, \qquad t > t_*,$$

where $\Gamma := \epsilon(1+\int_0^{t_*}|\psi_{a_p,\pm}(t_1)|\,\mathrm{d}t_1)$. Now Gronwall's lemma (cf. [4]) implies $|\psi_{a_p,\pm}(t)| \le \Gamma e^{\epsilon(t-t_*)}$ for $t > t_*$. ∎

THEOREM 6.4. *The function U has a holomorphic extension to $\{\zeta \in \mathbb{C} : \operatorname{Re}\zeta > a\}$, and U and $U^{(k)}$ $(k \geq 1)$ satisfy the representation formulas*

$$\begin{aligned} U(z+a) &= U_\infty^+ e^{i(z+a)} \left(1 + \int_0^\infty e^{-tz}\psi_{a,+}(t)\,\mathrm{d}t\right) \\ &\quad + U_\infty^- e^{-i(z+a)} \left(1 + \int_0^\infty e^{-tz}\psi_{a,-}(t)\,\mathrm{d}t\right), \end{aligned} \tag{6.10a}$$

$$\begin{aligned} U^{(k)}(z+a) &= U_\infty^+ e^{i(z+a)} \left(i^k + \int_0^\infty (i-t)^k e^{-tz}\psi_{a,+}(t)\,\mathrm{d}t\right) \\ &\quad + U_\infty^- e^{-i(z+a)} \left((-i)^k + \int_0^\infty (-i-t)^k e^{-tz}\psi_{a,-}(t)\,\mathrm{d}t\right) \end{aligned} \tag{6.10b}$$

for $\operatorname{Re}(z) > 0$ *and* $a \geq a_p$.

Proof. Let $\gamma_1^R(t) := 1 + it$, $-R \leq t \leq R$ (cf. Figure 6.2(a)). Then

$$U(a+r) = \lim_{R\to\infty} \frac{1}{2\pi i} \int_{\gamma_1^R} e^{rs}\hat{U}_a(s)\,\mathrm{d}s$$

for $a > a_p$ and $r \geq 0$ by the inversion theorem for the Fourier transform. Now

$$\frac{1}{2\pi i} \int_{\gamma_1^R} e^{rs}\hat{U}_a(s)\,\mathrm{d}s = -\frac{1}{2\pi i} \int_{\gamma_2^R} e^{rs}\hat{U}_a(s)\,\mathrm{d}s$$

by virtue of Cauchy's integral theorem. Due to (5.2), (5.3), and (5.6d) the function $\hat{U}$ decays of order $|\hat{U}_a(s)| = \mathcal{O}\big(|s|^{-1}\big)$ as $|s| \to \infty$ uniformly for all directions. Therefore, the integrals from B to C, from D to E, and from F to A vanish asymptotically as $R \to \infty$. Moreover, given $\epsilon > 0$, there exists $\delta > 0$ such that $|\int_{\pi/2}^{\pi/2+\delta} e^{rs_R(\tau)}\hat{U}_a(s_R(\tau))s_R'(\tau)\,\mathrm{d}\tau| \leq \pi\epsilon$ for all $R \geq 1$, where $s_R(\tau) := i + R\exp(i\tau)$. Due to the exponential decay of the integrand, there exists $R_0 \geq 1$ such that $|\int_{\pi/2+\delta}^{\pi} e^{rs_R(\tau)}\hat{U}_a(s_R(\tau))s_R'(\tau)\,\mathrm{d}\tau| \leq \pi\epsilon$ for $R \geq R_0$. Both estimates together imply that $|(2\pi i)^{-1}\int_C^D e^{rs}\hat{U}_a(s)\,\mathrm{d}s| \leq \epsilon$ for $R \geq R_0$. Analogously, it can be shown that the integral from E to F tends to 0 as $R \to \infty$. A computation similar to that in the proof of Lemma 6.1 shows that the integrals around $\pm i$ converge to $\operatorname{Res}_{\pm i}\hat{U}_a e^{\pm ir}$ as $R \to \infty$. The integrals along $S_{\pm i}$ converge to $\operatorname{Res}_{\pm i}\hat{U}_a \int_0^\infty e^{r(\pm i - t)}\psi_{a,\pm}(t)\,\mathrm{d}t$ as $R \to \infty$. This yields (6.10a) for real $z \geq 0$. Differentiating (6.10a) and changing the order of differentiation and integration, which is possible by Lebesgue's dominated convergence theorem and (6.9), we obtain (6.10b). It is obvious that (6.10a) defines a holomorphic extension of U. ∎

By (6.10a) we can decompose any Fourier mode U satisfying (5.1) into an outgoing part and an incoming part. For a solution u to the full partial differential equation (2.1) a corresponding decomposition is not always possible. For example, the solution $u(x) = e^{i\kappa x_1}$ for $p = q = 0$ does not decay like $\mathcal{O}\big(\rho^{-(d-1)/2}\big)$. Since the Sommerfeld radiation condition implies such a behavior (cf. [2, sect. 2.2]) and since incoming solutions are complex conjugates of outgoing solutions, u cannot be decomposed into an outgoing and an incoming part. The reason that Theorem 6.4 does not carry over in full extent to the partial differential equation (2.1) is linked to the fact that the condition numbers of the matrices L_a in the next corollary increase exponentially with $|\lambda_j|$.

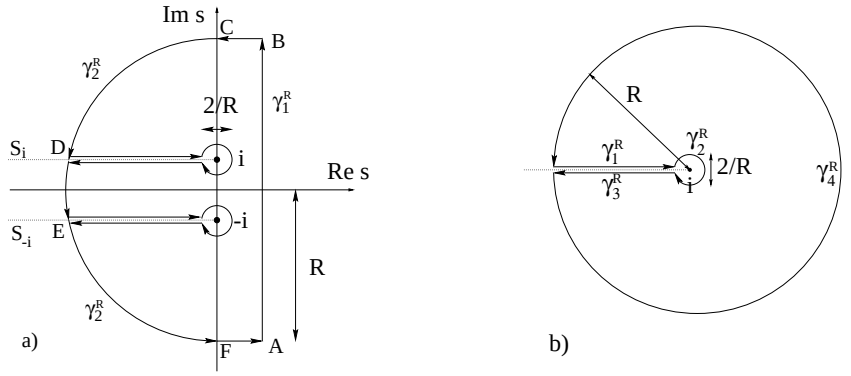

FIG. 6.2. *Integration paths in the proofs of Theorem* 6.4 *and Proposition* 6.6.

COROLLARY 6.5. *The matrix* L_a *defined by*

$$\begin{pmatrix} U(a) \\ U'(a) \end{pmatrix} = L_a \begin{pmatrix} U_\infty^+ \\ U_\infty^- \end{pmatrix}$$

via (6.10a) *and* (6.10b) *is regular. Hence, there exists* $(U(a), U'(a)) \neq 0$ *such that* $\operatorname{Res}_{-i} \hat{U}_a = 0$. *If* $\operatorname{Res}_{-i} \hat{U}_a = 0$, *then* $\hat{U}_a$ *is holomorphic in* $\mathbb{C}\backslash(S_i \cup \{i\})$; *i.e., it satisfies the pole condition.*

Proof. Let $L_a(U_\infty^+, U_\infty^-)^T = 0$. Since U solves a linear second order differential equation, $U(r) = U'(r) = 0$ implies that $U \equiv 0$, and hence $U_\infty^+ = U_\infty^- = 0$. Hence, L_a is regular. If $\operatorname{Res}_{-i} \hat{U}_a = 0$, then $[U_a](-i - t) = 0$, and therefore $[w](-i - t) = 0$ for all $t > 0$; i.e., w is continuous in the lower half-plane. Using Morera's theorem and a contour deformation around the cut S_{-i} it can be shown that w is holomorphic in $\mathbb{C}\backslash(S_i \cup \{i\})$. As $w(-i) = 0$, $\hat{U}_a$ is holomorphic in $\mathbb{C}\backslash(S_i \cup \{i\})$ as well. ∎

Finally, we need a representation formula for $\hat{U}_a$ in terms of the cut function.

PROPOSITION 6.6. *Let* $\operatorname{Res}_{-i} \hat{U}_a = 0$. *Then* $\hat{U}_a(s)$ *satisfies the representation formula*

$$\hat{U}_a(s) = -\frac{\operatorname{Res}_i \hat{U}_a}{i - s} - \int_0^\infty \frac{\operatorname{Res}_i \hat{U}_a \psi_{a,+}(t)}{i - t - s} \, \mathrm{d}t, \qquad s \in \mathbb{C}\backslash S_i. \tag{6.11}$$

Proof. Due to Corollary 6.5 the assumption $\operatorname{Res}_{-i} \hat{U}_a = 0$ implies that $\hat{U}_a$ is holomorphic in $\mathbb{C}\backslash(S_i \cup \{i\})$. Therefore, Cauchy's formula

$$\hat{U}_a(s) = \frac{1}{2\pi i} \int_{\gamma_1^R + \gamma_2^R + \gamma_3^R + \gamma_4^R} \frac{\hat{U}_a(s_1) \, \mathrm{d}s_1}{s_1 - s}$$

with the contour shown in Figure 6.2(b) holds true. The integral over γ_2^R converges to the first term on the right-hand side of (6.11). Recall from the proof of Theorem 6.4 that $\hat{U}_a(s) = \mathcal{O}(|s|^{-1})$ as $|s| \to \infty$ uniformly for all directions. Hence, the integral over γ_4^R tends to 0 as $R \to \infty$ since the integrand is of order $\mathcal{O}(|s|^{-2})$. Finally, the integrals over γ_1^R and γ_3^R yield the integral term in (6.11). ∎

7. Asymptotic expansion of the far field. The following result is a simple consequence of Theorem 6.4.

THEOREM 7.1. *Let $m \in \{0,1,2,\dots\}$, and assume that $U_\infty^+ = 0$ or $U_\infty^- = 0$, respectively. Then U and U' satisfy the asymptotic formulas*

$$U(z) = U_\infty^\pm e^{\pm iz}\left(1 + \sum_{l=0}^{m-1} \frac{\psi_{0,\pm}^{(l)}(0)}{z^{l+1}} + \mathcal{O}\Big(\frac{1}{|z|^{m+1}}\Big)\right), \tag{7.1}$$

$$U'(z) = U_\infty^\pm e^{\pm iz}\left(\pm i + \sum_{l=0}^{m-1} \frac{\pm i\psi_{0,\pm}^{(l)}(0) - l\psi_{0,\pm}^{(l-1)}(0)}{z^{l+1}} + \mathcal{O}\Big(\frac{1}{|z|^{m+1}}\Big)\right),$$

respectively, for $z \to \infty$ such that $|\arg z| \le \varphi < \frac{\pi}{2}$. Here $0 \cdot \psi_{0,\pm}^{(-1)}(0) := 0$.

Proof. Note that the integral term in (6.10a) is the Laplace transform of $\psi_{a,\pm}$. Due to (6.8) we may choose $a = 0$. Using the asymptotic formula

$$(\mathcal{L}f)(z) = \sum_{l=0}^{m-1} \frac{f^{(l)}(0)}{z^{l+1}} + \mathcal{O}\big(|z|^{-m-1}\big), \tag{7.2}$$

$z \to \infty, |\arg z| \le \varphi < \pi/2$, which holds for bounded functions $f \in C^m([0,\infty))$ (cf. [5, p. 47]), (6.10a), and Lemma 6.2, we immediately obtain (7.1). The asymptotic formula for U' follows analogously from (6.10b) and the identity $\frac{d^l}{dt^l}\left((\pm i - t)\psi_{0,\pm}(t)\right)\big|_{t=0} = \pm i\psi_{0,\pm}^{(l)}(0) - l\psi_{0,\pm}^{(l-1)}(0)$. ∎

As a special case of the previous theorem we reproduce the asymptotic formula for the Hankel functions for large arguments (cf. [21]).

COROLLARY 7.2. *The Hankel functions $H_j^{(1)}$ of the first kind of order j satisfy*

$$H_j^{(1)}(z) = \sqrt{\frac{2}{\pi z}} e^{i(z - \frac{j\pi}{2} - \frac{\pi}{4})}\left(\sum_{k=0}^{m}\left\{\prod_{l=1}^{k} \frac{j^2 - (l-\frac{1}{2})^2}{-2ilz}\right\} + \mathcal{O}\big(|z|^{-m-1}\big)\right)$$

for $z \to \infty$ such that $|\arg z| \le \varphi < \frac{\pi}{2}$ ($m \ge 0$).

Proof. With $P(t) = e^{-at}t(\frac{1}{4} - j^2)$, $U_\infty^+ = \sqrt{\frac{2}{\pi}}\exp\left(-i\frac{j\pi}{2} - i\frac{\pi}{4}\right)$ we get $H_j^{(1)}(\rho) = \rho^{-1/2}U(\rho)$. Using the identity $\frac{1}{t(t-2i)} = \frac{1}{-2it}\sum_{l=0}^{\infty} t^l(2i)^{-l}$ and (6.4) we obtain

$$\begin{aligned}
\psi_{0,+}(0) &= \frac{j^2 - \frac{1}{4}}{-2i},\\
\psi_{0,+}^{(k+1)}(0) &= \left(\frac{k+1}{2i} + \frac{1}{2i(k+2)}\left(\frac{1}{4} - j^2\right)\right)\psi_{0,+}^{(k)}(0)\\
&= \frac{1}{-2i(k+2)}\left(j^2 - \left(k + \frac{3}{2}\right)^2\right)\psi_{0,+}^{(k)}(0).
\end{aligned}$$

Now the assertion follows from (7.1). ∎

8. Spectral properties of the Dirichlet-to-Neumann map. Let $\mathcal{H}_j$ denote the solution to (4.1) with $U_\infty^+ = 1$ and $U_\infty^- = 0$. For the Helmholtz equation in $\mathbb{R}^2$ we have $H_j^{(1)}(\rho) = \sqrt{\frac{2}{\pi\rho}}\exp(-i\frac{j\pi}{2} - i\frac{\pi}{4})\mathcal{H}_{2j}(\rho)$. A complete orthonormal system in $L^2(\Gamma_a)$ is given by $\varphi_j^a(a\hat{x}) := a^{-\frac{d-1}{2}}\varphi_j(\hat{x})$ with the eigenfunctions φ_j of $\tilde{\Delta}_{\hat{x}}$ introduced in section 4. We expect that the solution to (2.1) satisfying the pole condition and

the boundary condition $\mathrm{Tr}_{\Gamma_a} u = f$ ($f \in H^{1/2}(\Gamma_a)$) is

$$u(\rho\hat{x}) = \sum_{j=1}^{\infty} \langle f, \varphi_j^a \rangle \, \rho^{-\frac{d-1}{2}} \frac{\mathcal{H}_j(\rho)}{\mathcal{H}_j(a)} \varphi_j(\hat{x}) \tag{8.1}$$

for $\rho \geq a$ and $\hat{x} \in S^{d-1}$. Since the Dirichlet-to-Neumann map $\mathrm{DtN} : H^{1/2}(\Gamma_a) \to H^{-1/2}(\Gamma_a)$ satisfies $(\mathrm{DtN} f)(\rho\hat{x}) = \frac{\partial}{\partial\rho} u(\rho\hat{x})|_{\rho=a}$, this leads to the definition

$$(\mathrm{DtN} f)(\rho\hat{x}) := \sum_{j=1}^{\infty} \mathrm{dtn}(\lambda_j) \, \langle f, \varphi_j \rangle \, \varphi_j(\hat{x}) \tag{8.2}$$

with the eigenvalues

$$\mathrm{dtn}(\lambda_j) = \frac{\left(\rho^{-\frac{d-1}{2}} \mathcal{H}_j(\rho)\right)' \big|_{\rho=a}}{a^{-\frac{d-1}{2}} \mathcal{H}_j(a)} = \frac{\mathcal{H}_j'(a)}{\mathcal{H}_j(a)} - \frac{d-1}{2a}. \tag{8.3}$$

The Sobolev norm on Γ_a of index $s \in \mathbb{R}$ is given by

$$\|f\|^2_{H^s(\Gamma_a)} = \|(I - \Delta_{\Gamma_a})^{s/2} f\|^2_{L^2(\Gamma_a)} \sim \sum_{j=1}^{\infty} (1 - \lambda_j)^s \, |\langle f, \varphi_j^a \rangle|^2$$

(cf. [20, Chap. 4]). Hence, properties 1–3 in Proposition 3.1 are equivalent to

$$|\mathrm{dtn}(\lambda_j)| = \mathcal{O}\left(\sqrt{|\lambda_j|}\right), \qquad j \to \infty, \tag{8.4a}$$

$$\mathrm{Re}(-\mathrm{dtn}(\lambda_j) + l_j) \geq 0 \qquad \text{for some sequence } |l_j| = \mathrm{o}\left(\sqrt{|\lambda_j|}\right), \tag{8.4b}$$

$$\mathrm{Im}\, \mathrm{dtn}(\lambda_j) > 0 \qquad \text{for all } j. \tag{8.4c}$$

LEMMA 8.1. *Let U satisfy the assumptions of sections 5–7, and let $U_\infty^- = 0$. Then*

$$\mathrm{Im}\, U'(\rho)\overline{U(\rho)} = \left|U_\infty^+\right|^2 \qquad \textit{for all } \rho \geq a. \tag{8.5}$$

Proof. Set $\tilde{p}(a + r) := (\mathcal{L}P)(r)$. Taking the imaginary part of

$$\begin{aligned} 0 &= \int_a^\rho (U'' + (1 + \tilde{p})U) \, \overline{U} \, \mathrm{d}\rho_1 \\ &= U'(\rho)\overline{U(\rho)} - U'(a)\overline{U(a)} + \int_a^\rho \left(-|U'|^2 + (1 + \tilde{p}) \, |U|^2\right) \mathrm{d}\rho_1 \end{aligned}$$

yields $\mathrm{Im}\, U'(\rho)\overline{U(\rho)} = \mathrm{Im}\, U'(a)\overline{U(a)} = \text{const}$. The constant can be evaluated using Theorem 7.1 by taking the limit $\rho \to \infty$. ∎

Equation (8.5) with $\rho = a$ implies (8.4c) after dividing by $|U(a)|^2$. Next, we will prove (8.4a) and (8.4b). Let $\nu_j = \sqrt{-\lambda_j}$, and let $\psi_{\nu,a,+}$ denote the solution to (6.2a) with $P(t) = \check{p}_a(t) - \nu_j^2 t e^{-at}$. Since $\lambda_j \to -\infty$ as $j \to \infty$, it follows that $\nu_j \to \infty$. For looking at this limit process, we may assume w.l.o.g. that $p_2 = \check{p}_a'(0) = 0$ by setting $\nu_j = \sqrt{-p_2 - \lambda_j}$. Multiplying (6.2a) by $t(t-2i)$, applying the Laplace transform, and

using the identity $\mathcal{L}(\int_0^t f(t-t_1)g(t_1)\,\mathrm{d}t_1) = (\mathcal{L}f)\cdot(\mathcal{L}g)$ yields the ordinary differential equation

$$\left(\partial_z^2 + 2i\partial_z + p(z) - \nu_j^2 z^{-2}\right) v(z;\nu_j) = 0 \tag{8.6}$$

for $v(z;\nu_j) := 1 + (\mathcal{L}\psi_{\nu,0,+})(z)$. Here and in the following we use the variables $z = \rho + i\sigma$ with $\rho, \sigma \in \mathbb{R}$. Since

$$\mathcal{H}_j(z) = e^{iz} v(z;\nu_j) \tag{8.7}$$

due to (6.10a), (8.6) can alternatively be derived immediately from (4.1).

In this section f' denotes the usual derivative of a holomorphic function f, whereas $\dot{f}$ denotes the partial derivative of f with respect to σ. By the chain rule, $\dot{f} = if'$, so $-\ddot{v} + 2\dot{v} + (p - \nu^2 z^{-2})v = 0$, where the argument (z) of p and the arguments (z,ν) of v have been omitted. Hence, the logarithmic derivative $\chi(z;\nu) := \frac{\dot{v}(z;\nu)}{v(z;\nu)}$ satisfies the Riccati differential equation

$$\dot{\chi}(z;\nu) + \chi^2(z;\nu) - 2\chi(z;\nu) = p(z) - \nu^2 z^{-2}. \tag{8.8}$$

It follows from Plancherel's theorem and (6.9) that

$$\int_{-\infty}^{\infty} |v(\rho + i\sigma;\nu) - 1|^2 \,\mathrm{d}\sigma = \frac{1}{2\pi}\|\psi_{\nu,\rho,+}\|_{L^2}^2 < \infty,$$
$$\int_{-\infty}^{\infty} |\dot{v}(\rho + i\sigma;\nu)|^2 \,\mathrm{d}\sigma = \frac{1}{2\pi}\|it\psi_{\nu,\rho,+}\|_{L^2}^2 < \infty.$$

Therefore, the Lebesgue measure of the sets $A_\epsilon(\rho,\nu) := \{\sigma : |v(\rho+i\sigma)-1| > \epsilon \text{ or } |\dot{v}(\rho+i\sigma)| > \epsilon\} < \infty$ is finite for all $\epsilon > 0$. Hence, for all $\rho \geq a$ and all $\nu \geq 0$ there exists a sequence σ_l such that $\sigma_l \notin A_{1/l}(\rho,\nu)$ and $\sigma_l > l$. This implies

$$\lim_{l\to\infty} \chi(\rho + i\sigma_l;\nu) = 0. \tag{8.9}$$

We now construct an approximation to $\chi(\rho + i\sigma;\nu)$ for $\sigma \geq 0$ by formal computations and then prove its validity. We rewrite (8.8) as $\dot{\chi} = -(\chi - 1 + \gamma_1)(\chi - 1 - \gamma_1)$ with $\gamma_1(z;\nu) := \sqrt{1 + p(z) - \nu^2 z^{-2}}$. Here and in the following we choose the negative real axis as the branch cut of the square root function. Neglecting the term $\dot{\chi}$ yields the two possible approximations $1 + \gamma_1$ and $1 - \gamma_1$. Only the latter of these approximations has the right behavior as $\sigma \to \infty$. The "error function" $\Delta_1 := \chi - 1 + \gamma_1$ satisfies the differential equation

$$\dot{\Delta_1} = \dot{\gamma}_1 - (\Delta_1 - 2\gamma_1)\Delta_1. \tag{8.10}$$

Since this equation has the same structure as (8.8), we can apply the same procedure as above to (8.10) and hopefully get a better approximation to χ. This process may be repeated recursively as follows: Set $\gamma_0 := 1$ and assume we have constructed a function γ_j $(j = 1, 2, \dots)$ such that

$$\chi = 1 - \gamma_j + \Delta_j, \tag{8.11}$$

where Δ_j satisfies the differential equation

$$\dot{\Delta_j} = -(\Delta_j - 2\gamma_j)\Delta_j + \dot{\gamma}_j - \dot{\gamma}_{j-1}. \tag{8.12}$$

This equation can be rewritten as $\dot{\Delta}_j = -(\Delta_j - \gamma_j - \gamma_{j+1})(\Delta_j - \gamma_j + \gamma_{j+1})$ with

$$\gamma_{j+1} := \sqrt{\gamma_j^2 + \dot{\gamma}_j - \dot{\gamma}_{j-1}}. \tag{8.13}$$

The function $\Delta_{j+1} := \Delta_j - \gamma_j + \gamma_{j+1}$ satisfies (8.11) and (8.12) with j replaced by $j+1$.

It turns out that the approximation of order $j = 2$ is the lowest that is sufficient for our purposes. In the appendix we establish the following bounds on $\Delta_2 = \chi - 1 + \gamma_2$.

LEMMA 8.2. *Given $0 < a < A < \infty$ there exist constants $\Gamma, N > 0$ such that for all $\rho \in [a, A]$ and all $\nu \geq N$*

$$|\Delta_2(\rho + i\sigma; \nu)| \leq \begin{cases} 2, & 0 \leq \sigma < \Gamma/\nu, \\ \Gamma/(\sigma\nu), & \Gamma/\nu \leq \sigma < \nu, \\ \Gamma/\sigma^2, & \nu \leq \sigma. \end{cases} \tag{8.14}$$

Moreover,

$$\gamma_2(\rho + i\sigma; \nu)^2 = 1 - \frac{\nu^2}{(\rho + i\sigma)^2}\left(1 + \mathcal{O}\left(\frac{1}{\nu}\right)\right) \tag{8.15}$$

as $\nu \to \infty$ uniformly for $\rho \in [a, A]$ and $\sigma \geq 0$.

It follows from (8.7) that $\frac{\mathcal{H}_j'(z)}{\mathcal{H}_j(z)} = i + \frac{v'(z;\nu_j)}{v(z;\nu_j)} = i(1 - \chi(z;\nu_j))$. Using (8.11), (8.14), and (8.15) we obtain

$$\frac{\mathcal{H}_j'(z)}{\mathcal{H}_j(z)} = i(\gamma_2(z;\nu_j) - \Delta_2(z;\nu_j)) = -\frac{\nu_j}{z} + \mathcal{O}(1) \tag{8.16}$$

as $j \to \infty$, which holds uniformly for z satisfying $\operatorname{Re} z \in [a, A]$ and $\operatorname{Im} z \in [0, S]$ for any $S \geq 0$. For $z = a$ this implies (8.4a) and (8.4b).

COROLLARY 8.3. *Given $a < R_2 < \infty$ and $S \geq 0$, there exist constants $C, N > 0$ such that*

$$\left|\frac{\mathcal{H}_j^{(l)}(\rho + i\sigma)}{\mathcal{H}_j(a + ib)}\right| \leq C\left(\frac{\nu_j}{|\rho + i\sigma|}\right)^l \left|\frac{a + ib}{\rho + i\sigma}\right|^{\nu_j} \tag{8.17}$$

for all $\nu_j \geq N$, $a \leq \rho \leq R_2$, $0 \leq b, \sigma \leq S$, and $l = 0, 1, 2$.

Proof. It follows from (8.16) that

$$\frac{\mathcal{H}_j(\rho + i\sigma)}{\mathcal{H}_j(a + ib)} = \exp\left(\int_{a+ib}^{\rho+i\sigma} \frac{\mathcal{H}_j'(\zeta_1)}{\mathcal{H}_j(\zeta_1)}\,\mathrm{d}\zeta_1\right) = \left(\frac{a + ib}{\rho + i\sigma}\right)^{\nu_j} \exp(\mathcal{O}(1)).$$

This implies (8.17) for $l = 0$. Together with (8.16) we obtain (8.17) for $l = 1$. The case $l = 2$ follows from differential equation (4.1). ∎

Let us summarize our results.

THEOREM 8.4. *For $f \in H^{1/2}(\Gamma_a)$ there exists a unique solution u to (2.1) in $\{x : |x| > a\}$ satisfying the pole condition and the boundary condition $\operatorname{Tr} u = f$ on Γ_a. u is given by the series (8.1), which converges uniformly on compact subsets of $\{x : |x| > a\}$ together with all its term-by-term derivatives of order ≤ 2. The corresponding Dirichlet-to-Neumann $\mathrm{DtN} f := \frac{\partial u}{\partial \nu}\big|_{\Gamma_a}$ is given by (8.2). It satisfies the assumptions of Proposition 3.1. Consequently, the variational problem (3.1) has a*

unique solution, which can be to extended to a solution of (2.1) *in the exterior domain such that the pole condition is satisfied.*

Proof. Assume that u is a solution for $f = 0$. We apply Lemma 8.1 to the Fourier modes U_j. Due to the pole condition we have $U_{j,\infty}^- = 0$. Since $U_j(a) = 0$, it follows from (8.5) that $U_{j,\infty}^+ = 0$. Corollary 6.5 implies that U_j has vanishing Cauchy data $U_j(a) = U_j'(a) = 0$. Hence $U_j = 0$. This proves uniqueness.

Convergence of the series (8.1) and its term-by-term derivatives as well as the series (8.2) follow from Corollary 8.3 and the estimates

$$\|\varphi_j\|_{C^l} \le C\|\varphi_j\|_{H^{l+d/2}} \le C\sqrt{1-\lambda_j}^{l+d/2} \tag{8.18}$$

($l = 0, 1, \dots$) on the eigenfunctions φ_j derived from Sobolev's embedding theorem on S^{d-1} (cf. [20, sect. 4.3]). Note that no division by zero can occur in the series (8.1) and (8.2) due to (8.5) since $\mathcal{H}_j(a) = 0$ would imply $\mathcal{H}_{j,\infty}^+ = 0$, which contradicts $\mathcal{H}_{j,\infty}^+ = 1$.

The assumptions of Proposition 3.1 have been established above using the equivalent formulation (8.4). The fact that we can extend the solution u^{int} to (3.1) by setting $f = \mathrm{Tr}_{\Gamma_a} u^{\mathrm{int}}$ follows from the Cauchy–Kovalevskaya theorem and elliptic regularity results. ∎

Finally, we establish an estimate for $|\mathcal{H}_j(a)|$ for large j. For the special case of Hankel functions it agrees with a well-known formula, which can be derived from the series representation of the Hankel functions (cf. [2, 21]).

PROPOSITION 8.5. *For any $a > a_p$ we have*

$$|\mathcal{H}_j(a)| = \exp\left(\nu_j \ln\frac{2\nu_j}{ea} + \mathcal{O}(\ln \nu_j)\right), \qquad j \to \infty. \tag{8.19}$$

Proof. It follows from the definition of χ and σ_l before (8.9) that

$$1 = \lim_{l\to\infty} |v(a + i\sigma_l; \nu_j)| = \exp\left(\mathrm{Re}\int_0^\infty \chi(a + i\sigma; \nu_j)\,\mathrm{d}\sigma\right)|v(a; \nu_j)|,$$

i.e., $|\mathcal{H}_j(a)| = \exp(-\mathrm{Re}\int_0^\infty \chi(a+i\sigma;\nu_j)\,\mathrm{d}\sigma)$. By virtue of Lemma 8.2, $\mathrm{Re}\int_0^\infty \Delta_2(a + i\sigma;\nu)\,\mathrm{d}\sigma = \mathcal{O}\big(\nu^{-1}\ln\nu\big)$ as $\nu \to \infty$. It can be seen from (8.15) that there exists a constant $C > 0$ such that $1 - \mathrm{Re}\,\gamma_2(a + i\sigma;\nu) \le 0$ and $1 - \mathrm{Re}\,\gamma_2 = (1 - \mathrm{Re}\sqrt{1-(\nu/z)^2})(1 + \mathcal{O}\big(\nu^{-1}\big))$ uniformly for $\sigma \ge C/\nu$ as $\nu \to \infty$. Moreover, we have $\int_0^{C/\nu} \mathrm{Re}\,|\gamma_2(a + i\sigma;\nu)|\,\mathrm{d}\sigma = \mathcal{O}(1)$. Hence,

$$\begin{aligned}
&\int_0^\infty \mathrm{Re}\,\chi(a + i\sigma;\nu)\,\mathrm{d}\sigma \\
&\quad= \int_{C/\nu}^\infty \left(1 - \mathrm{Re}\sqrt{1 - \frac{\nu^2}{(a+i\sigma)^2}}\right)\mathrm{d}\sigma\left(1 + \mathcal{O}\left(\frac{1}{\nu}\right)\right) + \mathcal{O}(1)\,.
\end{aligned}$$

Finally,

$$\begin{aligned}
&\int_{C/\nu}^\infty \left(1 - \mathrm{Re}\sqrt{1 - \frac{\nu^2}{(a+i\sigma)^2}}\right)\mathrm{d}\sigma = \mathrm{Re}\int_{a+iC/\nu}^{a+i\infty}\left(1 - \sqrt{1-\frac{\nu^2}{z^2}}\right)\frac{\mathrm{d}z}{i} \\
&= \mathrm{Re}\left(iz\left(-1 + \sqrt{1-\frac{\nu^2}{z^2}}\right) + \nu\ln\left(\frac{\nu}{z} - i\sqrt{1-\frac{\nu^2}{z^2}}\right)\right)\Big|_{z=a+iC/\nu}^{z=a+i\infty} \\
&= \nu - \nu\ln\frac{2\nu}{a} + \mathcal{O}(1)\,, \qquad \nu \to \infty.
\end{aligned}$$

This completes the proof. ∎

9. Equivalence to Sommerfeld's radiation condition. Crucial tools in the proofs of this section are the following uniform estimates of the cut functions.

LEMMA 9.1. *There exist constants $C, N \geq 0$ such that the estimates*

$$|\psi_{\nu,a,+}(t)| \leq C\nu^2 e^{-t(a-a_p)} \left(\frac{|\sqrt{t} + \sqrt{t-2i}|}{\sqrt{2}} \right)^{2\nu}, \tag{9.1a}$$

$$|\psi'_{\nu,a,+}(t)| \leq C \frac{\nu^3 e^{-t(a-a_p)}}{\sqrt{t|t-2i|}} \left(\frac{|\sqrt{t} + \sqrt{t-2i}|}{\sqrt{2}} \right)^{2\nu} \tag{9.1b}$$

hold true for all $t > 0$ and all $\nu \geq N$. If $p = 0$, then (9.1) is valid with $a_p = 0$, $C = \frac{1}{2}$, and $N = \sqrt{2}$.

Proof. Due to (6.8) it suffices to prove (9.1) for $a = 0$. Set $\check{p}_0(t) := e^{at}\check{p}_a(t)$ and recall that we have assumed w.l.o.g. that $\check{p}'_0(0) = 0$. Multiplying (6.2a) by $t(t-2i)$, differentiating twice, and dividing by $t(t-2i)$ yields the integrodifferential equation

$$\begin{aligned} \psi''_{\nu,0,+}(t) = {} & \frac{\nu^2 - 2}{t(t-2i)} \psi_{\nu,0,+}(t) - 4\frac{t-i}{t(t-2i)} \psi'_{\nu,0,+}(t) \\ & - \int_0^t \frac{\check{p}''_0(t-t_1)}{t(t-2i)} \psi_{\nu,0,+}(t_1)\, \mathrm{d}t_1 - \frac{\check{p}''_0(t)}{t(t-2i)}. \end{aligned} \tag{9.2}$$

Here $P(t) = -\nu^2 t + \check{p}_0(t)$ in (6.2a). We will derive bounds on the function

$$y(t) := \begin{pmatrix} y_1(t) \\ y_2(t) \end{pmatrix} = \begin{pmatrix} \psi_{\nu,0,+}(t) \\ \zeta_\nu(t)^{-1} \psi'_{\nu,0,+}(t) \end{pmatrix},$$

where $\zeta_\nu(t) := \frac{\sqrt{\nu^2-2}}{\sqrt{t(t-2i)}}$. The function ζ_ν is chosen such that both components of y have approximately the same size, i.e., such that ζ_ν approximates the logarithmic derivative $\psi'_{\nu,0,+}/\psi_{\nu,0,+}$. Using (9.2) and $\operatorname{Re}(\psi_{\nu,0,+}\overline{\psi'_{\nu,0,+}}) = \operatorname{Re}(\overline{\psi_{\nu,0,+}}\psi'_{\nu,0,+})$ we get

$$\begin{aligned} \frac{1}{2}\frac{d}{dt}|y(t)|^2 = {} & \operatorname{Re}\left(\left(1 + \frac{\zeta_\nu^2}{|\zeta_\nu|^2}\right) \psi_{\nu,0,+}\overline{\psi'_{\nu,0,+}} - 3\frac{t-i}{t(t-2i)} \frac{|\psi'_{\nu,0,+}|^2}{|\zeta_\nu|^2} \right) \\ & - \operatorname{Re}\left(\frac{\check{p}''_0(t)}{t(t-2i)} \frac{\overline{\psi'_{\nu,0,+}}}{|\zeta_\nu|^2} + \int_0^t \frac{\check{p}''_0(t-t_1)}{t(t-2i)} \psi_{\nu,0,+}(t_1)\, \mathrm{d}t_1 \frac{\overline{\psi'_{\nu,0,+}}}{|\zeta_\nu|^2} \right). \end{aligned} \tag{9.3}$$

Using the identity $|1 + z^2| = 2\operatorname{Re} z$ with $z = \zeta_\nu/|\zeta_\nu|$ and the inequalities $2|ab| \leq |a|^2 + |b|^2$ and $\operatorname{Re}\zeta_\nu > 0$ we obtain

$$\left|1 + \frac{\zeta_\nu^2}{|\zeta_\nu|^2}\right| \cdot \left|\psi_{\nu,0,+}\overline{\psi'_{\nu,0,+}}\right| \leq \operatorname{Re}(\zeta_\nu) \left(|y_1|^2 + |y_2|^2\right).$$

Moreover, note that $\operatorname{Re}\frac{t-i}{t(t-2i)} = \frac{2+t^2}{t(t^2+4)} > 0$. If $p = 0$, this implies $\frac{1}{2}\frac{d}{dt}|y(t)|^2 \leq \operatorname{Re}(\zeta_\nu(t))|y(t)|^2$ and hence, by Gronwall's lemma,

$$|y(t)|^2 \leq \exp\left(2\int_0^t \operatorname{Re}\zeta_\nu(t_1)\, \mathrm{d}t_1 \right) |y(0)|^2.$$

Here $|y(0)| = |\psi_{\nu,0,+}(0)| = \frac{1}{2}\nu^2$ due to (6.4a). Using the indefinite integral $\int \big(t(t-2i)\big)^{-1/2}\,\mathrm{d}t = 2\ln(\sqrt{t}+\sqrt{t-2i})$ and the estimate $\sqrt{\nu^2-2} < \nu$ for $\nu \geq \sqrt{2}$, we obtain the assertion for the case $p = 0$.

Next we are going to derive a bound on $|y(t)|$ for $t \leq 1$ and general p. The inequality $-x^2 + 2xy - y^2 \leq 0$ for $x, y \in \mathbb{R}$ yields

$$-3\frac{2+t^2}{\nu^2|t-2i|}|\psi'_{\nu,0,+}|^2 + \frac{|\check{p}_0''(t)|}{\nu^2}|\psi'_{\nu,0,+}| \leq \frac{|t-2i|}{12(2+t^2)}\frac{|\check{p}_0''(t)|^2}{\nu^2}.$$

Moreover, $\int_0^t |\frac{\check{p}_0''(t-t_1)}{t(t-2i)}\psi_{\nu,0,+}(t_1)|\,\mathrm{d}t_1 \leq C\max_{0\leq t_1\leq t|}|y_1(t_1)|$ for $0 \leq t \leq 1$. Hence, (9.3) implies

$$\frac{1}{2}\frac{d}{dt}|y(t)|^2 < \mathrm{Re}(\zeta_\nu(t))|y(t)|^2 + \frac{C}{\nu^2} + \frac{C}{\nu}\max_{0\leq t_1\leq t}|y(t_1)|^2 \tag{9.4}$$

with a constant C independent of ν. Let $\varphi(t)$ be the solution to the initial value problem

$$\frac{1}{2}\varphi'(t) = \left(\frac{C}{\nu} + \mathrm{Re}(\zeta_\nu(t))\right)\varphi(t) + \frac{C}{\nu^2}, \qquad \varphi(0) = |y(0)|^2. \tag{9.5}$$

We claim that $|y(t)|^2 < \varphi(t)$ for $0 < t \leq 1$. Assume on the contrary that the set $M := \{0 < t \leq 1 : |y(t)|^2 \geq \varphi(t)\}$ is not empty, and let $t_* := \inf M$. Then $t_* > 0$ since $\frac{d}{dt}|y(0)|^2 < \varphi'(0)$. Moreover, it follows from the definition of t_* that $\varphi'(t_*) \leq \frac{d}{dt}|y(t_*)|^2$. On the other hand, $\max_{0\leq t\leq t_*}|y(t)|^2 \leq \max_{0\leq t\leq t_*}\varphi(t) = \varphi(t_*)$. Hence, $\frac{d}{dt}|y(t_*)|^2 < \varphi'(t_*)$ due to (9.4) and (9.5). This is a contradiction. Hence, $|y(t)|^2 < \varphi(t)$ for $0 < t \leq 1$. From the explicit solution

$$\begin{aligned}\varphi(t) = \exp\left(\int_0^t 2\left(\frac{C}{\nu} + \mathrm{Re}\,\zeta_\nu(t_2)\right)\mathrm{d}t_2\right)|y(0)|^2 \\ + \frac{2C}{\nu^2}\int_0^t \exp\left(\int_{t_1}^t 2\left(\frac{C}{\nu} + \mathrm{Re}\,\zeta_\nu(t_2)\right)\mathrm{d}t_2\right)\mathrm{d}t_1\end{aligned}$$

it follows that $\varphi(t) \leq C\nu^4\exp(2ta_p + \int_0^t 2\,\mathrm{Re}\,\zeta_\nu(t_2)\,\mathrm{d}t_2)$. This implies (9.1) for $0 < t \leq 1$.

Now we will prove (9.1) for $t \geq 1$. We may assume $|y(t)| \neq 0$. Otherwise (9.1) is trivially satisfied at t, and we have to apply the following argument separately on all intervals where $|y|$ does not vanish. Dividing (9.3) by $|y(t)|$ and using (4.4a) with $k = 2$ we obtain

$$|y(t)|' = \frac{1}{2|y(t)|}\frac{d}{dt}|y(t)|^2 \leq \mathrm{Re}(\zeta_\nu(t))|y(t)| + \frac{C}{t|(t-2i)\zeta_\nu(t)|}\eta(t)$$

with $\eta(t) := e^{a_p t}(1 + \int_0^t e^{-a_p t_1}|y(t_1)|\,\mathrm{d}t_1)$. Inserting the identities

$$|y(t)| = e^{a_p t}\left\{e^{-a_p t}\eta(t)\right\}' = \eta'(t) - a_p\eta(t), \tag{9.6a}$$

$$|y(t)|' = \eta''(t) - a_p\eta'(t) \tag{9.6b}$$

and using the estimate $\frac{C}{t|(t-2i)\zeta_\nu(t)|} \leq a_p\,\mathrm{Re}\,\zeta_\nu(t)$, which holds for all $t \geq 1$ and ν sufficiently large, we obtain $\eta'' \leq (a_p + \mathrm{Re}\,\zeta_\nu)\,\eta'$. This implies $\eta'(t) \leq \eta'(1)\exp(a_p(t-$

$1) + \int_1^t \operatorname{Re}\zeta_\nu(t_1)\,\mathrm{d}t_1)$ due to Gronwall's lemma. Now it follows from (9.6a) and (9.1) for $t = 1$ that $|y(t)| \le Ce^{a_p t}(\frac{|1+\sqrt{1-2i}|}{\sqrt{2}})^{2\nu}$ for $t > 1$. ∎

COROLLARY 9.2. *For $k \in \{0, 1, \dots\}$ and $m \in \{0, 1\}$ there exist constants $C, \sigma > 0$ such that for all $a > a_p$ and all $\nu_j \ge N$*

$$\frac{\|t^k \psi^{(m)}_{\nu_j,a,+}\|_{L^1}}{|\mathcal{H}_j(a)|} \le \frac{C}{(a-a_p)^{k+1-m}} \exp\left(\nu_j\left(\sigma + \ln\frac{a}{a-a_p}\right)\right). \tag{9.7}$$

Proof. We use the estimate

$$\frac{|\sqrt{t}+\sqrt{t-2i}|}{\sqrt{2}} \le \begin{cases} \gamma\sqrt{t}, & t \ge 1, \\ \gamma, & 0 \le t < 1 \end{cases}$$

with $\gamma := \frac{1+\sqrt{5}}{\sqrt{2}}$. Using Stirling's formula $\Gamma(x+1) = \exp(x\ln\frac{x}{e} + \mathcal{O}(\ln x))$ as $x \to \infty$, we obtain

$$\begin{aligned}
&\int_0^\infty e^{-t(a-a_p)} \left(\frac{|\sqrt{t}+\sqrt{t-2i}|}{\sqrt{2}}\right)^{2\nu} t^k \,\mathrm{d}t \\
&\le \gamma^{2\nu} \int_0^\infty e^{-(a-a_p)t} t^{\nu+k} \,\mathrm{d}t + \gamma^{2\nu} \int_0^1 e^{-(a-a_p)t} \,\mathrm{d}t \\
&\le \gamma^{2\nu} \left((a-a_p)^{-\nu-k-1}\Gamma(\nu+k+1) + 1\right) \\
&\le \frac{C}{(a-a_p)^{k+1}} \exp\left(\nu\ln\gamma^2 - \nu\ln(a-a_p) + \nu\ln\frac{\nu+k}{e} + \mathcal{O}(\ln\nu)\right).
\end{aligned}$$

Together with (9.1a) and (8.19) this implies (9.7) for $m = 0$. The case $m = 1$ follows analogously from (9.1b) using $\sqrt{t|t-2i|} \ge t$. ∎

THEOREM 9.3. *Assume that u satisfies (2.1) in $\{x \in \mathbb{R}^d : |x| > a_*\}$ such that $U(a_*, \cdot) \in L^2(S^{d-1})$ and that $\operatorname{Res}_{-i} \hat{U}_{j,a_*} = 0$ for all j. Let a be sufficiently large such that $\sigma + \ln\frac{a_*}{a-a_p} < 0$. Then the following are true:*

1. *The functions*

$$u_\infty(\hat{x}) := \sum_j \frac{U_j(a)}{\mathcal{H}_j(a)} \varphi_j(\hat{x}), \tag{9.8a}$$

$$\Psi_a(t, \hat{x}) := \sum_j \frac{U_j(a)}{\mathcal{H}_j(a)} \psi_{\nu_j,a,+}(t)\varphi_j(\hat{x}) \tag{9.8b}$$

are well defined for all $t \ge 0$ and $\hat{x} \in S^{d-1}$. Moreover, given $m \in \{0, 1\}$ and $k, l \in \{0, 1, \dots\}$, there exists a constant $C > 0$ such that

$$\|u_\infty\|_{C^l(S^{d-1})} \le C\|U(a_*, \cdot)\|_{L^2}, \tag{9.9a}$$

$$\int_0^\infty t^k \left\| \frac{\partial^m}{\partial t^m} \Psi_a(t, \cdot) \right\|_{C^l(S^{d-1})} \mathrm{d}t \le C\|U(a_*, \cdot)\|_{L^2}, \tag{9.9b}$$

and the series (9.8a) and (9.8b) converge with respect to all of these norms.

2. *The formulas (2.7) and (2.9) hold true. Equation (2.7) may be differentiated any number of times both with respect to ρ and $\hat{x}$, and integration and differentiation may be interchanged.*

Proof. Due to (6.10a) the assumption $\operatorname{Res}_{-i} \hat{U}_{j,a_*} = 0$ implies that

$$U_j(\rho) = \frac{U_j(a_*)}{\mathcal{H}_j(a_*)} \mathcal{H}_j(\rho) \tag{9.10}$$

for all $\rho \geq a_*$. It follows from Corollary 8.3 that

$$|U_j(a)| = |U_j(a_*)| \left| \frac{\mathcal{H}_j(a)}{\mathcal{H}_j(a_*)} \right| \leq C \, |U_j(a_*)| \left(\frac{a_*}{a} \right)^{\nu_j}. \tag{9.11}$$

Choose J such that $\nu_j \geq N$ for $j \geq J$, N given in Lemma 9.1. Using Corollary 9.2 and the bound (8.18) we obtain

$$\begin{aligned} &\sum_{j \geq J} |U_j(a)| \, \|\varphi_j\|_{C^l(S^{d-1})} \frac{\|t^k \psi^{(m)}_{\nu_j,a,+}\|_{L^1}}{|\mathcal{H}_j(a)|} \\ &\leq C \sum_{j \geq J} \frac{(1+\nu_j^2)^{l/2+d/4}}{(a-a_p)^{k+1-m}} \exp\left(\nu_j \Big(\sigma + \ln \frac{a}{a-a_p} + \ln \frac{a_*}{a} \Big) \right) |U_j(a_*)| \,. \end{aligned} \tag{9.12}$$

Using Lemma 6.3 for $j < J$ and applying Cauchy's inequality yields (9.9b). (Note that the L^2-norm and the right-hand side of (9.9b) could be replaced by any positive or negative Sobolev norm.) Inequality (9.9a) follows analogously from (8.18), (8.19), and (9.11).

To prove (2.7) for fixed $\hat{x} \in S^{d-1}$, we set $\psi_{a,+} = \psi_{\nu_j,a,+}$ and $U^+_\infty = \frac{U_j(a)}{\mathcal{H}_j(a)} \varphi_j(\hat{x})$ in (6.10a). Then $U(\rho)$ in (6.10a) is given by $U_j(\rho)\varphi_j(\hat{x})$ due to (9.10). Now the assertion follows by summing up over j and using (9.9). The differentiability properties of (2.7) are shown analogously using (6.10b) instead of (6.10a) and replacing $\varphi_j(\hat{x})$ by a derivative of φ_j at $\hat{x}$. Equation (2.9) follows in the same manner from (6.2a) multiplied by U^+_∞. ∎

Note that u_∞ may be interpreted as a delta peak of the cut function Ψ_a at $t = 0$. In other words, the formulas (2.7) and (2.9) remain valid if we formally replace $\Psi_a(t, \hat{x})$ by $\Psi_a(t, \hat{x}) + \delta_0(t) u_\infty(\hat{x})$ and then set $u_\infty = 0$.

THEOREM 9.4. *A bounded solution u to the differential equation* (2.1) *satisfies the Sommerfeld radiation condition* (2.5) *if and only if it satisfies the pole condition.*

Proof. Let us first assume that u satisfies the Sommerfeld radiation condition (2.5), and let U be defined by (2.2). Then

$$\frac{\partial}{\partial \rho} U(\rho, \hat{x}) - \left(i + \frac{d-1}{2\rho} \right) U(\rho, \hat{x}) = \mathrm{o}(1), \qquad \rho \to \infty, \tag{9.13}$$

uniformly for $\hat{x} \in S^{d-1}$. Therefore, the Fourier coefficients $U_j(\rho) := \langle U(\rho, \cdot), \varphi_j \rangle$ satisfy

$$U_j'(\rho) - \left(i + \frac{d-1}{2\rho} \right) U_j(\rho) = \mathrm{o}(1), \qquad \rho \to \infty.$$

By virtue of Theorem 7.1 this is equivalent to $\operatorname{Res}_{-i} \hat{U}_{j,a} = 0$. It follows that $U_j(\rho) = U_j(a)\mathcal{H}_j(\rho)/\mathcal{H}_j(a)$. Here a is chosen such that the assumption of Theorem 9.3 is satisfied. A comparison of Fourier coefficients shows that $\hat{U}_a(s, \hat{x}) = \sum_j \frac{U_j(a)}{\mathcal{H}_j(a)} \varphi_j(\hat{x}) \hat{\mathcal{H}}_{j,a}(s)$

for $\operatorname{Re} s > 0$ and $\hat{x} \in S^{d-1}$. We claim that for $\hat{x} \in S^{d-1}$ a holomorphic extension of $\hat{U}_a(\cdot, \hat{x})$ to $\mathbb{C}\backslash S_i$ is given by the function

$$s \mapsto -e^{-ia} \left(\frac{u_\infty(\hat{x})}{i-s} + \int_0^\infty \frac{\Psi_a(t,\hat{x})}{i-t-s} \,\mathrm{d}t \right). \tag{9.14}$$

Due to the estimates (9.9) this function is well defined and holomorphic in $\mathbb{C}\backslash S_i$. To show that it coincides with $\hat{U}_a(s,\hat{x})$ for $\operatorname{Re} s > 0$, we use Proposition 6.6 and the identity $\operatorname{Res}_i \hat{\mathcal{H}}_{j,a} = e^{-ia}$, which follows from (6.7) and the definition of $\mathcal{H}_j$. The boundedness of $s \mapsto \int_{S^{d-1}} |\frac{\partial}{\partial s} \hat{U}_a(s,\hat{x})|^2 \,\mathrm{d}\hat{x}$ follows from (9.9b) using Cauchy's inequality.

Now assume that u satisfies the pole condition, and let $\hat{U}_a(\cdot,\hat{x})$ be defined by (2.3). Using a standard corollary to Lebesgue's dominated convergence theorem and the boundedness assumption in the pole condition, it follows that the Fourier coefficients $\hat{U}_{j,a}(s) := \langle \hat{U}_a(s,\cdot), \varphi_j \rangle$ satisfy $\operatorname{Res}_{-i} \hat{U}_{j,a} = 0$. Differentiating (2.7) once and using a partial integration we get

$$\begin{aligned} \frac{\partial}{\partial \rho} U(\rho,\hat{x}) - iU(\rho,\hat{x}) &= -\int_0^\infty e^{-t(\rho-a)} t \Psi_a(t,\hat{x}) \,\mathrm{d}t \\ &= -\frac{1}{\rho-a} \int_0^\infty e^{-t(\rho-a)} \frac{\partial}{\partial t} \left\{ t\Psi_a(t,\hat{x}) \right\} \,\mathrm{d}t. \end{aligned}$$

By virtue of (9.9b), the integral term on the right-hand side of this equation is uniformly bounded for $\hat{x} \in S^{d-1}$. Since U is also uniformly bounded, this implies (9.13), which is equivalent to (2.5). □

We mention that (2.6) holds true with u_∞ and Ψ_a defined by (9.8). This follows from the Sokhotski–Plemelj formula (cf. [6]) and the fact that the function (9.14) coincides with $\hat{U}_a(\cdot,\hat{x})$.

We have constructed a solution (u_∞, Ψ_a) to the system (2.9), (2.10) if $f(\hat{x}) = U(a,\hat{x})$ and if the assumptions of Theorem 9.3 are satisfied. Uniqueness of this solution follows from the uniqueness of the corresponding system for each Fourier mode.

Appendix. Proof of Lemma 8.2. We may assume w.l.o.g. that $\Delta_2(\rho+i\sigma) \neq 0$ for all $\rho \in [a,A]$ and $\sigma \in \mathbb{R}$. Otherwise, if $\Delta_2(\rho_0+i\sigma_0) = 0$, then $\Delta_2(\rho_0+i\sigma;\nu) = 0$ for all $\sigma \in \mathbb{R}$ due to the uniqueness of initial value problems for (8.12), and then (8.14) is trivially satisfied for $\rho = \rho_0$. Our proof is based on the observation that the function $\sigma \mapsto |\Delta_2(\rho+i\sigma;\nu)|$ is decreasing at the point σ if and only if $\partial_\sigma(|\Delta_2(\rho+i\sigma;\nu)|^2) \leq 0$, if and only if $\operatorname{Re}(\dot{\Delta}_2/\Delta_2)(\rho+i\sigma;\nu) \leq 0$ (divide by $|\Delta_2(\rho+i\sigma;\nu)|^2$). Due to (8.12), $\sigma \mapsto |\Delta_2(\rho+i\sigma;\nu)|$ is decreasing at σ if and only if $\Delta_2(\rho+i\sigma;\nu) \in G(\rho+i\sigma;\nu)$, where

$$G(z;\nu) := \left\{ \delta \in \mathbb{C} : \operatorname{Re}\left[-\delta + 2\gamma_2(z;\nu) + \frac{\dot{\gamma}_2(z;\nu) - \dot{\gamma}_1(z;\nu)}{\delta} \right] \leq 0 \right\}.$$

Introducing the variable x for the expression in brackets and solving a quadratic equation for δ shows that $G = G^+ \cup G^-$ with

$$G^\pm := \left\{ \left(\gamma_2 - \frac{x}{2}\right) \left(1 \pm \sqrt{1 + \frac{\dot{\gamma}_2 - \dot{\gamma}_1}{(\gamma_2 - x/2)^2}} \right) : \operatorname{Re} x \leq 0 \right\}.$$

For the following arguments we introduce the strips $S_\lambda := \{\rho+i\sigma : a \leq \rho \leq A, \sigma \geq \lambda\}$ ($\lambda \geq 0$) in the complex plane. Note that there exist constants $C, N > 0$ such that

$$\frac{1}{|z\gamma_1|} = \frac{1}{\nu |\sqrt{\nu^{-2} z^2 (1+p) - 1}|} = \begin{cases} \frac{C}{\nu}, & \sigma \leq \nu, \\ \frac{C}{\sigma}, & \sigma > \nu \end{cases} \tag{A.1}$$

for all $z \in S_0$ and all $\nu \geq N$ and that

$$\dot\gamma_1 = i\frac{\nu^2}{z^3\gamma_1}\left(1+\frac{z^3\dot p}{2\nu^2}\right). \tag{A.2}$$

As $\gamma_2^2 - 1 = \gamma_1^2 - 1 - \dot\gamma_1$, (8.15) follows from (A.1) and (A.2). Using this and $\gamma_2 = \frac{i\nu}{z}\sqrt{1-\nu^{-2}z^2+\mathcal{O}(\nu^{-1})}$, it can be shown that there exist constants $C, N > 0$ such that

$$|z|\operatorname{Re}\gamma_2(z) \geq \begin{cases} C\nu\sigma, & 0 \leq \sigma < 1, \\ C\nu, & 1 \leq \sigma < \nu, \\ C\sigma, & \nu \leq \sigma \end{cases} \tag{A.3}$$

for all $\nu \geq N$ and all $z \in S_0$. As $\gamma_2 = \gamma_1\sqrt{1+\frac{\dot\gamma_1}{\gamma_1^2}}$, we have

$$\dot\gamma_2 - \dot\gamma_1 = \dot\gamma_1\left(\sqrt{1+\frac{\dot\gamma_1}{\gamma_1^2}}-1\right) + \left(1+\frac{\dot\gamma_1}{\gamma_1^2}\right)^{-1/2}\left(\frac{\ddot\gamma_1}{\gamma_1} - 2\frac{\dot\gamma_1^2}{\gamma_1^2}\right).$$

Since $\frac{\dot\gamma_1}{\gamma_1^2} = \mathcal{O}\big(\frac{1}{\nu}\big)$ uniformly for $z \in S_0$ due to (A.1) and (A.2), we have

$$\dot\gamma_1\left(\sqrt{1+\frac{\dot\gamma_1}{\gamma_1^2}}-1\right) = \frac{1}{2}\left(\frac{\dot\gamma_1}{\gamma_1}\right)^2 + \mathcal{O}\left(\frac{\dot\gamma_1^3}{\gamma_1^4}\right) = \mathcal{O}\big(|z|^{-2}\big).$$

Moreover,

$$\frac{\ddot\gamma_1}{\gamma_1} = \frac{3\nu^2}{z^2(z\gamma_1)^2}\left(1+\frac{z^4\ddot p}{\nu^2}\right) - \frac{2i}{z^2}\left(\frac{\nu\dot\gamma_1}{\gamma_1^2}\right)\left(\frac{\nu}{z\gamma_1}\right)\left(1+\frac{z^3\dot p}{2i\nu^2}\right) = \frac{\mathcal{O}(1)}{z^2}$$

uniformly for $z \in S_0$, so

$$|\dot\gamma_2 - \dot\gamma_1| = \mathcal{O}\big(|z|^{-2}\big) \tag{A.4}$$

uniformly for $z \in S_0$. Hence,

$$\left|\frac{\dot\gamma_2-\dot\gamma_1}{(\gamma_2 - x/2)^2}\right| = \mathcal{O}\left(\frac{1}{|z|^2(\operatorname{Re}\gamma_2)^2}\right) = \begin{cases} \mathcal{O}\big((\nu\sigma)^{-2}\big), & 0 \leq \sigma < 1, \\ \mathcal{O}\big(\nu^{-2}\big), & 1 \leq \sigma < \nu, \\ \mathcal{O}\big(\sigma^{-2}\big), & \nu \leq \sigma \end{cases}$$

uniformly for $z \in S_0$ and $\operatorname{Re} x \leq 0$ (cf. (A.3)). Now the Taylor formula $\sqrt{1+\epsilon} = 1 + \epsilon/2 + \mathcal{O}\big(\epsilon^2\big)$ $(\epsilon \to 0)$ implies that there exist constants $\Gamma, N > 0$ such that

$$\begin{aligned} &\left|\left(\gamma_2 - \frac{x}{2}\right)\left(1-\sqrt{1+\frac{\dot\gamma_2-\dot\gamma_1}{(\gamma_2-x/2)^2}}\right)\right| \\ &= \left|\left(\gamma_2-\frac{x}{2}\right)\left(1-1-\frac{1}{2}\frac{\dot\gamma_2-\dot\gamma_1}{(\gamma_2-x/2)^2} + \mathcal{O}\left(\left|\frac{\dot\gamma_2-\dot\gamma_1}{(\gamma_2-x/2)^2}\right|^2\right)\right)\right| \\ &\leq \frac{1}{2}\left|\frac{\dot\gamma_2-\dot\gamma_1}{\operatorname{Re}\gamma_2}\right| + \mathcal{O}\left(\frac{|\dot\gamma_2-\dot\gamma_1|}{|\operatorname{Re}\gamma_2|^3}\right) \leq \begin{cases} \Gamma(\sigma\nu)^{-1}, & \Gamma/\nu \leq \sigma < \nu, \\ \Gamma/\sigma^2, & \nu \leq \sigma \end{cases} \end{aligned}$$

for all $\nu \geq N$, $z \in S_{\Gamma/\nu}$, and $\operatorname{Re} x \geq 0$. Performing an analogous computation for $G^+(z;\nu)$, we obtain that for $\nu \geq N$

$$G^-(z;\nu) \subset \begin{cases} \{\zeta : |\zeta| \leq \Gamma/(\sigma\nu)\}, & \Gamma/\nu \leq \sigma < \nu, \\ \{\zeta : |\zeta| \leq \Gamma/\sigma^2\}, & \nu \leq \sigma, \end{cases} \tag{A.5a}$$

$$G^+(z;\nu) \subset \{\zeta : \operatorname{Re}\zeta \geq 1\}, \qquad \Gamma/\nu \leq \sigma. \tag{A.5b}$$

Now we are going to show that (A.5) and (8.9) imply (8.14) for $z \in S_{\Gamma/\nu}$. Let $\rho_0 \in [a, A]$. By virtue of (8.9) and the fact that $\lim_{\sigma\to\infty}(1 - \gamma_2(\rho_0 + i\sigma;\nu)) = 0$ for all ν, there exists a sequence $\Gamma/\nu = \sigma_0 < \sigma_1 < \cdots$ such that $\lim_{l\to\infty}\sigma_l = \infty$ and $|\Delta_2(\rho_0+i\sigma_l;\nu)| < 1/(l+1)$ for $l \geq 1$. We may also arrange that $\partial_\sigma|\Delta_2(\rho_0+i\sigma_l;\nu)| < 0$. Then the maximum of the function $\sigma \mapsto |\Delta_2(\rho_0 + i\sigma;\nu)|$ on the interval $[\sigma_l, \sigma_{l+1}]$ is attained at the point $\sigma_l^* \in [\sigma_l, \sigma_{l+1})$, and $\partial_\sigma|\Delta_2(\rho_0+i\sigma_l^*;\nu)| \leq 0$, i.e., $\Delta(\rho_0+i\sigma_l^*;\nu) \in G(\rho_0+i\sigma_l^*;\nu)$. If $\Delta(\rho_0+i\sigma_0;\nu) \in G^+(\rho_0+i\sigma_0;\nu)$, then, due to (A.5b) and the choice of the σ_l's, there exists a largest $\tilde\sigma \in (\sigma_l^*, \sigma_{l+1})$ such that $|\Delta_2(\rho_0 + i\tilde\sigma;\nu)| = \frac{1}{2}$, and $\Delta_2(\rho_0 + i\tilde\sigma;\nu) \in G(\rho_0 + i\sigma_*;\nu)$ since $\partial_\sigma|\Delta(\rho_0 + i\tilde\sigma;\nu)| \leq 0$. This contradicts (A.5). Hence, $\Delta(\rho_0 + i\sigma_l^*;\nu) \in G^-(\rho_0 + i\sigma_l^*;\nu)$, and (8.14) follows from (A.5a).

It remains to show (8.14) for $0 \leq \sigma \leq \Gamma/\nu$. In this case, there exist constants $C, N > 0$ such that

$$\operatorname{Re}\frac{\dot\Delta_2}{\Delta_2} = -\operatorname{Re}\Delta_2 + 2\operatorname{Re}\gamma_2 + \operatorname{Re}\frac{\dot\gamma_2 - \dot\gamma_1}{\Delta_2} \geq -C$$

if $\Delta_2(z;\nu)$ is in the annulus $1 \leq |\Delta_2(z;\nu)| \leq 2$ and $\nu \geq N$ (cf. (A.3) and (A.4)). Since

$$|\Delta_2(\rho + i\sigma;\nu)| = \left|\Delta_2\left(\rho + i\frac{\Gamma}{\nu};\nu\right)\right| \exp\left(\int_{\Gamma/\nu}^{\sigma} \operatorname{Re}\frac{\dot\Delta_2(\rho + i\sigma_1;\nu)}{\Delta_2(\rho + i\sigma_1;\nu)}\,\mathrm{d}\sigma_1\right)$$

and since $|\Delta_2(\rho + i\Gamma/\nu;\nu)| \leq 1$, it follows that $|\Delta_2(\rho+i\sigma;\nu)| \leq \exp(C(\Gamma/\nu - \sigma)) \leq 2$ for $0 \leq \sigma \leq \Gamma/\nu$ and $\nu \geq \max(N, C\Gamma/\ln 2)$. □

WELL-POSEDNESS OF VORTEX SHEETS WITH SURFACE TENSION*

DAVID M. AMBROSE†

Abstract. We study the initial value problem for two-dimensional, periodic vortex sheets with surface tension. We allow the upper and lower fluids to have different densities. Without surface tension, the vortex sheet is ill-posed: it exhibits the well-known Kelvin–Helmholtz instability. In the linearized equations of motion, surface tension removes the instability. It has been conjectured that surface tension also makes the full problem well-posed. We prove that this conjecture is correct using energy methods. In particular, for the initial value problem for vortex sheets with surface tension with sufficiently smooth data, it is proved that solutions exist locally in time, are unique, and depend continuously on the initial data. The analysis uses two important ideas from the numerical work of Hou, Lowengrub, and Shelley. First, the tangent angle and arclength of the vortex sheet are used rather than Cartesian variables. Second, instead of a purely Lagrangian formulation, a special tangential velocity is used in order to simplify the evolution equations. A special case of the result is well-posedness of water waves with surface tension; this is the first proof (with surface tension) which allows the wave to overturn.

Key words. vortex sheet, surface tension, Kelvin–Helmholtz instability

1. Introduction.

The classical vortex sheet is the interface between two incompressible, inviscid, irrotational, density-matched two-dimensional fluids moving past each other, neglecting surface tension. In this situation, all of the vorticity is concentrated on the interface. At each time, the sheet can be viewed as a curve in the complex plane. The curve, z, is parameterized by a Lagrangian spatial variable, α. The curve evolves according to the Birkhoff–Rott integral (see page 141 of [Saf95]),

$$z_t^*(\alpha,t) = \frac{1}{2\pi i}\mathrm{PV}\int_{-\infty}^{\infty} \frac{\gamma(\alpha')}{z(\alpha,t)-z(\alpha',t)}\,d\alpha'. \tag{1.1}$$

The $*$ denotes complex conjugation; γ is the vortex sheet strength. Notice that γ is not a function of time. This problem has been well studied and has been found to be ill-posed in the usual sense (although it can be thought of as well-posed in analytic function spaces). In particular, it exhibits the well-known Kelvin–Helmholtz instability: in the linearization of the evolution equations about equilibrium, Fourier modes with high wave numbers grow without bound. Equation (1.1) neglects the effect of surface tension at the interface. Surface tension is a restoring force, and when surface tension is accounted for in the equations of motion, Fourier modes of high wave number remain bounded in the linearization. For this reason, it had been conjectured that surface tension makes the full problem well-posed [Bir62]. Taking this further, Beale, Hou, and Lowengrub demonstrated that even far from equilibrium, surface tension makes the linearized equations well-posed [BHL93]. Iguchi, Tanaka, and Tani have shown that the full problem is well-posed if the initial state is sufficiently close

to the flat equilibrium and if the interface height is a function of horizontal position [ITT97]. The present work removes these restrictions, proving that the full problem is well-posed even for large initial data, confirming Birkhoff's conjecture.

Hou, Lowengrub, and Shelley have efficiently computed vortex sheets with surface tension by treating the part of the evolution equations related to surface tension carefully [HLS97]. They recast the evolution equations in two important ways. First, they choose to compute dependent variables which are naturally related to the surface tension. In particular, surface tension enters the evolution equations in the form $\gamma_t = \frac{1}{\mathrm{We}}\kappa_\alpha$, where κ is the curvature of the vortex sheet and We is the Weber number. The Weber number is a dimensionless parameter that is inversely proportional to the surface tension; the case without surface tension corresponds to $\mathrm{We} = \infty$. (Recall that without surface tension, $\gamma_t = 0$.) To simplify this curvature term in the evolution equations, Hou, Lowengrub, and Shelley describe the curve by its tangent angle and arclength rather than by the Cartesian variable, z. We use the notation s for arclength and θ for the tangent angle the curve forms with the horizontal. The strength of this choice of variables lies in the relationship $\kappa = \theta_\alpha / s_\alpha$.

Second, Hou, Lowengrub, and Shelley observe that while the normal velocity of the vortex sheet must be obtained from (1.1), the same is not true of the tangential velocity. By adding an arbitrary tangential velocity, T, to the evolution of z, the shape of the curve is not changed (i.e., the tangential velocity only serves to reparameterize the curve). A careful choice of T essentially reduces the problem by one dependent variable by making s_α independent of α. With this choice of T, if the curve is initially parameterized by arclength (normalized so that α is between 0 and 2π), then it will always remain that way.

The choice of tangential velocity also changes the evolution equation for γ. In addition to simplifying the curvature term, it also introduces new terms proportional to $T - \mathbf{W} \cdot \hat{\mathbf{t}}$. Here, $\mathbf{W}$ is the real form of (1.1) and $\hat{\mathbf{t}}$ is the tangent vector to the curve. In the purely Lagrangian formulation of the problem, T was equal to $\mathbf{W} \cdot \hat{\mathbf{t}}$, so these terms did not appear.

The main conclusion of this paper is that the vortex sheet with surface tension is well-posed in Sobolev spaces. In particular, this means that given periodic initial conditions $z(\cdot, 0) \in H^r$ and $\gamma(\cdot, 0) \in H^{r-3/2}$ for r large enough, there is some interval of time in which a solution to the vortex sheet evolution equations exists. This solution is unique, has the same regularity as the initial conditions, and depends continuously on the initial data. We first prove this for the case in which the upper and lower fluids have the same density, and then for the case of arbitrary densities.

In the proof, we use ideas from the numerical work of Hou, Lowengrub, and Shelley. That is, we use their tangential velocity and analyze the evolution of θ and L, the length of one period of the vortex sheet, rather than z. This simplifies the analysis considerably since many of the leading terms in the evolution equations are linear as functions of θ and γ.

The analysis uses energy methods. We first form approximations to the three evolution equations by convolving parts of the equations with approximations to the Dirac δ function. We then show that solutions to these approximated equations exist by using the Picard theorem for differential equations on Banach spaces; this requires proving that the time derivatives in the approximated equations are Lipschitz continuous.

We then define an energy function, E, for the approximate solutions. The energy function is related to the Sobolev norms of θ and γ and has no clear physical inter-

pretation. Much of the difficulty in the problem is to find the proper definition of the energy function. Finding the correct energy balance between θ and γ is very much complicated by the nonlinearities in the evolution equations. After finding the correct form of the energy, we estimate its growth and find

$$\frac{dE}{dt} \leq C_1 \exp\{C_2 E\} \tag{1.2}$$

for some positive constants C_1 and C_2.

Proving this estimate requires understanding various integral operators (including some singular integral operators), as well as estimating nonlinear terms. Also, the terms with the highest number of spatial derivatives need to be handled specially. This is similar to the numerical work. For computational reasons, Hou, Lowengrub, and Shelley introduced a small-scale decomposition (SSD) of the problem [HLS94]. That is, they identified terms which were unstable at small spatial scales and computed them by an implicit method while the remaining terms were treated explicitly. Their decomposition was

$$\theta_t = \frac{2\pi^2}{L^2} H(\gamma_\alpha) + P,$$

$$\gamma_t = \frac{2\pi}{L\mathrm{We}} \theta_{\alpha\alpha} + Q.$$

H is the Hilbert transform; P and Q represent all the terms which were computed explicitly. An important difference between this work and that of Hou, Lowengrub, and Shelley lies in the SSD. The two terms they identified as the most important for computational reasons also need to be treated carefully in the energy estimates. We identify an additional term which is significant to the analysis. Unlike the two principal terms in the SSD, this term is nonlinear as a function of θ and γ. The new term appears in the γ_t equation and is a consequence of the choice of tangential velocity. We write the new decomposition for γ_t as

$$\gamma_t = \frac{2\pi}{L\mathrm{We}} \theta_{\alpha\alpha} + \frac{2\pi^2}{L^2} \gamma H(\gamma\theta_\alpha) + \widetilde{Q}.$$

This raises an interesting question about the computing: Is there a benefit to changing the SSD in the numerical method to include this nonlinear term?

The estimate (1.2) implies that solutions of the approximate equations exist on a time interval independent of the mollification parameter, and they are uniformly bounded during that time interval. Another estimate then implies that solutions of the approximate equations form a Cauchy sequence (for different values of the mollification parameter) and thus converge to a strong solution of the original system.

A consequence of the existence proof is that development of a singularity in finite time implies that either the vortex sheet must intersect itself or the energy must blow up. These are the very kinds of singularities observed in [HLS97]. In their computations, vortex sheets developed two kinds of singularities when the surface tension was small: roll-up of the sheet and curvature singularities. Curvature singularities were also found by Siegel in an approximation to the vortex sheet with surface tension [Sie95]. (Curvature singularities correspond to the energy blowing up.) We do not address here whether or not singularities actually occur; this is a topic for future research.

After proving well-posedness in the case of fluids of the same density, we then prove the same results in the case of arbitrary densities. The proof is not significantly different from the earlier case. A special case of this result is when the upper fluid has density zero; this is the case of water waves with surface tension. Neglecting surface tension, Wu has proved well-posedness of water waves in both two and three dimensions [Wu97], [Wu99]. Iguchi has proved well-posedness of water waves with surface tension, but only when the height of the wave is a function of horizontal position [Igu01]. There is no such restriction in this paper.

In section 2, we rewrite and mollify the evolution equations for the vortex sheet with surface tension in the density-matched case. In section 3, we then state several technical lemmas we will need which demonstrate the boundedness of some useful operators. In section 4, we prove a priori estimates on the growth of solutions to the mollified initial value problem. We use these a priori estimates in section 5 to demonstrate existence and uniqueness of solutions to first the mollified problem and then the nonmollified problem. In section 6, we extend this result to the case in which the two fluids have different densities.

2. Evolution equations. In this section, we first discuss various operators that we will use throughout the paper. We then discuss in some detail the evolution equations for the exact vortex sheet with surface tension. Finally, we will apply mollifiers to the evolution equations to obtain an approximated set of evolution equations.

2.1. The Hilbert transform and associated operators. We begin with background information on some operators that we will use. The Hilbert transform, H, of a function $f : \mathbb{R} \to \mathbb{R}$ is defined by

$$Hf(\alpha) = \frac{1}{\pi} \mathrm{PV} \int_{-\infty}^{\infty} \frac{f(\alpha')}{\alpha - \alpha'} \, d\alpha'. \tag{2.1}$$

In Fourier space, H is a multiplier; that is, $\mathcal{F}(Hf)(\xi) = -i\mathrm{sgn}(\xi)\mathcal{F}f(\xi)$, where $\mathcal{F}$ is the Fourier transform. This implies that H is bounded from L^2 to L^2, and in fact $\|Hg\|_{L^2} = \|g\|_{L^2}$ and $H^2 g = -g$ whenever $\mathcal{F}g(0) = 0$. We will be concerned with functions which are periodic, and we will not want to consider the Hilbert transform as an integral over the entire real line. For 2π-periodic f we can sum over periodic images in (2.1) (see page 167 of [AF97]) to get

$$Hf(\alpha) = \frac{1}{2\pi} \mathrm{PV} \int_{0}^{2\pi} f(\alpha') \cot \frac{1}{2}(\alpha - \alpha') \, d\alpha'. \tag{2.2}$$

The Hilbert transform commutes with differentiation. We will sometimes denote differentiation by a subscript, and sometimes by application of an operator D. For example, f_α and $D_\alpha f$ both denote the derivative of f with respect to α. We define the operator Λ to be a derivative followed by the Hilbert transform: $\Lambda = HD_\alpha$. In Fourier space, we have $\mathcal{F}\Lambda f(\xi) = 2\pi|\xi|\mathcal{F}f(\xi)$. This implies that

$$\left(\int f^2 + f\Lambda f \, d\alpha \right)^{1/2}$$

is an equivalent norm to $\|f\|_{1/2}$. Also, Λ is self-adjoint.

We will also frequently use commutators of certain operators. We define $[H, f]g$ to be $H(fg) - fH(g)$. This is typically a smoothing operator; details are discussed in Lemma 3.7 and Corollary 3.8.

2.2. The exact evolution equations. Consider any curve $z(\alpha,t) = x(\alpha,t) + iy(\alpha,t)$ in the complex plane satisfying $z(\alpha+2\pi,t) = z(\alpha,t) + 2\pi$. Give the curve periodic normal velocity U and periodic tangential velocity T. Call the unit tangent and normal vectors to the curve $\hat{\mathbf{t}}$ and $\hat{\mathbf{n}}$, respectively. The tangent angle that the curve forms with the horizontal, θ, satisfies $\theta = \arctan(y_\alpha/x_\alpha)$. The derivative of arclength satisfies $s_\alpha^2 = x_\alpha^2 + y_\alpha^2$. Differentiating these two equations in time, we find that the evolution equations for θ and s_α are

$$\theta_t = \frac{1}{s_\alpha} U_\alpha + \frac{T}{s_\alpha}\theta_\alpha, \tag{2.3}$$

$$s_{\alpha t} = T_\alpha - \theta_\alpha U. \tag{2.4}$$

Also, the length of one period of the curve is $L(t) = \int_0^{2\pi} s_\alpha d\alpha$. This implies the evolution equation

$$L_t = \int_0^{2\pi} s_{\alpha t}\, d\alpha = -\int_0^{2\pi} \theta_\alpha U\, d\alpha. \tag{2.5}$$

For the vortex sheet, the normal velocity must be given by $U = \mathbf{W}\cdot\hat{\mathbf{n}}$, where $\mathbf{W}$ is the complex conjugate of the Birkhoff–Rott integral (1.1) expressed as a real vector:

$$\mathbf{W}(\alpha) = \frac{1}{2\pi}\mathrm{PV}\int \gamma(\alpha')\frac{(-(y(\alpha)-y(\alpha')), x(\alpha)-x(\alpha'))}{(x(\alpha)-x(\alpha'))^2 + (y(\alpha)-y(\alpha'))^2}\, d\alpha'.$$

In the Lagrangian formulation, $\mathbf{W} = (x_t, y_t)$.

We have some freedom in choosing T, so we use this freedom to make $s_{\alpha t}$ independent of α. Following [HLS94], we set $s_{\alpha t}(\alpha,t) = L_t(t)/2\pi$ in (2.4). Integrating to solve for T, we have

$$T(\alpha,t) = \int_0^\alpha \theta_{\alpha'} U \mathrm{d}\alpha' + \frac{\alpha}{2\pi} L_t. \tag{2.6}$$

We have set $T(0,t) = 0$ for simplicity. Now, if the curve is initially parameterized so that $s_\alpha = L/2\pi$, it will remain that way.

The time derivative of the vortex sheet strength can be found by combining Bernoulli's equation for potential flow with the Laplace–Young condition for the pressure jump across the interface (the pressure jump is proportional to curvature). The derivation is a more general form of the derivation in [BMO82]; details can be found in [Amb02]. The resulting evolution equation is

$$\gamma_t = \frac{1}{\mathrm{We}} D_\alpha\left(\frac{\theta_\alpha}{s_\alpha}\right) + D_\alpha\left(\frac{(T - \mathbf{W}\cdot\hat{\mathbf{t}})\gamma}{s_\alpha}\right). \tag{2.7}$$

Before attempting any analysis, we rewrite the evolution equations. We will need the geometric identity

$$\hat{\mathbf{t}}_\alpha \cdot \hat{\mathbf{n}} = \theta_\alpha. \tag{2.8}$$

Also, the following calculation is useful many times:

$$\begin{aligned} D_\alpha(T - \mathbf{W}\cdot\hat{\mathbf{t}}) &= T_\alpha - \mathbf{W}_\alpha\cdot\hat{\mathbf{t}} - \mathbf{W}\cdot\hat{\mathbf{t}}_\alpha \\ &= \theta_\alpha U + \frac{L_t}{2\pi} - \mathbf{W}_\alpha\cdot\hat{\mathbf{t}} - (\mathbf{W}\cdot\hat{\mathbf{n}})(\hat{\mathbf{t}}_\alpha\cdot\hat{\mathbf{n}}) = \frac{L_t}{2\pi} - \mathbf{W}_\alpha\cdot\hat{\mathbf{t}}. \end{aligned} \tag{2.9}$$

We have used (2.8) to see an important cancellation between the two θ_α terms. We will see soon that the $\mathbf{W}_\alpha \cdot \hat{\mathbf{t}}$ term which remains is similar to the Hilbert transform of θ_α, so the smoothness of the terms that canceled is not exactly the issue. The presence of the Hilbert transform in the term that remains is critical.

We are ready to begin rewriting the system of evolution equations (2.3), (2.5), (2.7). We expand U_α in (2.3):

$$\theta_t = \frac{2\pi}{L}(\mathbf{W}\cdot\hat{\mathbf{n}})_\alpha + \frac{2\pi}{L}T\theta_\alpha = \frac{2\pi}{L}(\mathbf{W}_\alpha\cdot\hat{\mathbf{n}}) + \frac{2\pi}{L}(T - \mathbf{W}\cdot\hat{\mathbf{t}})\theta_\alpha. \tag{2.10}$$

We now rewrite γ_t, using $s_\alpha = L/2\pi$ and (2.9):

$$\gamma_t = \frac{2\pi}{L}\frac{\theta_{\alpha\alpha}}{\mathrm{We}} + \frac{2\pi}{L}\left(\frac{L_t}{2\pi} - \mathbf{W}_\alpha\cdot\hat{\mathbf{t}}\right)\gamma + \frac{2\pi}{L}(T - \mathbf{W}\cdot\hat{\mathbf{t}})\gamma_\alpha. \tag{2.11}$$

We finish rewriting θ_t and γ_t by simplifying $\mathbf{W}_\alpha\cdot\hat{\mathbf{n}}$ and $\mathbf{W}_\alpha\cdot\hat{\mathbf{t}}$. To do this, we switch from real to complex notation. Define $\Phi : \mathbb{R}^2 \to \mathbb{C}$ to be the mapping $(a,b)\mapsto a+ib$. We denote by $z = x + iy$ the image under this mapping of our dependent variables (x, y). The following are then true:

$$\Phi(\hat{\mathbf{t}}) = \frac{2\pi z_\alpha}{L}, \qquad \Phi(\hat{\mathbf{n}}) = \frac{2\pi i z_\alpha}{L}. \tag{2.12}$$

Furthermore, the formula for a dot product is

$$\mathbf{a}\cdot\mathbf{b} = \mathrm{Re}\left(\Phi(\mathbf{a})\Phi(\mathbf{b})^*\right). \tag{2.13}$$

Under this mapping, we have for $\mathbf{W}$

$$\Phi(\mathbf{W})^* = \frac{1}{2\pi i}\mathrm{PV}\int \frac{\gamma(\alpha')}{z(\alpha) - z(\alpha')}\, d\alpha'. \tag{2.14}$$

We rewrite this slightly:

$$\Phi(\mathbf{W})^* = \frac{1}{2\pi i}\mathrm{PV}\int \left(\frac{\gamma(\alpha')}{z_\alpha(\alpha')}\right)\frac{z_\alpha(\alpha')}{z(\alpha) - z(\alpha')}\, d\alpha'.$$

We are interested in non-self-intersecting curves such that $z(\alpha) - \alpha$ is 2π-periodic, which implies

$$\frac{\gamma(\alpha)}{z_\alpha(\alpha)}\mathrm{PV}\int \frac{z_\alpha(\alpha')}{z(\alpha) - z(\alpha')}\, d\alpha' = 0.$$

(This can be seen by taking a branch of the logarithm.) Subtracting this from $\Phi(\mathbf{W})^*$ and taking a derivative, we get

$$\begin{aligned}
\Phi(\mathbf{W})^*_\alpha &= \frac{1}{2\pi i}D_\alpha\mathrm{PV}\int \left(\frac{\gamma(\alpha')}{z_\alpha(\alpha')} - \frac{\gamma(\alpha)}{z_\alpha(\alpha)}\right)\frac{z_\alpha(\alpha')}{z(\alpha) - z(\alpha')}\, d\alpha' \\
&= \frac{1}{2\pi i}\mathrm{PV}\int \left(\frac{\gamma(\alpha')}{z_\alpha(\alpha')} - \frac{\gamma(\alpha)}{z_\alpha(\alpha)}\right)\frac{-z_\alpha(\alpha')z_\alpha(\alpha)}{(z(\alpha) - z(\alpha'))^2}\, d\alpha' \\
&= \frac{-z_\alpha(\alpha)}{2\pi i}\mathrm{PV}\int \left(\frac{\gamma(\alpha')}{z_\alpha(\alpha')} - \frac{\gamma(\alpha)}{z_\alpha(\alpha)}\right) D_{\alpha'}\left(\frac{1}{z(\alpha) - z(\alpha')}\right)\, d\alpha'.
\end{aligned}$$

We integrate this by parts to get

$$\Phi(\mathbf{W})^*_\alpha(\alpha) = \frac{z_\alpha(\alpha)}{2\pi i}\mathrm{PV}\int\left(\frac{\gamma_\alpha(\alpha')}{z_\alpha(\alpha')} - \frac{\gamma(\alpha')z_{\alpha\alpha}(\alpha')}{z^2_\alpha(\alpha')}\right)\frac{1}{z(\alpha)-z(\alpha')}\,d\alpha'. \tag{2.15}$$

We approximate $z(\alpha)-z(\alpha')$ by the leading term from its Taylor series, $z_\alpha(\alpha')(\alpha-\alpha')$, to rewrite (2.15) as $\Phi(\mathbf{A}_1)^* + \Phi(\mathbf{R}_1)^* + \Phi(\mathbf{A}_2)^* + \Phi(\mathbf{R}_2)^*$, where

$$\Phi(\mathbf{A}_1)^* = \frac{z_\alpha(\alpha)}{2\pi i}\mathrm{PV}\int\frac{\gamma_\alpha(\alpha')}{z_\alpha(\alpha')}\left[\frac{1}{z_\alpha(\alpha')(\alpha-\alpha')}\right]\,d\alpha', \tag{2.16}$$

$$\Phi(\mathbf{A}_2)^* = -\frac{z_\alpha(\alpha)}{2\pi i}\mathrm{PV}\int\frac{\gamma(\alpha')z_{\alpha\alpha}(\alpha')}{z^2_\alpha(\alpha')}\left[\frac{1}{z_\alpha(\alpha')(\alpha-\alpha')}\right]\,d\alpha'. \tag{2.17}$$

The remainders from approximating $z(\alpha)-z(\alpha')$ are

$$\Phi(\mathbf{R}_1)^* = \frac{z_\alpha(\alpha)}{2\pi i}\mathrm{PV}\int\frac{\gamma_\alpha(\alpha')}{z_\alpha(\alpha')}\left[\frac{1}{z(\alpha)-z(\alpha')} - \frac{1}{z_\alpha(\alpha')(\alpha-\alpha')}\right]\,d\alpha', \tag{2.18}$$

$$\Phi(\mathbf{R}_2)^* = -\frac{z_\alpha(\alpha)}{2\pi i}\mathrm{PV}\int\frac{\gamma(\alpha')z_{\alpha\alpha}(\alpha')}{z^2_\alpha(\alpha')}\left[\frac{1}{z(\alpha)-z(\alpha')} - \frac{1}{z_\alpha(\alpha')(\alpha-\alpha')}\right]\,d\alpha'. \tag{2.19}$$

We rewrite $\mathbf{A}_1$ to show that it equals a smooth term plus a scalar multiple of $\hat{\mathbf{n}}$.

$$\Phi(\mathbf{A}_1)^* = \frac{z_\alpha}{2i}H\left(\frac{\gamma_\alpha}{z^2_\alpha}\right) = \frac{1}{2iz_\alpha}H(\gamma_\alpha) + \frac{z_\alpha}{2i}\left[H,\frac{1}{z^2_\alpha}\right](\gamma_\alpha).$$

We can write this as

$$\Phi(\mathbf{A}_1)^* = \frac{\pi}{L}\left(\frac{2\pi i z_\alpha}{L}\right)^* H(\gamma_\alpha) + \frac{z_\alpha}{2i}\left[H,\frac{1}{z^2_\alpha}\right](\gamma_\alpha).$$

We define $\mathbf{B}_1$ to be Φ^{-1} of the conjugate of the second term, and we use (2.12) to see that $\mathbf{A}_1 = \frac{\pi}{L}H(\gamma_\alpha)\hat{\mathbf{n}} + \mathbf{B}_1$. Similarly, we compute

$$\Phi(\mathbf{A}_2)^* = -\frac{z_\alpha}{2i}H\left(\frac{\gamma z_{\alpha\alpha}}{z^3_\alpha}\right) = -\frac{1}{2iz_\alpha}H\left(\frac{\gamma z_{\alpha\alpha}}{z_\alpha}\right) - \frac{z_\alpha}{2i}\left[H,\frac{1}{z^2_\alpha}\right]\left(\frac{\gamma z_{\alpha\alpha}}{z_\alpha}\right).$$

We look at $\mathbf{A}_2$ separately when taking the inner product with $\hat{\mathbf{t}}$ and $\hat{\mathbf{n}}$. We define $\mathbf{B}_2$ in the analogous way to $\mathbf{B}_1$. Using (2.12) and (2.13), we see that

$$\mathbf{A}_2\cdot\hat{\mathbf{t}} - \mathbf{B}_2\cdot\hat{\mathbf{t}} = \mathrm{Re}\left(-\frac{\pi}{iL}H\left(\frac{\gamma z_{\alpha\alpha}}{z_\alpha}\right)\right) = -\frac{\pi}{L}H\left(\gamma\mathrm{Re}\left\{\frac{2\pi z_{\alpha\alpha}}{L}\left(\frac{2\pi i z_\alpha}{L}\right)^*\right\}\right).$$

Using (2.12), (2.13), and (2.8), we see that this simplifies. In particular,

$$\mathrm{Re}\left\{\frac{2\pi z_{\alpha\alpha}}{L}\left(\frac{2\pi i z_\alpha}{L}\right)^*\right\} = \hat{\mathbf{t}}_\alpha\cdot\hat{\mathbf{n}} = \theta_\alpha.$$

This implies $\mathbf{A}_2\cdot\hat{\mathbf{t}} = -\frac{\pi}{L}H(\gamma\theta_\alpha) + \mathbf{B}_2\cdot\hat{\mathbf{t}}$. Similarly,

$$\mathbf{A}_2\cdot\hat{\mathbf{n}} = -\frac{\pi}{L}H\left(\gamma\hat{\mathbf{t}}_\alpha\cdot\hat{\mathbf{t}}\right) + \mathbf{B}_2\cdot\hat{\mathbf{n}}.$$

Since $\hat{\mathbf{t}}$ is a unit vector, $\hat{\mathbf{t}}_\alpha \cdot \hat{\mathbf{t}} = 0$, so $\mathbf{A}_2 \cdot \hat{\mathbf{n}} = \mathbf{B}_2 \cdot \hat{\mathbf{n}}$. We can now write

$$\mathbf{W}_\alpha \cdot \hat{\mathbf{n}} = \frac{\pi}{L} H(\gamma_\alpha) + \mathbf{m} \cdot \hat{\mathbf{n}}, \qquad \mathbf{W}_\alpha \cdot \hat{\mathbf{t}} = -\frac{\pi}{L} H(\gamma\theta_\alpha) + \mathbf{m} \cdot \hat{\mathbf{t}}, \tag{2.20}$$

where

$$\mathbf{m} = \mathbf{R}_1 + \mathbf{R}_2 + \mathbf{B}_1 + \mathbf{B}_2. \tag{2.21}$$

Finally, we can restate our initial value problem as

$$\theta_t = \boxed{\frac{2\pi^2}{L^2} H(\gamma_\alpha)} + \frac{2\pi}{L}(T - \mathbf{W} \cdot \hat{\mathbf{t}})\theta_\alpha + \frac{2\pi \mathbf{m} \cdot \hat{\mathbf{n}}}{L}, \tag{2.22}$$

$$\gamma_t = \boxed{\frac{2\pi}{L}\frac{\theta_{\alpha\alpha}}{\mathrm{We}} + \frac{2\pi^2 \gamma}{L^2} H(\gamma\theta_\alpha)} + \frac{2\pi}{L}(T - \mathbf{W} \cdot \hat{\mathbf{t}})\gamma_\alpha + \frac{\gamma(L_t - 2\pi \mathbf{m} \cdot \hat{\mathbf{t}})}{L}, \tag{2.23}$$

$$L_t = -\int_0^{2\pi} \theta_\alpha U \, d\alpha \tag{2.24}$$

subject to the initial conditions

$$\theta(\alpha, 0) = \theta_0(\alpha), \quad \gamma(\alpha, 0) = \gamma_0(\alpha), \quad L(0) = L_0. \tag{2.25}$$

The boxed terms are those which will need to be treated most carefully in the energy estimates.

2.3. The mollified equations. Our strategy for proving existence of solutions for the vortex sheet is as follows: First, we introduce mollifiers to the right-hand sides of the evolution equations. The purpose of this is to turn the right-hand sides into bounded functions of θ, γ, and L in certain Sobolev spaces. Thus, we need to include mollifiers only on terms which feature derivatives of θ and γ. The presence of the mollifiers will allow us to prove existence of solutions to the mollified equations for an amount of time which depends on the mollification parameter. We will need to know bounds on the mollified solutions which are independent of the mollification parameter, ε, in order to establish existence of solutions on a time interval independent of ε. We will then be able to pass to the limit as ε goes to zero and establish existence of solutions to the nonmollified equations.

We now state the mollified equations; we will define the new terms involved in these equations next.

$$\theta_t^\varepsilon = \boxed{\frac{2\pi^2}{L^{\varepsilon 2}} H\chi^\varepsilon(\gamma_\alpha^\varepsilon)} + \frac{2\pi}{L^\varepsilon}\chi^\varepsilon\left((T^\varepsilon - \mathbf{W}^\varepsilon \cdot \hat{\mathbf{t}}^\varepsilon)\chi^\varepsilon\theta_\alpha^\varepsilon\right) + \frac{2\pi \mathbf{m}^\varepsilon \cdot \hat{\mathbf{n}}^\varepsilon}{L^\varepsilon} + \mu^\varepsilon, \tag{2.26}$$

$$\gamma_t^\varepsilon = \boxed{\frac{2\pi\chi^\varepsilon\theta_{\alpha\alpha}^\varepsilon}{L^\varepsilon \mathrm{We}} + \frac{2\pi^2}{L^{\varepsilon 2}} H((\gamma^\varepsilon)^2\chi^\varepsilon\theta_\alpha^\varepsilon)} + \frac{2\pi}{L^\varepsilon}\chi^\varepsilon\left((T^\varepsilon - \mathbf{W}^\varepsilon \cdot \hat{\mathbf{t}}^\varepsilon)\chi^\varepsilon\gamma_\alpha^\varepsilon\right) + m_\gamma^\varepsilon, \tag{2.27}$$

$$L_t^\varepsilon = -\int_0^{2\pi} \theta_\alpha^\varepsilon U^\varepsilon \, d\alpha. \tag{2.28}$$

These equations are taken together with the initial conditions

$$\theta^\varepsilon(\alpha, 0) = \theta_0(\alpha), \quad \gamma^\varepsilon(\alpha, 0) = \gamma_0(\alpha), \quad L^\varepsilon(0) = L_0. \tag{2.29}$$

We remark that in some of the terms with the mollification operator, χ^ε, it appears once, while in other terms χ^ε appears twice. When χ^ε appears twice in a term, it is so that we can perform integration by parts in later estimates. In particular, this will be important at the end of the proof of Theorem 4.3.

We assume χ^ε to be a self-adjoint smoothing operator which commutes with derivatives and the Hilbert transform. For example, χ^ε could be convolution with an approximation to the Dirac mass. We need the following lemmas for χ^ε; proofs can be found on page 131 of [MB02]. In what follows, unless otherwise noted, all Sobolev spaces are of functions which are periodic with period 2π. The norm can thus be found by integrating over any interval of length 2π.

LEMMA 2.1. *For $f \in H^{m-k}$ and $k \in \{0, 1, 2, \dots\}$, we have $\chi^\varepsilon f \in H^m$ and*

$$\|\chi^\varepsilon f\|_m \leq \frac{c}{\varepsilon^k}\|f\|_{m-k}.$$

LEMMA 2.2. *For $f \in H^1$ and $\varepsilon,\ \varepsilon' > 0$,*

$$\left\|\chi^\varepsilon f - \chi^{\varepsilon'} f\right\|_0 \leq \max(\varepsilon, \varepsilon')\|f\|_1.$$

In the θ_t^ε equation, the μ^ε term has no counterpart in the nonmollified equation. It appears here to enforce the condition that $z^\varepsilon(\alpha) - \alpha$ be 2π-periodic. We do this because knowing that the tangent angle is periodic does not imply that the underlying curve is periodic. If we make the definition

$$P(t) = \int_\alpha^{\alpha+2\pi} z_\alpha^\varepsilon(\alpha', t)\ d\alpha',$$

then we would like to know that $P(t) = 2\pi$. (It is clear that P is independent of α since it is the integral of a periodic function over one period.) We assume that the initial data satisfies $P(0) = 2\pi$. We will choose μ such that $P'(t) = 0$. Let $\widetilde{\theta_t^\varepsilon} = \theta_t^\varepsilon - \mu^\varepsilon$. Since $z_\alpha = \frac{L}{2\pi}e^{i\theta}$, we see

$$P'(t) = \int_\alpha^{\alpha+2\pi}\left[\frac{L_t^\varepsilon z_\alpha^\varepsilon}{L^\varepsilon} + i\theta_t^\varepsilon z_\alpha^\varepsilon\right]d\alpha' = \int_\alpha^{\alpha+2\pi}\left[\frac{L_t^\varepsilon z_\alpha^\varepsilon}{L^\varepsilon} + i\widetilde{\theta_t^\varepsilon} z_\alpha^\varepsilon\right]d\alpha' + i\mu^\varepsilon\int_\alpha^{\alpha+2\pi} z_\alpha^\varepsilon\ d\alpha'.$$

This tells us that by defining μ^ε by

$$\mu^\varepsilon(t) = -\frac{\displaystyle\int_\alpha^{\alpha+2\pi}\left[\frac{L_t^\varepsilon z_\alpha^\varepsilon}{L^\varepsilon} + i\widetilde{\theta_t^\varepsilon} z_\alpha^\varepsilon\right]d\alpha'}{\displaystyle i\int_\alpha^{\alpha+2\pi} z_\alpha^\varepsilon\ d\alpha'}, \tag{2.30}$$

we guarantee that $P'(t) = 0$. This implies that $z^\varepsilon(\alpha) - \alpha$ is always 2π-periodic. We remark that for the nonmollified equations, it can be shown that $z(\alpha) - \alpha$ remains 2π-periodic. We refer the reader to [Amb02] for this calculation.

Before defining the mollified quantities $m^\varepsilon,\ T^\varepsilon$, etc., we must first define z^ε and $\mathbf{W}^\varepsilon$. We start with z^ε:

$$z^\varepsilon(\alpha, t) = z^\varepsilon(0, t) + \int_0^\alpha \frac{L^\varepsilon(t)}{2\pi}\cos(\theta^\varepsilon(\alpha', t)) + i\frac{L^\varepsilon(t)}{2\pi}\sin(\theta^\varepsilon(\alpha', t))\ d\alpha'.$$

Although it is frequently unimportant, we define $z^\varepsilon(0,t)$ for completeness. Since we have chosen $T(0,t) = 0$, we see that $z_t^\varepsilon(0,t) = (\mathbf{W}\cdot\hat{\mathbf{n}})\Phi(\hat{\mathbf{n}})(0,t)$; that is, $z^\varepsilon(0,t)$ evolves only by the normal velocity. Using (2.12) and (2.13), this means

$$z_t^\varepsilon(0,t) = \mathrm{Re}\left(\Phi(\mathbf{W}^\varepsilon)^*(0,t)\frac{2\pi i z_\alpha^\varepsilon(0,t)}{L^\varepsilon(t)}\right)\frac{2\pi i z_\alpha^\varepsilon(0,t)}{L^\varepsilon(t)}.$$

Integrating this in time yields $z^\varepsilon(0,t)$. Without loss of generality, we can choose $z^\varepsilon(0,0) = 0$. We introduce $z_d^\varepsilon(\alpha,t) = z^\varepsilon(\alpha,t) - z^\varepsilon(0,t)$ since we will usually not need $z(0,t)$. Notice that $D_\alpha z^\varepsilon = D_\alpha z_d^\varepsilon$. We will also use the similar notation $z_d(\alpha,t) = z(\alpha,t) - z(0,t)$, as necessary.

We now turn our attention to defining $\mathbf{W}^\varepsilon$. In order to do this, we first rewrite the nonmollified $\mathbf{W}$. Since we are looking for curves, z, with the property that $z(\alpha)-\alpha$ is 2π-periodic, we rewrite (2.14) so that the integral is over one period:

$$\Phi(\mathbf{W})^*(\alpha) = \frac{1}{4\pi i}\mathrm{PV}\int_{b-\pi}^{b+\pi}\gamma(\alpha')\left[\cot\frac{1}{2}(z(\alpha)-z(\alpha'))\right]\,d\alpha'. \tag{2.31}$$

Here, b is any real number. We rewrite this in order to isolate its most important part. In particular, we rewrite the quantity in brackets as

$$\left(\frac{1}{z_\alpha(\alpha')}\cot\frac{1}{2}(\alpha-\alpha')\right) + \left(\cot\frac{1}{2}(z(\alpha)-z(\alpha')) - \frac{1}{z_\alpha(\alpha')}\cot\frac{1}{2}(\alpha-\alpha')\right).$$

Then (2.31) becomes

$$\Phi(\mathbf{W})^*(\alpha) = \frac{1}{2i}H\left(\frac{\gamma}{z_\alpha}\right) + \mathcal{K}[z]\gamma, \tag{2.32}$$

where we define the integral operator $\mathcal{K}[z]$ as

$$\mathcal{K}[z]f(\alpha) = \frac{1}{4\pi i}\int_{b-\pi}^{b+\pi} f(\alpha')\left[\cot\frac{1}{2}(z_d(\alpha)-z_d(\alpha')) - \frac{1}{z_\alpha(\alpha')}\cot\frac{1}{2}(\alpha-\alpha')\right]\,d\alpha'. \tag{2.33}$$

Since we are interested in curves, z, which are non-self-intersecting, $\mathcal{K}[z]$ is not a singular integral operator. To take advantage of this, we write the cotangent as a function which is analytic at the origin plus a singular part:

$$\cot(w) = \frac{1}{w} + G(w). \tag{2.34}$$

This lets us rewrite $\mathcal{K}$ as $\mathcal{K}_1 + \mathcal{K}_2$, where

$$\mathcal{K}_1[z]f(\alpha) = \frac{1}{2\pi i}\int_{b-\pi}^{b+\pi} f(\alpha')\left[\frac{1}{z_d(\alpha)-z_d(\alpha')} - \frac{1}{z_\alpha(\alpha')(\alpha-\alpha')}\right]\,d\alpha', \tag{2.35}$$

$$\mathcal{K}_2[z]f(\alpha) = \frac{1}{4\pi i}\int_{b-\pi}^{b+\pi} f(\alpha')\left[G\left(\frac{1}{2}(z_d(\alpha)-z_d(\alpha'))\right) - \frac{1}{z_\alpha(\alpha')}G\left(\frac{1}{2}(\alpha-\alpha')\right)\right]\,d\alpha'. \tag{2.36}$$

We make definite choices of b in these integrals. For $\mathcal{K}_1$, we choose $b = \pi$ so that we integrate over $[0, 2\pi]$. For $\mathcal{K}_2$, we choose b so that the interval of integration avoids the

poles of G. From (2.34), we see that the poles of G are the nonzero integral multiples of π. Thus, we choose $b = \alpha$ in $\mathcal{K}_2$ so that the maximum difference between α and α' is π. This will be discussed further in the next section. We are now able to define $\mathbf{W}^\varepsilon$ similarly to (2.32):

$$\Phi(\mathbf{W}^\varepsilon)^*(\alpha) = \frac{1}{2i} H\left(\frac{\gamma^\varepsilon}{z_\alpha^\varepsilon}\right)(\alpha) + \mathcal{K}_1[z^\varepsilon]\gamma^\varepsilon(\alpha) + \mathcal{K}_2[z^\varepsilon]\gamma^\varepsilon(\alpha). \tag{2.37}$$

The definitions of the remaining mollified quantities are routine. The tangent and normal vectors to the mollified curve are given by

$$\Phi(\hat{\mathbf{t}}^\varepsilon) = \frac{2\pi z_\alpha^\varepsilon}{L^\varepsilon}, \qquad \Phi(\hat{\mathbf{n}}^\varepsilon) = \frac{2\pi i z_\alpha^\varepsilon}{L^\varepsilon}.$$

The mollified version of U is given by $U^\varepsilon = \mathbf{W}^\varepsilon \cdot \hat{\mathbf{n}}^\varepsilon$. Notice that by defining U^ε, we have completed the definition of L_t^ε in (2.28). T^ε is defined by replacing θ and U by their mollified versions in (2.6). $\mathbf{m}^\varepsilon$ is also defined much as before, with

$$\mathbf{m}^\varepsilon = \mathbf{R}_1^\varepsilon + \mathbf{R}_2^\varepsilon + \mathbf{B}_1^\varepsilon + \mathbf{B}_2^\varepsilon. \tag{2.38}$$

The terms $\mathbf{R}_1^\varepsilon$, $\mathbf{R}_2^\varepsilon$, $\mathbf{B}_1^\varepsilon$, and $\mathbf{B}_2^\varepsilon$ are defined the same way as the nonmollified versions but in terms of z^ε and γ^ε instead of z and γ.

In the mollified equations, we introduced m_γ^ε. This is because we would like both of the γ factors to be inside the Hilbert transform in the second of the important terms in (2.23). Thus, we define $\mathbf{m}_\gamma^\varepsilon$ to be the collection of terms

$$m_\gamma^\varepsilon = \frac{\gamma^\varepsilon(L_t^\varepsilon - 2\pi \mathbf{m}^\varepsilon \cdot \hat{\mathbf{t}}^\varepsilon)}{L^\varepsilon} - [H, \gamma^\varepsilon]\left(\frac{2\pi^2 \gamma^\varepsilon \chi^\varepsilon \theta_\alpha^\varepsilon}{{L^\varepsilon}^2}\right). \tag{2.39}$$

3. Preliminaries. We will need to use a variety of routine estimates for integral operators and other functions in terms of θ and γ. We begin with an estimate for the composition of two functions; see page 11 of [Tay96] for the proof.

LEMMA 3.1. *If F is smooth and u is in $H^k \cap L^\infty$, then $\|F(u)\|_k \le c(1 + \|u\|_k)$. The constant, c, depends on $|F^{(j)}u|_\infty$ for j between 0 and k.*

The next lemma gives a bound for z in terms of θ and L. This is important since z occurs frequently in our integral operators but not in our energy function.

LEMMA 3.2. *Let s be a positive integer. If $\theta \in H^{s-1}$, then $z_d \in H^s$ and $\|z_d\|_s \le cL(1 + \|\theta\|_{s-1})$.*

Proof. We use the fact that $D_\alpha z_d = D_\alpha z$, and we use the following equivalent norm for $z_d \in H^s$:

$$\|z_d\|_s = \sum_{j=0}^{s} \|D_\alpha^j z_d\|_0 = \|z_d\|_0 + \sum_{j=0}^{s-1} \|D_\alpha^j z_\alpha\|_0 = \|z_d\|_0 + \|z_\alpha\|_{s-1}.$$

Recall the definition

$$z_d(\alpha, t) = \int_0^\alpha \frac{L(t)}{2\pi} e^{i\theta(\alpha', t)}\, d\alpha'.$$

Clearly, the H^0 norm of this is bounded by a constant times L. To bound $\|z_\alpha\|_{s-1}$, we use Lemma 3.1 with the formula $z_\alpha = \frac{L}{2\pi} e^{i\theta}$ to see that $\|z_\alpha\|_{s-1} \le cL(1 + \|\theta\|_{s-1})$. Notice that c is independent of θ since $|e^{i\theta}|_\infty = 1$. This concludes the proof of the lemma. ∎

We will also need a standard interpolation lemma for Sobolev spaces. The Sobolev spaces we use are for periodic functions.

LEMMA 3.3. *If $f \in H^s$, and m is a real number such that $s > m > 0$, then*

$$\|f\|_m \ \leq \ c\|f\|_s^{m/s}\|f\|_0^{1-m/s}.$$

Proof. We use Hölder's inequality for series in the form

$$\sum_{\xi=-\infty}^{\infty} a_\xi b_\xi w_\xi \leq \left(\sum_{\xi=-\infty}^{\infty} a_\xi^p w_\xi\right)^{1/p} \left(\sum_{\xi=-\infty}^{\infty} b_\xi^q w_\xi\right)^{1/q},$$

where $\frac{1}{p} + \frac{1}{q} = 1$. We use as weights $w_\xi = (\mathcal{F}f(\xi))^2$. We calculate

$$\begin{aligned} (3.1) \qquad & \sum_{\xi=-\infty}^{\infty} (1+|\xi|^2)^m (\mathcal{F}f(\xi))^2 \\ & \leq \left(\sum_{\xi=-\infty}^{\infty} (1+|\xi|^2)^s (\mathcal{F}f(\xi))^2\right)^{m/s} \left(\sum_{\xi=-\infty}^{\infty} (\mathcal{F}f(\xi))^2\right)^{1-m/s}. \end{aligned}$$

This completes the proof. ∎

In simplifying the integral operator $\mathcal{K}_1$, we find divided differences to be very useful. We have the integral representation formulae for the divided differences q_1 and q_2:

$$q_1(\alpha,\alpha') = \frac{z_d(\alpha) - z_d(\alpha')}{\alpha - \alpha'} = \int_0^1 z_\alpha\left(t\alpha + (1-t)\alpha'\right)\, dt,$$

$$q_2(\alpha,\alpha') = \frac{z_d(\alpha) - z_d(\alpha') - z_\alpha(\alpha)(\alpha-\alpha')}{(\alpha-\alpha')^2} = \int_0^1 (t-1) z_{\alpha\alpha}\left((1-t)\alpha + t\alpha'\right)\, dt.$$

The next lemma gives bounds for the divided differences in terms of z. Rather than include a proof, we refer the reader to [BHL93]. (The proof makes use of the integral representations above.) The version of the lemma in [BHL93] was not for periodic functions, but that is not an important difference.

LEMMA 3.4. *Let $z_d \in H^m[a,b]$ and $k \leq m-1$. Then in either α or α', $q_1 \in H^{m-1}[a,b]$ and $q_2 \in H^{m-2}[a,b]$. Furthermore, there are the bounds*

$$\|q_1\|_{m-1} \ \leq \ c\|z_d\|_m, \qquad \|q_2\|_{m-2} \ \leq \ c\|z_d\|_m.$$

Remark. This lemma is true for any function in H^m, not only for z_d.

It now becomes important that we consider only curves z which are non-self-intersecting. In particular, when we specify that z is non-self-intersecting, we require that it satisfy the following estimate for some $\bar{c} > 0$ and for all α and α':

$$(3.2) \qquad \bar{c} < \left|\frac{z_d(\alpha) - z_d(\alpha')}{\alpha - \alpha'}\right|.$$

In addition to ruling out self-intersections, this condition also guarantees that the curve z has no cusps.

We also begin to consider only triples (θ, γ, L) which lie in a bounded set. To do this, we define the energy for a triple (θ, γ, L). Our energy function is

$$E(t) = E^0(t) + L^2(t) + \sum_{j=2}^{r} E^j(t), \tag{3.3}$$

where $E^0(t) = \|\theta\|_0^2 + \|\gamma\|_0^2$ and

$$E^j(t) = \frac{1}{2}\int (D_\alpha^{j-1}\theta)^2 + \frac{\pi \mathrm{We}}{L}(D_\alpha^{j-2}\gamma)\Lambda(D_\alpha^{j-2}\gamma) + \frac{\gamma^2\pi^2\mathrm{We}^2}{L^2}(D_\alpha^{j-2}\gamma)^2 \, d\alpha \tag{3.4}$$

for $j \geq 2$. We write $E^j = E_1^j + E_2^j + E_3^j$. We make the assumptions that

$$2\pi \, < \, L, \qquad E(t) \, < \, \bar{d}, \tag{3.5}$$

where $\bar{d}$ is some positive constant. This implies that the H^{r-1} norm of θ, the $H^{r-3/2}$ norm of γ, and the size of L are all bounded above by a constant. We have also assumed that L is bounded below by 2π. We make this assumption for technical reasons (related to the proof of Theorem 5.1). That L is bounded below by 2π is automatically true for any nontrivial curve z such that $z(\alpha) - \alpha$ is 2π-periodic. By Lemma 3.2, (3.5) also implies that the H^r norm of z_d is bounded by a constant. When choosing $\bar{c}$ and $\bar{d}$, we make sure that $\bar{c}$ is small enough and $\bar{d}$ is large enough so that conditions (3.2) and (3.5) are satisfied by the initial data.

Remark on minimal regularity. In the definition of the energy function (3.3), we have introduced an integer r. In what follows, we will be assuming the initial data θ_0 to be in H^{r-1} and γ_0 to be in $H^{r-3/2}$. We will sometimes make an assumption that "r is large enough." This means that we are assuming $r > k$, where k is an absolute constant. We do not determine here the minimal value of k which is necessary to make our proofs hold. This is because this would surely not be sharp.

We prove now that the operator $\mathcal{K} = \mathcal{K}_1 + \mathcal{K}_2$ defined in (2.35) and (2.36) is smooth.

LEMMA 3.5. *Let s be an integer such that $s \geq 2$. If $z_d \in H^s$, then $\mathcal{K}[z] : H^1 \to H^{s-1}$ and, in particular, there are positive constants C_1 and C_2 such that*

$$\|\mathcal{K}[z]f\|_{s-1} \leq C_1\|f\|_1 \exp\{C_2\|z_d\|_s\}.$$

Similarly, $\mathcal{K}[z] : H^0 \to H^{s-2}$, and $\|\mathcal{K}[z]f\|_{s-2} \leq C_1\|f\|_0 \exp\{C_2\|z_d\|_s\}$.

Proof. We will deal with $\mathcal{K}_1$ and $\mathcal{K}_2$ separately. We begin by taking $s-1$ derivatives of $\mathcal{K}_1[z]f$.

$$D_\alpha^{s-1}\mathcal{K}_1[z]f(\alpha) = \frac{1}{2\pi i}\int_0^{2\pi} f(\alpha')D_\alpha^{s-1}\left[\frac{1}{z_d(\alpha) - z_d(\alpha')} - \frac{1}{z_\alpha(\alpha')(\alpha - \alpha')}\right] d\alpha'.$$

We apply one of the $s-1$ derivatives to the quantity in brackets.

$$D_\alpha^{s-1}\mathcal{K}_1[z]f(\alpha) = \frac{1}{2\pi i}\int_0^{2\pi} f(\alpha')D_\alpha^{s-2}\left[-\frac{z_\alpha(\alpha)}{(z_d(\alpha) - z_d(\alpha'))^2} + \frac{1}{z_\alpha(\alpha')(\alpha - \alpha')^2}\right] d\alpha'.$$

We rearrange the factors of z_α and write the quantity in brackets as an α'-derivative.

$$D_\alpha^{s-1}\mathcal{K}_1[z]f(\alpha) = \frac{1}{2\pi i}\int_0^{2\pi} \frac{f(\alpha')}{z_\alpha(\alpha')}D_\alpha^{s-2}D_{\alpha'}\left[-\frac{z_\alpha(\alpha)}{z_d(\alpha) - z_d(\alpha')} + \frac{1}{\alpha - \alpha'}\right] d\alpha'.$$

We integrate this by parts and estimate it, recognizing that the quantity in brackets is a ratio of divided differences.

$$|D_\alpha^{s-1}\mathcal{K}_1[z]f(\alpha)| = \left|\frac{1}{2\pi i}\int_0^{2\pi} D_{\alpha'}\left(\frac{f(\alpha')}{z_\alpha(\alpha')}\right) D_\alpha^{s-2}\left[\frac{z_\alpha(\alpha)}{z_d(\alpha)-z_d(\alpha')} - \frac{1}{\alpha-\alpha'}\right]\,d\alpha'\right|$$

$$\leq c\left\|\frac{f}{z_\alpha}\right\|_1 \left\|\frac{q_2}{q_1}\right\|_{s-2} \leq c\|f\|_1 \left\|\frac{1}{z_\alpha}\right\|_1 \|q_2\|_{s-2} \left\|\frac{1}{q_1}\right\|_{s-2}. \tag{3.6}$$

Using (3.2) and Lemma 3.1, we estimate $\|1/q_1\|_{s-2} \leq c(1+\|q_1\|_{s-2})$. Similarly, since $|z_\alpha| = L/2\pi$, we use Lemma 3.1 to estimate

$$\left\|\frac{1}{z_\alpha}\right\|_1 \leq c(1+\|z_\alpha\|_1). \tag{3.7}$$

To finish the estimate for $\mathcal{K}_1$, we use Lemma 3.4 and (3.6) to conclude

$$\|\mathcal{K}_1[z]f\|_{s-1} \leq C_1\|f\|_1 \exp\{C_2\|z_d\|_s\}. \tag{3.8}$$

We calculate $D_\alpha^{s-1}\mathcal{K}_2[z]f$. It is

$$\frac{1}{2\pi i}\int_{\alpha-\pi}^{\alpha+\pi} f(\alpha')D_\alpha^{s-1}\left[G\left(\frac{1}{2}(z_d(\alpha)-z_d(\alpha'))\right) - \frac{1}{z_\alpha(\alpha')}G\left(\frac{1}{2}(\alpha-\alpha')\right)\right]\,d\alpha'. \tag{3.9}$$

The largest number of derivatives which fall on z_d is $s-1$, and we assumed $z_d \in H^s$. We can estimate the factor of $1/z_\alpha$ in H^{s-1} similarly to (3.7). It is important to notice that the poles of G have been avoided. That is, $z_d(\alpha)-z_d(\alpha')$ cannot approach any multiple of 2π because of the periodicity of $z(\alpha)-\alpha$ and the condition (3.2). By (3.5), we know that z_d is in a bounded set, and we also know that G is analytic. So, we can use Lemma 3.1 to conclude that

$$\|\mathcal{K}_2[z]f\|_{s-1} \leq C_1\|f\|_0 \exp\{C_2\|z_d\|_s\}. \tag{3.10}$$

Combining (3.8) and (3.10), we have proved the lemma. □

We also need a Lipschitz-type estimate for $\mathcal{K}$. We state the lemma here, but we refer the reader to [Amb02] for the proof.

LEMMA 3.6. *Given z and z' in H^r which satisfy* (3.2) *and* (3.5), *we have the Lipschitz estimate*

$$\|\mathcal{K}[z]f - \mathcal{K}[z']f\|_1 \leq c\|\theta-\theta'\|_1\|f\|_1.$$

The proof is routine. It involves considering $\mathcal{K}_1$ and $\mathcal{K}_2$ individually. For $\mathcal{K}_1$, Lipschitz estimates on the divided differences q_1 and q_2 are used. For $\mathcal{K}_2$, Lipschitz estimates for the function G defined in (2.34) are used.

We will frequently need estimates regarding the smoothness of the commutator of the Hilbert transform and multiplication by a smooth function.

LEMMA 3.7. *For $\psi \in H^s$, the operator $[H,\psi]$ is bounded from H^0 to H^{s-1}. Also, $[H,\psi]$ is bounded from H^{-1} to H^{s-2}. For $i=0$ or $i=-1$, we have*

$$\|[H,\psi]f\|_{s-1+i} \leq c\|f\|_i\|\psi\|_s.$$

Proof. We begin by writing $[H,\psi]$ as an integral operator:

$$[H,\psi]f(\alpha) = \frac{1}{2\pi i}\int_b^{b+2\pi} f(\alpha')\Big(\psi(\alpha')-\psi(\alpha)\Big)\cot\left(\frac{1}{2}(\alpha-\alpha)\right)\,d\alpha'.$$

Since the functions are periodic, we may choose $b = \alpha$, so that the maximum difference between α and α' is π. We can write the kernel as

$$\left(\frac{\psi(\alpha) - \psi(\alpha')}{\alpha - \alpha'}\right)\left((\alpha - \alpha')\cot\frac{1}{2}(\alpha - \alpha')\right).$$

The first part of this product is a divided difference, and the second part is an analytic function on the domain in which we are interested. The lemma now follows from Lemma 3.4 and from the generalized Young's inequality [Fol95]. For $g \in H^{-1}$, we integrate by parts once; otherwise, the proof is similar. □

COROLLARY 3.8. *For $s \geq 3$ and $\psi \in H^s$, the operator $[H, \psi]$ is bounded from H^{s-2} to H^s. For $s \geq 4$ and $\psi \in H^{s-1/2}$, $[H, \psi]$ is bounded from H^{s-2} to $H^{s-1/2}$. For $i = 0$ or $i = -1/2$, we have the estimates $\|[H, \psi]f\|_{s+i} \leq c\|f\|_{s-2}\|\psi\|_{s+i}$.*

Proof. Let $g \in H^{s-2}$. We compute $D_\alpha^s[H, \psi]g$ by using the product rule for $s - 2$ of the derivatives.

$$\begin{aligned} D_\alpha^s[H, \psi]g &= D_\alpha^2(D_\alpha^{s-2}(H(\psi g) - \psi H(g))) \\ &= D_\alpha^2 \sum_{k=0}^{s-2} \binom{s-2}{k} \left[H((D_\alpha^k\psi)(D_\alpha^{s-k-2}g)) - (D_\alpha^k\psi)(HD_\alpha^{s-k-2}g)\right]. \end{aligned}$$

We consider the summands separately in the cases $k = 0$, $k = 1$, and $k > 1$. The simplest case is $k > 1$, for then the highest number of derivatives on g is $s - 4$ and the highest number of derivatives on ψ is $s - 2$. The products of these terms are thus in H^2, which is fortunate since we are taking two derivatives of the sum. Thus, the H^0 norms of these terms are bounded by $c\|\psi\|_s\|g\|_{s-2}$. When $k = 0$, we have

$$D_\alpha^2 H(\psi D_\alpha^{s-2}g) - D_\alpha^2(\psi H D_\alpha^{s-2}(g)) = D_\alpha^2[H, \psi](D_\alpha^{s-2}(g)).$$

Lemma 3.7 applies to this term, so its H^0 norm is bounded by $c\|\psi\|_3\|g\|_{s-2}$. The $k = 1$ term is similarly bounded by $c\|\psi\|_3\|g\|_{s-2}$. This proves the first part of the corollary. The proof for $\psi \in H^{s-1/2}$ is similar. □

The final lemma we will need is about commutator operators associated with taking a large number of derivatives. This lemma, though, relies on another lemma about norms of products of functions in Sobolev spaces.

LEMMA 3.9. *Suppose $s > 1/2$ and $s \geq s' \geq 0$. If $f \in H^s$ and $g \in H^{s'}$, then $fg \in H^{s'}$ with the estimate*

$$\|fg\|_{s'} \leq c\|f\|_s\|g\|_{s'}.$$

We do not prove this lemma here. Instead, we refer the reader to page 366 of [Bea81]. The version of the lemma in [Bea81] is for functions on $\mathbb{R}^3$, but the proof of Lemma 3.9 is essentially the same. We are now prepared to give our final lemma.

LEMMA 3.10. *If k is a positive integer such that $k \geq 2$, s is a positive real number, $f \in H^{s+k}$, and $g \in H^{s+k-1}$, then the following estimate for commutators of derivatives holds:*

$$\|D_\alpha^k(fg) - fD_\alpha^k g\|_s \leq c\|f\|_{s+k}\|g\|_{s+k-1}.$$

Proof. We first notice that the product rule implies that $D_\alpha^k(fg) - fD_\alpha^k g = \sum_{j=1}^k \binom{k}{j}(D_\alpha^{k-j}g)(D_\alpha^j f)$. We now use the triangle inequality:

$$\left\|D_\alpha^k(fg) - fD_\alpha^k g\right\|_s \leq \sum_{j=1}^k \binom{k}{j} \left\|(D_\alpha^{k-j}g)(D_\alpha^j f)\right\|_s. \tag{3.11}$$

Lemma 3.9 implies that each of these individual summands can be bounded by $c\|f\|_{s+k}\|g\|_{s+k-1}$. This completes the proof, but we illustrate this with an example. If $k = 3$ and $s = 1/2$, then (3.11) reads

$$\begin{aligned}(3.12)\quad &\left\|(D_\alpha^3 f)g + 3(D_\alpha^2 f)(D_\alpha g_\alpha) + 3(D_\alpha f)(D_\alpha^2 g)\right\|_{1/2} \\ &\qquad \leq \left\|(D_\alpha^3 f)g\right\|_{1/2} + 3\left\|(D_\alpha^2 f)(D_\alpha g)\right\|_{1/2} + 3\left\|(D_\alpha f)(D_\alpha^2 g)\right\|_{1/2}.\end{aligned}$$

Lemma 3.9 implies that the first term on the right-hand side of (3.12) can be bounded by $c\|f\|_{7/2}\|g\|_{3/2}$, the second can be bounded by $c\|f\|_{7/2}\|g\|_{3/2}$ (or by $c\|f\|_{5/2}\|g\|_{5/2}$), and the third can be bounded by $c\|f\|_{5/2}\|g\|_{5/2}$. The sum of these can then be bounded by $c\|f\|_{7/2}\|g\|_{5/2}$. □

4. A priori estimates. We wish to consider solutions of the initial value problem which lie in a particular Banach space, $H^{r-1} \times H^{r-3/2} \times \mathbb{R}$. We call this space $\mathcal{B}$. Our solutions, (θ, γ, L), will be contained in an open subset, $\mathcal{O}$, of $\mathcal{B}$; in particular, $\mathcal{O}$ is the subset of $\mathcal{B}$ in which the conditions (3.2) and (3.5) hold. Notice that this open set depends on the particular choice of $\bar{c}$ and $\bar{d}$. The norm of $(\theta, \gamma, L) \in \mathcal{B}$ is defined to be $\|\theta\|_{r-1} + \|\gamma\|_{r-3/2} + |L|$.

The goal of this section is to provide a bound on the growth of the energy of a solution to the mollified initial value problem. We begin by providing routine estimates of quantities related to θ, γ, and L. These estimates hold for both the mollified and for the nonmollified quantities. Throughout this section, all constants are independent of α, t, and ε, but they may depend on r, $\bar{c}$, $\bar{d}$, or the Weber number.

LEMMA 4.1. *If $|z_\alpha(\alpha, t)| = L(t)/2\pi$, $L(t) > 2\pi$, and $z_\alpha \in H^{r-1}([a, b])$, then $1/z_\alpha$ is in H^{r-1} with the estimate*

$$\left\|\frac{1}{z_\alpha}\right\|_{r-1} \leq c(1 + \|z_\alpha\|_{r-1}),$$

where c depends on r and on the interval $[a, b]$.

Proof. We use Lemma 3.1 with $F(u) = 1/u$. The assumption that

$$\left|\frac{1}{z_\alpha}\right| = \frac{2\pi}{L} < 1$$

implies that $|F^{(j)}u|_\infty < 1$ for all j. Thus, we have proved the lemma and the constant c is independent of both α and t. □

We will use Lemma 4.1 at some points in the proof of Lemma 4.2.

LEMMA 4.2. *For $(\theta, \gamma, L) \in \mathcal{O}$, the following bounds hold:*

$$\|\mathbf{W}\|_0 \leq C_1\|\gamma\|_1 \exp\{C_2\|z_d\|_1\}, \tag{4.1}$$

$$|L_t| \leq C\|\theta\|_1\|\mathbf{W}\|_0, \tag{4.2}$$

$$\|\mathbf{m}\|_{r-1} \leq C_1\|\gamma\|_{r-2} \exp\{C_2\|z_d\|_r\}, \tag{4.3}$$

$$\|m_\gamma\|_{r-3/2} \leq C\|\gamma\|_{r-3/2}(|L_t| + \|\mathbf{m} \cdot \hat{\mathbf{t}}\|_{r-1} + \|\gamma\|_{r-2}\|\theta\|_{r-1}), \tag{4.4}$$

$$\|D_\alpha(T - \mathbf{W} \cdot \hat{\mathbf{t}})\|_{r-2} \leq C(|L_t| + \|\theta\|_{r-1}\|\gamma\|_{r-2} + \|\mathbf{m} \cdot \hat{\mathbf{t}}\|_{r-1}), \tag{4.5}$$

$$|\mu^\varepsilon(t)| \leq c(|L_t^\varepsilon| + \|\gamma^\varepsilon\|_1 + \|T^\varepsilon - \mathbf{W}^\varepsilon \cdot \hat{\mathbf{t}}^\varepsilon\|_0\|\theta^\varepsilon\|_1 + \|\mathbf{m}^\varepsilon\|_0). \tag{4.6}$$

Proof. The bounds (4.1), (4.2), (4.3), (4.4), and (4.5) hold for both the mollified and for the nonmollified quantities. In (4.6), however, we make the ε-dependence explicit because there is no nonmollified counterpart to μ^ε.

Proof. We use the representation $\Phi(\mathbf{W})^* = \frac{1}{2i} H(\frac{\gamma}{z_\alpha}) + \mathcal{K}[z]\gamma$ to estimate $\|\mathbf{W}\|_0$. In making this estimate, we make use of Lemma 3.5. Thus,

$$\|\mathbf{W}\|_0 \;\le\; c_1 \left(\|\gamma\|_0 \left| \frac{1}{z_\alpha} \right|_\infty + \|\gamma\|_1 \exp\{c_2 \|z_d\|_1\} \right).$$

To estimate $|1/z_\alpha|_\infty$, we use that $|z_\alpha| = L/2\pi$ and $2\pi < L$. This implies the estimate $\|\mathbf{W}\|_0 \;\le\; c_3 \|\gamma\|_1 \exp\{c_2 \|z_d\|_1\}$.

We turn to L_t. From (2.28) we easily compute

$$|L_t| \le \int_0^{2\pi} |\theta_\alpha| |U| \; d\alpha \;\le\; c \|\theta\|_1 \|\mathbf{W} \cdot \hat{\mathbf{n}}\|_0 \;\le\; c \|\theta\|_1 \|\mathbf{W}\|_0 |\hat{\mathbf{n}}|_\infty.$$

Since $\hat{\mathbf{n}}$ is a unit vector, $|\hat{\mathbf{n}}|_\infty = 1$. This implies the bound (4.2).

We see from (2.38) that $\mathbf{m}$ is made up of two kinds of terms: commutators and integral remainder operators. We write $\mathbf{m} = (\mathbf{m} \cdot \hat{\mathbf{t}})\hat{\mathbf{t}} + (\mathbf{m} \cdot \hat{\mathbf{n}})\hat{\mathbf{n}}$, and bound the normal and tangential parts separately. We use Corollary 3.8 on the commutators and Lemma 3.5 on the integral remainder operators. More specifically, in the tangential part, the commutator is

$$\mathbf{B}_1 \cdot \hat{\mathbf{t}} + \mathbf{B}_2 \cdot \hat{\mathbf{t}} = \mathrm{Re} \left(\frac{z_\alpha^2}{2iL} \left[H, \frac{1}{z_\alpha^2} \right] \left(\gamma_\alpha - \frac{\gamma z_{\alpha\alpha}}{z_\alpha} \right) \right).$$

By Corollary 3.8, we can bound its H^{r-1} norm by

$$c \|z_\alpha\|_{r-1}^2 \left\| \frac{1}{z_\alpha} \right\|_{r-1} \left\| \frac{\gamma z_{\alpha\alpha}}{z_\alpha} - \gamma_\alpha \right\|_{r-3}.$$

By Lemma 4.1, $\|1/z_\alpha\|_{r-1} \le c(1 + \|z_\alpha\|_{r-1})$. Similarly,

$$\left\| \frac{\gamma z_{\alpha\alpha}}{z_\alpha} - \gamma_\alpha \right\|_{r-3} \le c \|\gamma\|_{r-3} (1 + \|z_\alpha\|_{r-2})^2 + \|\gamma\|_{r-2}$$

By applying Lemma 3.5 to the other part of $\mathbf{m} \cdot \hat{\mathbf{t}}$, which is $\mathbf{R}_1 \cdot \hat{\mathbf{t}} + \mathbf{R}_2 \cdot \hat{\mathbf{t}}$, we see that it is bounded in H^{r-1} by

$$\left(\left\| \frac{\gamma_\alpha}{z_\alpha} \right\|_1 + \left\| \frac{\gamma z_{\alpha\alpha}}{z_\alpha^2} \right\|_1 \right) C_1 \exp\{C_2 \|z_d\|_r\} \|z_d\|_r.$$

This is in turn bounded by

$$\left(\|\gamma\|_2 (1 + \|z_d\|_2) + \|\gamma\|_1 (1 + \|z_d\|_3)^3 \right) C_1 \exp\{C_2 \|z_d\|_r\} \|z_d\|_r.$$

As long as $r \ge 4$, we can put all of this into one bound, namely,

$$\|\mathbf{m} \cdot \hat{\mathbf{t}}\|_{r-1} \le C_1 \|\gamma\|_{r-2} \exp\{C_2 \|z_d\|_r\}.$$

The estimate for $\mathbf{m} \cdot \hat{\mathbf{n}}$ is similar, and this leads to the bound (4.3). Note that the bound on m_γ also requires the use of Corollary 3.8.

The bound on $D_\alpha(T - \mathbf{W} \cdot \hat{\mathbf{t}})$ is immediate from (2.9) and (2.20). To bound $|\mu^\varepsilon|$, we begin with the denominator in (2.30). Using (3.2), we have

$$\left| iL^\varepsilon \int_\alpha^{\alpha+2\pi} z_\alpha^\varepsilon(\alpha') \; d\alpha' \right| \;\ge\; 2\pi |\bar{c} L^\varepsilon| \;\ge\; 4\pi^2 \bar{c}. \tag{4.7}$$

Next, we look at the numerator of $|\mu^\varepsilon|$; it can be expressed as

$$\left| \int_\alpha^{\alpha+2\pi} \left[\frac{L_t^\varepsilon z_\alpha^\varepsilon}{L^\varepsilon} + \frac{2\pi i z_\alpha^\varepsilon}{L^\varepsilon} \left(\frac{\pi}{L^\varepsilon} (H\chi^\varepsilon \gamma_\alpha^\varepsilon) + \chi^\varepsilon [(T^\varepsilon - \mathbf{W}^\varepsilon \cdot \hat{\mathbf{t}}^\varepsilon)\chi^\varepsilon \theta_\alpha^\varepsilon] + \mathbf{m}^\varepsilon \cdot \hat{\mathbf{n}}^\varepsilon \right) \right] d\alpha' \right|.$$

Using Lemma 2.1 and the fact that $|z_\alpha^\varepsilon / L^\varepsilon| < c$, we bound this by

$$c(|L_t^\varepsilon| + \|\gamma_\alpha^\varepsilon\|_0 + \|T^\varepsilon - \mathbf{W}^\varepsilon \cdot \hat{\mathbf{t}}^\varepsilon\|_0 \|\theta_\alpha^\varepsilon\|_0 + \|\mathbf{m}\|_0).$$

Combined with (4.7), this clearly implies the estimate (4.6). □

We are now ready to prove the main estimate.

THEOREM 4.3. *Let $(\theta, \gamma, L) \in C([0,T); \mathcal{O})$ be a solution to the mollified initial value problem for the vortex sheet with surface tension* ((2.26), (2.27), (2.28), *and* (2.29)). *If the initial data θ_0 is in H^{r-1} and γ_0 is in $H^{r-3/2}$, where the integer r is large enough, then there exists a time $T^* > 0$ and positive constants C_1 and C_2 such that for all t satisfying $t \le T < T^*$,*

$$E(t) \le -\frac{\ln(e^{-C_2 E(0)} - C_1 C_2 t)}{C_2}. \tag{4.8}$$

The time T^* depends only upon the initial data, r, the Weber number, and the set $\mathcal{O}$.

Proof. Recall the definition of the energy in (3.3) and (3.4). We compute the time derivative of the energy. Our conclusion will be that for some positive constants C_1 and C_2,

$$\frac{dE}{dt} \le C_1 \exp\{C_2 E\}.$$

Demonstrating this bound will prove the theorem since this differential inequality has a solution until time $T^* = \frac{e^{-C_2 E(0)}}{C_1 C_2}$, and until that time, the bound (4.8) holds.

We first compute $\frac{dE_1^j}{dt}$. From the definition of E_1^j, we have

$$\frac{dE_1^j}{dt} = \int (D_\alpha^{j-1}\theta)(D_\alpha^{j-1}\theta_t)\, d\alpha.$$

Plugging in from (2.26) for θ_t, this is

$$\begin{aligned} \frac{dE_1^j}{dt} = {} & \int (D_\alpha^{j-1}\theta) \left(\frac{2\pi^2}{L^2} H\chi^\varepsilon (D_\alpha^j \gamma) \right) d\alpha \\ & + \int (D_\alpha^{j-1}\theta) D_\alpha^{j-1} \left(\chi^\varepsilon \left(\frac{2\pi}{L} (T - \mathbf{W}\cdot\hat{\mathbf{t}})\chi^\varepsilon D_\alpha \theta \right) \right) d\alpha \\ & + \int 2\pi (D_\alpha^{j-1}\theta) \left(\frac{D_\alpha^{j-1}(\mathbf{m}\cdot\hat{\mathbf{n}})}{L} + \mu \right) d\alpha. \end{aligned} \tag{4.9}$$

We rewrite the second integral in (4.9) simply by adding and subtracting. This is because the most important term from that integral comes when all of the $j-1$ derivatives fall on θ:

$$\begin{aligned} & \int (D_\alpha^{j-1}\theta) D_\alpha^{j-1} \left(\chi^\varepsilon \left(\frac{2\pi}{L} (T - \mathbf{W}\cdot\hat{\mathbf{t}})\chi^\varepsilon D_\alpha \theta \right) \right) d\alpha \\ & \qquad = \int (D_\alpha^{j-1}\theta)\chi^\varepsilon \left(\frac{2\pi}{L} (T - \mathbf{W}\cdot\hat{\mathbf{t}})\chi^\varepsilon D_\alpha^j \theta \right) d\alpha \\ & \quad + \int (D_\alpha^{j-1}\theta)\chi^\varepsilon \left(\frac{2\pi}{L} \left[D^{j-1}((T - \mathbf{W}\cdot\hat{\mathbf{t}})\chi^\varepsilon D_\alpha \theta) - (T - \mathbf{W}\cdot\hat{\mathbf{t}})\chi^\varepsilon D_\alpha^j \theta \right] \right) d\alpha. \end{aligned} \tag{4.10}$$

We introduce the notation

$$\frac{dE_1^j}{dt} = P_1^j + V_1^j + B_1^j + B_2^j,$$

where P_1^j is the first integral on the right-hand side of (4.9), V_1^j is the first term on the right-hand side of (4.10), B_1^j is the second term on the right-hand side of (4.10), and B_2^j is the third integral on the right-hand side of (4.9). Notice that P_1^j corresponds to the boxed term in (2.26). P_1^j will cancel with another term we will see soon; this will be the primary cancellation and will demonstrate the usefulness of the surface tension in this problem. V_1^j is a transport term which we will discuss in more detail later. Notice that if we were using the purely Lagrangian tangential velocity ($T = \mathbf{W} \cdot \hat{\mathbf{t}}$), there would be no transport term. Both of the B terms are bounded in terms of our energy, as we will now show.

To demonstrate that the B terms are bounded, we make frequent use of Lemma 4.2. We start with B_1^j. The factor $D_\alpha^{j-1}\theta$ that multiplies the difference in B_1^j can clearly be bounded by $cE^{1/2}$. Using Lemma 3.10, we bound the quantity in brackets by $c\|T - \mathbf{W} \cdot \hat{\mathbf{t}}\|_{j-1}\|\theta\|_{j-1}$. By Lemma 4.2 and the definition of the energy function, we can conclude that $B_1^j \leq C_1 \exp\{C_2 E\}$.

We estimate B_2^j by $cE^{1/2}\|\mathbf{m} \cdot \hat{\mathbf{n}} + \mu\|_{j-1}$. Recall that j is at most r. The Sobolev algebra property implies $\|\mathbf{m} \cdot \hat{\mathbf{n}} + \mu\|_{r-1} \leq c\|\mathbf{m}\|_{r-1}\|\hat{\mathbf{n}}\|_{r-1} + c|\mu|$. Lemma 4.2 tells us that $\|\mathbf{m}\|_{r-1} \leq C_1\|\gamma\|_{r-2}\exp\{C_2\|z_d\|_r\}$, and by the definition of $\hat{\mathbf{n}}$ we can bound $\|\hat{\mathbf{n}}\|_{r-1}$ by $\|z_d\|_r$. Also, Lemma 3.2 gives the bound $\|z_d\|_r \leq cL(1+\|\theta\|_{r-1})$. Similarly, we could use Lemma 4.2 to bound $|\mu|$ in terms of the norms of θ and γ. These estimates combine to yield the estimate $B_2^j \leq C_1 \exp\{C_2 E\}$.

We next take the time derivative of E_2^j. This is

$$\frac{dE_2^j}{dt} = \frac{\pi \mathrm{We}}{L}\int (D_\alpha^{j-2}\gamma_t)\Lambda(D_\alpha^{j-2}\gamma)\, d\alpha - \frac{\pi \mathrm{We} L_t}{L^2}\int (D_\alpha^{j-2}\gamma)\Lambda(D_\alpha^{j-2}\gamma)\, d\alpha.$$

We plug in for γ_t from (2.27). We use the following notation:

$$\frac{dE_2^j}{dt} = P_2^j + S_1^j + V_2^j + B_3^j + B_4^j + B_5^j,$$

where

$$P_2^j = \int \frac{2\pi^2}{L^2}(\chi^\varepsilon D_\alpha^j \theta)(\Lambda D_\alpha^{j-2}\gamma)\, d\alpha,$$

$$S_1^j = \int \frac{2\pi^3 \mathrm{We}}{L^3} H(\gamma^2 \chi^\varepsilon D_\alpha^{j-1}\theta)(\Lambda D_\alpha^{j-2}\gamma)\, d\alpha, \tag{4.11}$$

and

$$V_2^j = \int \left(\chi^\varepsilon \left(\frac{2\pi^2 \mathrm{We}}{L^2}(T - \mathbf{W} \cdot \hat{\mathbf{t}})\chi^\varepsilon D_\alpha^{j-1}\gamma\right)\right)\Lambda(D_\alpha^{j-2}\gamma)\, d\alpha.$$

Notice that P_2^j and S_1^j correspond to the boxed terms in (2.27). The primary cancellation that we mentioned earlier is between P_1^j and P_2^j. If there were no surface tension in the problem ($\mathrm{We} = \infty$), P_2^j would not be here. S_1^j will be involved in the

secondary cancellation, along with a term from E_3^j which we will soon see. S_1^j is the reason we need to include the unusual term E_3^j in the energy function at all. V_2^j is a transport term which we will deal with later. Again, if we were using the purely Lagrangian tangential velocity ($T = \mathbf{W} \cdot \hat{\mathbf{t}}$), the transport term would not be present.

We look now at the more easily bounded terms.

$$B_3^j = \int \frac{2\pi^3 \mathrm{We}}{L^3} \Lambda(D_\alpha^{j-2}\gamma) H \left[D_\alpha^{j-2}(\gamma^2 \chi^\varepsilon \theta_\alpha) - (\gamma^2 \chi^\varepsilon D_\alpha^{j-1}\theta) \right] \, d\alpha. \tag{4.12}$$

Like S_1^j, this corresponds to the second of the boxed terms in (2.27). This term is very similar to B_1^j. The next term,

$$B_4^j = \int \frac{2\pi^2 \mathrm{We}}{L^2} \chi^\varepsilon \left[D_\alpha^{j-2}((T - \mathbf{W} \cdot \hat{\mathbf{t}})\gamma_\alpha) - (T - \mathbf{W} \cdot \hat{\mathbf{t}}) D_\alpha^{j-1}\gamma \right] \Lambda(D_\alpha^{j-2}\gamma) \, d\alpha, \tag{4.13}$$

is related to V_2^j and is also very similar to B_1^j. Both B_3^j and B_4^j can be bounded in terms of the energy by a straightforward application of Lemmas 3.10 and 4.2. Finally, the term

$$B_5^j = \int \frac{\pi \mathrm{We}}{L} (D_\alpha^{j-2} m_\gamma) \Lambda(D_\alpha^{j-2}\gamma) - \frac{\pi \mathrm{We}}{L^2} L_t (D_\alpha^{j-2}\gamma) \Lambda(D_\alpha^{j-2}\gamma) \, d\alpha$$

can be bounded by a straightforward application of Lemma 4.2, as was B_2^j.

We can now see the primary cancellation:

$$P_1^j + P_2^j = \int \frac{2\pi^2}{L^2} \left[(D_\alpha^{j-1}\theta)(H\chi^\varepsilon(D_\alpha^j \gamma)) + (\chi^\varepsilon D_\alpha^j \theta)(\Lambda D_\alpha^{j-2}\gamma) \right] \, d\alpha. \tag{4.14}$$

Using the facts that χ^ε is self-adjoint and commutes with D_α, that $\Lambda = HD_\alpha$, and integrating by parts on the second of the two terms, we see that

$$P_1^j + P_2^j = \int \frac{2\pi^2}{L^2} \left[(D_\alpha^{j-1}\theta)(H\chi^\varepsilon(D_\alpha^j \gamma)) - (D_\alpha^{j-1}\theta)(H\chi^\varepsilon D_\alpha^j \gamma) \right] \, d\alpha = 0.$$

We remark here that this cancellation occurs because of the surface tension term in the evolution equation for γ. Without this cancellation, we would not be able to bound the growth of the norm of the solution.

Continuing, we take the time derivative of E_3^j. As we said earlier, the only reason to include E_3^j in the energy is to cancel S_1^j. Using (2.27) to substitute for γ_t, we write

$$\frac{dE_3^j}{dt} = S_2^j + B_6^j,$$

where

$$S_2^j = \int \frac{\gamma^2 \pi^2 \mathrm{We}^2}{L^2} (D_\alpha^{j-2}\gamma) \left(D_\alpha^{j-2} \left(\frac{2\pi \chi^\varepsilon \theta_{\alpha\alpha}}{L\mathrm{We}} \right) \right) \, d\alpha \tag{4.15}$$

will be the term which is involved in this secondary cancellation. This corresponds to the first of the boxed terms in (2.27). The rest of the terms are more easily bounded.

They are

$$B_6^j = \int \left[\frac{\gamma^2\pi^2 \mathrm{We}^2}{L^2}(D_\alpha^{j-2}\gamma)\left(D_\alpha^{j-2}\left(\frac{2\pi^2}{L^2}H(\gamma^2\chi^\varepsilon\theta_\alpha)\right)\right) \right.$$
$$+\frac{\gamma^2\pi^2 \mathrm{We}^2}{L^2}(D_\alpha^{j-2}\gamma)\left(D_\alpha^{j-2}\chi^\varepsilon\left(\frac{2\pi}{L}(T-\mathbf{W}\cdot\hat{\mathbf{t}})\chi^\varepsilon\gamma_\alpha\right)\right)$$
$$+\frac{\gamma^2\pi^2 \mathrm{We}^2}{L^2}(D_\alpha^{j-2}\gamma)(D_\alpha^{j-2}m_\gamma)$$
$$\left.+\frac{\gamma\gamma_t\pi^2 \mathrm{We}^2}{L^2}(D_\alpha^{j-2}\gamma)^2 - \frac{2\gamma^2\pi^2 \mathrm{We}^2}{L^3}L_t(D_\alpha^{j-2}\gamma)^2\right] d\alpha.$$

The bounds for the B terms are very similar to those done earlier and are based on Lemma 4.2. We will not perform these estimates here. We do remark that the term γ_t on the last line can be bounded in terms of the energy because it includes only low derivatives of θ and γ.

We can now see the secondary cancellation. From (4.11) and (4.15) we have

$$S_1^j + S_2^j = \int \frac{2\pi^3 \mathrm{We}}{L^3}H(\gamma^2\chi^\varepsilon D_\alpha^{j-1}\theta)(\Lambda D_\alpha^{j-2}\gamma) + \frac{\gamma^2\pi^2 \mathrm{We}^2}{L^2}(D_\alpha^{j-2}\gamma)\left(D_\alpha^{j-2}\left(\frac{2\pi\chi^\varepsilon\theta_{\alpha\alpha}}{L\mathrm{We}}\right)\right) d\alpha. \tag{4.16}$$

We rewrite the first term using the fact that Λ is self-adjoint and that $H\Lambda = -D_\alpha$. We slightly rearrange the second term.

$$S_1^j + S_2^j = \int \frac{2\pi^3 \mathrm{We}}{L^3}\left[- D_\alpha\Big(\gamma^2(\chi^\varepsilon D_\alpha^{j-1}\theta)\Big)(D_\alpha^{j-2}\gamma) + \gamma^2(\chi^\varepsilon D_\alpha^j\theta)(D_\alpha^{j-2}\gamma)\right] d\alpha.$$

We expand the first D_α using the product rule. The cancellation occurs, and we are left with

$$S_1^j + S_2^j = -\int \frac{4\pi^3\gamma\gamma_\alpha \mathrm{We}}{L^3}[(\chi^\varepsilon D_\alpha^{j-1}\theta)(D_\alpha^{j-2}\gamma)]\, d\alpha.$$

This can clearly be bounded by cE^2 (since r is large enough).

Next we turn our attention to the transport terms, V_1^j and V_2^j. Recall that V_1^j is defined as the first integral on the right-hand side of (4.10). We rewrite V_1^j using the fact that χ^ε is self-adjoint.

$$V_1^j = \int (\chi^\varepsilon D_\alpha^{j-1}\theta)(\chi^\varepsilon D_\alpha^j\theta)\left(\frac{2\pi}{L}(T-\mathbf{W}\cdot\hat{\mathbf{t}})\right) d\alpha.$$

Since the terms with θ form a perfect derivative, we integrate by parts. (This is why we placed χ^ε twice in the corresponding term in (2.26).)

$$V_1^j = -\frac{1}{2}\int (\chi^\varepsilon D_\alpha^{j-1}\theta)^2\left(\frac{2\pi}{L}D_\alpha(T-\mathbf{W}\cdot\hat{\mathbf{t}})\right) d\alpha.$$

This is clearly bounded in terms of the energy.

The transport term V_2^j is a little different because of the presence of the Λ operator.

$$V_2^j = \frac{2\pi^2 \mathrm{We}}{L^2} \int (T - \mathbf{W}\cdot\hat{\mathbf{t}}) \chi^\varepsilon D_\alpha^{j-1} \gamma \Lambda(\chi^\varepsilon D_\alpha^{j-2} \gamma) \, d\alpha. \tag{4.17}$$

In general, if we have an integral of the form $\int g f_\alpha \Lambda(f) \, d\alpha$, we rewrite it using the fact that the adjoint of H is $-H$.

$$\int g f_\alpha \Lambda(f) \, d\alpha = -\int H(g f_\alpha) f_\alpha \, d\alpha.$$

We then pull the factor of g through the Hilbert transform to get

$$\int g f_\alpha \Lambda(f) \, d\alpha = -\int g \Lambda(f) f_\alpha \, d\alpha - \int ([H,g] f_\alpha) f_\alpha \, d\alpha.$$

We add $\int g f_\alpha \Lambda(f) \, d\alpha$ to both sides and we find that

$$\int g f_\alpha \Lambda(f) \, d\alpha = -\frac{1}{2} \int ([H,g] f_\alpha) f_\alpha \, d\alpha.$$

We integrate this by parts and apply Lemma 3.7 to bound this by $c\|g\|_3 \|f\|_0^2$. Making the appropriate choice of f and g, (4.17) can then be bounded in terms of the energy (since r is large enough).

We have now proven that

$$\frac{dE}{dt} \leq C_1 \exp\{C_2 E\}.$$

As we remarked at the beginning of the proof, this proves the theorem. □

5. Existence of solutions. In this section, we demonstrate existence of solutions to the mollified initial value problem. We then show that these solutions converge (as the mollification parameter tends to zero) to a solution of the nonmollified problem. We demonstrate that this solution to the nonmollified problem is unique and has the same regularity as the initial data.

THEOREM 5.1. *Given $(\theta_0, \gamma_0, L_0) \in \mathcal{O}$, there exists a unique solution to the mollified initial value problem for the vortex sheet with surface tension* ((2.26), (2.27), (2.28), (2.29)) *which satisfies the non-self-intersection condition* (3.2) *and the boundedness condition* (3.5). *There exists a time $T^\varepsilon > 0$ such that the solution, $(\theta^\varepsilon, \gamma^\varepsilon, L^\varepsilon)$, is in $C^1([0,T^\varepsilon); \mathcal{O})$. T^ε depends on ε, r, $\mathcal{O}$, and $\|(\theta_0, \gamma_0, L_0)\|_{\mathcal{B}}$.*

Proof. Define $\mathbf{F}_\varepsilon : \mathcal{B} \to \mathcal{B}$ by letting its three components F_ε^1, F_ε^2, and F_ε^3 be the right-hand sides of (2.26), (2.27), and (2.28), respectively. (It is clear that the range of $\mathbf{F}_\varepsilon$ is contained in $\mathcal{B}$ from the presence of the mollifiers in the evolution equations and from Lemma 4.2.) Let two triples, $X = (\theta, \gamma, L)$ and $X' = (\theta', \gamma', L')$, be in $\mathcal{O}$. Since the mollified equations can be viewed as a system of ODEs on a Banach space, we use the Picard theorem to prove existence of solutions (see page 78 of [Zei86]). To do this, we need to show the bound $\|\mathbf{F}_\varepsilon(X) - \mathbf{F}_\varepsilon(X')\|_{\mathcal{B}} \leq c\|X - X'\|_{\mathcal{B}}$. Here, the constant c is allowed to depend on ε.

Using the triangle inequality in the obvious way, we break $\|\mathbf{F}_\varepsilon(X) - \mathbf{F}_\varepsilon(X')\|_{\mathcal{B}}$ into manageable pieces. We begin by looking at the part of $\|F_\varepsilon^1(X) - F_\varepsilon^1(X')\|_{\mathcal{B}}$ which

comes from the first term in (2.26):

$$\left\| \frac{2\pi^2}{L^2} H\chi^\varepsilon(\gamma_\alpha) - \frac{2\pi^2}{L'^2} H\chi^\varepsilon(\gamma'_\alpha) \right\|_{r-1} \leq \left\| \frac{2\pi^2}{L^2} H\chi^\varepsilon(\gamma_\alpha - \gamma'_\alpha) \right\|_{r-1} + \left\| \left(\frac{2\pi^2}{L^2} - \frac{2\pi^2}{L'^2} \right) H\chi^\varepsilon(\gamma'_\alpha) \right\|_{r-1}.$$

Using Lemma 2.1 and the bounds (3.5), we can bound this by $\frac{c}{\varepsilon^2}\|X - X'\|_{\mathcal{B}}$. The second term in (2.26) contributes

$$\left\| \chi^\varepsilon \left(\frac{2\pi}{L}(T - \mathbf{W}\cdot\hat{\mathbf{t}})\chi^\varepsilon\theta_\alpha - \frac{2\pi}{L'}(T' - \mathbf{W}'\cdot\hat{\mathbf{t}}')\chi^\varepsilon\theta'_\alpha \right) \right\|_{r-1} \leq \frac{c}{\varepsilon^{r-1}} \left\| \frac{2\pi}{L}(T - \mathbf{W}\cdot\hat{\mathbf{t}})\chi^\varepsilon\theta_\alpha - \frac{2\pi}{L'}(T' - \mathbf{W}'\cdot\hat{\mathbf{t}}')\chi^\varepsilon\theta'_\alpha \right\|_0. \tag{5.1}$$

We add and subtract twice to bound this by a constant (which depends on ε) times

$$\left\| \left(\frac{2\pi}{L} - \frac{2\pi}{L'} \right)(T - \mathbf{W}\cdot\hat{\mathbf{t}})\chi^\varepsilon\theta_\alpha \right\|_0 + \left\| \frac{2\pi}{L'}((T - \mathbf{W}\cdot\hat{\mathbf{t}}) - (T' - \mathbf{W}'\cdot\hat{\mathbf{t}}'))\chi^\varepsilon\theta_\alpha \right\|_0 + \left\| \frac{2\pi}{L'}(T' - \mathbf{W}'\cdot\hat{\mathbf{t}}')\chi^\varepsilon(\theta_\alpha - \theta'_\alpha) \right\|_0. \tag{5.2}$$

Notice that the first of these three terms involves the difference $L - L'$, and the third involves the difference $\theta - \theta'$. Because of the bounds (3.5), Lemma 4.2, and Lemma 2.1 we can bound these two terms by $c\|X - X'\|_{\mathcal{B}}$. So, we only need to pay special attention to

$$\left\| (T - \mathbf{W}\cdot\hat{\mathbf{t}}) - (T' - \mathbf{W}'\cdot\hat{\mathbf{t}}') \right\|_0.$$

We can easily bound this by $c\|X - X'\|_{\mathcal{B}}$ using (2.6), (2.28), (2.37), and Lemma 3.6. We have now concluded that (5.1) is bounded by $c\|X - X'\|_{\mathcal{B}}$. Continuing in this manner, we get that

$$\|\mathbf{F}_\varepsilon(X) - \mathbf{F}_\varepsilon(X')\|_{\mathcal{B}} \leq c\|X - X'\|_{\mathcal{B}},$$

where the constant depends on ε. Since $\mathbf{F}_\varepsilon$ is Lipschitz, we know that solutions to the mollified equations exist for at least a short time. □

Using Theorem 4.3, we can improve this to demonstrate existence of solutions for some amount of time independent of ε.

COROLLARY 5.2. *There exists a time $T > 0$ such that solutions of the mollified initial value problem, $(\theta^\varepsilon, \gamma^\varepsilon, L^\varepsilon)$, are in $C^1([0,T);\mathcal{O})$. T does not depend on ε.*

Proof. A consequence of the Picard theorem for (autonomous) ODEs on a Banach space (see page 78 of [Zei86]) is that solutions may be continued as long as the solution does not leave an open ball. This is analogous to the standard continuation theorem for ODEs on $\mathbb{R}^n$. Recall that we chose the constants $\bar{c}$ and $\bar{d}$ such that the initial data are in the set $\mathcal{O}$. We need to check that solutions $(\theta^\varepsilon, \gamma^\varepsilon, L^\varepsilon)$ cannot leave the open set $\mathcal{O}$ until some time which does not depend on ε. Note that since $z^\varepsilon(\alpha) - \alpha$ is 2π-periodic, the condition $L^\varepsilon > 2\pi$ is automatically satisfied. By (4.8), we see that if the initial data satisfy (3.5), then the solution satisfies (3.5) as long as

$$-\frac{\ln(e^{-C_2E(0)} - C_1C_2t)}{C_2} < \bar{d}. \tag{5.3}$$

Since we have imposed the condition (5.3) at time $t = 0$ on the data, and since the left-hand side is a continuous function of time, there is a time T_1 such that (5.3) is satisfied for all $t < T_1$.

For the condition (3.2), we know again that it is satisfied by the initial data. Recall that we have given the name q_1 to the quantity inside the absolute value on the right-hand side. If we can show that $|D_t q_1|$ is bounded independently of ε, then that will guarantee that (3.2) is satisfied at least for some amount of time which does not depend on ε. By the Sobolev lemma and Lemma 3.4, we have

$$|D_t q_1|_\infty \ \leq \ c\|D_t q_1\|_1 \ \leq \ c\|D_t z_d^\varepsilon\|_2.$$

This reduces the question to showing that $\|D_t z_d^\varepsilon\|_2$ is bounded independently of ε. We recall the definition $z_d^\varepsilon(\alpha,t) = \int_0^\alpha \frac{L^\varepsilon(t)}{2\pi} e^{i\theta^\varepsilon(\alpha',t)}\,d\alpha'$. Taking the time derivative of this equation, and using the definitions of θ_t^ε and L_t^ε and the bounds (3.5), we see that $\|D_t z_d^\varepsilon\|_2$ is bounded by a constant independent of ε. (It is important that at present we are only attempting to bound a small number of derivatives of z_d^ε.) This proves the corollary. □

We can now prove that the mollified solutions converge in a low norm as the mollification parameter tends to zero. For convenience, we denote by $\mathcal{B}'$ the space $H^1 \times H^{1/2} \times \mathbb{R}$.

THEOREM 5.3. *Solutions $(\theta^\varepsilon, \gamma^\varepsilon, L^\varepsilon)$ of the mollified initial value problem form a Cauchy sequence in $C([0,T];\mathcal{B}')$.*

Proof. Define E_d, the energy function for the difference of two solutions with different values of the mollification parameter, as $E_d^1 + E_d^0 + (L^\varepsilon - L^{\varepsilon'})^2$. Here,

$$E_d^1 = \frac{1}{2}\int (D_\alpha(\theta^\varepsilon - \theta^{\varepsilon'}))^2 + \frac{\pi \mathrm{We}}{L^\varepsilon}(\gamma^\varepsilon - \gamma^{\varepsilon'})\Lambda(\gamma^\varepsilon - \gamma^{\varepsilon'}) + \frac{(\gamma^\varepsilon)^2\pi^2\mathrm{We}^2}{{L^\varepsilon}^2}(\gamma^\varepsilon - \gamma^{\varepsilon'})^2\,d\alpha,$$

$$E_d^0 = \frac{1}{2}\int (\theta^\varepsilon - \theta^{\varepsilon'})\Lambda(\theta^\varepsilon - \theta^{\varepsilon'}) + \frac{\pi \mathrm{We}}{L^\varepsilon}(\gamma^\varepsilon - \gamma^{\varepsilon'})^2 + (\theta^\varepsilon - \theta^{\varepsilon'})^2\,d\alpha.$$

Since both solutions satisfy the same initial conditions, $E_d(0) = 0$. We now wish to estimate how this energy changes over time.

$$\begin{aligned}
\frac{dE_d^1}{dt} &= \int D_\alpha(\theta_t^\varepsilon - \theta_t^{\varepsilon'})D_\alpha(\theta^\varepsilon - \theta^{\varepsilon'}) + \frac{\pi\mathrm{We}}{L^\varepsilon}(\gamma_t^\varepsilon - \gamma_t^{\varepsilon'})\Lambda(\gamma^\varepsilon - \gamma^{\varepsilon'}) \\
&\quad + \left(\frac{\gamma^\varepsilon \pi \mathrm{We}}{L^\varepsilon}\right)^2 (\gamma_t^\varepsilon - \gamma_t^{\varepsilon'})(\gamma^\varepsilon - \gamma^{\varepsilon'}) \\
&\quad + \left[-\frac{\pi\mathrm{We}L_t^\varepsilon}{(L^\varepsilon)^2}(\gamma^\varepsilon - \gamma^{\varepsilon'})\Lambda(\gamma^\varepsilon - \gamma^{\varepsilon'}) + \pi^2\mathrm{We}^2\left(\left(\frac{\gamma^\varepsilon}{L^\varepsilon}\right)^2\right)_t (\gamma^\varepsilon - \gamma^{\varepsilon'})^2\right] \\
&= F_1 + F_2 + F_3 + F_4.
\end{aligned}$$

The estimate of the growth of E_d is very similar to the estimate in Theorem 4.3.

We start with F_1, plugging in for θ_t^ε and $\theta_t^{\varepsilon'}$ from (2.26).

$$F_1 = \int \left(\frac{2\pi^2}{{L^\varepsilon}^2}H(\chi^\varepsilon \gamma_{\alpha\alpha}^\varepsilon) - \frac{2\pi^2}{{L^{\varepsilon'}}^2}H(\chi^{\varepsilon'}\gamma_{\alpha\alpha}^{\varepsilon'})\right)(\theta_\alpha^\varepsilon - \theta_\alpha^{\varepsilon'})\,d\alpha + G_1, \tag{5.4}$$

where G_1 is the remainder. Notice that the integral in (5.4) corresponds to the boxed term in (2.26). We now look at F_2, plugging in for γ_t^ε and $\gamma_t^{\varepsilon'}$ from (2.27).

$$F_2 = \int \frac{\pi \mathrm{We}}{L^\varepsilon}\left(\frac{2\pi}{L^\varepsilon}\frac{\chi^\varepsilon \theta^\varepsilon_{\alpha\alpha}}{\mathrm{We}} - \frac{2\pi}{L^{\varepsilon'}}\frac{\chi^{\varepsilon'}\theta^{\varepsilon'}_{\alpha\alpha}}{\mathrm{We}}\right)\Lambda(\gamma^\varepsilon - \gamma^{\varepsilon'})\, d\alpha \tag{5.5}$$
$$+ \int \frac{\pi \mathrm{We}}{L^\varepsilon}\left(\frac{2\pi^2}{L^{\varepsilon 2}}H(\gamma^{\varepsilon 2}\chi^\varepsilon\theta^\varepsilon_\alpha) - \frac{2\pi^2}{L^{\varepsilon' 2}}H(\gamma^{\varepsilon' 2}\chi^{\varepsilon'}\theta^{\varepsilon'}_\alpha)\right)\Lambda(\gamma^\varepsilon - \gamma^{\varepsilon'})\, d\alpha + G_2,$$

where G_2 is the remainder. Again, the integrals in (5.5) correspond to the boxed terms in (2.27).

In adding F_1 and F_2, we see a cancellation very much like (4.14), the primary cancellation in the proof of Theorem 4.3. To see this, use the name I_1 for the sum of the integral in (5.4) and the first integral in (5.5). We integrate the piece from (5.4) by parts to see

$$I_1 = \int -\left(\frac{2\pi^2}{L^{\varepsilon 2}}\Lambda(\chi^\varepsilon\gamma^\varepsilon) - \frac{2\pi^2}{L^{\varepsilon' 2}}\Lambda(\chi^{\varepsilon'}\gamma^{\varepsilon'})\right)(\theta^\varepsilon_{\alpha\alpha} - \theta^{\varepsilon'}_{\alpha\alpha}) \tag{5.6}$$
$$+ \left(\frac{2\pi^2}{L^{\varepsilon 2}}\chi^\varepsilon\theta^\varepsilon_{\alpha\alpha} - \frac{2\pi^2}{L^\varepsilon L^{\varepsilon'}}\chi^{\varepsilon'}\theta^{\varepsilon'}_{\alpha\alpha}\right)\Lambda(\gamma^\varepsilon - \gamma^{\varepsilon'})\, d\alpha.$$

We add and subtract in order to adjust the factors of L and the operators χ.

$$\begin{aligned} I_1 = &-\int \left(\frac{2\pi^2}{L^{\varepsilon 2}}\Lambda(\chi^\varepsilon\gamma^\varepsilon) - \frac{2\pi^2}{L^{\varepsilon 2}}\Lambda(\chi^\varepsilon\gamma^{\varepsilon'})\right)(\theta^\varepsilon_{\alpha\alpha} - \theta^{\varepsilon'}_{\alpha\alpha})\, d\alpha \\ &-\int \left(\frac{2\pi^2}{L^{\varepsilon 2}}\Lambda(\chi^\varepsilon\gamma^{\varepsilon'}) - \frac{2\pi^2}{L^{\varepsilon' 2}}\Lambda(\chi^\varepsilon\gamma^{\varepsilon'})\right)(\theta^\varepsilon_{\alpha\alpha} - \theta^{\varepsilon'}_{\alpha\alpha})\, d\alpha \\ &-\int \left(\frac{2\pi^2}{L^{\varepsilon' 2}}\Lambda(\chi^\varepsilon\gamma^{\varepsilon'}) - \frac{2\pi^2}{L^{\varepsilon' 2}}\Lambda(\chi^{\varepsilon'}\gamma^{\varepsilon'})\right)(\theta^\varepsilon_{\alpha\alpha} - \theta^{\varepsilon'}_{\alpha\alpha})\, d\alpha \\ &+\int \left(\frac{2\pi^2}{L^{\varepsilon 2}}\chi^\varepsilon\theta^\varepsilon_{\alpha\alpha} - \frac{2\pi^2}{L^{\varepsilon 2}}\chi^\varepsilon\theta^{\varepsilon'}_{\alpha\alpha}\right)\Lambda(\gamma^\varepsilon - \gamma^{\varepsilon'})\, d\alpha \\ &+\int \left(\frac{2\pi^2}{L^{\varepsilon 2}}\chi^\varepsilon\theta^{\varepsilon'}_{\alpha\alpha} - \frac{2\pi^2}{L^\varepsilon L^{\varepsilon'}}\chi^\varepsilon\theta^{\varepsilon'}_{\alpha\alpha}\right)\Lambda(\gamma^\varepsilon - \gamma^{\varepsilon'})\, d\alpha \\ &+\int \left(\frac{2\pi^2}{L^\varepsilon L^{\varepsilon'}}\chi^\varepsilon\theta^{\varepsilon'}_{\alpha\alpha} - \frac{2\pi^2}{L^\varepsilon L^{\varepsilon'}}\chi^{\varepsilon'}\theta^{\varepsilon'}_{\alpha\alpha}\right)\Lambda(\gamma^\varepsilon - \gamma^{\varepsilon'})\, d\alpha. \end{aligned} \tag{5.7}$$

The first and fourth of these integrals cancel exactly because χ^ε is self-adjoint. We look at the second integral; we integrate it by parts, and since r is large enough, we use the uniform bound of Theorem 4.3 to bound $\|\chi^\varepsilon\gamma^{\varepsilon'}_{\alpha\alpha}\|$ by a constant. Thus, the second integral can be bounded by $c|L^\varepsilon - L^{\varepsilon'}|\|\theta^\varepsilon - \theta^{\varepsilon'}\|_1$, which can in turn be bounded by cE_d. Similarly, the fifth integral can be bounded by cE_d.

The third and sixth integrals involve differences of χ^ε and $\chi^{\varepsilon'}$. We integrate the third integral by parts, and using the uniform bound of Theorem 4.3, we see that it is bounded by $c\|\theta^\varepsilon - \theta^{\varepsilon'}\|_1\|\chi^\varepsilon\gamma^{\varepsilon'} - \chi^{\varepsilon'}\gamma^{\varepsilon'}\|_2$. Using Lemma 2.2 together with Theorem 4.3, we can bound this by $c\max\{\varepsilon,\varepsilon'\}E_d^{1/2}$. Similarly, the sixth integral can be bounded by $c\max\{\varepsilon,\varepsilon'\}E_d^{1/2}$.

We leave out the remaining details of the estimate of E_d because they are very similar to what we have just done and to the estimate in the proof of Theorem 4.3.

More details can be found in [Amb02]. The result is

$$\frac{dE_d}{dt} \;\leq\; cE_d + c\max\{\varepsilon,\varepsilon'\}E_d^{1/2}.$$

This can be restated as $\frac{dE_d^{1/2}}{dt} \leq cE_d^{1/2} + c\max\{\varepsilon,\varepsilon'\}$. Since E_d is initially zero, we solve the differential inequality to see that

$$E_d^{1/2} \;\leq\; \max\{\varepsilon,\varepsilon'\}(e^{ct}-1). \tag{5.8}$$

We wish to relate this to the norms of θ, γ, and L. From the definition of E_d, it is apparent that $\|(\theta^\varepsilon - \theta^{\varepsilon'}, \gamma^\varepsilon - \gamma^{\varepsilon'}, L^\varepsilon - L^{\varepsilon'})\|_{\mathcal{B}'} \leq CE_d^{1/2}$. Using (5.8) with this, and taking the supremum in time, we have

$$\sup_{0\leq t\leq T} \|(\theta^\varepsilon - \theta^{\varepsilon'}, \gamma^\varepsilon - \gamma^{\varepsilon'}, L^\varepsilon - L^{\varepsilon'})\|_{\mathcal{B}'} \;\leq\; C\max\{\varepsilon,\varepsilon'\}(e^{cT}-1).$$

Thus, solutions do form a Cauchy sequence in $C([0,T];H^1\times H^{1/2}\times\mathbb{R})$. □

We now know that the solutions of the mollified problem, $(\theta^\varepsilon,\gamma^\varepsilon,L^\varepsilon)$, approach a limit as $\varepsilon\to 0$. Call this limit (θ,γ,L). We prove that (θ,γ,L) is a solution to the nonmollified initial value problem, that this solution is unique, and that the solution is in the space $C([0,T];\mathcal{O})$.

In order to do this, we first prove that the limit of the mollified solutions is weakly continuous in time. That is, we will show that $\theta\in C_W([0,T];H^{r-1})$ and $\gamma\in C_W([0,T];H^{r-3/2})$. For $s\in\mathbb{R}$, the statement $u\in C_W([0,T];H^s)$ means that $u(t)\in H^s$ for all $t\in[0,T]$, and for all $\psi\in H^{-s}$, the duality pairing $\langle u(t),\psi\rangle$ is a continuous function of time.

THEOREM 5.4. *The limit of the solutions to the mollified initial value problem found in the previous theorem, (θ,γ,L), is in $C([0,T];H^m\times H^{m'}\times\mathbb{R})$ for all $1\leq m< r-1$ and $1/2\leq m'<r-3/2$, and it is also in $C_W([0,T];\mathcal{O})$. Furthermore, (θ,γ,L) is a solution to the exact evolution equations for the vortex sheet with surface tension* ((2.22), (2.23), (2.24)).

Proof. We have found a triple $(\theta,\gamma,L)\in C([0,T];H^1\times H^{1/2}\times\mathbb{R})$, which is the limit of the solutions of the mollified equations, $(\theta^\varepsilon,\gamma^\varepsilon,L^\varepsilon)$. Recall that the conclusion of Theorem 4.3 is that

$$\sup_{0\leq t\leq T}\|(\theta^\varepsilon,\gamma^\varepsilon,L^\varepsilon)\|_{\mathcal{B}}\leq C.$$

Since $\mathcal{B}$ is a Hilbert space, its unit ball is weakly compact. Thus, $(\theta^\varepsilon,\gamma^\varepsilon,L^\varepsilon)$ must have a weak limit in $\mathcal{B}$. Since $\mathcal{B}\subset H^1\times H^{1/2}\times\mathbb{R}$, this weak limit must be (θ,γ,L). Thus, $(\theta,\gamma,L)\in\mathcal{B}$.

We can now apply Lemma 3.3 to the differences $\theta^\varepsilon-\theta$ and $\gamma^\varepsilon-\gamma$. The conclusion is that

$$\|\theta^\varepsilon-\theta\|_m \;\leq\; C\|\theta^\varepsilon-\theta\|_0^{1-\frac{m}{r-1}}\|\theta^\varepsilon-\theta\|_{r-1}^{\frac{m}{r-1}},$$

$$\|\gamma^\varepsilon-\gamma\|_{m'} \;\leq\; C\|\gamma^\varepsilon-\gamma\|_0^{1-\frac{m'}{r-3/2}}\|\gamma^\varepsilon-\gamma\|_{r-3/2}^{\frac{m'}{r-3/2}}.$$

Notice that the right-hand sides of these inequalities go to zero uniformly on $[0,T]$. This implies $(\theta,\gamma,L)\in H^m\times H^{m'}\times\mathbb{R}$ for all $1\leq m<r-1$ and all $\frac{1}{2}\leq m'<r-\frac{3}{2}$.

This regularity is enough to conclude that (θ, γ, L) is a solution to the nonmollified system (2.22), (2.23), (2.24).

We now show that $(\theta, \gamma, L) \in C_W([0,T]; \mathcal{B})$. Let $\eta > 0$ be given. Let $\phi \in H^{-(r-1)}$ be given. For any m satisfying $1 \le m < r-1$, let $\tilde{\phi} \in H^{-m}$ be given such that

$$\left\| \phi - \tilde{\phi} \right\|_{-(r-1)} \le \frac{\eta}{3}. \tag{5.9}$$

We know that such a $\tilde{\phi}$ can be found since H^s is dense in $H^{s'}$ whenever $s' < s$. We show that the difference of the duality pairings of θ and θ^ε with ϕ can be made small uniformly in time:

$$\langle \phi, \theta^\varepsilon \rangle - \langle \phi, \theta \rangle = \langle \phi - \tilde{\phi}, \theta^\varepsilon \rangle + \langle \tilde{\phi}, \theta^\varepsilon - \theta \rangle + \langle \tilde{\phi} - \phi, \theta \rangle. \tag{5.10}$$

The two of these involving $\phi - \tilde{\phi}$ can be bounded by $\eta/3$ using (5.9) and the uniform bound on θ and θ^ε in H^{r-1}. For the term involving $\theta - \theta^\varepsilon$, we choose ε small enough so that $\|\theta - \theta^\varepsilon\|_m \le \frac{\eta}{3}$. Thus, (5.10) is bounded by η. Since η was arbitrary and since these bounds are all uniform in time, and since θ^ε is in $C([0,T]; H^{r-1})$, we conclude that $\theta \in C_W([0,T]; H^{r-1})$. A similar argument applies to γ. Thus, we conclude that $(\theta, \gamma, L) \in C_W([0,T]; \mathcal{B})$. □

Before proving the highest regularity theorem for solutions of the nonmollified problem, we first need uniqueness of these solutions.

THEOREM 5.5. *Solutions $(\theta, \gamma, L) \in \mathcal{B}$ of the exact initial value problem for the vortex sheet with surface tension* ((2.22), (2.23), (2.24), (2.25)) *are unique.*

We do not prove this theorem here. The proof is very similar to the proof of Theorem 5.3 because both proofs require that the difference of two solutions be estimated. This theorem is simpler than Theorem 5.3 because of the absence of the χ operators in the nonmollified problem. The proof is contained in [Amb02].

We can now demonstrate our highest regularity theorem: $(\theta, \gamma, L) \in C([0,T]; \mathcal{B})$. Because we already know that $(\theta^\varepsilon, \gamma^\varepsilon, L^\varepsilon)$ converges to (θ, γ, L) in the weak topology, we need to show only that $\|(\theta, \gamma, L)\|_{\mathcal{B}}$ is continuous in time. To do this, we make use of the time-reversibility of our equations.

THEOREM 5.6. *Solutions (θ, γ, L) of the exact initial value problem for the vortex sheet with surface tension* ((2.22), (2.23), (2.24), (2.25)) *are in $C([0,T]; \mathcal{B})$.*

Since $(\theta, \gamma, L) \in C_W([0,T]; \mathcal{B})$, we see that L is continuous and, by Fatou's lemma,

$$\|\theta_0\|_{r-1}^2 \le \liminf_{t \to 0^+} \|\theta(t)\|_{r-1}^2, \tag{5.11}$$

$$\|\gamma_0\|_{r-3/2}^2 \le \liminf_{t \to 0^+} \|\gamma(t)\|_{r-3/2}^2. \tag{5.12}$$

Also, by (4.8), we have the estimate $\limsup_{t \to 0^+} E(t) \le E(0)$. Since $\liminf(a) + \liminf(b) \le \liminf(a+b)$, we can combine (5.11) and (5.12) to get $\liminf_{t \to 0^+} E(t) \ge E(0)$. Thus, the energy is right-continuous at the initial time. To see that $\|(\theta, \gamma, L)\|_{\mathcal{B}}$ is also right-continuous at the initial time, we look at the various parts of the energy. First, we consider E_3^j, where j is at most r. Its definition is

$$E_3^j(t) = \frac{1}{2} \int_0^{2\pi} \frac{\gamma^2(\alpha,t)\pi^2 \mathrm{We}^2}{L^2(t)} (D_\alpha^{j-2} \gamma(\alpha,t))^2 \, d\alpha.$$

Since we already know that $\gamma \in C([0,T]; H^{r-2})$, we can conclude that E_3^j is continuous. Similarly, we know that E_1^j and E_2^j are continuous for j at most $r-1$. Also,

we already know that L and $E^0 = \|\theta\|_0^2 + \|\gamma\|_0^2$ are continuous. This tells us that the difference between E and the parts of the energy which we know to be individually continuous is continuous. In particular, we now know that

$$E_1^r(t) + E_2^r(t) = \frac{1}{2}\int_0^{2\pi} (D_\alpha^{r-1}\theta(\alpha,t))^2 + \frac{\pi \mathrm{We}}{L(t)}(D_\alpha^{r-2}\gamma(\alpha,t))\Lambda(D_\alpha^{r-2}\gamma(\alpha,t))\, d\alpha$$

is continuous. Combining this with the lower-order terms, it means

$$\|\theta\|_{r-1}^2 + \frac{\pi \mathrm{We}}{L}\|\gamma\|_{r-3/2}^2 \tag{5.13}$$

is right-continuous at the initial time. Notice that (5.11) and (5.12) imply that $\|\theta\|_{r-1}$ and $\|\gamma\|_{r-3/2}$ are right lower semicontinuous at the initial time, and we already know that L is right-continuous at the initial time. Since the sum (5.13) is right-continuous at the initial time, this implies that $\|\theta\|_{r-1}$ and $\|\gamma\|_{r-3/2}$ are each right-continuous at the initial time.

Given a time $T' \in (0,T)$, we can interpret T' as a new initial time. We know that $(\theta(T'), \gamma(T'), L(T'))$ satisfies conditions (3.2) and (3.5). Thus, we could repeat our arguments for existence of mollified solutions starting at time T', and we would find that a solution to the nonmollified equations exists on some time interval around T'. By Theorem 5.5, the solution we found starting from $t = 0$ and the solution we found starting from $t = T'$ must be the same. Using the argument by which we showed that solutions are right-continuous at $t = 0$, we see that solutions are right-continuous at $t = T'$. Since all of our analysis works with time reversed, we can also conclude that solutions are left-continuous at $t = T'$. Similarly, we can show that solutions are also left-continuous at the final time, $t = T$. We conclude that $(\theta, \gamma, L) \in C([0,T], \mathcal{B})$. ∎

We also have the following theorem that demonstrates that the solutions of the initial value problem are continuous in a low norm of the initial data.

THEOREM 5.7. *If $(\theta, \gamma, L) \in \mathcal{B}$ and $(\theta', \gamma', L') \in \mathcal{B}$ are both solutions of the exact initial value problem for the vortex sheet with surface tension for the interval of time $[0,T]$, with the corresponding initial data $(\theta_0, \gamma_0, L_0) \in \mathcal{O}$ and $(\theta_0', \gamma_0', L_0') \in \mathcal{O}$, then*

$$\sup_{0\le t\le T} \|(\theta - \theta', \gamma - \gamma', L - L')\|_{\mathcal{B}'} \;\le\; \|(\theta_0 - \theta_0', \gamma_0 - \gamma_0', L_0 - L_0')\|_{\mathcal{B}'} \exp\{cT\}.$$

We do not include the proof of this theorem since it is very similar to those of Theorems 5.3 and 5.5.

6. The case of fluids with different densities. Thus far, we have considered only the case in which the upper and lower fluids both have the same density. Our method also proves well-posedness in the general case of arbitrary densities. We define the Atwood ratio, At, to be

$$\mathrm{At} = \frac{\rho_1 - \rho_2}{\rho_1 + \rho_2},$$

where ρ_1 is the density of the lower fluid and ρ_2 is the density of the upper fluid.

This section of the paper consists of three subsections. In the first, we give the evolution equation for γ in the two-density case and we rewrite it; this is similar to what we have already done for the density-matched case in section 2. This new evolution equation is actually an integral equation for γ_t. In the second subsection, we discuss the solvability of the integral equation and give estimates for quantities related to the integral operator. In the final subsection, we state the existence theorem for the vortex sheet in the two-density case.

6.1. The new γ_t equation. In considering $\mathrm{At} \neq 0$, the evolution equations for θ and L do not change. The new evolution equation for γ is

$$\gamma_t = \frac{2\pi\theta_{\alpha\alpha}}{L\mathrm{We}} + \frac{2\pi}{L} D_\alpha \left((T - \mathbf{W}\cdot\hat{\mathbf{t}})\gamma \right) - 2\mathrm{At} \left(\frac{L}{2\pi}\mathbf{W}_t \cdot \hat{\mathbf{t}} + \frac{\pi^2}{L^2}\gamma\gamma_\alpha - (T - \mathbf{W}\cdot\hat{\mathbf{t}})\mathbf{W}_\alpha \cdot \hat{\mathbf{t}} \right). \tag{6.1}$$

If $\mathrm{At} = 0$, then this is just the same equation as (2.7). This equation for γ_t can be derived by a variation on the argument presented in [BMO82]; this derivation is included in [Amb02]. There is a small error in this form of the equation in [HLS94] and [HLS97], but it appears correctly in [CH96].

We need to rewrite this equation, similarly to the way we rewrote all of the evolution equations in section 2. We focus first on expanding the factor which multiplies the Atwood ratio. We begin by writing out $\frac{L}{2\pi}\mathbf{W}_t \cdot \hat{\mathbf{t}}$, with the goal of separating it into important and routine pieces:

$$\begin{aligned} \frac{L}{2\pi}\mathbf{W}_t \cdot \hat{\mathbf{t}} &= \mathrm{Re}\left(z_\alpha \Phi(\mathbf{W}_t)^*\right) \\ &= \mathrm{Re}\left\{ \frac{z_\alpha(\alpha)}{4\pi i}\mathrm{PV}\int \gamma_t(\alpha')\cot\frac{1}{2}(z(\alpha) - z(\alpha'))\, d\alpha' \right\} \\ &\quad - \mathrm{Re}\left\{ \frac{z_\alpha(\alpha)}{4\pi i}\mathrm{PV}\int \frac{\gamma(\alpha')}{2}(z_t(\alpha) - z_t(\alpha'))\csc^2\frac{1}{2}(z(\alpha) - z(\alpha'))\, d\alpha' \right\}. \end{aligned} \tag{6.2}$$

We make the definition of an integral operator, $\mathcal{J}[z]$, to be

$$\mathcal{J}[z]f(\alpha) = -\mathrm{PV}\int f(\alpha')\mathrm{Re}\left(i z_\alpha(\alpha)\cot\frac{1}{2}(z(\alpha) - z(\alpha')) \right) d\alpha'.$$

Notice that we can write $\mathcal{J}[z]$ as

$$\mathcal{J}[z]f(\alpha) = -2\pi\mathrm{Re}\left(i z_\alpha H\left(\frac{f}{z_\alpha}\right)\right) + 4\pi\mathrm{Re}(z_\alpha \mathcal{K}[z]f(\alpha)), \tag{6.3}$$

with $\mathcal{K} = \mathcal{K}_1 + \mathcal{K}_2$ defined in (2.35) and (2.36). We can now write

$$\frac{L}{2\pi}\mathbf{W}_t \cdot \hat{\mathbf{t}} = \frac{1}{4\pi}\mathcal{J}[z]\gamma_t + R_3,$$

where R_3 is the second term on the right-hand side of (6.2). Estimates for $\mathcal{J}[z]$ are the subject of the next subsection.

We will now expand R_3. As we have done many times in section 2, we multiply and divide the integrand in R_3 by $z_\alpha(\alpha')$ and then recognize that part of the integrand is an α'-derivative. We integrate by parts to get

$$\begin{aligned} R_3 &= -\mathrm{Re}\left\{ \frac{z_\alpha(\alpha)}{4\pi i}\mathrm{PV}\int \frac{\gamma(\alpha')}{z_\alpha(\alpha')} z_{\alpha t}(\alpha')\cot\frac{1}{2}(z(\alpha) - z(\alpha'))\, d\alpha' \right\} \\ &\quad + \mathrm{Re}\left\{ \frac{z_\alpha(\alpha)}{4\pi i}\mathrm{PV}\int D_{\alpha'}\left(\frac{\gamma(\alpha')}{z_\alpha(\alpha')}\right)(z_t(\alpha) - z_t(\alpha'))\cot\left(\frac{1}{2}(z(\alpha) - z(\alpha'))\right) d\alpha' \right\}. \end{aligned} \tag{6.4}$$

We write $R_3 = R_4 + R_5$, with R_4 equal to the first term on the right-hand side of (6.4) and R_5 equal to the second. We can rewrite R_5 as

$$R_5 = \mathrm{Re}\left\{ \frac{z_\alpha}{2i}[H, z_t]\left(\frac{1}{z_\alpha} D_\alpha\left(\frac{\gamma}{z_\alpha}\right)\right)\right\} + \mathrm{Re}\left\{ z_\alpha z_t \mathcal{K}[z]\left(D_\alpha\left(\frac{\gamma}{z_\alpha}\right)\right) - z_\alpha \mathcal{K}[z]\left(z_t D_\alpha\left(\frac{\gamma}{z_\alpha}\right)\right)\right\}. \tag{6.5}$$

R_4 is more important, and we continue to expand it. To begin to do this, we write

$$R_4 = -\mathrm{Re}\left\{ \frac{z_\alpha}{2i} H\left(\frac{\gamma}{z_\alpha^2} z_{\alpha t}\right)\right\} - \mathrm{Re}\left\{ z_\alpha \mathcal{K}[z]\left(\frac{\gamma}{z_\alpha} z_{\alpha t}\right)\right\}.$$

In order to understand this, we look at $z_{\alpha t}$:

$$z_{\alpha t} = \left(\frac{L}{2\pi} e^{i\theta}\right)_t = \frac{L_t}{2\pi} e^{i\theta} + \frac{L}{2\pi} i\theta_t e^{i\theta} = \frac{L_t}{L} z_\alpha + i\theta_t z_\alpha. \tag{6.6}$$

Using (6.6), and substituting from (2.22) for θ_t, we have

$$\begin{aligned} R_4 = &- \mathrm{Re}\left\{ z_\alpha \mathcal{K}[z]\left(\frac{\gamma}{z_\alpha} z_{\alpha t}\right)\right\} - \mathrm{Re}\left\{ \frac{z_\alpha}{2i} H\left(\frac{L_t \gamma}{L z_\alpha}\right)\right\} \\ &- \mathrm{Re}\left\{ \frac{z_\alpha}{2} H\left(\frac{2\pi^2 \gamma H(\gamma_\alpha)}{L^2 z_\alpha}\right)\right\} - \mathrm{Re}\left\{ \frac{z_\alpha}{2} H\left(\frac{2\pi\gamma(T - \mathbf{W}\cdot\hat{\mathbf{t}})\theta_\alpha}{L z_\alpha}\right)\right\} \\ &- \mathrm{Re}\left\{ \frac{z_\alpha}{2} H\left(\frac{2\pi\gamma \mathbf{m}\cdot\hat{\mathbf{n}}}{L z_\alpha}\right)\right\}. \end{aligned} \tag{6.7}$$

We still need to rewrite the third and fourth of these terms so that we can see more clearly the most important part of R_4. We begin by bringing γ/z_α outside of the first Hilbert transform in the third term:

$$-\mathrm{Re}\left\{ \frac{z_\alpha}{2} H\left(\frac{2\pi^2 \gamma H(\gamma_\alpha)}{L^2 z_\alpha}\right)\right\} = \frac{\pi^2}{L^2}\gamma\gamma_\alpha - \mathrm{Re}\left\{ \frac{\pi^2 z_\alpha}{L^2}\left[H, \frac{\gamma}{z_\alpha}\right](H(\gamma_\alpha))\right\}. \tag{6.8}$$

Similarly, in the fourth term, we bring $(T - \mathbf{W}\cdot\hat{\mathbf{t}})/z_\alpha$ outside of the Hilbert transform:

$$-\mathrm{Re}\left\{ \frac{z_\alpha}{2} H\left(\frac{2\pi\gamma(T - \mathbf{W}\cdot\hat{\mathbf{t}})\theta_\alpha}{L z_\alpha}\right)\right\} = \frac{\pi(T - \mathbf{W}\cdot\hat{\mathbf{t}})}{L} H(\gamma\theta_\alpha) - \mathrm{Re}\left\{ \frac{\pi z_\alpha}{L}\left[H, \frac{(T - \mathbf{W}\cdot\hat{\mathbf{t}})}{z_\alpha}\right](\gamma\theta_\alpha)\right\}. \tag{6.9}$$

Finally, this allows us to write

$$\frac{L}{2\pi}\mathbf{W}_t\cdot\hat{\mathbf{t}} = \frac{1}{4\pi}\mathcal{J}[z]\gamma_t - \frac{\pi(T - \mathbf{W}\cdot\hat{\mathbf{t}})}{L} H(\gamma\theta_\alpha) + \frac{\pi^2}{L^2}\gamma\gamma_\alpha + R_5 + R_6, \tag{6.10}$$

where R_6 is a collection of terms from the right-hand sides of (6.7), (6.8), and (6.9). To be specific, R_6 is defined by

$$\begin{aligned} R_6 = &-\mathrm{Re}\left\{ z_\alpha \mathcal{K}[z]\left(\frac{\gamma}{z_\alpha} z_{\alpha t}\right)\right\} - \mathrm{Re}\left\{ \frac{z_\alpha}{2i} H\left(\frac{L_t\gamma}{L z_\alpha}\right)\right\} - \mathrm{Re}\left\{ \frac{z_\alpha}{2} H\left(\frac{2\pi\gamma\mathbf{m}\cdot\hat{\mathbf{n}}}{L z_\alpha}\right)\right\} \\ &- \mathrm{Re}\left\{ \frac{\pi^2 z_\alpha}{L^2}\left[H, \frac{\gamma}{z_\alpha}\right](H(\gamma_\alpha))\right\} - \mathrm{Re}\left\{ \frac{\pi z_\alpha}{L}\left[H, \frac{(T - \mathbf{W}\cdot\hat{\mathbf{t}})}{z_\alpha}\right](\gamma\theta_\alpha)\right\}. \end{aligned} \tag{6.11}$$

Since our present goal is to rewrite equation (6.1), we also would like to expand $(T - \mathbf{W}\cdot\hat{\mathbf{t}})\mathbf{W}_\alpha\cdot\hat{\mathbf{t}}$. We can do this using (2.20):

$$(T - \mathbf{W}\cdot\hat{\mathbf{t}})\mathbf{W}_\alpha\cdot\hat{\mathbf{t}} = -\frac{\pi(T-\mathbf{W}\cdot\hat{\mathbf{t}})}{L}H(\gamma\theta_\alpha) + (T-\mathbf{W}\cdot\hat{\mathbf{t}})m\cdot\hat{\mathbf{t}}. \tag{6.12}$$

We can now use (6.10) and (6.12) to expand the factor which multiplies 2At in (6.1); notice the cancellation which occurs between $H(\gamma\theta_\alpha)$ terms:

$$\begin{aligned}\frac{L}{2\pi}\mathbf{W}_t\cdot\hat{\mathbf{t}} + \frac{\pi^2}{L^2}\gamma\gamma_\alpha - (T-\mathbf{W}\cdot\hat{\mathbf{t}})\mathbf{W}_\alpha\cdot\hat{\mathbf{t}} \\ = \left(\frac{1}{4\pi}\mathcal{J}[z]\gamma_t + -\frac{\pi(T-\mathbf{W}\cdot\hat{\mathbf{t}})}{L}H(\gamma\theta_\alpha) + \frac{\pi^2}{L^2}\gamma\gamma_\alpha + R_5 + R_6\right) + \frac{\pi^2}{L^2}\gamma\gamma_\alpha \\ - (T-\mathbf{W}\cdot\hat{\mathbf{t}})\left(-\frac{\pi}{L}H(\gamma\theta_\alpha) + \mathbf{m}\cdot\hat{\mathbf{t}}\right) \\ = \frac{1}{4\pi}\mathcal{J}[z]\gamma_t + 2\frac{\pi^2}{L^2}\gamma\gamma_\alpha + R_5 + R_6 - (T-\mathbf{W}\cdot\hat{\mathbf{t}})\mathbf{m}\cdot\hat{\mathbf{t}}.\end{aligned} \tag{6.13}$$

Before we give our final rewritten form of (6.1), we recall how we previously rewrote the term $\frac{2\pi}{L}D_\alpha((T-\mathbf{W}\cdot\hat{\mathbf{t}})\gamma)$:

$$\begin{aligned}\frac{2\pi}{L}D_\alpha((T-\mathbf{W}\cdot\hat{\mathbf{t}})\gamma) = \frac{2\pi^2}{L^2}H\left(\gamma^2\theta_\alpha\right) + \frac{2\pi}{L}(T-\mathbf{W}\cdot\hat{\mathbf{t}})\gamma_\alpha \\ + \frac{\gamma(L_t - 2\pi\mathbf{m}\cdot\hat{\mathbf{t}})}{L} - \frac{2\pi^2}{L^2}[H,\gamma](\gamma\theta_\alpha).\end{aligned} \tag{6.14}$$

Combining (6.1) with (6.13) and (6.14), we have

$$\gamma_t = -\frac{\mathrm{At}}{2\pi}\mathcal{J}[z]\gamma_t + \frac{2\pi}{L}\frac{\theta_{\alpha\alpha}}{\mathrm{We}} + \frac{2\pi^2}{L^2}H\left(\gamma^2\theta_\alpha\right) + \left(\frac{2\pi}{L}(T-\mathbf{W}\cdot\hat{\mathbf{t}}) - \frac{4\mathrm{At}\pi^2}{L^2}\right)\gamma_\alpha + m_{\mathrm{At}}, \tag{6.15}$$

where m_{At} is given by

$$m_{\mathrm{At}} = \frac{\gamma(L_t - 2\pi\mathbf{m}\cdot\hat{\mathbf{t}})}{L} - \frac{2\pi^2}{L^2}[H,\gamma](\gamma\theta_\alpha) - 2\mathrm{At}\left[R_5 + R_6 - (T-\mathbf{W}\cdot\hat{\mathbf{t}})\mathbf{m}\cdot\hat{\mathbf{t}}\right]. \tag{6.16}$$

We now introduce mollifiers to the new γ_t equation:

$$\begin{aligned}\gamma_t^\varepsilon = -\frac{\mathrm{At}}{2\pi}\mathcal{J}[z^\varepsilon]\gamma_t^\varepsilon + \frac{2\pi}{L^\varepsilon}\frac{\chi^\varepsilon\theta^\varepsilon_{\alpha\alpha}}{\mathrm{We}} + \frac{2\pi^2}{{L^\varepsilon}^2}H\left((\gamma^\varepsilon)^2\chi^\varepsilon\theta^\varepsilon_\alpha\right) \\ + \chi^\varepsilon\left(\left(\frac{2\pi}{L^\varepsilon}(T^\varepsilon - \mathbf{W}^\varepsilon\cdot\hat{\mathbf{t}}^\varepsilon) - \frac{4\mathrm{At}\pi^2}{{L^\varepsilon}^2}\right)\chi^\varepsilon\gamma^\varepsilon_\alpha\right) + m^\varepsilon_{\mathrm{At}}.\end{aligned} \tag{6.17}$$

The reader may want to compare this equation with (2.27). Notice that the operator $\mathcal{J}$ is not mollified, but it does make use of the mollified curve z^ε. The term $m^\varepsilon_{\mathrm{At}}$ is defined by replacing all of the quantities on the right-hand side of (6.16) with their mollified counterparts.

6.2. Estimates for $\mathcal{J}[z^\varepsilon]$. Now that we have given the new mollified evolution equation, we are ready to begin estimating the new system. In this subsection, we give two lemmas relating to the integral operator $\mathcal{J}[z^\varepsilon]$.

LEMMA 6.1. *The operator* $\left(I + \frac{\mathrm{At}}{2\pi}\mathcal{J}[z^\varepsilon]\right)^{-1}$ *is bounded from* H^0 *to* H^0, *where* I *is the identity operator.*

We do not include a proof here; see [BMO82] or the discussion in the appendix of [BHL96]. In the next lemma, the energy function E appears. The definition of the energy is the same as we used in the density-matched case; see (3.3) and (3.4).

LEMMA 6.2. *If* $r \geq 4$, $\theta^\varepsilon \in H^{r-1}$, *and* $\gamma^\varepsilon \in H^{r-3/2}$, *then* $\mathcal{J}[z^\varepsilon](\gamma_t^\varepsilon) \in H^{r-1}$. *Furthermore,* $\|\mathcal{J}[z^\varepsilon](\gamma_t^\varepsilon)\|_{r-1} \leq C_1 \exp\{C_2 E\}$.

Proof. We begin by making the definition

$$\tau^\varepsilon = \frac{2\pi}{L^\varepsilon}\frac{\chi^\varepsilon\theta^\varepsilon_{\alpha\alpha}}{\mathrm{We}} + \frac{2\pi^2}{L^{\varepsilon 2}}H\left((\gamma^\varepsilon)^2\chi^\varepsilon\theta^\varepsilon_\alpha\right) + \chi^\varepsilon\left(\left(\frac{2\pi}{L^\varepsilon}(T^\varepsilon - \mathbf{W}^\varepsilon\cdot\hat{\mathbf{t}}^\varepsilon) - \frac{4\mathrm{At}\pi^2}{L^{\varepsilon 2}}\right)\chi^\varepsilon\gamma^\varepsilon_\alpha\right) + m^\varepsilon_{\mathrm{At}}. \tag{6.18}$$

This allows us to write (6.17) as

$$\gamma^\varepsilon_t = \left(I + \frac{\mathrm{At}}{2\pi}\mathcal{J}[z^\varepsilon]\right)^{-1}\tau^\varepsilon.$$

Since we can see from (6.18) that the most singular term in τ^ε is proportional to $\theta^\varepsilon_{\alpha\alpha}$ and we have assumed $\theta^\varepsilon \in H^{r-1}$, we conclude $\tau^\varepsilon \in H^{r-3} \subset H^0$. Lemma 6.1 now implies that $\gamma^\varepsilon_t \in H^0$.

Next, we use (6.3) to show that $\mathcal{J}[z^\varepsilon](\gamma^\varepsilon_t)$ is in H^{r-2}. By pulling $1/z_\alpha$ out of the Hilbert transform, we rewrite the first part of (6.3):

$$-2\pi\mathrm{Re}\left(iz^\varepsilon_\alpha H\left(\frac{f}{z^\varepsilon_\alpha}\right)\right) = -2\pi\mathrm{Re}\left(iH(f)\right) - 2\pi\mathrm{Re}\left(iz^\varepsilon_\alpha\left[H,\frac{1}{z^\varepsilon_\alpha}\right]f\right).$$

Since the first part of the right-hand side is zero, we have

$$\mathcal{J}[z^\varepsilon](\gamma^\varepsilon_t) = -2\pi\mathrm{Re}\left(iz^\varepsilon_\alpha\left[H,\frac{1}{z^\varepsilon_\alpha}\right]\gamma^\varepsilon_t\right) + 4\pi\left(\mathrm{Re}(z^\varepsilon_\alpha\mathcal{K}[z^\varepsilon]\gamma^\varepsilon_t(\alpha))\right). \tag{6.19}$$

We use Lemma 3.7 on the first of these terms and Lemma 3.5 on the second; since $z^\varepsilon_\alpha \in H^{r-1}$, this demonstrates that $\mathcal{J}[z^\varepsilon](\gamma_t) \in H^{r-2}$. Since $\gamma^\varepsilon_t = -\frac{\mathrm{At}}{2\pi}\mathcal{J}[z^\varepsilon](\gamma^\varepsilon_t) + \tau^\varepsilon$, we see that $\gamma^\varepsilon_t \in H^{r-3}$.

In estimating (6.19) just now, we used that $\gamma^\varepsilon_t \in H^0$. Now that we know $\gamma^\varepsilon_t \in H^{r-3}$, we can estimate (6.19) again. By again using Lemma 3.5, but this time using Corollary 3.8 in place of Lemma 3.7, we conclude that $\mathcal{J}[z^\varepsilon](\gamma_t) \in H^{r-1}$. ∎

6.3. The new existence theorem. Our goal is to prove that solutions to the evolution equations exist for the new system (i.e., replacing the old γ_t equation with (6.1)). To prove this we need to modify the proofs to the previous theorems, but the definition of the energy function is exactly the same as it was before. In the earlier case, we needed two kinds of estimates: the first kind was a bound on the growth of the energy. In Lemma 6.3 below, we demonstrate that the new term m_{At} is bounded in terms of the energy. The second kind of estimate we needed involved differences between two solutions—for example, in the proof of Theorem 5.5. We will not prove

the second kind for the new γ_t equation, but the proofs are straightforward and very much like what we have already done.

LEMMA 6.3. *The term m_{At} is bounded in terms of the energy:*

$$\|m_{\mathrm{At}}\|_{r-3/2} \leq C_1 \exp\{C_2 E\}.$$

Proof. We can see from (6.16) that many of these terms are familiar. It is clear from Lemma 4.2 and from the definition of the energy that the $H^{r-3/2}$ norm of the first two terms on the right-hand side of (6.16) is bounded in terms of the energy. Similarly, it is clear that the final term in the brackets in (6.16), $(T - \mathbf{W} \cdot \hat{\mathbf{t}})m \cdot \hat{\mathbf{t}}$, is bounded in terms of the energy. We see from (6.11) that the $H^{r-3/2}$ norm of R_6 can be bounded in terms of the energy by straightforward applications of Lemma 3.5, Corollary 3.8, and Lemma 4.2.

To estimate R_5, it is clear from (6.5) that we need to be able to estimate z_t. To do this, we first remark that (2.26) and Lemma 4.2 imply that $\theta_t \in H^{r-5/2}$ when $\gamma \in H^{r-3/2}$ and $\theta \in H^{r-1}$. Next, we notice that (6.6) implies that $z_t \in H^{r-3/2}$. Using Corollary 3.8 and Lemma 3.5, we can now bound the $H^{r-3/2}$ norm of R_5 in terms of the energy. This completes the proof of the lemma. ∎

We now know from Lemmas 6.2 and 6.3 that all of the terms in the evolution equation for γ which appear only when the Atwood ratio is nonzero can be bounded in terms of the energy. Since the energy function is the same as in the density-matched case, this means that the proofs of the new existence, uniqueness, and continuous dependence theorems are only trivially different from the proofs in the previous case. In summary, we have the following.

THEOREM 6.4. *Given the initial condition $(\theta_0, \gamma_0, L_0) \in \mathcal{O}$, there exists a unique solution to the exact initial value problem for the vortex sheet with surface tension in the two-density case given by* (2.22), (6.1), (2.24), *and* (2.25) *which satisfies the non-self-intersection condition* (3.2) *and the boundedness condition* (3.5). *There exists a time $T > 0$ such that the solution, (θ, γ, L), is in $C^1([0,T]; \mathcal{O})$. T depends on r, $\mathcal{O}$, the Weber number, and $\|(\theta_0, \gamma_0, L_0)\|_{\mathcal{B}}$.*

ANALYSIS OF OIL TRAPPING IN POROUS MEDIA FLOW*

M. BERTSCH†, R. DAL PASSO†, AND C. J. VAN DUIJN‡

Abstract. We analyze a one-dimensional nonlinear convection-diffusion equation describing the flow of water and oil through a porous medium composed of two types of rock with different permeability. We prove existence, uniqueness, and regularity properties, as well as matching conditions between the two rock types.

Key words. degenerate parabolic equation, porous media flow, existence, uniqueness, qualitative properties, matching conditions

1. Introduction and problem formulation.

It is well known that capillary forces, combined with spatial variations of rock properties, considerably reduce the recovery factor of an oil reservoir. For instance, it is difficult to remove oil from parts of the reservoir with small scale heterogeneities. Sometimes the oil may even remain trapped; see, for instance, [K, W]. This is clearly a difficult problem, mainly due to the complex nature of rock (soil) heterogeneities.

To understand oil trapping in heterogeneous media more quantitatively, [DMN] considered the case of a 2-phase water-oil flow which is perpendicular to an interface, separating two types of rock, across which the permeability changes abruptly. Under simplifying assumptions this leads to a one-dimensional flow problem which allowed them to investigate the role of convection and capillary diffusion in relation to the discontinuous permeability. They used formal asymptotics and numerical techniques. In this paper we will take their formulation as a starting point. The aim is to analyze the structure of the model equations resulting in existence, uniqueness, and regularity properties, as well as matching conditions between the two rock types.

Following [DMN] (further references are given there), the one-dimensional flow of water and oil through a porous medium is described by a nonlinear convection-diffusion equation for the reduced water saturation $S = S(x,t)$, with $0 \le S \le 1$. This equation has the form

$$\Phi \frac{\partial S}{\partial t} + \frac{\partial}{\partial x}\left\{ q f_w(S) + k(x) H(s) \frac{\partial p}{\partial x} \right\} = 0, \tag{1.1}$$

where Φ (porosity) and q (discharge) are positive constants, and where the functions $f_w,\ H : [0,1] \to [0,\infty)$ satisfy $f_w(0) = 0,\ f_w(S) > 0$ for $0 < S \le 1$ (typically convex-concave behavior) and $H(0) = H(1) = 0,\ H(S) > 0$ for $0 < S < 1$. Further $k(x)$ denotes permeability and p capillary pressure. Situating the discontinuity in

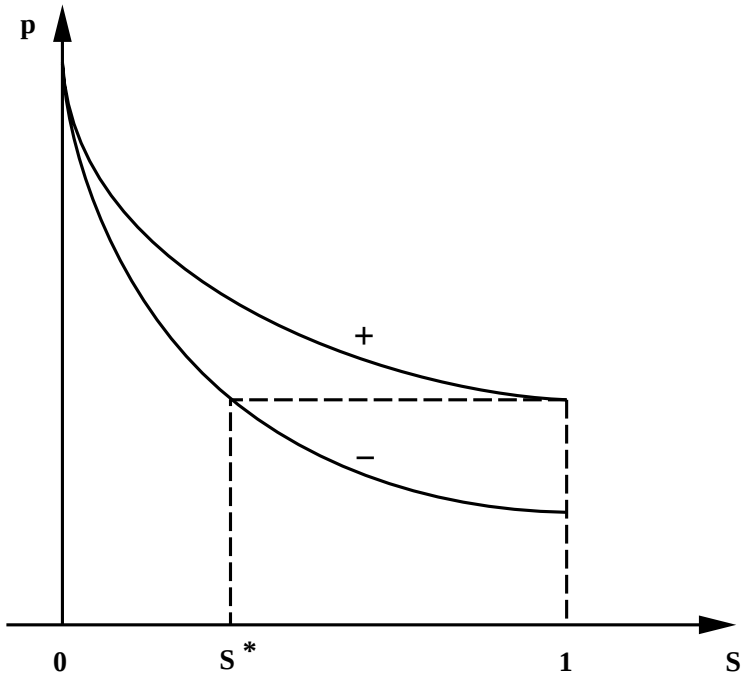

FIG. 1. *Capillary pressure curves for fine* (+) *and coarse* (−) *material. Here* $J(1) > 0$*, so an entry pressure exists.*

permeability at $x = 0$, we have

$$k(x) = \begin{cases} k^- & \text{for} \quad x < 0, \\ k^+ & \text{for} \quad x > 0. \end{cases} \tag{1.2}$$

Without loss of generality we take $0 < k^+ < k^- < \infty$. This means that coarse material occupies $\{x < 0\}$ and fine material $\{x > 0\}$. The flow is in positive x-direction.

For the capillary pressure the Leverett model [L] was used. With $\sigma > 0$ denoting interfacial tension, this means

$$p = p(x, S) = \sigma \frac{J(S)}{\sqrt{k(x)/\Phi}} \qquad \text{for} \quad 0 < S \leq 1, \tag{1.3}$$

where the Leverett function J is strictly decreasing in $(0, 1]$ with $J(1) \geq 0$. The quantity $\sqrt{k/\Phi}$ may be associated with the mean pore diameter, and the J-Leverett function is typical for the lithology of the porous medium. When $J(1) > 0$, the medium has an entry pressure given by $J(1)/\sqrt{k/\phi}$. This is the minimum pressure needed for the oil to enter a medium that is saturated by water. In this paper we assume $J(1) > 0$ and show that the occurrence of an entry pressure causes trapping of oil at the interface when the medium changes from coarse to fine. Figure 1 shows two typical capillary pressure functions, the top curve for fine material ($x > 0$), the bottom curve for coarse material ($x < 0$).

Because k is discontinuous, the capillary pressure may be discontinuous as well. This makes the interpretation of (1.1) across $x = 0$ difficult. To circumvent this problem, [DMN] considered (1.1) for $x < 0$ and $x > 0$, with matching conditions at

$x = 0$. One condition is obvious. Conservation of mass across $x = 0$ requires that the fluxes to the left and right of $x = 0$ be equal:

$$(\widetilde{\mathrm{M}}_1) \qquad \left(qf_w + k^- H \frac{\partial p}{\partial x}\right)_{x=0^-} = \left(qf_w + k^+ H \frac{\partial p}{\partial x}\right)_{x=0^+}$$

for all $t > 0$. A condition related to the pressure was obtained by a formal regularization procedure. Replacing in (1.1) $k(x)$ by C^∞ approximations $k_n(x)$, according to

$$k_n(x) = \begin{cases} k^- & \text{for} \quad x \le -\dfrac{1}{n}, \\ \varphi(nx) & \text{for} \quad -\dfrac{1}{n} < x < \dfrac{1}{n}, \\ k^+ & \text{for} \quad x \ge \dfrac{1}{n}, \end{cases} \tag{1.4}$$

with φ smooth ($\varphi(-1) = k^-$, $\varphi(1) = k^+$, and $\varphi' \le 0$), blowing up the transition region by $x \to nx$ and letting $n \to \infty$, we found the following. Let S^* be defined by the relation

$$\frac{J(S^*)}{\sqrt{k^-}} = \frac{J(1)}{\sqrt{k^+}} > 0, \tag{1.5}$$

and let S^- and S^+ denote, respectively, the left and right limits of S at $x = 0$. Then for all $t > 0$ (see also Figure 1),

$$(\widetilde{\mathrm{M}}_2) \qquad \begin{cases} \dfrac{J(S^-)}{\sqrt{k^-}} = \dfrac{J(S^+)}{\sqrt{k^+}} & \text{if} \quad S^- \le S^* \quad \text{(pressure continuous)}, \\ S^+ = 1 & \text{if} \quad S^- > S^* \quad \text{(positive pressure jump)}. \end{cases}$$

Instead of analyzing (1.1) and conditions $(\widetilde{\mathrm{M}}_{1-2})$ in the form presented above, we shall consider a further simplified model problem, without losing essential characteristic features. We take in (1.1)

$$f(S) = S, \quad H(S) = 1 - S, \quad \text{and} \quad J(S) = 2 - S.$$

After a trivial scaling, the following equations result for the oil saturation $u = 1 - S$:

$$u_t + f_x = 0 \qquad (u \ge 0), \tag{1.6}$$

$$f = u - N_c\, k\, u\, p_x, \tag{1.7}$$

$$p = \frac{1 + u}{\sqrt{k(x)}}, \tag{1.8}$$

where f denotes the flux and N_c the dimensionless capillary number

$$N_c = \frac{\sigma\sqrt{K\phi}}{q\mu_w L}.$$

Here K is a characteristic k-value, L a characteristic length scale, and μ_w the water viscosity. By an additional scaling we may set $N_c = 1$. Further, k is given by (1.2) and the subscripts t and x denote partial differentiation.

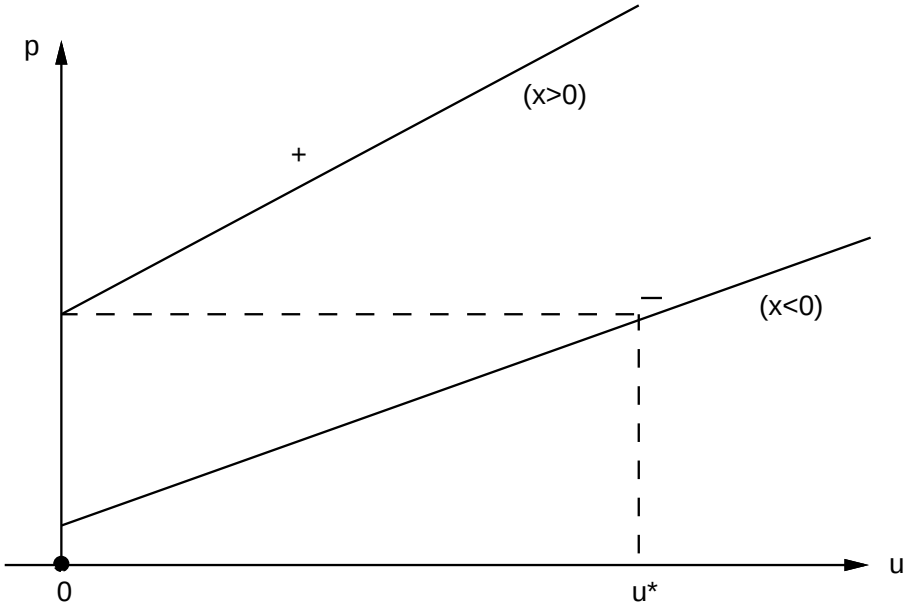

FIG. 2. *Transformed capillary pressures.*

We solve (1.6)–(1.8) in the subdomains

$$Q^{\pm} = \{(x,t) : x \in \mathbb{R}^{\pm},\ t \in (0,\infty)\},$$

with transformed matching conditions at $x = 0$. These are

$$[f] = 0 \qquad \text{in} \quad (0,\infty), \tag{M$_1$}$$

and (see Figure 2)

$$\begin{cases} \dfrac{1+u^-}{\sqrt{k^-}} = \dfrac{1+u^+}{\sqrt{k^+}} & \text{if} \quad u^- \geq u^* \\ u^+ = 0 & \text{if} \quad u^- < u^* \end{cases} \qquad \text{in} \quad (0,\infty),$$

or, equivalently,

$$u^+[p] = 0\ , \quad [p] \geq 0 \quad \text{in} \quad (0,\infty). \tag{M$_2$}$$

Here $u^* = \sqrt{\frac{k^-}{k^+}} - 1$. As before, $u^{\pm} = u^{\pm}(t) = u(0\pm,t)$, $[u] = u^+ - u^-$, and f and p have similar notation.

At $t = 0$ we prescribe

$$u(\cdot,0) = u_0(\cdot) \quad \text{in} \quad \mathbb{R}, \tag{1.9}$$

with u_0 satisfying

$$\text{(H)} \qquad \begin{cases} u_0 : \mathbb{R} \to [0,\infty), \quad \operatorname{supp}(u_0) \subset \mathbb{R} \text{ is bounded;} \\ u_0 \text{ uniformly Lipschitz continuous in } \mathbb{R}\backslash\{0\}; \\ u_0^+[p_0] = 0, \quad f_0 := u_0 - \dfrac{\sqrt{k}}{2}(u_0^2)' \in BV(\mathbb{R}\backslash\{0\}). \end{cases}$$

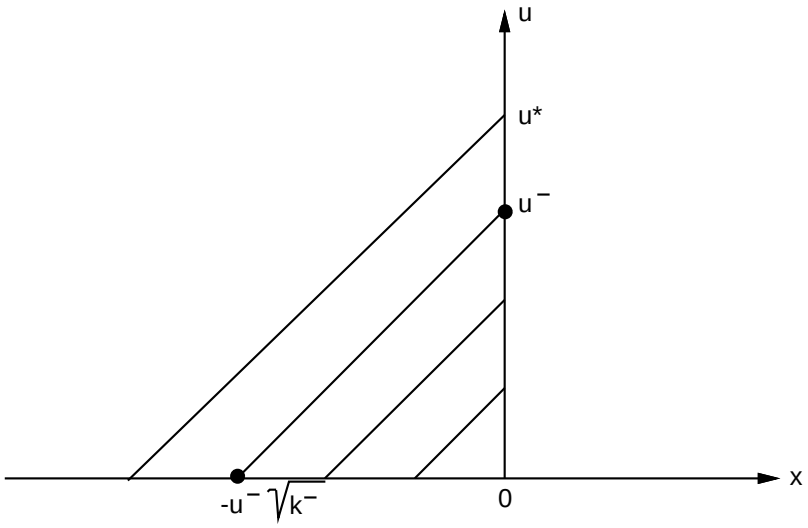

FIG. 3. *Admissible steady state solutions* ($u^- \le u^*$).

The pressure condition at $t = 0$ is needed to construct an approximate sequence $\{u_{0n}\}$ for which the corresponding fluxes $f_{0n} := u_{0n} - k_n u_{0n}(p_{0n})'$ are uniformly bounded in $BV(\mathbb{R})$. This in turn will imply $f \in L^\infty((0,\infty);\ BV(\mathbb{R}))$, which is a crucial point in the existence proof. If the k_n are taken as in (1.4), then $[p_0] \ge 0$ is needed as well. We will return to this in section 2 and in the appendix.

For steady state solutions, the role of (M_2) can be seen explicitly. Assume $u = u(x)$ only, with $u(-\infty) = u(+\infty) = 0$. Then

$$f = u - k\,up' = 0 \qquad \text{in} \quad \mathbb{R}\backslash\{0\}. \tag{1.10}$$

Using $u \ge 0$, we obtain

$$u(x) = 0 \qquad \text{for} \quad x > 0.$$

Hence the first condition in (M_2) is always satisfied. Given any $u^- \ge 0$, we see that

$$u(x) = \left(u^- + \frac{1}{\sqrt{k^-}}\,x\right)_+ \tag{1.11}$$

satisfies (1.10) for $x < 0$. Here $(\ \cdot\ )_+ := \max\{\cdot, 0\}$. However, only for $u^- \in [0, u^*]$ we have $[p] \ge 0$. Thus we have a family of admissible steady state solutions, as shown in Figure 3.

Integrating the maximal steady state gives the maximal amount of oil that can be trapped to the left of the permeability discontinuity. It is given by

$$\bar{M} = \frac{1}{2}(u^*)^2\sqrt{k^-}. \tag{1.12}$$

Next we give the weak formulation of the trapping problem. Because the flux is expected to be continuous across $x = 0$, it will be defined globally in the formulation.

The saturation (and pressure) will be considered in the subdomains Q^- and Q^+ separately. Let

$$Q^0 := Q^- \cup Q^+ \quad \text{and} \quad Q := \mathbb{R} \times (0, \infty).$$

Combining the saturation equations and the matching conditions gives the following.

Problem P. Find $u : Q^0 \to [0, \infty)$, $f : Q \to \mathbb{R}$ such that

(i) u, $(u^2)_x \in L^\infty(Q^0)$; u is uniformly continuous in Q^0;

(ii) $f \in L^\infty((0, \infty); BV(\mathbb{R}))$;

(iii) $f = u - \frac{\sqrt{k}}{2}(u^2)_x$ a.e. in Q^0 and $\int_Q (u\zeta_t + f\zeta_x)dxdt + \int_{\mathbb{R}} u_0(x)\zeta(x, 0)dx = 0$ for all $\zeta \in H^1(Q) \cap C(\bar{Q})$, with compact support in $\bar{Q}$;

(iv) $u^+[p] = 0$ and $[p] \geq 0$ in $(0, \infty)$, where $p := \frac{1+u}{\sqrt{k}}$ in Q^0.

To prove existence we apply a k-regularization as in (1.4). This yields a sequence of approximating problems on Q for which we derive the necessary estimates. This is done in section 2. In section 3 we consider the limit $n \to \infty$ giving existence for Problem P, with u satisfying a porous media equation ($m = 2$) with linear convection in Q^0. Clearly (M_2) is satisfied. The weak equation in (iii) implies $[f] = 0$ a.e. in $(0, \infty)$. The comparison principle, with uniqueness as a consequence, is shown in section 4. In section 5 we give sufficient conditions for oil trapping; i.e., conditions that imply $u(x, t) = 0$ for $x > 0$ and for all $t > 0$. Finally, in section 6, we present some closing remarks about nonuniqueness, waiting times, and optimal regularity.

In a recent paper [DMP] considered oil transport in a multilayered porous medium. This work involves a discontinuous permeability which varies periodically in space. Using homogenization techniques they derived effective (upscaled) transport equations for the case where the periodicity length is small compared to the characteristic length L. In their analysis matching conditions ($\widetilde{M}_1$) and ($\widetilde{M}_2$) play a crucial role. They lead to a macroscopic irreducible oil saturation.

2. The approximate problem. In this section we study the approximate equation in which k is replaced by the smooth function k_n, defined by (1.4). Together with k we also need to approximate the initial value u_0. We construct approximations u_{0n}, so that the corresponding fluxes

$$f_{0n} := u_{0n} - k_n u_{0n} p'_{0n}, \qquad p_{0n} := \frac{1 + u_{0n}}{\sqrt{k_n}} \tag{2.1}$$

have a uniformly bounded total variation. In addition we require that each u_{0n} is strictly positive to eliminate the degeneracy of the equation at points where u vanishes. The existence of such u_{0n} is given in the following lemma. Since the proof is quite technical, it is given in the appendix.

LEMMA 2.1. *Let $n \in \mathbb{N}$ and let k_n be defined by* (1.4). *Suppose u_0 satisfies hypothesis* (H) *and in addition*

$$[p_0] = \frac{1 + u_0^+}{\sqrt{k^+}} - \frac{1 + u_0^-}{\sqrt{k^-}} \geq 0. \tag{2.2}$$

Then there exist $u_{0n} \in W^{1,\infty}(\mathbb{R})$ and $\varepsilon_n \in \mathbb{R}^+$ such that

(i) *$u_{0n} \geq \varepsilon_n > 0$ in $\mathbb{R}$, and $u_{0n}(x) = \varepsilon_n$ for $|x|$ sufficiently large;*

(ii) *u_{0n} is uniformly bounded in $\mathbb{R}$, and f_{0n}, defined by* (2.1), *is uniformly bounded in $BV(\mathbb{R})$;*

(iii) *As* $n \to \infty$,

$$u_{0n} \to u_0 \quad \textit{uniformly in } \mathbb{R}\backslash\{0\}$$

and

$$u_{0n} - \varepsilon_n \to u_0 \quad \textit{in } L^1(\mathbb{R}).$$

For each $n \in \mathbb{N}$ we consider the approximate problem

$$(\mathrm{P}_n) \qquad \begin{cases} u_t + u_x = (k_n u\, p_x)_x, \quad p = \dfrac{1+u}{\sqrt{k_n}} \quad \text{in } Q, \\ u(x,0) = u_{0n}(x) \quad \text{for } x \in \mathbb{R}. \end{cases}$$

In the remainder of this section we prove the following results.

THEOREM 2.2. *Let* u_{0n} *be given by Lemma* 2.1. *Then problem* (P_n) *has a solution* $u_n \in C^\infty(Q) \cap C(\bar{Q})$ *such that*

(i) $0 < u_n \le \mathcal{C}$ *in* Q, *where* $\mathcal{C}$ *does not depend on* n;

(ii) $f_n := u_n - k_n u_n (\frac{1+u_n}{\sqrt{k_n}})_x$ *is uniformly bounded in* $L^\infty([0,\infty); BV(\mathbb{R}))$;

(iii) u_n *is uniformly continuous in* $\{\mathbb{R}\backslash(-\varepsilon,\varepsilon)\} \times [0,\infty)$ *for all* $\varepsilon > 0$.

Proof. Since $u_{0n} \ge \varepsilon_n > 0$ in $\mathbb{R}$, problem (P_n) is nondegenerate at $t = 0$. Hence it has a unique local (with respect to t) classical solution u_n; see, for instance, [LSU] and [F]. This solution can be continued as long as it remains bounded and bounded away from zero. Let $Q_{T_n} := \mathbb{R} \times (0, T_n)$ denote the maximal existence domain for u_n.

A positive lower bound follows from the maximum principle. Indeed, if we set $L_n := \max_{\mathbb{R}} |(\sqrt{k_n})''|$ we observe that the solution of the initial value problem

$$(\mathrm{LB}) \qquad \begin{cases} s' = -L_n s(1+s) \quad \text{for} \quad t > 0, \\ s(0) = \varepsilon_n \end{cases}$$

is a subsolution for problem (P_n). Hence if s_n denotes the solution of (LB), we have

$$u_n(x,t) \ge s_n(t) > 0 \quad \text{for} \quad (x,t) \in Q_{T_n}. \tag{2.3}$$

Before proving a uniform upper bound for u_n, we observe that the flux f_n is uniformly bounded in Q_{T_n}. A straightforward calculation yields for f_n the linear equation

$$f_t = a_n f_{xx} + b_n f_x, \tag{2.4}$$

where

$$a_n(x,t) := u_n \sqrt{k_n}, \qquad b_n(x,t) := -\frac{f_n}{u_n} - \frac{u_n k_n'}{2\sqrt{k_n}}. \tag{2.5}$$

Hence, by the maximum principle

$$||f_n||_{L^\infty(Q_{T_n})} \le ||f_{0n}||_{L^\infty(\mathbb{R})} \le \mathcal{C} \tag{2.6}$$

for all $n \in \mathbb{N}$.

We use this estimate to demonstrate a uniform upper bound for u_n in Q_{T_n}. As a first observation we note that (2.6) implies the differential inequality

$$|u_n - \sqrt{k^-}\, u_n u_{nx}| \le \mathcal{C} \quad \text{in} \quad \left(-\infty, -\frac{1}{n}\right] \times [0, T_n). \tag{2.7}$$

Then the upper bound for u_n in this set is immediate if we can control the decay of u_n as $x \to -\infty$. This decay results from the following argument.

Let $\bar{u}_n$ be a steady state solution satisfying

$$\begin{cases} u - k_n u\, p' = \varepsilon_n, \qquad p = \dfrac{1+u}{\sqrt{k_n}} \quad \text{in } \mathbb{R}, \\ u(\pm\infty) = \varepsilon_n. \end{cases}$$

Clearly, $\bar{u}_n(x) = \varepsilon_n$ for all $x \geq \frac{1}{n}$. The corresponding pressure $\bar{p}_n$ satisfies

$$\begin{cases} k_n(p\sqrt{k_n} - 1)p' = p\sqrt{k_n} - 1 - \varepsilon_n \quad \text{for} \quad x < \dfrac{1}{n}, \\ p\left(\dfrac{1}{n}\right) = \dfrac{1+\varepsilon_n}{\sqrt{k^+}}. \end{cases}$$

At points where $\bar{p}_n' = 0$, we must have $\bar{p}_n > 0$ and $\bar{p}_n'' < 0$. We use this to obtain $\bar{p}_n' > 0$ and $\bar{p}_n > \frac{1+\varepsilon_n}{\sqrt{k^-}}$ on $(-\infty, \frac{1}{n})$, and $\bar{p}_n(x) \to \frac{1+\varepsilon_n}{\sqrt{k^-}}$ as $x \to -\infty$. In particular, $\bar{u}_n(x) \to \varepsilon_n$ exponentially as $x \to -\infty$ and $\bar{u}_n - \varepsilon_n \in L^1(\mathbb{R})$, uniformly in $n \in \mathbb{N}$.

Now using Lemma 2.1(iii) and an argument as in the proof of Theorem 4.1, one finds for $t > 0$ the L^1-contraction

$$\int_{\mathbb{R}} |u_n(x,t) - \bar{u}_n(x)|dx \leq \int_{\mathbb{R}} |u_{0n}(x) - \bar{u}_n(x)|dx.$$

This inequality controls the behavior of u_n as $|x| \to \infty$. Combined with (2.7) it gives the upper bound in $(-\infty, -\frac{1}{n}] \times (0, T_n)$. Arguing similarly for $x > \frac{1}{n}$, we conclude that for all $n \in \mathbb{Z}^+$

$$u_n(x,t) \leq \mathcal{C} \quad \text{for} \quad |x| \geq \frac{1}{n}, \quad 0 \leq t < T_n. \tag{2.8}$$

To obtain the upper bound in the remaining strip $[-\frac{1}{n}, \frac{1}{n}] \times [0, T_n)$ we express (2.6) in terms of the pressure p_n:

$$|p_n\sqrt{k_n} - 1 - k_n(p_n\sqrt{k_n} - 1)p_{nx}| \leq \mathcal{C}. \tag{2.9}$$

By (2.8), $p_n(\pm\frac{1}{n}, t)$ is uniformly bounded. Then (2.9) implies that p_n, and thus u_n, is uniformly bounded as well.

The uniform upper bound, together with lower bound (2.3), guarantees existence for all $t > 0$. Hence, $T_n = \infty$ for each $n \in \mathbb{N}$. This completes the proof of (i).

The proof of (ii) is a direct consequence of Lemma 2.1(ii) and the total variation estimate for the flux in Lemma 2.4 below.

We conclude by proving (iii). The boundedness of u_n and the flux estimate (2.7) imply that u_n is uniformly Hölder continuous (exponent $\frac{1}{2}$) with respect to x in $\{(x,t) : x < -\frac{1}{n},\ t > 0\}$. The same result holds in $\{(x,t) : x > \frac{1}{n},\ t > 0\}$. The smoothness and boundedness of the coefficients in the u_n-equation allow us to apply [G1], yielding that u_n is uniformly Hölder continuous (exponent $\frac{1}{4}$) with respect to t in $\{(x,t) : |x| > \frac{1}{n},\ t > 0\}$. Since, for fixed $\varepsilon > 0$, $\frac{1}{n} < \varepsilon$ for n large enough, this proves (iii) and completes the proof of Theorem 2.2. □

Remark 2.3. It is not difficult to show that the steady states $\bar{u}_n$, corresponding to $k = k_n$ and $\bar{u}_n(\pm\infty) = \varepsilon_n$, approximate the maximal steady state in Figure 3. In essence this follows from $\bar{u}_n(x) = \varepsilon_n$ for all $x \geq \frac{1}{n}$ and, using the pressure equation,

$$0 < \bar{p}_n\left(\frac{1}{n}\right) - \bar{p}_n\left(-\frac{1}{n}\right) = \int_{-\frac{1}{n}}^{+\frac{1}{n}} \frac{1}{k_n} \frac{\bar{p}_n(x)\sqrt{k_n} - 1 - \varepsilon_n}{\bar{p}_n(x)\sqrt{k_n} - 1}\, dx \to 0$$

as $n \to \infty$.

It remains to prove the following lemma used in the proof of Theorem 2.2.

LEMMA 2.4. *Let u_{0n} be given by Lemma 2.1 and let u_n be the corresponding solution of problem* (P_n). *Then*

$$TV_{\mathbb{R}}(f_n(t)) \le TV_{\mathbb{R}}(f_{0n}) \qquad \textit{for all} \quad t > 0.$$

Proof. Each flux f_n satisfies the linear problem

$$\begin{cases} f_t = a_n f_{xx} + b_n f_x & \text{in } Q, \\ f(x,0) = f_{0n}(x) & \text{for} \quad x \in \mathbb{R}, \end{cases}$$

where a_n and b_n, defined in (2.5), are bounded functions and where f_{0n} has uniformly bounded variation. First we proceed formally. Let us fix $\varepsilon > 0$ and calculate (dropping the subscript n)

$$\begin{aligned} \frac{d}{dt}\int_{\mathbb{R}} \left\{ \sqrt{f_x^2 + \varepsilon} - \sqrt{\varepsilon} \right\} &= \int_{\mathbb{R}} \frac{f_x}{\sqrt{f_x^2+\varepsilon}} (a f_{xx} + b f_x)_x \\ &= -\varepsilon \int_{\mathbb{R}} \frac{f_{xx}(a f_{xx} + b f_x)}{(f_x^2+\varepsilon)^{3/2}}. \end{aligned}$$

Integrating in time gives, for any $t > 0$,

$$\begin{aligned} \int_{\mathbb{R}} \left\{ \sqrt{f_x^2(t) + \varepsilon} - \sqrt{\varepsilon} \right\} - \int_{\mathbb{R}} \left\{ \sqrt{{f'_{0n}}^2 + \varepsilon} - \sqrt{\varepsilon} \right\} &= -\varepsilon \int_{\mathbb{R}\times(0,t)} \frac{a f_{xx}^2 + b f_x f_{xx}}{(f_x^2+\varepsilon)^{3/2}} \\ &\le -\int_{\mathbb{R}\times(0,t)} \frac{\varepsilon f_x}{(f_x^2+\varepsilon)^{3/2}}\, b f_{xx}. \end{aligned}$$

Since

$$\left| \frac{\varepsilon f_x}{(f_x^2+\varepsilon)^{3/2}} \right| \le 1$$

and

$$\frac{\varepsilon f_x}{(f_x^2+\varepsilon)^{3/2}} \to 0, \quad \text{pointwise in } Q \text{ as } \varepsilon \to 0,$$

the boundedness of b and Lebesgue's dominated convergence theorem imply

$$\int_{\mathbb{R}} |f_x(t)| \le \int_{\mathbb{R}} |f'_{0n}|,$$

provided $f_{xx} \in L^1(\mathbb{R}\times(0,t))$. To complete the proof of the lemma we need to make this argument rigorous.

It is enough to apply a mollifier to the initial function f_{0n} of the linear flux problem. This ensures the smoothness up to $t = 0$ necessary to carry out the above calculations. ∎

3. Existence for Problem P. Let u_n be the solution of problem (P_n) as stated in Theorem 2.2. By a standard argument there exist a subsequence of $\{u_n\}$, denoted again by $\{u_n\}$, and $u \in L^\infty(Q) \cap C((\mathbb{R}^- \cup \mathbb{R}^+) \times [0,\infty))$ such that

$$u_n \to u \quad \text{in } C_{\mathrm{loc}}((\mathbb{R}^- \cup \mathbb{R}^+) \times [0,\infty))$$

as $n \to \infty$. We show the following theorem.

THEOREM 3.1. *u is a solution of Problem* P.

Proof. Clearly u is a (weak) solution of the equation

$$u_t + u_x = \frac{1}{2}\sqrt{k^\pm}(u^2)_{xx} \quad \text{in } Q^\pm$$

and

$$f = u - \frac{1}{2}\sqrt{k^\pm}\,(u^2)_x \in L^\infty([0,\infty);\ BV(\mathbb{R}^\pm)).$$

The boundedness of u and f implies that u^2 is uniformly Lipschitz continuous with respect to x in Q^0. Hence the following quantities are well defined for each $t > 0$:

$$u^\pm(t), \qquad f^\pm(t), \qquad \text{and} \qquad p^\pm(t) = \frac{1 + u^\pm(t)}{\sqrt{k^\pm}}.$$

Using the equation

$$u_t + f_x = 0 \qquad \text{a.e. in } Q^\pm$$

and again the boundedness of f, we obtain as in [DP] that the functions

$$t \to u^\pm(t)$$

are continuous in $[0,\infty)$.

Next we claim

$$f^+(t) = f^-(t) \quad \text{for almost all } t > 0. \tag{3.1}$$

Indeed, using the asymptotic behavior of $u_n(x,t)$ as $|x| \to \infty$, we find, for $n \to \infty$,

$$\int_{\mathbb{R}} (u_n(x,t) - \varepsilon_n)dx = \int_{\mathbb{R}} (u_{0n}(x) - \varepsilon_n)dx \to \int_{\mathbb{R}} u_0(x)dx$$

and hence

$$\int_{\mathbb{R}} u(x,t)dx = \int_{\mathbb{R}} u_0(x)dx \quad \text{for all} \quad t > 0,$$

which expresses conservation of mass. This identity implies

$$\begin{aligned} 0 &= \lim_{\delta \to 0^+} \left(\int_{-\infty}^{-\delta} u(x,t)dx + \int_{\delta}^{\infty} u(x,t)dx - \int_{-\infty}^{-\delta} u_0(x)dx - \int_{\delta}^{\infty} u_0(x)dx \right) \\ &= \int_0^t (f^+(s) - f^-(s))ds \quad \text{for all} \quad t > 0. \end{aligned}$$

Together with the equations in $Q^\pm$, equality (3.1) implies the weak form (iii) of Problem P.

It remains to prove

$$u^+[p] = 0 \quad \text{and} \quad [p] \geq 0 \quad \text{for all} \quad t > 0. \tag{3.2}$$

For this purpose we study u_n and p_n in the interval $(-\frac{1}{n}, \frac{1}{n})$. Since k_n changes rapidly there, we make the blow-up

$$y = nx \qquad \text{for} \quad -\frac{1}{n} < x < \frac{1}{n}.$$

Knowing that the fluxes f_n are uniformly bounded, we obtain

$$|u_n - nk_n u_n (p_n)_y| \leq \mathcal{C}.$$

Thus for appropriate $\mathcal{C} > 0$ we have

$$|u_n (p_n)_y| \leq \frac{\mathcal{C}}{n},$$

or

$$\left| (u_n^2)_y - \frac{\varphi'}{\varphi} u_n (1 + u_n) \right| \leq \frac{\mathcal{C}}{n} \tag{3.3}$$

for all $-1 < y < 1$ and $t > 0$.

Hence u_n^2 are Lipschitz continuous in $[-1, 1]$ uniformly with respect to n and t. Up to a subsequence, $u_n \to u$ uniformly in $[-1, 1]$, as $n \to \infty$, for all $t > 0$; in particular $u(-1, t) = u^-(t)$ and $u(1, t) = u^+(t)$. In addition, it follows easily from (3.3) that u satisfies

$$(u^2)_y = \frac{\varphi'}{\varphi} u(1 + u) \tag{3.4}$$

in $\{(y, t) : -1 < y < 1,\ t > 0\}$. Since φ' is nonpositive, u is decreasing. Thus, if $u^+(t) > 0$, we have $u(y, t) > 0$ in $[-1, 1]$ and (3.4) reduces to

$$u_y = \frac{\varphi'}{2\varphi}(1 + u). \tag{3.5}$$

A straightforward calculation gives $[p] = 0$.

Next suppose $u^+(t) = 0$. We have to show $[p] \geq 0$. If $u^-(t) = 0$, we get

$$[p] = \frac{1}{\sqrt{k^+}} - \frac{1}{\sqrt{k^-}} > 0.$$

If $u^-(t) > 0$, define $\tilde{y} := \sup\{y \in [-1, 1] : u(y, t) > 0\}$ and solve (3.5) in $[-1, \tilde{y}]$. This gives

$$\frac{1 + u^-}{\sqrt{k^-}} = \frac{1}{\sqrt{\varphi(\tilde{y})}} \leq \frac{1}{\sqrt{k^+}},$$

which implies $[p] \geq 0$ and $u^-(t) \leq u^*$. □

4. The comparison principle. We start with some preliminary observations for solutions (u, f) of Problem P. Choosing test functions with support in $Q^{\pm}$, we obtain

$$\int_{Q^{\pm}} u\zeta_t + \int_{Q^{\pm}} \left(u - \frac{\sqrt{k^{\pm}}}{2}(u^2)_x \right)\zeta_x = 0.$$

Thus away from $x = 0$ we have two weak equations of "porous media" type $(m = 2)$ with linear convection, implying

$$u_t + \left(u - \frac{\sqrt{k^{\pm}}}{2}(u^2)_x \right)_x = 0 \quad \text{a.e. in } Q^{\pm} \tag{4.1}$$

and

$$\operatorname{supp}(u(t)) \text{ is bounded in } \mathbb{R} \tag{4.2}$$

for all $t \in [0, \infty)$. Further, using hypothesis (H), we can apply the Bernstein argument of [A] in the truncated domain

$$Q^{\delta} := \mathbb{R}\backslash(-\delta, \delta) \times (0, \infty) \qquad (\text{for } \delta > 0, \text{ fixed})$$

to obtain

$$||u_x||_{L^{\infty}(Q^{\delta})} \leq C(\delta). \tag{4.3}$$

We use this to derive an estimate on u_t in Q^{δ}. Let u be a smooth solution of (4.1) in the sense of the usual "porous media" approximations, and let $\xi : \mathbb{R} \to [0, 1]$ be an even C^1 cut-off function satisfying

$$\xi(x) = \begin{cases} 0 & \text{for} \quad 0 \leq x \leq \delta/2, \\ 1 & \text{for} \quad \delta \leq x \leq L, \\ 0 & \text{for} \quad x \geq L + 1 \end{cases}$$

for any $L > \delta$. Multiplying (4.1) by $\xi^2 u_t$ gives

$$\int_{Q_\tau} \xi^2 u_t^2 = -\int_{Q_\tau} \xi^2 u_t u_x - \int_{Q_\tau} \xi\xi' \sqrt{k} u_t (u^2)_x - \int_{Q_\tau} \xi^2 \frac{\sqrt{k}}{2}\, u_{xt}\, (u^2)_x,$$

where $Q_\tau = \mathbb{R} \times (0, \tau)$ with $\tau > 0$ arbitrarily chosen. Using $u_{xt}(u^2)_x = u(u_x^2)_t$, the last integral becomes

$$\int_{\mathbb{R}} \xi^2 \frac{\sqrt{k}}{2}\, u u_x^2 \Big|_0^{\tau} - \int_{Q_\tau} \xi^2 \frac{\sqrt{k}}{2}\, u_t u_x^2.$$

Then (i) of Problem P and (4.3) in $Q^{\delta/2}$ give

$$\int_{Q_\tau} \xi^2 u_t^2 \leq C(\delta, \tau),$$

implying

$$u_t \in L^2_{\text{loc}}(\bar{Q^{\delta}}). \tag{4.4}$$

We are now in a position to prove the following theorem.

THEOREM 4.1. *Let (u_1, f_1) and (u_2, f_2) be weak solutions of Problem* P *corresponding to initial values u_{01} and u_{02}, respectively. Then $u_{01} \le u_{02}$ in $\mathbb{R}$ implies $u_1 \le u_2$ in Q^0.*

Proof. Let $\tau > 0$ be arbitrary. In the weak equation for the difference

$$\int_Q \{(u_1 - u_2)\zeta_t + (f_1 - f_2)\zeta_x\} + \int_{\mathbb{R}} \zeta(u_{01} - u_{02}) = 0,$$

we take the test function

$$\zeta = \xi\psi S_\varepsilon(u_1^2 - u_2^2),$$

where the following hold:

(i) ξ is an even C^1 cut-off function near $x = 0$,

$$\xi(x) = \begin{cases} 0 & \text{for} \quad 0 \le x \le \delta/2, \\ 1 & \text{for} \quad x \ge \delta, \end{cases} \qquad \xi'(x) \ge 0 \text{ for } \delta/2 < x < \delta.$$

(ii) ψ is a C^1 cut-off function near $t = \tau$,

$$\psi(t) = \begin{cases} 1 & \text{for} \quad 0 \le t \le \tau - \mu, \\ 0 & \text{for} \quad \tau \le t, \end{cases} \qquad \psi'(t) \le 0 \text{ for } \tau - \mu < t < \tau.$$

(iii) $S_\varepsilon : \mathbb{R} \to [0, 1]$ is given by

$$S_\varepsilon(r) = \begin{cases} 0, & r \le 0, \\ \dfrac{r}{\sqrt{r^2 + \varepsilon^2}}, & r > 0. \end{cases}$$

Here δ, μ, and ε are small positive parameters. Note that for $\varepsilon \searrow 0$

$$\left.\begin{array}{l} S_\varepsilon(r) \to \chi_{\{r>0\}} := \left\{ \begin{array}{ll} 1, & r > 0, \\ 0, & r \le 0, \end{array} \right. \\ r S_\varepsilon'(r) \to 0 \end{array}\right\} \quad \text{pointwise in } \mathbb{R}. \tag{4.5}$$

Integrating the first term by parts gives

$$\begin{aligned} &\int_{Q_\tau} (u_1 - u_2)_t\, \xi\psi S_\varepsilon(u_1^2 - u_2^2) \\ &\quad = \int_{Q_\tau} (f_1 - f_2)\psi \Big\{ \xi' S_\varepsilon(u_1^2 - u_2^2) + \xi S_\varepsilon'(u_1^2 - u_2^2)(u_1^2 - u_2^2)_x \Big\} \\ &\quad \le \int_{Q_\tau} (f_1 - f_2)\, \psi\xi' S_\varepsilon(u_1^2 - u_2^2) + \int_{Q_\tau} (u_1 - u_2)\, \psi\xi S_\varepsilon'(u_1^2 - u_2^2)(u_1^2 - u_2^2)_x. \end{aligned}$$

For fixed $\mu, \delta > 0$, we first let $\varepsilon \searrow 0$. Using (4.5), we have

$$(u_1 - u_2)\psi\xi S_\varepsilon'(u_1^2 - u_2^2) \to 0 \quad \text{pointwise in } Q_\tau.$$

Hence by (4.4) we obtain

$$\int_{Q_\tau} \xi\psi((u_1 - u_2)_+)_t \le \int_{Q_\tau} (f_1 - f_2)\psi\xi' \chi_{\{u_1 > u_2\}}.$$

Next we let $\mu \searrow 0$. This gives

$$\begin{aligned}\int_{\mathbb{R}} & \xi(u_1-u_2)_+(\tau)\\ &\le \int_0^\tau \left\{ \int_{-\delta}^{-\delta/2} (f_1-f_2)\xi' \chi_{\{u_1>u_2\}} + \int_{\delta/2}^{\delta} (f_1-f_2)\xi' \chi_{\{u_1>u_2\}} \right\} \\ &=: \int_0^\tau \{I_\delta^- + I_\delta^+\}.\end{aligned} \tag{4.6}$$

Let $t \in (0,\tau)$ be chosen such that f^-, f^+ exist. Consider the possibilities:

(i) $u_1^+ \neq u_2^+$, say $u_1^+ > u_2^+$. Then $u_1 > u_2$ in a right neighborhood of $x=0$ and $\chi_{\{u_1>u_2\}} = 1$ in $(\delta/2,\delta)$ for δ sufficiently small. The pressure conditions (M_2) give $u_1^- > u_2^-$: if $u_2^+ > 0$, then $[p_1]=[p_2]=0$ implies $u_1^- > u_2^-$; if $u_2^+ = 0$, then $u_2^- \le u^*$, while $u_1^- > u^*$. Therefore also $\chi_{\{u_1>u_2\}} = 1$ in $(-\delta,-\delta/2)$. As a consequence

$$\lim_{\delta\searrow 0}(I_\delta^- + I_\delta^+) = [f_1]-[f_2] = 0.$$

(ii) $u_1^+ = u_2^+$. Now we need to compare the corresponding fluxes. Suppose that $f_1^+ = f_2^+$. Then

$$\sup_{(\delta/2,\delta)} (f_1-f_2)\chi_{\{u_1>u_2\}} \to 0 \quad \text{as} \quad \delta \searrow 0,$$

and the same applies in $(-\delta,-\delta/2)$. Thus again

$$\lim_{\delta\searrow 0}(I_\delta^- + I_\delta^+) = 0.$$

If $f_1^+ > f_2^+$, then $(u_1^2)_x < (u_2^2)_x$ and therefore $u_1 < u_2$ in $(\delta/2,\delta)$. Thus

$$I_\delta^- + I_\delta^+ = I_\delta^- \le 0 \qquad \text{for } \delta > 0 \text{ sufficiently small.}$$

Finally, if $f_1^+ < f_2^+$, then $(u_1^2)_x > (u_2^2)_x$ and $u_1 > u_2$ in $(\delta/2,\delta)$. Thus $\lim_{\delta\searrow 0} I_\delta^+ = f_1^+ - f_2^+$. Furthermore, since

$$(f_1-f_2)\xi'\chi_{\{u_1>u_2\}} \le (f_1-f_2)\xi' \quad \text{in } (-\delta,-\delta/2),$$

$$\limsup_{\delta\searrow 0}(I_\delta^- + I_\delta^+) \le 0.$$

Combining these results, we obtain from (4.6)

$$u_1(\cdot,\tau) - u_2(\cdot,\tau) \le 0 \qquad \text{in} \quad \mathbb{R}\backslash\{0\},$$

which proves the theorem. □

As an immediate consequence we have the following.

COROLLARY 4.2. *Problem* P *has at most one solution* (u,f).

5. Oil trapping. The steady state solutions shown in Figure 3 suggest that oil may be trapped at the interface between coarse and fine material. Indeed, if $u_0(x) = 0$ for $x > 0$ and if for some $u^- \in (0, u^*]$

$$u_0(x) \le \left(u^- + \frac{1}{\sqrt{k^-}}\, x \right)_+ \qquad \text{for} \quad x < 0,$$

then the comparison principle guarantees

$$u(x,t) \le \left(u^- + \frac{1}{\sqrt{k^-}}\, x \right)_+ \qquad \text{for all} \quad (x,t) \in Q^-$$

and

$$u = 0 \quad \text{in} \quad Q^+.$$

The following theorem explains trapping in terms of the oil mass. For convenience, let

$$\bar{u}(x) := \begin{cases} \left(u^* + \frac{1}{\sqrt{k^-}}\, x \right)_+ & \text{for} \quad x < 0, \\ 0 & \text{for} \quad x > 0 \end{cases}$$

denote the maximal admissible steady state having $\bar{M}$, given by (1.12), as corresponding mass.

THEOREM 5.1. *Let u_0 satisfy hypothesis* (H) *and let*

$$\int_{-\infty}^{x} u_0(s)ds \ge \int_{-\infty}^{x} \bar{u}(s)ds \qquad \text{for} \quad x < 0.$$

Then the solution of Problem P *satisfies*

$$\int_{-\infty}^{0} u(s,t)ds \ge \bar{M} \qquad \text{for all} \quad t > 0.$$

Proof. Fix any $\delta > 0$ and set

$$V_\delta(x,t) = \int_{-\infty}^{x} u(s,t)ds + \delta \qquad \text{for} \quad (x,t) \in \bar{Q}.$$

Then $V_\delta \in C(\bar{Q}), V(\cdot,t) \in C^1((-\infty,0]) \cup C^1([0,\infty))$ for all $t > 0$, and

$$V_\delta = \delta \ \text{ to the left of the support of } u \text{ in } Q^-,$$

$$V_\delta = \int_{\mathbb{R}} u_0(s)ds + \delta \ \text{ to the right of the support of } u \text{ in } Q^+.$$

As a consequence $V_\delta \ge \bar{M}$ in Q^+, and it satisfies

$$V_t + V_x - \sqrt{k^-} V_x V_{xx} = 0 \qquad \text{a.e. in} \quad Q^-. \tag{5.1}$$

Setting

$$\bar{v}(x) := \int_{-\infty}^{x} \bar{u}(s)ds \qquad \text{for} \quad x \in (-\infty, 0],$$

we have

$$V_\delta > \bar{v} \qquad \text{in} \quad Q_t^- := (-\infty, 0] \times (0, t)$$

for t sufficiently small. Let

$$t_0 = \sup\{t > 0 : V_\delta > \bar{v} \quad \text{in} \quad Q_t^-\}.$$

Below we show $t_0 = \infty$. Suppose $t_0 < \infty$. Then there exists $(x_0, t_0) \in \bar{Q^-}$ such that

$$V_\delta > \bar{v} \qquad \text{in} \quad Q_{t_0}^- \tag{5.2}$$

and

$$V_\delta(x, t_0) \geq \bar{v}(x) \qquad \text{for all} \quad x \in (-\infty, 0] \quad \text{with} \quad V_\delta(x_0, t_0) = \bar{v}(x_0). \tag{5.3}$$

We first rule out $x_0 = 0$.

If $x_0 = 0$, we distinguish the three following cases:

(i) $u(0^-, t_0) > u^*$. Then we have

$$\frac{\partial V_\delta}{\partial x}(0^-, t_0) = u(0^-, t_0) > u^* \ = \frac{d\bar{v}}{\partial x}(0^-).$$

This contradicts (5.3).

(ii) $u(0^-, t_0) < u^*$. By continuity there exists $\varepsilon > 0$ such that $u(0^-, t) < u^*$ and $u(0^+, t) = 0$ for $t_0 - \varepsilon < t < t_0$. Since $f^-(t) = f^+(t) \leq 0$ for almost all $t \in (t_0 - \varepsilon, t_0)$ (see also section 6), we find from integrating the u-equation in $(-\infty, 0) \times (t_0 - \varepsilon, t_0)$

$$\int_{-\infty}^{0} u(s, t_0) ds - \int_{-\infty}^{0} u(s, t_0 - \varepsilon) ds = -\int_{t_0 - \varepsilon}^{t_0} f^-(t) dt \geq 0.$$

Hence

$$V_\delta(0, t_0 - \varepsilon) \leq V_\delta(0, t_0) = \bar{v}(0),$$

which contradicts (5.2).

(iii) $u(0^-, t_0) = u^*$. Then $V_\delta(0^-, t_0) = \bar{v}(0)$ as well as

$$\frac{\partial V_\delta}{\partial x}(0^-, t_0) = \frac{d\bar{v}}{dx}(0^-) = u^*.$$

Using (5.1) locally in Q^- and the strong maximum principle, we again obtain a contradiction.

Hence $x_0 \neq 0$ and $V_\delta(0, \cdot) > \bar{v}(0)$ in $[0, t_0]$. We then apply the comparison principle to (5.1) in $Q_{t_0}^-$ to find $V_\delta > \bar{v}$ in $(-\infty, 0] \times [0, t_0]$. This shows that $t_0 = \infty$. As a consequence $V_\delta > \bar{v}$ in $\bar{Q^-}$ for any $\delta > 0$, which implies the assertion of the theorem. □

Similarly we show the following.

THEOREM 5.2. *Let u_0 satisfy hypothesis* (H) *and let*

$$\int_x^\infty u_0(s) ds \leq \int_x^\infty \bar{u}(s) ds \qquad \textit{for } x \in \mathbb{R}.$$

Then

$$u = 0 \qquad \textit{in } \bar{Q}^+.$$

6. Closing remarks. In this section we briefly discuss some qualitative properties of solutions of Problem P.

6.1. Nonuniqueness. In the proof of the comparison principle, implying uniqueness, we have used the pressure condition

$$[p] \geq 0. \tag{6.1}$$

By means of a counterexample we show here that uniqueness fails if we drop condition (6.1). Let u_0 satisfy the structural properties

$$(\tilde{\mathrm{H}}) \qquad \begin{cases} u_0(x) = 0 \quad \text{if} \quad x > 0, \quad u_0 \not\equiv \bar{u} \quad \text{in} \ \mathbb{R}, \\ \bar{u}(x) \leq u_0(x) \leq (u^* + \delta x)_+ \quad \text{if} \ \ x < 0 \ \ \text{for some} \ \ 0 < \delta < \dfrac{1}{\sqrt{k^-}}. \end{cases}$$

Based on the results of section 5, we expect that the corresponding solution u of Problem P will have a nontrivial component in Q^+; i.e., $u \not\equiv 0$ in Q^+. We will construct a second solution $\tilde{u}$ which solves Problem P, except condition (6.1), and which satisfies $\tilde{u} \equiv 0$ in Q^+. This construction is based on a modification of k. Instead of (1.2) we consider

$$\tilde{k}_n(x) = \begin{cases} k^- & \text{for} \quad x < 0, \\ \kappa & \text{for} \quad 0 < x < \dfrac{1}{n}, \\ k^+ & \text{for} \quad x > \dfrac{1}{n}, \end{cases} \tag{6.2}$$

where $0 < \kappa < k^+ < k^-$, and we let $n \to \infty$.

THEOREM 6.1. *Let u_0 satisfy hypotheses* (H) *and* ($\tilde{\mathrm{H}}$) *and let u denote the unique solution of Problem* P. *Then*

(i) *$u \not\equiv 0$ in Q^+;*

(ii) *there exists a second solution $\tilde{u}$ of Problem* P, *except* (6.1), *which satisfies $\tilde{u} \equiv 0$ in Q^+.*

Proof. We first show that $u \not\equiv 0$ in Q^+. Arguing by contradiction, we assume

$$u(0^+, t) = 0 \qquad \text{for all} \quad t > 0.$$

Using $[p] \geq 0$ and $u \geq \bar{u}$ in Q, we conclude

$$u(0^-, t) = u^* \qquad \text{for all} \quad t > 0.$$

Hence u solves in Q^- the problem

$$(\mathrm{P}^-) \qquad \begin{cases} u_t + (u - \sqrt{k^-} u u_x)_x = 0 & \text{in} \quad Q^-, \\ u(0,t) = u^* & \text{for} \quad t > 0, \\ u(x,0) = u_0(x) & \text{for} \quad x < 0. \end{cases}$$

Now observe that $\bar{z} := (u^* + \delta x)_+$ is a supersolution for problem (P^-). Hence the solution $z(x,t)$ of problem (P^-) with initial data $z(\cdot, 0) = \bar{z}(x)$ is decreasing with respect to time and converges to a steady state solution $s(x)$. By comparison $s \geq \bar{u}$ in $\mathbb{R}^-$, but since $\bar{u}$ is maximal we have

$$s = \bar{u} \qquad \text{in} \ \ \mathbb{R}^-.$$

Using

$$\bar{u}(x) \le u(x,t) \le z(x,t) \qquad \text{for all} \quad (x,t) \in Q^-,$$

we obtain

$$\lim_{t\to\infty} u(x,t) = \bar{u}(x) \qquad \text{uniformly in} \ \ x < 0.$$

Combining this result with $u \equiv 0$ in Q^+, we find

$$\lim_{t\to\infty} \int_{-\infty}^{+\infty} u(x,t)ds \to \int_{-\infty}^{+\infty} \bar{u}(x)dx < \int_{-\infty}^{+\infty} u_0(x)dx,$$

which contradicts mass conservation for u.

Next we use (6.2) to explain the construction of $\tilde{u}$. As a first observation we note that the class of steady state solutions of the equation

$$\left(u - \tilde{k}_n \left(\frac{1+u}{\sqrt{\tilde{k}_n}} \right)' \right)' = 0 \qquad \text{in} \quad \mathbb{R},$$

having compact support and satisfying (M_1) and (M_2), has the same structure as the one shown in Figure 3, but with $u^* = \sqrt{\frac{k^-}{k^+}} - 1$ replaced by $\tilde{u}^* = \sqrt{\frac{k^-}{\kappa}} - 1$. In particular this class does not depend on n. For κ sufficiently small we find, for $\bar{\tilde{u}}$, the maximal steady state

$$u_0 \le \bar{\tilde{u}} \qquad \text{in} \quad \mathbb{R}.$$

As a consequence, the solution $\tilde{u}_n$ of the problem

$$\begin{cases} u_t + \left(u - \tilde{k}_n \left(\dfrac{1+u}{\sqrt{\tilde{k}_n}} \right)_x \right)_x & \text{in} \quad Q, \\ u(x,0) = u_0(x) \qquad \text{for} \quad x \in R \end{cases}$$

satisfies

$$\tilde{u}_n(x,t) \le \bar{\tilde{u}}(x) \qquad \text{for all} \quad (x,t) \in Q.$$

In particular

$$\tilde{u}_n \equiv 0 \qquad \text{in} \quad Q^+$$

for all $n \in \mathbb{Z}^+$. Finally, letting $n \to \infty$, $\tilde{u}_n$ converges along subsequences to a function $\tilde{u} = \tilde{u}(x,t)$ which satisfies all properties required for Problem P except (6.1). □

6.2. Waiting times and optimal regularity. Numerical simulations reported in [DMN] show that the right free boundary of u has a "waiting time" when it reaches the permeability discontinuity. The free boundary becomes stagnant there, while the oil saturation increases. It continues whenever the pressure exceeds the entry pressure of the low permeable region.

The following makes this precise.

THEOREM 6.2. *Let u_0 satisfy hypothesis* (H) *and let* $\mathrm{supp}(u_0) \subset \mathbb{R}^-$. *Further, let the solution u of Problem* P *satisfy $u \not\equiv 0$ in Q^+. Set*

$$t_1 := \lim_{\varepsilon\to 0} \sup\{\tau > 0 : u \equiv 0 \ \ \textit{in} \ \ (-\varepsilon,\infty) \times (0,\tau)\}$$

and

$$t_2 := \sup\{\tau > 0 : u \equiv 0 \quad in \quad \mathbb{R}^+ \times (0,\tau)\}.$$

Then

$$0 < t_1 < t_2 < \infty \qquad (t_2 - t_1 \text{ is the waiting time})$$

and

$$u(0^-, t_1) = 0, \qquad u(0^-, t_2) = u^*.$$

Proof. Clearly t_1 and t_2 are well defined. Continuity of $u^{\pm}(t)$ and (M_2) imply directly $t_2 > t_1$ and $u(0^-, t_1) = 0$.

Suppose $u(0^-, t_2) < u^*$. By continuity, there exists $\delta > 0$ such that $u(0^-, t) < u^*$, and thus $u(0^+, t) = 0$, for $t_2 \le t < t_2 + \delta$. Thus $u \equiv 0$ in $\mathbb{R}^+ \times (0, t_2 + \delta)$, contradicting the definition of t_2. □

Next we consider the case where the oil initially is positioned in the fine material ($x > 0$). If the initial position is sufficiently close to the interface at $x = 0$, diffusion may drive the oil towards $x = 0$, i.e., against the flow, where it will penetrate the coarse material. This follows from the transformation $y = x - t,\ t = t$ and by considering an appropriate subsolution for the resulting porous media equation; see [G2].

Supposing the oil reaches $x = 0$, we have the following result.

THEOREM 6.3. *Let u_0 satisfy hypothesis* (H) *and let* $\operatorname{supp}(u_0) \subset \mathbb{R}^+$. *Further, let the solution u of Problem* P *satisfy $u \not\equiv 0$ in Q^-. Set*

$$t_1 := \sup\{\tau > 0 : u \equiv 0 \quad in \quad \mathbb{R}^- \times (0,\tau)\}.$$
$$t_2 := \sup\{\tau > 0 : u(0^+, t) = 0 \quad for \quad 0 < t < \tau\}.$$

Then

$$0 < t_1 < t_2 \le \infty.$$

In addition, there exists $t \in (t_1, t_2)$ such that for some $A > 0$

$$u(x,t) = A\sqrt{x}(1 + o(1)) \qquad as \quad x \to 0^+.$$

Proof. By the finite speed of propagation we have $t_1 > 0$. Continuity of $u(0^-, \cdot)$ implies $u(0^-, t_1) = 0$ and $u(0^-, t) \le u^*$ and hence $u(0^+, t) = 0$ for all t in an upper neighborhood of t_1. Hence $t_2 > t_1$. If $u(0^-, t) \le u^*$ for all $t > 0$, we have $t_2 = \infty$. Since $u \not\equiv 0$ in $\mathbb{R}^- \times (t_1, t_2)$ and $u(0^+, \cdot) = 0$ in (t_1, t_2), there exists $t \in (t_1, t_2)$ such that

$$f(t) = f^-(t) = f^+(t) < 0.$$

Hence, for this t fixed, setting $f(t) = -\mathcal{C}(\mathcal{C} > 0)$,

$$u - \sqrt{k^+} u u_x = -\mathcal{C}(1 + o(1)) \qquad \text{as} \quad x \to 0^+,$$

giving

$$\frac{1}{2}u^2(x,t) = \frac{\mathcal{C}}{\sqrt{k^+}} x(1 + o(1)) \qquad \text{as} \quad x \to 0^+. \qquad \square$$

Appendix. Proof of Lemma 2.1. Let $\varepsilon_n > 0$ be such that

$$\varepsilon_n = o\left(\frac{1}{n}\right) \qquad \text{as} \quad n \to \infty,$$

and set

$$u_{0n}(x) = \begin{cases} \sqrt{u_0^2(x - \frac{1}{n}) + \varepsilon_n^2} & \text{if} \quad x > \dfrac{1}{n}, \\ \sqrt{(u_0^+)^2 + \varepsilon_n^2} & \text{if} \quad x = \dfrac{1}{n}, \end{cases}$$

where $u_0^+ = \lim_{x \searrow 0} u_0(x)$. Since $|u_{0n}'(x)| \le |u_0'(x - \frac{1}{n})|$ for $x > \frac{1}{n}$, the uniform Lipschitz continuity of u_0 in $\mathbb{R}^+$ implies

$$u_{0n} \text{ is uniform Lipschitz continuous in } [\tfrac{1}{n}, \infty].$$

Since

$$f_0 = u_0 - \frac{1}{2}\sqrt{k^+}(u_0^2)' \qquad \text{in} \quad \mathbb{R}^+,$$

$$f_{0n} = u_{0n} - \frac{1}{2}\sqrt{k^+}(u_{0n}^2)' \qquad \text{in} \quad \left[\frac{1}{n}, \infty\right),$$

the total variation of $(u_0^2)'$ in $\mathbb{R}^+$, $TV_{\mathbb{R}^+}((u_0^2)')$, is bounded, and since $(u_{0n}^2)'(x) = (u_0^2)'(x - \frac{1}{n})$,

$$TV_{(\frac{1}{n}, \infty)}(f_{0n}) \to TV_{\mathbb{R}^+}(f_0) \qquad \text{as} \quad n \to \infty. \tag{A.1}$$

In order to extend u_{0n} to the interval $[-\frac{1}{n}, \infty]$ we distinguish two different cases: $u_0^+ > 0$ and $u_0^+ = 0$. At this point we remind the reader that the constant u^* is defined by

$$\frac{1 + u^*}{\sqrt{k^-}} = \frac{1}{\sqrt{k^+}}\,, \qquad \text{i.e.,} \quad u^* = \sqrt{\frac{k^-}{k^+}} - 1.$$

(i) *Case* $u_0^+ > 0$. We define u_{0n} in $[-\frac{1}{n}, \frac{1}{n})$ by the relation $p_{0n} = p_{0n}(\frac{1}{n})$ in $[-\frac{1}{n}, \frac{1}{n})$, i.e.,

$$u_{0n}(x) = -1 + \sqrt{\frac{k_n(x)}{k^+}}\left(1 + \sqrt{(u_0^+)^2 + \varepsilon_n^2}\right).$$

In particular, as $n \to \infty$,

$$\begin{aligned} u_{0n}(-\tfrac{1}{n}) &= -1 + \sqrt{\frac{k^-}{k^+}}\left(1 + \sqrt{(u_0^+)^2 + \varepsilon_n^2}\right) \\ &\to -1 + \sqrt{\frac{k^-}{k^+}}(1 + u_0^+) = u_0^-, \end{aligned} \tag{A.2}$$

where we have used, by hypothesis (H), $[p_0] = 0$ if $u_0^+ > 0$. Since $u_{0n}(-\frac{1}{n}) > u_0^-$, there exist $\delta_n > 0$ such that

$$u_{0n}\left(-\frac{1}{n}\right) = \sqrt{(u_0^-)^2 + \delta_n^2}. \tag{A.3}$$

It follows directly from the construction of u_{0n} that

$$TV_{(-\frac{1}{n},\frac{1}{n})}(f_{0n}) = -u_{0n}\left(\frac{1}{n}\right) + u_{0n}\left(-\frac{1}{n}\right) \to -[u_0] \quad \text{as} \quad n \to \infty \tag{A.4}$$

and

$$f_{0n}\left(\frac{1}{n}+\right) - f_{0n}\left(\frac{1}{n}-\right) = -\frac{1}{2}\sqrt{k^+}(u_{0n}^2)'\left(\frac{1}{n}+\right) = -\frac{1}{2}\sqrt{k^+}(u_0^2)'(0^+). \tag{A.5}$$

(ii) *Case* $u_0^+ = 0$. Since $[p_0] \geq 0$, $u_0^+ = 0$ implies that

$$0 \leq u_0^- \leq -1 + \sqrt{\frac{k^-}{k^+}} = u^*.$$

Hence

$$(1+\varepsilon_n)\sqrt{k^-} > \sqrt{k^-} \geq \sqrt{k^+}(1+u_0^-),$$

and there exist $\delta_n > 0$ such that

$$\begin{cases} \delta_n \to 0 \quad \text{as} \quad n \to \infty, \\ (1+\varepsilon_n)\sqrt{k^-} > \sqrt{k^+}\left(1+\sqrt{(u_0^-)^2+\delta_n^2}\right), \\ \sqrt{(u_0^-)^2+\delta_n^2} > \varepsilon_n. \end{cases}$$

These two inequalities imply that for some $\kappa_n \in (k^+, k^-)$

$$(1+\varepsilon_n)\sqrt{k^-} = \sqrt{\kappa_n}\left(1+\sqrt{(u_0^-)^2+\delta_n^2}\right).$$

Then there exists $x_n \in (-\frac{1}{n}, \frac{1}{n})$ such that

$$k_n(x_n) = \kappa_n,$$

and we define u_{0n} in $[-\frac{1}{n}, \frac{1}{n})$ by the relations

$$u_{0n}(x) \equiv u_{0n}\left(\frac{1}{n}\right) \quad (=\varepsilon_n) \qquad \text{if} \quad x_n \leq x < \frac{1}{n}$$

and

$$p_{0n}(x) \equiv p_{0n}(x_n) \quad \left(= \frac{1+\varepsilon_n}{\sqrt{\kappa_n}}\right) \qquad \text{if} \quad -\frac{1}{n} < x < x_n.$$

By the definition of κ_n and p_{0n}, the latter relation can be written as

$$u_{0n}(x) = -1 + \sqrt{\frac{k_n(x)}{k^-}}\left(1+\sqrt{(u_0^-)^2+\delta_n^2}\right) \qquad \text{if} \quad -\frac{1}{n} \leq x < x_n.$$

In particular we have

$$u_{0n}' \leq 0 \text{ in } \left(-\frac{1}{n}, x_n\right) \text{ and } u_{0n}\left(-\frac{1}{n}\right) = \sqrt{(u_0^-)^2+\delta_n^2} \to u_0^- \qquad \text{as } n \to \infty, \tag{A.6}$$

and

$$TV_{(-\frac{1}{n},x_n)}(f_{0n}) = TV_{(-\frac{1}{n},x_n)}(u_{0n}) \to -[u_0] \qquad \text{as } n \to \infty. \tag{A.7}$$

Since $|k_n^-| \le \frac{\mathcal{C}}{n}$ and $\varepsilon_n = o(\frac{1}{n})$ as $n \to \infty$, and since

$$f_{0n}(x) = \varepsilon_n + \frac{1}{2}\varepsilon_n(1+\varepsilon_n)\frac{k_n'(x)}{\sqrt{k_n(x)}} \qquad \text{if} \quad x_n < x < \frac{1}{n},$$

it follows that

$$TV_{(x_n,\frac{1}{n})}(f_{0n}) \to 0 \qquad \text{as} \quad n \to \infty. \tag{A.8}$$

In addition, as $n \to \infty$,

$$f_{0n}\left(\frac{1}{n}+\right) - f_{0n}\left(\frac{1}{n}-\right) \to -\frac{1}{2}\sqrt{k^+}(u_0^2)'(0^+) \tag{A.9}$$

and

$$f_{0n}(x_n^+) - f_{0n}(x_n^-) = \frac{1}{2}\varepsilon_n(1+\varepsilon_n)\frac{k_n'(x_n)}{\sqrt{\kappa_n}} \to 0. \tag{A.10}$$

Combining (A.6)–(A.10) gives

$$TV_{(-\frac{1}{n},\frac{1}{n})}(f_{0n}) \to -[u_0] \qquad \text{as} \quad n \to \infty. \tag{A.11}$$

Finally we have to define $u_{0n}(x)$ for $x < -\frac{1}{n}$. In view of (A.3) and (A.6) it seems natural to set

$$u_{0n}(x) = \sqrt{u_0^2\left(x+\frac{1}{n}\right) + \delta_n^2} \qquad \text{if} \quad x < -\frac{1}{n}. \tag{A.12}$$

Arguing as in the interval $(\frac{1}{n},\infty)$, we obtain as $n \to \infty$

$$TV_{(-\infty,-\frac{1}{n})}(f_{0n}) \to TV_{\mathbb{R}^-}(f_0) \tag{A.13}$$

and

$$f_{0n}\left(\left(-\frac{1}{n}\right)+\right) - f_{0n}\left(\left(-\frac{1}{n}\right)-\right) \to \frac{1}{2}\sqrt{k^-}(u_0^2)'(0^-). \tag{A.14}$$

Combining (A.1), (A.13), and (A.14) with, respectively, (A.4), (A.5) if $u_0^+ > 0$ and (A.9), (A.11) if $u_0^+ = 0$, we find

$$TV_{\mathbb{R}}(f_{0n}) \to TV_{\mathbb{R}}(f_0) \quad \text{as} \quad n \to \infty.$$

Now, if $\delta_n = \varepsilon_n$, u_{0n} satisfies all properties of Lemma 2.1. In general, however, $\delta_n \neq \varepsilon_n$ and we have to correct the construction of u_{0n} in $(-\infty,-\frac{1}{n})$. Since $u_{0n}(-\frac{1}{n}) > u_{0n}(\frac{1}{n}) \ge \varepsilon_n$, we can still use definition (A.12) in a neighborhood of $x = -\frac{1}{n}$. Since k_n is constant in $(-\infty,-\frac{1}{n})$, the expression for the flux is simply

$$f_{0n} = u_{0n} - \frac{1}{2}\sqrt{k^-}(u_{0n}^2)' \qquad \text{in} \quad \left(-\infty,-\frac{1}{n}\right).$$

Therefore it is not difficult to change slightly the definition of u_{0n} such that $u_{0n} \ge \varepsilon_n$ in $\mathbb{R}$ and $u_{0n}(x) = \varepsilon_n$ for $-x$ sufficiently large. We leave the details to the reader.

AN EXAMPLE OF CATASTROPHIC SELF-FOCUSING IN NONLINEAR OPTICS?*

ÉRIC DUMAS†

Abstract. As the wavelength ε goes to zero, the slowly varying envelope approximation allows one to replace the fields (solutions to Maxwell equations) with profile solutions to a nonlinear Schrödinger equation (NLS). Depending on the model, this equation may be critical and focusing, and then admits explosive solutions. In this case, the approximation breaks down, and, for ε fixed, the fields may be globally defined in time, and smooth. This happens in the case of Maxwell–Bloch equations [P. Donnat and J. Rauch, *Arch. Ration. Mech. Anal.*, 136 (1996), pp. 291–303], [E. Dumas, *Existence globale pour les systèmes de Maxwell-Bloch*, in Séminaire École Polytechnique, 2002–2003, Ecole Polytechnique, Palaiseau, France], of the anharmonic oscillator with saturated nonlinearity [J. L. Joly, G. Métivier, and J. Rauch, *SIAM J. Math. Anal.*, 227 (1996), pp. 903–913], and of propagation in a ferromagnetic medium [J. L. Joly, G. Métivier, and J. Rauch, *Ann. Henri Poincaré*, 1 (2000), pp. 307–340], [H. Haddar, *Modèles asymptotiques en ferromagnétisme: Couches minces et homogénéisation*, Ph.D. thesis, thèse INRIA-École Nationale des Ponts et Chaussées, 2000].

We analyze the question of self-focusing for a wave equation in space dimension 2; the same techniques apply to usual models in greater dimensions. We give a new representation of the fields in terms of oscillating profiles, ruled by focusing rays. Furthermore, we prove that the approximation by an explosive solution of NLS is valid up to a time of the order of a negative power of $\ln(1/\varepsilon)$ before explosion; this exhibits an amplification of the fields by a positive power of $\ln(1/\varepsilon)$ between $t = 0$ and that time.

1. Introduction.

A standard model for describing the propagation of an electromagnetic wave through a field responsive (or Kerr) medium is the coupling of Maxwell equations with an anharmonic oscillator (cf. [3], [2]):

$$\begin{cases} \partial_t E = -\text{curl } B - \partial_t P, \\ \partial_t B = \text{curl } E, \\ \varepsilon^2 \partial_t^2 P + \nabla_P V(P) = \gamma E. \end{cases} \tag{1}$$

Here, (E, B) is the electromagnetic field, and P is the polarization of the medium. The physically relevant fields also satisfy $\text{div}\,(E + P) = \text{div}\, B = 0$, which is true for all times as soon as it is at one given time. The response of matter is given by a nonlinear spring force, with the same frequency $1/\varepsilon$ as the wave. Many other models are available, including magnetic effects (Landau–Lifshitz model; see [14]) or quantum descriptions (Bloch equations; see [18]); but all these systems can be approximated by a single equation, in the regime we describe now.

For a small amplitude wave, slowly modulated in space and time, the so-called "slowly varying envelope approximation" (see [16, pp. 32–38] and [17]) leads to a *nonlinear Schrödinger equation* (NLS). This approximation is also used in other physical

†Laboratoire de Mathématiques et Physique Théorique, Parc de Grandmont, 37200 Tours, France. Present address: Université Grenoble 1, BP 74, 100, rue des Mathématiques, Domaine Universitaire, 38402 Saint Martin d'Hères, France (edumas@ujf-grenoble.fr, http://www-fourier.ujf-grenoble.fr/∼edumas/).

contexts, such as water waves and plasma waves, showing that NLS is a canonical equation, capturing the essential features of nonlinear wave dynamics (see [23] for a survey). In the case of Maxwell equations with an anharmonic oscillator, the potential V is replaced by its Taylor expansion at the origin,

$$V(P) \simeq \alpha|P|^2 - \beta|P|^4,$$

and the vector $u = (E, B, P, \varepsilon\partial_t P)$ is approximated by $u_{app} = \varepsilon\mathcal{U}(\varepsilon t, y_1, y_2)e^{i\frac{y_3+t}{\varepsilon}}$, $\mathcal{U} = (\mathcal{E}, \mathcal{B}, \mathcal{P}, \mathcal{Q})$. The fields must be polarized,

$$\mathcal{E} = \begin{pmatrix} K \\ L \\ 0 \end{pmatrix}, \ \mathcal{B} = c_1 \begin{pmatrix} L \\ -K \\ 0 \end{pmatrix}, \ \mathcal{P} = c_2 \begin{pmatrix} K \\ L \\ 0 \end{pmatrix}, \ \mathcal{Q} = ic_3 \begin{pmatrix} K \\ L \\ 0 \end{pmatrix}, \tag{2}$$

and the amplitudes $K(T, y_1, y_2), L(T, y_1, y_2)$ are solutions to

$$i\partial_t \begin{pmatrix} K \\ L \end{pmatrix} - \kappa_1 \Delta_{y_1,y_2} \begin{pmatrix} K \\ L \end{pmatrix} - \kappa_2(|K|^2 + |L|^2) \begin{pmatrix} K \\ L \end{pmatrix} = 0. \tag{3}$$

This is a critical NLS equation in space dimension 2, possibly with *focusing* nonlinearity ($\kappa_1\kappa_2 > 0$), depending on the details of the model (i.e., on the coefficients α and β).

This approximation can be rigorously justified in the case of a general hyperbolic system of nonlinear partial differential equations (see [5]), for ε small enough, on any time interval $[0, t_1/\varepsilon]$ such that the solution of (3) remains smooth on $[0, t_1]$. (Similar results hold for water waves in the limit of long waves, leading to the Korteveg–de Vries equation or Boussinesq equation; see [19], [20], [21].) However, a time $t_\star$ of explosion for a solution to (3) is usually thought of as an indication of *self-focusing*: a variation of the refractive index of the medium induces curved light rays, which concentrate in the region of maximal refractive index. But, to our knowledge, there is no rigorous result linking the explosion of the profile (solution to NLS) and the behavior of the exact solution u.

First, the slowly varying envelope assumption (from which (3) is derived) is violated in this region, where fields become too large. Second, the electromagnetic field may be globally defined in time (and smooth), even if the profile $\mathcal{U}$ explodes in finite time: in [6], Donnat and Rauch consider two-level Maxwell–Bloch systems. This result is extended in [8] to general Maxwell–Bloch systems, following ideas of Joly, Métivier, and Rauch [13] and Haddar [11] concerning the Landau–Lifshitz model. In [12], Joly, Métivier, and Rauch deal with (1), when the potential V is *saturated*: if the second and third derivatives of V are bounded, $H^2(\mathbb{R}^3)$ initial data generate global solutions to (1).

In this paper, we investigate further the mechanism of self-focusing, evaluating more precisely how long the Schrödinger approximation is valid. We present our method for the simplest (i.e., with the lowest space dimension) hyperbolic equation allowing transverse diffraction, a scalar wave equation in space dimension 2:

$$\Box u + iF(\partial_t u) = 0, \text{ with } F(z) = |z|^4 z. \tag{4}$$

THEOREM 1.1. *Fix $t_\star > 0$, and define*

$$a_0(t, Y) := (t_\star - t)^{-1/2} e^{i\frac{Y^2-1}{2(t_\star-t)}} R\left(\frac{Y}{t_\star - t}\right), \text{ with } R(Y) = \frac{3^{1/4}}{\sqrt{\text{ch }(2Y)}}. \tag{5}$$

There are $\varepsilon_0, C > 0$ such that for all $\varepsilon \in]0, \varepsilon_0]$, the initial value problem associated with (4)*, for initial data*

$$\begin{cases} u^\varepsilon_{|t=0} = \varepsilon a_0\left(0, y_2/\sqrt{\varepsilon}\right) e^{iy_1/\varepsilon}, \\ \partial_t u^\varepsilon_{|t=0} = \dfrac{i}{\varepsilon} u^\varepsilon_{|t=0} + \mathcal{O}(\varepsilon) \text{ in } \mathcal{S}(\mathbb{T}_\varepsilon \times \mathbb{R}), \text{ with } \mathbb{T}_\varepsilon \text{ the torus } \mathbb{R}/(2\pi\varepsilon), \end{cases}$$

admits a unique smooth solution $u^\varepsilon \in \mathcal{C}^1(\mathcal{S}(\mathbb{T}_\varepsilon \times \mathbb{R}))$ for $t \in [0, t_\star - C(\ln 1/\varepsilon)^{-1/3}]$. Furthermore, as $\varepsilon \to 0$, we have the approximation

$$\left\| \partial_t u^\varepsilon - i a_0\left(t, y_2/\sqrt{\varepsilon}\right) e^{i\frac{y_1+t}{\varepsilon}} \right\|_{L^\infty_y} = o\left(\|a_0(t)\|_{L^\infty}\right).$$

The link with the physical context above will be clearer after a few remarks.

Remark 1.1. From the profile $a_0(t, Y)e^{i\theta}$, in which we substitute $Y = y_2/\sqrt{\varepsilon}$, $\theta = (y_1 + t)/\varepsilon$, we recover the long-time setting leading to (3) after rescaling: replace (t, y) by $\sqrt{\varepsilon}(t, y)$, and $\sqrt{\varepsilon}$ by ε. We have chosen these scales so as to give an alternative description of u^ε in terms of curved phases and focusing rays. See section 4 and [7]. Once rescaled, Theorem 1.1 shows that the slowly varying envelope approximation for (4) can be justified up to times $\frac{1}{\varepsilon}(t_\star - C(\ln 1/\varepsilon)^{-1/3})$—compare with the previous t_1/ε, when $t_1 < t_\star$ is fixed.

Remark 1.2. The same method can be applied to a general hyperbolic system of PDEs, also in higher dimension (see Remark 2.1), provided that the NLS equation for the envelope, analogous to (3), is critical and focusing. For example, in the case of system (1), with space dimension 3 and cubic nonlinearity ($\nabla_P V(P) = 2\alpha P - 4\beta|P|^2 P$ for suitable α and β), the exact solution $u = (E, B, P, \varepsilon\partial_t P)$ is approximated in $L^\infty([t_\star - C(\ln 1/\varepsilon)^{-1/3}] \times \mathbb{R}^3)$ via $K_{app} = (t_\star - \varepsilon t)^{-1} e^{i\frac{|y_1, y_2|^2 - 1}{2(t_\star - \varepsilon t)}} R_2(\frac{y_1}{t_\star - \varepsilon t}, \frac{y_2}{t_\star - \varepsilon t}) e^{i\frac{y_3 + t}{\varepsilon}}$ from (2), with $R_2 \in \mathcal{S}(\mathbb{R}^2)$ a positive solution to $-\Delta R + R - R^3 = 0$.

Remark 1.3. Equation (4) preserves only $\|\partial_{t,y} u\|_{L^2}$ (taking the real part of (4) times $\partial_t \overline{u}$). This is not sufficient to guarantee global existence of u: when the maximal existence time $t^\star$ of a smooth solution u is finite, the quantity $\|\partial_t u(t)\|_{L^\infty}$ explodes as $t \to t^\star$. Thus, the standard proofs of global existence, such as for small data (see [22]), consist in controlling $\|\partial_t u(t)\|_{L^\infty}$ by t and the initial data. Here, $\|\partial_{t,y} u\|_{L^2}$ does not allow this control. The theorem doesn't prove that u^ε (with ε fixed) explodes at $t = t_\star$ but shows an amplification of $\|\partial_t u\|_{L^\infty}$ by a factor $(\ln 1/\varepsilon)^{-1/6}$ between $t = 0$ and $t = t_\star - C(\ln 1/\varepsilon)^{-1/3}$.

Remark 1.4. Global existence is achieved in the other limit: ε fixed, $t_\star \to 0$, which corresponds to small initial data. Saturation, replacing the nonlinearity $F(z)$ by $G^\varepsilon(z) = \frac{|z|^4 z}{1 + \varepsilon z^3}$, also ensures global existence of u^ε, as in [12]. Thus, the mechanism of catastrophic self-focusing seems to be as follows: first, a concentration due to linear focusing of rays ("self-focusing"); second, activation of nonlinear effects by this amplification. Blow-up ("catastrophic" self-focusing) then depends on the strength of the nonlinearity: saturation stops the development of the singularity, but without saturation, or special geometric properties (see [13], [11] about the Landau–Lifshitz model, and [6], [8] about Maxwell–Bloch systems), one is inclined to think that blow-up occurs.

Remark 1.5. In fact, the slowly varying envelope approximation used here necessarily produces a Schrödinger equation with a restrictive kind of nonlinearity: namely, the first nonvanishing term in the Taylor expansion of the original nonlinearity. Since

the structure of the nonlinear terms is crucial for blow-up, there are also attempts for understanding the role played by various perturbations of NLS: see [9] and [4].

The paper is organized as follows:

Section 2: (formal) definition of the explosive profile a_0 via the conformal invariance of NLS.

Section 3: Wentzel–Kramers–Brillouin (WKB) asymptotics. A corrector a_c is defined to get a better approximation.

Section 4: thanks to nonuniqueness of the profile representation, we give an alternative description of u^ε based on focusing nonplanar phases.

Section 5: proof of Theorem 1.1. We first change scales (section 5.1) and look at $U(x) = u(t, y_1/\varepsilon, y_2/\sqrt{\varepsilon})$, 2π-periodic in y_1. In section 5.2, we write down energy estimates for the residual $\partial_t V = \partial_t U - \partial_t U_{app}$ ($\|\partial_t V\|_{L^\infty}$ is then controlled by Sobolev's inequality). This is the notable difference between this work and [15], where the authors need global existence of the (small) approximate solution, whereas we "follow" the explosive approximate solution up to some boundary layer before $t_\star$. This boundary layer appears when requiring the corrector a_c to remain small compared to a_0 (section 5.3) and in the bootstrap argument showing $\|\partial_t V\|_{L^\infty} \ll \|\partial_t U_{app}\|_{L^\infty}$ (section 5.4).

2. From the wave equation to explosive solutions of NLS. A classical technique for constructing explosive solutions to NLS comes from the pseudoconformal invariance of this equation (see [10]): if $b(t, Y)$ is a solution to

$$2i\partial_t u - \partial_Y^2 u - |u|^4 u = 0, \tag{6}$$

then, for all $t_\star \in \mathbb{R}$, we define another solution by

$$a(t, Y) := \left(t^{1/2} e^{iY^2/2t} b\right)\left(\frac{1}{t_\star - t}, \frac{Y}{t_\star - t}\right) = (t_\star - t)^{-1/2} e^{iY^2/2(t_\star - t)} b\left(\frac{1}{t_\star - t}, \frac{Y}{t_\star - t}\right).$$

When seeking a solution u to (4) in the "slowly varying envelope" form $u^\varepsilon(x) = \varepsilon \mathcal{U}^\varepsilon(t, y_2/\sqrt{\varepsilon}, (y_1 + t)/\varepsilon)$ with a profile $\mathcal{U}^\varepsilon(t, Y, \theta) \in \mathcal{C}^2([0, t_\star[\times \mathbb{R} \times \mathbb{T})$ (periodic w.r.t. the last variable, θ), the chain rule leads to the following equation:

$$[2\partial_t \partial_\theta - \partial_Y^2]\mathcal{U}^\varepsilon + \varepsilon \partial_t^2 \mathcal{U}^\varepsilon + i|\partial_\theta \mathcal{U}^\varepsilon + \varepsilon \partial_t \mathcal{U}^\varepsilon|^4 (\partial_\theta \mathcal{U}^\varepsilon + \varepsilon \partial_t \mathcal{U}^\varepsilon) = 0. \tag{7}$$

When $\mathcal{U}^\varepsilon$ satisfies (7), u^ε above is a solution to (6).

In order to let these quantities vanish at first order (see the WKB expansions in section 3), it is then natural to look for a profile $u_0(t, Y, \theta)$ such that

$$[2\partial_t \partial_\theta - \partial_Y^2]u_0 + i|\partial_\theta u_0|^4 \partial_\theta u_0 = 0. \tag{8}$$

There are explicit solutions to this equation. When $u_0 = b(t, Y)e^{i\theta}$, it is equivalent to require that b satisfies (6), and $b(t, Y) = e^{-it/2} R(Y)$ is a solution, with $R(Y) = 3^{1/4}(\mathrm{ch}\,(2Y))^{-1/2}$ (the unique positive solution of $R'' - R + R^5 = 0$, up to translation).

Now, use the pseudoconformal invariance of (6) to get a solution $u_0(t, Y, \theta) = a_0(t, Y)e^{i\theta}$ to (8):

$$a_0(t, Y) = (t_\star - t)^{-1/2} e^{i(Y^2 - 1)/2(t_\star - t)} R\left(\frac{Y}{t_\star - t}\right). \tag{9}$$

For all $t \in [0, t_\star[$, $a_0(t) \in \mathcal{S}(\mathbb{R})$, and a_0 explodes at $t = t_\star$ ($\|a_0(t)\|_{L^\infty} = 3^{1/4}(t_\star - t)^{-1/2}$).

Remark 2.1. The same construction is possible in higher dimension N: the pseudoconformal transform is $u(t,x) \mapsto t^{-N/2}e^{-i|x|^2/2t}\overline{u}(1/t, x/t)$. Then $-\Delta R + R - R^{1+4/N} = 0$ also has a solution in $\mathcal{S}$, and the same is valid for the equation $-\Delta R + mR + g(R) = 0$, $m = cst$, under suitable behavior of g at the origin and at infinity (see [1]).

3. WKB expansions and initial data for u^ε. If we want to deduce from an approximate solution $\varepsilon\mathcal{U}^\varepsilon(t, y_2/\sqrt{\varepsilon}, (y_1+t)/\varepsilon)$ the existence of an exact solution to (4), we must construct a solution to (7) to higher order than $\varepsilon u_0(t, y_2/\sqrt{\varepsilon}, (y_1+t)/\varepsilon)$. That's why we need a corrector for the first profile u_0. The general form for $\mathcal{U}^\varepsilon_{app}$ (from [5]) has two such correctors: $\mathcal{U}^\varepsilon_{app} = \varepsilon(u_0 + \sqrt{\varepsilon}u_1 + \varepsilon u_2)$. Here, when u_1 vanishes at $t = 0$, we can let it vanish for all times. Thus, we set

$$u^\varepsilon_{app}(x) = \varepsilon\mathcal{U}^\varepsilon_{app}(t, y_2/\sqrt{\varepsilon}, (y_1+t)/\varepsilon), \quad \mathcal{U}^\varepsilon_{app} = u_0 + \varepsilon u_c = (a_0 + \varepsilon a_c)(t, Y)e^{i\theta}.$$

Proposition 3.1. *We have the (formal) WKB expansion*

$$\Box u^\varepsilon_{app} + i|\partial_t u^\varepsilon_{app}|\partial_t u^\varepsilon_{app} = (\mathcal{E}_0 + \varepsilon\mathcal{E}_1 + \mathcal{R}^\varepsilon)(t, y_2)e^{i\frac{y_1+t}{\varepsilon}}, \tag{10}$$

with

$$\begin{aligned}
\mathcal{E}_0(t,Y) &= 2i\partial_t a_0 - \partial_Y^2 a_0 - |a_0|^4 a_0,\\
\mathcal{E}_1(t,Y) &= 2i\partial_t a_c - \partial_Y^2 a_c + \partial_t^2 a_0 + G(a_0, a_c),\\
G(a_0, a_c) &= -|a_0|^4(\partial_t a_0 + i a_c) + 4i a_0|a_0|^2 Re(a_0(\partial_t\overline{a_0} + i\overline{a_c})),\\
\mathcal{R}^\varepsilon(t,Y) &= \varepsilon^2\partial_t^2 a_c + iF((i+\varepsilon\partial_t)(a_0 + \varepsilon a_c)) + F(a_0) - \varepsilon G(a_0, a_c).
\end{aligned}$$

We can construct a_0 and a_c such that $\mathcal{E}_0 = \mathcal{E}_1 = 0$: such an $a_0 \in \mathcal{C}^\infty([0, t_\star[\times\mathbb{R})$ is given by (9), and $\mathcal{E}_1 = 0$ is a linear Schrödinger equation, which has a unique solution for any $a_{c|_{t=0}} \in L^2(\mathbb{R})$.

Our goal is to show the existence of an exact solution u^ε to (4) close to $\varepsilon u_0(t, y_2/\sqrt{\varepsilon}, (y_1+t)/\varepsilon)$. Towards this end, we choose

$$a_{c|_{t=0}} = 0, \tag{11}$$

which provides us with a (unique) corrector $a_c \in \mathcal{C}^\infty([0, t_\star[\times\mathbb{R})$. Next, we take the simplest initial data for u^ε, in view of evaluating $u^\varepsilon - u^\varepsilon_{app}$:

$$\begin{cases} u^\varepsilon{}_{|_{t=0}} = u^\varepsilon_{app}{}_{|_{t=0}},\\ \partial_t u^\varepsilon{}_{|_{t=0}} = \partial_t u^\varepsilon_{app}{}_{|_{t=0}}. \end{cases} \tag{12}$$

Remark 3.1. (i) We can compute $\partial_t u^\varepsilon_{app}{}_{|_{t=0}}$ in terms of the function R, since a_0 is known explicitly, and $\partial_t a_c$ is given by the equation $\mathcal{E}_1 = 0$, so that

$$\partial_t a_{c|_{t=0}} = \frac{i}{2}\left[\partial_t^2 a_0 - |a_0|^4\partial_t a_0 + 2ia_0|a_0|^2(a_0\partial_t\overline{a_0} + \overline{a_0}\partial_t a_0)\right]_{|_{t=0}}. \tag{13}$$

(ii) Since the data are $2\pi\varepsilon$-periodic in y_1, the standard uniqueness argument shows that so is $u^\varepsilon(t)$ for each time.

4. Linear focusing. We can give an alternative profile description of the data in (12): $u^\varepsilon{}_{|t=0}$ also has a representation via $\tilde{u}_0^0 \in \mathcal{S}(\mathbb{R}\times\mathbb{T})$,

$$u^\varepsilon{}_{|t=0} = \varepsilon \tilde{u}_0^0\left(\frac{y_2}{\sqrt{\varepsilon}}, \frac{y_1+y_2^2/2t_\star}{\varepsilon}\right), \text{ where } \tilde{u}_0^0(Y,\theta) = t_\star^{-1/2} e^{-i/2t_\star} R\left(\frac{Y}{t_\star}\right) e^{i\theta}.$$

Similarly,

$$\partial_t u^\varepsilon{}_{|t=0} = \Bigg(i t_\star^{-1/2} R\left(\frac{Y}{t_\star}\right) + \varepsilon \Bigg[\frac{i}{2} t_\star^{-5/2} Y^2 R\left(\frac{Y}{t_\star}\right) + t_\star^{-5/2} Y R'\left(\frac{Y}{t_\star}\right) + \frac{1}{2} t_\star^{-3/2}(1 - i t_\star^{-1}) R\left(\frac{Y}{t_\star}\right)\Bigg] e^{-i/2t_\star} e^{i\theta}\Bigg)_{|_{Y=y_2/\sqrt{\varepsilon}, \theta=(y_1+y_2^2/2t_\star)/\varepsilon}} + \varepsilon^2 \partial_t a_{c|_{t=0, Y=y_2/\sqrt{\varepsilon}}} e^{i y_1/\varepsilon},$$

and $e^{i\frac{y_1+y_2^2/2t_\star}{\varepsilon}}$ also factors in the last term (see (13) in Remark 3.1).

Thus, we have a new profile representation of the initial data, with oscillations involving the *curved* phase $y_1 + y_2^2/2t_\star$. Now, defining v^ε such that

$$\begin{cases} \Box v^\varepsilon + iF(\partial_t v^\varepsilon) = 0, \\ v^\varepsilon{}_{|t=0} = u^\varepsilon{}_{|t=0}, \\ \partial_t v^\varepsilon{}_{|t=0} = i\sqrt{1+(y_2/t_\star)^2}\, v^\varepsilon{}_{|t=0}, \end{cases}$$

we have two different ways of analyzing v^ε:

1. Plane phases:

$$\begin{aligned} \partial_t v^\varepsilon{}_{|t=0} &= i\left(\sqrt{1+\varepsilon(Y/t_\star)^2}\, u_{0|t=0}\right)(y_2/\sqrt{\varepsilon}, y_1/\varepsilon) \\ &= i\left(u_{0|t=0} + \mathcal{O}_{\mathcal{S}(\mathbb{R}\times\mathbb{T})}(\varepsilon)\right)(y_2/\sqrt{\varepsilon}, y_1/\varepsilon), \end{aligned}$$

and from [5], for each $\underline{t} < t_\star$, when ε is small enough,

$$u^\varepsilon = \varepsilon \mathcal{U}^\varepsilon\left(t, \frac{y_2}{\sqrt{\varepsilon}}, \frac{y_1+t}{\varepsilon}\right), \quad v^\varepsilon = \varepsilon \mathcal{V}^\varepsilon\left(t, \frac{y_2}{\sqrt{\varepsilon}}, \frac{y_1+t}{\varepsilon}\right), \quad \text{and } \|\mathcal{U}^\varepsilon - \mathcal{V}^\varepsilon\|_{\cap H^s} \underset{\varepsilon\to 0}{\longrightarrow} 0,$$

so that $\|\partial_t u^\varepsilon - \partial_t v^\varepsilon\|_{L^\infty} \underset{\varepsilon\to 0}{\longrightarrow} 0$ uniformly on $[0, \underline{t}]$.

2. Curved phases: since

$$\begin{cases} v^\varepsilon{}_{|t=0} = \varepsilon \tilde{u}_0^0\left(y_2/\sqrt{\varepsilon}, \phi_0/\varepsilon\right), \\ \partial_t v^\varepsilon{}_{|t=0} = i|\partial_y \phi_0| \tilde{u}_0^0\left(y_2/\sqrt{\varepsilon}, \phi_0/\varepsilon\right) \end{cases}$$

with $\phi_0 = y_1 + y_2^2/2t_\star$, on each time interval $[0, \underline{t}]$, [7] ensures the representation $v^\varepsilon = \varepsilon \tilde{\mathcal{V}}^\varepsilon(t, \frac{y_2}{\sqrt{\varepsilon}}, \frac{\phi}{\varepsilon})$, where ϕ is characteristic for the d'Alembertian operator:

$$\partial_t \phi = |\partial_y \phi| \quad \text{and} \quad \phi_{|t=0} = y_1 + y_2^2/2t_\star.$$

This phase is implicitly determined by the "ray method": $\phi(t,y) = \phi_0(z)$, where z is the origin (at $t=0$) of the ray through (t,y) (which here is a straight line):

$$y - z + t\frac{\nabla\phi_0(z)}{|\nabla\phi_0(z)|} = 0.$$

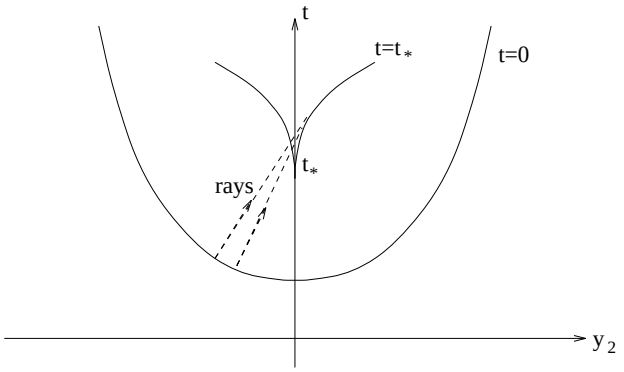

FIG. 4.1. *The graph of* $\phi(t, y_1, .)$ *at* $t = 0$ *and* $t = t_\star$.

Direct computations show that the rays focus exactly at time $t = t_\star$ (generating a caustic, where ϕ is no longer smooth). This is illustrated by Figure 4.1.

Remark 4.1. Here, ϕ can be determined explicitly (before $t = t_\star$) by solving analytically a fourth degree algebraic equation. However, the region of interest is the set of the "first" rays to focus, corresponding to $y_2 = 0$. On these rays, one easily computes that the gradient (w.r.t. t, y) of ϕ is the same as that of the linear phase $y_1 + t$. This indicates that planar and nonplanar phase representations correspond to similar oscillations and give two different ways of understanding the amplitude's behavior.

5. Existence and approximation of u^ε. We prove a slightly stronger approximation than in Theorem 1.1.

THEOREM 5.1. *When* $C > 0$ *is sufficiently large, and for all* $\alpha > 0$, *as* $\varepsilon \to 0$,

$$\left\|\partial_t u^\varepsilon - \partial_t u^\varepsilon_{app}\right\| = o(\varepsilon^{2-\alpha}) \text{ in } L^\infty((0, t_\star - C(\ln 1/\varepsilon)^{-1/3}) \times \mathbb{R}^2).$$

5.1. Rescaling. So as to evaluate the lifespan of u^ε, we look for the times during which $\|\partial_t u^\varepsilon\|_{L^\infty}$ is finite. With the idea of giving an approximation of u^ε, we define $v^\varepsilon := u^\varepsilon - u^\varepsilon_{app}$ and try to verify $\|\partial_t v^\varepsilon\|_{L^\infty} \ll \left\|\partial_t u^\varepsilon_{app}\right\|_{L^\infty}$.

We make use of the wave equation satisfied by v^ε. It provides us with energy estimates for $\partial_{t,y} v^\varepsilon$, which bound $\|\partial_t v^\varepsilon\|_{L^\infty}$, thanks to the Sobolev inequality. However, these direct computations are too crude, because of Remark 3.1(ii): u^ε and u^ε_{app} are $2\pi\varepsilon$-periodic in y_1, and so is v^ε. Thus, estimating $\|\partial_t v^\varepsilon\|_{L^\infty}$ by $\|\partial_t v^\varepsilon\|_{H^s}$, we lose a factor ε^s. That's why we finally try to control $\|\partial_t V^\varepsilon\|_{L^\infty}$, where

$$V^\varepsilon(t, y) := v^\varepsilon(t, \varepsilon y_1, \sqrt{\varepsilon} y_2). \tag{14}$$

In the same way, set $(U^\varepsilon, U^\varepsilon_{app}, R^\varepsilon)(x) := (u^\varepsilon, u^e_{app} p, r^\varepsilon)(t, \varepsilon y_1, \sqrt{\varepsilon} y_2)$ (where $r^\varepsilon(x) = \mathcal{R}^\varepsilon(t, y_2/\sqrt{\varepsilon}) e^{i\frac{y_1+t}{\varepsilon}}$ from section 3).

Notation 5.1. We write $a \preceq b$ when there is a constant C such that $a \leq Cb$.

5.2. Energy estimates for the error $\partial_t V^\varepsilon$. From the relation (14), subtracting (4) and (10) and using Taylor's formula for $F(z) = |z|^4 z$ (as a differentiable function on $\mathbb{R}^2$), we get

$$(\partial_t^2 - \varepsilon^{-2}\partial_{y_1}^2 - \varepsilon^{-1}\partial_{y_2}^2) V^\varepsilon = -i \left(\int_0^1 dF \left(\partial_t U^\varepsilon_{app} + r \partial_t V^\varepsilon \right) dr \right) . \partial_t V^\varepsilon - R^\varepsilon. \tag{15}$$

Consider $\int_{(-\pi\times\pi)\times\mathbb{R}} 2\mathrm{Re}((15)\times\partial_t\overline{V^\varepsilon})dy$. This gives

$$\frac{d}{dt}\Big(\|\partial_t V^\varepsilon\|_{L^2}^2+\varepsilon^{-2}\|\partial_{y_1}V^\varepsilon\|_{L^2}^2+\varepsilon^{-1}\|\partial_{y_2}V^\varepsilon\|_{L^2}^2\Big)$$
$$\preceq\Big(\big\|\partial_t U_{app}^\varepsilon\big\|_{L^\infty}^4+\|\partial_t V^\varepsilon\|_{L^\infty}^4\Big)\|\partial_t V^\varepsilon\|_{L^2}^2+\|R^\varepsilon\|_{L^2}\|\partial_t V^\varepsilon\|_{L^2},$$

so that, writing $N(V^\varepsilon):=(\|\partial_t V^\varepsilon\|_{L^2}^2+\varepsilon^{-2}\|\partial_{y_1}V^\varepsilon\|_{L^2}^2+\varepsilon^{-1}\|\partial_{y_2}V^\varepsilon\|_{L^2}^2)^{1/2}$ and $I_k:=\big\|\partial_t U_{app}^\varepsilon\big\|_{L^\infty}^k+\|\partial_t V^\varepsilon\|_{L^\infty}^k$,

$$\frac{d}{dt}N(V^\varepsilon)\preceq I_4N(V^\varepsilon)+\|R^\varepsilon\|_{L^2}. \tag{16}$$

Differentiating (15), in the same manner we get

$$\frac{d}{dt}N(\partial_yV^\varepsilon)\preceq I_4N(\partial_yV^\varepsilon)+I_3\big\|\partial_t\partial_yU_{app}^\varepsilon\big\|_{L^2}\|\partial_tV^\varepsilon\|_{L^\infty}+\|\partial_yR^\varepsilon\|_{L^2}, \tag{17}$$

and for any second order derivative ∂_y^2,

$$\frac{d}{dt}N(\partial_y^2V^\varepsilon)\preceq I_3\Big(\big\|\partial_t\partial_y^2U_{app}^\varepsilon\big\|_{L^2}\|\partial_tV^\varepsilon\|_{L^\infty}+\big\|\partial_t\partial_yU_{app}^\varepsilon\big\|_{L^2}\|\partial_t\partial_yV^\varepsilon\|_{L^\infty}\Big)$$
$$+\big\|\partial_y^2R^\varepsilon\big\|_{L^2}+I_4N(\partial_y^2V^\varepsilon). \tag{18}$$

Adding (16)–(18), using Sobolev's inequality and Gronwall's lemma, since $V^\varepsilon_{|_{t=0}}=\partial_tV^\varepsilon_{|_{t=0}}=0$, we have

$$\|\partial_tV^\varepsilon\|_{L^\infty}\preceq N(V^\varepsilon,\partial_yV^\varepsilon,\partial_y^2V^\varepsilon)\preceq e^{CJ(t)}\int_0^t\|R^\varepsilon\|_{H^2}dt', \tag{19}$$

where $J(t)=\int_0^t[I_4+I_3(\|\partial_t\partial_yU_{app}^\varepsilon\|+\|\partial_t\partial_y^2U_{app}^\varepsilon\|+\|\partial_t\partial_yU_{app}^\varepsilon\|)]dt'$.

5.3. Defining the boundary layer for the corrector. We first define an interval $[0,\underline{t}(\varepsilon)]$ where $U_{app}^\varepsilon\simeq U_0^\varepsilon:=\varepsilon u_0(t,y_2,y_1+\frac{t}{\varepsilon})$, i.e., where $U_c^\varepsilon:=\varepsilon^2u_c(t,y_2,y_1+\frac{t}{\varepsilon})$ is a corrector to this quantity.

PROPOSITION 5.2. *When $t_\star-t>C(\ln 1/\varepsilon)^{-1/3}$ for some C ($\gg1$),*

$$\|\partial_tU_c^\varepsilon\|_{W^{1,\infty}}\ll\|\partial_tU_{app}^\varepsilon\|_{W^{1,\infty}}\quad\text{and}\quad\|\partial_tU_c^\varepsilon\|_{H^2}\ll\|\partial_tU_{app}^\varepsilon\|_{H^2}.$$

Proof. We use the equation $\mathcal{E}_1=0$ from section 3 to obtain energy estimates. Since $\partial_t[a_c(t,y_2)e^{i(y_1+t/\varepsilon)}]=(\partial_ta_c+\frac{i}{\varepsilon}a_c)e^{i(y_1+t/\varepsilon)}$, we have to estimate $\|a_c\|_{H^s_Y}$ and $\|\partial_ta_c\|_{H^s_Y}$, $s=1,2$:

$$\frac{d}{dt}\|a_c\|_{H^1}\preceq\|\partial_t^2a_0\|_{H^1}+\||a_0|^4\partial_ta_0\|_{H^1}$$
$$+\Big(\|a_0\|_{L^\infty}^4+\|a_0\|_{L^\infty}^3\|\partial_Ya_0\|_{L^\infty}\Big)\|a_c\|_{H^1}, \tag{20}$$

$$\frac{d}{dt}\|\partial_ta_c\|_{H^1}\preceq\|\partial_t^3a_0\|_{H^1}+\||a_0|^3|\partial_ta_0|^2\|_{H^1}+\||a_0|^4\partial_t^2a_0\|_{H^1}$$
$$+\Big(\|a_0\|_{L^\infty}^3\|\partial_ta_0\|_{W^{1,\infty}}+\|a_0\|_{L^\infty}^2\|\partial_ta_0\|_{L^\infty}\|\partial_Ya_0\|_{L^\infty}\Big)\|a_c\|_{H^1}$$
$$+\Big(\|a_0\|_{L^\infty}^4+\|a_0\|_{L^\infty}^3\|\partial_Ya_0\|_{L^\infty}\Big)\|\partial_ta_c\|_{H^1}, \tag{21}$$

$$\frac{d}{dt}\|a_c\|_{H^2} \preceq \|\partial_t^2 a_0\|_{H^2} + \||a_0|^4\partial_t a_0\|_{H^2} + \Big(\|a_0\|_{L^\infty}^4 + \|a_0\|_{L^\infty}^3\|\partial_Y a_0\|_{L^\infty} + \|a_0\|_{L^\infty}^2\|\partial_Y a_0\|_{L^\infty}^2 + \|a_0\|_{L^\infty}^3\big\|\partial_Y^2 a_0\big\|_{L^\infty}\Big)\|a_c\|_{H^2}, \tag{22}$$

(23)
$$\begin{aligned}\frac{d}{dt}\|\partial_t a_c\|_{H^2} \preceq{}& \|\partial_t^3 a_0\|_{H^2} + \||a_0|^3|\partial_t a_0|^2\|_{H^2} + \||a_0|^4\partial_t^2 a_0\|_{H^2}\\ &+ \Big(\|a_0\|_{L^\infty}^3\|\partial_t a_0\|_{W^{1,\infty}} + \|a_0\|_{L^\infty}^2\|\partial_t a_0\|_{L^\infty}\|\partial_Y a_0\|_{L^\infty}\\ &\quad + \|a_0\|_{L^\infty}\|\partial_t a_0\|_{W^{1,\infty}}\|\partial_Y a_0\|_{L^\infty}^2 + \|a_0\|_{L^\infty}^2\|\partial_t a_0\|_{L^\infty}\big\|\partial_Y^2 a_0\big\|_{L^\infty}\\ &\quad + \|a_0\|_{L^\infty}^3\big\|\partial_t\partial_Y^2 a_0\big\|_{L^\infty}\Big)\|a_c\|_{H^2}\\ &+ \Big(\|a_0\|_{L^\infty}^4 + \|a_0\|_{L^\infty}^3\|\partial_Y a_0\|_{L^\infty} + \|a_0\|_{L^\infty}^2\|\partial_Y a_0\|_{L^\infty}^2\\ &\quad + \|a_0\|_{L^\infty}^3\big\|\partial_Y^2 a_0\big\|_{L^\infty}\Big)\|\partial_t a_c\|_{H^2}.\end{aligned}$$

Note that we can compute the exact value of the norm of a_0 from the formula (5):

$$\forall\alpha,\ \ \|(\partial_{t,Y})^\alpha a_0\|_{L^\infty} = C(t_\star - t)^{-1/2-|\alpha|},\ \ \|(\partial_{t,Y})^\alpha a_0\|_{L^2} = C(t_\star - t)^{-|\alpha|}. \tag{24}$$

Thus, from (20)–(24), Gronwall's lemma implies that there are $C > 0$, $\mu \in \mathbb{R}$ such that

$$\|a_c, \partial_t a_c\|_{H^2_Y} \preceq (t_\star - t)^\mu e^{C(t_\star - t)^{-3}}. \tag{25}$$

Now, simply check that out of the boundary layer $t_\star - t \le C(\ln 1/\varepsilon)^{-1/3}$ (with C big enough), we have

$$\begin{aligned}&\|\partial_t U_c^\varepsilon\|_{L^\infty} \preceq \varepsilon^2\|\partial_t a_c\|_{H^1} + \varepsilon\|a_c\|_{H^1} \ll \|\partial_t U_0^\varepsilon\|_{L^\infty} \sim (t_\star - t)^{-1/2},\\ &\|\partial_t\partial_y U_c^\varepsilon\|_{L^\infty} \preceq \varepsilon^2\|\partial_t a_c\|_{H^2} + \varepsilon\|a_c\|_{H^2} \ll \|\partial_t\partial_y U_0^\varepsilon\|_{L^\infty} \sim (t_\star - t)^{-3/2},\\ &\|\partial_t\partial_y U_c^\varepsilon\|_{L^2} \preceq \varepsilon^2\|\partial_t a_c\|_{H^1} + \varepsilon\|a_c\|_{H^1} \ll \|\partial_t\partial_y U_0^\varepsilon\|_{L^2} \sim (t_\star - t)^{-1}.\end{aligned}$$ □

5.4. Endgame: Proof of Theorem 5.1. We now take advantage of (19): in view of Proposition 5.2, when $t_\star - t \le C(\ln 1/\varepsilon)^{-1/3}$,

$$\|\partial_t V^\varepsilon\|_{L^\infty} \preceq e^{C\tilde J(t)}\int_0^t \|R^\varepsilon\|_{H^2}dt', \tag{26}$$

where $R^\varepsilon(x) = \mathcal{R}^\varepsilon(t, y_2)e^{i(y_1 + t/\varepsilon)}$ is given by section 3, and

$$\begin{aligned}\tilde J(t) &= \int_0^t \Big[\tilde I_4 + \tilde I_3\left(\|\partial_t\partial_y U_0^\varepsilon\|_{L^2} + \|\partial_t\partial_y U_0^\varepsilon\|_{L^\infty}\right)\Big]dt',\\ \tilde I_k &= \big\|\partial_t U_{app}^\varepsilon\big\|_{L^\infty}^k + \|\partial_t V^\varepsilon\|_{L^\infty}^k.\end{aligned}$$

Hence, (26) is a relation of the form $\varphi \le \psi e^{\varphi^4}$ for $\varphi(t) := C\|\partial_t V^\varepsilon\|_{L^\infty((0,t)\times\mathbb{R}^2)}$. Even if ψ is "small," this does not imply that φ is: on the contrary, it could be very large. But since here $\varphi_{|t=0} = 0$, continuity w.r.t. t forces that *as long as* (26) is

valid, φ has to be "small." Thus, for each $\varepsilon \in]0,1]$, we look for the maximal time $\underline{t}(\varepsilon) \in]0, t_\star - C(\ln 1/\varepsilon)^{-1/3}]$, until which

$$\|\partial_t V^\varepsilon\|_{L^\infty} \leq \|\partial_t U_0^\varepsilon\|_{L^\infty} \sim (t_\star - t)^{-1/2}, \tag{27}$$

and we replace $\tilde{I}_k$ by $\hat{I}_k := 2\,\|\partial_t U_0^\varepsilon\|_{L^\infty}^k$.

Since (from (24)) $\hat{I}_k(t) \sim (t_\star - t)^{-2}$,

$$\|\partial_t V^\varepsilon\|_{L^\infty} \leq \varepsilon^2 (t_\star - t)^\mu e^{C(t_\star - t)^{-2}}, \tag{28}$$

and the right-hand side is much smaller than $(t_\star - t)^{-1/2}$ as soon as $t_\star - t > C'(\ln 1/\varepsilon)^{-1/2}$, with C' sufficiently large. As ε goes to zero, $(\ln 1/\varepsilon)^{-1/2} \ll (\ln 1/\varepsilon)^{-1/3}$, so that the condition $t_\star - t > C(\ln 1/\varepsilon)^{-1/3}$ is the relevant one.

Furthermore, for each $\alpha > 0$, possibly increasing C, (28) shows that (27) is improved to $\|\partial_t V^\varepsilon\|_{L^\infty((0,t_\star - C(\ln 1/\varepsilon)^{-1/3})\times\mathbb{R}^2)} = o(\varepsilon^{2-\alpha})$.

SPARSE EVALUATION OF COMPOSITIONS OF FUNCTIONS USING MULTISCALE EXPANSIONS*

ALBERT COHEN†, WOLFGANG DAHMEN‡, AND RONALD DEVORE§

Abstract. This paper is concerned with the estimation and evaluation of wavelet coefficients of the *composition* $\mathcal{F}\circ u$ of two functions $\mathcal{F}$ and u from the wavelet coefficients of u. Our main objective is to show that certain sequence spaces that can be used to measure the sparsity of the arrays of wavelet coefficients are stable under a class of nonlinear mappings $\mathcal{F}$ that occur naturally, e.g., in nonlinear PDEs. We indicate how these results can be used to facilitate the sparse evaluation of arrays of wavelet coefficients of compositions at asymptotically optimal computational cost. Furthermore, the basic requirements are verified for several concrete choices of nonlinear mappings. These results are generalized to compositions by a multivariate map $\mathcal{F}$ of several functions $u_1,\dots,u_n$ and their derivatives, i.e., $\mathcal{F}(D^{\alpha_1}u_1,\dots,D^{\alpha_n}u_n)$.

Key words. nonlinear mappings, thresholding, tree structures, adaptive evaluation of nonlinear operators

1. Introduction.

This paper is concerned with the estimation and evaluation of the wavelet coefficients of a *composition* of two functions $\mathcal{F}$ and u, where u is given in terms of a wavelet expansion. Our interest in this subject stems from recent developments of *adaptive wavelet schemes* for the numerical solution of several types of initial or boundary value problems for PDEs. Such schemes typically rely on the sparsity of the wavelet representation of the solution allowing for data compression, as well as the ability to perform accurate numerical computations in the compressed representation. For initial value problems, *dynamically adaptive* schemes introduced in [20] require a reliable prediction of significant wavelet coefficients from the current state when progressing to the next time level. In the case of hyperbolic conservation laws, this question was first addressed in [19] and further discussed in [12]. Here one has to estimate the action of the nonlinear terms defining the convective fluxes on the current approximation in its multiscale representation. Another related example is the wavelet analysis of turbulent incompressible flows where such estimates are related to the energy transfer between different scales; see, e.g., [18] and [17]. For boundary value problems, adaptive wavelet schemes also require the tracking of the significant coefficients as the iterative solution process progresses; see, e.g., [1], [5], [9], and [10].

In all these examples, we are interested in the following general question: does composition with $\mathcal{F}$ preserve the *sparsity* of the wavelet coefficients of the function u? By the sparsity, we mean that only a quantifiable relatively small set of these

coefficients is needed to recover the underlying function (with accuracy measured in a given norm) to within some target accuracy. It is well known that sparsity of wavelet coefficients in this sense is closely related (in fact equivalent) to the *regularity* of the function with respect to certain scales of Besov spaces; see, e.g., [16]. Hence the above issue is closely connected with the question, how is the regularity of a given function u affected by the composition with some nonlinear function $\mathcal{F}$, or, more generally, given some regularity spaces $\mathcal{R}_i$, $i = 1, \ldots, m$, what is the image of $\prod_{i=1}^m \mathcal{R}_i$ under the mapping

$$(u_1(\cdot), \ldots, u_m(\cdot)) \to \mathcal{F}(\cdot, u_1(\cdot), \ldots, u_m(\cdot))?$$

This mapping is often referred to as a Nemytskij operator. The mapping properties of Nemytskij operators between Besov spaces were treated by several authors, and the reader is referred, e.g., to [3], [4], [22], and, for a detailed treatment, to the book by Runst and Sickel [21]. Sharp results are indeed available on the amount of smoothness which can be expected for $\mathcal{F}(u)$ given the smoothness of u, under fairly general assumptions on $\mathcal{F}$. Thus, in principle, in all cases covered by these results the sparsity of the wavelet coefficients of compositions can be predicted fairly well. However, these results tell us neither *which* coefficients of compositions $\mathcal{F}(u)$ are significant, based on knowledge about u, nor how to calculate them efficiently once they have been identified, which is a crucial issue in the perspective of numerical computations. The objective of the present paper is therefore also to develop concepts and tools for treating this latter problem.

Our paper is organized as follows. We present the problem formulation in section 2, which involves the wavelet discretization $\mathbf{F}$ of the mapping $\mathcal{F}$ as well as a notion of *tree structure* in the organization of wavelet coefficients. We prove in section 3 that this mapping preserves sparsity, under some general assumptions describing the stability and local action of $\mathbf{F}$ in the space-scale domain. We also present specific algorithms that construct sparse approximants with a prescribed accuracy ε at asymptotically optimal cost. This type of scheme is needed for the adaptive solution process of nonlinear operator equations; see [11]. We shall prove in section 4 the validity of the required assumptions for general local nonlinear mappings of subcritical type. Finally, the generalization of these results to compositions of the form $\mathcal{F}(D^{\alpha_1}u_1, \ldots, D^{\alpha_n}u_n)$ between a multivariate map $\mathcal{F}$ and the derivatives of several functions $u_1, \ldots, u_n$ is discussed in section 5.

2. Problem formulation.

2.1. Background and wavelet prerequisites. To explain the relevant features of the problem it suffices to describe the following (simple) example in a little more detail. Consider the nonlinear boundary value problem of the form

$$-\Delta u + \mathcal{F}(u) = f \ \text{ in } \ \Omega, \ \ u = 0 \ \text{ on } \ \partial\Omega, \tag{2.1}$$

where $\Omega \subset \mathbb{R}^d$ is some open bounded domain. The variational formulation of (2.1) in the space $H = H_0^1(\Omega)$ reads as follows: find $u \in H_0^1(\Omega)$ such that

$$\int_\Omega \nabla u \cdot \nabla v + \int_\Omega \mathcal{F}(u)v = \int_\Omega fv \tag{2.2}$$

for all $v \in H_0^1(\Omega)$. Here $H_0^1(\Omega)$ is the usual Sobolev space of distributions with first order weak derivatives in $L_2(\Omega)$ vanishing on the boundary $\partial\Omega$ in the sense of

traces. (Of course, other boundary conditions may also be considered.) For (2.2) to be meaningful $\mathcal{F}$ should map $H_0^1(\Omega)$ into its dual $H^{-1}(\Omega)$. This is perhaps the simplest instance of a variational problem inducing a bijective mapping from a Hilbert space H onto its dual H'.

For more general problems, H is a product of closed subspaces H^t of Sobolev spaces determined, e.g., by homogeneous boundary conditions on part of the domain boundary; see, e.g., [10] for examples. For simplicity we will confine the subsequent discussion to the case of a single model space $H = H^t$ for some $t > 0$.

2.2. Wavelet discretization. As already explained, we are motivated by adaptive numerical methods based on discretizing the variational formulation (2.2) in a wavelet basis $\Psi = \{\psi_\lambda : \lambda \in \mathcal{J}\}$. The indices λ encode scale, spatial location, and the type of the wavelet ψ_λ. We will denote by $|\lambda|$ the *scale* associated with ψ_λ. We shall consider only compactly supported wavelets, i.e., the supports of the wavelets scale, as follows:

$$S_\lambda := \operatorname{supp} \psi_\lambda, \quad c_0 2^{-|\lambda|} \le \operatorname{diam} S_\lambda \le C_0 2^{-|\lambda|}, \tag{2.3}$$

with $c_0, C_0 > 0$ absolute constants. The index set $\mathcal{J}$ has the following structure $\mathcal{J} = \mathcal{J}_\phi \cup \mathcal{J}_\psi$, where $\mathcal{J}_\phi$ is finite and indexes the scaling functions on a fixed coarsest level j_0. $\mathcal{J}_\psi$ indexes the "true wavelets" ψ_λ with $|\lambda| > j_0$. From compactness of the supports we know that at each level, the set $\mathcal{J}_j := \{\lambda \in \mathcal{J} : |\lambda| = j\}$ is finite. In fact, one has $\#\mathcal{J}_j \sim 2^{jd}$ with constants depending on the underlying bounded domain.

As already explained in the introduction, our evaluation algorithms will rely on a tree structure associated to the set of wavelet indices. In the simplest case of a one-dimensional basis $\psi_\lambda = \psi_{j,k} = 2^{j/2}\psi(2^j \cdot -k)$, this structure is obvious: each index (j,k) has two children $(j+1, 2k)$ and $(j+1, 2k+1)$. A similar tree structure can be associated to all available constructions of wavelet bases on a multidimensional domain: each index λ then has $m(\lambda) \ge 2$ children μ such that $|\mu| = |\lambda| + 1$, where $m(\lambda)$ might vary from one index to another but is uniformly bounded by some fixed K. We shall use the notation $\mu \prec \lambda$ in order to express that μ is a descendent of λ in the tree. Moreover, $\mu \preceq \lambda$ means that μ either is a descendent of λ or equals λ. We also have the property

$$\mu \prec \lambda \Rightarrow S_\mu \subset S_\lambda. \tag{2.4}$$

One key feature is that Ψ is a *Riesz basis* of the relevant space $H = H^t$. This means that every $v \in H$ has a unique expansion $v = \sum v_\lambda \psi_\lambda$ and that there exist some constants c, C independent of v such that

$$c\|(v_\lambda)_{\lambda\in\mathcal{J}}\| \le \left\| \sum_{\lambda\in\mathcal{J}} v_\lambda \psi_\lambda \right\|_H \le C\|(v_\lambda)_{\lambda\in\mathcal{J}}\|, \tag{2.5}$$

where $\|(v_\lambda)_{\lambda\in\mathcal{J}}\|^2 = \sum_{\lambda\in\mathcal{J}} |v_\lambda|^2$ denotes the $\ell_2(\mathcal{J})$-norm. In particular, the wavelets will always be assumed to be normalized in H, i.e., $\|\psi_\lambda\|_H = 1$. We abbreviate by

$$\mathbf{v} = (v_\lambda)_{\lambda\in\mathcal{J}}$$

the corresponding sequence of wavelet coefficients. Details on the construction of wavelet bases for Sobolev spaces of general domains can be found in [6], [7], [14].

Note that, by duality, (2.5) is equivalent to

$$C^{-1}\|(\langle w, \psi_\lambda\rangle)_{\lambda\in\mathcal{J}}\| \le \|w\|_{H'} \le c^{-1}\|(\langle w, \psi_\lambda\rangle)_{\lambda\in\mathcal{J}}\|, \quad w \in H', \tag{2.6}$$

where $\langle\cdot,\cdot\rangle$ denotes the duality pairing between H and H'. Clearly the quantities $\langle w,\psi_\lambda\rangle$ are the coordinates of $w\in H'$ with respect to the *dual* Riesz basis $\tilde\Psi$ to Ψ.

Since, as pointed out above, the nonlinearity $\mathcal{F}$ is supposed to map H into H' we shall therefore describe $w=\mathcal{F}(u)$ by its inner product sequence $\mathbf{w}=(w_\lambda)_{\lambda\in\mathcal{J}}$ with

$$w_\lambda=\langle w,\psi_\lambda\rangle,\quad \lambda\in\mathcal{J}. \tag{2.7}$$

We shall denote by $\mathbf{F}$ the corresponding *discrete* nonlinear map

$$\mathbf{u}\mapsto\mathbf{w}=\mathbf{F}(\mathbf{u})=(\langle\mathcal{F}(u),\psi_\lambda\rangle)_{\lambda\in\mathcal{J}}. \tag{2.8}$$

A key issue in the applications mentioned above can roughly be described as follows. Suppose that $u\in H$ can be approximated in the energy norm $\|\cdot\|_H$ within a tolerance ε by a linear combination of $N(\varepsilon,u)$ wavelets ψ_λ. What is the number $N(\varepsilon,\mathcal{F}(u))$ of dual wavelets needed to recover $\mathcal{F}(u)$ within tolerance ε? Note that, due to the *norm equivalences* (2.5) and (2.6), this can be restated as follows: Supposing that the wavelet coefficients $\mathbf{u}$ of $u\in H$ can be approximated in $\ell_2(\mathcal{J})$ with accuracy ε by a finitely supported vector involving only $N(\varepsilon,u)$ nonzero terms, how many entries of the sequence $\mathbf{F}(\mathbf{u})$ are needed to approximate $\mathbf{F}(\mathbf{u})$ in $\ell_2(\mathcal{J})$? Thus in the wavelet coordinate domain *all* approximations take place in $\ell_2(\mathcal{J})$. In brief, when does sparse approximability of $\mathbf{u}$ imply sparse approximability of $\mathbf{F}(\mathbf{u})$?

Questions of the above type are by now well understood for *linear* operators and their wavelet representations, as we shall now describe. In this context, the level of sparsity of $\mathbf{u}$ is measured by the *smallest* $\tau\le 2$ such that $\mathbf{u}\in\ell_\tau^w(\mathcal{J})$. Here $\ell_\tau^w(\mathcal{J})$ is the collection of all $\mathbf{u}\in\ell_2(\mathcal{J})$ which satisfy

$$\#\{\lambda\in\mathcal{J}:|u_\lambda|>\eta\}\le C\eta^{-\tau},\quad \eta>0. \tag{2.9}$$

In fact, $\ell_\tau^w(\mathcal{J})$ is a (quasi-)normed linear space endowed with the norm

$$\|\mathbf{u}\|_{\ell_\tau^w(\mathcal{J})}:=\sup_{\eta>0}\eta[\#\{\lambda\in\mathcal{J}:|u_\lambda|>\eta\}]^{1/\tau}. \tag{2.10}$$

An equivalent norm is given by the quantity

$$\sup_{n>0}n^{1/\tau}u_n^*, \tag{2.11}$$

where $(u_n^*)_{n>0}$ is a nonincreasing rearrangement of $(|u_\lambda|)_{\lambda\in\mathcal{J}}$. Note that if $\tau<2$, we have[1]

$$\|\mathbf{u}\|\ \lesssim\ \|\mathbf{u}\|_{\ell_\tau^w(\mathcal{J})}. \tag{2.12}$$

Moreover, defining the error of *best N-term approximation* in $\ell_2(\mathcal{J})$

$$\sigma_N(\mathbf{u}):=\inf_{\#\operatorname{supp}\mathbf{v}\le N}\|\mathbf{u}-\mathbf{v}\|=\left(\sum_{n>N}|u_n^*|^2\right)^{1/2}, \tag{2.13}$$

one has the following characterization [9].

[1]Here and later we use the notation $a\ \lesssim\ b$ if $a\le Cb$ with an absolute constant C independent of all parameters on which a,b depend.

PROPOSITION 2.1. *For* $\mathbf{u} \in \ell_2(\mathcal{J})$ *and* $s > 0$, *one has* $\sigma_N(\mathbf{u}) \lesssim N^{-s}$ *if and only if* $\mathbf{u} \in \ell^w_\tau(\mathcal{J})$ *with*

$$\frac{1}{\tau} = s + \frac{1}{2}. \tag{2.14}$$

Moreover,

$$\sigma_N(\mathbf{u}) \lesssim N^{-s}\|\mathbf{u}\|_{\ell^w_\tau(\mathcal{J})}. \tag{2.15}$$

Thus the smaller τ is, the fewer terms are needed to achieve a desired target accuracy for $\mathbf{u} \in \ell^w_\tau(\mathcal{J})$. In the case where $\mathbf{F}(\mathbf{u}) = \mathbf{A}\mathbf{u}$ is a linear operator bounded in $\ell_2(\mathcal{J})$, it is shown in [9] that this operator maps $\ell^w_\tau(\mathcal{J})$ into itself provided that it can be approximated by sparse matrices $\mathbf{A}_N$ with N entries per rows and columns at the rate $\|\mathbf{A} - \mathbf{A}_N\|_{\ell_2(\mathcal{J})} \lesssim N^{-r}$ for some $r > \frac{1}{\tau} - \frac{1}{2}$. Moreover, it is also shown how to practically build N-term approximations $\mathbf{w}_N$ of $\mathbf{w} = \mathbf{A}\mathbf{u}$, which fulfill the optimal rate $\|\mathbf{w}_N - \mathbf{w}\|_{\ell_2(\mathcal{J})} \lesssim N^{-s}$, from similar approximations of $\mathbf{u}$ at $\mathcal{O}(N)$ computational cost.

2.3. Tree structures and weak spaces. When dealing with nonlinear mappings, the following slight modification of these notions turns out to be appropriate. The approximants will be constrained by imposing a *tree structure* to the set of indices identifying the active coefficients. We shall say that a set $\mathcal{T} \subset \mathcal{J}$ is a *tree* if $\lambda \in \mathcal{T}$ implies $\mu \in \mathcal{T}$ whenever $\lambda \prec \mu$.

If the tree $\mathcal{T} \subset \mathcal{J}$ is finite, we define the set $\mathcal{L} = \mathcal{L}(\mathcal{T})$ of *outer leaves* as the set of those indices outside the tree such that their parent belongs to the tree

$$\mathcal{L} := \{\lambda \in \mathcal{J} : \lambda \notin \mathcal{T},\ \lambda \prec \mu \Longrightarrow\ \mu \in \mathcal{T}\}. \tag{2.16}$$

We shall make use of the following easily verifiable equivalence:

$$\#\mathcal{T} \sim \#\mathcal{L}, \tag{2.17}$$

where the constants depend only on K. Defining

$$\Gamma_\lambda := \{\mu \in \mathcal{J} : \mu \preceq \lambda\}, \tag{2.18}$$

the tree with root node λ, one easily verifies that

$$\mathcal{J} \setminus \mathcal{T} = \bigcup_{\lambda \in \mathcal{L}(\mathcal{T})} \Gamma_\lambda. \tag{2.19}$$

We are now interested in the approximation of $\mathbf{u}$ by an N-term approximation $\mathbf{v}$, where the support of $\mathbf{v}$ is assumed in addition to have a tree structure. A natural counterpart to classical best N-term approximation error, discussed in the previous section, is therefore given by redefining σ_N according to

$$\sigma_N(\mathbf{u}) := \inf\{\|u - v\| \ :\ \#(\mathrm{supp}(\mathbf{v})) \le N \ \text{ and } \ \mathrm{supp}(\mathbf{v}) \text{ is a tree}\}. \tag{2.20}$$

We define $\mathcal{A}^s$ as the class of vectors $\mathbf{u}$ such that

$$\sigma_N(\mathbf{u}) \lesssim N^{-s} \tag{2.21}$$

and the corresponding quasi norm

$$\|\mathbf{u}\|_{\mathcal{A}^s} := \sup_{N>0} N^s \sigma_N(\mathbf{u}). \tag{2.22}$$

In contrast to best N-term approximation, the practical determination of a best N-term tree approximant is not a simple task. In particular, when $\mathbf{u}$ is a finite vector, the main difficulty is to build such an approximation without searching through all possible subtrees, which would result in exponential complexity in N. In [2], two algorithms have been proposed which construct near best trees in linear time, based on the evaluation of the local residuals

$$\tilde{u}_\lambda := \left(\sum_{\mu \in \Gamma_\lambda} |u_\mu|^2 \right)^{1/2}. \tag{2.23}$$

Note that

$$\|\mathbf{u} - \mathbf{u}|_{\mathcal{T}}\|^2 = \sum_{\lambda \in \mathcal{L}(\mathcal{T})} \tilde{u}_\lambda^2. \tag{2.24}$$

More precisely, given a tolerance ε, the algorithms proposed in [2] allow us to build a tree $\mathcal{T} = \mathcal{T}(\varepsilon, \mathbf{u})$ such that

$$\|\mathbf{u} - \mathbf{u}|_{\mathcal{T}}\| \le \varepsilon \tag{2.25}$$

with the following property: whenever a tree $\tilde{\mathcal{T}}$ satisfies $\|\mathbf{u} - \mathbf{u}|_{\tilde{\mathcal{T}}}\| \le c\varepsilon$, then $\#(\mathcal{T}) \le C\#(\tilde{\mathcal{T}})$, where c, C are fixed constants independent of $\mathbf{u}$ and ε.

A simpler alternative to building tree approximants is to perform thresholding on the residual sequence $\tilde{u}_\lambda$. Indeed, one readily verifies that $\mu \preceq \lambda$ implies $\tilde{u}_\lambda \ge \tilde{u}_\mu$, i.e., for any $\eta > 0$ the set

$$\mathcal{T}_\eta = \mathcal{T}_\eta(\mathbf{u}) := \{\lambda \,:\, |\tilde{u}_\lambda| > \eta\} \tag{2.26}$$

has tree structure. Thus, thresholding with respect to the modified sequences $\tilde{\mathbf{u}}$ creates trees. This motivates us to define

$${}_t\ell^w_\tau(\mathcal{J}) := \{\mathbf{u} \in \ell_2(\mathcal{J}) : \tilde{\mathbf{u}} \in \ell^w_\tau(\mathcal{J})\}, \quad \|\mathbf{u}\|_{{}_t\ell^w_\tau(\mathcal{J})} := \|\tilde{\mathbf{u}}\|_{\ell^w_\tau(\mathcal{J})}. \tag{2.27}$$

Clearly, we have $\|\mathbf{u}\|_{\ell^w_\tau(\mathcal{J})} \le \|\mathbf{u}\|_{{}_t\ell^w_\tau(\mathcal{J})}$ and

$$\#\mathcal{T}_\eta(\mathbf{u}) \le \eta^{-\tau} \|\mathbf{u}\|^\tau_{{}_t\ell^w_\tau(\mathcal{J})}. \tag{2.28}$$

Therefore, the spaces ${}_t\ell^w_\tau(\mathcal{J})$ can also be used to quantify the sparseness of sequences subject to the tree structure constraint. In fact, one has the following counterpart to Proposition 2.1.

PROPOSITION 2.2. *Let* $\mathbf{u}_\eta := \mathbf{u}|_{\mathcal{T}_\eta}$. *Then* $\mathbf{u} \in {}_t\ell^w_\tau(\mathcal{J})$ *implies the error estimate*

$$\|\mathbf{u} - \mathbf{u}_\eta\| \lesssim \eta^{1-\tau/2} \|\mathbf{u}\|^{\tau/2}_{{}_t\ell^w_\tau(\mathcal{J})} \lesssim [\#(\mathcal{T}_\eta)]^{-s} \|\mathbf{u}\|_{{}_t\ell^w_\tau(\mathcal{J})}, \tag{2.29}$$

with $s = 1/\tau - 1/2$. *Therefore* ${}_t\ell^w_\tau(\mathcal{J})$ *is contained in* $\mathcal{A}^s$.

Proof. Let $\mathcal{L}_\eta := \mathcal{L}(\mathcal{T}_\eta)$ denote the set of outer leaves of the tree $\mathcal{T}_\eta$. By (2.19), (2.24) and using (2.28), one has

$$\begin{aligned} \|\mathbf{u} - \mathbf{u}_\eta\|^2 &= \sum_{\lambda \notin \mathcal{T}_\eta} |u_\lambda|^2 = \sum_{\lambda \in \mathcal{L}_\eta} \tilde{u}_\lambda^2 \le \#\mathcal{L}_\eta \eta^2 \\ &\lesssim \#\mathcal{T}_\eta \eta^2 \le \|\mathbf{u}\|^\tau_{{}_t\ell^w_\tau(\mathcal{J})} \eta^{2-\tau}, \end{aligned} \tag{2.30}$$

where we have used (2.17). This confirms the first estimate in (2.29). Since again by definitions (2.27) and (2.28), $\eta \le \|\mathbf{u}\|_{{}_t\ell^w_\tau(\mathcal{J})}(\#\mathcal{T}_\eta)^{-1/\tau}$, the second estimate follows from (2.30). ∎

Note, however, that in the above proposition, we do not have a converse result which would state that the decay property $\|\mathbf{u}-\mathbf{u}_\eta\| \lesssim [\#(\mathcal{T}_\eta)]^{-s}$ implies that $\mathbf{u}$ is in ${}_t\ell^w_\tau(\mathcal{J})$. In particular ${}_t\ell^w_\tau(\mathcal{J})$ is strictly contained in $\mathcal{A}^s$.

Of course, the question arises which property of u implies that the array of wavelet coefficients $\mathbf{u}$ belongs to ${}_t\ell^w_\tau(\mathcal{J})$ and in turn to $\mathcal{A}^s$.

Remark 2.3. Let $H = H^t$. Then $u \in B^{t+sd}_q(L_{\tau'})$ implies $\mathbf{u} \in {}_t\ell^w_\tau(\mathcal{J})$ whenever $\frac{1}{\tau'} < \frac{1}{\tau} = s + \frac{1}{2}$ and $0 < q \le \infty$.

Sketch of proof. It is enough to prove this for $B^{t+sd}_\infty(L_{\tau'})$ and $\tau < \tau' \le 2$, because the remaining cases follow by embeddings. The condition $u \in B^{t+sd}_\infty(L_{\tau'})$ says that the H^t-normalized wavelet coefficients u_λ of u satisfy

$$\left(\sum_{|\lambda|=j} |u_\lambda|^{\tau'}\right)^{1/\tau'} \lesssim 2^{-jd\delta},$$

where $\delta := s + \frac{1}{2} - \frac{1}{\tau'} > 0$ is the discrepancy measuring the "distance" of $B^{t+sd}_\infty(L_{\tau'})$ from the critical embedding line. From this one derives also that $(\sum_{|\lambda|=j} |\tilde{u}_\lambda|^{\tau'})^{1/\tau'} \lesssim 2^{-jd\delta}$, $j \in \mathbb{N}$. This, in turn, implies that the function $\tilde{u}$ with wavelet coefficients $\tilde{\mathbf{u}}$ belongs to $B^{t+sd}_\infty(L_{\tau'})$. By Corollary 4.2 in [8], the best N-term approximation of $\tilde{u}$ in H^t has order N^{-s}. Therefore, by Proposition 2.1, $\tilde{\mathbf{u}} \in \ell^w_\tau(\mathcal{J})$, which, by (2.27) means that $\mathbf{u} \in {}_t\ell^w_\tau(\mathcal{J})$ as claimed. ∎

We therefore have at our disposal two distinct notions of tree approximation rates expressed by the spaces $\mathcal{A}^s$ and ${}_t\ell^w_\tau(\mathcal{J})$. We can now restate the above questions in the following way:

- Does $\mathbf{F}$ map a sequence $\mathbf{u} \in \mathcal{X}$ into a sequence $\mathbf{w} = \mathbf{F}(\mathbf{u}) \in \mathcal{X}$ for $\mathcal{X} = \mathcal{A}^s$ or ${}_t\ell^w_\tau(\mathcal{J})$?
- Can we compute asymptotically optimal sparse approximations of $\mathbf{w} = \mathbf{F}(\mathbf{u})$ from asymptotically optimal sparse approximations of $\mathbf{u}$ in one of the two senses above?

Note that a positive answer to the second question gives a positive answer to the first question in a constructive way. Our next section will give precise answers to these questions for both $\mathcal{A}^s$ and ${}_t\ell^w_\tau(\mathcal{J})$.

3. Sparsity preserving discrete operators.

3.1. General assumptions. We shall use two general assumptions on the function $\mathbf{F}$. The first assumption expresses the fact that $\mathcal{F}$ is a *stable transformation* from H to H'.

Assumption 1. $\mathbf{F}$ is a Lipschitz map from ℓ_2 into itself. More precisely, we assume that we have

$$\|\mathbf{F}(\mathbf{u}) - \mathbf{F}(\mathbf{v})\| \le C\|\mathbf{u}-\mathbf{v}\|, \quad \text{with } C = C(\sup\{\|\mathbf{u}\|, \|\mathbf{v}\|\}), \tag{3.1}$$

where $x \mapsto C(x)$ is a positive nondecreasing function.

The fact that the constant C might grow with the norm of $\mathbf{u}$ and $\mathbf{v}$ accounts for the nonlinearity of the transformation. In the context of solving operator equations of the type (2.1), the norms of the arguments of $\mathbf{F}$ will remain bounded (by the $\|\cdot\|_H$-norm of the solution up to the achieved precision) so we can think of C as a constant.

We shall actually use a local version of this stability assumption which will be a direct consequence of (3.1) whenever the nonlinear function $\mathcal{F}$ is local in the physical space: if D is a subdomain of Ω, we have

$$\|(\mathbf{F}(\mathbf{u}) - \mathbf{F}(\mathbf{v}))|_{\{\lambda : S_\lambda \subset D\}}\| \leq C\|(\mathbf{u} - \mathbf{v})|_{\{\lambda : S_\lambda \cap D \neq \emptyset\}}\|, \tag{3.2}$$

with C depending on $\|\mathbf{u}\|$ and $\|\mathbf{v}\|$ as for the global estimate.

The second assumption describes the *local action of* $\mathbf{F}$ in the space-scale domain of wavelet coefficients.

Assumption 2. If $\mathbf{w} = \mathbf{F}(\mathbf{u})$ for a finitely supported $\mathbf{u}$, we have the estimate

$$|w_\lambda| \leq C \sup_{\mu\,:\,S_\mu \cap S_\lambda \neq \emptyset} |u_\mu| 2^{-\gamma(|\lambda| - |\mu|)} \ \text{ with } \ C = C(\|\mathbf{u}\|) \tag{3.3}$$

for all $\lambda \in \mathcal{J}_\psi$, where $\gamma > d/2$ and $x \mapsto C(x)$ is a positive nondecreasing function.

A typical value of γ is

$$\gamma := r + t + d/2, \tag{3.4}$$

where r reflects the smoothness and order of vanishing moments of the wavelets, i.e., $\psi_\lambda \in C^r$ and $\int_\Omega x^m \psi_\lambda(x) dx = 0$ for $|m| = m_1 + \cdots + m_d < r$. We shall see in the next section that all these assumptions are fulfilled for a fairly general class of local composition operators.

3.2. Tree expansions. Given a tree $\mathcal{T}$, we shall make use of the following expansion process. Given any $\lambda \in \mathcal{J}$, we define $\Phi_0(\lambda) = \{\lambda\}$. If $\Phi_{k-1}(\lambda)$ has already been defined, then we define $\Phi_k(\lambda)$ as the set of all μ, $|\mu| = |\lambda| - k$ such that $S_\mu \cap S_{\mu'} \neq \emptyset$ for some $\mu' \in \Phi_{k-1}(\lambda)$. We define $\Phi(\lambda) := \cup_{k=0}^{|\lambda|} \Phi_k(\lambda)$. We then define the expansion $\tilde{\mathcal{T}}$ as

$$\tilde{\mathcal{T}} := \cup_{\lambda \in \mathcal{T}} \Phi(\lambda). \tag{3.5}$$

Let us note that by construction $\tilde{\mathcal{T}}$ has the following property.

Expansion Property. *If $\mu \in \tilde{\mathcal{T}}$ and $\mu' \in \mathcal{J}$, then*

$$\left.\begin{array}{c} |\mu'| < |\mu| \\ S_{\mu'} \cap S_\mu \neq \emptyset \end{array}\right\} \implies \mu' \in \tilde{\mathcal{T}}. \tag{3.6}$$

The following lemma (see, e.g., [13], [15]) shows that $\tilde{\mathcal{T}}$ has size comparable to $\mathcal{T}$ and that the supports S_λ associated to the outer leaves $\mathcal{L}(\tilde{\mathcal{T}})$ do not overlap too much, a property that we shall use when dealing with the space ${}_t\ell_\tau^w(\mathcal{J})$.

Lemma 3.1. *There exist constants C_1 and C_2 such that for any finite tree $\mathcal{T}$, we have the following.*

(i) $\#(\tilde{\mathcal{T}}) \leq C_1 \#(\mathcal{T})$.

(ii) *For all $\lambda \in \mathcal{L}(\tilde{\mathcal{T}})$ there exist at most C_2 indices $\mu \in \mathcal{L}(\tilde{\mathcal{T}})$ such that $S_\mu \cap S_\lambda \neq \emptyset$.*

Proof. We show first the existence of the constant C_1. To this end, it suffices to show that for each $\mu \in \tilde{\mathcal{T}}$ there exists a *reference element* $\lambda \in \mathcal{T}$ such that $|\lambda| = |\mu|$ and $\operatorname{dist}(S_\lambda, S_\mu) \leq C_0 2^{-|\mu|}$, with C_0 the constant of (2.3). Now any $\mu \in \tilde{\mathcal{T}}$ is in $\Phi_k(\lambda')$ for some $\lambda' \in \mathcal{T}$. We prove by induction on k that there is such a reference

element. For $k = 0$, $\mu = \lambda'$ so we can take $\lambda = \lambda'$. Suppose that we have proven the existence of such a reference element for all $\mu' \in \Phi_{k-1}(\lambda')$ and let μ be an index that has been added in the construction of $\Phi_k(\lambda')$. By the definition of $\Phi_k(\lambda')$ there is a $\mu' \in \Phi_{k-1}(\lambda')$ such that $S_\mu \cap S_{\mu'} \neq \emptyset$. By our induction assumption, there is a reference element $\bar{\lambda} \in \mathcal{T}$, with $|\bar{\lambda}| = |\mu'|$, such that $\operatorname{dist}(S_{\mu'}, S_{\bar{\lambda}}) \leq C_0 2^{-|\mu'|}$. It follows that

$$\operatorname{dist}(S_\mu, S_{\bar{\lambda}}) \leq C_0 2^{-|\mu'|} + \operatorname{diam}(S_{\mu'}) \leq C_0 2^{-|\mu'|} + C_0 2^{-|\mu'|} = C_0 2^{-|\mu|}.$$

Hence, we can take the parent $\lambda \in \mathcal{T}$ of $\bar{\lambda}$ as our reference element for μ.

To confirm the existence of C_2, note that when $\nu, \mu \in \mathcal{L}(\tilde{\mathcal{T}})$ and $S_\nu \cap S_\mu \neq \emptyset$, then $||\nu| - |\mu|| \leq 1$. In fact, suppose that $|\nu| < |\mu| - 1$. Then, for the parent μ' of μ we have $S_\nu \cap S_{\mu'} \neq \emptyset$, since $S_\mu \subset S_{\mu'}$ according to (2.4). Since $\mu' \in \tilde{\mathcal{T}}$ and $|\mu'| > |\nu|$ we conclude $\nu \in \tilde{\mathcal{T}}$, which is a contradiction. This completes the proof. ∎

3.3. The main result in the $\mathcal{A}^s$ case. We first consider the questions raised at the end of the previous section in the $\mathcal{A}^s$ case. Given a tolerance ε we wish to construct a near best tree for approximating $\mathbf{F}(\mathbf{u})$ with accuracy ε, based on the knowledge of $\mathbf{u}$. To this end, suppose that $\mathcal{T}(\varepsilon, \mathbf{u})$ is the near best tree obtained by one of the algorithms in [2] and which satisfies (2.25). For $j = 0, 1, \ldots$, we define

$$\mathcal{T}_j := \mathcal{T}\left(\frac{2^j \varepsilon}{1+j}, \mathbf{u}\right), \tag{3.7}$$

and the corresponding expanded trees $\tilde{\mathcal{T}}_j$ according to the above procedure. By construction these trees are nested in the sense that $\tilde{\mathcal{T}}_j \subset \tilde{\mathcal{T}}_{j-1}$. We define the difference sets

$$\Delta_j := \tilde{\mathcal{T}}_j \setminus \tilde{\mathcal{T}}_{j+1}. \tag{3.8}$$

In order to build a tree which will be adapted to $\mathbf{w} = \mathbf{F}(\mathbf{u})$, we introduce

$$\alpha := \frac{2}{2\gamma - d} > 0, \tag{3.9}$$

where γ is the constant in (3.3), and for each $\mu \in \Delta_j$, we define the *influence set*

$$\Lambda_{\varepsilon,\mu} := \{\lambda \,:\, S_\lambda \cap S_\mu \neq \emptyset \text{ and } |\lambda| \leq |\mu| + \alpha j\}. \tag{3.10}$$

We then define $\mathcal{T}$ by

$$\mathcal{T} := \mathcal{J}_\phi \cup \left(\cup_{\mu \in \tilde{\mathcal{T}}_0} \Lambda_{\varepsilon,\mu}\right). \tag{3.11}$$

We notice that by construction $\mathcal{T}$ has the structure of an expanded tree. Note that an equivalent way of defining $\mathcal{T}$ would be

$$\mathcal{T} := \mathcal{J}_\phi \cup \tilde{\mathcal{T}}_0 \cup \left(\cup_{\mu \in \tilde{\mathcal{T}}_0} \tilde{\Lambda}_{\varepsilon,\mu}\right), \tag{3.12}$$

with

$$\tilde{\Lambda}_{\varepsilon,\mu} := \{\lambda \,:\, S_\lambda \cap S_\mu \neq \emptyset \text{ and } |\mu| \leq |\lambda| \leq |\mu| + \alpha j\}. \tag{3.13}$$

THEOREM 3.2. *Given any* $\mathbf{u}$ *and* $\mathcal{T}$ *defined by* (3.11)*, we have the error estimate*

$$\|\mathbf{F}(\mathbf{u}) - \mathbf{F}(\mathbf{u})|_{\mathcal{T}}\| \lesssim \varepsilon. \tag{3.14}$$

Moreover, if $\mathbf{u} \in \mathcal{A}^s$ *for* $0 < s < \frac{2\gamma - d}{2d}$*, we have the estimate*

$$\#(\mathcal{T}) \lesssim \|\mathbf{u}\|_{\mathcal{A}^s}^{1/s} \varepsilon^{-1/s} + \#(\mathcal{J}_\phi). \tag{3.15}$$

We therefore have $\mathbf{F}(\mathbf{u}) \in \mathcal{A}^s$ *and*

$$\|\mathbf{F}(\mathbf{u})\|_{\mathcal{A}^s} \lesssim 1 + \|\mathbf{u}\|_{\mathcal{A}^s}. \tag{3.16}$$

The constants in these above inequalities depend only on $\|\mathbf{u}\|$*, the space dimension* d*, and the parameter* s*.*

Proof. In order to prove (3.14), we first notice that according to Assumption 1, we have

$$\|\mathbf{F}(\mathbf{u}) - \mathbf{F}(\mathbf{u}|_{\tilde{\mathcal{T}}_0})\| \lesssim \varepsilon, \tag{3.17}$$

with a constant depending on $\|\mathbf{u}\|$. Since one therefore has the trivial estimate $\|(\mathbf{F}(\mathbf{u}) - \mathbf{F}(\mathbf{u}|_{\tilde{\mathcal{T}}_0})|_{\mathcal{T}}\| \lesssim \varepsilon$, it suffices to show that $\|\mathbf{w}_\varepsilon - \mathbf{w}_\varepsilon|_{\mathcal{T}}\| \lesssim \varepsilon$, where $\mathbf{w}_\varepsilon := \mathbf{F}(\mathbf{u}|_{\tilde{\mathcal{T}}_0}) = (w_{\varepsilon,\lambda})$. We then remark that Assumption 2 implies the cruder estimate

$$|w_{\varepsilon,\lambda}|^2 \lesssim \sum_{\mu \in \tilde{\mathcal{T}}_0, S_\mu \cap S_\lambda \neq \emptyset} |u_\mu|^2 2^{-2\gamma(|\lambda| - |\mu|)}, \tag{3.18}$$

and for $\lambda \notin \mathcal{T}$ and $\mu \in \Delta_j$ such that $S_\mu \cap S_\lambda \neq \emptyset$, we always have $|\lambda| - |\mu| \geq \alpha j$. Finally we notice that by definition

$$\sum_{\mu \in \Delta_j} |u_\mu|^2 = \|\mathbf{u}|_{\tilde{\mathcal{T}}_j} - \mathbf{u}|_{\tilde{\mathcal{T}}_{j+1}}\|^2 \lesssim \frac{2^{2j}\varepsilon^2}{(1+j)^2}. \tag{3.19}$$

Combining these facts, we obtain

$$\begin{aligned}
\|\mathbf{w}_\varepsilon - \mathbf{w}_\varepsilon|_{\mathcal{T}}\|^2 &= \sum_{\lambda \notin \mathcal{T}} |w_{\varepsilon,\lambda}|^2 \lesssim \sum_{\lambda \notin \mathcal{T}} \sum_{\mu \in \tilde{\mathcal{T}}_0, S_\mu \cap S_\lambda \neq \emptyset} |u_\mu|^2 2^{-2\gamma(|\lambda| - |\mu|)} \\
&= \sum_{\mu \in \tilde{\mathcal{T}}_0} |u_\mu|^2 \sum_{\lambda \notin \mathcal{T}, S_\mu \cap S_\lambda \neq \emptyset} 2^{-2\gamma(|\lambda| - |\mu|)} \\
&= \sum_{j \geq 0} \sum_{\mu \in \Delta_j} |u_\mu|^2 \sum_{\lambda \notin \mathcal{T}, S_\mu \cap S_\lambda \neq \emptyset} 2^{-2\gamma(|\lambda| - |\mu|)} \\
&\lesssim \sum_{j \geq 0} \sum_{\mu \in \Delta_j} |u_\mu|^2 \sum_{k \geq 0} 2^{(d-2\gamma)(\alpha j + k)} \lesssim \sum_{j \geq 0} 2^{(d-2\gamma)\alpha j} \sum_{\mu \in \Delta_j} |u_\mu|^2 \\
&\lesssim \sum_{j \geq 0} 2^{(d-2\gamma)\alpha j} \frac{2^{2j}\varepsilon^2}{(1+j)^2} = \sum_{j \geq 0} \frac{\varepsilon^2}{(1+j)^2} \lesssim \varepsilon^2.
\end{aligned}$$

In order to prove (3.15), we notice that according to (3.12), for each $\mu \in \Delta_j$, we add at most $C 2^{\alpha j d}$ indices to $\mathcal{J}_\phi \cup \tilde{\mathcal{T}}_0$ in the construction of $\mathcal{T}$. Therefore, we have

$$\#(\mathcal{T}) \leq \#(\mathcal{J}_\phi) + \#(\tilde{\mathcal{T}}_0) + C \sum_{j \geq 0} 2^{\alpha j d} \#(\Delta j)$$

$$\lesssim \#(\mathcal{J}_\phi) + \|\mathbf{u}\|_{\mathcal{A}^s}^{1/s}\varepsilon^{-1/s}\left(1+\sum_{j\geq 0}2^{(\alpha d-1/s)j}(1+j)^{1/s}\right)$$
$$\lesssim \#(\mathcal{J}_\phi) + \|\mathbf{u}\|_{\mathcal{A}^s}^{1/s}\varepsilon^{-1/s},$$

where we have used the fact that $\alpha d - 1/s < 0$, which is equivalent to the restriction $s < \frac{2\gamma-d}{2d}$. The estimate (3.16) is then a direct consequence of (3.15). ∎

Note that since we have used Assumptions 1 and 2 in the above proof, the constants in both estimates (3.15) and (3.16) are of the form $C(\|\mathbf{u}\|)$, where $x \mapsto C(x)$ is a positive nondecreasing function.

3.4. The main result in the ${}_t\ell^w_\tau(\mathcal{J})$ case. In order to deal with the ${}_t\ell^w_\tau(\mathcal{J})$ case, we shall build the tree for $\mathbf{F}(\mathbf{u})$ in a slightly different way. To this end, we fix $\eta > 0$ and we define the tree $\mathcal{T}_\eta$ obtained by thresholding the local residuals $\tilde{u}_\lambda$ at level η according to (2.26) and its expanded version $\tilde{\mathcal{T}}_\eta$.

Then for all $\mu \in \tilde{\mathcal{T}}_\eta$, we define the number $n(\mu)$ satisfying

$$\eta 2^{\gamma n(\mu)} \leq |u_\mu| < \eta 2^{\gamma(n(\mu)+1)}. \tag{3.20}$$

We then define the *influence set*

$$\Lambda_{\eta,\mu} := \{\lambda \,:\, S_\lambda \cap S_\mu \neq \emptyset \text{ and } |\lambda| \leq |\mu| + [n(\mu)]_+\} \tag{3.21}$$

and a tree for the approximation of $\mathbf{F}(\mathbf{u})$ by

$$\mathcal{T} := \mathcal{J}_\phi \cup \left(\cup_{\mu\in\tilde{\mathcal{T}}_\eta}\Lambda_{\eta,\mu}\right). \tag{3.22}$$

We notice that by construction $\mathcal{T}$ has the structure of an expanded tree. Note that an equivalent way of defining $\mathcal{T}$ would be

$$\mathcal{T} := \mathcal{J}_\phi \cup \tilde{\mathcal{T}}_\eta \cup \left(\cup_{\mu\in\tilde{\mathcal{T}}_\eta}\tilde{\Lambda}_{\eta,\mu}\right), \tag{3.23}$$

with

$$\tilde{\Lambda}_{\eta,\mu} := \{\lambda \,:\, S_\lambda \cap S_\mu \neq \emptyset \text{ and } |\mu| \leq |\lambda| \leq |\mu| + [n(\mu)]_+\}. \tag{3.24}$$

THEOREM 3.3. *Given any $\mathbf{u} \in \ell_2(\mathcal{J})$ and $\mathcal{T}$ defined by* (3.23)*, one has the coefficient size estimate*

$$|\tilde{w}_\lambda| \lesssim \eta \text{ if } \lambda \notin \mathcal{T}, \tag{3.25}$$

where the $\tilde{w}_\lambda$ are defined for $\mathbf{w} = \mathbf{F}(\mathbf{u})$ according to (2.23)*. If in addition $\mathbf{u} \in {}_t\ell^w_\tau(\mathcal{J})$ for some $d/\gamma < \tau < 2$, then we have the cardinality estimate*

$$\#(\mathcal{T}) \lesssim \|\mathbf{u}\|^\tau_{{}_t\ell^w_\tau(\mathcal{J})}\eta^{-\tau} + \#(\mathcal{J}_\phi). \tag{3.26}$$

Moreover, we have $\mathbf{F}(\mathbf{u}) \in {}_t\ell^w_\tau(\mathcal{J})$ and

$$\|\mathbf{F}(\mathbf{u})\|_{{}_t\ell^w_\tau(\mathcal{J})} \lesssim 1 + \|\mathbf{u}\|_{{}_t\ell^w_\tau(\mathcal{J})}. \tag{3.27}$$

The constants in these above inequalities depend only on $\|\mathbf{u}\|$, the space dimension d, and the parameter τ in the case of (3.26)*.*

Proof. In order to prove (3.25), we first consider the restricted vector $\mathbf{u}_\eta = \mathbf{u}|_{\tilde{\mathcal{T}}_\eta}$ and its image $\mathbf{w}_\eta := \mathbf{F}(\mathbf{u}_\eta) = (w_{\lambda,\eta})$. For $\lambda \notin \mathcal{T}$ and for all $\mu \in \tilde{\mathcal{T}}_\eta$ such that $S_\mu \cap S_\lambda \neq \emptyset$, we have by (3.21) the inequality $|\lambda| - |\mu| \geq [n(\mu)]_+$. Therefore, remarking that $\lambda \in \mathcal{J}_\psi$, the local action assumption (3.3) implies

$$|w_{\lambda,\eta}| \lesssim \eta. \tag{3.28}$$

Moreover, if ν is such that $S_\nu \cap S_\lambda \neq \emptyset$ and $|\nu| = |\lambda| + l$, we also have $|\nu| - |\mu| \geq [n(\mu)]_+ + l$ and therefore, for each $\mu \in \tilde{\mathcal{T}}_\eta$, the better estimate

$$|w_{\nu,\eta}| \lesssim 2^{-\gamma l}\eta. \tag{3.29}$$

It follows that

$$|\tilde{w}_{\lambda,\eta}|^2 \lesssim \eta^2 \left(\sum_{l \geq 0} 2^{(d-2\gamma)l} \right) \lesssim \eta^2, \tag{3.30}$$

since by assumption $\gamma > d/2$.

Next, we remark that for $\lambda \in \mathcal{L}(\mathcal{T})$, we have

$$\begin{aligned} \left| |\tilde{w}_{\lambda,\eta}|^2 - |\tilde{w}_\lambda|^2 \right| &\leq (|\tilde{w}_{\lambda,\eta}| + |\tilde{w}_\lambda|)|\tilde{w}_{\lambda,\eta} - \tilde{w}_\lambda| \\ &\leq (2|\tilde{w}_{\lambda,\eta}| + |\tilde{w}_{\lambda,\eta} - \tilde{w}_\lambda|)|\tilde{w}_{\lambda,\eta} - \tilde{w}_\lambda| \\ &\lesssim (\eta + \|(\mathbf{w} - \mathbf{w}_\eta)|_{\Gamma_\lambda}\|)\|(\mathbf{w} - \mathbf{w}_\eta)|_{\Gamma_\lambda}\|. \end{aligned} \tag{3.31}$$

Now observe that, according to (3.2),

$$\begin{aligned} \|(\mathbf{w} - \mathbf{w}_\eta)|_{\Gamma_\lambda}\| &= \|(\mathbf{w} - \mathbf{w}_\eta)|_{\{\mu : S_\mu \subseteq S_\lambda\}}\| \\ &\lesssim \|(\mathbf{u} - \mathbf{u}_\eta)|_{\{\mu : S_\mu \cap S_\lambda \neq \emptyset\}}\| \\ &= \left(\sum_{\mu \notin \tilde{\mathcal{T}}_\eta, S_\mu \cap S_\lambda \neq \emptyset} |u_\mu|^2 \right)^{1/2} \\ &\leq \left(\sum_{\mu \in \mathcal{L}(\tilde{\mathcal{T}}_\eta), S_\mu \cap S_\lambda \neq \emptyset} |\tilde{u}_\mu|^2 \right)^{1/2} \lesssim \eta, \end{aligned}$$

where the last inequality involves the constant C_2 from Lemma 3.1. Combining this with (3.30) and (3.31), we obtain the size estimate (3.25).

To prove (3.26) we define the trees

$$\tilde{\mathcal{T}}_j := \tilde{\mathcal{T}}_{\eta 2^{\gamma j}}. \tag{3.32}$$

From (2.28) and Lemma 3.1, we infer that $\mathbf{u} \in {}_t\ell^w_\tau(\mathcal{J})$ implies

$$\#(\tilde{\mathcal{T}}_j) \lesssim \eta^{-\tau} 2^{-\gamma\tau j} \|\mathbf{u}\|^\tau_{{}_t\ell^w_\tau(\mathcal{J})}. \tag{3.33}$$

Writing

$$\tilde{\Lambda}_\eta = \bigcup_{j \geq 0} \bigcup_{\mu \in \tilde{\mathcal{T}}_j \setminus \tilde{\mathcal{T}}_{j+1}} \Lambda_{\eta,\mu}, \tag{3.34}$$

so that

$$\bigcup_{\mu\in\tilde{\mathcal{T}}_j\setminus\tilde{\mathcal{T}}_{j+1}}\Lambda_{\eta,\mu}\subseteq\tilde{\mathcal{T}}_j\cup\bigcup_{\mu\in\tilde{\mathcal{T}}_j\setminus\tilde{\mathcal{T}}_{j+1}}\{\lambda:S_\lambda\cap S_\mu\neq\emptyset,\ |\mu|<|\lambda|\le|\mu|+[n(\mu)]_+\},$$

and remarking that, by (3.20) and (3.21), $n(\mu)=j$ for $\mu\in\tilde{\mathcal{T}}_j\setminus\tilde{\mathcal{T}}_{j+1}$, we obtain in view of (3.33)

$$\begin{aligned}\#\left(\bigcup_{\mu\in\tilde{\mathcal{T}}_j\setminus\tilde{\mathcal{T}}_{j+1}}\Lambda_{\eta,\mu}\right)&\lesssim 2^{dj}\#(\tilde{\mathcal{T}}_j\setminus\tilde{\mathcal{T}}_{j+1})+\#(\tilde{\mathcal{T}}_j)\\&\lesssim\|\mathbf{u}\|^\tau_{t\ell^w_\tau(\mathcal{J})}\eta^{-\tau}2^{(d-\gamma\tau)j}.\end{aligned}\tag{3.35}$$

Since $d-\gamma\tau<0$, by summing over $j\ge0$, we obtain

$$\#(\tilde\Lambda_\eta)\lesssim\|\mathbf{u}\|^\tau_{t\ell^w_\tau(\mathcal{J})}\eta^{-\tau},\tag{3.36}$$

and adding the cardinality of $\mathcal{J}_\phi$, we thus obtain (3.26).

In order to obtain the estimate (3.27), we first notice that (3.36) already indicates that we have the estimate

$$\|(\tilde w_\lambda)_{\lambda\in\mathcal{J}_\psi}\|_{\ell^w_\tau(\mathcal{J})}\lesssim\|\mathbf{u}\|_{t\ell^w_\tau(\mathcal{J})}.\tag{3.37}$$

For the remaining indices $\lambda\in\mathcal{J}_\phi$, we can write

$$\|(\tilde w_\lambda)_{\lambda\in\mathcal{J}_\phi}\|_{\ell^w_\tau(\mathcal{J})}\le\|(\tilde w_\lambda)_{\lambda\in\mathcal{J}_\phi}\|_{\ell_\tau}\le[\#(\mathcal{J}_\phi)]^{1/\tau-1/2}\|(\tilde w_\lambda)_{\lambda\in\mathcal{J}_\phi}\|\lesssim\|\mathbf{w}\|,$$

so that we have $\|\mathbf{w}\|_{t\ell^w_\tau(\mathcal{J})}\lesssim\|\mathbf{u}\|_{t\ell^w_\tau(\mathcal{J})}+\|\mathbf{w}\|$. Since by Assumption 1,

$$\|\mathbf{w}\|\lesssim\|\mathbf{F}(0)\|+\|\mathbf{u}\|\lesssim1+\|\mathbf{u}\|\lesssim1+\|\mathbf{u}\|_{t\ell^w_\tau(\mathcal{J})},\tag{3.38}$$

the estimate (3.27) follows. □

Note that since we have used Assumptions 1 and 2 in the above proof, the constants in both estimates (3.25) and (3.27) are of the form $C(\|\mathbf{u}\|)$, where $x\mapsto C(x)$ is a positive nondecreasing function.

Remark 3.1. The limitation $d/\gamma<\tau<2$ in Theorem 3.3 is exactly equivalent to the limitation $0<s<\frac{2\gamma-d}{2d}$ in Theorem 3.2 with $s=1/2-1/\tau$.

Remark 3.2. In both Theorems 3.2 and 3.3, the presence of the constant term in the right side of (3.16) and (3.27), and of the $\#(\mathcal{J}_\phi)$ term on the right side of (3.15) and (3.26), can be avoided if the local action estimate (3.3) remains valid also for $\lambda\in\mathcal{J}_\phi$. The tree $\mathcal{T}$ is then constructed without systematic inclusion of $\mathcal{J}_\phi$, and the proofs of the new estimates are analogous. This is the case for certain classes of linear mappings; see Proposition 7.4 in [11].

3.5. Adaptive evaluation schemes. Adaptive wavelet schemes for variational problems of the type (2.2) rest on two conceptual steps. First (2.2) is formulated in wavelet coordinates as an equivalent problem over $\ell_2(\mathcal{J})$ as follows:

$$\mathbf{Au}+\mathbf{F}(\mathbf{u})=\mathbf{f},\tag{3.39}$$

where $\mathbf{A}=(\langle\nabla\psi_\lambda,\nabla\psi_\nu\rangle)_{\lambda,\nu\in\mathcal{J}}$ is the wavelet representation of Δ and $\mathbf{f}=(\langle f,\psi_\lambda\rangle)_{\lambda\in\mathcal{J}}$. The second step is to devise an iterative scheme for numerically solving (3.39). This

iteration requires the approximate evaluation of $\mathbf{A}\mathbf{u}^n$ and $\mathbf{F}(\mathbf{u}^n)$ with some dynamically updated tolerance, where $\mathbf{u}^n$ is the current finitely supported iterate. How to deal with the linear part $\mathbf{A}\mathbf{u}^n$ has been explained in [9]. The remaining task may therefore be formulated as follows: given a target accuracy $\varepsilon > 0$, and some finitely supported $\mathbf{v} \in \ell_2(\mathcal{J})$, compute $\mathbf{F}(\mathbf{v})$ with accuracy ε at a possibly moderate computational expense.

The way of tackling this task involves two steps : (i) identify an optimal tree such that the restriction of $\mathbf{F}(\mathbf{v})$ to such a tree can be predicted to approximate $\mathbf{F}(\mathbf{v})$ at the desired accuracy, and (ii) numerically compute the coordinates of $\mathbf{F}(\mathbf{v})$ restricted to this tree. We shall not engage (ii) except to mention the paper [15], which treats this topic once (i) has been solved. On the other hand, the results in sections 3.3 and 3.4 allow us to solve (i). We shall again distinguish between near best tree approximation and thresholding the local residual.

When working with near best tree approximation as in section 3.3, Theorem 3.2 provides us with a construction of the required tree, according to the following algorithm.

ALGORITHM EV1. *Given the inputs $\varepsilon > 0$ and $\mathbf{v}$ with finite support do the following:*

Step 1. *Invoke the algorithm in* [2] *to compute the trees*

$$\mathcal{T}_j := \mathcal{T}\left(\frac{2^j\varepsilon}{C_0(j+1)}, \mathbf{v}\right), \tag{3.40}$$

where $C_0 = C_0(\|\mathbf{v}\|)$ is the constant involved in (3.14), *for $j = 0, \dots, J$, and stop for the smallest J such that $\mathcal{T}_J$ is empty (we always have $J \lesssim \log_2(\|\mathbf{v}\|/\varepsilon)$).*

Step 2. *Derive the expanded trees $\tilde{\mathcal{T}}_j$, the layers Δ_j, and the outcome tree $\mathcal{T}$ according to* (3.11).

The following theorem summarizes the properties of Algorithm EV1.

THEOREM 3.4. *Given the inputs $\epsilon > 0$, a nonlinear function F such that $\mathbf{F}$ satisfies Assumptions* 1 *and* 2, *and a finitely supported vector $\mathbf{v}$, the output tree $\mathcal{T}$ has the following properties:*

P1: $\|\mathbf{F}(\mathbf{v}) - \mathbf{F}(\mathbf{v})|_{\mathcal{T}}\| \le \epsilon$.

P2: *For any $0 < s < \frac{2\gamma - d}{2d}$ (see Theorem* 3.2*),*

$$\#(\mathcal{T}) \le C\|\mathbf{v}\|_{\mathcal{A}^s}^{1/s}\epsilon^{-1/s} + \#(\mathcal{J}_\phi) =: N_\varepsilon, \tag{3.41}$$

with C a constant depending only on the constants appearing in Theorem 3.2.

P3: *Moreover, the number of computations needed to find $\mathcal{T}$ is bounded by $C(N_\varepsilon + \#\mathcal{T}(\mathbf{v}))$, where N_ε is the right-hand side of* (3.41) *and $\mathcal{T}(\mathbf{v})$ is the smallest tree containing* $\operatorname{supp}\mathbf{v}$.

Proof. Properties P1 and P2 directly follow from Theorem 3.2. Property P3 is a consequence of the optimality property of the algorithm in [2]. First, the application of this algorithm requires the array $\tilde{\mathbf{v}}$ whose entries serve as local error terms. $\tilde{\mathbf{v}}$ can be computed by summing the squares of the v_λ starting from the leaves of $\mathcal{T}(\mathbf{v})$ towards the roots. The number of operations remains proportional to $\#(\mathcal{T}(\mathbf{v}))$. Moreover, the additional cost of computing each tree $\mathcal{T}_j$, making use of the previously computed tree, is bounded by $C\#(\mathcal{T}_j)$ and therefore by $C\|\mathbf{v}\|_{\mathcal{A}^s}^{1/s}\epsilon^{-1/s}2^{-j/s}(j+1)^{1/s}$. Summing over j we obtain that the total cost remains bounded by the right side of (3.41) and $\#(\mathcal{T}(\mathbf{v}))$. ∎

When working with trees obtained by thresholding the local residuals as in section 3.4, Theorem 3.2 does not provide us with a direct construction of the required tree.

In order to build this tree, we first note that if $\mathcal{T}$ is the tree obtained by (3.23) for some given threshold η, and if $\mathcal{L}$ is the set of its outer leaves, we have the estimate

$$\|\mathbf{v} - \mathbf{F}(\mathbf{v})\|^2 \leq C_0^2 \#(\mathcal{L})\eta^2, \tag{3.42}$$

where C_0 is the constant of the inequality (3.25). Therefore we can invoke the following algorithm based on geometrically updated thresholds $\eta_j = 2^{-j}$.

ALGORITHM EV2. *Given the inputs $\epsilon > 0$ and $\mathbf{v}$ with finite support, initialize with $j = 0$ and do the following:*

Step 1. *Given j compute the predicted tree $\mathcal{T}$ and its outer leaves $\mathcal{L}$ for $\eta = \eta_j = 2^{-j}$. Compute the corresponding error estimator $\varepsilon_0 = C_0^2 \#(\mathcal{L})\eta_j^2$ and proceed to Step* 2.

Step 2. *If $\epsilon_j \leq \epsilon$, terminate the algorithm and take $\mathcal{T}$ as output. If $\epsilon_j > \epsilon$, replace j by $j + 1$ and return to Step* 1.

The following theorem summarizes the properties of Algorithm EV2.

THEOREM 3.5. *Given the inputs $\epsilon > 0$, a nonlinear function F such that $\mathbf{F}$ satisfies Assumptions* 1 *and* 2, *and a finitely supported vector $\mathbf{v}$, the output tree $\mathcal{T}$ has the following properties:*

P1: $\|\mathbf{F}(\mathbf{v}) - \mathbf{F}(\mathbf{v})|_{\mathcal{T}}\| \leq \epsilon$.

P2: *For any $d/\gamma < \tau < 2$ (see Theorem* 3.3*),*

$$\#(\mathcal{T}) \leq C\|\mathbf{v}\|^{1/s}_{{}_t\ell^w_\tau(\mathcal{J})}\epsilon^{-1/s} + \#(\mathcal{J}_\phi), \tag{3.43}$$

with C a constant depending only on the constants appearing in Theorem 3.3.

P3: *Moreover, the number of computations needed to find $\mathcal{T}$ is also bounded by the right side of* (3.43) *plus $\#(\mathcal{T}(\mathbf{v}))$, where $\mathcal{T}(\mathbf{v})$ denotes again the smallest tree containing the support of $\mathbf{v}$.*

Proof. Since the vector $\mathbf{v}$ is finite, it belongs to all ${}_t\ell^w_\tau(\mathcal{J})$. From (3.26) of Theorem 3.3, we have at step j

$$\#(\mathcal{T}) \lesssim 2^{j\tau}\|\mathbf{v}\|^\tau_{{}_t\ell^w_\tau(\mathcal{J})} + \#(\mathcal{J}_\phi), \tag{3.44}$$

from which it follows that ϵ_j tends to 0 as $j \to \infty$. Therefore, the algorithm must terminate at some finite value j^*. It follows from (3.42) that for the tree $\mathcal{T}$ obtained at step j^*, we have

$$\|\mathbf{F}(\mathbf{v}) - \mathbf{F}(\mathbf{v})|_{\mathcal{T}}\|^2 \leq \epsilon^2, \tag{3.45}$$

which proves P1.

In order to prove P2, we start with (3.26), which gives for $\mathcal{T}$ obtained at step j^*

$$\#(\mathcal{T}) \lesssim \|\mathbf{v}\|^\tau_{{}_t\ell^w_\tau(\mathcal{J})}\eta_{j^*}^{-\tau} + \#(\mathcal{J}_\phi) = C_0^\tau\|\mathbf{v}\|^\tau_{{}_t\ell^w_\tau(\mathcal{J})}\epsilon_{j^*}^{-\tau}(\#(\mathcal{L}))^{\tau/2} + \#(\mathcal{J}_\phi). \tag{3.46}$$

We continue under the assumption that the first term on the far right side of (3.46) is bigger than the second, since otherwise we are done. We recall now that $\#(\mathcal{T}) \sim \#(\mathcal{L})$ and that $\epsilon \leq \epsilon_{j^*-1} \leq 4\varepsilon_{j^*}$ because the sets $\mathcal{L}$ increase when j increases. Using this information back in (3.46) gives

$$\#(\mathcal{T})^{1-\tau/2} \lesssim \|\mathbf{v}\|^\tau_{{}_t\ell^w_\tau(\mathcal{J})}\epsilon^{-\tau}. \tag{3.47}$$

Therefore P2 follows by raising both sides of (3.47) to the power $1/(1 - \tau/2)$ because $s = 1/\tau - 1/2$, and hence $1 - \tau/2 = s\tau$.

Finally, to prove P3 we note that the thresholding requires the knowledge of $\tilde{\mathbf{v}}$. The same arguments as in the proof of P3 in Theorem 3.4 yield the contribution of $\#(\mathcal{T}(\mathbf{v}))$ to the operations count. Moreover, once $\tilde{\mathbf{v}}$ is known, the number of additional computations used in the algorithm is bounded by $C(\|\mathbf{v}\|^{\tau}_{t\ell^w_\tau(\mathcal{J})}\eta_0^{-\tau}+\#(\mathcal{J}_\phi))$ at iteration 0. Given the tree at stage j, which allows one to avoid corresponding comparisons, the additional work needed to determine the tree at stage $j+1$ is bounded by $C\|\mathbf{v}\|^{\tau}_{t\ell^w_\tau(\mathcal{J})}\eta_j^{-\tau}$. Summing up over j, we derive P3. ∎

4. Verification of the basic assumptions. We shall show in this section that Assumptions 1 and 2 hold for nonlinear mappings of the form $\mathcal{F}(u)(x) = \mathcal{F}(u(x))$, where $\mathcal{F}$ is a univariate function which satisfies growth conditions at infinity of the type

$$|\mathcal{F}^{(n)}(x)| \le C(1+|x|)^{[p-n]_+}, \quad x \in \mathbb{R},\ n = 0, 1, \dots, n^*, \tag{4.1}$$

for some $p \ge 0$ and n^* a positive integer. Clearly $\mathcal{F}(u) = u^p$ is of this type for all n^* if p is an integer, and with n^* the integer part of p otherwise.

4.1. Verification of Assumption 1. The verification of Assumption 1 is a classical result in the case where $H = H^t(\Omega)$, $t \ge 0$, or when H is a closed subspace of $H^t(\Omega)$ determined, e.g., by homogeneous boundary conditions, such as $H_0^t(\Omega)$ (the closure in the $\|\cdot\|_{H^t}$-norm of smooth functions with compact support in the open bounded domain Ω).

PROPOSITION 4.1. *Assume that $\mathcal{F}$ satisfies* (4.1) *for some $p \ge 0$ and $n^* \ge 0$. Then $\mathcal{F}$ maps H to H' under the restriction*

$$0 \le p \le p^* := \frac{d+2t}{d-2t} \tag{4.2}$$

when $t < d/2$, and with no restriction otherwise. If in addition $n^* \ge 1$, then we also have under the same restriction

$$\|\mathcal{F}(u) - \mathcal{F}(v)\|_{H'} \le C\|u-v\|_H, \tag{4.3}$$

where $C = C(\max\{\|u\|_H, \|v\|_H\})$ and $x \to C(x)$ is nondecreasing, and therefore Assumption 1 *holds.*

Proof. For $u \in H$ and $\varphi \in H$, we write

$$|\langle \mathcal{F}(u), \varphi\rangle| \le C\left[\int_\Omega |\varphi| + \int_\Omega |\varphi||u|^p\right]. \tag{4.4}$$

The first term is bounded according to

$$\int_\Omega |\varphi| \le |\Omega|^{1/2}\|\varphi\|_{L_2} \le |\Omega|^{1/2}\|\varphi\|_H. \tag{4.5}$$

For the second term, we use Hölder's inequality to obtain

$$\int_\Omega |\varphi||u|^p \le \|\varphi\|_{L_q}\|u\|^p_{L_{pq'}}, \tag{4.6}$$

where $\frac{1}{q} + \frac{1}{q'} = 1$. Taking q such that $q = pq' = pq/(q-1)$, i.e., $q = p+1$, this gives

$$\int_\Omega |\varphi||u|^p \le \|\varphi\|_{L_{p+1}}\|u\|^p_{L_{p+1}}. \tag{4.7}$$

We then note that when $t < d/2$, $H = H^t$ is continuously embedded in L_{p+1} if and only if $p \leq p^*$, and this embedding holds for all $p \geq 0$ when $t \geq d/2$. We therefore conclude that

$$\|\mathcal{F}(u)\|_{H'} \leq C(1 + \|u\|_H^p). \tag{4.8}$$

Therefore, $\mathcal{F}$ maps H to H' provided that $p \leq p^*$ when $t < d/2$, and for all $p \geq 0$ otherwise.

For the stability property, we use the inequality

$$|\mathcal{F}(u) - \mathcal{F}(v)| \leq C|u - v|(1 + |u| + |v|)^{[p-1]_+}, \tag{4.9}$$

which is a consequence of (4.1) with $n = 1$. Therefore, one has for all $\varphi \in H$

$$|\langle \mathcal{F}(u) - \mathcal{F}(v), \varphi \rangle| \leq C \left[\int_\Omega |\varphi||u - v| + \int |\varphi||u - v|(|u| + |v|)^{[p-1]_+} \right]. \tag{4.10}$$

The first term is simply bounded by

$$\int_\Omega |\varphi||u - v| \leq \|\varphi\|_{L_2} \|u - v\|_{L_2} \leq \|\varphi\|_H \|u - v\|_H. \tag{4.11}$$

If $p \leq 1$, the second term is bounded analogously. If $p > 1$, we apply Hölder's inequality twice, again with $q = p + 1$, to obtain

$$\int_\Omega |\varphi||u - v|(|u| + |v|)^{p-1} \leq \|\varphi\|_{L_{p+1}} \|u - v\|_{L_{p+1}} \left(\|u\|_{L_{p+1}} + \|v\|_{L_{p+1}} \right)^{p-1}. \tag{4.12}$$

Using again the Sobolev embedding, these factors are controlled by $\|\varphi\|_H$, $\|u - v\|_H$, and $(\|u\|_H + \|v\|_H)^{p-1}$, so that we obtain

$$\|\mathcal{F}(u) - \mathcal{F}(v)\|_{H'} \leq C\|u - v\|_H, \tag{4.13}$$

which is exactly (3.1). ∎

Next we want to prove the local version (3.2) of Assumption 1. For a given subdomain D, we define a vector $\bar{\mathbf{v}} = (\bar{v}_\lambda)$ such that $\bar{v}_\lambda = v_\lambda$ if $S_\lambda \cap D \neq \emptyset$, and $\bar{v}_\lambda = u_\lambda$ otherwise. It follows that

$$\|(\mathbf{u} - \mathbf{v})|_{\{\lambda : S_\lambda \cap D \neq \emptyset\}}\| = \|\mathbf{u} - \bar{\mathbf{v}}\|. \tag{4.14}$$

Denoting by $v, \bar{v}$ the corresponding functions $v = \sum_{\lambda \in \mathcal{J}} v_\lambda \psi_\lambda$, $\bar{v} = \sum_{\lambda \in \mathcal{J}} \bar{v}_\lambda \psi_\lambda$, we clearly have $v = \bar{v}$ on D so that

$$\mathbf{F}(\bar{\mathbf{v}})_\lambda = \langle \mathcal{F}(\bar{v}), \psi_\lambda \rangle = \langle \mathcal{F}(v), \psi_\lambda \rangle = \mathbf{F}(\mathbf{v})_\lambda \tag{4.15}$$

whenever $S_\lambda \subset D$. It follows that

$$\|(\mathbf{F}(\mathbf{u}) - \mathbf{F}(\mathbf{v}))|_{\{\lambda : S_\lambda \subset D\}}\| \leq \|\mathbf{F}(\mathbf{u}) - \mathbf{F}(\bar{\mathbf{v}})\|. \tag{4.16}$$

Therefore, the local stability estimate (3.2) follows by combining (4.14) and (4.16) together with the global stability estimate (3.1). ∎

4.2. Verification of Assumption 2. For the verification of Assumption 2, we shall assume that either (4.1) is valid or that

$$|\mathcal{F}^{(n)}(x)| \le C(1+|x|)^{p-n}, \quad n \le p, \qquad \text{and } \mathcal{F}^{(n)}(x) = 0, \quad n > p, \tag{4.17}$$

with p an integer. We shall show in the next theorem that whenever $\mathcal{F}$ satisfies either (4.1) or (4.17), then it satisfies Assumption 2 with $\gamma = r + t + d/2$. Our reason for separating the two cases (4.1) and (4.17) is that in the latter case we can take a larger value for r. We recall the critical index p^* defined by (4.2).

THEOREM 4.1. *Assume that the wavelets ψ_λ belong to C^m and have (for those $\lambda \in \mathcal{J}_\psi$) vanishing moments of order m (i.e., are orthogonal to $\mathbb{P}_{m-1}$ the space of polynomials of total degree at most $m-1$) for some positive integer m. Then Assumption 2 holds for $\gamma = r + t + d/2$ with the following value of r:*

(i) *If $t \ge d/2$ and $\mathcal{F}$ satisfies (4.1) for some $p \ge 0$, then $r = \min\{m, n^*\}$.*
(ii) *If $t < d/2$ and $\mathcal{F}$ satisfies (4.1) with $0 \le p < p^*$, then $r = \lceil \min\{m, p, n^*\} \rceil$.*
(iii) *If $t \ge d/2$ and $\mathcal{F}$ satisfies (4.17) for some $p > 0$, then $r = m$.*
(iv) *If $t < d/2$ and $\mathcal{F}$ satisfies (4.17) for some $0 \le p < p^*$, then $r = m$.*

Proof. Suppose that u has a finite wavelet expansion. We assume that $r \ge 1$ and leave the simpler case $r = 0$ to the reader (this case only occurs in (ii) when $p < 1$). Since the wavelets $\psi_\lambda \in \mathcal{J}_\psi$ have at least r vanishing moments, we have

$$\begin{aligned} |w_\lambda| &= |\langle w, \psi_\lambda \rangle| = \inf_{P \in \Pi_{r-1}} |\langle w - P, \psi_\lambda \rangle| \\ &\lesssim |w|_{W^r(L_\infty(S_\lambda))} 2^{-r|\lambda|} 2^{-(t+d/2)|\lambda|} = |w|_{W^r(L_\infty(S_\lambda))} 2^{-\gamma|\lambda|}, \end{aligned} \tag{4.18}$$

where $w(x) = \mathcal{F}(u(x))$. Using the chain rule, any rth order derivative of w can be written as a finite sum of functions of the form

$$\mathcal{F}^{(k)}(u) D^{\beta_1} u \cdots D^{\beta_k} u, \quad k = 1, \dots, r, \tag{4.19}$$

where $|\beta_1| + \cdots + |\beta_k| = r$ with the usual notation $|\beta_i| := \beta_{i,1} + \cdots + \beta_{i,d}$. Therefore, one has

$$|w|_{W^r(L_\infty(S_\lambda))} \lesssim \max_{k=1,\dots,r} \max_{|\beta_1|+\cdots+|\beta_k|=r} \|\mathcal{F}^{(k)}(u)\|_{L_\infty(S_\lambda)} \prod_{i=1}^{k} \|D^{\beta_i} u\|_{L_\infty(S_\lambda)}. \tag{4.20}$$

To bound the right side of (4.20), we recall that

$$\|D^{\beta_i} u\|_{L_\infty(S_\lambda)} \lesssim \|u\|_{L_\infty(S_\lambda)}^{1-|\beta_i|/r} |u|_{W^r(L_\infty(S_\lambda))}^{|\beta_i|/r}. \tag{4.21}$$

This gives for $k = 1, \dots, r$

$$\begin{aligned} \|\mathcal{F}^{(k)}(u)\|_{L_\infty(S_\lambda)} \prod_{i=1}^{k} \|D^{\beta_i} u\|_{L_\infty(S_\lambda)} &\lesssim \|\mathcal{F}^{(k)}(u)\|_{L_\infty(S_\lambda)} \|u\|_{L_\infty(S_\lambda)}^{k-1} \\ &\quad \times |u|_{W^r(L_\infty(S_\Lambda))}. \end{aligned} \tag{4.22}$$

We shall finish the proof by separating it into two cases depending on the size of $\|u\|_{L_\infty(S_\lambda)}$.

Case $\|u\|_{L_\infty(S_\lambda)} \ge 1$. In this case, (4.20), (4.22), and the bounds (4.1) and (4.17) give

$$|w|_{W^r(L_\infty(S_\lambda))} \lesssim \|u\|_{L_\infty(S_\lambda)}^{M} |u|_{W^r(L_\infty(S_\lambda))}, \tag{4.23}$$

where $M := \max\{p, r\} - 1$ in cases (i) and (ii), and $M := p - 1$ in cases (iii) and (iv). We can bound the norms on the right side of (4.23) by using the Besov spaces $B^s_\infty(L_\infty)$, $s \geq 0$. They satisfy the norm equivalences

$$\|v\|_{B^s_\infty(L_\infty(S_\lambda))} \sim \sup_{S_\mu \cap S_\lambda \neq \emptyset} \left(2^{s|\mu|}\|v_\mu \psi_\mu\|_{L_\infty}\right) = \sup_{S_\mu \cap S_\lambda \neq \emptyset} \left(2^{(s+\delta)|\mu|}|v_\mu|\right) \tag{4.24}$$

with $\delta := \frac{d}{2} - t$. Here we used the fact that the H-normalization of the wavelets implies $\|\psi_\mu\|_{L_\infty} \sim 2^{\delta|\mu|}$. We also recall the embedding estimates

$$\|u\|_{W^s(L_\infty(S_\lambda))} \lesssim \|u\|_{B^{s+\varepsilon}_\infty(L_\infty(S_\lambda))} \tag{4.25}$$

for any fixed $\varepsilon \in]0, 1[$ and all $s \geq 0$. Using all of this in (4.23), we obtain

$$\begin{aligned} |w|_{W^r(L_\infty(S_\lambda))} &\lesssim \left(\sup_{S_\mu \cap S_\lambda \neq \emptyset} 2^{(\delta+\varepsilon)|\mu|}|u_\mu|\right)^M \left(\sup_{S_\mu \cap S_\lambda \neq \emptyset} 2^{(r+\delta+\varepsilon)|\mu|}|u_\mu|\right) \\ &= \left(2^{(\delta+\varepsilon)|\mu_0|}|u_{\mu_0}|\right)^M \left(2^{(r+\delta+\varepsilon)|\mu_1|}|u_{\mu_1}|\right), \end{aligned} \tag{4.26}$$

where μ_0 and μ_1 are the maximizing indices. If $\delta < 0$ (i.e., $t > d/2$), we can take $\epsilon < |\delta|$ and obtain the bound

$$|w|_{W^r(L_\infty(S_\lambda))} \lesssim \|\mathbf{u}\|^M (2^{(r+\delta+\varepsilon)|\mu_1|}|u_{\mu_1}|) \leq \|\mathbf{u}\|^M \sup_{S_\mu \cap S_\lambda \neq \emptyset} 2^{r|\mu|}|u_\mu|, \tag{4.27}$$

which verifies Assumption 2 in this case. If $\delta > 0$, then $|\mu_1| \geq |\mu_0|$ and $p < p_*$ and $M = p - 1$, and so we obtain

$$|w|_{W^r(L_\infty(S_\lambda))} \lesssim \|\mathbf{u}\|^M (2^{(r+p\delta+p\varepsilon)|\mu_1|}|u_{\mu_1}|) \leq \|\mathbf{u}\|^M \sup_{S_\mu \cap S_\lambda \neq \emptyset} 2^{(r+t+d/2)\mu|}|u_\mu|, \tag{4.28}$$

provided $p\epsilon < (p^* - p)\delta$. So we have completed the proof in this case.

Case $\|u\|_{L_\infty(S_\lambda)} < 1$. In this case, starting from (4.22) and using either (4.1) or (4.17), we obtain

$$\begin{aligned} |w|_{W^r(L_\infty(S_\lambda))} &\lesssim |u|_{W^r(L_\infty(S_\lambda))} \lesssim \|u\|_{B^{r+\varepsilon}_\infty(L_\infty(S_\lambda))} \\ &\lesssim \sup_{S_\mu \cap S_\lambda \neq \emptyset} 2^{(r+\delta+\epsilon)|\mu|}|u_\mu| \lesssim \sup_{S_\mu \cap S_\lambda \neq \emptyset} 2^{(r+d/2+t)\mu|}|u_\mu|, \end{aligned} \tag{4.29}$$

provided $\varepsilon < 2t$. Therefore, we have verified Assumption 2 in this case as well. ∎

5. Multiple arguments and derivatives. In this final section, we shall extend the previous results to more general nonlinear operators of the form

$$(u_1, \ldots, u_n) \mapsto w = \mathcal{F}(D^{\alpha_1}u_1, \ldots, D^{\alpha_n}u_n), \tag{5.1}$$

acting from $H \times \cdots \times H$ to its dual H' (note that $\alpha_i = (\alpha_{i,1}, \ldots, \alpha_{i,d})$ are multi-indices). These include multilinear operators as particular cases. Here we shall indicate the appropriate generalizations of the results in the two previous sections with brief sketches of proofs since they are quite similar but notationally heavier.

5.1. Sparsity preserving discrete operators. Denoting by $\mathbf{u}_i = (u_{i,\lambda})$ the arrays of the wavelet coefficients of the function u_i, $\mathbf{u} = (\mathbf{u}_1, \dots, \mathbf{u}_n)$, and $\mathbf{F}$ the corresponding discrete mapping

$$\mathbf{F}(\mathbf{u}) := (\langle \mathcal{F}(D^{\alpha_1} u_1, \dots, D^{\alpha_n} u_n), \psi_\lambda \rangle_{\lambda \in \mathcal{J}}, \tag{5.2}$$

we introduce the following generalization of the basic assumptions.

Assumption 1. $\mathbf{F}$ is a Lipschitz map from $(\ell_2)^n$ into ℓ_2:

$$\|\mathbf{F}(\mathbf{u}) - \mathbf{F}(\mathbf{v})\| \le C \sum_{i=1}^n \|\mathbf{u}_i - \mathbf{v}_i\|, \tag{5.3}$$

with $C = C(\max_i\{\|\mathbf{u}_i\|, \|\mathbf{v}_i\|\})$, where $x \mapsto C(x)$ is a positive nondecreasing function.

The local version of this stability assumption now reads

$$\|(\mathbf{F}(\mathbf{u}) - \mathbf{F}(\mathbf{v}))|_{\{\lambda : S_\lambda \subset D\}}\| \le C \sum_{i=1}^n \|(\mathbf{u}_i - \mathbf{v}_i)|_{\{\lambda : S_\lambda \cap D \neq \emptyset\}}\| \tag{5.4}$$

for any domain D.

Assumption 2. For any finitely supported $\mathbf{u}$ (i.e., with all $\mathbf{u}_i$ finitely supported) and $\mathbf{w} = \mathbf{F}(\mathbf{u})$, we have the estimate

$$|w_\lambda| \le C \sup_{\mu \,:\, S_\lambda \cap S_\mu \neq \emptyset} \left(\sum_{i=1}^n |u_{i,\mu}| \right) 2^{-\gamma(|\lambda| - |\mu|)} \tag{5.5}$$

for all $\lambda \in \mathcal{J}_\psi$, where $\gamma > d/2$, $C = C(\max_i \|\mathbf{u}_i\|)$, and $x \mapsto C(x)$ is a positive nondecreasing function.

In order to generalize the construction of the near best approximation tree from section 3.3, we construct for a prescribed accuracy ε the trees $\tilde{\mathcal{T}}_{j,i}$ for each component $\mathbf{u}_i$ in the same way as we constructed $\tilde{\mathcal{T}}_j$ in section 3.3. We then define

$$\tilde{\mathcal{T}}_j := \cup_{i=0}^n \tilde{\mathcal{T}}_{j,i} \ \text{ and } \ \Delta_j := \tilde{\mathcal{T}}_j \setminus \tilde{\mathcal{T}}_{j+1}. \tag{5.6}$$

The tree $\mathcal{T}$ is then constructed as before, according to (3.11).

THEOREM 5.1. *With this definition of* $\mathcal{T}$ *and under the above generalized Assumptions* 1 *and* 2, *if* $\mathbf{u} \in (\mathcal{A}^s)^n$, *we obtain that the same conclusions as in Theorem* 3.2 *also hold.*

Sketch of proof. As in the proof of Theorem 3.2, we start by invoking the stability property, which leads us to estimate $\|\mathbf{w}_\varepsilon - \mathbf{w}_\varepsilon|_{\mathcal{T}}\|$, where $\mathbf{w}_\varepsilon := \mathbf{F}(\mathbf{u}|_{\tilde{\mathcal{T}}_0})$. We use the estimate

$$|w_{\varepsilon,\lambda}|^2 \ \lesssim \ \sum_{\mu \in \tilde{\mathcal{T}}_0, S_\mu \cap S_\lambda \neq \emptyset} \left[\sum_{i=1}^n |u_{i,\mu}|^2 \right] 2^{-2\gamma(|\lambda| - |\mu|)}, \tag{5.7}$$

together with

$$\sum_{\mu \in \Delta_j} \sum_{i=1}^n |u_{i,\mu}|^2 = \|\mathbf{u}|_{\tilde{\mathcal{T}}_j} - \mathbf{u}|_{\tilde{\mathcal{T}}_{j+1}}\|^2 \ \lesssim \ \frac{2^{2j}\varepsilon^2}{(1+j)^2}, \tag{5.8}$$

in order to derive $\|\mathbf{w}_\varepsilon - \mathbf{w}_\varepsilon|_{\mathcal{T}}\| \lesssim \varepsilon$ in a similar way as in the proof of Theorem 3.2. The estimate on $\#(\mathcal{T})$ also remains the same using that $\#(\Delta_j) \le \#(\mathcal{T}_j) \le \sum_{i=1}^n \#(\mathcal{T}_{j,i})$. ∎

In order to generalize the construction of the residual thresholding tree from section 3.4, we fix a threshold $\eta > 0$ and define for all $\mu \in \mathcal{J}$ the number $n(\mu)$ satisfying

$$\eta 2^{\gamma n(\mu)} \leq \max_i |u_{i,\mu}| < \eta 2^{\gamma(n(\mu)+1)}, \tag{5.9}$$

where $u_{i,\mu}$ are the coefficients of $\mathbf{u}_i$. We then define the influence sets $\Lambda_{\eta,\mu}$ and the tree $\mathcal{T}$ in a similar way as in (3.21) and (3.23), with $\tilde{\mathcal{T}}_\eta = \cup_{i=1}^n \tilde{\mathcal{T}}_\eta(\mathbf{u}_i)$ and $\tilde{\mathcal{T}}_\eta(\mathbf{u}_i)$ the expansion of the tree $\mathcal{T}_\eta(u_i)$.

THEOREM 5.2. *With this definition of $\mathcal{T}$ and under the above generalized Assumptions* 1 *and* 2*, if $\mathbf{u} \in (\ell^w_\tau(\mathcal{J}))^n$, we obtain that the same conclusions as in Theorem* 3.3 *hold.*

Sketch of proof. As in the proof of Theorem 3.3, in order to prove (3.25) we first consider the restricted vector $\mathbf{u}_\eta = \mathbf{u}|_{\tilde{\mathcal{T}}_\eta}$ and its image $\mathbf{w}_\eta := \mathbf{F}(\mathbf{u}_\eta) = (w_{\lambda,\eta})$. Using (5.5), we obtain that for any $\lambda \notin \mathcal{T}$, we have $|\tilde{w}_{\lambda,\eta}| \lesssim \eta$. We then use (5.4) in a similar way in order to derive (3.25).

In order to prove (3.26), we use the trees $\tilde{\mathcal{T}}_j := \tilde{\mathcal{T}}_{\eta 2^{\gamma j}}$ to decompose $\mathcal{T}$ into layers indexed by j as in the proof of Theorem 3.3. We then proceed in a similar way to derive (3.26), remarking that

$$\#(\tilde{\mathcal{T}}_j) \lesssim \eta^{-\tau} 2^{-\gamma\tau j} \sup_i \|\mathbf{u}_i\|^\tau_{{}_t\ell^w_\tau(\mathcal{J})}, \tag{5.10}$$

and that, according to (5.9) and (3.21), $n(\mu) = j$ for $\mu \in \tilde{\mathcal{T}}_j \setminus \tilde{\mathcal{T}}_{j+1}$.

Finally, we prove

$$\|\mathbf{w}\|_{{}_t\ell^w_\tau(\mathcal{J})} \lesssim 1 + \sup_i \|\mathbf{u}_i\|_{{}_t\ell^w_\tau(\mathcal{J})} \tag{5.11}$$

by the same arguments as in the proof for Theorem 3.3. □

The generalization of Algorithms EV1 and EV2 is straightforward, as is the following proposition.

PROPOSITION 5.1. *If $\mathbf{u} \in \mathcal{X}$ with $\mathcal{X} = (\mathcal{A}^s)^n$ (resp., $({}_t\ell^w_\tau(\mathcal{J}))^n$), the tree $\mathcal{T}$ produced by Algorithm* EV1 *(resp.,* EV2*) for target accuracy ε satisfies*

$$\#(\mathcal{T}) \lesssim \sup_i \|\mathbf{u}_i\|^{1/s}_{\mathcal{X}} \varepsilon^{-1/s} + \#(\mathcal{J}_\phi), \tag{5.12}$$

with $s = 1/\tau - 1/2$, under the restriction $d/\gamma < \tau < 2$.

5.2. Verification of the basic assumptions. Recalling that the nonlinear map has the form $\mathcal{F}(D^{\alpha_1}u_1, \ldots, D^{\alpha_n}u_n)$, we shall therefore replace (4.1) by growth assumptions of the type

$$|D^\beta \mathcal{F}(x_1, \ldots, x_n)| \leq C \prod_{i=1}^n (1 + |x_i|)^{[p_i - \beta_i]_+}, \quad |\beta| = 0, 1, \ldots, n^*, \tag{5.13}$$

for some $p_i \geq 0$ and n^* a positive integer. For notational simplicity, we shall write

$$\mathcal{F}(u) = \mathcal{F}(D^{\alpha_1}u_1, \ldots, D^{\alpha_n}u_n), \quad \text{with } u = (u_1 \ldots, u_n). \tag{5.14}$$

We then obtain the following generalization of Proposition 4.1.

PROPOSITION 5.2. *Assume that the growth assumptions* (5.13) *hold at least with* $n^* = 0$. *Then* $\mathcal{F}$ *maps* $H \times \cdots \times H$ *to* H' *whenever* $H = H^t$ *and* $t \geq 0$ *satisfies*

$$\left[\frac{1}{2} - \frac{t}{d}\right]_+ + \sum_{i=1}^n p_i \left[\frac{1}{2} - \frac{t}{d} + \frac{|\alpha_i|}{d}\right]_+ < 1. \tag{5.15}$$

If in addition $n^* = 1$, *then we also have under the same restriction*

$$\|\mathcal{F}(u) - \mathcal{F}(v)\|_{H'} \leq C \sum_{i=1}^n \|u_i - v_i\|_H, \tag{5.16}$$

where $C = C(\max_i\{\|u_i\|_H, \|v_i\|_H\})$ *and* $x \to C(x)$ *is nondecreasing, and therefore Assumption* 1 *holds.*

Sketch of proof. For $u_i \in H$ and $\varphi \in H$, we write

$$|\langle \mathcal{F}(u), \varphi\rangle| \leq C \int_\Omega |\varphi| \prod_{i=1}^n (1 + |D^{\alpha_i} u_i|)^{p_i}. \tag{5.17}$$

In view of (5.15), we can choose positive numbers r and r_i, $i = 1, \ldots, n$, such that $\frac{1}{r} + \sum_{i=1}^n \frac{p_i}{r_i} = 1$ and

$$\frac{1}{r} > \frac{1}{2} - \frac{t}{d} \ \text{ and } \ \frac{1}{r_i} > \frac{1}{2} - \frac{t}{d} + \frac{|\alpha_i|}{d}. \tag{5.18}$$

It follows that H^t is continuously embedded in L_r and $W^{|\alpha_i|}(L_{r_i})$. We can apply Hölder's inequality to obtain

$$|\langle \mathcal{F}(u), \varphi\rangle| \leq C\|\varphi\|_{L_r} \prod_{i=1}^n (1 + \|D^{\alpha_i} u_i\|_{L_{r_i}}^{p_i}), \tag{5.19}$$

where we have used the fact that Ω is a bounded domain in order to control $\int_\Omega 1$ by a constant. In this way, we obtain

$$\|\mathcal{F}(u)\|_{H'} \leq C \prod_{i=1}^n (1 + \|D^{\alpha_i} u_i\|_H^{p_i}). \tag{5.20}$$

For the stability property, we use the inequality

$$|\mathcal{F}(u) - \mathcal{F}(v)| \leq C \sum_{i=1}^n |D^{\alpha_i} u_i - D^{\alpha_i} v_i| \prod_{k=1}^n (1 + |D^{\alpha_k} u_k| + |D^{\alpha_k} v_k|)^{[p_k - \delta_{i,k}]_+}, \tag{5.21}$$

with δ the Kronecker delta. Therefore, when estimating $|\langle \mathcal{F}(u) - \mathcal{F}(v), \varphi\rangle|$ for $\varphi \in H$, we are led to expressions of the form

$$E_i = \int_\Omega |\varphi| |D^{\alpha_i} u_i - D^{\alpha_i} v_i| \prod_{k=1}^n (1 + |D^{\alpha_k} u_k| + |D^{\alpha_k} v_k|)^{[p_k - \delta_{i,k}]_+} \tag{5.22}$$

for each i. Using Hölder's inequality, we obtain

$$E_i \leq C\|\varphi\|_{L_r} \|D^{\alpha_i} u_i - D^{\alpha_i} v_i\|_{L_q} \prod_{k=1}^n \left(1 + \|D^{\alpha_k} u_k\|_{L_{r_k}}^{[p_k - \delta_{i,k}]_+} + \|D^{\alpha_k} v_k\|_{L_{r_k}}^{[p_k - \delta_{i,k}]_+}\right)$$

whenever

$$\frac{1}{r}+\frac{1}{q}+\sum_{k=1}^{n}\frac{[p_k-\delta_{i,k}]_+}{r_k}=1. \tag{5.23}$$

In view of (5.15), we can choose positive numbers r, q, and r_i satisfying condition (5.23) such that

$$\frac{1}{r}>\frac{1}{2}-\frac{t}{d},\quad \frac{1}{q}>\frac{1}{2}-\frac{t}{d}+\frac{|\alpha_i|}{d},\quad \text{and}\quad \frac{1}{r_k}>\frac{1}{2}-\frac{t}{d}+\frac{|\alpha_k|}{d}. \tag{5.24}$$

Therefore, the Sobolev embedding gives

$$E_i\le C\|\varphi\|_H\|u_i-v_i\|_H, \tag{5.25}$$

and therefore Assumption 1 holds. ∎

The local version (3.2) of Assumption 1 is derived in the same way as in section 4.2. Note that the condition (5.15) does not yield the optimal condition (4.2) in the simple case $n=1$ and $\alpha_1=0$ due to the strict inequality but that we anyway need this strict inequality in order to obtain the validity of Assumption 2 according to Theorem 4.1.

For the proof of Assumption 2, we again treat separately the polynomial case for which we have the growth condition

$$|D^\beta\mathcal{F}(x_1,\dots,x_n)|\le C\prod_{i=1}^{n}(1+|x_i|)^{p_i-\beta_i},\quad \beta_i\le p_i, \tag{5.26}$$

and $D^\beta\mathcal{F}=0$ if $\beta_i>p_i$ for some i, where p_i are positive integers.

THEOREM 5.3. *Assume that the wavelets belong to C^m and have vanishing moments of order m (i.e., are orthogonal to $\mathbb{P}_{m-1}$ the space of polynomials of total degree at most $m-1$) for some positive integer m. Then Assumption 2 holds for $\gamma=r+t+d/2$ with the following values of r:*

(i) *If $\mathcal{F}$ satisfies (5.13) with p such that $\sum_{i=1}^n p_i[d/2-t+|\alpha_i|]_+<d/2+t$, then $r=\lceil\min\{m,n^*,p^*\}\rceil$, where $p^*=\min\{p_i\ :\ i \text{ s.t. } d/2-t+|\alpha_i|>0\}$.*

(ii) *If $\mathcal{F}$ satisfies (5.26) with p such that $\sum_{i=1}^n p_i[d/2-t+|\alpha_i|]_+<d/2+t$, then $r=m$.*

Sketch of proof. We shall prove (i); the other case is similar. We shall also assume that $r\ge 1$ and leave the simpler case $r=0$ to the reader. As in the proof of Theorem 4.1 we start from the estimate

$$|w_\lambda|\ \lesssim\ |w|_{W^r(L_\infty(S_\lambda))}2^{-\gamma|\lambda|}, \tag{5.27}$$

where $w(x)=\mathcal{F}(u(x))$. Using the chain rule, any rth order derivative of w can be written as a finite sum of functions of the form

$$D^\nu\mathcal{F}(D^{\alpha_1}u_1,\dots,D^{\alpha_n}u_n)G_\nu,\quad |\nu|=1,\dots,r, \tag{5.28}$$

where

$$G_\nu=\prod_{i=1}^{n}\prod_{j=1}^{\nu_i}D^{\beta_{i,j}+\alpha_i}u_i, \tag{5.29}$$

and $\sum_{i=1}^n \sum_{j=1}^{\nu_i} |\beta_{i,j}| = r$. Therefore, one has

$$|w|_{W^r(L_\infty(S_\lambda))} \lesssim \max_{|\nu|\le r} A_\nu, \tag{5.30}$$

where

$$A_\nu := \|D^\nu \mathcal{F}(D^{\alpha_1}u, \dots, D^{\alpha_n}u_n)\|_{L_\infty(S_\lambda)} \|G_\nu\|_{L_\infty(S_\lambda)}. \tag{5.31}$$

To bound $\|G_\nu\|_{L_\infty(S_\lambda)}$, we use the estimate for intermediate derivatives (4.21) and find with $r_i := \sum_{j=1}^{\nu_i} |\beta_{i,j}|$ that

$$\|G_\nu\|_{L_\infty(S_\lambda)} \lesssim \prod_{i=1}^n |u_i|^{\nu_i - 1}_{W^{|\alpha_i|}(L_\infty(S_\lambda))} |u_i|_{W^{r_i+|\alpha_i|}(L_\infty(S_\lambda))}. \tag{5.32}$$

We now invoke (5.13) and obtain that

$$\begin{aligned} A_\nu &\le \prod_{i=1}^n (1 + |u_i|_{W^{|\alpha_i|}(L_\infty(S_\lambda))})^{(p_i-\nu_i)_+} |u_i|^{\nu_i-1}_{W^{|\alpha_i|}(L_\infty(S_\lambda))} |u|_{W^{r_i+|\alpha_i|}(L_\infty(S_\lambda))} \\ &\le \prod_{i=1}^n |u_i|^{M_i}_{W^{|\alpha_i|}(L_\infty(S_\lambda))} |u|_{W^{r_i+|\alpha_i|}(L_\infty(S_\lambda))}, \end{aligned} \tag{5.33}$$

where $M_i = \max(p_i, r_i) - 1$ if $|u_i|_{W^{|\alpha_i|}(L_\infty(S_\lambda))} \ge 1$, and $M_i = 0$ otherwise.

Each term appearing in the last product in (5.33) can be bounded by Besov norms. The arguments used in deriving (4.28) and (4.29) give

$$|u_i|^{M_i}_{W^{|\alpha_i|}(L_\infty(S_\lambda))} |u|_{W^{r_i+|\alpha_i|}(L_\infty(S_\lambda))} \lesssim \|\mathbf{u}\|^{M_i} 2^{(r_i+(M_i+1)(|\alpha_i|+\delta+\epsilon))|\mu_i|} |u_{i,\mu_i}|, \tag{5.34}$$

where μ_i is a maximizing index. Let $\mu^* := \max_i \mu_i$. We place (5.34) into (5.33). Each term $|u_{i,\mu_i}|$, $\mu_i \ne \mu^*$, we pull out of the product by the majorant $\|\mathbf{u}\|$. This then gives

$$A_\nu \lesssim \prod_{i=1}^n \|\mathbf{u}\|^{M_i} 2^{(r_i+(M_i+1)(|\alpha_i|+\delta+\epsilon))|\mu_i|} |u_{i,\mu_i}| \lesssim \|\mathbf{u}\|^M \left[\sum_{i=1}^n |u_{i,\mu^*}|\right] 2^{\tilde\gamma|\mu^*|}, \tag{5.35}$$

with $M = \sum_{i=1}^n M_i$ and

$$\tilde\gamma = r + \sum_{i=1}^n (1 + M_i)(\varepsilon + [d/2 - t + |\alpha_i|]_+). \tag{5.36}$$

Now, consider any term in the sum which is not zero. If $M_i \ne 0$, then $M_i + 1 = \max(p_i, r_i) \le \max(p_i, r) = p_i$ because $r \le p_i$. If $M_i = 0$, then $M_i + 1 = 1 \le p_i$ because by definition $r \le p^* \le p_i$, and we have assumed $r \ge 1$. Using this information in (5.36) shows that

$$\tilde\gamma \le r + \sum_{i=1}^n p_i(\varepsilon + [d/2 - t + |\alpha_i|]_+) \le \gamma, \tag{5.37}$$

provided ϵ is sufficiently small. □

UNIQUE CONTINUATION FOR AN ELASTICITY SYSTEM WITH RESIDUAL STRESS AND ITS APPLICATIONS*

GEN NAKAMURA† AND JENN-NAN WANG‡

Abstract. In this paper we prove the unique continuation property for an elasticity system with small residual stress. The constitutive equation of this elasticity system differs from that of the isotropic elasticity system by $T + (\nabla u)T$, where T is the residual stress tensor. It turns out this elasticity system becomes anisotropic due to the existence of residual stress T. The main technique in the proof is Carleman estimates. Having proved the unique continuation property, we study the inverse problem of identifying the inclusion or cavity.

Key words. unique continuation property, residual stress, probe method

1. Introduction.

Let $\mathcal{B}$ be an isotropic elastic body with residual stress, and let the reference configuration of $\mathcal{B}$ be Ω, a bounded open set in $\mathbb{R}^n$ with smooth boundary. The residual stress is modeled by a symmetric, smooth, second-rank tensor $T(x) = (t_{ij}(x))_{1\le i,j\le n}$ satisfying

$$\partial_{x_j} t_{ij} = 0 \quad \text{in } \Omega, \quad 1 \le i \le n, \tag{1.1}$$

and

$$t_{ij}\nu_j = 0 \quad \text{on } \partial\Omega, \quad 1 \le i \le n, \tag{1.2}$$

where $\nu = (\nu_1, \dots, \nu_n)$ is the unit outer normal to $\partial\Omega$. Hereafter, we adopt the summation convention. Let $u : \Omega \to \mathbb{R}^n$ be the displacement vector; then the first Piola–Kirchhoff stress is written as

$$\begin{aligned}\sigma = {} & T + (\nabla u)T + \lambda(\mathrm{tr}\epsilon)I + 2\mu\epsilon + \beta_1(\mathrm{tr}\epsilon)(\mathrm{tr}T)I + \beta_2(\mathrm{tr}T)\epsilon \\ & + \beta_3((\mathrm{tr}\epsilon)T + \mathrm{tr}(\epsilon T)I) + \beta_4(\epsilon T + T\epsilon),\end{aligned}$$

where λ, μ are the Lamé moduli, $\beta_1, \dots, \beta_4$ are material parameters, and

$$\epsilon = Sym(\nabla u) = \frac{1}{2}(\nabla u + (\nabla u)^t)$$

is the strain tensor [18]. Moreover, we assume that the Lamé moduli satisfy the strong ellipticity condition

$$\mu(x) > \delta > 0, \ \lambda(x) + 2\mu(x) > \delta > 0 \qquad \forall x \in \Omega \tag{1.3}$$

and

$$\beta_3 = \beta_4 = 0,$$

i.e.,

$$\sigma = T + (\nabla u)T + \tilde{\lambda}(\mathrm{tr}\epsilon)I + 2\tilde{\mu}\epsilon, \tag{1.4}$$

where

$$\tilde{\lambda} = \lambda + \beta_1(\mathrm{tr}T), \quad \tilde{\mu} = \mu + \frac{1}{2}\beta_2(\mathrm{tr}T).$$

With the constitutive equation (1.4), the elasticity system considered here is quite close to the one studied by Robertson [22]. Hoger [8] also considered an elasticity system with residual stress where she used the constitutive equation

$$\sigma = T + (\nabla u)T - \frac{1}{2}(\epsilon T + T\epsilon) + \tilde{\lambda}(\mathrm{tr}\epsilon)I + 2\tilde{\mu}\epsilon$$

in her study.

Now the stationary elasticity system is expressed as

$$(Lu)_i = (\nabla \cdot \sigma)_i + \omega^2\rho(x)u_i = \partial_j\sigma_{ij} + \omega^2\rho(x)u_i = 0 \quad \text{in } \Omega,\ 1 \le i \le n,\ \omega \in \mathbb{R}, \tag{1.5}$$

where $\rho(x) > 0$ is the density of the medium. In another setting, if we define the elasticity tensor $\mathbb{C}$ with components

$$C_{ijkl} = \tilde{\lambda}\delta_{ij}\delta_{kl} + (\tilde{\mu}\delta_{jl} + t_{jl})\delta_{ik} + \tilde{\mu}\delta_{il}\delta_{jk} \tag{1.6}$$

and denote

$$(\mathbb{C}E)_{ij} = C_{ijkl}E_{kl} \quad \text{for any matrix} \quad E,$$

then (1.5) is equivalent to

$$(Lu)_i = (\nabla \cdot \mathbb{C}\nabla u)_i + \omega^2\rho u_i = \partial_j(C_{ijkl}\partial_l u_k) + \omega^2\rho u_i = 0 \quad \text{in } \Omega,\ 1 \le i \le n.$$

It is clear to see that (1.5) is an anisotropic elasticity system. In this paper, we will investigate the (weak) unique continuation property (UCP) for the system (1.5); i.e., if $u \in H^2_{\mathrm{loc}}(\Omega)$ is a solution to (1.5) in Ω and vanishes in a nonempty open subset of Ω, then u vanishes identically in Ω.

The UCP for differential equations has a long history. Many deep results about scalar elliptic equations or elliptic systems have been established. We refer the reader to [3] and references therein for details. Recently, few attempts have been made at studying the UCP for systems of equations in mathematical physics such as the Dirac equations and the Maxwell equations [4], [15], [20], [23], [24]. Here we mention two interesting articles [24] and [20] in which Vogelsang and Ōkaji, respectively, proved the strong UCP for the Maxwell system with anisotropic coefficients. In this paper we pay attention to the elasticity system. Several results of weak continuation property for the inhomogeneous isotropic elasticity have been obtained in [1], [5] (stationary) and [6], [14] (nonstationary). Moreover, a strong UCP was recently proven by Alessandrini and Morassi [2]. Unlike the isotropic case, the UCP for the inhomogeneous anisotropic elasticity has not been fully explored.

Our study of the UCP for the inhomogeneous anisotropic elasticity is motivated by its application to inverse problems. It was first recognized by Lax [17] that the Runge approximation property is a consequence of the weak UCP. The Runge approximation property is shown to be a useful technique in dealing with some inverse

problems, especially the inverse problem of recovering inclusions or cavities (see [13], [9], [10], [11], [12], [16], and references therein). It should be noted that the Runge approximation property with constraint for the anisotropic elasticity were proved in [11] and [12]. However, the elasticity tensor there is assumed to be either homogeneous or real-analytic. The weak UCP is an obvious fact in these two situations.

To prove the UCP for the general inhomogeneous anisotropic elasticity is very challenging and difficult. Here we want to consider the system (1.5) which has the simplest form of anisotropy. It turns out we are able to establish the UCP for (1.5), provided the residual stress is sufficiently small. Our main idea comes from Weck's recent article [25], where he proved the UCP for the isotropic elasticity system with zeroth or first order perturbations which contains the results previous obtained by [1], [5]. Weck actually proved something more, namely, he established the UCP for a rather general system of second order differential inequalities with the Laplacian principal part. Like much of the literature on the UCP, the key step in [25] is to prove appropriate Carleman estimates. Here we will adopt Weck's approach to (1.5) with small residual stress, but we have to work a little harder to derive the desired Carleman estimates because we need to deal with variable coefficients second order principal parts due to the presence of residual stress. As indicated previously, having established the UCP, we can prove the Runge approximation property for (1.5) with constraints on Dirichlet data. With this tool at hand, we can solve the inverse problem of identifying inclusions or cavities inside an elastic body with small residual stress by the localized Dirichlet-to-Neumann map using the methods in [11] and [12].

This paper is organized as follows. In section 2, we state and prove the UCP for (1.5) with small residual stress based on suitable Carleman estimates. The derivation of these Carleman estimates is given in section 3. In section 4, we will discuss the application of UCP for (1.5) to the aforementioned inverse problem. In the paper, C stands for a generic constant, and its value may vary from line to line.

2. Unique continuation. To begin, let us denote $v_i = u_i$ for $1 \le i \le n$ and $v_{n+1} = \partial_i u_i$. Then, it follows from (1.5) that

$$
\begin{aligned}
0 &= (Lu)_i \\
&= (\tilde{\mu}\Delta + t_{kj}\partial_j\partial_k)v_i + (\tilde{\lambda}+\tilde{\mu})\partial_i v_{n+1} + (\partial_j t_{kj})\partial_k v_i + (\partial_i\tilde{\lambda})v_{n+1} \\
&\quad + (\partial_j\tilde{\mu})(\partial_i v_j + \partial_j v_i) + \omega^2\rho v_i \\
&= (\tilde{\mu}\Delta + t_{kj}\partial_j\partial_k)v_i + R_i^{(1)}(v_1,\dots,v_n,v_{n+1}) \quad \text{in } \Omega,\ 1 \le i \le n,
\end{aligned} \tag{2.1}
$$

where $R_i^{(1)}$'s are some first order differential operators. Next, by taking the divergence of (1.5), we obtain that

$$
\begin{aligned}
0 &= \partial_i(Lu)_i \\
&= ((\tilde{\lambda}+2\tilde{\mu})\Delta + t_{kj}\partial_j\partial_k)v_{n+1} + 2(\partial_i\tilde{\mu})\Delta v_i + (\partial_i t_{kj})\partial_j\partial_k v_i + 2\partial_i(\tilde{\lambda}+\tilde{\mu})\partial_i v_{n+1} \\
&\quad + (\partial_j t_{kj})\partial_k v_{n+1} + (\partial_i\partial_j t_{kj})\partial_k v_i + (\Delta\tilde{\lambda})v_{n+1} + (\partial_i\partial_j\tilde{\mu})(\partial_i v_j + \partial_j v_i) \\
&\quad + \omega^2(\partial_i\rho)v_i + \omega^2\rho v_{n+1} \\
&= ((\tilde{\lambda}+2\tilde{\mu})\Delta + t_{kj}\partial_j\partial_k)v_{n+1} + R^{(2)}(v_1,\dots,v_n) + R_{n+1}^{(1)}(v_1,\dots,v_{n+1}),
\end{aligned} \tag{2.2}
$$

where $R^{(2)}$ is a pure second order differential operator and $R^{(1)}_{n+1}$ is a first order differential operator, respectively. It should be mentioned that $R^{(2)}$ acts only on $v_1, \dots, v_n$. In view of (1.3), we can see that if

$$\max_{kj} \|t_{kj}\|_{L^\infty(\Omega)} < \varepsilon \tag{2.3}$$

with $\varepsilon \ll 1$, then

$$\tilde{\mu} > \delta' > 0 \quad \text{and} \quad \tilde{\lambda} + 2\tilde{\mu} > \delta' > 0 \quad \forall x \in \Omega.$$

With (2.1) and (2.2) in mind, motivated by Weck's paper [25], we will prove the UCP for the following system of differential inequalities:

$$\begin{aligned} &|A_1(x,\partial)u^1| \le CQ(u^1,u^2)^{1/2}, \\ &|A_2(x,\partial)u^2| \le C\left\{\sum_{ijk}|\partial_i\partial_j u^1_k| + Q(u^1,u^2)^{1/2}\right\}, \end{aligned} \tag{2.4}$$

where $u^l : \Omega \to \mathbb{R}^{m_l}, m_l \in \mathbb{Z}_+$(positive integers) and $A_l(x,\partial) = a^l_{ij}\partial_i\partial_j$ with real symmetric matrix (a^l_{ij}), $l = 1, 2$, and $Q(u^1,u^2) = \sum_{ikl}(|\partial_i u^l_k|^2 + |u^l_k|^2)$.

THEOREM 2.1. *Let $a^l_{ij} \in W^{1,\infty}(\Omega)$ and $(u^1,u^2) \in H^2_{loc}(\Omega)\times H^2_{loc}(\Omega)$ satisfy* (2.4). *Then there exists an $\varepsilon > 0$ such that if*

$$\max_{ij} \|a^l_{ij}(x) - \delta_{ij}\|_{L^\infty(\Omega)} < \varepsilon, \tag{2.5}$$

then (u^1,u^2) vanishes identically in Ω if it vanishes in a nonempty open subset of Ω.

Theorem 2.1 immediately implies the UCP for (1.5) with small residual stress.

COROLLARY 2.2. *Let coefficients $\lambda, \mu, \beta_1, \beta_2, t_{kj}$ belong to $W^{2,\infty}(\Omega)$, and let ρ be in $W^{1,\infty}(\Omega)$. Then there exists an $\varepsilon > 0$ such that if* (2.3) *is satisfied with this ε, then the system* (1.5) *possesses the UCP.*

The proof of Theorem 2.1 relies on the following Carleman estimates.

PROPOSITION 2.3. *Assume that the differential operators A_1 and A_2 satisfy the assumptions in Theorem* 2.1. *Let $r_0 < 1$ and $U_{r_0} = \{u \in C^\infty_0(\mathbb{R}^n \setminus \{0\}) : \operatorname{supp}(u) \subset B_{r_0}\}$, where B_{r_0} is the ball centered at the origin with radius r_0. Then there exist positive constants β_0 and ε_0 such that if* (2.5) *is satisfied with $\varepsilon \le \varepsilon_0$, then for all $\beta \ge \beta_0$ and $u \in U_{r_0}$ we have that*

$$\int r^{-\sigma}\psi^2 \sum_{ij}|\partial_i\partial_j u|^2 dx \le C\int r^{-\sigma}\psi^2(\beta^2 r^{-2\beta-2}|\nabla u|^2 + |A_l u|^2)dx \tag{2.6}$$

and

$$\beta^2\int r^{-\sigma-\beta-1}\psi^2(|\nabla u|^2 + |u|^2)dx \le C\int r^{-\sigma}\psi^2|A_l u|^2 dx \tag{2.7}$$

for $l = 1, 2$, where $r = |x|$, $\psi = \exp(r^{-\beta})$, and $\sigma = \sigma_0 + c\beta$ with $\sigma_0, c \in \mathbb{R}$.

The proof of Proposition 2.3 is postponed until the next section. Here we want to prove Theorem 2.1 based on this proposition.

Proof of Theorem 2.1. It suffices to prove the theorem for the case $m_1 = m_2 = 1$. Let (u^1,u^2) vanish in a neighborhood of $x_0 \in \Omega$. Without loss of generality, we assume

$x_0 = 0$. We set $\tilde{r} = \min\{1/2, \mathrm{dist}(0, \partial\Omega)\}$. Now let $\chi \in C_0^\infty(\mathbb{R}^n)$ be a cut-off function satisfying $0 \le \chi \le 1$, $\chi|_{B_{\tilde{r}/2}} = 1$, and $\mathrm{supp}(\chi) \subset B_{\tilde{r}}$. Denote $v_l = \chi u^l$, $l = 1, 2$. From (2.4) we have that

$$
\begin{aligned}
&|A_1 v_1| \le C(e(v_1) + e(v_2))^{1/2} + f_1, \\
&|A_2 v_2| \le C\left[\sum_{ij} |\partial_i \partial_j v_1| + (e(v_1) + e(v_2))^{1/2}\right] + f_2,
\end{aligned} \tag{2.8}
$$

where $e(v) = |\nabla v|^2 + |v|^2$ and f_l is supported in $B_{\tilde{r}} \setminus B_{\tilde{r}/2}$ for $l = 1, 2$. It follows from (2.8) that

(2.9)
$$
I := \gamma \int r^{-\beta} \psi^2 |A_1 v_1|^2 dx + \int r \psi^2 |A_2 v_2|^2 dx \le C\left(F + G + \int r\psi^2 \sum_{ij} |\partial_i \partial_j v_1|^2 dx\right),
$$

where

$$
\begin{aligned}
F &= \gamma \int r^{-\beta} \psi^2 f_1^2 dx + \int r \psi^2 f_2^2 dx, \\
G &= \int (r + \gamma r^{-\beta}) \psi^2 (e(v_1) + e(v_2)) dx.
\end{aligned}
$$

Here γ is a large positive parameter which will be chosen later on. By the standard approximation argument, we can see that v_1 and v_2 satisfy estimates (2.6) and (2.7). Taking $\sigma = -1$ in the estimate (2.6) for $l = 1$ and substituting it into (2.9) yield

$$
I \le C\left(F + G + \int r\psi^2 |A_1 v_1|^2 dx + \beta^2 \int r^{-2\beta - 1} \psi^2 |\nabla v_1|^2 dx\right). \tag{2.10}
$$

Replacing the last term of (2.10) with the help of (2.7) for $\sigma = \beta$ and $l = 1$, we obtain that

$$
I \le C\left(F + G + \int r^{-\beta} \psi^2 |A_1 v_1|^2 dx\right). \tag{2.11}
$$

Now taking γ sufficiently large, we can absorb the last term of (2.11) and get

$$
I \le C(F + G). \tag{2.12}
$$

From now on we fix the parameter γ.

Next using $\sigma = \beta$ in (2.7) for $l = 1$ and $\sigma = -1$ in (2.7) for $l = 2$, we find that

$$
\begin{aligned}
H &:= \beta^2 \int r^{-2\beta - 1} \psi^2 e(v_1) dx + \beta^2 \int r^{-\beta} \psi^2 e(v_2) dx \\
&\le C\left(\int r^{-\beta} \psi^2 |A_1 v_1|^2 dx + \int r \psi^2 |A_2 v_2|^2 dx\right).
\end{aligned} \tag{2.13}
$$

Combining (2.12) and (2.13) gives

$$
H \le C(F + G) \le C\left(F + \int (r + \gamma r^{-\beta}) \psi^2 (e(v_1) + e(v_2)) dx\right). \tag{2.14}
$$

Now observing that $r < r^{-\beta} < \beta r^{-\beta} < \beta r^{-2\beta-1}$ when $r \le \tilde{r}$ and $\beta > 1$, we obtain from (2.14) that

$$H \le C\left(F + \beta \int r^{-2\beta-1}\psi^2 e(v_1)dx + \beta \int r^{-\beta}\psi^2 e(v_2)dx\right). \tag{2.15}$$

Taking β sufficiently large in (2.15), we get that

$$H \le CF,$$

i.e.,

$$\beta^2 \int r^{-2\beta-1}\psi^2 e(v_1)dx + \beta^2 \int r^{-\beta}\psi^2 e(v_2)dx \le C\left(\int r^{-\beta}\psi^2 f_1^2 dx + \int r\psi^2 f_2^2 dx\right),$$

from which we immediately have

$$\beta^2 \int_{B_{\tilde{r}/2}} r^{-\beta}\psi^2(v_1^2 + v_2^2)dx \le C \int_{B_{\tilde{r}}\setminus B_{\tilde{r}/2}} r^{-\beta}\psi^2(f_1^2 + f_2^2)dx. \tag{2.16}$$

Since $r^{-\beta}\psi^2$ is a strictly decreasing function, (2.16) implies that

$$\beta^2 \int_{B_{\tilde{r}/2}} (v_1^2 + v_2^2)dx \le C \int_{B_{\tilde{r}}\setminus B_{\tilde{r}/2}} (f_1^2 + f_2^2)dx,$$

and therefore $(v_1, v_2) = 0$ on $B_{\tilde{r}/2}$ if we choose β sufficiently large. Clearly, (u^1, u^2) must be zero throughout Ω. □

3. Proof of Carleman estimates. This section is devoted to the proof of Proposition 2.3. It suffices to prove (2.6) and (2.7) for A_1. Therefore, we denote $a_{ij}^1 = a_{ij}$ and $A_1 = A$. To prove (2.6), we first recall the following estimate in [25]:

$$\int r^{-\sigma}\psi^2 \sum_{ij} |\partial_i\partial_j u|^2 dx \le C \int r^{-\sigma}\psi^2(\beta^2 r^{-2\beta-2}|\nabla u|^2 + |\Delta u|^2)dx$$

(see [25, Lemma 2]), from which we have that

$$\begin{aligned}\int r^{-\sigma}\psi^2 \sum_{ij} |\partial_i\partial_j u|^2 dx &\le C \int r^{-\sigma}\psi^2(\beta^2 r^{-2\beta-2}|\nabla u|^2 + |Au|^2 + |\Delta u - Au|^2)dx \\ &\le C \int r^{-\sigma}\psi^2\left(\beta^2 r^{-2\beta-2}|\nabla u|^2 + |Au|^2 + \varepsilon^2 \sum_{ij} |\partial_i\partial_j u|^2\right)dx.\end{aligned}$$

Thus, choosing ε small enough immediately implies the estimate (2.6).

The proof of (2.7) is lengthy. Here we will adopt some techniques from [21], [25], and [26]. Let $\phi = \psi^{-1}$ and $u = r^{\tau/2}\phi z$. Then

$$\begin{aligned} r^{-\sigma/2}\psi Au &= r^{-\sigma/2}\psi A(r^{\tau/2}\phi z) \\ &= r^{-\sigma/2}\psi[r^{\tau/2}\phi Az + 2a_{ij}\partial_i z\partial_j(r^{\tau/2}\phi) + zA(r^{\tau/2}\phi)].\end{aligned}$$

By virtue of the inequality $(a+b+c)^2 \ge 2ab + 2bc$, we have that

$$\begin{aligned}\int r^{-\sigma}\psi^2|Au|^2 dx &\ge 4\int r^{-\sigma}\psi^2 a_{ij}\partial_i z\partial_j(r^{\tau/2}\phi)r^{\tau/2}\phi Az dx \\ &\quad + 4\int r^{-\sigma}\psi^2 a_{ij}\partial_i z\partial_j(r^{\tau/2}\phi)zA(r^{\tau/2}\phi)dx.\end{aligned} \tag{3.1}$$

With the choice of $\tau = \sigma + \beta + 2$, we can compute

$$\begin{aligned} I &:= \int r^{-\sigma}\psi^2 a_{ij}\partial_i z \partial_j (r^{\tau/2}\phi) r^{\tau/2}\phi A z dx \\ &= \beta \int a_{ij}\partial_i z x_j A z dx + \tau/2 \int r^{\beta} a_{ij}\partial_i z x_j A z dx. \end{aligned}$$

It is readily seen that the leading term (for large β) of I is $\beta \int a_{ij}\partial_i z x_j A z dx$. Repeated integration by parts shows that

$$\begin{aligned} 2\int a_{ij}\partial_i z x_j A z dx &= 2\int a_{ij}\partial_i z x_j a_{kl}\partial_k\partial_l z dx \\ &= -\int \partial_i z \partial_l (a_{kl}a_{ij}x_j)\partial_k z dx + \int \partial_k z \partial_i (a_{kl}a_{ij}x_j)\partial_l z dx \\ &\quad - \int \partial_l z \partial_k (a_{kl}a_{ij}x_j)\partial_i z dx. \end{aligned} \tag{3.2}$$

Using (3.2), we obtain that

$$\begin{aligned} |I| &\le C\beta \left| \int \partial_i z \partial_l (a_{kl}a_{ij}x_j)\partial_k z dx \right| \\ &\le C\beta \|\nabla z\|^2 \\ &\le C\beta (\|\nabla (r^{-\tau/2}\psi)u\|^2 + \|r^{-\tau/2}\psi \nabla u\|^2) \\ &\le C\left(\beta^3 \int r^{-\sigma-3\beta-4}\psi^2 |u|^2 dx + \beta \int r^{-\sigma-\beta-2}\psi^2 |\nabla u|^2 dx\right). \end{aligned} \tag{3.3}$$

Next we observe that

$$\begin{aligned} J &:= \int r^{-\sigma}\psi^2 a_{ij}\partial_i z \partial_j (r^{\tau/2}\phi) z A (r^{\tau/2}\phi) dx \\ &= \beta \int r^{-\sigma+\tau/2-\beta-2}\psi a_{ij}\partial_i z x_j z A (r^{\tau/2}\phi) dx \\ &\quad + \tau/2 \int r^{-\sigma+\tau/2-2}\psi a_{ij}\partial_i z x_j z A (r^{\tau/2}\phi) dx. \end{aligned}$$

Straightforward calculations show that

$$\partial_i\partial_j \phi = (\beta^2 x_i x_j r^{-2\beta-4} + \beta\delta_{ij} r^{-\beta-2} - \beta(\beta+2) x_i x_j r^{-\beta-4})\phi$$

and

$$\partial_i\partial_j r^{\tau/2} = (\tau/2)(\tau/2-2) r^{\tau/2-4} x_i x_j + (\tau/2) r^{\tau/2-2}\delta_{ij}.$$

So the leading term of J is

$$\beta^3 \int r^{-2\beta-4} a_{ij}\partial_i z x_j a_{kl} x_k x_l z dx.$$

Note that we have chosen $\tau = \sigma + \beta + 2$. Performing the integration by parts, we can

see that

$$\begin{aligned}
&\beta^3 \int r^{-2\beta-4} a_{ij}\partial_i z x_j a_{kl} x_k x_l z dx \\
&= -\frac{1}{2}\beta^3 \int z\partial_i (r^{-2\beta-4} a_{ij} x_j a_{kl} x_k x_l) z dx \\
&\geq (1-o(\beta))\beta^4 \int r^{-2\beta-6} a_{ij} x_i x_j a_{kl} x_k x_l |z|^2 dx \\
&\geq (1-o(\beta))\beta^4 (1-O(\varepsilon)) \int r^{-2\beta-2} |z|^2 dx \\
&\geq (1-o(\beta))\beta^4 (1-O(\varepsilon)) \int r^{-\sigma-3\beta-4} \psi^2 |u|^2 dx,
\end{aligned}$$

where $0 \leq o(\beta) \to 0$ as $\beta \to \infty$ and $O(\varepsilon)$ is a positive constant bounded by $C\varepsilon$. In other words, we have that

$$J \geq (1-o(\beta))\beta^4 (1-O(\varepsilon)) \int r^{-\sigma-3\beta-4} \psi^2 |u|^2 dx. \tag{3.4}$$

Notice that we need to keep track of the leading constant here in order to obtain the desired estimate. Combining (3.1), (3.3), and (3.4) gives

$$\begin{aligned}
&\int r^{-\sigma}\psi^2 |Au|^2 dx + C\left(\beta^3 \int r^{-\sigma-3\beta-4}\psi^2 |u|^2 dx + \beta \int r^{-\sigma-\beta-2}\psi^2 |\nabla u|^2 dx\right) \\
&\geq 4(1-o(\beta))\beta^4 (1-O(\varepsilon)) \int r^{-\sigma-3\beta-4}\psi^2 |u|^2 dx,
\end{aligned}$$

from which we can derive that

$$\begin{aligned}
&\int r^{-\sigma}\psi^2 |Au|^2 dx + C\beta \int r^{-\sigma-\beta-2}\psi^2 |\nabla u|^2 dx \\
&\qquad \geq 4(1-o(\beta))\beta^4 (1-O(\varepsilon)) \int r^{-\sigma-3\beta-4}\psi^2 |u|^2 dx.
\end{aligned} \tag{3.5}$$

By the ellipticity condition and performing the integration by parts, we can get that

$$\begin{aligned}
&(1-O(\varepsilon)) \int r^{-\sigma-\beta-2}\psi^2 |\nabla u|^2 dx \\
&\leq \int r^{-\sigma-\beta-2}\psi^2 a_{ij}\partial_i u \partial_j u dx \\
&\leq \left| \int u\partial_i (r^{-\sigma-\beta-2}\psi^2) a_{ij}\partial_j u dx \right| + \left| \int r^{-\sigma-\beta-2}\psi^2 u \partial_i (a_{ij})\partial_j u dx \right| \\
&\quad + \left| \int r^{-\sigma-\beta-2}\psi^2 u a_{ij}\partial_i\partial_j u dx \right| \\
&:= K_1 + K_2 + K_3.
\end{aligned} \tag{3.6}$$

Using the relation $|ab| \le (a^2+b^2)/2$, we can estimate

$$
\begin{aligned}
K_1 &= \left| \int u \partial_i (r^{-\sigma-\beta-2}\psi^2) a_{ij} \partial_j u dx \right| \\
&\le \int (2+o(\beta))\beta r^{-\sigma-2\beta-4}\psi^2 |u a_{ij} x_i \partial_j u| dx \\
&\le (2+o(\beta))\beta^2(1+O(\varepsilon)) \int r^{-\sigma-3\beta-4}\psi^2 |u|^2 dx \\
&\quad + (1+O(\varepsilon))/2 \int r^{-\sigma-\beta-2}\psi^2 |\nabla u|^2 dx.
\end{aligned} \tag{3.7}
$$

Likewise, for K_2 and K_3, we have that

$$
K_2 \le C \left(r_0^\beta \int r^{-\sigma-3\beta-4}\psi^2 |u|^2 dx + r_0^{\beta+2} \int r^{-\sigma-\beta-2}\psi^2 |\nabla u|^2 dx \right) \tag{3.8}
$$

and

$$
K_3 \le C \left(r_0^\beta \beta^2 \int r^{-\sigma-3\beta-4}\psi^2 |u|^2 dx + \beta^{-2} \int r^{-\sigma}\psi^2 |Au|^2 dx \right). \tag{3.9}
$$

Plugging (3.7), (3.8), and (3.9) into (3.6) and multiplying the new inequality by β^2, we obtain that

$$
\begin{aligned}
&\beta^2(1-O(\varepsilon)) \int r^{-\sigma-\beta-2}\psi^2 |\nabla u|^2 dx \\
&\le (2+o(\beta))\beta^4(1+O(\varepsilon)) \int r^{-\sigma-3\beta-4}\psi^2 |u|^2 dx + \beta^2(1+O(\varepsilon))/2 \int r^{-\sigma-\beta-2}\psi^2 |\nabla u|^2 dx \\
&\quad + C \left(r_0^\beta \beta^2 \int r^{-\sigma-3\beta-4}\psi^2 |u|^2 dx + r_0^{\beta+2}\beta^2 \int r^{-\sigma-\beta-2}\psi^2 |\nabla u|^2 dx \right) \\
&\quad + C \left(r_0^\beta \beta^4 \int r^{-\sigma-3\beta-4}\psi^2 |u|^2 dx + \int r^{-\sigma}\psi^2 |Au|^2 dx \right).
\end{aligned} \tag{3.10}
$$

Adding (3.10) to (3.5) and taking β sufficiently large and ε small enough, we conclude that

$$
\beta^4 \int r^{-\sigma-3\beta-4}\psi^2 |u|^2 dx + \beta^2 \int r^{-\sigma-\beta-2}\psi^2 |\nabla u|^2 dx \le C \int r^{-\sigma}\psi^2 |Au|^2 dx,
$$

which immediately implies (2.7).

4. Applications to inverse problems. In this section we will discuss the application of the UCP for (1.5) to the inverse problem of identifying inclusions or cavities by boundary measurements. To begin, assume that D is an open subset of Ω with Lipschitz boundary such that $\Omega \setminus \bar{D}$ is connected. The domain D stands forthe region of the inclusion or cavity embedded in Ω. Let the reference elasticity tensor $\mathbb{C}(x)$ with components $C_{ijkl}(x)$ be defined by (1.6), i.e.,

$$
C_{ijkl} = \tilde{\lambda}\delta_{ij}\delta_{kl} + (\tilde{\mu}\delta_{jl} + t_{jl})\delta_{ik} + \tilde{\mu}\delta_{il}\delta_{jk},
$$

where $\tilde{\lambda} = \lambda + \beta_1(\mathrm{tr}T)$ and $\tilde{\mu} = \mu + (1/2)\beta_2(\mathrm{tr}T)$. Here we require that the Lamé moduli satisfy the strong convexity condition

$$
\mu(x) > \delta > 0 \quad \text{and} \quad n\lambda(x) + 2\mu(x) > \delta > 0 \quad \forall\, x \in \Omega \tag{4.1}
$$

and T satisfies

$$ET \cdot E \geq (\varepsilon/2)|E|^2,$$

which is equivalent to

$$\mathbb{C}(x)E \cdot E \geq \kappa E_{ij}E_{ij} = \kappa|E|^2, \quad \kappa(\varepsilon) > 0, \ \forall\ x \in \Omega \tag{4.2}$$

for all matrices E, provided that ε in (2.3) is sufficiently small. It is obvious that (4.1) implies (1.3). Next we assume that $\tilde{\mathbb{C}}$ is some fourth-rank tensor such that $\mathbb{C} + \chi_D\tilde{\mathbb{C}}$ satisfies the strong convexity condition (4.2), where χ_D denotes the characteristic function of D. Moreover, suppose that $\tilde{\mathbb{C}}$ satisfies the jump condition

(4.3)
$$\forall\ x \in \partial D, \ \exists\ C_x > 0, \ \exists\ \delta_x > 0 \text{ such that } \tilde{\mathbb{C}}(y)E \cdot E \geq C_x|E|^2 \text{ or } \tilde{\mathbb{C}}(y)E \cdot E \leq -C_x|E|^2$$

for almost all $y \in B_{\delta_x}(x) \cap D$ and all real matrices E. Let all components of $\mathbb{C}(x)$ and $\tilde{\mathbb{C}}(x)$ be in $L^\infty(\Omega)$. Then it is easy to show that there exists a unique solution $u \in H^1(\Omega)$ to

$$\begin{cases} \nabla \cdot ((\mathbb{C} + \chi_D\tilde{\mathbb{C}})\nabla u) = 0 & \text{in } \Omega, \\ u = f & \text{on } \partial\Omega \end{cases}$$

for any $f \in H^{1/2}(\partial\Omega)$. In this case, the domain D is an inclusion. So we can define the Dirichlet-to-Neumann (displacement-to-traction) map $\Lambda_I : H^{1/2}(\partial\Omega) \to H^{-1/2}(\partial\Omega)$ by

$$\Lambda_I(f) = (\mathbb{C}\nabla u)\nu|_{\partial\Omega}.$$

Equivalently, Λ_I can be defined by the formula

$$\langle \Lambda_I(f), g\rangle = \int_\Omega (\mathbb{C} + \chi_D\tilde{\mathbb{C}})\nabla u \cdot \nabla v dx,$$

where $v \in H^1(\Omega)$ with $v|_{\partial\Omega} = g$. We are interested in the following inverse problem:

IP.A. *Reconstruct the inclusion D from the knowledge of $\Lambda_I(f)_{\Gamma_0}$ for infinitely many $f \in H^{1/2}(\partial\Omega)$ with $\operatorname{supp}(f) \subset \Gamma_0$, where Γ_0 is a nonempty subset of $\partial\Omega$.*

Likewise, in the extreme case, if the tensor $\tilde{\mathbb{C}}$ becomes $-\mathbb{C}$, then the domain D corresponds to a cavity. In the same way, we can prove that there exists a unique solution $u \in H^1(\Omega \setminus \bar{D})$ to the boundary value problem

$$\begin{cases} \nabla \cdot (\mathbb{C}\nabla u) = 0 & \text{in } \Omega \setminus \bar{D}, \\ (\mathbb{C}\nabla u)\nu = 0 & \text{on } \partial D, \quad (\mathbb{C}\nabla u)\nu = g \quad \text{on } \partial\Omega \end{cases}$$

for any $g \in H^{1/2}(\partial\Omega)$. Therefore, we can define the Dirichlet-to-Neumann map $\Lambda_C : H^{1/2}(\partial\Omega) \to H^{-1/2}(\partial\Omega)$ by

$$\Lambda_C(g) = (\mathbb{C}\nabla u)\nu|_{\partial\Omega}.$$

Similarly, we will consider the following inverse problem:

IP.B. *Reconstruct the cavity D from the knowledge of $\Lambda_C(g)|_{\Gamma_0}$ for infinitely many g with $\operatorname{supp}(g) \subset \Gamma_0$.*

Note that uniqueness theorems of determining the inclusion or cavity embedded in an elastic body have been established in [11] and [12], where the reference medium is assumed to be either inhomogeneous isotropic or anisotropic with homogeneous or analytic elasticity tensors. Besides, a reconstruction algorithm for recovering the cavity is given in [12]. A similar algorithm can be developed for the inclusion case. Here we want to extend their results to the elasticity system with residual stress (1.5). To this end, we will need the Runge approximation property with constraint for (1.5), which is a consequence of the UCP (see Corollary 2.2). Its proof can be found in [12].

PROPOSITION 4.1. *Assume that all coefficients of* $\mathbb{C}$ *are in* $W^{2,\infty}(\Omega)$ *and the residual stress satisfies* (2.3) *with* ε *given in Corollary* 2.2. *Let* U *and* Ω *be two open bounded domains with Lipschitz and* C^2 *boundaries, respectively, such that* $\bar{U} \subset \Omega$. *Denote* Γ_0 *a subset of the boundary* $\partial\Omega$. *Let* $u \in H^1(U)$ *satisfy*

$$\nabla \cdot (\mathbb{C}\nabla u) = 0 \quad \text{in} \quad U.$$

Then for any compact subset $K \subset U$ *such that* $\Omega \setminus K$ *is connected and any* $\tilde{\varepsilon} > 0$ *there exists* $w \in H^1(\Omega)$ *satisfying*

$$\nabla \cdot (\mathbb{C}\nabla w) = 0 \quad \text{in} \quad \Omega$$

with $\operatorname{supp}(w|_{\partial\Omega}) \subset \Gamma_0$ *such that*

$$\|w - u\|_{H^1(K)} < \tilde{\varepsilon}.$$

Remark. The reason for using C^2 boundary on Ω is that we want to extend all coefficients of $\mathbb{C}$ into a larger domain $\tilde{\Omega}$ and the newly extended coefficients have the same regularity $W^{2,\infty}$ in $\tilde{\Omega}$.

Having the Runge approximation property Proposition 4.1 at hand, we now can apply the methods in [11] and [12] to solve IP.A and IP.B. It should be pointed out that the reference elasticity tensor in [11] and [12] satisfies the full symmetry properties, i.e.,

$$C_{ijkl} = C_{klij} = C_{jikl}.$$

Nevertheless, it is not hard to check that the proofs in [11] and [12] are still valid if we only assume $C_{ijkl} = C_{klij}$, which is the case for the elasticity system with residual stress (1.5). For IP.A, we prove the following theorem (see [11]).

THEOREM 4.2 (identification of inclusion). *Let the domain* Ω *have* C^2 *boundary. Assume that the elasticity tensor* $\mathbb{C}$ *given by* (1.6) *possesses* $W^{2,\infty}(\Omega)$ *coefficients satisfying* (4.1). *Furthermore, the residual stress tensor* T *in* $\mathbb{C}$ *satisfies the smallness condition described in Corollary* 2.2. *Let* $(D_1, \tilde{\mathbb{C}}_1)$ *and* $(D_2, \tilde{\mathbb{C}}_2)$ *be two inclusions such that* $\mathbb{C} + \chi_{D_i}\tilde{\mathbb{C}}_i$ *and* $\tilde{\mathbb{C}}_i$ *satisfy* (4.2) *and* (4.3), *respectively, and* $\Omega \setminus \bar{D}_i$ *is connected,* $i = 1, 2$. *If*

$$\Lambda_{I_1}(f) = \Lambda_{I_2}(f) \quad \text{on} \quad \Gamma_0$$

for all $f \in H^{1/2}(\partial\Omega)$ *with* $\operatorname{supp}(f) \subset \Gamma_0$, *then*

$$D_1 = D_2.$$

The proof of Theorem 4.2 is based on integral inequalities

$$\int_D \{\mathbb{C}^{-1} - (\mathbb{C} + \tilde{\mathbb{C}})^{-1}\}\mathbb{C}\nabla w \cdot \mathbb{C}\nabla w dx \le \langle (\Lambda_I - \Lambda_0)f, f\rangle \le \int_D \tilde{\mathbb{C}}\nabla w \cdot \nabla w dx, \tag{4.4}$$

where $w \in H^1(\Omega)$ solves

$$\begin{cases} \nabla \cdot (\mathbb{C}\nabla w) = 0 \quad \text{in} \quad \Omega, \\ w|_{\partial\Omega} = f. \end{cases} \tag{4.5}$$

Here $\mathbb{C}^{-1}$ (or $(\mathbb{C}+\tilde{\mathbb{C}})^{-1}$) is called the compliance tensor (see, e.g., [7]). Notice that we do not assume $\tilde{\mathbb{C}}_1 = \tilde{\mathbb{C}}_2$ in Theorem 4.2. Also, the regularity of the medium inside of the inclusions is only assumed to be essentially bounded. Theorem 4.2 provides the uniqueness of determining the inclusion embedded in an elastic body with small residual stress by the localized Dirichlet-to-Neumann map. For the sake of completeness, we want to briefly describe a reconstruction algorithm for identifying the inclusion. Let $y \in \Omega$ and $G_0(\cdot; y)$ be the fundamental solution for the operator $\nabla \cdot \mathbb{C}(y)\nabla$ (see, e.g., [19]). One can find $e(\cdot; y)$ such that

$$\nabla \cdot (\mathbb{C}(x)\nabla e(\cdot; y)) = 0 \quad \text{in} \quad \Omega \setminus \{y\}$$

and

$$(e(\cdot; y) - G_0(\cdot - y; y)b)_{y\in\Omega} \quad \text{is bounded in } H^1(\Omega),$$

where b is a nonzero constant vector. Note that if $y \in \partial D$, then

$$\int_{D\cap B_r(y)} |\nabla\{G_0(x-y;y)b\}|^2 dx = \infty \tag{4.6}$$

for any ball $B_r(y)$ centered at y with radius r and nonzero vector b. The symmetric version of (4.6) has been proved in [11], i.e.,

$$\int_{D\cap B_r(y)} |Sym\nabla\{G_0(x-y;y)b\}|^2 dx = \infty,$$

which clearly implies (4.6).

A continuous map $c : [0,1] \to \bar{\Omega}$ is called a *needle* if it satisfies (i) $c(0), c(1) \in \partial\Omega$; (ii) $c(t) \in \Omega$ for $0 < t < 1$. In view of Proposition 4.1, we can see that for each needle and $t \in (0,1)$, there exists a sequence $\{f_j\} = \{f_j(\cdot; c(t))\}$ in $H^{1/2}(\partial\Omega)$ with $\text{supp}(f_j) \subset \Gamma_0$ such that the solution w_j of (4.5) with $f = f_j$ satisfies $w_j \to e(\cdot; c(t))$ in $H^1_{loc}(\Omega \setminus \{c(t') : 0 < t' \le t\})$ as $j \to \infty$. We call $\{f_j\}$ a fundamental sequence with respect to Γ_0. For each needle c, define

$$t(c) = \sup\{0 < s < 1 : C(t) \in \Omega \setminus \bar{D} \ (0 < t < s)\}.$$

It should be noted that $0 < t(c) \le 1$, and if $t(c) = 1$, then c never touches ∂D. On the other hand, if $t(c) < 1$, then c touches ∂D at $t = t(c)$ at the first time. Since $\Omega \setminus \bar{D}$ is connected, we have that

$$\partial D = \{c(t(c)) : c \text{ is a needle and } t(c) < 1\}. \tag{4.7}$$

Let Λ_0 be the Dirichlet-to-Neumann map associated with the boundary value problem (4.5). Denote

$$\mathcal{I}_I(t,c) = \lim_{j\to\infty} \langle (\Lambda_I - \Lambda_0) f_j(\cdot; c(t)), f_j(\cdot; c(t)) \rangle$$

and

$$\mathcal{T}_I(c) = \left\{ 0 < s < 1 : \mathcal{I}_I \text{ exists } \forall\ 0 < t < s \text{ and } \sup_{0<t<s} |\mathcal{I}_I(t,c)| < \infty \right\}.$$

Using (4.3), (4.4), and (4.6) and pursuing the arguments in [11], we can show that $\mathcal{T}_I(c) = (0, t(c))$, and therefore $t(c) = \sup \mathcal{T}_I(c)$ (see similar arguments in [12]). In summary, we have a reconstruction algorithm for determining the inclusion as follows.

Reconstruction algorithm for IP.A.

(i) *For each needle c and each $t \in (0,1)$, find the fundamental sequence $\{f_j(\cdot; c(t))\}$ with respect to Γ_0.*

(ii) *Compute $\mathcal{T}_I(c)$ and set $t(c) = \sup \mathcal{T}_I(c)$.*

(iii) *Use the formula* (4.7) *to reconstruct ∂D.*

Now for IP.B, we show the following (see [12]).

Theorem 4.3 (identification of cavity). *Let the assumptions in Theorem* 4.2 *on Ω and $\mathbb{C}$ hold. Assume that D_1 and D_2 are two cavities and $\Omega \setminus \bar{D}_1$ and $\Omega \setminus \bar{D}_2$ are connected. Let*

$$\Lambda_{C_1}(f) = \Lambda_{C_2}(f) \quad \text{on} \quad \Gamma_0$$

for all $f \in H^{1/2}(\partial\Omega)$ with $\operatorname{supp}(f) \subset \Gamma_0$. Then $D_1 = D_2$.

As for reconstructing the cavity, we follow the lines of the above algorithm and define

$$\mathcal{I}_C(t,c) = \lim_{j\to\infty} \langle (\Lambda_0 - \Lambda_C) f_j(\cdot; c(t)), f_j(\cdot; c(t)) \rangle$$

and

$$\mathcal{T}_C(c) = \left\{ 0 < s < 1 : \mathcal{I}_C \text{ exists } \forall\ 0 < t < s \text{ and } \sup_{0<t<s} \mathcal{I}_C(t,c) < \infty \right\}.$$

Note that $\langle (\Lambda_0 - \Lambda_C) f, f \rangle \geq 0$ for all $f \in H^{1/2}(\partial\Omega)$. Now using (4.6) and the inequalities

$$\frac{1}{M} \int_D |\nabla e(x; c(t))|^2 dx \leq \mathcal{I}_C(t,c) \leq M \int_D |\nabla e(x; c(t))|^2 dx$$

for some constant $M > 0$, one can prove that $\mathcal{T}_C(c) = (0, t(c))$ and thus $t(c) = \sup \mathcal{T}_C(c)$ (see the arguments in [12]). So a reconstruction algorithm for identifying the cavity is described as follows.

Reconstruction algorithm for IP.B.

(i) *For each needle c and each $t \in (0,1)$, find the fundamental sequence $\{f_j(\cdot; c(t))\}$ with respect to Γ_0.*

(ii) *Compute $\mathcal{T}_C(c)$ and set $t(c) = \sup \mathcal{T}_C(c)$.*

(iii) *Use the formula* (4.7) *to reconstruct ∂D.*

Acknowledgment. The authors would like to thank MSRI for providing a very stimulating research environment and partial financial support.

INSTABILITY OF SOME IDEAL PLANE FLOWS*

ZHIWU LIN†

Abstract. We prove the instability of large classes of steady states of the two-dimensional Euler equation. For an odd shear flow, beginning with the Rayleigh equation, we define a family of operators depending on some positive parameter. Then we use infinite determinants to keep track of the signs of the eigenvalues of these operators. The existence of purely growing modes follows from a continuation argument. Employing a new analysis of neutral modes together with a rigorous justification of Tollmien's classical method, we obtain a sharp condition for linear and hence nonlinear instability of a general class of bounded shear flows. We obtain similar results for bounded rotating flows and unbounded shear flows.

Key words. Rayleigh's equation, neutral limiting mode, shear flow instability

1. Introduction. In this paper, we study the hydrodynamic stability problem for plane shear flows and rotating flows. The purpose is to get some sufficient conditions for linear instability and hence nonlinear instability. For plane shear flows, this problem has a long history, going back to scientists such as Rayleigh and Kelvin in the nineteenth century. The vorticity form of the incompressible two-dimensional Euler equation in a bounded domain D with smooth boundary ∂D is

$$\partial_t \omega + u \cdot \bigtriangledown \omega = 0 \quad \text{in } \mathbf{R}_t \times D$$

or

$$\partial_t \Delta\psi + \frac{\partial \psi}{\partial y}\frac{\partial}{\partial x}\Delta\psi - \frac{\partial \psi}{\partial x}\frac{\partial}{\partial y}\Delta\psi = 0, \tag{1}$$

where ψ is the stream function, $\omega = -\Delta\psi$ is the vorticity, and $u = (\frac{\partial \psi}{\partial y}, -\frac{\partial \psi}{\partial x})$ is the velocity. We consider the basic steady state flow $\mathbf{U}_0 = U(y)\,\mathbf{i}$, a parallel shear flow in the x-direction, in the flow domain $D = \{(x,y) \mid y_1 \le y \le y_2\}$ with rigid walls at $y = y_1, y_2$. This means u is tangential, or ψ is constant on each wall. The linearized equation of (1) around $\mathbf{U}_0$ is

$$\partial_t \Delta\tilde{\psi} + U\frac{\partial}{\partial x}\Delta\tilde{\psi} - U''\frac{\partial \tilde{\psi}}{\partial x} = 0, \tag{2}$$

where $\tilde{\psi}$ is constant on $y = y_j$ $(j = 1, 2)$. Taking $\tilde{\psi} = \phi(y)\, e^{i\alpha(x-ct)}$ with α the wave number (positive real) in the x-direction and $c = c_r + ic_i$ the complex wave speed, we obtain from (2) the Rayleigh equation

$$(U - c)\left(\frac{d^2}{dy^2} - \alpha^2\right)\phi - U''\phi = 0 \tag{3}$$

*Received by the editors April 24, 2002; accepted for publication (in revised form) January 31, 2003; published electronically July 18, 2003.

with $\phi(y_1) = \phi(y_2) = 0$. We will also consider unbounded shear flows where one of y_1, y_2 is infinity, with the boundary condition $\phi(y) \to 0$ as $y \to \infty$.

So for shear flows, the instability problem is reduced to studying the Rayleigh equation (3). The flow is linearly unstable if some nontrivial solution to (3) with $c_i > 0$ exists. A classical result of Lord Rayleigh [16] is the necessary condition for instability that the basic velocity profile should have an inflection point at some point $y = y_s$, that is, $U''(y_s) = 0$. This condition was later improved by Fjørtoft [10]. Howard's semicircle theorem [14] says that any unstable eigenvalue $c = c_r + ic_i$ must lie in the semicircle

$$\left(c_r - \frac{1}{2}(U_{\min} + U_{\max})\right)^2 + c_i^2 \le \left(\frac{1}{2}(U_{\min} - U_{\max})\right)^2. \tag{4}$$

However, very few sufficient conditions for instability are known. In 1935, Tollmien [23] obtained an unstable solution to (3) by formally perturbing around a neutral mode (c real) for symmetric flows in class $\mathcal{K}^+$ (defined below). The original presentation was improved by C. C. Lin [17] and the asymptotic growth rate was found. Even in recent treatises such as [20], the main instability result mentioned is Tollmien's. However, as indicated by Friedlander and Howard [12], in all these references the existence of an unstable mode had to be *assumed* in a neighborhood of the neutral mode. The assumption of analytic dependence between the parameters α and c (complex) also lacked justification. These assumptions are rigorously justified in this paper. Here we get a sharp condition for the instability of a class of flows.

Let us describe the setting of the problem. First we define a class of flows having some inflection point. By an inflection value we mean the value of U at an inflection point.

DEFINITION 1.1. *The flow $U(y)$ is in class $\mathcal{K}$ if U is a $\mathbf{C}^2$ function on a interval $[y_1, y_2]$, and there exists some inflection value U_s such that*

$$K(y) := -U''(y) / (U(y) - U_s) \tag{5}$$

is nonnegative and bounded in $[y_1, y_2]$. If K is positive on $[y_1, y_2]$, we say that U is in class $\mathcal{K}^+$.

A typical example of such a flow is $U = \cos my$ or $\sin my$. Now we consider any flow in class $\mathcal{K}$. If (ϕ_s, α_s) is a solution to the Sturm–Liouville problem

$$\phi_s'' - \alpha_s^2 \phi_s + K\phi_s = 0, \ \phi = 0 \quad \text{at } y = y_1, y_2, \tag{6}$$

then $(\phi, \alpha, c) = (\phi_s, \alpha_s, U_s)$ is a special solution (a so-called neutral mode) to the Rayleigh equation (3). Let $\alpha_{\max}$ be the largest wave number so that a neutral mode exists. That is,

$$-\alpha_{\max}^2 = \inf_{\phi \in \mathbf{H}_0^1(y_1, y_2)} \frac{\int_{y_1}^{y_2} \left(|\phi'|^2 - K(y)|\phi|^2\right) dy}{\int_{y_1}^{y_2} |\phi|^2 \, dy}. \tag{7}$$

Throughout this paper, we assume that the right-hand side of (7) is negative. Otherwise, the shear flow was proved to be linearly stable by Drazin and Howard [8]. It was also proved in [8] that instability is possible only for wave numbers α such that $0 < \alpha < \alpha_{\max}$. Howard [15] estimated the maximal number of possible unstable modes for a fixed wave number. However, it still was not clear whether there exists

some unstable mode for each α in that range. Recently, Friedlander and Howard [12] studied the special flow $U(y) = \cos my$, using a continued fractions technique and a numerical method. For this flow they proved that for all $0 < \alpha < \alpha_{\max}$, there exists some growing mode for the Rayleigh equation.

In this paper, we rigorously prove that for any flow of class $\mathcal{K}^+$ and for all $0 < \alpha < \alpha_{\max}$, there does indeed exist an unstable solution to the Rayleigh equation (3). This is our main theorem.

THEOREM 1.2. *Suppose the steady state is in class $\mathcal{K}^+$. Let $-\alpha_{\max}^2$ be the lowest eigenvalue of $-\frac{d^2}{dy^2} - K(y)$, which is assumed to be negative. For all $\alpha \in (0, \alpha_{\max})$, there is an unstable solution (with $\operatorname{Im} c > 0$) to* (3).

The unstable interval $(0, \alpha_{\max})$ is sharp in the sense that there is linear stability if $\alpha \geq \alpha_{\max}$ or $-\frac{d^2}{dy^2} - K(y)$ is nonnegative. We can also treat plane rotating flows in an annulus. In this case, the analogue of the Rayleigh equation becomes

$$(\Omega - c)\left(D_* D - n^2/r^2\right)\phi - r^{-1}(rD^2\Omega + 3D\Omega)\phi = 0, \tag{8}$$

with $\phi(R_1) = \phi(R_2) = 0$, $0 < R_1 \leq r \leq R_2$. Here $\Omega(r)$ is the angular velocity of the steady state, $D_* = \frac{d}{dr} + \frac{1}{r}$, $D = \frac{d}{dr}$, and n is some integer. We have the following result analogous to Theorem 1.2.

THEOREM 1.3. *For the rotating case, if*

$$K(r) := -\left(rD^2\Omega + 3D\Omega\right)/(\Omega - \Omega_s) \tag{9}$$

is positive and $\Omega(R_1) \neq \Omega(R_2)$, then a necessary and sufficient condition for instability is that there exists $\alpha > 1$ such that the equation

$$\left(D_* D - \alpha^2/r^2\right)\phi + r^{-1}K(r)\phi = 0 \tag{10}$$

has some nontrivial solution with $\phi(R_1) = \phi(R_2) = 0$. This is equivalent to the condition

$$-\alpha_{\max}^2 := \inf_{\phi \in \mathbf{H}_0^1(R_1, R_2)} \frac{\int_{R_1}^{R_2} r\left(\frac{d}{dr}\phi\right)^2 dr - \int_{R_1}^{R_2} K(r)\phi^2 dr}{\int_{R_1}^{R_2} \frac{1}{r}\phi^2 dr} < -1. \tag{11}$$

In the case that $K(r)$ is positive and $\Omega(R_1) = \Omega(R_2)$, a sufficient condition for instability is that

$$-\alpha_{\max}^2 := \inf_{\phi \in \mathbf{H}_0^1(R_1, R_2)} \frac{\int_{R_1}^{R_2} r\left(\frac{d}{dr}\phi\right)^2 dr - \int_{R_1}^{R_2} K(r)\phi^2 dr}{\int_{R_1}^{R_2} \frac{1}{r}\phi^2 dr} < -4. \tag{12}$$

Let us return to shear flows that are not in class $\mathcal{K}^+$. If a shear flow is odd but there is no assumption on the sign of $K(y)$, we can still get a sufficient condition for instability.

THEOREM 1.4. *Assume $U(y)$ is odd in $[-a, a]$ and define*

$$K(y) := -U''(y)/U(y). \tag{13}$$

If K is bounded and the operator $-\frac{d^2}{dy^2} - K(y)$ with zero boundary values at $\pm a$ has a negative eigenvalue, then there is a solution to the Rayleigh equation (3) *with $c = i\lambda_0$ (here $\lambda_0 > 0$) for some range of wave numbers. Specifically, if $-\alpha_0^2 < -\alpha_1^2 < \cdots < -\alpha_{k_0}^2 < 0$ denote all the negative eigenvalues of $-\frac{d^2}{dy^2} - K(y)$, then we have a*

purely growing instability for α *belonging to the intervals* $(\alpha_1, \alpha_0) \cup \cdots \cup (\alpha_{2k-1}, \alpha_{2k-2}) \cdots \cup (\alpha_{k_0}, \alpha_{k_0-1})$ *(if* k_0 *odd) or to the intervals* $(\alpha_1, \alpha_0) \cup \cdots \cup (\alpha_{2k-1}, \alpha_{2k-2}) \cdots \cup (\alpha_{k_0-1}, \alpha_{k_0-2})$ *(if* k_0 *even).*

We can extend Theorems 1.2 and 1.4 to the case of unbounded shear flows.

THEOREM 1.5. (i) *(class* $\mathcal{K}^+$*) Assume* $U(y)$ *is in* $\mathbf{C}^2(-\infty, +\infty)$, $U(y) \to U(\pm\infty)$ *as* $y \to \pm\infty$, *and* $U(y)$ *takes the values* $U(\pm\infty)$ *at only a finite number of points. We consider the flows such that* $K(y)$ *defined by* (5) *is bounded, positive, and* $\lim_{y\to\pm\infty} K(y) = 0$. *Let* $-\alpha_0^2$ *be the lowest eigenvalue of* $-\frac{d^2}{dy^2} - K(y)$ *on* $\mathbf{H}^2(\mathbf{R})$, *which is assumed to be negative. Then for each* α *in* $(0, \alpha_0)$, *there is instability. This condition is sharp in the sense that if* $\alpha \geq \alpha_0$ *or* $-\frac{d^2}{dy^2} - K(y)$ *is nonnegative, then there is linear stability. The same result holds for the shear flows defined in the half line.*

(ii) *(odd flows) Assume* $U(y)$ *is in* $\mathbf{C}^2(-\infty, +\infty)$, *odd, and* $K(y)$ *defined by* (13) *is bounded and* $\lim_{y\to\pm\infty} K(y) = 0$. *If* $-\alpha_0^2 < -\alpha_1^2 < \cdots < -\alpha_k^2 < \cdots < 0$ *denote all the negative eigenvalues of the operator* $-\frac{d^2}{dy^2} - K(y)$ *on* $\mathbf{H}^2(\mathbf{R})$, *then we have a purely growing instability for* α *belonging to the intervals* $(\alpha_1, \alpha_0) \cup (\alpha_3, \alpha_2) \cup \cdots \cup (\alpha_{2k-1}, \alpha_{2k-2}) \cdots$.

Now let us sketch the main ideas of the proofs. For the proof of Theorem 1.4, we define a family of elliptic operators A_λ depending on the positive parameter λ where $c = i\lambda$. The problem is reduced to finding some λ_0 such that A_{λ_0} has a kernel. The operator A_λ is nonnegative when λ is large and A_λ has an odd number of eigenvalues when λ tends to 0. The idea then is to use an infinite determinant to keep track of the sign of the eigenvalues of A_λ as λ varies from 0 to ∞.

For the proofs of Theorems 1.2 and 1.3, we carefully use the neutral modes. In the literature, neutral modes have usually been used as the base modes, from which unstable modes have been obtained by the perturbation argument of Tollmien. The novelty of this paper is to utilize a different property of neutral modes: the neutral wave numbers are the possible boundary points of the set of all unstable wave numbers. Thus if we knew all these possible neutral wave numbers and the instability properties around them, we could deduce the stability properties at all the wave numbers. Indeed for our purpose we only need to understand the neutral modes from which the unstable modes can issue. We call them the neutral limiting modes to distinguish them from the usual neutral modes, which are just the solutions to the Rayleigh equation with real c.

DEFINITION 1.6. *The triple* (c_s, α_s, ϕ_s) *with* c_s *real and* α_s *positive is said to be a neutral limiting mode if it is the limit of the growing solution sequence* (c_k, α_k, ϕ_k) *(with* $\operatorname{Im} c_k > 0$*) of the Rayleigh equation* (3). *The precise notions of convergence of* ϕ_k *to* ϕ_s *will be made clear in Lemma* 3.6. *Formally* (c_s, α_s, ϕ_s) *ought to satisfy the Rayleigh equation*

$$(U - c_s)\left(\frac{d^2}{dy^2} - \alpha_s^2\right)\phi_s - U''\phi_s = 0. \tag{14}$$

We call c_s *the neutral limiting phase speed and* α_s *the neutral limiting wave number.*

Here in the above definition, the convergence of $\{c_k\}$ is guaranteed by Howard's semicircle theorem (4). From (4) we also know that c_s must lie in the range of $U(y)$. The importance of neutral limiting modes lies in the fact that the neutral limiting wave numbers are the possible boundary points of the set of all unstable wave numbers (see Theorem 3.9). The knowledge of the instability near every neutral limiting wave number will allow us to determine the instability in the whole range of wave numbers.

For that purpose, first we need to know what all the neutral limiting modes are. In general, it is difficult to get a simple answer. But we have the following simple characterization in case the flow is in class $\mathcal{K}$.

THEOREM 1.7. *If the flow is in class $\mathcal{K}$, then for any neutral limiting mode (c_s, α_s, ϕ_s) with positive α_s, the phase speed must be $c_s = U_s$ and the function ϕ_s must solve*

$$-\frac{d^2}{dy^2}\phi_s + \frac{U''}{U - U_s}\phi_s = -\alpha_s^2 \phi_s \tag{15}$$

with $\phi_s(y_1) = \phi_s(y_2) = 0$.

In the physics literature [17], [6], for a monotone flow it was shown heuristically by using Reynolds stress that the neutral limiting phase speed must be U_s. Using some lemmas of Sattinger [22], we rigorously prove the same result for large classes of flows. For flows in class $\mathcal{K}$, we have some uniform a priori bound on the $\mathbf{H}^2$ norm of unstable eigenfunctions. This enables us to deduce the other conclusions in the theorem.

Furthermore, for a flow in the class $\mathcal{K}^+$, we also obtain the instability property near the neutral wave numbers. This is done by rigorously verifying Tollmien's argument. By combining it with the boundary point property of neutral limiting wave numbers (Theorem 3.9), we obtain an unstable mode for each α in $(0, \alpha_{\max})$.

To prove Theorem 1.5, we truncate the unbounded flow to get a sequence of bounded flows. Then by applying Theorems 1.2 and 1.4 to truncated flows, we get a sequence of approximating unstable solutions. We can show that the sequence obtained converges to a nontrivial function, which is an unstable solution to the Rayleigh equation in the unbounded case.

In [1] Bardos, Guo, and Strauss rigorously proved nonlinear instability from the existence of growing modes under a certain assumption for flows defined on bounded domains. For rotating flows as in Theorem 1.3, that assumption is satisfied. For shear flows as in Theorem 1.2, we assume the x-direction is P-periodic, with the wave number α being multiples of $\frac{2\pi}{P}$. Then the result in [1] can still apply. The nonlinear instability proved in [1] is in the $\mathbf{L}^2$ norm of the vorticity. In [13], Grenier proved nonlinear instability from the existence of growing modes for very general shear flows. In particular, nonlinear instability of shear flows in [13] can be proved in unbounded spaces. Thus the flows in Theorem 1.5 are also nonlinearly unstable. Note that the nonlinear instability in [13] is in the $\mathbf{L}^\infty$ and $\mathbf{L}^2$ norms of velocity.

We can generalize most of Theorem 1.2 of this paper to general shear flows in the class $\mathcal{F}$ (see Definition 3.1). Thus we can treat any flow with a monotone velocity profile $U(y)$ or any flow that satisfies a differential equation $U''(y) = g(U(y))\,k(y)$ for some function $k(y) > 0$. The details will appear in a forthcoming paper. In [19], we use the method of section 2 to treat linear instability of general ideal plane flows.

The paper is organized as follows. In section 2, we prove Theorem 1.4 for odd flows. We study the neutral limiting modes in section 3. Section 4 is devoted to the proof of Theorem 1.2. In section 5, we give the proof of Theorem 1.3 for the rotating case. We treat unbounded shear flows in section 6.

2. Odd flows. We divide the proof of Theorem 1.4 into several steps. First we reduce the problem to the eigenvalue problem of an ODE system. Let $c = i\lambda\,(\lambda > 0)$ and $\phi = f + ih$; then (3) becomes

$$\left(-\frac{d^2}{dy^2} + \alpha^2\right)(f + ih) + \left(\frac{U''U}{U^2 + \lambda^2} + i\frac{\lambda U''}{U^2 + \lambda^2}\right)(f + ih) = 0.$$

Comparing the real and imaginary parts of (3) and using the definition of $K(y)$, we get

$$-\frac{d^2}{dy^2}f+\alpha^2 f-K(y)f+K(y)\frac{\lambda^2}{\lambda^2+U(y)^2}f+K(y)\frac{\lambda U(y)}{\lambda^2+U(y)^2}h=0, \tag{16a}$$

$$-\frac{d^2}{dy^2}h+\alpha^2 h-K(y)h-K(y)\frac{\lambda U(y)}{\lambda^2+U(y)^2}f+K(y)\frac{\lambda^2}{\lambda^2+U(y)^2}h=0 \tag{16b}$$

with $f=h=0$ at $y=-a,a$. If we denote

$$A_0=\begin{pmatrix} -\frac{d^2}{dy^2}+\alpha^2-K(y) & 0 \\ 0 & -\frac{d^2}{dy^2}+\alpha^2-K(y) \end{pmatrix}$$

and

$$B_\lambda=K(y)\begin{pmatrix} \frac{\lambda^2}{\lambda^2+U(y)^2} & \frac{\lambda U(y)}{\lambda^2+U(y)^2} \\ -\frac{\lambda U(y)}{\lambda^2+U(y)^2} & \frac{\lambda^2}{\lambda^2+U(y)^2} \end{pmatrix},$$

$A_\lambda=A_0+B_\lambda$. Then (16) becomes

$$A_\lambda\begin{pmatrix} f \\ h \end{pmatrix}=0.$$

The common domain for the operators A_λ is

$$\mathcal{H}=\left\{(f,h)\mid f,h\in\left(\mathbf{H}^2(-a,a)\cap\mathbf{H}_0^1(-a,a)\right)\text{ and }f\text{ odd, }h\text{ even}\right\}.$$

Let

$$\mathcal{X}=\left\{(f,h)\mid f,h\in\mathbf{L}^2(-a,a)\text{ with }f\text{ odd, }h\text{ even}\right\}.$$

Here $\mathcal{H}$, $\mathcal{X}$ are complex spaces. Due to the oddness of $U(y)$, $A_\lambda:\mathcal{H}\to\mathcal{X}$. In the following $\|.\|$ denotes the $\mathbf{L}^2$ norm. We have the following simple characterization of A_λ.

LEMMA 2.1. *A_λ is a densely defined closed operator, and for any ξ in its resolvent set $\rho(A_\lambda)$, $(\xi-A_\lambda)^{-1}$ is a trace class operator. The eigenvalues of A_λ appear in complex conjugate pairs and are all discrete with finite multiplicity.*

Proof. Denote

$$A=\begin{pmatrix} -\frac{d^2}{dy^2} & 0 \\ 0 & -\frac{d^2}{dy^2} \end{pmatrix}$$

with $D(A)=\mathcal{H}$. Then clearly $(\xi-A)^{-1}$ is a trace class operator for any $\xi\in\rho(A)$ and we have

$$\left\|(A+k)^{-1}\right\|\le\frac{1}{k}$$

for any $k>0$. On the other hand, $A_\lambda-A$ are uniformly bounded operators, and suppose $\|A_\lambda-A\|\le M$. We have

$$A_\lambda+k=A+k+A_\lambda-A=\left(1+(A_\lambda-A)(A+k)^{-1}\right)(A+k).$$

If $M < k$, then $-k \in \rho(A_\lambda)$ and

$$(A_\lambda + k)^{-1} = (A+k)^{-1}\left(1 + (A_\lambda - A)(A+k)^{-1}\right)^{-1}.$$

This is the multiplication of a bounded operator with a trace class operator, so it is also in trace class. For any $\xi \in \rho(A_\lambda)$, from formula

$$(\xi - A_\lambda)^{-1} = (-k - A_\lambda)^{-1} + (\xi + k)(\xi - A_\lambda)^{-1}(-k - A_\lambda)^{-1},$$

we can see that $(\xi - A_\lambda)^{-1}$ is in trace class.

Now the conclusions about the eigenvalues of A_λ follow from the trace class property just proved and the fact that the coefficients of A_λ are real. □

Now we study the semigroup generated by $-A_\lambda$. Notice that $-A_\lambda$ is a bounded perturbation of

$$A = \begin{pmatrix} \frac{d^2}{dy^2} & 0 \\ 0 & \frac{d^2}{dy^2} \end{pmatrix},$$

which generates the diffusion semigroup. Then by the bounded perturbation theorem of semigroups, we know that $-A_\lambda$ generates a strongly continuous semigroup. Denote $T_\lambda(t) = \exp(-tA_\lambda)$. Then there exists some C, ω positive (independent of λ) such that

$$\|T_\lambda(t)\| \le Ce^{\omega t}.$$

We have the following characterization of $T_\lambda(t)$.

LEMMA 2.2. *For all $t > 0$, $T_\lambda(t)$ is in trace class.*

Proof. First we claim that $A_\lambda T_\lambda(t)$ is a bounded operator. Assuming the claim, the theorem follows easily since we have for any $\xi \in \rho(A)$

$$T_\lambda(t) = (\xi - A_\lambda)^{-1}\left((\xi - A_\lambda)T_\lambda(t)\right),$$

which is the multiplication of a trace class operator with a bounded operator, so it is in trace class.

We shall now prove the claim, which is due to the smoothing effect of $T_\lambda(t)$. We need to show only that $AT_\lambda(t)$ is bounded. For this purpose we study the evolution equation associated with $T_\lambda(t)$.

$$\frac{d}{dt}f = \frac{d^2}{dy^2}f - \alpha^2 f + K(y)f - K(y)\frac{\lambda^2}{\lambda^2 + U(y)^2}f - K(y)\frac{\lambda U(y)}{\lambda^2 + U(y)^2}h, \tag{17a}$$

$$\frac{d}{dt}h = \frac{d^2}{dy^2}h - \alpha^2 h + K(y)h + K(y)\frac{\lambda U(y)}{\lambda^2 + U(y)^2}f - K(y)\frac{\lambda^2}{\lambda^2 + U(y)^2}h \tag{17b}$$

with $f(0) = f_0$, $h(0) = h_0$. Now to show the claim, it suffices to prove

$$\left\|\frac{d^2}{dy^2}f(t)\right\|_2, \left\|\frac{d^2}{dy^2}h(t)\right\|_2 \le C(t)\left(\|f_0\|_2 + \|h_0\|_2\right).$$

We denote (17) by

$$\frac{d}{dt}f = \frac{d^2}{dy^2}f + R_1(f,h), \tag{18a}$$

$$\frac{d}{dt}h = \frac{d^2}{dy^2}h + R_2(f,h). \tag{18b}$$

Then it is easy to see that

$$\begin{aligned}\|R_1\|_2, \|R_2\|_2 &\le C_0 \left(\|f(t)\|_2 + \|h(t)\|_2\right) \\ &\le C_0 C e^{\omega t} \left(\|f_0\|_2 + \|h_0\|_2\right).\end{aligned}$$

So from the regularity theory of the linear parabolic equation, we have

$$\begin{aligned}\left\|\frac{d^2}{dy^2} f(t)\right\|_2, \left\|\frac{d^2}{dy^2} h(t)\right\|_2 &\le C'(t) \left(\|f(t)\|_2 + \|h(t)\|_2 + \|R_1\|_2 + \|R_2\|_2\right) \\ &\le C''(t) \left(\|f_0\|_2 + \|h_0\|_2\right).\end{aligned}$$

Thus the claim is proved. □

From Lemmas 2.1 and 2.2, we know that the eigenvalues of A_λ and $T_\lambda(t)$ are discrete with finite multiplicity and that

$$\sigma(T_\lambda(t)) \setminus \{0\} = \exp\left(-t\sigma(A_\lambda)\right).$$

Now denote all the distinct eigenvalues of A_λ (arranged with nondecreasing real part) by $\mu_1(\lambda), \mu_2(\lambda), \ldots, \mu_k(\lambda), \ldots$, with multiplicities $n_1, n_2, \ldots, n_k, \ldots$. We define the infinite determinant of $Id - T_\lambda(1)$ as

$$d(\lambda) = \prod_{k=1}^{\infty} \left(1 - \exp\left(-\mu_k(\lambda)\right)\right)^{n_k}.$$

Since $T_\lambda(1)$ is a trace class operator and $\mu_k(\lambda)$ appears in complex conjugate pairs, $d(\lambda)$ is a finite real number. From the definition of $d(\lambda)$, we know that the sign of $d(\lambda)$ is determined only by the number of negative real eigenvalues of A_λ. If this number is odd, then $d(\lambda)$ is negative. And $d(\lambda)$ is positive if the number is even. Here we always assume A_λ has no kernel, since otherwise we have already obtained a solution to the Rayleigh equation.

We define three sets

$$S_- = \{\lambda > 0 |\ d(\lambda) < 0\}, \quad S_+ = \{\lambda > 0 |\ d(\lambda) > 0\}, \quad S_0 = \{\lambda > 0 |\ d(\lambda) = 0\}.$$

We will show that S_-, S_+ are nonempty open sets. Then the theorem follows easily, as we shall now show.

Proof of Theorem 1.4. We claim that S_0 is nonempty. Otherwise we would have $(0, +\infty) = S_- \cup S_+$, which is impossible, since S_-, S_+ are two disjoint open sets. So there must exist some $\lambda_0 > 0$ such that $d(\lambda_0) = 0$. Then there exists k so that $1 - \exp\left(-\mu_k(\lambda_0)\right) = 0$. So $\mu_k(\lambda_0) = 0$ and A_{λ_0} has a nontrivial kernel (f, h). This means that $c = i\lambda_0$, $\phi = f + ih$ is a solution to Rayleigh's equation (3). □

The next several lemmas prove the properties of S_-, S_+ that we need.

LEMMA 2.3. *S_+ is nonempty.*

Proof. Because for any real vector (f, h),

$$\begin{aligned}\left((f,h), A_\lambda \begin{pmatrix} f \\ h \end{pmatrix}\right) &= \left(\left(-\frac{d^2}{dy^2} + \alpha^2 - K(y) + K(y) \frac{\lambda^2}{\lambda^2 + U(y)^2}\right) f, f\right) \\ &\quad + \left(\left(-\frac{d^2}{dy^2} + \alpha^2 - K(y) + K(y) \frac{\lambda^2}{\lambda^2 + U(y)^2}\right) h, h\right) \\ &> 0\end{aligned}$$

when λ is large, A_λ is a positive operator. Thus all its real eigenvalues are positive, so that $d(\lambda) > 0$ for λ large. □

LEMMA 2.4. *S_- is nonempty.*

Proof. From the assumptions of Theorem 1.4 and the definition of operator A_0, we know that $d(0) < 0$. We will show that for λ small, $d(\lambda) < 0$.

First we claim that

(i) for any eigenvalue $\mu(\lambda)$ of A_λ, we have $|\mathrm{Im}\,\mu(\lambda)| < \|K\|_\infty$;

(ii) there exists positive ε_1, δ_1 such that if $0 \le \lambda < \delta_1$, then for any eigenvalue $\mu(\lambda)$ of A_λ, we have $|\mathrm{Re}\,\mu(\lambda)| > \varepsilon_1$.

Proof of claim (i). Let (f, h) be the eigenfunction with $\|f\|_2 + \|h\|_2 = 1$. Taking inner products with the conjugate $(\bar{f},\ \bar{h})$ on both sides of

$$A_\lambda \begin{pmatrix} f \\ h \end{pmatrix} = \mu(\lambda) \begin{pmatrix} f \\ h \end{pmatrix} \tag{19}$$

and comparing the imaginary parts, we get

$$\begin{aligned} |\mathrm{Im}\,\mu(\lambda)| &\le \left| 2\|K\|_\infty \mathrm{Im} \int_{-a}^{a} \frac{\lambda U(y)}{\lambda^2 + U(y)^2} f\bar{h}dy \right| \\ &\le \|K\|_\infty \frac{1}{2} (\|f\|_2 + \|h\|_2)^2 = \frac{1}{2}\|K\|_\infty . \end{aligned}$$

Proof of claim (ii). Supposing it is not true, we could find a sequence $\lambda_n \to 0$, μ_n being an eigenvalue of A_{λ_n}, and $\mathrm{Re}\,\mu_n \to 0$. Let (f_n, h_n) be the corresponding eigenfunction and $\|f_n\|_2 + \|h_n\|_2 = 1$. By (i), $\{\mu_n\}$ is a bounded sequence. We can find a subsequence such that $\mu_{n_k} \to \mu_0$, so that μ_0 is purely imaginary. We still denote the subsequence by $\{\mu_n\}$.

From the equation satisfied by the eigenfunction (f_n, h_n), we get

$$\|f_n\|_{\mathbf{H}^2}, \|g_n\|_{\mathbf{H}^2} \le C(\|f\|_2 + \|h\|_2) = C$$

from elliptic regularity theory by noticing that the coefficients in (19) are uniformly bounded. Thus there exists a subsequence such that $(f_{n_k}, g_{n_k}) \to (f_0, g_0)$ weakly in $\mathbf{H}^2$ and strongly in $\mathbf{H}^1$. Moreover,

$$\begin{aligned} \left\| (A_0 - \mu_0) \begin{pmatrix} f_{n_k} \\ h_{n_k} \end{pmatrix} \right\| \le & \|K\|_\infty \left(\left\| \frac{\lambda_{n_k}^2}{\lambda_{n_k}^2 + U(y)^2} \right\|_2 + \left\| \frac{\lambda_{n_k} U(y)}{\lambda_{n_k}^2 + U(y)^2} \right\|_2 \right) \\ & \times \left(\|f_{n_k}\|_\infty + \|h_{n_k}\|_\infty \right) + |\mu_{n_k} - \mu_0| \left(\|f_{n_k}\|_2 + \|h_{n_k}\|_2 \right) \\ \le & C \left(\left\| \frac{\lambda_{n_k}^2}{\lambda_{n_k}^2 + U(y)^2} \right\|_2 + \left\| \frac{\lambda_{n_k} U(y)}{\lambda_{n_k}^2 + U(y)^2} \right\|_2 + |\mu_{n_k} - \mu_0| \right) \end{aligned}$$

tends to zero as $\lambda_{n_k} \to 0$. Thus we have $\mu_0 \in \sigma(A_0)$, which is a contradiction to the fact that A_0 has no eigenvalue lying on the imaginary axis. So claim (ii) is proved.

Let Λ be the infimum of real part of eigenvalues of A_λ. Λ is finite since A_λ is uniformly bounded from below. Define

$$D = \left\{ (x, y) \ | \Lambda - 1 < x < -\frac{\varepsilon_1}{2},\ -\|K\|_\infty < y < \|K\|_\infty \right\}$$

and $\Gamma = \partial D$. From claim (ii), if $\lambda < \delta_1$, all eigenvalues of A_λ with negative real part lie in D. Define the Riesz projection as

$$P_\lambda = \frac{1}{2\pi i} \oint_\Gamma (k - A_\lambda)^{-1} \, dk \tag{20}$$

and $R(P_\lambda)$ its range, where $\lambda \geq 0$ and the Γ-integral is in the counterclockwise sense. Then by the definition of $d(\lambda)$

$$sign \; d(\lambda) = (-1)^{\dim R(P_\lambda)}. \tag{21}$$

To prove the lemma, it suffices to show that $\|P_\lambda - P_0\| \to 0$ as $\lambda \to 0$. If so, then $\dim(R(P_\lambda)) = \dim(R(P_0))$ if λ is small enough. By the definition of P_0, $\dim(R(P_0))$ is the number of negative eigenvalues of A_0 on the space $\mathcal{H}$, which is equal to that of the operator $-\frac{d^2}{dy^2} + \alpha^2 - K(y)$ on the space $\mathbf{H}^2(-a,a) \cap \mathbf{H}_0^1(-a,a)$. This is due to the fact that any eigenfunction of $-\frac{d^2}{dy^2} + \alpha^2 - K(y)$ is either odd or even when $K(y)$ is even. With α lying in the intervals of Theorem 1.4, $-\frac{d^2}{dy^2} + \alpha^2 - K(y)$ has an odd number of negative eigenvalues, so $\dim(R(P_0))$ is odd. Thus when λ is small enough, $\dim(R(P_\lambda))$ is odd, which implies that $d(\lambda)$ is negative by (21) so that S_- is not empty.

To show $\|P_\lambda - P_0\| \to 0$, we note that

$$\begin{aligned}
&\left\| B_\lambda \begin{pmatrix} f \\ h \end{pmatrix} \right\| \leq \|K\|_\infty \left(\left\| \frac{\lambda^2}{\lambda^2 + U(y)^2} \right\|_2 + \left\| \frac{\lambda U(y)}{\lambda^2 + U(y)^2} \right\|_2 \right) (\|f\|_\infty + \|h\|_\infty) \\
&\leq C \|K\|_\infty \left(\left\| \frac{\lambda^2}{\lambda^2 + U(y)^2} \right\|_2 + \left\| \frac{\lambda U(y)}{\lambda^2 + U(y)^2} \right\|_2 \right) \left(\left\| A_0 \begin{pmatrix} f \\ h \end{pmatrix} \right\| + \left\| \begin{pmatrix} f \\ h \end{pmatrix} \right\| \right) \\
&= C(\lambda) \left(\left\| A_0 \begin{pmatrix} f \\ h \end{pmatrix} \right\| + \left\| \begin{pmatrix} f \\ h \end{pmatrix} \right\| \right),
\end{aligned}$$

where

$$C(\lambda) = C \|K\|_\infty \left(\left\| \frac{\lambda^2}{\lambda^2 + U(y)^2} \right\|_2 + \left\| \frac{\lambda U(y)}{\lambda^2 + U(y)^2} \right\|_2 \right) \to 0$$

as $\lambda \to 0$ by dominant convergence. Since $\Gamma \subset \sigma(A_\lambda)$ if $\lambda < \delta_1$ and Γ is compact, it follows that $\| (\xi - A_\lambda)^{-1} \|$ is uniformly bounded by some constant M independent of $\xi \in \Gamma$. Then we have

$$\begin{aligned}
\left\| (\xi - A_\lambda)^{-1} - (\xi - A_0)^{-1} \right\| &= \left\| (\xi - A_\lambda)^{-1} B_\lambda (\xi - A_0)^{-1} \right\| \\
&\leq \left\| (\xi - A_\lambda)^{-1} \right\| \left\| B_\lambda (\xi - A_0)^{-1} \right\| \\
&\leq MC(\lambda) \left(\left\| A_0 (\xi - A_0)^{-1} \right\| + \left\| (\xi - A_0)^{-1} \right\| \right) \\
&\leq MC(\lambda) \left(1 + \left\| \xi (\xi - A_0)^{-1} \right\| + \left\| (\xi - A_0)^{-1} \right\| \right).
\end{aligned}$$

So as $\lambda \to 0$, $\| (\xi - A_\lambda)^{-1} - (\xi - A_0)^{-1} \| \to 0$ uniformly for $\xi \in \Gamma$. Thus $\|P_\lambda - P_0\| \to 0$ if $\lambda \to 0$. □

LEMMA 2.5. *S_- and S_+ are open sets.*

Proof. We will show that S_- is open. The proof for S_+ is the same. Suppose $\lambda_0 \in S_-$. Let $b > 0$ be such that there is no eigenvalue of A_{λ_0} with real part b. Then by the same argument as in the last lemma, there exists $\varepsilon_1, \delta_1 > 0$ such that if $|\lambda - \lambda_0| < \delta_1$, then for any eigenvalue $\mu(\lambda)$ of A_λ, we have $|\operatorname{Re}\mu(\lambda) - b| > \varepsilon_1$. Let Λ be the infimum of real part of eigenvalues of A_λ. Define

$$D = \left\{(x,y) \ |\Lambda - 1 < x < -\frac{\varepsilon_1}{2} + b, \ -\|K\|_\infty < y < \|K\|_\infty\right\}$$

and $\Gamma = \partial D$. Then all eigenvalues of A_λ with real part smaller than b lie in D and $\Gamma \subset \sigma(A_\lambda)$ provided $|\lambda - \lambda_0| < \delta_1$. Define P_λ by (20). Then $\|P_\lambda - P_{\lambda_0}\| \to 0$ as $|\lambda - \lambda_0| \to 0$, since A_λ is analytic for $\lambda > 0$. So $\dim(R(P_\lambda)) = \dim(R(P_{\lambda_0}))$ if $|\lambda - \lambda_0|$ is small enough. Let $\mu_1, \mu_2, \ldots, \mu_N$ be all the distinct eigenvalues of A_{λ_0} in D. Let m_k be the multiplicity of μ_k. Now for each μ_k, we can take a small ball $B_k = B(\mu_k; r_k)$ such that there are no other eigenvalues of A_{λ_0} in it besides μ_k. And by taking r_k small enough we can suppose that B_k does not intersect with the imaginary axis if $\operatorname{Re}\mu_k \neq 0$, and B_k does not intersect with the real axis if $\operatorname{Re}\mu_k = 0$. Also B_k does not intersect with Γ. They are disjoint with others, and for the conjugate eigenvalue we take the same radius. Then if $|\lambda - \lambda_0|$ is small enough, by analytic perturbation theory, there are exactly m_k eigenvalues (counting multiplicity) of A_λ in each B_k. Since $\dim(R(P_\lambda)) = \dim(R(P_{\lambda_0}))$, these are all the eigenvalues of A_λ in D. Now notice that for each B_k and its conjugate one, if we multiply all the eigenvalues of A_λ in them, the sign is the same as for A_{λ_0}. So in the definition of $d(\lambda)$, the part corresponding to the multiplication of all eigenvalues of A_λ with real part smaller than b is of the same sign with the λ_0 case. Thus it is negative if $|\lambda - \lambda_0|$ is small. While the other part of multiplication is always positive, we proved that $d(\lambda)$ is negative when $|\lambda - \lambda_0|$ is small. This finishes the proof of the lemma. □

It is easy to see that we can get the following abstract version by the same proof.

THEOREM 2.6. *Consider a family of real operators $A_\lambda = -A + B_\lambda$ $(\lambda \in (0, +\infty))$ with the same domain $\mathcal{H}$. We assume the following:*

(I) *B_λ is bounded and norm continuous for positive λ.*

(II) *A generates a generalized parabolic semigroup; that is, $\exp(tA)$ is in trace class and $A\exp(tA)$ is bounded.*

(III) *When λ is sufficiently large, A_λ has no eigenvalue with negative real part.*

(IV) *When λ tends to 0, A_λ tend to A_0 in the sense that*

$$\|(A_\lambda - A_0)\phi\| \leq c(\lambda)\left(\|A_0\phi\| + \|\phi\|\right),$$

$c(\lambda) \to 0$ as $\lambda \to 0^+$ for any function $\phi \in \mathcal{H}$. Then if A_0 has an odd number of negative eigenvalues and no kernel, there must exist some $\lambda_0 > 0$ such that A_{λ_0} has a nontrivial kernel.

We can also treat the periodic and Neumann boundary conditions for the Rayleigh equation by the same method. The conclusion and the proofs are direct analogues of Theorem 1.4.

Example 2.7 (doubly symmetric flows). Theorem 1.4 could be used to treat some nonodd flows.

Suppose that $U(y)$ is even on $(0, 2d)$ with respect to its midpoint d and is odd on $(0, d)$ with respect to its midpoint $\frac{d}{2}$. In that case, we could treat the sinuous (even mode) and varicose (odd mode) separately by studying the Rayleigh equation on $[0, d]$, taking the boundary condition at d to be either $\phi'(d) = 0$ or $\phi(d) = 0$. We could treat the varicose case by Theorem 1.4.

The flow $U(y) = \cos(my)$ on $[-\pi, \pi]$ was treated in [12]. If m is odd, then $U(y)$ is in the class we described above. For varicose modes, we can restrict the problem to $[0, \pi]$ and furthermore restrict the function space to be the space $\mathcal{P}_j$ spanned by $\sin ny$ $(n = j + mp)$. Here j is a fixed integer in $[1, [m/2]]$. Then the space $\mathcal{P}_j$ is invariant under the operator A_λ corresponding to $U(y) = \cos(my)$. Notice that if

$$m^2 - (m-j)^2 < \alpha^2 < m^2 - j^2,$$

then $-\frac{d^2}{dy^2} + \alpha^2 - m^2$ has only one negative eigenvalue on $\mathcal{P}_j$. Thus from Theorem 1.4, we know that there is a purely growing unstable mode. This was proved in [12] by a continued fractions technique. It was also shown in [12] by numerical computation that if α is small, there is no purely growing mode.

3. Neutral limiting modes. In this section, we study properties of the possible neutral limiting modes. For a certain class of flows, we get a simple characterization of the neutral limiting phase speed c_s. For flows of class $\mathcal{K}$, we get a complete characterization as in Theorem 1.7.

DEFINITION 3.1. *A velocity profile $U(y)$ is said to be in class $\mathcal{F}$ if for each number c in the range of U but not an inflection value, U'' takes the same sign at all points where $U(y) = c$.*

Some examples in class $\mathcal{F}$ are a monotone flow, a symmetric flow with monotone half part, and a flow satisfying $U''(y) = g(U(y))\, k(y)$ for some function g and $k(y) > 0$. It is readily seen that $\mathcal{K} \subset \mathcal{F}$.

Remark 3.2. We mention two simple facts we will use later.

(i) For a $\mathbf{C}^2$ flow $U(y)$, if c is not an inflection value, then $U(y) = c$ can only hold at a finite number of points.

(ii) For a $\mathbf{C}^2$ flow $U(y)$, if there exists some inflection value U_s such that the function

$$K(y) := -U''(y) / (U(y) - U_s) \tag{22}$$

is bounded on $[y_1, y_2]$, then $U(y) - U_s = 0$ can only hold at a finite number of points.

For the proof of (i), we notice that $U''(y_0) \neq 0$ at any point $y_0 \in \{U(y) = c\}$, since c is not an inflection value. So y_0 is an isolated point of $\{U(y) = c\}$. Therefore $\{U(y) = c\}$ is a finite set. For (ii) we observe that $\phi = U(y) - U_s$ solves a second order regular ODE

$$\phi'' + K(y)\,\phi = 0$$

on $[y_1, y_2]$. So the zeros of ϕ cannot cluster in the interval.

THEOREM 3.3. *If $U(y)$ is in class $\mathcal{F}$, then the neutral limiting phase speed must be an inflection value.*

Note that in Definition 1.6, α_s is positive. If $\alpha_s = 0$, then the neutral limiting phase speed might not be the inflection value. A counterexample is $U(y) = \cos(6y)$, $y \in (-\pi, \pi)$. The numerical computation in [12] indicated that when $\alpha_s = 0$, the neutral limiting phase speed is $c_s = -1$ while the inflection value is 0.

For the proof of this theorem, we need several lemmas from the literature, which we state without proof. The first one is an important equality which was first used to prove Rayleigh's criterion.

LEMMA 3.4. *Let ϕ be a solution of* (3) *with complex eigenvalue $c = c_r + ic_i$ $(c_i \neq 0)$, and let*

$$J_q(\phi) = \int_{y_1}^{y_2} \left(|\phi'|^2 + \alpha^2 |\phi|^2 + \frac{U''(U-q)}{|U-c|^2} |\phi|^2 \right) dy. \tag{23}$$

Then $J_q(\phi) = 0$ for every real number q.

Proof. We multiply the Rayleigh equation

$$\left(\frac{d^2}{dy^2} - \alpha^2 \right) \phi - \frac{U''}{U-c}\phi = 0$$

by ϕ^* ($*$ denotes the complex conjugate) and integrate it to get

$$\int_{y_1}^{y_2} \left(|\phi'|^2 + \alpha^2 |\phi|^2 + \frac{U''}{U-c} |\phi|^2 \right) dy = 0.$$

Comparing real and imaginary parts, we get

$$\int_{y_1}^{y_2} \left(|\phi'|^2 + \alpha^2 |\phi|^2 + \frac{U''(U-c_r)}{|U-c|^2} |\phi|^2 \right) dy = 0, \tag{24}$$

$$\int_{y_1}^{y_2} \frac{U''}{|U-c|^2} |\phi|^2 \, dy = 0. \tag{25}$$

Combining (24) and (25), we get the conclusion. □

We also need some results from [22]. In the following we use the notation in [22]. Let c be any real number in the range of $U(y)$ and let $z_1 < z_2 < \cdots < z_{k_c}$ be the zeros of $U(y) - c$. Here we assume k_c is finite. In the following we always consider the cases in Remark 3.2, so this assumption is valid. We denote by S_0 the complement of the set of points $\{z_i\}$ in the interval $[y_1, y_2]$. Let $z_0 = y_1$ and $z_{k_c+1} = y_2$. Then we have the following lemma.

LEMMA 3.5. *Let ϕ satisfy* (3) *with positive α and c as above on S_0, where ϕ is sectionally continuous on the open intervals (z_j, z_{j+1}), $j = 0, 1, \ldots, k_c$. Then ϕ cannot vanish at both endpoints of any of the intervals (z_j, z_{j+1}) unless it vanishes identically on that interval.*

Proof. This lemma was proved in [22], where it was used for a different purpose, namely, to show that for a fixed wave number there are only a finite number of unstable eigenvalues of the Rayleigh equation under some conditions. Here we give the proof for completeness.

The Rayleigh equation (3) can be rewritten as

$$\left((U-c)\phi' - U'\phi \right)' = \alpha^2 (U-c)\phi. \tag{26}$$

Suppose $\phi(z_i+) = \phi(z_{i+1}-) = 0$ and study (26) in $[z_i, z_{i+1}]$. From the definition of z_i, $U - c$ has constant sign in (z_i, z_{i+1}).

If $z_i \neq y_1$ $(i \neq 0)$, then $U(z_i) - c = 0$. Let $\tilde{z} \leq z_{i+1}$ be the nearest zero of ϕ in $(z_i, z_{i+1}]$. Since (26) is a real equation, we may assume ϕ is real and nonnegative on the interval $(z_i, \tilde{z})$ and that $\phi'(z_i) \geq 0$ and $\phi'(\tilde{z}) \leq 0$. Integrating (26) over $(z_i, \tilde{z})$, we get

$$(U(\tilde{z}) - c)\phi'(\tilde{z}) = \alpha^2 \int_{z_i}^{\tilde{z}} \phi(U-c)dz',$$

since ϕ vanishes at the endpoints $z_i, \tilde{z}$.

If $\tilde{z} = z_{i+1,}$ then the left-hand side above must be zero. Hence ϕ is identically zero on (z_i, z_{i+1}). On the other hand, if $\tilde{z} < z_{i+1}$, then $U(\tilde{z}) \neq c$ and

$$\phi'(\tilde{z}) = \alpha^2 \int_{z_i}^{\tilde{z}} \frac{(U(z') - c)}{(U(\tilde{z}) - c)} \phi(z')\, dz',$$

which could not hold true unless $\phi \equiv 0$ on $[z_i, \tilde{z}]$. But the second order ODE (26) is regular on (z_i, z_{i+1}). Thus z could not be a cluster point of a nontrivial solution ϕ. Thus ϕ must be identically zero on (z_i, z_{i+1}).

If $i = 0$, then we repeat the same argument with the right endpoint of the interval (y_1, z_1). □

LEMMA 3.6. *Let* $\{(c_k, \alpha_k, \phi_k)\,(\text{with } \operatorname{Im} c_k > 0)\}_{k=1}^{\infty}$ *be the solutions to the Rayleigh equation* (3) *and* $\|\phi_k\| = 1$, *and* (c_k, α_k) *converges to* (c_s, α_s) *with positive* α_s. *Then* ϕ_k *converges uniformly to a function* ϕ_s *on any compact subset of* S_0, ϕ_s'' *exists on* S_0, *and* ϕ_s *satisfies* (14).

The case when α_k is independent of k was proved in [22], but the proof can be applied to the current case without much change. The basic idea is that on compact subsets of S_0, the function $1/(U(y) - c_k)$ is uniformly bounded, so we get a uniform bound on the derivatives of ϕ_k up to second order.

Proof of Theorem 3.3. Let (c_s, α_s, ϕ_s) be a neutral limiting mode and assume c_s is not an inflection value. First we show that the ϕ_s obtained by Lemma 3.6 is not identically zero. Otherwise suppose $\phi_s \equiv 0$. Let $z_1, z_2, \ldots, z_m$ be all the zeros of $U(y) - c_s$, which by Remark 3.2 is finite. Then by the assumption of the theorem and the definition of class $\mathcal{F}$, all $U''(z_i)$ have the same sign, say positive. Let $E_\delta = \{y \in [y_1, y_2] \mid |y - z_i| < \delta \text{ for some } i\}$. Then $E_\delta^c \subset S_0$ and $U''(y) > 0$ for $y \in E_\delta$ if δ small enough. Take $q = \min U(y) - 1$ and assume $\|\phi_k\|_2 = 1$. Then

$$\begin{aligned} J_q(\phi_k) &= \int_{y_1}^{y_2} \left(|\phi_k'|^2 + \alpha_k^2 |\phi_k|^2 + \frac{U''(U-q)}{|U - c_k|^2} |\phi_k|^2 \right) dy \\ &\geq \alpha_k^2 + \int_{E_\delta^c} \frac{U''(U-q)}{|U - c_k|^2} |\phi_k|^2\, dy + \int_{E_\delta} \frac{U''(U-q)}{|U - c_k|^2} |\phi_k|^2\, dy \\ &\geq \alpha_k^2 - \sup_{E_\delta^c} \frac{|U''(U-q)|}{(U - c_k)^2} \int_{E_\delta^c} |\phi_k|^2\, dy. \end{aligned}$$

Since ϕ_k converges to $\phi_s \equiv 0$ uniformly on E_δ^c, we have

$$\lim_{k \to \infty} \inf J_q(\phi_k) \geq \alpha_s^2.$$

So for large k, $J_q(\phi_k) \neq 0$, which is a contradiction to Lemma 3.4.

So by Lemma 3.5, there is some z_i such that $\phi_s(z_i) \neq 0$. Then

$$\int_{E_\delta} \frac{U''(U-q)}{|U - c_s|^2} |\phi_s|^2\, dy \geq \int_{|y - z_i| < \delta} \frac{U''}{|U - c_s|^2} |\phi_s|^2\, dy = +\infty$$

since c_s is not an inflection value. By Fatou's lemma,

$$\lim_{k \to \infty} \inf \int_{E_\delta} \frac{U''(U-q)}{|U - c_k|^2} |\phi_k|^2\, dy = +\infty.$$

So from

$$J_q(\phi_k) \geq \int_{E_\delta} \frac{U''(U-q)}{|U - c_k|^2} |\phi_k|^2\, dy - \sup_{E_\delta^c} \frac{U''(U-q)}{|U - c_k|^2},$$

we get $\lim_k \inf J_q(\phi_k) = +\infty$, which is a contradiction to the fact that $J_q(\phi_k) = 0$ (Lemma 3.4). Thus c_s must be an inflection value. This ends the proof of Theorem 3.3. □

To show Theorem 1.7, we need to get some a priori estimate for the sequence of unstable solutions $\{\phi_k\}$ in Definition 1.6. We have the following.

LEMMA 3.7. *For the flow $U(y)$ in class $\mathcal{K}$, if ϕ is the solution to* (3) *with* $\operatorname{Im} c > 0$, *then we have*

$$\int_{y_1}^{y_2} \left(|\phi'|^2 + \alpha^2 |\phi|^2\right) dy < \int_{y_1}^{y_2} K(y) |\phi|^2 dy \tag{27}$$

and

$$\int_{y_1}^{y_2} \left(|\phi''|^2 + 2\alpha^2 |\phi'|^2 + \alpha^4 |\phi|^2\right) dy < \|K\|_\infty \int_{y_1}^{y_2} K(y) |\phi|^2 dy. \tag{28}$$

Proof. Inequality (27) was obtained in [8], but we prove it here for completeness. Denote $c = c_r + ic_i$ $(c_i > 0)$. By Lemma 3.4, for any real q

$$\int_{y_1}^{y_2} \left(|\phi'|^2 + \alpha^2 |\phi|^2 + \frac{U''(U-q)}{|U-c_r|^2 + c_i^2} |\phi|^2\right) dy = 0. \tag{29}$$

Let $q = U_s - 2(U_s - c_r)$. Then

$$\begin{aligned}
\int_{y_1}^{y_2} \left(|\phi'|^2 + \alpha^2 |\phi|^2\right) dy &= \int_{y_1}^{y_2} K(y) \frac{(U-U_s)(U-q)}{|U-c_r|^2 + c_i^2} |\phi|^2 dy \\
&= \int_{y_1}^{y_2} K(y) \frac{(U-U_s)^2 + 2(U-U_s)(U_s-c_r)}{|U-c_r|^2 + c_i^2} |\phi|^2 dy \\
&= \int_{y_1}^{y_2} K(y) \frac{(U-c_r)^2 - (U_s-c_r)^2}{|U-c_r|^2 + c_i^2} |\phi|^2 dy \\
&< \int_{y_1}^{y_2} K(y) |\phi|^2 dy.
\end{aligned}$$

This proves (27).

In (29), let $q = U_s$, we get by (27)

$$\int_{y_1}^{y_2} K(y) \frac{(U-U_s)^2}{|U-c_r|^2 + c_i^2} |\phi|^2 dy = \int_{y_1}^{y_2} \left(|\phi'|^2 + \alpha^2 |\phi|^2\right) dy < \int_{y_1}^{y_2} K(y) |\phi|^2 dy. \tag{30}$$

We shall show that

$$\int_{y_1}^{y_2} \left(|\phi''|^2 + 2\alpha^2 |\phi'|^2 + \alpha^4 |\phi|^2\right) dy - \int_{y_1}^{y_2} \frac{(U'')^2 |\phi|^2}{|U-c_r|^2 + c_i^2} dy = 0, \tag{31}$$

which was first proved in [2]. For completeness we now give the proof of (31). We multiply the Rayleigh equation

$$\left(\frac{d^2}{dy^2} - \alpha^2\right)\phi - \frac{U''}{U-c}\phi = 0$$

by $(\phi^*)''$ and integrate it to get

$$\int_{y_1}^{y_2} \left((\phi^*)'' \left(\phi'' - \alpha^2 \phi\right)\right) = \int_{y_1}^{y_2} \left((\phi^*)'' \frac{U''}{U-c}\phi\right). \tag{32}$$

By integration by parts,

$$LHS \text{ of } (32) = \int_{y_1}^{y_2} \left(|\phi''|^2 + \alpha^2 |\phi'|^2\right) dy.$$

Using the Rayleigh equation for ϕ^*, we have

$$\begin{aligned} RHS \text{ of } (32) &= \int_{y_1}^{y_2} \left(\left(\alpha^2\phi^* + \left(\frac{U''}{U-c}\phi\right)^*\right)\left(\frac{U''}{U-c}\phi\right)\right) dy \\ &= \alpha^2 \int_{y_1}^{y_2} \frac{U''|\phi|^2}{U-c} dy + \int_{y_1}^{y_2} \frac{(U'')^2 |\phi|^2}{|U-c_r|^2 + c_i^2} dy. \end{aligned}$$

So

$$\begin{aligned} \int_{y_1}^{y_2} \left(|\phi''|^2 + \alpha^2 |\phi'|^2\right) dy &= \operatorname{Re} RHS \\ &= \alpha^2 \int_{y_1}^{y_2} \frac{U''(U-c_r)|\phi|^2}{|U-c_r|^2 + c_i^2} dy + \int_{y_1}^{y_2} \frac{(U'')^2 |\phi|^2}{|U-c_r|^2 + c_i^2} dy \\ &= -\alpha^2 \left(\int_{y_1}^{y_2} \left(|\phi'|^2 + \alpha^2 |\phi|^2\right) dy\right) + \int_{y_1}^{y_2} \frac{(U'')^2 |\phi|^2}{|U-c_r|^2 + c_i^2} dy, \end{aligned}$$

by (29) with $q = c_r$. Now (31) follows.

Then inequality (28) follows easily from (5), (30), and (31). □

Remark 3.8 (stability). The inequality (27) was used in [8] to prove that there is no unstable solution to (3) when $\alpha \geq \alpha_{\max}$. Indeed, from (27), if there exists some solution ϕ with $\operatorname{Im} c > 0$, then

$$\begin{aligned} -\alpha^2 &> \frac{\int_{y_1}^{y_2} \left(|\phi'|^2 - K(y)|\phi|^2\right) dy}{\int_{y_1}^{y_2} |\phi|^2 dy} \\ &\geq \inf_{\phi \in \mathbf{H}_0^1(y_1,y_2)} \frac{\int_{y_1}^{y_2} \left(|\phi'|^2 - K(y)|\phi|^2\right) dy}{\int_{y_1}^{y_2} |\phi|^2 dy} = \alpha_{\max}^2. \end{aligned}$$

This proves that the condition in Theorem 1.2 is sharp for instability.

Proof of Theorem 1.7. Given (c_s, α_s, ϕ_s), let $\{(c_k, \alpha_k, \phi_k)\}$ (with $\operatorname{Im} c_k > 0$) be a sequence of solutions to the Rayleigh equation (3), as in Definition 1.6 of the introduction. Here we take $\|\phi_k\|_2 = 1$. By Theorem 3.3, $c_k \to U_s$. From Lemma 3.7, we get

$$\int_{y_1}^{y_2} \left(|\phi_k'|^2 + |\phi_k''|^2\right) dy < \max\left\{\|K\|_\infty^2, 1\right\}.$$

So there is a subsequence $\{\phi_{n_k}\}$ of $\{\phi_k\}$ and $\phi_0 \in \mathbf{H}^2 \cap \mathbf{H}_0^1(y_1, y_2)$ such that

$$\|\phi_{n_k} - \phi_0\|_{C^1} \to 0 \quad \text{and} \quad \|\phi_0\|_2 = 1.$$

Taking limits in

$$\left(\frac{d^2}{dy^2}-\alpha_{n_k}^2\right)\phi_{n_k}-\frac{U''}{U-c_{n_k}}\phi_{n_k}=0,$$

we get

$$-\frac{d^2}{dy^2}\phi_0+\frac{U''}{U-U_s}\phi_0=-\alpha_s^2\phi_0.$$

From the definition of ϕ_s, we have $\phi_s=\phi_0$ and thus the conclusion of Theorem 1.7 follows. □

THEOREM 3.9. *Let $U(y)$ be in class $\mathcal{K}$. Then the set Ξ of all unstable wave numbers is open. Any boundary point α of Ξ must satisfy the condition that $-\alpha^2$ is a negative eigenvalue of $-\frac{d^2}{dy^2}-K(y)$ in $\mathbf{H}^2\cap\mathbf{H}_0^1(y_1,y_2)$.*

Proof. If $\alpha\in\Xi$, then there exists c with $\operatorname{Im}c>0$ such that the Rayleigh equation (3) has some solution ϕ. Let

$$\psi=\left(\frac{d^2}{dy^2}-\alpha^2\right)\phi,\quad B_\alpha\psi:=U\psi-U''\left(\frac{d^2}{dy^2}-\alpha^2\right)^{-1}\psi.$$

Then from (3) we have $B_\alpha\psi=c\psi$. It is easy to see that $\sigma_{ess}(B_\alpha)=[U_{\min},U_{\max}]$. So c is some discrete eigenvalue of B_α. Since B_α is norm continuous in α, for any α' near α, there is also a complex c' in the spectrum of $B_{\alpha'}$. So Ξ is open. From the definition of neutral limiting modes, we know immediately that the boundary points of Ξ are neutral limiting wave numbers. Then the other conclusion in the theorem follows from Theorem 1.7. □

From Theorem 3.9, we know that in order to determine Ξ, we only need to know the instability property near any neutral limiting wave number. This is the basis of our method in the next section for obtaining a sufficient condition for instability.

4. Proof of Theorem 1.2. Let the steady flow $U(y)$ be in the class $\mathcal{K}^+$. To prove Theorem 1.2, we need to study the instability near each neutral limiting wave number. Tollmien [23] heuristically showed that unstable modes exist near a neutral mode for a symmetric flow in class $\mathcal{K}^+$. This was later reconsidered and the asymptotic growth rate was found by C. C. Lin [17]. However, the existence of unstable modes near a neutral mode had still not been rigorously proved. Another approach was recently given in [20] for a monotone flow in class $\mathcal{K}^+$, where the implicit function theorem was invoked to get existence. However, because the differentiability condition was only established on half of a neighborhood, the standard implicit function theorem does not apply. Moreover, the convergence to the neutral eigenfunction in their computation was not specified. Thus, as far as we are aware, a complete proof of Tollmien's argument does not yet exist.

Therefore in this section, we rigorously prove a perturbation result of Tollmien type for flows in class $\mathcal{K}^+$. The existence of an unstable mode is established when the wave number is slightly to the left of a neutral wave number.

THEOREM 4.1. *Suppose $U(y)$ is in class $\mathcal{K}^+$ and (ϕ_s,α_s,U_s) with $\alpha_s>0$ satisfies*

$$-\frac{d^2}{dy^2}\phi_s+\frac{U''}{U-U_s}\phi_s=-\alpha_s^2\phi_s \tag{33}$$

with $\phi_s(y_1) = \phi_s(y_2) = 0$. *Then there exists* $\varepsilon_0 < 0$ *such that if* $\varepsilon_0 < \varepsilon < 0$, *there is a nontrivial solution* ϕ_ε *to the Rayleigh equation*

$$(U - U_s - c(\varepsilon))\left(\frac{d^2}{dy^2} - \alpha(\varepsilon)^2\right)\phi_\varepsilon - U''\phi_\varepsilon = 0$$

with $\phi_\varepsilon(y_1) = \phi_\varepsilon(y_2) = 0$. *Here* $\alpha(\varepsilon) = \sqrt{\varepsilon + \alpha_s^2}$ *is the perturbed wave number and* $U_s + c(\varepsilon)$ *is an unstable eigenvalue with* $\operatorname{Im} c(\varepsilon) > 0$. *Moreover, the function* $c(\varepsilon)$ *is differentiable in* $(\varepsilon_0, 0)$ *and*

$$\lim_{\varepsilon \to 0-} c(\varepsilon) = 0, \tag{34}$$

$$\lim_{\varepsilon \to 0-} c'(\varepsilon) = \frac{\int_{y_1}^{y_2} \phi_s^2(y)\, dy}{i\pi \sum_{k=1}^{l} \left(|U'|^{-1} K\phi_s^2\right)|_{y=a_k} + \mathcal{P}\int_{y_1}^{y_2} \left(K(y)\phi_s^2(y)\right)/(U(y) - U_s)\, dy}, \tag{35}$$

where $a_1, \ldots, a_l$ *are the inflection points such that* $U(a_k) = U_s$, $k = 1, \ldots, l$, *and* $\mathcal{P}\int_{y_1}^{y_2}$ *denotes the Cauchy principal part.*

Remark 4.2. As mentioned in Remark 3.2, the number of points where U takes the value U_s is finite. In formula (35), we have

$$\sum_{k=1}^{l} \left(|U'|^{-1} K\phi_s^2\right)|_{y=a_k} > 0.$$

This is due to the following two facts:

(a) The function ϕ_s must be nonzero at at least one of the points a_k. This is a corollary of Lemma 3.5, where $c = U_s$ and $z_j = a_j$.

(b) We have $U'(a_k) \neq 0$ for each k. Otherwise there exists some k such that $U'(a_k) = 0$. Then it is easy to see that $K(a_k) = \infty$, which is contradictory to our assumption that K is bounded.

Proof of Theorem 4.1. Define $\phi_1(y; c, \varepsilon)$ and $\phi_2(y; c, \varepsilon)$ to be the solutions of

$$-\frac{d^2}{dy^2}\phi + \frac{U''}{U - U_s - c}\phi + \left(\alpha_s^2 + \varepsilon\right)\phi = 0, \tag{36}$$

with $\phi_1(y_1) = 0$, $\phi_1'(y_1) = \phi_s'(y_1)$ and $\phi_2(y_1) = -\frac{1}{\phi_s'(y_1)}$, $\phi_2'(y_1) = 0$. Here $\varepsilon < 0$ and $\operatorname{Im} c > 0$. Then ϕ_1, ϕ_2 are analytic in the upper half-plane as a function of c and ϕ_1, ϕ_2 are independent with Wronskian 1. Now define $I(c, \varepsilon) = \phi_1(y_2; c, \varepsilon)$. The existence of a solution to the Rayleigh equation is equivalent to the existence of a root of I with $\operatorname{Im} c > 0$. It will be proved by a modified Newton method, i.e., by finding a fixed point of

$$c \to c - \frac{I(c, \varepsilon)}{\partial I/\partial c\,|_{(c,\varepsilon)=(0,0)}}\ .$$

Letting

$$N(t, y; \varepsilon, c) = \phi_1(t; \varepsilon, c)\,\phi_2(y; \varepsilon, c) - \phi_2(t; \varepsilon, c)\,\phi_1(y; \varepsilon, c),$$

we will show that

$$\frac{\partial I}{\partial \varepsilon} = \int_{y_1}^{y_2} N\left(y, y_2; \varepsilon, c\right) \phi_1\left(y; c, \varepsilon\right) dy \tag{37}$$

and

$$\frac{\partial I}{\partial c} = \int_{y_1}^{y_2} N\left(y, y_2; \varepsilon, c\right) \frac{U''(y)}{\left(U(y) - U_s - c\right)^2} \phi_1\left(y; c, \varepsilon\right) dy. \tag{38}$$

In order to prove (37) and (38), notice that for (c', ε') close to (c, ε) with $\operatorname{Im} c' > 0$, the function $\phi_1\left(y; c', \varepsilon'\right)$ satisfies

$$\begin{aligned} -\frac{d^2}{dy^2}\phi + \frac{U''}{U - U_s - c}\phi + \left(\alpha_s^2 + \varepsilon\right)\phi \\ = \left[\frac{-U''(y)\left(c' - c\right)}{\left(U(y) - U_s - c\right)\left(U(y) - U_s - c'\right)} - \left(\varepsilon' - \varepsilon\right)\right]\phi. \end{aligned}$$

So

$$\begin{aligned} \phi_1\left(y; c', \varepsilon'\right) = \phi_1\left(y; c, \varepsilon\right) \\ - \int_{y_1}^{y} N\left(t, y; \varepsilon, c\right) \left[\frac{-U''(t)\left(c' - c\right)}{\left(U(t) - U_s - c\right)\left(U(t) - U_s - c'\right)} - \left(\varepsilon' - \varepsilon\right)\right] \phi_1\left(t; c', \varepsilon'\right) dt. \end{aligned}$$

Thus, letting $y = y_2$,

$$\begin{aligned} I\left(c', \varepsilon'\right) = I\left(c, \varepsilon\right) \\ + \int_{y_1}^{y_2} N\left(t, y_2; \varepsilon, c\right) \left[\frac{U''(t)\left(c' - c\right)}{\left(U(t) - U_s - c\right)\left(U(t) - U_s - c'\right)} + \left(\varepsilon' - \varepsilon\right)\right] \phi_1\left(t; c', \varepsilon'\right) dt. \end{aligned}$$

Identities (37) and (38) follow from this identity by letting (c', ε') tend to (c, ε).

Now define the triangle

$$\Delta_{(R,b)} = \left\{c_r + i c_i \mid \ |c_r| < R c_i, 0 < c_i < b\right\}$$

and the Cartesian product

$$E_{(R,b_1,b_2)} = \Delta_{(R,b_1)} \times \left(-b_2, 0\right),$$

where $b_1, b_2 > 0$.

We make the following claims:

(a) For fixed R, $(c, \varepsilon) \in E_{(R,b_1,b_2)}$, $\phi_1\left(y; c, \varepsilon\right)$ uniformly converges to $\phi_s(y)$ in $C^1[y_1, y_2]$ as $c \to 0$, $\varepsilon \to 0-$. That is, for any $\delta > 0$, there exists some $b_0 > 0$ such that

$$\left\|\phi_1\left(y; c, \varepsilon\right) - \phi_s(y)\right\|_{C^1} \leq \delta$$

for $b_1, b_2 < b_0$, $(c, \varepsilon) \in E_{(R,b_1,b_2)}$.

(b) The same conclusion holds true for $\phi_2\left(y; c, \varepsilon\right)$. We denote $\phi_2\left(y; 0, 0\right) = \phi_z(y)$, so that $\phi_z\left(y_2\right) = -\frac{1}{\phi_s'(y_2)}$. Then $\phi_2\left(y; c, \varepsilon\right)$ uniformly converges to $\phi_z(y)$ in $C^1[y_1, y_2]$ for $(c, \varepsilon) \in E_{(R,b_1,b_2)}$, $c \to 0$, $\varepsilon \to 0-$.

Proof of claim (a). Indeed, if it is not true, then there exists $\delta_0 > 0$ and a sequence $\{(c_k, \varepsilon_k)\}_{k=1}^{\infty}$, $(c_k, \varepsilon_k) \to (0,0)$, $|\operatorname{Re} c_k| < R \operatorname{Im} c_k$ such that

$$\|\phi_1(y; c_k, \varepsilon_k) - \phi_s(y)\|_{C^1} \geq \delta_0.$$

Since $|\operatorname{Re} c_k| < R \operatorname{Im} c_k$ and $\operatorname{Im} c_k < b_0$, we have

$$\left|\frac{U''(y)}{U(y) - U_s - c_k}\right| \leq |K(y)| + |K(y)| \left|\frac{c_k}{U(y) - U_s - c_k}\right| \leq |K(y)| \left(1 + \sqrt{R^2+1}\right).$$

Thus

$$\left\|\frac{U''(y)}{U(y) - U_s - c_k}\right\|_{\infty} \leq \|K\|_{\infty} \left(1 + \sqrt{R^2+1}\right). \tag{39}$$

Let $\phi_k = \phi_1(y; c_k, \varepsilon_k)$; then we have uniform bound for $\|\phi_k\|_{C^2}$ because ϕ_k satisfies an ODE (36) with uniformly bounded coefficients and the same initial value. So by the Ascoli–Arzelà lemma, there is a subsequence $\{\phi_{k_i}\}$ and a function $\phi_0 \in C^1[y_1, y_2]$ such that

$$\|\phi_{k_i} - \phi_0\|_{C^1} \to 0$$

as $k_i \to \infty$. Since ϕ_{k_i} satisfies Rayleigh's equation, ϕ_0 satisfies

$$-\frac{d^2}{dy^2}\phi_0 + \frac{U''}{U - U_s}\phi_0 = -\alpha_s^2 \phi_0,$$

with $\phi_0(y_1) = 0, \phi_0'(y_1) = \phi_s'(y_1)$; thus $\phi_0 = \phi_s$. So $\|\phi_{k_i} - \phi_s\|_{C^1} \to 0$, which is a contradiction to our assumption. Claim (b) follows similarly.

In the appendix we prove that

$$\frac{\partial I}{\partial \varepsilon} \to -\frac{1}{\phi_s'(y_2)} \int_{y_1}^{y_2} \phi_s^2(y)\, dy \tag{40}$$

and

$$\frac{\partial I}{\partial c} \to \frac{1}{\phi_s'(y_2)} \left(i\pi \sum_{k=1}^{l} \left(|U'|^{-1} K \phi_s^2 \right)|_{y=a_k} + \mathcal{P} \int_{y_1}^{y_2} \left(K(y) \phi_s^2(y) \right) / \left(U(y) - U_s \right) dy \right) \tag{41}$$

uniformly in $E_{(R,b_1,b_2)}$ as $c \to 0, \varepsilon \to 0-$. Denote these limits by

$$B = -\frac{1}{\phi_s'(y_2)} \int_{y_1}^{y_2} \phi_s^2(y)\, dy,$$

$$C = \frac{1}{\phi_s'(y_2)} \mathcal{P} \int_{y_1}^{y_2} \left(K(y) \phi_s^2(y) \right) / \left(U(y) - U_s \right) dy,$$

$$D = \frac{\pi}{\phi_s'(y_2)} \sum_{k=1}^{l} \left(|U'|^{-1} K \phi_s^2 \right)|_{y=a_k},$$

where a_k $(k = 1, \ldots, l)$ are the inflection points. Denote

$$f(c, \varepsilon) = I(c, \varepsilon) - B\varepsilon - (C + Di)\, c$$

and

$$h(c,\varepsilon) = -\frac{B}{C+iD}\varepsilon - \frac{f(c,\varepsilon)}{C+iD}.$$

Then by the uniform convergence of (40) and (41), for any $\delta_0 > 0$, there exists b_0 so that when $b_1, b_2 < b_0$ we have

$$\left|\frac{\partial f}{\partial c}\right|, \left|\frac{\partial f}{\partial \varepsilon}\right| < \delta_0 \quad \forall (c,\varepsilon) \in E_{(R,b_1,b_2)}. \tag{42}$$

So for any (c,ε), (c',ε') in the convex set $E_{(R,b_1,b_2)}$,

$$|f(c,\varepsilon) - f(c',\varepsilon')| \le \delta_0 (|\varepsilon - \varepsilon'| + |c - c'|). \tag{43}$$

Now in (43) we let $(c',\varepsilon') \to (0,0)$ and notice that

$$\lim_{(c',\varepsilon')\to(0,0)} f(c',\varepsilon') = \lim_{(c',\varepsilon')\to(0,0)} I(c',\varepsilon') = \lim_{(c',\varepsilon')\to(0,0)} \phi_1(y_2; c',\varepsilon') = \phi_s(y_2) = 0,$$

so we obtain

$$|f(c,\varepsilon)| \le \delta_0 (|\varepsilon| + |c|) \ \forall (c,\varepsilon) \in E_{(R,b_1,b_2)}. \tag{44}$$

Note that for fixed ε, a zero of $I(c,\varepsilon)$ is a fixed point of $c \to h(c,\varepsilon)$. Let $R = 4\left|\frac{C}{D}\right|$ if $C \neq 0$ and $R = 1$ if $C = 0$. Notice that by Remark 4.2, $BD < 0$. Denote

$$Q = \sqrt{R^2+1}\frac{-2DB}{C^2+D^2} + 1.$$

Let

$$\delta_0 = \frac{1}{2}\min\left\{\frac{|BC|}{Q(C^2+D^2)}, \frac{-BD}{Q(C^2+D^2)}, 1\right\}\sqrt{C^2+D^2}$$

if $C \neq 0$ and

$$\delta_0 = \frac{1}{2}\min\left\{\frac{-BD}{Q(C^2+D^2)}, 1\right\}\sqrt{C^2+D^2}$$

if $C = 0$. There exists b_0 such that if $b_1, b_2 < b_0$, then (44) and (42) hold. We choose

$$b_2 = \min\left\{\frac{C^2+D^2}{-2DB\sqrt{R^2+1}}, 1\right\} b_0, \qquad b_1 = Qb_2.$$

Fix $\varepsilon \in (-b_2, 0)$ and let

$$b(\varepsilon) = \frac{-2DB}{C^2+D^2}\varepsilon.$$

We will prove that

$$h(\cdot,\varepsilon) : \Delta_{(R,b(\varepsilon))} \to \Delta_{(R,b(\varepsilon))} \text{ is a contraction map,} \tag{45}$$

with contraction ratio no greater than $\frac{1}{2}$ for all $-b_2 < \varepsilon < 0$.

Assuming (45), the theorem follows easily. Indeed, for each $\varepsilon \in (-b_2, 0)$ there exists a unique $c(\varepsilon) \in \Delta_{(R,b(\varepsilon))}$ so that $h(c(\varepsilon), \varepsilon) = c(\varepsilon)$. Since for fixed ε, $h(c, \varepsilon)$ is analytic in $\Delta_{(R,b_1)}$ and uniformly contracting, we know that $c(\varepsilon)$ is the unique fixed point in $\Delta_{(R,b_1)}$ and is differentiable with respect to ε in the interval $(-b_2, 0)$ (see [5, p. 25]). We now let $\varepsilon_0 = -b_2$. Since $c(\varepsilon) \in \Delta_{(R,b(\varepsilon))}$, we have

$$\lim_{\varepsilon \to 0-} c(\varepsilon) = 0.$$

From $I(c(\varepsilon), \varepsilon) = 0$, we obtain

$$c'(\varepsilon) = -\frac{\partial I/\partial \varepsilon}{\partial I/\partial c}.$$

So by (40) and (41), we have

$$\lim_{\varepsilon \to 0-} c'(\varepsilon) = \frac{\int_{y_1}^{y_2} \phi_s^2(y)\, dy}{i\pi \sum_{k=1}^{l} \left(|U'|^{-1} K \phi_s^2 \right) |_{y=a_k} + \mathcal{P} \int_{y_1}^{y_2} \left(K(y) \phi_s^2(y) \right) / \left(U(y) - U_s \right) dy}.$$

This proves (35), and the proof of Theorem 4.1 is complete assuming (45).

Now we prove (45). By our choices of δ_0, b_0, b_1, b_2, and (42), we know

$$\left| \frac{\partial h}{\partial c} \right| = \frac{1}{\sqrt{C^2 + D^2}} \left| \frac{\partial f}{\partial c} \right| \le \frac{1}{\sqrt{C^2 + D^2}} \delta_0 \le \frac{1}{2} \ \forall (c, \varepsilon) \in E_{(R,b_1,b_2)}.$$

Thus h is uniformly contracting with ratio no greater than $\frac{1}{2}$ for each fixed $\varepsilon \in (-b_2, 0)$. We still need to show that $h(c, \varepsilon)$ maps $\Delta_{(R,b(\varepsilon))}$ to itself. If $C \neq 0$, by (44) and the definitions of $b(\varepsilon), Q$, and δ_0, we have

$$\left| \frac{f(c, \varepsilon)}{C + iD} \right| \le \delta_0 \frac{|c| + |\varepsilon|}{\sqrt{C^2 + D^2}} \le \frac{\delta_0}{\sqrt{C^2 + D^2}} \left(1 + \sqrt{R^2 + 1} \frac{-2DB}{C^2 + D^2} \right) |\varepsilon| = \frac{\delta_0 |\varepsilon| Q}{\sqrt{C^2 + D^2}}$$

$$\le \frac{1}{2} \min \left\{ \frac{|BC|}{C^2 + D^2}, \frac{-BD}{C^2 + D^2} \right\} |\varepsilon|. \tag{46}$$

Substituting (46) into

$$\operatorname{Re} h = \frac{-BC}{C^2 + D^2} \varepsilon - \operatorname{Re} \frac{f(c, \varepsilon)}{C + iD},$$

we readily get

$$\frac{1}{2} \frac{|BC|}{C^2 + D^2} |\varepsilon| \le |\operatorname{Re} h| \le 2 \frac{|BC|}{C^2 + D^2} |\varepsilon|. \tag{47}$$

In the same way we get

$$\frac{1}{2} \frac{-BD}{C^2 + D^2} |\varepsilon| \le \operatorname{Im} h \le 2 \frac{-BD}{C^2 + D^2} |\varepsilon| = b(\varepsilon). \tag{48}$$

Combining (47) and (48), we have

$$|\operatorname{Re} h| \le 4 \left| \frac{C}{D} \right| \operatorname{Im} h = R \operatorname{Im} h.$$

So $h \in \Delta_{(R,b(\varepsilon))}$. The proof for the case $C = 0$ is the same. This proves (45), and thus the proof of Theorem 4.1 is complete. □

Proof of Theorem 1.2. Let $-\alpha_m^2 < -\alpha_{m-1}^2 < \cdots < -\alpha_1^2 < 0$ be all the negative eigenvalues of $-\frac{d^2}{dy^2} + K(y)$. Here $\alpha_m = \alpha_{\max}$ as defined by (7). Combining Theorems 3.9 and 4.1, we deduce that if $\alpha \in (0, \alpha_m)$ and $\alpha \neq \alpha_i \, (i = 1, \ldots, m)$, then there exists an unstable mode.

Now we investigate the possibility of an instability at $\alpha = \alpha_i \, (i = 1, \ldots, m)$. For each $\alpha \in (\alpha_i, \alpha_{i+1})$, we know that there exists some unstable eigenvalue $c(\alpha) = c_r(\alpha) + ic_i(\alpha)$ with $c_i > 0$. We claim that

$$\text{as } \alpha \to \alpha_i+, \ c_i(a) \text{ has some lower bound } \delta > 0. \tag{49}$$

Assuming (49), we now show the existence of an unstable eigenvalue at α_i. We take a sequence $\{(c_k, \alpha_k, \phi_k)\}_{k=1}^{\infty}$ with $\alpha_k \to \alpha_i+$ and $\operatorname{Im} c_k \geq \delta > 0$. The function ϕ_k with $\|\phi_k\|_2 = 1$ satisfies the Rayleigh equation

$$-\frac{d^2}{dy^2}\phi_k + \frac{U''}{U - c_k}\phi_k = -\alpha_k^2 \phi_k. \tag{50}$$

By Lemma 3.7, there is an a priori bound for $\|\phi_k\|_{\mathbf{H}^2}$, so there exists some nonzero function $\phi_0 \in \mathbf{H}^2$ such that $\phi_k \to \phi_0$ strongly in $\mathbf{H}^1$. Note that c_k is bounded by (4). Suppose $c_k \to c_0$ with $\operatorname{Im} c_0 \geq \delta$. Now

$$\left\| \frac{U''}{U - c_k} \right\|_{\infty} \leq \frac{\|U''\|_{\infty}}{\delta},$$

so we can pass to the limit in (50) to deduce that ϕ_0 is a weak solution to

$$-\frac{d^2}{dy^2}\phi_0 + \frac{U''}{U - c_0}\phi_0 = -\alpha_i^2 \phi_0.$$

Since $\operatorname{Im} c_0 > 0$, $\frac{U''}{U - c_0}$ is a smooth function. So by elliptic regularity theory, ϕ_0 is a classical solution. Thus at $\alpha = \alpha_i$, we get an unstable eigenvalue c_0.

Proof of (49). If it is not true, then there exists a sequence $\{(c_k, \alpha_k, \phi_k)\}_{k=1}^{\infty}$ of solutions to Rayleigh's equation, with $\alpha_k \to \alpha_i+$ and $\operatorname{Re} c_k \to c_s$, $\operatorname{Im} c_k \to 0+$. By Theorem 1.7, c_s must equal U_s. From the proof of Theorem 1.7, we know that $\phi_k \to \phi_s$ in $C^1[y_1, y_2]$, where ϕ_s is a solution to

$$-\frac{d^2}{dy^2}\phi_s + \frac{U''}{U - U_s}\phi_s = -\alpha_i^2 \phi_s. \tag{51}$$

Multiplying (51) by ϕ_k and subtracting ϕ_s times (50), then integrating from y_1 to y_2, we get

$$\left(\alpha_k^2 - \alpha_i^2\right) \int_{y_1}^{y_2} \phi_s \phi_k dy = -\left(c_k - U_s\right) \int_{y_1}^{y_2} \frac{U'' \phi_s \phi_k}{\left(U - c_k\right)\left(U - U_s\right)} dy.$$

Let

$$A_k = \int_{y_1}^{y_2} \phi_s \phi_k dy, \ B_k = -\int_{y_1}^{y_2} \frac{U'' \phi_s \phi_k}{\left(U - c_k\right)\left(U - U_s\right)} dy.$$

Then

$$\lim_{k\to\infty} A_k = \int_{y_1}^{y_2} |\phi_s|^2 \, dy. \tag{52}$$

In the appendix we will prove

$$\lim_{k\to\infty} B_k = \mathcal{P}\int_{y_1}^{y_2} \frac{K(y)\,\phi_s^2}{(U-U_s)} dy + i\pi \sum_{k=1}^{l} \left(|U'|^{-1} K\phi_s^2 \right) |_{y=a_k}. \tag{53}$$

Now we have

$$\lim_{k\to\infty} \frac{A_k}{B_k} = \frac{\int_{y_1}^{y_2} |\phi_s|^2 \, dy}{\mathcal{P}\int_{y_1}^{y_2} \frac{K(y)\phi_s^2}{(U-U_s)} dy + i\pi \sum_{k=1}^{l} \left(|U'|^{-1} K\phi_s^2 \right) |_{y=a_k}} = a + ib$$

with $b < 0$. Thus if k is large enough,

$$\operatorname{Im} c_k = \left(\alpha_k^2 - \alpha_i^2\right) \operatorname{Im} \frac{A_k}{B_k} < 0,$$

which is a contradiction. So (49) is proved and the proof of Theorem 1.2 is complete. □

We also have the following result about the instability at $\alpha = 0$.

LEMMA 4.3. *If $U(y_1) \neq U(y_2)$, then at $\alpha = 0$ there is also some unstable solution to the Rayleigh equation.*

Proof. Let $\{(c_k, \alpha_k, \phi_k)\}_{k=1}^{\infty}$ be a sequence of unstable solutions with $\alpha_k \to 0+$. It suffices to prove that there is some positive lower bound for $\{\operatorname{Im} c_k\}$. Indeed the existence of an unstable solution at $\alpha = 0$ would follow by the same argument as in the proof of Theorem 1.2.

Assume there is no lower bound. Then $\operatorname{Im} c_k \to 0$, $\operatorname{Re} c_k \to c$. Then ϕ_k converges to a neutral solution $\phi_0 \in \mathbf{H}^2 \cap \mathbf{H}_0^1$ satisfying equation

$$(U-c)\,\phi_0'' - U''\phi_0 = 0 \tag{54}$$

sectionally in each (z_i, z_{i+1}). Here we use the same notation as immediately before Lemma 3.5. We now show that ϕ_0 cannot vanish at any zero $z_1, \ldots, z_{k_c}$ of $U - c$. Indeed, if it is not true, we suppose $\phi_0(z_i) = 0$ and consider (54) in (z_i, z_{i+1}). Then

$$\left((U-c)\,\phi_0' - U'\phi_0\right)(y) \equiv \left((U-c)\,\phi_0' - U'\phi_0\right)(z_i) = 0$$

for all y in the interval (z_i, z_{i+1}). So ϕ_0 and $U - c$ are linearly dependent in (z_i, z_{i+1}). Thus $\phi_0(z_{i+1}) = 0$. Repeating the process, we know that $\phi_0(z_i) = 0$ for all $i = 1, \ldots, k_c$ and there is some constant b such that $U(y) - c = b\phi_0(y)$ for all y in (y_1, y_2). This implies that $U(y_1) = U(y_2) = 0$, which is a contradiction.

Thus ϕ_0 takes a nonzero value at each zero of $U - c$ and ϕ_0 is the limit of unstable eigenfunctions. By the proof of Theorem 3.3 we know that c must equal U_s. Now by the argument in the last part of the proof of Theorem 1.2, we know that there is no perturbation of the neutral mode at $\alpha = 0$ to its right neighborhood. This contradiction shows that the $\operatorname{Im} c_k$ has some positive lower bound. The proof of the lemma is finished. □

Remark 4.4. If $U(y_1) = U(y_2)$, it is possible that at $\alpha = 0$ there is no unstable solution to (3). One such example is $U(y) = \cos 6y$, whose complete spectrum was found in [12] and for which there is no growing mode at $\alpha = 0$.

5. Rotating flows. In this section, we consider the radially symmetric steady flows in an annulus $0 < R_1 \le r \le R_2$. Using polar coordinates (r, θ), we rewrite the vorticity equation (1) as

$$\partial_t \Delta\psi + \frac{1}{r}\frac{\partial\psi}{\partial\theta}\frac{\partial}{\partial r}\Delta\psi - \frac{\partial\psi}{\partial r}\frac{1}{r}\frac{\partial}{\partial\theta}\Delta\psi = 0.$$

Here ψ is the stream function and

$$(u_r, u_\theta) = \left(\frac{1}{r}\frac{\partial\psi}{\partial\theta}, -\frac{\partial\psi}{\partial r}\right), \qquad \omega = -\Delta\psi = \frac{1}{r}\frac{\partial}{\partial r}(ru_\theta) - \frac{1}{r}\frac{\partial u_r}{\partial\theta}$$

are the velocity and vorticity, respectively. And ψ is constant on $r = R_j$ $(j = 1, 2)$. The steady flow is $(u_r, u_\theta) = (0, r\Omega)$, with $\Omega = \Omega(r)$ the steady angular velocity. The linearized equation about this steady flow is

$$\partial_t \Delta\tilde{\psi} + \Omega\frac{\partial}{\partial\theta}\Delta\tilde{\psi} + \left(\frac{\partial}{\partial r}Z\right)\frac{1}{r}\frac{\partial\tilde{\psi}}{\partial\theta} = 0, \tag{55}$$

with $\tilde{\psi}$ constant on $r = R_j$ $(j = 1, 2)$ and the steady vorticity $Z = 2\Omega + r\frac{d\Omega}{dr}$. Taking $\tilde{\psi}(r, \theta, t) = \phi(r)\exp(st + in\theta)$ and letting $D_* = \frac{d}{dr} + \frac{1}{r}$, $D = \frac{d}{dr}$ (following the notation in [6]), we rewrite (55) as

$$(s + in\Omega)\left(D_*D - n^2/r^2\right)\phi - inr^{-1}(rD^2\Omega + 3D\Omega)\phi = 0, \tag{56}$$

with $\phi(R_1) = \phi(R_2) = 0$ and n a positive integer. Letting $c = \frac{s}{in}$, we get the rotating Rayleigh equation (8). Instability would mean that there exists a solution to (8) with $\operatorname{Im} c > 0$. In this section we study the flows such that the function $K(r)$ defined by (9) is positive and bounded, which we still denote by class $\mathcal{K}^+$.

We are interested only in the case when α is a positive integer of the following extended Rayleigh equation:

$$(\Omega - c)\left(D_*D - \alpha^2/r^2\right)\phi - r^{-1}(rD^2\Omega + 3D\Omega)\phi = 0, \tag{57}$$

with $\phi(R_1) = \phi(R_2) = 0$. However, by embedding the original problem into a family of problems (57) depending on a continuous positive parameter α, we can use the same idea as in the shear flow case. For that purpose, first we need to prove the rotating versions of some results used in the shear flow case. We give detailed proofs only when they are really different. First is the extension of Lemma 3.5 to the rotating case. Let $r_1 < r_2 < \cdots < r_{k_c}$ be the zeros of $\Omega(y) - c$ and let S_0 be the complement of the set of points $\{r_i\}$ in the interval $[R_1, R_2]$. Here c is any real number in the range of $\Omega(y)$. Let $r_0 = R_1$ and $r_{k_c+1} = R_2$. Note that for the rotating flows in class $\mathcal{K}^+$, k_c is finite for any c by the same argument as in Remark 3.2.

LEMMA 5.1. *Let ϕ satisfy (57) on S_0 with real $\alpha > 1$ and real c in the range of Ω. We assume ϕ is sectionally continuous on the open intervals (r_j, r_{j+1}), $j = 0, 1, \ldots, k_c$. Then ϕ cannot vanish at both endpoints of any of the intervals (r_j, r_{j+1}) unless it vanishes identically in that interval.*

Proof. The function ϕ satisfies

$$(\Omega - c)\left(D_*D - \alpha^2/r^2\right)\phi - r^{-1}(rD^2\Omega + 3D\Omega)\phi = 0,$$

which is the same as

$$(\Omega - c)D^2\phi - \phi D^2\Omega + (\Omega - c)r^{-1}D\phi - 3r^{-1}\phi D\Omega = (\Omega - c)\frac{\alpha^2}{r^2}\phi.$$

We multiply both sides of the above by r^2 to get

$$(\Omega - c)r^2 D^2\phi - r^2\phi D^2\Omega + (\Omega - c)rD\phi - 3r\phi D\Omega = (\Omega - c)\alpha^2\phi. \tag{58}$$

We have

$$\begin{aligned} LHS &= (\Omega - c)\left[D^2\left(r^2\phi\right) - 4rD\phi - 2\phi\right] - r^2\phi D^2\Omega + (\Omega - c)\, rD\phi - 3r\phi D\Omega \\ &= (\Omega - c)D^2\left(r^2\phi\right) - r^2\phi D^2\Omega - 3\left(D\left(r\phi\right)(\Omega - c) + r\phi D\Omega\right) + \phi(\Omega - c) \\ &= D\left((\Omega - c)D\left(r^2\phi\right) - r^2\phi D\Omega\right) - 3D\left(\left(r\phi\right)(\Omega - c)\right) + \phi(\Omega - c). \end{aligned}$$

So (58) becomes (using $'$ to replace D)

$$\left((\Omega - c)\left(r^2\phi\right)' - r^2\phi\Omega'\right)' - 3\left(\left(r\phi\right)(\Omega - c)\right)' = \left(\alpha^2 - 1\right)\phi(\Omega - c). \tag{59}$$

Suppose ϕ vanishes at r_i and r_{i+1}. Here we mean $\phi\left(r_i+\right)$ for $\phi\left(r_i\right)$ and $\phi\left(r_{i+1}-\right)$ for $\phi\left(r_{i+1}\right)$ when studying (59) in $[r_i, r_{i+1}]$. From the definition of r_i we know that $\Omega - c$ has constant sign in (r_i, r_{i+1}). If $r_i \neq R_1\, (i \neq 0)$, then $\Omega\left(r_i\right) - c = 0$. Let $\tilde{r} \leq r_{i+1}$ be the nearest zero of ϕ in $(r_i, r_{i+1}]$. Since (59) is a real equation, we may assume ϕ is real and nonnegative on the interval $(r_i, \tilde{r})$ and that $\left(r^2\phi\right)'\left(r_i\right) \geq 0$ and $\left(r^2\phi\right)'(\tilde{r}) \leq 0$. Integrating (59) over $\left(r_i, \tilde{r}\right)$, we get

$$\left(\Omega(\tilde{r}) - c\right)\left(r^2\phi\right)'(\tilde{r}) = \left(\alpha^2 - 1\right)\int_{r_i}^{\tilde{r}} \phi(\Omega - c)dr',$$

since ϕ vanishes at the endpoints $r_i, \tilde{r}$.

If $\tilde{r} = r_{i+1,}$ then the left-hand side above must be zero. Hence ϕ is identically zero on (r_i, r_{i+1}). On the other hand, if $\tilde{r} < r_{i+1}$, then $\Omega(\tilde{r}) \neq c$ and

$$\left(r^2\phi\right)'(\tilde{r}) = \left(\alpha^2 - 1\right)\int_{r_i}^{\tilde{r}} \frac{\left(\Omega\left(r'\right) - c\right)}{\left(\Omega(\tilde{r}) - c\right)}\phi\left(r'\right)dr',$$

which could not hold true unless $\phi = 0$ on $[r_i, \tilde{r}]$. But the second order ODE (58) is regular on (r_i, r_{i+1}); thus $\tilde{r}$ could not be a cluster point of nontrivial ϕ. Thus ϕ must be identically zero on $\left(r_i, r_{i+1}\right)$.

If $i = 0$, then we repeat the same argument with the right endpoint of the interval $\left(R_1, r_1\right)$. □

We need Howard's semicircle theorem for the rotating case, which seems not to have been proven in the literature. So we give a proof here.

LEMMA 5.2. *If $\alpha > 1$, then for the extended Rayleigh equation* (57) *to have a solution, c (with $\operatorname{Im} c > 0$) must lie in the semicircle*

$$\left(c_r - \frac{1}{2}\left(\Omega_{\min} + \Omega_{\max}\right)\right)^2 + c_i^2 \leq \left(\frac{1}{2}\left(\Omega_{\min} - \Omega_{\max}\right)\right)^2, \tag{60}$$

where $\Omega_{\min}$ and $\Omega_{\max}$ are the minimum and maximum of $\Omega(r)$ in $[R_1, R_2]$.

Proof. Let ϕ be a solution to (57). As in the proof of the last lemma, ϕ satisfies (59), which we can rewritten as

$$\left(r\left(\phi'(\Omega - c)r - \left((\Omega - c)r\right)'\phi\right)\right)' = \left(\alpha^2 - 1\right)\phi(\Omega - c). \tag{61}$$

The above identity is equivalent to

$$\left(r^3(\Omega-c)^2\left(\frac{\phi}{(\Omega-c)r}\right)'\right)' = \left(\alpha^2-1\right)\phi(\Omega-c). \tag{62}$$

Now $\psi = \frac{\phi}{(\Omega-c)r}$ is a regular function since $\operatorname{Im} c \neq 0$. Then (62) becomes

$$\left(r^3(\Omega-c)^2\psi\right)' = \left(\alpha^2-1\right) r(\Omega-c)^2\psi. \tag{63}$$

Multiplying (63) by ψ^* (conjugate of ψ) and integrating it, we obtain

$$\int_{R_1}^{R_2}(\Omega-c)^2\left(r^3\left|\psi'\right|^2+\left(\alpha^2-1\right)r\left|\psi\right|^2\right)dr = 0. \tag{64}$$

The rest of the proof is the same as in the case of shear flows [14], [6]. We repeat it here for completeness. Let

$$P \equiv r^3\left|\psi'\right|^2+\left(\alpha^2-1\right)r\left|\psi\right|^2.$$

Then (64) becomes

$$\int_{R_1}^{R_2}(\Omega-c)^2 P\ dr = 0. \tag{65}$$

The function P is nonnegative and not identically zero. Comparing the real and imaginary parts of (65), we get

$$\int_{R_1}^{R_2}\left((\Omega-c_r)^2-c_i^2\right)P\ dr = 0 \quad \text{and} \quad 2c_i\int_{R_1}^{R_2}(\Omega-c_r)P\ dr = 0. \tag{66}$$

Observe that

$$\begin{aligned} 0 &\geq \int_{R_1}^{R_2}\left(\Omega-\Omega_{\min}\right)\left(\Omega-\Omega_{\max}\right)P\ dr \\ &= \int_{R_1}^{R_2}\left\{\left(c_r^2+c_i^2\right)-\left(\Omega_{\min}+\Omega_{\max}\right)c_r+\Omega_{\min}\Omega_{\max}\right\}P\ dr, \end{aligned}$$

where (66) is used. So

$$\left(c_r^2+c_i^2\right)-\left(\Omega_{\min}+\Omega_{\max}\right)c_r+\Omega_{\min}\Omega_{\max} \leq 0$$

and the conclusion follows. □

We also have an a priori bound for unstable solutions. The proof of the following lemma is essentially the same as that of Lemma 3.7 in the shear flow case. So we state only the result.

LEMMA 5.3. *Denote* $\omega(r) = rD^2\Omega+3D\Omega$. *For any solution* (α, c, ϕ) *to* (57) *with* α *real positive,* $c = c_r + ic_i\,(c_i > 0)$, *and* $\|\phi\|_2 = 1$, *we have the identities*

$$\int_{R_1}^{R_2} r\left|D\phi\right|^2 dr + \alpha^2\int_{R_1}^{R_2}\frac{1}{r}\left|\phi\right|^2 dr + \int_{R_1}^{R_2}\frac{\omega(r)\left|\phi\right|^2(\Omega-q)}{\left|\Omega-c\right|^2}dr = 0\ \forall q\in\mathbf{R}, \tag{67}$$

$$\int_{R_1}^{R_2}\left(\left|D_*D\phi\right|^2 r^3+2\alpha^2 r\left|D\phi\right|^2 dr+\alpha^4\frac{1}{r}\left|\phi\right|^2\right)dr=\int_{R_1}^{R_2} r\frac{\omega\left(r\right)^2}{\left|\Omega-c\right|^2}\left|\phi\right|^2 dr. \tag{68}$$

For a flow of class $\mathcal{K}^+$, we have the inequalities

$$\int_{R_1}^{R_2}\left(r\left(D\phi\right)^2+\alpha^2\frac{1}{r}\left|\phi\right|^2\right)dr<\int_{R_1}^{R_2} K\left(r\right)\phi^2 dr \tag{69}$$

and

$$\int_{R_1}^{R_2}\left(\left|D_*D\phi\right|^2 r^3+2\alpha^2 r\left|D\phi\right|^2 dr+\alpha^4\frac{1}{r}\left|\phi\right|^2\right)dr<R_2\left\|\omega\right\|_\infty\int_{R_1}^{R_2} K\left(r\right)\phi^2 dr. \tag{70}$$

In particular, we have the a priori estimate $\left\|\phi\right\|_{\mathbf{H}^2}\leq C\left(\Omega\right)$, where $C\left(\Omega\right)$ is some constant depending only on Ω.

Indeed, (67), (68), (69), (70) are the analogues of (29), (31), (27), and (28), respectively. Their proofs are similar to that of the shear flow case.

Remark 5.4. From (69) we see that a necessary condition for instability in the rotating case is

$$\inf_{\phi\in\mathbf{H}_0^1(R_1,R_2)}\frac{\int_{R_1}^{R_2} r\left(D\phi\right)^2 dr-\int_{R_1}^{R_2} K\left(r\right)\phi^2 dr}{\int_{R_1}^{R_2}\frac{1}{r}\phi^2 dr}<-1,$$

since α must be a positive integer.

We now define the neutral limiting modes for the rotating case.

DEFINITION 5.5. *The triple (c_s,α_s,ϕ_s) with c_s real and $\alpha_s>1$ is said to be a neutral limiting mode if it is the limit of growing solutions (c_k,α_k,ϕ_k) (with $\operatorname{Im}c_k>0$) of the extended Rayleigh equation* (57). *The precise notion of convergence of ϕ_k to ϕ_s is made clear in Lemma* 5.6. *Formally (c_s,α_s,ϕ_s) ought to satisfy*

$$\left(\Omega-c_s\right)\left(D_*D-\alpha_s^2/r^2\right)\phi_s-r^{-1}\omega\left(r\right)\phi_s=0. \tag{71}$$

We call c_s the neutral limiting phase speed and α_s the neutral limiting wave number.

The following is the analogue of Lemma 3.6.

LEMMA 5.6. *Let $\{(c_k,\alpha_k,\phi_k)\,(\text{with}\operatorname{Im}c_k>0)\}_{k=1}^{\infty}$ be the solutions to the extended Rayleigh equation* (57) *with $\left\|\phi_k\right\|=1$, and let (c_k,α_k) converge to (c_s,α_s) with $\alpha_s>1$. Then ϕ_k converges uniformly to a function ϕ_s on any compact subset of S_0, ϕ_s'' exists on S_0, and ϕ_s satisfies* (71).

We state the following results about neutral limiting modes without proof. They are the analogues of Theorems 1.7 and 3.9, respectively.

LEMMA 5.7. *If the rotating flow is in class $\mathcal{K}^+$, then for any neutral limiting mode (c_s,α_s,ϕ_s) with $\alpha_s>1$, we must have $c_s=\Omega_s$, and $\phi_s\in\mathbf{H}^2\cap\mathbf{H}_0^1\left(R_1,R_2\right)$ must satisfy*

$$\left(D_*D-\alpha_s^2/r^2\right)\phi_s+r^{-1}K\left(r\right)\phi_s=0. \tag{72}$$

LEMMA 5.8. *Let $\Omega\left(y\right)$ be as in Theorem* 1.3. *Let Ξ be the set of all unstable wave numbers greater than* 1. *Then Ξ is open and any real boundary point α_s of Ξ is either* 1 *or some wave number satisfying* (72) *for some nontrivial ϕ_s in $\mathbf{H}^2\cap\mathbf{H}_0^1\left(R_1,R_2\right)$.*

We also have a perturbation result near neutral modes, the analogue of Theorem 4.1.

THEOREM 5.9. *Suppose* $\Omega(y)$ *is in class* $\mathcal{K}^+$ *and* $(\phi_s, \alpha_s, \Omega_s)$ $(\alpha_s > 1)$ *satisfies*

$$(\Omega - \Omega_s)\left(D_*D - \alpha_s^2/r^2\right)\phi_s - r^{-1}\omega(r)\phi_s = 0, \tag{73}$$

with $\phi_s(R_1) = \phi_s(R_2) = 0$. *Then there exists* $\varepsilon_0 < 0$ *such that if* $\varepsilon_0 < \varepsilon < 0$, *there is a nontrivial solution* ϕ_ε *to the extended Rayleigh equation*

$$(\Omega - \Omega_s - c(\varepsilon))\left(D_*D - \alpha(\varepsilon)^2/r^2\right)\phi_\varepsilon - r^{-1}\omega(r)\phi_\varepsilon = 0,$$

with $\phi_\varepsilon(R_1) = \phi_\varepsilon(R_2) = 0$. *Here* $\alpha(\varepsilon) = \sqrt{\varepsilon + \alpha_s^2}$ *is the perturbed wave number and* $\Omega_s + c(\varepsilon)$ *is an unstable eigenvalue with* $\operatorname{Im} c(\varepsilon) > 0$. *The function* $c(\varepsilon)$ *is differentiable in* $(-\varepsilon_0, 0)$ *and*

$$\lim_{\varepsilon \to 0-} c(\varepsilon) = 0,$$

$$\lim_{\varepsilon \to 0-} c'(\varepsilon) = \frac{\int_{R_1}^{R_2} \frac{1}{r}\phi_s^2(r)\,dr}{i\pi \sum_{k=1}^{l}\left(|\Omega'|^{-1} K\phi_s^2\right)|_{y=r_k} + P\int_{R_1}^{R_2}\left(K(r)\phi_s^2(r)\right)/\left(\Omega(r) - \Omega_s\right)dr}, \tag{74}$$

where $r_1, \ldots, r_l$ *are the points such that* $\Omega(r) = \Omega_s$ *and* $\mathcal{P}\int_{y_1}^{y_2}$ *denotes the Cauchy principal part.*

Proof of Theorem 1.3. If (11) is satisfied, we know that for any $\alpha \in (1, \alpha_{\max})$, there is an unstable solution to the extended Rayleigh equation (57). The proof is essentially the same as that of Theorem 1.2, by using Theorem 5.9 and Lemma 5.8, so we skip it here. If condition (12) is satisfied, then $\alpha_{\max} > 2$, and we get instability at $n = 2$ for the rotating Rayleigh equation (8).

Now we turn to the case when $1 < \alpha_{\max} \le 2$ and $\Omega(R_1) \ne \Omega(R_2)$. We want to show that there exists an unstable mode for $n = 1$. This is the bottom case for rotating flows. Now for each $\alpha \in (1, \alpha_{\max})$, we already have an unstable mode. We shall show that the growth rate $\operatorname{Im} c(\alpha)$ has some positive lower bound when α tends to 1. Assuming this, we can find some unstable mode for $\alpha = 1$ by using the same argument as in the proof of Theorem 1.2.

We now prove that $\operatorname{Im} c(\alpha)$ has some positive lower bound. The argument we use here is similar to that in the proof of Lemma 4.3. Supposing otherwise, we can find a sequence $\{(c_k, \alpha_k, \phi_k)\}_{k=1}^{\infty}$ with $\alpha_k \to 1+$, $\operatorname{Im} c_k \to 0$, $\operatorname{Re} c_k \to c$. The convergence of $\{c_k\}$ is guaranteed by (60), from which we also know that c is in the range of Ω. Because of Lemma 5.3, $\|\phi_k\|_{\mathbf{H}^2}$ is uniformly bounded. So there exists some nonzero ϕ_0 in $\mathbf{H}^2 \cap \mathbf{H}_0^1$ such that a subsequence $\{\phi_{n_k}\}$ converges to it in the $\mathbf{C}^1$ sense. By passing to the limit in the equation

$$(\Omega - c_{n_k})\left(D_*D - \alpha_{n_k}^2/r^2\right)\phi_{n_k} - r^{-1}(rD^2\Omega + 3D\Omega)\phi_{n_k} = 0,$$

we deduce that the function ϕ_0 satisfies

$$(\Omega - c)\left(D_*D - 1/r^2\right)\phi_0 - r^{-1}(rD^2\Omega + 3D\Omega)\phi_0 = 0 \tag{75}$$

sectionally in each (r_i, r_{i+1}). Here $r_1 < r_2 < \cdots < r_{k_c}$ are the zeros of $\Omega(y) - c$ and $r_0 = R_1$, $r_{k_c+1} = R_2$. By (59), ϕ_0 satisfies

$$\left((\Omega - c)\left(r^2\phi_0\right)' - r^2\phi_0\Omega'\right)' - 3\left((r\phi_0)(\Omega - c)\right)' = 0,$$

which is equivalent to

$$\left(r\left(((\Omega-c)r)'\phi_0-\phi_0'(\Omega-c)r\right)\right)'=0. \tag{76}$$

From (76), we deduce that ϕ_0 must be nonzero at each point $r_i\,(i=1,\ldots,k_c)$. Indeed, supposing otherwise, by the same argument as in the proof of Lemma 4.3, we can show that there is some constant b such that $(\Omega(r)-c)r=b\phi_0(r)$ in $[R_1,R_2]$. This implies that $\Omega(R_1)=\Omega(R_2)$, a contradiction. Now by the same argument as in the last part of the proof of Theorem 1.2, we can show that there is no perturbation of the neutral mode at $\alpha=1$ to its right neighborhood. This contradiction shows that $\operatorname{Im}c(\alpha)$ is bounded below and $\operatorname{Im}c>0$. Thus ϕ_0 satisfying (75) is an unstable solution to the rotating Rayleigh equation (8).

Combining this result with Remark 5.4, we deduce that the condition (11) is sharp for instability when $\Omega(R_1)\neq\Omega(R_2)$. This finishes the proof of Theorem 1.3. □

6. Unbounded flows. We now consider the unbounded shear flows. We prove Theorem 1.5(i) only for the flow $U(y)$ defined on $(-\infty,+\infty)$. The proof of Theorem 1.5(i) for the shear flows defined on the half line is similar. The flow with $U(-\infty)=U(+\infty)$ is called a jet and the one with $U(-\infty)\neq U(+\infty)$ is called a shear layer, as in [7].

Proof of Theorem 1.5(i). We divide the proof into several steps.

Step 1. First we observe that for any real c, $U(y)=c$ holds for only a finite number of points. Otherwise, there exists some real c_0 and an infinite sequence $\{y_n\}$ such that $U(y_n)=c_0$ for each n. Then $\{y_n\}$ must be bounded by our condition that $U(\pm\infty)$ are obtained at only a finite number of points. So there exists some y_0 such that a subsequence $\{y_{n_k}\}$ converges to it. Since $U(y)$ is a $\mathbf{C}^2$ function, we deduce that $U(y_0)=c_0$ and $U'(y_0)=U''(y_0)=0$. So y_0 is an inflection point and c_0 equals the inflection value U_s. But then $K(y)$ defined by (5) is unbounded at y_0 since $U'(y_0)=0$. This is a contradiction.

Since $K(y)\to 0$ as $y\to\infty$, it is easy to see that $-\frac{d^2}{dy^2}-K(y)$ is a relatively compact perturbation of $-\frac{d^2}{dy^2}$ defined on $\mathbf{H}^2(\mathbf{R})$. So by Weyl's theorem [21]

$$\sigma_{\mathrm{ess}}\left(-\frac{d^2}{dy^2}-K(y)\right)=\sigma_{\mathrm{ess}}\left(-\frac{d^2}{dy^2}\right)=(0,+\infty).$$

Thus $-\frac{d^2}{dy^2}-K(y)$ has only a discrete set of negative eigenvalues which can accumulate only at 0. Let $-\alpha_0^2<-\alpha_1^2<\cdots<-\alpha_k^2<\cdots<0$ denote all the negative eigenvalues of the operator $-\frac{d^2}{dy^2}-K(y)$ on $\mathbf{H}^2(\mathbf{R})$. We fix some α in $(0,\alpha_0)$ and assume $\alpha\neq\alpha_i$ for each $i\geq 1$. Let $I_n=(-n,n)$ and let L_n denote the operator $-\frac{d^2}{dy^2}-K(y)$ on $\mathbf{H}^2(I_n)\cap\mathbf{H}_0^1(I_n)$. Take n large enough so that all the inflection points of $K(y)$ are included in I_n. Denote by $-\alpha_{0,n}^2$ the lowest eigenvalue of L_n. Then by the result of [3], $-\alpha_{0,n}^2$ converges to $-\alpha_0^2$ as n tends to infinity. So by taking n large enough, α is in $(0,\alpha_{0,n})$. Now since $U(y)|_{I_n}$ is clearly in class $\mathcal{K}^+$, by applying Theorem 1.2 to this truncated flow, we obtain a solution ϕ_n in $\mathbf{H}^2(I_n)\cap\mathbf{H}_0^1(I_n)$ satisfying the Rayleigh equation with c_n $(\operatorname{Im}c_n>0)$, that is,

$$(U-c_n)\left(\frac{d^2}{dy^2}-\alpha^2\right)\phi_n-U''\phi_n=0 \tag{77}$$

in I_n.

Step 2. Now we have a sequence $\{(\phi_n, c_n)\}$ satisfying (77) with $\|\phi_n\|_{\mathbf{L}^2(I_n)} = 1$. By Lemma 3.7, we have $\|\phi_n\|_{\mathbf{H}^2(I_n)} \leq C$ (where C is some constant depending only on $\|K\|_\infty$). We extend ϕ_n to a function in $\mathbf{H}^2(\mathbf{R})$ by setting it to be zero on I_n^c. For convenience, we still use ϕ_n to denote the extended function. Then $\|\phi_n\|_{\mathbf{H}^2(\mathbf{R})} \leq C$. So ϕ_n converges weakly in $\mathbf{H}^2(\mathbf{R})$ to a function $\phi_0 \in \mathbf{H}^2(\mathbf{R})$. We shall show that ϕ_0 is not identically zero.

Let n_0 be sufficiently large such that

$$K(y) < \frac{1}{2}\alpha^2 \quad \text{if} \quad y \in I_{n_0}^c.$$

From (27) we have

$$\int_{I_n} \left(|\phi_n'|^2 + \alpha^2 |\phi_n|^2 \right) dy < \int_{I_n} K(y) |\phi_n|^2 \, dy. \tag{78}$$

For any $n > n_0$, from (78) and $K > 0$ we have

$$\begin{aligned} \int_{I_{n_0}} K(y) |\phi_n|^2 \, dy &> \alpha^2 - \int_{I_{n_0}^c \cap I_n} K(y) |\phi_n|^2 \, dy \\ &> \alpha^2 - \frac{1}{2}\alpha^2 \int_{I_{n_0}^c \cap I_n} |\phi_n|^2 \, dy \\ &> \frac{1}{2}\alpha^2. \end{aligned} \tag{79}$$

Since ϕ_n converges strongly in $\mathbf{H}^1(I_{n_0})$ to ϕ_0, from (79) we get

$$\int_{I_{n_0}} K(y) |\phi_0|^2 \, dy \geq \frac{1}{2}\alpha^2.$$

This shows that ϕ_0 is nontrivial.

Step 3. By Howard's semicircle theorem (see (4)), $\{c_n\}$ is bounded. Supposing c_n to converge to c_0, we shall show that $\operatorname{Im} c_0 > 0$. Otherwise, c_0 is some real number in the range of $U(y)$. From the a priori $\mathbf{H}^2$ bound provided by Lemma 3.7, we deduce that ϕ_n converges to ϕ_0 locally in $\mathbf{C}^1$. Suppose $z_1 < \cdots < z_{k_0}$ are all the points such that $U(z_i) = c_0$. Then by taking limit $k \to \infty$ in (77), we deduce that ϕ_0 satisfies

$$(U - c_0) \left(\frac{d^2}{dy^2} - \alpha^2 \right) \phi_0 - U'' \phi_0 = 0 \tag{80}$$

within each interval $(-\infty, z_1)$, $(z_1, z_2), \ldots, (z_{k_0}, \infty)$. Since $\phi_0 \neq 0$, by the proof of Lemma 3.5, we deduce that $\phi_0(z_i) \neq 0$ for some z_i. Then by the same argument as in the proof of Theorem 3.3, we know that c_0 must be an inflection value of $U(y)$, which can only be U_s. Now

$$\frac{U''}{U - c_0} = -K(y)$$

is a bounded continuous function and ϕ_0 is in $\mathbf{C}^1$. So from (80), ϕ_0 satisfies

$$\left(\frac{d^2}{dy^2} - \alpha^2 \right) \phi_0 + K(y) \phi_0 = 0$$

on $\mathbf{R}$ and $\phi_0 \in \mathbf{H}^2(\mathbf{R})$. Thus $-\alpha^2$ is a negative eigenvalue of

$$-\frac{d^2}{dy^2} - K(y)$$

on $\mathbf{H}^2(\mathbf{R})$, which is a contradiction to our assumption that $\alpha \neq \alpha_i$ for all i. So we must have $\operatorname{Im} c_0 > 0$.

Now $\frac{U''}{U-c_0}$ is a bounded continuous function. By passing to limits in (77), we deduce that $\phi_0 \neq 0$ satisfies the Rayleigh equation (3) on the whole line, with $\operatorname{Im} c_0 > 0$. We thus get instability for each wave number α in $(0, \alpha_0)$ such that $\alpha \neq \alpha_i (i \geq 1)$.

Step 4. Now we investigate the possibility of an instability at $\alpha = \alpha_i (i \geq 1)$. The argument is the same as in the proof of Theorem 1.2 for the case when a wave number equals some neutral limiting wave number. We only sketch it here. For each $\alpha > \alpha_i$, we get instability by the previous steps. The main point is still to show that the growth rate $\operatorname{Im} c(\alpha)$ has some positive lower bound when $\alpha \to \alpha_i +$. Supposing otherwise, we get a sequence $\{(c_k, \alpha_k, \phi_k)\}_{k=1}^{\infty}$ of solutions to Rayleigh's equation (3), with $\alpha_k \to \alpha_i +$ and $\operatorname{Re} c_k \to c_s$, $\operatorname{Im} c_k \to 0 +$. It is not difficult to see that we can extend Theorem 1.7 to the current case, so c_s must equal U_s. By the same argument as in Step 2, we deduce that ϕ_k converges to some $\phi_s \neq 0$ weakly in $\mathbf{H}^2(\mathbf{R})$ and locally in $\mathbf{C}^1$. Now ϕ_s satisfies

$$-\frac{d^2}{dy^2}\phi_s + \frac{U''}{U-U_s}\phi_s = -\alpha_i^2 \phi_s. \tag{81}$$

By Remark 7.2 in the appendix, the analogues of the two limits (52) and (53) still hold true. That is, we have

$$\int_{\mathbf{R}} \phi_k \phi_s \to \int_{\mathbf{R}} |\phi_s|^2 \, dy \tag{82}$$

and

$$\int_{\mathbf{R}} \frac{K(y)\phi_s \phi_k}{U-c_k} dy \to \mathcal{P}\int_{\mathbf{R}} \frac{K(y)\phi_s^2}{(U-U_s)} dy + i\pi \sum_{i=1}^{l} \left(|U'|^{-1} K \phi_s^2 \right)|_{y=a_i}. \tag{83}$$

Here $a_1, \ldots, a_l$ are all the inflection points and $c_k \to U_s$ with $\operatorname{Im} c_k > 0$. Then the rest of the proof just follows what we did in the last part of the proof of Theorem 1.2. So we skip it here. □

Proof of Theorem 1.5(ii). Assume ϕ is odd on the whole line. Fix α in the interval $(\alpha_{2k_0-1}, \alpha_{2k_0-2})$ for some k_0. Using the same notation as in Step 1 of the proof of (i), we get the truncated operator L_n defined on $I_n = (-n, n)$. Let $-\alpha_{0,n}^2 < -\alpha_{1,n}^2 < \cdots < -\alpha_{k,n}^2 < \cdots < 0$ be all the negative eigenvalues of L_n. By the result in [3], L_n has at least $2k_0$ negative eigenvalues when n is large enough and $(-\alpha_{0,n}^2, \ldots, -\alpha_{2k_0-1,n}^2)$ converges to $\left(-\alpha_0^2, \ldots, -\alpha_{2k_0-1}^2\right)$ as n tends to infinity. So for n large enough, α is in the interval $(\alpha_{2k_0-1,n}, \alpha_{2k_0-2,n})$. Since $U(y)|_{I_n}$ is odd, by Theorem 1.4 we obtain an unstable solution ϕ_n satisfying (77) in I_n, with $c_n = i\lambda_n$ $(\lambda_n > 0)$. We get the same a priori bound as in Lemma 3.7 directly as follows. By Lemma 3.5 with $q = 0$, we have

$$\int_{I_n} \left(|\phi_n'|^2 + \alpha^2 |\phi_n|^2 + \frac{U''U}{|U - i\lambda_n|^2} |\phi_n|^2 \right) dy = 0.$$

Thus

$$\int_{I_n}\left(\left|\phi_n'\right|^2+\alpha^2\left|\phi_n\right|^2\right)dy=\int_{I_n}K(y)\frac{U^2}{U^2+\lambda_n^2}\left|\phi_n\right|^2dy$$
$$\leq\int_{I_n}\left|K(y)\right|\left|\phi_n\right|^2dy. \tag{84}$$

Similarly, we get from (31) that

$$\int_{I_n}\left(\left|\phi_n''\right|^2+2\alpha^2\left|\phi_n'\right|^2+\alpha^4\left|\phi\right|^2\right)dy<\int_{I_n}K(y)^2\left|\phi_n\right|^2dy. \tag{85}$$

From (84) and (85), we have $\|\phi_n\|_{\mathbf{H}^2(\mathbf{R})}\leq C\left(\|K\|_\infty\right)$. So ϕ_n converges to some ϕ_0 weakly in $\mathbf{H}^2(\mathbf{R})$. Let λ_n converge to some nonnegative λ_0. By the same argument as in Steps 2 and 3 of the proof of (i), we show that $\phi_0\neq 0$ and $\lambda_0>0$. Then we get an unstable solution ϕ_0 to the Rayleigh equation on the whole line, with the unstable eigenvalue $c=i\lambda_0$. The proof of Theorem 1.5(ii) is thus finished. □

Using the same argument as in the proof of Lemma 4.3, we can show that if $U(-\infty)\neq U(+\infty)$ (the shear layer case), then at $\alpha=0$ there is also an unstable solution to the Rayleigh equation. This coincides with the conclusion in [7], which was deduced from the asymptotic expansion in the long wave limit.

7. Appendix. In this appendix, we prove some asymptotic formulas used in the proof of Theorems 4.1 and 1.2.

LEMMA 7.1. *Assume a sequence of differentiable functions* $\{\psi_k\}_{k=1}^\infty$ *converges in* $C^1[y_1,y_2]$ *to* $\psi_0(y)$. *Let* $c_k=p_k+ib_k\,(b_k>0)$ *converge to* 0. *Denote* $W_k(y)=U(y)-U_s-p_k$. *Then we have following limits:*

$$\lim_{k\to\infty}\int_{y_1}^{y_2}\frac{\psi_k(y)W_k(y)}{W_k(y)^2+b_k^2}dy=\mathcal{P}\int_{y_1}^{y_2}\frac{\psi_0(y)}{U(y)-U_s}dy, \tag{86}$$

$$\lim_{k\to\infty}\int_{y_1}^{y_2}\frac{\psi_k(y)W_k(y)^3}{\left(W_k(y)^2+b_k^2\right)^2}dy=\mathcal{P}\int_{y_1}^{y_2}\frac{\psi_0(y)}{U(y)-U_s}dy, \tag{87}$$

$$\lim_{k\to\infty}\int_{y_1}^{y_2}\frac{\psi_k(y)b_k}{W_k(y)^2+b_k^2}dy=\pi\sum_{i=1}^{l}\left(\left|U'\right|^{-1}\psi_0\right)|_{y=a_i}, \tag{88}$$

$$\lim_{k\to\infty}\int_{y_1}^{y_2}\frac{\psi_k(y)b_k^3}{\left(W_k(y)^2+b_k^2\right)^2}dy=\frac{1}{2}\pi\sum_{i=1}^{l}\left(\left|U'\right|^{-1}\psi_0\right)|_{y=a_i}, \tag{89}$$

$$\lim_{k\to\infty}\int_{y_1}^{y_2}\frac{\psi_k(y)b_k^2W_k}{\left(W_k(y)^2+b_k^2\right)^2}dy=\lim_{k\to\infty}\int_{y_1}^{y_2}\frac{\psi_k(y)b_k^3}{\left(W_k(y)^2+b_k^2\right)^2}dy=0. \tag{90}$$

Here $a_1,\ldots,a_l$ *are all the points such that* $U(y)=U_s$, *and we assume* $U'(y)\neq 0$ *at each* a_k.

Proof. Let $\|\psi_k\|_{\mathbf{C}^1} \leq M$ (independent of k). For $\delta_0 > 0$, we can find $r_0 > 0$ such that $|U'(y)| \geq \delta_0$ for all y in the set $E_{r_0} = \cup_{i=1}^{l} I(a_i; r_0)$. Here $I(a_i; r_0) = (a_i - r_0, a_i + r_0)$. Taking k large enough, then we know there are exactly l points such that $W_k(y) = 0$, one in each $I(a_i; r_0)$, which we denote by $a_i^{(k)}$.

Proof of (86). By the definition of Cauchy principal part, for any $\varepsilon > 0$, there exists some $r_1 > 0$ such that if $0 < r < r_1$, then

$$\left| \int_{E_r^c} \frac{\psi_0(y)}{U(y) - U_s} dy - \mathcal{P} \int_{y_1}^{y_2} \frac{\psi_0(y)}{U(y) - U_s} dy \right| < \frac{\varepsilon}{3}. \tag{91}$$

Now

$$\frac{\psi_k(y) W_k(y)}{W_k(y)^2 + b_k^2} \to \frac{\psi_0(y)}{U(y) - U_s}$$

in E_r^c uniformly as $k \to \infty$. So if k is large enough, then

$$\left| \int_{E_r^c} \frac{\psi_k(y) b_k}{W_k(y)^2 + b_k^2} dy - \int_{E_r^c} \frac{\psi_0(y)}{U(y) - U_s} dy \right| < \frac{\varepsilon}{3}. \tag{92}$$

Let $r < \min\{r_0, r_1\}$. We estimate the integral on each $I(a_i; r)$. Suppose U is increasing on $I(a_1; r)$. Let

$$t = W_k(y), \quad t_1^k = W_k(a_1 + r), \quad t_0^k = W_k(a_1 - r),$$

$$\tilde{\psi}_k(t) = \psi_k(W_k(t)) \frac{1}{U'(W_k(t))}.$$

Then

$$\int_{I(a_1;r)} \frac{\psi_k(y) W_k(y)}{W_k(y)^2 + b_k^2} dy$$

$$= \int_{t_0^k}^{t_1^k} \frac{\tilde{\psi}_k(t)\, t}{t^2 + b_k^2} dt = \tilde{\psi}_k(0) \int_{t_0^k}^{t_1^k} \frac{t}{t^2 + b_k^2} dt + \left(\int_{t_0^k}^{t_1^k} \frac{\left(\tilde{\psi}_k(t) - \tilde{\psi}_k(0)\right) t}{t^2 + b_k^2} dt \right) = I + II.$$

We have

$$\left| t_1^k - t_0^k \right| \leq \|U'\|_\infty 2r,$$

and $|\tilde{\psi}_k'(t)| \leq M'$ (independent of k) in $I(a_1; r)$. So

$$\|II\| \leq M' \left| t_1^k - t_0^k \right| \leq M' \|U'\|_\infty 2r.$$

And

$$I = \tilde{\psi}_k(0) \frac{1}{2} \ln \frac{t_1^k + b_k^2}{t_0^k + b_k^2}$$

tends to zero as k tends to infinity for any fixed $r > 0$. Thus by choosing r small enough and then letting k large, we have

$$\left| \int_{E_r} \frac{\psi_k(y) W_k(y)}{W_k(y)^2 + b_k^2} dy \right| < \frac{\varepsilon}{3}.$$

Combining with (91) and (92), we have for k large enough

$$\left| \int_{y_1}^{y_2} \frac{\psi_k(y) W_k(y)}{W_k(y)^2 + b_k^2} dy - \mathcal{P} \int_{y_1}^{y_2} \frac{\psi_0(y)}{U(y) - U_s} dy \right| < \varepsilon.$$

This ends the proof of (86).

We prove (87) and (90) in the same way.

Proof of (88). For any fixed r,

$$\lim_{k\to\infty} \int_{E_r^c} \frac{\psi_k(y) b_k}{W_k(y)^2 + b_k^2} dy = 0.$$

So we only need to consider the integral on each small interval $I(a_i; r)$. Using the same notation as above, we have

$$\begin{aligned} &\int_{I(a_1;r)} \frac{\psi_k(y) b_k}{W_k(y)^2 + b_k^2} dy \\ &= \int_{t_0^k}^{t_1^k} \frac{\tilde{\psi}_k(t) b_k}{t^2 + b_k^2} dt = \tilde{\psi}_k(0) \int_{t_0^k}^{t_1^k} \frac{b_k}{t^2 + b_k^2} dt + \left(\int_{t_0^k}^{t_1^k} \frac{\left(\tilde{\psi}_k(t) - \tilde{\psi}_k(0)\right) b_k}{t^2 + b_k^2} dt \right) = I + II. \end{aligned}$$

Then it is easy to see

$$|II| \le \frac{1}{2} M' \left| t_1^k - t_0^k \right| \le M' \|U'\|_\infty r.$$

Since

$$\lim_{k\to\infty} \tilde{\psi}_k(0) = \lim_{k\to\infty} \psi_k\left(a_1^{(k)}\right) \frac{1}{U'\left(a_1^{(k)}\right)} = \psi_0(a_1) \frac{1}{U'(a_1)},$$

$$\lim_{k\to\infty} t_1^k = U(a_1 + r) - U(a_1) > 0, \quad \lim_{k\to\infty} t_0^k = U(a_1 - r) - U(a_1) < 0$$

so we have

$$\lim_{k\to\infty} I = \lim_{k\to\infty} \tilde{\psi}_k(0) \int_{\frac{t_0^k}{b_k}}^{\frac{t_0^k}{b_k}} \frac{1}{t^2 + 1} dt = \psi_0(a_1) \frac{1}{U'(a_1)} \int_{-\infty}^{+\infty} \frac{1}{t^2 + 1} dt = \pi \psi_0(a_1) \frac{1}{U'(a_1)}.$$

Summing the contributions from each $I(a_i; r)$, we deduce (88). The proof of (89) is the same by noticing that

$$\int_{\mathbf{R}} \frac{1}{(1 + t^2)^2} dt = \frac{1}{2}\pi. \qquad \square$$

Now (53) follows directly from the above lemma. Indeed letting $\psi_k = K(y) \phi_s \phi_k$, $c_k = p_k + i b_k$, we can write B_k in (53) as

$$B_k = \int_{y_1}^{y_2} \frac{\psi_k(y) W_k(y)}{W_k(y)^2 + b_k^2} dy + i \int_{y_1}^{y_2} \frac{\psi_k(y) b_k}{W_k(y)^2 + b_k^2} dy.$$

Since

$$\psi_k \to \psi_0 = K(y) \phi_s^2 \quad \text{in } C^1[y_1, y_2] \text{ as } k \to \infty,$$

by (86) and (88) we have

$$\lim_{k\to\infty} B_k = \mathcal{P}\int_{y_1}^{y_2} \frac{K(y)\,\phi_s^2}{(U-U_s)}dy + i\pi\sum_{k=1}^{l}\left(\left|U'\right|^{-1} K\phi_s^2\right)|_{y=a_k}.$$

Remark 7.2. *The limit* (53) *still holds for the case* $[y_1, y_2] = (-\infty, +\infty)$ *or* $(0, +\infty)$ *under the assumption that* $\{\phi_k\}_{k=1}^{\infty}$ *converges weakly in* $\mathbf{L}^2(y_1, y_2)$ *and locally in* C^1 *to* $\phi_0(y)$. *To see it, we notice that for fixed* $r_0 > 0$,

$$\lim_{k\to\infty}\int_{\mathbf{R}/E_{r_0}} \frac{K(y)\,\phi_s\phi_k W_k(y)}{W_k(y)^2 + b_k^2}dy = \int_{\mathbf{R}/E_{r_0}} \frac{K(y)\,\phi_s^2}{U(y) - U_s}dy$$

by weak convergence of ϕ_k. *We can deal with the integral on each small interval* $I(a_i; r_0)$ *in the same way as in the proof of Lemma* 7.1, *noticing that the* $\mathbf{C}^1$ *norm of* ϕ_k *is locally uniformly bounded.*

To prove (41) we need the following lemma.

LEMMA 7.3. *Assume a sequence of differentiable functions* $\{\Gamma_k\}_{k=1}^{\infty}$ *converges in* $C^1[y_1, y_2]$ *to* $\Gamma_0(y)$. *Let* $c_k = p_k + ib_k$ *converge to* 0, *where* $b_k > 0$ *and* $|p_k| \le Rb_k$. *Then we have*

(93)
$$\lim_{k\to\infty} -\int_{y_1}^{y_2} \frac{U''(y)\,\Gamma_k(y)}{(U - U_s - c_k)^2}dy = \mathcal{P}\int_{y_1}^{y_2} \frac{K(y)\,\Gamma_0(y)}{U(y) - U_s}dy + i\pi\sum_{i=1}^{l}\left(\left|U'\right|^{-1} K\phi_0\right)|_{y=a_i}.$$

Proof. Denote $W_k(y) = U(y) - U_s - p_k$. We have

$$\begin{aligned}
&\int_{y_1}^{y_2} \frac{-U''(y)\,\Gamma_k(y)}{(U - U_s - c_k)^2}dy\\
&= \int_{y_1}^{y_2} \frac{K(y)\,\Gamma_k(y)\,(U(y) - U_s)}{(W_k(y) - ib_k)^2}dy\\
&= \int_{y_1}^{y_2} \frac{K(y)\,\Gamma_k(y)\,(W_k + p_k)\left(W_k^2 + 2ib_kW_k - b_k^2\right)}{(W_k^2 + b_k^2)^2}dy\\
&= \int_{y_1}^{y_2} \frac{K(y)\,\Gamma_k(y)\,W_k^3}{(W_k^2 + b_k^2)^2}dy + 2i\int_{y_1}^{y_2} \frac{K(y)\,\Gamma_k(y)\,b_kW_k^2}{(W_k^2 + b_k^2)^2}dy - \int_{y_1}^{y_2} \frac{K(y)\,\Gamma_k(y)\,W_kb_k^2}{(W_k^2 + b_k^2)^2}dy\\
&\qquad + \int_{y_1}^{y_2} \frac{K(y)\,\Gamma_k(y)\,p_k\left(W_k^2 - b_k^2\right)}{(W_k^2 + b_k^2)^2}dy + 2i\int_{y_1}^{y_2} \frac{K(y)\,\Gamma_k(y)\,p_kb_kW_k}{(W_k^2 + b_k^2)^2}dy\\
&= I + II + III + IV + V\ .
\end{aligned}$$

Now we estimate each term separately. By (87) in Lemma 7.1, we have

$$\lim_{k\to\infty} I = \mathcal{P}\int_{y_1}^{y_2} \frac{K(y)\,\Gamma_0(y)}{U(y) - U_s}dy.$$

By (88) and (89), we have

$$\begin{aligned}\lim_{k\to\infty} II &= 2i\left(\lim_{k\to\infty}\int_{y_1}^{y_2}\frac{K(y)\Gamma_k(y)b_k}{W_k^2+b_k^2}dy-\lim_{k\to\infty}\int_{y_1}^{y_2}\frac{K(y)\Gamma_k(y)b_k^3}{\left(W_k^2+b_k^2\right)^2}dy\right)\\ &= 2i\left(\pi\sum_{i=1}^{l}\left(|U'|^{-1}K\phi_0\right)|_{y=a_i}-\frac{1}{2}\pi\sum_{i=1}^{l}\left(|U'|^{-1}K\phi_0\right)|_{y=a_i}\right)\\ &= i\pi\sum_{i=1}^{l}\left(|U'|^{-1}K\phi_0\right)|_{y=a_i}.\end{aligned}$$

By (90), $\lim_{k\to\infty} III = 0$. Notice that

$$\begin{aligned}IV &= \frac{p_k}{b_k}\int_{y_1}^{y_2}\frac{K(y)\Gamma_k(y)b_k\left(W_k^2+b_k^2-2b_k^2\right)}{\left(W_k^2+b_k^2\right)^2}dy\\ &= \frac{p_k}{b_k}\left(\int_{y_1}^{y_2}\frac{K(y)\Gamma_k(y)b_k}{W_k^2+b_k^2}dy-2\int_{y_1}^{y_2}\frac{K(y)\Gamma_k(y)b_k^3}{\left(W_k^2+b_k^2\right)^2}dy\right)\\ &= \frac{p_k}{b_k}VI.\end{aligned}$$

By (88) and (89), we have

$$\begin{aligned}\lim_{k\to\infty} VI &= \lim_{k\to\infty}\int_{y_1}^{y_2}\frac{K(y)\Gamma_k(y)b_k}{W_k^2+b_k^2}dy-2\lim_{k\to\infty}\int_{y_1}^{y_2}\frac{K(y)\Gamma_k(y)b_k^3}{\left(W_k^2+b_k^2\right)^2}dy\\ &= \pi\sum_{i=1}^{l}\left(|U'|^{-1}K\ \Gamma_0\right)|_{y=a_i}-2\frac{1}{2}\pi\sum_{i=1}^{l}\left(|U'|^{-1}K\ \Gamma_0\right)|_{y=a_i}\\ &= 0.\end{aligned}$$

Combining it with the fact that $|p_k| \le Rb_k$, we have $\lim_{k\to\infty} IV = 0$. Now for the last term, we have

$$V = 2i\frac{p_k}{b_k}\int\frac{K(y)\Gamma_k(y)b_k^2W_k}{\left(W_k^2+b_k^2\right)^2}dy = 2i\frac{p_k}{b_k}VII.$$

By (90), $\lim_{k\to\infty} VII = 0$. Thus we also have $\lim_{k\to\infty} V = 0$ since $|p_k| \le Rb_k$.

Combining the five terms above, we get (93). □

Proof of (41). We must show that (41) holds uniformly in $E_{(R,b_1,b_2)}$. Supposing otherwise, we can find some $\delta_0 > 0$ and a sequence (c_k, ε_k) in E_{R,b_1,b_2} with $\max\left\{b_1^k, b_2^k\right\}$ tending to 0 such that

$$\left|\frac{\partial I}{\partial c}(c_k,\varepsilon_k)-(C+iD)\right| > \delta_0,$$

where

$$C+iD = \frac{1}{\phi_s'(y_2)}\left(i\pi\sum_{k=1}^{l}\left(|U'|^{-1}K\phi_s^2\right)|_{a_k}+\mathcal{P}\int_{y_1}^{y_2}\left(K(y)\phi_s^2(y)\right)/\left(U(y)-U_s\right)dy\right).$$

But

$$\frac{\partial I}{\partial c}(c_k, \varepsilon_k) = \int_{y_1}^{y_2} \frac{-U''(y)\,\Gamma_k(y)}{(U - U_s - c_k)^2} dy,$$

where

$$\Gamma_k(y) = -N(y, y_2; \varepsilon_k, c_k)\,\phi_1(y; c_k, \varepsilon_k).$$

Since Γ_k converges in $\mathbf{C}^1$ to

$$-N(y, y_2; 0, 0)\,\phi_1(y; 0, 0) = \frac{1}{\phi_s'(y_2)}\phi_s^2(y),$$

Lemma 7.3 implies

$$\begin{aligned}
&\lim_{k\to\infty} \frac{\partial I}{\partial c}(c_k, \varepsilon_k) \\
&= \frac{1}{\phi_s'(y_2)} \left(i\pi \sum_{k=1}^{l} \left(|U'|^{-1} K \phi_s^2 \right)|_{a_k} + \mathcal{P} \int_{y_1}^{y_2} \left(K(y)\,\phi_s^2(y) \right) / \left(U(y) - U_s \right) dy \right) \\
&= C + iD,
\end{aligned}$$

which is a contradiction. Thus the uniform convergence of (41) is proved.

Acknowledgments. The author is truly indebted to his advisor, Walter Strauss, for continuous encouragement, guidance, and many helpful discussions. He especially thanks Louis Howard, whose very helpful comments and discussions have improved this paper. The author also thanks Yan Guo and Claude Bardos for useful comments and discussions. Finally, he would like to thank the referee for his comments.

ASYMPTOTIC BEHAVIOR TO DISSIPATIVE QUASI-GEOSTROPHIC FLOWS*

MARIA E. SCHONBEK† AND TOMAS P. SCHONBEK‡

Abstract. We consider the long time behavior of solutions of dissipative quasi-geostrophic (DQG) flows with subcritical powers. The flow under consideration is described by the nonlinear scalar equation

$$\frac{\partial\theta}{\partial t} + u\cdot\nabla\theta + \kappa(-\triangle)^{\alpha}\theta = f, \quad \theta|_{t=0} = \theta_0.$$

Rates of decay are obtained for both the solutions and higher derivatives in different Sobolev spaces.

Key words. quasi-geostrophic, decay, Fourier splitting

1. Introduction. In this paper we are concerned with the long time behavior of the solutions to a special case of surface two-dimensional dissipative quasi-geostrophic (DQG) flows with subcritical powers α:

$$\frac{\partial\theta}{\partial t} + u\cdot\nabla\theta + \kappa(-\triangle)^{\alpha}\theta = f, \qquad \theta|_{t=0} = \theta_0. \tag{1.1}$$

Here $\alpha \in (0,1]$, $\kappa > 0$, $\theta(t)$ is a real function of two space variables $x \in \mathbb{R}^2$ and a time variable t. The function $\theta(t) = \theta(x,t)$ represents the potential temperature. The fluid velocity u is determined from θ by a stream function ψ,

$$(u_1, u_2) = \left(-\frac{\partial\psi}{\partial x_2}, \frac{\partial\psi}{\partial x_1}\right), \tag{1.2}$$

where the function ψ satisfies

$$(-\triangle)^{\frac{1}{2}}\psi = -\theta.$$

Equation (1.1) is obtained when dissipative mechanisms are incorporated into the inviscid two-dimensional quasi-geostrophic (2DQG) equation. The 2DQG equation is derived from the general quasi-geostrophic (GQG) equations by reduction to the special case of solutions with constant potential vorticity in the interior and constant buoyancy frequency [3]. For information on the GQG equations we refer the reader to [8]. The fractional power $\alpha = 1/2$ is perhaps the most interesting one since it corresponds to a fundamental model of quasi-geostrophic equations; see [4] and [8]. As pointed out in [4], "Dimensionally the 2DQG equation with $\alpha = 1/2$ is the analogue of the 3D Navier–Stokes equations."

Two main problems will be considered. In the first, the power α will range in the interval $(\frac{1}{2}, 1]$. In this case when $\alpha \in (1/2, 1]$ it is known that the solutions are smooth on the torus; see [4]. In [16] Wu establishes regularity of solutions for certain type of data and forcing functions. Here we obtain smooth solutions in $\mathbb{R}^2$ by establishing uniform bounds in the H^m norms for solutions with appropriate data and forcing term. Interest will then be focused on the analysis of the asymptotic behavior of the energy of derivatives of all orders.

To establish decay in $H^m(\mathbb{R}^n)$ spaces the main tool will be the Fourier splitting method [11], [12]. This technique and others were used to treat solutions to parabolic conservation laws and Navier–Stokes equations. What makes the approach different here is that unlike the case of parabolic conservation laws and Navier–Stokes equations the dissipative mechanism is not given by a straightforward Laplacian but by a fractional power of the Laplacian, and new estimates are necessary. Before even addressing questions of decay new estimates are necessary to establish uniform bounds for the derivatives.

Some of the proofs presented in this paper consider only the case when $\alpha \in (1/2, 1]$; these proofs could be extended to the case $\alpha \in (0, 1]$, provided there was an a priori bound (possibly time dependent) of the derivatives of the solutions in the space L^2. In particular the estimate obtained by Wu in [16] could be used once a uniform bound on the $W^{1,\infty}$ norm of the velocity u is established.

The second question we address is the decay of the solutions in L^p. Given the decay in L^2 obtained in [4], the new H^m decay obtained in the first part of the paper will immediately yield, via a Gagliardo–Nirenberg inequality, decay in all L^p spaces with $p \geq 2$. Decay rate in L^p had already been obtained in [16], for $p > 1$. The problem now is to improve this decay by imposing conditions on the initial data which insure the decay of the L^1 norm of the solutions. Two cases are considered. First, the weak solution will be analyzed when $\alpha = 1/2$ and decay will be shown in L^1. Second, decay is established for solutions in $W^{q,p}$, $p \geq 2$ and $q \geq 1$, in the case where $\alpha \in (1/2, 1]$.

1.1. Notation and preliminaries. The Fourier transform of $v \in \mathcal{S}(\mathbb{R}^2)$ is defined by $\widehat{v}(\xi) = (2\pi)^{-1} \int_{\mathbb{R}^2} e^{-ix\cdot\xi} v(x)\, dx$. It is then extended as usual to $\mathcal{S}'$. Given a multi-index $\gamma = (\gamma_1, \gamma_2)$ and $m = |\gamma| = \gamma_1 + \gamma_2$, we denote

$$\partial^\gamma = \frac{\partial^{|\gamma|}}{\partial_{x_1}^{\gamma_1} \partial_{x_2}^{\gamma_2}}$$

and

$$D^m = \sum_{|\alpha|=m} \partial^\gamma.$$

If k is a nonnegative integer, $W^{k,p}(\mathbb{R}^2)$ will be, as is standard, the Sobolev space consisting of functions in $L^p(\mathbb{R}^2)$ whose generalized derivatives up to order k belong to $L^p(\mathbb{R}^2)$. As usual, when $p = 2$, then $W^{k,2}(\mathbb{R}^2) = H^k(\mathbb{R}^2)$, where (also as usual) the space H^s is defined for all $s \in \mathbb{R}$ as the space of all $f \in \mathcal{S}'$ such that $(1+|\xi|^2)^{s/2} \hat{f}(\xi) \in L^2$.

Following Constantin and Wu [4], we denote by

$$\Lambda = (-\triangle)^{\frac{1}{2}} \tag{1.3}$$

the operator defined by $\widehat{\Lambda f}(\xi) = |\xi|\hat{f}(\xi)$. More generally, if $s \geq 0$, we define Λ^s by

$$\widehat{\Lambda^s f}(\xi) = |\xi|^s \hat{f}(\xi).$$

Clearly $\Lambda^s f$ is well defined (and in L^2) if $f \in H^s$. More generally, one can define the domain of Λ^s as consisting of all elements $f \in \mathcal{S}'$ such that $\hat{f}$ is a function (i.e., locally integrable); it is then clear that the definition given above defines $\Lambda^s f$ as a tempered distribution.

We denote by $\mathcal{R}_1, \mathcal{R}_2$ the Riesz transforms in $\mathbb{R}^2$; i.e., $\widehat{\mathcal{R}_j f}(\xi) = -i(\xi_j/|\xi|)\hat{f}(\xi)$. The operator $\mathcal{R}^\perp$, taking scalar-valued functions to vector-valued functions, is defined by

$$\mathcal{R}^\perp f = (-\partial_{x_2}\Lambda^{-1} f, \partial_{x_1}\Lambda^{-1} f) = (-\mathcal{R}_2 f, \mathcal{R}_1 f). \tag{1.4}$$

The relation between u and θ in (1.1) can then briefly be stated as $u = \mathcal{R}^\perp\theta$.

If F is a function defined on $\mathbb{R}^2 \times [0,\infty)$, we define for $t \geq 0$ the function $F(t)$ on $\mathbb{R}^2$ by $F(t)(x) = F(x,t)$. For such F, the Fourier transform (and inverse Fourier transform) is always with respect to the space variables; thus

$$\hat{F}(\xi,t) = \widehat{F(t)}(\xi)$$

for all $t \geq 0$. The letters C, C_0, C_1, etc., will denote generic positive constants, which may vary from line to line during computations.

2. Uniform estimates. In this section we suppose $\alpha \in (1/2, 1]$. We show that $\Lambda^\beta\theta$ decays in the L^2 norm for $\beta \geq 0$; in particular we establish the uniform boundedness of the solution θ in H^m if the initial datum $\theta_0 \in H^m$. Our results in Theorem 2.4 can easily be adapted to the torus and as such extend those of Constantin and Wu [4, Theorem 2.1]. The decay we obtain in this section is not optimal but is needed to obtain the optimal rate of decay in the next section. In the last part of this section we establish uniform estimates on the L^∞ norms of the solutions. These estimates are obtained by bounding the L^1 norm of $\hat{\theta}$. We will need to use Theorem 3.1 from [4] and state it here for ease of reference.

THEOREM 2.1. *Let $\alpha \in (0,1]$ and $\theta_0 \in L^1 \cap L^2$. Assume that $f \in L^1([0,\infty); L^2)$, satisfying*

$$\|f(t)\|_2 \leq C_0(1+t)^{-\frac{1}{\alpha}-1}, \quad |\hat{f}(\xi,t)| \leq C_0|\xi|\alpha \tag{2.1}$$

for some constant C_0. Then there exists a weak solution θ of the 2DQG equation

$$\frac{\partial\theta}{\partial t} + u\cdot\nabla\theta + \kappa(-\triangle)^\alpha\theta = f, \quad \theta|_{t=0} = \theta_0 \tag{2.2}$$

such that

$$\|\theta(\cdot,t)\|_{L^2(\mathbb{R}^2)} \leq C(t+1)^{-\frac{1}{2\alpha}}, \tag{2.3}$$

where C is a constant depending on the L^1 and L^2 norms of θ_0, on the $L^1(L^2)$ norm of f, and on C_0.

We also need the following Sobolev type estimate.

LEMMA 2.2. *Let $2 < p < \infty$ and let $\sigma = 1 - \frac{2}{p}$. There exists a constant $C \geq 0$ such that if $f \in \mathcal{S}'$ is such that $\hat{f}$ is a function, then*

$$\|f\|_p \leq C\|\Lambda^\sigma f\|_2.$$

Proof. Since $\hat{f}$ is a function, we have $\hat{f}(\xi) = |\xi|^{-\sigma}|\xi|^{\sigma}\hat{f}(\xi)$. Taking the inverse Fourier transform, we get $f = I_\sigma(\Lambda^\sigma f)$, where I_σ is the Riesz potential of order σ. It is well known (cf. [13, Chapter V, Theorem 1]) that I_σ is bounded from $L^2(\mathbb{R}^2)$ to $L^p(\mathbb{R}^2)$ if $\frac{1}{p} = \frac{1}{2} - \frac{\sigma}{2}$. The lemma follows. □

Next, a simple observation connecting the L^2 norms of the temperature and the velocity (or transport term) that will be used repeatedly.

Remark 2.3. Let $1 < p < \infty$. There exists a constant C_p depending only on p such that

$$\|\Lambda^\beta u(t)\|_p \le C_p \|\Lambda^\beta \theta(t)\|_p \tag{2.4}$$

for all $\beta \ge 0$, $t \ge 0$. If $p = 2$, this inequality can be strengthened to

$$\|\Lambda^\beta u(t)\|_2 = \|\Lambda^\beta \theta(t)\|_2. \tag{2.5}$$

In fact, (2.4) is immediate from the fact that $u = \mathcal{R}^\perp\theta$, the fact that the Riesz transforms commute with Λ^β, and the boundedness of the Riesz transforms in L^p. Concerning (2.5), it suffices to observe that

$$\widehat{\Lambda^\beta u}(\xi, t) = \frac{i}{|\xi|}(\xi_2, \xi_1)|\xi|^\beta \hat{\theta}(\xi, t)$$

and the norm equality follows.

We are ready to state and prove the main result of this section. This first theorem gives a uniform bound for the derivatives of the solution $\theta(t)$ of the 2DQG and, for a sufficiently fast decaying f, an auxiliary rate of decay that will be improved in the next section.

THEOREM 2.4. *Let $\alpha \in (1/2, 1]$, $\beta \ge \alpha$, and assume q satisfies $2/(2\alpha - 1) < q < \infty$. Suppose $\theta_0 \in L^1 \cap L^2$, $\Lambda^\beta\theta_0 \in L^2$, $f \in L^1([0,\infty] : L^q \cap L^2)$ satisfies* (2.1) *and $\Lambda^{\beta-\alpha} f \in L^2((0,\infty), L^2)$. If θ is a solution to* (1.1) *with initial datum θ_0, then*

$$\|\Lambda^\beta\theta(t)\|_{L^2} \le C_0(1+t)^{-\frac{1}{2\alpha}} + C_1\left(\int_0^t \|\Lambda^{\beta-\alpha} f(s)\|_2^2\, ds\right)^{1/2} \tag{2.6}$$

for $t \ge 0$, where C_0, C_1 are constants depending only on norms of the initial datum and f. In particular, if $f = 0$, then

$$\|\Lambda^\beta\theta(t)\|_{L^2} \le C_0(1+t)^{-\frac{1}{2\alpha}} \tag{2.7}$$

for all $t \ge 0$.

Remark 2.5. In [4, Theorem 2.1] the authors assume, in case $\beta < 1$, that $q = 2/(1-\beta)$. This choice is consistent with our more general one, since it is also assumed in [4] that $\beta + 2\alpha > 2$, which implies $2/(1-\beta) > 2/(2\alpha - 1)$. The assumption $\theta_0 \in L^1 \cap L^2$ (as well as f satisfying (2.1)) is needed to apply Theorem 2.1.

Proof. The first part of the proof we present is formal. At the end of the proof we give a sketch on how to make the arguments rigorous. To obtain (2.6) multiply both sides of (1.1) by $\Lambda^{2\beta}\theta(t)$ and integrate in space:

$$\begin{aligned} &\frac{1}{2}\frac{d}{dt}\int_{\mathbb{R}^2} |\Lambda^\beta\theta(t)|^2\, dx + \kappa \int_{\mathbb{R}^2} |\Lambda^{\alpha+\beta}\theta(t)|^2\, dx \\ &\quad = -\int_{\mathbb{R}^2} (u\cdot\nabla\theta)\Lambda^{2\beta}\theta\, dx + \int_{\mathbb{R}^2} f\Lambda^{2\beta}\theta.\, dx. \end{aligned} \tag{2.8}$$

We estimate the second term on the right-hand side of the last equation by

$$\int_{\mathbb{R}^2} f\Lambda^{2\beta}\theta\,dx \le \frac{\kappa}{8}\int_{\mathbb{R}^2}|\Lambda^{\alpha+\beta}\theta(t)|^2\,dx + \frac{2}{\kappa}\int_{\mathbb{R}^2}|\Lambda^{\beta-\alpha}f|^2\,dx. \tag{2.9}$$

Estimating the first term will take a little longer. We claim that there exists a constant $C(\kappa,\theta_0,f)$, depending only on the initial datum θ_0, the $L^1(0,\infty,L^q)$ norm of the external force f, and κ such that

$$\left|\int_{\mathbb{R}^2}(u\cdot\nabla\theta)\Lambda^{2\beta}\theta\,dx\right| \le \frac{\kappa}{8}\|\Lambda^{\alpha+\beta}\theta\|_2^2 + C(\theta_0,f,\kappa)\|\Lambda^{s+1-(2/p)}\theta\|_2^2, \tag{2.10}$$

where $s=\beta-\alpha+1$, p is determined by $\frac{1}{p}+\frac{1}{q}=\frac{1}{2}$, and q is as in the statement of the theorem. The meaning of s,p,q will not change for the remainder of this proof. To establish the claim, we begin observing that because $\operatorname{div} u=0$ we can write

$$u\cdot\nabla\theta = \operatorname{div}(u\theta) - \theta\operatorname{div}u = \operatorname{div}(u\theta);$$

thus, by Plancherel, Hölder, and again Plancherel,

$$\begin{aligned}\left|\int_{\mathbb{R}^2}(u\cdot\nabla\theta)\Lambda^{2\beta}\theta\,dx\right| &= \left|\int_{\mathbb{R}^2}(\xi_1\widehat{\theta u_1}(\xi)+\xi_1\widehat{\theta u_2}(\xi))|\xi|^{2\beta}\hat\theta(\xi)\,d\xi\right| \\ &\le \sum_{i=1}^{2}\int_{\mathbb{R}^2}|\xi|^{\beta-\alpha+1}|\widehat{\theta u_i}(\xi)||\xi|^{\alpha+\beta}|\hat\theta(\xi)|\,d\xi \\ &\le \sum_{i=1}^{2}\|\Lambda^{\beta-\alpha+1}(\theta u_i)\|_2\|\Lambda^{\alpha+\beta}\theta\|_2;\end{aligned}$$

hence

$$\left|\int_{\mathbb{R}^2}(u\cdot\nabla\theta)\Lambda^{2\beta}\theta\,dx\right| \le \frac{\kappa}{8}\|\Lambda^{\alpha+\beta}\theta\|_2^2 + \frac{2}{\kappa}\sum_{i=1}^{2}\|\Lambda^s(\theta u_i)\|_2^2. \tag{2.11}$$

We estimate $\|\Lambda^s(\theta u_i)\|_2$ by the calculus inequality, getting

$$\|\Lambda^s(\theta u_i)\|_2 \le C\left(\|u_i\|_q\|\Lambda^s\theta\|_p + \|\theta\|_q\|\Lambda^s u_i\|_p\right)$$

for $i=1,2$. This inequality follows easily by combining Hölder's inequality with the Gagliardo–Nirenberg and Young inequalities; see also inequality (3.1.59) on page 74 of [14]. Since $u_i=\pm\mathcal{R}_j\theta$ $(i,j\in\{1,2\},\ i\ne j)$ and the Riesz transforms commute with Λ and are bounded in L^p, L^q (notice that $2<p,q<\infty$), we have $\|\Lambda^s u_i\|_p \le C\|\Lambda^s\theta\|_p$ and $\|u_i\|_q \le C\|\theta\|_q$ for $i=1,2$. Applying this to the previous estimate, we get

$$\|\Lambda^s(\theta u_i)\|_2 \le C\|\theta\|_q\|\Lambda^s\theta\|_p \tag{2.12}$$

for $i=1,2$. To continue, we estimate $\|\theta\|_q$ by the following maximum principle:

$$\|\theta\|_{L^q} \le \|\theta_0\|_{L^q} + \int_0^t\|f(\tau)\|_{L^q}\,d\tau. \tag{2.13}$$

For details on this inequality and its proof we refer the reader to [10], [1], but we briefly describe the main idea, as given by Wu [15]. Specifically, (2.13) follows by multiplying both sides of (1.1) by $q|\theta|^{q-2}\theta$ and integrating with respect to x to get

$$\frac{d}{dt}\|\theta\|_{L^q}^q \le q\left(\int|\theta|^{q-2}\theta f\,dx - \int|\theta|^{q-2}\theta(u\cdot\nabla\theta)\,dx - \int|\theta|^{q-2}\theta\kappa(-\triangle)^\alpha\theta)\,dx\right).$$

One sees that the second integral on the right is zero. The last integral on the right can be shown to be positive [10], [15]. Thus

$$\frac{d}{dt}\|\theta\|_{L^q}^q \le q\int |\theta|^{q-2}\theta f\,dx \le q\|f\|_{L^q}\|\theta\|_{L^q}^{q-1},$$

and (2.13) follows. Because $f \in L^1(0,\infty;L^q)$, we proved that

$$\|\Lambda^s(\theta u_i)\|_2 \le C(\theta_0, f)\|\Lambda^s\theta\|_p$$

for $i = 1, 2$, where $C_0(\theta_0, f)$ is independent of t, depends only on θ_0, f. By Lemma 2.2,

$$\|\Lambda^s(\theta u_i)\|_2 \le C(\theta_0, f)\|\Lambda^{s+1-(2/p)}\theta\|_2$$

for $i = 1, 2$. Using this in (2.11), (2.10) follows, establishing our claim, with $C(\kappa, \theta_0, f) = \frac{4}{\kappa}C(\theta_0, f)^2$. Combining (2.8), (2.9), and (2.10) yields

$$\frac{1}{2}\frac{d}{dt}\|\Lambda^\beta\theta(t)\|_2^2 + \frac{3\kappa}{4}\|\Lambda^{\alpha+\beta}\theta(t)\|_2^2 \le C_0\|\Lambda^\gamma\theta\|_2^2 + \frac{2}{\kappa}\|\Lambda^{\beta-\alpha}f\|_2^2, \tag{2.14}$$

where $C_0 = C(\kappa, \theta_0, f)$ and we introduced $\gamma = s+1-\frac{2}{p} = \beta-\alpha+2(1-\frac{1}{p})$. To continue estimating, let $B_M = \{\xi : |\xi|^2 \le M\}$, with $M > 0$ to be determined appropriately below. The choice $2/(2\alpha-1) < q < \infty$ implies $\frac{1}{2} > \frac{1}{p} = \frac{1}{2} - \frac{1}{q} > 1-\alpha$, and hence $\frac{1}{p} + \alpha - 1 > 0$. Thus $\gamma = \alpha+\beta-2(\frac{1}{p}+\alpha-1) < \alpha+\beta$ and

$$\begin{aligned}\|\Lambda^\gamma\theta(t)\|_2^2 dx &= \int_{B_M} |\xi|^{2\gamma}|\hat\theta(t)|^2\,d\xi + \int_{B_M^c} |\xi|^{2\gamma}|\hat\theta(t)|^2\,d\xi \\ &\le M^{2\gamma}\|\theta(t)\|_2^2 + M^{-4(\frac{1}{p}+\alpha-1)}\|\Lambda^{\alpha+\beta}\theta(t)\|_2^2.\end{aligned}$$

Selecting M large enough to satisfy $M^{-4(\frac{1}{p}+\alpha-1)} < \kappa/(4C_0)$, it follows that

$$C_0\|\Lambda^\gamma\theta(t)\|_2^2 dx \le \frac{\kappa}{4}\|\Lambda^{\alpha+\beta}\theta(t)\|_2^2 + C_0M^{2\gamma}\|\theta(t)\|_2^2. \tag{2.15}$$

Next,

$$\begin{aligned}\|\Lambda^{\alpha+\beta}\theta\|_2^2 &\ge \int_{B_M^c} |\xi|^{2(\alpha+\beta)}|\hat\theta|^2\,d\xi \ge M^{2\alpha}\int_{B_M^c} |\xi|^{2\beta}|\hat\theta|^2\,d\xi \\ &= M^2\alpha\|\Lambda^\beta\theta\|_2^2 - M^{2\alpha}\int_{B_M} |\xi|^{2\beta}|\hat\theta|^2\,d\xi,\end{aligned}$$

implying

$$\|\Lambda^{\alpha+\beta}\theta\|_2^2 \ge M^2\alpha\|\Lambda^\beta\theta\|_2^2 - M^{2(\alpha+\beta)}\|\theta(t)\|_2^2. \tag{2.16}$$

By Theorem 3.1 in [4] (stated as Theorem 2.1 in this article), $\|\theta(t)\|_2$ decays at the rate of $(1+t)^{-1/\alpha}$. Using this estimate in (2.15) and (2.16), and then returning to (2.14), we get

$$\frac{d}{dt}\|\Lambda^\beta\theta(t)\|_2^2 + \kappa M^{2\alpha}\|\Lambda^\beta\theta(t)\|_2^2 \le \tilde C_0 M^c(1+t)^{-1/a} + \frac{2}{\kappa}\|\Lambda^{\beta-\alpha}f(t)\|_2^2, \tag{2.17}$$

where $\tilde{C}_0$ is a new constant depending only on f, θ_0, κ and $c = \max(2\gamma, 2\alpha + 2\beta)$. For convenience, let $\nu = \kappa M^{2\alpha}$. Multiplying both sides of (2.17) by $e^{\nu t}$ and integrating in time we see that

$$\|\Lambda^\beta \theta(t)\|_2^2 \le e^{-\nu t}\|\Lambda^\beta \theta_0\|_2^2 + \tilde{C}_0 M^c \int_0^t e^{-\nu(t-s)}(s+1)^{-\frac{1}{\alpha}}\,ds + \frac{2}{\kappa}\int_0^t e^{-\nu(t-s)}\|\Lambda^{\beta-\alpha} f(s)\|_2^2\,ds.$$

The desired estimate (2.6) now follows, since

$$\int_0^t e^{-\nu(t-s)}(1+s)^{-\frac{1}{\alpha}}\,ds \le C(1+t)^{-\frac{1}{\alpha}}, \tag{2.18}$$

$$\int_0^t e^{-\nu(t-s)}H(s)\,ds \le \int_0^t H(s)\,ds \tag{2.19}$$

for all $t \ge 0$, some C.

This completes the formal part of the proof. To make the above arguments rigorous, apply the same proof to the "retarded mollifications θ_n," which are solutions of the sequence of approximate equations

$$\frac{\partial \theta_n}{\partial t} + u_n \cdot \nabla \theta_n + \kappa(-\triangle)^\alpha \theta_n = f, \tag{2.20}$$

where $u_n = \Psi_{\delta_n}(\theta_n)$ is obtained from θ_n by

$$\Psi_{\delta_n}(\theta_n) = \int_0^t \phi(\tau)\mathcal{R}^\perp \theta_n(t - \delta_n \tau)\,d\tau, \tag{2.21}$$

and $\mathcal{R}^\perp$ is defined by (1.4).

The function ϕ is smooth and has support in $[1,2]$, and $\int_0^\infty \phi(t)\,dt = 1$. This construction is similar to the one used by Caffarelli, Kohn, and Nirenberg in [2] for solutions to the Navier–Stokes equations. It is easy to see that for each n the values of u_n depend only on the values of θ_n in $[t - 2\delta_n, t - \delta_n]$. As stated in [4] the θ_n converge to a weak solution θ and strongly in L^2 almost everywhere in t. Since the bounds for the $\Lambda^\beta \theta_n$ are independent of n it follows that they hold for the limiting solution θ.

This concludes the proof of the theorem. □

Remark 2.6. In proving Theorem 2.4 we estimated (see (2.19))

$$\int_0^t e^{-\nu(t-s)}\|\Lambda^{\beta-\alpha} f(s)\|_2^2\,ds \le \int_0^t \|\Lambda^{\beta-\alpha} f(s)\|_2^2\,ds$$

to get the second term on the right-hand side of (2.6). The assumption $f = 0$ then causes the L^2 norm of $\Lambda^\beta \theta(t)$ to decay in time. However, by (2.18), it follows that we have decay of this norm as long as $\|\Lambda^{\beta-\alpha} f\|_2$ decays fast enough. For example, if

$$\|\Lambda^{\beta-\alpha} f(t)\|_2 \le C(1+t)^{-\delta}$$

for some $\delta > 0$, then (2.7) can be replaced by

$$\|\Lambda^\beta \theta(t)\|_{L^2} \le C_0(1+t)^{-\min(\frac{1}{2\alpha}, \delta)}, \tag{2.22}$$

where C_0 only depends on f and the initial datum θ_0.

The remainder of this section deals with obtaining L^∞ bounds of the solution—more precisely, L^1 bounds of the Fourier transform of the solution. If the hypotheses of Theorem 2.4 are satisfied with $\beta > 1$, it is clear that $\hat{\theta}(t) \in L^1$ and $\|\hat{\theta}(t)\|_1$ is uniformly bounded in t. In fact, $\theta \in L^2 \cap \tilde{H}^\beta = H^\beta$, and hence

$$\int_{\mathbb{R}^2} |\hat{\theta}(\xi)|\, d\xi \le C \left(\int_{\mathbb{R}^2} (1+|\xi|^2)^\beta |\hat{\theta}(\xi)|^2\, d\xi \right)^{1/2}$$

with

$$C = \left(\int_{\mathbb{R}^2} (1+|\xi|^2)^{-\beta} |\, d\xi \right)^{1/2} < \infty.$$

In the next lemma, we show that we also have $\hat{\theta}(t) \in L^1$, with a uniformly bounded L^1 norm, if $\beta = 1$.

The next lemma gives an a priori bound of the L^1 norm of $\hat{\theta}(t)$. It then suffices to establish a local existence theorem to obtain a global uniform bound.

LEMMA 2.7 (a priori bound). *Assume the hypothesis of Theorem* 2.4 *with* $\beta \ge 1$. *If* $\beta = 1$, *assume also that* $\hat{\theta}_0 \in L^1$ *and that* $\hat{f} \in L^1(0,\infty,L^1)$. *It follows that there exists* $C \ge 0$ *such that*

$$\|\hat{\theta}(t)\|_1 \le C$$

for all $t \ge 0$

Remark 2.8. The hypothesis on f in case $\beta = 1$ can be considerably weakened, but the proof becomes somewhat more involved.

Proof. Since we only want an a priori bound the proof is formal. The case $\beta > 1$ was dealt with in the remarks preceding this lemma; we assume from now on that $\beta = 1$. By Theorem 2.4, there exists $C \ge 0$ such that

$$\|\nabla\theta(t)\|_2 = \|\Lambda\theta(t)\|_2 \le C$$

for all $t \ge 0$. An easy calculation yields

$$\hat{\theta} = e^{-\kappa|\xi|^{2\alpha}t}\hat{\theta_0} - \int_0^t e^{-\kappa|\xi|^{2\alpha}(t-s)} \widehat{u\cdot\nabla\theta}\, ds + H(t),$$

where

$$H(t) = \int_0^t e^{-\kappa|\xi|^{2\alpha}(t-s)} \hat{f}(s)\, ds.$$

By the additional hypothesis on f, it is obvious that $H(t)$ is uniformly bounded in the L^1 norm. Hence

$$\|\hat{\theta}(t)\|_1 \le \|\hat{\theta_0}\|_1 + \int_0^t \|e^{-\kappa|\xi|^{2\alpha}(t-s)} \widehat{u\cdot\nabla\theta}\|_1\, ds + C, \tag{2.23}$$

where C is chosen so that $\|H(t)\|_1 \le C$ for all $t \ge 0$. Since the first term of the right-hand side of (2.23) is bounded by hypothesis, we need to bound only the second

term. For this purpose, we split it into two parts for an appropriate value of $\epsilon > 0$ as follows.

$$\int_0^t \|e^{-\kappa|\xi|^{2\alpha}(t-s)}\widehat{u\cdot\nabla\theta}\|_1\,ds = I + II,$$

where, if $t \geq \epsilon$,

$$I = \int_0^{t-\epsilon} \|\widehat{u\cdot\nabla\theta}\|_1\,ds,$$
$$II = \int_{t-\epsilon}^t \|e^{-\kappa|\xi|^{2\alpha}(t-s)}\widehat{u\cdot\nabla\theta}\|_1\,ds;$$

if $0 \leq t < \epsilon$, then $I = 0$ and $II = \int_0^t \|\widehat{u\cdot\nabla\theta}\|_1\,ds$. We begin bounding II, assuming $t > \epsilon$.

$$II \leq \int_{t-\epsilon}^t \|e^{-\kappa|\xi|^{2\alpha}(t-s)}\|_2\|\widehat{u\cdot\nabla\theta}\|_2\,ds \leq C\int_{t-\epsilon}^t \frac{1}{(t-s)^{\frac{1}{2\alpha}}}\|\nabla\theta\|_2\|u\|_\infty\,ds$$
$$\leq C\sup_{t\geq 0}\|\nabla\theta(t)\|_2 \sup_{0\leq s\leq t}\|\hat\theta(s)\|_1\epsilon^{1-\frac{1}{2\alpha}},$$

where we used the fact that $\|u(t)\|_\infty \leq C\|\hat u(t)\|_1 \leq C\|\hat\theta(t)\|_1$, since the components of $\hat u$ are obtained multiplying $\hat\theta$ by functions of absolute value 1. Since $\|\nabla\theta(t)\|_2$ is bounded in t, we can select $\epsilon > 0$ so that

$$II \leq \frac{1}{2}\sup_{0\leq s\leq t}\|\hat\theta(s)\|_1 \tag{2.24}$$

for all $t \geq \epsilon$. Assuming now $t < \epsilon$, we estimate essentially the same way to get

$$II \leq C\sup_{t\geq 0}\|\nabla\theta(t)\|_2 \sup_{0\leq s\leq t}\|\hat\theta(s)\|_1\int_0^t (t-s)^{-\frac{1}{2\alpha}}\,ds \leq C\sup_{0\leq s\leq t}\|\hat\theta(s)\|_1\epsilon^{1-\frac{1}{2\alpha}}.$$

Decreasing the size of $\epsilon > 0$ if necessary, we can assume that (2.24) also holds for $0 < t < \epsilon$.

To bound I, we use the fact that $\|u(s)\|_2 = \|\theta(s)\|_2 \leq C(1+s)^{-1/2\alpha} \leq C$, $\|\nabla\theta(s)\|_2 \leq C$ for all $s \geq 0$ (some constant C). We assume $t \geq \epsilon$ (otherwise $I = 0$).

$$I \leq \int_0^{t-\epsilon} \|e^{-\kappa|\xi|^{2\alpha}(t-s)}\|_1\|\widehat{u\cdot\nabla\theta}\|_\infty\,ds \leq C\int_0^{t-\epsilon}\frac{1}{(t-s)^{\frac{1}{\alpha}}}\|\widehat{u\cdot\nabla\theta}\|_\infty\,ds$$
$$\leq C\int_0^{t-\epsilon}\frac{1}{(t-s)^{\frac{1}{\alpha}}}\|u\|_2\|\nabla\theta\|_2\,ds \leq C\int_0^{t-\epsilon}\frac{1}{(t-s)^{\frac{1}{\alpha}}}\,ds.$$

The last integral is bounded by $C\epsilon^{1-\frac{1}{\alpha}}$ if $\alpha < 1$, by $C\log(1/\epsilon)$ if $\alpha = 1$, and in either case by a constant since ϵ has been fixed. In other words I is bounded independently of t; using this and (2.24) in (2.23), we get

$$\|\hat\theta(t)\|_1 \leq C + \frac{1}{2}\sup_{0\leq s\leq t}\|\hat\theta(s)\|_1$$

for all $t \geq 0$, C independent of t. The lemma follows. □

COROLLARY 2.9. *Under the hypotheses of Lemma* 2.7 *one has that* $\|\theta(t)\|_\infty$, $\|\hat{u}(t)\|_1$, *and* $\|u(t)\|_\infty$ *are uniformly bounded in* t.

Proof. Since the components of u are Riesz transforms of θ (hence, the components of $\hat{u}$ differ from $\hat{\theta}$ by factors of absolute value 1), it is immediate from Lemma 2.7 that $\|\hat{u}(t)\|_1$ is uniformly bounded in time. The uniform bound on the L^∞ norms now follows. □

The next lemma gives the local existence for solutions with data θ_0, where $\theta_0 \in H^1$ and $\hat{\theta_0} \in L^1$

LEMMA 2.10. *Let* $\theta_0 \in H^1$ *and* $\hat{\theta_0} \in L^1$, *and let* f *satisfy the hypothesis of Theorem* 2.4. *Let* $\alpha \in (1/2, 1]$, $\beta = 1$. *Then there exists* $T > 0$ *and a solution* θ *of* (1.1) *such that* $\theta \in L^\infty([0,T] : H^1)$ *and* $\hat{\theta} \in L^\infty([0,T] : L^1)$.

Proof. The proof follows by a straightforward application of the contraction mapping theorem to the sequence of solutions of the equations

$$\frac{\partial \theta_n}{\partial t} + (-\mathcal{R}_2\theta_{n-1}, \mathcal{R}_1\theta_{n-1}) \cdot \nabla\theta_n + \kappa(-\triangle)^\alpha \theta_n = f,$$
$$\theta|_{t=0} = \theta_0. \qquad \square$$

THEOREM 2.11. *Under the conditions of Theorem* 2.4 *there exists a global solution* $\theta \in L^\infty([0,\infty) : H^1)$ *such that* $\hat{\theta} \in L^\infty([0,\infty) : L^1)$.

Proof. Combine the two last lemmas. □

3. H^m and fractional derivative decay. In this section we improve the decay of the derivatives of order β of the solution θ of (1.1), assuming the external force $f = 0$. The decay established in the last section is not optimal but does provide the stepping stone to obtain the optimal decay, that is, a decay rate which coincides with that of the underlying linear part. The main tool used is the Fourier splitting method (see [11], [12]). The solutions considered here are supposed to be smooth. The assumption that the external force is zero is not essential. The same results can be obtained when $f \neq 0$, provided $\|\Lambda^{\beta-\alpha} f\|_2$ decays sufficiently fast (see Remark 2.6 above and Corollary 3.4 at the end of this section). The proof is the same as the one presented below, with the addition of a term that decays sufficiently fast by hypothesis.

We assume throughout this section that $\alpha \in (\frac{1}{2}, 1]$, $m \geq \alpha$, and θ is the solution of (1.1) (with $f = 0$ until further notice) such that $\theta_0 = \theta(0)$ satisfies $\theta_0 \in L^1(\mathbb{R}^2) \cap H^m(\mathbb{R}^2)$. The hypotheses of Theorem 2.4 are thus satisfied for any $\beta \in [\alpha, m]$. The numbers p, q are as in the previous section: $\frac{1}{p} + \frac{1}{q} = \frac{1}{2}$, $0 < \frac{1}{q} < \alpha - \frac{1}{2}$.

Before improving the rate of decay of the derivatives of θ, we state some of the immediate consequences of Theorem 2.4.

COROLLARY 3.1. *Under the assumptions mentioned above, the following estimates hold for* $t \geq 0$:

$$\|\theta(t)\|_{H^m} \leq C(1+t)^{-\frac{1}{2\alpha}}, \tag{3.1}$$

$$\|u(t)\|_{H^m} \leq C(1+t)^{-\frac{1}{2\alpha}}, \tag{3.2}$$

with C *a constant depending only on norms of the initial datum; moreover, if* $m \geq 1$, *with* r *any exponent in* $[2, \infty)$, *then*

$$\|\theta(t)\|_r \leq C_r(1+t)^{-\frac{1}{2\alpha}}, \quad 0 \leq \gamma \leq \beta - 1, \tag{3.3}$$

$$\|\Lambda^\gamma u(t)\|_r \leq C_r(1+t)^{-\frac{1}{2\alpha}}, \quad 0 \leq \gamma \leq \beta - 1, \tag{3.4}$$

with C_r a constant depending only on norms of the initial datum and r.

Proof. Since $H^m = \{g \in L^2 : \Lambda^m g \in L^2\}$, inequality (3.1) is immediate from Theorem 2.4; inequality (3.2) follows then from Remark 2.3. Inequalities (3.3), (3.4) follow from these and Sobolev's theorem. □

The next theorem will give the optimal rate of decay for the derivatives in the sense that it coincides with the decay rate of the underlying linear part.

THEOREM 3.2. *Assume θ is a solution of* (2.2) *with data $\theta_0 \in L^1 \cap H^m$. Then*

$$\|\Lambda^\beta \theta(t)\|_{L^2} \le C(t+1)^{-\frac{\beta+1}{2\alpha}}, \tag{3.5}$$

where C is a constant which depends only on the norms of the initial datum.

Proof. The proof is based on an appropriately modified Fourier splitting method, combined with the preliminary estimates of the last section. We will assume $\alpha < 1$; refer to [5] for the case $\alpha = 1$.

Assume $\alpha \le \beta \le m$. We return to the derivation of inequality (2.14) in the proof of Theorem 2.4, recalling that $C(\kappa, \theta_0, f) = \frac{4}{\kappa} C(\theta_0, f)^2$ and $C(\theta_0, f)$ was a bound for $\|\theta(t)\|_q$ given by the maximum principle. If we forego this bound, we obtain directly, for some constant C_1, all $t \ge 0$,

$$\frac{1}{2}\frac{d}{dt}\|\Lambda^\beta\theta(t)\|_2^2 + \frac{3\kappa}{4}\|\Lambda^{\alpha+\beta}\theta(t)\|_2^2 \le C_1\|\theta(t)\|_q^2\|\Lambda^{\beta-\alpha+1-\frac{2}{p}}\theta(t)\|_2^2. \tag{3.6}$$

Because $\beta < \beta - a + 1 - \frac{2}{p} < \alpha + \beta$, with $\delta > 0$ such that $\beta - a + 1 - \frac{2}{p} = (1-\delta)\beta + \delta(\alpha + \beta)$, we have

$$\|\Lambda^{\beta-\alpha+1-\frac{2}{p}}\theta(t)\|_2^2 \le \|\Lambda^\beta\theta(t)\|_2^{2(1-\delta)}\|\Lambda^{\alpha+\beta}\theta(t)\|_2^{2\delta} \le \frac{\kappa}{4C_0}\|\Lambda^\beta\theta(t)\|_2^2 + C_2\|\Lambda^{\alpha+\beta}\theta(t)\|_2^2,$$

where we take C_0 so that $C_1\|\theta(t)\|_q^2 \le C_0$ for all $t \ge 0$, C_2 being determined by this choice. Inequality (3.6) can be modified to

$$\frac{1}{2}\frac{d}{dt}\|\Lambda^\beta\theta(t)\|_2^2 + \frac{\kappa}{2}\|\Lambda^{\alpha+\beta}\theta(t)\|_2^2 \le C_2\|\theta(t)\|_q^2\|\Lambda^\beta\theta(t)\|_2^2. \tag{3.7}$$

For $t \ge 0$ set

$$S(t) = \left\{\xi : |\xi|^{2\alpha} \le \frac{\mu}{\kappa(t+1)}\right\},$$

where μ is chosen so that $\mu > \frac{\beta+1}{\alpha} + 1$. Then

$$\begin{aligned}
\|\Lambda^{\alpha+\beta}\theta(t)\|_2^2 &= \int_{\mathbb{R}^2} |\xi|^{2(\alpha+\beta)}|\theta(t)|^2\,d\xi \\
&\ge \frac{2\mu}{3\kappa(t+1)}\int_{S(t)^c} |\xi|^{2\beta}|\theta(t)|^2\,d\xi \\
&= \frac{2\mu}{3\kappa(t+1)}\left(\|\Lambda^\beta\theta(t)\|_2^2 - \int_{S(t)} |\xi|^{2\beta}|\theta(t)|^2\,d\xi\right) \\
&\ge \frac{2\mu}{3\kappa(t+1)}\left(\|\Lambda^\beta\theta(t)\|_2^2 - \left(\frac{2\mu}{3\kappa(t+1)}\right)^{\frac{\beta}{\alpha}}\|\theta(t)\|_2^2\right);
\end{aligned}$$

estimating $\|\theta(t)\|_2$ by const$\cdot(1+t)^{-1/(2\alpha)}$ and putting it into (3.7) we get, after we estimate the factor $\|\theta(t)|_q^2$ in (3.7) by $C(t+1)^{-\frac{1}{\alpha}}$ (Corollary 3.1),

$$\frac{1}{2}\frac{d}{dt}\|\Lambda^\beta\theta(t)\|_2^2+\frac{\mu}{2(t+1)}\|\Lambda^\beta\theta(t)\|_2^2\le C(t+1)^{-\frac{1}{\alpha}}\|\Lambda^\beta\theta\|_2^2+C(t+1)^{-\frac{\beta+1}{\alpha}-1}. \tag{3.8}$$

Assume proved, for some λ, $0<\lambda<(\beta+1)/\alpha$, some $C\ge 0$, and all $t\ge 0$, that

$$\|\Lambda^\beta\theta\|_2^2\le C(t+1)^{-\lambda}. \tag{3.9}$$

Then using this in (3.8) we obtain, after multiplying by the integrating factor $2(t+1)^\mu$,

$$\frac{d}{dt}\left((t+1)^\mu\|\Lambda^\beta\theta(t)\|_2^2\right)\le C(t+1)^{\mu-\frac{1}{\alpha}-\lambda}+C(t+1)^{\mu-\frac{\beta+1}{\alpha}-1}.$$

Integrating from 0 to t, and then dividing by $(t+1)^{-\mu}$,

$$\|\Lambda^\beta\theta(t)\|_2^2\le\|\Lambda^\beta\theta(0)\|_2^2+C)(t+1)^{-\mu}+C(t+1)^{1-\frac{1}{\alpha}-\lambda}+C(t+1)^{-\frac{\beta+1}{\alpha}}.$$

It follows that in (3.9) we can replace λ by $\min(\lambda+\frac{1}{\alpha}-1,\frac{\beta+1}{\alpha})$. Since $\frac{1}{\alpha}-1>0$, we are done. □

COROLLARY 3.3. *Under the conditions of the last theorem it follows that the solutions to 2DQG equations have the decay in L^p*

$$\|D^j u\|_p\le C_p(t+1)^{-\frac{1}{\alpha}[\frac{j+2}{2}-\frac{1}{p}]}.$$

Proof. Use the estimates in Theorem 3.2 and [4] combined with a Gagliardo–Nirenberg inequality.

$$\|D^j u\|_p\le C_p\|u\|_2^{1-a}\|D^{j+1}\|_2^a, \tag{3.10}$$

where $a=1-\frac{2}{j+1}\frac{1}{p}$. Thus

$$\|D^j u\|_p\le C_p(t+1)^{-[(1-a)\frac{1}{2\alpha}+a\frac{j+2}{2\alpha}]}. \tag{3.11}$$

Replacing a with its definition gives the expected decay. □

In the case that $f\ne 0$ we can obtain the same results of Theorem 3.2, provided f decays at the appropriate rate. We state this more precisely in the following corollary.

COROLLARY 3.4. *Under the conditions of Theorem* 3.2*, suppose f satisfies* (2.1) *and*

$$\|\Lambda^{\beta-\alpha}f(\cdot,t)\|_2^2\le C(1+t)^{-\frac{\beta+1}{2}-1}. \tag{3.12}$$

If θ is a solution to (2.2) *with data θ_0, then*

$$\|\Lambda^\beta\theta(t)\|_{L^2}\le Ct^{-\frac{\beta+1}{2\alpha}}, \tag{3.13}$$

where C is constant which depends only on the L^2 norm of the data and f.

Proof. The proof follows the same steps of the last theorem. □

4. L^1 and improved L^p decay. In this section we consider the decay in L^p spaces for $p\in[1,\infty]$. New conditions on the data will be necessary to insure decay of the solutions in the L^p norms when $p\in[1,2)$, mainly that a Riesz potential of the data lies in the corresponding L^p space.

We first consider the L^1 decay of the solutions for the special case when $\alpha=1/2$. In the more general case when $\alpha\in(\frac{1}{2},1)$ the L^1 decay for derivatives of higher order will be obtained. The case of $\alpha=1$ is the easiest since the linear part is the heat equation.

4.1. Linear asymptotics. Let $\alpha \in (0,1]$, $\kappa > 0$. We consider the linear equation

$$\frac{\partial \theta}{\partial t} + \kappa(-\triangle)^{\alpha}\theta = 0 \tag{4.1}$$

in $\mathbb{R}^2 \times \mathbb{R}$; the solution $\theta = \theta(x,t)$ is a function of a space variable $x \in \mathbb{R}^2$ and a time variable $t \geq 0$. Without loss of generality, we assume $\kappa = 1$.

The function G_α will be defined for $\alpha \in (0,1]$ by

$$\hat{G}_\alpha(\xi,t) = e^{-|\xi|^{2\alpha}t}.$$

The solution θ of (4.1) with initial datum θ_0 is then given by

$$\theta(t) = e^{t\Lambda^{2\alpha}}\theta_0 = G_a(t) * \theta_0.$$

We recall once again that if $0 < \beta < 2$, the Riesz potential I_β is defined in the Fourier variables by

$$\widehat{(I_\beta w)}(\xi) = \frac{\widehat{w}(\xi)}{|\xi|^\beta}.$$

Then we can write

$$\partial^\gamma \theta(t) = (\partial^\gamma \Lambda^\beta G_a)(t) * (I_\beta \theta_0). \tag{4.2}$$

By a standard change of variables, since $n = 2$, it follows that

$$(\partial^\gamma \Lambda^\beta G_\alpha)(x,t) = t^{-(\frac{\beta}{2\alpha}+\frac{|\gamma|}{2\alpha}+\frac{1}{\alpha})}(\partial^\gamma \Lambda^\beta G_\alpha)(t^{-\frac{1}{2\alpha}}x, 1). \tag{4.3}$$

Hence, by the Hausdorff–Young inequality,

$$\|\partial^\gamma \theta(t)\|_p \leq t^{-(\frac{\beta}{2\alpha}+\frac{|\gamma|}{2\alpha}+\frac{1}{\alpha}[1-\frac{1}{p}])}\|\partial^\gamma \Lambda^\beta G_\alpha(1)\|_p \|I_\beta \theta_0\|_1 \tag{4.4}$$

for all $t \geq 0$, $1 \leq p \leq \infty$. Thus, in order to establish the L^p decay of $\partial^\gamma\theta(t)$ it will suffice to prove that $\partial^\gamma \Lambda^\beta G_\alpha(1)$ is in L^p. We do this in the next lemma.

LEMMA 4.1. *Assume $\alpha \geq \frac{1}{2}$ and let $p \in [1,\infty]$. Then $\partial^\gamma \Lambda^\beta G_\alpha(1) \in L^p$ for all $\beta \geq 0$ and all multi-indices $\gamma = (\gamma_1, \gamma_2)$.*

Proof. Since

$$\widehat{\partial^\gamma \Lambda^\beta G_\alpha}(1)(\xi) = \xi^\gamma |\xi|^\beta e^{-|\xi|^{2\alpha}}$$

is integrable, it follows that $\partial^\gamma \Lambda^\beta G_\alpha(1) \in L^\infty$ (for all $\alpha > 0$). All that remains to be proved is that $\partial^\gamma \Lambda^\beta G_\alpha(1) \in L^1$.

We consider two cases: $\alpha > \frac{1}{2}$ and $\alpha = \frac{1}{2}$. Assume first that $\alpha > \frac{1}{2}$. It is not hard to see that

$$\begin{aligned}\left|\Delta\left(\widehat{\partial^\gamma \Lambda^\beta G_\alpha}\right)(\xi,1)\right| &= \left|\Delta\left(\xi^\gamma |\xi|^\beta e^{-|\xi|^{2\alpha}}\right)\right| \\ &\leq C(1+|\xi|^N)|\xi|^{|\gamma|+\beta+2\alpha-2}e^{-|\xi|^{2\alpha}}\end{aligned}$$

for some constants $C, N \geq 0$, all $\xi \in \mathbb{R}^2$. It follows that $|\Delta(\widehat{\partial^\gamma \Lambda^\beta G_\alpha})(\xi,1)|^2$ near 0 behaves like $|\xi|^{2|\gamma|+2\beta+2\alpha-4}$, which is integrable since, because $\alpha > \frac{1}{2}$, $2|\gamma|+2\beta+4\alpha-$

$4 \geq 4\alpha - 4 > -2$. It follows that $\Delta(\widehat{\partial^\gamma \Lambda^\beta G_\alpha})(1)$ is in L^2; hence so is $|x|^2 \partial^\gamma \Lambda^\beta G_\alpha(1)$. It being clear that $G_\alpha(1) \in L^2$, it follows that $(1+|x|^2)\partial^\gamma \Lambda^\beta G_\alpha(1)$ is in L^2; since $(1+|x|^2)^{-1}$ is in L^2, the proof that $\partial^\gamma \Lambda^\beta G_\alpha(1)$ is in L^1 is complete.

Assume now that $\alpha = \frac{1}{2}$. Then

$$\begin{aligned}\Lambda^\beta G_{\frac{1}{2}}(x,1) &= \frac{1}{2\pi}\int_{\mathbb{R}^2} |\xi|^\beta e^{ix\cdot\xi} e^{-|\xi|}\, d\xi \\ &= \frac{1}{2\pi}\int_0^{2\pi}\int_0^\infty r^{\beta+1} e^{-r(1-ix\sin\theta)}\, dr\, d\theta \\ &= \frac{\Gamma(\beta+2)}{2\pi}\int_0^{2\pi} \frac{d\theta}{(1-ix\sin\theta)^{\beta+2}}.\end{aligned}$$

From the last expression it is immediate that $\partial^\gamma \Lambda^\beta G_\alpha(1) \in L^1(\mathbb{R}^2)$ if $\beta + |\gamma| > 0$. It remains to be seen whether the same is true if $\beta = 0$, $\gamma = 0$. However, in this case the integral is easily computed by residues; one has

$$G_{\frac{1}{2}}(x,1) = \frac{1}{2\pi}\int_0^{2\pi} \frac{d\theta}{(1-ix\sin\theta)^2} = \frac{1}{4(1+|x|^2)^{3/2}}.$$

The last expression is clearly integrable over $\mathbb{R}^2$. □

Remark 4.2. The last lemma is valid for $\alpha \in (0, 1/2)$, provided $\beta + |\gamma| \geq 1$. In fact, essentially the same proof as for the case $\alpha > \frac{1}{2}$ applies. The only relation α, β, γ had to satisfy for the argument to be valid was $2|\gamma| + 2\beta + 4\alpha - 4 > -2$, which clearly holds if $\alpha > 0$ and $\beta + |\gamma| \geq 1$.

The results in the remainder of this section are based on the ideas described in [5] to study the L^1 decay for solutions to viscous conservation laws.

THEOREM 4.3. *Let $\alpha \in (0,1]$, let $0 < \beta$, and assume that $I_\beta \theta_0 \in L^1(\mathbb{R}^2)$. Let $\gamma = (\gamma_1, \gamma_2)$ be a multi-index; assume $|\gamma| + \beta \geq 1$ if $\alpha < \frac{1}{2}$. Set*

$$A = \lim_{|\xi|\to 0} \frac{\widehat{\theta}_0(\xi)}{|\xi|^\beta} = \int_{\mathbb{R}^2} (I_\beta \theta_0)(x)\, dx. \tag{4.5}$$

Let $\theta(t) = e^{-t\Lambda^{2\alpha}}\theta_0 = G_a(t) * \theta_0$ be the solution of (4.1) *with initial datum θ_0. Then, for $1 \leq p \leq \infty$,*

$$\|\partial^\gamma \theta(t)|_p \leq C t^{-\frac{\beta}{2\alpha} - \frac{|\gamma|}{2\alpha} - (1-\frac{1}{p})\frac{1}{\alpha}} \|I_\beta \theta_0\|_1 \tag{4.6}$$

for all $t > 0$ and $C = C(\beta, \gamma)$ independent of t and θ_0. Moreover,

$$t^{\frac{\beta}{2\alpha} + \frac{|\gamma|}{2\alpha} + (1-\frac{1}{p})\frac{1}{\alpha}} \|\partial^\gamma \theta(t) - A\partial^\gamma \Lambda^\beta G_\alpha(t)\|_p \to 0 \tag{4.7}$$

as $t \to \infty$.

Proof. By Lemma 4.1 (see also Remark 4.2) we have $\partial^\gamma \Lambda^\beta G_\alpha \in L^p$. Writing

$$\partial^\gamma \theta(t) = (\partial^\gamma \Lambda^\beta G_\alpha(t)) * I_\beta \theta_0,$$

in view of Lemma 4.1, (4.6) is immediate from (4.4) $C = \|\partial^\gamma \Lambda^\beta G_\alpha(1)\|_p$.

For the proof of (4.7), we can write

$$\begin{aligned}&\left|\partial^\gamma \theta(x,t) - A\partial^\gamma \Lambda^\beta G_\alpha(x,t)\right| \\ &\leq \int_{\mathbb{R}^2} \left|(\partial^\gamma \Lambda^\beta G_\alpha)(x-y,t) - (\partial^\gamma \Lambda^\beta G_\alpha)(x,t)\right| |I_\beta \theta_0(y)|\, dy \\ &\leq \left(\int_{\mathbb{R}^2} |I_\beta \theta_0(y)|\, dy\right)^{\frac{p-1}{p}} \left(\int_{\mathbb{R}^2} \left|(\partial^\gamma \Lambda^\beta G_\alpha)(x-y,t) - (\partial^\gamma \Lambda^\beta G_\alpha)(x,t)\right|^p |I_\beta \theta_0(y)|\, dy\right)^{1/p}.\end{aligned}$$

Raising to the power p, integrating with respect to x, and changing the variables by $z = xt^{-\frac{1}{2\alpha}}$, combined with the self-similar form of G_α (see (4.3)), leads to the following expression:

$$\begin{aligned}
&\|\partial^\gamma\theta(t) - A\partial^\gamma\Lambda^\beta G_\alpha(t)\|_p^p \\
&\le \|I_\beta\theta_0\|_1^{p-1}\int_{\mathbb{R}^2\times\mathbb{R}^2}\left|(\partial^\gamma\Lambda^\beta G_\alpha)(x-y,t) - (\partial^\gamma\Lambda^\beta G_\alpha)(x,t)\right|^p |I_\beta\theta_0(y)|\ dxdy \\
&= t^{-\frac{p}{2\alpha}(\beta+|\gamma|+2(1-\frac{1}{p}))}\|I_\beta\theta_0\|_1^{p-1} \\
&\quad\times\int_{\mathbb{R}^2\times\mathbb{R}^2}\left|(\partial^\gamma\Lambda^\beta G_\alpha)(z-t^{-\frac{1}{2}}y,1) - (\partial^\gamma\Lambda^\beta G_\alpha)(z,1)\right|^p |I_\beta\theta_0(y)|\ dxdy.
\end{aligned}$$

To complete the proof of (4.7) we need to show only that

$$\lim_{t\to\infty}\int_{\mathbb{R}^2\times\mathbb{R}^2}\left|(\partial^\gamma\Lambda^\beta G_\alpha)(z-t^{-\frac{1}{2}}y,1) - (\partial^\gamma\Lambda^\beta G_\alpha)(z,1)\right|^p |I_\beta\theta_0(y)|\ dxdy = 0. \tag{4.8}$$

The Fourier transforms of all the derivatives of the function $\partial^\gamma\Lambda^\beta G(1)$ are in L^1; it follows that this function is infinitely many times differentiable, with all derivatives bounded. Thus the integrand in (4.8) converges uniformly to 0 over compact subsets of $\mathbb{R}^2\times\mathbb{R}^2$. Moreover, by Lemma 4.1, the function (and its derivatives) are in L^p. By this L^P-integrability, and the integrability of $I_\beta\theta_0$, one can find for each $\epsilon > 0$ a compact subset K_ϵ of $\mathbb{R}^2\times\mathbb{R}^2$ such that

$$\int_{(\mathbb{R}^2\times\mathbb{R}^2)\setminus K_\epsilon}\left|(\partial^\gamma\Lambda^\beta G_\alpha)(z-t^{-\frac{1}{2}}y,1) - (\partial^\gamma\Lambda^\beta G_\alpha)(z,1)\right|^p |I_\beta\theta_0(y)|\ dxdy < \epsilon.$$

This and the aforementioned uniform convergence prove (4.8). This completes the proof of the theorem. ∎

Remark 4.4. In the case $\alpha = 1$ we recall that in [7], [6] Miyakawa obtained the L^1 decay of $e^{t\Delta}u_0$ provided the $|x|^\beta$-momentum of the data is bounded. The assumption on the Riesz potential is weaker than the one assumed by Miyakawa; see [5].

We also obtain the following as an immediate corollary to Lemma 4.1.

COROLLARY 4.5. *Let $\alpha \in (0,1]$, let $0 < \beta$, and assume that $I_\beta\theta_0 \in L^p(\mathbb{R}^2)$, $1 \le p \le \infty$. Let $\gamma = (\gamma_1,\gamma_2)$ be a multi-index; assume $|\gamma| + \beta \ge 1$ if $\alpha < \frac{1}{2}$. Then there exists a constant $C \ge 0$ such that*

$$\|\partial^\gamma e^{-t\Lambda^{2\alpha}}\theta_0\|_p \le Ct^{-\frac{\beta}{2\alpha}-\frac{|\gamma|}{2\alpha}}\|I_\beta\theta_0\|_p \tag{4.9}$$

for all $t > 0$.

Proof. By (4.2), (4.3), and the Hausdorff–Young inequality,

$$\begin{aligned}
\|\partial^\gamma e^{-t\Lambda^{2\alpha}}\theta_0\|_p &\le t^{-\frac{\beta}{2\alpha}-\frac{|\gamma|}{2\alpha}-\frac{1}{\alpha}}\|\partial^\gamma\Lambda^\beta G_\alpha(t^{-\frac{1}{2\alpha}}\cdot,1)\|_1\|I_\beta\theta_0(t)\|_p \\
&= t^{-\frac{\beta}{2\alpha}-\frac{|\gamma|}{2\alpha}}\|\partial^\gamma\Lambda^\beta G_\alpha(1)\|_1\|I_\beta\theta_0(t)\|_p,
\end{aligned}$$

and the result follows from Lemma 4.1. ∎

4.2. Nonlinear asymptotics. The next step is to use the results from the last section to get the decay of the solutions to the geostrophic equations in L^1 and with that improve the decay of the solutions in L^p. The decay will be obtained by estimating the solutions via their integral representation. We note that the decay

below might not be optimal. So as to be able to include the critical case $\alpha = \frac{1}{2}$, we recall the following result due to Constantin, Cordoba, and Wu [1].

THEOREM 4.6. *There exists a constant c_∞ such that for any $\theta_0 \in H^2(\mathbb{R}^2)$ with $\|\theta_0\|_{H^2} \le c_\infty$, the equation*

$$\theta_t + u \cdot \nabla\theta + \Lambda\theta = 0$$

has a unique global solution θ with initial datum θ_0 satisfying

$$\|\theta(t)\|_{H^2} \le \|\theta_0\|_{H^2}$$

for all $t \ge 0$.

Combining this theorem with Theorem 2.1 and using the Gagliardo–Nirenberg inequalities, one obtains for this solution θ, $u = \mathcal{R}^\perp\theta$

$$\|\theta(t)\|_\infty \le C\|\theta\|_2^{\frac{1}{2}}\|\Lambda^2\theta\|_2^{\frac{1}{2}} \le C\|\theta_0\|_{H_2}^{\frac{1}{2}}(1+t)^{-\frac{1}{2}}, \tag{4.10}$$

$$\|u(t)\|_\infty \le C\|u\|_2^{\frac{1}{2}}\|\Lambda^2 u\|_2^{\frac{1}{2}} \le C\|\theta_0\|_{H_2}^{\frac{1}{2}}(1+t)^{-\frac{1}{2}}, \tag{4.11}$$

and by Hölder,

$$\|\nabla\theta(t)\|_2 \le \|\theta(t)\|_2^{\frac{1}{2}}\|\Lambda^2\theta(t)\|_2^{\frac{1}{2}} \le \|\theta_0\|_{H_2}^{\frac{1}{2}}(1+t)^{-\frac{1}{2}}. \tag{4.12}$$

We assume θ is this solution in case $\alpha = \frac{1}{2}$.

THEOREM 4.7. *Let $\beta > 0$, assume that $I_\beta\theta_0 \in L^1(\mathbb{R}^2)$, and let θ be the solution of the homogeneous DQG equation with initial datum θ_0.*

(i) *Assume $\frac{1}{2} \le \alpha < 1$. Then*

$$\|\theta(t)\|_1 \le Ct^{-\nu}$$

for all $t > 0$, some constant C, where

$$\nu = \begin{cases} \min(\beta, \frac{1}{2}) & \text{if} \quad \alpha = \frac{1}{2}, \\ \min(\frac{\beta}{2\alpha}, \frac{1}{2\alpha}) & \text{if} \quad \frac{1}{2} < \alpha < 1. \end{cases}$$

(ii) *Assume $\alpha = 1$. Then*

$$\|\theta(t)\|_1 \le \begin{cases} Ct^{-\frac{\beta}{2}} & \text{if} \quad \beta < 1, \\ Ct^{-\frac{1}{2}}\log(t+1) & \text{if} \quad \beta \ge 1 \end{cases}$$

for some constant C.

Proof. Write the solution by its integral representation,

$$\theta(t) = G_\alpha(t) * \theta_0 + \int_0^t G_\alpha(s) * (u \cdot \nabla\theta)(t-s)\, ds = G_\alpha(t) * \theta_0 + I(t). \tag{4.13}$$

From the last section it follows that

$$\|G_\alpha(t) * \theta_0\|_1 \le Ct^{-\frac{\beta}{2\alpha}}\|I_\beta\theta_0\|_1, \tag{4.14}$$

and the theorem reduces to proving that

$$I(t) = \int_0^t \|G_\alpha(s) * (u \cdot \nabla\theta)(t-s)\|_1\, ds \le C(1+t)^{-\nu}$$

is appropriately bounded. By Hausdorff–Young, Hölder, and the fact that $u\nabla\theta = \operatorname{div}(u\theta)$,

$$I(t) = \int_0^{t/2} \|G_\alpha(s) * (u\cdot\nabla\theta)(t-s)\|_1\,ds + \int_{t/2}^t \|\nabla G_\alpha(s) * (u\theta)(t-s)\|_1\,ds$$
$$\le \int_0^{t/2} \|G_\alpha(s)\|_1\|u(t-s)\|_2\|\nabla\theta(t-s)\|_2\,ds + \int_{t/2}^t \|\nabla G_\alpha(s)\|_1\|u(t-s)\|_2\|\theta(t-s)\|_2\,ds$$
$$= J(t) + K(t).$$

By the results of the last section we have

$$\|G_\alpha(s)\|_1 = \|G_\alpha(1)\|_1 = C, \tag{4.15}$$

$$\|\nabla G_\alpha(s)\|_1 = s^{-\frac{1}{2\alpha}}\|\nabla G_\alpha(1)\|_1 = Cs^{-\frac{1}{2\alpha}}, \tag{4.16}$$

with C a constant depending only on α. We also have

$$\|u(t-s)\|_2\|\nabla\theta(t-s)\|_2 \le \begin{cases} (1+t)^{-3/2} & \text{if} \quad \alpha = \frac{1}{2}, \\ (1+t)^{-\frac{3}{2\alpha}} & \text{if} \quad \frac{1}{2} < \alpha \le 1. \end{cases}$$

The estimate for $\alpha = \frac{1}{2}$ comes from Theorem 2.1 and (4.12), the one for $\alpha > \frac{1}{2}$ from Theorem 3.2. Using this and (4.15) we get, with $\mu = \frac{3}{2}$ if $\alpha = \frac{1}{2}$, $\mu = \frac{3}{2\alpha}$, otherwise

$$J(t) \le C\int_0^{t/2} (1+t-s)^{-\mu}\,ds \le C(1+t)^{1-\mu},$$

since in all cases $\mu > 1$. Note that $\mu - 1 = \frac{1}{2}$ when $\mu = \frac{3}{2}$, and for all other μ's it follows that $\mu - 1 \ge \frac{1}{2\alpha}$, so $\mu - 1 \ge \nu$ in all cases. Thus

$$J(t) \le C(1+t)^{-\nu}, \tag{4.17}$$

and we are done with the estimate for J. To estimate $K(t)$ we use (4.16) and the fact that $\|u(t-s)\|_2\|\theta(t-s)\|_2 \le C(1+t-s)^{-\frac{1}{\alpha}}$ to get

$$K(t) \le C\int_{t/2}^t s^{-\frac{1}{2\alpha}}(1+t-s)^{-\frac{1}{\alpha}}\,ds \le \begin{cases} Ct^{-\frac{1}{2\alpha}} & \text{if} \quad \frac{1}{2} \le \alpha < 1, \\ Ct^{-\frac{1}{2}}\log t & \text{if} \quad \alpha = 1. \end{cases} \tag{4.18}$$

The conclusion of the theorem follows now from (4.13) and (4.14), using (4.17) and (4.18) to bound $I(t) = J(t) + K(t)$. □

Derivatives of the solution θ can be similarly bounded, at least if $\alpha > \frac{1}{2}$. We have the following theorem.

THEOREM 4.8. *Let $\beta > 0$. Assume $I_\beta\theta_0 \in L^1(\mathbb{R}^2)$, $\theta_0 \in H^m$ for some $m \ge 1$, and let γ be a multi-index, $|\gamma| \le m-1$. Then*

$$\|\partial^\gamma\theta(t)\|_1 \le \begin{cases} Ct^{-\min(\frac{\beta+|\gamma|}{2\alpha}, \frac{|\gamma|+1}{2\alpha})}, & \frac{1}{2} < \alpha < 1, \\ Ct^{-\min(\frac{\beta+|\gamma|}{2\alpha}, \frac{|\gamma|+1}{2\alpha})}\log(t+1), & \alpha = 1. \end{cases}$$

Proof. Proceeding as in the proof of Theorem 4.7, we get

$$\|\partial^\gamma\theta(t)\|_1 \le \|\partial^\gamma G_\alpha(t) * \theta_0\|_1 + J_\gamma(t) + K_\gamma(t),$$

where the terms on the right-hand side now have the following interpretations and bounds:

$$\|\partial^\gamma G_\alpha(t) * \theta_0\|_1 \le Ct^{-\frac{\beta+|\gamma|}{2\alpha}}$$

by (4.6). For the second term, using the estimates in Theorem 3.2 we obtain first

$$\begin{aligned}\|\partial^\gamma(u\cdot\nabla\theta)(t-s)\|_1 &\le \sum_{|\gamma_1|+|\gamma_2|=|\gamma|+1} c_{\gamma_1,\gamma_2}\|\partial^{\gamma_1}u(t-s)\|_2\|\partial^{\gamma_2}\theta(t-s)\|_2\\ &\le C(1+t-s)^{-\frac{|\gamma|+3}{2\alpha}}\end{aligned} \tag{4.19}$$

(the coefficients c_{γ_1,γ_2} coming from Leibniz's formula); hence (since $3-2\alpha\ge 1$)

$$J_\gamma(t)=\int_0^{t/2}\|G_\alpha(s)\|_1\|\partial^\gamma(u\cdot\nabla\theta)(t-s)\|_1\,ds \le C(t+1)^{-\frac{|\gamma|+3-2\alpha}{2\alpha}} \le C(t+1)^{-\frac{|\gamma|+1}{2\alpha}}.$$

For the third term we use the fact that $\|\nabla\partial^\gamma G_\alpha(t)\| = Ct^{-\frac{|\gamma|+1}{2\alpha}}$ and, as in Theorem 4.7, that

$$\|u(t-s)\theta(t-s)\|_1 \le (1+t-s)^{-\frac{1}{\alpha}}$$

to get

$$K_\gamma(t)=\int_{t/2}^t\|\nabla\partial^\gamma G_\alpha(s)\|_1\|(u\theta)(t-s)\|_1\,ds \le \begin{cases} Ct^{-\frac{|\gamma|+1}{2\alpha}} & \text{if} \quad \frac12<\alpha<1,\\ Ct^{-\frac{|\gamma|+1}{2}}\log(t+1) & \text{if} \quad \alpha=1.\end{cases}$$

The theorem follows. □

Finally, we see that the solution θ is asymptotically equivalent to the self-similar solution of the linear equation, at least if $\beta<1$. For a given $\beta>0$, (4.3) shows that the self-similar solution $\partial^\gamma\Lambda^\beta G_\alpha$ of the linear equation decays in the L^1 norm at the rate of $t^{-\frac{\beta+|\gamma|}{2\alpha}}$ as $t\to\infty$. Theorem 4.8 shows that the derivative ∂^γ of the solution of the nonlinear equation (with datum θ_0 satisfying $I_\beta\theta_0\in L^1$) decays (at least) at the same rate if $\beta<1$. By asymptotic equivalence, we mean that the difference of θ and the self-similar solution of the linear equation decays at a better rate.

THEOREM 4.9. *Assume $0<\beta<1$ and that the hypotheses of Theorem 4.8 hold. Then, with*

$$A=A_\beta=\int_{\mathbb{R}^2}(I_\beta\theta_0)(x)\,dx,$$

one has

$$\lim_{t\to\infty} t^{\frac{\beta+|\gamma|}{2\alpha}}\left\|\partial^\gamma\theta(t)-A\partial^\gamma\Lambda^\beta G_\alpha(t)\right\|_1=0.$$

Proof. We have

$$\partial^\gamma\theta(t)-A\partial^\gamma\Lambda^\beta G_\alpha(t)=\partial^\gamma(G_a(t)*\theta_0)-A\partial^\gamma\Lambda^\beta G_\alpha(t)+\int_0^t\partial^\gamma G_\alpha(s)*(u\cdot\nabla\theta)(t-s)\,ds,$$

and by Theorem 4.3 it suffices to prove that

$$\lim_{t\to\infty} t^{\frac{\beta+|\gamma|}{2\alpha}}H(t)=0, \tag{4.20}$$

where

$$H(t) = \int_0^t \|\partial^\gamma G_\alpha(s) * (u \cdot \nabla\theta)(t-s)\|_1 \, ds.$$

This is, however, immediate from the proof of Theorem 4.8. In fact, we have $H \le J_\gamma + K_\gamma$, where J_γ, K_γ are as in the proof of Theorem 4.8. It follows that $H(t)$ decays at the rate of either $t^{-\frac{|\gamma|+1}{2\alpha}}$ $(\alpha < 1)$ or $t^{-\frac{|\gamma|+1}{2\alpha}} \log t$ $(\alpha = 1)$; in either case (4.20) holds because $\beta < 1$. □

COROLLARY 4.10. *Under the conditions of Theorem* 4.9 *if* $|\gamma| = 0$*, the conclusion of the theorem is also valid for the case* $\alpha = \frac{1}{2}$.

Proof. The proof follows the same lines as that of Theorem 4.9. □

Acknowledgments. The authors would like to express their thanks to the anonymous referees for many very helpful and thoughtful comments and suggestions.

ON THE EXISTENCE OF A WEAK SOLUTION TO A TWO-DIMENSIONAL FREE-BOUNDARY PROBLEM WITH A NONLINEAR FLUX CONDITION*

E. CASELLA†

Abstract. The main result of this paper is a global existence theorem for a two-dimensional free-boundary problem with a nonlinear boundary condition in suitable Sobolev spaces. The existence result is proved by using some a priori estimates and the Schauder fixed point theorem.

Key words. Stefan problem, free-boundary problem, nonlinear flux

AMS subject classifications. 80A22, 35R35

DOI. 10.1137/S0036141002410411

1. Introduction. In the present paper we consider a free-boundary problem concerning the evolution of a heated viscous incompressible fluid with a nonlinear boundary condition on the temperature. Problems of this kind have been studied by several authors; see, for instance, Fasano and Primicerio [11], Cannon and DiBenedetto [4, 5], Damlamian and Kenmochi [9], and Visintin [16].

We consider a coupling between the Navier–Stokes equations and the Stefan equation. Some papers have been devoted to the coupling of these equations; see Cannon and DiBenedetto [5], Cannon, DiBenedetto, and Knightly [6], and Wang [18]. One of the main novelties of this paper is the analysis of a simplified approximate method to couple the two equations. We propose an approximate method (see section 2) that does not impose a vanishing velocity in the solid part. This particular model, analyzed in Casella and Giangi [7], is a simplification of the exact one introduced by Cannon, DiBenedetto, and Knightly [6] and by Wang [18]. Its interest relies on the fact that the existence of weak solutions can be proved in a more straightforward way. Furthermore, this model (coupled with finite differences or finite elements) provides some numerical methods which are very simple to implement and which give results in good agreement with experimental data. In particular, Rady and Mohanty [15] have applied it to the melting of gallium and soldification of tin in a square cavity; Brent, Voller, and Reid [2] and Giangi and Stella [12] to a melting problem; and Giangi, Stella, and Kowalewski [13] to a freezing water problem.

In the present paper we apply this model to a classical problem with nonlinear flux. We consider a fluid that can take a phase transition in a bounded open set $\Omega \subset \mathbb{R}^2$. We suppose that the boundary $\Gamma = \partial\Omega$ is a smooth one-dimensional manifold and that Ω is locally situated on one side of Γ. We consider a homogeneous Dirichlet condition for the velocity field. Concerning the temperature, we impose a Dirichlet condition on part of the boundary and a suitable nonlinear flux condition on the rest. In particular, the flux may depend in a nonlinear way on the temperature. In this case, it is possible to study the physical problem of irradiation with the so-called Stefan–Boltzmann law. This may be used to describe, for example, the electron flux

in a rarefied gas. The model equation, which we have in mind, is

$$\frac{\partial \theta}{\partial n} = \eta(\theta^4 - \theta_0^4),$$

where θ and θ_0 are, respectively, the temperature of the boundary and that of the source, while η is a physical parameter. The main result of this paper is a global existence theorem in suitable Sobolev spaces for the Stefan problem with convection and nonlinear flux. In particular, existence is proved by considering a sequence of approximating problems, for which a priori estimates are obtained. The limit then provides a weak solution for the original problem.

The paper is organized as follows. In section 2 we describe the mathematical model. In section 3 we define some notation. In section 4 we give the notion of weak solution, and we state and prove the main result.

2. Formulation of the problem. Suppose that in a region Ω of $\mathbb{R}^2$ a Newtonian and incompressible fluid undergoes a change of phase at a fixed temperature. In general, there are in the fluid convective motions, originated by a body force $\mathbf{f}$ which depends on the temperature θ of the fluid.

In what follows, Q denotes the space-time cylinder $\Omega \times (0,T)$, where $0 < T \in \mathbb{R}$ and Ω is a bounded open set in $\mathbb{R}^2$ of Lipschitz class, filled by the fluid.

We define $\Omega(0) := \Omega \times \{0\}$ and assume that Γ_2 is an open subset of Γ of positive one-dimensional Hausdorff measure, and we set $\Sigma := \Gamma_2 \times (0,T)$ and $\Gamma_1 := \Gamma \setminus \Gamma_2$.

The phase-transition temperature is denoted by 0, and the following temperature-phase rule is assumed:

$$\theta \geq 0 \quad \text{in the liquid region} \quad \text{and} \quad \theta \leq 0 \quad \text{in the solid region.}$$

Let M_1 be a real positive constant and let α be the maximal monotone graph defined by

$$\alpha(\theta) = \begin{cases} \{\theta + M_1\} & \text{if } \theta > 0, \\ [-M_1, M_1] & \text{if } \theta = 0, \\ \{\theta - M_1\} & \text{if } \theta < 0. \end{cases} \tag{2.1}$$

The following constitutive relation between the enthalpy w and the temperature θ of the fluid holds:

$$w \in \alpha(\theta).$$

The term β is a function which depends on the temperature:

$$\beta(\theta) = \begin{cases} C\,\theta & \text{if } \theta < 0, \\ 0 & \text{if } \theta \geq 0, \end{cases} \tag{2.2}$$

where C is a *large* real positive constant.

By assuming the Boussinesq approximation, the system of partial differential equations we are going to study is

$$\frac{\partial w}{\partial t} - k\Delta\theta + \mathbf{v} \cdot \nabla\theta = 0 \quad \text{in } Q, \tag{2.3}$$

$$\frac{\partial \mathbf{v}}{\partial t} - \nu\Delta\mathbf{v} + (\mathbf{v} \cdot \nabla)\mathbf{v} + \nabla p + \beta(\theta)\mathbf{v} = \mathbf{f}(\theta) \quad \text{in } Q, \tag{2.4}$$

$$\nabla \cdot \mathbf{v} = 0 \quad \text{in } Q, \tag{2.5}$$

$$w \in \alpha(\theta) \quad \text{a.e. in } Q,$$

where k and ν are given real positive constants and p is the pressure of the fluid. The previous system is supplemented by the following initial and boundary conditions:

$$w(\mathbf{x},0) = w_0(\mathbf{x}) \quad \text{in } \Omega(0), \tag{2.6}$$

$$\mathbf{v}(\mathbf{x},0) = \mathbf{v}_0(x) \quad \text{in } \Omega(0), \tag{2.7}$$

$$\theta = 0 \quad \text{on } \Gamma_1 \times (0,T), \tag{2.8}$$

$$\frac{\partial \theta}{\partial \mathbf{n}} = -g(\theta) \quad \text{on } \Gamma_2 \times (0,T),$$

$$\mathbf{v} = \mathbf{0} \quad \text{on } \Gamma \times (0,T). \tag{2.9}$$

We observe that in the solid region the term $\beta(\theta)$ has the effect of a constraint: when the temperature θ decreases, $\beta(\theta)$ increases and the solution $\mathbf{v}$ of the velocity equation becomes small. On the other hand, the definition of β implies that, where θ is larger than 0, the velocity equation is equivalent to the Navier–Stokes system.

3. Notation and function spaces. In this section we provide a brief description of the function spaces that shall be used in what follows. We shall need the following Banach spaces:

$$\mathcal{W} := \{u \in H^1(\Omega) : u = 0 \text{ on } \Gamma_1\},$$

$$H := \{\mathbf{v} \in L^2(\Omega) : \mathbf{v} \cdot \mathbf{n} = 0 \ \text{ on } \Gamma \quad \text{and} \quad \operatorname{div} \mathbf{v} = 0\},$$

$$V := \{\mathbf{v} \in H^1(\Omega) : \mathbf{v} = \mathbf{0} \ \text{ on } \Gamma \quad \text{and} \quad \operatorname{div} \mathbf{v} = 0\}.$$

By recalling the generalized Poincaré inequality, the spaces $\mathcal{W}$ and V are equipped with the norms

$$\|u\|_{\mathcal{W}} := \|\nabla u\|_{L^2(\Omega)} \quad \text{and} \quad \|\mathbf{v}\|_V := \|\nabla \mathbf{v}\|_{L^2(\Omega)}.$$

Let us consider the trilinear and continuous form $b : V \times V \times V \to R$ defined as

$$b(\mathbf{u},\mathbf{v},\mathbf{w}) := \sum_{i,j=1}^{2} \int_\Omega u_i \, (D_i v_j) \, w_j \, dx,$$

and let $B : V \times V \to V'$ be the continuous operator given by

$$\langle B(\mathbf{u},\mathbf{v}), \mathbf{w} \rangle_{V',V} = b(\mathbf{u},\mathbf{v},\mathbf{w}) \quad \forall \mathbf{w} \in V.$$

Finally, we denote by γ_0 the trace operator

$$\gamma_0 : L^2(0,T;\mathcal{W}) \to L^2(0,T;H^{\frac{1}{2}}(\Gamma_2))$$

and by G the operator defined by

$$G : \{z \in L^2(0,T;\mathcal{W}) : \ g(x,t,\gamma_0 z(x,t)) \in L^2(\Sigma)\} \longrightarrow L^2(0,T;\mathcal{W}')$$

$$\langle G(z), s \rangle_{L^2(0,T;\mathcal{W}'),L^2(0,T;\mathcal{W})} = \int_0^T \int_{\Gamma_2} g(\gamma_0 z) \, \gamma_0 s \, d\sigma \, dt.$$

The interpolation theory provides the following compactness result (the Lions–Aubin theorem), which will be fundamental in proving the main proposition of this paper.

THEOREM 3.1. *For $i = 0, 1$ let $1 < p_i < +\infty$. Let B, B_0, B_1 be Banach spaces, and let B_0, B_1 be reflexive and such that $B_0 \subset B \subset B_1$. Let the inclusion $B_0 \hookrightarrow B$ be compact and the inclusion $B \hookrightarrow B_1$ be continuous.*

Then the embedding $L^{p_0}(0,T;B_0) \cap W^{1,p_1}(0,T;B_1) \hookrightarrow L^{p_0}(0,T;B)$ is compact.

In what follows, as usual, we shall denote by $c_i, i \in \mathbb{N}$, some real positive constants.

4. An existence result. The aim of this section is to prove the existence of a weak solution to the problem described by (2.3)–(2.9).

DEFINITION 4.1. *Let*

$$w_0 \in L^2(\Omega),\ \mathbf{v}_0 \in H,$$

$$\mathbf{f} : R \to \mathbb{R}^2 \text{ a Lipschitz function} : \mathbf{f}(0) = \mathbf{0}.$$

Let g be a function defined on $\Sigma \times \mathbb{R}$, which satisfies some further properties that shall be introduced later. A weak solution *of* (2.3)–(2.9) *is a pair $(w, \mathbf{v})$ such that*

$$w \in L^2(Q) : \theta = \alpha^{-1}(w) \in L^2(0,T;\mathcal{W}), \quad g(x,t,\gamma_0[\theta(x,t)]) \in L^2(\Sigma),$$

$$\mathbf{v} \in L^2(0,T;V) \cap L^\infty(0,T;H),$$

which satisfies

$$\begin{aligned}
&\int_Q \left(-w\frac{\partial \varphi}{\partial t} + k\,\nabla\theta\cdot\nabla\varphi + (\mathbf{v}\cdot\nabla\theta)\varphi \right) dx\,dt \\
&= -\int_0^T \int_{\Gamma_2} g(\gamma_0\theta)\varphi\,d\sigma\,dt + \int_\Omega w^0\varphi(\cdot\,,0)\,dx \\
&\forall\,\varphi \in C^\infty(\overline{Q}) \quad \textit{such that} \quad \varphi = 0 \quad \textit{on} \quad \Gamma_1 \quad \textit{and} \quad \varphi(x,T) = 0 \quad \forall x \in \Omega;
\end{aligned}$$

$$\begin{aligned}
&\int_Q \left(-\mathbf{v}\cdot\frac{\partial \boldsymbol{\psi}}{\partial t} + \nu\,\nabla\mathbf{v} : \nabla\boldsymbol{\psi} + \{(\mathbf{v}\cdot\nabla)\mathbf{v}\}\cdot\boldsymbol{\psi} + \beta(\theta)\mathbf{v}\cdot\boldsymbol{\psi} \right) dx\,dt \\
&= \int_Q \mathbf{f}(\theta)\cdot\boldsymbol{\psi}\,dx\,dt + \int_\Omega \mathbf{v}^0\cdot\boldsymbol{\psi}(\cdot\,,0)\,dx \\
&\forall\,\boldsymbol{\psi} \in C^\infty(\overline{Q}) \quad \textit{such that} \quad \boldsymbol{\psi} = \mathbf{0}\ \textit{on}\ \Gamma,\ \operatorname{div}\boldsymbol{\psi} = 0\ \textit{and}\ \boldsymbol{\psi}(x,T) = 0 \quad \forall x \in \Omega.
\end{aligned}$$

THEOREM 4.2. *Assume that $-M_1 \le w_0 \le M_1$ and that for each $(x,t) \in \Sigma$ the real function*

$$\xi \longrightarrow g(x,t,\xi)$$

is nondecreasing monotone and such that $g(x,t,0) = 0$. Furthermore, let $g(x,t,\xi)$ belong to $L^2(\Sigma)$ for each $\xi \in \mathbb{R}$. Then there exists a weak solution for system (2.3)–(2.9) *such that θ and $w \in L^\infty(Q)$. In particular,*

$$-M_1 \le w \le M_1 \quad \textit{a.e. in } Q.$$

Proof. We prove the previous result via approximation, a priori estimates, and a limit procedure.

4.1. A collection of approximate problems. As a first step we approximate the maximal monotone graph α defined in (2.1).

Let $\{\alpha_m\}_{m\in\mathbb{N}}$ be a sequence of odd smooth functions such that

1. for suitable ζ_0, ζ_1, and c, real positive constants independent of m,

$$\zeta_0 \le \alpha_m'(u) \le \zeta_1 \text{ for } |u| > \frac{2}{m} \quad \text{and} \quad \zeta_0 \le \alpha_m'(u) \le cm \text{ for } |u| \le \frac{2}{m}; \tag{4.1}$$

2. $\{\delta_m\}_{m\in\mathbb{N}} := \{\alpha_m^{-1}\}_{m\in\mathbb{N}}$ is a sequence of odd functions, strongly converges to $\delta(u) := \alpha^{-1}(u)$ uniformly on compact sets, and is such that

$$\delta_m(M_1) > 0, \quad 0 < \frac{1}{cm} \le \delta_m' \le \zeta_0^{-1} \quad \forall m \in \mathbb{N}. \tag{4.2}$$

We refer to [4] for more details on the construction and regularity of the sequences $\{\alpha_m\}_{m\in\mathbb{N}}$ and $\{\delta_m\}_{m\in\mathbb{N}}$. Now let g_m be a sequence in $C^1(\overline{\Sigma}\times\mathbb{R})$ such that

1. for each $(x,t)\in\Sigma$ and $m\in\mathbb{N}$ the real map $\xi \mapsto g_m(x,t,\xi)$ is nondecreasing monotone;
2. the sequence $g_m(x,t,\xi)$ converges to $g(x,t,\xi)$ pointwise on $\Sigma\ \forall\,\xi\in\mathbb{R}$;
3. there exists a function $F\in L^2(\Sigma)$ such that

$$\forall \xi\in\mathbb{R} \quad |g_m(x,t,\xi) - g(x,t,\xi)| \le F(x,t) \quad \text{on } \Sigma;$$

4. the sequence g_m satisfies the inequalities

$$g_m(x,t,\delta_m(-M_1)) \le 0 \quad \text{and} \quad g_m(x,t,\delta_m(M_1)) \ge 0 \quad \text{on } \Sigma.$$

Also let $-M_1 \le w_{0,m} \le M_1$ be a sequence in $L^2(\Omega)$ and let $\mathbf{v}_{0,m}$ be a sequence in V such that

$$w_{0,m} \to w_0 \text{ strongly in } L^2(\Omega) \quad \text{and} \quad \mathbf{v}_{0,m} \to \mathbf{v}_0 \text{ strongly in } H.$$

We now consider the following auxiliary problem. Find $(w_m, \mathbf{v}_m)$ in $L^2(Q)\times L^2(0,T;V) \cap L^\infty(0,T;H) : \theta_m := \delta_m(w_m) \in L^2(0,T;\mathcal{W})$ and

$$\begin{aligned}
&\int_Q \left(-w_m\frac{\partial\varphi}{\partial t} + (\mathbf{v}_m\cdot\nabla\theta_m)\varphi + k\nabla\theta_m\cdot\nabla\varphi\right) dx\,dt \\
&= -\int_0^T\int_{\Gamma_2} g_m(\theta_m)\,\varphi\,d\sigma\,dt + \int_\Omega w_{0,m}\,\varphi(x,0)\,dx \\
&\forall\,\varphi\in C^\infty(\overline{Q}), \quad \varphi = 0 \quad \text{on } \Gamma_1, \quad \varphi(x,T) = 0 \ \ \forall x\in\Omega;
\end{aligned}$$

$$\begin{aligned}
&\int_Q -\mathbf{v}_m\cdot\frac{\partial\boldsymbol{\psi}}{\partial t} + \{(\mathbf{v}_m\cdot\nabla)\mathbf{v}_m\}\cdot\boldsymbol{\psi} + \nu\nabla\mathbf{v}_m : \nabla\boldsymbol{\psi} + \beta(\theta_m)\mathbf{v}_m\cdot\boldsymbol{\psi}\,dx\,dt \\
&= \int_Q \mathbf{f}(\theta_m)\cdot\boldsymbol{\psi}\,dx\,dt + \int_\Omega \mathbf{v}_{0,m}\cdot\boldsymbol{\psi}(x,0)\,dx \\
&\forall\,\boldsymbol{\psi}\in C^\infty(\overline{Q}), \quad \boldsymbol{\psi} = 0 \quad \text{on } \Gamma, \quad \operatorname{div}\boldsymbol{\psi} = 0, \quad \boldsymbol{\psi}(x,T) = 0 \ \ \forall x\in\Omega.
\end{aligned}$$

We employ a Galerkin procedure to solve the previous problem. We consider in $L^2(\Omega)$ the basis $\{z_i\}$ of complete orthonormal polynomials. We also introduce the orthonormal basis $\{\mathbf{w}_i\}$ of H generated by the Stokes problems

$$\begin{cases} -\Delta\mathbf{w}_i + \nabla p = \lambda_i\mathbf{w}_i \text{ in } \Omega, \\ \operatorname{div}\ \mathbf{w}_i = 0 \text{ in } \Omega, \\ \mathbf{w}_i = 0 \text{ on } \Gamma, \end{cases}$$

where p is a scalar function representing a pressure.

The initial data $w_{0,m}$ and $\mathbf{v}_{0,m}$ are represented as

$$w_{0,m}(x) = \sum_{i=1}^{\infty} c^0_{m,i}\, z_i(x), \quad \mathbf{v}_{0,m}(x) = \sum_{i=1}^{\infty} d^0_{m,i}\, \mathbf{w}_i(x), \quad \text{where } c^0_{m,i}, d^0_{m,i} \in \mathbb{R}.$$

For any fixed $l \in \mathbb{N}$, we denote by P_l the $L^2(\Omega)$-projection over the span generated by $z_1, \dots, z_l$, and we set

$$\mathbf{v}^*_l(x,t) = \sum_{i=1}^{l} d^{l,*}_i(t)\mathbf{w}_i(x), \quad d^{l,*}_i(t) \in C^1[0,T] \qquad \text{for } i = 1, \dots, l.$$

We wish to find $w_{m,l}(x,t) = \sum_{i=1}^{l} c^l_{m,i}(t) z_i(x)$, with the real functions $c^l_{m,i} \in C^1[0,T]$ for $i = 1, \dots, l$, such that $\theta_{m,l} := \delta_m(w_{m,l})$ and the Stefan problem

$$\text{(4.3)} \qquad \begin{cases} \dfrac{\partial w_{m,l}}{\partial t} - \nu\Delta\theta_{m,l} + \mathbf{v}^*_l \cdot \nabla\theta_{m,l} = 0 \quad \text{in } Q, \\ \theta_{m,l} = 0 \quad \text{on } \Gamma_1 \times (0,T), \\ \dfrac{\partial \theta_{m,l}}{\partial \mathbf{n}} = -g_m(\theta_{m,l}) \quad \text{on } \Gamma_2 \times (0,T), \\ w_{m,l}(x,0) = P_l(w_{0,m}) \quad \text{in } \Omega \end{cases}$$

with prescribed convection $\mathbf{v}^*_l$ is satisfied in the sense of the projection over the span generated by $z_1, \dots, z_l$. The previous equations form a linear differential system for the real functions $c^l_{m,i}(t)$. With a standard argument, one can easily prove that this system has a maximal solution on the time interval $(0,T)$.

We now denote by π_l the H-projection onto the linear space of $\mathbf{w}_1, \dots, \mathbf{w}_l$, and we employ the function $w_{m,l}$ thus obtained to construct $\mathbf{v}_{m,l} = \sum_{i=1}^{l} d^l_{m,i}(t)\mathbf{w}_i$, solution, in the sense of the projection over the span generated by $\mathbf{w}_1, \dots, \mathbf{w}_l$, of the system

$$\text{(4.4)} \qquad \begin{cases} \dfrac{\partial \mathbf{v}_{m,l}}{\partial t} - \nu\Delta\mathbf{v}_{m,l} + (\mathbf{v}_{m,l} \cdot \nabla)\mathbf{v}_{m,l} + \beta(\delta_m(w_{m,l}))\mathbf{v}_{m,l} = \mathbf{f}(\delta_m(w_{m,l})) \text{ in } Q, \\ \text{div } \mathbf{v}_{m,l} = 0 \quad \text{in } Q, \\ \mathbf{v}_{m,l} = \mathbf{0} \quad \text{on } \Gamma, \\ \mathbf{v}_{m,l}(x,0) = \pi_l(\mathbf{v}_{0,m}) \quad \text{in } \Omega. \end{cases}$$

It can be shown easily that there exists a unique solution of the previous nonlinear differential system for the real functions $d^l_{m,i}(t)$ on the interval $(0,T)$. For $l \in \mathbb{N}$, let B be a ball in $L^\infty(0,T)^l$ with a large enough radius and let $F_l : B \to F_l(B)$ be the function defined as

$$F_l(d^*_1(t), \dots, d^*_l(t)) = (d^l_{m,1}(t), \dots, d^l_{m,l}(t)).$$

By using the Schauder fixed point theorem, we prove that, for each l belonging to $\mathbb{N}$, the map F_l has a fixed point. To check that F_l satisfies all the hypotheses of the Schauder fixed point theorem, some a priori estimates are required.

4.2. Some a priori estimates. We now set $z_{m,l} := (w_{m,l}-M_1)^+-(w_{m,l}+M_1)^-$ and multiply the first equation in (4.3) by $z_{m,l}$. We get that

$$\int_\Omega \frac{\partial w_{m,l}}{\partial t} z_{m,l}\,dx + \int_\Omega \nabla\theta_{m,l}\cdot\nabla z_{m,l}\,dx + \int_\Omega (\mathbf{v}_l^*\cdot\nabla\theta_{m,l})\ z_{m,l}\,dx + \int_{\Gamma_2} g_m(\theta_{m,l})\ z_{m,l}\,d\sigma = 0. \tag{4.5}$$

We claim that

$$\int_\Omega \nabla\theta_{m,l}\cdot\nabla z_{m,l}\,dx \geq 0, \tag{4.6}$$

$$\int_\Omega (\mathbf{v}_l^*\cdot\nabla\theta_{m,l})\ z_{m,l}\,dx = 0, \tag{4.7}$$

$$\int_{\Gamma_2} g_m(\theta_{m,l})\ z_{m,l}\,dx \geq 0. \tag{4.8}$$

The first statement is trivial. Concerning (4.7), by the definition of $z_{m,l}$ and by integrating by parts we get

$$\begin{aligned}
&\int_{\{w_{m,l}<-M_1\}\cup\{w_{m,l}>M_1\}} (\mathbf{v}_l^*\cdot\nabla\theta_{m,l}) z_{m,l}\,dx \\
&\qquad = -\int_{\{w_{m,l}<-M_1\}\cup\{w_{m,l}>M_1\}} (\mathbf{v}_l^*\cdot\nabla z_{m,l})\theta_{m,l}\,dx \\
&\qquad = -\int_{\{w_{m,l}<-M_1\}\cup\{w_{m,l}>M_1\}} (\mathbf{v}_l^*\cdot\nabla w_{m,l})\delta_m(w_{m,l})\,dx \\
&\qquad = -\int_{\{w_{m,l}<-M_1\}\cup\{w_{m,l}>M_1\}} \mathbf{v}_l^*\cdot\nabla\left(\int_{-M_1}^{w_{m,l}}\delta_m(s)ds\right)dx.
\end{aligned}$$

Observing that $\int_{-M_1}^{M_1}\delta_m(s)ds = 0$ and integrating by parts again, we obtain (4.7). We now prove (4.8). Clearly,

$$\int_{\Gamma_2} g_m(\theta_{m,l})\ z_{m,l}\,dx\,dt = \int_{\{w_{m,l}>M_1\}} g_m(\theta_{m,l})\ z_{m,l}\,dx + \int_{\{w_{m,l}<-M_1\}} g_m(\theta_{m,l})\ z_{m,l}\,dx.$$

Since for $w_{m,l} > M_1$ we have $g_m(\theta_{m,l}) \geq g_m(\delta_m(M_1)) \geq 0$ and for $w_{m,l} < -M_1$ we have $g_m(\theta_{m,l}) \leq g_m(\delta_m(-M_1)) \leq 0$, it follows that

$$\int_{\{w_{m,l}>M_1\}} g_m(\theta_{m,l})\ z_{m,l}\,dx \geq 0 \quad\text{and}\quad \int_{\{w_{m,l}<-M_1\}} g_m(\theta_{m,l})\ z_{m,l}\,dx \geq 0.$$

By using (4.6), (4.7), and (4.8), from (4.5) we obtain

$$\frac{1}{2}\frac{d}{dt}\|z_{m,l}\|^2_{L^2(\Omega)} \le 0.$$

By integrating the previous inequality in time from 0 to t, and by observing that $z_{m,l}(0) = 0$, it follows that $z_{m,l}(t) = 0\ \forall t \in [0,T]$. Consequently,

$$-M_1 \le w_{m,l} \le M_1 \ \text{ in } \overline{Q}. \tag{4.9}$$

We now take $w_{m,l}$ as a test function in the first equation of system (4.3). After integrating by parts, we get

$$\int_\Omega \frac{\partial w_{m,l}}{\partial t} w_{m,l}\,dx + \int_\Omega \nabla\theta_{m,l}\cdot\nabla w_{m,l}\,dx = -\int_{\Gamma_2} g_m(\theta_{m,l})\ w_{m,l}\,dx.$$

Since δ_m is a sequence of smooth nondecreasing monotone functions, (4.9) implies

$$\delta_m(-M_1) \le \theta_{m,l} \le \delta_m(M_1) \ \text{ in } \overline{Q}.$$

Hence,

$$\begin{aligned}\frac{1}{2}\frac{d}{dt}\|w_{m,l}\|^2_{L^2(\Omega)} + \int_\Omega \alpha_m^{'}|\nabla\theta_{m,l}|^2\,dx &\le \int_{\Gamma_2} |g_m(\gamma_0\theta_{m,l})|\ |\gamma_0 w_{m,l}|\,dx \\ &\le M_1 \max(\|g_m(\delta_m(-M_1))\|_{L^1(\Gamma_2)}, \|g_m(\delta_m(M_1))\|_{L^1(\Gamma_2)}).\end{aligned} \tag{4.10}$$

By using (4.1), (4.2), and the monotonicity of the functions g_m, it follows that, for m sufficiently large,

$$\max(\|g_m(\delta_m(-M_1))\|_{L^1(\Gamma_2)}, \|g_m(\delta_m(M_1))\|_{L^1(\Gamma_2)}) \le c_1. \tag{4.11}$$

By (4.1), (4.10), and (4.11), we also get

$$\frac{1}{2}\frac{d}{dt}\|w_{m,l}\|^2_{L^2(\Omega)} + \zeta_0\int_\Omega |\nabla\theta_{m,l}|^2\,dx \le c_2.$$

Hence, since the sequence $w_{m,l}$ is bounded in $L^\infty(Q)$, by integrating in time the previous inequality it follows that there exists a real positive constant c_3 such that

$$\|\theta_{m,l}\|_{L^2(0,T;\mathcal{W})} \le c_3. \tag{4.12}$$

We now multiply the first equation in (4.4) by $\mathbf{v}_{m,l}$. By standard calculations and using (4.12), we obtain that

$$\|\mathbf{v}_{m,l}\|_{L^\infty(0,T;L^2(\Omega))} \le c_4 \quad \text{and} \quad \|\mathbf{v}_{m,l}\|_{L^2(0,T;V)} \le c_4. \tag{4.13}$$

4.3. Application of the Schauder fixed point theorem. To prove that the map F_l satisfies all the hypotheses of the Schauder fixed point theorem, we have to check that F_l is well-defined and compact. Let us consider the ball B of radius c_4, where c_4 is the constant appearing in (4.13), and let $\{d_1^*(t),\dots,d_l^*(t)\}$ in B. Since the first inequality in (4.13) implies that

$$\left(\sum_{i=1}^{l}\{d^l_{m,i}(t)\}^2\right)^{\frac{1}{2}} \le c_4 \quad \forall t \in [0,T],$$

it follows that $F_l(d_1^*(t),\dots,d_l^*(t)) \in B$. Hence, F_l maps the ball B into itself. Moreover, as we shall prove, the sequence $\{\frac{\partial \mathbf{v}_{m,l}}{\partial t}\}_{l\in\mathbb{N}}$ is uniformly bounded in $L^2(Q)$. Consequently, $F_l(d_1^*(t),\dots,d_l^*(t)) \in H^1(0,T)^l \subset L^\infty(0,t)^l$. Since $H^1(0,T)^l$ is compactly embedded in $L^\infty(0,t)^l$, the map F_l is compact.

We now show that there exists a constant $C(m,\, \|\mathbf{v}_{0,m}\|_V)$ depending on m and on the norm of $\mathbf{v}_{0,m}$ in V but which is independent of l such that

$$\left\| \frac{\partial \mathbf{v}_{m,l}}{\partial t} \right\|_{L^2(Q)} \le C(m,\, \|\mathbf{v}_{0,m}\|_V).$$

Let A_s be the Stokes operator. By multiplying the first equation in (4.4) by $\lambda_i \mathbf{w}_i$, we obtain

$$\int_\Omega \left(\lambda_i \frac{\partial \mathbf{v}_{m,l}}{\partial t} \mathbf{w}_i + \beta(\theta_{m,l})\, \mathbf{v}_{m,l}\, A_s \mathbf{w}_i \right) dx + \nu \langle A_s \mathbf{w}_i,\, \mathbf{v}_{m,l} \rangle$$
$$+ b(\mathbf{v}_{m,l}, \mathbf{v}_{m,l}, A_s \mathbf{w}_i) = \int_\Omega \mathbf{f}(\theta_{m,l}) A_s \mathbf{w}_i \, dx.$$

It follows that

$$\frac{1}{2}\frac{d}{dt}\|\mathbf{v}_{m,l}\|_V^2 + \frac{\nu}{2}\|A_s \mathbf{v}_{m,l}\|_{L^2(\Omega)}^2 \le \sigma_{m,l}\|\mathbf{v}_{m,l}\|_V^2 + c_5 \|\theta_{m,l}\|_{L^2(\Omega)}^2, \tag{4.14}$$

where $\sigma_{m,l} = c_6(\|\mathbf{v}_{m,l}\|_{L^2(\Omega)}^2 \|\mathbf{v}_{m,l}\|_V^2 + \|\theta_{m,l}\|_{\mathcal{W}}^2)$. Since the sequence $\{\theta_{m,l}\}_{l\in\mathbb{N}}$ is bounded in $L^\infty(0,T;L^2(\Omega))$ and $\int_0^T \sigma_{m,l}\, dt < +\infty$, by the Gronwall lemma the sequence $\{\mathbf{v}_{m,l}\}_{l\in\mathbb{N}}$ is also bounded in $L^\infty(0,T;V)$. Back to (4.14), we obtain that

$$\nu \|A_s \mathbf{v}_{m,l}\|_{L^2(Q)}^2 \le \|\mathbf{v}_{m,l}(0)\|_V^2 + 2\int_0^T \left(\sigma_{m,l}\, \|\mathbf{v}_{m,l}(t)\|_V^2 + c_5 \|\theta_{m,l}\|_{L^2(\Omega)}^2 \right) dt,$$

which yields that $\{\mathbf{v}_{m,l}\}_{l\in\mathbb{N}}$ is bounded in $L^2(0,T;H^2(\Omega))$. Since

$$\frac{\partial \mathbf{v}_{m,l}}{\partial t} = -\nu A_s \mathbf{v}_{m,l} - B(\mathbf{v}_{m,l}, \mathbf{v}_{m,l}) - [\beta(\theta_{m,l}) + f(\theta_{m,l})]\, \mathbf{v}_{m,l}$$

and in two dimensions the inequality

$$\|B(\mathbf{u},\, \mathbf{u})\|_{L^2(\Omega)}^2 \le c_7 \|\mathbf{u}\|_V^2\, \|\mathbf{u}\|_{L^2(\Omega)} \|A_s \mathbf{u}\|_{L^2(\Omega)} \quad \forall\, \mathbf{u} \in V \cap H^2(\Omega)$$

holds, the sequence $\{\frac{\partial \mathbf{v}_{m,l}}{\partial t}\}_{l\in\mathbb{N}}$ is bounded in $L^2(Q)$ by a constant depending on m but not on l.

Hence, we conclude that F_l has a fixed point $\mathbf{v}_{m,l} \in \operatorname{span}\langle \mathbf{w}_1, \dots, \mathbf{w}_l \rangle$. This point can be written as

$$\mathbf{v}_{m,l} = \sum_{i=1}^{l} \tilde{d}_{m,i}(t) \mathbf{w}_i.$$

Let

$$\varphi_s = \sum_{i=1}^{s} d_i(t) z_i(x), \quad \boldsymbol{\psi}_s = \sum_{i=1}^{s} \nu_i(t) \mathbf{w}_i(x) \quad d_i, \nu_i \in C^1[0,T], \quad d_i(T) = \nu_i(T) = 0.$$

Then $\theta_{m,l}$ and $\mathbf{v}_{m,l}$ satisfy for $l > s$

$$\begin{aligned}\int_Q \alpha_m^{'} \frac{\partial \theta_{m,l}}{\partial t}\varphi_s + \nabla\theta_{m,l}\cdot\nabla\varphi_s + \{\mathbf{v}_{m,l}\cdot\nabla\theta_{m,l}\}\varphi_s dx\,dt \\ = -\int_0^T \int_{\Gamma_2} g_m(\theta_{m,l})\,\varphi_s\,d\sigma\,dt;\end{aligned} \tag{4.15}$$

$$\begin{aligned}\int_Q \frac{\partial \mathbf{v}_{m,l}}{\partial t}\boldsymbol{\psi}_s + \nu\nabla\mathbf{v}_{m,l} : \nabla\boldsymbol{\psi}_s + \{(\mathbf{v}_{m,l}\cdot\nabla)\mathbf{v}_{m,l}\}\boldsymbol{\psi}_s + \beta(\theta_{m,l})\,\mathbf{v}_{m,l}\,\boldsymbol{\psi}_s\,dx\,dt \\ = \int_Q \mathbf{f}(\theta_{m,l})\boldsymbol{\psi}_s\,dx\,dt.\end{aligned} \tag{4.16}$$

4.4. Passage to the limit for $l \to \infty$. The preceding a priori estimates show that the two sequences $\{\theta_{m,l}\}_{l\in\mathbb{N}}$ and $\{\mathbf{v}_{m,l}\}_{l\in\mathbb{N}}$ are weakly compact, respectively, in $L^\infty(Q)\cap L^2(0,T;\mathcal{W})$ and $L^\infty(0,T;H)\cap L^2(0,T;V)$. Therefore, two subsequences can be selected and relabeled with l in such a way that for $m \in \mathbb{N}$ fixed, as $l \to +\infty$

$$w_{m,l} \longrightarrow w_m \text{ weakly star in } L^\infty(Q),$$

$$\theta_{m,l} \longrightarrow \theta_m \text{ weakly in } L^2(0,T;\mathcal{W}) \quad \text{and} \quad \text{weakly star in } L^\infty(Q),$$

$$\mathbf{v}_{m,l} \longrightarrow \mathbf{v}_m \text{ weakly in } L^2(0,T;V) \quad \text{and} \quad \text{weakly star in } L^\infty(0,T;H).$$

By the continuity of the trace operator γ_0, we have

$$\|G_m(\theta_{m,l})\|_{L^2(\mathcal{W}')} \le c_8. \tag{4.17}$$

By (4.17), since $\frac{\partial w_{m,l}}{\partial t} = k\Delta\theta_{m,l} - \mathbf{v}_{m,l}\cdot\nabla\theta_{m,l}$, we get that the sequences $\{w_{m,l}\}_{l\in\mathbb{N}}$ and $\{\theta_{m,l}\}_{l\in\mathbb{N}}$ are bounded in $H^1(0,T;\mathcal{W}^{'})$. By Theorem 3.1, there exists a subsequence, relabeled by l, such that for $l \to +\infty$ and $m \in \mathbb{N}$ fixed

$$\theta_{m,l} \to \theta_m \text{ strongly in } L^2(Q) \quad \text{and} \quad \mathbf{v}_{m,l} \to \mathbf{v}_m \text{ strongly in } L^2(0,T;H). \tag{4.18}$$

By passing to the limit for $l \to +\infty$ in (4.15) and (4.16), we prove that θ_m and $\mathbf{v}_m$ satisfy

$$\begin{aligned}\int_Q \alpha_m' \frac{\partial \theta_m}{\partial t}\varphi_s + \nabla\theta_m\cdot\nabla\varphi_s + \{\mathbf{v}_m\cdot\nabla\theta_m\}\varphi_s dx\,dt \\ = -\int_0^T \int_{\Gamma_2} g_m(\theta_m)\varphi_s\,d\sigma\,dt;\end{aligned} \tag{4.19}$$

$$\begin{aligned}\int_Q \frac{\partial \mathbf{v}_m}{\partial t}\boldsymbol{\psi}_s + \nu\nabla\mathbf{v}_m : \nabla\boldsymbol{\psi}_s + \{(\mathbf{v}_m\cdot\nabla)\mathbf{v}_m\}\boldsymbol{\psi}_s + \beta(\theta_m)\mathbf{v}_m\boldsymbol{\psi}_s\,dx\,dt \\ = \int_Q \mathbf{f}(\theta_m)\boldsymbol{\psi}_s\,dx\,dt.\end{aligned} \tag{4.20}$$

We now pass to the limit in the constitutive relation $w_{m,l} = \alpha_m(\theta_{m,l})$. It follows from (4.1) that

$$\|w_{m,l} - \alpha_m(\theta_m)\|_{L^2(Q)} \leq m^2 \|\theta_{m,l} - \theta_m\|_{L^2(Q)}.$$

Consequently, by (4.18), for $l \to +\infty$,

$$w_{m,l} = \alpha_m(\theta_{m,l}) \to \alpha_m(\theta_m) \quad \text{strongly in } L^2(Q).$$

By the uniqueness of the weak limit of $w_{m,l}$ in $L^2(Q)$, it can be seen that $w_m = \alpha_m(\theta_m)$. We now claim that

$$\int_0^T \int_{\Gamma_2} g_m(\theta_{m,l})\, \varphi_s \to \int_0^T \int_{\Gamma_2} g_m(\theta_m)\, \varphi_s.$$

It is a well-known result that for every $\varepsilon > 0$ there exists a constant $C(\varepsilon)$ such that

$$\int_0^T \int_{\Gamma_2} |\theta_{m,l} - \theta_m|^2 \, d\sigma \, dt \leq \varepsilon \|\nabla\theta_{m,l} - \nabla\theta_m\|^2_{L^2(Q)} + C(\varepsilon)\|\theta_{m,l} - \theta_m\|^2_{L^2(Q)}.$$

Since the norm $\|\nabla\theta_{m,l} - \nabla\theta_m\|_{L^2(Q)}$ is equibounded by a constant (depending on m but not on l) and the sequence $\theta_{m,l}$ strongly converges to θ_m in $L^2(Q)$, the above inequality implies that for $l \to \infty$

$$\theta_{m,l} \to \theta_m \quad \text{strongly in } L^2(\Sigma). \tag{4.21}$$

Moreover, there exists a constant $c(m)$, depending on m, such that

$$\|g_m(x,t,\theta_{m,l}) - g_m(x,t,\theta_m)\|_{L^1(\Sigma)} \leq c(m)\|\theta_{m,l}(x,t) - \theta_m(x,t)\|_{L^1(\Sigma)}.$$

Hence, by (4.21), for $l \to \infty$

$$\int_0^T \int_{\Gamma_2} g_m(\theta_{m,l})\, \varphi_s d\sigma \, dx \longrightarrow \int_0^T \int_{\Gamma_2} g_m(\theta_m)\, \varphi_s d\sigma \, dx.$$

4.5. Passage to the limit for $m \to \infty$. To conclude the proof we have to pass to the limit for $m \to \infty$.

We take as test functions in (4.19) and (4.20), respectively, w_m and $\mathbf{v}_m$. By standard calculations, we find that the sequences $\{w_m\}_{m\in\mathbb{N}}$ and $\{\mathbf{v}_m\}_{m\in\mathbb{N}}$ are uniformly bounded in $L^\infty(Q) \cap L^2(0,T;\mathcal{W}) \cap H^1(0,T;\mathcal{W}')$ and in $L^2(0,T;V) \cap L^\infty(0,T;H) \cap H^1(0,T;V')$ by a real positive constant not depending on m. By virtue of Theorem 3.1, the sequences $\{\theta_m\}_{m\in\mathbb{N}}$ and $\{\mathbf{v}_m\}_{m\in\mathbb{N}}$ strongly converge in $L^2(Q)$ and in $L^2(0,T;H)$, respectively, to θ and $\mathbf{v}$.

We now show that $\theta = \alpha^{-1}(w)$. By the monotonicity of the sequence δ_m, for every $s \in L^\infty(Q)$

$$\begin{aligned} &\int_0^T \int_\Omega [\delta_m(w_m(x,t)) - \delta_m(s(x,t))](w_m(x,t) - s(x,t))\, dx\, dt \\ &\qquad = \int_0^T \int_\Omega [\theta_m(x,t) - \delta_m(s)](w_m - s)\, dx\, dt \geq 0. \end{aligned} \tag{4.22}$$

We remark that

$$\int_0^T \int_\Omega \delta_m(w_m) w_m = \int_0^T \int_\Omega \theta_m w_m \, dx \, dt \longrightarrow \int_0^T \int_\Omega \theta w \, dx \, dt.$$

Since $\delta_m \to \alpha^{-1}$ in $C^0(\mathbb{R})$, by passing to the limit for $m \to \infty$ in (4.22), we get

$$\int_0^T \int_\Omega [\theta(x,t) - \alpha^{-1}(s(x,t))](w(x,t) - s(x,t)) \, dx \, dt \geq 0 \quad \forall s \in L^\infty(Q). \tag{4.23}$$

Since the real function α^{-1} is monotone, (4.23) implies that

$$\int_0^T \int_\Omega [\theta - \alpha^{-1}(w)](w - s) \, dx \, dt \geq 0 \quad \forall s \in L^\infty(Q),$$

from which we get

$$\theta = \alpha^{-1}(w) \quad \text{a.e. in } Q.$$

We now claim that

$$\int_0^T \int_{\Gamma_2} g_m(\theta_m) \gamma_0 \varphi \, dx \longrightarrow \int_0^T \int_{\Gamma_2} g(\gamma_0 \theta) \gamma_0 \varphi \, dx \quad \forall \varphi \in C^\infty(\overline{Q}).$$

Since the sequence $g_m(\theta_m)$ is bounded in $L^2(\Sigma)$, it follows that $g_m(\theta_m)$ weakly converges to ξ in $L^2(\Sigma)$. We prove that $\xi = g(\gamma_0 \theta)$. By virtue of the monotonicity of the functions g_m,

$$\int_\Sigma [g_m(\theta_m) - g_m(\gamma_0 s)] \gamma_0(\theta_m - s) \, dx \, dt \geq 0 \quad \forall s \in L^2(0,T; H^1(\Omega)) : \gamma_0 s \in L^\infty(\Sigma).$$

For $m \to \infty$,

$$\int_0^T \int_{\Gamma_2} g_m(\theta_m) \theta_m \, dx \, dt \to \int_0^T \int_{\Gamma_2} \xi(\gamma_0 \theta) dx \, dt.$$

On the other hand, by Lebesgue's dominate convergence theorem

$$g_m(x,t,\gamma_0 s(x,t)) \to g(x,t,\gamma_0 s(x,t)) \quad \text{strongly in } L^2(\Sigma).$$

It follows that

$$\int_0^T \int_{\Gamma_2} [\xi - g(\gamma_0 s)] \gamma_0(\theta - s) \, dx \geq 0 \quad \forall s \in L^2(0,T; H^1(\Omega)) : \gamma_0 s \in L^\infty(\Sigma).$$

Since g is a monotone function, we conclude that

$$\xi = g(\gamma_0 \theta) \quad \text{a.e. on } \Sigma. \qquad \square$$

GLOBAL EXISTENCE OF SMOOTH SOLUTIONS OF THE *N*-DIMENSIONAL EULER–POISSON MODEL*

G. ALÌ†

Abstract. The global existence of smooth solutions of the Cauchy problem for the N-dimensional Euler–Poisson model for semiconductors is established, under the assumption that the initial data is a perturbation of a stationary solution of the drift-diffusion equations with zero electron velocity, which is proved to be unique. The resulting evolutionary solutions converge asymptotically in time to the unperturbed state. The singular relaxation limit is also discussed.

Key words. Euler–Poisson, semiconductors, asymptotic behavior, smooth solutions

1. Introduction.

Hydrodynamic models for semiconductors were introduced about thirty years ago [8, 9] to describe the electron flow in semiconductor devices when the transport of energy plays a crucial role, as in submicron devices or in the occurrence of high field phenomena [39]. These models all consist of a set of balance laws for the moments of the electron distribution density, derived from the infinite hierarchy of moment equations of the semiclassical Boltzmann equation for semiconductors, coupled with the electric potential through a Poisson equation. Closure relations for the moment fluxes and the collision terms can be determined by using the maximum entropy principle [33, 18], physically set in the framework of extended thermodynamics [40, 30] (see [6], and also [5, 7] for a review).

In this paper, we consider the Euler–Poisson model, obtained from the first three moments: electron density, momentum, and energy. In rescaled variables, let n, $\boldsymbol{u} = (u^1, \dots, u^N)$, p, e, T, and ϕ denote the electron number density, the electron velocity, the electron pressure, the electron internal energy, the electron temperature, and the electric potential, respectively. All the dependent variables are functions of $(\boldsymbol{x}, t) \equiv (x^1, \dots, x^N, t) \in \mathbb{R}^N \times \mathbb{R}$. The (nondimensional) Euler–Poisson model consists of a hydrodynamic part,

$$\frac{\partial n}{\partial t} + \sum_{r=1}^{N} \partial_r (n u^r) = 0, \tag{1.1}$$

$$\frac{\partial}{\partial t}(n u^i) + \sum_{r=1}^{N} \partial_r \left(n u^i u^r + p \delta^{ir} \right) = n \partial_i \phi - \frac{n u^i}{\tau}, \tag{1.2}$$

$$\begin{aligned} \frac{\partial}{\partial t} \left(\frac{n |\boldsymbol{u}|^2}{2} + e \right) + \sum_{r=1}^{N} \partial_r \left[\left(\frac{n |\boldsymbol{u}|^2}{2} + e + p \right) u^r \right] \\ = \sum_{r=1}^{N} n u^r \partial_r \phi - \frac{1}{\sigma} \left[\frac{n |\boldsymbol{u}|^2}{2} + \left(\frac{\partial e}{\partial T} \right)_n (T - T^*) \right], \end{aligned} \tag{1.3}$$

supplemented by the Poisson equation

$$\Delta\phi = n - b. \tag{1.4}$$

Here, $\partial_r = \partial/\partial x^r$, $\Delta = \sum_{r=1}^N \partial_r^2$, $|\boldsymbol{u}|^2 = \sum_{r=1}^N (u^r)^2$, and δ^{ir} is the Kronecker symbol, equal to 1 if $i = r$, and equal to 0 otherwise. The positive constants τ and σ are the (rescaled) momentum relaxation time and the (rescaled) energy relaxation time, respectively, T^* is the (constant) equilibrium temperature, and the function $b(\boldsymbol{x})$ is the doping profile, satisfying the conditions

$$b \in L^\infty(\mathbb{R}^N), \qquad \sup_{\boldsymbol{x}\in\mathbb{R}^N} b(\boldsymbol{x}) = b^+ \geq \inf_{\boldsymbol{x}\in\mathbb{R}^N} b(\boldsymbol{x}) = b^- > 0, \tag{1.5}$$

$$Db \equiv (\partial_1 b, \partial_2 b, \dots, \partial_N b) \in H^s(\mathbb{R}^N), \qquad s > \frac{N}{2} + 1. \tag{1.6}$$

Consistent with extended thermodynamics, the system (1.1)–(1.4) is closed once we specify a convex state function $e(n, S)$, which satisfies the differential relation

$$d\left(\frac{e}{n}\right) = T d\left(\frac{S}{n}\right) - p d\left(\frac{1}{n}\right). \tag{1.7}$$

Then the temperature T and the pressure p are given as functions of the number density n and of the entropy S by the relations

$$T = \frac{\partial e}{\partial S}, \qquad p = \frac{\partial e}{\partial n} n + \frac{\partial e}{\partial S} S - e. \tag{1.8}$$

In particular, the partial derivative of e with respect to T keeping n constant, which appears in (1.3), can be expressed as

$$\left(\frac{\partial e}{\partial T}\right)_n = T \left(\frac{\partial S}{\partial T}\right)_n = \frac{\partial e/\partial S}{\partial T/\partial S}.$$

We expect (1.1)–(1.4) to determine a unique solution once we specify initial data for the hydrodynamical quantities (that is, for the electron velocity and for two thermodynamic variables) and appropriate boundary conditions. Heuristically speaking, when we extend the Euler–Poisson equations to the whole space, we do not have the problem of modeling contacts or insulated parts of the boundary. All we need to do is look for an equilibrium state and require that the state described by the solution be equal to that equilibrium state at infinity. In fact, we will prove the existence of a unique state $(n^*, \boldsymbol{u}^*, S^*, D\phi^*)$ in total thermodynamic equilibrium [1], which allows us to assign conditions at infinity for the hydrodynamic variables and the electric field. This result is consistent with the one-dimensional analysis [36, 37], which shows that it is natural to assign initially the electric field $E^i = \partial_i \phi$ compatibly with the Poisson equation instead of specifying the electric potential at infinity.

With this motivation, the system (1.1)–(1.4) is supplemented with the initial data

$$\begin{aligned} &n(\boldsymbol{x}, 0) = n_0(\boldsymbol{x}), \quad u^i(\boldsymbol{x}, 0) = u_0^i(\boldsymbol{x}), \\ &S(\boldsymbol{x}, 0) = S_0(\boldsymbol{x}), \quad \partial_i\phi(\boldsymbol{x}, 0) = E_0^i(\boldsymbol{x}), \end{aligned} \tag{1.9}$$

with

$$\sum_{i=1}^N \partial_i E_0^i = n_0 - b, \tag{1.10}$$

and with the boundary conditions

$$(1.11)\qquad \begin{aligned} &n(\boldsymbol{x},t)-n^*(\boldsymbol{x}),\quad u^i(\boldsymbol{x},t)-u^{*i}(\boldsymbol{x}),\\ &S(\boldsymbol{x},t)-S^*(\boldsymbol{x}),\quad E^i(\boldsymbol{x},t)-E^{*i}(\boldsymbol{x})\in H^s(\mathbb{R}^N),\qquad s>\frac{N}{2}+1. \end{aligned}$$

Here, we have introduced the electric field $E^{*i}=\partial_i\phi^*$. Of course, the condition (1.11) tells us much more than the behavior of the solution at infinity, but it also sets the natural functional space needed to study the global existence of smooth solutions of a hyperbolic system. In addition, we require that the electric flux be zero at infinity, that is,

$$(1.12)\qquad \frac{\partial \boldsymbol{E}}{\partial t}\in H^s(\mathbb{R}^N),\qquad s>\frac{N}{2}+1.$$

The only requirement for the unperturbed state is that

$$(1.13)\qquad \tau\sigma\,\|Dn^*\|_{L^2}^2<C^*$$

for a certain constant C^* which depends only on the equation of state and on $b^{\pm}$.

Now, we assume that the initial data is sufficiently close to the state in total thermodynamic equilibrium; that is, the differences

$$n_0(\boldsymbol{x})-n^*(\boldsymbol{x}),\quad u_0^i(\boldsymbol{x})-0,\quad S_0(\boldsymbol{x})-S^*(\boldsymbol{x}),\quad E_0^i(\boldsymbol{x})-E^{*i}(\boldsymbol{x})$$

belong to $H^s(\mathbb{R}^N)$, $s>\frac{N}{2}+1$, and their H^s-norms are small enough. Under these assumptions, we will show that the solution of the initial value problem (1.1)–(1.4) exists uniquely and globally in time and that it is a classical solution for $t>0$. Moreover, it decays exponentially in the H^s-norm to the stationary solution, according to the estimate

$$(1.14)\qquad \begin{aligned} &\|(n-n^*,\boldsymbol{u},S-S^*,\boldsymbol{E}-\boldsymbol{E}^*)(\cdot,t)\|_{H^s}^2\\ &\le Ke^{-c\tau t}\,\|(n-n^*,\boldsymbol{u},S-S^*,\boldsymbol{E}-\boldsymbol{E}^*)(\cdot,0)\|_{H^s}^2, \end{aligned}$$

with K and c positive constants which depend only on the equation of state, $e=e(n,S)$, on the equilibrium density, n^*, and on the product of the relaxation times, $\tau\sigma$. These results extend similar results obtained in [3] for the one-dimensional Euler–Poisson model.

Some remarks are in order. First, the condition (1.6) for the doping profile is just a technical one. In fact, the H^s-norm of b can be arbitrarily large, and we can assume the doping to be approximated by an appropriate function satisfying (1.6). Nevertheless, the condition (1.13) for $\|Dn^*\|_{L^2}$ can be read as a severe restriction for $\|Db\|_{L^2}$, which rules out the possibility of dopings with a sharp short well discontinuity, at least when $\tau\sigma$ is not small. This is a consequence of Theorem 3.1, where we prove some a priori estimates which ensure the existence of an equilibrium state. The restriction on the doping profile can be removed in the one-dimensional case, at least for a polytropic equation of state, as shown in [3]. We expect a similar result to hold also for higher space dimensions, although the proof may require different techniques from the ones used in this work.

Second, the smallness of the initial velocity and of $\|Db\|_{L^2}$ restricts implicitly our results to the subsonic case. Under transonic and supersonic flow conditions, the issue of global existence for the full hydrodynamic model remains essentially an open problem, since smooth solutions cease to exist in finite time [12].

A third remark concerns the singular relaxation limit, that is, the behavior of the solutions of the Euler–Poisson equations as the momentum relaxation time τ tends to zero and the product $\tau\sigma$ tends to a positive constant. We will show in section 4 that the estimate (1.14) is sufficient to establish the relaxation limit under the scaling $\tau t \to t$, $\boldsymbol{u}/\tau \to \boldsymbol{u}$. This limit provides a connection between the class of (hyperbolic) hydrodynamic models and the class of (parabolic) energy-transport models [2, 4]. For a review of the energy-transport models we refer to [13].

The Cauchy problem and the initial-boundary value problem of the one-dimensional hydrodynamic model for semiconductors and its relaxation limit have been studied extensively by many authors for isentropic flows, both in the stationary case [16, 20] and in the evolutionary case [11, 28, 29, 34, 36, 37, 41, 45, 46]. For the full Euler–Poisson model with additional heat conductivity, a preliminary numerical and theoretical study can be found in [21]. More recently, for the same model, the global existence of smooth solutions in a bounded domain for small initial data has been proved in [10, 47], under the assumption that the doping profile is close enough to a constant function. In [10], the singular relaxation hyperbolic–parabolic limit is also studied, assuming a uniform bound for an appropriate combination of the relaxation times. For the Euler–Poisson, in [3] the asymptotic behavior of solutions to the Cauchy problem and the convergence to the steady state solution are proven. Gasser and Natalini [22] have studied the zero relaxation convergence of the weak solutions to the corresponding drift-diffusion equations.

Very little is known so far in the multidimensional case. Besides the local classical solutions obtained in [31, 35], only steady state solutions in the subsonic case [17] and dynamic solutions with geometrical structure (symmetry) [11, 19, 25, 26] or without vorticity [23] have been studied. The existence of global smooth solutions for the general multidimensional model have been established in [24] for the isentropic case and in [27] for the full hydrodynamic system with heat conduction.

The approach followed in this paper relies essentially on the extended thermodynamic formulation of the system (1.1)–(1.4), that is, on the Legendre duality of the pressure and the internal energy expressed by (1.8). In particular, using new high order estimates, we are able to obtain arbitrarily smooth solutions if the initial data is smooth enough (in the sense of $H^s(\mathbb{R}^N)$ for any $s > N/2 + 1$). The proof of the estimate (1.14) extends energy methods already used for the one-dimensional model in [3] and for the parabolic energy-transport model in [14, 15] (see also [1]). To our knowledge, similar energy estimates appeared for the first time in the classical paper [38]. We mention also the recent paper [44], which studies the existence of smooth solutions for a general class of hyperbolic systems with relaxation.

The plan of the paper is the following. In section 2, we introduce the notation for the derivatives and for the norms that will be used throughout the paper. Also, we state some technical lemmas, whose proofs are given in the appendix. In section 3, we study the equilibrium states and their existence and their dependence on the doping profile. The subsequent section is the main section of the paper, where we state and prove the theorems concerning the global existence of a classical solution to the Euler–Poisson system and its singular relaxation limit. All these results depend on a key a priori estimate, which is established in the last two sections. Namely, in section 5 we study the positive definiteness of some Liapunov functionals which are used in the proof of the a priori estimate. The proof itself is given in section 6.

2. Notation and basic lemmas. We start this section by introducing two different notations for the components of the kth derivative operator [43]. The derivative

operator is defined by

$$D = (\partial_1, \partial_2, \dots, \partial_N).$$

Then, for any $k \geq 0$, the kth derivative operator is defined by

$$D^0 \stackrel{\text{def}}{=} I, \qquad D^k \stackrel{\text{def}}{=} DD^{k-1}, \qquad k \geq 1.$$

Let J be a k-tuple of integers between 1 and N, $J = (j_1, \dots, j_k)$. We set

$$\partial_J = \partial_{j_1}\partial_{j_2}\cdots\partial_{j_k},$$

and $|J| = k$, the total order of differentiation. Since partial derivatives with different indices commute, it is convenient to introduce an alternative notation. Let α be an N-tuple of nonnegative integers, $\alpha = (\alpha_1, \dots, \alpha_N)$. We set

$$\partial^\alpha = \partial_1^{\alpha_1}\partial_2^{\alpha_2}\cdots\partial_N^{\alpha_N}.$$

The total order of derivation is $|\alpha| = \sum_{i=1}^N \alpha_i$. If $|J| = |\alpha| = k$ and $f \in C^k(\mathbb{R}^N)$, then

$$\partial_J f = \partial^\alpha f,$$

with $\alpha_i = \#\{l : j_l = i\}$. In this case, we write $\alpha = \alpha(J)$.

For any $f, g \in C^k(\mathbb{R}^N)$, we consider $D^k f$, $D^k g$ as vectors in $(C^0)^{N^k}$ and define the Euclidean norm and scalar product

$$\left|D^k f\right| = \left(\sum_{|J|=k} (\partial_J f)^2\right)^{1/2}, \qquad D^k f \cdot D^k g = \sum_{|J|=k} (\partial_J f)(\partial_J g).$$

Using the α-multi-index notation, we have

$$\left|D^k f\right| = \left(\sum_{|\alpha|=k} \nu(\alpha)(\partial^\alpha f)^2\right)^{1/2}, \qquad D^k f \cdot D^k g = \sum_{|\alpha|=k} \nu(\alpha)(\partial^\alpha f)(\partial^\alpha g),$$

with

$$\nu(\alpha) = \#\{J : \alpha = \alpha(J)\} = \frac{k!}{\alpha!}, \qquad \alpha! = \alpha_1! \cdots \alpha_N!.$$

We can extend these definitions to a vector-valued function $\boldsymbol{v} = (v^1, \dots, v^N) \in (C^k(\mathbb{R}^N))^N$ by

$$\left|D^k \boldsymbol{v}\right| = \sum_{r=1}^N \sum_{|J|=k} (\partial_J v^r)^2, \qquad D^k \boldsymbol{v} \cdot D^k \boldsymbol{w} = \sum_{r=1}^N \sum_{|J|=k} (\partial_J v^r)(\partial_J w^r).$$

The symbol $\otimes$ will denote the tensorial product, which combines two symmetric tensors with k and l indices to give a symmetric tensor with $k+l$ indices. In particular, we have the following formula for the kth derivative of the product of two functions:

$$D^k(fg) = \sum_{r=0}^k \binom{k}{r} (D^r f) \otimes (D^{k-r} g). \tag{2.1}$$

All the functional spaces will be considered on $\mathbb{R}^N$, so we will omit the argument. We will use the following norms:

$$\|f\| = \|f\|_{L^2} = \left(\int |f(\boldsymbol{x})|^2 \, d\boldsymbol{x} \right)^{\frac{1}{2}},$$
$$\|f\|_{H^k} = \sum_{i=0}^{k} \left\| D^i f \right\|,$$
$$\|f\|_{L^\infty} = \sup_{\boldsymbol{x} \in \mathbb{R}^N} |f(\boldsymbol{x})|,$$
$$\|f\|_{C^k} = \sum_{i=0}^{k} \left\| D^i f \right\|_{L^\infty}.$$

In the following, the symbol C will denote a generic positive constant. Sometimes we will write $C(a_1, \dots, a_m)$ to signify that the generic constant C depends on the arguments $a_1, \dots, a_m$. We will use the following classical lemma [35, 32].

LEMMA 2.1 (Moser-type calculus). *If f, $g \in H^k \cap L^\infty$, then we have*

$$\left\| D^k(fg) \right\| \leq C(k) \left(\|f\|_{L^\infty} \left\| D^k g \right\| + \|g\|_{L^\infty} \left\| D^k f \right\| \right). \tag{2.2}$$

If $f \in H^k$, $Df \in L^\infty$, $g \in H^{k-1} \cap L^\infty$, then we have

$$\left\| D^k(fg) - f D^k(g) \right\| \leq C(k) \left(\|Df\|_{L^\infty} \left\| D^{k-1} g \right\| + \|g\|_{L^\infty} \left\| D^k f \right\| \right). \tag{2.3}$$

If $F(w)$ is a smooth vector-valued function and $f(\boldsymbol{x})$ is a continuous function which takes values into a compact subset of the domain Ω of F, with $f \in H^k \cap L^\infty$, then we have

$$\left\| D^k F(f) \right\| \leq C(k, F, \|f\|_{L^\infty}) \left\| D^k f \right\|, \tag{2.4}$$

where

$$C(k, F, \|f\|_{L^\infty}) = C(k) \left| \frac{\partial F}{\partial w} \right|_{C^{k-1}} \left(\sum_{\mu=1}^{k} \|f\|_{L^\infty}^{\mu-1} \right),$$

with

$$\left| \frac{\partial F}{\partial w} \right|_{C^k} = \sup_{w \in \Omega} \sum_{i=0}^{k} \left| \left(\frac{\partial}{\partial w} \right)^i F(w) \right|.$$

We also use the following results, which will be proved in the appendix.

LEMMA 2.2. *If $1 \leq j \leq k$ and $D^j f$, $g \in H^{k-j}$, then we have*

$$\left\| D^k(fg) - \sum_{r=0}^{j-1} \binom{k}{r} (D^r f) \otimes (D^{k-r} g) \right\| \leq C(k, j) \left\| D^j f \right\|_{H^{k-j}} \|g\|_{H^{k-j}}. \tag{2.5}$$

LEMMA 2.3. *If $F(w)$ is a smooth vector-valued function and $f(\boldsymbol{x})$, $g(\boldsymbol{x})$ are continuous functions which take values into a compact subset of the domain Ω of F, with $g \in L^\infty$, $Dg \in H^{k-1}$, and $f - g \in H^k \cap L^\infty$, then we have*

$$\left\| D^k(F(f) - F(g)) \right\| \leq C(F, f, g) \left(\left\| D^k(f - g) \right\| + \|Dg\|_{H^{k-1}} \|f - g\|_{H^{k-1}} \right), \tag{2.6}$$

$$\left\| D^k(F(f) - F(g)) - \frac{\partial F}{\partial w}(g) D^k(f - g) \right\| \leq C(F, f, g) \left(\|f - g\|_{L^\infty} \left\| D^k(f - g) \right\| + \|Dg\|_{H^{k-1}} \|f - g\|_{H^{k-1}} \right), \tag{2.7}$$

where the constant C depends on the C^k-norm of the derivative of F, on $\|g\|_{L^\infty}$, and on $\|f-g\|_{L^\infty}$.

COROLLARY 2.4. *Under the same hypothesis as that of Lemma 2.3, we have*

$$\begin{aligned}(2.8)\qquad &\left\|D^{k-1}(F(f)Df-F(g)Dg)\right\|\\ &\quad\le C(F,f,g)(\left\|D^k(f-g)\right\|+\|Dg\|_{H^{k-1}}\|f-g\|_{H^{k-1}}),\\ (2.9)\qquad &\left\|D^{k-1}(F(f)Df-F(g)Dg)-F(g)D^k(f-g)\right\|\\ &\quad\le C(F,f,g)(\|f-g\|_{L^\infty}\left\|D^k(f-g)\right\|+\|Dg\|_{H^{k-1}}\|f-g\|_{H^{k-1}}).\end{aligned}$$

Moreover, assuming $Dg\in H^k\cap L^\infty$ and $D(f-g)\in L^\infty$, we have

$$\begin{aligned}(2.10)\qquad &\Big\|D^k\left[F(f)\partial f-F(g)\partial g\right]-F(f)D^k\partial(f-g)\\ &\quad-kD\left[F(g)\right]\otimes D^{k-1}\left[\partial(f-g)\right]-\frac{\partial F}{\partial w}(g)D^k(f-g)\partial g\Big\|\\ &\qquad\le C(F,f,g)(\|f-g\|_{C^1}\left\|D^k(f-g)\right\|+\|Dg\|_{H^k}\|f-g\|_{H^{k-1}}),\end{aligned}$$

where the constant C depends on the C^k-norm of the derivative of F, on $\|g\|_{C^1}$, and on $\|f-g\|_{C^1}$.

We close this section with a technical lemma.

LEMMA 2.5. *If $f\in H^k$, $k>1$, then for any positive constants K and η we can choose positive $\eta_1,\dots,\eta_k$ such that*

$$(2.11)\qquad \sum_{j=1}^{k}\eta_j\|f\|_{H^{j-1}}\left\|D^jf\right\|\le K\left(\eta\|f\|^2+\sum_{j=1}^{k}\eta_j\left\|D^jf\right\|^2\right).$$

In particular, the thesis of the lemma is satisfied by

$$\eta_j=2\eta\left(\frac{K^2}{1+K^2}\right)^j.$$

All the results of this section hold also when f and g are vector-valued functions.

3. Total thermodynamic equilibrium. In this section we characterize a state in total thermodynamic equilibrium [1] and show that it satisfies the drift-diffusion equation with zero electron flux. The main result of the section is the proof of the a priori estimates (3.11)–(3.12), which guarantee the existence of such a state. Moreover, we prove that there exists a unique state in total thermodynamic equilibrium.

A state $(n^*,\boldsymbol{u}^*,S^*,\phi^*)$ in total thermodynamic equilibrium is characterized by the conditions

$$(3.1)\qquad \boldsymbol{u}^*=0,$$

$$(3.2)\qquad \left(\frac{\partial e}{\partial n}\right)^*=\phi^*+\text{constant},\qquad \left(\frac{\partial e}{\partial S}\right)^*=T^*=\text{constant}.$$

Moreover, the electron density is related to the electric potential by the Poisson equation

$$(3.3)\qquad \Delta\phi^*=n^*-b.$$

Deriving the second relation in (1.8) and using (3.2), it is possible to see that (n^*, S^*, ϕ^*) satisfies the stationary drift-diffusion model

$$\begin{aligned} Dp^* &= n^* D\phi^*, \\ \Delta\phi^* &= n^* - b, \end{aligned} \tag{3.4}$$

with the constraint

$$\left(\frac{\partial e}{\partial S}\right)^* = T^*. \tag{3.5}$$

In other words, $(n, \boldsymbol{u}, S, \phi) = (n^*, 0, S^*, \phi^*)$ is a stationary solution of the Euler–Poisson system.

Two other relevant identities can be recovered by deriving (3.2) and solving for Dn^* and DS^*. We obtain

$$DS^* = -\left(\frac{\partial T/\partial n}{\partial T/\partial S}\right)^* Dn^*, \tag{3.6}$$

$$\left(\frac{H(e)}{\partial T/\partial S}\right)^* Dn^* = D\phi^*, \tag{3.7}$$

where the superscript * denotes evaluation at equilibrium, and the Hessian determinant of e, $H(e)$, is defined by

$$H(e) = \frac{\partial^2 e}{\partial n^2}\frac{\partial^2 e}{\partial S^2} - \left(\frac{\partial^2 e}{\partial n \partial S}\right)^2. \tag{3.8}$$

We remark that both $H(e)$ and $\partial T/\partial S = \partial^2 e/\partial S^2$ are positive, due to the convexity of $e(n, S)$.

For a polytropic equation of state,

$$e = \Gamma \exp\left(\frac{S}{\Gamma n}\right) n^\gamma, \qquad \Gamma = \frac{1}{\gamma - 1},$$

the identities (3.6) and (3.7) reduce to

$$DS^* = \left(\frac{S^*}{n^*} - 1\right) Dn^*, \qquad \frac{T^*}{n^*} Dn^* = D\phi^*.$$

In this case, the entropy at equilibrium is given by

$$S^* = -n^* \log\left(\frac{n^*}{T^{*\Gamma}}\right).$$

In the remainder of this section, we consider the system

$$\begin{aligned} \Theta(n^*, S^*) Dn^* &= D\phi^*, \\ \Delta\phi^* &= n^* - b, \end{aligned} \tag{3.9}$$

where

$$\Theta(n, S) = \frac{H(e)}{\partial^2 e/\partial S^2} \geq 0, \tag{3.10}$$

and S^* is given as a function of n^* through (3.5). In the following, we will regard Θ as a function of density only and write $\Theta(n, S(n)) = \Theta(n)$.

THEOREM 3.1 (a priori estimates). *Let b satisfy* (1.5) *and* (1.6). *If $(n^*, \phi^*) \in C^2$ is a solution of* (3.9), *with $n^* - b \in H^s$, $s > \frac{N}{2} + 1$, then the following estimates hold:*

$$\inf_{\boldsymbol{x}\in\mathbb{R}^N} b(\boldsymbol{x}) \le n^*(\boldsymbol{x}) \le \sup_{\boldsymbol{x}\in\mathbb{R}^N} b(\boldsymbol{x}), \tag{3.11}$$

$$\|n^* - b\|^2_{H^{s+1}} \le C_s(\Theta, b)\, \|Db\|^2_{H^s}\,, \tag{3.12}$$

$$\|Dn^*\|^2_{H^s} \le c_s(\Theta, b)\, \|Db\|^2_{H^s}\,, \tag{3.13}$$

where the constants C_s and c_s depend only on the function $\Theta(n)$, $n \in [b^-, b^+]$, and on the function b.

Proof. Since $n^* - b \in H^s$, we have

$$\lim_{|\boldsymbol{x}|\to\infty} [n^*(\boldsymbol{x}) - b(\boldsymbol{x})] = 0.$$

Then, for any arbitrary small constant $\delta \ge 0$ there exists $A \ge 0$ such that

$$b(\boldsymbol{x}) - \delta \le n^*(\boldsymbol{x}) \le b(\boldsymbol{x}) + \delta \qquad \text{for all } |\boldsymbol{x}| \ge A. \tag{3.14}$$

Suppose that inside the open ball of radius A there exists a point $\boldsymbol{x}_0$ at which the density reaches its minimum, that is,

$$n^*(\boldsymbol{x}_0) = \min_{|\boldsymbol{x}|<A} n^*(\boldsymbol{x}).$$

Then we have $Dn^*(\boldsymbol{x}_0) = 0$, and $D^2 n^*(\boldsymbol{x}_0)$ is a positive definite quadratic form. This, in particular, implies $\Delta n^*(\boldsymbol{x}_0) \ge 0$. Using (3.9), we can write a second order partial differential equation for n^*,

$$D \cdot (\Theta(n^*) Dn^*) = n^* - b. \tag{3.15}$$

It follows that $n^*(\boldsymbol{x}_0) - b(\boldsymbol{x}_0) = \Theta(n^*(\boldsymbol{x}_0))\Delta n^*(\boldsymbol{x}_0) \ge 0$, and thus

$$n^*(\boldsymbol{x}) \ge n^*(\boldsymbol{x}_0) \ge b^- \qquad \text{for all } |\boldsymbol{x}| < A. \tag{3.16}$$

Combining (3.14) and (3.16), we can conclude

$$n^*(\boldsymbol{x}) \ge b^- - \delta \qquad \text{for all } \boldsymbol{x} \in \mathbb{R}^N.$$

The arbitrariness of δ yields the first inequality in (3.11). The proof of the second inequality is perfectly analogous.

Next, we prove the inequalities (3.12) and (3.13). Since n^* satisfies (3.11), we can find two positive constants Θ^-, Θ^+ such that

$$\Theta^- \le \Theta(n^*(\boldsymbol{x})) \le \Theta^+ \qquad \text{for all } \boldsymbol{x} \in \mathbb{R}^N. \tag{3.17}$$

Moreover, using Moser's calculus and (3.11), for any $k > 0$ there exists a constant θ_{k-1}, depending on $|d\Theta/dn|_{C^{k-1}}$ and b^+, such that

$$\left\|D^k(\Theta^* Dn^*) - \Theta^* D^{k+1} n^*\right\| \le \theta_{k-1}\, \|Dn^*\|^2_{H^{k-1}}\,, \tag{3.18}$$

with $\Theta^* = \Theta(n^*)$.

We multiply (3.15) by n^*-b and integrate over the whole space. After integration by parts, we obtain

$$\begin{aligned}\|n^*-b\|^2 &= -\int \Theta^* D(n^*-b)\cdot Dn^* \\ &\le -\frac{1}{2}\int \Theta^* |D(n^*-b)|^2 + \frac{1}{2}\int \Theta^* |Db|^2 ,\end{aligned}$$

which implies

$$\|n^*-b\|^2 + \frac{1}{2}\Theta^- \|D(n^*-b)\|^2 \le \frac{1}{2}\Theta^+ \|Db\|^2 . \tag{3.19}$$

Using (3.19), we find

$$\|Dn^*\|^2 \le 2(\|D(n^*-b)\|^2 + \|Db\|^2) \le c_0 \|Db\|^2 , \tag{3.20}$$

with

$$c_0 = 2\left(1+\frac{c_0'}{\Theta^-}\right), \qquad c_0' = \Theta^+.$$

The proof of (3.12), (3.13) follows from the estimates

$$\left\|D^k(n^*-b)\right\|^2 + \frac{1}{2}\Theta^- \left\|D^{k+1}(n^*-b)\right\|^2 \le \frac{1}{2}c_k' \|Db\|_{H^k}^2 , \tag{3.21}$$

$$\|Dn^*\|_{H^k}^2 \le c_k \|Db\|_{H^k}^2 , \tag{3.22}$$

with

$$c_k' = \frac{1}{\Theta^-}\left(\Theta^{+2} + \theta_{k-1}^2 c_{k-1}^2 \|Db\|_{H^{k-1}}^2\right), \tag{3.23}$$

$$c_k = 2\left(1+\frac{1}{\Theta^-}\sum_{j=0}^{k} c_j'\right). \tag{3.24}$$

To prove these estimates, we proceed by induction. Assuming that (3.21), (3.22) hold for $k-1$, we apply the operator of derivation D^k to (3.15) and multiply scalarly times $D^k(n^*-b)$. Integrating by parts, we obtain

$$\begin{aligned}\left\|D^k(n^*-b)\right\|^2 &= -\int \Theta^* \left|D^{k+1}(n^*-b)\right|^2 \\ &\quad -\int D^{k+1}(n^*-b)\cdot\left[D^k(\Theta^* Dn^*) - \Theta^* D^{k+1}(n^*-b)\right].\end{aligned}$$

Using the Cauchy–Schwarz inequality, recalling (3.18), and applying the induction hypothesis, we have

$$\begin{aligned}&\left\|D^k(n^*-b)\right\|^2 \le -\Theta^- \left\|D^{k+1}(n^*-b)\right\|^2 \\ &\qquad + \left\|D^{k+1}(n^*-b)\right\|\left(\theta_{k-1}c_{k-1}\|Db\|_{H^{k-1}}^2 + \Theta^+\left\|D^{k+1}b\right\|\right) \\ &\le -\Theta^-\left\|D^{k+1}(n^*-b)\right\|^2 \\ &\qquad + \left\|D^{k+1}(n^*-b)\right\|\left(\Theta^{+2}+\theta_{k-1}^2c_{k-1}^2\|Db\|_{H^{k-1}}^2\right)^{\frac{1}{2}}\|Db\|_{H^k} \\ &\le -\frac{1}{2}\Theta^-\left\|D^{k+1}(n^*-b)\right\|^2 + \frac{1}{2\Theta^-}\left(\Theta^{+2}+\theta_{k-1}^2c_{k-1}^2\|Db\|_{H^{k-1}}^2\right)\|Db\|_{H^k}^2 ,\end{aligned}$$

which is equivalent to (3.21).

Finally, using (3.21), we have

$$\begin{aligned}
\|Dn^*\|^2_{H^k} &\le \|Dn^*\|^2_{H^{k-1}} + 2\left(\left\|D^{k+1}(n^*-b)\right\|^2 + \left\|D^{k+1}b\right\|^2\right)\\
&\le c_{k-1}\|Db\|^2_{H^{k-1}} + 2\left(\frac{c'_k}{\Theta^-}\|Db\|^2_{H^k} + \left\|D^{k+1}b\right\|^2\right)\\
&\le 2\left(1+\frac{1}{\Theta^-}\sum_{j=0}^{k-1}c'_j\right)\|Db\|^2_{H^{k-1}} + 2\left(\frac{c'_k}{\Theta^-}\|Db\|^2_{H^k} + \left\|D^{k+1}b\right\|^2\right)\\
&\le 2\left(1+\frac{1}{\Theta^-}\sum_{j=0}^{k}c'_j\right)\|Db\|^2_{H^k},
\end{aligned}$$

which concludes the proof of the lemma. ∎

THEOREM 3.2 (existence and uniqueness of the total equilibrium state). *Let b satisfy* (1.5) *and* (1.6). *Then there exists a unique solution $(n^*,\phi^*)\in C^2$ of* (3.9), *with $n^*-b\in H^s$, $s>\frac{N}{2}+1$.*

Proof. Using a fixed point argument, it is possible to prove the existence of a solution which satisfies the hypothesis of Theorem 3.1. Since the proof is standard, we omit the details. For the uniqueness, let us assume that both (n^*,ϕ^*) and $(n^\star,\phi^\star)$ satisfy (3.9) and n^*-b, $n^\star-b\in H^s$. Then, using Moser's calculus, $\pi(n^*)-\pi(n^\star)\in H^s$ for any smooth function $\pi(n)$. In particular, we consider a function π such that $d\pi/dn=\Theta$. It follows that for any $\delta\ge 0$ there exists $A\ge 0$ such that

$$-\delta \le \pi(n^*(\boldsymbol{x})) - \pi(n^\star(\boldsymbol{x})) \le \delta \qquad \text{for all } |\boldsymbol{x}|\ge A. \tag{3.25}$$

We prove by contradiction that the inequalities in (3.25) hold also for all $|\boldsymbol{x}|\le A$. In fact, let us assume that

$$\pi(n^*(\bar{\boldsymbol{x}})) - \pi(n^\star(\bar{\boldsymbol{x}})) \equiv \max_{|\boldsymbol{x}|\le A}\left[\pi(n^*(\boldsymbol{x})) - \pi(n^\star(\boldsymbol{x}))\right] > \delta. \tag{3.26}$$

Then we have

$$D\left[\pi(n^*(\bar{\boldsymbol{x}})) - \pi(n^\star(\bar{\boldsymbol{x}}))\right] = 0, \qquad \Delta\left[\pi(n^*(\bar{\boldsymbol{x}})) - \pi(n^\star(\bar{\boldsymbol{x}}))\right] \le 0.$$

Subtracting (3.9) for the two solutions, we find

$$D(\pi(n^*)-\pi(n^\star)) = D(\phi^*-\phi^\star), \qquad \Delta(\phi^*-\phi^\star) = n^*-n^\star,$$

which implies

$$n^*(\bar{\boldsymbol{x}}) - n^\star(\bar{\boldsymbol{x}}) = \Delta\left[\pi(n^*(\bar{\boldsymbol{x}})) - \pi(n^\star(\bar{\boldsymbol{x}}))\right] \le 0.$$

Since $d\pi/dn=\Theta\ge 0$, we end up with

$$\pi(n^*(\bar{\boldsymbol{x}})) - \pi(n^\star(\bar{\boldsymbol{x}})) \le 0, \tag{3.27}$$

which contradicts (3.26). Thus, the second inequality in (3.25) holds for all $\boldsymbol{x}$. In a similar way, we can prove that the first inequality in (3.25) is globally valid. In conclusion, we have proved that

$$|\pi(n^*)-\pi(n^\star)| \le \delta \qquad \text{for all } \delta\ge 0. \tag{3.28}$$

It follows that $\pi(n^*)=\pi(n^\star)$, and therefore $n^*=n^\star$. ∎

4. Global existence in time and asymptotic decay of the perturbation. In this section we state and prove the main theorem of the paper, Theorem 4.3, asserting the global existence in time of classical solutions of (1.1)–(1.4), which are perturbations of an equilibrium state, and the decay of these solutions to the unperturbed state. Also, we study the relaxation of the hydrodynamic solutions, that is, their asymptotic behavior as the relaxation time τ tends to zero, assuming that $\sigma\tau$ tends to $\beta > 0$.

First, we show that the hyperbolic–elliptic system (1.1)–(1.4), with the initial data (1.9), (1.10), is equivalent to a symmetric, hyperbolic system, with a nonlocal source term, for the hydrodynamic variables and the electric field $D\phi$.

From (1.1)–(1.4) and (1.7), we find the entropy balance equation,

$$\frac{\partial S}{\partial t} + \sum_{r=1}^{N} \partial_r (S u^r) = Q, \tag{4.1}$$

with

$$Q = \frac{1}{T}\left\{ \frac{n\,|\boldsymbol{u}|^2}{\tau} - \frac{1}{\sigma}\left[\frac{n\,|\boldsymbol{u}|^2}{2} + \left(\frac{\partial e}{\partial T}\right)_n (T - T^*) \right] \right\}.$$

Recalling (1.1), the condition (1.10) on the initial data and (1.12), it is possible to show that the constraint (1.4) can be replaced by the nonlocal evolutionary equation

$$\frac{\partial \boldsymbol{E}}{\partial t} + D\Delta^{-1} D \cdot (n\boldsymbol{u}) = 0. \tag{4.2}$$

As noted in [24], the symbol $\nabla\Delta^{-1}\nabla\cdot$ can be written as a sum of products of Riesz's transforms. Then, by the L^2 boundedness of the Riesz transform [42], for any function $\boldsymbol{w}$ in $(H^s)^N$, $s \geq 0$, we have

$$\left\| \nabla\Delta^{-1}\nabla \cdot \boldsymbol{w} \right\|_{H^s} \leq C_R \left\| \boldsymbol{w} \right\|_{H^s} \tag{4.3}$$

for some positive constant C_R. Equations (1.1), (1.2), (4.1), (4.2) constitute a quasilinear system of partial differential equations with a nonlocal source term. It can be written in the form

$$\frac{\partial U}{\partial t} + \sum_{j=1}^{N} A_j(U)\partial_j U = B(U, \boldsymbol{x}), \tag{4.4}$$

with $U = (n, \boldsymbol{u}, S, \boldsymbol{E})$ and

$$A_j(U) = \begin{pmatrix} u^j & n\boldsymbol{e}_j & 0 & 0 \\ \frac{1}{n}\frac{\partial p}{\partial n}\boldsymbol{e}^j & u^j I & \frac{1}{n}\frac{\partial p}{\partial S}\boldsymbol{e}^j & 0 \\ 0 & S\boldsymbol{e}_j & u^j & 0 \\ 0 & 0 & 0 & 0 \end{pmatrix},$$

$$B(U, \boldsymbol{x}) = \begin{pmatrix} 0 \\ \boldsymbol{E} - \frac{\boldsymbol{u}}{\tau} \\ Q \\ -D\Delta^{-1} D \cdot (n\boldsymbol{u}) \end{pmatrix}.$$

Here,

$$I = (\delta^{ij})_{1\leq i,j\leq N}, \qquad \boldsymbol{e}^j = (\delta^{ij})_{1\leq i\leq N}, \qquad \boldsymbol{e}_j = (\boldsymbol{e}^j)^T.$$

The differential part of system (4.4) is hyperbolic and symmetric in Friedrichs's sense: for any $U \in G \equiv \{U : n > 0\}$ there is a positive definite symmetric matrix $\tilde{A}_0(U)$ smoothly varying with U, and a positive constant c, so that, for all $U \in G$,

1. $cV \cdot V \le (\tilde{A}_0(U)V) \cdot V \le c^{-1}V \cdot V$ for all $V \in G$;
2. $\tilde{A}_j(U) = \tilde{A}_0(U)A_j(U)$ is symmetric.

Specifically, recalling (1.8), the symmetry condition is satisfied with

$$\tilde{A}_0(U) = \begin{pmatrix} \frac{\partial^2 e}{\partial n^2} & 0 & \frac{\partial^2 e}{\partial n \partial S} & 0 \\ 0 & nI & 0 & 0 \\ \frac{\partial^2 e}{\partial n \partial S} & 0 & \frac{\partial^2 e}{\partial S^2} & 0 \\ 0 & 0 & 0 & I \end{pmatrix}.$$

It is well known that a system which is hyperbolic and symmetric in Friedrichs's sense admits locally a unique classical solution in H^s, $s > N/2 + 1$, if the initial data belong to H^s (cf. [35]). Using (4.3), we can easily extend this result to prove the local existence of a solution to (4.4) which is a perturbation of an equilibrium state. We introduce the notation $\delta F(U) = F(U) - F(U^*)$ for any function $F(U)$, where $U^* = (n^*, 0, S^*, \boldsymbol{E}^*)$, with $\boldsymbol{E}^* = D\phi^*$, is the equilibrium state given by (3.9). We can consider the perturbations

$$\delta n = n - n^*, \qquad \delta \boldsymbol{u} = \boldsymbol{u}, \qquad \delta S = S - S^*, \qquad \delta \boldsymbol{E} = \boldsymbol{E} - \boldsymbol{E}^*.$$

We also use the obvious notation

$$U_0(\boldsymbol{x}) = U(\boldsymbol{x}, 0), \qquad \delta U_0(\boldsymbol{x}) = U_0(\boldsymbol{x}) - U^*(\boldsymbol{x}).$$

The perturbation δU satisfies the system

$$\frac{\partial \delta U}{\partial t} + \sum_{j=1}^{N} A_j(U)\partial_j \delta U = \delta B(U, \boldsymbol{x}) - \sum_{j=1}^{N} \delta A_j(U)\partial_j U^*. \tag{4.5}$$

In particular, from (1.4) and $(3.9)_2$, we derive immediately

$$D \cdot \delta \boldsymbol{E} = \delta n. \tag{4.6}$$

Since the differential structure of (4.5) and (4.4) is the same, we can state immediately the following theorem.

THEOREM 4.1 (local existence and uniqueness). *Let $\tau\sigma \neq 0$ and $\delta U_0 \in H^s$, with $s > \frac{N}{2} + 1$. Then there is a time $T > 0$ such that the equations* (4.5) *have a unique classical solution $\delta U(x,t) \in C^1(\mathbb{R}^N \times [0,T))$, with*

$$\delta U \in C^0([0,T], H^s) \cap C^1([0,T], H^{s-1}).$$

This local classical solution can be prolonged locally if the initial data is close enough to the equilibrium solution. The prolongation of a local solution given by Theorem 4.1 resides entirely on the following lemma, whose proof will be given later in subsequent sections.

LEMMA 4.2. *Assuming $0 < \tau < \sigma$ and $Dn^* \in H^s(\mathbb{R}^N)$, let $\delta U = (\delta n, \delta \boldsymbol{u}, \delta S, \delta \boldsymbol{E})$ be the solution of* (4.5) *given by Theorem* 4.1*, and let $\delta \hat{U} = (\delta n, \delta S, \delta \boldsymbol{E})$. There exist positive constants C^*, ϵ, c, and K such that if*

$$\tau\sigma \left\| Dn^* \right\|^2 \le C^*$$

and

$$\frac{1}{\tau^2}\left\|\boldsymbol{u}(\cdot,t)\right\|_{H^s}^2+\left\|\delta\hat{U}(\cdot,t)\right\|_{H^s}^2\leq\epsilon^2\quad\textit{for all } t\in[0,T],$$

then the following a priori estimates hold:

$$\left\|\boldsymbol{u}(\cdot,t)\right\|_{H^s}^2\leq Ke^{-\frac{ct}{\tau}}\left\|\delta U(\cdot,0)\right\|_{H^s}^2\quad\textit{for all } t\in[0,T], \tag{4.7}$$

$$\left\|\delta\hat{U}(\cdot,t)\right\|_{H^s}^2\leq Ke^{-c\tau t}\left\|\delta U(\cdot,0)\right\|_{H^s}^2\quad\textit{for all } t\in[0,T]. \tag{4.8}$$

The constants C^*, ϵ, c, and K depend only on the equation of state $e=e(n,S)$, on the equilibrium density n^*, and on the product of the relaxation times, $\sigma\tau$.

In Lemma 4.2, we keep explicit track of the relaxation time τ, since we are going to study the limit $\tau\to 0$ at the end of this section. If τ is a given constant, the statement of the lemma simplifies. In particular, if we assume $0<\tau\leq 1$, we have

$$e^{-\frac{ct}{\tau}}\leq e^{-c\tau t}, \tag{4.9}$$

and the two estimates (4.7), (4.8) can be comprised into a single estimate.

Now, we are ready to state the global existence theorem announced at the beginning of this section.

THEOREM 4.3 (global existence and asymptotic decay). *Under the same hypothesis as that of Lemma* 4.2, *if $\tau\leq 1$ and $\delta U_0\in H^s$, there exists positive constants C^* and ϵ such that if*

$$\tau\sigma\left\|Dn^*\right\|^2\leq C^*$$

and

$$\frac{1}{\tau^2}\left\|\boldsymbol{u}_0\right\|_{H^s}^2+\left\|\delta\hat{U}_0\right\|_{H^s}^2<\epsilon'^2, \tag{4.10}$$

then the equations (4.5) *have the unique classical solution $\delta U(x,t)\in C^1(\mathbb{R}\times[0,\infty))$. Furthermore,*

$$\delta U\in C^0([0,\infty),H^s)\cap C^1([0,\infty),H^{s-1})$$

and

$$\left\|\delta U(\cdot,t)\right\|_{H^s}^2\leq Ke^{-c\tau t}\left\|\delta U(\cdot,0)\right\|_{H^s}^2, \tag{4.11}$$

where c and K are positive constants given by Lemma 4.2.

Proof. Theorem 4.1 yields immediately the local H^s existence of the unique classical solution to the initial value problem for (4.4). We introduce the constant $\epsilon_1=\epsilon/\sqrt{2K}<\epsilon$, where ϵ is given by Lemma 4.2, and assume that the inequality (4.10) is satisfied with $\epsilon'=\epsilon_1$. By continuity, we can determine a time $T_1>0$ such that

$$\frac{1}{\tau^2}\left\|\boldsymbol{u}(\cdot,t)\right\|_{H^s}^2+\left\|\delta\hat{U}(\cdot,t)\right\|_{H^s}^2\leq\epsilon_1^2\quad\text{for all } t\in[0,T_1]. \tag{4.12}$$

The inequality (4.12) is still satisfied if we choose $\epsilon'=\min\{\epsilon_1,\epsilon_1 cT_1/2\}$ in (4.10). We will prove that this choice of ϵ' is sufficient to ensure

$$\frac{1}{\tau^2}\left\|\boldsymbol{u}(\cdot,t)\right\|_{H^s}^2+\left\|\delta\hat{U}(\cdot,t)\right\|_{H^s}^2<\epsilon^2\quad\text{for all } t\geq 0. \tag{4.13}$$

We proceed by contradiction and assume that there exists $\bar{T} > T_1$ such that (4.13) is satisfied for all $0 \le t < \bar{T}$, and

$$\frac{1}{\tau^2}\left\|\boldsymbol{u}(\cdot,\bar{T})\right\|_{H^s}^2 + \left\|\delta\hat{U}(\cdot,\bar{T})\right\|_{H^s}^2 = \epsilon^2. \tag{4.14}$$

Using Lemma 4.2, we get

$$\frac{1}{\tau^2}\left\|\boldsymbol{u}(\cdot,\bar{T})\right\|_{H^s}^2 \le K\epsilon'^2 \sup_{0<\tau\le 1}\left\{\tau^{-2}e^{-\frac{cT_1}{\tau}}\right\} = \begin{cases} K\epsilon'^2 e^{-cT_1} & \text{if} \quad \dfrac{cT_1}{2} \ge 1, \\ K\epsilon'^2\left(\dfrac{2}{ecT_1}\right)^2 & \text{if} \quad \dfrac{cT_1}{2} < 1. \end{cases}$$

If $cT_1/2 \ge 1$, we have $\epsilon' = \epsilon_1$ and conclude that

$$\frac{1}{\tau^2}\left\|\boldsymbol{u}(\cdot,\bar{T})\right\|_{H^s}^2 \le K\epsilon_1^2 e^{-cT_1} \le \frac{\epsilon^2}{2e^2} < \frac{\epsilon^2}{2}.$$

If $cT_1/2 < 1$, we have $\epsilon' = \epsilon_1 cT_1/2$, and we find

$$\frac{1}{\tau^2}\left\|\boldsymbol{u}(\cdot,\bar{T})\right\|_{H^s}^2 \le K\left(\frac{\epsilon_1 cT_1}{2}\right)^2\left(\frac{2}{ecT_1}\right)^2 = \frac{\epsilon^2}{2e^2} < \frac{\epsilon^2}{2}.$$

Using Lemma 4.2, it is simple to see that

$$\left\|\delta\hat{U}(\cdot,\bar{T})\right\|_{H^s}^2 \le K\epsilon'^2 \sup_{0<\tau\le 1}\left\{e^{-\tau cT_1}\right\} = K\epsilon'^2 < \frac{\epsilon^2}{2}.$$

It follows that

$$\frac{1}{\tau^2}\left\|\boldsymbol{u}(\cdot,\bar{T})\right\|_{H^s}^2 + \left\|\delta\hat{U}(\cdot,\bar{T})\right\|_{H^s}^2 < \epsilon^2, \tag{4.15}$$

which contradicts (4.14). Therefore, (4.13) holds true. Using Lemma 4.2, the local solution can be prolonged for all times and the estimates (4.7) and (4.8) hold globally. The final estimate (4.11) is obtained by adding (4.7) and (4.8) and recalling (4.9). ∎

We remark that the constants in the estimate (4.11) are independent on τ. We can use this fact to study the behavior of the solution as τ tends to zero, assuming that $\tau\sigma$ tends to a certain positive constant β. We define the rescaled variables

$$U'(\boldsymbol{x},t') \equiv (n',\boldsymbol{u}',S',E')(\boldsymbol{x},t') = \left(n,\frac{1}{\tau}\boldsymbol{u},S,E\right)\left(\boldsymbol{x},\frac{1}{\tau}t'\right)$$

and the initial data

$$U'(\boldsymbol{x},0) = U_0'(\boldsymbol{x}) \equiv (n_0,\boldsymbol{u}_0',S_0,E_0)(\boldsymbol{x}).$$

In other words, we are assuming that $\boldsymbol{u}(\boldsymbol{x},0) = \tau\boldsymbol{u}_0'(\boldsymbol{x})$. The rescaled variables satisfy the system

$$A^\tau\frac{\partial U'}{\partial t'} + \sum_{j=1}^N A_j'(U')\partial_j U' = B'(U',\boldsymbol{x}), \tag{4.16}$$

with $A^\tau = \mathrm{diag}(1, \tau^2 I, 1, I)$ and

$$A'_j(U') = \begin{pmatrix} u'^j & n'\boldsymbol{e}_j & 0 & 0 \\ \frac{1}{n'}\frac{\partial p'}{\partial n'}\boldsymbol{e}^j & \tau^2 u'^j I & \frac{1}{n'}\frac{\partial p'}{\partial S'}\boldsymbol{e}^j & 0 \\ 0 & S'\boldsymbol{e}_j & u'^j & 0 \\ 0 & 0 & 0 & 0 \end{pmatrix},$$

$$B'(U', \boldsymbol{x}) = \begin{pmatrix} 0 \\ \boldsymbol{E}' - \boldsymbol{u}' \\ \frac{n'}{T'}\left\{\left(1 - \frac{\tau}{2\sigma}\right)|\boldsymbol{u}'|^2 - \frac{1}{2\tau\sigma}\left(\frac{\partial e'}{\partial T'}\right)_{n'}(T' - T^*)\right\} \\ -D\Delta^{-1}D \cdot (n'\boldsymbol{u}') \end{pmatrix}.$$

In terms of the rescaled variables, the estimate (4.11) becomes

$$\tau^2 \left\|\boldsymbol{u}'(\cdot, t')\right\|^2_{H^s} + \left\|\delta\hat{U}'(\cdot, t')\right\|^2_{H^s} \leq Ke^{-ct'}\left(\tau^2 \left\|\boldsymbol{u}'(\cdot, 0)\right\|^2_{H^s} + \left\|\delta\hat{U}'(\cdot, 0)\right\|^2_{H^s}\right). \tag{4.17}$$

Since $\sigma\tau$ is strictly positive and bounded, this estimate is uniformly valid as τ tends to zero, and the limit function is a solution of (4.16) with $\tau = 0$ and $\sigma\tau = \beta$. Then it is immediate to derive the following singular limit result.

THEOREM 4.4 (relaxation). *Let as assume that $\tau\sigma$ tends to $\beta > 0$ as τ tends to 0. For any fixed $\tau > 0$, let $U = (n^\tau, \boldsymbol{u}^\tau, S^\tau, \boldsymbol{E}^\tau)(\boldsymbol{x}, t)$ be a global solution of (4.4), satisfying (4.7), and let $\hat{U}^\tau = (n^\tau, S^\tau, \boldsymbol{E}^\tau)(\boldsymbol{x}, t)$. Then there exists some function $\hat{U}^0 = (n^0, S^0, \boldsymbol{E}^0)$ which is a smooth solution of (4.16), with $\tau = 0$, and such that, as τ tends to zero,*

$$(\hat{U}^\tau - \hat{U}^*)\left(\boldsymbol{x}, \frac{1}{\tau}t'\right) \to (\hat{U}^0 - \hat{U}^*)(\boldsymbol{x}, t') \quad \text{in } C([0, \infty); H^s).$$

Furthermore,

$$\left\|(\hat{U}^0 - \hat{U}^*)(\cdot, t')\right\|^2_{H^s} \leq K'e^{-c't'}\left\|(\hat{U}^0 - \hat{U}^*)(\cdot, 0)\right\|^2_{H^s}, \tag{4.18}$$

where c' and K' are positive constants.

5. Positive definiteness of some functionals of Liapunov type. This section deals with the positive definiteness of some functionals of Liapunov type which will be used in the subsequent section. The main results are summarized in Lemma 5.3.

We fix an integer $s > N/2 + 1$ and introduce the energy densities

$$\mathcal{H}_0 = \frac{n}{2}|\boldsymbol{u}|^2 - \frac{\lambda_0 n}{\sigma n^*}\boldsymbol{u} \cdot \delta\boldsymbol{E} + \frac{1}{2}|\delta\boldsymbol{E}|^2 + e - e^* - \left(\frac{\partial e}{\partial n}\right)^* \delta n - \left(\frac{\partial e}{\partial S}\right)^* \delta S, \tag{5.1}$$

$$\mathcal{H}_i = \frac{n}{2}\left|D^i\boldsymbol{u}\right|^2 - \frac{\lambda_i n}{\sigma n^*}D^i\boldsymbol{u} \cdot D^i\delta\boldsymbol{E} + \frac{1}{2}\left|D^i\delta\boldsymbol{E}\right|^2 + \frac{1}{2}\frac{\partial^2 e}{\partial n^2}\left|D^i\delta n\right|^2 + \frac{\partial^2 e}{\partial n \partial S}D^i\delta n \cdot D^i\delta S + \frac{1}{2}\frac{\partial^2 e}{\partial S^2}\left|D^i\delta S\right|^2, \quad 1 \leq i \leq s. \tag{5.2}$$

Here, λ_0 and λ_i are positive constants. With an appropriate choice of these constants, $\mathcal{H}_0$ and $\mathcal{H}_i$ are positive semidefinite, as asserted by the following lemma.

LEMMA 5.1. *If $0 < \tau < \sigma$, $\sigma\tau \geq \beta > 0$, $\lambda_i < \min\{1/2, \beta \inf n^*\}$, and $|\delta n| < \inf |n^*|$, then there exist positive constants $k_{\mathcal{H}}$, $K_{\mathcal{H}}$ (depending only on β, λ_i, $e(n,S)$ and n^*) such that $\mathcal{H}_i$ satisfies*

$$k_{\mathcal{H}} \left|D^i \delta U\right|^2 \leq \mathcal{H}_i \leq K_{\mathcal{H}} \left|D^i \delta U\right|^2.$$

Proof. We can decompose the energy densities as

$$\mathcal{H}_i = g_i(D^i\delta n, D^i \delta S) + h_i(D^i \boldsymbol{u}, D^i \delta \boldsymbol{E}), \quad i \geq 0, \tag{5.3}$$

where, for any $X^i, Y^i \in \mathbb{R}^{N^i} \times \mathbb{R}^{N^i}$ and $\boldsymbol{X}^i, \boldsymbol{Y}^i \in (\mathbb{R}^{N^i})^N \times (\mathbb{R}^{N^i})^N$, the quadratic forms g_i and h_i are defined by

$$g_i(X^i, Y^i) = \begin{cases} e(n^* + X^i, S^* + Y^i) - e^* - \left(\dfrac{\partial e}{\partial n}\right)^* X^i - \left(\dfrac{\partial e}{\partial S}\right)^* Y^i, & i = 0, \\ \dfrac{1}{2}\dfrac{\partial^2 e}{\partial n^2}\left|X^i\right|^2 + \dfrac{\partial^2 e}{\partial n \partial S} X^i \cdot Y^i + \dfrac{1}{2}\dfrac{\partial^2 e}{\partial S^2}\left|Y^i\right|^2, & i > 0, \end{cases}$$

$$h_i(\boldsymbol{X}^i, \boldsymbol{Y}^i) = \frac{n}{2}\left|\boldsymbol{X}^i\right|^2 - \frac{\lambda_i n}{\sigma n^*} \boldsymbol{X}^i \cdot \boldsymbol{Y}^i + \frac{1}{2}\left|\boldsymbol{Y}^i\right|^2, \quad i \geq 0.$$

The positive definiteness of g_i follows from the convexity of the internal energy with respect to n and S. We consider the following inequality:

$$\tau \left|\boldsymbol{X}^i \cdot \boldsymbol{Y}^i\right| \leq n^* \tau^2 \left|\boldsymbol{X}^i\right|^2 + \frac{1}{4n^*}\left|\boldsymbol{Y}^i\right|^2.$$

Then it is possible to derive

$$\begin{aligned} h_i(\boldsymbol{X}^i, \boldsymbol{Y}^i) &\geq \frac{n}{2}\left(1 - \frac{2\lambda_i \tau}{\sigma}\right)\left|\boldsymbol{X}^i\right|^2 + \frac{1}{2}\left(1 - \frac{\lambda_i}{\sigma\tau n^*} + \left(1 - \frac{\delta n}{n^*}\right)\frac{\lambda_i}{2\sigma\tau n^*}\right)\left|\boldsymbol{Y}^i\right|^2 \\ &\geq \frac{n}{2}\left(1 - 2\lambda_i\right)\left|\boldsymbol{X}^i\right|^2 + \frac{1}{2}\left(1 - \frac{\lambda_i}{\sigma\tau n^*}\right)\left|\boldsymbol{Y}^i\right|^2. \end{aligned}$$

Here, we have used $\tau < \sigma$, $|\delta n| < \inf n^*$. Recalling that $\sigma\tau \geq \beta$ and $\lambda_i < \min\{1/2, \beta \inf n^*\}$, the thesis of the lemma follows immediately. ∎

Now, we introduce the functionals

$$\begin{aligned} \mathcal{D}_0 = \frac{n^*}{2\tau}(1 - 2\bar{C}_R\lambda_0)\left|\boldsymbol{u}\right|^2 + \frac{1}{\sigma}\Bigg\{ &\frac{\lambda_0}{2}|\delta \boldsymbol{E}|^2 + \frac{\lambda_0}{(n^*)^2}\left(\frac{\partial p}{\partial S}\right)^* [\delta n D S^* \\ &- \delta S D n^*] \cdot \delta \boldsymbol{E} + \left[\left(\frac{\partial S}{\partial T}\right)_n \left(\frac{\partial T}{\partial n}\right)^2 + \frac{\lambda_0}{n}\frac{\partial p}{\partial n}\right]^* \delta n^2 \\ &+ \left(2\frac{\partial T}{\partial n} + \frac{\lambda_0}{n}\frac{\partial p}{\partial S}\right)^* \delta n \delta S + \left(\frac{\partial T}{\partial S}\right)^* \delta S^2 \Bigg\}, \end{aligned} \tag{5.4}$$

$$\begin{aligned} \mathcal{D}_i = \frac{n^*}{2\tau}(1 - 2\bar{C}\lambda_i)\left|D^i \boldsymbol{u}\right|^2 + \frac{1}{\sigma}\Bigg\{ &\frac{\lambda_i}{2}\left|D^i \delta \boldsymbol{E}\right|^2 \\ &+ \left[\left(\frac{\partial S}{\partial T}\right)_n \left(\frac{\partial T}{\partial n}\right)^2 + \frac{\lambda_0}{n}\frac{\partial p}{\partial n}\right]^* \left|D^i \delta n\right|^2 \\ &+ \left(2\frac{\partial T}{\partial n} + \frac{\lambda_i}{n}\frac{\partial p}{\partial S}\right)^* D^i \delta n \cdot D^i \delta S + \left(\frac{\partial T}{\partial S}\right)^* \left|D^i \delta S\right|^2 \Bigg\}, \quad i \geq 1, \end{aligned} \tag{5.5}$$

with $\bar{C} = \sup n^* / \inf n^*$, $\bar{C}_R = \bar{C} C_R$. The constant C_R is defined by (4.3), and we have $\bar{C}_R \geq \bar{C} \geq 1$. We prove that the quadratic forms $\mathcal{D}_0$ and $\mathcal{D}_i$ are positive definite with an appropriate choice of λ_0 and λ_i.

LEMMA 5.2. *Let $0 < \tau < \sigma$, $\lambda_i < 1/2\bar{C}_R$, and*

$$0 < \lambda_0 < \inf \left\{ \frac{H(e)}{\left(\frac{1}{2n}\frac{\partial p}{\partial S}\right)^2 \left(1 + 2\Theta \frac{|Dn|^2}{n^2}\right)} \right\}^*, \qquad 0 < \lambda_i < \inf \left\{ \frac{H(e)}{\left(\frac{1}{2n}\frac{\partial p}{\partial S}\right)^2} \right\}^*,$$

where $H(e)$ and Θ are defined by (3.8) *and* (3.10)*, respectively. Then there exist positive constants $k_{\mathcal{D}}$, $K_{\mathcal{D}}$ (depending only on λ_i, $e(n,S)$, and n^*) such that $\mathcal{D}_i$ ($i \geq 0$) satisfies*

$$k_{\mathcal{D}} \left(\frac{1}{\tau} \left| D^i \boldsymbol{u} \right|^2 + \frac{1}{\sigma} \left| D^i \delta \hat{U} \right|^2 \right) \leq \mathcal{D}_i \leq K_{\mathcal{D}} \left(\frac{1}{\tau} \left| D^i \boldsymbol{u} \right|^2 + \frac{1}{\sigma} \left| D^i \delta \hat{U} \right|^2 \right). \tag{5.6}$$

Proof. We can decompose the quadratic form $\mathcal{D}_0$ as

$$\mathcal{D}_0(\boldsymbol{u}, \delta \boldsymbol{E}, \delta n, \delta S) = \frac{n^*}{2\tau}(1 - 2\bar{C}_R \lambda_0) + \frac{1}{\sigma} \tilde{\mathcal{D}}(\delta \hat{U}).$$

The coefficient of $|\boldsymbol{u}|^2$ is positive, since $\lambda_0 < 1/2\bar{C}_R$. The matrix associated to the quadratic form $\tilde{\mathcal{D}}$ with respect to $\delta \hat{U}$ is

$$A = \begin{pmatrix} \frac{\lambda_0}{2} I & \frac{\lambda_0}{2n^2}\frac{\partial p}{\partial S} DS & -\frac{\lambda_0}{2n^2}\frac{\partial p}{\partial S} Dn \\ \frac{\lambda_0}{2n^2}\frac{\partial p}{\partial S}(DS)^T & \left(\frac{\partial S}{\partial T}\right)_n \left(\frac{\partial T}{\partial n}\right)^2 + \frac{\lambda_0}{n}\frac{\partial p}{\partial n} & \frac{\partial T}{\partial n} + \frac{\lambda_0}{2n}\frac{\partial p}{\partial S} \\ -\frac{\lambda_0}{2n^2}\frac{\partial p}{\partial S}(Dn)^T & \frac{\partial T}{\partial n} + \frac{\lambda_0}{2n}\frac{\partial p}{\partial S} & \frac{\partial T}{\partial S} \end{pmatrix}^*.$$

The matrix A is positive definite if its determinant is positive together with the determinants of the following minors:

$$\left(\frac{\partial T}{\partial S} \right)^*, \qquad \begin{pmatrix} \left(\frac{\partial S}{\partial T}\right)_n \left(\frac{\partial T}{\partial n}\right)^2 + \frac{\lambda_0}{n}\frac{\partial p}{\partial n} & \frac{\partial T}{\partial n} + \frac{\lambda_0}{2n}\frac{\partial p}{\partial S} \\ \frac{\partial T}{\partial n} + \frac{\lambda_0}{2n}\frac{\partial p}{\partial S} & \frac{\partial T}{\partial S} \end{pmatrix}^*.$$

Explicitly, these conditions amount to

$$\left(\frac{\partial T}{\partial S}\right)^* > 0,$$

$$\lambda_0 \left(H(e) - \lambda_0 \left(\frac{1}{2n}\frac{\partial p}{\partial S} \right)^2 \right)^* > 0,$$

$$\frac{\lambda_0^2}{2} \left(H(e) - \lambda_0 \left(\frac{1}{2n}\frac{\partial p}{\partial S} \right)^2 \left(1 + \frac{2Dn \cdot Dp}{n^3} \right) \right)^* > 0.$$

Recalling (3.4) and (3.9), we see that

$$\left(1 + \frac{2Dn \cdot Dp}{n^3} \right)^* = \left(1 + \frac{2Dn \cdot D\phi}{n^2} \right)^* = \left(1 + 2\Theta \frac{|Dn|^2}{n^2} \right)^* \geq 1.$$

Then the previous inequalities are satisfied altogether if

$$0 < \lambda_0 < \inf \left\{ \frac{H(e)}{\left(\frac{1}{2n}\frac{\partial p}{\partial S}\right)^2 \left(1 + 2\Theta \frac{|Dn|^2}{n^2}\right)} \right\}^*,$$

which holds by hypothesis. We can conclude that $\mathcal{D}_0$ is positive definite. Then we can determine appropriate constants $k_{\mathcal{D}}$, $K_{\mathcal{D}}$, independent on τ and σ, such that (5.6) holds for $i = 0$. In the same way, after replacing λ_0 with λ_i and putting $Dn^* = 0$ in the matrix A, it is possible to prove the positive definiteness of $\mathcal{D}_i$, $i \geq 1$. ∎

The following lemma is a useful combination of Lemmas 5.1 and 5.2.

LEMMA 5.3. *If* $0 < \tau < \sigma$, $\sigma\tau \geq \beta > 0$, $|\delta n| < \inf |n^*|$, *and*

$$\lambda_i < \min\left\{ \frac{1}{2\bar{C}_R}, \beta \inf n^* \right\}, \quad \lambda_i < \inf \left\{ \frac{H(e)}{\left(\frac{1}{2n}\frac{\partial p}{\partial S}\right)^2 \left(1 + 2\Theta \frac{|Dn|^2}{n^2}\right)} \right\}^*, \quad i \geq 0, \tag{5.7}$$

then there exist some positive constants $k_{\mathcal{H}}$, $K_{\mathcal{H}}$, $k_{\mathcal{D}}$, $K_{\mathcal{D}}$ *(depending only on* λ_i, $e(n, S)$, n^*, *and* β*) such that the functions* $\mathcal{H}_i$ *and* $\mathcal{D}_i$ *(*$i \geq 0$*) satisfy*

$$k_{\mathcal{H}} \left\| D^i \delta U \right\|^2 \leq \int \mathcal{H}_i \, d\boldsymbol{x} \leq K_{\mathcal{H}} \left\| D^i \delta U \right\|^2, \tag{5.8}$$

$$\begin{aligned} k_{\mathcal{D}} \left(\frac{1}{\tau} \left\| D^i \boldsymbol{u} \right\|^2 + \frac{1}{\sigma} \left\| D^i \delta \hat{U} \right\|^2 \right) \\ \leq \int \mathcal{D}_i \, d\boldsymbol{x} \leq K_{\mathcal{D}} \left(\frac{1}{\tau} \left\| D^i \boldsymbol{u} \right\|^2 + \frac{1}{\sigma} \left\| D^i \delta \hat{U} \right\|^2 \right). \end{aligned} \tag{5.9}$$

6. A priori estimates. This section is entirely devoted to the proof of Lemma 4.2. For some fixed positive number T, we assume that a solution δU of (4.5) exists and $\delta U(\boldsymbol{x}, t) \in H^s(\mathbb{R}^N)$ for an integer $s > N/2 + 1$ for all $t \in (0, T)$. We introduce the vector

$$\delta U_\tau = \left(\delta n, \frac{1}{\tau} \boldsymbol{u}, \delta S, \delta \boldsymbol{E} \right) \tag{6.1}$$

and define

$$\mathcal{U}(T) = \sup_{0 \leq t \leq T} \left\| \delta U_\tau(\cdot, t) \right\|_{H^s}. \tag{6.2}$$

Using the standard Sobolev inequalities, there exists a positive constant $C_{\mathcal{U}}$ such that

$$\sup_{0 \leq t \leq T} \left\| \delta U_\tau(\cdot, t) \right\|_{C^r} \leq C_{\mathcal{U}} \mathcal{U}(T), \qquad r < s - \frac{N}{2}. \tag{6.3}$$

For any function $f \in H^s$, we introduce the norm

$$\|f\|_{\eta,s}^2 = \sum_{i=0}^{s} \eta_i \|f\|_{H^s}^2,$$

where $\eta_0 = 1$, and η_i, $i = 1, 2, \ldots, s$, are positive constants to be determined. Also, we introduce the energy

$$\mathcal{W} = \int \left(\sum_{i=0}^{s} \eta_i \mathcal{H}_i \right) d\boldsymbol{x}, \tag{6.4}$$

where the energy densities $\mathcal{H}_i$ are defined by (5.1), (5.2), and the constants λ_i, $i \geq 0$, are chosen according to the condition (5.7). Then, using Lemma 5.3, it is immediate to see that $\mathcal{W}$ is equivalent to the H^s-norm of δU. Lemma 4.2 follows from the subsequent energy estimate.

LEMMA 6.1. *If $0 < \tau < \sigma$ and $Dn^* \in H^s(\mathbb{R}^N)$, there exist positive constants C^* (depending only on the function $e(n,S)$ and on $b^{\pm}$), ϵ, η_i, $i = 1, 2, \dots, s$, such that if*

$$\sigma\tau \left\| Dn^* \right\|^2 \leq C^* \tag{6.5}$$

and the solution is so small that $\mathcal{U}(T) \leq \epsilon$, then the following a priori estimate holds for $t \in [0,T]$:

$$\left\| \boldsymbol{u}(\cdot,t) \right\|_{\eta,s} \leq \frac{\mathcal{W}(0)}{k_{\mathcal{H}}} e^{-\frac{ct}{\tau}}, \qquad \left\| \delta\hat{U}(\cdot,t) \right\|_{\eta,s} \leq \frac{\mathcal{W}(0)}{k_{\mathcal{H}}} e^{-c\tau t}, \tag{6.6}$$

where the constant c depends only on the equation of state, on the equilibrium state, and on the product $\tau\sigma$, and $k_{\mathcal{H}}$ is given by (5.8).

Proof. To begin with, we consider the function $\mathcal{H}_0$ defined by (5.1). Deriving with respect to t, using (1.1)–(1.3), (4.1), and (4.2), and integrating on the whole space, we obtain

$$\begin{aligned}
\frac{d}{dt}\int \mathcal{H}_0 \, d\boldsymbol{x} &= \int \left\{ \frac{\partial}{\partial t}\left(\frac{n}{2}|\boldsymbol{u}|^2 + e \right) - \left(\frac{\partial e}{\partial n} \right)^* \frac{\partial n}{\partial t} - \left(\frac{\partial e}{\partial S} \right)^* \frac{\partial S}{\partial t} \right. \\
&\quad \left. + \delta\boldsymbol{E} \cdot \frac{\partial \delta\boldsymbol{E}}{\partial t} - \frac{\lambda_0}{\sigma n^*} \left[n\boldsymbol{u} \cdot \frac{\partial \delta\boldsymbol{E}}{\partial t} + \frac{\partial}{\partial t}(n\boldsymbol{u}) \cdot \delta\boldsymbol{E} \right] \right\} d\boldsymbol{x} \\
&= \int \left\{ n\boldsymbol{u} \cdot \boldsymbol{E} + TQ - \frac{1}{\tau} n \left| \boldsymbol{u} \right|^2 + \phi^* D \cdot (n\boldsymbol{u}) \right. \\
&\quad - T^*Q - \delta\boldsymbol{E} \cdot D\Delta^{-1} D \cdot (n\boldsymbol{u}) + \frac{\lambda_0}{\sigma n^*} n\boldsymbol{u} \cdot D\Delta^{-1} D \cdot (n\boldsymbol{u}) \\
&\quad \left. + \frac{\lambda_0}{\sigma n^*} \left[D \cdot (n\boldsymbol{u} \otimes \boldsymbol{u}) + D\,(p - p^*) - n\delta\boldsymbol{E} - \delta n \boldsymbol{E}^* + \frac{n\boldsymbol{u}}{\tau} \right] \cdot \delta\boldsymbol{E} \right\} d\boldsymbol{x}.
\end{aligned} \tag{6.7}$$

Integrating by parts and observing that $\delta\boldsymbol{E}$ is a gradient, it is immediate to see that

$$\int \left\{ n\boldsymbol{u} \cdot \boldsymbol{E} + \phi^* D \cdot (n\boldsymbol{u}) - \delta\boldsymbol{E} \cdot D\Delta^{-1} D \cdot (n\boldsymbol{u}) \right\} d\boldsymbol{x} = 0.$$

Moreover, using the estimate (4.3), we get

$$\int \left\{ \frac{\lambda_0}{\sigma n^*} n\boldsymbol{u} \cdot D\Delta^{-1} D \cdot (n\boldsymbol{u}) \right\} d\boldsymbol{x} \leq \frac{\lambda_0 C_R}{\sigma \inf n^*} \left\| n\boldsymbol{u} \right\|^2.$$

Also, by Schwarz's inequality, and recalling the first condition in (5.7), we have

$$\begin{aligned}
&\int \frac{\lambda_0 n}{\sigma n^*} \left(-\delta\boldsymbol{E} + \frac{\boldsymbol{u}}{\tau} \right) \cdot \delta\boldsymbol{E} \, d\boldsymbol{x} \\
&\leq \int \left\{ \frac{n}{2\tau} \left| \boldsymbol{u} \right|^2 - \frac{\lambda_0 n}{2\sigma n^*} \left(2 - \frac{\lambda_0}{\sigma\tau n^*} \right) \left| \delta\boldsymbol{E} \right|^2 \right\} d\boldsymbol{x} \\
&\leq \int \left\{ \frac{n}{2\tau} \left| \boldsymbol{u} \right|^2 - \frac{\lambda_0 n}{2\sigma n^*} \left| \delta\boldsymbol{E} \right|^2 \right\} d\boldsymbol{x}.
\end{aligned} \tag{6.8}$$

Using these results in (6.7), we find

$$\frac{d}{dt}\int \mathcal{H}_0\,d\boldsymbol{x} \le -\int\left\{\frac{n}{2\tau}\left(1-\lambda_0\frac{2\tau C_R n}{\sigma\inf n^*}\right)|\boldsymbol{u}|^2 - Q\delta T + \frac{\lambda_0 n}{2\sigma n^*}|\delta\boldsymbol{E}|^2\right\}d\boldsymbol{x} + \int\left\{\frac{\lambda_0}{\sigma n^*}\delta\boldsymbol{E}\cdot\left[D\cdot(n\boldsymbol{u}\otimes\boldsymbol{u}) + D\,(p-p^*) - \delta n\boldsymbol{E}^*\right]\right\}d\boldsymbol{x} \equiv I_{01}+I_{02}, \tag{6.9}$$

where

$$Q\delta T = \left(1-\frac{\tau}{2\sigma}\right)\frac{n}{T}\delta T\frac{|\boldsymbol{u}|^2}{\tau} - \frac{1}{\sigma T}\left(\frac{\partial e}{\partial T}\right)_n(\delta T)^2.$$

Taylor expanding $T(n,S)$ and $e(n,S)$ around (n^*,S^*), and recalling that $\tau<\sigma$, we can estimate

$$I_{01} \le C\mathcal{U}\left(\frac{1}{\tau}\|\boldsymbol{u}\|^2 + \frac{1}{\sigma}\left\|\delta\hat{U}\right\|^2\right) - \int\left\{\frac{n^*}{2\tau}(1-2\bar{C}_R\lambda_0)|\boldsymbol{u}|^2 + \frac{1}{\sigma T^*}\left(\frac{\partial e}{\partial T}\right)_n^*\left[\left(\frac{\partial T}{\partial n}\right)^*\delta n + \left(\frac{\partial T}{\partial S}\right)^*\delta S\right]^2 + \frac{\lambda_0}{2\sigma}|\delta\boldsymbol{E}|^2\right\}d\boldsymbol{x}, \tag{6.10}$$

where $\bar{C}_R = C_R\sup n^*/\inf n^* \ge 1$.

To estimate I_{02}, we integrate by parts and use (4.6). We obtain

$$\begin{aligned} I_{02} &= -\int\frac{\lambda_0\tau n}{\sigma n^*}\left[(\boldsymbol{u}\cdot D)\delta\boldsymbol{E} - \frac{Dn^*}{n^*}(\boldsymbol{u}\cdot\delta\boldsymbol{E})\right]\cdot\frac{\boldsymbol{u}}{\tau}\,d\boldsymbol{x} \\ &\quad -\int\frac{\lambda_0}{\sigma}\left[(p-p^*)\left(\frac{\delta n}{n^*} - \frac{1}{(n^*)^2}\delta\boldsymbol{E}\cdot Dn^*\right) + \frac{\delta n}{(n^*)^2}\delta\boldsymbol{E}\cdot Dp^*\right]d\boldsymbol{x} \\ &\le C\mathcal{U}\left(\frac{1}{\tau}\|\boldsymbol{u}\|^2 + \frac{1}{\sigma}\left\|\delta\hat{U}\right\|^2\right) - \int\frac{\lambda_0\delta n}{\sigma n^*}\left[\left(\frac{\partial p}{\partial n}\right)^*\delta n + \left(\frac{\partial p}{\partial S}\right)^*\delta S\right]d\boldsymbol{x} \\ &\quad -\int\frac{\lambda_0}{\sigma}\left(\frac{1}{n^2}\frac{\partial p}{\partial S}\right)^*(\delta n DS^* - \delta S Dn^*)\cdot\delta\boldsymbol{E}\,d\boldsymbol{x}. \end{aligned} \tag{6.11}$$

Using (6.10) and (6.11) in (6.7), we find

$$\frac{d}{dt}\int\mathcal{H}_0\,d\boldsymbol{x} \le -\int\mathcal{D}_0\,d\boldsymbol{x} + \tau C_0'\mathcal{U}\left\|\delta U_\tau\right\|^2, \tag{6.12}$$

where C_0' is a positive constant and $\mathcal{D}_0$ is the quadratic form defined by (5.4). In conclusion, using (5.9), at order zero we can estimate the energy as

$$\frac{d}{dt}\left(\int\mathcal{H}_0\,d\boldsymbol{x}\right) \le -k_{\mathcal{D}}\left(\frac{1}{\tau}\|\boldsymbol{u}\|^2 + \frac{1}{\sigma}\left\|\delta\hat{U}\right\|^2\right) + \tau C_0'\mathcal{U}\left\|\delta U_\tau\right\|^2. \tag{6.13}$$

Next, we consider the function $\mathcal{H}_k$, defined by (5.2), with $1\le k\le s$. We can write

$$\begin{aligned} \frac{d}{dt}\int\mathcal{H}_k\,d\boldsymbol{x} &= \int\frac{\partial}{\partial t}\left\{\frac{1}{2}n\left|D^k\boldsymbol{u}\right|^2 + \frac{1}{2}\left|D^k\delta\boldsymbol{E}\right|^2\right\}d\boldsymbol{x} \\ &\quad +\int\frac{\partial}{\partial t}\left\{\frac{1}{2}\frac{\partial^2 e}{\partial n^2}\left|D^k\delta n\right|^2 + \frac{\partial^2 e}{\partial n\partial S}D^k\delta n\cdot D^k\delta S + \frac{1}{2}\frac{\partial^2 e}{\partial S^2}\left|D^k\delta S\right|^2\right\}d\boldsymbol{x} \\ &\quad -\int\frac{\partial}{\partial t}\left\{\frac{\lambda_k n}{\sigma n^*}D^k\boldsymbol{u}\cdot D^k\delta\boldsymbol{E}\right\}d\boldsymbol{x} = I_1+I_2+I_3. \end{aligned} \tag{6.14}$$

Using the perturbation equation (4.5), we find

$$
\begin{aligned}
I_1 &= -\int \left\{ D\cdot(n\boldsymbol{u})\frac{1}{2}\left|D^k\boldsymbol{u}\right|^2 + D^k\delta\boldsymbol{E}\cdot D^k(n\boldsymbol{u}) \right.\\
&\left. + nD^k\boldsymbol{u}\cdot D^k\left[(\boldsymbol{u}\cdot D)\boldsymbol{u} + \frac{1}{n}Dp - \frac{1}{n^*}Dp^* - \delta\boldsymbol{E} + \frac{\boldsymbol{u}}{\tau}\right]\right\} d\boldsymbol{x}\\
&= -\int nD^k\boldsymbol{u}\cdot\left[D^k((\boldsymbol{u}\cdot D)\boldsymbol{u}) - (\boldsymbol{u}\cdot D)(D^k\boldsymbol{u})\right] d\boldsymbol{x}\\
&- \int D^k\delta\boldsymbol{E}\cdot\left[D^k(n\boldsymbol{u}) - nD^k\boldsymbol{u}\right] d\boldsymbol{x} - \int nD^k\boldsymbol{u}\cdot D^k\left(\frac{1}{n}Dp - \frac{1}{n^*}Dp^*\right) d\boldsymbol{x}\\
&- \int \frac{n}{\tau}\left|D^k\boldsymbol{u}\right|^2 d\boldsymbol{x} \equiv I_{11} + I_{12} + I_{13} + I_{14}.
\end{aligned}
$$

Applying Lemma 2.1, the first integral in the previous expression can be estimated as

$$
\begin{aligned}
I_{11} &\le \|n\|_{L^\infty}\left\|D^k\boldsymbol{u}\right\|\sum_{r=1}^{N}\left\|D^k(u^r(\partial_r\boldsymbol{u})) - u^rD^k(\partial_r\boldsymbol{u})\right\|\\
&\le C\left\|D^k\boldsymbol{u}\right\|\sum_{r=1}^{N}\left(\|Du^r\|_{L^\infty}\left\|D^{k-1}\partial_r\boldsymbol{u}\right\| + \|\partial_r\boldsymbol{u}\|_{L^\infty}\left\|D^ku^r\right\|\right)\\
&\le \tau C\mathcal{U}\left\|D^k\boldsymbol{u}\right\|^2.
\end{aligned}
\tag{6.15}
$$

In a similar way, we find

$$
\begin{aligned}
I_{12} &\le \left\|D^k\delta\boldsymbol{E}\right\|\left(\left\|D^k(\delta n\boldsymbol{u})\right\| + \|\delta n\|_{L^\infty}\left\|D^k\boldsymbol{u}\right\| + \left\|D^k(n^*\boldsymbol{u}) - n^*D^k\boldsymbol{u}\right\|\right)\\
&\le C\left\|D^k\delta\boldsymbol{E}\right\|\left(\|\delta n\|_{L^\infty}\left\|D^k\boldsymbol{u}\right\| + \|\boldsymbol{u}\|_{L^\infty}\left\|D^k\delta n\right\| + \|Dn^*\|_{H^{k-1}}\|\boldsymbol{u}\|_{H^{k-1}}\right)\\
&\le \tau C\mathcal{U}\left\|D^k\delta\hat{U}\right\|\left(\frac{1}{\tau}\left\|D^k\boldsymbol{u}\right\| + \left\|D^k\delta\hat{U}\right\|\right)\\
&+ C\|Dn^*\|_{H^{k-1}}\|\boldsymbol{u}\|_{H^{k-1}}\left\|D^k\delta\boldsymbol{E}\right\|.
\end{aligned}
\tag{6.16}
$$

Using the Corollary 2.4, we can estimate

$$
\begin{aligned}
I_{13} &\le C\left(\left\|\delta\hat{U}\right\|_{C^1}\left\|D^k\delta\hat{U}\right\| + \|Dn^*\|_{H^k}\left\|\delta\hat{U}\right\|_{H^{k-1}}\right)\|D^k\boldsymbol{u}\|\\
&- \sum_{r=1}^{N}\int D^ku^r\cdot\left\{\frac{\partial p}{\partial n}D^k\partial_r\delta n + \frac{\partial p}{\partial S}D^k\partial_r\delta S\right.\\
&+ knD\left(\frac{1}{n}\frac{\partial p}{\partial n}\right)^*\otimes D^{k-1}(\partial_r\delta n) + knD\left(\frac{1}{n}\frac{\partial p}{\partial S}\right)^*\otimes D^{k-1}(\partial_r\delta S)\\
&+ n\left[\frac{\partial}{\partial n}\left(\frac{1}{n}\frac{\partial p}{\partial n}\right)^*D^k\delta n + \frac{\partial}{\partial S}\left(\frac{1}{n}\frac{\partial p}{\partial n}\right)^*D^k\delta S\right]\partial_rn^*\\
&\left.+ n\left[\frac{\partial}{\partial n}\left(\frac{1}{n}\frac{\partial p}{\partial S}\right)^*D^k\delta n + \frac{\partial}{\partial S}\left(\frac{1}{n}\frac{\partial p}{\partial S}\right)^*D^k\delta S\right]\partial_rS^*\right\} d\boldsymbol{x}\\
&\le C\left(\mathcal{U}\left\|D^k\delta\hat{U}\right\| + \|Dn^*\|_{H^k}\left\|\delta\hat{U}\right\|_{H^{k-1}}\right)\|D^k\boldsymbol{u}\|\\
&- \sum_{r=1}^{N}\int D^ku^r\cdot\partial_r\left\{\frac{\partial p}{\partial n}D^k\delta n + \frac{\partial p}{\partial S}D^k\delta S\right\} d\boldsymbol{x}
\end{aligned}
\tag{6.17}
$$

$$-\sum_{r=1}^{N}\int D^k u^r\cdot\left\{kn^*D\left(\frac{1}{n}\frac{\partial p}{\partial n}\right)^*\otimes D^{k-1}(\partial_r\delta n)\right.$$
$$\left.+kn^*D\left(\frac{1}{n}\frac{\partial p}{\partial S}\right)^*\otimes D^{k-1}(\partial_r\delta S)-\frac{1}{n^*}\partial_r p^* D^k\delta n\right\}d\boldsymbol{x}.$$

Next, we turn our attention to I_2. We can write

$$\begin{aligned}
I_2 &= -\int\left\{\left(\frac{\partial^2 e}{\partial n^2}D^k\delta n+\frac{\partial^2 e}{\partial n\partial S}D^k\delta S\right)D^kD\cdot(n\boldsymbol{u})\right.\\
&+\left(\frac{\partial^2 e}{\partial n\partial S}D^k\delta n+\frac{\partial^2 e}{\partial S^2}D^k\delta S\right)D^k[D\cdot(S\boldsymbol{u})-Q]\\
&\left.-\frac{1}{2}\frac{\partial}{\partial t}\frac{\partial^2 e}{\partial n^2}D^k\delta nD^k\delta n-\frac{\partial}{\partial t}\frac{\partial^2 e}{\partial n\partial S}D^k\delta nD^k\delta S-\frac{1}{2}\frac{\partial}{\partial t}\frac{\partial^2 e}{\partial S^2}D^k\delta SD^k\delta S\right\}d\boldsymbol{x}\\
&=\int\left\{\frac{1}{2}\left|D^k\delta n\right|^2\left[\frac{\partial}{\partial t}\frac{\partial^2 e}{\partial n^2}+D\cdot\left(\frac{\partial^2 e}{\partial n^2}\boldsymbol{u}\right)\right]+D^k\delta n\cdot D^k\delta S\left[\frac{\partial}{\partial t}\frac{\partial^2 e}{\partial n\partial S}\right.\right.\\
&\left.\left.+D\cdot\left(\frac{\partial^2 e}{\partial n\partial S}\boldsymbol{u}\right)\right]+\frac{1}{2}\left|D^k\delta S\right|^2\left[\frac{\partial}{\partial t}\frac{\partial^2 e}{\partial S^2}+D\cdot\left(\frac{\partial^2 e}{\partial S^2}\boldsymbol{u}\right)\right]\right\}d\boldsymbol{x}\\
&-\int\left\{\left(\frac{\partial^2 e}{\partial n^2}D^k\delta n+\frac{\partial^2 e}{\partial n\partial S}D^k\delta S\right)\cdot\left[D^kD\cdot(n\boldsymbol{u})-nD^kD\cdot\boldsymbol{u}-(\boldsymbol{u}\cdot D)D^k\delta n\right]\right.\\
&\left.+\left(\frac{\partial^2 e}{\partial n\partial S}D^k\delta n+\frac{\partial^2 e}{\partial S^2}D^k\delta S\right)\cdot\left[D^kD\cdot(S\boldsymbol{u})-SD^kD\cdot\boldsymbol{u}-(\boldsymbol{u}\cdot D)D^k\delta S\right]\right\}d\boldsymbol{x}\\
&-\int\left[n\left(\frac{\partial^2 e}{\partial n^2}D^k\delta n+\frac{\partial^2 e}{\partial n\partial S}D^k\delta S\right)+S\left(\frac{\partial^2 e}{\partial n\partial S}D^k\delta n+\frac{\partial^2 e}{\partial S^2}D^k\delta S\right)\right]D^kD\cdot\boldsymbol{u}\,d\boldsymbol{x}\\
&+\int\left(\frac{\partial^2 e}{\partial n\partial S}D^k\delta n+\frac{\partial^2 e}{\partial S^2}D^k\delta S\right)D^kQ\,d\boldsymbol{x}=I_{21}+I_{22}+I_{23}+I_{24}.
\end{aligned}$$

In order to estimate I_{21}, we observe that, for any function $a(n,S)$,

$$\begin{aligned}
\frac{\partial a}{\partial t}+D\cdot(a\boldsymbol{u})&=\left(a-\frac{\partial a}{\partial n}n-\frac{\partial a}{\partial S}S\right)D\cdot\boldsymbol{u}+\frac{\partial a}{\partial S}Q\\
&\le C\left(\|D\boldsymbol{u}\|_{L^\infty}+\frac{1}{\tau}\|\boldsymbol{u}\|_{L^\infty}^2+\frac{1}{\sigma}\left\|\delta\hat{U}\right\|_{L^\infty}^2\right)\le\tau C\mathcal{U}.
\end{aligned}$$

We can conclude that

$$I_{21}\le\tau C\mathcal{U}\left\|D^k\delta\hat{U}\right\|^2. \tag{6.18}$$

To estimate I_{22}, we recall that $n=n^*+\delta n$, $S=S^*+\delta S$. Then, posing $\mu=n,S$ and using Moser's calculus, we can estimate

$$\begin{aligned}
&\left\|D^kD\cdot(\delta\mu\boldsymbol{u})-\delta\mu D^kD\cdot\boldsymbol{u}-(\boldsymbol{u}\cdot D)D^k\delta\mu\right\|\\
&\le\left\|D^k(\delta\mu D\cdot\boldsymbol{u})-\delta\mu D^kD\cdot\boldsymbol{u}\right\|+\left\|D^k(\boldsymbol{u}\cdot D\delta\mu)-(\boldsymbol{u}\cdot D)D^k\delta\mu\right\|\\
&\le C(\|D\boldsymbol{u}\|_{L^\infty}\left\|D^k\delta\mu\right\|+\|D\delta\mu\|_{L^\infty}\left\|D^k\boldsymbol{u}\right\|)\\
&\le\tau C\mathcal{U}\left(\frac{1}{\tau}\left\|D^k\boldsymbol{u}\right\|+\left\|D^k\delta\hat{U}\right\|\right).
\end{aligned} \tag{6.19}$$

Also, recalling Lemma 2.2, we have

$$
\begin{aligned}
(6.20)\quad & \left\|D^k D\cdot(\mu^*\boldsymbol{u})-\mu^* D^k D\cdot\boldsymbol{u}-D^k\boldsymbol{u}\cdot D\mu^*-kD\mu^*\otimes(D^{k-1}(D\cdot\boldsymbol{u}))\right\| \\
&\le \left\|D^k(\mu^* D\cdot\boldsymbol{u})-\mu^* D^k D\cdot\boldsymbol{u}-kD\mu^*\otimes(D^{k-1}(D\cdot\boldsymbol{u}))\right\| \\
&+\sum_{r=1}^N\left\|D^k(u^r\partial_r\mu^*)-D^k u^r\partial_r\mu^*\right\| \\
&\le C\left\|D^2\mu^*\right\|_{H^{k-2}}\|D\cdot\boldsymbol{u}\|_{H^{k-2}}+C\sum_{r=1}^N\|D\partial_r\mu^*\|_{H^{k-1}}\|u^r\|_{H^{k-1}} \\
&\le C\left\|D^2\mu^*\right\|_{H^{k-1}}\|\boldsymbol{u}\|_{H^{k-1}}.
\end{aligned}
$$

Using (6.19) and (6.20) we obtain

$$
\begin{aligned}
&I_{22}\le\tau C\mathcal{U}\left(\frac{1}{\tau}\left\|D^k\boldsymbol{u}\right\|+\left\|D^k\delta\hat{U}\right\|\right)\left\|D^k\delta\hat{U}\right\|+C\left\|D^2n^*\right\|_{H^{k-1}}\|\boldsymbol{u}\|_{H^{k-1}}\left\|D^k\delta\hat{U}\right\| \\
&-\int\left\{\left(\frac{\partial^2 e}{\partial n^2}D^k\delta n+\frac{\partial^2 e}{\partial n\partial S}D^k\delta S\right)^*\cdot\left[D^k\boldsymbol{u}\cdot Dn^*+kDn^*\otimes(D^{k-1}(D\cdot\boldsymbol{u}))\right]\right. \\
&\left.+\left(\frac{\partial^2 e}{\partial n\partial S}D^k\delta n+\frac{\partial^2 e}{\partial S^2}D^k\delta S\right)^*\cdot\left[D^k\boldsymbol{u}\cdot DS^*+kDS^*\otimes(D^{k-1}(D\cdot\boldsymbol{u}))\right]\right\}d\boldsymbol{x} \\
&=\tau C\mathcal{U}\left(\frac{1}{\tau}\left\|D^k\boldsymbol{u}\right\|+\left\|D^k\delta\hat{U}\right\|\right)\left\|D^k\delta\hat{U}\right\|+C\left\|D^2n^*\right\|_{H^{k-1}}\|\boldsymbol{u}\|_{H^{k-1}}\left\|D^k\delta\hat{U}\right\| \\
&-\int\left\{D^k\delta n\cdot\left[D^k\boldsymbol{u}\cdot D\left(\frac{\partial e}{\partial n}\right)^*+kD\left(\frac{\partial e}{\partial n}\right)^*\otimes(D^{k-1}(D\cdot\boldsymbol{u}))\right]\right. \\
&\left.+D^k\delta S\cdot\left[D^k\boldsymbol{u}\cdot D\left(\frac{\partial e}{\partial S}\right)^*+kD\left(\frac{\partial e}{\partial S}\right)^*\otimes(D^{k-1}(D\cdot\boldsymbol{u}))\right]\right\}d\boldsymbol{x} \\
&=\tau C\mathcal{U}\left(\frac{1}{\tau}\left\|D^k\boldsymbol{u}\right\|+\left\|D^k\delta\hat{U}\right\|\right)\left\|D^k\delta\hat{U}\right\|+C\left\|D^2n^*\right\|_{H^{k-1}}\|\boldsymbol{u}\|_{H^{k-1}}\left\|D^k\delta\hat{U}\right\| \\
&-\sum_{r=1}^N\int D^k\delta n\cdot\left[D^k u^r\partial_r\phi^*+kD\phi^*\otimes(D^{k-1}(\partial_r u^r))\right]d\boldsymbol{x}.
\end{aligned}
$$

Here, we have used the equilibrium condition (3.2). Integrating two times by parts, we arrive at the estimate

$$
\begin{aligned}
(6.21)\quad & I_{22}\le\tau C\mathcal{U}\left(\frac{1}{\tau}\left\|D^k\boldsymbol{u}\right\|+\left\|D^k\delta\hat{U}\right\|\right)\left\|D^k\delta\hat{U}\right\| \\
&+C\left\|D^2n^*\right\|_{H^{k-1}}\|\boldsymbol{u}\|_{H^{k-1}}\left\|D^k\delta\hat{U}\right\| \\
&-\sum_{r=1}^N\int D^k u^r\cdot\left[D^k\delta n\partial_r\phi^*+kD\phi^*\otimes(D^{k-1}(\partial_r\delta n))\right]d\boldsymbol{x}.
\end{aligned}
$$

Next, using (1.8) and integrating by parts, we can write

$$
(6.22)\qquad I_{23}=\sum_{r=1}^N\int D^k u^r\cdot\partial_r\left(\frac{\partial p}{\partial n}D^k\delta n+\frac{\partial p}{\partial S}D^k\delta S\right)d\boldsymbol{x}.
$$

This term cancels out with the first integral on the right-hand side of (6.17). Next, we come to I_{24}. We observe that

$$\begin{aligned}
&\left\| D^k Q + \frac{1}{\sigma}\left(\frac{\partial S}{\partial T}\right)_n D^k \delta T \right\| \\
&= \tau \left\| \left(1 - \frac{\tau}{2\sigma}\right) D^k \left(\frac{n\,|\boldsymbol{u}|^2}{T\tau^2} \right) - \frac{1}{\sigma\tau}\left[D^k \left(\left(\frac{\partial S}{\partial T}\right)_n \delta T \right) - \left(\frac{\partial S}{\partial T}\right)_n D^k \delta T \right] \right\| \\
&\le \tau C \mathcal{U} \left(\frac{1}{\tau} \left\| D^k \boldsymbol{u} \right\| + \left\| D^k \delta \hat{U} \right\| \right) + \tau C \left\| D n^* \right\|_{H^{k-1}} \left\| \delta \hat{U} \right\|_{H^{k-1}}.
\end{aligned}$$

Then, proceeding as before, we find

$$\begin{aligned}
I_{24} &= \int \left(\frac{\partial T}{\partial n} D^k \delta n + \frac{\partial T}{\partial S} D^k \delta S \right) \left(D^k Q + \frac{1}{\sigma} \frac{\partial S}{\partial T} D^k \delta T \right) d\boldsymbol{x} \\
&- \int \frac{1}{\sigma} \frac{\partial S}{\partial T} \left(\frac{\partial T}{\partial n} D^k \delta n + \frac{\partial T}{\partial S} D^k \delta S \right) \left(D^k \delta T - \frac{\partial T}{\partial n} D^k \delta n - \frac{\partial T}{\partial S} D^k \delta S \right) d\boldsymbol{x} \\
&- \int \frac{1}{\sigma} \frac{\partial S}{\partial T} \left(\frac{\partial T}{\partial n} D^k \delta n + \frac{\partial T}{\partial S} D^k \delta S \right)^2 d\boldsymbol{x} \\
&\le \tau C \mathcal{U} \left(\frac{1}{\tau} \left\| D^k \boldsymbol{u} \right\| + \left\| D^k \delta \hat{U} \right\| \right) \left\| D^k \delta \hat{U} \right\| \\
&+ \tau C \left\| D n^* \right\|_{H^{k-1}} \left\| \delta \hat{U} \right\|_{H^{k-1}} \left\| D^k \delta \hat{U} \right\| \\
&- \int \frac{1}{\sigma} \left(\frac{\partial S}{\partial T} \right)^* \left[\left(\frac{\partial T}{\partial n} \right)^* D^k \delta n + \left(\frac{\partial T}{\partial S} \right)^* D^k \delta S \right]^2 d\boldsymbol{x}.
\end{aligned} \tag{6.23}$$

Summing up, using (6.15), (6.16), (6.17), (6.18), (6.21), (6.22), and (6.23), we obtain the estimate

$$\begin{aligned}
I_1 + I_2 &\le \tau C \mathcal{U} \left\| D^k \delta U_\tau \right\|^2 + \tau C \left\| D n^* \right\|_{H^k} \left\| \delta U_\tau \right\|_{H^{k-1}} \left\| D^k \delta U_\tau \right\| \\
&- \sum_{r=1}^{N} \int D^k u^r \cdot k \left\{ \left[D\phi^* + n^* D \left(\frac{1}{n} \frac{\partial p}{\partial n} \right)^* \right] \otimes D^{k-1} (\partial_r \delta n) \right. \\
&\left. + n^* D \left(\frac{1}{n} \frac{\partial p}{\partial S} \right)^* \otimes D^{k-1} (\partial_r \delta S) \right\} d\boldsymbol{x} - \int \frac{n}{\tau} \left| D^k \boldsymbol{u} \right|^2 d\boldsymbol{x} \\
&- \int \frac{1}{\sigma} \left(\frac{\partial S}{\partial T} \right)^* \left[\left(\frac{\partial T}{\partial n} \right)^* D^k \delta n + \left(\frac{\partial T}{\partial S} \right)^* D^k \delta S \right]^2 d\boldsymbol{x}, \\
&\le \tau C \mathcal{U} \left\| D^k \delta U_\tau \right\|^2 + \tau C \left\| D n^* \right\|_{H^k} \left\| \delta U_\tau \right\|_{H^{k-1}} \left\| D^k \delta U_\tau \right\| \\
&+ c^* \left\| D n^* \right\| \left\| D^k \boldsymbol{u} \right\| \left\| D^k \delta \hat{U} \right\| - \int \frac{n}{\tau} \left| D^k \boldsymbol{u} \right|^2 d\boldsymbol{x} \\
&- \int \frac{1}{\sigma} \left(\frac{\partial S}{\partial T} \right)^* \left[\left(\frac{\partial T}{\partial n} \right)^* D^k \delta n + \left(\frac{\partial T}{\partial S} \right)^* D^k \delta S \right]^2 d\boldsymbol{x},
\end{aligned} \tag{6.24}$$

where the constant c^* depends only on the function $e(n, S)$ and on $b^{\pm}$.

Next, we consider I_3.

$$
\begin{aligned}
I_3 &= \int \frac{\lambda_k}{\sigma n^*} \left\{ n D^k \boldsymbol{u} \cdot D^k \left(D\Delta^{-1} D \cdot (n\boldsymbol{u}) \right) + D \cdot (n\boldsymbol{u}) D^k \boldsymbol{u} \cdot D^k \delta \boldsymbol{E} \right. \\
&\left. + n D^k \left(\boldsymbol{u} \cdot D\boldsymbol{u} + \frac{1}{n} Dp - \frac{1}{n^*} Dp^* - \delta \boldsymbol{E} + \frac{1}{\tau} \boldsymbol{u} \right) \cdot D^k \delta \boldsymbol{E} \right\} d\boldsymbol{x} \\
&= \int \frac{\lambda_k n}{\sigma n^*} D^k \boldsymbol{u} \cdot D^k \left(D\Delta^{-1} D \cdot (n\boldsymbol{u}) \right) d\boldsymbol{x} \\
&+ \int \frac{\lambda_k}{\sigma n^*} \left[D \cdot (n\boldsymbol{u}) D^k \boldsymbol{u} + n D^k ((\boldsymbol{u} \cdot D)\boldsymbol{u}) \right] \cdot D^k \delta \boldsymbol{E} \, d\boldsymbol{x} \\
&+ \int \frac{\lambda_k n}{\sigma n^*} D^k \left[\frac{1}{n} Dp - \frac{1}{n^*} Dp^* \right] \cdot D^k \delta \boldsymbol{E} \, d\boldsymbol{x} \\
&\int \frac{\lambda_k n}{\sigma n^*} \left(D^k \delta \boldsymbol{E} - \frac{1}{\tau} D^k \boldsymbol{u} \right) \cdot D^k \delta \boldsymbol{E} \, d\boldsymbol{x} \equiv I_{31} + I_{32} + I_{33} + I_{34}.
\end{aligned}
$$

We can estimate I_{31} immediately as

$$
\begin{aligned}
I_{31} &\leq \frac{\lambda_k}{\sigma \inf n^*} \left\| n D^k \boldsymbol{u} \right\| \left\| D^k D\Delta^{-1} D \cdot (n\boldsymbol{u}) \right\| \\
&= \frac{\lambda_k}{\sigma \inf n^*} \left\| n D^k \boldsymbol{u} \right\| \left\| D^{k-1} D \cdot (n\boldsymbol{u}) \right\| \\
&\leq \frac{\lambda_k}{\sigma \inf n^*} \left\| n D^k \boldsymbol{u} \right\| \left(\left\| D^k (n\boldsymbol{u}) - n D^k \boldsymbol{u} \right\| + \left\| n D^k \boldsymbol{u} \right\| \right) \\
&\leq \frac{\lambda_k}{\sigma \inf n^*} \left\| n D^k \boldsymbol{u} \right\|^2 + \frac{C}{\sigma} \left\| D^k \boldsymbol{u} \right\| \left(\| Dn^* \|_{L^\infty} \left\| D^{k-1} \boldsymbol{u} \right\| \right. \\
&\left. + \left\| D^k n^* \right\| \| \boldsymbol{u} \|_{L^\infty} + \| \boldsymbol{u} \|_{L^\infty} \left\| D^k \delta n \right\| + \| \delta n \|_{L^\infty} \left\| D^k \boldsymbol{u} \right\| \right) \\
&\leq \frac{\lambda_k}{\sigma \inf n^*} \left\| n D^k \boldsymbol{u} \right\|^2 \\
&+ \tau C \left\| D^k \delta U_\tau \right\| \left(\| Dn^* \|_{H^{k-1}} \| \delta U_\tau \|_{H^{k-1}} + \mathcal{U} \left\| D^k \delta U_\tau \right\| \right).
\end{aligned} \tag{6.25}
$$

For I_{32}, integrating by parts, recalling that $\delta \boldsymbol{E} = D\delta\phi$, and using (4.6), we find

$$
\begin{aligned}
I_{32} &\leq C \frac{\lambda_k}{\sigma} \left(\| n \|_{L^\infty} \| D\boldsymbol{u} \| + \| \boldsymbol{u} \|_{L^\infty} \| Dn \| \right) \left\| D^k \boldsymbol{u} \right\| \left\| D^k \delta \boldsymbol{E} \right\| \\
&+ \sum_{j,r=1}^{N} \int \frac{\lambda_k}{\sigma} \partial_j D^{k-1} ((\boldsymbol{u} \cdot D) u^r) \cdot \left\{ \frac{n}{n^*} \partial_j D^{k-1} \delta E^r \right\} d\boldsymbol{x} \\
&\leq C \frac{\lambda_k}{\sigma \tau} \mathcal{U} \left\| D^k \boldsymbol{u} \right\| \left\| D^k \delta \boldsymbol{E} \right\| \\
&- \sum_{j,r=1}^{N} \int \frac{\lambda_k}{\sigma} D^{k-1} ((\boldsymbol{u} \cdot D) u^r) \cdot \partial_j \left\{ \frac{n}{n^*} \partial_r D^{k-1} \delta E^j \right\} d\boldsymbol{x} \\
&\leq \tau C \mathcal{U} \left\| D^k \delta U_\tau \right\|^2 + \frac{\lambda_k}{\sigma} \sum_{r=1}^{N} \left\| D^{k-1} ((\boldsymbol{u} \cdot D) u^r) \right\| \left\{ \left\| \frac{n}{n^*} \partial_r D^{k-1} \delta n \right\| \right. \\
&\left. + \left\| D \left(\frac{\delta n}{n^*} \right) \right\|_{L^\infty} \left\| \partial_r D^{k-1} \delta \boldsymbol{E} \right\| \right\} \\
&\leq \tau C \mathcal{U} \left\| D^k \delta U_\tau \right\|^2 + \frac{C}{\sigma} \| \boldsymbol{u} \|_{L^\infty} \left\| D^k \boldsymbol{u} \right\| \left(\left\| D^k \delta n \right\| + \| \delta n \|_{C^1} \left\| D^k \delta \boldsymbol{E} \right\| \right).
\end{aligned} \tag{6.26}
$$

In a similar way, we find

$$
\begin{aligned}
I_{33} &= -\int \frac{\lambda_k}{\sigma} D^{k-1}\left(\frac{1}{n}Dp - \frac{1}{n^*}Dp^*\right)\cdot \sum_{r=1}^{N}\partial_r\left\{\frac{n}{n^*}D^{k-1}\partial_r\delta\boldsymbol{E}\right\}\,d\boldsymbol{x}\\
&\le \frac{\lambda_k}{\sigma}\left\|D^{k-1}\left(\frac{Dp}{n}-\frac{Dp^*}{n^*}\right)\right\|\left\|\sum_{r=1}^{N}\partial_r\left(\frac{\delta n}{n^*}\right)D^{k-1}\partial_r\delta\boldsymbol{E}+\frac{\delta n}{n^*}D^k\delta n\right\|\\
&+\frac{\lambda_k}{\sigma}\left\|D^{k-1}\left(\frac{Dp}{n}-\frac{Dp^*}{n^*}\right)-\left(\frac{1}{n}\frac{\partial p}{\partial n}\right)^* D^k\delta n-\left(\frac{1}{n}\frac{\partial p}{\partial S}\right)^* D^k\delta S\right\|\left\|D^k\delta n\right\|\\
&-\int\frac{\lambda_k}{\sigma}\left\{\left(\frac{1}{n}\frac{\partial p}{\partial n}\right)^* D^k\delta n+\left(\frac{1}{n}\frac{\partial p}{\partial S}\right)^* D^k\delta S\right\}\cdot D^k\delta n\,d\boldsymbol{x}.
\end{aligned}
$$

Using Lemma 2.3 and Corollary 2.4, we can estimate

$$
\begin{aligned}
I_{33} &\le \tau C\mathcal{U}\left\|D^k\delta U_\tau\right\|^2+\tau C\left\|Dn^*\right\|_{H^k}\left\|\delta U_\tau\right\|_{H^{k-1}}\left\|D^k\delta U_\tau\right\|\\
&-\int\frac{\lambda_k}{\sigma}\left\{\left(\frac{1}{n}\frac{\partial p}{\partial n}\right)^* D^k\delta n+\left(\frac{1}{n}\frac{\partial p}{\partial S}\right)^* D^k\delta S\right\}\cdot D^k\delta n\,d\boldsymbol{x}.
\end{aligned}
\tag{6.27}
$$

Proceeding as in (6.8), we find

$$
I_{34}\le\int\left\{\frac{n}{2\tau}\left|D^k\boldsymbol{u}\right|^2-\frac{\lambda_0 n}{2\sigma n^*}\left|D^k\delta\boldsymbol{E}\right|^2\right\}d\boldsymbol{x}.
\tag{6.28}
$$

In conclusion, using (6.25), (6.26), (6.27), and (6.28), we can estimate I_3 as

$$
\begin{aligned}
I_3 &\le \tau C\mathcal{U}\left\|D^k\delta U_\tau\right\|^2+\tau C\left\|Dn^*\right\|_{H^k}\left\|\delta U_\tau\right\|_{H^{k-1}}\left\|D^k\delta U_\tau\right\|\\
&-\int\frac{\lambda_k}{\sigma}\left\{\left(\frac{1}{n}\frac{\partial p}{\partial n}\right)^* D^k\delta n+\left(\frac{1}{n}\frac{\partial p}{\partial S}\right)^* D^k\delta S\right\}\cdot D^k\delta n\,d\boldsymbol{x}\\
&-\int\left\{\frac{\lambda_k}{2\sigma}\left|D^k\delta\boldsymbol{E}\right|^2-\left(\frac{1}{2\tau}+\frac{\lambda_k\sup n^*}{\sigma\inf n^*}\right)n^*\left|D^k\boldsymbol{u}\right|^2\right\}d\boldsymbol{x}.
\end{aligned}
\tag{6.29}
$$

Using the estimates (6.24) and (6.29) in (6.14), we find

$$
\begin{aligned}
\frac{d}{dt}\int\mathcal{H}_k\,d\boldsymbol{x} &\le -\int\mathcal{D}_k\,d\boldsymbol{x}+c^*\left\|Dn^*\right\|\left\|D^k\boldsymbol{u}\right\|\left\|D^k\delta\hat{U}\right\|\\
&+\tau C_k'\mathcal{U}\left\|D^k\delta U_\tau\right\|^2+\tau C_k''\left\|Dn^*\right\|_{H^k}\left\|\delta U_\tau\right\|_{H^{k-1}}\left\|D^k\delta U_\tau\right\|,
\end{aligned}
\tag{6.30}
$$

where C_k' and C_k'' are positive constants which depend only on the equilibrium state and on $\sigma\tau$. Next, we observe that the assumption

$$
\sigma\tau\left\|Dn^*\right\|^2\le C^*\equiv\frac{k_{\mathcal{D}}^2}{4c^{*2}}
\tag{6.31}
$$

implies

$$
\begin{aligned}
&c^*\left\|Dn^*\right\|\left\|D^k\boldsymbol{u}\right\|\left\|D^k\delta\hat{U}\right\|\\
&\le\frac{1}{2}c^*\left\|Dn^*\right\|\left(\frac{k_{\mathcal{D}}}{2\tau c^*\left\|Dn^*\right\|}\left\|D^k\boldsymbol{u}\right\|^2+\frac{2\tau c^*\left\|Dn^*\right\|}{k_{\mathcal{D}}}\left\|D^k\delta\hat{U}\right\|^2\right)\\
&\le\frac{k_{\mathcal{D}}}{4}\left(\frac{1}{\tau}\left\|D^k\boldsymbol{u}\right\|^2+\frac{1}{\sigma}\left\|D^k\delta\hat{U}\right\|^2\right).
\end{aligned}
\tag{6.32}
$$

Thus, using (5.9) and the assumption (6.31), we obtain

$$\frac{d}{dt}\int \mathcal{H}_k\,d\boldsymbol{x} \le -\frac{3}{4}k_{\mathcal{D}}\left(\frac{1}{\tau}\left\|D^k\boldsymbol{u}\right\|^2+\frac{1}{\sigma}\left\|D^k\delta\hat{U}\right\|^2\right) + \tau C_k'\mathcal{U}\left\|D^k\delta U_\tau\right\|^2+\tau C_k''\left\|Dn^*\right\|_{H^k}\left\|\delta U_\tau\right\|_{H^{k-1}}\left\|D^k\delta U_\tau\right\|. \tag{6.33}$$

Next, we use (6.13) and (6.33) in order to estimate the energy $\mathcal{W}$, given by (6.4). We find

$$\frac{d\mathcal{W}}{dt}=\sum_{k=0}^{s}\eta_k\frac{d}{dt}\int\mathcal{H}_k\,d\boldsymbol{x}\le-\tau k_{\mathcal{D}}^*\left(\left\|\delta U_\tau\right\|^2+\frac{3}{4}\sum_{k=1}^{s}\eta_k\left\|D^k\delta U_\tau\right\|^2\right) +\tau C'\mathcal{U}\sum_{k=0}^{s}\eta_k\left\|D^k\delta U_\tau\right\|^2+\tau C''\left\|Dn^*\right\|_{H^s}\sum_{k=1}^{s}\eta_k\left\|\delta U_\tau\right\|_{H^{k-1}}\left\|D^k\delta U_\tau\right\|, \tag{6.34}$$

with

$$k_{\mathcal{D}}^*=\frac{k_{\mathcal{D}}}{\max\{1,\tau\sigma\}},\qquad C'=\max\{C_0',C_1',\dots,C_s'\},\qquad C''=\max\{C_1'',\dots,C_s''\}.$$

Recalling Lemma 2.5, we pose

$$\eta=2,\qquad K=\frac{k_{\mathcal{D}}^*}{4C''\left\|Dn^*\right\|_{H^s}}$$

and choose

$$\eta_k=2\eta\left(\frac{K^2}{1+K^2}\right)^k,\qquad k=1,\dots,s.$$

Then it follows that

$$C''\left\|Dn^*\right\|_{H^s}\sum_{k=1}^{s}\eta_k\left\|\delta U_\tau\right\|_{H^{k-1}}\left\|D^k\delta U_\tau\right\| \le\frac{k_{\mathcal{D}}^*}{4}\left(2\left\|\delta U_\tau\right\|^2+\sum_{k=1}^{s}\eta_k\left\|D^k\delta U_\tau\right\|^2\right). \tag{6.35}$$

Using (6.35) in (6.34), we get

$$\frac{d\mathcal{W}}{dt}\le-\tau\left(\frac{k_{\mathcal{D}}^*}{2}-C'\mathcal{U}\right)\sum_{k=0}^{s}\eta_k\left\|D^k\delta U_\tau\right\|^2.$$

If the solution satisfies

$$\mathcal{U}(T)\le\epsilon\equiv\frac{k_{\mathcal{D}}^*}{4C'}, \tag{6.36}$$

we have

$$\frac{d\mathcal{W}}{dt}\le-\frac{\tau k_{\mathcal{D}}^*}{4}\sum_{k=0}^{s}\eta_k\left\|D^k\delta U_\tau\right\|^2. \tag{6.37}$$

After integration with respect to time and recalling Lemma 5.3, we find

$$\left\|D^k\delta U(\cdot,t)\right\|^2_{\eta,s} \le K - \tau c\int_0^t \left\|D^k\delta U_\tau(\cdot,t')\right\|^2_{\eta,s}\,dt', \tag{6.38}$$

with

$$K = \frac{\mathcal{W}(0)}{k_{\mathcal{H}}} \qquad c = \frac{k^*_{\mathcal{D}}}{4k_{\mathcal{H}}}. \tag{6.39}$$

In particular, from (6.38) we can derive

$$\left\|D^k\boldsymbol{u}(\cdot,t)\right\|^2_{\eta,s} \le K - \frac{c}{\tau}\int_0^t \left\|D^k\boldsymbol{u}(\cdot,t')\right\|^2_{\eta,s}\,dt', \tag{6.40}$$

$$\left\|D^k\delta\hat{U}(\cdot,t)\right\|^2_{\eta,s} \le K - \tau c\int_0^t \left\|D^k\delta\hat{U}(\cdot,t')\right\|^2_{\eta,s}\,dt'. \tag{6.41}$$

The sought a priori estimate follows immediately from (6.40) and (6.41) after applying Gronwall's lemma. ∎

Appendix. In this appendix, we prove Lemmas 2.2, 2.3, 2.4, and 2.5.

Proof of Lemma 2.2. From the identity (2.1), we find

$$\left\|D^k(fg) - \sum_{r=0}^{j-1}\binom{k}{r}(D^r f)\otimes(D^{k-r}g)\right\| \le \sum_{r=0}^{k-j}\binom{k}{j+r}\left\|D^r(D^j f)\right\|\left\|D^{k-j-r}g\right\|.$$

Using Schwarz's inequality, we obtain the thesis. ∎

Proof of Lemma 2.3. If $k=1$, we find immediately that

$$\begin{aligned}
&\|D(F(f)-F(g))\| \le \left|\frac{\partial F}{\partial w}\right|_{C^0}\|D(f-g)\| + \left\|\frac{\partial F}{\partial w}(f)-\frac{\partial F}{\partial w}(g)\right\|\|Dg\|,\\
&\left\|D(F(f)-F(g)) - \frac{\partial F}{\partial w}(f)D(f-g)\right\|\\
&\le \left\|\left(\frac{\partial F}{\partial w}(f)-\frac{\partial F}{\partial w}(g)\right)D(f-g)\right\| + \left\|\frac{\partial F}{\partial w}(f)-\frac{\partial F}{\partial w}(g)\right\|\|Dg\|.
\end{aligned}$$

The estimates (2.6) and (2.7) follow from the identity

$$\frac{\partial F}{\partial w}(f)-\frac{\partial F}{\partial w}(g) = \left\{\int_0^1 \frac{\partial}{\partial w}\frac{\partial F}{\partial w}(g+\lambda(f-g))d\lambda\right\}(f-g). \tag{A.1}$$

Next, let α be an N-tuple of nonnegative integers, with $|\alpha| = k \ge 2$. Then we have

$$\begin{aligned}
&D^\alpha(F(f)-F(g)) \qquad\qquad (A.2)\\
&\quad= \sum_{\mu_1+\cdots+\mu_r=\alpha} C_\mu\left[(D^{\mu_1}f)\cdots(D^{\mu_r}f)F^{(r)}(f) - (D^{\mu_1}g)\cdots(D^{\mu_r}g)F^{(r)}(g)\right]\\
&\quad= \sum_{\mu_1+\cdots+\mu_r=\alpha} C_\mu\Big\{D^{\mu_1}(f-g)\cdots D^{\mu_r}(f-g)F^{(r)}(f) + \Big[(D^{\mu_1}f)\cdots(D^{\mu_r}f)\\
&\qquad - (D^{\mu_1}g)\cdots(D^{\mu_r}g) - D^{\mu_1}(f-g)\cdots D^{\mu_r}(f-g)\Big]F^{(r)}(f)\\
&\qquad + (D^{\mu_1}g)\cdots(D^{\mu_r}g)\left[F^{(r)}(f)-F^{(r)}(g)\right]\Big\},
\end{aligned}$$

where $F^{(r)}$ denotes the rth derivative of F with respect to its argument. We write $f = g+(f-g)$ in (A.2), evaluate the L^2-norm, and use the Cauchy–Schwarz inequality. Then the Gagliardo–Nirenberg inequality yields

$$\|D^{\mu_1}(f-g)\cdots D^{\mu_r}(f-g)\| \le C\,\|f-g\|_{L^\infty}^{r-1}\left\|D^k(f-g)\right\|. \tag{A.3}$$

Furthermore, we have

$$\begin{aligned}
&\left\|(D^{\mu_1}g)\cdots(D^{\mu_r}g)\left[F^{(r)}(f)-F^{(r)}(g)\right]\right\| \\
&\le \|(D^{\mu_1}g)\cdots(D^{\mu_r}g)\|\left\|F^{(r)}(f)-F^{(r)}(g)\right\| \\
&\le C\,\|g\|_{L^\infty}^{r-1}\left\|D^k g\right\|\left\|\left\{\int_0^1\left(\frac{\partial F^{(r)}}{\partial w}\right)(g+\lambda(f-g))d\lambda\right\}(f-g)\right\| \\
&\le C\left|F^{(r+1)}\right|_{C^0}\|g\|_{L^\infty}^{r-1}\left\|D^k g\right\|\|f-g\|.
\end{aligned} \tag{A.4}$$

Also, for $r \ge 2$, we find

$$\begin{aligned}
&\|(D^{\mu_1}f)\cdots(D^{\mu_r}f)-(D^{\mu_1}g)\cdots(D^{\mu_r}g)-D^{\mu_1}(f-g)\cdots D^{\mu_r}(f-g)\| \\
&\le C\sum_{i=1}^{r-1}\|D^{\mu_1}(f-g)\cdots D^{\mu_i}(f-g)\|\,\|(D^{\mu_{i+1}}g)\cdots(D^{\mu_r}g)\| \\
&\le C\sum_{i=1}^{r-1}\|f-g\|_{L^\infty}^{i-1}\left\|D^{|\mu_1+\cdots+\mu_i|}(f-g)\right\|\|g\|_{L^\infty}^{r-i-1}\left\|D^{k-|\mu_1+\cdots+\mu_i|}g\right\|.
\end{aligned} \tag{A.5}$$

In (A.5), we note that the number i of derivatives of $f-g$ cannot exceed $|\mu_1+\cdots+\mu_i|$, and the number $r-i$ of derivatives of g cannot exceed $k-|\mu_1+\cdots+\mu_i|$. Using the estimates (A.3), (A.4), (A.5), we find

$$\begin{aligned}
&\|D^\alpha(F(f)-F(g))\| \le C\sum_{i=1}^{k}\left|F^{(i)}\right|_{C^0}\|f-g\|_{L^\infty}^{i-1}\left\|D^k(f-g)\right\| \\
&+C\sum_{r=1}^{k-1}\sum_{i=1}^{r}\sum_{j=1}^{k-r}\left|F^{(i+j)}\right|_{C^0}\|f-g\|_{L^\infty}^{i-1}\|g\|_{L^\infty}^{j-1}\|D^r(f-g)\|\,\left\|D^{k-r}g\right\| \\
&+C\sum_{j=1}^{k}\left|F^{(j+1)}\right|_{C^0}\|g\|_{L^\infty}^{j-1}\|f-g\|\,\left\|D^k g\right\| \\
&\le C\left|\frac{\partial F}{\partial w}\right|_{C^{k-1}}\left(\sum_{i=1}^{k}\|f-g\|_{L^\infty}^{i-1}\right)\left\|D^k(f-g)\right\| \\
&+C\left|\frac{\partial F}{\partial w}\right|_{C^k}\left(\sum_{i=1}^{k}\sum_{j=1}^{k}\|f-g\|_{L^\infty}^{i-1}\|g\|_{L^\infty}^{j-1}\right)\sum_{r=0}^{k-1}\|D^r(f-g)\|\,\left\|D^{k-r}g\right\|.
\end{aligned} \tag{A.6}$$

The estimate (2.6) follows immediately, with

$$C(F,f,g) = C\left|\frac{\partial F}{\partial w}\right|_{C^k}\left(\sum_{i=1}^{k}\sum_{j=1}^{k}\|f-g\|_{L^\infty}^{i-1}\|g\|_{L^\infty}^{j-1}\right).$$

To prove (2.7), we proceed in the same way to obtain

$$
\begin{aligned}
(\mathrm{A}.7)\quad & \left\| D^\alpha (F(f)-F(g)) - \frac{\partial F}{\partial w}(f) D^\alpha (f-g) \right\| \\
& \le \left\| \left(\frac{\partial F}{\partial w}(f) - \frac{\partial F}{\partial w}(g) \right) D^\alpha (f-g) \right\| \\
& + C \left| \frac{\partial F}{\partial w} \right|_{C^{k-1}} \left(\sum_{i=2}^{k} \|f-g\|_{L^\infty}^{i-2} \right) \|f-g\|_{L^\infty} \left\| D^k (f-g) \right\| \\
& + C \left| \frac{\partial F}{\partial w} \right|_{C^{k}} \left(\sum_{i=1}^{k} \sum_{j=1}^{k} \|f-g\|_{L^\infty}^{i-1} \|g\|_{L^\infty}^{j-1} \right) \sum_{r=0}^{k-1} \|D^r (f-g)\| \, \left\| D^{k-r} g \right\| .
\end{aligned}
$$

The estimate (2.7) follows from the identity (A.1). ∎

Proof of Corollary 2.4. The proof of (2.8) and (2.9) is perfectly analogous to the proof of (2.6) and (2.7). To prove (2.10), we observe that

$$
\begin{aligned}
& \Big\| D^k \left[F(f)\partial f - F(g)\partial g \right] - F(f) D^k \partial (f-g) \\
& - kD\left[F(g)\right] \otimes D^{k-1}\left[\partial (f-g)\right] - \frac{\partial F}{\partial w}(g) D^k (f-g) \partial g \Big\| \\
& \le \left\| D^k \left[(F(f)-F(g))\partial (f-g) \right] - (F(f)-F(g)) D^k \partial (f-g) \right\| \\
& + \left\| D^k \left[F(g)\partial (f-g) \right] - F(g) D^k \partial (f-g) - kD\left[F(g)\right] \otimes D^{k-1}\left[\partial (f-g)\right] \right\| \\
& + \left\| D^k \left[(F(f)-F(g))\partial g \right] - D^k (F(f)-F(g)) \partial g \right\| \\
& + \left\| D^k \left[F(f)-F(g) \right] - \frac{\partial F}{\partial w}(g) D^k (f-g) \right\| \|\partial g\|_{L^\infty} .
\end{aligned}
$$

The thesis follows from Lemmas 2.1, 2.2, and 2.3. ∎

Proof of Lemma 2.5. Using the Cauchy–Schwarz inequality, we have

$$
\begin{aligned}
& \sum_{j=1}^{k} \eta_j \|f\|_{H^{j-1}} \left\| D^j f \right\| \le \frac{1}{2} \sum_{j=1}^{k} \eta_j \left(\frac{1}{\alpha_j} \|f\|_{H^{j-1}}^2 + \alpha_j \left\| D^j f \right\|^2 \right) \\
& = \frac{1}{2} \sum_{j=1}^{k} \eta_j \alpha_j \left\| D^j f \right\|^2 + \frac{1}{2} \sum_{j=1}^{k} \sum_{i=0}^{j-1} \frac{\eta_j}{\alpha_j} \left\| D^i f \right\|^2 \\
& = \frac{1}{2} \sum_{j=1}^{k} \eta_j \alpha_j \left\| D^j f \right\|^2 + \frac{1}{2} \sum_{j=0}^{k-1} \sum_{i=j+1}^{k} \frac{\eta_i}{\alpha_i} \left\| D^j f \right\|^2 \\
& = \frac{1}{2} \eta_k \alpha_k \left\| D^k f \right\|^2 + \frac{1}{2} \sum_{j=1}^{k-1} \left\{ \eta_j \alpha_j + \sum_{i=j+1}^{k} \frac{\eta_i}{\alpha_i} \right\} \left\| D^j f \right\|^2 + \frac{1}{2} \sum_{i=1}^{k} \frac{\eta_i}{\alpha_i} \|f\|^2 ,
\end{aligned}
$$

where α_j, $j = 1, \dots, k$, are constants to be chosen. The thesis amounts to proving that we can choose η_j and α_j, $j = 1, \dots, k$, such that

$$
\begin{aligned}
& \eta_k \alpha_k = 2K \eta_k , \\
& \eta_j \alpha_j + \sum_{i=j+1}^{k} \frac{\eta_i}{\alpha_i} = 2K \eta_j , \quad j = 1, \dots, k-1 ,
\end{aligned}
$$

$$\sum_{i=1}^{k} \frac{\eta_i}{\alpha_i} = 2K\eta.$$

Recursively, we obtain

$$\begin{aligned}
&2K - \alpha_k = 0,\\
&2K - \alpha_j = \sum_{i=j+1}^{k} \frac{\eta_i}{\alpha_i \eta_j} = \sum_{i=j+2}^{k} \frac{\eta_i}{\alpha_i \eta_j} + \frac{\eta_{j+1}}{\alpha_{j+1}\eta_j}\\
&\qquad = \left(2K - \alpha_{j+1} + \frac{1}{\alpha_{j+1}}\right) \frac{\eta_{j+1}}{\eta_j} > 0, \quad j = 1, \dots, k-1,\\
&\eta_1 \left(2K - \alpha_1 + \frac{1}{\alpha_1}\right) = 2K\eta.
\end{aligned}$$

Then we can choose

$$\begin{aligned}
&\alpha_j = 2(1-\beta_j)K, \quad j = 1, \dots, k-1, \qquad \alpha_k = 2K,\\
&\eta_1 = \frac{2K\eta}{2K - \alpha_1 + \frac{1}{\alpha_1}}, \qquad \eta_j = \frac{2K\beta_{j-1}\eta_{j-1}}{2K - \alpha_j + \frac{1}{\alpha_j}}, \quad j = 2, \dots, k,
\end{aligned}$$

for any constants $\beta_j < 1$, $j = 1, \dots, k-1$. In particular, choosing $\beta_j = 1/2$, we get the simple expression

$$\eta_j = 2\eta \left(\frac{K^2}{1+K^2}\right)^j, \quad j = 1, \dots, k. \qquad \square$$

DUBUC–DESLAURIERS SUBDIVISION FOR FINITE SEQUENCES AND INTERPOLATION WAVELETS ON AN INTERVAL*

J. M. DE VILLIERS†, K. M. GOOSEN†, AND B. M. HERBST‡

Abstract. In this paper we consider a method of adapting Dubuc–Deslauriers subdivision, which is defined for bi-infinite sequences, to accommodate sequences of finite length. After deriving certain useful properties of the Dubuc–Deslauriers refinable function on $\mathbb{R}$, we define a multiscale finite sequence of functions on a bounded interval, which are then proved to be refinable. Using this fact, the resulting adapted interpolatory subdivision scheme for finite sequences is then shown to be convergent. Corresponding interpolation wavelets on an interval are defined, and explicit formulations of the resulting decomposition and reconstruction algorithms are calculated. Finally, we give two numerical examples on signature smoothing and two-dimensional feature extraction of the subdivision and wavelet algorithms.

Key words. subdivision, interpolation, refinable functions, wavelets, bounded interval

1. Introduction.

Consider the following simple iterative procedure: Let M be the linear space of bi-infinite vector-valued sequences $c = \{c_j\} = \{c_j : j \in \mathbb{Z}\}$, and begin with an ordered sequence $c^{(0)} \in M$, called the *initial control points*. From these points, generate a new sequence $c^{(1)}$ of control points in M where the even-indexed new control points interpolate the old ones. In contrast to standard interpolation procedures, subdivision schemes generate the new points by taking a linear combination of the old control points. For example, if one generates the new points using

$$c^{(1)}_{2j} = c^{(0)}_j \quad \text{and} \quad c^{(1)}_{2j+1} = \tfrac{1}{2}(c^{(0)}_j + c^{(0)}_{j+1}), \quad j \in \mathbb{Z}, \tag{1.1}$$

then the odd-indexed new points are generated halfway between the old ones. This step can of course be repeated indefinitely, roughly "doubling" the number of points at each step. In this case the points fill in or converge to the straight lines connecting the initial control points (see Figure 1). Thus we obtain a continuous piecewise linear curve. In general, the existence and smoothness of this limit curve depend on the choice of the coefficients of the linear combination. The initial task is to find suitable choices for these coefficients which (i) ensure convergence to a limit curve, and (ii) yield appropriate smoothness of the limit curve.

In general, given a finitely supported real-valued sequence a, we define the corresponding subdivision operator $S : M \to M$ by

$$(Sc)_j = \sum_k a_{j-2k} c_k, \quad j \in \mathbb{Z}, \quad c \in M. \tag{1.2}$$

(a) *The original control points* ($\star$). (b) *The new control points* ($\circ$) *after one iteration.*

FIG. 1. *Illustration of the iterative procedure* (1.1).

Unless stated otherwise we sum over all the integers. The resulting subdivision scheme is then defined, for a given initial sequence $c \in M$, by

$$c^{(0)} = c, \quad c^{(r+1)} = Sc^{(r)}, \quad r = 0, 1, \ldots, \tag{1.3}$$

or, equivalently,

$$c^{(0)} = c, \quad c^{(r)} = S^r c, \quad r = 1, \ldots. \tag{1.4}$$

The sequence $a = \{a_j\}$ is called the *mask* of the subdivision scheme.

There is no unique or best way of obtaining a mask. One possibility is to demand that if the original control points fall on a polynomial of degree $2N + 1$, then the newly generated control points must also lie on the same polynomial. This is, in fact, the idea behind Dubuc–Deslauriers subdivision [15, 12], which is a symmetric interpolatory scheme. In section 2.1, we develop this idea to eventually calculate an explicit formulation of the resulting mask sequence $\{a_j\}$.

To investigate the convergence of Dubuc–Deslauriers subdivision, we first refer to a result by Micchelli [24], according to which there exists a compactly supported fundamental interpolant $\phi \in C(\mathbb{R})$ which is refinable with respect to the sequence $\{a_j\}$. We then deduce, in Theorem 2.1, further properties of ϕ, including polynomial reproduction and information on its zeros, which prove to be necessary for our arguments in the subsequent two sections. It can then be shown as in Theorem 2.2 below that Dubuc–Deslauriers subdivision converges in the sense that, at each step of the iteration, the subdivision sequence lies entirely on the limit curve.

The Dubuc–Deslauriers subdivision operator has the form (1.2) and is therefore formulated for bi-infinite sequences. In section 3 we consider the case of finite sequences and propose a method to adapt Dubuc–Deslauriers subdivision to this situation. We base our construction on a multiscale finite sequence of fundamental interpolants $\{\phi_j^r\}$ defined on a bounded interval. Away from the boundaries the integer shifts of the original functions ϕ suffice, while the adjustments in the proximity of the boundaries preserve the polynomial reproduction property of ϕ. The resulting

adapted interpolatory subdivision scheme, which corresponds to Dubuc–Deslauriers subdivision away from the boundaries, then also preserves the above-mentioned polynomial filling property. In fact, most results derived in this paper depend on these polynomial filling or polynomial reproduction properties.

Our main result, as proved in Theorem 3.2, is that, on each fixed level r, the sequence $\{\phi_j^r\}$ is refinable in the sense that the function ϕ_j^r can be expressed as a finite linear combination of the (finite) sequence $\{\phi_j^{r+1}(2\,\bullet)\}$. Using this result, it is then a simple matter to prove, in Theorem 3.3, that our adapted Dubuc–Deslauriers subdivision for finite sequences converges. We end section 3 by calculating an explicit formulation for this adapted scheme.

The refinability of the sequence $\{\phi_j^r\}$ allows a multiresolutional construction of interpolation wavelets on an interval, and we pursue this idea in section 4. The main result of this section is the direct sum (nonorthogonal) space decomposition of Theorem 4.1, by virtue of which we obtain compactly supported symmetric interpolation wavelets. By giving up orthogonality we describe here the construction of symmetric interpolation wavelets resulting in finite decomposition and reconstruction formulas with rational coefficients given by the values of certain Lagrange polynomials at half integers. Also, a connection between interpolation wavelet decomposition on an interval and the adapted subdivision of section 3 is explained.

Alternative approaches to the construction of wavelets on an interval include work by Daubechies [11, section 10.7] and Cohen, Daubechies, and Vial [9], in which periodization and related methods are used for the construction of orthonormal wavelet bases on an interval. In the spline setting, explicit constructions of symmetric biorthogonal spline wavelets on an interval, as well as the corresponding decomposition and reconstruction algorithms, appear in Chui and Quak [8], Quak and Weyrich [25], Chui and de Villiers [6], and Chui [5, section 7.3.2].

The connection between the compactly supported orthonormal wavelets of Daubechies [10, 11] and Dubuc–Deslauriers subdivision has been noted by several authors (see, e.g., [24, section 3]) and exploited for the construction of biorthogonal interpolatory wavelets by Beylkin and Saito [4] and Bertoluzza and Naldi [2, 3]. A further study of the relationship between interpolation processes and wavelets construction appears in the paper [21] by Lee, Sharma, and Tan.

The idea, as used here in section 4, to construct interpolation wavelets by means of a nonorthogonal linear space decomposition and an interpolation operator has been studied for wavelets on $\mathbb{R}$ by Chui and Li [7] and used in the context of the Sweldens lifting scheme in [27].

Our interpolation wavelet decomposition and reconstruction algorithms for finite data sets, as given by (4.32), (4.33), and (3.34)–(3.38) below, are identical to those derived by Aràndiga, Donat, and Harten [1, equations (55) and (56)]. Making use of ideas developed by Harten [17, 18], these authors derive their equations from a general framework—our approach has the advantage that it allows an explicit construction of the underlying refinable sequence $\{\phi_j^r\}$ as demonstrated by our equation (3.12). This is perhaps closer to the unpublished work of Donoho [13] in the sense that both are based on the principle of polynomial extrapolation. An essential difference, however, lies in the way in which the associated nested sequence of linear spaces $\{V_r\}$ is defined. While Donoho's construction is consistently based on a polynomial extrapolation operator, we define the linear space V_r as the span of the sequence $\{\phi_j^r\}$. The nesting property of the $\{V_r\}$ then follows from the refinability of $\{\phi_j^r\}$, as proved in Theorem 3.2 below.

Note that the wavelets constructed in this manner do not have vanishing moments —the mean of our wavelet is not zero. In this regard our wavelets are similar to those mentioned by Mallat [22, p. 301]. We show, however, that the corresponding interpolation wavelet space can be characterized in terms of a projection operator which is exact on polynomials, thereby causing the interpolation wavelet coefficients of a function to be relatively small in those regions where the function exhibits local polynomial-like behavior. For the construction of (nonorthogonal) interpolation wavelets on the interval with vanishing moments, we refer to Donoho [14].

In [26], Schröder and Sweldens develop algorithms implementing interpolation wavelets on an interval without providing detailed proofs.

The main algorithms are illustrated in the final section using examples from signature verification and two-dimensional image processing.

2. Dubuc–Deslauriers subdivision for bi-infinite sequences. In this section we introduce Dubuc–Deslauriers subdivision as an optimally local curve filling iterative procedure which reproduces polynomials of a given odd degree. We next prove the existence of an associated refinable function, which is then shown to provide a limit curve for the Dubuc–Deslauriers subdivision scheme.

2.1. Construction of the mask. For a given nonnegative integer N, consider the problem of finding a minimally supported mask a such that the $(2N+1)$th degree polynomial filling property

$$\sum_k a_{j-2k} p(k) = p\left(\frac{j}{2}\right), \quad j \in \mathbb{Z}, \quad p \in \pi_{2N+1}, \tag{2.1}$$

holds. Here π_{2N+1} denotes the linear space of polynomials of degree $\leq 2N+1$.

For this purpose we introduce the Lagrange fundamental polynomials $L_k \in \pi_{2N+1}$, $k = -N, \ldots, N+1$, as defined by

$$L_k(x) = \prod_{k \neq j = -N}^{N+1} \frac{x-j}{k-j}, \quad x \in \mathbb{R}, \quad k = -N, \ldots, N+1, \tag{2.2}$$

for which

$$L_k(j) = \delta_{k,j}, \quad k, j = -N, \ldots, N+1, \tag{2.3}$$

and

$$\sum_{k=-N}^{N+1} p(k) L_k(x) = p(x), \quad x \in \mathbb{R}, \quad p \in \pi_{2N+1}. \tag{2.4}$$

Setting $j = 0$ and $j = 1$ in (2.1), and using (2.3) and (2.4), the equation (2.1) implies

$$\left.\begin{aligned} a_{2j} + \sum_{k \notin \{-N,\ldots,N+1\}} a_{2k} L_{-j}(k) &= \delta_{j,0}, \\ a_{2j+1} + \sum_{k \notin \{-N,\ldots,N+1\}} a_{1-2k} L_{-j}(k) &= L_{-j}\left(\tfrac{1}{2}\right), \end{aligned}\right\} \; j = -N-1, \ldots, N. \tag{2.5}$$

A necessary condition for a minimally supported mask $a = \{a_j\}$ to satisfy (2.1) is thus

$$a_{2j} = \delta_{j,0}, \qquad j \in \mathbb{Z}, \tag{2.6a}$$

$$a_{2j+1} = L_{-j}\left(\tfrac{1}{2}\right), \quad j = -N-1, \dots, N, \tag{2.6b}$$

$$a_{2j+1} = 0, \qquad j \geq N+1 \text{ or } j \leq -N-2. \tag{2.6c}$$

The choice (2.6) is also sufficient to fulfill (2.1). In fact, if $j = 2m,\ \ m \in \mathbb{Z}$, then, for $p \in \pi_{2N+1}$, (2.6a) implies

$$\sum_k a_{j-2k} p(k) = \sum_k a_{2m-2k} p(k) = \sum_k a_{2k} p(m-k) = p(m) = p\left(\frac{j}{2}\right),$$

whereas if $j = 2m+1,\ m \in \mathbb{Z}$, then (2.6b), (2.6c), and (2.4) give

$$\sum_k a_{j-2k} p(k) = \sum_k a_{2k+1} p(m-k) = \sum_{k=-N-1}^{N} L_{-k}\left(\tfrac{1}{2}\right) p(m-k) = p\left(m+\tfrac{1}{2}\right) = p\left(\frac{j}{2}\right).$$

Hence the subdivision scheme corresponding to the mask (2.6), which was introduced by Deslauriers and Dubuc in [12], is indeed a minimally supported mask sequence $a = \{a_j\}$ for which (2.1) holds.

Observe that (1.2) implies, with reference to (1.3), the interpolatory property

$$c_{2j}^{(r+1)} = c_j^{(r)}, \quad j \in \mathbb{Z}, \ \ r = 0, 1, \dots, \tag{2.7}$$

by virtue of which Dubuc–Deslauriers subdivision is called an *interpolatory* scheme.

We now derive an explicit expression for the mask. Since, for $k \in \{-N, \dots, N+1\}$, we have

$$\prod_{k \neq j = -N}^{N+1} \left(\tfrac{1}{2} - j\right) = \frac{1}{2^{2N+1}} \, \frac{1}{1-2k} \prod_{j=-N-1}^{N} (2j+1) = \frac{(-1)^N}{2^{4N+1}} \frac{1}{2k-1} \left[\frac{(2N+1)!}{N!}\right]^2$$

and

$$\prod_{k \neq j = -N}^{N+1} (k-j) = (-1)^{N+1+k} (N+k)!(N+1-k)!,$$

we deduce from (2.6) and (2.2) that the Dubuc–Deslauriers mask sequence $a = \{a_j\}$ has the explicit formulation

$$\left.\begin{aligned} a_{2j+1} &= \frac{N+1}{2^{4N+1}} \binom{2N+1}{N} \frac{(-1)^j}{2j+1} \binom{2N+1}{N+j+1}, && j = -N-1, \dots, N, \\ a_{2j} &= \delta_{j,0}, && j = -N, \dots, N, \\ a_j &= 0, && |j| \geq 2N+2. \end{aligned}\right\} \tag{2.8}$$

For example, if $N = 1$, (2.8) gives

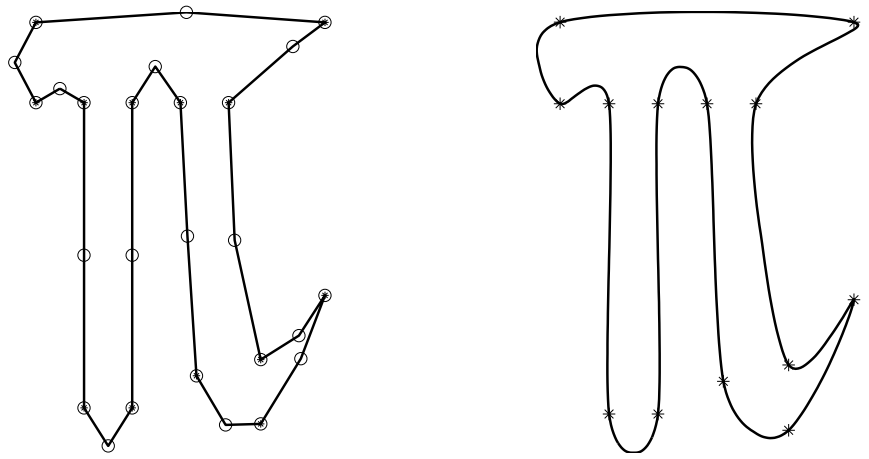
$$a_{2j+1} = \begin{cases} -\frac{1}{16}, & j = -2, \\ \frac{9}{16}, & j = -1, \\ \frac{9}{16}, & j = 0, \\ -\frac{1}{16}, & j = 1, \\ 0 & \text{otherwise.} \end{cases}$$

From (2.8) observe that the mask coefficients are symmetric, i.e.,

$$a_j = a_{-j}, \quad j \in \mathbb{Z}. \tag{2.9}$$

Therefore we call Dubuc–Deslauriers subdivision a *symmetric* scheme.

For $N = 0$, note that (2.8), (1.2), and (1.3) yield, for $r = 0$, the iteration procedure in (1.1). This subdivision scheme converges to a continuous piecewise linear function which interpolates the original control points (see Figure 1). In contrast, subdivision with the mask obtained by setting $N = 1$ in (2.8) converges to a smoother function, while still interpolating the original control points (see Figure 2). Incidentally, this example is not completely arbitrary. In fact Knuth based his construction of TEX fonts on ideas remarkably similar to subdivision schemes [19, Chapter 2], more than 10 years before the Dubuc–Deslauriers scheme was introduced in [12].



(a) *Original control points* ($\star$) *and one step of the subdivision algorithm* ($\circ$).

(b) *Original control points with limit curve.*

FIG. 2. *Illustration of Dubuc–Deslauriers subdivision for* $N = 1$.

We now show that, for any given initial sequence $c \in M$, the Dubuc–Deslauriers subdivision sequence $\{c^{(r)} : r = 0, 1, \dots\} \subset M$ converges to a limit curve which will be specified in terms of an associated refinable function.

2.2. The corresponding refinable function. Before investigating the convergence of Dubuc–Deslauriers subdivision, we establish the existence and properties of

the corresponding refinable function, following an approach employed by Micchelli in [24] (see also [16]).

THEOREM 2.1. *For any given nonnegative integer N, let the sequence $a = \{a_j\}$ be chosen as in* (2.6). *Then there exists a compactly supported function $\phi \in C(\mathbb{R})$ such that*

$$\phi(x) = \sum_j a_j \phi(2x - j), \quad x \in \mathbb{R}; \tag{2.10}$$

$$\phi(j) = \delta_{j,0}, \quad j \in \mathbb{Z}; \tag{2.11}$$

$$\phi(x) = 0, \quad x \notin (-2N - 1, 2N + 1); \tag{2.12}$$

$$\sum_j p(j)\phi(x - j) = p(x), \quad x \in \mathbb{R}, \quad p \in \pi_{2N+1}; \tag{2.13}$$

$$\phi(x) = \phi(-x), \quad x \in \mathbb{R}; \tag{2.14}$$

$$\phi\left(\frac{j}{2}\right) = a_j, \quad j \in \mathbb{Z}; \tag{2.15}$$

$$\phi(2N + 1 - 2^{-j}(N - \tfrac{1}{2} - k)) = 0, \quad k = 0, 1, \dots, \quad j = 0, 1, \dots. \tag{2.16}$$

Proof. The existence of a compactly supported function of $\phi \in C(\mathbb{R})$ satisfying the properties (2.10), (2.11), and (2.12) was proven in [24, Lemma 3.1, Theorem 4.1, and Corollary 4.1].

To prove (2.13), suppose $\ell \in \{0, 1, \dots, 2N + 1\}$, $k \in \mathbb{Z}$, and $r \in \{0, 1, \dots\}$. We shall prove that

$$\sum_j j^\ell \phi\left(\frac{k}{2^r} - j\right) = \left(\frac{k}{2^r}\right)^\ell, \tag{2.17}$$

which then implies (2.13), since the set $\{\frac{k}{2^r} : k \in \mathbb{Z}, \quad r = 0, 1, \dots\}$ is dense in $\mathbb{R}$, and since ϕ is a compactly supported continuous function on $\mathbb{R}$.

Noting that (2.17) is an immediate consequence of (2.11) if $r = 0$, we assume next that $r \geq 1$. Then, using consecutively (2.10), (2.1), and (2.11), we get

$$\begin{aligned}
\sum_j j^\ell \phi\left(\frac{k}{2^r} - j\right) &= \sum_j j^\ell \sum_m a_m \phi\left(\frac{k}{2^{r-1}} - 2j - m\right) \\
&= \sum_m \left[\sum_j a_{m-2j} j^\ell\right] \phi\left(\frac{k}{2^{r-1}} - m\right) \\
&= \frac{1}{2^\ell} \sum_m m^\ell \phi\left(\frac{k}{2^{r-1}} - m\right) \\
&\;\;\vdots \\
&= \frac{1}{2^{\ell r}} \sum_m m^\ell \phi(k - m) = \left(\frac{k}{2^r}\right)^\ell.
\end{aligned}$$

Similarly, the property (2.14) will be proved if we can show that, for $k \in \mathbb{Z}$ and $r \in \{0, 1, \dots\}$,

$$\phi\left(\frac{k}{2^r}\right) = \phi\left(-\frac{k}{2^r}\right). \tag{2.18}$$

For $r = 0$, (2.18) follows from (2.11), whereas for $r = 1$, it follows from (2.10), (2.9), and (2.11) that $\phi(-\frac{k}{2}) = \sum_j a_j \phi(-k - j) = \sum_j a_j \phi(-k + j) = \sum_j a_j \phi(k - j) = \phi(\frac{k}{2})$. If $r \geq 2$, we also use (1.2) to deduce that

$$\begin{aligned}
\phi\left(-\frac{k}{2^r}\right) &= \sum_j a_j \phi\left(-\frac{k}{2^{r-1}} - j\right) \\
&= \sum_j a_j \phi\left(-\frac{k}{2^{r-1}} + j\right) \\
&= \sum_j a_j \sum_\ell a_{-\ell} \phi\left(-\frac{k}{2^{r-2}} + 2j - \ell\right) \\
&= \sum_\ell \left[\sum_j a_{\ell-2j} a_j\right] \phi\left(-\frac{k}{2^{r-2}} + \ell\right) \\
&= \sum_\ell (Sa)_\ell \phi\left(-\frac{k}{2^{r-2}} + \ell\right) \\
&\;\;\vdots \\
&= \sum_\ell \left(S^{r-1}a\right)_\ell \phi(-k + \ell) = (S^{r-1}a)_k. \qquad (2.19)
\end{aligned}$$

A similar strategy shows that

$$\phi\left(\frac{k}{2^r}\right) = (S^{r-1}a)_k,$$

which, together with (2.19), proves (2.18) for $r \geq 2$.

Property (2.15) is an immediate consequence of (2.10) and (2.11).

Finally, we prove (2.16) by induction. For $j = 0$, property (2.16) follows from (2.15) and (2.6c). To advance the inductive hypothesis from j to $j + 1$, we use (2.10) and (2.6c) to deduce that, for $k \in \{0, 1, \dots\}$,

$$\begin{aligned}
\phi(2N + 1 - 2^{-(j+1)}(N - \tfrac{1}{2} - k)) &= \sum_\ell a_\ell \phi(4N + 2 - 2^{-j}(N - \tfrac{1}{2} - k) - \ell) \\
&= \sum_{\ell=0}^{4N+2} a_{2N+1-\ell} \phi(2N + 1 - 2^{-j}(N - \tfrac{1}{2} - [k + 2^j \ell])).
\end{aligned}$$

Using (2.12) we complete the proof. □

Remarks.

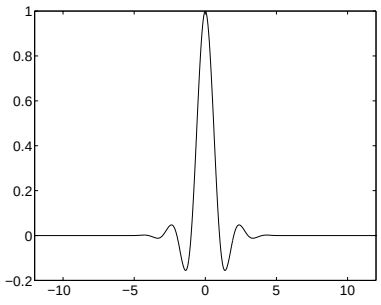
1. Equations (2.10) and (2.15) imply

$$\phi(x) = \sum_j \phi\left(\frac{j}{2}\right) \phi(2x - j), \quad x \in \mathbb{R}. \tag{2.20}$$

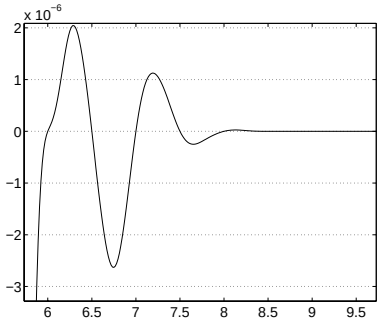
2. Equations (2.14) and (2.16) imply

$$\phi(-2N-1+2^{-j}(N-\tfrac{1}{2}-k))=0, \quad k=0,1,\ldots, \quad j=0,1,\ldots. \tag{2.21}$$

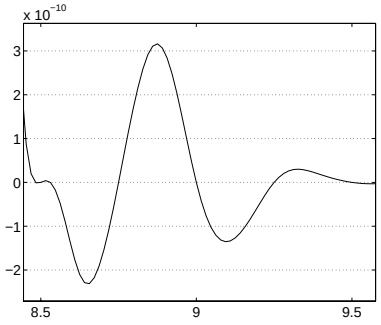
3. For $k \geq N$, (2.16) and (2.21) hold because the argument falls outside the support of ϕ, while for $k = 0, 1, \ldots, N-1$ the argument falls within the support. This in turn implies that ϕ has an infinite number of zeros within its support and that these zeros are clustered more densely toward the edges of the support, as illustrated in Figure 3.
4. A detailed study of the regularity of ϕ as a function of N is given in [12].



(a) ϕ *for* $N = 5$.



(b) *Magnification of* ϕ.



(c) *Further magnification of* ϕ.

FIG. 3. *Illustration of the refinable function with clustered zeros.*

2.3. Convergence of the subdivision scheme. We now show that the Dubuc–Deslauriers subdivision scheme converges in the sense that, for each $r \in \{0, 1, \ldots, \}$, the sequence $c^{(r)}$ lies entirely on the limit curve.

THEOREM 2.2. *For each initial sequence* $c = \{c_j\} \in M$, *the Dubuc–Deslauriers subdivision scheme* (1.3), (1.2), *and* (2.6) *converges to the function*

$$f(x) = \sum_j c_j \phi(x-j), \quad x \in \mathbb{R}, \tag{2.22}$$

with ϕ *defined as in Theorem* 2.1, *in the sense that*

$$c_k^{(r)} = f\left(\frac{k}{2^r}\right), \quad k \in \mathbb{Z}, \quad r = 0, 1, \ldots. \tag{2.23}$$

Proof. If $r = 0$, then (2.23) follows from (2.11). For $r \geq 1$, we use (2.10), (1.2), (1.3), and (2.11) to deduce, for $k \in \mathbb{Z}$,

$$\begin{aligned} f\left(\frac{k}{2^r}\right) &= \sum_j c_j \phi\left(\frac{k}{2^r} - j\right) \\ &= \sum_j c_j \sum_\ell a_{\ell-2j} \phi\left(\frac{k}{2^{r-1}} - \ell\right) \\ &= \sum_\ell (Sc)_k \phi\left(\frac{k}{2^{r-1}} - \ell\right) \\ &\;\;\vdots \\ &= \sum_\ell (S^r c)_\ell \phi(k-\ell) = (S^r c)_k = c_k^{(r)}, \end{aligned}$$

the last equality by virtue of (1.4). ∎

3. A modified subdivision scheme for finite sequences. The algorithms for bi-infinite sequences, as described in the previous sections, are applied mainly in the case of periodic sequences. For finitely supported sequences these algorithms must be modified to accommodate the boundaries. We consider here a method of adapting the Dubuc–Deslauriers subdivision scheme of section 2 to the situation where the initial sequence c is finite.

3.1. Construction of a modified scheme. We first show that refinable functions defined on an interval allow one to construct a subdivision scheme for finite sequences. We derive the specific properties of these refinable functions from those of the refinable (on $\mathbb{R}$) function ϕ of section 2, with appropriate modifications near the boundaries.

With N as in section 2, assume n is a positive integer with $n \geq 4N + 2$, and let r be a nonnegative integer. On the basis of Theorem 2.1, and the subsequent equation (2.20), we seek to construct a sequence $\{\phi_j^r\} = \{\phi_j^r : j = 0, 1, \ldots, 2^r n, \quad r = 0, 1, \ldots\}$ such that, for each fixed r,

$$\phi_j^r \in C[0, 2^r n], \quad j = 0, 1, \ldots, 2^r n; \tag{3.1}$$

$$\phi_j^r(x) = 0, \; x \notin \begin{cases} [0, 2N+1+j), & j = 0, 1, \ldots, 2N+1, \\ (-2N-1+j, 2N+1+j), & j = 2N+2, \ldots, 2^r n - 2N - 2, \\ (-2N-1+j, 2^r n], & j = 2^r n - 2N - 1, \ldots, 2^r n; \end{cases} \tag{3.2}$$

$$\phi_j^r(k) = \delta_{j,k}, \quad j, k = 0, 1, \ldots, 2^r n; \tag{3.3}$$

$$\sum_{j=0}^{2^r n} p(j) \phi_j^r(x) = p(x), \quad x \in [0, 2^r n], \quad p \in \pi_{2N+1}; \tag{3.4}$$

$$\phi_j^r(x) = \sum_{k=0}^{2^{r+1} n} \phi_j^r\left(\frac{k}{2}\right) \phi_k^{r+1}(2x), \quad x \in [0, 2^r n], \quad j = 0, 1, \ldots, 2^r n. \tag{3.5}$$

Denoting the linear space of vector-valued sequences

$$c = \{c_j\} = \{c_j : j = 0, 1, \dots, 2^r n\}$$

by M_r, the subdivision operator sequence $\{S_r : r = 0, 1, \dots, \dots\}$ for $S_r : M_r \to M_{r+1}$ is then defined by

$$(S_r c)_j = \sum_{k=0}^{2^r n} \phi_k^r \left(\frac{j}{2}\right) c_k, \quad j = 0, 1, \dots, 2^{r+1} n. \tag{3.6}$$

The corresponding subdivision scheme is defined by

$$c^{(0)} = c \in M_0, \quad c^{(r+1)} = S_r c^{(r)}, \quad r = 0, 1, \dots, \tag{3.7}$$

or, equivalently,

$$c^{(0)} = c, \quad c^{(r+1)} = S_r(\dots(S_1(S_0 c))\dots), \quad r = 0, 1, \dots. \tag{3.8}$$

Observe that (3.3), (3.6), and (3.7) imply

$$c_{2j}^{(r+1)} = c_j^{(r)}, \quad j = 0, 1, \dots, 2^r n, \quad r = 0, 1, \dots, \tag{3.9}$$

i.e., the subdivision scheme (3.6)–(3.7) is interpolatory, whereas (3.4) implies

$$\sum_{k=0}^{2^r n} \phi_k^r \left(\frac{j}{2}\right) p(k) = p\left(\frac{j}{2}\right), \quad j = 0, 1, \dots, 2^{r+1} n, \quad p \in \pi_{2N+1}, \tag{3.10}$$

according to which the subdivision scheme (3.6)–(3.7) has the $(2N+1)$th degree polynomial filling property. In (3.6)–(3.10) we have obtained the analogues of, respectively, (1.2), (1.3), (1.4), (2.7), and (2.1).

To find a sequence $\{\phi_j^r\}$ satisfying (3.1)–(3.5), we observe from (2.12) and (2.13) that

$$\sum_{j=0}^{2^r n} p(j)\phi(x-j) = \sum_j p(j)\phi(x-j) = p(x), \quad x \in [2N, 2^r n - 2N], \quad p \in \pi_{2N+1}. \tag{3.11}$$

Thus, the sequence $\{\phi(\cdot - j)\}$ provides suitable refinable functions away from the boundaries. The boundary modifications can again be based on property (2.1). Using arguments similar to the ones which led to the construction of the mask (2.6), we define, for each fixed $r \in \{0, 1, \dots\}$, the sequence $\{\phi_j^r\}$ on the interval $[0, 2^r n]$ by

$$\phi_j^r(x) = \phi(x-j) + \sum_{k=-2N}^{-1} L_{j-N}(k-N)\phi(x-k), \quad j = 0, 1, \dots, 2N+1, \tag{3.12a}$$

$$\phi_j^r(x) = \phi(x-j), \quad j = 2N+2, \dots, 2^r n - 2N - 2, \tag{3.12b}$$

$$\phi_j^r(x) = \phi_{2^r n - j}^r(2^r n - x), \quad j = 2^r n - 2N - 1, \dots, 2^r n, \tag{3.12c}$$

where the sequence $\{L_k : k = -N, \dots, N+1\} \subset \pi_{2N+1}$ is given by (2.2). Examples are plotted in Figure 4.

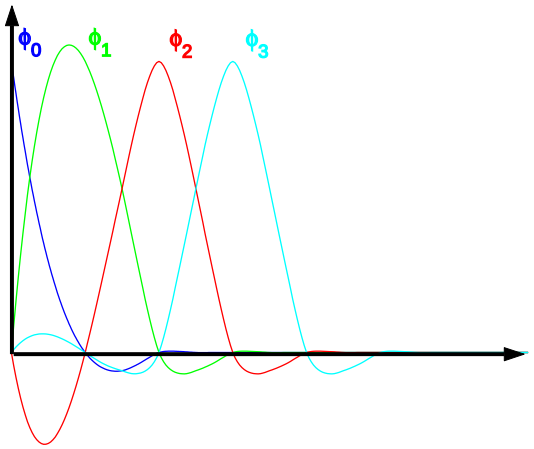


FIG. 4. *Illustration of definition* (3.12) *with* $N = 1$.

Using

$$\phi\left(N + \frac{3}{2} + k\right) = 0, \quad k = 0, 1, 2, \ldots, \tag{3.13}$$

and

$$\phi\left(-N - \frac{3}{2} - k\right) = 0, \quad k = 0, 1, 2, \ldots, \tag{3.14}$$

which follow from (2.16) and (2.21), we prove the following useful properties of the sequence $\{\phi_j^{(r)}\}$.

PROPOSITION 3.1. *For given nonnegative integers* N *and* r*, let* n *be an integer with* $n \geq 4N + 2$*. Then the sequence* $\{\phi_j^r\}$*, as defined by* (3.12)*, satisfies*

$$\phi_j^r(x) = \phi(x - j), \qquad x \in [2N, 2^r n - 2N], \quad j = 0, 1, \ldots, 2^r n, \tag{3.15}$$

$$\phi_j^r(x) = L_{j-N}(x - N), \quad x \in [0, 1], \quad j = 0, \ldots, 2N + 1, \tag{3.16}$$

$$\phi_j^r\left(\frac{k}{2}\right) = \begin{cases} L_{j-N}(\frac{k}{2} - N), & k = 0, \ldots, 2N + 1, \\ \phi(\frac{k}{2} - j), & k = 2N, \ldots, \end{cases} \qquad j = 0, \ldots, 2N + 1. \tag{3.17}$$

Proof. For $j = 0, \ldots, 2^r n - 2N - 2$, (3.15) follows from the definition (3.12) and the finite support (2.12) of ϕ. It therefore suffices to prove (3.15) for $j = 2^r n - 2N - 1, \ldots, 2^r n$. But then, from (3.12c), and (3.12a),

$$\phi_j^r(x) = \phi_{2^r n - j}^r(2^r n - x) = \phi(-x + j) = \phi(x - j),$$

by virtue of (2.14).

To prove (3.16), suppose $x \in [0, 1]$ and $j \in \{0, 1, \ldots, 2N+1\}$. Then (3.12a), (2.3),

and (2.12) yield

$$\phi_j^r(x) = \sum_{k=-2N}^{2N+1} L_{j-N}(k-N)\phi(x-k)$$
$$= \sum_k L_{j-N}(k-N)\phi(x-k) = L_{j-N}(x-N),$$

by virtue of (2.13).

For the proof of (3.17), we first let $k \in \{0,1,\dots,2N+1\}$ and $j \in \{0,1,\dots,2N+1\}$. Then, using consecutively (3.12a), (2.3), (3.14), (2.12), and (2.13), we get

$$\phi_j^r\left(\frac{k}{2}\right) = \phi\left(\frac{k}{2}-j\right) + \sum_{\ell=-2N}^{-1} L_{j-N}(\ell-N)\phi\left(\frac{k}{2}-\ell\right) \tag{3.18}$$
$$= \sum_{\ell=-2N}^{2N+1} L_{j-N}(\ell-N)\phi\left(\frac{k}{2}-\ell\right)$$
$$= \sum_{\ell=-2N}^{3N+1} L_{j-N}(\ell-N)\phi\left(\frac{k}{2}-\ell\right)$$
$$= \sum_{\ell} L_{j-N}(\ell-N)\phi\left(\frac{k}{2}-\ell\right)$$
$$= L_{j-N}\left(\frac{k}{2}-N\right). \tag{3.19}$$

Next, for $k \in \{2N+2,\dots\}$ and $j \in \{0,1,\dots,2N+1\}$, we see that (3.18) holds again, and the bottom part of (3.17) therefore follows since $\phi(\frac{k}{2}-\ell) = 0,\ \ell = -2N,\dots,-1$, by virtue of (2.11) and (3.13).

To complete the proof of (3.17), it remains to show that for $j \in \{0,1,\dots,2N+1\}$, we have

$$\phi\left(\frac{k}{2}-j\right) = L_{j-N}\left(\frac{k}{2}-N\right) \quad \text{for} \quad k = 2N \text{ and } k = 2N+1. \tag{3.20}$$

For $k = 2N$, the property (3.20) is a consequence of (2.11) and (2.3), whereas for $k = 2N+1$ we use (2.15) and (2.6b) to deduce that

$$\phi\left(\frac{k}{2}-j\right) = a_{2N+1-2j} = L_{j-N}\left(\frac{1}{2}\right) = L_{j-N}\left(\frac{k}{2}-N\right). \qquad \square$$

Remark. Observe from (3.15) and (3.12a), (3.12b), together with the support properties (3.2) and (2.12), that

$$\phi_j^r(x) = \phi(x-j), \quad x \in [2N, 2^r n], \quad j = 0,1,\dots,2^r n - 2N - 2. \tag{3.21}$$

3.2. The refinability of the sequence $\{\phi_j^r\}$. Analogous to the bi-infinite case, our proof in section 3.3 below of the convergence of the subdivision scheme will depend on the refinability of the sequence $\{\phi_j^r\}$, as proved in this section.

THEOREM 3.2. *The sequence $\{\phi_j^r\}$, as defined in* (3.12)*, satisfies the properties* (3.1)–(3.5).

Proof. The properties (3.1)–(3.3) are immediate consequences of (2.11) and (2.12).

To prove (3.4), we choose $p \in \pi_{2N+1}$ and assume first that $x \in [0, 2N)$. Using (3.2), (3.12a), (3.12b), (2.4), (2.12), and (2.13) consecutively, one has

$$\begin{aligned}\sum_{j=0}^{2^r n} p(j)\phi_j^r(x) &= \sum_{j=0}^{4N} p(j)\phi_j^r(x) \\ &= \sum_{j=0}^{4N} p(j)\phi(x-j) + \sum_{k=-2N}^{-1}\left[\sum_{j=0}^{2N+1} p(j)L_{j-N}(k-N)\right]\phi(x-k) \\ &= \sum_{j=-2N}^{4N} p(j)\phi(x-j) = \sum_{j} p(j)\phi(x-j) = p(x).\end{aligned}$$

For $x \in [2N, 2^r n - 2N]$, the property (3.4) follows from (3.15) and (3.11). Similar arguments establish polynomial reproduction for $x \in (2^r n - 2N, 2^r n]$.

To prove the refinability (3.5), assume first that $j \in \{0, 1, \ldots, 2N+1\}$ and $x \in [0, 2N)$. Then (3.12a) and (2.3) imply

$$\phi_j^r(x) = \sum_{k=-2N}^{2N+1} L_{j-N}(k-N)\phi(x-k).$$

Now, use the refinement equation (2.20), together with the support property (2.12), to obtain

$$\phi_j^r(x) = \sum_{\ell=-2N}^{6N}\left[\sum_{k=-2N}^{2N+1} L_{j-N}(k-N)\phi\left(\frac{\ell}{2}-k\right)\right]\phi(2x-\ell). \tag{3.22}$$

For the first part of the sum in (3.22) we get, from (2.11), (3.13), (3.14), the polynomial reproduction (2.13), and definition (3.12a),

$$\begin{aligned}&\sum_{\ell=-2N}^{2N+1}\left[\sum_{k=-2N}^{2N+1} L_{j-N}(k-N)\phi\left(\frac{\ell}{2}-k\right)\right]\phi(2x-\ell) \\ &= \sum_{\ell=-2N}^{2N+1}\left[\sum_{k} L_{j-k}(k-N)\phi\left(\frac{\ell}{2}-k\right)\right]\phi(2x-\ell) \\ &= \sum_{\ell=-2N}^{2N+1} L_{j-N}\left(\frac{\ell}{2}-N\right)\phi(2x-\ell) \\ &= \sum_{\ell=-2N}^{-1} L_{j-N}\left(\frac{\ell}{2}-N\right)\phi(2x-\ell) + \sum_{\ell=0}^{2N+1} L_{j-N}\left(\frac{\ell}{2}-N\right)\phi_\ell^{r+1}(2x) \\ &\qquad - \sum_{k=-2N}^{-1}\left[\sum_{\ell=0}^{2N+1} L_{j-N}\left(\frac{\ell}{2}-N\right)L_{\ell-N}(k-N)\right]\phi(2x-k) \\ &= \sum_{\ell=0}^{2N+1} L_{j-N}\left(\frac{\ell}{2}-N\right)\phi_\ell^{r+1}(2x) \;=\; \sum_{\ell=0}^{2N+1}\phi_j^r\left(\frac{\ell}{2}\right)\phi_\ell^{r+1}(2x),\end{aligned} \tag{3.23}$$

having also used the polynomial reproduction (2.4) and (3.17).

For the remaining part of the sum in (3.22), we use the interpolatory properties (2.3) and (2.11), as well as (3.13) and (3.17), to obtain

$$\begin{aligned}
&\sum_{\ell=2N+2}^{6N}\left[\sum_{k=-2N}^{2N+1} L_{j-N}(k-N)\phi\left(\frac{\ell}{2}-k\right)\right]\phi(2x-\ell)\\
&\quad=\sum_{\ell=2N+2}^{6N}\phi\left(\frac{\ell}{2}-j\right)\phi(2x-\ell)\\
&\quad=\sum_{\ell=2N+2}^{6N}\phi_j^r\left(\frac{\ell}{2}\right)\phi_\ell^{r+1}(2x)=\sum_{\ell=2N+2}^{2^{r+1}n}\phi_j^r\left(\frac{\ell}{2}\right)\phi_\ell^{r+1}(2x), \qquad (3.24)
\end{aligned}$$

where we also used the definition (3.12b) and the inequality $n \geq 4N+2$. Combining (3.22), (3.23), and (3.24) then yields the result (3.5) for $j \in \{0,1,\ldots,2N+1\}$ and $x \in [0,2N)$.

Next, for $j \in \{0,1,\ldots,2N+1\}$ and $x \in [2N, 2N+1+j)$, we use Proposition 3.1, Theorem 2.1, and (3.13) to get

$$\begin{aligned}
\phi_j^r(x)=\phi(x-j)&=\sum_k \phi\left(\frac{k}{2}-j\right)\phi(2x-k)\\
&=\sum_{k=2N}^{4N+2j+2}\phi\left(\frac{k}{2}-j\right)\phi(2x-k)\\
&=\sum_{k=2N}^{4N+2j+2}\phi_j^r\left(\frac{k}{2}\right)\phi_k^{r+1}(2x)\\
&=\sum_{k=0}^{2^{r+1}n}\phi_j^r\left(\frac{k}{2}\right)\phi_k^{r+1}(2x),
\end{aligned}$$

since $n \geq 4N+2$, thereby establishing (3.5) for this subcase.

For $j \in \{0,1,\ldots,2N+1\}$ and $x \in [2N+1+j, 2^r n]$, we deduce from (3.2), (3.17), (2.11), and (3.13) that

$$\begin{aligned}
\sum_{k=0}^{2^{r+1}n}\phi_j^r\left(\frac{k}{2}\right)\phi_k^{r+1}(2x)&=\sum_{k=2N+2+2j}^{4N+1+2j}\phi_j^r\left(\frac{k}{2}\right)\phi_k^{r+1}(2x)\\
&=\sum_{k=2N+2+2j}^{4N+1+2j}\phi\left(\frac{k}{2}-j\right)\phi_k^{r+1}(2x) \;=\; 0=\phi_j^r(x),
\end{aligned}$$

by virtue of the top part of (3.2). Hence we have established equation (3.5) for all $j \in \{0,1,\ldots,2N+1\}$.

Now consider the case $j \in \{2N+2,\ldots,2^r n-2N-2\}$ and $x \in (-2N-1+j,\ 2N+1+j)$. We use definition (3.12b), (2.20), (2.12), as well as (3.13) and the finite

support property (3.2), to find that

$$\begin{aligned}\phi_j^r(x) = \phi(x-j) &= \sum_{k=-2N-1+2j}^{2N+1+2j} \phi\left(\frac{k}{2}-j\right)\phi(2x-k)\\ &= \sum_{k=-2N-1+2j}^{2N+1+2j} \phi\left(\frac{k}{2}-j\right)\phi_k^{r+1}(2x)\\ &= \sum_{k=0}^{2^{r+1}n} \phi\left(\frac{k}{2}-j\right)\phi_k^{r+1}(2x)\\ &= \sum_{k=0}^{2^{r+1}n} \phi_j^r\left(\frac{k}{2}\right)\phi_k^{r+1}(2x),\end{aligned}$$

based on the inequalities $-2N-1+2j \geq 2N+3$ and $2N+1+2j \leq 2^{r+1}n-2N-3$.

For $j \in \{2N+2,\ldots,2^r n-2N-2\}$ and $x \in [0,-2N-1+j]$, we use (3.2), (3.12b), (2.11), and (3.14) to get

$$\sum_{k=0}^{2^{r+1}n} \phi_j^r\left(\frac{k}{2}\right)\phi_k^{r+1}(2x) \;=\; \sum_{k=0}^{-2N-2+2j} \phi\left(\frac{k}{2}-j\right)\phi_k^{r+1}(2x) \;=\; 0 \;=\phi_j^r(x).$$

Similarly, for $j \in \{2N+2,\ldots,2^r n-2N-2\}$ and $x \in [2N+1+j,\ 2^r n]$, with (3.13), we have

$$\sum_{k=0}^{2^{r+1}n} \phi_j^r\left(\frac{k}{2}\right)\phi_k^{r+1}(2x) \;=\; \sum_{k=2N+2+2j}^{2^{r+1}n} \phi\left(\frac{k}{2}-j\right)\phi_k^{r+1}(2x) \;=\; 0 \;=\phi_j^r(x).$$

Hence (3.5) also holds for $j \in \{2N+2,\ldots,2^r n-2N-2\}$.

Finally, let $j \in \{2^r n-2N-1,\ldots,2^r n\}$ and $x \in [0,2^r n]$. Then (3.12c), together with the fact that (3.5) holds for $j \in \{0,1,\ldots,2N+1\}$, gives

$$\begin{aligned}\phi_j^r(x) &= \phi_{2^r n-j}^r(2^r n-x)\\ &= \sum_{k=0}^{2^{r+1}n} \phi_{2^r n-j}^r\left(\frac{k}{2}\right)\phi_k^{r+1}\left(2^{r+1}n-2x\right)\\ &= \sum_{k=0}^{2^{r+1}n} \phi_{2^r n-j}^r\left(2^r n-\frac{k}{2}\right)\phi_{2^{r+1}n-k}^{r+1}(2^{r+1}n-2x)\\ &= \sum_{k=0}^{2^{r+1}n} \phi_j^r\left(\frac{k}{2}\right)\phi_{2^{r+1}n-k}^{r+1}(2^{r+1}n-2x).\end{aligned}$$

We claim that

$$\phi_{2^{r+1}n-k}^{r+1}(2^{r+1}n-2x) = \phi_k^{r+1}(2x), \quad x \in [0,2^r n], \quad k=0,1,\ldots,2^{r+1}n, \tag{3.25}$$

which, if true, completes the proof of the theorem. Definition (3.12c) implies that (3.25) is true for $k \in \{0,1,\ldots,2N+1\} \cup \{2^r n-2N-1,\ldots,2^r n\}$, whereas if $k \in \{2N+2,\ldots,2^r n-2N-2\}$, we find that (3.12b) and (2.14) yield, for $x \in [0,2^r n]$,

$$\phi_{2^{r+1}n-k}^{r+1}(2^{r+1}n-2x) = \phi(k-2x) = \phi(2x-k) = \phi_k^{r+1}(2x). \qquad \square$$

3.3. Convergence of the modified subdivision scheme. We now prove the analogue of Theorem 2.2 for *finite* subdivision sequences.

THEOREM 3.3. *For each initial sequence $c = \{c_j\} \in M_0$, the subdivision scheme* (3.6)–(3.7) *converges to the function*

$$g(x) = \sum_{j=0}^{n} c_j \phi_j(x), \quad x \in [0, n], \tag{3.26}$$

with $\phi_j = \phi_j^0$ defined as in (3.12)*, in the sense that*

$$c_k^{(r)} = g\left(\frac{k}{2^r}\right), \quad k = 0, 1, \ldots, 2^r n, \quad r = 0, 1, \ldots. \tag{3.27}$$

Proof. Repeatedly using (3.5), (3.6), (3.7), and eventually (3.3), for $k \in \{0, 1, \ldots, 2^r n\}$ and $r \in \{0, 1, \ldots\}$, we obtain

$$\begin{aligned} g\left(\frac{k}{2^r}\right) &= \sum_{j=0}^{n} c_j \phi_j^0\left(\frac{k}{2^r}\right) \\ &= \sum_{j=0}^{n} c_j \sum_{\ell=0}^{2n} \phi_j^0\left(\frac{\ell}{2}\right) \phi_\ell^1\left(\frac{k}{2^{r-1}}\right) \\ &= \sum_{\ell=0}^{2n} c_\ell^{(1)} \phi_\ell^1\left(\frac{k}{2^{r-1}}\right) \\ &\;\;\vdots \\ &= \sum_{\ell=0}^{2^r n} c_\ell^{(r)} \phi_\ell^r(k) = c_k^{(r)}. \end{aligned}$$

□

3.4. An explicit formulation. We derive an explicit formulation for the subdivision scheme (3.6)–(3.7).

Let $c \in M_r$. Then, from the subdivision operator definition (3.6), we obtain

$$(S_r c)_{2j+1} = \sum_{k=0}^{2^r n} \phi_k^r\left(j + \tfrac{1}{2}\right) c_k, \quad j = 0, 1, \ldots, 2^r n - 1, \tag{3.28}$$

and thus, using also (3.12b), (3.14), and the top of (3.17), we get

$$(S_r c)_{2j+1} = \sum_{k=0}^{2N+1} L_{k-N}\left(j + \tfrac{1}{2} - N\right) c_k, \quad j = 0, 1, \ldots, N. \tag{3.29}$$

Next, we claim that

$$(S_r c)_{2j+1} = \sum_{k=-N+j}^{N+1+j} L_{k-j}\left(\tfrac{1}{2}\right) c_k, \quad j = N+1, \ldots, 2^r n - 2N - 2. \tag{3.30}$$

Indeed, if $j \in \{N+1, \ldots, 2N-1\}$, then (3.28), (3.2), (3.17), (3.12b), (2.15), and (2.6c) yield

$$(S_r c)_{2j+1} = \sum_{k=0}^{4N} \phi\left(j + \tfrac{1}{2} - k\right) c_k = \sum_{k=-N+j}^{N+1+j} a_{2j+1-2k} c_k,$$

and (3.30) then follows from (2.6b) for that range of j. Similarly, if $j \in \{2N, \ldots, 2^r n - 2N - 2\}$, we additionally use (3.15) to get

$$(S_r c)_{2j+1} = \sum_{k=0}^{2^r n} \phi\left(j + \tfrac{1}{2} - k\right) c_k = \sum_{k=-N+j}^{N+1+j} a_{2j+1-2k} c_k,$$

which, together with (2.6b), then proves (3.30).

For $j \in \{2^r n - 2N - 1, \ldots, 2^r n - 1\}$, we first note the symmetry

$$\phi_k^r(x) = \phi_{2^r n-k}^r(2^r n - x), \quad x \in [0, 2^r n], \quad k = 0, 1, \ldots, 2^r n, \tag{3.31}$$

which follows from (3.12c), and the fact that, for $k \in \{2N + 2, \ldots, 2^r n - 2N - 2\}$, (3.12b) and (2.14) give

$$\phi_{2^r n-k}^r(2^r n - x) = \phi(k - x) = \phi(x - k) = \phi_k^r(x).$$

Thus, from (3.31),

$$\begin{aligned} \phi_k^r\left(j + \tfrac{1}{2}\right) = \phi_{2^r n-k}^r\left((2^r n - 1 - j) + \tfrac{1}{2}\right), \qquad & k = 0, 1, \ldots, 2^r n, \\ & j = 2^r n - 2N - 1, \ldots, 2^r n - 1. \end{aligned} \tag{3.32}$$

Combining (3.29), (3.30), (3.32), and using (3.9), we find that the subdivision scheme (3.6)–(3.7) has, for a given initial sequence $c^{(0)} = c \in M_0$, the explicit formulation

$$\left.\begin{aligned} c_{2j}^{(r+1)} &= c_j^{(r)}, && j = 0, 1, \ldots, 2^r n, \\ c_{2j+1}^{(r+1)} &= \sum_{k=0}^{2^r n} a_{j,k}^{(r)} c_k^{(r)}, && j = 0, 1, \ldots 2^r n - 1, \end{aligned}\right\} \quad r = 0, 1, \ldots, \tag{3.33}$$

where

$$a_{j,k}^{(r)} = \begin{cases} L_{k-N}\left(j + \frac{1}{2} - N\right), & k = 0, 1, \ldots, 2N + 1, \\ 0, & k = 2N + 2, \ldots, 2^r n, \end{cases} \quad \begin{array}{l} j = 0, 1, \ldots, N - 1, \\ \text{(if } N \geq 1\text{)}, \end{array} \tag{3.34}$$

$$a_{j,k}^{(r)} = \begin{cases} L_{k-j}(\frac{1}{2}), & k = -N + j, \ldots, N + 1 + j, \\ 0, & k \in [0, -N - 1 + j] \cup [N + 2 + j, 2^r n], \end{cases} \quad j = N, \ldots, 2^r n - N - 1, \tag{3.35}$$

$$a_{j,k}^{(r)} = a_{2^r n-1-j,2^r n-k}^{(r)}, \quad k = 0, 1, \ldots, 2^r n, j = 2^r n - N, \ldots, 2^r n - 1. \tag{3.36}$$

Explicit formulations of (3.34) and (3.35) are now obtained by using a calculation similar to the one which yielded the top of (2.8). We find that, for $k = 0, 1, \ldots, 2N+1$ and $j = 0, 1, \ldots, N - 1$,

$$L_{k-N}(j + \tfrac{1}{2} - N) = \frac{(-1)^{j+k}}{2^{4N+1}} \frac{1}{2j + 1 - 2k} \frac{(2j + 1)!(4N + 1 - 2j)!}{(2N - j)!(2N + 1 - k)!j!k!}, \tag{3.37}$$

whereas for $k = -N + j, \dots, N + 1 + j$ and $j = N, \dots, 2^r n - N - 1$,

$$L_{k-j}(\tfrac{1}{2}) = \frac{N+1}{2^{4N+1}} \binom{2N+1}{N} \frac{(-1)^{j+k}}{2j+1-2k} \binom{2N+1}{N+1+j-k}. \tag{3.38}$$

For example, if $N = 1$, (3.34) and (3.38) give

$$a_{0,k}^{(r)} = \begin{cases} \frac{5}{16}, & k = 0, \\ \frac{15}{16}, & k = 1, \\ -\frac{5}{16}, & k = 2, \\ \frac{1}{16}, & k = 3, \\ 0, & k = 4, \dots, 2^r n. \end{cases}$$

4. Interpolation wavelets on an interval. We show how the refinable sequence $\{\phi_j^r : j = 0, 1, \dots, 2^r n,\ r = 0, 1, \dots\}$ of section 3 can be used to explicitly construct interpolation wavelets on an interval. Our definition in (4.10) below coincides, in an inner region bounded away from the endpoints, with the definition of interpolation wavelets on $\mathbb{R}$ as given in, e.g., [7, equation (1.11)], [22, p. 300], and [27, p. 193].

4.1. Decomposition based on interpolation. Let the integers N and $n \geq 4N + 2$ be as in section 3, and let R be a given positive integer. We define the linear space sequence $\{V_r : r = 0, 1, \dots, R\}$ by

$$V_r = \operatorname{span}\{\phi_j^r(2^{r-R}\,\bullet) : j = 0, 1, \dots, 2^r n\}, \quad r = 0, 1, \dots, R, \tag{4.1}$$

and the linear operator sequence $\{P_r : r = 0, 1, \dots, R\}$ for $P_r : C[0, 2^R n] \to V_r$ by

$$(P_r f)(x) = \sum_{j=0}^{2^r n} f(2^{R-r} j)\phi_j^r(2^{r-R} x), \quad x \in [0, 2^R n], \quad r = 0, 1, \dots, R. \tag{4.2}$$

It follows from (3.3) that P_r is an interpolation operator, which means that, for each $f \in C[0, 2^R n]$,

$$(P_r f)(2^{R-r} j) = f(2^{R-r} j), \quad j = 0, \dots, 2^r n, \quad r = 0, 1, \dots, R. \tag{4.3}$$

Also, a proof based on (3.3) shows that P_r is a projection on V_r. Thus,

$$P_r f = f, \quad f \in V_r. \tag{4.4}$$

Furthermore, (3.4) gives

$$\sum_{j=0}^{2^r n} p(2^{R-r} j)\phi_j^r(2^{r-R} x) = p(x), \quad x \in [0, 2^R n], \quad p \in \pi_{2N+1}, \quad r = 0, 1, \dots, R, \tag{4.5}$$

by virtue of which

$$\pi_{2N+1} \subset V_r, \quad r = 0, 1, \dots, R, \tag{4.6}$$

where here π_{2N+1} is restricted to the interval $[0, 2^R n]$.

Since (3.5) yields the refinement equation

$$\phi_j^r(2^{r-R}x) = \sum_{k=0}^{2^{r+1}n} \phi_j^r\left(\frac{k}{2}\right)\phi_k^{r+1}(2^{r+1-R}x), \quad x \in [0, 2^R n], \quad j = 0, 1, \ldots, 2^r n, \quad r = 0, \ldots, R-1, \tag{4.7}$$

we have the nesting property

$$V_r \subset V_{r+1}, \quad r = 0, 1, \ldots, R-1. \tag{4.8}$$

Based on (3.3) one can prove that for each fixed r the set $\{\phi_j^r(2^{r-R}\bullet) : j = 0, 1, \ldots, 2^r n\}$ is linearly independent on $[0, 2^R n]$, and thus, from (4.1), we have

$$\dim V_r = 2^r n + 1, \quad r = 0, 1, \ldots, R. \tag{4.9}$$

Now define the sequence $\{\psi_j^r\} = \{\psi_j^r : j = 0, 1, \ldots, 2^r n - 1,\ r = 0, 1, \ldots, R-1\}$ by

$$\psi_j^r(x) = \phi_{2j+1}^{r+1}(x), \quad x \in [0, 2^R n], \quad j = 0, 1, \ldots, 2^r n - 1, \quad r = 0, 1, \ldots, R-1, \tag{4.10}$$

with corresponding linear spaces

$$W_r = \text{ span}\{\psi_j^r(2^{r+1-R}\bullet) : j = 0, 1, \ldots, 2^r n - 1\}, \quad r = 0, 1, \ldots, R-1. \tag{4.11}$$

From (4.10) and (4.1) it follows that

$$W_r \subset V_{r+1}, \quad r = 0, 1, \ldots, R-1. \tag{4.12}$$

If U, V, and W are linear spaces, we use the direct sum notation $U = V \oplus W$ to denote the fact that, for each $f \in V$, there exist $g \in V$ and $h \in W$ such that $f = g + h$, and with g and h uniquely determined by f.

The following direct sum decomposition result holds.

THEOREM 4.1.

$$V_{r+1} = V_r \oplus W_r, \quad r = 0, 1, \ldots, R-1, \tag{4.13}$$

with V_r and W_r defined by (4.1) *and* (4.11).

To prove Theorem 4.1, we first introduce the linear spaces U_r and X_r, where

$$U_r = \{f - P_r f : f \in V_{r+1}\}, \quad r = 0, 1, \ldots, R-1, \tag{4.14}$$

with P_r defined by (4.2), and

$$X_r = \{f \in V_{r+1} : f(2^{R-r}j) = 0, \quad j = 0, 1, \ldots, 2^r n\}, \quad r = 0, 1, \ldots, R-1, \tag{4.15}$$

in terms of which the following preliminary result holds.

PROPOSITION 4.2. *The linear spaces V_r, W_r, U_r, and X_r, as defined by* (4.1), (4.11), (4.14), *and* (4.15), *satisfy*

$$W_r = U_r = X_r, \quad r = 0, 1, \ldots, R-1; \tag{4.16}$$

$$V_r \cap W_r = \{0\}, \quad r = 0, 1, \ldots, R-1. \tag{4.17}$$

Proof. First, we show that $U_r = X_r$. If $g \in U_r$, then (4.2) and (4.3) yield $g(2^{R-r}j) = 0,\ j = 0, \ldots, 2^r n$, i.e., $g \in X_r$, so that $U_r \subset X_r$. If $g \in X_r$, then (4.2) and (4.15) imply $P_r g = 0$; hence, $g = f - P_r f$ with $f = g$, and thus, since also $f \in X_r \subset V_{r+1}$ from (4.15), we have from (4.14) that $g \in U_r$. Consequently, $X_r \subset U_r$.

Next, we prove that $W_r \subset X_r$. If $g \in W_r$, there exists a coefficient sequence $\{c_0, \ldots, c_{2^r n-1}\}$ such that $g(x) = \sum_{\ell=0}^{2^r n-1} c_\ell \psi_\ell^r(2^{r+1-R}x),\ x \in [0, 2^R n]$. But then, from (4.10), we have

$$g(2^{R-r}j) = \sum_{\ell=0}^{2^r n-1} c_\ell \phi_{2\ell+1}^{r+1}(2j) = 0, \quad j \in \{0, 1, \ldots, 2^r n\},$$

by virtue of (3.3). Definition (4.15) then implies that $g \in X_r$. So, $W_r \subset X_r$.

We now show that $U_r \subset W_r$, thereby completing the proof of (4.16). Suppose therefore that $g \in U_r$, so that, from (4.14) and (4.1), there exists a coefficient sequence $\{c_j : j = 0, 1, \ldots, 2^{r+1}n\}$ such that the function $f \in V_{r+1}$ given by

$$f(x) = \sum_{j=0}^{2^{r+1}n} c_j \phi_j^{r+1}(2^{r+1-R}x), \quad x \in [0, 2^R n], \tag{4.18}$$

satisfies the equation

$$g(x) = f(x) - (P_r f)(x), \quad x \in [0, 2^R n]. \tag{4.19}$$

However, from (4.2), (4.18), (3.3), and (3.5), we obtain

$$\begin{aligned}
(P_r f)(x) &= \sum_{\ell=0}^{2^{r+1}n} \left[\sum_{k=0}^{2^r n} \phi_\ell^{r+1}(2k) \phi_k^r(2^{r-R}x) \right] c_\ell \\
&= \sum_{\ell=0}^{2^r n} c_{2\ell} \phi_\ell^r(2^{r-R}x) \\
&= \sum_{\ell=0}^{2^r n} c_{2\ell} \sum_{k=0}^{2^{r+1}n} \phi_\ell^r\left(\frac{k}{2}\right) \phi_k^{r+1}(2^{r+1-R}x) \\
&= \sum_{\ell=0}^{2^r n} c_{2\ell} \phi_{2\ell}^{r+1}(2^{r+1-R}x) \\
&\quad + \sum_{\ell=0}^{2^r n} c_{2\ell} \sum_{k=0}^{2^r n-1} \phi_\ell^r\left(k + \tfrac{1}{2}\right) \phi_{2k+1}^{r+1}(2^{r+1-R}x).
\end{aligned} \tag{4.20}$$

Also, from (4.18),

$$f(x) = \sum_{j=0}^{2^r n} c_{2j} \phi_{2j}^{r+1}(2^{r+1-R}x) + \sum_{j=0}^{2^r n-1} c_{2j+1} \phi_{2j+1}^{r+1}(2^{r+1-R}x). \tag{4.21}$$

Combining (4.19), (4.20), and (4.21) yields

$$g(x) = \sum_{j=0}^{2^r n-1} \left[c_{2j+1} - \sum_{k=0}^{2^r n} c_{2k} \phi_k^r\left(j + \tfrac{1}{2}\right) \right] \phi_{2j+1}^{r+1}(2^{r+1-R}x), \tag{4.22}$$

which, together with (4.11), (4.10), implies that $g \in W_r$. Thus $U_r \subset W_r$, thereby completing our proof of (4.16).

Finally, to prove (4.17), suppose $f \in V_r \cap W_r$. Then (4.4) and (4.2) imply that, for $x \in [0, 2^R n]$,

$$f(x) = (P_r f)(x) = \sum_{j=0}^{2^r n} f(2^{R-r} j)\phi_j^r(2^{r-R}x) = 0,$$

after noting from (4.16) that $f \in X_r$ and then using the definition (4.15). □

We can now prove Theorem 4.1.

Proof. Let $r \in \{0, 1, \ldots, R-1\}$ be fixed. Take any $f \in V_{r+1}$ and define $g = P_r f$ and $h = f - P_r f$. Then (4.2) implies that $g \in V_r$, whereas (4.14) and (4.16) imply that $h \in W_r$. We have therefore shown that there exist functions $g \in V_r$ and $h \in W_r$ such that $f = g + h$. It remains to be proven that g and h are uniquely determined by f. But, if $g_0 \in V_r$ and $h_0 \in W_r$ were such that $f = g_0 + h_0$, then $u = g_0 - g \in V_r$ and $v = h - h_0 \in W_r$, with $u = v$. Thus $u \in V_r \cap W_r$ and $v \in V_r \cap W_r$, and the desired uniqueness result follows from (4.17). □

From (4.13) one concludes that $\dim W_r = \dim V_{r+1} - \dim V_r$, so that (4.9) leads to

$$\dim W_r = 2^r n, \quad r = 0, 1, \ldots, R-1. \tag{4.23}$$

Hence, based on the definition (4.11), we conclude that the set $\{\psi_j^r(2^{r+1-R}\,\bullet) : j = 0, 1, \ldots, 2^r n - 1\}$ is linearly independent on $[0, 2^R n]$ and therefore is a basis for W_r.

We have therefore established, for each fixed $r \in \{0, 1, \ldots, R-1\}$, an *interpolation wavelet basis* $\{\psi_j^r(2^{r+1-R}\,\bullet) : j = 0, 1, \ldots, 2^r n - 1\}$ for the *interpolation wavelet space* W_r. The elements of the sequence $\{\psi_j^r\}$ are called *interpolation wavelets*. Examples for $N = 1$ are plotted in Figure 5.

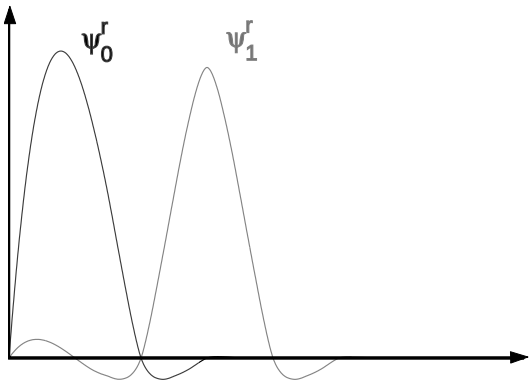

FIG. 5. *Boundary interpolation wavelets with* $N = 1$.

In the next section, we derive the corresponding decomposition and reconstruction algorithms.

4.2. Decomposition and reconstruction algorithms. To obtain the decomposition algorithm, let $r \in \{0, 1, \ldots, R-1\}$ be fixed, and suppose $f_{r+1} \in V_{r+1}$ is given by

$$f_{r+1}(x) = \sum_{j=0}^{2^{r+1}n} c_j^{(r+1)} \phi_j^{r+1}(2^{r+1-R}x), \quad x \in [0, 2^R n]. \tag{4.24}$$

According to Theorem 4.1, and for the bases $\{\phi_j^r\}$ and $\{\psi_j^r\}$ of V_r and W_r, we know that there exist unique coefficient sequences $\{c_j^{(r)} : j = 0, 1, \ldots, 2^r n\}$ and $\{d_j^{(r)} : j = 0, 1, \ldots, 2^r n - 1\}$ such that the functions $f_r \in V_r$ and $g_r \in W_r$ defined by

$$f_r(x) = \sum_{j=0}^{2^r n} c_j^{(r)} \phi_j^r(2^{r-R}x), \quad x \in [0, 2^R n], \tag{4.25}$$

and

$$g_r(x) = \sum_{j=0}^{2^r n-1} d_j^{(r)} \psi_j^r(2^{r+1-R}x), \quad x \in [0, 2^R n], \tag{4.26}$$

satisfy

$$f_{r+1} = f_r + g_r. \tag{4.27}$$

In particular, observe that we then have the *interpolation wavelet decomposition*

$$f_R = f_0 + \sum_{j=0}^{R-1} g_j.$$

Moreover,

$$f_r = P_r f_{r+1} \tag{4.28}$$

and

$$g_r = f_{r+1} - P_r f_{r+1}. \tag{4.29}$$

The coefficients $\{d_j^{(r)}\}$ in (4.26) are called the *interpolation wavelet coefficients*.

Using (4.24), (4.10), and (4.29), and the argument which led to (4.22), we obtain, for all $x \in [0, 2^R n]$,

$$\sum_{j=0}^{2^r n-1} d_j^{(r)} \psi_j^r(2^{r+1-R}x) = \sum_{j=0}^{2^r n-1} \left[c_{2j+1}^{(r+1)} - \sum_{k=0}^{2^r n} c_{2k}^{(r+1)} \phi_k^r\left(j + \tfrac{1}{2}\right) \right] \psi_j^r(2^{r+1-R}x).$$

Since $\{\psi_j^r(2^{r+1-R}\,\bullet) : j = 0, 1, \ldots, 2^r n - 1\}$ is a linearly independent set on $[0, 2^R n]$, we have

$$d_j^{(r)} = c_{2j+1}^{(r+1)} - \sum_{k=0}^{2^r n} c_{2k}^{(r+1)} \phi_k^r\left(j + \tfrac{1}{2}\right), \quad j = 0, 1, \ldots, 2^r n - 1. \tag{4.30}$$

Next, using (4.25), (4.28), (4.2), and (3.3) we get, for all $x \in [0, 2^R n]$,

$$\begin{aligned} \sum_{j=0}^{2^r n} c_j^{(r)} \phi_j^r(2^{r-R}x) = f_r(x) &= (P_r f_{r+1})(x) \\ &= \sum_{j=0}^{2^r n} \left[\sum_{\ell=0}^{2^{r+1} n} c_\ell^{(r+1)} \phi_\ell^{r+1}(2j) \right] \phi_j^r(2^{r-R}x) \\ &= \sum_{j=0}^{2^r n} c_{2j}^{(r+1)} \phi_j^r(2^{r-R}x). \end{aligned}$$

Since the set $\{\phi_j^r(2^{r-R}\bullet) : j = 0, 1, \ldots, 2^r n\}$ is linearly independent on $[0, 2^R n]$, we deduce that

$$c_j^{(r)} = c_{2j}^{(r+1)}, \quad j = 0, 1, \ldots, 2^r n. \tag{4.31}$$

Now observe from (3.28), (3.7), and (3.33) that

$$\phi_k^r(j + \tfrac{1}{2}) = a_{j,k}^{(r)}, \quad k = 0, 1, \ldots, 2^r n, \quad j = 0, 1, \ldots, 2^r n - 1,$$

which, together with (4.30) and (4.31), then yield, for a given data sequence $\{c_j^{(R)} : j = 0, 1, \ldots, 2^R n\}$, the following interpolation wavelet algorithms.

Decomposition algorithm:

$$\left.\begin{aligned} c_j^{(r)} &= c_{2j}^{(r+1)}, && j = 0, 1, \ldots, 2^r n, \\ d_j^{(r)} &= c_{2j+1}^{(r+1)} - \sum_{k=0}^{2^r n} a_{j,k}^{(r)} c_{2k}^{(r+1)}, && j = 0, 1, \ldots, 2^r n - 1, \end{aligned}\right\} r = R-1, R-2, \ldots, 0. \tag{4.32}$$

Reconstruction algorithm:

$$\left.\begin{aligned} c_{2j}^{(r+1)} &= c_j^{(r)}, && j = 0, 1, \ldots, 2^r n, \\ c_{2j+1}^{(r+1)} &= d_j^{(r)} + \sum_{k=0}^{2^r n} a_{j,k}^{(r)} c_k^{(r)}, && j = 0, 1, \ldots, 2^r n - 1, \end{aligned}\right\} r = 0, 1, \ldots, R-1. \tag{4.33}$$

Here the coefficient sequence $\{a_{j,k}^{(r)} : k = 0, 1, \ldots, 2^r n,\ j = 0, 1, \ldots, 2^r n - 1,\ r = 0, 1, \ldots, R-1\}$ is defined by (3.34), (3.35), (3.36), with explicit formulations in (3.37) and (3.38).

Suppose $f \in C[0, 2^R n]$, with the integers R and n suitably chosen. The sequence $\{f_r : r = R-1, R-2, \ldots, 0\}$ is then defined by (4.28), with $f_R = f$, whereas the sequence $\{g_r : r = R-1, R-2, \ldots, 0\}$ is defined by (4.29). The coefficient sequences $\{c_j^{(r)} : j = 0, 1, \ldots, 2^r n,\ r = R, R-1, \ldots, 0\}$ and $\{d_j^{(r)} : j = 0, 1, \ldots, 2^r n - 1,\ r = R-1, R-2, \ldots, 0\}$ are computed recursively by means of (4.32). In particular, observe that since (4.2) and (4.25) yield

$$\sum_{j=0}^{2^R n} c_j^{(R)} \phi_j^R(x) = f_R(x) = (P_R f)(x) = \sum_{j=0}^{2^R n} f(j) \phi_j^R(x),$$

we have $c_j^{(R)} = f(j),\ j = 0, 1, \ldots, 2^R n$, and thus the interpolation wavelet decomposition algorithm (4.32) can, in this context, be rewritten as

$$\left.\begin{aligned} c_j^{(r)} &= f(2^{R-r} j), && j = 0, 1, \ldots, 2^r n, \\ d_j^{(r)} &= f(2^{R-r-1}(2j+1)) - \sum_{k=0}^{2^r n} a_{j,k}^{(r)} f(2^{R-r} k), && j = 0, 1, \ldots, 2^r n - 1, \end{aligned}\right\} \tag{4.34}$$

$$r = R-1, R-2, \ldots, 0.$$

The reconstruction is then performed by means of (4.33).

At this stage, it is of interest to point out the following relationship between the interpolation wavelet procedure (4.34), (4.33) and the interpolatory subdivision scheme (3.33).

After the decomposition with (4.34) has been performed, suppose that we set the interpolation wavelet coefficients

$$d_j^{(r)} = 0, \quad j = 0, 1, \ldots, 2^r n - 1, \quad r = 0, 1, \ldots, R - 1, \tag{4.35}$$

at each successive step of the reconstruction phase (4.33). The final reconstructed (and smoothed) function is then

$$f_R(x) = \sum_{j=0}^{2^R n} c_j^{(R)} \phi_j^R(x), \quad x \in [0, 2^R n], \tag{4.36}$$

with, as is clear from the top parts of (4.33) and (4.34), and (3.3),

$$f_R(2^R k) = c_{2^R k}^{(R)} = f(2^R k), \quad k = 0, 1, \ldots, n.$$

Now observe that the zero values (4.35) substituted into the bottom part of (4.33) yield precisely the bottom part of the subdivision formula (3.33).

Hence the interpolation wavelet decomposition and reconstruction scheme described above is equivalent to the following interpolatory subdivision scheme:

Choose $c = c^{(0)} = f(2^R k), \ \ k = 0, 1, \ldots,$ and apply the interpolatory subdivision scheme (3.33). According to Theorem 3.3, this scheme converges to the limit curve

$$g(x) = \sum_{j=0}^{n} f(2^R j) \phi_j^0(x), \quad x \in [0, n]. \tag{4.37}$$

Then, using the refinement equation (3.5), as well as (3.6)–(3.7), we get

$$\begin{aligned} g(x) &= \sum_{j=0}^{n} c_j^{(0)} \phi_j^0(x) \\ &= \sum_{j=0}^{n} c_j^{(0)} \sum_{\ell=0}^{2n} \phi_j^0 \left(\frac{\ell}{2} \right) \phi_j^1(2x) \\ &= \sum_{\ell=0}^{2n} c_\ell^{(1)} \phi_j^1(2x) \\ &\ \ \vdots \\ &= \sum_{\ell=0}^{2^R n} c_\ell^{(R)} \phi_j^R(2^R x) = f_R(2^R x) \end{aligned}$$

from (4.36). Hence,

$$g(x) = f_R(2^R x), \quad x \in [0, n]. \tag{4.38}$$

The subdivision approach therefore has the significant advantage of providing an efficient iterative procedure for the construction of the function f_R in (4.36).

Finally, suppose in the decomposition procedure defined by the algorithm (4.34) we have, for some given polynomial $p \in \pi_{2N+1}$, and for a fixed $r \in \{R-1, R-2, \ldots, 0\}$, that there exists an integer $\mu \in [0, 2^r n]$ such that

$$f(x) = p(x), \quad x \in [\alpha, \beta],$$

where

$$\alpha = \max\{0, 2^{R-r}(\mu - 2N)\}, \qquad \beta = \min\{2^R n, 2^{R-r}(\mu + 2N)\}.$$

Then, using also (4.34), (4.30), (3.2), and (3.4), we find

$$\begin{aligned} d_\mu^{(r)} &= p(2^{R-r-1}(2\mu+1)) - \sum_{k=\max\{0,\mu-2N\}}^{k=\min\{2^r n,\mu+2N\}} p(2^{R-r}k)\phi_k^r\left(\mu + \tfrac{1}{2}\right) \\ &= p(2^{R-r-1}(2\mu+1)) - \sum_{k=0}^{2^r n} p(2^{R-r}k)\phi_k^r\left(\mu + \tfrac{1}{2}\right) = 0. \end{aligned}$$

Hence the interpolation wavelet coefficients $d_j^{(r)}$ corresponding, according to (3.2), to those regions in $[0, 2^R n]$ where the function f has polynomial-like behavior can be expected to be small relative to the interpolation wavelet coefficients $d_j^{(r)}$ corresponding to those regions in $[0, 2^R n]$ where f exhibit nonpolynomial-like behavior.

For example, choose the function f in (4.34) as the cubic cardinal B-spline, with an arbitrary choice of the integers R and n. The B-spline consists of four cubic polynomial pieces joined together in such a way that the second derivative of the B-spline is continuous, while the third derivative has jump discontinuities at the nodes. Now choose $N = 1$ to ensure, by the above argument, that the wavelet coefficients $d_j^{(r)}$, $r = R-1, R-2, \ldots, 0$, are zero in the regions where f is identical to a polynomial and nonzero in the regions where the third derivative has a jump discontinuity.

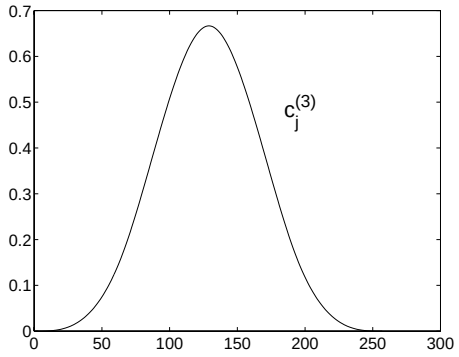

FIG. 6. *Cubic B-spline, sampled at* 257 *equally spaced points.*

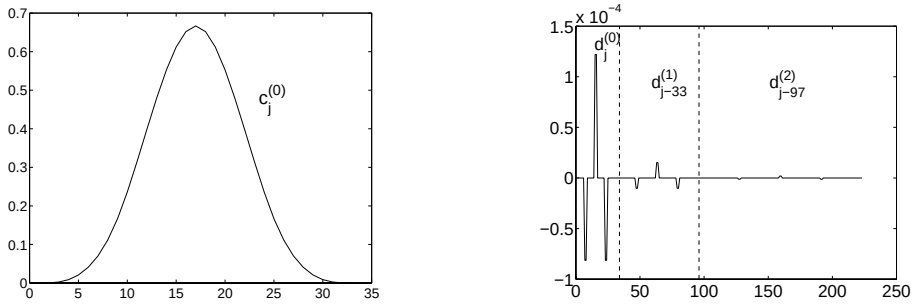
In Figure 6, we have chosen $R = 3$ and $n = 32$ and plotted the sequence of sampled values $c_j^{(3)} = f(j)$ versus their indices. Figure 7 shows the result of the interpolation wavelet decomposition algorithm (4.34), where the resulting coefficients are also plotted versus their indices.

We observe that the average values $c_j^{(0)}$, as shown in Figure 7(a), consist of precisely every eighth value of the original B-spline. What is of more interest is the set



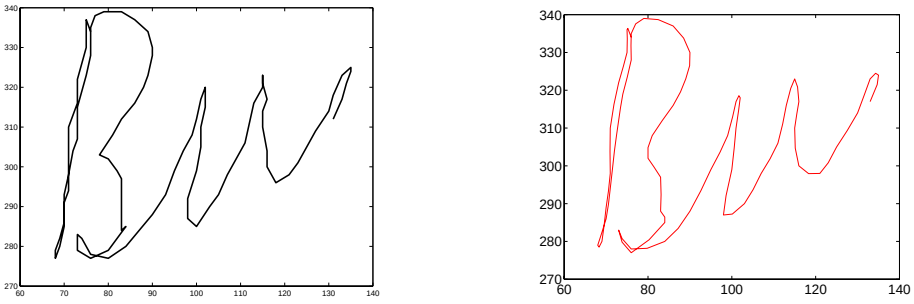
(a) *Average component.* (b) *Detail components.*

FIG. 7. *Third level decomposition of the B-spline of Figure* 6.

of detail components shown in Figure 7(b). Note that, as expected, the interpolation wavelet coefficients $d_j^{(r)}$, $r = 2, 1, 0$, are nonzero only where the B-spline has jump discontinuities in its third derivative.

5. Examples. In this section we illustrate the interpolation wavelets by applying them to two practical problems. Of course we do not claim that the schemes described above are more efficient in practice than any of the alternatives. This would require a detailed study, which we leave for future consideration. These examples merely serve to illustrate the theory developed above. Note in particular how the interpolation wavelet decomposition on an interval avoids any edge artifacts.

5.1. Signature smoothing. Figure 8(a) shows part of a signature that was captured by a digitized tablet. One clearly sees the quantization effect of the underlying grid of this particular tablet. Almost all applications require that the signature should be smoothed. We therefore applied a single level of the interpolation wavelet decomposition (4.34) with $N = 1$. All the detail coefficients were set equal to zero, and a single reconstruction step was performed using the zero detail coefficients. The result is the smoothed signature in Figure 8(b). Note that we follow standard practice by displaying only the discrete coefficients $c_j^{(R)}$, connected by straight line segments. This is different from the smooth curve given by (4.36).

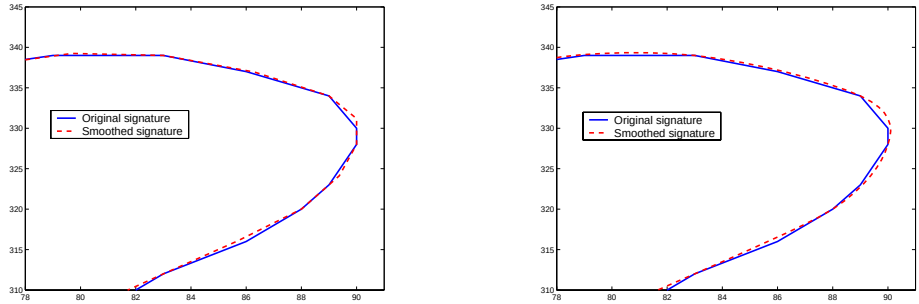


(a) *Original signature sample.* (b) *Smoothed signature.*

FIG. 8. *Illustration of smoothing with interpolation wavelet decomposition.*

A closer look at the original and reconstructed signature is given in Figure 9. Note from Figure 9(a) how every other data point stays the same (due to the interpolation property). The remaining points, however, are calculated in such a way that the

result is a smoother signature. In fact, this procedure is exactly the same as if we discarded every other data point of the original signature and then applied one step of the subdivision scheme with $N = 1$ to the result, as described in section 4. As mentioned above we plot only the data points connected by straight lines, and not the smooth curve f_R described by (4.36). An efficient way of calculating f_R is by subdivision: according to the argument leading from (4.36) to (4.38), each step of the subdivision scheme doubles the number of points on the curve f_R. The result of two more subdivision steps is shown in Figure 9(b). Note how the reconstructed curve has become noticeably smoother.



(a) *A single reconstruction step.* (b) *After two more subdivision steps.*

FIG. 9. *Magnification of original and smoothed signature.*

Note that the main problem in this case is that the data points themselves are corrupted by noise. Insisting that the data points are interpolated is therefore not the best way to proceed. In this case noninterpolatory schemes such as Lane–Riesenfeld [20] (see also [23, Chapter 2]) might prove beneficial. Even in this less than ideal situation, the interpolation wavelets provide a surprisingly good smoothing, with no artificial edge effects.

5.2. Two-dimensional interpolation wavelet decomposition. For our second example we use the well-known painting by Salvador Dali, *Gala Contemplating the Mediterranean*, Figure 10(a), the original of which can be seen in the Dali museum in Figueres, Spain. Although painted in 1976, it is a beautiful illustration of Dali's awareness of images on different scales, in this case, a portrait of Abraham Lincoln, the 16th president of the United States of America, and Gala, Dali's wife, looking out to sea.

Constructing a two-dimensional tensor product from the interpolation wavelet (4.10) (see, e.g., [5, section 6.4]) allows us to perform a two-dimensional decomposition of Dali's painting, as illustrated in Figure 10(b). Note how clearly the image of Abraham Lincoln is captured by the average component, displayed in the top left-hand corner of Figure 10(b). The remaining part of the figure consists of the various detail components.

Now we set the detail components equal to zero, and then reconstruct according to a two-dimensional reconstruction algorithm also based on the tensor product interpolation wavelet. The result, as shown in Figure 11(a), is the image of Abraham Lincoln interpolated back onto the original grid of Figure 10(a). If we set the average component equal to zero, and then reconstruct, we obtain the image in Figure 11(b), which contains all the areas of sharp transition which are absent from Figure 11(a).

COMPETING SPECIES NEAR A DEGENERATE LIMIT*

V. HUTSON†, Y. LOU‡, K. MISCHAIKOW§, AND P. POLÁČIK¶

Abstract. We consider a competitive reaction-diffusion model of two species in a bounded domain which are identical in all aspects except for their birth rates, which differ by a function g. Under a fairly weak hypothesis, the semitrivial solutions always exist. Our analysis provides a description of the stability of these solutions as a function of the diffusion rate μ and the difference between the birth rates g. In the case in which the magnitude of g is small we provide a fairly complete characterization of the stability in terms of the zeros of a single function. In particular, we are able to show that for any fixed number n, one can choose the difference function g from an open set of possibilities in such a way that the stability of the semitrivial solutions changes at least n times as the diffusion μ is varied over $(0, \infty)$. This result allows us to make conclusions concerning the existence of coexistence states. Furthermore, we show that under these hypotheses, coexistence states are unique if they exist.

The biological implication is that there is a delicate balance between resource utilization and dispersal rates which can have a dramatic impact with regards to extinction. Furthermore, we show that there is no optimal form of resource utilization. To be more precise, given a fixed diffusion rate and a particular spatially dependent utilization of resources which are expressed in terms of the birth rate, there always exists a birth rate, which on average is the same but differs pointwise, which allows the corresponding species to invade.

Key words. competing species, dispersal rate, spatial heterogeneity, reaction-diffusion systems

1. Introduction.

We study the semilinear parabolic system

$$u_t = \mu \Delta u + u(\alpha(x) - u - v), \tag{1.1a}$$

$$v_t = \mu \Delta v + v(\beta(x) - u - v) \tag{1.1b}$$

in $\Omega \times (0, \infty)$, where Ω is a bounded region in $\mathbb{R}^N$ with smooth boundary $\partial\Omega$. On $\partial\Omega \times (0, \infty)$, we impose the homogeneous Neumann boundary condition

$$\frac{\partial u}{\partial n} = \frac{\partial v}{\partial n} = 0, \tag{1.1c}$$

where n is the outward unit normal vector on $\partial\Omega$. The diffusion rate μ is a positive constant, while the intrinsic growth rates $\alpha(x), \beta(x)$ are nonconstant functions in Ω.

To motivate this work, consider first the single equation

$$u_t = \mu\Delta u + u(\alpha(x) - u) \qquad \text{in } \Omega \times (0,\infty), \qquad \frac{\partial u}{\partial n} = 0 \qquad \text{on } \partial\Omega \times (0,\infty). \tag{1.2}$$

If $\int_\Omega \alpha > 0$ and α is Hölder continuous in $\overline{\Omega}$, then it is well known that there exists a unique positive equilibrium solution $\tilde{u}$ satisfying

$$\mu\Delta\tilde{u} + \tilde{u}(\alpha - \tilde{u}) = 0 \qquad \text{in } \ \Omega, \qquad \frac{\partial \tilde{u}}{\partial n} = 0 \qquad \text{on } \ \partial\Omega. \tag{1.3}$$

Furthermore, $\tilde{u}$ depends smoothly on μ, is asymptotically stable, and is the global attractor for the set of nontrivial, nonnegative initial conditions. In a slight abuse of language we shall refer to a solution with this property as a *global attractor*. When it is important to express the dependence on μ we will write $\tilde{u}(x,\mu)$. Equations of this form have attracted considerable attention in biology, where u might represent the density of an organism. The fact that $\tilde{u}$ is a global attractor can be interpreted as a statement that the species survives.

One of the fundamental driving forces in evolution is competition. An elementary, but not unreasonable, approach to understanding the relative fitness of two such organisms is to couple two equations of the form of (1.2) in a competitive manner. Using the classical Lotka–Volterra interaction terms we are led to the system

$$\begin{aligned} u_t &= \mu\Delta u + u(\alpha(x) - u - bv), \\ v_t &= \nu\Delta v + v(\beta(x) - cu - v), \end{aligned} \tag{1.4}$$

assuming Neumann boundary conditions again. In a suitable ordering, (1.4) defines a strongly monotone semiflow on the cone of continuous vector functions with both components positive. This has strong implications for the global dynamics. In particular, combining general results on monotone semiflows with special features of (1.4), one can prove that either there is a coexistence steady state (that is, a steady state with both components positive) or else for each solution in the cone one of the components tends to 0 as $t \to \infty$ (see [He, HSW]). Our goal here is to gain an understanding of the relationship between diffusion rates, spatial heterogeneity, and competitive coupling. In the tradition of bifurcation theory, this suggests looking for a system which is an organizing center for these parameters.

With this in mind consider the following degenerate version of (1.4):

$$\begin{aligned} u_t &= \mu\Delta u + u(\alpha(x) - u - v), \\ v_t &= \mu\Delta v + v(\alpha(x) - u - v). \end{aligned} \tag{1.5}$$

Obviously in this system u and v play an identical role, and hence for each fixed μ there is a set of nonnegative equilibria $\{(s\tilde{u}, (1-s)\tilde{u}) \mid 0 \le s \le 1\}$. Furthermore, this set of equilibria is the global attractor for the set of nontrivial nonnegative initial conditions. Thus, the ultimate goal would be to provide a complete unfolding of the degenerate system in the directions of the general systems taking the form of (1.4). This would provide us with detailed information concerning the existence, multiplicity, and stability of the equilibria, along with an understanding of the global dynamics.

Unfortunately, we are far from attaining this goal. However, this paper can be viewed as a natural addition to a series of work [HLMV, DHMP, HLM, HMP] in which we have obtained partial results. In particular, in [DHMP] the case of $b = c = 1$ and $\beta = \alpha$, α being a nonconstant function, was analyzed. Without loss

of generality assume that $\nu > \mu$ (otherwise (1.5) is recovered). The result, under no further hypotheses, is that $(\tilde{u}, 0)$ is the global attractor for the set of positive initial conditions. Observe that this implies that there are no other equilibria in the cone of positive functions. Biologically this suggests that if the two species interact identically with the environment, then the slower diffuser always survives and the faster diffuser is always driven to extinction. As is shown in [HMP], corresponding results are not always true if, in addition, one assumes that the reproductive rate α is periodic in time.

To gain an understanding of the importance of this phenomena as compared to the effects of relative strengths of competition, the case of $\nu > \mu$, $b > 1$, $c < 1$, and $\alpha = \beta$ was considered in [HLM]. Here we wish to consider similar questions; however, our focus is on the interaction between diffusion rates and the form of the heterogeneity of the environment. This justifies the assumption that $b = c = 1$. Furthermore, to make progress on this problem we have assumed that $\mu = \nu$, which results in system (1.1).

This system was studied in [HLMV], motivated by the following biological question. Consider a species with spatially dependent reproductive rate $\beta(x)$. The form of β may be regarded as reflecting the manner in which the resources are utilized. Suppose now that there is a mutation leading to another phenotype with a spatially distinct reproductive rate $\alpha(x)$ but otherwise identical. Typically, the initial population of the mutant species will be very small. Problem (1.1) may be taken to be a model representing the first stage in speciation, with different species differing only in the spatial dependence of their reproductive rate. A well-known example is the different beak size in "Darwin's finches" [G]. There are two key questions. First, under what circumstances will this mutant invade? Second, if it does invade, will it go to fixation, i.e., force extinction of the original phenotype, or will there be coexistence, which one would regard as a speciation event? Mathematically this leads to the system (1.1). The analysis of such a system when the difference between α and β is small occupies a major portion of the present paper. Our results go some way towards clarifying the question of the existence of a coexistence state and its dependence on the size of the difference between α and β and on the value of the diffusion coefficient. In a number of situations we are able to give a complete description of the global dynamics. We shall return to a discussion of the implications of our results at the end of this section.

Turning now to a description of the results, we start by recalling a few conclusions from [HLMV]. Let $\tilde{v}$ be a positive solution of

$$\mu\Delta\tilde{v} + \tilde{v}(\beta - \tilde{v}) = 0 \quad \text{in } \Omega, \qquad \frac{\partial\tilde{v}}{\partial n} = 0 \quad \text{on } \partial\Omega. \tag{1.6}$$

As was remarked earlier, if $\int_\Omega \beta > 0$, and β is Hölder continuous in $\overline{\Omega}$, then $\tilde{v}$ is uniquely determined and depends smoothly on μ. Observe that the solutions $\tilde{u}$ of (1.2) and $\tilde{v}$ of (1.6) define equilibria $(\tilde{u}, 0)$ and $(0, \tilde{v})$ of (1.1).

It was shown in [HLMV] that if $\int_\Omega \alpha > \int_\Omega \beta > 0$, then for large enough μ, $(\tilde{u}, 0)$ is a global attractor. Thus, in particular, $(\tilde{u}, 0)$ is asymptotically stable and $(0, \tilde{v})$ is unstable. From the biological perspective this implies that the species u always drives the species v to extinction, no matter what the initial data may be. On the other hand, [HLMV] also demonstrates that if $\alpha_+ - \beta_+$ (α_+ denotes the positive part of α) changes sign, then for small enough μ both semitrivial states $(\tilde{u}, 0)$ and $(0, \tilde{v})$ of (1.1) are unstable. This in turn implies that there is at least one stable coexistence state of (1.1), i.e., an equilibrium (u, v) of (1.1) with $u, v > 0$ on $\overline{\Omega}$.

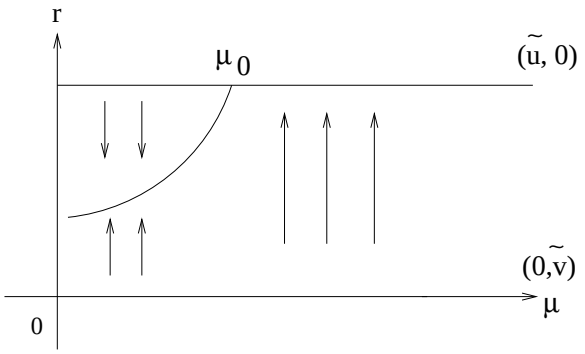

FIG. 1. *Expected bifurcation diagram of coexistence states of* (1.1): *for* $\mu > \mu_0$, $(\tilde{u}, 0)$ *is the global attractor of* (1.1); *for* $\mu < \mu_0$, (1.1) *has a coexistence state which is stable and possibly the global attractor of* (1.1). *In this and all other figures, the vertical axis is* $r = \|u\|/(\|u\| + \|v\|)$, *where* $\|\cdot\|$ *is the* L^2 *norm.*

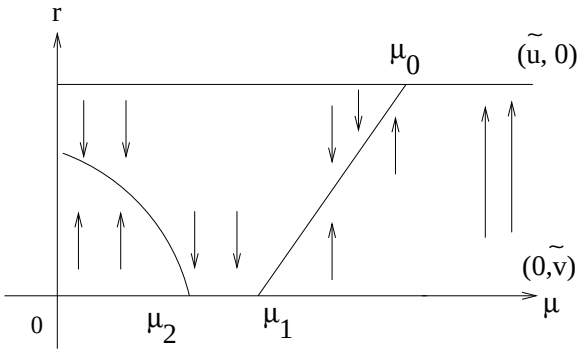

FIG. 2. *Another possible bifurcation diagram suggested by computation.*

The simplest interpretation of these results suggests the following scenario. As μ decreases from a large value, a branch of coexistence states of (1.1) bifurcates from $(\tilde{u}, 0)$ at some value μ_0 and remains in the interior of the positive cone for all $\mu < \mu_0$; see Figure 1. This would suggest some type of monotone relation between the stability of $(\tilde{u}, 0)$ and the rate of diffusion. Surprisingly, according to [HLMV], numerical computations show that this simple situation is not always the case. For reasonable choices of α and β, the branch of coexistence states bifurcating from $(\tilde{u}, 0)$ at μ_0 can reach $(0, \tilde{v})$, which becomes globally attracting for some range of μ as μ decreases. Eventually another branch of coexistence states of (1.1) bifurcates from $(0, \tilde{v})$ and remains in the positive cone for the rest of μ; see Figure 2.

It is worthwhile comparing these figures. In Figure 1, the species u can always invade when rare, that is, $(0, \tilde{v})$ is unstable for any μ; in Figure 2, the species u cannot invade when rare if $\mu \in (\mu_2, \mu_1)$, and indeed $(0, \tilde{v})$ is the global attractor of (1.1) for this range of μ. This is surprising because for the above-mentioned numerical computations species u was chosen to have better than average reproductive rate resource utilization than species v; i.e., it was assumed that $\int_\Omega \alpha > \int_\Omega \beta$. These numerical results also show that there need not be a monotone relation between stability (in the case of $(0, \tilde{v})$) and the rate of diffusion. Furthermore, the coexistent

states can appear and disappear as a function of the diffusion rate.

These observations suggest that the task of characterizing the equilibria for (1.1) will not be trivial. In fact, recall that, given the degenerate equation (1.5) and letting μ vary over $(0,\infty)$, one has a two-dimensional set of degenerate equilibria. Setting

$$\alpha(x) := \beta(x) + \tau g(x), \tag{1.7}$$

and treating both τ and μ as parameters, one might be inclined to conclude that the structure of the set of possible equilibria and their stability obtained from an arbitrary perturbation would be beyond a simple description. Remarkably, as we shall demonstrate, this is not the case.

Using (1.7) we rewrite (1.1) as

$$u_t = \mu\Delta u + u\big[\beta(x) + \tau g(x) - u - v\big], \tag{1.8a}$$

$$v_t = \mu\Delta v + v\big[\beta(x) - u - v\big], \tag{1.8b}$$

$$\frac{\partial u}{\partial n} = \frac{\partial v}{\partial n} = 0, \tag{1.8c}$$

where $\tau > 0$. The following assumption guarantees the existence of semitrivial equilibria for all diffusion rates.

A1. β is a C^1 nonconstant function on $\overline{\Omega}$ and $\int_\Omega \beta(x)\,dx > 0$.

A2. g is a C^1 function on $\overline{\Omega}$ satisfying $\int_\Omega g(x)\,dx \geq 0$.

On occasion we will make use of the slightly stronger condition:

A2$^+$. g is a C^1 function on $\overline{\Omega}$ satisfying $\int_\Omega g(x)\,dx > 0$.

Observe that if $g(x) > 0$ for all $x \in \Omega$, then $\alpha(x) > \beta(x)$. As was mentioned above, this case was studied in [HLMV]. Here we concentrate on the case when g changes sign. Although not assumed explicitly, this property is a consequence of the hypotheses of most of our theorems.

We remark that our regularity requirement on β, g can be relaxed at several places. For the sake of simplicity, however, we assume $\beta, g \in C^1(\overline{\Omega})$ throughout the paper.

Though unmotivated at the moment, it will soon become clear that the following function plays an essential role in all our analyses. Let $G : [0,\infty) \to \mathbb{R}$ be defined by

$$G(\mu) = \begin{cases} \displaystyle\int_\Omega g(x)\tilde{v}^2(x,\mu)\,dx & \text{if } \mu > 0, \\ \displaystyle\int_\Omega g(x)\beta_+^2(x)\,dx & \text{if } \mu = 0. \end{cases} \tag{1.9}$$

The fact that $\tilde{v}^2(x,\mu)$ is a smooth function of μ and [HLMV, Theorem 4.1] implies that G is differentiable on $(0,\infty)$ and continuous at 0. Note in particular that, under condition A2$^+$, G can assume a nonpositive value only if g changes sign.

We begin our study by analyzing the stability of $(0,\tilde{v})$ and confirm the numerical indication that the stability can change, and indeed can do so more than once, as the diffusion rate μ is varied.

THEOREM 1.1. *Suppose that* A1 *and* A2$^+$ *hold. If* $G(0) < 0$*, then there exists a unique* $\tau_0 > 0$ *such that*

(i) $\tau > \tau_0$ *implies that* $(0,\tilde{v})$ *is unstable for any* μ;

(ii) $\tau < \tau_0$ *implies that* $(0,\tilde{v})$ *changes stability*[1] *at least once as* μ *varies from zero to infinity. It changes stability at least twice, provided the following additional*

[1]We say a steady state changes stability at μ_0 if for $\mu \approx \mu_0$ it is stable on one side of μ_0 and unstable on the other side of μ_0.

condition is satisfied:

$$g > 0,\ \beta > 0 \quad \text{on a nonempty set} \quad \Omega^+ \subset \Omega. \tag{1.10}$$

As mentioned earlier, the instability of $(0, \tilde{v})$ means that the species u with low density can successfully invade. Theorem 1.1 qualitatively illustrates how the invasion of species relies on its diffusion rate and the difference between its intrinsic growth rate and that of its competitor. The invasion of species has always been an active and important subject in biology, and we refer to [SK, CC] and references therein for some recent biological and mathematical developments.

Theorem 1.1 immediately raises two questions:

1. What are the values of μ where $(0, \tilde{v})$ changes stability?
2. If there are coexistence states bifurcating from $(0, \tilde{v})$ or $(\tilde{u}, 0)$, what can be said about their stability and how does this influence the global dynamics?

In general, these are hard questions to answer, but for small τ we shall give fairly complete answers, and shall obtain some partial understanding when τ is large.

For small τ, the roots of G approximate the values of μ where $(0, \tilde{v})$ and $(\tilde{u}, 0)$ change stability. Stated differently, if $(0, \tilde{v})$ or $(\tilde{u}, 0)$ changes stability at $\mu = \mu_\tau$, then as $\tau \to 0+$, either $\mu_\tau \to 0$ or $\mu_\tau \to \bar{\mu}$ with $G(\bar{\mu}) = 0$. With some further minor assumptions on G the converse is also true. The precise statement is given in the following theorem (see Figure 3).

THEOREM 1.2. *Assume* A1 *and* A2. *Let* $G^{-1}(0) = \{\mu_1 < \cdots < \mu_k\}$. *Furthermore, assume that* $G'(\mu_i) \neq 0$ *for every* $1 \le i \le k$. *Fix* $\eta \in (0, \mu_1)$. *Then there exists some* $\tau_0 > 0$ *and functions* $\mu_i^*(\tau), \mu_{i,*}(\tau) : (0, \tau_0) \to (\eta, \infty)$, $i = 1, \dots, k$, *such that*

$$\mu_{1,*}(\tau) < \mu_1^*(\tau) < \mu_{2,*}(\tau) < \mu_2^*(\tau) < \cdots < \mu_{k,*}(\tau) < \mu_k^*(\tau), \tag{1.11a}$$

$$\lim_{\tau \to 0} \mu_{i,*}(\tau) = \lim_{\tau \to 0} \mu_i^*(\tau) = \mu_i, \qquad 1 \le i \le k, \tag{1.11b}$$

and for $\mu \in [\eta, \mu_k^*(\tau))$, (1.8) *has a coexistence state if and only if* $\mu \in \bigcup_{i=1}^k (\mu_{i,*}(\tau), \mu_i^*(\tau))$. *Moreover, for* $\mu \ge \eta$, *any coexistence state of* (1.8) *is the global attractor of* (1.8).

Under the stricter assumption A2$^+$, $\mu_k^*(\tau)$ *can be chosen such that* (1.8) *has no coexistence states for* $\mu > \mu_k^*(\tau)$, *and* $(\tilde{u}, 0)$ *is the global attractor.*

We remark that A2 is not needed for the first statement of the theorem. If g is strictly positive, then $G^{-1}(0) = \emptyset$, and hence the theorem is vacuously true. A more subtle point is the assumption that $G'(\mu_i) \neq 0$. Recall that μ enters into the definition of G indirectly, via $\tilde{v}(x, \mu)$; thus it is neither evident that this is a generic condition nor that G can have arbitrarily many roots. We clarify these issues in the next proposition.

Let $C^1(\overline{\Omega})$ be equipped with the standard norm:

$$\|g\| = \sup_{x \in \Omega} (|g(x)| + |Dg(x)|).$$

Let U be an open set in $C^1(\overline{\Omega})$. We say that a statement holds for generic $g \in U$ if the set of functions g for which the statement holds contains the intersection of countably many open and dense subsets of U. Such an intersection is dense by Baire's theorem.

PROPOSITION 1.3.

(i) *Let* β *satisfy* A1. *Then for generic* $g \in C^1(\overline{\Omega})$, 0 *is a regular value of the function* G; *that is,* $G'(\mu) \neq 0$ *whenever* $G(\mu) = 0$.

(ii) *For generic* $\beta \in U = \{\beta \in C^1(\overline{\Omega}) : \int_\Omega \beta > 0\}$ *the following holds: given any nonnegative integer* k, *there exists* $g \in U$ *such that* G *has at least* k *nondegenerate zeros.*

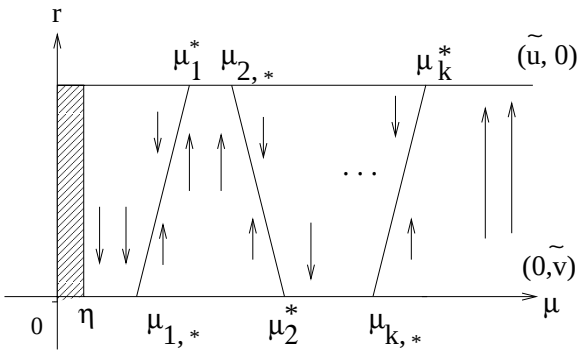

FIG. 3. *Bifurcation diagram of coexistence states of* (1.8) *when* τ *is small and* μ *is bounded away from zero.*

Theorem 1.2 handles the case where τ is small and μ is bounded away from zero. What happens when both τ and μ are small? As was indicated earlier, for fixed τ, both $(\tilde{u}, 0)$ and $(0, \tilde{v})$ are unstable if μ is small enough. In view of Figure 3, for fixed τ, either $(\tilde{u}, 0)$ or $(0, \tilde{v})$ will change stability at least once when $\mu \in (0, \eta]$. The following result gives a characterization of this bifurcation point when τ and μ are both small.

THEOREM 1.4. *Suppose that* A1 *and* A2 *hold and that* $\beta > 0$ *in* $\bar{\Omega}$. *Denote by* μ_1 *the smallest positive root of* G *and assume that* $G'(\mu_1) \neq 0$. *Let* $\mu_1^*(\tau)$ *and* $\mu_{1,*}(\tau)$ *be as in Theorem* 1.2.

(i) *If* $G(0) < 0$, *there exists* $\tau_0 > 0$ *such that for every* $\tau \leq \tau_0$, $(\tilde{u}, 0)$ *is unstable for* $\mu < \mu_1^*(\tau)$. *Furthermore, there exists a unique* $\mu_0(\tau) \in (0, \mu_{1,*}(\tau))$ *such that* $(0, \tilde{v})$ *is unstable for* $\mu < \mu_0(\tau)$ *and stable for* $\mu \in (\mu_0(\tau), \mu_{1,*}(\tau))$ *(see Figure* 4a*). Moreover,* $\mu_0(\tau)$ *satisfies*

$$\lim_{\tau \to 0} \frac{\tau}{\mu_0(\tau)} = \inf_{\left\{\psi \in H^1 : \int_\Omega g\beta^2\psi^2 > 0\right\}} \frac{\int_\Omega \beta^2 |\nabla\psi|^2}{\int_\Omega g\beta^2\psi^2} > 0. \tag{1.12}$$

(ii) *If* $G(0) > 0$, *there exists* $\tau_0 > 0$ *such that for every* $\tau \leq \tau_0$, $(0, \tilde{v})$ *is unstable for* $\mu < \mu_1^*(\tau)$. *Furthermore, there exists a unique* $\mu_0(\tau) \in (0, \mu_{1,*}(\tau))$ *such that* $(\tilde{u}, 0)$ *is unstable for* $\mu < \mu_0(\tau)$ *and stable for* $\mu \in (\mu_0(\tau), \mu_{1,*}(\tau))$ *(see Figure* 4b*). Moreover,* $\mu_0(\tau)$ *satisfies*

$$\lim_{\tau \to 0} \frac{\tau}{\mu_0(\tau)} = \inf_{\left\{\psi \in H^1 : \int_\Omega g\beta^2\psi^2 < 0\right\}} \frac{\int_\Omega \beta^2 |\nabla\psi|^2}{-\int_\Omega g\beta^2\psi^2} > 0. \tag{1.13}$$

From Figure 4a we see that a branch of coexistence states bifurcate from $(0, \tilde{v})$ at $\mu = \mu_0(\tau)$. We suspect that if $G(0) < 0$ and $\tau \ll 1$, for $0 < \mu < \mu_0(\tau)$, (1.8) has a unique coexistence state and it is the global attractor of (1.8). We also believe that for $\mu \in (\mu_0, \mu_{1,*}(\tau))$, $(0, \tilde{v})$ is the global attractor of (1.8). However, these questions remain open.

Again, motivated by biology the following question is natural. Given a dispersal rate μ, is there a birth rate $\beta(x)$ that is "optimal" in the sense that an invading mutant with intrinsic growth rate $\beta(x) + \tau g(x)$ necessarily dies out? Mathematically, this is equivalent to asking that $(0, \tilde{v}(x, \mu))$ be stable for all sufficiently small τ, no matter how g is chosen. In order not to bias the result, e.g., by allowing one phenotype to have a higher reproductive rate at every point, it is reasonable to impose an additional

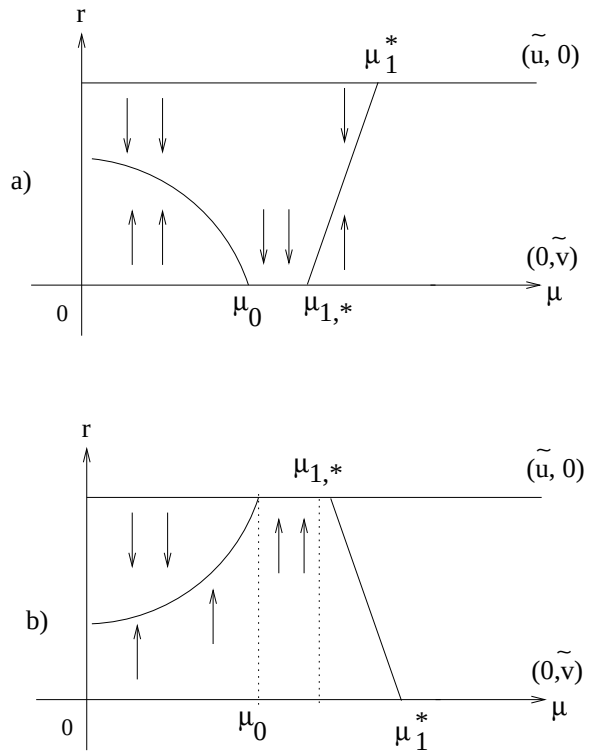

FIG. 4. *Bifurcation diagrams of coexistence states for* $\tau \ll 1$, $\mu < \mu_{1,*}$ *and* (a) $\int_\Omega g\beta^2 < 0$, (b) $\int_\Omega g\beta^2 > 0$.

global "fairness" assumption $\int_\Omega g(x)\,dx = 0$. However, Theorem 1.2 indicates that the stability of $(0, \tilde{v}(x,\mu))$ is determined by the sign of $G(\mu)$. Therefore, if $(0, \tilde{v}(x,\mu))$ is stable under a perturbation in the direction of $g(x)$, then it is unstable under a perturbation in the opposite direction $-g(x)$. In particular, given a particular environment and dispersal rate, there is no optimal birth rate.

The instability of $(0, \tilde{v}(x,\mu))$ indicates that a new mutant can easily invade and suggests the possibility of coexistence. This leads to the following question: for any fixed μ, can one always find g such that there is a coexistence for all small $\tau > 0$? Interestingly, the answer depends on the relation of μ to a single value μ^* depending only on β and Ω. Of course, as we know from the previous results, if the coexistence is to hold for all small τ, then g must be chosen such that $G(\mu) = \int_\Omega \tilde{v}^2(\cdot,\mu)g = 0$.

THEOREM 1.5. *Assume* A1. *There exists a unique* $\mu^* > 0$, *depending only on* β *and* Ω, *with the following properties:*

(i) *If* $\mu > \mu^*$, (1.8) *has no coexistence state for any* g *satisfying* A2, *provided* $0 < \tau < \tau_0$, *where* $\tau_0 = \tau_0(g)$.

(ii) *If* $\mu < \mu^*$, *then there exists a nonempty open subset* U *of*

$$\left\{ g \in C^1(\overline{\Omega}) : \int_\Omega \tilde{v}^2(\cdot,\mu)g = 0 \text{ and } \int_\Omega g > 0 \right\}$$

(with the topology induced from $C^1(\overline{\Omega})$*) such that* (1.8) *has a coexistence state that is the global attractor of* (1.8), *provided* $g \in U$ *and* $0 < \tau < \tau_0$, *where* $\tau_0 = \tau_0(g)$.

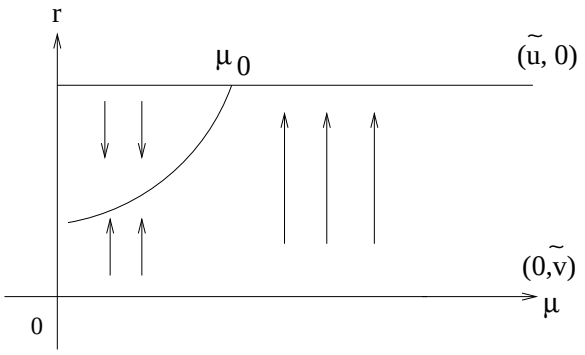

FIG. 5. *Bifurcation diagram of coexistence states of* (1.8) *when* $\tau \gg 1$.

Thus $\mu = \mu^*$ is a critical value for the diffusion rate above which if an invasion can occur, then the invading mutant necessarily goes to fixation. Below μ^*, invasions leading to either fixations or coexistence are possible, depending on the choice of g.

From the point of view of biology, a possible objection to Theorem 1.5 is that the requirement $\int_\Omega \tilde{v}^2(\cdot,\mu)g = 0$ is not generic, and therefore statement (ii) is not applicable. However, stability properties of coexistence equilibria, examined in detail in section 5, guarantee their persistence. Thus if one chooses τ small but bounded away from zero, then coexistence occurs for nonempty open sets of functions g (not restricted to U) and diffusion rates μ. Furthermore, if one thinks of the change in the birth rate as being caused by a mutation, then it makes sense to think of τ as having some finite, though possibly small, size.

We now turn to the case of large τ. In this setting, assuming A2$^+$, it is not hard to show that $(0,\tilde{v})$ is unstable for any μ. On the other hand, $(\tilde{u},0)$ changes stability at least once as μ varies from ∞ to 0. This prompts the following question: given $\tau \gg 1$, what is the range of values of μ for which $(\tilde{u},0)$ changes stability? To this end, set

$$\Omega^+ = \{x \in \Omega : g(x) > 0\}, \quad \Omega^- = \{x \in \Omega : g(x) < 0\}, \quad \Gamma = \{x \in \bar{\Omega} : g(x) = 0\}.$$

In the next theorem we shall assume that the closure of Ω^- is a nonempty subset of Ω and that $\beta > 0$ on $\bar{\Omega}$. This guarantees that there is a unique value $\mu_0 > 0$ such that the linear problem

$$\mu_0 \Delta\phi + \beta(x)\phi = 0 \quad \text{in } \Omega^-, \qquad \phi > 0 \quad \text{in } \Omega^-, \qquad \phi = 0 \quad \text{on } \Gamma \tag{1.14}$$

has a solution.

THEOREM 1.6 (see Figure 5). *Assume* A1, A2$^+$, *that the closure of* Ω^- *is a nonempty subset of* Ω, $g \in C^2(\overline{\Omega})$, $\nabla g \neq 0$ *on* Γ, *and that* $\beta > 0$ *on* $\bar{\Omega}$. *Let* μ_0 *be the value introduced above. Then the following statements hold true:*

(i) *There exists* $\tau_0 > 0$ *such that if* $\tau \geq \tau_0$, *then* $(0,\tilde{v})$ *is unstable for any* $\mu > 0$.

(ii) *For any* $\epsilon > 0$, *there exists* $\tau_1 = \tau_1(\epsilon)$ *such that if* $\tau \geq \tau_1$, *then* $(\tilde{u},0)$ *is unstable for* $\mu \leq \mu_0 - \epsilon$ (*this implies that* (1.8) *has a stable coexistence state for* $\mu \leq \mu_0 - \epsilon$), *and* $(\tilde{u},0)$ *is the global attractor of* (1.8) *for* $\mu \geq \mu_0 + \epsilon$.

To have an overview of the results presented here, it may be helpful to the reader to refer to Figure 6, which is sketched from computed results. This shows a sequence of bifurcation curves for various values of τ. This sketch suggests of course a great deal more than we have proved.

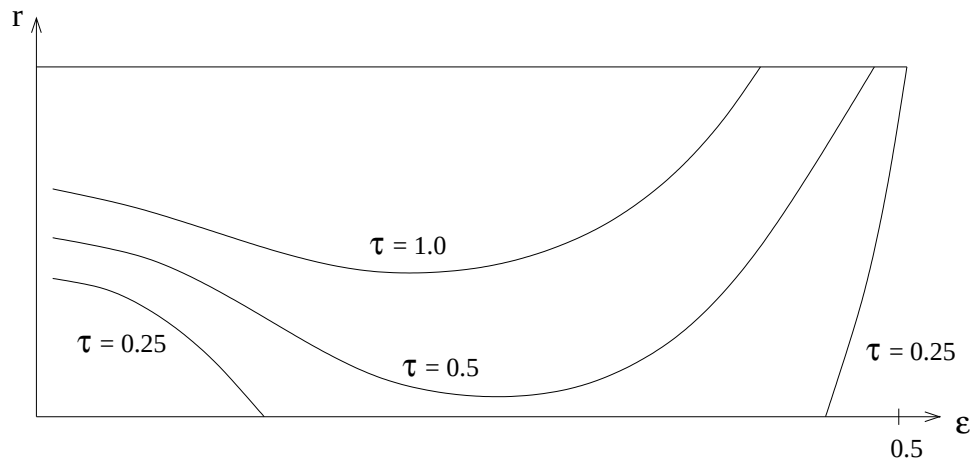

FIG. 6. *Sketch based on computation with* $\beta(x) = 1-\cos(\pi x)$, $g(x) = 0.25+\cos(\pi x)$, $\Omega = (0,1)$, *and* $\epsilon = \sqrt{\mu}$.

We conclude with some remarks on the implications for the biological considerations which motivate this model. The first issue highlighted by the analysis, and one which we suggest is very striking, is the following. We have shown that for a large class of functions g, and for small τ, representing small variations of the phenotype, the stability of the two phenotypes varies with diffusion in a complex manner, and one which appears to be highly unintuitive. In particular, there is no monotonicity with respect to the diffusion rate μ. As is shown in Figure 3 (and proved in Theorem 1.2 and Proposition 1.3) the stability may change back and forth several times as μ changes. Furthermore, unless μ is large, this has no relation to the total resource utilizations, $\int_\Omega \beta$ and $\int_\Omega(\beta + \tau g)$. This is surprising. From the observer's point of view, this suggests that without careful measurement and elaborate experiments, it is totally unpredictable which species will survive.

A second comment is that mutation leads to multiple opportunities for coexistence and thus potentially for speciation. For small τ, which is more realistic biologically, this only happens for narrow ranges of μ, but as τ increases, the ranges widen. Nonetheless, it suggests that there is no surprise in finding a large range of coexisting phenotypes which differ only in one, sometimes small, manner, which is the precise manner in which they utilize the resources of the environment. Indeed, Theorem 1.5 ensures that, given μ, there is a large class of functions for which there will be (stable) coexistence.

Finally, we make a comment on the role of the diffusion μ as one of the bifurcation parameters. This appears to be a relevant mathematical tool for modeling situations when changes in the environment or mutation affect the diffusion rates of the species. One can think of the direct effects caused by changes in climate (temperature, rainfall) or indirect effects of changes in the biotic environment (resources). The bifurcation problem is appropriate in the study of long-term changes—those that occur at a much slower rate than the growth of the species. If they occur on a comparable time scale, a diffusion problem with time-dependent diffusion coefficients may be a more appropriate model.

This paper is organized as follows: In section 2 we summarize basic material concerning local and global stability of equilibria. In section 3 we prove Theorem 1.1.

We study the $\tau \ll 1$ case in section 4, where Theorems 1.2–1.5 are established. In section 5, we consider the $\tau \gg 1$ case and prove Theorem 1.6. Some tedious computations needed in the proof of Theorem 1.2 are carried out in Appendix A. Appendix B is devoted to the proof of Proposition 1.3.

2. Preliminaries. In this section we summarize basic properties of equilibria of (1.8) related to their stability. We start by making more precise the statements given in the introduction regarding the scalar equation

$$\mu\Delta\tilde{u} + \tilde{u}(\beta - \tilde{u}) = 0 \quad \text{in } \Omega, \qquad \frac{\partial\tilde{u}}{\partial n} = 0 \quad \text{on } \partial\Omega. \tag{2.1}$$

It is well known that for each $\beta \in C(\overline{\Omega})$ with $\int_\Omega \beta > 0$, there exists a unique positive solution $\tilde{u} \in H^2(\Omega)$ of this problem; it is a classical solution if β is Hölder continuous. It is further known (see, e.g., [He, sect. III.28]) that $\tilde{u}$ is the global attractor for the corresponding parabolic problem: the solution of (1.2) with any nonnegative nonzero initial condition $u_0 \in C(\overline{\Omega})$ converges as $t \to \infty$ to $\tilde{u}$. Also $\tilde{u}$ is linearly stable, which is to say that all eigenvalues of the linearized operator $-\Delta - (\beta - 2\tilde{u})$, under Neumann boundary condition, are positive. In particular $\tilde{u}$ is a nondegenerate equilibrium; hence, by the implicit function theorem, it depends analytically (as a $W^{2,p}(\Omega)$-valued function for any $p > 1$) on $\mu \in (0, \infty)$ and $\beta \in C(\overline{\Omega})$.

At several places below we shall use asymptotic behavior of the positive solution $\tilde{v} = \tilde{v}(\cdot, \mu)$ of (2.1) when $\mu \to 0$ or ∞. The following properties have been proved in [HLMV]:

$$\tilde{v} \to \beta_+ \quad \text{in } L^\infty(\Omega) \qquad \text{as } \mu \to 0+, \tag{2.2a}$$

$$\tilde{v} \to \frac{1}{|\Omega|}\int_\Omega \beta \quad \text{in } L^\infty(\Omega) \quad \text{as } \mu \to \infty. \tag{2.2b}$$

Let us now turn to the system (1.8). By standard theory (see, e.g., [L, H1]), it defines a smooth dynamical system on

$$\mathcal{X} := C(\overline{\Omega}) \times C(\overline{\Omega}).$$

We understand the notions of stability and asymptotic stability of equilibria of (1.8) with respect to the topology of $\mathcal{X}$. We restrict our attention to physically relevant solutions, that is, solutions with nonnegative initial conditions. They are positive for all times by the maximum principle. We say an equilibrium (u_e, v_e) is the *global attractor* if it is stable and for each nontrivial $(u_0, v_0) \in \mathcal{X}$ with $u_0 \geq 0$, $v_0 \geq 0$ one has $(u(\cdot,t), v(\cdot,t)) \to_{\mathcal{X}} (u_e, v_e)$ as $t \to \infty$, where $(u(\cdot,t), v(\cdot,t))$ is the solution of (1.8) with the initial conditions

$$u(\cdot, 0) = u_0, \quad v(\cdot, 0) = v_0.$$

An equilibrium (u_e, v_e) with both components positive is called a *coexistence state* (or coexistence equilibrium); (u_e, v_e) is a *semitrivial equilibrium* if one component is positive and the other one is zero.

Let us now assume hypothesis A1 to be satisfied. Then system (1.8) has two semitrivial equilibria $(\tilde{u}, 0)$ and $(0, \tilde{v})$ for each $\mu > 0$ and each τ sufficiently small (for each $\tau > 0$ if also A2 is satisfied). They are given by the unique solutions of the corresponding scalar equations.

Due to the competitive Lotka–Volterra structure of the system, knowledge of equilibria and their stability is in some cases sufficient for complete understanding of the global dynamics of (1.8). We recall a few results to that effect (see [He, Chap. IV]):

(a) If there is no coexistence state, then one of the semitrivial equilibria is unstable and the other one is the global attractor.
(b) If there is a unique coexistence state and it is stable, then it is the global attractor (in particular, both semitrivial equilibria are unstable).
(c) If all coexistence states are asymptotically stable, then there is at most one of them, so either (a) or (b) applies.

Let us now discuss in some detail the linearized stability of an equilibrium (u, v). We thus consider the eigenvalue problem

$$\mu\Delta\varphi + (\beta + \tau g - 2u - v)\varphi + (-u)\psi = -\lambda\varphi \quad \text{in } \Omega, \tag{2.3a}$$

$$\mu\Delta\psi + (-v)\varphi + (\beta - u - 2v)\psi = -\lambda\psi \quad \text{in } \Omega, \tag{2.3b}$$

$$\frac{\partial\varphi}{\partial n} = \frac{\partial\psi}{\partial n} = 0 \qquad \text{on } \partial\Omega. \tag{2.3c}$$

It is well known (see, e.g., [He]) that if (u, v) is a coexistence state, one can put this eigenvalue problem in the context of spectral theory of compact strongly positive operators with respect to the order cone

$$\mathcal{C} = \{(\phi, \psi) \in \mathcal{X} : \phi \geq 0,\ \psi \leq 0\}.$$

In particular, using the Krein–Rutman theorem [De, He], one can show that (2.3) has an eigenvalue λ (called *the principal eigenvalue of* (2.3)), which has the following properties: it is real, algebraically simple, and all other eigenvalues have their real part greater than λ. Moreover, λ corresponds to an eigenfunction in the interior of $\mathcal{C}$, and it is the only eigenvalue with an eigenfunction in $\mathcal{C}$. The linearized stability criterion for (u, v) can be expressed in terms of the principal eigenvalue: (u, v) is asymptotically stable if $\lambda > 0$; it is unstable if $\lambda < 0$.

When (u, v) is a semitrivial equilibrium, for example, $(u, v) = (u, 0)$, then (2.3) simplifies to a triangular system

$$\mu\Delta\varphi + (\beta + \tau g - 2u)\varphi + (-u)\psi = -\lambda\varphi \quad \text{in } \Omega, \tag{2.4a}$$

$$\mu\Delta\psi + (\beta - u)\psi = -\lambda\psi \quad \text{in } \Omega, \tag{2.4b}$$

$$\frac{\partial\varphi}{\partial n} = 0 \qquad \text{on } \partial\Omega, \tag{2.4c}$$

$$\frac{\partial\psi}{\partial n} = 0 \qquad \text{on } \partial\Omega. \tag{2.4d}$$

Again one can examine the eigenvalues using a suitable positive operator (see [He]). This time, however, such a positive operator is not strongly positive (the reason is that the second equation decouples), and one gets weaker conclusions from the general theory. Nonetheless, employing the triangular structure, one can still establish the existence of a principal eigenvalue, that is, a simple real eigenvalue which is smaller than the real part of any other eigenvalue. Specifically, the principal eigenvalue coincides with the principal eigenvalue of the scalar eigenvalue problem (2.4b), (2.4d) (see [HMP, Lem. 3.2] for the proof of this fact; the corresponding eigenfunction for the system is $(0, -\psi) \in \mathcal{C}$, where $\psi > 0$ is the principal eigenfunction of (2.4b), (2.4d)).

Similarly, if $(u, v) = (0, v)$, then the principal eigenvalue of (2.3) coincides with the principal eigenvalue of the scalar problem

$$\mu\Delta\varphi + (\beta + \tau g - v)\varphi = -\lambda\varphi \quad \text{in } \Omega, \qquad \frac{\partial\varphi}{\partial n} = 0 \quad \text{on } \partial\Omega. \tag{2.5}$$

We remark that since the principal eigenvalue is always simple, it inherits the smoothness properties of the data in the problem. In particular, we consider below the principal eigenvalue of (2.5), $v = \tilde{v}(\cdot, \mu)$ being the positive solution of (1.6). As remarked above, $v(\cdot, \mu)$ is analytic in μ as a $W^{2,p}(\Omega)$-valued function (for any $p > 1$). Therefore, by standard analytic perturbation theory (see [K1]), the principal eigenvalue of (2.5) is an analytic function of $\tau > 0$ and $\mu > 0$.

3. Invasion of new species. As pointed out in the introduction, biologically it is important to understand the invasion of new species with low density. Mathematically, the invasion of species is determined by the stability of $(0, \tilde{v})$. This section is devoted to the study of this, and in particular we are interested in discovering conditions under which $(0, \tilde{v})$ will change stability twice (or more) as μ varies from ∞ to 0. The principal aim is to prove Theorem 1.1.

Recall that $\tilde{v} = \tilde{v}(\cdot, \mu) > 0$ is the unique positive solution of (1.6). As mentioned in section 2, for the stability of $(0, \tilde{v})$, it suffices to determine the sign of the principal eigenvalue, denoted by $\lambda_1 = \lambda_1(\mu, \tau)$, of the linear eigenvalue problem

$$\mu\Delta\varphi + (\beta + \tau g - \tilde{v})\varphi = -\lambda\varphi \quad \text{in } \Omega, \qquad \frac{\partial\varphi}{\partial n}\Big|_{\partial\Omega} = 0. \tag{3.1}$$

For any $\mu > 0$, set

$$C(\mu) := \inf_{\left\{\phi \in H^1(\Omega) : \int_\Omega g\tilde{v}^2\phi^2 > 0\right\}} \frac{\int_\Omega \tilde{v}^2|\nabla\phi|^2}{\int_\Omega g\tilde{v}^2\phi^2}. \tag{3.2}$$

LEMMA 3.1. *The following holds under the standing assumption $\tau > 0$:*

$$\lambda_1 > 0 \Leftrightarrow \tau < \mu C(\mu); \tag{3.3a}$$

$$\lambda_1 = 0 \Leftrightarrow \tau = \mu C(\mu); \tag{3.3b}$$

$$\lambda_1 < 0 \Leftrightarrow \tau > \mu C(\mu). \tag{3.3c}$$

Proof. Let $\varphi_1 > 0$ be an eigenfunction corresponding to the principal eigenvalue λ_1 of (3.1). Set $\psi = \varphi_1/\tilde{v}$. It is straightforward to see that $\psi > 0$ satisfies

$$\mu\nabla\cdot(\tilde{v}^2\nabla\psi) + \tau g\tilde{v}^2\psi = -\lambda_1\tilde{v}^2\psi \qquad \text{in } \Omega, \tag{3.4a}$$

$$\frac{\partial\psi}{\partial n}\Big|_{\partial\Omega} = 0. \tag{3.4b}$$

Suppose first that $\int_\Omega g\tilde{v}^2 > 0$. Dividing (3.4a) by ψ and integrating in Ω we have

$$\lambda_1\int_\Omega \tilde{v}^2 = -\left[\mu\int_\Omega \frac{\tilde{v}^2}{\psi^2}\,|\nabla\psi|^2 + \tau\int_\Omega g\tilde{v}^2\right] < 0, \tag{3.5}$$

so that $\lambda_1 < 0$. On the other hand, it is obvious (by taking $\phi = 1$ in (3.2)) that $C(\mu) = 0$. This proves (3.3) when $\int_\Omega g\tilde{v}^2 > 0$. The case $\int_\Omega g\tilde{v}^2 = 0$ can be handled in a similar way.

Next assume $\int_\Omega g\tilde{v}^2 < 0$. By the variational characterization (3.2) we know (see [F]) that $C(\mu) > 0$, and there exists $\tilde{\psi} > 0$ such that $\tilde{\psi}$ satisfies

$$\nabla\cdot(\tilde{v}^2\nabla\tilde{\psi}) + C(\mu)g\tilde{v}^2\tilde{\psi} = 0 \qquad \text{in } \Omega, \tag{3.6a}$$

$$\frac{\partial\tilde{\psi}}{\partial n}\Big|_{\partial\Omega} = 0. \tag{3.6b}$$

Notice that $\lambda_1 = \lambda_1(\mu, \tau)$, as a function of τ, is concave [K1]. It is easy to see that $\lambda_1(\mu, 0) = 0$ from (3.4) (with corresponding eigenfunction $\psi = 1$), and it follows from (3.6) that $\lambda_1(\mu, \mu C(\mu)) = 0$. Therefore $\lambda_1(\mu, \tau) > 0$ for $0 < \tau < \mu C(\mu)$, and $\lambda_1(\mu, \tau) < 0$ for $\tau > \mu C(\mu)$. This completes the proof of Lemma 3.1. □

Proof of Theorem 1.1. The assumptions of the theorem and asymptotic properties (2.2) yield

$$\lim_{\mu \to 0+} G(\mu) = \int_\Omega g\beta_+^2 < 0, \tag{3.7a}$$

$$\lim_{\mu \to +\infty} G(\mu) = \left(\int_\Omega g\right)\left(\int_\Omega \beta/|\Omega|\right)^2 > 0. \tag{3.7b}$$

Hence $G(\mu) = 0$ has at least one positive root. Let $\underline{\mu} \le \overline{\mu}$ denote the smallest and largest positive root of G, respectively. Recall that $C(\mu) > 0$ if $G(\mu) < 0$, and $C(\mu) = 0$ if $G(\mu) \ge 0$ (see the proof of Lemma 3.1). This ensures that $C(\mu) = 0$ for $\mu \ge \bar{\mu}$, and $C(\mu) > 0$ for $0 < \mu < \underline{\mu}$.

Choose $\phi = 1/\tilde{v}$ in (3.2): since $\int_\Omega g > 0$ and $\tilde{v} \to \beta_+$ uniformly as $\mu \to 0$, we see that

$$0 \le \mu C(\mu) \le \frac{-\mu \int_\Omega \nabla\left(\frac{1}{\tilde{v}}\right)\nabla\tilde{v}}{\int_\Omega g} = \frac{\mu \int_\Omega \frac{1}{\tilde{v}}\,\Delta\tilde{v}}{\int_\Omega g} = \frac{\int_\Omega(\tilde{v} - \beta)}{\int_\Omega g} \to \frac{\int_\Omega(\beta_+ - \beta)}{\int_\Omega g}$$

as $\mu \to 0$. This ensures that $\mu C(\mu)$ is bounded. Moreover, if (1.10) is satisfied, then

$$\mu C(\mu) \to 0 \qquad \text{as } \mu \to 0+\,. \tag{3.8}$$

Indeed, choose a smooth nonzero function ϕ with compact support in Ω^+. Then for all small $\mu > 0$, we have

$$\int_\Omega g\tilde{v}^2\phi^2 = \int_{\Omega^+} g\tilde{v}^2\phi^2 \approx \int_{\Omega^+} g\beta^2\phi^2 > 0$$

(so that ϕ is an admissible test function in (3.2)) and

$$C(\mu) \le \frac{\int_{\Omega^+} \tilde{v}^2|\nabla\phi|^2}{\int_{\Omega^+} g\tilde{v}^2\phi^2} \to \frac{\int_{\Omega^+} \beta^2|\nabla\phi|^2}{\int_{\Omega^+} g\beta^2\phi^2};$$

hence $\mu C(\mu) \to 0$.

We verify that

$$\tau_0 := \sup_{0<\mu<\infty} \mu C(\mu) \tag{3.9}$$

has the properties stated in the theorem. If $\tau > \tau_0$, then $\tau > \mu C(\mu)$ for any $\mu \in (0, \infty)$. By Lemma 3.1, this implies that $(0, \tilde{v})$ is unstable for any μ. On the other hand, if $0 < \tau < \tau_0$, then $\tau - \mu C(\mu)$ has at least one root and, by (3.8), it has at least two roots if condition (1.10) is satisfied. We claim that $\mu \mapsto \tau - \mu C(\mu)$ actually changes sign, and it does so at least twice if (1.10) is satisfied. By Lemma 3.1, this proves that $(0, \tilde{v})$ changes stability, and it does so at least twice if (1.10) holds.

To prove the claim, it suffices to exclude the possibility that $\mu C(\mu) \equiv \tau$ in some interval of μ, say $[\mu_1, \mu_2]$. We argue by the contradiction: if this is the case, by

Lemma 3.1 we see that $\lambda_1(\mu,\tau)\equiv 0$ for $\mu\in[\mu_1,\mu_2]$. Since λ_1 is an analytic function of μ (see section 2), $\lambda_1\equiv 0$ for any $\mu>0$. However, (2.2b), (3.5), and A2$^+$ imply that $\lambda_1(\mu,\tau)<0$ for large values of μ—a contradiction. □

The above proof shows that if $\mu>\overline{\mu}$, then for $\tau>0$ we have $\tau>\mu C(\mu)$, and hence $(0,\tilde{v})$ is unstable. For future reference we state this in a more precise form as the following.

COROLLARY 3.2. *Assume* A1, A2$^+$ *are satisfied. Further assume that for some* $\overline{\mu}>0$ *one has* $G(\mu)\neq 0$ *for* $\mu>\overline{\mu}$ *(hence* $G(\mu)>0$ *for* $\mu>\overline{\mu}$*, by* (3.7b)*). Then for any* $\mu>\overline{\mu}$ *and* $\tau>0$ *the semitrivial equilibrium* $(0,\tilde{v})$ *is unstable.*

4. Two similar competing species. In this section we consider the case τ positive but small; i.e., the two competing species are very similar. In subsection 4.1 we shall discuss the coexistence states and the dynamics of (1.8) for $\tau\ll 1$ and μ bounded away from zero. Theorem 1.2 will be proved in this subsection. In subsection 4.2 we shall establish Theorem 1.4, which covers the remaining case $\tau\ll 1$ and $\mu\ll 1$. Finally in subsection 4.3 we shall address some biological questions and prove Theorem 1.5. As can be seen later, Theorem 1.5 is supplementary to the results of subsection 4.1 as it gives more detailed information on the bifurcation diagram of coexistence states of (1.8).

4.1. Dynamics of (1.8) for $\tau\ll 1$ and μ bounded away from zero. The main purpose of this subsection is to prove Theorem 1.2. As will become clear later, Theorem 1.2 is a consequence of the following result.

THEOREM 4.1. *Assume* A1. *For any* $\tilde{\mu}>0$ *the following statements hold true:*

(i) *If* $G(\tilde{\mu})\neq 0$, *then there exists* $\epsilon>0$ *such that for* $\mu\in(\tilde{\mu}-\epsilon,\tilde{\mu}+\epsilon)$ *and* $\tau\in(0,\epsilon)$ *problem* (1.8) *has no coexistence states.*

(ii) *If* $G(\tilde{\mu})=0$ *and* $G'(\tilde{\mu})\neq 0$, *then for any sufficiently small* $\epsilon>0$, *there exists* $\tilde{\tau}=\tilde{\tau}(\epsilon)>0$ *with the following property. For every* $\tau\in(0,\tilde{\tau})$, *there exist* $\mu_*<\mu^*$ *with* $\mu_*,\mu^*\in(\tilde{\mu}-\epsilon,\tilde{\mu}+\epsilon)$ *such that for* $\mu\in[\tilde{\mu}-\epsilon,\tilde{\mu}+\epsilon]$, (1.8) *has a coexistence state if and only if* $\mu\in(\mu_*,\mu^*)$*; moreover, any coexistence state, if it exists, is the global attractor of* (1.8).

A crucial step in the proof of the theorem is a local bifurcation analysis. For $\tau\approx 0$, we look for triples (u,v,μ) that satisfy

$$\begin{aligned}
&\mu\Delta u+u(\beta(x)+\tau g(x)-u-v)=0, && x\in\Omega,\\
&\mu\Delta v+v(\beta(x)-u-v)=0, && x\in\Omega,\\
&\frac{\partial u}{\partial n}=\frac{\partial v}{\partial n}=0 \quad \text{on } \partial\Omega
\end{aligned} \tag{4.1}$$

and that are close to the curve $\Upsilon_{\tilde{\mu}}\times\{\tilde{\mu}\}$, where

$$\Upsilon_\mu:=\{(s\tilde{v}(\cdot,\mu),(1-s)\tilde{v}(\cdot,\mu)):s\in[0,1]\}.$$

Note that for any μ, $\Upsilon_\mu\times\{\mu\}$ is a curve of solutions of (4.1) for $\tau=0$. Also, for any small τ, (4.1) has the semitrivial solutions

$$\begin{aligned}
&(0,\tilde{v}(\cdot,\mu),\mu) \quad \text{(independent of } \tau),\\
&(\tilde{u}(\cdot,\mu,\tau),0,\mu),
\end{aligned} \tag{4.2}$$

where $\tilde{u}(\cdot,\mu,\tau)$ is the positive solution of (1.3) with $\alpha(x):=\beta(x)+\tau g(x)$.

For the functional analytic framework of the local analysis we introduce the following spaces:

$$Y = L^p(\Omega) \times L^p(\Omega),$$
$$X = \left\{ (y,z) \in W^{2,p}(\Omega) \times W^{2,p}(\Omega) : \frac{\partial y}{\partial n} = \frac{\partial z}{\partial n} = 0 \text{ on } \partial\Omega \right\},$$
$$X_2 = \left\{ (y,z) \in X : \int_\Omega (y(x) - z(x))\tilde{v}(x,\tilde{\mu})\, dx = 0 \right\},$$

where $p > N/2$ (so that $W^{2,p}(\Omega) \hookrightarrow C(\overline{\Omega})$).

PROPOSITION 4.2. *Let the hypotheses of Theorem* 4.1 *be satisfied. Then there exist a neighborhood U of the curve $\Upsilon_{\tilde{\mu}} \times \{\tilde{\mu}\}$ in $X \times (0,\infty)$ and $\delta > 0$ with the following properties:*

(i) *If $G(\tilde{\mu}) \neq 0$, then for $\tau \in (0,\delta)$ there are no solutions of* (4.1) *in U other than the semitrivial solutions* (4.2).

(ii) *If $G(\tilde{\mu}) = 0$ and $G'(\tilde{\mu}) \neq 0$, then for $\tau \in (0,\delta)$ the set of solutions of* (4.1) *in U consists of the semitrivial solutions and of the set $\Xi \cap U$, where Ξ is a smooth curve given by*

$$\Xi = \{(u(\tau,s), v(\tau,s), \mu(\tau,s)) : \ -\delta \le s \le 1+\delta\}. \tag{4.3}$$

Here $(\tau,s) \mapsto (u(\tau,s), v(\tau,s)) \in X$ and $(\tau,s) \mapsto \mu(\tau,s) \in (0,\infty)$ are smooth functions on $[0,\delta) \times (-\delta, 1+\delta)$ satisfying the following relations:

$$(u(\tau,0), v(\tau,0)) = (0, \tilde{v}(\cdot, \mu(\tau,0))), \tag{4.4}$$
$$(u(\tau,1), v(\tau,1)) = (\tilde{u}(\cdot, \mu(\tau,1), \tau), 0), \tag{4.5}$$
$$(u(0,s), v(0,s), \mu(0,s)) = (s\tilde{v}(\cdot,\tilde{\mu}), (1-s)\tilde{v}(\cdot,\tilde{\mu}), \tilde{\mu}). \tag{4.6}$$

In other words, a branch of coexistence states bifurcates from the branch of semitrivial equilibria $(\tilde{u}, 0)$ at $\mu = \mu(\tau,1)$ and meets the other branch of semitrivial equilibria $(0,\tilde{v})$ at $\mu = \mu(\tau,0)$. For $\tau = 0$ the branch coincides with with $\Upsilon_{\tilde{\mu}}$.

Note that from (4.6) it follows that the functions $u(\tau,s)$, $v(\tau,s)$, $\mu(\tau,s)$ have the following expansions for $-\delta \le s \le 1+\delta$ and $\tau \to 0$:

$$\begin{aligned} u(\tau,s) &= s\tilde{v}(\cdot,\tilde{\mu}) + \tau u_1(s) + O(\tau^2), \\ v(\tau,s) &= (1-s)\tilde{v}(\cdot,\tilde{\mu}) + \tau v_1(s) + O(\tau^2), \\ \mu(\tau,s) &= \tilde{\mu} + \tau\tilde{\mu}_1(s) + O(\tau^2), \end{aligned} \tag{4.7}$$

where $(u_1, v_1) \in X$ and $\tilde{\mu}_1 \in (0,\infty)$ are smooth functions of s. We will use these expansions below.

Proof of Proposition 4.2. For any triple (u,v,μ) near $\Upsilon_{\tilde{\mu}} \times \{\tilde{\mu}\}$, (u,v) can be written in a unique way as

$$(u,v) = (s\tilde{v}(\cdot,\mu), (1-s)\tilde{v}(\cdot,\mu)) + (y,z), \tag{4.8}$$

where $s \in \mathbb{R}$ and $(y,z) \in X_2$, and they are in or near $[0,1]$ and $\{(0,0)\}$, respectively. We shall thus look for solutions of (4.1) in this form. For that, an explicit expression of s and (y,z) in (4.8) will be useful. Writing (4.8) as

$$(u, v - \tilde{v}(\cdot,\mu)) = s(\tilde{v}(\cdot,\mu), -\tilde{v}(\cdot,\mu)) + (y,z),$$

we find s and (y,z) from

$$(y,z) = Q(\mu)(u, v-\tilde{v}(\cdot,\mu)),$$
$$s(\tilde{v}(\cdot,\mu), -\tilde{v}(\cdot,\mu)) = (I-Q(\mu))(u, v-\tilde{v}(\cdot,\mu)),$$

where I is the identity on X and $Q(\mu)$ is the projection of X onto X_2 along the subspace

$$X_1(\mu) := \operatorname{span}\{(\tilde{v}(\cdot,\mu), -\tilde{v}(\cdot,\mu))\}.$$

(Note that $X_1(\mu)$ is a complement of X_2 in X for $\mu \approx \tilde{\mu}$.) In particular, we find the following values of s and (y,z) for semitrivial equilibria:

$$(0,\tilde{v}(\cdot,\mu)) = (0,\tilde{v}(\cdot,\mu)) + (0,0) \quad (\text{i.e., } s=0,\ (y,z)=(0,0)), \tag{4.9a}$$
$$(\tilde{u}(\cdot,\mu,\tau),0) = (s\tilde{v}(\cdot,\mu),(1-s)\tilde{v}(\cdot,\mu)) + (\eta(\tau,\mu),\zeta(\tau,\mu)),\ \text{with } s=\sigma(\tau,\mu), \tag{4.9b}$$

where (η,ζ) and σ are smooth functions of (τ,μ) taking values in X_2 and $\mathbb{R}$, respectively. Clearly,

$$\sigma(0,\mu) = 1, \qquad (\eta(0,\mu),\zeta(0,\mu)) = (0,0), \tag{4.10}$$

as $\tilde{u}(\cdot,\mu,0) = v(\cdot,\mu)$.

For a small $\delta > 0$ let H be the map on

$$X \times (-\delta,\delta) \times (-\delta, 1+\delta) \times (\tilde{\mu}-\delta, \tilde{\mu}+\delta)$$

defined by

$$H(y,z,\tau,s,\mu) = \begin{bmatrix} \mu\Delta y - (y+z)s\tilde{v}(\cdot,\mu) + (\beta - \tilde{v}(\cdot,\mu))y - (y+z)y + \tau g s\tilde{v}(\cdot,\mu) + \tau g y \\ \mu\Delta z - (y+z)(1-s)\tilde{v}(\cdot,\mu) + (\beta-\tilde{v}(\cdot,\mu))z - (y+z)z \end{bmatrix}.$$

Note that, since $X \hookrightarrow C(\overline{\Omega}) \times C(\overline{\Omega}) \hookrightarrow Y$, H is well defined and smooth (in fact polynomial) as a Y-valued map. To find solutions of (4.1), we need to solve the equation

$$H(y,z,\tau,s,\mu) = 0, \tag{4.11}$$

with $(y,z) \in X_2$. It will be useful, however, to examine properties of $H(y,z,\tau,s,\mu)$ for $(y,z) \in X$. From the form of the solutions of (4.1) mentioned above (see (4.2) and the text preceding it) and by (4.9), we have

$$H(0,0,0,s,\mu) \equiv 0 \quad (s \in (-\delta, 1+\delta),\ \mu \in (\tilde{\mu}-\delta,\tilde{\mu}+\delta)), \tag{4.12a}$$
$$H(0,0,\tau,0,\mu) \equiv 0 \quad (\tau \in (-\delta,\delta),\ \mu \in (\tilde{\mu}-\delta,\tilde{\mu}+\delta)), \tag{4.12b}$$
$$H(\eta(\tau,\mu),\zeta(\tau,\mu),\tau,\sigma(\tau,\mu),\mu) \equiv 0 \quad (\tau \in (-\delta,\delta),\ \mu \in (\tilde{\mu}-\delta,\tilde{\mu}+\delta)). \tag{4.12c}$$

Define

$$L(s,\mu) := D_{(y,z)}H(0,0,0,s,\mu) \in \mathcal{L}(X,Y).$$

It is a standard consequence of the compactness of the embedding $W^{2,p}(\Omega) \hookrightarrow L^p(\Omega)$ that $L(s,\mu)$ is a Fredholm operator of zero index. By the definition of H, the vector $(\tilde{v}(\cdot,\mu), -\tilde{v}(\cdot,\mu))$ is in the kernel of $L(s,\mu)$. Put differently, $(\tilde{v}(\cdot,\mu), -\tilde{v}(\cdot,\mu))$ is an

eigenfunction corresponding to the eigenvalue 0 of $L(s,\mu)$, when $L(s,\mu)$ is viewed as an operator on Y with domain X. Since $\tilde{v}(\cdot,\mu) > 0$, zero must be a simple eigenvalue (cf. section 2) and we have

$$\ker L(s,\mu) = \operatorname{span}\{(\tilde{v}(\cdot,\mu), -\tilde{v}(\cdot,\mu))\} = X_1(\mu).$$

Let $P(s,\mu)$ be the continuous linear projection of Y onto $X_1(\mu)$ along the range of $L(s,\mu)$ (the range $R(L(s,\mu))$ is a closed subspace of Y of codimension one). We can write $P(s,\mu)$ explicitly as follows:

$$P(s,\mu)(y,z) = \frac{(1-s)\int_\Omega \tilde{v}(\cdot,\mu)y - s\int_\Omega \tilde{v}(\cdot,\mu)z}{\int_\Omega \tilde{v}^2(\cdot,\mu)} \left(\tilde{v}(\cdot,\mu), -\tilde{v}(\cdot,\mu)\right). \tag{4.13}$$

To verify this formula, one needs to show that

$$R(P(s,\mu)) = X_1(\mu), \quad (P(s,\mu))^2 = P(s,\mu), \quad \text{and } P(s,\mu)L(s,\mu) = 0.$$

The first property is obvious; the other two follow from a straightforward computation, which is left to the reader. Formula (4.13) in particular implies

$$Y_2(s,\mu) := R(L(s,\mu)) = \left\{(y,z) \in Y : (1-s)\int_\Omega \tilde{v}(\cdot,\mu)y - s\int_\Omega \tilde{v}(\cdot,\mu)z = 0\right\}.$$

Also note that $(s,\mu) \mapsto P(s,\mu)$ is smooth (in the operator norm). Following the Lyapunov–Schmidt scenario, we now consider the system

$$P(s,\mu)H(y,z,\tau,s,\mu) = 0, \tag{4.14a}$$

$$(I - P(s,\mu))H(y,z,\tau,s,\mu) = 0, \tag{4.14b}$$

where $(y,z) \in X_2$ and I is the identity on Y. If μ is sufficiently close to $\tilde{\mu}$ (and we make δ small enough for that to hold for all $\mu \in (\tilde{\mu}-\delta, \tilde{\mu}+\delta)$), then

$$\ker(L(s,\mu)) \cap X_2 = \{0\}.$$

It follows that $L(s,\mu)$ is an isomorphism of X_2 onto $Y_2(s,\mu)$. By the implicit function theorem, we can thus solve (4.14b) for (y,z), which leads to the following conclusion. There exist $\delta_1 > 0$, a neighborhood V of $(0,0) \in X_2$, and a smooth function

$$(\tau,s,\mu) \mapsto (y(\tau,s,\mu), z(\tau,s,\mu)) : (-\delta_1,\delta_1) \times (-\delta_1, 1+\delta_1) \times (\tilde{\mu}-\delta_1, \tilde{\mu}+\delta_1) \to X_2$$

such that $(y(0,s,\mu), z(0,s,\mu)) = (0,0)$ and $(y,z,\tau,s,\mu) \in V \times (-\delta_1,\delta_1) \times (-\delta_1, 1+\delta_1) \times (\tilde{\mu}-\delta_1, \tilde{\mu}+\delta_1)$ satisfies (4.11) if and only if $(y,z) = (y(\tau,s,\mu), z(\tau,s,\mu))$ and (τ,s,μ) solves the bifurcation equation

$$P(s,\mu)H(y(\tau,s,\mu), z(\tau,s,\mu), \tau, s, \mu) = 0.$$

By (4.12b), (4.12c), y and z necessarily satisfy

$$\begin{aligned} (y(\tau,0,\mu), z(\tau,0,\mu)) &= (0,0), \\ (y(\tau,\sigma(\tau,\mu),\mu), z(\tau,\sigma(\tau,\mu),\mu)) &= (\eta(\tau,\mu), \zeta(\tau,\mu)). \end{aligned} \tag{4.15}$$

Now, defining $\xi(\tau,s,\mu)$ by

$$\xi(\tau,s,\mu)\left(\tilde{v}(\cdot,\mu), -\tilde{v}(\cdot,\mu)\right) = P(s,\mu)H(y(\tau,s,\mu), z(\tau,s,\mu), \tau, s, \mu),$$

the bifurcation equation is equivalent to

$$\xi(\tau, s, \mu) = 0. \tag{4.16}$$

We immediately have the following solutions of (4.16):

$$\xi(0, s, \mu) \equiv \xi(\tau, 0, \mu) \equiv \xi(\tau, \sigma(\tau, \mu), \mu) \equiv 0. \tag{4.17}$$

These identities hold because for each of the indicated values of $(\tau, s, \mu) \in (-\delta_1, \delta_1) \times (-\delta_1, 1 + \delta_1) \times (\tilde{\mu} - \delta_1, \tilde{\mu} + \delta_1)$, there is a solution $(y, z) \in V$ of (4.11); see (4.12) (we make δ_1 smaller, if necessary, so that the solutions are indeed contained in V). Recall in passing that, from these solutions, the triples $(\tau, 0, \mu)$ and $(\tau, \sigma(\tau, \mu), \mu)$ correspond to semitrivial equilibria of (4.1); see (4.9), (4.15).

It follows from (4.17) that

$$\xi(\tau, s, \mu) \equiv s(\sigma(\tau, \mu) - s)\tau\xi_1(\tau, s, \mu)$$

for some smooth function $\xi_1(\tau, s, \mu)$. Solutions of (4.16) different from (4.17) are found by solving

$$\xi_1(\tau, s, \mu) = 0. \tag{4.18}$$

Observe that

$$\partial_\tau \xi(0, s, \mu) \equiv s(1 - s)\xi_1(0, s, \mu),$$

as $\sigma(0, \mu) \equiv 1$. The derivative on the left-hand side is computed from

$$\begin{aligned}\big(\tilde{v}(\cdot, \mu), -\tilde{v}(\cdot, \mu)\big)\partial_\tau \xi(0, s, \mu) &= \partial_\tau (P(s, \mu)H(y(\tau, s, \mu), z(\tau, s, \mu), \tau, s, \mu)) \,\big|_{\tau=0} \\ &= P(s, \mu)H_\tau(0, 0, 0, s, \mu) + P(s, \mu)L(s, \mu)(y_\tau, z_\tau) \\ &= P(s, \mu)H_\tau(0, 0, 0, s, \mu)\end{aligned}$$

(recall that $R(L(s, \mu)) = \ker P(s, \mu)$). Using (4.13), we find

$$P(s, \mu)H_\tau(0, 0, 0, s, \mu) = P(s, \mu)\big(sg\tilde{v}(\cdot, \mu), 0\big) = \frac{s(1 - s)\int_\Omega g\tilde{v}^2}{\int_\Omega \tilde{v}^2}\,\big(\tilde{v}(\cdot, \mu), -\tilde{v}(\cdot, \mu)\big).$$

Thus

$$\partial_\tau \xi(0, s, \mu) = \frac{s(1 - s)G(\mu)}{\int_\Omega \tilde{v}^2},$$

i.e.,

$$\xi_1(0, s, \mu) = \frac{G(\mu)}{\int_\Omega \tilde{v}^2}. \tag{4.19}$$

To complete the proof, consider first the case $G(\tilde{\mu}) \neq 0$. Making δ_1 yet smaller, if necessary, we infer from (4.19) that (4.18) has no solution in $(-\delta_1, \delta_1) \times (-\delta_1, 1 + \delta_1) \times (\tilde{\mu} - \delta_1, \tilde{\mu} + \delta_1)$. This implies statement (i) of Proposition 4.2.

Now assume $G(\tilde{\mu}) = 0$. Then

$$\partial_\mu \xi_1(0, s, \mu) \,\big|_{\mu=\tilde{\mu}} = \frac{G'(\tilde{\mu})}{\int_\Omega \tilde{v}^2(x, \tilde{\mu})}.$$

If $G'(\tilde{\mu}) \neq 0$, the implicit function theorem implies that for some $\delta_2 > 0$, all solutions of (4.18) in $(-\delta_2, \delta_2) \times (-\delta_2, 1+\delta_2) \times (\tilde{\mu}-\delta_2, \tilde{\mu}+\delta_2)$ are given by

$$\mu = m(\tau, s), \qquad \tau \in (-\delta_2, \delta_2), \quad s \in (-\delta_2, 1+\delta_2),$$

where $m(\tau, s)$ is a smooth function satisfying $m(0, s) \equiv \tilde{\mu}$. Thus, in addition to the immediate solutions (4.17), the bifurcation equation (4.16) has the family of solutions

$$\{(\tau, s, m(\tau, s)) : \tau \in (-\delta_2, \delta_2),\ s \in (-\delta_2, 1+\delta_2)\}. \tag{4.20}$$

In this family, the point $(\tau, 0, m(\tau, 0))$ is also contained in the set of solutions found in (4.17), and it corresponds to the semitrivial solution $(0, \tilde{v}(\cdot, \mu))$ of (4.1) with $\mu = m(\tau, 0)$ (see the remarks following (4.17)). Next we look for points $(\tau, s, m(\tau, s))$ in the family corresponding to the semitrivial equilibria $(\tilde{u}(\cdot, \mu, \tau), 0)$. Referring to the remarks following (4.17) again, we see that s and τ are found from the equation

$$s = \sigma(\tau, m(\tau, s)). \tag{4.21}$$

Since $\sigma(0, \mu) \equiv 1$, for $\tau \approx 0$ there is a unique solution $s = \bar{s}(\tau)$ of (4.21), and it depends smoothly on τ. Hence for each fixed $\tau \approx 0$, $(\tau, \bar{s}(\tau), m(\tau, \bar{s}(\tau)))$ is a point contained in the family (4.20) which corresponds to the semitrivial solution $(\tilde{u}(\cdot, \mu, \tau), 0)$ of (4.1) with $\mu = m(\tau, \bar{s}(\tau))$.

Using the scaled variable $\tilde{s} = s\bar{s}(\tau)$, we now define

$$\begin{aligned} u(\tau, s) &= \tilde{s}\tilde{v}(\cdot, m(\tau, \tilde{s})) + y(\tau, \tilde{s}, m(\tau, \tilde{s})), \\ v(\tau, s) &= (1-\tilde{s})\tilde{v}(\cdot, m(\tau, \tilde{s})) + z(\tau, \tilde{s}, m(\tau, \tilde{s})), \\ \mu(\tau, s) &= m(\tau, \tilde{s}) \quad (\tilde{s} = s\bar{s}(\tau)). \end{aligned}$$

Clearly, these are smooth functions of $(\tau, s) \in (-\delta, \delta) \times (-\delta, 1+\delta)$ if δ is sufficiently small, and $(u(\tau, s), v(\tau, s))$ is a solution of (4.1) for $\mu = m(\tau, s)$. By construction, these solutions, together with the semitrivial equilibria, contain all solutions of (4.1) in a small neighborhood of $\Upsilon_{\tilde{\mu}} \times \{\tilde{\mu}\}$ for $\tau \in (-\delta, \delta)$. The relations $(y(0, s, \mu), z(0, s, \mu)) = (0, 0)$, $m(0, s) = \tilde{\mu}$, and $\bar{s}(0) = 1$ imply (4.6). The correspondences between the solutions $(\tau, \bar{s}(\tau), m(\tau, \bar{s}(\tau)))$, $(\tau, 0, \mu(0, \tau))$ of (4.16) and the semitrivial equilibria, as discussed above, imply (4.4), (4.5). This completes the proof. □

The next lemma shows that by the local analysis we have found all coexistence states.

LEMMA 4.3. *Let the hypotheses of Theorem* 4.1 *be satisfied. Then given any neighborhood U of the curve $\Upsilon_{\tilde{\mu}} \times \{\tilde{\mu}\}$ in $X \times (0, \infty)$ there exists $\delta > 0$ such that for $\tau \in (-\delta, \delta)$ all solutions (u, v, μ) of* (4.1) *with $u, v \geq 0$ and $|\mu - \tilde{\mu}| \leq \delta$ are contained in U.*

Proof. The conclusion follows once we prove the following claim. If $\tau_j \to 0+$, $\mu_j \to \tilde{\mu}$, and (u_j, v_j, μ_j) is a sequence of solutions of (4.1) with $\tau = \tau_j$, $\mu = \mu_j$ such that $u_j, v_j \geq 0$, then (u_j, v_j) approaches the curve $\Upsilon_{\tilde{\mu}}$.

By the maximum principle, we have the following a priori bound on the nonnegative solutions:

$$u_j \leq \sup(\beta(x) + \tau g(x)), \quad v_j \leq \sup \beta(x).$$

Since $\tau_j \to 0+$, $\mu_j \to \tilde{\mu}$, by standard elliptic estimates (see [GT]), passing to a

subsequence we may assume that $(u_j, v_j) \to (\hat{u}, \hat{v})$ in X, where $\hat{u},\ \hat{v} \geq 0$ in $\bar{\Omega}$, and

$$\tilde{\mu}\Delta\hat{u} + \hat{u}(\beta - \hat{u} - \hat{v}) = 0 \quad \text{in} \quad \Omega, \tag{4.22a}$$

$$\tilde{\mu}\Delta\hat{v} + \hat{v}(\beta - \hat{u} - \hat{v}) = 0 \quad \text{in} \quad \Omega, \tag{4.22b}$$

$$\frac{\partial\hat{u}}{\partial n} = \frac{\partial\hat{v}}{\partial n} = 0 \quad \text{on} \quad \partial\Omega. \tag{4.22c}$$

Since any solution $(\hat{u}, \hat{v})$ of (4.22) with $\hat{u},\ \hat{v} \geq 0$ is contained on the curve $\Upsilon_{\tilde{\mu}}$, the claim follows. □

In the remainder of the subsection, we simplify the notation by writing

$$\tilde{v} = \tilde{v}(x, \tilde{\mu}).$$

For other values of μ we keep the notation $\tilde{v}(x, \mu)$.

The next crucial step is the stability of coexistence states on the curve Ξ: Let

$$(u, v, \mu) = (u(\tau, s), v(\tau, s), \mu(\tau, s)) \in \Xi,$$

and consider the corresponding linear eigenvalue problem (2.3). When $\tau = 0$, we have $(u, v) = (s\tilde{v}, (1 - s)\tilde{v})$ and (2.3) has an eigenvalue $\lambda = 0$, the corresponding eigenfunction being $(\tilde{v}, -\tilde{v})$. Since $\tilde{v} > 0$, $\lambda = 0$ is the principal eigenvalue (see section 2); in particular, it is (algebraically) simple and all other eigenvalues are positive. By standard spectral perturbation theory [K2], for $|\tau| \ll 1$, (2.3) has a unique eigenvalue, denoted by $\lambda(\tau, s)$ such that $\lim_{\tau\to 0} \lambda(\tau, s) = 0$, and all the other eigenvalues of (2.3) are positive and uniformly bounded away from zero for any $s \in [0, 1]$ and small positive τ. Hence the sign of $\lambda(\tau, s)$ determines the stability of coexistence states on Ξ. Note that

$$\lambda(\tau, 0) = \lambda(\tau, 1) = 0 \tag{4.23}$$

for $\mu(\tau, 0)$ and $\mu(\tau, 1)$ are bifurcation points (points of intersections of Ξ with the branches of semitrivial solutions). It is not hard to check that $\lambda_\tau(0, s) = 0$ (see Appendix A) and Proposition 4.4 below gives a formula for $\lambda_{\tau\tau}(0, s)$; the proof is a straightforward but tedious computational exercise and is given in Appendix A. For the formulation we introduce some notation. Let $H = L^2(\Omega)$ be the usual Hilbert space with norm $\|\cdot\|$ and inner product $(\cdot, \cdot)$. Take the linear subspace spanned by $\tilde{v}$ to be Θ and let $\Theta^\perp$ be its orthogonal complement. Denote the domain and kernel of a linear operator $\mathcal{L}$ by $\mathrm{dom}(\mathcal{L})$ and $\ker(\mathcal{L})$, respectively, so $\mathcal{L} : \mathrm{dom}(\mathcal{L}) \to H$. Consider the formally self-adjoint operator $\tilde{\mu}\Delta + \beta - \tilde{v}$ and define in the standard manner the self-adjoint operator on H corresponding to zero Neumann boundary conditions. We thus have the self-adjoint operators

$$\mathcal{L} = \tilde{\mu}\Delta + \beta - \tilde{v},$$
$$\mathcal{L} - \tilde{v} = \tilde{\mu}\Delta + \beta - 2\tilde{v}.$$

Since the principal eigenvalue of $\mathcal{L}$ is 0 (the eigenfunction is $\tilde{v}$), it is straightforward to show that $\mathcal{L} - \tilde{v}$ has the bounded inverse $(\mathcal{L} - \tilde{v})^{-1}$ on H, and we define $\mathcal{L}^{-1}$ on $\Theta^\perp$ by setting $\mathcal{L}^{-1}\phi = \psi$ if and only if $\mathcal{L}\psi = \phi$ and $\phi, \psi \in \Theta^\perp$.

PROPOSITION 4.4. *For $0 \le s \le 1$ and $0 < \tau \ll 1$, the following statements hold:*
(i)

$$\lambda(\tau, s) = s(1-s)\tau^2 \left\{ \frac{2}{\int_\Omega \tilde{v}^2} \int_\Omega g\tilde{v} \left[(\mathcal{L} - \tilde{v})^{-1} - \mathcal{L}^{-1} \right] g\tilde{v} + C_1(\tau, s)\tau \right\},$$

where $C_1(\tau, s)$ is some constant uniformly bounded for $s \in [0,1]$ and $\tau \ll 1$.
(ii) *With $\tilde{\mu}_1$ as in* (4.7), *one has*

$$\tilde{\mu}_1(s) = \frac{1}{G'(\tilde{\mu})} \int_\Omega g\tilde{v} \left[2s(\mathcal{L} - \tilde{v})^{-1}(g\tilde{v}) + (1-2s)\mathcal{L}^{-1}(g\tilde{v}) \right].$$

Note that, by our assumption, $G(\tilde{\mu}) = \int g\tilde{v}^2 = 0$, so that $\mathcal{L}^{-1}(g\tilde{v})$ is well defined.

LEMMA 4.5. *The following holds for any nontrivial $\varphi \in \Theta^\perp$:*

$$\int_\Omega \varphi \left[(\mathcal{L} - \tilde{v})^{-1} - \mathcal{L}^{-1} \right] \varphi > 0. \tag{4.24}$$

Proof. For $\tau > 0$ let

$$h(\tau) = \int_\Omega \varphi (\mathcal{L} - \tau\tilde{v})^{-1} \varphi. \tag{4.25}$$

Since $\mathcal{L} - \tau\tilde{v}$ is invertible for $\tau > 0$, h is well defined. We claim that h is strictly increasing. To prove this set $\Phi = (\mathcal{L} - \tau\tilde{v})^{-1}\varphi$. It is easy to check that

$$\frac{\partial \Phi}{\partial \tau} = (\mathcal{L} - \tau\tilde{v})^{-1}(\tilde{v}\Phi). \tag{4.26}$$

Then

$$\begin{aligned} \frac{dh}{d\tau} &= \int_\Omega \varphi \frac{\partial \Phi}{\partial \tau} = \int_\Omega \varphi (\mathcal{L} - \tau\tilde{v})^{-1}(\tilde{v}\Phi) \\ &= \int_\Omega (\mathcal{L} - \tau\tilde{v})^{-1}\varphi \cdot \tilde{v}\Phi \qquad \text{(self-adjointness of } (\mathcal{L} - \tau\tilde{v})^{-1}) \\ &= \int_\Omega \tilde{v}\Phi^2 > 0. \end{aligned} \tag{4.27}$$

The last inequality in (4.27) is strict since $\Phi \not\equiv 0$. In particular, we have $h(1) > \lim_{\tau \to 0+} h(\tau)$. In the following we show that

$$\lim_{\tau \to 0+} h(\tau) = \int_\Omega \varphi \mathcal{L}^{-1} \varphi \tag{4.28}$$

for every $\varphi \in \Theta^\perp$, from which (4.24) follows.

To prove (4.28), let $Mu := \tilde{v}u$ for $u \in H$. We always assume that $\tau > 0$ is small and that C_i are strictly positive constants independent of τ. Note that $\mathcal{L}\,\mathrm{dom}(\mathcal{L}) = \Theta^\perp$, $\mathcal{L}^{-1}\Theta^\perp \sqsubset \Theta^\perp$, and

$$\|\mathcal{L}^{-1}\| \le C_1, \tag{4.29a}$$

$$(-\mathcal{L}\phi, \phi) \ge C_2\|\phi\|^2, \qquad \phi \in \Theta^\perp \cap \mathrm{dom}(\mathcal{L}), \tag{4.29b}$$

$$\|M\| \le C_3, \tag{4.29c}$$

$$(Mu, u) \ge C_4\|u\|^2, \qquad u \in H. \tag{4.29d}$$

Consider the equation

$$(\mathcal{L}-\tau M)u=\varphi,\qquad \varphi\in\Theta^{\perp}. \tag{4.30}$$

We claim that for the solution u of (4.30) (that is, $u=(\mathcal{L}-\tau M)^{-1}\varphi$) we have

$$\|u\|\le C_5\|\varphi\|. \tag{4.31}$$

To prove this assertion, put $u=a\tilde{v}+\phi$, where $a\in\mathbb{R}$, $\phi\in\Theta^{\perp}$. Substituting in (4.30), we have

$$\mathcal{L}\phi-\tau aM\tilde{v}-\tau M\phi=\varphi. \tag{4.32}$$

Take the inner product with $\tilde{v}$ and use (4.29c) and (4.29d):

$$|a|=|(M\phi,\tilde{v})/(M\tilde{v},\tilde{v})|\le C_6\|\phi\|. \tag{4.33}$$

Take the inner product of (4.32) with $-\phi$ and use (4.29b), (4.29c), and (4.33), obtaining

$$\begin{aligned} C_2\|\phi\|^2 &\le(-\mathcal{L}\phi,\phi)=-(\varphi,\phi)-\tau a(M\tilde{v},\phi)-\tau(M\phi,\phi)\\ &\le\|\varphi\|\|\phi\|+\tau(C_6+1)C_3\|\phi\|^2, \end{aligned} \tag{4.34}$$

which implies that

$$\|\phi\|\le C_7\|\varphi\| \tag{4.35}$$

if τ is small enough. Estimates (4.33) and (4.35) prove claim (4.31).

For u given by (4.30) set

$$w=\frac{1}{\tau}\left(u-\mathcal{L}^{-1}\varphi+\frac{(M\mathcal{L}^{-1}\varphi,\tilde{v})}{(M\tilde{v},\tilde{v})}\,\tilde{v}\right). \tag{4.36}$$

It is easy to check that

$$(\mathcal{L}-\tau M)w=\varphi_1, \tag{4.37}$$

where

$$\varphi_1=M\mathcal{L}^{-1}\varphi-\frac{(M\mathcal{L}^{-1}\varphi,\tilde{v})}{(M\tilde{v},\tilde{v})}\,M\tilde{v}\in\Theta^{\perp}. \tag{4.38}$$

Obviously $\|\varphi_1\|\le C_8\|\varphi\|$, so using (4.31) on (4.37) with φ_1, w replacing φ, u, respectively, we find that $\|w\|\le C_5\|\varphi_1\|\le C_9\|\varphi\|$.

Finally, for any $\varphi\in\Theta^{\perp}$, from (4.36)

$$h(\tau)=(\varphi,u)=(\varphi,\mathcal{L}^{-1}\varphi)+\tau(\varphi,w). \tag{4.39}$$

Since $\|w\|$ is uniformly bounded, we deduce that, as required, $\lim_{\tau\to0+}h(\tau)=(\varphi,\mathcal{L}^{-1}\varphi)$. This proves Lemma 4.5. □

Proof of Theorem 4.1. By Proposition 4.2 and Lemma 4.3, for $\mu\approx\tilde{\mu}$ and $\tau\approx0$, all coexistence states lie on the branch Ξ. On the branch we have

$$\mu(\tau,s)=\tilde{\mu}+\tau\tilde{\mu}_1(s)+\tau^2H(\tau,s)$$

for some smooth function H. By Proposition 4.4 and Lemma 4.5, $\tilde{\mu}_1$ is a nonconstant affine function, and thus for small τ, $\mu(\tau,\cdot)$ is strictly monotone. It follows that the first statement of the theorem holds with

$$\mu_* = \min_{s\in[0,1]} \mu(\tau,s), \qquad \mu_* = \max_{s\in[0,1]} \mu(\tau,s)$$

and that the coexistence state is unique for each fixed $\mu \in (\mu_*,\mu^*)$. By Proposition 4.4 and Lemma 4.5, we also have $\lambda(\tau,s) > 0$ for small τ, and thus the coexistence state is stable. As noted in section 2, the uniqueness and stability of the coexistence state implies that it is the global attractor. The theorem is proved. □

We end this subsection by applying Theorem 4.1 to the proof of Theorem 1.2.

Proof of Theorem 1.2. In view of Theorem 4.1 and Lemma 4.3, by the standard compactness argument, the dynamics and the structures of the coexistence state are clear for values of μ in any compact subset of $(0,\infty)$. To complete the proof of Theorem 1.2, it suffices to show that under the stronger assumption A2$^+$, $(\tilde{u},0)$ is the global attractor of (1.8) for $\mu > \mu_k^*(\tau)$. By Corollary 3.2 and Theorem 4.1, we see that $(0,\tilde{v})$ is unstable for $\mu > \mu_{k,*}(\tau)$. Therefore in view of property (a) of system (1.8) (see section 2), it suffices to show that (1.8) has no coexistence state for $\mu \geq \mu_k^*(\tau)$. By Lemma 4.3 and Theorem 4.1, it suffices to prove this for sufficiently large μ and positive bounded τ. To this end, we argue by contradiction. Suppose that there exist sequences τ_j uniformly bounded and $\mu_j \to \infty$ such that (1.8) has coexistence states $\{(u_j,v_j)\}_{j=1}^{\infty}$ with $(\tau,\mu) = (\tau_j,\mu_j)$. Set $\hat{u}_j = u_j/\|u_j\|_\infty$, $\hat{v}_j = v_j/\|v_j\|_\infty$. It is easy to check that $\hat{u}_j, \hat{v}_j$ satisfy

$$\mu_j \Delta \hat{u}_j + \hat{u}_j(\beta + \tau_j g - u_j - v_j) = 0 \qquad \text{in} \quad \Omega, \tag{4.40a}$$

$$\mu_j \Delta \hat{v}_j + \hat{v}_j(\beta - u_j - v_j) = 0 \qquad \text{in} \quad \Omega, \tag{4.40b}$$

$$\frac{\partial \hat{u}_j}{\partial n} = \frac{\partial \hat{v}_j}{\partial n} = 0 \qquad \text{on} \quad \partial\Omega. \tag{4.40c}$$

Since τ_j is uniformly bounded, by standard elliptic estimates (see [GT]) and passing to a subsequence we may assume that $(\hat{u}_j,\hat{v}_j) \to (\hat{u},\hat{v})$ in $C^2(\overline{\Omega})$. Since $\mu_j \to \infty$ and $\|\hat{u}_j\|_\infty = \|\hat{v}_j\|_\infty = 1$, it is easy to see that $\hat{u} \equiv 1$ and $\hat{v} \equiv 1$. That is, $(\hat{u}_j,\hat{v}_j) \to (1,1)$ uniformly. By Lemma A.1, $\int_\Omega g u_j v_j = 0$ for all j, i.e., $\int_\Omega g \hat{u}_j \hat{v}_j = 0$. Passing to the limit we get $\int_\Omega g = 0$, which contradicts our assumption $\int_\Omega g > 0$. This completes the proof of Theorem 1.2. □

4.2. Dynamics of (1.8) for $\tau \ll 1$ and $\mu < \mu_{1,*}$. The goal of this subsection is to establish Theorem 1.4. We shall consider the case $\int_\Omega g\beta^2 < 0$ only since the case $\int_\Omega g\beta^2 > 0$ is very similar. In this subsection $\tilde{v}$ stands for $\tilde{v}(\cdot,\mu)$, and $\tilde{v}_\mu$ stands for $\frac{\partial \tilde{v}}{\partial \mu}(\cdot,\mu)$.

Proof of Theorem 1.4. We first consider the stability of $(0,\tilde{v})$. Recall that $C(\mu)$ is defined as in (3.2), $C(\mu) > 0$ if $G(\mu) < 0$, and $C(\mu) = 0$ if $G(\mu) \geq 0$. Since $C(\mu)$ is the principal eigenvalue, it is a smooth function of μ. By Lemma 3.1, it suffices to solve the equation $\tau = \mu C(\mu)$ for τ, μ small.

We claim that the following hold:

$$\lim_{\mu\to 0+} C(\mu) = C^* := \inf_{\left\{\psi\in H^1 : \int_\Omega g\beta^2\psi^2 > 0\right\}} \frac{\int_\Omega \beta^2 |\nabla\psi|^2}{\int_\Omega g\beta^2\psi^2}, \tag{4.41a}$$

$$\lim_{\mu\to 0+} \mu C'(\mu) = 0. \tag{4.41b}$$

Note that $C^* > 0$ because $\int_\Omega g\beta^2 < 0$. Assuming (4.41), we prove (i) of Theorem 1.4 (the proof of (ii) is quite analogous). Set $F(\tau,\mu) = \tau - \mu C(\mu)$. Since $\frac{\partial F}{\partial \mu} \to -C^*$ as $\mu \to 0+$, by the implicit function theorem we see that there exists $\eta_1, \eta_2 > 0$ such that for every $0 < \tau < \eta_1$, there exists a unique $\mu_0 = \mu_0(\tau) \in (0, \eta_2)$ such that $\tau > \mu C(\mu)$ when $0 < \mu < \mu_0$, $\tau = \mu_0 C(\mu_0)$, and $\tau < \mu C(\mu)$ when $\mu_0 < \mu \le \eta_2$. By Lemma 3.1, this proves that $(0, \tilde{v})$ is unstable for $\mu < \mu_0$ and stable for $\mu_0 < \mu \le \eta_2$. Choose $\eta = \eta_2$ in Theorem 1.2. From the proof of Theorem 1.2 we see that $(0, \tilde{v})$ does not changes its stability for $\eta_2 \le \mu < \mu_{1,*}$ and $\tau < \tau_0(\eta_2)$. Hence for $\tau < \min\{\eta_1, \tau_0(\eta_2)\}$, $(0, \tilde{v})$ is unstable for $\mu < \mu_0$ and stable for $\mu_0 < \mu < \mu_{1,*}$.

To prove (1.12), observe that as $\lim_{\tau\to 0+} \mu_0(\tau) = 0$, we have by (4.41a)

$$\frac{\tau}{\mu_0(\tau)} = C(\mu_0(\tau)) \to C^*. \tag{4.42}$$

It remains to prove the instability of $(\tilde{u}, 0)$ for suitable μ when $\int_\Omega g\beta^2 < 0$. It suffices to show that the principal eigenvalue, denoted by λ_1, of the problem

$$\mu\Delta\varphi + (\beta - \tilde{u})\varphi = -\lambda\varphi \quad \text{in } \Omega, \qquad \frac{\partial\varphi}{\partial n}\Big|_{\partial\Omega} = 0 \tag{4.43}$$

is negative. Observe that $\varphi/\tilde{u}$ satisfies

$$\nabla\cdot\Big(\tilde{u}^2\nabla\frac{\varphi}{\tilde{u}}\Big) - \frac{\tau}{\mu}\, g\tilde{u}^2\frac{\varphi}{\tilde{u}} = -\frac{\lambda}{\mu}\,\tilde{u}^2\,\frac{\varphi}{\tilde{u}} \qquad \text{in } \ \Omega, \qquad \frac{\partial}{\partial n}\Big(\frac{\varphi}{\tilde{u}}\Big)\Big|_{\partial\Omega} = 0. \tag{4.44}$$

Hence λ_1 can be characterized as

$$\lambda_1 = \inf_{\{\psi\in H^1:\psi\neq 0\}} \frac{\mu\int_\Omega \tilde{u}^2|\nabla\psi|^2 + \tau\int_\Omega g\tilde{u}^2\psi^2}{\int_\Omega \tilde{u}^2\psi^2}\,. \tag{4.45}$$

By letting $\psi \equiv 1$ in (4.45), we have $\lambda_1 \le \tau\int_\Omega g\tilde{u}^2/\int_\Omega \tilde{u}^2$. Note that $\int_\Omega g\tilde{u}^2 \to \int_\Omega g(\beta+\tau g)_+^2$ as $\lim_{\mu\to 0+}\tilde{u} = (\beta+\tau g)_+$. For sufficiently small τ, $(\beta+\tau g)_+ = \beta+\tau g$ since $\beta > 0$, and $\int_\Omega g(\beta+\tau g)_+^2 < 0$ since $\int_\Omega g\beta^2 < 0$. Therefore there exist $\eta_3, \eta_4 > 0$ such that $\lambda_1 < 0$ for $0 < \mu \le \eta_3$ and $\tau \le \eta_4$. This proves the instability of $(\tilde{u}, 0)$ for $\mu \le \eta_3$; for $\mu \ge \eta_3$, choose $\eta = \eta_3$ in Theorem 1.2. From the proof of Theorem 1.2 we see that $(\tilde{u}, 0)$ does not change its stability for $\mu \in [\eta_3, \mu_1^*)$ if $\tau < \tau_0(\eta_3)$. This shows that $(\tilde{u}, 0)$ is unstable for $\mu \in (\mu_0, \mu_1^*)$ provided that $\tau < \min\{\eta_4, \tau_0(\eta_3)\}$. Thus, the theorem follows from (4.41).

Hence it suffices to establish (4.41). Since $\beta > 0$ in $\bar{\Omega}$, $\tilde{v} \to \beta$ uniformly when $\mu \to 0+$ (cf. (2.2a)), and thus (4.41a) follows by a standard argument.

For (4.41b), by the definition of $C(\mu)$, there exists $\Phi > 0$ such that

$$\int_\Omega \tilde{v}^2\nabla\Phi\cdot\nabla\Psi = C(\mu)\int_\Omega g\tilde{v}^2\Phi\Psi \tag{4.46}$$

for every $\Psi \in H^1(\Omega)$. We can normalize Φ so that $\|\Phi\|_{L^2(\Omega)} = 1$. Differentiate (4.46) with respect to μ, obtaining

$$2\int_\Omega \tilde{v}\tilde{v}_\mu\nabla\Phi\cdot\nabla\Psi + \int_\Omega \tilde{v}^2\nabla\Phi_\mu\nabla\Psi = C'\int_\Omega g\tilde{v}^2\Phi\Psi + 2C\int_\Omega g\tilde{v}\tilde{v}_\mu\Phi\Psi + C\int_\Omega g\tilde{v}^2\Phi_\mu\Psi \tag{4.47}$$

for every $\Psi \in H^1(\Omega)$, where $C' = dC/d\mu$. Letting $\Psi = \Phi$ in (4.47), we have

$$C' \int_\Omega g\tilde{v}^2\Phi^2 = 2\int_\Omega \tilde{v}\tilde{v}_\mu |\nabla\Phi|^2 - 2C\int_\Omega g\tilde{v}\tilde{v}_\mu\Phi^2, \tag{4.48}$$

where (4.46) has been used again.

We first observe that $\|\Phi\|_{H^1}$ is uniformly bounded for small μ: to see this, set $\Psi = \Phi$ in (4.46). As $\tilde{v} \to \beta > 0$ uniformly and $\|\Phi\|_{L^2} = 1$, we get $\|\nabla\Phi\|_{L^2} \le K_1$, where K_1 is independent of μ when $\mu \ll 1$. This proves that $\|\Phi\|_{H^1}$ is uniformly bounded.

Next we show that $\int_\Omega g\tilde{v}^2\Phi^2 \ge K_2 > 0$ for some K_2 independent of μ. We argue by contradiction: if not, suppose that $\int_\Omega g\tilde{v}^2\Phi^2 \to 0$ as $\mu \to 0$. By the Sobolev embedding theorem (see [A]), we may assume, passing to a sequence if necessary, that $\Phi \to \Phi_0$ weakly in H^1 and strongly in L^2. This implies that $\Phi_0 \ge 0$ a.e. in Ω, $\|\Phi_0\|_{L^2(\Omega)} = 1$, and by (4.46) $\int_\Omega \beta^2\nabla\Phi_0 \cdot \nabla\Psi = 0$ for every $\Psi \in H^1$. Therefore the only possibility is $\Phi_0 \equiv 1$. However, this is impossible since $\int_\Omega g\tilde{v}^2\Phi^2 \to \int_\Omega g\beta^2 < 0$, which contradicts $\int_\Omega g\tilde{v}^2\Phi^2 \to 0$ as $\mu \to 0$. Therefore

$$\|\Phi\|_{H^1} \le K_3, \qquad \int_\Omega g\tilde{v}^2\Phi^2 \ge K_2 > 0, \tag{4.49}$$

provided that $\mu \ll 1$.

By (4.48) and (4.49), to prove (4.41b) we need to show only that $\mu\tilde{v}_\mu \to 0$ uniformly as $\mu \to 0+$. To this end, differentiating (1.3) with respect to μ we have

$$\mu\Delta\tilde{v}_\mu + (\beta - 2\tilde{v})\tilde{v}_\mu + \Delta\tilde{v} = 0 \quad \text{in } \Omega, \qquad \frac{\partial\tilde{v}_\mu}{\partial n} = 0 \quad \text{on } \partial\Omega. \tag{4.50}$$

Choose $x_\mu \in \overline{\Omega}$ such that $\tilde{v}_\mu(x_\mu) = \max_{\overline{\Omega}} \tilde{v}_\mu$. We have

$$(\beta - 2\tilde{v})\tilde{v}_\mu + \Delta\tilde{v} = -\mu\Delta\tilde{v}_\mu \ge 0$$

at $x = x_\mu$. This is obvious if $x_\mu \in \Omega$; for $x_\mu \in \partial\Omega$ it follows from the boundary condition (cf. Proposition 2.2 of [LN]).

Note that $\beta - 2\tilde{v} \to -\beta < 0$ uniformly as $\mu \to 0$. Therefore for $0 < \mu \ll 1$, we have $\tilde{v}_\mu(x_\mu) \le K_4\|\Delta\tilde{v}\|_\infty$ for some positive constant K_4 which is independent of μ. That is, $\max_{\overline{\Omega}} \tilde{v}_\mu \le K_4\|\Delta\tilde{v}\|_\infty$. Similarly we can show that $\min_{\overline{\Omega}} \tilde{v}_\mu \ge -K_5\|\Delta\tilde{v}\|_\infty$. Hence we have $\|\tilde{v}_\mu\|_{L^\infty} \le K_6\|\Delta\tilde{v}\|_{L^\infty}$. Therefore

$$\mu\|\tilde{v}_\mu\|_{L^\infty} \le K_6\mu\|\Delta\tilde{v}\|_{L^\infty} = K_6\|\tilde{v}(\beta - \tilde{v})\|_{L^\infty} \le K_7\|\beta - \tilde{v}\|_{L^\infty} \to 0 \tag{4.51}$$

as $\mu \to 0+$. This implies that (4.41b) holds. □

Remark 4.6. We conjecture that for τ small, if there is a coexistence state of (1.8), it is always unique and is the global attractor of (1.8). The following weaker uniqueness result may be proved, but we omit the proof here: suppose that the assumptions in Theorems 1.2 and 1.4 hold. Then for any $\eta > 0$, there exists $\hat{\tau}(\eta) > 0$ such that if $0 < \tau \le \hat{\tau}$ and $\mu \ge \eta\tau$, (1.8) has at most one coexistence state; moreover, if a coexistence state exists, it must be the global attractor of (1.8).

4.3. Coexistence or fixation? We now turn to the question raised in the introduction as to whether there are mutants (which mathematically are represented by functions g) which invade but always (that is, for all small $\tau > 0$) yield coexistence. Recall from the remarks in the introduction that necessarily $G(\mu) = \int_\Omega g(x)\tilde{v}^2(x,\mu) =$

0, so the question is to discover whether there are functions g satisfying this requirement which lead to coexistence for all small τ.

To answer this question, first recall that near any μ with $G(\mu) = 0$ and $G'(\mu) \neq 0$, we have shown that there is a branch of positive coexistence states which connects both branches of semitrivial coexistence states $(\tilde{u}, 0)$ and $(0, \tilde{v})$. Moreover, for each μ, there exists at most one coexistence state; if it exists, it is stable and the global attractor of (1.8). Therefore the question is basically about the location of the two ends of this bifurcation branch. From Proposition 4.2, we know that this branch of coexistence states can be represented by a smooth curve as

(4.52)
$$(u, v, \mu) = \left(s\tilde{v} + \tau u_1(\cdot, s) + O(\tau^2), (1-s)\tilde{v} + \tau v_1(\cdot, s) + O(\tau^2), \mu + \tau\tilde{\mu}_1(s) + O(\tau^2)\right),$$

where $s \in (0, 1)$. By Proposition 4.4(ii), $\tilde{\mu}_1(s)$ is given as

$$\tilde{\mu}_1(s) = \frac{1}{G'(\mu)} \int_\Omega g\tilde{v} \left[2s(\mathcal{L} - \tilde{v})^{-1}(g\tilde{v}) + (1-2s)\mathcal{L}^{-1}(g\tilde{v})\right]. \tag{4.53}$$

It is now clear that the answer to the above question depends on whether $\tilde{\mu}_1(0)$ and $\tilde{\mu}_1(1)$ have opposite signs under the assumption $\int_\Omega g\tilde{v}^2 = 0$. It is easy to see that $\operatorname{sign}(\tilde{\mu}_1(0)) = \operatorname{sign}(-G'(\mu))$ since by (4.53),

$$\tilde{\mu}_1(0)G'(\mu) = \int_\Omega g\tilde{v}\mathcal{L}^{-1}(g\tilde{v}) \leq 0. \tag{4.54}$$

The inequality in (4.54) is in fact strict since $g\tilde{v} \in \Theta^\perp$ and the self-adjoint operator $\mathcal{L}^{-1}$ from $\Theta^\perp$ to $\Theta^\perp$ is negative.

Therefore it remains to find the sign of $\tilde{\mu}_1(1)$, i.e., the sign of

$$I(\mu, g) := \int_\Omega g\tilde{v} \left[2(\mathcal{L} - \tilde{v})^{-1} - \mathcal{L}^{-1}\right](g\tilde{v}). \tag{4.55}$$

Note that $I(\mu, -g) = I(\mu, g)$, thus the sign of $\int g$ is irrelevant in our computations. It is easy to see that Theorem 1.5 follows from the next result.

THEOREM 4.7. *There exists a (unique) $\mu^* > 0$, depending only on β and Ω, with the following properties:*

(i) *If $\mu > \mu^*$, then $I(\mu, g) < 0$ for any g satisfying $\int_\Omega g\tilde{v}^2(\cdot, \mu) = 0$.*

(ii) *If $\mu < \mu^*$, then there exists a nonempty open subset U of*

$$\left\{g \in C^1(\overline{\Omega}) : \int_\Omega g\tilde{v}^2(\cdot, \mu) = 0\right\}$$

such that $I(\mu, g) > 0$ for any $g \in U$.

Proof. Consider the following linear eigenvalue problem with weight function $\tilde{v}$:

$$-\mu\Delta\varphi - \beta\varphi = \lambda\tilde{v}\varphi \quad \text{in } \Omega, \qquad \frac{\partial\varphi}{\partial n}\Big|_{\partial\Omega} = 0. \tag{4.56}$$

Denote the eigenvalues of (4.56) by $\lambda_1 < \lambda_2 \leq \lambda_3 \cdots$ and the corresponding eigenfunctions by $\varphi_1, \varphi_2, \ldots$; from the definition of $\tilde{v}$ we see that $\lambda_1 \equiv -1$ for any μ, and φ_1 is a scalar multiple of $\tilde{v}$. The eigenfunctions can be chosen such that the following hold:

(a) $\int_\Omega \tilde{v}\varphi_i^2 = 1$, $i \geq 1$.

(b) $\int_\Omega \tilde{v}\varphi_i\varphi_j = 0$, $i \neq j$, $i, j \geq 1$. In particular, $\int_\Omega \tilde{v}^2\varphi_i = 0$ for any $i \geq 2$.

(c) $\{\varphi_i\}_{i=1}^{\infty}$ is a basis for the Hilbert space $L^2(\Omega,\tilde{v}) := \{\psi : \int_\Omega \tilde{v}\psi^2 < \infty\}$, with the inner product

$$\langle \phi, \psi \rangle = \int_\Omega \tilde{v}\phi\psi. \tag{4.57}$$

Now for any function φ satisfying $\int_\Omega \varphi\tilde{v} = 0$ (and in particular for $\varphi = g\tilde{v}$) $\varphi/\tilde{v}$ is orthogonal to $\tilde{v}$ in $L^2(\Omega,\tilde{v})$. Therefore

$$\frac{\varphi}{\tilde{v}} = \sum_{i=2}^{\infty} a_i\varphi_i, \tag{4.58}$$

where the convergence of (4.58) is in the $L^2(\Omega,\tilde{v})$ norm, which is equivalent to convergence in the L^2 norm. It is easy to check that the following hold:

$$\begin{aligned} (\mu\Delta + \beta - \tilde{v})^{-1}(\tilde{v}\varphi_i) &= \frac{\varphi_i}{-\lambda_i - 1} + c_i\tilde{v}, \qquad i \geq 2, \\ 2(\mu\Delta + \beta - 2\tilde{v})^{-1}(\tilde{v}\varphi_i) &= \frac{2\varphi_i}{-\lambda_i - 2}, \qquad i \geq 2, \end{aligned} \tag{4.59}$$

where c_i is some constant. Notice that $\lambda_i + 1 > 0$ for any $i \geq 2$ since $\lambda_1 = -1$. It follows from (4.59) that

$$(2(\mathcal{L} - \tilde{v})^{-1} - \mathcal{L}^{-1})(\tilde{v}\varphi_i) = \frac{-\lambda_i\varphi_i}{(\lambda_i + 2)(\lambda_i + 1)} - c_i\tilde{v}, \qquad i \geq 2. \tag{4.60}$$

Therefore from (4.58) and (4.60),

$$\int_\Omega \varphi(2(\mathcal{L} - \tilde{v})^{-1} - \mathcal{L}^{-1})\varphi = -\sum_{i=2}^{\infty} \frac{a_i^2\lambda_i}{(\lambda_i + 2)(\lambda_i + 1)}. \tag{4.61}$$

In the calculation of (4.61), the terms involving c_i vanish because $\int_\Omega \varphi\tilde{v} = 0$. Note that the λ_i depend on μ. Applying (4.61), (4.58) to $\varphi = g\tilde{v}$ and noting that $I(\mu, g)$ is continuous in g, we see that Theorem 4.7 follows from the following lemma. ∎

LEMMA 4.8. *There exists a unique $\mu^* > 0$ such that $\lambda_2(\mu) > 0$ if $\mu > \mu^*$, and $\lambda_2(\mu) < 0$ if $\mu < \mu^*$.*

Proof. Recall that φ_1 is a multiple of $\tilde{v}$, and thus by the variational characterization of eigenvalues we see that

$$\lambda_2(\mu) = \inf_{\varphi \in Q_\mu} \frac{\int_\Omega \left[\mu|\nabla\varphi|^2 - \beta\varphi^2\right]}{\int_\Omega \tilde{v}\varphi^2}, \tag{4.62}$$

where the set Q_μ is defined by

$$Q_\mu := \left\{ \varphi \in H^1(\Omega), \int_\Omega \varphi\tilde{v}^2 = 0 \right\}. \tag{4.63}$$

Notice that $\tilde{v} \to \beta_+$ uniformly as $\mu \to 0$. Therefore by choosing a suitable test function in (4.62) we see that $\lambda_2(\mu) < 0$ for sufficiently small μ; on the other hand, $\tilde{v} \to \int_\Omega \beta/|\Omega|$ uniformly as $\mu \to \infty$. Therefore standard arguments imply that $\lambda_2(\mu) > 0$ for large μ. In fact, $\lambda_2(\mu)/\mu \geq c > 0$ for some constant $c > 0$ when μ is large. This implies that $\lambda_2(\mu) = 0$ has at least one root. For the uniqueness, we need the following result.

Claim. If $\lambda_2(\mu_0) = 0$ for some $\mu_0 > 0$, then for $\mu \approx \mu_0$, $\lambda_2(\mu) < 0$ ($\mu < \mu_0$) and $\lambda_2(\mu) > 0$ ($\mu > \mu_0$).

To prove this assertion, consider the operator on $L^2(\Omega, \tilde{v})$ defined by

$$\tilde{\mathcal{L}}(\mu)\varphi = -\frac{1}{\tilde{v}}\,(\mu\Delta\varphi + \beta\varphi) \tag{4.64}$$

with domain $H^2_N(\Omega) := \{\psi \in H^2(\Omega), \frac{\partial\psi}{\partial n}|_{\partial\Omega} = 0\}$. Assume that for some μ_0 we have $\lambda_2(\mu_0) = 0$ for the second eigenvalue of $\tilde{\mathcal{L}}(\mu_0)$ and that this eigenvalue has multiplicity k. Let φ_i^0, $i = 1, \dots, k$, be an $L^2(\Omega, \tilde{v})$-orthonormal basis of the eigenspace of the eigenvalue 0. By standard perturbation theory (see [K2]), there exist functions $\varphi_i(\mu)$, $i = 1, \dots, k$, defined and smooth for μ in a neighborhood of μ_0 such that

$$\varphi_i(\mu^0) = \varphi_i^0, \qquad i = 1, \dots, k, \tag{4.65}$$

the space

$$X(\mu) := \operatorname{span}\{\varphi_i(\mu) : i = 1, \dots, k\} \tag{4.66}$$

is invariant under $\tilde{\mathcal{L}}(\mu)$, and the functions $\varphi_i(\mu)$ are orthonormal. (Note that $\varphi_i(\mu)$ may not be eigenfunctions of $\tilde{\mathcal{L}}(\mu)$.) Now, with respect to the basis $\varphi_i(\mu)$, the restriction of $\tilde{\mathcal{L}}(\mu)$ to $X(\mu)$ is represented by the matrix

$$M(\mu) = \left(\langle\tilde{\mathcal{L}}(\mu)\varphi_i, \varphi_j\rangle\right)_{1\le i,j\le k} = -\left(\int_\Omega (\mu\Delta + \beta)\varphi_i\varphi_j\right)_{1\le i,j\le k}. \tag{4.67}$$

We have $M(\mu_0) = 0$ and

$$M'(\mu_0) = \left(\int_\Omega \nabla\varphi_i^0\nabla\varphi_j^0\right)_{1\le i,j\le k}. \tag{4.68}$$

To prove (4.68), observe that

$$\begin{aligned}\frac{d}{d\mu}\int_\Omega (\mu\Delta + \beta)\varphi_i\varphi_j &= \int_\Omega \Delta\varphi_i\varphi_j + \int_\Omega (\mu\Delta + \beta)\,\frac{\partial\varphi_i}{\partial\mu}\,\varphi_j + \int_\Omega (\mu\Delta + \beta)\varphi_i\,\frac{\partial\varphi_j}{\partial\mu}\\ &= -\int_\Omega \nabla\varphi_i\nabla\varphi_j + \int_\Omega \frac{\partial\varphi_i}{\partial\mu}\,(\mu\Delta + \beta)\varphi_j + \int_\Omega (\mu\Delta + \beta)\varphi_i\,\frac{\partial\varphi_j}{\partial\mu}\\ &= I + II + III, \end{aligned} \tag{4.69}$$

where in the second equality the self-adjointness of the operator $\mu\Delta + \beta$ has been used. Obviously, $I \to -\int \nabla\varphi_i^0\nabla\varphi_j^0$ as $\mu \to \mu_0$. For II, as $\mu \to \mu_0$, $(\mu\Delta + \beta)\varphi_j \to (\mu_0\Delta + \beta)\varphi_j^0 \equiv 0$ since $\lambda_2(\mu_0) = 0$. This implies that $II \to 0$ as $\mu \to \mu_0$. A similar conclusion holds for III.

It remains to show that the matrix $M'(\mu_0)$ is positive definite. For any $\zeta = (\zeta_1, \dots, \zeta_k)$, set

$$\bar{\varphi} = \sum_{i=1}^k \zeta_i\varphi_i^0. \tag{4.70}$$

Then

$$\sum_{i,j=1}^k \int_\Omega \nabla\varphi_i^0\nabla\varphi_j^0\zeta_i\zeta_j = \int_\Omega |\nabla\bar{\varphi}|^2 \ge 0. \tag{4.71}$$

If the equality in (4.71) holds, then $\bar{\varphi}$ is equal to some constant, say c_1. By the equations for φ_i^0, we see that $\mu_0 \Delta \bar{\varphi} + \beta \bar{\varphi} = 0$, which implies that $\beta c_1 = 0$. That is, $c_1 = 0$. Hence $\bar{\varphi} = 0$. Since the φ_i^0 are orthogonal to each other in $L^2(\Omega, \tilde{v})$, we see that $\zeta_i = 0$ for all i. This together with (4.71) proves that the matrix $M'(\mu_0)$ is positive definite. Hence for μ close to μ_0, all eigenvalues of $M(\mu)$ are positive when $\mu > \mu_0$, and negative when $\mu < \mu_0$. □

5. The case $\tau \gg 1$. The goal of this section is to study (1.8) with $\tau \gg 1$, and Theorem 1.6 will be established. Throughout this section, we assume the hypotheses of the theorem to be satisfied.

LEMMA 5.1. *If τ is sufficiently large, $(0, \tilde{v})$ is unstable for any $\mu > 0$.*

Proof. It suffices to show that the principal eigenvalue, denoted by λ_1, of the linear eigenvalue problem (2.5) is negative. Note that λ_1 can be characterized by

$$\lambda_1 = \inf_{\{\varphi \in H^1 : \varphi \neq 0\}} \frac{\int_\Omega \left[\mu |\nabla \varphi|^2 - (\beta + \tau g - \tilde{v}) \varphi^2\right]}{\int_\Omega \varphi^2}. \tag{5.1}$$

With $\varphi = \tilde{v}$ in (5.1) we have

$$\lambda_1 \leq -\frac{\tau \int_\Omega g \tilde{v}^2}{\int_\Omega \tilde{v}^2} \tag{5.2}$$

for every $\tau > 0$ and $\mu > 0$. Since $\lim_{\mu \to +\infty} \tilde{v} = \int_\Omega \beta / |\Omega|$ uniformly (see (2.2b)) and $\int_\Omega g > 0$, there exists $\bar{\mu}$ such that if $\mu \geq \bar{\mu}$, $\int_\Omega g \tilde{v}^2 > 0$. Therefore for $\mu \geq \bar{\mu}$ and $\tau > 0$, $\lambda_1 < 0$.

Next we consider the case $0 < \mu \leq \bar{\mu}$: Choose a test function φ such that $\varphi \geq 0$, $\varphi \not\equiv 0$, and $\operatorname{supp} \varphi \sqsubset \Omega^+$. Then by (5.1) and the boundedness of $\tilde{v}(\cdot, \mu)$ (see (2.2a)), if $\tau \gg 1$ and $0 < \mu \leq \bar{\mu}$, we have

$$\lambda_1 \leq \frac{\int_\Omega \left[\bar{\mu} |\nabla \varphi|^2 + \tilde{v} \varphi^2\right] - \tau \int_\Omega g \varphi^2}{\int_\Omega \varphi^2} < 0. \tag{5.3}$$

This completes the proof of Lemma 5.1. □

The above lemma yields (i) of Theorem 1.6. We next prove (ii).

Proof of Theorem 1.6(ii). Recall that $\tilde{u} = \tilde{u}(x, \mu, \tau)$ is the unique positive solution of (1.3) with $\alpha = \beta + \tau g$, and the stability of $(\tilde{u}, 0)$ relative to (1.8) is determined by the sign of the principal eigenvalue of the linear eigenvalue problem (2.4b), (2.4d).

Claim. Let $\tilde{\Omega}$ be any compact subset of Ω^-. Then, as $\tau \to +\infty$ and $\tau/\mu \to +\infty$, $\tilde{u}/\mu \to 0$ uniformly with respect to $x \in \tilde{\Omega}$.

To establish this assertion, choose a domain $\hat{\Omega}$ such that $\tilde{\Omega} \sqsubset\sqsubset \hat{\Omega} \sqsubset\sqsubset \Omega^-$, where $\sqsubset\sqsubset$ means the inclusion of the closure of a given domain. By Proposition A.1 of [HLM] and the comparison arguments given there, for some $k_1 > 0$ one has $\tilde{u} \leq k_1 \tau^{2/3} \mu^{1/3}$ in Ω^- for $\tau \gg 1$ and $\tau/\mu \gg 1$. Here and below, $k_1, k_2, \ldots$ are constants independent of τ and μ, provided that both τ and τ/μ are sufficiently large.

Set $\hat{u} = \tilde{u} / \left(\tau^{2/3} \mu^{1/3}\right)$. Since $g < 0$ in $\hat{\Omega}$, we have

$$-\mu \Delta \hat{u} \leq -k_2 \tau \hat{u} \quad \text{in } \hat{\Omega}, \qquad \hat{u}\big|_{\partial \hat{\Omega}} \leq k_3 \tag{5.4}$$

for sufficiently large τ and τ/μ. Let w_τ be the unique solution of

$$-\mu \Delta w_\tau = -k_2 \tau w_\tau \quad \text{in } \hat{\Omega}, \qquad w_\tau\big|_{\partial \hat{\Omega}} = k_3. \tag{5.5}$$

It can be shown that

$$w_\tau(x) \le k_4 \exp\left[-k_5 \operatorname{dist}(x, \partial\hat{\Omega})(\tau/\mu)^{1/2}\right] \tag{5.6}$$

for every $x \in \hat{\Omega}$, where k_4 and k_5 are positive constants independent of x and large τ and τ/μ. Indeed, for any fixed $x \in \hat{\Omega}$, let B_x denote the ball centered at x with radius $\operatorname{dist}(x, \partial\hat{\Omega})$. Let z be the unique solution of

$$\mu\Delta z = k_2\tau z \quad \text{in } B_x, \qquad z|_{\partial B_x} = k_3. \tag{5.7}$$

By the maximum principle, $w_\tau \le k_3$ in $\hat{\Omega}$. Hence by the comparison principle, $w_\tau \le z$ in B_x. It is easy to see that z is radially symmetric, from which it can be shown that there are positive constants k_4, k_5, independent of τ, τ/μ, and x, such that $z(x) \le k_4 \exp[-k_5 \operatorname{dist}(x, \partial\hat{\Omega})(\tau/\mu)^{1/2}]$. This proves (5.6).

By the comparison principle, $\hat{u} \le w_\tau$ in $\hat{\Omega}$. Hence for $\tilde{u}$ we have, as $\tau/\mu \to +\infty$,

$$\tilde{u}(x)/\mu \le k_4(\tau/\mu)^{2/3} \exp\left[-k_5 \operatorname{dist}(x, \partial\hat{\Omega})(\tau/\mu)^{1/2}\right] \to 0 \tag{5.8}$$

for any $x \in \tilde{\Omega} \sqsubset\sqsubset \hat{\Omega}$. This proves the claim.

To continue with the proof of assertion (ii), let μ_0 be as in the theorem and fix $\epsilon > 0$. For $\mu \le \mu_0 - \epsilon$ and τ sufficiently large we want to choose a ψ such that

$$II := \int_\Omega \left[\mu|\nabla\psi|^2 - (\beta - \tilde{u})\psi^2\right] < 0, \tag{5.9}$$

which will yield the instability of $(\tilde{u}, 0)$. To this end, choose some $\tilde{\Omega} \sqsubset\sqsubset \Omega^-$ such that the number $\tilde{\mu}$, uniquely determined by the requirement that there exist a solution of the problem

$$\tilde{\mu}\Delta\tilde{\varphi} + \beta\tilde{\varphi} = 0 \quad \text{in} \quad \tilde{\Omega}, \qquad \tilde{\varphi} > 0 \quad \text{in } \tilde{\Omega}, \qquad \tilde{\varphi}|_{\partial\tilde{\Omega}} = 0, \tag{5.10}$$

satisfies $\tilde{\mu} \in \left(\mu_0 - \frac{\epsilon}{2}, \mu_0\right)$. We refer here to standard continuity and monotonicity properties of principal eigenvalues (see the definition of μ_0). Set

$$\psi = \begin{cases} \tilde{\varphi}(x), & x \in \tilde{\Omega}, \\ 0 & \text{otherwise.} \end{cases} \tag{5.11}$$

Then it is easy to check that for $\mu \le \mu_0 - \epsilon$,

$$\begin{aligned} II &= \int_{\tilde{\Omega}} \left[\mu|\nabla\tilde{\varphi}|^2 - (\beta - \tilde{u})\tilde{\varphi}^2\right] \\ &= \int_{\tilde{\Omega}} \left[\left(\frac{\mu}{\tilde{\mu}} - 1\right)\beta + \tilde{u}\right]\tilde{\varphi}^2 \\ &\le \int_{\tilde{\Omega}} \left[\left(\frac{\mu_0 - \epsilon}{\mu_0 - \epsilon/2} - 1\right)\beta + \tilde{u}\right]\tilde{\varphi}^2 \\ &\le \left[\|\tilde{u}\|_{L^\infty(\tilde{\Omega})} - \frac{\epsilon}{2\mu_0}\min_{\bar{\Omega}}\beta\right]\int_{\tilde{\Omega}} \tilde{\varphi}^2 < 0, \end{aligned} \tag{5.12}$$

provided that $\tau \gg 1$ since $\tilde{u} \to 0$ uniformly in $\tilde{\Omega}$.

Next we consider the case $\mu \geq \mu_0 + \epsilon$ and show that $(\tilde{u}, 0)$ is the global attractor of (1.8) provided that $\tau \gg 1$. Since $(0, \tilde{v})$ is unstable in this case, the result will follow if the existence of a coexistence equilibrium is ruled out. We proceed by contradiction, assuming (u, v) is a coexistence state of (1.8) for a sequence of values $\mu \geq \mu_0 + \epsilon$ and $\tau \to +\infty$.

First consider the case when $\mu/\tau \to 0$. Since $v > 0$, we see that u/τ is a subsolution to the following problem:

$$\frac{\mu}{\tau}\Delta w_+ + w_+\left(\frac{\|\beta\|_\infty}{\tau} + g - w_+\right) = 0 \qquad \text{in } \Omega, \qquad \frac{\partial w_+}{\partial n}\Big|_{\partial\Omega} = 0. \tag{5.13}$$

As discussed in section 2, (5.13) has a unique positive solution w_+ which is globally attractive for the corresponding logistic parabolic equation. Therefore, by a standard super-sub solution method we conclude that $u/\tau \leq w_+$. Similarly, since $\beta \geq 0$ and $\|v\|_\infty \leq \|\beta\|_\infty$, u/τ is a supersolution of

$$\frac{\mu}{\tau}\Delta w_- + w_-\left(-\frac{\|\beta\|_\infty}{\tau} + g - w_-\right) = 0 \qquad \text{in } \Omega, \qquad \frac{\partial w_-}{\partial n}\Big|_{\partial\Omega} = 0. \tag{5.14}$$

Thus $u/\tau \geq w_-$ for the positive solution w_- of (5.14). It is not difficult to prove (cp. [HMP, proof of Lemma 3.4]) that both w_+ and w_- converge to g_+ uniformly as $\tau \to \infty$ and $\mu/\tau \to 0+$. This proves that $u/\tau \to g_+$ uniformly as $\mu/\tau \to 0$ and $\tau \to \infty$. Multiplying the equation for v by any $\varphi \in H^1(\Omega)$ and integrating it over Ω we have

$$\mu \int_\Omega \nabla v \cdot \nabla \varphi = \int_\Omega v\varphi(\beta - v - u). \tag{5.15}$$

It is easy to see that $\|v\|_{L^\infty}$ and $\|\nabla v\|_{L^2}$, and so $\|v\|_{H^1}$, are uniformly bounded. Therefore by the Sobolev embedding theorem, passing to a sequence if necessary, $v \to \bar{v}$ weakly in H^1, strongly in L^2 as $\mu/\tau \to 0$. Obviously, $\bar{v} \geq 0$ a.e. in Ω. Dividing (5.15) by τ and passing to the limit, we have

$$\int_\Omega g_+ \bar{v}\varphi = 0 \tag{5.16}$$

for every $\varphi \in H^1$. This implies that $\bar{v} = 0$ a.e. in Ω^+. Therefore $v \to 0$ weakly in $H^1(\Omega^+)$, and by the trace theorem (see [A]), $\bar{v}|_\Gamma = 0$.

We claim that $\bar{v} = 0$ a.e. in Ω^-. To prove this, choose $\varphi \in C_0^\infty(\Omega^-)$ in (5.15). For any coexistence state of (1.8), by the comparison principle we have $u \leq \tilde{u}$. Hence it follows from the claim above that $u/\mu \to 0$ uniformly in any compact subset of Ω^- as $\mu/\tau \to 0$ and $\tau \to \infty$. Dividing (5.15) by μ and passing to the limit we have either $\mu \to \bar{\mu}$ for some $\bar{\mu} \in (\mu_0, \infty)$ and

$$\int_{\Omega^-} \nabla \bar{v} \cdot \nabla \varphi = \bar{\mu}^{-1} \int_{\Omega^-} \varphi \bar{v}(\beta - \bar{v}), \qquad \varphi \in C_0^\infty(\Omega^-), \tag{5.17}$$

or $\bar{\mu} = \infty$. When $\bar{\mu} = \infty$, we see that $\bar{v}$ is a harmonic function, which together with $\bar{v}|_\Gamma = 0$ ensures that $\bar{v} = 0$ a.e. in Ω^-. When $\bar{\mu} < \infty$, since $\bar{v}|_\Gamma = 0$, by standard elliptic regularity we see that $\bar{v}$ is a classical solution of

$$\bar{\mu}\Delta \bar{v} + \bar{v}(\beta - \bar{v}) = 0 \quad \text{in } \Omega^-, \qquad \bar{v}|_\Gamma = 0, \qquad \bar{v} \geq 0 \quad \text{in } \Omega^-. \tag{5.18}$$

To show that $\bar{v} = 0$ a.e. in Ω^-, we argue by contradiction: If not, then by the strong maximum principle and the Hopf boundary lemma (see [PW, GNN]), $\bar{v} > 0$ in Ω^- and $\partial\bar{v}/\partial n < 0$, where n is the unit outward normal to $\partial\Omega$. Multiplying (5.18) by $\varphi_0 > 0$ (a solution of (1.14) corresponding to μ_0) and integrating in Ω^- we have

$$\left[-\frac{\bar{\mu}}{\mu_0} + 1\right] \int_{\Omega^-} \beta\varphi_0\bar{v} = \int_{\Omega^-} \varphi_0\bar{v}^2 > 0, \tag{5.19}$$

which is a contradiction since $\bar{\mu} > \mu_0$.

Therefore $\bar{v} = 0$ a.e. in Ω^-, and thus $\bar{v} = 0$ a.e. in Ω. Hence we see that $v \to 0$ weakly in $H^1(\Omega)$ and strongly in $L^2(\Omega)$. We shall use this to reach a contradiction. To this end, set $\hat{v} = v/\|v\|_{L^2}$. Then $\|\hat{v}\|_{L^2} = 1$ and $\hat{v}$ satisfies

$$\mu \int_\Omega \nabla\hat{v} \cdot \nabla\varphi = \int_\Omega \hat{v}\varphi(\beta - v - u) \tag{5.20}$$

for every $\varphi \in H^1(\Omega)$.

Since $\|\hat{v}\|_{L^2} = 1$, by letting $\varphi = \hat{v}$ in (5.20) we see that $\|\nabla\hat{v}\|_{L^2}$ is uniformly bounded, i.e., $\|\hat{v}\|_{H^1}$ is uniformly bounded. Hence we may assume that $\hat{v} \to v^*$ weakly in H^1 and strongly in L^2. In particular, this implies that $\|v^*\|_{L^2(\Omega)} = 1$, $v^* \geq 0$ a.e. in Ω. Similarly, as before we can show that $\int_\Omega v^*\varphi g_+ = 0$ for every $\varphi \in H^1(\Omega)$. Then $v^* = 0$ a.e. in Ω^+ and $v^*|_\Gamma = 0$. Again, by passing to a sequence if necessary, we may assume that $\mu \to \bar{\mu} \in (0, \infty]$. If $\bar{\mu} < \infty$, by similar argument as before we see that v^* solves

$$\bar{\mu}\Delta v^* + \beta v^* = 0 \quad \text{in } \Omega^-, \qquad v^*|_\Gamma = 0. \tag{5.21}$$

Note that $v^* \geq 0$, and $\|v^*\|_{L^2(\Omega^-)} = \|v^*\|_{L^2(\Omega)} = 1$ since $v^* = 0$ a.e. in Ω^+. By the strong maximum principle, $v^* > 0$ in Ω^-. This implies that $\bar{\mu} = \mu_0$, which is a contradiction! When $\bar{\mu} = \infty$, since $u/\mu \to 0$ uniformly in any compact subset of Ω^- we see that v^* is a harmonic function, which implies that $v^* = 0$ in Ω^- because $v^*|_\Gamma = 0$. This is again impossible since $\|v^*\|_{L^2(\Omega^-)} = 1$.

It remains to handle the case of $\mu/\tau \to \gamma$ for some $\gamma \in (0, \infty]$. For this case, it can be shown, by passing to a sequence if necessary, that u/τ converges to some positive function uniformly. (Arguments here are similar to those used in the case $\mu/\tau \to 0$ and are omitted.) This implies that $\beta(x) - u - v$ is strictly negative in Ω for large τ. However, by integrating the equation of v in Ω, we get $\int_\Omega v(\beta(x) - u - v) = 0$, which is a contradiction since v is positive in Ω. This completes the proof. □

Remark 5.2. Let $\mu^*(\tau)$ denote any value of μ where $(\tilde{u}, 0)$ changes stability. Theorem 1.6 simply says that $\lim_{\tau\to\infty} \mu^*(\tau) = \mu_0$. We suspect that such μ^* is unique, and any coexistence state of (1.8), if it exists, should also be unique and globally stable.

Appendix A. Proof of Proposition 4.4. The proof of Proposition 4.4 is given here after establishing some preliminary computational results. Throughout, (u, v) will be a coexistence state of (1.8), $\tilde{\mu}_1, u_1, v_1$ are given by (4.7), and (φ, ψ) is the solution of (2.3) corresponding to the eigenvalue $\lambda(\tau, s)$. Throughout the appendix we assume that $G(\tilde{\mu}) = 0$, where G is given by (1.9). We normalize (φ, ψ) such that $\int_\Omega \varphi^2 + \int_\Omega \psi^2 = 2\int_\Omega \tilde{v}^2$ and $\varphi > 0 > \psi$. In particular, for $\tau = 0$ $\varphi = \tilde{v}$, $\psi = -\tilde{v}$.

LEMMA A.1. *The following statements hold:*

(i)

$$\int_\Omega guv = 0. \tag{A.1}$$

(ii)

$$\lambda(\tau, s) = -\tau \int_\Omega g(\varphi v + \psi u) \Big/ \int (\varphi v - \psi u). \tag{A.2}$$

Note that by (4.7) and the normalization of (φ, ψ), we have for small $\tau > 0$

$$\varphi v - \psi u = \tilde{v}^2 + O(\tau)$$

and

$$\int_\Omega g(\varphi v + \psi u) = (1 - 2s) \int_\Omega g\tilde{v}^2 + O(\tau) = O(\tau).$$

In particular, the denominator in (A.2) is nonzero for small τ, and (A.2) implies

$$\lambda_\tau(0, s) = 0.$$

Proof of Lemma A.1. (i) Multiply (1.8a) by v, (1.8b) by u and subtract, obtaining

$$\mu(v\Delta u - u\Delta v) + \tau guv = 0. \tag{A.3}$$

The result follows on integrating (A.3) over Ω.

(ii) Multiply (2.3a) by v, (2.3b) by u and subtract, obtaining

$$-\lambda(\tau, s)(\varphi v - \psi u) = v\left[\mu\Delta\varphi + \varphi(\beta + \tau g - u - v)\right] - u\left[\mu\Delta\psi + \psi(\beta - u - v)\right]. \tag{A.4}$$

Integrating (A.4) over Ω and using (1.8) we deduce that

$$\begin{aligned} -\lambda(\tau, s) \int (\varphi v - \psi u) &= \int_\Omega \varphi\left[\mu\Delta v + v(\beta + \tau g - u - v)\right] - \int_\Omega \psi\left[\mu\Delta u + u(\beta - u - v)\right] \\ &= \tau \int_\Omega g(\varphi v + \psi u). \qquad \square \end{aligned}$$

Set

$$A = (\mathcal{L} - \tilde{v})^{-1}(\tilde{\mu}_1 \Delta\tilde{v}), \tag{A.5a}$$

$$B = (\mathcal{L} - \tilde{v})^{-1}(g\tilde{v}), \tag{A.5b}$$

$$C = \mathcal{L}^{-1}(g\tilde{v}), \tag{A.5c}$$

and expand the eigenfunctions φ, ψ in the form

$$\varphi = \tilde{v} + \tau\varphi_1(\cdot, s) + \tau^2\varphi_2(\cdot, \tau, s), \tag{A.6a}$$

$$\psi = -\tilde{v} + \tau\psi_1(\cdot, s) + \tau^2\psi_2(\cdot, \tau, s). \tag{A.6b}$$

Lemma A.2. *For some $\gamma_i \in \mathbb{R}$, we have*

(i)

$$u_1 = -s\left[A + sB + (1 - s)C\right] + \gamma_1\tilde{v}, \tag{A.7a}$$

$$v_1 = -(1 - s)\left[A + sB - sC\right] - \gamma_1\tilde{v}, \tag{A.7b}$$

(ii)

$$\varphi_1 = -A - 2sB + (2s-1)C + \gamma_2\tilde{v}, \tag{A.8a}$$

$$\psi_1 = A + (2s-1)B - (2s-1)C - \gamma_2\tilde{v}. \tag{A.8b}$$

Proof. (i) From direct calculation u_1, v_1 satisfy zero Neumann boundary conditions on $\partial\Omega$, and the following hold in Ω:

$$\tilde{\mu}\Delta u_1 + (\beta - \tilde{v})u_1 + s\tilde{v}(g - u_1 - v_1) + s\tilde{\mu}_1\Delta\tilde{v} = 0, \tag{A.9a}$$

$$\tilde{\mu}\Delta v_1 + (\beta - \tilde{v})v_1 + (1-s)\tilde{v}(-u_1 - v_1) + (1-s)\tilde{\mu}_1\Delta\tilde{v} = 0. \tag{A.9b}$$

Multiplying (A.9a), (A.9b) by $(1-s)$ and s, respectively, and subtracting, we find that

$$\mathcal{L}[(1-s)u_1 - sv_1] + s(1-s)g\tilde{v} = 0,$$

from which it follows on taking the inverse and using definition (A.5c) that

$$(1-s)u_1 - sv_1 = -s(1-s)C + \gamma_3\tilde{v}. \tag{A.10}$$

Adding (A.9a) and (A.9b) we have in a similar manner

$$u_1 + v_1 = -A - sB. \tag{A.11}$$

Then (A.7) follows from (A.10) and (A.11) by straightforward manipulation.

(ii) Since $\lambda_\tau(0,s) = 0$, it is easy to check that φ_1 and ψ_1 satisfy the following in Ω, together with zero Neumann boundary conditions:

$$\mathcal{L}\varphi_1 - s\tilde{v}(\varphi_1 + \psi_1) + \tilde{\mu}_1\Delta\tilde{v} + \tilde{v}(g - u_1 - v_1) = 0, \tag{A.12a}$$

$$\mathcal{L}\psi_1 - (1-s)\tilde{v}(\varphi_1 + \psi_1) - \tilde{\mu}_1\Delta\tilde{v} + \tilde{v}(u_1 + v_1) = 0. \tag{A.12b}$$

Adding (A.12a) and (A.12b), we have by an argument similar to that used in the previous lemma

$$\varphi_1 + \psi_1 = -B. \tag{A.13}$$

By (A.11), $u_1 + v_1 = -A - sB$. Substituting this and (A.13) in (A.12a), we obtain the equation which determines φ_1 up to an additive term $\gamma_4\tilde{v}$. Using definitions (A.5), it is easy to see that φ_1 given by (A.8a) satisfies that equation, which verifies (A.8a). This and (A.13) yield (A.8b). □

LEMMA A.3. *The following holds:*

$$\int_\Omega g\tilde{v}[2A + 2sB + (1-2s)C] = 0. \tag{A.14}$$

Proof. By (4.7) and (A.1),

$$0 = \int_\Omega guv = \tau\int_\Omega g\tilde{v}[sv_1 + (1-s)u_1] + O(\tau^2)$$

since $\int_\Omega g\tilde{v}^2 = 0$. Therefore

$$\int_\Omega g\tilde{v}[sv_1 + (1-s)u_1] = 0. \tag{A.15}$$

The result follows from (A.15) together with (A.7). □

Proof of Proposition 4.4. The result is a consequence of the following calculation of the denominator and numerator of (A.2). In the following $H_i(\tau, s)$ denote quantities that are uniformly bounded for $s \in [0,1]$ and small τ. From (A.6),

$$\int_\Omega (\varphi v - \psi u) = \int_\Omega \tilde{v}^2 + \tau H_1(\tau, s). \tag{A.16}$$

We now use (A.7) and (A.8) successively, obtaining

$$\begin{aligned}\int_\Omega g(\varphi v + \psi u) &= (1-2s)\int_\Omega g\tilde{v}^2 + \tau \int_\Omega g\tilde{v}[v_1 - u_1 + (1-s)\varphi_1 + s\psi_1] + \tau^2 H_2(\tau, s)\\ &= \tau \int_\Omega g\tilde{v}[(4s-2)A + (6s^2-4s)B + (-1+6s-6s^2)C] + \tau^2 H_3(\tau, s). \qquad \text{(A.17)}\end{aligned}$$

From (A.14) and (A.17),

$$\int_\Omega g(\varphi v + \psi u) = 2s(1-s)\tau \int_\Omega g\tilde{v}(C-B) + \tau^2 H_4(\tau, s). \tag{A.18}$$

As a consequence of (A.2), (A.16), and (A.18) we have

$$\lambda(\tau, s) = \tau^2 \left[\frac{2s(1-s)\int_\Omega g\tilde{v}(B-C)}{\int_\Omega \tilde{v}^2} + \tau H_5(\tau, s) \right]. \tag{A.19}$$

Since $\lambda(\tau, 0) = \lambda(\tau, 1) \equiv 0$ for all τ (see (4.23)), we have $H_5(0, \tau) = H_5(1, \tau) \equiv 0$. This implies that we can write H_5 as $H_5(\tau, s) = s(1-s)H_6(\tau, s)$. This proves part (i) of Proposition 4.4.

Part (ii) follows directly from Lemma A.3 and the relation

$$A = \tilde{\mu}_1 (\mathcal{L} - \tilde{v})^{-1} (\Delta \tilde{v}) = -\tilde{\mu}_1 \tilde{v}_\mu.$$

The latter equality is obtained by differentiating the equation for $\tilde{v}$ with respect to μ. □

Appendix B. Proof of Proposition 1.3. (i) Fix any β satisfying A1, and define the map

$$\Psi : (\mu, g) \mapsto \Psi(\mu, g) := \int_\Omega \tilde{v}^2(x, \mu) g(x)\, dx : (0, \infty) \times C^1(\overline{\Omega}) \to \mathbb{R}.$$

Then Ψ is smooth, it is linear in g, and, since $\tilde{v} > 0$, $\Psi(\mu, \cdot)$ is surjective. Thus 0 is a regular value of Ψ. Consequently, by the parametric transversality theorem [AR, Q, H2], for generic $g \in C^1(\overline{\Omega})$, 0 is a regular value of $G = \Psi(\cdot, g)$. This proves statement (i).

(ii) Fix any sequence $0 < \mu_1 < \mu_2 < \cdots$. We claim that for generic $\beta \in U = \{\beta \in C^1(\overline{\Omega}) : \int_\Omega \beta > 0\}$ the following condition holds for all $k = 1, 2, \ldots$:

$$\tilde{v}^2(\cdot, \mu_1), \ldots, \tilde{v}^2(\cdot, \mu_{k+1}) \text{ are linearly independent functions.} \tag{B.1}$$

Suppose for the moment that the claim is true. Observe that (B.1) allows us to choose a function $\tilde{g} \in C^1(\overline{\Omega})$ such that

$$\int_\Omega \tilde{g}(x)\tilde{v}^2(x, \mu_i)\, dx \int_\Omega \tilde{g}(x)\tilde{v}^2(x, \mu_{i+1})\, dx < 0 \quad (i = 1, \ldots, k) \tag{B.2}$$

(for example, we can choose $\tilde{g}$ as a linear combination of the functions in (B.1)). Then, for any g in a sufficiently small neighborhood of $\tilde{g}$, the function G has at least k zeros (at least one per each interval (μ_i, μ_{i+1})). By (i), we can choose g in this neighborhood such that G has only simple zeros, and, replacing $\tilde{g}$ by $-\tilde{g}$ if necessary, we can in addition take $\tilde{g} \in U$. Conclusion (ii) thus follows from our claim.

To prove the claim, it is clearly sufficient to show that for each fixed k, the set of all $\beta \in U$ for which (B.1) holds is open and dense in U. The openness is obvious, as $\tilde{v}$ is a continuous function of β. To prove the density, fix any $\tilde{\beta} \in U$. Arbitrarily close to $\tilde{\beta}$, we have to find $\beta \in U$ for which (B.1) holds. To this end let $0 = \lambda_1 < \lambda_2 \le \lambda_3 \cdots$ be the eigenvalues of $-\Delta$ on Ω under Neumann boundary condition. Let $\phi_1, \phi_2, \dots$ be an orthonormal basis of $L^2(\Omega)$ consisting of the corresponding eigenfunctions. Clearly, we can find $\bar{\beta} \in U$, as close to $\tilde{\beta}$ as we wish, such that

$$\beta_j := \int_\Omega (\bar{\beta}(x) - 1)\phi_j(x)\,dx = \int_\Omega \bar{\beta}(x)\phi_j(x)\,dx \neq 0 \quad (j = 2, 3, \dots); \tag{B.3}$$

that is, the Fourier coefficients of $\bar{\beta}$ with respect to the eigenfunctions are all nonzero (the first one is positive, as $\bar{\beta} \in U$). We further show that arbitrarily close to 1 there is a constant $\delta < 1$ such that (B.1) holds for

$$\beta = 1 - \delta + \delta\bar{\beta}.$$

This will complete the proof of density.

Denote the solution of (1.6) with $\beta = 1 - \delta + \delta\bar{\beta}$ by $\tilde{v}(\cdot, \mu, \delta)$. Observe that

$$\delta \mapsto \tilde{v}(\cdot, \mu, \delta) \in L^2(\Omega)$$

is an analytic function. Consider the Gram determinant

$$D(\delta) = \det\left(\int_\Omega \tilde{v}^2(x, \mu_i, \delta)\tilde{v}^2(x, \mu_j, \delta)\,dx\right)_{i,j=1}^{k+1}.$$

We have $D(\delta) \neq 0$ if and only if

$$\tilde{v}^2(\cdot, \mu_1, \delta), \dots, \tilde{v}^2(\cdot, \mu_{k+1}, \delta) \text{ are linearly independent functions.} \tag{B.4}$$

Since $\delta \mapsto D(\delta)$ is analytic, the desired property (i.e., $D(\delta) \neq 0$ for any $\delta < 1$ sufficiently close to 1) is established, provided $D \not\equiv 0$. To prove the latter we examine the limit $\delta \to 0$. At $\delta = 0$, we have the following equation for $\tilde{v}(\cdot, \mu, 0)$:

$$\mu\Delta v + (1 - v)v = 0 \quad \text{in } \Omega, \qquad \frac{\partial v}{\partial n} = 0 \quad \text{on } \partial\Omega.$$

Thus $\tilde{v}(\cdot, \mu, 0) \equiv 1$. As $\tilde{v}(\cdot, \mu, \delta)$ is a nondegenerate solution, we can expand

$$\tilde{v}(\cdot, \mu, \delta) = 1 + \delta z(\cdot, \mu) + O(\delta^2)$$

and find the equation for z to be

$$\mu\Delta z - z + \bar{\beta} - 1 = 0 \quad \text{in } \Omega, \qquad \frac{\partial z}{\partial n} = 0 \quad \text{on } \partial\Omega.$$

By an eigenfunction expansion,

$$z(\cdot, \mu) = \sum_{\ell=1}^{\infty} \frac{\beta_\ell}{\mu\lambda_\ell + 1}\phi_\ell,$$

where β_ℓ, $\ell = 1, 2, \ldots$, are the Fourier coefficients of $\bar{\beta} - 1$; cf. (B.3). Now,

$$\tilde{v}^2(\cdot, \mu_j, \delta) = 1 + 2\delta z(\cdot, \mu_j) + O(\delta^2), \quad j = 1, \ldots, k+1.$$

These functions are linearly independent if such are the functions

$$\delta Q z(\cdot, \mu_j) + O(\delta^2), \quad j = 1, \ldots, k+1, \tag{B.5}$$

where $Qu = u - \int u$ is the orthogonal projection with kernel $\operatorname{span}\{\phi_1\}$. Clearly, (B.5) are linearly independent for all small $\delta > 0$ if and only if the functions $Qz(\cdot, \mu_j)$ are linearly independent. This is equivalent to the independence of the $k+1$ infinite vectors

$$\left(\frac{\beta_\ell}{\mu_j \lambda_\ell + 1} \right)_{\ell=2}^{\infty}, \quad j = 1, \ldots, k+1,$$

and a sufficient condition for this is the independence of the $k+1$ vectors in $\mathbb{R}^{k+1}$

$$\left(\frac{\beta_{\ell_i}}{\mu_j \lambda_{\ell_i} + 1} \right)_{i=1}^{k+1}, \quad j = 1, \ldots, k+1, \tag{B.6}$$

for some choice of indices ℓ_i. We choose the ℓ_i such that $\tilde{\lambda}_i := \lambda_{\ell_i}$, $i = 1, \ldots, k+1$, are mutually distinct. To test for the independence, we compute the determinant of the matrix with rows (B.6). It is easy to check by listing the obvious roots of the determinant that

$$\begin{aligned} \det \left(\frac{\beta_{\ell_i}}{\mu_j \tilde{\lambda}_i + 1} \right)_{i,j=1}^{k+1} &= \prod_{m=1}^{k+1} \frac{\beta_{\ell_m}}{\lambda_m} \det \left(\frac{1}{\mu_j + \tilde{\lambda}_i^{-1}} \right)_{i,j=1}^{k+1} \\ &= \prod_{m=1}^{k+1} \frac{\beta_{\ell_m}}{\lambda_m} \prod_{1 \le i,j \le k+1} \frac{1}{\mu_j + \tilde{\lambda}_i^{-1}} \prod_{1 \le i < j \le k+1} (\mu_j - \mu_i) \prod_{1 \le i < j \le k+1} (\tilde{\lambda}_j^{-1} - \tilde{\lambda}_i^{-1}). \end{aligned}$$

Since $\beta_i \neq 0$ (see (B.3)), our choice of $\tilde{\lambda}_j$ implies that the determinant is nonzero. Therefore the vectors (B.6) and the functions (B.5) are linearly independent. This completes the proof. □

VISCOUS APPROXIMATION OF STRONG SHOCKS OF SYSTEMS OF CONSERVATION LAWS*

FREDERIC ROUSSET†

Abstract. We consider a piecewise smooth solution of a one-dimensional hyperbolic system of conservation laws with a single Lax or overcompressive noncharacteristic shock. We show that it is a zero dissipation limit assuming that there exist linearly stable viscous profiles associated with the discontinuities. In particular, following the approach of [Grenier and Rousset, *Comm. Pure Appl. Math.*, 54 (2001), pp. 1343–1385], we replace the smallness condition obtained by energy methods in [Goodman and Xin, *Arch. Ration. Mech. Anal.*, 121 (1992), pp. 235–265] in the case of Lax shocks by a weaker spectral assumption which is sharp.

Key words. vanishing viscosity, stability of viscous shocks

1. Introduction.

Consider a one-dimensional system of conservation laws

$$u_t + f(u)_x = 0 \tag{1}$$

with a smooth flux $f : \mathbb{R}^n \to \mathbb{R}^n$. We assume that (1) is hyperbolic: there exist smooth matrices $P(u)$, $D(u)$ such that $P(u)^{-1} f'(u) P(u) = D(u)$, where $D(u)$ is a diagonal matrix. The eigenvalues of D will be denoted by $\lambda_1(u), \dots, \lambda_n(u)$. We consider a piecewise smooth solution u which is a distributional solution of (1) in the domain $\mathbb{R} \times [0, T^*]$ with a single shock; that is to say that $u(x,t)$ is smooth at any point (x,t), $x \neq s(t)$, where $x = s(t)$ is a smooth curve in the (x,t) plane. Moreover the limits

$$\partial_x^k u^-(t) := \partial_x^k u(s(t) - 0, t) = \lim_{x \to s(t)^-} \partial_x^k u(x,t),$$

$$\partial_x^k u^+(t) := \partial_x^k u(s(t) + 0, t) = \lim_{x \to s(t)^+} \partial_x^k u(x,t)$$

exist. We also assume that the shock is a noncharacteristic Lax or overcompressive shock that is

$$\lambda_1(u^-(t)), \dots, \lambda_{n-i^-}(u^-(t)) < s'(t) < \lambda_{n-i^-+1}(u^-(t)) < \cdots < \lambda_n(u^-(t)), \tag{2}$$

$$\lambda_1(u^+(t)), \dots, \lambda_{i^+}(u^+(t)) < s'(t) < \lambda_{i^++1}(u^+(t)) < \cdots < \lambda_n(u^+(t)), \tag{3}$$

$i^- + i^+ = n + q + 1$. We have a Lax shock when $q = 0$ and an overcompressive shock when $q > 0$. A general conjecture is that the admissible solutions of (1) can be obtained as limits of solutions of

$$u_t^\varepsilon + f(u^\varepsilon)_x = \varepsilon u_{xx}^\varepsilon \tag{4}$$

when ε tends to zero. This conjecture has been proved for scalar conservation laws by using the maximum principle [19] and for some special 2×2 systems (for which a weak maximum principle holds) by the method of compensated compactness [4]. This conjecture motivated the work of Goodman and Xin [8], who have shown that a solution of (1) with a Lax shock is the limit of a solution of (4) under a smallness assumption on the amplitude of the shock

$$\sup_{t\in[0,T]} |u(s(t)+0,t) - u(s(t)-0,t)| \leq \eta_0, \tag{5}$$

η_0 being sufficiently small.[1] Under this smallness assumption and in the case of Lax shocks, they have built an approximate solution u^{app} of (4) thanks to the method of matched asymptotic expansions. More precisely, away from the shock there is an outer expansion

$$O(x,t) = u(x,t) + \varepsilon u_1(x,t) + \varepsilon^2 u_2(x,t), \tag{6}$$

where u is the piecewise smooth solution of (1) that we considered, and u_i, $i \geq 2$, are solutions of some linear hyperbolic systems. Similarly, near the shock there is an inner expansion

$$I(x,t) = V(\xi,t) + \varepsilon V_1(\xi,t) + \varepsilon^2 V_2(\xi,t), \tag{7}$$

where $\xi = \frac{x-s(t)}{\varepsilon} + \delta(t)$ is the stretched variable. We also have an expansion of $\delta(t)$ which is a perturbation of the shock position:

$$\delta(t) = \delta_0(t) + \varepsilon\delta_1(t).$$

Note that it is actually possible to get expansions at every order by assuming more regularity on u.

The viscous shock profile $V(\xi,t)$ is a solution of

$$V_\xi = f(V) - f(u^-(t)) - s'(t)(V - u^-(t)) \tag{8}$$

such that

$$\lim_{\xi\to\pm\infty} V(\xi,t) = u^\pm(t). \tag{9}$$

The higher order terms are solutions of some linear ordinary differential equations. Taking a smooth function m such that $m(x) = 1$ when $|x| \leq 1$ and $m(x) = 0$, when $|x| \geq 2$, one finally gets an approximate solution of (4),

$$u^{app}(x,t) = m\left(\frac{x-s(t)}{\varepsilon^\gamma}\right) I(x,t) + \left(1 - m\left(\frac{x-s(t)}{\varepsilon^\gamma}\right)\right) O(x,t) + d(x,t), \tag{10}$$

where d is a higher order correction term that allows us to put the error term in conservative form (see section 2.2 for more details), and $\gamma \in (\frac{2}{3}, 1)$. The approximate solution u^{app} then solves

$$u^{app}_t + f(u^{app})_x - \varepsilon u^{app}_{xx} = \left(f(u^{app}) - f(u^{app} - d)\right)_x.$$

[1] More recently the convergence of u^ε was proved in [1] if the initial data of (4) has sufficiently small total variation.

It is then shown that a solution u^ε of (4) with initial condition $u^{app}(x,0)$ tends to u^{app} when ε goes to zero. As explained in [7], it is better to deal with an integrated equation when we study the stability of shocks. It relies on the fact that in case $\lambda_x < 0$ the scalar equation

$$v_t + \lambda(x)v_x = 0$$

has a better behavior than the equation

$$v_t + (\lambda(x)v)_x = 0$$

when we make energy estimates. Actually, the first one gives

$$\frac{d}{dt}\int_{\mathbb{R}} v^2(t,x)\,dx - \int_{\mathbb{R}} \lambda_x v^2\,dx = 0,$$

and hence $\frac{d}{dt}\int_{\mathbb{R}} v^2(t,x)\,dx \le 0$, as the second one gives

$$\frac{d}{dt}\int_{\mathbb{R}} v^2(t,x)\,dx + \int_{\mathbb{R}} \lambda_x v^2\,dx = 0,$$

which does not have the good sign. Consequently, as in [8], we set $w_x = u^\varepsilon - u^{app}$, which gives

$$w_t + f'(u^{app})w_x - \varepsilon w_{xx} = Q(u^{app}, w_x) + (f(u^{app}) - f(u^{app} - d)), \tag{11}$$

$$w(x,0) = 0.$$

The error term $Q(u^{app}, w_x)$ is $\mathcal{O}(|w_x|^2)$. The convergence of w_x to zero is shown in [8] by means of energy estimates. This method leads to a smallness assumption on the amplitude of the shock. Consequently, the convergence is shown only for weak shocks satisfying (5). The same kind of result with a more precise description of the convergence and the study of the evolution of an initial layer into a shock layer is shown in [20] using the method of approximate Green's functions in [14], but there is still the restriction (5). These results can be seen as a kind of generalization of the results of [7], [12], [18] about the asymptotic stability of weak viscous shock profiles. Nevertheless, the smallness assumption is not sharp even when we study the linear stability of shock profiles. There are strong shocks for which a viscous shock profile $V(\xi,\tau)$ associated is linearly stable for zero-mass perturbation; that is to say that the solutions of

$$\partial_t u + \partial_\xi(f'(V(\xi,\tau))u) - \partial_{\xi\xi}u = 0,$$

$$u(\xi,0) = \partial_\xi u_0(\xi)$$

tend to zero when $t \to +\infty$. However, when the shock does not satisfy a smallness assumption, the classical energy estimates are not sufficient to prove the stability. The main difficulty is due to the fact that the energy tends to zero when $t \to +\infty$ but not in a monotonous way. To conclude, refined methods are needed as in [10], [21]. Note that these methods do not apply in our time-dependent case since they both rely on the Laplace transform. The aim of this paper is to show the convergence of u^ε towards u^{app} when the viscous profiles are linearly stable using the method of [9]. This implies the result of [8] in the case of weak Lax shocks.

We now present our hypotheses more precisely. First we assume the following:

(H0) $\forall t \in [0, T^*]$, there exists a viscous profile which is a solution of (8), (9). Moreover in the case of overcompressive shocks ($q \geq 1$), we make the generic assumption that there exists a q-dimensional manifold of profiles $\varphi(\xi, t, h)$, $h \in U$, U being a vicinity of zero in $\mathbb{R}^q$.

Note that thanks to (2) and (3), $u^+(t)$ and $u^-(t)$ are hyperbolic rest points for the ordinary differential equation (8); consequently, we have for any α, β,

$$|\partial_t^\alpha \varphi(\xi, t, h)) - \partial_t^\alpha u^+(t)| \leq e^{-\omega\xi} \ \forall \xi \geq 0, \quad |\partial_t^\alpha \varphi(\xi, t, h)) - \partial_t^\alpha u^-(t)| \leq e^{\omega\xi} \ \forall \xi \leq 0,$$

$$|\partial_\xi^\alpha \varphi(\xi, t, h)| \leq e^{-\omega|\xi|}, \ |\partial_h^\beta \varphi(\xi, t, h)| \leq e^{-\omega|\xi|} \ \forall \xi$$

for some $\omega > 0$.

Let us formalize the notion of linear stability. Consider for each $\tau \in [0, T^*]$ the operators

$$\mathcal{L}_\tau v = v_{\xi\xi} - \Big(f'(\varphi(\xi, \tau, 0)) - s'(\tau)\Big) v_\xi$$

and

$$\tilde{L}_\tau v = v_{\xi\xi} - \Big(f'(\varphi(\xi, \tau, 0) - s'(\tau)) v\Big)_\xi$$

in L^p with domain $W^{2,p}$ for $p < +\infty$. For each time τ we want the profile $\varphi(\xi, \tau, 0)$ to be linearly stable. As stated in [21], it is equivalent to the Evans function criterion

(H) $\forall \tau \in [0, T^*]$, $\tilde{L}_\tau$ is such that $\tilde{D}_\tau(\lambda) \neq 0 \, \forall \lambda, \Re\, \lambda \geq 0$, $\lambda \neq 0$, and $\tilde{D}_\tau^{(q+1)}(0) \neq 0$,

where $\tilde{D}_\tau$ is the Evans function of $\tilde{L}_\tau$. We refer to [6] and [21] for the definition of the Evans function. This hypothesis means that $\tilde{L}_\tau$ does not have eigenvalues in the closed right half plane and that zero is semisimple in the effective spectrum. (We again refer to [21] for the definition of the effective spectrum.) This hypothesis is necessary for the linear stability of Lax shocks and overcompressive shocks as stated in [21]. Note that (H) can be checked by energy methods in the case of weak shocks. We point out that this hypothesis has an equivalent form (see [21]):

(H′) $\forall \tau \in [0, T^*]$, the "integrated operator" $\mathcal{L}_\tau$ is such that $\mathcal{D}_\tau(\lambda) \neq 0 \, \forall \lambda, \Re\lambda \geq 0$,

where $\mathcal{D}_\tau$ is the Evans function associated with $\mathcal{L}_\tau$. This second form is more useful for our work since we deal with an integrated equation (11). Note that we can prove by a direct computation that $\mathcal{D}_\tau(0) = \tilde{D}_\tau^{(q+1)}(0)$. Note also that this is another justification of the better behavior of the "integrated" equation explained in [7]. We finally point out that the assumption $\tilde{D}_\tau^{(q+1)}(0) \neq 0$ implies that the eigenspace of $\tilde{L}_\tau$ associated with the eigenvalue zero is generated by $\varphi_\xi, \varphi_{h^1}, \ldots, \varphi_{h^q}$.

The main theorems of this paper are as follows.

THEOREM 1. *Assume* (H0) *and* $\tilde{D}'_\tau(0) \neq 0$ *for any* $\tau \in [0, T^*]$ *in the case of Lax shocks and* $\tilde{D}_0^{(q+1)}(0) \neq 0$ *in the case of overcompressive shocks; then there exists an approximate solution of* (4) *defined on* $[0, T]$ *for some* $T > 0$. *Moreover, in the case of Lax shocks, we have* $T = T^*$.

THEOREM 2. *Assume* (H0) *and* (H)*; then we have*

$$||u^\varepsilon - u^{app}||_{L^\infty([0,T], L^1(\mathbb{R}))} \to 0$$

and

$$||u^\varepsilon - u^{app}||_{L^\infty([0,T]\times\mathbb{R})} \to 0$$

when ε tends to zero. Consequently, we have

$$||u^\varepsilon - u||_{L^\infty([0,T],L^1(\mathbb{R}))} \to 0$$

and, for any $\eta \in (0,1)$,

$$\sup_{0\le t\le T,\ |x-s(t)|\ge\varepsilon^\eta} |u^\varepsilon(x,t) - u(x,t)| \to 0$$

when ε tends to zero. Moreover, in the case of Lax shocks, we have $T^* = T$.

We can also get a convergence in $L^\infty([0,T], W^{m,1}(\mathbb{R}))$, where m depends only on the regularity of u. Note that this theorem is sharp since (H) is necessary for linear stability of each profile and since we can expect that linear instability implies nonlinear instability as in [3]. Moreover this theorem implies the result of [8] up to a change of L^2-type to L^1-type Sobolev space.

In the first part of this paper, we prove Theorem 1, and we show that the error term of the approximate solution satisfies the same estimates as in [8]. The fact that even if we assume that $\tilde{D}_\tau^{(q+1)} \neq 0$ for any $\tau \in [0, T^*]$, we may have $T < T^*$ in the case of overcompressive shocks will appear in this construction. Actually, since we also look for a perturbation $h(t)$ in U of the viscous profile, the construction can be led only for small t since in general $U \neq \mathbb{R}^n$. A motivating example is given in [5]. Hence the convergence will be shown only for T sufficiently small. It seems to be related to the "instability" of overcompressive shocks that is pointed out in [13].

Next, we set $z = x - s(t) + \varepsilon\delta(t)$; hence (11) becomes

$$\begin{aligned} &\tilde{w}_t + \Big(f'(\tilde{u}^{app}(z,t)) - s'(t) + \varepsilon\delta'(t)\Big)\tilde{w}_z - \varepsilon\tilde{w}_{zz} \\ &= Q(\tilde{u}^{app}, \tilde{w}_z) + (f(\tilde{u}^{app}) - f(\tilde{u}^{app} - \tilde{d})), \end{aligned} \tag{12}$$

where $\tilde{u}^{app}(z,t) = u^{app}(z + s(t) - \varepsilon\delta(t), t)$, $\tilde{d}(z,t) = d(z + s(t) - \varepsilon\delta(t))$, and $\tilde{w}(z,t) = w(z + s(t) - \varepsilon\delta(t), t)$. We note that now the viscous shock is located at $z = 0$. In the second part of this paper, we use the iterative construction of Green's functions described in [9] to get a Green's function for the operator

$$\mathcal{L}^\varepsilon w = w_t + (f'(\tilde{u}^{app}) - s'(t) + \varepsilon\delta'(t))w_z - \varepsilon w_{zz}$$

and to derive uniform estimates in ε on the L^1 norm of this Green's function. To use this method, we construct an approximate Green's function. This function is obtained by combining approximate Green's functions away from the shock and the exact Green's function for the shock problem with frozen time in the viscous profiles built in [21]. Finally we show the nonlinear convergence using a standard argument for parabolic equations as in [10].

2. Construction and estimates on the error term of the approximate solution. In this section we explain how the hypothesis (H) allows us to make the same construction as in [8] with the same type of estimates on the error term but without using the smallness assumption (5).

2.1. Proof of Theorem 1. We look for an outer expansion under the form (6) where u_1, u_2 are smooth up to $x = s(t)$, but since we also want to deal with overcompressive shocks, we look for an inner expansion under the more general form

$$I(x,t) = \varphi(\xi, t, h_0(t)) + \varepsilon\Big(\partial_h\varphi(\xi, t, h_0(t))h_1(t) + V_1(\xi,t)\Big) + \varepsilon^2 V_2(\xi,t),$$

where ξ is still under the form $\xi = \frac{x-s(t)}{\varepsilon} + \delta(t)$, φ is a solution of

$$\varphi_\xi = f(\varphi) - f(u^-(t)) - s'(t)(\varphi - u^-(t)),$$

$\varphi(-\infty, t, h_0(t)) = u^-(t)$, and $\varphi(+\infty, t, h_0(t)) = u^+(t)$. In the case of Lax shocks, we have $h_0(t) = 0$ and $h_1(t) = 0$. In the case of overcompressive shocks, $h_0(t)$ is a parametrization of the viscous profiles. The method of matched asymptotic expansion leads to

$$u_{1t} + (f'(u)u_1)_x = u_{xx}, \tag{13}$$

$$u_{2t} + (f'(u)u_2)_x = u_{1xx} + (f''(u)(u_1,u_1))_x \tag{14}$$

for the outer expansion and to

$$V_{1\xi\xi} = \Big((f'(\varphi) - s'(t))V_1\Big)_\xi + \delta_0'(t)\varphi_\xi + \partial_h\varphi h_0'(t) + \varphi_t, \tag{15}$$

$$\begin{aligned} V_{2\xi\xi} = {} & \Big((f'(\varphi) - s'(t))V_2\Big)_\xi + \delta_1'(t)\varphi_\xi + \partial_h\varphi h_1'(t) \\ & + (\partial_t\partial_h\varphi + \delta_0'\partial_\xi\partial_h\varphi + \partial_h^2\varphi\cdot h_0')\cdot h_1 \\ & + \Big(f''(\varphi)(\partial_h\varphi h_1 + V_1, \partial_h\varphi h_1 + V_1)\Big)_\xi + V_{1t} + \delta_0' V_{1\xi} \end{aligned} \tag{16}$$

for the inner expansion. Here we have used

$$(\partial_h\varphi)_{\xi\xi} = \Big((f'(\varphi) - s'(t))\partial_h\varphi\Big)_\xi.$$

Moreover we want the two solutions to be valid in an intermediate zone. This gives the matching conditions

$$V_1(\xi,t) = u_1^\pm(t) + (\xi - \delta_0)\partial_x u^\pm(t) + o(1), \tag{17}$$

$$\begin{aligned} V_2(\xi,t) = {} & u_2^\pm(t) + (\xi-\delta_0)\partial_x u_1^\pm(t) - \delta_1(t)\partial_x u^\pm(t) \\ & + \frac{1}{2}(\xi-\delta_0)^2\partial_x^2 u^\pm(t) + o(1) \end{aligned} \tag{18}$$

when $\xi \to \pm\infty$.

We give the construction of u_1, V_1, δ_0, and h_0, which are built simultaneously. The construction of u_2, V_2, δ_1, and h_1 will be similar. As in [8], it is convenient to deal with bounded solutions; hence we first lift the dominant term in the asymptotic expansion (17) by choosing D_1 smooth such that

$$D_1(\xi,t) = \begin{cases} \xi\partial_x u(s(t)-0,t), & \xi < -1, \\ \xi\partial_x u(s(t)+0,t), & \xi > 1. \end{cases}$$

Consequently, $U_1 = V_1 - D_1$ solves

$$U_{1\xi\xi} - \Big((f'(\varphi) - s'(t))U_1\Big)_\xi = \delta_0'(t)\varphi_\xi + \partial_h\varphi h_0'(t) + g(\xi,t,h_0(t)),$$

where

$$g(\xi,t,h_0(t)) = \Big((f'(\varphi)-s')D_1\Big)_{\xi} + \partial_t\varphi(\xi,t,h_0(t)). \tag{19}$$

Note that

$$g(\xi,t,h_0(t)) = \Big(f'(u^{\pm})-s'\Big)\partial_x u^{\pm} + \frac{d}{dt}u^{\pm}(t) + \mathcal{O}(e^{-\alpha|\xi|}), \qquad \alpha>0.$$

Hence

$$|g(\xi,t,h_0(t))| \le Ce^{-\alpha|\xi|},$$

since thanks to (1)

$$\partial_t u^{\pm} + f'(u^{\pm})\partial_x u^{\pm} = 0.$$

Moreover (17) becomes

$$U_1(\xi,t) = u_1^{\pm}(t) - \delta_0\partial_x u_0^{\pm}(t) + o(1), \qquad \xi\to\pm\infty. \tag{20}$$

Setting

$$G(\xi,t,h_0(t)) = \int_0^{\xi} g(\eta,t,h_0(t))\,d\eta, \tag{21}$$

we get

$$\begin{aligned} U_{1\xi} - \Big(f'(\varphi)-s'(t)\Big)U_1 = \delta_0'(t)\varphi + \int_0^{\xi}\partial_h\varphi(\zeta,t,h(t))h_0'(t)\,d\zeta \\ + G(\xi,t,h_0(t)) + c(t), \end{aligned} \tag{22}$$

where $c(t)$ is an integration constant.

We have to solve the coupled systems (13), (22), (20). The first step of the proof is to show that with t, δ_0, h_0 fixed we can find a solution of (22) having limits at $\pm\infty$ which depend on t, δ_0, h_0. Then, using these limits and the matching conditions (20), we rewrite (13) as a hyperbolic initial boundary value problem where δ_0 and h_0 are also unknown. We use the techniques of [11], [16] to solve it. Finally using the δ_0 and h_0 obtained, we take the corresponding solutions of (22) which have limits which by construction verify the matching condition (20).

Let us consider the homogeneous ordinary differential system

$$v_{\xi} = \Big(f'(\varphi)-s'(t)\Big)v. \tag{23}$$

Since

$$\begin{aligned} |f'(\varphi)-f'(u^+(t))| &\le e^{-\alpha\xi}, \qquad \xi\ge 0,\\ |f'(\varphi)-f'(u^-(t))| &\le e^{\alpha\xi}, \qquad \xi\le 0, \end{aligned}$$

and since $f'(u^+(t))-s'(t)$, $f'(u^-(t))-s'(t)$ do not have eigenvalues on the imaginary axis thanks to (2), (3), Proposition 1 in [2, Chap. 2] concerning the roughness of exponential dichotomy states that the differential system (23) has an exponential dichotomy on both half lines. Hence we can use Lemma 4.2 of [17]. Let us denote

by $C_b(\mathbb{R})$ the space of continuous bounded functions on $\mathbb{R}$ and by $C_b^1(\mathbb{R})$ the space of C^1 functions bounded together with their derivative. We consider the linear operator A_{t,h_0} defined from C_b^1 to C_b^0 by

$$A_{t,h_0}v = v' - \Big(f'(\varphi) - s'(t)\Big)v.$$

Lemma 4.2 of [17] states that A_{t,h_0} is a Fredholm operator. The index of A_{t,h_0} is $\dim E + \dim F - n$, where E and F are the stable and unstable subspaces of (23); that is to say

$$E = \{x \in \mathbb{R}^n,\ \exists v \text{ solution of (23)}, v(0) = x,\ v(+\infty) = 0\},$$
$$F = \{x \in \mathbb{R}^n,\ \exists v \text{ solution of (23)}, v(0) = x,\ v(-\infty) = 0\}.$$

Using [2] again, E has the same dimension as the stable subspace of

$$v' = \Big(f'(u^+(t)) - s'(t)\Big)v,$$

i.e., i^+, thanks to (3). Similarly F has the same dimension as the unstable subspace of

$$v' = \Big(f'(u^-(t)) - s'(t)\Big)v,$$

i.e., i^-, thanks to (2). Consequently, the index of the Fredholm operator (A_{t,h_0}) is $q+1$. Moreover, in the case of Lax shocks, our assumption $\tilde{D}_t'(0) \neq 0$ for any $t \in [0, T^*]$ implies that $\ker\ A_t = \mathrm{Span}(\varphi_\xi)$ (in this case, there is no dependence on h); hence $\dim \ker A_t = 1$ and A_t is onto. In the case of overcompressive shocks, by continuity we have $\tilde{D}_{t,h_0}^{(q+1)}(0) \neq 0$ for any $t \in [0, T]$, for some positive T, and for any h_0 in a vicinity of zero in $\mathbb{R}^q$, where $\tilde{D}_{t,h_0}$ is the Evans function of the operator

$$\tilde{L}_{t,h_0}v = v_{\xi\xi} - \Big((f'(\varphi(\xi,t,h_0)) - s'(t))v\Big)_\xi.$$

Consequently $\ker\ A_{t,h_0} = \mathrm{Span}(\varphi_\xi, \varphi_{h^1}, \ldots, \varphi_{h^q})$; hence $\dim \ker A_{t,h_0} = q+1$ and A_{t,h_0} is onto. Finally, there exists a bounded solution U_1 of (22) in a closed supplementary of the kernel for any $t \in [0, T^*]$, $\delta_0 \in \mathbb{R}$ in the case of Lax shocks and for any $t \in [0, T]$, $\delta_0 \in \mathbb{R}$ and h_0 in a vicinity of zero in the case of overcompressive shocks.

We now show that every bounded solution U_1 of (22) actually has limits at both $\pm\infty$ which do not depend on its choice, and we compute them. For $\xi \geq 0$, we have

$$U_{1\xi} = \Big(f'(u^+(t)) - s'(t)\Big)U_1 + F, \tag{24}$$

where

$$F = \Big(f'(\varphi) - f'(u^+(t))\Big)U_1 + \delta_0'\varphi + \int_0^\xi \partial_h\varphi \cdot h_0'(t) + G + c$$

is bounded and such that

$$\lim_{\xi\to+\infty} F = \delta_0' u^+ + \int_0^{+\infty} \partial_h\varphi \cdot h_0' + G^+ + c,$$

where we denote $\lim_{\xi\to+\infty} G$ by G^+. Denoting by $r_i^+(t)$ and $a_i^+(t)$ eigenvectors and eigenvalues of $f'(u^+(t)) - s'(t)$, we can write

$$U_1(\xi,t) = \sum_{i=1}^{n} \alpha_i(\xi,t) r_i^+(t),$$
$$F(\xi,t) = \sum_{i=1}^{n} F_i(\xi,t) r_i^+(t).$$

Hence, we get

$$\alpha_{i\xi} = a_i^+(t)\alpha_i + F_i.$$

Consequently, we get the expression of α_i:

$$\alpha_i(\xi,t) = -\int_x^{+\infty} F_i(z,t) e^{a_i^+(t)(\xi-z)}\, dz \qquad \text{if } a_i^+(t) > 0,$$
$$\alpha_i(\xi,t) = Ce^{a_i^+(t)x} + \int_0^x F_i(z,t) e^{a_i^+(t)(\xi-z)}\, dz \qquad \text{if } a_i^+(t) < 0.$$

Hence, in both cases we find that $\alpha_i(\xi,t) = -\frac{1}{a_i}\lim_{\xi\to+\infty} F_i + \mathcal{O}(e^{-\omega\xi})$, $\omega > 0$, when $\xi \to +\infty$. Consequently, we have shown

(25)
$$\lim_{\xi\to+\infty} U_1(\xi,t) = -\Big(f'(u^+(t)) - s'(t)\Big)^{-1}\left(\delta_0'(t)u^+(t) + \int_0^{+\infty} \partial_h\varphi \cdot h_0' + G_+(t,h_0(t)) + c(t)\right).$$

Similarly, we can show

(26)
$$\lim_{\xi\to-\infty} U_1(\xi,t) = -\Big(f'(u^-(t)) - s'(t)\Big)^{-1}\left(\delta_0'(t)u^-(t) + \int_0^{-\infty} \partial_h\varphi \cdot h_0' + G^-(t,h_0(t)) + c(t)\right).$$

Going back to (20), we must also have

$$\lim_{\xi\to+\infty} U_1 = u_1^+(t) - \delta_0(t)\partial_x u^+(t), \tag{27}$$
$$\lim_{\xi\to-\infty} U_1 = u_1^-(t) - \delta_0(t)\partial_x u^-(t). \tag{28}$$

We now set $A^+(t) = f'(u^+(t)) - s'(t)$, $A^-(t) = f'(u^-(t)) - s'(t)$. By combining (25), (27), (26), (28) and eliminating $c(t)$, we get

$$\begin{aligned} A^+(t)u_1^+(t) - A^-(t)u_1^-(t) = {} & \delta_0(A^+(t)\partial_x u^+(t) - A^-(t)\partial_x u^-(t)) \\ & - \delta_0'(u^+(t) - u^-(t)) - \partial_h m \cdot h_0' - (G^+ - G^-), \end{aligned} \tag{29}$$

where

$$m(t,h_0) = \int_{-\infty}^{+\infty} (\varphi(\xi,t,h_0) - \varphi(\xi,t,0))\, d\xi.$$

Using (1) and (21), we get

$$A^+\partial_x u^+ - A^-\partial_x u^- = -\frac{d}{dt}(u^+ - u^-)$$

and

$$G^+ - G^- = -\frac{d}{dt}(u^+ - u^-) + \int_{-\infty}^{+\infty} \partial_t \varphi(\xi, t, h_0) d\xi.$$

Hence we can rewrite (29) as

$$A^+ u_1^+ - A^- u_1^- + \frac{d}{dt}\Big(\delta_0(u^+ - u^-) + m(t, h_0)\Big) = \frac{d}{dt}(u^+ - u^-). \tag{30}$$

We want to use (30) to solve (13). We first rewrite (13) as a hyperbolic initial boundary value problem. Let

$$W(z,t) = \begin{pmatrix} u_1(z + s(t), t) \\ u_1(s(t) - z, t) \end{pmatrix}$$

be the new unknown. We get that W solves

$$W_t + \big(\mathbb{A}(z,t)W\big)_z = S, \qquad z > 0, \tag{31}$$

where

$$\mathbb{A}(z,t) = \begin{pmatrix} f'(u_0(z + s(t), t)) - s'(t) & 0 \\ 0 & -(f'(u(s(t) - z, t)) - s'(t)) \end{pmatrix}$$

and

$$S = \begin{pmatrix} u_{zz}(s(t) + z, t) \\ u_{zz}(s(t) - z, t) \end{pmatrix}.$$

Note that

$$\mathbb{A}(0,t) = \begin{pmatrix} A^+(t) & 0 \\ 0 & -A^-(t) \end{pmatrix}.$$

Hence thanks to (2), (3) the boundary $\{z = 0\}$ is noncharacteristic for (31).

We first give the end of the proof in the case of Lax shocks. In this case $q = 0$, and we can forget the dependence on h_0. Consequently, (31), (30) is a linear system. We can solve it with initial conditions $W(z,0) = W_0(z)$, $\delta_0(0) = 0$, where W_0 is a smooth function which satisfies suitable compatibility conditions at 0 with the source term S to get a solution W sufficiently smooth to build the next terms of the asymptotic expansion. Using [16], it suffices to check the well-posedness for every $s \in [0, T^*]$ for the system

$$W_t + \mathbb{A}(0,s)W_z = 0, \qquad z > 0, \tag{32}$$

$$A^+(s)u_1^+(t) - A^-(s)u_1^-(t) + \delta_0'(t)(u^+(s) - u^-(s)) = 0, \tag{33}$$

where

$$W(0,t) = \begin{pmatrix} u_1^+(t) \\ u_1^-(t) \end{pmatrix}.$$

This system is similar to the one which arises in the study of linear stability of inviscid shocks [16]. The system (32), (33) is well posed if there is no nonzero solution under the form

$$W(z,t) = e^{\tau t} X(z), \qquad X(+\infty) = 0, \qquad \Re\tau > 0, \tag{34}$$

$$\delta_0(t) = e^{\tau t} d_0. \tag{35}$$

In our one-dimensional setting, this condition is equivalent to the Majda–Liu condition

$$\Delta(s) = \det\Big(r^+_{i^++1}(s), \dots, r^+_n(s), r^-_1(s), \dots, r^-_{n-i^-}(s), u^+(s) - u^-(s)\Big) \neq 0 \ \forall s \in [0, T^*].$$

Using [22, Proposition 5.3], we have

$$\tilde{D}'_s(0) = \Gamma\Delta(s).$$

Hence our hypothesis $\tilde{D}'_s(0) \neq 0$ implies the Majda–Liu condition. Consequently, using [11], [15], [16], there exists W and δ_0 which are solutions of (32), (33) defined on $[0, T^*]$. We now choose a bounded solution U_1 of (22), W and δ_0 being known. This solution satisfies the matching condition thanks to the choice of W and δ_0. This ends the proof in the case of Lax shocks.

In the case of overcompressive shocks, (30) is a nonlinear equation in h_0. Using the techniques of [16], [15], there exist W, δ_0, and h_0 solutions of (31), (30) with initial conditions $W(0,z) = W_0(z)$, $\delta_0(0) = 0$, $h_0(0) = 0$ defined on $[0,T]$ for some positive T if we have well-posedness for the linearized system

$$W_t + \mathbb{A}(0,0)W_z = 0,$$

$$A^+(0)u_1^+(t) - A^-(0)u_1^-(0) + \delta_0'(t)(u^+(0) - u^-(0)) + m_h(0,0)h_0'(t) = 0.$$

Thanks to [11], [16], this linear system is well posed if there is no nonzero solution (W, δ_0, h_0) under the form (34), (35) and

$$h_0(t) = e^{\tau t} H, \qquad h \in \mathbb{R}^q.$$

This is equivalent to

$$\Delta = \det\Big(r^+_{i^++1}(0), \dots, r^+_n(0), r^-_1(0), \dots, r^-_{n-i^-}(0), u^+(0) - u^-(0), \\ \partial_{h^1} m(0,0), \dots, \partial_{h^q} m(0,0)\Big) \neq 0.$$

Using [22, Proposition 6.2], we have

$$\tilde{D}_0^{(q+1)}(0) = \Gamma\Delta.$$

Hence $\Delta \neq 0$ since $\tilde{D}_0^{(q+1)}(0) \neq 0$. The end of the proof is similar to the case of Lax shocks.

2.2. Bounds on the error terms of the approximate solution. In the following we will denote $\varphi(\xi,t,h_0(t))$ by $V(\xi,t)$. Since we want to integrate the equation, we need to choose an approximate solution of (4) with an error term in a conservative form. If we choose an approximate solution under the basic form

$$u^{app}(x,t)=m\left(\frac{x-s(t)}{\varepsilon^\gamma}\right)I(x,t)+\left(1-m\left(\frac{x-s(t)}{\varepsilon^\gamma}\right)\right)O(x,t),$$

we find that

$$u_t^{app}+f(u^{app})_x-\varepsilon u_{xx}^{app}=q,$$

where $q(x,t)=\sum_{i=1}^3 q_i(x,t)$,

$$q_1(x,t)=(1-m)\Bigg\{\left(f(O)-f(u)-\varepsilon f'(u)u_1-\varepsilon^2 f'(u)u_2-\frac{1}{2}f''(u)(u_1,u_1)\right)_x - \varepsilon^3 u_{2xx}\Bigg\},$$

$$q_2(x,t)=m\Bigg\{\left(f(I)-f(V)-\varepsilon f'(V)V_1-\varepsilon^2 f'(V)V_2-\frac{1}{2}\varepsilon^2 f''(V)(V_1,V_1)\right)_x + \varepsilon^2\left(\delta_1'(t)\partial_\xi\partial_h\varphi+\delta_1'V_{1\xi}+\partial_t\partial_h\varphi+V_{2t}+\delta' V_{2\xi}\right)\Bigg\},$$

$$\begin{aligned}q_3(x,t)=\;&m_t\left(I-O\right)-\varepsilon m_{xx}(I-O)-2\varepsilon m_x\left(I-O\right)_x+m_x\left(f(I)-f(O)\right)\\&+\left(f(mI+(1-m)O)_x-\left(mf(I)+(1-m)f(O)\right)\right)_x.\end{aligned}$$

Consequently, the error is not in a conservative form. Hence, following the idea of [8], we choose an approximate solution in the form (10),

$$u^{app}(x,t)=m\left(\frac{x-s(t)}{\varepsilon^\gamma}\right)I(x,t)+\left(1-m\left(\frac{x-s(t)}{\varepsilon^\gamma}\right)\right)O(x,t)+d(x,t),$$

where d is such that

$$d_t-\varepsilon d_{xx}=-q(x,t),$$

$$d(0,x)=d_0(x).$$

Thanks to this choice, u^{app} now solves

$$u_t^{app}+(f'(u^{app}))_x-\varepsilon u_{xx}^{app}=(f(u^{app}-d)-f(u^{app}))_x,$$

and we will be able to integrate the equation. Let us set $R^\varepsilon(z,t)=f(\tilde{u}^{app}-\tilde{d})-f(\tilde{u}^{app})$, which is the error term of the approximate solution in (12). Recall that we have set $z=x-s(t)+\varepsilon\delta(t)$. We show the following.

PROPOSITION 3. *There exists a positive constant C independent of ε such that $\forall$ $\gamma\in(\frac{2}{3},1)$, $t\in[0,T]$,*

$$||R^\varepsilon(\cdot,t)||_{L^1}\le C\varepsilon^{3\gamma},\quad ||R_t^\varepsilon(\cdot,t)||_{L^1}\le C\varepsilon^{3\gamma-\frac{1}{2}},\quad ||R_{tt}^\varepsilon(\cdot,t)||_{L^1}\le C\varepsilon^{3\gamma-1},$$

$$||R^\varepsilon_z(\cdot,t)||_{L^1} \le C\varepsilon^{3\gamma-1}, \quad ||R^\varepsilon_{zz}(\cdot,t)||_{L^1} \le C\varepsilon^{2\gamma-\frac{1}{2}}.$$

Proof. We have a result similar to that of [8] thanks to the matching conditions

$$||\tilde q(\cdot,t)||_{L^1} + ||\tilde q(\cdot,t)_t||_{L^1} + ||\tilde q_{tt}(\cdot,t)||_{L^1} \le C\varepsilon^{3\gamma}$$

and

$$||\tilde q||_{L^\infty} + ||\tilde q_z(\cdot,t)||_{L^1} \le C\varepsilon^{2\gamma}.$$

Next since $\tilde d(z,t) = d(x+s(t)-\varepsilon\delta(t),t)$, $\tilde d$ is a solution of

$$\tilde d_t - (s'(t)-\varepsilon\delta(t))\tilde d_z - \varepsilon\tilde d_{zz} = -\tilde q(z,t), \tag{36}$$

with the initial condition $\tilde d(z,0)=0$. Consequently, we can write

$$\tilde d(z,t) = \int_0^t \int_{-\infty}^{+\infty} k^\varepsilon(z-y,t,\tau)\tilde q(y,\tau)\,dyd\tau,$$

where

$$k^\varepsilon(z,t,\tau) = \frac{1}{\sqrt{4\pi\varepsilon(t-\tau)}} \exp\left(-\frac{\left(z+\int_\tau^t s'(\mu)-\varepsilon\delta'(\mu)\,d\mu\right)^2}{4\varepsilon(t-\tau)}\right).$$

Since $||k(\cdot,t,\tau)||_{L^1} + \sqrt{\varepsilon}||k_z(\cdot,t,\tau)||_{L^1}$ is independent of ε, we get

$$||\tilde d(\cdot,t)||_{L^1} \le C\varepsilon^{3\gamma}, \qquad ||\tilde d_z(\cdot,t)||_{L^1} \le C\varepsilon^{3\gamma-\frac{1}{2}},$$

$$||\tilde d(\cdot,t)||_{L^\infty} \le C\varepsilon^{2\gamma}, \qquad ||\tilde d_z(\cdot,t)||_{L^\infty} \le C\varepsilon^{2\gamma-\frac{1}{2}}.$$

To bound $||\tilde d_t(\cdot,t)||_{L_1}$ and $||\tilde d_{tt}(\cdot,t)||_{L_1}$, we take the time derivative of (36) and get

$$(\tilde d_t)_t - (s'(t)-\varepsilon\delta(t))(\tilde d_t)_z - \varepsilon(\tilde d_t)_{zz} = \tilde q_t + (s'(t)-\varepsilon\delta(t))\tilde d_z,$$

with the initial condition $\tilde d_t(z,0) = \tilde q(z,0)$. Hence we can write

$$\begin{aligned}\tilde d_t(z,t) = &\int_{-\infty}^{+\infty} k^\varepsilon(z-y,t,0)\tilde q(y,0)\,dy \\ &+ \int_0^t\int_{-\infty}^{+\infty} k^\varepsilon(z-y,t,\tau)(\tilde q_t + (s'(\tau)-\varepsilon\delta(\tau))\tilde d_z)(y,\tau)\,dyd\tau.\end{aligned}$$

This leads to

$$||\tilde d_t(\cdot,t)||_{L^1} \le C\varepsilon^{3\gamma-\frac{1}{2}}, \qquad ||\tilde d_{tz}(\cdot,t)||_{L^1} \le C\varepsilon^{3\gamma-1}.$$

The bound for $||\tilde d_{tt}||_{L^1}$ is obtained by taking again the time derivative of the equation and using the bound on $||\tilde d_{tz}(\cdot,t)||_{L^1}$. To get the bound on $||\tilde d_{zz}||_{L^1}$, we take the derivative of (36) with respect to z. To end the proof of the proposition, we use the Taylor formula, the previous bounds, and

$$||\tilde u^{app}||_{L^\infty} + ||\tilde u^{app}_t||_{L^\infty} + ||\tilde u^{app}_{tt}||_{L^\infty} + \varepsilon||\tilde u^{app}_z||_{L^\infty} + \varepsilon^2||\tilde u^{app}_{zz}||_{L^\infty} \le C,$$

where C is independent of ε. ∎

3. The Green's function for a pure viscous profile problem. Here we recall part of the results of [21] about the behavior of the Green's function $G_\tau^S(t,x,y)$ of the operator

$$L_\tau^\varepsilon u = \partial_t u - \left(f'\left(V\left(\frac{x}{\varepsilon},\tau\right)\right) - s'(\tau)\right) u_x - \varepsilon u_{xx}.$$

The Green's function is a solution of $L_\tau^\varepsilon G_\tau^S = 0$ for $t>0$ such that

$$\lim_{t\to 0^+} G_\tau^S(t,x,y) = \delta_y(x) I_n$$

and

$$G_\tau^S(t,x,y) = 0, \qquad t<0.$$

Note that

$$G_\tau^S(t,x,y) = \frac{1}{\varepsilon} G_\tau^{HZ}\left(\frac{t}{\varepsilon},\frac{x}{\varepsilon},\frac{y}{\varepsilon}\right), \tag{37}$$

where $G_\tau^{HZ}(t,x,y)$ is the Green's function of the operator

$$L_\tau u = \partial_t u - \left(f'(V(x,\tau)) - s'(\tau)\right) u_x - u_{xx}$$

studied very precisely in [21]. We will denote by $a_j^+(\tau)$, $r_j^+(\tau)$ the eigenvalues and the associated eigenvectors of $f'(u^+(\tau)) - s'(\tau)$ and by $a_j^-(\tau)$, $r_j^-(\tau)$ the eigenvalues and the associated eigenvectors of $f'(u^-(\tau)) - s'(\tau)$. Using (37) and [21], we get the following.

THEOREM 4 (Zumbrun–Howard [21]). *Under hypothesis* (H), *we have*

$$\begin{aligned} G_\tau^S(t,x,y) = &\sum_{j,a_j^+(\tau)>0} \mathcal{O}\left(\frac{\exp\left(-\frac{\left(x-a_j^+(\tau)t\right)^2}{M\varepsilon t}\right)}{\sqrt{\varepsilon t}}\right) r_j^+(\tau)\chi_{x\geq 0} \\ &+ \sum_{j,a_j^-(\tau)<0} \mathcal{O}\left(\frac{\exp\left(-\frac{\left(x-a_j^-(\tau)t\right)^2}{M\varepsilon t}\right)}{\sqrt{\varepsilon t}}\right) r_j^-(\tau)\chi_{x\leq 0} + \mathcal{O}\left(\frac{e^{-\frac{(x-y)^2}{M\varepsilon t}}}{\sqrt{\varepsilon t}} e^{-\sigma\frac{t}{\varepsilon}}\right), \end{aligned} \tag{38}$$

$$\begin{aligned} \partial_x G_\tau^S(t,x,y) = &\sum_{j,a_j^+(\tau)>0} \mathcal{O}\left(\frac{\exp\left(-\frac{\left(x-a_j^+(\tau)t\right)^2}{M\varepsilon t}\right)}{\varepsilon t}\right) r_j^+(\tau)\chi_{x\geq 0} \\ &+ \sum_{j,a_j^-(\tau)<0} \mathcal{O}\left(\frac{\exp\left(-\frac{\left(x-a_j^-(\tau)t\right)^2}{M\varepsilon t}\right)}{\varepsilon t}\right) r_j^-(\tau)\chi_{x\leq 0} + \mathcal{O}\left(\frac{e^{-\frac{(x-y)^2}{M\varepsilon t}}}{\varepsilon t} e^{-\sigma\frac{t}{\varepsilon}}\right), \end{aligned} \tag{39}$$

where M and σ are positive constants, and

$$\chi_{z\leq 0} = \begin{cases} 1 & \text{if } z\leq 0, \\ 0 & \text{if } z>0. \end{cases}$$

All the $\mathcal{O}$'s stand for linear forms which are uniformly bounded in (t,x) and locally bounded in y.

Note that we do not use the whole expansion of the Green's function obtained in [21]. We use simplified (and weaker) bounds since we only need estimates for bounded y. Indeed the far field behavior will be handled by another Green's function in our iterative construction. Moreover, there are no excited terms thanks to the hypothesis $\mathcal{D}_\tau(0) \neq 0$ since we deal with an integrated equation. Similar weaker estimates were obtained in [9] for boundary layers.

4. The Green's function for the general operator $\mathcal{L}_\varepsilon$. The aim of this section is to prove the following theorem.

THEOREM 5. *There exists a Green's function $G(t,\tau,x,y)$ of $\mathcal{L}_\varepsilon$ defined for $0 \leq \tau,\ t \leq T,\ z,\ y \in \mathbb{R}$ such that $G(t,\tau,z,y) = 0$ if $t < \tau$ and*

$$\sup_{0\leq\tau\leq T,y} \int_0^T \int_{\mathbb{R}} |G(t,\tau,z,y)|\,dzdt + \sqrt{\varepsilon} \sup_{0\leq\tau\leq T,y} \int_0^T \int_{\mathbb{R}} |\partial_z G(t,\tau,z,y)|\,dzdt \tag{40}$$

is bounded uniformly in ε.

Proof. We use the iterative construction of the Green's functions given in [9]. We choose an approximate Green's function $G^{app}(t,\tau,z,y)$ under the form

$$G^{app}(t,\tau,z,y) = \sum_{k=1}^{N} S_k(t,\tau,z,y)\Pi_k(\tau,y),$$

where $S_k(t,\tau,z,y)$ are Green's kernels and $\Pi_k \in \mathcal{C}^\infty([0,T]\times\mathbb{R},\mathcal{L}(\mathbb{R}^n))$ are such that

$$||\Pi_k(t,x)v|| \leq C||v|| \qquad \forall x \geq 0,\ t \in [0,T],\ v \in \mathbb{R}^n$$

and

$$\sum_k \Pi_k = \mathrm{Id}.$$

For each S_k, we define the error $R_k(t,\tau,z,y) = \mathcal{L}_\varepsilon S_k$. We then define the matrix of errors $\mathcal{M}(T_1,T_2) = (\sigma_{kl}(T_1,T_2))_{1\leq k,l\leq N}$, where

$$\sigma_{kl}(T_1,T_2) = \sup_{T_1\leq\tau\leq T_2,\ y\in \mathrm{supp}\ \Pi_l} \int_{T_1}^{T_2} \int_{\mathbb{R}} |\Pi_k(t,z)R_l(t,\tau,z,y)|\,dzdt.$$

This matrix describes how each part of the approximate Green's function is handled at the next step of the iterative method. Theorem 5 of [9] states that to prove (40), it suffices to check that there exists η such that $T_2 - T_1 \leq \eta$ implies

$$\lim_{p\to+\infty} \mathcal{M}^p(T_1,T_2) = 0.$$

Let us now introduce some definitions that are necessary for the construction of our approximate Green's function. We use two smooth cut-off functions χ^+ and χ^- such that

$$\chi^+(z) = \begin{cases} 0 & \text{if } z \leq 1, \\ 1 & \text{if } z \geq 2 \end{cases} \qquad \text{and} \qquad \chi^-(z) = \begin{cases} 0 & \text{if } z \geq -1, \\ 1 & \text{if } z \leq -2. \end{cases}$$

We also assume that the cut-off function m already used was under the form $(1-\chi^+)(1-\chi^-)$. We denote by $P^\pm(t,z)$, $D^\pm(t,z)$ matrices such that

$$f'(u(z+s(t),t))-s'(t)=P^+D^+(P^+)^{-1}\qquad\forall z>0,$$

$$f'(u(z+s(t),t))-s'(t)=P^-D^-(P^-)^{-1}\qquad\forall z<0,$$

and $D^\pm(\pm z,t)=\operatorname{diag}(\lambda_1(u(s(t)\pm z,t))-s'(t),\dots,\lambda_n(u(s(t)\pm z,t))-s'(t))$ if $z>0$. Setting

$$\lambda_i^+(z,t)=\begin{cases}\lambda_i(u(z+s(t),t))-s'(t) & \text{if } z>0,\\ \lambda_i(u(s(t)+0,t))-s'(t) & \text{if } z\le 0\end{cases}$$

and

$$\lambda_i^-(z,t)=\begin{cases}\lambda_i(u(z+s(t),t))-s'(t) & \text{if } z<0,\\ \lambda_i(u(s(t)-0,t))-s'(t) & \text{if } z\ge 0,\end{cases}$$

we define the characteristic curves $X_i^\pm(t,\tau,y)$ by

$$\partial_t X_i^\pm(t,\tau,y)=\lambda_i^\pm(X_i^\pm(t,\tau,y),t),\qquad t\ge\tau,$$

with initial data $X_i^\pm(\tau,\tau,y)=y$. As in [9], we first make a stronger hypothesis than (2), (3) and assume that

$$|\lambda_k(z,t)|\ge C\qquad\forall z,t. \tag{41}$$

This hypothesis will be removed in the last part of the proof of the theorem by a localization argument.

We also define the projections

$$\begin{aligned}\mathcal{P}^+_{out}(t,z)&=P^+(t,z)D^+_{out}(t,z)(P^+)^{-1}(t,z),\\ \mathcal{P}^+_{in}(t,z)&=P^+(t,z)D^+_{in}(t,z)(P^+)^{-1}(t,z),\\ \mathcal{P}^-_{out}(t,z)&=P^-(t,z)D^-_{out}(t,z)(P^-)^{-1}(t,z),\\ \mathcal{P}^-_{in}(t,z)&=P^-(t,z)D^-_{in}(t,z)(P^-)^{-1}(t,z),\end{aligned}$$

where

$$\begin{aligned}D^+_{out}&=\operatorname{diag}(0,\dots,0,1,\dots 1),\ \text{with } p+1 \text{ null coefficients},\\ D^+_{in}&=\operatorname{diag}(1,\dots,1,0,\dots,0),\ \text{with } p \text{ unit coefficients},\\ D^-_{out}&=\operatorname{diag}(1,\dots,1,0,\dots,0),\ \text{with } p-1 \text{ unit coefficients},\\ D^-_{in}&=\operatorname{diag}(0,\dots,0,1,\dots,1),\ \text{with } p \text{ unit coefficients}.\end{aligned}$$

Let

$$G_T^\pm(t,\tau,z,y)=\operatorname{diag}\left(\frac{e^{-\frac{(z-X_i^\pm(t,\tau,y))^2}{4\varepsilon(t-\tau)}}}{\sqrt{4\pi\varepsilon(t-\tau)}}\right).$$

We define the Green's functions for the incoming and outgoing waves as

$$G^+_{out}(t,\tau,z,y) = \chi^+\left(\frac{z}{M_1\varepsilon}\right) P^+(t,z)D^+_{out}(t,z)G_T(t,\tau,z,y)(P^+(\tau,y))^{-1} = \chi^+\tilde{G}^+_{out},$$
$$G^+_{in}(t,\tau,z,y) = \chi^+\left(\frac{z}{M_1\varepsilon}\right) P^+(t,z)D^+_{in}(t,z)G_T(t,\tau,z,y)(P^+(\tau,y))^{-1} = \chi^+\tilde{G}^+_{in},$$
$$G^-_{out}(t,\tau,z,y) = \chi^-\left(\frac{z}{M_1\varepsilon}\right) P^-(t,z)D^-_{out}(t,z)G_T(t,\tau,z,y)(P^-(\tau,y))^{-1} = \chi^-\tilde{G}^-_{out},$$
$$G^-_{in}(t,\tau,z,y) = \chi^-\left(\frac{z}{M_1\varepsilon}\right) P^-(t,z)D^-_{in}(t,z)G_T(t,\tau,z,y)(P^-(\tau,y))^{-1} = \chi^-\tilde{G}^-_{in},$$

where $M_1 > 0$ is to be chosen. We also define

$$G^{shock}(t,\tau,z,y) = m\left(\frac{z}{M_3\varepsilon}\right) G^S_\tau(t-\tau,z,y),$$

where G^S_τ was defined in section 3. The kernels of the theorem of [9] will be $S_1 = S_2 = G^-_{out}$, $S_3 = G^-_{in}$, $S_4 = G^{shock}$, $S_5 = G^+_{in}$, $S_6 = S_7 = G^+_{out}$. The truncation functions will be

$$\Pi_1(\tau,y) = \chi^-\left(\frac{y}{M_2\varepsilon}\right)\left(1-\chi^-\left(\frac{2y}{M_3\varepsilon}\right)\right)\mathcal{P}^-_{out}(\tau,y),$$
$$\Pi_2(\tau,y) = \chi^-\left(\frac{2y}{M_3\varepsilon}\right)\mathcal{P}^-_{out}(\tau,y),$$
$$\Pi_3(\tau,y) = \chi^-\left(\frac{y}{M_2\varepsilon}\right)\mathcal{P}^-_{in}(\tau,y),$$
$$\Pi_4(\tau,y) = m\left(\frac{y}{M_2\varepsilon}\right),$$
$$\Pi_5(\tau,y) = \chi^+\left(\frac{y}{M_2\varepsilon}\right)\mathcal{P}^+_{in}(\tau,y),$$
$$\Pi_6(\tau,y) = \chi^+\left(\frac{2y}{M_3\varepsilon}\right)\mathcal{P}^+_{out}(\tau,y),$$
$$\Pi_7(\tau,y) = \chi^+\left(\frac{y}{M_2\varepsilon}\right)\left(1-\chi^+\left(\frac{2y}{M_3\varepsilon}\right)\right)\mathcal{P}^+_{out}(\tau,y).$$

The constants M_1, M_2, and M_3 are such that $M_1 \le 4M_2 \le 16M_3$ and will be carefully chosen at the end of the proof. G_1 and G_5 describe the creation and propagation of outgoing waves in a vicinity of the shock layer, G_2 and G_6 describe the creation and propagation of outgoing waves away from the shock layer, G_3 and G_7 describe the creation and propagation of ingoing waves, and G_4 describes the dynamics of the shock layer. Note that with this choice we get a relevant approximate Green's function since $G^{app}(\tau,\tau,z,y) = \delta_y(z)I_n$. Moreover G^{app} satisfies the estimate (40); hence we can use Theorem 5 of [9]. We have to compute $\mathcal{M}$, which is the aim of the following lemmas. For any error term $E(t,\tau,z,y)$, we use the notation

$$||E|| = \sup_{0\le\tau\le T, y\in\mathbb{R}} \int_\tau^T \int_{-\infty}^{+\infty} |E(t,\tau,z,y)|\, dzdt.$$

The following lemma of [9] is crucial for the estimations of the error terms. Consequently, we recall it for the sake of completeness.

4.1. A technical lemma. Let us define for some trajectory $X(t)$ such that $X(0)=0$

$$I(y)=\int_0^{+\infty}\int_0^{+\infty}\exp\Big(-\frac{(x-y-X(t))^2}{t}\Big)\exp(-\sigma x)\frac{dxdt}{\sqrt{t}},$$

$$J(y)=\int_0^{+\infty}\int_0^{+\infty}\exp\Big(-\frac{(x-y-X(t))^2}{t}\Big)\exp(-\sigma x)\frac{dxdt}{t},$$

$$K(y)=\frac{1}{M}\int_0^{+\infty}\int_M^{2M}\exp\Big(-\frac{(x-y-X(t))^2}{t}\Big)\frac{dxdt}{\sqrt{t}},$$

$$L(y)=\frac{1}{M}\int_0^{+\infty}\int_M^{2M}\exp\Big(-\frac{(x-y-X(t))^2}{t}\Big)\frac{dxdt}{t},$$

LEMMA 6 (see [9]).

(i) *If $\gamma\geq X'(t)\geq\delta>0$, then $I(y)$ and $J(y)$ are bounded uniformly in $y\geq 0$ and go to 0 as $y\to+\infty$.*

(ii) *If $-\gamma\leq X'(t)\leq-\delta<0$, then $I(y)$ and $J(y)$ are bounded uniformly in $y\geq 0$.*

(iii) *If $\gamma\geq X'(t)\geq\delta>0$, then $K(y)$ and $L(y)$ are bounded uniformly in $y\geq 0$ and M and go to 0 as $y-2M$ goes to $+\infty$.*

(iv) *If $-\gamma\leq X'(t)\leq-\delta<0$, then $K(y)$ and $L(y)$ are bounded uniformly in $y\geq 0$ and M.*

Note that as $xe^{-x^2}\leq Ce^{-x^2/2}$ the same result is true if we replace $J(y)$ by

$$\int_0^{+\infty}\int_0^{+\infty}\frac{|x-y-X(t)|}{t}\exp\Big(-\frac{(x-y-X(t))^2}{t}\Big)\exp(-\sigma x)\frac{dxdt}{\sqrt{t}}$$

and $L(y)$ by

$$\frac{1}{M}\int_0^{+\infty}\int_M^{2M}\frac{|x-y-X(t)|}{t}\exp\Big(-\frac{(x-y-X(t))^2}{t}\Big)\frac{dxdt}{\sqrt{t}}.$$

Moreover if $M\geq 0$,

$$\int_0^{+\infty}\int_M^{+\infty}\exp\Big(-\frac{(x-y-X(t))^2}{t}\Big)\exp(-\sigma x)\frac{dxdt}{\sqrt{t}}\leq e^{-\sigma M}I(y-M)$$

and therefore goes to 0 as $M\to+\infty$, provided that $y\geq M$, and similarly for J.

Note also that we have opposite results according to the direction of the transport if we study the integrals for x varying in $(-\infty,0)$ or in $(-2M,-M)$ when y goes to $-\infty$.

4.2. Bounds on the error terms of the shock Green's function. Call $E^S(t,\tau,z,y)$ this error term; we have

$$E^S(t,\tau,z,y)=\mathcal{L}_\varepsilon\left(m\left(\frac{z}{M_3\varepsilon}\right)G^S_\tau(t-\tau,z,y)\right).$$

As in [9], we split it into an evolution error

$$E_1^S = m\left(\frac{z}{M_3\varepsilon}\right)\mathcal{L}_\varepsilon G_\tau^S$$

and a truncation error

$$E_2^S = \left(\frac{1}{M_3\varepsilon}m'\left(\frac{z}{M_3\varepsilon}\right)(f'(u^{app}) - s'(t) + \varepsilon\delta'(t)) - \frac{1}{M_3^2\varepsilon}m''\left(\frac{z}{M_3\varepsilon}\right)\right)G_\tau^S - \frac{2}{M_3}m'\left(\frac{z}{M_3\varepsilon}\right)\partial_x G_\tau^S. \tag{42}$$

We then split E_2^S into four parts: the ingoing parts at the right- and left-hand sides of the shock and the outgoing part at the right- and left-hand sides of the shock

$$E_{2in}^{S+} = \chi_{z\geq 0}\mathcal{P}_{in}^+ E_2^S, \qquad E_{2out}^{S+} = \chi_{z\geq 0}\mathcal{P}_{out}^+ E_2^S,$$

$$E_{2in}^{S-} = \chi_{z\leq 0}\mathcal{P}_{in}^- E_2^S, \qquad E_{2out}^{S-} = \chi_{z\leq 0}\mathcal{P}_{out}^- E_2^S.$$

Estimates on these terms are given by the following lemma.

LEMMA 7. *We have*

(i) $||1_{|y|\leq 2M_2\varepsilon}E_1^S(t,\tau,z,y)||_{L^\infty_{\tau,y},L^1_{t,z}} \leq C_1(T+\varepsilon^{2\gamma-1})$,

(ii) $||1_{|y|\leq 2M_2\varepsilon}E_{2out}^{S+}(t,\tau,z,y)||_{L^\infty_{\tau,y},L^1_{t,z}} + ||1_{|y|\leq 2M_2\varepsilon}E_{2out}^{S-}(t,\tau,z,y)||_{L^\infty_{\tau,y},L^1_{t,z}} \leq C_2$,

(iii) $||1_{|y|\leq 2M_2\varepsilon}E_{2in}^{S+}(t,\tau,z,y)||_{L^\infty_{\tau,y},L^1_{t,z}} + ||1_{|y|\leq 2M_2\varepsilon}E_{2in}^{S-}(t,\tau,z,y)||_{L^\infty_{\tau,y},L^1_{t,z}} \leq C_3 + C_4 T$,

where C_1 is locally bounded in M_2 and M_3, C_2 and C_4 are locally bounded in M_2 (uniformly in M_3), and C_3, which depends on M_2 and M_3, goes to 0 as $M_3 \to +\infty$.

Note that $2\gamma - 1 > 0$.

Proof. We give only the proof for the "+" terms, that is, estimates for $z \geq 0$, since the proof for the other side is completely symmetric. Let us begin with the evolution error. We have

$$E_1^S = m\left(\frac{z}{M_3\varepsilon}\right)\left(f'\left((1-m)\left(\frac{z-\varepsilon\delta(t)}{\varepsilon^\gamma}\right)O(z+s(t)-\varepsilon\delta(t),t) + m\left(\frac{z-\varepsilon\delta(t)}{\varepsilon^\gamma}\right)I\left(\frac{z}{\varepsilon},t\right) + \tilde{d}(z,t)\right) - f'\left(V\left(\frac{z}{\varepsilon},\tau\right)\right) + (s'(t)-s'(\tau)) + \varepsilon\delta(t)\right)\partial_z G_\tau^S.$$

Hence

$$|E_1^S| \leq m\left(\frac{z}{M_3\varepsilon}\right)(|t-\tau| + \varepsilon^\gamma)|\partial_z G_\tau^S|$$

since for ε sufficiently small, we have $m(\frac{z}{M_3\varepsilon})(1-m)(\frac{z-\varepsilon\delta(t)}{\varepsilon^\gamma}) = 0\ \forall t \in [0,T]$. It leads

to estimate

$$\alpha_{1,j} = \int_\tau^T \int_0^{2M_3\varepsilon} \frac{1}{\varepsilon} e^{-\frac{(z-a_j^+(\tau)(t-\tau))^2}{\varepsilon(t-\tau)}}\, dzdt,$$
$$\alpha_{1,r} = \int_\tau^T \int_0^{2M_3\varepsilon} e^{-\sigma\frac{t-\tau}{\varepsilon}} e^{-\frac{(z-y)^2}{\varepsilon(t-\tau)}}\, dzdt,$$
$$\tilde{\alpha}_{1,j} = \varepsilon^\gamma \int_\tau^T \int_0^{2M_3} \frac{e^{-\frac{(z-a_j^+(\tau)(t-\tau))^2}{\varepsilon(t-\tau)}}}{\varepsilon(t-\tau)}\, dzdt,$$
$$\tilde{\alpha}_{1,r} = \varepsilon^\gamma \int_\tau^T \int_0^{2M_3\varepsilon} \frac{e^{-\sigma\frac{t-\tau}{\varepsilon}} e^{-\frac{(z-y)^2}{\varepsilon(t-\tau)}}}{\varepsilon(t-\tau)}\, dzdt.$$

The integrals $\alpha_{1,j}$ and $\alpha_{1,r}$ are obviously bounded by $2M_3T$. To bound $\tilde{\alpha}_{1,j}$, we set $\tilde{z} = \frac{z-\alpha_j^+(t-\tau)}{\sqrt{\varepsilon(t-\tau)}}$, giving an $\mathcal{O}(\varepsilon^{\gamma-\frac{1}{2}}\sqrt{T})$ bound. We easily get a similar bound for $\tilde{\alpha}_{1,r}$. Hence (i) is proved.

We now prove (ii). Using (42) and estimates on G_τ^S and $\partial_x G_\tau^S$, given in Theorem 5, we have to bound

$$\beta_{1,j} = \frac{1}{M_3\varepsilon} \int_\tau^T \int_{M_3\varepsilon}^{2M_3\varepsilon} \frac{e^{-\frac{(z-a_j^+(\tau)(t-\tau))^2}{\varepsilon(t-\tau)}}}{\sqrt{\varepsilon(t-\tau)}}\, dzdt,$$
$$\beta_{2,j} = \frac{1}{M_3\varepsilon} \int_\tau^T \int_{M_3\varepsilon}^{2M_3\varepsilon} \frac{e^{-\frac{(z-a_j^+(\tau)(t-\tau))^2}{\varepsilon(t-\tau)}}}{\varepsilon(t-\tau)}\, dzdt,$$
$$\beta_{1,r} = \frac{1}{M_3} \int_\tau^T \int_{M_3\varepsilon}^{2M_3\varepsilon} \frac{e^{-\frac{(z-y)^2}{\varepsilon(t-\tau)}}}{\sqrt{\varepsilon(t-\tau)}} e^{-\frac{\sigma(t-\tau)}{\varepsilon}}\, dzdt,$$
$$\beta_{2,r} = \frac{1}{M_3} \int_\tau^T \int_{M_3\varepsilon}^{2M_3\varepsilon} \frac{e^{-\frac{(z-y)^2}{\varepsilon(t-\tau)}}}{\varepsilon(t-\tau)} e^{-\frac{\sigma(t-\tau)}{\varepsilon}}\, dzdt,$$

To bound $\beta_{1,j}$ and $\beta_{2,j}$, we set $\tilde{z} = \frac{z}{\varepsilon}$ and $s = \frac{t-\tau}{\varepsilon}$ and use Lemma 6. To bound $\beta_{1,r}$ and $\beta_{2,r}$, we set $\tilde{z} = \frac{z-y}{\sqrt{\varepsilon(t-\tau)}}$ and then set $s = \frac{t-\tau}{\varepsilon}$. We get $\mathcal{O}(\frac{1}{M_3})$ bounds.

It remains to prove (iii). Thanks to Theorem 4, we can write for $z \geq 0$

$$G_\tau^S(t-\tau, z, y) = \mathcal{P}_{out}^+(\tau, 0)\tilde{G}(t, \tau, z, y) + R(t, \tau, z, y),$$

where $\tilde{G}$ is bounded by Gaussians which travel at speeds $a_j^+(\tau, 0)$ and R is the residual term bounded by $\frac{1}{\varepsilon(t-\tau)} e^{-\frac{(z-y)^2}{M\varepsilon(t-\tau)}} e^{-\sigma\frac{t-\tau}{\varepsilon}}$. Consequently, we get

$$|\mathcal{P}_{in}^+(t, z) G_\tau^S| \leq C\left((|t-\tau| + z)\,|\tilde{G}| + |R|\right).$$

Similarly, since

$$m'\left(\frac{z}{M_3\varepsilon}\right) f'(u^{app}) = m'\left(\frac{z}{M_3\varepsilon}\right) f'\left(V\left(\frac{z}{\varepsilon}, t\right) + \mathcal{O}(\varepsilon^\gamma)\right)$$
$$= m'\left(\frac{z}{M_3\varepsilon}\right) f'(u(z + s(t), t)) + \mathcal{O}\left(e^{-\alpha\frac{z}{\varepsilon}} + \varepsilon^\gamma\right),$$

we get

$$\left| m'\left(\frac{z}{M_3\varepsilon}\right)\mathcal{P}^+_{in}(t,z)f'(u^{app})G^S_\tau \right| \leq \left(|t-\tau|+|z|+e^{-\alpha\frac{z}{\varepsilon}}+\varepsilon^\gamma\right)|\tilde{G}|+|R|.$$

Using also the polarization of $\partial_z G^S_\tau$ given in Theorem 2, we get

$$|\mathcal{P}^+_{in}(t,z)\partial_z G^S_\tau| \leq C((|t-\tau|+z+\varepsilon^\gamma)|\tilde{G}|+|R|).$$

Hence E^{S+}_{2in} is bounded by terms like $\beta_{1,r}$, $\beta_{2,r}$, $\alpha_{1,j}$, $\alpha_{1,r}$ which have already been bounded and by

$$\gamma_{1,j} = \frac{1}{M_3\varepsilon}\int_\tau^T\int_{M_3\varepsilon}^{2M_3\varepsilon} x\frac{e^{-\frac{(z-a^+_j(\tau)(t-\tau))^2}{\varepsilon(t-\tau)}}}{\sqrt{\varepsilon(t-\tau)}}\,dzdt,$$

$$\gamma_{2,j} = \frac{1}{M_3}\int_\tau^T\int_{M_3\varepsilon}^{2M_3\varepsilon} x\frac{e^{-\frac{(z-a^+_j(\tau)(t-\tau))^2}{\varepsilon(t-\tau)}}}{\varepsilon(t-\tau)}\,dzdt,$$

$$\gamma_{3,j} = \frac{1}{M_3\varepsilon}\int_\tau^T\int_{M_3\varepsilon}^{2M_3\varepsilon} e^{-\alpha\frac{z}{\varepsilon}}\frac{e^{-\frac{(z-\lambda_j(t-\tau))^2}{\varepsilon(t-\tau)}}}{\sqrt{\varepsilon(t-\tau)}}\,dzdt.$$

We have

$$\gamma_{1,j} \leq 2\int_\tau^T\int_0^{+\infty}\frac{e^{-\frac{(z-a^+_j(\tau)(t-\tau))^2}{\varepsilon(t-\tau)}}}{\sqrt{\varepsilon(t-\tau)}}\,dzdt \leq 2\sqrt{\pi}T.$$

Similarly, we have the estimate $\gamma_{2,j} \leq 2\sqrt{\pi}\sqrt{\varepsilon T}$. Finally $\gamma_{3,j} \leq e^{-\alpha M_3}\beta_{1,j}$, which ends the proof since $\beta_{1,j}$ is uniformly bounded in M_3. □

4.3. Bounds on the error terms of $G^\pm_{out}$. In this section, we compute and estimate the error terms of G^+_{out} and G^-_{out}. These error terms are respectively denoted by R^+_{out} and R^-_{out}. As usual we write $R^\pm_{out} = E^\pm_{1out} + E^\pm_{2out}$, where $E^\pm_{1out} = \chi_\pm\left(\frac{z}{M\varepsilon}\right)\mathcal{L}^\varepsilon G^\pm_{out}$ is the evolution error and $E^\pm_{2out}$ is the truncation error.

LEMMA 8. *Let $M \geq M_2$. We have*

$$||1_{y\geq M\varepsilon}E^+_{1out}(t,\tau,z,y)|| + ||1_{y\leq -M\varepsilon}E^-_{1out}(t,\tau,z,y)|| \leq C_5(T+\varepsilon^{2\gamma-1})+C_6,$$

where C_5 is independent of M_1, M_2, and M_3, and where C_6, which depends only on M, goes to 0 as $M \to +\infty$. Moreover,

$$||1_{y\geq M\varepsilon}E^+_{2out}(t,\tau,z,y)|| + ||1_{y\leq -M\varepsilon}E^-_{2out}(t,\tau,z,y)|| \leq C_7(M)$$

with

$$\lim_{M\to+\infty} C_7(M) = 0.$$

Note that since $\gamma > \frac{2}{3}$, we have a good bound in ε for $||E^\pm_{1out}||$.

Proof. We give only the outlines of the proof since it is almost the same as in [9, section 5.3]. Note that here *in* and *out* stand for the direction of the transport according to the shock, whereas in [9] they stand for the direction of the transport according to the domain. Let us consider, for example, the "+" term. The proof

for the "−" term is symmetric. Compared to [9], the only terms that are different are those involving $f'(u^{app})$. More precisely, as $f'(u^{app})$ is uniformly bounded in ε as $A^{int}(t,x) + A^b\left(t, \frac{x}{\varepsilon}\right)$ was in [9], the truncation error is already studied in [9]. The only new term which has to be studied is

$$\chi^+\left(\frac{z}{M_1\varepsilon}\right)(f'(u^{app}) - f'(u(z+s(t),t)))P^+D^+_{out}\partial_z G_T(P^+)^{-1}.$$

Note that for $z \geq M_1\varepsilon$,

$$\begin{aligned}
|f'(u^{app}) - f'(u(z+s(t),t)| &\leq Cm\Big(\frac{z-\varepsilon\delta(t)}{\varepsilon^\gamma}\Big)\Big(\Big|V\Big(\frac{z}{\varepsilon},t\Big) - u(z+s(t),t)\Big| + \mathcal{O}(\varepsilon^\gamma)\Big)\\
&\leq C\Big(e^{-\alpha\frac{z}{\varepsilon}} + \varepsilon^\gamma\\
&\quad + m\Big(\frac{z-\varepsilon\delta(t)}{\varepsilon^\gamma}\Big)|u(z+s(t),t) - u(s(t)+0,t)|\Big)\\
&\leq C\left(e^{-\alpha\frac{z}{\varepsilon}} + \varepsilon^\gamma\right)
\end{aligned}$$

since $m(\frac{z-\varepsilon\delta(t)}{\varepsilon^\gamma})$ vanishes for $z \geq 2\varepsilon^\gamma + \varepsilon\delta(t)$. The term involving $e^{-\alpha\frac{z}{\varepsilon}}$ is already bounded in [9] thanks to Lemma 6. Consequently, it remains only to bound

$$\delta_j = \varepsilon^\gamma \int_\tau^T \int_{M_1\varepsilon}^{+\infty} \frac{|z - X_j^+|}{(\varepsilon(t-\tau))^{\frac{3}{2}}} e^{-\frac{(z-X_j^+)^2}{\varepsilon(t-\tau)}}\, dzdt.$$

Setting $\tilde{z} = \frac{x - X_j^+}{\sqrt{\varepsilon(t-\tau)}}$, we get

$$\delta_j \leq C\varepsilon^{\gamma-\frac{1}{2}}\sqrt{T} \leq C(T + \varepsilon^{2\gamma-1}). \qquad \square$$

4.4. Bounds on the error terms of G^{in}. In this section, we estimate the error terms of G^+_{in}, and G^-_{in}. These terms are respectively denoted by R^+_{in} and R^-_{in}. As usual we write $R^\pm_{in} = E^\pm_{1in} + E^\pm_{2in}$, where $E^\pm_{1in} = \chi_\pm\left(\frac{z}{M\varepsilon}\right)\mathcal{L}^\varepsilon\tilde{G}^\pm_{in}$ is the evolution error and $E^\pm_{2in}$ is the truncation error.

LEMMA 9. *We have*

$$||1_{y\geq M_2\varepsilon}E^+_{1in}|| + ||1_{y\leq -M_2\varepsilon}E^-_{1in}|| \leq C_8(T + \varepsilon^{2\gamma-1}) + C_9,$$

where C_8 is locally bounded in M_1 and $C_9 \to 0$ when $M_1 \to +\infty$. Moreover

$$||1_{y\geq M_2\varepsilon}E^+_{2in}|| + ||1_{y\leq -M_2\varepsilon}E^-_{2in}|| \leq C_{10},$$

where C_{10} is bounded uniformly in M_1.

We do not give the proof of this lemma since it is very similar to the proof of the corresponding lemma in [9]. The minor changes that we have to bring in the proof of [9] are already explained in the previous section. We point out only that the estimate on the truncation error is worse than in the previous section. It relies on the different estimates on $K(y)$ and $L(y)$ according to the direction of the transport in Lemma 6.

4.5. End of the proof with (41). Combining all the previous estimates, we can write the matrix of errors $\mathcal{M}(0,T)$ as

$$M = \begin{pmatrix} \eta(M_2) & \eta(M_3) & \eta(M_1) & \eta(M_3) & 0 & 0 & 0 \\ \eta(M_2) & \eta(M_3) & \eta(M_1) & C & 0 & 0 & 0 \\ \eta(M_2) & \eta(M_3) & \eta(M_1) & \eta(M_3) & 0 & 0 & 0 \\ \eta(M_2) & \eta(M_3) & C & \eta(M_3) & C & \eta(M_3) & \eta(M_2) \\ 0 & 0 & 0 & \eta(M_3) & \eta(M_1) & \eta(M_3) & \eta(M_2) \\ 0 & 0 & 0 & C & \eta(M_1) & \eta(M_3) & \eta(M_2) \\ 0 & 0 & 0 & \eta(M_3) & \eta(M_1) & \eta(M_3) & \eta(M_2) \end{pmatrix},$$

where "$\eta(M_1)$" stands for the coefficients which go to 0 as $M_1 \to +\infty$ (independently of M_2 and M_3), $T \to 0$ and $\varepsilon \to 0$, "$\eta(M_2)$" stands for coefficients which go to 0 as $M_2 \to +\infty$ (M_1 being fixed, but independently of M_3), $T \to 0$ and $\varepsilon \to 0$, and "$\eta(M_3)$" stands for the coefficients which go to 0 as $M_3 \to +\infty$ (M_1 and M_2 being fixed), $T \to 0$ and $\varepsilon \to 0$, and where C is a constant depending on M_1, M_2 (but independent of M_3). Next we conclude as in [9]. Let $\alpha < \frac{1}{1000}$, we first fix M_1 and T_1, ε_1 such that for $T \le T_1$, $\varepsilon \le \varepsilon_1$ all the $\eta(M_1)$ are smaller than α. Next we fix M_2, and we can reduce T_1 and ε_1 such that all the $\eta(M_2)$ are smaller than α. Finally, by taking M_3 sufficiently large, and by reducing T_1 and ε_1 we can make $\eta(M_3)$ arbitrarily small. After the choice of M_1, M_2, T_1, and ε_1 the constants are fixed. Using a perturbation argument, we have to consider only the powers of

$$\tilde{\mathcal{M}} = \begin{pmatrix} \alpha & 0 & \alpha & 0 & 0 & 0 & 0 \\ \alpha & 0 & \alpha & C & 0 & 0 & 0 \\ \alpha & 0 & \alpha & 0 & 0 & 0 & 0 \\ \alpha & 0 & C & 0 & C & 0 & \alpha \\ 0 & 0 & 0 & 0 & \alpha & 0 & \alpha \\ 0 & 0 & 0 & C & \alpha & 0 & \alpha \\ 0 & 0 & 0 & 0 & \alpha & 0 & \alpha \end{pmatrix}.$$

Since the eigenvalues of $\mathcal{M}$ are 0 and 2α, the theorem with assumption (41) is proved.

4.6. Without (41). In this section we only assume (2), (3). By continuity, inequalities (2), (3) are still true for $-4\eta \le z \le 4\eta$. We again use Theorem 5 of [9] with

$$\Pi_1 = \chi^+\left(\frac{y}{\eta}\right), \quad \Pi_2 = \chi^-\left(\frac{y}{\eta}\right), \quad \Pi_3 = m\left(\frac{y}{\eta}\right),$$

and

$$S_1 = \chi^+\left(\frac{4z}{\eta}\right) G_T^+, \qquad S_2 = \chi^-\left(\frac{4z}{\eta}\right) G_T^-,$$

$$S_3 = m\left(\frac{z}{2\eta}\right) G,$$

where G is the Green's function that was constructed in the previous section. Since the errors corresponding to each S_i are as small as we want if we choose T and ε small (T being independent of ε), Theorem 5 of [9] allows us to conclude.

5. Convergence of $\tilde{w}$. In this section we prove Theorem 2. To prove the convergence of $\tilde{w}$ to zero, we use a standard argument for parabolic equations as in [10], [9]. Local existence of a smooth solution for (12) with initial condition $\tilde{w}(z,0)=0$ is classical; hence we define

$$T^\varepsilon = \sup\left\{T_1 \in [0,T],\ \exists \tilde{w} \text{ solution on } \mathbb{R}\times[0,T_1),\ E(T_1)\le 1\right\}, \tag{43}$$

where

$$E(T_1)=\int_0^{T_1}\int_{-\infty}^{+\infty} \frac{|\tilde{w}|}{\varepsilon^{3\gamma-\alpha}}+\frac{|\tilde{w}_z|}{\varepsilon^{3\gamma-\alpha-\frac{1}{2}}}+\frac{|\tilde{w}_t|}{\varepsilon^{3\gamma-2\alpha-\frac{1}{2}}}+\frac{|\tilde{w}_{tz}|}{\varepsilon^{3\gamma-2\alpha-1}} + \frac{|\tilde{w}_{zz}|}{\varepsilon^{3\gamma-3\alpha-\frac{3}{2}}}+\frac{|\tilde{w}_{tt}|}{\varepsilon^{3\gamma-3\alpha-1}}+\frac{|\tilde{w}_{ttz}|}{\varepsilon^{3\gamma-3\alpha-\frac{3}{2}}}+\frac{|\tilde{w}_{tzz}|}{\varepsilon^{3\gamma-4\alpha-2}}\,dzdt;$$

the small positive constant α will be carefully chosen in the following. Note that we have

$$||\tilde{w}_z||_{L^\infty(\mathbb{R}\times[0,T_1])} \le ||\tilde{w}_{tzz}||_{L^1(\mathbb{R}\times[0,T_1])} \le \varepsilon^{3\gamma-4\alpha-2} \le 1 \tag{44}$$

as soon as $\varepsilon \le 1$ if we choose $\gamma \in (\frac{2}{3},1)$, and $\alpha>0$ so small that $3\gamma-4\alpha-2>0$. There are two possibilities:

(i) $T^\varepsilon = T$,

(ii) $T^\varepsilon < T$ and $E(T^\varepsilon)=1$.

Let us assume that we are in the second case. From now on, we will denote by C a generic number which may depend on T but which is independent of ε. Moreover, until the end of the proof, we set

$$||\tilde{w}|| = ||\tilde{w}||_{L^1(\mathbb{R}\times[0,T^\varepsilon])}, \qquad ||\tilde{w}||_\infty = ||\tilde{w}||_{L^\infty(\mathbb{R}\times[0,T^\varepsilon])}.$$

Since $\tilde{w}$ is a solution of (12), we have for all $t\in[0,T^\varepsilon)$,

$$\tilde{w}(z,t)=\int_0^t\int_{-\infty}^{+\infty} G(t,\tau,z,y)(R^\varepsilon(z,\tau)+Q(\tilde{u}^{app},\tilde{w}_z))\,dyd\tau, \tag{45}$$

where G is the Green's function built in the previous section. Consequently, using (40) and Proposition 3, we get

$$||\tilde{w}|| \le C(\varepsilon^{3\gamma}+||Q(\tilde{u}^{app},\tilde{w}_z)||).$$

Since

$$Q(\tilde{u}^{app},\tilde{w}_z)=\int_0^1 (1-\mu)f''(\tilde{u}^{app}+\mu\tilde{w}_z)\,d\mu\cdot(\tilde{w}_z,\tilde{w}_z), \tag{46}$$

we get, thanks to (44),

$$||Q(\tilde{u}^{app},\tilde{w})|| \le C||\tilde{w}_z||_\infty||\tilde{w}_z|| \le C\varepsilon^{6\gamma-5\alpha-\frac{5}{2}}.$$

Hence

$$\frac{||\tilde{w}||}{\varepsilon^{3\gamma-\alpha}} \le C(\varepsilon^\alpha+\varepsilon^{3\gamma-4\alpha-\frac{5}{2}}). \tag{47}$$

Note that we can choose $\gamma \in (\frac{2}{3}, 1)$ and $\alpha > 0$ such that $3\gamma - 4\alpha - \frac{5}{2} > 0$. Going back to (45), we also have

$$\tilde{w}_z(z,t) = \int_0^t \int_{-\infty}^{+\infty} \partial_z G(t,\tau,z,y)(R^\varepsilon(z,\tau) + Q(\tilde{u}^{app}, \tilde{w}_z))\, dyd\tau.$$

Hence, again using (40), we get

$$\frac{||\tilde{w}_z||}{\varepsilon^{3\gamma-\alpha-\frac{1}{2}}} \leq C(\varepsilon^\alpha + \varepsilon^{3\gamma-4\alpha-\frac{5}{2}}). \tag{48}$$

Next we take the time derivative of (12) to obtain

$$\begin{aligned}(\tilde{w}_t)_t + (f'(\tilde{u}^{app}) - s'(t) + \varepsilon\delta'(t))(\tilde{w}_t)_z - \varepsilon(\tilde{w}_t)_{zz} \\ = R^\varepsilon_t + \partial_t Q(\tilde{u}^{app}, w_z) - \partial_t(f'(\tilde{u}^{app}) - s'(t) + \varepsilon\delta'(t))\tilde{w}_z,\end{aligned} \tag{49}$$

with the initial condition

$$\tilde{w}_t(z,0) = R^\varepsilon(z,0) \tag{50}$$

given by (12). Hence, again using the Green's function, we can write

$$\begin{aligned}\tilde{w}_t(z,t) = \int_{-\infty}^{+\infty} G(t,0,z,y)R^\varepsilon(z,0)\, dy \\ + \int_0^t \int_{-\infty}^{+\infty} G(t,\tau,z,y)\Big(R^\varepsilon_t + \partial_t Q(\tilde{u}^{app}, w_z) - \partial_t(f'(\tilde{u}^{app}) - s'(t) + \varepsilon\delta'(t))\tilde{w}_z\Big).\end{aligned} \tag{51}$$

Consequently, thanks to (40) and Proposition 3, we get

$$||\tilde{w}_t|| \leq C(\varepsilon^{3\gamma-\frac{1}{2}} + \varepsilon^{3\gamma-\alpha-\frac{1}{2}} + ||\partial_t Q(\tilde{u}^{app}, w_z)||).$$

Taking the time derivative of (46), we get

$$||\partial_t Q(\tilde{u}^{app}, w_z)|| \leq C(||\tilde{w}_{zt}||||\tilde{w}_{tzz}|| + ||\tilde{w}_z||||\tilde{w}_{tzz}||) \leq C\varepsilon^{6\gamma-6\alpha-3}. \tag{52}$$

This gives the estimate

$$\frac{||\tilde{w}_t||}{\varepsilon^{3\gamma-2\alpha-\frac{1}{2}}} \leq C(\varepsilon^\alpha + \varepsilon^{3\gamma-4\alpha-\frac{5}{2}}). \tag{53}$$

Taking the derivative with respect to z of (51) and again using (40), we also get

$$\frac{||\tilde{w}_{tz}||}{\varepsilon^{3\gamma-2\alpha-1}} \leq C(\varepsilon^\alpha + \varepsilon^{3\gamma-3\alpha-\frac{5}{2}}). \tag{54}$$

Next we use (12) to express $||\tilde{w}_{zz}||$. We get

$$||\tilde{w}_{zz}|| \leq \frac{C}{\varepsilon}(||\tilde{w}_t|| + ||R^\varepsilon|| + ||Q(\tilde{u}^{app}, \tilde{w}_z)||.$$

Hence

$$\frac{||\tilde{w}_{zz}||}{\varepsilon^{3\gamma-3\alpha-\frac{3}{2}}} \leq C(\varepsilon^\alpha + \varepsilon^{3\gamma-\alpha-2}). \tag{55}$$

The next step is to take the time derivative of (49), which gives

$$\begin{aligned}&(\tilde{w}_{tt})_t + (f'(\tilde{u}^{app}) - s'(t) + \varepsilon\delta'(t))(\tilde{w}_{tt})_z - \varepsilon(\tilde{w}_{tt})_{zz}\\ &= R^{\varepsilon}_{tt} + \partial_{tt}Q(\tilde{u}^{app}, \tilde{w}_z) - 2\partial_t(f'(\tilde{u}^{app}) - s'(t) + \varepsilon\delta'(t))\tilde{w}_{zt}\\ &\quad - \partial_{tt}(f'(\tilde{u}^{app}) - s'(t) + \varepsilon\delta'(t))\tilde{w}_z.\end{aligned}$$

Using (50) now, we get

$$\tilde{w}_{tz}(z,0) = R^{\varepsilon}_z(z,0), \qquad \tilde{w}_{tzz} = R^{\varepsilon}_{zz}(z,0). \tag{56}$$

Hence, also using (49) and Proposition 3, we get

$$||\tilde{w}_{tt}(\cdot,0)|| \leq C(\varepsilon^{3\gamma-1} + \varepsilon^{2\gamma+\frac{1}{2}}) \leq C\varepsilon^{3\gamma-1},$$

since $\gamma < \frac{3}{2}$.

Consequently, again using the Green's function, we get

$$||\tilde{w}_{tt}|| \leq C(\varepsilon^{3\gamma-1} + \varepsilon^{3\gamma-2\alpha-1} + \varepsilon^{3\gamma-\alpha-\frac{1}{2}} + ||\partial_{tt}Q(\tilde{u}^{app}, \tilde{w}_t)||). \tag{57}$$

It remains to estimate $||\partial_{tt}Q(\tilde{u}^{app}, \tilde{w}_t)||$; we have

$$\begin{aligned}||\partial_{tt}Q(\tilde{u}^{app}, \tilde{w}_z)|| &\leq C(||\tilde{w}_{ztt}||||\tilde{w}_z|| + ||\tilde{w}_{ztt}||||\tilde{w}_{zt}|| + ||\ |\tilde{w}_{zt}|^2||)\\ &\leq C(\varepsilon^{6\gamma-7\alpha-\frac{7}{2}} + ||\ |\tilde{w}_{zt}|^2||).\end{aligned}$$

Since

$$||\ |\tilde{w}_{zt}|^2|| \leq \int_0^T \int_{-\infty}^{+\infty} \left(\int_{-\infty}^{z} |\tilde{w}_{zzt}(t,y)|dy\right)\left(\int_0^t |\tilde{w}_{ztt}(s,z)|ds + |\tilde{w}_{zt}(0,z)|\right) dzdt,$$

we get, thanks to (56),

$$||\ |\tilde{w}_{zt}|^2|| \leq C\varepsilon^{6\gamma-7\alpha-\frac{7}{2}}.$$

Consequently, going back to (57), we have shown

$$\frac{||\tilde{w}_{tt}||}{\varepsilon^{3\gamma-3\alpha-1}} \leq C(\varepsilon^{\alpha} + \varepsilon^{3\gamma-4\alpha-\frac{5}{2}}). \tag{58}$$

As previously shown, we also have, thanks to the estimate on the derivative of the Green's function,

$$\frac{||\tilde{w}_{ttz}||}{\varepsilon^{3\gamma-3\alpha-\frac{3}{2}}} \leq (\varepsilon^{\alpha} + \varepsilon^{3\gamma-4\alpha-\frac{5}{2}}). \tag{59}$$

Finally, thanks to (49), (52), and Proposition 3, we find

$$\frac{||\tilde{w}_{tzz}||}{\varepsilon^{3\gamma-4\alpha-2}} \leq C(\varepsilon^{\alpha} + \varepsilon^{3\gamma-\alpha-2}). \tag{60}$$

To conclude, we choose $\gamma \in (\frac{2}{3}, 1)$ and $\alpha > 0$ such that $3\gamma - 4\alpha - \frac{5}{2} > 0$ and collect (47), (48), (53), (54), (55), (58), (59), (60), which gives us

$$E(T^{\varepsilon}) \leq C\varepsilon^{\beta}$$

for some $\beta > 0$. Consequently the equality is impossible in (ii), hence $T^\varepsilon = T$ and

$$E(T) \leq 1.$$

Moreover since

$$||u^\varepsilon - u^{app}||_{L^\infty([0,T],L^1(\mathbb{R}))} = ||\tilde{w}_z||_{L^\infty([0,T],L^1(\mathbb{R}))} \leq ||\tilde{w}_{tz}|| \leq \varepsilon^{3\gamma-2\alpha-1}$$

and

$$||u^\varepsilon - u^{app}||_{L^\infty([0,T]\times\mathbb{R})} = ||\tilde{w}_z||_{L^\infty(\mathbb{R}\times[0,T])} \leq ||\tilde{w}_{tzz}||_{L^1(\mathbb{R}\times[0,T])} \leq \varepsilon^{3\gamma-4\alpha-2}$$

the theorem is proved.

Acknowledgments. I thank Emmanuel Grenier and Denis Serre for many fruitful discussions.

TRAVELING WAVES OF BISTABLE DYNAMICS ON A LATTICE*

PETER W. BATES†, XINFU CHEN‡, AND ADAM J. J. CHMAJ§

Abstract. We prove the existence of stationary or traveling waves in a lattice dynamical system arising in the theory of binary phase transitions. The system allows infinite-range couplings with positive and negative weights. The allowance for negative coupling coefficients precludes the possibility of a maximum principle. Instead, a weakened type of ellipticity is stipulated that is used with spectral theory in a perturbative fixed point argument to construct a traveling wave when the nonlinearity is unbalanced and the coupling is sufficiently strong. When the nonlinearity is balanced, a variational technique is used to obtain stationary waves, which are then analyzed in more detail for strong couplings. From a physical perspective these models are important since long-range and indefinite interactions occur in nature and can lead to pattern formation. Our results provide conditions under which patterned states tend to be swept away by traveling waves even when the interaction is of excitatory-inhibitory type. The results also have implications for the numerical analysis of spatially discretized reaction-diffusion equations, where it is important to know whether solutions to the discretized equations converge to solutions to the continuum equation as the mesh size tends to zero.

Key words. lattice dynamical system, long-range indefinite coupling, spectral theory, global minimizer

1. Introduction.

We consider the heteroclinic traveling wave problem for the lattice dynamical system

$$\dot{u}_n = \frac{1}{\varepsilon^2} \sum_{k=-\infty}^{\infty} \alpha_k u_{n-k} - f(u_n), \qquad n \in \mathbb{Z}, \tag{1.1}$$

where $0 < \varepsilon$, $\sum_k \alpha_k = 0$, $\alpha_0 < 0$, $\alpha_{-k} = \alpha_k$, and f is a smooth bistable function with nondegenerate zeros at ± 1 and an intermediate zero at $q \in (-1, 1)$. Thus, we seek a solution having the form $u_n(t) = u(\varepsilon n + ct)$ for some constant c and with the profile satisfying $u(\pm\infty) = \pm 1$. We shall not assume positivity of the α_k's for $k \neq 0$; there may be some which are negative, but we assume that $\sum_{k>0} \alpha_k k^2 > 0$ (without loss of generality we take this sum to be 1). We will assume another (spectral) positivity condition, but the foregoing describes the basic problem under consideration. The symmetry, $\alpha_{-k} = \alpha_k$, is suggested by the application to material science as indicated below, but it also assures that the convolution operator on the right in (1.1) is self-adjoint in ℓ^2.

Setting $u_n(t) = u(\varepsilon n + ct)$ and using the properties of the α_k's, we may write the traveling wave equation for (1.1) in variable $x = \varepsilon n + ct$ as

$$cu' - \sum_{k>0} \alpha_k k^2 \frac{u(x+k\varepsilon) + u(x-k\varepsilon) - 2u(x)}{(k\varepsilon)^2} + f(u) = 0. \tag{1.2}$$

We seek a solution u such that $u(\pm\infty) = \pm 1$.

Formally, as $\varepsilon \to 0$, we obtain the traveling wave equation for the bistable reaction-diffusion equation or Allen–Cahn equation:

$$cu' - u'' + f(u) = 0 \ \text{ in } \ \mathbb{R}, \qquad u(\pm\infty) = \pm 1. \tag{1.3}$$

It is well known (e.g., [13]) that (1.3) has a unique (up to translation) traveling wave profile, u_0, and a unique wave speed, c_0. Furthermore, $u_0' > 0$, and the operator obtained by setting $c = c_0$ and linearizing the left-hand side of (1.3) at u_0 has 0 as a simple isolated eigenvalue, the remaining spectrum being in the open right half-plane [16, section 5.4]. With this nondegeneracy of the wave u_0, it is therefore natural to hope that for $\varepsilon > 0$ and sufficiently small, (1.2) also has a unique traveling wave $(u_\varepsilon, c_\varepsilon)$ close to (u_0, c_0). This is a singular perturbation problem, however, and intuition is not always correct in such problems. In the case that $c_0 \neq 0$, which is equivalent to $\int_{-1}^{1} f(u)du \neq 0$ (we say that f is unbalanced), and under certain positivity conditions on the set of coefficients $\{\alpha_k\}$, we prove that there is a locally unique traveling wave for $\varepsilon > 0$ and sufficiently small. In the case that $c_0 = 0$, under slightly stronger assumptions on the α_k's, we prove that there is a stationary wave for *all* $\varepsilon > 0$, but when ε is small the solution is not unique. The proofs in the two cases are completely different, the first being obtained through a perturbation argument and the second through a variational argument.

When $c_0 \neq 0$, we use the Fredholm alternative and a contraction mapping argument to obtain a locally unique solution near (u_0, c_0). However, there are hurdles to overcome due to the facts that the linearized operator is not self-adjoint, and it is a bounded, nonlocal operator which is in some sense approximating an unbounded, local operator.

In the case that $c_0 = 0$ (f is balanced), the linearized operator is now self-adjoint, but, in addition to the approximation difficulties mentioned above, there is a loss of regularity since (1.2) is not even a differential equation, unlike the case when $c_0 \neq 0$. To compensate, we slightly strengthen the spectral positivity assumption on $\{\alpha_k\}$ but still allow some terms to be negative. A variational argument employing Fourier analysis is used to prove the existence of a stationary wave profile for any $\varepsilon > 0$. Thus, the result is global in ε in contrast to the perturbative nature of the result for $c_0 \neq 0$. The argument involves splitting the energy functional into a part which we call *kinetic energy* and a part which we call *potential energy*. By the assumptions on $\{\alpha_k\}$, the kinetic energy is nonnegative and the potential energy is coercive. This assures that any minimizing sequence of transition states has a convergent subsequence. However, because of the long-range and indefinite interaction terms, one cannot conclude that transitions are monotone, and in fact it is difficult to localize the transitions of the terms in the minimizing sequence. It can be shown that transitions have a minimal "cost" and that a pair of well-separated transitions costs more than a single transition. These ideas are used to obtain convergence of a subsequence of suitably translated members of a minimizing sequence to an energy minimizing state which has a single transition. This minimizer is the desired stationary wave. Uniqueness is not assured.

In fact, for $\varepsilon > 0$ sufficiently small, using a minimax argument we show the existence of a second wave, in sharp contrast to the continuum case.

Concerning the origins of (1.1), consider the free energy of an Ising-like spin system on a lattice, Λ, with spins taking values (probabilistically) in an interval, I, and which interact in pairs according to the spin values and their separation. Assume that the "temperature" is below critical so that two stable spin-phases exist.

Consistent with the second law of thermodynamics, we postulate that the spin field $\{u_r\}_{r\in\Lambda}$ evolves according to the negative gradient of the free energy. The resulting dynamical system is (1.1) in the case that $\Lambda = \mathbb{Z}$, the integers. This was described in some detail in [1], where it was also shown that, in general, the coefficients $\{\alpha_k\}$ may not all be nonnegative and that f may not be balanced, even without an external field. Because the interaction coefficients represent an aggregate of different forces, α_k may change sign with k, as in the Lennard–Jones potential (see [18]). The subscript k refers to the separation between a pair of interacting lattice sites, and so it is natural that we take $\alpha_{-k} = \alpha_k$.

In taking ε small, we are considering the case where the pairwise interaction is very large, which may be the case when the lattice sites are very closely packed.

Another motivation for studying (1.1) is that one may want to establish a rigorous connection between continuum theory and numerical approximations. In that case, ε is obviously proportional to the mesh size. Noticeably, in [5], only approximate solutions of (1.2) were constructed, although an exact solution would be of more use.

The nearest neighbor version of (1.1), using the finite difference approximation of the second derivative, was studied in [17] and [21]. We note that even in that special case our result improves upon the result in [21] to some extent. There the author considered the usual discretization of the Nagumo equation and constructed traveling waves for mesh size ε small enough, of the form $u_n(t) = u(n - ct)$ with $c \neq 0$. In this paper, we show not only that those waves have nonzero speed but also that the scaled profile converges to u_0 as $\varepsilon \searrow 0$. Furthermore, we find stationary waves for all $\varepsilon > 0$ when f is balanced.

There have been many recent works on other versions of (1.1) besides those mentioned above (see, for instance, [3], [8], [9], [1], [19], [14], [15], and [20], the latter of which has a review and other references). A discrete time version was studied in [10]. Continuum but nonlocal versions were studied in [2], [4], [11], [6], [7], and [12], for example. However, for most of these results the authors assume that the interaction is nonnegative. In that case a comparison principle holds, providing some type of compactness and allowing the construction of unique monotone traveling waves.

An interesting feature of (1.1), first discussed in [17], is that for some unbalanced nonlinearities, waves are "pinned"; that is, $\int_{-1}^{1} f(u)du \neq 0$, but the wave has zero velocity. Some recent results concerning pinned states may also be found in [19] and [1], where coupling with positive and negative weights is also allowed. Of course, that is only for ε sufficiently large, as our results show. That the usual propagation criterion ($\int_{-1}^{1} f(u)du \neq 0$) holds for ε sufficiently small is also established in [1] for the case $a_k \geq 0$ when $k \neq 0$.

For brevity and to suggest what is to follow, we introduce the notation

$$\Delta_\varepsilon u \equiv \frac{1}{\varepsilon^2} \sum_{k>0} \alpha_k (u(x + \varepsilon k) + u(x - \varepsilon k) - 2u(x)). \tag{1.4}$$

Thus, we study

$$c_\varepsilon u_\varepsilon{}' - \Delta_\varepsilon u_\varepsilon + f(u_\varepsilon) = 0 \ \text{ on } \ \mathbb{R}, \quad u_\varepsilon(\pm\infty) = \pm 1. \tag{1.5}$$

We now give explicitly the assumptions on f and the coefficients $\{\alpha_k\}$ and state our results.

Even though (1.5) contains only α_k's with positive indices, in (A2) below we mention the symmetry and mean value conditions on the coefficients to remind the reader of the origins of (1.5). Assume the following:

(A1) $f \in C^2(\mathbb{R})$ has exactly three zeros, -1, $q \in (-1,1)$, and 1, with $f_u(\pm 1) > 0$.

(A2) $\sum_{k\in\mathbb{Z}} \alpha_k = 0$, $\alpha_{-k} = \alpha_k$, $\sum_{k>0} \alpha_k k^2 > 0$ (without loss of generality we take this sum to be 1), $\sum_{k>0} |\alpha_k| k^2 < \infty$, and $A(z) \equiv \sum_{k>0} \alpha_k (1 - \cos(kz)) \geq 0$ for all $z \in [0, 2\pi]$.

Note that $A(z) \geq 0$ for all $z \in [0, 2\pi]$ implies $\sum_{k>0} \alpha_k k^2 \geq 0$ (since $A''(0) \geq 0$).

THEOREM 1. *Suppose that* $\int_{-1}^{1} f(u)du \neq 0$. *Assume that* f *satisfies* (A1) *and* $\{\alpha_k\}$ *satisfy* (A2). *Then there exists a positive constant* ε^* *such that for every* $\varepsilon \in (0, \varepsilon^*)$, *problem* (1.5) *admits at least one solution,* $(c_\varepsilon, u_\varepsilon)$, *which is locally unique in* $H^1(\mathbb{R})$ *up to translation and which has the property that*

$$\lim_{\varepsilon \searrow 0} (c_\varepsilon, u_\varepsilon) = (c_0, u_0) \quad \text{in } \mathbb{R} \times H^1(\mathbb{R}).$$

In the case that $c_0 = 0$ (i.e., $\int_{-1}^{1} f(u)du = 0$) the stationary wave equation derived from (1.1) becomes a functional equation rather than a functional *differential* equation, and it does not necessarily produce a solution that is defined at points other than the integers. Given a stationary solution $\{u_n^\varepsilon\}$ to (1.1) with $\lim_{n\to\pm\infty} = \pm 1$, one may construct a solution u_n^ε to (1.5) on $\mathbb{R}$ with $c_\varepsilon = 0$ by

$$u_\varepsilon(x) = \sum u_n^\varepsilon \chi_n^\varepsilon(x), \tag{1.6}$$

where χ_n^ε is the characteristic function of the interval $(\varepsilon(n - 1/2), \varepsilon(n + 1/2)]$.

Clearly, translates of u_ε are also stationary solutions to (1.5). While u_ε constructed in this way is not continuous, we may consider the continuous linear interpolant $\tilde{u}_\varepsilon$ of u_n^ε defined by

$$\tilde{u}_\varepsilon(x) = \sum [u_n^\varepsilon + (x/\varepsilon - n)(u_{n+1}^\varepsilon - u_n^\varepsilon)] \chi_n^\varepsilon(x - \varepsilon/2) \tag{1.7}$$

to compare with u_0.

As far as existence is concerned, the fact that from (1.1) we have only a functional equation suggests that conditions stronger than (A2) are needed. Also, since (1.1) involves indices from all $\mathbb{Z}$, unlike (1.5), which has only $k > 0$, we recall the initial symmetry and mean value conditions on the coefficients α_k. We will require the following:

(A3) $\sum_{k\in\mathbb{Z}} \alpha_k = 0$, $\alpha_{-k} = \alpha_k$, $\sum_{k>0} \alpha_k k^2 = 1$, $\sum_{k>0} |\alpha_k| k^2 < \infty$, and for $z \in (0, 2\pi)$, $A(z) \equiv \sum_{k>0} \alpha_k (1 - \cos(kz)) > 0$.

The main results in this case are summarized in the following theorem.

THEOREM 2. *Suppose that* $\int_{-1}^{1} f(u)du = 0$. *Assume that* f *satisfies* (A1) *and* $\{\alpha_k\}$ *satisfy* (A3). *Then for any* $\varepsilon > 0$ *there exists a stationary solution,* $\{u_n^\varepsilon\}$, *to* (1.1) *with* $\lim_{n\to\pm\infty} = \pm 1$. *Furthermore, with* u_ε *and* $\tilde{u}_\varepsilon$ *defined by* (1.6) *and* (1.7), *respectively,*

$$\lim_{\varepsilon \searrow 0} u_\varepsilon = u_0 \quad \text{in } L^\infty(\mathbb{R}) \quad \text{and} \quad \lim_{\varepsilon \searrow 0} \tilde{u}_\varepsilon = u_0 \quad \text{in } H^1(\mathbb{R}).$$

Finally, for $\varepsilon > 0$ *and sufficiently small, there exists a second stationary solution* ${u_\varepsilon}^2$ *to* (1.5), *not a translate of* u_ε, *with* $\lim_{\varepsilon \searrow 0} u_\varepsilon = u_0$ *in* $L^\infty(\mathbb{R})$.

Remark 1. The bistable nonlinearity f can have more zeros. What we require is that for some $c = c_0$ there exists a traveling wave solution, u_0, to (1.3) which approaches ± 1 exponentially fast as x approaches $\pm\infty$.

Remark 2. Conditions regarding $A(z)$ in (A2) and (A3) are weak ellipticity conditions or positivity conditions on the operator in the spectral sense. The decay condition on the interaction coefficients translates to a regularity condition in transform space. In particular, (A2) says that $\{\alpha_k\}$ are the Fourier coefficients of a smooth, nonpositive, even, 2π-periodic function which is strictly quadratic at 0. It follows that, even though many of these coefficients may be negative, $\sum_{k>0} \alpha_k > 0$ and $\sum_{k>0} k\alpha_k > 0$. We will not need these last two observations in our proofs, but we believe that they do shed more light on the restrictions imposed by (A2). To prove the first, one need only note that $A(z)$ is nonconstant, nonnegative, with mean $\sum_{k>0} \alpha_k$. The second may be seen by observing that $v(x,y) \equiv \sum_{k>0} \alpha_k e^{-yk} \cos(kx)$ is harmonic on $(-2\pi, 2\pi) \times (0,\infty)$ having a strict maximum at $(0,0)$, and so $0 > v_y(0,0) = -\sum_{k>0} k\alpha_k$.

Remark 3. It is natural to ask if the above conditions are vacuous or difficult to meet with coefficients that change sign. The simplest example may be had for only nearest and second-nearest neighbor interactions. Then (A3) is equivalent to $\alpha_1 > 0$ and $\alpha_2 \geq -\alpha_1/4$ (allowing α_2 to be negative). As another example we take the case of only three nonzero weights. Then (A3) is satisfied if, e.g., $\alpha_2 = \alpha_3 > 0$ and $\alpha_1 > -M\alpha_2$, where $0 < M \equiv \min_{z\in[0,2\pi]}(2 - \cos(2z) - \cos(3z))/(1 - \cos z)$. Note that in the second example α_1 need not be positive. Finally, (A3) holds for small (but global in range) perturbations of the usual finite difference approximation of the Laplacian.

Remark 4. It is also natural to ask whether or not our conditions (A2) or (A3) are sharp. The condition that $\sum_{k>0} \alpha_k k^2 = 1$ (or just the positivity of that sum) is clearly what is needed to even formally approximate the Laplacian. We have no proof that the positivity of $A(z)$ is needed, though we suspect that it is. To support our beliefs consider the case where $\alpha_0 = -1/8, \alpha_1 = -1/4, \alpha_2 = 5/16$, $\alpha_{-k} = \alpha_k$, and all other coefficients are zero. Then (A2) is violated only by $A(z)$ taking on negative values on the interval $(z_0, 2\pi - z_0) \subset [0, 2\pi]$ where $\cos(z_0) = -3/5$.

Now take $\varepsilon = 1$ and $f(u) = u \pm 1$ for $\pm u < 0$ with $f(0) = 0$. One can check that there are no solutions $\{u_n\}$ with $u_n \to \pm 1$ as $n \to \pm\infty$ and with $u_n > 0$ for $\pm n > 0$.

Even without requiring the extra condition that u_n change sign only at $n = 0$ and assuming only that f is bistable and balanced with $f'(\pm 1) = 1$, there is strong evidence against the existence of a connecting orbit between $u = 1$ and $u = -1$: If the recurrence relation involving the u_n's is written as a four-dimensional discrete dynamical system, then $u = -1$ has only a one-dimensional unstable manifold and $u = 1$ has only a one-dimensional stable manifold. Thus, generically, these one-dimensional curves will not meet in the four-dimensional phase space.

Returning to the above example with piecewise linear f but now taking $\varepsilon = 1/4$, one can easily show that there is an odd ($u_n = -u_{1-n}$ for $n > 0$) stationary solution that approaches stationary solutions approximately given by $\{\mp 1 \pm 0.1 \cos n\theta\}$ for some $\theta \neq 0$ as $n \to \mp\infty$ and another odd stationary solution that approaches stationary solutions approximately given by $\{\mp 1 \pm 0.05 \sin n\theta\}$ as $n \to \mp\infty$. We believe that these two connections to oscillatory states form a barrier to the existence of connections between -1 and $+1$. It is worth noting that neither of the connections to oscillatory states takes on the value 0 and therefore f can be modified in a neighborhood of zero so that it is smooth.

Part I. Nonstationary waves. Here we assume that $\int_{-1}^{1} f(s)ds \neq 0$.

2. Reformulation of the problem. Let $(c_0, u_0(x))$ be the unique solution to

$$c_0 u_0' - u_0'' + f(u_0) = 0 \ \text{ in } \ \mathbb{R}, \qquad u_0(\pm\infty) = \pm 1, \quad u(0) = 0. \tag{2.1}$$

Then $c_0 = \int_1^{-1} f(s)ds / \int_{\mathbb{R}} (u_0'(x))^2 dx \neq 0$. We write

$$u_\varepsilon = u_0 + \phi_\varepsilon, \qquad \phi_\varepsilon \in H^1(\mathbb{R}).$$

Then the traveling wave problem (1.5) is equivalent to finding $(c_\varepsilon, \phi_\varepsilon) \in \mathbb{R} \times H^1(\mathbb{R})$ such that

$$\mathcal{L}^+_{\varepsilon,\delta}\phi_\varepsilon = \mathcal{R}(c_\varepsilon, \phi_\varepsilon), \tag{2.2}$$

where

$$\mathcal{L}^\pm_{\varepsilon,\delta}\phi = \{\pm c_0 \tfrac{d}{dx} - \Delta_\varepsilon + f_u(u_0(x)) + \delta\}\phi \qquad \text{for all } \ \phi \in H^1(\mathbb{R}), \tag{2.3}$$

$$\mathcal{R}(c, \phi) = (c_0 - c)(u_0' + \phi') + (\Delta_\varepsilon - \tfrac{d^2}{dx^2})u_0 + \delta\,\phi - \mathbf{N}(u_0, \phi), \tag{2.4}$$

$$\mathbf{N}(u_0, \phi) = f(u_0 + \phi) - f(u_0) - f_u(u_0)\phi, \tag{2.5}$$

and $\delta > 0$ is a small positive constant chosen at our convenience. The operator $\mathcal{L}^-_{\varepsilon,\delta}$ is introduced since it is the adjoint of $\mathcal{L}^+_{\varepsilon,\delta}$, and we find it more efficient to study them together.

We shall show in the next section that $\mathcal{L}^+_{\varepsilon,\delta}$ has a bounded inverse $(\mathcal{L}^+_{\varepsilon,\delta})^{-1}$ from $L^2(\mathbb{R})$ to $H^1(\mathbb{R})$, and that when restricted to the orthogonal complement of $u_0' e^{-c_0 x}$, $(\mathcal{L}^+_{\varepsilon,\delta})^{-1}$ is bounded independent of ε and δ (for sufficiently small positive ε). Hence, for every small $\phi \in H^1(\mathbb{R})$, we choose $c_\varepsilon = c_\varepsilon(\phi)$ such that $\mathcal{R}(c_\varepsilon(\phi), \phi)$ is orthogonal to $u_0' e^{-c_0 x}$. Then we define $\tilde{\phi} = (\mathcal{L}^+_{\varepsilon,\delta})^{-1}\mathcal{R}(c_\varepsilon(\phi), \phi)$. In section 4, we shall show that the mapping $\phi \to \tilde{\phi}$ is a contraction and thus possesses a fixed point, in some small ball in $H^1(\mathbb{R})$, thereby establishing the existence of a solution to (1.5).

The introduction of a small positive δ serves dual purposes: (i) It makes the operator $\mathcal{L}^+_{\varepsilon,\delta}$ invertible, so that one does not have to worry about the kernel; (ii) the translation invariance of (1.5) is removed by requiring $\mathcal{R}$ to be orthogonal to $u_0' e^{-c_0 x}$. With positive δ, $(\mathcal{L}^+_{\varepsilon,\delta})^{-1}\mathcal{R}$ automatically selects the required solution; in this way one avoids the arbitrary addition of a multiple of u_0' which is in the kernel of the limiting operator with $\delta = 0$. Thus, it makes the proof more efficient.

In what follows, $\|\cdot\|_{L^2}$, $\|\cdot\|_{L^\infty}$, and $\|\cdot\|_{H^i}$ $(i = 1, 2)$ denote the norms of the spaces $L^2(\mathbb{R})$, $L^\infty(\mathbb{R})$, and $H^i(\mathbb{R})$, respectively. Also,

$$(\phi, \psi) \equiv \int_{\mathbb{R}} \phi\psi\, dx; \qquad \phi \perp \psi \quad \Longleftrightarrow \quad (\phi, \psi) = 0.$$

We end this section with a few properties of Δ_ε which may be useful in other contexts.

LEMMA 3. *Let Δ_ε be defined as in* (1.4)*, where $\{\alpha_k\}$ satisfy* (A2)*. Then*

(1) *for any $\phi \in L^\infty(\mathbb{R})$ with $\phi'' \in L^2(\mathbb{R})$, $\|\Delta_\varepsilon\phi - \phi''\|_{L^2} \to 0$ as $\varepsilon \searrow 0$;*

(2) *for any $\phi \in H^1(\mathbb{R})$, $(\Delta_\varepsilon\phi, \phi') = 0$;*

(3) *for any $\phi, \psi \in L^2(\mathbb{R})$, $(\Delta_\varepsilon\phi, \psi) = (\phi, \Delta_\varepsilon\psi)$ and $(\Delta_\varepsilon\phi, \phi) \leq 0$.*

The proof follows from a straightforward calculation and is omitted. We point out only that, by a Fourier transform and Parseval's identity,

$$(\Delta_\varepsilon \phi, \phi) = -\frac{1}{\varepsilon^2 \pi} \int_{\mathbb{R}} \sum_{k>0} \alpha_k (1 - \cos(\varepsilon k \xi)) \Big| \mathcal{F}[\phi] \Big|^2 \, d\xi, \tag{2.6}$$

where $\mathcal{F}[\phi](\xi) = \int_{\mathbb{R}} e^{\mathbf{i}\, x\xi} \phi(x)\, dx$.

Remark 5. As one can see from our proof, properties (1)–(3) are all that are required of Δ_ε for the assertion of Theorem 1 to hold.

3. The invertibility of $\mathcal{L}^{\mp}_{\varepsilon,\delta}$. In this section, we prove the following theorem.

THEOREM 4. *There exist a positive constant C_0 and a positive function $\varepsilon_0(\cdot) : \mathbb{R}^+ \to \mathbb{R}^+$ such that for every $\delta > 0$ and every $\varepsilon \in (0, \varepsilon_0(\delta))$, $\mathcal{L}^{\pm}_{\varepsilon,\delta}$ is a homeomorphism from $H^1(\mathbb{R})$ to $L^2(\mathbb{R})$ and*

$$\Big\| (\mathcal{L}^{\pm}_{\varepsilon,\delta})^{-1} \psi \Big\|_{H^1} \le C_0 \Big\{ \|\psi\|_{L^2} + \tfrac{1}{\delta} |(\psi, \phi_0^{\mp})| \Big\}, \tag{3.1}$$

where $\phi_0^{\pm}$ is as in (3.3) *below. Consequently, for all $\delta > 0$ and $\varepsilon \in (0, \varepsilon_0(\delta))$,*

$$\| (\mathcal{L}^{\pm}_{\varepsilon,\delta})^{-1} \psi \|_{H^1} \le C_0 \, \|\psi\|_{L^2} \qquad \text{for all } \psi \in L^2 \ \text{ with } \ \psi \perp \phi_0^{\pm}. \tag{3.2}$$

To prove this theorem, we need a few preparations.

3.1. The limiting operator $\mathcal{L}_0^{\pm}$. To study the operator $\mathcal{L}^{\pm}_{\varepsilon,\delta}$, we begin by studying the $\varepsilon \to 0$ limit case, where Δ_ε becomes $\frac{d^2}{dx^2}$. Hence, we introduce operators $\mathcal{L}_0^{\pm}$ and functions $\phi_0^{\pm}$ by

$$\begin{gathered} \mathcal{L}_0^{\pm} \phi \equiv \pm c_0 \phi' - \phi'' + f_u(u_0) \phi \,, \\ \phi_0^{+} = u_0' \,/\, \|u_0'\|_{L^2}, \quad \phi_0^{-} = u_0' e^{-c_0 x} \,/\, \|u_0' e^{-c_0 x}\|_{L^2} \,. \end{gathered} \tag{3.3}$$

LEMMA 5. *Let $\mathcal{L}_0^{\pm}$ and $\phi_0^{\pm}$ be as in* (3.3). *The following hold:*
(1) *$\phi_0^{\pm} \in H^2(\mathbb{R})$ and $\mathcal{L}_0^{\pm} \phi_0^{\pm} = 0$.*
(2) *For every $\psi \in L^2(\mathbb{R})$, the problem*

$$\mathcal{L}_0^{\pm} \phi = \psi, \qquad \phi \in H^2 \ \text{ with } \ \phi \perp \phi_0^{\pm}$$

has a unique solution ϕ if and only if $\psi \perp \phi_0^{\mp}$. In addition, there exists a positive constant C_1, which depends only on f, such that

$$\|\phi\|_{H^2} \le C_1 \| \mathcal{L}_0^{\pm} \phi \|_{L^2} \qquad \text{for all } \ \phi \in H^2(\mathbb{R}) \ \text{ satisfying } \ \phi \perp \phi_0^{\pm}.$$

(3) *There exists a positive constant C_2, depending only on f, such that for every $\delta > 0$,*

$$\|\phi\|_{H^2} \le C_2 \Big\{ \|\psi\|_{L^2} + \frac{1}{\delta} |(\psi, \phi_0^{\mp})| \Big\} \qquad \text{for all } \ \phi \in H^2(\mathbb{R}), \quad \text{where } \ \psi = \mathcal{L}_0^{\pm} \phi + \delta \phi. \tag{3.4}$$

Parts (1) and (2), we believe, can be found in the literature. Here, for completeness, we provide an elementary proof. In fact, $\mathcal{L}_0^{\pm} + \delta$ is invertible, as can be seen by the same argument used in subsection 3.3.

Proof. (1) The assertion $\mathcal{L}_0^{\pm}\phi_0^{\pm} = 0$ follows by differentiating $c_0u_0' - u_0'' + f(u_0) = 0$ and a direct evaluation. We note that for some positive constants $a_{\pm}$, depending only on f,

$$u_0' \sim a_{\pm} \exp\left\{\left(c_0/2 \mp \sqrt{c_0^2/4 + f_u(\pm 1)}\right) x\right\} \quad \text{as} \quad x \to \pm\infty,$$

so that $\phi_0^{\pm} \in H^2(\mathbb{R})$. For later use, we remark that for some positive constant C,

$$\phi_0^{\pm}(x) \int_0^x \frac{dy}{\phi_0^{\pm}(y)} \le C, \quad \frac{1}{[\phi_0^{\pm}(x)]^2} \int_x^{\infty} [\phi_0^{\pm}(y)]^2\, dy \le C \qquad \text{for all } x > 0. \tag{3.5}$$

Similar estimates also hold for $x < 0$.

(2) Since for every $\phi \in H^2(\mathbb{R})$, $(\mathcal{L}_0^{\pm}\phi, \phi_0^{\mp}) = (\phi, \mathcal{L}_0^{\mp}\phi_0^{\mp}) = 0$, a necessary condition for $\mathcal{L}_0^{\pm}\phi = \psi$ to have a solution is $\psi \perp \phi_0^{\mp}$. We now show that this is also sufficient.

By using the method of variation of constants, one finds a special solution ϕ_{sp} to $\mathcal{L}_0^{\pm}\phi = \psi$ is given by

$$\phi_{sp}(x) = \phi_0^{\pm}(x) \int_0^x \frac{1}{\phi_0^{+}(y)\phi_0^{-}(y)}\, dy \int_y^{\infty} \phi_0^{\mp}(z)\psi(z)dz.$$

Using (3.5), we have, for all $y > 0$,

$$\left| \int_y^{\infty} \phi_0^{\mp}\psi \right| \le \sqrt{\textstyle\int_y^{\infty} \psi^2 \int_y^{\infty} (\phi_0^{\mp})^2} \le C\phi_0^{\mp} \sqrt{\textstyle\int_y^{\infty} \psi_2}\,.$$

Thus, for $x > 0$,

$$|\phi_{sp}(x)| \le C\phi_0^{\pm}(x) \int_0^x (\phi_0^{\pm})^{-1} \sqrt{\textstyle\int_y^{\infty} \psi^2}.$$

Hence, by (3.5), $\|\phi_{sp}\|_{L^{\infty}((0,\infty))} \le C\|\psi\|_{L^2}$. Also, by l'Hôpital's rule, $\lim_{x\to\infty} \phi_{sp}(x) = 0$.

Now if $\psi \perp \phi_0^{\mp}$, then $\int_y^{\infty} \phi_0^{\mp}\psi = \int_y^{-\infty} \phi_0^{\mp}\psi$. In a manner similar to the case where x is positive, one can show that $\|\psi\|_{L^{\infty}(-\infty,0)} \le C\|\psi\|_{L^2}$ and $\lim_{x\to-\infty} \phi_{sp}(x) = 0$. Using the differential equation and an energy estimate, we then can conclude that $\|\phi_{sp}\|_{H^2} \le C\|\psi\|_{L^2}$.

Now for $\phi \equiv \phi_{sp} - (\phi_{sp}, \phi_0^{\pm})\phi_0^{\pm}$, we have $\mathcal{L}_0^{\pm}\phi = \psi$, $\phi \perp \phi_0^{\pm}$, and $\|\phi\|_{H^2} \le C\|\psi\|_{L^2}$.

Solutions to $\mathcal{L}_0^{\pm}\phi = \psi$ with $\phi \perp \phi_0^{\pm}$ are unique since $\mathcal{L}_0^{\pm}\phi = 0$ has two linearly independent solutions, $\phi_0^{\pm}$ and $\phi_0^{\pm} \int_0^x \frac{1}{\phi_0^{+}\phi_0^{-}}$, the latter being unbounded.

(3) We consider separately the cases when δ is large, small, and intermediate.

(i) First we consider $\delta \ge \delta_1 \equiv 1 + \|f_u(u_0)\|_{L^{\infty}}$. Let $\phi \in H^2$ be arbitrary and set $\psi = \mathcal{L}_0^{\pm}\phi + \delta\phi$. Then $(\mathcal{L}_0^{\pm}\phi + \delta\phi\,,\, \phi) = (\psi, \phi)$, so that $(\delta - \|f_u(u_0)\|_{L^{\infty}})\|\phi\|_{L^2} \le \|\psi\|_{L^2}$. It then follows from $\pm c_0\phi' - \phi'' = \psi - (f_u(u_0) + \delta)\phi$ that $\|\phi\|_{H^2} \le C\|\psi\|_{L^2}$ for some C independent of δ. Hence, (3.4) holds.

(ii) Next we consider $\delta \in (0, \delta_0]$, where $\delta_0 > 0$ is to be defined later. Again, set $\psi = \mathcal{L}_0^{\pm}\phi + \delta\phi$, where $\phi \in H^2$ is arbitrary. Decompose $\phi = (\phi, \phi_0^{\pm})\phi_0^{\pm} + \phi^{\perp}$. Then $\mathcal{L}_0^{\pm}\phi^{\perp} = \psi - \delta\phi$, so that, from the second part of assertion (2),

$$\|\phi^{\perp}\|_{H^2} \le C_1\{\|\psi\|_{L^2} + \delta\|\phi\|_{L^2}\}. \tag{3.6}$$

In addition, $\psi-\delta\phi \perp \phi_0^{\mp}$; that is, $(\psi,\phi_0^{\mp})=\delta(\phi,\phi_0^{\mp})=\delta(\phi,\phi_0^{\pm})(\phi_0^{+},\phi_0^{-})+\delta(\phi^{\perp},\phi_0^{\mp})$. It then follows that, denoting $\sigma=(\phi_0^{+},\phi_0^{-})=\int_{\mathbb{R}}(u_0')^2e^{-c_0x}dx/(\|u_0'\|_{L^2}\|u_0'e^{-c_0x}\|_{L^2})$,

$$\sigma|(\phi,\phi_0^{\pm})|\le\|\phi^{\perp}\|_{L^2}+\frac{1}{\delta}|(\psi,\phi_0^{\mp})|\,.$$

Adding twice (3.6) to the above, we then obtain

$$\sigma|(\phi,\phi_0^{\pm})|+\|\phi^{\perp}\|_{H^2}\le\frac{1}{\delta}|(\psi,\phi_0^{\mp})|+2C_1\|\psi\|_{L^2}+2\delta C_1\|\phi\|_{L^2}.$$

It follows, as $\sigma<1$ and $\|\phi\|_{L^2}\le\|\phi^{\perp}\|_{L^2}+|(\phi,\phi_0^{\pm})|$, that

$$(\sigma-2\delta C_1)\|\phi\|_{L^2}\le 2C_1\|\psi\|_{L^2}+\frac{1}{\delta}|(\psi,\phi_0^{\mp})|.$$

Taking $\delta_0=\sigma/(4C_1)$ we conclude that if $\delta\in(0,\delta_0]$, then $\|\phi\|_{L^2}\le\frac{4C_1}{\sigma}\{\|\psi\|_{L^2}+\frac{1}{\delta}|(\psi,\phi_0^{\pm})|\}$. Hence, (3.4) holds with C_2 independent of δ.

(iii) Finally we consider $\delta\in[\delta_0,\delta_1]$. Since $\phi_0^{\pm}$ is a positive solution to $\mathcal{L}_0^{\pm}\phi=0$, by Liouville's theorem, $(\mathcal{L}_0^{\pm}+\delta)\phi=0$ does not have any nontrivial bounded solution. Define $\tilde\Lambda^{\pm}(\delta)=\inf_{\|\phi\|_{H^2}=1}\|\mathcal{L}_0^{\pm}\phi+\delta\phi\|_{L^2}$, and $\hat\Lambda^{\pm}=\inf_{\delta\in[\delta_0,\delta_1]}\tilde\Lambda^{\pm}(\delta)$. We claim that $\hat\Lambda^{\pm}>0$, and hence (3.4) holds with C_2 independent of δ. To show that $\hat\Lambda^{\pm}>0$, take a sequence $\{(\delta_j,\phi_j)\}$ minimizing $\|\mathcal{L}_0^{\pm}\phi+\delta\phi\|_{L^2}$. Writing $\psi_j=\mathcal{L}_0^{\pm}\phi_j+\delta_j\phi_j$, we may assume that $\delta_j\to\delta\in[\delta_0,\delta_1]$, $\phi_j\to\phi$ weakly in $H^2(\mathbb{R})$ and strongly in $L^2_{loc}(\mathbb{R})$, and $\psi_j\to\psi$ weakly in $L^2(\mathbb{R})$. One can show that ϕ is a weak, and hence strong, solution to $\mathcal{L}_0^{\pm}\phi+\delta\phi=\psi$, and by the weak lower semicontinuity of the norm, $\|\psi\|_{L^2}\le\hat\Lambda^{\pm}$. If $\hat\Lambda^{\pm}=0$, then $\psi=0$ and hence $\phi=0$.

On the other hand, Cauchy's inequality applied to

$$-\|\phi_j''\|_{L^2}^2+(f_u(u_0)\phi_j,\phi_j'')\ge(\mathcal{L}_0^{\pm}\phi_j+\delta_j\phi_j,\phi_j'')=(\psi_j,\phi_j'')$$

and squaring gives

$$2\|f_u(u_0)\|_{L^\infty}^2\|\phi_j\|_{L^2}^2\ge\|\phi_j''\|_{L^2}^2-2\|\psi_j\|_{L^2}^2.$$

Using this together with (3.9) and (3.10) below, one finds

$$\int_{|x|\le m}\phi_j^2\ge\bar C_3\|\phi_j\|_{H^2}^2-\bar C_4\|\psi_j\|_{L^2}^2$$

for some positive constants $\bar C_3$ and $\bar C_4$. The constant m is defined below, but the basic idea is that because of the asymptotic values of $f_u(u_o)$, one can localize the mass of ϕ_j. Passing to the limit gives

$$\int_{|x|\le m}\phi^2\ge\bar C_3>0,$$

contradicting $\phi\equiv0$. This completes the proof. □

3.2. Bound for the inverse of $\mathcal{L}_{\varepsilon,\delta}^{\pm}$. For every positive δ and ε, we define

$$\Lambda^{\pm}(\varepsilon,\delta)=\inf_{\|\phi\|_{H^1}=1}\Big\{\|\,\mathcal{L}_{\varepsilon,\delta}^{\pm}\phi\,\|_{L^2}+\frac{1}{\delta}|(\mathcal{L}_{\varepsilon,\delta}^{\pm}\phi\,,\,\phi_0^{\mp})|\Big\},\quad\Lambda^{\pm}(\delta)=\liminf_{\varepsilon\searrow0}\Lambda^{\pm}(\varepsilon,\delta).$$

(3.7)

LEMMA 6. *There exists a positive constant C_0 such that $\Lambda^{\pm}(\delta) > 2/C_0$ for all $\delta > 0$.*

Proof. Let $\delta > 0$ be any fixed positive constant. By the definition of $\Lambda^{\pm}(\delta)$, there exists a sequence $\{(\varepsilon_j, \phi_j)\}_{j=1}^{\infty}$ in $(0,1) \times H^1(\mathbb{R})$ such that $\lim_{j\to\infty} \varepsilon_j = 0$, $\|\phi_j\|_{H^1} = 1$ for all j, and $\psi_j \equiv \mathcal{L}^{\pm}_{\varepsilon_j,\delta}\phi_j$ satisfies

$$\lim_{j\to\infty} \Big\{ \|\psi_j\|_{L^2} + \frac{1}{\delta}|(\psi_j,\, \phi_0^{\pm})| \Big\} = \Lambda^{\pm}(\delta).$$

By taking a subsequence if necessary, we can assume that there exist functions $\phi \in H^1$ and $\psi \in L^2$ such that, as $j \to \infty$,

$$\begin{aligned} \phi_j &\longrightarrow \phi \quad \text{in } L^2_{\mathrm{loc}}(\mathbb{R}) \text{ and weakly in } H^1(\mathbb{R}), \\ \psi_j &\longrightarrow \psi \quad \text{weakly in } L^2(\mathbb{R}). \end{aligned}$$

By the weak lower semicontinuity of the $L^2(\mathbb{R})$ norm, $\|\psi\|_{L^2} + \frac{1}{\delta}|(\psi, \phi_0^{\mp})| \le \Lambda^{\pm}(\delta)$.

For any test function $\zeta \in C_0^{\infty}(\mathbb{R})$, $(\psi_j, \zeta) = (\mathcal{L}^{\pm}_{\varepsilon_j,\delta}\phi_j,\, \zeta) = (\phi_j, \mathcal{L}^{\mp}_{\varepsilon_j,\delta}\zeta)$. Since $\lim_{\varepsilon\searrow 0} \|\Delta_\varepsilon\zeta - \zeta''\|_{L^2} = 0$, sending $j \to \infty$ we obtain $(\psi, \zeta) = (\phi,\, (\mathcal{L}_0^{\mp} + \delta)\zeta)$ for all $\zeta \in C_0^{\infty}(\mathbb{R})$. That is, $\phi \in H^1(\mathbb{R})$ is a weak solution to $(\mathcal{L}_0^{\pm} + \delta)\phi = \psi$. An elliptic estimate then shows that ϕ is in $H^2(\mathbb{R})$. Consequently, by Lemma 5(3),

$$\|\phi\|_{H^2} \le C_2\Big\{ \|\psi\|_{L^2} + \frac{1}{\delta}|(\psi, \phi_0^{\mp})| \Big\} \le C_2\Lambda^{\pm}(\delta). \tag{3.8}$$

It remains to find a positive lower bound of $\|\phi\|_{L^2}$.

First of all, using $(\mathcal{L}^{\pm}_{\varepsilon_j,\delta}\phi_j, \phi_j') = (\psi_j, \phi_j')$ and the identity $(\Delta_\varepsilon\phi_j, \phi_j') = 0 = (\phi_j, \phi_j')$, we obtain $\pm c_0\|\phi_j'\|_{L^2}^2 = (\psi_j, \phi_j') - (f_u(u_0)\phi_j, \phi_j')$. Cauchy's inequality then gives

$$\|f_u(u_0)\|_{L^\infty}\|\phi_j\|_{L^2} \ge |c_0|\, \|\phi_j'\|_{L^2} - \|\psi_j\|_{L^2},$$

which implies

$$2\|f_u(u_0)\|_{L^\infty}^2\|\phi_j\|_{L^2}^2 \ge c_0^2\|\phi_j'\|_{L^2}^2 - 2\|\psi_j\|_{L^2}^2. \tag{3.9}$$

Let m be a positive constant such that

$$0 < a \equiv \tfrac{1}{2}\min\{f_u(1), f_u(-1)\} = \min_{|x|\ge m}\{f_u(u_0(x))\}.$$

Using $(\psi_j, \phi_j) = (\mathcal{L}^{\pm}_{\varepsilon_j,\delta}\phi_j, \phi_j)$, the identity $(\phi_j', \phi_j) = 0$, and the fact $(-\Delta_{\varepsilon_j}\phi_j, \phi_j) \ge 0$, we obtain

$$\begin{aligned} (\psi_j, \phi_j) &\ge (f_u(u_0)\phi_j, \phi_j) \ge \min_{|x|\ge m}\{f_u(u_0)\}\int_{|x|\ge m}\phi_j^2 - \|f_u(u_0)\|_{L^\infty}\int_{|x|\le m}\phi_j^2 \\ &= a\|\phi_j\|_{L^2}^2 - (a + \|f_u(u_0)\|_{L^\infty})\int_{|x|\le m}\phi_j^2. \end{aligned}$$

Therefore,

$$(a + \|f_u(u_0)\|_{L^\infty})\int_{|x|\le m}\phi_j^2 \ge a\|\phi_j\|_{L^2}^2 - (\phi_j, \psi_j) \ge \tfrac{a}{2}\|\phi_j\|_{L^2}^2 - \tfrac{1}{2a}\|\psi_j\|_{L^2}^2. \tag{3.10}$$

Adding a small multiple ($\frac{a}{2(2\|f_u(u_0)\|_{L^\infty}^2+c_0^2)}$ in fact) of (3.9), we see that there exist positive constants C_3 and C_4, which depend on $|c_0|>0$ and f, such that

$$\int_{|x|\le m}\phi_j^2 \ge C_3\|\phi_j\|_{H^1}^2 - C_4\|\psi_j\|_{L^2}^2 = C_3 - C_4\|\psi_j\|_{L^2}^2.$$

Sending $j\to\infty$ we then conclude that

$$\int_{|x|\le m}\phi^2 \ge C_3 - C_4\Lambda^{\pm}(\delta). \tag{3.11}$$

In view of (3.8), we then obtain $\Lambda^{\pm}(\delta)^2 \ge \sqrt{C_3/(C_2^2+C_4)} \equiv 2/C_0$. This completes the proof. □

Remark 6. From the proof one sees that the condition $c_0\neq 0$ plays a key role, for it ensures the boundedness of $\{\phi_j\}$ in $H^1(\mathbb{R})$ and hence guarantees (3.11) for the weak limit.

3.3. Proof of Theorem 4. Now we are ready to complete the proof of Theorem 4.

Let $\delta>0$ be fixed. Since $\Lambda^{\pm}(\delta)\ge 2/C_0$, there exists $\varepsilon_0(\delta)>0$ such that $\Lambda(\varepsilon,\delta)\ge 1/C_0$ for every $\varepsilon\in(0,\varepsilon_0(\delta)]$. Now we consider the operator $\mathcal{L}^{\pm}_{\varepsilon,\delta}$ with $\varepsilon\in(0,\varepsilon_0(\delta)]$.

First of all, $\mathcal{L}^{\pm}_{\varepsilon,\delta}$ is a bounded operator from $H^1(\mathbb{R})$ to $L^2(\mathbb{R})$. Also, by the definition and the lower bound of $\Lambda^{\pm}(\varepsilon,\delta)$, $\mathcal{L}^{\pm}_{\varepsilon,\delta}$ is a homeomorphism from $H^1(\mathbb{R})$ to its image $\mathcal{L}^{\pm}_{\varepsilon,\delta}(H^1(\mathbb{R}))$, and the inverse $(\mathcal{L}^{\pm}_{\varepsilon,\delta})^{-1}$ from $\mathcal{L}^{\pm}_{\varepsilon,\delta}(H^1(\mathbb{R}))\subseteq L^2(\mathbb{R})$ to $H^1(\mathbb{R})$ is bounded by $1/\Lambda^{\pm}(\varepsilon,\delta)\le C_0$. As a consequence of the boundedness, we see that $\mathcal{L}^{\pm}_{\varepsilon,\delta}(H^1(\mathbb{R}))$ is closed in $L^2(\mathbb{R})$.

It remains to show that $\mathcal{L}^{\pm}_{\varepsilon,\delta}(H^1(\mathbb{R}))=L^2(\mathbb{R})$. Indeed, if this were not true, there would exist a nontrivial $\psi\in L^2(\mathbb{R})$ orthogonal to $\mathcal{L}^{\pm}_{\varepsilon,\delta}(H^1(\mathbb{R}))$, i.e., $0=(\mathcal{L}^{\pm}_{\varepsilon,\delta}\phi,\psi)=(\phi,\mathcal{L}^{\mp}_{\varepsilon,\delta}\psi)$ for all $\phi\in H^1(\mathbb{R})$. In particular, $(\phi,\mathcal{L}^{\mp}_{\epsilon,\delta}\psi)=0$ for all $\phi\in C_0^\infty(\mathbb{R})$, and therefore the weak derivative of ψ is in $L^2(\mathbb{R})$. Consequently, $\mp c_0\psi' = (\Delta_\varepsilon - f_u(u_0)-\delta)\psi$ is in $L^2(\mathbb{R})$ since $\psi\in L^2(\mathbb{R})$. Thus, $\psi\in H^1(\mathbb{R})$ and $\mathcal{L}^{\mp}_{\varepsilon,\delta}\psi=0$. By the definition and the positivity of $\Lambda(\varepsilon,\delta)$, we then conclude that $\psi=0$ and therefore obtain a contradiction. Thus $\mathcal{L}^{\pm}_{\varepsilon,\delta}(H^1(\mathbb{R}))=L^2(\mathbb{R})$, and this completes the proof.

4. Existence of traveling waves.

Proof of Theorem 1. Let δ and η be small positive constants to be determined later. We define

$$\mathbf{X}_\eta \equiv \{\phi\in H^1(\mathbb{R}) \ : \ \|\phi\|_{H^1}\le\eta\}.$$

For every $\phi\in\mathbf{X}_\eta$, let $c_\varepsilon=c_\varepsilon(\phi)$ be the (unique) constant such that $\mathcal{R}(c_\varepsilon,\phi)\perp\phi_0^-$, i.e.,

$$c_\varepsilon(\phi)\equiv c_0 + \frac{(\Delta_\varepsilon u_0 - u_0'',\,\phi_0^-)+\delta(\phi,\phi_0^-)-(\mathbf{N}(u_0,\phi),\phi_0^-)}{(u_0',\phi_0^-)+(\phi',\phi_0^-)}. \tag{4.1}$$

We define $\mathbf{T}:\mathbf{X}_\eta\subset H^1(\mathbb{R})\to H^1(\mathbb{R})$ by

$$\mathbf{T}\phi = (\mathcal{L}^{+}_{\varepsilon,\delta})^{-1}\mathcal{R}(c_\varepsilon(\phi),\phi). \tag{4.2}$$

We now show that $\mathbf{T}$ maps $\mathbf{X}_\eta$ into itself and is a contraction, so that it possesses a fixed point, which, after adding u_0, gives a solution to (1.5), thereby completing the proof.

Since $\mathcal{R}(c_\varepsilon(\phi),\phi) \perp \phi_0^-$, we derive from Theorem 4 that

$$\|\mathbf{T}\phi\|_{H^1} \le C_0\|\mathcal{R}(c_\varepsilon(\phi),\phi)\|_{L^2} \quad \text{for all } \phi \in \mathbf{X}_\eta, \text{ and} \tag{4.3}$$

$$\|\mathbf{T}\phi_1 - \mathbf{T}\phi_2\|_{H^1} \le C_0\|\mathcal{R}(c_\varepsilon(\phi_1),\phi_1) - \mathcal{R}(c_\varepsilon(\phi_2),\phi_2)\|_{L^2} \quad \text{for all } \phi_1,\phi_2 \in \mathbf{X}_\eta. \tag{4.4}$$

Now we estimate the right-hand sides.

Let $\hat\sigma$ be defined as

$$\hat\sigma = \frac{1}{2}(u_0', \phi_0^-) = \frac{\int_{\mathbb{R}} {u_0'}^2 e^{-c_0 x}}{2(\int_{\mathbb{R}} {u_0'}^2 e^{-2c_0 x})^{1/2}} > 0.$$

Then $(u_0' + \phi', \phi_0^-) = 2\hat\sigma + (\phi', \phi_0^-) \ge 2\hat\sigma - \eta \ge \hat\sigma$ if we require $\eta \le \hat\sigma$.

To estimate the nonlinear term $\mathbf{N}(u_0,\phi)$, we first recall the embedding $\|\phi\|_{L^\infty} \le \|\phi\|_{H^1}$ for every $\phi \in H^1$. Hence, setting $M = \sup_{|s|\le 1+\hat\sigma} |f_{uu}(s)|$, we have

$$|\mathbf{N}(u_0,\phi)| \le M\eta|\phi| \quad \text{and} \quad |\mathbf{N}(u_0,\phi_1) - \mathbf{N}(u_0,\phi_2)| \le M\eta|\phi_1 - \phi_2|$$

pointwise for all $\phi, \phi_1, \phi_2 \in \mathbf{X}_\eta$.

By the definition of $c_\varepsilon(\phi)$ in (4.1), for all $\phi, \phi_1, \phi_2 \in \mathbf{X}_\eta$,

$$|c_\varepsilon(\phi) - c_0| \le \hat\sigma^{-1}\{\|\Delta_\varepsilon u_0 - u_0''\|_{L^2} + (\delta + M\eta)\eta\}$$

and

$$|c_\varepsilon(\phi_1) - c_\varepsilon(\phi_2)| \le \|\phi_1 - \phi_2\|_{L^2}\hat\sigma^{-2}\{\|\Delta_\varepsilon u_0 - u_0''\|_{L^2} + (\hat\sigma + \eta)(\delta + M\eta)\}\,.$$

Therefore, using the expression for $\mathcal{R}(c_\varepsilon(\phi),\phi)$ in (2.4) we can estimate

$$\begin{aligned}\|\mathcal{R}(c_\varepsilon(\phi),\phi)\|_{L^2} &\le |c_\varepsilon(\phi) - c_0|(\|u_0'\| + \eta) + \|\Delta_\varepsilon u_0 - u_0''\|_{L^2} + \delta\eta + M\eta^2 \\ &\le \eta\{1 + \hat\sigma^{-1}(\|u_0'\| + \eta)\}\{\eta^{-1}\|\Delta_\varepsilon u_0 - u_0''\|_{L^2} + \delta + M\eta\}\end{aligned}$$

and

$$\begin{aligned}&\|\mathcal{R}(c_\varepsilon(\phi_1),\phi_1) - \mathcal{R}(c_\varepsilon(\phi_2),\phi_2)\|_{L^2} \\ &\le \{|c_\varepsilon(\phi_1) - c_0| + \delta + M\eta\}\|\phi_1 - \phi_2\|_{L^2} + (\|u_0'\|_{L^2} + \eta)|c_\varepsilon(\phi_1) - c_\varepsilon(\phi_2)| \\ &\le \|\phi_1 - \phi_2\|_{L^2}\hat\sigma^{-2}\{\hat\sigma + \eta + \|u_0'\|_{L^2}\}\{\|\Delta_\varepsilon u_0 - u_0''\|_{L^2} + (\hat\sigma + \eta)(\delta + M\eta)\}.\end{aligned}$$

It then follows from (4.3) and (4.4) that there exists a positive constant C_5, which is independent of δ, ε and $\eta \in (0, \hat\sigma]$, such that

$$\|\mathbf{T}\phi\|_{H^1} \le \eta C_5\{\eta^{-1}\|\Delta_\varepsilon u_0 - u_0''\|_{L^2} + \delta + M\eta\}$$

and

$$\|\mathbf{T}\phi_1 - \mathbf{T}\phi_2\|_{H^1} \le C_5\big\{\|\Delta_\varepsilon u_0 - u_0''\|_{L^2} + \delta + M\eta\big\}\|\phi_1 - \phi_2\|_{H^1}.$$

Now we fix

$$\delta = \frac{1}{4C_5} \qquad \text{and} \qquad \eta = \min\Big\{\hat\sigma, \frac{1}{4MC_5}\Big\}.$$

We select a small positive ε^* such that $\varepsilon^* \le \varepsilon_0(\delta)$ (cf. Theorem 4) and

$$\sup_{\varepsilon\in(0,\varepsilon^*]} \|\Delta_\varepsilon u_0 - u_0''\|_{L^2} \le \frac{\min\{1,\eta\}}{4C_5}\,.$$

We then conclude that for any fixed $\varepsilon \in (0,\varepsilon^*]$, $\mathbf{T}$ maps $\mathbf{X}_\eta$ into itself and is a contraction. This completes the proof.

Remark 7. From the proof, one sees that the solution to (1.5) is locally unique.

Part II. Stationary waves. Here we assume that $\int_{-1}^{1} f = 0$, and hence $c_0 = 0$.

5. Assumptions and results. By the assumption that f is balanced, it is the derivative of a double equal-well potential; more precisely, since $f_u(\pm1) > 0$ we may write

$$f(u) = F_u(u), \quad \text{where} \quad F(\pm1) = 0 \ \text{ and } \quad F(u) \ge m_0(1-u^2)^2 \tag{5.1}$$

for a positive constant m_0 and $u \in [-2,2]$. When u is outside $[-2,2]$, we assume that F is bounded away from zero and approaches infinity as $|u| \to \infty$. We look for a function u_ε such that

$$-\Delta_\varepsilon u_\varepsilon + f(u_\varepsilon) = 0 \quad \text{ for all } x \in \mathbb{R}, \qquad \lim_{x\to\pm\infty} u_\varepsilon(x) = \pm1. \tag{5.2}$$

Observe that if u_ε is a solution, then for every $x_0 \in \mathbb{R}$, if we define $u_n = u_\varepsilon(x_0 + n\varepsilon)$ for all $n \in \mathbb{Z}$, then $\{u_n\}_{n=-\infty}^{\infty}$ satisfies

$$\begin{cases} -\varepsilon^{-2}\sum_{k>0}\alpha_k(u_{n+k} + u_{n-k} - 2u_n) + f(u_n) = 0 \quad \text{ for all } \ n \in \mathbb{Z}, \\ \qquad\qquad \lim_{n\to\pm\infty} u_n = \pm1. \end{cases} \tag{5.3}$$

On the other hand, if a sequence $\{u_n\}$ satisfies (5.3), then the function $u_\varepsilon = \sum_n u_n\chi_n^\varepsilon$ is a solution to (5.2) where χ_n^ε is the characteristic function of the set $(\varepsilon(n-1/2), \varepsilon(n+1/2)]$, i.e.,

$$\chi_n^\varepsilon(x) = \begin{cases} 1 & \text{if } \ x \in (\varepsilon(n-1/2), \varepsilon(n+1/2)], \\ 0 & \text{otherwise.} \end{cases} \tag{5.4}$$

Hence, the solvability of (5.2) and (5.3) are equivalent.

In what follows, $\sum_{n=-\infty}^{\infty}$ is denoted by $\sum_n$. Also a sequence $\{u_n\}$ is identified with a function u defined by $u(x) = \sum_n u_n\chi_n^\varepsilon(x)$, where $\chi_n^\varepsilon(\cdot)$ is as in (5.4).

To show that (5.2) or (5.3) admits a solution, we need the stronger assumption, (A3) given in the introduction, than we needed for the nonstationary wave case. A useful consequence is given here. Let

$$B(\zeta) \equiv \sum_{k>0} \alpha_k \frac{\sin^2\frac{k\zeta}{2}}{\sin^2\frac{\zeta}{2}} = \sum_{k>0}\alpha_k\Big|\sum_{\ell=0}^{k-1} e^{\mathbf{i}\,\ell\,\zeta}\Big|^2, \quad \zeta \in \mathbb{R}. \tag{5.5}$$

Notice that $B(\cdot)$ is 2π-periodic and even. It can be expanded as a Fourier cosine series:

$$B(\zeta) = \frac{b_0}{2} + \sum_{\ell>0} b_\ell\cos(\ell\zeta) \ \text{ for } \zeta \in \mathbb{R}, \quad \text{where } \ b_\ell = \frac{1}{\pi}\int_0^{2\pi} B(\zeta)\cos(\ell\zeta)\,d\zeta. \tag{5.6}$$

We assert the following.

LEMMA 7. *Assume* (A3). *Then $B(\zeta)$ is uniformly positive, bounded, and in $H^{1/2}([0,2\pi])$; that is, there exists a positive constant B_∞ such that*

$$\frac{1}{B_\infty} \le B(\zeta) \le B_\infty \qquad \text{for all } \zeta \in \mathbb{R}, \tag{5.7}$$

$$\sum_{\ell>0} \ell\, b_\ell^2 < \infty. \tag{5.8}$$

Proof. By (A3), $B(z) > 0$ and twice differentiable on $(0, 2\pi)$ and by l'Hôpital's rule, $\lim_{z\to 0,2\pi} B(z) = 1$. This shows that B is bounded above and below by positive constants. To show the regularity, it is convenient to write the Fourier series for B as

$$\sum_{k=-\infty}^{\infty} a_k \cos(kz).$$

We have

$$\sum_{k=-\infty}^{\infty} \alpha_k(1-\cos(kz)) = 2\sum_{k=-\infty}^{\infty} a_k \cos(kz)(1-\cos(z)).$$

It follows that

$$\alpha_k = a_{k+1} + a_{k-1} - 2a_k \qquad \text{for } \ k \neq 0.$$

This may be inverted to give

$$a_k = \sum_{j>0} j\alpha_{k+j}.$$

Now, $B \in H^{\frac{1}{2}}$ is equivalent to the convergence of $\sum_{k>0} k a_k^2$. In light of the above, we have

$$\begin{aligned}
\sum_{k>0} k a_k^2 &= \sum_{k>0} k \sum_{j>0} j\alpha_{j+k} \sum_{i>0} i\alpha_{i+k} \\
&\le \sum_{k>0}\sum_{j>k}\sum_{i>k} k\frac{(j-k)}{j^2}\frac{(i-k)}{i^2}|\alpha_j| j^2 |\alpha_i| i^2 \\
&= \sum_{j>0}\sum_{i>0}\Big(\sum_{k=1}^{\min\{j-1,i-1\}} k\frac{(j-k)}{j^2}\frac{(i-k)}{i^2}\Big)|\alpha_j| j^2 |\alpha_i| i^2.
\end{aligned}$$

The proof is completed by observing that the sum over k is bounded by $\frac{3}{4}$ and the other sums are finite by (A3). ∎

We will derive some energy estimates and then prove the existence part of Theorem 2.

THEOREM 8. *Assume that $f(u)$ satisfies* (5.1) *and $\{\alpha_k\}_{k=1}^{\infty}$ satisfies* (A3). *Then for every $\varepsilon > 0$, problem* (5.2) *or problem* (5.3) *admits at least one solution.*

We use a minimization method with an energy $\mathbf{E}$ defined by

$$\mathbf{E}[u] = \mathcal{E}_{ki}[u] + \mathcal{E}_{po}[u], \quad \mathcal{E}_{po}[u] = 2\int_{\mathbb{R}} F(u)\,dx, \quad \mathcal{E}_{ki}[u] = -\int_{\mathbb{R}} u\Delta_\varepsilon u\,dx, \tag{5.9}$$

where "po" stands for potential and "ki" for kinetic. We show that $\mathbf{E}[\cdot]$ has a minimizer in the following space

$$\mathbf{X} \equiv \left\{ u = \sum_n u_n \chi_n^\varepsilon \ : \ \sum_{n=0}^{\infty} |1-u_n|^2 + \sum_{n=-1}^{-\infty} |1+u_n|^2 < \infty \right\}. \tag{5.10}$$

LEMMA 9. *If $u^\varepsilon \in \mathbf{X}$ satisfies $\mathbf{E}[u^\varepsilon] = \inf_{u\in\mathbf{X}} \mathbf{E}[u]$, then u^ε solves* (5.3).

The proof follows a standard variation technique and is omitted. We only remark that if $u \in \mathbf{X}$, then $\Delta_\varepsilon u \in L^2(\mathbb{R})$, due to the assumption that $\sum_k |\alpha_k|\, k^2 < \infty$.

6. The energy. First we write the kinetic energy $-(\Delta_\varepsilon u, u)$ in a convenient form for piecewise constant functions.

LEMMA 10. *Let $u(x) = \sum_n u_n \chi_n^\varepsilon$ and $v(x) = \sum_n v_n \chi_n^\varepsilon$. Assume that $\sum_n (u_{n+1}-u_n)^2 < \infty$ and $\sum_n (v_{n+1}-v_n)^2 < \infty$. Then*

$$(-\Delta_\varepsilon u, v) = \frac{1}{2\pi\varepsilon} \int_0^{2\pi} B(\zeta)\phi(\zeta)\overline{\psi(\zeta)}\, d\zeta, \tag{6.1}$$

where $B(\zeta)$ is as in (5.5),

$$\phi(\zeta) = \sum_n (u_{n+1}-u_n) e^{\mathbf{i}n\zeta}, \quad \text{and} \quad \psi(\zeta) = \sum_m (v_{m+1}-v_m) e^{\mathbf{i}m\zeta}\ . \tag{6.2}$$

Consequently,

$$\mathcal{E}_{ki}[u] = \frac{1}{2\pi\varepsilon} \int_0^{2\pi} B(\zeta) \Big|\phi(\zeta)\Big|^2 d\zeta.$$

Proof. By definition,

$$\begin{aligned}
(-\Delta_\varepsilon u, v) &= \frac{1}{\varepsilon^2} \sum_{k>0} \alpha_k \Big\{ -\Big(u(x+\varepsilon k) - u(x), v(x)\Big) + \Big(u(x) - u(x-\varepsilon k), v(x)\Big)\Big\} \\
&= \frac{1}{\varepsilon^2} \sum_{k>0} \alpha_k \Big(u(x+\varepsilon k) - u(x), v(x+\varepsilon k) - v(x)\Big) \\
&= \frac{1}{2\pi\varepsilon^2} \sum_{k>0} \alpha_k \int_{\mathbb{R}} \mathcal{F}[u(x+\varepsilon k) - u(x)] \overline{\mathcal{F}[v(x+\varepsilon k) - v(x)]}\, d\xi
\end{aligned}$$

by Parseval's identity, where $\mathcal{F}[u]$ is the Fourier transform of u; see (2.6). For any $h > 0$,

$$\begin{aligned}
&(1 - e^{\mathbf{i}\varepsilon\xi})\, \mathcal{F}[u(x+h) - u(x)] \\
&= \mathcal{F}[u(x+h) - u(x) - u(x+h-\varepsilon) + u(x-\varepsilon)] \\
&= \mathcal{F}[u(x+h) - u(x+h-\varepsilon)] - \mathcal{F}[u(x) - u(x-\varepsilon)] \\
&= \sum_n (u_{n+1} - u_n) \int_{\varepsilon(n+1/2)}^{\varepsilon(n+3/2)} e^{\mathbf{i}x\xi} dx (e^{-\mathbf{i}h} - 1) \\
&= \frac{(1 - e^{\mathbf{i}\varepsilon\xi}) e^{-\mathbf{i}h\xi/2} \sin(h\xi/2)}{\xi/2} \sum_n (u_{n+1} - u_n) e^{\mathbf{i}(n+1/2)\varepsilon\xi}.
\end{aligned}$$

It then follows that

$$\mathcal{F}[u(x) - u(x-h)] = e^{-\mathbf{i}h\xi/2} \frac{\sin(h\xi/2)}{\xi/2} \sum_n (u_{n+1} - u_n) e^{\mathbf{i}\varepsilon\xi(n+1/2)}.$$

Consequently, defining ϕ and ψ as in (6.2), we have

$$(-\Delta_\varepsilon u, v) = \frac{1}{2\pi}\int_{\mathbb{R}} \sum_{k>0} \alpha_k \Big(\frac{2\sin(k\varepsilon\xi/2)}{\varepsilon\xi}\Big)^2 \phi(\varepsilon\xi)\overline{\psi(\varepsilon\xi)}\, d\xi$$
$$= \frac{1}{2\pi\varepsilon}\int_{\mathbb{R}} \frac{\sum_{k>0} 4\alpha_k \sin^2(k\zeta/2)}{\zeta^2}\phi(\zeta)\overline{\psi(\zeta)}\, d\zeta$$

after the change of variables, $\zeta = \varepsilon\xi$. As all the functions, except ζ^2, in the integrand are 2π-periodic,

$$(-\Delta_\varepsilon u, v) = \frac{1}{2\pi\varepsilon}\int_0^{2\pi} \Big(\sum_{k>0} 4\alpha_k \sin^2\frac{k\zeta}{2}\Big)\phi(\zeta)\overline{\psi(\zeta)}\sum_\ell \frac{1}{(\zeta+2\pi\ell)^2}\,.$$

The assertion of the lemma thus follows from the identity $\sum_\ell \frac{1}{(\zeta+2\pi\ell)^2} = \frac{1}{4\sin^2(\zeta/2)}$ for all ζ and the definition of $B(\zeta)$ in (5.5). ∎

With the assumption on B we immediately have the following.

LEMMA 11. *For every $u \in \mathbf{X}$,*

$$\frac{1}{\varepsilon B_\infty}\sum_n (u_{n+1}-u_n)^2 \le \mathcal{E}_{ki}[u] \le \frac{B_\infty}{\varepsilon}\sum_n (u_{n+1}-u_n)^2. \tag{6.3}$$

7. An energy decomposition. When all α_k's, $k > 0$, are nonnegative, the energy of any nonmonotonic function can be decreased by removing the "bumps" of the function. In our current situation where some of the α_k's may be negative, we cannot use this modification. Indeed, an energy minimizer may not necessarily be monotonic. Hence, to show that an energy minimizer satisfies needed asymptotic behavior as $x \to \pm\infty$ requires special treatment.

For convenience we denote by m_0 a positive constant such that

$$f_u > m_0 \qquad \text{in } (-1-m_0, -1+m_0)\cup(1-m_0, 1+m_0). \tag{7.1}$$

Also, we denote, for every positive integer M,

$$\bar{b}_M \equiv \sqrt{\textstyle\sum_{\ell\ge M} \ell\, b_\ell^2}\,, \tag{7.2}$$

where $\{b_\ell\}$ are the Fourier coefficients of B. Clearly, $\lim_{M\to\infty}\bar{b}_M = 0$.

LEMMA 12. *Let M be any fixed positive integer. Assume that $\mathbf{E}[u] < \infty$ and $|u+1| \le m_0$ on $(-\varepsilon/2, \varepsilon(M+1/2)]$. Then for any $\eta \in (0,1)$,*

$$\mathbf{E}[u^r] + \mathbf{E}[u^l] \le \tfrac{(1+\bar{b}_M B_\infty)}{1-\eta}\mathbf{E}[u] + \tfrac{2B_\infty}{\eta(1-\eta)}\Big\{\frac{\max_{0\le n<M}|u_n+1|^2}{\varepsilon M} + \sum_{0\le n<M}\frac{(u_{n+1}-u_n)^2}{\varepsilon}\Big\},$$

where

$$u^r = -1+\theta(1+u), \quad u^l = -1+(1-\theta)(1+u), \quad \theta = \sum_{n\ge 0}\min\Big\{\frac{n}{M}\,, 1\Big\}\chi_n^\varepsilon.$$

Notice that $\theta = 0$ for $x \le \varepsilon/2$ and $\theta = 1$ for $x \ge (M-1/2)\varepsilon$. It then follows that $u^r = -1, u^l = u$ for $x \le \varepsilon/2$ and $u^r = u, u^l = -1$ for $x > (M-1/2)\varepsilon$. This lemma shows that if u is in a "resting" state for a large interval, i.e., both

$\varepsilon^{-1}\sum_{0\le n<M}|u_{n+1}-u_n|^2$ and $\max_{0\le n<M}|u_n+1|$ are small, then the energy of u can be decomposed as the sum of the energy of u^r and that of u^l. In particular, it eliminates the possibility of energy minimizers having transition layers in "remote" locations. This property will be a key in our proof of the existence of an energy minimizer with required asymptotics at $x=\pm\infty$.

Proof. First we compare the potential energy. Since $F(-1)=0$,

$$\mathcal{E}_{po}[u]-(\mathcal{E}_{po}[u^r]+\mathcal{E}_{po}[u^l])=\sum_{1\le n\le M-1}2\varepsilon\,\{F(u_n)-F(u_n^r)-F(u_n^l)\}.$$

For each $n\in\{1,\dots,M-1\}$, we can calculate, using $F(z)=\int_{-1}^{z}f(s)\,ds=\int_0^{1+z}f(s-1)\,ds$,

$$F(u_n)-F(u_n^r)-F(u_n^l)=\Big\{\int_0^{u_n+1}-\int_0^{\theta_n(u_n+1)}-\int_0^{(1-\theta_n)(u_n+1)}\Big\}f(s-1)\,ds$$
$$=\int_0^{u_n+1}\Big\{f(s-1)-\theta_n f(\theta_n s-1)-(1-\theta_n)f((1-\theta_n)s-1)\Big\}\,ds\ge 0,$$

since $f(-1)=0$, $f_u(s-1)>0$ for all $s\in(-m_0,m_0)$, and $1+u_n\in(-m_0,m_0)$. Therefore,

$$\mathcal{E}_{po}[u^r]+\mathcal{E}_{po}[u^l]\le\mathcal{E}_{po}[u].$$

Next we compare the kinetic energy. For simplicity, we denote $\phi(\zeta)=\sum_n(u_{n+1}-u_n)e^{\mathbf{i}n\zeta}$, $\phi^r(\zeta)=\sum_n(u^r_{n+1}-u^r_n)e^{\mathbf{i}n\zeta}$, and $\phi^l(\zeta)=\sum_n(u^l_{n+1}-u^l_n)e^{\mathbf{i}n\zeta}$. Since $u=u^r+u^l+1$, we have $\phi=\phi^r+\phi^l$. Consequently, by the expression for the kinetic energy in Lemma 10,

$$\mathcal{E}_{ki}[u]-\mathcal{E}_{ki}[u^r]-\mathcal{E}_{ki}[u^l]=\frac{1}{\pi\varepsilon}\int_0^{2\pi}B(\zeta)\,\mathrm{Re}\{\phi^r(\zeta)\overline{\phi^l(\zeta)}\}\,d\zeta, \tag{7.3}$$

where Re represents the real part of a complex valued function. Note that the summation for ϕ^r indeed runs only for $n\ge 0$ and that for ϕ^l for $n\le M-1$. Hence, we can write

$$B\,\mathrm{Re}\{\phi^r\overline{\phi^l}\}=\mathrm{I}+\mathrm{II}+\mathrm{III}+\mathrm{IV},\qquad\text{where}$$
$$\mathrm{I}\equiv\mathrm{Re}\Big\{B\overline{\phi^l}\sum_{0\le n<M}(u^r_{n+1}-u^r_n)e^{\mathbf{i}n\zeta}\Big\},$$
$$\mathrm{II}\equiv\mathrm{Re}\Big\{B\phi^r\sum_{0\le m<M}(u^l_{m+1}-u^l_m)e^{-\mathbf{i}m\zeta}\Big\},$$
$$\mathrm{III}\equiv-B\,\mathrm{Re}\Big\{\sum_{0\le n<M}(u^r_{n+1}-u^r_n)e^{\mathbf{i}n\zeta}\sum_{0\le m<M}(u^l_{m+1}-u^l_m)e^{-\mathbf{i}m\zeta}\Big\},$$
$$\mathrm{IV}\equiv\sum_{n\ge M}\sum_{m<0}(u_{n+1}-u_n)(u_{m+1}-u_m)B(\zeta)\cos([n-m]\zeta),$$

where in IV we have used $u^r_n=u_n$ for $n\ge M$, and similarly $u^l_m=u_m$ for $m\le 0$.

We now estimate the contribution of each of the terms. First, for any $\eta>0$,

$$\Big|\frac{1}{\pi\varepsilon}\int_0^{2\pi}\mathrm{I}\,d\zeta\Big|\le 2\Big(\frac{1}{2\pi\varepsilon}\int_0^{2\pi}B|\phi^l|^2\Big)^{1/2}\Big(\frac{B_\infty}{\varepsilon}\sum_{0\le n<M}(u^r_{n+1}-u^r_n)^2\Big)^{1/2}$$
$$\le\eta\,\mathcal{E}_{ki}[u^l]+\frac{B_\infty}{\eta\,\varepsilon}\sum_{0\le n<M}(u^r_{n+1}-u^r_n)^2\,.$$

Similarly,

$$\Big|\frac{1}{\pi\varepsilon}\int_0^{2\pi} \mathrm{II}\, d\zeta\Big| \le \eta\, \mathcal{E}_{ki}[u^r] + \frac{B_\infty}{\eta\,\varepsilon}\sum_{0\le n<M}(u^l_{n+1}-u^l_n)^2\,.$$

Next,

$$\begin{aligned}\Big|\frac{1}{\pi\varepsilon}\int_0^{2\pi} \mathrm{III}\Big| &\le \frac{2B_\infty}{\varepsilon}\Big(\sum_{0\le n<M}(u^r_{n+1}-u^r_n)^2\Big)^{1/2}\Big(\sum_{0\le m<M}(u^l_{m+1}-u^l_m)^2\Big)^{1/2}\\ &\le \frac{B_\infty}{\varepsilon}\Big\{\sum_{0\le n<M}(u^r_{n+1}-u^r_n)^2+\sum_{0\le m<M}(u^l_{m+1}-u^r_m)^2\Big\}.\end{aligned}$$

To estimate IV, we use the definition of the Fourier coefficients b_ℓ to obtain

$$\begin{aligned}\Big|\frac{1}{\pi\varepsilon}\int_0^{2\pi} \mathrm{IV}\Big| &\le \frac{1}{\varepsilon}\Big(\sum_{n\ge M}(u_{n+1}-u_n)^2\sum_{m<0}(u_{m+1}-u_m)^2\sum_{n\ge M}\sum_{m<0}b^2_{n-m}\Big)^{1/2}\\ &\le \frac{\tilde b_M}{2\varepsilon}\sum_n |u_{n+1}-u_n|^2 \le \tilde b_M B_\infty \mathcal{E}_{ki}[u],\end{aligned}$$

where

$$\tilde b_M = \Big(\sum_{n\ge M}\sum_{m<0} b^2_{n-m}\Big)^{1/2} = \Big(\sum_{\ell\ge M+1}(\ell-M)b^2_\ell\Big)^{1/2} \le \bar b_M\,.$$

Combining these estimates, we then obtain

$$\begin{aligned}\mathcal{E}_{ki}[u^r]+\mathcal{E}_{ki}[u^l]-\mathcal{E}_{ki}[u] &\le \eta\{\mathcal{E}_{ki}[u^r]+\mathcal{E}_{ki}[u^l]\}+\bar b_M B_\infty \mathcal{E}_{ki}[u]\\ &\quad+\frac{2B_\infty}{\eta\,\varepsilon}\sum_{0\le n<M}\Big\{(u^r_{n+1}-u^r_n)^2+(u^l_{n+1}-u^l_n)^2\Big\}.\end{aligned}$$

It remains to estimate the last term. We note that

$$u^r_{n+1}-u^r_n = \theta_{n+1}(u_{n+1}-u_n)+(\theta_{n+1}-\theta_n)(u_n+1)$$

and

$$u^l_{n+1}-u^l_n = (1-\theta_{n+1})(u_{n+1}-u_n)-(\theta_{n+1}-\theta_n)(u_n+1).$$

It then follows that

$$(u^r_{n+1}-u^r_n)^2+(u^l_{n+1}-u^l_n)^2 \le 2(u_{n+1}-u_n)^2+2(\theta_{n+1}-\theta_n)^2(u_n+1)^2.$$

Finally, using $\theta_{n+1}-\theta_n = 1/M$ for all $n = 0,\dots,M-1$ we obtain

$$\begin{aligned}(1-\eta)(\mathcal{E}_{ki}[u^r]+\mathcal{E}_{ki}[u^l]) &\le (1+\bar b_M B_\infty)\mathcal{E}_{ki}[u]\\ &\quad+\frac{4B_\infty}{\eta}\Big\{\frac{\max_{0\le n<M}|u_n+1|^2}{\varepsilon M}+\frac{1}{\varepsilon}\sum_{0\le n<M}(u_{n+1}-u_n)^2\Big\}.\end{aligned}$$

This completes the proof. □

For later applications, we provide an energy lower bound.

LEMMA 13. *There exists a positive constant e_0 such that $\mathbf{E}[u] \geq e_0$ if u changes sign at least once, i.e., $u_n u_{n+1} \leq 0$ for some $n \in \mathbb{Z}$, where $u = \sum_n u_n \chi_n^\varepsilon$.*

Proof. By translation if necessary, we can assume that $u_0 u_1 \leq 0$.

(i) If $\min\{|u_0|, |u_1|\} \leq 1/2$, then $\mathbf{E}[u] \geq 2\varepsilon(F(u_0)+F(u_1)) \geq 2\varepsilon \min_{|s|\leq 1/2} F(s) > 0$.

(ii) If $\min\{|u_0|, |u_1|\} > 1/2$, then since $u_0 u_1 \leq 0$, we have $|u_1 - u_0| \geq 1/2$. It then follows from (6.3) that $\mathbf{E}(u) \geq (B_\infty \varepsilon)^{-1} |u_1 - u_0|^2 \geq 1/(4B_\infty \varepsilon)$.

Combining both cases we then obtain the assertion of the lemma with

$$e_0 = \min\left\{ 2\varepsilon \min_{|s|\leq 1/2}\{F(s)\},\ 1/(4B_\infty\varepsilon) \right\}. \qquad \square$$

8. Existence of a stationary wave. With all these preparations, we can now prove existence of a solution.

THEOREM 14. *For every $\varepsilon > 0$, there exists at least one function $u^\varepsilon \in \mathbf{X}$ such that*

$$\mathbf{E}[u^\varepsilon] = \mathrm{E}(\varepsilon) \equiv \inf_{u\in\mathbf{X}} \mathbf{E}[u]. \tag{8.1}$$

Consequently, problem (5.2) *or* (5.3) *admits at least one solution.*

Proof. Note that $\mathrm{E}(\varepsilon)$ is finite since $\mathbf{E}[u] < \infty$ for the test function u defined by $u = 1$ for $x > \varepsilon/2$ and $u = -1$ for $x \leq \varepsilon/2$. Hence, there exists a sequence $\{u^j\}_{j=1}^\infty$ in $\mathbf{X}$ such that as $j \to \infty$, $\mathbf{E}[u^j] \searrow \mathrm{E}(\varepsilon)$. We write $u^j = \sum_n u_n^j \chi_n^\varepsilon$. By a translation if necessary, we can assume that $x = \varepsilon/2$ is the first place where u^j changes sign; i.e., $u_n^j < 0$ for all $n \leq 0$, and $u_1^j \geq 0$.

Clearly $\{u_n^j\}$ are uniformly bounded for all n and j, since for each n and j, $2F(u_n^j) \leq \frac{1}{\varepsilon}\mathbf{E}[u^j] \leq \frac{1}{\varepsilon}\mathrm{E}(\varepsilon) + 1$, and $\lim_{|s|\to\infty} F(s) = \infty$. Thus, by a diagonal limit process, we can extract a subsequence of $\{u^j\}$, which we still denote by $\{u^j\}$, such that for every n, $\lim_{j\to\infty} u_n^j = u_n^\varepsilon$ for some $u_n^\varepsilon \in \mathbb{R}$. Set $u^\varepsilon = \sum_n u_n^\varepsilon \chi_n^\varepsilon$. We claim that $u^\varepsilon \in \mathbf{X}$ and u^ε is an energy minimizer.

First, we consider the potential energy of u^ε. We have

$$\begin{aligned}\sum_n F(u_n^\varepsilon) &= \lim_{N\to\infty} \sum_{|n|\leq N} F(u_n^\varepsilon) \\ &= \lim_{N\to\infty} \liminf_{j\to\infty} \sum_{|n|\leq N} F(u_n^j) \leq \liminf_{j\to\infty} \sum_n F(u_n^j).\end{aligned}$$

Next we consider the kinetic energy. Set $\phi^j(\zeta) = \sum_n (u_{n+1}^j - u_n^j) e^{\mathbf{i}\, n\zeta}$. By (6.3),

$$\|\phi^j\|^2_{L^2((0,2\pi))} = 2\pi \sum_n |u_{n+1}^j - u_n^j|^2 \leq 2\pi\varepsilon B_\infty\, \mathbf{E}[u^j].$$

Thus, $\{\phi^j(\cdot)\}_{j=1}^\infty$ is a bounded sequence in $L^2((0,2\pi))$, and we can extract a subsequence, which we still denote by $\{\phi^j\}$, such that for some $\phi^\varepsilon \in L^2((0,2\pi))$, as $j \to \infty$,

$$\phi^j \longrightarrow \phi^\varepsilon \qquad \text{weakly in } \ L^2((0,2\pi)).$$

As weak convergence in $L^2((0,2\pi))$ implies the convergence of the Fourier coefficients, it follows that

$$\phi^\varepsilon = \sum_n (u_{n+1}^\varepsilon - u_n^\varepsilon) e^{\mathbf{i} n\zeta}.$$

Using $|\phi^\varepsilon|^2 = |\phi^j|^2 - |\phi^\varepsilon - \phi^j|^2 + 2\mathrm{Re}\{\phi^\varepsilon\overline{(\phi^\varepsilon - \phi^j)}\} \le |\phi^j|^2 + 2\mathrm{Re}\{\phi^\varepsilon\overline{(\phi^\varepsilon - \phi^j)}\}$, we conclude that, since $B(\zeta)$ is bounded and nonnegative,

$$\int_0^{2\pi} B(\zeta)|\phi^\varepsilon(\zeta)|^2 \le \liminf_{j\to\infty} \int_0^{2\pi} B(\zeta)|\phi^j(\zeta)|^2.$$

Therefore,

$$\mathbf{E}[u^\varepsilon] \le \liminf_{j\to\infty} \mathbf{E}[u^j] = \mathrm{E}(\varepsilon).$$

It remains to show that $u^\varepsilon \in \mathbf{X}$.

First of all, the boundedness of $\mathcal{E}_{po}[u^\varepsilon] = 2\varepsilon\sum_n F(u_n^\varepsilon)$ implies that $\sum_n |(u_n^\varepsilon)^2 - 1|^2 < \infty$. Consequently,

$$\lim_{|n|\to\infty} (u_n^\varepsilon)^2 = 1. \tag{8.2}$$

As $u_n^j < 0$ for all $n \le 0$ and all j, we conclude that $u_n^\varepsilon \le 0$ for all $n \le 0$, so that $\lim_{n\to-\infty} u_n^\varepsilon = -1$, and $\sum_{n\le 0} |u_n^\varepsilon + 1|^2 < \infty$.

It remains to show that $\lim_{n\to\infty} u_n^\varepsilon = 1$.

The finiteness of $\|\phi^\varepsilon\|^2_{L^2((0,2\pi))} = 2\pi\sum_n |u_{n+1}^\varepsilon - u_n^\varepsilon|^2$ implies that there are only finitely many n where $|u_{n+1} - u_n| > 1$. Consequently, from (8.2), either $\lim_{n\to\infty} u_n^\varepsilon = 1$, which concludes our proof, or $\lim_{n\to\infty} u_n^\varepsilon = -1$, which we show below is impossible.

Suppose, on the contrary, that $\lim_{n\to\infty} u_n^\varepsilon = -1$. Let $\eta \in (0,1)$ be any fixed number, and let M be any fixed positive integer. For any $\hat{n}$ sufficiently large, applying Lemma 12 (with the origin at point $\varepsilon\hat{n}$) to u^j and using $|u_{n+1}^j - u_n^j| \le |u_{n+1}^j + 1| + |u_n^j + 1|$, we obtain

$$\mathbf{E}[u^{jr}] + \mathbf{E}[u^{jl}] \le \frac{1 + \bar{b}_M B_\infty}{1-\eta}\mathbf{E}[u^j] + C(\varepsilon,\eta,M) \max_{\hat{n}\le n\le \hat{n}+M} |u_n^j + 1|^2,$$

where $u^{jr} = u, u^{jl} = -1$ for $x \ge (\hat{n} + M + 1/2)\varepsilon$ and $u^{jr} = -1, u^{jl} = u$ for $x \le (\hat{n} - 1/2)\varepsilon$.

Note that $u^{jr} \in \mathbf{X}$, so that $\mathbf{E}[u^{jr}] \ge \mathrm{E}(\varepsilon)$. Also u^{jl} experiences a sign change, so, by Lemma 13, $\mathbf{E}[u^{jl}] \ge e_0$. Thus,

$$e_0 + \mathrm{E}(\varepsilon) \le \frac{1 + \bar{b}_M B_\infty}{1-\eta}\mathbf{E}[u^j] + C(\varepsilon,\eta,M) \max_{\hat{n}\le n\le \hat{n}+M} |u_n^j + 1|^2.$$

Sending j to ∞ then gives

$$e_0 + \mathrm{E}(\varepsilon) \le \frac{1 + \bar{b}_M B_\infty}{1-\eta}\mathrm{E}(\varepsilon) + C(\varepsilon,\eta,M) \max_{\hat{n}\le n\le \hat{n}+M} |u_n^\varepsilon + 1|^2.$$

Sending $\hat{n}$ to ∞ and using $\lim_{n\to\infty} u_n^\varepsilon = -1$, we further obtain $e_0 + \mathrm{E}(\varepsilon) \le \frac{1+\bar{b}_M B_\infty}{1-\eta}\mathrm{E}(\varepsilon)$. Finally, sending $M \to \infty$ first and then $\eta \to 0$, we obtain $e_0 + \mathrm{E}(\varepsilon) \le \mathrm{E}(\varepsilon)$, a contradiction. This contradiction shows that $u^\varepsilon \in \mathbf{X}$. This concludes the proof. ∎

9. Convergence of minimizers to u_0 as $\varepsilon \to 0$. In this section, we establish the convergence part of Theorem 2.

THEOREM 15. *Let $\{u^\varepsilon\}_{\varepsilon>0}$ be the energy minimizing solutions to (5.3) obtained above, translated so that $x = \varepsilon/2$ is the first place where $u^\varepsilon = \sum_n u_n^\varepsilon \chi_n^\varepsilon$ experiences a sign change; i.e., $u_n^\varepsilon < 0$ for all $n \le 0$ and $u_1^\varepsilon \ge 0$. Then*

$$\lim_{\varepsilon \searrow 0} u_\varepsilon = u_0 \qquad \text{in } \ L^\infty(\mathbb{R}),$$
$$\lim_{\varepsilon \searrow 0} (\tilde{u}_\varepsilon - u_0) = 0 \qquad \text{in } \ H^1(\mathbb{R}),$$

where $\tilde{u}^\varepsilon$ is the "companion" of u^ε obtained by a linear interpolation of the node values of u^ε at εn, $n \in \mathbb{Z}$:

$$\tilde{u}^\varepsilon(x) = \sum_n \left\{ u_n^\varepsilon + \frac{(x - \varepsilon n)}{\varepsilon}(u_{n+1}^\varepsilon - u_n^\varepsilon) \right\} \chi_n^\varepsilon(x - \varepsilon/2).$$

To prove the theorem, we need an upper bound on the minimum energy.

LEMMA 16. *Let $\mathrm{E}(\varepsilon) = \mathbf{E}[u^\varepsilon]$ be the minimum of the energy. Then*

$$\limsup_{\varepsilon \searrow 0} \mathrm{E}(\varepsilon) \le \mathrm{E}(0) \equiv \int_{\mathbb{R}} \left\{ \tfrac{1}{2}(u_0')^2 + F(u_0) \right\} dx\,. \tag{9.1}$$

The proof follows by taking u_0 as a test function and using the fact that $\Delta_\varepsilon u_0 - u_0'' \to 0$ in $L^2(\mathbb{R})$. We omit the details.

Proof of Theorem 15. Note that $\tilde{u}^\varepsilon$ is Lipschitz continuous. Also

$$\|\tilde{u}^{\varepsilon\prime}\|_{L^2(\mathbb{R})}^2 = \varepsilon \sum_n \left(\frac{u_{n+1} - u_n}{\varepsilon} \right)^2 \le B_\infty \mathrm{E}(\varepsilon)$$

is uniformly bounded for all $\varepsilon \in (0, 1]$. In addition, $\tilde{u}^\varepsilon$ and u^ε are close in $L^2(\mathbb{R})$ since

$$\|u^\varepsilon - \tilde{u}^\varepsilon\|_{L^2}^2 = \frac{\varepsilon}{12} \sum_n (u_{n+1} - u_n)^2 \le \frac{\varepsilon^2 B_\infty}{12} \mathrm{E}(\varepsilon).$$

Hence, we can interchange $\tilde{u}^\epsilon$ and u^ϵ freely.

Since

$$2 \int_{\mathbb{R}} F(u^\varepsilon) = 2\varepsilon \sum_n F(u_n^\varepsilon) < \mathrm{E}(\varepsilon),$$

we see that $\{\tilde{u}^\varepsilon\}_{0<\varepsilon<1}$ is a bounded family in $H^1((-R, R))$ for any $R > 1$. Hence, there exists a sequence $\{\varepsilon_j\}_{j=1}^\infty$ and a function $u^0 \in H^1_{\mathrm{loc}}(\mathbb{R})$ such that as $j \to \infty$, $\varepsilon_j \to 0$ and

$$\tilde{u}^{\varepsilon_j} - u^0 \longrightarrow 0 \quad \text{weakly in } H^1(\mathbb{R}) \text{ and uniformly in } C^0([-R, R]) \text{ for every } R > 1.$$

Consequently,

$$u^\varepsilon \longrightarrow u^0 \quad \text{ in } L^\infty((-R, R)) \text{ for any } R > 1.$$

Taking any test function $\zeta(\cdot) \in C_0^\infty(\mathbb{R})$, we obtain by passing to the limit in the identity $(u^\varepsilon, -\Delta_\varepsilon \zeta) + (f(u^\varepsilon), \zeta) = 0$ that $(u^0, -\zeta'') + (f(u^0), \zeta) = 0$. That is, u^0 is a weak solution to $-(u^0)'' + f(u^0) = 0$, and consequently, since $(u^0)' \in L^2(\mathbb{R})$, u^0 is a classical solution to $-(u^0)'' + f(u^0) = 0$.

Since $u^\varepsilon \le 0$ for all $x \le 0$, we have $u^0 \le 0$ for all $x \le 0$. Also, from $u^\varepsilon(\varepsilon/2) \ge 0$ we see that $u^0(0) = 0$. Note that u_0 is the only solution to $-u'' + f(u) = 0$ with the property that (1) $u(0) = 0$, (2) $u \le 0$ for $x < 0$, and (3) $\int_{\mathbb{R}} F(u)dx < \infty$. We then conclude that $u^0 = u_0$. The uniqueness of the limit then implies that the whole family $\{u^\varepsilon\}$ converges to u_0 as $\varepsilon \searrow 0$.

Next we show that $u^\varepsilon \to u_0$ in $L^\infty(\mathbb{R})$. It suffices to show that $u^\varepsilon(x) \to \pm 1$ as $x \to \pm\infty$, uniformly in ε. By symmetry, we need only consider $x \to -\infty$.

For this purpose, let $J \gg 1$ be any large integer. First of all, there exists a small positive ε_1 such that for all $\varepsilon \in (0, \varepsilon_1]$, $|u^\varepsilon - u_0| \le 1/J$ on the interval $[-2J, 0]$. Consequently, $|u^\varepsilon + 1| \le 2/J \le m_0$ on $[-2J, -J]$, since u_0 approximates -1 exponentially fast as $x \to -\infty$.

Now consider the interval $x \in [-2J, -J]$. There exists an interval $[x^\varepsilon, x^\varepsilon + 1] \subset [-2J, -J]$ such that

$$\int_{x^\varepsilon}^{x^\varepsilon+1} |\tilde{u}^{\varepsilon\prime}|^2 \le \frac{1}{J}\int_{-2J}^{-J} |\tilde{u}^{\varepsilon\prime}|^2 \le \frac{B_\infty}{J}\mathbf{E}[u^\varepsilon].$$

That is,

$$\sum_{n\in[x^\varepsilon/\varepsilon,(x^\varepsilon+1)/\varepsilon]} \varepsilon\Big|\frac{u^\varepsilon_{n+1} - u^\varepsilon_n}{\varepsilon}\Big|^2 \le \frac{B_\infty \mathbf{E}[u^\varepsilon]}{J}.$$

Consequently, taking $\eta = 1/\sqrt{J}$ and $M = 1/\varepsilon$ (we can assume that $1/\varepsilon$ is an integer), we obtain from the energy decomposition, Lemma 12 (with origin at x^ε), that

$$\begin{aligned}(1 - J^{-1/2})(\mathbf{E}[u^{\varepsilon r}] + \mathbf{E}[u^{\varepsilon l}]) &\le (1 + \bar{b}_{1/\varepsilon}B_\infty)\mathbf{E}[u^\varepsilon] \\ &\quad + 2\sqrt{J}B_\infty\left\{\max_{x\in[x^\varepsilon,x^\varepsilon+1]}|u^\varepsilon + 1|^2 + \frac{1}{\varepsilon}\sum_{n\in[x^\varepsilon/\varepsilon,(x^\varepsilon+1)/\varepsilon]}|u^\varepsilon_{n+1} - u^\varepsilon_n|^2\right\} \\ &\le (1 + \bar{b}_{1/\varepsilon}B_\infty)\mathbf{E}[u^\varepsilon] + C/\sqrt{J}\,,\end{aligned}$$

where C is independent of $\varepsilon \in (0, \varepsilon_1]$ and J. As $u^{\varepsilon r} \in \mathbf{X}$, $\mathbf{E}[u^{\varepsilon r}] \ge \mathbf{E}[u^\varepsilon]$. It then follows that

$$\mathbf{E}[u^{\varepsilon l}] \le C(1/\sqrt{J} + \bar{b}_{1/\varepsilon}).$$

Note that $u^\varepsilon = u^{\varepsilon l}$ for $x \le x^\varepsilon$. We have

$$\begin{aligned}\mathbf{E}[u^{\varepsilon l}] &\ge \sum_{n\le x^\varepsilon/\varepsilon}\Big\{\frac{1}{B_\infty\varepsilon}|u_{n+1} - u_n|^2 + 2\varepsilon F(u^\varepsilon)\Big\} \\ &\ge \frac{2\sqrt{2}}{\sqrt{B_\infty}}\sum_{n\le x^\varepsilon/\varepsilon}|u_{n+1} - u_n|\sqrt{F(u_\varepsilon)} \\ &\ge \frac{2\sqrt{2}}{\sqrt{B_\infty}}\Big|\int_{-1}^{u^\varepsilon(x)}\sqrt{F(s)}ds - O(\sqrt{\varepsilon})\Big|\end{aligned}$$

for any $x \le x^\varepsilon$, since $\sum_{n\le m}|u^\varepsilon_{n+1} - u^\varepsilon_n|\sqrt{F(u^\varepsilon)}$ is not less than a Riemann sum for the integral $|\int_{-1}^{u^\varepsilon_m}\sqrt{F(s)}ds|$ with mesh size no bigger than $\sup_n|u^\varepsilon_{n+1} - u^\varepsilon_n| = O(\sqrt{\varepsilon})$.

We obtain, for all $x \le -2J$ and $\varepsilon \in (0, \varepsilon_1]$,

$$\Big| \int_{-1}^{u^\varepsilon(x)} \sqrt{F(s)} ds \Big| \le C(1/\sqrt{J} + \sqrt{\varepsilon} + \bar{b}_{1/\varepsilon}),$$

where C is independent of J and ε. This inequality implies that $u^\varepsilon \to -1$ as $x \to -\infty$, uniformly in ε. Thus, $u^\varepsilon \to u_0$ uniformly on $\mathbb{R}$.

Finally, we show that $\tilde{u}^\varepsilon - u_0 \to 0$ in $H^1(\mathbb{R})$. First of all, we have

$$(-\Delta_\varepsilon(u^\varepsilon - u_0), u^\varepsilon - u_0) + (f(u^\varepsilon) - f(u_0), u^\varepsilon - u_0) = (\Delta_\varepsilon u_0 - u_0'', u^\varepsilon - u_0).$$

Here, for simplicity, we shall not distinguish between the functions $u_0, u_0^\varepsilon \equiv \sum_n u_0(n\varepsilon)\chi_n^\varepsilon$, and $\tilde{u}_0^\varepsilon = \sum_n \{u_0(n\varepsilon) + [x/\varepsilon - n][u(\varepsilon n + \varepsilon) - u_0(n\varepsilon)]\}\chi_n^\varepsilon(x - \varepsilon/2)$, since with a small error added, one can change from one to the other.

Using (6.3), we have

$$\begin{aligned}(-\Delta_\varepsilon(u^\varepsilon - u_0), u^\varepsilon - u_0) &\ge \frac{1}{B_\infty\, \varepsilon} \sum_n |(u_{n+1}^\varepsilon - u_n^\varepsilon) - (u_{0(n+1)} - u_{0n})|^2 \\ &= \frac{1}{B_\infty} \int_{\mathbb{R}} |\tilde{u}^{\varepsilon\prime} - u_0'|^2\, dx.\end{aligned}$$

Let m_0 be as in (7.1). Then by the $L^\infty(\mathbb{R})$ convergence of u^ε to u_0, there is a positive constant $M > 0$ such that $\{f(u^\varepsilon) - f(u_0)\}\{u^\varepsilon - u_0\} \ge m_0(u^\varepsilon - u_0)^2$ for all $|x| \ge M$ and small enough ε. Thus,

$$(f(u^\varepsilon) - f(u_0), u^\varepsilon - u^0) \ge m_0 \|u^\varepsilon - u_0\|^2 - (m_0 + \|f_u\|_{L^\infty}) \int_{|x|<M} |u^\varepsilon - u_0|^2.$$

In conclusion, for all small enough ε,

$$\frac{1}{B_\infty} \|\tilde{u}^{\varepsilon\prime} - u_0'\|_{L^2}^2 + m_0 \|u^\varepsilon - u_0\|_{L^2}^2 \le C\|u^\varepsilon - u_0\|_{L^2(-M,M)}^2 + |(\Delta_\varepsilon u_0 - u_0'', u^\varepsilon - u_0)|.$$

Sending $\varepsilon \to 0$ and using the inequality $|(\Delta_\varepsilon u_0 - u_0'', u^\varepsilon - u_0)| \le \|\Delta_\varepsilon u_0 - u_0''\|_{L^1(\mathbb{R})} \|u^\varepsilon - u_0\|_{L^\infty}$, we conclude that $\tilde{u}^\varepsilon - u^0 \to 0$ in $H^1(\mathbb{R})$. This completes the proof. ∎

10. Nonuniqueness of stationary wave for small ε. In this section, we show that for small ε, (5.3) admits another solution, which is close to, but different from, any translation of that solution obtained in the previous sections via the energy minimization technique.

10.1. An eigenvalue estimate. First we investigate the operator

$$\mathcal{L}_\varepsilon \phi \equiv -\Delta_\varepsilon \phi + f_u(u_0)\phi \tag{10.1}$$

for functions which are constant on every interval $(\varepsilon(n - 1/2), \varepsilon(n + 1/2)]$, $n \in \mathbb{Z}$, lying in the space

$$\mathbf{X}_0 \equiv \left\{ \phi = \sum_n \phi_n \chi_n^\varepsilon \ : \ \sum_n \phi_n^2 < \infty \right\}.$$

We define

$$\begin{aligned}\Lambda(\varepsilon) &\equiv \inf_{\phi \in \mathbf{X}_0, \|\phi\|_{L^2} = 1, \phi(0) = 0} \Big\{ \| - \Delta_\varepsilon \phi + f_u(u_0)\phi\|_{L^2(\mathbb{R} \setminus (-\varepsilon/2, \varepsilon/2])} \Big\}, \\ \Lambda_0 &\equiv \liminf_{\varepsilon \searrow 0} \Lambda(\varepsilon)\ .\end{aligned}$$

LEMMA 17. $\Lambda_0 > 0$. *Consequently,* $\Lambda(\varepsilon) > \Lambda_0/2$ *for all small positive* ε.

Proof. We use the same idea as that for the nonbalanced potential case. Let $\{\varepsilon_j, \phi_j, \psi_j\}$ be a sequence such that $\lim_{j\to\infty} \varepsilon_j = 0$, $\lim_{j\to\infty} \|\psi_j\|_{L^2(\mathbb{R}\setminus(-\varepsilon_j/2,\varepsilon_j/2])} = \Lambda_0$, and for each $j \geq 1$, $\varepsilon_j > 0, \phi_j \in \mathbf{X}_0, \|\phi_j\|_{L^2} = 1$, $\phi_j = 0$ on $(-\varepsilon_j/2, \varepsilon_j/2]$, and $\psi_j = -\Delta_{\varepsilon_j}\phi_j + f_u(u_0)\phi_j$.

Using the identity $(-\Delta_{\varepsilon_j}\phi_j, \phi_j) + (f_u(u_0)\phi_j, \phi_j) = (\psi_j, \phi_j)$, that $\phi_j = 0$ on $(-\varepsilon_j/2, \varepsilon_j/2]$, and Lemma 11, we obtain

$$\frac{1}{B_\infty}\|\tilde{\phi}_j'\|^2 + \int_{\mathbb{R}} f(u_0)\phi_j^2 \leq \|\phi_j\|_{L^2}\|\psi_j\|_{L^2(\mathbb{R}\setminus(-\varepsilon_j/2,\varepsilon_j/2])},$$

where $\tilde{\phi}_j$ is the linear interpolant of ϕ at node points. It then follows that $\|\tilde{\phi}'\|_{L^2}$ is uniformly bounded. Consequently, $\|\phi_j - \tilde{\phi}_j\|_{L^2(\mathbb{R})}$ is of size $O(\varepsilon_j^2)$.

Thus, we can select a subsequence from $\{\tilde{\phi}_j, \psi_j\}$, still denoted by $\{\tilde{\phi}_j, \psi_j\}$, such that for some $\phi \in H^1(\mathbb{R})$ and $\psi \in L^2(\mathbb{R})$,

$$\begin{aligned} \tilde{\phi}_j &\longrightarrow \phi \qquad \text{in } L^2_{\text{loc}}(\mathbb{R}) \text{ and weakly in } H^1(\mathbb{R}), \\ \psi_j &\longrightarrow \psi \qquad \text{weakly in } L^2_{\text{loc}}(\mathbb{R}\setminus\{0\}). \end{aligned}$$

In addition, $\phi(0) = 0$. In the weak formulation, one can show that $-\phi'' + f(u_0)\phi = \psi$ in $\mathbb{R}\setminus\{0\}$. By an estimate similar to (3.10), (3.11), we conclude that $\Lambda_0 > 0$. This completes the proof. ∎

10.2. Energy minimizer with constraint. For every $\alpha \in (-1, 1)$ we define

$$\mathbf{X}_\alpha \equiv \left\{ u = \sum_n u_n \chi_n^\varepsilon \;:\; u_0 = \alpha,\ \sum_{n>0} |1 - u_n|^2 + \sum_{n<0} |1 + u_n|^2 < \infty \right\}.$$

Define

$$E(\alpha, \varepsilon) \equiv \inf_{u\in\mathbf{X}_\alpha} \mathbf{E}[u], \quad \mathrm{E}(\varepsilon) = \inf_{\alpha\in(-1,1)} E(\alpha, \varepsilon).$$

We note that $\mathrm{E}(\varepsilon)$ is the energy of the minimizer we studied in the previous sections.

LEMMA 18. *There exists* $\varepsilon_0 > 0$ *such that for every* $\alpha \in [-1/2, 1/2]$ *and* $\varepsilon \in (0, \varepsilon_0]$, *there exists* $u_\varepsilon^\alpha \in \mathbf{X}_\alpha$ *such that* $\mathbf{E}[u_\varepsilon^\alpha] = E(\alpha, \varepsilon)$.

Proof. The proof follows the same lines as that of Theorem 8. We can extract a (weak) limit from a minimizing sequence. This limit is a minimizer if it is in $\mathbf{X}_\alpha$. To show this, we follow the same contradiction argument as before, obtaining the inequality $\tilde{e}_0 + \mathrm{E}(\varepsilon) \leq E(\alpha, \varepsilon)$, where $\tilde{e}_0$ is the minimum energy among all functions which take the value α at the origin. To contradict $\tilde{e}_0 + \mathrm{E}(\varepsilon) \leq E(\alpha, \varepsilon)$, we have to assume that ε is small. In fact, for small ε, $\mathrm{E}(\varepsilon) = \mathrm{E}(0) + o(1)$ (Theorem 14), and $\tilde{e}_0 > C(\min\{\int_{-1}^{\alpha} \sqrt{F(s)}ds, \int_{\alpha}^{1} \sqrt{F(s)}ds\} - O(\sqrt{\varepsilon}))$. Also, taking an appropriate test function shows that $E(\alpha, \varepsilon) \leq \mathrm{E}(0) + o(1)$. Therefore, $\tilde{e}_0 + E(\varepsilon) > E(\alpha, \varepsilon)$ for all small positive ε and all $\alpha \in [-1/2, 1/2]$. This inequality shows that the limit of the minimizer has the correct asymptotics, thereby establishing the existence of a minimizer u_ε^α. We omit the details. ∎

LEMMA 19. *For every* $\delta > 0$, *there exists* $\varepsilon_1(\delta) > 0$ *such that if* $\varepsilon \in (0, \varepsilon_1(\delta)], \alpha \in [-1/2, 1/2]$ *and* $u_\varepsilon^\alpha \in \mathbf{X}_\alpha$ *is a minimizer of* $\mathbf{E}[u]$ *in* $\mathbf{X}_\alpha$, *then* $\|u_\varepsilon^\alpha - u_0(z(\alpha) + \cdot)\|_{L^2\cap L^\infty} \leq \delta$, *where* $z(\alpha)$ *is the point satisfying* $u_0(z(\alpha)) = \alpha$.

The proof follows the same lines as that of Theorem 14 and is omitted.

LEMMA 20. *There exists $\varepsilon_2 > 0$ such that for every $\varepsilon \in (0, \varepsilon_2]$ and $\alpha \in [-1/2, 1/2]$, the minimizer $u_\varepsilon^\alpha \in \mathbf{X}_\alpha$ for $\mathbf{E}[u]$ in $\mathbf{X}_\alpha$ is unique.*

Proof. Let $u_\epsilon^{\alpha,1}$ and $u_\varepsilon^{\alpha,2}$ be two minimizers. Set $\phi = u_\varepsilon^{\alpha,1} - u_\varepsilon^{\alpha,2}$. Then ϕ satisfies the equation

$$-\Delta_\varepsilon \phi + f_u(u_0(\bar{z}(\alpha) + x))\phi = r(x, \phi(x))\phi \quad \text{for all } x \in \mathbb{R} \setminus (-\varepsilon/2, \varepsilon/2],$$

where $r(x, \phi(x)) \equiv \int_0^1 [f_u(u^{\alpha,1}(x) + s\phi(x)) - f_u(u_0(\bar{z}(\alpha) + x))]ds$ and $\bar{z}(\alpha)$ is an integer multiple of ε with $|z(\alpha) - \bar{z}(\alpha)| \le \varepsilon/2$. In view of the previous lemma, we see that when $\varepsilon \le \varepsilon_1(\delta)$, $|r(x, \phi(x))| \le C\delta$, where C is a constant depending only on f. Hence, by the eigenvalue estimate in Lemma 17,

$$\|\phi\|_{L^2} \le \frac{\|r(\cdot, \phi(\cdot))\|_{L^\infty}}{\Lambda(\varepsilon)} \|\phi\|_{L^2(\mathbb{R}\setminus(-\varepsilon/2, \varepsilon/2])}.$$

From this we conclude that $\phi = 0$ if we take $\delta = \Lambda_0/(4C)$ and let ε be small enough such that $\Lambda(\varepsilon) \ge \Lambda_0/2$. This completes the proof. ∎

LEMMA 21. *For every $\varepsilon \in (0, \varepsilon_2]$, $E(\alpha, \varepsilon)$ is continuously differentiable in $\alpha \in (-1/2, 1/2)$ and*

$$\frac{d}{d\alpha} E(\alpha, \varepsilon) = 2\varepsilon\{-\Delta_\varepsilon u_\varepsilon^\alpha + f(u_\varepsilon^\alpha)\}\Big|_{x=0}. \tag{10.2}$$

Consequently, u_ε^α solves (5.2) if and only if $\frac{d}{d\alpha} E(\alpha, \varepsilon) = 0$.

Proof. Denote by $L(\alpha, \varepsilon)$ the right-hand side of (10.2). Since the uniqueness of u_ε^α implies the continuity of u_ε^α in α, $L(\alpha, \varepsilon)$ is continuous in $\alpha \in (-1/2, 1/2)$.

For any small positive h, we have

$$\begin{aligned} E(\alpha + h, \varepsilon) &\le \mathbf{E}[u_\varepsilon^\alpha + h\chi_\varepsilon^0] \\ &= E(\alpha, \varepsilon) + L(\alpha, \varepsilon)h + \varepsilon(-\Delta_\varepsilon \chi_\varepsilon^0, \chi_\varepsilon^0)h^2 + 2\varepsilon\{F(\alpha + h) - F(\alpha) - f(\alpha)h\}. \end{aligned}$$

Similarly, we have

$$E(\alpha, \varepsilon) \le E(\alpha + h, \varepsilon) - L(\alpha + h, \varepsilon)h + O(h^2).$$

It then follows that, for all small positive h,

$$L(\alpha + h, \varepsilon) + O(h) \le \frac{E(\alpha + h, \varepsilon) - E(\alpha, \varepsilon)}{h} \le L(\alpha, \varepsilon) + O(h). \tag{10.3}$$

The assertion (10.2) thus follows by letting $h \searrow 0$.

Note that the minimizer u_ε^α in $\mathbf{X}_\alpha$ satisfies $-\Delta_\varepsilon u_\varepsilon^\alpha + f(u_\varepsilon^\alpha) = 0$ in $\mathbb{R} \setminus (-\varepsilon/2, \varepsilon/2]$. Hence, u_ε^α solves (5.2) if and only if $\frac{d}{d\alpha} E(\alpha, \varepsilon) = 0$. ∎

The final part of Theorem 2 is that which gives a second stationary wave for $\varepsilon > 0$ sufficiently small.

THEOREM 22. *For every $\varepsilon \in (0, \varepsilon_2]$, problem (5.3) admits at least two solutions, u_ε^1 and u_ε^2, which differ by more than translation, and as $\varepsilon \to 0$, $\|u_\varepsilon^i - u_0\|_{L^\infty(\mathbb{R})} \to 0$, $i = 1, 2$.*

Proof. Let u_ε be one of the global minimizers given in Theorem 14. We write $u_\varepsilon = \sum_n u_n^\varepsilon \chi_n^\varepsilon$. Let $(a, b) \subset [-1/2, 1/2]$ be an interval such that for some integers n_1 and n_2, $a = u_{n_1}^\varepsilon < b = u_{n_2}^\varepsilon$.

Consider the differentiable function $E(\alpha, \varepsilon)$ for $\alpha \in [a, b]$.

If $E(\alpha,\varepsilon)$ is a constant function, then every u_ε^α is a solution to (5.2), and hence we have a continuum of solutions to (5.3).

If $E(\alpha,\varepsilon)$ is not a constant function, then as it attains the global minimum $\mathrm{E}(\varepsilon)$ at $\alpha = a$ and $\alpha = b$, there exists at least a local maximum of $E(\cdot,\varepsilon)$ attained at some $c \in (a,b)$, at which $\frac{d}{d\alpha}E(c,\varepsilon) = 0$. Consequently, the local saddle $u_\varepsilon^c \in \mathbf{X}_c$ is a solution to (5.3). Clearly, u_ε^c is different from any translation of u_ε since their energies are different. Translating u_ε^c and using Lemma 19 completes the proof. □

Remark 8. (1) We do not know if (5.2) admits a continuous solution. If this is true, then $E(\alpha,\varepsilon)$ is simply a constant function and (5.2) has a continuum of truly different solutions, even though they are obtained by translating the underlying continuous profile. It is shown in [14], for example, that starting with a particular wave profile, such as $u(x) = \tanh(\mu x)$, one can reverse engineer a nonlinearity so that this is a traveling wave for a discrete bistable equation with nearest neighbor coupling. For the profile given here, the equation is

$$cu'(x) = \frac{1}{\varepsilon^2}[u(x+1) - 2u(x) + u(x-1)] - c\mu(1-u(x)^2) - \frac{2}{\varepsilon^2}\frac{u(x)}{1+(1-u(x)^2)\sinh^2\mu} + \frac{2u(x)}{\varepsilon^2}.$$

(2) If $f(u)$ is odd and α_k decays to zero exponentially fast in k (e.g., only finitely many nonzero α_k's), one can show that $E(\alpha,\varepsilon) - E(\varepsilon)$ is small beyond any power of ε. The idea is as follows.

Write, as an asymptotic approximation,

$$\Delta_\varepsilon \sim \frac{d^2}{dx^2} + \sum_{n=2}^{\infty} \varepsilon^{2n} a_n \frac{d^{2n}}{dx^{2n}}\ .$$

One looks for an asymptotic solution

$$u_\varepsilon \sim u_0(x) + \sum_{n=1}^{\infty} \varepsilon^n U_n(x), \qquad \text{with } U_n(x) = -U_n(-x),$$

to the equation

$$-u_\varepsilon'' + f(u_\varepsilon) - \sum_{n=2}^{\infty} \varepsilon^{2n} a_n \frac{d^{2n}}{dx^{2n}} u_\varepsilon \sim 0.$$

One can show that all U_n, $n = 1, 2, \dots$, exist, and are uniquely determined, by using the symmetry assumption. For more details, see Chen et al. [5].

Now fix any order of approximation, K, desired. Set $u_\varepsilon^K = u_0 + \sum_{n=1}^K \varepsilon^k U_k(x)$. Then

$$-\Delta u_\varepsilon^K + f(u_\varepsilon^K) = O(\varepsilon^{K+1}) \qquad \text{on } \mathbb{R}.$$

For any $\alpha \in [-1/2, 1/2]$, let $z = z^{\varepsilon,K}(\alpha)$ be such that $u_\varepsilon^K(z) = \alpha$. Define $u_\varepsilon^{K,\alpha}(x) = \sum_n u_\varepsilon^K(z + \varepsilon n)\chi_n^\varepsilon$.

Consider the function $\tilde{E}(\alpha,\varepsilon) = \mathbf{E}[u_\varepsilon^{K,\alpha}]$. Since $u_\varepsilon^{K,\alpha}$ satisfies (5.3) up to order ε^{K+1}, one can show that $\frac{d}{d\alpha}\tilde{E}(\alpha,\varepsilon) = O(\varepsilon^{K+1})$ and hence is almost independent of α. On the other hand, following our proof of uniqueness of u_ε^α, one can show that $\|u_\varepsilon^\alpha - u_\varepsilon^{K,\alpha}\|_{L^2}$ is of order ε^{K+1}. Thus, $E(\alpha,\varepsilon) = \tilde{E}(\alpha,\varepsilon) + O(\varepsilon^{K+1})$. As K is arbitrary, we see that $E(\alpha,\varepsilon)$ is a constant, subject to a correction which is smaller than any power of ε, asymptotically.

Remark 9. The uniqueness of u_ε^α indeed implies that $u_\varepsilon^\alpha(\cdot)$ is monotonic in the range $[-1/2, 1/2]$. The reason is as follows. Suppose on the contrary that $u_\varepsilon^\alpha(\cdot)$ is not monotonic in this range. Then, by translation, it attains a local maximum, say $a \in (-1/2, 1/2]$, at the origin. Set $c = u_\varepsilon^a(\varepsilon)$ and $B(\alpha) = u_\varepsilon^\alpha(-\varepsilon)$, and let α vary from a to c. Then $B(a) = u_\varepsilon^a(-\varepsilon) \le a$ and $B(c) = u_\varepsilon^c(-\varepsilon) = u_\varepsilon^a(0) = a \ge c$. Thus, by the continuity of $B(\cdot)$, there exists $\hat\alpha \in [c, a]$ such that $B(\hat\alpha) = \hat\alpha$; that is, $u_\varepsilon^{\hat\alpha}(0) = u^{\hat\alpha}(-\varepsilon)$. Hence, by the uniqueness, we must have $u^{\hat\alpha}(-\varepsilon + \cdot) = u^{\hat\alpha}(\cdot)$, which is impossible. Therefore, in the range $[-1/2, 1/2]$, $u_\varepsilon^\alpha(\cdot)$ is monotonic. Of course, as ε becomes smaller, the interval $[-1/2, 1/2]$ can be made arbitrarily close to $(-1, 1)$. We are not sure whether or not u_ε^α is monotonic overall.

SOLVING TIME-HARMONIC SCATTERING PROBLEMS BASED ON THE POLE CONDITION II: CONVERGENCE OF THE PML METHOD*

THORSTEN HOHAGE†, FRANK SCHMIDT‡, AND LIN ZSCHIEDRICH‡

Abstract. In this paper we study the PML method for Helmholtz-type scattering problems with radially symmetric potential. The PML method consists of surrounding the computational domain with a perfectly matched sponge layer. We prove that the approximate solution obtained by the PML method converges exponentially fast to the true solution in the computational domain as the thickness of the sponge layer tends to infinity. This is a generalization of results by Lassas and Somersalo based on boundary integral equation techniques. Here we use techniques based on the pole condition instead. This makes it possible to treat problems without an explicitly known fundamental solution.

Key words. transparent boundary conditions, perfectly matched layer, pole condition

AMS subject classification. 65N12

DOI. 10.1137/S0036141002406485

1. Introduction. Since the first paper on the subject by Bérenger in 1994 [1], the perfectly matched layer (PML) method has become very popular due to its accuracy, simplicity, and flexibility. In this article we explore the connections between the PML method for time-harmonic scattering problems and the methods based on the pole condition, which are discussed in [4]. We start with a brief summary of the derivation of the PML equations. Let $u(r,\hat{x})$ denote the solution to the scattering problem in a coordinate system consisting of a radial variable $r > 0$ and a vector of angular variables $\hat{x}$. The first step of the PML method consists of a complex extension of the solution $u(\cdot,\hat{x})$ along some given path $\gamma : [a,\infty) \to \mathbb{C}$, $a > 0$, which satisfies

$$\gamma(a) = a, \qquad \operatorname{Re}\gamma(r) = r \text{ and } \operatorname{Im}\gamma'(r) \geq 0 \text{ for } r > a.$$

In Cartesian coordinates the so-called Bérenger solution $u^{(\mathrm{B})}(r,\hat{x}) := u(\gamma(r),\hat{x})$ satisfies a Helmholtz-type equation with an anisotropic damping tensor. If u is outgoing, then $u^{(\mathrm{B})}(r,\hat{x})$ decays exponentially as $r \to \infty$. On the other hand, $u^{(\mathrm{B})}(r,\hat{x})$ grows exponentially if u is an incoming field. Therefore, the Sommerfeld radiation condition for u is equivalent to the boundedness of $u^{(\mathrm{B})}(r,\hat{x})$. In a second step, the boundedness condition for $u^{(\mathrm{B})}(r,\hat{x})$ is replaced by the zero Dirichlet condition $u^{(\mathrm{B})}(\rho,\hat{x}) = 0$ at some finite distance $\rho > a$. We end up with an elliptic boundary value problem on a bounded domain, which can be solved by standard finite element codes.

The analysis in this paper is based on the work of Collino and Monk [2] and Lassas and Somersalo [8]. We show that, for the Helmholtz equation with a radially symmetric potential, the solution to the PML equations converges exponentially to the true solution within the ball $\{x : |x| < a\}$ as $\rho \to \infty$. In [9] Lassas and Somersalo show

the exponential convergence of the PML method for general convex computational domains, but constant exterior potentials. In [7] the PML method for Maxwell's equations is interpreted as a complexification of the metric. Our proof proceeds along the same lines as in [8], but we replace integral equation techniques with a representation formula derived in [4]. This allows us to treat problems for which no fundamental solution is known explicitly. In particular, as shown in numerical experiments, the method converges for inhomogeneous exterior domains involving waveguide structures; see [5, 6, 10]. However, the analysis presented in this paper covers only radially symmetric potentials.

We also show that there exists a close connection between the exponential decay of Bérenger solutions and the pole condition. The former condition always implies the latter, and under certain conditions on the singularities in the Laplace domain, the converse implication holds true as well. As a consequence, the class of applications of the PML method and methods based on the pole condition is almost the same within the class of time-harmonic scattering problems. For a comparison of the numerical performance of the two methods, we refer to [6]. A potential advantage of methods based on the pole condition is the possibility to evaluate the exterior field numerically by a representation formula if the location and the type of the singularities in the Laplace domain are known. This is particularly relevant if a fundamental solution is not known explicitly. Otherwise, the exterior field can be evaluated by Green's representation formula.

The plan of this paper is as follows. In section 2 we introduce the class of problems considered in this paper and the corresponding Dirichlet-to-Neumann (DtN) map. Section 3 deals with the analytic continuation properties of the solution and the relation to the pole condition. In section 4 a more detailed derivation of the PML equations is given. Finally, in section 5 we prove our main theorem on the exponential convergence of the solutions to the PML equations as $\rho \to \infty$.

2. Helmholtz scattering problem and the DtN-operator. We are concerned with Helmholtz-type scattering problems

$$\Delta u(x) + k^2(x)\, u(x) = 0 \text{ in } \mathbb{R}^d \setminus K, \tag{2.1a}$$

$$\frac{\partial}{\partial \nu} u|_{\partial K} = f, \tag{2.1b}$$

$$\lim_{r\to\infty} r^{\frac{d-1}{2}} \left(\frac{\partial u}{\partial r} - i\kappa u \right) = 0. \tag{2.1c}$$

Here $K \subset \mathbb{R}^d$ denotes a compact smooth set, $f \in H^{-1/2}(\partial K)$, and ν is the normal vector on ∂K pointing to the interior of K. We assume that k is a bounded, continuous function which is given by

$$k^2(x) = (1 + p(|x|))\,\kappa^2 \text{ for } |x| \geq a_*.$$

Here $p\left(t^{-1}\right) = \sum_{m=2}^{\infty} p_m t^m$ has a convergence radius greater than $\frac{1}{a_p}$, $a_p \in (0, \infty]$ with $a_* > a_p$. As proved in [4] the above system has a unique solution. We are interested only in the restriction of the solution to the interior domain $\Omega_a = B_a^d \setminus \overline{K}$, where $a > a_*$. We denote $u^{(\mathrm{int})}(x) = u(x)$, $x \in \Omega_a$. $u^{(\mathrm{int})}$ is the unique solution to the variational problem

$$\int_{\Omega_a} \nabla u \nabla \overline{v}\, \mathrm{d}x - \int_{\Omega_a} k^2 u \overline{v}\, \mathrm{d}x - \int_{S_a^{d-1}} \mathrm{DtN}_a u \overline{v}\, \mathrm{d}s = \int_{\partial K} f \overline{v}\, \mathrm{d}s \tag{2.2}$$

for all $v \in H^1(\Omega_a)$ (see [4]). The corresponding boundary value problem is

$$\Delta u^{(\mathrm{int})} + k^2 u^{(\mathrm{int})} = 0 \quad \text{in } \Omega_a, \tag{2.3a}$$

$$\partial_n u^{(\mathrm{int})} = f \quad \text{on } \partial K, \tag{2.3b}$$

$$\partial_r u^{(\mathrm{int})} - \mathrm{DtN}_a u^{(\mathrm{int})} = 0 \quad \text{on } S_a^{d-1}. \tag{2.3c}$$

Here $S_a^{d-1} := \left\{x \in \mathbb{R}^d \,:\, |x| = a\right\}$ and $\mathrm{DtN}_a : H^{1/2}\left(S_a^{d-1}\right) \to H^{-1/2}\left(S_a^{d-1}\right)$ denotes the DtN map defined as follows. Given $g \in H^{1/2}\left(S_a^{d-1}\right)$

$$\mathrm{DtN}_a g = \partial_r u^{(\mathrm{ext})}|_{S_a^{d-1}},$$

where $u^{(\mathrm{ext})}$ is the unique solution to the exterior problem

$$\Delta u^{(\mathrm{ext})} + k^2 u^{(\mathrm{ext})} = 0 \text{ in } D_{a,\infty}, \tag{2.4a}$$

$$u^{(\mathrm{ext})}|_{\partial S_a^{d-1}} = g, \tag{2.4b}$$

$$\lim_{r\to\infty} r^{\frac{d-1}{2}} \left(\frac{\partial u^{(\mathrm{ext})}}{\partial r} - i\kappa u^{(\mathrm{ext})}\right) = 0. \tag{2.4c}$$

Here and in the following we use the notation

$$D_{\theta_1,\theta_2} = B_{\theta_2}^d \setminus \overline{B_{\theta_1}^d}, \qquad D_{\theta_1,\infty} = \mathbb{R}^d \setminus \overline{B_{\theta_1}^d}. \tag{2.5}$$

We call the boundary condition (2.3c) transparent because it leads to the exact solution in the interior domain without any spurious reflections. It can be seen from the above definition of the DtN_a-operator that the boundary condition (2.3c) is nonlocal. In particular, it is not given by a finite sum of differential operators acting on the boundary S_a^{d-1}. Due to the presence of the potential p, neither an integral representation nor a series representation of the DtN_a-operator is known explicitly. Therefore, it cannot be used directly for a finite element approximation of the interior problem. Nevertheless it will provide the theoretical framework of our convergence proof, where we interpret the action of the sponge layer as a perturbation of the DtN_a-operator.

3. The pole condition and analytic continuation of the exterior solution. We introduce polar coordinates $r > 0$ and $\hat{x} \in S_1^{d-1}$ in $\mathbb{R}^d$. With a slight misuse of notation, we use the same letter for exterior fields in polar and Cartesian coordinates, i.e., $u(r,\hat{x}) = u(r\hat{x})$. If u is a solution to the boundary problem (2.4), we will show that $u(\cdot,\hat{x})$ has a holomorphic extension to $\mathbb{C}_a^{++} = \{z \in \mathbb{C} \,:\, \mathrm{Re}\, z > a,\ \mathrm{Im}\, z \geq 0\}$. Recall that the Laplace operator in polar coordinates is given by $\frac{1}{r^{d-1}}\partial_r\left(r^{d-1}\partial_r\right) + \frac{1}{r^2}\Delta_{\hat{x}}$, where $\Delta_{\hat{x}}$ denotes the Laplace–Beltrami operator on the unit sphere. We replace the real coordinate r with the complex variable z and define

$$\Delta_z = \frac{1}{z^{d-1}}\frac{\partial}{\partial z} z^{d-1} \frac{\partial}{\partial z} + \frac{1}{z^2}\Delta_{\hat{x}}.$$

As usual, we define $\frac{\partial}{\partial z} f(z) := \lim_{\tilde{z}\in\mathbb{C}_a^{++}\to z} \frac{f(\tilde{z})-f(z)}{\tilde{z}-z}$. Thus, ∂_z is a one-sided derivative on the real axis. We consider nonstandard boundary value problems of the form

$$\Delta_z u(z,\hat{x}) + k^2(z)\, u(z,\hat{x}) = 0, \qquad z \in \mathbb{C}_{z_0}^{++},\ \hat{x} \in S_1^{d-1}, \tag{3.1a}$$

$$u(z_0,\cdot) = \tilde{g}, \tag{3.1b}$$

$$\lim_{\mathrm{Re}\, z\to\infty} z^{\frac{d-1}{2}} \left(\frac{\partial}{\partial z} u - i\kappa u\right) = 0, \tag{3.1c}$$

where boundary condition (3.1b) has to be understood in the sense of the trace operator. We will also have to consider the case $\operatorname{Im} z_0 > 0$, where we seek a solution defined on $\mathbb{C}^{++}_{z_0} = \{z \in \mathbb{C} : \operatorname{Re} z > \operatorname{Re} a,\ \operatorname{Im} z \geq \operatorname{Im} z_0\}$. Since the energy argument in [4, Lemma 8.1] is no longer valid in this case, we cannot guarantee uniqueness in general. However, we will show in Lemma 5.3 that uniqueness is given if z_0 satisfies certain conditions. The next theorem is a generalization of [4, Theorems 8.4 and 9.3] for complex arguments. Since the proof is almost the same, it is omitted here.

THEOREM 3.1. *Let $z_0 \in \mathbb{C}^{++}_a$ and assume that (3.1) with $\tilde{g} = 0$ has only the trivial solution. Then the following hold true:*

1. *There exists a unique solution $u \in C^2\left(\mathbb{C}^{++}_{z_0} \times S_1^{d-1}\right)$ to (3.1) for all $\tilde{g} \in H^{1/2}\left(S_1^{d-1}\right)$.*
2. *There exist functions $u_\infty \in C^\infty\left(S_1^{d-1}\right)$ and $\Psi \in C^1\left(\mathbb{R}_+ \times S_1^{d-1}\right)$ and a constant $\tilde{a} > \operatorname{Re} z_0$ such that the above solution is given by*

$$u(z,\hat{x}) = z^{\frac{1-d}{2}} e^{i\kappa z}\left(u_\infty(\hat{x}) + \int_0^\infty e^{-t(z-\tilde{a})}\Psi(t,\hat{x})\,\mathrm{d}t\right) \tag{3.2}$$

for $\operatorname{Re} z \geq \tilde{a}$. $\Psi(t,\hat{x})$ decays exponentially as $t \to \infty$. The formula (3.2) may be differentiated any number of times with respect to both z and $\hat{x}$; integration and differentiation may be interchanged. Moreover, given $m \in \{0,1\}$ and $l \in \{0,1,\dots\}$, there exists a constant $C > 0$ such that

$$\left\|u_\infty\right\|_{C^l\left(S_1^{d-1}\right)} \leq C\left\|\tilde{g}\right\|_{L^2}, \tag{3.3}$$

$$\int_0^\infty t^k \left\|\frac{\partial^m}{\partial t^m}\Psi(t,\cdot)\right\|_{C^l\left(S_1^{d-1}\right)} \mathrm{d}t \leq C\left\|\tilde{g}\right\|_{L^2}. \tag{3.4}$$

Let us consider the restriction $v_a(z) := u(z+a,\hat{x})$, $z \in \mathbb{C}^{++}_0$, of the solution to a ray with direction $\hat{x} \in S_1^{d-1}$. It follows from (3.2), (3.3), and (3.4) that

$$v_a \text{ has a holomorphic extension to } \mathbb{C}^{++}_0 \text{ and} \tag{3.5a}$$

$$\sup_{z \in \mathbb{C}^{++}_0} |e^{-i\kappa z} v_a(z)| < \infty, \tag{3.5b}$$

i.e., that $v_a(z)$ decays exponentially as $\operatorname{Im} z \to \infty$. Since, for an incoming wave, $v_a(z)$ grows exponentially as $\operatorname{Im} z \to \infty$, the exponential decay of $v_a(z)$ as $\operatorname{Im} z \to \infty$ characterizes outgoing waves. At the same time it is the foundation of the PML method.

The pole condition is an alternative characterization of outgoing waves, which is also the basis of numerical algorithms (cf. [5, 6]). For the differential equation (2.1a), (2.1c), we have shown in [4] that the Laplace transform $\hat{v}_a(s) := \int_0^\infty e^{-rs} v_a(r)\,\mathrm{d}r$, $\operatorname{Re} s > 0$, satisfies the condition

$$\hat{v}_a \text{ has a holomorphic extension to } \{s \in \mathbb{C} : \operatorname{Im} s < \tilde{\kappa}\}, \tag{3.6a}$$

$$\sup_{\operatorname{Im} s < 0} |s + i\tilde{\kappa}||\hat{v}_a(s + i\tilde{\kappa})| < \infty \tag{3.6b}$$

for $\tilde{\kappa} \leq \kappa$. For general differential equations, e.g., problems with waveguides, we do not have a proof that either (3.5) or (3.6) is an appropriate characterization of outgoing waves sufficient to show both existence and uniqueness of a solution. Let us now look at the relation between the conditions (3.5) and (3.6).

THEOREM 3.2. *Let $\tilde{\kappa} < \kappa$ and $\tilde{a} > a$. If $v_a : (0,\infty) \to \mathbb{C}$ satisfies (3.5), then $v_{\tilde{a}}(r) := v_a(r + \tilde{a} - a)$ satisfies (3.6).*

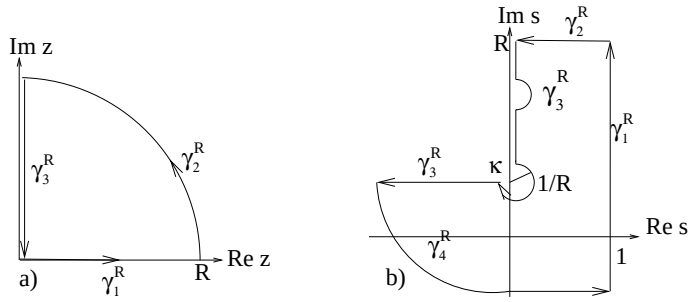

FIG. 3.1. *Relation of the pole condition and the exponential decay of the Bérenger functions.*

Proof. For the contour in Figure 3.1(a), we have $\int_{\gamma_1^R+\gamma_2^R+\gamma_3^R} e^{-sz} v_{\tilde{a}}(z)\,\mathrm{d}z = 0$ for all $R > 0$ by Cauchy's integral theorem. Since $\lim_{R\to\infty} \int_{\gamma_2^R} e^{-sz} v_{\tilde{a}}(z)\,\mathrm{d}z = 0$ for $\operatorname{Re} s > 0$ and $\operatorname{Im} s \le 0$ due to (3.5), it follows that

$$\hat{v}_{\tilde{a}}(s) = \lim_{R\to\infty} \int_{\gamma_1^R} e^{-sz} v_{\tilde{a}}(z)\,\mathrm{d}z = -\lim_{R\to\infty} \int_{\gamma_3^R} e^{-sz} v_{\tilde{a}}(z)\,\mathrm{d}z = \int_0^\infty e^{-sit} v_{\tilde{a}}(it)\, i\mathrm{d}t.$$

A partial integration yields

$$(s + i\tilde{\kappa})\hat{v}_{\tilde{a}}(s + i\tilde{\kappa}) = v_{\tilde{a}}(0) + \int_0^\infty e^{-sit + s\tilde{\kappa}t} v'_{\tilde{a}}(it)\, i\mathrm{d}t. \tag{3.7}$$

Differentiating Cauchy's formula $v_a(z) = (2\pi i)^{-1} \int_{\{|\zeta - z| = \epsilon\}} v_a(\zeta)(\zeta - z)^{-1}\,\mathrm{d}\zeta$ with $z = it + \tilde{a} - a$ and $0 < \epsilon < \tilde{a} - a$ and using assumption (3.5b), we obtain

$$|v'_{\tilde{a}}(it)| = |v'_a(it + \tilde{a} - a)| \le \sup_{|\zeta - z| \le \epsilon} \epsilon^{-1} |v_a(\zeta)| \le Ce^{-\kappa t}$$

for all $t > 0$ with some constant $C > 0$. Since $\tilde{\kappa} < \kappa$, the integrand in (3.7) decays exponentially with t for $\operatorname{Im} s \le 0$. This shows that (3.6) holds true. ∎

We immediately obtain the following.

COROLLARY 3.3. *If $u \in C(\mathbb{C}^{++}_{a_*} \times S_1^{d-1})$ is holomorphic in the first variable and satisfies*

$$\sup_{z \in \mathbb{C}^{++}_{a_*}, \hat{x} \in S^{d-1}} |e^{-i\kappa z} z^{\frac{d-1}{2}} u(z, \hat{x})| < \infty \tag{3.8}$$

for $\kappa > 0$, then u satisfies the pole condition; i.e., the functions $\hat{U}_a(s, \hat{x}) := \int_0^\infty e^{-sr}(r + a)^{(d-1)/2} u(r + a, \hat{x})\,\mathrm{d}r$, initially defined for $\Re s > 0$, have holomorphic extensions to $\{s \in \mathbb{C} : \Im s < 0\}$ for all $\hat{x} \in S^{d-1}$ and all $a > a_*$.

The converse, that the pole condition implies the exponential decay of the Bérenger function, follows from the representation formula (3.2) for problems of the form (2.1). The basic idea of the proof of this formula is a contour deformation in the Fourier inversion formula

$$v_a(r) = \frac{1}{2\pi i} \lim_{R\to\infty} \int_{\gamma_1^R} e^{sr} \hat{v}_a(s)\,\mathrm{d}s, \qquad r > 0$$

(cf. Figure 3.1(b)). We assume that v_a is smooth and satisfies (3.6). Then we have $\lim_{R\to\infty}\int_{\gamma_2^R+\gamma_4^R} e^{sz}\hat{v}_a(s)\,\mathrm{d}s = 0$, and it follows from Cauchy's integral theorem that

$$v_a(z) = -\frac{1}{2\pi i}\lim_{R\to\infty}\int_{\gamma_3^R} e^{sz}\hat{v}_a(s)\,\mathrm{d}s \tag{3.9}$$

for $z > 0$. Here the path γ_3^R is chosen such that the distance to the singularities of $\hat{v}_a(s)$ is $\geq 1/R$. If the above limit exists, not only for $z > 0$ but also for $z \in \mathbb{C}_0^{++}$, we obtain the desired extension of v_a to $\mathbb{C}_0^{++}$. However, without further information on the singularities, we cannot guarantee that this limit exists and use it to estimate $|v_a(z)|$ for $z \in \mathbb{C}_0^{++}$. Only if $\hat{v}_a$ is sufficiently well behaved can we derive the bound (3.5b).

4. The PML equations. We assume that $\gamma(r) = r\left(1 + \frac{i}{r}\int_a^r \sigma(t)\,\mathrm{d}t\right)$ with a function $\sigma \in C^1([a,\infty),[0,\infty))$ satisfying

$$\sigma(a) = 0, \tag{4.1a}$$

$$\sup_{r\geq a}\sigma(r) < \infty, \tag{4.1b}$$

$$\lim_{r\to\infty}\inf_{r'\geq r}\sigma(r') > 0. \tag{4.1c}$$

Let u denote the solution to (3.1). Then the Bérenger function defined by

$$u^{(\mathrm{B})}(r,\hat{x}) = u(\gamma(r),\hat{x}) \tag{4.2}$$

solves the boundary value problem

$$\frac{1}{\gamma^{d-1}\gamma'}\frac{\partial}{\partial r}\left(\frac{\gamma^{d-1}}{\gamma'}\frac{\partial}{\partial r}u^{(\mathrm{B})}\right) + \frac{1}{\gamma^2}\Delta_{\hat{x}}u^{(\mathrm{B})} + k^2(\gamma(r))\,u^{(\mathrm{B})} = 0, \tag{4.3a}$$

$$u^{(\mathrm{B})}(a',\cdot) = \tilde{g}. \tag{4.3b}$$

If $a' = a$ and $\tilde{g} = g$, we have $u^{(\mathrm{B})}(a\hat{x}) = u^{(\mathrm{ext})}(a\hat{x})$ and $\partial_r u^{(\mathrm{B})}(a\hat{x}) = \partial_r u^{(\mathrm{ext})}(a\hat{x})$ due to (4.1a). Thus concerning the variational formulation of the inner domain problem, $u^{(\mathrm{B})}$ is as good as $u^{(\mathrm{ext})}$.

LEMMA 4.1. *Under the assumptions of Theorem* 3.1 *with* $z_0 = \gamma(a')$*, the boundary value problem* (4.3) *has a unique solution* $u^{(\mathrm{B})}$ *in* $H^1(D_{a',\infty})$ *for all* $\tilde{g} \in H^{1/2}(S_1^{d-1})$*. It satisfies* $\|u^{(\mathrm{B})}\|_{H^1} \leq C\|\tilde{g}\|_{H^{1/2}(S_1^{d-1})}$ *with a constant* C *independent of* $\tilde{g}$*.*

Proof. Let u denote the solution to (3.1), and let $u^{(\mathrm{B})}$ be defined by (4.2). It follows from Theorem 3.1(2) that there exist constants C and $\tilde{a} > a'$ such that $\|u^{(\mathrm{B})}\|_{H^1(D_{\tilde{a},\infty})} \leq C\|\tilde{g}\|_{L^2}$. In order to show that $\|u^{(\mathrm{B})}\|_{H^1(D_{a',\tilde{a}})} \leq C\|\tilde{g}\|_{H^{1/2}}$, we consider a Fourier expansion

$$u^{(\mathrm{B})}(r,\hat{x}) = \sum_{j=1}^{\infty}\tilde{g}_j R_j(r)\varphi_j(\hat{x}). \tag{4.4}$$

Here $\{\varphi_j,\lambda_j : j\in\mathbb{N}\}$ is a complete orthonormal system of eigenfunctions and eigenvalues of the Laplace–Beltrami operator $\Delta_{\hat{x}}$ on the sphere S_1^{d-1}, $\tilde{g}_j = \int_{S_1^{d-1}}\tilde{g}\varphi_j\,\mathrm{d}s$, and $R_j(a') = 1$. By virtue of the orthogonality of the Fourier modes with respect to

the H^1-norm we have

$$\begin{aligned}\|u^{(\mathrm{B})}\|^2_{H^1(D_{a',\tilde{a}})} &= \sum_{j=1}^{\infty} |\tilde{g}_j|^2 \left\{ \|R_j(r)\varphi(\hat{x})\|^2_{L^2(D_{a',\tilde{a}})} + \|\operatorname{grad} R_j(r)\varphi(\hat{x})\|^2_{L^2(D_{a',\tilde{a}})} \right\} \\ &= \sum_{j=1}^{\infty} |\tilde{g}_j|^2 \int_{a'}^{\tilde{a}} r^{d-1} \left\{ \left(1 - \frac{\lambda_j}{r^2}\right) |R_j(r)|^2 + |R_j'(r)|^2 \right\} \mathrm{d}r.\end{aligned}$$

Since $R_j = (\frac{\gamma(\kappa a')}{\gamma(\kappa r)})^{\frac{d-1}{2}} \frac{\mathcal{H}_j(\gamma(\kappa r))}{\mathcal{H}_j(\gamma(\kappa a'))}$ in the notation of [4, Corollary 8.3], there exists a constant N such that

$$|R_j^{(l)}(r)| \le C\sqrt{-\lambda_j}^{\,l} \left|\frac{\gamma(a')}{\gamma(r)}\right|^{\sqrt{-\lambda_j}} \tag{4.5}$$

for all $j \ge N$, $a' \le r \le \tilde{a}$, and $l = 0, 1$ with a generic constant C independent of j. Plugging this into the previous equation and using the estimate $|\gamma(a')/\gamma(r)| \le |\gamma(a')|(r^2 + \operatorname{Im}\gamma(a')^2)^{-1/2}$ yields

$$\|u^{(\mathrm{B})}\|^2_{H^1(D_{a',\tilde{a}})} \le C \sum_{j=1}^{\infty} (1 + |\lambda_j|^{1/2}) |\tilde{g}_j|^2 \le C \|\tilde{g}\|^2_{H^{1/2}}$$

since $\|\tilde{g}\|^2_{H^{1/2}} = \sum_j (1 + |\lambda|)^{1/2} |\tilde{g}_j|^2$.

Assume now that $u^{(B)} \in H^1(D_{a',\infty})$ is any solution to (4.3) not necessarily related to a solution of (3.1) by (4.2). By [4, Theorem 6.4] and assumption (4.1c), the Fourier coefficients $u_j^{(\mathrm{B})}(r) := \int_{S_1^{d-1}} u^{(\mathrm{B})}(r,\cdot)\varphi_j \,\mathrm{d}s$ are linear superpositions of an exponentially decreasing function proportional to R_j and an exponentially increasing function. It follows from the orthogonality of the Fourier modes and the boundedness of $\|u^{(B)}\|_{H^1}$ that $u_j^{(\mathrm{B})}(r) = \tilde{g}_g R_j(r)$ as in (4.4). This shows uniqueness of a solution to (4.3). ∎

LEMMA 4.2. *In Cartesian coordinates* (4.3a) *has the form* $\Delta_\gamma u + k_\gamma^2 u = 0$, *where* $k_\gamma^2(r) = k^2(\gamma(r))$ *and*

$$\Delta_\gamma = \nabla \cdot A_\gamma \nabla + b_\gamma \nabla.$$

$A_\gamma \in C^1\left([a,\infty), \mathbb{C}^{d\times d}\right)$ *and* $b_\gamma \in C^0\left([a,\infty), \mathbb{C}^{1\times d}\right)$ *satisfy*

$$A_\gamma(r,\hat{x}) = G_{\hat{x}}^{\mathrm{T}} \operatorname{diag}\left(\frac{1}{(\gamma'(r))^2}, \frac{r^2}{\gamma^2(r)}, \ldots, \frac{r^2}{\gamma^2(r)}\right) G_{\hat{x}}, \tag{4.6a}$$

$$b_\gamma(r,\hat{x}) = \left(\frac{d-1}{r} - \frac{d-1}{\gamma(r)\gamma'(r)} - \frac{\gamma''(r)}{(\gamma'(r))}, 0, \ldots, 0\right) G_{\hat{x}} \tag{4.6b}$$

for any orthogonal matrix $G_{\hat{x}}$ *whose first line is* $\hat{x}$.

Proof. Let $\Delta_\gamma u$ be defined by the first two terms in (4.3a). Then

$$\begin{aligned}\int_{D_{a,\infty}} \Delta_\gamma u \overline{v} \,\mathrm{d}x = &\int_a^\infty \int_{S^{d-1}} r^{d-1} \left[\frac{1}{\gamma^{d-1}\gamma'} \frac{\partial}{\partial r}\left(\frac{\gamma^{d-1}}{\gamma'}\frac{\partial}{\partial r} u\right) + \frac{1}{\gamma^2}\Delta_{\hat{x}} u\right] \overline{v} \,\mathrm{d}s \,\mathrm{d}r \\ = &-\int_a^\infty \int_{S^{d-1}} r^{d-1} \left[\frac{1}{(\gamma')^2}\frac{\partial}{\partial r} u \frac{\partial}{\partial r}\overline{v} + \frac{1}{\gamma^2}\nabla_{\hat{x}} u \cdot \nabla_{\hat{x}}\right] \overline{v} \,\mathrm{d}s \,\mathrm{d}r \\ &-\int_a^\infty \int_{S^{d-1}} r^{d-1} \left[\left(\frac{d-1}{r} - \frac{d-1}{\gamma\gamma'} - \frac{\gamma''}{(\gamma')^3}\right)\frac{\partial}{\partial r} u\right] \overline{v} \,\mathrm{d}x\end{aligned}$$

for $u, v \in C_0^\infty(D_{a,\infty})$, where $\nabla_{\hat{x}}$ denotes the surface gradient on S_1^{d-1}. Recall that $\nabla_{\hat{x}} u(r,\hat{x})$ is the projection of $r\nabla u(r\hat{x})$ to the tangential plane, which is orthogonal to $\hat{x}$. Since this projection is given by $G_{\hat{x}}^{\mathrm{T}} \operatorname{diag}(0,1,\dots,1) G_{\hat{x}}$ we get

$$\nabla_{\hat{x}} u(r,\hat{x}) = r G_{\hat{x}}^{\mathrm{T}} \operatorname{diag}(0,1,\dots,1) G_{\hat{x}} \nabla u(r\hat{x}).$$

Analogously, $\hat{x}\frac{\partial}{\partial r} u(r,\hat{x}) G_{\hat{x}}^{\mathrm{T}} \operatorname{diag}(1,0,\dots,0) G_{\hat{x}} \nabla u(r\hat{x})$. Therefore

$$\frac{\partial}{\partial r} u(r,\hat{x}) \frac{\partial}{\partial r} \overline{v(r,\hat{x})} = (\nabla u(r\hat{x}))^{\mathrm{T}} G_{\hat{x}}^{\mathrm{T}} \operatorname{diag}(1,0,\dots,0) G_{\hat{x}} \nabla \overline{v(r\hat{x})},$$
$$\nabla_{\hat{x}} u(r,\hat{x}) \cdot \nabla_{\hat{x}} \overline{v(r,\hat{x})} = r^2 (\nabla u(r\hat{x}))^{\mathrm{T}} G_{\hat{x}}^{\mathrm{T}} \operatorname{diag}(0,1,\dots,1) G_{\hat{x}} \nabla \overline{v(r\hat{x})}.$$

Inserting this yields $\int_{D_{a,\infty}} \Delta_\gamma u \overline{v}\,\mathrm{d}x = \int_{D_{a,\infty}} A_\gamma \nabla u \cdot \nabla \overline{v} + b_\gamma \nabla u \overline{v}\,\mathrm{d}x$ for all $v \in C_0^\infty(D_{a,\infty})$. This implies the asserted form of Δ_γ. To prove the regularity of A_γ and b_γ we may choose $G_{\hat{x}}$ such that it locally depends smoothly on $\hat{x}$. ∎

LEMMA 4.3. *The operator $\frac{\gamma\gamma'}{r}\Delta_\gamma$ is strongly elliptic on $D_{a,\infty}$.*

Proof. By (4.6a) we must show that there exists $\delta > 0$ with

$$\max_{a \le r < \infty} \left\{ \operatorname{Re} \frac{\gamma(r)}{r\gamma'(r)}, \operatorname{Re} \frac{r\gamma'(r)}{\gamma(r)} \right\} > \delta > 0.$$

This follows from the assumption (4.1b) since $\operatorname{Re}(\frac{\gamma}{r\gamma'}) = \frac{1+\sigma\frac{1}{r}\int_a^r \sigma(t)\,\mathrm{d}t}{1+\sigma^2} \ge \frac{1}{1+\max\sigma^2}$ and $\operatorname{Re}(\frac{r\gamma'}{\gamma}) = \frac{1+\sigma\frac{1}{r}\int_a^r \sigma(t)\,\mathrm{d}t}{1+\left(\frac{1}{r}\int_a^r \sigma(t)\,\mathrm{d}t\right)^2} \ge \frac{1}{1+\max\sigma^2}$. ∎

So far, we have replaced the exterior Helmholtz problem (2.4) with the Bérenger problem (4.3), which is still posed on an unbounded domain. Motivated by the exponential decay of $u^{(\mathrm{B})}$, we restrict (4.3) onto a bounded domain, say $D_{a,\rho}$, $\rho > a$, and impose a zero Dirichlet boundary condition on the artificial boundary S_ρ^{d-1}. This yields the so-called PML system

$$\Delta_\gamma u + k_\gamma^2 u = 0, \quad x \in D_{a,\rho}, \tag{4.7a}$$
$$u|_{S_a^{d-1}} = g, \tag{4.7b}$$
$$u|_{S_\rho^{d-1}} = 0. \tag{4.7c}$$

We define $\mathrm{DtN}_{a,\rho}^{(\mathrm{PML})} : H^{1/2}(S_a^{d-1}) \to H^{-1/2}(S_a^{d-1})$ by

$$\mathrm{DtN}_{a,\rho}^{(\mathrm{PML})} g = \partial_r u_\rho^{(\mathrm{PML})}\Big|_{S_a^{d-1}}.$$

To derive a reformulation of (2.2) with DtN_a replaced with $\mathrm{DtN}_{a,\rho}^{(\mathrm{PML})}$ which does not involve a DtN-operator, we extend A_γ, b_γ, and k_γ to Ω_a by Id, $[0,\dots,0]$, and k^2, respectively, and introduce the Hilbert space $H_{(0)}^1(\Omega_\rho) := \{v \in H^1(\Omega_\rho) : v|_{S_\rho^{d-1}} = 0\}$. Then the variational formulation of the total PML system is

$$\int_{\Omega_\rho} (A_\gamma \nabla u) \overline{\nabla v} + b_\gamma \nabla u \overline{v} + k_{\mathrm{PML}}^2 u \overline{v}\,\mathrm{d}x = \int_{\partial K} f \overline{v}\,\mathrm{d}s \qquad \text{for all } v \in H_{(0)}^1(\Omega_\rho). \tag{4.8}$$

This problem can be solved by standard finite element codes. Using elliptic regularity results, it is easy to show that any solution to (2.2) with DtN_a replaced with $\mathrm{DtN}_{a,\rho}^{(\mathrm{PML})}$ can be extended to a solution of (4.8), and conversely the restriction of any solution to (4.8) is a solution to (2.2) with DtN_a replaced with $\mathrm{DtN}_{a,\rho}^{(\mathrm{PML})}$. In the next sections we show that (4.8) has a unique solution $u_\rho^{(\mathrm{PML})}$ for ρ large enough and suitable γ and that $u_\rho^{(\mathrm{PML})}$ converges exponentially fast to the true solution in the interior domain Ω_a.

5. Convergence analysis. In the following we are repeatedly concerned with boundary value problems of type (4.3) and (4.7) on domains D_{θ_1,θ_2}, defined in (2.5). For a compact notation of these problems we make the following definitions.

DEFINITION 5.1. *Let $a < \theta_1 < \theta_2 < \infty$ be given. We define the operators*

$$\mathcal{L}_{\theta_1,\theta_2} : H^1(D_{\theta_1,\theta_2}) \to H^{-1}(D_{\theta_1,\theta_2}) \times H^{1/2}\left(S^{d-1}_{\theta_1}\right) \times H^{1/2}\left(S^{d-1}_{\theta_2}\right)$$

and

$$\mathcal{L}_{\theta_1,\infty} : H^1_{\mathrm{loc}}(D_{\theta_1,\infty}) \to \mathcal{D}'(D_{\theta_1,\infty}) \times H^{1/2}\left(S^{d-1}_{\theta_1}\right)$$

by $u \mapsto (\Delta_\gamma u + k_\gamma^2 u, u|_{S^{d-1}_{\theta_1}}, u|_{S^{d-1}_{\theta_2}})$ and $u \mapsto (\Delta_\gamma u + k_\gamma^2 u, u|_{S^{d-1}_{\theta_1}})$, respectively.

Remark 5.2. A function $u \in H^1(D_{a,\infty})$ solves the Bérenger system (4.3) if and only if it satisfies $\mathcal{L}_{a,\infty} u = (0, g)$. A function $u \in H^1(D_{a,\rho})$ solves the PML system (4.7) if and only if it satisfies $\mathcal{L}_{a,\rho} u = (0, g, 0)$.

For the proof of the following lemma we restrict the class of admissible paths γ by the following condition: There exist constants $a' > a$ and $\sigma_0 > 0$ such that

$$\gamma(r) = (1 + i\sigma_0)\, r \tag{5.1a}$$

for $r \geq a'$. Later we will also need that

$$\kappa^2 |\alpha_0|^2 |p(\alpha_0 r)| < \frac{\min\left(1, \kappa^2\right)\sigma_0}{|\alpha_0|} \tag{5.1b}$$

for $r \geq a'$ with $\alpha_0 := (1 + i\sigma_0)$. This can always be achieved by increasing the value of a'. For simplicity we also assume $a' \geq 1$. Condition (5.1a) means that γ is a straight line in the complex plane for $r \geq a'$. It is easily checked that $\Delta_\gamma = \frac{1}{\alpha_0^2}\Delta$ for $r \geq a'$. Therefore (4.3a) is equivalent to

$$\left(\Delta + \alpha_0^2 k^2(\alpha_0 |x|)\right) u^{(\mathrm{B})} = 0, \quad |x| > a'; \tag{5.2}$$

i.e., $u^{(\mathrm{B})}$ satisfies a Helmholtz equation with a complex wave number for $|x| > a'$.

LEMMA 5.3. *The following hold true:*

1. *The operator $\mathcal{L}^{-1}_{a',\infty}$ is well defined and bounded from $\{0\} \times H^{1/2}\left(S^{d-1}_{a'}\right)$ to $H^1(D_{a',\infty})$.*
2. *The operator $\mathcal{L}_{a',\rho}$ has a bounded inverse for $\rho > a' + 1$, where a' is defined in (5.1). There exists a constant C such that $\left\|\mathcal{L}^{-1}_{a',\rho}\right\| \leq C\rho$ for all $\rho > a' + 1$.*
3. *$\mathcal{L}_{\theta_1,\theta_2}$ is a Fredholm operator with index zero for all $a < \theta_1 < \theta_2 < \infty$.*

Proof. (1) The assertion follows from Lemma 4.1 if we can show that a solution u to (3.1) with $\tilde{g} = 0$ and $z_0 = \gamma(a')$ must vanish. Let $u_j(r) := \int_{S^{d-1}_1} u(r,\cdot)\varphi_j \,\mathrm{d}s$ denote the Fourier coefficients of u. Due to (5.2) it satisfies $r^{-d+1}(r^{d-1}u_j'(r))' - \lambda_j r^{-2} u_j(r) + k^2(\alpha_0 r)u_j(r) = 0$. By (3.1b) it satisfies $u_j(a') = 0$. Moreover, by [4, Theorem 6.4] and (3.1c), $u_j(r)$ decreases exponentially as $r \to \infty$. Therefore, we can multiply the differential equation by $r^{d-1}\overline{u_j(r)}$ and integrate by parts to obtain

$$\int_{a'}^{\infty} -r^{d-1}|u_j'(r)|^2 - r^{d-3}\lambda_j |u_j(r)|^2 + \alpha_0^2 k^2(\alpha r) r^{d-1} |u_j(r)|^2 \,\mathrm{d}r = 0.$$

Taking the imaginary part of this equation gives $u_j = 0$ since

$$\mathrm{Im}\left(\alpha_0^2 k^2(\alpha_0 r)\right) \geq \kappa^2 2\sigma_0 - \kappa^2 \left|\alpha_0^2 p(\alpha_0 r)\right| > \frac{\kappa^2 \sigma_0}{|\alpha_0|} - \kappa^2 \left|\alpha_0^2 p(\alpha_0 r)\right| > 0$$

for all $r \geq a'$ by virtue of assumption (5.1b).

(2) Let $(f, h_{a'}, h_\rho) \in H^{-1}(D_{a',\rho}) \times H^{1/2}\left(S^{d-1}_{a'}\right) \times H^{1/2}\left(S^{d-1}_{\rho}\right)$. We introduce the operator $\widetilde{\mathcal{L}} : H^1(D_{a',\rho}) \to H^{-1}(D_{a,\rho})$ with

$$\widetilde{\mathcal{L}} u := \left[\Delta + (1 + p(\alpha_0|x|))\,\kappa^2\alpha_0^2\right] u.$$

Due to (5.2) we have to show that the boundary value problem

$$\widetilde{\mathcal{L}} u = \alpha_0^2 f, \tag{5.3a}$$

$$u|_{S^d_{a'}} = h_{a'}, \qquad u|_{S^d_\rho} = h_\rho \tag{5.3b}$$

has a unique solution $u \in H^1(D_{a',\rho})$ and that $\|u\| \leq C\rho \|(f, h_{a'}, h_\rho)\|$ with a constant C independent of $(f, h_{a'}, h_\rho)$ and ρ. To this end we reformulate (5.3) as a problem in $H^1_0(D_{a',\rho})$. Let $R_{a',\rho}$ denote a right inverse of the trace mapping $H^1(D_{a',\rho}) \to H^{1/2}\left(S^{d-1}_{a'}\right) \times H^{1/2}\left(S^{d-1}_{\rho}\right)$, $u \mapsto (u|_{S^{d-1}_{a'}}, u|_{S^{d-1}_{\rho}})$, and let $\mathcal{A}, \mathcal{P} : H^1_0(D_{a',\rho}) \to H^1_0(D_{a',\rho})$ be the operators defined by

$$\left\langle \left(\Delta w + \kappa^2\alpha_0^2 w\right), \overline{v}\right\rangle = (\mathcal{A}w, v),$$
$$\left\langle \kappa^2\alpha_0^2 p(\alpha_0|x|) w, \overline{v}\right\rangle = (\mathcal{P}w, v)$$

for all $w, v \in H^1_0(D_{a',\rho})$. Finally, let $\mathcal{J} : H^{-1}(D_{a',\rho}) = H^1_0(D_{a',\rho})' \to H^1_0(D_{a',\rho})$ denote the canonical isomorphism. Then u solves (5.3) if and only if $w := u - R_{a',\rho}(h_{a'}, h_\rho)$ satisfies

$$(\mathcal{A} + \mathcal{P}) w = \alpha_0^2 \mathcal{J} f - \mathcal{J}\widetilde{\mathcal{L}} R_{a',\rho}(h_{a'}, h_\rho). \tag{5.4}$$

Since

$$\operatorname{Im}\left(\frac{1}{\alpha_0}\mathcal{A}u, u\right) = \frac{\sigma_0}{1+\sigma_0^2}\left\langle \nabla u, \overline{\nabla u}\right\rangle + \kappa^2\sigma_0\langle u, \overline{u}\rangle,$$

we have

$$\frac{\min\left(1, \kappa^2\right)\sigma_0}{1+\sigma_0^2}\|u\|^2 \leq \operatorname{Im}\left(\frac{1}{\alpha_0}\mathcal{A}u, u\right) \leq \frac{1}{|\alpha_0|}\|\mathcal{A}u\|\|u\|$$

for all $u \in H^1_0(D_{a',\rho})$. This implies that $\mathcal{A}$ is boundedly invertible with $\|\mathcal{A}^{-1}\| \leq \frac{|\alpha_0|}{\min(1,\kappa^2)\sigma_0}$. Since $\|\mathcal{P}\| < \frac{\min(1,\kappa^2)\sigma_0}{|\alpha_0|}$ by virtue of assumption (5.1b), it follows that $\|\mathcal{A}^{-1}\mathcal{P}\| \leq c < 1$ with a constant c independent of ρ. Therefore, $\mathcal{A}+\mathcal{P} = \mathcal{A}(I+\mathcal{A}^{-1}\mathcal{P})$ is invertible and $\|(\mathcal{A}+\mathcal{P})^{-1}\| \leq \|A\|(1-c)^{-1} \leq C$ with a constant C independent of ρ. It follows from (5.4) that

$$\|u\| \leq C\|\mathcal{J}(\alpha_0^2 f - \widetilde{\mathcal{L}} R_{a',\rho}(h_{a'}, h_\rho))\| + \|R_{a',\rho}(h_{a'}, h_\rho)\|.$$

As both $\|\mathcal{J}\|$ and $\|\mathcal{J}\widetilde{\mathcal{L}}\|$ are uniformly bounded with respect to ρ, it remains to estimate the norm of $R_{a',\rho}$. We select a right inverse $R_{1,2}$ of the trace mapping $H^1(D_{1,2}) \to H^{1/2}\left(S^{d-1}_1\right) \times H^{1/2}\left(S^{d-1}_2\right)$, $u \mapsto (u|_{S^{d-1}_1}, u|_{S^{d-1}_2})$. Using $R_{1,2}$ we define $R_{a',\rho}$ by

$$R_{a',\rho}(h_{a'}, h_\rho)(r\hat{x}) := \left[R_{1,2}(h_{a'}(a'\cdot), h_\rho(\rho/2\cdot))\right]\left(\frac{\rho + r - 2a'}{\rho - a'}\hat{x}\right).$$

Recall that $a' \geq 1$, $\rho \geq 2$ and that

$$\left\|f\right\|_{H^{1/2}\left(S_\theta^{d-1}\right)} = \theta^{(d-1)/2} \left\| \left(1-\theta^{-2}\Delta_{\hat{x}}\right)^{1/4} f\left(\theta^{-1}\cdot\right) \right\|_{L^2\left(S_1^{d-1}\right)}.$$

Now

$$\begin{aligned}
&\left\|R_{a',\rho}\left(h_{a'},h_\rho\right)\right\| \leq C\rho^{d/2} \max\left\{ \left\|h_{a'}\left(a'\cdot\right)\right\|_{H^{1/2}\left(S_1^{d-1}\right)}, \left\|h_\rho\left(\rho/2\cdot\right)\right\|_{H^{1/2}\left(S_2^{d-1}\right)} \right\} \\
&\leq C\rho^{d/2} \max\left\{ \frac{\left(a'\right)^{1/2}}{\left(a'\right)^{(d-1)/2}} \left\|h_{a'}\right\|_{H^{1/2}\left(S_{a'}^{d-1}\right)}, \frac{2^{(d-1)/2}}{\rho^{(d-1)/2}} \left(\frac{\rho^2}{4}\right)^{1/4} \left\|h_\rho\right\|_{H^{1/2}\left(S_\rho^{d-1}\right)} \right\} \\
&\leq C\rho \max\left\{ \left\|h_{a'}\right\|_{H^{1/2}\left(S_{a'}^{d-1}\right)}, \left\|h_\rho\right\|_{H^{1/2}\left(S_\rho^{d-1}\right)} \right\}.
\end{aligned}$$

Therefore, $\left\|R_{a',\rho}\right\| \leq C\rho$ with C independent of ρ.

(3) We use Theorem 13.4 in [11]. The case $d > 2$ is clear. For $d = 2$ we must show that Δ_γ is properly elliptic. By definitions 10.5.2 and 10.5.3 in [11] and (4.6a), it suffices to show that the polynomial $P(z) = \frac{1}{(\gamma'(r))^2} + z^2 \frac{r^2}{\gamma^2(r)}$ has one root with $\operatorname{Im} z > 0$ and one root with $\operatorname{Im} z < 0$. The roots are given by $z_\pm = i\frac{\gamma(r)}{r\gamma'(r)}$. Since $\operatorname{Re}(\frac{\gamma}{r\gamma'}) = \frac{1+\sigma\frac{1}{r}\int_a^r \sigma(t)\,\mathrm{d}t}{1+\sigma^2} \geq \frac{1}{1+\max\sigma^2}$, the assertion follows from (4.1b). ∎

We emphasize that in the previous lemma we did not prove the existence of a solution to the PML system (4.7) or equivalently the existence of a solution to $\mathcal{L}_{a,\rho}u = (0,g,0)$. This will be done in the following for ρ large enough by a technique proposed by Lassas and Somersalo in [8]. The key idea is to introduce propagation operators which allow an equivalent formulation of the Bérenger and PML problems on a fixed domain. Then the PML problem can be interpreted as a perturbed Bérenger problem.

DEFINITION 5.4. *Let $a' < a'' \leq \rho$ with $a' > a$ given by* (5.1). *The* propagation operators $P_{a''}^{(\rho)}$, $P_{a''}^{(\infty)} : H^{1/2}\left(S_{a'}^{d-1}\right) \to H^{1/2}\left(S_{a''}^{d-1}\right)$ *are defined by*

$$\begin{aligned}
P_{a''}^{(\rho)} h &= \mathcal{L}_{a',\rho}^{-1}\left(0,h,0\right)|_{S_{a''}^{d-1}}, \\
P_{a''}^{(\infty)} h &= \mathcal{L}_{a',\infty}^{-1}\left(0,h\right)|_{S_{a''}^{d-1}}.
\end{aligned}$$

LEMMA 5.5. *For $a' < a'' \leq \rho$ with $a' > a$ given by* (5.1), *the following hold true:*

1. *The restriction of $u^{(\mathrm{B})}$ to $D_{a,a''}$ is the unique solution in $u \in H^1\left(D_{a,a''}\right)$ to the equation*

$$\mathcal{L}_{a,a''}u = \left(0,g,P_{a''}^{(\infty)}\left(u|_{S_{a'}^{d-1}}\right)\right). \tag{5.5}$$

2. *Let $u \in H^1\left(D_{a,\rho}\right)$ satisfy* (4.7a). *Then u satisfies* (4.7b) *and* (4.7c) *if and only if*

$$\mathcal{L}_{a,a''}u|_{D_{a,a''}} = \left(0,g,P_{a''}^{(\rho)}\left(u|_{S_{a'}^{d-1}}\right)\right). \tag{5.6}$$

Proof. (1) $u^{(\mathrm{B})}$ satisfies (5.5) by construction. Let u be any solution of (5.5) and $w = \mathcal{L}_{a',\infty}^{-1}(0,u|_{S_{a'}^{d-1}})$. Then $w|_{S_{a'}^{d-1}} = u|_{S_{a'}^{d-1}}$ and $w|_{S_{a''}^{d-1}} = u|_{S_{a''}^{d-1}}$. We conclude that $w = u = \mathcal{L}_{a',a''}^{-1}(0,w|_{S_{a'}^{d-1}}, w|_{S_{a''}^{d-1}})$ in $B_{a''} \setminus \bar{B}_{a'}$. Therefore, the function

$$W(x) = \begin{cases} u(x), & x \in B_{a''}^d \setminus \overline{B_a^d}, \\ w(x), & x \in \mathbb{R}^d \setminus \overline{B_{a''}^d}, \end{cases}$$

solves $\mathcal{L}_{a,\infty}W = (0,g)$. Hence $W = u^{(\mathrm{B})}$, and in particular $u = u^{(\mathrm{B})}|_{B_{a''}\setminus\overline{B_a^d}}$.

(2) Any solution u to (4.7) solves (5.6) by construction. Conversely, let $u \in H^1(D_{a,\rho})$ satisfy (4.7a) and (5.6) and let $w = \mathcal{L}_{a',\rho}^{-1}(0, u|_{S_{a'}^{d-1}}, 0)$. Then $w|_{S_{a'}^{d-1}} = u|_{S_{a'}^{d-1}}$ and, as a consequence of (5.6), $w|_{S_{a''}^{d-1}} = u|_{S_{a''}^{d-1}}$. It follows from the invertibility of $\mathcal{L}_{a',a''}$ that $u(x) = w(x)$ for all $x \in B_{a''}^d \setminus B_{a'}^d$. By the unique continuation principle for elliptic equations (see [3, Section 8.3]), we conclude that $u(x) = w(x)$ for $x \in B_\rho^d \setminus B_{a'}^d$. In particular u satisfies (4.7c). (4.7b) is an immediate consequence of (5.6). ∎

Again, we did not prove that (5.6) has a solution.

LEMMA 5.6. *For $a' < a''$ with $a' > a$ given by* (5.1)*, the following hold true:*

1. $P_{a''}^{(\infty)}$ *is a compact operator.*
2. *There exists a constant C such that for all $\rho > a''$ and all $h \in H^{1/2}\left(S_{a'}^{d-1}\right)$*

$$\left\|P_\rho^{(\infty)}h\right\|_{H^{1/2}} \le Ce^{-\kappa\sigma_0\rho}\left\|h\right\|_{H^{1/2}}. \tag{5.7}$$

3. *There exists a constant C such that for all $\rho > a''$*

$$\left\|P_{a''}^{(\infty)} - P_{a''}^{(\rho)}\right\| \le C\rho e^{-\kappa\sigma_0\rho}. \tag{5.8}$$

Proof. (1) By (4.4) we have $(P_{a''}^{(\infty)}h)(a''\hat{x}) = \sum_{j=1}^\infty \hat{h}_j R_j(a'')\varphi_j(\hat{x})$, where $\hat{h}_j := \int_{S_1^{d-1}} h(a'\cdot)\varphi_j \,\mathrm{d}s$. Since $\lim_{j\to\infty} R_j(a'') = 0$ due to (4.5), $P_{a''}^{(\infty)}$ is compact as an operator norm limit of the finite rank operators defined by the truncated series.

(2) Let $h \in H^{1/2}\left(S_{a'}^{d-1}\right)$ be given and define $u := \mathcal{L}_{a',\infty}^{-1}(0,h)$. By Theorem 3.1 (2), with $z_0 = \gamma(a') = (1+i\sigma_0)r$ and $\tilde{g}(\hat{x}) = h(a'\hat{x})$, we have

$$u(r\hat{x}) = \left[(1+i\sigma_0)\,r\right]^{\frac{1-d}{2}} e^{i\kappa r - \kappa\sigma_0 r}\left(u_\infty(\hat{x}) + \int_0^\infty e^{-t((1+i\sigma_0)r-\tilde{a})}\Psi(t,\hat{x})\,\mathrm{d}t\right).$$

Further it follows from the estimates (3.3) and (3.4) that there exists a constant C such that for all $z \in \mathbb{C}_{z_0}^{++}$

$$\left\|u_\infty\right\|_{H^{1/2}\left(S_1^{d-1}\right)} + \left\|\int_0^\infty e^{-t(z-\tilde{a})}\Psi(t,\cdot)\,\mathrm{d}t\right\|_{H^{1/2}\left(S_1^{d-1}\right)} \le C\left\|\tilde{g}\right\|_{L^2\left(S_1^{d-1}\right)}.$$

Using $\left\|f\right\|_{H^{1/2}\left(S_\rho^{d-1}\right)} = \rho^{(d-1)/2}\left\|\left(1-\rho^{-2}\Delta_{\hat{x}}\right)^{1/4} f\left(\rho^{-1}\cdot\right)\right\|_{L^2\left(S_1^{d-1}\right)}$, we get

$$\|P_\rho^{(\infty)}h\|_{H^{1/2}} = \|u|_{S_\rho^{d-1}}\|_{H^{1/2}} \le Ce^{-\kappa\sigma_0\rho}\left\|\tilde{g}\right\|_{L^2\left(S_1^{d-1}\right)} \le Ce^{-\kappa\sigma_0\rho}\left\|h\right\|_{H^{1/2}\left(S_{a'}^{d-1}\right)}.$$

(3) Let $h \in H^{1/2}\left(S_{a'}^{d-1}\right)$ be given. By the definition of $P_{a''}^{(\infty)}$ and $P_{a''}^{(\rho)}$, we have $P_{a''}^{(\infty)}h - P_{a''}^{(\rho)}h = \mathrm{Tr}_{S_{a''}^{d-1}}\mathcal{L}_{a',\rho}^{-1}(0,0,P_\rho^{(\infty)}h)$. Using Lemma 5.3 (3) and (5.7), we obtain

$$\left\|P_{a''}^{(\infty)}h - P_{a''}^{(\rho)}h\right\|_{H^{1/2}} = \left\|\mathrm{Tr}_{S_{a''}^{d-1}}\right\|\left\|\mathcal{L}_{a',\rho}^{-1}\right\|\left\|P_\rho^{(\infty)}h\right\| \le C\rho e^{-\kappa\sigma_0\rho}\left\|h\right\|,$$

which yields (5.8). ∎

PROPOSITION 5.7. *There exists a constant $\rho_0 > a$ such that* (4.7) *has a unique solution for $\rho \ge \rho_0$. The operator $\mathrm{DtN}_{a,\rho}^{(\mathrm{PML})}$ is well defined for $\rho \ge \rho_0$, and there exists a constant C such that*

$$\left\|\mathrm{DtN}_a - \mathrm{DtN}_{a,\rho}^{(\mathrm{PML})}\right\| \le C\rho e^{-\kappa\sigma_0\rho}. \tag{5.9}$$

Here we use the operator norm of $L\left(H^{1/2}\left(S_a^{d-1}\right), H^{-1/2}\left(S_a^{d-1}\right)\right)$.

Proof. Define the operator

$$\mathcal{K} : H^1\left(B_{a''}^d \setminus \overline{B_a^d}\right) \to H^{-1}\left(B_{a''}^d \setminus B_a^d\right) \times H^{1/2}\left(S_a^{d-1}\right) \times H^{1/2}\left(S_{a''}^{d-1}\right)$$

by $u \mapsto (0, 0, P_{a''}^{(\infty)} u|_{S_{a'}^{d-1}})$. By Lemma 5.5 (1) $u^{(\mathrm{B})}$ satisfies

$$\mathcal{L}_{a,a''} u^{(\mathrm{B})} - \mathcal{K} u^{(\mathrm{B})} = (0, g, 0)\,. \tag{5.10}$$

The operator $\mathcal{L}_{a,a''}$ is of Fredholm index zero and $\mathcal{K}$ is compact by Proposition 5.6 (1). Hence, $\mathcal{L}_{a,a''} - \mathcal{K}$ also has Fredholm index zero. Assume that u_0 satisfies (5.10) with $g = 0$. Then $\mathcal{L}_{a,a''} u_0 = (0, 0, P_{a''}^{(\infty)} u_0|_{S_{a'}^{d-1}})$, and hence by Lemma 5.5 (1), $u_0 = \mathcal{L}_{a,\infty}^{-1}(0, 0) = 0$. Thus, $(\mathcal{L}_{a,a''} - \mathcal{K})^{-1}$ exists.

Next, consider the system (5.6). The same argument as above yields an equation

$$\left(\mathcal{L}_{a,a''} - \widetilde{\mathcal{K}}\right) u_\rho^{(\mathrm{PML})} = (0, g, 0) \tag{5.11}$$

with $\widetilde{\mathcal{K}} u = (0, 0, P_{a'',\rho} \mathrm{Tr}_{a'})$. Applying $(\mathcal{L}_{a,a''} - \mathcal{K})^{-1}$ to both sides of (5.11) yields

$$\left(I + \left(\mathcal{K} - \widetilde{\mathcal{K}}\right)\right) u_\rho^{(\mathrm{PML})} = u^{(\mathrm{B})}. \tag{5.12}$$

As $(\mathcal{K} - \widetilde{\mathcal{K}})u = (0, 0, (P_{a''}^{(\infty)} - P_{a''}^{(\rho)})\mathrm{Tr}_{a'})$ it follows from Proposition 5.6 (3) that $\|\mathcal{K} - \widetilde{\mathcal{K}}\| \le C\rho e^{-\kappa\sigma_0\rho}$. Therefore (5.12) is solvable by a Neumann series for ρ large enough, and we conclude that

$$\left\|u^{(\mathrm{B})} - u_\rho^{(\mathrm{PML})}\right\|_{H^1\left(D_{a,a''}\right)} \le \frac{C\rho e^{-\kappa\sigma_0\rho}}{1 - C\rho e^{-\kappa\sigma_0\rho}} \left\|u^{(\mathrm{B})}\right\| \le C\rho e^{-\kappa\sigma_0\rho} \|g\|. \tag{5.13}$$

To finish the proof, it remains to show that any $u \in H^1\left(D_{a,a''}\right)$ satisfying $\nabla \cdot A_\gamma \nabla u + b_\gamma \nabla u + k_\gamma^2 u = 0$ has a normal derivative $\partial_r u|_{S_a^{d-1}} \in H^{-1/2}\left(S_a^{d-1}\right)$ which satisfies $\left\|\partial_r u|_{S_a^{d-1}}\right\|_{H^{-1/2}} \le C\|u\|_{H^1}$ with some constant $C > 0$ independent of u. To see this we choose a right inverse $R_a : H^{1/2}\left(S_a^{d-1}\right) \to H^1\left(D_{a,a''}\right)$ of the trace operator $\varphi \mapsto \varphi|_{S_a^{d-1}}$ satisfying $\mathrm{supp}\, R_a\varphi \subset D_{a,\frac{a+a''}{2}}$ for all $\varphi \in H^{1/2}\left(S_a^{d-1}\right)$. Given $\varphi \in H^{1/2}\left(S_a^{d-1}\right)$, we multiply the differential equation by $R_a\varphi$, integrate, and formally use the Gauss divergence theorem and the identity $A_\gamma(a, \hat{x}) = \mathrm{Id}$ to obtain

$$\left\langle \partial_r u|_{S_a^{d-1}}, \varphi \right\rangle = \int_{D_{a,\rho}} -A_\gamma \nabla u \cdot \overline{\nabla R_a\varphi} + b_\gamma \cdot \nabla u \overline{R_a\varphi} + k_\gamma^2 u \overline{R_a\varphi}\, \mathrm{d}x.$$

Since the right-hand side of this equation is bounded by $C\|u\|_{H^1}\|\varphi\|_{H^{1/2}}$, we have proved the existence of $\partial_r u \in H^{-1/2}\left(S_a^{d-1}\right)$ and the asserted bound. Hence,

$$\left\|\mathrm{DtN}_a g - \mathrm{DtN}_{a,\rho}^{(\mathrm{PML})} g\right\|_{H^{-1/2}} \le C\left\|u_\rho^{(\mathrm{PML})} - u^{(\mathrm{B})}\right\|_{H^1\left(D_{a,a''}\right)}.$$

Together with (5.13) this implies the estimate (5.9). ∎

THEOREM 5.8. *After possibly increasing the constant* ρ_0 *in Proposition* 5.7*, there exists a constant* $C > 0$ *such that the variational problem* (4.8) *has a unique solution* $u_\rho^{(\mathrm{PML})} \in H^1_{(0)}(\Omega_\rho)$ *for all* $\rho \ge \rho_0$ *satisfying*

$$\left\|u^{(\mathrm{B})} - u_\rho^{(\mathrm{PML})}\right\|_{H^1(\Omega_a)} \le C\rho e^{-\kappa\sigma_0\rho}. \tag{5.14}$$

Proof. We introduce the operators $\mathcal{L}, \mathcal{G}, \mathcal{G}_\rho : H^1(\Omega) \to H^1(\Omega)$ with

$$\begin{aligned}(\mathcal{L}u, v) &= \langle \operatorname{grad} u, \operatorname{grad} \overline{v} \rangle - \langle k^2 u, \overline{v} \rangle,\\ (\mathcal{G}u, v) &= \int_{S_a^{d-1}} \mathrm{DtN}_a u \overline{v} \, \mathrm{d}s,\\ (\mathcal{G}_\rho u, v) &= \int_{S_a^{d-1}} \mathrm{DtN}_{a,\rho}^{\mathrm{PML}} u \overline{v} \, \mathrm{d}s\end{aligned}$$

for all $u, v \in H^1(\Omega_a)$. Moreover, we define $F \in H^1(\Omega_a)$ by $(F, v) = \int_{\partial K} f \overline{v} \, \mathrm{d}s$, $v \in H^1(\Omega_a)$. Then $(\mathcal{L}+\mathcal{G})u^{(\mathrm{int})} = F$ and $(\mathcal{L}+\mathcal{G}_\rho) u_\rho^{(\mathrm{PML})}\big|_{\Omega_a} = F$. Since we know that $\mathcal{L}+\mathcal{G}$ is boundedly invertible (cf. [4]), it follows by a Neumann series argument that there exist constants $C, \epsilon > 0$ such that $\mathcal{L}+\mathcal{G}_\rho$ is invertible for $\|\mathcal{G} - \mathcal{G}_\rho\|_{H^1} < \epsilon$ and

$$\|u_\rho^{(\mathrm{PML})}\big|_{\Omega_a} - u\|_{H^1} \le C \|\mathcal{G} - \mathcal{G}_\rho\|_{H^1} \le C \|\mathrm{DtN}_a - \mathrm{DtN}_{a,\rho}^{(\mathrm{PML})}\|.$$

Now the assertion follows from Proposition 5.7. ∎

A PARABOLIC CROSS-DIFFUSION SYSTEM FOR GRANULAR MATERIALS*

GONZALO GALIANO†, ANSGAR JÜNGEL‡, AND JULIÁN VELASCO†

Abstract. We analyze a cross-diffusion system of parabolic equations for the relative concentration and the dynamic repose angle of a mixture of two different granular materials in a long rotating drum. The main feature of the system is the ability to describe the axial segregation of the two granular components. The existence of global-in-time weak solutions is shown for arbitrary large cross-diffusion by using entropy-type inequalities and approximation arguments. The uniqueness of solutions is proved if cross-diffusion is not too large. Furthermore, we derive a sufficient condition on the parameters to have nonsegregation. Finally, numerical simulations illustrate the long-time coarsening of the segregation bands in the drum.

Key words. strongly nonlinear parabolic system, cross-diffusion, segregation, existence of weak solutions, uniqueness of solutions, entropy-type estimates

1. Introduction.

One important feature of granular materials, consisting of different components, is their ability to segregate under external agitation rather than further mixing [21]. Consider a long cylinder rotating about its longitudinal axis which is partially filled with a mixture of two different kinds of granular particles. The mixture of grains may exhibit both radial and axial size segregation. Roughly speaking, radial segregation occurs during the first few revolutions of the drum and is often followed by slow axial segregation. Axial segregation leads to either a stable array of concentration bands or, after a very long time, to complete segregation [2, 3, 24].

In this paper we are interested in the existence analysis of a specific model for granular materials derived in [3]. Consider a mixture of two kinds of particles with volume concentrations $u_1,\ u_2 \in [0,1]$ placed in a horizontal long narrow rotating cylinder of length $L > 0$. Let $u = u_1 - u_2 \in [-1,1]$ be the relative concentration of the mixture. Introduce the so-called dynamic angle of repose θ as the arctangent of the average slope of the free surface of the mixture, which is assumed to be flat (see Figure 1.1). The variables u and θ are assumed to be constant in each cross section of the drum and depend therefore only on the axial coordinate $z \in \Omega = (0,L)$ and on the time $t > 0$.

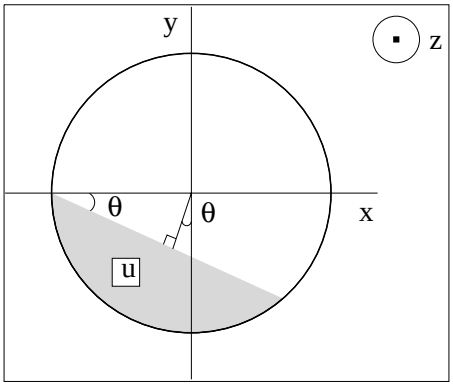

FIG. 1.1. *Relative concentration u and dynamical angle of repose θ in the geometry of the cross section of a rotating drum. The gray region indicates the mixture partially filling the drum. The variables u and θ are assumed to be constant in each cross section.*

In [3] the following cross-diffusion system for the evolution of u and θ was derived:

$$u_t - (\nu u_z - (1-u^2)\theta_z)_z = 0, \tag{1.1}$$

$$\theta_t - (\gamma u + \theta)_{zz} + \theta = \mu u \quad \text{in } Q_T := \Omega \times (0,T), \tag{1.2}$$

where the subindices denote partial derivatives. The model (1.1)–(1.2) is obtained by averaging the mass conservation laws for the two components of the granular matter over the cross section of the cylinder, under the main assumptions that the mass of grains in each cross section of the drum remains constant and that the grains separate predominantly near the surface of the drum, whereas in the bulk of the drum particles are equally advected by the bulk flow (see [3] for details of the derivation).

The positive constant ν is related to the Fickian diffusion constants arising in the surface fluxes of the two materials. The constant $\gamma > 0$ is proportional to the difference of the Fickian diffusivities. Finally, μ is related to the difference of the static repose angles of the two kind of particles.

We impose as in [3, 20] periodic boundary conditions and initial conditions for u and θ, as we are not interested in effects due to the boundary conditions:

$$\begin{aligned} &u(0,\cdot) = u(L,\cdot), \quad u_z(0,\cdot) = u_z(L,\cdot) \\ &\theta(0,\cdot) = \theta(L,\cdot), \quad \theta_z(0,\cdot) = \theta_z(L,\cdot) \\ &u(\cdot,0) = u_0, \qquad \theta(\cdot,0) = \theta_0 \end{aligned} \qquad \begin{aligned} &\text{in } (0,T), \\ &\\ &\text{in } \Omega. \end{aligned} \tag{1.3}$$

In the physical literature, periodic boundary conditions have been employed in numerical simulations of the dynamics of the granular materials in order to eliminate boundary effects [3, 20]. The subsequent analysis also works for no-flux and Dirichlet boundary conditions (with appropriate changes of the obtained estimates).

We remark that the problem is intrinsically one-dimensional in space since the equations are obtained by averaging over the cross section. For a two-dimensional model we refer, for instance, to [10].

The terms $((1-u^2)\theta_z)_z$ and γu_{zz} in (1.1)–(1.2) are called *cross-diffusion* terms [17]. We remark that segregation effects due to cross-diffusion are well known in population dynamics, and related cross-diffusion systems have been studied in mathematical biology (see, e.g., [18, 22]).

Segregation phenomena of granular material in rotating drums have been intensively investigated in the physical literature. For instance, radial segregation has been investigated numerically using particle methods [10] and analytically using leading-order analysis [6] or shock-wave analysis [14]. Axial segregation has been simulated, for instance, in [2, 3, 20] and analyzed in [3, 5, 16]. For more references, particularly for experimental studies, we refer to the monograph [21] and the review paper [19].

Mathematically, the evolution problem (1.1)–(1.2) has a full and nonsymmetric diffusion matrix:

$$A := \begin{pmatrix} \nu & -(1-u^2) \\ \gamma & 1 \end{pmatrix}.$$

Problems with full diffusion matrices also arise, for instance, in semiconductor theory [7], population dynamics [18], and nonequilibrium thermodynamics [9]. As a consequence, no classical maximum principle arguments and no regularity theory as for single equations are generally available for such problems.

Notice that there are values for u and the parameters ν and γ for which the above matrix A is *not* positive definite in the sense that $x^\top Ax < 0$ may hold for some x. The ellipticity of the system (1.1)–(1.2) is guaranteed if $4\nu > \gamma$ (and $|u| \le 1$). For these values, the existence of global-in-time solutions of (1.1)–(1.3) can be proved using standard techniques. The question arises if it is possible to prove the existence of global weak solutions for *any* values of the parameters $\nu > 0$ and $\gamma > 0$. In this paper we give a positive answer to this question.

The key of the existence analysis is the observation that the system (1.1)–(1.2) possesses a functional whose time derivative is uniformly bounded in time if $|u| < 1$. Indeed, using the functions $\phi(u)$, where

$$\phi(s) := \frac{\gamma}{2}\log\frac{1+s}{1-s} \qquad \text{for } -1 < s < 1,$$

and θ in the weak formulation of (1.1) and (1.2), respectively, and adding the resulting equations leads to the inequality

$$\frac{d}{dt}\int_0^L \left(\Phi(u) + \frac{1}{2}\theta^2\right)dz + \int_0^L (\gamma\nu u_z^2 + \theta_z^2)dz = \int_0^L (\mu u\theta - \theta^2)dz \le c, \tag{1.4}$$

where $c > 0$ depends only on μ and L. Here the function $\Phi(s) := \frac{\gamma}{2}(1-s)\log(1-s) + \frac{\gamma}{2}(1+s)\log(1+s) \ge 0$ is the primitive of ϕ such that $\Phi(0) = 0$. Observe that this estimate is purely formal since the values $|u| = 1$ are possible.

The estimate (1.4) has an important consequence. With the change of unknowns $u = g(v)$, where g is the inverse of ϕ, i.e., $g : \mathbb{R} \to (-1, 1)$ is given by

$$g(s) := \frac{e^{2s/\gamma} - 1}{e^{2s/\gamma} + 1}, \tag{1.5}$$

the system (1.1)–(1.2) becomes, for $|u| < 1$,

$$g(v)_t - (\nu g'(v)v_z - (1-g(v)^2)\theta_z)_z = 0, \tag{1.6}$$

$$\theta_t - (\gamma g'(v)v_z + \theta_z)_z + \theta = \mu g(v). \tag{1.7}$$

Since $\gamma g' = 1 - g^2$, the diffusion matrix of the transformed problem

$$B := \begin{pmatrix} \nu g'(v) & -(1-g(v)^2) \\ \gamma g'(v) & 1 \end{pmatrix} \tag{1.8}$$

satisfies for *any* values of $\nu > 0$ and $\gamma > 0$

$$(x,y)B(x,y)^\top = \nu g'(v)|x|^2 + |y|^2 \geq 0 \quad \forall x, y \in \mathbb{R}.$$

The fact that the above transformation of variables leads to a system of elliptic equations for all values of the parameters can be related to some analytical work on more general equations. Indeed, this fact is in some sense related to the equivalence between the existence of an entropy and the symmetrizability of hyperbolic conservation laws or parabolic systems [8, 15]. Using the definition of the (generalized) "entropy"

$$\eta(s) := g(s)s - \chi(s) + \chi(0) \tag{1.9}$$

from [4] (first used in [1]), where $\chi' = g$, gives $\eta(v) = \Phi(g(v)) = \Phi(u)$, with Φ as above. In this sense, the functional $\Phi(u(t)) + \theta(t)^2/2$ can be interpreted as an "entropy" for the system (1.1)–(1.2) as long as $|u| < 1$. However, notice that the matrix B is *not* symmetric but satisfies the inequality $x^\top Bx > 0$ for all $x \neq 0$, which is sufficient for our existence analysis. The question of whether this observation leads to an existence theory for elliptic systems with general full diffusion matrices is under investigation [12].

In order to make the above "entropy" estimate rigorous, we have to overcome the difficulties near the points where $|u| = 1$. For the transformed problem (1.6)–(1.7) this difficulty translates into the fact that the matrix B does not satisfy the *uniform* positive definiteness condition. Therefore, we have to approximate (1.6)–(1.7) appropriately; see section 2.

Our main existence result is as follows.

THEOREM 1.1. *Let γ, $\nu > 0$, $\mu \geq 0$, and u_0, $\theta_0 \in L^2(\Omega)$ with $-1 \leq u_0 \leq 1$ in Ω. For any $T > 0$, there exists a weak solution (u, θ) of (1.1)–(1.2) such that*

$$\begin{gathered} u, \theta \in H^1(0,T;(H^1_{\rm per}(\Omega))') \cap L^2(0,T;H^1_{\rm per}(\Omega)), \\ -1 \leq u \leq 1 \quad \text{in } Q_T = \Omega \times (0,T). \end{gathered} \tag{1.10}$$

As explained above, the main difficulties of the proof of this theorem are that the system (1.1)–(1.2) is generally not positive definite and no maximum principle to show $|u| \leq 1$ is available. Nevertheless, we are able to prove the existence of solutions for *any* values of ν and γ and thus for *arbitrary* large cross-diffusion.

The proof consists of three steps. First, instead of using the transformation g, we make a change of unknowns which takes into account the singular points $|u| = 1$ (section 2.1). Then the parabolic problem is discretized in time by a recursive sequence of elliptic equations which can be solved each by Schauder's fixed point theorem (section 2.2). Finally, a priori bounds independent of the time discretization parameter are obtained from an inequality similar to (1.4), and standard compactness results lead to the existence of a solution of the original problem (1.1)–(1.2) (section 2.3). The bound on u can be proved by using Stampacchia's truncation method in the approximate problem.

We notice that for $\gamma = 0$, the diffusion matrix for (1.1)–(1.2) becomes tridiagonal, and thus the problem can be solved, for instance, by methods employed in chemotaxis problems [11].

Besides the existence analysis we show two additional results. We prove the uniqueness of solutions in a slightly smaller class of functions if the cross-diffusion is not too large (section 3).

THEOREM 1.2. *Let $\gamma < 4\nu$. Then under the assumptions of Theorem* 1.1 *there exists at most one solution (u, θ) of* (1.1)–(1.2) *in the class of functions satisfying* (1.10) *and $\theta \in L^\infty(0, T; H^1_{\rm per}(\Omega))$.*

Furthermore, we derive a sufficient condition on the parameters in order to get nonsegregation, i.e., convergence of the transient solutions to the constant steady state given by

$$\bar{u} = \frac{1}{L}\int_0^L u_0(z)dz, \quad \bar{\theta} = \frac{1}{L}\int_0^L \theta_0(z)dz.$$

The rate of convergence turns out to be exponential (section 4).

THEOREM 1.3. *Let the assumptions of Theorem* 1.1 *hold and assume that $|u_0| \le c < 1$ in Ω for some $c < 1$, $\mu\bar{u} = \bar{\theta}$ and*

$$\frac{\nu\gamma}{\mu^2} > \frac{L^4}{8(L^2+1)}. \tag{1.11}$$

Then there exist constants $c_0 > 0$, depending on u_0, θ_0, and constants $\delta_1, \delta_2 > 0$, depending on the parameters, such that for all $t > 0$,

$$\|u(t) - \bar{u}\|_{L^2(\Omega)} \le c_0 e^{-\delta_1 t}, \quad \|\theta(t) - \bar{\theta}\|_{L^2(\Omega)} \le c_0 e^{-\delta_2 t}.$$

The constants c_0 and δ_1, δ_2 are defined in (4.1) and (4.4), respectively. The proof of the above result is based on careful estimates using the "entropy" (1.9). Aranson, Tsimring, and Vinokur [3] have determined from linear stability theory that the condition $\mu > \nu$ is necessary to have size segregation. The assumption (1.11) shows that the condition $\mu > \nu$ need *not* be sufficient. In fact, there are parameter values for which *both* $\mu > \nu$ *and* (1.11) hold; i.e., the granular materials are not segregating (see section 5).

Clearly, the dynamics of granular segregation pattern is of much greater interest for the applications than nonsegregation conditions. Therefore, our result must be seen as a first step in the understanding of segregation dynamics.

Finally, we present in section 5 some numerical examples illustrating the segregation or nonsegregation behavior.

2. Proof of Theorem 1.1.

2.1. Ideas of the proof. In this section we present and explain the approximations needed in the proof of Theorem 1.1. As already mentioned in the introduction, the function g provides an "entropy" estimate only if $|u| < 1$. Since $u = \pm 1$ is possible, we use another change of unknowns which includes the points $u = \pm 1$. Let the assumptions of Theorem 1.1 hold and let $\alpha > 1$. Define the transformation $u = g_\alpha(v)$ with $g_\alpha : [-s_\alpha, s_\alpha] \to [-1, 1]$, given by

$$g_\alpha(s) := \alpha\frac{e^{2\alpha s/\gamma} - 1}{e^{2\alpha s/\gamma} + 1} \quad \text{and} \quad s_\alpha := \frac{\gamma}{2\alpha}\log\frac{\alpha+1}{\alpha-1}. \tag{2.1}$$

Observe that for $\alpha \to 1$, g_α equals g on $\mathbb{R}$; see (1.5). As the range of g_α is $[-1, 1]$, the critical points $u = \pm 1$ are included in that transformation. In the following we fix some $\alpha > 1$ and again write g for g_α.

With this change of unknown we obtain the system (1.6)–(1.7), with periodic boundary conditions for v and θ and initial conditions

$$v(\cdot, 0) = v_0 := g^{-1}(u_0), \quad \theta(\cdot, 0) = \theta_0 \qquad \text{in } \Omega. \tag{2.2}$$

The new diffusion matrix B is given by (1.8). It holds for any $(x,y)\in\mathbb{R}^2$

$$\begin{aligned}(x,y)B(x,y)^\top &= \nu g'(v)x^2+y^2+\big(\gamma g'(v)-(1-g(v)^2)\big)\,xy\\ &= \nu g'(v)x^2+y^2+(\alpha^2-1)xy.\end{aligned}$$

Clearly, if $\alpha=1$, the matrix satisfies $x^\top Bx>0$ for all $x\neq 0$, and it seems reasonable that this will also be the case for $\alpha>1$ sufficiently close to 1. In fact, let (v,θ) be a weak solution to (1.1)–(1.2) and use v and θ as test functions in the weak formulation of (1.6)–(1.7), respectively, to obtain the identity

$$\begin{aligned}&\int_\Omega\left(G(v(t))+\frac{1}{2}\theta(t)^2\right)dz+\int_0^t\int_\Omega\left(\nu g'(v)^2v_z^2+\theta_z^2+\theta^2\right)dzdt\\ &\quad=\int_\Omega\left(G(v_0)+\frac{1}{2}\theta_0^2\right)dz-(\alpha^2-1)\int_0^t\int_\Omega v_z\theta_z dzdt+\int_0^t\int_\Omega\mu g(v)\theta dzdt,\end{aligned}$$

where G is defined by $G'(s)=sg'(s)$ and $G(0)=0$, i.e.,

$$G(s)=\frac{2\alpha s}{\gamma}\,\frac{e^{2\alpha s/\gamma}}{e^{2\alpha s/\gamma}+1}+\log\frac{2}{e^{2\alpha s/\gamma}+1}. \tag{2.3}$$

Since $|g|$ is bounded by 1 and $g'\geq(\alpha^2-1)/\gamma$ in $[-s_\alpha,s_\alpha]$ (see Lemma 2.2), we can estimate

$$\begin{aligned}&\int_\Omega\left(G(v(t))+\frac{1}{2}\theta(t)^2\right)dz+\int_0^t\int_\Omega\left(\frac{\nu}{\gamma}(\alpha^2-1)v_z^2+\theta_z^2\right)dzdt\\ &\quad\leq\int_\Omega\left(G(v_0)+\frac{1}{2}\theta_0^2\right)dz-(\alpha^2-1)\int_0^t\int_\Omega v_z\theta_z dzdt+\int_0^t\int_\Omega(\mu|\theta|-\theta^2)dzdt,\end{aligned} \tag{2.4}$$

as long as $-s_\alpha\leq v\leq s_\alpha$ in Q_t. Choosing $\alpha>1$ small enough and applying Young's inequality, it is possible to control the second integral on the right-hand side by the integrals on the left-hand side. This gives the estimates $v_z\in L^2(0,T;L^2(\Omega))$ and $\theta\in L^2(0,T;H^1_{\rm per}(\Omega))$. The inequality (2.4) is made rigorous in Lemma 2.6 for a time-discretized version of (1.6)–(1.7).

Still there remain two difficulties: the elliptic operator corresponding to (1.6)–(1.7) is not uniformly elliptic (since g' is only positive, but not uniformly positive in $\mathbb{R}$), and we have to deal with time derivatives in $g(v)$ (instead of having time *and* space derivatives in v). The first difficulty can be overcome by adding a small number $\varepsilon>0$ to the diffusion term containing $\nu g'(v)$ and passing to the limit $\varepsilon\to 0$ after solving the approximate problem. To overcome the second difficulty we approximate the system by a semidiscrete problem in time (backward Euler method). This method is also interesting from a numerical point of view; see, e.g., [13].

2.2. A semidiscrete problem. The main objective of this section is to prove that for given $\tau>0$ and $(\tilde w,\tilde\theta)\in(H^1_{\rm per}(\Omega))^2$, there exists a solution $(w,\xi)\in(H^1_{\rm per}(\Omega))^2$, satisfying $-s_\alpha\leq w\leq s_\alpha$ in Ω, of the problem

$$\frac{1}{\tau}(g(w)-g(\tilde w))-\big(\nu g'(w)w_z-(1-g(w)^2)\xi_z\big)_z=0, \tag{2.5}$$

$$\frac{1}{\tau}(\xi-\tilde\theta)-(\gamma g'(w)w_z+\xi_z)_z+\xi=\mu g(w)\quad\text{in }\Omega. \tag{2.6}$$

This system is a time-discretized version of (1.6)–(1.7). The function $g(s)$ is defined as in (2.1), but we allow for arguments $s \in \mathbb{R}$. We shall use the following notion of weak solution.

DEFINITION 2.1. *The pair* (w, ξ) *is called a* weak solution *of* (2.5)–(2.6) *if* $(w, \xi) \in (H^1_{\rm per}(\Omega))^2$, $-s_\alpha \le w \le s_\alpha$ *in* Ω, *the initial conditions in* (1.3) *are satisfied in the sense of* $(H^1_{\rm per}(\Omega))'$, *and for every* $(\varphi, \psi) \in (H^1_{\rm per}(\Omega))^2$ *we have*

$$\frac{1}{\tau}\int_\Omega (g(w) - g(\tilde w))\varphi dz + \int_\Omega \big(\nu g'(w)w_z - (1-g(w)^2)\xi_z\big)\varphi_z dz = 0, \tag{2.7}$$

$$\frac{1}{\tau}\int_\Omega (\xi - \tilde\theta)\psi dz + \int_\Omega (\gamma g'(w)w_z + \xi_z)\psi_z dz + \int_\Omega \xi\psi dz = \mu\int_\Omega g(w)\psi dz. \tag{2.8}$$

As explained in section 2.1, we approximate the system (2.5)–(2.6) by a system where an additional ellipticity constant $\varepsilon > 0$ is introduced: Find $(w, \xi) \in (H^1_{\rm per}(\Omega))^2$ such that in Ω

$$\frac{1}{\tau}(g(w) - g(\tilde w)) - \big((\nu g'(w) + \varepsilon)w_z - (1-g(w)^2)_+\xi_z\big)_z + \varepsilon w = 0, \tag{2.9}$$

$$\frac{1}{\tau}(\xi - \tilde\theta) - (\gamma g'(w)w_z + \xi_z)_z + \xi = \mu g(w), \tag{2.10}$$

where $s_+ = \max\{0, s\}$.

The following properties of the function g can be easily shown.

LEMMA 2.2. *The function* $g : \mathbb{R} \to (-\alpha, \alpha)$ *defined by* (2.1) *satisfies* $g \in C^\infty(\mathbb{R}) \cap W^{1,\infty}(\mathbb{R})$ *and*

$$0 < g' \le \alpha^2/\gamma \quad \text{in } \mathbb{R}, \qquad g' \ge (\alpha^2 - 1)/\gamma \quad \text{in } [-s_\alpha, s_\alpha]. \tag{2.11}$$

Fix $\alpha > 1$ *such that* $2(\alpha^2 - 1) \le \nu/2\gamma$ *and define* $h_1, h_2 : \mathbb{R} \to \mathbb{R}$ *by*

$$h_1 := \nu g' - \delta|\gamma g' - (1-g^2)_+|, \quad h_2 := 1 - \frac{1}{\delta}|\gamma g' - (1-g^2)_+|,$$

with $2(\alpha^2 - 1) \le \delta \le \nu/2\gamma$. *Then*

$$h_1 > 0, \quad h_2 \ge 1/2 \quad \text{in } \mathbb{R}, \quad \text{and} \quad h_1 \ge \frac{\nu}{2\gamma}(\alpha^2 - 1) \quad \text{in } [-s_\alpha, s_\alpha]. \tag{2.12}$$

We prove the existence of a solution of (2.9)–(2.10) using Schauder's fixed point theorem. In order to define the fixed point operator, we consider first the following linearized problem: Let $(\hat w, \hat\xi) \in (L^2(\Omega))^2$ be given and find $(w, \xi) \in (H^1_{\rm per}(\Omega))^2$ such that

$$-\big((\nu g'(\hat w) + \varepsilon)w_z - (1-g(\hat w)^2)_+\xi_z\big)_z + \varepsilon w = \frac{1}{\tau}(g(\tilde w) - g(\hat w)), \tag{2.13}$$

$$-(\gamma g'(\hat w)w_z + \xi_z)_z + \xi = \mu g(\hat w) + \frac{1}{\tau}(\tilde\theta - \hat\xi) \tag{2.14}$$

in Ω. The definition of a weak solution of problem (2.13)–(2.14) is similar to Definition 2.1.

LEMMA 2.3. *Let* $(\tilde w, \tilde\theta) \in (H^1_{\rm per}(\Omega))^2$ *and* $(\hat w, \hat\xi) \in (L^2(\Omega))^2$ *be given. Then there exists a unique weak solution of problem* (2.13)–(2.14).

Proof. We define the bilinear form $a : (H^1_{\rm per}(\Omega))^2 \times (H^1_{\rm per}(\Omega))^2 \to \mathbb{R}$,

$$a((w,\xi),(\varphi,\psi)) := \int_\Omega \big[\big((\nu g'(\hat w)+\varepsilon)w_z - (1-g(\hat w)^2)_+\xi_z\big)\varphi_z + \varepsilon w\varphi\big]\,dz \\ + \int_\Omega \big((\gamma g'(\hat w)w_z + \xi_z)\psi_z + \xi\psi\big)dz,$$

and the linear functional $f : (L^2(\Omega))^2 \to \mathbb{R}$,

$$f(\varphi,\psi) := \frac{1}{\tau}\int_\Omega \big((g(\tilde w)-g(\hat w))\varphi + (\tilde\theta-\hat\xi)\psi\big) + \mu\int_\Omega g(\hat w)\psi.$$

In order to apply the Lax–Milgram lemma, we have to check that a is continuous and coercive in $(H^1_{\rm per}(\Omega))^2 \times (H^1_{\rm per}(\Omega))^2$ and that f is continuous in $(L^2(\Omega))^2$. The continuity of a and f follows easily from the pointwise bounds of g and g' and the regularity of $\tilde w$, $\tilde\theta$, $\hat w$, and $\hat\xi$. For the coercivity of a we estimate

$$\begin{aligned} a((w,\xi),(w,\xi)) &= \int_\Omega \big((\nu g'(\hat w)+\varepsilon)|w_z|^2 + |\xi_z|^2 + \varepsilon|w|^2 + |\xi|^2\big)dz \\ &\quad + \int_\Omega \big((\gamma g'(\hat w) - (1-g(\hat w)^2)_+)w_z\xi_z\big)dz \\ &\ge \int_\Omega \big((\varepsilon + h_1(\hat w))|w_z|^2 + h_2(\hat w)|\xi_z|^2 + \varepsilon|w|^2 + |\xi|^2\big)dz \end{aligned}$$

using Young's inequality, where the functions h_1 and h_2 are defined in Lemma 2.2. The bounds (2.12) then imply that

$$a((w,\xi),(w,\xi)) \ge \min\{\varepsilon, 1/2\}\left(\|w\|^2_{H^1_{\rm per}(\Omega)} + \|\xi\|^2_{H^1_{\rm per}(\Omega)}\right),$$

and the coercivity of a is proved. ∎

LEMMA 2.4. *Let $(\tilde w,\tilde\theta) \in (H^1_{\rm per}(\Omega))^2$. Then there exists a unique weak solution of problem* (2.9)–(2.10).

Proof. We use the Schauder fixed point theorem. For this define the map $S : (L^2(\Omega))^2 \to (L^2(\Omega))^2$ by $S(\hat w,\hat\xi) = (w,\xi)$, where (w,ξ) is the weak solution of (2.13)–(2.14). We have to check that S is continuous and compact and that the set

$$\Lambda := \big\{u \in (L^2(\Omega))^2 : u = \lambda S(u)\big\}$$

for $\lambda \in [0,1]$ is bounded. The continuity of S follows by standard arguments. The compactness of S is just a consequence of the compactness of the embedding $H^1_{\rm per}(\Omega) \subset L^2(\Omega)$.

It remains to show that Λ is bounded. If $\lambda = 0$, then $\Lambda = \{(0,0)\}$ is trivially bounded. For $\lambda \in (0,1]$, the equation $S(\hat w,\hat\xi) = \frac{1}{\lambda}(\hat w,\hat\xi)$ is equivalent to

$$\int_\Omega \left(\big((\nu g'(\hat w)+\varepsilon)\hat w_z - (1-g(\hat w)^2)_+\hat\xi_z\big)_z\varphi_z + \varepsilon\hat w\varphi\right)dz = \frac{\lambda}{\tau}\int_\Omega (g(\tilde w)-g(\hat w))\varphi dz,$$

$$\int_\Omega \left((\gamma g'(\hat w)\hat w_z + \hat\xi_z)\psi_z + \hat\xi\psi\right)dz = \lambda\int_\Omega \left(\mu g(\hat w) + \frac{1}{\tau}(\tilde\theta-\hat\xi)\right)\psi dz.$$

Using $(\varphi,\psi)=(\hat{w},\hat{\xi})$ as a test function, adding the resulting integral identities, and applying Young's inequality as in (2.12), we obtain

$$\int_\Omega \big((\varepsilon+h_1(\hat{w}))|\hat{w}_z|^2+h_2(\hat{w})|\hat{\xi}_z|^2+\varepsilon|\hat{w}|^2+|\hat{\xi}|^2\big)dz = \frac{\lambda}{\tau}\int_\Omega (g(\tilde{w})-g(\hat{w}))\hat{w}dz + \lambda\int_\Omega\left(\mu g(\hat{w})+\frac{1}{\tau}(\tilde{\theta}-\hat{\xi})\right)\hat{\xi}dz.$$

Using again Young's inequality on the right-hand side of this equation and employing the estimate (2.12), we deduce

$$\int_\Omega \big(\varepsilon(|\hat{w}_z|^2+|\hat{w}|^2)+|\hat{\xi}_z|^2+|\hat{\xi}|^2\big)dz \le \frac{\lambda^2}{\tau^2\varepsilon}\int_\Omega (g(\tilde{w})-g(\hat{w}))^2dz+\frac{2\lambda^2}{\tau^2}\int_\Omega\tilde{\theta}^2dz + 2(\lambda\mu)^2\int_\Omega |g(\hat{w})|^2dz,$$

and since $g\in L^\infty(\mathbb{R})$, the assertion follows. ∎

In the following we derive uniform bounds for the solution of (2.9)–(2.10) which allow us to pass to the limit $\varepsilon\to 0$. This proves the existence of a solution of (2.5)–(2.6). We need the following auxiliary result, whose proof is standard.

LEMMA 2.5. *Let $\varphi\in C(\mathbb{R})$ be nondecreasing with $\varphi(0)=0$ and define $\Phi\in C^1(\mathbb{R})$ by $\Phi(s):=\int_0^s g'(\sigma)\varphi(\sigma)d\sigma$. Then it holds for all $s,t\in\mathbb{R}$ that*

$$\Phi(s)-\Phi(t)\le (g(s)-g(t))\varphi(s). \tag{2.15}$$

LEMMA 2.6. *Let $(\tilde{w},\tilde{\xi})\in (H^1_{\rm per}(\Omega))^2$ be such that $-s_\alpha\le\tilde{w}\le s_\alpha$ in Ω and let $(w_\varepsilon,\xi_\varepsilon)\in(H^1_{\rm per}(\Omega))^2$ be a solution of (2.9)–(2.10). Then the following estimates hold:*

$$-s_\alpha\le w_\varepsilon\le s_\alpha \quad \text{in } \Omega, \tag{2.16}$$

$$\int_\Omega\Big(G(w_\varepsilon)+\frac{1}{2}\xi_\varepsilon^2\Big)dz+C\tau\int_\Omega(|w_{\varepsilon z}|^2+|\xi_{\varepsilon z}|^2+|\xi_\varepsilon|^2)dz \le \int_\Omega\Big(G(\tilde{w})+\frac{1}{2}\tilde{\xi}^2\Big)dz+C'\tau \tag{2.17}$$

for some positive constants C, C' independent of ε and τ, and for G defined in (2.3).

In addition, there exists a subsequence of $(w_\varepsilon,\xi_\varepsilon)$ (not relabeled) such that $(w_\varepsilon,\xi_\varepsilon)\rightharpoonup(w,\xi)$ weakly in $(H^1_{\rm per}(\Omega))^2$ and strongly in $(L^2(\Omega))^2$ as $\varepsilon\to 0$, and (w,ξ) is a weak solution of problem (2.5)–(2.6).

Proof. We use $\varphi(w_\varepsilon):=\max(w_\varepsilon-s_\alpha,0)$ as a test function in the weak formulation of (2.9). Since φ is increasing and $\varphi(0)=0$ we can employ Lemma 2.5. Let Φ be defined as in Lemma 2.5. Then, together with the identities $(1-g(s)^2)_+\varphi'(s)=0$ for all $s\in\mathbb{R}$ and $\Phi(\tilde{w})=0$, we obtain

$$0\ge\frac{1}{\tau}\int_\Omega(g(w_\varepsilon)-g(\tilde{w}))\varphi(w_\varepsilon)dx\ge\int_\Omega(\Phi(w_\varepsilon)-\Phi(\tilde{w}))dx=\int_\Omega\Phi(w_\varepsilon)dx.$$

This implies $\Phi(w_\varepsilon)=0$ and therefore $w_\varepsilon\le s_\alpha$ in Ω. In a similar way we deduce $w_\varepsilon\ge -s_\alpha$ in Ω. Observe that these bounds imply that $(1-g(w_\varepsilon)^2)_+=1-g(w_\varepsilon)^2$ in Ω.

Now we use $(w_\varepsilon, \xi_\varepsilon)$ as a test function in the weak formulation of problem (2.9)–(2.10). Adding the corresponding integral identities and using property (2.15) we get, after multiplication by τ,

$$\int_\Omega \Big(G(w_\varepsilon) + \frac{1}{2}\xi_\varepsilon^2\Big)dz + \tau\int_\Omega \big(h_1(w_\varepsilon)|w_{\varepsilon z}|^2 + h_2(w_\varepsilon)|\xi_{\varepsilon z}|^2 + |\xi_\varepsilon|^2\big)dz \\ \le \mu\tau\int_\Omega g(w_\varepsilon)\xi_\varepsilon dz + \int_\Omega \Big(G(\tilde{w}) + \frac{1}{2}\tilde{\xi}^2\Big)dz.$$

Applying Young's inequality and the bounds (2.11) and (2.12) for g', h_1, and h_2, we deduce (2.17).

Finally, the uniform estimates (2.16) and (2.17) imply the existence of a subsequence (not relabeled) of $(w_\varepsilon, \xi_\varepsilon)$ and of a pair $(w, \xi) \in (H^1_{\rm per}(\Omega))^2$ such that, as $\varepsilon \to 0$,

$$w_\varepsilon \overset{*}{\rightharpoonup} w \quad \text{weakly* in } L^\infty(\Omega), \tag{2.18}$$

$$\begin{aligned} w_{\varepsilon z} &\rightharpoonup w_z \quad \text{weakly in } L^2(\Omega), \\ \xi_\varepsilon &\rightharpoonup \xi \quad \text{weakly in } H^1_{\rm per}(\Omega). \end{aligned} \tag{2.19}$$

In fact, the convergences (2.18) and (2.19) imply $w_\varepsilon \rightharpoonup w$ weakly in $H^1_{\rm per}(\Omega)$ and thus, by the compactness of the embedding $H^1_{\rm per}(\Omega) \subset L^2(\Omega)$, we deduce for a subsequence, as $\varepsilon \to 0$, $w_\varepsilon \to w$, and $\xi_\varepsilon \to \xi$ strongly in $L^2(\Omega)$ and a.e. in Ω. These convergence results and the continuity of g and g' allow us to pass to the limit $\varepsilon \to 0$ in the weak formulation of problem (2.9)–(2.10) and to identify (w, ξ) as a weak solution of (2.5)–(2.6). ∎

2.3. End of the proof of Theorem 1.1. Let $T > 0$ and $N \in \mathbb{N}$ be given and let $\tau = T/N$ be the time step. We define recursively pairs $(v^k, \theta^k) \in (H^1_{\rm per}(\Omega))^2$, $k = 1, \ldots, N$, as the weak solution of the problem (2.5)–(2.6) corresponding to the data $(\tilde{w}, \tilde{\theta}) = (v^{k-1}, \theta^{k-1})$, and with $(v^0, \theta^0) = (v_0, \theta_0)$. Then we define the piecewise constant functions

$$v^\tau(x,t) := v^k(x) \quad \text{and} \quad \theta^\tau(x,t) := \theta^k(x) \quad \text{if } (x,t) \in \Omega \times ((k-1)\tau, k\tau]$$

for $k = 1, \ldots, N$ and introduce the discrete entropies

$$\eta^k := \int_\Omega \Big(G(v^k) + \frac{1}{2}|\theta^k|^2\Big)dz, \quad \eta^\tau(t) := \int_\Omega \Big(G(v^\tau(\cdot,t)) + \frac{1}{2}|\theta^\tau(\cdot,t)|^2\Big)dz. \tag{2.20}$$

We have the following consequence of Lemma 2.6.

COROLLARY 2.7. *There exist uniform bounds with respect to τ for the norms*

$$\|\eta^\tau\|_{L^\infty(0,T)}, \quad \|v^\tau\|_{L^2(0,T;H^1_{\rm per}(\Omega))}, \quad \|g(v^\tau)\|_{L^2(0,T;H^1_{\rm per}(\Omega))}, \quad \text{and} \quad \|\theta^\tau\|_{L^2(0,T;H^1_{\rm per}(\Omega))}.$$

In addition,

$$-s_\alpha \le v^\tau \le s_\alpha \quad \text{in } Q_T = \Omega \times (0,T). \tag{2.21}$$

Proof. From the "entropy" inequality (2.17) we obtain

$$\eta^m - \eta^0 = \sum_{k=1}^m (\eta^k - \eta^{k-1}) \le C'm\tau - C\tau\sum_{k=1}^m \int_\Omega (|v_z^k|^2 + |\theta_z^k|^2 + |\theta^k|^2)dz$$

for $m = 1, \dots, N$. Taking the maximum over m yields

$$\|\eta^\tau\|_{L^\infty(0,T)} + C\int_{Q_T} \big(|v_z^\tau|^2 + |\theta_z^\tau|^2 + |\theta^\tau|^2\big)dzdt \le \eta^0 + C'T.$$

Since both g and g' are smooth and bounded we also deduce the estimate for the norm $\|g(v^\tau)\|_{L^2(0,T;H^1_{\rm per}(\Omega))}$. Finally, (2.21) follows directly from (2.16). ∎

We need uniform estimates of the time derivatives. For this, we introduce the shift operator and linear interpolations in time. For $t \in ((k-1)\tau, k\tau]$, $k = 1, \dots, N$, we define $\sigma_\tau v^\tau(\cdot,t) := v^{k-1}$ and $\sigma_\tau\theta^\tau(\cdot,t) := \theta^{k-1}$ in Ω. Setting $\delta t := (t/\tau - (k-1)) \in [0,1]$, we introduce

$$\tilde g^\tau := g(\sigma_\tau v^\tau) + \delta t\big(g(v^\tau) - g(\sigma_\tau v^\tau)\big), \quad \tilde\theta^\tau := \sigma_\tau\theta^\tau + \delta t\big(\theta^\tau - \sigma_\tau\theta^\tau\big) \tag{2.22}$$

in Q_T.

LEMMA 2.8. *There exist uniform bounds with respect to τ for the norms*

$$\|\tilde g_t^\tau\|_{L^2(0,T;(H^1_{\rm per}(\Omega))')}, \quad \|\tilde g^\tau\|_{L^2(0,T;H^1_{\rm per}(\Omega))\cap L^\infty(Q_T)},$$
$$\|\tilde\theta_t^\tau\|_{L^2(0,T;(H^1_{\rm per}(\Omega))')}, \quad \textit{and} \quad \|\tilde\theta^\tau\|_{L^2(0,T;H^1_{\rm per}(\Omega))}.$$

Proof. From the definition (2.22) of $\tilde g^\tau$ and (2.5) we compute

$$\tilde g_t^\tau = \frac{1}{\tau}\big(g(v^\tau) - g(\sigma_\tau v^\tau)\big) = \big(\nu g'(v^\tau)v_z^\tau - (1 - g(v^\tau)^2)\theta_z^\tau\big)_z.$$

Using the boundedness of g' in $\mathbb{R}$ and Corollary 2.7 we obtain a uniform bound for $\|\tilde g_t^\tau\|_{L^2((0,T;H^1_{\rm per})')}$. Moreover, since g is bounded, it is clear that $\tilde g^\tau \in L^\infty(Q_T)$ for any $\tau \ge 0$. We also have

$$\tilde g_z^\tau = \delta t g'(v^\tau)v_z^\tau + (1-\delta t)g'(\sigma_\tau v^\tau)(\sigma_\tau v^\tau)_z. \tag{2.23}$$

Since $(\sigma_\tau v^\tau)_z = \sigma_\tau v_z^\tau$, the $L^\infty(Q_T)$ bound for $\tilde g^\tau$ together with (2.23) and Corollary 2.7 implies a uniform bound for $\|\tilde g^\tau\|_{L^2(0,T;H^1_{\rm per}(\Omega))}$. In a similar way we obtain uniform estimates for $\tilde\theta^\tau$. ∎

Proof of Theorem 1.1. The functions v^τ, θ^τ, $\tilde g^\tau$, $\tilde\theta^\tau$ satisfy the weak formulation

$$\int_0^T \langle \tilde g_t^\tau, \varphi\rangle dt + \int_{Q_T} \big(\nu g'(v^\tau)v_z^\tau - (1-g(v^\tau)^2)\theta_z^\tau\big)\varphi_z dzdt = 0, \tag{2.24}$$

$$\int_0^T \langle \tilde\theta_t, \psi\rangle dt + \int_{Q_T} \big(\gamma g'(v^\tau)v_z^\tau + \theta_z^\tau\big)\psi_z dzdt + \int_{Q_T} \theta^\tau\psi dydt$$
$$= \mu\int_{Q_T} g(v^\tau)\psi dzdt \tag{2.25}$$

for any $\varphi, \psi \in L^2(0,T;H^1_{\rm per}(\Omega))$. The estimates of Lemma 2.8 allow us to extract a subsequence (not relabeled) such that, as $\tau \to 0$,

$$\tilde g_t^\tau \rightharpoonup u_t \quad \text{weakly in } L^2(0,T;(H^1_{\rm per}(\Omega))'), \tag{2.26}$$

$$\tilde g^\tau \rightharpoonup u \quad \text{weakly in } L^2(0,T;H^1_{\rm per}(\Omega)), \tag{2.27}$$

$$\tilde g^\tau \overset{*}{\rightharpoonup} u \quad \text{weakly* in } L^\infty(Q_T),$$

$$\tilde\theta_t^\tau \rightharpoonup \theta_t \quad \text{weakly in } L^2(0,T;(H^1_{\rm per}(\Omega))'), \tag{2.28}$$

$$\tilde\theta^\tau \rightharpoonup \theta \quad \text{weakly in } L^2(0,T;H^1_{\rm per}(\Omega)). \tag{2.29}$$

The compact embedding $H^1_{\rm per}(\Omega)\subset L^\infty(\Omega)$, the convergence results (2.26)–(2.29), and Aubin's lemma [23] imply, up to a subsequence,

$$\begin{aligned}(2.30)\qquad \tilde g^\tau &\to u \quad \text{strongly in } L^2(0,T;L^\infty(\Omega)),\\ \tilde\theta^\tau &\to \theta \quad \text{strongly in } L^2(0,T;L^\infty(\Omega)).\end{aligned}$$

Moreover, Corollary 2.7 yields the existence of a subsequence such that

$$\begin{aligned}(2.31)\qquad v^\tau &\rightharpoonup v \quad \text{weakly in } L^2(0,T;H^1_{\rm per}(\Omega)),\\ v^\tau &\overset{*}{\rightharpoonup} v \quad \text{weakly* in } L^\infty(Q_T),\\ g(v^\tau) &\rightharpoonup \hat u \quad \text{weakly in } L^2(0,T;H^1_{\rm per}(\Omega)),\\ \theta^\tau &\rightharpoonup \hat\theta \quad \text{weakly in } L^2(0,T;H^1_{\rm per}(\Omega)).\end{aligned}$$

It holds that $\tilde g^\tau - g(v^\tau)=\tau(\delta t-1)\tilde g_t^\tau$, and therefore, by Lemma 2.8,

$$(2.32)\qquad \|\tilde g^\tau - g(v^\tau)\|_{L^2(0,T;(H^1_{\rm per})')}\to 0 \quad \text{as } \tau\to 0.$$

Hence, $u=\hat u$. In a similar way we obtain $\theta=\hat\theta$. Finally,

$$\begin{aligned}&\|g(v^\tau)-u\|_{L^1(0,T;L^2(\Omega))}\\ &\le \|g(v^\tau)-\tilde g^\tau\|_{L^1(0,T;L^2(\Omega))}+\|\tilde g^\tau-u\|_{L^1(0,T;L^2(\Omega))}\\ &\le \|g(v^\tau)-\tilde g^\tau\|^{1/2}_{L^1(0,T;(H^1_{\rm per}(\Omega))')}\|g(v^\tau)-\tilde g^\tau\|^{1/2}_{L^1(0,T;H^1_{\rm per}(\Omega))}\\ &\quad +\|\tilde g^\tau-u\|_{L^1(0,T;L^2(\Omega))}\\ &\le C\|g(v^\tau)-\tilde g^\tau\|^{1/2}_{L^2(0,T;(H^1_{\rm per}(\Omega))')}+\|\tilde g^\tau-u\|_{L^1(0,T;L^2(\Omega))}\\ (2.33)\qquad &\to 0\end{aligned}$$

as $\tau\to 0$. Therefore, $g(v^\tau)\to u$ strongly in $L^1(0,T;L^2(\Omega))$ and a.e. in Q_T. Now, letting $\tau\to 0$ in (2.24)–(2.25), we obtain, for $\varphi,\psi\in L^2(0,T;H^1_{\rm per}(\Omega))$,

$$(2.34)\qquad \int_0^T\langle u_t,\varphi\rangle dt+\int_{Q_T}\big(\nu u_z-(1-u^2)\theta_z\big)\varphi_z dzdt=0,$$

$$(2.35)\qquad \int_0^T\langle \theta_t,\psi\rangle dt+\int_{Q_T}\big(\gamma u_z+\theta_z\big)\psi_z dzdt+\int_{Q_T}\theta\psi dz=\mu\int_{Q_T}u\psi dzdt.$$

This proves Theorem 1.1. □

3. Proof of Theorem 1.2. Let (u_1,θ_1) and (u_2,θ_2) be two weak solutions of (1.1)–(1.3) with the same initial data satisfying (1.10) and $\theta_1\in L^\infty(0,T;H^1_{\rm per}(\Omega))$. Set $Q_t=\Omega\times(0,t)$. The equations satisfied by $u=u_1-u_2$ and $\theta=\theta_1-\theta_2$ read

$$(3.1)\qquad u_t-\nu u_{zz}+\theta_{zz}=\big((u_1+u_2)u\theta_{1z}+u_2^2\theta_z\big)_z,$$

$$(3.2)\qquad \theta_t-\theta_{zz}+\theta=\gamma u_{zz}+\mu u.$$

Take u and θ as test functions in the weak formulations of (3.1) and (3.2), respectively, and add (3.2), multiplied by some number $a>0$, and (3.1) to obtain

$$\begin{aligned}&\frac12\int_\Omega(u(t)^2+a\theta(t)^2)dz+\int_{Q_t}(\nu u_z^2+a\theta_z^2+a\theta^2)dzdt\\ (3.3)\qquad &=\int_{Q_t}(1-a\gamma-u_2^2)u_z\theta_z dzdt+a\mu\int_{Q_t}u\theta dzdt-\int_{Q_t}(u_1+u_2)u\theta_{1z}u_z dzdt.\end{aligned}$$

We apply Young's inequality to the second integral on the right-hand side:

$$a\mu\int_{Q_t} u\theta dzdt \le \frac{a\mu^2}{2}\int_{Q_t} u^2 dzdt + \frac{a}{2}\int_{Q_t}\theta^2 dzdt.$$

For the third integral on the right-hand side of (3.3) we use the Gagliardo–Nirenberg inequality

$$\|u\|_{L^\infty(\Omega)} \le C_0\|u\|_{H^1(\Omega)}^{1/2}\|u\|_{L^2(\Omega)}^{1/2} \quad \forall u\in H^1(0,L)$$

and the Young inequality

$$x^{1/2}y^{3/2} \le \frac{\varepsilon}{2}x^2 + C(\varepsilon)y^2 \quad \forall x,y\ge 0,\ \varepsilon>0.$$

Then, with the abbreviation $C_1 = 2C_0\|\theta_{1z}\|_{L^\infty(0,T;L^2(\Omega))} < \infty$ and $|u_1|, |u_2| \le 1$,

$$\begin{aligned}
&\int_{Q_t}(u_1+u_2)u\theta_{1z}u_z dzdt \\
&\le 2\|u\|_{L^2(0,t;L^\infty(\Omega))}\|\theta_{1z}\|_{L^\infty(0,t;L^2(\Omega))}\|u_z\|_{L^2(0,t;L^2(\Omega))} \\
&\le C_1\|u\|_{L^2(0,t;L^2(\Omega))}^{1/2}\left(\|u\|_{L^2(Q_t)}^2 + \|u_z\|_{L^2(Q_t)}^2\right)^{1/4}\|u_z\|_{L^2(0,t;L^2(\Omega))} \\
&\le C_1\left(\|u\|_{L^2(Q_t)}\|u_z\|_{L^2(Q_t)} + \|u\|_{L^2(Q_t)}^{1/2}\|u_z\|_{L^2(Q_t)}^{3/2}\right) \\
&\le \frac{\varepsilon}{2}\|u_z\|_{L^2(Q_t)}^2 + \frac{C_1^2}{2\varepsilon}\|u\|_{L^2(Q_t)}^2 + \frac{\varepsilon}{2}\|u_z\|_{L^2(Q_t)}^2 + C(\varepsilon)C_1^4\|u\|_{L^2(Q_t)}^2.
\end{aligned}$$

With these inequalities we can estimate (3.3) as

$$\begin{aligned}
&\frac12\left(\|u(t)\|_{L^2(\Omega)}^2 + a\|\theta(t)\|_{L^2(\Omega)}^2\right) + \frac{a}{2}\|\theta\|_{L^2(Q_t)}^2 \\
&\le -\int_{Q_t}\left(-(|1-a\gamma|+1)|u_z||\theta_z| + (\nu-\varepsilon)u_z^2 + a\theta_z^2\right) \\
&\quad + \left(\frac{a\mu^2}{2} + \frac{C_1^2}{2\varepsilon} + C(\varepsilon)C_1^4\right)\|u\|_{L^2(Q_t)}^2. \qquad (3.4)
\end{aligned}$$

It can be easily seen that the quadratic form

$$A(x,y) = -(|1-a\gamma|+1)xy + (\nu-\varepsilon)x^2 + ay^2, \quad x,y\ge 0,$$

is positive definite if we choose $a = 1/\gamma$ and $\varepsilon = \nu - \gamma/4 > 0$ (since $\gamma < 4\nu$ by assumption). Then Gronwall's lemma applied to (3.4) implies that $u(t) = \theta(t) = 0$ in Ω for any $t > 0$. This proves Theorem 1.2. □

4. Proof of Theorem 1.3. Let (u,θ) be a weak solution of (1.1)–(1.3) given by Theorem 1.1. Let $\alpha > 1$ and set

$$c_0 = \frac12\int_0^L\left(\gamma(u_0+1)\ln\frac{1+u_0}{1+\bar u} + \gamma(1-u_0)\ln\frac{1-u_0}{1-\bar u} + (\theta_0-\bar\theta)\right)dz. \qquad (4.1)$$

Notice that c_0 is well defined even if $u_0(z) = \pm 1$. For the proof of Theorem 1.3 we need the following lemma.

LEMMA 4.1. *Define the function* $\psi : [-1,1] \to \mathbb{R}$ *by*

$$\psi(u) = \frac{\gamma}{2\alpha} \ln\left(\frac{\alpha+u}{\alpha+\bar{u}}\,\frac{\alpha-\bar{u}}{\alpha-u}\right).$$

Then the function $\Psi : [-1,1] \to \mathbb{R}$*, defined by*

$$\Psi(u) = \frac{\gamma}{2\alpha}(\alpha+u)\ln\frac{\alpha+u}{\alpha+\bar{u}} + \frac{\gamma}{2\alpha}(\alpha-u)\ln\frac{\alpha-u}{\alpha-\bar{u}},$$

satisfies for all $u \in [-1,1]$

$$\Psi'(u) = \psi(u), \quad \Psi''(u) = \frac{\gamma}{\alpha^2-u^2}, \quad \Psi(u) \ge \frac{\gamma}{2\alpha^2}(u-\bar{u})^2.$$

The lemma follows from Taylor expansion around $\bar{u}$:

$$\Psi(u) = \Psi(\bar{u}) + \Psi'(\bar{u})(u-\bar{u}) + \frac{1}{2}\Psi''(\xi)(u-\bar{u})^2 \ge \frac{\gamma}{2\alpha^2}(u-\bar{u})^2.$$

Proof of Theorem 1.3. We use $\psi(u) \in L^\infty(Q_T) \cap L^2(0,T;H^1_{\rm per}(\Omega))$ and $\theta - \bar{\theta} \in L^2(0,T;H^1_{\rm per}(\Omega))$ as test functions in the weak formulation of (1.1) and (1.2), respectively, and add the resulting equations:

$$\begin{aligned}(4.2)\qquad &\int_\Omega \left(\Psi(u(t)) + \frac{1}{2}(\theta(t)-\bar{\theta})^2\right)dz + \int_{Q_t}(\nu\psi'(u)u_z^2 + \theta_z^2)dzdt \\ &= \int_\Omega \left(\Psi(u_0) + \frac{1}{2}(\theta_0-\bar{\theta})^2\right)dz + \int_{Q_t}((1-u^2)\psi'(u)-\gamma)u_z\theta_z dzdt \\ &\quad + \int_{Q_t}(\mu u-\theta)(\theta-\bar{\theta})dzdt.\end{aligned}$$

For the second integral on the right-hand side we use Young's inequality:

$$\begin{aligned}&\int_{Q_t}((1-u^2)\psi'(u)-\gamma)u_z\theta_z dzdt = \gamma\int_{Q_t}\frac{1-\alpha^2}{\alpha^2-u^2}u_z\theta_z dzdt \\ &\le \frac{\nu\gamma}{2}(\alpha^2-1)^{1/2}\int_{Q_t}\frac{u_z^2}{\alpha^2-u^2}dzdt + \frac{\gamma}{2\nu}(\alpha^2-1)^{3/2}\int_{Q_t}\frac{\theta_z^2}{\alpha^2-u^2}dzdt \\ &\le \frac{\nu\gamma}{2}(\alpha^2-1)^{1/2}\int_{Q_t}\frac{u_z^2}{\alpha^2-u^2}dzdt + \frac{\gamma}{2\nu}(\alpha^2-1)^{1/2}\int_{Q_t}\theta_z^2 dzdt.\end{aligned}$$

Since $\mu\bar{u} = \bar{\theta}$, the last integral on the right-hand side of (4.2) becomes

$$\begin{aligned}\int_{Q_t}(\mu u-\theta)(\theta-\bar{\theta})dzdt &= \mu\int_{Q_t}(u-\bar{u})(\theta-\bar{\theta})dzdt - \int_{Q_t}(\theta-\bar{\theta})^2 dzdt \\ &\le \frac{\mu^2\delta}{2}\int_{Q_t}(u-\bar{u})^2 dzdt + \left(\frac{1}{2\delta}-1\right)\int_{Q_t}(\theta-\bar{\theta})^2 dzdt,\end{aligned}$$

where we choose

$$\frac{L^2}{2(L^2+2)} < \delta < \frac{4\nu\gamma}{\mu^2 L^2}.$$

This is possible by assumption (1.11). We employ Lemma 4.1 to estimate the first integral on the left-hand side of (4.2):

$$\int_\Omega \left(\Psi(u(t)) + \frac{1}{2}(\theta(t)-\bar\theta)^2\right) dz \geq \int_\Omega \left(\frac{\gamma}{2\alpha^2}(u(t)-\bar u)^2 + \frac{1}{2}(\theta(t)-\bar\theta)^2\right) dz.$$

Finally, the second term on the left-hand side of (4.2) can be estimated by using the Poincaré inequality

$$\|v-\bar v\|_{L^2(\Omega)} \leq \frac{L}{\sqrt{2}}\|v_z\|_{L^2(\Omega)} \quad \forall v \in H^1_{\rm per}(\Omega) \text{ with } \bar v = \int_0^L v(z)dz.$$

We obtain

$$\int_{Q_t} (\nu\psi'(u)u_z^2 + \theta_z^2)dzdt \geq \int_{Q_t} \left(\frac{2\nu\gamma}{L^2}\,\frac{(u-\bar u)^2}{\alpha^2-u^2} + \frac{2}{L^2}(\theta-\bar\theta)^2\right) dzdt.$$

Putting the above estimates together, we infer from (4.2) that

$$\begin{aligned}(4.3)\qquad &\int_\Omega \left(\frac{\gamma}{2\alpha^2}(u(t)-\bar u)^2 + \frac{1}{2}(\theta(t)-\bar\theta)^2\right) dz \\ &\leq c_0^2 + \int_{Q_t}\left(\frac{\mu^2\delta}{2} - \frac{2\nu\gamma}{L^2} + \frac{\nu\gamma}{L^2}(\alpha^2-1)^{1/2}\right)\frac{(u-\bar u)^2}{\alpha^2-u^2}dzdt \\ &\quad + \left(\frac{1}{2\delta} - \frac{L^2+2}{L^2} + \frac{\gamma}{\nu L^2}(\alpha^2-1)^{1/2}\right)\int_{Q_t}(\theta-\bar\theta)^2 dzdt.\end{aligned}$$

Observing that

$$\frac{(u-\bar u)^2}{\alpha^2-u^2} \geq \frac{(u-\bar u)^2}{\alpha^2},$$

we can let $\alpha \to 1$ in (4.3) to obtain

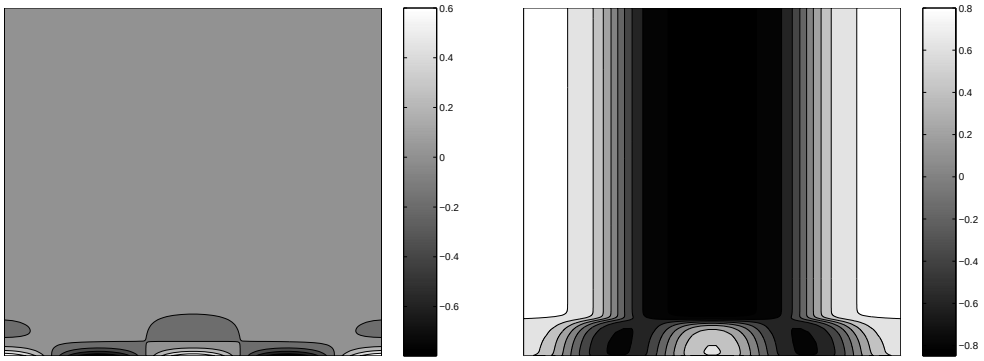
$$\begin{aligned}\frac{1}{2}\int_\Omega \left(\gamma(u(t)-\bar u)^2 + (\theta(t)-\bar\theta)^2\right) dz \leq c_0^2 &- \int_{Q_t}\left(\frac{2\nu\gamma}{L^2} - \frac{\mu^2\delta}{2}\right)(u-\bar u)^2 dzdt \\ &- \left(\frac{L^2+2}{L^2} - \frac{1}{2\delta}\right)\int_{Q_t}(\theta-\bar\theta)^2 dzdt.\end{aligned}$$

Defining

$$(4.4)\qquad \delta_1 = \frac{4\nu}{L^2} - \frac{\mu^2\delta}{\gamma} > 0, \quad \delta_2 = \frac{2(L^2+2)}{L^2} - \frac{1}{\delta} > 0,$$

the theorem follows from Gronwall's lemma. ∎

5. Numerical examples. In this section we illustrate by numerical experiments the long-time coarsening of the segregation bands in a drum. For the numerical discretization, we use a time-discretized version of (1.6)–(1.7) (backward Euler scheme), as motivated by the existence analysis of section 2,instead of discretizing (1.1)–(1.2)



(a) $L = 1$, $0 \le t \le 0.159$. (b) $L = 30$, $0 \le t \le 3049$.

FIG. 5.1. $\gamma = 2$, $\mu = 3$, $\nu = 2$, $u_0(z) = 0.8\cos(4\pi z/L)$, $N = 50$.

directly. The space discretization is performed by using finite differences. The nonlinear system is solved by a simple fixed point strategy.

In the following examples, we illustrate the segregation behavior of the component u of the solutions of (1.1)–(1.2). The behavior relies on three important conditions. First, condition (1.11) ensures the convergence of u to a constant steady state. Second, the authors of [3] conjectured that the condition $\mu > \nu$ is a necessary condition to have segregation. This conjecture arises from a linear stability analysis sketched in [3], showing that perturbations of the form $\exp(\lambda t + 2\pi z/\ell)$, where $\lambda \in \mathbb{R}$ and $\ell > 0$ is the wavelength of the perturbations, are unstable if $\mu > \nu + 4\pi^2(\nu+\gamma)/\ell^2$. Therefore, this instability is captured only if the length L of the domain satisfies the third condition

$$L > 2\pi\sqrt{(\gamma+\nu)/(\mu-\nu)}. \tag{5.1}$$

In Figure 5.1 we present the behavior of u in the (z,t)-plane for two different domain lengths. The number of grid points is $N = 50$. The parameters in Figure 5.1(a) satisfy $\mu > \nu$ and (1.11) but *not* (5.1). We observe convergence of u to a constant steady state. We expect this behavior in view of Theorem 1.3. This example shows that the condition $\mu > \nu$ is *not* sufficient for segregation. The parameters in Figure 5.1(b) satisfy the segregation condition (5.1) but not (1.11). The granular materials segregate since the length of the cylinder is large enough, as claimed by the linear stability analysis.

Figure 5.2 shows that (1.11) is a sufficient but not necessary condition to have nonsegregation. Indeed, the parameters are chosen such that (1.11) is not satisfied, but the granular materials do not segregate.

A more detailed view of the same segregation phenomena as above but with a larger number of bands is presented in Figure 5.3. The parameters do not satisfy (1.11) but (5.1) holds. Thus, we expect segregation. The initial short-wave perturbations produce decaying standing waves (Figure 5.3(a)). The segregated bands emerge, and we observe metastable long-wave bands. Finally, after a long time, the system segregates again (Figure 5.3(b)). This illustrates the very slow coarsening of the band structure (see [3]).

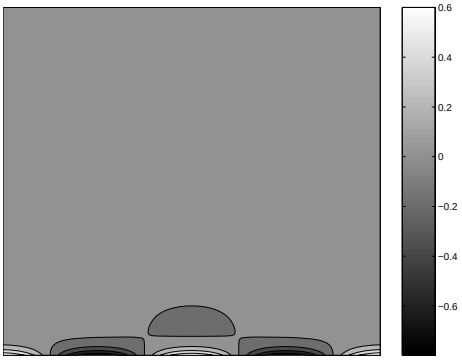


FIG. 5.2. $L = 4$, $\gamma = 2$, $\mu = 2$, $\nu = 3$, $u_0(z) = 0.8\cos(4\pi z/L)$, $N = 50$.

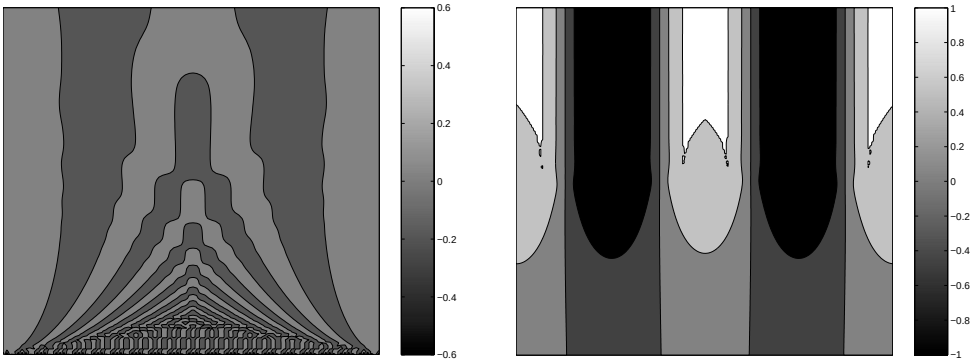

(a) $0 \le t \le 1.06$. (b) $4.8 \le t \le 8.9$.

FIG. 5.3. $\gamma = 100$, $\mu = 40$, $\nu = 0.5$, $L = 30$, $u_0(z) = 0.75\cos(80\pi z/L)$, $N = 1000$.

Acknowledgment. The authors thank the anonymous referees for their suggestions.

ON THE CAUCHY PROBLEM FOR A NONLINEAR KOLMOGOROV EQUATION*

ANDREA PASCUCCI† AND SERGIO POLIDORO†

Abstract. We consider the Cauchy problem related to the partial differential equation

$$Lu \equiv \Delta_x u + h(u)\partial_y u - \partial_t u = f(\cdot, u),$$

where $(x, y, t) \in \mathbb{R}^N \times \mathbb{R} \times]0, T[$, which arises in mathematical finance and in the theory of diffusion processes. We study the regularity of solutions regarding L as a perturbation of an operator of Kolmogorov type. We prove the existence of local classical solutions and give some sufficient conditions for global existence.

Key words. nonlinear degenerate Kolmogorov equation, interior regularity, Hörmander operators

1. Introduction.

In this paper we study the Cauchy problem

$$Lu = f(\cdot, u) \qquad \text{in } S_T \equiv \mathbb{R}^{N+1} \times]0, T[, \tag{1.1}$$

$$u(\cdot, 0) = g \qquad \text{in } \mathbb{R}^{N+1}, \tag{1.2}$$

where L is the nonlinear operator defined by

$$Lu = \Delta_x u + h(u)\partial_y u - \partial_t u, \tag{1.3}$$

$(x, y, t) = z$ denotes the point in $\mathbb{R}^N \times \mathbb{R} \times \mathbb{R}$, and Δ_x is the Laplace operator acting in the variable $x \in \mathbb{R}^N$. We assume that f, g, and h are globally Lipschitz continuous functions.

One of the main features of operator (1.3) is the strong degeneracy of its characteristic form due to the lack of diffusion in the y-direction, so that (1.1)–(1.2) may include the Cauchy problem for the Burgers equation, when $h(u) = u$, $g = g(y)$, and $f \equiv 0$. On the other hand, L can be considered as nonlinear version of the operator

$$K = \Delta_x + x_1\partial_y - \partial_t, \tag{1.4}$$

which was introduced by Kolmogorov [17] and has been extensively studied by Kuptsov [12] and Lanconelli and Polidoro [14]. Among the known results of K, we recall that every solution to $Ku = 0$ is smooth; thus we may expect some regularity properties also for the solutions to (1.1).

Problem (1.1)–(1.2) arises in mathematical finance as well as in the study of nonlinear physical phenomena such as the combined effects of diffusion and convection of matter.

Escobedo, Vazquez, and Zuazua [8] prove that there exists a unique distributional solution to (1.1)–(1.2) satisfying an entropy condition that generalizes the one by Kruzhkov [11]. This solution is characterized in the *vanishing viscosity* sense; i.e., it is the limit of a sequence of classical solutions to Cauchy problems related to the regularized operator

$$L_\varepsilon u = \Delta_x u + \varepsilon^2 \partial_y^2 u + h(u)\partial_y u - \partial_t u. \tag{1.5}$$

Vol'pert and Hudjaev [19] prove similar existence and uniqueness results in a space of bounded variation functions whose spatial derivatives are square integrable with respect to (w.r.t.) a suitable weight. In this framework, it is natural to consider bounded and integrable initial data g and nonlinearities of the form $h(u) = u^{p-1}$ for $p \in]1, \frac{N+2}{N+1}[$.

Our paper is mainly motivated by the theory of agents' decisions under risk, arising in mathematical finance. The problem is the representation of agents' preferences over consumption processes. Antonelli, Barucci, and Mancino [1] propose a utility functional that takes into account aspects of decision making such as the agents' habit formation, which is described as a smoothed average of past consumption and expected utility. In that model the processes utility and habit are described by a system of backward-forward stochastic differential equations. The solution of such a system, as a function of consumption and time, satisfies the Cauchy problem (1.1)–(1.2). Our regularity assumption on f, g, h is required by the financial model, since these functions appear in the backward-forward system as Lipschitz continuous coefficients.

In the paper by Antonelli and Pascucci [2] an existence result, in the case $N = 1$, is proved by probabilistic techniques that exploit the properties of the solutions to the system of backward-forward stochastic differential equations related to (1.1)–(1.2). In [2], the existence of a viscosity solution, in the sense of [7], is proved. The solution is defined in a suitably small strip $\mathbb{R}^2 \times [0, T]$ and satisfies the following conditions:

$$\begin{aligned} |u(x,y,t) - u(x',y',t)| &\le c_0(|x - x'| + |y - y'|), \\ |u(x,y,t) - u(x,y,t')| &\le c_0(1 + |(x,y)|)|t - t'|^{\frac{1}{2}} \end{aligned} \tag{1.6}$$

for every $(x, y), (x', y') \in \mathbb{R}^2, t, t' \in [0, T]$, where c_0 is a positive constant that depends on the Lipschitz constants of f, g, and h. Concerning the regularity of u, we remark that the results by Caffarelli and Cabré [3] and Wang [20, 21] do not apply to our operator.

In this paper we prove the existence of a classical solution u to problem (1.1)–(1.2) by combining the analysis on Lie groups with the standard techniques for the Cauchy problem related to degenerate parabolic equations. We say that u is a classical solution if $\partial_{x_j x_k} u$, $j, k = 1, \dots, N$, the directional derivative

$$z \longmapsto Yu(z) = \frac{\partial u}{\partial \nu_z}(z), \qquad \nu(z) = (0, h(u(z)), -1),$$

are continuous functions, and (1.1)–(1.2) are verified at every point. Our main result is the following.

THEOREM 1.1. *There exists a positive T and a unique function $u \in C(S_T)$, verifying estimates* (1.6) *on $\overline{S}_T$, which is a classical solution to* (1.1)–(1.2).

We stress that the regularity stated above is natural for the problem under consideration. Indeed, although Yu is the sum of the more simple terms $h(u)\partial_y u$ and

$\partial_t u$, it is not true in general that they are continuous functions. Further regularity properties of solutions can be obtained under additional conditions. For instance, in [5, 6] in collaboration with Citti, we considered the nonlinear equation in three variables,

$$\partial_{xx} u + u\partial_y u - \partial_t u = 0, \tag{1.7}$$

which is a special case of (1.1). Assuming a hypothesis formally analogous to the classical Hörmander condition, we proved that the viscosity solution u of (1.7) constructed in [2] actually is a C^∞ classical solution.

In this paper we give a direct proof of the existence of a classical solution to the Cauchy problem (1.1)–(1.2) by using analytical methods. The regularity part in Theorem 1.1 is based on a modification of the classical freezing method, introduced by Citti in [4] for the study of the Levi equation. More precisely, for any $\bar{z} \in S_T$, we approximate L by the linear operator

$$L_{\bar{z}} = \Delta_x + (h(u(\bar{z})) + x_1 - \bar{x}_1)\,\partial_y - \partial_t, \tag{1.8}$$

and we represent a solution u in terms of its fundamental solution. Note that up to a straightforward change of coordinates, $L_{\bar{z}}$ is the Kolmogorov operator (1.4), and hence an explicit expression of the fundamental solution of $L_{\bar{z}}$ is available. Also note that $L_{\bar{z}}$ is a good approximation of L in the sense that, by (1.6), we have

$$|Lu(z) - L_{\bar{z}} u(z)| = |u(z) - u(\bar{z}) - (x_1 - \bar{x}_1)|\,|\partial_y u(z)| \le c_0 d(\bar{z}, z),$$

where $d(\bar{z}, z)$ is the standard parabolic distance.

The existence part of Theorem 1.1 relies on the Bernstein technique. We explicitly note that the nonlinearity in (1.3) is not monotone; therefore a maximum principle for the operator $Lv + h'(u)v^2$, which occurs when we differentiate both sides of (1.1) w.r.t. y, does not hold unless we assume condition (1.6).

We end this introduction with a remark about the existence of global solutions. We first note that the space of functions characterized by conditions (1.6) is, in some sense, optimal for the existence of local classical solutions. Indeed the linear growth of the initial data g does not allow, in general, solutions that are defined at every time $t > 0$, as the following example given in [2] shows. Consider the problem (1.7), with $f \equiv 0$ and $g(x, y) = x + y$: a direct computation shows that $u(x, y, t) = \frac{x+y}{1-t}$ is the unique solution to the problem and blows up as $t \to 1$. This fact is expected since, if u grows as a linear function, then its Cole–Hopf transformed function grows as $\exp(y^2)$, which is the critical case for the parabolic Cauchy problem. Next we give a simple sufficient condition for the global existence of classical solutions.

THEOREM 1.2. *Let f, g, and h be globally Lipschitz continuous functions. Suppose that g is nonincreasing w.r.t. y, that f is nondecreasing w.r.t. y, and that there exists $c_0 \in\ ]0, c_1]$ such that*

$$c_0(u - v) \le h(u) - h(v) \tag{1.9}$$

for every $u, v \in \mathbb{R}$. Then the Cauchy problem (1.1)–(1.2) has a solution u that is defined in $\mathbb{R}^{N+1} \times \mathbb{R}^+$.

This paper is organized as follows. In section 2 we prove Theorem 1.1, and in section 3 we prove the existence of a viscosity solution of (1.1)–(1.2). Section 4 is devoted to the proof of Theorem 1.2.

2. Classical solutions. In this section we prove Theorem 1.1. We first state an existence and uniqueness result of a strong solution u to problem (1.1)–(1.2). And then we prove that u is a solution in the classical sense. We say that a continuous function u is a strong solution to (1.1)–(1.2) if $u \in H^1_{\rm loc}(S_T)$, $\partial_{x_j x_k} u \in L^2_{\rm loc}(S_T)$, $j,k = 1,\dots,N$, it satisfies equation (1.1) a.e., and it assumes the initial datum g.

THEOREM 2.1. *If T is suitably small, there exists a unique strong solution of* (1.1)–(1.2) *verifying estimates* (1.6) *on* $\overline{S}_T$.

The proof of Theorem 2.1 is postponed to section 3. We remark that in the above statement, we consider the term

$$Yu = h(u)\partial_y u - \partial_t u$$

as a sum of weak derivatives. Here we aim to prove that Yu is a continuous function and that it coincides with the directional derivative w.r.t. the vector $\nu_z = (0, h(u), -1)$, namely,

$$Y(u(z)) = \frac{\partial u}{\partial \nu_z}(z) \qquad \forall z \in S_T. \tag{2.1}$$

In what follows, when we consider a function F that depends on many variables, to avoid any ambiguity we shall systematically write the directional derivative introduced in (2.1) as

$$Y(z)F(\cdot,\zeta) = \frac{\partial F(\cdot,\zeta)}{\partial \nu_z}(z).$$

Our technique is inspired by the recent paper [6], where, in collaboration with Citti, we developed some ideas for a general study of a nonlinear equation of the form (1.4). We recall the following lemma, which has been proved in Lemma 3.1 of [6], for the Cauchy problem (1.7). We state the lemma for the operator (1.3) and omit the proof, since it is analogous to the one given in [6].

LEMMA 2.2. *Let v be a continuous function defined in S_T. Assume that its weak derivatives $v_y, v_t \in L^2_{loc}$ and that the limit*

$$\lim_{\delta \to 0} \frac{v(z + \delta \nu_z) - v(z)}{\delta}$$

exists and is uniform w.r.t. z in compact subsets of S_T. Then

$$\frac{\partial v}{\partial \nu_z}(z) = (h(u)\partial_y v - \partial_t v)(z) \qquad \text{a.e. } z \in S_T.$$

We next prove Theorem 1.1 by using a representation formula of the strong solution u in terms of the fundamental solution of the operator $L_{\bar z}$ introduced in (1.8). We define the first order operators (vector fields)

$$X_j = \partial_{x_j},\ j = 1,\dots,N, \qquad Y_{\bar z} = (h(u(\bar z)) + x_1 - \bar x_1)\,\partial_y - \partial_t. \tag{2.2}$$

Thus we can rewrite the operator $L_{\bar z}$ in the standard form

$$L_{\bar z} = \sum_{j=1}^{N} X_j^2 + Y_{\bar z}. \tag{2.3}$$

Let us recall some preliminary facts about real analysis on nilpotent Lie groups. More details about this topic can be found in [15] and [18]. We define on $\mathbb{R}^{N+2}$ the composition law

$$\theta \oplus \theta' = \left(\theta_1 + \theta'_1, \dots, \theta_N + \theta'_N, \theta_{N+1} + \theta'_{N+1}, \theta_{N+2} + \theta'_{N+2} + \frac{1}{2}(\theta_1\theta'_{N+1} - \theta_{N+1}\theta'_1)\right)$$

and the dilations group

$$\delta_\lambda(\theta) = (\lambda\theta_1, \dots, \lambda\theta_N, \lambda^2\theta_{N+1}, \lambda^3\theta_{N+2}), \qquad \lambda > 0.$$

We remark that $G = (\mathbb{R}^{N+2}, \oplus)$ is a nilpotent stratified Lie group which, in the case $N = 1$, coincides with the standard Heisenberg group. Since the Jacobian $J\delta_\lambda$ equals λ^{N+5}, the homogeneous dimension of G w.r.t. $(\delta_\lambda)_{\lambda>0}$ is the natural number $Q = N + 5$. A norm which is homogeneous w.r.t. this dilations group is given by

$$\|\theta\| = \left(|\theta_1|^6 + \dots + |\theta_N|^6 + |\theta_{N+1}|^3 + |\theta_{N+2}|^2\right)^{\frac{1}{6}}.$$

Let $\nabla_{\bar z} = (X_1, \dots, X_N, Y_{\bar z}, \partial_y)$ be the gradient naturally associated to $L_{\bar z}$ and consider any $z \in \mathbb{R}^{N+2}$. The exponential map

$$E_{\bar z}(\theta, z) = \exp(\langle \theta, \nabla_{\bar z}\rangle)(z)$$

is a global diffeomorphism and induces a Lie group structure on $\mathbb{R}^{N+2}$ whose product is defined by

$$\zeta \circ z = E_{\bar z}\left(\left(E^{-1}_{\bar z}(\zeta, 0) \oplus E^{-1}_{\bar z}(z, 0)\right), 0\right),$$

and it can be explicitly computed as

$$\zeta \circ z = (x + \xi, y + \eta - t\xi_1, t + \tau).$$

Moreover, a control distance $d_{\bar z}$ in $(\mathbb{R}^{N+2}, \circ)$ is defined by

$$\begin{aligned} d_{\bar z}(z, \zeta) &= \|E^{-1}_{\bar z}\left(\zeta^{-1} \circ z, 0\right)\| \\ &= \left(|x - \xi|^6 + |t - \tau|^3 + \left|y - \eta + (t - \tau)\left(h(u(\bar z)) + \frac{x_1 - \xi_1 - 2\bar x_1}{2}\right)\right|^2\right)^{\frac{1}{6}}, \end{aligned} \tag{2.4}$$

where ζ^{-1} is the inverse in the group law "$\circ$". We denote by $\Gamma_{\bar z}(z, \zeta)$ the fundamental solution of $L_{\bar z}$ with pole in ζ and evaluated at z. We refer to [12, 14, 13, 9] for known results about $\Gamma_{\bar z}$. The following bound holds:

$$\Gamma_{\bar z}(z, \zeta) = \Gamma_{\bar z}(\zeta^{-1} \circ z, 0) \le c d_{\bar z}(z, \zeta)^{-Q+2}, \tag{2.5}$$

where the constant c continuously depends on $\bar z$. We are now in a position to prove Theorem 1.1.

Proof of Theorem 1.1. By Theorem 2.1 there exists a unique strong solution of (1.1)–(1.2) verifying (1.6) in $\overline{S}_T$ for T suitably small. In order to prove that u is a classical solution, we represent it in terms of the fundamental solution $\Gamma_{\bar z}$:

$$(u\varphi)(z) = \int_{S_T} \Gamma_{\bar z}(z, \zeta)\left(U_{1,\bar z}(\zeta) - U_{2,\bar z}(\zeta)\right) d\zeta \equiv I_1(z) - I_2(z) \tag{2.6}$$

for every $\varphi \in C_0^\infty(S_T)$, where

$$U_{1,\bar z} = \varphi f(\cdot,u) + uL_{\bar z}\varphi + 2\langle \nabla_x u, \nabla_x \varphi\rangle,$$
$$U_{2,\bar z} = (h(u) - h(u(\bar z)) - (x_1 - \bar x_1))\,\partial_y u\varphi$$

are bounded functions with compact support. Therefore it is straightforward to prove that $u\varphi \in C^{1+\alpha}_{d_{\bar z}}$, $\alpha \in]0,1[$, where $C^{k+\alpha}_{d_{\bar z}}$ denotes the space of Hölder continuous functions w.r.t. the control distance $d_{\bar z}$. In particular, by choosing $\varphi \equiv 1$ in a compact neighborhood K of $\bar z$, we have that

$$X_j u(z) = \int X_j(z)\Gamma_{\bar z}(\cdot,\zeta)\,(U_{1,\bar z}(\zeta) - U_{2,\bar z}(\zeta))\,d\zeta, \qquad z \in K,\ j = 1,\dots,N,$$

and

$$|X_j u(z) - X_j u(\zeta)| \le c d_{\bar z}(z,\zeta)^\alpha \qquad \forall z,\zeta \in K,\ \alpha \in]0,1[. \tag{2.7}$$

This proves the Hölder continuity of the first order derivatives of u. Let us now consider the second order derivatives $X_j X_h u$, $j,k,= 1,\dots,N$, and Yu.

We next prove the existence of the directional derivative $Yu(\bar z)$ by studying separately the terms I_1, I_2. Since Y is the unique nonlinear vector field to be considered, the proof of our result for the derivatives $X_j X_h u$ is simpler and will be omitted.

The term I_2. We set

$$J(\bar z) = \int_{S_T} Y(\bar z)\Gamma_{\bar z}(\cdot,\zeta)U_{2,\bar z}(\zeta)d\zeta.$$

We remark that J is well defined and continuous since, by (1.6), we have

$$|U_{2,\bar z}(\zeta)| \le c\ d_{\bar z}(\bar z,\zeta). \tag{2.8}$$

We denote by $\chi \in C^\infty([0,+\infty[,[0,1])$ a cut-off function such that

$$\chi(s) = 0 \ \text{ for } \ 0 \le s \le \frac{1}{2}, \qquad \chi(s) = 1 \ \text{ for } \ s \ge 1,$$

and we set

$$I_{2,\delta}(z) = \int_{S_T} \Gamma_{\bar z}(z,\zeta)\chi\left(\frac{d_{\bar z}(\bar z,\zeta)}{\bar c\ \delta^{\frac12}}\right) U_{2,\bar z}(\zeta)d\zeta, \qquad \bar c,\delta > 0.$$

In what follows we shall assume $d_{\bar z}(\bar z, z) \le \delta^{\frac12}$; then by the triangular inequality

$$d_{\bar z}(\bar z,\zeta) \le c\ \left(d_{\bar z}(\bar z, z) + d_{\bar z}(z,\zeta)\right), \tag{2.9}$$

we can choose $\bar c$ suitably large so that

$$\chi\left(\frac{d_{\bar z}(\bar z,\zeta)}{\bar c\ \delta^{\frac12}}\right) = 0 \qquad \text{if } \ d_{\bar z}(z,\zeta) < \delta^{\frac12},$$

and, as a consequence, $I_{2,\delta}$ is smooth for any $\delta > 0$. We claim that

$$\sup_{d_{\bar z}(\bar z,z) \le \delta^{\frac12}} |I_{2,\delta}(z) - I_2(z)| \le c\ \delta^{\frac32}, \tag{2.10}$$

$$\sup_{d_{\bar z}(\bar z,z) \le \delta^{\frac12}} |Y_{\bar z} I_{2,\delta}(z) - J(\bar z)| \le c\ \delta^{\frac12}|\log(\delta)| \tag{2.11}$$

for some positive constant c. We postpone the proof of (2.10)–(2.11) to the end.

Let us now compute the derivative $\frac{\partial I_2}{\partial \nu_{\bar z}}(\bar z)$. For every positive δ we have

$$\left|\frac{I_2(\bar z+\delta\nu_{\bar z})-I_2(\bar z)}{\delta}-J(\bar z)\right| \le \left|\frac{I_{2,\delta}(\bar z+\delta\nu_{\bar z})-I_{2,\delta}(\bar z)}{\delta}-J(\bar z)\right| + \left|\frac{I_2(\bar z+\delta\nu_{\bar z})-I_{2,\delta}(\bar z+\delta\nu_{\bar z})}{\delta}\right| + \left|\frac{I_2(\bar z)-I_{2,\delta}(\bar z)}{\delta}\right|.$$

We first note that, using the expression (2.4), we find $d_{\bar z}(\bar z,\bar z+\delta\nu_{\bar z})=\delta^{\frac12}$. Thus, by (2.10) and by the mean value theorem, there exists a $\delta_0\in\,]0,\delta[$ such that

$$\begin{aligned}\left|\frac{I_2(\bar z+\delta\nu_{\bar z})-I_2(\bar z)}{\delta}-J(\bar z)\right| &\le \left|\left(h(u(\bar z))\partial_y I_{2,\delta}-\partial_t I_{2,\delta}\right)(\bar z+\delta_0\nu_{\bar z})-J(\bar z)\right|+c\delta^{\frac12}\\ &= |Y_{\bar z}I_{2,\delta}(\bar z+\delta_0\nu_{\bar z})-J(\bar z)|+c\delta^{\frac12}\le c\,\delta^{\frac12}|\log\delta|,\end{aligned}$$

where the last inequality follows from (2.11). Therefore we have

$$\frac{\partial I_2}{\partial \nu_z}(z)=J(z),$$

and, by Lemma 2.2, we get (2.1).

We are left with the proof of (2.10)–(2.11). We assume $d_{\bar z}(\bar z,z)\le\delta^{\frac12}$. By (2.8) and (2.5), we have

$$|I_{2,\delta}(z)-I_2(z)|\le c\int_{d_{\bar z}(z,\zeta)<\delta^{\frac12}} d_{\bar z}(z,\zeta)^{-Q+2}d_{\bar z}(\bar z,\zeta)d\zeta$$

(since, by (2.9), $d_{\bar z}(\bar z,\zeta)<c\delta^{\frac12}$, and by using the homogeneous polar coordinates)

$$\le\ \delta^{\frac12}\int_{\varrho<\delta^{\frac12}}\varrho^{-Q+2+Q-1}d\varrho=c\delta^{\frac32}.$$

This proves (2.10). Next we recall the following estimate which immediately follows by the mean value theorem:

$$|Y_{\bar z}(z)\Gamma_{\bar z}(\cdot,\zeta)-Y_{\bar z}(\bar z)\Gamma_{\bar z}(\cdot,\zeta)|\le c d_{\bar z}(\bar z,z)d_{\bar z}(\bar z,\zeta)^{-Q-1} \tag{2.12}$$

for $d_{\bar z}(\bar z,\zeta)\ge\bar c\,d_{\bar z}(\bar z,z)$. Then we have

$$\begin{aligned}|Y_{\bar z}I_{2,\delta}(z)-J(\bar z)| &\le \int|Y_{\bar z}(z)\Gamma_{\bar z}(\cdot,\zeta)-Y_{\bar z}(\bar z)\Gamma_{\bar z}(\cdot,\zeta)|\,\chi\left(\frac{d_{\bar z}(\bar z,\zeta)}{\bar c\ \delta^{\frac12}}\right)|U_{2,\bar z}(\zeta)|d\zeta\\ &\quad+\int_{d_{\bar z}(\bar z,\zeta)<\delta^{\frac12}}|Y_{\bar z}(\bar z)\Gamma_{\bar z}(\cdot,\zeta)U_{2,\bar z}(\zeta)|d\zeta\end{aligned}$$

(by (2.12) and since the second term can be estimated as before)

$$\le c\delta^{\frac12}\int_{d_{\bar z}(\bar z,\zeta)>\bar c\delta^{\frac12}} d_{\bar z}(\bar z,\zeta)^{-Q-1}|U_{2,\bar z}(\zeta)|d\zeta+c\delta^{\frac12}=c\delta^{\frac12}|\log(\delta)|.$$

This concludes the proof of (2.11).

The term I_1. Let $G(z,\zeta) = g(\zeta^{-1} \circ z)$, where g is a smooth function. A direct computation gives

$$Y_{\bar z}(z)G(\cdot,\zeta) = R_{\bar z}(\zeta)G(z,\cdot), \tag{2.13}$$

where

$$R_{\bar z}(\zeta) = -Y_{\bar z}(\zeta) - (x_1 - \xi_1)\partial_\eta$$

(see [16, p. 295] for a general statement of this result). We aim to prove that

$$Y(\bar z)I_1 = \int_\Omega Y(\bar z)\Gamma_{\bar z}(\cdot,\zeta)\left(U_{1,\bar z}(\zeta) - U_{1,\bar z}(\bar z)\right)d\zeta + U_{1,\bar z}(\bar z)\int_{\partial\Omega}\Gamma_{\bar z}(\bar z,\zeta)\langle R_{\bar z}(\zeta),\nu(\zeta)\rangle d\sigma, \tag{2.14}$$

where ν is the outer normal to the set $\Omega = \mathrm{supp}(\varphi)$, for which we assume that the divergence theorem holds. By (2.5), the homogeneity of the fundamental solution, and the Hölder continuity of $U_{1,\bar z}$, the function

$$V(z) = \int_\Omega Y(z)\Gamma_{\bar z}(\cdot,\zeta)\left(U_{1,\bar z}(\zeta) - U_{1,z}(z)\right)d\zeta + U_{1,\bar z}(z)\int_{\partial\Omega}\Gamma_{\bar z}(z,\zeta)\langle R_{\bar z}(\zeta),\nu(\zeta)\rangle d\sigma(\zeta) \tag{2.15}$$

is well defined. Let K be a compact subset of Ω. We set, for $\delta > 0$,

$$I_{1,\delta}(z) = \int_\Omega \Gamma_{\bar z}(z,\zeta)\chi\left(\frac{d_{\bar z}(z,\zeta)}{\delta}\right)U_{1,\bar z}(\zeta)d\zeta,$$

where χ is the cut-off function previously introduced. We choose δ suitably small so that

$$\chi\left(\frac{d_{\bar z}(z,\zeta)}{\delta}\right) = 1 \tag{2.16}$$

for any $z \in K, \zeta \in \partial\Omega$. Clearly $I_{1,\delta}$ is a smooth function, and differentiating we get

$$\begin{aligned} Y_{\bar z}(z)I_{1,\delta} &= \int_\Omega Y_{\bar z}(z)\left(\Gamma_{\bar z}(\cdot,\zeta)\chi\left(\frac{d_{\bar z}(\cdot,\zeta)}{\delta}\right)\right)\left(U_{1,\bar z}(\zeta) - U_{1,\bar z}(z)\right)d\zeta \\ &\quad + U_{1,\bar z}(z)\int_\Omega Y_{\bar z}(z)\left(\Gamma_{\bar z}(\cdot,\zeta)\chi\left(\frac{d_{\bar z}(\cdot,\zeta)}{\delta}\right)\right)d\zeta. \end{aligned} \tag{2.17}$$

By (2.13) and the divergence theorem, we have

$$\begin{aligned} \int_\Omega Y_{\bar z}(z)\left(\Gamma_{\bar z}(\cdot,\zeta)\chi\left(\frac{d_{\bar z}(\cdot,\zeta)}{\delta}\right)\right)d\zeta &= \int_\Omega R_{\bar z}(\zeta)\left(\Gamma_{\bar z}(z,\cdot)\chi\left(\frac{d_{\bar z}(z,\cdot)}{\delta}\right)\right)d\zeta \\ &= \int_{\partial\Omega}\Gamma_{\bar z}(z,\zeta)\chi\left(\frac{d_{\bar z}(z,\zeta)}{\delta}\right)\langle R_{\bar z}(\zeta),\nu(\zeta)\rangle d\sigma(\zeta). \end{aligned} \tag{2.18}$$

Then, by (2.18) and (2.16), the last terms in (2.17) and (2.15) are equal. Hence we get

$$\begin{aligned} &|V(z) - Y_{\bar z}(z)I_{1,\delta}| \\ &= \left|\int_{\delta_{\bar z}(z,\zeta)\le\delta} Y_{\bar z}(z)\left(\Gamma_{\bar z}(\cdot,\zeta)\left(1 - \chi\left(\frac{d_{\bar z}(\cdot,\zeta)}{\delta}\right)\right)\right)\left(U_{1,\bar z}(\zeta) - U_{1,\bar z}(z)\right)d\zeta\right| \\ &\le C\int_{\delta_{\bar z}(z,\zeta)\le\delta}\left(d_{\bar z}(z,\zeta)^{-Q} + \Gamma_{\bar z}(z,\zeta)\frac{d_{\bar z}(z,\zeta)^{-1}}{\delta}\right)d_{\bar z}(z,\zeta)^\alpha d\zeta \le C\delta^\alpha. \end{aligned}$$

Since the constant C continuously depends on $\bar{z}$, we have that $Y_{\bar{z}}(z)I_{1,\delta}$ converges to V as $\delta \to 0$ uniformly on K. Since $I_{1,\delta}$ converges to I_1 we get (2.14). This completes the proof of Theorem 1.1. □

3. A priori estimates. In this section we prove Theorem 2.1 by using a modification of the classical Bernstein method. Here we adopt the notation of [10, Chap. 3], which we briefly recall for the reader's convenience. Given a bounded domain Ω in $\mathbb{R}^{N+2}$ and $\alpha \in \ ]0,1[$, $\overline{C}_\alpha(\Omega)$ denotes the space of Hölder continuous functions w.r.t. the parabolic distance

$$d(z,z') \equiv |x-x'| + |y-y'| + |t-t'|^{\frac{1}{2}},$$

i.e., the family of all functions u on Ω for which

$$\overline{|u|}_\alpha^\Omega = \overline{|u|}_\alpha = |u|_0 + \sup_\Omega \frac{|u(z)-u(z')|}{d(z,z')^\alpha} < \infty,$$

where $|u|_0^\Omega = |u|_0 = \sup_\Omega |u|$. The spaces of Hölder continuous functions $\overline{C}_{k+\alpha}$, $k \in \mathbb{N}$, are defined straightforwardly. We set

$$B_r = \{(x,y) \in \mathbb{R}^N \times \mathbb{R} \ \mid \ |(x,y)| < r\}, \qquad S_{r,T} = B_r \times \ ]0,T[, \quad T,r>0. \tag{3.1}$$

The "parabolic" boundary of the cylinder $S_{r,T}$ is defined by

$$\partial_p S_{r,T} = (B_r \times \{0\}) \cup (\partial B_r \times [0,T]). \tag{3.2}$$

Given two points $z, z' \in S_{r,T}$ in (3.1), we denote by d_z the distance from z to the parabolic boundary $\partial_p S_{r,T}$ (cf. (3.2)), and $d_{zz'} = \min\{d_z, d_{z'}\}$. We set

$$|u|_\alpha^{S_{r,T}} = |u|_\alpha = |u|_0 + \sup_{S_{r,T}} d_{zz'}^\alpha \frac{|u(z)-u(z')|}{d(z,z')^\alpha}.$$

The space of all functions u with finite norm $|u|_\alpha^{S_{r,T}}$ is denoted by $C_\alpha(S_{r,T})$. The spaces $C_{k+\alpha}$ of Hölder continuous functions of higher order are defined analogously. We say that $u \in C_{k+\alpha,\mathrm{loc}}(S_T)$ if $u \in C_{k+\alpha}(S_{r,T})$ for every $r>0$.

We consider the Cauchy problem

$$L^\varepsilon u = f(\cdot,u) \qquad \text{in } \ S_T \equiv \mathbb{R}^{N+1} \times \ ]0,T[, \tag{3.3}$$

$$u(\cdot,0) = g \qquad \text{in } \ \mathbb{R}^{N+1}, \tag{3.4}$$

where L^ε, $\varepsilon > 0$, is the regularized operator in (1.5). We assume that the functions f, g, h are globally Lipschitz continuous; then there exists a positive constant c_1 such that

$$\begin{aligned} &c_1 \geq \max\{\text{Lipschitz constants of } f,g,h\},\\ &|h(v)| \leq c_1\sqrt{1+v^2}, \qquad |g(x,y)| \leq c_1\sqrt{1+|(x,y)|^2},\\ &|f(x,y,t,v)| \leq c_1\sqrt{1+|(x,y,t,v)|^2}, \qquad (x,y,t,v) \in S_T \times \mathbb{R}. \end{aligned} \tag{3.5}$$

The following result holds.

THEOREM 3.1. *There exist two positive constants T, c that depend only on the constant c_1 in (3.5) such that for every $\varepsilon > 0$ and $\alpha \in \ ]0,1[$ the Cauchy problem*

(3.3)–(3.4) *has a unique solution* $u^\varepsilon \in C_{2+\alpha,\mathrm{loc}}(S_T) \cap C\left(\overline{S}_T\right)$ *verifying the following* ε*-uniform estimates:*

$$|u^\varepsilon_{x_i}|_0, |u^\varepsilon_y|_0 \le 4c_1, \qquad i = 1, \dots, N, \tag{3.6}$$

$$|u^\varepsilon(x,y,t+s) - u^\varepsilon(x,y,t)| \le c\sqrt{1+|(x,y)|^2}\ |s|^{\frac{1}{2}}, \tag{3.7}$$

$$|u^\varepsilon(x,y,t)| \le 2c_1\sqrt{1+|(x,y,t)|^2} \qquad \forall (x,y,t) \in \overline{S}_T. \tag{3.8}$$

Before proving Theorem 3.1, we introduce some further notation. If $\chi = \chi(x,y) \in C_0^\infty\left(\mathbb{R}^{N+1}\right)$ is a cut-off function such that $\chi = 1$ in $B_{\frac{1}{2}}$ and $\mathrm{supp}(\chi) \subset B_1$, we set

$$\chi_n(x,y) = \chi\left(\frac{x}{n}, \frac{y}{n}\right), \quad f_n = f\chi_n, \quad g_n(\cdot,t) = g\chi_n, \quad h_n(\cdot,v) = h(v)\chi_n, \quad n \in \mathbb{N}, \tag{3.9}$$

so that, by (3.5) and readjusting the constant c_1 if necessary, we have

$$|\nabla\chi_n|_0 \le \frac{|\nabla\chi|_0}{n}, \qquad |\nabla g_n| \le c_1,$$
$$|\nabla_{x,y} f_n(x,y,t,v)| \le |\chi_n \nabla_{x,y} f| + \frac{c_1\,|\nabla\chi|_0}{n}\sqrt{1+n^2+T^2+v^2} \le c_1$$

if $\frac{|v|}{n}$ is bounded and $t \in [0,T]$.

Finally, fixing $n \in \mathbb{N}$ and $\varepsilon > 0$, we consider the linearized Cauchy–Dirichlet problem

$$L^{\varepsilon,n}_v u \equiv \Delta_x u + \varepsilon^2 u_{yy} + h_n(\cdot,v)\partial_y u - \partial_t u = f_n(\cdot,v) \qquad \text{in } S_{n,T}, \tag{3.10}$$

$$u = g_n \qquad \text{in } \partial_p S_{n,T}. \tag{3.11}$$

Given $\alpha \in]0,1[$, we assume that the coefficient v in (3.10)–(3.11) belongs to the space $\overline{C}_{1+\alpha}(S_{n,T})$ and satisfies the estimates

$$|v(x,y,t)| \le 2c_1\sqrt{1+|(x,y)|^2} \qquad \text{in } S_{n,T}, \tag{3.12}$$

$$|v_{x_i}|_0 \le 4c_1, \qquad i = 1, \dots, N, \tag{3.13}$$

$$|v_y|_0 \le 4c_1. \tag{3.14}$$

Then a classical solution $u \in \overline{C}_{2+\alpha}(S_{n,T})$ to (3.10)–(3.11) exists by known results (see, for example, [10, Chap. 3, Thm. 7], since $h_n(\cdot,v), f_n(\cdot,v) \in \overline{C}_{1+\alpha}(S_{n,T})$, $g_n \in C^\infty\left(\overline{S}_{n,T}\right)$, and the compatibility condition $L^{\varepsilon,n}_v g_n = f_n = 0$ holds on ∂B_n. Once we have given the following ε-uniform a priori estimates, the proof of Theorem 3.1 is rather standard.

LEMMA 3.2. *Under the above assumptions, there exists* $T > 0$ *such that, for any* $n \in \mathbb{N}$*, every classical solution of* (3.10)–(3.11) *verifies* (3.12)–(3.14).

Proof. Let u be a classical solution of (3.10)–(3.11). We prove estimate (3.12) for u by applying the maximum principle to the functions $H \pm u$, where H is defined as

$$H(x,y,t) = (c_1 + \mu t)\sqrt{1+|(x,y)|^2}$$

and μ is to be suitably fixed. Keeping in mind (3.5) and (3.12), it is easily verified that

$$\begin{aligned} L^{\varepsilon,n}_v H(x,y,t) &\le \frac{(1+\varepsilon^2)(c_1+\mu T)}{\sqrt{1+|(x,y)|^2}} + ((c_1+\mu T)\,c_1 - \mu)\sqrt{1+|(x,y)|^2} \\ &\le -|f_n(x,y,t,v(x,y,t))| \end{aligned}$$

if $\mu, \frac{1}{T}$ are suitably large. On the other hand, by (3.5), $H|_{\partial_p S_{n,T}} \geq |g_n|$. Therefore, by the maximum principle, we infer that

$$|u| \leq H \leq 2c_1\sqrt{1+|(x,y)|^2} \qquad \text{if } T \leq \frac{c_1}{\mu}.$$

Next we prove estimate (3.14) for the y-derivative of u. Our method is based on the maximum principle. We start by proving a gradient estimate for u on the parabolic boundary of $S_{n,T}$. Since $u \in \overline{C}_{2+\alpha}(S_{n,T})$, it is clear that $\nabla_{x,y}u = \nabla_{x,y}g_n$ in $B_n \times \{0\}$. In order to estimate $\nabla_{x,y}u$ on $\partial B_n \times]0,T[$, we employ the classical argument of the barrier functions on the cylinder $Q \equiv S_{n,T} \setminus S_{\frac{n}{2},T}$. More precisely, given $(x_0,y_0,t_0) \in \partial B_n \times]0,T[$, we set

$$w(x,y) = 4c_1\langle (x-x_0, y-y_0), \nu\rangle,$$

where ν is the inner normal to Q at (x_0,y_0,t_0). Then we have

$$L_v^{\varepsilon,n}(w \pm u) = \pm f_n(\cdot, v) = 0 \qquad \text{in } Q,$$

since f_n and h_n vanish on Q. On the other hand, it is straightforward to verify that $|u| \leq w$ on $\partial_p Q$. Therefore, by the maximum principle, we get $|u| \leq w$ and, in particular,

$$|\nabla_{x,y}u(x_0,y_0,t_0)| \leq |\nabla_{x,y}w(x_0,y_0)| \leq 4c_1. \tag{3.15}$$

Now we are in a position to prove estimate (3.14) for u. We differentiate equation (3.10) w.r.t. the variable y and then multiply it by $e^{-2\lambda t}u_y$. Denoting $\omega = \left(e^{-\lambda t}u_y\right)^2$, we obtain

$$\begin{aligned} L_v^{\varepsilon}\omega &= e^{-2\lambda t}L_v^{\varepsilon}u_y^2 + 2\lambda\omega \\ &= 2\left(e^{-2\lambda t}\left(|\nabla_x u_y|^2 + \varepsilon^2 u_{yy}^2 + u_y\left((f_n)_y + (f_n)_v v_y\right)\right) + \omega\left(\lambda - h'(v)v_y\right)\right) \\ &\geq 2\left(e^{-2\lambda t}u_y\left((f_n)_y + (f_n)_v v_y\right) + \omega\left(\lambda - h'(v)v_y\right)\right). \end{aligned} \tag{3.16}$$

Hence, by setting $w = \omega - (4c_1)^2$, we get from (3.16)

$$L_v^{\varepsilon}w \geq 2\sqrt{\omega}\left(-|(f_n)_y| - |v_y(f_n)_v| + \sqrt{\omega}\left(\lambda - |h'v_y|\right)\right)$$

(by (3.5), (3.14), and by the elementary inequality $\sqrt{\omega} \geq \frac{\sqrt{2}}{2}(4c_1 + \operatorname{sgn}(w)\sqrt{|w|})$)

$$\geq \sqrt{2\omega}\left(\sqrt{2}c_1\left(2\sqrt{2}\left(\lambda - 4c_1^2\right) - 4c_1 - 1\right) + \left(\lambda - 4c_1^2\right)\operatorname{sgn}(w)\sqrt{|w|}\right)$$

(for $\lambda = \lambda(c_1)$ suitably large)

$$\geq c\sqrt{\omega|w|}\operatorname{sgn}(w) \tag{3.17}$$

for some positive constant $c = c(c_1)$. By contradiction, we want to prove that $w \leq 0$ in $S_{n,T}$. It will follow that

$$|u_y| \leq c_1 e^{\lambda t},$$

which implies (3.16) if $T = T(c_1) > 0$ is sufficiently small. Let z_0 be the maximum of w on $\overline{Q}_T$. If $w(z_0) > 0$, then $z_0 \in S_{n,T} \setminus \partial_p S_{n,T}$, since by (3.15) $w \leq 0$ on $\partial_p S_{n,T}$. This leads to a contradiction, since by (3.17)

$$0 \geq L_v^{\varepsilon}w(z_0) \geq c\sqrt{\omega(z_0)w(z_0)} > 0.$$

This concludes the proof of (3.14). By a similar technique, we prove estimate (3.13) of the x-derivatives of u:

$$|u_{x_k}|_0 \leq 4c_1, \qquad k = 1, \dots, N.$$

We set

$$\omega = \left(e^{-\lambda t} u_{x_k}\right)^2, \qquad w = \omega - (4c_1)^2.$$

Differentiating (3.10) w.r.t. x_k and multiplying it by $e^{-2\lambda t} u_{x_k}$, we get

$$\begin{aligned} L_v^\varepsilon w &= e^{-2\lambda t} L_v^\varepsilon u_{x_k}^2 + 2\lambda\omega \\ &= 2\left(e^{-2\lambda t} u_{x_k} \left((f_n)_{x_k} + v_{x_k}\left((f_n)_v - u_y h'\right)\right) + \lambda\omega\right) \end{aligned}$$

(by (3.5), (3.13), and estimate (3.14) of u_y previously proved)

$$\geq c\sqrt{\omega|w|}\operatorname{sgn}(w),$$

if $\lambda = \lambda(c_1)$ is suitably large, for some positive constant c which depends only on c_1. As before, we infer that $w \leq 0$, which yields (3.13). □

We are in a position to prove Theorem 3.1.

Proof of Theorem 3.1. In order to prove the existence of a unique classical solution to (3.3)–(3.4), we consider, for every $\varepsilon > 0$ and $n \in \mathbb{N}$, the Cauchy–Dirichlet problem

$$\Delta_x u + \varepsilon^2 u_{yy} + h_n(\cdot, u)\partial_y u - \partial_t u = f_n(\cdot, u) \qquad \text{in } S_{n,T}, \tag{3.18}$$

$$u = g_n \qquad \text{in } \partial_p S_{n,T}. \tag{3.19}$$

We split the proof into four steps: We first use Schauder's fixed point theorem to solve the above problem. Then we let n go to infinity under the assumption that the coefficients are smooth. Next we prove estimates (3.6), (3.7), and (3.8). Finally we remove the smoothness assumption.

First step. Assume that f, g, h are C^∞ functions. We fix $\alpha \in]0,1[$, $n \in \mathbb{N}$ and denote by $\mathcal{W}$ the family of functions $v \in \overline{C}_{1+\alpha}(S_{n,T})$ such that

$$\overline{|v|}_{1+\alpha} \leq M, \tag{3.20}$$

$$|v(x,y,t)| \leq 2c_1\sqrt{1 + |(x,y)|^2} \qquad \text{in } S_{n,T}, \tag{3.21}$$

$$|v_{x_i}|_0 \leq 4c_1, \qquad i = 1, \dots, N, \tag{3.22}$$

$$|v_y|_0 \leq 4c_1, \tag{3.23}$$

where the positive constants M, T will be suitably chosen later. Clearly, $\mathcal{W}$ is a closed, convex subset of $\overline{C}_{1+\alpha}(S_{n,T})$. We define a transformation $u \equiv \mathcal{Z}v$ on $\mathcal{W}$ by choosing u as the unique classical solution of the linear Cauchy–Dirichlet problem (3.10)–(3.11). If we show that

(i) $\mathcal{Z}(\mathcal{W})$ is precompact in $\overline{C}_{1+\alpha}(S_{n,T})$;
(ii) $\mathcal{Z}$ is a continuous operator;
(iii) $\mathcal{Z}(\mathcal{W}) \subseteq \mathcal{W}$,

then we are done. The proof of (i) and (ii) is quite standard and relies on the following two estimates of u (see, for example, [10, Chap. 3, Thm. 6 and Chap. 7, Thm. 4]:

$$\overline{|u|}_{2+\alpha} \leq c\left(\overline{|g_n|}_{2+\alpha} + \overline{|f_n(\cdot, v)|}_\alpha\right) \leq \bar{c}\left(\overline{|g_n|}_{2+\alpha} + \overline{|v|}_\alpha\right) \tag{3.24}$$

for some constant $\bar{c} > 0$ dependent on $\varepsilon, n, M, \alpha$;

$$\overline{|u|}_{1+\delta} \le \widetilde{c}\left(|f_n|_0 + |L_v^\varepsilon g_n|_0 + \overline{|g_n|}_{1+\delta}\right), \qquad \delta \in]0,1[, \tag{3.25}$$

for some positive constant $\widetilde{c}$ dependent on ε, n, δ but not on M. Besides, (iii) is exactly the content of Lemma 3.2. Therefore, by Schauder's theorem, the operator $\mathcal{Z}$ has a fixed point u in $\mathcal{W}$.

Note that, by (3.6), a comparison principle in the space $\mathcal{W}$ does hold; therefore u is the unique classical solution of problem (3.18)–(3.19) verifying estimates (3.6) and (3.8). Moreover, by a standard bootstrap argument, $u \in C^\infty(S_{n,T})$.

Second step. We fix $\varepsilon > 0$ and denote by u^n the solution of the Cauchy–Dirichlet problem (3.18)–(3.19), whose existence has been proved in the previous step. We now want to obtain the solution of the Cauchy problem (3.3)–(3.4) letting n go to infinity.

Fixing $k \in \mathbb{N}$, we consider the sequence $(u^n \chi_{4k})_{n \ge 4k}$, where χ is the cut-off function introduced in (3.9). Then we have

$$\begin{aligned} L^\varepsilon_{u^n}(u^n\chi_{4k}) &= f_{4k}(\cdot, u_n) + 2\left(\langle \nabla_x u^n, \nabla_x \chi_{4k}\rangle + \varepsilon^2 \partial_y u^n \partial_y \chi_{4k}\right) + u^n L^\varepsilon_{u_n}\chi_{4k} \\ &\equiv F_{n,4k} \qquad \text{on } S_{4k,T}, \\ (u^n\chi_{4k})\,|_{\partial_p S_{4k,T}} &= g_{4k}. \end{aligned}$$

By classical Hölder estimates, we deduce

$$\overline{|u^n|}^{S_{2k,T}}_{\delta} \le \overline{|u^n\chi_{4k}|}^{S_{4k,T}}_{1+\delta} \le c\left(|F_{n,4k}|_0^{S_{4k,T}} + |L^\varepsilon_{u^n} g_{4k}|_0^{S_{4k,T}} + \overline{|g_{4k}|}^{S_{4k,T}}_{1+\delta}\right) \le \bar{c}$$

for every $n \ge 4k$ and $\delta \in]0,1[$, where $\bar{c} = \bar{c}(\delta, \varepsilon, c_1, k)$ does not depend on n. Moreover, since

$$\begin{aligned} L^\varepsilon_{u^n}(u^n\chi_{2k}) &= F_{n,2k} \qquad \text{on } S_{4k,T}, \\ (u^n\chi_{2k})\,|_{\partial_p S_{2k,T}} &= g_{2k}, \end{aligned}$$

we obtain

$$\overline{|u^n|}^{S_{k,T}}_{2+\delta} \le \overline{|u^n\chi_{2k}|}^{S_{2k,T}}_{2+\delta} \le c\left(\overline{|F_{n,2k}|}^{S_{2k,T}}_{\delta} + \overline{|g_{2k}|}^{S_{2k,T}}_{2+\delta}\right) \le \bar{\bar{c}} \qquad \forall n \ge 4k,$$

where $\bar{\bar{c}} = \bar{\bar{c}}(\delta, \varepsilon, c_1, k)$ does not depend on n.

Then, by the Ascoli–Arzelà theorem and Cantor's diagonal argument, we can extract from u^n a subsequence $\overline{|\ |}_{2+\alpha}$-convergent on compacts of S_T for every $\alpha \in]0,1[$ to the solution u^ε of (3.18)–(3.19) verifying estimates (3.6) and (3.8). The uniqueness of u^ε follows again from standard results.

Third step. We still assume $f, g, h \in C^\infty \cap \mathrm{Lip}$. We aim to prove estimate (3.7) for the solution u^ε found in the previous step. We fix $(\bar{x}, \bar{y}) \in \mathbb{R}^n \times \mathbb{R}$ and set

$$w(x,y,t) = u^\varepsilon(x, \varepsilon y, t)\bar{\chi}(x, \varepsilon y), \qquad \varepsilon > 0,\ (x,y,t) \in S_T,$$

where $\bar{\chi}(x,y) = \chi(x - \bar{x}, y - \bar{y})$ and χ is the cut-off function in (3.9). We have

$$(\Delta_x + \partial_{yy} - \partial_t) w = \Psi^\varepsilon \qquad \text{on } S_T,$$

where

$$\begin{aligned} \Psi^\varepsilon(x,y,t) = \Big[&\bar{\chi}\left(f(\cdot, u^\varepsilon) - h(u^\varepsilon)u^\varepsilon_y\right) + u^\varepsilon\left(\Delta_x\bar{\chi} + \varepsilon^2\bar{\chi}_{yy}\right) \\ &+ 2\left(\langle \nabla_x u^\varepsilon, \nabla_x\bar{\chi}\rangle + \varepsilon^2 u^\varepsilon_y \bar{\chi}_y\right)\Big](x, \varepsilon y, t), \qquad (x,y,t) \in S_T. \end{aligned}$$

Denoting by $\Gamma_H(z;\zeta)$ the fundamental solution of the heat operator in $\mathbb{R}^{N+2}$ with pole at $\zeta=(\xi,\eta,\tau)$ and evaluated in $z=(x,y,t)$, we have the following representation of w:

$$\begin{aligned} w(z) &= \int_0^t \int_{\mathbb{R}^{N+1}} \Gamma_H(z;\zeta)\Psi^\varepsilon(\zeta)d(\xi,\eta)d\tau \\ &- \int_{\mathbb{R}^{N+1}} \Gamma_H(z;\xi,\eta,0)g\bar{\chi}(\xi,\varepsilon\eta)d(\xi,\eta) \equiv I_1(z)-I_2(z). \end{aligned} \tag{3.26}$$

In order to estimate I_1, it suffices to note that, by (3.5), (3.6), and (3.8), we have that

$$|\Psi^\varepsilon|_0 \le c\sqrt{1+|(\bar{x},\bar{y})|^2}, \tag{3.27}$$

with c dependent only on c_1. Hence, by an elementary argument, we get

$$|I_1(x,y,t+s)-I_1(x,y,t)| \le c\sqrt{1+|(\bar{x},\bar{y})|^2}\ |s|^{\frac{1}{2}} \qquad \forall (x,y,t)\in S_T,\ s\in[-t,T-t], \tag{3.28}$$

where c depends only on c_1.

To estimate I_2, we begin by noting that a simple change of variables gives

$$I_2(x,y,t)=\int_{\mathbb{R}^{N+1}} \Gamma_H(\xi,\eta,1;0)g\bar{\chi}\left(x-\xi\sqrt{t},\varepsilon(y-\eta\sqrt{t})\right)d\xi d\eta.$$

Then

$$\begin{aligned} &|I_2(x,y,t+s)-I_2(x,y,t)| \le \int_{\mathbb{R}^{N+1}} \Gamma_H(\xi,\eta,1;0) \\ &\cdot \left| g\bar{\chi}\left(x-\xi\sqrt{t+s},\varepsilon(y-\eta\sqrt{t+s})\right) - g\bar{\chi}\left(x-\xi\sqrt{t},\varepsilon(y-\eta\sqrt{t})\right)\right| d\xi d\eta \end{aligned}$$

(by the mean value theorem, for some constant $c=c(c_1)>0$)

$$\begin{aligned} &\le c\sqrt{1+|(\bar{x},\bar{y})|^2}\ \left|\sqrt{t+s}-\sqrt{t}\right| \int_{\mathbb{R}^{N+1}} \Gamma_H(\xi,\eta,1;0)\left(|\xi|+\varepsilon|\eta|\right)d\xi d\eta \\ &\le c\sqrt{1+|(\bar{x},\bar{y})|^2}\ \sqrt{2|s|} \qquad \forall (x,y,t)\in S_T,\ s\in[-t,T-t], \end{aligned} \tag{3.29}$$

where c depends only on c_1.

Then, by the definition of w and by (3.26), we obtain

$$u^\varepsilon(\bar{x},\bar{y},t)=I_1\left(\bar{x},\frac{\bar{y}}{\varepsilon},t\right)-I_2\left(\bar{x},\frac{\bar{y}}{\varepsilon},t\right),$$

and estimate (3.7) follows from (3.28), (3.29).

Fourth step. We finally consider the general case where f,g,h are only assumed to be globally Lipschitz continuous. We use the standard mollifiers to approximate f,g,h uniformly on compacts by some sequences (f_n), (g_n), (h_n) in $C^\infty\cap\mathrm{Lip}$ that verify the estimates (3.5). Since the interval $[0,T]$ of existence of the solution constructed in the second step does not depend on the regularity of the coefficients, we may employ the usual density argument to find a function u^ε which is the unique classical solution of (3.3)–(3.4). □

Proof of Theorem 2.1. By Theorem 3.1, there exists a sequence

$$u^{\varepsilon_n} \in C_{2+\alpha,\mathrm{loc}}\left(S_T\right) \cap C\left(\overline{S}_T\right),$$

with $\varepsilon_n \downarrow 0$, such that every function u^{ε_n} is a solution of (3.3)–(3.4) with $\varepsilon = \varepsilon_n$ and verifies (1.6) for a constant c_0 that does not depend on n, and (u^{ε_n}) converges uniformly on compact subsets of $\overline{S}_T$ to a function u.

Arguing as in [6, Lem. 2.4], we can prove the following a priori estimates of Caccioppoli type for the derivatives of the functions (u^{ε_n}): if $\varphi \in C_0^\infty\left(S_T\right)$, there exists a positive constant c which depends only on f, φ and on the constant c_0 in (1.6) such that

$$\sum_{j=1}^{N} \left(\|u^{\varepsilon_n}_{x_j x_j}\varphi\|_2 + \|u^{\varepsilon_n}_{x_j y}\varphi\|_2 \right) + \varepsilon_n \|u^{\varepsilon_n}_{yy}\varphi\|_2 + \|u^{\varepsilon_n}_{t}\varphi\|_2 \le c \tag{3.30}$$

for every n. Therefore, up to a subsequence, $\partial_{x_j,x_k} u^{\varepsilon_n}$, $\varepsilon_n^2 \partial_{yy} u^{\varepsilon_n}$, $\partial_y u^{\varepsilon_n}$, and $\partial_t u^{\varepsilon_n}$ weakly converge in $L^2_{\mathrm{loc}}(S_T)$ to $\partial_{x_j,x_k} u$, 0, $\partial_y u$, and $\partial_t u$, respectively. Hence $u \in H^1_{\mathrm{loc}}(S_T), \partial_{x_j x_k} u \in L^2_{\mathrm{loc}}(S_T)$ for $j,k = 1,\dots,N$, and (1.1) is satisfied a.e.

The uniqueness of the solution can be proved as in [2, Prop. 5.1]. Indeed, since (u^{ε_n}) converges uniformly on compact sets, it is standard to prove that the limit u is a viscosity solution of (1.1)–(1.2) satisfying (1.6). Then the uniqueness of u follows by the comparison principle for viscosity solutions. □

4. Global existence. The main purpose of this section is to prove Theorem 1.2 by a simple continuation argument which relies on a bound of the gradient of u.

Proof of Theorem 1.2. The local existence result stated in Theorem 3.1 and a standard argument ensure that there exist an interval $I = [0, \overline{T}[$, where $\overline{T} \in \mathbb{R}^+$ or $\overline{T} = +\infty$, and a solution $u \in C^2(\mathbb{R}^{N+1} \times I)$ to problem (1.1)–(1.2), which cannot be defined for $t \ge \overline{T}$. We claim that our assumptions on f, g, and h yield $\overline{T} = +\infty$. To this end, we consider the local solution $u \in C^2(\mathbb{R}^{N+1} \times [0,T])$, which has been constructed in Theorem 3.1, and we denote by c_T the spatial Lipschitz constant corresponding to the strip S_T:

$$c_T = \inf \Big\{ c > 0 : |u(x,y,t) - u(x',y',t)| \le c(|x-x'|^2 + |y-y'|^2)^{1/2} \\ \forall (x,y,t),(x',y',t) \in \mathbb{R}^{N+1} \times [0,T] \Big\}.$$

We explicitly note that if $\overline{T} \ne +\infty$, then $c_t \to +\infty$ as $t \to \overline{T}$; hence a bound of the form

$$c_t \le c e^{kt} \tag{4.1}$$

for some positive constants c, k will prove our claim.

In order to prove (4.1) we first observe that, as in the proof of Theorem 3.1, it is not restrictive to assume that f, g, and h are smooth and that u is the classical solution of the regularized equation (1.5). We next show that

$$0 \le -u_y \le \frac{c_1}{c_0} + 1, \tag{4.2}$$

$$|u_{x_j}| \le c_1 e^{kt} \quad \text{for} \quad j = 1,\dots,N \tag{4.3}$$

for every $(x,y,t) \in S_T$, where c_1 is the Lipschitz constant defined in (3.5) and $k > 0$ does not depend on ε. To prove the first inequality in (4.2) we set $w(x,y,t) = e^{-\lambda t} u_y(x,y,t)$ for some $\lambda > 0$, and we note that since u is smooth, w is a solution to

$$\begin{cases} L_\varepsilon w = e^{-\lambda t} f_y + (\lambda - h'(u) u_y + f_u) w & \text{in } S_T, \\ w(\,\cdot\,, 0) = g_y. \end{cases}$$

By our assumptions $f_y \geq 0, g_y \leq 0, c_0 \leq h' \leq c_1$ and also by Theorem 3.1, $h'(u)u_y + f_u$ is bounded in S_T. Then $\lambda - h'(u)u_y + f_u > 0$ for suitably large λ and, as a consequence, $w \leq 0$ by the maximum principle. This proves the first inequality in (4.2). To prove the second one we set $w(x,y,t) = \frac{1}{2}\big(u_y^2(x,y,t) - \lambda^2\big)$, $\lambda > 0$, and argue as in the proof of Theorem 3.1: w is a solution to

$$\begin{cases} L_\varepsilon w = |\nabla_x u_y|^2 + \varepsilon^2 u_{yy}^2 - u_y(h'(u)u_y^2 - u_y f_u - f_y) & \text{in } S_T, \\ w(\,\cdot\,, 0) = \frac{1}{2}\big(g_y^2 - \lambda^2\big). \end{cases}$$

Since $u_y \leq 0$, we may choose λ sufficiently large (for instance, $\lambda = \frac{c_1}{c_0} + 1$) so that the right-hand side of the above differential equation is positive when $w > 0$. Then the second inequality in (4.2) follows again from the maximum principle.

We finally consider the function $w(x,y,t) = e^{-2\lambda t}\frac{u_{x_j}^2}{2} - \frac{c_1^2}{2}$ for $j = 1, \ldots, N$. Clearly $w(x,y,0) \leq 0$ and

$$\begin{aligned} L_\varepsilon w &= e^{-2\lambda t}\left(u_{x_j}^2(\lambda - h'(u)u_y + f_u) + |\nabla_x u_{x_j}|^2 + \varepsilon^2 u_{x_j,y}^2 + u_{x_j} f_{x_j}\right) \\ &\geq e^{-2\lambda t}\left(u_{x_j}^2(\lambda + f_u) + u_{x_j} f_{x_j}\right) \end{aligned}$$

by (4.2). Since $w \geq 0$ implies $|u_{x_j} f_{x_j}| \leq u_{x_j}^2$ then, for suitably large λ, we find $L_\varepsilon w \leq 0$ for $w \geq 0$ and prove (4.3) as above. This gives (4.1) and concludes the proof of Theorem 1.2. □

Remark 4.1. Hypothesis (1.9) on h is related to the natural assumptions in the theory of conservation laws. A simple counterexample shows that we cannot drop this condition. Indeed if $h(u) = -u$, $f \equiv 0$ and $g(x,y) = x - y$, then $u(x,y,t) = \frac{x-y}{1-t}$.

A GLOBAL STABILITY CRITERION FOR SCALAR FUNCTIONAL DIFFERENTIAL EQUATIONS*

EDUARDO LIZ†, VICTOR TKACHENKO‡, AND SERGEI TROFIMCHUK§

Abstract. We consider scalar delay differential equations $x'(t) = -\delta x(t) + f(t, x_t)$ $(*)$ with nonlinear f satisfying a sort of negative feedback condition combined with a boundedness condition. The well-known Mackey–Glass-type equations, equations satisfying the Yorke condition, and equations with maxima all fall within our considerations. Here, we establish a criterion for the global asymptotical stability of a unique steady state to $(*)$. As an example, we study Nicholson's blowflies equation, where our computations support the Smith conjecture about the equivalence between global and local asymptotical stabilities in this population model.

Key words. delay differential equations, global stability, Yorke condition, Schwarz derivative, Nicholson's blowflies equation

1. Introduction.

We start by considering the simple autonomous linear equation

$$x'(t) = -\delta x(t) + ax(t-h), \tag{1.1}$$

governed by friction ($\delta \geq 0$) and delayed negative feedback ($a < 0$). Necessary and sufficient conditions for the asymptotic stability of (1.1) are well known [5]. For example, in the simplest case $\delta = 0$, (1.1) is asymptotically stable if and only if $-ah \in (0, \pi/2)$. If we allow for a variable delay in (1.1), we obtain the equation

$$x'(t) = -\delta x(t) + ax(t-h(t)),\ 0 \leq h(t) \leq h, \tag{1.2}$$

whose stability analysis is more complicated than that of the autonomous case. Nevertheless several sharp stability conditions were established for (1.2). The first of them is due to Myshkis (see [5, p. 164]) and it states that in the case $\delta = 0$ the inequality $-a \sup_{\mathbb{R}} h(t) < 3/2$ guarantees the asymptotic stability in (1.2). This condition is sharp (this fact was established by Myshkis himself). In particular, the upper bound $3/2$ cannot be increased to $\pi/2$. Later on, the result by Myshkis was improved by different authors, the most celebrated extensions being those of Yorke [17] and Yoneyama [16] (both for $\delta = 0$). Finally, the Myshkis condition has been recently generalized [6] for $\delta > 0$: equation (1.2) is asymptotically stable if

$$-\frac{\delta}{a} \exp(-h\delta) > \ln \frac{a^2 - a\delta}{\delta^2 + a^2}. \tag{1.3}$$

We note that for every fixed a, δ, and $h > 0$, condition (1.3) is sharp, and in the limit case $\delta = 0$ it coincides with the Myshkis condition. Here the sharpness means that if a, δ, h do not satisfy (1.3), then the asymptotic stability of (1.2) can be destroyed by an appropriate choice of a periodic delay $h(t)$ (see [6, Theorem 4.1]). Returning to (1.1), we can observe that (1.3) approximates exceptionally well the exact stability domain for (1.1) given in [5]; see Figure 2.1, where the domains of local (dashed line) and global (solid line) stability are shown in coordinates $(-a/\delta, \exp(-\delta h))$. When $\delta = 0$, we obtain $3/2$ as an approximation for $\pi/2$.

It is a rather surprising fact that the sharp global stability condition (1.3) works not only for linear equations but also for a variety of nonlinear delay differential equations of the form

$$x'(t) = -\delta x(t) + f(t, x_t), \quad (x_t(s) \stackrel{\text{def}}{=} x(t+s),\ s \in [-h, 0]), \tag{1.4}$$

where $f : \mathbb{R} \times \mathcal{C} \to \mathbb{R}$, $\mathcal{C} \stackrel{\text{def}}{=} C[-h, 0]$, is a measurable functional satisfying the additional condition (H) given below. Due to the rather general form of (H), (1.4) incorporates, possibly after some transformations, some of the most celebrated delay equations, such as equations satisfying the Yorke condition [17], equations of Wright [5, 8], Lasota–Wazewska and Mackey–Glass [2, 7, 10], and equations with maxima [6, 11]. Solutions to some of these equations can exhibit chaotic behavior so that the analysis of their global stability is of great importance—at least during the first stage of the investigation (see [7, p. 148] for further discussion). As an example, in section 2 we consider Nicholson's blowflies equation, for which our computations support the conjecture of Smith posed in [14].

Let us explain briefly the nature of our further assumptions. In part, they are motivated by the sharp stability results for (1.4) obtained in [17] ($\delta = 0$) and [6] ($\delta > 0$) under the assumption that for some $a < 0$ and for all $\phi \in \mathcal{C}$, the following Yorke condition holds:

$$a\mathcal{M}(\phi) \le f(t, \phi) \le -a\mathcal{M}(-\phi). \tag{1.5}$$

Here $\mathcal{M} : \mathcal{C} \to \mathbb{R}$ is the monotone continuous functional (sometimes called the Yorke functional) defined by $\mathcal{M}(\phi) = \max\{0, \max_{s\in[-h,0]} \phi(s)\}$. In general, f satisfying (1.5) is nonlinear in ϕ. On the other hand, in some sense it has a "quasi-linear" form (for example, $f(\phi) = \max_{s\in[-h,0]} \phi(s)$ can be written as $f(\phi) = \phi(-s_\phi)$). In particular, f is sublinear in ϕ, which makes impossible the application of the results from [6, 17] to the strongly nonlinear cases such as the celebrated Wright equation

$$x'(t) = a(1 - \exp(-x(t-h))),\ a < 0, \tag{1.6}$$

which is also globally asymptotically stable if $-ah \in (0, 3/2)$. Roughly speaking, the Yorke $3/2$-stability condition does not imply the Wright $3/2$-stability result. Our recent studies [8] of (1.6) revealed the following interesting fact: the essential feature of the function $f(x) = a(1 - \exp(-x))$ in (1.6) allowing the extension of the Wright $3/2$-stability result to some other nonlinearities is the position of the graph of f with respect to the graph of the rational function $r(x) = ax/(1 + bx)$ which coincides with f, f', and f'' at $x = 0$. This suggests the idea to consider a "rational in $\mathcal{M}$" version of the "linear in $\mathcal{M}$" condition (1.5) to manage the strongly nonlinear cases of (1.4). Therefore, we will assume the following conditions (H):

(H1) $f : \mathbb{R} \times \mathcal{C} \to \mathbb{R}$ satisfies the Carathéodory condition (see [5, p. 58]). Moreover, for every $q \in \mathbb{R}$ there exists $\vartheta(q) \ge 0$ such that $f(t, \phi) \le \vartheta(q)$ almost everywhere on $\mathbb{R}$ for every $\phi \in C$ satisfying the inequality $\phi(s) \ge q, s \in [-h, 0]$.

(H2) There are $b \geq 0,\ a < 0$ such that

$$(1.7)\quad f(t,\phi) \geq \frac{a\mathcal{M}(\phi)}{1+b\mathcal{M}(\phi)} \text{ for all } \phi \in \mathcal{C};$$

$$(1.8)\quad f(t,\phi) \leq \frac{-a\mathcal{M}(-\phi)}{1-b\mathcal{M}(-\phi)} \text{ for all } \phi \in \mathcal{C} \text{ such that } \min_{s\in[-h,0]} \phi(s) > -b^{-1} \in [-\infty, 0).$$

(H) is a kind of negative feedback condition combined with a boundedness condition; they will cause solutions to remain bounded and to tend to oscillate about zero. Furthermore, (H) implies that $x = 0$ is the unique steady state solution for (1.4) with $\delta > 0$. On the other hand, (H) does not imply that the initial value problems for (1.4) have a unique solution. In any case, the question of uniqueness is not relevant for our purposes. Notice finally that if (H2) holds with $b = 0$ (which is precisely (1.5)), then (H1) is satisfied automatically with $\vartheta(q) = -aM(-q)$.

Now we are ready to state the main result of this work.

THEOREM 1.1. *Assume that* (H) *holds and let* $x : [\alpha, \omega) \to \mathbb{R}$ *be a solution of* (1.4) *defined on the maximal interval of existence. Then* $\omega = +\infty$ *and* x *is bounded on* $[\alpha, +\infty)$. *If, additionally, condition* (1.3) *holds, then* $\lim_{t\to+\infty} x(t) = 0$. *Furthermore, condition* (1.3) *is sharp within the class of equations satisfying* (H)*: for every triple* $a < 0,\ \delta > 0,\ h > 0$ *which does not meet* (1.3), *there is a nonlinearity* f *satisfying* (H) *and such that the equilibrium* $x(t) = 0$ *of the corresponding equation* (1.4) *is not asymptotically stable.*

It should be noticed that in this paper we do not consider the limit cases when $b = 0$ and/or $\delta = 0$. When $b = 0, \delta > 0$, Theorem 1.1 was proved in [6, Theorem 2.9]. The limit case $\delta = 0,\ b \geq 0$ can be addressed by adapting the proofs in [8]. Here, due to the elimination of the friction term $-\delta x$, an additional condition is necessary (see [9] for details). In this latter case, (1.3) takes the limit form $-ah \in (0, 3/2)$.

REMARK 1.1. *The set of four parameters* ($h > 0, \delta > 0, a < 0, b > 0$) *can be reduced. Indeed, the change of time* $\tau = \delta t$ *transforms* (1.4) *into the same form but with* $\delta = 1$. *Finally, since* $\mathcal{M}$ *is a positively homogeneous functional* ($\mathcal{M}(k\phi) = k\mathcal{M}(\phi)$ *for every* $k \geq 0$, $\phi \in \mathcal{C}$), *and since the global attractivity property of the trivial solution of* (1.4) *is preserved under the simple scaling* $x = b^{-1}y$, *the exact value of* $b > 0$ *is not important and we can assume that* $b = 1$. *Also, the change of variables* $x = -y$ *transforms* (1.4) *into* $y'(t) = -\delta y(t) + [-f(t, -y_t)]$ *so that it suffices that at least one of the two functionals* $f(t,\phi), -f(t,-\phi)$ *satisfies* (1.7) *and* (1.8).

To prove Theorem 1.1, in sections 3 and 4 we will construct and study several one-dimensional maps which inherit the stability properties of (1.4). The form of these maps depends strongly on the parameters: in fact, we will split the domain of all admissible parameters given by (1.3) into several disjoint parts, and each one-dimensional map will be associated to a part. Some of the maps are rather simple, and an elementary analysis is sufficient to study their stability properties. Some other maps are more complicated: for example, the proof of Lemma 3.6 involves the concept of the Schwarz derivative, whose definition and several properties are recalled below. Unfortunately, several important one-dimensional maps appear in an implicit form, and though this form may be simple, its analysis requires considerable effort. For the convenience of the reader, the hardest and most technical parts of our estimations are placed in an appendix (section 6). In section 2, we will show the significance of the hypotheses (H) again by applying Theorem 1.1 to the well-known Nicholson blowflies equation.

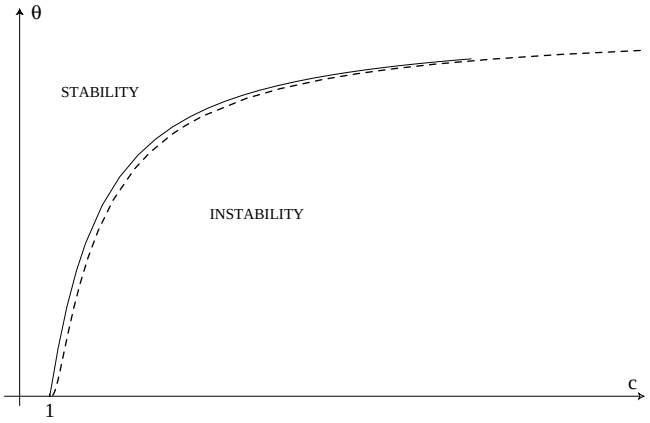

FIG. 2.1. *Domains of global and local stability in coordinates* (c, θ), $c = -a/\delta$, $\theta = \exp(-\delta h)$.

2. On the Smith conjecture and equations with nonpositive Schwarzian.

2.1. A global stability condition. In this section we will apply our results to the delay differential equation

$$N'(u) = -\delta N(u) + pN(u-h)e^{-\gamma N(u-h)},\ h > 0, \tag{2.1}$$

used by W. S. C. Gurney, S. P. Blythe, and R. M. Nisbet in 1980 to describe the dynamics of Nicholson's blowflies (see, for example, [1, section 3.6] or [14, p. 112]). Here p is the maximum per capita daily egg production rate, $1/\gamma$ is the size at which the population reproduces at its maximum rate, δ is the per capita daily adult death rate, h is the generation time, and $N(u)$ is the size of population at time u. In view of the biological interpretation, we consider only positive solutions of (2.1). If $p \le \delta$, then (2.1) has only one constant solution $x \equiv 0$. For $p > \delta$, the equation has an unstable constant solution $x \equiv 0$ and a unique positive equilibrium $N^* = \gamma^{-1}\ln(p/\delta)$. Global stability in (2.1) (when all positive solutions tend to the equilibrium N^*) has been studied by various authors by using different methods (see [2, 3, 14] for more references). Nevertheless, the exact global stability condition was not found. In this aspect, the work [14], where the conjecture about the equivalence between local and global asymptotic stabilities for (2.1) was posed (see [14, p. 116]), is of special interest for us. Indeed, an application of our main result to (2.1) strongly supports this conjecture, showing a surprising proximity between the boundaries of local and global stability domains; see Figure 2.1 and the following theorem.

THEOREM 2.1. *The positive equilibrium N^* of Nicholson's blowflies equation* (2.1) *is globally asymptotically stable if either $c \in (-1, 0]$ or*

$$\theta > c\ln[(c^2+c)/(c^2+1)]\,,\ c > 0, \tag{2.2}$$

where $\theta = \exp(-\delta h)$, $c = \ln(p/\delta) - 1$.

It follows from the observation given below (1.3) that condition (2.2) is sharp within the class of equations $N'(u) = -\delta N(u) + pN(u-\rho(u))e^{-\gamma N(u-\rho(u))}$ with variable delay $\rho : \mathbb{R} \to [0, h]$.

As can be seen from (2.2), not all parameters are independent in (2.1). Indeed, if we set $\tau = h\delta, u = t/\delta, q = p/\delta, x(t) = \gamma N(u)$, then (2.1) takes the form

$$x'(t) = -x(t) + g(x(t-\tau)), \tag{2.3}$$

where $g(x) = qx\exp(-x)$. For every $q > 1$, it has a unique positive equilibrium $x(t) \equiv \ln q$, which is globally asymptotically stable if $\ln(q) \le 2$ (see [3]). The change of variables $x(t) = \ln q + y(t)$ reduces (2.3) to the equation $y'(t) = -y(t) + w(y(t-\tau))$, where $w(y) = (y + \ln q)e^{-y} - \ln q$. In section 5, we will show that the nonlinearity $w(y)$ satisfies the following conditions (W) within some domain which attracts all nonnegative solutions of (2.3):

(W1) $w \in C^3(\mathbb{R}, \mathbb{R})$, $xw(x) < 0$ for $x \neq 0$, and $w'(0) < 0$.

(W2) w is bounded below and has at most one critical point $x^* \in \mathbb{R}$ which is a local extremum.

(W3) The Schwarz derivative $(Sw)(x) = w'''(x)(w'(x))^{-1} - (3/2)\left(w''(x)(w'(x))^{-1}\right)^2$ of w is nonnegative: $(Sw)(x) \le 0$ for all $x \neq x^*$.

Since $w'(0) = \ln(e\delta/p) < 0$ and $w''(0) > 0$ if $\ln q > 2$, Theorem 2.1 is a consequence of the following results.

LEMMA 2.2 (see [8]). *Let w meet conditions* (W) *and $w''(0) > 0$. Then the functional $f(t, \phi) = w(\phi(-h))$ satisfies hypotheses* (H) *with $a = w'(0)$ and $b = -w''(0)/(2w'(0))$.*

COROLLARY 2.3. *Suppose that w satisfies* (W) *and $w''(0) > 0$. If* (1.3) *holds with $a = w'(0)$, then the trivial steady state attracts all solutions of the delay differential equation*

$$x'(t) = -\delta x(t) + w(x(t-h)),\ \delta > 0. \tag{2.4}$$

Corollary 2.3 can be applied in a similar way to obtain global stability conditions for the positive equilibrium of other delay differential equations arising in biological models. For example, we can mention the celebrated Mackey–Glass equation proposed in 1977 to model blood cell populations (see, e.g., [10]), which is of the form (2.4) with $w(x) = b/(1 + x^n)$, $b > 0$, $n > 1$. Another important model that can be considered within our approach is the Wazewska-Czyzewska and Lasota equation describing the erythropoietic (red blood cell) system. In this case $w(x) = b_1\exp(-b_2 x)$, $b_i > 0$.

As proved in [8], the conclusion of Corollary 2.3 also holds for $\delta = 0$ by replacing (1.3) with its limit form $-ah \le 3/2$. In the particular case of the Wright equation, this result coincides with the 3/2-stability theorem by Wright (see [8] for more details).

2.2. The Smith and Wright conjectures revisited. Let us look again at Figure 2.1, which shows the boundaries of the domains of local and global asymptotic stability for the Nicholson equation; this observation (as well as Proposition 3.3 stated below) suggests the following.

CONJECTURE 2.1. *Under conditions* (W), *the trivial solution of* (2.4) *is globally attracting if it is locally asymptotically stable.*

An interesting particularity of Conjecture 2.1 is that it coincides with the celebrated Wright conjecture if we take $\delta = 0$, $w(x) = a(1 - \exp(-x))$, and it coincides with the Smith conjecture if we take Nicholson's blowflies equation.

Now, the following result was obtained in [15] as a simple consequence of an elegant approach toward stable periodic orbits for (2.4) with Lipschitz nonlinearities.

PROPOSITION 2.4 (see [15]). *For every $\alpha \ge 0$ there exists a smooth strictly decreasing function w satisfying* (W1), (W2), *$-w'(0) = \alpha$, and such that* (2.4) *has a nontrivial periodic solution which is hyperbolic, stable, and exponentially attracting with asymptotic phase (so therefore* (2.4) *is not globally stable).*

Proposition 2.4 shows clearly that the strong dependence between local (at zero) and global asymptotical stabilities of (2.4) cannot be explained only with the concepts

presented in (W1), (W2). We notice here that the condition of negative Schwarz derivative in (2.4) appears naturally also in some other contexts of the theory of delay differential equations; see, e.g., [10, sections 6–9], where it is explicitly used, and [5, Theorem 7.2, p. 388], where the condition $Sw < 0$ is implicitly required.

3. Preliminary stability analysis of (1.4). Throughout the paper, in view of Remark 1.1, we assume that $\delta = 1$ in (1.4) and $b = 1$ in (1.7), (1.8). Hence, with $\theta \stackrel{\text{def}}{=} \exp(-h)$, (1.3), (1.4), (1.7), and (1.8) take, respectively, the forms

$$-\theta/a > \ln \frac{a^2 - a}{a^2 + 1}; \tag{3.1}$$

$$x'(t) = -x(t) + f(t, x_t); \tag{3.2}$$

$$f(t, \phi) \geq r(\mathcal{M}(\phi)) \text{ for all } \phi \in \mathcal{C}; \tag{3.3}$$

$$f(t, \phi) \leq r(-\mathcal{M}(-\phi)) \text{ for all } \phi \in \mathcal{C} \text{ such that } \min_{s \in [-h, 0]} \phi(s) > -1, \tag{3.4}$$

where the rational function $r(x) = ax/(1+x)$ will play a key role in our constructions. In this section, we establish that the "linear" approximation to (3.1) of the form

$$-\theta/a > -(a+1)/(a^2+1) \tag{3.5}$$

implies the global stability of (3.2) (note here that $\ln(1 + x) < x$ is true for $x > 0$).

In what follows we will use some properties of the Schwarz derivative. The following lemma can be checked by direct computation.

LEMMA 3.1. *If g and f are functions which are at least C^3, then $S(f \circ g)(x) = (g'(x))^2 (Sf)(g(x)) + (Sg)(x)$. As a consequence, the inverse f^{-1} of a smooth diffeomorphism f with $Sf > 0$ has negative Schwarzian: $Sf^{-1} < 0$.*

We will also need the following lemma from [13].

LEMMA 3.2 (see [13, Lemma 2.6]). *Let $q : [\alpha, \beta] \to [\alpha, \beta]$ be a C^3 map with $(Sq)(x) < 0$ for all x. If $\alpha < \gamma < \beta$ are consecutive fixed points of some iteration $g = q^N$ of q, $N \geq 1$, and $[\alpha, \beta]$ contains no critical point of g, then $g'(\gamma) > 1$.*

This lemma allows us to prove the following proposition, which plays a central role in our analysis.

PROPOSITION 3.3. *Let $q : [\alpha, \beta] \to [\alpha, \beta]$ be a C^3 map with a unique fixed point γ and with at most one critical point x^* (maximum). If γ is locally asymptotically stable and the Schwarzian derivative $(Sq)(x) < 0$ for all $x \neq x^*$, then γ is the global attractor of q.*

Proof. Let W be the connected component of the open set $S = \{x \in [\alpha, \beta] : \lim_{k \to +\infty} q^k(x) = \gamma\}$ which contains γ. Clearly, $g(W) \subset W$. If $W \neq [\alpha, \beta]$, then we have three possibilities: $W = [\alpha, r)$, $W = (l, \beta]$, or $W = (l, r)$, $\alpha < l < r < \beta$.

If $W = [\alpha, r)$, then $q(r) = \lim_{\epsilon \to 0+} q(r - \epsilon) \leq r \leq q(r)$, a contradiction with the fact that q does not have fixed points in $[\alpha, \beta]$ different from γ. The case $W = (l, \beta]$ is completely analogous.

In the case $W = (l, r)$, by the same arguments, it should hold that $q(l) = r$, $q(r) = l$. Thus $l < \gamma < r$ are consecutive fixed points of $g = q^2$ and $g'(\gamma) = (q'(\gamma))^2 \leq 1$. By Lemma 3.2, $x^* \in (l, r)$, and therefore $q(x^*) < r$. Since q has a maximum at x^*, $r > q(x^*) \geq q(l)$, a contradiction.

Hence $W = [\alpha, \beta]$, and therefore $\{\gamma\}$ attracts each point of $[\alpha, \beta]$. This implies that γ is the global attractor of q (see [4, Chapter 2]). ∎

Now we are in a position to begin the stability analysis of (3.2).

LEMMA 3.4. *Suppose that* (H) *holds and let* $x : [\alpha - h, \omega) \to \mathbb{R}$ *be a solution of* (3.2) *defined on the maximal interval of existence. Then* $\omega = +\infty$ *and* $M = \limsup_{t\to\infty} x(t)$, $m = \liminf_{t\to\infty} x(t)$ *are finite. Moreover, if* $m \geq 0$ *or* $M \leq 0$, *then* $M = m = \lim_{t\to\infty} x(t) = 0$.

Proof. Note that (3.3) implies that $f(t, \phi) \geq a$ for all $t \in \mathbb{R}$ and $\phi \in \mathcal{C}$. Next, if $q \leq x_\alpha(s) \leq Q$, $s \in [-h, 0]$, then for all $t \in [\alpha, \omega)$, we have

$$x(t) = \exp(-(t-\alpha))x(\alpha) + \int_\alpha^t \exp(-(t-s))f(s, x_s)ds \geq a + (\min\{q, a\} - a)\exp(-(t-\alpha)) \geq \min\{q, a\}. \tag{3.6}$$

Next, (H1) implies that $f(s, x_s) \leq \vartheta(\min\{q, a\})$ for all $s \geq \alpha$, so that

$$x(t) \leq \max\{Q, 0\} + \vartheta(\min\{q, a\}),\ t \in [\alpha, \omega).$$

Hence $x(t)$ is bounded on the maximal interval of existence, which implies the boundedness of the right-hand side of (3.2) along $x(t)$. Thus $\omega = +\infty$ due to the corresponding continuation theorem (see [5, Chapter 2]).

Next, suppose, for example, that $M = \limsup_{t\to\infty} x(t) \leq 0$. Thus we have $\lim_{t\to\infty} \mathcal{M}(x_t) = 0$ so that, by virtue of (3.3), $f(t, x_t) \geq \inf_{s\geq t} a\mathcal{M}(x_s)/(1+\mathcal{M}(x_s)) \stackrel{\text{def}}{=} a(t)$, where $a : [\alpha, +\infty) \to (-\infty, 0]$ is nondecreasing and continuous, with $\lim_{t\to+\infty} a(t) = 0$. Thus, by (3.6), $x(t) \geq \exp(-(t-\beta))x(\beta) + a(\beta)$ for all $t \geq \beta > \alpha$. This implies that $m = \liminf_{t\to\infty} x(t) = 0$ so that $M = 0$. □

LEMMA 3.5. *Suppose that* (H) *holds and let* $x : [\alpha - h, \infty) \to \mathbb{R}$ *be a solution of* (3.2). *If* x *has a negative local minimum at some point* $s > \alpha$, *then* $\mathcal{M}(x_s) > 0$. *Analogously, if* x *has a positive local maximum at* $t > \alpha$, *then* $\mathcal{M}(-x_t) > 0$.

Proof. If $x(u) \leq 0$ for all $u \in [s - h, s]$, then $x'(s) \geq -x(s) + r(\mathcal{M}(x_s)) > 0$, a contradiction. The other case is similar. □

LEMMA 3.6. *Suppose that* (H) *holds and let* $x : [\alpha - h, \infty) \to \mathbb{R}$ *be a solution of* (3.2). *If* (3.5) *holds, then* $\lim_{t\to\infty} x(t) = 0$.

Proof. Let $M = \limsup_{t\to\infty} x(t)$, $m = \liminf_{t\to\infty} x(t)$. In view of Lemma 3.4, we only have to consider the case $m < 0 < M$, since otherwise ($m \geq 0$ or $M \leq 0$) we have a nonoscillatory solution to (3.2), which tends to zero as $t \to +\infty$. Thus in what follows we will consider only the oscillating solutions $x(t)$. In this case there are two sequences of points t_j, s_j of local maxima and local minima, respectively, such that $x(t_j) = M_j \to M, x(s_j) = m_j \to m$, and $s_j, t_j \to +\infty$ as $j \to \infty$.

First we prove that $M = m = 0$ if $a(1-\theta) > -1$. Indeed, for each s_j we can find $\varepsilon_j \to 0+$ such that $0 < \mathcal{M}(x_s) < M + \varepsilon_j$ for all $s \in [s_j - h, s_j]$. Next, by Lemma 3.5, there exists $h_j \in [0, h]$ such that $x(s_j - h_j) = 0$. Therefore, by the variation of constants formula,

$$m_j = \int_{s_j-h_j}^{s_j} e^{s-s_j} f(s, x_s)ds \geq \int_{s_j-h_j}^{s_j} e^{s-s_j} r(\mathcal{M}(x_s))ds \geq r(M + \varepsilon_j)(1-\theta).$$

As a limit form of this inequality, we get $m \geq r(M)(1-\theta)$. Hence $m > -1$ and we can use (3.4) for $\phi = x_t$ with sufficiently large t. Thus, in a similar way, we obtain that

$$M_j = \int_{t_j-h_j^*}^{t_j} e^{s-t_j} f(s, x_s)ds \leq \int_{t_j-h_j^*}^{t_j} e^{s-t_j} r(-\mathcal{M}(-x_s))ds \leq r(m - \varepsilon_j^*)(1-\theta)$$

for some sequences $\varepsilon_j^* \to 0+$ and $h_j^* \in [t_j - h, t_j]$. Hence we obtain $M \le r(m)(1-\theta) \le r(r(M)(1-\theta))(1-\theta)$. This gives $M^2 \le M(a(1-\theta)-1)$, which is only possible when $M = 0$.

Now, assume that $a(1-\theta) \le -1$. Since $m \ge r(M)(1-\theta) > a$ (see the first part of the proof), we conclude that $r^{-1}(m) = m/(a-m) > 0$ is well defined. Next, for s_j we can find a sequence of positive $\epsilon_j \to 0$ such that $m_j < m + \epsilon_j < 0$. We claim that $x(s_j - h_j) \ge r^{-1}(m + \epsilon_j)$ for some $h_j \in [0, h]$. Indeed, in the opposite case, $x(s) < r^{-1}(m + \epsilon_j)$ for all s in some open neighborhood of $[s_j - h, s_j]$. Thus $f(s, x_s) \ge r(\mathcal{M}(x_s)) > m + \epsilon_j$ for all s close to s_j. Finally, $x'(s) > -x(s) + m + \epsilon_j > 0$ almost everywhere in some neighborhood of s_j, contradicting the choice of s_j.

Next, there exists a sequence of positive $\epsilon_j^* \to 0$ such that $x(s) < M + \epsilon_j^*$ for all $s \in [s_j - h, s_j]$. Therefore, by the variation of constants formula,

$$\begin{aligned} m_j = x(s_j) &= e^{-h_j} x(s_j - h_j) + \int_{s_j - h_j}^{s_j} e^{s - s_j} f(s, x_s) ds \\ &\ge e^{-h_j} r^{-1}(m + \epsilon_j) + \int_{s_j - h_j}^{s_j} e^{s - s_j} r(\mathcal{M}(x_s)) ds \\ &\ge e^{-h_j} r^{-1}(m + \epsilon_j) + r(M + \epsilon_j^*)(1 - e^{-h_j}) \ge \theta r^{-1}(m + \epsilon_j) + r(M + \epsilon_j^*)(1 - \theta), \end{aligned}$$

so that $m - \theta r^{-1}(m) \ge r(M)(1-\theta) \ge a(1-\theta)$. This implies that $m \ge a(1-\theta)(a-m)/(a-m-\theta) > -1$, where the last inequality is evident when $1 + a(1-\theta) = 0$ and follows from the relations $m < 0 \le (a^2(1-\theta) + a - \theta)/(1 + a(1-\theta))$ otherwise. Since $m > -1$ we can use (3.4) for $\phi = x_t$ with sufficiently large t. Thus, in a similar way, we obtain that

$$\begin{aligned} M_j = x(t_j) = e^{-h_j^\#} x(t_j - h_j^\#) + \int_{t_j - h_j^\#}^{t_j} e^{s - t_j} f(s, x_s) ds \le e^{-h_j^\#} r^{-1}(M - \varepsilon_j) \\ + \int_{t_j - h_j^\#}^{t_j} e^{s - t_j} r(-\mathcal{M}(-x_s)) ds \le \theta r^{-1}(M - \varepsilon_j) + r(m - \varepsilon_j^*)(1 - \theta) \end{aligned}$$

for some sequences $\varepsilon_j, \varepsilon_j^* \to 0+$ and $h_j^\# \in [t_j - h, t_j]$. Thus $\psi(M) \stackrel{\text{def}}{=} M - \theta r^{-1}(M) \le r(m)(1-\theta)$. Now, $\psi : (a, +\infty) \to \mathbb{R}$ is a strictly increasing bijection so that $\chi(x) = \psi^{-1}((1-\theta) r(x))$ is well defined and strictly decreases on $(-1, +\infty)$. A direct computation shows that $\chi(-1^-) = +\infty$ and that $\chi(+\infty) = \psi^{-1}((1-\theta)a) > -1$. Therefore $\chi : [\chi(+\infty), \chi^2(+\infty)] \to [\chi(+\infty), \chi^2(+\infty)]$. Moreover, since $M \le \chi(m),\ m \ge \chi(M)$, we conclude that $m, M \in [\chi(+\infty), \chi^2(+\infty)]$ and that $[m, M] \subset \chi([m, M])$. Next, for $x > a$ we obtain by direct computation that $(S\psi)(x) = -6\theta a(a^2 - 2xa + x^2 - \theta a)^{-2} > 0$.

Since $(Sr)(x) = 0$ for all $x > -1$, it follows from Lemma 3.1 that

$$(S\chi)(x) = ((1-\theta) r'(x))^2 (S\psi^{-1})((1-\theta) r(x)) < 0.$$

Finally, by (3.5), $\chi'(0) = (1-\theta)a^2/(a-\theta) \in (-1, 0)$ so that we apply Proposition 3.3 (where we set $q = \chi$, $[\alpha, \beta] = [\chi(+\infty), \chi^2(+\infty)]$, and $\gamma = 0$) to conclude that $\chi^k([\alpha, \beta]) \to 0$ as $k \to \infty$. Since $[m, M] \subseteq \chi^k([m, M]) \subseteq \chi^k([\alpha, \beta])$ for all integers $k \ge 1$, it is clear that $m = M = 0$. □

4. Proof of the main result. The analysis done in the previous section shows that the only case that remains to be considered is when

$$0 < \ln \frac{a^2 - a}{a^2 + 1} < -\theta/a \le -\frac{a+1}{a^2+1}.$$

This case will be studied in the present section: we start describing a finer decomposition of the above-indicated domain of parameters (denoted below as $\mathcal{D}$).

4.1. Notation and domains. In what follows, we will always assume that $h > 0$ and $a < -1$, and we will use the following notation:

$$\theta = \exp(-h); \quad \lambda = \exp(\theta/a); \quad a_* = a + \frac{\theta}{1-\theta}; \quad \mu = -\frac{1}{a};$$

$$\alpha(a,\theta) = (1-a)\exp(\theta/a) + a;$$

$$\beta(a,\theta) = -\frac{a^2 + \exp(\theta/a)(1-2a+2\theta(a-1)) - (1-a)^2\exp(2\theta/a)}{a^2 + (a-a^2)\exp(\theta/a)};$$

$$\gamma(a,\theta) = a^3\alpha(a,\theta)\frac{1-\theta+\ln\theta}{2-\theta+\ln\theta}; \quad \mathcal{R}(r) = \mathcal{R}(r,a,\theta) = \frac{\alpha(a,\theta)r}{1-\beta(a,\theta)r}.$$

Obviously, $\theta,\ \mu \in (0,1),\ a_* > a$, and $\gamma(a,\theta)$ is well defined for all $\theta \in (0.16, 1)$, where it can be checked that $2 - \theta + \ln\theta > 0$. Next, we will need the following four curves considered within the open square $(\theta,\mu) \in (0,1)^2$:

$$\Pi_1 = \left\{(\theta,\mu)\ :\ \theta = \Pi_1(\mu) \stackrel{\text{def}}{=} \frac{1-\mu}{1+\mu^2}\right\};\ \Pi_2 = \left\{(\theta,\mu)\ :\ \theta = \Pi_2(\mu) \stackrel{\text{def}}{=} \frac{1}{\mu}\ln\frac{1+\mu}{1+\mu^2}\right\};$$
$$\Pi_3 = \left\{(\theta,\mu)\ :\ \theta = \Pi_3(\mu) \stackrel{\text{def}}{=} \frac{95-108\mu}{5(19+5\mu)}\right\};\ \Pi_4 = \left\{(\theta,\mu)\ :\ \theta = \Pi_4(\mu) \stackrel{\text{def}}{=} 0.8\right\}.$$

The geometric relations existing between curves Π_1–Π_4 are shown schematically on Figure 4.1. Notice that all three curves $\Pi_j,\ j \neq 4$, have the following asymptotics at zero: $\Pi_j(\mu) = 1 - k_j\mu + o(\mu)$, where $k_1 = 1, k_2 = 1.5, k_3 = 1.4$. An elementary analysis shows that Π_3 does not intersect Π_1 and Π_2 when $\theta \in (0.8, 1)$. Next, to prove our main result, we will have to use different arguments for the different domains of parameters a, h. For this purpose, we introduce here the following three subsets $\mathcal{D}, \mathcal{D}^*, \mathcal{S}$ of $(0,1)^2$:

$$\mathcal{D} = \{(\theta,\mu) : \Pi_2(\mu) \le \theta \le \Pi_1(\mu)\};$$

$$\mathcal{D}^* = \mathcal{D} \setminus \mathcal{S},\ \text{where } \mathcal{S} = \{(\theta,\mu) \in \mathcal{D} :\ \theta \in [0.8, 1),\ \Pi_3(\mu) \le \theta \le \Pi_1(\mu)\}.$$

We can see that $\mathcal{D}$ is situated between Π_1 and Π_2, while the sector $\mathcal{S}$ is placed among Π_1, Π_3, and Π_4. Sometimes it will be more convenient for us to use the coordinates (a,θ) instead of (θ,μ); we will preserve the same symbols for the domains and curves considered both in (a,θ) and (θ,μ).

Let us end this subsection indicating several useful estimations which will be of great importance for the proof of our main result.

LEMMA 4.1. *We have $\alpha(a,\theta) > 0$, $\beta(a,\theta) > 0$, and $a\alpha(a,\theta)/(1-a\beta(a,\theta)) > -1$ for all $(a,\theta) \in \mathcal{D}$. Next, if $(a,\theta) \in \mathcal{S}$, then $\gamma(a,\theta) < 1$.*

The proof of the lemma is given in section 6 (Lemmas 6.1, 6.2, and 6.3).

4.2. One-dimensional map $F : \mathbf{I} \to \mathbb{R}$. Throughout this subsection, we will suppose that $(a,\theta) \in \mathcal{D}$. Therefore $a(\theta-1)/\theta - 1 > 0$ so that the interval $I = (-1, a(\theta-1)/\theta - 1)$ is not empty. Furthermore, $t_1 = t_1(z) = -\ln(1 - z/r(z)) \in [-h, 0]$

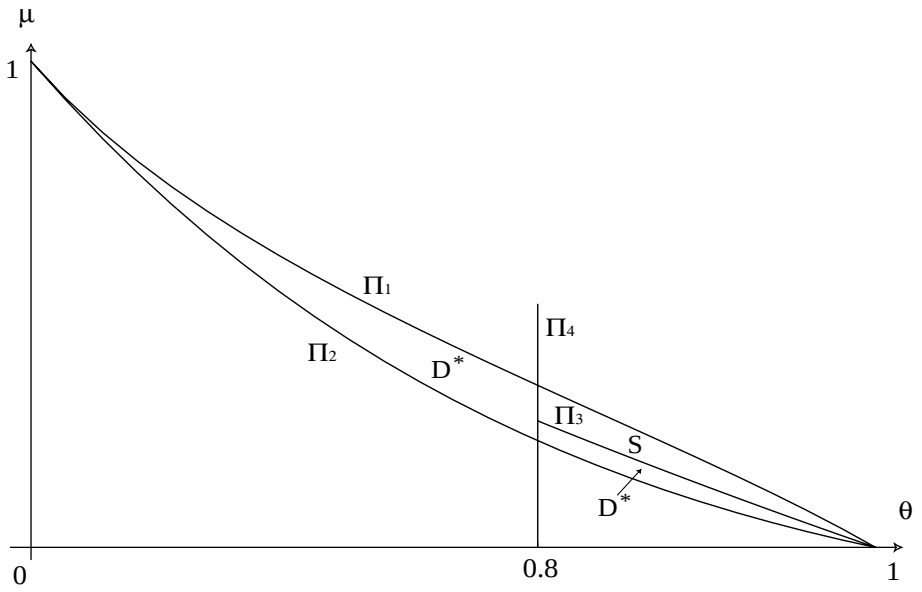

FIG. 4.1. *Domains of global stability in coordinates* (θ, μ).

for every $z \in I \setminus \{0\}$. Consider now the map $F : I \to \mathbb{R}$ defined in the following way:

$$F(z) = \begin{cases} 0 & \text{if } z = 0; \\ \min\limits_{t\in[0,h]} y(t,z) & \text{if } z \in I \text{ and } z > 0; \\ \max\limits_{t\in[0,h]} y(t,z) & \text{if } z \in (-1,0), \end{cases}$$

where $y(t,z)$ is the solution of the initial value problem $y(s,z) = z,\ s \in [t_1(z) - h, t_1(z)],\ z \in I$, for

$$y'(t) = -y(t) + r(y(t-h)). \tag{4.1}$$

Observe that $y(0,z) = 0$ for all $z \in I$ since $y(t,z) = r(z)(1 - \exp(-t))$ for all $t \in [t_1(z), t_1(z) + h]$. The following lemma explains why we have introduced such F (moreover, condition (3.1) says precisely that $F'(0) > -1$; see section 6.2).

LEMMA 4.2. *Let $x(t)$ be a solution of (3.2) and set $M = \limsup_{t\to\infty} x(t)$, $m = \liminf_{t\to\infty} x(t)$. If $m, M \in I$, then $m \geq F(M)$ and $M \leq F(m)$.*

Proof. Consider two sequences of extremal values $m_j = x(s_j) \to m$, $M_j = x(t_j) \to M$ such that $s_j \to +\infty, t_j \to +\infty$ as $j \to \infty$. Let $\varepsilon > 0$ be such that $(m - \varepsilon, M + \varepsilon) \subset I$. Then $m_j \geq m - \varepsilon$ and $M_j \leq M + \varepsilon$ for big j. We will prove that $m \geq F(M)$, the case $M \leq F(m)$ being completely analogous.

By Lemma 3.5, we can find $\tau_j \in [s_j - h, s_j]$ such that $x(\tau_j) = 0$ while $x(t) < 0$ for $t \in (\tau_j, s_j]$. Next, $v_j = \tau_j + t_1(M+\varepsilon) \geq \tau_j - h$ because of $M + \varepsilon \in I$. Thus the solution $y(t)$ of (4.1) with initial condition $y(s) = M + \varepsilon,\ s \in [v_j - h, v_j]$, satisfies $y(\tau_j) = 0$ while $M + \varepsilon \equiv y(t) \geq x(t)$ for all $t \in [v_j - h, v_j]$. Furthermore, for all $s \in [v_j, \tau_j]$, we have $\mathcal{M}(x_s) \leq M + \varepsilon$ so that, by (3.3), $f(s, x_s) \geq r(\mathcal{M}(x_s)) \geq r(M + \varepsilon)$, and

$$y(t) - x(t) = \int_{\tau_j}^{t} e^{-(t-s)}[r(M+\varepsilon) - f(s, x_s)]ds \geq 0,\ t \in [v_j, \tau_j],$$

proving that $y(t) \geq x(t)$ for all $t \in [\tau_j - h, \tau_j]$. Now, for $t \in (\tau_j, s_j]$,

$$y(t) - x(t) = \int_{\tau_j}^{t} \exp\{-(t-s)\}(r(y(s-h)) - f(s, x_s))ds \leq 0, \tag{4.2}$$

since $f(s, x_s) \geq r(\mathcal{M}(x_s)) \geq r(\mathcal{M}(y_s)) = r(y(s-h))$. Hence, by (4.2), $m_j = x(s_j) \geq y(s_j) \geq F(M+\varepsilon)$, which proves that $m \geq F(M)$. □

To study the properties of F, we use its more explicit form given below.

LEMMA 4.3. *Set $r^{-1}(u) = u/(a-u)$. For $z \in I$, $(F(z) - r(z))z \geq 0$ and*

$$\theta = \int_{r(z)}^{F(z)} \frac{du}{r^{-1}(u) - r(z)}. \tag{4.3}$$

Proof. Let us consider $z > 0$, the case $z < 0$ being similar. Consider the solution $y(t, z)$ of (4.1), and recall that $y(t, z) = z$ for $t \in [t_1 - h, t_1]$, where $t_1 = -\ln(1 - z/r(z)) \in [-h, 0]$. Next, $y(t, z) = r(z)(1 - \exp(-t))$, $t \in [t_1, t_1 + h]$, so that $y(0, z) = 0$ and $y'(h, z) = -y(h, z)$. Therefore $F(z) = y(t_*, z)$ at some point $t_* \in (t_1 + h, h)$, where also $y'(t_*, z) = 0$.

Since $t_* \in [t_1 + h, h]$, by the variation of constants formula we have

$$y(t_*, z) = F(z) = e^{-(t_* - h)} \left[y(t_1 + h, z)e^{t_1} + \int_{t_1}^{t_* - h} e^v r(y(v, z))dv \right]. \tag{4.4}$$

On the other hand, $y'(t_*, z) = 0 = -y(t_*, z) + r(y(t_* - h, z))$, so that $F(z) = y(t_*, z) = r(y(t_* - h, z)) \geq r(z)$ and $r^{-1}(F(z)) = y(t_* - h, z) = r(z)[1 - \exp\{-(t_* - h)\}]$. Thus

$$t_* - h = \ln(r(z)/[r(z) - r^{-1}(F(z))]).$$

Now let $y(v, z) = w$ (so that $\exp(v) = r(z)/(r(z) - w)$); then

$$\int_{t_1}^{t_* - h} e^v r(y(v, z))dv = \int_{z}^{r^{-1}(F(z))} r(w) d\frac{r(z)}{r(z) - w}$$

$$= r(z) \left[\frac{r(z)}{z - r(z)} - \frac{F(z)}{r^{-1}(F(z)) - r(z)} + \int_{z}^{r^{-1}(F(z))} \frac{dr(w)}{w - r(z)} \right].$$

Now putting the last expression and the values of t_1, $t_* - h$ in (4.4), we get (4.3). □

Finally, we state an important technical lemma whose proof can be found in Lemmas 6.5 and 6.6 of the appendix.

LEMMA 4.4. *Assume that $(a, \theta) \in \mathcal{D}$. Then $F(z) < \mathcal{R}(r(z))$ if $z \in ((a\beta - 1)^{-1}, 0)$, and $F(z) > \mathcal{R}(r(z))$ if $z \in (0, a(\theta - 1)/\theta - 1)$, where $\mathcal{R}$ is defined in subsection 4.1.*

We will also consider $\mathcal{F} : (a_*, +\infty) \to \mathbb{R}$ defined by $\mathcal{F}(x) = F(x/(a - x))$. It can be easily seen that $\mathcal{F}(r(z)) = F(z)$ for all $z \in I$.

4.3. One-dimensional map $F_1 : [0, +\infty) \to (a, 0]$. By definition, for $z \geq 0$, $F_1(z) = \min_{t \in [0,h]} y(t)$, where $y(t, z)$ satisfies (4.1) and has the initial value $y(s, z) = (1 - e^{-s})r(z)$, $s \in [-h, 0]$. We will need the following lemma.

LEMMA 4.5. *Let $x(t)$ be a solution of (3.2) and set $M = \limsup_{t \to \infty} x(t)$, $m = \liminf_{t \to \infty} x(t)$. If $(a, \theta) \in \mathcal{D}$, then $m \geq F_1(M)$.*

Proof. Take $\varepsilon, s_j, t_j, m_j, M_j, \tau_j$ as in the first two paragraphs of the proof of Lemma 4.2. Then, for $t \in [\tau_j - h, \tau_j]$, we have

$$x(t) = \int_{\tau_j}^{t} e^{-(t-u)} f(u, x_u) du \le \int_{\tau_j}^{t} e^{-(t-u)} r(M+\varepsilon) du = y(t - \tau_j, M + \varepsilon).$$

Thus, if $u \in [s_j - h, s_j]$, then $\mathcal{M}(x_u(s)) \le \mathcal{M}(y_u(s, M+\varepsilon))$ so that

$$f(u, x_u) \ge r(\mathcal{M}(y_u(s, M+\varepsilon))) = r(r(M)(1 - e^{-(u-h-\tau_j)})).$$

This implies that

$$\begin{aligned} m_j = x(s_j) &\ge \int_{\tau_j}^{s_j} e^{-(s_j-u)} r(r(M)(1 - e^{-(u-h-\tau_j)})) du \\ &= \int_{\tau_j}^{s_j} e^{-(s_j-u)} r(y(u-h, M+\varepsilon)) du = y(s_j - \tau_j, M+\varepsilon) \ge F_1(M+\varepsilon). \end{aligned}$$

Since $\varepsilon > 0$ and $m_j \to m$ are arbitrary, the lemma is proved. ∎

LEMMA 4.6. *Set $r_1(z) = r(r(z)(1 - e^h))$. For $z > 0$ we have that $F_1(z) > a$ and*

$$\frac{r_1(z)\theta}{r(z)} = \int_{r_1(z)}^{F_1(z)} \frac{du}{r^{-1}(u) - r(z)}. \tag{4.5}$$

Proof. Take $t_* \in (0, h)$ such that

$$F_1(z) = y(t_*, z) = \int_0^{t_*} e^{-(t_*-u)} r(r(z)(1 - e^{-(u-h)})) du. \tag{4.6}$$

Since $y'(h) > 0$, we have that $y'(t_*) = 0$, and therefore $F_1(z) = y(t_*) = -y'(t_*) + r(y(t_* - h)) = r(y(t_* - h)) > a$. This implies that $r^{-1}(F_1(z)) = y(t_* - h) = r(z)(1 - \exp\{-(t_* - h)\})$, from which

$$t_* - h = \ln(r(z)/[r(z) - r^{-1}(F_1(z))]). \tag{4.7}$$

Now, using (4.7) and setting $\xi = r(z)(1 - e^{-(u-h)})$ in (4.6), we obtain

$$\begin{aligned} F_1(z) &= -(r(z) - r^{-1}(F_1(z))) \int_{r(z)(1-e^h)}^{r^{-1}(F_1(z))} r(\xi) d\frac{1}{\xi - r(z)} \\ &= -(r(z) - r^{-1}(F_1(z))) \left(\frac{r(\xi)}{\xi - r(z)} \Bigg|_{r(z)(1-e^h)}^{r^{-1}(F_1(z))} + \int_{r(z)(1-e^h)}^{r^{-1}(F_1(z))} \frac{dr(\xi)}{\xi - r(z)} \right). \end{aligned}$$

Simplifying this relation, we obtain (4.5). ∎

We conclude this section by stating two lemmas which compare F_1 and the associated function $\mathcal{F}_1(r) \stackrel{\text{def}}{=} F_1(r/(a-r))$ with rational functions. The proofs of these statements are based on rather careful estimations of identity (4.5) and are given in Lemmas 6.7, 6.10, and 6.11 in the appendix. (It should be noted that $\mathcal{R}$ approximates $\mathcal{F}_1$ extremely well so that a very meticulous analysis of (4.5) is needed.)

LEMMA 4.7. *If $(a, \theta) \in \mathcal{D}^*$ and $z \ge a(\theta - 1)/\theta - 1$, then $F_1(z) > \mathcal{R}(r(z))$.*

LEMMA 4.8. *If $(a, \theta) \in \mathcal{S}$ and $z > 0$, then*

$$\mathcal{F}_1(r(z)) > \frac{1 + \ln\theta - \theta}{2 + \ln\theta - \theta} \frac{ar(z)}{1 + r(z)\frac{1+\ln\theta-\theta}{1-\theta}} = \mathcal{R}_2(r(z)). \tag{4.8}$$

Furthermore, $\mathcal{R}_2(a) > -1$ and $r(\mathcal{R}_2(a)) < 1/\beta$.

4.4. Proof of Theorem 1.1. Let $x : [\alpha - h, \infty) \to \mathbb{R}$ be a solution of (3.2) and set $M = \limsup_{t\to\infty} x(t)$, $m = \liminf_{t\to\infty} x(t)$. We will reach a contradiction if we assume that $m < 0 < M$. (Note that the cases $M \le 0$ and $m \ge 0$ were already considered in Lemma 3.4.)

First suppose that $(a, \theta) \in \mathcal{S}$. By Lemmas 4.5 and 4.8, we obtain that

$$m \ \ge \ F_1(M) = \mathcal{F}_1(r(M)) \ > \ \mathcal{R}_2(r(M)) > -1. \tag{4.9}$$

Now take an arbitrary $z \ge 0$. Since $r(z) \in (a, 0]$ and $\mathcal{R}_2(z)$ is increasing on $(a, 0]$, we get $r(\mathcal{R}_2(r(z))) < 1/\beta$ due to Lemma 4.8. Therefore, the rational function $\lambda \stackrel{\text{def}}{=} \mathcal{R} \circ r \circ \mathcal{R}_2 \circ r : [0, \infty) \to [0, \infty)$ is well defined. By Lemmas 4.2 and 4.4, we obtain

$$M \le \mathcal{F}(r(m)) < \mathcal{R}(r(\mathcal{R}_2(r(M)))) = \lambda(M).$$

On the other hand, due to the inequality $\lambda'(0) = \gamma(a, \theta) < 1$ (see Lemma 4.1), we obtain that $\lambda(z) < z$ for all $z > 0$, a contradiction.

Now let $(a, \theta) \in \mathcal{D}^*$ and define the rational function $R : [0, +\infty) \to (-\infty, 0]$ as $R = \mathcal{R} \circ r$. We note that (3.1) implies $R'(0) = a\alpha(a, \theta) \in (-1, 0)$. Next,

$$m > R(M) > \mathcal{R}(a) > -1. \tag{4.10}$$

Indeed, if $M \le a(\theta - 1)/\theta - 1$, then Lemmas 4.2 and 4.4 imply that $m \ge F(M) > \mathcal{R}(r(M)) = R(M)$. If $M \ge a(\theta - 1)/\theta - 1$, then Lemmas 4.5 and 4.7 give that $m \ge F_1(M) > \mathcal{R}(r(M)) = R(M)$. The last inequality in (4.10) follows from Lemma 4.1. Finally, applying Lemmas 4.2 and 4.4, and using (4.10) and the inequality $R \circ R(x) < x$, $x > 0$, which holds since $(R \circ R)'(0) = (R'(0))^2 < 1$, we obtain that

$$M \le F(m) < \mathcal{R}(r(m)) < \mathcal{R}(r(R(M))) = R(R(M)) < M,$$

a contradiction.

To prove the second part of Theorem 1.1 take $a < 0$ and $h > 0$ such that (3.1) is not satisfied. Then, by Theorem 2.9 from [6] there is a continuous functional f satisfying (1.5) and such that the equilibrium $x(t) = 0$ in (3.2) is not locally asymptotically stable.

5. Some estimations of the global attractor for (2.3). To complete the proof of Theorem 2.1, we need to estimate the bounds of the global attractor to (2.3). We start by stating a result from [3].

LEMMA 5.1 (see [3]). *Let $q > 1$. Then there exist finite positive limits*

$$M = \limsup_{t\to\infty} x(t)\,, \ \ m = \liminf_{t\to\infty} x(t)$$

for every nonnegative solution $x(t) \not\equiv 0$ of (2.3). Moreover, $[m, M] \subseteq g([m, M])$ and $[m, M] \subseteq g_1([m, M])$, where $g_1 = \theta \ln q + (1 - \theta)g$, $\theta = \exp(-\tau)$.

Since the global stability of (2.3) for $\ln q \in (0, 2]$ was already proved in [3], we can suppose that $\ln q > 2$. In this case the minimal root x_1 of equation $g(x_1) = \ln q$ belongs to the interval $(0, 1)$. Note that $x = 1 < \ln q$ is the point of absolute maximum for g and $g_1 = (1 - \theta)g + \theta \ln q$, so that $g(1) > \ln q$ and $g_1(1) > \ln q$. We will use the information about the values of g and g_1 at $x_1 < 1 < \ln q$ in the subsequent analysis.

Now, let us consider an arbitrary solution $x(t)$ of (2.3) and its bounds m, M defined in Lemma 5.1. It is clear that if we prove the existence of $m_* = m_*(q)$ such

that $m \geq m_*(q) > x_1$ and $m_*(q)$ does not depend on $x(t)$, then the change of variables $y = x - \ln q$ transforms (2.3) into an equation satisfying (W) within the domain of attraction, and therefore Theorem 1.1 can be applied.

Since $[m, M] \subseteq g([m, M])$, we obtain immediately that either $m = M = \ln q$ or $m < \ln q < M$. In the first case the theorem is proved, so we will consider the second possibility. Next, since $z < g(z)$ for $z \in (0, \ln q)$, we have that $g(m) > m$ and

$$[m, M] \subseteq g([m, M]) \subseteq [\min\{g(m), g(M)\}, g(1)] = [g(M), g(1)].$$

Hence, $[m, M] \subseteq g([g(M), g(1)]) \subseteq [\min\{g^2(1), g^2(M)\}, g(1)]$. On the other hand, since $g(M) < \ln q$ we get analogously that $g^2(M) > g(M)$. Next, since g is decreasing on $[1, +\infty)$ and $g(1) \geq M$ we find that $g^2(1) \leq g(M)$. Thus $g^2(1) \leq g(M) < g^2(M)$ so that $\min\{g^2(1), g^2(M)\} = g^2(1)$ and $[m, M] \subseteq [g^2(1), g(1)]$. Therefore $m \geq g(g(1))$. Since the inequality $m \geq g_1(g_1(1))$ can be proved analogously, the proof of theorem will be completed if we establish that $m_*(q) = \max\{g^2(1), g_1^2(1)\} > x_1$. We have the following:

(i) $g^2(1) > x_1$ *for all* $\ln q \in [2, 2.833157]$. This is an obvious fact if $g^2(1) \geq 1$, so that we need only consider the case $x_1, g^2(1) \in (0, 1)$. Since g is increasing on $(0, 1)$, the inequality $g^2(1) > x_1$ is equivalent to $g^3(1) > g(x_1) = \ln q$ in this case. Finally, a direct computation shows that

$$g^3(1) - \ln q = q^3 e^{-1-q/e} \exp(-q^2 e^{-1-q/e}) - \ln q > 0$$

whenever $\ln q \in [2, 2.833157]$.

(ii) $g_1^2(1) > x_1$ *for all* $\ln q > 2.5$. First, let us note that $x_1 \leq \ln q + y_1$, where

$$y_1 = \left(2 - \ln q - \sqrt{(\ln q)^2 + 4 \ln q - 4}\right)/2$$

is the negative root of $\tilde{g}(y) = (y + \ln q)(1 - y + y^2/2) - \ln q$. Indeed, with $x = y + \ln q$ and $y \in (y_1, 0)$, we have that $g(x) - \ln q = qxe^{-x} - \ln q = (y + \ln q)e^{-y} - \ln q \geq \tilde{g}(y) > 0$.

Since $g_1^2(1) \geq g_1(+\infty) = \theta \ln q$, to finish the proof of (ii), it suffices to show that $\theta \ln q \geq \ln q + y_1$. Taking into account (2.2) and using the inequality $\ln(1 + x) \geq x/(1 + x)$, we obtain that

$$\begin{aligned}(\theta - 1)\ln q - y_1 &= (\theta - 1)(1 + c) - y_1 \geq (1 + c)(-1 + c \ln((c^2 + c)/(c^2 + 1))) - y_1 \\ &\geq -2 - \frac{2 - \ln q - \sqrt{(\ln q)^2 + 4 \ln q - 4}}{2} \geq 0 \quad \text{for} \quad \ln q \geq 5/2.\end{aligned}$$

6. Appendix.

6.1. Preliminary estimations.

LEMMA 6.1. *For all* $(a, \theta) \in \mathcal{D}$, *we have that* $\alpha(a, \theta) > 0$, $\beta(a, \theta) > 0$, *and*

$$T(a, \theta) \stackrel{\text{def}}{=} (a^2 - a)\beta(a, \theta)(1 - \theta) + \alpha(a, \theta) - (1 - \theta) \geq 0.$$

Proof. Since $a(\theta - 1) > 1$ for all $(a, \theta) \in \mathcal{D}$ and

$$\begin{aligned} &1 + x < \exp(x) < 1 + x + x^2/2 \quad \text{for } x < 0, \\ &\exp(x) > 1 + x + x^2/2 + x^3/6 \quad \text{for } x > 0, \end{aligned} \tag{6.1}$$

we have $\alpha(a,\theta) = (1-a)\exp(\theta/a) + a > (1-a)(1+\theta/a) + a = 1 - \theta + \theta/a > 0$. Analogously, $\beta(a,\theta) > 0$ for all $(a,\theta) \in \mathcal{D}$ because of the following chain of relations:

$$
\begin{aligned}
&- a\alpha(a,\theta)\beta(a,\theta)e^{-\theta/a} = a^2 e^{-\theta/a} - (1-a)^2 e^{\theta/a} + (1 - 2a + 2\theta(a-1)) \\
&\geq a^2\left(1 - \frac{\theta}{a} + \frac{\theta^2}{2a^2} - \frac{\theta^3}{6a^3}\right) - (1-a)^2\left(1 + \frac{\theta}{a} + \frac{\theta^2}{2a^2}\right) + (1 - 2a + 2\theta(a-1)) \\
&= \frac{\theta}{6a^2}(-3\theta - a(\theta^2 - 6\theta + 6)) > \frac{\theta(2\theta a - 2a - \theta)}{2a^2} > 0.
\end{aligned}
$$

To prove that $T(a,\theta) \geq 0$ for all $(a,\theta) \in \mathcal{D}$, we replace α, β with their values in αT:

$$
\begin{aligned}
\alpha(a,\theta)T(a,\theta) = {} & a(2a - a^2 - a\theta + a^2\theta - 1 + \theta) \\
& + 2\theta(a-1)(-2a + a\theta + 1 - \theta)\lambda - (1-a)^2(-a + a\theta - \theta)\lambda^2.
\end{aligned} \tag{6.2}
$$

It should be noticed that $-a + a\theta - \theta = a(\theta - 1) - \theta > 1 - \theta > 0$. Similarly, $2\theta(a-1)(-2a + a\theta + 1 - \theta) < 0$ so that $T(a,\theta) \geq 0$ if

$$
\theta(-a + a\theta - \theta)(4a^4)^{-1}[-\theta(-\theta + a\theta - 2a)^2 + 4(\theta - 1)a^3] > 0,
$$

where the last expression was obtained from (6.2) by replacing $\lambda = \exp(\theta/a)$ by $1 + \theta/a + \theta^2/2a^2 > \exp(\theta/a)$. Taking into account that $a(\theta-1) > 1$ and $\theta < 1$ for $(a,\theta) \in \mathcal{D}$, we end the proof of this lemma by noting that $4(\theta-1)a^3 - \theta(\theta - a\theta + 2a)^2 \geq 4a^2 - (\theta - a\theta + 2a)^2 = (-4a - \theta + a\theta)\theta(1-a) > 0$. □

LEMMA 6.2. *For all $(a,\theta) \in \mathcal{D}$ one has*

$$
\frac{a\alpha(a,\theta)}{1 - a\beta(a,\theta)} > -1. \tag{6.3}
$$

Proof. It follows directly from the definitions of $\alpha(a,\theta)$ and $\mathcal{D}$ that $a\alpha(a,\theta) > -1$ for all $(a,\theta) \in \mathcal{D}$. Now, (6.3) follows from the fact that $a\beta(a,\theta) < 0$ if $(a,\theta) \in \mathcal{D}$. □

LEMMA 6.3. *If $(a,\theta) \in \mathcal{S}$, then $\gamma(a,\theta) < 1$.*

Proof. Notice that $(a,\theta) \in \mathcal{S}$ implies that $\theta \in [0.8, 1)$ and $\theta > \Pi_3(-1/a)$ (or, equivalently, $a > \pi_3(\theta) \stackrel{\text{def}}{=} -1/\Pi_3^{-1}(\theta) = (108 + 25\theta)(95\theta - 95)^{-1}$). Here Π_3^{-1} is the inverse function of Π_3. Next we prove the inequality

$$
\frac{1 - \theta + \ln\theta}{2 - \theta + \ln\theta} + \frac{(\theta-1)^2(2-\theta)}{2} > 0, \quad \theta \in [0.8, 1), \tag{6.4}
$$

which is equivalent to the relation

$$
\Xi(q) \stackrel{\text{def}}{=} q(q-2)(q^2+1) + (2 + q^2 - q^3)\ln(q+1) > 0, \quad q \in [-0.2, 0),
$$

with $\theta = q + 1$ (note that $1 - q + \ln(q+1) > 0$ for $q \in [-0.2, 0)$). To do that, we will need the following approximation of $\ln(1+q)$ when $q \in [-0.2, 0)$:

$$
\ln(1+q) > q - 0.5q^2 + 0.4q^3, \quad q \in [-0.2, 0). \tag{6.5}
$$

(Indeed, function $y(x) = \ln(1+x) - (x - 0.5x^2 + 0.4x^3)$ has exactly one critical point $x = -1/6$ on $[-0.2, 0)$, and $y(-0.2) = 0.00005644\ldots > 0$, $y(0) = 0$.) Inequality (6.5) implies that $\Xi(q) \geq -0.1q^3(5q + 2 - 9q^2 + 4q^3)$. Now, since $(5q + 2 - 9q^2 + 4q^3) > 0$ for all $q \in [-0.2, 0)$, we have that $\Xi(q) > 0$, and thus (6.4) is proved.

Next, due to (6.1) and (6.4),

$$\gamma(a,\theta) \le a^3\left(1-\theta+\frac{\theta}{a}-\frac{\theta^2}{2a}+\frac{\theta^2}{2a^2}\right)\frac{(\theta-1)^2(\theta-2)}{2} = w(a,\theta),$$

so that $\gamma(\pi_3(\theta),\theta) \le w(\pi_3(\theta),\theta)$. Now, $w(\pi_3(\theta),\theta)$ is a fifth degree polynomial, and an elementary analysis shows that $w(\pi_3(\theta),\theta) < 1$ for all $\theta \in [0.8, 1)$. Since

$$\partial w(a,\theta)/\partial a = 0.25(2-\theta)(\theta-1)^2[a(\theta-1)(2a+2\theta)+a(4a(\theta-1)-2\theta)] < 0,$$

we conclude that $\gamma(a,\theta) \le w(a,\theta) < 1$ for $a > \pi_3(\theta)$. □

LEMMA 6.4. *Let* $(a,\theta) \in \mathcal{D}$ *and* $r > -1/4$. *Set* $\mathcal{J}(r) = \mathcal{I}(N(r))$, *where* $\mathcal{I}(N) = N\coth(\nu N/2)$, $\nu = -\theta/a$, $N(r) = \sqrt{1+4r}$. *Then* $\mathcal{J}'(0) > 0$ *and*

$$\mathcal{J}(r) \le \mathcal{J}(0) + \mathcal{J}'(0)r = \frac{1+\lambda}{1-\lambda} + \left(2\frac{1+\lambda}{1-\lambda} + \frac{4\theta\lambda}{a(1-\lambda)^2}\right)r. \tag{6.6}$$

Proof. Set $k(N) = e^{2\nu N} - 2\nu N e^{\nu N} - 1 > 0$; then $k(0) = 0$ and $k'(N) = 2\nu e^{\nu N}[e^{\nu N} - 1 - \nu N] > 0$ for all $N > 0$. Hence $\mathcal{I}'(N) = k(N)/(e^{\nu N}-1)^2 > 0$ and $\mathcal{J}'(0) = \mathcal{I}'(1)N'(0) > 0$.

Next, since $dN/dr = 2(1+4r)^{-1/2} = 2/N$, $d^2N/dr^2 = -4/N^3$, we obtain that

$$\begin{aligned}\mathcal{J}''(r) &= \frac{\partial^2\mathcal{I}(N(r))}{\partial r^2} = \frac{\partial^2\mathcal{I}(N)}{\partial N^2}\left(\frac{\partial N(r)}{\partial r}\right)^2 + \frac{\partial\mathcal{I}(N)}{\partial N}\left(\frac{\partial^2 N(r)}{\partial r^2}\right)\\ &= \frac{4[-e^{3\nu N} + e^{2\nu N}(2\nu^2N^2 - 2\nu N + 1) + e^{\nu N}(2\nu^2N^2 + 2\nu N + 1) - 1]}{N^3(e^{\nu N}-1)^3}\\ &= \frac{\sum_{j=0}^{+\infty} p_j(\nu N)^j}{N^3(e^{\nu N}-1)^3} < 0, \quad \text{since } (\nu N) > 0,\ p_j = 0,\ j = 0,\dots,5, \text{ and}\end{aligned}$$

$$p_j = \frac{4}{(j-2)!}\left(\frac{-3^j + 2^j + 1}{j(j-1)} + \frac{-2^j+2}{j-1} + 2^{j-1} + 2\right) < 0,\ j \ge 6.$$

Thus $\mathcal{J}(r) \le \mathcal{J}(0) + \mathcal{J}'(0)r$ and (6.6) is proved. □

6.2. Properties of function *F*. To study the properties of functions $F : I \to \mathbb{R}$ and $\mathcal{F} : J = (a_*, +\infty) \to \mathbb{R}$, defined in subsection 4.2, it will be more convenient to use the integral representation (4.3) instead of the original definition of F. It should be noted that conditions $xF(x) < 0$, $(F(x) - r(x))x > 0$, $x \in I \setminus \{0\}$, define F in a unique way: moreover F and $\mathcal{F}$ are continuous and smooth at 0 with $\mathcal{F}'(0) = \alpha(a,\theta)$, $\mathcal{F}''(0) = 2\alpha(a,\theta)\beta(a,\theta)$. We have taken into consideration these facts to define the rational functions R and $\mathcal{R}$ (see subsection 4.2); however, since we do not use these characteristics of F anywhere, their proof is omitted here.

LEMMA 6.5. *Assume that* $r \in [a_*, 0]$. *Then*

$$\mathcal{F}(r) > \alpha\, r/(1-\beta r) = \mathcal{R}(r). \tag{6.7}$$

Proof. 1. First, suppose that $4r + 1 > 0$ and $r \ne 0$. Since $0 > \mathcal{F}(r) > r$, we have, for every $z \in [r, \mathcal{F}(r)]$ and $a < 0$,

$$r^{-1}(z) = z/(a-z) = (z/a)(1 + (z/a) + (z/a)^2 + \cdots) > (z/a) + (z/a)^2. \tag{6.8}$$

Hence

$$\theta = \int_r^{\mathcal{F}(r)} \frac{dz}{z(a-z)^{-1} - r} < \int_r^{\mathcal{F}(r)} \frac{dz}{\frac{z}{a} + (\frac{z}{a})^2 - r} = a \int_{r/a}^{\mathcal{F}(r)/a} \frac{du}{u + u^2 - r}. \tag{6.9}$$

Now, since for $r < 0$ the roots $\alpha_1 = (-1 - \sqrt{1+4r})/2$, $\alpha_2 = (-1 + \sqrt{1+4r})/2$ of the equation $u^2 + u - r = 0$ are negative, we obtain

$$a \int_{r/a}^{\mathcal{F}(r)/a} \frac{du}{u + u^2 - r} = -\frac{a}{\sqrt{1+4r}} \ln \left(\frac{\mathcal{F}(r) - a\alpha_1}{\mathcal{F}(r) - a\alpha_2} \, \frac{r - a\alpha_2}{r - a\alpha_1} \right) > \theta. \tag{6.10}$$

The last inequality implies that

$$\frac{\mathcal{F}(r) - a\alpha_1}{\mathcal{F}(r) - a\alpha_2} \, \frac{r - a\alpha_2}{r - a\alpha_1} > \exp\left(\frac{\theta\sqrt{1+4r}}{-a} \right) \stackrel{\text{def}}{=} \omega(r) \geq 1. \tag{6.11}$$

Taking into account that $\mathcal{F}(r) - a\alpha_2 < 0$ and $r - a\alpha_1 < 0$, and replacing α_1, α_2 in (6.11) by their values, we obtain

$$\mathcal{F}(r) > \frac{r(2a^2 - a + a\frac{\omega(r)+1}{\omega(r)-1}\sqrt{1+4r})}{2r + a + a\frac{\omega(r)+1}{\omega(r)-1}\sqrt{1+4r}}.$$

Next, since $\mathcal{J}(r) = \frac{\omega(r)+1}{\omega(r)-1}\sqrt{1+4r}$, we can apply Lemma 6.4 to see that

$$\begin{aligned} \mathcal{F}(r) &> \frac{r(2a - 1 + \mathcal{J}(r))}{2r/a + 1 + \mathcal{J}(r)} \geq \frac{r(2a - 1 + \mathcal{J}(0) + \mathcal{J}'(0)r)}{2r/a + 1 + \mathcal{J}(0) + \mathcal{J}'(0)r} \\ &= \frac{r(\lambda + a(1-\lambda)) + \frac{1}{2}\mathcal{J}'(0)(1-\lambda)r^2}{1 + (\frac{1-\lambda}{a} + \frac{1}{2}\mathcal{J}'(0)(1-\lambda))r} \stackrel{\text{def}}{=} \mathcal{L}(r). \end{aligned} \tag{6.12}$$

Now, $\mathcal{L}(r) = (a_1 r + a_2 r^2)/(1 + a_3 r)$, with $a_1 > 0, a_2 > 0$. Moreover, since $0 < \mathcal{J}(r) \leq \mathcal{J}(0) + \mathcal{J}'(0)r$, all denominators in (6.12) are positive so that $1 + a_3 r > 0$. Next,

$$a_1 a_3 - a_2 = (\lambda + a(1-\lambda))\left(\frac{1-\lambda}{a} + \frac{1}{2}\mathcal{J}'(0)(1-\lambda) \right) - \frac{1}{2}\mathcal{J}'(0)(1-\lambda) \leq 0. \tag{6.13}$$

Indeed, the last inequality is equivalent to the obvious relation

$$\frac{\lambda + a(1-\lambda)}{a} < 0 \leq \frac{1}{2}(1-\lambda)(1-a)\mathcal{J}'(0).$$

(Notice that $\alpha = \lambda + a(1-\lambda) > 0$, while, by Lemma 6.4, $\mathcal{J}'(0) > 0$.)

Finally, since the inequality $(a_1 r + a_2 r^2)(1 + a_3 r)^{-1} \geq a_1 r(1 + (a_3 - a_2/a_1)r)^{-1}$ holds for $r < 0,\ a_1 > 0,\ a_2 > 0,\ 1 + a_3 r > 0,\ a_1 a_3 \leq a_2$, we obtain

$$\mathcal{F}(r) > \frac{a_1 r}{1 + (a_3 - \frac{a_2}{a_1})r} = \frac{r(\lambda + a(1-\lambda))}{1 + (\frac{1-\lambda}{a} + \mathcal{J}'(0)\frac{1-\lambda}{2} - \frac{\mathcal{J}'(0)(1-\lambda)}{2(\lambda + a(1-\lambda))})r} = \mathcal{R}(r).$$

Hence the statement of the lemma is proved for $r \in (-1/4, 0)$. As an important consequence of the first part of the proof, we get the relation

$$\lim_{r \to -1/4} \frac{r(2a^2 - a + a\frac{\omega(r)+1}{\omega(r)-1}\sqrt{1+4r})}{2r + a + a\frac{\omega(r)+1}{\omega(r)-1}\sqrt{1+4r}} = \frac{a^2(1-\theta) + \theta a/2}{\theta(2a-1) - 4a^2} \geq \mathcal{R}(-1/4),$$

which will be used in the next stage of proof.

2. The case $r = -1/4$. From (6.9), evaluated at $r = -1/4$, we get $\theta < (-2a^2)/(2\mathcal{F}(-1/4) + a) + (4a^2)/(2a-1)$, so that

$$\mathcal{F}(-1/4) > \frac{a^2(1-\theta) + \theta a/2}{\theta(2a-1) - 4a^2} \geq \mathcal{R}(-1/4).$$

3. Assume now that $4r + 1 < 0$. We have

$$a\int_{r/a}^{\mathcal{F}(r)/a} \frac{du}{u + u^2 - r} = \frac{2a}{\sqrt{-4r-1}}\left(\arctan\frac{2\mathcal{F}(r)+a}{a\sqrt{-4r-1}} - \arctan\frac{2r+a}{a\sqrt{-4r-1}}\right). \tag{6.14}$$

By (6.9) and (6.14), we obtain

$$2\mathcal{F}(r) + a > a\sqrt{-4r-1}\,\frac{\frac{2r+a}{a\sqrt{-4r-1}} + \tan\frac{\theta\sqrt{-4r-1}}{2a}}{1 - \frac{2r+a}{a\sqrt{-4r-1}}\tan\frac{\theta\sqrt{-4r-1}}{2a}}.$$

Now, since $\tan x \leq x + x^3/3$ for $x \in (-\pi/2, 0)$ and $a < 0$, we obtain

$$\mathcal{F}(r) > r\frac{a^2(1-\theta) + \theta a/2 + \theta^3(-r-\frac{1}{4})(\frac{1}{2a}-1)(3)^{-1}}{a^2 - \theta(r+\frac{a}{2}) - \theta^3(-r-\frac{1}{4})(\frac{a}{2}+r)(3a^2)^{-1}} = G(r). \tag{6.15}$$

Therefore it will be sufficient to establish that $G(r) \geq \mathcal{R}(r)$ for $r < -1/4$. First, note that by the second part of the proof

$$G(-1/4) = \frac{a^2(1-\theta) + \theta a/2}{\theta(2a-1) - 4a^2} \geq \mathcal{R}(-1/4).$$

Let us consider now the function $H(r) = G(r) - \mathcal{R}(r)$ for $r \leq 0$. Since $G(r) = G_1(r)/G_2(r)$, where G_j are polynomials in r of second degree, $H(r)$ can be written as

$$H(r) = \frac{G_1(r)(1-\beta r) - \alpha r G_2(r)}{G_2(r)(1-\beta r)} = \frac{H_1(r)}{H_2(r)}, \tag{6.16}$$

so that H is a quotient of two polynomials of third degree with $H_2(r) > 0$ for $r \leq 0$. We get $\lim_{r\to-\infty} G(r) = a^2(1 - 1/(2a)) > 0$, and therefore $H(-\infty) = \lim_{r\to-\infty} H(r) > 0$. Furthermore, $H(0) = 0$ and

$$H'(0) = \frac{1 - \theta(1-\frac{1}{2a}) + \frac{\theta^3}{12a^2}(1-\frac{1}{2a})}{1 - \frac{\theta}{2a} + \frac{\theta^3}{24a^3}} - (a + e^{\frac{\theta}{a}}(1-a)) = \frac{\sum_{k=5}^{+\infty} p_k\theta^k}{1 - \frac{\theta}{2a} + \frac{\theta^3}{24a^3}} > 0,$$

since the denominator of the last fraction is positive and $p_{2m+1} > 0$, $p_{2m} < 0$, $p_{2m+1} + p_{2m+2} > 0$ for $m \geq 2$. Here we use the formula

$$p_k = \frac{a-1}{a^k k!}\left(1 - \frac{k}{2} + \frac{k(k-1)(k-2)}{24}\right),\ k \geq 5.$$

Finally, since $H(-1/4) = G(-1/4) - \mathcal{R}(-1/4) \geq 0$, there exists at least one zero of $H(r)$ in the interval $[-1/4, 0)$. $H_1(r)$ is a polynomial of third degree in r, and therefore it cannot have more than three zeros. Hence, since $H(-\infty) > 0$ and $H(-1/4) \geq 0$, we obtain that $H(r) \geq 0$ if $r < -1/4$. □

LEMMA 6.6. *If $(a, \theta) \in \mathcal{D}$, then $\mathcal{F}(r) < \mathcal{R}(r)$ for all $r \in (0, 1/\beta)$.*

Proof. By definition of $\mathcal{F}$, we have that $z > 0$ if $r > 0$ and $z \in [\mathcal{F}(r), r]$. We begin the proof by assuming that $r \in (0, a^2 - a)$. Since $z > 0, a < 0$, we find that $z(a-z)^{-1} < z/a + z^2/a^2$. Therefore, (6.9) holds under our present conditions. Now, since $r > 0$, the roots of equation $u^2 + u - r = 0$ are $\alpha_1 = (-1 - \sqrt{1+4r})/2 < 0$, $\alpha_2 = (-1+\sqrt{1+4r})/2 > 0$. Next, since $\mathcal{F}(r) - a\alpha_1 < r - a\alpha_1 < 0$ for all $r \in (0, a^2-a)$, we obtain that the relations (6.10), (6.11) hold in the new situation, and therefore

$$\mathcal{F}(r) < \frac{a^2\alpha_1\alpha_2(\omega(r)-1) + ar(\alpha_1 - \omega(r)\alpha_2)}{-a\alpha_2 + r + \omega(r)(a\alpha_1 - r)} = \frac{r(2a^2 - a + a\frac{\omega(r)+1}{\omega(r)-1}\sqrt{1+4r})}{2r + a + a\frac{\omega(r)+1}{\omega(r)-1}\sqrt{1+4r}},$$

where the denominator is positive for every $r \in (0, a^2 - a)$. Now, recall that $\mathcal{J}(r) = \frac{\omega(r)+1}{\omega(r)-1}\sqrt{1+4r}$; applying Lemma 6.4, we obtain $\mathcal{J}(r) \le \mathcal{J}(0) + \mathcal{J}'(0)r$. Next, since for all $r \in (0, a^2 - a)$ we have that $2r/a + 1 + \mathcal{J}(r) = -2(a(\omega(r)-1))^{-1}(-a\alpha_2 + r + \omega(r)(a\alpha_1 - r)) > 0$, and the function $p(x) = (r(2a-1+x))(2r/a+1+x)^{-1}$ is increasing in x, we get $\mathcal{F}(r) < \mathcal{L}(r)$ (compare with (6.12)). Now, $(a_1 r + a_2 r^2)(1 + a_3 r)^{-1} \le a_1 r(1 + (a_3 - a_2/a_1)r)^{-1}$ if $a_1 a_3 - a_2 \le 0,\ r > 0,\ a_1 > 0,\ a_2 > 0$. Therefore, by (6.13), $\mathcal{L}(r) \le \mathcal{R}(r)$.

Now we assume that $r \ge a^2 - a$. Taking into account that $z(a-z)^{-1} < 0$ for $z > 0$, we obtain the inequality

$$\theta = \int_r^{\mathcal{F}(r)} \frac{dz}{z(a-z)^{-1} - r} < \int_r^{\mathcal{F}(r)} \frac{dz}{-r} = \frac{\mathcal{F}(r) - r}{-r},$$

so that $\mathcal{F}(r) < r(1-\theta)$. Finally, the inequality $r(1-\theta) \le \mathcal{R}(r) = \alpha r/(1-\beta r)$ is equivalent to $r \ge (1-\theta-\alpha)/((1-\theta)\beta)$, which holds for all $r \ge a^2 - a$ due to the relation $a^2 - a \ge (1-\theta-\alpha)/((1-\theta)\beta)$, established in Lemma 6.1. □

6.3. Properties of function F_1 in the domain $\mathcal{D}^*$. Suppose now that $(a, \theta) \in \mathcal{D}^*$. We study some properties of function F_1 and the associated function $\mathcal{F}_1 : (a, 0) \to \mathbb{R}$ defined as $\mathcal{F}_1(r(z)) = F_1(z)$, which, by Lemma 4.6, satisfies

$$\frac{r_1(r)\theta}{r} = \int_{r_1(r)}^{\mathcal{F}_1(r)} \frac{dz}{r^{-1}(z) - r}, \quad \text{where } r_1(r) = \frac{ar(\theta-1)}{\theta + r(\theta-1)}.$$

LEMMA 6.7. *Assume that $(a, \theta) \in \mathcal{D}^*$ and that the inequalities $a < r \le a_* = a + \theta/(1-\theta)$ hold. Then $\mathcal{F}_1(r) > \mathcal{R}(r)$.*

Proof. Since $r_1(r) < \mathcal{F}_1(r) < 0$ and $a_* < -1$ for $(a, \theta) \in \mathcal{D}^*$, using (6.8) we get

$$\frac{r_1(r)\theta}{r} < \int_{r_1(r)}^{\mathcal{F}_1(r)} \frac{dz}{\frac{z}{a} + (\frac{z}{a})^2 - r} = a\int_{r_1(r)/a}^{\mathcal{F}_1(r)/a} \frac{du}{u + u^2 - r}.$$

The last integral can be transformed as in (6.14) to obtain

$$\frac{r_1(r)\theta}{r} < \frac{2a}{\sqrt{-4r-1}}\left(\arctan\frac{2\mathcal{F}_1(r)+a}{a\sqrt{-4r-1}} - \arctan\frac{2r_1+a}{a\sqrt{-4r-1}}\right).$$

Therefore

$$\varsigma_1 \stackrel{\text{def}}{=} \arctan\frac{2\mathcal{F}_1(r)+a}{a\sqrt{-4r-1}} < \arctan\frac{2r_1+a}{a\sqrt{-4r-1}} + \frac{\theta r_1\sqrt{-4r-1}}{2ar} \stackrel{\text{def}}{=} \varsigma_2 + \varsigma_3,$$

and since $\varsigma_1, \varsigma_2 \in (0, \pi/2), \varsigma_3 < 0$, we obtain

$$2\mathcal{F}_1(r) + a > a\sqrt{-4r-1}\,\frac{\frac{2r_1+a}{a\sqrt{-4r-1}} + \tan\frac{\theta r_1\sqrt{-4r-1}}{2ar}}{1 - \frac{2r_1+a}{a\sqrt{-4r-1}}\tan\frac{\theta r_1\sqrt{-4r-1}}{2ar}}.$$

Since $\tan x < x + x^3/3$ for $x \in (-\pi/2, 0)$, we have

$$\mathcal{F}_1(r) > \frac{A_1(P)r + A_2(P)r^2}{B_0(P) + B_1(P)r + B_2(P)r^2} = G_1(r, P, a, \theta), \tag{6.17}$$

where

$$A_1(P) = (1-\theta)P + \frac{\theta}{2a}P^2 + \frac{\theta^3}{24a^3}(2a-P)P^3, \quad A_2(P) = \frac{\theta^3}{6a^3}(2a-P)P^3,$$
$$B_0(P) = 1 - \frac{\theta P}{2a} + \frac{\theta^3P^3}{24a^3}, \quad B_1(P) = -\frac{\theta P^2}{a^2} + \frac{\theta^3P^3}{6a^3} + \frac{\theta^3P^4}{12a^4}, \quad B_2(P) = \frac{\theta^3P^4}{3a^4},$$
$$P = P(r, a, \theta) = r_1/r = \frac{a(\theta-1)}{\theta + r(\theta-1)}.$$

After substitution of the value of P into (6.17), we get

$$\mathcal{F}_1(r) > G_1(r, P(r, a, \theta), a, \theta) \stackrel{\text{def}}{=} \mathcal{G}_1(r, a, \theta) = \frac{rM(r, a, \theta)}{N(r, a, \theta)},$$

where

$$\begin{aligned} M(r, a, \theta) &= 24(A_1(P) + A_2(P)r)(\theta + r(\theta-1))^4 \\ &= -(\theta-1)^2 a[13\theta^3 - \theta^5 - 2\theta^2(\theta-1)(\theta+3)(3\theta-8)r \\ &\quad -4\theta(2\theta^2-15)(\theta-1)^2r^2 + 24(\theta-1)^3r^3], \\ N(r, a, \theta) &= 24(B_0(P) + B_1(P)r + B_2(P)r^2)(\theta + r(\theta-1))^4 = 35\theta^4 - 9\theta^5 \\ &\quad +\theta^7 - 3\theta^6 + \theta^3(\theta-1)(7\theta^3 - 17\theta^2 - 47\theta + 153)r + 12\theta^2(\theta^3 - 2\theta^2 \\ &\quad -6\theta + 19)(\theta-1)^2r^2 - 12\theta(3\theta-11)(\theta-1)^3r^3 + 24(\theta-1)^4r^4. \end{aligned}$$

To prove our lemma, it suffices to check the inequality $\mathcal{G}_1(r, a, \theta) \geq \mathcal{R}(r)$ for $r \in [a, a_*]$. First, considering $N(r, a, \theta) = N(r, \theta)$ as a polynomial in r of the form $N(r, a, \theta) = \sum_{k=0}^{4} N_k(\theta)r^k$, we can check that $(-1)^k N_k(\theta) > 0$ for $\theta \in (0, 1)$, and therefore, for all $\theta \in (0, 1)$ and $r < 0$,

$$N(r, a, \theta) = 24(B_0(P) + B_1(P)r + B_2(P)r^2)(\theta + r(\theta-1))^4 > 0. \tag{6.18}$$

Since $N(r, a, \theta) > 0$, $1 - \beta r > 0$ (recall that $\beta(a, \theta) > 0$ in the domain $\mathcal{D}$), the inequality $rM(r, a, \theta)/N(r, a, \theta) \geq \alpha r/(1 - r\beta)$ is equivalent to

$$Q(r, a, \theta) \stackrel{\text{def}}{=} (1 - r\beta(a, \theta))M(r, a, \theta) - \alpha(a, \theta)N(r, a, \theta) \leq 0. \tag{6.19}$$

Now, an easy comparison of $\mathcal{G}_1(a_*, a, \theta) = G_1(a_*, 1, a, \theta)$ with $G(a_*)$ given in (6.15) shows that the inequality (6.19) is fulfilled for $r = a_*$. In the next two lemmas, we will prove that $\partial Q(r, a, \theta)/\partial r > 0$ for all $r \in [a, a_*]$. Therefore, since $Q(a_*, a, \theta) \leq 0$, we obtain $Q(r, a, \theta) \leq 0$ for $r \in [a, a_*]$, which proves that $\mathcal{F}_1(r) > \mathcal{R}(r)$. □

LEMMA 6.8. *$S(r,a,\theta)=\frac{\partial}{\partial r}Q(r,a,\theta)>0$ at the point $r=a_*$.*

Proof. Recall that we are interested in the case $r=a_*$ (when $P=1$). By (6.19) and the above definitions of $M(r,a,\theta), N(r,a,\theta)$,

$$Q(r,a,\theta)=24(\theta+r(\theta-1))^4((A_1(P)+A_2(P)r)(1-\beta r)-\alpha(B_0(P)+B_1(P)r+B_2(P)r^2)).$$

Next, setting $P'=\partial P(r,a,\theta)/\partial r\mid_{r=a_*}=-a^{-1}$, $A_j'=\partial A_j(a,\theta,P)/\partial P|_{P=1}$, $B_j'=\partial B_j(a,\theta,P)/\partial P|_{P=1}$, $A_j=A_j(a,\theta,1), B_j=B_j(a,\theta,1)$, we obtain that

$$\partial Q(r,a,\theta)/\partial r|_{r=a_*}=24(Q_1(r,a,\theta)+Q_2(r,a,\theta)), \tag{6.20}$$

where

$$\begin{aligned}Q_1&=4a^3(\theta-1)^4((A_1+A_2a_*)(1-\beta a_*)-\alpha(B_0+B_1a_*+B_2a_*^2))\\&\quad+a^4(\theta-1)^4((A_1'+A_2'a_*)(1-\beta a_*)-\alpha(B_0'+B_1'a_*+B_2'a_*^2))P';\\Q_2&=a^4(\theta-1)^4(A_2-\beta A_1-\alpha B_1-2a_*\beta A_2-2a_*\alpha B_2).\end{aligned}$$

Now, for the convenience of the reader, the following part of the proof will be divided into several steps.

Step (i): $Q_2(r,a,\theta)>0$. Indeed, consider the second degree polynomial

$$\chi_1(r)\stackrel{\text{def}}{=}(A_1+A_2r)(1-\beta r)-\alpha(B_0+B_1r+B_2r^2).$$

Notice that $\chi_1(r)=\frac{H_1(r)}{r}$, where H_1 is defined in (6.16). This implies that the unique critical point of χ_1 belongs to $(-1/4,+\infty)$ and that $\chi_1(+\infty)=-\infty$. Hence $\chi_1'(r)>0$ for all $r<-1/4$ so that $Q_2(\theta,a,r)=a^4(\theta-1)^4\chi_1'(r)>0$.

Step (ii). The following inequality holds:

$$(A_1'+A_2'a_*)(B_0+B_1a_*+B_2a_*^2)-(A_1+A_2a_*)(B_0'+B_1'a_*+B_2'a_*^2)>0. \tag{6.21}$$

Indeed, the left-hand side of (6.21) can be transformed into

$$\begin{aligned}&\frac{1}{576a^6(1-\theta)^3}(-\theta^6(3\theta+1)^3+12\theta^6(3\theta+1)^2(\theta-1)a\\&-24\theta^4(\theta-1)(3\theta+1)(2\theta^3-2\theta^2+3\theta-5)a^2+32\theta^3(2\theta^4-2\theta^3+18\theta^2\\&-39\theta-9)(\theta-1)^2a^3-48\theta^2(8\theta^3-41\theta^2+30\theta-9)(\theta-1)^2a^4\\&-576\theta(\theta^2-\theta+2)(\theta-1)^3a^5+576(\theta-1)^4a^6).\end{aligned} \tag{6.22}$$

Taking into account that $\eta\stackrel{\text{def}}{=}(\theta-1)a>1$, the sum of the first two terms in (6.22) is positive:

$$-\theta^6(3\theta+1)^3+12\theta^6(3\theta+1)^2(\theta-1)a=\theta^6(3\theta+1)^2(-(3\theta+1)+12(\theta-1)a)>0.$$

The other terms in (6.22) can be written as

$$\begin{aligned}&a^2(-24\theta^4(\theta-1)(3\theta+1)(2\theta^3-2\theta^2+3\theta-5)\\&+32\theta^3(2\theta^4-2\theta^3+18\theta^2-39\theta-9)(\theta-1)\eta\\&-48\theta^2(8\theta^3-41\theta^2+30\theta-9)\eta^2-576\theta(\theta^2-\theta+2)\eta^3+576\eta^4)\stackrel{\text{def}}{=}a^2\Upsilon(\theta,\eta).\end{aligned}$$

By the Taylor formula,

$$\Upsilon(\theta,\eta)=\Upsilon(\theta,1)+(\eta-1)\partial\Upsilon(\theta,1)/\partial\eta+0.5(\eta-1)^2\partial^2\Upsilon(\theta,\eta_1)/\partial\eta^2, \tag{6.23}$$

where $\eta_1 \in [1,2]$. It is easy to verify that

$$\begin{aligned}\Upsilon(\theta,1) &= -8(\theta-1)^2[\theta^4(18\theta^3-2\theta^2+27\theta-81)+(108\theta^3-54\theta^2-72)] > 0,\\ \partial\Upsilon(\theta,1)/\partial\eta &= 32(\theta-1)[(2\theta^6+18\theta^4+36)(\theta-1)-45\theta^2(\theta-1)^2-36] > 0,\\ \partial^2\Upsilon(\theta,\eta)/\partial\eta^2 &= 3456\eta(2\eta-\theta(\theta^2-\theta+2))-96\theta^2(8\theta^3-41\theta^2+30\theta-9) > 0.\end{aligned}$$

(Here we use the inequality $8\theta^3-41\theta^2+30\theta-9<0,\ \theta\in[0,1]$.)

Finally, by (6.23), $\Upsilon(\theta,\eta)>0$ for $\theta\in(0,1), \eta\in(1,2)$.

Step (iii). We have

$$\varrho \stackrel{\text{def}}{=} (B_0'+B_1'a_*+B_2'a_*^2)(B_0+B_1a_*+B_2a_*^2)^{-1} < 1. \tag{6.24}$$

Indeed, taking into account (6.18), the latter inequality is equivalent to

$$(\upsilon \stackrel{\text{def}}{=}) \qquad \frac{\theta^3}{12a^3}+a_*\left(-\frac{\theta}{a^2}+\frac{\theta^3}{3a^3}+\frac{\theta^3}{4a^4}\right)+\frac{\theta^3}{a^4}a_*^2<1.$$

Now, we know that $|a_*|\le|a|$ and $|a^{-1}|<1-\theta$ (so that $\theta/|a|<1/4$). Therefore $\upsilon<1/4+(1/3)(1/16)+1/16<1$.

Step (iv): $Q_1(r,a,\theta)>0$. First, using (6.18) and (6.21), we obtain that

$$\begin{aligned}&(A_1'+A_2'a_*)(1-\beta a_*)-\alpha(B_0'+B_1'a_*+B_2'a_*^2)\\ &\ge \varrho((A_1+A_2a_*)(1-\beta a_*)-\alpha(B_0+B_1a_*+B_2a_*^2)).\end{aligned}$$

Next, using inequality (6.19), which was proved at $r=a_*$, we find that

$$(A_1+A_2a_*)(1-\beta a_*)-\alpha(B_0+B_1a_*+B_2a_*^2)=\frac{Q(a_*,a,\theta)}{24(\theta+a_*(\theta-1))^4}<0.$$

Therefore,

$$Q_1(r,a,\theta)\ge a^3(\theta-1)^4((A_1+A_2a_*)(1-\beta a_*)-\alpha(B_0+B_1a_*+B_2a_*^2))(4-\varrho)>0.$$

Step (v). Recalling (6.20) and Steps (i) and (iv), we finish the proof of the lemma. □

LEMMA 6.9. *$S(r,a,\theta)>0$ for $r\in[a,a_*]$.*

Proof. Differentiating function Q given by (6.19), we obtain

$$\begin{aligned}S(r,a,\theta)=\sum_{i=0}^{3}S_i(\theta,a)r^i &= 96(\theta-1)^4(\beta a(\theta-1)-\alpha)r^3\\ &+(-12(\theta-1)^4a\theta(2\theta^2-15)\beta+36\theta(\theta-1)^3(3\theta-11)\alpha-72(\theta-1)^5a)r^2\\ &+(-4a\theta^2(\theta-1)^3(\theta+3)(3\theta-8)\beta-24\theta^2(\theta-1)^2(\theta^3-2\theta^2-6\theta+19)\alpha\\ &+8a\theta(\theta-1)^4(2\theta^2-15))r\\ &+a(\theta-1)^2\theta^3(13-\theta^2)\beta-\theta^3(\theta-1)(7\theta^3-17\theta^2-47\theta+153)\alpha\\ &+2a\theta^2(\theta-1)^3(\theta+3)(3\theta-8).\end{aligned}$$

Now, inequalities $S_i(a,\theta)r^i<0,\ i=3,2,1,0$, are equivalent to $a\theta(\theta-1)\beta>T_i(a,\theta)$, where

$$T_3(a,\theta)=\theta\alpha,\quad T_2(a,\theta)=\frac{-6a(\theta-1)^2+3\theta(3\theta-11)\alpha}{2\theta^2-15},$$

$$T_1(a,\theta) = \frac{2a(\theta-1)^2(2\theta^2-15) - 6\theta(\theta^3-2\theta^2-6\theta+19)\alpha}{3\theta^2+\theta-24},$$

$$T_0(a,\theta) = \frac{2a(\theta-1)^2(3\theta^2+\theta-24) - \theta(7\theta^3-17\theta^2-47\theta+153)\alpha}{\theta^2-13}.$$

Next, for $(a,\theta) \in \mathcal{D}^*$, the following inequalities hold:

$$T_3(a,\theta) > T_2(a,\theta), \tag{6.25}$$

$$T_2(a,\theta) > T_1(a,\theta), \tag{6.26}$$

$$T_1(a,\theta) > T_0(a,\theta). \tag{6.27}$$

Indeed, taking into account that $\alpha = (1-a)\exp(\theta/a)+a$, inequality (6.26) is equivalent to

$$\begin{aligned} &4\theta^6 - 8\theta^5 - 41\theta^4 + 108\theta^3 + 99\theta^2 - 312\theta - 306 \\ &+ 3\theta(4\theta^5 - 8\theta^4 - 45\theta^3 + 106\theta^2 + 97\theta - 306)e^{\theta/a}(1-a)a^{-1} < 0. \end{aligned} \tag{6.28}$$

Since $3\theta(4\theta^5-8\theta^4-45\theta^3+106\theta^2+97\theta-306) < 0$, it is sufficient to prove (6.28) for the maximum value in a of the function $\frac{1-a}{-a}e^{\frac{\theta}{a}}$. The derivative of this function is equal to $-e^{\theta/a}(a\theta-a-\theta)/a^3$, and it is positive if $a < \theta/(\theta-1)$. Hence, it is sufficient to verify (6.28) at $a = \pi_1(\theta) = -1/\Pi_1^{-1}(\theta) = (1+\sqrt{1+4\theta(1-\theta)})/(2(\theta-1))$ if $\theta \in (0, 0.8]$, and at $a = \pi_3(\theta) = -1/\Pi_3^{-1}(\theta) = (133+25(\theta-1))/(95(\theta-1))$ if $\theta \in [0.8, 1)$.

Using (6.1) and replacing the value $a = \pi_3(\theta)$ in (6.28), we get the following expression:

$$\begin{aligned} \frac{q^2}{2(133+25q)^3}[&-40522972 + 220135634q - 410248779q^2 + 204446752q^3 + 279016108q^4 \\ &+ 23396520q^5 - 209505145q^6 - 30804850q^7 + 35072100q^8 + 7581000q^9], \end{aligned}$$

which is negative for $\theta = q+1 \in [0.8, 1)$. Direct computations show that (6.28) holds if $a = \pi_1(\theta)$ and $\theta \in [0, 0.8]$.

Analogously, inequality (6.25) is equivalent to

$$-(6 - 3\theta^2 + 6\theta + 2\theta^3) - \theta(18 - 9\theta + 2\theta^2)e^{\theta/a}(1-a)a^{-1} < 0. \tag{6.29}$$

Using (6.1) and substituting the value $a = \pi_3(\theta)$ in (6.29), we get the expression

$$\begin{aligned} \frac{q^2}{2(133+25q)^3}[&-4465209 - 971090q - 12743680q^2 \\ &- 5731130q^3 - 2242475q^4 + 1103900q^5 - 1263500q^6], \end{aligned}$$

which is negative for $\theta = q+1 \in [0.8, 1)$. Direct computations show again that (6.29) is satisfied for $a = \pi_1(\theta)$ and $\theta \in [0, 0.8]$.

Finally, (6.27) is equal to

$$\begin{aligned} &(\theta^6 - 16\theta^5 + 2\theta^4 + 226\theta^3 + 63\theta^2 - 570\theta - 762) \\ &+ \theta(15\theta^5 - 32\theta^4 - 212\theta^3 + 550\theta^2 + 813\theta - 2190)e^{\theta/a}(1-a)a^{-1} < 0. \end{aligned} \tag{6.30}$$

Next, employing (6.1) and using the value $a = \pi_3(\theta)$ in (6.30), we get the expression

$$\frac{q^2}{2(133+25q)^3}[-14595952 + 471367808q - 1571124744q^2 - 18258802q^3 + 723267159q^4 + 399356020q^5 - 311046000q^6 - 73063100q^7 + 42576625q^8 + 9476250q^9],$$

which is negative for $\theta = q + 1 \in [0.8, 1)$. Direct computations also show in this case that (6.30) holds if $a = \pi_1(\theta)$ and $\theta \in [0, 0.8]$.

To finish the proof of this lemma, we take an arbitrary $r \in [a, a_*]$ (so that $r = a_* k, k \geq 1$) and write function $S(r, a, \theta)$ in the form

$$S(r, a, \theta) = \sum_{i=0}^{3} S_i(a, \theta) a_*^i k^i = k^3 \left(S_3 a_*^3 + \frac{1}{k} S_2 a_*^2 + \frac{1}{k^2} S_1 a_* + \frac{1}{k^3} S_0 \right).$$

First, note that $S_3 a_*^3 > 0$. Indeed, if $S_3 a_*^3 \leq 0$, then, in view of (6.25)–(6.27), $S_i a_*^i \leq 0$ for $i = 0, 1, 2$, and therefore $S(a_*, a, \theta) \leq 0$, contradicting Lemma 6.8. Next, the conclusion of Lemma 6.9 is obvious if $S_i a_*^i \geq 0$ for all $i = 0, 1, 2$. Finally, if $S_i a_*^i \leq 0$ and $S_{i+1} a_*^{i+1} > 0$ for some i, then using the above representation for $S(r, a, \theta)$ and relations (6.26)–(6.27), it is easy to see that $S(r, a, \theta) \geq S(a_*, a, \theta) > 0$ for $r \in [a, a_*]$. □

6.4. Properties of function F_1 in the domain $\mathcal{S}$.

LEMMA 6.10. *If $r \in (a, 0)$ and $h \leq 1$, then*

$$\mathcal{F}_1(r) > \frac{1 - h - e^{-h}}{2 - h - e^{-h}} \frac{ar}{1 + r\frac{1-h-e^{-h}}{1-e^{-h}}} = \mathcal{R}_2(r). \tag{6.31}$$

Proof. Take $z > 0$ and consider the point $t_* \in (0, h)$ defined in (4.6); by Lemma 4.6, $F_1(z) > a$. Since $r(r(z)(1 - e^{-(s-h)})) < 0$ for all $s \in (0, h)$, it follows from (4.6) that

$$\begin{aligned} \mathcal{F}_1(r(z)) = F_1(z) &> e^{-(t^*-h)} \int_0^h e^{s-h} r(r(z)(1 - e^{-(s-h)}))ds \\ &= \frac{r(z) - r^{-1}(F_1(z))}{r(z)} \int_{-h}^0 e^u r(r(z)(1 - e^{-u}))du \\ &= \phi(r(z)) - r^{-1}(F_1(z))\psi(r(z)), \end{aligned} \tag{6.32}$$

where

$$\psi(x) = \phi(x)/x, \ \phi(x) = \int_{-h}^0 e^u r(x(1 - e^{-u}))du.$$

Applying Jensen's inequality [12, p. 110] to the last integral, we obtain that

$$\begin{aligned} \phi(x) &= \int_{-h}^0 (1 - e^{-h}) r(x(1 - e^{-u})) d\left(e^u/(1 - e^{-h})\right) \\ &\geq (1 - e^{-h}) r\left(\frac{\int_{-h}^0 x(e^u - 1)du}{1 - e^{-h}} \right) = \frac{ax(1 - h - e^{-h})}{1 + x\frac{1-h-e^{-h}}{1-e^{-h}}} \stackrel{\text{def}}{=} x\mathcal{H}(x). \end{aligned} \tag{6.33}$$

Denote $\psi = \psi(r)$, $\phi = \phi(r)$, $\mathcal{F}_1 = \mathcal{F}_1(r)$. Now, for $r < 0$, (6.32) implies that $\mathcal{F}_1 > \phi - (\mathcal{F}_1\psi)/(a - \mathcal{F}_1)$. Since $a - \mathcal{F}_1 < 0$, we conclude that

$$\mathcal{F}_1^2 - \mathcal{F}_1(\phi + \psi + a) + a\phi > 0. \tag{6.34}$$

Next we prove that, under our assumptions,

$$(\psi+\phi+a)^2-4a\phi>(\psi+\phi-a-2\psi_0)^2\geq 0, \tag{6.35}$$

where $\psi_0=a(1-h-e^{-h})$. Indeed, (6.35) amounts to

$$\psi(\psi_0 r+a+\psi_0)>\psi_0(a+\psi_0).$$

Since $\psi_0 r+a+\psi_0<0$, the latter inequality is equivalent to

$$\psi<\frac{\psi_0(a+\psi_0)}{\psi_0 r+a+\psi_0}=\frac{a(1-h-e^{-h})}{1+r\frac{1-h-e^{-h}}{2-h-e^{-h}}}\stackrel{\text{def}}{=}\mathcal{G}(r),$$

which holds because for $a<0, r<0, h\leq 1$ we have $\mathcal{H}(r)<\mathcal{G}(r)$, and because, by (6.33), $\psi(r)\leq\mathcal{H}(r)$. Now, the inequalities $a\phi(r(z))>0$, (6.35) and the continuous dependence of $\phi(r),\psi(r),\mathcal{F}_1(r)$ on $r\in(a,0)$ imply that the quadratic polynomial $y(x)=x^2-x(\phi+\psi+a)+a\phi$ has two roots $x_1=x_1(r)<x_2=x_2(r)$ with the same sign and that this sign is the same for all $r\in(a,0)$. Similarly, by (6.34), we have that either $\mathcal{F}_1(r)<x_1(r)$ or $\mathcal{F}_1(r)>x_2(r)$ for all $r\in(a,0)$. Since $\mathcal{F}_1(0^-)=0>x_1(0^-)=\psi_0+a$, we conclude that $x_1(r),x_2(r)$ are negative for all $r\in(a,0)$, and $\mathcal{F}_1(r)>x_2(r)$. In other words,

$$\begin{aligned}\mathcal{F}_1&>\frac{1}{2}(\psi+\phi+a+\sqrt{(\psi+\phi+a)^2-4a\phi})\\&=\frac{2a\phi}{\psi+\phi+a-\sqrt{(\psi+\phi+a)^2-4a\phi}}\geq\frac{2a\phi}{2(a+\psi_0)},\end{aligned}\tag{6.36}$$

where the last inequality is due to the following consequence of (6.35):

$$\sqrt{(\psi+\phi+a)^2-4a\phi}\geq -a+\phi+\psi-2\psi_0.$$

Finally, combining (6.33) and (6.36), we obtain (6.31). □

LEMMA 6.11. *Assume that* $(a,\theta)\in\mathcal{S}$. *Then* $r(\mathcal{R}_2(a))<\beta^{-1}$.

Proof. Step (i). In the new variables $q=\theta-1, k=a(\theta-1)$, the expression for $\mathcal{R}_2(a)$ takes the form

$$\mathcal{R}_2(a)=\frac{-q+\ln(q+1)}{1-q+\ln(q+1)}\frac{k^2}{q^2-k(-q+\ln(q+1))}.$$

Next we prove that

$$\mathcal{R}_2(a)\geq\frac{6k^2(q-1)}{3kq^2-4kq+12+6k}\stackrel{\text{def}}{=}\bar{R}_2(q,k) \tag{6.37}$$

for all $q\in[-0.2,0), k\in[1,1.5]$. (Note that for $(a,\theta)\in\mathcal{D}$, the inequalities $1\leq a(\theta-1)\leq 1.5$ hold.) Indeed, we have

$$\mathcal{R}_2(a)-\bar{R}_2=\frac{-k^2C(q,k)}{(1-q+L)(-q^2-kq+kL)(3kq^2-4kq+12+6k)},$$

where $L=\ln(1+q)$, and

$$\begin{aligned}C(q,k)=&\,q(6q^3-12q^2+3kq^2+6q-8kq-12)\\&+(14kq+12-9kq^2+6q^2-6q^3)L+6k(q-1)L^2.\end{aligned}$$

Next, the following inequalities hold in an obvious way for $q \in [-0.2, 0)$ and $k \in [1, 1.5]$:

$$1 - q + \ln(1+q) \geq 1 - q + q/(1+q) > 0,$$
$$3kq^2 - 4kq + 12 + 6k > 0,$$
$$-q^2 - kq + k\ln(1+q) < -q^2 < 0.$$

Thus $C(q,k) > 0$ will imply that $\mathcal{R}_2(a) > \bar{R}_2$. Now, in view of (6.5) and the obvious inequalities $\min_{\{q\in[-0.2,0),k\in[1,1.5]\}}(14kq + 12 - 9kq^2 + 6q^2 - 6q^3) \geq 7.26 > 0$ and $6k(q-1) < 0$, we obtain that $C(q,k) > (q^3/50)(-168kq^3 + 48kq^4 - 120q^3 + 255kq^2 + 270q^2 - 150q - 110kq - 50k - 60) \geq -0.356176q^3 > 0$.

Step (ii). Using the new variables, we obtain the following expression for α:

$$\alpha(a,\theta) = \alpha(k/q, 1+q) = (1 - k/q)\exp(q(q+1)/k) + k/q.$$

We will prove that $\alpha > -q(24k^2 - 12k - 7q)/(24k^2) \stackrel{\text{def}}{=} \bar{\alpha} > 0$. Indeed, since $\exp(x) > 1 + x + x^2/2 + x^3/6$ for all $x = q(1+q)/k < 0$, we get

$$\alpha(q,k) - \bar{\alpha} > q^2(24k)^{-3}[4q^4 + (12-4k)q^3 + 12q^2 + (-12k^2 + 12k + 4)q + k],$$

where the right-hand side is positive for all $q \in [-0.2, 0), k \in [1, 1.5]$.

Step (iii). Set $E = \exp(\frac{q(q+1)}{k})$. Here we prove that

$$\alpha\beta = -k/q - (q/k)(-2q + 2k - 1)E + (k-q)^2(kq)^{-1}E^2$$
$$< \bar{\beta}_0 \stackrel{\text{def}}{=} q^2(q+1)[2k^2 - q(k + 2k^2) + q^2(9 - 11k + 2k^2)](6k^4)^{-1}.$$

Indeed, due to (6.1) and since $\frac{-q}{k}(-2q + 2k - 1) > 0$, $\frac{(k-q)^2}{kq} < 0$, we obtain

$$\bar{\beta}_0 - \alpha\beta > (1/6)(q/k)^4(q+1)(-8q^2 + 10kq - 16q + 1) > 0$$

if $q \in [-0.2, 0)$, $k \in [1, 1.5]$.

Step (iv). First, note that $\bar{R}_2(q,k) > -1$ for all $q \in [-0.2, 0), k \in [1, 1.5]$ so that $r(\bar{R}_2(q,k))$ and $r(\mathcal{R}_2(a))$ are well defined. Moreover, since r is strictly decreasing over $(-1, 0)$, by virtue of (6.37) we get

$$0 < r(\mathcal{R}_2(a)) < r(\bar{R}_2) = \frac{6k^3(q-1)}{q[3kq^2 + q(6k^2 - 4k) - 6k^2 + 6k + 12]}. \tag{6.38}$$

Step (v). The above steps imply that

$$r(\mathcal{R}_2(a))\beta = r(\mathcal{R}_2(a))\alpha\beta/\alpha < r(\bar{R}_2)\bar{\beta}_0/\bar{\alpha}.$$

Hence, Lemma 6.8 will be proved if we show that $r(\bar{R}_2)\bar{\beta}_0/\bar{\alpha} - 1 < 0$. We have

$$r(\bar{R}_2)\frac{\bar{\beta}_0}{\bar{\alpha}} - 1 = \frac{\sum_{i=0}^4 Z_i q^i}{(3kq^2 - 4qk + 12 + 6k - 6k^2 + 6qk^2)(-12k - 7q + 24k^2)}, \tag{6.39}$$

where $Z_0 = 24k(6k^3 - 7k^2 - 9k + 6)$, $Z_1 = -144k^4 + 120k^3 - 114k^2 + 42k + 84$, $Z_2 = -2k(36k^2 + 93k - 94)$, $Z_3 = 3k(16k^2 + 8k + 7)$, $Z_4 = -24k(k-1)(2k-9)$.

Now, in view of (6.38), we have that the denominator of the right-hand side of (6.39) is positive for all $q \in [-0.2, 0), k \in [1, 1.5]$. Therefore it suffices to prove that $\sum_{i=0}^4 Z_i q^i < 0$; we finish the proof by observing that, for $q \in [-0.2, 0)$, $k \in [1, 1.5]$,

$$Z_0 + Z_1 q \leq Z_0 - 0.2Z_1 = 0.3(2k-3)(288k^3 + 112k^2 - 154k - 5) - 21.3 < 0,$$
$$Z_2 q^2 = -2kq^2(36k^2 + 93k - 94) < 0,$$
$$Z_3 + Z_4 q \geq Z_3 - 0.2Z_4 = 57.6k^3 - 28.8k^2 + 64.2k > 0. \qquad \square$$

Acknowledgment. The authors are greatly indebted to an anonymous referee for his/her valuable suggestions, which helped them to improve the exposition of the results.

ON THE OVERSAMPLING OF AFFINE WAVELET FRAMES*

BRODY DYLAN JOHNSON†

Abstract. The properties of oversampled affine frames are considered here with two main goals in mind. The first goal is to generalize the approach of Chui and Shi [*Proc. Amer. Math. Soc.*, 121 (1994), pp. 511–517], [*SIAM J. Math. Anal.*, 28 (1997), pp. 213–232] to the matrix oversampling setting for expanding, lattice-preserving dilations, whereby we obtain a new proof of the second oversampling theorem for affine frames. The second oversampling theorem, proven originally by Ron and Shen [*J. Funct. Anal.*, 148 (1997), pp. 408–447] via Gramian analysis, states that oversampling an affine frame with dilation M by a matrix P will result in a frame with the same bounds (after renormalization), provided that P and M satisfy a certain relative primality condition. In this case, the matrix P is said to be admissible for M. The second goal of this work is to examine the compatibility of admissible oversampling with the refinable affine frames arising from a certain class of scaling functions. In this setting we show that oversampling dual affine systems by an admissible P preserves the multiresolution structure and, from this fact, that the oversampled systems remain dual. We then show that the admissibility of P is also sufficient to endow the dual oversampled systems with a discrete wavelet transform. The novelty of this work lies both in our approach to the second oversampling theorem as well as our consideration of oversampling in the context of multiresolution analysis.

Key words. affine system, oversampling, wavelet, multiresolution analysis

1. Introduction.

Unless otherwise stated, M will denote a fixed $n \times n$ dilation matrix with integer entries such that each eigenvalue λ of M satisfies $|\lambda| > 1$. We will refer to $M \in GL_n(\mathbb{R})$ as *expanding* if its eigenvalues satisfy this latter condition. Thus M is a $\mathbb{Z}^n$-lattice preserving, expanding dilation. The unitary dilation operator on $L^2(\mathbb{R}^n)$ induced by M will be denoted D and is defined by $Df(x) := |\det M|^{\frac{1}{2}} f(Mx)$ for $f \in L^2(\mathbb{R}^n)$. For $u \in \mathbb{R}^n$, let T_u denote the usual translation operator, i.e., $T_u f(x) := f(x-u)$. With these basic ingredients we may now recall the definition of an affine system.

DEFINITION 1.1. *Let $\Psi = \{\psi_1, \dots, \psi_L\} \subset L^2(\mathbb{R}^n)$. The affine system generated by Ψ, denoted $X(\Psi)$, is the collection*

$$X(\Psi) = \{\psi_{\ell;j,k} : 1 \le \ell \le L, j \in \mathbb{Z}, k \in \mathbb{Z}^n\},$$

where $\psi_{\ell;j,k} := D^j T_k \psi_\ell$.

Our interest lies in those affine systems that constitute frames for $L^2(\mathbb{R}^n)$.

DEFINITION 1.2. *Let $\mathbb{H}$ be a Hilbert space. The collection $\{h_j\}_{j\in J} \subset \mathbb{H}$ is a frame for $\mathbb{H}$ if there exist constants $A, B > 0$ such that for all $f \in \mathbb{H}$*

$$A\|f\|_{\mathbb{H}}^2 \le \sum_{j\in J} |\langle f, h_j\rangle_{\mathbb{H}}|^2 \le B\|f\|_{\mathbb{H}}^2. \tag{1.1}$$

The constants A and B are referred to as the lower and upper frame bounds, respectively. In the case that $A = B$ the frame is said to be *tight*. If only the right

inequality holds, the system is called a *Bessel system*, and in this case B is referred to as the Bessel bound. We say two frames for $\mathbb{H}$, $\{h_j\}_{j\in J}$ and $\{\tilde{h}_j\}_{j\in J}$, are *dual frames* if for each $f \in \mathbb{H}$ we have

$$f = \sum_{j\in J} \langle f, \tilde{h}_j \rangle h_j. \tag{1.2}$$

Let $GL_n(\mathbb{Z})$ denote the set of all $n \times n$ matrices with integer entries having nonzero determinant. Given $P \in GL_n(\mathbb{Z})$, we now define the oversampled affine system generated by a family Ψ relative to P.

DEFINITION 1.3. *Let $\Psi = \{\psi_1, \ldots, \psi_L\} \subset L^2(\mathbb{R}^n)$. The oversampled affine system generated by Ψ relative to $P \in GL_n(\mathbb{Z})$, denoted $X^P(\Psi)$, is the collection*

$$X^P(\Psi) := \{\psi^P_{\ell;j,k} : 1 \le \ell \le L, j \in \mathbb{Z}, k \in \mathbb{Z}^n\},$$

where $\psi^P_{\ell;j,k} := \frac{1}{\sqrt{p}} D^j T_{P^{-1}k} \psi_\ell$ and $p := |\det P|$.

The factor $\frac{1}{\sqrt{p}}$ in Definition 1.3 compensates for the increase in the density of the lattice of translations caused by the oversampling. This allows us to compare the frame bounds of the oversampled and nonoversampled systems.

This notion of oversampling was introduced by Chui and Shi in [2] when they proved that oversampling a dyadic affine frame ($M = 2$) in one dimension by p odd preserves the frame bounds. In [3], Chui and Shi later extended this result to the multivariate case in which the dilation $M \in GL_n(\mathbb{Z})$ is expanding and $P = pI$ with $\gcd(p, |\det M|) = 1$. The result is referred to there as the second oversampling theorem. Since the one-dimensional result appeared, several other researchers have investigated the problem of bound-preserving oversampling for affine frames. In the case that $M, P \in GL_n(\mathbb{Z})$ with M expanding, Ron and Shen have used their Gramian analysis to show that a relative primality condition on the lattices $M^T\mathbb{Z}^n$ and $P^T\mathbb{Z}^n$ is sufficient for bound-preserving oversampling [7]. More recently, the work of Laugesen [6] provides another approach to the second oversampling theorem, which employs the concept of almost periodicity. In [6] it is observed that the conditions on M and P for bound-preserving oversampling described in [7] and [6] are equivalent. We should also mention that Chui, Czaja, Maggioni, and Weiss have developed a notion of tightness-preserving oversampling based on the characterization of affine tight-frames [1]. In their work the dilation matrix M is not required to have integer entries; however, the result applies only to tight-frames.

During the revision of this paper the author became aware of an interesting work by Hernández et al. [4] in which the various embodiments of oversampling are unified into a single theory, including quasi-affine systems as well as oversampled affine systems.

The techniques used by Ron and Shen in [7] and Laugesen in [6] are quite different from those used originally by Chui and Shi in [2]. In each case a notion of relative primality between the dilation matrix and the oversampling matrix has proven essential in the proof of the second oversampling theorem. One of the goals of our work is to extend the original ideas of Chui and Shi to the matrix oversampling case with a careful development of the relative primality conditions. These conditions are introduced in section 2, where we define a notion of admissible oversampling and develop related elementary results. In section 3 we present our version of the second oversampling theorem.

The second goal of this work is to explore the compatibility of admissible oversampling with multiresolution analysis. In section 4 we restrict our attention to dual

refinable affine systems associated with a certain class of scaling functions. We introduce multiresolution operators for the oversampled systems and show that they behave much like those associated with the original affine systems. This allows us to prove that the duality of refinable affine frames is preserved under admissible oversampling. Finally, we show that admissible oversampling endows the dual oversampled systems with a discrete wavelet transform (DWT).

To close the section let us note that we will adopt the following definition for the Fourier transform, $\hat{f}$, of $f \in L^2(\mathbb{R}^n)$:

$$\hat{f}(\xi) = \int_{\mathbb{R}^n} f(x) e^{-i\langle \xi, x\rangle} dx.$$

2. Admissible oversampling matrices. Given a candidate oversampling matrix, $P \in GL_n(\mathbb{Z})$, we are concerned with the quotient group $P^{-1}\mathbb{Z}^n/\mathbb{Z}^n$. Let $\{\theta_r\}_{r=0}^{p-1}$ be a complete set of distinct coset representatives of the quotient group $P^{-1}\mathbb{Z}^n/\mathbb{Z}^n$, where again $p = |\det P|$. In the following proposition we consider conditions on P such that the action of M on $P^{-1}\mathbb{Z}^n/\mathbb{Z}^n$ is nice.

PROPOSITION 2.1. *Suppose $M, P \in GL_n(\mathbb{Z})$ with $m := |\det M|$ and $p := |\det P|$. Let $\{\theta_r\}_{r=0}^{p-1}$ be a complete set of distinct coset representatives of $P^{-1}\mathbb{Z}^n/\mathbb{Z}^n$ with $\theta_0 = 0$. Suppose $PMP^{-1} \in GL_n(\mathbb{Z})$. Then $\{M\theta_r\}_{r=0}^{p-1}$ is a complete set of representatives of $P^{-1}\mathbb{Z}^n/\mathbb{Z}^n$ if and only if M and P satisfy $M^{-1}\mathbb{Z}^n \bigcap P^{-1}\mathbb{Z}^n = \mathbb{Z}^n$.*

Proof. The statement is trivial if $p = 1$. We proceed to prove the result in the case that $p \geq 2$.

($\Rightarrow$) By way of contradiction assume that $M^{-1}\mathbb{Z}^n \bigcap P^{-1}\mathbb{Z}^n \supsetneq \mathbb{Z}^n$. Then there exists θ_{r_0}, $1 \leq r_0 \leq p-1$, such that $\theta_{r_0} \in \left(P^{-1}\mathbb{Z}^n \bigcap M^{-1}\mathbb{Z}^n\right) \setminus \mathbb{Z}^n$. This implies that $M\theta_{r_0} \equiv 0 \pmod{\mathbb{Z}^n}$, which means $\{M\theta_r\}_{r=0}^{p-1}$ cannot be a complete set of representatives of $P^{-1}\mathbb{Z}^n/\mathbb{Z}^n$. This is a contradiction.

($\Leftarrow$) The condition $PMP^{-1} \in GL_n(\mathbb{Z})$ implies that $Mx \in P^{-1}\mathbb{Z}^n$ if $x \in P^{-1}\mathbb{Z}^n$; i.e., the multiplication map induced by M maps $P^{-1}\mathbb{Z}^n$ into itself. Suppose $\{M\theta_r\}_{r=0}^{p-1}$ is not a complete set of coset representatives of $P^{-1}\mathbb{Z}^n/\mathbb{Z}^n$. Then there is some θ_{r_0}, $1 \leq r_0 \leq p-1$, such that $M\theta_{r_0} \in \mathbb{Z}^n$, which implies that $\theta_{r_0} \in M^{-1}\mathbb{Z}^n$. Since $r_0 \neq 0$, $\theta_{r_0} \notin \mathbb{Z}^n$, implying that $\theta_{r_0} \in \left(P^{-1}\mathbb{Z}^n \bigcap M^{-1}\mathbb{Z}^n\right) \setminus \mathbb{Z}^n$, and we have $M^{-1}\mathbb{Z}^n \bigcap P^{-1}\mathbb{Z}^n \supsetneq \mathbb{Z}^n$, a contradiction. ∎

DEFINITION 2.2. *Let $P \in GL_n(\mathbb{Z})$. P is an admissible oversampling matrix for M if $PMP^{-1} \in GL_n(\mathbb{Z})$ and $M^{-1}\mathbb{Z}^n \bigcap P^{-1}\mathbb{Z}^n = \mathbb{Z}^n$. If the matrix M is clear from the context we will simply say that P is admissible.*

In the terminology of the preceding proposition, notice that if $\gcd(m, p) = 1$, then $M^{-1}\mathbb{Z}^n \bigcap P^{-1}\mathbb{Z}^n = \mathbb{Z}^n$. Indeed, suppose $\theta \in \left(M^{-1}\mathbb{Z}^n \bigcap P^{-1}\mathbb{Z}^n\right)$. Since the order of θ divides both m and p we conclude that $\theta \in \mathbb{Z}^n$.

Example 1. Consider the following examples of admissible oversampling matrices.

(a) Let $M = \begin{pmatrix} 1 & 1 \\ -1 & 1 \end{pmatrix}$, the Quincunx dilation matrix, and let $P = \begin{pmatrix} 3 & 1 \\ -2 & 1 \end{pmatrix}$. It is easy to check that PMP^{-1} has integer entries and, in light of the previous remark, that P is admissible.

(b) Let $M = mI_n$, where $m \geq 2$ is an integer and I_n is the $n \times n$ identity matrix. Clearly, $PMP^{-1} \in GL_n(\mathbb{Z})$ for all $P \in GL_n(\mathbb{Z})$, which means a sufficient condition for P to be admissible is that $\gcd(m, |\det P|) = 1$.

Given that P is admissible, Proposition 2.1 tells us that the mapping $\theta_r \mapsto M\theta_r$, $0 \leq r \leq p-1$, acts to permute the coset representatives of $P^{-1}\mathbb{Z}^n/\mathbb{Z}^n$. Let σ be the permutation of $\{0, \ldots, p-1\}$ such that $\theta_{\sigma(r)} \equiv M\theta_r \pmod{\mathbb{Z}^n}$ in $P^{-1}\mathbb{Z}^n$. Let σ^{-1} be the associated inverse permutation. The following result, which replaces Lemma 2 of [2] in this setting, describes a basic property of the permutation σ.

LEMMA 2.3. *Let $j_0 \in \mathbb{Z}$. If $P \in GL_n(\mathbb{Z})$ is admissible, then for $j \geq j_0$ and $0 \leq r \leq p-1$, $\theta_{\sigma^j(r)} \equiv M^{j-j_0}\theta_{\sigma^{j_0}(r)}$ $(mod\, \mathbb{Z}^n)$ in $P^{-1}\mathbb{Z}^n$.*

Proof. The statement holds trivially for $j = j_0$. By induction, assume the formula holds for j, and we will derive the formula for $j+1$. Proposition 2.1 and the definition of σ imply that

$$\theta_{\sigma^{j+1}(r)} \equiv M\theta_{\sigma^j(r)} \equiv M^{j+1-j_0}\theta_{\sigma^{j_0}(r)} \pmod{\mathbb{Z}^n}. \qquad \square$$

COROLLARY 2.4. *Let $j, j_0 \in \mathbb{Z}$ with $j \geq j_0$, and suppose $P \in GL_n(\mathbb{Z})$ is admissible. For $0 \leq r \leq p-1$,*

$$\{D^j T_{\theta_{\sigma^j(r)}+k}\psi_\ell : 1 \leq \ell \leq L, k \in \mathbb{Z}^n\} = \{T_{M^{-j_0}\theta_{\sigma^{j_0}(r)}} D^j T_k \psi_\ell : 1 \leq \ell \leq L, k \in \mathbb{Z}^n\}.$$

3. The second oversampling theorem. We now seek to describe our version of the second oversampling theorem, generalizing the approach of Chui and Shi introduced in [2]. We begin by demonstrating the preservation of Bessel bounds for admissible oversampling, which follows essentially from Proposition 2.1.

LEMMA 3.1. *Suppose $X(\Psi)$ is a Bessel system with bound $B > 0$ relative to an expanding dilation matrix $M \in GL_n(\mathbb{Z})$. If $P \in GL_n(\mathbb{Z})$ is an admissible oversampling matrix, then $X^P(\Psi)$ is a Bessel system with the same bound.*

Proof. The fact that $X(\Psi)$ is Bessel with bound $B > 0$ implies for each $f \in L^2(\mathbb{R}^n)$ that

$$\sum_{\ell=1}^{L}\sum_{j\geq 0}\sum_{k\in\mathbb{Z}^n}\sum_{r=0}^{p-1}\frac{1}{p}\left|\langle T_{-\theta_r} f, \psi_{\ell;j,k}\rangle\right|^2 \leq B\|f\|^2.$$

We now relate this sum to the inner products of the oversampled system, $X^P(\Psi)$:

$$\begin{aligned}
\sum_{\ell=1}^{L}\sum_{j\geq 0}\sum_{k\in\mathbb{Z}^n}\sum_{r=0}^{p-1}\frac{1}{p}\left|\langle T_{-\theta_r} f, \psi_{\ell;j,k}\rangle\right|^2 &= \sum_{\ell=1}^{L}\sum_{j\geq 0}\sum_{k\in\mathbb{Z}^n}\sum_{r=0}^{p-1}\frac{1}{p}\left|\langle f, D^j T_{M^j\theta_r+k}\psi_\ell\rangle\right|^2 \\
\text{(by Proposition 2.1)} \quad &= \sum_{\ell=1}^{L}\sum_{j\geq 0}\sum_{k\in\mathbb{Z}^n}\frac{1}{p}\left|\langle f, D^j T_{P^{-1}k}\psi_\ell\rangle\right|^2 \\
&= \sum_{\ell=1}^{L}\sum_{j\geq 0}\sum_{k\in\mathbb{Z}^n}\left|\langle f, \psi^P_{\ell;j,k}\rangle\right|^2.
\end{aligned}$$

Letting $J \geq 0$ and observing that $\|D^J f\|^2 = \|f\|^2$ it is easily shown that for each $f \in L^2(\mathbb{R}^n)$

$$\sum_{\ell=1}^{L}\sum_{j\geq -J}\sum_{k\in\mathbb{Z}^n}\left|\langle f, \psi^P_{\ell;j,k}\rangle\right|^2 \leq B\|f\|^2.$$

Letting $J \to \infty$ we see that $X^P(\Psi)$ is a Bessel system with upper bound B. $\square$

Given an admissible oversampling matrix we can use the permutation σ guaranteed by Proposition 2.1 to rewrite the oversampled system as the union of appropriate

affine-like systems, one for each coset of $P^{-1}\mathbb{Z}^n/\mathbb{Z}^n$. Namely,

$$X^P(\Psi) = \bigcup_{r=0}^{p-1} \frac{1}{\sqrt{p}} S_r \quad \text{(disjointly)},$$

where $S_r := \{D^j T_{\theta_{\sigma^j(r)}+k}\psi_\ell : 1 \le \ell \le L, j \in \mathbb{Z}, k \in \mathbb{Z}^n\}$. S_0 is precisely $X(\Psi)$, while the remaining collections S_r, $1 \le r \le p-1$, are slightly more complicated. This decomposition plays a key role in our proof of the second oversampling theorem.

THEOREM 3.2 (second oversampling theorem). *Suppose $X(\Psi)$ is a frame with lower and upper bounds $A, B > 0$, respectively, relative to an expanding dilation matrix $M \in GL_n(\mathbb{Z})$. If $P \in GL_n(\mathbb{Z})$ is an admissible oversampling matrix, then $X^P(\Psi)$ is a frame with the same bounds.*

Remark. In [6], Laugesen shows that if $X(\Psi)$ and $X(\tilde{\Psi})$ are dual frames and P is admissible, then $X^P(\Psi)$ and $X^P(\tilde{\Psi})$ are also dual frames. This statement will be proven in the next section (see Theorem 4.4 below) for a certain class of refinable functions.

Proof. The preservation of the upper bound was discussed above; hence, it suffices to demonstrate the lower bound. Since $S_0 = X(\Psi)$, S_0 is a frame with lower bound A. It is, therefore, sufficient to prove that each of the collections S_r, $1 \le r \le p-1$, is a frame with lower bound A.

Fix r, $1 \le r \le p-1$, and let $f \in L^\infty_c(\mathbb{R}^n)$, the dense subset of $L^2(\mathbb{R}^n)$ consisting of essentially bounded functions of compact support. It is sufficient to demonstrate the lower bound for such an f. Suppose that $\operatorname{supp} f \subset K$, where K is a compact subset of $\mathbb{R}^n$ containing 0. Let $R := \operatorname{diam} K$. Lastly, let $\lambda_- > 1$ and λ_+ be the strict lower and upper bounds, respectively, for the moduli of the eigenvalues of M.

1. For $j_0 \in \mathbb{Z}$, let $f^r_{j_0} = T_{-M^{-j_0}\theta_{\sigma^{j_0}(r)}} f$. By defining $K^r_{j_0} := K - M^{-j_0}\theta_{\sigma^{j_0}(r)}$ we see that $\operatorname{supp} f^r_{j_0} \subset K^r_{j_0}$. Observe that by Corollary 2.4 we have

$$\begin{aligned}
\sum_{g\in S_r} |\langle f, g\rangle|^2 &= \sum_{\ell=1}^{L}\sum_{j\in\mathbb{Z}}\sum_{k\in\mathbb{Z}^n} \left|\langle f, D^j T_{\theta_{\sigma^j(r)}+k}\psi_\ell\rangle\right|^2 \\
&= \sum_{\ell=1}^{L}\sum_{j\ge j_0}\sum_{k\in\mathbb{Z}^n} \left|\langle f^r_{j_0}, D^j T_k \psi_\ell\rangle\right|^2 + \sum_{\ell=1}^{L}\sum_{j<j_0}\sum_{k\in\mathbb{Z}^n} \left|\langle f, D^j T_{\theta_{\sigma^j(r)}+k}\psi_\ell\rangle\right|^2 \\
&\ge \sum_{\ell=1}^{L}\sum_{j\in\mathbb{Z}}\sum_{k\in\mathbb{Z}^n} \left|\langle f^r_{j_0}, \psi_{\ell;j,k}\rangle\right|^2 - \sum_{\ell=1}^{L}\sum_{j<j_0}\sum_{k\in\mathbb{Z}^n} \left|\langle f^r_{j_0}, \psi_{\ell;j,k}\rangle\right|^2 \\
&\ge A\|f\|^2 - \sum_{\ell=1}^{L}\sum_{j<j_0}\sum_{k\in\mathbb{Z}^n} \left|\langle f^r_{j_0}, \psi_{\ell;j,k}\rangle\right|^2.
\end{aligned}$$

   We are left to prove that the latter sum tends to 0 as $j_0 \to -\infty$.

2. Let $\varepsilon > 0$. Let us adopt the notation

$$S^r_{j_0}(f) = \sum_{\ell=1}^{L}\sum_{j<j_0}\sum_{k\in\mathbb{Z}^n} \left|\langle f^r_{j_0}, \psi_{\ell;j,k}\rangle\right|^2.$$

   Estimating the inner product of $f^r_{j_0}$ with $\psi_{\ell;j,k}$ by

$$\left|\langle f^r_{j_0}, \psi_{\ell;j,k}\rangle\right|^2 \le \|f^r_{j_0}\|^2 \, \|\psi_{\ell;j,k}\chi_{K^r_{j_0}}\|^2 \le \|f\|^2 \int_{M^j K^r_{j_0}} |\psi_\ell(x-k)|^2 dx,$$

we obtain a bound on $S^r_{j_0}(f)$:

$$S^r_{j_0}(f) \leq \|f\|^2 \sum_{\ell=1}^{L} \sum_{j<j_0} \sum_{k\in\mathbb{Z}^n} \int_{M^j K^r_{j_0}-k} |\psi_\ell(x)|^2 dx.$$

We will break up the sum over j into two pieces, corresponding to $j < j_0 - J$ and $j_0 - J \leq j < j_0$, where $J > 0$ will be fixed below (independent of j_0). Since M is expanding it is well known that there exists $\beta \geq 1$ such that for $x \in \mathbb{R}^n$ and $j > 0$ we have the estimates

$$\beta^{-1}\lambda_-^j \|x\| \leq \|M^j x\| \leq \beta\lambda_+^j \|x\|$$

and

$$\beta^{-1}\lambda_+^{-j} \|x\| \leq \|M^{-j} x\| \leq \beta\lambda_-^{-j} \|x\|,$$

where $\beta \geq 1$ depends on λ_-, λ_+, and M.
We now make a pair of technical assumptions that will be used below, each of which relies on the expanding property of M.

(a) We may assume j_0 is negative and sufficiently less than 0 such that

$$R < \frac{1}{2}\|M^{-j_0}\theta_{\sigma^{j_0}(r)}\|.$$

(b) We will assume $J > 0$ is such that $\lambda_-^J > 2\beta^{-1}(R + \|\theta_{\sigma^{j_0}(r)}\|)$.

3. Let us first handle the terms for which $j < j_0 - J$. Consider the set

$$E := \bigcup_{j<j_0-J} M^j K^r_{j_0} = \bigcup_{j<j_0-J} \big(M^j(K - M^{-j_0}\theta_{\sigma^{j_0}(r)})\big).$$

Our first estimate involves replacing the sum over j by integration over E, which requires the that the sets $\{M^j K^r_{j_0}\}_{j<j_0-J}$ have finite overlaps which can be bounded independently of j_0. Supposing for the moment that this is the case, we have

$$I_1 := \|f\|^2 \sum_{\ell,k} \sum_{j<j_0-J} \int_{M^j K^r_{j_0}-k} |\psi_\ell(x)|^2 dx \leq C\|f\|^2 \sum_{\ell,k} \int_{E-k} |\psi_\ell(x)|^2 dx.$$

We now investigate the disjointness of $\{M^j K^r_{j_0}\}_{j<j_0-J}$. Suppose that

$$M^{j_1} K^r_{j_0} \bigcap M^{j_2} K^r_{j_0} \neq \emptyset,$$

with $j_1 > j_2$; then $M^{j_1-j_2} K^r_{j_0} \bigcap K^r_{j_0} \neq \emptyset$. Thus it suffices to prove that there exists $j_1 > 0$ (independent of j_0) such that $M^j K^r_{j_0} \bigcap K^r_{j_0} = \emptyset$ for all $j \geq j_1$. For $x \in K^r_{j_0}$ we have by assumption (a) that

$$\|x\| \leq R + \|M^{-j_0}\theta_{\sigma^{j_0}(r)}\| \leq \frac{3}{2}\|M^{-j_0}\theta_{\sigma^{j_0}(r)}\|$$

and

$$\|x\| \geq \|M^{-j_0}\theta_{\sigma^{j_0}(r)}\| - R \geq \frac{1}{2}\|M^{-j_0}\theta_{\sigma^{j_0}(r)}\|.$$

Again using the expanding property of M, we have for $x \in K_{j_0}^r$ and $j > 0$

$$\|M^j x\| \geq \frac{1}{\beta}\lambda_-^j \frac{1}{2}\|M^{-j_0}\theta_{\sigma^{j_0}(r)}\|.$$

Hence, a sufficient condition for the disjointness of the sets $M^j K_{j_0}^r$ and $K_{j_0}^r$ is

$$\frac{1}{\beta}\lambda_-^j \frac{1}{2}\|M^{-j_0}\theta_{\sigma^{j_0}(r)}\| \geq \frac{3}{2}\|M^{-j_0}\theta_{\sigma^{j_0}(r)}\|,$$

or, equivalently,

$$\lambda_-^j \geq 3\beta.$$

Again, since M is expanding we have $\lambda_- > 1$, so we may choose $j_1 > 0$ to be the smallest j for which this last inequality holds.

4. Returning to the estimate from step 3 above, we will next fix J large enough to control the term I_1. Let us examine a typical j in the sum defining I_1, which is of the form $j = j_0 - J - j_1$ with $j_1 \geq 1$. If $x \in M^j K_{j_0}^r$, then

$$\|x\| \leq \beta\lambda_-^{j_0-J-j_1}R + \beta\lambda_-^{-J-j_1}\|\theta_{\sigma^{j_0}(r)}\| \leq \beta\lambda_-^{-J-j_1}\big(R + \|\theta_{\sigma^{j_0}(r)}\|\big),$$

where we have used the assumption that $j_0 < 0$ and β is as above. We conclude that if $x \in E$, then $\|x\| \leq \lambda_-^{-J-1}\big(R + \|\theta_{\sigma^{j_0}(r)}\|\big) \leq \frac{1}{2}$ by the assumption (b) above regarding J. This means that $\operatorname{diam} E \leq 1$, implying that any distinct integer translates of E are disjoint. While the definition of E above does depend on both j_0 and J, we just showed that the measure of E can be made arbitrarily small independent of j_0, by choosing J sufficiently large. Since each $\psi_\ell \in L^2(\mathbb{R}^n)$ the dominated convergence theorem allows us to fix $J > 0$ so large that $I_1 < \varepsilon$ independent of j_0.

5. We now estimate the terms in $S_{j_0}^r(f)$ for $j_0 - J \leq j < j_0$ with J fixed as in the last step. It suffices to consider an arbitrary term of this sort, which can be written as $j = j_0 - j_1$ with $1 \leq j_1 \leq J$. By definition, $M^j K_{j_0}^r = M^{j_0-j_1}K - M^{-j_1}\theta_{\sigma^{j_0}(r)}$, where $M^{-j_1}\theta_{\sigma^{j_0}(r)}$ is one of $p-1$ constants depending on j_0. Hence,

$$I_{2,j} := \sum_{\ell,k}\int_{M^j K_{j_0}^r - k} |\psi_\ell(x)|^2 dx = \sum_{\ell,k}\int_{M^{j_0-j_1}K - M^{-j_1}\theta_{\sigma^{j_0}(r)} - k} |\psi_\ell(x)|^2 dx.$$

Applying the dominated convergence theorem we may choose j_0 sufficiently less than zero such that $I_{2,j} < \varepsilon$.

By definition we have

$$S_{j_0}^r = I_1 + \sum_{j=j_0-J}^{j_0-1} I_{2,j},$$

so, combining all the estimates, we have shown that $S_{j_0}^r \to 0$ as $j_0 \to -\infty$. Thus, S_r is a frame with lower bound A for each r, $0 \leq r \leq p-1$, completing the proof. ∎

4. Oversampling and multiresolution analysis. Consider two families of generating functions, $\Psi := \{\psi_1, \dots, \psi_L\}$ and $\tilde{\Psi} := \{\tilde{\psi}_1, \dots, \tilde{\psi}_L\} \subset L^2(\mathbb{R}^n)$. Let us assume that the families are produced by refinement with scaling functions $\varphi, \tilde{\varphi} \in \mathbb{E}$, respectively, where $\mathbb{E} := \{f \in L^2(\mathbb{R}^n) : [\hat{f}, \hat{f}] \in L^\infty(\mathbb{T}^n)\}$. Recall that $[f, g]$, the *bracket product of* $f, g \in L^2(\mathbb{R}^n)$, is defined by

$$[f, g] = \sum_{k \in \mathbb{Z}^n} T_{2\pi k} f \overline{T_{2\pi k} g}.$$

Adopting the convention that $\psi_0 := \varphi$ and $\tilde{\psi}_0 := \tilde{\varphi}$ for notational convenience, we have the refinement identities

$$\hat{\psi}_\ell(M^T \xi) = m_\ell(\xi)\hat{\varphi}(\xi) \text{ and } \hat{\tilde{\psi}}_\ell(M^T \xi) = \tilde{m}_\ell(\xi)\hat{\tilde{\varphi}}(\xi) \tag{4.1}$$

for $0 \le \ell \le L$ and a.e. $\xi \in \mathbb{R}^n$, where $m_\ell, \tilde{m}_\ell \in L^\infty(\mathbb{T}^n)$ for $0 \le \ell \le L$. We assume here that $M \in GL_n(\mathbb{Z})$ is expansive. Finally, we assume that the filters satisfy the generalized Smith–Barnwell equations for the dilation M; namely, for $0 \le s \le m-1$ we have

$$\sum_{\ell=0}^{L} \overline{m_\ell(\xi)} \tilde{m}_\ell(\xi + 2\pi (M^T)^{-1} \vartheta_s) = \delta_{0,s} \quad \text{a.e. } \xi \in \mathbb{T}^n, \tag{4.2}$$

where $\{\vartheta_s\}_{p=0}^{m-1}$ is a complete set of distinct coset representatives of $\mathbb{Z}^n / M^T \mathbb{Z}^n$, $m := |\det M|$, and $\delta_{0,s}$ is the Kronecker delta. Implicitly assumed here is the fact that $\vartheta_0 = 0$. Together, the scaling functions and filters specify the generating families Ψ and $\tilde{\Psi}$ that define the affine systems $X(\Psi)$ and $X(\tilde{\Psi})$. We will rely on some basic properties of this class of refinable affine systems as found in [5].

Given that these two systems are dual frames for $L^2(\mathbb{R}^n)$ we are interested in two properties of the resulting oversampled systems. First, we will investigate when the oversampled affine systems $X^P(\Psi)$ and $X^P(\tilde{\Psi})$ relative to a matrix $P \in GL_n(\mathbb{Z})$ are again dual frames. Second, we will examine the scaling equations associated with the oversampled system and determine conditions on the oversampling matrix that endow the oversampled system with a bonafide DWT. We conclude the section by reconciling the conditions required for these two properties.

4.1. Multiresolution operators and duality. Our analysis will involve multiresolution operators that arise naturally as generalizations of the orthogonal projections found in the orthonormal MRA case. The affine approximation and detail operators at the scale $j \in \mathbb{Z}$, $\mathcal{P}_j$ and $\mathcal{Q}_j$, respectively, act on $f \in L^2(\mathbb{R}^n)$ by

$$\mathcal{P}_j f := \sum_{k \in \mathbb{Z}^n} \langle f, \tilde{\varphi}_{j,k} \rangle \varphi_{j,k} \text{ and } \mathcal{Q}_j f := \sum_{\ell=1}^{L} \sum_{k \in \mathbb{Z}^n} \langle f, \tilde{\psi}_{\ell;j,k} \rangle \psi_{\ell;j,k}, \tag{4.3}$$

whereas the oversampled affine approximation and detail operators at the scale j, $\mathcal{P}_j^P$ and $\mathcal{Q}_j^P$, respectively, are defined similarly by

$$\mathcal{P}_j^P f := \sum_{k \in \mathbb{Z}^n} \langle f, \tilde{\varphi}_{j,k}^P \rangle \varphi_{j,k}^P \text{ and } \mathcal{Q}_j^P f := \sum_{\ell=1}^{L} \sum_{k \in \mathbb{Z}^n} \langle f, \tilde{\psi}_{\ell;j,k}^P \rangle \psi_{\ell;j,k}^P. \tag{4.4}$$

We have the following basic properties for $\mathcal{P}_j$ and $\mathcal{Q}_j$.

LEMMA 4.1 (see [5]). *Suppose* $\varphi, \tilde{\varphi} \in \mathbb{E}$ *and* $\Psi, \tilde{\Psi} \subset L^2(\mathbb{R}^n)$ *are such that* (4.1) *and* (4.2) *hold.*

(a) $\mathcal{P}_j$ *and* $\mathcal{Q}_j$ *are bounded operators on* $L^2(\mathbb{R}^n)$ *for each* $j \in \mathbb{Z}$.
(b) $\mathcal{P}_j + \mathcal{Q}_j = \mathcal{P}_{j+1}$ *for each* $j \in \mathbb{Z}$.
(c) *For each* $f \in L^2(\mathbb{R}^n)$, $\lim_{j\to-\infty} \|\mathcal{P}_j f\| = 0$.
(d) *If* $X(\Psi)$ *and* $X(\tilde{\Psi})$ *are dual frames for* $L^2(\mathbb{R}^n)$, *then for each* $f \in L^2(\mathbb{R}^n)$ *we have*

$$f = \lim_{j\to\infty} \mathcal{P}_j f = \sum_{j\in\mathbb{Z}} \mathcal{Q}_j f. \tag{4.5}$$

Our objective is to establish similar properties for the oversampled multiresolution operators armed with this information. We begin by expressing the oversampled multiresolution operators in terms of the original affine counterparts.

PROPOSITION 4.2. *Let* $\varphi, \tilde{\varphi} \in \mathbb{E}$. *Let* $P \in GL_n(\mathbb{Z})$. *For each* $j \in \mathbb{Z}$, $\mathcal{P}_j^P$ *and* $\mathcal{Q}_j^P$ *are bounded operators on* $L^2(\mathbb{R}^n)$, *and we have*

(a) $\mathcal{P}_j^P = \frac{1}{p}\sum_{r=0}^{p-1} T_{M^{-j}\theta_r} \mathcal{P}_j T_{-M^{-j}\theta_r}$,
(b) $\mathcal{Q}_j^P = \frac{1}{p}\sum_{r=0}^{p-1} T_{M^{-j}\theta_r} \mathcal{Q}_j T_{-M^{-j}\theta_r}$.

Proof. It is sufficient to derive (a). We have for each $f \in L^2(\mathbb{R}^n)$

$$\begin{aligned}
\mathcal{P}_j^P f &= \sum_{k\in\mathbb{Z}^n} \langle f, \tilde{\varphi}_{j,k}^P \rangle \varphi_{j,k}^P \\
&= \frac{1}{p}\sum_{r=0}^{p-1} \sum_{k\in\mathbb{Z}^n} \langle f, D^j T_{\theta_r+k}\tilde{\varphi}\rangle D^j T_{\theta_r+k}\varphi \\
&= \frac{1}{p}\sum_{r=0}^{p-1} \sum_{k\in\mathbb{Z}^n} \langle T_{-M^{-j}\theta_r} f, D^j T_k \tilde{\varphi}\rangle T_{M^j\theta_r} D^j T_k \varphi \\
&= \frac{1}{p}\sum_{r=0}^{p-1} T_{M^{-j}\theta_r} \mathcal{P}_j T_{-M^{-j}\theta_r} f. \qquad \square
\end{aligned}$$

It is important to realize that the representations of $\mathcal{P}_j^P$ and $\mathcal{Q}_j^P$ above are independent of the choice of coset representatives. This is because $\mathcal{P}_j$ and $\mathcal{Q}_j$ are invariant under conjugation by translation operators over $M^{-j}\mathbb{Z}^n$. Indeed, for each $f \in L^2(\mathbb{R}^n)$ and $k_0 \in \mathbb{Z}^n$ we have

$$\begin{aligned}
T_{M^{-j}k_0} \mathcal{P}_j T_{-M^{-j}k_0} f &= \sum_{k\in\mathbb{Z}^n} \langle T_{-M^{-j}k_0} f, D^j T_k \tilde{\varphi}\rangle T_{M^{-j}k_0} D^j T_k \varphi \\
&= \sum_{k\in\mathbb{Z}^n} \langle f, T_{M^{-j}k_0} D^j T_k \tilde{\varphi}\rangle T_{M^{-j}k_0} D^j T_k \varphi \\
&= \sum_{k\in\mathbb{Z}^n} \langle f, D^j T_{k+k_0} \tilde{\varphi}\rangle D^j T_{k+k_0} \varphi \\
&= \mathcal{P}_j f.
\end{aligned}$$

Since any two representatives of the same coset in $P^{-1}\mathbb{Z}^n/\mathbb{Z}^n$ differ by an element of $\mathbb{Z}^n$ the claim follows. This independence is particularly important for the following proposition.

PROPOSITION 4.3. *Let* $\varphi, \tilde{\varphi} \in \mathbb{E}$. *If* $P \in GL_n(\mathbb{Z})$ *is an admissible oversampling matrix, then for each* $j \in \mathbb{Z}$

$$\mathcal{P}_j^P + \mathcal{Q}_j^P = \mathcal{P}_{j+1}^P.$$

Proof. The condition on the oversampling matrix P guarantees that $\{M\theta_r\}_{r=0}^{p-1}$ is a complete set of coset representatives for $P^{-1}\mathbb{Z}^n/\mathbb{Z}^n$. This fact, together with the previous proposition, implies that for $f \in L^2(\mathbb{R}^n)$

$$\begin{aligned}
\mathcal{P}_j^P f + \mathcal{Q}_j^P f &= \frac{1}{p}\sum_{r=0}^{p-1}\left(T_{M^{-j}\theta_r}\mathcal{P}_j T_{-M^{-j}\theta_r} f + T_{M^{-j}\theta_r}\mathcal{Q}_j T_{-M^{-j}\theta_r} f\right)\\
&= \frac{1}{p}\sum_{r=0}^{p-1} T_{M^{-j}\theta_r}\mathcal{P}_{j+1} T_{-M^{-j}\theta_r} f\\
&= \frac{1}{p}\sum_{r=0}^{p-1} T_{M^{-(j+1)}M\theta_r}\mathcal{P}_{j+1} T_{-M^{-(j+1)}M\theta_r} f\\
&= \frac{1}{p}\sum_{r=0}^{p-1} T_{M^{-(j+1)}\theta_r}\mathcal{P}_{j+1} T_{-M^{-(j+1)}\theta_r} f\\
&= \mathcal{P}_{j+1}^P f. \qquad \square
\end{aligned}$$

We are now in the position to examine the duality of the oversampled systems.

THEOREM 4.4. *Suppose $\varphi, \tilde{\varphi} \in \mathbb{E}$ and $\Psi, \tilde{\Psi} \subset L^2(\mathbb{R}^n)$ are such that* (4.1) *and* (4.2) *hold. If $X(\Psi)$ and $X(\tilde{\Psi})$ are dual frames and $P \in GL_n(\mathbb{Z})$ is an admissible oversampling matrix, then $X^P(\Psi)$ and $X^P(\tilde{\Psi})$ are dual frames with the same bounds as $X(\Psi)$ and $X(\tilde{\Psi})$, respectively. Moreover, for each $f \in L^2(\mathbb{R}^n)$ we have*

$$f = \lim_{j\to\infty} \mathcal{P}_j^P f = \sum_{j\in\mathbb{Z}} \mathcal{Q}_j^P f = f \tag{4.6}$$

and

$$\lim_{j\to-\infty} \|\mathcal{P}_j^P f\| = 0. \tag{4.7}$$

Proof. For this class of scaling functions we use the corresponding properties of $\mathcal{P}_j$ and $\mathcal{Q}_j$ contained in Lemma 4.1. Let $f \in L^2(\mathbb{R}^n)$. Since $\mathcal{P}_j^P$ is the finite sum of translated versions of $\mathcal{P}_j$ we conclude (4.7) directly from Lemma 4.1(c) and Proposition 4.2. By Lemma 4.1(d) we also have that $\mathcal{P}_j f \to f$ in $L^2(\mathbb{R}^n)$ as $j \to \infty$, from which we will obtain the first equality of (4.6) by approximation. Indeed, for each $u \in \mathbb{R}^n$ we have the estimate

$$\begin{aligned}
\|T_{M^{-j}u}\mathcal{P}_j T_{-M^{-j}u} f - f\| &\le \|T_{M^{-j}u} f - f\| + \|T_{M^{-j}u}\mathcal{P}_j T_{-M^{-j}u} f - T_{M^{-j}u} f\|\\
&\le \|T_{M^{-j}u} f - f\| + \|\mathcal{P}_j T_{-M^{-j}u} f - f\|\\
&\le \|T_{M^{-j}u} f - f\| + \|\mathcal{P}_j f - f\| + \|\mathcal{P}_j T_{-M^{-j}u} f - \mathcal{P}_j f\|\\
&\le \|T_{M^{-j}u} f - f\| + \|\mathcal{P}_j f - f\| + C\|T_{-M^{-j}u} f - f\|.
\end{aligned}$$

Each of the three terms in this estimate tend to zero as $j \to \infty$, and thus the first equality of (4.6) follows by summing the above as $u = \theta_r$, $0 \le r \le p-1$.

By Theorem 3.2, we have that $X^P(\Psi)$ and $X^P(\Psi)$ are frames with the same bounds as their respective affine counterparts. Lastly, the second equality of (4.6) follows from a telescoping argument using Proposition 4.3 and the fact that the oversampled systems are Bessel, thereby implying that $X^P(\Psi)$ and $X^P(\tilde{\Psi})$ are indeed dual. $\square$

Remark. We should note that in many cases the assumption in Theorem 4.4 that the original affine systems are actually dual frames may be avoided. For example, in [8] Ron and Shen have derived sufficient conditions (assuming a weak smoothness condition on the refinable family) involving identities of the form (4.2) under which a pair of refinable affine Bessel systems will constitute dual frames.

4.2. Discrete wavelet transform. Throughout this section we assume that $P \in GL_n(\mathbb{Z})$ is an admissible oversampling matrix for the dilation M. Recall that the refinement equations (4.1) can be written in the space domain as

$$\psi_{\ell;j,k} = m^{\frac{1}{2}} \sum_{r\in\mathbb{Z}^n} \alpha_{\ell;r}\varphi_{j+1,r+Mk}$$

for $0 \le \ell \le L$, $j \in \mathbb{Z}$, and $k \in \mathbb{Z}^n$, where $m_\ell(\xi) = \sum_{r\in\mathbb{Z}^n} \alpha_{\ell;r}e^{-i\langle\xi,r\rangle}$. We omit the analogous formulas for the dual functions and filters. We can obtain a similar formula for the oversampled system by observing that

$$\begin{aligned}\psi^P_{\ell;j,k} = \frac{1}{\sqrt{p}}\psi_{\ell;j,P^{-1}k} &= \sqrt{m}\sum_{r\in\mathbb{Z}^n} \alpha_{\ell;r}\frac{1}{\sqrt{p}}\varphi_{j+1,r+MP^{-1}k}\\ &= \sqrt{m}\sum_{r\in\mathbb{Z}^n} \alpha_{\ell;r}\frac{1}{\sqrt{p}}\varphi_{j+1,P^{-1}(Pr+\tilde{M}k)}\\ &= \sqrt{m}\sum_{r\in\mathbb{Z}^n} \alpha_{\ell;r}\varphi^P_{j+1,Pr+\tilde{M}k},\end{aligned}$$

where $\tilde{M} := PMP^{-1}$. Notice that because P is admissible $\tilde{M}$ has integer entries. Letting $\alpha^P_{\ell;r}$ be the coefficient sequence given by

$$\alpha^P_{\ell;r} := \begin{cases}\alpha_{\ell;s}, & r = Ps, s \in \mathbb{Z}^n,\\ 0 & \text{otherwise,}\end{cases}$$

we arrive at

$$\psi^P_{\ell;j,k} = \sqrt{m}\sum_{r\in\mathbb{Z}^n} \alpha^P_{\ell;r}\varphi^P_{j+1,r+\tilde{M}k}.$$

Thus, given $f \in L^2(\mathbb{R}^n)$ the sequence of inner products $\{\langle f, \psi^P_{\ell;j,k}\rangle\}_{k\in\mathbb{Z}^n}$ is given by

$$\langle f, \psi^P_{\ell;j,k}\rangle = \sqrt{m}\sum_{r\in\mathbb{Z}^n}\sum_{r\in\mathbb{Z}^n} \overline{\alpha^P_{\ell;r}}\langle f, \varphi^P_{j+1,r+\tilde{M}k}\rangle$$

for $0 \le \ell \le L$ and $j \in \mathbb{Z}$. To those familiar with subband coding theory, this is immediately recognizable as a convolution followed by a downsampling operation. Note that the downsampling is relative to $\tilde{M}$ rather than M, as for the original affine system. We would like this decomposition to be reversible, meaning that the sequence $\{\langle f, \varphi_{j+1,k}\rangle\}_{k\in\mathbb{Z}^n}$ should be recoverable from the sequences $\{\langle f, \psi_{\ell;j,k}\rangle\}_{k\in\mathbb{Z}^n}$, $0 \le \ell \le L$, by first upsampling each sequence by $\tilde{M}$ and then summing the respective convolutions with the dual filter coefficient sequences $\tilde{\alpha}^P_{\ell;r}$. It is well known that this is equivalent to the coefficient sequences $\alpha^P_{\ell;r}$ and $\tilde{\alpha}^P_{\ell;r}$ satisfying the filter equations (4.2) with $\tilde{M}$ instead of M. Letting m^P_ℓ be defined by

$$m^P_\ell(\xi) = \sum_{r\in\mathbb{Z}^n} \alpha^P_{\ell;r}e^{-i\langle\xi,r\rangle}$$

for $0 \le \ell \le L$, we have $m_\ell^P(\xi) = m_\ell(P^T\xi)$ by the definition of $\alpha_{\ell;r}^p$. The necessary generalized Smith–Barnwell equations are thus

$$\sum_{\ell=0}^{L} \overline{m_\ell^P(\xi)}\tilde{m}_\ell^P(\xi + 2\pi(\tilde{M}^T)^{-1}\tilde{\vartheta}_s) = \delta_{0,s} \tag{4.8}$$

for a.e. $\xi \in \mathbb{T}^n$ and $0 \le s \le m-1$, where $\{\tilde{\vartheta}_s\}_{s=0}^{m-1}$ is a complete set of coset representatives of $\mathbb{Z}^n/\tilde{M}^T\mathbb{Z}^n$ with $\tilde{\vartheta}_s = 0$. In terms of the original filters, (4.8) is equivalent to

$$\sum_{\ell=0}^{L} \overline{m_\ell(\xi)}\tilde{m}_\ell(\xi + 2\pi P^T(\tilde{M}^T)^{-1}\tilde{\vartheta}_s) = \delta_{0,s} \tag{4.9}$$

for $0 \le s \le m-1$, because $m_\ell^P(\xi) = m_\ell(P^T\xi)$. With the following theorem we describe a condition on the oversampling matrix that reduces (4.9) to (4.2), giving a condition under which the dual oversampled affine systems have an associated DWT.

THEOREM 4.5. *Let $P \in GL_n(\mathbb{Z})$ be an admissible oversampling matrix, and assume that P also satisfies $(P^T)^{-1}\mathbb{Z}^n \bigcap (\tilde{M}^T)^{-1}\mathbb{Z}^n = \mathbb{Z}^n$. Then* (4.2) *and* (4.9) *are equivalent.*

Proof. It is sufficient to prove that $\{M^TP^T(\tilde{M}^T)^{-1}\tilde{\vartheta}_s\}_{s=0}^{m-1}$ is a complete set of representatives for $\mathbb{Z}^n/M^T\mathbb{Z}^n$. In other words we need to show only that

$$(M^T)^{-1}\mathbb{Z}^n = \bigcup_{s=0}^{m-1} \left(P^T(\tilde{M}^T)^{-1}\tilde{\vartheta}_s + \mathbb{Z}^n\right).$$

Observing that $\{(\tilde{M}^T)^{-1}\tilde{\vartheta}_s\}_{s=0}^{m-1}$ is a complete set of representatives of $(\tilde{M}^T)^{-1}\mathbb{Z}^n/\mathbb{Z}^n$ our problem is equivalent to showing that if $\{\gamma_s\}_{s=0}^{m-1}$ is a complete set of distinct coset representatives for $(\tilde{M}^T)^{-1}\mathbb{Z}^n/\mathbb{Z}^n$, then $\{P^T\gamma_s\}_{s=0}^{m-1}$ is a compete set of coset representatives for $(M^T)^{-1}\mathbb{Z}^n/\mathbb{Z}^n$.

The first bit of business is to establish that $P^T\gamma_s \in (M^T)^{-1}\mathbb{Z}^n$. This requires for each $x \in \mathbb{Z}^n$ a corresponding $y \in \mathbb{Z}^n$ such that $P^T(\tilde{M}^T)^{-1}x = (M^T)^{-1}y$ or, equivalently, that $M^TP^T(\tilde{M}^T)^{-1}$ has integer entries. Computing this we see

$$M^TP^T(\tilde{M}^T)^{-1} = M^TP^T(P^T)^{-1}(M^T)^{-1}P^T = P^T,$$

which clearly has integer entries.

We now proceed by way of contradiction. Suppose that $\{P^T\gamma_s\}_{s=0}^{m-1}$ is not a complete set of coset representatives. Then $P^T\gamma_{s_0} \in \mathbb{Z}^n$ for some s_0, $1 \le s_0 \le m-1$. Since $\gamma_{s_0} \notin \mathbb{Z}$ this implies that $(P^T)^{-1}\mathbb{Z}^n \bigcap (\tilde{M}^T)^{-1}\mathbb{Z}^n \supsetneq \mathbb{Z}^n$, a contradiction. ∎

4.3. Reconciliation of the hypotheses. In the last subsection we found a relationship between the dilation matrix, M, and the oversampling matrix, P, that is sufficient for the existence of a DWT for the oversampled system. This condition essentially ensures that the perfect reconstruction filter equations for the matrix $\tilde{M} := PMP^{-1}$ are equivalent to those associated with M. It turns out that this condition is automatically satisfied for all admissible oversampling matrices.

THEOREM 4.6. *Let $M, P \in GL_n(\mathbb{Z})$ such that $\tilde{M} := PMP^{-1} \in GL_n(\mathbb{Z})$. Then*

$$P^{-1}\mathbb{Z}^n \bigcap M^{-1}\mathbb{Z}^n = \mathbb{Z}^n \tag{4.10}$$

and

$$(P^T)^{-1}\mathbb{Z}^n \bigcap (\tilde{M}^T)^{-1}\mathbb{Z}^n = \mathbb{Z}^n \tag{4.11}$$

are equivalent.

Proof. We prove the result step by step.

1. By symmetry, it is sufficient to prove (4.10) implies (4.11). Indeed, letting $M' = \tilde{M}^T$ and $P' = P^T$ we have $(\tilde{M}')^T = M$ and $(P')^T = P$.
2. Consider (4.11). If $x \in (\tilde{M}^T)^{-1}\mathbb{Z}^n \bigcap (P^T)^{-1}\mathbb{Z}^n$, then $x = (\tilde{M}^T)^{-1}r = (P^T)^{-1}s$ for some $r, s \in \mathbb{Z}^n$. This allows us to write

$$(\tilde{M}^T)^{-1}\mathbb{Z}^n \bigcap (P^T)^{-1}\mathbb{Z}^n = \left\{(P^T)^{-1}s : s \in \mathbb{Z}^n \text{ and } (P^T)^{-1}M^T s \in \mathbb{Z}^n\right\}.$$

   Letting $S = \{s \in \mathbb{Z}^n : (P^T)^{-1}M^T s \in \mathbb{Z}^n\}$, we have $(\tilde{M}^T)^{-1}\mathbb{Z}^n \bigcap (P^T)^{-1}\mathbb{Z}^n = (P^T)^{-1}S$. Thus, (4.11) is equivalent to $S = P^T\mathbb{Z}^n$.
3. $P^T\mathbb{Z}^n \subseteq S$. *Proof.* Let $s \in P^T\mathbb{Z}^n$, and write $s = P^T x$, $x \in \mathbb{Z}^n$. Then $(P^T)^{-1}M^T P^T x = \tilde{M}^T x \in \mathbb{Z}^n$ because $\tilde{M}$ has integer entries. Hence, $s \in S$.
4. We now provide an unusual characterization of S. It is easy to see that $x \in \mathbb{Z}^n$ if and only if $\langle x, y\rangle \in \mathbb{Z}$ for all $y \in \mathbb{Z}^n$. Thus, $s \in S$ if and only if $\langle (P^T)^{-1}M^T s, y\rangle \in \mathbb{Z}$ for all $y \in \mathbb{Z}^n$. This, in turn, is equivalent to $s \in S$ if and only if $\langle s, My\rangle \in \mathbb{Z}$ for all $y \in P^{-1}\mathbb{Z}^n$.
5. Recall from Proposition 2.1 that (4.10) is equivalent to $\{M\theta_r\}_{r=0}^{p-1}$ being a complete set of coset representatives for $P^{-1}\mathbb{Z}^n/\mathbb{Z}^n$. In other words, (4.10) allows us to write $u \in P^{-1}\mathbb{Z}^n$ as $u = y + Mv$, where $y \in \mathbb{Z}^n$ and $v \in P^{-1}\mathbb{Z}^n$. Notice that if $u \notin \mathbb{Z}^n$, then $v \notin \mathbb{Z}^n$. This will be used below.
6. $S \subseteq P^T\mathbb{Z}^n$. *Proof.* Let $s \in \mathbb{Z}^n$, and suppose that $s \notin P^T\mathbb{Z}^n$. Then there exists $u \in P^{-1}\mathbb{Z}^n \setminus \mathbb{Z}^n$ such that $\langle s, u\rangle \notin \mathbb{Z}$. As explained above, (4.10) allows us to write $u = y + Mv$, where $y \in \mathbb{Z}^n$ and $v \in P^{-1}\mathbb{Z}^n$. Since $u \notin \mathbb{Z}^n$, we must have $v \notin \mathbb{Z}^n$. Then $\langle s, u\rangle = \langle s, y\rangle + \langle s, Mv\rangle \notin \mathbb{Z}$, and since $\langle s, y\rangle \in \mathbb{Z}$ we conclude that $\langle s, Mv\rangle \notin \mathbb{Z}$. Hence, $s \notin S$. ∎

Theorem 4.6 shows that the additional assumption of (4.11) in Theorem 4.5 is redundant and that the dual oversampled affine systems always have an associated DWT if P is admissible.

COROLLARY 4.7. *If $P \in GL_n(\mathbb{Z})$ is an admissible oversampling matrix, then* (4.2) *and* (4.9) *are equivalent.*

5. Discussion of related work. With the number of variations on this theme of bound-preserving oversampling, some comparisons are in order. In particular, we will discuss in detail how our work relates to that of Chui and Shi, Ron and Shen, and Laugesen.

As mentioned in the introduction, the problem of identifying sufficient conditions for the bound-preserving oversampling of affine frames started with Chui and Shi in the one-dimensional setting with dyadic wavelets frames and oversampling by an odd integer [2]. Our proof for Theorem 3.2 is an adaptation of that given in [2] to the n-dimensional case for expansive dilations $M \in GL_n(\mathbb{Z})$ and admissible oversampling matrices P. Chui and Shi improved on their one-dimensional result in [3], extending the second oversampling theorem to expanding dilations $M \in GL_n(\mathbb{Z})$ (i.e., λ an eigenvalue of M implies $|\lambda| > 1$) and $P = pI_n$, with $\gcd(p, \det M) = 1$. This version of the second oversampling theorem also allows for the replacement of the $\mathbb{Z}^n$-translations by $b\mathbb{Z}^n$-translations, where $b > 0$. We will see below, more generally, that this case

actually follows from the $\mathbb{Z}^n$-translation case, which means that Theorem 3.2 implies each of the results of Chui and Shi.

We turn now to the Gramian analysis of Ron and Shen. The version of the second oversampling theorem offered by Ron and Shen in [7] achieves the result of Theorem 3.2, provided that $M \in GL_n(\mathbb{Z})$ is expansive and $P \in GL_n(\mathbb{Z})$ satisfies

$$P^T\mathbb{Z}^n \bigcap (M^T)^j\mathbb{Z}^n = (M^T)^j P^T\mathbb{Z}^n \tag{5.1}$$

for each $j \geq 0$. We will see that this rather complicated expression is actually equivalent to our notion of admissibility. Let us begin by showing that (5.1) implies that P is admissible in terms of Definition 2.2. The $j = 1$ statement of (5.1) says that

$$P^T\mathbb{Z}^n \bigcap M^T\mathbb{Z}^n = M^T P^T\mathbb{Z}^n,$$

which is equivalent to

$$\mathbb{Z}^n \bigcap (P^T)^{-1}M^T\mathbb{Z}^n = (P^T)^{-1}M^T P^T\mathbb{Z}^n =: \tilde{M}^T\mathbb{Z}^n,$$

from which we conclude that $\tilde{M} := PMP^{-1} \in GL_n(\mathbb{Z})$. Moreover, we have

$$P^T\mathbb{Z}^n \bigcap M^T\mathbb{Z}^n = M^T P^T\mathbb{Z}^n \Leftrightarrow (\tilde{M}^T)^{-1}\mathbb{Z}^n \bigcap (P^T)^{-1}\mathbb{Z}^n = \mathbb{Z}^n.$$

But by Theorem 4.6 we have

$$(\tilde{M}^T)^{-1}\mathbb{Z}^n \bigcap (P^T)^{-1}\mathbb{Z}^n = \mathbb{Z}^n \Leftrightarrow M^{-1}\mathbb{Z}^n \bigcap P^{-1}\mathbb{Z}^n = \mathbb{Z}^n,$$

implying that P satisfies our admissibility condition.

For the reverse implication, assume P is admissible according to Definition 2.2. Using the notation of Proposition 2.1 we have that $\{M^j\theta_r\}_{r=0}^{p-1}$ is a complete set of coset representatives for $P^{-1}\mathbb{Z}^n/\mathbb{Z}^n$ for each $j \geq 0$. This is achieved by successively applying the proposition to the collection $\{M^{j-1}\theta_r\}_{r=0}^{p-1}$. Note that since $PMP^{-1} \in GL_n(\mathbb{Z})$, it follows that $PM^jP^{-1} = \tilde{M}^j \in GL_n(\mathbb{Z})$. Thus, Proposition 2.1 implies that

$$M^{-j}\mathbb{Z}^n \bigcap P^{-1}\mathbb{Z}^n = \mathbb{Z}^n.$$

Theorem 4.6 now guarantees

$$M^{-j}\mathbb{Z}^n \bigcap P^{-1}\mathbb{Z}^n = \mathbb{Z}^n \Leftrightarrow (\tilde{M}^T)^{-j}\mathbb{Z}^n \bigcap (P^T)^{-1}\mathbb{Z}^n = \mathbb{Z}^n,$$

but we also have

$$(\tilde{M}^T)^{-j}\mathbb{Z}^n \bigcap (P^T)^{-1}\mathbb{Z}^n = \mathbb{Z}^n \Leftrightarrow (M^T)^j\mathbb{Z}^n \bigcap P^T\mathbb{Z}^n = (M^T)^j P^T\mathbb{Z}^n.$$

This string of equivalences shows that our notion of admissibility is equivalent to (5.1).

Finally, we compare our version of the second oversampling theorem to the one of Laugesen [6]. Laugesen handles two kinds of dilation matrices $M \in GL_n(\mathbb{Z})$: the *expanding* and *amplifying* dilations. The expanding dilations include, but are not limited to, the expansive dilations considered in this work, while the class of amplifying matrices includes such dilations as $\begin{pmatrix} 2 & 0 \\ 0 & 1 \end{pmatrix}$. Thus, Laugesen's result applies to a larger class of dilations than Theorem 3.2.

Laugesen also considers translations over the lattice $b\mathbb{Z}^n$, where $b \in GL_n(\mathbb{R})$ commutes with M. This generalization is not essential, as we will now describe using notation as in Theorem 3.2. Let us denote the affine system generated by $\Psi \subset L^2(\mathbb{R}^n)$ relative to translations over $b\mathbb{Z}^n$ by $X_b(\Psi)$ and, similarly, the associated oversampled system $\{D^j T_{bP^{-1}k}\psi_\ell : 1 \le \ell \le L, j \in \mathbb{Z}, k \in \mathbb{Z}^n\}$ by $X_b^P(\Psi)$. For $b \in GL_n(\mathbb{R})$, let D_b be the unitary dilation operator mapping $f \in L^2(\mathbb{R}^n)$ to $D_b f := |\det b|^{\frac{1}{2}} f(b\cdot)$. Suppose that $X_b(\Psi)$ is a frame for $L^2(\mathbb{R}^n)$ with lower bound A and upper bound B. We then have for each $f \in L^2(\mathbb{R}^n)$

$$A\|f\|^2 \le \sum_{\ell=1}^{L} \sum_{j\in\mathbb{Z}} \sum_{k\in\mathbb{Z}^n} \left|\langle D_b^{-1} f, D^j T_{bk}\psi_\ell\rangle\right|^2 \le B\|f\|^2.$$

Using the fact that b and M commute we obtain for each $f \in L^2(\mathbb{R}^n)$

$$A\|f\|^2 \le \sum_{\ell=1}^{L} \sum_{j\in\mathbb{Z}} \sum_{k\in\mathbb{Z}^n} \left|\langle f, D^j T_k D_b\psi_\ell\rangle\right|^2 \le B\|f\|^2.$$

This argument shows that $X_b(\Psi)$ is a frame with bounds A, B if and only if $X(D_b\Psi)$ is a frame with the same bounds. If P is admissible, then using Theorem 3.2 we conclude that $X^P(D_b\Psi)$ is a frame with bounds A, B. Thus, for each $f \in L^2(\mathbb{R}^n)$ we have

$$A\|f\|^2 \le \sum_{\ell=1}^{L} \sum_{j\in\mathbb{Z}} \sum_{k\in\mathbb{Z}^n} \left|\langle D_b f, D^j T_{P^{-1}k} D_b\psi_\ell\rangle\right|^2 \le B\|f\|^2,$$

from which it follows that

$$A\|f\|^2 \le \sum_{\ell=1}^{L} \sum_{j\in\mathbb{Z}} \sum_{k\in\mathbb{Z}^n} \left|\langle f, D^j T_{bP^{-1}k}\psi_\ell\rangle\right|^2 \le B\|f\|^2.$$

Hence, if M and P satisfy the hypotheses of Theorem 3.2 and $X_b(\Psi)$ is a frame with bounds A, B, then the preceding argument shows that Theorem 3.2 is sufficient to conclude that $X_b^P(\Psi)$ is a frame with the same bounds.

We will now discuss how the notion of admissibility for an oversampling matrix P in [6] is equivalent to ours. Laugesen uses a notion of relative primality for $M, P \in GL_n(\mathbb{Z})$ in which M *is prime relative to* P if $M^T\mathbb{Z}^n \bigcap P^T\mathbb{Z}^n \subseteq M^T P^T\mathbb{Z}^n$. In [6], given a dilation M (which we will assume is expansive), an oversampling matrix $P \in GL_n(\mathbb{Z})$ is admissible if $PMP^{-1} \in GL_n(\mathbb{Z})$ and M is prime relative to P. Observe that

$$M^T\mathbb{Z}^n \bigcap P^T\mathbb{Z}^n \subseteq M^T P^T\mathbb{Z}^n \Leftrightarrow (P^T)^{-1}\mathbb{Z}^n \bigcap (\tilde{M}^T)^{-1}\mathbb{Z}^n \subseteq \mathbb{Z}^n, \tag{5.2}$$

where $\tilde{M} = PMP^{-1}$. On the other hand, since $P^T, \tilde{M}^T \in GL_n(\mathbb{Z})$ we have

$$\mathbb{Z}^n \subseteq (P^T)^{-1}\mathbb{Z}^n \bigcap (\tilde{M}^T)^{-1}\mathbb{Z}^n.$$

It follows that under the hypothesis that $PMP^{-1} \in GL_n(\mathbb{Z})$, M being prime relative to P requires equality rather than containment in (5.2). In light of Theorem 4.6 we see that the notion of admissibility in [6] is equivalent to ours.

Acknowledgments. The author would like to thank Eugenio Hernández, Guido Weiss, and Edward Wilson for their comments and suggestions in the preparation of this paper.

NONLINEAR STABILITY OF SEMIDISCRETE SHOCK WAVES*

S. BENZONI-GAVAGE†, P. HUOT‡, AND F. ROUSSET§

Abstract. The orbital stability of possibly large semidiscrete shock waves is considered. These waves are traveling wave solutions of discrete in space and continuous in time systems of conservation laws, which constitute a class of lattice dynamical systems (LDSs). The underlying lattice $\Delta x\mathbb{Z}$ is by nature not invariant by change of frame. Thus semidiscrete shock waves cannot really be transformed into stationary waves, unlike other kinds of approximate shock waves (e.g., viscous or relaxation shocks). This implies that the linearization of the LDS about a given semidiscrete shock wave yields a nonautonomous linear LDS, which cannot be tackled by means of Laplace transform in time. However, viewing the LDS as a finite-difference PDE and performing afterall the change of frame, the profile becomes a stationary solution of the transformed equation. Then, linearizing about the profile, we get an evolution finite-difference PDE in which the spatial operator L, a delayed and advanced differential operator, plays a crucial role in our stability analysis. In particular, we point out an integral formula relating the Green's function of the linearized LDS to the Green's function G_λ of $(\lambda - L)$. Specializing to the upwind scheme, we take advantage of the material introduced in an earlier work [S. Benzoni-Gavage, *J. Dynam. Differential Equations*, 14 (2002), pp. 613–674], in particular of an Evans function, to decompose the Green's function similarly as Zumbrun et al. did for other approximate shock waves. This decomposition relies on explicit representations of the projections involved in the exponential dichotomies and their extensions through the gap lemma. It enables us in turn to prove the orbital stability of the wave, provided that the Evans function D does not vanish in the right half-plane but on the discrete set $2i\pi\sigma\mathbb{Z}$ (σ being the speed of the wave) and that D has a simple root at 0. Additionally, we show that this spectral stability condition is satisfied at least for (extreme) weak shocks. Our spectral stability condition, and more specifically the $D'(0) \neq 0$ part, appears to be a relaxed version of the requirement of Chow, Mallet-Paret, and Shen [*J. Differential Equations*, 149 (1998), pp. 248–291], which we show to be too strong for traveling waves in conservative LDSs.

Key words. lattice dynamical system, traveling wave, Green's function, orbital stability

1. Introduction.

Besides numerical analysis, which is concerned with the convergence of numerical schemes, the study of qualitative features of schemes on fixed meshes is of interest to apprehend computer simulations. When the scheme is discrete in space and continuous in time, it is also called a lattice dynamical system (LDS), and when it is fully discrete it is called a coupled map lattice (CML). LDSs and CMLs are also interesting from a purely analytical point of view. They are believed to exhibit richer structures than evolution PDEs, similar to discrete dynamical systems compared to ODEs. The existence and stability of special, traveling wave solutions is still a wide open problem for most LDSs and CMLs. In particular, no direct method is known to tackle the existence of traveling waves in CMLs. A very nice approach was proposed by Chow, Mallet-Paret, and Shen [6], who were able to deduce the existence of discrete traveling waves from the existence of stable enough semidiscrete traveling

waves. However, their general theorems were designed for, and basically apply to, *scalar dissipative* equations (in connection with reaction-diffusion equations). Here we are interested in *conservative systems*, having in mind the schemes discretizing hyperbolic systems of conservation laws.

We proved in earlier papers the existence of semidiscrete shock waves of small enough amplitude by means of a center manifold argument. In [2], we dealt with the basic *upwind scheme*, valid when all characteristic speeds are of the same sign. The center manifold theorem used in [1] came from the standard theory of *delay differential equations*. In [3], we were able to generalize our existence result to more general schemes, by first proving a center manifold theorem for *functional differential equations of mixed type* (i.e., with both delay and advance). In the present paper, we are concerned with the time asymptotic stability of these semidiscrete waves. This problem was first addressed in [2], where we constructed an *Evans function*, presumably encoding the linearized stability of the wave, regardless of its amplitude. Our first purpose is to clarify this claim. In particular, we shall make the connection with the approach of Chow, Mallet-Paret, and Shen [6] and show that their stability condition is in fact too restrictive in our context. The stability condition we propose instead is, in terms of the Evans function, the same as the one derived by Zumbrun et al. for viscous shock waves [8, 24, 23] and also relaxation shocks [18]. The drawback of this approach is that, up to the present day, we have been able to construct the Evans function only for the upwind scheme. However, this construction is basically linked to *exponential dichotomies*. On this topic, some recent results obtained simultaneously and independently by Härterich, Sandstede, and Scheel [10] and Mallet-Paret and Verduyn Lunel [17] for delayed and advanced differential operators indicate that it might be possible to define and take advantage of an Evans function for more general schemes. This is why within this paper we consider general schemes whenever it is possible. The other important point is that we aim at dealing with waves of arbitrary amplitude. This makes at least two basic differences with the approach adopted by Bianchini in his nevertheless very interesting related work [5].

Going through the contents, section 2 provides all the background necessary for our analysis. We discuss the assumptions on the scheme, recall the existence result of [3], and prove a corollary giving uniform bounds on the profile and its derivatives. These bounds will in turn enable us to prove the stability of small amplitude profiles (Theorem 3.9) by means of an energy method in the manner of Goodman [9] (also see [13] for fully discrete shocks of rational speed), thus providing an example where our spectral stability condition holds. In section 3, we concentrate on the spectral stability of semidiscrete shocks, making the connection with Chow, Mallet-Paret, and Shen's approach [6]. In particular, we show spectral mapping properties between the bounded operator $\mathcal{R}$ considered in [6] (made out of the solution operator of the LDS linearized about the wave and the shift operator, in a rather natural way as we explain in section 3.1) and the delayed and advanced differential operator L obtained after a not natural (because it does not preserve the lattice) change of frame. The interplay between the two approaches eventually appears to be very useful to gain insight. This should be clear to the reader from the derivation of the Green's function in section 4.1. Before that, we build in section 3.7 all the material necessary to have suitable decompositions of that Green's function. In the meanwhile, we also recall the construction of the Evans function. That part of our work is for the moment restricted to the upwind scheme. However, it is to be noted that the argument given at the end of section 3.7 is valid for all schemes. It shows that Chow, Mallet-Paret, and Shen's

spectral condition fails for *conservative systems*, thus stressing the interest of our alternative approach. Also valid for general schemes is our Theorem 4.2, giving the Green's function of the linearized LDS in terms of a Cauchy integral for the Green's function G_λ of $(\lambda - L)$. From section 4.2, we specialize the upwind scheme, for which we have explicit representations of the projections involved in the decomposition of the Green's function G_λ (Proposition 4.4 and Theorem 4.7). Eventually, we arrive at a decomposition of G_λ (Theorem 4.8) that is analogous to those obtained by Zumbrun et al. in different contexts [24, 23, 18]. This enables us to prove suitable pointwise estimates (Theorem 4.11) on the Green's function of the linearized LDS by choosing appropriates shiftings of the contour. In fact, we make use of simple, pointwise straight contours, as in [23, 18]. Although not surprising, the interesting point is that we recover in those estimates some heat kernels with diffusion coefficients corresponding to the viscosity matrix of the scheme. This gives an a posteriori interpretation of the scheme's properties in terms of the modified (viscous) system of conservation laws. Finally, we deduce from Theorem 4.11 the orbital nonlinear stability in all discrete spaces[1]

$$\mathcal{L}^\alpha(\mathbb{Z};\mathbb{R}^N) \;=\; \left\{ v=(v_j)_{j\in\mathbb{Z}}\,;\sum_{j\in\mathbb{Z}} |v_j|^\alpha \;<\; +\infty \right\}, \quad \alpha \geq 1,$$

with respect to small enough summable perturbations (i.e., in $\mathcal{L}^1$), of semidiscrete shocks that satisfy our spectral assumption. This is our Theorem 5.1, in which the expected rates of decay are also obtained.

2. Semidiscrete conservative systems.

2.1. Background. We consider a conservative semidiscrete scheme

$$\frac{dv_j}{dt} \;+\; \frac{1}{\Delta x}\;\big(\, g(v_{j-p+1},\dots,v_{j+q}) - g(v_{j-p},\dots,v_{j+q-1})\,\big) = 0, \tag{2.1}$$

where p and q are given integers. For the most classical schemes p and q are in fact less than or equal to 1. We are interested in *systems*, and thus the unknowns v_j are vector valued, say, in $\mathbb{R}^N$.

We equivalently look at (2.1) as an LDS operating on sequences $v=(v_j)_{j\in\mathbb{Z}}$,

$$\frac{dv}{dt} \;=\; \mathcal{G}(v), \tag{2.2}$$

where by definition

$$\mathcal{G}(v)_j = G(v_{j-p},\dots,v_{j+q}) := -\tfrac{1}{\Delta x}\,\big(g(v_{j-p+1},\dots,v_{j+q}) - g(v_{j-p},\dots,v_{j+q-1})\big)\,. \tag{2.3}$$

The form of $\mathcal{G}$ in (2.3) actually characterizes finitely supported LDSs that are *conservative*, in the sense that constants are solutions of (2.2) and that solutions associated with summable initial data are *mass preserving* (i.e., $\sum v$ is independent of t). Conversely, it is well known and easy to show that a finitely supported mapping $\mathcal{G}$, vanishing on constants and such that $\sum \mathcal{G}(v) = 0$ for all summable v, is necessarily of the form (2.3).

[1] Our somewhat unusual notation is intended to reserve the notation ℓ^m for left eigenvectors of the system.

We are concerned with the stability of traveling wave solutions of (2.1), approximating shock waves of the underlying continuous system of conservation laws

$$\partial_t u + \partial_x f(u) = 0, \tag{2.4}$$

with

$$f(u) := g(u, \dots, u). \tag{2.5}$$

Those traveling waves are referred to as semidiscrete shock waves. Our motivation is not the convergence of the scheme (2.1) as $\Delta x \to 0$, which is still an open problem in general (see, however, the very interesting recent work by Bianchini [5], dealing with small total variations solutions). Rather, we address the long time behavior of (2.2) for initial data close to a possibly large reference semidiscrete shock. The question is of interest in itself, since very few results are known on the nonlinear stability of traveling waves in vector valued LDSs. Furthermore, part of our motivation was to investigate the possibility of obtaining fully discrete profiles from semidiscrete ones. Indeed, the existence of semidiscrete profiles has been shown in earlier works [1, 3]. But the existence of traveling wave solutions of the fully discrete (explicit) scheme

$$v^{n+1} = \mathcal{H}(v^n) := v^n + \Delta t\, \mathcal{G}(v^n) \tag{2.6}$$

remains an open problem in general. Discrete shock profiles must solve a "boundary value problem"

$$V(j - \eta) = H(V(j-p), \dots, V(j+q)), \qquad V(\pm\infty) = u_\pm, \tag{2.7}$$

where η is the *discrete wave speed* and H is just related to $\mathcal{H}$ by the formula

$$\mathcal{H}(v)_j =: H(v_{j-p}, \dots, v_{j+q}).$$

This problem has received much attention in the last few decades, but, up to now, the existence results are limited to η rational [15] and η *Diophantine* [14]. In other respects, the work of Chow, Mallet-Paret, and Shen [6] has *provided a unified treatment of* —discrete traveling—*waves irrespective of whether their speed is rational or irrational* (sic), showing in particular (Theorem B) that the existence of *spectrally stable* semidiscrete traveling waves implies the existence of fully discrete traveling waves for small enough time step Δt. In this paper, we show that the spectral requirement of Chow, Mallet-Paret, and Shen is in fact too strong for shock waves and propose a way to relax it in terms of an Evans function.

Our main purpose is to show the nonlinear stability, with a shift, of semidiscrete shocks. It is to be noted that this result would directly follow from Theorem A in [6] if their spectral requirement were satisfied.

We introduce below rather standard assumptions. Namely, we assume that g is at least of class $\mathcal{C}^2$. To avoid confusion with left eigenvectors appearing below, we denote by $\mathcal{L}^\alpha(\mathbb{Z};\mathbb{R}^N)$, or simply $\mathcal{L}^\alpha$, the Banach space of sequences with values in $\mathbb{R}^N$ of which the αth power is summable on $\mathbb{Z}$. Then $\mathcal{G}$ obviously maps $\mathcal{L}^\alpha$ into $\mathcal{L}^\alpha$ for all $\alpha \geq 1$ (for this we need only that g be Lipschitz). We point out that $\mathcal{G}$ is of class $\mathcal{C}^r$ if g is so—the "only if" part being also true when considering the smoothness of $\mathcal{G}$ on $\mathcal{L}^1$. Next, we assume that the exact flux f is *strictly hyperbolic* in some connected domain $\mathcal{U}$ of $\mathbb{R}^N$; that is, the Jacobian matrix $A(u) := df(u)$ has N distinct real eigenvalues denoted by

$$a^1(u) < \cdots < a^N(u). \tag{2.8}$$

As usual, we introduce a basis of eigenvectors, $\{r^1(u),\dots,r^N(u)\}$, and the dual basis $\{\ell^1(u),\dots,\ell^N(u)\}$. This means that

$$L(u)\,A(u)\,R(u) \;=\; \operatorname{diag}\,(a^1(u),\dots,a^N(u)) \;=:\; a(u),$$

where

$$L(u) := \begin{pmatrix} -\ell^1(u)- \\ \vdots \\ -\ell^N(u)- \end{pmatrix} \quad \text{and} \quad R(u) := \begin{pmatrix} | & & | \\ r^1(u) & \cdots & r^N(u) \\ | & & | \end{pmatrix}.$$

For later use, we also define $r^{N+j} = r^j$ and $\ell^{N+j} = \ell^j$; that is, the superscripts numbering the eigenvectors are in fact viewed in $\mathbb{Z}/N\mathbb{Z}$. Furthermore, we assume that there is a $k \in \{1,\dots,N\}$ such that the kth characteristic field is *genuinely nonlinear*. We thus choose r^k so that

$$da^k(u)\cdot r^k(u) \;>\; 0 \quad \forall u \in \mathcal{U}. \tag{2.9}$$

The exact system of conservation laws (2.4) is known to admit shock wave solutions of the form $u(x,t) = U(x-\sigma t)$ with U being a step function connecting a "left state" u_- to a "right state" u_+, and the speed σ being related to u_- and u_+ by the Rankine–Hugoniot condition

$$f(u_+) - f(u_-) \;=\; \sigma\,(u_+ - u_-). \tag{2.10}$$

Shock wave solutions are also submitted to an admissibility criterion. A convenient criterion is the one due to Lax [11]. It is relevant at least for shocks of small strength, that is, when the endstates are close enough.

DEFINITION 2.1 (Lax [11]). *A triple (u_-,u_+,σ) is called a k-shock if and only if the Rankine–Hugoniot condition* (2.10) *holds, together with the following inequalities:*

$$\begin{aligned} a^k(u_+) < \sigma < a^k(u_-), \\ a^{k-1}(u_-) < \sigma < a^{k+1}(u_+). \end{aligned} \tag{2.11}$$

The existence of k-shocks (of small strength) is implied by the genuine nonlinearity of the kth characteristic field (see [11] or any textbook on hyperbolic conservation laws).

2.2. Assumptions on the scheme. We proved in [3] the existence of semidiscrete shocks of small strength under two basic assumptions on the scheme, namely dissipativeness and nonresonance, plus a "technical" one. More precisely, we denote for $l \in \{-p+1,\dots,q\}$

$$C^l(u) := \partial_l g(u,\dots,u). \tag{2.12}$$

Note that C^l is matrix valued (in $\mathbb{R}^{N\times N}$) and because of (2.5) we have

$$\sum_{l=-p+1}^{q} C^l(u) \;=\; A(u).$$

We also introduce the so-called viscosity matrix

$$Q(u) := \sum_{l=-p+1}^{q} (1-2l)\,C^l(u). \tag{2.13}$$

(H1) *Dissipativeness.* There exists $\mu > 0$ so that

$$Q(u) \geq \mu I \qquad \forall u \in \mathcal{U}. \tag{2.14}$$

(H2) *Nonresonance.* For all $u \in \mathcal{U}$, $\sigma \neq 0$, and z in $i\mathbb{R} \setminus \{0\}$,

$$\Delta(\sigma; z, u) := \sigma z I + (\mathrm{e}^{-z} - 1) \sum_{l=-p+1}^{q} \mathrm{e}^{zl} C^l(u) \quad \in \mathrm{GL}_N(\mathbb{C}). \tag{2.15}$$

(H3) *Joint reduction.* For all $l \in \{-p+1, \dots, q\}$ and all $u \in \mathcal{U}$,

$$C^l(u) A(u) = A(u) C^l(u). \tag{2.16}$$

These assumptions are discussed in [3]. For the existence of semidiscrete shocks, dissipativeness is required only in the kth characteristic direction. But we need more for stability. This is why we have strengthened the assumption (H1) here. However, the examples given in [3], the generalized Lax–Friedrichs schemes (or Rusanov scheme) and the Godunov scheme away from sonic points, are still valid. More generally, it is to be noted that for any 3-point scheme the assumptions (H1) and (H3) together imply (H2). As a matter of fact, in that case we can adopt the simpler (and more standard) notations

$$D = C^0 \qquad \text{and} \qquad C := -C^1$$

in such a way that

$$Q = C + D \qquad \text{and} \qquad A = D - C.$$

Then the "characteristic matrix" defined in (2.15) just reads

$$\Delta(\sigma; z, u) = \sigma z I + \mathrm{e}^{-z} D(u) + \mathrm{e}^{z} C(u) - Q(u).$$

After simultaneous diagonalization, the coefficients of this matrix are, for $z = i\xi$ with $\xi \in \mathbb{R}$, of the form

$$i(\sigma\xi - a \sin\xi) + q(\cos\xi - 1).$$

This is clearly nonzero for $\sigma \neq 0$ and $q \neq 0$, unless ξ equals zero.

2.3. Existence of semidiscrete shocks. Semidiscrete shocks are by definition traveling wave solutions of (2.1) connecting an endstate u_- at $-\infty$ to another endstate u_+ at $+\infty$. Of course, stationary waves are also solutions of the fully discrete scheme, and they enter the rational framework of Majda and Ralston [15]. Here we consider only nonstationary waves.

DEFINITION 2.2. *A semidiscrete profile associated with a k-shock (u_-, u_+, σ) with $\sigma \neq 0$ is a solution of* (2.1) *of the form*

$$v_j(t) = V(j - st), \qquad s := \sigma/\Delta x,$$

such that

$$v_j(t) \xrightarrow[j \to \pm\infty]{} u_\pm. \tag{2.17}$$

Equivalently, V must solve the "boundary value problem"

$$\sigma V'(x) = g(V(x-p+1),\dots,V(x+q)) - g(V(x-p),\dots,V(x+q-1)), \tag{2.18}$$

$$V(\pm\infty) = u_\pm. \tag{2.19}$$

We recall from [3] the following.

THEOREM 2.3. *Assuming that the flux f is strictly hyperbolic, that the kth characteristic field is genuinely nonlinear, and that the scheme satisfies the requirements in* (H1)–(H3), *there is a $\varepsilon > 0$ such that all k-shocks (u_-, u_+, σ) of strength smaller than ε admit a (one-parameter family of) semidiscrete profiles.*

2.4. Properties of semidiscrete shocks. In addition to the pure existence result in Theorem 2.3, we can show the following, which will be extensively used in the stability analysis.

PROPOSITION 2.4. *In the framework of Theorem* 2.3, *there exists $C > 0$ such that the profiles associated with shocks lying in a small enough neighborhood, say, of size ε, of a nonsonic point satisfy*

$$|V(x) - u_\pm| \le C\varepsilon, \quad |V'(x)| \le C\varepsilon, \quad |V''(x)| \le C\varepsilon^2 \tag{2.20}$$

for all $x \in \mathbb{R}$ and

$$\begin{aligned} &|V'(x+l)| \le C\,|V'(x)| \quad \forall x \in \mathbb{R} \text{ and } l \in \{-p,\dots,q\},\\ &|V'(x)| \quad\ \le C\,\big(a^k(V(x-1)) - a^k(V(x))\big) \quad \forall x \in \mathbb{R}. \end{aligned} \tag{2.21}$$

Furthermore, those profiles are exponentially decaying. There exist $\theta_\pm$ so that $\mp\theta_\pm > 0$ and

$$|V(x) - u_\pm| \le C\,\mathrm{e}^{\theta_\pm x} \tag{2.22}$$

for all $x \in \mathbb{R}$.

The estimates in (2.20) are the same as for viscous profiles. The estimates in (2.21) are designed to deal with the mixing of continuous and discrete derivatives.

Proof. We recall that semidiscrete profiles were found in [3] on a $(N+1)$-dimensional center manifold, containing the N-dimensional vector space of constant solutions of (2.18). It is not difficult to see that the dynamics on that manifold is given by a system of ODEs of the form

$$\begin{cases} y_m' = \ell^m F(y), & m \ne k,\ m \ne N+1,\\ y_k' = y_{N+1} + c\,\ell^k F(y),\\ y_{N+1}' = \ell^k F(y), \end{cases} \tag{2.23}$$

where the ℓ^m are suitably normalized left eigenvectors of $A(u_i)$ and u_i denotes the (nonsonic) bifurcation point, c is a scalar, and the nonlinear term $F(y)$ is such that $F(y_1,\dots,y_N,0) = 0$ (the N-dimensional vector space of fixed points being precisely $\{y_{N+1} = 0\}$). The first estimate in (2.20) comes from the fact that connecting orbits stay globally in the neighborhood of u_i, and the second one follows in a standard way from the profile equation (2.18) and the mean value theorem. The third one is, as for viscous profiles, a little bit more subtle. We first note that, in a neighborhood of 0 of size ε,

$$F(y) = \mathcal{O}(\varepsilon^2).$$

This is due only to the fact that, by definition of F, $F(0) = 0$ and $dF(0) = 0$. Hence, for any (global) solution of (2.23) lying in that neighborhood, we have

$$y'_m = \mathcal{O}(\varepsilon^2) \quad \text{for} \quad m \neq k \qquad \text{and} \quad y'_k = \mathcal{O}(\varepsilon)$$

(uniformly on $\mathbb{R}$). Now, differentiating (2.23), we infer that

$$y''_m = \mathcal{O}(\varepsilon^2) \quad \forall m.$$

Recalling that $V(x)$ can be recovered from its coordinates $y(x)$ through a formula

$$V(x) = \sum_{m=1}^{N} y_m(x)\, r_m(u_i) + h(y(x)),$$

where the function h is such that $h(0) = 0$, $dh(0) = 0$ (by construction of the center manifold), and differentiating twice, we see that $V'' = \mathcal{O}(\varepsilon^2)$ uniformly on $\mathbb{R}$.

The estimates in (2.21) require a finer knowledge of the behavior of profiles at infinity. If u_0 is close to, but different from, u_i, and the corresponding constant solution of (2.18), $V \equiv u_0$, has coordinates $(y_1^0, \dots, y_N^0, 0)$, we have

$$\ell^k \frac{\partial F}{\partial y_{N+1}}\,(y_1^0, \dots, y_N^0, 0) = \vartheta(u_0),$$

where $\vartheta(u_0)$ is the root of $\det\Delta(\sigma, \vartheta, u_0)$ bifurcating from 0. And, as already shown in [3], we have $\vartheta(u_-) > 0$ and $\vartheta(u_+) < 0$ if $u_\pm$ are the endstates of a k-shock close to u_i. Additionally, the corresponding connecting orbits lie on an invariant curve, which crosses the space $\{y_{N+1} = 0\}$ transversally at points $(y_1^\pm, \dots, y_N^\pm, 0)$ (see [3, Lemma 6.2]). This is due to the fact that solutions of (2.18)–(2.19) must solve the integrated equation

$$\sigma\, V(x) - \int_{-1}^{0} g(V(x+\theta-p+1), \dots, V(x+\theta+q))\, d\theta = \sigma\, u_\pm - f(u_\pm). \tag{2.24}$$

Observe that this integration procedure restores hyperbolicity of the endpoints. As a matter of fact, linearizing (2.24) about $V \equiv u_\pm$, we get

$$\sigma\, V(x) - \int_{-1}^{0} \sum_{l=-p+1}^{q} C^l(u_\pm)\, V(x+\theta+l)\, d\theta = 0. \tag{2.25}$$

We obtain the "characteristic matrix" of this equation by looking for exponential solutions, in the same way as the matrix Δ is obtained from the linearized version of the original equation (2.18). Unsurprisingly, we find the matrix $\Delta(\sigma; z, u_\pm)/z$, which is nonsingular for all $z \in i\mathbb{R}$. And in the neighborhood of $z = 0$, there is only one point, $z = \vartheta(u_\pm)$, for which it is singular, its kernel being spanned by $r^k(u_\pm)$. In other words, $x \mapsto r^k(u_\pm)\, \mathrm{e}^{\vartheta(u_\pm)x}$ is a solution of (2.25). Returning to the center manifold, the invariant curve containing connecting orbits can be parametrized by y_{N+1} in the neighborhood of $(y_1^\pm, \dots, y_N^\pm, 0)$ Therefore, those orbits are *scalar-like*, and we are just led to study the behavior of solutions tending to 0 as $x \to \pm\infty$ of scalar ODEs of the form $y'_{N+1} = f^\pm(y_{N+1})$, with $f^\pm(0) = 0$ and $(f^\pm)'(0) = \vartheta(u_\pm)$. An elementary lemma then shows the existence of nonzero constants $c_\pm$ so that

$$y_{N+1}(x) \sim c_\pm\, \mathrm{e}^{\vartheta(u_\pm)x} \quad \text{as} \quad x \to \pm\infty.$$

This implies that $V(x) - u_\pm$ behaves accordingly. Therefore, the observation made above on solutions of (2.25) implies that

$$V(x) - u_\pm \sim c\, r^k(u_\pm)\, \mathrm{e}^{\vartheta(u_\pm)x}, \quad x \to \pm\infty,$$

for some nonzero constant c. In particular, this implies (2.22). Besides this asymptotic behavior, we also know that V' does not vanish, since solutions of (2.23) do not reach any fixed point in finite time. Combining these two facts, we get the first estimate in (2.21). Next, we observe that, for ε small enough, y_k' vanishes only at fixed points (characterized by $y_{N+1} = 0$). Furthermore, (2.23) implies that

$$da^k(V) \cdot V' = y_{N+1}\,(\, da^k(u_i) \cdot r^k(u_i) + \mathcal{O}(\varepsilon)\,)$$

does not vanish either, for ε small enough, because of (2.9). By (2.11), this means that $a^k \circ V$ is monotonically decaying. Using the mean value theorem and the previous observations, we get the second estimate in (2.21). ∎

3. Spectral stability of semidiscrete shocks. There are basically two approaches to the spectral stability of a semidiscrete traveling wave. One way was proposed by Chow, Mallet-Paret, and Shen [6]. They exhibited the linear operator, which we denote by $\mathcal{R}$ below, that encodes the spectral stability of rather general semidiscrete traveling waves. Some features of their approach are presented in section 3.1. However, their abstract theorems are intended to be applied to equations of reaction-diffusion type. We show in section 3.5 below that their spectral condition fails for conservative LDSs. The other possible approach seems more classical. It consists of forcing the wave to be stationary through a change of frame, as usual in traveling wave analysis. This approach is at first glance questionable since the lattice is not preserved by the change of frame. But it will appear to be complementary to the first one and especially useful to gain insight.

3.1. The LDS point of view. From now on, we fix a semidiscrete shock, denoted by $u_j(t) = U(j - st)$, in order to avoid confusion with general solutions of (2.1). Unless otherwise specified, it is not necessarily of small amplitude.

Without loss of generality, we assume that s, or equivalently σ, is positive. We introduce

$$T := 1/s = \Delta x/\sigma,$$

which is the time taken for the shock to travel across one mesh.[2] This is characteristic of all waves traveling with speed σ, as it can be formalized using the *shift* operator. If $\mathcal{T}$ is defined by

$$(\mathcal{T} \cdot v)_j := v_{j-1}$$

for any sequence $v = (v_j)_{j\in\mathbb{Z}}$, then traveling waves of speed σ are characterized by

$$v(t+T) = \mathcal{T} \cdot v(t). \tag{3.1}$$

As a matter of fact, (3.1) obviously holds if $v_j(t) = V(j - st)$ and, conversely, if (3.1) holds, then, defining $V(x) := v_0(-Tx)$, we have by induction

$$v_j(t) = V(j - st)$$

for all $j \in \mathbb{Z}$ and all t. This simple remark is nonetheless crucial in what follows.

[2]From place to place, we shall do a rescaling in order to have $\Delta x = 1$ and thus simplify the writing. But it is worth keeping in mind the dimensionality of the various quantities: T (time), s (frequency), Δx (distance), σ (speed).

Other important observations are that $\mathcal{T}$ is an isometry in all the spaces $\mathcal{L}^\alpha$ and that $\mathcal{T}$ commutes with the nonlinear mapping $\mathcal{G}$, that is,

$$\mathcal{T}\,\mathcal{G} \;=\; \mathcal{G}\,\mathcal{T}.$$

Following along the lines of [6], a first step in the stability analysis of the special solution u is to linearize (2.2) about u. This yields the *nonautonomous* linear LDS

$$\frac{dv}{dt} \;=\; D\mathcal{G}(u)\cdot v. \tag{3.2}$$

We denote by $\mathcal{S}$ the solution operator of (3.2). By definition, for all solutions v of (3.2) and all times $t \geq t_0$ we have

$$v(t) \;=\; \mathcal{S}(t,t_0)\cdot v(t_0).$$

Differentiating once the relation $du/dt \;=\; \mathcal{G}(u)$ and applying (3.1) to $v = u'$ we easily see that

$$\mathcal{T}\cdot u'(0) \;=\; \mathcal{S}(T,0)\cdot u'(0).$$

This means that $u'(0)$ is an eigenvector of the operator

$$\mathcal{R} \;:=\; \mathcal{T}^{-1}\,\mathcal{S}(T,0) \tag{3.3}$$

for the eigenvalue 1. We point out that since U is exponentially decaying (see section 2.4), this holds true in any space $\mathcal{L}^\alpha$, $1 \leq \alpha \leq \infty$.

Another simple remark makes use of the following properties.

PROPOSITION 3.1 (Chow, Mallet-Paret, and Shen [6]). *The shift operator $\mathcal{T}$ and the solution operator $\mathcal{S}$ of* (3.2) *satisfy the identities*

$$\mathcal{S}(t+T,T) \;=\; \mathcal{T}\,\mathcal{S}(t,0)\,\mathcal{T}^{-1} \qquad \forall t \geq 0, \tag{3.4}$$

$$(\,\mathcal{T}^{-1}\,\mathcal{S}(T,0)\,)^n \;=\; \mathcal{T}^{-n}\,\mathcal{S}(nT,0). \tag{3.5}$$

Proof. Regarding (3.4), it is sufficient to show that both sides applied to any sequence satisfy the linear LDS

$$\frac{dv}{dt} \;=\; D\mathcal{G}(\mathcal{T}u)\cdot v$$

and coincide at $t = 0$. And (3.5) is proved by induction, using (3.4). ∎

Equation (3.5) also reads

$$\mathcal{R}^n \;=\; \mathcal{T}^{-n}\,\mathcal{S}(nT,0).$$

Now assume that the operator $\mathcal{R}$ has an eigenvalue ζ of modulus greater than 1. There is a sequence w so that $\mathcal{R}w \;=\; \zeta\,w$. Then we have by (3.5)

$$\mathcal{S}(nT,0)\cdot w \;=\; \zeta^n\,\mathcal{T}^n\cdot w,$$

which shows that the solution $v(t) \;= \mathcal{S}(t,0)\cdot w$ of (3.2) blows up in all spaces $\mathcal{L}^\alpha$ as t tends to infinity.

Chow, Mallet-Paret, and Shen have proved in [6] the following nonlinear result, which shows that the operator $\mathcal{R}$ fully encodes the stability of the semidiscrete traveling wave u.

THEOREM 3.2 (Chow, Mallet-Paret, and Shen [6]). *If a traveling wave solution u of* (2.2) *satisfies the following spectral stability conditions, in terms of the $\mathcal{R}$ defined in* (3.3) *acting on $\mathcal{L}^\infty$,*

(i) *the spectrum of* $\mathcal{R}$ *is*

$$\Sigma(\mathcal{R}) \subset \{\zeta;\ |\zeta| < 1\} \cup \{1\} \tag{3.6}$$

and

(ii) *the eigenvalue* 1 *is simple,*

then u *is orbitally stable in* $\mathcal{L}^\infty$.

Chow, Mallet-Paret, and Shen have applied their theorem to a semidiscrete (scalar) Nagumo equation. In what follows we investigate (i) and (ii) in the context of conservative systems.

We shall show that (i) holds at least in two cases, namely, for scalar shocks and for shocks of small enough amplitude. The proof will proceed in several steps. First of all, we show in section 3.4 that the location of the essential spectrum of $\mathcal{R}$ can be determined in a rather standard way by Fourier analysis. Using an observation of Chow, Mallet-Paret, and Shen [6], the essential spectrum of $\mathcal{R}$ is seen to coincide with the essential spectrum of a modified operator $\mathcal{R}_0$ associated with a "fake profile." Together with some Fourier analysis of the autonomous systems about the endstates, this enables us to prove that (i) holds for the essential spectrum of $\mathcal{R}$. With regard to the point spectrum of $\mathcal{R}$, we observe that it is tightly related to the point spectrum of a differential operator with delay and advance. This operator L appears naturally when we look at (2.1) as a delayed and advanced PDE and perform a change of frame that makes the wave stationary; see section 3.2. We show that any nonzero eigenvalue of $\mathcal{R}$ reads $\exp(\Lambda/\sigma)$ with λ an eigenvalue of L and that their multiplicities coincide. Constructing an Evans function for L [2] then yields a necessary condition for the point spectrum of $\mathcal{R}$ to lie in the unit disk. In other respects, for shocks of small strength, we can perform some energy estimates on the LDS (2.1), in the spirit of the work of Goodman on viscous shocks [9]. This enables us to show that the point spectrum of $\mathcal{R}$ does lie in the unit disk.

But we shall also show that (ii) must fail. In fact, this is reminiscent of the viscous shock wave analysis. Computing the local behavior of the Evans function about 0 yields a sufficient condition for (ii) to hold true in $\mathcal{L}^2$. This condition is the same as for viscous shocks and is satisfied for shocks of small strength. But we show that, like for viscous shocks, there are too many bounded solutions of the equation $L \cdot Y = 0$. Hence condition (ii) does not hold in $\mathcal{L}^\infty$, contrary to what is required by Chow, Mallet-Paret, and Shen.

3.2. The change of frame point of view. The other point of view alluded to above was already used in [2]. It starts from the following (formal) observation. Solutions of the LDS (2.1) may be regarded as restrictions to $\mathbb{Z} \times \mathbb{R}^+$ of solutions of a "finite difference-PDE." Indeed, rewriting $v_j(t) = V(j\Delta x, t)$ as a solution of (2.1), we have

$$\begin{aligned} \frac{\partial V}{\partial t} + \frac{1}{\Delta x}\ & (g(V(x-(p-1)\Delta x,t),\dots,V(x+q\Delta x,t)) \\ & - g(V(x-p\Delta x,t),\dots,V(x+(q-1)\Delta x,t))) = 0. \end{aligned} \tag{3.7}$$

Introducing the change of variables $(\widetilde{x} := (x - \sigma t)/\Delta x, \widetilde{t} := t/\Delta x)$, $V(x,t) = \widetilde{V}(\widetilde{x},\widetilde{t})$ is a solution of (3.7) if and only if $\widetilde{V}$ solves

$$\frac{\partial \widetilde{V}}{\partial \widetilde{t}} - \sigma \frac{\partial \widetilde{V}}{\partial \widetilde{x}} + g(\widetilde{V}(\widetilde{x}-p+1,\widetilde{t}),\dots,\widetilde{V}(\widetilde{x}+q,\widetilde{t})) - g(\widetilde{V}(\widetilde{x}-p,\widetilde{t}),\dots,\widetilde{V}(\widetilde{x}+q-1,\widetilde{t})) = 0.$$

Dropping the tildes, this equation reads

$$\partial_t V - \sigma\,\partial_x V + g(V(x-p+1,t),\dots,V(x+q,t)) - g(V(x-p,t),\dots,V(x+q-1,t)) = 0, \tag{3.8}$$

of which semidiscrete profiles, solving (2.18), are obviously stationary solutions. Linearizing (3.8) about a stationary solution U yields the linear finite-difference PDE

$$\partial_t V - L\cdot V = 0, \tag{3.9}$$

where L is the spatial operator defined by

$$(L\cdot V)(x) = \sigma\,V'(x) - \sum_{l=-p}^{q} (\partial_l g(\,U(x-p+1),\dots,U(x+q)\,) - \partial_{l+1} g(\,U(x-p),\dots,U(x+q-1)\,)\cdot V(x+l). \tag{3.10}$$

We have adopted here the convention that

$$\partial_{-p} g \equiv 0 \qquad \text{and} \qquad \partial_{q+1} g \equiv 0.$$

To facilitate the reading, we shall use more compact notations, just writing

$$(L\cdot V)(x) = \sigma\,V'(x) - \sum_{l=-p}^{q} (\,C^l(x) - C^{l+1}(x-1)\,)\cdot V(x+l)$$

with

$$C^l(x) := \partial_l g(\,U(x-p+1),\dots,U(x+q)\,).$$

This is an abuse of notation since the matrices C^l were originally defined as functions of a (single) state $u\in\mathbb{R}^N$. Consistently, $C^l(\pm\infty)$ will stand for $C^l(u_\pm)$ and will merely be denoted by $C^l_\pm$.

We see on its definition (3.10) that L is a closed unbounded operator on $L^2(\mathbb{R})$, with dense domain H^1 in L^2. An easy preliminary result is the following.

PROPOSITION 3.3. *The operator L defined by* (3.10) *is the infinitesimal generator of a strongly continuous semigroup on $L^2(\mathbb{R})$.*

Proof. This follows from a consequence of the Hille–Yosida theorem. Since L is closed with dense domain, it is sufficient to prove that the resolvent set of L contains a ray $\{\lambda\in(M,+\infty)\}$ and that the resolvent enjoys the estimate

$$\|\,(\lambda - L\,)^{-1}\| \le \frac{1}{\lambda - M}$$

for $\lambda > M$ (see [19, p. 12]).[3] So assume that $(\lambda - L)\cdot V = W$. Taking the inner product with V gives the equality

$$\lambda\,\|V\|^2_{L^2(\mathbb{R})} + \int_{\mathbb{R}} V(x)\sum_{l=-p}^{q}(C^l(x) - C^{l+1}(x-1))\,dx = \langle\,V\,,\,W\,\rangle_{L^2(\mathbb{R})}.$$

[3] In fact, this result follows from our more precise Lemma 4.1 on the Green's function of $\lambda - L$; this is why we just show the estimate of the resolvent here.

Then by Cauchy–Schwarz inequality and the invariance of the L^2 norm under translation we get

$$(\,\lambda\,-\,2(p+q+1)\,\gamma\,)\,\|V\|_{L^2(\mathbb{R})}\,\le\,\|W\|_{L^2(\mathbb{R})},$$

where

$$\gamma\,:=\,\max\{\,\|\,C^l(x)\,\|_{\mathbb{R}^{N\times N}}\,;\;l\in\{-p+1,\dots,q\}\,,\;x\in\mathbb{R}\,\}.\qquad\square$$

In fact, a slightly more general energy estimate than in the above proof shows that any complex number λ satisfying $\mathrm{Re}\lambda > 2(p+q+1)\,\gamma$ belongs to the resolvent set of L. Of course, a natural spectral stability condition for the stationary solution U is that the whole open right half-plane lies in the resolvent set of L. This actually holds true simultaneously with the spectral condition (i) of Theorem 3.2 on the operator $\mathcal{R}$, due to the spectral mapping results that we show in the next subsections.

3.3. Link between the two points of view. It is clear that solutions V of (3.9) are related to solutions of (3.2) through the equality

$$v_j(t)\,=\,V(j\,-\,\sigma t/\Delta x\,,\,t/\Delta x\,).$$

In particular, at $t = T = \Delta x/\sigma$ we find that

$$v_j(T)\,=\,V(j-1,1/\sigma).$$

We can interpret this relation in terms of operators. Denoting by e^{tL} the semigroup associated with L and by P the mapping

$$\begin{array}{rccc} P\,: & \mathcal{C}(\mathbb{R}) & \to & \mathcal{L}^\infty \\ & V & \mapsto & (V(j))_{j\in\mathbb{Z}}, \end{array}$$

the previous equality means that

$$\mathcal{R}P\,=\,P\,\mathrm{e}^{\sigma^{-1}L}$$

on the domain ($H^1\subset\mathcal{C}(\mathbb{R})$) of L. This suggests that the spectrum of $\mathcal{R}$ is related to that of L. Even though P is obviously not invertible, we can prove some spectral mapping results. We study separately the essential spectrum and the point spectrum (i.e., the set of eigenvalues).

For clarity, we recall that the essential spectrum of an operator L can be defined by

$$\Sigma_{\mathrm{ess}}(L)\,=\,\{\,\lambda\in\mathbb{C}\,;\;(L\,-\,\lambda)\;\text{is }\textit{not}\text{ Fredholm index }0\,\}. \tag{3.11}$$

An alternative definition is that λ belongs to $\Sigma_{\mathrm{ess}}(L)$ if and only if λ belongs to the spectrum of $L+K$ for any compact operator K. Both definitions are equivalent for closed operators (see [22, p. 15]). With the first definition, it is clear that the whole spectrum $\Sigma(L)$ consists of the union of $\Sigma_{\mathrm{ess}}(L)$ and the set of eigenvalues.

3.4. Essential spectrum.

LEMMA 3.4. *The essential spectrum of the operator $\mathcal{R}$ defined in* (3.3) *and the essential spectrum of the operator L defined in* (3.10) *are such that*

$$\begin{aligned} &\Lambda(u_\pm)\,\subset\,\Sigma_{ess}(L)\,\subset\,\bigcup_{u\in\mathcal{U}}\Lambda(u)\,=:\,\Lambda,\\ &\Lambda(u)\,:=\,\{\,\lambda\in\mathbb{C}\,;\;\exists\xi\in\mathbb{R},\;\det\,(\,\Delta(\sigma;i\xi,u)\,-\,\lambda\,)\,=\,0\,\}, \end{aligned} \tag{3.12}$$

where the matrix Δ is defined as in (2.15)*, and*

$$\mathrm{e}^{\sigma^{-1}\Lambda(u_\pm)} \subset \Sigma_{ess}(\mathcal{R})\backslash\{0\} \subset \mathrm{e}^{\sigma^{-1}\Lambda}. \tag{3.13}$$

Proof. We begin with (3.12). The basic step consists of showing that $\Lambda(u_\pm)$ is exactly the spectrum of the asymptotic operator, $L_\pm$, defined by

$$(L_\pm \cdot V)(x) = \sigma V'(x) + \sum_{l=-p}^{q} (C_\pm^{l+1} - C_\pm^l) \cdot V(x+l). \tag{3.14}$$

Using Fourier transform, we readily see that λ belongs to $\Sigma(L_\pm)$ if and only if there exists $\xi \in \mathbb{R}$ so that the characteristic equation

$$\det(\Delta(\sigma; i\xi, u_\pm) - \lambda) = 0 \tag{3.15}$$

holds. This is precisely the definition of $\Lambda(u_\pm)$. Hence $\Sigma(L_\pm) = \Lambda(u_\pm)$. In fact, this is pure essential spectrum, as the following argument shows when applied to $L_\pm$ instead of L. For λ belongs to $\Sigma_{\mathrm{ess}}(L)$ as soon as there exists a sequence $(V^n)_{n\in\mathbb{N}}$, with $V^n \in H^1$ (the domain of L), which is orthonormal in L^2 and such that $(L-\lambda)V^n$ tends to 0 as n goes to ∞ (this easily implies that λ belongs to the spectrum of $L+K$ for any compact operator K). Now, (3.15) implies the existence of a vector r such that the function $V : x \mapsto \mathrm{e}^{i\xi x} r$ is an approximate eigenfunction of $L_\pm$; i.e., $(L_\pm - \lambda)V = 0$, but V does not belong to the domain of $L_\pm$. To construct a sequence V^n that fulfills the above requirements, it suffices to choose suitably supported $\mathcal{C}^\infty$ functions χ^n and take $V^n = \chi^n V/\|\chi^n V\|$. This is rather classical. The reader may check that a possible choice is

$$\begin{cases} \chi^n(x) = 1, & |x \mp 2n^2| \le n, \\ \chi^n(x) = \chi^1(x), & n \le |x \mp 2n^2| \le n+1, \\ \chi^n(x) = 0, & |x \mp 2n^2| \ge n+1. \end{cases}$$

This works because the supports of the χ^n do not intersect and the L^2 norms of $\chi^n V$ are $\mathcal{O}(n^{1/2})$, while the L^2 norms of $(L-\lambda)(\chi^n V)$ remain bounded, since $(L_\pm - \lambda)V = 0$ and the coefficients of L are converging rapidly enough (namely, exponentially fast) to the coefficients of $L_\pm$ at $\pm\infty$.

Hence all points of $\Sigma(L_\pm) = \Lambda(u_\pm)$ belong to $\Sigma_{\mathrm{ess}}(L)$. The other inclusion in (3.12) requires a tougher piece of analysis, for which we refer to a work by Mallet-Paret [16]. For if λ does not belong to Λ, in particular it is not in $\Sigma(L_\pm)$, and then the variational operator $(L-\lambda)$ is asymptotically hyperbolic according to the definition of Mallet-Paret. Therefore, by Theorems A and B in [16], $(L-\lambda)$ is Fredholm and its index depends only on $L_\pm$. The computation of the index is based on the spectrum flow formula (Theorem C in [16]), considering a homotopy connecting L_- to L_+. The simplest one is given by L_θ, the constant coefficient operator about $u(\theta)$, where $\theta \mapsto u(\theta)$ is any smooth curve between u_- and u_+. If $\lambda \notin \Lambda$, then, for all θ, $(L_\theta - \lambda)$ is hyperbolic in the sense of Mallet-Paret. Consequently, we find that the index of $(L-\lambda)$ equals 0, which precisely means that λ is not in the essential spectrum of L. This completes the proof of (3.12).

Regarding $\mathcal{R}$, a similar procedure works. It is to some extent easier due to the boundedness of $\mathcal{R}$. We first look at the spectrum of $\mathcal{R}_\pm = \mathcal{T}^{-1}\mathcal{S}_\pm(T)$, with $\mathcal{S}_\pm(t)$ the solution operator of the autonomous LDS

$$\frac{dv}{dt} = D\mathcal{G}(u_\pm)\cdot v. \tag{3.16}$$

By a slight abuse of notation, $u_\pm$ here stands for the constant sequence $(u_\pm)$. Pointwisely, (3.16) reads

$$\frac{dv_j}{dt} + \frac{1}{\Delta x}\sum_{l=-p}^{q} (C_\pm^l - C_\pm^{l+1})\cdot v_{j+l} = 0. \tag{3.17}$$

Equation (3.17) can be solved through discrete Fourier transform. To be precise, we fix some notations. Any slowly growing sequence w (for instance, bounded) can be associated with a tempered distribution of period 2π

$$\mathcal{F}w := \sum_{j\in\mathbb{Z}} w_j\, e^{-ij\xi}.$$

And, conversely, a tempered distribution g of period 2π is associated with the slowly growing sequence $\overline{\mathcal{F}}g$ (of its Fourier coefficients) defined by

$$\big(\overline{\mathcal{F}}g\big)_j := \frac{1}{2\pi}\langle\, g\,,\, e^{ij\xi}\,\rangle_{\mathbb{R}/2\pi\mathbb{Z}}.$$

Of course, we have $\overline{\mathcal{F}}\mathcal{F} = I$ and $\mathcal{F}\overline{\mathcal{F}} = I$ on the corresponding spaces.

Using that $\mathcal{F}\mathcal{T}^{-l} = \mathrm{e}^{il\xi}\mathcal{F}$ for all l, we find that the solution operator of (3.16) is given by

$$\mathcal{S}_\pm(t) = \overline{\mathcal{F}}\exp\left(\frac{t}{\Delta x}\sum_{l=-p}^{q}\mathrm{e}^{il\xi}(C_\pm^{l+1} - C_\pm^l)\right)\mathcal{F}.$$

Therefore, for all v and w in $\mathcal{L}^\alpha(\mathbb{Z})$, the relation

$$(\mathcal{R}_\pm - \zeta)\cdot w = v \tag{3.18}$$

is by definition of $\mathcal{R}_\pm$ equivalent to

$$\exp\left(i\xi + \frac{1}{\sigma}\sum_{l=-p}^{q}\mathrm{e}^{il\xi}(C_\pm^{l+1} - C_\pm^l)\right)\cdot\mathcal{F}w - \zeta\,\mathcal{F}w = \mathcal{F}v.$$

Rewriting this with $\zeta = e^{\lambda/\sigma}$ and using the matrix Δ introduced in (2.15), we obtain that (3.18) is equivalent to

$$\zeta\, B_\pm(i\xi,\lambda)\,\mathcal{F}w = \mathcal{F}v, \qquad B_\pm(i\xi,\lambda) := \mathrm{e}^{(\,\Delta(\sigma;i\xi,u_\pm) - \lambda)/\sigma} - I.$$

The special form of Δ and Lyapunov's theorem show that the matrix $B_\pm(i\xi,\lambda)$ is singular for $\xi\in\mathbb{R}$ if and only if $(\,\Delta(\sigma;i\widetilde{\xi},u_\pm) - \lambda\,)$ is singular for some $\widetilde{\xi}\equiv\xi[2\pi]$. Equivalently, $(\,\Delta(\sigma;i\xi,u_\pm) - \widetilde{\lambda}\,)$ is singular for some $\widetilde{\lambda}\equiv\lambda[2i\pi\sigma]$; that is, ζ belongs to $\exp(\Lambda(u_\pm)/\sigma)$.

This implies that

$$\Sigma(\mathcal{R}_\pm)\backslash\{0\} = \mathrm{e}^{\sigma^{-1}\Lambda(u_\pm)}.$$

As a matter of fact, elements of $\exp(\Lambda(u_\pm)/\sigma)$ are obviously eigenvalues of $\mathcal{R}_\pm$ (here the eigenvectors are genuine ones in $\mathcal{L}^\infty$). Conversely, if ζ is not in $\exp(\Lambda(u_\pm)/\sigma)$,

according to an observation already made by Rustichini [21], there exists $\gamma > 0$ such that $(\,\Delta(\sigma; z, u_\pm) - \lambda\,)$ is not singular in the strip $\{\,|\mathrm{Re} z| \le \gamma\,\}$. Indeed, the roots of the holomorphic function

$$z \mapsto \det(\,\Delta(\sigma; z, u_\pm) - \lambda\,)$$

have their imaginary parts bounded in terms of their real parts. Hence, $B_\pm(z, \lambda)$ is nonsingular for $|\mathrm{Re} z| \le \gamma$. As a consequence (see, for instance, Lemma 9 in [2]), $\varphi^\pm := \overline{\mathcal{F}}(\,B_\pm(i\xi, \lambda)\,)$ is exponentially decaying at infinity (with rate $\beta < \gamma$). Therefore, $(3.18)_\pm$ is equivalent to

$$w = \varphi^\pm * v, \quad \text{i.e.,} \quad w_j = \sum_{k\in\mathbb{Z}} \varphi^\pm_{j-k}\, v_k \quad \forall j \in \mathbb{Z},$$

and we have a constant C so that

$$\|w\|_\infty \le C\, \|v\|_\infty.$$

This means that ζ belongs to the resolvent set of $\mathcal{R}_\pm$.

Now we make an observation that is useful to get information on the essential spectrum of $\mathcal{R}$. Considering the simpler operator $\mathcal{R}_0 = \mathcal{T}^{-1}\,\mathcal{S}_0(T)$, where $\mathcal{S}_0$ is the solution operator of the autonomous equation

$$\frac{dv}{dt} = D\mathcal{G}(u^0)\cdot v \tag{3.19}$$

associated with the (stationary) fake profile defined by $u^0_j := u_-$, $j < 0$, $u^0_j := u_+$, $j \ge 0$, it is known from [6, Lemma 7.2] that $\mathcal{R} - \mathcal{R}_0$ is compact. Therefore, $\Sigma_{\mathrm{ess}}(\mathcal{R}) = \Sigma_{\mathrm{ess}}(\mathcal{R}_0)$.

So (3.13) is equivalent to

$$\mathrm{e}^{\sigma^{-1}\,\Lambda(u_\pm)} \subset \Sigma_{\mathrm{ess}}(\mathcal{R}_0)\backslash\{0\} \subset \mathrm{e}^{\sigma^{-1}\,\Lambda}.$$

To show that $\zeta \in \mathrm{e}^{\sigma^{-1}\Lambda(u_\pm)}$ belongs to $\Sigma_{\mathrm{ess}}(\mathcal{R}_0)$, it is sufficient to find a sequence (w^n) with no limit point and $\|w^n\|_{\mathcal{L}^\infty} = 1$ such that $(\mathcal{R}_0 - \zeta)\, w^n$ tends to 0. (This is the same argument as the one used for L, except that we cannot use orthonormal sequences here.) On the contrary, if $\zeta \notin \mathrm{e}^{\sigma^{-1}\Lambda}$, we can show that $(\mathcal{R}_0 - \zeta)$ is Fredhlom index 0. The proof relies on pointwise estimates for the resolvent of both $\mathcal{R}_0$ and its *antiadjoint* $\mathcal{R}_0^*$. By this we mean, doing a slight abuse of notation, that $\mathcal{R}_0$ is the adjoint of $\mathcal{R}_0^*$. The latter is in fact related to the adjoint LDS

$$\frac{dz}{dt} = -\,(\,D\mathcal{G}(u^0)\,)^*\cdot z \tag{3.20}$$

through the formula $\mathcal{R}_0^* := \mathcal{S}_0^*(-T)\,\mathcal{T}$, where $\mathcal{S}_0^*$ is the solution operator on $\mathcal{L}^1(\mathbb{Z})$ of (3.20). For completeness, we recall those pointwise estimates in Proposition 3.5. That they imply $\mathcal{R}_0$ is Fredholm is a standard exercise. The calculation of the index uses again a homotopy argument. For more details, the reader may refer to [2, Section 4]. □

PROPOSITION 3.5. *For $\zeta \notin \mathrm{e}^{\sigma^{-1}\Lambda(u_-)} \bigcup \mathrm{e}^{\sigma^{-1}\Lambda(u_+)}$, there exists $C_0 > 0$ and $\beta > 0$ such that for $w \in \mathcal{L}^\infty$,*

$$|\,w_j\,| \le C_0\ (\,\|(\mathcal{R}_0 - \zeta)\cdot w\|_\infty + \ e^{-\,\beta\,|j|}\,\|w\|_\infty\,) \quad \forall j \in \mathbb{Z}, \tag{3.21}$$

and for $z \in \mathcal{L}^1$,

$$|\, z_j \,| \,\le\, C_0 \;(\, \|(\mathcal{R}_0^* - \bar{\zeta}) \cdot z\|_1 \,+\, e^{-\,\beta\,|j|}\, \|z\|_1 \,) \quad \forall j \in \mathbb{Z}. \tag{3.22}$$

Proof. The proof relies on Duhamel's formula

$$\mathcal{S}_0(t) \cdot w \,=\, \mathcal{S}_+(t) \cdot w \,+\, \int_0^t \mathcal{S}_+(t-\tau) \cdot (\,(D\mathcal{G}(u^0) \,-\, D\mathcal{G}(u_+))\mathcal{S}_0(\tau) \cdot w)\, d\tau \tag{3.23}$$

and convolution estimates. The rate β is imposed by the width of the vertical strip in which $(\,\Delta(\sigma; z, u_\pm) \,-\, \lambda\,)$ is nonsingular. See Propositions 3.4.1 and 3.4.2 in [2]. ∎

The proof of Lemma 3.4 actually shows that (3.12) holds with a restricted definition of Λ, $\cup\Lambda(u)$ for u describing a curve connecting u_- to u_+ in $\mathcal{U}$. We have left the whole set $\mathcal{U}$ for simplicity.

We complete this subsection by showing that our assumptions on the scheme eliminate the possibility of having unstable essential spectrum. By unstable we mean spectrum of positive real part regarding L and spectrum of modulus greater than 1 regarding $\mathcal{R}$. In view of Lemma 3.4, this amounts to showing that the set Λ lies in the right half-plane. In fact, we have a slightly more precise result.

THEOREM 3.6. *For* 3*-point schemes (i.e.,* $p = q = 1$*) satisfying* (H1) *and* (H3), *the operators* $\mathcal{R}$*, defined in* (3.3)*, and* L*, defined in* (3.10)*, are such that*

$$\Sigma_{ess}(\mathcal{R}) \,\subset\, \{\,\zeta \in \mathbb{C};\; |\zeta| < 1\} \cup \{1\},$$

$$\Sigma_{ess}(L) \,\subset\, \{\,\lambda \in \mathbb{C};\; \mathrm{Re}\lambda < 0\} \cup 2\,i\,\pi\,\sigma\,\mathbb{Z}.$$

Proof. In view of (3.12)–(3.13), this amounts to showing that for any $u \in \mathcal{U}$, for $\mathrm{Re}\lambda \ge 0$, and for $\lambda \notin 2\,i\,\pi\,\sigma\,\mathbb{Z}$,

$$\det(\,\Delta(\sigma; i\xi, u) \,-\, \lambda\,) \,\neq\, 0 \quad \forall\, \xi \in \mathbb{R}.$$

For 3-point schemes, this is easy. As a matter of fact, the coefficients of the diagonalized $\Delta(\sigma; i\xi, u)$ are of nonpositive real part, as already noticed in section 2.2. Hence $\Delta(\sigma; i\xi, u)$ does not have any eigenvalue of positive real part. Furthermore, $\Delta(\sigma; i\xi, u)$ has a purely imaginary eigenvalue only if ξ belongs to $2\pi\mathbb{Z}$, and then that eigenvalue is $\lambda = \sigma\xi$. For schemes with larger stencil, (H1) and (H3) imply that the real parts of the coefficients of the diagonalized $\Delta(\sigma; i\xi, u)$ have a local maximum at $\xi = 0$. With the additional assumption that those coefficients achieve their global maximum on $[-\pi, \pi]$ at $\xi = 0$, then we would get the same conclusion as for 3-point schemes. ∎

3.5. Point spectrum. With regard to the point spectrum of $\mathcal{R}$, an interesting preliminary result is the following.

PROPOSITION 3.7. *If* $\zeta \notin \exp(\Lambda/\sigma)$*, where* Λ *is defined as in* (3.12)*, and* ζ *is an eigenvalue of* $\mathcal{R}$ *in* $\mathcal{L}^\infty$*, then the corresponding eigenvector* w *is actually exponentially decaying and thus belongs to all the spaces* $\mathcal{L}^\alpha(\mathbb{Z})$ *for* $\alpha \in \mathbb{N}^*$.

Proof. The proof relies on a pointwise estimate similar to (3.21) but for $\mathcal{R}$ instead of $\mathcal{R}_0$. As a matter of fact, we can show the existence of a constant C and $\alpha > 0$ such that for all $w \in \mathcal{L}^\infty$

$$|\, w_j \,| \,\le\, C \;(\, \|(\mathcal{R} - \zeta) \cdot w\|_\infty \,+\, e^{-\,\alpha\,|j|}\, \|w\|_\infty \,) \quad \forall j \in \mathbb{Z}. \tag{3.24}$$

The proof of (3.24) is very similar to that of Proposition 3.5. Rewrite (3.2) as

$$\frac{dv}{dt} \,=\, D\mathcal{G}(u_\pm)\cdot v \,+\, \mathcal{E}^\pm v, \quad \mathcal{E}^\pm \,=\, D\mathcal{G}(u) \,-\, D\mathcal{G}(u_\pm),$$

and deduce that $v \,=\, (\mathcal{R} \,-\zeta)\cdot w$ is equivalent to

$$w \,=\, \varphi^\pm \,*\, \left(v \,-\, \mathcal{T}^{-1} \int_0^T \psi^\pm(T-t) * (\mathcal{E}^\pm \mathcal{S}(t)\cdot w)\, dt \right),$$

where the kernels $\varphi^\pm$ and $\psi^\pm$ decay exponentially fast at $\pm\infty$. More precisely, $\varphi^\pm$ decay at most like $e^{-\beta|j|}$, where $\beta > 0$ is determined by a spectral gap argument, and $\psi^\pm$ is an $\mathcal{O}(e^{-\delta|j|})$ for δ arbitrarily large. Using a uniform bound for $\mathcal{S}(t)$ for $t \in [0,T]$ and the exponential decay (2.22) of the profile, we obtain by a convolution estimate that

$$\int_0^T \psi^\pm(T-t) * (\mathcal{E}^\pm \mathcal{S}(t)\cdot w)\, dt \,\le\, C\, \mathrm{e}^{\theta_\pm\, j}\, \|w\|_\infty, \quad \pm j > 0.$$

Convolution by $\varphi^\pm$ eventually yields (3.24) with $\alpha = \min(\beta, \theta^-, -\theta^+)$. ∎

We can now prove a kind of spectral mapping theorem regarding the point spectrum of the operators $\mathcal{R}$ and L. It is in fact partly contained in [6]. The result about multiplicities seems to be new though.

THEOREM 3.8. *We consider the point spectrum, $\Sigma_p^\alpha(L)$, of the operator L defined by* (3.10) *on $W^{1,\alpha}$, $1 \le \alpha \le \infty$, and the point spectrum of the operator $\mathcal{R}$ defined in* (3.3) *and acting on $\mathcal{L}^\alpha$, that is,*

$$\Sigma_p^\alpha(\mathcal{R}) \,:=\, \{\zeta \in \mathbb{C}\,;\; \exists w \neq 0 \in \mathcal{L}^\alpha\,,\; \mathcal{R}\cdot w \,=\, \zeta\, w\,\}.$$

Then

$$\Sigma_p^\alpha(\mathcal{R})\backslash\{0\} \,=\, \mathrm{e}^{\sigma^{-1}\,\Sigma_p^\alpha(L)}. \tag{3.25}$$

Furthermore, if ζ is a nonzero eigenvalue of $\mathcal{R}$ and $\zeta = \mathrm{e}^{\lambda/\sigma}$, then the multiplicity of λ as an eigenvalue of L equals the multiplicity of ζ as an eigenvalue of $\mathcal{R}$.

Proof. Assume that $\mathcal{R}\cdot w \,=\, \zeta\, w$ and consider any λ such that $\zeta = \mathrm{e}^{\lambda/\sigma}$. We may preferably write

$$\mathrm{e}^{\lambda/\sigma} \,=\, \mathrm{e}^{\underline{\lambda}\, T}, \quad \text{with} \quad \underline{\lambda} := \frac{\lambda}{\Delta x}.$$

We associate with λ and w the evolving sequence

$$y(t) \,:=\, \mathrm{e}^{-\underline{\lambda} t}\, \mathcal{S}(t,0)\cdot w.$$

It obviously solves the LDS

$$\frac{dy}{dt} \,=\, (\, D\mathcal{G}(u) \,-\, \underline{\lambda}\,)\cdot y. \tag{3.26}$$

Furthermore, y is a traveling wave of speed s. As a matter of fact, it is easy to check that (3.1) holds for $v = y$. We have

$$y(t+T) \,=\, \mathrm{e}^{-\underline{\lambda}(t+T)}\, \mathcal{S}(t+T,0)\cdot w \,=\, \frac{\mathrm{e}^{-\underline{\lambda} t}}{\zeta}\, \mathcal{S}(t+T,T)\mathcal{S}(T,0)\cdot w.$$

By assumption on ζ and w and because of (3.4) we have

$$\mathcal{S}(t+T,T)\mathcal{S}(T,0)\cdot w \;=\; \zeta\,\mathcal{S}(t+T,T)\mathcal{T}\cdot w \;=\; \zeta\,\mathcal{T}\mathcal{S}(t,0)\cdot w,$$

and thus we conclude that $y(t+T) \;=\; \mathcal{T}\cdot y(t)$. Therefore, we have $y_j(t) \;=\; Y(j-st)$. Substituting in (3.26) and multiplying by Δx, we get

$$-\sigma\,Y'(x) \;=\; \sum_{l=-p}^{q} \partial_l G(\,U(x-p),\dots,U(x+q)\,)\cdot Y(x+l) \;-\; \lambda Y(x)$$

for $x = j - st$, that is, $(L-\lambda)\cdot Y \;=\; 0$. (Recall that $s\Delta x = \sigma$.)

Conversely, if $(L-\lambda)\cdot Y \;=\; 0$, then the sequence w defined by $w_j := Y(j)$ is an eigenvector of $\mathcal{R}$ for the eigenvalue $\mathrm{e}^{\lambda/\sigma}$. This follows from the fact that $y_j(t) := Y(j-st)$ solves (3.26); hence

$$\mathrm{e}^{\lambda t/\Delta x}\,y(t) \;=\; \mathcal{S}(t,0)\,y(0).$$

At $t = T$ this precisely means, since y is by construction a traveling wave, that

$$\mathrm{e}^{\lambda/\sigma}y(0) \;=\; \mathcal{R}\cdot y(0).$$

Observe that if $\mathrm{e}^{\widetilde{\lambda}/\sigma} = \mathrm{e}^{\lambda/\sigma}$, that is, if $\widetilde{\lambda} = \lambda + 2i\pi m\sigma$ with m an integer, then $(L-\widetilde{\lambda})$ and $(L-\lambda)$ are conjugated under the multiplication by $\mathrm{e}^{2i\pi mx}$. Therefore, the multiplicity of λ as an eigenvalue of L does not depend on the chosen representation of ζ. Furthermore, if Y and $\widetilde{Y}$ are, respectively, associated with λ and $\widetilde{\lambda}$, they yield the same eigenvector $w_j \;=\; Y(j) \;=\; \widetilde{Y}(j)$ of $\mathcal{R}$ since $\mathrm{e}^{2i\pi mj} \;=\; 1$. This argument shows that the geometric multiplicities of ζ and λ coincide.

With regard to the algebraic multiplicities, a similar but more technical argument works to show that they do coincide. We leave the general, cumbersome proof to the reader. For clarity, we present the proof in the case of double nonsemisimple eigenvalues. Assume that λ is a double, nonsemisimple eigenvalue of L. Then there exist Y and Z such that

$$L\cdot Y \;=\; \lambda Y, \qquad L\cdot Z \;=\; \lambda Z \;+\; Y.$$

Let y and z be defined by

$$y_j(t) \;:=\; Y(j-st), \qquad z_j(t) \;:=\; Z(j-st).$$

Then y solves (3.26), while z solves the LDS

$$\frac{dz}{dt} \;=\; (\,D\mathcal{G}(u) \;-\; \underline{\lambda}\,)\cdot z \;-\; \underline{y}, \tag{3.27}$$

where $\underline{\lambda} \;=\; \lambda/\Delta x$, as denoted above, and similarly $\underline{y} \;=\; y/\Delta x$. Hence by Duhamel's formula we get

$$\mathrm{e}^{\underline{\lambda}t}\,z(t) \;=\; \mathcal{S}(t,0)\cdot z(0) + \int_0^t \mathcal{S}(t,\tau)\cdot(-\mathrm{e}^{\underline{\lambda}\tau}\,\underline{y}(\tau))\,d\tau \;=\; \mathcal{S}(t,0)\cdot z(0) - \frac{t}{\Delta x}\,\mathcal{S}(t,0)\cdot y(0).$$

At $t = T$ this gives

$$\mathrm{e}^{\lambda T}z(0) \;=\; \mathcal{R}\cdot z(0) \;-\; \frac{1}{\sigma}\,\mathrm{e}^{\lambda/\sigma}\,y(0).$$

Therefore, $z(0)$ belongs to $\mathrm{Ker}(\mathcal{R}-\zeta)^2\backslash\mathrm{Ker}(\mathcal{R}-\zeta)$, which means that the algebraic multiplicity of ζ is at least 2. Conversely, if $\zeta \neq 0$ is a double, nonsemisimple eigenvalue of $\mathcal{R}$, there exist w and v such that

$$\mathcal{R}\cdot w \,=\, \zeta w, \qquad \mathcal{R}\cdot v \,=\, \zeta(\, v \,+\, w/\sigma\,).$$

Then both

$$y(t) \,:=\, \mathrm{e}^{-\frac{\lambda}{\Delta}t}\,\mathcal{S}(t,0)\cdot w$$

and

$$z(t) \,:=\, \mathrm{e}^{-\frac{\lambda}{\Delta}t}\left(\mathcal{S}(t,0)\cdot v \,-\, \frac{t}{\Delta x}\,\mathcal{S}(t,0)\cdot w\right)$$

are traveling waves of speed σ—this is proved using (3.4) again. Introducing Y and Z so that

$$y_j(t) \,=\, Y(j-st), \qquad z_j(t) \,=\, Z(j-st)$$

and reversing the computation done before, we see that

$$L\cdot Y \,=\, \lambda Y, \qquad L\cdot Z \,=\, \lambda Z \,+\, Y.$$

Thus the algebraic multiplicity of λ is at least 2. ∎

In view of Theorems 3.6 and 3.8, checking the stability condition in (3.6) amounts to showing that

$$\Sigma_{\mathrm{p}}(L) \,\subset\, \{\,\lambda\in\mathbb{C}\,;\ \mathrm{Re}\lambda<0\}\cup 2\,i\,\pi\,\sigma\,\mathbb{Z}.$$

In some special cases (scalar conservation laws or shocks of small amplitude), (3.6) can be checked through energy estimates. This is performed in the next section. For arbitrary shocks, $\Sigma_{\mathrm{p}}(L)$ is encoded in an Evans function, the construction of which was derived in [2] for the upwind scheme. There is some indication in very recent results due independently to Mallet-Paret and Verduyn Lunel [17] and Härterich, Sandstede, and Scheel [10] that an Evans function might also be constructed for general schemes. This is discussed in section 3.7. With regard to condition (ii) in Theorem 3.2, we also show in section 3.7 that it must fail. We propose a weaker condition, in terms of the Evans function, which ensures stability though.

3.6. Energy estimates. The aim of this section is to deduce from energy estimates the spectral condition (i) of Theorem 3.2 for the point spectrum of $\mathcal{R}$ in the case of small shocks. Our method is very much inspired from that of Goodman [9] (also see [13]). In particular, it relies on a special diagonalization process and on the trick that consists of "integrating" the variational system (2.2) *before* deriving estimates. However, some additional difficulties are due to the mixing of true derivatives with discrete derivatives. This is why we need rather fine properties of profiles, as they are stated in Proposition 2.4.

To simplify the writing, we perform here a rescaling and set $\Delta x = 1$. Also, for the sake of clarity, we present the energy estimates procedure in the case of the *upwind scheme*, for which $p = 1$, $q = 0$. But the very same method works for the more general scheme (2.1).

In the case $p = 1$, $q = 0$, the semidiscrete system (2.1), or (2.2), then reduces to

$$\frac{dv_j}{dt} + f(v_j) - f(v_{j-1}) = 0$$

and the linearized system (3.2) reduces to

$$\frac{dv_j}{dt} + A_j\, v_j - A_{j-1}\, v_{j-1} = 0, \tag{3.28}$$

where $A_j := A(u_j)$. The viscosity matrix here reduces to $Q = A$, and the dissipativeness requirement (H1) is that A has positive eigenvalues (which is, by the way, the appropriate condition for the linear stability of constant states). As for viscous shocks, a direct estimate on (3.28) is useless. To be convincing, let us multiply (3.28) by v_j and sum on j. We get

$$\frac{d}{dt}\left(\sum_{j=-\infty}^{+\infty} |v_j|^2\right) + 2\sum_{j=-\infty}^{+\infty} v_j\,(A_j\, v_j - A_{j-1}\, v_{j-1}) = 0.$$

Assuming for awhile that the matrices A_j are symmetric (for instance diagonal), we have the identity

$$2\langle v, Av - \mathcal{T}(Av)\rangle = \langle v - \mathcal{T}v, (\mathcal{T}A)(v - \mathcal{T}v)\rangle + \langle v, (A - \mathcal{T}A)v\rangle. \tag{3.29}$$

Here and below in this section, the brackets $\langle\ ,\ \rangle$ stand for the inner product in $\mathcal{L}^2(\mathbb{Z})$, and the associated norm will be denoted by $\|\ \|$. Substituting (3.29) in the previous equality, we obtain

$$\frac{d}{dt}\|v\|^2 + \langle v - \mathcal{T}v, (\mathcal{T}A)(v - \mathcal{T}v)\rangle + \langle v, (A - \mathcal{T}A)v\rangle = 0.$$

By (H1) and thus $A = Q > 0$, the term $\langle v - \mathcal{T}v, (\mathcal{T}A)(v - \mathcal{T}v)\rangle$ is nonnegative. But the term $\langle v, (A - \mathcal{T}A)v\rangle$ is typically not. For instance, in the scalar case, the characteristic speed a is decreasing along the profile and thus $(A - \mathcal{T}A)$ is nonpositive.

Similarly as for viscous shocks [9], this problem can be fixed by considering an "integrated" version of (3.28). Assume that $|\zeta| \geq 1$ and $\zeta \neq 1$ is an eigenvalue of $\mathcal{R}$, and w is a corresponding eigenvector. By Theorem 3.6, $\zeta \notin \exp(\Lambda/\sigma)$. Then Proposition 3.7 shows that w is summable and thus $v(t) := \mathcal{S}(t, 0)\cdot w$ is summable for all t. Furthermore, we see by summing (3.28) that $\sum_j v_j(t) = \sum_j w_j$. This is due to the conservativity of the scheme. In particular, this shows that $\sum \mathcal{R}\cdot w = \sum w$. But we also have by assumption on w that $\sum \mathcal{R}\cdot w = \zeta \sum w$. Therefore, since $\zeta \neq 1$, we must have

$$\sum_{j=-\infty}^{+\infty} w_j = 0.$$

This allows us to define

$$W_j := \sum_{i=-\infty}^{j} w_i = -\sum_{i=j+1}^{+\infty} w_i.$$

Furthermore, this new sequence W is exponentially decaying and thus belongs to all the spaces $\mathcal{L}^\alpha(\mathbb{Z})$ by Proposition 3.7. Now it is easy to see that $V_j(t) := \sum_{i=-\infty}^{j} v_i(t)$ satisfies the "integrated" LDS

$$\frac{dV_j}{dt} + A_j\,(V_j - V_{j-1}) = 0. \tag{3.30}$$

Performing a similar computation as on the original LDS and using the identity

$$2\,\langle v\,,\,A(v-\mathcal{T}v)\rangle = \langle v-\mathcal{T}v\,,\,A(v-\mathcal{T}v)\rangle + \langle v\,,\,(A-\mathcal{T}^{-1}A)\,v\rangle, \tag{3.31}$$

which is valid for symmetric matrices A_j, we obtain

$$\frac{d}{dt}\|V\|^2 + \langle V-\mathcal{T}V\,,\,A(V-\mathcal{T}V)\rangle + \langle V\,,\,(A-\mathcal{T}^{-1}A)\,V\rangle = 0.$$

We observe that the sign of $\langle V\,,\,(A-\mathcal{T}^{-1}A)\,V\rangle$ is now the good one, at least in the scalar case. For systems we must cope with the fact that, in general, the matrices A_j are not symmetric and that only $\langle V\,,\,(a^k-\mathcal{T}^{-1}a^k)\,V\rangle$ is nonnegative. This is done below by using two essential tools originally due to Goodman [9], a special diagonalization process and weights on the outgoing waves. We first state the theorem.

THEOREM 3.9. *Assuming* (H1), (H2), *and* (H3), *for sufficiently small shock profiles, the* $\mathcal{L}^1$ *solutions of* (3.2) *with zero mass are such that* $V_j := \sum_{i=-\infty}^{j} v_j$ *satisfy an estimate*

$$\tilde{\|}\,\mathcal{T}^{-1}V(T)\,\tilde{\|}^2_{\mathcal{L}^2} + \omega\int_0^T \|\,V(t) - \mathcal{T}V(t)\,\|^2_{\mathcal{L}^2}\,dt \le \tilde{\|}\,V(0)\,\tilde{\|}^2_{\mathcal{L}^2} \tag{3.32}$$

for some positive ω, *where* $\tilde{\|}\cdot\tilde{\|}$ *is an equivalent norm on* $\mathcal{L}^2$. *As a consequence,* $\mathcal{R}$ *does not have any eigenvalue* $\zeta \neq 1$ *with* $|\zeta| \ge 1$.

Proof. The last statement follows directly from (3.32) and the above argument. As a matter of fact, if $\mathcal{R}\cdot w = \zeta w$ with $|\zeta| \ge 1$ and $\zeta \neq 1$, then $v(t) = \mathcal{S}(t,0)\cdot w$ is such that $v(T) = \zeta\mathcal{T}\,v(0)$. Thus, taking the sum, $V(T) = \zeta\mathcal{T}\,V(0)$, and substituting in (3.32) we get a contradiction unless $|\zeta| = 1$ and $V \equiv \mathcal{T}V$. The latter equality implies by definition of V that $v = 0$ and thus also $w = 0$. So the whole proof is devoted to the energy estimate (3.32), which will appear to be a direct consequence of Lemma 3.10. More precisely, with the notations introduced below, (3.32) follows from (3.35) with

$$\tilde{\|}V\tilde{\|}^2_{\mathcal{L}^2} := \sum_{m\neq k} \|\phi^m(0)\,\ell^m(u(0))\,V\|^2 + \|\ell^k(u(0))\,V\|^2$$

and using the characterization of traveling waves in (3.1) for $\phi^m\,\ell^m$ and ℓ^k. ∎

Let us first describe the diagonalization process. To simplify the notations we write

$$\ell^m_j = \ell^m(u_j) \quad\text{and}\quad r^m_j = r^m(u_j).$$

The important property to have in mind is that the ℓ^m and r^m defined this way are traveling with speed s. Since the profile is exponentially decaying, it is now possible to renormalize ℓ^m and r^m in such a way that

$$\left(\frac{d}{dt}\ell^m_j\right)\cdot r^m_j \equiv \ell^m_j\cdot\frac{d}{dt}r^m_j \equiv 0. \tag{3.33}$$

This is achieved by considering

$$\widetilde{\ell}_j^m \,=\, \frac{1}{\nu_j^m}\,\ell_j^m \quad \text{and} \quad \widetilde{r}_j^m \,=\, \nu_j^m\, r_j^m,$$

with

$$\nu_j^m(t) \,:=\, \nu^m(j-st) \,=\, \exp\,\left(-\int_0^{j-st} \ell^m(U(x))\cdot\frac{d}{dx}\,r^m(U(x))\,dx\right).$$

It is important to note that the weight ν^m is traveling with the speed s, and thus also the new vectors $\widetilde{\ell}^m$ and $\widetilde{r}^m$. Furthermore, we easily check that $\widetilde{\ell}^m$ and $\widetilde{r}^m$ satisfy (3.33).

From now on, we drop the tildes and assume that (3.33) holds for all $m \in \{1,\dots,N\}$.

Further notations. We denote

$$L_j := \begin{pmatrix} -\ell_j^1- \\ \vdots \\ -\ell_j^N- \end{pmatrix} \quad \text{and} \quad R_j := \begin{pmatrix} | & & | \\ r_j^1 & \cdots & r_j^N \\ | & & | \end{pmatrix},$$

the square matrices made of eigenvectors satisfying (3.33), and

$$a_j \,=\, L_j\, A_j\, R_j \,=\, \text{diag}\,(a_j^1,\dots,a_j^N).$$

This is consistent with the notations introduced in section 2.1. And from now on in this section,

$$v_j \,:=\, L_j\cdot V_j,$$

which has nothing to do with the $v = V - \mathcal{T}V$—satisfying (3.28)—originally considered. We hope that this choice of notation will not be confusing to the reader. Observe that, conversely,

$$V_j \,=\, R_j\cdot v_j.$$

Multiplying (3.30) on the left by L_j, we get the LDS satisfied by v,

$$\frac{dv_j}{dt} \,+\, a_j\,(\,v_j \,-\, v_{j-1}\,) \,=\, \frac{dL_j}{dt}\,R_j\,v_j \,+\, a_j\,L_j\,(\,R_{j-1} \,-\, R_j\,)\,v_{j-1}. \tag{3.34}$$

Lemma 3.10. *Assuming that* (H1)–(H3) *hold,*[4] *there exist* $\varepsilon_0 > 0$, *weights* $\phi^m(t)$, *uniformly bounded from below in* $\mathcal{L}^\infty$ *and traveling with speed* s, *and* $\omega > 0$ *so that if the* k*-shock has an amplitude* $\varepsilon = |u_+ - u_-|$ *less than* ε_0 *and if* v *solves* (3.34), *then*

$$\begin{aligned}\sum_{m\neq k} \|\phi^m(T)v^m(T)\|^2 \,+\, \|v^k(T)\|^2 \,+\, \omega\int_0^T \|\,v \,-\, \mathcal{T}v\,\|^2 \\ \leq \sum_{m\neq k} \|\phi^m(0)v^m(0)\|^2 \,+\, \|v^k(0)\|^2.\end{aligned} \tag{3.35}$$

[4]We recall that for the upwind scheme, (H2) is implied by (H1), and (H3) is trivial.

Proof. The proof proceeds in two steps. We begin by showing that

(3.36)
$$\frac{d}{dt}\|v\|^2 + \frac{\mu}{2}\|v - \mathcal{T}v\|^2 + \frac{1}{2}\langle v^k, (a^k - \mathcal{T}^{-1}a^k)v^k\rangle \leq cst\,\langle \check{v}, (a^k - \mathcal{T}^{-1}a^k)\check{v}\rangle,$$

where $\check{v}$ is defined by $\check{v}^m = v^m$, $m \neq k$, and $\check{v}^k = 0$. Afterwards, we shall construct weights ϕ^m yielding estimates of the "outgoing waves" that can absorb the right-hand side of (3.36), thus showing that

$$\sum_{m\neq k} \|\phi^m(t)v^m(t)\|^2 + \|v(t)\|^2$$

is strictly decreasing with t.

Proof of (3.36). Taking the inner product of (3.34) with v we get

$$\frac{d}{dt}\|v\|^2 + 2\langle v, a(v - \mathcal{T}v)\rangle = 2\left\langle v, \frac{dL}{dt}Rv\right\rangle + 2\langle v, aL(\mathcal{T}R - R)\mathcal{T}v\rangle.$$

Applying the identity (3.31) to the diagonal matrix a, this also reads

$$\begin{aligned}\frac{d}{dt}\|v\|^2 + \langle v - \mathcal{T}v, a(v - \mathcal{T}v)\rangle + \langle v, (a - \mathcal{T}^{-1}a)v\rangle \\ = 2\left\langle v, \frac{dL}{dt}Rv\right\rangle + 2\langle v, aL(\mathcal{T}R - R)\mathcal{T}v\rangle.\end{aligned} \tag{3.37}$$

By (2.21) there is a constant such that

$$|a - \mathcal{T}^{-1}a| \leq cst\,(a^k - \mathcal{T}^{-1}a^k) = cst\,|a^k - \mathcal{T}^{-1}a^k|.$$

Hence we see that, if the right-hand side in (3.37) equals 0 (which occurs if the system (3.30) is already diagonal), (3.37) trivially implies (3.36). In order to deal with the general right-hand side, we use in a crucial way the special normalization of the eigenvectors (3.33). As a matter of fact, (3.33) implies that the diagonal coefficients of the matrices $\frac{dL_j}{dt}R_j$ are zero. (In fact, we need only that the coefficient $\frac{d\ell_j^k}{dt}r_j^k$ be zero.) And by (2.21) all the other coefficients are bounded by a constant times $(a_j^k - a_{j+1}^k)$. Therefore, for all $\gamma > 0$ there exists $c_\gamma > 0$ such that

$$2\left\langle v, \frac{dL}{dt}Rv\right\rangle \leq \gamma\langle v^k, (a^k - \mathcal{T}^{-1}a^k)v^k\rangle + c_\gamma\langle \check{v}, (a^k - \mathcal{T}^{-1}a^k)\check{v}\rangle.$$

The last term in (3.37) is the most complicated to deal with. We first split it as follows:

$$\langle v, aL(\mathcal{T}R - R)\mathcal{T}v\rangle = \langle v, aL(\mathcal{T}R - R)v\rangle + \langle v, aL(\mathcal{T}R - R)(\mathcal{T}v - v)\rangle.$$

The diagonal of the matrices $a_j L_j (R_{j-1} - R_j)$ occurring here is not necessarily zero. However, the diagonal coefficients are of order 2 in terms of the shock strength ε, and the other coefficients are of order 1, as we show just after. Consequently, for all $\gamma > 0$ there is a constant still denoted c_γ (up to augmenting the previous one) so that, on the one hand,

$$2\langle v, aL(\mathcal{T}R - R)v\rangle \leq (\varepsilon + \gamma)\langle v^k, (a^k - \mathcal{T}^{-1}a^k)v^k\rangle + c_\gamma\langle \check{v}, (a^k - \mathcal{T}^{-1}a^k)\check{v}\rangle,$$

and, on the other hand,

$$2\,\langle\, v\,,\, a\,L\,(\,\mathcal{T}R\,-\,R\,)\,(\,\mathcal{T}v\,-\,v\,)\,\rangle\,\le\,\gamma\,\|\,\mathcal{T}v\,-\,v\,\|^2+\,c_\gamma\,\varepsilon\,\langle\, v\,,\,(\,a^k\,-\,\mathcal{T}^{-1}a^k\,)\,v\,\rangle.$$

Collecting these estimates altogether and substituting the resulting inequality in (3.37), we obtain (3.36) by choosing $\gamma \le \mu/2$ (the lower bound of a which is positive by (H1)) and $\varepsilon \le \varepsilon_0 = (1-2\gamma)/(2(1+c_\gamma))$. □

Estimates on the matrices $L_j\,(\,R_{j-1}\,-\,R_j\,)$. We first note that

$$r^m_{j-1}(t)\,-\,r^m_j(t)\,=\,r^m_j(t+T)\,-\,r^m_j(t)\,=\,\int_t^{t+T}\,\frac{d}{d\tau}r^m(U(j-s\tau))\,d\tau$$

is bounded by a constant times $(\,a^k_j\,-\,a^k_{j+1}\,)$, in view of (2.21). Then, leading further the procedure, we see that

$$\ell^m_j(t)\,(\,r^m_{j-1}(t)\,-\,r^m_j(t)\,)\,=\,\int_t^{t+T}\,(\,\ell^m_j(t)\,-\,\ell^m_j(\tau)\,)\,\frac{d}{d\tau}r^m(U(j-s\tau))\,d\tau$$

because of (3.33), and thus

$$\ell^m_j(t)\,(\,r^m_{j-1}(t)\,-\,r^m_j(t)\,)\,=\,\int_t^{t+T}\,\int_\tau^t\,\frac{d}{d\theta}\ell^m(U(j-s\theta))\,d\theta\,\frac{d}{d\tau}r^m(U(j-s\tau))\,d\tau$$

is bounded by a constant times $(\,a^k_j\,-\,a^k_{j+1}\,)^2$, using twice (2.21). □

Proof of the outgoing waves estimates. The mth component of (3.34) reads

$$\frac{dv^m_j}{dt}\,+\,a^m_j\,(\,v^m_j\,-\,v^m_{j-1}\,)\,=\,\frac{d\ell^m_j}{dt}\,R_j\,v_j\,+\,a^m_j\,\ell^m_j\,(\,R_{j-1}\,-\,R_j\,)\,v_{j-1}.$$

We consider a weight of the form

$$\phi^m_j(t)\,:=\,\Phi^m(j-st)\,=\,\exp\,\left(\,\frac{M}{\underline{a}-s}\,\int_0^{j-st}\,\frac{d}{dx}\,a^k(U(x))\,dx\,\right),$$

where the constant M will be chosen large enough later on, and $\underline{a}$ is chosen in a way that either

$$a^m \le \underline{a} < s \quad \text{if} \quad m \le k-1$$

or

$$a^m \ge \underline{a} > s \quad \text{if} \quad m \ge k+1.$$

Observe that in all cases

$$\frac{a^m-s}{\underline{a}-s}\,\ge\,1.$$

Also observe that $\phi^m(t)$ is uniformly bounded from below and above in $\mathcal{L}^\infty$, *uniformly* in M, ε when $M\varepsilon < 1$. Then multiplying the previous equality by $\phi^m_j\,v^m_j$ and summing, we get

$$\frac{d}{dt}\langle\,v^m\,,\,\phi^m\,v^m\,\rangle\,+\,2\,\langle\,v^m\,,\,\phi^m\,a^m\,(\,v^m\,-\,\mathcal{T}v^m\,)\,\rangle$$

$$=\,2\,\left\langle\,v^m\,,\,\frac{d\phi^m}{dt}\,v^m\,\right\rangle\,+\,2\,\left\langle\,v\,,\,\phi^m\,\frac{d\ell^m}{dt}\,R\,v\,\right\rangle\,+\,2\,\langle\,v^m\,,\,\phi^m a^m\,\ell^m\,(\,\mathcal{T}R\,-\,R\,)\,\mathcal{T}v\,\rangle.$$

Applying the identity (3.31) to the scalar valued multiplier $\phi^m a^m$, this also reads

$$\begin{aligned}\frac{d}{dt}\langle\, v^m\,,\,\phi^m\, v^m\,\rangle\ &+\langle\, v^m\,-\mathcal{T}v^m\,,\,\phi^m a^m\,(\,v^m\,-\,\mathcal{T}v^m)\,\rangle\\ &+\left\langle\, v^m\,,\left(\,\phi^m a^m\,-\,\mathcal{T}^{-1}(\phi^m a^m)\,-\,\frac{d\phi^m}{dt}\,\right)v^m\,\right\rangle\\ &=2\left\langle\, v^m\,,\,\phi^m\frac{d\ell^m}{dt}\,R\,v\,\right\rangle+\,2\,\langle\, v^m\,,\,\phi^m a^m\,\ell^m\,(\,\mathcal{T}R\,-\,R\,)\,\mathcal{T}v\,\rangle.\end{aligned}\tag{3.38}$$

Due to the boundedness of ϕ^m, both terms in the right-hand side of (3.38) can be bounded exactly in the same way as their counterparts in (3.37). We are going to see that choosing M large enough and ε small enough such that $M\varepsilon<1$ makes the last term of the left-hand side larger than and thus absorbing the right-hand side. As a matter of fact, we have

$$\phi_j^m a_j^m\,-\,\phi_{j+1}^m a_{j+1}^m\,-\,\frac{d\phi_j^m}{dt}\,=\,(\,\phi_j^m\,-\,\phi_{j+1}^m\,)\,a_j^m\,-\,\frac{d\phi_j^m}{dt}\,+\,\phi_{j+1}^m\,(\,a_j^m\,-\,a_{j+1}^m\,).$$

The last term is bounded by $c\,(\,a_j^k-a_{j+1}^k\,)$, c a positive constant (independent of M). The remaining terms can be rearranged as

$$(\,\phi_j^m\,-\,\phi_{j+1}^m\,)\,a_j^m\,-\,\frac{d\phi_j^m}{dt}\,=\,\int_{t-T}^{t}\left((a_j^m(t)-s)\,\frac{d\phi_j^m}{dt}(\tau)\,+\,s\int_t^\tau\,\frac{d^2\phi_j^m}{dt^2}(\tau')\right)d\tau'\,d\tau.$$

By definition of ϕ^m and (2.21) we thus see that there are constants $\alpha>0$ and $c'>0$ so that for $M\varepsilon<1$

$$(\,\phi_j^m\,-\,\phi_{j+1}^m\,)\,a_j^m\,-\,\frac{d\phi_j^m}{dt}\,\geq\,\alpha\,M\,(1-c'\,\varepsilon)\,(\,a_j^k\,-\,a_{j+1}^k\,).$$

Choosing, for instance, $M\geq 4c/\alpha$ and $\varepsilon\,<\,1/4c'$, we get

$$\phi_j^m a_j^m\,-\,\phi_{j+1}^m a_{j+1}^m\,-\,\frac{d\phi_j^m}{dt}\,\geq\,\alpha\,\frac{M}{2}\,(\,a_j^k\,-\,a_{j+1}^k\,).$$

Substituting this in (3.38) and using the usual bound for the right-hand side, we have for all $\gamma>0$ a constant $c_\gamma>0$ so that

$$\begin{aligned}&\frac{d}{dt}\|\phi^m v^m\|^2\,+\,\alpha\,\frac{M}{2}\,\langle\, v^m\,,\,(\,a^k\,-\,\mathcal{T}^{-1}a^k\,)\,v^m\,\rangle\\ &\leq\,\gamma\,\|\,v\,-\mathcal{T}v\|^2\,+\,(\,\varepsilon(1+c_\gamma)\,+\,\gamma\,)\langle\, v^k\,,\,(\,a^k\,-\,\mathcal{T}^{-1}a^k\,)\,v^k\,\rangle\\ &+c_\gamma\,\langle\,\check{v}\,,\,(\,a^k\,-\,\mathcal{T}^{-1}a^k)\,\check{v}\,\rangle\end{aligned}\tag{3.39}$$

for $m\neq k$. □

Proof of (3.35). Summing (3.39) on m and adding the result to (3.36), we obtain the inequality

$$\sum_{m\neq k} \frac{d}{dt}\|\phi^m v^m\|^2 + \frac{d}{dt}\|v^k\|^2 + \frac{\mu}{2}\|v - \mathcal{T}v\|^2$$

$$+\frac{1}{2}\langle v^k, (a^k - \mathcal{T}^{-1}a^k)v^k,\rangle + \alpha\frac{M}{2}\sum_{m\neq k}\langle v^m, (a^k - \mathcal{T}^{-1}a^k)v^m\rangle$$

$$\leq \gamma\|v - \mathcal{T}v\|^2 + N(\varepsilon(1+c_\gamma)+\gamma)\langle v^k, (a^k - \mathcal{T}^{-1}a^k)v^k\rangle$$

$$+c'_\gamma\langle \check{v}, (a^k - \mathcal{T}^{-1}a^k)\check{v}\rangle,$$

where we have changed ϕ^m into $1+\phi^m$, which is harmless. Then, taking $\gamma \leq \min(\mu/4, 1/8N)$, $M\alpha \geq \max(4c'_\gamma, 1)$, and $\varepsilon < \min(1/(8N(1+c_\gamma)), 1/M)$, we find that

$$\frac{d}{dt}\left(\sum_{m\neq k}\|\phi^m v^m\|^2 + \|v^k\|^2\right) + \frac{\mu}{4}\|v - \mathcal{T}v\|^2$$

$$+\frac{1}{4}\langle v, (a^k - \mathcal{T}^{-1}a^k)v\rangle \leq 0.$$

The last term of the left-hand side being nonnegative, this proves (3.35) by integration in time. ∎

3.7. The Evans function. The notion of Evans function extends that of characteristic polynomial to infinite dimensional operators L. It must be analytic in $\mathrm{Re}\lambda > 0$ and vanish only at eigenvalues of L. Its construction is based on a shooting method, using solutions of the eigenvalue equations $(L-\lambda)\cdot W = 0$ that tend to 0 either at $-\infty$ or $+\infty$. In general, there are infinite dimensional subspaces of such solutions (called the unstable/stable manifolds), which seems helpless. However, in some cases, at least one of these subspaces is finite dimensional. This is the case for the operator L associated with the upwind scheme (i.e., for $p=1$, $q=0$), of which the unstable manifold is always of finite dimension. This enabled us to construct an Evans function in a previous work [2].

We shall recall hereafter some material from [2] that will be useful in section 5. Before that, we address the question for more general schemes. The first, convenient step consists of reformulating the eigenvalue equations $(L-\lambda)\cdot W = 0$ as a linear system of the form

$$\frac{d\mathbb{W}}{dx} = \mathbb{A}(x;\lambda)\,\mathbb{W}, \tag{3.40}$$

where $\mathbb{A}(x;\lambda)$ is an unbounded operator on the Hilbert space

$$H_0 := L^2((-p,q);\mathbb{C}^N)\times\mathbb{C}^N,$$

with dense domain

$$H_1 := \left\{(\phi,c)\in H_0\,;\ \phi\in H^1((-p,q);\mathbb{C}^N) \text{ and } \phi(0)=c\right\}.$$

Denoting by $\dot\phi$ the derivative of $\phi \in H^1(-p,q)$, $\mathbb{A}(x;\lambda)$ is defined by

$$\begin{array}{rccc} (3.41)\ \mathbb{A}(x;\lambda): & H_1 & \to & H_0 \\ & \begin{pmatrix} \phi \\ c \end{pmatrix} & \mapsto & \begin{pmatrix} \dot\phi \\ \sigma^{-1}\,\lambda\,c + \sigma^{-1}\,\displaystyle\sum_{l=-p}^{q} (C^l(x) - C^{l+1}(x-1))\cdot\phi(l) \end{pmatrix}, \end{array}$$

which makes sense because of the embedding of H^1 into $\mathcal{C}^0$. Accordingly, we define the asymptotic operators

$$\begin{array}{rccc} (3.42)\,\mathbb{A}_\pm(\lambda): & H_1 & \to & H_0 \\ & \begin{pmatrix} \phi \\ c \end{pmatrix} & \mapsto & \begin{pmatrix} \dot\phi \\ \sigma^{-1}\,\lambda\,c \,+\, \sigma^{-1}\,\displaystyle\sum_{l=-p}^{q} (\,C_\pm^l \,-\, C_\pm^{l+1}\,)\cdot\phi(l) \end{pmatrix}. \end{array}$$

It is not difficult to show (see Lemma 4.3 in [3]) that $\mathbb{A}_\pm(\lambda)$ has only isolated eigenvalues of finite multiplicities and that they are precisely the roots μ of the characteristic equation

$$\det\,(\,\Delta(\sigma;\mu,u_\pm) \,-\, \lambda\,) \,=\, 0. \tag{3.43}$$

In general, there is an infinity of such roots on either side of any vertical line. This is an argument against the construction of an Evans function. Another, though related, argument is that both the forward and the backward Cauchy problems for (3.40) are ill-posed. However, Evans functions basically rely on exponential dichotomies. Recent works about exponential dichotomies for mixed-type functional differential operators [10, 17] indicate that it might be possible to overcome the difficulty.

As far as we are concerned, we concentrate on the case with delay only. With $p=1$, $q=0$, the operator $\mathbb{A}$ reduces to

$$\begin{array}{rccc} (3.44)\ \mathbb{A}(x;\lambda): & H_1 & \to & H_0 \\ & \begin{pmatrix} \phi \\ c \end{pmatrix} & \mapsto & \begin{pmatrix} \dot\phi \\ \sigma^{-1}\,(\,\lambda\,c \,+\, A(x)\,\phi(0) \,-\, A(x-1)\,\phi(-1)\,) \end{pmatrix}. \end{array}$$

Then the system (3.40) is associated with a solution operator $(T_\lambda(x,y))_{x\ge y}$, depending analytically on λ; see Lemma 4 in [2]. The link with the delay differential equation $(\,L \,-\, \lambda)\,W \,=\, 0$, which reads

$$\sigma\,W'(x) \,-\, (\,A(x) \,+\, \lambda\,)\,W(x) \,+\, A(x-1)\,W(x-1) \,=\, 0,$$

is merely the following. We denote by Γ the projection

$$\begin{array}{rccc} \Gamma: & H_0 & \to & \mathbb{C}^N \\ & \begin{pmatrix} \phi \\ c \end{pmatrix} & \mapsto & c. \end{array}$$

Then for all $\phi \in H^1$, the problem

$$(\,L \,-\, \lambda)\,W \,=\, 0, \quad W(y+\theta) \,=\, \phi(\theta) \quad \forall\,\theta \in [-1,0],$$

admits a single solution, defined for $x \geq y$ by

$$W(x) \,=\, \Gamma\, \mathbb{W}(x) \quad \text{with} \quad \mathbb{W}(x) \,=\, T_\lambda(x,y) \begin{pmatrix} \phi \\ \phi(0) \end{pmatrix}.$$

We shall also need to consider the adjoint system

$$\frac{d\mathbb{Y}}{dx} \,=\, -\,\mathbb{A}(x;\lambda)^*\,\mathbb{Y}. \tag{3.45}$$

Although the operator $\mathbb{A}(x;\lambda)^*$ is awkward (its domain depends on x), the system (3.45) is associated with a backward solution operator $(T^*_\lambda(x,y))_{x\leq y}$, with the standard relationship

$$T^*_\lambda(x,y) \,=\, T_\lambda(y,x)^*.$$

For convenience, we identify the adjoint space H_0^* with $L^2(]0,1[;(\mathbb{C}^N)^*) \times (\mathbb{C}^N)^*$ through the inner product

$$\left\langle \begin{pmatrix} \psi & b \end{pmatrix}, \begin{pmatrix} \phi \\ c \end{pmatrix} \right\rangle \,:=\, \overline{b}\cdot c \,+\, \int_{-1}^{0} \overline{\psi(\theta+1)}\,\phi(\theta)\,d\theta.$$

Note that if $\mathbb{Y}(x,\lambda)$ is a solution of (3.45) and $\mathbb{W}(x,\lambda)$ is a solution of (3.40), then

$$\langle \mathbb{Y}(x,\lambda), \mathbb{W}(x,\lambda)\rangle \text{ is independent of } x. \tag{3.46}$$

Then we can see that $T^*_\lambda(x,y)$ is linked to solutions of the advanced differential equation $(L-\lambda)^* Y = 0$ as follows. By a slight abuse of notation, Γ also stands for

$$\begin{array}{rccc} \Gamma: & H_0^* & \to & \mathbb{C}^N \\ & \begin{pmatrix} \psi & , & b \end{pmatrix} & \mapsto & b. \end{array}$$

Then the problem

$$(L-\lambda)^* Y \,=\, 0, \quad Y(y+\theta) \,=\, -\,A(y+\theta-1)^{-1}\,\psi(\theta) \quad \forall\,\theta\in[0,1],$$

admits a single solution, defined for $x \leq y$ by

$$Y(x) \,=\, \Gamma\,\mathbb{Y}(x) \quad \text{with} \quad \mathbb{Y}(x) \,=\, T^*_\lambda(x,y)\,\big(\psi, -\,A(y-1)^{-1}\,\psi(0)\big).$$

See [2, pp. 636–639] for more details.

In the case where we are looking at $(p=1,\, q=0)$, (3.43) is equivalent to

$$\prod_{m=1}^{N} (\,\sigma\mu \,-\, a^m_\pm \,+\, a^m_\pm e^{-\mu} \,-\, \lambda\,) \,=\, 0,$$

with $a^m_\pm := a^k(u_\pm)$. We give below some preliminary results about this characteristic equation. Some of them are not required for constructing the Evans function but will be useful later.

LEMMA 3.11. *For $1 \leq m \leq N$, we consider the equation*

$$\sigma\mu - a^m_\pm + a^m_\pm e^{-\mu} - \lambda = 0. \tag{3.47}$$

For $\mathrm{Re}\lambda > 0$, (3.47) *admits a unique solution* μ *of positive real part, which depends analytically on* λ. *We denote it by* $\mu_\pm^m(\lambda)$. *It can be continued to the strip*

$$\Omega := \{\lambda,\, \mathrm{Re}\lambda \geq -\eta, |\mathrm{Im}\lambda| \leq \pi\sigma\}$$

for $\eta > 0$ *small enough.*

The root $\mu_\pm^m(\lambda)$ *remains bounded away from the imaginary axis when* λ *goes to* 0 *if and only if* $a_\pm^m > \sigma$.

On the contrary, if $a_\pm^m < \sigma$, $\mu_\pm^m(\lambda)$ *goes to* 0 *when* λ *goes to* 0 *and we have the expansion*

$$\mu_\pm^m(\lambda) = -\frac{\lambda}{a_\pm^m - \sigma} + \frac{a_\pm^m\,\lambda^2}{2(a_\pm^m - \sigma)^3} + \mathcal{O}(\lambda^3). \tag{3.48}$$

Returning to the case $a_\pm^m > \sigma$, *we also find a solution of* (3.47) *that behaves as in* (3.48) *when* λ *goes to* 0. *We denote this solution by* $\mu_\pm^{N+m}$, *which is of course of negative real part when* $\mathrm{Re}\lambda > 0$. *With the convention that* $a^{N+m} = a^m$, *these new roots satisfy the expansion in* (3.48). *In view of* (2.11), *there are* $N-k+1$ *such roots,* $\mu_-^{N+k}, \dots, \mu_-^{2N}$, *for the* $\pm = -$ *sign, and* $N-k$ *such roots,* $\mu_+^{N+k+1}, \dots, \mu_+^{2N}$, *for the* $\pm = +$ *sign.*

The root $\mu_\pm^m(\lambda)$ *is simple, provided that* $\lambda \neq \sigma\,(\log(a_\pm^m/\sigma) - a_\pm^m/\sigma + 1)$.

If $a_\pm^m > \sigma$, *then two of the above roots collide at* $\lambda = \sigma\,(\log(a_\pm^m/\sigma) - a_\pm^m/\sigma + 1)$, *namely,* $\mu_\pm^m = \mu_\pm^{N+m} = \log(a_\pm^m/\sigma)$ *(the indices* m *lying in* $\{k, \dots, N\}$ *for the* $\pm = -$ *sign and in* $\{k+1, \dots, N\}$ *for the* $\pm = +$ *sign). So, up to diminishing* η, *all roots* $\mu_\pm^m(\lambda)$ *are simple and analytic in* $\lambda \in \Omega$.

Finally, up to diminishing again η, *we can find* $r > \eta$ *so that*

$$(\Omega \backslash C_r) \cap \Sigma_{ess}(L) = \emptyset, \tag{3.49}$$

with

$$C_r := \{\lambda,\, \sup(|\mathrm{Re}\lambda|, |\mathrm{Im}\lambda|) \leq r\} \tag{3.50}$$

Proof. The first part is contained in [2, Lemma 12]. The next part follows from bifurcation analysis of (3.47) at $(\lambda, \mu) = (0, 0)$ and elementary calculations. The last assertion is a consequence of Lemma 3.4. The reader may find it helpful to refer to Figures 3.1 and 3.2. ∎

Thanks to these properties of the eigenvalues of $\mathbb{A}_\pm(\lambda)$, we can obtain decompositions of H_0 similar to those used in [2] for constructing our Evans function D. In fact, the construction of D made in [2], valid in $\{\mathrm{Re}\lambda > 0\} \cup \{0\}$, did not require eigenvectors associated with the $\mu_\pm^{N+m}$. But we shall need the modes $\mu_\pm^{N+m}$ to extend the Green's function to a full neighborhood of 0 (namely, C_r). This is why we state a result that is slightly different from Lemma 3 in [2].

LEMMA 3.12. *In the framework of Lemma* 3.11, *we introduce for* $\lambda \in \Omega$,

$$\Phi_\pm^m(\lambda) := \begin{pmatrix} \theta \mapsto e^{\mu_\pm^m(\lambda)\theta}\, r_\pm^m \\ r_\pm^m \end{pmatrix},$$

$$\Psi_\pm^m(\lambda) := \begin{pmatrix} \theta \mapsto -\,e^{-\overline{\mu_\pm^m(\lambda)}\theta}\, a_\pm^m\, \ell_\pm^m \quad , \quad \sigma\, \ell_\pm^m \end{pmatrix} / \sigma,$$

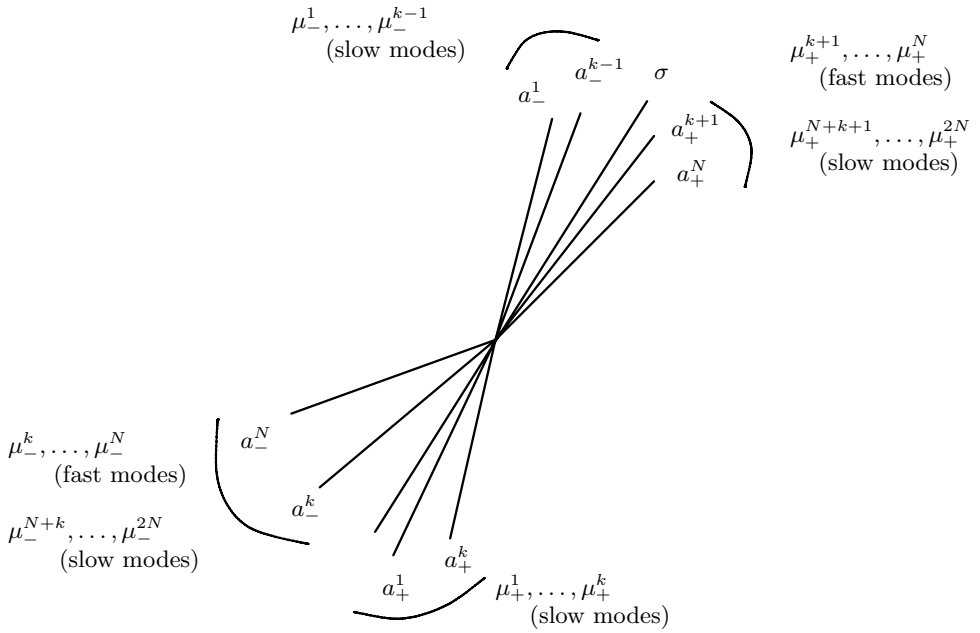

FIG. 3.1. *Characteristic speeds (in the (x,t)-plane) and the corresponding modes.*

which are eigenvectors of $\mathbb{A}_\pm(\lambda)$ and $\mathbb{A}_\pm(\lambda)^*$, respectively, associated with the eigenvalues $\mu_\pm^m(\lambda)$ and $\overline{\mu_\pm^m(\lambda)}$, and such that

$$\langle\, \Psi_\pm^n(\lambda)\,,\, \Phi_\pm^m(\lambda)\,\rangle \,=\, \delta_m^n.$$

(Here and below δ_m^n stands for the usual Kronecker symbol.) We have the decompositions

$$H_0 \,=\, \mathit{Span}\{\Phi_-^1(\lambda), \dots, \Phi_-^N(\lambda), \Phi_-^{N+k}(\lambda), \dots, \Phi_-^{2N}(\lambda)\}$$
$$\oplus\, \mathit{Span}\{\Psi_-^1(\lambda), \dots, \Psi_-^N(\lambda), \Psi_-^{N+k}(\lambda), \dots, \Psi_-^{2N}(\lambda)\}^\perp,$$

$$H_0 \,=\, \mathit{Span}\{\Phi_+^1(\lambda), \dots, \Phi_+^N(\lambda), \Phi_+^{N+k+1}(\lambda), \dots, \Phi_+^{2N}(\lambda)\}$$
$$\oplus\, \mathit{Span}\{\Psi_+^1(\lambda), \dots, \Psi_+^N(\lambda), \Psi_+^{N+k+1}(\lambda), \dots, \Psi_+^{2N}(\lambda)\}^\perp,$$

and the corresponding projections onto $\mathit{Span}\{\Phi_\pm^m(\lambda)\}$, $\mathit{Span}\{\Psi_\pm^m(\lambda)\}^\perp$ are analytic in λ and $\overline{\lambda}$, respectively, being defined by

$$Q_\pm(\lambda)\cdot\Phi \,=\, \sum_m \langle\, \Psi_\pm^m(\lambda)\,,\, \Phi\,\rangle\, \Phi_\pm^m(\lambda),$$

$$P_\pm(\lambda) \,=\, I_{H_0} \,-\, Q_\pm(\lambda).$$

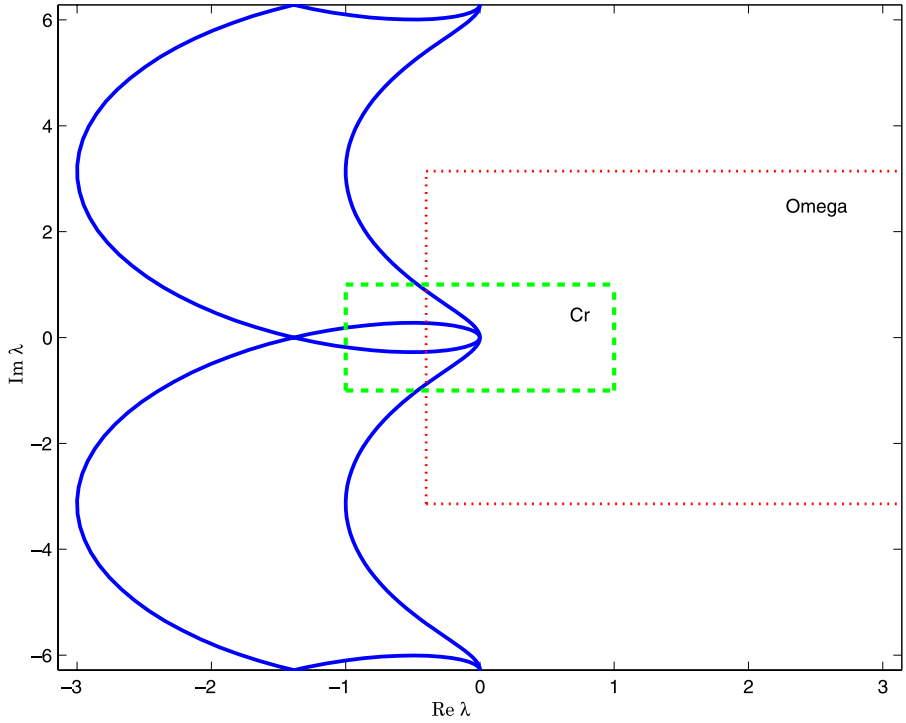

FIG. 3.2. *The sets Ω and C_r in the λ-plane. Thick curves represent typical plottings of $\Lambda(u)$ (with $\sigma = 1$), having equations of the form $\lambda = i\sigma\xi - a + ae^{-i\xi}$ ($\xi \in \mathbb{R}$) with either $a < \sigma$ (case without double points) or $a > \sigma$. For $u = u_\pm$, they signal that a root μ of (3.47) crosses the imaginary axis. Directions of crossings at $\lambda = 0$ are explicitly given in Lemma 3.11. From left to right across such a curve, there is a root μ of $\sigma\mu - a + ae^{-\mu} = \lambda$ crossing from left to right if $a < \sigma$ and from right to left if $a > \sigma$.*

Additionally, since all the eigenvalues of $\mathbb{A}_\pm(\lambda)$ but possibly the $\mu_\pm^m(\lambda)$ (the indices m lying in $\{1,\dots,N\} \cup \{N+k,\dots,2N\}$ for the $\pm = -$ sign and in $\{1,\dots,N\} \cup \{N+k+1,\dots,2N\}$ for the $\pm = +$ sign) lie in some fixed half-plane $\{\mathrm{Re}\mu \le \gamma_\pm < 0\}$ for all $\lambda \in C_r$, the semigroup associated with $\mathbb{A}_\pm(\lambda)$, $T_\lambda^\pm$, is exponentially decaying when restricted to the range of $P_\pm(\lambda)$. More precisely, for all $\alpha_\pm < \gamma_\pm$ there exists $C > 0$ so that

$$\left\| T_\lambda^\pm(x)\, P_\pm(\lambda) \right\| \le Ce^{-\alpha_\pm x} \quad \forall x \ge 0, \quad \forall \lambda \in C_r. \tag{3.51}$$

Proof. The proof is identical to that of Lemma 3 in [2]. ∎

Now, using the gap lemma construction, we can deduce decompositions of the space H_0 adapted to $\mathbb{A}(x,\lambda)$ on both half-lines $\mathbb{R}^\pm$.

For convenience, we shall use the following shortcuts:

$$M_- := \{1,\dots,N\} \cup \{N+k,\dots,2N\},$$

$$M_+ := \{1,\dots,N\} \cup \{N+k+1,\dots,2N\}.$$

LEMMA 3.13. *In the framework of Lemma 3.12, for all $m \in M_\pm$ there exist unique $\mathbb{W}_\pm^m$ and $\mathbb{Y}_\pm^m$ that are solutions on $\mathbb{R}^\pm$ of (3.40) and (3.45), respectively, having the*

following asymptotics:

$$\mathbb{W}^m_\pm(x,\lambda) = e^{\mu^m_\pm(\lambda)x}\Big(\Phi^m_\pm(\lambda) + \mathcal{O}(e^{\omega_\pm x})\Big) \quad \forall x \in \mathbb{R}^\pm, \tag{3.52}$$

$$\mathbb{Y}^m_\pm(x,\lambda) = e^{-\overline{\mu^m_\pm(\lambda)}x}\Big(\Psi^m_\pm(\lambda) + \mathcal{O}(e^{\omega_\pm x})\Big) \quad \forall x \in \mathbb{R}^\pm, \tag{3.53}$$

for some uniform $\omega_+ < 0 < \omega_-$ on compact subsets of Ω, are analytic in λ and satisfy the orthogonality relations

$$\langle\, \mathbb{Y}^n_\pm(x,\lambda)\,,\, \mathbb{W}^m_\pm(x,\lambda)\,\rangle \,=\, \delta^n_m. \tag{3.54}$$

Additionally, the projection onto Span$\{\mathbb{Y}^m_\pm(x,\lambda)\}^\perp$ defined by

$$P_\pm(x,\lambda)\cdot\Phi \,=\, \Phi \,-\, \sum_{m\in M_\pm} \langle\, \mathbb{Y}^m_\pm(x,\lambda)\,,\, \Phi\,\rangle\, \mathbb{W}^m_\pm(x,\lambda)$$

is such that the evolution operator $T_\lambda(x,y)$ associated with (3.40) *enjoys the following*

(i) *commutation property, $T_\lambda(x,y)P_\pm(y,\lambda) = P_\pm(x,\lambda)T_\lambda(x,y)$ for all $x \geq y \in \mathbb{R}_\pm$,*

(ii) *and decay estimate*

$$\|T_\lambda(x,y)P_\pm(y,\lambda)\| \leq Ce^{-\alpha_\pm(x-y)} \quad \forall x \geq y \in \mathbb{R}^\pm \tag{3.55}$$

for some $C \geq 0$ and $\alpha_\pm > 0$ independent of $\lambda \in C_r$.

Proof. The construction of the $\mathbb{W}^m_-$ (respectively, the $\mathbb{Y}^m_+$) was made in Proposition 2 (respectively, Proposition 3) and Lemma 7 in [2]. The construction of $\mathbb{W}^m_+$ for $x \geq x_0$ and of $\mathbb{Y}^m_-$ for $x \leq -x_0$ works the same way for x_0 large enough, through (revisited) Duhamel's principle and a fixed point argument. The main difficulty lies in extending $\mathbb{W}^m_+$ to the whole half-line $x \geq 0$ and $\mathbb{Y}^m_-$ to $x \leq 0$, which amounts to solving the backward Cauchy problem for (3.40) with data $\mathbb{W}^m_+(x_0)$ and the (forward) Cauchy problem for (3.45) with data $\mathbb{Y}^m_-(x_0)$. This can be overcome by using Lin's method [12, Theorem 3.3], provided that his basic assumptions hold, namely,

$$T_\lambda(x,y)\cdot\Phi \,\neq\, 0 \quad \forall x \geq y \in \mathbb{R}^-, \quad \forall \Phi \in H_0\backslash\{0\},$$

$$T^*_\lambda(x,y)\cdot\Psi \,\neq\, 0 \quad \forall x \leq y \in \mathbb{R}^+, \quad \forall \Psi \in H^*_0\backslash\{0\}.$$

In terms of the operator L, this requires that no (nontrivial) eigenfunction of L or L^* vanishes on an interval of length 1. Because of the invertibility of $A(x)$, an elementary calculation shows that this is obviously true.[5] ∎

Away from the essential spectrum, and in particular in $\Omega\backslash C_r$, we recover usual exponential dichotomies on $\mathbb{R}^\pm$ through the following alternate version of Lemma 3.13 (already pointed out in [2]).

LEMMA 3.14. *In the framework of Lemma* 3.13*, we define*

$$\Pi_\pm(x,\lambda) = I - \sum_{1\leq m\leq N} \mathbb{W}^m_\pm(x,\lambda)\mathbb{Y}^m_\pm(y,\lambda)$$

[5] For the more general, mixed-type operator, the same is true, provided that the extreme matrices, $C^q(x)$ and $C^{-p+1}(x)$, are invertible for all $x \in \mathbb{R}$. This is a crucial hypothesis, called *atomicity* in [17], to get exponential dichotomies; also see Hypothesis 1 in [10].

and

$$\Xi_\pm(x,\lambda) = I - \Pi_\pm(x,\lambda) = \sum_{1\le m\le N} \mathbb{W}^m_\pm(x,\lambda)\mathbb{Y}^m_\pm(x,\lambda), \tag{3.56}$$

where by abuse of notation all terms of the kind $\mathbb{W}\,\mathbb{Y}$ *stand for the operator*

$$\Phi \;\mapsto\; \langle\, \mathbb{Y}\,,\, \Phi\,\rangle\, \mathbb{W}.$$

Then we have
