There exist small parameters $c, \delta > 0$ such that for every $\bar{u} \in \mathrm{cl}\ \mathcal{E}_{c,\delta}$, where cl *denotes the closure in L^1_{loc}, the Cauchy problem* (1.1), (1.2) *has a global entropy admissible solution $u(t,x)$.*

THEOREM 2. *Assume that* (H1), (H2), *and the L^1 stability condition* (3.1) *are satisfied. Then there exists a closed domain $\mathcal{D} \subset L^1_{loc}(\mathbf{R}, \Omega)$, containing all continuous functions $\bar{u}$ satisfying* (i), (ii), (iii) *in Theorem* 1, *for some $c, \delta > 0$, and there exists a semigroup $S : \mathcal{D} \times [0, \infty) \longrightarrow \mathcal{D}$ such that*

(i) $||S(\bar{u},t)-S(\bar{v},s)||_{L^1} \leq L\cdot(|t-s|+||\bar{u}-\bar{v}||_{L^1})$ *for all* $\bar{u},\bar{v}\in\mathcal{D}$, *all* $t,s\geq 0$, *and a uniform constant* L, *depending only on the system* (1.1),

(ii) *for all* $\bar{u}\in\mathcal{D}$, *the trajectory* $t\mapsto S(\bar{u},t)$ *is the solution to* (1.1), (1.2) *given in Theorem* 1.

We now set other preliminaries. For each $i:1\dots n$ and $u\in\Omega$, call $\sigma\mapsto\mathcal{S}_i(u,\sigma)$ and $\sigma\mapsto\mathcal{R}_i(u,\sigma)$, the ith shock and the ith rarefaction curves through the point u [L, D]. In particular we have $\mathcal{R}_k(u_l,\theta)=\mathcal{R}_k(\theta)$. Both curves are defined at least locally, that is, for $\sigma\in(-c,c)$, and have second order contact at $\sigma=0$:

$$\mathcal{S}_i(u,\sigma)-\mathcal{R}_i(u,\sigma)=\mathcal{O}(1)|\sigma|^3. \tag{1.8}$$

The curves' parametrization is consistent with the normalization of the right eigenvectors r_i. That is, they are parametrized by arc-length if the ith characteristic field is linearly degenerate, and by the corresponding eigenvalue λ_i if the ith field is genuinely nonlinear:

$$\lambda_i(\mathcal{S}_i(u,\sigma))-\lambda_i(u)=\sigma=\lambda_i(\mathcal{R}_i(u,\sigma))-\lambda_i(u). \tag{1.9}$$

By this choice of parametrization we have

$$\mathcal{S}_i(\mathcal{S}_i(u,\sigma),-\sigma)=u. \tag{1.10}$$

The speed λ of a weak shock wave $(u^-,u^+=\mathcal{S}_i(u^-,\sigma))$ with strength $\sigma<0$ can be computed from the Rankine–Hugoniot identity:

$$f(u^+)-f(u^-)=\lambda\cdot(u^+-u^-). \tag{1.11}$$

Throughout the paper, by $\mathcal{O}(1)$ we mean any uniformly bounded function, depending only on the system (1.1). Any sufficiently small but positive constant is denoted by c. The Riemann data as in (1.3) is for simplicity denoted by (u^-,u^+).

The paper is constructed as follows. In sections 2 and 3 we present the stability conditions and their primary motivation. In section 4 we prove Theorem 1. The proof relies on the construction of approximate solutions by means of the wave front tracking algorithm [HR, BaJ], and applying the Glimm analysis in view of the BV stability condition. In section 9 we prove that the domain of applicability of these techniques actually contains the data with properties as in Theorem 1.

Toward the proof of Theorem 2, in section 6 we give the definition of the Lyapunov functional measuring the L^1 distance between the two approximate solutions constructed in section 4. The crucial observation for our construction is noting that in the initial time interval where the solutions are apart from each other, this distance decreases rapidly. A convenient tool to estimate the decrease is the first order rarefactions, introduced in section 5. For other times, the pointwise distance between solutions is calculated along shock curves, as in [BLY]. The decrease of the functional follows then from the assumed L^1 stability condition and the main concern of sections 7 and 8.

2. The weighted BV stability condition. In this section we discuss a stability condition guaranteeing the existence of solutions to the problem (1.1)(1.2) in the vicinity of the reference rarefaction wave (1.7). To motivate our approach we first recall the argument from [Le1, BM]. The stability conditions there were formulated in terms of the existence of a family of weights $w_i>0$, $i:1\dots n$, corresponding to different characteristic families of perturbation v, and depending on the location of

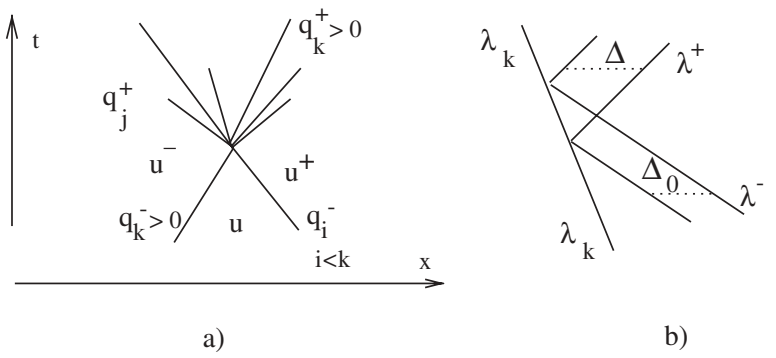

FIG. 2.1.

perturbing waves inside the reference pattern u_0. The conditions required that the weighted BV or L^1 norm of any solution of

$$v_t + Df(u_0)v_x + [D^2 f(u_0) \cdot v] \cdot (u_0)_x = 0$$

was nonincreasing in time.

Let $w_1 \dots w_{k-1}, w_{k+1} \dots w_n : (-c, \Theta + c) \longrightarrow \mathbf{R}_+$ be smooth, nonnegative functions defined along the rarefaction curve $\mathcal{R}_k$ in (1.4). We can extend this definition on the whole neighborhood Ω by setting

$$\forall i \neq k,\ \forall u \in \Omega \quad w_i(u) = w_i(\theta), \quad \text{where} \quad \lambda_k(u) = \lambda_k(\mathcal{R}_k(\theta)). \tag{2.1}$$

Consider an interaction of a weak ith wave with a small part of the rarefaction $\mathcal{R}_k$, located at the state $u = \mathcal{R}_k(\theta)$. To fix the ideas, assume that $i < k$ and call the strengths of the incoming waves and the states they join to u, respectively, $q_k^- > 0,\ q_i^-, u^-, u^+$ (as in Figure 2.1(a)). In particular, we have $u = \mathcal{R}_k(u^-, q_k^-)$ and $q_k^- = \theta - \lambda_k(u^-)$. The strengths of waves are computed in terms of change in the corresponding eigenvalue for genuinely nonlinear fields, or the arc-length of the rarefaction curve connecting the two states, for linearly degenerate fields. We thus remain consistent with the parametrization of the right eigenvectors, given in section 1. Now if q_k^- and q_i^- are small enough, the Riemann problem (u^-, u^+) has a self-similar solution composed of n outgoing waves having strengths $q_1^+ \dots q_n^+$. For the basic properties of this construction we refer to [L, Sm, B, D]. Assigning to each wave the weight w_i corresponding to its characteristic family and computed at the wave's left state, we now require that the weighted amount of perturbation decreases across the interaction, so that

$$\sum_{j \neq k} w_j^+ |q_j^+| < w_i^- |q_i^-|. \tag{2.2}$$

Recall the standard Taylor estimates [Sm]:

$$\begin{aligned} \forall j \neq k \qquad q_j^+ = \delta_{ij} \cdot q_i^- + \langle l_j(u), [r_i, r_k](u) \rangle \cdot q_i^- q_k^- \\ + \mathcal{O}(1) |q_i^- q_k^-| (|q_i^-| + |q_k^-|). \end{aligned} \tag{2.3}$$

Here $[r_i, r_k] = \mathrm{D}r_i \cdot r_k - \mathrm{D}r_k \cdot r_i$ stands for the Lie bracket of two vector fields, and δ_{ij} is the Kronecker delta.

In view of (2.3), we have

$$\begin{aligned}\forall j\neq k,i \qquad w_j^+|q_j^+| =& w_j(u)\cdot|\langle l_j(u),[r_i,r_k](u)\rangle|\cdot|q_i^-q_k^-|\\ &+\mathcal{O}(1)|q_i^-q_k^-|(|q_i^-|+|q_k^-|).\end{aligned}$$

On the other hand,

$$\begin{aligned}w_i^+q_i^+-w_i^-q_i^- =&(w_i^+-w_i^-)q_i^-+w_i^+(q_i^+-q_i^-)\\ =&-w_i'(\theta)\cdot q_i^-q_k^-+w_i(u)\cdot\langle l_i,[r_i,r_k]\rangle(u)\cdot q_i^-q_k^-\\ &+\mathcal{O}(1)|q_i^-q_k^-|(|q_i^-|+|q_k^-|).\end{aligned}$$

Hence,

$$\begin{aligned}w_i^+|q_i^+|-w_i^-|q_i^-| =&(\operatorname{sgn} q_i^-)\cdot(w_i^+q_i^+-w_i^-q_i^-)\\ =&\big\{w_i(u)\cdot\langle l_i,[r_i,r_k]\rangle(u)-w_i'(\theta)\big\}\cdot|q_i^-q_k^-|\\ &+\mathcal{O}(1)|q_i^-q_k^-|(|q_i^-|+|q_k^-|).\end{aligned}$$

Condition (2.2) is thus equivalent to

$$\left(\sum_{j\neq i,k}w_j(\theta)\cdot|\langle l_j,[r_i,r_k]\rangle(\mathcal{R}_k(\theta))|\right)+w_i(\theta)\cdot\langle l_i,[r_i,r_k]\rangle(\mathcal{R}_k(\theta))<w_i'(\theta). \tag{2.4}$$

Analogously, for $i>k$ one obtains

$$\left(\sum_{j\neq i,k}w_j(\theta)\cdot|\langle l_j,[r_k,r_i]\rangle(\mathcal{R}_k(\theta))|\right)+w_i(\theta)\cdot\langle l_i,[r_k,r_i]\rangle(\mathcal{R}_k(\theta))<-w_i'(\theta). \tag{2.5}$$

Define the $(n-1)\times(n-1)$ matrix function:

$$\begin{aligned}&\mathbf{P}(\theta)=[p_{ij}(\theta)]_{\substack{i,j:1\dots n,\\ i,j\neq k}} \quad \text{for } \theta\in[0,\Theta],\\ &p_{ij}(\theta)=\begin{cases}|\langle l_j,[r_i,r_k]\rangle(\mathcal{R}_k(\theta))| & \text{if } i\neq j,\\ \operatorname{sgn}(k-i)\cdot\langle l_i,[r_i,r_k]\rangle(\mathcal{R}_k(\theta)) & \text{if } i=j.\end{cases}\end{aligned}$$

Combining (2.4) and (2.5), we have proved the following.

LEMMA 2.1. *Condition* (2.2) *is equivalent to the following:*

$$\left[\begin{array}{l}\textit{BV stability condition: There exist positive smooth functions } w_1\dots w_{k-1},w_{k+1}\dots w_n:[0,\Theta]\to\mathbf{R}_+ \textit{ such that}\\ \\ \qquad\mathbf{P}(\theta)\cdot\begin{bmatrix}w_1(\theta)\\ \vdots\\ w_{k-1}(\theta)\\ w_{k+1}(\theta)\\ \vdots\\ w_n(\theta)\end{bmatrix}<\begin{bmatrix}w_1'(\theta)\\ \vdots\\ w_{k-1}'(\theta)\\ -w_{k+1}'(\theta)\\ \vdots\\ -w_n'(\theta)\end{bmatrix} \qquad \textit{for every } \theta\in(0,\Theta),\\ \\ \textit{where the above vector inequality is understood componentwise.}\end{array}\right. \tag{2.6}$$

Remark 2.2. Notice that because of the strict inequalities in (2.4) and (2.5), the condition (2.6) implies a stricter version of (2.2):

$$\sum_{j\neq k} w_j^+|q_j^+| < w_i^-|q_i^-| - c|q_i^- q_k^-|$$

for a small constant c.

Remark 2.3. The inequality in (2.6) is independent from rescaling $w_i \mapsto \alpha \cdot w_i$, for any $\alpha > 0$. Thus, in particular we may assume that

$$|w_i(u)| < 1 \quad \text{and} \quad ||\mathrm{D}w_i(u)|| < 1$$

for each i and every $u \in \Omega$.

Remark 2.4. If all $p_{ij}(\theta) \geq 0$, we can regard the quantity $w_i(\theta)$ as the measure of the amount of potential future interactions of the ith perturbation wave located at the state $\mathcal{R}_k(\theta)$. For $i < k$ each w_i is an increasing function of θ, and for $i > k$ each w_i is decreasing along the curve $\mathcal{R}_k$. Indeed, the slow waves ($\lambda_i < \lambda_k$ for $i < k$) travel in the direction of decreasing θ on the $t - x$ plane, and thus the bigger the parameter θ corresponding to their location is, the more potential contribution to the future amount of perturbation they create. The converse assertion is true for the fast waves of characteristic families $i > k$.

By an approximation argument, as the inequality in (2.6) is strict, we see that (2.2) also holds for any state $u \in \Omega_c$. For the more detailed discussion of condition (2.6) we refer to the paper [Le3]. In particular, we have the following.

LEMMA 2.5 [Le3]. *Let the condition* (2.6) *be satisfied. There exists* $c > 0$ *such that for every* $u^-, u^+ \in \Omega$ *with* $\lambda_k(u^+) - \lambda_k(u^-) > -c$, *the Riemann problem* (u^-, u^+) *for* (1.1) *has the unique self-similar solution attaining states in* Ω. *The solution is composed of* $n-1$ *weak waves of families* $1 \ldots k-1, k+1 \ldots n$ *and a* k*th wave which is either a weak shock or a rarefaction.*

Condition (2.6) is independent of the parametrization of the eigenvectors in Ω. The next lemma gathers several other properties of this condition.

LEMMA 2.6 [Le3]. *In any of the following cases* (2.6) *is satisfied:*

(i) *when the reference rarefaction is sufficiently weak, that is,* $0 < \Theta \ll 1$,

(ii) *when the reference rarefaction belongs to an extreme characteristic field (*$k = 1$ *or* n*),*

(iii) *when* (1.1) *has a coordinate system of Riemann invariants* [Sm, D, S].

In particular, any rarefaction wave in any 2×2 *system or the* 3×3 *system of Euler equations of gas dynamics* [D, Sm, Scho] *is BV stable.*

(iv) *For* $n = 3$ *and* $k = 2$, (2.6) *is equivalent to the existence of a positive solution* $v : [0, \Theta] \longrightarrow \mathbf{R}_+$ *to the Riccati equation:*

$$v'(\theta) = p_{12}(\theta) + [p_{11}(\theta) + p_{22}(\theta)] \cdot v(\theta) + p_{21}(\theta) \cdot v^2(\theta).$$

3. The weighted L^1 stability condition. The production matrix $\mathbf{P}$ in condition (2.6) accounts for the infinitesimal change of the strength of perturbation as it passes through the rarefaction fan (1.7). The elements of $\mathbf{P}(\theta)$ are second order coefficients in the Taylor expansion of the strength of waves produced through the interaction with a part of the large rarefaction $\mathcal{R}_k(\theta)$. In order to deal with the L^1 stability one is led to a "mass production" matrix $\mathbf{M}(\theta)$ whose components additionally account for the shifts in locations of the perturbing waves of different characteristic

families before and after the interaction. More precisely, define

$$\mathbf{M}(\theta) = [m_{ij}(\theta)]_{\substack{i,j:1\dots n,\\ i,j\neq k}} \quad \text{for } \theta \in [0,\Theta],$$

$$m_{ij}(\theta) = \begin{cases} p_{ij}(\theta)\cdot \dfrac{|\lambda_j-\lambda_k|}{|\lambda_i-\lambda_k|}(\mathcal{R}_k(\theta)) & \text{if } i\neq j,\\ p_{ij}(\theta) + \dfrac{\mathrm{D}\lambda_i\cdot r_k}{|\lambda_i-\lambda_k|}(\mathcal{R}_k(\theta)) & \text{if } i=j. \end{cases}$$

We have the following:

(3.1) L^1 *stability condition:* There exist positive smooth functions $w_1\dots w_{k-1}, w_{k+1}\dots w_n : [0,\Theta]\to \mathbf{R}_+$ such that the inequality in (2.6) is satisfied with $\mathbf{M}(\theta)$ replacing the matrix $\mathbf{P}(\theta)$.

Note that an observation as in Remark 2.3 remains valid.

A more restrictive version of (3.1), where all weights w_i are linear, was introduced in [BM] in the context of the well-posedness of the associated variational system.

LEMMA 3.1 [Le3]. *We have the following:*

(i) *Condition* (3.1) *is stronger than the BV stability condition* (2.6).

(ii) *The assertions of Lemma* 2.6 *hold in their respective versions.*

(iii) *For all* $i\neq j$ *and all* $\theta\in[0,\Theta]$ *there holds:* $m_{ij}(\theta) = |\langle l_j, \mathrm{D}r_i\cdot r_k\rangle(\mathcal{R}_k(\theta))|$ *and* $m_{ii}(\theta) = \operatorname{sgn}(k-i)\cdot\langle l_i, \mathrm{D}r_i\cdot r_k\rangle(\mathcal{R}_k(\theta))$.

We end this section by presenting a consequence of (3.1) which plays the same role as Lemma 2.1 and Remark 2.2 for the condition (2.6). Its proof will follow from the more general Lemma 8.2. To fix the ideas, let

$$\mathcal{S}_k(q_k^-)\circ\mathcal{S}_i(u,q_i^-) = \mathcal{S}_n(q_n^+)\circ\dots\mathcal{S}_1(u,q_1^+)$$

with $u\in\Omega$, $\{q_j^-\}_{j=i,k}$ small enough and $q_k^-\geq 0$. Then for a small uniform constant γ we have

$$\sum_{j\neq k} w_j^+|q_j^+|\cdot|\lambda_j^+-\lambda_k^+| < w_i^-|q_i^-|\cdot|\lambda_i^--\lambda_k^-| - \gamma|q_i^-q_k^-|.$$

Namely, the total weighted mass of perturbation decreases as it passes through the rarefaction wave (1.7). Recall [BM] that the ratio Δ/Δ_0 of shifts in the reflected or transmitted wave with respect to the shift in an incoming wave can be computed as $|\lambda^+-\lambda_k|/|\lambda^--\lambda_k|$. As in Figure 2.1(b), λ^- and λ^+ denote speeds of the modified waves before and after the interaction with a reference wave traveling with speed λ_k.

4. Existence of solutions: A proof of Theorem 1. Recall that given a Cauchy problem (1.1), (1.2) with $\bar u$ having small total variation, its solution can be obtained in the limit when $\epsilon\to 0$ of piecewise constant ϵ-approximations $u^\epsilon(t,x)$ constructed via the wave front tracking algorithm [BaJ, HR]. For the detailed description of the algorithm we refer to [B]. The crucial ingredient in proving the global existence of the approximate solutions and the compactness of its sequence is the Glimm functional [G] controlling the total variation of perturbation and the amount of the future interactions. Below we briefly discuss a natural modification of this standard construction, applicable when the reference pattern is a strong kth rarefaction $\mathcal{R}_k$ rather than a constant state. We then show that our Glimm-type functional Γ is indeed nonincreasing along any wave front tracking approximate solution, thanks to the BV stability condition (2.6).

DEFINITION 4.1. *Let* $\epsilon_0>0$. *By* $\mathcal{D}_{\epsilon_0}$ *we denote the set of piecewise constant functions* $v:\mathbf{R}\longrightarrow\mathbf{R}^n$ *enjoying the following properties:*

(i) $v(-\infty) = u_l,\ v(+\infty) = u_r$,
(ii) $v(x) \in \Omega$ *for all* $x \in \mathbf{R}$,
(iii) *all jumps in* v *have amplitudes smaller than* ϵ_0 *(and thus the corresponding Riemann problems admit the standard self-similar solution). We order the waves in these solutions according to their location and speed; for a wave* α, *we denote its characteristic family by* $i_\alpha : 1 \dots n$ *and its strength by* ϵ_α,
(iv) *setting* $\epsilon_\alpha^+ = \max(0, \epsilon_\alpha)$ *and* $\epsilon_\alpha^- = \max(0, -\epsilon_\alpha)$ *there holds*

$$\left| \left(\sum_{i_\alpha = k} \epsilon_\alpha^+ \right) - \Theta \right| + \left(\sum_{i_\alpha = k} \epsilon_\alpha^- \right) + \left(\sum_{i_\alpha \neq k} |\epsilon_\alpha| \right) \leq \epsilon_0. \tag{4.1}$$

Remark 4.2. *Let* v *satisfy* (i), (iii) *of Definition* 4.1 *and let the bound* (4.1) *hold with* ϵ_0 *exchanged by another parameter* δ. *Then if only* δ *is small enough with respect to* ϵ_0, *then* $v(x) \in \Omega_{2c}$ *for all* $x \in \mathbf{R}$ *implies* $v(x) \in \Omega_c$ *for all* $x \in \mathbf{R}$.

Take a function $u(0, \cdot) \in \mathcal{D}_{\epsilon_0}$ for some small $\epsilon_0 > 0$. Let $\epsilon \ll \epsilon_0$. Recall that the fundamental block for constructing the approximate solution $u^\epsilon(t, x)$ is provided by piecewise constant approximations of self-similar solutions to Riemann problems.

As customary, the nonphysical waves generated by the simplified Riemann solver are said to belong to the $(n+1)$th characteristic family. The simplified Riemann solver is used whenever one of the interacting waves is nonphysical or when the product of strengths of incoming waves is bigger than a threshold parameter $\rho(\epsilon)$. The details can be found in Chapter 7 of [B]. The associated nonphysical weight w_{n+1} is defined as follows:

$$w_{n+1}(u) = c \cdot \exp(-C \cdot \lambda_k(u)) \quad \text{for} \quad u \in \Omega, \tag{4.2}$$

for some suitable constants $c, C > 0$. Let w_k be a positive constant, strictly smaller than all other weights $w_i(u)$ defined in Ω by (2.6) and (2.1). Recall that given a weak ith wave, we associate with it the weight w_i computed at its left state.

DEFINITION 4.3. *Let* $u(0, \cdot) \in \mathcal{D}_{\epsilon_0}$, *with some small* $\epsilon_0 > 0$. *Let* u^ϵ *be the piecewise constant* ϵ*-approximate solution, given by the wave front tracking algorithm. Assume* t *is not an interaction time of fronts in* u^ϵ. *Using the notation of Definition* 4.1 *we set*

$$V(u^\epsilon(t, \cdot)) = \left| \left(\sum_{i_\alpha = k} \epsilon_\alpha^+ \right) - \Theta \right| + \left(\sum_{i_\alpha = k} \epsilon_\alpha^- \right) + \left(\sum_{i_\alpha \neq k} |\epsilon_\alpha| \right),$$

where the summations extend on all waves α *present in* $u^\epsilon(t, \cdot)$. *The quadratic interaction potential is defined:*

$$Q_0(u^\epsilon(t, \cdot)) = \sum_{(\alpha, \beta) \in \mathcal{A}} |\epsilon_\alpha \cdot \epsilon_\beta|,$$

with the set $\mathcal{A}$ *containing all couples of perturbation waves* (α, β) *in* $u^\epsilon(t, \cdot)$ *approaching each other. More precisely, assuming* $x_\alpha < x_\beta$, *we have* $(\alpha, \beta) \in \mathcal{A}$ *if and only if* $i_\alpha > i_\beta$ *or else* $i_\alpha = i_\beta$ *and at least one of the waves is a genuinely nonlinear shock. In both cases we require that none of the waves* α, β *is a positive* k*-wave. Finally, let*

$$Q_{large}(u^\epsilon(t, \cdot)) = \sum_{i_\alpha \neq k} w_{i_\alpha}(u^\epsilon(t, x_\alpha -)) \cdot |\epsilon_\alpha| + \sum_{i_\alpha = k} w_k \cdot \epsilon_\alpha^-,$$

$$Q = Q_0 + Q_{large}, \qquad \Gamma = V + \kappa \cdot Q,$$

for some large constant κ, to be determined later.

LEMMA 4.4. *Assume that the BV stability condition* (2.6) *holds. Then for some constants $c, \epsilon_0, \kappa > 0$ we have the following. Let $u(0,\cdot) \in \mathcal{D}_{\epsilon_0}$ and let u^ϵ be the corresponding piecewise constant approximate solution obtained through the wave front tracking algorithm. Then for any $t > 0$ when two wave fronts α and β interact, if $\Gamma(u^\epsilon(t-,\cdot)) \leq \epsilon_0$, then*

$$\begin{aligned} \Delta Q &= Q(u^\epsilon(t+,\cdot)) - Q(u^\epsilon(t-,\cdot)) \leq -c \cdot |\epsilon_\alpha \epsilon_\beta|, \\ \Delta\Gamma &= \Gamma(u^\epsilon(t+,\cdot)) - \Gamma(u^\epsilon(t-,\cdot)) \leq -c \cdot |\epsilon_\alpha \epsilon_\beta|. \end{aligned} \tag{4.3}$$

Proof. The proof consists of several cases, depending on whether the accurate or the simplified Riemann solver is used and whether the interaction involves a kth positive wave which we will view as a part of the reference rarefaction $\mathcal{R}_k$. We give only the main ideas; the detailed analysis is left to the reader.

Case 1. None of the interacting waves is a positive kth wave, and the interaction is solved by the accurate Riemann solver (Figure 4.1 (c)). By standard analysis [B] we have

$$\begin{aligned} \Delta V &= \mathcal{O}(1)|\epsilon_\alpha \epsilon_\beta|, \\ \Delta Q_0 &\leq -|\epsilon_\alpha \epsilon_\beta| + \mathcal{O}(1)\epsilon_0 \cdot |\epsilon_\alpha \epsilon_\beta|. \end{aligned}$$

Further,

$$\Delta Q_{large} \leq \left(\sum_{j \neq i_\alpha, i_\beta} w_j^{out} \cdot |\epsilon_j^{out}| \right) + \left(w_{i_\alpha}^{out} |\epsilon_\alpha^{out}| - w_{i_\alpha} |\epsilon_\alpha| \right) + \left(w_{i_\beta}^{out} |\epsilon_\beta^{out}| - w_{i_\beta} |\epsilon_\beta| \right).$$

Consequently, $\Delta Q_{large} \leq C \cdot |\epsilon_\alpha \epsilon_\beta|$, where the constant C depends linearly on the upper bound of the weights $\{w_i\}$ as well as their derivatives $\{Dw_i\}$. In view of Remark 2.3 and assuming ϵ to be small enough we thus obtain the first estimate in (4.3), which in turns yields the second one for large κ.

Case 2. Interaction of a wave of family $i_\beta \neq k$ with a kth positive wave ($i_\alpha = k,\ \epsilon_\alpha > 0$) solved by the accurate Riemann solver (Figure 4.1 (c)). As before, we obtain

$$\begin{aligned} \Delta V &= \mathcal{O}(1)|\epsilon_\alpha \epsilon_\beta|, \\ \Delta Q_0 &= \mathcal{O}(1)\epsilon_0 \cdot |\epsilon_\alpha \epsilon_\beta|. \end{aligned} \tag{4.4}$$

We view ΔQ_{large} as a function of the state $u \in \Omega$ attained by u^ϵ between the interacting fronts α and β and the strengths ϵ_α and ϵ_β:

$$\Delta Q_{large} = -w_{i_\alpha} \cdot |\epsilon_\alpha| + \sum_{j \neq k} w_j^{out} \cdot |\epsilon_j^{out}| = G(u, \epsilon_\alpha, \epsilon_\beta).$$

Choose $\theta \in [0, \Theta]$ such that $||u - \mathcal{R}_k(\theta)|| < \epsilon_0$. Since $G(u, \epsilon_\alpha, 0) = G(u, 0, \epsilon_\beta) = 0$, we have

$$\begin{aligned} &|G(u, \epsilon_\alpha, \epsilon_\beta) - G(\mathcal{R}_k(\theta), \epsilon_\alpha, \epsilon_\beta)| \\ &\qquad \leq |\epsilon_\alpha \epsilon_\beta| \cdot \int_0^1 \int_0^1 \left| \frac{\partial^2}{\partial \epsilon_\alpha \partial \epsilon_\beta} G(u, s\epsilon_\alpha, z\epsilon_\beta) - \frac{\partial^2}{\partial \epsilon_\alpha \partial \epsilon_\beta} G(\mathcal{R}_k(\theta), s\epsilon_\alpha, z\epsilon_\beta) \right| \mathrm{d}s\mathrm{d}z. \end{aligned}$$

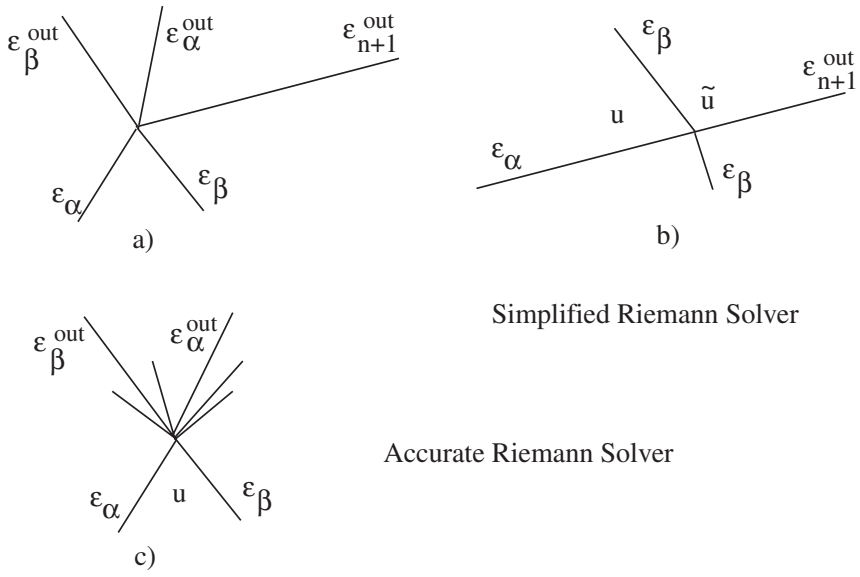

FIG. 4.1.

If only the constant c in the definition (1.5) of Ω is small enough, the integrand in the above estimate is as small as we wish. Thus in view of Remark 2.2 we obtain $\Delta Q_{large} \leq -c \cdot |\epsilon_\alpha \epsilon_\beta|$ for some different constant $c > 0$, taking w_k sufficiently small with respect to other weights. If ϵ is small enough and κ large, this implies (4.3).

We remark that if the interaction as in Case 2 is to be solved by the simplified Riemann solver (Figure 2.1 (a)), then (4.3) follows exactly as above provided we define ϵ_k^{out} to be equal to ϵ_k^{out} in the accurate solution and take the scaling constant c in (4.2) small with respect to other weights $w_i,\ i : 1 \dots n$.

Case 3. Interaction of a nonphysical front ($i_\alpha = n+1$) with a positive k-wave ($i_\beta = k,\ \epsilon_\beta > 0$) solved by the simplified Riemann solver (Figure 4.1 (b)). Again (4.4) is valid. Call u the left state of the wave α and call $\tilde{u}$ the state attained by u^ϵ between the two outgoing waves. Then

$$\begin{aligned}
\Delta Q_{large} &= w_{n+1}(\tilde{u}) \cdot |\epsilon_{n+1}^{out}| - w_{n+1}(u) \cdot |\epsilon_\alpha| \\
&\leq (w_{n+1}(\tilde{u}) - w_{n+1}(u)) \cdot |\epsilon_\alpha| + \mathcal{O}(1) w_{n+1}(\tilde{u}) \cdot |\epsilon_\alpha \epsilon_\beta| \\
&= c \cdot \exp(-C\lambda_k(\tilde{u})) \cdot [1 - \exp(-C\epsilon_\beta) + \mathcal{O}(1)\epsilon_\beta] \cdot |\epsilon_\alpha| \\
&= c \cdot \exp(-C\lambda_k(\tilde{u})) \cdot \left[\mathcal{O}(1) - \frac{\exp(C\epsilon_\beta) - 1}{\epsilon_\beta}\right] \cdot |\epsilon_\alpha \epsilon_\beta| \\
&\leq -c\frac{C}{4} \exp(-C\lambda_k(\tilde{u})) \cdot |\epsilon_\alpha \epsilon_\beta|
\end{aligned}$$

if only C in (4.2) is large enough. Taking ϵ_0 small and κ large, we conclude (4.3). ∎

Define now the domain

$$\bar{\mathcal{D}}_{\epsilon_0} = \text{cl}\,\{v \in \mathcal{D}_{\epsilon_0}, \quad \Gamma(v) \leq \epsilon_0\}, \tag{4.5}$$

where cl denotes the closure in L^1_{loc}. Relying on Lemma 4.4 and Remark 4.2, we obtain the following.

LEMMA 4.5. *In the setting of Lemma* 4.4, *an approximate solution* $u^\epsilon(t,x)$ *generated by the algorithm from initial data* $\bar u \in \bar{\mathcal{D}}_{\epsilon_0}$ *exists for all times* $t>0$ *and enjoys the following properties:*

(i) $||\bar u - u^\epsilon(0,\cdot)||_{L^1} \le \epsilon$,

(ii) u^ϵ *is piecewise constant, with jumps occurring along finitely many lines; jumps are of three types: shocks (and contact discontinuities), rarefaction fronts, and nonphysical waves; all jumps have strength* $<\epsilon_0$, *while all rarefaction fronts have strength* $<\epsilon$,

(iii) *along each shock or a rarefaction front not belonging to the* k*th family we have that its speed differs from the exact speed (Rankine–Hugoniot speed for shocks and the eigenvalue at the left state for rarefaction fronts) at most by* ϵ; *the speeds of all* k*-positive waves are exact (that is, equal to* λ_k *evaluated at the left state); all nonphysical waves travel with speed* $\hat\lambda$,

(iv) *at each time* $t\ge 0$ *the sum of strengths of nonphysical waves in* u^ϵ *is bounded by* ϵ,

(v) *for all* $t\ge 0$ *we have* $\Gamma(u^\epsilon(t,\cdot)) \le \epsilon_0$.

Now a standard argument yields that a subsequence of approximations u^ϵ converges to a solution of (1.1), (1.2) and that the domain $\bar{\mathcal{D}}_{\epsilon_0}$ is positively invariant with respect to the flow generated in this way. Again, all the details can be found in [B]. To prove Theorem 1 it thus suffices to show the following.

LEMMA 4.6. *Let* $\bar u \in \text{cl}\,\mathcal{E}_{c,\delta}$ *for sufficiently small* $c,\delta>0$, *as in Theorem* 1. *Then* $\bar u \in \bar{\mathcal{D}}_{\epsilon_0}$ *for some* $\epsilon_0=\epsilon_0(\delta)$ *and* $\lim_{\delta\to 0}\epsilon_0(\delta)=0$.

The proof will be given in section 9.

5. First order rarefactions. We call a positive kth wave located at y_0 at time $T>0$ a first order k-rarefaction wave if there exists a continuous curve $y(t)$ with $y(T)=y_0$ such that for almost all $t\in[0,T]$, $y(t)$ is the location of a positive kth wave. For each $t\in[0,+\infty)$ let $L^u(t)$ be the set of locations of first order k-rarefaction waves in u.

LEMMA 5.1. *Let* $u^\epsilon(t,x)$ *be as in Lemma* 4.5 *(in particular* $u^\epsilon(t,\cdot)\in\mathcal{D}_{\epsilon_0}$ *for all* $t\ge 0$*). Then*

$$\tilde V(t) := \left|\left(\sum_{x_\alpha\in L^u(t)}\epsilon_\alpha\right)-\Theta\right| + \left(\sum_{x_\alpha\notin L^u(t)}|\epsilon_\alpha|\right) = \mathcal{O}(1)\cdot\epsilon_0, \tag{5.1}$$

with the above summations extending on all waves α *present in* $u^\epsilon(t,\cdot)$. *Moreover, if* $y(t)$ *is continuous and* $y(t)\in L^u(t)$ *for almost all* $t\in[0,T]$, *then*

$$\forall t,s\in[0,T]\quad |\lambda_k(u^\epsilon(t,y(t)-)) - \lambda_k(u^\epsilon(s,y(s)-))| = \mathcal{O}(1)\cdot\epsilon_0. \tag{5.2}$$

Proof. Above $\tilde V(0)$ is understood as $\tilde V(t)$ for t close to 0. To prove (5.1) one defines new interaction potentials by the same formula as Q_0 and Q_{large} but treating positive kth waves located in $\mathbf{R}\setminus L^u(t)$ as perturbations. Then Lemma 4.4 and its proof are still valid, with V exchanged there to $\tilde V$. Thus the estimate in (5.1) follows.

In order to deduce (5.2) we may restrict our attention to the case $t=T$ and $s=0$. It is convenient to consider the evolution of the related functional

$$\tilde\Gamma(t) = |y'(t)-y'(0)| + \kappa\cdot\tilde V(t) + \kappa^2\cdot Q(t),$$

where $\tilde V(t)$ is defined as the sum of strengths of perturbation waves α in

$$\{x_\alpha < y(t) \text{ and } i_\alpha\ge k\}\cup\{x_\alpha>y(t) \text{ and } i_\alpha\le k\}$$

and $\kappa > 1$ is a large constant. We see that when $y(t)$ interacts with another wave α then $\Delta Q \le 0$, $\Delta y' = \mathcal{O}(1)|\epsilon_\alpha|$, and $\Delta \tilde{V} = -|\epsilon_\alpha|$. On the other hand, at any other time $\Delta y' = 0$ and $\Delta(\tilde{V} + \kappa Q) \le 0$. Thus $\tilde{\Gamma}$ is a nonincreasing function of t only if κ is large. Hence $|y'(T) - y'(0)| \le \tilde{\Gamma}(0) = \mathcal{O}(1)\epsilon_0$, and (5.2) follows since

$$y'(t) = \lambda_k(u^\epsilon(t, y(t)-))$$

for almost all $t \in [0, T]$. □

6. Lyapunov functional: A proof of Theorem 2. Toward a proof of Theorem 2, in this section we carry out the construction of the Lyapunov functional Φ. Following [LY, BLY], $\Phi(u, v)$ is supposed to control the L^1 distance between the two ϵ-approximate solutions $u, v : [0, \infty) \times \mathbf{R} \longrightarrow \mathbf{R}^n$ obtained by the wave front tracking algorithm and thus enjoying the properties in Lemma 4.5. Assuming the L^1 stability condition (3.1), the two crucial properties of Φ will be the following:

$$\Phi(u(t,\cdot), v(t,\cdot)) \le \Phi(u(s,\cdot), v(s,\cdot)) + C \cdot \epsilon \cdot (t - s), \tag{6.1}$$

$$\frac{1}{C} \cdot ||u(t,\cdot) - v(t,\cdot)||_{L^1} \le \Phi(u(t,\cdot), v(t,\cdot)) \le C \cdot ||u(t,\cdot) - v(t,\cdot)||_{L^1}, \tag{6.2}$$

for all $t > s \ge 0$ and a uniform constant $C > 0$ depending only on the system (1.1). In the remaining part of the article we will concentrate on proving (6.1), (6.2) for a functional Φ constructed below. Taking then $\mathcal{D} = \bar{\mathcal{D}}_{\epsilon_0}$, for a small $\epsilon_0 > 0$, the proof of Theorem 2 will follow by the already standard argument as in Chapter 8.3 of [B].

Fix a positive and small constant ν. Given piecewise constant functions u and v, let

$$T = \sup\Big\{t > 0; \quad \exists_x \quad |\lambda_k(u(t,x)) - \lambda_k(v(t,x))| > \nu\Big\}. \tag{6.3}$$

LEMMA 6.1. *T defined as above is finite.*

Proof. Notice that since the total strength of perturbation waves is of the order ϵ_0 at each time t, then taking $\epsilon \ll \epsilon_0$ we have

$$\sup_{t \ge 1, x} ||u(t,x) - \tilde{u}(t,x)|| + \sup_{t \ge 1, x} ||v(t,x) - \tilde{v}(t,x)|| = \mathcal{O}(1)\epsilon_0. \tag{6.4}$$

The functions $\tilde{u}$ and $\tilde{v} : [1, +\infty) \times \mathbf{R} \longrightarrow \mathbf{R}^n$ are smooth solutions to (1.1) with initial data

$$\tilde{u}(1,x) = u_0(1, \psi(x)), \quad \tilde{v}(1,x) = v_0(1, \phi(x)),$$

where ψ and $\phi : \mathbf{R} \longrightarrow \mathbf{R}$ are some increasing diffeomorphisms. We want to show that

$$\lim_{t \to +\infty} \sup |\lambda_k(\tilde{u}(t,x)) - \lambda_k(\tilde{v}(t,x))| = 0, \tag{6.5}$$

which in view of (6.4) and taking $\epsilon \ll \epsilon_0$ will imply that $T < +\infty$.

Notice that for each $t \ge 1$, $\tilde{u}$ is constant outside the interval

$$J_t^u = \big[\psi^{-1}(\lambda_k(u_l)) + \lambda_k(u_l) \cdot (t-1), \psi^{-1}(\lambda_k(u_r)) + \lambda_k(u_r) \cdot (t-1)\big]$$

and that it propagates along the straight lines—characteristics having slopes λ_k inside the region $\{(t,x);\ x\in J_t^u\}$. Consequently, one has

$$\sup_{x\in J_t^u\cap J_t^v}|\lambda_k(\tilde u(t,x))-\lambda_k(\tilde v(t,x))|\leq \frac{\max\limits_{w,z\in\{u_l,u_r\}}|\psi^{-1}(\lambda_k(w))-\phi^{-1}(\lambda_k(z))|}{t-1}, \tag{6.6}$$

where the interval J_t^v is defined as J_t^u, by means of the diffeomorphism ϕ. Obviously, the right-hand side of (6.6) vanishes as $t\to+\infty$. Likewise, $\sup_{x\notin J_t^u\cap J_t^v}|\lambda_k(\tilde u(t,x)-\lambda_k(\tilde v(t,x))|$ also converges to 0, because of the spreading of the rarefactions in $\tilde u$ and $\tilde v$. This establishes (6.5). □

The definition of the functional $\Phi(u,v)$ falls in two parts.

Case 1 *(the profiles* $\mathbf{u}$ *and* $\mathbf{v}$ *are apart from each other):* $\mathbf{t}\in[\mathbf{0},\mathbf{T}]$. Let $T>0$. Without loss of generality we may assume that for some x there holds $\lambda_k(u(t,x))>\lambda_k(v(t,x))+3\nu/4$ (the case of the opposite inequality may be treated similarily). Because of the estimate in (5.1) and taking $\epsilon_0\ll\nu$, there exists then a nonempty interval $I(T)=[z_0^-,z_0^+]$ such that $z_0^-\in L^u(T),\ z_0^+\in L^v(T)$ and

$$\forall x,y\in I(T)\quad \lambda_k(u(T,x))-\lambda_k(v(T,y))>\nu/2. \tag{6.7}$$

For $t\in[0,T]$ call $I(t)$ the space interval whose boundary is continuous polygonals $z^-(t)\in L^u(t),\ z^+(t)\in L^v(t)$ with $z^-(T)=z_0^-$ and $z^+(T)=z_0^+$. Notice that, taking ϵ_0 small enough, Lemma 5.1 yields

$$\forall t\in[0,T],\quad \forall x,y\in I(t)\quad \lambda_k(u(t,x))-\lambda_k(v(t,y))>\nu/3. \tag{6.8}$$

For all $t\in[0,T)$ the Lyapunov functional Φ is defined by the formula

$$\Phi(u,v)(t)=||u(t,\cdot)-v(t,\cdot)||_{L^1}+\kappa_1\cdot|I(t)|, \tag{6.9}$$

where $|I(t)|$ stands for the length of the interval $I(t)$ and κ_1 is a sufficiently large integer constant.

LEMMA 6.2. *If only* κ_1 *is large enough, then the functional* Φ *satisfies*

$$\Phi(u(t',\cdot),v(t',\cdot))\leq\Phi(u(t,\cdot),v(t,\cdot)), \tag{6.10}$$

$$||u(t,\cdot)-v(t,\cdot)||_{L^1}\leq\Phi(u(t,\cdot),v(t,\cdot))\leq C\cdot||u(t,\cdot)-v(t,\cdot)||_{L^1} \tag{6.11}$$

for all $0\leq t\leq t'\leq T$ *and a uniform constant* $C>0$.

Proof. The equivalence (6.11) of Φ with the L^1 distance follows in view of (6.8).

Denote by $\mathcal{J}(u)$ and $\mathcal{J}(v)$ the sets of all jumps in u and v, respectively. To prove (6.10) fix $t\in[0,T)$, which is not a time of interaction of any couple of fronts in u or v. We have

$$\begin{aligned}\frac{\mathrm{d}}{\mathrm{d}t}\Phi(u,v)(t)=&\\ \sum_{\alpha\in\mathcal{J}(u)\cup\mathcal{J}(v)}&\Big||u(x_\alpha+,t)-v(x_\alpha+,t)|-|u(x_\alpha-,t)-v(x_\alpha-,t)|\Big|\cdot\dot x_\alpha\\ &+\kappa_1\cdot\frac{\mathrm{d}}{\mathrm{d}t}|I(t)|.\end{aligned} \tag{6.12}$$

The first term in (6.12) is of the order of $\mathcal{O}(1)$ because of the finite speed of propagation, boundedness of $TV(u(t))$ and $TV(v(t))$, and

$$|u(x_\alpha+,t)-v(x_\alpha+,t)|-|u(x_\alpha-,t)-v(x_\alpha-,t)|=\mathcal{O}(1)|\epsilon_\alpha|.$$

On the other hand, in view of (6.8) we have $\mathrm{d}/\mathrm{d}t\ |I(t)|\le -\nu/4$. Thus if κ_1 is large with respect to the system constants and the prechosen ν, we obtain

$$\frac{\mathrm{d}}{\mathrm{d}t}\Phi(u,v)(t)\le 0.$$

Integrating in time we conclude (6.10). □

Case 2 *(***u** *and* **v** *close):* $\mathbf{t}\ge\mathbf{T}$. The Lyapunov functional Φ is defined as in [BLY, B]:

$$\Phi(u,v)=\int_{-\infty}^{+\infty}\sum_{i=1}^{n}W_i(x)\cdot w_i(x)\cdot|q_i(x)|\,\mathrm{d}x. \tag{6.13}$$

The scalar quantities $q_i(x)$ are, roughly speaking, the curvilinear coordinates of the vector $v(x)-u(x)$, computed along combinations of shock curves in Ω. The precise definition of W_i and w_i will be our concern in what follows.

The coordinates $\{q_i(x)\}_{i=1}^n$ are implicitely defined by

$$v(x)=\mathcal{S}_n(q_n(x))\circ\ldots\mathcal{S}_k(q_k(x))\circ\ldots\mathcal{S}_1(u(x),q_1(x)). \tag{6.14}$$

Such decomposition exists if ν is small enough, as $|\lambda_k(u(x,t))-\lambda_k(v(x,t))|\le\nu$ for all x and $t\ge T$. The weights $w_i(x)$ are given by

$$w_i(x)=w_i\Big(\mathcal{S}_{i-1}(q_{i-1}(x))\circ\ldots\mathcal{S}_1(u(x),q_1(x))\Big), \tag{6.15}$$

where the w_i's in the right-hand side are given by (2.1) and the L^1 stability condition (3.1). We see that the weights $w_i(x)$ in (6.15) are computed at the left states of the corresponding waves. Recall that $w_k>0$ is constant in Ω.

We will now define the functional weights $W_i(x)$. Recall that $i_\alpha\in\{1\ldots n+1\}$ is the family of the jump located at x_α with strength ϵ_α. Also, by $\mathcal{J}(u)$ and $\mathcal{J}(v)$ we denote the sets of all jumps in u and v. Let $\mathcal{P}(u)$ and $\mathcal{P}(v)$ be the respective subsets of $\mathcal{J}(u)$ and $\mathcal{J}(v)$, containing those α for which $i_\alpha\ne n+1$ and either $i_\alpha\ne k$ or $i_\alpha=k$ and $\epsilon_\alpha<0$.

Define the quantities $A_i(x)$ measuring the total amount of physical perturbation waves in u and v which approach the ith wave $q_i(x)$ located at x [BLY]. More precisely, when the ith field is linearly degenerate we set

$$A_i(x)=\left[\sum_{\substack{\alpha\in\mathcal{P}(u)\cup\mathcal{P}(v)\\ x_\alpha<x,\ i_\alpha>i}}+\sum_{\substack{\alpha\in\mathcal{P}(u)\cup\mathcal{P}(v)\\ x_\alpha>x,\ i_\alpha<i}}\right]|\epsilon_\alpha|.$$

For a genuinely nonlinear ith field

$$A_i(x) = \left[\sum_{\substack{\alpha\in\mathcal{P}(u)\cup\mathcal{P}(v)\\ x_\alpha<x,\ i_\alpha>i}} + \sum_{\substack{\alpha\in\mathcal{P}(u)\cup\mathcal{P}(v)\\ x_\alpha>x,\ i_\alpha<i}}\right]|\epsilon_\alpha| + \begin{cases} \left[\sum_{\substack{\alpha\in\mathcal{P}(u)\\ x_\alpha<x,\ i_\alpha=i}} + \sum_{\substack{\alpha\in\mathcal{P}(v)\\ x_\alpha>x,\ i_\alpha=i}}\right]|\epsilon_\alpha| & \text{if } q_i(x)<0,\\ \left[\sum_{\substack{\alpha\in\mathcal{P}(v)\\ x_\alpha<x,\ i_\alpha=i}} + \sum_{\substack{\alpha\in\mathcal{P}(u)\\ x_\alpha>x,\ i_\alpha=i}}\right]|\epsilon_\alpha| & \text{if } q_i(x)\geq 0. \end{cases}$$

Define

$$\forall i: 1\dots n \quad W_i(x) = 1 + \kappa_2(Q(u)+Q(v)) + \kappa_3 A_i(x) + \delta_{ik}\cdot\kappa_4|q_k(x)|. \tag{6.16}$$

Here Q stands for the Glimm's interaction potential from Definition 4.3 and δ_{ik} is the Kronecker delta. The (large) constants $\kappa_2,\kappa_3,\kappa_4$ are to be determined later; we see that as soon as they have been assigned, we can impose a suitably small bound on the amount of perturbation in u and v (by taking ϵ_0 small in (4.5), or in particular δ small in Theorem 1) so that

$$1\leq W_i(x)\leq 4 \qquad \text{for all } i,x. \tag{6.17}$$

This ends the definition of the functional Φ.

LEMMA 6.3. *The functional Φ constructed above satisfies* (6.1) *and*

$$\frac{1}{C}||u(t,\cdot)-v(t,\cdot)||_{L^1}\leq\Phi(u(t,\cdot),v(t,\cdot))\leq||u(t,\cdot)-v(t,\cdot)||_{L^1} \tag{6.18}$$

for all $t'>t\geq T$ and a uniform constant $C>0$ depending only on the system (1.1).

Proof. The equivalence of Φ with the L^1 distance as in (6.18) follows from (6.17) if we take the weights $\{w_i\}_{i=1}^n$ small enough.

To prove the estimate in (6.1), define $\lambda_i(x)$ as the Rankine–Hugoniot speed of the shock/contact $q_i(x)$.

Recall that a direct calculation [BLY] gives

$$\frac{\mathrm{d}}{\mathrm{d}t}\Phi(u(t),v(t)) = \sum_{\alpha\in\mathcal{J}(u)\cup\mathcal{J}(v)}\sum_{i=1}^n E_{\alpha,i}, \tag{6.19}$$

with

$$\begin{aligned} E_{\alpha,i} = {} & \left(W_i\cdot w_i\cdot|q_i|\right)(x_\alpha+)\cdot(\lambda_i(x_\alpha+)-\dot{x}_\alpha)\\ & -\left(W_i\cdot w_i\cdot|q_i|\right)(x_\alpha-)\cdot(\lambda_i(x_\alpha-)-\dot{x}_\alpha). \end{aligned} \tag{6.20}$$

Above $\dot{x}_\alpha$ denotes the speed of propagation of the wave α located at x_α. We will prove that

$$\frac{\mathrm{d}}{\mathrm{d}t}\Phi(u(t),v(t))\leq\mathcal{O}(1)\epsilon \tag{6.21}$$

for every time $t \geq T$ where the fronts in u or v do not interact. Indeed, this will be the goal of the next section.

Next, let t be such that say fronts ϵ_α and ϵ_β in u interact. It is easy to notice that for every x and i we have

$$A_i(t+, x) - A_i(t-, x) \leq \mathcal{O}(1)|\epsilon_\alpha \epsilon_\beta|.$$

On the other hand, by Lemma 4.4, the quantity $Q(u)$ decreases by the same order of magnitude. Thus if κ_2 in (6.16) is large enough, all functional weights $W_i(x)$ must decrease across the time t. Consequently, the whole functional Φ decreases as well. Based on these two observations and integrating (6.21) in time, we conclude (6.1). □

7. Stability estimates. In this section we want to establish the inequality (6.21) by estimating local terms $E_{\alpha,i}$ in (6.20). All calculations refer to a fixed jump $\alpha \in \mathcal{J}(v)$, propagating with speed $\dot{x}_\alpha$ and belonging to a characteristic family $i_\alpha : 1 \dots n+1$. When $\alpha \in \mathcal{J}(u)$, only minimal and obvious modifications of our arguments are required and so we leave them to the reader.

We first focus on the case $i_\alpha = n+1$. We will prove that

$$\sum_{i=1}^{n} E_{\alpha,i} \leq \mathcal{O}(1)|\epsilon_\alpha|. \tag{7.1}$$

Indeed,

$$\forall\ i \neq k \quad |w_i^+ q_i^+ - w_i^- q_i^-| + |\lambda_i^+ - \lambda_i^-| = \mathcal{O}(1)|\epsilon_\alpha|.$$

Also, for $i \neq k$ and if $\operatorname{sgn} q_i^- = \operatorname{sgn} q_i^+$ we have $W_i^+ = W_i^-$. On the other hand, if $\operatorname{sgn} q_i^- \neq \operatorname{sgn} q_i^+$, then $|q_i^+| + |q_i^-| = \mathcal{O}(1)|\epsilon_\alpha|$ and, consequently,

$$\sum_{i \neq k} E_{\alpha,i} \leq \mathcal{O}(1)|\epsilon_\alpha|.$$

In a similar manner, $E_{\alpha,k} \leq \mathcal{O}(1)|\epsilon_\alpha|$ if $\operatorname{sgn} q_k^- \neq \operatorname{sgn} q_k^+$. The same is true if $\operatorname{sgn} q_k^- = \operatorname{sgn} q_k^+$ because then

$$\Delta W_k = \mathcal{O}(1)|\epsilon_\alpha|.$$

The bound (7.1) is thus proven. Now, recalling Lemma 4.5(iv), (7.1) yields

$$\sum_{i_\alpha = n+1} \sum_{i=1}^{n} E_{\alpha,i} \leq \mathcal{O}(1)\epsilon. \tag{7.2}$$

Let now $i_\alpha : 1 \dots n$. Our goal will be to prove that

$$\sum_{i=1}^{n} E_{\alpha,i} = \mathcal{O}(1)\epsilon|\epsilon_\alpha|. \tag{7.3}$$

Recall that by Lemma 4.5 $|\epsilon_\alpha| < \epsilon$, whenever α is a rarefaction wave. In view of (1.8) and the definition (6.20) we may thus without loss of generality replace each rarefaction wave α by a (possibly nonentropic) shock having the original strength ϵ_α and the speed $\dot{x}_\alpha = \lambda_k(v(x_\alpha -))$. We will prove that with this modification the same

estimate as in (7.3) holds. For simplicity, we write $W_i^+ = W_i(x_\alpha+)$, $q_i^- = q_i(x_\alpha-)$, etc.

The proof falls in several cases. Throughout the calculations, we often use the estimates from section 8. When α is a part of the rarefaction $\mathcal{R}_k$, our estimates rely on the stability condition (3.1); the parameters w_k and ν are chosen so that the negative term in (8.3) overcomes extra contributions which are not of the order $\mathcal{O}(1)\epsilon_\alpha^2$. When α is a perturbation wave, our argument is essentially a modification of the one from [BLY]. We again adjust ν appropriately and then take the constant κ_3 in (6.16) to be large with respect to other quantities in the derived estimates. The parameter ϵ_0, measuring the amount of perturbing waves present at any time in both approximate solutions u and v, is always set to be as small as needed, in particular $\epsilon_0 \ll \nu$.

Case 1. $i_\alpha = k$ and $\epsilon_\alpha > 0$. Recall that by Lemma 4.5 we have $|\epsilon_\alpha| < \epsilon$. We will prove

$$\sum_{i=1}^{n} E_{\alpha,i} = \mathcal{O}(1)\epsilon_\alpha^2, \tag{7.4}$$

which will clearly imply (7.3). We first estimate

$$\begin{aligned}\sum_{i\neq k} E_{\alpha,i} =& \sum_{i\neq k} (\Delta W_i)\cdot w_i^-|q_i^-|(\lambda_i^- - \dot{x}_\alpha)\\ &+ \sum_{i\neq k} W_i^+ \cdot \left[w_i^+|q_i^+|(\lambda_i^+ - \dot{x}_\alpha) - w_i^-|q_i^-|(\lambda_i^- - \dot{x}_\alpha)\right].\end{aligned} \tag{7.5}$$

Fix $i \neq k$. Notice that if $\operatorname{sgn} q_i^+ \neq \operatorname{sgn} q_i^-$, then

$$|q_i^-| \leq |q_i^+ - q_i^-| \quad \text{and} \quad \Delta W_i = \mathcal{O}(1)\kappa_3\epsilon_0. \tag{7.6}$$

On the other hand, if $\operatorname{sgn} q_i^+ = \operatorname{sgn} q_i^-$, then $\Delta W_i = 0$. Thus the first summand in (7.5) can be estimated using Lemma 8.1:

$$\begin{aligned}&\sum_{i\neq k} (\Delta W_i)\cdot w_i^-|q_i^-|(\lambda_i^- - \dot{x}_\alpha)\\ &\qquad \leq \mathcal{O}(1)\kappa_3\epsilon_0 \cdot \left[\epsilon_\alpha \cdot \left(\sum_{s>k}|q_s^-|\right) + \epsilon_\alpha\cdot|q_k^-|^2 + \epsilon_\alpha^2\right].\end{aligned} \tag{7.7}$$

In order to deal with the second summand in (7.5), we notice that if $\operatorname{sgn} q_i^+ \neq \operatorname{sgn} q_i^-$, then by (7.6) and Lemma 8.1, there holds

$$\begin{aligned}&\left|w_i^+|q_i^+|(\lambda_i^+ - \dot{x}_\alpha) - w_i^-|q_i^-|(\lambda_i^- - \dot{x}_\alpha)\right|\\ &\qquad \leq \mathcal{O}(1)\left[\epsilon_\alpha \cdot \left(\sum_{s>k}|q_s^-|\right) + \epsilon_\alpha\cdot|q_k^-|^2 + \epsilon_\alpha^2\right].\end{aligned} \tag{7.8}$$

The same is true when $\operatorname{sgn} q_i^+ = \operatorname{sgn} q_i^-$, as in this case the left-hand side of (7.8) equals $|w_i^+ q_i^+(\lambda_i^+ - \dot{x}_\alpha) - w_i^- q_i^-(\lambda_i^- - \dot{x}_\alpha)|$ and so one can again employ the estimates

of Lemma 8.1. In view of Remark 2.3, combining (7.5), (7.7), and (7.8) we obtain

$$\begin{aligned}
&\sum_{i\neq k} W_i^+ \cdot \left[w_i^+|q_i^+|(\lambda_i^+ - \dot{x}_\alpha) - w_i^-|q_i^-|(\lambda_i^- - \dot{x}_\alpha)\right] \\
&\leq [1+\kappa_2(Q(u)+Q(v))] \cdot \sum_{i\neq k} \left[w_i^+|q_i^+|(\lambda_i^+ - \dot{x}_\alpha) - w_i^-|q_i^-|(\lambda_i^- - \dot{x}_\alpha)\right] \\
&\quad + \mathcal{O}(1)\kappa_1\epsilon_0 \cdot \left[\epsilon_\alpha \cdot \left(\sum_{s>k}|q_s^-|\right) + \epsilon_\alpha \cdot |q_k^-|^2 + \epsilon_\alpha^2\right].
\end{aligned} \tag{7.9}$$

Estimating the first term in the right-hand side of (7.9) by Lemma 8.3 and noting (7.7), the quantity in (7.5) can be further bounded by

$$\sum_{i\neq k} E_{\alpha,i} \leq -\frac{\gamma_1}{2}\epsilon_\alpha \cdot \left(\sum_{s>k}|q_s^-|\right) + \mathcal{O}(1) \cdot \left[\epsilon_\alpha \cdot |q_k^-|^2 + \epsilon_\alpha^2\right] \tag{7.10}$$

if ϵ_0 is small enough.

We now aim at establishing (7.4) by estimating the remaining term $E_{\alpha,k}$. We distinguish two subcases.

Subcase 1.1. $\operatorname{sgn} q_k^+ \neq \operatorname{sgn} q_k^-$. Then

$$\Delta W_k = \mathcal{O}(1)\kappa_4\epsilon_\alpha + \mathcal{O}(1)\kappa_3\epsilon_0.$$

Therefore we have

$$\begin{aligned}
(\Delta W_k)w_k|q_k^-|(\lambda_k^- - \dot{x}_\alpha) &\leq \mathcal{O}(1)w_k\epsilon_\alpha\left(\kappa_4\epsilon_\alpha + \kappa_3\epsilon_0\right) \cdot \left(\epsilon_\alpha + \sum_{s>k}|q_s^-|\right) \\
&\leq \mathcal{O}(1)w_k\kappa_1\epsilon_0\epsilon_\alpha \cdot \left(\epsilon_\alpha + \sum_{s>k}|q_s^-|\right) + \mathcal{O}(1)\kappa_4\epsilon_\alpha^2.
\end{aligned} \tag{7.11}$$

On the other hand,

$$\begin{aligned}
&W_k^+ w_k \left[|q_k^+|(\lambda_k^+ - \dot{x}_\alpha) - |q_k^-|(\lambda_k^- - \dot{x}_\alpha)\right] \\
&\qquad \leq \mathcal{O}(1)w_k\epsilon_\alpha\left[|\lambda_k^+ - \dot{x}_\alpha| + |\lambda_k^- - \dot{x}_\alpha|\right] \leq \mathcal{O}(1)w_k\epsilon_\alpha \cdot \left(\sum_{s>k}|q_s^-|\right).
\end{aligned} \tag{7.12}$$

Summing (7.11) and (7.12) we obtain

$$E_{\alpha,k} = \mathcal{O}(1)w_k\epsilon_\alpha \cdot \left(\sum_{s>k}|q_s^-|\right) + \mathcal{O}(1)\kappa_4\epsilon_\alpha^2. \tag{7.13}$$

The bound (7.4) now follows by (7.13) and (7.10) if only w_k is chosen suitably small with respect to the constant γ_1 and for small ϵ_0.

Subcase 1.2. $\operatorname{sgn} q_k^+ = \operatorname{sgn} q_k^-$. By Lemma 8.1, we have

$$\Delta|q_k| = (\operatorname{sgn} q_k)\cdot\epsilon_\alpha + \mathcal{O}(1)\epsilon_\alpha\left(|q_k^-|^2 + \left(\sum_{s>k}|q_s^-|\right) + \epsilon_\alpha\right).$$

Thus, if only ϵ_0 and ν are small enough,

$$(\text{sgn } q_k)\cdot\Delta|q_k|\geq\epsilon_\alpha/2.$$

Moreover,

$$\lambda_k^- - \dot{x}_\alpha = \mathcal{O}(1)\left(\sum_{s>k}|q_s^-|\right) + (\text{sgn } q_k)\cdot\left(-\frac{|q_k^-|}{2}+\mathcal{O}(1)|q_k^-|^2\right)+\mathcal{O}(1)\epsilon_\alpha^2. \tag{7.14}$$

Recall that $\Delta W_k=\kappa_4\Delta|q_k|$. Hence,

$$\begin{aligned}(\Delta W_k)\cdot w_k|q_k^-|(\lambda_k^- - \dot{x}_\alpha) &= \kappa_4 w_k\cdot(\Delta|q_k|)\cdot|q_k^-|(\lambda_k^- - \dot{x}_\alpha)\\ &= w_k\kappa_4\cdot\left[\mathcal{O}(1)\epsilon_\alpha|q_k^-|\left(\sum_{s>k}|q_s^-|\right)+\mathcal{O}(1)\epsilon_\alpha|q_k^-|^3\right.\\ &\qquad\left.-\ \frac{1}{2}(\Delta|q_k|)(\text{sgn } q_k)|q_k^-|^2\right]+\mathcal{O}(1)\kappa_4\epsilon_\alpha^2\\ &\leq w_k\cdot\left[\mathcal{O}(1)\kappa_4\epsilon_\alpha|q_k^-|\left(\sum_{s>k}|q_s^-|\right)+\mathcal{O}(1)\epsilon_\alpha|q_k^-|^2\right]\\ &\quad-\ w_k\frac{\kappa_4}{4}\epsilon_\alpha|q_k^-|^2+\mathcal{O}(1)\kappa_4\epsilon_\alpha^2.\end{aligned} \tag{7.15}$$

Now, using (7.14) and Lemma 8.1 we obtain

$$(q_k^+ - q_k^-)(\lambda_k^- - \dot{x}_\alpha) = -\frac{q_k^-\epsilon_\alpha}{2}+\mathcal{O}(1)\epsilon_\alpha\left(|q_k^-|^2+\left(\sum_{s>k}|q_s^-|\right)+\epsilon_\alpha\right). \tag{7.16}$$

On the other hand, by Lemma 8.1

$$q_k^+(\lambda_k^+ - \lambda_k^-) = \frac{q_k^-\epsilon_\alpha}{2}+\mathcal{O}(1)\epsilon_\alpha\left(|q_k^-|^2+\left(\sum_{s>k}|q_s^-|\right)+\epsilon_\alpha\right).$$

Thus, in view of (7.16),

$$q_k^+(\lambda_k^+ - \dot{x}_\alpha) - q_k^-(\lambda_k^- - \dot{x}_\alpha) = \mathcal{O}(1)\epsilon_\alpha\left(|q_k^-|^2+\left(\sum_{s>k}|q_s^-|\right)+\epsilon_\alpha\right).$$

The above bound combined with (7.15) yields

$$\begin{aligned}E_{\alpha,k} = w_k\cdot\Bigg[&-\frac{\kappa_4}{5}\epsilon_\alpha|q_k^-|^2+\mathcal{O}(1)\kappa_4\epsilon_\alpha|q_k^-|\left(\sum_{s>k}|q_s^-|\right)\\ &+\mathcal{O}(1)\epsilon_\alpha\left(\sum_{s>k}|q_s^-|\right)\Bigg]+\mathcal{O}(1)\kappa_4\epsilon_\alpha^2,\end{aligned} \tag{7.17}$$

if only the constant κ_4 is larger than several independent quantities $\mathcal{O}(1)$ in the above series of estimates. Combining (7.17) and (7.10) we obtain (7.4) for w_k small and κ_4 large enough.

Case 2. $i_\alpha \neq k$. Note that for $i \neq k$ the quantities $E_{\alpha,i}$ can be estimated exactly as in [BLY]; see also [B] of Chapter 8.2. On the other hand, for $i = k$

$$\Delta W_k = \kappa_3 \cdot \operatorname{sgn}\,(i_\alpha - k) \cdot |\epsilon_\alpha| + \kappa_4 \cdot \Delta|q_k|$$

and

$$\Delta|q_k| = \mathcal{O}(1)|\epsilon_\alpha| \cdot \sum_{i=1}^{n} |q_i^-| = \mathcal{O}(1)|\epsilon_\alpha|(\epsilon_0 + \nu).$$

Thus the term in $E_{\alpha,k}$ containing ΔW_k can be estimated as follows:

$$\begin{aligned}(\Delta W_k) w_k |q_k^-|(\lambda_k^- - \dot{x}_\alpha) \leq & -\kappa_3 w_k \epsilon_\alpha |q_k^-||\lambda_k^- - \dot{x}_\alpha| \\ & + \mathcal{O}(1)\kappa_4 w_k \epsilon_\alpha(\epsilon_0 + \nu)|q_k^-||\lambda_k^- - \dot{x}_\alpha| \\ \leq & -\frac{\kappa_3}{2} w_k \epsilon_\alpha |q_k^-||\lambda_k^- - \dot{x}_\alpha|,\end{aligned}$$

if only $\epsilon_0 + \nu$ is small enough. The analysis in [BLY] can thus be applied to get (7.3).

Case 3. $i_\alpha = k$ and $\epsilon_\alpha < 0$. If $|\epsilon_\alpha| < \epsilon$ and $|q_k^-| \leq 2|\epsilon_\alpha|$, then recalling that $\Delta W_k \leq W_k^- + W_k^+ \leq 8$ by (6.17), and using (8.64) from [B], we conclude (7.3). The same argumentation as on page 167 of [B] yields (7.3) when $q_k^+ < 0 < q_k^-$.

We will now focus on the case when q_k^- and q_k^+ have the same sign. In view of the analysis of Lemma 8.3 we have

$$\begin{aligned}\Delta W_k &= \kappa_3(\operatorname{sgn} q_k)|\epsilon_\alpha| + \kappa_4|q_k^+ - q_k^-| = \kappa_3(\operatorname{sgn} q_k)|\epsilon_\alpha| \\ &+ \kappa_4(\operatorname{sgn} q_k) \cdot \left[-|\epsilon_\alpha| + \mathcal{O}(1)|\epsilon_\alpha||q_k^-|^2 + \mathcal{O}(1)|\epsilon_\alpha| \left(\sum_{s>k} |q_s^-| \right) + \mathcal{O}(1)\epsilon_\alpha^2 \right].\end{aligned} \tag{7.18}$$

Recalling the formula (8.50) from [B],

$$\dot{x}_\alpha - \lambda_k^- = \frac{q_k^- + \epsilon_\alpha}{2} + \mathcal{O}(1) \left[|q_k^- + \epsilon_\alpha|(|q_k^-| + |\epsilon_\alpha|) + \sum_{s \neq k} |q_s^-| \right],$$

the estimate (7.18) implies for κ_3 large (also $\kappa_3 > 2\kappa_4$) and ϵ_0 small that

$$\begin{aligned}(\Delta W_k) w_k |q_k^-|(\lambda_k^- - \dot{x}_\alpha) \leq & -\frac{\kappa_3}{3} w_k |\epsilon_\alpha||q_k^-||q_k^- + \epsilon_\alpha| \\ & + \mathcal{O}(1)\kappa_3 w_k |\epsilon_\alpha||q_k^-| \cdot \left(\sum_{s \neq k} |q_s^-| \right) + \mathcal{O}(1)\kappa_4 \epsilon_\alpha^2.\end{aligned} \tag{7.19}$$

Now, by the same reasoning as in Chapter 8.2, page 165 [B], we see that for ν small and some constant $c > 0$, there holds

$$\begin{aligned}W_k w_k \Delta[|q_k|(\lambda_k - \dot{x}_\alpha)] + \sum_{i \neq k} E_{\alpha,i} \leq & -c\kappa_3 |\epsilon_\alpha| \sum_{s \in \mathcal{I}} |q_s^-| \\ & + \mathcal{O}(1)|\epsilon_\alpha| \left(|q_k^-||q_k^- + \epsilon_\alpha| + \sum_{s \neq k} |q_s^-| \right),\end{aligned} \tag{7.20}$$

$$\sum_{i\neq k}|q_i^-| \leq |q_k^-||q_k^- + \epsilon_\alpha| + 2\sum_{s\in\mathcal{I}}|q_s^-|. \tag{7.21}$$

The index set $\mathcal{I}$ is defined as $\mathcal{I} = \{i : 1\dots n;\ i \neq k \text{ and } \operatorname{sgn} q_i^- = \operatorname{sgn} q_i^+\}$. Thus (7.19) becomes by (7.21)

$$\begin{aligned}(\Delta W_k)w_k|q_k^-|(\lambda_k^- - \dot{x}_\alpha) \leq -\ \frac{\kappa_3}{4}w_k|\epsilon_\alpha||q_k^-||q_k^- + \epsilon_\alpha| \\ +\ \mathcal{O}(1)\kappa_3 w_k|\epsilon_\alpha||q_k^-|\cdot\left(\sum_{s\in\mathcal{I}}|q_s^-|\right) + \mathcal{O}(1)\kappa_4\epsilon_\alpha^2\end{aligned}$$

if only ν is small enough. In view of (7.20), this implies

$$\begin{aligned}\sum_{i=1}^n E_{\alpha,i} \leq -\ c\kappa_3|\epsilon_\alpha|\left(\sum_{s\in\mathcal{I}}|q_s^-|\right) + \mathcal{O}(1)|\epsilon_\alpha|\left(|q_k^-||q_k^- + \epsilon_\alpha| + \sum_{s\in\mathcal{I}}|q_s^-|\right) \\ -\ \frac{\kappa_3}{4}w_k|\epsilon_\alpha||q_k^-||q_k^- + \epsilon_\alpha| + \mathcal{O}(1)\kappa_3 w_k|\epsilon_\alpha||q_k^-|\cdot\left(\sum_{s\in\mathcal{I}}|q_s^-|\right) + \mathcal{O}(1)\kappa_4\epsilon_\alpha^2,\end{aligned}$$

and consequently we obtain (7.4) for κ_3 large.

8. Technical lemmas.

LEMMA 8.1. *Let*

$$v = \mathcal{S}_n(q_n^-)\circ\dots\mathcal{S}_1(u,q_1^-), \qquad \mathcal{S}_k(v,\epsilon_\alpha) = \mathcal{S}_n(q_n^+)\circ\dots\mathcal{S}_1(u,q_1^+),$$

with $u\in\Omega$ and $\{q_i^-\}_{i=1}^n, \epsilon_\alpha$ small enough. For every $i : 1\dots n$, call $\lambda_i^\pm$ the speed of the shock wave $q_i^\pm$, as in (1.11). *Let* E *be any quantity satisfying the bound*

$$\mathrm{E} = \mathcal{O}(1)|\epsilon_\alpha|\left\{|q_k^-|^2 + \sum_{s>k}|q_s^-| + |\epsilon_\alpha|\right\}.$$

Then

(i) $|q_k^+ - q_k^- - \epsilon_\alpha| + \sum_{i\neq k}|q_i^+ - q_i^-| = \mathrm{E}$,

(ii) $\lambda_k^+ - \lambda_k^- = \epsilon_\alpha/2 + \mathrm{E}$,

(iii) *for all $i<k$ we have $\lambda_i^+ - \lambda_i^- = \mathrm{E}$, while for all $i>k$ there is $\lambda_i^+ - \lambda_i^- = \mathcal{O}(1)|\epsilon_\alpha| + \mathrm{E}$.*

Proof. We will prove only (i), the other assertions following in similar manner. For every $i : 1\dots n$, introduce an auxiliary function G_i:

$$G_i(u, q_1^-\dots q_n^-, \epsilon_\alpha) = q_i^+ - q_i^-.$$

We have

$$\begin{aligned}G_i = \epsilon_\alpha\cdot\left[\frac{\partial G_i}{\partial\epsilon_\alpha}(u, q_1^-\dots q_k^-, q_i^- = 0 \text{ for } i>k, \epsilon_\alpha = 0) + \mathcal{O}(1)\sum_{s>k}|q_s^-|\right] \\ +\ \mathcal{O}(1)\epsilon_\alpha^2.\end{aligned} \tag{8.1}$$

Moreover,

$$G_i(u, q_1^- \dots q_k^-, q_i^- = 0 \text{ for } i > k, \epsilon_\alpha = 0) - \delta_{ik} \cdot \epsilon_\alpha = \mathcal{O}(1)||G(u_{k-1}^-, q_k^-, \epsilon_\alpha)||, \tag{8.2}$$

where the quantity G is defined as

$$G(u_{k-1}^-, q_k^-, \epsilon_\alpha) = \mathcal{S}_k(u_{k-1}^-, q_k^- + \epsilon_\alpha) - \mathcal{S}_k(\mathcal{S}_k(u_{k-1}^-, q_k^-), \epsilon_\alpha)$$

for $u_{k-1}^- = \mathcal{S}_{k-1}(q_{k-1}^-) \circ \dots \mathcal{S}_1(u, q_1^-)$. Since

$$\begin{aligned} G(u_{k-1}^-, q_k^- = q, \epsilon_\alpha = -q) &= G(u_{k-1}^-, q_k^- = q, \epsilon_\alpha = 0) \\ &= G(u_{k-1}^-, q_k^- = 0, \epsilon_\alpha = q) = 0, \end{aligned}$$

consequently we obtain

$$\frac{\partial^2 G}{\partial \epsilon_\alpha \partial q_k^-}(u_{k-1}^-, q_k^- = 0, \epsilon_\alpha = 0) = 0.$$

Thus

$$G(u_{k-1}^-, q_k^-, \epsilon_\alpha) = \mathcal{O}(1)(|\epsilon_\alpha| \cdot |q_k^-|^2 + \epsilon_\alpha^2),$$

which in view of (8.1) and (8.2) implies (i). ∎

We now prove a generalization of the observation in section 3.

LEMMA 8.2. *Assume that the L^1 stability condition* (3.1) *is satisfied. There exists a constant $\gamma > 0$, depending only on the weights $\{w_i(\theta)\}_{i \neq k}$ such that the following holds. Let $u, v, \epsilon_\alpha, \{q_i^\pm\}$ be as in Lemma* 8.1 *with all $\{q_i^-\}_{i \leq k}$ equal to 0 and $\epsilon_\alpha \geq 0$. By $w_i^\pm$ we denote the weight associated to the shock wave $q_i^\pm$, computed at its left state, by means of* (2.1). *Then*

$$\begin{aligned} &\sum_{i>k} \left[w_i^+ |q_i^+| \cdot (\lambda_i^+ - \lambda_k(v)) - w_i^- |q_i^-| \cdot (\lambda_i^- - \lambda_k(v)) \right] \\ &\qquad + \sum_{i<k} w_i^+ |q_i^+| \cdot |\lambda_i^+ - \lambda_k(v)| \leq -\gamma \epsilon_\alpha \cdot \sum_{i>k} |q_i^-|. \end{aligned} \tag{8.3}$$

Analogously, if

$$\begin{aligned} &\mathcal{S}_k(q_k^+) \circ \mathcal{S}_{k-1}(q_{k-1}^-) \circ \dots \mathcal{S}_1(u, q_1^-) \\ &\qquad = \mathcal{S}_n(q_n^+) \circ \dots \mathcal{S}_{k+1}(q_{k+1}^+) \circ \mathcal{S}_{k-1}(q_{k-1}^+) \circ \dots \mathcal{S}_1(q_1^+) \circ \mathcal{S}_k(u, \epsilon_\alpha) \end{aligned}$$

for some $u \in \Omega$ and $\{q_i^-\}_{i<k}$ with $\epsilon_\alpha \geq 0$, then

$$\begin{aligned} &\sum_{i<k} \left[w_i^+ |q_i^+| \cdot (\lambda_i^+ - \lambda_k(u)) - w_i^- |q_i^-| \cdot |\lambda_i^- - \lambda_k(u)| \right] \\ &\qquad + \sum_{i>k} w_i^+ |q_i^+| \cdot |\lambda_i^+ - \lambda_k(u)| \leq -\gamma \epsilon_\alpha \cdot \sum_{i<k} |q_i^-|. \end{aligned}$$

Proof. We prove only the formula (8.3); the second part of the lemma follows by the same method. By standard interaction estimates [Sm] we have

$$\begin{aligned}\forall\ i>k \qquad |q_i^+|-|q_i^-| \leq & \sum_{s>k,\ s\neq i}\epsilon_\alpha|q_s^-|\cdot|\langle l_i,[r_k,r_s]\rangle(v)| \\ & +\ \epsilon_\alpha|q_i^-|\cdot\langle l_i,[r_k,r_i]\rangle(v) \\ & +\ \mathcal{O}(1)\epsilon_\alpha\left(\sum_{s>k}|q_s^-|\right)\left(\sum_{s\geq k}|q_s^-|\right),\end{aligned} \tag{8.4}$$

$$\begin{aligned}\forall\ i<k \qquad |q_i^+| \leq & \sum_{s>k}\epsilon_\alpha|q_s^-|\cdot|\langle l_i,[r_k,r_s]\rangle(v)| \\ & +\ \mathcal{O}(1)\epsilon_\alpha\left(\sum_{s>k}|q_s^-|\right)\left(\sum_{s\geq k}|q_s^-|\right).\end{aligned} \tag{8.5}$$

Also we have

$$\forall\ i>k \quad w_i^+-w_i^- = \epsilon_\alpha\cdot w_i'(\lambda_k(v))+\mathcal{O}(1)\left[\epsilon_\alpha\cdot\left(\sum_{s>k}|q_s^-|\right)+\epsilon_\alpha^2\right], \tag{8.6}$$

$$\forall\ i>k \quad \lambda_i^+-\lambda_i^- = \epsilon_\alpha\cdot\langle \mathrm{D}\lambda_i,r_k\rangle(v)+\mathcal{O}(1)\left[\epsilon_\alpha\cdot\left(\sum_{s>k}|q_s^-|\right)+\epsilon_\alpha^2\right]. \tag{8.7}$$

Thus

$$\begin{aligned}&\sum_{i>k}|q_i^-|(w_i^+-w_i^-)|\lambda_i^+-\lambda_k(v)|+\sum_{i>k}|q_i^-|w_i^-(\lambda_i^+-\lambda_i^-) \\ &\quad\leq\sum_{i>k}w_i'(\lambda_k(v))\cdot\epsilon_\alpha|q_i^-|\cdot|\lambda_i(v)-\lambda_k(v)|+\sum_{i>k}w_i(v)\epsilon_\alpha|q_i^-|\cdot\langle \mathrm{D}\lambda_i,r_k\rangle(v) \\ &\quad+\ \mathcal{O}(1)\left[\epsilon_\alpha^2\cdot\left(\sum_{s>k}|q_s^-|\right)+\epsilon_\alpha\cdot\left(\sum_{s>k}|q_s^-|\right)^2\right].\end{aligned} \tag{8.8}$$

Moreover, by (8.4) one arrives at

$$\begin{aligned}&\sum_{i>k}w_i^+\cdot\left(|q_i^+|-|q_i^-|\right)|\lambda_i^+-\lambda_k(v)| \\ &\quad\leq\sum_{i>k}\epsilon_\alpha|q_i^-|\cdot\Bigg(w_i(v)|\lambda_i(v)-\lambda_k(v)|\cdot\langle l_i,[r_k,r_i]\rangle(v) \\ &\qquad\qquad+\sum_{s>k,\ s\neq i}w_s(v)|\lambda_s(v)-\lambda_k(v)|\cdot|\langle l_s,[r_i,r_k]\rangle(v)|\Bigg) \\ &\quad+\ \mathcal{O}(1)\epsilon_\alpha\left(\sum_{s>k}|q_s^-|\right)\left(\epsilon_\alpha+\sum_{s>k}|q_s^-|\right).\end{aligned} \tag{8.9}$$

Adding (8.8) and (8.9), and noting (8.5), we see that the left-hand side of (8.3) can be estimated as follows:

$$
\begin{aligned}
&\epsilon_\alpha \cdot \sum_{i>k} |q_i^-| \cdot |\lambda_i(v) - \lambda_k(v)| \cdot \Bigg[w_i'(\lambda_k(v)) + w_i(v) \cdot \frac{\langle \mathrm{D}\lambda_i, r_k\rangle(v)}{|\lambda_i(v) - \lambda_k(v)|} \\
&\qquad + w_i(u) \cdot \langle l_i, [r_k, r_i]\rangle(v) + \sum_{i\neq k,i} w_s(v) \frac{|\lambda_s(v) - \lambda_k(v)|}{|\lambda_i(v) - \lambda_k(v)|} \cdot |\langle l_s, [r_i, r_k]\rangle(v)| \Bigg] \qquad (8.10) \\
&\quad + \mathcal{O}(1)\epsilon_\alpha \left(\sum_{s>k} |q_s^-| \right) \left(\epsilon_\alpha + \sum_{s>k} |q_s^-| \right).
\end{aligned}
$$

Applying the inequality (3.1) with $\theta \in (-c, \Theta + c)$ such that $\lambda_k(v) = \lambda_k(\mathcal{R}_k(\theta))$ and by a compactness argument, we obtain that (8.10) is bounded by the quantity in the right-hand side of (8.3). The proof is done. ∎

LEMMA 8.3. *Assume that the L^1 stability condition* (3.1) *is satisfied. Let u, v, ϵ_α, $\{q_i^\pm\}_{i=1}^n$ be as in Lemma* 8.1, *with $\epsilon_\alpha \geq 0$. Then*

$$
\begin{aligned}
&\sum_{i\neq k} \left[w_i^+ |q_i^+| (\lambda_i^+ - \lambda_k(v)) - w_i^- |q_i^-| (\lambda_i^- - \lambda_k(v)) \right] \\
&\qquad\qquad \leq -\gamma_1 \cdot \epsilon_\alpha \cdot \left(\sum_{s>k} |q_s^-| \right) + \mathcal{O}(1) \left[\epsilon_\alpha \cdot |q_k^-|^2 + \epsilon_\alpha^2 \right]
\end{aligned}
$$

for some constant $\gamma_1 > 0$, depending only on weights $\{w_i(\theta)\}_{i=1}^n$ and the uniform system bounds $\mathcal{O}(1)$.

Proof. Let Ξ denote the left-hand side of the desired inequality. We write $\{\tilde{q}_s\}_{s=1}^n$ and $\{\hat{q}_s\}_{s=1}^n$ for the quantities introduced implicitly by

$$
\mathcal{S}_n(\tilde{q}_n) \circ \ldots \mathcal{S}_{k+1}(\tilde{q}_{k+1}) \circ \mathcal{S}_{k-1}(\tilde{q}_{k-1}) \circ \ldots \mathcal{S}_1(\tilde{q}_1) \circ \mathcal{S}_k(u_k, \tilde{q}_k) = \mathcal{S}_k(v, \epsilon_\alpha),
$$

$$
\mathcal{S}_k(v, \epsilon_\alpha) = \mathcal{S}_n(\hat{q}_n) \circ \ldots \mathcal{S}_1(\hat{q}_1) \circ \mathcal{S}_k(u_{k-1}, q_{k-1}^- + \tilde{q}_k),
$$

$$
u_{k-1} = \mathcal{S}_{k-1}(q_{k-1}^-) \circ \ldots \mathcal{S}_1(u, q_1^-) \quad \text{and} \quad u_k = \mathcal{S}_k(u_{k-1}, q_k^-).
$$

By $\tilde{w}_s, \hat{w}_s$ and $\tilde{\lambda}_s, \hat{\lambda}_s$, we naturally denote weights and speeds corresponding to the waves $\tilde{q}_s$ and $\hat{q}_s$. We then have

$$
\begin{aligned}
\Xi = &\Bigg\{ \sum_{i>k} \left[\tilde{w}_i |\tilde{q}_i| (\tilde{\lambda}_i - \lambda_k(v)) - w_i^- |q_i^-| (\lambda_i^- - \lambda_k(v)) \right] \\
&\qquad\qquad - \sum_{i<k} \tilde{w}_i |\tilde{q}_i| (\tilde{\lambda}_i - \lambda_k(v)) \Bigg\} \qquad (8.11) \\
&+ \sum_{i\neq k} w_i^+ |q_i^+| (\lambda_i^+ - \lambda_k(v)) - \sum_{i<k} w_i^- |q_i^-| (\lambda_i^- - \lambda_k(v)) \\
&- \sum_{i>k} \tilde{w}_i |\tilde{q}_i| (\tilde{\lambda}_i - \lambda_k(v)) + \sum_{i<k} \tilde{w}_i |\tilde{q}_i| (\tilde{\lambda}_i - \lambda_k(v)).
\end{aligned}
$$

Observe that $\tilde{q}_k = \epsilon_\alpha + \mathcal{O}(1)\epsilon_\alpha \cdot \left(\sum_{s>k} |q_s^-|\right)$. Using the same arguments as in the proof of Lemma 8.1, we arrive at

$$\left(\sum_{i\neq k} |\tilde{q}_i - \hat{q}_i|\right) + |\hat{q}_k| \leq \mathcal{O}(1) \cdot \left[\epsilon_\alpha |q_k^-|^2 + \epsilon_\alpha^2\right]. \tag{8.12}$$

A similar bound is true for the corresponding differences of $\hat{\lambda}_i$ and $\tilde{\lambda}_i$, and $\hat{w}_i$ and $\tilde{w}_i$. Estimating the first term in (8.11) in view of Lemma 8.3, we obtain

$$\begin{aligned}
\Xi \leq & -\gamma\epsilon_\alpha \cdot \left(\sum_{s>k} |q_s^-|\right) + \mathcal{O}(1) \cdot \left[\epsilon_\alpha \cdot |q_k^-|^2 + \epsilon_\alpha^2\right] \\
& + \sum_{i>k} \left[w_i^+ |q_i^+| (\lambda_i^+ - \lambda_k(v)) - \hat{w}_i |\hat{q}_i| (\hat{\lambda}_i - \lambda_k(v))\right] \\
& + \sum_{i<k} \left[w_i^+ |q_i^+| (\lambda_i^+ - \lambda_k(v)) - w_i^- |q_i^-| (\lambda_i^- - \lambda_k(v))\right] \\
& + \sum_{i<k} \hat{w}_i |\hat{q}_i| (\hat{\lambda}_i - \lambda_k(v)).
\end{aligned} \tag{8.13}$$

Now, by standard interaction estimates [L], we have

$$\begin{aligned}
& \sum_{i<k} \left|q_i^+ - (q_i^- + \hat{q}_i)\right| + \sum_{i>k} \left|q_i^+ - \hat{q}_i\right| \\
& = \mathcal{O}(1) \cdot \left[\left(\sum_{i<k} |\hat{q}_i|\right) \cdot \left(\sum_{i<k} |q_i^-|\right) + \left|q_k^- + \epsilon_\alpha\right| \cdot \left(\sum_{i\leq k} |\hat{q}_i|\right)\right] \\
& = \mathcal{O}(1)\epsilon_\alpha \cdot \left[\left(\sum_{s>k} |q_s^-|\right) + |q_k^-|^2 + \epsilon_\alpha\right] \cdot \left[\left(\sum_{s<k} |q_s^-|\right) + |q_k^-| + \epsilon_\alpha\right] \\
& = \mathcal{O}(1) \cdot \epsilon_\alpha \cdot \left(\sum_{s>k} |q_s^-|\right) \left[\left(\sum_{s<k} |q_s^-|\right) + |q_k^-|\right] + \mathcal{O}(1) \left[\epsilon_\alpha |q_k^-|^2 + \epsilon_\alpha^2\right].
\end{aligned} \tag{8.14}$$

Noting that $\left(\sum_{s<k} |q_s^-|\right) + |q_k^-| = \mathcal{O}(1) \cdot (\epsilon_0 + \nu)$, we obtain

$$\begin{aligned}
& \sum_{i>k} \left[w_i^+ |q_i^+| (\lambda_i^+ - \lambda_k(v)) - \hat{w}_i |\hat{q}_i| (\hat{\lambda}_i - \lambda_k(v))\right] \\
& \qquad = \mathcal{O}(1) \cdot (\epsilon_0 + \nu)\epsilon_\alpha \cdot \left(\sum_{s<k} |q_s^-|\right) + \mathcal{O}(1) \cdot \epsilon_\alpha |q_k^-|^2 + \mathcal{O}(1)\epsilon_\alpha^2.
\end{aligned}$$

In view of (8.14), exactly the same bound as above is valid for the terms:

$$\sum_{i<k} \left[w_i^+ |q_i^+| (\lambda_i^+ - \lambda_k(v)) + \hat{w}_i |\hat{q}_i| (\hat{\lambda}_i - \lambda_k(v)) - w_i^- |q_i^-| (\lambda_i^- - \lambda_k(v))\right].$$

Hence by (8.13) the lemma follows, if only the constant ϵ_0 and ν are small enough. ∎

9. A sufficient condition for admissibility of initial data: A proof of Lemma 4.6.

LEMMA 4.6. *Let $\bar{u} \in \mathrm{cl}\ \mathcal{E}_{c,\delta}$ for some sufficiently small $c, \delta > 0$, as in Theorem 1. Then $\bar{u} \in \bar{\mathcal{D}}_{\epsilon_0}$, defined in (4.5), for some $\epsilon_0 = \epsilon_0(\delta)$ and $\lim_{\delta \to 0} \epsilon_0(\delta) = 0$.*

Proof. 1. Without loss of generality we may assume that $\bar{u}$ is piecewise constant, consecutively attaining N states $u_l = u^0, u^1 \dots u^N = u_r$ in $\mathbf{R}^n$, that for each $\alpha : 1 \dots N-1$ we have $||u^{\alpha+1} - u^\alpha|| < \delta$, and that (i), (ii), (iii) as in Theorem 1 are satisfied. For $\alpha : 0 \dots N-1$ and $i : 1 \dots n$ define

$$\gamma_\alpha^i = \langle l_i(u^\alpha), u^{\alpha+1} - u^\alpha \rangle.$$

Note that the self-similar solution of each Riemann problem $(u^\alpha, u^{\alpha+1})$ is composed of n waves having corresponding strengths $\epsilon_\alpha^1 \dots \epsilon_\alpha^n$ with the following obvious estimate:

$$\sum_{\alpha=0}^{N-1} \sum_{i=1}^{n} |\gamma_\alpha^i - \epsilon_\alpha^i| \le \sum_{\alpha=0}^{N-1} ||u^{\alpha+1} - u^\alpha||^2 < \delta \cdot \sum_{\alpha=0}^{N-1} ||u^{\alpha+1} - u^\alpha|| = \mathcal{O}(1)\delta.$$

To simplify the presentation we will assume that $||r_k(u)|| = 1$ for all $u \in \Omega$. In order to prove the lemma it is thus enough to show that

$$\left| \left(\sum_{\alpha=0}^{N-1} (\gamma_\alpha^k)^+ \right) - |\mathcal{R}_k| \right| < \epsilon_0 \quad \text{and} \quad \sum_{\alpha=0}^{N-1} \left((\gamma_\alpha^k)^- + \sum_{i \neq k} |\gamma_\alpha^i| \right) < \epsilon_0, \tag{9.1}$$

where $|\mathcal{R}_k|$ denotes the arc-length of the curve $\mathcal{R}_k(\theta),\ \theta \in [0, \Theta]$.

2. Fix a small constant $c > 0$ and divide the set of discontinuities in $\bar{u}$ into three subsets:

$$G = \left\{ \alpha : 0 \dots N-1, \quad \left\| \frac{u^{\alpha+1} - u^\alpha}{||u^{\alpha+1} - u^\alpha||} - r_k(u^\alpha) \right\| < c \right\},$$

$$B' = \left\{ \alpha : 0 \dots N-1, \quad \left\| \frac{u^{\alpha+1} - u^\alpha}{||u^{\alpha+1} - u^\alpha||} + r_k(u^\alpha) \right\| < c \right\},$$

$$B = \{0 \dots N-1\} \setminus (G \cup B').$$

It follows that for all $\alpha \in G$

$$\left| \frac{\gamma_\alpha^k}{||u^{\alpha+1} - u^\alpha||} - 1 \right| + \sum_{i \neq k} \left| \frac{\gamma_\alpha^i}{||u^{\alpha+1} - u^\alpha||} \right| = \mathcal{O}(1)c.$$

Thus

$$\left| \sum_{\alpha \in G} (\gamma_\alpha^k)^+ - \sum_{\alpha \in G} ||u^{\alpha+1} - u^\alpha|| \right| + \sum_{\alpha \in G} \left((\gamma_\alpha^k)^- + \sum_{i \neq k} |\gamma_\alpha^i| \right) = \mathcal{O}(1) \cdot c|\mathcal{R}_k|. \tag{9.2}$$

On the other hand, for all $\alpha \in B \cup B'$

$$\left| \frac{\gamma_\alpha^k}{||u^{\alpha+1} - u^\alpha||} - 1 \right| + \sum_{i \neq k} \left| \frac{\gamma_\alpha^i}{||u^{\alpha+1} - u^\alpha||} \right| = \mathcal{O}(1). \tag{9.3}$$

3. Let $\mathcal{P}:\Omega_\delta \longrightarrow \mathcal{R}_k$ be the orthogonal projection of Ω_δ onto $\mathcal{R}_k$. Note that if $u=\mathcal{R}_k(\theta)$ for some $\theta\in[0,\Theta]$, then $D\mathcal{P}(u)\cdot v=\langle v, r_k(u)\rangle\cdot r_k(u)$. We have

$$||u^{\alpha+1}-u^\alpha||-||\mathcal{P}(u^{\alpha+1})-\mathcal{P}(u^\alpha)||\geq \mathcal{O}(1)\delta\cdot||u^{\alpha+1}-u^\alpha||. \tag{9.4}$$

Also, for each $\alpha\in B$, the cosine of the angle between the vectors $u^{\alpha+1}-u^\alpha$ and $r_k(u^\alpha)$ satisfies

$$\left|\cos\angle\left(u^{\alpha+1}-u^\alpha, r_k(u^\alpha)\right)\right|\leq 1-c^2/2.$$

Thus, for $\alpha\in B$ we have

$$\begin{aligned}||\mathcal{P}(u^{\alpha+1})-\mathcal{P}(u^\alpha)||&\leq |\langle u^{\alpha+1}-u^\alpha, r_k(u^\alpha)\rangle|+\mathcal{O}(1)\cdot\delta||u^{\alpha+1}-u^\alpha||\\&\leq\left(1-\frac{c^2}{2}+\mathcal{O}(1)\delta\right)\cdot||u^{\alpha+1}-u^\alpha||,\end{aligned}$$

and, consequently,

$$||u^{\alpha+1}-u^\alpha||-||\mathcal{P}(u^{\alpha+1})-\mathcal{P}(u^\alpha)||\geq\left[\frac{c^2}{2}+\mathcal{O}(1)\delta\right]\cdot||u^{\alpha+1}-u^\alpha||. \tag{9.5}$$

By (9.4) and (9.5) we receive

$$\begin{aligned}&\sum_{\alpha=0}^{N-1}\left(||u^{\alpha+1}-u^\alpha||-||\mathcal{P}(u^{\alpha+1})-\mathcal{P}(u^\alpha)||\right)\\&\qquad\geq\frac{c^2}{2}\sum_{\alpha\in B}||u^{\alpha+1}-u^\alpha||+\mathcal{O}(1)\cdot\delta\sum_{\alpha}^{N-1}||u^{\alpha+1}-u^\alpha||.\end{aligned} \tag{9.6}$$

4. On the other hand, with $c\ll 1$ we have that $||\mathcal{P}(u^{\alpha+1})-\mathcal{P}(u^\alpha)||\geq 1/2\cdot||u^{\alpha+1}-u^\alpha||$ for all $\alpha\in G\cup B'$. Hence,

$$\begin{aligned}&\sum_{\alpha=0}^{N-1}||u^{\alpha+1}-u^\alpha||-\sum_{\alpha=0}^{N-1}||\mathcal{P}(u^{\alpha+1})-\mathcal{P}(u^\alpha)||\\&\qquad\leq|\mathcal{R}_k|+\delta-\left(|\mathcal{R}_k|+\mathcal{O}(1)\delta-2\cdot\sum_{\alpha\in B'}||\mathcal{P}(u^{\alpha+1})-\mathcal{P}(u^\alpha)||\right)\\&\qquad\leq\mathcal{O}(1)\delta-\sum_{\alpha\in B'}||u^{\alpha+1}-u^\alpha||.\end{aligned}$$

In view of (9.6) we thus obtain

$$c^2\cdot\sum_{\alpha\in B}||u^{\alpha+1}-u^\alpha||=\mathcal{O}(1)\delta. \tag{9.7}$$

The estimates (9.2), (9.3), and (9.7) yield

$$\begin{aligned}\left|\left(\sum_{\alpha=0}^{N-1}(\gamma_\alpha^k)^+\right)-|\mathcal{R}_k|\right|&\leq\left|\left(\sum_{\alpha\in G}(\gamma_\alpha^k)^+\right)-\left(\sum_{\alpha\in G}||u^{\alpha+1}-u^\alpha||\right)\right|\\&\quad+\left|\left(\sum_{\alpha\in B}(\gamma_\alpha^k)^+\right)-\left(\sum_{\alpha\in B}||u^{\alpha+1}-u^\alpha||\right)\right|+\mathcal{O}(1)\delta\\&\leq\mathcal{O}(1)c+\mathcal{O}(1)\sum_{\alpha\in B}||u^{\alpha+1}-u^\alpha||+\mathcal{O}(1)\delta\\&=\mathcal{O}(1)\cdot(c+\delta/c^2+\delta).\end{aligned}$$

Taking $c^2 = \sqrt{\delta}$, we receive the first estimate in (9.1) with $\epsilon_0 = \mathcal{O}(1)\delta^{1/4}$. The second estimate follows in the same manner. □

Acknowledgments. I am grateful to the referees for pointing out a mistake in an earlier version of the paper. I thank Professor Alberto Bressan for suggesting this problem to me. I thank Professor Constantine Dafermos for encouragement and his interest in this work. I also thank my colleagues at the University of Chicago for providing the stimulating atmosphere which allowed me to finish this project.

BOUNDS FOR THE STEADY-STATE SEL'KOV MODEL FOR ARBITRARY p IN ANY NUMBER OF DIMENSIONS*

GARY M. LIEBERMAN†

Abstract. The Sel'kov model is a system of two differential equations which describe various complex biological and chemical systems. In this system there is an exponent p which must be allowed to be an arbitrary number greater than one according to the underlying model but is usually restricted in mathematical analyses. We show that the restriction is not necessary by proving some a priori estimates for all solutions of the system. The techniques for proof include some maximum principle arguments and the weak Harnack inequality. In fact our techniques apply to a much more general class of problems, including the Brusselator model.

Key words. elliptic equations, a priori estimates, Sel'kov model

1. Introduction. In 1968, Sel'kov [13] introduced a model for glycolysis that has become a standard for various complex biological, chemical, and biochemical systems. The steady-state form of this model is the following boundary value problem: Find nonnegative functions u and v such that

$$\theta\Delta u = \lambda(uv^p - 1) \text{ in } \Omega, \tag{1.1a}$$

$$\Delta v = \lambda(v - uv^p) \text{ in } \Omega, \tag{1.1b}$$

$$\frac{\partial u}{\partial \nu} = \frac{\partial v}{\partial \nu} = 0 \text{ on } \partial\Omega \tag{1.1c}$$

for positive parameters p, θ, and λ. Here, Ω is a bounded domain in $\mathbb{R}^n$ ($n \geq 1$) and $\partial/\partial\nu$ denotes the inner normal derivative. We refer the reader to [2] and [14] for a more detailed bibliography and discussion of the significance of this system.

This problem has the obvious constant solution $u \equiv 1$, $v \equiv 1$ (and this is the only constant solution), but Eilbeck and Furter [3] used numerical bifurcation methods to show that the one-dimensional problems has nonconstant solutions for suitable ranges of the parameters. More recently, Davidson and Rynne [2] and Wang [14] proved corresponding results in two and three dimensions. (In fact, their arguments apply to any number of dimensions, but their results are only stated for two and three dimensions because of the physical applications.) A key step in their arguments is an a priori estimate for all such solutions, but, when $n \geq 3$, they require an upper bound on p, namely, $p < n/(n-2)$. We shall show that no restriction on p is needed for this estimate and that a simpler approach can be used, which is independent of dimension. Our interest came from the theoretical side of the problem, but there is a more practical reason to investigate such a result: In Sel'kov's original paper, this parameter should be allowed to take on arbitrary values greater than one for physical reasons. It should also be noted that the proofs in [2] and [14] of their bifurcation and existence results along with our more general estimates give their results without the

†Department of Mathematics, Iowa State University, Ames, IA 50011 (lieb@iastate.edu).

restriction on p. For example, we have the following result, in which μ_i for $i = 1, 2, \ldots$ denote the positive eigenvalues of the Laplacian operator with Neumann conditions.

THEOREM 1.1. *Let λ, θ, and p be positive parameters, and suppose there is at least one index i such that*

$$\lambda(\lambda + \mu_i) < \theta\mu_i[\lambda(p-1) - \mu_i], \tag{1.2}$$

but there are no indices j such that

$$\lambda(\lambda + \mu_j) = \theta\mu_j[\lambda(p-1) - \mu_j]. \tag{1.3}$$

If the sum of the dimensions of the eigenspaces corresponding to all eigenvalues μ_i satisfying (1.2) *is odd, then there is a nonconstant solution to* (1.1).

The proof of this theorem is the same as for [14, Theorem 6.2] once we have the appropriate estimate. (In [14], it was also assumed that $p < n/(n-2)$ if $n \geq 3$, but this assumption was used only to derive the a priori estimate.)

The key new element in our approach is the use of a weak Harnack inequality, described in section 2. We prove our estimate in section 3 with some generalizations in section 4.

2. Some general results for elliptic equations. Our new element is the following result which is well known as a local result for weak supersolutions of linear elliptic equations (see, for example, [5, Theorem 8.18]).

LEMMA 2.1. *Let Ω be a bounded Lipschitz domain in $\mathbb{R}^n$. Let Λ be a nonnegative constant and suppose that $v \in W^{1,2}$ is a nonnegative weak solution of the inequalities*

$$\Delta v - \Lambda v \leq 0 \text{ in } \Omega, \quad \frac{\partial v}{\partial \nu} \leq 0 \text{ on } \partial\Omega. \tag{2.1}$$

Then, for any $q \in [1, n/(n-2))$, there is a constant C_0, determined only by q, Λ, and Ω, such that

$$\|v\|_{q;\Omega} \leq C_0 \inf_{\Omega} v. \tag{2.2}$$

Proof. The proof of [5, Theorem 8.18] is easily adapted to handle the boundary condition by using the argument in [10, Theorem 6.40]. (See also [7] for further details.) □

Similarly, we have the following Harnack inequality for weak solutions, which is an analogue of [5, Theorem 8.16]. (See also [11, Lemma 4.3] for a proof in smooth domains.)

LEMMA 2.2. *Let Ω be a bounded Lipschitz domain in $\mathbb{R}^n$. Let $c \in L^q(\Omega)$ for some $q > n/2$, and suppose that $v \in W^{1,2}$ is a nonnegative weak solution of the boundary value problem*

$$\Delta v + cv = 0 \text{ in } \Omega, \quad \frac{\partial v}{\partial \nu} = 0 \text{ on } \partial\Omega. \tag{2.3}$$

Then there is a constant C_1, determined only by $\|c\|_q$, q, and Ω such that

$$\sup_{\Omega} v \leq C_1 \inf_{\Omega} v. \tag{2.4}$$

We also have the following analogue of [12, Proposition 2.2].

LEMMA 2.3. *Let Ω be a bounded Lipschitz domain and let $g \in C(\overline{\Omega} \times \mathbb{R})$. If $w \in W^{1,2}$ is a weak solution of the inequalities*

$$\Delta w + g(x,w) \geq 0 \text{ in } \Omega, \quad \frac{\partial w}{\partial \nu} \geq 0 \text{ on } \partial\Omega, \tag{2.5}$$

and if there is a constant K such that $g(x,z) < 0$ for $z > K$, then $w \leq K$ a.e. in Ω.

Proof. Use the test function $(w-K)^+$ to see that

$$\int_{\{w>K\}} |Dw|^2\,dx \leq \int_{\{w>K\}} g(x,z)(w-K)\,dx.$$

The integral on the left-hand side of this inequality is nonnegative, while the integrand of the integral on the right-hand side is negative, so $\{w > K\}$ must have zero measure, as required. ∎

3. The main a priori estimates. We now look at nonnegative solutions of the system (1.1).

Our a priori estimate has the following simple form.

THEOREM 3.1. *Let P, Θ, and Λ be positive constants, and suppose that $0 < p \leq P$, $0 < \theta \leq \Theta$, and $0 < \lambda \leq \Lambda$. Write C_2 for the value of C_0 corresponding to $q = 1$ and set $\varepsilon = |\Omega|/C_2$. Then any nonnegative $W^{1,2}$ solution to (1.1) satisfies the inequalities*

$$\varepsilon \leq v \leq \Theta\varepsilon^{-P} + 1, \tag{3.1a}$$

$$\frac{1}{(\Theta\varepsilon^{-P}+1)^P} \leq u \leq \varepsilon^{-P}. \tag{3.1b}$$

Proof. We begin by noting (see equations (2.1) and (2.2) in [2]) that

$$\int_\Omega uv^p\,dx = \int_\Omega v\,dx = |\Omega|. \tag{3.2}$$

Next, v satisfies $\Delta v \leq \lambda v \leq \Lambda v$ in Ω, so Lemma 2.1 implies that

$$\int_\Omega v\,dx \leq C_2 \inf_\Omega v,$$

so $v \geq \varepsilon$ in Ω. (Note that $\inf v \leq 1$, so $\varepsilon \leq 1$.)

We see that $v^p \geq \varepsilon^P$ in Ω, so $\Delta u \geq (\lambda/\theta)[\varepsilon^P u - 1]$ in Ω. It follows from Lemma 2.3 that $u \leq \varepsilon^{-P}$ in Ω.

Next, we set $w = \theta u + v$. Then $\Delta w = \lambda(v-1)$, and $v - 1 > 0$ wherever $w > \theta\varepsilon^{-P} + 1$, so Lemma 2.3 now implies that $w \leq \theta\varepsilon^{-P} + 1$. Since $u \geq 0$, it follows that $v \leq \theta\varepsilon^{-P} + 1 \leq \Theta\varepsilon^{-P} + 1$.

Finally, we note that, at a minimum of u, we must have $uv^p - 1 \geq 0$, so $\inf u \geq 1/(\sup v)^p \geq 1/(\sup v)^P$. Hence, $u \geq (\Theta\varepsilon^{-P}+1)^{-P}$. ∎

When $p = 0$ (and $\lambda > 0$ and $\theta > 0$), it follows from (1.1a) and (1.1c) that $u \equiv 1$ and then (1.1b) and (1.1c) imply also that $v \equiv 1$. Similarly, if $\theta = 0$ (and $\lambda > 0$), we can rewrite (1.1a) as $uv^p - 1 = 0$, so (1.1b) becomes $\Delta v = \lambda[v-1]$, so $v \equiv 1$ and hence $u \equiv 1$ also. Hence, the estimate (3.1) is uniform over the ranges $0 \leq \theta \leq \Theta$ and $0 \leq p \leq P$. However, the restriction $\lambda > 0$ is clearly necessary, because, for $\lambda = 0$, any positive constants are solutions of the resulting system (unless we impose the additional assumptions (3.2), in which case the only solution is $u \equiv v \equiv 1$). On

the other hand, for $\lambda > 0$, the only constant solution is $u \equiv v \equiv 1$. The existence of nonconstant solutions is the focus of [2, section 4] and [14].

In fact, Wang [14, Theorem 3.1] provides estimates depending only on a lower bound for θ if $P < (n+2)/(2(n-2))$. Our next step is to improve this result by showing that the estimates are independent of θ for the larger range $P < n/(n-2)$.

THEOREM 3.2. *If $P < n/(n-2)$, then there is a constant C_3, determined only by P, Λ, and Ω such that $v \le C_3$ and $u \ge C_3$ in Ω.*

Proof. Without loss of generality, we may assume that $P > 1$. From the proof of Theorem 3.1, we need only to prove an upper bound for v which is independent of θ using the lower bound for v and the upper bound for u (which are already independent of θ). To this end, we set $c = 1 - uv^{p-1}$. Because $\inf v \le 1$, we have

$$|c| \le 1 + \sup u (\inf v)^{p-P} v^{P-1} \le 1 + \varepsilon^{-2P} v^{P-1}.$$

In addition, there is a constant $q > n/2$ (determined only by P and n) such that $(P-1)q < n/(n-2)$. Now Lemma 2.1 provides a constant C_4 (determined only by P, Λ, and Ω) such that

$$\|v\|_{(P-1)q} \le C_4 \inf v.$$

Therefore $c \in L^q$ and we have an estimate for $\|c\|_q$. It follows that v satisfies the hypotheses of Lemma 2.2, which then provides the required upper bound for v. ∎

In addition, higher regularity of u and v is an immediate consequence of estimates for solutions of linear equations. For example, [6, Theorem X.2.1] (see also [10, Theorem 6.44]) implies Hölder estimates for u and v. From this regularity, it follows that u and v have Hölder continuous kth-order derivatives ($k \ge 1$) provided $\partial\Omega$ has the same smoothness. (For the case $k = 1$, see [6, Theorem X.2.1] or [8, Theorem 5.1] and for $k = 2$, see [5, Theorem 6.20].)

4. Generalizations. It should be noted that the method here applies to a much broader class of problems than those explicitly described. Here, we suggest a few possibilities.

The first way in which we generalize our hypotheses is to emphasize which properties of the right-hand sides of our differential equations were actually used.

THEOREM 4.1. *Let f and g be continuous functions defined on $\Omega \times \mathbb{R}^2$, and suppose $u \in W^{1,2}$ and $v \in W^{1,2}$ are nonnegative solutions of the system*

$$\Delta u = f(x,u,v), \qquad \Delta v = g(x,u,v) \text{ in } \Omega \tag{4.1}$$

with boundary condition (1.1c). *Suppose also that f and g satisfy the following conditions:*

1. *There are constants α_1 and β_1 and a function $\gamma \in L^1(\Omega)$ such that*

$$\alpha f(x,z_1,z_2) + \beta g(x,z_1,z_2) + \gamma(x) \le z_2 \tag{4.2}$$

for all $(x,z_1,z_2) \in \Omega \times \mathbb{R}^2$ and

$$\int_\Omega \gamma(x)\,dx > 0. \tag{4.3}$$

2. *There is a positive constant δ such that $g(x,z_1,z_2) \le \delta z_2$.*

3. *There is a function* $M\colon (0,\infty) \to (0,\infty)$ *such that, for any* $\varepsilon > 0$, *we have* $f(x, z_1, z_2) > 0$ *for* $z_2 \geq \varepsilon$ *and* $z_1 > M(\varepsilon)$.
4. *There are a constant* $\alpha_2 \geq 0$ *and a function* $N\colon (0,\infty) \to (0,\infty)$ *such that, for any* $\varepsilon > 0$, *we have* $\alpha_2 f(x, z_1, z_2) + g(x, z_1, z_2) > 0$ *for* $z_1 \leq \varepsilon$ *and* $z_2 > N(\varepsilon)$.
5. *There is a function* $M_1\colon (0,\infty) \to (0,\infty)$ *such that, for any* $\varepsilon > 0$, *we have* $f(x, z_1, z_2) < 0$ *for* $z_2 \leq \varepsilon$ *and* $z_1 < M_1(\varepsilon)$.

Then there are positive constants K_1 *and* K_2 *determined only by* α_2, $\int_\Omega \gamma\,dx$, δ, Ω, M, M_1, *and* N *such that* $K_1 \leq u, v \leq K_2$ *in* Ω.

In fact, this form of our estimate applies to several related models. First, we consider the two-variable system first used by Sel'kov [13, equation (5)]. In our notation, we have

$$f(x,u,v) = \frac{\lambda}{\theta^2}\left[\frac{uv^p}{1+v^p+uv^p} - \nu_1\right], \quad g(x,u,v) = \lambda\left[\kappa v - \frac{uv^p}{1+v^p+uv^p}\right]$$

for positive constants λ, θ, κ, ν_1, and p. In [13], the parameter ν_1 is assumed small. Here, we assume only that it is less than one. Noting that

$$\frac{\theta^2 f}{\lambda\kappa} + \frac{g}{\kappa\lambda} = -\frac{\nu_1}{\kappa} + v, \tag{4.4}$$

we see that condition 1 holds with $\alpha = \theta^2/(\lambda\kappa)$, $\beta = 1/(\kappa\lambda)$, and $\gamma = \nu_1/\kappa$. We also have condition 2 with $\delta = \lambda\kappa$. For condition 3, we note that

$$\frac{uv^p}{1+v^p+uv^p} = \frac{u}{v^{-p}+1+u} \geq \frac{u}{\varepsilon^{-p}+1+u},$$

and this fraction can be made larger than ν_1 by taking u sufficiently large. From (4.4), we infer condition 4 with $N(\varepsilon) \equiv \nu_1/\kappa$, and condition 5 follows with $M_1(\varepsilon) = \nu_1/\varepsilon^p$ once we note that

$$f(x,u,v) \leq \frac{\lambda}{\theta^2}[uv^p - \nu_1].$$

Similarly, we can handle the Brusselator model (see [4], [1], etc.), in which

$$f(x,u,v) = \frac{\lambda}{\theta^2}[v^2u - Bv], \quad g(x,u,v) = \lambda[-A + (B+1)v - v^2u]$$

for positive constants A and B. (Note that we have relabeled variables compared with [4].) In this case, condition 1 holds with $\alpha = \theta^2/\lambda$, $\beta = 1/\lambda$, and $\gamma = A$. Condition 2 holds with $\delta = \lambda(B+1)$, and condition 3 holds with $M(\varepsilon) = B/\varepsilon$. Condition 4 holds with $\alpha_2 = \theta^2$ and $M_1(\varepsilon) \equiv A$. Finally, we have condition 5 with $M_1(s) = B/s$. Note that our estimates improve those in [1, section 3].

As another generalization, we can replace the Laplace operator by any self-adjoint, uniformly elliptic operator provided we replace the normal boundary condition by the conormal boundary condition. Specifically, we replace Δ by the linear operator $L = D_i(a^{ij}D_j)$, where $[a^{ij}]$ is an $n \times n$ positive-definite matrix-valued function defined on Ω such that

$$\mu|\xi|^2 \leq a^{ij}(x)\xi_i\xi_j \leq \frac{1}{\mu}|\xi|^2$$

for all $\xi \in \mathbb{R}^n$, all $x \in \Omega$, and some $\mu \leq 1$. (Of course, we observe the Einstein summation convention, that repeated indices are summed from 1 to n.) The boundary condition is then

$$a^{ij} D_j u \nu_i = a^{ij} D_j v \nu_i = 0.$$

The proofs of Theorems 3.1 and 4.1 are unchanged except that C_0 and C_1 (and hence C_2, etc.) now depend also on μ.

We can also generalize our results by replacing the Laplacian by a quasi-linear operator Q of the form

$$Qu = D_i(A^i(x, Du)),$$

with A satisfying the hypotheses

$$\zeta \cdot A(x, \zeta) \geq |\zeta|^m, \qquad |A(x, \zeta)| \leq a_0 |\zeta|^{m-1}$$

for some constants $m > 1$ and $a_0 > 0$. In this case, the appropriate weak Harnack and Harnack inequalities are proved by slight modification of the ones already mentioned. (See, for example, [5, Theorem 15.7] for a brief description of the necessary modifications for the weak Harnack inequality.) The power function t^m can also be further generalized as in [9].

Finally, it is possible to deal with other boundary conditions. For the Dirichlet boundary condition $u = \varphi$ and $v = \psi$, we cannot expect positive lower bounds for u and v unless φ and ψ are strictly positive, but an upper bound for u follows from [5, Theorem 3.7] and then an upper bound for v follows by applying that same theorem to $\theta u + v$. On the other hand, for the Robin condition

$$\theta \frac{\partial u}{\partial \nu} + \gamma_1 u = 0, \quad \frac{\partial v}{\partial \nu} + \gamma_2 v = 0,$$

with γ_1 and γ_2 bounded nonpositive functions, the weak Harnack and Harnack inequalities (with C_0 and C_1 also depending on bounds for γ_1 and γ_2) and the maximum principle still hold, so we still obtain a lower bound for v and an upper bound for u. When $\gamma_1 \leq \gamma_2$ or $P < n/(n-2)$, our arguments immediately give an upper bound for v. In general, we note that the supremum of $w = \theta u + v$ can be estimated in terms of Θ, Λ, P, Ω, and $\int w \, dx$. (See, for example [5, Theorem 8.16] and [10, Theorem 6.41].) This observation provides an upper bound for v and then the lower bound for u follows as before.

INITIAL BOUNDARY VALUE PROBLEMS FOR A QUASI-LINEAR PARABOLIC SYSTEM IN THREE-PHASE CAPILLARY FLOW IN POROUS MEDIA*

HERMANO FRID† AND VLADIMIR SHELUKHIN‡

Abstract. We study two types of initial boundary value problems for a quasi-linear parabolic system motivated by three-phase flows in porous media in the presence of capillarity effects. The first type of problem prescribes a mixed boundary condition, involving a combination of the value of the solution and its normal derivative at the boundary. The second type prescribes the value of the solution at the boundary, which is the so-called Dirichlet boundary condition. We prove the existence and uniqueness of smooth solution for the first type of initial boundary value problem, and we obtain the existence of a solution for the second one as a limit case of the first type. The main assumption about the diffusion matrix of the system is that it is triangular with strictly positive diagonal elements. Another interesting feature is concerned specifically with the application to three-phase capillary flow in a porous medium. Namely, we derive an important practical consequence of the assumption that the capillarity matrix is upper triangular, if we further impose that the second diagonal element depends only on the second variable, i.e., the second phase. We show that this mathematical assumption in turn provides an efficient method for the definition of the capillary pressures in the interior of the triangle of saturations through the solution of a well-posed boundary value problem for a linear hyperbolic system. Finally, as an example, we include the analysis of a special case of three-phase capillary flow model where the capillarity matrix is degenerate, but we are still able to solve it due to the particular form of the flux functions.

Key words. porous media, three-phase capillary flows, existence, uniqueness

1. Introduction.

We consider initial boundary value problems for 2×2 quasi-linear parabolic systems of the form

$$u_t + f(u)_x = (B(u)u_x)_x, \quad 0 < t < T, \quad x \in \Omega := (-1, 1), \tag{1.1}$$

motivated by one-dimensional three-phase capillary flows through a porous medium, say, an oil reservoir. Here,

$$u = \begin{pmatrix} u_1 \\ u_2 \end{pmatrix}, \quad f = \begin{pmatrix} f_1 \\ f_2 \end{pmatrix}, \quad B = \begin{pmatrix} B_{11} & B_{12} \\ B_{21} & B_{22} \end{pmatrix}.$$

We first explain our abstract results concerning (1.1) and then we discuss the application already mentioned.

We consider two initial boundary value problems for system (1.1):

$$\delta u_\eta + u = u_b \text{ at } |x| = 1, \ t > 0, \qquad u|_{t=0} = u_0(x), \ x \in \Omega \tag{1.2}$$

and

$$u = u_b \text{ at } |x| = 1,\ t > 0, \qquad u|_{t=0} = u_0(x),\ x \in \Omega, \tag{1.3}$$

where $\delta = \text{const} > 0$ and

$$u_\eta|_{x=\pm 1} = \pm u_x|_{x=\pm 1}, \quad u_b|_{x=\pm 1} = u_\pm(t).$$

Motivated by the application, the functions f_i, B_{ij}, $i, j = 1, 2$, are assumed to be defined and smooth over the closed triangle

$$\Delta := \{u \in \mathbb{R}^2 \,:\, 0 \le u_i,\ u_1 + u_2 \le 1\}, \tag{1.4}$$

and we take initial and boundary data satisfying

$$u_0(x), u_\pm(t) \in \Delta\ \forall x \in \Omega, t > 0. \tag{1.5}$$

We then seek for solutions to our problems (1.1), (1.2) and (1.1), (1.3) defined on $Q := \Omega \times (0, T)$ for any $T > 0$, which satisfy

$$u(t, x) \in \Delta\ \forall (x, t) \in Q. \tag{1.6}$$

For the mathematical analysis of the above problems, we need to assume that for certain constant $\nu > 0$ we have

$$B_{ii} \ge \nu, \quad i = 1, 2\ \forall u \in \Delta, \tag{1.7}$$

and that the matrix B is (upper) triangular, i.e.,

$$B_{21}(u) \equiv 0. \tag{1.8}$$

Concerning the behavior of the functions f_i and B_{ij} on the boundary of Δ, we assume the following:

$$f_1|_{u_1=0} = \text{const}, \quad f_2|_{u_2=0} = \text{const}, \quad (f_1 + f_2)|_{u_1+u_2=1} = \text{const}, \tag{1.9}$$

$$B_{12}|_{u_2=0} = 0, \quad (B_{11} - B_{12} - B_{22})|_{u_1+u_2=1} = 0. \tag{1.10}$$

As for the smoothness of the functions f_i, B_{ij} over Δ, we assume

$$f_i, \quad \frac{\partial f_i}{\partial u_j}, \quad B_{ij}, \quad \frac{\partial B_{ij}}{\partial u_k}, \quad \frac{\partial^2 B_{ij}}{\partial u_k \partial u_l} \in H^\beta(\Delta), \tag{1.11}$$

where $H^\beta(\Delta)$ is the space of Hölder continuous functions on Δ with $\beta \in (0, 1)$.

The initial and boundary data are also assumed to be in Hölder spaces:

$$u_0 \in H^{2+\beta}(\overline{\Omega}), \quad u_\pm(t) \in H^{1+\beta}([0, T]). \tag{1.12}$$

We can now state our result concerning the problem (1.1), (1.2).

THEOREM 1.1. *Let any $T > 0$ be given. Assume that the data $B(u)$, $f(u)$, $u_0(x)$, and $u_\pm(t)$ satisfy the conditions* (1.5), (1.7), (1.8), (1.9), (1.10), (1.11) *and* (1.12). *Suppose that the compatibility conditions*

$$\pm\delta u_0'(\pm 1) + u_0(\pm 1) = u_\pm(0)$$

are satisfied. Then problem (1.1), (1.2) *has a unique solution* $u(t,x)$ *such that* $u \in H^{2+\beta,1+\beta/2}(\overline{Q})$. *Moreover,* u *satisfies* (1.6).

The core of the proof is the application of Leray–Schauder's fixed-point theorem, which requires strong a priori estimates in Hölder spaces. This was also the approach followed in [4], where we considered the somewhat simpler case of periodic boundary conditions. It is, actually, the main point for dealing with nonlinear equations in the extensive theory developed by Ladyzhenskaya and Ural'ceva [7] and Ladyzhenskaya, Solonnikov, and Ural'ceva [6], which provide the basic tools of our approach. As is well known, the application of a fixed-point theorem to obtain a solution to an initial boundary value problem for a nonlinear PDE, in general, requires the definition of an operator in a suitable subset $\mathcal{U}$ of an appropriate space of functions. Such operator is usually given by means of the solution of a linear problem, that is, by associating with each element $v \in \mathcal{U}$ the solution $A(v)$ of a linear problem, and is such that its fixed points, that is, solutions of $A(u) = u$, solve our nonlinear problem. The Hölder spaces provide the standard setting in the context of smooth solutions. The a priori estimates in these spaces play then a twofold fundamental role. First, in order to provide bounds for the possible fixed points of the operator mentioned above, which will help us to conveniently define its domain. Second, these a priori estimates will also hold (with similar proof) for the solutions of the linear problems defining the mentioned operator, which in turn imply the properties required for the application of the fixed-point theorem. In our application of Leray–Schauder's theorem, as in [6], we need a priori estimates in the space of Hölder continuous functions, in space and time, for the solution u and its space derivative u_x. Roughly speaking, after obtaining the a priori estimate for u, to obtain the estimate for u_x, we differentiate the system with respect to x and regard the resulting equations as a linear system for $w = u_x$. In this way, the boundary condition (1.2) gives us the Hölder continuity of u_x at the boundary as a consequence of the regularity of u_b and the Hölder continuity of u in $\bar{Q}$, obtained in the first run. This is what turns problem (1.1), (1.2) easier to handle than problem (1.1), (1.3). The idea is then to obtain the solution of the latter as a limit case of the first one, when $\delta \to 0$. But, in doing that, we have to give up the context of classical solutions (up to the boundary) and content ourselves with a weaker notion of solution, which turns out to leave the question of uniqueness, for the moment, still open.

We now state our result concerning problem (1.1), (1.3).

THEOREM 1.2. *Let* $B(u)$ *and* $f(u)$ *be as in Theorem* 1.1. *Let the functions* $u_0(x)$ *and* $u_\pm(t)$ *satisfy* (1.5) *and* $u_0 \in L^2(\Omega)$, $u_\pm \in W^{1,1}(0,T)$. *Then problem* (1.1), (1.3) *has a solution* $u(t,x)$ *in the sense that* u *is a classical solution of* (1.1) *in* $Q := (0,T) \times (-1,1)$, *and* u *satisfies* (1.3) *in the sense of* $L^2(0,T)$, *for the boundary condition, and* $L^2(-1,1)$, *for the initial condition. Moreover, if* $u_\pm(t) \equiv 0$, $t \in [0,T]$, *and* $u_0 \in H^{2+\beta}(\overline{\Omega})$, *with* $u_0(\pm 1) = 0$, *then* $u(t,x)$ *is a classical solution of* (1.1) *in* Q, $u \in H^{\beta,\beta/2}(\overline{Q})$ *and the initial and boundary conditions are assumed in the usual sense for continuous functions. In any case the solution* u *satisfies* (1.6).

We prove Theorem 1.1 in sections 2 and 3. Theorem 1.2 is proved in section 4. Concerning correlated works on the theory of quasi-linear parabolic systems, we recall first that, in the well-known book of Ladyzhenskaya, Solonnikov, and Ural'ceva [6], the theory developed for linear and quasi-linear equations is applied to quasi-linear systems of the type (1.1) (in the multidimensional case, for any number of equations) where the diffusion matrix is a scalar multiple of the identity matrix. We also recall the results of Amann [2] which, in the case of 2×2 one-dimensional systems, require

$\frac{\partial f_2}{\partial u_1} \equiv 0$ and $\frac{\partial B_{22}}{\partial u_1} \equiv 0$, besides (1.7) and (1.8), and assume uniform boundedness of a certain Hölder norm of the local solution, in order to extent it to all values of time $t > 0$.

In section 5 we recall the basic facts about capillary multiphase flow in a porous medium. In this context one studies the evolution in time and space of the saturations of three immiscible fluid phases, say, oil, gas, and water, denoted by u_1, u_2, u_3, through a reservoir, which is assumed to be a (porous) solid cylinder with homogeneous cross sections. By saturation of a phase we mean the percentage of this phase in an infinitesimal pore, so that we must have $u_1 + u_2 + u_3 = 1$. In section 5, we describe how a system like (1.1) for the saturations u_1 and u_2 is derived from the mass conservation equations together with Darcy's basic law for flows in porous media. The dependent vector variable $u = (u_1, u_2)$ then must assume values in the triangle Δ defined in (1.4). By the formulas for the functions f_i and B_{ij}, derived from the mentioned basic facts, we easily check the validity of (1.9) and (1.10), when (1.8) holds. The physical diffusion matrix is diagonalizable with nonnegative eigenvalues everywhere in Δ, as shown in [1]. However, it may, in general, become singular at the boundary of Δ. So, to apply Theorems 1.1 and 1.2 one should, in general, add an artificial viscosity to the actual system.

Also in section 5, we discuss the mobility laws and capillary pressure laws which yield (1.8) and also the additional restriction

$$\frac{\partial B_{22}}{\partial u_1} = 0, \tag{1.13}$$

not needed in Theorems 1.1 and 1.2. The mobilities play a role in Darcy's law analogous to the coefficient of heat conduction in Fourier's law (see section 5). The capillary pressures, denoted here by P_1 and P_2, are defined by $P_1 = p_1 - p_3$ and $P_2 = p_2 - p_3$, where p_i is the pressure in the ith phase.

Actually, the main point of section 5 is a remarkable consequence of the mathematical assumptions (1.8) and (1.13) on the capillarity matrix. It is related with the problem of defining the capillary pressures in the interior of the triangle of saturations. As is well known by reservoir engineers, mobilities and capillary pressures can be plotted as functions of the saturations only in the case of flows where just two phases are present [10, 5], that is, when $u \in \partial\Delta$. While there are some widely accepted models which artificially prescribe the mobility functions in the interior of Δ, such as the one proposed by Stone [13], the same is no longer true for the functions representing the capillary pressures. Now, the constraints (1.8) and (1.13) amount to a linear hyperbolic system of partial differential equations for the capillary pressures P_1 and P_2, whose coefficients involve the mobility functions, for which we set the boundary conditions

$$P_i(u)|_{u_j=0} = \pi_i(u_i), \quad i, j = 1, 2, \quad j \neq i, \tag{1.14}$$

enforcing compatibility with the two-phase flow case, where the functions π_i can be obtained from two-phase flows experiments, as already mentioned. The result is a consistent recipe for defining the capillary pressures in the interior of the triangle of saturations, given the mobility functions everywhere defined therein! We call this procedure for determining P_1 and P_2 in the interior of Δ the *method of physical interpolation for capillary pressures*. As an example, we study in detail the case when the mobilities are linear functions of the corresponding phase saturation.

Finally, in section 6, the techniques developed in sections 2 to 5 are applied to the study of a particular degenerate reservoir fluid flow model. This model yields a

Dirichlet initial boundary value problem for a degenerate system of the form (1.1) where (1.8), (1.13), and yet $\frac{\partial f_2}{\partial u_1} = 0$ hold. In this case the second equation in (1.1) reads

$$\frac{\partial u_2}{\partial t} + \frac{\partial f_2(u_2)}{\partial x} = \frac{\partial}{\partial x}\left(B_{22}(u_2)\frac{\partial u_2}{\partial x}\right). \tag{1.15}$$

Since (1.6) must hold, (1.15) is not completely decoupled from the first equation in the corresponding system (1.1). Here, f and B in (1.1) have the form

$$f = \frac{1}{ku_2+1}\begin{pmatrix} u_1 \\ (1+k)u_2 \end{pmatrix}, \quad B = \begin{pmatrix} \alpha k_1(1-\xi)\pi_1'(\xi) & \xi(B_{11}-B_{22}) \\ 0 & \frac{k_1k_2u_2(1-u_2)\pi_2'(u_2)}{k_2u_2+k_1(1-u_2)} \end{pmatrix}, \tag{1.16}$$

where k_1, k_2 are positive constants, $k = \frac{k_2}{k_1} - 1$, $\xi = u_1(1-u_2)^{-1}$, and π_1, π_2 are given functions satisfying $\pi_1'(\xi) \geq 0$, $\pi_2'(u_2) \geq 0$.

The main difficulty here is that the matrix B is degenerate at $\partial\Delta$. The introduction of the variable ξ, so-called relative saturation, plays a decisive role in overcoming this difficulty. We then obtain the following result proved in section 6.

THEOREM 1.3. *Assume $\pi_1(\xi), \pi_2(u_2)$ are given smooth functions of $\xi, u_2 \in (0,1)$, with $\pi_1'(\xi) \geq 0$, $\pi_2'(u_2) \geq 0$, $0 < \xi < 1$, $0 < u_2 < 1$, and*

$$u_0 \in L^\infty(\Omega), \quad u_\pm \in W^{1,1}(0,T), \quad 0 < \delta \leq u_{2,\pm}(t) \leq 1-\delta, \quad \delta \leq \xi_\pm(t) \leq 1-\delta,$$

$$\delta \leq u_{2,0}(x) \leq 1-\delta, \quad \delta \leq \xi_0(x) \leq 1-\delta$$

for some $\delta \in (0,1)$, where

$$\xi_0 = \frac{u_{1,0}}{1-u_{2,0}}, \quad \xi_\pm = \frac{u_{1,\pm}}{1-u_{2,\pm}}.$$

Then, with f and B given by (1.16), *problem* (1.1), (1.3) *has a weak solution $u(t,x)$ such that*

$$u \in L^\infty(Q), \quad u_x \in L^2(Q), \quad u_t \in L^2(0,T;W^{-1,2}(\Omega)),$$

and the estimates

$$0 < \delta \leq u_2 \leq 1-\delta, \quad \delta \leq \xi \leq 1-\delta \tag{1.17}$$

hold.

2. A mixed initial boundary value problem. In this section, for given $\varepsilon, \delta > 0$, we consider the initial boundary value problem

$$u_t + f(u)_x = (B(u)u_x)_x + \varepsilon h, \quad (t,x) \in Q \equiv (0,T)\times\Omega, \quad \Omega = (-1,1), \tag{2.1}$$

$$\delta u_\eta + u = u_{b,\varepsilon} \quad \text{at} \quad |x| = 1, \quad u|_{t=0} = u_{0,\varepsilon}(x). \tag{2.2}$$

Here

$$u_\eta|_{x=\pm1} = \pm u_x, \quad u_b|_{x=\pm1} = u_\pm(t),$$
$$u_{i\pm,\varepsilon} = (1-\varepsilon)\left(\frac{\varepsilon}{2} + u_{i\pm}\right), \quad u_{i0,\varepsilon} = (1-\varepsilon)\left(\frac{\varepsilon}{2} + u_{i0}\right), \quad i = 1,2.$$

The function $h = (h_1, h_2)$ is any smooth map satisfying $h(\omega) \cdot \nu(\omega) < 0$, for all $\omega \in \partial\Delta$, with $\nu(\omega)$ the unit outer normal to $\partial\Delta$, defined everywhere in $\partial\Delta$, except at the vertices. For example, $h(u) = u_* - u$, where u_* is any point in the interior of Δ.

The problem (2.1), (2.2) should be considered as a perturbation of problem (1.1), (1.2). The inclusion of the perturbation term εh and the slight change in the initial and boundary data are necessary for the proof of the positive invariance of the triangle Δ in Lemma 2.1 below. However, we remark in advance that in all the remaining lemmas in this section, the constants c in the estimates do not depend on ε, which will easily allow to make $\varepsilon \to 0$ in the conclusion of the proof of Theorem 1.1, in the next section. In Lemmas 2.1 to 2.10 below, we omit the subscript ε when referring to the functions $u_{0,\varepsilon}(x)$, $u_{\pm,\varepsilon}(t)$.

LEMMA 2.1. *The solution u of* (2.1), (2.2) *takes values in* $\mathrm{int}(\Delta)$ *whenever u_0 and $u_\pm$ take values in Δ.*

Proof. We follow the method of positively invariant regions [12] (see also [11]). Let us denote $u_3 = 1 - u_1 - u_2$ and $G_i(u) = -u_i$, $i = 1, 2, 3$. Setting $z_i = G_i(u)$, we prove that $z_i < 0$ for each i. Clearly,

$$\max_{x\in\Omega} z_i(0, x) < 0, \quad i \in \{1, 2, 3\}.$$

Suppose there is a first time $t_1 > 0$ such that

$$\max_{x\in\Omega} z_i(t_1, x) = z_i(t_1, x_0) = 0$$

for some i. We consider separately the two cases $|x_0| < 1$ and $|x_0| = 1$. First, we observe that $x_0 = 1$ is impossible. Indeed, it follows from the equality

$$\delta z_{ix} + z_i = -u_{i,+\varepsilon} \tag{2.3}$$

that $z_{ix}(t_1, 1) < 0$, which gives a contradiction since $z_i(t_1, x) \le 0$, $x \in [-1, 1]$. Similarly, we prove that $x_0 = -1$ cannot hold either. So, the case $|x_0| = 1$ is ruled out.

Let us consider the case $|x_0| < 1$. Multiplying (2.1) by $\nabla_u G_i$ and using (1.9), (1.10), one arrives at

$$z_{it} + \alpha_i z_{ix} = (\mu_i z_{ix})_x + \varepsilon h \cdot \nabla_u G_i \quad \text{at} \quad (t_1, x_0), \tag{2.4}$$

where α_i and $\mu_i \ge 0$ are scalar functions of $u \in \{G_i(u) = 0\} \cap \Delta$. By the assumption,

$$z_i(t_1, x_0) = \max_{\substack{0\le\tau\le t_1 \\ |y|\le 1}} z_i(\tau, y).$$

Hence, we must have

$$z_{ix}(t_1, x_0) = 0, \quad z_{ixx}(t_1, x_0) \le 0, \quad z_{it}(t_1, x_0) \ge 0. \tag{2.5}$$

Due to the choice of h, we have

$$h \cdot \nabla_u G_i < 0 \quad \text{at} \quad (t_1, x_0).$$

Now, it follows from (2.4) that $z_{it}(t_1, x_0) < 0$, contradicting (2.5). ∎

LEMMA 2.2. *The estimate*

$$\|u_x\|_{L^2(Q)} + \delta \sum_{\pm} \int_0^T |u_x(t, \pm 1)|^2 dt \le c \tag{2.6}$$

holds with a constant c depending on ν and the norms $\|\dot{u}_\pm\|_{L^1(0,T)}$ and $\|h\|_{L^1(Q)}$. In particular, by (2.1)*, it follows that*

$$\|u_t\|_{L^2(0,T;W^{-1,2}(\Omega))} \le c \tag{2.7}$$

uniformly in ε and δ.

Proof. Denote

$$w = \frac{1-x}{2}u_- + \frac{1+x}{2}u_+ , \quad v = u - w.$$

Then we have from the second equation in (2.1) that

$$\frac{1}{2}\frac{d}{dt}\int_\Omega v_2^2 dx + \int_\Omega B_{22}|v_{2x}|^2 dx = v_2(B_{22}(v_{2x}+w_{2x}) - f_2)|_{-1}^{+1} + \int_\Omega v_{2x}(f_2 - B_{22}w_{2x}) - w_{2t}v_2 + \varepsilon h_2 v_2 \, dx.$$

Since

$$v|_{x=\pm 1} = \mp\delta(v_x + w_x)|_{x=\pm 1}$$

and $B_{22} \ge \nu$, estimate (2.6) for u_2 follows by the Cauchy inequality.

From the first equation in (2.1), we have

$$\frac{1}{2}\frac{d}{dt}\int_\Omega v_1^2 dx + \int_\Omega B_{11}|v_{1x}|^2 dx = v_1(B_{11}(v_{1x}+w_{1x}) + B_{12}u_{2x} - f_1)|_{-1}^{+1} - \int_\Omega v_{1x}(B_{11}w_{1x} + B_{12}u_{2x} - f_1) - w_{1t}v_1 + \varepsilon h_1 v_1 \, dx.$$

By the same argument, one can derive the claim of the lemma for the function u_1, using estimate (2.6) for u_2. ∎

Let $|u|_Q^{(\alpha)}$ denote the norm of the function $u(x,t)$ in the Hölder space $H^{\alpha,\alpha/2}(\overline{Q})$ (cf. [6]):

$$|u|_Q^{(\alpha)} = \sup_{\overline{Q}}|u(x,t)| + \sup_{x_1,x_2\in\overline{\Omega},t\in[0,T]}\frac{|u(x_1,t)-u(x_2,t)|}{|x_1-x_2|^\alpha} + \sup_{x\in\overline{\Omega},t_1t_2\in[0,T]}\frac{|u(x,t_1)-u(x,t_2)|}{|t_1-t_2|^{\alpha/2}}.$$

The following estimates depend, in general, on δ.

LEMMA 2.3. *There are constants c and $\alpha \in (0,1)$ such that*

$$|u_2|_Q^{(\alpha)} \le c. \tag{2.8}$$

Moreover, if $u_\pm \equiv 0$, the estimate (2.8) *holds uniformly in δ.*

Proof. Let $\zeta(t,x)$ be a test function with values between 0 and 1 and that is different from zero only for $x \in K_\rho$, the ball of radius ρ centered at $x^0 \in \overline{\Omega}$. Denote

$$\Omega_\rho = \overline{\Omega} \cap K_\rho = [x_-^0, x_+^0], \quad x_+^0 = \min\{1, x_0+\rho\}, \quad x_-^0 = \max\{-1, x_0-\rho\}.$$

Given $\delta' > 0$, we multiply the second equation in (2.1) by

$$\zeta^2 \max\{u_2 - k, 0\} \equiv \zeta^2 u_2^{(k)}, \quad k \geq -\delta',$$

and integrate over Ω_ρ. We have

$$\frac{1}{2}\frac{d}{dt}\int_{\Omega_\rho} \zeta^2 |u_2^{(k)}|^2\,dx + \int_{\Omega_\rho} \zeta^2 B_{22}|u_{2x}^{(k)}|^2\,dx = \zeta^2 B_{22} u_{2x} u_2^{(k)}|_{x_-^0}^{x_+^0} - \zeta^2 f_2 u_2^{(k)}|_{x_-^0}^{x_+^0}$$

$$- \int_{\Omega_\rho} 2\zeta\zeta_x B_{22} u_{2x} u_2^{(k)} - \zeta\zeta_t |u_2^{(k)}|^2 - f_2(2\zeta\zeta_x u_2^{(k)} + \zeta^2 u_{2x}^{(k)}) - \varepsilon h_2 \zeta^2 u_2^{(k)}\,dx.$$

Observe that

$$\delta u_x|_{x=\pm 1} = \pm(u_\pm - u)|_{x=\pm 1},$$

$$\zeta^2 B_{22} u_{2x} u_2^{(k)}|_{x_-^0}^{x_+^0} \leq \frac{1}{\delta}\zeta^2 B_{22} u_2^{(k)} u_{2+}|_{x=1} + \frac{1}{\delta}\zeta^2 B_{22} u_2^{(k)} u_{2-}|_{x=-1},$$

$$|\zeta^2 v^{(k)}|_{|x|=1} \leq |\int_{\Omega_\rho} \zeta^2 v_x^{(k)} + 2\zeta\zeta_x v^{(k)}\,dx| \tag{2.9}$$

for small ρ. Thus, using $B_{22} \geq \nu$,

$$\frac{1}{2}\frac{d}{dt}\int_{\Omega_\rho} \zeta^2 |u_2^{(k)}|^2\,dx + \nu\int_{\Omega_\rho} \zeta^2 |u_{2x}^{(k)}|^2\,dx \tag{2.10}$$
$$\leq \frac{\nu}{2}\int_{\Omega_\rho} \zeta^2 |u_{2x}^{(k)}|^2\,dx + c_1\int_{\Omega_\rho} |u_2^{(k)}|^2(|\zeta_x|^2 + |\zeta\zeta_t|) + \zeta^2 \mathbf{1}_{A_{k,\rho}(t)}\,dx,$$

where $A_{k,\rho}(t)$ is the intersection of the support of $u_2^{(k)}$ with K_ρ, and $\mathbf{1}_A$ is the characteristic function of the set A. Proceeding in an analogous way, we prove that (2.10) also holds with u_2 replaced by $-u_2$, for $k \leq 1 + \delta'$. These inequalities imply that u_2 belongs to a class $\mathcal{B}_2(Q \cup \Gamma, M, \gamma, r, \delta', \kappa)$ (see [6, Chapter II, sections 7 and 8]), with $\Gamma = \partial Q \setminus \{t = T\}$, $M = 1$, $r = 6$, $\kappa = 2$, and, hence, $u_2 \in H^{\alpha,\alpha/2}(\overline{Q})$ for some $\alpha \in (0, 1)$.

As for the last statement, indeed, in this case,

$$\zeta^2 B_{22} u_{2x} u_2^{(k)}\Big|_{x_-^0}^{x_+^0} = -\sum_{x=\pm 1} \frac{1}{\delta}\zeta^2 B_{22} u_2 u_2^{(k)} \leq 0,$$

and the constant c_1 in (2.10) does not depend on δ. ∎

LEMMA 2.4. *There is a constant c such that*

$$\max_{0\leq t\leq T}\left\{\int_\Omega u_{2x}^2\,dx + \delta\left(\sum_{x=\pm 1} u_{2x}^2\right)\right\} + \int_Q u_{2xx}^2 + u_{2x}^4 + u_{2t}^2\,dx\,dt \leq c. \tag{2.11}$$

Moreover, if $u_\pm \equiv 0$, the constant c in (2.11) *does not depend on δ.*

Proof. Let $\zeta(x)$ be the test function like above. We multiply the second equation in (2.1) by $(\zeta^2 u_{2x})_x$ and integrate over Ω_ρ. Using the equality

$$\delta\dot{u}_\eta + \dot{u} = \dot{u}_b \quad \text{at} \quad x = \pm 1,$$

and the Young inequality, we obtain that

$$\frac{1}{2}\frac{d}{dt}\left\{\int_{\Omega_\rho}\zeta^2 u_{2x}^2\,dx+\delta\left(\sum_{x=x_\pm^0}\zeta^2u_{2x}^2\right)\right\}+\nu\int_{\Omega_\rho}\zeta^2u_{2xx}^2\,dx\le J,$$

$$J\equiv\|\dot u_b\|_{C([0,T])}\times\sum_{x=x_\pm^0}|\zeta^2u_{2x}|+\frac{\nu}{4}\int_{\Omega_\rho}\zeta^2u_{2xx}^2\,dx$$
$$+c_*\int_{\Omega_\rho}\zeta^2u_{2x}^4dx+c\int_{\Omega_\rho}\zeta^2(u_{2x}^2+u_{1x}^2)+u_{2x}^2(\zeta_x^2+\zeta^2)+\zeta^2\,dx.$$

We estimate the first term in the right-hand side of the above identity using an inequality like (2.9) and, again, Young's inequality, in order to obtain

$$\|\dot u_b\|_{C([0,T])}\times\sum_{x=x_\pm^0}|\zeta^2u_{2x}|\le\frac{\nu}{4}\int_{\Omega_\rho}\zeta^2u_{2xx}^2\,dx+c_\nu\int_{\Omega_\rho}u_{2x}^2\zeta_x^2+\zeta^2\,dx.$$

Finally, we recall the inequality (see [6, Chapter II, Lemma 5.4])

$$\int_{K_\rho}\zeta^2v_x^4dx\le16\mathrm{osc}^2\{v,K_\rho\}\int_{K_\rho}2\zeta^2v_{xx}^2+\zeta^2v_x^2\,dx.\tag{2.12}$$

By Lemma 2.3,

$$\mathrm{osc}^2\{u_2,K_\rho\}\le c\rho^{\alpha_1},\quad\alpha_1<\alpha.$$

Now, the assertion of the lemma follows if we take ρ such that $32c_*\rho^\alpha<\nu/4$, where α is the constant from Lemma 2.3. □

LEMMA 2.5. *There are constants c and $\alpha\in(0,1)$ such that $|u_1|_Q^{(\alpha)}\le c$. Moreover, if $u_\pm\equiv0$, the constant c in Lemma 2.5 does not depend on δ.*

Proof. Let $\zeta(t,x)$ be a function like in Lemma 2.3. Then, given $\delta'>0$, for $k\ge-\delta'$,

$$\left(\frac{1}{2}\frac{d}{dt}\int_{\Omega_\rho}\zeta^2|u_1^{(k)}|^2\,dx+\int_{\Omega_\rho}\zeta^2B_{11}|u_{1x}^{(k)}|^2\,dx=J_1+J_2\ ,\quad J_1=\zeta^2B_{11}u_{1x}u_1^{(k)}\ \Big|_{x_-^0}^{x_+^0},\right.$$

$$J_2=\int_{\Omega_\rho}\zeta\zeta_tu_1^{(k)}-2\zeta\zeta_xB_{11}u_{1x}u_1^{(k)}+u_1^{(k)}\zeta^2\left[(B_{12}u_{2x})_x-\frac{\partial f_1}{\partial x}+\varepsilon h_1\right]dx.$$

We have

$$J_1\le\frac{1}{\delta}\sum_{x=\pm1}\zeta^2B_{11}u_{1,\pm}u_1^{(k)}\overset{(2.9)}{\le}\int_{\Omega_\rho}\frac{\nu}{4}\zeta^2|u_{1x}^{(k)}|^2+c\,\zeta_x^2|u_1^{(k)}|^2+\zeta^2\mathbf{1}_{A_{k,\rho}(t)}\,dx,$$

$$J_2\le\int_{\Omega_\rho}|u_1^{(k)}|^2(|\zeta\zeta_t|$$
$$+\zeta^2)\,dx+c\left(\int_{\Omega_\rho}\zeta\mathbf{1}_{A_{k,\rho}(t)}\,dx\right)^{1/2}\left(\int_{\Omega_\rho}\mathbf{1}_{A_{k,\rho}(t)}(1+u_{2x}^4+u_{2xx}^2\right)dx)^{1/2}.$$

As in Lemma 2.3, we can prove analogously that the above inequality also holds with u_1 replaced by $-u_1$ and $k\le1+\delta'$. Hence, (see [6, Chapter II, sections 7 and 8]) the

function u_1 belongs to the class $\mathcal{B}_2(Q\cup\Gamma, M, \gamma, r, \delta', \kappa)$, for some $\gamma > 0$, with $M = 1$, $r = 6$, $\kappa = 2$, and the lemma is proved. ∎

LEMMA 2.6. *There is a constant c such that*

$$\max_{0\le t\le T}\left\{\int_\Omega u_{1x}^2\,dx + \delta\sum_{x=\pm1}|u_{1x}|^2\right\} + \int_Q u_{1xx}^2 + u_{1x}^4 + u_{1t}^2\,dx\,dt \le c.$$

Moreover, if $u_\pm \equiv 0$, the constant c in the above lemma does not depend on δ.

Proof. Let $\zeta(x)$ be a test function like in Lemma 2.5. Then it follows from the first equation in (2.1) that

$$\frac{1}{2}\frac{d}{dt}\left\{\int_{\Omega_\rho}\zeta^2u_{1x}^2\,dx + \delta\left(\sum_{x=x_\pm^0}\zeta^2u_{1x}^2\right)\right\} + \nu\int_{\Omega_\rho}\zeta^2u_{1xx}^2\,dx \le cJ,$$

$$J = \|\dot u_b\|_{C([0,T])}\sum_{x=x_\pm^0}|\zeta^2u_{1x}| + \frac{\nu}{2}\int_{\Omega_\rho}\zeta^2u_{1xx}^2\,dx + \int_{\Omega_\rho}\zeta_x^2(u_{2x}^2 + u_{1x}^2 + u_{2xx}^2 + u_{2x}^4)\,dx$$
$$+ \int_{\Omega_\rho}\zeta^2(u_{1x}^4 + u_{2x}^4 + u_{1x}^2\zeta_x^2 + u_{2xx}^2 + u_{1x}^2 + 1 + u_{2x}^4\zeta_x^4 + u_{2x}^2\zeta_x^2).$$

Applying (2.12), one arrives at the conclusion of the lemma. ∎

LEMMA 2.7. *There is a constant c such that*

$$\int_Q |u_{ix}|^6\,dx\,dt \le c, \quad \int_Q |u_{ixx}|^3\,dx\,dt \le c, \quad \int_Q |u_{ix}u_{ixx}|^2\,dx\,dt \le c. \tag{2.13}$$

Proof. We start with the simple inequality

$$\int_Q |u_{ix}|^6\,dx\,dt \le \int_0^T \max_{x\in\Omega}|u_{ix}|^4\int_\Omega |u_{ix}|^2\,dx\,dt.$$

Observe that for any x and y,

$$v_x^2(x) - v_x^2(y) = 2\int_x^y v_{xx}v_x dz,$$

so

$$\max_{|x|<1} v_x^4 \le \|v_x\|_{L^2(\Omega)}^2 + 8\|v_{xx}\|_{L^2(\Omega)}^2\|v_x\|_{L^2(\Omega)}^2.$$

Hence,

$$\|u_{ix}\|_{L^6(Q)}^6 \le \|u_{ix}\|_{L^\infty(0,T;L^2(\Omega))}^4(1 + 8\|u_{ixx}\|_{L^2(Q)}^2) \le c,$$

and the first estimate of the lemma is proved.

Let us write the second equation in (2.1) as

$$\begin{cases} u_{2t} = B_{22}u_{2xx} + F, \\ F = \frac{\partial B_{22}}{\partial u_2}|u_{2x}|^2 - (\frac{\partial f_2}{\partial u_1}u_{1x} + \frac{\partial f_2}{\partial u_2}u_{2x}) + \frac{\partial B_{22}}{\partial u_1}u_{1x}u_{2x} + \varepsilon h_2. \end{cases} \tag{2.14}$$

By Lemmas 2.4 and 2.6, $\|F\|_{L^3(Q)} \le c$. Now, the theory of linear parabolic equations with smooth coefficients (see [6, Chapter IV, section 9]) can be applied to derive the estimate

$$\int_Q |u_{2xx}|^3 \, dx \, dt \le c, \tag{2.15}$$

which is the second estimate in (2.13) for u_2. The third estimate in (2.13) for u_2 follows because of the inequality

$$\int_Q |uv|^2 \, dx \, dt \le \left(\int_Q |u|^6 \, dx \, dt \right)^{1/3} \left(\int_Q |v|^3 \, dx \, dt \right)^{2/3}. \tag{2.16}$$

The first equation in (2.1) writes

(2.17)

$$\begin{aligned} u_{1t} &= B_{11} u_{1xx} + F, \\ F = u_{1x} &= \left(\frac{\partial B_{11}}{\partial u_1} u_{1x} + \frac{\partial B_{11}}{\partial u_2} u_{2x} \right) + u_{2x} \left(\frac{\partial B_{12}}{\partial u_1} u_{1x} + \frac{\partial B_{12}}{\partial u_2} u_{2x} \right) + B_{12} u_{2xx} \\ &\quad - \left(\frac{\partial f_1}{\partial u_1} u_{1x} + \frac{\partial f_1}{\partial u_2} u_{2x} \right) + \varepsilon h_1, \end{aligned}$$

where, as above, $\|F\|_{L^3(Q)} \le c$. Hence, the estimate (2.15) is also valid for u_{1xx}, which concludes the verification of the second estimate in (2.13). Now, the third estimate in (2.13) for u_1 follows also due to (2.16). ∎

LEMMA 2.8. *There are constants c and $\alpha \in (0,1)$ such that $|u_{2x}|_Q^{(\alpha)} \le c$.*

Proof. Let us differentiate the second equation in (2.1) with respect to x. The function $v := u_{2x}$ solves the linear equation

$$\begin{aligned} v_t &= (B_{22} v_x)_x + F_2 + g_x, \\ F_2 &= \frac{\partial^2 B_{22}}{\partial u_2^2} (u_{2x})^3 + 2 \frac{\partial B_{22}}{\partial u_2} u_{2x} u_{2xx} + \frac{\partial B_{22}}{\partial u_1} (u_{1xx} u_{2x} + u_{1x} u_{2xx}) \\ &\quad + \frac{\partial^2 B_{22}}{\partial u_1^2} u_{1x}^2 u_{2x} + 2 \frac{\partial^2 B_{22}}{\partial u_1 \partial u_2} u_{1x} u_{2x}^2, \\ g &= -\frac{\partial f_2}{\partial u_1} u_{1x} - \frac{\partial f_2}{\partial u_2} u_{2x} + \varepsilon h_2. \end{aligned}$$

By the above lemmas,

$$\|F_2\|_{q,r,Q} \equiv \left(\int \left(\int_\Omega F_2^q \right)^{r/q} dt \right)^{1/r} \le c, \quad \|g^2\|_{q,r,Q} \le c,$$

when $q = 2$, $r = 2$. Clearly, the constants q and r satisfy the conditions

$$\frac{1}{r} + \frac{1}{2q} = 1 - \kappa, \quad 0 < \kappa < \frac{1}{2}, \quad q \in [1, \infty], \quad r \in \left[\frac{1}{1-\kappa}, \frac{2}{1-2\kappa} \right],$$

with $\kappa = 1/4$. Moreover, it follows from the boundary conditions (2.2) and Lemma 2.3, that

$$\|v(t, \pm 1)\|_{H^{\alpha/2}([0,T])} \le c.$$

Thus, by the theory of linear parabolic equations (see [6, Chapter III, section 10])

$$|v|_Q^{(\alpha')} \le c$$

for some $\alpha' \le \alpha$. ∎

LEMMA 2.9. *There are constants c and $\alpha \in (0,1)$ such that $|u_{1x}|_Q^{(\alpha)} \le c$.*

Proof. Denoting $u_{1x} = v$ and differentiating the first equation in (2.1) with respect to x, we have

(2.18)

$$v_t = (B_{11}(u_1,u_2)v_x)_x + F_1 + g_{1x},$$

$$F_1 = u_{1xx}\left(\frac{\partial B_{11}}{\partial u_1}u_{1x} + \frac{\partial B_{11}}{\partial u_2}u_{2x}\right) + u_{1x}\left\{\frac{\partial B_{11}}{\partial u_1}u_{1xx} + u_{1x}\left(\frac{\partial^2 B_{11}}{\partial u_1^2}u_{1x} + \frac{\partial^2 B_{11}}{\partial u_1 \partial u_2}u_{2x}\right)\right.$$
$$\left. + \frac{\partial B_{11}}{\partial u_2}u_{2xx} + u_{2x}\left(\frac{\partial^2 B_{11}}{\partial u_1 \partial u_2}u_{1x} + \frac{\partial^2 B_{11}}{\partial u_2^2}u_{2x}\right)\right\},$$

$$g_1 = u_{2x}\left(\frac{\partial B_{12}}{\partial u_1}u_{1x} + \frac{\partial B_{12}}{\partial u_2}u_{2x}\right) + B_{12}u_{2xx} - \left(\frac{\partial f_1}{\partial u_1}u_{1x} + \frac{\partial f_1}{\partial u_2}u_{2x}\right) + \varepsilon h_1.$$

By Lemma 2.7, $\|F_1\|_{L^2(Q)} \le c$. With the estimate of Lemma 2.8 for u_{2x} at hand, the function F in (2.14) meets the estimate $\|F\|_{L^4(Q)} \le c$. It implies that

$$\|u_{2xx}\|_{L^4(Q)} \le c, \quad \|g_1\|_{L^4(Q)} \le c.$$

Now, one may treat (2.18) as a linear parabolic equation for v, with

$$\|F_1, g_1^2\|_{2,2,Q} \le c, \quad \|v(t,\pm 1)\|_{H^{\alpha/2}([0,T])} \le c.$$

By the same argument as in Lemma 2.8, we conclude that

$$|u_{1x}|_Q^{(\alpha')} \le c$$

for some $\alpha' < \alpha$. ∎

LEMMA 2.10. *Let*

$$u_0 \in H^{2+\beta}(\overline{\Omega}), \quad u_\pm \in H^{1+\beta/2}([0,T]), \quad 0 < \beta < 1,$$

and the compatibility conditions

$$\pm\delta u_0'(\pm 1) + u_0(\pm 1) = u_\pm(0) \tag{2.19}$$

be satisfied. Then there is a constant c such that solutions to problem (2.1), (2.2) *satisfy the estimate $|u|_Q^{(2+\beta)} \le c$. The constant c does not depend on ε but depends on T, $\|u_0|H^{2+\beta}(\overline{\Omega})\|$, $\|u_\pm|H^{1+\beta/2}([0,T])\|$, and the L^∞-norms of $f(u)$, $\nabla_u f$, $B_{ij}(u)$, $\nabla_u B_{ij}$, and $\nabla_u^2 B_{ij}$.*

Proof. First, we observe that the data $u_{0\varepsilon}$ and $u_{b\varepsilon}$ also satisfy the compatibility conditions (2.19). We know from the above lemmas that there are constants c and $\alpha \in (0,1)$ such that $|u_i, u_{ix}|_Q^{(\alpha)} \le c$. If $\gamma = \min\{\alpha, \beta\}$, it follows from the linear equation (2.14) that $|u_2|_Q^{(2+\gamma)} \le c$ (see [6, Chapter IV, section 5]). By the same argument, we conclude from (2.17) that $|u_1|_Q^{(2+\gamma)} \le c$. To increase γ up to β, one should return to problem (2.14), which now ensures that $|u_2|_Q^{(2+\beta)} \le c$. Next, one should pass to (2.17) to make sure that $|u_1|_Q^{(2+\beta)} \le c$. ∎

3. Existence and uniqueness. To prove the solvability of problem (2.1), (2.2), we apply a fixed-point argument in the form of the Leray–Schauder principle as in [6]. Let $\mathcal{B}$ be a Banach space of vector functions $u(t,x) \in \mathbb{R}^2$, having the bounded norm

$$\|u\|_{\mathcal{B}} = |u|_Q^{(\beta)} + |u_x|_Q^{(\beta)}.$$

Given $v \equiv (v_1, v_2) \in \mathcal{B}$ and $\lambda \in [0,1]$, we define $u = (u_1, u_2)$ as a solution to the linear problem

$$\begin{aligned} &u_{1t} + \lambda\left[\frac{\partial f_1(v)}{\partial x} - (B_{11}(v)u_{1x})_x - (B_{12}(v)u_{2x})_x - \varepsilon h_1(\mathbf{a})\right] = (1-\lambda)u_{1xx}, \\ &u_{2t} + \lambda\left[\frac{\partial f_2(v)}{\partial x} - (B_{22}(v)u_{2x})_x - \varepsilon h_2(v)\right] = (1-\lambda)u_{2xx}, \end{aligned} \tag{3.1}$$

$$\delta u_\eta + u = u_{b\varepsilon}, \quad u|_{t=0} = u_{0\varepsilon} = (1-\varepsilon)\left(\frac{\varepsilon}{2} + u_{01}, \frac{\varepsilon}{2} + u_{02}\right). \tag{3.2}$$

The second equation does not involve the function u_1. So, by the theory of linear parabolic equations, given $\lambda \in [0,1]$, the operator A_λ, which associates with each $v \in \mathcal{B}$ the solution $A_\lambda(v)$ of (3.1), (3.2), is well defined, and its fixed points are solutions to problem (2.1), (2.2) when $\lambda = 1$.

In order to apply Leray–Schauder theorem, as in [6], one must choose appropriately a domain $\mathcal{U}$ for the operators A_λ, $\lambda \in [0,1]$, and verify each of the conditions of the theorem. By repeating the arguments of the lemmas in section 2, one arrives at the a priori estimates for the fixed points u_λ of the operator A_λ:

$$u_\lambda \in \Delta, \quad |u_\lambda, u_{\lambda x}|_Q^{(\beta)} \le M,$$

where the constants M, M_1 are independent of λ. We choose as the domain of the operators A_λ the set

$$\mathcal{U} = \{u \in \mathcal{B} : u(x,t) \in \Delta', \quad |u_\lambda, u_{\lambda x}|_Q^{(\beta)} \le M'\},$$

where $\Delta' \subseteq \mathbb{R}^2$ is a closed set satisfying $\mathrm{int}(\Delta') \supset \Delta$ and $M' > M$. Clearly, $\mathcal{U}$ is the closure of a bounded connected open set in $\mathcal{B}$, and all the fixed points u_λ of A_λ are in the interior $\mathcal{U}$. This means that we have verified the first and most difficult of the following conditions for the application of Leray–Schauder theorem:

1. the boundary of $\mathcal{U}$ does not contain solutions of $A_\lambda(u) = u$;
2. the set $\cup_{\lambda\in[0,1]} A_\lambda(\mathcal{U})$ is compact in $\mathcal{B}$;
3. the mapping $(\lambda, v) \mapsto A_\lambda(v)$ is continuous from $\mathcal{U} \times [0,1]$ to $\mathcal{B}$;
4. the family of maps $\{v \mapsto A_\lambda(v)\}_{\lambda\in[0,1]}$ is equicontinuous on $\mathcal{U}$;
5. the operator A_0 has a unique fixed point in the interior of $\mathcal{U}$, and the mapping $v \mapsto v - A_0(v)$ has an inverse near this fixed point.

The verification of the conditions (2) to (4) above is immediate from all the preceding discussion in this section and section 2, while (5) follows immediately from the fact that $A_0(v)$ is in fact independent of v, that is, it is one and the same element of $\mathcal{B}$ for all v. Hence, problem (2.1), (2.2) has at least one solution in the Hölder space $H^{2+\beta,1+\beta/2}(\bar{Q})$. Uniqueness obtained in a standard way, by using the theory of linear equations with smooth coefficients (see [6, Chapter IV]). Thus, we have proved the following.

THEOREM 3.1. *Let the functions $f(u)$, $\nabla_u f$, $B_{ij}(u)$, $\nabla_u B_{ij}$, $\nabla_u^2 B_{ij}$, and the function $h(u)$ be Hölder continuous with the Hölder exponent $\beta \in (0,1)$. Let the*

conditions of Lemma 2.10 *be satisfied. Then problem* (2.1), (2.2) *has a unique solution* $u(t,x) \in H^{2+\beta,1+\beta/2}(\bar{Q})$ *such that* $u(t,x) \in \Delta$ *for each* $(t,x) \in Q$.

Proof of Theorem 1.1. Since the estimate of Lemma 2.10 does not depend on ε, there is a sequence $\varepsilon_k \downarrow 0$, such that the corresponding sequence u_k of solutions of problem (2.1), (2.2) converges to a function $u \in H^{2+\beta,1+\beta/2}(\overline{Q})$ in the norm $|\cdot|_Q^{(2+\gamma)}$ for any $\gamma < \beta$. Clearly, u solves the problem (1.1), (1.2). Thus, Theorem 1.1 is proved. □

4. Dirichlet boundary conditions.

Proof of Theorem 1.2. Let us consider the Dirichlet problem (1.1), (1.3). The estimates (2.6) and (2.7) are uniform with respect to $\delta \downarrow 0$. By the Aubin–Lions compactness theorem [8], they imply that there is a sequence u_k, $\delta_k \downarrow 0$, of solutions to problem (1.1), (1.2) and a function u such that

$$u \in L^\infty(Q), \quad u_x \in L^2(Q), \quad u_t \in L^2(0,T;W^{-1,2}(\Omega)), \tag{4.1}$$

$$u_k \to u \quad \text{in} \quad L^2(Q), \quad u(t,x) \in \Delta \quad \text{for each} \quad (t,x) \in Q.$$

Clearly, the function u solves (1.1) weakly. Now, given any open set Q' with $\overline{Q'} \subseteq Q$, we have that u_k is uniformly bounded in $H^{2+\beta,1+\beta/2}(\overline{Q'})$, so that $u \in H^{2+\beta,1+\beta/2}(\overline{Q'})$. In particular, u is a classical solution of (1.1) in Q. Due to estimate (2.6), the boundary condition $u|_{x=\pm 1} = u_\pm$ holds in $L^2(0,T)$. The inclusions (4.1) imply that $u \in C(0,T;L^2(\Omega))$, so the function u satisfies the initial condition $u|_{t=0} = u_0$ weakly in $L^2(\Omega)$. This proves the first part of Theorem 1.2. The last part is a consequence of the fact that, when $u_b = 0$, the estimates of Lemmas 2.2 to 2.5 are uniform in δ. Therefore, in this case we have $u \in H^{\beta,\beta/2}(\overline{Q})$ and, so, the last assertion follows. □

5. Basic equations of three-phase flow. For the reader's convenience we recall the underlying laws of multiphase flows in a porous medium [1]. We consider one-dimensional horizontal flows of three incompressible immiscible fluids formed in phases. The balance of masses is governed by the mass conservation equations

$$\frac{\partial}{\partial t}(m u_i \rho_i) + \frac{\partial}{\partial x}(\rho_i v_i) = 0, \quad \rho_i = \text{const}, \tag{5.1}$$

where m denotes porosity of the porous medium, u_i, ρ_i, and v_i are the saturation, density, and seepage velocity of the ith phase. The functions u_i satisfy the volume-balance equation

$$u_1 + u_2 + u_3 = 1. \tag{5.2}$$

The theory of multiphase flows in porous media is based on the following form of Darcy's law:

$$v_i = -k\lambda_i p_{ix}, \tag{5.3}$$

where k stands for the absolute permeability, p_i is the pressure of the ith phase, and λ_i is the mobility of the ith phase and it is assumed to be a function of $u = (u_1, u_2)$, that is, $\lambda_i = \lambda_i(u_1, u_2)$, $i = 1, 2, 3$. Experimentally, only the functions $\lambda_1(u_1, 0)$, $\lambda_2(0, u_2)$, $\lambda_3(u_1, 0)$, and $\lambda_3(0, u_2)$ are known, which correspond to mobilities in two-phase flows. But there are widely accepted models prescribing the mobility functions everywhere in Δ, based on the knowledge of them for two-phase flows, such as the one of Stone [13].

The capillary pressures are defined as pressure differences (cf., e.g., [10, 1, 3, 14]), and we assume here that they are functions of the saturations u_1, u_2, that is,

$$P_1(u_1,u_2)=p_1-p_3,\quad P_2(u_1,u_2)=p_2-p_3. \tag{5.4}$$

Similarly to what happens with the mobility functions, the capillary pressure functions are only known in practice in the case of two-phase flows. However, as opposed to the case of the mobility functions, so far there is no widely accepted way of defining these functions everywhere in Δ, assuming them to be known for two-phase flows. One of the main points in this section is the introduction of a new method to define the capillary pressures everywhere in Δ, assuming that they are known for two-phase flows and that the mobility functions are known everywhere in Δ.

Denote

$$\lambda=\sum_1^3\lambda_i,\quad f_i=\frac{\lambda_i}{\lambda},\qquad i=1,2,3. \tag{5.5}$$

For

$$v=\sum_1^3 v_i,$$

we find from (5.1) and (5.2) that $v_x=0$, so v depends on t only. We assume for simplicity that $k=m=1$ as well.

Eliminating the pressure derivative p_{3x}, we have from (2.3)

$$v_1=f_1(v(t)+\lambda_2P_{2x}-(\lambda_2+\lambda_3)P_{1x}),\quad v_2=f_2(v(t)+\lambda_1P_{1x}-(\lambda_1+\lambda_3)P_{2x}).$$

If we substitute these velocities into the first two equations in (5.1) and if we pass to the new time variable $t:=\int_0^t v(s)ds$, we reduce the function $v(t)$ to 1 and obtain a system of the form (1.1), where the 2×2-matrix B is given by

$$\begin{aligned}
B_{11}&=\frac{\lambda_1(\lambda_2+\lambda_3)}{\lambda}\frac{\partial P_1}{\partial u_1}-\frac{\lambda_1\lambda_2}{\lambda}\frac{\partial P_2}{\partial u_1},\quad B_{12}=-\frac{\lambda_1\lambda_2}{\lambda}\frac{\partial P_2}{\partial u_2}+\frac{\lambda_1(\lambda_2+\lambda_3)}{\lambda}\frac{\partial P_1}{\partial u_2},\\
B_{21}&=\frac{\lambda_2(\lambda_1+\lambda_3)}{\lambda}\frac{\partial P_2}{\partial u_1}-\frac{\lambda_1\lambda_2}{\lambda}\frac{\partial P_1}{\partial u_1},\quad B_{22}=-\frac{\lambda_1\lambda_2}{\lambda}\frac{\partial P_1}{\partial u_2}+\frac{\lambda_2(\lambda_1+\lambda_3)}{\lambda}\frac{\partial P_2}{\partial u_2}.
\end{aligned} \tag{5.6}$$

Since u is a saturation vector, we must have $u\in\Delta$. We assume that the mobilities λ_i satisfy the natural conditions (see, e.g., [1])

$$\lambda_i\ge 0,\quad \lambda_i|_{u_i=0}=0,\quad i\in\{1,2,3\}. \tag{5.7}$$

Let us describe our method for defining the capillary pressures everywhere in Δ, assuming that they are known for two-phase flows. It is based on the assumption of a special structure for the matrix B given by (5.6).

From the preceding discussion, in the system of the form (1.1) for the saturations derived above, the functions $P_i(u_1,u_2)$, $i=1,2$, appear only in the matrix B. We now impose that

$$B_{21}=0,\quad B_{22}=B_{22}(u_2)\ge 0,\quad B_{11}\ge 0\quad\text{in}\quad\Delta. \tag{5.8}$$

The hypothesis (5.8) means that the first and the third phases are not responsible for the amount of diffusion in the equation for the second phase. The first two conditions in (5.8) read

$$A\frac{\partial P_1}{\partial u_1} = \frac{\partial P_2}{\partial u_1}, \quad \frac{\partial P_2}{\partial u_2} = A\frac{\partial P_1}{\partial u_2} + \frac{\lambda B_{22}}{\lambda_2(\lambda_1+\lambda_3)}, \quad A = \frac{\lambda_1}{\lambda_1+\lambda_3}. \tag{5.9}$$

We study these equations for $P_i(u_1, u_2)$ in the case when the mobilities λ_i are linear functions:

$$\lambda_i = k_i u_i, \quad k_i = \text{const}. \tag{5.10}$$

A symmetry group analysis (see [9]), performed for system (5.9), suggests to look for solutions of the form

$$P_i = q_i(\xi) + Q_i(u_2), \quad \xi = \frac{u_1}{1-u_2} \equiv \frac{u_1}{u_1+u_3}. \tag{5.11}$$

It follows from (5.9) that the functions q_i and Q_i solve the system

$$\begin{aligned} &q_2'(\xi) = q_1'(\xi)A(\xi), \quad A = \frac{k_1\xi}{(k_1-k_3)\xi+k_3}, \quad Q_1'(u_2) = -\frac{k_0 B_{22}(u_2)}{1-u_2}, \\ &Q_2'(u_2) = B_{22}(u_2)\left(\frac{1}{k_3(1-u_2)} + \frac{1}{k_2 u_2}\right), \quad k_0 = \frac{k_3-k_1}{k_1 k_3}. \end{aligned} \tag{5.12}$$

Assume that the capillary pressure $P_1(u)$ is a given function of u_1 at the part of the boundary of the triangle Δ where $u_2 = 0$:

$$P_1|_{u_2=0} = \pi_1(u_1).$$

Assume also that the capillary pressure $P_2(u)$ is a given function of u_2 at the edge where $u_1 = 0$ of the triangle Δ:

$$P_2|_{u_1=0} = \pi_2(u_2).$$

It follows from (5.11) that

$$\pi_1(u_1) = q_1(u_1) + Q_1(0), \quad \pi_2(u_2) = q_2(0) + Q_2(u_2).$$

It is naturally to set

$$q_1(\xi) = \pi_1(\xi), \quad Q_2(u_2) = \pi_2(u_2).$$

Then the other functions $Q_1(u_2)$ and $q_2(\xi)$ are defined from (5.12) as follows:

$$q_2(\xi) = \int_0^\xi A(\xi)\pi_1'(\xi)d\xi, \quad B_{22}(u_2) = \frac{k_2 k_3 u_2(1-u_2)\pi_2'(u_2)}{k_2 u_2 + k_3(1-u_2)},$$

$$Q_1'(u_2) = -\frac{k_0}{1-u_2} B_{22}(u_2).$$

Thus, we arrive at the formulas for the capillary pressures

$$\begin{cases} P_1(u_1,u_2) = \pi_1(\xi) - \int_0^{u_2} \frac{k_0 k_2 k_3 u_2 \pi_2'(u_2)}{k_2 u_2 + k_3(1-u_2)} du_2 + \text{const}, \\ P_2(u_1,u_2) = \int_0^\xi A(\xi)\pi_1'(\xi)\, d\xi + \pi_2(u_2) + \text{const}. \end{cases} \tag{5.13}$$

We call the procedure yielding formulas (5.13) the *method of physical interpolation* since these formulas define the capillary pressures P_1 and P_2 in Δ from their values when $u_2 = 0$ and $u_1 = 0$, respectively.

Substituting (5.10) and (5.13) in (5.6), we get

$$B_{11} = k_1(1 - A(\xi))\pi_1'(\xi), \quad B_{22} = \frac{k_2 k_3 u_2(1-u_2)\pi_2'(u_2)}{k_2 u_2 + k_3(1-u_2)},$$

$$B_{21} = 0, \quad B_{12} = \xi(B_{11} - B_{22}). \tag{5.14}$$

When

$$\pi_1'(\xi) \geq 0, \quad \pi_2'(u_2) \geq 0,$$

system (1.1) is parabolic in Δ but degenerate at $\partial\Delta$.

Finally, we remark that the matrix B given by (5.14) satisfies

$$B_{12}|_{u_1=0} = 0, \quad B_{21} \equiv 0, \quad (B_{11} - B_{12} - B_{22})|_{u_1+u_2=1} = 0.$$

More generally, it is easy to verify that (5.7) implies that the functions B_{ij} of the general capillarity matrix given by (5.6) satisfy

$$B_{12}|_{u_1=0} = 0, \quad B_{21}|_{u_2=0} = 0, \quad (B_{11} + B_{21} - B_{21} - B_{22})|_{u_1+u_2=1} = 0. \tag{5.15}$$

It is also immediate to verify that (5.7) implies that the functions f_i defined in (5.5), for the general three-phase flow model, satisfy

$$f_1|_{u_1=0} = 0, \quad f_2|_{u_2=0} = 0, \quad (f_1 + f_2)|_{u_1+u_2=1} = 1. \tag{5.16}$$

Both (5.15) and (5.16) imply sufficient conditions in order to have $u(x,t) \in \Delta$ for any smooth solution of (1.1), which behaves nicely for $x \in \partial\Omega$.

6. A degenerate problem. Here, we study a particular system arising in petroleum reservoir fluid flows. We assume that mobilities are linear functions

$$\lambda_i = k_i u_i, \quad i \in \{1,2,3\}, \quad k_1 = k_3,$$

and the capillary pressures are given by the formulas (5.13). In this case, the flow is governed by the degenerate parabolic system

$$u_{1t} + f_1(u_1,u_2)_x = (B_{11}(u_1,u_2)u_{1x})_x + (B_{12}(u_1,u_2)u_{2x})_x, \tag{6.1}$$

$$u_{2t} + f_2(u_2)_x = (B_{22}(u_2)u_{2x})_x,$$

with

$$f_1 = \frac{u_1}{ku_2 + 1}, \quad f_2 = (1+k)\frac{u_2}{ku_2+1}, \quad k = \frac{k_2}{k_1} - 1,$$

and B_{11}, B_{22}, B_{12} are given by (5.14), with $k_1 = k_3$ (see (1.16)). The first and second equations in (6.1) are coupled through the condition $u(t,x) \in \Delta$, which can be written as

$$0 \leq u_i(t,x) \leq 1, \quad u_2(t,x) \leq 1 - u_1(t,x). \tag{6.2}$$

We consider the Dirichlet initial boundary value problem

$$u|_{x=\pm 1} = u_\pm(t), \quad u|_{t=0} = u_0(x). \tag{6.3}$$

Proof of Theorem 1.3. Consider the approximate nondegenerate problem

$$\begin{cases} u_t + f(u)_x = (B^\nu(u)u_x)_x, \\ \nu u_\eta + u = u_b^\nu \quad \text{at} \quad |x| = 1, \quad u|_{t=0} = u_0^\nu(x), \end{cases} \tag{6.4}$$

with

$$B_{11}^\nu = \nu + \chi_\nu(u_2)B_{11}, \quad B_{22}^\nu = \nu + \chi_\nu(u_2)B_{22}, \quad B_{12}^\nu = \chi_\nu(u_2)\xi(B_{11}^\nu - B_{22}^\nu),$$

$$u_0^\nu \in H^{2+\beta}(\overline{\Omega}), \quad u_0^\nu(x) \in \Delta, \quad u_\pm^\nu \in H^{1+\beta/2}([0,T]), \quad u_\pm^\nu(t) \in \Delta,$$

$$\pm\nu u_0^\nu(\pm 1) + u_0^\nu(\pm 1) = u_\pm^\nu(0),$$

$$\|u_\pm^\nu - u_\pm\|_{W^{1,1}(0,T)} \to 0, \quad \|u_0^\nu - u_0\|_{L^2(\Omega)} \to 0, \quad \text{as} \quad \nu \downarrow 0.$$

Here, $\chi_\nu(u_2)$ is a smooth function such that

$$\chi_\nu(u_2) = 1 \quad \text{if} \quad 0 \le u_2 \le 1 - \nu, \quad \chi_\nu(u_2) = 0 \quad \text{if} \quad 1 - \frac{\nu}{2} \le u_2 \le 1.$$

Clearly, the matrix B^ν satisfies the hypotheses of Theorem 1.1, and so we have the unique solvability of problem (6.4). We also observe that, under the conditions of Theorem 1.3 on the data u_0^ν and $u_\pm^\nu$, any smooth solution of problem (6.4) satisfies the a priori estimate

$$\delta \le u_2(t,x) \le 1 - \delta. \tag{6.5}$$

With this estimate at hand, the matrix B^ν, for small ν, reads

$$B_{11}^\nu = \nu + B_{11}, \quad B_{22}^\nu = \nu + B_{22}, \quad B_{12}^\nu = \xi(B_{11}^\nu - B_{22}^\nu). \tag{6.6}$$

We then have $B_{22}^\nu(u^\nu) \ge \delta^2$ uniformly for $\nu \downarrow 0$. Thus, the constant c in Lemma 2.2 does not depend on ν, and

$$\|u_{2x}^\nu\|_{L^2(Q)} \le c, \quad \|u_{2t}^\nu\|_{L^2(0,T;W^{-1,2}(\Omega))} \le c \tag{6.7}$$

uniformly in ν.

Taking into account the last equality in (6.6) for the entry B_{12}^ν, one can calculate from (6.4) that the function $\xi = u_1^\nu/(1 - u_2^\nu)$ solves the problem

$$\xi_t + \frac{\xi_x}{ku_2^\nu + 1} = (B_{11}^\nu \xi_x)_x - \frac{\xi_x u_{2x}^\nu (B_{11}^\nu + B_{22}^\nu)}{1 - u_2^\nu},$$

$$\frac{\nu(1 - u_2^\nu)}{1 - u_\pm^\nu}\xi_\eta + \xi = \xi_\pm \quad \text{at} \quad x = \pm 1, \quad \xi|_{t=0} = \xi_0(x).$$

As we saw in section 5, the variable ξ appears naturally when one is looking for invariant solutions of the homogeneous system corresponding to (5.9). It enables us to apply the maximum principle. By the latter,

$$\delta \le \xi(t,x) \le 1 - \delta\ , \tag{6.8}$$

uniformly in ν. Now, it is a consequence of (6.5) and (6.8) that

$$\delta^2 \le u_1^\nu(t,x) \le (1-\delta)^2, \quad B_{11}^\nu \ge \delta^2.$$

By the same argument as in Lemma 2.2, we have

$$\|u_{1x}^\nu\|_{L^2(Q)} \le c, \quad \|u_{1t}^\nu\|_{L^2(0,T;W^{-1,2}(\Omega))} \le c \tag{6.9}$$

uniformly in ν.

Estimates (6.7) and (6.9) imply by the Aubin–Lions compactness theorem that there are a sequence $u^n \equiv u^{\nu_n}$ and a function u such as described in Theorem 1.3 and such that

$$u^n(t,x) \to u(t,x) \quad \text{a.e. in} \quad Q, \quad u_x^n \to u_x \quad \text{weakly in} \quad L^2(Q).$$

Clearly, u is a weak solution of problem (6.1)–(6.3). Theorem 1.3 is proved. ∎

FINITE-TIME BLOWUP FOR WAVE EQUATIONS WITH A POTENTIAL*

BORISLAV YORDANOV† AND QI S. ZHANG†

Abstract. First we give a truly short proof of the major blowup result [T. C. Sideris, *J. Differential Equations*, 52 (1984), pp. 378–406] on higher-dimensional semilinear wave equations. Using this new method, we also establish blowup phenomenon for wave equations with a potential. This complements the recent interesting existence result by [V. Georgiev, C. Heiming, and H. Kubo, *Comm. Partial Differential Equations*, 26 (2001), pp. 2267–2303], where the blowup problem was left open.

Key words. semilinear wave equation, finite-time blowup

AMS subject classification. 35L70

DOI. 10.1137/S0036141004440198

1. Introduction.

We study the blowup of the solutions to the following semilinear wave equation:

$$\begin{cases} \Delta u - Vu - u_{tt} + |u|^p = 0 \quad \text{in} \quad \mathbf{R}^n \times (0,\infty), \\ u(x,0) = u_0(x), \quad u_t(x,0) = u_1(x) \quad \text{in} \quad \mathbf{R}^n, \end{cases} \tag{1.1}$$

where $\Delta = \Sigma_{i=1}^n \partial^2/\partial x_i^2$ is the Laplace operator and $V = V(x)$ is a potential. We consider dimensions $n \geq 3$ and exponents $p \in (1,\ p_c(n))$, where $p_c(n)$ is the positive root of the quadratic equation

$$(n-1)p^2 - (n+1)p - 2 = 0.$$

The number $p_c(n)$ is known as the critical exponent of the semilinear wave equation with $V = 0$ (see, e.g., [St]). The study of this equation has an interesting and exciting history. We will give only a brief summary here and refer the reader to [St], [L], [DL], and a recent paper [JZ] for details. Let the initial values be compactly supported and nonnegative. John [J] proved that for $n = 3$ and $1 < p < p_c(3)$, nontrivial solutions must blow up in finite time. If $p > p_c(3)$, global solutions exist for small initial values. Glassey [Gl1], [Gl2] established the same result in the case $n = 2$. Schaeffer [Sc] proved that the critical power $p = p_c(n)$ also belongs to the blowup case when $n = 2$, 3. In [GLS] the authors showed that when $p > p_c(n)$ and $n \geq 3$, (1.1) has global solutions for small initial values (see also [LS] and [T]). When $n \geq 4$ and $1 < p < p_c(n)$, the blowup result was proven by Sideris in [Si]. The proof is quite delicate, using sophisticated computation involving spherical harmonics. His proof was simplified in [R] and [JZ], where spherical harmonics still play an important role. In this paper we discover a truly short proof of the blowup result using only a simple test function. More importantly the proof carries over to the case when the potential V is positive. It is a well-known fact that the presence of potentials greatly increases the complexity of wave motion. In fact there is not much progress in either the existence or blowup

problems in higher-dimensional cases of (1.1). In the three-dimensional case, it is known that there exist global small solutions when $p > p_c(3)$ and $V \in C_0^\infty(\mathbf{R}^3)$ is nonnegative; see [GHK]. In the same case, [ST] establishes, among other things, a blowup result for some $V \leq 0$. The current paper complements the result of [GHK] in dimension $n = 3$ and shows the blowup of solutions in all dimensions $n \geq 3$ when $1 < p < p_c(n)$ and V is a nonnegative potential satisfying the following condition: There exist two functions ϕ_0, $\phi_1 \in C^2(\mathbf{R}^n)$ such that

$$\begin{cases} \Delta\phi_0 - V\phi_0 = 0, & C_0^{-1} \leq \phi_0(x) \leq C_0, \\ \Delta\phi_1 - V\phi_1 = \phi_1, & 0 < \phi_1(x) \leq C_1(1+|x|)^{-(n-1)/2}e^{|x|}, \end{cases} \tag{1.2}$$

with positive constants C_0 and C_1. We show (see Lemma 3.1) that this condition is satisfied by nonnegative potentials under very mild additional assumptions about regularity and behavior at infinity.

We consider compactly supported nonnegative data $(u_0, u_1) \in H^1(\mathbf{R}^n) \times L^2(\mathbf{R}^n)$:

$$u_0(x) \geq 0, \quad u_1(x) \geq 0 \quad \text{a.e.}, \quad u_0(x) = u_1(x) = 0 \quad \text{for} \quad |x| > R. \tag{1.3}$$

Our main result is the following theorem.

THEOREM 1.1. *Let (u_0, u_1) satisfy (1.3) and V satisfy (1.2). Suppose that problem (1.1) has a solution $(u, u_t) \in C([0,T),\ H^1(\mathbf{R}^n) \times L^2(\mathbf{R}^n))$ such that*

$$\operatorname{supp}(u, u_t) \subset \{(x,t) : |x| \leq t + R\}.$$

If $1 < p < p_c(n)$, then $T < \infty$.

In particular, the conclusion holds if V is locally Hölder continuous and $0 \leq V(x) \leq \frac{C}{1+|x|^{2+\delta}}$ for some C, $\delta > 0$ and all $x \in \mathbf{R}^n$.

When $V = 0$, we choose the functions

$$\begin{cases} \phi_0(x) = 1, \\ \phi_1(x) = \int_{S^{n-1}} e^{x\cdot\omega} d\omega, \quad \phi_1(x) \sim C_n|x|^{-(n-1)/2}e^{|x|} \quad \text{as} \quad |x| \to \infty. \end{cases}$$

Since condition (1.2) holds, we can apply Theorem 1.1 and deduce the well-known results of John [J] and Sideris [Si].

The proof of Theorem 1.1 is given in sections 2 and 3. To outline the method, we introduce

$$\begin{aligned} F_0(t) &= \int u(x,t)\phi_0(x)dx, \\ F_1(t) &= \int u(x,t)\psi_1(x,t)dx, \qquad \psi_1(x,t) = \phi_1(x)e^{-t}. \end{aligned} \tag{1.4}$$

The assumptions on u imply that $F_0(t)$ and $F_1(t)$ are well-defined C^2-functions for all t. By a standard procedure, we derive a nonlinear differential inequality for $F_0(t)$. We also derive a linear differential inequality for $F_1(t)$ and combine these to obtain a polynomial lower bound on $F_0(t)$ as $t \to \infty$. Theorem 1.1 is a consequence of the lower bound and the blowup result about nonlinear differential inequalities in Lemma 2.1.

In section 3 we prove the existence of ϕ_0 and ϕ_1 in (1.2) when V is locally Hölder continuous and $0 \leq V(x) \leq \frac{C}{1+|x|^{2+\delta}}$ for some $C, \delta > 0$ and all $x \in \mathbf{R}^n$. This relies on a latest sharp estimate of heat kernels with a potential.

2. Proof of Theorem 1.1. We will use the following well-known ODE result from, e.g., [Si, p. 386] to show that $F_0(t)$ in (1.4) blows up in finite time.

LEMMA 2.1. *Let $p > 1$, $a \geq 1$, and $(p-1)a > q-2$. If $F \in C^2([0,T))$ satisfies*
(a) $F(t) \geq K_0(t+R)^a$,
(b) $\frac{d^2F(t)}{dt^2} \geq K_1(t+R)^{-q}[F(t)]^p$,
with some positive constants K_0, K_1, and R, then $T < \infty$.

To show that F_0 satisfies the above differential inequalities for suitable a, q, we multiply (1.1) by ϕ_0 and integrate over $\mathbf{R}^n$. Condition (1.2) on ϕ_0 yields

$$\frac{d^2F_0(t)}{dt^2} = \int |u(x,t)|^p \phi_0(x)dx.$$

Note that for a fixed t, $u(\cdot,t) \in H_0^1(D_t)$ where D_t is the support of $u(\cdot,t)$. Hence the above equality is justified using integration by parts.

Estimating the right side by the Hölder inequality, we have

$$\int |u(x,t)|^p \phi_0(x)dx \geq \frac{\left|\int u(x,t)\phi_0(x)dx\right|^p}{\left(\int_{|x|\leq t+R} \phi_0(x)dx\right)^{p-1}}.$$

By condition (1.2),

$$\int_{|x|\leq t+R} \phi_0(x)dx \leq C_0 \mathrm{vol}\{x : |x| < t+R\} = C_0 \mathrm{vol}(\mathbf{B}^n)(t+R)^n.$$

Thus, we obtain the differential inequality

$$\frac{d^2F_0(t)}{dt^2} \geq L_1(t+R)^{-n(p-1)}|F_0(t)|^p \tag{2.1}$$

with some $L_1 > 0$.

To show that F_0 admits the lower bound in Lemma 2.1(a), we relate d^2F_0/dt^2 to F_1 using again (1.1) and the Hölder inequality:

$$\frac{d^2F_0(t)}{dt^2} = \int |u(x,t)|^p \phi_0(x)dx \geq \frac{\left|\int u(x,t)\psi_1(x,t)dx\right|^p}{\left(\int_{|x|\leq t+R} [\phi_0(x)]^{-1/(p-1)}[\psi_1(x,t)]^{p/(p-1)}dx\right)^{p-1}}.$$

By (1.2), the last inequality becomes

$$\frac{d^2F_0(t)}{dt^2} \geq \frac{C_0\,|F_1(t)|^p}{\left(\int_{|x|\leq t+R} [\psi_1(x,t)]^{p/(p-1)}dx\right)^{p-1}}. \tag{2.1$'$}$$

The following lemmas estimate the numerator and denominator, respectively, and provide a lower bound on d^2F_0/dt^2.

LEMMA 2.2. *Let V satisfy* (1.2) *and (u_0,u_1) satisfy* (1.3). *Assume that u meets the conditions of Theorem* 1.1. *Then for all $t \geq 0$,*

$$F_1(t) \geq \frac{1}{2}(1-e^{-2t})\int [u_0(x)+u_1(x)]\phi_1(x)dx + e^{-2t}\int u_0(x)\phi_1(x)dx \geq c > 0.$$

LEMMA 2.3. *Let $p > 1$. Assume that ϕ_0 and ϕ_1 satisfy condition* (1.2). *Then for all $t \geq 0$,*

$$\int_{|x|\leq t+R} [\psi_1(x,t)]^{p/(p-1)}dx \leq C(t+R)^{n-1-(n-1)p'/2},$$

where $p' = p/(p-1)$.

Taking the two lemmas for granted, we combine them with (2.1′) to obtain

$$\frac{d^2F_0(t)}{dt^2} \geq L_2(t+R)^{n-1-(n-1)p/2}, \quad t \geq 0,$$

where $L_2 > 0$. Integrating twice, we have the final estimate

$$F_0(t) \geq L_0(t+R)^{n+1-(n-1)p/2} + \frac{dF_0(0)}{dt}t + F_0(0)$$

with some $L_0 > 0$. When $1 < p < p_c(n)$, it is easy to check that $n+1-(n-1)p/2 > 1$. Hence the following estimate is valid when t is large:

$$F_0(t) \geq L_0(t+R)^{n+1-(n-1)p/2}. \tag{2.2}$$

Estimates (2.1) and (2.2) and Lemma 2.1 with parameters

$$a \equiv n+1-(n-1)p/2 \quad \text{and} \quad q \equiv n(p-1)$$

imply Theorem 1.1 for all exponents p such that

$$(p-1)(n+1-(n-1)p/2) > n(p-1)-2 \quad \text{and} \quad p > 1.$$

It is easy to see that the solution set is $p \in (1,\, p_c(n))$. The proof of Theorem 1.1 is complete, assuming Lemmas 2.2 and 2.3 and the validity of (1.2).

Proof of Lemma 2.2. We multiply (1.1) by a test function $\psi \in C^2(\mathbf{R}^{n+1})$ and integrate over $\mathbf{R}^n \times [0,\, t]$:

$$\begin{aligned} &\int_0^t \int u(\Delta\psi - V\psi - \psi_{ss})dxds + \int_0^t \int |u|^p\psi\, dxds \\ &\qquad = \int (u_s\psi - u\psi_s)dx|_{s=t} - \int (u_s\psi - u\psi_s)dx|_{s=0}. \end{aligned} \tag{2.3}$$

We will apply this identity to $\psi = \psi_1$. Notice that for a fixed t, $u(\cdot,t) \in H_0^1(D_t)$ where D_t is the support of $u(\cdot,t)$. Hence all terms involving lateral boundary vanish during integration by parts. Notice also that

$$(\psi_1)_t = -\psi_1, \quad \Delta\psi_1 - V\psi_1 - (\psi_1)_{tt} = 0,$$

and

$$\begin{aligned} \int (u_s\psi_1 - u(\psi_1)_s)dx|_{s=t} &= \int (u_t\psi_1 + u(\psi_1)_t)dx - 2\int u(\psi_1)_t dx \\ &= \frac{d}{dt}\int u\psi_1 dx + 2\int u\psi_1 dx. \end{aligned}$$

Hence, (2.3) becomes

$$\frac{dF_1(t)}{dt} + 2F_1(t) = \int [u_0(x) + u_1(x)]\phi_1(x)dx + \int_0^t \int |u(x,s)|^p\psi_1(x,s)dxds.$$

Since $\psi_1 > 0$, we conclude that

$$\frac{dF_1(t)}{dt} + 2F_1(t) \geq \int [u_0(x) + u_1(x)]\phi_1(x)dx.$$

We multiply by e^{2t} and integrate on $[0,\, t]$. Then

$$e^{2t}F_1(t) - F_1(0) \geq \frac{1}{2}(e^{2t}-1)\int [u_0(x)+u_1(x)]\phi_1(x)dx.$$

Dividing through by e^{2t}, we obtain the lower bound in Lemma 2.2. □

Proof of Lemma 2.3. Let $I(t)$ be the integral in Lemma 2.3. Condition (1.2) shows that

$$I(t) \leq \text{area}(\mathbf{S}^{n-1})C_1^{p/(p-1)}e^{-p't}\int_0^{t+R}(1+r)^{-(n-1)p'/2}e^{p'r}r^{n-1}dr,$$

where $p' = p/(p-1)$. Since $r < r+1$, it is sufficient to show that

$$I(t) \leq Ce^{-p't}\int_0^{t+R}(1+r)^{n-1-(n-1)p'/2}e^{p'r}dr \leq C(t+R)^{n-1-(n-1)p'/2}.$$

This estimate is evident after splitting the last integral into two parts:

$$\begin{aligned}\int_0^{(t+R)/2}(1+r)^{n-1-(n-1)p'/2}e^{rp'}dr &\leq (1+t+R)^{q_1}\int_0^{(t+R)/2}e^{p'r}dr\\ &\leq \frac{e^{p'R/2}}{p'}(1+t+R)^{q_1}e^{p't/2},\end{aligned}$$

where $q_1 = \max(0,\, n-1-(n-1)p'/2)$, and

$$\begin{aligned}\int_{(t+R)/2}^{t+R}(1+r)^{n-1-(n-1)p'/2}e^{p'r}dr &\leq 2^{-q_2}(1+t+R)^{n-1-(n-1)p'/2}\int_{(t+R)/2}^{t+R}e^{p'r}dr\\ &\leq \frac{2^{-q_2}e^{p'R}}{p'}(1+t+R)^{n-1-(n-1)p'/2}e^{p't},\end{aligned}$$

where $q_2 = \min(0,\, n-1-(n-1)p'/2)$. This proves Lemma 2.3. □

To complete the proof of Theorem 1.1, it remains to prove Lemma 3.1. In the special case $V = 0$, the next section is redundant.

3. Existence of the two functions in (1.2). In this section we prove the following lemma.

LEMMA 3.1. *Suppose V is locally Hölder continuous and $0 \leq V(x) \leq \frac{C}{1+|x|^{2+\delta}}$ for some $C, \delta > 0$ and all $x \in \mathbf{R}^n$. Then there exist two functions ϕ_0 and ϕ_1 satisfying* (1.2)*, i.e.,*

$$\begin{cases}\Delta\phi_0 - V\phi_0 = 0, & C_0^{-1} \leq \phi(x) \leq C_0,\\ \Delta\phi_1 - V\phi_1 = \phi_1, & 0 < \phi_1(x) \leq C_1(1+|x|)^{-(n-1)/2}e^{|x|}.\end{cases}$$

Proof. Let H_0 and H be the fundamental solutions of

$$\Delta u - u - u_t = 0, \qquad \Delta u - u - Vu - u_t = 0$$

in $\mathbf{R}^n \times (0,\infty)$, respectively. Then $H_0 = e^{-t}G_0$ and $H = e^{-t}G$, where G_0 and G are the fundamental solution of

$$\Delta u - u_t = 0, \qquad \Delta u - Vu - u_t = 0.$$

By Theorem 1.1(a) and Remark 1.1 in [Z1], there exists a positive constant c such that

$$cG_0(x,t;y,0) \le G(x,t;y,0) \le G_0(x,t;y,0) = \frac{c_n}{t^{n/2}} e^{-\frac{|x-y|^2}{4t}}$$

for all $x, y \in \mathbf{R}^n$ and $t > 0$. We should mention that the global lower bound is nontrivial since one needs to keep the exact coefficient $1/4$ in each exponential term.

Hence we have the following global bounds:

$$cH_0(x,t;y,0) \le H(x,t;y,0) \le H_0(x,t;y,0). \tag{3.1}$$

Let μ_0 be a positive solution of $\Delta\mu_0 - \mu_0 = 0$ such that

$$\mu_0(x) \sim e^{|x|}/(1+|x|)^{(n-1)/2}.$$

The existence of such μ_0 is well known and is explained in the introduction. Consider the function

$$u(x,t) \equiv \int_{\mathbf{R}^n} H(x,t;y,0)\mu_0(y)dy. \tag{3.2}$$

Since for fixed (x,t), $H(x,t;y,0)$ decays super-exponentially near infinity, the above integral is well defined. Moreover, u is a solution to

$$\Delta u - u - Vu - u_t = 0. \tag{3.3}$$

By (3.1) and (3.2) we have

$$c\int_{\mathbf{R}^n} H_0(x,t;y,0)\mu_0(y)dy \le u(x,t) \le \int_{\mathbf{R}^n} H_0(x,t;y,0)\mu_0(y)dy.$$

Since $\Delta\mu_0 - \mu_0 = 0$, it is clear from differentiation that

$$\mu_0(x) = \int_{\mathbf{R}^n} H_0(x,t;y,0)\mu_0(y)dy,$$

even though the right-hand side apparently depends on time. Indeed,

$$\begin{aligned}\frac{\partial}{\partial t}\int_{\mathbf{R}^n} H_0(x,t;y,0)\mu_0(y)dy &= -\int_{\mathbf{R}^n} (\Delta_y - 1)H_0(x,t;y,0)\mu_0(y)dy \\ &= -\int_{\mathbf{R}^n} H_0(x,t;y,0)(\Delta_y - 1)\mu_0(y)dy = 0.\end{aligned}$$

Here we observe that integration by parts is legitimate since, for fixed $t > 0$ and x, $H_0(x,t;y,0)$ has superexponential decay near infinity while μ_0 only grows exponentially.

Hence

$$c\mu_0(x) \le u(x,t) \le \mu_0(x). \tag{3.4}$$

Differentiating (3.3) with respect to t, we obtain

$$\begin{cases}\Delta u_t - u_t - Vu_t - (u_t)_t = 0, \quad (x,t) \in \mathbf{R}^n \times (0,\infty), \\ u_t|_{t=0} = \Delta\mu_0 - \mu_0 - V\mu_0 \le 0.\end{cases}$$

Here we remark that under our assumption that V is locally Hölder continuous, it is not clear whether u_{tt} exists. However, we can work on the finite difference of u_t and use a standard approximation argument to achieve the same result.

By the maximum principle, we know that $u_t(x,t) \le 0$ everywhere. This and (3.4) show that $u(x,t)$ converges to a function $\phi_1 = \phi_1(x)$ as $t \to \infty$. Moreover,

$$c\mu_0(x) \le \phi_1(x) \le \mu_0(x). \tag{3.5}$$

We are going to show that

$$\Delta\phi_1 - \phi_1 - V\phi_1 = 0. \tag{3.6}$$

To this end, let us consider the function $w = w(x,t) = \int_t^{t+1} u(x,s)ds$. Direct computation shows that

$$\Delta w(x,t) - w(x,t) - V(x)w(x,t) = u(x,t+1) - u(x,t).$$

It is also clear that $w(x,t) \to \phi_1(x)$ when $t \to \infty$. Let $\eta = \eta(x)$ be any function in $C_0^\infty(\mathbf{R}^n)$. Then we obtain

$$\begin{aligned}&\int_{\mathbf{R}^n} [w(x,t)\Delta\eta(x) - w(x,t)\eta(x) - V(x)w(x,t)\eta(x)]dx \\ &\quad = \int_{\mathbf{R}^n} [u(x,t+1) - u(x,t)]\eta(x)dx.\end{aligned}$$

Letting $t \to \infty$, we have

$$\int_{\mathbf{R}^n} [\phi_1(x)\Delta\eta(x) - \phi_1(x)\eta(x) - V(x)\phi_1(x)\eta(x)]dx = 0.$$

Since η is arbitrary and ϕ_1 is locally bounded, we know that ϕ_1 is a classical solution to (3.6), which also satisfies (3.5). This proves the existence of ϕ_1 in (1.2). The existence of ϕ_0 under our assumption is well known (see, e.g., [Z2, Theorem B]). In fact it can be proven by exactly the same method except that we drop the term $-u$ everywhere. □

Remark 3.1. The decay condition for V in Lemma 3.1 can be generalized. In [Z1], a necessary and sufficient condition for the validity of the sharp comparison result right before (3.1) was found for all nonnegative V. This class of V resembles the Kato class in mathematical physics. It overlaps with $L^{n/2}(\mathbf{R}^n)$. But they are not the same.

EXISTENCE OF TRAVELLING WAVES IN DISCRETE SINE-GORDON RINGS*

GUY KATRIEL†

Abstract. We prove existence results for travelling waves in discrete, damped, dc-driven sine-Gordon equations with periodic boundary conditions. Methods of nonlinear functional analysis are employed. Some unresolved questions are raised.

Key words. discrete sine-Gordon equation, Frenkel–Kontorova model, travelling waves

AMS subject classifications. 34C15, 34C60, 37N20, 78A55

DOI. 10.1137/S0036141004440174

1. Introduction. The damped, dc-driven discrete sine-Gordon equation, known also as the driven Frenkel–Kontorova model, with periodic boundary conditions, arises as a model of many physical systems, including circular arrays of Josephson junctions, the motions of dislocations in a crystal, the adsorbate layer on the surface of a crystal, ionic conductors, glassy materials, charge-density wave transport, sliding friction, as well as the mechanical interpretation as a model for a ring of pendula coupled by torsional springs (we refer to the reader [8, 10, 11] and the references therein). This model has thus become a fundamental one for nonlinear physics, and has been the subject of many theoretical, numerical, and experimental studies. The system of equations is

$$\phi_j'' + \Gamma\phi_j' + \sin(\phi_j) = F + K[\phi_{j+1} - 2\phi_j + \phi_{j-1}] \quad \forall j \in \mathbb{Z} \tag{1}$$

with the parameters $\Gamma > 0, K > 0, F > 0$, with the periodic boundary condition

$$\phi_{j+n}(t) = \phi_j(t) + 2\pi m \quad \forall j \in \mathbb{Z}, \tag{2}$$

where $m \geq 1$ (we note that in view of the boundary conditions we are really dealing with an n-dimensional system of ODE's rather than an infinite-dimensional one). In numerical simulations, as well as in experimental work on systems modelled by (1), (2), it is observed that solutions often converge to a travelling wave: a solution satisfying

$$\phi_j(t) = f\Big(t + j\frac{m}{n}T\Big), \tag{3}$$

where the waveform $f : \mathbb{R} \to \mathbb{R}$ is a function satisfying

$$f(t+T) = f(t) + 2\pi \quad \forall t \in \mathbb{R}. \tag{4}$$

The velocity of the travelling wave is given by

$$v = \frac{2\pi}{T}. \tag{5}$$

However, as has been pointed out in [10], even the *existence* of such a solution has not been proven, except for the case of small K in which existence of a travelling wave for some values of F had been proven in [4].

In the "superdamped" case, in which the second-derivative term in (1) is removed, there are very satisfactory results about existence and also global stability of travelling waves (see [1, Theorem 2],). Such results rely strongly on monotonicity arguments. Recently Baesens and MacKay [2] have managed to extend these arguments to the "overdamped" case of (1): their results apply when

$$\Gamma > 2\sqrt{2K+1}, \tag{6}$$

and say that there exists a travelling-wave solution which is globally stable if and only if (1), (2) does not have stationary solutions. We do not know whether in general the nonexistence of stationary solutions implies the existence of a travelling wave.

We note that a function f is a waveform if and only if it satisfies (4) and

$$f''(t) + \Gamma f'(t) + \sin(f(t)) = F + K\Big[f\Big(t + \frac{m}{n}T\Big) - 2f(t) + f\Big(t - \frac{m}{n}T\Big)\Big]. \tag{7}$$

Here we obtain several existence results for travelling waves under conditions not covered by the existing work, described above.

THEOREM 1. *Fixing any $\Gamma > 0$ and $K > 0$, and given any velocity $v > 0$, there exists a travelling-wave solution of* (1), (2) *with velocity v for an appropriate $F > 0$.*

THEOREM 2. *For any $F > 1$ there exists a travelling-wave solution of* (1), (2).

THEOREM 3. *Assume that n does not divide m. Fixing any $\tilde{F} > 0$ and $\tilde{\Gamma} > 0$, for all K sufficiently large there exists a travelling-wave solution of* (1), (2) *for any $F \geq \tilde{F}$ and $\Gamma \geq \tilde{\Gamma}$.*

THEOREM 4. *Fixing any $\tilde{F} > 0$ and $\tilde{K} > 0$, for all $\Gamma > 0$ sufficiently small there exists a travelling-wave solution of* (1), (2) *for any $F \geq \tilde{F}$ and $0 < K \leq \tilde{K}$.*

We remark that the assumption that n does not divide m cannot be removed from Theorem 3, since if n divides m the coupling term vanishes and (7), (4) reduce to the equation of a running solution of a dc-forced pendulum, which, fixing $\Gamma > 0$, is known to have a solution only when F exceeds a positive critical value [5].

It is interesting to note that Theorem 4 demonstrates that for some parameter ranges, there is coexistence of stationary solutions and travelling waves of (1), (2). Indeed, it is well known [3] that, fixing K, for F sufficiently small, there exist stationary solutions of (1), (2), and these obviously do not depend on Γ. Hence we can take $\Gamma > 0$ sufficiently small so that Theorem 4 ensures also the existence of travelling waves. This phenomenon cannot happen in the superdamped case, nor in the overdamped case in which (6) holds, since in these cases existence of stationary solutions implies that the ω-limit set of every orbit is contained in the set of stationary solutions [1, 2].

Along the way we will prove the following proposition.

PROPOSITION 5. *An upper bound for the velocity v of any travelling wave is given by*

$$v < \frac{F}{\Gamma}, \tag{8}$$

and a lower bound, in the case $F > 1$, is given by

$$v > \frac{F-1}{\Gamma}. \tag{9}$$

In the next section we prove the results stated above. In section 3 we discuss the meaning of our results in connection with existing numerical studies of the discrete sine-Gordon equation, and point out some further mathematical questions which arise from our results and remain open.

2. Proofs of the results. Our method of proof involves reformulating the problem as a fixed-point problem in a Banach space, and applying results of nonlinear functional analysis. Our approach is thus close in spirit to [6], which deals with travelling waves in globally coupled Josephson junctions.

We transform the problem (4), (7) by setting

$$f(t) = u(vt) + vt,$$

where the wave velocity v is defined by (5) and u satisfies

$$u(z + 2\pi) = u(z) \quad \forall z \in \mathbb{R}. \tag{10}$$

Equation (7) can then be written as

$$\begin{aligned} &v^2 u''(z) + \Gamma v u'(z) + \sin(z + u(z)) \\ &\qquad = F - \Gamma v + K\Big[u\Big(z + 2\pi\frac{m}{n}\Big) - 2u(z) + u\Big(z - 2\pi\frac{m}{n}\Big)\Big]. \end{aligned} \tag{11}$$

Dividing by v^2 and setting

$$\lambda = \frac{1}{v},$$

we rewrite (11) in the form

$$\begin{aligned} &u''(z) + \lambda\Gamma u'(z) + \lambda^2 \sin(z + u(z)) \\ &\qquad = \lambda^2 F - \lambda\Gamma + \lambda^2 K\Big[u\Big(z + 2\pi\frac{m}{n}\Big) - 2u(z) + u\Big(z - 2\pi\frac{m}{n}\Big)\Big]. \end{aligned} \tag{12}$$

We note that if $u(z)$ satisfies (10), (12), then so does $\tilde{u}(z) = u(z + c) + c$, for any $c \in \mathbb{R}$. Thus by adjusting c we may assume that u satisfies

$$\int_0^{2\pi} u(s)ds = 0. \tag{13}$$

We note now that if u satisfies (10),(12), then by integrating both sides of (12) over $[0, 2\pi]$ we obtain

$$F = \frac{\Gamma}{\lambda} + \frac{1}{2\pi}\int_0^{2\pi} \sin(s + u(s))ds. \tag{14}$$

We can thus rewrite (12) as

$$\begin{aligned} u''(z) + \lambda\Gamma u'(z) + \lambda^2 \sin(z + u(z)) &= \lambda^2 \frac{1}{2\pi}\int_0^{2\pi} \sin(s + u(s))ds \\ &+ \lambda^2 K\Big[u\Big(z + 2\pi\frac{m}{n}\Big) - 2u(z) + u\Big(z - 2\pi\frac{m}{n}\Big)\Big]. \end{aligned} \tag{15}$$

Conversely, if u satisfies (14) and (15), then it satisfies (12). We have thus reformulated our problem as: find solutions (λ, u) of (10), (13), (14), (15). The idea now is to

consider λ as a *parameter* in (15) and try to find solutions u satisfying (10), (13), (15), and then substitute λ and u into (14) to obtain the corresponding value of F. This is the same idea as used in the numerical method presented in [8], but here it is used as part of existence proofs. We have the following claim.

PROPOSITION 6. *For any value λ, there exists a solution u of* (15) *satisfying* (10), (13).

We note that this proposition immediately implies Theorem 1, since given any $v > 0$ it shows that we can solve (15) with $\lambda = \frac{1}{v}$, hence obtain a travelling wave with velocity v, for the value of F given by (14).

To prove Proposition 6 we will use the Schauder fixed-point theorem. We denote by X and Y the Banach spaces of real-valued functions:

$$X = \left\{ u \in H^2[0, 2\pi] \mid u(0) = u(2\pi),\ \ u'(0) = u'(2\pi),\ \ \int_0^{2\pi} u(s)ds = 0 \right\},$$

$$Y = \left\{ u \in L^2[0, 2\pi] \mid \int_0^{2\pi} u(s)ds = 0 \right\},$$

with the norm

$$\|u\|_Y = \Big(\frac{1}{2\pi} \int_0^{2\pi} (u(s))^2 ds\Big)^{\frac{1}{2}},$$

and by $L_\lambda : X \to Y$ the linear mapping

$$L_\lambda(u)(z) = u''(z) + \lambda\Gamma u'(z) - \lambda^2 K\Big[u\Big(z + 2\pi\frac{m}{n}\Big) - 2u(z) + u\Big(z - 2\pi\frac{m}{n}\Big)\Big].$$

We want to show that this mapping is invertible and to derive an upper bound for the norm of its inverse. Noting that any $u \in X$ can be decomposed in a Fourier series $u(z) = \sum_{l\neq 0} a_l e^{ilz}$ (with $a_{-l} = \overline{a_l}$), we apply L_λ to the Fourier elements, obtaining

$$L_\lambda(e^{ilz}) = \mu_l e^{ilz},$$

where

$$\mu_l = -l^2 - 2K\lambda^2\Big(\cos\Big(\frac{2\pi ml}{n}\Big) - 1\Big) + \lambda l\Gamma i,$$

so that

$$|\mu_l| = \Big[\Big(l^2 + 2K\lambda^2\Big(\cos\Big(\frac{2\pi ml}{n}\Big) - 1\Big)\Big)^2 + \lambda^2 l^2\Gamma^2\Big]^{\frac{1}{2}}, \tag{16}$$

which does not vanish if $\Gamma > 0$. Thus the mapping L_λ has an inverse satisfying $L_\lambda^{-1}(e^{ilz}) = \frac{1}{\mu_l} e^{ilz}$. Since L_λ^{-1} takes Y onto X, and since X is compactly embedded in Y, we may consider L_λ^{-1} as a mapping from Y to itself, in which case it is a *compact* mapping. We also note, using (16), that

$$\|L_\lambda^{-1}\|_{Y,Y} \le \max_{l\ge 1} \frac{1}{|\mu_l|} \le \frac{1}{\lambda\Gamma}. \tag{17}$$

We also define the nonlinear operator $N : Y \to Y$ by

$$N(u)(z) = -\sin(z + u(z)) + \frac{1}{2\pi}\int_0^{2\pi} \sin(s + u(s))ds.$$

It is easy to see that N is continuous, and that the range of N is contained in a bounded ball in Y, indeed we have

$$\|\sin(z+u(z))\|_{L_2} = \Big(\frac{1}{2\pi}\int_0^{2\pi} (\sin(s+u(s)))^2 ds\Big)^{\frac{1}{2}} \leq 1,$$

and since $N(u)$ is the orthogonal projection of $-\sin(z+u(z))$ into Y, we have

$$\|N(u)\|_Y \leq 1 \quad \forall u \in Y. \tag{18}$$

We can now rewrite the problem (10), (13), (15) as the fixed-point problem

$$u = \lambda^2 L_\lambda^{-1} \circ N(u). \tag{19}$$

The operator on the right-hand side is compact by the compactness of L_λ^{-1}, and has a bounded range by (17), (18), so that Schauder's fixed-point theorem implies that (19) has a solution, proving Proposition 6 (we note that by a simple bootstrap argument a solution in Y is in fact smooth). Moreover, defining

$$\Sigma = \{(\lambda, u) \in [0,\infty) \times Y \mid u = \lambda^2 L_\lambda^{-1} \circ N(u)\},$$

Rabinowitz's continuation theorem [7] implies that the connected component of Σ containing $(\lambda, u) = (0,0)$, which we denote by C, is unbounded in $[0,\infty) \times Y$. Since for any $\lambda_0 > 0$ we have, from (18), (19), the bound $\|u\|_Y \leq \frac{\lambda_0}{\Gamma}$ for solutions (λ, u) of (19) with $\lambda \in [0, \lambda_0]$, the unboundedness of the set C must be in the λ-direction, that is, there exists $(\lambda, u) \in C$ with arbitrarily large values of λ.

We can now consider the right-hand side of (14) as a functional on $(0,\infty) \times Y$:

$$\Phi(\lambda, u) = \frac{\Gamma}{\lambda} + \frac{1}{2\pi}\int_0^{2\pi} \sin(s+u(s))ds, \tag{20}$$

and our strategy in proving Theorems 2–4 is to prove solvability of the equation

$$\Phi(\lambda, u) = F, \quad (\lambda, u) \in \Sigma \tag{21}$$

(in fact we shall prove solvability of (21) with Σ replaced by $C \subset \Sigma$). We note that by the boundedness of the sine function we have

$$\lim_{\lambda \to 0+,\ (\lambda,u)\in C} \Phi(\lambda, u) = +\infty, \tag{22}$$

$$\limsup_{\lambda \to +\infty,\ (\lambda,u)\in C} \Phi(\lambda, u) \leq 1. \tag{23}$$

Since C is a connected set and Φ is continuous, (22) implies the following proposition.

PROPOSITION 7. *For any F satisfying*

$$F > \underline{F} \equiv \inf_{(\lambda,u)\in C} \Phi(\lambda, u), \tag{24}$$

there exists a travelling wave.

Since (23) implies that $\underline{F} \leq 1$, this proves Theorem 2.

We now prove the lower and upper bounds for the velocities of travelling waves given in Proposition 5. These follow from (5), (14) and the following proposition.

PROPOSITION 8. *For any* $(\lambda, u) \in \Sigma$ *with* $\lambda > 0$ *we have*

$$0 < \frac{\Gamma}{\lambda} < \Phi(\lambda, u) < \frac{\Gamma}{\lambda} + 1.$$

The upper bound follows immediately from the definition (20) of $\Phi(\lambda, u)$ since $\frac{1}{2\pi}\int_0^{2\pi} \sin(s + u(s))ds < 1$. The lower bound follows from the claim that

$$(\lambda, u) \in \Sigma \;\Rightarrow\; \int_0^{2\pi} \sin(s + u(s))ds > 0. \tag{25}$$

To prove this claim we multiply (15) by $1 + u'(z)$ and integrate over $[0, 2\pi]$, noting that

$$\begin{aligned}\int_0^{2\pi} u\Big(s + 2\pi\frac{m}{n}\Big)u'(s)ds &= \int_0^{2\pi} u(s)u'\Big(s - 2\pi\frac{m}{n}\Big)ds \\ &= -\int_0^{2\pi} u'(s)u\Big(s - 2\pi\frac{m}{n}\Big)ds,\end{aligned}$$

so that we obtain

$$(\lambda, u) \in \Sigma \Rightarrow \Gamma\frac{1}{2\pi}\int_0^{2\pi} (u'(s))^2 ds = \lambda\frac{1}{2\pi}\int_0^{2\pi} \sin(s + u(s))ds.$$

This proves (25) since the left-hand side is nonnegative and cannot vanish unless $u \equiv 0$, but $(\lambda, 0) \notin \Sigma$ for $\lambda > 0$.

We now turn to the proof of Theorem 3.

PROPOSITION 9. *Assume* n *does not divide* m *and* $\tilde{\Gamma} > 0$. *Given any* $\lambda_0 > 0$ *and* $\epsilon > 0$, *there exists* K_0 *such that for* $K \geq K_0$ *and* $\Gamma \geq \tilde{\Gamma}$ *we have that*

$$\Big|\frac{1}{2\pi}\int_0^{2\pi} \sin(s + u(s))ds\Big| < \epsilon \text{ if } (\lambda_0, u) \in \Sigma. \tag{26}$$

To see that Proposition 9 implies Theorem 3, we fix some $\tilde{F} > 0$, $\tilde{\Gamma} > 0$, and assume $\Gamma \geq \tilde{\Gamma}$. We choose $\lambda_0 > \frac{\Gamma}{\tilde{F}}$ and set $\epsilon = \tilde{F} - \frac{\Gamma}{\lambda_0}$. We then choose K_0 according to Proposition 9, so that (26) holds, which implies that when $K \geq K_0$ we have $\Phi(\lambda_0, u) < \tilde{F}$ for any u with $(\lambda_0, u) \in C$. Thus $\underline{F} < \tilde{F}$, where $\underline{F}$ is defined by (24), so Proposition 7 implies the existence of a travelling wave for any $F \geq \tilde{F}$.

We now prove Proposition 9. Let $\lambda_0 > 0$ and $\epsilon > 0$ be given. Assume $(\lambda_0, u) \in \Sigma$, so that (19) holds with $\lambda = \lambda_0$. Let (m, n) denote the greatest common divisor of m, n, and let

$$p = \frac{m}{(m, n)}, \qquad q = \frac{n}{(m, n)}.$$

Since we assume n does not divide m we have $q \geq 2$. Let Y_0 be the subspace of Y consisting of $\frac{2\pi}{q}$-periodic functions, and let Y_1 be its orthogonal complement in Y. We denote using P the orthogonal projection of Y to Y_0. Setting

$$u_0 = P(u), \qquad u_1 = (I - P)(u),$$

we have $u = u_0 + u_1$ with $u_0 \in Y_0$ and $u_1 \in Y_1$. Applying P and $I - P$ to (19), and noting that L_λ commutes with P, we have

$$u_0 = \lambda_0^2 L_{\lambda_0}^{-1} \circ P \circ N(u_0 + u_1), \tag{27}$$

$$u_1 = \lambda_0^2 L_{\lambda_0}^{-1} \circ (I-P) \circ N(u_0+u_1). \tag{28}$$

We will now use (16) to derive a bound for $\|L_{\lambda_0}^{-1}|_{Y_1}\|_{Y_1,Y_1}$ which goes to 0 as $K \to \infty$. We note that

$$\|L_{\lambda_0}^{-1}|_{Y_1}\|_{Y_1,Y_1} \leq \max_{l\geq 1,\ q\not| l} \frac{1}{|\mu_l|}, \tag{29}$$

so we need to find lower bounds for the $|\mu_l|$'s for which q does not divide l. We define

$$\rho = \max_{l\geq 1,\ q\not| l} \cos\Big(\frac{2\pi pl}{q}\Big)$$

and note that since p and q are coprime we have $\rho < 1$.

We define

$$\alpha = 2K\lambda_0^2(1-\rho) - \sqrt{K},$$

and we shall henceforth assume that K is sufficiently large so that $\alpha > 0$. For each $l \geq 1$ we have either $l^2 < \alpha$ or $l^2 \geq \alpha$, and we treat each of these cases separately.

(1) In case $l^2 < \alpha$, we have

$$l^2 + 2K\lambda_0^2(\rho - 1) < -\sqrt{K},$$

and by the definition of ρ,

$$\cos\Big(\frac{2\pi ml}{n}\Big) = \cos\Big(\frac{2\pi pl}{q}\Big) \leq \rho,$$

so that

$$l^2 + 2K\lambda_0^2\Big(\cos\Big(\frac{2\pi ml}{n}\Big) - 1\Big) < -\sqrt{K},$$

which by (16) implies

$$|\mu_l| > \sqrt{K}. \tag{30}$$

(2) In case $l^2 \geq \alpha$, we have, since (16) implies $|\mu_l| > \lambda_0 \Gamma l$,

$$|\mu_l| \geq \lambda_0\Gamma\sqrt{\alpha} \geq \lambda_0\tilde{\Gamma}\sqrt{\alpha} = \lambda_0\tilde{\Gamma}\Big[2K\lambda_0^2(1-\rho) - \sqrt{K}\Big]^{\frac{1}{2}}. \tag{31}$$

From (30), (31) we obtain that $\lim_{K\to\infty} |\mu_l| = +\infty$ uniformly with respect to $l \geq 1$ which are not multiples of q, hence by (29)

$$\lim_{K\to\infty} \|L_{\lambda_0}^{-1}|_{Y_1}\|_{Y_1,Y_1} = 0.$$

In particular, we may choose K_0 such that for $K \geq K_0$ we will have

$$\|L_{\lambda_0}^{-1}|_{Y_1}\|_{Y_1,Y_1} < \frac{\epsilon}{\lambda_0^2}.$$

By (28) and (18) this implies

$$\|u_1\|_Y \leq \epsilon. \tag{32}$$

Thus

$$\begin{aligned}\Big|\frac{1}{2\pi}\int_0^{2\pi}\sin(s+u(s))ds\Big| &\le \Big|\frac{1}{2\pi}\int_0^{2\pi}\sin(s+u_0(s))ds\Big| \\ &\quad + \Big|\frac{1}{2\pi}\int_0^{2\pi}[\sin(s+u(s))-\sin(s+u_0(s))]ds\Big| \\ &\le \Big|\frac{1}{2\pi}\int_0^{2\pi}\sin(s+u_0(s))ds\Big| + \frac{1}{2\pi}\int_0^{2\pi}|u_1(s)|ds. \qquad (33)\end{aligned}$$

From (32) and the Cauchy–Schwarz inequality we have

$$\frac{1}{2\pi}\int_0^{2\pi}|u_1(s)|ds \le \frac{1}{\sqrt{2\pi}}\Big(\int_0^{2\pi}(u_1(s))^2ds\Big)^{\frac{1}{2}} \le \epsilon. \qquad (34)$$

From trigonometry we have

$$\int_0^{2\pi}\sin(s+u_0(s))ds = \int_0^{2\pi}\sin(s)\cos(u_0(s))ds + \int_0^{2\pi}\cos(s)\sin(u_0(s))ds,$$

but the functions $\cos(u_0(s))$ and $\sin(u_0(s))$ are $\frac{2\pi}{q}$-periodic with $q \ge 2$, which implies that they are orthogonal to $\cos(s)$ and $\sin(s)$, so that we have

$$\int_0^{2\pi}\sin(s+u_0(s))ds = 0,$$

which together with (33) and (34) implies (26), concluding the proof of Proposition 9.

We now turn to the proof of Theorem 4. We first note that from (16) we have

$$|\mu_l| \ge \Big|l^2 + 2K\lambda^2\Big(\cos\Big(\frac{2\pi ml}{n}\Big) - 1\Big)\Big|,$$

so that if we assume

$$0 < \lambda < \lambda_0 = \frac{1}{\sqrt{8\tilde{K}}} \le \frac{1}{\sqrt{8K}},$$

then we have $|\mu_l| > \frac{1}{2}$ for all $l \ge 1$, hence $\|L_\lambda^{-1}\|_{Y,Y} < 2$, independently of Γ. From (19) we thus have

$$(\lambda, u) \in \Sigma,\ 0 < \lambda < \lambda_0 \ \Rightarrow\ \|u\|_Y < 2\lambda^2.$$

We now choose $\lambda_1 \le \lambda_0$ so that $2\lambda_1^2 \le \frac{1}{2}\tilde{F}$. Thus $(\lambda_1, u) \in \Sigma$ implies that

$$\begin{aligned}\Big|\frac{1}{2\pi}\int_0^{2\pi}\sin(s+u(s))ds\Big| &= \Big|\frac{1}{2\pi}\int_0^{2\pi}[\sin(s+u(s))-\sin(s)]ds\Big| \\ &\le \frac{1}{2\pi}\int_0^{2\pi}|u(s)|ds \le \|u\|_Y < 2\lambda_1^2 \le \frac{1}{2}\tilde{F}. \qquad (35)\end{aligned}$$

Finally, we choose Γ_0 so that

$$\frac{\Gamma_0}{\lambda_1} < \frac{1}{2}\tilde{F}. \qquad (36)$$

Relations (35) and (36) thus imply that when $0 < \Gamma < \Gamma_0$,

$$(\lambda_1, u) \in \Sigma \ \Rightarrow\ \Phi(\lambda_1, u) < \tilde{F},$$

so that we have $\underline{F} < \tilde{F}$, where $\underline{F}$ is defined by (24), hence Proposition 7 implies the existence of a travelling wave for any $F \ge \tilde{F}$.

3. Discussion and further questions. In the numerical and experimental explorations of the dynamics of sine-Gordon rings [8, 10, 11], a useful method of representation consists in displaying the velocity-force characteristic. In the case of the travelling waves studied here, since the velocity of the waves is given by $v = \frac{1}{\lambda}$, the velocity-force characteristic is the subset of the (F, v)-plane given by

$$\Big\{\Big(\Phi\Big(\frac{1}{v}, u\Big), v\Big) \;\Big|\; \Big(\frac{1}{v}, u\Big) \in \Sigma\Big\},$$

where the set Σ and the functional Φ are as defined in the previous section. Examining the velocity-force characteristic as numerically computed in [8, Figure 2], we see that F is a nonmonotone function of v. This means that for some values of F equation (21) has more than one solution, or in other words that there exist multiple travelling waves with different velocities for the same value of F. On the other hand, the fact that, according to the available numerical evidence F is a function of v, leads us to conjecture that, fixing $\Gamma > 0$ and $K > 0$ for each given velocity $v > 0$, there is a unique travelling wave with velocity v, for an appropriate F. Thus, our conjecture is that uniqueness holds in Theorem 1, or in other words that the fixed-point problem (19) always has a unique solution. Let us note that for $0 < \lambda < \Gamma$ it is easy to show, using (17), that the right-hand side of (19) is a contraction from Y to itself, hence we may replace the use of the Schauder fixed-point theorem by the Banach contraction-mapping principle, which implies uniqueness. Thus, at least for velocities $v > \frac{1}{\Gamma}$, we have uniqueness in Theorem 1. However, for lower velocities this argument does not work so a proof of the above conjecture will require some new idea.

The nonuniqueness of travelling waves for some values of the parameters Γ, K, F, mentioned above, implies important consequences for the dynamics of the discrete sine-Gordon ring, such as instability of some of the travelling waves, and bistability of travelling waves leading to hysteresis as the force F is varied. It would be interesting to determine whether these phenomena can occur in the large K and the small Γ regimes for which existence of a travelling wave has been proved in Theorems 3 and 4. Moreover, stationary solutions and travelling waves do not exhaust the dynamical repertoire of the discrete sine-Gordon equations in the underdamped case: quasi-periodic and chaotic behavior is reported in [8, 9, 11]. An interesting question is to determine conditions on the parameters which ensure that there exists at least one *locally asymptotically stable* travelling wave.

Returning to the issue of existence of travelling waves, which has been the focus of our investigation, we note an intriguing question which arises from our results, and remains unanswered.

Let us define, for fixed $\Gamma > 0$ and $K > 0$

$$F_0(\Gamma, K) = \inf\{F \geq 0 \mid \text{a travelling wave of (1), (2) exists}\}.$$

Theorem 2 implies that $F_0(\Gamma, K) \leq 1$ for all $\Gamma > 0$ and $K > 0$. Theorem 3 implies that, when n does not divide m, $\lim_{K\to\infty} F_0(\Gamma, K) = 0$. Theorem 4 implies that $\lim_{\Gamma\to 0} F_0(\Gamma, K) = 0$. Is it true, though, that for each $\Gamma > 0$ and $K > 0$ we have $F_0(\Gamma, K) > 0$? In other words, is it always true that (fixing $\Gamma > 0$ and $K > 0$) for sufficiently small $F > 0$ a travelling wave does not exist? We have not been able to prove or disprove this conjecture, and can only offer the following remarks.

(i) If Γ and K satisfy (6), then indeed $F_0(\Gamma, K) > 0$, since for sufficiently small F there exists a stationary solution of (1), (2), so the results of [2] imply that no travelling wave exists for small F. However, as we have remarked, Theorem 4 shows that in general travelling waves and stationary solutions may coexist.

(ii) If n divides m, then, as was noted in the introduction, the existence of travelling waves reduces to that of running solutions of the forced pendulum, hence it is well known that $F_0(\Gamma, K) > 0$ for all Γ and K. However, in the case that n divides m we also have noted that the result of Theorem 3 does not hold, so that the case that n divides m is rather special and may not be indicative of the general case.

(iii) The conjecture that $F_0(\Gamma, K) > 0$ is supported by the notion of "pinning"—the phenomenon whereby travelling waves are unable to propagate in discrete systems when the applied force is small. However, whether this effect indeed holds in general in underdamped systems (as opposed to the overdamped case—see (i) above) is unclear to the best of our knowledge. Moreover, it is conceivable that $F_0(\Gamma, K) = 0$ but pinning still occurs—if for small F a travelling wave exists but is unstable.

(iv) Since, by Proposition 8, we have $\Phi(\lambda, u) > 0$ for all $(\lambda, u) \in \Sigma$, $\lambda > 0$, we have that $F_0(\Gamma, K) = 0$ if and only if

$$\liminf_{\lambda \to +\infty,\ (\lambda,u)\in\Sigma} \Phi(\lambda, u) = 0.$$

Thus, determining whether the above equality can hold could be a route to resolving our question, but we have not been able to do so.

We conclude with one more question: clarify the connection, if any, between the travelling waves obtained in [4] for small values of $K > 0$ and those obtained by us for large values of K in Theorem 3.

AN ELLIPTIC PROBLEM RELATED TO PLANAR VORTEX PAIRS*

GONGBAO LI†, SHUSEN YAN‡, AND JIANFU YANG§

Abstract. In this paper, we study the existence and limiting behavior of the mountain pass solutions of the elliptic problem $-\Delta u = \lambda f(u - q(x))$ in $\Omega \subset R^2; u = 0$ on $\partial\Omega$, where q is a positive harmonic function. We show that the "vortex core" $A_\lambda = \{x \in \Omega : u_\lambda(x) > q(x)\}$ of the solution u_λ shrinks to a global minimum point of q on the boundary $\partial\Omega$ as $\lambda \to +\infty$. Furthermore, we show that for each strict local minimum x_0 point of $q(x)$ on the boundary $\partial\Omega$, there exists a solution u_λ whose vortex core shrinks to this strict local minimum point x_0 as $\lambda \to +\infty$.

Key words. vortex ring, free boundary problem

1. Introduction.

In cylindrical coordinates in R^3, a steady vortex ring corresponds mathematically to a Stokes stream function Ψ defined on a domain $\bar{\Omega} \subset R^2$, and an open set $A \subset \Omega$, called the cross-section of a steady vortex ring and unknown a priori, such that $\Psi \in C^1(\bar{\Omega}) \cap C^2(\Omega \backslash A)$ and satisfies the equations

$$-L\Psi = \begin{cases} \lambda r^2 f(\Psi) & \text{in } A, \\ 0 & \text{in } \Omega \backslash \bar{A}, \end{cases} \tag{1.1}$$

$$\Psi|_{\partial A} = 0, \quad \Psi|_{\partial\Omega} = -\frac{1}{2} W r^2 - k, \tag{1.2}$$

where $L = r(\partial/\partial r)(1/r\partial/\partial r) + \partial^2/\partial z^2$. The vorticity function f is supposed to be positive if $t > 0$ and equal to zero if $t \le 0$, while $W > 0$ and k are prescribed constants; λ is a positive parameter which is also regarded as prescribed.

When we study the steady plane flow of an inviscid fluid of uniform density, we are led to the following free-boundary problem:

$$-\Delta\Psi = \begin{cases} \lambda f(\Psi) & \text{in } A, \\ 0 & \text{in } \Omega \backslash \bar{A}, \end{cases} \tag{1.3}$$

$$\Psi|_{\partial A} = 0, \quad \Psi|_{\partial\Omega} = -W x_1 - k, \tag{1.4}$$

where Ω is a bounded domain in $\{(x_1, x_2) : x_1 > 0\} \subset R^2$, both Ψ and $A \subset \Omega$ are unknown, and $\Psi \in C^1(\bar{\Omega}) \cap C^2(\Omega \setminus A)$. See, for example, [11]. Let $A = \{x \in \Omega : \Psi(x) > Wx_1 + k\}$. Since $f(t) = 0$ if $t \leq 0$, problem (1.3)–(1.4) can be rewritten as

$$\begin{cases} -\Delta\Psi = \lambda f(\Psi) & \text{in } \Omega, \\ \Psi = -Wx_1 - k < 0 & \text{on } \partial\Omega. \end{cases} \tag{1.5}$$

In general, we shall consider the free boundary problem

$$-\Delta\Psi = \begin{cases} \lambda f(\Psi) & \text{in } A, \\ 0 & \text{in } \Omega \backslash \bar{A}, \end{cases} \tag{1.6}$$

$$\Psi|_{\partial A} = 0, \quad \Psi|_{\partial\Omega} = -q_0(x) < 0, \tag{1.7}$$

where $q_0(x)$ is a C^1 function defined on $\partial\Omega$. Problem (1.6), (1.7) can be reduced to the following problem:

$$\begin{cases} -\Delta w = \lambda f(w) & \text{in } \Omega \subset R^2, \\ w = -q_0(x) < 0 & \text{on } \partial\Omega. \end{cases} \tag{1.8}$$

Let $q(x)$ be the solution of

$$\begin{cases} -\Delta v = 0 & \text{in } \Omega, \\ v = q_0(x) & \text{on } \partial\Omega. \end{cases} \tag{1.9}$$

Then $q(x) > 0$ and $q(x)$ achieves its maximum and minimum on $\partial\Omega$.

Let $u = w + q(x)$. Then (1.8) becomes

$$\begin{cases} -\Delta u = \lambda f(u - q(x)) & \text{in } \Omega, \\ u = 0 & \text{on } \partial\Omega. \end{cases} \tag{1.10}$$

Our main objective is to obtain the existence result and investigate the asymptotic behavior of the solution pair (u_λ, A_λ) of problem (1.10) as $\lambda \to \infty$, where $A_\lambda = \{x \in \Omega : u_\lambda(x) > q(x)\}$.

The existence problems were considered in [1, 3, 5, 6, 8, 10, 11, 12]. Precisely, the work of [5, 6, 8, 11, 12] is related to constrained variation. Particularly, in Turkington's setting [12], the vorticity function f is unknown a priori, while in Badiani's work [5], the stream function Ψ for the flow satisfies the equation in (1.8) in a region bounded by the line of symmetry, where f is an increasing function that is unknown a priori either. Moreover, in [6, 8, 11], the parameter λ is a Lagrange multiplier and hence is not known a priori. From the existence point of view, the solutions obtained in [5, 6, 8, 11, 12] are related to the eigenvalue problem, so the corresponding eigenvalue λ is not arbitrary. In the works of [1, 3, 4, 10, 13, 14], the mountain pass lemma was used to get the existence results for a large class of nonlinearities $f(x, u)$ and any $\lambda > 0$. These results are related to "free variation" which provides more information for the existence.

The asymptotic behavior of the solution pair (u_λ, A_λ) of problem (1.10) as $\lambda \to \infty$ was initiated by the work of [6], where the desingularization problem was studied for a confined steady vortex ring. (The reader should refer to Appendix A in [6] for a

detailed explanation of the physical background of the problem.) The asymptotic behavior of solution pair (u_λ, A_λ) of problem (1.10) was studied by [4, 6, 13, 14] for vortex rings and vortex pairs. Particularly, it is proved that the cross-section A_λ of a steady vortex ring shrinks to a point, and a vortex ring degenerates into a singular vortex circle as $\lambda \to +\infty$. Moreover, the Stokes stream function Ψ_λ of a vortex ring converges to the Stokes stream function of the filament, which is the Green's function of the operator $-\Delta$ in Ω. In [6], the asymptotic behavior of the solutions obtained by the constrained variational method was discussed. There, the parameter λ is unknown a priori. As pointed out in [3], the existence result for given λ and $f(t)$, and the asymptotic behavior of the core as $\lambda \to +\infty$ are desirable in application. In [4], Ambrosetti and Yang freed the parameter λ. Using the mountain pass lemma, they discussed the existence of solutions and then studied the limiting behavior of the solution pair. The study of the limiting behavior of the solution pair relies on upper estimates of critical level and connectedness of the A_λ. These facts allow one to show that, under certain conditions as proposed in [4, 6], the solution u_λ satisfies

$$\frac{u_\lambda(\cdot)}{\lambda \int_\Omega f(u_\lambda - q(x))\,dx} - G(\cdot, x_\lambda) \to 0 \ \text{ in } \ W^{1,p}(\Omega) \tag{1.11}$$

as $\lambda \to \infty$, where $x_\lambda \in A_\lambda, 1 \le p < 2$, G is the Green's function of Ω.

It would be interesting to describe precisely the location of the core of A_λ as $\lambda \to \infty$. Our first result deals with the problem.

Suppose that $f(t) \in C^1(R^1)$ and satisfies the following conditions:

(f_1) If $t \le 0$, $f(t) = 0$.

(f_2) There is $\theta > 1$, such that $f'(t)t \ge \theta f(t) > 0 \ \forall\ t > 0$.

(f_3) There are $p_1 > 2$ and $C > 0$, such that $\forall t \ge 0$, $f(t) \le C(1 + t^{p_1 - 1})$.

(f_4) There are $p > 2$, $t_0 > 0$ and $a_0 > 0$, such that $f(t) \ge a_0 t^{p-1} \ \forall\ t \in [0, t_0]$.

We mention that (f_2) implies $tf(t) \ge (\theta + 1)F(t) > 0$ if $t > 0$, where $F(t) = \int_0^t f(s)\,ds$.

Define

$$I_\lambda(u) = \frac{1}{2}\int_\Omega |Du|^2\,dx - \lambda \int_\Omega F(u - q(x))\,dx, \quad u \in H_0^1(\Omega).$$

Using the mountain pass theorem, we know that I_λ has a critical point u_λ satisfying

$$I_\lambda(u_\lambda) = c_\lambda, \quad I'_\lambda(u_\lambda) = 0$$

with

$$c_\lambda = \inf_{w \in H_0^1(\Omega)} \max_{t \ge 0} I_\lambda(tw).$$

Our first result is as follows.

THEOREM 1.1. *Assume that $q_0(x)$ is not a constant. Then we have the following.*

(i) *A_λ is connected and $\mathrm{diam} A_\lambda \to 0$ as $\lambda \to +\infty$.*

(ii) *For any $x_\lambda \in A_\lambda$, suppose $x_\lambda \to x_0$. Then $q(x_0) = q_m := \min_{x \in \partial\Omega} q(x)$.*

(iii) *As $\lambda \to +\infty$,*

$$c_\lambda = \frac{2\pi q_m^2}{\ln \lambda}(1 + o(1)),$$

where $o(1) \to 0$ as $\lambda \to 0$.

(iv) *As* $\lambda \to +\infty$, *we have*

$$\frac{u_\lambda(\cdot)}{\lambda \int_\Omega f(u_\lambda - q(x))\,dx} - G(\cdot, x_\lambda) \to 0 \ \text{ in } \ W^{1,p}(\Omega), \tag{1.12}$$

where $x_\lambda \in A_\lambda, 1 \le p < 2$, G *is the Green's function of* Ω, *and*

$$\frac{u_\lambda}{\lambda \int_\Omega f(u_\lambda - q(x))\,dx} - G(\cdot, x_\lambda) \to 0 \ \text{ in } \ C^{1,\alpha}_{loc}(\Omega \setminus \{x_0\}), \tag{1.13}$$

where α *is any constant in* $(0,1)$.

From Theorem 1.1 we know that there is a solution of (1.10) whose cross-section A_λ shrinks to a global minimum point of q_0 on the boundary $\partial\Omega$. If q_0 has, for instance, k different local minimum points on $\partial\Omega$, does (1.10) possess at least k solution? It seems that there is not previous work in this direction. Our next result concerns the effect of the function $q_0(x)$ on the number of the solution pairs. It shows that each strictly local minimum point x_0 of q_0 on the boundary $\partial\Omega$ corresponds to a solution u_λ of (1.10) with A_λ shrinking to x_0 as $\lambda \to \infty$.

THEOREM 1.2. *Let* x_0 *be a strictly local minimum point of* $q(x)$ *on the boundary* $\partial\Omega$. *Then there exists a solution* u_λ *of* (1.10) *such that*

(i) A_λ *is connected and* $diam A_\lambda \to 0$ *as* $\lambda \to +\infty$;

(ii) *for any* $x_\lambda \in A_\lambda$, *we have* $x_\lambda \to x_0$ *as* $\lambda \to +\infty$.

For the case $q_0(x) = C$, let us point out that by using the estimates in sections 2 and 3, together with the technique in [6], it might prove that if $q_0(x) = C$, the core would shrink to a point x_0, which is a critical point of the Robin function $H(x,x)$, where $H(y,x)$ is the regular part of the Green's function of $-\Delta$ with Dirichlet boundary condition. In particular, if q_0 is a positive constant, the core lies in the interior of the domain. It is known that the Robin function $H(x,x)$ is related to the domain geometry and the domain topology. In the case $q_0 \neq C$, our results show that the vortex core shrinks to a point on the boundary no matter how close q_0 is to a constant. Then the effect from the boundary data is so strong that the effect from the domain is negligible. In other words, if $q_0(x) \neq C$, the location of the limit of the core as $\lambda \to \infty$ is not related to the Robin function $H(x,x)$.

This paper is arranged as follows. We first obtain an upper bound for c_λ in section 2. Then the connectedness of A_λ is shown in section 3. Theorems 1.1 and 1.2 are proven in sections 4 and 5, respectively.

2. Upper bound. We will analyze the limit behavior of u_λ as $\lambda \to +\infty$. First we will obtain an upper bound for c_λ. To this end, let $\bar{q} > 0$ be a constant. We consider a related problem in a ball B_δ:

$$\begin{cases} -\Delta u = \lambda f(u - \bar{q}) & \text{in } B_\delta, \\ u = 0 & \text{on } \partial B_\delta, \end{cases} \tag{2.1}$$

where $\delta > 0$ is a fixed constant.

Since $f(0) = 0$ and f is a C^1 function, it is superlinear at zero; i.e., $\lim_{t\to 0} \frac{f(t)}{t} = 0$. By (f_1)–(f_3), we may verify that for each $\lambda > 0$, (2.1) has a mountain pass solution with critical value defined as

$$c_{\lambda,\bar{q}} = \inf_{v \in H_0^1(B_\delta), v \not\equiv 0} \max_{t \ge 0} \Big(\frac{1}{2} t^2 \int_{B_\delta} |Dv|^2\,dx - \lambda \int_{B_\delta} F(tv - \bar{q})\,dx \Big)$$

by the mountain pass lemma [2].

To estimate $c_{\lambda,\bar{q}}$, we consider the following problem:

$$\begin{cases} -\Delta u = \lambda (u-\bar{q})_+^{p-1} & \text{in } B_\delta, \\ u = 0 & \text{on } \partial B_\delta, \end{cases} \tag{2.2}$$

where $p > 2$ is a fixed constant.

The existence of a solution for (2.2) can be proven in the following way.

First, we know from [2] that the problem

$$-\Delta \phi = \phi_+^{p-1} \quad \text{in } B_1,\ \phi \in H_0^1(B_1), \tag{2.3}$$

has a unique positive solution $\phi \in C^2(B_1(0))$, and by [9], ϕ is radially symmetric, i.e., $\phi(x) = \phi(r)$ with $r = |x|$.

Second, let ϕ be the solution of (2.3), and for any fixed $\delta > s > 0$, we know that

$$w = \lambda^{-\frac{1}{p-2}} s^{-\frac{2}{p-2}} \phi\left(\frac{r}{s}\right)$$

is the solution of

$$-\Delta w = \lambda w_+^{p-1} \quad \text{in } B_s,\ w \in H_0^1(B_s).$$

It is known that $\bar{q}\ln\frac{r}{\delta}/\ln\frac{s}{\delta}$ is the solution of

$$\begin{cases} -\Delta u = 0 & \text{for } s \le r \le \delta, \\ u = 0 & \text{on } r = \delta, \\ u = \bar{q} & \text{on } r = s. \end{cases} \tag{2.4}$$

Define

$$v_\lambda = \begin{cases} \bar{q} + \lambda^{-\frac{1}{p-2}} s^{-\frac{2}{p-2}} \phi(\frac{r}{s}) & \text{if } 0 \le r \le s, \\ \bar{q}\ln\frac{r}{\delta}/\ln\frac{s}{\delta} & \text{if } s \le r \le \delta. \end{cases}$$

Choose $s \in (0,\delta)$ such that $v_\lambda \in C^1(B_\delta(0))$; that is, s satisfies

$$\lambda^{-\frac{1}{p-2}} s^{-\frac{2}{p-2}} \frac{1}{s}\phi'(1) = \bar{q}\frac{1}{s}/\ln\frac{s}{\delta}.$$

Then we have

$$\frac{s/\delta}{(\ln\frac{\delta}{s})^{\frac{p-2}{2}}} = \lambda^{-\frac{1}{2}}\delta^{-1}\left(\frac{-\phi'(1)}{\bar{q}}\right)^{\frac{p-2}{2}}, \tag{2.5}$$

and v_λ is a solution of (2.2). We know from Lemma C.2 of [6] that for $\lambda > 0$ large, (2.5) has a unique solution s, which satisfies

$$s \sim \lambda^{-\frac{1}{2}} \ln^{\frac{p-2}{2}} \lambda. \tag{2.6}$$

We have the following estimate for the energy of v_λ.

Lemma 2.1.

$$\frac{1}{2}\int_{B_\delta(0)} |Dv_\lambda|^2\,dx - \frac{\lambda}{p}\int_{B_\delta(0)} (v_\lambda - \bar{q})_+^p\,dx = \frac{2\pi\bar{q}^2}{\ln\lambda}\left(1 + O\left(\frac{\ln(\ln\lambda)}{\ln\lambda}\right)\right) \tag{2.7}$$

as $\lambda \to \infty$.

Proof. A direct calculation by using (2.6) yields

$$\begin{aligned}\int_{B_\delta(0)} |Dv_\lambda|^2\,dx &= \int_{B_s(0)} |Dv_\lambda|^2\,dx + \int_{B_\delta(0)\setminus B_s(0)} |Dv_\lambda|^2\,dx\\ &= 2\pi\lambda^{-\frac{2}{p-2}} s^{-\frac{4}{p-2}} \frac{1}{s^2}\int_0^s r\left|\phi'\left(\frac{r}{s}\right)\right|^2 dr + 2\pi\bar q^2 \int_s^\delta \frac{1}{r}\Big/\left(\ln\frac{s}{\delta}\right)^2 dr\\ &= 2\pi\bar q^2\Big/\left(\ln\frac{\delta}{s}\right) + 2\pi\lambda^{-\frac{2}{p-2}} s^{-\frac{4}{p-2}} \int_0^1 r|\phi'(r)|^2\,dr \qquad (2.8)\\ &= 2\pi\bar q^2/(\ln(\lambda^{\frac{1}{2}}\ln^{-\frac{p-2}{2}}\lambda) + O(1)) + O\left(\frac{1}{\ln^2\lambda}\right)\\ &= \frac{4\pi\bar q^2}{\ln\lambda}\left(1 + O\left(\frac{\ln\ln\lambda}{\ln\lambda}\right)\right)\end{aligned}$$

and

$$\begin{aligned}\int_{B_\delta(0)} (v_\lambda - \bar q)_+^p\,dx &= \int_{B_s(0)} (v_\lambda - \bar q)^p\,dx = 2\pi\lambda^{-\frac{p}{p-2}} s^{-\frac{2p}{p-2}} \int_0^s r\phi^p\left(\frac{r}{s}\right) dr \qquad (2.9)\\ &= O(\lambda^{-\frac{p}{p-2}} s^{-\frac{2p}{p-2}} s^2) = O\left(\frac{1}{\lambda\ln^2\lambda}\right)\end{aligned}$$

as $\lambda \to \infty$. ∎

We are now ready to estimate $c_{\lambda,\bar q}$.

PROPOSITION 2.2.

$$\frac{2\pi\bar q^2}{\ln\lambda}\left(1 - O\left(\frac{1}{\ln\lambda}\right)\right) \le c_{\lambda,\bar q} \le \frac{2\pi\bar q^2}{\ln\lambda}\left(1 + O\left(\frac{\ln\ln\lambda}{\ln\lambda}\right)\right) \qquad (2.10)$$

as $\lambda \to +\infty$.

Proof. By (f_4), we know that there is a constant $b > 0$, such that

$$f(t) \ge bt^{p-1} \quad \forall\, t \in [0,1).$$

Let $v_{b\lambda}$ be the solution of (2.2), with λ replaced by $b\lambda$. Then we know that $|v_{b\lambda}| \le \bar q + 1$ if $\lambda > 0$ is large enough. See the formula for v_λ.

Consider

$$g(t) =: t^2 \int_{B_\delta(0)} |Dv_{b\lambda}|^2\,dx - \lambda \int_{B_\delta(0)} f(tv_{b\lambda} - \bar q)v_{b\lambda}\,dx.$$

Since f is superlinear at zero, we see that for $t > 0$ small, $g(t) > 0$. On the other hand, since $v_{b\lambda}$ is a solution of (2.2) and $|v_{b\lambda}| \le \bar q + 1$, we obtain

$$\begin{aligned}g(1) &= \int_{B_\delta(0)} |Dv_{b\lambda}|^2 - \lambda \int_{B_\delta(0)} f(v_{b\lambda} - \bar q)v_{b\lambda}\\ &\le \int_{B_\delta(0)} |Dv_{b\lambda}|^2 - \lambda b \int_{B_\delta(0)} (v_{b\lambda} - \bar q)_+^{p-1} v_{b\lambda} = 0.\end{aligned}$$

As a result, we know that there is a $\bar t \in (0,1]$, such that $g(\bar t) = 0$. Thus, by Lemma 2.1 and the fact that $\bar q > 0, v_{b\lambda} > 0$ and

$$\begin{aligned}&\max_{t\ge 0}\Big(\frac{1}{2}t^2 \int_{B_\delta(0)} |Dv_{b\lambda}|^2\,dx - \frac{1}{p}\int_{B_\delta(0)} \lambda b(tv_{b\lambda} - \bar q)_+^p\,dx\Big)\\ &= \frac{1}{2}\int_{B_\delta(0)} |Dv_{b\lambda}|^2\,dx - \frac{1}{p}\int_{B_\delta(0)} \lambda b(v_{b\lambda} - \bar q)_+^p\,dx,\end{aligned}$$

we obtain

$$\begin{aligned}
c_{\lambda,\bar q} \le & \max_{t\ge 0} I(tv_{b\lambda}) = I(\bar t v_{b\lambda}) = \frac{1}{2}\bar t^2 \int_{B_\delta(0)} |Dv_{b\lambda}|^2\,dx - \lambda \int_{B_\delta(0)} F(\bar t v_{b\lambda} - \bar q)\,dx \\
\le & \frac{1}{2}\bar t^2 \int_{B_\delta(0)} |Dv_{b\lambda}|^2\,dx - \frac{1}{p}\lambda \int_{B_\delta(0)} b(\bar t v_{b\lambda} - \bar q)_+^p\,dx \\
\le & \max_{t\ge 0}\Big(\frac{1}{2}t^2 \int_{B_\delta(0)} |Dv_{b\lambda}|^2\,dx - \frac{1}{p}\int_{B_\delta(0)} \lambda b(tv_{b\lambda} - \bar q)_+^p\,dx\Big) \\
= & \frac{2\pi\bar q^2}{\ln(b\lambda)}\left(1 + O\left(\frac{\ln\ln(b\lambda)}{\ln(b\lambda)}\right)\right) = \frac{2\pi\bar q^2}{\ln\lambda}\left(1 + O\left(\frac{\ln\ln\lambda}{\ln\lambda}\right)\right).
\end{aligned}$$

The upper bound thus follows.

It remains to prove the lower bound.

Let w_λ be the mountain pass solution of (2.1) with critical value $c_{\lambda,\bar q}$. By [9], we know that w_λ is radially symmetric and $w_\lambda'(r) < 0$. Since $c_{\lambda,\bar q} > 0$, we see that the set $\{x \in B_\delta : w_\lambda(x) > \bar q\}$ is not empty. In fact, otherwise, we would have $w_\lambda \equiv 0$ by (2.1) and the maximum principle. So there is unique $\bar s_\lambda \in (0,\delta)$, such that $w_\lambda(\bar s_\lambda) = \bar q$. Thus $-\Delta w_\lambda = 0$ if $x \in B_\delta(0) \setminus B_{\bar s_\lambda}(0)$, $-\Delta w_\lambda = \lambda f(w_\lambda - \bar q)$ if $x \in B_{\bar s_\lambda}(0)$. We may solve the boundary value problem $-\Delta w_\lambda = 0,\ x \in B_\delta(0) \setminus B_{\bar s_\lambda}(0)$ with $w_\lambda = 0$ if $|x| = \delta$ and $w_\lambda = \bar q$ if $|x| = \bar s_\lambda$ as (2.4). Therefore, letting $\tilde w_\lambda(r) = w_\lambda(r/\bar s_\lambda)$, we obtain

(2.11)

$$\begin{aligned}
c_{\lambda,\bar q} = & I(w_\lambda) = \frac{1}{2}\int_{B_\delta(0)\setminus B_{\bar s_\lambda}(0)} |Dw_\lambda|^2\,dx + \frac{1}{2}\int_{B_{\bar s_\lambda}(0)} |Dw_\lambda|^2\,dx - \lambda\int_{B_{\bar s_\lambda}(0)} F(w_\lambda - \bar q)\,dx \\
= & \frac{1}{2}\int_{B_\delta(0)\setminus B_{\bar s_\lambda}(0)} |Dw_\lambda|^2\,dx \\
& + \max_{t\ge 0}\Big(\frac{1}{2}t^2\int_{B_{\bar s_\lambda}(0)} |D(w_\lambda - \bar q)|^2\,dx - \lambda\int_{B_{\bar s_\lambda}(0)} F(t(w_\lambda - \bar q))\,dx\Big) \\
= & \frac{1}{2}\int_{B_\delta(0)\setminus B_{\bar s_\lambda}(0)} |Dw_\lambda|^2\,dx \\
& + \max_{t\ge 0}\Big(\frac{1}{2}t^2\int_{B_1(0)} |D(\tilde w_\lambda - \bar q)|^2\,dx - \lambda\bar s_\lambda^2\int_{B_1(0)} F(t(\tilde w_\lambda - \bar q))\,dx\Big) \\
= & \pi\bar q^2 \Big/ \left(\ln\frac{\delta}{\bar s_\lambda}\right) + \max_{t\ge 0}\Big(\frac{1}{2}t^2\int_{B_1(0)} |D(\tilde w_\lambda - \bar q)|^2\,dx - \lambda\bar s_\lambda^2\int_{B_1(0)} F(t(\tilde w_\lambda - \bar q))\,dx\Big) \\
\ge & \pi\bar q^2 \Big/ \left(\ln\frac{\delta}{\bar s_\lambda}\right) + \inf_{v\in H_0^1(B_1(0)),v\not\equiv 0}\max_{t\ge 0}\Big(\frac{1}{2}t^2\int_{B_1(0)} |Dv|^2\,dx - \lambda\bar s_\lambda^2\int_{B_1(0)} F(tv)\,dx\Big).
\end{aligned}$$

We claim that

$$\lambda\bar s_\lambda^2 > 1.$$

In fact, suppose that there are $\lambda_j \to +\infty$, such that

$$\lambda_j \bar s_{\lambda_j}^2 \le 1.$$

Then

$$\inf_{v\in H_0^1(B_1(0)),v\not\equiv 0}\max_{t\geq 0}\left(\frac{1}{2}t^2\int_{B_1(0)}|Dv|^2\,dx-\lambda_j\bar{s}_{\lambda_j}^2\int_{B_1(0)}F(tv)\,dx\right)$$
$$\geq \inf_{v\in H_0^1(B_1(0)),v\not\equiv 0}\max_{t\geq 0}\left(\frac{1}{2}t^2\int_{B_1(0)}|Dv|^2-\int_{B_1(0)}F(tv)\right)=:\bar{c}>0.$$

Thus, (2.11) yields $c_{\lambda_j,\bar{q}}\geq\bar{c}$. This is a contradiction because of $c_{\lambda_j,\bar{q}}\leq C/\ln\lambda_j$.

From $\lambda\bar{s}_\lambda^2>1$, we see $\frac{1}{\bar{s}_\lambda}<\lambda^{\frac{1}{2}}$. Using (2.11), we obtain

$$c_{\lambda,\bar{q}}\geq\pi\bar{q}^2/\left(\ln\frac{\delta}{\bar{s}_\lambda}\right)\geq\pi\bar{q}^2/(\ln(\delta\lambda^{\frac{1}{2}}))=\frac{2\pi\bar{q}^2}{\ln\lambda}\left(1-O\left(\frac{1}{\ln\lambda}\right)\right).\qquad\square$$

Let $x_0\in\partial\Omega$ be a point such that $q(x_0)=q_m=\min_{x\in\bar{\Omega}}q(x)$. We turn to the estimate of c_λ.

PROPOSITION 2.3. *For any small $\tau>0$, we have*

$$c_\lambda\leq\frac{2\pi(q_m+\tau)^2}{\ln\lambda}\left(1+O\left(\frac{\ln\ln\lambda}{\ln\lambda}\right)\right)\tag{2.12}$$

as $\lambda\to+\infty$.

Proof. For any $\tau>0$, take $\bar{x}_0\in\Omega$ close to x_0 and $\delta>0$ small so that

$$q(x)\leq q_m+\tau\quad\forall x\in B_\delta(\bar{x}_0).$$

Let $\bar{u}_\lambda\in H_0^1(B_\delta(\bar{x}_0))$ be the mountain pass solution of

$$-\Delta\bar{u}=\lambda(\bar{u}-(q_m+\tau))_+^{p-1}\quad\text{in } B_\delta(\bar{x}_0).$$

Then we deduce by Proposition 2.2 that

$$\begin{aligned}c_\lambda&\leq\max_{t\geq 0}I_\lambda(t\bar{u}_\lambda)\\&=\max_{t\geq 0}\left(\frac{1}{2}\int_{B_\delta(\bar{x}_0)}|Dt\bar{u}_\lambda|^2\,dx-\lambda\int_{B_\delta(\bar{x}_0)}F(t\bar{u}_\lambda-q(x))\,dx\right)\\&\leq\max_{t\geq 0}\left(\frac{1}{2}\int_{B_\delta(\bar{x}_0)}|Dt\bar{u}_\lambda|^2\,dx-\lambda\int_{B_\delta(\bar{x}_0)}F(t\bar{u}_\lambda-(q_m+\tau))\,dx\right)\\&=\frac{2\pi(q_m+\tau)^2}{\ln\lambda}\left(1+O\left(\frac{\ln\ln\lambda}{\ln\lambda}\right)\right)\end{aligned}\tag{2.13}$$

$\forall\tau>0.\qquad\square$

3. Connectedness of A_λ. Let u_λ be the mountain pass solution of (1.10) obtained in section 1 and $A_\lambda=\{x:u_\lambda(x)>q(x)\}$.

PROPOSITION 3.1. *A_λ is connected.*

Proof. We argue by contradiction. Suppose that A_λ has two components, A_1 and A_2. Let $\psi_i=u_\lambda-q(x)$ in A_i, $\psi_i=0$ for $x\in\Omega\setminus A_i, i=1,2$.

Let η_0 be a constant, which will be chosen later. Let $\widetilde{w}_\lambda=u_\lambda+s\psi_1-s\eta_0\psi_2$. It is easy to see that $\widetilde{w}_\lambda\in H_0^1(\Omega)$. Now we calculate $\max_{t\geq 0}I_\lambda(t\widetilde{w}_\lambda)$. We know that t_0 is a maximum point of $I_\lambda(t\widetilde{w}_\lambda)$ if and only if

$$t_0\int_\Omega|D\widetilde{w}_\lambda|^2\,dx=\lambda\int_\Omega f(t_0\widetilde{w}_\lambda-q(x))\widetilde{w}_\lambda\,dx.\tag{3.1}$$

In fact, if t_0 is a maximum point of $I_\lambda(t\tilde{w}_\lambda)$, it is clear that t_0 satisfies (3.1). On the other hand, from (f_2) we know that $\frac{d}{dt}\frac{f(t-q(x))}{t} > 0$ if $t > 0$; therefore

$$\begin{aligned}\frac{d}{dt}I(t\tilde{w}_\lambda) &= \frac{t\lambda}{t_0}\int_\Omega \tilde{w}_\lambda f(t_0\tilde{w}_\lambda - q(x))\,dx - \lambda\int_\Omega \tilde{w}_\lambda f(t\tilde{w}_\lambda - q(x))\,dx\\ &= t\lambda\int_\Omega\Big[\frac{f(t_0\tilde{w}_\lambda - q(x))}{t_0\tilde{w}_\lambda} - \frac{f(t\tilde{w}_\lambda - q(x))}{t\tilde{w}_\lambda}\Big]\tilde{w}_\lambda^2\,dx,\end{aligned}$$

which is positive if $t < t_0$ and negative if $t > t_0$. Thus, we have (3.1). Let

$$K(s,t) = t\int_\Omega |D\widetilde{w}_\lambda|^2\,dx - \lambda\int_\Omega f(t\widetilde{w}_\lambda - q(x))\widetilde{w}_\lambda\,dx.$$

Then, because u_λ is a solution, we obtain $K(0,1) = 0$ and

$$\begin{aligned}\frac{\partial K(0,t)}{\partial t}|_{t=1} = \frac{\partial K(0,1)}{\partial t} &= \int_\Omega |Du_\lambda|^2\,dx - \lambda\int_\Omega f'(u_\lambda - q(x))u_\lambda^2\,dx\\ &= \lambda\int_\Omega f(u_\lambda - q(x))u_\lambda\,dx - \lambda\int_\Omega f'(u_\lambda - q(x))u_\lambda^2\,dx < 0.\end{aligned} \tag{3.2}$$

Thus, by the implicit function theorem we know that for s small, there exists $t(s)$ which is differentiable such that $t(s) \to 1$ as $s \to 0$ and $K(s,t(s)) = 0$. On the other hand,

$$K_s(0,1) + K_t(0,1)t'(0) = 0.$$

Thus,

$$t'(0) = -\frac{K_s(0,1)}{K_t(0,1)}.$$

But by (f_2) we see that

(3.3)

$$\begin{aligned}K_s(0,1) &= 2\int_\Omega Du_\lambda D(\psi_1 - \eta_0\psi_2)\,dx - \lambda\int_\Omega f(u_\lambda - q(x))(\psi_1 - \eta_0\psi_2)\,dx\\ &\quad - \lambda\int_\Omega f'(u_\lambda - q(x))u_\lambda(\psi_1 - \eta_0\psi_2)\,dx\\ &= \lambda\int_\Omega f(u_\lambda - q(x))(\psi_1 - \eta_0\psi_2)\,dx - \lambda\int_\Omega f'(u_\lambda - q(x))u_\lambda(\psi_1 - \eta_0\psi_2)\,dx\\ &= \lambda\Big[\Big(\int_\Omega f(u_\lambda - q(x))\psi_1\,dx - \int_\Omega f'(u_\lambda - q(x))u_\lambda\psi_1\,dx\Big)\\ &\qquad - \eta_0\Big(\int_\Omega f(u_\lambda - q(x))\psi_2\,dx - \int_\Omega f'(u_\lambda - q(x))u_\lambda\psi_2\,dx\Big)\Big] = 0\end{aligned}$$

if

$$\eta_0 = \frac{\int_\Omega f(u_\lambda - q(x))\psi_1\,dx - \int_\Omega f'(u_\lambda - q(x))u_\lambda\psi_1\,dx}{\int_\Omega f(u_\lambda - q(x))\psi_2\,dx - \int_\Omega f'(u_\lambda - q(x))u_\lambda\psi_2\,dx} > 0.$$

With such $\eta_0 > 0$, we have $t'(0) = 0$. As a result,

$$t - 1 = t'(0)s + O(s^2) = O(s^2). \tag{3.4}$$

Now fix $s > 0$ small. Let $t(s)$ be the maximum point of $I_\lambda(t\widetilde{w}_\lambda)$. Then $K(s, t(s)) = 0$. Since $\mathrm{spt}\psi_1 \cap \mathrm{spt}\psi_2 = \emptyset$,

$$\begin{aligned}\int_\Omega |D\widetilde{w}_\lambda|^2\,dx &= \int_\Omega |Du_\lambda|^2\,dx + s^2\int_\Omega |D\psi_1|^2\,dx + \eta_0^2 s^2\int_\Omega |D\psi_2|^2\,dx\\ &\quad + 2s\int_\Omega Du_\lambda D\psi_1\,dx - 2\eta_0 s\int_\Omega Du_\lambda D\psi_2\,dx\\ &= \int_\Omega |Du_\lambda|^2\,dx + s^2\int_\Omega |D\psi_1|^2\,dx + \eta_0^2 s^2\int_\Omega |D\psi_2|^2\,dx\\ &\quad + 2s\lambda\int_\Omega f(u_\lambda - q(x))\psi_1\,dx - 2\eta_0 s\lambda\int_\Omega f(u_\lambda - q(x))\psi_2\,dx.\end{aligned} \tag{3.5}$$

Noting that $t(s) = 1 + O(s^2)$, we have

$$\begin{aligned}&\int_\Omega F(t(s)\widetilde{w}_\lambda - q(x))\,dx\\ &= \int_\Omega F(t(s)u_\lambda - q(x))\,dx + \int_\Omega f(t(s)u_\lambda - q(x))(s\psi_1 - \eta_0 s\psi_2)\,dx\\ &\quad + \frac{1}{2}\int_\Omega f'(t(s)u_\lambda - q(x))(s\psi_1 - \eta_0 s\psi_2)^2\,dx + O(s^{2+\sigma})\\ &= \int_\Omega F(t(s)u_\lambda - q(x))\,dx + \int_\Omega f(u_\lambda - q(x))(s\psi_1 - \eta_0 s\psi_2)\,dx\\ &\quad + \frac{1}{2}\int_\Omega f'(u_\lambda - q(x))(s^2\psi_1^2 + \eta_0^2 s^2\psi_2^2)\,dx + O(s^{2+\sigma}),\end{aligned} \tag{3.6}$$

where $\sigma > 0$. As a result,

$$\begin{aligned}&\max_{t\ge 0} I_\lambda(t\widetilde{w}_\lambda) = I_\lambda(t(s)\widetilde{w}_\lambda)\\ &\quad = \frac{1}{2}t^2(s)\int_\Omega |Du_\lambda|^2\,dx - \lambda\int_\Omega F(t(s)u_\lambda - q(x))\,dx\\ &\quad + \frac{1}{2}s^2\Big[\int_\Omega |D\psi_1|^2\,dx - \lambda\int_\Omega f'(u_\lambda - q(x))\psi_1^2\,dx\\ &\qquad + \eta_0^2\Big(\int_\Omega |D\psi_2|^2\,dx - \lambda\int_\Omega f'(u_\lambda - q(x))\psi_2^2\,dx\Big)\Big] + O(s^{2+\sigma}).\end{aligned} \tag{3.7}$$

Since

$$\begin{aligned}&\frac{1}{2}t^2(s)\int_\Omega |Du_\lambda|^2\,dx - \lambda\int_\Omega F(t(s)u_\lambda - q(x))\,dx\\ &\le \max_{t\ge 0} I_\lambda(tu_\lambda) = I_\lambda(u_\lambda) = c_\lambda\end{aligned}$$

and

$$\int_\Omega |D\psi_i|^2\,dx - \lambda\int_\Omega f'(u_\lambda - q(x))\psi_i^2\,dx = \lambda\int_\Omega (f(\psi_i) - f'(\psi_i)\psi_i)\psi_i\,dx < 0,$$

we obtain for s small enough that

$$\max_{t\ge 0} I_\lambda(t\widetilde{w}_\lambda) < c_\lambda = \inf_{u\in H_0^1(\Omega)}\max_{t\ge 0} I_\lambda(tu).$$

This is a contradiction. □

PROPOSITION 3.2. *diam$A_\lambda \to 0$ as $\lambda \to +\infty$.*

Proof. It is known from (2.12) that

$$I_\lambda(u_\lambda) \le \frac{C}{\ln\lambda}.$$

Since u_λ is a solution of (1.10), we deduce by (f_2) that

$$\begin{aligned} I_\lambda(u_\lambda) &= \frac{1}{2}\lambda \int_\Omega f(u_\lambda - q(x))u_\lambda \, dx - \lambda \int_\Omega F(u_\lambda - q(x)) \, dx \\ &= \lambda \int_\Omega \left(\frac{1}{2} f(u_\lambda - q(x))(u_\lambda - q(x)) - F(u_\lambda - q(x)) \right) dx \\ &+ \frac{\lambda}{2} \int_\Omega q(x) f(u_\lambda - q(x)) \, dx \\ &\ge \lambda \int_\Omega \left(\frac{1}{2} - \frac{1}{\theta + 1} \right) f(u_\lambda - q(x))(u_\lambda - q(x)) \, dx \\ &+ \frac{\lambda}{2} q_m \int_\Omega f(u_\lambda - q(x)) \, dx. \end{aligned}$$

As a result,

$$\lambda \int_\Omega f(u_\lambda - q(x)) \, dx \le \frac{C}{\ln\lambda},$$

$$\lambda \int_\Omega f(u_\lambda - q(x))(u_\lambda - q(x)) \, dx \le \frac{C}{\ln\lambda},$$

$$\|u_\lambda\|^2 = \int_\Omega |Du_\lambda|^2 \, dx = \lambda \int_\Omega f(u_\lambda - q(x))u_\lambda \, dx \le \frac{C}{\ln\lambda}.$$

Since A_λ is connected, thus we may prove $\big($as Theorem 5 of [4]; see also [7]$\big)$ that

$$\text{diam}A_\lambda \to 0 \ \text{ as } \ \lambda \to 0. \tag{3.8}$$

For the reader's convenience, we sketch the proof as follows.

Let $P, Q \in \bar{A}_\lambda$ be such that $|P - Q| = \text{diam}A_\lambda$, and consider a family of straight lines l_X passing through the point $X \in [P, Q]$. Denote by $L_X = [Y_X, Z_X]$ a segment in l_X such that $Y_X \in \partial\Omega, Z_X \in \partial A_\lambda$ and $\text{int}L_X \subset \Omega \backslash \bar{A}_\lambda$. Then one has

$$u_\lambda(Y_X) - u_\lambda(Z_X) = \int_{L_X} \frac{\partial u_\lambda}{\partial L_X} \, dL_X.$$

Note that $u_\lambda(Y_X) = 0$ while $u_\lambda(Z_X) = q(Z_X) \ge q_m > 0$; hence we obtain

$$q_m \le \left| \int_{L_X} \frac{\partial u_\lambda}{\partial L_X} \, dL_X \right| \le C \int_{L_X} |\nabla u_\lambda| \, dL_X.$$

Integrating with respect to X in $[P, Q]$ and using the Hölder inequality, we get

$$q_m |P - Q| \le c \int_{\overline{PQ}} dX \int_{L_X} |\nabla u_\lambda| \, dL_X \le C|P - Q|^{\frac{1}{2}} \|u_\lambda\|$$

which gives (3.8). □

Let $r_\lambda = \mathrm{diam} A_\lambda$. Then by Proposition 3.2, $r_\lambda \to 0$ as $\lambda \to +\infty$. Let $x_\lambda \in A_\lambda$ be such that $A_\lambda \subset B_{r_\lambda}(x_\lambda)$.

PROPOSITION 3.3. *There holds*

$$\frac{u_\lambda}{\lambda \int_\Omega f(u_\lambda - q(x))\,dx} - G(\cdot, x_\lambda) \to 0 \ \ in \ \ W^{1,p}(\Omega) \tag{3.9}$$

as $\lambda \to +\infty$, *where* $1 \le p < 2$.

Proof. We follow the arguments of Theorem 5.2 of [6]. Denote $h(\lambda) = \lambda \int_\Omega f(u_\lambda - q(x))\,dx$ and $G(x,y)$ the Green's function of $-\Delta$ in Ω, subject to the Dirichlet condition. Since

$$u_\lambda(y) = \lambda \int_{A_\lambda} G(x,y) f(u_\lambda(x) - q(x))\,dx$$

and

$$\frac{\lambda}{h(\lambda)} \int_{A_\lambda} f(u_\lambda(x) - q(x))\,dx = 1,$$

for $z(\lambda) \in A_\lambda$ we have

$$\frac{u_\lambda(y)}{h(\lambda)} - G(y, z(\lambda)) = \frac{\lambda}{h(\lambda)} \int_{A_\lambda} \{G(x,y) - G(y, z(\lambda))\} f(u_\lambda(x) - q(x))\,dx.$$

By the Minkowski inequality, there holds

$$\begin{aligned} &\left\| \frac{u_\lambda(\cdot)}{h(\lambda)} - G(\cdot, z(\lambda)) \right\|_{W^{1,p}(\Omega)} \\ \le &\frac{\lambda}{h(\lambda)} \int_{A_\lambda} \Big[\int_\Omega |\nabla_y (G(y,x) - G(y, z(\lambda))|^p\,dy \Big]^{\frac{1}{p}} f(u_\lambda(x) - q(x))\,dx. \end{aligned}$$

Lemma 5.1 of [6] yields

$$\int_\Omega |\nabla_y \{G(y,x) - G(y, z(\lambda))|^p\,dy \le C |x - z(\lambda)|^{2-p} \left(1 + \ln \left(\frac{\mathrm{diam}\Omega}{|x - z(\lambda)|} \right) \right)^2.$$

Since x and $z(\lambda)$ are both in A_λ, then $|x - z(\lambda)| \le \mathrm{diam} A_\lambda$. The conclusion follows from Proposition 3.2. □

PROPOSITION 3.4. *Let* $G(x,y)$ *be the Green's function of* $-\Delta$ *in* Ω, *subject to the Dirichlet condition. Then, for any* $\alpha \in (0,1)$,

$$\frac{u_\lambda}{\lambda \int_\Omega f(u_\lambda - q(x))\,dx} - G(\cdot, x_\lambda) \to 0 \ \ in \ \ C^{1,\alpha}(\Omega \setminus B_\delta(x_0))$$

as $\lambda \to +\infty$.

Proof. By Proposition 3.3, we know that

$$\frac{u_\lambda}{\lambda \int_\Omega f(u_\lambda - q(x))\,dx} - G(\cdot, x_\lambda) \to 0 \ \text{ in } \ W^{1,p}(\Omega) \tag{3.10}$$

for $x_\lambda \in A_\lambda$, where $1 \le p < 2$. On the other hand, for any $\delta > 0$, we have

$$A_\lambda \subset B_\delta(x_0)$$

for $\lambda > 0$ large enough, where $x_0 = \lim_{\lambda\to+\infty} x_\lambda$. Thus,

$$-\Delta u_\lambda = 0 \ \text{ in } \ \Omega \setminus B_\delta(x_0),$$

that is,

$$-\Delta v_\lambda := -\Delta\left(\frac{u_\lambda}{\lambda\int_\Omega f(u_\lambda - q(x))\,dx}\right) = 0 \ \text{ in } \ \Omega \setminus B_\delta(x_0).$$

By the L^p-estimate of the elliptic equation, we have for any $r > 0$

$$\|v_\lambda\|_{w^{2,r}(B_\tau(y_0))} \le C\|v_\lambda\|_{L^r(B_{2\tau}(y_0))}$$

for any $B_{2\tau}(y_0) \subset \Omega \setminus B_\delta(x_0)$. As

$$G(x, x_\lambda) = -\frac{1}{2\pi}\ln|x - x_\lambda| - R(x, x_\lambda) \quad \forall x \in \Omega,$$

where

$$\begin{cases} -\Delta_x R(x, x_\lambda) = 0, & x \in \Omega, \\ R(x, x_\lambda) = -\frac{1}{2\pi}\ln|x - x_\lambda|, & x \in \partial\Omega. \end{cases}$$

Clearly, $\left|-\frac{1}{2\pi}\ln|x - x_\lambda|\right| \le C$ on $\Omega \setminus B_\delta(x_0)$ and

$$\sup_{\partial B_\delta(x_0)\cap\bar\Omega} |R(x, x_\lambda)| = |R(y_\lambda, x_\lambda)|$$

for some $y_\lambda \in \partial B_\delta(x_0) \cap \bar\Omega$. If $|R(y_\lambda, x_\lambda)| \to +\infty$ as $\lambda \to +\infty$, then we may assume there exist subsequences $x_n := x_{\lambda_n}, y_n := y_{\lambda_n} \in \partial B_\delta(x_0) \cap \bar\Omega$ such that $x_n \to x_0$ and $y_n \to y_0 \in \partial B_\delta(x_0) \cap \bar\Omega$. Therefore, $R(x_0, y_0) = \infty$, which is a contradiction since $x_0 \ne y_0$. Hence

$$|G(x, x_\lambda)| \le C \quad \forall x \in \Omega \setminus B_\delta(x_0). \tag{3.11}$$

By (3.10) and (3.11), we know that

$$\|v_\lambda\|_{L^r(B_{2\tau}(y_0))} \le 1 + C\|G(\cdot, x_\lambda)\|_{L^r(B_{2\tau}(y_0))} \le C'.$$

Therefore, the conclusion follows. □

4. Proof of Theorem 1.1. We first get a lower bound for c_λ. Suppose that $x_\lambda \to x_0 \in \bar\Omega$. For any $\tau > 0$, let $\delta > 0$ be small enough such that

$$|q(x) - q(x_0)| < \tau \quad \forall x \in B_\delta(x_0).$$

Then we have the following proposition.

PROPOSITION 4.1. *The point x_0 is on the boundary $\partial\Omega$ and $q(x_0) = q_m = \min_{x\in\partial\Omega} q(x)$. Moreover,*

$$c_\lambda \ge \frac{2\pi(q(x_0) - \tau)^2}{\ln\lambda}\left(1 + O\left(\frac{\ln\ln\lambda}{\ln\lambda}\right)\right). \tag{4.1}$$

Proof. By Proposition 3.2, Proposition 3.4, and (3.11), we have

$$|u_\lambda(y)|, |Du_\lambda(y)| \le C\lambda\int_\Omega f(u_\lambda - q(x))\,dx \le \frac{1}{\ln\lambda} \quad \forall y \in \Omega \setminus B_{\frac{\delta}{2}}(x_0). \tag{4.2}$$

Let $\xi \in C_0^\infty(B_\delta(x_0)),\ 0 \le \xi \le 1$ and $\xi = 1$ in $B_{\frac{\delta}{2}}(x_0)$. Then

$$\int_\Omega |D(u_\lambda - \xi u_\lambda)|^2\,dx = \int_{\Omega\setminus B_{\frac{\delta}{2}}(x_0)} |D(u_\lambda - \xi u_\lambda)|^2\,dx \le \frac{C}{\ln^2\lambda}. \tag{4.3}$$

Choose $\tilde{t}_\lambda > 0$ such that

$$\begin{aligned}&\frac{1}{2}\int_{B_\delta(x_0)} |D(\tilde{t}_\lambda \xi u_\lambda)|^2\,dx - \lambda\int_{B_\delta(x_0)} F(\tilde{t}_\lambda \xi u_\lambda - (q(x_0)-\tau))\,dx\\ &= \max_{t\ge 0}\Big(\frac{1}{2}\int_{B_\delta(x_0)} |D(t\xi u_\lambda)|^2\,dx - \lambda\int_{B_\delta(x_0)} F(t\xi u_\lambda - (q(x_0)-\tau))\,dx\Big).\end{aligned}$$

We claim that $\tilde{t}_\lambda$ is bounded. In fact, let $\bar{t}_\lambda > 0$ be such that

$$\begin{aligned}&\frac{1}{2}\int_{B_\delta(x_0)} |D(\bar{t}_\lambda \xi u_\lambda)|^2\,dx - \lambda\int_{B_\delta(x_0)} F(\bar{t}_\lambda \xi u_\lambda - q(x))\,dx\\ &= \max_{t\ge 0}\Big(\frac{1}{2}\int_{B_\delta(x_0)} |D(t\xi u_\lambda)|^2\,dx - \lambda\int_{B_\delta(x_0)} F(t\xi u_\lambda - q(x))\,dx\Big).\end{aligned}$$

From $f(t-q(x)) \le f(t-(q(x_0)-\tau))\ \forall\ x \in B_\delta(x_0)$, we can check that $\tilde{t}_\lambda \le \bar{t}_\lambda$. Thus we just need to prove that $\bar{t}_\lambda$ is bounded.

Let $q_m = \min_{x\in\Omega} q(x)$. Take $R > 0$ large enough such that $\Omega \subset B_R(0)$. Then, we have

$$\begin{aligned}c_\lambda \ge& \inf_{v\in H_0^1(B_R(0)),v\not\equiv 0}\ \max_{t\ge 0}\Big(\frac{1}{2}t^2\int_{B_R(0)} |Dv|^2\,dx - \int_{B_R(0)} F(tv - q_m)\,dx\Big)\\ =&\frac{2\pi q_m^2}{\ln\lambda}(1+o(1)) \ge \frac{b}{\ln\lambda}\end{aligned}$$

for some $b > 0$. Thus, we obtain by (f_2) that

$$\lambda\int_\Omega f(u_\lambda - q(x))u_\lambda\,dx \ge \frac{b'}{\ln\lambda}, \tag{4.4}$$

where $b' > 0$ is a constant.

For $t \in [0,2]$, we define

$$g(t) =: t\int_{B_\delta(x_0)} |D(\xi u_\lambda)|^2\,dx - \lambda\int_{B_\delta(x_0)} f(t\xi u_\lambda - q(x))\xi u_\lambda\,dx.$$

It follows from Proposition 3.4 that for $x \in \Omega\setminus B_{\delta/2}(x_0)$, we have

$$|u_\lambda(x)| \le C\lambda\int_\Omega f(u_\lambda - q(x))\,dx \le \frac{C}{\ln\lambda}.$$

Since q is a positive harmonic function uniformly bounded below in $\bar{\Omega}$, we see that

$$t\xi u_\lambda - q(x) \le 0 \quad \forall\ t\in[0,2],\ x \in \Omega\setminus B_{\delta/2}(x_0)$$

for $\lambda > 0$ large enough. This, together with (4.3), gives

$$g(t) = t\int_\Omega |Du_\lambda|^2\,dx - \lambda\int_\Omega f(tu_\lambda - q(x))u_\lambda\,dx + O\Big(\frac{1}{\ln^2\lambda}\Big). \tag{4.5}$$

Define

$$h(\sigma) = (1+\sigma)\int_\Omega |Du_\lambda|^2\,dx - \lambda\int_\Omega f((1+\sigma)u_\lambda - q(x))u_\lambda\,dx.$$

Then $h(0)=0$, and by (f_2) and (4.4) we get

$$\begin{aligned}
h'(0) =& \int_\Omega |Du_\lambda|^2\,dx - \lambda\int_\Omega f'(u_\lambda - q(x))u_\lambda^2\,dx\\
=&\lambda\int_\Omega \Big(f(u_\lambda - q(x)) - f'(u_\lambda - q(x))u_\lambda\Big)u_\lambda\,dx\\
\le&\lambda\int_\Omega \Big(\theta^{-1}f'(u_\lambda - q(x))(u_\lambda - q(x)) - f'(u_\lambda - q(x))u_\lambda\Big)u_\lambda\,dx\\
\le& -c_1\lambda\int_\Omega f'(u_\lambda - q(x))(u_\lambda - q(x))u_\lambda\,dx\\
\le& -c_2\lambda\int_\Omega f(u_\lambda - q(x))u_\lambda\,dx \le -c_3/\ln\lambda,
\end{aligned}$$

where all the constants $c_i, i=1,2,3$, in the above relation are positive. As a result,

$$h(\sigma) \le -c_3\sigma/\ln\lambda + o(\sigma)$$

if $\sigma>0$. Thus

$$g(1+\sigma) = h(\sigma) + O\Big(\frac{1}{\ln^2\lambda}\Big) \le -c_3\sigma/\ln\lambda + o(\sigma) + O\Big(\frac{1}{\ln^2\lambda}\Big) < 0$$

if $\sigma>0$ is small enough and λ is large enough. Thus, $\bar t_\lambda \le 1+\sigma$. Therefore, we have proved that $\bar t_\lambda$, and thus $\tilde t_\lambda$ is bounded.

Using Proposition 3.4 again, we may deduce as (4.5) that for $\lambda>0$ large enough

$$\begin{aligned}
&\lambda\int_\Omega F(\tilde t_\lambda u_\lambda - q(x))\,dx - \lambda\int_\Omega F(\tilde t_\lambda \xi u_\lambda - q(x))\,dx\\
&= \lambda\int_{\Omega\setminus B_{\delta/2}(x_0)} F(\tilde t_\lambda u_\lambda - q(x))\,dx - \lambda\int_{\Omega\setminus B_{\delta/2}(x_0)} F(\tilde t_\lambda \xi u_\lambda - q(x))\,dx = 0.
\end{aligned} \tag{4.6}$$

By Proposition 2.2, (4.3), and (4.6), we have

$$\begin{aligned}
c_\lambda &= I_\lambda(u_\lambda) = \max_{t\ge0} I_\lambda(tu_\lambda)\\
&\ge I_\lambda(\tilde t_\lambda u_\lambda) = I_\lambda(\tilde t_\lambda\xi u_\lambda) + O\Big(\frac{1}{\ln^2\lambda}\Big)\\
&= \frac12\int_{B_\delta(x_0)} |D(\tilde t_\lambda\xi u_\lambda)|^2\,dx - \lambda\int_{B_\delta(x_0)} F(\tilde t_\lambda\xi u_\lambda - q(x))\,dx + O\Big(\frac{1}{\ln^2\lambda}\Big)\\
&\ge \frac12\int_{B_\delta(x_0)} |D(\tilde t_\lambda\xi u_\lambda)|^2\,dx - \lambda\int_{B_\delta(x_0)} F(\tilde t_\lambda\xi u_\lambda - (q(x_0)-\tau))\,dx + O\Big(\frac{1}{\ln^2\lambda}\Big)\\
&= \max_{t\ge0}\Big(\frac12\int_{B_\delta(x_0)} |D(t\xi u_\lambda)|^2\,dx - \lambda\int_{B_\delta(x_0)} F(t\xi u_\lambda - (q(x_0)-\tau))\,dx\Big) + O\Big(\frac{1}{\ln^2\lambda}\Big)\\
&\ge \inf_{v\in H_0^1(B_\delta(x_0))}\max_{t\ge0}\Big(\frac12\lambda\int_{B_\delta(x_0)} |D(tv)|^2\,dx - \lambda\int_{B_\delta(x_0)} F(tv - (q(x_0)-\tau))\,dx\Big)\\
&+ O\Big(\frac{1}{\ln^2\lambda}\Big)\\
&\ge \frac{2\pi(q(x_0)-\tau)^2}{\ln\lambda}\Big(1 + o\Big(\frac{\ln\ln\lambda}{\ln\lambda}\Big)\Big). \qquad \square
\end{aligned}$$

Proof of Theorem 1.1. We claim that $q(x_0) = q_m = \min_{x\in\partial\Omega} q(x)$. In fact, by Propositions 3.3 and 4.1, we have

$$\frac{2\pi(q(x_0)-\tau)^2}{\ln\lambda}(1-o(1)) \le c_\lambda \le \frac{2\pi(q_m+\tau)^2}{\ln\lambda}(1+o(1)) \quad \forall \tau > 0,$$

where $o(1) \to 0$ as $\lambda \to +\infty$. Therefore,

$$q_m \le q(x_0) \le q_m + 2\tau \quad \forall \tau > 0.$$

This completes the proof.

5. Proof of Theorem 1.2. Let $\bar{x}_0 \in \partial\Omega$ be a strict local minimum point of $q(x)$. Let $\delta > 0$ be small so that

$$q(x) > q(\bar{x}_0) \ \ \forall x \in B_\delta(\bar{x}_0) \cap (\bar{\Omega} \setminus \{\bar{x}_0\}).$$

Let

$$\bar{f}(x,t) = \chi_{B_\delta(\bar{x}_0)} f(t - q(x)),$$

where $\chi_{B_\delta(\bar{x}_0)}$ is the characteristic function of $B_\delta(\bar{x}_0)$. Consider

$$\begin{cases} -\Delta u = \lambda \bar{f}(x,u) & \text{in } \Omega, \\ u \in H_0^1(\Omega). \end{cases} \tag{5.1}$$

It is easy to check that (5.1) has a mountain pass solution $\bar{u}_\lambda$ with critical value $\bar{c}_\lambda$. Then $\bar{c}_\lambda$ has a upper bound as (2.12). Denote by $A_\lambda = \{x \in \Omega : \bar{u}(x)_\lambda > q(x)\}$ the vortex core of $\bar{u}_\lambda$. Then we have the following lemma.

LEMMA 5.1. *A_λ is connected.*

Proof. Let A_i be any component of A_λ. Then $A_i \cap B_\delta(\bar{x}_0) \neq \emptyset$. In fact, if $A_i \cap B_\delta(\bar{x}_0) = \emptyset$, then

$$-\Delta u_\lambda = 0 \ \text{ in } \ A_i; \quad u_\lambda = q(x) \ \text{ on } \ \partial A_i.$$

But $q(x)$ is harmonic; thus $u_\lambda = q(x)$ in A_i. This is a contradiction. The rest of the proof is the same as Proposition 3.1. Since $A_i \cap B_\delta(\bar{x}_0) \neq \emptyset$, η_0 as in the proof of Proposition 3.1 is well defined, and the coefficient in (3.7) in front of s^2 is negative. Then the conclusion follows in the same way. □

Let $x_\lambda \in A_\lambda$ and $x_\lambda \to x_0$.

LEMMA 5.2. $x_0 = \bar{x}_0$.

Proof. First, we have $x_0 \in \overline{B_\delta(\bar{x}_0)} \cap \bar{\Omega}$. If not, we could choose $\tilde{\delta} > 0$ small such that for λ large

$$A_\lambda \subset B_{\tilde{\delta}}(x_0) \subset \bar{\Omega} \setminus \overline{B_\delta(\bar{x}_0)}.$$

Thus, $A_\lambda \cap \overline{B_\delta(\bar{x}_0)} = \emptyset$. This is a contradiction, because as in the proof of Lemma 5.1, we know that $A_\lambda \cap \overline{B_\delta(\bar{x}_0)} \neq \emptyset$.

Since $q(x_0) = \min_{\overline{B_\delta(\bar{x}_0)} \cap \bar{\Omega}} q(x)$ and x_0 is the only point which attains the minimum in $B_\delta(x_0) \cap \bar{\Omega}$, we can prove $x_0 = \bar{x}_0$ in a similar way as in the proof of Theorem 1.1. Since $x_\lambda \to x_0$, we see $A_\lambda \subset B_\delta(x_0)$ for $\lambda > 0$ large. So $f(u_\lambda - q(x)) = 0$ for all $x \in \Omega \setminus B_\delta(x_0)$. As a result, u_λ is a solution of (1.10). □

Acknowledgments. The authors would like to thank the referees for their valuable suggestions.

BIFURCATIONS OF PERIODIC SOLUTIONS SATISFYING THE ZERO-HAMILTONIAN CONSTRAINT IN REVERSIBLE DIFFERENTIAL EQUATIONS*

R. E. BEARDMORE†, M. A. PELETIER‡, C. J. BUDD§, AND M. AHMER WADEE¶

Abstract. This is a study of the existence of bifurcation branches for the problem of finding even, periodic solutions in fourth-order, reversible Hamiltonian systems such that the Hamiltonian evaluates to zero along each solution on the branch. The class considered here is a generalization of both the Swift–Hohenberg and extended Fisher–Kolmogorov equations that have been studied in several recent papers. We obtain the existence of local bifurcations from a trivial solution under mild restrictions on the nonlinearity and obtain existence and disjointness results regarding the global nature of the resulting bifurcating continua for the case where the Hamiltonian has a *single-well* potential.

The local results rest on two abstract bifurcation theorems which also have applications to sixth-order problems and which show that the curves of zero-Hamiltonian solutions are contained within two-dimensional manifolds of solutions of both negative and positive Hamiltonian.

Key words. reversible Hamiltonian systems, Lyapunov–Schmidt reduction

1. Introduction.

In [25, 7, 28, 29, 36, 20, 9] the authors find periodic solutions of systems of Hamiltonian differential equations with the property of having *prescribed zero Hamiltonian*. In particular, existence theorems for even periodic orbits satisfying the zero-Hamiltonian constraint in certain fourth-order Hamiltonian systems have been derived by Peletier, Troy, and van den Berg using shooting techniques [35, 36]. While such shooting methods rely heavily on the particular form of the nonlinearities in a given problem and thus suffer from a lack of generality, the techniques do provide a great deal of quantitative information about the solutions. The problem of finding periodic solutions of Hamiltonian systems with prescribed *nonzero energy* has been studied extensively (see [31, 30] and more recently [4]).

The main contribution of this paper is to view the problem of finding zero-Hamiltonian periodic solutions of (1.1) as a one-parameter bifurcation problem from a zero solution, with either *period* or an external parameter playing the role of bifurcation parameter. To solve this bifurcation problem we formulate two abstract Hopf bifurcation theorems (Theorems 2.2 and 2.4) and deduce the existence of the desired

solutions as a corollary. The abstract results apply to reversible fourth-order Hamiltonian systems at 1:1 and m:n resonances, provided that the Hamiltonian is indefinite about the trivial solution. We call these *simple* and *double* bifurcations, respectively, as the theorems lead to either a single continuum or a pair of bifurcating continua of solutions. Furthermore, the proofs of the bifurcation theorems are easily modified to show that the zero-Hamiltonian solutions that we find actually lie within manifolds of solutions of positive and negative Hamiltonian.

The proofs of our abstract results are achieved using a Lyapunov–Schmidt reduction technique, as can be found in many texts [38, 2, 11], and the fact that we essentially have only one bifurcation parameter means that some of the global bifurcation results of [6] are applicable. Using arguments from the *configuration-space* formulation of fourth-order problems [34, 17, 29], we shall be able to find bifurcation invariants which demonstrate that the bifurcating continua form a countable collection of mutually disjoint sets. Subsequently, we shall be able to show that a simple bifurcation for fourth-order problems results in the existence of an unbounded (in a suitable sense) continuum of solutions, rather like the classical global Hopf bifurcation theorem described in [1]. The global aspect of the paper is peculiar to fourth-order equations and does not immediately apply to more general Hamiltonian systems (like the sixth-order problem [33, equation (2)] for which we also have local results). Consequently, we have what approaches a nonlinear Sturm–Liouville theory (which is well known in the context of elliptic two-point boundary-value problems [5]) for zero-Hamiltonian solutions of (1.1) given below.

A Lyapunov–Schmidt reduction procedure is specifically available for systems that are either reversible or Hamiltonian [37, 22]; however, we do not make use of those results in this paper. The reason for this is that it is not clear that studying the problem in a space of reduced dimension helps to elucidate the role played by the Hamiltonian constraint, and consequently we approach the problem ab initio.

So, consider the class of fourth-order differential equations

$$u'''' + pu'' + F_u(u) = 0, \tag{1.1}$$

where primes refer to differentiation with respect to x, p is a real parameter, and the function $F \in C^\omega(\mathbb{R})$ satisfies

(**F**) $F(0) = F_u(0) = 0 \quad \text{and} \quad F_{uu}(0) = 1.$

Here, $C^\omega(\mathbb{R})$ denotes the space of real-analytic functions on $\mathbb{R}$, and a subscript u denotes differentiation with respect to u. We shall assume *throughout* that F satisfies assumption (**F**) and is therefore positive in some neighborhood of $u = 0$. Note that the final condition in (**F**) is not restrictive as it can always be obtained from a suitable scaling of u and of time (denoted x), provided that $F_{uu}(0) > 0$.

Now (1.1) is reversible (see [8] for a discussion of reversible systems) and Hamiltonian, with Hamiltonian

$$H \equiv u'u''' - \frac{1}{2}u''^2 + \frac{1}{2}pu'^2 + F(u), \tag{1.2}$$

and when suitably scaled (see [36]), (1.1) provides the *extended Fisher–Kolmogorov* and *Swift–Hohenberg equations*, with $F_u(u) = \pm u(1 - u^2)$.

Fourth-order equations like (1.1) have a burgeoning literature, as can be seen from the recent studies in [3, 7, 24, 26, 27, 28, 29, 35, 36, 8, 12, 19, 18]; see, in particular, the recent monograph [25] and also [36, 20]. In these references it is shown, using a variety of variational, geometric, functional analytic, and elementary techniques, that

(1.1) may possess periodic, homoclinic, and heteroclinic solutions, with applications ranging from geology to buckling theory; in particular, zero-Hamiltonian periodic solutions play an important role in the study of cellular buckling (see [12, 19, 8] and the references therein; see also [9]).

We note at this stage that in order for a bifurcation from the trivial solution to occur as p varies, no further restrictions will be required on the nonlinearity F than those already given in assumption (**F**).

As an application of the results of the first part of the paper, we analyze the behavior of the simple bifurcating branch which connects to $(u,p) = (0,2)$ for the case

$$F(u;\epsilon) = \frac{1}{2}u^2 - \epsilon\left(\frac{1}{4}u^4 - \frac{1}{6}u^6\right), \tag{1.3}$$

where ϵ is a parameter that unfolds the degenerate problem from $\epsilon = 0$. In particular, we prove the existence of a fold bifurcation on this bifurcating branch, which was conjectured to exist in [19] and [12]. Finally, the results of some numerical calculations performed in AUTO will be presented, which indicate that similar behavior is observed for the multiple bifurcating branches which connect to the trivial solution at $p > 2$. We also compute the symmetry-breaking bifurcations on these branches and illustrate the subsequent connecting branches of solutions.

2. Bifurcation theorems. Let X, Y, and Z be Banach spaces, and $BL(X,Y)$ denote the space of continuous (bounded) linear maps from X to Y. We write X^* for the dual space of continuous linear functionals $BL(X,\mathbb{R})$. If $L \in BL(X,Y)$ and $U \subset X$ is a closed subspace of X, then $L|_U \in BL(U,Y)$ will denote the restriction of L to U. We shall use $\|\cdot\|_X$ to denote the norm on X, and $\mathrm{Iso}(X,Y)$ denotes the set of continuous linear isomorphisms from X to Y. Let $C^r_{2\pi}$ be the Banach space of 2π-periodic C^r functions from $[0,2\pi]$ to $\mathbb{R}^n$, endowed with a C^r norm.

If $f : X \to Z$ is a given smooth mapping, then $df(x)[h]$ will denote the Fréchet derivative of f. For higher derivatives, the k-form $d^k f(x)[h,\dots,h]$ will also be written as $d^k f(x)[h]^{(k)}$ for brevity. Partial derivatives of a function $f \in C^1(X \times Y, Z)$ will be written as $d_x f(x,y)[h] \in Z$ and $d_y f(x,y)[k] \in Z$, where $(h,k) \in X \times Y$, and higher derivatives will be written as in $d^2_{xy} f(x,y)[h,k]$. If $X = \mathbb{R}$, we will identify $d_x f(x,y)[h]$ with $h d_x f(x,y)[1]$, and we shall also write

$$d^k f(x)[h_1,\dots,h_k] = (\Pi_{j=1}^k h_j) d^k f(x)[1,\dots,1],$$

although we shall often omit the k-vector $[1,\dots,1]$ in this expression where no confusion results. Given $u, u_1, u_2 \in X$, we will write $\langle u\rangle \equiv \mathbb{R}\cdot u$ and $\langle u_1, u_2\rangle = \{\alpha_1 u_1 + \alpha_2 u_2 : \alpha_1, \alpha_2 \in \mathbb{R}\}$. For any continuous function v, we denote the delta functional by $\delta(v) \equiv v(0)$.

For completeness, let us recall the following. A linear mapping $L \in BL(X,Y)$ is said to be *Fredholm* if its range $\mathrm{ran}(L)$ is a closed subspace of Y with finite codimension and its null space $\ker(L)$ is a finite-dimensional subspace of X. Then

$$\mathrm{ind}(L) = \dim\ker(L) - \mathrm{codim}\ \mathrm{ran}(L)$$

is said to be the *Fredholm index* of L. We recall the following theorem, which gives a useful collections of facts that can be found in [32].

THEOREM 2.1. *If $L \in BL(X,Y)$ is Fredholm and $K \in BL(X,Y)$ is a compact linear operator, then $L + K \in BL(X,Y)$ is also Fredholm and* $\mathrm{ind}(L+K) = \mathrm{ind}(L)$.

As a consequence, if L is Fredholm of index zero and is injective, then it is an isomorphism. The set $\mathcal{F}$ of Fredholm operators is open in $BL(X,Y)$, and ind *is constant on connected components of $\mathcal{F}$.*

2.1. Statement of the abstract problem. Let $\psi \in Z^*, M \in C^\omega(X \times \mathbb{R}^2, Y)$, and $g \in C^\omega(X \times \mathbb{R}^2, Z)$; now consider the bifurcation problem

$$\mathcal{H}(u,p,\mu) \equiv \begin{pmatrix} M(u,p,\mu) \\ \psi(g(u,p,\mu)) \end{pmatrix} = \begin{pmatrix} 0 \\ 0 \end{pmatrix}, \tag{2.1}$$

where $u \in X$ and $\mu, p \in \mathbb{R}$ are parameters. Throughout, we shall write $\mathcal{H} = M \times \psi(g)$ for brevity. We intend that (2.1) represent an abstract formulation of finding periodic solutions of (1.1) with the property of having zero Hamiltonian; accordingly we shall call the functional $\psi \circ g$ the *energy* of (2.1). Since the functional H in (1.2) is of *quadratic order* at the origin, we impose this degree of degeneracy into the operator g. Hence we assume that

$$M(0,p,\mu) \equiv 0 \tag{2.2}$$

and

$$g(0,p,\mu) \equiv 0, \qquad d_u g(0,p,\mu) \equiv 0. \tag{2.3}$$

By the term *bifurcation* from the trivial solution $u = 0$ of (2.1) at $(u,p,\mu) = (0,p_0,\mu_0)$ we mean that there is a sequence $(u_n,p_n,\mu_n) \subset X\backslash\{0\} \times \mathbb{R}^2$ which satisfies

$$\mathcal{H}(u_n,p_n,\mu_n) \equiv 0, \quad u_n \to 0 \quad \text{and} \quad (p_n,\mu_n) \to (p_0,\mu_0) \quad \text{as } n \to \infty.$$

2.2. Local bifurcations. Let us now seek conditions under which there is a bifurcation of (2.1) from the trivial solution. The implicit function theorem applied to (2.1) shows that $(0,p_0,\mu_0)$ can be a bifurcation point for (2.1) only if

$$d_u M(0,p_0,\mu_0) \notin \mathrm{Iso}(X,Y). \tag{2.4}$$

Furthermore, if M is a assumed to be a Fredholm mapping, then a bifurcation can occur only when $d_u M(0,p_0,\mu_0)$ is *not* injective. Motivated by this, we shall now consider two such cases:

(i) $\dim\ker(d_u M(0,p_0,\mu_0)) = 1$,
(ii) $\dim\ker(d_u M(0,p_0,\mu_0)) = 2$.

Case (i) is reminiscent of the theorem on bifurcation from a simple eigenvalue and will give rise to a *unique* bifurcating continuum. In case (ii), however, we will be able to locate exactly *two* distinct bifurcating continua. Let us now proceed with the promised results.

THEOREM 2.2 (simple abstract Hopf bifurcation). *Suppose that* (2.2)–(2.3) *hold and that $d_u M(0,p_0,\mu_0) \in BL(X,Y)$ is Fredholm of index zero, where* $\ker(d_u M(0,p_0,\mu_0)) = \langle k \rangle$. *Suppose also that $X = \langle k \rangle \oplus U$, $V = \mathrm{ran}(d_u M(0,\mu_0,p_0), Y = \langle K \rangle \oplus V, P : Y \to V$ is the projection operator along $\langle K \rangle$, and Q is the projection onto $\langle K \rangle$ which is identified with $\mathbb{R}$.*

Suppose further that $\psi(d^2_{uu} g(0,p_0,\mu_0)[k,k]) = 0$ and that the operator $D \in BL(U \times \mathbb{R}^2, V \times \mathbb{R}^2)$ given by

$$D = \begin{pmatrix} P d_u M(0,p_0,\mu_0) & P d^2_{up} M(0,p_0,\mu_0)[k,1] & P d^2_{u\mu} M(0,p_0,\mu_0)[k,1] \\ 0 & Q d^2_{up} M(0,p_0,\mu_0)[k,1] & Q d^2_{u\mu} M(0,p_0,\mu_0)[k,1] \\ \psi(d^2_{uu} g[k,\cdot]) & \psi(d^3_{uup} g[k,k,1]) & \psi(d^3_{uu\mu} g[k,k,1]) \end{pmatrix}$$

is an isomorphism.

Then, $(0, p_0, \mu_0)$ *is a bifurcation point for* (2.1). *Moreover, there is an interval* I *containing* 0 *and a unique analytic branch* $\mathcal{B}$ *of solutions of* (2.1) *on which* $(u, p, \mu) = (u(\beta), p(\beta), \mu(\beta))$ *for* $\beta \in I$ *and which satisfies* $u(\beta) \neq 0$ *for* $\beta \neq 0, (u(0), p(0), \mu(0)) = (0, p_0, \mu_0)$. *Moreover, there results* $\|u(\beta) - \beta k\|_X = O(\beta^2)$ *as* $\beta \to 0$.

Proof. Let us express u in terms of the decomposition of X as $u = \beta k + r = \beta(k + \rho) \in \langle k \rangle \oplus U$; then (2.1) is equivalent to

$$(P + Q)M(\beta(k + \rho), p, \mu) = 0, \tag{2.5}$$

$$\psi(g(\beta(k + \rho), p, \mu)) = 0. \tag{2.6}$$

Using analyticity, it follows that there are analytic mappings $\tilde{M}$ and $\tilde{g}$ such that

$$M(\beta(k + \rho), p, \mu) = \beta d_u M(0, p, \mu)[k + \rho] + \beta^2 \tilde{M}(\beta, \rho, p, \mu)$$

and

$$\psi(g(\beta(k + \rho), p, \mu)) = \psi\left(\frac{\beta^2}{2} d^2_{uu} g(0, p, \mu)[k + \rho, k + \rho] + \frac{\beta^3}{2} \tilde{g}(\beta, \rho, p, \mu)\right).$$

As we are seeking nonzero solutions to (2.1), we can divide by appropriate powers of β in (2.5)–(2.6) and solve the equivalent problems

$$(P + Q)d_u M(0, p, \mu)[k + \rho] + \beta \tilde{M}(\beta, \rho, p, \mu) = 0, \tag{2.7}$$

$$\psi\left(d^2_{uu} g(0, p, \mu)[k + \rho, k + \rho] + \beta \tilde{g}(\beta, \rho, p, \mu)\right) = 0. \tag{2.8}$$

In turn, (2.7)–(2.8) is equivalent to

$$P\big(d_u M(0, p, \mu)[k + \rho] + \beta \tilde{M}(\beta, \rho, p, \mu)\big) = 0 \in V, \tag{2.9}$$

$$Q\big(d_u M(0, p, \mu)[k + \rho] + \beta \tilde{M}(\beta, \rho, p, \mu)\big) = 0 \in \mathbb{R}, \tag{2.10}$$

$$\psi\left(d^2_{uu} g(0, p, \mu)[k + \rho, k + \rho] + \beta \tilde{g}(\beta, \rho, p, \mu)\right) = 0 \in \mathbb{R}, \tag{2.11}$$

where the one-dimensional space $\langle K \rangle$ is identified with $\mathbb{R}$.

Let us now define (2.9)–(2.11) as $\Phi_1(\beta, \rho, p, \mu) = 0$, where Φ_1 is an analytic mapping of Banach spaces

$$\Phi_1 : \mathbb{R} \times U \times \mathbb{R}^2 \to V \times \mathbb{R}^2. \tag{2.12}$$

Under the stated assumptions it is clear that $\Phi_1(0, 0, p_0, \mu_0) = 0$, and one can show that $D = d_{\rho,p,\mu}\Phi_1(0, 0, p_0, \mu_0)$, noting $Q[d_u M(0, p_0, \mu_0)] = 0$ by definition. It now follows by the implicit function theorem that we may locally solve (2.9)–(2.10) for ρ, p, and μ as a function of β. The fact that $\rho(0) = 0$ completes the proof. ∎

The following result tells us that Theorem 2.2 is a special case of a more general result which says that the branch $\mathcal{B}$ of zero energy solutions from this theorem is formed from the intersection of a manifold of solutions of $M(u, p, \mu) = 0$ with the zero-energy surface $\{(u, p, \mu) : \psi(g(u, p, \mu)) = 0\}$.

THEOREM 2.3. *The curve of zero-energy solutions* $\mathcal{B}$ *from Theorem* 2.2 *is contained within a (locally) two-dimensional analytic manifold* $\mathcal{M}$ *of solutions of*

$$M(u, p, \mu) = 0 \tag{2.13}$$

of both positive and negative energy.

Proof (sketch). Repeat the same argument as in Theorem 2.2 but for the system

$$\mathcal{H}_\epsilon(u,p,\mu) \equiv \begin{pmatrix} M(u,p,\mu) \\ \psi(g(u,p,\mu)) - \epsilon \end{pmatrix} = \begin{pmatrix} 0 \\ 0 \end{pmatrix}. \tag{2.14}$$

One obtains a mapping $\Phi_1(\beta,\rho,p,\mu,\epsilon)$, entirely analogous to (2.12), such that

$$\Phi_1(0,0,p_0,\mu_0,0) = 0 \quad \text{and} \quad D = d_{\rho,p,\mu}\Phi_1(0,0,p_0,\mu_0,0).$$

One can then solve ρ, p, and μ locally as analytic functions of (β,ϵ). ∎

The following technical lemma shows that one can parameterize the bifurcating branch from Theorem 2.2 using one of p or μ as parameters, and this result will be used at a later stage in the paper.

LEMMA 2.1. *If $(u,p,\mu) = (u(\beta),p(\beta),\mu(\beta))$ is an element of the bifurcating branch $\mathcal{B}$ obtained in Theorem* 2.2, *then at least one of*

$$d_{u,p}(M \times \psi(g)) \quad \text{or} \quad d_{u,\mu}(M \times \psi(g)) \in BL(X \times \mathbb{R}, Y \times \mathbb{R})$$

(evaluated at (u,p,μ)) is an isomorphism for sufficiently small nonzero $|\beta|$.

Proof. Note from Theorem 2.2 that

$$\left|Qd^2_{up}M(0,p_0,\mu_0)[k,1]\right| + \left|Qd^2_{u\mu}M(0,p_0,\mu_0)[k,1]\right| \neq 0,$$

and let us therefore assume for definiteness that

$$Qd^2_{up}M(0,p_0,\mu_0)[k,1] \neq 0. \tag{2.15}$$

Now define the one-parameter family of linear mappings

$$L(\beta) \equiv \begin{pmatrix} d_uM(u(\beta),p(\beta),\mu(\beta)) & d_pM(u(\beta),p(\beta),\mu(\beta)) \\ \psi(d_ug(u(\beta),p(\beta),\mu(\beta)) & \psi(d_pg(u(\beta),p(\beta),\mu(\beta)) \end{pmatrix}$$

and note that this is an (at most) rank-two perturbation of a Fredholm mapping with index zero. It follows that we need to prove only that $L(\beta)$ is injective for $\beta \neq 0$.

Using analyticity, a straightforward but lengthy calculation shows that we may write $L(\beta) = L_0(\beta) + \beta L_1(\beta) + \frac{\beta^2}{2}L_2(\beta) + O(\beta^3)$, where

$$L_0(\beta) = \begin{pmatrix} d_uM & 0 \\ 0 & 0 \end{pmatrix},$$

$$L_1(\beta) = \begin{pmatrix} d^2_{uu}M[k+O(\beta),\cdot] & d^2_{up}M[k+O(\beta),\cdot] \\ \psi(d^2_{uu}g[k+O(\beta),\cdot]) & 0 \end{pmatrix},$$

and

$$L_2(\beta) = \begin{pmatrix} d^3_{uuu}M[k+O(\beta),k+O(\beta),\cdot] & d^3_{uup}M[k+O(\beta),k+O(\beta),\cdot] \\ \psi(d^3_{uuu}g[k+O(\beta),k+O(\beta),\cdot]) & \psi(d^3_{uup}g[k+O(\beta),k+O(\beta),\cdot]) \end{pmatrix},$$

where each of the given derivatives is evaluated at $(u,p,\mu) = (0,p(\beta),\mu(\beta))$. For $\beta \neq 0$, one can see that $L(\beta)$ is injective if and only if $T(\beta)$ is, where

$$\begin{aligned} T(\beta) = &\begin{pmatrix} d_uM & 0 \\ \psi(d^2_{uu}g[k+O(\beta),\cdot]) & 0 \end{pmatrix} \\ &+ \frac{\beta}{2}\begin{pmatrix} 2d^2_{uu}M[k+O(\beta),\cdot] & 2d^2_{up}M[k+O(\beta),\cdot] \\ \psi(d^3_{uuu}g[k+O(\beta),k+O(\beta),\cdot]) & \psi(d^3_{uup}g[k+O(\beta),k+O(\beta),\cdot]) \end{pmatrix} \\ &+ O(\beta^2). \end{aligned}$$

Again, each of the derivatives is evaluated at $(u,p,\mu)=(0,p(\beta),\mu(\beta))$.

Clearly $T(0)$ is not injective, but the fact that $d^2_{uu}g(0,p_0,\mu_0)[k,k]\neq 0$ implies

$$\ker(T(0))=\langle\kappa\rangle\subset X\times\mathbb{R},$$

where $\kappa=(0_X,1)\in X\times\mathbb{R}$. To prove that $T(\beta)$ is injective for small β it suffices to prove that

$$T'(0)\kappa\notin \operatorname{ran}(T(0)). \tag{2.16}$$

However

$$T'(0)=\frac{1}{2}\begin{pmatrix} 2d^2_{uu}M[k,\cdot] & 2d^2_{up}M[k,\cdot]\\ \psi(d^3_{uuu}g[k,k,\cdot]) & \psi(d^3_{uup}g[k,k,\cdot])\end{pmatrix},$$

evaluating derivatives at $(u,p,\mu)=(0,p_0,\mu_0)$, and $\operatorname{ran}(T(0))=\operatorname{ran}(d_uM(0,p_0,\mu_0))\times\operatorname{ran}(\psi(d^2_{uu}g(0,p_0,\mu_0)))$. It follows that $T'(0)\kappa\in\operatorname{ran}(T(0))$ can be satisfied only if

$$d^2_{up}M(0,p_0,\mu_0)[k,1]\in\operatorname{ran}(d_uM(0,p_0,\mu_0)),$$

but this contradicts (2.15). Finally, one can use an analogous argument to cover the case whereby $Qd^2_{u\mu}M(0,p_0,\mu_0)[k,1]\neq 0$. □

Next we consider case (ii), where $d_uM(0,p_0,\mu_0)$ has a two-dimensional null-space.

THEOREM 2.4 (double abstract Hopf bifurcation). *Suppose that* (2.2)–(2.3) *hold and* $\ker(d_uM(0,p_0,\mu_0))=W$, *where* $\dim(W)=2$ *with* $W=\langle k_1,k_2\rangle$. *Suppose further that* $X=W\oplus U$ *and*

$$Y=Z\oplus V,\qquad V=\operatorname{ran}(d_uH(0,p_0,\mu_0)),$$

where V *is closed,* $\dim(Z)=2$, *and* $Z=\langle u_1,u_2\rangle$.

Now, let $P:Y\to V$ *be the projection along* Z *and* $Q=I-P$. *For* $i=1,2$, *let* Q_i *be the projection of* Y *onto* $\langle u_i\rangle$ *(which we identify with* $\mathbb{R}$*) such that* $Q[y]=Q_1[y]u_1+Q_2[y]u_2$. *Set*

$$A=\psi(d^2_{uu}g(0,p_0,\mu_0)[k_2,k_2]),\qquad B=\psi(d^2_{uu}g(0,p_0,\mu_0)[k_1,k_2])$$

and

$$C=\psi(d^2_{uu}g(0,p_0,\mu_0)[k_1,k_1]).$$

Suppose that $C\neq 0, B^2>AC$, *and let* $\alpha_\pm$ *be the two (real nonzero distinct) roots of the quadratic equation* $A\alpha^2+2B\alpha+C=0$. *Suppose also that*

$$\det\begin{pmatrix} Q_1d^2_{up}M[k_1+\alpha_\pm k_2,1] & Q_1d^2_{u\mu}M[k_1+\alpha_\pm k_2,1]\\ Q_2d^2_{up}M[k_1+\alpha_\pm k_2,1] & Q_2d^2_{u\mu}M[k_1+\alpha_\pm k_2,1]\end{pmatrix}\neq 0$$

when $(u,p,\mu)=(0,p_0,\mu_0)$.

Then $(0,p_0,\mu_0)$ *is a bifurcation point for* (2.1). *Moreover, there is an interval* I *containing* 0 *and exactly two analytic branches* $\mathcal{B}_\pm$ *of solutions of* (2.1) *on which* $(u,p,\mu)=(u_\pm(\beta),p_\pm(\beta),\mu_\pm(\beta))$ *for* $\beta\in I$, *with* $u_\pm(0)\neq 0$ *for* $\beta\neq 0$ *and* $(u_\pm(0),p_\pm(0),\mu_\pm(0))=(0,p_0,\mu_0)$. *Moreover, there are analytic functions* $\alpha_\pm:I\to\mathbb{R}$ *and* $\rho:I\to V$ *such that* $\alpha_\pm(0)=\alpha_\pm$, $\|\rho(\beta)\|_Y=O(\beta)$ *as* $\beta\to 0$, *and* $u_\pm(\beta)=\beta k_1+\beta\alpha_\pm(\beta)k_2+\beta\rho(\beta)$.

Proof. Using the analyticity of M, let us write

$$M(u,p,\mu) = d_u M(0,p,\,\mu)[u] + \mathcal{O}(2)$$

and

$$g(u,p,\mu) = g(0,p,\mu) + d_u g(0,p,\mu)u + \frac{1}{2}d^2_{uu}g(0,p,\mu)[u,u] + \mathcal{O}(3),$$

where $\mathcal{O}(n)$ represents any function, $\Theta(u,p,\mu)$ say, where there is a $\gamma > 0$ such that $\|\Theta(u,p,\mu)\| \le \gamma\|u\|^n$ for all (u,p,μ) in a neighborhood of $(0,p_0,\mu_0)$.

Now let $u = \beta(k_1+\alpha k_2+\alpha\rho) \in W \oplus U$, and note that there is an analytic function ϕ_1 such that the equation $M(u,p,\mu) = 0$ is locally equivalent to

$$\beta d_u M(0,p,\mu)[k_1+\alpha k_2+\alpha\rho] + \beta^2\phi_1(\alpha,\beta,\rho,p,\mu) = 0. \tag{2.17}$$

We may also use the analyticity of g to write

$$g(\beta(k_1+\alpha k_2+\alpha\rho),p,\mu) = \frac{\beta^2}{2}d^2_{uu}g(0,p,\mu)[k_1+\alpha k_2+\alpha\rho]^{(2)} + \frac{\beta^3}{2}\phi_2(\alpha,\beta,\rho,p,\mu), \tag{2.18}$$

where ϕ_2 is another suitably defined analytic function. Now the equation $M(u,p,\mu) = 0$ is equivalent to

$$(P + u_1Q_1 + u_2Q_2)M(u,p,\mu) = 0,$$

and, after dividing (2.17) and (2.18) by β and β^2, respectively, we obtain the locally equivalent problem

$$P\left[d_u M(0,p,\mu)[k_1+\alpha k_2+\alpha\rho] + \beta\phi_1(\alpha,\beta,\rho,p,\mu)\right] = 0 \in V, \tag{2.19}$$

$$Q_1\left[d_u M(0,p,\mu)[k_1+\alpha k_2+\alpha\rho] + \beta\phi_1(\alpha,\beta,\rho,p,\mu)\right] = 0 \in \mathbb{R}, \tag{2.20}$$

$$Q_2\left[d_u M(0,p,\mu)[k_1+\alpha k_2+\alpha\rho] + \beta\phi_1(\alpha,\beta,\rho,p,\mu)\right] = 0 \in \mathbb{R}, \tag{2.21}$$

$$\psi\big(d^2_{uu}g(0,p,\mu)[k_1+\alpha k_2+\alpha\rho]^{(2)} + \beta\phi_2(\alpha,\beta,\rho,p,\mu)\big) = 0 \in \mathbb{R}. \tag{2.22}$$

Setting $\beta = 0, \rho = 0, p = p_0$, and $\mu = \mu_0$ in (2.19)–(2.22), we find an equation for α:

$$\psi(d^2_{uu}g(0,p,\mu)[k_1+\alpha k_2, k_1+\alpha k_2]) = 0. \tag{2.23}$$

From the definitions of A, B, and C given in the statement of the theorem, (2.23) is simply the equation $C + 2B\alpha + A\alpha^2 = 0$ with solutions $\alpha = \alpha_\pm$.

We now write (2.19)–(2.22) as $\Phi_2(\rho,p,\mu,\alpha,\beta) = 0$, say, where Φ_2 is an analytic mapping $\Phi_2 : U \times \mathbb{R}^4 \to V \times \mathbb{R}^3$. The derivative $d_{\rho,p,\mu,\alpha}\Phi_2(0,p_0,\mu_0,\alpha_\pm,0)$ is given by the operator matrix

$$L \equiv \begin{pmatrix} A_0 & B_0 & 0 \\ 0 & D_0 & 0 \\ E_0 & F_0 & G_0 \end{pmatrix} \in BL(U \times \mathbb{R}^3, V \times \mathbb{R}^3),$$

where

$$A_0 = \alpha_\pm P d_u M^0, \qquad B_0 = \left[P d^2_{up}M^0[k_1+\alpha_\pm k_2,1]\middle|\, P d^2_{u\mu}M^0[k_1+\alpha_\pm k_2,1]\right],$$

$$E_0 = 2\alpha_\pm \psi(d^2_{uu} g^0[\cdot, k_1 + \alpha_\pm k_2]), \qquad G_0 = 2\psi(d^2_{uu} g^0[k_2, k_1 + \alpha_\pm k_2]),$$

$$F_0 = \left[\psi(d^3_{uup} g^0[1, k_1 + \alpha_\pm k_2, k_1 + \alpha_\pm k_2]) \middle| \psi(d^3_{uu\mu} g^0[1, k_1 + \alpha_\pm k_2, k_1 + \alpha_\pm k_2])\right]$$

and

$$D_0 = \begin{pmatrix} Q_1 d^2_{up} M^0[k_1 + \alpha_\pm k_2, 1] & Q_1 d^2_{u\mu} M^0[k_1 + \alpha_\pm k_2, 1] \\ Q_2 d^2_{up} M^0[k_1 + \alpha_\pm k_2, 1] & Q_2 d^2_{u\mu} M^0[k_1 + \alpha_\pm k_2, 1] \end{pmatrix},$$

and a superscript zero $(^0)$ denotes evaluation of a function at $(u, p, \mu) = (0, p_0, \mu_0)$.

Clearly, for L to be an isomorphism we require $G_0 \neq 0$, that is, $\psi(d^2_{uu} g^0[k_2, k_1 + \alpha_\pm k_2]) \neq 0$, but this is just $B + \alpha_\pm A \neq 0$, which is true by assumption. Since $A_0 \in \mathrm{Iso}(U, V)$, L is an isomorphism if $\det(D_0) \neq 0$, and this is also an assumption. Using the implicit function theorem, we can now determine all of the variables as analytic functions of β locally to the *two points* $(\rho, p, \mu, \alpha, \beta) = (0, p_0, \mu_0, \alpha_\pm, 0)$. □

As was the case for Theorems 2.2 and 2.3, we can prove that the branches of zero-energy solutions $\mathcal{B}_\pm$ from Theorem 2.4 are obtained from the intersection of solutions of $M(u, p, \mu) = 0$ with the zero-energy surface.

THEOREM 2.5. *The two curves of zero-energy solutions $\mathcal{B}_\pm$ from Theorem* 2.4 *are each contained within (locally) two-dimensional analytic manifolds $\mathcal{M}_\pm$ of solutions of $M(u, p, \mu) = 0$ of both positive and negative energy. Moreover, $\mathcal{M}_+ \cap \mathcal{M}_- = \{(0, p_0, \mu_0)\}$.*

Proof. This is almost a verbatim repetition of the proof of Theorem 2.4, but modified to deal with an energy constraint of the form $\psi(g(u, p, \mu)) = \epsilon$. □

3. The existence of bifurcations for fourth- and sixth-order systems.

3.1. Preliminaries. In this section we shall apply Theorems 2.1 and 2.2 to find bifurcating branches of periodic solutions of (1.1) which have the zero-Hamiltonian property. To do so, we shall presume that a periodic solution of (1.1) has period T, where

$$T = \frac{2\pi}{\mu}$$

and μ is a priori unknown. Upon setting

$$t = \mu x,$$

a simple rescaling of (1.1) and (1.2) leads us to consider the *two-parameter* problem

$$M(u, p, \mu) \equiv \mu^4 u'''' + p\mu^2 u'' + F_u(u) = 0, \tag{3.1}$$

$$\psi(g(u, p, \mu)) \equiv \delta \left(\mu^4 u' u''' - \frac{1}{2}\mu^4 u''^2 + \frac{1}{2} p \mu^2 u'^2 + F(u) \right) = 0, \tag{3.2}$$

where primes now denote differentiation with respect to t. With regard to (2.1), ψ corresponds to δ, and g is the Hamiltonian which appears in (3.2); again we shall write $\mathcal{H} = M \times \psi(g)$ so that (3.1)–(3.2) corresponds to the equation $\mathcal{H} = 0$.

A natural setting for the application of these Theorems 2.1 and 2.2 is in the space of even functions of period 2π. Accordingly, let $X_e = \left\{ u \in C^4_{2\pi} : u(t) = u(-t) \right\}$ and

$Y_e = \{u \in C^0_{2\pi} : u(t) = u(-t)\}$, both endowed with their usual norms. We also define the *even-odd* subspaces

$$X_{eo} = \left\{ u \in X_e : u\left(\frac{\pi}{2} - t\right) = -u\left(\frac{\pi}{2} + t\right) \right\}$$

and

$$Y_{eo} = \left\{ u \in Y_e : u\left(\frac{\pi}{2} - t\right) = -u\left(\frac{\pi}{2} + t\right) \right\}.$$

For a given subspace $S \subset Z \subset L^2(0,\pi)$ we define its orthogonal complement by $S^\perp = \{u \in Z : \int_0^{2\pi} u(t)s(t)dt = 0 \ \ \forall s \in S\}$. In this way we obtain a map $\mathcal{H} \in C^\omega(X_e \times \mathbb{R}^2, Y_e \times \mathbb{R})$, and if F is even, then $\mathcal{H}$ also provides a map $\mathcal{H} \in C^\omega(X_{eo} \times \mathbb{R}^2, Y_{eo} \times \mathbb{R})$.

3.2. Simple bifurcation from $p = 2$. The following theorem shows that the zero-Hamiltonian problem associated with (1.1) has a simple bifurcation point to a locally unique and smooth branch of solutions from the point $p = 2$.

THEOREM 3.1. *Suppose that assumption* (**F**) *holds. Then there is an interval* $I \subset \mathbb{R}$ *and a unique analytic branch* $\beta \mapsto (u(\beta), p(\beta)) \in X_e \times \mathbb{R}$ *defined on* I *of nontrivial even periodic solutions of* (1.1) *with* zero Hamiltonian *and period* $T(\beta)$. *Moreover,* $u(\beta) \neq 0$ *if* $\beta \neq 0$,

$$T(0) = 2\pi, \ u(0) = 0, \ p(0) = 2, \text{ and } \|u(\beta)(t) - \beta\cos(t)\|_{C^4} = O(\beta^2)$$

as $\beta \to 0$. *If* F *is even, then the function* $t \mapsto u(\beta)(t)$ *is an element of* X_{eo} *for all* $\beta \in I$.

Proof. To prove this result we apply Theorem 2.2 to $\mathcal{H}(u, p, \mu) = 0$ with $X = X_e$ and $Y = Y_e$. Let $L(p,\mu)[a] \equiv d_u M(0,p,\mu)[a] = \mu^4 a'''' + p\mu^2 a'' + a$, and note that the bilinear form $\psi(d^2_{uu} g(0,p,\mu)[a,b])$ from Theorem 2.2 is given by

$$B(p,\mu)[a,b] = \delta\left(\mu^4(a'b''' + a'b''' - a''b'') + p\mu^2 a'b' + ab\right).$$

In order to verify the hypotheses of Theorem 2.2 let us seek a nonzero solution $a \in X_e$ to $L(p,\mu)a = 0$, that is,

$$\mu^4 a'''' + p\mu^2 a'' + a = 0, \quad \delta\left(\mu^4(2a'a''' - (a'')^2) + p\mu^2(a')^2 + a^2\right) = 0.$$

Since a is even and of period 2π, we seek solutions of the form $a(t) = \cos(mt)$, where m is an integer. This provides the equations $\alpha^4 - p\alpha^2 + 1 = 0, -\alpha^4 + 1 = 0$, where $\alpha = \mu m$, whence $\alpha^2 = 1$, so that $p = 2$ and $\mu = 1/m$. Seeking the solution of minimal period, we may set $m = 1$ and thus define $k(t) \equiv \cos(t)$ and record the fact that $\ker(L(2,1)) = \langle k \rangle$. Let us also define $K \equiv k$ for the purposes of Theorem 2.2 and note for the moment that k is an *even-odd* function.

We now form the decompositions $X_e = \langle k \rangle \oplus \langle k \rangle^\perp$ and $Y_e = \langle k \rangle \oplus \langle k \rangle^\perp$, so that $U = \langle k \rangle^\perp \subset X_e$ and $V = \langle k \rangle^\perp \subset Y_e$ in accordance with Theorem 2.2, and define the projection $Q : L^2(0, 2\pi) \to \mathbb{R}$ by

$$(Qu)(t) = \frac{1}{\pi}\int_0^{2\pi} u(t)k(t)dx, \quad u \in L^2(0, 2\pi),$$

and let $P = I - k \cdot Q$. Now, $\psi(d^3_{uup} g(0,p,\mu)[a,b,1]) = B_p(p,\mu)[a,b] = \delta(\mu^2 a'b')$, $d^3_{uu\mu} g(0,p,\mu)[a,b] = \delta(4\mu^3(a'b''' + a'b''' - a''b'') + 2p\mu a'b')$, and $d^2_{u\mu} M(0,p,\mu)[a] =$

$L_\mu(p,\mu)[a] = 4\mu^3 a'''' + 2p\mu a''$. Finally, $d^2_{up}M(0,p,\mu)[a,1] = \mu^2 a''$. Thus the remaining hypothesis of Theorem 2.2 is satisfied if the operator matrix D is nonsingular. On inspection of the relevant derivatives we find

$$D = \begin{pmatrix} P \circ L(2,1) & 0 & 0 \\ 0 & -1 & 0 \\ * & 0 & -4 \end{pmatrix} \in BL(U \times \mathbb{R}^2, V \times \mathbb{R}^2),$$

where $P \circ L(2,1) : U \to V$ is an isomorphism and $*$ is irrelevant to the calculation at hand. It follows that D is an isomorphism, and the result follows.

The second part of the theorem is proven in exactly the same way, simply observing the change of space, using X_{eo} rather than X_e. The uniqueness of the bifurcating branch in both X_e and X_{eo}, and the fact that $X_{eo} \subset X_e$, implies that $u(\beta) \in X_{eo}$ if F is even. □

Remark 1. In order to demonstrate that the application of Theorem 2.2 is not limited to fourth-order problems, we present the following example. In [33] the authors study the problem of finding periodic solutions for sixth-order problems using a variational approach, of which

$$u^{vi} + 5u^{iv} + pu'' + u - u^3 = 0 \tag{3.3}$$

is an example (see also [10]). Equation (3.3) has Hamiltonian

$$H \equiv \frac{1}{2}(u''')^2 + u^v u' - u^{iv}u'' + 5\left(u'u''' - \frac{1}{2}(u'')^2\right) + \frac{p}{2}(u')^2 + \frac{1}{2}u^2 - \frac{1}{4}u^4. \tag{3.4}$$

THEOREM 3.2. *The points* $(u,p) = (0, 4\frac{1}{4})$ *and* $(0, 1+4\sqrt{2})$ *are simple bifurcation points to even periodic solutions of* (3.3) *with zero Hamiltonian and with period near* $2\pi\sqrt{2}$ *and* $2\pi/\sqrt{1+\sqrt{2}}$, *respectively.*

The proof of Theorem 3.2 is very similar to that of Theorem 3.1, and so we omit it; note that the existence of a locally two-dimensional manifold of positive and negative Hamiltonian solutions also follows from Theorem 2.3.

3.3. Double bifurcations from $p > 2$. The following result shows that the interval $[2,\infty)$ contains a dense set of bifurcation points for (3.1)–(3.2).

THEOREM 3.3. *Suppose that assumption* (**F**) *holds. Then to each* $n, m \in \mathbb{N}$ *such that* $n \geq m+1$ *and* $\gcd(n,m) = 1$ *there is an interval* $I \subset \mathbb{R}$ *and exactly two analytic branches* $\beta \mapsto (u_\pm(\beta), p_\pm(\beta)) \in X_e \times \mathbb{R}$ *defined on* I *of even periodic solutions of* (1.1) *with zero Hamiltonian and period* $T_\pm(\beta)$. *Moreover,* $u_\pm(\beta) \neq 0$ *for* $\beta \neq 0$,

$$T_\pm(0) = 2\pi\sqrt{nm}, \quad u_\pm(0) = 0, \quad p_\pm(0) = \frac{n}{m} + \frac{m}{n},$$

and

$$\|u_\pm(\beta)(t) - \beta\left(m\cos(nt) \pm n\cos(mt)\right)\|_{C^4} = O(\beta^2)$$

as $\beta \to 0$.

Proof. Let us apply Theorem 2.4 to $\mathcal{H}(u,p,\mu) = 0$; to identify the functions k_1 and k_2 from Theorem 2.4, we consider the linearized problem

$$L(p,\mu)[a] \equiv \mu^4 a'''' + p\mu^2 a'' + a = 0$$

of (3.1) with $a \in X_e$. This linear equation admits an even 2π-periodic solution of the form $a(t) = \lambda_1 \cos(mt) + \lambda_2 \cos(nt)$ with integer m and n, provided that $\alpha_1 = (\mu m)^2$ and $\alpha_2 = (\mu n)^2$ both satisfy the equation $\alpha^2 - p\alpha + 1 = 0$. From this we obtain $\alpha_1\alpha_2 = 1$, so that $\mu = \mu_{n,m} \equiv \frac{1}{\sqrt{nm}}$ and $p = \alpha_1 + \alpha_2$, whence $p = p_{n,m} \equiv \frac{n}{m} + \frac{m}{n}$.

Hence we define $k_1(t) \equiv \cos(nt), k_2(t) \equiv \cos(mt)$, and $u_1 \equiv k_1, u_2 \equiv k_2$. Moreover, using $\psi(d^2_{uu} g(0, p_{n,m}, \mu_{n,m})[a, b]) = \delta(-\mu^4_{n,m} a''b'' + ab)$, we have

$$A = \frac{(n^2 - m^2)}{n^2}, \quad B = 0, \quad \text{and } C = -A,$$

so that $\alpha_\pm = \pm\frac{n}{m}$ in the notation of Theorem 2.4. With $Q_i(v) = \frac{1}{\pi}\int_0^{2\pi} v(t)u_i(t)dt$ for $i = 1, 2$, we find $d^2_{up}M(0, p_{n,m}, \mu_{n,m})[a, 1] = \mu^2_{n,m}a''$ and $d^2_{u\mu}M(0, p_{n,m}, \mu_{n,m})[a, 1] = 4\mu^3_{n,m}a'''' + 2p_{n,m}\mu_{n,m}a''$. We then evaluate the determinant from Theorem 2.4, which is $-4\mu^5_{n,m}\alpha_\pm n^2m^2(m^2 - n^2)$, and the result now follows since this is nonzero. ∎

If F is even, then all the bifurcations which occur for $p \geq 2$ are pitchforks because u is then a solution of (3.1)–(3.2) if and only if $-u$ is. The uniqueness properties of Theorems 2.2 and 2.4 and symmetry then imply that the parameterization of the solution branch satisfies $-u(\beta) = u(-\beta)$. From this we infer that the bifurcation diagram of $\|u(\beta)\|$ (with any suitable norm) plotted against $p(\beta)$ has a tongue-like appearance because of the density of the union of $p_{n,m}$ in $[2, \infty)$.

Remark 2. Theorem 3.3 was essentially known some time ago and can be found in an unpublished letter by J. F. Toland (1992), as referred to in [9, equation (5.1), p. 2486] for the case $F_u(u) = u - u^2$. This letter was communicated to the present authors by A. R. Champneys, and we express our gratitude for his help in this matter. A singularly perturbed version of (1.1) for this choice of nonlinearity was studied in [15] and more recently in [16], where the authors consider both homoclinic and periodic solutions, although the latter are not of zero Hamiltonian; see also [23].

As an aside, consider the equation

$$\frac{1}{12}v^{iv} + v'' + pv + v^3 + \frac{3}{4}v(vv'' + (v')^2), \tag{3.5}$$

taken from [21], with first integral

$$H \equiv \frac{1}{12}\left(v'''v' - \frac{1}{2}(v'')^2\right) + \frac{1}{2}(v')^2 + \frac{p}{2}v^2 + \frac{v^4}{4} + \frac{3}{8}(v')^2v^2. \tag{3.6}$$

Note that a parameter λ^2 appearing in [21] has been replaced here by p. This is not in the class of Hamiltonian systems given by (1.1), but Theorems 2.2 and 2.4 are still applicable.

THEOREM 3.4. *The point $p = 3$ is a simple bifurcation point to even periodic solutions of* (3.5) *with zero first integral and with period near $\pi\sqrt{2/3}$. For each $n, m \in \mathbb{N}$ such that $n > m$ and $\gcd(n, m) = 1$, the point $p_{n,m} = 12(\frac{n}{m} + \frac{m}{n})^{-2}$ is a double bifurcation point to such solutions with period near $\pi\sqrt{(n^2 + m^2)/3}$.*

The proof of Theorem 3.4 is an application of Theorem 2.4, which is entirely analogous to the proof of Theorem 3.3, so we omit the details.

3.4. Odd solutions for even *F*. Now let us suppose that F is an even function. If we define the spaces of odd functions, $X_o = \{u \in C^4_{2\pi} : u(t) = -u(-t)\}$ and $Y_o = \{u \in C^0_{2\pi} : u(t) = -u(-t)\}$, then $\mathcal{H}$ provides a map $\mathcal{H} \in C^\omega(X_o \times \mathbb{R}^2, Y_o \times \mathbb{R})$. This means that one can obtain odd zero-Hamiltonian solutions of (1.1) in a manner entirely

analogous to the way we found the even solutions. For this reason we give the following theorem without proof.

THEOREM 3.5. *If assumption* (**F**) *holds and F is even, then to each $n, m \in \mathbb{N}$ such that $n \geq m+1$ and $\gcd(n,m) = 1$ there is an interval $I \subset \mathbb{R}$ and exactly two analytic branches $\beta \mapsto (u_\pm(\beta), p_\pm(\beta)) \in X_e \times \mathbb{R}$ defined on I of odd periodic solutions of* (1.1) *with zero Hamiltonian and period $T_\pm(\beta) = 2\pi/\mu_\pm(\beta)$. Moreover, $u_p m(\beta) \neq 0$ for $\beta \neq 0$,*

$$T_\pm(0) = 2\pi\sqrt{nm}, \quad u_\pm(0) = 0, \quad p_\pm(0) = \frac{n}{m} + \frac{m}{n},$$

and

$$\|u_\pm(\beta)(t) - \beta\left(m\sin(nt) \pm n\sin(mt)\right)\|_{C^4} = O(\beta^2)$$

as $\beta \to 0$.

Of course, there is little point in formulating a version of Theorem 3.1 in this context, since that theorem already tells us that a branch of odd solutions of (1.1) can be found by shifting time.

It is possible to formulate an extension of the results proven in this section by considering a smooth one-parameter family of reversible vector fields on $\mathbb{R}^n$ which possesses a trivial branch of equilibrium solutions and a first integral. One could use Theorems 2.2 and 2.4 to formulate sufficient conditions for the bifurcation of zero-energy symmetric periodic solutions. However, for brevity we have not done this, and we restrict our attention to the properties of fourth-order systems.

3.5. Disjointness properties of solution sets. Motivated by Theorems 3.1 and 3.3, we define the following nonempty sets, assuming (**F**) to be true. Let

$$\Sigma \equiv \{(u,p,\mu) \in X_e \times \mathbb{R} \times \mathbb{R} : \mathcal{H}(u,p,\mu) = 0, u \neq 0, \mu > 0\}, \tag{3.7}$$

and let $\overline{\Sigma}$ denote the closure of Σ in $X_e \times \mathbb{R}^2$. For any pair $(n,m) \in \mathbb{N} \times \mathbb{N}$ such that $\gcd(n,m) = 1$, let $C(n,m)$ be the maximal connected subset of $\overline{\Sigma}$ which contains the point $(u,p,\mu) = (0, p_{n,m}, \mu_{n,m})$, and define the functional $\nu : \Sigma \to (2,\infty)$ by

$$\nu(u,p,\mu) = \|u\|_{C^4} + |p| + |\mu| + \frac{1}{|\mu|}. \tag{3.8}$$

Also, let

$$\Sigma_+ = \{(u,p,\mu) \in \Sigma : p > 0\}, \tag{3.9}$$

$\overline{\Sigma}_+$ be the closure of Σ_+, and $C_+(n,m)$ be the maximal connected subset of $C(n,m) \cap \overline{\Sigma}_+$ which contains the point $(u,p,\mu) = (0, p_{n,m}, \mu_{n,m})$.

We continue with a simple lemma which is used in the subsequent analysis. Throughout this section, # is used to represent the cardinality of a set, and we introduce a *potential* $V(u,u'')$ by writing (3.2) as

$$-\mu^2 u'\left(\mu^2 u''' + \frac{p}{2}u'\right) = V(u,u'') \equiv -\frac{1}{2}\mu^4 u''^2 + F(u).$$

LEMMA 3.1. *Suppose that $n, m \geq 1$ are distinct integers; then $\#\{t \in [0,\pi] : n\cos(nt) \pm m\cos(mt) = 0\} = \max(n,m)$ and $\#\{t \in [0,\pi] : m\cos(nt) \pm n\cos(mt) = 0\} = \min(n,m)$.*

The following two theorems provide bifurcation invariants that are invaluable to the study of the global nature of Σ.

THEOREM 3.6. *If assumption* (**F**) *holds and* $F(u) > 0$ *for* $u \neq 0$, *then the mapping*

$$\iota_1 : \Sigma \to \mathbb{N}; (u, p, \mu) \mapsto \#\{t \in [0, \pi] : u(t) = 0\}$$

is continuous and satisfies $\iota_1(C(n,m)\backslash\{(0, p_{n,m}, \mu_{n,m})\}) \equiv \min(n, m)$.

We postpone the proof of this theorem until after the following preliminary lemma.

LEMMA 3.2. *Let* $(u_k, p_k, \mu_k) \subset \Sigma$ *be a sequence with* $(u_k, p_k, \mu_k) \to (u, p, \mu) \in \Sigma$, *and suppose that there is a pair of sequences* $(t_k^1), (t_k^2) \subset [0, 2\pi]$ *such that* $|t_k^1 - t_k^2| \to 0$ *and* $u_k'(t_k^{1,2}) = 0$. *Then* $u_k(t_k^1)u_k(t_k^2) > 0$ *for sufficiently large* k.

Proof. For definiteness we assume that $t_k^1 < t_k^2$ and, seeking a contradiction, we also assume that $u_k(t_k^1)u_k(t_k^2) \leq 0$; we initially also assume that $u_k(t_k^1) < 0 < u_k(t_k^2)$. By the mean-value theorem there is a $T_k \in (t_k^1, t_k^2)$ such that $u_k''(T_k) = 0$, and taking the limit $k \to \infty$ gives the existence of a T such that $u'(T) = u''(T) = 0$. Using (3.2) yields $F(u(T)) = 0$ and therefore $u(T) = 0$, and since u is not identically zero, it follows that $u'''(T) \neq 0$.

We now assume without the loss of any generality that $\|u_k\|_{C^4} \leq \|u\|_{C^4} + 1 \equiv B$ and that $\frac{1}{2}\mu \leq \mu_k \leq \frac{3}{2}\mu$. By the smoothness of F and since $F(0) = F_u(0) = 0$, we may assume that there is a C such that

$$|F(w)| \leq \frac{C^2}{2}|w|^2 \quad \text{if } |w| \leq B.$$

Since $u_k'(t_k^{1,2}) = 0$, we have $V(u_k, u_k'') = -\frac{1}{2}\mu_k^4(u_k'')^2 + F(u_k) = 0$ at $t_k^{1,2}$, and therefore

$$|u_k''| \leq \frac{C}{\mu_k^2}|u_k| \leq \frac{4C}{\mu^2}|u_k| \quad \text{at } t_k^{1,2}. \tag{3.10}$$

If we define the function $v(t) = V(u_k(t), u_k''(t))$, then the mean-value theorem gives the existence of a $\tau_k \in (t_k^1, t_k^2)$ with $v'(\tau_k) = 0$. From (3.10), the orbit of u_k is a smooth curve in the u, u''-plane that connects $(u_k, u_k'')(t_k^1)$ (in the left half-plane) to $(u_k, u_k'')(t^2)$ (in the right half-plane) with end-points in the region $\{(u, u'') : |u''| \leq \frac{4C}{\mu^2}|u|\}$. By considering the tangent vector (u', u''') of this planar curve, it follows that there is a $\hat{\tau}_k \in (t_k^1, t_k^2)$ such that

$$|u_k'''(\hat{\tau}_k)| \leq \frac{4C}{\mu^2}|u_k'(\hat{\tau}_k)|. \tag{3.11}$$

When we take the limit $k \to \infty$, it follows from the estimate

$$\sup_{(t_k^1, t_k^2)} |u_k'| \leq |t_k^2 - t_k^1| \sup_{(t_k^1, t_k^2)} |u_k''|$$

that $u_k'''(\hat{\tau}_k) \to 0$. We therefore find that the limiting solution u satisfies $u'''(T) = 0$, which is a contradiction.

If the signs of u_k at $t_k^{1,2}$ are inverted, so that $u_k(t_k^2) < 0 < u_k(t_k^1)$, then the argument given above holds unchanged. If exactly one of the two values $u_k(t_k^{1,2})$ is zero for all k, then the argument holds in a similar way: in this case the curve in the u, u''-plane connects the origin to the other point. The existence of $\hat{\tau}_k$ satisfying (3.11)

follows as before. If both of the values of u_k are zero, then the curve is closed, and again a value of $\hat{\tau}_k$ can be found satisfying (3.11). This concludes the proof of the lemma. ∎

Proof of Theorem 3.6. Suppose that $(u,p,\mu) \in \Sigma$ and that $(u_k,p_k,\mu_k) \subset \Sigma$ satisfies $(u_k,p_k,\mu_k) \to (u,p,\mu)$ in $C^4 \times \mathbb{R}^2$.

We first note that if four or more zeros of u_k collide (counted according to algebraic multiplicity), say $0 \le t_k^1 \le t_k^2 \le t_k^3 \le t_k^4 \le 2\pi$ are all zeros of u_k that converge to T, then from the mean-value theorem we have $u(T) = u'(T) = u''(T) = u'''(T) = 0$, contradicting the assumption that $u \neq 0$.

On the other hand, if two or more zeros collide, then from the mean-value theorem again there is a T such that $u'(T) = 0$ and therefore $u''(T) = 0$ by (3.2). In order to avoid the same contradiction as above, necessarily $u'''(T) \neq 0$. This implies that the zero of u at $t = T$ is topologically transverse, which rules out the possibility that two transverse zeros coalesce.

We therefore are left with two cases: either three simple zeros collide or two zeros collide of which one is a double zero. In the first case, three simple zeros, there exist $t_k^{1,2}$ such that $u_k'(t_k^{1,2}) = 0$ and $t_k^{1,2} \to T$ as $k \to \infty$, and since the zeros are transverse, we can assume that u_k has opposite signs at t_k^1 and t_k^2. The conclusions of Lemma 3.2 show that this situation leads to a contradiction. In the second case we choose t_k^1 to be the nonsimple zero, and $\tau_k \in (t_k^1, t_k^2)$ to be an intermediate point such that $u'(\tau_k) = 0$. Again an application of Lemma 3.2 leads to a contradiction, and therefore the number of zeros of u_k eventually equals that of u. This shows that ι_1 is continuous on Σ and therefore constant on connected components of Σ.

In order to evaluate $\iota_1(u,p,\mu)$ for $(u,p,\mu) \in C(n,m)$ with $u \neq 0$ we use the representation of $C(n,m)$ at bifurcation given in Theorem 3.3. From Lemma 3.1 there results

$$\|u_\pm(\beta)(t) - \beta\,(m\cos(nt) \pm n\cos(mt))\,\|_{C^4} = O(\beta^2),$$

and hence $\#\{t \in [0,\pi] : u_\pm(\beta)(t) = 0\} = \min(n,m)$ follows for sufficiently small and nonzero β, and the theorem is proven. ∎

THEOREM 3.7. *If assumption* (**F**) *holds and* $F(u) > 0$ *for* $u \neq 0$*, then the mapping*

$$\iota_2 : \Sigma_+ \to \mathbb{N}; (u,p,\mu) \mapsto \#\{t \in [0,\pi] : u''(t) = 0\}$$

is continuous.

Proof. Let $(u,p,\mu) \in \Sigma_+$, and suppose that there is a $T \in [0,2\pi]$ such that

$$u''(T) = u'''(T) = 0.$$

The zero-Hamiltonian condition (3.2) then gives

$$\frac{1}{2}p\mu^2 u'(T)^2 + F(u(T)) = 0,$$

and the hypotheses on F ensure that $u'(T) = 0$ and $u(T) = 0$. It follows that $u = 0$, which contradicts the definition of Σ_+, and this contradiction implies that the zeros of u'' are transverse. Consequently, if $(u_n,p_n,\mu_n) \subset \Sigma_+$ is a sequence such that $(u_n,p_n,\mu_n) \to (u,p,\mu)$ in Σ_+, then $u_n'' \to u''$ in the C^1 topology. Hence u_n'' has the same number of zeros as u'' for all sufficiently large n, which shows that ι_2 is continuous as claimed. ∎

Theorem 3.7 immediately implies that ι_2 is constant on connected components of Σ_+, and from this observation we deduce the following.

COROLLARY 3.1. *Suppose that* (**F**) *holds and* $uF_u(u) \geq 0$ *for all* $u \in \mathbb{R}$*; then* $\Sigma_+ = \Sigma$*, and as a consequence,* $C_+(n,m) = C(n,m)$*. Moreover,*

$$\iota_2(C(n,m)\backslash\{(0,p_{n,m},\mu_{n,m})\}) = \max(n,m),$$

so that $C(n,m) \cap C(n',m')$ *is empty unless* $(n,m) = (n',m')$*.*

Proof. Multiplying (3.1) by u and integrating gives

$$p\mu^2 \int_0^{2\pi} (u')^2 dt = \int_0^{2\pi} \mu^4 (u'')^2 + uF_u(u) dt \geq \int_0^{2\pi} \mu^4 (u'')^2 dt \geq 0.$$

Hence if there is a solution of (3.1)–(3.2) with $p = 0$ and $\mu > 0$, it follows that $u'' \equiv 0$, so $u(t) = At + B$ for constants A and B. As u is periodic, $A = 0$, and as u must have zero Hamiltonian, $F(B) = 0$ is also true. The hypotheses ensure that $F(u) = 0$ only when $u = 0$ so that $B = 0$; hence $u(t) \equiv 0$ and so $\Sigma = \Sigma_+$, from which $C(n,m) = C_+(n,m)$ by definition.

Since $\iota_2 : \Sigma \to \mathbb{N}$ is continuous by Theorem 3.7, the set $\mathcal{C}$ defined by $\mathcal{C} \equiv C(n,m)\backslash\{(0,p_{n,m},\mu_{n,m})\}$ is a connected subset of Σ, because the intersection of $C(n,m)$ with some small ball, $C(n,m) \cap B_\delta(0,p_{n,m},\mu_{n,m})$, is path-connected for all sufficiently small $\delta > 0$. Hence ι_2 is constant on $\mathcal{C}$. In order to evaluate $\iota_2(u,p,\mu)$ with $(u,p,\mu) \in \mathcal{C}$ we use the representation of $C_+(n,m)$ at bifurcation from the trivial solution described in Theorem 3.3 and then apply Lemma 3.1. From Theorem 3.3 we have

$$\| u''_\pm(\beta)(t) + \beta mn \left(n\cos(nt) \pm m\cos(mt)\right) \|_{C^2} = O(\beta^2),$$

whence $\#\{t \in [0,\pi] : u''_\pm(\beta)(t) = 0\} = \max(n,m)$ follows for sufficiently small and nonzero β.

Finally, as (**F**) ensures that F is positive in a punctured neighborhood of zero, the condition $uF_u(u) \geq 0$ then ensures that $F(u) > 0$ if $u \neq 0$. Applying Theorem 3.6, we obtain $\iota_j(C(n,m)) = \iota_j(C(n',m'))$ for $j = 1,2$, and the last part of the corollary follows. ∎

Finally, we have the following theorem, which applies to *path-connected subsets* of Σ, although it provides no information regarding the behavior of *connected subsets* of Σ which are not path-connected.

THEOREM 3.8. *Suppose that* $F(u) > 0$ *for* $u \neq 0$*, and let* (u_s, p_s) *be a continuous path of solutions of* (1.1)*, where each* u_s *is defined on a sufficiently large subset of* $\mathbb{R}$ *and the path does not contain the equilibrium solution. If two zeros of* u'_s *collide, then multiplicity is preserved in and through the collision.*

Proof. We may assume that all collisions occur at $s = 0$ and $t = 0$. Note that if all u_s are defined on a common interval $I \subset \mathbb{R}$, then by standard elliptic estimates the solution curve is bounded in $C^k(I')$ for any $k \in \mathbb{N}$ and any compact interval $I' \subset I$. Since F is smooth, we can bound F by

$$|F(w)| \leq \frac{C^2 w^2}{2} \tag{3.12}$$

for, say, $|w| \leq 1$.

Note that $u'(0) = u''(0) = 0$ at $s = 0$, and therefore by (1.2), $F(u(0)) = 0$, which implies $u(0) = 0$. The nonconstancy hypothesis on each u_s implies that $u'''(0) \neq 0$.

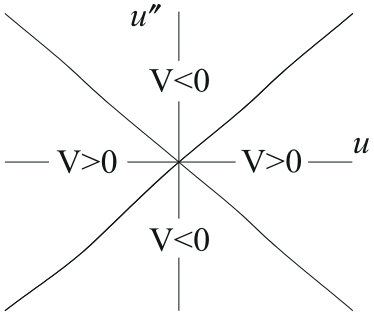

FIG. 3.1. *The configuration space u, u'' is partitioned according to the sign of V.*

This proves that multiplicity is conserved *in* the collision. Note that the zero at $(t, s) = (0, 0)$ is necessarily transverse.

To show that any subsequent perturbation preserves the multiplicity, we use some ideas from the analysis of the *configuration space* (u, u'') from [34, 17]; [29] contains a simplified description that is sufficient for our purposes. The structure of the configuration space and the set $\{V = 0\}$ is shown in Figure 3.1. Near the origin in this plane the set $\{V = 0\}$ consists of two curves that intersect in the origin. Near the origin the direction of these curves is bounded from above by $2C$, where C is the constant in (3.12).

At $s = 0$, we have $u(0) = u'(0) = u''(0)$, $u'''(0) \neq 0$, and therefore the orbit near $t = 0$ is represented in the u, u''-plane by a curve that remains inside the set $\{V \leq 0\}$ and intersects $\{V = 0\}$. We can choose appropriate translations of u_s, and small $\bar{t}, \bar{s} > 0$, such that we have the following:

1. $u_s(t)$ is defined for $(t, s) \in Q \equiv (-\bar{t}, \bar{t}) \times (-\bar{s}, \bar{s})$.
2. u_s depends smoothly on s in $C^4(-\bar{t}, \bar{t})$.
3. $u_s'''(t) \geq 0$ on Q (if not, then reverse time).
4. For each $s \in (-\bar{s}, \bar{s})$ we have $\pm u_s''(\pm\bar{t}) < 0$, and $V(u_s(\pm\bar{t}), u_s''(\pm\bar{t})) < 0$. This implies that no intersections of the solutions with $\{V = 0\}$ appear or disappear through the boundary $\pm\bar{t}$.
5. $u_s'''/u_s' \geq 4C$ on Q, where C is the constant in (3.12).

We write $\gamma_s \equiv \{(u_s(t), u_s''(t)) : -\bar{t} < t < \bar{t}\}$.

We now consider the alternatives for perturbation away from $s = 0$. First assume that $\bar{s}$ can be chosen such that $\gamma_s \cap \{V = 0\}$ has only one intersection for $0 < s < \bar{s}$; let this intersection be at $0 < t_s < \bar{s}$. The lower bound on the angle of the curve γ_s, given by condition 5 above, implies that γ_s intersects $\{V = 0\}$ only at the origin in the u, u''-plane. Since $u_0'(0) = 0$ and $u_0'''(0) \neq 0$, the smooth dependence of u_s on s implies that $u_s'''(t_s) \neq 0$ for s close to zero; therefore the requirement $u'(t_s)(u_s'''(t_s) + pu_s'(t_s)/2) = 0$ forces $u_s'(t_s) = 0$. Combining this with $u_s(t_s) = 0$ and taking the limit yields that the zero of u' at $s = 0$ is a double zero.

To cover the alternative case we assume that $\gamma_s \cap \{V = 0\}$ has at least two intersections for a sequence $0 < s_n < \bar{s}$, $s_n \downarrow 0$, at the points $0 < t_n < \tau_n < \bar{t}$. We have $\lim_{n\to\infty} t_n = \lim_{n\to\infty} \tau_n = 0$. With an argument similar to the one above, it follows that $u_{s_n}'(t_n) = u_{s_n}'(\tau_n) = 0$, and therefore the zero at $s = 0$ is of second order.

At any point where the orbit intersects $\{V = 0\}$, either $u' = 0$ or $u''' = -pu'/2$. Since at $s = 0$ we have $u' = 0$ and $u''' \neq 0$, under perturbation of s we have $u' = 0$ on the intersection of the orbit with $\{V = 0\}$. If we assume that under perturbation

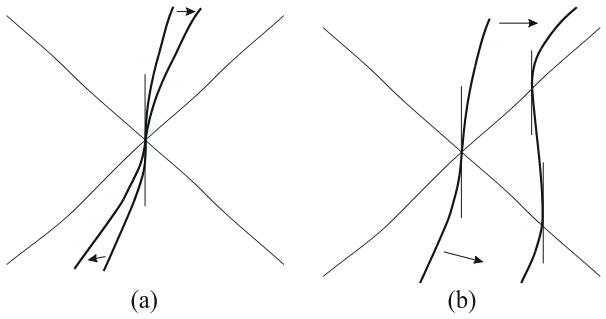

FIG. 3.2. *Two forms of perturbation:* (a) *if the curve continues to intersect* $\{V = 0\}$ *in the origin, then the tangent remains vertical;* (b) *a translation, on the other hand, creates new zeros of* u' *and therefore also conserves multiplicity.*

there is only one zero of u' (locally), then the intersection with $\{V = 0\}$ necessarily occurs at the origin in the u, u''-plane. Therefore the zero remains of multiplicity two.

Note that the only possible scenario is the reduction of multiplicity two to multiplicity zero. Multiplicity zero implies that while $u'(0) = 0$ at $s = 0$, this zero of u' disappears under perturbation. An inspection of the u, u''-plane (Figure 3.2) shows that such a perturbation is possible only if $u''' + pu'/2$, which is nonzero at $s = 0$, jumps to zero for $s \neq 0$. This contradicts the assumption of continuous dependence of the curve of solutions in C^k on the parameter s. □

4. Global bifurcations. Let us now briefly state some results from global real-analytic bifurcation theory for one-parameter problems as developed in [6]. The utility of this theory with respect to (2.1) is the fact that Lemma 2.1 identifies either p or μ which can be used as the bifurcation parameter. So, supposing that $\mathcal{U} \subset \mathbb{R} \times X$ is a given set and that $F : \mathbb{R} \times X \to Y$ is a real analytic map, define the set

$$S = \{(\lambda, x) \in \mathcal{U} : F(\lambda, x) = 0, d_x F(\lambda, x) \in \mathrm{Iso}(X, Y)\}.$$

Throughout this section the space $\mathbb{R} \times X$ is endowed with the norm $|\lambda| + \|x\|_X$, and a pair $(\lambda, x) \in S$ is said to be a regular solution of $F(\lambda, x) = 0$. While the theory developed in [6] is more powerful than we require, we shall use the following result, which is the statement of Theorem 7.4(iii) of this reference.

THEOREM 4.1. *Let* $\nu : \mathbb{R} \times X \to [0, \infty)$ *be a given function, and suppose that*

(i) S *is nonempty and* $\mathcal{U} \cap \mathcal{S}$ *is open in* $\mathcal{S}$, *where* $\mathcal{S} \equiv \{(\lambda, x) \in \mathbb{R} \times X : F(\lambda, x) = 0\}$,
(ii) $d_x F(\lambda, x)$ *is Fredholm of index zero for all* $(\lambda, x) \in \mathcal{U}$,
(iii) *subsets of* $\mathcal{S}$ *on which* ν *is bounded have compact closure,*
(iv) *there are* $\delta > 0, \lambda_0 \in \mathbb{R}$, *and an analytic function* $h : N_\delta(\lambda_0) \backslash \{\lambda_0\} \to S$, *where* $N_\delta(\lambda_0)$ *is a half-neighborhood of* λ_0, *such that* $\lim_{\lambda \to \lambda_0} h(\lambda) = 0$ *but* $(\lambda_0, 0) \notin \mathcal{U}$,
(v) *if* $\mathcal{A}_0$ *is the maximal path-connected subset of* S *which contains the graph of* h *and if* $(\xi_n) \subset \overline{S} \cap \mathcal{U}$ *is any convergent sequence with* $\xi_n \to \xi \notin \mathcal{U}$ *and* $\sup_n \nu(\xi_n) < \infty$, *then* $\xi = (\lambda_0, 0)$ *and* $\xi_n \in \mathcal{A}_0$ *for all* n *sufficiently large.*

Under conditions (i)–(v) *the maximal connected component of* $\overline{S} \cap \mathcal{U}$ *that contains* $\mathcal{A}_0$ *contains a path-connected subset* $\mathcal{P}$ *on which* ν *is unbounded.*

If we recall the definition of the sets Σ and Σ_+ in (3.7) and (3.9), respectively, then the reasoning in Corollary 3.1 ensures that $\Sigma_+ = \Sigma$ if $uF_u(u) \geq 0$ for all $u \in \mathbb{R}$.

From this observation we can obtain the following lemma.

LEMMA 4.1. *Suppose that* (**F**) *holds and* $uF_u(u) \geq 0$ *for* $u \in \mathbb{R}$*; then* $\nu(u,p,\mu)$ *(defined in* (3.8)*) is unbounded on a path-connected subset of* $C(1,1)$.

Proof. Let us verify the hypotheses of Theorem 4.1 in turn, where $\omega = \mu - 1, x = (u,\omega)$ and we write λ in place of p. To keep the notation consistent with Theorem 4.1, let $F \equiv M \times \psi(g)$ (the symbol $\mathcal{H}$ was used for this previously) and

$$\mathcal{U} \equiv \{(\lambda, x) = (p,u,\omega) \in \mathbb{R} \times X_e \times \mathbb{R} : \omega > -1, u \neq 0, \iota_1(u) = \iota_2(u) = 1\}.$$

We remark that $S \subset \Sigma \subset \mathcal{S},\ \mathcal{S} \cap \mathcal{U} \subset \Sigma$ and the space X referred to in Theorem 4.1 is $X_e \times \mathbb{R}$ and Y is $Y_e \times \mathbb{R}$.

(i) It follows from Lemma 2.1 that S is nonempty. (The argument assumes that $d_{u,p}(M \times \psi(g))$ is an isomorphism from Lemma 2.1, for if this is not the case, then we can repeat the argument of this proof using μ for λ rather than p.) One can see that the set $\mathcal{U} \cap \mathcal{S}$ is open in $\mathcal{S}$ as follows. Suppose, seeking a contradiction, that $\mathcal{U} \cap \mathcal{S}$ is not open in $\mathcal{S}$, so there is a $(\lambda_0, x_0) = (p_0, u_0, \omega_0) \in \mathcal{S} \cap \mathcal{U}$ and a sequence $(\lambda_n, x_n) = (p_n, u_n, \omega_n) \in \mathcal{S} \backslash \mathcal{U}$ such that $(\lambda_n, x_n) = (p_n, u_n, \omega_n) \to (\lambda_0, x_0) = (p_0, u_0, \omega_0)$.

Since $u_0 \neq 0$ and $u_n \overset{C^4}{\to} u_0$, it follows that $u_n \neq 0$, and as $\omega_0 > -1$, then $\omega_n > -1$, both for all sufficiently large n. Since ι_1 and ι_2 are continuous functions on Σ and Σ_+, respectively, and $\Sigma = \Sigma_+$ by the hypothesis on F, then $\iota_1(u_n) \to \iota_1(u_0) = 1$ as $n \to \infty$; but since ι_1 is integer-valued, this means that $\iota_1(u_n) \equiv 1$ for all n sufficiently large. Similar reasoning applies to ι_2. Consequently, $(\lambda_n, x_n) \in \mathcal{U}$ for all n sufficiently large, which is the required contradiction.

(ii) The operator $d_x F(\lambda, x)$ has the form

$$\begin{pmatrix} d_u M(u,p,\mu) & 0 \\ 0 & 0 \end{pmatrix} + K \in BL(X_e \times \mathbb{R}, Y_e \times \mathbb{R}),$$

where K is a continuous operator that has rank at most two and $d_u M(u,p,\mu)[h] = \mu^4 h'''' + p\mu^2 h'' + F_u(u)h \in BL(X_e, Y_e)$. However, the latter is a compact perturbation of the operator

$$E : h \mapsto \mu^4 h^{iv} + \theta h, \qquad E \in BL(X_e, Y_e).$$

Since $\mu > 0$, using a Fourier series argument, one can easily show that there is a θ such that E is an isomorphism of the given spaces. Consequently $d_x F(\lambda, x)$ is a compact perturbation of a Fredholm mapping of index zero, and therefore is itself Fredholm of index zero.

(iii) If $(u_n, p_n, \omega_n) \subset \mathcal{S}$ is a sequence such that $\omega_n = \mu_n - 1 > -1$ and

$$\nu(u_n, p_n, \mu_n) = \|u_n\|_{C^4} + |p_n| + |\omega_n + 1| + \frac{1}{|\omega_n + 1|}$$

is bounded, then there are p_0 and ω_0 such that $\omega_n \to \omega_0 \geq -1$ and $p_n \to p_0 \geq 0$. Now $\omega_0 \neq -1$ by the boundedness of ν, and therefore $u_n^v = -(\omega_n + 1)^{-4}(p_n(\omega_n + 1)^{-2} u_n''' + F_u(u_n)u_n')$ is also bounded, whence (u_n) converges to some $u_0 \in C^4$ as the embedding $C^5 \hookrightarrow C^4$ is compact, and therefore (p_n, u_n, ω_n) converges in $\mathbb{R} \times X_e \times \mathbb{R}$.

(iv) This part of the theorem follows from Theorem 2.2 and Lemma 2.1, where the bifurcating branch is represented by an analytic curve of regular solutions.

(v) If a ν-bounded sequence $(\xi_n) = (p_n, u_n, \omega_n) \subset \overline{S} \cap \mathcal{U}$ satisfies $\xi_n \to \xi = (p_0, u_0, \omega_0) \notin \mathcal{U}$, then the only viable possibility is that $u_0 = 0$, so that $(p, \mu) =$

$(p_0, \omega_0 + 1)$ is a bifurcation point from the trivial solution of (3.1)–(3.2). However, the *only* point at which such a bifurcation occurs in the set S is at the point $(u, p, \mu) = (0, 2, 1)$, so that $(u, \omega) = (0, 0)$. Hence property (v) is satisfied if $\mathcal{A}_0$ is defined to be the maximal path-connected subset of S which contains the graph of the bifurcating branch from Theorem 3.1. In this case let us note that $\lambda_0 = 2$.

This concludes the proof. □

Now define the functional on $X_e \times \mathbb{R}^2$ by

$$\overline{\nu}(u, p, \mu) = \|u\|_{C^4} + |p| + \frac{1}{|\mu|}.$$

In order to obtain a result analogous to the global Hopf bifurcation theorem of [1], we show that ν can actually become unbounded on $C(1,1)$ if and only if $\overline{\nu}$ is unbounded on $C(1,1)$.

THEOREM 4.2. *If* (**F**) *is satisfied and* $uF_u(u) \geq 0$, *then* $C(1,1)$ *contains a path-connected* $\overline{\nu}$*-unbounded subset.*

Proof. Suppose that ν is unbounded on $C(1,1)$ but that $\overline{\nu}$ is bounded on this set; it follows that there is a sequence $(u_n, p_n, \mu_n) \in C(1,1)$ such that $\|u_n\|_{C^4} + |p_n|$ is bounded, $u_n \neq 0$ for each n, and $|\mu_n| \to \infty$. However, since

$$\begin{aligned}\int_0^{2\pi} p\mu^2 (u'')^2 dt \geq \frac{1}{2\pi} \int_0^{2\pi} p\mu^2 (u')^2 &= \frac{1}{2\pi} \left(\int_0^{2\pi} \mu^4 (u'')^2 + uF_u(u) dt \right) \\ &\geq \frac{1}{2\pi} \int_0^{2\pi} \mu^4 (u'')^2 dt\end{aligned}$$

holds for any nontrivial solution in $C(1,1)$ by the Poincaré inequality, it follows that $\mu_n^2 \leq 2\pi p_n$, which is a contradiction. Therefore, by Lemma 4.1, ν is unbounded on a path-connected subset of $C(1,1)$, and the above contradiction implies that $\overline{\nu}$ must also be unbounded on this set. □

This theorem represents a partial global trichotomy for bifurcations of periodic orbits of (1.1), which says that the solution continuum $C(1,1)$ either has an unbounded sequence of orbits in phase-space or is unbounded with respect to either the parameter (p) or with the period (as occurs in the *blue-sky bifurcation* [13]). Unfortunately, due to assumption (v) of Theorem 4.1, it has not proven possible to use the same techniques to study the global existence properties of the branches $C(n,m)$ for $n > 1$.

5. Local secondary fold bifurcations. Another advantage of the approach taken in this paper as opposed to the shooting methods previously used in [35, 36] is that we can investigate the geometry of each bifurcating continuum by introducing an unfolding parameter, ϵ, into (3.1)–(3.2). We will now show that degeneracies present in (3.1)–(3.2) at $\epsilon = 0$ can unfold to give secondary fold bifurcations along the bifurcation branch when $\epsilon \neq 0$.

To illustrate this we shall consider (1.1) for the particular case given in (1.3). This has been studied in [19] (see also [12] for an asymptotic analysis of this problem using multiple scale techniques) as a model for an elastic rock layer on a *restiffening foundation*, with corresponding $\mathbb{Z}_2$-symmetric ODE

$$M_\epsilon(u, p, \mu) \equiv \mu^4 u'''' + p\mu^2 u'' + u - \epsilon(u^3 - u^5) \tag{5.1}$$

and even Hamiltonian

$$H_\epsilon(u, p, \mu) \equiv \mu^4 u' u''' - \frac{1}{2}\mu^4 u''^2 + \frac{1}{2} p\mu^2 u'^2 + \frac{1}{2}u^2 - \epsilon\left(\frac{1}{4}u^4 - \frac{1}{6}u^6\right). \tag{5.2}$$

As in the proof of Theorem 2.2, and therefore also in Theorem 3.1, we can obtain a local representation of the bifurcating branch of the zero-Hamiltonian problem associated with (5.1) from the bifurcation point $p = 2$ in the form $u_\epsilon(\beta) = \beta(k + \rho_\epsilon(\beta))$, where $\rho_\epsilon(\beta) = O(\beta)$ for fixed ϵ and is an analytic function of both β and ϵ near $(\beta, \epsilon) = (0, 0)$; here $k(t) = \cos(t)$. We now proceed with a calculation to find the Taylor expansion of $\rho_\epsilon(\beta)$ in order to determine the local geometry of the set of branches $C_\epsilon(1, 1)$. Throughout this section we shall write

$$r_\epsilon(\beta) = \beta\rho_\epsilon(\beta).$$

It is important to note that the existence of bifurcating solutions for this problem close to $p = 2$, as determined by Theorem 3.1, does not depend upon the value of ϵ. Indeed, using the implicit function theorem we simply find that for each ϵ sufficiently small and for suitable m, n, there is a bifurcating branch from $(p, \mu) = (p_{n,m}, \mu_{n,m})$ and this branch (that is, the local parametric representation of this branch) varies analytically with ϵ. This property also holds at $\epsilon = 0$, where the branches are pairs of lines. We also note that since $F_\epsilon(u)$ is an even function of u for each ϵ, $r_\epsilon(\cdot)$ is odd and $p_\epsilon(\cdot)$ and $\mu_\epsilon(\cdot)$ are even functions, forming a pitchfork bifurcation at $p = 2$.

We start our analysis by listing the Fréchet derivatives of the operator M_ϵ:

D1. $d_u M_\epsilon(u, p, \mu)[h] = \mu^4 h'''' + p\mu^2 h'' + h - \epsilon(3u^2 - 5u^4)h$,
D2. $d_u^2 M_\epsilon(u, p, \mu)[h_1, h_2] = -\epsilon h_1 h_2(6u - 20u^3)$,
D3. $d_u^3 M_\epsilon(u, p, \mu)[h_1, h_2, h_3] = -\epsilon h_1 h_2 h_3(6 - 60u^2)$,
D4. $d_u^4 M_\epsilon(u, p, \mu)[h_1, h_2, h_3, h_4] = 120\epsilon v h_1 h_2 h_3 h_4$,
D5. $d_u^5 M_\epsilon(u, p, \mu)[h_1, h_2, h_3, h_4, h_5] = 120\epsilon h_1 h_2 h_3 h_4 h_5$,

where $h_i \in X_e$ for each $i = 1, \ldots, 5$.

We denote the first derivative of $M_\epsilon(u, p, \mu)$ evaluated on the trivial solution branch $u = 0$ by $L \equiv d_u M_\epsilon(0, 2, 1)$; this operator is independent of ϵ. Suppose further that P is the projection of Y_e onto $\mathrm{ran}(L) = \langle k \rangle^\perp$ along $\langle k \rangle$; now define

$$L(p, \mu) \equiv d_u M_\epsilon(0, p, \mu).$$

We can solve the projected differential equation $P \circ N_\epsilon(\beta k + r, p, \mu) = 0$ for some function $r = r_\epsilon(\beta, p, \mu)$ near $(\beta, p, \mu, \epsilon) = (0, 2, 1; 0)$ using the implicit function theorem (we refer to the proof of Theorem 2.2 for details). From the uniqueness properties of the implicit function theorem if follows that $r_\epsilon(0, p, \mu) \equiv 0$, and if we repeatedly differentiate the identity $PM_\epsilon(\beta k + r_\epsilon(\beta, p, \mu), p, \mu) = 0$ with respect to β, then we shall obtain the Taylor coefficients of r_ϵ. This is a tedious exercise, so we omit the details, but one eventually obtains

R1. $P(d_u M_\epsilon[k + d_\beta r]) \equiv 0$,
R2. $P(d_u^2 M_\epsilon[k + d_\beta r, k + d_\beta r] + d_u M_\epsilon[d_\beta^2 r]) \equiv 0$,
R3. $P(d_u^3 M_\epsilon[k+d_\beta r]^3 + 2d_u^2 M_\epsilon[d_\beta^2 r, k+d_\beta r] + d_u^2 M_\epsilon[d_\beta^2 r, k+d_\beta r] + d_u M_\epsilon[d_\beta^3 r]) \equiv 0$,
R4. $P(d_u^4 M_\epsilon[k + d_\beta r]^4 + 6d_u^3 M_\epsilon[d_\beta^2 r, k + d_\beta r, k + d_\beta r] + 3d_u^2 M_\epsilon[d_\beta^3 r, k + d_\beta r] + 3d_u^2 M_\epsilon[d_\beta^2 r, d_\beta^2 r] + d_u M_\epsilon[d_\beta^4 r] + d_u^2 M_\epsilon[k + d_\beta r, d_\beta^3 r]) \equiv 0$,
R5. $P(d_u^5 M_\epsilon[k + d_\beta r]^5 + 10d_u^4 M_\epsilon[d_\beta^2 r, [k + d_\beta^3 r]^3] + 10d_u^3 M_\epsilon[d_\beta^3 r, k + d_\beta r, k + d_\beta r] + 3d_u^2 M_\epsilon[d_\beta^4 r, d_\beta r] + 10d_u^2 M_\epsilon[d_\beta^3 r, d_\beta^2 r] + 2d_u^2 M_\epsilon[d_\beta^4 r, d_\beta r] + d_u M_\epsilon[d_\beta^5 r]) \equiv 0$.

Evaluating these expressions at $\beta = 0$, that is, $u = r_\epsilon(0, p, \mu) = 0$, yields the following information. From R1 we have $PL(p, \mu)[k + d_\beta r(0, p, \mu; \epsilon)] = 0$, and because $L(p, \mu)k = (\mu^4 - p\mu^2 + 1)k \in \langle k \rangle$ we have $d_\beta r_\epsilon(0, p, \mu) \equiv 0$. The expression $d_\beta^2 r_\epsilon(0, p, \mu) = 0$ then follows from R2. Also, R3 gives

$$PL(p, \mu)d_\beta^3 r_\epsilon(0, p, \mu) = 6\epsilon P(k^3), \tag{5.3}$$

so that the third derivative of r_ϵ is not zero in general at $(u, p, \mu; \epsilon) = (0, 2, 1; \epsilon)$, but $d^3_\beta r_\epsilon(0, p, \mu)$ is seen to provide an $O(\epsilon)$ contribution to the Taylor expansion of r_ϵ. Using Taylor's theorem to expand $r_\epsilon(\beta, p, \mu)$ with respect to β and using the symmetry properties of r_ϵ (it is odd with respect to β), we may write $r_\epsilon(\beta, p, \mu) = \frac{\beta^3}{6} R^1_\epsilon(p, \mu) + O(\beta^5)$ for some operator $R^1_\epsilon(p, \mu)$ with range in $\langle k \rangle^\perp$.

We can determine R^1_ϵ as follows. In (5.3) seek an even Fourier series solution which is also orthogonal to k in X_e of the form $R^1_\epsilon(p, \mu) = \sum_{j=2}^\infty a_j \cos(jt)$, where the coefficients a_j remain to be determined. Since $k^3(t) = \frac{1}{4}(\cos(3t) + 3\cos(t))$, it follows that the only nonzero coefficient is a_3 and

$$R^1_\epsilon(p, \mu) = \frac{3\epsilon}{2} \frac{\cos(3\cdot)}{81\mu^4 - 9p\mu^2 + 1}.$$

Using R4 and setting $\beta = 0$, we find $d^4_\beta r_\epsilon(0, p, \mu) \equiv 0$, which of course also follows from symmetry. We may evaluate $d^5_\beta r_\epsilon(0, p, \mu)$ from R5, which simplifies to give

$$P(d^5_u M_\epsilon[k]^5 + 10 d^3_u M_\epsilon[k, k, d^3_\beta r_\epsilon] + d_u M_\epsilon[d^5_\beta r_\epsilon]) \equiv 0.$$

To find $d^5_\beta r_\epsilon(0, p, \mu)$ we solve the following linear equation for $w \in X_e \cap \langle k \rangle^\perp$,

$$\mu^4 w'''' + p\mu^2 w'' + w + P\left[60k^2 \frac{3\epsilon^2}{2} \frac{\cos(3\cdot)}{81\mu^4 - 9p\mu^2 + 1} + 120\epsilon k^5\right] = 0, \tag{5.4}$$

and then $d^5_\beta r_e(0, p, \mu) = w$. Since $k(t)^5 = \frac{1}{16}(\cos(5t) + 5\cos(3t) + 10\cos(t))$, $k(t)^2 = \frac{1}{2}(1 + \cos(2t))$, and $\cos(3t)\cos(2t) = \frac{1}{2}(\cos(5t) + \cos(t))$, we also solve (5.4) using a Fourier series expansion. Accordingly, taking $w(t) = \sum_{j=2}^\infty w_j \cos(jt)$, we find that all the coefficients w_j are zero, except when $j = 3$ or $j = 5$. In these cases

$$(81\mu^4 - 9p\mu^2 + 1)w_3 + 150\epsilon - \frac{45\epsilon^2}{81\mu^4 - 9p\mu^2 + 1} = 0$$

and

$$(625\mu^4 - 25p\mu^2 + 1)w_5 + 30\epsilon - \frac{90\epsilon^2}{2(81\mu^4 - 9p\mu^2 + 1)} = 0.$$

It follows that $r_\epsilon(\beta, p, \mu) = \frac{\beta^3}{6} R^1_\epsilon(p, \mu) + \frac{\beta^5}{120} R^2_\epsilon(p, \mu) + \frac{\beta^7}{720} d^7_\beta r_\epsilon(0, p, \mu) + O(\epsilon^2\beta^3)$, where

$$R^2_\epsilon(p, \mu) = -\epsilon\left(\frac{150}{4(81\mu^4 - 9p\mu^2 + 1)} \cos(3\cdot) + \frac{30}{4(625\mu^4 - 25p\mu^2 + 1)} \cos(5\cdot)\right) + O(\epsilon^2).$$

One can show by further differentiating that $d^6_\beta r_\epsilon(0, p, \mu) \equiv 0$, as we expect from symmetry, and the equation which determines $d^7_\beta r_\epsilon(0, p, \mu)$ shows this term to be of order $O(\epsilon^2)$. Higher derivatives of r_ϵ will also be of order $O(\epsilon^2)$.

Now $p_\epsilon(\beta)$ and $\mu_\epsilon(\beta)$ are even functions of β, and applying the zero-Hamiltonian constraint gives

$$\mu^4 \delta((k + \rho_\epsilon)''^2) = \delta\left((k + \rho_\epsilon)^2 - \frac{1}{2}\epsilon\beta^2(k + \rho_\epsilon)^4 + \frac{1}{3}\epsilon\beta^4(k + \rho_\epsilon)^6\right), \tag{5.5}$$

using a prime to denote $\frac{d}{dt}$. Seeking an expansion of the bifurcation branch about $(\epsilon, \beta) = (0, 0)$, we write

$$p_\epsilon(\beta) = 2 + \epsilon\left(P_1\beta^2 + P_2\beta^4\right) + O(\epsilon^2) \tag{5.6}$$

and

$$\mu_\epsilon(\beta) = 1 + \epsilon\left(\omega_1\beta^2 + \omega_2\beta^4\right) + O(\epsilon^2), \tag{5.7}$$

where P_1, P_2, ω_1, and ω_2 are real numbers to be determined. The highest power of β which exists in these expansions at $O(\epsilon)$ is the quartic because of the Taylor series we have found for $r_\epsilon(\beta)$. This is clear from (5.5), which contains terms of order $\epsilon\beta^2$ and $\epsilon\beta^4$ but not $\epsilon\beta^6$ or higher.

To determine ω_1 and ω_2 we substitute the expressions for $\rho_\epsilon = \frac{r_\epsilon}{\beta}$ and μ_ϵ into (5.5). Using $\delta(\rho) = \left(\frac{1}{256}\beta^2 - \frac{23}{4608}\beta^4\right)\epsilon + O(\epsilon^2)$ and $\delta(\rho'') = \left(-\frac{9}{256}\beta^2 + \frac{215}{4608}\beta^4\right)\epsilon + O(\epsilon^2)$, we then find $\frac{1}{(81\mu^4 - 9p\mu^2 + 1)} = \frac{1}{64} + O(\epsilon)$ and $\frac{1}{(625\mu^4 - 25p\mu^2 + 1)} = \frac{1}{576} + O(\epsilon)$. Setting $v = \beta(k + \rho) \in \langle k\rangle \oplus \langle k\rangle^\perp$ in (5.1) and projecting the result onto the span of $k(t) = \cos(t)$, we obtain

$$\mu^4 - p\mu^2 + 1 - \epsilon\beta^2\frac{1}{\pi}\int_0^{2\pi} k((k+\rho)^3 - \beta^2(k+\rho)^5)dt = 0. \tag{5.8}$$

We now use this information to equate coefficients at the appropriate orders to find

$$P_1 = -\frac{3}{4}, \quad P_2 = \frac{5}{8}, \quad \omega_1 = \frac{-9}{64}, \quad \text{and } \omega_2 = \frac{5}{48}. \tag{5.9}$$

5.1. Conditions for a fold bifurcation. The solution branch $C_\epsilon(1, 1)$ determined above, which branches from $p = 2$, can be continued from bifurcation in p for $p < 2$, or in μ for $\mu < 1$. When considered as a function of p, the branch has a fold bifurcation at some point, which we label p_F, and the same behavior is observed when the branch is continued in μ. The numerical calculations presented in the next section also indicate that the solution branch is restricted to the parameter range $p > p_F$ and $\mu > \mu_F$, although we have no proof of this claim.

We can now prove the following theorem.

THEOREM 5.1. *There is a neighborhood $I \subset \mathbb{R}$ of zero such that if $\epsilon \in I$, the zero-Hamiltonian branch $C_\epsilon(1, 1)$ associated with* (5.1)*, which bifurcates from $p = 2$ at $\mu = 1$, has a fold which occurs with respect to p at*

$$p_F(\epsilon) = 2 - \frac{9}{40}\epsilon + O(\epsilon^2). \tag{5.10}$$

There is also a fold in $C_\epsilon(1, 1)$ with respect to μ which occurs at

$$\mu_F(\epsilon) = 1 - \frac{243}{5120}\epsilon + O(\epsilon^2). \tag{5.11}$$

Proof. Using (5.6), (5.7), and (5.9), a fold bifurcation with respect to p occurs on the $C_\epsilon(1, 1)$ branch when the conditions $d_\beta p_\epsilon(\beta) = 0$ and $d^2_{\beta\beta} p_\epsilon(\beta) \neq 0$ are met. Applying the implicit function theorem when $\epsilon \neq 0$, these conditions are satisfied when $\beta^2 = \beta_F^2 \equiv 3/5 + \mathcal{O}(\epsilon)$, giving (5.10).

Similarly, a fold bifurcation with respect to μ occurs on the branch $C_\epsilon(1, 1)$ when $d_\beta \mu_\epsilon(\beta) = 0$ and $d^2_{\beta\beta}\mu_\epsilon(\beta) \neq 0$, and, provided $\epsilon \neq 0$, these conditions are satisfied when $\beta^2 = 27/40 + \mathcal{O}(\epsilon)$, giving (5.11). ∎

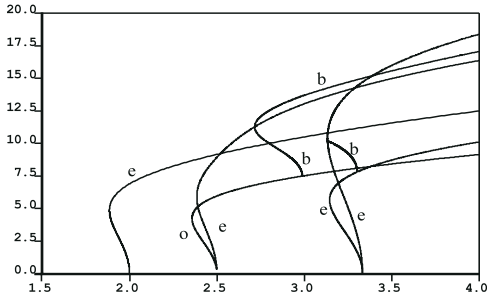

FIG. 6.1. *Bifurcations of zero-Hamiltonian periodic solutions from* $p = 2, p = 2\frac{1}{2}$, *and* $p = 3\frac{1}{3}$, *with* p *plotted horizontally against* $\|u'\|_{L^\infty}$ *vertically;* e *are even solutions,* o *are odd solutions, and* b *are solutions with* broken *symmetry.*

6. Numerical computations.

6.1. Preliminaries. We now describe a series of numerical calculations to determine solutions of the unscaled differential equation (1.1) with the restiffening foundation whose primary solution branch was studied in the previous section:

$$u'''' + pu'' + u - \epsilon(u^3 - u^5) = 0. \tag{6.1}$$

We augment this with the periodic boundary conditions $u(0) = u(T), u'(0) = u'(T)$, and $u'''(0) = u'''(T)$ and specify the phase by requiring $u'(0) = 0$. Finally, we impose the constraint that the Hamiltonian is zero, so that

$$u''(0) = \pm\sqrt{2(u(0)^2/2 - \epsilon(u(0)^4/4 - u(0)^6/6)}, \tag{6.2}$$

and we set $\epsilon = 1/2$ for the purposes of computation.

In (6.2) the positive root corresponds to the solution which is tangential to the rescaled eigensolution $e_-(x) \equiv n\cos(x\sqrt{m/n}) - m\cos(x\sqrt{n/m})$ at the bifurcation point $(u, p, \mu) = (0, p_{n,m}, \mu_{n,m})$, whereas the negative root corresponds to the solution which is tangential to the eigensolution $e_+(x) \equiv n\cos(x\sqrt{m/n}) + m\cos(x\sqrt{n/m})$. In order to follow the solution branches in p and to detect fold bifurcations, the collocation-based code *AUTO* [14] was used.

6.2. Calculation of the solution branches. We now illustrate three cases regarding the bifurcation of solutions of (6.1): the case $(n, m) = (1, 1)$, for which there is a unique bifurcating branch; the case $(n, m) = (2, 1)$, with $p_{2,1} = 2\frac{1}{2}$ and $\mu_{2,1} = \frac{1}{\sqrt{2}}$; and $(n, m) = (3, 1)$, for which $p_{3,1} = 3\frac{1}{3}$ and $\mu_{1,3} = \frac{1}{\sqrt{3}}$. Broadly speaking, higher values of n and m lead to similar solution branches.

Figure 6.1 shows the bifurcation branches which are proven to exist in Theorems 3.1 and 3.3, with p plotted against $\|u'\|_{L^\infty}$. The $(1, 1)$ branch has the form described in Theorem 5.1, and for the $p = 2\frac{1}{2}$ and $p = 3\frac{1}{3}$ cases one sees a similar geometry in that the branches initially bifurcate to the left, have fold bifurcations, and then persist for all values of p to the right of the fold point.

The following comments are in order regarding Figure 6.1 and the three points $p = 2, 2\frac{1}{2}$, and $3\frac{1}{3}$. Due to the $\mathbb{Z}_2$-symmetry of (6.1) and of the symmetry properties of the eigenfunctions when $(n, m) = (2, 1)$, if $u(t)$ is one even solution on the $(2, 1)$ branch, then so too is $-u(t + T/2)$. Therefore, in order to obtain a second *distinct* periodic solution, we apply Theorem 3.5 to give the existence of two branches of odd

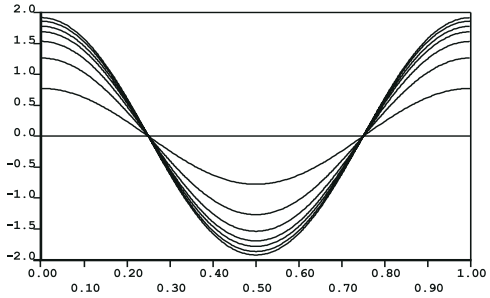

FIG. 6.2. *Solutions ($u(s)$ for $0 \le s \le 1$) bifurcating from $p = 2$, away from the bifurcation point. In accordance with Theorem* 2.2 *these are even about zero and odd about one-quarter.*

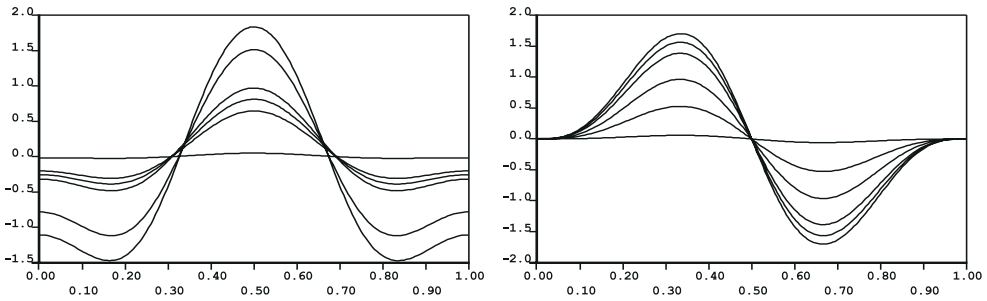

FIG. 6.3. *(left) Even solutions ($u(s)$ for $0 \le s \le 1$) bifurcating from $p = 2\frac{1}{2}$, away from the bifurcation point. (right) Odd solutions bifurcating from $p = 2\frac{1}{2}$.*

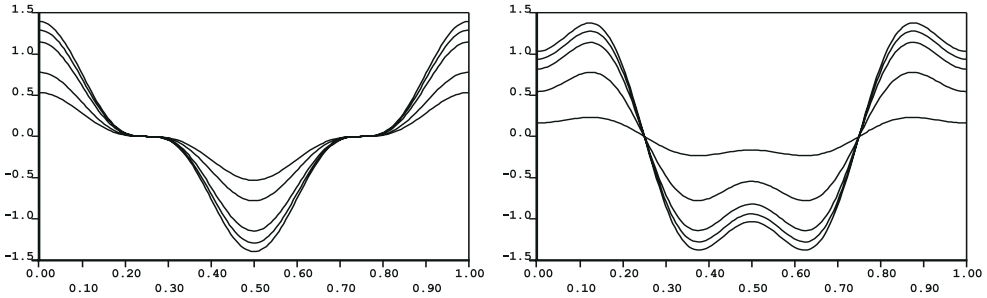

FIG. 6.4. *Solutions ($u(s)$ for $0 \le s \le 1$) bifurcating from $p = 3\frac{1}{3}$, away from the bifurcation point.*

solutions. Again, one of these branches of odd solutions can be obtained from the other by symmetry, and we therefore have plotted one of each even and odd branch in Figure 6.1. The solutions on this branch are shown in Figure 6.3.

Figures 6.2, 6.3, and 6.4 each show several solutions chosen from Figure 6.1 on the branches which connect to $p = 2, p = 2\frac{1}{2}$, and $p = 3\frac{1}{3}$, respectively, although the domain of each solution has been normalized to unity. (The information regarding the period of the solutions is given in Figure 6.5.) If we examine Figure 6.4, we notice that each of the solutions is even about zero and odd about one quarter. Consequently, the two branches of the solutions shown are in fact identical, up to a shift and a reflection, to the odd solutions which are obtained using Theorem 3.5.

Since $F(u)$ and $uF_u(u)$ are both positive for nonzero u when $\epsilon = 1/2$, the global

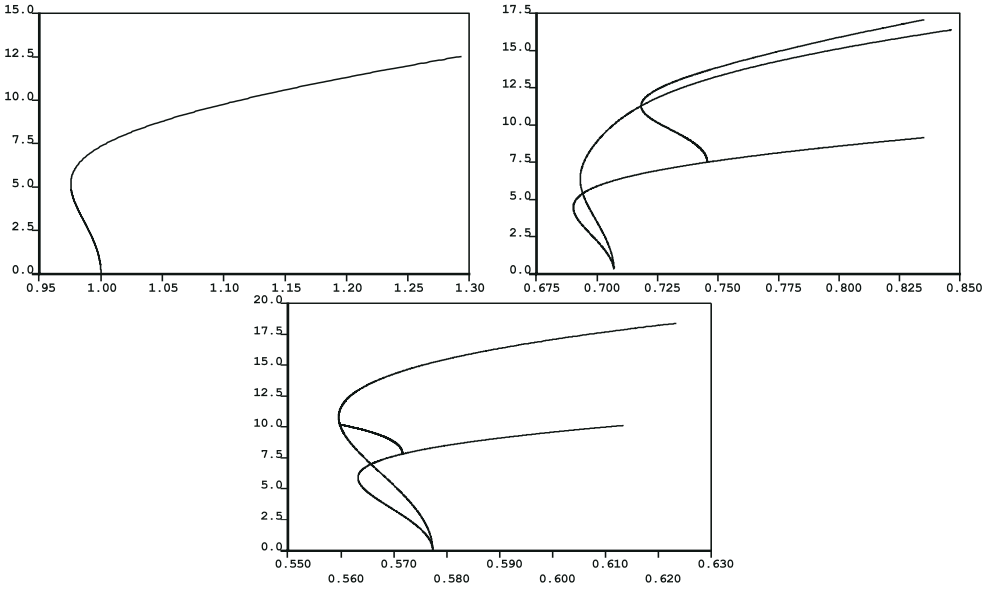

FIG. 6.5. *Period of solutions from Figure* 6.1 *(*$(1,1)$ *branch is top-left,* $(2,1)$ *top-right,* $(3,1)$ *bottom) with* $\mu = 2\pi/\text{period}$ *plotted horizontally and* $\|u'\|_{L^\infty}$ *vertically.*

bifurcation theorem (Theorem 4.2) applies to the $(1,1)$ branch, and the nodal properties are preserved along the resulting global branch in accordance with Theorems 3.6, 3.7, and 3.8. This is illustrated in each of Figures 6.2, 6.3, and 6.4.

Finally, note that the $(1,1)$ branch in Figure 6.1 appears to have no further bifurcations, whereas the $(2,1)$ and $(3,1)$ branches both have symmetry-breaking secondary bifurcation points. What is interesting about the resulting branches of unsymmetric solutions is that they form connections between the $(2,1)$ and $(3,1)$ branches. This indicates that it would be futile to seek generalizations of the results of section 3.5 to include the space of all periodic zero-Hamiltonian solutions of (1.1) and that the disjointness properties of the solution branches obtained in this paper are peculiar to spaces of symmetric solutions.

LAWS FOR THE CAPILLARY PRESSURE IN A DETERMINISTIC MODEL FOR FRONTS IN POROUS MEDIA*

BEN SCHWEIZER†

Abstract. We propose and analyze a model for sharp fronts in porous media, aiming at an investigation of the capillary pressure. Using the notion of microlocal patterns we analyze the local behavior of the system. Depending on the structure of the local patterns we can derive upscaled equations that characterize the capillary pressure and include the hysteresis effect that is known from the physical system.

Key words. homogenization, two-phase flow, front dynamics, microlocal pattern

1. Introduction. The investigation of fluid motion in porous media has attracted much interest in the fields of engineering, physics, and mathematics. A particular interest concerns the case when two immiscible fluids are contained in the porous material, e.g., water and oil in rock. Different suggestions were made for averaged equations for this two-fluid motion; most are variants of the very successful Muskat–Leverett equations. In these equations the motion of the two fluids is coupled via an equation

$$p_a - p_b = p_c(s), \tag{1.1}$$

where p_a and p_b are the pressure functions in the two fluids, s is the saturation of, say, fluid a, and p_c is the capillary pressure. Our aim is to derive (1.1) for a model system.

We refer the reader to [2, 5, 7, 9] for other approaches towards the justification of the Muskat–Leverett equations. Concerning modifications of the system see [3, 4]; note that the result of this work and of [10] suggests another modification. For an analysis of the upscaled system see [8].

The far aim would be the homogenization of the geometry of Figure 1(a). This goal seems to be out of reach due to the topological changes of the free boundary during its propagation. A simpler geometry is the filter geometry of Figure 1(b). Here in every single tube the free boundary has essentially only one degree of freedom, its average height. By the laws for surface tension and contact angles, the geometry implies for every tube k a relation between average height and typical pressure, $p = \mathcal{P}_0(h, k)$. We will study this simplified model. For a homogenization result for the filter geometry with the same methods see [11].

We observe the creation of local structures: when the pressure in tube k reaches its maximal value and the height exceeds the critical point, an instability occurs. The pressure lowers; therefore, locally, the flow goes toward tube k, the height increases further, and the process accelerates. Such an event has the temporal and spatial scale of the tube distance ε and we call it an explosion. We will verify the appearance of

these explosions and determine their form. The distribution of the explosions can be captured using the Young measure on patterns introduced by Alberti and Müller in [1]. We will derive a conditional result for the upscaled equations, i.e., the limit $\varepsilon \to 0$: if the patterns of the limit measure all have finite length, then upscaled equations with a prescribed capillary pressure along the front are satisfied in the limit.

1.1. A model for propagating fronts.

Geometry. The fluid occupies the domain $\Omega := (-1,1)\times(-1,0)$ and is described by a Darcy law. The front is located along the upper boundary

$$\Gamma := (-1,1) \times \{0\}.$$

Γ consists of two parts. On $\Gamma_2^\varepsilon \subset \Gamma$ the fluid is in contact with the matrix; with $\gamma \in (0,1/2)$ we write

$$\Gamma_2^\varepsilon := \varepsilon \cdot (\mathbb{Z} + (\gamma, 1-\gamma)) \cap \Gamma,$$

where we used the obvious identification $\Gamma \subset \mathbb{R}$. The small parameter ε describes the pore size in the medium; we will for simplicity always assume $\varepsilon = 1/N$ with $N \in \mathbb{N}$. A fluid-gas interphase is present along

$$\Gamma_1^\varepsilon := \varepsilon \cdot (\mathbb{Z} + (-\gamma, \gamma)) \cap \Gamma.$$

The free boundary is modeled with a height function

$$h^\varepsilon : \Gamma_1^\varepsilon \to \mathbb{R}.$$

Having in mind that the free boundary in the single tube has only one degree of freedom, we reinterpret h^ε as the average height and assume that h^ε is piecewise constant. We use the space $V_\varepsilon = Q_\varepsilon L^2(\mathbb{R})$ of functions that are constant on the intervals $\varepsilon \cdot ((-\gamma,\gamma)+k)$, $k \in \mathbb{Z}$. Here Q_ε is the L^2-projection to this subspace; it is obtained by replacing a function on Γ_1^ε with its averages on the disjoint intervals of length $2\gamma\varepsilon$.

Equations. We write the Darcy law in the scaling $v^\varepsilon = -\varepsilon \nabla p^\varepsilon$. This scaling is obtained by rescaling time and is appropriate to observe microscopic processes. Note that we assumed the permeability matrix to be the identity in order to simplify

notations. We study the problem

$$\partial_t h^\varepsilon(x_1,t) = -\varepsilon Q_\varepsilon \partial_2 p^\varepsilon(x_1,0,t) \qquad \forall (x_1,0)\in\Gamma_1^\varepsilon,\ \forall t, \tag{1.2}$$

$$p^\varepsilon(x_1,0,t) = \mathcal{P}_0\left(\frac{x_1}{\varepsilon}, \frac{h^\varepsilon(x_1,t)}{\varepsilon}\right) \qquad \forall (x_1,0)\in\Gamma_1^\varepsilon,\ \forall t, \tag{1.3}$$

$$\partial_2 p^\varepsilon(x_1,0,t) = 0 \qquad \forall (x_1,0)\in\Gamma_2^\varepsilon,\ \forall t, \tag{1.4}$$

$$-\Delta_x p^\varepsilon = 0 \qquad \text{in } \Omega\times(0,T). \tag{1.5}$$

Initial values for the height function are given and we always set $h^\varepsilon(x_1) = 0$ for $(x_1,0)\in\Gamma_2^\varepsilon$. The equations are complemented with the ε-independent boundary conditions. We impose periodicity on the lateral boundaries $\Sigma_\pm := \{(x_1,x_2)\in\bar\Omega \mid x_1 = \pm 1\}$. The presented methods apply also in the case of an impermeability condition. As a driving mechanism we choose a prescribed inflow on the lower boundary $\Gamma_0 := (-1,1)\times\{-1\}$,

$$-\partial_2 p^\varepsilon(x_1,-1,t) = V_0(x_1) \qquad \forall (x_1,-1)\in\Gamma_0,\ \forall t. \tag{1.6}$$

It is also possible to prescribe the pressure at the lower boundary. In either case and throughout our investigations we demand $p^\varepsilon|_{\Gamma_0}(t) > 0$ for all t. This assumption is made to simplify notations; upscaled equations in the general case follow by symmetry.

It is left to specify the material law $\mathcal{P}_0$ which prescribes the pressure-height dependence in each cell (we will always assume that $\mathcal{P}_0(\cdot,s)$ is constant on $(k-\gamma,k+\gamma)$ for every $k\in\mathbb{Z}$). A reasonable choice is the following. The material law of the cells is the same in every cell and a sawtooth function in $s = \frac{h}{\varepsilon}$,

$$\mathcal{P}_0(k,s) \equiv \mathcal{P}_0(s) = a_0\cdot s \mod a_0 s_0. \tag{1.7}$$

Here s_0 represents the volume of the single cell. The maximal pressure that is needed to advance the free boundary is

$$p_{\max} = a_0\cdot s_0.$$

A possible modification of this model is to allow the physical parameters $a_0 = a_0(k)$ and $s_0 = s_0(k)$ to depend on the position index k. If (a_0,s_0) is periodic in k, all results remain valid. We collect some first observations on the ε-problem. The proofs are straightforward and can be found in [11].

Remark 1.1. The ε-problem has a unique solution with $p^\varepsilon(t)\in H^1(\Omega)$ for all $t\in[0,T]$. The solution sequence p^ε satisfies uniform bounds in $L^\infty((0,T),L^\infty(\Omega))$ and in $L^2((0,T),H^1(\Omega))$.

The uniform bound of $p^\varepsilon\in L^\infty(\Omega)$ allows us to choose a subsequence $\varepsilon\to 0$ such that p^ε has a limit $p^0\in L^\infty(\Omega)$ in the sense of the weak-$\star$ convergence in L^∞,

$$p^\varepsilon \to p^0 \quad \text{in } L^\infty_w.$$

1.2. Main result. Our aim is to find equations for p^0 in order to describe the averaged behavior of the solutions p^ε. It turns out that, in general, p^0 is not uniquely determined. We will have to study the microscopic behavior of the family p^ε in order to find equations for p^0.

In the model equations with relation (1.7) the pressure p^ε has discontinuities. There are points $(x_1,0,t)\in\varepsilon\mathbb{Z}\times(0,T)$ in which the pressure drops from $p_{\max}$ to 0; we call them explosion points. We have already seen that we can expect a nontrivial

behavior in an ε-space-time neighborhood of explosion points. Generically, we expect that the explosion points do not cluster and that the limit patterns of explosions are finite (see Definition 2.8 for a precise statement). In fact, in [10] we analyze a stochastic system and find that explosion points cluster only with probability 0.

If all realized explosion patterns are finite, then the limit pressure p^0 satisfies the following upscaled system in the distributional sense (see Theorem 4.6 for details):

$$\Delta p^0 = 0 \qquad \text{in } \Omega, \tag{1.8}$$

$$-\partial_2 p^0 = V_0 \qquad \text{on } \Gamma_0, \tag{1.9}$$

and p^0 is periodic across $\Sigma_\pm$. On the boundary Γ it satisfies

$$p^0 \le p_{\max}, \tag{1.10}$$

$$\partial_t(\Theta \circ p^0) \le -\partial_2 p^0, \tag{1.11}$$

$$\partial_t(\Theta \circ p^0) = -\partial_2 p^0 \quad \text{on } \{(x_1,0) \in \Gamma \mid p^0(x_1,0) < p_{\max}\}. \tag{1.12}$$

The function Θ is defined in the stochastic case as an expected value. Since we consider the deterministic equation (1.7), its definition reduces to

$$\Theta'(\rho) = \left\langle \frac{2\gamma}{\mathcal{P}_0'(k, s_k(\rho))} \right\rangle = \frac{2\gamma}{a_0}, \tag{1.13}$$

where $s_k(\rho)$ is defined by $\mathcal{P}_0(k, s_k(\rho)) = \rho$. The microlocal patterns of the functions p^ε can be described.

Remarks on Theorem 4.6. (1) An assumption on the distribution of explosions is indeed necessary. Consider a family of solutions to the ε-problems that is ε-periodic in x_1-direction. In this case, the limiting pressure p^0 is constant along Γ, but has jumps from $p_{\max}$ to 0 at discrete times. The function p^0 does not solve the upscaled equation (1.12).

(2) We study a sawtooth function as a material law in (1.7). This law is not satisfactory for all applications. Unfortunately, in our proofs we need a condition on positivity of $\mathcal{P}_0'$ away from discontinuities, and this restricts our choices for $\mathcal{P}_0$. We conjecture that the overall picture about solution sequences and the upscaled equations remain valid for continuous functions $\mathcal{P}_0$.

(3) One can formally relate the upscaled equation (1.12) to well-known effective conductivity formulae. Differentiating (1.3) with respect to time and inserting (1.3), we find that $\partial_t p^\varepsilon$ essentially equals $-a_0 \partial_2 p^\varepsilon$. Dividing (1.12) by Θ', we find that $\partial_t p^0$ essentially equals $-\bar{a}\partial_2 p^\varepsilon$, where $\bar{a}$ is the harmonic mean of the a_0.

2. Microlocal patterns and possible patterns for fronts. We study solutions $(p^\varepsilon, h^\varepsilon)$ of (1.2)–(1.6) and are interested in the averaged behavior as it is expressed by the weak limit p^0. The goal is to derive averaged equations that characterize p^0.

We already observed that the equations have a nontrivial behavior on an ε-scale in time and in space. In this scaling we expect to see the filling procedure of the single pore: fluid enters the cell $\varepsilon(k-\gamma, k+\gamma)$ until the pressure reaches its maximal value $p_{\max}$. Now the pressure is set to zero and a pressure gradient of order $1/\varepsilon$ drives a refill procedure in which mass is transported from neighboring cells to cell k. It takes a time span of order ε and a spatial area with diameter of order ε to essentially reach again the pressure $p_{\max}$.

We want to find descriptions of this microscopic process. An adequate tool is that of microlocal patterns, introduced by Alberti and Müller in [1]. We outline aspects of this tool in this section.

Notation for measures. Let E be a locally compact Hausdorff space. We denote by $\mathcal{M}(E)$ the space of all finite real Borel measures on E. Let $C(E)$ be the space of continuous functions on E with compact support. Then $\mathcal{M}(E)$ can be identified with the dual of $C(E)$. Therefore bounded sequences in $\mathcal{M}(E)$ are precompact.

2.1. Construction of microlocal patterns. Let $u^\varepsilon : S \to \mathbb{R}$ be a sequence of functions on a compact set $S \subset \mathbb{R}^m$. We assume that for $C \in \mathbb{R}$ there holds $\|u^\varepsilon\|_{L^\infty} \le C$ for all $\varepsilon > 0$. Our aim is now to study the behavior of u^ε on the length scale ε. We therefore consider the blowup of u^ε, just as in asymptotic expansions or in the theory of two-scale convergence. Together with u^ε we consider the local pattern around $s \in S$, that is, the function

$$\mathbb{R}^m \ni t \mapsto R_s^\varepsilon u^\varepsilon(t) := u^\varepsilon(s + \varepsilon t)$$

(we assume that we extended trivially the original function u^ε outside S). The pattern $R_s^\varepsilon u^\varepsilon$ is bounded in $L^\infty(\mathbb{R}^m)$ by C. As the space of patterns we use the closed ball

$$K := \bar{B}_C(0) \subset L^\infty_w(\mathbb{R}^m),$$

where L^∞_w indicates that we use the weak-$\star$ topology on K. This makes K compact.

Since the pattern depends in an oscillatory fashion on s, one proceeds as in the construction of Young measures and considers instead of the values $R_s^\varepsilon u^\varepsilon \in K$ the measure ν_s^ε, the Dirac measure on K in the point $R_s^\varepsilon u^\varepsilon$.

DEFINITION 2.1 (measure of microlocal patterns). *Given a sequence $u^\varepsilon \in \bar{B}_C(0) \subset L^\infty(S)$ and the corresponding Dirac measures ν_s^ε, we define the measure ν^ε on $S \times K$ by*

$$S \times K \supset \bar{S} \times \bar{K} \mapsto \nu^\varepsilon(\bar{S}, \bar{K}) := \int_{\bar{S}} \nu_s^\varepsilon(\bar{K})\, de^\varepsilon(s)$$

for all Borel sets $\bar{S} \subset S$ and $\bar{K} \subset K$. The energy density $e^\varepsilon(s)$ still has to be specified; we always assume $\int_S de^\varepsilon(s) \le C'$. Then we can choose a subsequence $\varepsilon \to 0$ such that for a finite limit measure ν there holds in the sense of weak-$\star$ convergence

$$\nu = \lim_{\varepsilon \to 0} \nu^\varepsilon \in \mathcal{M}(S \times K).$$

We call ν the measure of microlocal patterns of the (sub)sequence.

We will also use the following two projections of ν. The projection μ of ν to S, which coincides with the energy density of ν,

$$S \supset \bar{S} \mapsto \mu(\bar{S}) := \nu(\bar{S} \times K) = \lim_{\varepsilon \to 0} \int_{\bar{S}} de^\varepsilon(s),$$

and the projection ν_K of ν to K,

$$\bar{K} \mapsto \nu_K(\bar{K}) := \nu(S \times \bar{K}).$$

The elements in the support of ν_K are the realized patterns.

Possible micropatterns. Our aim is to characterize the realized patterns of solution sequences in our model problem. The method is to successively exclude possibilities. A first concept is that of *possible micropatterns*. In the subsequent definition we assume that the sequence u^ε is a sequence of solutions to a given family of equations.

DEFINITION 2.2 (possible micropattern). *For a point $s \in S$ we say that $U_s : \mathbb{R}^m \to \mathbb{R}$ is a possible micropattern in s if there exist a sequence $\varepsilon \to 0$, boundary and initial conditions with a solution sequence u^ε, and a sequence of points $s_\varepsilon \to s$, such that*

$$U^\varepsilon_{s_\varepsilon} := R^\varepsilon_{s_\varepsilon} u^\varepsilon \to U_s \quad \text{in } K.$$

U is a possible micropattern, if it is a possible micropattern in some point s.

The concept of possible micropatterns does not allow us to study the distribution of patterns, but it gives a necessary condition for a pattern to be contained in the support of ν_K. In fact, an elementary proof yields the following result.

Remark 2.3. Every measure on patterns ν_K of a solution sequence u^ε has its support contained in the set of possible micropatterns.

The fundamental property of possible patterns is that they satisfy the rescaled equations (note that we loose boundary and initial conditions). This fact will lead to a characterization of possible micropatterns.

2.2. Possible patterns for the motion of fronts. As described, we expect ε-scale phenomena in the neighborhood of points (x,t) where p^ε has a jump, i.e., in explosion points. In order to study the local behavior, we define for a given $(x,t) = (x_1,0,t)$ the blowup of solutions

$$\begin{aligned} P^\varepsilon(y,\tau) = P^\varepsilon_{(x,t)}(y,\tau) &:= (R^\varepsilon_{(x,t)} p^\varepsilon)(y,\tau) = p^\varepsilon(x+\varepsilon y, t+\varepsilon\tau), \\ H^\varepsilon(y_1,\tau) = H^\varepsilon_{(x_1,t)}(y_1,\tau) &:= \frac{1}{\varepsilon}(R^\varepsilon_{(x_1,t)} h^\varepsilon)(y_1,\tau) \\ &= \frac{1}{\varepsilon} h^\varepsilon(x_1+\varepsilon y_1, t+\varepsilon\tau). \end{aligned}$$

For explosion points (x,t) we expect nontrivial limits of $(P^\varepsilon, H^\varepsilon)$ and our next aim is to determine the possible limits. We will call such limits explosion patterns.

The equations for $(P^\varepsilon, H^\varepsilon)$ are identical to (1.2)–(1.5), except that the factors ε are replaced by the factor 1 in (1.2) and (1.3). We have to substitute the boundary condition (1.6) by a condition on the asymptotic behavior at infinity.

The solutions P^ε are physically meaningful on space-time domains of size $\frac{1}{\varepsilon} \times \frac{1}{\varepsilon}$. After the trivial extension of the functions, their domains are

$$\begin{aligned} \bar\Omega &:= \mathbb{R} \times \mathbb{R}_-, & \bar\Gamma &:= \mathbb{R} \times \{0\} \equiv \mathbb{R}, \\ \bar\Gamma_1 &:= \mathbb{Z} + (-\gamma, \gamma), & \bar\Gamma_2 &:= \mathbb{Z} + (\gamma, 1-\gamma). \end{aligned}$$

In order to define the microlocal patterns we consider the functions $p^\varepsilon|_\Gamma : [-1,1] \times [0,T] \to \mathbb{R}$ and set $S := [-1,1] \times [0,T]$. A limit measure is found as $\nu \in \mathcal{M}(S \times K)$ with $K = \bar B_C(0) \subset L^\infty_w(\mathbb{R}^2)$. Note that $p^\varepsilon|_\Gamma$ determines uniquely its harmonic extension p^ε and the height function h^ε up to multiples of s_0. With this identification we can consider limit patterns also as functions $P : \bar\Omega \times \mathbb{R} \to \mathbb{R}$ and $H : \bar\Gamma \times \mathbb{R} \to [0, s_0)_{\text{per}}$.

We use the projection Q_1 defined as

$$(Q_1 f)(y) = \begin{cases} \dfrac{1}{2\gamma}\displaystyle\int_{k-\gamma}^{k+\gamma} f(\zeta)\, d\zeta & \text{for } y \in (k-\gamma, k+\gamma),\ k \in \mathbb{Z}, \\ f(y) & \text{for } y \in (k+\gamma, k+1-\gamma),\ k \in \mathbb{Z}. \end{cases}$$

Using Q_1 we can write the rescaled equations as (2.1)–(2.4). The next lemma states that every possible pattern is in fact a solution of these rescaled equations.

LEMMA 2.4. *Every possible micropattern (P, H) in a point $(x_1, 0, t)$ satisfies the rescaled equations*

$$\partial_\tau H(y_1, \tau) = -Q_1 \partial_2 P(y_1, 0, \tau) \qquad \forall (y_1, 0) \in \bar{\Gamma}_1, \tag{2.1}$$

$$P(y_1, 0, \tau) \in \hat{\mathcal{P}}_0(y_1, Q_1 H(y_1, \tau)) \qquad \forall (y_1, 0) \in \bar{\Gamma}_1, \tag{2.2}$$

$$\partial_2 P(y_1, 0, \tau) = 0 \qquad \forall (y_1, 0) \in \bar{\Gamma}_2, \tag{2.3}$$

$$-\Delta_y P(\cdot, \tau) = 0 \qquad \text{in } \bar{\Omega}, \tag{2.4}$$

for almost every $\tau \in \mathbb{R}$; $\hat{\mathcal{P}}_0$ is the multivalued function

$$\hat{\mathcal{P}}_0(k, s) = \begin{cases} \mathcal{P}_0(k, s) & \text{for } s \notin s_0\mathbb{Z}, \\ \{0, p_{\max}(k)\} & \text{for } s \in s_0\mathbb{Z}. \end{cases}$$

Additionally there holds

$$\|P\|_{L^\infty(\bar{\Omega})} \le C \qquad \forall t \in \mathbb{R}. \tag{2.5}$$

Remarks. (a) Inequality (2.5) must be interpreted as a boundary condition. (b) The well-posedness of the system can be shown by a limiting procedure with the help of Remark 1.1. (c) Remark A.1 suggests that the decay for $t \to +\infty$ is like t^{-1} (see also the appendix of [10]).

Proof. Let (P, H) be a possible micropattern. By definition there exist a solution sequence $(p^\varepsilon, h^\varepsilon)$ and points $s_\varepsilon = (x_\varepsilon, t_\varepsilon) \in \Gamma \times [0, T]$, such that the rescaled solutions $(P^\varepsilon_{s_\varepsilon}, H^\varepsilon_{s_\varepsilon})$ converge in L^∞_w to (P, H). For $H \neq 0$ one verifies $\varepsilon^{-1}\mathrm{dist}(x_\varepsilon, \varepsilon\mathbb{Z}) \to 0$; it is therefore no loss of generality to assume $x_\varepsilon \in \varepsilon\mathbb{Z}$. The sequence of rescaled solutions satisfies on increasing domains the rescaled equations (2.1)–(2.4).

We use the following weak form of the rescaled equations:

$$\int_{\mathbb{R}}\int_{\bar{\Omega}} \Delta_y \Phi \cdot P^\varepsilon_{s_\varepsilon} = -\int_{\mathbb{R}}\int_{\bar{\Gamma}_1} H^\varepsilon_{s_\varepsilon} \cdot \partial_\tau \Phi + \int_{\mathbb{R}}\int_{\bar{\Gamma}} P^\varepsilon_{s_\varepsilon}(y_1, 0, \tau) \cdot \partial_2 \Phi, \tag{2.6}$$

$$\int_{\mathbb{R}} Q_1 P^\varepsilon_{s_\varepsilon}(k, 0, \tau) \cdot \varphi(\tau)\, d\tau = \int_{\mathbb{R}} \mathcal{P}_0(k, Q_1 H^\varepsilon_{s_\varepsilon}(k, \tau)) \cdot \varphi(\tau)\, d\tau, \tag{2.7}$$

$$H^\varepsilon_{s_\varepsilon} - Q_1 H^\varepsilon_{s_\varepsilon} = 0, \quad P^\varepsilon_{s_\varepsilon}(\cdot, 0, \cdot) - Q_1 P^\varepsilon_{s_\varepsilon}(\cdot, 0, \cdot) = 0, \tag{2.8}$$

satisfied for all $\Phi \in C^2_0(\bar{\Omega} \cup \bar{\Gamma} \times \mathbb{R})$ with $\partial_2 \Phi = 0$ on $\bar{\Gamma}_2$ and $Q_1 \Phi|_{\bar{\Gamma}} = \Phi|_{\bar{\Gamma}}$, and all $\varphi \in C^0_0(\mathbb{R})$, $k \in \mathbb{Z}$. The equations are satisfied for all $\varepsilon < \varepsilon_0$, a threshold that depends on the support of the test functions and on k.

We can take the limit $\varepsilon \to 0$ along the subsequence in the weak equations. We find that (P, H) again solves the weak equations (2.6) and (2.8). In particular, P is harmonic, satisfies a homogeneous Neumann condition on $\bar{\Gamma}_2$, and is piecewise constant on $\bar{\Gamma}_1$ for a.e. τ. Together with the L^∞-estimate this implies spatial continuity

of P, and an L^∞-bound for $Q_1 \partial_\tau H$. Therefore (2.1), (2.3), and (2.4) are satisfied in the strong sense.

It remains to take the limit in the nonlinear material law in (2.7). We exploit the fact that $Q_1 H^\varepsilon$ converges uniformly on compact sets to $Q_1 H$, and conclude (2.2). ∎

Remark 2.5. If the maximal pressure $p_{\max} = p_{\max}(k)$ is independent of k, then every solution of (2.1)–(2.5) satisfies

$$P(x,t) \leq p_{\max} \qquad \forall x \in \bar{\Omega},\, t \in \mathbb{R}.$$

Proof. By the comparison principle for harmonic functions, $P(\cdot,t)$ is bounded on the finite domain $(-M,M)\times(-M,0)$ by the periodic harmonic functions q_M with

$$\begin{aligned} &q_M = p_{\max} \quad \text{on } \bar{\Gamma}_1, \qquad \partial_2 q_M = 0 \quad \text{on } \bar{\Gamma}_2, \\ &q_M = C \quad \text{on } (-M,M)\times\{-M\}. \end{aligned}$$

For $M \to \infty$ the sequence of functions q_M tends to $p_{\max}$ on every bounded set. This implies the result. ∎

PROPOSITION 2.6. *We consider a solution (P,H) of system (2.1)–(2.5). On the material law we assume $\partial_s \mathcal{P}_0 > 0$ on $(0,s_0)$. If $p_{\max}$ is independent of k, then (P,H) can only be*

(a) *a constant solution, $P(\cdot) \equiv p^* \in [0,p_{\max}]$ in $\bar{\Omega}\times\mathbb{R}$,*

(b) *a solution with simultaneous explosions at an explosion time T_0 and with an outlet pattern $\alpha \in \{0,1\}^{\mathbb{Z}}$,*

$$\begin{aligned} &P(\cdot, T_0+\tau) = p_{\max} \qquad \forall \tau < 0, \\ &P(\cdot, T_0+\tau) = P_\alpha(\cdot,\tau) \quad \forall \tau > 0. \end{aligned}$$

Here P_α is the explosion solution to the opening pattern α: P_α is the unique solution of (2.1)–(2.5) to the initial values

$$P_\alpha(y_1,0,t=0) = \begin{cases} p_{\max} & \text{for } y_1 \in (k-\gamma,k+\gamma),\ \alpha(k)=1, \\ 0 & \text{for } y_1 \in (k-\gamma,k+\gamma),\ \alpha(k)=0. \end{cases}$$

Proof. Let (P,H) be given. We claim that if the solution satisfies $P(\cdot,T_0) \not\equiv p_{\max}$ for some $T_0 \in \mathbb{R}$, then no explosion can happen at a later time.

We compare P in the neighborhood of a single cell, say

$$(y_1,y_2) \in R := (-1/2,1/2)\times(-1,0),$$

with the solution q of

$$\begin{aligned} \Delta_y q(t) &= 0 && \text{in } R,\ \forall t \in (T_0,\infty), \\ q(\cdot,0,t) &= q_0(t) && \text{on } (-\gamma,\gamma),\ \forall t \in (T_0,\infty), \\ \partial_2 q &= 0 && \text{on } (-1/2,-\gamma)\cup(\gamma,1/2), \\ q &= p_{\max} && \text{on } \partial R \backslash \bar{\Gamma}, \\ \partial_t q_0 &= -c_q \frac{1}{2\gamma} \int_{-\gamma}^{\gamma} \partial_2 q. \end{aligned}$$

The initial value for q_0 and the constant c_q remain to be chosen.

We claim that for $q_0(t=0) < p_{\max}$ the function q_0 remains below $p_{\max}$ for all times. Since the minimum of q is on Γ_1, there holds $-\partial_2 q \geq 0$ on Γ_1. For some positive $\bar{c}$ we have the estimate

$$\frac{1}{2\gamma}\int_{-\gamma}^{\gamma}(-\partial_2 q) \leq \bar{c}(p_{\max} - q_0).$$

This holds since the left-hand side is finite for fixed q_0 and a linear function of the difference $p_{\max} - q_0$. The estimate implies that q_0 grows with a speed at most proportional to $p_{\max} - q_0$. This implies that a convergence of q_0 to $p_{\max}$ has at most exponential rate.

We now use q as a comparison function for P. In a cell with $P(y_1, 0, T_0) < p_{\max}$ we choose $c_q > \sup_s \partial_s \mathcal{P}_0$ and $p_{\max} > q_0(t=T_0) > P(y_1,0,T_0)$. Then $P \leq q$ holds for $t = T_0$ on R. If $P = q$ for the first time at some point in R, coincidence holds also on a point of the boundary Γ_1, and we have $P = q$ along Γ_1, since both functions are constant. Then $-\partial_2 q \geq -\partial_2 P$ along Γ_1 and we find

$$\begin{aligned}\partial_t P = \partial_s \mathcal{P}_0 \cdot \partial_t H &= -\partial_s \mathcal{P}_0 \cdot \frac{1}{2\gamma}\int_{-\gamma}^{\gamma}\partial_2 P \\ &\leq -\partial_s \mathcal{P}_0 \cdot \frac{1}{2\gamma}\int_{-\gamma}^{\gamma}\partial_2 q < -c_q \frac{1}{2\gamma}\int_{-\gamma}^{\gamma}\partial_2 q = \partial_t q_0.\end{aligned}$$

Therefore $P \leq q$ holds for all times and also P does not reach the value $p_{\max}$ in finite time. In cells with $P(y_1, t) = p_{\max}$ the Hopf lemma implies $\partial_t P(y_1, 0, t) < 0$, and we can apply the above argument for $|t - T_0|$ small.

We claim that solutions without explosions are constants. In (A.4) of Proposition A.3, we demonstrate that a solution without explosions on the time interval $(0, \infty)$ converges to a constant function for $t \to \infty$, independent of the initial values. Since the solution (P, H) is defined for all negative times we conclude that $P(t)$ is constant for all t. The uniqueness of the solution P_α follows from the linearized stability. ∎

By the above proposition we know that there exist only a few possible micropatterns. Next we want to use this as information about microlocal patterns. To this end we have to choose an energy density.

DEFINITION 2.7. *The measure of microlocal patterns ν of the sequence p^ε is defined via the energy density e^ε, which we construct as a sum of Dirac measures. We define the finite set of explosion points by*

$$M^\varepsilon := \{s = (x_1, 0, t) \in \Gamma \times (0, T) \mid p^\varepsilon(s) = 0,\ x_1 \in \varepsilon\mathbb{Z}\},$$

and set

$$e^\varepsilon(\bar{S}) := \varepsilon \sum_{(x_1,0,t)\in M^\varepsilon \cap \bar{S}} s_0(x_1 \varepsilon^{-1}).$$

The set M^ε is finite, since $\partial_t p^\varepsilon > 0$ holds in points of M^ε. The sequence of measures e^ε is bounded. Since H^ε never passes a value in $s_0\mathbb{Z}$ in the negative direction, every explosion corresponds to a loss $\varepsilon 2\gamma s_0$ of fluid mass. Therefore in the space-time volume $\bar{S} = \Gamma \times (t_1, t_2)$ there holds by conservation of mass

$$|M^\varepsilon| \leq \frac{2}{\varepsilon} + \frac{\|V_0\|_{L^1}|t_2 - t_1|}{2\gamma\varepsilon \inf\{s_0(\cdot)\}},$$

which implies

$$e^\varepsilon(\bar S) \le \left(2 + \frac{\|V_0\|_{L^1}|t_2 - t_1|}{2\gamma \inf\{s_0(\cdot)\}}\right) \sup\{s_0(\cdot)\}.$$

Remark. The disadvantage of the above energy density e^ε is that it can be defined only in the case that explosions can be localized to a point; for a continuous $\mathcal{P}_0$-function we cannot define an analogue of it.

In the continuous case one could introduce an energy density by setting

$$\tilde e^\varepsilon(x,t) := \frac{1}{2\gamma}(v_2^\varepsilon(x,0,t))_+.$$

The two energy densities have many similarities; note the disadvantage of $\tilde e^\varepsilon$ that it can become positive also because of oscillations without explosions.

We saw that the qualitative behavior of the limit p^0 is different in the periodic situation and in the (expected) physical situation of explosions that are far from each other. The limit measure ν allows us to distinguish the two situations in terms of the explosion patterns. In the periodic case, the patterns will also be periodic; i.e., ν is supported on periodic and therefore infinite patterns. With the subsequent definition we distinguish the two cases.

DEFINITION 2.8. *We say that ν is of* finite type, *if for some constant $C_f \in \mathbb{N}$ there holds the following: every observable explosion pattern has at most C_f explosion points, i.e.,*

$$P_\alpha \in \operatorname{supp}(\nu_K) \Rightarrow |\alpha| := |\{k \in \mathbb{Z} : \alpha(k) = 1\}| \le C_f.$$

Consider the energy density e^ε and assume that ν is of finite type. Then

$$\operatorname{supp}(\nu_K) \subset \bigcup_{\alpha\in A} \{P_\alpha\} \quad \text{with } A \subset \{\alpha \in \{0,1\}^{\mathbb{Z}} : |\alpha| \le C_f\}.$$

The limit measure ν can then be written as

$$\nu(\bar S \times \bar K) = \sum_{\alpha\in A} \int_{\bar S} \eta_\alpha(\bar K) d\mu_\alpha(s), \tag{2.9}$$

where μ_α are measures on $\Gamma \times [0,T]$ and η_α is the Dirac measure on K on the explosion solution P_α.

We exploited that the constant pressure solutions do not contribute to the energy and in (2.9) that A is countable.

3. Limit measures of finite type and regions without explosions. We continue our study of a sequence of solutions $(p^\varepsilon, h^\varepsilon)$ and their L^∞_w-limit p^0. In order to derive and even to formulate upscaled equations for p^0 we need some regularity result for p^ε and p^0. In the case that the limit measure ν is of finite type, a fundamental regularity statement holds: loosely speaking, spatial averages of the pressure p^0 cannot have jumps in time. This, in turn, helps us to find regions without explosions: points with $p^0 < p_{\max}$ have neighborhoods in which the ε-system is without explosions for all small ε. Note that the pointwise statement $p^0 < p_{\max}$ has to be interpreted in an appropriate way for the L^∞-function p^0. Regularity properties of p^ε in regions without explosions will be exploited in section 4.

We start with a crucial observation: if the average pressure of the ε-system is below $p_{\max}$ in a small area, then there cannot be explosions.

LEMMA 3.1 (quantitative Hopf lemma/near field effect). *Let $q : [-1,1]\times[-1,0] \to \mathbb{R}$ be a harmonic function, periodic in the first variable, and continuous up to the boundary, with $0 \le q \le p_{\max}$. Let $x \in [-1,1] \times \{0\} \equiv [-1,1]_{\mathrm{per}}$ be a point with $q(x) = p_{\max}$ and*

$$\frac{1}{2\delta}\int_{x-\delta}^{x+\delta} q(\xi)\, d\xi = \rho < p_{\max}.$$

Then the Neumann derivative in x has a lower bound

$$\partial_2 q(x) \ge c_H(\delta,\rho)$$

with $c_H(\delta,\rho) \to +\infty$ for fixed $\rho < p_{\max}$ and $\delta \to 0$.

COROLLARY 3.2. *There exists $\delta_0 > 0$ depending only on $\|V_0\|_{L^\infty}$, $p_{\max}$, and ρ, such that for small ε every solution p^ε of (1.2)–(1.6) with*

$$p^\varepsilon_\delta(x,t) := \frac{1}{2\delta}\int_{x-\delta}^{x+\delta} p^\varepsilon(\xi,t)\, d\xi \le \rho \qquad \forall t \in (t_1,t_2)$$

satisfies the following for $\delta < \delta_0$: p^ε has no explosion in $(x-\delta, x+\delta)\times(t_1,t_2)$.

Proof. In order to have an explosion in (x,t) we must have $\lim_{\tau \nearrow t} p^\varepsilon(x,\tau) = p_{\max}$ and $\lim_{\tau\nearrow t}(-\partial_2 p^\varepsilon(x,t)) \ge 0$. If we assume that $p^\varepsilon \le p_{\max}$ holds in the whole domain, Lemma 3.1 yields that $-\partial_2 p^\varepsilon$ is negative for small δ, and no explosion is possible. In the general case we decompose p^ε into one part p_A with the boundary values p^ε on Γ_1^ε and $\partial_2 p_A = 0$ on Γ_0, and a remainder p_B with vanishing values on Γ_1^ε and $-\partial_2 p_B = V_0$ on Γ_0, both with $\partial_2 p_{A,B} = 0$ on Γ_2^ε. Then $|\partial_2 p_B|$ is uniformly bounded and p_A is bounded by $p_{\max}$, so Lemma 3.1 applies to p_A. We conclude that $\partial_2 p_A(x,t)$ is large and that no explosion is possible. ∎

Proof of Lemma 3.1. We can assume $(x,t) = (0,0)$. The lemma follows from an argument that is related to rearrangement. For given ρ and δ, the Neumann derivative is minimal if $q = p_{\max}$ in a neighborhood $(-s,s)$ of x and $q = 0$ in the region $s < |x| < \delta$, where s is chosen such that $2sp_{\max} = \int_{-\delta}^{\delta} q = 2\delta\rho$. This can be seen as follows. The quantity $\partial_2 q(0,0)$ is decreased if we modify the Dirichlet boundary values on $(-\delta,\delta)$ by adding a nonnegative multiple of the function $v : (-1,1) \to \mathbb{R}$,

$$v(x) := \begin{cases} +1 & \text{for } |x| \in (x_1, x_1+r),\\ -1 & \text{for } |x| \in (x_2, x_2+r),\\ 0 & \text{else} \end{cases}$$

for $0 < x_1 < x_1 + r < x_2$ or $0 > x_1 > x_1 - r > x_2$. The harmonic extension $\bar v$ of v satisfies $\partial_2 \bar v(0) \le 0$, since $\bar v$ is nonnegative in a neighborhood of 0 by the monotonicity of the Green's function.

The above modifications allow a redistribution of the boundary values of q. It allows us to compare $\partial_2 q(0)$ with $\partial_2 q_\delta(0)$, where q_δ is the solution of the periodic problem

$$\begin{aligned} \Delta q &= 0 && \text{in } (-1,1)\times(-1,0),\\ q &= w && \text{on } (-1,1)\times\{0\},\\ q &= p_{\max} && \text{on } (-1,1)\times\{-1\}, \end{aligned}$$

with the boundary values

$$w(x) := \begin{cases} 0 & \text{for } s < |x| < \delta, \\ p_{\max} & \text{else.} \end{cases}$$

The number $s := \sigma\delta := \frac{\rho}{p_{\max}}\delta$ is determined by the integral condition $\int_{-\delta}^{\delta} w = 2\delta\rho$. From the Hopf lemma we know that $c_H(\delta,\rho) := \partial_2 q_\delta(0) > 0$.

In order to show $c_H(\delta,\rho) \to +\infty$ for $\delta \to 0$ it remains to consider the family of harmonic functions q_δ for $s = \sigma\delta$ and σ fixed. On the domain $\mathbb{R} \times \mathbb{R}_-$ we find the general solution q_δ by rescaling q_1: $q_\delta(x) = q_1(x/\delta)$. We calculate

$$\partial_2 q_\delta(0) = \frac{1}{\delta}\partial_2 q_1(0) \to \infty$$

for $\delta \to 0$. On the bounded domain the asymptotic behavior remains unchanged and we find the result. □

LEMMA 3.3. *Assume that the measure ν is of finite type. Let $0 < c < 1$ be an arbitrary number that we interpret as an explosion density. Then there is no subsequence $\varepsilon_k \to 0$ such that in the ε_k-systems there happen $\frac{c}{\varepsilon_k}$ explosions simultaneously.*

Proof. We present here the proof in the case that ν_K is supported only on the pattern P_0 of the single explosion. The proof in the general case requires only additional notational effort.

Step 1. We consider a sequence $\beta_N \in \{0,1\}^{\{-N,\dots,N\}}$ (patterns) with $|\beta_N| := \big|\{x \in \{-N,\dots,N\} \mid \beta_N(x) = 1\}\big| \geq c \cdot 2N$.

Claim. There exist a number $\rho > 0$, a distance $d \in \mathbb{N}$, and a subsequence $N \to \infty$ such that all β_N realize the distance d at least with density ρ, i.e.,

$$\big|\{x \in \{-N,\dots,N\} \mid \beta_N(x) = 1,\, \beta_N(x+d) = 1\}\big| \geq \rho \cdot 2N \quad \forall N.$$

We argue by contradiction and assume that the claim is not true. With d_0 applications we find that for every $\rho > 0$ and $d_0 \in \mathbb{N}$, there exists $N_0 > 0$ such that for all $N \geq N_0$ the distances $d = 1, 2, \dots, d_0$ are realized with density less than ρ. We calculate for large N the density of β_N. On $d_0\rho \cdot 2N$ points we have no restriction, on the remaining places we have at most $2N/(d_0+1)$ values 1. We calculate for the density

$$c \leq \frac{|\beta_N|}{2N} \leq \frac{d_0\rho \cdot 2N + 2N/(d_0+1)}{2N} = d_0\rho + \frac{1}{d_0+1}.$$

Since ρ and d_0 were arbitrary we arrive at a contradiction.

Step 2. We assume that for a subsequence $\varepsilon_k \to 0$ there are $\frac{c}{\varepsilon_k}$ simultaneous explosions. We claim that this contradicts the fact that no pattern of length 2 is contained in the limit measure ν.

We set $N = 1/\varepsilon$ and denote by t^ε the time instance of the simultaneous explosions. For $x \in \mathbb{Z}$ we set $\beta_N(x) = 1$ if at position $(\varepsilon x, t^\varepsilon)$ the ε-problem has an explosion, i.e., $p^\varepsilon(\varepsilon x, t^\varepsilon) = 0$, $\beta_N(x) = 0$ otherwise. By the above claim, for some $\rho > 0$, $d \in \mathbb{N}$, and a subsequence $N \to \infty$, β_N realizes the distance d of values 1 at least ρN times, say at positions $\{x_i\}$. Let $\bar{K}$ be a neighborhood of the single explosion P_0 in K, such that all patterns $k \in K$ with an explosion in $x_1 = d$ are not contained in $\bar{K}$. Then there are ρ/ε points $s_i = (\varepsilon x_i, t^\varepsilon)$ at which $R^\varepsilon_s p^\varepsilon$ is not contained in $\bar{K}$. Therefore

$$\nu^\varepsilon(S \times \bar{K}) \leq \nu^\varepsilon(S \times K) - \rho \inf\{s_0\}.$$

On the other hand, by assumption, we have

$$\nu^\varepsilon \to \mu \otimes \delta_{P_0} \in \mathcal{M}(S \times K),$$

which implies

$$\begin{aligned}\mu(S) &= \lim_{\varepsilon\to 0} \nu^\varepsilon(S \times \bar{K}) \le \lim_{\varepsilon\to 0} \nu^\varepsilon(S \times K) - \rho \inf\{s_0\} \\ &= \mu(S) - \rho \inf\{s_0\},\end{aligned}$$

a contradiction. □

Note that the result of the above lemma could be improved: not only can we not have $O(N)$ explosions at the same time instance, but it is also impossible to realize $O(N)$ explosions in a time span of length $O(\varepsilon)$. Even if in Proposition 2.6 we showed that in the limit patterns explosions happen simultaneously, this need not be true for the ε-problem. Nevertheless, the statement of Lemma 3.3 will be sufficient for our purposes.

We next prove an auxiliary result on the maximal gain of fluid-mass in a test volume in a short time.

LEMMA 3.4. *In every domain $W = B_\delta(x) \times (-1, 0)$, the maximal total inward flow through the lateral boundaries $\Sigma_\pm = \{x \pm \delta\} \times (-1, 0)$ can be estimated with arbitrary $\delta_0 > \delta$ by*

$$\begin{aligned}\int_{t_1}^{t_2} \int_\Sigma \partial_n p^\varepsilon \le{}& 2p_{\max} \frac{t_2 - t_1}{\delta_0 - \delta} \\ &+ 4\gamma(\delta_0 - \delta) \sup\{s_0\} + 2(t_2 - t_1)(\delta_0 - \delta)\|V_0\|_\infty.\end{aligned} \tag{3.1}$$

In particular, the bound can be chosen arbitrarily small for $t_2 - t_1$ small.

Proof. We do the calculations for the right boundary $\Sigma_{x+\delta} := \{x + \delta\} \times (-1, 0)$. The average total flow to the left between $x + \delta$ and $x + \delta_0$ is

$$\begin{aligned}\int_{t_1}^{t_2} \frac{1}{\delta_0 - \delta} \int_{x+\delta}^{x+\delta_0} \int_{-1}^{0} \partial_1 p^\varepsilon &\le \frac{1}{\delta_0 - \delta} \int_{t_1}^{t_2} \left(\int_{\Sigma_{x+\delta_0}} p^\varepsilon - \int_{\Sigma_{x+\delta}} p^\varepsilon \right) \\ &\le p_{\max} \frac{t_2 - t_1}{\delta_0 - \delta}.\end{aligned}$$

Then there is an intermediate value $z \in (x + \delta, x + \delta_0)$ where the average total flow is realized,

$$\int_{\Sigma_z} \int_{t_1}^{t_2} \partial_1 p^\varepsilon \le p_{\max} \frac{t_2 - t_1}{\delta_0 - \delta}.$$

By incompressibility, the maximal total flow through $\Sigma_{x+\delta}$ is the sum of two contributions: (1) the flow through Σ_z in the time interval (t_1, t_2), (2) the total inward flow through the upper boundary $(x+\delta, z) \times \{0\}$ and the lower boundary $(x+\delta, z) \times \{-1\}$. The total volume that can be released on Γ between $x + \delta$ and z is bounded by $2\gamma(\delta_0 - \delta) \cdot \sup\{s_0\}$. Formula (3.1) follows, with the factor 2 we include the left boundary. □

If the limit measure ν is of finite type we expect that the typical distance between explosions is large compared to ε. The following proposition verifies and sharpens this statement. Let us imagine that at temporal distances $O(\sqrt{\varepsilon})$ there happen $1/\sqrt{\varepsilon}$

explosions. Then the spatio-temporal distance between two explosions is always large compared to ε. Nevertheless, $1/\varepsilon$ explosions happen in a given spatio-temporal region. With such a construction it is also possible to have $1/\varepsilon$ explosions in an arbitrarily short time span Δt. The next proposition excludes this possibility for our evolution equations.

PROPOSITION 3.5. *If the measure ν is of finite type, then the marginal $\mu(\Gamma, \cdot) \in \mathcal{M}([0,T])$ of the measure ν, $\mu(\Gamma, (t_1, t_2)) := \nu(\Gamma \times (t_1, t_2) \times K)$, contains no atoms,*

$$\mu(\Gamma \times \{t\}) = 0 \quad \forall t \in (0, T]. \tag{3.2}$$

Proof. We assume that the limit measure $\mu(\Gamma, \cdot)$ contains an atom. Then for some $\bar{t}$,

$$e := \liminf_{\Delta t \to 0} \mu(\Gamma \times (\bar{t} - \Delta t, \bar{t} + \Delta t)) > 0. \tag{3.3}$$

The interpretation is that along the subsequence $\varepsilon \to 0$ we find $O(e/\varepsilon)$ explosions in the time span $(\bar{t} - \Delta t, \bar{t} + \Delta t)$.

To arrive at a contradiction we first choose $\Delta\rho$ small compared to e. The smallness will be specified towards the end of our calculations. We now fix $\delta > 0$. The required smallness for δ depends only on the numbers e and $\Delta\rho$, and on the boundary data V_0. Note that choosing $\delta > 0$ small we find, by Corollary 3.2,

$$\begin{aligned} &p_\delta^\varepsilon(x,t) < p_{\max} - \Delta\rho \quad \forall t \in (t_1, t_2) \\ &\quad \Rightarrow \text{no explosions happen in } B_\delta(x) \times (t_1, t_2). \end{aligned} \tag{3.4}$$

Given δ, we find a position $x \in [-1, 1]$ such that

$$\limsup_{\Delta t \to 0} \mu(B_\delta(x) \times (\bar{t} - \Delta t, \bar{t} + \Delta t)) \geq e \cdot \delta.$$

Using periodicity of the domain we can assume $x \in (-1 + \delta, 1 - \delta)$. We now fix Δt small, such that $\mu(B_\delta(x) \times (\bar{t} - \Delta t, \bar{t} + \Delta t)) \geq \frac{e\delta}{2}$, and such that additionally for a given constant $c_g > 0$ (depending on δ) there holds

$$\frac{e\delta}{16} \geq \|V_0\|_\infty \cdot 4\delta |\Delta t| + c_g \sqrt{\Delta t}.$$

We next choose ε small enough to have

$$\mu^\varepsilon(B_\delta(x) \times (\bar{t} - \Delta t, \bar{t} + \Delta t)) \geq \frac{1}{2} \mu(B_\delta(x) \times (\bar{t} - \Delta t, \bar{t} + \Delta t)),$$

and that there are no c/ε explosions at the same time instance (a small c is chosen in dependence of e and δ). The latter property is insured for small ε by Lemma 3.3. For this ε, we set $t_1 \in [\bar{t} - \Delta t, \bar{t} + \Delta t]$ to be the moment of the first explosion in $B_\delta(x)$, and set $t_2 = \bar{t} + \Delta t$. We introduce the time instance t^ε at which half of the explosions in $B_\delta(x) \times [t_1, t_2]$ have happened. At this point Lemma 3.3 guarantees that some explosions must happen after this time instance.

We can estimate the number of explosions of the ε-system in the test volume by

$$\begin{aligned} \mu^\varepsilon(B_\delta(x) \times (t_1, t^\varepsilon]) &\geq \frac{1}{2} \mu^\varepsilon(B_\delta(x) \times (\bar{t} - \Delta t, \bar{t} + \Delta t)) \\ &\geq \frac{1}{4} \mu(B_\delta(x) \times (\bar{t} - \Delta t, \bar{t} + \Delta t)) \geq \frac{e\delta}{8}. \end{aligned}$$

This means that in the ε-system at least $(e\delta)/(8\varepsilon \sup\{s_0\})$ explosions happen in $B_\delta(x) \times [t_1, t^\varepsilon]$. We will show that this implies that the average pressure is below $p_{\max}$ in t^ε and will conclude with Corollary 3.2. It remains to verify the implication

$$\text{loss of mass in explosions } \Rightarrow \text{ loss of pressure.}$$

In what follows we will use the estimate for the lateral inflow

$$\int_{t_1}^{t_2} \int_\Sigma \partial_n p^\varepsilon \le c_g \sqrt{\Delta t} \tag{3.5}$$

for small Δt, which follows from Lemma 3.4 if we choose $\delta_0 = \delta + \sqrt{t_2 - t_1}$. We calculate the gain of fluid mass in the ε-system by adding the inflow into the box from below and the loss due to explosions; in the following we consider only values of h^ε in $[0, s_0]$; i.e., in an explosion we set h^ε to zero. For all $t \in (t^\varepsilon, \bar{t} + \Delta t)$,

$$\begin{aligned}
&\int_{B_\delta(x) \cap \Gamma_{\bar{1}}^\varepsilon} \varepsilon^{-1} h^\varepsilon(\xi, \tau)\, d\xi \Big|_{\tau = t_1}^{t} \\
&\quad \le \|V_0\|_\infty \cdot 2\delta 2 |\Delta t| + c_g \sqrt{\Delta t} - \mu^\varepsilon(B_\delta(x) \times (t_1, t^\varepsilon)) \\
&\quad \le \|V_0\|_\infty \cdot 4\delta |\Delta t| + c_g \sqrt{\Delta t} - \frac{e\delta}{8} \le -\frac{e\delta}{16}.
\end{aligned}$$

We see that a decrease of fluid mass of order $O(1)$ took place in the test volume. We want to conclude from this that the average pressure also decreased by the order $O(1)$. We have to compare the effect of loss of mass with an effect that has the potential to increase the average pressure: redistribution of mass.

This effect is controlled in the following. We know that the average pressure at time t_1 satisfies $p_\delta^\varepsilon(x) \ge p_{\max} - \Delta\rho$, since an explosion happens at this time instance. Until time t the values of h^ε change, but although some of them might increase, we verify that this is not a large contribution. We sum over $x_i \in \varepsilon\mathbb{Z}$ with $x_i \in B_\delta(x)$,

$$\begin{aligned}
\frac{1}{2\delta} \sum_i (h^\varepsilon(x_i, t) - h^\varepsilon(x_i, t_1))_+ &\le \frac{1}{2\delta} \sum_i \left(\varepsilon \frac{p_{\max}}{a_0(i)} - h^\varepsilon(x_i, t_1) \right) \\
&= \frac{\varepsilon}{2\delta} \sum_i \frac{1}{a_0(i)} (p_{\max} - p^\varepsilon(x_i, t_1)) \\
&\le \frac{1}{\inf\{a_0\}} \frac{1}{2\delta} \frac{1}{2\gamma} \int_{B_\delta(x) \cap \Gamma_{\bar{1}}^\varepsilon} (p_{\max} - p^\varepsilon(\cdot, t_1)) \\
&\le \frac{1}{\inf\{a_0\}} \cdot \Delta\rho + o(1).
\end{aligned}$$

In the last line we used that in the limit $\varepsilon \to 0$ the two averages $\frac{1}{2\delta \cdot 2\gamma} \int_{B_\delta(x) \cap \Gamma_{\bar{1}}^\varepsilon} p$ and $\frac{1}{2\delta} \int_{B_\delta(x)} p$ coincide. Except for boundary effects, both expressions define linear and translation invariant averages of the values $p(x_i)$. The boundary effects vanish for $\varepsilon \to 0$ and the two expressions asymptotically coincide with the arithmetic mean of the values $p(x_i)$.

We can now calculate an upper bound for the average pressure at an arbitrary

time instance $t \in (t^\varepsilon, t_2]$,

$$\begin{aligned}\int_{B_\delta(x)} p^\varepsilon(\xi,t)\ d\xi &\le \int_{B_\delta(x)} p^\varepsilon(\xi,t_1)\ d\xi \\ &\quad + \sum_i (h^\varepsilon(x_i,t) - h^\varepsilon(x_i,t_1))_- \cdot \inf\{a_0\} \\ &\quad + \sum_i (h^\varepsilon(x_i,t) - h^\varepsilon(x_i,t_1))_+ \cdot \sup\{a_0\} + o(1) \\ &\le 2\delta p_{\max} + \sum_i (h^\varepsilon(x_i,t) - h^\varepsilon(x_i,t_1)) \cdot \inf\{a_0\} \\ &\quad + \sum_i (h^\varepsilon(x_i,t) - h^\varepsilon(x_i,t_1))_+ \cdot (\sup\{a_0\} - \inf\{a_0\}) + o(1) \\ &\le 2\delta p_{\max} - \frac{1}{2\gamma}\frac{e\delta}{16} \cdot \inf\{a_0\} + 2\delta \cdot C\Delta\rho + o(1)\end{aligned}$$

for $\varepsilon \to 0$. The corrector $o(1)$ takes into account that the p-average over $B_\delta(x)$ coincides only asymptotically with the p-average over $B_\delta(x) \cap \Gamma_1^\varepsilon$. Dividing by 2δ we find for small ε

$$\frac{1}{2\delta}\int_{B_\delta(x)} p^\varepsilon(\xi,t)\ d\xi \le p_{\max} - \Delta\rho \qquad \forall t \in (t^\varepsilon, t_2),$$

if $\Delta\rho$ was chosen small compared to e. We know that in the ball $B_\delta(x)$ there happen explosions in the time interval (t^ε, t_2). This is in contradiction with the fact that for our choice of δ, below the average pressure $p_{\max} - \Delta\rho$, there can be no explosions by Corollary 3.2. □

In case that ν is of finite type, the measure μ has a direct physical interpretation. For every set $\bar{S} = \Gamma \times (t_1, t_2)$ the number $\mu(\bar{S})$ is the weighted number of explosions in $\bar{S}$. If $s_0(k) = 1$ for all k, then

$$\mu(\bar{S}) = \nu(\bar{S} \times K) = \lim_{\varepsilon \to 0} \left(\varepsilon \cdot \#\{\text{explosions in } \bar{S}\}\right),$$

the limit taken along the chosen subsequence. In the general case μ measures the total mass of fluid that is lost in explosions.

Our next aim is to show the following relation between the measure of limit patterns and spatial averages of the limit pressure $p_\delta^0(x,t)$. Loosely speaking, we show

$$\nu \text{ of finite type } \Rightarrow\ p_\delta^0 \text{ has no jumps.}$$

In order to show this statement, by Proposition 3.5, it remains to verify that if $\mu(\Gamma, \cdot)$ contains no atoms, then p_δ^0 has no jumps. By definition, the functions p_δ^0 are Lipschitz continuous in x for every t. In order to state regularity properties in time, we choose as a representative of p_δ^0 the temporal maximal function,

$$p_\delta^0(x,t) = \limsup_{r \searrow 0} \frac{1}{2r}\int_{t-r}^{t+r} p_\delta^0(x,\tau)\ d\tau.$$

In the following we work with this representative of p_δ^0.

PROPOSITION 3.6. *Assume that the measure $\mu(\Gamma,\cdot)$ contains no atoms. If in a point $(x,\bar t\,)$ the average pressure is not maximal,*

$$p^0_\delta(x,\bar t\,)=\rho<p_{\max}, \tag{3.6}$$

then there exist $\rho_0<p_{\max}$, $\varepsilon_0>0$, and $t_1<\bar t<t_2$ with

$$p^\varepsilon_\delta(x,t)\le\rho_0 \quad \forall t\in(t_1,t_2),\ \varepsilon<\varepsilon_0, \tag{3.7}$$

$$p^0_\delta(x,t)\le\rho_0 \quad \forall t\in(t_1,t_2). \tag{3.8}$$

The number ρ_0 does not depend on δ.

Proof. Our emphasis in this proposition lies on finding $t_1<\bar t$; in this part the assumption on μ is used. The proof has similarity with the proof of Proposition 3.5, but this time we use the converse implication

$$\text{loss of pressure } \Rightarrow \text{ loss of mass in explosions.}$$

We choose $\Delta\rho$ small compared to $p_{\max}-\rho$. Let us assume that for a subsequence $\varepsilon\to0$ and a sequence $t_1^\varepsilon\nearrow\bar t$ there holds

$$p^\varepsilon_\delta(x,t_1^\varepsilon)\ge p_{\max}-\Delta\rho.$$

From (3.6) we conclude that there exists $t^\varepsilon>t_1^\varepsilon$ arbitrarily close to $\bar t$ with

$$p^\varepsilon_\delta(x,t^\varepsilon)\le\rho+\Delta\rho.$$

This follows from the fact that spatio-temporal averages of p^ε converge to the corresponding averages of p^0. Exploiting that the pressure in t_1^ε is large, we verify that redistribution of mass between the cells is a small effect,

$$\begin{aligned}\frac{1}{2\delta}\sum_i(h^\varepsilon(x_i,t^\varepsilon)-h^\varepsilon(x_i,t_1^\varepsilon))_+ &\le \frac{1}{2\delta}\sum_i\left(\varepsilon\frac{p_{\max}}{a_0(i)}-h^\varepsilon(x_i,t_1^\varepsilon)\right)\\ &=\frac{\varepsilon}{2\delta}\sum_i\frac{1}{a_0(i)}(p_{\max}-p^\varepsilon(x_i,t_1^\varepsilon))\le c_h.\end{aligned}$$

For small ε the constant c_h can be chosen as $c_h=C\Delta\rho$ with C independent of δ. Our next aim is to conclude that the average height is decreased. We calculate

$$\begin{aligned}\rho-p_{\max}+2\Delta\rho &\ge \frac{1}{2\delta}\int_{B_\delta(x)}p^\varepsilon(\xi,\tau)\,d\xi\Big|_{t_1^\varepsilon}^{t^\varepsilon}\\ &\ge\frac{1}{2\delta 2\gamma}\int_{B_\delta(x)\cap\Gamma_1^\varepsilon}p^\varepsilon(\xi,\tau)\,d\xi\Big|_{t_1^\varepsilon}^{t^\varepsilon}+o(1)\\ &\ge\frac{1}{2\delta}\sum_i(h^\varepsilon(x_i,t^\varepsilon)-h^\varepsilon(x_i,t_1^\varepsilon))_+\cdot\inf\{a_0\}\\ &\quad+\frac{1}{2\delta}\sum_i(h^\varepsilon(x_i,t^\varepsilon)-h^\varepsilon(x_i,t_1^\varepsilon))_-\cdot\sup\{a_0\}+o(1)\\ &\ge c_h\cdot(\inf\{a_0\}-\sup\{a_0\})+o(1)\\ &\quad+\frac{1}{2\delta}\sum_i(h^\varepsilon(x_i,t^\varepsilon)-h^\varepsilon(x_i,t_1^\varepsilon))\cdot\sup\{a_0\}.\end{aligned}$$

For small ε and small $\Delta\rho$ we conclude for the change in the average height

$$\frac{1}{2\delta}\sum_i (h^\varepsilon(x_i,t^\varepsilon) - h^\varepsilon(x_i,t_1^\varepsilon))\cdot \sup\{a_0\} \le \rho - p_{\max} + (3+C)\Delta\rho < 0,$$

an order $O(1)$ loss of volume. As in the preceding proposition, for $t^\varepsilon - t_1^\varepsilon$ small enough, this cannot be induced by outflow on lateral or lower sides. Therefore, there are $O(1/\varepsilon)$ explosions and we have $\mu^\varepsilon(\Gamma\times(t_1,t_2)) \ge c > 0$ for all $t_2 > \bar t$ and for a subsequence $\varepsilon \to 0$. In the limit we find $\mu(\Gamma\times(t_1,t_2)) \ge c$; since t_1 and t_2 are arbitrary we found an atom of $\mu(\Gamma,\cdot)$ and thus a contradiction.

The construction of t_2 follows the same pattern. We calculate that an increase in pressure requires an increase in volume of order $O(1)$. This cannot be compensated by lateral inflow, inflow from below, or redistribution effects. Then there must be a gain of volume through the upper boundary Γ—a contradiction since no "negative explosions" are possible.

Property (3.8) follows from (3.7). Note that at first we find

$$p_\delta^0(x,t) \le \rho_0 \qquad \text{a.e. } t\in(t_1,t_2).$$

By the choice of the representative p_δ^0 we conclude that the inequality holds for all t. ∎

COROLLARY 3.7. *Assume that ν is of finite type. Let $s=(x,\bar t)\in\Gamma\times(0,T)$ be a point with*

$$\limsup_{\delta\to 0} p_\delta^0(s) = \rho < p_{\max}.$$

Then there exist $\delta_0>0$, $\varepsilon_0>0$, and $\Delta t>0$ such that for all $\varepsilon<\varepsilon_0$ there are no explosions in $B_{\delta_0}(x)\times(\bar t-\Delta t,\bar t+\Delta t)$, i.e.,

$$\mu^\varepsilon((x-\delta_0,x+\delta_0)\times(\bar t-\Delta t,\bar t+\Delta t)) = 0.$$

Proof. The result follows from inequality (3.7) using Corollary 3.2. Note that we have to pick a small δ in dependence of $\rho_0 < p_{\max}$; here we use that ρ_0 in Proposition 3.6 does not depend on δ. The conclusion remains valid if lim sup is replaced by lim inf in the assumption. ∎

4. Upscaled equations. Our aim is to derive the physical laws for the averaged pressure. On the boundary we expect a law relating the increase of pressure with the parameters pressure and normal velocity, and we write

$$p^0 < p_{\max} \Rightarrow \partial_t p^0 = \alpha(p^0, -\partial_2 p^0),$$
$$p^0 = p_{\max} \Rightarrow \partial_t p^0 = \alpha(p^0, -\partial_2 p^0)_-$$

for some function α. The first implication expresses that, as long as the maximally sustained pressure is not yet achieved, there is an increase of the pressure according to the local rules of filling pores. A flow towards the boundary increases the filling height of the single pore and, due to the monotonicity of the law $\mathcal{P}_0$, the pressure will increase. The second implication describes the situation once the maximally sustained pressure is achieved. A backward flow lowers the pressure according to the averaged law. A further flow towards the boundary results in explosions and cannot increase the pressure.

For the mathematical interpretation of the above equations some care must be applied. For $p^0 \in L^\infty$ we will interpret the condition $p^0 < p_{\max}$ as

$$\limsup_{\delta \to 0} p^0_\delta(x,t) < p_{\max}.$$

On the right-hand side of the equations $\partial_2 p^0|_\Gamma$ has a meaning as a distribution. But, for the second implication, it is not clear how to take the negative part of this distribution in some parts of the boundary, the full expression in others. We should show the following relations along Γ:

$$p^0 \le p_{\max} \quad \text{a.e. on } \Gamma, \tag{4.1}$$

$$p^0(x,t) < p_{\max} \Rightarrow \partial_t p^0 = \alpha(p^0, -\partial_2 p^0), \tag{4.2}$$

$$\partial_t p^0 \le \alpha(p^0, -\partial_2 p^0) \quad \text{as distributions on } \Gamma. \tag{4.3}$$

The first inequality is immediate, since every p^ε satisfies the inequality. The evolution equation is (4.2) and it is interpreted in the sense of distributions in a neighborhood of (x,t). Inequality (4.3) is a lift-off condition. In the case of linear laws it can be shown just as (4.2). In the nonlinear case the proof is more involved, since in the situation of (4.3) the solution has less regularity properties than in the situation of (4.2).

Our aim is to homogenize the law $p^\varepsilon(\varepsilon i) = \mathcal{P}_0(i, \varepsilon^{-1} h^\varepsilon(\varepsilon i))$. The function $\mathcal{P}_0$ depends in an oscillatory fashion on x, and the function h^ε will in general also have an oscillatory behavior. Therefore a homogenization limit has to be performed. The key in the proofs is to assure regularity properties of p^ε. We want to analyze not only linear laws as in (1.7), but also more general nonlinear models.

DEFINITION 4.1. *We speak of a nonlinear model if the laws $\mathcal{P}_0(i,\cdot)$ are nonlinear $s_0(i)$-periodic functions with $\max \mathcal{P}_0(i,\cdot) = \mathcal{P}_0(i, s_0(i)) = p_{\max}$ and $0 < a_1 \le \mathcal{P}_0'(i,\cdot) \le a_2 < \infty$ for all i, $s \in (0, s_0(i))$. We say that the nonlinear model satisfies the linear regularity properties if the statement of Lemma 4.2 for the linear law holds also for the laws $\mathcal{P}_0(i,\cdot)$.*

An example of a nonlinear model that satisfies the linear regularity is given by the choice $\mathcal{P}_0(i,\cdot) = \mathcal{P}_0(s)$ with some strictly monotonically increasing function $\mathcal{P}_0 : [0, s_0) \to \mathbb{R}$.

We modify the function p^0 on a set of vanishing measure such that

$$p^0(x,t) = \limsup_{\delta \to 0} p^0_\delta(x,t).$$

LEMMA 4.2. *We consider linear laws $\mathcal{P}_0(i,\cdot)$ and we assume that the box $(x-\delta_0, x+\delta_0) \times (t-\Delta t, t+\Delta t)$ contains no explosions. Then there is a neighborhood $U \subset \Gamma \times \mathbb{R}$ of (x,t) in which the pressure $p^\varepsilon(\cdot,t)$ is continuous with modulus of continuity independent of ε and t.*

For every $\Delta\rho > 0$ there exist $\delta, \varepsilon_0 > 0$ such that for all $(x_1,\tau), (x_2,\tau) \in U$,

$$|p^\varepsilon(x_1,\tau) - p^\varepsilon(x_2,\tau)| \le \Delta\rho \qquad \forall |x_1 - x_2| < \delta,\ \varepsilon < \varepsilon_0, \tag{4.4}$$

$$|p^0(x_1,\tau) - p^0(x_2,\tau)| \le \Delta\rho \qquad \forall |x_1 - x_2| < \delta, \tag{4.5}$$

$$|p^\varepsilon(\xi,\tau) - p^\varepsilon_{\delta'}(x_1,\tau)| \le \Delta\rho \qquad \forall \xi \in B_{\delta'}(x_1),\ \varepsilon < \varepsilon_0,\ 0 < \delta' < \delta. \tag{4.6}$$

In the nonlinear case, (4.4) *and* (4.6) *hold for all τ except for an exceptional set of arbitrary small measure which can be prescribed together with $\Delta\rho$.*

Proof. In Proposition A.3 we show (4.4). It implies that local averages of p^0 satisfy the same inequality and we can conclude (4.5) by the theorem of Lebesgue. Inequality (4.6) is a direct consequence of (4.4).

In the nonlinear case, given $\Delta\rho$, we choose first κ and ε_0 such that the errors introduced by p_B and $p_{A,2}$ are small compared to $\Delta\rho$. By the uniform continuity of $p_{A,1}$ for most of the time we can choose δ small in order to satisfy (4.4). ∎

Remark 4.3 (partial continuity of p^0). Assume finiteness of ν and linearity of the laws $\mathcal{P}_0$. Let $s_0 = (x_0, t_0)$ be a boundary point with $p^0(s_0) < p_{\max}$. Then in a neighborhood U of s_0 the function p^0 is continuous in (x, t). Everywhere holds the equality

$$p^0(x,t) = \lim_{\delta\to 0} p^0_\delta(x,t). \tag{4.7}$$

Proof. By definition of the representative p^0 there holds

$$\limsup_{\delta\to 0} p^0_\delta(s_0) < p_{\max}.$$

Then Corollary 3.7 yields the existence of a neighborhood without explosions. Note that this holds also in points with $\liminf_{\delta\to 0} p^0_\delta(s_0) < p_{\max}$. Lemma 4.2 yields the existence of a smaller neighborhood U of (x_0, t_0) such that p^0 is uniformly continuous in x for a.e. t, with modulus of continuity independent of t. Furthermore Proposition A.3 yields uniform estimates for $\partial_t p^0_A|_\Gamma \in L^2$ in a space-time neighborhood of (x_0, t_0). They imply that

$$p^0_\delta(x,t) \quad \text{is continuous in } t.$$

We conclude that p^0 is continuous in (x, t).

We can now conclude (4.7). In points s with $\liminf_{\delta\to 0} p^0_\delta(s) < p_{\max}$ it is a consequence of the continuity of p^0. In the other case we have

$$p_{\max} = \liminf_{\delta\to 0} p^0_\delta(s) \le \limsup_{\delta\to 0} p^0_\delta(s) \le p_{\max}.$$

This implies again (4.7). ∎

With the above regularity properties of p^ε and p^0 we can now homogenize the law $\mathcal{P}_0$. As a model we have chosen a uniform law with $s_0(i) = s_0$ and $a_0(i) = a_0$ independent of the position i. In this case the expression (4.8) can be trivially calculated and equals $1/a_0$. We use the general expressions below in order to include stochastic and nonlinear models.

ASSUMPTION 4.4 (ergodicity). *Consider for $\rho \in (0, p_{\max})$ the expression*

$$\lim_{\varepsilon\to 0} \frac{\varepsilon}{2\delta} \sum_i \frac{1}{\mathcal{P}_0'(i, s_i)}, \tag{4.8}$$

where s_i are the unique solutions of $\mathcal{P}_0(i, s_i) = \rho$. The sum is taken over all indices i with $\varepsilon i \in B_\delta(x)$.

We assume on the function $\mathcal{P}_0$ that the above limit exists for all x and δ and that it is independent of x and δ.

An example of an ergodic material is a k_0-periodic function $\mathcal{P}_0$.

PROPOSITION 4.5 (a law for p^0 in regions without explosions). *Let the ergodicity assumption, Assumption 4.4, be satisfied and $R = (x - \delta_0, x + \delta_0) \times (t - \Delta t, t + \Delta t)$*

be a region without explosions. Then in R there holds in the sense of distributions in (x,t)

$$\partial_t \left[\Theta(p^0(x,t))\right] = -\partial_2 p^0(x,t), \tag{4.9}$$

where the function Θ satisfies

$$\Theta'(\rho) = \lim_{\varepsilon\to 0} 2\gamma \frac{\varepsilon}{2\delta} \sum_i \frac{1}{\mathcal{P}_0'(i,s_i)} \quad \forall \rho \in (0, p_{\max}). \tag{4.10}$$

On the right-hand side appears the expression of Assumption 4.4.

We emphasize that the above proposition holds also in the case of a nonlinear model without additional regularity assumptions.

Proof. We start the proof from the differentiated version of the microscopic pressure law $p^\varepsilon = \mathcal{P}_0(\varepsilon^{-1}h^\varepsilon)$ in a point $x_i = \varepsilon i$,

$$\partial_t p^\varepsilon(x_i,t) = \mathcal{P}_0'(i, \varepsilon^{-1}h^\varepsilon(x_i,t)) \cdot \varepsilon^{-1}\partial_t h^\varepsilon(x_i,t). \tag{4.11}$$

We have a one-to-one correspondence between pressure p^ε and height h^ε in every point x_i,

$$p^\varepsilon(x_i) = \mathcal{P}_0(i, \varepsilon^{-1}h^\varepsilon(x_i)) \quad \text{or} \quad h^\varepsilon(x_i) = \varepsilon H_0(i, p^\varepsilon(x_i)).$$

We introduce the functions Φ_i satisfying $\Phi_i(0) = 0$ and

$$\Phi_i'(\rho) = \frac{1}{\mathcal{P}_0'(i, H_0(i,\rho))}.$$

We now divide (4.11) by $\mathcal{P}_0'$ and, using (1.2), write the equation as

$$\frac{d}{dt}\Phi_i(p^\varepsilon(x_i,t)) = \varepsilon^{-1}\partial_t h^\varepsilon(x_i,t) = \frac{1}{\varepsilon 2\gamma}\int_{x_i-\gamma\varepsilon}^{x_i+\gamma\varepsilon} (-\partial_2 p^\varepsilon(\xi,t))\, d\xi.$$

Since we do not have knowledge on limits of time derivatives, we use the time integrated form. We additionally have to average over the spatial variable and use therefore the following time and space integrated equation:

$$\begin{aligned} &\frac{1}{\Delta t}\frac{\varepsilon}{2\delta}\sum_i [\Phi_i(p^\varepsilon(x_i, t+\Delta t)) - \Phi_i(p^\varepsilon(x_i,t))] \\ &\quad = \frac{1}{\Delta t}\frac{1}{2\gamma}\int_t^{t+\Delta t} (-\partial_2 p_\delta^\varepsilon(x,\tau))\, d\tau. \end{aligned} \tag{4.12}$$

We used here that taking x_1-spatial averages and the operator ∂_2 can be interchanged. The right-hand side converges for $\varepsilon \to 0$ as a distribution,

$$\frac{1}{\Delta t}\int_t^{t+\Delta t} (-\partial_2 p_\delta^\varepsilon)\, d\tau \to \frac{1}{\Delta t}\int_t^{t+\Delta t} (-\partial_2 p_\delta^0)\, d\tau.$$

Here the convergence of the integrand is interpreted as

$$\begin{aligned} &\int_\Gamma (-\partial_2 p_\delta^\varepsilon(x,\tau)) \cdot \varphi(x)\, dx \\ &\quad := -\int_\Gamma p_\delta^\varepsilon(x,\tau)\cdot \partial_2\varphi(x)\, dx + \int_\Omega p_\delta^\varepsilon(x,y,\tau)\cdot \Delta\varphi(x,y)\, dx\, dy \\ &\quad \to -\int_\Gamma p_\delta^0(x,\tau)\cdot \partial_2\varphi(x)\, dx + \int_\Omega p_\delta^0(x,y,\tau)\cdot \Delta\varphi(x,y)\, dx\, dy \\ &\quad =: \int_\Gamma (-\partial_2 p_\delta^0(x,\tau))\cdot\varphi(x)\, dx \end{aligned}$$

for all periodic $\varphi \in C^2(\Omega)$ with compact support in $\Omega \cup \Gamma$. In the convergence we used that $p^\varepsilon|_\Gamma \to p^0|_\Gamma$ in L^∞_w, and accordingly the convergence of $p^\varepsilon_\delta|_\Gamma$.

We next consider the left-hand side of (4.12) and its limit as $\varepsilon \to 0$. We choose the function $\Theta(\rho)$ of (4.10) as the average

$$\Theta(\rho) := \lim_{\varepsilon\to 0} 2\gamma \frac{\varepsilon}{2\delta} \sum_i \Phi_i(\rho).$$

Since averages of Φ_i' exist, averages of Φ_i also exist. We now have to use the fact that p^ε has no oscillations in x for most values of t. We pick a small $\Delta\rho > 0$ and choose $\delta_0 > 0$ small to satisfy

$$|p^\varepsilon(x_i,t) - p^\varepsilon_\delta(x,t)| \le \Delta\rho \qquad \forall x_i = \varepsilon i \in B_\delta(x),\ \delta < \delta_0,\ t \in \mathcal{T}_{\delta_0}.$$

Here we use Lemma 4.2. In the linear case we can choose $\mathcal{T}_{\delta_0} = (t_1, t_2)$; in the nonlinear case $\mathcal{T}_{\delta_0}$ is an (ε-dependent) subset of (t_1, t_2). For small $\delta_0 > 0$ the measure $|\mathcal{T}_{\delta_0}|$ is arbitrarily close to $|t_2 - t_1|$.

We next exploit that the averages p^ε_δ are uniformly continuous (Proposition A.3), and that we can choose a subsequence $\varepsilon \to 0$ such that $p^\varepsilon_\delta \to p^0_\delta$ uniformly in R. We use this to write

$$|p^\varepsilon(x_i,t) - p^0_\delta(x,t)| \le \Delta\rho + o(1) \qquad \forall i,\ \forall t \in \mathcal{T}_{\delta_0}.$$

With our knowledge on oscillations of p^ε we can now use

$$\begin{aligned} |\Phi_i(p^\varepsilon(x_i,t)) - \Phi_i(p^0_\delta(x,t))| &\le \sup_i \|\Phi_i'\|_\infty \cdot |p^\varepsilon(x_i,t) - p^0_\delta(x,t)| \\ &\le \frac{1}{a_1}(\Delta\rho + o(1)) \qquad \forall i,\ \forall t \in \mathcal{T}_{\delta_0} \end{aligned}$$

to perform the replacement

$$\frac{\varepsilon}{2\delta}\sum_i \Phi_i(p^\varepsilon(x_i,t)) = \frac{\varepsilon}{2\delta}\sum_i \Phi_i(p^0_\delta(x,t)) + O(\Delta\rho) + o(1) \quad \forall t \in \mathcal{T}_{\delta_0}.$$

In what follows we have to consider the expressions as distributions in time and use a test function $\phi(t)$ with compact support in (t_1, t_2). We conclude

$$\begin{aligned} &\int_{t_1}^{t_2} \frac{\varepsilon}{2\delta}\sum_i \Phi_i(p^\varepsilon(x_i,t))\phi(t)\,dt \\ &\quad= \int_{t_1}^{t_2} \frac{\varepsilon}{2\delta}\sum_i \Phi_i(p^0_\delta(x,t))\phi(t)\,dt + O(\Delta\rho) + o(1) + o_\delta(1) \\ &\quad\to \frac{1}{2\gamma}\int_{t_1}^{t_2} \Theta(p^0_\delta(x,t))\phi(t)\,dt + O(\Delta\rho) + o_\delta(1), \end{aligned}$$

with $o_\delta(1) \to 0$ for $\delta_0 \to 0$, since averages of Φ_i are bounded and $\mathcal{T}_{\delta_0}$ has large measure. In taking the limit $\varepsilon \to 0$ we used the ergodicity assumption.

We write (4.12) now with a discrete integration by parts,

$$\begin{aligned} &-\int_{t_1}^{t_2} \Theta(p^0_\delta(x,t))\frac{\phi(t) - \phi(t-\Delta t)}{\Delta t}\,dt \\ &\quad= -\int_{t_1}^{t_2} \partial_2 p^0_\delta(x,t)\ \frac{1}{\Delta t}\int_t^{t+\Delta t} \phi(\tau)\,d\tau\,dt + \frac{2}{\Delta t}O(\Delta\rho) + o_\delta(1). \end{aligned}$$

We take the limit $\delta \to 0$ using that along a subsequence $\delta \to 0$ the functions p^0_δ converge to p^0 pointwise a.e. Since now δ_0 can also be chosen small, we find in the sense of distributions in x

$$-\int_{t_1}^{t_2} \Theta(p^0(\cdot,t)) \frac{\phi(t)-\phi(t-\Delta t)}{\Delta t}\,dt = -\int_{t_1}^{t_2} \partial_2 p^0(\cdot,t)\ \frac{1}{\Delta t}\int_t^{t+\Delta t} \phi(\tau)\,d\tau\,dt + \frac{2}{\Delta t}O(\Delta\rho).$$

Since $\Delta\rho$ was arbitrary, the equation holds also without the error term. Since Δt also was arbitrary, we find the result. □

In the following theorem we collect all the upscaled equations. The principal assumption of the theorem is that ν is of finite type. Thinking of periodic solutions of period $k\varepsilon$ in x_1, we know that such an assumption is necessary. The assumption can be replaced by "with probability 1" in the case of stochastic equations.

THEOREM 4.6. *We consider a subsequence p^ε of solutions to* (1.2)–(1.6) *with a limit measure ν of finite type. Let p^0 be the limit of p^ε in L^∞_w and in the weak topology of $L^2((0,T),H^1(\Omega))$. Then there exists a representative p^0 that is harmonic for all t and which satisfies*

$$0 \le p^0(x,t) \le p_{\max} \qquad \forall x \in \Gamma,\ \forall t. \tag{4.13}$$

Every point $(x,t) \in \Gamma \times (0,T)$ with

$$p^0(x,t) < p_{\max}$$

has a neighborhood in $\Gamma \times (0,T)$ on which

$$\partial_t \Theta(p^0) = -\partial_2 p^0 \tag{4.14}$$

holds in the sense of distributions. Everywhere on $\Gamma \times (0,T)$ holds the corresponding inequality

$$\partial_t \Theta(p^0) \le -\partial_2 p^0. \tag{4.15}$$

In the nonlinear case the same properties hold. To conclude (4.15) *we have to assume that the nonlinear equations satisfy the linear regularity property of Definition* 4.1. *Without this assumption we only have the weak lift-off condition* (4.22).

We make some remarks on this theorem.

Boundary values on Γ. The formal definition of the limit function is as follows. We choose a subsequence $\varepsilon \to 0$ such that $p^\varepsilon|_\Gamma$ converge in L^∞_w to some limit $p^0_\Gamma \in L^\infty(\Gamma)$. The weak limit $p^0 \in L^2((0,T),H^1(\Omega))$ satisfies

$$\int_\Gamma p^0_\Gamma \cdot \partial_2 \varphi = \int_\Omega p^0 \cdot \Delta\varphi \qquad \text{a.e. } t \in (0,T)$$

for all $\varphi \in C^2_0(\Omega \cup \Gamma)$ with $\varphi = 0$ on Γ. This shows that p^0 is a harmonic function with boundary values p^0_Γ.

Initial values. If $p^\varepsilon(t=0) = P_0$ is continuous and satisfies $P_0|_\Gamma < p_{\max}$, then by the regularity results all functions p^0_δ are continuous in a neighborhood and have the initial values $(P_0)_\delta$. Therefore $p^0(t=0) = P_0$.

The lift-off condition (4.15). In all points $p^0 < p_{\max}$, (4.14) describes the evolution. Without a lift-off condition p^0 could remain on the level $p_{\max}$ even if the fluid flows backward into the domain. Therefore a condition of lift-off is necessary in order to close the system. We emphasize that weaker conditions may be sufficient; relevant is that the left-hand side in (4.15) is negative in regions where the right-hand side is negative.

In the derivation of (4.15) we face the problem that a pointwise analysis is necessary. Loosely speaking, in some points we have to argue with the help of regularity of p^ε in order to find the law, in other points we use $p^\varepsilon \geq p_{\max} - \Delta\rho$ in order to find the law. Such pointwise analysis is in conflict with the use of distributional limits as in the proof of Proposition 4.5.

The analysis proceeds in three steps. In section 2.2 we characterized the possible patterns of the system. In section 3 we showed that, if all limit patterns are finite, averages of the pressure cannot have jumps (Proposition 3.6) and that every point with nonmaximal limit pressure has a neighborhood without explosions (Corollary 3.7). Based on these observations we derive the upscaled equations.

Proof. All assertions of the theorem are already shown except for (4.15). In the case of linear laws it can easily be derived following the lines of Proposition 4.5, starting from the inequality in (4.12). The point is that for linear laws the information that p^ε is close to p^ε_δ is not needed.

In the general case the subsequent proposition establishes with (4.16) a pointwise inequality for the pressure decay. It describes on a microscopic scale the condition of lift-off and is the key for the proof.

Using (4.16) in the first inequality and the Lebesgue convergence theorem in the second (the boundedness from below of the integrand is verified in Proposition 4.7), we calculate for nonnegative smooth test functions ϕ with compact support in $(\Omega \cup \Gamma) \times (0,T)$

$$\begin{aligned}
&\int_0^T \int_\Gamma \frac{\Theta(p^0(x,0,t+\Delta t)) - \Theta(p^0(x,0,t))}{\Delta t} \phi(x,t)\,dx\,dt \\
&\quad \leq \int_0^T \int_\Gamma \liminf_{\delta\to 0} \liminf_{y\nearrow 0} \frac{1}{\Delta t} \int_t^{t+\Delta t} (-\partial_2 p^0_\delta(x,y,\tau))\,d\tau \phi(x,t)\,dx\,dt \\
&\quad \leq \liminf_{\delta\to 0} \liminf_{y\nearrow 0} \int_0^T \int_\Gamma \frac{1}{\Delta t} \int_t^{t+\Delta t} (-\partial_2 p^0_\delta(x,y,\tau))\,d\tau \phi(x,t)\,dx\,dt \\
&\quad = \liminf_{\delta\to 0} \liminf_{y\nearrow 0} \int_0^T \left\{ \int_{\Omega\cap\{x_2<y\}} \frac{1}{\Delta t} \int_t^{t+\Delta t} p^0_\delta(\tau)\,d\tau \cdot \Delta\phi\,dx_1\,dx_2 \right. \\
&\qquad\qquad \left. - \int_{\Omega\cap\{x_2=y\}} \frac{1}{\Delta t} \int_t^{t+\Delta t} p^0_\delta(\tau)\,d\tau \cdot \partial_2\phi\,dx_1 \right\} dt \\
&\quad = \liminf_{\delta\to 0} \int_0^T \left\{ \int_\Omega \frac{1}{\Delta t} \int_t^{t+\Delta t} p^0_\delta(\tau)\,d\tau \cdot \Delta\phi\,dx_1\,dx_2 \right. \\
&\qquad\qquad \left. - \int_\Gamma \frac{1}{\Delta t} \int_t^{t+\Delta t} p^0_\delta(\tau)\,d\tau \cdot \partial_2\phi\,dx_1 \right\} dt
\end{aligned}$$

$$= \int_0^T \left\{ \int_\Omega \frac{1}{\Delta t} \int_t^{t+\Delta t} p^0(\tau)\ d\tau \cdot \Delta\phi\, dx_1\, dx_2 \right.$$
$$\left. - \int_\Gamma \frac{1}{\Delta t} \int_t^{t+\Delta t} p^0(\tau)\, d\tau \cdot \partial_2\phi\, dx_1 \right\} dt$$
$$= \int_0^T \left\langle \frac{1}{\Delta t} \int_t^{t+\Delta t} (-\partial_2 p^0(\tau))\, d\tau, \phi \right\rangle dt.$$

Since Δt was arbitrary, this proves the claim in the case of linear regularity. The general case is treated in Corollary 4.8. □

PROPOSITION 4.7 (pointwise lift-off condition). *Let $\Delta t > 0$ be given. We assume that the equations satisfy the linear regularity. Then for a.e. point $(x, 0, t_0)$ there holds with*

$$V := \liminf_{\delta\to 0} \liminf_{y\nearrow 0} \frac{1}{\Delta t} \int_{t_0}^{t_0+\Delta t} \left(-\partial_2 p^0_\delta(x, y, t)\right) dt$$

the inequality

$$\frac{\Theta(p^0(x, 0, t_0 + \Delta t)) - \Theta(p^0(x, 0, t_0))}{\Delta t} \le V. \tag{4.16}$$

The expression $\liminf_{y\nearrow 0} \frac{1}{\Delta t} \int_{t_0}^{t_0+\Delta t} (-\partial_2 p^0_\delta(x, y, t))\, dt$ is bounded from below independent of δ and (x, t_0), and $\frac{1}{\Delta t} \int_{t_0}^{t_0+\Delta t} (-\partial_2 p^0_\delta(x, y, t))\, dt$ is bounded from below for every fixed δ by a constant independent of y.

Proof. An inspection of the subsequent proof and in particular inequality (4.19) shows the bounds

$$\frac{\Theta(0) - \Theta(p_{\max})}{\Delta t} \le \liminf_{y\nearrow 0} \frac{1}{\Delta t} \int_{t_0}^{t_0+\Delta t} (-\partial_2 p^0_\delta(x, y, t))\, dt,$$
$$\frac{\Theta(0) - \Theta(p_{\max})}{\Delta t} - \sup_{-1<y<0} g_\delta(y) \le \frac{1}{\Delta t} \int_{t_0}^{t_0+\Delta t} (-\partial_2 p^0_\delta(x, y, t))\, dt.$$

These imply the uniform estimates that are necessary in order to apply the Lebesgue convergence theorem. In particular V is bounded from below and we can use in the following $V > -\infty$.

We will consider here the most interesting case of maximal pressure in (x, t_0), $\liminf_{\delta\to 0} p^0_\delta(x, 0, t_0) = p_{\max}$. In the other case we find a region without explosions and can base the proof on the regularity of p^0 in $(x, 0, t_0)$. The claimed inequality is immediate in the case $V \ge 0$, since Θ is monotonically increasing. We can therefore assume from now on that $V < 0$.

To show (4.16) we first fix ΔV small compared to $|V|$, and $\Delta\rho$ small compared to $|V| \cdot \Delta t$. Next we choose $\delta > 0$ small enough to have

$$\liminf_{y\nearrow 0} \frac{1}{\Delta t} \int_{t_0}^{t_0+\Delta t} (-\partial_2 p^0_\delta(x, y, t))\, dt \le V + \Delta V,$$

$p^0_\delta(x, 0, t_0) \ge p_{\max} - \Delta\rho$, and a third smallness condition which depends on V and Δt and is made explicit later. Now we choose $y < 0$ close to 0 to have $g_\delta(y)$ small

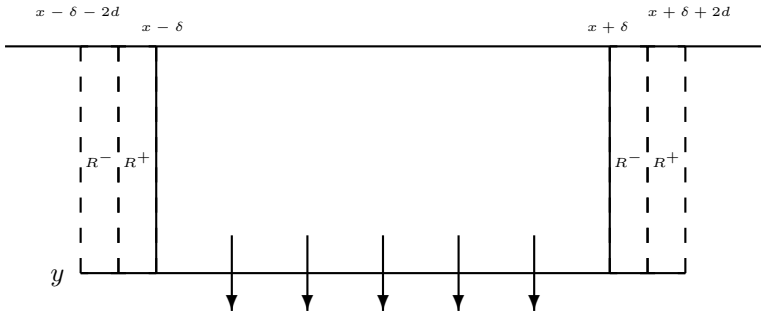

FIG. 2. *For the proof of Proposition* 4.7.

compared to $|V|$ ($g_\delta(y)$ is introduced later), and

$$\frac{1}{\Delta t}\int_{t_0}^{t_0+\Delta t}(-\partial_2 p_\delta^0(x,y,t))\,dt \le V + 2\Delta V. \tag{4.17}$$

We finally choose ε_0 small in order to have $p_\delta^\varepsilon(x,0,t_0^\varepsilon) \ge p_{\max} - 2\Delta\rho$ for all $\varepsilon < \varepsilon_0$ along the subsequence and in points $t_0^\varepsilon \to t_0$. Furthermore, ε_0 is chosen small enough to have

$$\frac{1}{\Delta t}\int_{t_0^\varepsilon}^{t_0+\Delta t}(-\partial_2 p_\delta^\varepsilon(x,y,t))\,dt \le V + 3\Delta V \tag{4.18}$$

for all $\varepsilon < \varepsilon_0$. At this point we exploited to have $y < 0$ fixed; in the interior of Ω spatial derivatives of time averages of the pressure p^ε converge.

By calculating the total flow into the box $R_{\delta,y}(x) := \{(x_1,x_2) : x-\delta < x_1 < x+\delta, y < x_2 < 0\}$ as illustrated in Figure 2, we verify the inequality

$$2\gamma\frac{1}{\Delta t}\left[\frac{\varepsilon}{2\delta}\sum_i \Phi_i(p^\varepsilon(x_i,\tau))\right]_{\tau=t_0^\varepsilon}^{t_0+\Delta t} \le V + 3\Delta V + g_\delta(y) + o(1) \tag{4.19}$$

for $\varepsilon \to 0$. The left-hand side measures the increase of volume on the upper boundary. On the right-hand side $V + 3\Delta V$ measures the maximal inflow into $R_{\delta,y}$ through the lower boundary as it was calculated in (4.18). $g_\delta(y)$ shall be a bound for ε-limits of the inflow through the lateral boundaries, multiplied by γ/δ. Then (4.19) follows as (4.12), since explosions only lower the left-hand side. The crucial point is now to find a bound $g_\delta(y)$ with $\lim_{y\nearrow 0} g_\delta(y) = 0$.

Construction of the bound $g_\delta(y)$. In the case of C^0 flows, that is, C^1 pressure fields, one concludes immediately that the flow through a slice of length $|y|$ is of order $|y|$. Here we only have some kind of continuity of the pressure field. Therefore, the estimate will be only of lower order, and the proof becomes more involved.

The basis for the proof is the following observation. For every (x,t) we consider the rectangles $R^- := R^-_{d,y}(x) := \{(x_1,x_2) : x < x_1 < x+d,\ y < x_2 < 0\}$ and $R^+ := R^+_{d,y}(x) := \{(x_1,x_2) : x+d < x_1 < x+2d,\ y < x_2 < 0\}$. Then for every aspect ratio $r := d/y$ the following limits coincide:

$$\lim_{y\to 0,\ d=ry}\frac{1}{|R^-|}\int_{R^-}\int_{t_0}^{t_0+\Delta t} p^0 = \lim_{y\to 0,\ d=ry}\frac{1}{|R^+|}\int_{R^+}\int_{t_0}^{t_0+\Delta t} p^0. \tag{4.20}$$

This follows from $p^0 \in L^2(0,T;H^1(\Omega))$. Time integrals of p^0 are in $H^1(\Omega)$, and for $q \in H^1(\Omega)$ holds (we use $R^- + te_1$ to denote the box R^-, translated to the right by t),

$$\begin{aligned}\frac{1}{d\cdot y}\left(\int_{R^+} q - \int_{R^-} q\right) &= \frac{1}{d\cdot y}\int_0^d dt \int_{R^- + te_1} (\partial_1 q)\\ &\le \frac{1}{y}\left(\int_{R^-\cup R^+} |\partial_1 q|^2\right)^{1/2} |2d\cdot y|^{1/2} \to 0\end{aligned}$$

for $y \to 0$ and fixed aspect ratio. We used that $|\partial_1 q|^2$ is in $L^1(\Omega)$ and therefore integrals over vanishing domains vanish.

We now conclude from (4.20) the estimate on $g_\delta(y)$. A weighted average of the horizontal flow in the box $R := \{(x_1,x_2) : x+\delta < x_1 < x+\delta+2d,\ y < x_2 < 0\}$ is (with $x_0 := x+\delta+d$)

$$\begin{aligned}\frac{1}{d}\int_R \partial_1 p^\varepsilon(x_1,x_2)\cdot\frac{d-|x_1-x_0|}{d}\,dx_1\,dx_2 &= \frac{1}{d^2}\left[\int_{R^+} p^\varepsilon - \int_{R^-} p^\varepsilon\right]\\ \to \frac{1}{r}\left[\frac{1}{|R^+|}\int_{R^+} p^0 - \frac{1}{|R^-|}\int_{R^-} p^0\right].&\end{aligned}$$

By (4.20) time integrals over this term become arbitrarily small for small y. For every small $|y|$ we find a corresponding d' such that the flow through the lateral side $\{(x_1,x_2) \mid x_1 = x+\delta+d',\ y < x_2 < 0\}$ is small.

We are not allowed to change the parameter δ, but we must show that the inflow through the lateral side $x_1 = x+\delta$ is small. To this end we use the aspect ratio r that can be chosen freely. The pressure along Γ is bounded and therefore the vertical velocity satisfies in the interior an estimate $|\partial_2 p^\varepsilon(x,y)| \le C_1|y|^{-1}$ by the representation formula (see, e.g., [6, p. 22]). We find that the total vertical inflow through $\{(x_1,x_2) \mid x+\delta < x_1 < x+\delta+2d,\ x_2 = y\}$ can be bounded by $d\cdot C_1/|y| = C_1\cdot r$. Choosing a small aspect ratio r we have a bound for the vertical inflow from below.

The vertical inflow from above is bounded by $C_2\cdot d$ since no negative explosions can occur. This contribution to $g_\delta(y)$ is therefore also small for small d (independent of the aspect ratio). Putting the results together we find that choosing r and then $|y|$ small, the total inflow through $x+\delta$ is bounded by a small number $g_\delta(y)$.

Conclusions from (4.19). As a first step we write (4.19) as

$$\begin{aligned}\frac{\varepsilon}{2\delta}\sum_i \Phi_i(p^\varepsilon(x_i,t_0+\Delta t)) \le \frac{\varepsilon}{2\delta}\sum_i \Phi_i(p^\varepsilon(x_i,t_0^\varepsilon))&\\ + \frac{\Delta t}{2\gamma}\left(V + 3\Delta V + g_\delta(y)\right) + o(1).&\end{aligned}$$

Since the derivatives of Φ_i are bounded, we conclude

$$p_\delta^\varepsilon(x,0,t_0+\Delta t) \le \rho < p_{\max},$$

where ρ depends only on $V<0$ and Δt, and not on δ. As in the proof of Proposition 3.6 we conclude that there is some $\rho_0 < p_{\max}$ independent of δ and $t_1 < t_0+\Delta t$ such that

$$p_\delta^\varepsilon(x,0,t) \le \rho_0 \qquad \forall t \in [t_1, t_0+\Delta t].$$

We said that a third smallness condition on δ should be satisfied. We demand that δ is small compared to $\delta_H(\rho_0)$ with δ_H from Lemma 3.1. With this choice we know that there are no explosions in the region $(x-\delta, x+\delta)\times(t_1, t_0+\Delta t)$.

We now fix a new small parameter $\sigma > 0$. Given σ we pick a new, smaller $\delta > 0$, repeat the above steps of the proof and find new $y < 0$ and $\varepsilon_0 > 0$. For the new δ we can assume by Lemma 4.2 that

$$|p^\varepsilon(\xi, 0, t_0+\Delta t) - p^\varepsilon_\delta(x, 0, t_0+\Delta t)| \le \sigma \qquad \forall \xi \in (x-\delta, x+\delta).$$

Here we used the linear regularity property.

The functions p^ε_δ are uniformly continuous in a neighborhood of $(x, 0, t_0+\Delta t)$ by Proposition A.3 and therefore $p^\varepsilon_\delta \to p^0_\delta$ is a uniform convergence for a subsequence. Along this subsequence we now take limits in (4.19),

$$\begin{aligned}
&\limsup_{\varepsilon\to 0} 2\gamma\frac{\varepsilon}{2\delta}\sum_i \Phi_i(p^\varepsilon(x_i, t_0+\Delta t)) \\
&\le \limsup_{\varepsilon\to 0} 2\gamma\frac{\varepsilon}{2\delta}\sum_i \Phi_i(p^\varepsilon_\delta(x, 0, t_0+\Delta t)) + C\sigma \\
&= \limsup_{\varepsilon\to 0} 2\gamma\frac{\varepsilon}{2\delta}\sum_i \Phi_i(p^0_\delta(x, 0, t_0+\Delta t)) + C\sigma \\
&= \Theta(p^0_\delta(x, 0, t_0+\Delta t)) + C\sigma.
\end{aligned}$$

For the second term we have, by $p^\varepsilon_\delta(x, t^\varepsilon_0) \ge p_{\max} - 2\Delta\rho$,

$$\liminf_{\varepsilon\to 0} 2\gamma\frac{\varepsilon}{2\delta}\sum_i \Phi_i(p^\varepsilon(x_i, t^\varepsilon_0)) \ge \Theta(p_{\max}) - C\Delta\rho.$$

We take $\limsup_{\varepsilon\to 0}$ in (4.19) and find

$$\begin{aligned}
&\frac{\Theta(p^0_\delta(x, 0, t_0+\Delta t)) - \Theta(p^0_\delta(x, 0, t_0))}{\Delta t} \\
&\qquad \le V + 3\Delta V + g_\delta(y) + C\sigma + C\Delta\rho.
\end{aligned} \tag{4.21}$$

We take the limit $y \nearrow 0$ and then $\delta \to 0$ using that $p^0_\delta \to p^0$ for a.e. $(x, 0, t)$. We find inequality (4.16) up to the error terms. Since ΔV, σ, and $\Delta\rho$ were arbitrary, we find the result. ∎

The assumption of linear regularity was used in the above proof only towards the end in order to replace p^ε by p^ε_δ in the evaluation of the laws Φ_i. We can also restrict ourselves with the conclusion that

$$\frac{\varepsilon}{2\delta}\sum_i \Phi_i(p^\varepsilon(x_i, t_0+\Delta t)) \le \Theta(p_{\max}) - C_1$$

for all small ε implies for some $c > 0$

$$p^0_\delta(x, t_0+\Delta t) \le p_{\max} - c\,C_1,$$

since the derivatives of Φ_i are bounded. We find the following corollary to the above proof.

Corollary 4.8 (weak lift-off condition). *We consider the nonlinear case and do not assume linear regularity. There exists $c > 0$ such that in every point (x, t_0) and for every $\Delta t > 0$,*

$$\liminf_{\delta\to 0} p^0_\delta(x, t_0+\Delta t) \le p_{\max} + c\ V\Delta t \tag{4.22}$$

with V as in Proposition 4.7.

With Theorem 4.6 we have derived a system of upscaled equations that is satisfied by every weak limit p^0 of the pressure functions p^ε. We have to verify that we have found all necessary information on the limit system. To this end we showed in [11] that solutions of the upscaled system of Theorem 4.6 are unique, at least for a linear function Θ. The uniqueness also implies the weak convergence of the initial sequence p^ε to the solution p^0 of the limit system.

5. Conclusions and outlook. We performed an analysis of a deterministic model for the motion of fronts in porous media. Upscaled equations were found under the hypothesis that limit patterns are finite. The limit equations include a hysteresis effect of the system: during imbibition, i.e., under inflow conditions and after a transition time, the pressure along the boundary coincides everywhere with $p_{\max}$; this value can therefore be interpreted as the capillary pressure of imbibition. When changing the boundary conditions to drainage, i.e., an outflow condition along the bottom, the system undergoes again a transitional regime before the capillary pressure of drainage (zero in our case) is reached.

An open question concerns the uniqueness of solutions of the upscaled system in the nonlinear case, that is, with the weak lift-off condition. It is desirable to extend the results to more general geometries and to more general equations for the fluid. We expect that in such systems the principle feature, the appearance of isolated explosions, remains the same.

We emphasize that the upscaled equations derived in this work form a mesoscopic model of a two-phase flow since the position of the front is still resolved. Desirable is the derivation of macroscopic laws from our mesoscopic results.

Appendix A. Regularity properties away from explosions. In this appendix we consider only regions without explosions. We expect that in this case the solution is regular. In order to get a feeling for the smoothing properties of the equations, we first consider the above equations omitting the projection Q_ε.

Remark A.1. The unique classical solution u^0 of

$$\Delta u^0(t) = 0 \qquad \text{in } \mathbb{R} \times \mathbb{R}_-, \tag{A.1}$$

$$\partial_t u^0 = -\lambda \partial_2 u^0 \qquad \text{on } \mathbb{R}, \tag{A.2}$$

with initial condition $u^0(x_1, 0, 0) = \operatorname{sgn}(x_1)$ and satisfying the uniform bounds $0 \le u^0 \le 1$ is given by

$$u^0(t, x) = \frac{2}{\pi} \arctan\left(\frac{x_1}{\lambda t}\right). \tag{A.3}$$

Proof. We demonstrate how to find u^0 in the self-similar form $u^0(x, t) = U(\frac{x}{t})$. The function U is harmonic in the lower half-plane and on $\{(x_1, x_2) \mid x_2 = 0\}$ it satisfies

$$x_1 \cdot \partial_1 U = \partial_2 U.$$

We use a complex differentiable function $f : \mathbb{C}^- \to \mathbb{C}$ to find $U = \operatorname{Re} f$. The condition on the real line translates into

$$\operatorname{Re}(z \cdot f' - i f') = 0.$$

We set $z \cdot f' - i f' = ci$ for a real number c and find

$$f' = c\frac{i}{z - i} = c\frac{-1}{1 + iz} = c\frac{1 - i\bar{z}}{|1 + iz|^2}.$$

This implies

$$\partial_1 U = \operatorname{Re} f' = \frac{c}{1+|x_1|^2}$$

on the real line. Using $U(x_1) \to \pm 1$ for $x_1 \to \pm\infty$ determines the constant c to be $2/\pi$ and yields the result. The x_1-derivative of U inside the domain is calculated as $\partial_1 U(x_1, x_2) = \frac{1-x_2}{(1-x_2)^2+x_1^2}$; this yields the complete form of U,

$$U(x_1, x_2) = \frac{2}{\pi} \arctan\left(\frac{x_1}{1-x_2}\right). \qquad \square$$

The explicit solution above gives us an idea of how solutions to the original equations (1.2)–(1.5) behave qualitatively. Unfortunately, the picture may change in many respects once the coefficients in $\partial_t p^\varepsilon(\cdot, 0, t) = -a(\cdot) Q_\varepsilon \partial_2 p^\varepsilon(\cdot, 0, t)$ depend on x_1. But one useful property remains valid as one can see by using the exact solution as a comparison function.

Remark A.2. Consider the original equations (1.2)–(1.5) with initial values

$$p^\varepsilon(x_1, 0, 0) = \begin{cases} 0 & \text{for } x_1 < 0, \\ 1 & \text{for } x_1 > 0. \end{cases}$$

Then for every $\delta > 0$ there exists a constant C such that

$$p^\varepsilon(-\delta, 0, t) \le Ct \qquad \forall t.$$

PROPOSITION A.3. *We study solutions $p^\varepsilon : (-1,1) \times (-1,0) \times (0,t) \to \mathbb{R}$ of the original equations (1.2)–(1.5) for $V_0 \in C^1$ and with (piecewise) linear laws $\mathcal{P}_0$. If no explosions happen on $(-\delta_0, \delta_0) \times (0,t)$, then, for every $0 < \delta < \delta_0$, the family $p^\varepsilon(\cdot, 0, t)$ is uniformly continuous in $(-\delta, \delta)$.*

In the case of nonlinear laws, for every $\delta < \delta_0$, $0 < t_1 < t$, and arbitrary $\kappa > 0$ we can write $p^\varepsilon|_\Gamma$ as $p^\varepsilon|_\Gamma = p_A + p_B = p_{A,1} + p_{A,2} + p_B$ with

$$\begin{aligned} \partial_t p_A &\in L^2((t_1,t) \times (-\delta,\delta)), & \|p_A\| &\le C(\kappa), \\ p_{A,1} &\in L^2((t_1,t), H^1(-\delta,\delta)), & \|p_{A,1}\| &\le C(\kappa), \\ p_{A,2} &\in L^2((t_1,t), L^\infty(-\delta,\delta)), & \|p_{A,2}\| &\le C\varepsilon^\alpha, \\ p_B &\in L^\infty((t_1,t) \times (-\delta,\delta)), & \|p_B\| &\le \kappa. \end{aligned}$$

In particular, all spatial averages p^ε_δ of p^ε are uniformly continuous on $(t_1,t) \times (-\delta,\delta)$. The constant $\alpha > 0$ is independent of ε, p^ε, δ, and κ.

A solution for $\varepsilon = 1$ on the extended domain $\mathbb{R} \times (-\infty, 0) \times (0, \infty)$ without explosions satisfies

$$|p^\varepsilon(x_1, 0, t) - p^\varepsilon(0, 0, t)| \to 0 \quad \text{for} \quad t \to \infty, \tag{A.4}$$

independent of the initial values.

Proof. Idea: Assume that there are no explosions at all. Then we write the linear laws as

$$\partial_t p^\varepsilon(\cdot, 0, \tau) = -a^\varepsilon(\cdot) Q_\varepsilon \partial_2 p^\varepsilon(\cdot, 0, \tau) \quad \text{on } \Gamma_1^\varepsilon, \ \forall \tau \in (0, t).$$

In this case we can show uniform estimates for $\partial_t p^\varepsilon|_\Gamma \in L^\infty((3t/4,t),L^2(\Gamma))$. These are at the same time bounds for $Q_\varepsilon \partial_2 p^\varepsilon|_\Gamma = -\frac{1}{a^\varepsilon(\cdot)}\partial_t p^\varepsilon|_\Gamma$. We can decompose p^ε into the "macroscopic" part, the harmonic, periodic function p_m satisfying $\partial_2 p_m = Q_\varepsilon \partial_2 p^\varepsilon$ on Γ, and a remainder $u^\varepsilon = p^\varepsilon - p_m$. In Lemma A.4 we show that u^ε is small in L^∞. The elliptic regularity theory yields uniform estimates for $p_m \in L^\infty((t/2,t),C^\alpha(\Gamma))$ for $\alpha < 1/2$. This yields the claim.

We now show the estimate for $\partial_t p^\varepsilon$ in the case of $\delta_0 = 1$ (no explosions along Γ). By the energy estimate for $p^\varepsilon \in L^2((0,t),H^1(\Omega))$ we find a time instance $t_1 < t/2$ such that $p^\varepsilon(t_1) \in H^1(\Omega)$ satisfies an ε-independent bound. We multiply $\Delta p^\varepsilon = 0$ by $\partial_t p^\varepsilon$ and find

$$\begin{aligned}\int_{\Gamma_0} V_0 \partial_t p^\varepsilon &= \int_\Omega \nabla p^\varepsilon \cdot \partial_t \nabla p^\varepsilon - \int_{\Gamma_1^\varepsilon} \partial_2 p^\varepsilon \cdot \partial_t p^\varepsilon \\ &= \int_\Omega \partial_t \frac{1}{2}|\nabla p^\varepsilon|^2 + \int_{\Gamma_1^\varepsilon} \frac{1}{a^\varepsilon(\cdot)}|\partial_t p^\varepsilon|^2.\end{aligned}$$

This yields an estimate for $\partial_t p^\varepsilon|_{\Gamma_1^\varepsilon} \in L^2((t_1,T)\times\Gamma_1^\varepsilon)$. We find a time instance t_2, $t_1 < t_2 < 3t/4$, with bounded (by an ε-independent constant) $\partial_t p^\varepsilon(t_2)|_{\Gamma_1^\varepsilon} \in L^2$. We multiply the differentiated equation $\partial_t \Delta p^\varepsilon = 0$ by $\partial_t p^\varepsilon$ and find

$$\begin{aligned}\int_{\Gamma_0} \partial_t V_0 \partial_t p^\varepsilon &= \int_\Omega |\partial_t \nabla p^\varepsilon|^2 - \int_{\Gamma_1^\varepsilon} \partial_t \partial_2 p^\varepsilon \cdot \partial_t p^\varepsilon \\ &= \int_\Omega |\partial_t \nabla p^\varepsilon|^2 + \partial_t \int_{\Gamma_1^\varepsilon} \frac{1}{2}\frac{1}{a^\varepsilon(\cdot)}|\partial_t p^\varepsilon|^2 - \int_{\Gamma_1^\varepsilon} \frac{1}{2}\frac{\partial_t(a^\varepsilon(p^\varepsilon))}{(a^\varepsilon)^2}|\partial_t p^\varepsilon|^2.\end{aligned}$$

In the case of a linear law a^ε is independent of p^ε and therefore the last term vanishes. An integration yields the claimed estimate for $\partial_t p^\varepsilon|_\Gamma \in L^\infty((t_2,t),L^2(\Gamma))$.

In the case of a nonlinear law the coefficient $a(x_1,t)$ depends on $p^\varepsilon(x_1,0,t)$, and the term containing $\partial_t a^\varepsilon |\partial_t p^\varepsilon|^2$ cannot be controlled by the other two terms. Nevertheless, the argument leading to the estimate for

$$\partial_t p^\varepsilon|_{\Gamma_1^\varepsilon} \in L^2((t_1,T)\times\Gamma_1^\varepsilon)$$

remains valid. With $p_A = p^\varepsilon$ and $p_B = 0$ we found the claimed decomposition. The estimates for the x_1-derivative of $p_{A,1} := p_m$ follow for harmonic functions from the estimates for the Neumann boundary values.

We now study the general case $\delta_0 < 1$. We choose $\Delta t < t$ small (depending on δ_0 and ρ), and consider from now on the solution only on the time interval $(t-\Delta t, t)$, the coefficients a^ε are always given by the original solution. We now decompose the solution into a part p_A with the initial values of p^ε and without explosions on Γ, and a second part p_B that captures the evolution of the explosions. Then on p_A the above arguments for $\delta_0 = 1$ can be applied. The function p_B is small on $(t-\Delta t, t)\times(-\delta_0/2, \delta_0/2)$ for Δt small by the maximum principle of Remark A.2.

Formula (A.4) follows from a scaling argument,

$$|p^\varepsilon(x_1,0,t) - p^\varepsilon(0,0,t)| = |p^{\varepsilon/t}(x_1/t,0,1) - p^{\varepsilon/t}(0,0,1)|,$$

where the scaled solution $p^{\varepsilon/t}$ has initial values $p^{\varepsilon/t}(x_1/t,0,0) = p^\varepsilon(x_1,0,0)$. The result follows from the uniform continuity of $p^{\varepsilon/t}$ at time 1, since x_1/t is arbitrarily close to 0. Note that we have to modify the solutions $p^{\varepsilon/t}|_{(-1,1)\times(-1,0)}$ on the boundary

in order to guarantee their periodicity. Applying the above argument with an initial time close to 1, this change introduces only a small error term in the expression $p^{\varepsilon/t}(x_1/t,0,1)-p^{\varepsilon/t}(0,0,1)$. ∎

LEMMA A.4. *Let u^ε be a sequence of periodic harmonic functions on $\Omega=(-1,1)\times(-1,0)$ satisfying a harmonic Neumann condition on the lower boundary and with the following properties on the upper boundary $\Gamma=(-1,1)\times\{0\}$:*

$$\begin{aligned} Q_\varepsilon\partial_2 u^\varepsilon &= 0,\\ g^\varepsilon := u^\varepsilon - Q_\varepsilon u^\varepsilon &\quad \text{satisfies } \|\partial_{x_1} g^\varepsilon|_{\Gamma_1^\varepsilon}\|_{L^2}\le C. \end{aligned}$$

Then $u^\varepsilon|_\Gamma\to 0$ in $L^\infty(\Gamma)$ for $\varepsilon\to 0$ independent of the sequence g^ε.

Proof. Note that we have the technical difficulty of $g^\varepsilon\notin H^1$ in general. We therefore introduce a new projection $\tilde Q_\varepsilon$ such that $\tilde Q_\varepsilon v=Q_\varepsilon v$ on Γ_1^ε with $\tilde Q_\varepsilon$ bounded in $\mathcal{L}(H^1(\Gamma),H^1(\Gamma))$. For $v\in L^2(\Gamma)$ we can use $\tilde v$, the harmonic function on Ω that satisfies $\tilde v|_{\Gamma_1^\varepsilon}=Q_\varepsilon v|_{\Gamma_1^\varepsilon}$ and $\partial_2\tilde v=0$ on Γ_2^ε, together with periodicity and a harmonic Neumann condition on the lower boundary. We set $\tilde Q_\varepsilon v:=\tilde v$.

With this modified projection we can consider the bounded sequence $w^\varepsilon:=u^\varepsilon|_\Gamma-\tilde Q_\varepsilon u^\varepsilon|_\Gamma\in H^1(\Gamma)$. We multiply $\Delta u^\varepsilon=0$ by u^ε to find

$$\begin{aligned} \int_\Omega|\nabla u^\varepsilon|^2 &= \int_\Gamma \partial_2 u^\varepsilon\ u^\varepsilon = \int_{\Gamma_1^\varepsilon}\partial_2 u^\varepsilon\ u^\varepsilon\\ &= \int_{\Gamma_1^\varepsilon}\partial_2 u^\varepsilon\ (u^\varepsilon-\tilde Q_\varepsilon u^\varepsilon) = \int_\Gamma \partial_2 u^\varepsilon\ w^\varepsilon. \end{aligned}$$

Since the family w^ε is bounded in $H^1(\Gamma)$ and $\partial_2 u^\varepsilon|_\Gamma\in H^{-1}(\Gamma)$ is bounded by $u^\varepsilon|_\Gamma\in L^2(\Gamma)$, we find an a priori bound for $u^\varepsilon\in H^1(\Omega)$.

In order to show the L^∞-convergence of u^ε we use again the above calculation and the fact that the family of functions $\partial_2 u^\varepsilon|_\Gamma\in H^{-1/2}(\Gamma)$ is bounded. We claim that the functions w^ε vanish in $H^{1/2}(\Gamma)$ at the rate $\varepsilon^{1/4}$. The functions w^ε are bounded in $C^{1/2}(\Gamma)$ and have vanishing averages on all intervals $\varepsilon(k-\gamma,k+\gamma)$. Therefore they satisfy an L^∞-estimate $\|w^\varepsilon\|_{L^\infty}\le C\sqrt{\varepsilon}$. Additionally $w^\varepsilon\in H^1(\Gamma)$ is bounded. By an interpolation between $L^2(\Gamma)$ and $H^1(\Gamma)$ we conclude that $\|w^\varepsilon\|_{H^{1/2}(\Gamma)}\le C\varepsilon^{1/4}$. We conclude that $u^\varepsilon\in H^1(\Omega)$ vanishes at the rate $\varepsilon^{1/8}$. We use an inverse estimate of an L^∞-norm in terms of an L^q-norm (exploiting that u^ε is constant on ε-intervals up to the error w^ε of order $O(\sqrt{\varepsilon})$), and a trace theorem with $q>8$ to find

$$\begin{aligned} \|u^\varepsilon\|_{L^\infty(\Gamma)} &\le C\left[\sqrt{\varepsilon}+\varepsilon^{-1/q}\|u^\varepsilon\|_{L^q(\Gamma)}\right]\\ &\le C(q)\left[\sqrt{\varepsilon}+\varepsilon^{-1/q}\|u^\varepsilon\|_{H^1(\Omega)}\right]\le C\varepsilon^{1/8-1/q}. \end{aligned}$$

This shows the assertion. ∎

DELAYED LOSS OF STABILITY IN NONAUTONOMOUS DIFFERENTIAL EQUATIONS WITH RETARDED ARGUMENT*

BERNHARD LANI-WAYDA† AND KLAUS R. SCHNEIDER‡

Abstract. Assume that zero is a stable equilibrium of an ODE $\dot{x} = f(x, \lambda)$ for parameter values $\lambda < \lambda_0$ and becomes unstable for $\lambda > \lambda_0$. If we suppose that $\lambda(t)$ varies slowly with t, then, under some conditions, the trajectories of the nonautonomous ODE $\dot{x} = f(x, \lambda(t))$ stay close to zero even long after $\lambda(t)$ has crossed the value λ_0. This phenomenon is called "delayed loss of stability" and is well known for ODEs. In this paper, we describe an analogous phenomenon for delay equations of the form $\dot{x}(t) = f(t, x(t-1))$. We study an example which requires combining linearization at zero with estimates on the nonlinear behavior away from zero, and where we obtain an explicit estimate on the time until the growth of $|x(t)|$ becomes "visible."

Key words. nonautonomous delay equations, slowly changing parameters, delayed loss of stability, decay and growth of oscillations

1. Introduction.

Dynamical systems as mathematical models of real life processes depend on several parameters which are assumed to be fixed within some time period (see, e.g., [4], [12], [1]). The influence of a parameter λ on the behavior of a dynamical system is studied within the framework of bifurcation theory. Suppose now that a relevant system parameter λ changes very slowly in time, for example, because of an aging process. In the model equation, one can then replace the parameter λ by $\lambda(\varepsilon t)$, where $\varepsilon > 0$ is a small. (The new equation is then nonautonomous.) The so-called dynamic bifurcation theory is concerned with the investigation of the corresponding changes of the system behavior [1]. A special phenomenon, known as *delayed loss of stability*, can lead to dramatic consequences (e.g., thermal explosion [7]). For ordinary differential equations (ODEs), this effect is well known and has been studied from different points of view [3], [13], [2], [14].

Let us illustrate the phenomenon by considering the simple linear equation

$$\dot{y}(t) = k(\varepsilon t) y(t), \tag{1.1}$$

where $\varepsilon > 0$ is small, such that the coefficient $k(\varepsilon t)$ in (1.1) changes slowly in time. Setting $\varepsilon t = \tau$, $y(t) = y(\tau/\varepsilon) = x(\tau)$, we get from (1.1)

$$\varepsilon \frac{dx}{d\tau} = k(\tau) x. \tag{1.2}$$

Concerning the function k, we suppose the following.

(A) $k : \mathbb{R} \longrightarrow \mathbb{R}$ is continuous, strictly increasing, and there exist numbers $\tau_- < \tau_0 < \tau_+$ such that

$$k(\tau) < 0 \quad \text{for } \tau < \tau_0, \qquad k(\tau) > 0 \quad \text{for } \tau > \tau_0, \quad \int_{\tau_-}^{\tau_+} k(\tau) d\tau = 0. \tag{1.3}$$

The so-called associated system to (1.2) reads

$$\frac{dx}{d\sigma} = k(\tau)x(\sigma), \tag{1.4}$$

where τ in the right-hand side has to be considered as a parameter and σ is the independent variable. From hypothesis (A) it follows that the equilibrium $x = 0$ of the associated equation (1.4) is stable for $\tau < \tau_0$ and unstable for $\tau > \tau_0$; that is, it changes its stability at $\tau = \tau_0$.

The solution $x(\cdot, \tau_-, x_-)$ of (1.1) satisfying $x(\tau_-, \tau_-, x_-) = x_-$ is explicitly given by

$$x(\tau, \tau_-, x_-) = x_- \exp\left\{\frac{1}{\varepsilon}\int_{\tau_-}^{\tau} k(s)ds\right\}.$$

We see that if k satisfies assumption (A), then $x(\tau, \tau_-, x_-)$ is exponentially decaying for $\tau_- < \tau < \tau_0$ and stays near $x = 0$ also for some time interval $\tau_0 < \tau < \hat{\tau}$ with $\hat{\tau} < \tau_+$, during which $x = 0$ is an unstable equilibrium of (1.4). Obviously, analyticity of the equation is inessential for this simple phenomenon (but plays a role in connection with more refined results as, e.g., [13]).

The main goal of this paper is to describe a similar effect for differential-delay equations, where we restrict ourselves to simplest cases.

As a preparation, we consider in section 2 the constant coefficient equation

$$\dot{x}(t) = cx(t-1), \tag{1.5}$$

with $c \in [-3\pi/4, -\pi/4]$. It is well known that the zero solution of (1.5) is stable for $c \in (-\pi/2, 0)$, and unstable if $c < -\pi/2$. Contrary to the ODE case, the exponential rate of growth or decay is not directly given by c but has to be estimated. We provide such estimates. As further preparatory background material, section 2 contains a simple version of the variation-of-constants formula for the case of inhomogeneous equations with nonconstant coefficient.

In section 3 we compare solutions of

$$\dot{x}(t) = g(t, x(t-1))$$

(with nonlinear g) on successive time intervals I_i to solutions of the equation

$$\frac{dx}{dt} = c_i x(t-1),$$

with constants c_i which are values of $\partial_2 g(\cdot, 0)$ on I_i. In Theorem 3.2, we obtain estimates that express the phenomenon of delayed loss of stability for differential-delay equations. In section 4 we treat the example equation

$$\dot{x}(t) = (-\pi/4 - \varepsilon t)\arctan(x(t-1)).$$

Here, we study the initial value problem with the initial segment identically 1, and estimate the time until the solution is close enough to zero by a method that is not based on linearization. Theorem 3.2 is then applicable to the motion close to zero, and we obtain a lower bound for the time t_1 until the solution reaches absolute value 1 again. (This is to be understood in the sense that certainly $|x(t)| \le 1$ for $t \le t_1$.)

We do not rigorously prove the (essentially obvious) fact that the solution grows again after the coefficient has crossed the stability border, but give a heuristic argument for this in section 4.

Notation. For bounded functions φ on $[-1,0]$, the sup-norm is denoted by $|\varphi|$. Generally, we use the symbol $\|\ \|_\infty$ for the sup-norm of bounded functions on some domain.

Let $\mathbf{C}$ denote the space of continuous functions on $[-1,0]$ with the max-norm. Assume that $G : \mathbb{R}\times\mathbf{C} \to \mathbb{R}$ is continuous, is locally Lipschitz continuous with respect to the second argument, and satisfies a linear growth condition

$$|G(t,\varphi)| \le L(t)(1+|\varphi|) \quad (t\in\mathbb{R},\ \varphi\in\mathbf{C})$$

with $L : \mathbb{R} \longrightarrow \mathbb{R}_0^+$ continuous. Then, for $\varphi \in \mathbf{C}$ and $\tau \in \mathbb{R}$, there is a unique continuous function $x^{G,\varphi,\tau} : [\tau-1,\infty] \longrightarrow \mathbb{R}$ such that

$$x_\tau^{G,\varphi,\tau} = \varphi, \quad \dot{x}^{G,\varphi,\tau}(t) = G(t, x_t^{G,\varphi,\tau}) \quad \text{for } t \ge \tau.$$

(At $t=\tau$, the derivative is to be read as right-side derivative.) The symbol x_t, as usual, denotes the segment of the function x at time t, that is, $x_t(\theta) = x(t+\theta)$, $-1 \le \theta \le 0$.

We shall need solutions of *linear* equations also for discontinuous initial values; let $\mathbf{J}$ denote the space of functions $\varphi : [-1,0] \longrightarrow \mathbb{R}$ which are continuous on $[-1,0)$ but possibly have a jump discontinuity at 0 (i.e., $\lim_{t\longrightarrow 0, t<0}\varphi(t)$ exists). We use the sup-norm $|\ |$ also on this space, and we introduce the weaker norm $|\ |_*$ on $\mathbf{J}$ defined by

$$|\psi|_* := |\psi(0)| + \int_{-1}^{0} |\psi(s)|\,ds.$$

Using the space $\mathbf{J}$ is a simple approach to variation of constants which suffices for our purposes.

2. Linear equations. First we consider linear equations of the type

$$\dot{x}(t) = a(t)x(t-1). \tag{a}$$

The proof of Proposition 2.1 below uses mainly simple standard arguments, in combination with known results for initial segments in $\mathbf{C}$. With a view to the paper's length, it is omitted. A detailed proof is available from the authors.

PROPOSITION 2.1. *Let $\tau, T \in \mathbb{R}$, $\tau < T$, and let $a : [\tau,T] \longrightarrow \mathbb{R}$ be continuous.*

(a) *For $\psi \in \mathbf{J}$ and $s \in [\tau,T]$ there exists a unique solution $x^{a,\psi,s} : [s-1,T] \longrightarrow \mathbb{R}$ of the initial value problem $\dot{x}(t) = a(t)x(t-1)$, $x_s = \psi$.*

(b) *The map*

$$F : (\mathbf{J}, |\ |_*) \times \{(s,t)\in[\tau,T]^2 \mid s\le t\} \ni (\psi,s,t) \mapsto x^{a,\psi,s}(t) \in \mathbb{R}$$

is continuous.

(c) *If $a \in C^1$ and $T \ge \tau+3$, then for $t \ge \tau+3$, $t \le T$ the segment $x_t^{a,\psi,\tau}$ is C^2.*

Our aim is to express solutions of (a) with a slowly varying coefficient by solutions of the constant coefficient equation

$$\dot{x}(t) = c\cdot x(t-1) \quad (c\in\mathbb{R}). \tag{c}$$

First, we provide more detailed information on (c) for values of c around the stability border $-\pi/2$. For $c \in \mathbb{R}$, let $\Sigma_c \subset \mathbb{C}$ denote the set of zeroes of the characteristic function $\lambda \mapsto \lambda - c \cdot \exp(-\lambda)$ associated with (c).

PROPOSITION 2.2. *For $c \in (-\infty, -e^{-1})$, the set Σ_c has the form*

$$\Sigma_c = \{\lambda_k(c) \mid k \in \mathbb{N}_0\} \cup \{\overline{\lambda_k(c)} \mid k \in N_0\},$$

where $\lambda_k(c) = \rho_k(c) + i\omega_k(c)$, $\overline{\lambda_k(c)} = \rho_k(c) - i\omega_k(c)$ $(k \in \mathbb{N}_0)$, and $\omega_k(c) \in (2k\pi, (2k+1)\pi)$. The following properties hold:

(a) *$\rho_k(c) > \rho_{k+1}(c)$ $(k \in \mathbb{N}_0)$, so that $\rho_0(c) = \max \operatorname{Re} \Sigma_c$.*

(b) *$\rho_0(-\pi/2) = 0$.*

(c) *For $c \in [-3\pi/4, -\pi/4]$, $\rho_0'(c)$ exists and $\rho_0'(-\pi/2) = \frac{-2\pi}{4+\pi^2}$. Further, $\omega_0(c) \in (\pi/4, \pi)$, and*

$$-\frac{4(\pi+2)}{\pi^2} \le \rho_0'(c) \le -\frac{4(\pi-2)}{3\pi^2}, \quad \text{and}$$

$$\rho_0(c) \le \begin{cases} -|c+\pi/2|\dfrac{4(\pi-2)}{3\pi^2} & \text{if } c > -\pi/2, \\ |c+\pi/2|\dfrac{4(\pi+2)}{\pi^2} & \text{if } c \le -\pi/2. \end{cases}$$

(d) *$|\rho_0(c)| \le (\pi+2)/\pi \le 2$ for $c \in [-3\pi/4, -\pi/4]$.*

Proof. The assertions on Σ_c and property (a) follow from Theorem 5 in [15]. Writing $\lambda = \rho + i\omega$, the characteristic equation $\lambda = c\exp(-\lambda)$ is equivalent to the equations

$$\rho = ce^{-\rho}\cos\omega, \quad \omega = -ce^{-\rho}\sin\omega.$$

Note that $\sin\omega = 0$ would imply $\omega = 0$, but we know already that for $c < -e^{-1}$ there exist no real roots of the characteristic equation. Hence, we can restrict ourselves to the case $\sin\omega \neq 0$, and we obtain from the above two equations $\omega = -c\exp(\omega\cot\omega)\sin\omega$. Setting

$$\chi(\omega) := \frac{\omega}{\sin\omega}\exp(-\omega\cot\omega) \quad \text{for } \omega \in \mathbb{R} \setminus \{k\pi \mid k \in \mathbb{Z}\},$$

the last equation is equivalent to

$$\chi(\omega) = -c. \tag{2.1}$$

The function χ is discussed in [15]. One has

$$\chi'(\omega) = \frac{\chi(\omega)}{\omega}[(1-\omega\cot\omega)^2 + \omega^2]; \tag{2.2}$$

χ and χ' are positive on $(0,\pi)$, with $\chi(\omega) \longrightarrow e^{-1}$ as $\omega \longrightarrow 0$, and $\chi(\omega) \longrightarrow \infty$ as $\omega \longrightarrow \pi$, $\omega < \pi$. For $c \in (-\infty, -e^{-1})$, the number $\omega_0(c)$ is the unique solution of (2.1) in $(0,\pi)$ and $\rho_0(c) = -\omega_0(c)\cot\omega_0(c) = \log\frac{-c\sin\omega_0(c)}{\omega_0(c)}$, so we have

$$\rho_0(c) = \log(-c) + \log\sin\omega_0(c) - \log\omega_0(c). \tag{2.3}$$

Obviously $\chi(\pi/2) = \pi/2$, so $\omega_0(-\pi/2) = \pi/2$ and $\rho_0(-\pi/2) = 0$. Properties (a) and (b) are proved.

(c) It follows from the inverse function theorem and from (2.3) that ω_0 and ρ_0 are differentiable functions on $(-\infty, -e^{-1})$, in particular, on $[-3\pi/4, -\pi/4]$. Using (2.2) we obtain, for $c \in (-\infty, -e^{-1})$,

$$\begin{aligned}\omega_0'(c) &= -\frac{1}{\chi'(\omega_0(c))} = -\frac{\omega_0(c)}{\chi(\omega_0(c))[(1-\omega_0(c)\cot\omega_0(c))^2+\omega_0(c)^2]}\\ &= \frac{\omega_0(c)}{c[(1-\omega_0(c)\cot\omega_0(c))^2+\omega_0(c)^2]},\end{aligned}$$

and from (2.3) we get

$$\begin{aligned}\rho_0'(c) &= \frac{1}{c} + \omega_0'(c)\left(\cot\omega_0(c) - \frac{1}{\omega_0(c)}\right) = \frac{1}{c} + \frac{\omega_0(c)\cot\omega_0(c)-1}{c[(1-\omega_0(c)\cot\omega_0(c))^2+\omega_0(c)^2]}\\ &= \frac{1}{c}\left(1 + \frac{\omega_0(c)\cot\omega_0(c)-1}{[(1-\omega_0(c)\cot\omega_0(c))^2+\omega_0(c)^2]}\right).\end{aligned}$$

In particular, we see that $\rho_0'(-\pi/2) = \frac{-2}{\pi}(1+\frac{-1}{1+\pi^2/4}) = \frac{-2\pi}{4+\pi^2}$, which is the first assertion of (c). Note now that $\chi(\pi/4) = \frac{\pi/4}{\sqrt{2}/2}\exp(-\pi/4) = \frac{\pi\sqrt{2}}{4}\exp(-\pi/4) < \frac{\pi}{4}\frac{\sqrt{2}}{1+\pi/4} < \pi/4$, so $\omega_0(-\pi/4) > \pi/4$. It follows that

$$\omega_0([-3\pi/4, -\pi/4]) \subset (\pi/4, \pi). \tag{2.4}$$

Further, for all $\omega > 0$ and $u \in \mathbb{R}$, one has $|\frac{u}{u^2+\omega^2}| \le \frac{1}{2\omega}$. With (2.4) we conclude that

$$\left|\frac{\omega_0(c)\cot\omega_0(c)-1}{[(1-\omega_0(c)\cot\omega_0(c))^2+\omega_0(c)^2]}\right| \le \frac{1}{2\omega_0(c)} \le \frac{2}{\pi}.$$

With the above expression for $\rho_0'(c)$, we now obtain that $\rho_0'(c) \in \frac{1}{c}[1-2/\pi, 1+2/\pi]$ for $c \in [-3\pi/4, -\pi/4]$, so for these c one has $(1+2/\pi)(-4/\pi) \le \rho_0'(c) \le (1-2/\pi)(-4/3\pi)$, or

$$-\frac{4(\pi+2)}{\pi^2} \le \rho_0'(c) \le -\frac{4(\pi-2)}{3\pi^2}.$$

The estimates on $\rho_0(c)$ in part (c) follow by integration.

(d) It follows from (b) and (c) that for $c \in [-3\pi/4, -\pi/4]$ one has

$$|\rho_0(c)| \le \frac{\pi}{4}\frac{4(\pi+2)}{\pi^2} = \frac{\pi+2}{\pi} \le 2. \qquad \square$$

It is known that for $c < -e^{-1}$ and $\rho > \rho_0(c)$, there exists $K > 0$ such that all solutions $x^{c,\varphi,\tau}$ of (c) satisfy an estimate of the form $|x^{c,\varphi,\tau}(t)| \le K\exp(\rho(t-\tau))|\varphi|$ for $t \ge \tau$. (Compare, e.g., Corollary 6.1, page 215 of [9], and the definition of the constant K given in the proof of Lemma 6.2, page 213 of the same reference.) Analogous results hold for much more general linear equations. We now derive a similar estimate with an explicit value for K, and with $\rho = \rho_0(c)$, for the special case of (c).

PROPOSITION 2.3. *Set* $K := [4 + 15(3\pi/4) + 24(3\pi/4)^2]e^4$, *and let* $c \in [-3\pi/4, -\pi/4]$ *and* $t, s \in \mathbb{R}$, $t \ge s$.

(a) *For* $\psi \in C^2([-1,0],\mathbb{R})$, *one has* $|x^{c,\psi,s}(t)| \le (4|\psi| + 7|\psi'| + 13|\psi''|)e^{\rho_0(c)(t-s)}$.

(b) *For* $\varphi \in \mathbf{J}$, *one has* $|x^{c,\varphi,s}(t)| \le |\varphi|K\exp[\rho_0(c)(t-s)]$.

Proof. Since (c) is autonomous, it suffices to prove the assertions for the case $s = 0$. For $t > 0$, we have for $\varphi \in \mathbf{C}$ the series expansion

$$x^{c,\varphi,0}(t) = \sum_{\mu \in \Sigma_c} (\mathrm{pr}_\mu\, \varphi) \exp(\mu t),$$

where $\mathrm{pr}_\mu\, \varphi = \frac{1}{1+\mu}[\varphi(0) + \mu \int_{-1}^{0} e^{-\mu s}\varphi(s)ds]$ (see [15, Theorem 6], or [10, Lemma 6.8], or [5, Theorem 6.3, and Corollary 6.4 of Chapter V and formula (3.3) on p. 106]).

Claim: For $\psi \in C^2([-1,0],\mathbb{R})$ and for all $\mu \in \Sigma_c$, one has

$$|\,\mathrm{pr}_\mu\, \psi| \le \frac{(3\pi/4)|\psi| + 4|\psi'| + e^2|\psi''|}{|\mu(1+\mu)|}.$$

Proof. If $\mu \in \Sigma_c$, then $\mu = ce^{-\mu}$, so $e^\mu = c/\mu$. Using partial integration twice, we calculate

$$\mu \int_{-1}^{0} e^{-\mu s}\psi(s)ds = -\psi(0) + \frac{c}{\mu}\psi(-1) + \frac{1}{\mu}\left[\frac{c}{\mu}\psi'(-1) - \psi'(0)\right] + \frac{1}{\mu}\int_{-1}^{0} e^{-\mu s}\psi''(s)\,ds.$$

It follows that

$$|\,\mathrm{pr}_\mu\, \psi| \le \frac{1}{|1+\mu|}\left[\frac{|c|}{|\mu|}|\psi| + \frac{1}{|\mu|}\left(\frac{|c|}{|\mu|}+1\right)|\psi'| + \frac{1}{|\mu|}\int_{-1}^{0}|e^{-\mu s}|\,ds\cdot|\psi''|\right].$$

Since $c \in [-3\pi/4, \pi/4]$, we know from Proposition 2.2 that

$$\Sigma_c = \{\rho_k(c) \pm i\omega_k(c) \mid k \in \mathbb{N}_0\},$$

that $\omega_k(c) \ge 2k\pi$ for $k \ge 1$, and that $\omega_0(c) \ge \pi/4$. In particular, $|c|/|\mu| \le (3\pi/4)/(\pi/4) = 3$ for $\mu \in \Sigma_c$. Further, it follows from Proposition 2.2(d) that for $s \in [-1,0]$ we have $|e^{-\mu s}| \le e^{|\rho_0(c)|} \le e^2$. Thus we obtain

$$|\,\mathrm{pr}_\mu\, \psi| \le \frac{1}{|1+\mu|}\left[\frac{3\pi/4}{\mu}|\psi| + \frac{1}{|\mu|}4|\psi'| + \frac{e^2}{|\mu|}|\psi''|\right].$$

The claim is proved. For $\psi \in C^2([-1,0],\mathbb{R})$, we have

$$\begin{aligned}
\sum_{\mu\in\Sigma_c} |\,\mathrm{pr}_\mu\, \psi| &\le 2\cdot \sum_{\substack{\mu\in\Sigma_c,\\ \mathrm{Im}\,\mu>0}} |\,\mathrm{pr}_\mu\, \psi| \\
&\le 2\sum_{k=0}^{\infty}[(3\pi/4)|\psi| + 4|\psi'| + e^2|\psi''|]\frac{1}{|\omega_k(c)|(|\omega_k(c)|+1)} \\
&\le 2\left(\frac{3\pi}{4}|\psi| + 4|\psi'| + e^2|\psi''|\right)\left\{\frac{1}{\pi/4(1+\pi/4)} + \sum_{k=1}^{\infty}\frac{1}{(2k\pi)^2}\right\} \\
&\le 2\left(\frac{3\pi}{4}|\psi| + 4|\psi'| + e^2|\psi''|\right)\left\{\frac{1}{(3/4)\cdot(7/4)} + \frac{1}{4\pi^2}\frac{\pi^2}{6}\right\} \\
&\le 2\left(\frac{3\pi}{4}|\psi| + 4|\psi'| + e^2|\psi''|\right)\frac{17}{21} \le \frac{19/2}{2}\frac{17}{21}|\psi| + \frac{8\cdot 17}{21}|\psi'| + \frac{15\cdot 17}{21}|\psi''| \\
&\le 4|\psi| + 7|\psi'| + 13|\psi''|.
\end{aligned}$$

Now we obtain from the series expansion, and from $|e^{\mu t}| \le e^{\rho_0(c)t}$ for $\mu \in \Sigma_c$, that

$$|x^{c,\psi,0}(t)| \le \sum_{\mu\in\Sigma_c} |\operatorname{pr}_\mu \psi| e^{\rho_0(c)t} \le (4|\psi| + 7|\psi'| + 13|\psi''|)e^{\rho_0(c)t}.$$

Assertion (a) is proved.

(b) We know from Proposition 2.2(d) that $|\rho_0(c)| \le 2$, and hence we have

$$e^{|\rho_0(c)|} \le e^2. \tag{2.5}$$

Let $\varphi \in \mathbf{J}$. For $t \in [0,1]$, we have (using (2.1))

$$\begin{aligned} |x^{c,\varphi,0}(t)| &\le |\varphi|(1+|c|t) \le |\varphi|(1+|c|)e^{-\rho_0(c)t}e^{\rho_0(c)t} \\ &\le |\varphi|(1+|c|)e^2 e^{\rho_0(c)t}. \end{aligned} \tag{2.6}$$

Moreover, one has $x_1^{c,\varphi,0} \in C^1$, although $\dot{x}^{c,\varphi,0}$ may have a jump discontinuity at 1.

Similarly, we have for $t \in [1,2]$

$$|x^{c,\varphi,0}(t)| \le |\varphi|(1+|c|)^2 e^{-\rho_0(c)t}e^{\rho_0(c)t} \le |\varphi|(1+|c|)^2 e^4 e^{\rho_0(c)t}. \tag{2.7}$$

Set $\psi := x_2^{c,\varphi,0}$; then $\psi \in C^2$, since $x_1^{c,\varphi,0} \in C^1$, and we have

$$|\psi| \le (1+|c|)^2|\varphi|, \qquad |\psi'| \le |c| \cdot |x_1^{c,\varphi,0}| \le |c|(1+|c|)|\varphi|, \qquad |\psi''| \le c^2|\varphi|. \tag{2.8}$$

Using part (a), and inequality (2.5) for the last step, we obtain for $t \ge 2$

$$\begin{aligned} |x^{c,\varphi,0}(t)| &= |x^{c,\psi,2}(t)| = |x^{c,\psi,0}(t-2)| \\ &\le (4|\psi| + 7|\psi'| + 13|\psi''|)e^{\rho_0(c)(t-2)} \\ &\le [4(1+|c|)^2|\varphi| + 7|c|(1+|c|)|\varphi| + 13|c|^2|\varphi|]e^{\rho_0(c)(t-2)} \\ &\le [4 + 15|c| + 24|c|^2]e^4 e^{\rho_0(c)t}|\varphi|. \end{aligned}$$

We see from (2.6) and (2.7) that this estimate also holds for $t \in [0,2]$. The assertion of (b) now follows from $|c| \le 3\pi/4$. □

Next, we need some preparations concerning the inhomogeneous linear equation

$$\dot{x}(t) = a(t)x(t-1) + h(t). \tag{a,h}$$

We assume that a and h are continuous on an interval $[\tau, T]$. For $t \in [\tau, T]$ we define a segment $\hat{h}(t) \in \mathbf{J}$ by setting

$$\hat{h}(t)(\theta) := \begin{cases} h(t), & \theta = 0, \\ 0, & \theta \in [-1, 0). \end{cases}$$

Note that $|\hat{h}(t) - \hat{h}(s)| = |h(t) - h(s)|$ for $s, t \in [\tau, T]$, so that the map $\hat{h} : [\tau, T] \longrightarrow (\mathbf{J}, |\,|)$, $t \mapsto \hat{h}(t)$ is continuous.

Recall the notation $x^{a,\psi,s}$ for the solution of $\dot{y}(t) = a(t)y(t-1)$ starting with ψ at time s. We now see from continuity of $\hat{h}$ and from Proposition 2.1(b) that, for $t \in [\tau, T]$, the function $[\tau, T] \ni s \mapsto x^{a,\hat{h}(s),s}(t)$ is continuous. In particular, the integral $\int_\tau^t x^{a,\hat{h}(s),s}(t)ds$ exists, simply as a Riemann integral of a continuous function.

The following result is known but stated in somewhat different notation in the literature (see, e.g., [8, Theorem 16.3 and formula (16.17)] or [9, formula (2.2), p. 173]).

LEMMA 2.4 (variation of constants). *For $\psi \in \mathbf{C}$, the solution $x^{a,h,\psi,\tau}$ of (a,h) with $x^{a,h,\psi,\tau}_\tau = \psi$ satisfies*

$$x^{a,h,\psi,\tau}(t) = x^{a,\psi,\tau}(t) + \int_\tau^t x^{a,\hat{h}(s),s}(t)ds \quad \text{for } t \geq \tau.$$

In the next section we use Lemma 2.4 to compare solutions of nonautonomous and nonlinear equations of the type

$$\dot{x}(t) = g(t, x(t-1)), \tag{g}$$

to solutions of constant coefficient equations. This is done on successive intervals, where we "adapt" the constant coefficient to the coefficient $a(t) := \partial_2 g(t,0)$ of the linearization of (g) on each interval. Thus we obtain Theorem 3.2, which provides upper estimates on the values of solutions close to zero in terms of exponential functions. Here the real part $\rho_0(a(r))$ of the leading eigenvalue for the "frozen" coefficient equation $\dot{y}(t) = a(r)y(t-1)$ enters in a formula which resembles the expression for the solution of a scalar linear ODE with varying coefficient.

Theorem 3.2 is applied to the example equation $\dot{x}(t) = (-\pi/4 - \varepsilon t)\arctan(x(t-1))$ in section 4, where it serves to control the motion near zero.

3. Nonlinear nonautonomous equations. We consider (g) from above, where we assume that $g : \mathbb{R} \times \mathbb{R} \to \mathbb{R}$ is continuous, and has two continuous derivatives w.r. to the second argument. Further, we assume that for all t one has $g(t,0) = 0$ and that $|\partial_2^2 g|$ has a finite supremum which we denote by $\|\partial_2^2 g\|$. For a bounded function a on an interval $[s,t]$, we use the notation

$$V_a(s,t) := \sup_{\tau\in[s,t]} a(\tau) - \inf_{\tau\in[s,t]} a(\tau).$$

Using Lemma 2.4, we can now obtain an estimate on solutions of nonautonomous and nonlinear equations.

LEMMA 3.1. *Let $\varphi \in \mathbf{C}$, $T \geq 1$, $s \in \mathbb{R}$, and let $g : \mathbb{R} \times \mathbb{R} \to \mathbb{R}$ be as above. Set $a(t) := \partial_2 g(t,0)$ for $t \in \mathbb{R}$. Assume that $c \in a([s, s+T]) \cap [-3\pi/4, -\pi/4]$. Set $V := V_a(s, s+T)$, and with K from Proposition 2.3 set*

$$K_V := \max\{K, 1 + 3\pi/4 + V\}, \quad L_V := K_V e^2.$$

Let $x : [s-1, \infty) \to \mathbb{R}$ be the solution of (g) with $x_s = \varphi$, and assume that $\tau \in [s, s+T]$ and $\xi \geq 0$ are such that $|x_t| \leq \xi$ for all $t \in [s,\tau]$. Then, for all $t \in [s,\tau]$, one has

$$|x_t| \leq L_V|\varphi| \exp[(\rho_0(c) + L_V V + L_V\|\partial_2^2 g\|\xi/2) \cdot (t-s)].$$

Proof. For $t \in [s, s+T]$, there exists $r_t \in (0,1)$ such that

$$\begin{aligned} g(t, x(t-1)) &= \partial_2 g(t,0)x(t-1) + [\partial_2^2 g(t, r_t x(t-1))/2]x(t-1)^2 \\ &= cx(t-1) + (\partial_2 g(t,0) - c)x(t-1) + [\partial_2^2 g(t, r_t x(t-1))/2]x(t-1)^2 \\ &= cx(t-1) + (a(t) - c)x(t-1) + [\partial_2^2 g(t, r_t x(t-1))/2]x(t-1)^2. \end{aligned}$$

Thus, with $h(t) := (a(t)-c)x(t-1) + [\partial_2^2 g(t, r_t x(t-1))/2]x(t-1)^2$ for $t \in [s, s+T]$, one has for these t

$$\dot{x}(t) = cx(t-1) + h(t).$$

Further, for $t \in [s, \tau]$ one has

$$|\hat{h}(t)| \le V|x(t-1)| + (\|\partial_2^2 g\|/2)x(t-1)^2 \le [V + \|\partial_2^2 g\|\xi/2] \cdot |x(t-1)|.$$

It follows from Lemma 2.4 and from Proposition 2.3(b) that, for $t \in [s, \tau]$,

$$\begin{aligned}
|x(t)| &= \left| x^{c,\varphi,s}(t) + \int_s^t x^{c,\hat{h}(\sigma),\sigma}(t)\, d\sigma \right| \\
&\le K|\varphi| \exp[\rho_0(c)(t-s)] + K \int_s^t \exp[\rho_0(c)(t-\sigma)]|\hat{h}(\sigma)|\, d\sigma \\
&\le K \left\{ |\varphi| \exp[\rho_0(c)(t-s)] + [V + \|\partial_2^2 g\|\xi/2] \int_s^t \exp[\rho_0(c)(t-\sigma)]|x(\sigma-1)|\, d\sigma \right\}.
\end{aligned}$$

Set $W := [V + (\|\partial_2^2 g\|\xi/2)]$. If now $t \in [s+1, \tau]$ (in case $s+1 \le \tau$) and $\theta \in [-1, 0]$, then

$$\begin{aligned}
|x(t+\theta)| &\le K \left\{ |\varphi| \exp[\rho_0(c)(t+\theta-s)] + W \int_s^{t+\theta} \exp[\rho_0(c)(t+\theta-\sigma)]|x(\sigma-1)|\, d\sigma \right\} \\
&\le K \exp(|\rho_0(c)|) \left\{ |\varphi| \exp[\rho_0(c)(t-s)] + W \int_s^{t+\theta} \exp[\rho_0(c)(t-\sigma)]|x_\sigma|\, d\sigma \right\} \\
&\le K \exp(|\rho_0(c)|) \left\{ |\varphi| \exp[\rho_0(c)(t-s)] + W \int_s^{t} \exp[\rho_0(c)(t-\sigma)]|x_\sigma|\, d\sigma \right\}.
\end{aligned}$$

Hence, for $t \in [s+1, \tau]$, it follows trivially that with $K_V := \max\{K, 1 + 3\pi/4 + V\}$ we have

(3.1)
$$|x_t| \le K_V \exp(|\rho_0(c)|) \left\{ |\varphi| \exp[\rho_0(c)(t-s)] + W \int_s^t \exp[\rho_0(c)(t-\sigma)]|x_\sigma|\, d\sigma \right\}.$$

For $t \in [s, s+1] \cap [s, \tau]$, we obtain (using the differential equation and the definition of K_V) that

$$\begin{aligned}
|x_t| &\le |\varphi| + \int_{-1}^0 (|c| + V)|\varphi|\, ds = |\varphi|(1 + |c| + V) \\
&\le |\varphi|(1 + 3\pi/4 + V) \le K_V|\varphi|.
\end{aligned}$$

The right-hand side of (3.1) is, for $t \in [s, s+1]$, obviously bounded below by $K_V|\varphi|$. Hence, (3.1) holds also for $t \in [s, s+1]$.

Now, setting $y(t) := \exp[-\rho_0(c)t]|x_t|$ for $t \in [s, \tau]$, we obtain from (3.1) and (2.5) that

$$\begin{aligned}
y(t) &\le K_V \exp(|\rho_0(c)|) \left\{ |\varphi| \exp[-\rho_0(c)s] + W \int_s^t y(\sigma)\, d\sigma \right\} \\
&\le K_V e^2 \left\{ |\varphi| \exp[-\rho_0(c)s] + W \int_s^t y(\sigma)\, d\sigma \right\} \\
&= L_V \left\{ |\varphi| \exp[-\rho_0(c)s] + W \int_s^t y(\sigma)\, d\sigma \right\}.
\end{aligned}$$

It follows from Gronwall's lemma that for $t \in [s, \tau]$ one has

$$y(t) \le L_V|\varphi| \exp[-\rho_0(c)s] \exp[L_V W(t-s)].$$

Hence we conclude

$$\begin{aligned} |x_t| &\le L_V|\varphi| \exp[\rho_0(c)(t-s)] \exp[L_V W(t-s)] \\ &= L_V|\varphi| \exp[(\rho_0(c) + L_V V + L_V \|\partial_2^2 g\|\xi/2) \cdot (t-s)]. \end{aligned}$$ □

We are now prepared for the proof of a delayed loss of stability estimate for nonlinear nonautonomous equations of type (g). Again, we restrict attention to the case where $\partial_2 g(\cdot, 0)$ takes values in $[-3\pi/4, -\pi/4]$. Recall the definition of $V_a(s,t)$ for $s \le t$.

THEOREM 3.2. *Let $t_- \in \mathbb{R}$, let g be as above, and assume that the function defined by $a(t) := \partial_2 g(t, 0)$ takes values in $[-3\pi/4, -\pi/4]$. Assume that there exists $T \ge 1$ and $V \ge 0$ such that one has for all $s \ge t_-$*

$$V_a(s, s+T) \le V. \tag{3.2}$$

Let $\varphi \in \mathbf{J}$, and let $x : [t_- - 1, \infty) \to \mathbb{R}$ be the solution of (g) with $x_{t_-} = \varphi$. Assume that $t_+ \ge t_-$ and $\xi \ge 0$ are such that

$$\forall t \in [t_-, t_+] : |x_t| \le \xi.$$

Define L_V as in Lemma 3.1*, and set*

$$C := C(V, T, \xi) := L_V V + L_V \|\partial_2^2 g\|\xi/2 + \log(L_V)/T.$$

Finally, for $t, s \in \mathbb{R}$, $t \ge s \ge t_-$, set

$$u(t,s) := \exp\left[\int_s^t (\rho_0(a(r)) + C)\, dr\right].$$

(a) *Then one has for all $t \in [t_-, t_+]$*

$$|x_t| \le |\varphi| L_V u(t, t_-).$$

(b) *With $c_- := \frac{4(\pi-2)}{3\pi^2}$, $c_+ := \frac{4(\pi+2)}{\pi^2}$, the following estimates hold:*

If $t, s \in [t_-, t_+]$, $s \le t$, and $a(\cdot) \ge -\pi/2$ on $[s,t]$, then

$$u(t,s) \le \exp\left[\int_s^t (-c_-|a(s) + \pi/2| + C)\, ds\right].$$

If $t, s \in [t_-, t_+]$, $s \le t$, and $a(\cdot) \le -\pi/2$ on $[s,t]$, then

$$u(t,s) \le \exp\left[\int_s^t (c_+|a(s) + \pi/2| + C)\, ds\right].$$

Remarks. 1. The first estimate in (b) implies (not necessarily monotonous) decay of $|x_t|$, as long as $a(s) \ge -\pi/2$ and $c_-|a(s) + \pi/2| \ge C$. One can expect the second inequality to hold only if the term $\|\partial_2^2 g\|\xi/2$ is small enough, i.e., if the solution x takes sufficiently small values. This is natural since the decay is an effect of the linearization at zero.

If one wants to obtain decay for "large" initial values φ, it is necessary to combine the estimate of Theorem 3.2(a) with different methods, as we do in the example in section 4. While the method of linearization close to zero is "universal," the possibilities to obtain a decay estimate far from zero depend both on the initial value and on the specific nonlinearity. We explain the basic idea for doing this in our example at the beginning of section 4.

2. If one obtains $|x_{t_0}| < |\varphi|$ for some $t_0 \in [t_-, t_+]$, then the second inequality in b) can be used to give a lower estimate for the length of the time interval on which $|x_t| \le |\varphi|$. Note that, as soon as $\rho_0(a(t)) > 0$ (in fact, as soon as $\rho_0(a(t)) + C > 0$), the function $t \mapsto u(t, t_-)$ starts to increase exponentially with t, and typically one has to expect that the solution x does the same. We do not prove this rigorously, but give a heuristic argument: For the constant coefficient equation with an unstable (complex) leading eigenvalue, all solutions, except the ones starting in a subspace S of codimension 2, exhibit the growth associated with that unstable eigenvalue. The functions in S are rapidly oscillating (have two or more zeroes per time unit). The same behavior is to be expected from equations with slowly varying coefficient. This could be proved by comparison to the constant coefficient case on successive "long" intervals, which is also our method of proving Theorem 3.2. In the example of section 4, the solution under consideration is slowly oscillating (has zeroes further apart than 1) and hence will certainly exhibit growth behavior corresponding to the leading eigenvalue of the constant coefficient approximation.

Proof of Theorem 3.2. Set $\tilde{C} := \tilde{C}(V, \xi) := L_V V + L_V \|\partial_2^2 g\| \xi/2$. For $t \ge t_-$, set $\eta(t) := \exp[\int_{t_-}^t (\rho_0(a(s)) + \tilde{C})\, ds] = \exp[\int_{t_-}^t (\rho_0(a(s))\, ds] \exp[\tilde{C}(t - t_-)]$. Consider φ and x as in the theorem.

Claim. If $t \in [t_- + (j-1)T, t_- + jT]$ for some $j \in \mathbb{N}$, and $t \le t_+$, then

$$|x_t| \le |\varphi| L_V^j \eta(t).$$

Proof. (induction on j.) The case $j = 1$: Assume $t \in [t_-, t_- + T]$. From the mean value theorem, there exists $\tau = \tau(t) \in [t_-, t]$ such that

$$\int_{t_-}^t \rho_0(a(s)) ds = (t - t_-)\rho_0(a(\tau)).$$

Applying Lemma 3.1 with $s := t_-$, $\tau := T$, $c := a(\tau)$, one obtains

$$\begin{aligned} |x_t| &\le L_V |\varphi| \exp[(\rho_0(c) + L_V V + L_V \|\partial_2^2 g\| \xi/2)(t - t_-)] \\ &= L_V |\varphi| \exp\left[\int_{t_-}^t (\rho_0(a(s)) + \tilde{C})\, ds\right] \\ &= |\varphi| L_V \eta(t), \end{aligned}$$

which is the assertion for $j = 1$.

Assume now that the assertion holds for some $j \in \mathbb{N}$ and that $t \in [t_- + jT, t_- + (j+1)T]$, $t \le t_+$. Set $\psi := x_{t_- + jT}$. Then the induction hypotheses gives $|\psi| \le |\varphi| L_V^j \eta(t_- + jT)$. From the case $j = 1$, applied with $t_- + jT$ in place of t_-, one obtains for the solution $y : [t_- + jT - 1, \infty) \to \mathbb{R}$ of (g) with $y_{t_- + jT} = \psi$ that

$$|y_t| \le |\psi| L_V \exp\left[\int_{t_- + jT}^t (\rho_0(a(s)) + \tilde{C})\, ds\right].$$

Together with the estimate on $|\psi|$, we conclude

$$|x_t| = |y_t| \le |\varphi| L_V^j \eta(t_- + jT) L_V \exp\left[\int_{t_-+jT}^{t} (\rho_0(a(s)) + \tilde{C})\, ds\right]$$
$$= |\varphi| L_V^{j+1} \eta(t).$$

The claim is proved.

Now let $t \in [t_-, t_+]$, and set $j := \min\{n \in \mathbb{N} \mid t_- + nT > t\}$. Then $t_- + (j-1)T \le t < t_- + jT$, and from the above claim we get $|x_t| \le |\varphi| L_V^j \eta(t)$. Note that

$$L_V^{j-1} = \exp\left[\frac{(j-1)T\log(L_V)}{T}\right] \le \exp\left[(t-t_-)\frac{\log(L_V)}{T}\right] = \exp\left[\int_{t_-}^{t} \frac{\log(L_V)}{T} ds\right].$$

Recalling the definition of η, and noting that $\tilde{C} + \log(L_V)/T = C$, we obtain

$$|x_t| \le |\varphi| L_V \exp\left[\int_{t_-}^{t} (\rho_0(a(s)) + \tilde{C} + \log(L_V)/T)\, ds\right] = |\varphi| L_V u(t, t_-),$$

that is, assertion (a). Assertion (b) follows from the estimates on ρ_0 from Proposition 2.2(c). □

4. An example. For $\varepsilon \in (0, 0.01]$, we set

$$g(t,x) := (-\pi/4 - \varepsilon t)\arctan(x),$$

and we consider the solution $x : [-1, \infty) \longrightarrow \mathbb{R}$ of (g) with the constant function equal to 1 as initial segment. (The dependence of all objects on ε is not denoted.) Note that $a(t) := \partial_2 g(t, 0)$ satisfies $a(t) \in [-3\pi/4, -\pi/4]$ as long as $t \in [0, \pi/2\varepsilon]$. Further, for these t and for $y \in \mathbb{R}$, one has

$$|\partial_2^2 g(t,y)| \le |-3\pi/4| \sup_{z\in\mathbb{R}} |2z/(1+z^2)^2| \le 2 \cdot 3\pi/4 \le 5.$$

(It is not essential that these properties do not hold for t outside the interval $[0, \pi/2\varepsilon]$, in which we will be interested.)

As already remarked, we need to prove decay of our solution x from the constant value 1 to values near zero first, before Theorem 3.2 becomes applicable to the motion near zero. We briefly explain our basic approach in achieving this: The solution x is oscillating about zero, with zeroes z_i, $i = 1, 2, \dots$, and extremal values m_i occurring at the times $z_i + 1$. It is easy to obtain an estimate of the form $|g(t,y)| \le q|y|$ for our g, where $q \in (0,1)$. We conclude that the m_i form a geometrically decreasing sequence: $m_{i+1} \le q m_i$. This implies exponential decay of $|x(t)|$, if the z_i are not too far apart. However, since it would be difficult to obtain an upper bound on $z_{i+1} - z_i$, we also consider the theoretically possible (although practically not occurring) case of "long" distances between z_i and z_{i+1} (in Proposition 4.3 below). On such intervals, the negative feedback forces the solution to decay monotonously, and we prove an exponential estimate also in this case. While the first argument is based on the estimate $|\arctan(y)| \le |y|$ (the feedback is "weak" enough), this second argument uses the estimate $|\arctan(y)| \ge (\pi/4)|y|$ if $|y| \le 1$ (the negative feedback is "strong" enough).

We carry out the details now.

PROPOSITION 4.1. *The solution x is slowly oscillating; that is, there exists a sequence $(z_1, z_2, \dots)$ in $\mathbb{R}$ such that $0 < z_1 < z_2 < \cdots$ and such that the z_i are precisely the zeroes of x, and $z_{i+1} - z_i > 1$ for all $i \in \mathbb{N}$. The extrema of x on $(0, \infty)$ occur at the times $\mu_i := z_i + 1 \in (z_i, z_{i+1})$, so we have*

$$z_1 < \mu_1 = z_1 + 1 < z_2 < \mu_2 = z_2 + 1 < \cdots .$$

Further, one has $z_1 \le 2$.

Proof. Assume that x has no zero on some interval of the form $[t_0, \infty)$. Then the negative feedback property $g(t, y)y < 0$ $(t > 0, y \in \mathbb{R} \setminus \{0\})$ implies that $x(t) \longrightarrow 0$ $(t \longrightarrow \infty)$, so there exists $t_1 \ge t_0$ with $|x(\cdot)| \le 0.1$ on $[t_1, \infty)$. Now setting $\alpha(t) := \int_0^1 \partial_2 g(t, sx(t-1))\, ds$, the function x satisfies $\dot{x}(t) = \alpha(t)x(t-1)$ for $t \ge t_1$, and for these t one has

$$\alpha(t) \le -(\pi/4) \min_{|y| \le 0.1} \arctan'(y) = -(\pi/4) \cdot 100/101 < -\exp(-1).$$

We can now apply Theorem 8 in [6] (with $n := 1$, $r := 1$, $\eta(t, -1) := 0$, $\eta(t, \theta) := \alpha(t)$ for $\theta \in (-1, 0]$, and with $q(t, \theta) := -\eta(t, \theta)$); in particular, the last inequality shows that condition (A4) of that theorem is satisfied. It follows that x has infinitely many zeroes on $[t_1, \infty)$, in contradiction to our assumption.

We know now that x must have infinitely many zeroes. It follows from the fact that the segment x_0 has no zero, and from the fact that the zero-counting Liapunov functional used in [11] does not increase in time, that x is slowly oscillating (see [11], Theorem 2.1). The assertion about extrema is now clear, in view of the differential equation.

We now prove $z_1 \le 2$: On $[0, 1]$, we have

$$\dot{x}(t) = (-\pi/4 - \varepsilon t) \arctan(1) \le (-\pi/4)(\pi/4) = -\pi^2/16,$$

and hence $x(1) \le 1 - \pi^2/16$. On the other hand, for $t \in [0, 1]$, one obtains (using $\varepsilon \le 0.01$) that $\dot{x}(t) \ge (-\pi/4 - \varepsilon)(\pi/4) \ge -10/16 = -5/8$, so $x(t) \ge 1 - (5/8)t$ for these t. It follows from $|\arctan(y)| \ge |(\pi/4)y|$ if $|y| \le 1$ that for $t \in [1, 2]$ one has

$$\dot{x}(t) \le -(\pi/4)(\pi/4)[1 - (5/8)(t-1)].$$

Hence, integrating, we obtain

$$\begin{aligned} x(2) &\le 1 - (\pi^2/16) - (\pi^2/16)[1 - (5/8)(1/2)] = 1 - (\pi^2/16) - (\pi^2/16) \cdot (11/16) \\ &= 1 - (27\pi^2/256) \le 1 - 27 \cdot 9.5/256 = 1 - 256.5/256 < 0, \end{aligned}$$

and consequently x has a first zero z_1 in $[1, 2]$. □

Set $m_i := |x(\mu_i)|$ for $i \in \mathbb{N}$; then $m_i = \max_{t \in [z_i, z_{i+1}]} |x(t)|$. We first focus attention on the time interval $(0, \pi/16\varepsilon]$. Let $J \in \mathbb{N}$ be such that the extrema of x in this interval occur at the times $\mu_1, \dots, \mu_J$. The following estimate exploits the fact that for t in $[0, \pi/16\varepsilon]$ one has $|g(t, y)| \le q|y|$ $(y \in \mathbb{R})$ with some $q \in (0, 1)$.

PROPOSITION 4.2. *For $t \in [0, z_{J+1}]$ one has $|x(t)| \le 1$. Further, with $q := 5\pi/16$, one has*

$$m_{i+1} \le q m_i \quad \text{if } i \in \{1, \dots, J-1\}.$$

Proof. Note that $|\arctan(y)| \le |y|$ for $y \in \mathbb{R}$. As long as $t \le \pi/16\varepsilon$, we thus have

$$|g(t, y)| \le (\pi/4 + \pi/16)|y| = 5\pi/16|y| = q|y|.$$

Since $|x(\cdot)| \le 1$ on $[0, z_1]$, we have $m_1 \le q < 1$. Further, if $i \in \{1, \dots, J-1\}$, we obtain (using $z_{i+1} - z_i > 1$) that

$$m_{i+1} = \left| \int_{z_{i+1}}^{z_{i+1}+1} g(s, x(s-1))\, ds \right| \le \int_{z_{i+1}-1}^{z_{i+1}} q|x(s)|ds \le q m_i.$$

Together with $|x(\cdot)| \le 1$ on $[0, \mu_1]$ and the fact that $|x(\cdot)|$ decreases on $[\mu_J, z_{J+1}]$, it follows that $|x(\cdot)| \le 1$ on $[0, z_{J+1}]$. ∎

Next, we give a decay estimate for the case that $\mu_i - \mu_{i-1}$ is "large."

PROPOSITION 4.3. *Assume $i \in \{2, \dots, J+1\}$ and $\mu_{i-1} + 1 \le z_i$. Then for all $j \in \mathbb{N}_0$ with $\mu_{i-1} + j \le z_i$ one has*

$$|x(\mu_{i-1} + j)| \le q^{j-1} m_{i-1}.$$

Proof. The estimate is trivial for $j = 0$. Since $|x(\cdot)|$ decreases on $[\mu_{i-1}, z_i]$ and $m_{i-1} \le 1$, we have $|x(\cdot)| \le 1$ on $[\mu_{i-1}, z_i]$, and $|x(\mu_{i-1}+1)| \le m_{i-1}$. Hence the assertion holds for $j = 1$. Now if $j \in \mathbb{N}$ and $[\mu_{i-1} + j, \mu_{i-1} + j + 1] \subset [\mu_{i-1}, z_i]$, we obtain (using $|\arctan(y)| \ge (\pi/4)|y|$ if $|y| \le 1$, and the monotonicity of $|x(\cdot)|$ on $[\mu_{i-1} + j - 1, \mu_{i-1} + j]$) that

$$\begin{aligned}
|x(\mu_{i-1} + j + 1)| &= \left| x(\mu_{i-1} + j) + \int_{\mu_{i-1}+j}^{\mu_{i-1}+j+1} g(s, x(s-1))\, ds \right| \\
&\le |x(\mu_{i-1} + j)| - \min_{s \in [\mu_{i-1}+j-1, \mu_{i-1}+j]} |g(s+1, x(s))| \\
&\le |x(\mu_{i-1} + j)| - (\pi/4)|\arctan(x(\mu_{i-1} + j))| \\
&\le |x(\mu_{i-1} + j)| - (\pi^2/16)|x(\mu_{i-1} + j)| \\
&= [(16 - \pi^2)/16]|x(\mu_{i-1} + j)| \le q|x(\mu_{i-1} + j)|.
\end{aligned}$$

For $j \in \mathbb{N}$ with $\mu_{i-1} + j \le z_i$, it follows inductively that

$$|x(\mu_{i-1} + j)| \le q^{j-1}|x(\mu_{i-1} + 1)| \le q^{j-1} m_{i-1}. \qquad ∎$$

Proposition 4.2 above relates the value m_i to the index i, but not to the time μ_i at which it occurs. This is achieved in the next result.

PROPOSITION 4.4. *With the negative number $\lambda := \log(q)/4$, one has*

$$m_j \le q^{-1} \exp(\lambda \mu_j) \quad (j = 1, \dots, J).$$

Proof. Let $i \in \{2, \dots, J\}$. If $z_i - \mu_{i-1} \le 2$, then $\mu_i - \mu_{i-1} \le 3 < 4$ and

$$m_i/m_{i-1} \le q = \exp(4\lambda) \le \exp(\lambda(\mu_i - \mu_{i-1})). \tag{4.1}$$

Consider now the case $z_i - \mu_{i-1} > 2$. Then, setting

$$j_1 := \max\{j \in \mathbb{N} \mid \mu_{i-1} + j + 1 \le z_i\},$$

we obtain from Proposition 4.3 that

$$|x(\mu_{i-1} + j_1)| \le q^{j_1 - 1} m_{i-1}.$$

Note that $[z_i - 1, z_i] \subset [\mu_{i-1} + j_1, z_i]$, and hence $|x(t)| \le |x(\mu_{i-1} + j_1)|$ for $t \in [z_i - 1, z_i]$. We infer from the differential equation that

$$m_i \le q|x(\mu_{i-1} + j_1)| \le q q^{j_1 - 1} m_{i-1} = q^{j_1} m_{i-1}.$$

Now, from the definition of j_1,

$$\mu_i - \mu_{i-1} = z_i + 1 - \mu_{i-1} \le \mu_{i-1} + j_1 + 3 - \mu_{i-1} = j_1 + 3 \le 4j_1,$$

and thus

$$m_i/m_{i-1} \le q^{j_1} = \exp(\lambda \cdot 4j_1) \le \exp(\lambda(\mu_i - \mu_{i-1})),$$

and we see that (4.1) also holds in the second case.

We conclude that for $j \in \{1, \dots, J\}$ one has

$$\begin{aligned} m_j &= m_1 \prod_{i=2}^{j} (m_i/m_{i-1}) \le m_1 \prod_{i=2}^{j} \exp(\lambda(\mu_i - \mu_{i-1})) \\ &= m_1 \exp[\lambda(\mu_j - \mu_1)] = m_1 \exp(-\lambda\mu_1) \exp(\lambda\mu_j), \end{aligned}$$

where the product is to be read as 1 if $j = 1$. Since $m_1 \le 1$ (Proposition 4.2) and $\mu_1 = z_1 + 1 \le 3 < 4$ (Proposition 4.1), it follows that $m_j \le \exp(-4\lambda)\exp(\lambda\mu_j) = q^{-1}\exp(\lambda\mu_j)$. ∎

We can now obtain an exponential decay estimate for x (which is not based on linearization at zero) for the time interval $[0, \pi/16\varepsilon]$.

COROLLARY 4.5. *For $t \in [0, \pi/16\varepsilon]$, one has $|x_t| \le 2q^{-3}\exp(\lambda t)$.*

Proof. 1. For $t \in [0, \mu_1]$, one has $|x_t| \le 1$, and $\mu_1 \le 3 < 4$ implies

$$2q^{-3}\exp(\lambda t) \ge 2q^{-3}\exp(4\lambda) = 2q^{-2} > 1,$$

so the assertion is true for these t.

2. Let $t \in [\mu_1, \pi/16\varepsilon]$. There exists $i \in \{2, \dots, J+1\}$ with $t \in [\mu_{i-1}, \mu_i]$.

Case 1: $t \le \mu_{i-1} + 2$. We have $|x(s)| \le m_{i-1}$ for $s \in [z_{i-1}, z_i]$, and

$$|\dot{x}(s)| \le |(-\pi/4 - \pi/16)| m_{i-1} = q m_{i-1} \le m_{i-1}$$

for $s \in [z_i, t]$ if $t \ge z_i$. In this case, $t - z_i \le \mu_{i-1} + 2 - z_i \le 2$, so $|x(s)| \le 2m_{i-1}$ for $s \in [z_i, t]$. With Proposition 4.4, it follows that

$$\begin{aligned} |x_t| &\le 2m_{i-1} \le 2q^{-1}\exp(\lambda\mu_{i-1}) = 2q^{-1}\exp(\lambda(\mu_{i-1} - t))\exp(\lambda t) \\ &\le 2q^{-1}\exp(-2\lambda)\exp(\lambda t) \le 2q^{-2}\exp(\lambda t). \end{aligned}$$

Case 2: $t > \mu_{i-1} + 2$. Then $z_i = \mu_i - 1 \ge t - 1 \ge \mu_{i-1} + 1$. Setting $j_1 := \max\{j \in \mathbb{N} \mid \mu_{i-1} + j \le \min\{t, z_i\}\}$, we obtain from Proposition 4.3 that

$$|x(\mu_{i-1} + j_1)| \le q^{j_1 - 1} m_{i-1}.$$

Subcase 2a: $t \le z_i$. Then $j_1 \ge 2$, and $t - (\mu_{i-1} + j_1) \le 1$, and it follows from Propositions 4.3 and 4.4 that

$$\begin{aligned} |x_t| &\le |x_{\mu_{i-1}+j_1}| = |x(\mu_{i-1} + j_1 - 1)| \le q^{j_1 - 2} m_{i-1} \\ &\le q^{j_1 - 2} q^{-1} \exp(\lambda\mu_{i-1}) = q^{-1}\exp[4\lambda(j_1 - 2)]\exp(\lambda\mu_{i-1}) \\ &\le q^{-1}\exp[\lambda(j_1 - 2)]\exp(\lambda\mu_{i-1}) = q^{-1}\exp(\lambda t)\exp[\lambda(j_1 - 2 + \mu_{i-1} - t)] \\ &\le q^{-1}\exp(-3\lambda)\exp(\lambda t) \le q^{-2}\exp(\lambda t). \end{aligned}$$

Subcase 2b: $t > z_i$. Then $t \in [z_i, \mu_i] = [z_i, z_i + 1]$. From Subcase 2a, applied to z_i, we obtain $|x_{z_i}| \le q^{-2}\exp(\lambda z_i)$. For $s \in [z_i, t]$, one has $\dot{x}(s) \le |(-\pi/4 - \pi/16)|\,|x_{z_i}| \le q q^{-2}\exp(\lambda z_i)$. It follows that

$$\begin{aligned} |x_t| &\le q^{-2}\exp(\lambda z_i) = q^{-2}\exp(\lambda t)\exp(\lambda(z_i - t)) \\ &\le q^{-2}\exp(-\lambda)\exp(\lambda t) \le q^{-3}\exp(\lambda t). \end{aligned}$$

From part 1 and the different cases of part 2, the asserted estimate is obtained. ∎

Combining the above estimate with the ones which were obtained from linearization at zero in Theorem 3.2, we can now provide a lower estimate on the length of the time interval on which $|x(t)| \le 1$. Since our solution x is slowly oscillating, exponential growth is to be expected (and certainly seen in numerical simulation) after the coefficient crosses $-\pi/2$, and the solution will also reach the amplitude 1 of the starting segment again (at some time bounded below by our estimate). We do not pursue a formal proof of this; compare the second remark following Theorem 3.2.

With c_- and c_+ from Theorem 3.2, we set $c_1 := \lambda\pi/16 - c_+\pi^2/16 - 5c_-\pi^2/512$ and $c_2 := c_+\pi/4 + c_-\pi/32$. Note that $c_1 < 0 < c_2$.

THEOREM 4.6. *There exists $\varepsilon_0 \in (0, 0.01]$ such that for $\varepsilon \in (0, \varepsilon_0]$ the function $t \mapsto |x_t|$ decreases to values below ε on the interval $[0, \pi/4\varepsilon]$, and then reaches the value $\sqrt{\varepsilon}$ again not before the time $|c_1/2c_2\varepsilon|$. (In particular, $|x_t| \le 1$ on the interval $[0, c_1/2c_2\varepsilon]$.)*

Proof. With K from Proposition 2.3, we set $L := Ke^2$. There exists $\varepsilon_0 \in (0, 0.01]$ such that for $\varepsilon \in (0, \varepsilon_0]$ the following estimates hold:

$$2q^{-3}\exp(\lambda\pi/16\varepsilon) \le \varepsilon, \tag{4.2}$$

$$5L\sqrt{\varepsilon} \le c_-\pi/32, \tag{4.3}$$

$$L2q^{-3}\exp[(\lambda\pi/16 - c_-\pi^2/512)/\varepsilon)] \le \varepsilon, \tag{4.4}$$

$$|\log(q^3\sqrt{\varepsilon}/2L)| \le |c_1|/2\varepsilon. \tag{4.5}$$

Let now $\varepsilon \in (0, \varepsilon_0]$. We set $T := T(\varepsilon) := 1/\sqrt{\varepsilon}$. We then have for all $s \in \mathbb{R}$

$$V_a(s, s+T) = \varepsilon T = \sqrt{\varepsilon} \le 1.$$

It follows that with $V := \sqrt{\varepsilon}$ and with K_V, L_V as in Lemma 3.1, one has $K_V = K$ and $L_V = Ke^2 = L$. Further, we have $\log(L_V)/T = \sqrt{\varepsilon}\log(L)$.

We set $\xi := \sqrt{\varepsilon}$; then the constant $C = C(V, T, \xi)$ from Theorem 3.2 satisfies

$$C \le L\sqrt{\varepsilon} + 5L\sqrt{\varepsilon}/2 + \log(L)\sqrt{\varepsilon} \le 5L\sqrt{\varepsilon}.$$

From Corollary 4.5 and (4.2), we obtain that

$$|x_{\pi/16\varepsilon}| \le 2q^{-3}\exp(\lambda\pi/16\varepsilon) \le \varepsilon < \xi.$$

Now we set $t_- := \pi/16\varepsilon$, and $t_+ := \min\{\inf\{t > t_- \mid |x_t| > \xi\}, \pi/2\varepsilon\}$, and we apply Theorem 3.2. It follows that with $u(t, t_-)$ defined as in that theorem, one has

$$\forall t \in [t_-, t_+] : |x_t| \le L2q^{-3}\exp(\lambda\pi/16\varepsilon)u(t, t_-).$$

Next, we estimate $u(t, s)$ for t, s in different time intervals. Note that for $t \in \mathbb{R}$, one has $|a(t) + \pi/2| = |-\pi/4 + \pi/2 - \varepsilon t| = |\pi/4 - \varepsilon t|$. Thus, for $t \in [\pi/16\varepsilon, 3\pi/16\varepsilon]$, we have $|a(t) + \pi/2| \ge \pi/16$. It follows from Theorem 3.2(b) and (4.3) that, for these t,

$$\begin{aligned} u(t, \pi/16\varepsilon) &\le \exp\left[\int_{\pi/16\varepsilon}^{t} (-c_-\pi/16 + C)\, ds\right] \\ &\le \exp\left[\int_{\pi/16\varepsilon}^{t} (-c_-\pi/16 + 5L\sqrt{\varepsilon})\, ds\right] \\ &\le \exp\left[\int_{\pi/16\varepsilon}^{t} (-c_-\pi/32)\, ds\right] = \exp[(-c_-\pi/32)(t - \pi/16\varepsilon)]. \end{aligned} \tag{4.6}$$

With $t_0 := \pi/4\varepsilon$, we have $a(t_0) = -\pi/2$. For $t \in [3\pi/16\varepsilon, t_0]$, one has

$$\rho_0(a(t)) + C \le C \le 5L\sqrt{\varepsilon},$$

and for these t one has from the definition of $u(\cdot,\cdot)$ and from (4.3) that

$$\begin{aligned} u(t, 3\pi/16\varepsilon) &\le \exp[5L\sqrt{\varepsilon}(t - 3\pi/16\varepsilon)] \le \exp[5L\sqrt{\varepsilon}\pi/16\varepsilon] \\ &\le \exp[c_-\pi^2/512\varepsilon]. \end{aligned} \tag{4.7}$$

Combining (4.6) and (4.7), we see that

$$\begin{aligned} |x_{t_0}| &\le L2q^{-3}\exp[\lambda\pi/16\varepsilon]u(t_0, 3\pi/16\varepsilon)u(3\pi/16\varepsilon, \pi/16\varepsilon) \\ &\le L2q^{-3}\exp[\lambda\pi/16\varepsilon + c_-\pi^2/512\varepsilon - c_-(\pi/32)(\pi/8\varepsilon)] \\ &= L2q^{-3}\exp[(\lambda\pi/16 - c_-\pi^2/512)/\varepsilon]. \end{aligned}$$

Now (4.4) shows that $|x_{t_0}| \le \varepsilon < \xi$, in particular, $t_+ > t_0$.

Finally, for $t \in [t_0, t_+]$ we have $|a(t) + \pi/2| \le \pi/4$. Using part (b) of Theorem 3.2, together with the inequalities $C \le 5L\sqrt{\varepsilon}$ and (4.3), one sees that

$$u(t, t_0) \le \exp[(c_+\pi/4 + C)(t - t_0)] \le \exp[(c_+\pi/4 + c_-\pi/32)(t - \pi/4\varepsilon)]. \tag{4.8}$$

Combining the estimates (4.6), (4.7), and (4.8), we conclude that for $t \in [t_0, t_+]$ one has

$$\begin{aligned} |x_t| &\le L2q^{-3}\exp[(\lambda\pi/16 - c_-\pi^2/512)/\varepsilon \\ &\qquad - (c_+\pi/4 + c_-\pi/32)(\pi/4\varepsilon) + (c_+\pi/4 + c_-\pi/32)t] \\ &= L2q^{-3}\exp[(\lambda\pi/16 - c_+\pi^2/16 - 5c_-\pi^2/512)/\varepsilon + (c_+\pi/4 + c_-\pi/32)t] \\ &= L2q^{-3}\exp[c_1/\varepsilon + c_2 t]. \end{aligned}$$

First case: $t_+ < \pi/2\varepsilon$. Then

$$L2q^{-3}\exp[c_1/\varepsilon + c_2 t_+] \ge \xi = \sqrt{\varepsilon}, \quad \text{so } t_+ \ge [\log(q^3\sqrt{\varepsilon}/2L) - c_1/\varepsilon]/c_2.$$

Using (4.5), we infer $t_+ \ge -c_1/2c_2\varepsilon$. Thus, $|x_t|$ reaches the value $\xi = \sqrt{\varepsilon}$ again not earlier than this time.

Second case: $t_+ = \pi/2\varepsilon$. Then the function $t \mapsto |x_t|$ is bounded by $\sqrt{\varepsilon}$ on the interval $[t_0, \pi/2\varepsilon]$. From the expressions for c_1 and c_2, it is not difficult to see that $|c_1/2c_2| < \pi/2$. Hence, the assertion also holds in the second case. □

Remark. The estimate in Theorem 4.6 is, of course, quantitatively correct only in the sense that it predicts a "growth" time of order $1/\varepsilon$. Further, the upper bound 0.01 for ε, which we used above, is only of a technical nature.

INTEGRAL FUNCTIONALS AND THE GAP PROBLEM: SHARP BOUNDS FOR RELAXATION AND ENERGY CONCENTRATION*

GIUSEPPE MINGIONE† AND DOMENICO MUCCI†

Abstract. We consider integral functionals of the type $F(u) := \int_\Omega f(x,u,Du)\ dx$ exhibiting a gap between the coercivity and the growth exponent

$$L^{-1}|Du|^p \le f(x,u,Du) \le L(1+|Du|^q), \qquad 1<p<q, \qquad 1 \le L < +\infty\,.$$

We give lower semicontinuity results and conditions ensuring that the relaxed functional $\overline{F}$ is equal to $\int_\Omega Qf(x,u,Du)\ dx$, where Qf denotes the usual quasi-convex envelope; our conditions are sharp. Indeed, we also provide counterexamples where such an integral representation fails, showing that energy concentrations appear in the relaxation procedure leading to a measure representation of $\overline{F}$ with a nonzero singular part, which is explicitly computed. The main point in our analysis is that such relaxation results depend in a subtle way on the interaction between the ratio q/p and the degree of regularity of the integrand f with respect to the variable x. Our results extend theorems for nonconvex integrals due to Fonseca and Malý and Kristensen; the energies we treat are related to strongly anisotropic settings.

Key words. relaxation, gap phenomenon, quasi-convexity, nonstandard growth conditions

1. Introduction.

In recent years there has been increasing interest in variational integrals defined on Sobolev spaces and exhibiting a gap between the growth and coercivity exponents

$$\int_\Omega f(x,u,Du)\ dx\,; \qquad L^{-1}|Du|^p \le f(x,u,Du) \le L(1+|Du|^q), \qquad L \ge 1, \tag{1.1}$$

where $1<p<q<+\infty$, $u:\Omega \to \mathbb{R}^N$ and Ω is a domain in $\mathbb{R}^n$. The main issues treated in this setting are concerned with the lower semicontinuity, relaxation, and regularity of minimizers of such functionals. Therefore a great many analytical techniques have been developed; examples of papers devoted to such an issue are [1], [8], [24], [25], [33], [34], and [40]. In particular, in the paper [24] Fonseca and Malý addressed the issue of the relaxation and the lower semicontinuity of quasi-convex functionals satisfying (1.1) with $f \equiv f(Du)$. They succeeded in proving that

$$\int_\Omega f(Du)\ dx \le \liminf_k \int_\Omega f(Du_k)\ dx \tag{1.2}$$

for any sequence of functions $u_k \in W^{1,q}(\Omega;\mathbb{R}^N)$ weakly converging to u, $u_k \rightharpoonup u$, in $W^{1,p}(\Omega;\mathbb{R}^N)$; moreover they proved that the relaxed functional (when considered with respect to the weak topology of $W^{1,p}(\Omega;\mathbb{R}^N)$) is a Radon measure, say μ_u. Also see the work of Kristensen [33], [34], and [36] concerning this type of result. The

previous theorems are valid, provided the gap between p and q, measured in terms of the ratio q/p, is not too large, depending on the dimension n, i.e.,

$$\frac{q}{p} < \frac{n}{n-1}\ ; \tag{1.3}$$

see [24] and [37] for discussion on the optimality of (1.3); see also [40], [30]. Subsequently, in [8], Bouchitté, Fonseca, and Malý also proved that the density of the absolutely continuous part (with respect to the Lebesgue measure) of μ_u coincides with the quantity $Qf(Du)$, where $Qf(\cdot)$ denotes the quasi-convex envelope of f (see [14]). A main problem of the issue is, at this stage, saying something about the *singular part* of μ_u. In a more recent paper [1], Acerbi, Bouchitté, and Fonseca examined the nonautonomous case $f \equiv f(x, Du)$, analyzing the relaxed functional and proving, under the main assumption of convexity of the function $z \mapsto f(x, z)$, that the existence of the singular part of the measure μ_u is related to the presence of the Lavrentiev phenomenon that such functionals typically present, i.e., the impossibility to approximate in energy a given function $u \in W^{1,p}$ with $W^{1,q}$-functions. In particular, they prove that, if there is no Lavrentiev phenomenon at u, then there is no singular part of the measure μ_u. Note that the significance of the situation of the paper [1] (even if f is considered to be convex with respect to the gradient variable) lies in the combination of the facts that f both depends on x and exhibits a gap. Needless to say there is no Lavrentiev gap when one of the two previous conditions fails (by a well-known convolution argument based on the convexity of f and Jensen inequality). This suggests that, when dealing with functionals as in (1.1), the presence of the x and, even worse, of both x and u determines a critical situation. In any case not much is known about the relaxed functional and the singular part of μ_u in the general case (1.1); compare [9, Chap. 21] for a partial result. It is important to note that all the analysis in [1] is based on the convexity of f. Let us explicitly remark that the techniques of the previous works do not apply to quasi-convex energy densities of the type $f(x, Du)$ without imposing severe restrictions on the way the function f depends on x.

The aim of this paper is to investigate such an issue, concentrating on some classes of nonconvex functionals as in (1.1) that will have to satisfy certain structure assumptions but that, nevertheless, will allow the consideration of a large class of functionals not covered in the available literature. For ease of exposition we assume that

$$F(u) \equiv F(u, \Omega) := \int_\Omega f(x, Du)\ dx \tag{1.4}$$

and consider the relaxed functional (see also Remark 2.1 below)

$$\overline{F}(u, \Omega) := \inf \left\{ \liminf_{k \to +\infty} F(u_k, \Omega) \quad | \quad \{u_k\} \subset W^{1,q}_{\mathrm{loc}}(\Omega; \mathbb{R}^N), \ u_k \rightharpoonup u \ \text{ in } \ W^{1,p}(\Omega; \mathbb{R}^N) \right\}. \tag{1.5}$$

The problem we address is: proving measure representation properties of the relaxed functional, representing its absolute continuous part and finally discovering whether or not in the relaxation procedure a singular part emerges. Moreover, the problem of finding explicit examples of singular parts of μ_u, when the Lavrentiev phenomenon

does occur is also relevant. In this direction very few results are available in the literature; see [12], [25], [26], [40], [42].

Due to the lack of a general theory, our analysis starts, and largely proceeds, by considering some model examples. Let us consider the following relevant ones:

$$F_1(u) := \int_\Omega |Du|^{p(x)}\,dx \qquad\qquad F_2(u) := \int_\Omega (|Du|^p + a(x)|Du|^q)\,dx, \tag{1.6}$$

where $p \le p(x) \le q$ and $0 \le a(x) \le L < +\infty$ are continuous functions.

What we are going to discover in the following is that, in such a situation, the form of the relaxed functional is linked to a subtle interplay between the gap of the functional and the regularity of the energy density $f(x, Du)$ with respect to the variable x. Roughly speaking, and, for the sake of clarity, referring to F_2, we are going to show that the larger the gap between p and q, the higher the regularity required on the function $f(x, \cdot)$. Indeed, we shall see that for any functional of the type in (1.1) controlled by F_2 in the sense

$$L^{-1}(|z|^p + a(x)|z|^q) \le f(x, z) \le L(|z|^p + a(x)|z|^q + 1), \qquad L \ge 1,$$

the relaxed functional described in (1.5) is exactly

$$\int_\Omega Qf(x, Du)\,dx,$$

provided the function $a(x)$ is α-Hölder continuous and the following bound is satisfied:

$$\frac{q}{p} \le \frac{n+\alpha}{n}. \tag{1.7}$$

Therefore, no energy concentration appears in the relaxation procedure. This condition must clearly be compared to the one appearing in (1.3): the difference is that the regularity of f with respect to the variable x comes into play via the exponent α. Now, though this bound may appear of a technical nature (at least looking at the proof) the interesting thing is that it actually turns out to be sharp: indeed, we build a functional, which is exactly F_2 for a particular choice of the function $a(x)$, for which the relaxation process does not lead to Radon measure, but rather to a Borel measure, in the form of an infinite Dirac mass concentrated in one point. This can be done as soon as the bound in (1.7) is violated; note that this counterexample can be obtained already in the scalar case $N = 1$ and in the case of convex integrals. A similar situation occurs when considering the relaxation problem for functional F_1, where another condition, in some sense similar to (1.7), involving the oscillations and the regularity of the exponent function $p(x)$ must be considered; see (5.6) below and section 8.

But let us give an outlook on the content of this paper. To be general, we shall treat functionals like the one in (1.1) and satisfying the following additional structure assumption:

$$L^{-1}\psi(x, |z|) \le f(x, z) \le L(\psi(x, |z|) + 1), \tag{1.8}$$

where $\psi(x, |z|)$ is a suitable convex function with (p, q) growth (with respect to z), typical examples being the energy densities of the functionals F_1 and F_2; see Remark 3.1 below. Therefore, we shall not deal with typical examples of quasi-convex energy

densities such as $|z|^p + |\det z|$ as considered, for example, in [40], [25], [24]. In order to prove the integral representation, a key point will be certain continuity estimates on the maximal function with respect to the function $\psi(x, |z|)$ and the density of smooth maps in energy; see sections 4 and 5. This is the point where bounds as in (1.7) come into the play. Then we proceed building in sections 7 and 8 the counterexamples proving the sharpness of our assumptions. It is worth pointing out that all the counterexamples we work out are developed in the scalar case ($N = 1$).

Finally, let us say that for the sake of brevity we confine our analysis to integral functionals of the type in (1.1), which already incorporate all the technical and applicative significance of the present issues; the same results can be extended without serious additional efforts to integrands of the type $f \equiv f(x, u, Du)$.

2. Notation and preliminary results. In what follows, Ω is always a fixed open subset of $\mathbb{R}^n$ and $\mathcal{A}$ is the family of its open subsets; if $A, B \in \mathcal{A}$, by $A \subset\subset B$ we mean that the closure $\overline{A}$ of A is a compact set contained in B, and by $\mathcal{A}_0$ we denote the class of all $A \in \mathcal{A}$ such that $A \subset\subset \Omega$. Also, $B_r(x)$ denotes the ball of radius $r > 0$ centered at $x \in \mathbb{R}^n$ and $B_r := B_r(0)$. We will denote $L^p(\Omega; \mathbb{R}^N)$ and $W^{1,p}(\Omega; \mathbb{R}^N)$, $p \geq 1$, the standard Lebesgue and Sobolev spaces of functions $u : \Omega \to \mathbb{R}^N$; for the sake of brevity these spaces will be also denoted omitting the dependence on the target space, e.g., $W^{1,p}(\Omega)$, $L^p(\Omega)$, and so on. As customary, in the rest of the paper c will denote an unspecified positive constant, possibly varying from line to line; the relevant connections will be emphasized when needed while more peculiar occurrences will be stressed by $c_1, c_2, \widetilde{c}$, etc. We will consider nonnegative variational functionals $F : L^1(\Omega; \mathbb{R}^N) \to [0, +\infty]$ of the type

$$F(u) = \begin{cases} \displaystyle\int_\Omega f(x, Du(x))\, dx & \text{if } u \in C^1(\Omega; \mathbb{R}^N), \\ +\infty & \text{elsewhere on } L^1(\Omega; \mathbb{R}^N), \end{cases}$$

where $f : \Omega \times \mathbb{R}^{N \times n} \to [0, +\infty)$ is a Borel measurable function satisfying a nonstandard growth condition, see (3.1) and (3.2). We are interested in the study of the relaxed functional of F with respect to the strong $L^1(\Omega; \mathbb{R}^N)$ convergence, i.e., the lower semicontinuous envelope of F with respect to the $L^1(\Omega; \mathbb{R}^N)$ topology. To show measure property and integral representation of the relaxed functional we make use of the localization method, which considers at the same time the dependence on the function and on the open set. To this aim, we will work with nonnegative variational functionals $F : L^1(\Omega; \mathbb{R}^N) \times \mathcal{A} \to [0, +\infty]$ of the form

$$F(u, A) := \begin{cases} \displaystyle\int_A f(x, Du(x))\, dx & \text{if } u \in C^1(A; \mathbb{R}^N), \\ +\infty & \text{elsewhere on } L^1(\Omega; \mathbb{R}^N) \end{cases} \tag{2.1}$$

for any open set $A \in \mathcal{A}$. Also, for every $A \in \mathcal{A}$, we denote by $\overline{F}(\cdot, A)$ the relaxed functional of $F(\cdot, A)$ with respect to the strong $L^1(\Omega; \mathbb{R}^N)$ convergence, given for all $u \in L^1(\Omega; \mathbb{R}^N)$ by

$$\overline{F}(u, A) := \inf \Big\{ \liminf_{k \to +\infty} F(u_k, A) \quad | \quad \{u_k\} \subset L^1(\Omega; \mathbb{R}^N), \ u_k \to u \text{ in } L^1(\Omega; \mathbb{R}^N) \Big\}. \tag{2.2}$$

Remark 2.1. Since each sequence $\{u_k\} \subset L^1(A; \mathbb{R}^N)$ converging to u strongly in $L^1(A; \mathbb{R}^N)$ can be extended to a sequence $L^1(\Omega; \mathbb{R}^N)$-converging to u, if $\overline{F}(u, A) <$

$+\infty$ by (2.1) we have

$$\overline{F}(u,A)=\inf\Big\{\liminf_{k\to+\infty}\int_A f(x,Du_k(x))\,dx \quad | \quad \{u_k\}\subset C^1(A;\mathbb{R}^N), \\ u_k\to u \ \text{ in } \ L^1(A;\mathbb{R}^N)\Big\}.$$

We explicitly remark that whenever the function f satisfies the following (p,q)-growth condition:

$$L^{-1}|z|^p\le f(x,z)\le L(1+|z|^q),\qquad 1<p<q<+\infty,\qquad 1\le L,$$

then the previous relaxed functional coincides with the one following, analyzed in [1] [8] [24]:

$$\overline{F}(u,A)=\inf\Big\{\liminf_{k\to+\infty}\int_A f(x,Du_k(x))\,dx \quad | \quad \{u_k\}\subset W^{1,q}_{\rm loc}(A;\mathbb{R}^N), \\ u_k\rightharpoonup u \ \text{ in } \ W^{1,p}(A;\mathbb{R}^N)\Big\}.$$

To show the measure property we recall some well-known facts about set functions.

DEFINITION 2.2. *A function $\alpha:\mathcal{A}\to[0,+\infty]$ is called an increasing set function if $\alpha(\emptyset)=0$ and $\alpha(A)\le\alpha(B)$ if $A\subseteq B$. An increasing set function α is said to be subadditive if*

$$\alpha(A\cup B)\le\alpha(A)+\alpha(B)$$

for all $A,B\in\mathcal{A}$, and it is said to be superadditive if

$$\alpha(A\cup B)\ge\alpha(A)+\alpha(B)$$

for all $A,B\in\mathcal{A}$ with $A\cap B=\emptyset$; finally α is said to be inner regular if for all $A\in\mathcal{A}$

$$\alpha(A)=\sup\{\alpha(B)\mid B\in\mathcal{A}\,,\quad B\subset\subset A\}.$$

Remark 2.3. Since $f\ge 0$, then $\overline{F}(u,\cdot)$ is an increasing set function for every $u\in L^1(\Omega;\mathbb{R}^N)$. Moreover, by definition of relaxation one directly obtains that $\overline{F}(u,\cdot)$ is superadditive. Finally, we denote by $\overline{F}_-(u,\cdot)$ the inner regular envelope of $\overline{F}(u,\cdot)$, given by

$$\overline{F}_-(u,C):=\sup\{\overline{F}(u,B)\mid B\in\mathcal{A}\,,\ B\subset\subset C\} \tag{2.3}$$

for every $C\in\mathcal{A}$, so that $\overline{F}(u,\cdot)$ is inner regular if $\overline{F}(u,\cdot)\equiv\overline{F}_-(u,\cdot)$ on $\mathcal{A}$. We will apply the following criterion due to De Giorgi–Letta [18]; compare also [9, sect. 10.2].

THEOREM 2.4 (measure property criterion). *Let $\alpha:\mathcal{A}\to[0,+\infty]$ be an increasing set function. Then the following statements are equivalent:*

(i) *α is the trace on $\mathcal{A}$ of a Borel measure on Ω;*
(ii) *α is subadditive, superadditive, and inner regular;*
(iii) *the set function $\widetilde{\alpha}(E):=\inf\{\alpha(A)\mid A\in\mathcal{A},\ E\subset A\}$ defines a Borel measure on Ω.*

We recall a celebrated lower semicontinuity result first obtained by De Giorgi [17] and due to Ioffe [32] in the following general form.

THEOREM 2.5 (L^1-semicontinuity). *Let A be a bounded open set of $\mathbb{R}^n$ and let $g:A\times\mathbb{R}^N\times\mathbb{R}^{N\times n}\to[0,+\infty)$ be a Carathéodory function such that $g(x,u,\cdot)$ is convex for every $u\in\mathbb{R}^N$ and for a.e. $x\in A$. Then the functional*

$$G(u):=\int_A g(x,u(x),Du(x))\,dx$$

is lower semicontinuous on $W^{1,1}(A;\mathbb{R}^N)$ *with respect to the weak convergence in* $W^{1,1}(A;\mathbb{R}^N)$.

We end this section by stating an elementary lemma which is a version of De Giorgi's slicing argument.

LEMMA 2.6 (slicing lemma revisited). *Let* $\{f_k\}$ *be a sequence of nonnegative functions in* $L^1(B_1)$ *with*

$$\sup_k \int_{B_1} f_k \, dx \le M < +\infty.$$

Then, fixed $0 < s < t < 1$, *for every* $\epsilon > 0$ *there exist* $N \equiv N(\epsilon, M)$, *an integer* $1 \le h \le N$, *and a (not relabelled) subsequence* $\{f_k\}$ *such that*

$$\sup_k \int_{A_h} f_k \, dx \le \epsilon,$$

where, for $i \in \{0, 1, 2, \dots, N-1\}$,

$$A_i := B_{s_{i+1}} \setminus B_{s_i} \qquad \text{and} \qquad s_i := s + \frac{t-s}{N} \, i.$$

Proof. Choose N in such a way that $N\epsilon > M$. It follows that for each $k \in \mathbb{N}$ there exists $i \equiv i(k)$ such that

$$\int_{A_{i(k)}} f_k \, dx \le \frac{M}{N},$$

and the assertion follows via a standard compactness argument. □

3. Measure property of the relaxed functional. In this section we consider nonnegative variational functionals $F : L^1(\Omega;\mathbb{R}^N) \times \mathcal{A} \to [0, +\infty]$ of the form (2.1) for any open set $A \in \mathcal{A}$, where $f : \Omega \times \mathbb{R}^{N\times n} \to [0, +\infty)$ is a Borel measurable function satisfying a nonstandard growth condition of the form

$$\alpha \, \psi(x, |z|) \le f(x, z) \le b(x) + \beta \, \psi(x, |z|) \tag{3.1}$$

for a.e. $x \in \Omega$ and all $z \in \mathbb{R}^{N\times n}$. Also, for every $A \in \mathcal{A}$, we denote by $\overline{F}(\cdot, A)$ the relaxed functional of $F(\cdot, A)$ with respect to the strong $L^1(\Omega;\mathbb{R}^N)$ convergence, given for all $u \in L^1(\Omega;\mathbb{R}^N)$ by (2.2).

Here $0 < \alpha \le \beta < +\infty$, $b(x)$ is a nonnegative function in $L^1(\Omega)$, and $\psi : \Omega \times [0, +\infty) \to [0, +\infty)$ is a suitable Borel function satisfying the following properties:

(i) $t \mapsto \psi(x, t)$ is nondecreasing and convex for a.e. $x \in \Omega$, with $\psi(x, 0) \equiv 0$;

(ii) for every open set $A \in \mathcal{A}_0$ there exist $1 < c = c(A) < +\infty$ and $1 < p = p(A) \le q = q(A) < +\infty$ such that for a.e. $x \in A$ we have

$$\begin{aligned} c^{-1} t^p \le \psi(x, t) &\le c\,(t^q + 1) \qquad \forall\, t \ge 0, \\ \psi(x, \lambda t) &\le c \max\{\lambda^q, \lambda^p\} \psi(x, t) \qquad \forall\, t \ge 0\,,\ \lambda \ge 0\,, \\ \psi(x, t_1 + t_2) &\le c\, 2^{q-1} (\psi(x, t_1) + \psi(x, t_2)) \qquad \forall\, t_1\,,\, t_2 \ge 0. \end{aligned} \tag{3.2}$$

Remark 3.1. Note that the third property in (3.2) follows from the second one and from the convexity of $\psi(x, \cdot)$. Moreover, by monotonicity and convexity of $\psi(x, \cdot)$, it follows that $z \mapsto \psi(x, |z|)$ is convex for a.e. $x \in \Omega$. Therefore our analysis of functionals with a gap in the sense of (1.1) is confined to those special functionals

with an energy density satisfying (3.1); these also satisfy (1.1) in view of (i), for a suitable choice of (p, q). Observe that the second property in (3.2) is a sort of $\triangle_2$ condition for the function $t \mapsto \psi(x,t)$, uniform with respect to x.

We introduce the following classes of measurable functions in $L^1(A;\mathbb{R}^N)$ and $W^{1,1}(A;\mathbb{R}^N)$, for every $A \in \mathcal{A}$:

$$\begin{aligned} L^{\psi}(A;\mathbb{R}^N) &:= \{u \in L^1(A;\mathbb{R}^N) \mid \ \psi(x,|u(x)|) \in L^1(A)\},\\ W^{\psi}(A;\mathbb{R}^N) &:= \{u \in W^{1,1}(A;\mathbb{R}^N) \mid u \in L^{\psi}(A;\mathbb{R}^N), \quad Du \in L^{\psi}(A;\mathbb{R}^{N\times n})\},\\ W^{\psi}_{\mathrm{loc}}(A;\mathbb{R}^N) &:= \{u \in L^1(A;\mathbb{R}^N) \mid u_{|B} \in W^{\psi}(B;\mathbb{R}^N) \quad \forall\, B \in \mathcal{A},\, B \subset\subset A\}. \end{aligned}$$

Note that, by definition of ψ, these are all convex sets; by (3.2) one infers that $W^{\psi}_{\mathrm{loc}}(A;\mathbb{R}^N)$ is a vector space. We remark that if $A \in \mathcal{A}_0$, these spaces, when equipped with a suitable norm via a suitable Jague function and under certain assumptions, become Banach spaces known as Orlicz–Musielak spaces; these are currently the object of intensive investigation (see, for instance, [43], [22], [19], [20], [31]).

DEFINITION 3.2. *We say that $W^{\psi}(\Omega;\mathbb{R}^N)$ satisfies a Sobolev type property if, for any function $u \in L^1(\Omega;\mathbb{R}^N)$ and every open set $A \in \mathcal{A}_0$ with Lipschitz boundary such that $\int_A \psi(x,|Du|)\,dx < +\infty$, we have*

$$\int_B \psi(x,|u(x)|)\,dx \le C\left(\int_B \psi(x,|Du(x)|)\,dx + \int_B |u(x)|\,dx\right)^{\beta} \quad \forall\, B \in \mathcal{A}_0,\ B \subset\subset A,$$

where $C, \beta \in [1,+\infty)$ are constants, possibly depending on A. Moreover, we say that $W^{\psi}(\Omega;\mathbb{R}^N)$ satisfies a Rellich's-type property if, for every function $u \in L^1_{\mathrm{loc}}(\Omega;\mathbb{R}^N)$, every open set $A \in \mathcal{A}_0$ with Lipschitz boundary, and every $\{u_j\} \subset W^{1,1}(A;\mathbb{R}^N)$ with $u_j \to u$ strongly in $L^1(A;\mathbb{R}^N)$ and $\sup_j \int_A \psi(x,|Du_j|)\,dx < +\infty$, we have

$$\lim_{j\to+\infty} \int_A \psi(x,|u_j - u|)\,dx = 0.$$

In particular, if $W^{\psi}(\Omega;\mathbb{R}^N)$ satisfies a Sobolev-type property, we easily obtain for every $A \in \mathcal{A}$

$$W^{\psi}_{\mathrm{loc}}(A;\mathbb{R}^N) = \{u \in L^1(A;\mathbb{R}^N) \mid Du \in L^{\psi}(B;\mathbb{R}^{N\times n}) \quad \forall\, B \in \mathcal{A},\, B \subset\subset A\}. \tag{3.3}$$

In this section we prove the following.

THEOREM 3.3 (measure property). *Let $F : L^1(\Omega;\mathbb{R}^N) \times \mathcal{A} \to [0,+\infty]$ be as in* (2.1)*, with f as in* (3.1)*, and $\psi : \Omega \times [0,+\infty) \to [0,+\infty)$ satisfying* (i) *and* (ii) *above. Suppose that $W^{\psi}(\Omega;\mathbb{R}^N)$ satisfies a Sobolev and a Rellich-type property. Then, for every function $u \in L^1(\Omega;\mathbb{R}^N)$, the functional $\overline{F}(u,\cdot)$ is the trace on $\mathcal{A}$ of a Borel measure on Ω.*

Example 3.4. Of course, $\psi(x,|z|) := |z|^p$, $p > 1$, verifies Theorem 3.3. Here we outline two important classes of convex functions satisfying the hypotheses of Theorem 3.3. The first one is the case of dependence on x on the growth exponent, i.e.,

$$\psi(x,|z|) := |z|^{p(x)}, \tag{3.4}$$

where $p : \Omega \to (1,+\infty)$ is any fixed continuous function with $p(x) > 1$ for every $x \in \Omega$. It is easy to show that $|z|^{p(x)}$ satisfies (3.2), since for every $A \in \mathcal{A}_0$ we have

$1 < p(A) \equiv \inf_A p(x) \le \sup_A p(x) \equiv q(A) < +\infty$. Moreover, in [13] it is shown that $|z|^{p(x)}$ satisfies both a Sobolev and a Rellich-type property. The second example is

$$\psi(x, |z|) := |z|^p + a(x)\,|z|^q, \tag{3.5}$$

where $1 < p \le q < +\infty$ and $a(x) \in L^\infty(\Omega)$, with $a(x) \ge 0$. Of course, the Sobolev and Rellich-type property hold if $q < p^*$, where p^* is the Sobolev conjugate of p, i.e., $p^* = np/(n-p)$ if $p < n$, $p^* = +\infty$ if $p \ge n$.

Before proving Theorem 3.3, we give some preliminary results. The following lemma is a straightforward consequence of the previous definitions and Theorem 2.5.

LEMMA 3.5. *Under the hypotheses of Theorem* 3.3*, let $A \in \mathcal{A}_0$ and u be a function in $L^1(\Omega;\mathbb{R}^N)$ such that $\overline{F}(u, A) < +\infty$. Then $u \in W^{\psi}_{\mathrm{loc}}(A;\mathbb{R}^N)$ and*

$$\int_A \psi(x, |Du|)\,dx \le \frac{1}{\alpha}\,\overline{F}(u, A) < +\infty.$$

Let us now recall that if A', A are open sets in $\mathcal{A}$, with $A' \subset\subset A$, a cut-off function between A' and A is a smooth function $\phi \in C_0^\infty(\Omega)$ with $\operatorname{spt}\phi \subset A$, $0 \le \phi \le 1$ and $\phi \equiv 1$ on A'.

Due to growth condition (3.1), we now obtain the following fundamental L^ψ estimate. The proof is a readaptation of [9, sect. 12.2], taking into account the new growth conditions dictated by (3.2). We omit it for the sake of brevity.

LEMMA 3.6 (fundamental estimate). *Under the hypotheses of Theorem* 3.3*, for all open sets $A, A', B \in \mathcal{A}$, with $A' \subset\subset A$, and for every $\sigma > 0$, there exists a constant $M_\sigma > 0$ such that for every $u, v \in L^1(\Omega;\mathbb{R}^N)$ there exists a cut-off function ϕ between A' and A such that*

$$\begin{aligned} F(\phi u + (1-\phi)v, A' \cup B) \;\le\; & (1+\sigma)(F(u, A) + F(v, B)) \\ & + M_\sigma \int_{A \cap B} \psi(x, |u - v|)\,dx + \sigma. \end{aligned} \tag{3.6}$$

By using the Rellich-type property and the fundamental estimate above, and following arguments from [42], it is possible to prove a weak subadditivity property for the set function $\overline{F}(w, \cdot)$.

LEMMA 3.7 (weak subadditivity). *Under the hypotheses of Theorem* 3.3*, for every $w \in L^1(\Omega;\mathbb{R}^N)$ we have*

$$\overline{F}(w, A' \cup B) \le \overline{F}(w, A) + \overline{F}(w, B) \tag{3.7}$$

for every $A', A \in \mathcal{A}$, with $A' \subset\subset A$, and every $B \in \mathcal{A}$ such that B has a Lipschitz boundary.

We are now going to give the following proof.

Proof of Theorem 3.3. *Step* 1*: the case $f(x, Du) := \psi(x, |Du|)$.* Define $\Psi : L^1(\Omega;\mathbb{R}^N) \times \mathcal{A} \to [0, +\infty]$ by

$$\Psi(u, A) := \begin{cases} \displaystyle\int_A \psi(x, |Du(x)|)\,dx & \text{if } u \in C^1(A;\mathbb{R}^N), \\ +\infty & \text{elsewhere on } L^1(\Omega;\mathbb{R}^N), \end{cases} \tag{3.8}$$

and let $\overline{\Psi}(\cdot, A)$ be the $L^1(\Omega)$-lower semicontinuous envelope of $\Psi(\cdot, A)$ for every $A \in \mathcal{A}$. Finally, let $\overline{\Psi}_-(u, \cdot)$ be the inner regular envelope of $\overline{\Psi}(u, \cdot)$ (see (2.3)), i.e., for every $u \in L^1(\Omega;\mathbb{R}^N)$,

$$\overline{\Psi}_-(u, C) := \sup\{\overline{\Psi}(u, B) \mid B \in \mathcal{A},\ B \subset\subset C\}, \qquad C \in \mathcal{A}. \tag{3.9}$$

Making use of a convexity argument, we are able to prove inner regularity. We omit the details of the proof of (3.17) and (3.18) and refer to [42, Prop. 3.1] for a similar computation (see also Remark 2.3).

PROPOSITION 3.8 (inner regularity). *Let* $f(x,z) := \psi(x,|z|)$ *and* $\Psi : L^1(\Omega;\mathbb{R}^N) \times \mathcal{A} \to [0,+\infty]$ *be given by* (3.8). *Then for every* $u \in L^1(\Omega;\mathbb{R}^N)$ *the increasing set function* $\overline{\Psi}(u,\cdot)$ *is inner regular, i.e., for every* $C \in \mathcal{A}$

$$\overline{\Psi}(u,C) = \overline{\Psi}_-(u,C), \tag{3.10}$$

where $\overline{\Psi}_-(u,C)$ *is given by* (3.9).

Proof. By the monotonicity of $\overline{\Psi}(u,\cdot)$, it suffices to show that "$\le$" holds in (3.10), in case $\overline{\Psi}_-(u,C) < +\infty$. To this aim, for every $\epsilon > 0$ and $j \in \mathbb{N}_0 := \mathbb{N} \cup \{0\}$, let $A^j \in \mathcal{A}_0$ be such that $A^j \subset\subset A^{j+1} \subset\subset C$, A^j has a Lipschitz boundary so that $|\partial A^j| = 0$, $C = \cup_j A_j$ and

$$\overline{\Psi}_-(u,C) - \epsilon\, 2^{-j} \le \overline{\Psi}(u,A^j) \le \overline{\Psi}_-(u,C) \qquad \forall\, j \in \mathbb{N}_0. \tag{3.11}$$

For every $j \in \mathbb{N}_0$, let $\{u_h^j\}_h \subset L^1(\Omega)$, obviously depending also on ϵ, be such that

$$\lim_{h\to+\infty} \|u_h^j - u\|_{L^1(\Omega)} = 0 \quad \text{ and } \quad \overline{\Psi}(u,A^j) = \liminf_{h\to+\infty} \Psi(u_h^j, A^j) < +\infty\,. \tag{3.12}$$

Possibly passing to a subsequence, we can suppose that $u_h^j \to u$ a.e. on Ω,

$$\sup_h \int_{A^j} \psi(x,|Du_h^j|)\,dx < +\infty,$$

$\{u_{h|A^j}^j\}_h \subset C^1(A^j)$, and that the lower limit in (3.12) is a limit. Then, by the Rellich-type property (Definition 3.2) and (3.12)

$$\lim_{h\to+\infty} \int_{A^j} \psi(x,|u_h^j - u|)\,dx = 0 \qquad \forall\, j \in \mathbb{N}_0. \tag{3.13}$$

Set $A^{-1} := \emptyset$ and let us consider a partition of unity $\{\phi_j\}_{j\in\mathbb{N}_0}$ relative to the open covering of C given by $\{A^{j+1} \setminus \overline{A}^{j-1}\}_{j\in\mathbb{N}_0}$. More precisely, for every $j \in \mathbb{N}_0$ we have that $\phi_j \in C_0^1(A^{j+1} \setminus \overline{A}^{j-1})$ and

$$0 \le \phi_j(x) \le 1\,, \quad \sum_{j=0}^{+\infty} \phi_j(x) = 1 \qquad \forall\, x \in C\,. \tag{3.14}$$

For every $j \in \mathbb{N}$, let $h(j) \in \mathbb{N}$ be chosen later, set $v_j := u_{h(j)}^j$, and

$$w_\epsilon(x) := \sum_{j=1}^{+\infty} \phi_{j-1}(x)\, v_j(x), \qquad x \in C. \tag{3.15}$$

Note that, since $v_{j|A^j} \in C^1(A^j)$, we have that $\phi_{j-1}(x)\, v_j(x) \in C_0^1(C)$ for every $j \in \mathbb{N}$. Moreover, since every x in C has a neighborhood contained at most in the union of three sets of the type $A^{j+1} \setminus \overline{A}^{j-1}$, for every $x \in C$ the infinite sum in the right-hand side of (3.15) reduces to a finite one, hence $w_\epsilon \in C^1(C)$ for every $\epsilon > 0$.

Taking $w_\epsilon \equiv u$ in $\Omega \setminus C$, for every $t \in]0,1[$ the function tw_ϵ belongs to $L^1(\Omega)$ and by (3.14)

$$\|tw_\epsilon - u\|_{L^1(\Omega)} \le t \sum_{j=1}^{+\infty} \int_{A^j} |u^j_{h(j)} - u|\, dx + (1-t)\, \|u\|_{L^1(\Omega)}. \tag{3.16}$$

Now, it is possible to choose the sequence $\{h(j)\}$ so that by (3.16)

$$tw_\epsilon \to u \quad \text{in } L^1(\Omega) \text{ as } \epsilon \to 0^+ \text{ and } t \to 1^-. \tag{3.17}$$

Moreover, taking account of the convexity of $z \to \psi(x,|z|)$, since $0 \le \phi_{j-1} \le 1$ and the sum in (3.15) is locally finite, arguing as in [42, Prop. 3.1], by (3.11), (3.12), and (3.13) we can choose $\{h(j)\}$ so that for any $t \in]0,1[$ we also have

$$\int_C \psi(x,|tDw_\epsilon|)\, dx \le \overline{\Psi}_-(u,C) + 5\epsilon + (1-t)\, \epsilon < +\infty. \tag{3.18}$$

In particular, since $tw_\epsilon \in C^1(C)$, by (3.8) we have $\overline{\Psi}(tw_\epsilon, C) = \int_C \psi(x, t|Dw_\epsilon|)\, dx$. Finally, as $\epsilon \to 0^+$ and $t \to 1^-$, by (3.18) and (3.17) we obtain that $\overline{\Psi}(u,C) \le \overline{\Psi}_-(u,C)$ and hence the assertion. □

Now, since the increasing set function $\overline{\Psi}(u,\cdot)$ is inner regular, and $\overline{\Psi}(u,\cdot)$ is superadditive, thanks to Theorem 2.4 we obtain measure property of $\overline{\Psi}(u,\cdot)$, for every $u \in L^1(\Omega;\mathbb{R}^N)$, if we show that $\overline{\Psi}(u,\cdot)$ is subadditive.

PROPOSITION 3.9 (subadditivity). *For every $w \in L^1(\Omega;\mathbb{R}^N)$ we have*

$$\overline{\Psi}(w, A\cup B) \le \overline{\Psi}(w,A) + \overline{\Psi}(w,B) \qquad \forall\, A, B \in \mathcal{A}. \tag{3.19}$$

Proof. By inner regularity (Proposition 3.8), it is well known that weak subadditivity (Lemma 3.7 with $F = \Psi$) yields (3.19) for any $A, B \in \mathcal{A}$, provided B has a Lipschitz boundary. In fact, for any $C \in \mathcal{A}$ with $C \subset\subset A \cup B$, by enlarging the subset $C \setminus \overline{B}$ a bit, we can find $A' \subset\subset A$ such that $C \subset A' \cup B$, which yields, by (3.7), $\overline{\Psi}(w,C) \le \overline{\Psi}(w, A'\cup B) \le \overline{\Psi}(w,A) + \overline{\Psi}(w,B)$, and hence (3.19), by inner regularity, letting $C \nearrow A \cup B$. Finally, to prove (3.19) for any $B \in \mathcal{A}$, in case $\overline{\Psi}(w, A\cup B) < +\infty$, for each small $\epsilon > 0$ take $C \subset\subset A\cup B$ such that by inner regularity $\overline{\Psi}(w,C) \ge \overline{\Psi}(w, A\cup B) - \epsilon$. We can find an open set $\widetilde{B} \in \mathcal{A}$ with $C \setminus \overline{A} \subset\subset \widetilde{B} \subset B$ and such that $\widetilde{B}$ has a Lipschitz boundary. Then since $C \subset A \cup \widetilde{B}$,

$$\begin{aligned} \overline{\Psi}(w, A\cup B) &\le \overline{\Psi}(w,C) + \epsilon \\ &\le \overline{\Psi}(w, A\cup \widetilde{B}) + \epsilon \\ &\le \overline{\Psi}(w,A) + \overline{\Psi}(w,\widetilde{B}) + \epsilon \\ &\le \overline{\Psi}(w,A) + \overline{\Psi}(w,B) + \epsilon, \end{aligned}$$

and hence we obtain (3.19), letting $\epsilon \to 0^+$. In case $\overline{\Psi}(w, A\cup B) = +\infty$, take $C \subset\subset A \cup B$ with $\overline{\Psi}(w,C) > 1/\epsilon$, so that arguing as before

$$\epsilon^{-1} \le \overline{\Psi}(w,C) \le \overline{\Psi}(w, A\cup\widetilde{B}) \le \overline{\Psi}(w,A) + \overline{\Psi}(w,\widetilde{B}) \le \overline{\Psi}(w,A) + \overline{\Psi}(w,B)$$

and hence (3.19) follows by again letting $\epsilon \to 0^+$. □

Step 2: Measure property of $\overline{F}(u,\cdot)$. Consider now any Borel function f as in Theorem 3.3. We first prove the following.

PROPOSITION 3.10 (inner regularity). *For every $w \in L^1(\Omega;\mathbb{R}^N)$, $\overline{F}(w,\cdot)$ is an inner regular set function.*

Proof. Since $\overline{F}(w,\cdot)$ is an increasing set function, if $\overline{F}_-(w,\cdot)$ is defined by (2.3), it suffices to prove that

$$\overline{F}(w,C) \le \overline{F}_-(w,C) \tag{3.20}$$

for every fixed open set $C \in \mathcal{A}$ and every function $w \in L^1(\Omega)$ such that $\overline{F}_-(w,C) < +\infty$. To this aim note that growth condition (3.1) yields the estimate

$$\alpha\, \overline{\Psi}(w,A) \le \overline{F}(w,A) \le \int_A b(x)\,dx + \beta\, \overline{\Psi}(w,A) \tag{3.21}$$

for every $w \in L^1(\Omega)$ and $A \in \mathcal{A}$, where Ψ is given by (3.8), and the same estimate with $\overline{\Psi}_-$ and $\overline{F}_-$, respectively, instead of $\overline{\Psi}$ and $\overline{F}$ in (3.21). In particular, by the monotonicity and the inner regularity of $\overline{\Psi}(w,\cdot)$ (see Proposition 3.8)

$$\overline{\Psi}(w,A) \le \overline{\Psi}(w,C) = \overline{\Psi}_-(w,C) \le \frac{1}{\alpha}\overline{F}_-(w,C) < +\infty \tag{3.22}$$

for every $A \in \mathcal{A}$ with $A \subset C$. For every $\epsilon > 0$, we can choose an open set $A_\epsilon \in \mathcal{A}$ with a Lipschitz boundary and such that $A_\epsilon \subset\subset C$ so that, by inner regularity of $\overline{\Psi}(w,\cdot)$ and absolute continuity of $b(x) \in L^1(\Omega)$,

$$\overline{\Psi}(w,C) \le \overline{\Psi}(w,A_\epsilon) + \epsilon \qquad \text{and} \qquad 0 \le \int_{C\setminus A_\epsilon} b(x)\,dx \le \epsilon. \tag{3.23}$$

Also, let $B_\epsilon := C \setminus \overline{A}_\epsilon \in \mathcal{A}$, so that if $\widetilde{\Psi}(w,\cdot)$ is the Borel measure given by the extension of $\overline{\Psi}(w,\cdot)$ to Ω (see (iii) in Theorem 2.4), by (3.23) we have

$$\overline{\Psi}(w,B_\epsilon) = \overline{\Psi}(w,C) - \widetilde{\Psi}(w,\overline{A}_\epsilon) \le \overline{\Psi}(w,C) - \overline{\Psi}(w,A_\epsilon) \le \epsilon. \tag{3.24}$$

Moreover, there exists a sequence $\{v_j\} \subset L^1(\Omega)$, converging to w in $L^1(\Omega)$, such that $v_{j|B_\epsilon} \in C^1(B_\epsilon)$ for every j and

$$\overline{\Psi}(w,B_\epsilon) = \lim_{j\to+\infty} \int_{B_\epsilon} \psi(x,|Dv_j|)\,dx < +\infty. \tag{3.25}$$

In particular, by (3.1), (3.23), and (3.25)

$$\liminf_{j\to+\infty} F(v_j,B_\epsilon) \le \int_{C\setminus A_\epsilon} b(x)\,dx + \beta \lim_{j\to+\infty} \Psi(v_j,B_\epsilon) \le \epsilon + \beta\, \overline{\Psi}(w,B_\epsilon). \tag{3.26}$$

Choose now $A', A \in \mathcal{A}_0$ such that A has a Lipschitz boundary and $A_\epsilon \subset\subset A' \subset\subset A \subset \subset C$. Since $\overline{F}(w,A) < +\infty$, there exists a sequence $\{u_j\} \subset L^1(\Omega)$, converging to w in $L^1(\Omega)$, such that $u_{j|A} \in C^1(A)$ for every j and

$$\overline{F}(w,A) = \lim_{j\to+\infty} \int_A f(x,Du_j)\,dx < +\infty. \tag{3.27}$$

By the fundamental estimate (Lemma 3.6) applied with u_j on A and v_j on B_ϵ, for any $\sigma > 0$, we can find $M_\sigma > 0$ and a sequence $\{\phi_j\}$ of smooth cut-off functions between A' and A such that

$$\begin{aligned} F(w_j, A' \cup B_\epsilon) \;\le\; & (1+\sigma)(F(u_j,A) + F(v_j,B_\epsilon)) \\ & + M_\sigma \int_{A\cap B_\epsilon} \psi(x,|u_j - v_j|)\,dx + \sigma, \end{aligned} \tag{3.28}$$

where $w_j := \phi_j u_j + (1-\phi_j)v_j$. By (3.25), (3.27), and (3.1) we have

$$\sup_j \int_{A\cap B_\epsilon} (\psi(x,|Du_j|) + \psi(x,|Dv_j|))\,dx < +\infty.$$

Moreover, $A\cap B_\epsilon = A\setminus \overline{A}_\epsilon \in \mathcal{A}_0$, whereas $A_\epsilon \subset\subset A$, and hence $A\cap B_\epsilon$ has a Lipschitz boundary given by the disjoint union $\partial A \cup \partial A_\epsilon$. Then, by the Rellich-type property (Definition 3.2) and (3.2), we conclude that

$$\lim_{j\to+\infty} \int_{A\cap B_\epsilon} \psi(x,|u_j - v_j|)\,dx = 0.$$

Then, since $w_j = \phi_j u_j + (1-\phi_j)v_j \to w$ in $L^1(\Omega)$, by (3.28), (3.27), and (3.26) we obtain

$$\begin{aligned} \overline{F}(w, A'\cup B_\epsilon) &\le \liminf_{j\to+\infty} F(w_j, A'\cup B_\epsilon) \\ &\le (1+\sigma)(\overline{F}(w,A) + \epsilon + \beta\,\overline{\Psi}(w,B_\epsilon)) + \sigma. \end{aligned} \tag{3.29}$$

Finally, since $B_\epsilon = C\setminus\overline{A}_\epsilon$ yields $A'\cup B_\epsilon = C$, taking $\epsilon > 0$ small so that $\epsilon(1+\beta)\le\sigma$, by (3.24) and (3.29)

$$\overline{F}(w,C) \le (1+\sigma)(\overline{F}(w,A)+\sigma) + \sigma \le (1+\sigma)(\overline{F}_-(w,C)+\sigma) + \sigma$$

and hence (3.20) holds by the arbitrariness of $\sigma > 0$. □

Since we have just proved that $\overline{F}(w,\cdot)$ is inner regular for every $w \in L^1(\Omega;\mathbb{R}^N)$, arguing as in Proposition 3.9, by weak subadditivity (3.7) we obtain that $\overline{F}(w,\cdot)$ is subadditive. Since $\overline{F}(w,\cdot)$ is trivially superadditive, by Theorem 2.4 the proof of Theorem 3.3 is complete. □

4. Integral representation of the relaxed functional. In this section we show that, under suitable hypotheses on the function $\psi(x,t)$ defined in the previous section, the relaxed functional $\overline{F}(u,A)$ obtained in Theorem 3.3 is of variational type.

DEFINITION 4.1. *We say that a sequence* $\{u_j\} \subset W^\psi_{\rm loc}(\Omega;\mathbb{R}^N)$ *converges to* $u \in W^\psi_{\rm loc}(\Omega;\mathbb{R}^N)$ *strongly in* $W^\psi_{\rm loc}(\Omega;\mathbb{R}^N)$ *if for every* $A \in \mathcal{A}_0$

$$\lim_{j\to+\infty} \int_A (\psi(x,|u_j-u|) + \psi(x,|Du_j - Du|))\,dx = 0. \tag{4.1}$$

Remark 4.2. If $u_j \to u$ in $W^\psi_{\rm loc}(\Omega;\mathbb{R}^N)$, then by (3.2), $u_j \to u$ in $L^1_{\rm loc}(\Omega;\mathbb{R}^N)$. Moreover, $\psi(x,|Du_j|) \to \psi(x,|Du|)$ in $L^1_{\rm loc}(\Omega)$ too. In fact, by the monotonicity of $\psi(x,\cdot)$, for every $A \in \mathcal{A}_0$ we estimate

$$\psi(x,|Du_j|) \le c\,2^{q-1}(\psi(x,|Du_j - Du|) + \psi(x,|Du|))$$

for a.e. $x \in A$, where $c = c(A)$ and $q = q(A)$ are given by (3.2); hence it suffices to apply the dominated convergence theorem.

DEFINITION 4.3. *If* $f \in L^1_{\rm loc}(\Omega)$, *define the maximal function* $M(f)$ *by*

$$(Mf)(x) := \sup_{r>0}(M_{(r)}f)(x), \qquad \textit{where} \qquad (M_{(r)}f)(x) := \frac{1}{|B_r(x)|}\int_{B_r(x)\cap\Omega} |f(y)|\,dy.$$

DEFINITION 4.4. *We say that the function ψ enjoys the maximal property if, for every bounded open set $A \in \mathcal{A}_0$ and every function $f \in L^1(A)$ with $\psi(x,|f(x)|) \in L^1(A)$, we have*

$$\int_A \psi(x,|(Mf)(x)|)\,dx \le C\left(\int_A \psi(x,|f(x)|)\,dx + 1\right)^{\beta}, \tag{4.2}$$

where $C, \beta \in (1,+\infty)$ are positive constants possibly depending on n, A, and ψ.

DEFINITION 4.5. *We say that the function $\psi(x,|z|)$ satisfies the density property if for every $u \in W^{\psi}_{\mathrm{loc}}(\Omega;\mathbb{R}^N)$ there exists a sequence of smooth functions $\{u_j\} \subset C^{\infty}_0(\Omega;\mathbb{R}^N)$ such that $u_j \to u$ in $W^{\psi}_{\mathrm{loc}}(\Omega;\mathbb{R}^N)$. If in addition $u \in W^{\psi}(\Omega;\mathbb{R}^N)$, then we also require that $u_j \to u$ in $L^1(\Omega;\mathbb{R}^N)$.*

Let us observe the following relation between the definitions given above.

PROPOSITION 4.6. *The maximal property implies the density property.*

Proof. It is a consequence of the Lebesgue dominated convergence theorem; we shall keep the notation introduced for Definition 4.3. Let $\{\varphi_\epsilon\}_{\epsilon\in(0,1)}$, be a family of standard mollifiers and let $w \in W^{\psi}_{\mathrm{loc}}(\Omega;\mathbb{R}^N)$ with $w_\epsilon(x) := w * \varphi_\epsilon(x)$ for every $x \in \Omega$ such that $dist(x,\partial\Omega) \ge 2\epsilon$. Observe that by the very definition of convolution and maximal function it follows that $|w_\epsilon(x)| \le (Mw)(x)$ for every $x \in A$ such that $\operatorname{dist}(x,\partial A) \ge 2\epsilon$. Now take an increasing sequence of open subsets $A_j \nearrow \Omega$ such that $A_j \subset\subset A_{j+1} \subset \Omega$ and define a related sequence of cut-off functions $\eta_j \in C^{\infty}_0(A_{j+1})$ such that $\eta_j \equiv 1$ on A_j, and finally we define $w_j := \eta_j w_{1/j}$; clearly $w_{1/j} \in C^{\infty}_0(\Omega)$. Now let $A \subset\subset \Omega$, being an open subset; there exists $j_0 \in \mathbb{N}$ such that $A \subset A_j$ whenever $j \ge j_0$. For such values of j we observe that by the fact that ψ is nondecreasing with respect to the last variable, we find

$$\int_A \psi(x,|w_{1/j}(x)|)\,dx \le \int_A \psi(x,|(Mw)(x)|)\,dx \le C\int_A (\psi(x,|w(x)|)+1)\,dx,$$

$$\int_A \psi(x,|Dw_{1/j}(x)|)\,dx \le \int_A \psi(x,|(MDw)(x)|)\,dx \le C\int_A (\psi(x,|Dw(x)|)+1)\,dx,$$

where C depends also on $\int_A \psi(x,|w(x)|)\,dx$ and $\int_A \psi(x,|Dw(x)|)\,dx$; see Definition 4.4. Therefore, since

$$\psi(x,|w_{1/j}(x)|) \to \psi(x,|w(x)|) \qquad \text{and} \qquad \psi(x,|Dw_{1/j}(x)|) \to \psi(x,|Dw(x)|)$$

a.e., by Remark 4.2 such a convergence also holds in $L^1(A)$. Now we conclude, using the third property in (3.2), as follows:

$$\int_A \psi(x,|w_{1/j}(x)-w(x)|)\,dx \le c\int_A \psi(x,|w_{1/j}(x)|)\,dx + c\int_A \psi(x,|w(x)|)\,dx,$$

$$\int_A \psi(x,|Dw_{1/j}(x)-Dw(x)|)\,dx \le c\int_A \psi(x,|Dw_{1/j}(x)|)\,dx + c\int_A \psi(x,|Dw(x)|)\,dx,$$

and the conclusion follows from a well-known variant of Lebesgue's dominated convergence theorem. Finally, it easy to see that if $w \in L^1(\Omega;\mathbb{R}^N)$, then $w_{1/j} \to w$ in $L^1(\Omega;\mathbb{R}^N)$. □

Before stating the representation results, we recall that a Borel function $\varphi : \Omega \times \mathbb{R}^n \times \mathbb{R}^{N\times n} \to \mathbb{R}$ is called quasi-convex in the sense of Morrey [41] if, for a.e. $x_0 \in \Omega$, every $u_0 \in \mathbb{R}^n$, $z_0 \in \mathbb{R}^{N\times n}$, every bounded open set A of $\mathbb{R}^n$, and every function $\phi \in C_0^1(A;\mathbb{R}^N)$, we have

$$|A|\,\varphi(x_0,u_0,z_0) \le \int_A \varphi(x_0,u_0,z_0+D\phi(x))\,dx.$$

Moreover, the quasi-convex envelope Qf of a function $f(x,u,z)$ is the greatest function $\varphi(x,u,z)$, which is quasi-convex, being less than or equal to f (see [14], [15]).

THEOREM 4.7. *Under the hypotheses of Theorem* 3.3*, suppose, in particular, that* $\psi(x,t)$ *satisfies the density property; see Definition* 4.5*. Then for every* $A \in \mathcal{A}$ *we have*

$$\overline{F}(u,A) = \begin{cases} \displaystyle\int_A \varphi(x,Du(x))\,dx & \text{if } u \in W^{\psi}_{\mathrm{loc}}(A;\mathbb{R}^N), \\ +\infty & \text{elsewhere on } L^1(\Omega;\mathbb{R}^N), \end{cases} \tag{4.3}$$

where $\varphi : \Omega\times\mathbb{R}^{N\times n} \to [0,+\infty)$ *is a quasi-convex function satisfying growth condition* (3.1) *for a.e.* $x \in \Omega$ *and all* $z \in \mathbb{R}^N$.

Example 4.8. In case $\psi(x,|z|) := |z|^{p(x)}$, let $p : \Omega \to]1,+\infty)$ be a continuous function satisfying the following local estimate about the modulus of continuity: for all $A \in \mathcal{A}_0$,

$$\exists\,\gamma_A > 0 : \quad |p(x)-p(y)| \le \frac{\gamma_A}{|\log|x-y||} \quad \forall\, x,y \in A\,, \quad 0<|x-y|<\frac{1}{2}. \tag{4.4}$$

Then in Proposition 5.2 we show that $\psi(x,|z|)$ satisfies the maximal property and therefore the density property (this result is actually contained in [19] and extended here to a more general class of functions). As a consequence, Theorem 4.7 holds. Similarly, in case $\psi(x,|z|) := |z|^p + a(x)\,|z|^q$, suppose in particular that $a(x)$ is a bounded nonnegative Hölder continuous function in $C^{0,\alpha}(\Omega)$, for some $0<\alpha\le 1$, and

$$1 < p \le q \le \frac{n+\alpha}{n}\,p. \tag{4.5}$$

Then from Proposition 5.1 it follows that the function $|z|^p + a(x)\,|z|^q$ satisfies the maximal property and Theorem 4.7 holds also in this case.

In order to prove Theorem 4.7, we make use of the following readaptation of the classical integral representation theorem [11, Thm. 1.1] in the setting of W^{ψ}-spaces.

PROPOSITION 4.9. *Suppose* $\psi(x,t)$ *is as in Theorem* 4.7*. Let* $\mathcal{F} : L^1(\Omega;\mathbb{R}^N)\times\mathcal{A} \to [0,+\infty]$ *satisfy the following conditions:*

(i) (locality) $\mathcal{F}$ *is local, i.e.,* $\mathcal{F}(u,A) = \mathcal{F}(v,A)$ *for every* $A \in \mathcal{A}$ *and* $u,v \in L^1(\Omega;\mathbb{R}^N)$ *with* $u = v$ *a.e. on* A*;*

(ii) (measure property) *for all* $u \in L^1(\Omega;\mathbb{R}^N)$ *the set function* $\mathcal{F}(u,\cdot)$ *is increasing, and is the trace on* $\mathcal{A}$ *of a Borel measure;*

(iii) (growth conditions) *there exist* $\beta > 0$ *and* $b(x) \in L^1_{\mathrm{loc}}(\Omega)$ *such that*

$$0 \le \mathcal{F}(u,A) \le \int_A (b(x) + \beta\,\psi(x,|Du(x)|))\,dx$$

for all $u \in W^{\psi}(\Omega;\mathbb{R}^N)$ *and* $A \in \mathcal{A}$*;*

(iv) (translation invariance in u) $\mathcal{F}(u+c,A)=\mathcal{F}(u,A)$ *for all* $u\in L^1(\Omega;\mathbb{R}^N)$, $A\in\mathcal{A}$, $c\in\mathbb{R}^N$;

(v) (lower semicontinuity) $\mathcal{F}(\cdot,A)$ *is sequentially lower semicontinuous with respect to the strong convergence in* $L^1(\Omega;\mathbb{R}^N)$ *for all* $A\in\mathcal{A}$.

Then there exists a Carathéodory function $\varphi:\Omega\times\mathbb{R}^{N\times n}\to[0,+\infty)$ *such that*

$$\mathcal{F}(u,A)=\int_A\varphi(x,Du(x))\,dx \tag{4.6}$$

for every $A\in\mathcal{A}$ *and for every* $u\in L^1(\Omega;\mathbb{R}^N)$ *such that* $u_{|A}\in W^{\psi}_{\rm loc}(A;\mathbb{R}^N)$*; in addition, the function* $\varphi(x,\cdot)$ *is quasi-convex in* $\mathbb{R}^{N\times n}$ *for a.e.* $x\in\Omega$ *and satisfies the growth condition*

$$0\le\varphi(x,z)\le b(x)+\beta\,\psi(x,|z|) \tag{4.7}$$

for a.e. $x\in\Omega$ *and all* $z\in\mathbb{R}^{N\times n}$.

Proof. We recall that a function $u\in L^1(\Omega;\mathbb{R}^N)$ is piecewise affine in Ω if there exists a countable family $\{\Omega_i\}_{i\in I}$ of disjoint open subsets of Ω and a Borel subset N of Ω with $|N|=0$ such that $\Omega=(\bigcup_{i\in I}\Omega_i)\bigcup N$ and $u_{|\Omega_i}$ is affine on each Ω_i.

Step 1: Following [16, Thm. 20.1] or [9, Thm. 9.1], we find a Carathéodory function φ satisfying (4.7), such that (4.6) holds for all $A\in\mathcal{A}$ and all piecewise affine on $u\in W^{\psi}(\Omega)$.

Step 2: $\mathcal{F}(u,A)\le\int_A\varphi(x,Du(x))\,dx$ *for* $u\in W^{\psi}(\Omega;\mathbb{R}^N)$ *and* $A\in\mathcal{A}$. By Step 1 and in particular by (4.7), we have that for every $A'\in\mathcal{A}_0$ the functional

$$u\mapsto\int_{A'}\varphi(x,Du(x))\,dx \tag{4.8}$$

is continuous with respect to the $W^{\psi}_{\rm loc}(\Omega)$ convergence (Definition 4.1). Moreover, by the density property of ψ, the following density result can be achieved via the approximation argument in [21, Chap. X, Prop. 2.1].

LEMMA 4.10. *If* ψ *satisfies the hypotheses of Theorem* 4.7*, then for every function* u *in* $W^{\psi}(\Omega;\mathbb{R}^N)$ *there exists a sequence* $\{u_j\}\subset W^{\psi}(\Omega;\mathbb{R}^N)$ *of functions that are piecewise affine on* Ω *and such that* $u_j\to u$ *both in* $L^1(\Omega;\mathbb{R}^N)$ *and in* $W^{\psi}_{\rm loc}(\Omega;\mathbb{R}^N)$.

Now, let $u\in W^{\psi}(\Omega)$ and $A\in\mathcal{A}$. By Lemma 4.10 there exists a sequence $\{u_j\}$ of functions in $W^{\psi}(\Omega)$ that are piecewise affine on Ω and such that $u_j\to u$ in $L^1(\Omega)$ and in $W^{\psi}_{\rm loc}(\Omega)$. Then by lower semicontinuity v) of $\mathcal{F}$, Step 1 and the continuity of the functional (4.8) in $W^{\psi}_{\rm loc}(\Omega)$, we obtain for every $A'\in\mathcal{A}_0$, $A'\subset\subset A$,

$$\mathcal{F}(u,A')\le\liminf_{j\to+\infty}\mathcal{F}(u_j,A')=\lim_{j\to+\infty}\int_{A'}\varphi(x,Du_j(x))\,dx=\int_{A'}\varphi(x,Du(x))\,dx.$$

Since $\mathcal{F}(u,\cdot)$ is a measure, taking the limit as $A'\nearrow A$ we get by the monotone convergence theorem

$$\mathcal{F}(u,A)\le\int_A\varphi(x,Du(x))\,dx \tag{4.9}$$

for every $u\in W^{\psi}(\Omega)$ and $A\in\mathcal{A}$.

Step 3: $\mathcal{F}(u,A)=\int_A\varphi(x,Du(x))\,dx$ *for* $u\in W^{\psi}(\Omega;\mathbb{R}^N)$ *and* $A\in\mathcal{A}$. Fix $u\in W^{\psi}(\Omega)$ and let $A,A'\in\mathcal{A}$ with $A'\subset\subset A$. We modify the function u in the

following way: take $A'' \in \mathcal{A}_0$ such that $A' \subset\subset A'' \subset\subset \Omega$, let ϕ be a cut-off function between A' and A'', and set $\widetilde{u} := \phi u$. Since $\widetilde{u}$ has compact support, by (3.2) we obtain that $\widetilde{u} \in W^\psi(\Omega)$ and that $\widetilde{u} + v \in W^\psi(\Omega)$ for every $v \in W^\psi(\Omega)$. Consider the functional $G : L^1(\Omega) \times \mathcal{A} \to [0, +\infty]$ defined by

$$G(v, B) := \mathcal{F}(v + \widetilde{u}, B).$$

Then G satisfies all hypotheses of Proposition 4.9. Indeed, (i), (ii), (iv), and (v) are trivially satisfied, whereas for all $v \in W^\psi(\Omega)$ and all $B \in \mathcal{A}$ we have

$$\begin{aligned} 0 \le G(v, B) = \mathcal{F}(v + \widetilde{u}, B) &\le \int_B (b(x) + \beta\, \psi(x, |D\widetilde{u} + Dv|))\, dx \\ &\le \int_B (g(x) + \gamma\, \psi(x, |Dv|))\, dx, \end{aligned}$$

where $\gamma = 2^{q-1} c\, \beta$ and $g(x) = b(x) + 2^{q-1}\, c\, \psi(x, |D\widetilde{u}(x)|) \in L^1_{\mathrm{loc}}(\Omega)$, with $c = c\,(A'')$ and $q = q(A'')$ given by (3.2). Therefore, from Steps 1 and 2 above, it follows that there exists a Carathéodory function $g : \Omega \times \mathbb{R}^{N \times n} \to [0, +\infty)$, satisfying (4.7) with γ and $g(x)$ instead of β and $b(x)$, such that

$$G(v, B) \le \int_B g(x, Dv(x))\, dx \qquad \forall\, v \in W^\psi(\Omega)\,, \quad \forall\, B \in \mathcal{A}\,, \tag{4.10}$$

with equality for v piecewise affine in Ω. In addition, arguing as for (4.8), we can prove that for every $B' \in \mathcal{A}_0$ the functional

$$v \mapsto \int_{B'} g(x, Dv(x))\, dx \tag{4.11}$$

is continuous in $W^\psi_{\mathrm{loc}}(\Omega)$. We now prove that

$$\mathcal{F}(u, A') = \int_{A'} \varphi(x, Du(x))\, dx\,; \tag{4.12}$$

since $\mathcal{F}(u, \cdot)$ is a measure, taking $A' \nearrow A$ we will obtain (4.6) for all $A \in \mathcal{A}$ and $u \in W^\psi(\Omega)$. By Lemma 4.10 there exists a sequence $\{u_j\}$ of functions in $W^\psi(\Omega)$, piecewise affine in Ω, such that $u_j \to \widetilde{u}$ in $L^1(\Omega)$ and in $W^\psi_{\mathrm{loc}}(\Omega)$. Then, using the locality (i) of $\mathcal{F}$, Steps 1 and 2, (4.10), and the continuity of the functionals (4.8) and (4.11), we obtain

$$\begin{aligned} \int_{A'} g(x, 0)\, dx &= G(0, A') = \mathcal{F}(\widetilde{u}, A') = \mathcal{F}(u, A') \le \int_{A'} \varphi(x, Du)\, dx \\ &= \int_{A'} \varphi(x, D\widetilde{u})\, dx = \lim_{j \to +\infty} \int_{A'} \varphi(x, Du_j)\, dx = \lim_{j \to +\infty} \mathcal{F}(u_j, A') \\ &= \lim_{j \to +\infty} G(u_j - \widetilde{u}, A') \le \lim_{j \to +\infty} \int_{A'} g(x, D(u_j - \widetilde{u}))\, dx \\ &= \int_{A'} g(x, 0)\, dx \end{aligned}$$

and (4.12) is proved.

Step 4: $\mathcal{F}(u, A) = \int_A \varphi(x, Du(x))\, dx$ for $u_{|A} \in W^\psi_{\mathrm{loc}}(A; \mathbb{R}^N)$ and $A \in \mathcal{A}$. If $u \in L^1(\Omega)$, $A \in \mathcal{A}$, and $u_{|A} \in W^\psi_{\mathrm{loc}}(A)$, then for every $A' \in \mathcal{A}_0$, $A' \subset\subset A$, we can

find a function $v \in W^{\psi}(\Omega)$ such that $v_{|A'} = u_{|A'}$ (it suffices to take $v = \phi u$, where $\phi \in C_0^{\infty}(\Omega)$ is a cut-off function between A' and A'', with $A' \subset\subset A'' \subset\subset A$). Then, by the locality of $\mathcal{F}$ and Step 3, we have

$$\mathcal{F}(u, A') = \mathcal{F}(v, A') = \int_{A'} \varphi(x, Dv(x))\, dx = \int_{A'} \varphi(x, Du(x))\, dx,$$

and we obtain the assertion as $A' \nearrow A$, by the measure property of $\mathcal{F}$.

Step 5*: Quasi-convexity of* φ. It is enough to prove that, for every $A \in \mathcal{A}_0$ with a Lipschitz boundary, $\varphi(x, \cdot)$ is quasi-convex on $\mathbb{R}^{N\times n}$ for a.e. $x \in A$. If $A \in \mathcal{A}_0$ is fixed and $c = c(A)$, $q = q(A)$, by (3.2) the restriction $\varphi : A \times \mathbb{R}^{N\times n} \to [0, +\infty)$ is a Carathéodory integrand with

$$0 \le \varphi(x, z) \le b(x) + \beta\, \psi(x, |z|) \le b(x) + \beta\, (c\, |z|^q + 1),$$

where $b(x) \in L^1(A)$. In addition, by lower semicontinuity (v), the functional (4.8) is sequentially weakly lower semicontinuous on $W^{1,q}(A)$; hence by [10, Thm. 4.1.5] we obtain that $f(x, \cdot)$ is quasi-convex in $\mathbb{R}^{N\times n}$ for a.e. $x \in A$. □

Proof of Theorem 4.7. We apply Proposition 4.9 to the relaxed functional $\overline{F}(u, A)$. Indeed, the locality property (i) is well known (see e.g., [16, Prop. 16.15]), the measure property (ii) is proved in Theorem 3.3, and growth condition (iii) follows from (3.21), whereas (iv) and (v) are trivially satisfied. Therefore, Proposition 4.9 implies that (4.6) holds for all $u \in W^{\psi}_{\mathrm{loc}}(A)$ and $A \in \mathcal{A}$, with φ quasi-convex in z. Finally (3.21) and (3.8) yield the growth estimate (3.1) for φ and the integral representation (4.3) on all of $L^1(\Omega)$. □

We are now able to state the following theorem.

THEOREM 4.11. *Under the hypotheses of Theorem* 4.7*, suppose that* ψ *enjoys the maximal property. Then, if* f *is a Carathéodory integrand, the function* φ *in* (4.3) *is equal to the quasi-convex envelope of* $z \mapsto f(x, z)$.

This is an easy consequence of Theorem 4.7 and of the following lower semicontinuity result, which we state in full generality.

THEOREM 4.12 (lower semicontinuity). *Under the hypotheses of Theorem* 4.7*, suppose that* ψ *enjoys the maximal property. Let* $\varphi : \Omega \times \mathbb{R}^N \times \mathbb{R}^{N\times n} \to [0, +\infty)$ *be a quasi-convex Carathéodory function satisfying*

$$0 \le \varphi(x, u, z) \le b(x) + C\, (\psi(x, |u|) + \psi(x, |z|)), \tag{4.13}$$

where $C > 1$ *and* $b(x) \in L^1_{\mathrm{loc}}(\Omega)$ *with* $b(x) \ge 0$. *Then for every sequence* $\{u_k\} \subset W^{1,1}(\Omega; \mathbb{R}^N)$ *with* $u_k \to u$ *in* $L^1(\Omega; \mathbb{R}^N)$ *and*

$$\sup_k \int_{\Omega} \psi(x, |Du_k(x)|)\, dx < +\infty \tag{4.14}$$

we have that $u \in W^{\psi}_{\mathrm{loc}}(\Omega; \mathbb{R}^N)$, $\psi(x, |Du|) \in L^1(\Omega)$, *and*

$$\int_{\Omega} \varphi(x, u(x), Du(x))\, dx \le \liminf_{k\to+\infty} \int_{\Omega} \varphi(x, u_k(x), Du_k(x))\, dx. \tag{4.15}$$

Proof. Our starting point is the classical lower semicontinuity proof of Acerbi and Fusco for quasi-convex integrals with p-growth. Hence we refer to the proof of [2, Thm. II.4], where we will point out the differences. The main ingredients are the

density property in $W^\psi(\Omega;\mathbb{R}^N)$ and the fact that ψ enjoys the maximal property; see Definitions 4.5 and 4.4. Set now for every Borel set $A \subset \Omega$

$$\mathcal{F}(u,A) := \int_A \varphi(x,u(x),Du(x))\,dx.$$

We divide the rest of the proof into four steps.

Step 1: $u \in W^\psi_{\mathrm{loc}}(\Omega;\mathbb{R}^N)$ and $\int_\Omega \psi(x,|Du|)\,dx < +\infty$. Setting $\Omega_j := \{x \in \Omega \mid |x| < j \text{ and } \operatorname{dist}(x,\partial\Omega) > 1/j\} \in \mathcal{A}_0$, if $p = p(\Omega_j) > 1$ is given by (3.2), passing to a subsequence we have that $u_k \rightharpoonup u$ weakly in $W^{1,p}(\Omega_j)$, and hence weakly in $W^{1,1}(\Omega_j)$. Then we can apply Theorem 2.5 with $A = \Omega_j$ and $g(x,u,z) = \psi(x,|z|)$ to obtain

$$\int_{\Omega_j} \psi(x,|Du|)\,dx \le \liminf_{k\to+\infty} \int_{\Omega_j} \psi(x,|Du_k|)\,dx$$

for every j. Hence (4.14) gives $\psi(x,|Du|) \in L^1(\Omega)$ and finally (3.3) yields $u \in W^\psi_{\mathrm{loc}}(\Omega)$.

Step 2: Preliminary reductions. Since the supremum of lower semicontinuous functions is lower semicontinuous, we can restrict to prove (4.15) on a ball (or a hypercube) compactly contained in Ω. Hence, relabelling by Ω such ball, which we shall take for the sake of simplicity as B_1, and possibly passing to a subsequence, which we relabel $\{u_k\}$, we can suppose that the lower limit in (4.15) is a finite limit. Moreover, we can suppose that (3.2) holds on the whole of Ω. Then, setting $z_k := u_k - u$, by (3.2) and Step 1 we have that (4.14) holds for $\{z_k\}$. Hence, the Sobolev-type property (Definition 3.2) yields that $\{z_k\} \subset W^\psi(\Omega)$ and there exists $M < +\infty$ such that

$$\sup_k \int_\Omega (\psi(x,|z_k|) + \psi(x,|Dz_k|))\,dx < M. \tag{4.16}$$

By applying the density property (Definition 4.5) to z_k, since φ is a Carathéodory function satisfying (4.13), by the Dominated convergence theorem, we can find for each k a sequence $\{w_j\} \subset C^\infty(\Omega)$ such that $w_j \to z_k$ in $L^1(\Omega)$ as $j \to +\infty$ and

$$\lim_{j\to+\infty} \mathcal{F}(u+w_j,A) = \mathcal{F}(u+z_k,A) \qquad \forall\, A \subset\subset \Omega.$$

Again, using the fact that the supremum of a family of lower semicontinuous integrals is semicontinuous, taking a smaller ball Ω, we can finally assume the sequence $\{z_k\}$ to be in $C^\infty(\Omega)$.

Step 3: The case $\operatorname{supp} z_k \subset \Omega$. First, we extend each z_k to the whole $\mathbb{R}^n$ by letting $z_k \equiv 0$ outside Ω. We define (according to [2])

$$(M^* z_k)(x) := (Mz_k)(x) + \sum_{i=1}^n (MD_i z_k)(x). \tag{4.17}$$

We observe that if the support of u is contained in Ω, then $(Mv)(x)$ as defined in Definition 4.4 coincides with the standard maximal function as employed in [2].

By (3.2), (4.16), (4.17), and the fact that ψ enjoys the maximal property (Definition 4.4), we have

$$\sup_k \int_\Omega \psi(x,(M^* z_k^{(i)})(x))\,dx < +\infty \qquad \forall\, i = 1,\dots,N,$$

where $z_k = (z_k^{(1)}, \dots, z_k^{(N)})$, hence we can apply the Biting lemma [2, Lemma I.7] to obtain for each $\epsilon > 0$ a (not relabelled) subsequence $\{z_k\}$, a set $A_\epsilon \subset \Omega$, with $|A_\epsilon| < \epsilon$, and a real number $\delta > 0$ such that

$$\sup_k \int_B \psi(x, (M^* z_k^{(i)})(x))\, dx < \epsilon \qquad \forall\, i = 1, \dots, N \tag{4.18}$$

for every Borel set $B \subset \Omega \setminus A_\epsilon$ with $|B| < \delta$. Also, let $\eta : \mathbb{R}^+ \to \mathbb{R}^+$ be a continuous increasing function, with $\eta(0) = 0$, such that for every measurable set $B \subset \Omega$

$$\int_B [b(x) + C(\psi(x, |u(x)|) + \psi(x, |Du(x)|))]\, dx < \eta(|B|). \tag{4.19}$$

From this point on we shall closely follow the proof of Theorem II.4 from [2]. Once λ, $H^\lambda_{i,k}$, H^λ_k, $g_k^{(i)}$, $v^{(i)}$, g_k, and v are defined as in [2, Thm. II.4], by (4.19), (4.18), and growth condition (4.13), since $|(\Omega \setminus A_\epsilon) \setminus H^\lambda_{i,k}| < \delta$, if q and c are given by (3.2) with $A = \Omega$, we obtain

$$\begin{aligned}
&\mathcal{F}(u + g_k, (\Omega \setminus A_\epsilon) \setminus H^\lambda_k)\\
&\le c\, 2^{q-1} \left\{ \eta(N\epsilon) + c\,(n, \Omega) \int\limits_{(\Omega \setminus A_\epsilon) \setminus H^\lambda_k} \psi(x, \lambda)\, dx \right\}\\
&\le c\, 2^{q-1} \left\{ \eta(N\epsilon) + c\,(n, \Omega) \sum_{i=1}^N \int\limits_{(\Omega \setminus A_\epsilon) \setminus H^\lambda_{i,k}} \psi(x, (M^* z_k^{(i)})(x))\, dx \right\}\\
&\le c\, 2^{q-1} \{ \eta(N\epsilon) + N \cdot c\,(n, \Omega)\, \epsilon \} = o_\epsilon,
\end{aligned}$$

where $o_\epsilon \to 0$ when $\epsilon \to 0$; this last estimate replaces the one at the top of p. 131 in [2]. The rest of the proof in this case follows [2, Thm. II.4].

Step 4: The general case $\{z_k\} \subset C^\infty(\Omega)$. In the following we adopt the notation of Lemma 2.6. We fix $0 < s < t < 1$ and take $\epsilon \in (0, 1)$; according to Lemma 2.6 (applied to $f_k := \psi(x, |Dz_k|)$) we select $N \equiv N(\epsilon, M)$ and M is from (4.16) (recall that we already reduced to the case $\Omega \equiv B_1$). Therefore we find a thin layer A_h and a not-relabelled subsequence $\{z_k\}$ such that

$$\sup_k \int_{A_h} \psi(x, |Dz_k|) + \psi(x, |Du|))\ dx \le \epsilon. \tag{4.20}$$

Now we take a cut-off function η between B_{s_h} and $B_{s_{h+1}}$ such that $\|D\eta\| \le 2N/(t-s)$ and define $\tilde z_k := \eta z_k$. Since $D\tilde z_k = D\eta \otimes z_k + \eta\, Dz_k$ and by (3.2)

$$\int_{B_1} \psi(x, |D\tilde z_k|)\, dx \le c \int_{B_1} (\psi(x, |Dz_k|)\, dx + \psi(x, |z_k|))\, dx$$

for some absolute constant $c > 0$ possibly depending on B_1 and η, by (4.16) we obtain that (4.14) holds for $\{\tilde z_k\}$. Therefore, by Step 3 and condition $\operatorname{supp} \tilde z_k \subset B_{s_{h+1}}$,

$$\int_{B_s} f(x, Du)\, dx \le \liminf_{k \to +\infty} \int_{B_{s_{h+1}}} f(x, Du + D\tilde z_k)\, dx. \tag{4.21}$$

As a consequence, again by (3.2)

$$\begin{aligned}\int_{B_{s_{h+1}}} f(x,Du+D\tilde{z}_k)\,dx &= \int_{B_{s_h}} f(x,Du+Dz_k)\,dx+\int_{A_h} f(x,Du+D\tilde{z}_k)\,dx\\ &\le \int_{B_1} f(x,Du+Dz_k)\,dx\\ &\quad +c\int_{A_h}(\psi(x,|Du|)+\psi(x,|Dz_k|))\,dx\\ &\quad +c(\|D\eta\|_\infty)\int_{B_1}\psi(x,|z_k|)\,dx.\end{aligned}$$

Therefore, using (4.20) and combining with (4.21), since by the Rellich-type property $\int_{B_1}\psi(x,|z_k|)\,dx\to 0$ as $k\to+\infty$, we obtain

$$\int_{B_s} f(x,Du)\,dx \le \lim_{k\to+\infty}\int_{B_1} f(x,Du+Dz_k)\,dx+o_\epsilon,$$

with $o_\epsilon\to 0^+$ as $\epsilon\to 0^+$. Finally the full statement follows by first letting $\epsilon\to 0$ and then $s\to 1^-$. □

5. Continuity estimates for the maximal function. Throughout this section we always assume that Ω is a bounded open set. We will prove that in case $\psi(x,t)$ is equal to $t^{p(x)A(t)}$ or to $t^p+a(x)\,t^q$, under suitable hypotheses in both cases ψ enjoys the maximal property, as described in Definition 4.4.

PROPOSITION 5.1. *Let $0\le a(x)\le L$ be such that $a(x)\in C^{0,\alpha}(\Omega)$, where $0<\alpha\le 1$ and (4.5) holds. Then for every function $f\in L^1(\Omega)$ with*

$$\int_\Omega (|f(x)|^p+a(x)\,|f(x)|^q)\,dx<+\infty$$

we have

$$\begin{aligned}&\int_\Omega (|(Mf)(x)|^p+a(x)\,|(Mf)(x)|^q)\,dx\\ &\qquad\le \widetilde{C}\left(\int_\Omega (|f(x)|^p+a(x)\,|f(x)|^q)\,dx+1\right)^{q/p},\end{aligned}\tag{5.1}$$

where $\widetilde{C}$ is a positive constant depending on n, Ω, p, q, L, $[a]_{0,\alpha}$.

Proof. Let us first prove that for every $x\in\Omega$ and $r>0$,

$$a(x)\,|(M_{(r)}f)(x)|^q\le |(M_{(r)}(a(\cdot)^{1/q}f))(x)|^q+C\,|(M_{(r)}f)(x)|^p\cdot\|f\|^{q-p}_{L^p(\Omega)}.\tag{5.2}$$

Denoting $B=B_r(x)$ for simplicity and

$$a_r(x):=\inf\{a(y)\mid y\in\Omega,\,|y-x|<r\},$$

trivially if $|B\cap\Omega|>0$, then

$$a_r(x)\,|(M_{(r)}f)(x)|^q\le\left|\frac{1}{|B|}\int_{B\cap\Omega}a(y)^{1/q}|f(y)|\,dy\right|^q=|(M_{(r)}(a(\cdot)^{1/q}f))(x)|^q.\tag{5.3}$$

Moreover

$$(a(x)-a_r(x))\,|(M_{(r)}f)(x)|^q\le(a(x)-a_r(x))\,|(M_{(r)}f)(x)|^{q-p}\cdot|(M_{(r)}f)(x)|^p,\tag{5.4}$$

whereas by (4.5) we have $\alpha/(q-p) \geq n/p$, and hence, for $0 < r \leq 1$, we estimate $r^{\alpha/(q-p)} \leq r^{n/p}$. Then, by Hölder inequality, since $f \in L^p(\Omega)$,

$$(a(x) - a_r(x))\,|(M_{(r)}f)(x)|^{q-p} \leq [a]_{0,\alpha} \cdot |r^{n/p} \cdot |B_r|^{-1/p}\,\|f\|_{L^p(\Omega)}|^{q-p} \leq C\,\|f\|^{q-p}_{L^p(\Omega)}. \tag{5.5}$$

Also, (5.5) trivially holds if $r > 1$, since $a(x)$ is bounded. Now, (5.3), (5.4), and (5.5) yield (5.2) so that, taking the supremum on r and passing to the integrals on Ω, since $f \in L^p(\Omega)$ and $a(\cdot)^{1/q}\, f \in L^q(\Omega)$, by the standard Hardy–Littlewood maximal theorem [45, Thm. 1, Sec. I.1] we obtain

$$\int_\Omega (|(Mf)(x)|^p + a(x)\,|(Mf)(x)|^q)\,dx \leq C\,\left(\int_\Omega |f(x)|^p\,dx\right)^{q/p} + C\int_\Omega a(x)\,|f(x)|^q\,dx$$

and finally (5.1). □

The next proposition extends a result due to Diening [19].

PROPOSITION 5.2. *Let $A : \mathbb{R}^+ \to \mathbb{R}^+$ be a continuous function with $1 < s_1 \leq A(t) \leq s_2 < +\infty$ and such that $t \to t^{\bar p A(t)}$ is nondecreasing and convex in $\mathbb{R}^+$ for every $\bar p > 1$. Moreover, let $p : \Omega \to (1, +\infty)$ be a uniformly continuous function such that $\inf_\Omega p(x) > 1$ and for some $C_0 > 1$*

$$|p(x) - p(y)| \leq \frac{C_0}{|\log|x-y||} \quad \forall\, x, y \in \Omega\,, \quad 0 < |x-y| < \frac{1}{2}. \tag{5.6}$$

Set $1 < p := s_1 \inf_\Omega p(x) \leq s_2 \sup_\Omega p(x) =: q < +\infty$. Then, for every function $f \in L^1(\Omega)$ such that $\int_\Omega |f(x)|^{p(x)A(|f(x)|)}\,dx < +\infty$, we have

$$\int_\Omega |(Mf)(x)|^{p(x)A(|(Mf)(x)|)}\,dx \leq \widetilde{C}\,\left(\int_\Omega |f(x)|^{p(x)A(|f(x)|)}\,dx + 1\right)^{q/p}, \tag{5.7}$$

where $\widetilde{C}$ is a positive constant depending on n, Ω, p, q, s_1, s_2.

Remark 5.3. With a slightly different proof it is possible to obtain the following inequality:

$$\int_\Omega A(|(Mf)(x)|)\cdot|(Mf)(x)|^{p(x)}\,dx \leq \widetilde{C}\,\left(\int_\Omega A(|f(x)|)\cdot|f(x)|^{p(x)}\,dx + 1\right)^{q/p}$$

in the case $t \to t^{\bar p}\,A(t)$ is convex for any $\bar p > 1$ and $t^{s_1} \leq A(t) \leq L(1 + t^{s_2})$ where, this time, $s_2 \geq s_1 > 1$, $q := \sup p(x) + s_2$ and $p := \inf p(x) + s_1$.

Proof. First of all we can assume f is defined on the whole $\mathbb{R}^n$ by letting $f \equiv 0$ outside Ω so that

$$(M_{(r)}f)(x) = \frac{1}{|B_r(x)|}\int_{B_r(x)} |f(y)|\,dy$$

in any case; this will allow us to apply the Jensen inequality in the second inequality from (5.10). Let us first prove that for every $x \in \Omega$ and $r > 0$

$$|(M_{(r)}f)(x)|^{p(x)A(|(M_{(r)}f)(x)|)} \leq \gamma\,[(M_{(r)}|f(\cdot)|^{p(\cdot)A(|f(\cdot)|)})(x) + 1], \tag{5.8}$$

where

$$\gamma := c\,\left(\int_\Omega |f(x)|\,dx + 1\right)^{q-p} \tag{5.9}$$

and c depends on n, p, and q. Set, for every ball $B \subset \mathbb{R}^n$ with $|B \cap \Omega| > 0$,

$$p_B^- := \inf_{x \in B \cap \Omega} p(x), \qquad p_B^+ := \sup_{x \in B \cap \Omega} p(x),$$

and we have

$$|B|^{p_B^- - p_B^+} \le c(n, p, q).$$

Indeed, the previous inequality is trivial when $r > 1/4$ and is a consequence of (5.6) in the other case. Since $z \mapsto |z|^{p_B^- A(|z|)}$ is convex, and $f(\cdot)^{p_B^- A(|f(\cdot)|)} \in L^1(B)$, by Jensen inequality, denoting $B = B_r(x)$ for simplicity, we have

$$\begin{aligned} |(M_{(r)}f)(x)|^{p(x)A(|(M_{(r)}f)(x)|)} &= |(M_{(r)}f)(x)|^{(p(x)-p_B^-)A(|(M_{(r)}f)(x)|)} \\ &\times |(M_{(r)}f)(x)|^{(p_B^-)A(|(M_{(r)}f)(x)|)} \\ &\le \gamma\, |B|^{(p_B^- - p(x))s_2} |(M_{(r)}f)(x)|^{(p_B^-)A(|(M_{(r)}f)(x)|)} \qquad (5.10) \\ &\le c\,\gamma\, M_{(r)}[f(\cdot)^{p_B^- A(|f(\cdot)|)}] \\ &\le c\,\gamma\, M_{(r)}[f(\cdot)^{p(\cdot)A(|f(\cdot)|)}] + c. \end{aligned}$$

Now setting $q(x) := p(x)\, s_1/p > 1$, since $\inf_\Omega p(x) > 1$, then

$$p/s_1 > 1 \quad \text{and} \quad \int_\Omega \Big(|f(x)|^{q(x)A(|f(x)|)}\Big)^{p/s_1}\, dx < +\infty,$$

and we can use the boundedness of the maximal operator as follows:

$$\begin{aligned} \int_\Omega |(M|f(\cdot)|^{q(\cdot)A(|f(\cdot)|)})(x)|^{p/s_1}\, dx &\le c \int_\Omega (|f(x)|^{q(x)A(|f(x)|)})^{p/s_1}\, dx \qquad (5.11) \\ &= c \int_\Omega |f(x)|^{p(x)A(|f(x)|)}\, dx, \end{aligned}$$

where the above constant c depends on n, Ω, and p/s_1. Applying (5.8) (which is a pointwise inequality) with $q(x)$ instead of $p(x)$, we finally obtain, also using (5.9), (5.11), and Hölder inequality,

$$\begin{aligned} &\int_\Omega |(Mf)(x)|^{p(x)A(|(Mf)(x)|)}\, dx \\ &= \int_\Omega (|(Mf)(x)|^{q(x)A(|(Mf)(x)|)})^{p/s_1}\, dx \\ &\le c \left(\int_\Omega |f(x)|^p\, dx + 1\right)^{(q-p)/p} \int_\Omega (\,[(M|f(\cdot)|^{q(\cdot)A(|f(\cdot)|)})(x) + 1])^{p/s_1}\, dx \\ &\le c \left(\int_\Omega |f(x)|^p\, dx + 1\right)^{(q-p)/p} \cdot \int_\Omega (|f(x)|^{p(x)A(|f(x)|)} + 1)\, dx. \end{aligned}$$

Therefore (5.7) immediately follows as $p \le \inf_\Omega p(x)\, A(|f(x)|)$. ∎

Remark 5.4. It is interesting to note that conditions (4.5) and (5.6) are sharp in order to guarantee the validity of the maximal property, that is, (5.1) and (5.7), respectively. This is again a consequence of the counterexamples in sections 7 and 8 below. Indeed, suppose (4.5) and (5.6) fail to hold but (5.1) and (5.7) are satisfied; then by Proposition 4.6 the density property also holds true and in turn Theorem 4.7 would imply that $\overline{F}(u, A)$ is an absolutely continuous Radon measure as soon as $Du \in L^{\psi}(A; \mathbb{R}^N)$, in the case $F \equiv F_2$ and $F \equiv F_1$, respectively (see (1.6)). This is in contrast to the counterexamples presented in sections 7 and 8, where it is shown that, in general, the failure of (4.5) and (5.6) causes the rising of a singular Borel measure in the relaxation procedure (see, in particular, Theorem 7.4 for (4.5) and Theorem 8.3 for (5.6)). This observation, together with the forthcoming examples in sections 7 and 8, clarifies the unifying role of the continuity assumptions of the type (4.5) and (5.6).

6. Models and applications. In this section we want to outline how to apply the previous results to general classes of functionals, including many model examples available in the literature to which standard relaxation techniques do not apply. If $\{\psi_i\}_i$ is a finite collection of functions satisfying (i) and (ii) from section 3 together with the maximal property (and hence also satisfying the density property by Proposition 4.6), then the new function defined by

$$\overline{\psi}(x,t) := \sum_i a_i(x)\, \psi_i(x,t), \qquad L^{-1} \le a_i(x) \le L < +\infty,$$

also enjoys the same properties. Using this simple observation it immediately follows that the maximal estimates of the previous section allow the use of the model examples introduced there as building blocks to construct new functionals to which our theory applies. The main point we would like to stress here is that the model functionals presented in section 5 describe the way the presence of the variable x in the energy density f modifies the growth with respect to the gradient variable z. Using the previous observation, Theorem 4.12 may be applied, via the maximal estimates of section 5 and Proposition 4.6, in the cases when

$$\begin{aligned}
\psi_1(x,|z|) &:= a(x)\,|z|^{p(x)} \log(1+|z|)\,, \qquad L^{-1} \le a(x) \le L,\\
\psi_2(x,|z|) &:= A(|z|)^{p(x)}\,, \qquad |z| \le A(|z|) \le L(1+|z|),\\
\psi_3(x,|z|) &:= (e+|z|^2)^{p(x)(\theta_1+\theta_2 \sin\log\log(e+|z|^2))} \qquad \text{for suitable } \theta_1,\ \theta_2,\\
\psi_4(x,|z|) &:= f_p(x,|z|) + a(x) f_q(x,|z|)\,,\\
&\quad\ |z|^s \le f_s(x,|z|) \le L(1+|z|^s), \quad s = p, q, \quad 0 \le a(x) \le L.
\end{aligned}$$

In turn, any finite combination of ψ_i works, and so on. Let us observe that energies related to ψ_1 appear in the context of Prandtl–Eyring fluids (see [27]), while ψ_2 is related to electrorheological fluids (see [44] and [4]). The function ψ_3 has been studied in the setting of functionals with nonstandard growth conditions in [29] while $|z|^{p(x)}$ and ψ_4 have been introduced, in the context of homogenization theory, by Zhikov [46]. Finally we want to briefly mention that the results of the previous sections could be extended to the case of the so-called anisotropic functionals, i.e., functionals in which each direction is penalized with a different exponent. Functionals of this type come

up when studying reinforced materials. In this case (3.1) is replaced by

$$L^{-1}\sum_{i=1}^{n} a_i(x)|D_i u|^{p_i(x)} \le f(x,Du) \le L\left(1+\sum_{i=1}^{n} a_i(x)|D_i u|^{p_i(x)}\right), \qquad 1 \le L < +\infty,$$

where, in the models for reinforced materials, the exponents are constants: $p_i(x) \equiv p_i \equiv$ constant.

7. A sharp example with energy concentration. Let $\Omega = B_1$, the unit ball of $\mathbb{R}^n$, and $f(x,z) := |z|^p + a(x)\,|z|^q$; see Example 3.4, where $a(x)$ is a suitable bounded nonnegative function in $C^{0,\alpha}(B_1)$ for some $0 < \alpha \le 1$.

In this section we will first show (Theorem 7.4) that energy concentration does occur in the process of relaxation in the case (4.5) is violated, more precisely, when

$$1 < p < n < n+\alpha < q < p^*, \tag{7.1}$$

where, as usual, $p^* := np/(n-p)$. Second, if in particular

$$q > n\,(1+\alpha) \qquad \text{and} \qquad n\,\frac{1+\alpha}{2+\alpha} < p < n, \tag{7.2}$$

we are then able to give a complete representation of the relaxed functional (Theorem 7.6). We emphasize here that it is a significant feature of our analysis that the examples proposed in this section and the next already work in the scalar case $N = 1$, in which we specialize henceforth. For every $0 < \alpha \le 1$, we define

$$a(x) := \max\left\{\left(x_n^2 - \sum_{i=1}^{n-1} x_i^2\right), 0\right\}^{\alpha} |x|^{-\alpha}, \qquad x = (x_1,\dots,x_n) \in \mathbb{R}^n, \tag{7.3}$$

so that $a(x) \in C^{0,\alpha}(\mathbb{R}^n)$ and $a(x) > 0$ in the open cone

$$C^+ := \left\{ x \in \mathbb{R}^n \mid x_n^2 - \sum_{i=1}^{n-1} x_i^2 > 0 \right\}.$$

By (7.1) the assumptions of Theorem 3.3 are satisfied (see Example 3.4). Then in this section we denote by $F(u,A)$ and $\overline{F}(u,A)$ the functionals given by (2.1) and (2.2), respectively, with $\Omega = B_1$ and, when not specified differently, $f(x,z) := |z|^p + a(x)\,|z|^q$, where $a(x)$ is given by (7.3) and (7.1) holds, so that $\overline{F}(u,A)$ satisfies the measure property.

Remark 7.1. For every $u \in L^1(B_1)$ and $A \in \mathcal{A}$, it is possible to find a sequence $\{u_k\} \in L^1(B_1)$ with $u_k \to u$ in $L^1(B_1)$ and $u_{k|A} \in W^{1,q}(A)$ for every $k \in \mathbb{N}$. Moreover, since

$$f(x,z) \le |z|^p + \|a\|_{L^\infty(B_1)}\,|z|^q \le c(1+|z|^q),$$

by Remark 2.1, for every $A \in \mathcal{A}$ and $u \in L^1(B_1)$,

$$\overline{F}(u,A) = \inf\left\{ \liminf_{k\to+\infty} \int_A (|Du_k|^p + a(x)\,|Du_k|^q)\,dx \quad | \quad \{u_k\} \subset W^{1,q}_{\mathrm{loc}}(A), \; u_k \to u \text{ in } L^1(A) \right\}. \tag{7.4}$$

Let us now introduce some notation. If $n = 2$, we are going to use the following polar coordinates:

$$x_1 = \rho \sin \phi \,, \quad x_2 = \rho \cos \phi \,, \qquad \rho \geq 0 \,,\ 0 \leq \phi \leq 2\pi.$$

If $n \geq 3$, we use the spherical coordinate transformation $x = F(\rho, \phi, \Theta)$, $\Theta := (\theta_1, \ldots, \theta_{n-2})$, where $(\phi, \Theta) \in I(\phi, \Theta) := [0, \pi] \times \left(\prod_{i=1}^{n-3} [0, \pi] \right) \times [0, 2\pi]$ and

$$x_1 = \rho \sin \phi \cdot \prod_{j=1}^{n-2} \cos \theta_j \,, \qquad x_{n-1} = \rho \sin \phi \sin \theta_1 \,, \qquad x_n = \rho \cos \phi,$$
$$x_i = \rho \sin \phi \cdot \prod_{j=1}^{n-1-i} \cos \theta_j \cdot \sin \theta_{n-i} \,, \qquad i = 2, \ldots, n-2.$$

Moreover, for any function u on $\mathbb{R}^n$, in what follows we will always denote

$$\widetilde{u}(\rho, \phi, \Theta) := u(F(\rho, \phi, \Theta))$$

the corresponding function written in spherical coordinates. For example, if $a(x)$ is given by (7.3), we have

$$\widetilde{a}(\rho, \phi, \Theta) = (\rho \, (\cos(2\phi))^+)^\alpha, \qquad C^+ = \{x = F(\rho, \phi, \Theta) \mid \cos(2\phi) > 0\},$$

where y^+ denotes the positive part of real number y, i.e., $y^+ := \max\{y, 0\}$. Finally,

$$\partial C^+ := \left\{ x \in \mathbb{R}^n \mid x_n^2 = \sum_{i=1}^{n-1} x_i^2 \right\} = \{x = F(\rho, \phi, \Theta) \mid \cos(2\phi) = 0\}$$

is the boundary of C^+, for every $0 < \beta < \pi/4$

$$C^\beta := \{x = F(\rho, \phi, \Theta) \mid \cos(2\phi) > c_\beta\}, \qquad c_\beta := \cos\left(\frac{\pi}{2} - 2\beta \right)$$

is the subset of C^+ given by a cone of smaller angle and, for $0 < r < 1$,

$$C_r^+ := C^+ \cap B_r \,, \qquad\qquad C_r^\beta := C^\beta \cap B_r$$

is the intersection with the open ball B_r of radius r; moreover, we introduce the following "half cones":

$$\begin{aligned} {+C_r^\beta} &:= \{x \equiv F(\rho, \phi, \Theta) \in C_r^\beta \mid 0 \leq \phi < \pi/4 - \beta\}, \\ {-C_r^\beta} &:= \{x \equiv F(\rho, \phi, \Theta) \in C_r^\beta \mid 3\pi/4 + \beta < \phi \leq \pi\}, \end{aligned}$$

being the upper and the lower part, respectively, of C_r^β; accordingly, we define

$$\begin{aligned} {+C_r^+} &:= \{x \equiv F(\rho, \phi, \Theta) \in C_r^+ \mid 0 \leq \phi < \pi/4\}, \\ {-C_r^+} &:= \{x \equiv F(\rho, \phi, \Theta) \in C_r^+ \mid 3\pi/4 < \phi \leq \pi\}. \end{aligned}$$

The following result will allow us to consider the traces in the origin of a function with finite energy in the cone C_r^β (see (7.8)) in the case (7.1) holds.

LEMMA 7.2. *Let $u \in L^1(B_r)$, $0 < r < 1$, be such that $\int_{B_r} a(x) \, |Du|^q \, dx < +\infty$, where $a(x)$ is given by (7.3) and $q > n + \alpha$. Then for every $n < s < q$, with $q/s > (n + \alpha)/n$, we have $\int_{C_r^\beta} |Du|^s \, dx < +\infty$ for every $0 < \beta < \pi/4$. In particular,*

$u \in C^{0,1-n/s}(+\overline{C}_r^\beta)$ and $u \in C^{0,1-n/s}(-\overline{C}_r^\beta)$, i.e., there exists a constant c, depending only on $\int_{B_r} a(x)\,|Du|^q\,dx$ such that

$$\begin{aligned} &|u(x_1)-u(x_2)| \le c|x_1-x_2|^{1-n/s} && \forall\, x_1, x_2 \in +\overline{C}_r^\beta,\\ &|u(y_1)-u(y_2)| \le c|y_1-y_2|^{1-n/s} && \forall\, y_1, y_2 \in -\overline{C}_r^\beta. \end{aligned} \tag{7.5}$$

Proof. First note that $a(x)^{s/(s-q)} \in L^1(C_r^\beta)$. In fact, by the area formula [23, 3.2.3] we have

$$\begin{aligned} &\int_{C_r^\beta} a(x)^{s/(s-q)}\,dx\\ &\le c(n) \int_{[0,\pi/4-\beta]\cup[3\pi/4+\beta,\pi]} \frac{(\sin\phi)^{n-2}}{(\cos(2\phi))^{\alpha s/(q-s)}}\,d\phi \int_{C_r^\beta} |x|^{\alpha s/(s-q)}\,dx\\ &\le c(n)\, c_\beta^{\alpha s/(s-q)} \int_0^r \rho^{n-1+\alpha s/(s-q)}\,d\rho, \end{aligned}$$

which is finite since $n+\alpha s/(s-q) > 0$ if $q/s > (n+\alpha)/n$. Then by Hölder inequality we have

$$\int_{C_r^\beta} |Du|^s\,dx \le \left(\int_{C_r^\beta} a(x)|Du|^q\,dx\right)^{s/q} \cdot \left(\int_{C_r^\beta} a(x)^{s/(s-q)}\,dx\right)^{(q-s)/q} < +\infty. \tag{7.6}$$

The assertions concerning Hölder continuity follow via Sobolev embedding theorem and Morrey's theorem, since $s > n$. ∎

With a stronger assumption on the exponent q—that is, replacing (7.1) by (7.2)—we can similarly prove the following lemma.

LEMMA 7.3. *Under the hypotheses of Lemma 7.2, suppose, in particular, that $q > n\,(1+\alpha)$. Then for every $n < s < q/(1+\alpha)$ with $q/s > 1+\alpha$, we have $\int_{C_r^+} |Du|^s\,dx < +\infty$ and hence $u \in C^{0,1-n/s}(+\overline{C}_r^+)$ and $u \in C^{0,1-n/s}(-\overline{C}_r^+)$, with estimates analogous to (7.5) with $\beta = 0$.*

Proof. Now we have $a(x)^{s/(s-q)} \in L^1(C_r^+)$. In fact, for $n \ge 3$ ($n = 2$ is similar)

$$\begin{aligned} &\int_{C_r^+} a(x)^{s/(s-q)}\,dx\\ &= c(n) \int_{[0,\pi/4]\cup[3\pi/4,\pi]} \frac{(\sin\phi)^{n-2}}{(\cos(2\phi))^{\alpha s/(q-s)}}\,d\phi \int_0^r \rho^{n-1+\alpha s/(s-q)}\,d\rho, \end{aligned} \tag{7.7}$$

which is finite since $1/(\cos(2\phi))^+ \in L^{\alpha s/(q-s)}(0,2\pi)$ as $q/s > 1+\alpha$. Then (7.6) holds again, with C_r^+ instead of C_r^β. The rest follows as for Lemma 7.2. ∎

Traces at $0_{\mathbb{R}^n}$. Let $u \in L^1(B_1)$ be such that $a(x)\,|Du|^q \in L^1_{\mathrm{loc}}(A)$ for some open set $A \in \mathcal{A} = \mathcal{A}(B_1)$ with $0_{\mathbb{R}^n} \in A$. Since $B_r \subset\subset A$ for r sufficiently small, if $q > n+\alpha$ by Lemma 7.2, we can therefore define for every $0 < \beta < \pi/4$

$$\lambda_1 := \lim_{\substack{\rho\to 0^+\\ \phi\in[0,\pi/4-\beta]}} \widetilde{u}(\rho,\phi,\Theta)\,, \qquad \lambda_2 := \lim_{\substack{\rho\to 0^+\\ \phi\in[3\pi/4+\beta,\pi]}} \widetilde{u}(\rho,\phi,\Theta) \tag{7.8}$$

($\phi \in [0,\pi/4-\beta]\cup[7\pi/4+\beta,2\pi)$ and $\phi \in [3\pi/4+\beta, 5\pi/4-\beta]$, respectively, if $n = 2$), where the finite limits exist uniformly in Θ since u is Hölder continuous up to the closure of both $+C_r^\beta$ and $-C_r^\beta$. Moreover, if $q > n\,(1+\alpha)$ by Lemma 7.3, we obtain

(7.8) with $\beta = 0$, i.e., the traces in the origin do exist in both the upper and lower half cones of C^+.

We will now prove the following result, which actually shows that (4.5) is a sharp condition to prevent energy concentration in the process of relaxation.

THEOREM 7.4. *Let $F(u, A)$ and $\overline{F}(u, A)$ be given by* (2.1) *and* (2.2) *with $\Omega = B_1$ and $f(x, z) := |z|^p + a(x)\,|z|^q$, where $a(x)$ is given by* (7.3) *and* (7.1) *holds. Let $0_{\mathbb{R}^n} \in A \in \mathcal{A}$ and $|Du|^p + a(\cdot)\,|Du|^q \in L^1_{\rm loc}(A)$, so that* (7.8) *holds. Then, if $\lambda_1 \neq \lambda_2$, we have $\overline{F}(u, A) = +\infty$; hence an infinite singular measure is concentrated in the origin.*

Example 7.5. In particular, for $n \geq 3$, if $u_0 : B_1 \to \mathbb{R}$ is given in spherical coordinates by

$$\widetilde{u}_0(\rho, \phi, \Theta) := \begin{cases} 1 & \text{if} \quad 0 \leq \phi \leq \pi/4, \\ \sin(2\phi) & \text{if} \quad \pi/4 \leq \phi \leq 3\pi/4, \\ -1 & \text{if} \quad 3\pi/4 \leq \phi \leq \pi, \end{cases} \tag{7.9}$$

and similarly for $n = 2$, then, since $\lambda_1 = 1$ and $\lambda_2 = -1$, there is energy concentration in the origin, i.e.,

$$\overline{F}(u_0, A) = +\infty \qquad \forall\, A \in \mathcal{A} \quad \text{such that} \quad 0_{\mathbb{R}^n} \in A. \tag{7.10}$$

Proof of Theorem 7.4. We argue by contradiction supposing that $\overline{F}(u, A) < +\infty$. Then we pick a radius $r > 0$ such that $B_r \subset A$ and a sequence $\{u_k\} \subset C^1(B_r)$ such that $u_k \to u$ in $L^1(B_r)$ and a.e. and

$$\lim_{k \to +\infty} \int_{B_r} (|Du_k|^p + a(x)\,|Du_k|^q)\, dx = \overline{F}(u, B_r) < +\infty.$$

By the Hölder estimates in Lemma 7.2 we obtain that the sequence $\{u_k\} \subset C^1(B_r)$ is equi-uniformly continuous, on both $+\overline{C}^{\beta}_r$ and $-\overline{C}^{\beta}_r$; since each u_k is continuous, this yields that the sequence $\{u_k\} \subset C^1(B_r)$ is equi-uniformly continuous on the whole $\overline{C}^{\beta}_r$. Then by the Ascoli–Arzelà theorem, up to a not-relabelled subsequence, $u_k \to u$ uniformly on $\overline{C}^{\beta}_r$, which, in turn, yields to the continuity of u at $0_{\mathbb{R}^n}$. This is a contradiction since $\lambda_1 \neq \lambda_2$ makes the function u discontinuous at $0_{\mathbb{R}^n}$. □

With a bit more effort, if (7.2) holds we are able to prove the following complete representation result.

THEOREM 7.6. *Let $F(u, A)$ and $\overline{F}(u, A)$ be given by* (2.1) *and* (2.2) *with $\Omega = B_1$ and let $f(x, z)$ be a Carathéodory function such that*

$$c_1\,(|z|^p + a(x)\,|z|^q) \leq f(x, z) \leq c_2\,(|z|^p + a(x)\,|z|^q + 1) \tag{7.11}$$

for a.e. $x \in \Omega$ and all $z \in \mathbb{R}^n$, where $c_2 > c_1 > 0$. If $a(x)$ is given by (7.3) *and* (7.2) *holds, then we have*

$$\overline{F}(u, A) = \begin{cases} \displaystyle\int_A (Cf)(x, Du)\, dx + \mu(u, A) & \text{if } |Du|^p + a(\cdot)\,|Du|^q \in L^1(A), \\ +\infty & \text{elsewhere on } L^1(\Omega), \end{cases} \tag{7.12}$$

where Cf denotes the usual convexification of f and $\mu(u, \cdot)$ is an infinite singular measure concentrated in the origin. More precisely, we have

$$\mu(u, A) = \begin{cases} 0 & \text{if} \quad 0_{\mathbb{R}^n} \notin A, \\ \chi^{\lambda_1}_{\lambda_2} & \text{if} \quad 0_{\mathbb{R}^n} \in A, \end{cases} \tag{7.13}$$

where λ_1 *and* λ_2 *are defined by* (7.8) *and*

$$\chi_{\lambda_2}^{\lambda_1} := \begin{cases} 0 & \text{if} \quad \lambda_1 = \lambda_2, \\ +\infty & \text{if} \quad \lambda_1 \neq \lambda_2. \end{cases}$$

Proof. We will first give the proof in the case

$$f(x,z) := |z|^p + a(x)\,|z|^q.$$

The first part of the statement is trivial. In fact, following Lemma 3.5, Theorem 2.5 yields that if $\overline{F}(u,A) < +\infty$ for some $A \in \mathcal{A}$, then $|Du|^p + a(\cdot)\,|Du|^q \in L^1(A)$. Moreover, we note that for every $A \in \mathcal{A}$ with $A \subset\subset (B_1 \setminus \partial C^+)$ we have that $L^{-1} \leq a(x) \leq L$ on $A^+ := A \cap C^+$, for some positive constant L depending on A, whereas $a(x) = 0$ on $A \setminus A^+$. Hence, by convexity of $z \mapsto |z|^p + L\,|z|^q$ and by the dominated convergence theorem, if $\overline{F}(u,A) < +\infty$, we can easily find a sequence of smooth maps $\{u_k\} \in C^1(A)$ with $u_k \to u$ in $L^1(A)$ and

$$\lim_{k\to+\infty} \int_A (|Du_k(x)|^p + a(x)\,|Du_k(x)|^q)\,dx = \int_A (|Du(x)|^p + a(x)\,|Du(x)|^q)\,dx.$$

Then, by (7.4) and by inner regularity of $\overline{F}(u,\cdot)$, for every $A \in \mathcal{A}$ with $A \cap \partial C^+ = \emptyset$ we have that

$$\overline{F}(u,A) = \int_A (|Du(x)|^p + a(x)\,|Du(x)|^q)\,dx \tag{7.14}$$

if $u \in L^1(B_1)$ is such that $|Du|^p + a(\cdot)\,|Du|^q \in L^1(A)$. As a consequence, we infer that the absolute continuous part of the measure $\overline{F}(u,\cdot)$ is the integral given in (7.12), and that its singular part $\mu(u,\cdot)$ is concentrated in the $(n-1)$-dimensional cone ∂C^+.

We now show that there is no energy concentration on open sets which do not contain the origin.

PROPOSITION 7.7. *Under the hypotheses of Theorem* 7.6, *if* $A \in \mathcal{A}$, $0_{\mathbb{R}^n} \notin A$, *and* $|Du|^p + a(\cdot)\,|Du|^q \in L^1(A)$, *then* $\mu(u,A) = 0$ *in* (7.12) *and hence*

$$\overline{F}(u,A) = \int_A (|Du|^p + a(x)\,|Du|^q)\,dx.$$

Proof. We adapt the approximation and reflection arguments of Lemmas 3.4 and 3.5 in [22]. Indeed, following this paper it is possible to show that for every $A' \in \mathcal{A}_0$, with $A' \subset\subset A$, there exists a sequence of functions $\{u_k\} \subset W^{1,q}(A')$ such that $u_k \to u$ in $L^1(A')$ and

$$\lim_{k\to+\infty} \int_{A'} (|Du_k|^p + a(x)\,|Du_k|^q)\,dx = \int_{A'} (|Du|^p + a(x)\,|Du|^q)\,dx.$$

Then, by (7.4), this yields

$$\overline{F}(u,A') \leq \int_{A'} (|Du|^p + a(x)\,|Du|^q)\,dx,$$

and hence, by inner regularity, letting $A' \nearrow A$ one obtains the assertion by the fact that $\mu(u,A) \geq 0$. We explicitly remark that in [22] the proof is given for the case in which the function $a(x)$ is replaced (in polar coordinates) by

$$\widetilde{a}(\rho,\phi,\Theta) = \rho^\alpha \cos(2\phi)^+.$$

Then the proof is achieved, taking advantage of the fact that the function $\cos(2\phi)$ satisfies the so-called Muckenhoupt condition A_q; this gives the possibility to build an approximation procedure based on a reflection argument (where the Muckenhoupt property enters). It is easy to see that the same argumentation works here for the function $(\cos(2\phi))^\alpha$, which comes from the study of our case. □

Now let $0_{\mathbb{R}^n} \in A \in \mathcal{A}$ and $|Du|^p + a(\cdot)\,|Du|^q \in L^1_{\mathrm{loc}}(A)$. By Theorem 7.4, it follows that $\mu(u, A) = +\infty$ if $\lambda_1 \neq \lambda_2$ in (7.8). To conclude with (7.13), it then remains to show that $\mu(u, A) = 0$ if $\lambda_1 = \lambda_2$. To this aim, by (7.4) it suffices to prove the following proposition.

PROPOSITION 7.8. *Let $0_{\mathbb{R}^n} \in A \in \mathcal{A}$ and $u \in L^1(B_1)$ be such that $|Du|^p + a(\cdot)\,|Du|^q \in L^1_{\mathrm{loc}}(A)$, with $\lambda_1 = \lambda_2$ in (7.8). Then for each $\epsilon > 0$ there exists a sequence $\{w_k\} \subset W^{1,q}(A)$ such that $w_k \to u$ in $L^1(A)$ and*

$$\liminf_{k\to+\infty} \int_A (|Dw_k|^p + a(x)\,|Dw_k|^q)\,dx \le \int_A (|Du|^p + a(x)\,|Du|^q)\,dx + \epsilon. \tag{7.15}$$

Proof. Observe that we may and do assume that the right-hand side of (7.15) is finite. We will denote by ν the outward unit normal to ∂B_R and by $\tau := (\tau_1, \dots, \tau_{n-1})$ an orthonormal basis to the tangent $(n-1)$-space to ∂B_R. Then, setting $D_\tau u := (D_{\tau_1} u, \dots, D_{\tau_{n-1}} u)$, we have that $|Du|^2 = |D_\nu u|^2 + |D_\tau u|^2$. Also, if $u \in W^{1,p}(B_1)$ and $0 < R < 1$, we will denote by $\mathbf{T}_R u := \mathbf{T}[\partial B_R] u$ the usual trace operator: that is, $T_R u \in W^{1-\frac{1}{p},p}(\partial B_R)$ is the trace of u on ∂B_R.

Now fix $0 < \delta < \operatorname{dist}(0_{\mathbb{R}^n}, \partial A)$ and let $r \in (0, \delta/2)$. Then, by Remark 7.1 and Proposition 7.7, we select a sequence $\{u_k\} \subset W^{1,q}(A \setminus \overline{B}_r)$ such that $u_k \to u$ in $L^1(A \setminus \overline{B}_r)$ and

$$\begin{aligned} &\lim_{k\to+\infty} \int_{A\setminus B_r} (|Du_k|^p + a(x)\,|Du_k|^q)\,dx \\ &\qquad = \overline{F}(u, A \setminus \overline{B}_r) \\ &\qquad = \int_{A\setminus B_r} (|Du|^p + a(x)\,|Du|^q)\,dx < +\infty. \end{aligned} \tag{7.16}$$

Up to passing to a not-relabelled subsequence, by uniform convexity, (7.16) yields

$$\lim_{k\to+\infty} \int_{A\setminus B_r} (|Du_k - Du|^p + a(x)\,|Du_k - Du|^q)\,dx = 0.$$

In particular, by an estimate similar to (7.6), with $\beta = 0$, which is allowed since now (7.2) is in force (see also (7.7)), we have

$$\lim_{k\to+\infty} \int_{(B_{2r}\setminus B_r)\cap C^+} |Du_k - Du|^s\,dx = 0$$

for some $s > n$. As a consequence, by Sobolev, Morrey, and Rellich's theorems, passing again to a not-relabelled subsequence, we can select $R \in (r, 2r)$ such that $\mathbf{T}_R u \in W^{1,p}(\partial B_R) \cap W^{1,q}(\partial B_R \cap C^+)$, $\mathbf{T}_R u_k \in W^{1,q}(\partial B_R)$ for every k,

$$\begin{aligned} &\int_{\partial B_R} (|D_\tau u_k|^p + a(x)\,|D_\tau u_k|^q)\,d\mathcal{H}^{n-1} \\ &\qquad \le \int_{\partial B_R} (|D_\tau u|^p + a(x)\,|D_\tau u|^q)\,d\mathcal{H}^{n-1} + \frac{\epsilon}{3} R, \end{aligned} \tag{7.17}$$

$$\int_{\partial B_R} |u_k-\lambda|^p\,d\mathcal{H}^{n-1} \le \int_{\partial B_R} |u-\lambda|^p\,d\mathcal{H}^{n-1} + \frac{\epsilon}{3}\,R^{p-1}, \tag{7.18}$$

$$\int_{\partial B_R\cap C^+} |u_k-\lambda|^q\,d\mathcal{H}^{n-1} \le \int_{\partial B_R\cap C^+} |u-\lambda|^q\,d\mathcal{H}^{n-1} + \frac{\epsilon}{3}\,R^{q-\alpha-1}, \tag{7.19}$$

where $\lambda := \lambda_1 = \lambda_2$ is given by (7.8). Now define

$$v_k(x) := \begin{cases} u_k(x) & \text{if} \quad x \in A\setminus \overline{B}_R, \\ \dfrac{|x|}{R}\left(u_k\Big(R\dfrac{x}{|x|}\Big)-\lambda\right)+\lambda & \text{if} \quad x\in B_R. \end{cases} \tag{7.20}$$

Trivially $\{v_k\}\subset L^q(A)$ and $v_k\to u$ in $L^1(A\setminus B_R)$, whereas, since for a.e. $x\in B_R$

$$|Dv_k(x)|^2 = R^{-2}\left|u_k\Big(R\frac{x}{|x|}\Big)-\lambda\right|^2 + \left|D_\tau u_k\Big(R\frac{x}{|x|}\Big)\right|^2,$$

we infer

$$\int_{B_R}|Dv_k|^q\,dx \le c(q)\int_{\partial B_R}(R^{1-q}\cdot|u_k-\lambda|^q + R\cdot|D_\tau u_k|^q)\,d\mathcal{H}^{n-1}$$

and hence $\{v_k\}\subset W^{1,q}(A)$. We now show that, using the aforementioned information, for any $r\in(0,\delta/2)$ we can find $R\in(r/2,r)$ such that

$$\begin{aligned} &\liminf_{k\to+\infty}\int_A (|Dv_k|^p + a(x)\,|Dv_k|^q)\,dx \\ &\qquad \le \int_{A\setminus B_R}(|Du|^p + a(x)\,|Du|^q)\,dx + O(R) + \epsilon, \end{aligned} \tag{7.21}$$

where $O(R)\to 0^+$ as $R\to 0^+$. To this end, since $|a(x)|\le R^\alpha$ for $x\in B_R$, we first estimate

$$\begin{aligned} &\int_{B_R}(|Dv_k|^p + a(x)\,|Dv_k|^q)\,dx \\ &\le c\,(p,q)\Big\{R^{1-p}\int_{\partial B_R}|u_k-\lambda|^p\,d\mathcal{H}^{n-1} \\ &\quad + R^{1+\alpha-q}\int_{\partial B_R\cap C^+}|u_k-\lambda|^q\,d\mathcal{H}^{n-1} \\ &\quad + R\int_{\partial B_R}(|D_\tau u_k|^p + a(x)\,|D_\tau u_k|^q)\,d\mathcal{H}^{n-1}\Big\}. \end{aligned} \tag{7.22}$$

We now make use of the following embedding result (see [42, Lem. 5.8] for a proof).

LEMMA 7.9. *If $u\in W^{1,p}(B_\delta)$ with $1\le p<n$, $B_\delta\subset\mathbb{R}^n$ being the n-ball of radius δ, and $\lambda\in\mathbb{R}$, then for a.e. $0<R<\delta$ we have*

$$\begin{aligned} &R^{1-p}\int_{\partial B_R}|u-\lambda|^p\,d\mathcal{H}^{n-1} \\ &\le c\,(n,p)\left\{\int_{B_R}|Du|^p\,dx + \left(\int_{B_R}|u-\lambda|^{p^*}\,dx\right)^{p/p^*}\right\}, \end{aligned} \tag{7.23}$$

where $p^* := np/(n-p)$ *is the Sobolev conjugate of* p.

Now, condition $B_\delta \subset\subset A$ yields that $u(\cdot) - \lambda \in W^{1,p}(B_\delta)$. Then, by (7.18), (7.23), the Sobolev embedding theorem, and absolute continuity, we obtain

$$R^{1-p} \int_{\partial B_R} |u_k - \lambda|^p \, d\mathcal{H}^{n-1} \leq O(R) + \frac{\epsilon}{3}. \tag{7.24}$$

Recall now that since $a(\cdot)|Du|^q \in L^1(A)$, by Lemma 7.3 and Morrey's theorem [5, Thm. 5.4], since both $\pm C_R^+$ have Lipschitz boundaries, we have

$$|u(x) - u(y)| \leq c \, \|Du\|_{L^s(\pm C_R^+)} \, |x-y|^{1-n/s} \qquad \forall \, x, y \in \pm C_R^+,$$

where $c > 0$ is an absolute constant and $s > n$. In particular, by (7.8), with $\lambda = \lambda_1 = \lambda_2$, for every $x \in \partial B_R \cap C^+$ we then infer

$$|u(x) - \lambda| \leq c_0 \, \|Du\|_{L^s(C_R^+)} \, R^{1-n/s}. \tag{7.25}$$

Now, since by (7.7) (with $r = 1$)

$$c_2 := \|a(\cdot)^{-1}\|_{L^{s/(q-s)}(C_1^+)} = \left(\int_{C_1^+} a(x)^{s/(s-q)} \, dx \right)^{(q-s)/s} < +\infty,$$

by homogeneity of $a(x)$ we compute

$$\|a(\cdot)^{-1}\|_{L^{s/(q-s)}(C_R^+)} = c_2 \, R^{(n(q-s)-\alpha s)/s}. \tag{7.26}$$

Moreover, by (7.6) (with $\beta = 0$) and (7.26) we estimate

$$\begin{aligned} \|Du\|^q_{L^s(C_R^+)} &\leq \|a(\cdot)\,|Du|^q\|_{L^1(C_R^+)} \cdot \|a(\cdot)^{-1}\|_{L^{s/(q-s)}(C_R^+)} \\ &= \|a(\cdot)\,|Du|^q\|_{L^1(C_R^+)} \cdot c_2 \, R^{(n(q-s)-\alpha s)/s}. \end{aligned}$$

As a consequence, by (7.25) we have

$$|u(x) - \lambda|^q \leq {c_0}^q \, R^{q-nq/s} \, \|a(\cdot)\,|Du|^q\|_{L^1(C_R^+)} \cdot c_2 \, R^{(n(q-s)-\alpha s)/s}$$

for every $x \in \partial B_R \cap C^+$ and hence

$$\begin{aligned} &R^{1+\alpha-q} \int_{\partial B_R \cap C^+} |u - \lambda|^q \, d\mathcal{H}^{n-1} \\ &\leq c(n) \, R^{n+\alpha-q} \, {c_0}^q \, c_2 \, R^{q-nq/s} \, R^{(n(q-s)-\alpha s)/s} \, \|a(\cdot)\,|Du|^q\|_{L^1(C_R^+)} \\ &= C \, \|a(\cdot)\,|Du|^q\|_{L^1(C_R^+)}. \end{aligned}$$

Then, by absolute continuity and (7.19) we obtain

$$\begin{aligned} R^{1+\alpha-q} \int_{\partial B_R \cap C^+} |u_k - \lambda|^q \, d\mathcal{H}^{n-1} &\leq C \, \|a(\cdot)\,|Du|^q\|_{L^1(C_R^+)} + \frac{\epsilon}{3} \\ &\leq O(R) + \frac{\epsilon}{3}. \end{aligned} \tag{7.27}$$

Finally, since $|Du|^p + a(\cdot)\,|Du|^q \in L^1(B_\delta)$, setting

$$f(\rho) := \int_{\partial B_\rho} (|D_\tau u|^p + a(x)\,|D_\tau u|^q) \, d\mathcal{H}^{n-1}, \qquad 0 < \rho < \delta,$$

by the coarea formula, one has $f(\rho) \in L^1(0,\delta)$. Therefore, since $f(\rho) \geq 0$, we have $\liminf_{\rho\to 0^+} \rho \cdot f(\rho) = 0$. As a consequence, without loss of generality we can choose R so that $R \cdot f(R) = O(R)$ and hence, by (7.17),

$$R \int_{\partial B_R} (|D_\tau u_k|^p + a(x)\,|D_\tau u_k|^q)\, d\mathcal{H}^{n-1} \leq O(R) + \frac{\epsilon}{3}. \tag{7.28}$$

Then, by (7.24), (7.27), and (7.28), the right-hand side of (7.22) is smaller than $O(R) + \epsilon$ and, finally, by lower semicontinuity and (7.16), we obtain (7.21).

We finally make use of a diagonal argument, as follows. We first select $r_j \searrow 0$ and $R_j \in (r_j, 2r_j)$ as above; then for any fixed j via (7.20) we define $\{u_k^{(j)}\} \subset W^{1,q}(A \backslash B_{r_j})$ so that $u_k^{(j)} \to u$ in $L^1(A \setminus B_{r_j})$ and (7.16) holds with $r = r_j$; we then construct $\{v_k^{(j)}\} \subset W^{1,q}(A)$ such that $v_k^{(j)} \to u$ in $L^1(A \setminus B_{R_j})$ and (7.21) holds with $R = R_j$. Finally, we set $w_k := w_k^{(k)}$, so that $\{w_k\} \subset W^{1,q}(A)$, $w_k \to u$ in $L^1(A)$, and by (7.21)

$$\begin{aligned}
&\liminf_{k\to+\infty} \int_A (|Dw_k|^p + a(x)\,|Dw_k|^q)\, dx \\
&\leq \liminf_{k\to+\infty} \left\{ \int_{A\setminus B_{R_k}} (|Du|^p + a(x)\,|Du|^q)\, dx + O(R_k) + \epsilon \right\}
\end{aligned}$$

so that (7.15) holds, as required. □

End of the Proof of Theorem 7.6. In order to prove Theorem 7.6 for general integrands f, since we have shown that the density property (Definition 4.5) holds out of the origin, arguing as in Proposition 4.9, and taking into account that $Qf \equiv Cf$ in the scalar case $N = 1$, we obtain (7.12) where the singular measure $\mu(u,\cdot)$ is concentrated in the origin. Finally, (7.13) follows from growth condition (7.11). □

8. Another sharp example with energy concentration. In this section we describe another counterexample, involving probably the finest analysis of the paper; we show that if $\Omega = B_1$, the unit ball of $\mathbb{R}^2$, and $f(x,z) := |z|^{p(x)}$, where $p : \Omega \to (1,+\infty)$ is a suitable continuous exponent, energy concentration does occur in the process of relaxation in case (4.4) is violated: more precisely, following Zhikov [46] we set

$$p(x) := 2 + \frac{x_1 x_2}{|x|} \left(\log\left(\frac{2}{|x|} \right) \right)^{-t}, \qquad x = (x_1, x_2) \in B_1, \tag{8.1}$$

where $0 < t < 1$ is fixed. In this case the assumptions of Theorem 3.3 (see Example 3.4) hold, while those of Theorems 4.11 and 4.12 are not satisfied (see Example 4.8). Zhikov considered in [46] the homogeneous extension $\overline{u}(x) := \varphi(x/|x|)$ on B_1 of the function φ defined in standard polar coordinates $x = (\cos\theta, \sin\theta)$ on ∂B_1 by

$$\varphi(\theta) := \begin{cases} 1 & \text{if} \quad -\alpha \leq \theta \leq \pi/2 + \alpha, \\ 2(\theta + \alpha - \pi)/(4\alpha - \pi) & \text{if} \quad \pi/2 + \alpha \leq \theta \leq \pi - \alpha, \\ 0 & \text{if} \quad \pi - \alpha \leq \theta \leq 3\pi/2 + \alpha, \\ 2(\theta - \alpha - 3\pi/2)(\pi - 4\alpha) & \text{if} \quad 3\pi/2 + \alpha \leq \theta \leq 2\pi - \alpha, \end{cases} \tag{8.2}$$

where $0 < \alpha \ll \pi/4$ is a fixed small angle. Of course $|Du|^{p(x)} \in L^1(\Omega)$, but Zhikov showed that the Dirichlet problem for the $p(x)$-energy with boundary condition $\overline{u}$

on ∂B_1 is not regular, i.e., the infimum over $W^{1,p(x)}$-maps is strictly less that the infimum over smooth maps. For future purposes, we remark that the key point in Zhikov's argument is the summability near 0 of the function $\rho \mapsto \rho^{-1+c(\log(2\rho^{-1}))^{-t}}$ for any $0 < t < 1$ and $c > 0$, since for some $c_1, c_2 \equiv c_1, c_2(c) > 0$ we have

$$\begin{aligned} \int_0^1 \rho^{-1+c(\log(2\rho^{-1}))^{-t}}\, d\rho &\leq e^{c(\log 2)^{1-t}} \int_0^1 \rho^{-1}\, e^{-c\,(\log(2\rho^{-1}))^{1-t}}\, d\rho \\ &= c_1 \int_{\log 2}^{+\infty} e^{-c_2\, x^{1-t}}\, dx < +\infty. \end{aligned} \tag{8.3}$$

Moreover, for convenience, we also note that

$$\int_{\log 2}^{+\infty} x^t e^{-c_2\, x^{1-t}}\, dx < +\infty \qquad \forall\, t \in]0,1[\,, \quad c_2 > 0. \tag{8.4}$$

In this section we denote by $F(u, A)$ and $\overline{F}(u, A)$ the functionals given by (2.1) and (2.2), respectively, where $\Omega = B_1$ and $f : B_1 \times \mathbb{R}^2 \to [0, +\infty)$ is a Carathéodory function satisfying (8.7), where $p(x)$ is given by (8.1), so that $\overline{F}(u, A)$ satisfies the measure property (see Example 3.4). Since $p(x)$ satisfies (4.4) out of the origin (it is actually Lipschitz continuous far from the origin), we infer that energy concentration can occur only in $x = 0_{\mathbb{R}^2}$. More precisely, by Theorems 4.7 and 4.11 (see Example 4.8) we immediately obtain the following proposition.

PROPOSITION 8.1. *Let $u \in L^1(B_1)$ be such that $|Du|^{p(x)} \in L^1_{\mathrm{loc}}(A)$ for some open set $A \subset B_1$ with $0_{\mathbb{R}^2} \notin A$, where $p(x)$ is given by* (8.1). *Then*

$$\overline{F}(u, A) = \int_A |Du(x)|^{p(x)}\, dx. \tag{8.5}$$

Now we define, for every $0 < \beta < \pi/4$, the open cones

$$\begin{gathered} C^\beta \equiv +C^\beta := \{x = \rho\, e^{i\theta} \mid \beta < \theta < \pi/2 - \beta\}, \\ -C^\beta := \{-x \mid x \in C^\beta\}\,, \qquad \pm C^\beta_r := \pm C^\beta \cap B_r. \end{gathered}$$

Since inside $\pm C^\beta$ we have $p(x) > 2$ and $p(x) \to 2^+$ very rapidly as $x \to 0_{\mathbb{R}^2}$, we are able to define the traces in the origin of a function with finite energy in the cones $\pm C^\beta_r$, see (8.6). Of course we do not have at our disposal a standard estimate of the type in Lemma 7.2, since in our case $p(x) \to 2$ (the borderline case of Sobolev embedding) as $x \to 0$; anyway, we are able to prove the following theorem.

THEOREM 8.2 (trace theorem). *Let $u \in L^1(B_1)$ be such that $|Du|^{p(x)} \in L^1_{\mathrm{loc}}(A)$ for some open set $A \subset B_1$ with $0_{\mathbb{R}^2} \in A$, where $p(x)$ is given by* (8.1). *Then for every $0 < \beta < \pi/4$ the following finite limits exist:*

$$\lambda_1 := \lim_{\substack{x \to 0_{\mathbb{R}^2} \\ x \in \overline{C}^\beta_r}} u(x) \qquad \text{and} \qquad \lambda_2 := \lim_{\substack{x \to 0_{\mathbb{R}^2} \\ x \in -\overline{C}^\beta_r}} u(x). \tag{8.6}$$

In particular, if $r > 0$ is such that $B_r \subset\subset A$, we have that u is a continuous function up to the boundary of both the cones $\pm C^\beta_r$.

Thanks to Theorem 8.2, as in Theorem 7.4 we show that there is energy concentration in the origin if the traces in (8.6) take different values, for example, when

$$u(x) \equiv \overline{u}(x) := \varphi(x/|x|),$$

with φ given by (8.2).

THEOREM 8.3. *Let $F(u,A)$ and $\overline{F}(u,A)$ be given by* (2.1) *and* (2.2)*, with $\Omega = B_1$ and $f(x,z)$ being a Carathéodory function such that*

$$c_1\,|z|^{p(x)} \le f(x,z) \le c_2\,(|z|^{p(x)}+1), \tag{8.7}$$

where $p(x)$ is given by (8.1) *and $c_2 > c_1 > 0$. Moreover, let $u \in L^1(B_1)$ be such that $|Du|^{p(x)} \in L^1_{\rm loc}(A)$ for some open set $A \subset B_1$ with $0_{\mathbb{R}^2} \in A$. Then, if $\lambda_1 \neq \lambda_2$ in* (8.6)*, it follows that $\overline{F}(u,A) = +\infty$.*

Remark 8.4. In contrast to the previous section, this time we do not give the complete representation of the relaxed functional (that is, an analogue of Theorem 7.6), confining ourselves to emphasizing the main concentration phenomenon in the origin. This, for the sake of brevity: indeed, severe technical complications intervene in the upper bound estimate for the energy in the case $\lambda_1 = \lambda_2$. Regardless, it should be possible to obtain the same complete representation of the type in Theorem 7.6 also in this case.

Proof of Theorem 8.2. It is not restrictive to suppose

$$A = B_1 \qquad \text{and} \qquad \int_{B_1} |Du|^{p(x)}\,dx < +\infty.$$

Moreover, we will show the existence of the first limit in (8.6), the second limit being treated the same way. We remind the reader that in the following $c > 1$ continues to denote a constant possibly varying from line to line; we shall emphasize the relevant connections.

Step 1*: Dyadic type sequences.* We consider a sequence $\{y_k\} \subset \overline{C}^{\beta}_r$ of the type

$$y_k := r_k(\cos\theta_k, \sin\theta_k), \tag{8.8}$$

where $\theta_k \in [\beta, \pi/2-\beta]$ and $r_k \to 0^+$ is a decreasing sequence such that

$$L^{-1}/2^k \le r_k \le L/2^k \tag{8.9}$$

with $L \in [1,+\infty)$. We have

$$|y_k - y_{k+1}| \le |y_k|\cdot|\theta_k - \theta_{k+1}| + |r_k - r_{k+1}| \le (\pi+1)\,r_k. \tag{8.10}$$

By applying Morrey's theorem to the closure of the smooth set

$$S_k := C^{\beta} \cap B^{L2^{-k}}_{L^{-1}2^{-(k+1)}},$$

where $B^R_r := B_R \setminus B_r$, we have

$$|u(y_k) - u(y_{k+1})| \le c\,b_k\,|y_k - y_{k+1}|^{1-2/p_k}, \tag{8.11}$$

where

$$p_k = 2 + c_\beta\left(\log(L2^{k+2})\right)^{-t}, \qquad c_\beta := \frac{\sin(2\beta)}{2} > 0, \qquad b_k := \frac{3}{p_k - 2}, \tag{8.12}$$

and c is an absolute constant depending on L and $\int_{S_k}(|Du|^{p(x)}+1)\,dx$, and hence on $\int_{B_1}|Du|^{p(x)}\,dx$. Note that we used the fact that $u \in W^{1,p_k}(S_k)$ since $p(x) \ge p_k$ whenever $x \in S_k$. For comments on the validity of the previous inequality, and, in

particular, the determination of the constant b_k, see Remark 8.5. Then for k large so that $(\pi+1)\, r_k < 1$, by (8.9) and (8.10) we have

$$\begin{aligned} |u(y_k) - u(y_{k+1})| &\leq c\, b_k\, |y_k - y_{k+1}|^{1-2/p_k} \\ &\leq c\, b_k\, (2^{-k})^{(c_\beta/3)\,(\log(L2^{k+2}))^{-t}} \\ &\leq c\, b_k\, e^{\widehat{c}\,(\log(2^{k+2}))^{-t}\,\log(2^{-k})} \\ &\leq c\,(\log(2^{k+2}))^t\, e^{-\widehat{c}\,(\log(2^{k+2}))^{1-t}}, \end{aligned}$$

where c and $\widehat{c}$ are positive constants depending on β, L, and $\int_{B_1}(|Du|^{p(x)}+1)\,dx$. Therefore,

$$\sum_{k=1}^{+\infty} |u(y_k) - u(y_{k+1})| \leq c \sum_{k=1}^{+\infty} (k+2)^t e^{-\widehat{c}\,(\log 2)^{1-t}\,(k+2)^{1-t}} < +\infty,$$

the last series being convergent by (8.4). Observe that the constant c depends on L and $\int_{B_1}(|Du|^{p(x)}+1)\,dx$ and $\widehat{c}$ depends on β, L; moreover $\widehat{c} \to 0$ as $\beta \to 0$ or when $L \to +\infty$ whereas, by the definition of b_k, it follows that $c \to +\infty$ as $\beta \to 0$. Therefore we have that the sequence $u(y_k)$ converges to a certain limit value $l < +\infty$.

Step 2*: Comparing dyadic type sequences.* Now take $\{y_k^1\}$ and $\{y_k^2\}$, two sequences as in (8.8) satisfying (8.9) with different constants L_1, L_2, and define $L = \max\{L_1, L_2\}$. Arguing as in the previous step, there exist l_1, l_2 such that $u(y_k^1) \to l_1$ and $u(y_k^2) \to l_2$. As in (8.10) we also deduce that

$$|y_k^1 - y_k^2| \leq c_3(L)/2^k.$$

With the same notation as in (8.12) (with everything adapted to the new value of the constant L), we find

$$\begin{aligned} |u(y_k^1) - u(y_k^2)| &\leq c\frac{|y_k^1 - y_k^2|^{1-2/p_k}}{p_k - 2} \\ &\leq c\,(k+2)^t e^{(-\widehat{c})\,(\log 2)^{1-t}\,(k+2)^{1-t}} \to 0, \end{aligned}$$

where $\widehat{c} \equiv \widehat{c}(\beta, L) > 0$ and c depends both on L and $\int_{B_1}(|Du|^{p(x)}+1)\,dx$, as in the previous step. Therefore we infer $l_1 = l_2$.

Step 3*: Conclusion.* It suffices to show that if $\{x_k\} \subset \overline{C}_r^\beta \setminus \{0_{\mathbb{R}^2}\}$ converges to $0_{\mathbb{R}^2}$, then $u(x_k) \to l$, where l is defined as the limit of any sequence of Step 1. Note that by Step 2 we have that l does not depend on such a choice. Therefore we pick $\lambda_1 := l$ in (8.6). In turn, it suffices to show that from $\{x_k\}$ it is possible to select a subsequence $\{z_k\}$ such that $u(z_k) \to l$. To this aim we let $x_k := \widetilde{\rho}_k(\cos\widetilde{\varphi}_k, \sin\widetilde{\varphi}_k)$ and we pass to a subsequence $z_k := \rho_k(\cos\varphi_k, \sin\varphi_k)$ such that $\rho_{k+1} \leq 4^{-1}\rho_k$. Next we consider the new sequence $\{y_k\}$, built as follows. First we define $\{\widetilde{r}_k\}$ as the decreasing rearrangement of the set $\{\rho_k \mid k \in \mathbb{N}\} \cup \{2^{-k} \mid k \in \mathbb{N}\} \equiv A \cup B$. Then, from this sequence we build yet another sequence by dropping certain terms: we delete $\widetilde{r}_h$ if and only if $\widetilde{r}_h \in B \setminus A$ and moreover $\widetilde{r}_{h+1} \in A$. (Roughly speaking, after rearranging the pieces of the original sequence A with those from the dyadic type sequence B, we delete all the terms from $B \setminus A$ which come immediately before a term of the sequence A. Observe that since we have chosen $\{\rho_k\}$ such that $\rho_{k+1} \leq \rho_k/4$, then between any two terms of the type 2^{-k} and 2^{-k-1} it falls at most one term of $A \setminus B$; moreover, in the new sequence all the terms of the original A do appear and, in the case in which they go to zero faster than 2^{-k}, they are interpolated by the dyadic numbers.)

Relabelling, we finally get $\{r_k\}$; then we set $y_k := r_k(\cos\theta_k, \sin\theta_k)$, where $\theta_k = \varphi_j$ if $r_k \in A$ and $r_k = \rho_j$ for some $j \in \mathbb{N}$, while $\theta_k = \pi/4$ otherwise. The sequence $\{y_k\}$ is now of the type in (8.8), for a suitable constant L. Therefore by Steps 1 and 2 it follows that $u(y_k) \to l$ and so does $\{u(z_k)\}$, being a subsequence of $\{u(y_k)\}$. The proof is now complete. □

Remark 8.5. Here we briefly justify the validity of the inequality (8.11). It is well known that if we let

$$R := (0,1) \times (\beta, \pi/2 - \beta),$$

then for any function $v \in W^{1,s}(R)$, with $s > 2$, Morrey's imbedding inequality takes the form

$$|v(x) - v(y)| \le \frac{c}{1 - 2/s} |x - y|^{1-2/s} \left(\int_R |Dv(z)|^s \, dz \right)^{1/s}, \tag{8.13}$$

where c is an absolute constant. This can be inferred from [5, p. 110]; similar inequalities are valid for general parallelepipeds in higher dimensions. Then we infer (8.11) from the previous inequality, letting of course $s := p_k$, via a simple change of variable argument and the use of polar coordinates. The details follow. Using the nonsingular map

$$\phi_k : (\rho, \theta) \in R \to g_k(\rho)(\cos\theta, \sin\theta) \in S_k,$$

$$g_k(\rho) := (L2^{-k} - L^{-1}2^{-(k+1)})\rho + L^{-1}2^{-(k+1)},$$

it turns out that

$$\Phi_k \equiv \phi_k^{-1} : (x_1, x_2) \in S_k \to (f_k(|x|), \arctan(x_2/x_1)) \in R,$$

where

$$f_k(\rho) := (L2^{-k} - L^{-1}2^{-(k+1)})^{-1}(t - L^{-1}2^{-(k+1)}),$$

and the following relations hold:

$$||D\phi_k||_\infty \le c\, 2^{-k}, \qquad ||D\Phi_k||_\infty \le c\, 2^k,$$

$$\det D\phi_k = g_k(\rho)(L2^{-k} - L^{-1}2^{-(k+1)}) > 0, \qquad |\det D\phi_k|^{-1} \le c4^k,$$

where $c \equiv c(L)$ denotes an absolute constant independent of $k \in \mathbb{N}$. Finally, if $u \in W^{1,s}(S_k)$, then $v := u \circ \phi_k \in W^{1,s}(R)$; therefore, using (8.13), the change of variable formula, and the previous relations, we get, with $x, y \in S_k$ and $\phi_k(\tilde{x}) = x$ and $\phi_k(\tilde{y}) = y$,

$$\begin{aligned}
|u(x) - u(y)| &= |v(\tilde{x}) - v(\tilde{y})| \\
&\le \frac{c\,s}{s-2} |\tilde{x} - \tilde{y}|^{1-2/s} ||Dv||_{L^s(R)} \\
&\le \frac{c\,s}{s-2} ||D\Phi_k||_\infty^{1-2/s} ||D\phi_k||_\infty |||\det D\phi_k|^{-1}||_\infty^{1/s} |x - y|^{1-2/s} \\
&\qquad \times \left(\int_R |Du(\phi_k(\rho,\theta))|^s \det D\phi_k \, d\rho \, d\theta \right)^{1/s} \\
&\le \frac{c\,s}{s-2} |x - y|^{1-2/s} \left(\int_{S_k} |Du(x)|^s \, dx \right)^{1/s},
\end{aligned}$$

and (8.11) follows by taking $s := p_k$, observing that $\max p(x) \le 3$; also, from the previous estimates, the constant c clearly depends on L and blows up when so L does. Regardless, c is independent of $k \in \mathbb{N}$.

Proof of Theorem 8.3. As for the proof of Theorem 7.6 we shall restrict ourselves, without loss of generality, to the case $f(x,z) := |z|^{p(x)}$. Arguing as for Theorem 7.4, it then suffices to prove the following proposition.

PROPOSITION 8.6. *Let $\{u_j\} \subset C^1(B_r)$ be such that $u_j \to u$ in $L^1(B_r)$ and a.e. in B_r and*

$$\sup_j \int_{C_r^\beta} |Du_j|^{p(x)}\,dx + \sup_j \int_{-C_r^\beta} |Du_j|^{p(x)}\,dx < +\infty.$$

Then, possibly passing to subsequences, $u_j \to u$ uniformly on the closure of $C_r^\beta \cup -C_r^\beta$. Therefore, $\lambda_1 = \lambda_2$ in (8.6).

Proof. Due to a.e. convergence $u_j \to u$, by the Ascoli–Arzelà theorem it suffices to show that $\{u_j\}$ is equi-uniformly continuous on the closure of C_r^β and of $-C_r^\beta$. We make use of the following lemma.

LEMMA 8.7. *Let $v \in C^1(B_r)$ be such that $\int_{C_r^\beta} |Dv|^{p(x)}\,dx < +\infty$; there exist a nondecreasing nonnegative function $g : \mathbb{R}^+ \to \mathbb{R}^+$, depending on $p(x)$ and β, with $g(R) \to 0^+$ as $R \to 0^+$ and constants $\widehat{c}_1$, depending only on $\int_{C_r^\beta} |Dv|^{p(x)}\,dx$, and β, $\widehat{c}_2$ depending only on β, both independent of the function v, such that*

$$|v(x) - v(y)| \le \widehat{c}_1 \min\left\{B(R)d^{\widehat{c_2}(\log(2/R))^{-t}},\, g(S)\right\} \tag{8.14}$$

for every $x, y \in \overline{C}_r^\beta \setminus \{0\}$. Here $d := |x-y| \le 1$, $S := \max\{|x|,|y|\}$, $R := \min\{|x|,|y|\}$, and $B(R)$ is a function depending only on R and such that it is bounded on every interval of the type $[R_0, 1]$, $R_0 > 0$. The same result holds replacing $\overline{C}_r^\beta$ by $-\overline{C}_r^\beta$.

Proof. We treat only the case of $\overline{C}_r^\beta$, the proof for $-\overline{C}_r^\beta$ being similar. By applying Morrey's theorem to the set $C_1^\beta \setminus C_{R/2}^\beta$ we infer

$$|v(x) - v(y)| \le c\,B(R)|x-y|^{c_\beta\,(\log(4/R))^{-t}},$$

where $c_\beta := \sin(2\beta)/2 > 0$, $B(R)$ depends only on R and the constant c depends on $\int_{C_r^\beta} |Du|^{p(x)}\,dx$; observe that $B(R)$ is given by Morrey's imbedding inequality, and it turns out that $B(R) \to +\infty$ when $R \to 0$; this gives the first estimate for (8.14). In order to get the second estimate we argue as follows: if $k \in \mathbb{N}$ is such that $2^{-k} \le |x| < 2^{-k+1}$, and $x_i := 2^{-i}(\cos(\pi/4), \sin(\pi/4))$, arguing as in Theorem 8.2 (compare Remark 8.5) and setting $p(\rho) := 2 + c_\beta\,(\log(2/\rho))^{-t}$, we also infer

$$\begin{aligned}
|v(x) - v(0_{\mathbb{R}^2})| &\le |v(x) - v(x_k)| + \sum_{i=k}^{+\infty} |v(x_i) - v(x_{i+1})| \\
&\le c\,\frac{|x - x_k|^{1-2/p(2^{-k})}}{p(2^{-k}) - 2} + c\sum_{i=k}^{+\infty} \frac{|x_i - x_{i+1}|^{1-2/p(2^{-(i+1)})}}{p(2^{-(i+1)}) - 2} \\
&\le c\sum_{i=k}^{+\infty} \log(2^{i+1})^t (2^{-(i+1)})^{(c_\beta/3)\log(2^{i+1})^{-t}} \\
&\le c\sum_{i=k}^{+\infty} (i+1)^t e^{-\widehat{c}\,(\log 2)^{1-t}\,(i+1)^{1-t}} \\
&=: cA_k.
\end{aligned}$$

Observe that, as for Theorem 8.2, the constant $c > 0$ depends only on $\int_{C_r^\beta} |Dv|^{p(x)}\,dx$ and β, while $\widehat{c} > 0$ depends only on β, and moreover $c \to +\infty$ when $\beta \to 0$ while $\widehat{c} \to 0$ when $\beta \to 0$; this follows by Remark 8.5 replacing S_k by $\widetilde{S}_k := C^\beta \cap B^{2^{-k+1}}_{2^{-k}}$ (thereby taking $L = 1$). As before, it has been used that $u \in W^{1,p(2^{-k})}(\widetilde{S}_k)$.

In the same way, if $2^{-h} \le |y| < 2^{-h+1}$ for some $h \in \mathbb{N}$, then

$$|v(y) - v(0_{\mathbb{R}^2})| \le A_h$$

and by the triangle inequality

$$|v(x) - v(y)| \le 2\max\{A_k, A_h\} = 2A_{\min\{k,h\}}.$$

Then, since $A_k \to 0$ as $k \to +\infty$ (see (8.4)), we conclude by setting

$$g(S) := \begin{cases} A_k & \text{if} \quad 2^{-k} \le S < 2^{-k+1}, \\ A_1 & \text{if} \quad S \ge 1/2; \end{cases}$$

clearly, $g(S) \to 0$ if and only if $S \to 0$. □

End of Proofs of Proposition 8.6 *and Theorem* 8.3. Let $\{u_j\} \subset C^1(B_r)$ be the sequence as in the statement; as explained at the beginning of the proof of Proposition 8.6, it suffices to prove that $\{u_j\}$ is equi-uniformly continuous on the closure of C_r^β, and in turn this is equivalent to proving the equi-uniform continuity on $\overline{C}_r^\beta \setminus \{0\}$. We have to prove that for any $\varepsilon > 0$ there exists $\delta \equiv \delta(\epsilon) > 0$ such that whenever $x, y \in \overline{C}_r^\beta \setminus \{0\}$ satisfy $|x - y| \le \delta$, then $|u_j(x) - u_j(y)| \le \epsilon$ for every $j \in \mathbb{N}$. We argue by contradiction; if it were not so, there would exist $\epsilon_0 > 0$ such that for any positive integer h there exist $j(h) \in \mathbb{N}$, $x_h, y_h \in \overline{C}_r^\beta \setminus \{0\}$ and a function $v_h := u_{j(h)}$ such that

$$d_h := |x_h - y_h| \le 1/h \tag{8.15}$$

but

$$|v_h(x_h) - v_h(y_h)| > \epsilon_0. \tag{8.16}$$

By the estimate (8.14), if we set $S_h := \max\{|x_h|, |y_h|\} > 0$, then (8.16) implies that $g(S_h) \ge \epsilon_0/c_1 > 0$ (where c_1 is independent of $h \in \mathbb{N}$, as observed in Lemma 8.7), and so there exists $S_0 > 0$ such that $S_h \ge S_0$ for every $h \in \mathbb{N}$. In turn, if we let $R_h := \min\{|x_h|, |y_h|\} > 0$, by (8.15) we get that $R_h \ge R_0 := S_0/2 > 0$ for every index $h > 2/S_0$. Hence, by (8.14) we get

$$B(R_h) d_h^{\widehat{c}_2 (\log(2/R_h))^{-t}} < \widetilde{B} d_h^{\widehat{c}_2 (\log(2/R_0))^{-t}} \to 0, \qquad \widetilde{B} = \max_{[R_0,1]} B(R),$$

and applying again (8.14) and (8.16) yields

$$0 < \epsilon_0 \le \limsup_{h \to +\infty} |v_h(x_h) - v_h(y_h)| \le \lim_{h \to +\infty} \widehat{c}_1 B(R_h) d_h^{\widehat{c}_2 (\log(2/R_h))^{-t}} = 0,$$

which is impossible. Therefore, $\{u_j\}$ is equi-uniformly continuous and the proofs are complete. □

NETWORK APPROXIMATION FOR EFFECTIVE VISCOSITY OF CONCENTRATED SUSPENSIONS WITH COMPLEX GEOMETRY*

LEONID BERLYAND†, LILIANA BORCEA‡, AND ALEXANDER PANCHENKO§

Abstract. We study suspensions of rigid particles (inclusions) in a viscous incompressible fluid. The particles are close to touching one another, so that the suspension is near the packing limit, and the flow at small Reynolds number is modeled by the Stokes equations. The objective is to determine the dependence of the effective viscosity $\langle\mu\rangle$ on the geometric properties of the particle array. We study spatially irregular arrays, for which the volume fraction alone is not sufficient to estimate the effective viscosity. We use the notion of the interparticle distance parameter δ, based on the Voronoi tessellation, and we obtain a discrete network approximation of $\langle\mu\rangle$, as $\delta \to 0$. The asymptotic formulas for $\langle\mu\rangle$, derived in dimensions two and three, take into account translational and rotational motions of the particles. The leading term in the asymptotics is rigorously justified in two dimensions by constructing matching upper and lower variational bounds on $\langle\mu\rangle$. While the upper bound is obtained by patching together local approximate solutions, the construction of the lower bound cannot be obtained by a similar local analysis because the boundary conditions at fluid-solid interfaces must be resolved for all particles simultaneously. We observe that satisfying these boundary conditions, as well as the incompressibility condition, amounts to solving a certain algebraic system. The matrix of this system is determined by the total number of particles and their coordination numbers (number of neighbors of each particle). We show that the solvability of this system is determined by the properties of the network graph (which is uniquely defined by the array of particles) as well as by the conditions imposed at the external boundary.

Key words. effective viscosity, discrete network, variational bounds, concentrated suspension

1. Introduction.

In this paper, we obtain and justify approximate formulas for the effective viscosity $\langle\mu\rangle$ of a highly concentrated suspension of solid particles in a viscous incompressible fluid. We study generic, nonperiodic spatial distributions of particles and focus on a particular type of highly concentrated suspension, which can be approximately modeled on the macroscale by a single phase fluid, called the effective fluid. The effective viscosity is determined from the equality of the viscous dissipation rates in the suspension and the effective fluid. This is a classical approach that goes back to Einstein [14], who approximated the effective viscosity in the limit of an infinitely small particle concentration (the so-called dilute limit). Further results for dilute suspensions can be found in [3] and the references therein.

While in the dilute limit the interactions between the particles are negligible, the case of finite (nonsmall) concentrations is much harder to analyze because these interactions must be taken into account. In [25], an asymptotic expansion of the effective viscosity was constructed assuming a periodic distribution of particles. In

[25], the formal two-scale homogenization was carried out under the assumption that the number of particles tends to infinity while their total volume remains constant. In this case, the distances between the particles are of the order of their sizes, which is the key feature of the so-called finite (moderate) concentration regime.

By contrast, our interest lies in the high concentration regime, where the particles are close to touching one another, so the typical interparticle distances are much smaller than their sizes. In this case, the hydrodynamic interactions lead to the blow-up of the dissipation rate in the thin gaps between the closely spaced particles. Note that the effective fluid can be either Newtonian [15] or non-Newtonian [1, 2, 4, 24]. We consider only the former case, following [15, 16, 27] (see also [19] for a review of physical data). Also, we consider only noncolloidal suspensions, which means that hydrodynamic interactions are much stronger than Brownian interactions, so the latter can be neglected. For effective rheology of colloidal suspensions, one may consult [12].

For periodic arrays of particles [15, 16, 27], the estimation of the effective viscosity reduces to solving the flow problem locally, in a thin gap between two neighboring particles. In [15], this is done by a formal asymptotic method, similar to the well-known lubrication approximation, which takes into account only the translational motions of particles along the lines of their centers. The contributions of rotations and shear-type translations are neglected in [15]. In [16], a more general formula for the effective viscosity is obtained, which combines the results in [15] and [14] for dilute and high concentration regimes, respectively. In [27], the definition of the effective viscosity involves the traction exerted by the fluid on a single sphere. This traction satisfies an integral equation derived and solved (for a cubic periodic lattice) in [27]. Note in particular that the periodicity assumption in [27] reduces the boundary conditions on the surface of the particles to just a rigid body rotation (no translations).

In this paper, we consider generic, nonperiodic arrays, where different particles have different translational and rotational body motions. Since the rigid motions of the particles are not known a priori, the effective viscosity cannot be obtained simply by solving a local problem in the gap between adjacent particles. The motion of one particle influences the motion of all the particles in the array and, to find the effective viscosity, we must solve the global problem. A key ingredient in our method of solution is the so-called discrete network approximation.

Discrete network models have been used in the engineering and physics literature [21, 17, 28, 29], although the relation between the continuum problem and the discrete network has not been established. The first rigorous mathematical characterization of high-contrast media, in terms of discrete networks, was obtained for electromagnetic transport problems in [8, 9, 10, 11], where the electrical conductivity (and permittivity) were modeled as exponentials of the form $e^{S(x)/\epsilon}$. This continuum high-contrast model is due to Kozlov [22], where S is a smooth, Morse function and where $\epsilon \ll 1$, such that small variations of S are highly amplified by the exponential, thus giving the high contrast. Kozlov's model is especially useful in the context of imaging [10], where the medium is not known and it is approximated by a generic, high-contrast continuum. The high-contrast continuum model leads to an explicit characterization of two-dimensional flow of DC (AC) electric current in the material, in terms of a network of resistors (and capacitors), which is uniquely defined by the distribution of critical points of S. Explicitly, in the DC case, the nodes of the network are the local maxima of the electrical conductivity function (i.e., of S) and the branches of the network connect adjacent nodes through the saddle points of S. The resistor associated with each branch is determined by the conductivity and by the curvatures of S at

the saddle point, respectively. The boundary currents and voltages of the asymptotic network are also uniquely defined by S and by the boundary conditions specified for the continuum problem, so the asymptotic results in [9, 10, 11] give more than the homogenized electrical properties of the high contrast continuum. They give that the Neumann-to-Dirichlet map of the continuum problem is asymptotically equivalent to the discrete Neumann-to-Dirichlet map of the asymptotic network, in the limit $\epsilon \to 0$ [9, 11]. All the results in [8, 9, 10, 11] apply to the two-dimensional case for all smooth functions S with isolated, nondegenerate critical points. Extensions to three dimensions are straightforward for a special class of functions S, but for a general S, the network approximation may not apply.

In [5], another network approximation has been developed for a scalar, DC conductivity problem which models dispersive high contrast composites. In this case, $S(x)$ is the characteristic function of the particles, the high-contrast parameter is $\epsilon = 0$ (perfectly conducting particles), and the asymptotic analysis is carried out in the limit of the interparticle distance parameter δ tending to zero. The particle radii are not treated as small parameters, and the number of the particles is sufficiently large but bounded from above by $N_{\max}$, where $N_{\max}$ is the maximal close packing number. In [5], the connectivity patterns and the interparticle distance parameter for irregular spatial arrays of particles are rigorously defined using Voronoi tessellation. It is demonstrated that the network approximation is an efficient numerical tool, capable of capturing various percolation effects as well as effects due to the polydispersity of particles. This approach also allows for analytical error estimates, subsequently obtained in [6].

In [6, 8, 9, 10, 11, 5], the network approximation was rigorously justified by employing variational duality. The key point is the construction of trial functions, the electric potential and current density for the direct and dual variational problems, respectively. The choice of trial functions depends on both the mathematical and the physical features of the problem. For example, the construction of trial functions in [5] is essentially different from those in [8, 9, 10, 11], and it requires the development of new mathematical tools. While the upper bound can be obtained by patching together the appropriate test functions based on the local analysis of [20], such a straightforward approach does not work for the lower bound. The difficulty in obtaining the latter lies in the construction of trial functions for the dual problem, when the boundary conditions on the surfaces of the particles cannot be satisfied independently for each particle, and one must deal with all inclusions simultaneously. The dual (lower) bound was obtained in [5] by constructing an approximate, divergence-free trial electric current density in the gap between adjacent particles and extending it to zero elsewhere in the domain. Then, the network equations are used to choose the unknown parameters in the dual trial field, so that the boundary conditions on the surface of the particles are satisfied exactly. Note, however, that this construction is specialized to the scalar, electrical conductivity problem, and does not admit a generalization to vectorial problems.

In this work, we study the vectorial problem described by Stokes's flow in a closely packed suspension with rigid particles. Since the array of particles is irregular, our construction uses the interparticle distance parameter introduced in [5], based on the Voronoi tessellation. Due to the high concentration of particles of finite size, in a fixed volume, the particles are close to touching. Thus, we assume that distances δ^{ij} between adjacent particles $D^{(i)}$ and $D^{(j)}$ become infinitesimally small, but positive. More precisely, we say that $c\delta \leq \delta^{ij} \leq \delta$ for all pairs $D^{(i)}$, $D^{(j)}$ of neighboring particles, where $0 < c < 1$ is fixed and where δ is the small parameter of the problem.

We are interested in the asymptotics of the effective viscosity as $\delta \to 0$, while the particle radii a_i are kept fixed and the number of particles N approaches $N_{\max}$, from below.

The goal of this paper is twofold. The first objective is to obtain a method for estimating the effective viscosity which captures explicitly the effects of the complex geometry (the irregular distribution of the location and size of the particles). This is done in both two and three dimensions, and our derivation is based on the generalization of the lubrication approximation technique. We take into account all possible translations and rotations of the rigid particles in the suspension, which we quantify by constant vectors $\mathbf{T}^{(p)}$ and $\boldsymbol{\omega}^{(p)}$, respectively, for $1 \le p \le N$. Using the linearity of the problem, we approximate first the velocity, pressure, and stress in the gaps (necks) between the particles for translational and rotational motions, separately, and then we superpose the results. The lubrication analysis is local for each gap, and by summing the contribution of all the gaps, we obtain the discrete approximation of $\langle \mu \rangle$, parameterized in terms of the rigid body translational and rotational velocities $\mathbf{T}^{(p)}$ and $\boldsymbol{\omega}^{(p)}$, respectively, for $1 \le p \le N$. These rigid body motions are not arbitrary, but they are calculated by solving a system of linear equations, which corresponds to the conditions of mechanical equilibrium for all particles in the suspension.

For the reader interested mainly in numerical estimation of the effective viscosity, we describe our approach in Remark 3.1. (See also the forthcoming paper [7], where the effective viscosity was computed for several boundary conditions and various particle arrays by adapting the approach developed in this paper.)

The second objective of the paper is to provide a rigorous mathematical justification of the asymptotic approximation of the effective viscosity. The rigorous justification of the leading order term in the asymptotic approximation is done here in two dimensions. The most subtle part of this justification is the construction of the dual trial function for the lower bound on the effective viscosity. None of the techniques developed previously in [5, 6, 8, 9, 10, 11] for constructing trial functions for the dual problem work here. There are two main difficulties in the construction of the bounds on the effective viscosity. The first difficulty is that the trial functions must be divergence free in the fluid domain. The second difficulty is raised by the boundary conditions on fluid-solid interfaces. While these issues can be handled in the upper bound construction with an approach inspired by the work in [5, 6, 8, 9, 10, 11], the dual problem is significantly more challenging because the trial fields are tensors. In the dual problem, neither of the above two difficulties can be resolved by doing local analysis, that is, by choosing approximate solutions in each gap followed by patching these solution together. First, we must consider the global problem to ensure that the boundary conditions are satisfied for all inclusions at once. Second, we show that the divergence-free requirement on the stress trial fields is also global, analogous to the interface conditions. Then, we observe that the solvability of a certain algebraic system is sufficient to ensure that these two global requirements are satisfied. The size of the matrix of the linear system is determined by N, the total number of particles, and by their coordination number (number of neighbors). The solvability of the system, in turn, is determined by the connectivity and the coordination numbers of the network graph corresponding to the particle array, as well as by the conditions at the external boundary. We present geometric conditions for the network graph (topology) so that this linear system is solvable. In particular, we point out that these conditions are satisfied by network graphs which model typical close packing configurations.

The paper deals with irregular spatial arrays of particles. In this case, the total

volume fraction of particles (the only parameter in the formulas from [14, 15]) is not sufficient for estimating the effective viscosity. Instead of a formula, we give an algorithm, which essentially reduces computation of the effective viscosity to solving a linear algebraic system for translational and angular velocities of particles. The gain here is that we obtain an accurate yet computationally inexpensive approximation for the effective viscosity, which, unlike the above mentioned formulas, takes into account variable distances between neighboring particles. Note that variability in these distances for a fixed total volume fraction of particles may result in significant changes in the effective properties due to percolation effects (see [6]).

The focus of this paper is on derivation and, particularly, analytical justification of this algorithm, while its implementation will be investigated elsewhere. (See, for example, the forthcoming [7], where both shear and compression boundary conditions for various arrays of particles are investigated.) This paper, however, contains results of immediate practical interest, such as determination of the order of magnitude of the effective viscosity in the interparticle distance parameter δ. An interesting feature of the vectorial problem that distinguishes it from the scalar case considered in [5, 6, 8, 9, 10, 11] is that the order of magnitude of the effective viscosity depends crucially on the geometry of the particle array and on the boundary conditions. For the scalar problem, the order of magnitude is the same for all networks satisfying a natural connectedness assumption [5], which is not the case in our vectorial problem. In section 6.2.6 we give a sufficient condition on the particle array such that the effective viscosity blows up at the rate $\delta^{-3/2}$, in two dimensions, and the leading term in the asymptotics of $\langle\mu\rangle$ is given by the so-called spring network approximation, in which only the translational motions of adjacent particles, along the axis of their centers, are taken into account. In this case, the rotations of the particles do not contribute to the leading term of the asymptotics of $\langle\mu\rangle$. If an array does not satisfy this condition, the blow up rate may be a weaker ($\delta^{-1/2}$), in which case rotational contributions cannot be ignored. A detailed study of this phenomenon is presented in the forthcoming [7], where we also use network approximation to explain the discrepancy, observed in [31], between the effective shear viscosity formulas for periodic arrays and estimates obtained from experimental results and numerical simulations.

In this paper, we give the rigorous justification of the spring network approximation. An important physical problem is to calculate the second order term in $\langle\mu\rangle$, which depends on the rotational motions of particles. The two-term (formal) asymptotics obtained here provide physical insight and the quantitative estimate of the contributions of rotations, as well as the effects of variable size distribution. Rigorous justification of these formulas requires a more careful lower bound construction than we attempt here, and it remains an interesting and challenging open problem.

Our study is motivated by the problem of transport of highly concentrated slurries, which arises in numerous industrial applications ranging from construction engineering to combustion processes [30, 32]. It is often necessary to use slurries with high solid content (highly packed). The transport of such slurries is impeded by the fact that their effective viscosity is very high. Thus the goal is to find an optimal balance between the effective viscosity and the concentration of the solid phase. The first step in achieving this goal is to obtain relatively simple formulas which show how the effective viscosity depends on the control parameters (e.g., geometrical parameters, such as the particle size distributions, particle locations, and shapes). The network approximation we propose here can be used in the prediction of optimal properties of such slurries.

The paper is organized as follows. In section 2, we give the mathematical formu-

lation of the problem. Section 3 deals with the discrete network approximation of the effective viscosity. We also give here, and in section 4, the lubrication approximation of $\langle\mu\rangle$, in two and three dimensions. In section 5, we construct the upper bound on the effective viscosity, which accounts for both translational and rotational motions of the inclusions. In section 6, we give the rigorous justification of the spring network approximation of the effective viscosity. This accounts just for the leading order term in the asymptotics of the effective viscosity of the high contrast, closely packed suspension of particles. Finally, in section 7, we give a summary and conclusions.

2. Formulation of the problem.

2.1. The Stokes flow problem.

Consider a cube

$$\Omega = \left\{ \mathbf{x} = \sum_{j=1}^{n} x_j \, \mathbf{e}_j, \;\; -L \le x_j \le L, \; 1 \le j \le n \right\} \tag{2.1}$$

of volume $|\,\Omega\,| = (2L)^n$, where $n = 2$ or 3 and where $\{\mathbf{e}_1, \ldots, \mathbf{e}_n\}$ is an orthonormal basis. We suppose that Ω is filled with N, nonoverlapping, rigid balls (particles) $D^{(j)}$ of radius a_j, suspended in an incompressible fluid of viscosity μ. We study the Stokes flow of this suspension, where the fluid occupies the perforated, connected domain

$$\Omega_F = \Omega \setminus \bigcup_{j=1}^{N} D^{(j)}. \tag{2.2}$$

We are particularly interested in concentrated suspensions with volume fraction

$$\alpha = 1 - \frac{|\,\Omega_F\,|}{|\,\Omega\,|}, \tag{2.3}$$

close to maximal packing (neighboring particles are close to touching).

Let $\mathbf{u}(\mathbf{x})$ be the velocity field at point $\mathbf{x} \in \Omega_F$ and let $\mathcal{E}(\mathbf{x})$ be the rate of strain tensor

$$\mathcal{E}(\mathbf{x}) = \frac{1}{2}[\nabla\mathbf{u}(\mathbf{x}) + (\nabla\mathbf{u}(\mathbf{x}))^T], \tag{2.4}$$

which satisfies

$$\operatorname{trace}\mathcal{E}(\mathbf{x}) = \operatorname{div}\mathbf{u}(\mathbf{x}) = 0 \tag{2.5}$$

by incompressibility. The stress in the fluid is

$$\mathcal{S}(\mathbf{x}) = -P(\mathbf{x})I + 2\mu\mathcal{E}(\mathbf{x}), \tag{2.6}$$

where μ is the viscosity, P is the hydrostatic pressure, and I denotes the unit tensor. In the rigid balls, $\mathcal{E} = 0$. In the absence of external forces, the velocity field $\mathbf{u}(\mathbf{x})$ in the fluid satisfies Stokes's equation

$$\operatorname{div}\mathcal{S}(\mathbf{x}) = \mu\Delta\mathbf{u}(\mathbf{x}) - \nabla P(\mathbf{x}) = \mathbf{0} \tag{2.7}$$

and the incompressibility constraint (2.5).

Let us denote by $\partial\Omega^+$ and $\partial\Omega^-$ the top and bottom parts of the external boundary $\partial\Omega$, respectively,

$$\partial\Omega^+ = \{\mathbf{x} \in \partial\Omega : x_n = L\} \quad \text{and} \quad \partial\Omega^- = \{\mathbf{x} \in \partial\Omega : x_n = -L\}. \tag{2.8}$$

In this paper, we work with the model boundary conditions prescribed as follows. On $\partial\Omega^+ \cup \partial\Omega^-$, the velocity satisfies

$$\mathbf{u}(\mathbf{x}) = \mathbf{g}(x), \quad \text{where } \mathbf{g}(\mathbf{x}) = \begin{cases} -\dfrac{\mathbf{e_n}}{2L} & \text{on } \partial\Omega^-, \\ \dfrac{\mathbf{e_n}}{2L} & \text{on } \partial\Omega^+, \end{cases} \tag{2.9}$$

and the remaining part of $\partial\Omega$ is traction free,

$$\mathcal{S}(\mathbf{x})\ \mathbf{n}(\mathbf{x}) = \mathbf{0} \quad \text{for } \mathbf{x} \in \partial\Omega \setminus \left\{\partial\Omega^+ \cup \partial\Omega^-\right\}. \tag{2.10}$$

At the surface of each rigid ball $D^{(j)}$, the velocity satisfies

$$\mathbf{u}(\mathbf{x}) = \boldsymbol{\omega}^{(j)} \times (a_j \mathbf{n}^{(j)})(\mathbf{x}) + \mathbf{T}^{(j)} \quad \text{on } \partial D^{(j)}, \quad j = 1, 2, \ldots, N, \tag{2.11}$$

where $\boldsymbol{\omega}^{(j)}$, $\mathbf{T}^{(j)}$ are constant but unknown rotational and translational velocities of $D^{(j)}$ and where $\mathbf{n}^{(j)}(\mathbf{x})$ is the outer normal at $\partial D^{(j)}$. Finally, since each rigid ball is in equilibrium, the total force and torque exerted on $D^{(j)}$ by the fluid must be zero,

$$\int_{\partial D^{(j)}} \mathcal{S}\mathbf{n}^{(j)}\, ds = \mathbf{0} \ \text{ and } \ \int_{\partial D^{(j)}} \mathbf{n}^{(j)} \times \mathcal{S}\mathbf{n}^{(j)}\, ds = \mathbf{0} \text{ for } j = 1, 2, \ldots, N. \tag{2.12}$$

It is known that (2.7) and (2.5), with boundary conditions (2.9), (2.11), and (2.12), have a unique solution $\mathbf{u}(\mathbf{x})$, at least in the weak sense, with components in $H^1(\Omega_F)$.

2.2. The effective viscosity. The rate of viscous dissipation of the energy is given by [23]

$$E = \frac{1}{2}\int_{\Omega_F} (\mathcal{S}(\mathbf{x}), \mathcal{E}(\mathbf{x}))\ d\mathbf{x}, \tag{2.13}$$

where $(\cdot, \cdot)$ denotes the Frobenius tensor inner product

$$(\mathcal{S}(\mathbf{x}), \mathcal{E}(\mathbf{x})) = \sum_{i,j=1}^{n} \mathcal{S}_{ij}(\mathbf{x})\, \mathcal{E}_{ij}(\mathbf{x}). \tag{2.14}$$

Integrating by parts and using (2.5), (2.6), (2.9), (2.10), (2.11), and the identity

$$(\mathcal{S}, \mathcal{E}) = -P \operatorname{trace} \mathcal{E} + 2\mu(\mathcal{E}, \mathcal{E}) = \frac{\mu}{2}(\nabla\mathbf{u} + (\nabla\mathbf{u})^T, \nabla\mathbf{u} + (\nabla\mathbf{u})^T), \tag{2.15}$$

we obtain

$$E = \frac{1}{2}\int_{\partial\Omega^+\cup\partial\Omega^-} \frac{\mathbf{e}_n}{2L} \cdot \mathcal{S}(\mathbf{x})\mathbf{e}_n\, ds - \frac{1}{2}\sum_{j=1}^{N}\int_{\partial D^{(j)}} (\boldsymbol{\omega}^{(j)} \times \mathbf{n}^{(j)}(\mathbf{x}) + \mathbf{T}^{(j)}) \cdot \mathcal{S}(\mathbf{x})\mathbf{n}^{(j)}\, ds. \tag{2.16}$$

Furthermore, due to the balance equations (2.12), the integrals at the surface of the particles vanish and (2.13) can be rewritten as

$$E = \frac{1}{4L}\int_{\partial\Omega^+\cup\partial\Omega^-} \mathbf{e}_n \cdot \mathcal{S}(\mathbf{x})\, \mathbf{e}_n\, ds. \tag{2.17}$$

The effective viscosity $\langle\mu\rangle$ is defined by the equation

$$\frac{\langle\mu\rangle}{\mu} = \frac{E}{E^0} = \frac{\displaystyle\int_{\partial\Omega^+\cup\partial\Omega^-} \mathbf{e}_n \cdot \mathcal{S}(\mathbf{x})\,\mathbf{e}_n\,ds}{\displaystyle\int_{\partial\Omega^+\cup\partial\Omega^-} \mathbf{e}_n \cdot \mathcal{S}^0(\mathbf{x})\,\mathbf{e}_n\,ds}, \tag{2.18}$$

where $\mathcal{S}^0(\mathbf{x})$ is the stress tensor that would occur in Ω, in the absence of all the particles, under the same external boundary conditions (2.9), (2.10), and where E^0 is the corresponding rate of dissipation (see, for example, [15]). An equivalent definition of $\langle\mu\rangle$ can be obtained directly from (2.13) and (2.15) by equating the viscous dissipation rates

$$\langle\mu\rangle \int_\Omega \left(\mathcal{E}^0, \mathcal{E}^0\right) d\mathbf{x} = \mu \int_{\Omega_F} (\mathcal{E}, \mathcal{E})\, d\mathbf{x}. \tag{2.19}$$

We note that the definition of the effective viscosity, via the dissipation rate, is introduced in [3] for dilute suspensions, where the energy of the particulate phase is negligible. However, since the particles are rigid and condition (2.12) holds, the total mechanical energy of the particles is conserved. Thus, definitions (2.18) and (2.19) can be used as well for the suspensions considered in this paper.

2.3. The variational principles. The dissipation rate (2.13) or, equivalently, the effective viscosity (2.18), have a primal and dual variational formulation. The primal variational principle is widely known (see, for example, [13]),

$$E = \min_{\mathbf{u}\in\mathcal{U}} W_{\Omega_F}(\mathbf{u}), \text{ where } W_{\Omega_F}(\mathbf{u}) = \frac{\mu}{4}\sum_{i,j=1}^{n}\int_{\Omega_F}\left(\frac{\partial u_i(\mathbf{x})}{\partial x_j} + \frac{\partial u_j(\mathbf{x})}{\partial x_i}\right)^2 d\mathbf{x}, \tag{2.20}$$

and where the function space $\mathcal{U}$ of admissible velocity fields is

$$\mathcal{U} = \left\{\mathbf{u} = \sum_{j=1}^{n} u_j\,\mathbf{e}_j,\ u_j \in H^1(\Omega_F),\ j = 1\ldots n,\ \operatorname{div}\mathbf{u} = 0,\ (2.9) \text{ and } (2.11) \text{ hold}\right\}. \tag{2.21}$$

Note that the minimizer in (2.20) is the solution of the Stokes flow equation (2.7), where $P(\mathbf{x})$ is the Lagrange multiplier for the incompressibility constraint $\operatorname{div}\mathbf{u}(\mathbf{x})=0$.

The dual variational principle[1] is

$$E = \max_{\mathcal{S}\in\mathcal{F}}\left\{\frac{1}{2L}\int_{\partial\Omega^+\cup\partial\Omega^-}\mathbf{e}_n\cdot\mathcal{S}(\mathbf{x})\,\mathbf{e}_n\,ds - \frac{1}{4\mu}\int_{\Omega_F}\left[(\mathcal{S}(\mathbf{x}),\mathcal{S}(\mathbf{x})) - \frac{(\operatorname{trace}\mathcal{S}(\mathbf{x}))^2}{n}\right]d\mathbf{x}\right\}, \tag{2.22}$$

where we maximize over the space $\mathcal{F}$ of admissible stress fields

$$\begin{aligned}\mathcal{F} = \{&\mathcal{S}\in\mathbb{R}^{n\times n},\ \mathcal{S} = \mathcal{S}^T,\ \operatorname{div}\mathcal{S} = \mathbf{0},\ \mathcal{S}_{ij}\in L^2(\Omega_F),\\ &i,j = 1,\ldots,n,\ (2.10) \text{ and } (2.12) \text{ hold}\}.\end{aligned} \tag{2.23}$$

The maximizer in (2.22) is the stress field $\mathcal{S}(\mathbf{x})$, which determines the minimizing velocity field $\mathbf{u}(\mathbf{x})$ in (2.20) by Newton's law (2.6), where

$$P(\mathbf{x}) = -\frac{\operatorname{trace}\mathcal{S}(\mathbf{x})}{n}. \tag{2.24}$$

[1]For the derivation, see Appendix A in the preprint version of this article, available at http://www.math.wsu.edu/math/faculty/panchenko/welcome.html.

3. The discrete approximation of the effective viscosity. Intuitively, in highly packed suspensions, we expect that most energy is dissipated in the thin gaps between the rigid particles. Let us then define the local dissipation rate in a gap Π, between two adjacent particles in Ω_F, by

$$W_\Pi(\mathbf{u}) = \mu \int_\Pi (\mathcal{E}(\mathbf{u}), \mathcal{E}(\mathbf{u}))\, d\mathbf{x}. \tag{3.1}$$

In this paper, we show that, in the asymptotic limit of infinitesimally small gap thickness

$$\frac{\delta}{a} = \max_{j,k} \frac{\delta^{jk}}{a} \to 0, \tag{3.2}$$

the effective viscosity is determined by the sum of local dissipation rates (3.1) over all the gaps in Ω_F. In a highly packed suspension, the rate of dissipation of the energy can be written as an asymptotic series, in the limit (3.2), with the first and second terms blowing up at different rates (as powers or at least logarithmically in a/δ). The remainder of the series is $O(1)$.

3.1. Connectivity patterns for densely packed suspensions. In the case of regular (cubic, hexagonal, etc.) arrays of particles in Ω, the volume fraction is sufficient to describe the distance between the particles and therefore the effective behavior of the suspension. However, for general distributions of particles in highly packed suspensions, one has to consider irregular connectivity patterns.

Let us consider an arbitrary distribution of particles $D^{(i)}$, centered at $\mathbf{x}^{(i)} \in \Omega$, for $i = 1, 2, \ldots, N$. We suppose that N is close to $N_{\max}$ such that particles can get close to touching one another. The concept of adjacent particles is essential to the analysis, and, to make it rigorous, we use Voronoi tessellations.

DEFINITION 3.1. *The Voronoi cell V_i, corresponding to $\mathbf{x}^{(i)}$, is the polyhedron*

$$V_i = \{\mathbf{x} \in \overline{\Omega} \text{ such that } |\, \mathbf{x} - \mathbf{x}^{(i)} \,| \leq |\, \mathbf{x} - \mathbf{x}^{(j)} \,| \quad \text{for all } j = 1, 2, \ldots, N,\ j \neq i\}.$$

The plane faces of V_i can lie either on $\partial\Omega$ or in the interior of Ω. On each face of V_i that lies inside Ω,

$$|\, \mathbf{x} - \mathbf{x}^{(i)} \,| = |\, \mathbf{x} - \mathbf{x}^{(j)} \,| \quad \text{for some } i \neq j.$$

In Figure 1, we illustrate a Voronoi tessellation in two dimensions.

DEFINITION 3.2. *Given the Voronoi tessellation and an arbitrary $D^{(i)}$, for $i = 1, 2, \ldots, N$, we define the set of indices of its neighbors as $\mathcal{N}_i = \{j \in \mathbb{N}, j \neq i$, such that V_i and V_j have a common face$\}$. The coordination number of $D^{(i)}$ is equal to the cardinal number of $\mathcal{N}_i$.*

Neighboring particles $D^{(i)}$ and $D^{(j)}$ are separated by a gap (neck) Π^{ij} (see Figure 3) of minimum thickness,

$$\delta^{ij} = |\, \mathbf{x}^{(i)} - \mathbf{x}^{(j)} \,| - (a_i + a_j), \tag{3.3}$$

and width $R^{ij} = O(a^{ij})$, where

$$a^{ij} = \frac{2a_i a_j}{a_i + a_j}. \tag{3.4}$$

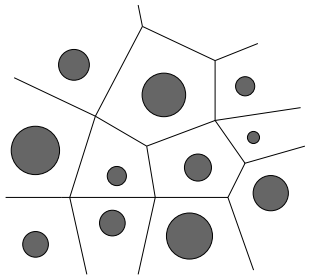

FIG. 1. *Two dimensional Voronoi tessellation.*

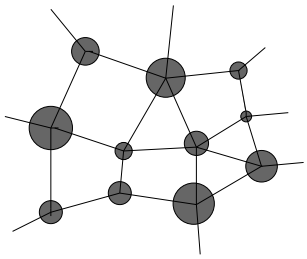

FIG. 2. *The Delaunay graph.*

Then the topology of network Γ, needed in the asymptotic approximation of $\langle\mu\rangle$, in the limit $\delta^{ij}/a^{ij} \to 0$, for $i = 1, \dots, N$ and $j \in \mathcal{N}_i$, is uniquely defined, as follows.

DEFINITION 3.3. *The interior vertices of the network (graph)* Γ *are given by* $\mathbf{x}^{(i)}$*, the locations of the centers of particles* $D^{(i)}$ *in* Ω *for* $i = 1, 2, \dots, N$*. The interior branches (edges)* b^{ij} *of the network connect vertices* $\mathbf{x}^{(i)}$ *and* $\mathbf{x}^{(j)}$ *(*$j \in \mathcal{N}_i$*) through the gaps (necks)* Π^{ij}*. For Voronoi cells* V_i *with faces belonging to* $\partial\Omega^+ \bigcup \partial\Omega^-$*, we join* $\mathbf{x}^{(i)}$ *with* $\partial\Omega^{\pm}$ *through a normal segment* $\tilde{b}^i$ *(exterior branch or edge) and we call the intersection* $\tilde{\mathbf{x}}^{(i)}$ *an exterior vertex. Finally, we let* $\mathcal{B}$ *be the set of indices* i *corresponding to the boundary Voronoi cells, that is, the cells at least one face of which belongs to* $\partial\Omega^+ \cup \partial\Omega^-$*.*

ASSUMPTION 3.1. *We assume that the distances between the neighboring balls are bounded below by* $c\delta$*, where* $c > 0$ *is fixed and* δ *is the small parameter of the problem. Thus the length of each edge in the graph is larger than* $2A + c\delta$*, where* A *is the smallest ball radius.*

Note that Γ is the Delaunay graph, which is dual to the Voronoi tessellation. The Delaunay graph for the two-dimensional tessellation of Figure 1 is shown in Figure 2. Note also the following properties of Γ,[2] which we use in the analysis.

Property 3.1. Γ is connected in the sense that each pair of interior vertices can be connected by a path consisting entirely of interior edges.

Property 3.2. Suppose there exists a Voronoi cell contained strictly inside Ω. Then there exists a closed path consisting entirely of interior edges.

Property 3.3. At least two edges originate at each interior vertex of Γ.

3.2. The two-term discrete asymptotic approximation. The asymptotic approximation of the viscous dissipation rate in the high-contrast suspension is obtained by summing the local dissipation rates $W_{\Pi^{ij}}$ in the gaps Π^{ij} between $D^{(i)}$ and $D^{(j)}$ for $i = 1, \dots, N$ and $j \in \mathcal{N}_i$. Then, focusing attention on one such gap (see Figure 3), we introduce a local system of coordinates $(x_1, \dots, x_n)$ in Π^{ij}, with the origin at $(\mathbf{x}^{(i)} + \mathbf{x}^{(j)})/2$ and coordinate x_n measured along the axis of the centers, pointing from $\mathbf{x}^{(j)}$ toward $\mathbf{x}^{(i)}$. The width of the gap is $R^{ij} = O(a^{ij})$ and the height (thickness) is

$$h(r) = \delta^{ij} + a_i\left(1 - \sqrt{1 - \frac{r^2}{a_i^2}}\right) + a_j\left(1 - \sqrt{1 - \frac{r^2}{a_j^2}}\right), \quad r = \sqrt{\sum_{k=1}^{n-1} x_k^2} \le R^{ij}. \tag{3.5}$$

[2]For the proof, see Appendix B in the preprint version of this article, available at http://www.math.wsu.edu/math/faculty/panchenko/welcome.html.

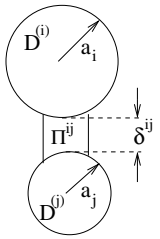

FIG. 3. *Two nearby particles $D^{(i)}$ and $D^{(j)}$ of radii a_i and a_j, respectively, separated by a gap δ^{ij}.*

The dissipation rate density $\mu(\mathcal{E},\mathcal{E})$ is expected to be highest at radial distances $r \ll \min(a_i, a_j)$, so, in the calculation of $W_{\Pi^{ij}} = \mu \int_{\Pi^{ij}} (\mathcal{E},\mathcal{E}) d\mathbf{x}$, we can approximate the spherical surfaces by paraboloids and the thickness of the gap by

$$h(r) \approx \delta^{ij} + \frac{r^2}{a^{ij}}. \tag{3.6}$$

3.2.1. The two-dimensional discrete approximation of $\langle\mu\rangle$. Clearly, $W_{\Pi^{ij}}$ depends on the velocity at the top and bottom surfaces of the gap, where $x_2 = \pm h(x_1)/2$, in two dimensions. Using boundary conditions (2.11) at $\partial D^{(i)}$ and $\partial D^{(j)}$, and approximating the outer normals as $\mathbf{n}^{(i)} \approx \frac{x_1}{a_i}\mathbf{e}_1 - \mathbf{e}_2$ and $\mathbf{n}^{(j)} \approx \frac{x_1}{a_j}\mathbf{e}_1 + \mathbf{e}_2$, by the normal vectors to the parabolas touching the disks (see (3.6)), we have

$$\begin{aligned}\mathbf{u}\left(x_1, \pm\frac{h(x_1)}{2}\right) \approx{}& \pm (T_2^{(i)} - T_2^{(j)})\frac{\mathbf{e}_2}{2} \pm (T_1^{(i)} - T_1^{(j)} + a_i\omega^{(i)} + a_j\omega^{(j)})\frac{\mathbf{e}_1}{2} \\ & \pm (\omega^{(i)} - \omega^{(j)}) x_1 \mathbf{e}_2 + \boldsymbol{\mathcal{R}},\end{aligned} \tag{3.7}$$

where

$$\boldsymbol{\mathcal{R}} = [T_2^{(i)} + T_2^{(j)} + (\omega^{(i)} + \omega^{(j)})x_1]\frac{\mathbf{e}_2}{2} + (T_1^{(i)} + T_1^{(j)} + a_i\omega^{(i)} - a_j\omega^{(j)})\frac{\mathbf{e}_1}{2}. \tag{3.8}$$

Equation (3.7) can be viewed as a decomposition of $\mathbf{u}$ in the following elementary velocity fields:

1. The first elementary velocity field in (3.7) is $\mathbf{u}_{\rm sp}$, and it solves the Stokes equations in Π^{ij} with boundary conditions

$$\mathbf{u}_{\rm sp}\left(x_1, \pm\frac{h(x_1)}{2}\right) = \pm(T_2^{(i)} - T_2^{(j)})\frac{\mathbf{e}_2}{2}. \tag{3.9}$$

We can associate $\mathbf{u}_{\rm sp}$ with the oscillatory motion, along $\mathbf{e}_2$, of two particles joined by a spring, with elastic constant $C_{\rm sp}^{ij} = O((a^{ij}/\delta^{ij})^{3/2})$ (see sections 4, 5, and 6). The velocity $(T_2^{(i)} - T_2^{(j)})/2$ of the particles is constant and unknown, so far. It is to be determined later from the global conditions of mechanical equilibrium of all inclusions in the suspension.

2. The second term in (3.7), denoted by $\mathbf{u}_{\rm sh}$, satisfies the Stokes equations in Π^{ij} with boundary conditions

$$\mathbf{u}_{\rm sh}\left(x_1, \pm\frac{h(x_1)}{2}\right) = \pm(T_1^{(i)} - T_1^{(j)} + a_i\omega^{(i)} + a_j\omega^{(j)})\frac{\mathbf{e}_1}{2}. \tag{3.10}$$

This accounts for a shear strain in the gap, where the fluid moves to the right and left, at the top and bottom surfaces of Π^{ij}, respectively, at the constant, unknown velocity $(T_1^{(i)} - T_1^{(j)} + a_i\omega^{(i)} + a_j\omega^{(j)})/2$. The contribution of this term to the dissipation rate is $C_{\rm sh}^{ij} = O(\sqrt{a^{ij}/\delta^{ij}})$ (see sections 4, 5).

3. The third term in (3.7) corresponds to a shear strain in the gap due to rotations. The boundary conditions are given by

$$\mathbf{u}_{\rm rot}\left(x_1, \pm\frac{h(x_1)}{2}\right) = \pm(\omega^{(i)} - \omega^{(j)})x_1\mathbf{e}_2, \tag{3.11}$$

as if the fluid were pushed and pulled, in direction $\mathbf{e}_2$, on the left and right sides of Π^{ij}, respectively (see Figure 6). The contribution of this term to the dissipation rate is $C_{\rm rot}^{ij} = O(\sqrt{a^{ij}/\delta^{ij}})$ (see sections 4, 5).

4. Finally, the remainder $\boldsymbol{\mathcal{R}}$ corresponds to a constant, $O(1)$ shear strain in the gap and, as such, it gives an $O(1)$ contribution to $W_{\Pi^{ij}}$ (see sections 4, 5).

In section 4, we obtain the formal asymptotic approximation

$$W_{\Pi^{ij}} \approx C_{\rm sp}^{ij}(T_2^{(i)} - T_2^{(j)})^2 + C_{\rm sh}^{ij}(T_1^{(i)} - T_1^{(j)} + a_i\omega^{(i)} + a_j\omega^{(j)})^2 + C_{\rm rot}^{ij}(\omega^{(i)} - \omega^{(j)})^2 + O(1), \tag{3.12}$$

where

$$C_{\rm sp}^{ij} = \frac{3\pi\mu}{4}\left(\frac{a^{ij}}{\delta^{ij}}\right)^{\frac{3}{2}} + \frac{12\pi\mu}{5}\sqrt{\frac{a^{ij}}{\delta^{ij}}},\quad C_{\rm sh}^{ij} = \frac{\pi\mu}{2}\sqrt{\frac{a^{ij}}{\delta^{ij}}},\ \text{and}\ C_{\rm rot}^{ij} = \frac{9\pi\mu}{16}\sqrt{\frac{a^{ij}}{\delta^{ij}}}. \tag{3.13}$$

The approximation (3.12) applies to interior inclusions $D^{(i)}$. For $i \in \mathcal{B}$, we have $D^{(i)}$ joined to a fictitious disk of infinite radius (i.e., $\partial\Omega^+$ or $\partial\Omega^-$) and the harmonic average of the radii is $a^i = 2a_i$. Given boundary conditions (2.9) at $\partial\Omega^{\pm}$, we have, similar to (3.12),

$$W_{\Pi^i} \approx C_{\rm sp}^{i}(T_2^{(i)} - \mathbf{g}\cdot\mathbf{e}_2)^2 + C_{\rm sh}^{i}(T_1^{(i)} - \mathbf{g}\cdot\mathbf{e}_1 + a_i\omega^{(i)})^2 + C_{\rm rot}^{i}(2\omega^{(i)})^2 + O(1), \tag{3.14}$$

where $C_{\rm sp}^i$, $C_{\rm sh}^i$, and $C_{\rm rot}^i$ are given by (3.13), with a^{ij} replaced by $a^i = 2a_i$ and δ^{ij} replaced by δ^i, the distance between $\partial D^{(i)}$ and the upper or lower boundary $\partial\Omega^{\pm}$.

Next, we approximate E by summing the local dissipation rates in all gaps Π^{ij} for $i = 1, \ldots, N$, $i \notin \mathcal{B}$, $j \in \mathcal{N}_i$, and Π^i for $i \in \mathcal{B}$. For this purpose, let us rename the orthonormal basis vectors in each gap Π^{ij} as

$$\mathbf{q}^{ij} = \frac{\mathbf{x}^{(i)} - \mathbf{x}^{(j)}}{|\mathbf{x}^{(i)} - \mathbf{x}^{(j)}|}$$

and $\mathbf{p}^{ij}$ = the rotated $\mathbf{q}^{ij}$, clockwise, by $\pi/2$, in the two-dimensional plane. In the boundary gaps Π^i, joining a particle $D^{(i)}$ with $\partial\Omega^{\pm}$, these vectors are called $\mathbf{q}^i$ and $\mathbf{p}^i$, respectively. The discrete approximation of $\langle\mu\rangle$ is given by (2.19), with the right-hand side

$$\begin{aligned} E \approx \min_{\mathbf{T},\omega} \sum_{i=1}^{N} \sum_{\substack{j\in\mathcal{N}_i \\ j<i}} &\{C_{\rm sp}^{ij}[(\mathbf{T}^{(i)} - \mathbf{T}^{(j)})\cdot\mathbf{q}^{ij}]^2 + C_{\rm sh}^{ij}[(\mathbf{T}^{(i)} - \mathbf{T}^{(j)})\cdot\mathbf{p}^{ij} + a_i\omega^{(i)} + a_j\omega^{j}]^2 \\ &+ C_{\rm rot}^{ij}(\omega^{(i)} - \omega^{(j)})^2\} + \sum_{i\in\mathcal{B}}\{C_{\rm sp}^{i}[(\mathbf{T}^{(i)} - \mathbf{g})\cdot\mathbf{q}^{i}]^2 + C_{\rm rot}^{i}(2\omega^{(i)})^2 \\ &+ C_{\rm sh}^{i}[(\mathbf{T}^{(i)} - \mathbf{g})\cdot\mathbf{p}^{i} + a_i\omega^{(i)}]^2\}. \end{aligned} \tag{3.15}$$

Note that in (3.15) we minimize a quadratic functional, over translational and rotational velocities $\mathbf{T}^{(i)}$ and $\omega^{(i)}$, for $i = 1, \ldots, N$, respectively. This is equivalent to solving the Euler–Lagrange equations

$$\sum_{j\in\mathcal{N}_i} \{C^{ij}_{\rm sp}[(\mathbf{T}^{(i)} - \mathbf{T}^{(j)})\cdot\mathbf{q}^{ij}]\mathbf{q}^{ij} + C^{ij}_{\rm sh}[(\mathbf{T}^{(i)} - \mathbf{T}^{(j)})\cdot\mathbf{p}^{ij} + a_i\omega^{(i)} + a_j\omega^{(j)}]\mathbf{p}^{ij}\}$$
$$+\,\mathbf{F}_{\mathcal{B}}(\mathbf{T}^{(i)},\omega^{(i)}) = \mathbf{0}, \tag{3.16}$$

$$\sum_{j\in\mathcal{N}_i} \{C^{ij}_{\rm sh}[(\mathbf{T}^{(i)} - \mathbf{T}^{(j)})\cdot\mathbf{p}^{ij} + \omega^{(i)} + \omega^{(j)}] + C^{ij}_{\rm rot}(\omega^{(i)} - \omega^{(j)})\}$$
$$+\,\mathcal{M}_{\mathcal{B}}(\mathbf{T}^{(i)},\omega^{(i)}) = 0 \tag{3.17}$$

for all $i = 1, \ldots, N$, where

$$\mathbf{F}_{\mathcal{B}}(\mathbf{T}^{(i)},\omega^{(i)}) = \begin{cases} C^{i}_{\rm sp}[(\mathbf{T}^{(i)} - \mathbf{g})\cdot\mathbf{q}^{i}]\mathbf{q}^{i} + C^{i}_{\rm sh}[(\mathbf{T}^{(i)} - \mathbf{g})\cdot\mathbf{p}^{i} + a_i\omega^{(i)}]\mathbf{p}^{i} & \text{if } i\in\mathcal{B}, \\ \mathbf{0} \ \text{ otherwise,} \end{cases} \tag{3.18}$$

$$\mathcal{M}_{\mathcal{B}}(\mathbf{T}^{(i)},\omega^{(i)}) = \begin{cases} C^{i}_{\rm sh}[(\mathbf{T}^{(i)} - \mathbf{g})\cdot\mathbf{p}^{i} + a_i\omega^{(i)}] + 4C^{i}_{\rm rot}\omega^{(i)} & \text{if } i\in\mathcal{B}, \\ 0 \ \text{ otherwise.} \end{cases} \tag{3.19}$$

These are the equations of force and torque balance of the inclusions, and the minimization in (3.15) ensures that the rigid body translational and rotational velocities are chosen in such a way that the suspension is in mechanical equilibrium.

3.2.2. The three-dimensional discrete approximation of $\langle\boldsymbol{\mu}\rangle$. Consider the local system of coordinates described at the beginning of section 3.2 in three dimensions. Similar to our two-dimensional calculation, we write

$$\begin{aligned} \mathbf{u}\left(x_1, x_2, \pm\frac{h(x_1,x_2)}{2}\right) \approx{}& \pm(T_3^{(i)} - T_3^{(j)})\frac{\mathbf{e}_3}{2} \pm (T_1^{(i)} - T_1^{(j)} - a_i\omega_2^{(i)} - a_j\omega_2^{(j)})\frac{\mathbf{e}_1}{2} \\ & \pm (T_2^{(i)} - T_2^{(j)} + a_i\omega_1^{(i)} + a_j\omega_1^{(j)})\frac{\mathbf{e}_2}{2} \pm (\omega_1^{(i)} - \omega_1^{(j)})\frac{x_2\mathbf{e}_3}{2} \\ & \mp (\omega_2^{(i)} - \omega_2^{(j)})\frac{x_1\mathbf{e}_3}{2} + \boldsymbol{\mathcal{R}}, \end{aligned} \tag{3.20}$$

where the remainder is

$$\begin{aligned} \boldsymbol{\mathcal{R}} = {}& (T_3^{(i)} + T_3^{(j)})\frac{\mathbf{e}_3}{2} + (T_1^{(i)} + T_1^{(j)} - a_i\omega_2^{(i)} + a_j\omega_2^{(j)})\frac{\mathbf{e}_1}{2} \\ & + (T_2^{(i)} + T_2^{(j)} + a_i\omega_1^{(i)} - a_j\omega_1^{(j)})\frac{\mathbf{e}_2}{2} + (\omega_1^{(i)} + \omega_1^{(j)})\frac{x_2\mathbf{e}_3}{2} \\ & - (\omega_2^{(i)} - \omega_2^{(j)})\frac{x_1\mathbf{e}_3}{2}. \end{aligned} \tag{3.21}$$

As in two dimensions, we associate the first term in (3.20), due to the motion of the inclusions along the axis of their centers, with the oscillatory motion of two particles

joined by a spring of elastic constant $C^{ij}_{\rm sp} = O(a^{ij}/\delta^{ij})$. The next two terms in (3.20) correspond to shear strains in the gap, where the fluid is pulled in the positive and negative directions of $\mathbf{e_1}$ and $\mathbf{e}_2$ at the top and bottom surfaces of Π^{ij}, respectively. The contribution of these terms to the dissipation rate is $C^{ij}_{\rm sh} = O(\ln a^{ij}/\delta^{ij})$. The fourth and fifth terms in (3.20) correspond to a shear strain in the gap as well, but now the fluid is pushed and pulled, in direction $\mathbf{e}_3$, on opposite sides of the axis of Π^{ij}, respectively. The contribution of these terms to the dissipation rate is $C^{ij}_{\rm rot} = O(\ln a^{ij}/\delta^{ij})$. Finally, the remainder $\boldsymbol{\mathcal{R}}$ gives an $O(1)$ contribution to $W_{\Pi^{ij}}$.

A formal asymptotic analysis, which is very similar to the two-dimensional one in section 4 and, as such, is not detailed here, gives

$$\begin{aligned} W_{\Pi^{ij}} \approx\ & C^{ij}_{\rm sp}(T_3^{(i)} - T_3^{(j)})^2 + C^{ij}_{\rm rot}[(\omega_1^{(i)} - \omega_1^{(j)})^2 + (\omega_2^{(i)} - \omega_2^{(j)})^2] \\ & + C^{ij}_{\rm sh}[(T_1^{(i)} - T_1^{(j)} - a_i\omega_2^{(i)} - a_j\omega_2^{(j)})^2 \\ & \qquad + (T_2^{(i)} - T_2^{(j)} + a_i\omega_1^{(i)} + a_j\omega_1^{(j)})^2] + O(1), \end{aligned} \tag{3.22}$$

where

$$C^{ij}_{\rm sp} = \frac{3\pi\mu a^{ij}}{4}\left(\frac{a^{ij}}{\delta^{ij}}\right) + \frac{9\pi\mu a^{ij}}{5}\ln\frac{a^{ij}}{\delta^{ij}},\quad C^{ij}_{\rm sh} = \frac{\pi\mu a^{ij}}{2}\ln\frac{a^{ij}}{\delta^{ij}},\ \text{and}\ C^{ij}_{\rm rot} = \frac{9\pi\mu a^{ij}}{16}\ln\frac{a^{ij}}{\delta^{ij}}(a^{ij})^2. \tag{3.23}$$

If $i \in \mathcal{B}$, $D^{(i)}$ is joined to $\partial\Omega^{\pm}$ through gap Π^i and we obtain (see section 3.2.1)

$$\begin{aligned} W_{\Pi^i} \approx\ & C^i_{\rm sp}(T_3^{(i)} - \mathbf{g}\cdot\mathbf{e}_3)^2 + C^i_{\rm rot}[(2\omega_1^{(i)})^2 + (2\omega_2^{(i)})^2] \\ & + C^i_{\rm sh}[(T_1^{(i)} - \mathbf{g}\cdot\mathbf{e}_1 - a_i\omega_2^{(i)})^2 + (T_2^{(i)} - \mathbf{g}\cdot\mathbf{e}_2 + a_i\omega_1^{(i)})^2] + O(1) \end{aligned} \tag{3.24}$$

with constants $C^i_{\rm sp}$, $C^i_{\rm sh}$, and $C^i_{\rm rot}$ given by (3.23), where a^{ij} is replaced by $a^i = 2a_i$ and δ^{ij} is replaced by δ^i, the distance between $\mathbf{x}^{(i)}$ and the upper or lower boundary.

The discrete approximation of the viscous dissipation rate E in the suspension is given by the sum of the local dissipation rates in all gaps Π^{ij} for $i = 1, \ldots, N,\ i \notin \mathcal{B}$, $j \in \mathcal{N}_i$, and Π^i, for $i \in \mathcal{B}$. Let us then introduce, in gap Π^{ij}, the orthonormal vectors

$$\mathbf{q}^{ij} = \frac{\mathbf{x}^{(i)} - \mathbf{x}^{(j)}}{|\mathbf{x}^{(i)} - \mathbf{x}^{(j)}|},\ \mathbf{r}^{ij} = \text{ the rotated } \mathbf{q}^{ij},$$
$$\text{in the plane } \mathcal{P}^{ij},\ \text{clockwise, by } \frac{\pi}{2},\ \text{and } \mathbf{p}^{ij} = \mathbf{r}^{ij} \times \mathbf{q}^{ij},$$

where $\mathbf{p}^{ij}$, $\mathbf{r}^{ij}$, and $\mathbf{q}^{ij}$ play the role of $\mathbf{e}_1$, $\mathbf{e}_2$, and $\mathbf{e}_3$, respectively, in the above calculation of $W_{\Pi^{ij}}$. Since plane $\mathcal{P}^{ij}$ is not uniquely defined by $\mathbf{q}^{ij}$, there are infinitely many choices of $\mathbf{r}^{ij}$, although they give the same dissipation rate $W_{\Pi^{ij}}$. Let us then pick $\mathcal{P}^{ij}$ arbitrarily but ensure, at the same time, that when indices i and j are interchanged, we have

$$\mathcal{P}^{ij} = \text{span}\{\mathbf{q}^{ij}, \mathbf{r}^{ij}\} = \text{span}\{\mathbf{q}^{ji}, \mathbf{r}^{ji}\} = \mathcal{P}^{ji}$$

or, equivalently,

$$\mathbf{q}^{ij} = -\mathbf{q}^{ji},\ \mathbf{r}^{ij} = -\mathbf{r}^{ji},\ \text{and}\ \mathbf{p}^{ij} = \mathbf{p}^{ji} \quad \text{for all } i = 1, \ldots, N,\ i \neq \mathcal{B},\ j \in \mathcal{N}_i.$$

For $i \in \mathcal{B}$, $D^{(i)}$ is joined with $\partial\Omega^{\pm}$ by gap Π^i, and the unit vectors are denoted by $\mathbf{p}^i$, $\mathbf{r}^i$, and $\mathbf{q}^i$, respectively. Then, the discrete approximation of the effective viscosity is given by (2.19), with the right-hand side

$$
\begin{aligned}
E \approx \min_{\mathbf{T},\omega} \sum_{i=1}^{N} \sum_{\substack{j \in \mathcal{N}_i \\ j<i}} & \{C_{\rm sp}^{ij}[(\mathbf{T}^{(i)} - \mathbf{T}^{(j)}) \cdot \mathbf{q}^{ij}]^2 + C_{\rm rot}^{ij}[(\boldsymbol{\omega}^{(i)} - \boldsymbol{\omega}^{(j)}) \cdot \mathbf{p}^{ij}]^2 \\
& + C_{\rm rot}^{ij}[(\boldsymbol{\omega}^{(i)} - \boldsymbol{\omega}^{(j)}) \cdot \mathbf{r}^{ij}]^2 + C_{\rm sh}^{ij}[(\mathbf{T}^{(i)} - \mathbf{T}^{(j)}) \cdot \mathbf{p}^{ij} \\
& - (a_i \boldsymbol{\omega}^{(i)} + a_j \boldsymbol{\omega}^{(j)}) \cdot \mathbf{r}^{ij}]^2 \\
& + C_{\rm sh}^{ij}[(\mathbf{T}^{(i)} - \mathbf{T}^{(j)}) \cdot \mathbf{r}^{ij} + (a_i \boldsymbol{\omega}^{(i)} + a_j \boldsymbol{\omega}^{(j)}) \cdot \mathbf{p}^{ij}]^2\} \\
& + \sum_{i \in \mathcal{B}} \{C_{\rm sp}^{i}[(\mathbf{T}^{(i)} - \mathbf{g}) \cdot \mathbf{q}^{i}]^2 \\
& \qquad + C_{\rm rot}^{i}[(2\boldsymbol{\omega}^{(i)} \cdot \mathbf{p}^{i})^2 + (2\boldsymbol{\omega}^{(i)} \cdot \mathbf{r}^{i})^2] \\
& \qquad + C_{\rm sh}^{i}[(\mathbf{T}^{(i)} - \mathbf{g}) \cdot \mathbf{p}^{i} - a_i \boldsymbol{\omega}^{(i)} \cdot \mathbf{r}^{i}]^2 \\
& \qquad + C_{\rm sh}^{i}[(\mathbf{T}^{(i)} - \mathbf{g}) \cdot \mathbf{r}^{i} + a_i \boldsymbol{\omega}^{(i)} \cdot \mathbf{p}^{i}]^2\} + O(1).
\end{aligned} \tag{3.25}
$$

Finally, as in section 3.2.1, the minimization in (3.25), over translational and rotational velocities $\mathbf{T}^{(i)}$ and $\boldsymbol{\omega}^{(i)}$ for $i = 1, \ldots, N$, ensures that all the inclusions in the suspension are in mechanical equilibrium.

Remark 3.1 (computation of the effective viscosity). We now summarize the steps necessary to compute the effective viscosity in problem (2.7)–(2.12). First, compute the approximate dissipation rate E by minimizing the quadratic functional (3.15) (in two dimensions) or (3.25) (in three dimensions). Next, solve the Stokes equations in the domain Ω (see (2.1)) with viscosity equal to one and boundary conditions given by (2.9), (2.10). Then compute the corresponding strain rate $\mathcal{E}^0 = 1/2(\nabla \mathbf{u}^0 + \nabla^T \mathbf{u}^0)$ and the normalized dissipation rate $\int_\Omega \mathcal{E}_{ij}^0 \mathcal{E}_{ij}^0 d\mathbf{x}$. Finally, compute the approximate value of the effective viscosity by the formula

$$
\langle \mu \rangle = \frac{E}{\int_\Omega \mathcal{E}_{ij}^0 \mathcal{E}_{ij}^0 d\mathbf{x}}. \tag{3.26}
$$

When the contributions of rotations can be neglected, the leading term in (3.26) is given by the leading term in the formula (6.85). Note that this term corresponds to the spring network approximation, which takes into account only motions of particles along the line of their centers. Detailed analysis of computational formulas for $\langle \mu \rangle$, based on the approach developed in this paper, for various boundary conditions and different arrays of particles, is presented in [7].

4. The local dissipation rate in a gap between two adjacent particles. Formal asymptotics in two dimensions. We begin our estimation of E with a formal asymptotic analysis which extends the lubrication approximations in [15, 16, 27] beyond the leading term by accounting for all possible rigid body motions of the inclusions in the suspension. To find E, we construct a velocity field in Ω_F which satisfies boundary conditions (2.11) but solves the Stokes equations approximately in the following sense: Since the density $\mu(\mathcal{E}, \mathcal{E})$ of the viscous dissipation rate is very high near the axis of the centers of adjacent inclusions $D^{(i)}$ and $D^{(j)}$, we approximate $\mathbf{u}$ in each gap Π^{ij} by the solution of the Stokes problem between two parallel plates, at distance h (which we pretend is a constant) apart, and we calculate the corresponding

rate of strain $\mathcal{E}$. Then we integrate over the gap to obtain the local dissipation rate

$$W_{\Pi^{ij}} \approx \int_{-a^{ij}}^{a^{ij}} dx_1 \int_{-\frac{h(x_1)}{2}}^{\frac{h(x_1)}{2}} dx_2 \, \mu\left(\mathcal{E},\mathcal{E}\right).$$

Since most energy is dissipated in the gaps, we expect that the contribution to E from the region outside the gaps remains uniformly bounded in the limit $\delta \to 0$.

Let us denote by E^{a} the approximation of the dissipation rate, obtained with the formal asymptotic, lubrication type, approach. Since E^{a} is a heuristic estimate, it requires rigorous justification, which we give in sections 5 and 6, where we calculate upper and lower variational bounds on E that match E^{a} to leading order. Nevertheless, both bounds are inspired to some extent by the calculation of E^{a}, so we describe next, in detail, our formal asymptotic analysis.

We begin by recalling the local system of coordinates (x_1, x_2) in gap Π^{ij}, as defined in section 3.2. At the surface of $D^{(i)}$, the velocity is given by

$$\mathbf{u}\mid_{\partial D^{(i)}} = (T_1^{(i)} + a_i\omega^{(i)})\mathbf{e}_1 + (T_2^{(i)} + a_i\omega^{(i)}n_1^{(i)})\mathbf{e}_2 - a_i\omega^{(i)}(n_2^{(i)}+1)\mathbf{e}_1,$$

and the two components of the outer normal at $\partial D^{(i)}$ are $n_1^{(i)} = \frac{x_1}{a_i}$ and $n_2^{(i)} = -\sqrt{1-\frac{x_1^2}{a_i^2}}$. Similarly,

$$\mathbf{u}\mid_{\partial D^{(j)}} = (T_1^{(j)} - a_j\omega^{(j)})\mathbf{e}_1 + (T_2^{(j)} + a_j\omega^{(j)}n_1^{(j)})\mathbf{e}_2 - a_j\omega^{(j)}(n_2^{(j)}-1)\mathbf{e}_1,$$

where $n_1^{(j)} = \frac{x_1}{a_j}$ and $n_2^{(j)} = \sqrt{1-\frac{x_1^2}{a_j^2}}$. Equivalently, we rewrite the boundary conditions on $\mathbf{u}$ as

(4.1)

$$\begin{aligned}\mathbf{u}\left(x_1, \pm\frac{h}{2}\right) = &\pm\left(T_1^{(i)} - T_1^{(j)} + \omega^{(i)}\sqrt{a_i^2-x_1^2} + \omega^{(j)}\sqrt{a_j^2-x_1^2}\right)\frac{\mathbf{e}_1}{2} \pm (T_2^{(i)} - T_2^{(j)})\frac{\mathbf{e}_2}{2}\\ &\pm(\omega^{(i)}-\omega^{(j)})\frac{x_1\mathbf{e}_2}{2} + \left(T_1^{(i)} + T_1^{(j)} + \omega^{(i)}\sqrt{a_i^2-x_1^2} - \omega^{(j)}\sqrt{a_j^2-x_1^2}\right)\frac{\mathbf{e}_1}{2}\\ &+(T_2^{(i)} + T_2^{(j)})\frac{\mathbf{e}_2}{2} + (\omega^{(i)}+\omega^{(j)})\frac{x_1\mathbf{e}_2}{2} \approx \mathbf{u}^{\mathrm{a}}\left(x_1, \pm\frac{h}{2}\right),\end{aligned}$$

where $\mathbf{u}^{\mathrm{a}}$ is an approximation of the velocity field near the axis of the gap (i.e., for $x_1/a^{ij} \ll 1$, where the density of the dissipation rate is highest). The boundary conditions on $\mathbf{u}^{\mathrm{a}}$ are

$$\begin{aligned}\mathbf{u}^{\mathrm{a}}\left(x_1, \pm\frac{h}{2}\right) = &\pm(T_1^{(i)} - T_1^{(j)} + a_i\omega^{(i)} + a_j\omega^{(j)})\frac{\mathbf{e}_1}{2}\\ &\pm(T_2^{(i)} - T_2^{(j)})\frac{\mathbf{e}_2}{2} \pm (\omega^{(i)}-\omega^{(j)})\frac{x_1\mathbf{e}_2}{2}\\ &+(T_1^{(i)} + T_1^{(j)} + a_i\omega^{(i)} - a_j\omega^{(j)})\frac{\mathbf{e}_1}{2}\\ &+(T_2^{(i)} + T_2^{(j)})\frac{\mathbf{e}_2}{2} + (\omega^{(i)}+\omega^{(j)})\frac{x_1\mathbf{e}_2}{2},\end{aligned}$$

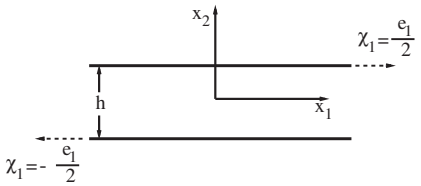

FIG. 4. *The setup for the calculation of* $\boldsymbol{\chi}_1$.

and, using the linearity of the problem, we decompose $\mathbf{u}^{\mathrm{a}}$ as

$$\mathbf{u}^{\mathrm{a}} = (T_1^{(i)} - T_1^{(j)} + a_i\omega^{(i)} + a_j\omega^{(j)})\boldsymbol{\chi}_1 + (T_2^{(i)} - T_2^{(j)})\boldsymbol{\chi}_2 + (\omega^{(i)} - \omega^{(j)})\boldsymbol{\lambda} + \boldsymbol{\mathcal{R}}, \tag{4.2}$$

where $\boldsymbol{\chi}_1, \boldsymbol{\chi}_2, \boldsymbol{\lambda}$, and $\boldsymbol{\mathcal{R}}$ are elementary velocity fields satisfying

$$\boldsymbol{\chi}_k\left(x_1, \frac{h}{2}\right) = -\boldsymbol{\chi}_k\left(x_1, -\frac{h}{2}\right) = \frac{1}{2}\mathbf{e}_k, \quad k = 1, 2, \tag{4.3}$$

$$\boldsymbol{\lambda}\left(x_1, \frac{h}{2}\right) = -\boldsymbol{\lambda}\left(x_1, -\frac{h}{2}\right) = \frac{x_1}{2}\mathbf{e}_2, \tag{4.4}$$

$$\begin{aligned}\boldsymbol{\mathcal{R}}\left(x_1, \pm\frac{h}{2}\right) &= [T_2^{(i)} + T_2^{(j)} + (\omega^{(i)} + \omega^{(j)})x_1]\frac{\mathbf{e}_2}{2} \\ &\quad + (T_1^{(i)} + T_1^{(j)} + a_i\omega^{(i)} - a_j\omega^{(j)})\frac{\mathbf{e}_1}{2}.\end{aligned} \tag{4.5}$$

We approximate all elementary velocity fields in the decomposition (4.2) by solving the simplified Stokes flow problem between two parallel plates at distance h (treated as constant) apart.

Clearly, velocity field

$$\boldsymbol{\mathcal{R}}(x_1, x_2) = [T_2^{(i)} + T_2^{(j)} + (\omega^{(i)} + \omega^{(j)})x_1]\frac{\mathbf{e}_2}{2} + (T_1^{(i)} + T_1^{(j)} + a_i\omega^{(i)} - a_j\omega^{(j)})\frac{\mathbf{e}_1}{2} \tag{4.6}$$

is divergence free and satisfies (2.7) for a constant pressure field. Moreover, its rate of strain is uniformly bounded in the asymptotic limit $\delta^{ij}/a^{ij} \to 0$ and the contribution of $\boldsymbol{\mathcal{R}}$ to the local dissipation rate in Π^{ij} is negligible.

Velocity field $\boldsymbol{\chi}_1$. As we zoom in near the axis of the centers $\mathbf{x}^{(i)}$ and $\mathbf{x}^{(j)}$, the top and bottom boundaries of Π^{ij} which belong to ∂D_i and $\partial D^{(j)}$, respectively, are approximated by parallel planes which move in opposite directions, as shown in Figure 4. Using separation of variables, we find

$$\boldsymbol{\chi}_1(x_1, x_2) = \left[\frac{x_2}{h} + \frac{C}{2\mu}\left(x_2^2 - \frac{h^2}{4}\right)\right]\mathbf{e}_1. \tag{4.7}$$

Integrating,[3] we obtain

$$W^{\chi_1}_{\Pi^{ij}} = \frac{\mu}{4}\int_{-a^{ij}}^{a^{ij}} dx_1 \int_{-\frac{h(x_1)}{2}}^{\frac{h(x_1)}{2}} dx_2 \left(\nabla\boldsymbol{\chi}_1 + \nabla\boldsymbol{\chi}_1^T, \nabla\boldsymbol{\chi}_1 + \nabla\boldsymbol{\chi}_1^T\right) \approx \frac{\pi\mu}{2}\sqrt{\frac{a^{ij}}{\delta^{ij}}} + O(1). \tag{4.8}$$

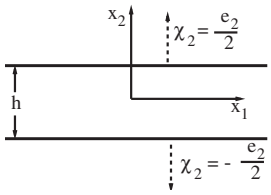

FIG. 5. *The setup for the calculation of* $\boldsymbol{\chi}_2$.

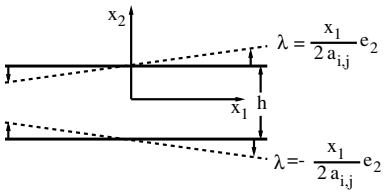

FIG. 6. *The setup for the calculation of* $\boldsymbol{\lambda}$.

Velocity field $\boldsymbol{\chi}_2$. We approximate $\boldsymbol{\chi}_2$ by the velocity of an incompressible fluid between two parallel plates which move at constant speed away from each other along the axis $\mathbf{e}_2$ (see Figure 5). Separating variables, we obtain

$$\boldsymbol{\chi}_2(x_1,x_2) \approx \frac{6x_1}{h}\left(\frac{x_2^2}{h^2}-\frac{1}{4}\right)\mathbf{e}_1 + \left[\frac{3x_2}{2h} - 2\left(\frac{x_2}{h}\right)^3\right]\mathbf{e}_2, \tag{4.9}$$

$$p(x_1,x_2) \approx \frac{6\mu x_1^2}{h^3} - \frac{6\mu}{h}\left(\frac{x_2^2}{h^2}-\frac{1}{4}\right) + C. \tag{4.10}$$

Then,

$$\begin{aligned} W_{\Pi^{ij}}^{\chi_2} &= \frac{\mu}{4}\int_{-a^{ij}}^{a^{ij}} dx_1 \int_{-\frac{h(x_1)}{2}}^{\frac{h(x_1)}{2}} dx_2 \left(\nabla\boldsymbol{\chi}_2 + \nabla\boldsymbol{\chi}_2^T, \nabla\boldsymbol{\chi}_2 + \nabla\boldsymbol{\chi}_2^T\right) \\ &\approx \frac{3\pi\mu}{4}\left(\frac{a^{ij}}{\delta^{ij}}\right)^{\frac{3}{2}} + \frac{12\pi\mu}{5}\sqrt{\frac{a^{ij}}{\delta^{ij}}} + O(1). \end{aligned} \tag{4.11}$$

Velocity field $\boldsymbol{\lambda}$. The setup for the calculation of $\boldsymbol{\lambda}$ is shown in Figure 6. In this case, the approximate solution is

$$\boldsymbol{\lambda}(x_1,x_2) \approx \frac{3x_1^2}{h}\left(\frac{x_2^2}{h^2}-\frac{1}{4}\right)\mathbf{e}_1 + \left(\frac{3x_1}{2}\frac{x_2}{h} - 2\frac{x_1x_2^3}{h^3}\right)\mathbf{e}_2, \tag{4.12}$$

$$p(x_1,x_2) \approx \frac{2\mu x_1^3}{h^3} - \frac{6\mu x_1}{h}\left(\frac{x_2^2}{h^2}-\frac{1}{4}\right), \tag{4.13}$$

and

$$W_{\Pi^{ij}}^{\lambda} = \frac{\mu}{4}\int_{x_1=-a^{ij}}^{a^{ij}} dx_1 \int_{x_2=-\frac{h(x_1)}{2}}^{\frac{h(x_1)}{2}} dx_2 (\nabla\boldsymbol{\lambda} + \nabla\boldsymbol{\lambda}^T, \nabla\boldsymbol{\lambda} + \nabla\boldsymbol{\lambda}^T) \approx \frac{9\pi\mu}{16}\sqrt{\frac{a^{ij}}{\delta}}(a^{ij})^2 + O(1). \tag{4.14}$$

[3]The integration is done in MAPLE.

Finally, using straightforward MAPLE calculations, we find that the contributions to $W_{\Pi^{ij}}$ of all the cross terms such as $(\nabla\boldsymbol{\chi}_1 + \nabla\boldsymbol{\chi}_1^T, \nabla\boldsymbol{\chi}_2 + \nabla\boldsymbol{\chi}_2^T)$ is $O(1)$. Gathering all the results, we have

$$
\begin{aligned}
W_{\Pi^{ij}} \approx & \left[\frac{3\pi\mu}{4}\left(\frac{a^{ij}}{\delta^{ij}}\right)^{\frac{3}{2}} + \frac{12\pi\mu}{5}\sqrt{\frac{a^{ij}}{\delta^{ij}}}\right](T_2^{(i)} - T_2^{(j)})^2 \\
& + \frac{\pi\mu}{2}\sqrt{\frac{aij}{\delta^{ij}}}(T_1^{(i)} - T_1^{(j)} + a_i\omega^{(i)} + a_j\omega^{(j)})^2 \\
& + \frac{9\pi\mu}{16}\sqrt{\frac{a^{ij}}{\delta^{ij}}}(a^{ij})^2(\omega^{(i)} - \omega^{(j)})^2 + O(1).
\end{aligned} \tag{4.15}
$$

This is precisely the result (3.12), and the approximation E^{a} of the viscous dissipation rate in the suspension is obtained by summing contributions (4.15) of all the gaps, as explained in section 3.2.

5. The upper bound. Any test velocity field $\mathbf{u} \in \mathcal{U}$ gives an upper bound on the viscous dissipation rate E when used in variational principle (2.20). However, of all choices of $\mathbf{u}$, we are interested in those that give tight, correct-to-leading-orders bounds on E. In this section, we give the construction of such a velocity field in two dimensions. We begin with the construction of $\mathbf{u}$ in the gap Π^{ij} between two adjacent particles $D^{(i)}$ and $D^{(j)}$ (see section 5.1), and, to capture the important features of the flow, we use the formal asymptotic analysis of section 4 as a guide. Then in section 5.2, we extend $\mathbf{u}$ to the remainder of the domain, where the flow is diffuse and, as such, contributes to $O(1)$ terms in E.

5.1. Definition of the trial velocity field u in a gap $\boldsymbol{\Pi^{ij}}$. The local construction of section 4 captures the important features of the flow in the gap Π^{ij} between adjacent particles $D^{(i)}$ and $D^{(j)}$. However, since the gap thickness $h(x_1)$ is not a constant (as it is treated in section 4), $\mathbf{u}^{\mathrm{a}}$ derived in section 4 is not divergence free and, therefore, it is not an admissible trial field in variational principle (2.20). In this section, we modify the velocity field calculated in section 4 in such a way that the incompressibility condition is satisfied and yet the effect of the corrections on E is minimal.

Using (4.1), (4.2), and the linearity of the problem, we decompose trial velocity field $\mathbf{u}$ as

$$
\begin{aligned}
\mathbf{u}(\mathbf{x}) = & (T_1^{(i)} - T_1^{(j)} + a_i\omega^{(i)} + a_j\omega^{(j)})\boldsymbol{\chi}_1(\mathbf{x}) + (T_2^{(i)} - T_2^{(j)})\boldsymbol{\chi}_2(\mathbf{x}) \\
& + (\omega^{(i)} - \omega^{(j)})\boldsymbol{\lambda}(2) + \boldsymbol{\mathcal{R}}(\mathbf{x}) + \boldsymbol{\mathcal{C}}(\mathbf{x}),
\end{aligned} \tag{5.1}
$$

where $\boldsymbol{\mathcal{R}}$ is given by (4.6), $\boldsymbol{\chi}_1, \boldsymbol{\chi}_2$, and $\boldsymbol{\lambda}$ satisfy boundary conditions (4.3) and (4.4), and

$$
\begin{aligned}
\boldsymbol{\mathcal{C}}\left(x_1, \pm\frac{h(x_1)}{2}\right) = & \left(\sqrt{1 - \frac{x_1^2}{a_i^2}} + \sqrt{1 - \frac{x_1^2}{a_j^2}} - 2\right)\left(\pm\frac{\omega^{(i)} + \omega^{(j)}}{2} + \frac{\omega^{(i)} - \omega^{(j)}}{2}\right)\frac{\mathbf{e}_1}{2} \\
& + \left(\sqrt{1 - \frac{x_1^2}{a_i^2}} - \sqrt{1 - \frac{x_1^2}{a_j^2}}\right)\left(\pm\frac{\omega^{(i)} - \omega^{(j)}}{2} + \frac{\omega^{(i)} + \omega^{(j)}}{2}\right)\frac{\mathbf{e}_1}{2}.
\end{aligned} \tag{5.2}
$$

Elementary velocity fields $\boldsymbol{\chi}_1, \boldsymbol{\chi}_2$, and $\boldsymbol{\lambda}$ have been approximated in section 4. Here, we modify their expression to ensure that they are divergence free in the gap of variable thickness $h(x_1)$. Velocity field $\boldsymbol{\mathcal{C}}$ accounts for the curvature of the gap and it has been omitted in section 4. In this section, we calculate an admissible field $\boldsymbol{\mathcal{C}}$ and we show that its influence on E is $O(1)$.

Velocity field $\boldsymbol{\chi}_1$. Using the formal asymptotic analysis of section 4, we have that

$$\boldsymbol{\chi}_1(x_1, x_2) \sim \frac{x_2}{h(x_1)}\mathbf{e}_1. \tag{5.3}$$

However, the right-hand side in (5.3) is not divergence free, so we correct (5.3) as

$$\boldsymbol{\chi}_1(x_1, x_2) = \nabla^\perp F(x_1, x_2), \quad \text{where } F(x_1, x_2) = -\frac{x_2^2}{2h(x_1)} - \frac{h(x_1)}{8} \tag{5.4}$$

and $\nabla^\perp = (-\partial/\partial x_2, \partial/\partial x_1)$. Then,

$$\boldsymbol{\chi}_1(x_1, x_2) = \frac{x_2}{h(x_1)}\mathbf{e}_1 + \frac{1}{2}\frac{dh(x_1)}{dx_1}\left(\frac{x_2^2}{h^2(x_1)} - \frac{1}{4}\right)\mathbf{e}_2, \quad \text{div}\boldsymbol{\chi}_1(x_1, x_2) = 0 \tag{5.5}$$

and, on the top/bottom parts of boundary $\partial\Pi^{ij}$, $\boldsymbol{\chi}_1(x_1, x_2 = \pm h(x_1)/2) = \pm\mathbf{e}_1/2$. The calculation of local rate of dissipation $W^{\chi_1}_{\Pi^{ij}}$ is now straightforward and the result coincides with (4.8).

Velocity field $\boldsymbol{\chi}_2$. The formal asymptotic analysis of section 4 gives

$$\boldsymbol{\chi}_2(x_1, x_2) \sim \frac{6x_1}{h(x_1)}\left(\frac{x_2^2}{h^2(x_1)} - \frac{1}{4}\right)\mathbf{e}_1 + \left[\frac{3x_2}{2h(x_1)} - 2\left(\frac{x_2}{h(x_1)}\right)^3\right]\mathbf{e}_2, \tag{5.6}$$

but, since h is, in truth, a function of x_1, (5.6) is not divergence free and cannot be used as such in the upper bound calculation. Instead, we define the trial field

$$\boldsymbol{\chi}_2(x_1, x_2) = \nabla^\perp F(x_1, x_2), \quad \text{where } F(x_1, x_2) = -\frac{2x_1x_2^3}{h^3(x_1)} + \frac{3x_1x_2}{2h(x_1)}. \tag{5.7}$$

The corresponding local dissipation rate $W^{\chi_2}_{\Pi^{ij}}$ is

$$W^{\chi_2}_{\Pi^{ij}} = \frac{3\pi\mu}{4}\left(\frac{a^{ij}}{\delta^{ij}}\right)^{\frac{3}{2}} + \frac{27\pi\mu}{10}\sqrt{\frac{a^{ij}}{\delta^{ij}}} + O(1) \tag{5.8}$$

and we note that it coincides, with leading order, with (4.11).

Velocity field $\boldsymbol{\lambda}$. We define a divergence free trial field $\boldsymbol{\lambda}$, which is approximately equal to (4.12), as

$$\boldsymbol{\lambda}(x_1, x_2) = \nabla^\perp F(x_1, x_2), \quad \text{where } F(x_1, x_2) = \left(\frac{3x_1^2x_2}{4h(x_1)} - \frac{x_1^2x_2^3}{h^3(x_1)}\right), \tag{5.9}$$

Then $\boldsymbol{\lambda}(x_1, x_2 = \pm h(x_1)/2) = \pm\frac{x_1}{2}\mathbf{e}_2$, and the corresponding local rate of dissipation $W^{\lambda}_{\Pi^{ij}}$ is given by (4.14).

Velocity field $\boldsymbol{\mathcal{C}}(\mathbf{x})$. We define trial field $\boldsymbol{\mathcal{C}}(\mathbf{x})$ as

$$\boldsymbol{\mathcal{C}}(x_1, x_2) = (\omega^{(i)} + \omega^{(j)})\nabla^\perp F(x_1, x_2) + (\omega^{(i)} - \omega^{(j)})\nabla^\perp G(x_1, x_2), \tag{5.10}$$

where

$$F(x_1,x_2) = \left(1-\frac{1}{2}\sqrt{1-\frac{x^2}{a_i^2}}-\frac{1}{2}\sqrt{1-\frac{x^2}{a_j^2}}\right)\left(\frac{x_2^2}{2h(x_1)}+\frac{h(x_1)}{8}\right)$$

$$+\int_0^{x_1}\frac{h(s)}{8}\frac{d}{ds}\left(\sqrt{1-\frac{s^2}{a_i^2}}+\sqrt{1-\frac{s^2}{a_i^2}}\right)ds$$

$$+\left(\frac{1}{2}\sqrt{1-\frac{x_1^2}{a_i^2}}-\frac{1}{2}\sqrt{1-\frac{x_1^2}{a_j^2}}\right)\left(-\frac{x_2}{2}+\frac{3h(x_1)x_2}{2}-\frac{2x_2^3}{h(x_1)}\right)$$

$$-\int_0^{x_1}\left(\frac{3h(s)x_2}{2h(x_1)}-\frac{2h(s)x_2^3}{h^3(x_1)}\right)\times\left[\left(\frac{1}{4}-\frac{h(s)}{2}\right)\left(\frac{s/a_i^2}{\sqrt{1-s^2/a_i^2}}-\frac{s/a_j^2}{\sqrt{1-s^2/a_j^2}}\right)\right.$$

$$\left.+\frac{dh(s)}{ds}\left(\sqrt{1-s^2/a_i^2}-\sqrt{1-s^2/a_j^2}\right)\right]ds$$

and

$$G(x_1,x_2) = -\left(\frac{1}{2}\sqrt{1-\frac{x_1^2}{a_i^2}}-\frac{1}{2}\sqrt{1-\frac{x_1^2}{a_j^2}}\right)\left(\frac{x_2^2}{2h(x_1)}-\frac{h(x_1)}{4}\right)$$

$$-\frac{1}{4}\int_0^{x_1}\frac{dh(s)}{ds}\frac{\sqrt{1-s^2/a_i^2}-\sqrt{1-s^2/a_j^2}}{2}ds$$

$$+\frac{x_2}{2}+\frac{\sqrt{1-x_1^2/a_i^2}+\sqrt{1-x_1^2/a_j^2}}{2}\left(-\frac{x_2}{2}+\frac{3h(x_1)x_2}{2}-\frac{2x_2^3}{h(x_1)}\right)$$

$$-\int_0^{x_1}\left(\frac{3h(s)x_2}{2h(x_1)}-\frac{2h(s)x_2^3}{h^3(x_1)}\right)\times\left[\left(\frac{1}{4}-\frac{h(s)}{2}\right)\left(\frac{s/a_i^2}{\sqrt{1-s^2/a_i^2}}+\frac{s/a_j^2}{\sqrt{1-s^2/a_j^2}}\right)\right.$$

$$\left.+\frac{dh(s)}{ds}\left(\sqrt{1-s^2/a_i^2}+\sqrt{1-s^2/a_j^2}\right)\right]ds.$$

Although the expression (5.10) is rather complicated, it can be checked with straightforward calculations (which we have done in MAPLE) that it satisfies boundary conditions (5.2) and, as such, it is an admissible trial field, which gives a local rate of dissipation $W^{\mathcal{C}}_{\Pi^{ij}} = O(1)$.

Finally, we find through MAPLE calculations that the contribution of the cross terms to $W_{\Pi^{ij}}$ is $O(1)$.

We have now defined a trial velocity field that satisfies the exact boundary conditions on the top and bottom boundaries of the gap Π^{ij}, is divergence free, and, most important, gives an upper bound on the gap dissipation rate which agrees, with leading order, with the formal asymptotic result of section 4.

5.2. Extension of the trial velocity field u outside the gaps between the particles in suspension. Let us denote the union of all gaps by U_Π and define the complement in Ω_F of the union of all gaps

$$U_E = \Omega_F \setminus U_\Pi. \tag{5.11}$$

We wish to extend the trial velocity field $\mathbf{u}$ from the gaps Π^{ij} to U_E, so that the leading order terms of the dissipation rate are not affected. Clearly, when there are many particles in the suspension, the set U_E is the union of many disjoint, connected components, which we denote by C_j. Let us then focus attention on one such component and drop the subscript j. To avoid boundary corners in the connected component C, we take a slightly larger domain $\tilde{C} \subset \Omega_F$ such that $C \subset \tilde{C}$ and $\partial\tilde{C}$ is smooth.[4] Note that the construction of section 5.1 gives a trial velocity of the form $\mathbf{u} = \nabla^\perp F$ and, since the gap thickness is $h = O(a) \gg \delta^{ij}$ at $\partial\Pi^{ij} \cap \partial\tilde{\mathcal{C}}$, the first and second derivatives of F are uniformly bounded on $\partial\tilde{\mathcal{C}}$, as $\delta \to 0$. We now wish to extend $\mathbf{u}$ to the interior of $\tilde{C}$.

Let us take a $\gamma > 0$, independent of δ, and define the boundary layer

$$C_\gamma = \{\mathbf{x} \in \tilde{C} \text{ such that } \operatorname{dist}(\mathbf{x}, \partial\tilde{C}) < \gamma\}. \tag{5.12}$$

Since the arcs in $\partial\tilde{C}$ are independent of δ, we can choose a cover $\mathcal{P}_j$, $j = 1, 2, \ldots, J$ independent of δ, and a subordinate partition of unity ϕ_j with support $\phi_j = \tilde{\mathcal{P}}_j \subset \mathcal{P}_j$ such that $\tilde{\mathcal{P}}_j \cap \tilde{C} \subset C_\gamma$. Then let us extend $\mathbf{u}$ in $\tilde{\mathcal{P}}_j$ and, for simplicity of notation, drop the index j.

In $\tilde{\mathcal{P}}$, define local coordinates $\mathbf{y} = (y_1, y_2)$, such that $y_2 = 0$ at $\partial\tilde{\mathcal{P}} \cap \partial\tilde{\mathcal{C}}$, and $\tilde{\mathcal{P}} \cap \tilde{\mathcal{C}}$ is mapped into a tensor product of intervals $I_1(y_1) \times I_2(y_2)$, for $y_2 > 0$. Take then a smooth function $g(y_2)$, which vanishes outside interval $I_2(y_2)$ and, at $y_2 = 0$, $g(0) = 1$, and define the extension of F, from $\tilde{\mathcal{P}} \cap \partial\tilde{\mathcal{C}}$ to $\tilde{\mathcal{P}} \cap \tilde{\mathcal{C}}$, as[5]

$$F(y_1, y_2) = g(y_2)\left[F(y_1, 0) + y_2 \frac{\partial F(y_1, 0)}{\partial y_2}\right]. \tag{5.13}$$

Clearly, the extended F is smooth and its first derivatives are equal to the previously specified values on $\tilde{\mathcal{P}} \cap \partial\tilde{\mathcal{C}}$. We also have

$$\|F(y_1, y_2)\|_{H^2(I_1 \times I_2)} \le A \tag{5.14}$$

with A, independent of δ. Repeating the same procedure, we extend F to all $\tilde{\mathcal{P}}_j \cap \tilde{\mathcal{C}}$, $j = 1, \ldots, J$, or, equivalently, to $\tilde{\mathcal{C}}$. Then, taking $\mathbf{u} = \nabla^\perp F$, we have div $\mathbf{u} = 0$, and the strain tensor $\mathcal{E}(\mathbf{u})$ with components in $L^2(\tilde{C})$ and a corresponding viscous dissipation rate

$$\int_{\tilde{C}} \mu\left(\mathcal{E}(\mathbf{u}), \mathcal{E}(\mathbf{u})\right) d\mathbf{x} \le A|\tilde{C}|. \tag{5.15}$$

We end this section with the remark that it is not necessary that $\tilde{C}$ lie inside Ω_F for estimate (5.15) to hold (see Figure 7). Indeed, even if the connected component C

[4] $\partial\tilde{C}$ is the union of arcs which lie either inside a gap Π^{ij} or on the boundary of a surrounding particle.

[5] Note that (5.13) is a simplified version of the classic Borel construction in [18, Theorem 1.2.6].

intersects the exterior boundary $\partial\Omega$, we can always extend F to a smooth H^2 function supported away from the corners of $\partial\Omega$, and (5.15) follows.

Gathering all the results in this section, we have, in the notation of section 3.2.1, the upper bound

(5.16)
$$
\begin{aligned}
E \le \min_{\mathbf{T},\omega} \sum_{i=1}^{N} \sum_{\substack{j\,\in\,\mathcal{N}_i \\ j\,<\,i}} & \left\{ \left[\frac{3\pi\mu}{4} \left(\frac{a^{ij}}{\delta^{ij}} \right)^{\frac{3}{2}} + \frac{27\pi\mu}{10} \sqrt{\frac{a^{ij}}{\delta^{ij}}} \right] [(\mathbf{T}^{(i)} - \mathbf{T}^{(j)}) \cdot \mathbf{q}^{ij}]^2 \right. \\
& + \frac{\pi\mu}{2} \sqrt{\frac{a^{ij}}{\delta^{ij}}} [(\mathbf{T}^{(i)} - \mathbf{T}^{(j)}) \cdot \mathbf{p}^{ij} + a_i \omega^{(i)} + a_j \omega^{j}]^2 \\
& \left. + \frac{9\pi\mu}{16} \sqrt{\frac{a^{ij}}{\delta^{ij}}} \left(\omega^{(i)} a^{ij} - \omega^{(j)} a^{ij} \right)^2 \right\} \\
& + \sum_{i \in \mathcal{B}} \left\{ \left[\frac{3\pi\mu}{4} \left(\frac{2a_i}{\delta^i} \right)^{\frac{3}{2}} + \frac{27\pi\mu}{10} \sqrt{\frac{2a_i}{\delta^i}} \right] [(\mathbf{T}^{(i)} - \mathbf{g}) \cdot \mathbf{q}^{i}]^2 \right. \\
& \qquad + \frac{9\pi\mu}{16} \sqrt{\frac{2a_i}{\delta^i}} (2\omega^{(i)})^2 (a^{ij})^2 \\
& \qquad \left. + \frac{\pi\mu}{2} \sqrt{\frac{2a_i}{\delta^i}} [(\mathbf{T}^{(i)} - \mathbf{g}) \cdot \mathbf{p}^{i} + a_i \omega^{(i)}]^2 \right\} + O(1),
\end{aligned}
$$

where, for the boundary nodes $i \in \mathcal{B}$, δ^i is the distance between $\partial D^{(i)}$ and the upper or lower boundary $\partial\Omega^{\pm}$.

6. Rigorous justification of the leading-order spring network approximation. In this section, we derive and justify rigorously the spring network approximation in two dimensions (recall section 3.2.1) by constructing a lower bound on E, which agrees with (5.16), to $O\big(\big(\frac{a}{\delta}\big)^{\frac{3}{2}}\big)$.

6.1. A simplified upper bound. Since the leading order term is not affected by the rotations of the particles, we set in (5.16) $\omega^{(i)} = 0$ for all $i = 1, \dots, N$, and we obtain a less precise but simplified upper bound

(6.1)
$$
\begin{aligned}
E \le W_{\Omega_F}(\mathbf{u}) = \min_{\mathbf{T}} \sum_{i=1}^{N} \sum_{\substack{j\,\in\,\mathcal{N}_i \\ j\,<\,i}} & \left\{ \left[\frac{3\pi\mu}{4} \left(\frac{a^{ij}}{\delta^{ij}} \right)^{\frac{3}{2}} + \frac{27\pi\mu}{10} \sqrt{\frac{a^{ij}}{\delta^{ij}}} \right] [(\mathbf{T}^{(i)} - \mathbf{T}^{(j)}) \cdot \mathbf{q}^{ij}]^2 \right. \\
& \left. + \frac{\pi\mu}{2} \sqrt{\frac{a^{ij}}{\delta^{ij}}} [(\mathbf{T}^{(i)} - \mathbf{T}^{(j)}) \cdot \mathbf{p}^{ij}]^2 \right\} + \sum_{i \in \mathcal{B}} \left\{ \left[\frac{3\pi\mu}{4} \left(\frac{2a_i}{\delta^i} \right)^{\frac{3}{2}} + \frac{27\pi\mu}{10} \sqrt{\frac{2a_i}{\delta^i}} \right] [(\mathbf{T}^{(i)} - \mathbf{g}) \cdot \mathbf{q}^{i}]^2 \right. \\
& \qquad \left. + \frac{\pi\mu}{2} \sqrt{\frac{2a_i}{\delta^i}} [(\mathbf{T}^{(i)} - \mathbf{g}) \cdot \mathbf{p}^{i}]^2 \right\} + O(1).
\end{aligned}
$$

Except for the $O(1)$ term, the right-hand side of (6.1) involves the minimization of a quadratic form in the translation velocities $\mathbf{T}^{(i)}$ for $i = 1, \dots, N$, and the minimum

is achieved by the solution of the linear system of equations,

$$\sum_{j\in\mathcal{N}_i}\left\{\left[\frac{3\pi\mu}{4}\left(\frac{a^{ij}}{\delta^{ij}}\right)^{\frac{3}{2}}+\frac{27\pi\mu}{10}\sqrt{\frac{a^{ij}}{\delta^{ij}}}\right][(\mathbf{T}^{(i)}-\mathbf{T}^{(j)})\cdot\mathbf{q}^{ij}]\mathbf{q}^{ij}\right.$$
$$\left.+\frac{\pi\mu}{2}\sqrt{\frac{a^{ij}}{\delta^{ij}}}[(\mathbf{T}^{(i)}-\mathbf{T}^{(j)})\cdot\mathbf{p}^{ij}]\mathbf{p}^{ij}\right\}+\mathbf{F}_{\mathcal{B}}(\mathbf{T}^{(i)})=\mathbf{0}\quad\text{for } 1\le i\le N, \tag{6.2}$$

where

$$\mathbf{F}_{\mathcal{B}}(\mathbf{T}^{(i)})$$
$$=\begin{cases}\left[\dfrac{3\pi\mu}{4}\left(\dfrac{2a_i}{\delta^i}\right)^{\frac{3}{2}}+\dfrac{27\pi\mu}{10}\sqrt{\dfrac{2a_i}{\delta^i}}\right][(\mathbf{T}^{(i)}-\mathbf{g})\cdot\mathbf{q}^i]\mathbf{q}^i+\dfrac{\pi\mu}{2}\sqrt{\dfrac{2a_i}{\delta^i}}[(\mathbf{T}^{(i)}-\mathbf{g})\cdot\mathbf{p}^i]\mathbf{p}^i & \text{if } i\in\mathcal{B},\\ \mathbf{0} \text{ otherwise.}\end{cases} \tag{6.3}$$

Next, we prove the unique solvability of these equations.

PROPOSITION 6.1. *The linear system of* (6.2) *has a unique solution,*

$$\boldsymbol{\tau}=(T_1^{(1)},T_2^{(1)},\dots,T_1^{(N)},\dots,T_2^{(N)})^T\in\mathbb{R}^{2N},$$

where superscript T stands for transpose.

Proof. Let us write the upper bound (6.1) in compact form as

$$E\le\min_{\boldsymbol{\tau}}\,(\boldsymbol{\tau}\cdot A\boldsymbol{\tau}-2\boldsymbol{\tau}\cdot\mathbf{f})+r+O(1), \tag{6.4}$$

where matrix $A\in\mathbb{R}^{2N\times 2N}$ is symmetric, $\mathbf{f}\in\mathbb{R}^{2N}$, and $r\in\mathbb{R}$. We prove the unique solvability of (6.2) (i.e., of $A\boldsymbol{\tau}=\mathbf{f}$) by showing that A is positive definite. Since we take the limit $\delta\to 0$, we have from (6.1) and (6.4) that

$$\begin{aligned}\boldsymbol{\tau}\cdot A\boldsymbol{\tau}&=\sum_{i=1}^{N}\sum_{\substack{j\in\mathcal{N}_i\\ j<i}}\left\{\left[\frac{3\pi\mu}{4}\left(\frac{a^{ij}}{\delta^{ij}}\right)^{\frac{3}{2}}+\frac{27\pi\mu}{10}\sqrt{\frac{a^{ij}}{\delta^{ij}}}\right][(\mathbf{T}^{(i)}-\mathbf{T}^{(j)})\cdot\mathbf{q}^{ij}]^2\right.\\ &\quad\left.+\frac{\pi\mu}{2}\sqrt{\frac{a^{ij}}{\delta^{ij}}}[(\mathbf{T}^{(i)}-\mathbf{T}^{(j)})\cdot\mathbf{p}^{ij}]^2\right\}\\ &\quad+\sum_{i\in\mathcal{B}}\left\{\left[\frac{3\pi\mu}{4}\left(\frac{2a_i}{\delta^i}\right)^{\frac{3}{2}}+\frac{27\pi\mu}{10}\sqrt{\frac{2a_i}{\delta^i}}\right](\mathbf{T}^{(i)}\cdot\mathbf{q}^i)^2+\frac{\pi\mu}{2}\sqrt{\frac{2a_i}{\delta^i}}(\mathbf{T}^{(i)}\cdot\mathbf{p}^i)^2\right\}\\ &\ge C\delta^{-\frac{1}{2}}\sum_{i=1}^{N}\sum_{\substack{j\in\mathcal{N}_i\\ j<i}}[(\mathbf{T}^{(i)}-\mathbf{T}^{(j)})\cdot\mathbf{q}^{ij}]^2+[(\mathbf{T}^{(i)}-\mathbf{T}^{(j)})\cdot\mathbf{p}^{ij}]^2\\ &\quad+C\delta^{-\frac{1}{2}}\sum_{i\in\mathcal{B}}[(\mathbf{T}^{(i)}\cdot\mathbf{q}^i)^2+(\mathbf{T}^{(i)}\cdot\mathbf{p}^i)^2]\\ &=C\delta^{-\frac{1}{2}}\left(\sum_{i=1}^{N}\sum_{\substack{j\in\mathcal{N}_i\\ j<i}}|\,\mathbf{T}^{(i)}-\mathbf{T}^{(j)}\,|^2+\sum_{i\in\mathcal{B}}|\,\mathbf{T}^{(i)}\,|^2\right)=\boldsymbol{\tau}\cdot\tilde{A}\boldsymbol{\tau},\end{aligned} \tag{6.5}$$

where C is independent of δ and matrix $\tilde{A}$ is clearly symmetric, nonnegative definite. To show that $\tilde{A}$ is, in fact, positive definite, let us suppose that there exists a nontrivial $\boldsymbol{\tau}$ in the null space of $\tilde{A}$. Then, by (6.5), we have $\mathbf{T}^{(i)} - \mathbf{T}^{(j)} = 0$ for $i = 1, \dots, N$, $j \in \mathcal{N}_i$, and $\mathbf{T}^{(i)} = 0$ for $i \in \mathcal{B}$. Since the graph Γ is connected (Property 3.1), this implies $\mathbf{T}^{(i)} = 0$ for all $i = 1, \dots, N$ or, equivalently, $\boldsymbol{\tau} = \mathbf{0}$. However, this contradicts our initial assumption on $\boldsymbol{\tau}$, so the null space of $\tilde{A}$ must be trivial. This implies, in turn, that A is positive definite and that the linear system of (6.2) is uniquely solvable. ∎

Remark 6.1. In the remainder of this paper, we denote by $\mathbf{u}$ the trial velocity field constructed in section 5, where all rotational velocities $\omega^{(i)}$ are set to zero and where translational velocities $\mathbf{T}^{(i)}$ solve linear system of equations (6.2) for $1 \le i \le N$. In particular, in gap Π^{ij}, connecting adjacent disks $D^{(i)}$ and $D^{(j)}$, the trial field is

$$\mathbf{u}(\mathbf{x}) = [(\mathbf{T}^{(i)} - \mathbf{T}^{(j)}) \cdot \mathbf{e}_1]\boldsymbol{\chi}_1(\mathbf{x}) + [(\mathbf{T}^{(i)} - \mathbf{T}^{(j)}) \cdot \mathbf{e}_2]\boldsymbol{\chi}_2(\mathbf{x}) + \frac{1}{2}(\mathbf{T}^{(i)} + \mathbf{T}^{(j)}), \tag{6.6}$$

where $\boldsymbol{\chi}_1$ and $\boldsymbol{\chi}_2$ are given by (5.5) and (5.7), respectively. Note that this trial field yields upper bound (see (6.1))

$$E \le W_{\Omega_F}(\mathbf{u}) \tag{6.7}$$

when used in variational principle (2.20).

6.2. Lower Bound.

6.2.1. Outline of the construction. Given a subdomain M of Ω_F, define a functional

$$W_M^*(\mathcal{S}) = \int_{\partial\Omega \cap \bar{M}} \mathbf{g} \cdot \mathcal{S}\mathbf{n} ds - \int_M F(\mathcal{S}) d\mathbf{x}, \tag{6.8}$$

where $\bar{M}$ is the closure of M, $\mathbf{g}$ is defined by (2.9),

$$F(\mathcal{S}) = \frac{1}{4\mu}\left[(\mathcal{S}, \mathcal{S}) - \frac{1}{2}(\text{trace } \mathcal{S})^2\right], \tag{6.9}$$

and $\mathcal{S}$ is a symmetric (stress) tensor in $\mathcal{F}$. In the context of this paper, subdomain M stands for either a gap Π^{ij} between adjacent particles or a connected component $\mathcal{C}$ in U_E, where the flow is diffuse (see section 5.2). Then $W_{\Omega_F}^*$ is given by the sum of $W_M^*(\mathcal{S})$ for all such disjoint subdomains in Ω_F. For any $\mathcal{S} \in \mathcal{F}$, we have by dual variational principle (2.22)

$$W_{\Omega_F}^\star(\mathcal{S}) \le E \le W_{\Omega_F}(\mathbf{u}). \tag{6.10}$$

Our goal in this section is to construct a trial tensor $\mathcal{S} \in \mathcal{F}$ such that $W_{\Omega_F}^\star(\mathcal{S})$ matches leading order upper bound $W_{\Omega_F}(\mathbf{u})$.

The construction of the trial tensor $\mathcal{S}$ proceeds as follows.

Step 1. In an ideal case, where $\hat{\mathbf{u}}$ and $\hat{\mathcal{S}}$, the minimizer and maximizer of the direct and dual problems (2.20) and (2.22), respectively, would be known, the constitutive equations for the incompressible fluid would give

$$\int_M F(\hat{\mathcal{S}}) d\mathbf{x} = W_M(\hat{\mathbf{u}}) = \mu \int_M (\mathcal{E}(\mathbf{u}), \mathcal{E}(\mathbf{u}))\, d\mathbf{x}, \tag{6.11}$$

and, by integration by parts,

$$\int_{\partial\Omega\cap\bar{M}} \mathbf{g}\cdot\hat{\mathcal{S}}\mathbf{n}\,ds = 2W_M(\hat{\mathbf{u}}). \tag{6.12}$$

However, we don't know $\hat{\mathbf{u}}$, so we use instead trial velocity field $\mathbf{u}$ described in Remark 6.1. With this $\mathbf{u}$, we find, as a first step in our construction, an approximate pressure P and the corresponding approximate stress tensor $\mathcal{S}_0 = 2\mu\mathcal{E}(\mathbf{u}) - P\mathcal{I}$.

For this purpose, let us focus on a gap Π^{ij}, where $\mathcal{S}_0$ satisfies

$$\int_{\Pi^{ij}} F(\mathcal{S}_0)d\mathbf{x} = W_{\Pi^{ij}}(\mathbf{u}) = O\left(\left(\frac{a^{ij}}{\delta^{ij}}\right)^{\frac{3}{2}}\right). \tag{6.13}$$

Note, however, that $\mathcal{S}_0 \notin \mathcal{F}$ because $\mathrm{div}\mathcal{S}_0 \neq \mathbf{0}$, so we define the trial tensor in Π^{ij} as

$$\mathcal{S} = \mathcal{S}_0 - \mathcal{K},$$

where $\mathcal{K}$ is a compensating tensor chosen such that $\mathrm{div}\,(\mathcal{S}_0 - \mathcal{K}) = 0$ in Π, and

$$\int_{\Pi^{ij}} F(\mathcal{S})d\mathbf{x} = W_{\Pi^{ij}}(\mathbf{u}) + O\left(\sqrt{\frac{a^{ij}}{\delta^{ij}}}\right). \tag{6.14}$$

Step 2. This is the crucial step in the construction of the lower bound. In Step 1, we obtained tensor $\mathcal{S}(\mathbf{x})$ in Π^{ij} and, in particular, on the portion of $\partial D^{(j)}$ which belongs to the neck Π^{ij}. In the second step, we extend $\mathcal{S}$ to the remaining parts of $\partial D^{(j)}$, so that the net force and torque conditions (2.12) hold. Such an extension cannot be constructed for each $\partial D^{(j)}$ individually. Recall that U_Π is the union of all gaps. For each connected component $\mathcal{C}$ of the set $U_E = \Omega_F\backslash U_\Pi$, where the flow is diffuse, we must have

$$\int_{\partial\mathcal{C}} \mathcal{S}\mathbf{n}\,ds = \mathbf{0} \tag{6.15}$$

for any divergence free extension of $\mathcal{S}$, from Π to $\mathcal{C}$. But, since each $\partial\mathcal{C}$ contains parts of the boundaries of several neighboring disks, the extensions of $\mathcal{S}$ to the boundaries of these disks must be coupled. An attempt to satisfy the balance of forces and torques (2.12) for an individual disk $D^{(j)}$ influences the balance on all neighboring disks. Since these disks have other neighbors as well (recall that the graph Γ is connected), the extension of $\mathcal{S}$ from the necks Π^{ij} to the remaining parts of $\partial D^{(j)}$, for $1 \le j \le N$, is a global problem.

Note that a similar difficulty arises in the scalar problem of electrical conduction [5], where a simple construction of the dual trial field (which is a vector flux) is given as follows. In a gap Π^{ij}, the dual trial field is taken as the vector $\mathbf{j} = (0, \zeta(x_1))$, where ζ is a smooth function of x_1, the local coordinate in the direction orthogonal to the axis of symmetry of the gap. Outside the union of all gaps, the dual trial field is extended to $\mathbf{0}$. While this choice satisfies the divergence-free condition locally in each subdomain of Ω_F, one must ensure that the total flux through $\partial D^{(j)}$ intersected with the union of all the gaps connected with $D^{(j)}$ is zero for all $1 \le j \le N$ as well. The latter condition is satisfied in [5] by setting

$$\int_{\partial D^{(i)}\cap\Pi^{ij}} \mathbf{j}\cdot\mathbf{n}^{(i)}\,ds = J_{\Pi^{ij}},$$

where J_Π is the net current flowing through the corresponding branch of the asymptotic network (graph Γ). More explicitly, the condition of flux balance at $\partial D^{(j)}$ is formulated as Kirchhoff's current law at the node $\mathbf{x}^{(j)}$ in the asymptotic network.

While in the scalar problem, the two conditions (divergence free and flux balance) on the dual trial field can be dealt with separately in the vectorial problem that we consider here, they appear to be coupled, and one cannot simply generalize the construction in [5] to find an admissible $\mathcal{S} \in \mathcal{F}$. We introduce in section 6.2.3 our novel construction of the extension of $\mathcal{S}$, which is divergence free and satisfies the momentum balance equations for all disks.

Step 3. Extend the tensor $\mathcal{S}$, defined so far in the gaps and at $\partial D^{(j)}$ for $1 \leq j \leq N$, to the whole Ω_F. The main point of this step is to control the energy of the extension in such a way that

$$W^*_{\Omega_F \setminus U_\Pi}(\mathcal{S}) \ll O(\delta^{-\frac{3}{2}}). \tag{6.16}$$

Step 4. In this step we gather all the results of the previous steps and show that $W_{\Omega_F}(\mathbf{u})$ and $W^\star_{\Omega_F}(\mathcal{S})$ are the same leading order.

6.2.2. The trial field $\mathcal{S}$ in a gap. We begin our construction of $\mathcal{S}$ in a gap Π^{ij}, with the help of velocity field (6.6). Recall from sections 4 and 5 that (6.6) is divergence free and, furthermore, it is an approximate solution of Stokes's equations in the following sense: if the gap thickness h were a constant, we would have curl $\triangle \mathbf{u} = 0$, the pressure would be well defined by $\mu \triangle u = \nabla P$, and the stress

$$\mathcal{S}_0 = 2\mu \mathcal{E}(\mathbf{u}) - P\mathcal{I}$$

would be divergence free. However, in truth, gap Π^{ij} is not flat and the condition $\mathrm{div}\mathcal{S} = 0$ that any dual trial field $\mathcal{S}$ must satisfy needs to be ensured for the variable thickness $h(x_1)$. In that case, Δu is not a gradient of a scalar function, so we introduce an approximate pressure P and a compensating symmetric tensor $\mathcal{K}$ such that

$$\mathcal{S} = \mathcal{S}_0 - \mathcal{K} \tag{6.17}$$

is divergence free. Because $\mathrm{div}\,\mathbf{u} = 0$, we have

$$\begin{aligned} F(\mathcal{S}_0) &= \frac{1}{4\mu}\left[(\mathcal{S}_0, \mathcal{S}_0) - \frac{1}{2}(\mathrm{trace}\ \mathcal{S}_0)^2\right] \\ &= \frac{1}{4\mu}\left[(2\mu\mathcal{E}(\mathbf{u}) - P\mathcal{I}, 2\mu\mathcal{E}(\mathbf{u}) - P\mathcal{I}) - 2P^2\right] = \mu\left(\mathcal{E}(\mathbf{u}), \mathcal{E}(\mathbf{u})\right) \end{aligned}$$

and

$$\int_{\Pi^{ij}} F(\mathcal{S}_0) d\mathbf{x} = W_{\Pi^{ij}}(\mathbf{u}) = O\left(\frac{a^{ij}}{\delta^{ij}}^{\frac{3}{2}}\right), \tag{6.18}$$

so to get a lower bound that matches the upper one to leading order, we wish that

$$\int_{\Pi^{ij}} \left[F(\mathcal{S}) - F(\mathcal{S}_0)\right] d\mathbf{x} = O\left(\sqrt{\frac{a^{ij}}{\delta^{ij}}}\right). \tag{6.19}$$

This can be accomplished, for example, by choosing P and $\mathcal{K}$ to satisfy

$$\int_{\Pi^{ij}} (\mathcal{S}_0, \mathcal{K})\, d\mathbf{x} = O\left(\sqrt{\frac{a^{ij}}{\delta^{ij}}}\right) \text{ and } \int_{\Pi^{ij}} (\mathcal{K}, \mathcal{K})\, d\mathbf{x} = O\left(\sqrt{\frac{a^{ij}}{\delta^{ij}}}\right) \tag{6.20}$$

since

$$F(\mathcal{S}) - F(\mathcal{S}_0) = -2\,(\mathcal{S}_0, \mathcal{K}) + (\mathcal{K}, \mathcal{K}) + \text{trace } \mathcal{S}_0 \text{ trace } \mathcal{K} - \frac{1}{2}(\text{trace } \mathcal{K})^2.$$

Let us then begin our search for $\mathcal{K}$ by rewriting equation $\text{div}\mathcal{S} = \mathbf{0}$, in terms of the components of $\mathcal{K}$, as

$$\begin{aligned} \partial_{x_1}\mathcal{K}_{11} + \partial_{x_2}\mathcal{K}_{12} &= R_1, \\ \partial_{x_1}\mathcal{K}_{12} + \partial_{x_2}\mathcal{K}_{22} &= R_2, \end{aligned} \tag{6.21}$$

where the discrepancy vector

$$\mathbf{R} = \text{div } \mathcal{S}_0 = \mu\triangle\mathbf{u} - \nabla P \tag{6.22}$$

depends on the choice of P. We define the approximate pressure by

$$P(\mathbf{x}) = \mu\int_{-h/2}^{x_2} \triangle u_2(s_1, s_2)ds_2 + \mu\int_{-R^{ij}}^{x_1} r_1(s_1)ds_1, \tag{6.23}$$

where $r_1(x_1)$ is given in terms of the Laplacian of the first component of $\mathbf{u}$ as

$$\Delta u_1(x_1, x_2) = r_1(x_1) + r_2(x_1, x_2). \tag{6.24}$$

Then we set the first entry $\mathcal{K}_{11}$ in the compensating tensor to zero, and we find from (6.21) that

$$\mathcal{K}_{12}(\mathbf{x}) = \int_{-h/2}^{x_2} R_1(s_1, s_2)ds_2, \qquad \mathcal{K}_{22}(\mathbf{x}) = -\int_{-R^{ij}}^{x_1} R_1(s_1, s_2)ds_2 \tag{6.25}$$

for discrepancy vector

$$\mathbf{R}(\mathbf{x}) = \mu\triangle\mathbf{u}(\mathbf{x}) - \nabla P(\mathbf{x}) = \begin{pmatrix} \mu\triangle u_1(\mathbf{x}) - \partial_{x_1}P(\mathbf{x}) \\ 0 \end{pmatrix}. \tag{6.26}$$

Now, to verify that estimates (6.20) hold, we note that the components of $\Delta\mathbf{u}$ are sums of terms of the form

$$\text{const } \frac{x_1^k x_2^l}{h(x_1)^m} \tag{6.27}$$

for some nonnegative integers k, l, m, and that we have the following estimate.

LEMMA 6.1. *For k even, there exists a positive constant c such that*

$$\int_{\Pi^{ij}} \frac{x_1^k x_2^l}{h^m} d\mathbf{x} \le c\int_{-R^{ij}}^{R^{ij}} h^{\frac{k}{2}+l+1-m} dx_1. \tag{6.28}$$

If k is odd, then

$$\int_{\Pi^{ij}} \frac{x_1^k x_2^l}{h^m} d\mathbf{x} = 0. \tag{6.29}$$

Moreover, for any positive integer p, we have

$$\int_{-R^{ij}}^{R^{ij}} \frac{dx_1}{(\delta^{ij} + x_1^2/a^{ij})^p} = O\left(\left(\frac{a^{ij}}{\delta^{ij}}\right)^{p-\frac{1}{2}}\right). \tag{6.30}$$

Proof. To prove (6.30), we write $\int_{-R^{ij}}^{R^{ij}}(\delta^{ij}+x_1^2/a^{ij})^{-p}dx_1 = \mathcal{I}_1+\mathcal{I}_2$, where

$$\mathcal{I}_1 = \int_{-\sqrt{\delta^{ij}}}^{\sqrt{\delta^{ij}}} \frac{dx_1}{(\delta^{ij}+x_1^2/a^{ij})^p}.$$

Scaling x_1 by $\sqrt{\delta^{ij}}$, we get

$$I_1 = (\delta^{ij})^{1/2-p}\int_{-1}^{1}\frac{dt}{(1+t^2/a^{ij})^p} = c_1(p,a^{ij})(\delta^{ij})^{1/2-p},$$

where c_1 is independent of δ^{ij}. For $\mathcal{I}_2$, we have

$$\begin{aligned}\mathcal{I}_2 &= 2\int_{\sqrt{\delta^{ij}}}^{R^{ij}}\frac{dx_1}{(\delta^{ij}+x_1^2/a^{ij})^p} \le 2\int_{\sqrt{\delta^{ij}}}^{R^{ij}}\left(\frac{a^{ij}}{x_1^2}\right)^p dx_1\\ &= \frac{2}{2p-1}[(\delta ij)^{\frac{1}{2}-p}-(R^{ij})^{1-2p}] \le c_2(p)(\delta^{ij})^{1/2-p}\end{aligned}$$

and the proof of (6.30) is complete. Identity (6.29) follows immediately because the integrand is an odd function of x_1. Finally, (6.29) and $x_1^2/a^{ij} < h(x_1)$ imply (6.28). ∎

In light of Lemma 6.1, we obtain with explicit calculations that (6.20) holds and, therefore,

$$\int_{\Pi^{ij}} F(\mathcal{S})d\mathbf{x} = W_{\Pi^{ij}}(\mathbf{u}) + O\left(\sqrt{\frac{a^{ij}}{\delta^{ij}}}\right). \tag{6.31}$$

In the next section, we extend $\mathcal{S}$ from Π^{ij} to $\partial D^{(i)}$ and $\partial D^{(j)}$ in such a way that the net force and torque on $D^{(i)}$ and $D^{(j)}$ vanish. For that purpose, we need to examine the integrals of $\mathcal{S}\mathbf{n}$ over various parts of $\partial\Pi^{ij}$. We show that, roughly speaking, the integrals of $\mathcal{S}\mathbf{n}$ over opposite sides of $\partial\Pi^{ij}$ cancel each other. To make this precise, let us denote the lateral parts of $\partial\Pi^{ij}$ by

$$L_\pm = \left\{(x_1,x_2) : x_1 = \pm R^{ij}, -\frac{1}{2}h(R^{ij})) < x_2 < \frac{1}{2}h(R^{ij})\right\}.$$

Proposition 6.2.

$$\int_{L_+}\mathcal{S}\mathbf{n}\,ds + \int_{L_-}\mathcal{S}\mathbf{n}\,ds = 0.$$

Proof. Since $\mathcal{S}\mathbf{n} = (\mathcal{S}_{11}(\pm R^{ij},x_2),\mathcal{S}_{12}(\pm R^{ij},x_2))^T$ on $L_\pm$, we must show that

$$\int_{-\frac{h(R^{ij})}{2}}^{\frac{h(R^{ij})}{2}}\mathcal{S}_{1k}(-R^{ij},x_2)dx_2 = \int_{-\frac{h(R^{ij})}{2}}^{\frac{h(R^{ij})}{2}}\mathcal{S}_{1k}(R^{ij},x_2)dx_2 \quad \text{for } k=1,2. \tag{6.32}$$

This, in turn, follows by direct calculation from the expression of trial stress field $\mathcal{S}$ constructed above. ∎

Remark 6.2. Since $\operatorname{div}\mathcal{S}=0$ in Π^{ij}, $\int_{\partial\Pi^{ij}}\mathcal{S}\mathbf{n}\,ds = 0$ and, by Proposition 6.2, we have for the top and bottom parts of $\partial\Pi^{ij}$,

$$\int_{\partial D^{(i)}\cap\overline{\Pi^{ij}}}\mathcal{S}\mathbf{n}^{(i)}\,ds = -\int_{\partial D^{(j)}\cap\overline{\Pi^{ij}}}\mathcal{S}\mathbf{n}^{(j)}\,ds. \tag{6.33}$$

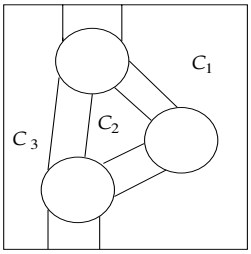

FIG. 7. *Three-disk network. Connected components.*

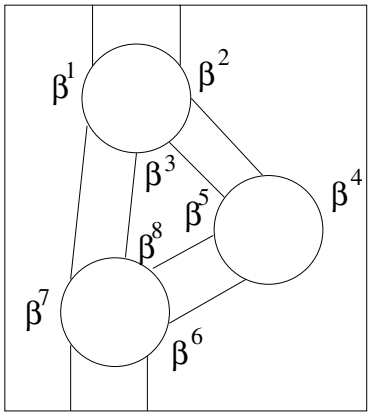

FIG. 8. *Three-disk network. Designation of the vector integrals* $\boldsymbol{\beta}^j$.

6.2.3. Extension of $\mathcal{S}$ to the boundaries of the disks. In section 6.2.2, we defined $\mathcal{S}$ in Π^{ij} and, in particular, on $\partial D^{(j)} \cap \overline{\Pi^{ij}}$. Here, we wish to extend $\mathcal{S}$ to the whole boundary $\partial D^{(j)}$ in such a way that

$$\int_{\partial D^{(j)}} \mathcal{S}\mathbf{n}^{(j)}\, ds = \mathbf{0} \quad \text{and} \quad \int_{\partial \mathcal{C}} \mathcal{S}\mathbf{n}\, ds = \mathbf{0} \tag{6.34}$$

for any connected component $\mathcal{C}$ of diffuse flow in $U_E = \Omega_F \setminus U_\Pi$ and for all $j = 1, \ldots, N$. We note that $\partial D^{(j)} \cap \overline{U}_E$ is a union of circular, complementary arcs, and we let vectors $\boldsymbol{\beta}^k$ denote the unknown integrals of $\mathcal{S}\mathbf{n}^{(j)}$ over various parts of $\partial D^{(j)} \cap \overline{U}_E$ for $1 \le j \le N$. We begin by showing that there exist vectors $\boldsymbol{\beta}^k$ consistent with (6.34). This is done first for a simple, three-disk network and is generalized later to N disks. Then we construct $\mathcal{S}$ on $\partial D^{(j)} \cap \overline{U}_E$ for $1 \le j \le N$ so the integral of $\mathcal{S}\mathbf{n}^{(j)}$ over the kth complementary arc is equal to $\boldsymbol{\beta}^k$ for all k.

Part I: A simple, three-disk network. To simplify the presentation, let us begin by considering a simple three-disk network, as shown in Figure 7, where there are three connected regions $\mathcal{C}_1$, $\mathcal{C}_2$, and $\mathcal{C}_3$ of diffuse flow.

The unknown integrals of $\mathcal{S}\mathbf{n}$ over the complementary arcs in $\partial D^{(j)} \cap \overline{U}_E$ for $j = 1, 2, 3$ are denoted by $\boldsymbol{\beta}^k$, $1 \le k \le 8$ (see Figure 8). We also let $\mathbf{F}^k$, and $\mathbf{B}^k$ for $1 \le k \le 5$ be the known integrals of $\mathcal{S}\mathbf{n}$ over the parts of $\partial D^{(j)} \cap \bar{U}_\Pi$ and the lateral segments of the gaps, respectively (see Figure 9 and recall Proposition 6.2). Finally, for connected components $\mathcal{C}_1$ and $\mathcal{C}_3$, we need $\mathcal{S}\mathbf{n}$ on the exterior boundaries $\partial\Omega \setminus \overline{U_\Pi}$ of the domain. On the vertical segments of the external boundary, we set $\mathcal{S} = 0$,

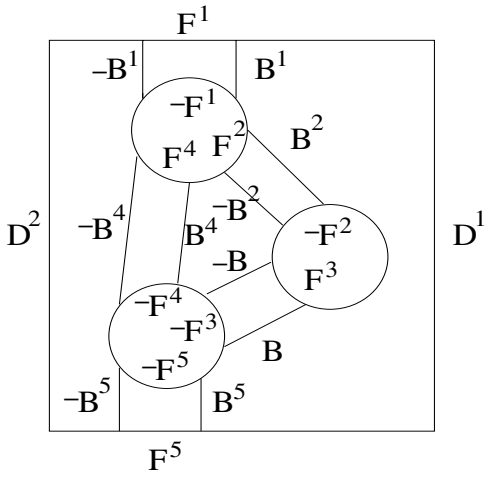

FIG. 9. *Three-disk network. Right-hand sides.*

and on the horizontal segments, we let $\mathcal{S}$ be constant. Letting $\mathbf{D}^1$ and $\mathbf{D}^2$ be the net traction over $\partial\mathcal{C}_3 \cap \partial\Omega$ and $\partial\mathcal{C}_1 \cap \partial\Omega$, respectively, we can now write (6.34) as

$$\mathbf{F}^1 + \mathbf{D}^1 + \mathbf{F}^5 + \mathbf{D}^2 = 0, \tag{6.35}$$

$$\begin{array}{llll} \boldsymbol{\beta}^1+ \ \boldsymbol{\beta}^2+ \ \boldsymbol{\beta}^3 = \ \mathbf{Q}^1, & & \mathbf{Q}^1 = -\mathbf{F}^2 \ -\mathbf{F}^4 \ +\mathbf{F}^1, \\ \boldsymbol{\beta}^4+ \ \boldsymbol{\beta}^5 = \ \mathbf{Q}^2, & \text{where} & \mathbf{Q}^2 = -\mathbf{F}^3 \ +\mathbf{F}^2, \\ \boldsymbol{\beta}^6+ \ \boldsymbol{\beta}^7+ \ \boldsymbol{\beta}^8 = \ \mathbf{Q}^3, & & \mathbf{Q}^3 = \ \mathbf{F}^3 \ +\mathbf{F}^4 \ +\mathbf{F}^5, \end{array} \tag{6.36}$$

and

$$\begin{array}{llll} \boldsymbol{\beta}^2+ \ \boldsymbol{\beta}^4+ \ \boldsymbol{\beta}^6 = \ \mathbf{Q}^4, & & \mathbf{Q}^4 = -\mathbf{B}^1 \ -\mathbf{B}^2 \ -\mathbf{B}^3 \ -\mathbf{B}^5 \ -\mathbf{D}^1, \\ \boldsymbol{\beta}^3+ \ \boldsymbol{\beta}^5+ \ \boldsymbol{\beta}^8 = \ \mathbf{Q}^5, & \text{where} & \mathbf{Q}^5 = -\mathbf{B}^4 \ +\mathbf{B}^2 \ +\mathbf{B}^3, \\ \boldsymbol{\beta}^1+ \ \boldsymbol{\beta}^7 = \ \mathbf{Q}^6, & & \mathbf{Q}^6 = \ \mathbf{B}^1 \ +\mathbf{B}^4 \ +\mathbf{B}^5 \ -\mathbf{D}^2. \end{array} \tag{6.37}$$

We now have an undetermined system of six vectorial equations (6.36), (6.37), with eight unknown vectors $\boldsymbol{\beta}^k$ for $1 \le k \le 8$ with right-hand sides satisfying constraint (6.35).

PROPOSITION 6.3. *There exist solutions of the linear system of* (6.36), (6.37).

Proof. Note that the vector system (6.36), (6.37) is equivalent to two scalar systems with the same matrix for the components of $\boldsymbol{\beta}^j$. It is therefore sufficient to prove the proposition for any one of the two scalar systems. The matrix A is

$$A = \begin{pmatrix} 1 & 1 & 1 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 1 & 1 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 1 & 1 & 1 \\ 0 & 1 & 0 & 1 & 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 & 1 & 0 & 0 & 1 \\ 1 & 0 & 0 & 0 & 0 & 0 & 1 & 0 \end{pmatrix}, \tag{6.38}$$

and we denote its rows by $\mathbf{a}_j$ for $1 \le j \le 6$. We call the first three rows in A disk-rows or simply d-rows, and the last three rows c-rows (in reference to the connected

components $\mathcal{C}_j$). We observe that each arc in $\partial D^{(j)} \cap \overline{U_E}$ belongs to exactly one disk and one connected component and thus exactly two entries in each column are equal to 1. Moreover, matrix A possesses the following two-ones property: one of these unit entries appears in a d-row and another appears in a c-row.

Next, we show that each equation in (6.36), (6.37) is a linear combination of the other five. Indeed, summing up first the equations in (6.36) and then those in (6.37), we obtain

$$\sum_{j=1}^{8} \boldsymbol{\beta}^j = \mathbf{F}_1 + \mathbf{F}_5 \quad \text{and} \quad \sum_{j=1}^{8} \boldsymbol{\beta}^j = -(\mathbf{D}_1 + \mathbf{D}_2),$$

respectively. These equations are consistent by (6.35), which gives $\mathbf{F}_1 + \mathbf{F}_5 = -(\mathbf{D}_1 + \mathbf{D}_2)$, and the rows of A are clearly linearly dependent.

Let us then eliminate from the original system of equations one equation, say, the first one, and show that the reduced system is solvable. Let A_R be the matrix of the reduced system. The rows of A_R are $\mathbf{a}_j$ with $2 \le j \le 6$. We show next that the rows of A_R are linearly independent (i.e., $\text{rank} A_R = 5$), and then that the existence of solutions follows from standard linear algebra.

Arguing by contradiction, suppose that there exists a k, between 2 and 6, such that $\mathbf{a}_k$ is a linear combination of $\mathbf{a}_p$ for $2 \le p \le 6$, $p \ne k$. Explicitly, we have

$$\mathbf{a}_k = \sum_{m=2, m\ne k}^{6} \lambda_m \mathbf{a}_m, \tag{6.39}$$

where not all λ_m are zero. By the two-ones property, three rows $\mathbf{a}_4, \mathbf{a}_5, \mathbf{a}_6$ have a unit entry at a column where all other rows of A_R have zeros. Take, for example, row $\mathbf{a}_4$. It has a unit entry in column 2, whereas the other four remaining rows $\mathbf{a}_j, 2 \le j \le 6, j \ne 4$, have zeros in this column. Hence, (6.39) implies that $k \ne 4$. The same argument shows that $k \ne 5$, $k \ne 6$. When $k = 2$ or 3, direct inspection of the first column of A_R shows that λ_6 from (6.39) is zero. Similarly we obtain $\lambda_4 = \lambda_5 = 0$. Then (6.39) reduces to $\mathbf{a}_2 = \lambda \mathbf{a}_3$, which is impossible since $\mathbf{a}_2$ and $\mathbf{a}_3$ are linearly independent. ∎

Part II: A general, N disk network with M connected components. Analogous to (6.36), we write the momentum balance equations on the boundary of each disk $D^{(j)}$ for $1 \le j \le N$. We call these equations d-equations. Furthermore, analogous to (6.37), we write the equations for each connected component $\mathcal{C}_p$, $1 \le p \le M$, where $M \ge N$. These are referred to as c-equations. As above, we consider the scalar system of $N + M$ equations for the components of unknown vectors $\boldsymbol{\beta}^p$, $1 \le p \le P$ ($P = 8$ in the example with three disks). This linear system is referred to as the d-c-system. Similar to the case of three disks, the right-hand side of the system involves integrals of $\mathcal{S}\mathbf{n}$ over parts of $\partial\Omega$ which do not belong to gaps. We assume that $\mathcal{S}$ is extended to the external boundary $\partial\Omega$ so that condition $\int_{\partial\Omega} \mathcal{S}\mathbf{n}\, ds = \mathbf{0}$ holds.

The solvability of the d-c-system is determined by matrix A, which has $M + N$ rows $\mathbf{a}_i$, $i = 1, \dots, M + N$, and P columns. The rows of A that correspond to d-equations are called d-rows, and those remaining are called c-rows. The entries of A are again either 0 or 1. Since each complementary arc in $\partial D^{(j)} \cap \overline{U_E}$ belongs to exactly one disk and one connected component, we observe that in each column of A, exactly two entries are equal to 1. One of these entries appears in a d-row and the other in a c-row. (A has the two-ones property.)

In what follows, we recall from section 3.1 that network Γ is a Delaunay graph corresponding to a Voronoi tessellation of Ω. We restrict our attention to the case of large N (for technical reasons it is sufficient to have $N \geq 3$) and consider only Voronoi tessellations with at least one Voronoi cell being strictly inside Ω. We also make use of Properties 3.1 to 3.3 of Γ.

THEOREM 6.1. *The d-c-system has a solution.*

Proof. First, we show that the d-c-system is underdetermined (i.e., $P > M + N$). Indeed, by Property 3.2, at least two edges of Γ originate from each interior vertex (which is the center of some disk $D^{(i)}$). Then $P \geq 2N$. Next, by Property 3.3, there exists a closed path which consists of interior edges. Therefore, there exists a connected component $\mathcal{C}_j$ with its closure disjoint from $\partial\Omega$ and, as such, there are at least three edges and three arcs in $\partial\mathcal{C}_j$. If the connected component would contain parts of $\partial\Omega$, there would be at least two arcs in its boundary. Thus[6] $2M < P$ and, since $P \geq 2N$, $P > M + N$. ∎

Next, we show that matrix A of the d-c-system has linearly dependent rows. Indeed, similar to the case of three disks, we have that the sum of the d-equations is equal to the sum of k-equations. Then we eliminate the first equation in the d-c-system and we denote by A_R the reduced $(M + N - 1) \times P$ matrix. To finish the proof of the theorem, we now show that the reduced system is full rank.

LEMMA 6.2. *The rank of A_R is $M + N - 1$.*

Proof. We argue by contradiction. Assume that the rows of A_R are linearly dependent, that is, for some $k > 1$,

$$\mathbf{a}_k = \sum_{m \neq k, m=2}^{M+N} \lambda_m \mathbf{a}_m, \tag{6.40}$$

where at least one λ_m is nonzero. The strategy of the proof is as follows. We introduce a multistep procedure where on each consecutive step l we have a set X_l of d-rows and a set Y_l of c-rows. We show that the rows from $X_l \cup Y_l$ cannot appear on the left-hand side of (6.40). Furthermore, we show that if either of these rows are present in the right-hand side of (6.40), then the coefficients λ_m in front of these rows in (6.40) must be zero. The process is stopped after L steps, when either all d-rows are included in $\cup_{l=1}^{L} X_l$ or all c-rows belong to $\cup_{l=1}^{L} Y_l$. At that point, (6.40) contains only d-rows (or only c-rows). Then the lemma follows from the linear independence of the d-rows and (c-rows), respectively.

Before giving the multistep procedure, let us introduce some notation. Given a collection of disks $S = \{D^{(i_1)}, D^{(i_2)}, \ldots, D^{(i_k)}\}$, denote by $\mathcal{C}(S)$ the set of all connected components of $\Omega_F \setminus U_\Pi$ adjacent to a disk in S. Also, given a collection Q of connected components $\mathcal{C}_j$, denote by $D(Q)$ the set of all disks having an arc in common with the boundary of an element of Q. Moreover, since there is a one-to-one correspondence between a disk and a d-row, use X_l to denote both the sets of disks and the corresponding sets of d-rows. Similarly, use the same notation for the set Y_l of connected components and the corresponding set of c-rows.

The multistep procedure is as follows.

Step 1. Set $X_1 = D^{(1)}$ and $Y_1 = \mathcal{C}(X_1)$. The set Y_1 consists of all connected components adjacent to $D^{(1)}$. We also identify X_1 with the d-row $\mathbf{a}_1$. Recall that X_1 is eliminated in the above reduction. The two-ones property implies that for each $\mathbf{a}_j \in Y_1$, there is a column of A_R with the only nonzero entry belonging to row $\mathbf{a}_j$.

[6] Note that, in fact, for large N and M, we have $P > 3M - O(1)$ as $M \to \infty$.

This is the single-one property and it follows from the two-ones property after the elimination of X_1. This shows that if $\mathbf{a}_k \in Y_1$, it cannot appear in the left-hand side of (6.40) and so it appears in the right-hand side of (6.40) with coefficient $\lambda^k = 0$.

Step 2. Let $X_2 = D(Y_1) \setminus X_1$ and observe that X_2 consists of all disks except $D^{(1)}$, which have a part of the boundary in common with one of the connected components in Y_1. Then define $Y_2 = \mathcal{C}(X_2) \setminus Y_1$. The elements of Y_2 are connected components which do not belong to Y_1 and whose boundary intersects the boundary of some disk from X_2. Again, none of the vectors in $X_2 \cup Y_2$ can be in the left-hand side of (6.40) and so they must be in the right-hand side of (6.40), with corresponding coefficients λ_m equal to zero.

Step 3. Define Y_l, X_l recursively by

$$X_l = D(Y_{l-1}) \setminus X_{l-1}, \quad Y_l = \mathcal{C}(X_l) \setminus Y_{l-1}.$$

The elements of X_l are disks that do not belong to X_{l-1} and whose boundary intersects the boundary of some connected component in Y_{l-1}. The set Y_l consists of the connected components which do not belong to Y_{l-1} and whose boundary intersects the boundary of some disk in X_l. Repeating the argument used in the previous step, we show that all corresponding λ_m must be zero.

By Property 3.2 of graph Γ, sets Y_l and X_l are nonempty, unless for some L, $Y_{L-1} = Y_L = \Omega_F \setminus U_\Pi$, or $X_L = X_{L-1} = \{D^{(1)}, \dots, D^{(N)}\}$. Then we stop the process and note that the rows remaining in (6.40) are either all d-rows or all c-rows. By the two-ones property, we obtain that if a d-row has a unit entry in some column, the other d-rows have zeros in the same column. Hence all d-rows are linearly independent. The same reasoning yields linear independence of all c-rows. This means that by the time we stop the process, all vectors possibly remaining in (6.40) are linearly independent and that the coefficients λ_m in front of these rows must be zero. This finishes the proof of Lemma 6.2 and of Theorem 6.1. □

Remark 6.3. The above iterative procedure can be illustrated as follows. Remove a disk $D^{(1)}$ from Ω. This disk has adjacent connected components, say, three of them, if there are three edges originating from $\mathbf{x}^{(1)}$. Remove these connected components. Now, the just-removed connected components were adjacent to three disks (second generation of disks) which are neighbors of $D^{(1)}$. Remove the second generation of disks and consider the remaining connected components (second generation of connected components) adjacent to them. Remove the second generation of connected components. The remaining neighbors of second generation disks are called third generation disks. Remove them and consider the remaining connected components adjacent to third-generation disks. Continue removing objects from Ω until there is nothing left. Due to the connectedness of the graph, the process does not stop until all the disks and all the connected components are removed.

Part III. Extending $\boldsymbol{\mathcal{S}}$ to $\boldsymbol{\partial D^{(j)} \cap \overline{U_E}}$. We wish to define a trial tensor $\mathcal{S}$ along the pth complementary arc in $\partial D^{(j)} \cap \overline{U_E}$ such that its integral is equal to $\boldsymbol{\beta}^p$ for some $1 \le j \le N$ and for $1 \le p \le P$. This ensures that conditions (6.34) hold and the existence of vectors $\boldsymbol{\beta}^p$ has been proved in Parts I and II. However, the trial stress tensor must also satisfy the balance of angular momentum

$$\int_{\partial D^{(j)}} \mathbf{n}^{(j)} \times \mathcal{S}\mathbf{n}^{(j)}\, ds = \mathbf{0} \tag{6.41}$$

for all $1 \le j \le N$. Let us then focus attention on one disk, say, $D^{(j)}$, of radius a_j centered at $\mathbf{x}^{(j)}$. At $\partial D^{(j)}$, $\mathbf{x} = \mathbf{x}^{(j)} + a_j \mathbf{n}^{(j)}$, so we rewrite (6.41) as

$$\mathbf{x}_0 \times \int_{\partial D^{(j)}} \mathcal{S}\, \mathbf{n}^{(j)}\, ds + a_j \int_{\partial D^{(j)}} \mathbf{n}^{(j)} \times \mathcal{S}\mathbf{n}^{(j)}\, ds = \mathbf{0}.$$

Due to (6.34), the first integral is zero, and (6.41) reduces to

$$\int_{\partial D} \mathbf{n}^{(j)} \times \mathcal{S}\mathbf{n}^{(j)}\, ds = \mathbf{0}.$$

Let $\boldsymbol{\tau}$ be the tangent unit vector at $\partial D^{(j)}$, pointing in the clockwise direction. Since $\mathcal{S}\mathbf{n}^{(j)} = (\mathcal{S}\mathbf{n}^{(j)} \cdot \boldsymbol{\tau})\boldsymbol{\tau} + (\mathcal{S}\mathbf{n}^{(j)} \cdot \mathbf{n}^{(j)})\mathbf{n}^{(j)}$ and $\boldsymbol{\tau} \cdot \mathbf{n}^{(j)} = 0$, we have

$$0 = \int_{\partial D^{(j)}} \mathbf{n}^{(j)} \times \mathcal{S}\mathbf{n}^{(j)}\, ds = \mathbf{k} \int_{\partial D^{(j)}} \mathcal{S}\mathbf{n}^{(j)} \cdot \boldsymbol{\tau}\, ds,$$

where $\mathbf{k} = \mathbf{n}^{(j)}(\mathbf{x}) \times \boldsymbol{\tau}(\mathbf{x})$ is a constant (independent of $\mathbf{x}$) unit vector, orthogonal to the two-dimensional plane and pointing into it. Therefore, any tensor $\mathcal{S}$ obeying the balance of angular momentum (6.41) satisfies

$$\int_{\partial D^{(j)} \cap \overline{U_E}} \mathcal{S}\mathbf{n}^{(j)} \cdot \boldsymbol{\tau}\, ds = - \int_{\partial D^{(j)} \cap \overline{U}_\Pi} \mathcal{S}\mathbf{n}^{(j)} \cdot \boldsymbol{\tau}\, ds. \tag{6.42}$$

Now, since $\mathcal{S}$ is already defined in U_Π, we estimate the integral in the right-hand side of (6.42). In the local coordinates of gap Π^{ij}, a complementary arc in $\partial D^{(j)} \cap \overline{\Pi^{ij}}$ is given by equation $f(x_1, x_2) = x_2 - \delta^{ij}/2 - a_j + \sqrt{a_j^2 - x_1^2} = 0$. Then

$$\mathbf{n}^{(j)} = \frac{1}{a_j} \begin{pmatrix} x_1 \\ -(a_j^2 - x_1^2)^{1/2} \end{pmatrix}, \qquad \boldsymbol{\tau} = \frac{1}{a_j} \begin{pmatrix} (a_j^2 - x_1^2)^{1/2} \\ x_1 \end{pmatrix}. \tag{6.43}$$

Using the explicit expression of $\mathcal{S}$ from section 6.2.2 and Lemma 6.1, we obtain

$$\int_{\partial D^{(j)} \cap \overline{\Pi^{ij}}} \mu \mathcal{E}(\mathbf{u})\mathbf{n}^{(j)} \cdot \boldsymbol{\tau}\, ds = O\left(\sqrt{\frac{a^{ij}}{\delta^{ij}}}\right) \tag{6.44}$$

and

$$\int_{\partial D^{(j)} \cap \overline{\Pi^{ij}}} \mathcal{K}\mathbf{n}^{(j)} \cdot \boldsymbol{\tau}\, ds = O(1). \tag{6.45}$$

Let $\mathcal{A}_{\Pi^{ij}}$ be a complementary arc from $\partial D^{(j)} \cap \overline{U_E}$ adjacent to gap Π^{ij} and oriented in the clockwise direction. We wish to construct tensor $\mathcal{S}$ on $\mathcal{A}_{\Pi^{ij}}$ so that

$$\int_{\mathcal{A}_{\Pi^{ij}}} \mathcal{S}\mathbf{n}^{(j)}\, ds = \boldsymbol{\beta} \tag{6.46}$$

and

$$\int_{\mathcal{A}_{\Pi^{ij}}} \mathcal{S}\mathbf{n}^{(j)} \cdot \boldsymbol{\tau} ds = -\rho. \tag{6.47}$$

Here, $\boldsymbol{\beta}$ is found by solving the d-c-system, and ρ stands for the sum of the integrals in (6.44), (6.45). Parameterize $\mathcal{A}_{\Pi^{ij}}$ as follows:

$$\mathcal{A}_{\Pi^{ij}} = \{(x_1, x_2) \in \partial D^{(j)} : x_1 = a_j \cos t, x_2 = a_j \sin t,\ t \in [0, \alpha]\}. \tag{6.48}$$

Then we rewrite (6.46), (6.47) as

$$a\int_0^\alpha (\mathcal{S}_{11}(t)\cos t - \mathcal{S}_{12}\sin t)dt = \beta_1, \tag{6.49}$$

$$a_j\int_0^\alpha (\mathcal{S}_{12}(t)\cos t - \mathcal{S}_{22}\sin t)dt = \beta_2,$$

$$a_j\int_0^\alpha (\mathcal{S}_{11}(t)\cos t\sin t - \mathcal{S}_{22}\sin t\cos t)dt = -\rho.$$

To accomplish the task of this section, we now set the components $\mathcal{S}_{kl}$ of our trial tensor on $\mathcal{A}_{\Pi^{ij}}$ to constant values satisfying (6.49). This implies that

$$M\begin{pmatrix}\mathcal{S}_{11}\\ \mathcal{S}_{12}\\ \mathcal{S}_{13}\end{pmatrix} = \begin{pmatrix}\boldsymbol{\beta}_1/a_j\\ \boldsymbol{\beta}_2/a_j\\ -\rho/a_j\end{pmatrix}, \tag{6.50}$$

where

$$M = \begin{pmatrix}\sin\alpha & \cos\alpha - 1 & 0\\ 0 & \sin\alpha & \cos\alpha - 1\\ 1/2\sin^2\alpha & 0 & -1/2\sin^2\alpha\end{pmatrix}$$

and $\det(M) = \sin^2\alpha\cos\alpha\,(1-\cos\alpha)$. Thus, unless $\alpha = 0, \pi/2$ or π, (6.50) is uniquely solvable, and our extension of $\mathcal{S}$ to the complementary arc $\mathcal{A}_{\Pi^{ij}}$ is complete. Finally, all cases of α that make M singular can be eliminated. Indeed, $\alpha = 0$ is discarded by the observation that it implies an empty $\mathcal{A}_{\Pi^{ij}}$. The other cases, $\alpha = \pi/2$ or π, can also be avoided by modifying the length of $\mathcal{A}_{\Pi^{ij}}$, i.e., by changing slightly the widths of gaps Π^{ij} adjacent to $\mathcal{A}_{\Pi^{ij}}$.

6.2.4. Extension of $\mathcal{S}$ in the set U_E of connected components. The goal of this section is to extend $\mathcal{S}$ outside the gaps in such a way that the dual dissipation rate in U_E is much smaller than $O(\delta^{-3/2})$. First, we show that the components of the extended $\mathcal{S}$ at complementary arcs $\mathcal{A}_{\Pi^{ij}} \in \partial D^{(j)}$ (see section 6.2.3) for $1 \le j \le N$ and $i \in \mathcal{N}_j$ are bounded, pointwise by $C_{kl}\delta^{-1/2}$. Then we consider the extension of $\mathcal{S}$ from $\mathcal{A}^+ = \overline{U_\Pi} \cap \partial\Omega^+$ and $\mathcal{A}^- = \overline{U_\Pi} \cap \partial\Omega^-$ (the parts of $\partial\Omega^\pm$ included in gaps) to the whole $\partial\Omega$ and we prove the pointwise estimate $|\mathcal{S}_{kl}| \le C_{kl}\delta^{-1/2}$ for $k, l = 1, 2$. Finally, we extend $\mathcal{S}$ in the interior of U_E and show that the dissipation rate there is at most $O(\delta^{-1})$. Once this is done, the first three steps in the outline of section 6.2.1 would be completed. The fourth step in section 6.2.1 is accomplished in section 6.2.6, where we give the main theorem of the paper.

Part I: Estimates on the boundaries of the disks. To prove the desired pointwise estimates of the components of $\mathcal{S}$ at $\partial D^{(i)}$ for $1 \le i \le N$, we need the following proposition.

PROPOSITION 6.4. *For each disk $D^{(i)}$, we have*

$$\sum_{j\in\mathcal{N}_i}\int_{\partial D^{(i)}\cap\overline{\Pi^{ij}}} \mathcal{S}\mathbf{n}^{(i)}\,ds = O(\delta^{-1/2}) \quad \textit{for } i = 1, \dots, N.$$

This proposition states that if we fix a disk $D^{(i)}$ and consider the forces that act on each arc in $\partial D^{(i)} \cap \overline{U_\Pi}$, then the sum of these forces over all the arcs is $O(\delta^{-1/2})$,

whereas the force on each disk may be of order $\delta^{-3/2}$. Thus, we have a cancellation of terms due to the fact that the forces depend on translation velocities $\mathbf{T}^{(i)}$, the solutions of network equations (6.2). This is yet another manifestation of the global nature of the lower bound construction, which cannot be obtained by simply patching together trial functions obtained in each gaps Π^{ij}.

Proof of Proposition 6.4. Fix a gap Π^{ij} which joins disks $D^{(i)}$ and $D^{(j)}$ and use (6.22) to calculate

$$\int_{\Pi^{ij}} (\mu\triangle\mathbf{u} - \nabla P)\cdot\mathbf{u}d\mathbf{x} = \int_{\Pi^{ij}} \text{div}\,(2\mu\mathcal{E}(\mathbf{u}) - P\mathcal{I})\cdot\mathbf{u}d\mathbf{x},$$

where $\mathbf{u}$ is defined by (6.6). The approximate pressure P is defined by (6.23). Integrating by parts, using the symmetry of $\mathcal{E}$ and the incompressibility of $\mathbf{u}$, we have

$$\int_{\Pi^{ij}} (\mu\triangle\mathbf{u} - \nabla P)\cdot\mathbf{u}d\mathbf{x} = -2\mu\int_{\Pi^{ij}} \mathcal{E}(\mathbf{u})\cdot\mathcal{E}(\mathbf{u})d\mathbf{x} + \int_{\partial\Pi^{ij}} \mathcal{S}_0\mathbf{n}\cdot\mathbf{u}\,ds. \tag{6.51}$$

Recall that $\mu\triangle\mathbf{u} - \nabla P = \text{div}\,\mathcal{S}_0 = \text{div}\,\mathcal{K}$, where $\mathcal{K}$ is the compensating tensor defined in (6.25). Write $\mathcal{S}_0 = \mathcal{S} + \mathcal{K}$ and integrate by parts to obtain

$$2\mu\int_{\Pi^{ij}} \mathcal{E}(\mathbf{u})\cdot\mathcal{E}(\mathbf{u})d\mathbf{x} = \int_{\partial\Pi^{ij}} \mathcal{S}\mathbf{n}\cdot\mathbf{u}d\Gamma + \int_{\Pi^{ij}} \mathcal{K}\cdot\mathcal{E}(\mathbf{u})d\mathbf{x}. \tag{6.52}$$

In section 6.2.2 we showed that $\int_{\Pi} \mathcal{K}\cdot\mathcal{E}(\mathbf{u})d\mathbf{x} = O(\delta^{-1/2})$. Then rewrite the first integral in the right-hand side of (6.52) as

$$\int_{\partial\Pi^{ij}} \mathcal{S}\mathbf{n}\cdot\mathbf{u}ds = \int_{\partial D^{(i)}\cap\partial\Pi^{ij}} \mathcal{S}\mathbf{n}^{(i)}\cdot\mathbf{u}\,ds + \int_{\partial D^{(j)}\cap\partial\Pi^{ij}} \mathcal{S}\mathbf{n}^{(j)}\cdot\mathbf{u}\,ds + \int_{\partial U_E\cap\partial\Pi^{ij}} \mathcal{S}\mathbf{n}\cdot\mathbf{u}\,ds$$

$$= \int_{\partial D^{(i)}\cap\partial\Pi^{ij}} \mathcal{S}\mathbf{n}^{(i)}\cdot\mathbf{T}^{(i)}\,ds + \int_{\partial D^{(j)}\cap\partial\Pi^{(ij)}} \mathcal{S}\mathbf{n}^{(j)}\cdot\mathbf{T}^{(j)}\,ds + \int_{\partial U_E\cap\partial\Pi^{ij}} \mathcal{S}\mathbf{n}\cdot\mathbf{u}\,ds$$

$$+ \int_{\partial D^{(i)}\cap\partial\Pi^{ij}} \mathcal{S}\mathbf{n}^{(i)}\cdot(\mathbf{u} - \mathbf{T}^{(i)})ds + \int_{\partial D^{(j)}\cap\partial\Pi^{ij}} \mathcal{S}\mathbf{n}^{(i)}\cdot(\mathbf{u} - \mathbf{T}^{(j)})ds.$$

However, by Proposition 6.2, we have

$$\int_{\partial D^{(i)}\cap\partial\Pi^{ij}} \mathcal{S}\mathbf{n}^{(i)}\cdot\mathbf{u}ds = -\int_{\partial D^{(j)}\cap\partial\Pi^{ij}} \mathcal{S}\mathbf{n}^{(j)}\cdot\mathbf{u}ds,$$

and using the constructed $\mathcal{S}$ and $\mathbf{u}$ (see sections 6.1 and 6.2.2) and Lemma 6.1 gives

$$\int_{\partial\Pi^{ij}} \mathcal{S}\mathbf{n}\cdot\mathbf{u}ds = (\mathbf{T}^{(i)} - \mathbf{T}^{(j)})\cdot\int_{\partial D^{(i)}\cap\partial\Pi^{ij}} \mathcal{S}\mathbf{n}^{(i)}ds + O(\delta^{-1/2}).$$

Finally, combining this with (6.52) yields

$$W_{\Pi^{ij}}(\mathbf{u}) = \frac{1}{2}(\mathbf{T}^{(i)} - \mathbf{T}^{(j)})\cdot\int_{\partial D^{(i)}\cap\partial\Pi^{ij}} \mathcal{S}\mathbf{n}^{(i)}ds + O(\delta^{-1/2}). \tag{6.53}$$

Next, recall that $W_{\Pi^{ij}}(\mathbf{u})$ in the left-hand side of (6.53) is a quadratic form in $\mathbf{T}^{(i)} - \mathbf{T}^{(j)}$ for $i = 1,\dots,N$ and $j \in \mathcal{N}_i$ (see section 6.1). Denote the matrix of this

quadratic form by $A(\delta)$. From the definition (6.6) of $\mathbf{u}$, it follows that $\mathcal{S}$ is a linear function of $\mathbf{T}^i - \mathbf{T}^j$, so we write

$$\frac{1}{2}\int_{\partial D^{(i)}\cap\partial\Pi^{ij}} \mathcal{S}\mathbf{n}^{(i)}ds = B(\delta)(\mathbf{T}^{(i)} - \mathbf{T}^{(j)}), \tag{6.54}$$

where the matrix $B(\delta)$ is independent of $\mathbf{T}^i, \mathbf{T}^j$. Then the first term in the right-hand side of (6.53) is a quadratic form in $\mathbf{T}^{(i)} - \mathbf{T}^{(j)}$. Replacing the terms in (6.53) with the corresponding quadratic forms, we obtain

$$(\mathbf{T}^{(i)} - \mathbf{T}^{(j)}) \cdot A(\delta)(\mathbf{T}^{(i)} - \mathbf{T}^{(j)}) = (\mathbf{T}^{(i)} - \mathbf{T}^{(j)}) \cdot B(\delta)(\mathbf{T}^{(i)} - \mathbf{T}^{(j)}) + O(\delta^{-1/2}). \tag{6.55}$$

Summing up over all disks $D^{(i)}, i = 1, \dots, N$, and then differentiating with respect to the components of a fixed vector $\mathbf{T}^{(i)}$, we have

$$\sum_{j\in\mathcal{N}_i} A(\delta)(\mathbf{T}^{(i)} - \mathbf{T}^{(j)}) = \sum_{j\in\mathcal{N}_i} B(\delta)(\mathbf{T}^{(i)} - \mathbf{T}^{(j)}) + O(\delta^{-1/2}) \tag{6.56}$$

for each disk $D^{(i)}, i = 1, \dots, N$. However, by the network equations (6.2), the left-hand side in (6.56) is zero and so

$$0 = \sum_{j=1}^{J_i} B(\delta)(\mathbf{T}^i - \mathbf{T}^j) + O(\delta^{-1/2}).$$

This completes the proof of Proposition 6.4. ∎

Part II: Controlled extension of $\mathcal{S}$ to $\partial\Omega$. In this step, we deal with the extension of $\mathcal{S}$ from $\mathcal{A}^{\pm}$ to $\partial\Omega$.

PROPOSITION 6.5.

$$\int_{\mathcal{A}^+} \mathcal{S}\mathbf{n}\, ds + \int_{\mathcal{A}^-} \mathcal{S}\mathbf{n}\, ds = O(\delta^{-1/2}).$$

Proof. Since $\mathcal{S}$ is divergence free in each gap Π^{ij}, we have

$$\sum_{ij}\int_{\partial\Pi^{ij}} \mathcal{S}\mathbf{n}\, ds = \mathbf{0}, \tag{6.57}$$

where the sum is taken over all gaps. If a gap is connected to $\partial\Omega$, its boundary consists of a segment from $\mathcal{A}^+$ or $\mathcal{A}^-$, an arc which belongs to one of the disks, and two lateral segments. The boundary of an interior gap contains two disk arcs and two lateral segments. By Proposition 6.2, the sum of the integrals over the lateral parts of $\partial\Pi^{ij}$ is zero. Thus (6.57) reduces to

$$\int_{\mathcal{A}^+\cup\mathcal{A}^-} \mathcal{S}\mathbf{n}\, ds + \sum_{j=1}^{N}\int_{\partial D^{(j)}\cap\overline{U}_\Pi} \mathcal{S}\mathbf{n}\, ds = 0,$$

where the sum is taken over all disks. By Proposition 6.4,

$$\sum_{j=1}^{N}\int_{\partial D^{(j)}\cap\overline{U}_\Pi} \mathcal{S}\mathbf{n}\, ds = O(\delta^{-1/2}),$$

and Proposition 6.5 follows. ∎

To obtain pointwise estimates on the complementary arcs, we restrict our attention to the example of a three-disk network from Figure 7 and to the corresponding algebraic system (6.36), (6.37). Generalizing our arguments to the general case of N disks is straightforward.

Let us denote the vector $\mathbf{F}^1 + \mathbf{F}^5$ by $-\mathbf{P}$. By Proposition 6.5, $\mathbf{P} = O(\delta^{-1/2})$. Define $\mathcal{S} = 0$ on the lateral part of $\partial\Omega$. On $\partial\Omega^+ \setminus \mathcal{A}^+$ (or $\partial\Omega^- \setminus \mathcal{A}^-$), we choose the constant components $\mathcal{S}_{11} = 0$,

$$\mathcal{S}_{12} = \pm\frac{1}{2}\frac{\mathbf{P}_1}{|\partial\Omega^+ \setminus \mathcal{A}^+|}, \quad \mathcal{S}_{22} = \pm\frac{1}{2}\frac{\mathbf{P}_2}{|\partial\Omega^+ \setminus \mathcal{A}^+|},$$

where $|\cdot|$ denotes the length of a curve. Then

$$\int_{\partial\Omega^+\setminus\mathcal{A}^+} \mathcal{S}\mathbf{n}\, ds = \int_{\partial\Omega^-\setminus\mathcal{A}^-} \mathcal{S}\mathbf{n}\, ds = \frac{1}{2}\mathbf{P}, \quad \int_{\partial\Omega} \mathcal{S}\mathbf{n}\, ds = 0,$$

and

$$\sup_{\partial\Omega\setminus(\mathcal{A}^+\cup\mathcal{A}^-)} |\mathcal{S}_{kl}| \le c_{kl}\delta^{-1/2}, \quad k,l = 1,2, \tag{6.58}$$

with c_{kl} independent of δ. Thus, we can define $\mathcal{S}$ on $\partial\Omega \setminus (\mathcal{A}^+ \cup \mathcal{A}^-)$ so that (6.35) is satisfied and

$$\mathbf{D}^1 = O(\delta^{-1/2}), \quad \mathbf{D}^1 = O(\delta^{-1/2}). \tag{6.59}$$

From the definitions of $\mathbf{u}, P$, and $\mathcal{S}$, it follows that $|\mathcal{S}_{kl}|$ are pointwise bounded independent of δ on the lateral parts of the gap boundaries. Hence,

$$\mathbf{B}^j = O(1) \quad \text{for } 1 \le j \le 4. \tag{6.60}$$

Moreover, by Proposition 6.4,

$$-\mathbf{F}^1 + \mathbf{F}^3 + \mathbf{F}^4 = O(\delta^{-1/2}), \quad -\mathbf{F}^2 + \mathbf{F}^3 = O(\delta^{-1/2}), \quad -\mathbf{F}^4 - \mathbf{F}^3 - \mathbf{F}^5 = O(\delta^{-1/2}), \tag{6.61}$$

and, combining (6.59)–(6.61), we see that the components of the right-hand side of the algebraic system (6.36), (6.37) are bounded by $c\delta^{-1/2}$ with c independent of δ. Since the matrix of this algebraic system is independent of δ as well, we can choose a solution of (6.36), (6.37) so that all its components are bounded by $c\delta^{-1/2}$ with c independent of δ. This means that for each complementary arc in $\partial D^{(j)} \cap \partial U_E$, $1 \le j \le 8$, $\int_{\partial D^{(j)}\cap\partial U_E} \mathcal{S}\mathbf{n} ds = O(\delta^{-1/2})$. The latter implies that the right-hand side of algebraic system (6.50) is bounded by $c\delta^{-1/2}$ and, since matrix M is independent of δ and invertible, we can find a stress field $\mathcal{S}$ at the boundaries of the disks which is bounded by $c\delta^{-1/2}$ with c independent of δ. Then for each complementary arc, we have

$$\sup_{\partial D^{(j)}\cap\partial U_E} |\mathcal{S}_{kl}| \le c_{ij}\delta^{-1/2} \quad \text{for } 1 \le j \le N \tag{6.62}$$

with c_{ij} independent of δ.

The boundary of each connected component $\mathcal{C}_j$ of U_E consists of complementary arcs, pieces of the external boundary $\partial\Omega$, and lateral parts of gap boundaries. Thus

the estimates (6.58), (6.62) and the uniform estimates on the lateral segments yield the following.

PROPOSITION 6.6. *For each connected component $\mathcal{C}_j$ of U_E, we have*

$$\sup_{\partial\mathcal{C}_j} |\mathcal{S}_{kl}| \le c_j \delta^{-1/2}, \quad k,l = 1,2,$$

with c_j independent of δ.

Part III: Extension from the boundary, to the connected components. Now, $\mathcal{S}$ is defined on the boundary of each connected component $\mathcal{C}_j$ of $U_E = \Omega_F \setminus U_\Pi$. Moreover, we have

$$\int_{\partial\mathcal{C}_j} \mathcal{S}\mathbf{n}\, ds = 0 \tag{6.63}$$

and

$$\sup_{\partial\mathcal{C}_j} |\mathcal{S}(\mathbf{x})| \le c\delta^{-1/2} \tag{6.64}$$

with c independent of δ. Next, we construct a divergence-free extension of $\mathcal{S}$ from ∂U_E to U_E.

PROPOSITION 6.7. *Let $\mathcal{C}_j \subset U_E$ be a connected component, and let $\mathcal{S}$ be the trial tensor defined on $\partial\mathcal{C}_j$ satisfying* (6.63), (6.64). *Then there exists an extension $\hat{\mathcal{S}} \in L^2(\mathcal{C}_j)$ in $\mathcal{C}_j$ such that* $\operatorname{div}\hat{\mathcal{S}} = 0$ *in $\mathcal{C}_j$, $\hat{\mathcal{S}} = \mathcal{S}$ on $\partial\mathcal{C}_j$ and*

$$\int_{\mathcal{C}_j} \hat{\mathcal{S}} \cdot \hat{\mathcal{S}}\, ds \le c\delta^{-1}$$

with c independent of δ.

This proposition is proved using the same techniques as those in section 5.2.[7]

6.2.5. Estimates of the dual dissipation functional in the gaps. In our proof of the main theorem of the paper (see section 6.2.6), we use the following estimate.

PROPOSITION 6.8. *Let* $\mathbf{u}$ *be defined by* (6.6) *and let $\mathcal{S}$ be the trial tensor defined by* (6.17) *and* (6.23)–(6.25). *Then*

$$W^*_{U_\Pi}(\mathcal{S}) = W_{U_\Pi}(\mathbf{u}) + O(\delta^{-1/2}). \tag{6.65}$$

Proof. By (6.8), we have $W^*_{U_\Pi} = \int_{\partial\Omega\cap\overline{U}_\Pi} \mathbf{g}\cdot\mathcal{S}\mathbf{n} ds - \int_{U_\Pi} F(\mathcal{S}) d\mathbf{x}$. Let us then estimate first the boundary integral. Fix a gap Π and consider $\int_{\partial\Pi} \mathcal{S}\mathbf{n}\cdot\mathbf{u}\, ds$. Integrating by parts using the definition of $\mathcal{S}$, the incompressibility of $\mathbf{u}$, and (6.18), we get

$$\int_{\partial\Pi} \mathcal{S}\mathbf{n}\cdot\mathbf{u}\, ds = 2W_\Pi(\mathbf{u}) - \int_\Pi \mathcal{K}\cdot\mathcal{E}(\mathbf{u}) d\mathbf{x}. \tag{6.66}$$

The integral $\int_\Pi \mathcal{K}\cdot\mathcal{E}(\mathbf{u}) d\mathbf{x}$ is estimated using the explicit expressions of $\mathcal{K}$ and $\mathcal{E}(\mathbf{u})$ and then by applying Lemma 6.1. These calculations, already carried out in section

[7] See also Appendix C in the preprint version of this article, available at http://www.math.wsu.edu/math/faculty/panchenko/welcome.html.

6.2.2 show that the integral in the right-hand side of (6.66) is $O(\delta^{-1/2})$. Summing up over all gaps, we have

$$\int_{\partial U_\Pi} \mathcal{S}\mathbf{n}\cdot\mathbf{u}\,ds = 2W_{U_\Pi}(\mathbf{u}) + O(\delta^{-1/2}). \tag{6.67}$$

Since ∂U_Π is a union of circular arcs, lateral segments that belong to the gap boundaries, and a set $(\partial\Omega\cap\bar{U}_\Pi)\subset\partial\Omega$, we write

$$\begin{aligned}\int_{\partial\Omega\cap\overline{U}_\Pi} \mathbf{g}\cdot\mathcal{S}\mathbf{n}\,ds \;&= \int_{\partial U_\Pi}\mathbf{u}\cdot\mathcal{S}\mathbf{n}\,ds\\ &\quad -\sum_{j=1}^{N}\mathbf{T}^{(j)}\cdot\int_{\partial D^{(j)}\cap\overline{U}_\Pi}\mathcal{S}\mathbf{n}\,ds\\ &\quad -\int_{\partial U_\Pi\setminus(\cup_j\partial D^{(j)})}\mathbf{u}\cdot\mathcal{S}\mathbf{n}\,ds + O(\delta^{-1/2}).\end{aligned} \tag{6.68}$$

Here, we use the same technique that gave (6.53) from (6.52). By Proposition 6.4, the sum of the second and third terms in the right-hand side of (6.68) is $O(\delta^{-1/2})$. Hence,

$$\int_{\partial\Omega\cap\overline{U}_\Pi}\mathbf{g}\cdot\mathcal{S}\mathbf{n}\,ds = \int_{\partial U_\Pi}\mathbf{u}\cdot\mathcal{S}\mathbf{n}\,ds + O(\delta^{-1/2}). \tag{6.69}$$

Combining (6.67) and (6.69), we obtain

$$\int_{\partial\Omega\cap\overline{U}_\Pi}\mathbf{g}\cdot\mathcal{S}\mathbf{n}\,ds = 2W_{U_\Pi}(\mathbf{u}) + O(\delta^{-1/2}). \tag{6.70}$$

Finally, to estimate the second integral in the definition of $W^*_{U_\Pi}$, we apply section 6.14 and sum up over all gaps:

$$\int_{U_\Pi} F(\mathcal{S})d\mathbf{x} = W_{U_\Pi}(\mathbf{u}) + O(\delta^{-1/2}). \tag{6.71}$$

The estimate (6.65) follows from (6.70) and (6.71). □

We remark here that construction of the lower bound which accounts for rotations (with the error term $O(1)$) requires developing more sophisticated techniques even for periodic densely packed arrays, and this will be addressed elsewhere.

6.2.6. The main theorems. The trial field for the upper bound (6.7) is constructed by patching up the local approximate solutions (6.6), which depend on the translational particle velocities $\mathbf{T}^{(i)}, i=1,\dots,N$, minimizing the quadratic functional

$$\begin{aligned}Q = \sum_{i=1}^{N}\sum_{\substack{j\in\mathcal{N}_i\\ j<i}}&\left\{\left[\frac{3\pi\mu}{4}\left(\frac{a}{\delta^{ij}}\right)^{\frac{3}{2}} + \frac{27\pi\mu}{10}\sqrt{\frac{a}{\delta^{ij}}}\right][(\mathbf{T}^{(i)}-\mathbf{T}^{(j)})\cdot\mathbf{q}^{ij}]^2\right.\\ &\left.+\frac{\pi\mu}{2}\sqrt{\frac{a}{\delta^{ij}}}[(\mathbf{T}^{(i)}-\mathbf{T}^{(j)})\cdot\mathbf{p}^{ij}]^2\right\}\\ &+\sum_{i\in\mathcal{B}}\left\{\left[\frac{3\pi\mu}{4}\left(\frac{2a}{\delta^{i}}\right)^{\frac{3}{2}} + \frac{27\pi\mu}{10}\sqrt{\frac{2a}{\delta^{i}}}\right][(\mathbf{T}^{(i)}-\mathbf{g})\cdot\mathbf{q}^{i}]^2\right.\\ &\left.+\frac{\pi\mu}{2}\sqrt{\frac{2a}{\delta^{i}}}[(\mathbf{T}^{(i)}-\mathbf{g})\cdot\mathbf{p}^{i}]^2\right\}.\end{aligned} \tag{6.72}$$

In this section we introduce the corresponding dissipation rate

$$E_2 = \min_{\substack{\mathbf{T}^{(i)} \\ i=1,\dots,N}} Q = Q(\mathbf{T}^{(i)}_{min}, i = 1, \dots, N). \tag{6.73}$$

By Proposition 6.1, the minimizing collection of vectors $\mathbf{T}^{(i)}_{min}$ (solving the system (6.2)) is unique.

Since the error terms appearing in the construction of the lower bound are of order δ^{-1} (recall Proposition 6.7), we need to make sure that $E_2 \geq c\delta^{-3/2}$ with c independent of δ. So far, we know from the upper bound in section 6.1 that if $(\mathbf{T}^{(i)} - \mathbf{T}^{(j)})_2 \neq 0$, the local dissipation rate in each gap Π^{ij} blows up as $\delta^{-3/2}$. Otherwise, the rate of growth is at most $\delta^{-1/2}$. The vectors $\mathbf{T}^{(i)}_{min}$ are solutions of a (large) system of network equations (6.2) and, until these are solved, we cannot say whether the quantities $((\mathbf{T}^{(i)}_{min} - \mathbf{T}^{(j)}_{min}) \cdot \mathbf{q}^{ij})^2$ vanish as $\delta \to 0$. That is, we cannot determine the global rate of blow up of E_2 as $\delta \to 0$. In the scalar case of electrical conduction, it has been shown in [5] that for all connected graphs, the total energy blows up at the same rate as the energy in each gap. In the vectorial case considered here, connectivity is not sufficient to ensure the analogous property. The global rate of blow up depends on other geometrical characteristics of a connected graph (e.g., the coordination number; see [7] for details).

The functional Q depends on the interparticle distances $\delta^{ij} = \delta d^{ij}$, where the rescaled distances d^{ij} do not depend on δ, and $0 < c \leq d^{ij} \leq 1$ for all pairs of neighboring disks. To study asymptotic behavior of Q as $\delta \to 0$, we factor out the powers of δ and write

$$Q(\mathbf{T}^{(1)}, \dots, \mathbf{T}^{(N)}) = \delta^{-3/2}\widehat{Q}(\mathbf{T}^{(1)}, \dots, \mathbf{T}^{(N)}) + \delta^{-1/2}Q'(\mathbf{T}^{(1)}, \dots, \mathbf{T}^{(N)}), \tag{6.74}$$

where the coefficients of Q and Q' do not depend on δ, and

$$\widehat{Q} = \sum_{i=1}^{N} \sum_{\substack{j \in \mathcal{N}_i \\ j < i}} A^{ij}[(\mathbf{T}^{(i)} - \mathbf{T}^{(j)}) \cdot \mathbf{q}^{ij}]^2 + \sum_{i \in \mathcal{B}} A^i[(\mathbf{T}^{(i)} - \mathbf{g}) \cdot \mathbf{q}^i]^2 \tag{6.75}$$

with

$$A^{ij} = \frac{3\pi\mu}{4}\left(\frac{a}{d^{ij}}\right)^{\frac{3}{2}}, \qquad A^i = \frac{3\pi\mu}{4}\left(\frac{2a}{d^i}\right)^{\frac{3}{2}}. \tag{6.76}$$

Note that our boundary conditions (2.9) correspond to $\mathbf{g} = \pm\mathbf{e}_2$ on $\partial\Omega^{\pm}$ and by Definition 3.3, $\mathbf{q}^i = \pm\mathbf{e}_2$ on $\partial\Omega^{\pm}$. We keep the general notation in (6.75) because it may be applied to more general boundary conditions. In this section we use the rescaled dissipation rate

$$\widehat{E} = \min_{\substack{\mathbf{T}^{(i)} \\ i=1,\dots,N}} \widehat{Q}, \tag{6.77}$$

which does not depend on δ, and the corresponding minimizers $\widehat{\mathbf{T}^{(i)}}, i = 1, \dots, N$. From (6.72) and (6.74),

$$\delta^{-3/2}\widehat{E} \leq \delta^{-3/2}\widehat{Q}(\mathbf{T}^{(i)}_{min}) \leq E_2 = Q(\mathbf{T}^{(i)}_{min}) \leq Q(\widehat{\mathbf{T}^{(i)}}) = \delta^{-3/2}\widehat{E} + \delta^{-1/2}Q'(\widehat{\mathbf{T}^{(i)}}). \tag{6.78}$$

Since Q' and $\widehat{\mathbf{T}^{(i)}}$ are independent of δ, (6.78) and (6.73) yield $\delta^{-3/2}\widehat{E} \le E_2 \le \delta^{-3/2}\widehat{E} + O(\delta^{-1/2})$ and thus

$$E_2 = \delta^{-3/2}\widehat{E} + O(\delta^{-1/2}). \tag{6.79}$$

Therefore, the inequality

$$\widehat{E} > 0 \tag{6.80}$$

would imply $E_2 = O(\delta^{-3/2})$ as $\delta \to 0$, and the leading term of the asymptotics of E_2 would be determined by minimizing the δ-independent functional $\widehat{Q}$.

In this paper, we consider a mathematical model for uniformly closely packed suspensions. For geometrical arrays of particles which correspond to such suspensions, the inequality (6.80) does hold. The detailed investigation of geometric properties of arrays for which (6.80) does or does not hold under various external boundary conditions is a subject of a separate investigation carried out in [7]. Here, we describe only one sufficient condition for validity of (6.80), discuss its physical relevance, and present an example which illustrates this condition.

Uniform, closely packed geometries can be modeled by the so-called densely packed quasi-triangular graphs. Roughly speaking, these are graphs such that each particle in the corresponding array has six neighbors, and the interparticle distances are uniformly small. More precisely, a quasi-triangular graph Γ is defined as follows. We start with a graph Γ' in Ω such that the interior vertices of Γ' are points of the triangular periodic lattice. Then Γ is obtained by perturbing the locations of the vertices of Γ' in such a way that if two vertices were neighbors, they would remain neighbors. Moreover, a vertex of Γ' is connected to $\partial\Omega$ if and only if the corresponding vertex of Γ is connected to $\partial\Omega$. More precisely, let Γ denote a network graph, and let Γ' be a graph corresponding to a periodic triangular lattice restricted to Ω. We also define K and K' to be (topological) complexes associated with Γ and Γ', respectively. We say that the graph Γ is quasi-triangular if K and K' are combinatorially equivalent. (The definition of combinatorial equivalence can be found, for instance, in [26, p. 4].)

To define the close packing condition for such graphs, recall that the interior vertices of Γ' are the centers of disks of radius a and that the corresponding periodic lattice is closely packed if the interparticle distance $\delta = l - 2a \ll 1$, where l denotes the length of an interior edge. For a densely packed quasi-triangular graph, we require that

$$\max_{ij} \delta^{ij} = \max_{ij}(l^{ij} - 2a) \ll 1, \tag{6.81}$$

where the maximum is taken over all pairs of neighbors and l^{ij} is the length of the corresponding interior edge of Γ.

In [7], we prove that (6.80) holds for a quasi-triangular graph under the close packing condition. An example of a network satisfying (6.80) is presented in the appendix.

We now formulate the main theorems.

THEOREM 6.2. *Let E be the dissipation rate* (2.20) *equal to the effective viscosity $\langle\mu\rangle$ up to a constant normalizing factor (see* (2.19)*). Then as $\delta \to 0$,*

$$E \le E_2 + O(1) \tag{6.82}$$

and

$$E_2 + O(\delta^{-1}) \le E, \tag{6.83}$$

where E_2 is the minimum of the quadratic form (6.72).

THEOREM 6.3. *For uniform, closely packed geometries such that condition* (6.80) *holds, the rescaled effective viscosity (dissipation rate) E defined by* (2.20) *has the asymptotic representation*

$$E = \delta^{-3/2}\widehat{E} + O(\delta^{-1}) \quad \text{as } \delta \to 0, \tag{6.84}$$

where $\widehat{E}$ is a minimum of the quadratic form $\widehat{Q}$ defined by (6.75).

COROLLARY 6.1. *Let $\langle\mu\rangle$ be the effective viscosity defined by* (2.19)*, and let the conditions of Theorem* 6.3 *hold. Then*

$$\langle\mu\rangle = \frac{\widehat{E}}{\int_\Omega(\mathcal{E}(\mathbf{u}^0),\mathcal{E}(\mathbf{u}^0))d\mathbf{x}}\delta^{-3/2} + O(\delta^{-1}) \quad \text{as } \delta \to 0, \tag{6.85}$$

where $\mathbf{u}^0$ solves the Stokes equation $\Delta\mathbf{u}^0 - \nabla P^0 = 0$ in Ω with the boundary conditions (2.9) *and* (2.10).

Proof of the Theorem 6.2. Let us define the trial tensor $\mathcal{S}$ in Ω_F as follows. In each gap Π^{ij}, we use formula (6.17), and in each connected component $\mathcal{C}_l$ of $U_E = \Omega_F \setminus U_\Pi$, we let $\mathcal{S}$ be an extension from $\partial\mathcal{C}_l$, as given in Proposition 6.7. Note that, through our construction, we have ensured that $\mathcal{S} \in \mathcal{F}$ and, as such, it is an admissible trial field for the dual variational problem (2.22). Furthermore, let $\mathbf{u} \in \mathcal{U}$, defined by (6.6), be the trial function for primal variational problem (2.20).

Let us evaluate the dual functional $W^*_{\Omega_F}(\mathcal{S})$ defined in (6.8) and (6.9). Since $\mathcal{S}\mathbf{n} = 0$ on $\partial\Omega \setminus (\partial\Omega^+ \cup \partial\Omega^-)$,

$$W^*_{\Omega_F}(\mathcal{S}) = \int_{\partial\Omega^+\cup\partial\Omega^-} \mathbf{g}\cdot\mathcal{S}\mathbf{n}ds - \int_{\Omega_F} F(\mathcal{S})d\mathbf{x}.$$

First, we estimate the boundary integral. By Proposition 6.6, $|\mathcal{S}| \le c\delta^{-1/2}$ on $(\partial\Omega^+ \cup \partial\Omega^-) \setminus \partial U_\Pi$, and $\mathbf{g}$ is independent of δ. Hence,

$$\int_{\partial\Omega^+\cup\partial\Omega^-} \mathbf{g}\cdot\mathcal{S}\mathbf{n}ds = \int_{(\partial\Omega^+\cup\partial\Omega^-)\cap\partial U_\Pi} \mathbf{g}\cdot\mathcal{S}\mathbf{n}ds + O(\delta^{-1/2}). \tag{6.86}$$

Next, we use the notation from (5.11) to write

$$\int_{\Omega_F} F(\mathcal{S})d\mathbf{x} = \int_{U_\Pi} F(\mathcal{S})d\mathbf{x} + \int_{U_E} F(\mathcal{S})d\mathbf{x}. \tag{6.87}$$

The second integral in the right-hand side of (6.87) is $O(\delta^{-1})$ by Proposition 6.7. Using (6.8) with $M = U_\Pi$ and taking into account the boundary conditions (2.10), we write

$$\int_{(\partial\Omega^+\cup\partial\Omega^-)\cap\partial U_\Pi} \mathbf{g}\cdot\mathcal{S}\mathbf{n}ds - \int_{U_\Pi} F(\mathcal{S})d\mathbf{x} = W^*_{U_\Pi}(\mathcal{S}), \tag{6.88}$$

and, combining (6.88) with (6.86) and (6.87), we obtain

$$W^*_{\Omega_F}(\mathcal{S}) = W^*_{U_\Pi}(\mathcal{S}) + O(\delta^{-1}). \tag{6.89}$$

Now Proposition 6.8 and (6.1), (6.72), and (6.73) imply

$$W^*_{\Omega_F}(\mathcal{S}) = W_{U_\Pi}(\mathbf{u}) + O(\delta^{-1}) = E_2 + O(\delta^{-1}). \tag{6.90}$$

Applying the direct and dual variational principles (2.20)–(2.21), (2.22)–(2.23) with the trial fields $\mathbf{u}$ defined in (6.6) and $\mathcal{S}$ defined in the beginning of the proof, we obtain

$$W^*_{\Omega_F}(\mathcal{S}) \le E \le W_{\Omega_F}(\mathbf{u}), \tag{6.91}$$

and the estimates (6.82) and (6.83) follow. □

Proof of Theorem 6.3. The inequalities (6.82) and (6.83) imply $E = E_2 + O(\delta^{-1})$. Together with (6.79), this yields $E = \widehat{E}\delta^{-3/2} + O(\delta^{-1})$, which gives the representation (6.84) provided (6.80) holds. □

7. Summary. In this paper we obtain and rigorously justify an asymtotic formula for the effective viscosity of a suspension of closely packed solid particles in a viscous Newtonian fluid. This formula accounts for variable distances between particles which form a nonperiodic (e.g., random) array.

The rigorous justification is presented in two dimensions. It is based on a construction of matching to the leading order lower and upper bounds by means of two, dual to each other, variational principles for the effective viscosity. The key point here is the construction of the lower bound, which accounts for all pairwise interactions between neighboring particles as well as for the incompressibility condition in the fluid domain. These interactions influence each other over the entire domain, leading to considerable difficulties in the construction of the corresponding trial function.

In both three and two dimensions, we obtain formal asymptotics formulas for the effective viscosity for nonperiodic arrays of particles of different sizes. For a particular case of a periodic array when identical particles move toward each other (along the line which joins their centers), the leading term in our formulas recovers the formal asymptotics previously obtained by [15, 16]. Our formulas also contain lower order terms which take into account the rotations and movements of adjacent particles in directions orthogonal to the axis of their centers. In our formal asymptotic analysis, we develop the corresponding generalization of the lubrication approximation.

While the previously obtained asymptotic formulas [15, 16, 27] capture the dependence of the effective viscosity on the volume fraction in a periodic array of closely packed particles, the network approximation proposed in this work also accounts for other geometrical characteristics such as variable distances between particles and the coordination number (the number of neighboring particles).

Appendix. Proof of estimate (6.80). Here we prove that (6.80) holds for the spring network corresponding to the graph in Figure 10.

PROPOSITION 7.1. *Let* $\widehat{Q}$ *be the rescaled dissipation rate* (6.75) *corresponding to the network in Figure* 10. *Then* $\min \widehat{Q} > 0$.

Proof. The functional $\widehat{Q}$ is of the form

$$\begin{aligned}\widehat{Q} = {} & A^{12}((\mathbf{T}^{(1)} - \mathbf{T}^{(2)}) \cdot \mathbf{q}^{12})^2 + A^{13}((\mathbf{T}^{(1)} - \mathbf{T}^{(3)}) \cdot \mathbf{q}^{13})^2 + A^{23}((\mathbf{T}^{(2)} - \mathbf{T}^{(3)}) \cdot \mathbf{q}^{23})^2 \\ & + A^{24}((\mathbf{T}^{(2)} - \mathbf{T}^{(4)}) \cdot \mathbf{q}^{24})^2 + A^{1}((\mathbf{T}^{(1)} - \tfrac{1}{2}\mathbf{e}_2) \cdot \mathbf{e}_2)^2 + A^{2}((\mathbf{T}^{(2)} - \tfrac{1}{2}\mathbf{e}_2) \cdot \mathbf{e}_2)^2 \\ & + A^{3}((\mathbf{T}^{(3)} + \tfrac{1}{2}\mathbf{e}_2) \cdot \mathbf{e}_2)^2 + A^{4}((\mathbf{T}^{(4)} + \tfrac{1}{2}\mathbf{e}_2) \cdot \mathbf{e}_2)^2,\end{aligned} \tag{7.1}$$

where $A^{ij}, A^i, i, j = 1, 2, \dots, 4$, are given by (6.76). We show that $\min_{\mathbf{T}^{(i)}, i=1,2\dots,4} \widehat{Q} > 0$. Arguing by contradiction, assume that $\min \widehat{Q} = 0$. This is possible only if the minimizing set of vectors $\mathbf{T}^{(i)}$ satisfies the system of equations

$$(\mathbf{T}^{(1)} - \mathbf{T}^{(2)}) \cdot \mathbf{q}^{12} = 0, \quad (\mathbf{T}^{(1)} - \mathbf{T}^{(3)}) \cdot \mathbf{q}^{13} = 0, \quad (\mathbf{T}^{(2)} - \mathbf{T}^{(3)}) \cdot \mathbf{q}^{23} = 0, \tag{7.2}$$

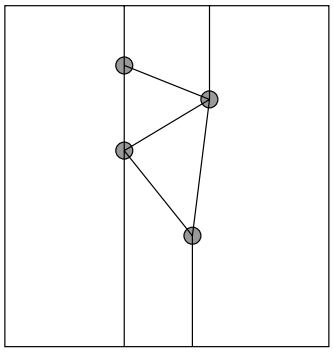

FIG. 10. *A four-disk network.*

$$(\mathbf{T}^{(2)} - \mathbf{T}^{(4)}) \cdot \mathbf{q}^{24} = 0, \qquad (\mathbf{T}^{(3)} - \mathbf{T}^{(4)}) \cdot \mathbf{q}^{34} = 0, \tag{7.3}$$

$$\mathbf{T}^{(1)} \cdot \mathbf{e_2} = \frac{1}{2}, \quad \mathbf{T}^{(2)} \cdot \mathbf{e_2} = \frac{1}{2}, \quad \mathbf{T}^{(3)} \cdot \mathbf{e_2} = -\frac{1}{2}, \quad \mathbf{T}^{(4)} \cdot \mathbf{e_2} = -\frac{1}{2}. \tag{7.4}$$

To write this system of nine equations in a more compact form $A\mathbf{z} = \mathbf{b}$, introduce a 1×8 vector of unknowns,

$$\mathbf{z} = (\mathbf{T}^{(1)}, \mathbf{T}^{(2)}, \mathbf{T}^{(3)}, \mathbf{T}^{(4)})^T.$$

The right-hand side of (7.2)–(7.4) is a 1×9 vector $\mathbf{b}$ that has the entries $b_i = 0, i = 1, 2, \ldots, 5$, $b_6 = b_7 = \frac{1}{2}$, $b_8 = b_9 = -\frac{1}{2}$. Performing (partial) Gaussian elimination on the transpose of the augmented matrix $(A \mid \mathbf{b})^T$, we find that it is similar to the matrix

$$C = \begin{pmatrix} \hat{\mathbf{q}}^{12} & \hat{\mathbf{q}}^{13} & \hat{\mathbf{o}} & \hat{\mathbf{o}} & \hat{\mathbf{o}} & \hat{\mathbf{e}}_2 & \hat{\mathbf{o}} & \hat{\mathbf{o}} & \hat{\mathbf{o}} \\ \hat{\mathbf{o}} & \hat{\mathbf{q}}^{13} & \hat{\mathbf{q}}^{23} & \hat{\mathbf{q}}^{24} & \hat{\mathbf{o}} & \hat{\mathbf{e}}_2 & \hat{\mathbf{e}}_2 & \hat{\mathbf{o}} & \hat{\mathbf{o}} \\ \hat{\mathbf{o}} & \hat{\mathbf{o}} & \hat{\mathbf{o}} & \hat{\mathbf{q}}^{24} & \hat{\mathbf{q}}^{34} & \hat{\mathbf{e}}_2 & \hat{\mathbf{e}}_2 & \hat{\mathbf{e}}_2 & \hat{\mathbf{o}} \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 1 & 1 & 1 & 1 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & -1 & -1 \end{pmatrix}. \tag{7.5}$$

Here

$$\begin{pmatrix} \hat{\mathbf{q}}^{12} & \hat{\mathbf{q}}^{13} & \hat{\mathbf{o}} & \hat{\mathbf{o}} & \hat{\mathbf{o}} & \hat{\mathbf{e}}_2 & \hat{\mathbf{o}} & \hat{\mathbf{o}} & \hat{\mathbf{o}} \end{pmatrix}$$

is a shorthand notation for two rows:

$$\mathbf{c}_1 = \begin{pmatrix} q_1^{12} & q_1^{13} & 0 & 0 & 0 & 0 & 0 & 0 & 0 \end{pmatrix}$$

and

$$\mathbf{c}_2 = \begin{pmatrix} q_2^{12} & q_2^{13} & 0 & 0 & 0 & 0 & 0 & 1 & 0 \end{pmatrix},$$

and, similarly, the other two boldfaced rows in (7.5) are the shorthand notation for the four rows $\mathbf{c}_3, \ldots, \mathbf{c}_6$. The last two rows of C in (7.5) are denoted by $\mathbf{c}_7, \mathbf{c}_8$.

To show that $\mathbf{c}_j$, $j = 1, 2, \ldots, 8$, are linearly independent, argue by contradiction. When $\mathbf{c}_j$ are linearly dependent, there exist λ_j, $j = 1, 2, \ldots, 8$, not all zero, such that

$$\sum_{j=1}^{8} \lambda_j \mathbf{c}_j = 0. \tag{7.6}$$

Let us take the sixth and seventh columns in the vector equation (7.6). Then (7.6) yields the equations

$$\lambda_2 + \lambda_4 + \lambda_6 + \lambda_7 = 0 \quad \text{and} \quad \lambda_4 + \lambda_6 + \lambda_7 = 0. \tag{7.7}$$

Thus $\lambda_2 = 0$. Next, consider the first column in (7.6) to obtain $\lambda_1 q_1^{12} + \lambda_2 q_2^{12} = 0$. Note that q_1^{12} cannot be zero since the edge e^{12} connects the boundary vertices 1, 2, and thus cannot be vertical. Hence $\lambda_1 = 0$. Next, consider columns 2 and 3 in (7.6). Since $\lambda_1 = \lambda_2 = 0$, from (7.6) we obtain two equations for λ_3, λ_4:

$$\begin{aligned} \lambda_3 q_1^{13} + \lambda_4 q_2^{13} &= 0, \\ \lambda_3 q_1^{23} + \lambda_4 q_2^{23} &= 0. \end{aligned} \tag{7.8}$$

Since $\mathbf{q}^{13}, \mathbf{q}^{23}$ are linearly independent, $\lambda_3 = \lambda_4 = 0$.

Consider columns four and five in (7.6). Since λ_3, λ_4 are zero, we obtain two equations for λ_5, λ_6:

$$\begin{aligned} \lambda_5 q_1^{24} + \lambda_4 q_2^{24} &= 0, \\ \lambda_3 q_1^{34} + \lambda_4 q_2^{34} &= 0. \end{aligned} \tag{7.9}$$

Linear independence of $\mathbf{q}^{24}, \mathbf{q}^{34}$ implies $\lambda_5 = \lambda_6 = 0$. Returning to (7.7), we see that $\lambda_7 = 0$. Finally, considering column 9, we obtain the equation for λ_8,

$$\lambda_7 - \lambda_8 = 0, \tag{7.10}$$

which yields $\lambda_8 = 0$. Thus, all λ_j must be zero, and we arrive at a contradiction, which yields $\operatorname{rank}(A \mid \mathbf{b}) = 8$. Applying the same Gaussian elimination to A^T, we see that $\operatorname{rank}(A) = 7$ and thus $\operatorname{rank}(A \mid \mathbf{b}) > \operatorname{rank}(A)$. This means that the system (7.2)–(7.4) has no solutions, and the minimum of $\widehat{Q}$ must be positive. ∎

Remark 7.1. A quasi-triangular structure of the graph is sufficient for positivity of $\widehat{Q}$. The proof of the Proposition 7.1 shows that if a graph contains a triangulated path (see Figure 10), then $\widehat{Q} > 0$ for the external boundary conditions (2.9), (2.10). We now explain heuristically why triangulization ensures positivity of $\widehat{Q}$. Start from vertices $1, 2$ in Figure 10. They are connected by the nonvertical edge e^{12}, which implies $\lambda_1 = 0$. We next add vertex 3 and observe that it is connected to vertices $1, 2$ by noncollinear edges e^{12}, e^{23}, which are adjacent sides of a triangle 123. The noncollinearity of these edges implies $\lambda_3 = \lambda_4 = 0$. Next, add vertex 4 to obtain triangle 234 and, as before, noncollinearity of the edges e^{34}, e^{42} implies $\lambda_5 = \lambda_6 = 0$. Finally, since e^{34} is nonvertical, $\lambda_7 = \lambda_8 = 0$. This argument also admits a straightforward generalization to a triangulated path of n vertices.

DYNAMICAL SCALING IN SMOLUCHOWSKI'S COAGULATION EQUATIONS: UNIFORM CONVERGENCE*

GOVIND MENON† AND ROBERT L. PEGO‡

Abstract. We consider the approach to self-similarity (or dynamical scaling) in Smoluchowski's coagulation equations for the solvable kernels $K(x,y) = 2, x+y$ and xy. We prove the uniform convergence of densities to the self-similar solution with exponential tails under the regularity hypothesis that a suitable moment have an integrable Fourier transform. For the discrete equations we prove uniform convergence under optimal moment hypotheses. Our results are completely analogous to classical local convergence theorems for the normal law in probability theory. The proofs rely on the Fourier inversion formula and the solution by the method of characteristics for the Laplace transform.

Key words. coagulation equations, dynamic scaling, self-similar solutions, complex characteristics

1. Introduction.

Smoluchowski's coagulation equation

$$\partial_t n(t,x) = \frac{1}{2}\int_0^x K(x-y,y)n(t,x-y)n(t,y)dy - \int_0^\infty K(x,y)n(t,x)n(t,y)dy \tag{1.1}$$

is a widely studied mean-field model for cluster growth [4, 8, 17]. We study the evolution of $n(t,x)$, the number of clusters of mass x per unit volume at time t, which coalesce by binary collisions with a symmetric rate kernel $K(x,y)$. Equation (1.1) has been used as a model of cluster growth in a surprisingly diverse range of fields such as physical chemistry, astrophysics, and population dynamics (see [4] for a review of applications). In addition, over the past few years a rich mathematical theory has been developed for these equations. Aldous [1] provides an excellent introduction.

Many kernels in applications are homogeneous; that is, $K(\alpha x, \alpha y) = \alpha^\gamma K(x,y)$, $x, y, \alpha > 0$, for some exponent γ [4]. A mathematical problem of scientific interest is to study self-similar or dynamical scaling behavior for homogeneous kernels. There are no general mathematical results for this problem despite an extensive scientific literature (especially formal asymptotics and numerics [12, 13, 18]). It is known that γ plays a crucial role. On physical grounds, we expect solutions to (1.1) to conserve the total mass $\int_0^\infty xn(t,x)dx$. When $K(x,y) \le 1+x+y$ (corresponding to $0 \le \gamma \le 1$), mass-conserving solutions exist globally in time under suitable moment hypotheses on initial data [5]. It is then typical in applications to assert that the solutions approach "scaling form" [13, 18], but there is no rigorous mathematical justification for this in general.

For a large class of kernels satisfying $(xy)^{\gamma/2} \leq K(x,y)$ with $1 < \gamma < 2$, it is known that there is no solution that preserves mass for all time. This breakdown phenomenon is known as *gelation*. It was first demonstrated by McLeod [14] with an explicit solution for the kernel $K = xy$. A general result using only the growth of the kernel was proved probabilistically by Jeon [9] (see also [6] for a simple analytical proof). It is natural to ask whether the blow-up is self-similar, but there are no general results on this problem yet.

There are a number of results, however, for the "solvable" kernels $K = 2$, $x + y$, and xy (see [15] and references therein; also see [13]). A remarkable feature of these kernels is that the problem of dynamical scaling can be understood quite deeply by analogy with classical limit theorems in probability theory. For example, an analogue to the classical Lévy–Khintchine representation for infinitely divisible laws was proved by Bertoin [2] for eternal solutions to Smoluchowski's equation with kernel $K = x + y$. Eternal solutions are defined for all $t \in (-\infty, \infty)$, meaning that they model coagulation processes "infinitely divisible" under Smoluchowski dynamics. Later, we proved [15] that the domains of attraction of self-similar solutions (in the sense of weak convergence of measures) can be characterized by almost power-law behavior of the tails of the initial size distribution. This is analogous to the characterization of the weak domains of attraction of the Lévy stable laws [7]. An essential component in both proofs is a simple solution formula for the Laplace transform of n that is widely known [4]. These results may be used as a basis for refined convergence theorems, as we now explain.

A general theme in probabilistic limit theorems is the interplay between moment and regularity hypotheses and the topology of convergence. In this article, we develop one aspect of this idea. Under stronger regularity hypotheses, the weak convergence results of [15] will be strengthened to obtain uniform convergence of densities using the Fourier transform. This method is classical in probability theory and is used to prove uniform convergence of densities in the central limit theorem [7, Theorem XV.5.2]. Feller's argument in [7] is simple and robust, and our main contribution is to show that it extends naturally to Smoluchowski's equation. The key new idea is to use the method of characteristics in the right half of the complex plane to obtain strong decay estimates on the Laplace transform. A broader contribution of this work and [15] is to show that the analytical methods used to prove classical limit theorems in probability apply to a wider range of problems involving scaling phenomenon for integral equations of convolution type.

Let us briefly connect our results to previous work: the only uniform convergence theorems in the literature are that of Kreer and Penrose for the kernel $K = 2$ [11] and closely connected work of da Costa [3]. In this article, for $K = 2$ and $x + y$ we present theorems on uniform convergence to the self-similar solutions with exponential tails for the continuous and discrete Smoluchowski equations. For $K = xy$, we prove uniform convergence of densities to self-similar form as t approaches the gelation time T_{gel}. For $K = 2$, we strengthen the result of Kreer and Penrose and simplify the proof. Their decay hypothesis on the initial data ($n_0(x) \leq Ce^{-ax}$) is weakened to an (almost) optimal moment hypothesis, and their regularity hypothesis ($n_0 \in C^2$) is weakened to a little bit more than continuity. For $K = x+y$ the convergence theorem is new. Study of the kernel $K = xy$ is reduced to $K = x+y$ by a well-known change of variables [4]. Uniform convergence to the self-similar solutions with "fat" or "heavy" tails is a more delicate issue, which will not be considered here.

Our uniform convergence theorems may be stated in a unified manner as follows

for the continuous Smoluchowski equations with kernels $K(x,y) = 2$, $x+y$, and xy, corresponding to $\gamma = 0, 1, 2$, respectively. Presuming the γth and $(\gamma+1)$st moments are finite, we may scale x and n so both moments are initially 1. For the multiplicative kernel this ensures that the gelation time $T_{\rm gel} = 1$. Let $T_\gamma = \infty$ for $\gamma = 0, 1$ and $T_\gamma = T_{\rm gel} = 1$ for $\gamma = 2$. The self-similar solutions with exponential tails are explicitly given by [15]

$$n(t,x) = \frac{m_\gamma(t)}{\lambda_\gamma(t)^{\gamma+1}}\,\hat{n}_{*,\gamma}\left(\frac{x}{\lambda_\gamma(t)}\right), \tag{1.2}$$

where, for $\hat{x} \geq 0$,

$$\hat{n}_{*,0}(\hat{x}) = e^{-\hat{x}}, \qquad \hat{x}\hat{n}_{*,1}(\hat{x}) = \hat{x}^2\hat{n}_{*,2}(\hat{x}) = \frac{1}{\sqrt{2\pi}}\hat{x}^{-1/2}e^{-\hat{x}/2}, \tag{1.3}$$

and

$$m_0(t) = t^{-1}, \quad m_1(t) = 1, \quad m_2(t) = (1-t)^{-1}, \tag{1.4}$$

$$\lambda_0(t) = t, \quad \lambda_1(t) = e^{2t}, \quad \lambda_2(t) = (1-t)^{-2}. \tag{1.5}$$

Our sufficient conditions for uniform convergence to these self-similar solutions for the continuous Smoluchowski equations are summarized by the following result.

THEOREM 1.1. *Let $n_0 \geq 0$, $\int_0^\infty x^\gamma n_0(x)dx = \int_0^\infty x^{1+\gamma}n_0(x)dx = 1$. Assume that the Fourier transform of $x^{1+\gamma}n_0$ is integrable, and let $n(t,x)$ be the solution to Smoluchowski's equation with initial data $n_0(x)$ and $K = 2$, $x+y$ or xy, for $\gamma = 0, 1$, or 2. Then the rescaled solution*

$$\hat{n}(t,\hat{x}) = \frac{\lambda_\gamma(t)^{1+\gamma}}{m_\gamma(t)}n(t,\hat{x}\lambda_\gamma(t))$$

satisfies

$$\lim_{t\to T_\gamma}\sup_{\hat{x}>0}\hat{x}^{1+\gamma}\,|\hat{n}(t,\hat{x}) - \hat{n}_{*,\gamma}(\hat{x})| = 0.$$

It has been traditional to treat the discrete Smoluchowski equations separately from the continuous equations. Yet, within the framework of measure valued solutions [15, 16], the discrete Smoluchowski equations simply correspond to the special case of a lattice distribution, a measure valued solution supported on the lattice $h\mathbb{N}$ and taking the form $\nu_t = \sum_{l=1}^\infty n_l(t)\delta_{hl}(x)$, where $\delta_{hl}(x)$ is a Dirac delta at hl. If h is maximal we call ν_t a lattice measure with *span* h. The coefficients n_l satisfy the discrete Smoluchowski equations

$$\partial_t n_l(t) = \frac{1}{2}\sum_{j=1}^{l-1}\kappa_{l-j,j}n_{l-j}(t)n_j(t) - \sum_{j=1}^{\infty}\kappa_{l,j}n_l(t)n_j(t), \tag{1.6}$$

where $\kappa_{l,j} = K(lh, jh)$. Physically, this case is of importance, since some mass aggregation processes (e.g., polymerization) have a fundamental unit of mass (e.g., a monomer). The uniform convergence theorems for the continuous Smoluchowski equations have a natural extension to this case.

THEOREM 1.2. *Let $\nu_0 \geq 0$ be a lattice measure with span h such that $\int_0^\infty x^\gamma\nu_0(dx) = \int_0^\infty x^{1+\gamma}\nu_0(dx) = 1$. Then with*

$$\hat{l} = \frac{lh}{\lambda_\gamma(t)}, \quad \hat{n}_l(t) = \frac{1}{h}\frac{\lambda_\gamma(t)^{1+\gamma}}{m_\gamma(t)}n_l(t),$$

we have

$$\lim_{t\to T_\gamma} \sup_{l\in\mathbb{N}} \hat{l}^{1+\gamma} \left|\hat{n}_l(t) - \hat{n}_{*,\gamma}(\hat{l})\right| = 0.$$

Let us comment on the hypotheses in Theorems 1.1 and 1.2. The moment hypotheses in both theorems are essentially the same. $\int_0^\infty x^\gamma \nu_0(dx) = 1$ is the natural hypothesis for existence and uniqueness of solutions [15]. The other moment condition $\int_0^\infty x^{1+\gamma}\nu_0(dx) = 1$ is of a different character. It implies that n_0 or ν_0 is in the weak domain of attraction of the self-similar solution with exponential tail, under a rescaling $n(t,x) \longrightarrow \hat{n}(\hat{t},\hat{x})$ that fixes both moments

$$\int_0^\infty \hat{x}^\gamma \hat{n}(\hat{t},\hat{x})d\hat{x} = \int_0^\infty \hat{x}^{\gamma+1}\hat{n}(\hat{t},\hat{x})d\hat{x} = 1 \quad \text{for all } \hat{t} \geq 0.$$

The hypothesis that the $(\gamma+1)$st moment is finite is almost optimal. The weak domain of attraction under a broader class of rescalings is a bit bigger, as it allows for a weak divergence $\int_0^y x^{1+\gamma}\nu_0(dx) \sim L(y)$ as $y \to \infty$ for a slowly varying function $L(y)$ [15]. Thus, Theorem 1.2 shows that within the class of lattice measures, the weak convergence of measures almost implies uniform convergence of the coefficients.

Theorem 1.1 requires an additional hypothesis on integrability of a suitable Fourier transform. This is a regularity hypothesis that is the analogue of the hypothesis for uniform convergence to the normal law used by Feller [7]. One may heuristically understand the role of regularity as follows. Equation (1.1) is hyperbolic and discontinuities in the initial data persist for all finite times. On the other hand, the self-similar solutions in (1.3) are analytic. Thus, one expects that some regularity on the initial data is necessary to obtain uniform convergence to a self-similar solution. Loosely speaking, regularity of the initial data $n_0(x)$ translates into a decay hypothesis on its Fourier transform. We need only the weak decay implied by integrability.

We do not know if this assumption is optimal, or if it may be weakened further. We briefly comment on this issue here; it will not be considered in the rest of the paper. The space of functions with integrable Fourier transforms is of great interest in harmonic analysis. Precisely, for $f \in L^1(\mathbb{R})$, let F be its Fourier transform. Then the space

$$A(\mathbb{R}) = \{f \in L^1(\mathbb{R}) | F \in L^1(\mathbb{R})\}$$

is a closed subalgebra of $L^1(\mathbb{R})$ known as the Wiener algebra [10]. Integrability of F implies that f is continuous. But it also implies more. It is known that functions in $A(\mathbb{R})$ possess some delicate regularity properties. For example, a function in $A(\mathbb{R})$ has a logarithmic modulus of continuity in a neighborhood where it is monotonic. It is definitely not obvious whether this regularity is truly necessary to obtain uniform convergence. If $v_0(ik) = \int_0^\infty e^{-ikx}x^{1+\gamma}n_0(x)dx$ is integrable, it also follows that $v_0 \in H^1(\mathbb{R}) \cap A(\mathbb{R})$, since v_0 is the boundary limit of an analytic function (the Laplace transform of $x^{1+\gamma}n_0$). Here H^1 denotes the classical Hardy space. This is turn means that v_0 has some hidden regularity and integrability properties. It is worth remarking that the precise characterization of $A(\mathbb{R})$ remains an outstanding open problem in harmonic analysis (though several sufficient conditions are known; see [10]).

2. Uniform convergence of densities for the constant kernel $K = 2$.

2.1. Evolution of the Laplace transform. Let $\mathbb{C}_+ = \{z \in \mathbb{C} \mid \operatorname{Re} z > 0\}$ and $\bar{\mathbb{C}}_+ = \{z \in \mathbb{C} \mid \operatorname{Re} z \geq 0\}$. We let

$$N(t,z) = \int_0^\infty e^{-zx} n(t,x)\,dx, \quad z \in \bar{\mathbb{C}}_+,$$

denote the Laplace transform of the number density n. We take the Laplace transform of (1.1) with $K = 2$, and its limit as $z \to 0$, to see that $N(t,z)$ solves

$$\partial_t N = N^2 - 2N(t,0)N, \quad \partial_t N(t,0) = -N(t,0)^2. \tag{2.1}$$

Without loss of generality, we may suppose that the initial time $t = 1$. We will always assume that the initial data is normalized such that

$$\int_0^\infty n(1,x)\,dx = \int_0^\infty x n(1,x)\,dx = 1. \tag{2.2}$$

If the initial number of clusters, $\int_0^\infty n(1,x)dx$, and the mass, $\int_0^\infty xn(1,x)dx$, are finite, we may always assume that (2.2) holds after rescaling x and n. We solve the second equation in (2.1) to see that the total number of clusters decreases according to

$$\int_0^\infty n(t,x)\,dx = N(t,0) = t^{-1}, \quad t \geq 1. \tag{2.3}$$

We hold z fixed and integrate (2.1) in t to obtain the solution

$$N(t,z) = \frac{1}{t}\frac{N(1,z)}{t(1-N(1,z)) + N(1,z)}. \tag{2.4}$$

The evolution preserves mass. Indeed, if we differentiate (2.4) with respect to z, we find

$$\int_0^\infty xn(t,x)\,dx = -\partial_z N(t,0) = -\partial_z N(1,0) = \int_0^\infty xn(1,x)\,dx = 1. \tag{2.5}$$

2.2. Approach to self-similarity. A special case of the weak convergence result of [15], also given by Leyvraz [13], is obtained as follows: Observe that for each fixed $s \in \bar{\mathbb{C}}_+$, equations (2.3), (2.4), and (2.5) imply

$$tN(t,st^{-1}) = \frac{N(1,st^{-1})}{t(1-N(1,st^{-1})) + N(1,st^{-1})} \underset{t\to\infty}{\longrightarrow} \frac{1}{1+s}. \tag{2.6}$$

It is classical that the pointwise convergence of Laplace transforms is equivalent to weak convergence of measures [7, Theorem XIII.1.2a]. Thus, (2.6) implies that rescaled solutions to Smoluchowski's equations converge weakly. Let us be more precise about the rescaling. We define the similarity variables

$$\tau = \log t, \quad \hat{x} = \frac{x}{t} = e^{-\tau}x, \quad s = tz = e^\tau z \tag{2.7}$$

and the rescaled number distribution

$$\hat{n}(\tau,\hat{x}) = e^{2\tau} n(e^\tau, e^\tau \hat{x}) = t^2 n(t,x). \tag{2.8}$$

Observe that this rescaling preserves *both* total number and mass, that is,

$$\int_0^\infty \hat{n}(\tau,\hat{x})d\hat{x} = \int_0^\infty \hat{x}\hat{n}(\tau,\hat{x})d\hat{x} = 1, \quad \tau \geq 0. \tag{2.9}$$

We denote the Laplace transform of $\hat{n}(\tau,\hat{x})$ by

$$u(\tau,s) = \int_0^\infty e^{-s\hat{x}}\hat{n}(\tau,\hat{x})\,d\hat{x} = e^\tau N(e^\tau, se^{-\tau}) = tN(t,z). \tag{2.10}$$

In these variables, the pointwise convergence of (2.6) takes the simple form

$$\lim_{\tau\to\infty} u(\tau,s) = \frac{1}{1+s} =: u_{*,0}(s), \quad s \in \bar{\mathbb{C}}_+, \tag{2.11}$$

where $u_{*,0}(s)$ denotes the Laplace transform of

$$\hat{n}_{*,0}(\hat{x}) = e^{-\hat{x}}, \quad \hat{x} \geq 0, \tag{2.12}$$

the profile for the self-similar solution in (1.2). Now, (2.11) is equivalent to

$$\hat{n}(\tau,\hat{x})\,d\hat{x} \to \hat{n}_{*,0}(\hat{x})\,d\hat{x}$$

as $\tau \to \infty$, in the sense of weak convergence of measures.

Our goal is to strengthen this to uniform convergence in both continuous and discrete cases, under appropriate hypotheses on initial data. For the continuous Smoluwchowski equation (1.1) we prove the following theorem.

THEOREM 2.1. *Let $n(1,x) \geq 0$, $\int_0^\infty n(1,x)\,dx = \int_0^\infty xn(1,x)\,dx = 1$. Assume that the Fourier transform of $xn(1,x)$ is integrable. Then in terms of the rescaling in* (2.7)–(2.8) *we have*

$$\lim_{\tau\to\infty} \sup_{\hat{x}>0} \hat{x}|\hat{n}(\tau,\hat{x}) - \hat{n}_{*,0}(\hat{x})| = 0, \tag{2.13}$$

where $\hat{n}_{*,0}(\hat{x}) = e^{-\hat{x}}$ is the similarity profile in (2.12).

The proof of this theorem extends to treat uniform convergence of coefficients for solutions of the discrete equations (1.6) under only the hypothesis that the zeroth and first moments are finite; see Theorem 2.2 below.

Observe that we prove uniform convergence of the weighted densities $\hat{x}\hat{n}(\tau,\hat{x})$. The reason can be ascribed to use of the Fourier–Laplace inversion formula. We cannot apply the inversion formula directly to $u_{*,0}$ as it is not integrable on the imaginary axis ($|u_{*,0}(ik)| \sim |k|^{-1}$ as $|k| \to \infty$). The slow decay of the Fourier transform is caused by the jump discontinuity at $x = 0$, since $\hat{n}_{*,0}(x) = 0$ for $x < 0$. In order to gain a uniform convergence result, we smooth this discontinuity and consider the mass density $\hat{x}\hat{n}$. Its Laplace transform we denote by

$$v(\tau,s) = -\partial_s u(\tau,s) = \int_0^\infty e^{-s\hat{x}}\hat{x}\hat{n}(\tau,\hat{x})\,d\hat{x}. \tag{2.14}$$

Differentiating (2.11), we obtain a corresponding self-similar profile, with

$$v_{*,0}(s) := \frac{1}{(1+s)^2}, \qquad |v_{*,0}(ik)| = \frac{1}{1+k^2},\ k \in \mathbb{R}. \tag{2.15}$$

2.3. Evolution on characteristics. The explicit solution for $u(\tau, s)$ and $v(\tau, s)$ can be obtained directly by substituting (2.10) into (2.4). But we rederive the solution to make explicit the geometric idea underlying the proof of Theorem 2.1. The same ideas underlie the proof of Theorem 3.1 for the additive kernel and are more easily understood here. We use the change of variables (2.7) and (2.10) in (2.1), and the conservation of moments in (2.9), to obtain the equation of evolution for u:

$$\partial_\tau u + s\partial_s u = -u(1-u). \tag{2.16}$$

The solution of (2.16) may be described by the method of characteristics. A characteristic curve $s(\tau; \tau_0, s_0)$ is the solution to

$$\frac{ds}{d\tau} = s, \quad s(\tau; \tau_0, s_0) = s_0 \in \bar{\mathbb{C}}_+. \tag{2.17}$$

Explicitly,

$$s(\tau; \tau_0, s_0) = e^{\tau - \tau_0} s_0. \tag{2.18}$$

Equation (2.17) is an autonomous differential equation in $\bar{\mathbb{C}}_+$ and may be thought of geometrically. For fixed $s_0 \in \bar{\mathbb{C}}_+$ the trajectory of the characteristic curve $s(\tau; \tau_0, s_0), \tau \in \mathbb{R}$, is a ray in $\bar{\mathbb{C}}_+$ emanating from the origin. In particular, the imaginary axis is invariant under the flow of (2.17). Equation (2.18) shows that the characteristics expand uniformly outward at the rate e^τ. Along characteristics we have

$$\frac{du}{d\tau} = -u(1-u), \tag{2.19}$$

which may be integrated to obtain the solution

$$u(\tau, s) = \frac{u(\tau_0, s_0)e^{-(\tau-\tau_0)}}{1 - u(\tau_0, s_0)(1 - e^{-(\tau-\tau_0)})}. \tag{2.20}$$

We need to estimate the decay of the derivative $v = -\partial_s u$. Differentiating (2.16), we see that on characteristics the derivative solves

$$\frac{dv}{d\tau} = -2(1-u)v. \tag{2.21}$$

We integrate (2.21) using (2.20) to find

$$v(\tau, s) = \frac{v(\tau_0, s_0)e^{-2(\tau-\tau_0)}}{\big(1 - u(\tau_0, s_0)(1 - e^{-(\tau-\tau_0)})\big)^2}. \tag{2.22}$$

For $\tau \geq \tau_0$ we may take absolute values in (2.20) and (2.22) to obtain the decay estimates

$$|u(\tau, s)| \leq \frac{|u(\tau_0, s_0)|e^{-(\tau-\tau_0)}}{1 - |u(\tau_0, s_0)|(1 - e^{-(\tau-\tau_0)})} \tag{2.23}$$

and

$$|v(\tau, s)| \leq \frac{|v(\tau_0, s_0)|e^{-2(\tau-\tau_0)}}{\big(1 - |u(\tau_0, s_0)|(1 - e^{-(\tau-\tau_0)})\big)^2} \leq \frac{|v(\tau_0, s_0)|e^{-2(\tau-\tau_0)}}{\big(1 - |u(\tau_0, s_0)|\big)^2}. \tag{2.24}$$

2.4. Proof of Theorem 2.1. 1. We use the Fourier–Laplace inversion formula

$$\hat{x}(\hat{n}(\tau,\hat{x}) - \hat{n}_{*,0}(\hat{x})) = \frac{1}{2\pi}\int_{\mathbb{R}} e^{ik\hat{x}}\left(v(\tau,ik) - v_{*,0}(ik)\right)\,dk. \tag{2.25}$$

Thus, in order to prove (2.13) it suffices to show

$$\lim_{\tau\to\infty}\int_{\mathbb{R}} |v(\tau,ik) - v_{*,0}(ik)|\,dk = 0. \tag{2.26}$$

2. Let $\varepsilon \in (0,\frac{1}{2})$ and put $R = \varepsilon^{-1}$. We will prove (2.26) by estimating the integral separately in three regions: $|k| \le R$, $R \le |k| \le Re^{\tau-T}$, and $Re^{\tau-T} \le |k|$ for $\tau \ge T$, where $T > 0$ will be chosen sufficiently large, depending on ε and the initial data v_0. This is essentially the same decomposition used in the proof of uniform convergence in the central limit theorem by Feller [7, Theorem XV.5.2]. The main new idea here is the use of the decay estimates (2.24) and the method of characteristics in the regions where $R \le |k|$.

3. $|k| \le R$: Recall that the pointwise convergence of Laplace transforms (2.11) is equivalent to $\hat{n}(\tau,\hat{x})\,d\hat{x} \to \hat{n}_{*,0}(\hat{x})\,d\hat{x}$ in the sense of weak convergence of measures. Combined with (2.9) this also implies that the mass measures $\hat{x}\hat{n}(\tau,\hat{x})\,d\hat{x}$ converge weakly to $\hat{x}\hat{n}_{*,0}(\hat{x})\,d\hat{x}$ as $\tau \to \infty$. But this implies $v(\tau,ik)$ converges to $v_{*,0}(ik)$ uniformly for $|k| \le R$ [7, Theorem XV.3.2]. Therefore,

$$\lim_{\tau\to\infty}\int_{-R}^{R} |v(\tau,ik) - v_{*,0}(ik)|\,dk = 0. \tag{2.27}$$

4. It remains to consider $|k| \ge R$. It is sufficient to consider only $k \ge R$, since $|v(\tau,ik)| = |v(\tau,-ik)|$. We will control $v(\tau,ik)$ and $v_{*,0}$ separately:

$$\int_R^\infty |v(\tau,ik) - v_{*,0}(ik)|\,dk \le \int_R^\infty |v(\tau,ik)|\,dk + \int_R^\infty |v_{*,0}(ik)|\,dk.$$

But $|v_{*,0}(ik)| = (1+|k|^2)^{-1}$ by (2.15), so that

$$\int_R^\infty |v_{*,0}(ik)|\,dk \le R^{-1} = \varepsilon.$$

In the rest of the proof we estimate $\int_R^\infty |v(\tau,ik)|dk$.

5. Since $u(\tau,ik) \to u_{*,0}(ik)$ and $v(\tau,ik) \to v_{*,0}$ as $\tau \to \infty$ for each real k, using (2.11) and (2.15) we may choose $T > 0$ such that

$$\sup_{\tau\ge T} |u(\tau,iR)| \le R^{-1} = \varepsilon, \quad \sup_{\tau\ge T} |v(\tau,iR)| \le R^{-2}. \tag{2.28}$$

6. $R \le k \le Re^{\tau-T}$: The control obtained from (2.28) propagates outward along characteristics as τ increases. Precisely, whenever $\tau \ge T$, for any k such that $R \le k \le Re^{\tau-T}$ we have $ik = e^{\tau-\tau_0}iR$, where $\tau_0 \ge T$. By (2.18) this means that $ik = s(\tau;\tau_0,s_0)$, with $s_0 = iR$. Then the decay estimate (2.24) and the boundary control (2.28) imply

$$|v(\tau,ik)| \le \frac{|v(\tau_0,iR)|e^{-2(\tau-\tau_0)}}{\left(1-|u(\tau_0,iR)|\right)^2} \le \frac{1}{(1-\varepsilon)^2}R^{-2}\left(\frac{R}{k}\right)^2 \le 4k^{-2}. \tag{2.29}$$

Integrating this estimate we obtain

$$\int_R^{Re^{\tau-T}} |v(\tau,ik)|\,dk \le \int_R^\infty 4k^{-2}\,dk = 4R^{-1} = 4\varepsilon.$$

7. $Re^{\tau-T} \le k$: For brevity, let $\tilde{R} = Re^{-T}$. With $u_0(s) := u(0,s)$, $v_0(s) := v(0,s)$, we use (2.24) and (2.18) with $\tau_0 = 0$ to obtain

$$\int_{\tilde{R}e^\tau}^\infty |v(\tau,ik)|\,dk \le e^{-2\tau}\int_{\tilde{R}e^\tau}^\infty \frac{|v_0(ike^{-\tau})|}{\left(1-|u_0(ike^{-\tau})|\right)^2}dk$$
$$= e^{-\tau}\int_{\tilde{R}}^\infty \frac{|v_0(ik')|}{\left(1-|u_0(ik')|\right)^2}dk' \le \left(\sup_{|k'|\ge\tilde{R}} \frac{1}{\left(1-|u_0(ik')|\right)^2}\right) e^{-\tau}\|v_0\|_{L^1},$$

where $k' = ke^{-\tau}$. Since $|u_0(ik')| < 1$ for $k' \ne 0$ and $u_0(ik') \to 0$ as $k \to \infty$ by the Riemann–Lebesgue lemma, we have $\sup_{|k'|\ge\tilde{R}}(1-|u_0(ik')|)^{-2} < \infty$.

8. Putting together the estimates we have obtained, it follows that for τ sufficiently large, the integral in (2.26) is less than 12ε. This completes the proof.

2.5. The discrete Smoluchowski equations. We consider measure solutions of the form $\nu_t = \sum_{l=1}^\infty n_l(t)\delta_{hl}(x)$, where $\delta_{hl}(x)$ denotes a Dirac mass at hl. To avoid redundancy, we always assume that h is the *span* of the lattice, that is, the maximal $h > 0$ so that all initial clusters, and thus clusters at any time $t > 0$, are concentrated on $h\mathbb{N}$. We will call ν_t a lattice measure with span h. Notice that if the initial number of clusters and the mass are finite, by rescaling n_l and h we may assume that $\int_0^\infty \nu_1(dx) = \int_0^\infty x\nu_1(dx) = 1$. Under these conditions, the weak convergence theorem of [15] asserts that $\lim_{t\to\infty} tN(t,s/t) = u_{*,0}(s)$. We show that this theorem may be strengthened by use of Fourier series. The Fourier transform of ν_t is the Fourier series

$$N(t,ik) = \sum_{l\in\mathbb{N}} n_l(t)e^{-ilhk}, \qquad k \in \mathbb{R},$$

which has minimal period $2\pi/h$. Thus $n_l(t) = (h/2\pi)\int_{-\pi/h}^{\pi/h} e^{ilhk}N(t,ik)\,dk$, or

$$t^2 n_l(t) = \frac{h}{2\pi}\int_{-\pi e^\tau/h}^{\pi e^\tau/h} \exp(ilhke^{-\tau})u(\tau,ik)\,dk, \tag{2.30}$$

in similarity variables from (2.10). We integrate by parts and let

$$\hat{l} = lhe^{-\tau} = lht^{-1}, \quad \hat{n}_l(t) = h^{-1}t^2 n_l(t) \tag{2.31}$$

to obtain

$$\hat{l}\hat{n}_l(t) = tln_l(t) = \frac{1}{2\pi}\int_{-\pi e^\tau/h}^{\pi e^\tau/h} e^{i\hat{l}k}v(\tau,ik)\,dk. \tag{2.32}$$

As in Theorem 2.1, we expect the right-hand side to converge to $\hat{l}\hat{n}_{*,0}(\hat{l})$ as $\tau \to \infty$, indeed uniformly for $\hat{l} \in ht^{-1}\mathbb{N}$.

THEOREM 2.2. *Let $\nu_1 \ge 0$ be a lattice measure with span h such that $\int_0^\infty \nu_1(dx) = \int_0^\infty x\nu_1(dx) = 1$. Then with the scaling* (2.31) *we have*

$$\lim_{t\to\infty}\sup_{l\in\mathbb{N}} \hat{l}\left|\hat{n}_l(t) - \hat{n}_{*,0}(\hat{l})\right| = 0. \tag{2.33}$$

Proof. By (2.32) and the continuous Fourier inversion formulas, it suffices to show that

$$\lim_{\tau\to\infty}\sup_{\hat{l}\geq 0}\left|\int_{-\pi e^{\tau}/h}^{\pi e^{\tau}/h} e^{i\hat{l}k}v(\tau,ik)\,dk-\int_{\mathbb{R}} e^{i\hat{l}k}v_{*,0}(ik)\,dk\right|=0.$$

As earlier, it suffices to consider $k>0$. The integrals

$$\int_{-R}^{R}|v(\tau,ik)-v_{*,0}(ik)|\,dk,\quad \int_{R}^{\tilde{R}e^{\tau}}|v(\tau,ik)|\,dk,\quad \int_{R}^{\infty}|v_{*,0}(ik)|\,dk,$$

with $\tilde{R}=Re^{-T}$, are controlled exactly as in the proof of Theorem 2.1. It only remains to estimate the integral of $|v(\tau,ik)|$ over the region $\tilde{R}e^{\tau}<k<\pi e^{\tau}/h$. We assume that $\pi/h>\tilde{R}$, for otherwise there is nothing to prove. But then by the formula (2.18), the uniform decay estimate (2.24), and the change of variables $k'=ke^{-\tau}$, we have

$$\int_{\tilde{R}e^{\tau}}^{\pi e^{\tau}/h}|v(\tau,ik)|\,dk\leq e^{-\tau}\int_{\tilde{R}}^{\pi/h}\frac{|v_0(ik')|}{|1-u_0(ik')(1-e^{-\tau})|^2}dk'.$$

Since the domain of integration is finite, it suffices to show that the integrand is uniformly bounded in time. Since $|v_0(ik)|\leq 1$, it is only necessary to control the denominator. But $u_0(ik)=\sum_{l\in\mathbb{N}}n_l(0)e^{-ilkh}$ with $n_l(0)\geq 0$. Therefore, $|u_0(ik)|\leq 1$, and [7, Lemma XV.1.4] yields that

$$u_0(ik)=1\quad\text{if and only if}\quad k=\frac{2\pi m}{h},\qquad m\in\mathbb{Z}.$$

In particular, we have the strict inequality

$$\min_{k\in[\tilde{R},\frac{\pi}{h}]}|1-u_0(ik)|\geq\delta>0.$$

Therefore,

$$\left|1-u_0(ik)(1-e^{-\tau})\right|\geq|1-u_0(ik)|-|u_0(ik)|e^{-\tau}\geq\delta-e^{-\tau}\geq\frac{\delta}{2}$$

for sufficiently large τ. Thus,

$$\int_{\tilde{R}e^{\tau}}^{\pi e^{\tau}/h}|v(\tau,ik)|\,dk\leq\frac{2\pi}{\delta h}e^{-\tau}.\qquad\square$$

3. Uniform convergence of densities for the additive kernel.

3.1. Rescaling and approach to self-similarity. In this section we prove the analogues of Theorems 2.1 and 2.2 for the additive kernel. The essential geometric ideas of the proof are similar to the previous section. However, the trajectories of the characteristic curves $s(t;t_0,s_0)$ in the complex plane are no longer rays, and the proofs require more careful analysis. As earlier, we will work with the explicit solution formula for an appropriate Laplace transform. For $z\in\bar{\mathbb{C}}_+$ we define

$$\Phi(t,z)=\int_0^{\infty}\left(1-e^{-zx}\right)n(t,x)dx. \tag{3.1}$$

We observe that $1-e^{-zx} = zx+O(z^2x^2)$ as $x \to 0$. We use Φ instead of the standard Laplace transform of n because the latter may not be well defined: for example, the similarity profile $\hat{n}_{*,1}$ in (1.3) satisfies $\hat{n}_{*,1}(x) \sim Cx^{-3/2}$ as $x \to 0$. More generally, one needs the initial data to have only a finite first moment for existence and uniqueness of a solution to (1.1) in the case of the additive kernel [15]. A deeper reason for this choice of variables (and notation) is probabilistic: (3.1) is the Lévy–Khintchine formula for the Laplace exponent of a subordinator with no drift [2]. We will always assume that the initial data n_0 satisfies the moment conditions

$$\int_0^\infty x n_0(x)dx = 1, \quad \int_0^\infty x^2 n_0(x)dx = 1. \tag{3.2}$$

We substitute (3.1) in (1.1) and use (3.2) to see that $\Phi(t,z)$ solves the equation

$$\partial_t \Phi - \Phi \partial_z \Phi = -\Phi, \quad \Phi(0,z) = \int_0^\infty (1-e^{-zx}) n_0(x)dx. \tag{3.3}$$

As shown in [15] by the method of characteristics, (3.3) has a unique solution for $z > 0$, $t > 0$ which is analytic with derivative $\partial_z\Phi$ completely monotone in z and satisfying $\partial_z\Phi(t,0) = 1$ for all t. For each $t > 0$ then, $\partial_z\Phi(t,\cdot)$ is the Laplace transform of a probability measure, so its domain contains $\bar{\mathbb{C}}_+$ and (3.3) holds by analytic continuation for $z \in \mathbb{C}_+$, $t > 0$.

In contrast with (2.4), it is not obvious that a suitable rescaling will lead to convergence to self-similar form. This point is discussed in [15, sect.7], and we refer the reader to that article for motivation for the following change of variables. We define the similarity variables

$$\hat{x} = xe^{-2t}, \quad s = ze^{2t} \tag{3.4}$$

and the rescaled number density

$$\hat{n}(t,\hat{x}) = e^{4t} n(t, \hat{x}e^{2t}) = e^{4t} n(t,x). \tag{3.5}$$

We also define the rescaled Laplace transforms

$$\varphi(t,s) = e^{2t}\Phi(t,e^{-2t}s) = \int_0^\infty (1-e^{-s\hat{x}})\hat{n}(t,\hat{x})d\hat{x}. \tag{3.6}$$

Part of the motivation for the rescaling (3.4) and (3.5) is that this choice preserves *both* moment conditions in (3.2). That is, we have

$$\int_0^\infty \hat{x}\hat{n}(t,\hat{x})d\hat{x} = \int_0^\infty \hat{x}^2\hat{n}(t,\hat{x})d\hat{x} = 1, \quad t \geq 0. \tag{3.7}$$

This should be compared with (2.9) for the constant kernel. The mass measure plays the same role here as the number measure did for $K = 2$. Thus, we denote its Laplace transform by the same letter, and let

$$u(t,s) = \partial_s\varphi(t,s) = \int_0^\infty e^{-s\hat{x}}\hat{x}\hat{n}(t,\hat{x})d\hat{x}. \tag{3.8}$$

By Theorem 7.1 in [15] (also see [13, Appendix G]), the assumptions in (3.2) imply that the rescaled mass measures converge to the similarity profile, with

$$\hat{x}\hat{n}(t,\hat{x})d\hat{x} \to \hat{x}\hat{n}_{*,1}(\hat{x})d\hat{x} = \frac{1}{\sqrt{2\pi}}\hat{x}^{-1/2}e^{-\hat{x}/2}d\hat{x}, \quad t \to \infty, \tag{3.9}$$

in the sense of weak convergence of measures. It then follows from [7, Theorem XIII.1.2] that (3.9) is equivalent to

$$\lim_{t\to\infty} u(t,s) = \frac{1}{\sqrt{1+2s}} =: u_{*,1}(s), \quad s \in \bar{\mathbb{C}}_+. \tag{3.10}$$

Our goal is to strengthen (3.9) to uniform convergence of densities for (1.1) and uniform convergence of coefficients for (1.6). For the continuous Smoluchowski equations we prove the following theorem.

THEOREM 3.1. *Suppose* $n_0(x) \geq 0$, $\int_0^\infty x n_0(x)dx = \int_0^\infty x^2 n_0(x)dx = 1$. *Suppose also that the Fourier transform of* $x^2 n_0$ *is integrable. Then in terms of the rescaling* (3.4)–(3.5) *we have*

$$\lim_{t\to\infty} \sup_{\hat{x}>0} \hat{x}^2 |\hat{n}(t,\hat{x}) - \hat{n}_{*,1}(\hat{x})| = 0, \tag{3.11}$$

where $\hat{n}_{*,1}(\hat{x})$ *is the similarity profile defined in* (1.3).

Once Theorem 3.1 is established, it is relatively straightforward to obtain the analogous result for the discrete Smoluchowski equations; see Theorem 3.6 below. Thus, most of our effort is devoted to Theorem 3.1.

Observe that we prove uniform convergence of the weighted density $\hat{x}^2\hat{n}(t,\hat{x})$. As in the previous section, this is because Theorem 3.1 is proved using the Fourier–Laplace inversion formula. Since $|u_{*,1}(ik)| \sim |k|^{-1/2}$ as $|k| \to \infty$, $u_{*,1}$ is not integrable on the imaginary axis. This divergence is due to the fact that $\hat{n}_{*,1}(\hat{x}) = 0$ for $\hat{x} < 0$ and $\hat{x}\hat{n}_{*,1}(\hat{x}) \sim C\hat{x}^{-1/2}$ as $\hat{x} \to 0^+$. As earlier, we resolve the situation by considering the transform of the next moment. Let

$$v(t,s) = -\partial_s u(t,s) = \int_0^\infty e^{-s\hat{x}} \hat{x}^2 \hat{n}(t,\hat{x}) d\hat{x}, \quad s \in \bar{\mathbb{C}}_+. \tag{3.12}$$

We integrate and differentiate (3.10) to obtain

$$\varphi_{*,1}(s) = \sqrt{1+2s} - 1, \quad v_{*,1}(s) = (1+2s)^{-3/2}, \quad s \in \bar{\mathbb{C}}_+. \tag{3.13}$$

3.2. Characteristics and estimates. The equations of evolution for φ and u are

$$\partial_t \varphi + (2s - \varphi)\partial_s \varphi = \varphi, \tag{3.14}$$

$$\partial_t u + (2s - \varphi)\partial_s u = -u(1-u). \tag{3.15}$$

In what follows, we first derive solution formulas to (3.14) by the method of characteristics. We then show that the solution map for the characteristic equation is never degenerate and that characteristics flow out of the right half into the left half of the complex plane as t increases. For most parts of our analysis, it will suffice to study characteristics in the right half plane only. But for one part, we need to study characteristics that start in the right half plane but move into the left half plane.

We use the notation $s(t; t_0, s_0)$ to denote the solution to

$$\frac{ds}{dt} = 2s - \varphi, \quad s(t_0; t_0, s_0) = s_0. \tag{3.16}$$

Along the characteristic curve $s(t; t_0, s_0)$, we have

$$\frac{d\varphi}{dt} = \varphi \quad \text{and} \quad \frac{du}{dt} = -u(1-u). \tag{3.17}$$

We integrate (3.17) to obtain

$$\varphi(t,s) = e^{t-t_0}\varphi(t_0,s_0), \quad u(t,s) = \frac{u(t_0,s_0)e^{-(t-t_0)}}{1-u(t_0,s_0)(1-e^{-(t-t_0)})}. \tag{3.18}$$

We now substitute for $\varphi(t,s)$ from (3.18) in (3.16) and integrate to obtain the explicit solution

$$e^{-2(t-t_0)}s(t;t_0,s_0) = s_0 - \varphi(t_0,s_0)(1-e^{-(t-t_0)}). \tag{3.19}$$

This equation can also be rewritten in two other useful forms, namely

$$e^{-2(t-t_0)}\,(s-\varphi(t,s)) = (s_0-\varphi(t_0,s_0)) \tag{3.20}$$

and

$$\frac{\varphi(t,s)}{s} = \frac{(\varphi(t_0,s_0)/s_0)e^{-(t-t_0)}}{1-(\varphi(t_0,s_0)/s_0)(1-e^{-(t-t_0)})}. \tag{3.21}$$

The method of characteristics also yields an explicit solution for $v(t,s)$. We differentiate (3.15) to obtain

$$\frac{dv}{dt} = -3(1-u)v. \tag{3.22}$$

We substitute for u from (3.18) and integrate (3.22) to obtain

$$v(t,s) = \frac{v(t_0,s_0)e^{-3(t-t_0)}}{\big(1-u(t_0,s_0)(1-e^{-(t-t_0)})\big)^3}. \tag{3.23}$$

Let $\varphi_0(s) := \varphi(0,s)$, and similarly $u_0(s) := u(0,s)$, $v_0(s) := v(0,s)$. Since $u = \partial_s\varphi$ and $\varphi(t,0) = 0$, the moment conditions (3.2) and the identity $\varphi_0(s)/s = \int_0^1 u_0(\tau s)\,d\tau$ imply

$$|u_0(s)| \le 1, \quad |v_0(s)| \le 1, \quad |\varphi_0(s)| \le |s|, \quad s \in \bar{\mathbb{C}}_+. \tag{3.24}$$

These inequalities are strict for $s \neq 0$ because $xn_0(x)\,dx$ is not a lattice measure [7, Lemma XV.1.4]. Taking $t_0 = 0$ at first, for $t \ge t_0$ we take absolute values in (3.18) and (3.23) to see that $|u|$ and $|v|$ decay along characteristics according to

$$|u(t,s)| \le \frac{|u(t_0,s_0)|e^{-(t-t_0)}}{1-|u(t_0,s_0)|(1-e^{-(t-t_0)})}, \tag{3.25}$$

$$|v(t,s)| \le \frac{|v(t_0,s_0)|e^{-3(t-t_0)}}{(1-|u(t_0,s_0)|)^3}. \tag{3.26}$$

From (3.25) and the fact that $|u_0(s_0)| < 1$ for $s_0 \neq 0$, and a similar estimate using (3.21) and $|\varphi_0(s_0)/s_0| < 1$, it follows that

$$|u(t,s)| < 1, \quad |\varphi(t,s)/s| < 1, \quad t \ge 0,\ s \neq 0. \tag{3.27}$$

Then (3.25) and (3.26) hold also for any $t_0 \ge 0$ if $t \ge t_0$.

Let us also note the uniform outward growth of characteristics implied by (3.27). Using (3.27) together with (3.16) we obtain

$$|s| \le \frac{d|s|}{dt} \le 3|s|. \tag{3.28}$$

Thus, $|s_0|e^{(t-t_0)} \le |s| \le e^{3(t-t_0)}|s_0|$. We will refine this crude estimate in the proof of Theorem 3.1, but we note here that $|s(t;t_0,s_0)|$ is a strictly increasing function of t.

In addition to the decay along characteristics, we will need the following uniform Riemann–Lebesgue lemma. Let $C_R = \{s \in \bar{\mathbb{C}}_+ \mid |s| = R\}$ denote the semicircle of radius R in the right half plane.

LEMMA 3.2. *Let $g(x) \in L^1(0,\infty)$ and $G(s) = \int_0^\infty e^{-sx} g(x)dx$. Then*

$$\lim_{R\to\infty} \sup_{s\in C_R} |G(s)| = 0. \tag{3.29}$$

Proof. Let $\varepsilon > 0$. We choose a step function $g_\varepsilon = \sum_{k=1}^K c_k 1_{[a_k,b_k]}$ so that $\|g - g_\varepsilon\|_{L^1} < \varepsilon$. But then, $\|e^{-sx}(g-g_\varepsilon)\|_{L^1} < \varepsilon$. Therefore, for $s \in \bar{\mathbb{C}}_+$,

$$|G(s)| \le \varepsilon + \left|\int_0^\infty e^{-sx} g_\varepsilon(x)dx\right| = \varepsilon + \left|\sum_{k=1}^K c_k \int_{a_k}^{b_k} e^{-sx}dx\right| \le \varepsilon + \frac{C_\varepsilon}{|s|}. \qquad \square$$

We apply this lemma and (3.7) to $g(\hat{x}) = \hat{x}^j \hat{n}(t,\hat{x})$ for $j = 1,2$ to infer that for every $t \ge 0$, as $|s| \to \infty$ with $\operatorname{Re} s \ge 0$, we have

$$|u(t,s)| \to 0, \quad |v(t,s)| \to 0, \quad \left|\frac{\varphi(t,s)}{s}\right| \to 0. \tag{3.30}$$

3.3. Geometry of the characteristic map in the complex plane. In this subsection, we study the solution formula (3.19). Our goal is to delineate some key properties of the map $s_0 \mapsto s(t;t_0,s_0)$ for $t, t_0 \ge 0$.

Let $\mathbb{C}_+$ denote the open right half plane. We let Ω_t denote the image of $\mathbb{C}_+$ under the map $s_0 \mapsto s(t;0,s_0)$, and let Γ_t denote the image of the imaginary axis under the same map. We aim to prove the following.

LEMMA 3.3.

(i) *For any $t > 0$, Γ_t is a C^2 curve that passes through the origin but otherwise lies in the open left half plane. On Γ_t, $\operatorname{Re} s$ is a C^2 function of $\operatorname{Im} s$.*

(ii) *Ω_t is the component of the complex plane to the right of Γ_t. Consequently $\Gamma_t = \partial\Omega_t$ and $\Omega_t \supset \bar{\mathbb{C}}_+ \setminus \{0\}$.*

(iii) *Whenever $t_1 \ge t_0 \ge 0$, the map $s_0 \mapsto s_1 = s(t_1;t_0,s_0)$ is one to one from $\bar{\Omega}_{t_0}$ onto $\bar{\Omega}_{t_1}$. It is C^2 on $\bar{\Omega}_{t_0}$ and analytic in Ω_{t_0}. The inverse map is given by $s_1 \mapsto s_0 = s(t_0;t_1,s_1)$ and is C^2 on $\bar{\Omega}_{t_1}$ and analytic in Ω_{t_1}.*

(iv) *Whenever $t_1 \ge 0$ and $s_1 \in \bar{\mathbb{C}}_+$, the backward characteristic curve $s(t_0;t_1,s_1)$, $t_0 \in [0,t_1]$, lies in $\bar{\mathbb{C}}_+$.*

Proof. We first establish part (iii), taking $t_0 = 0$ at first. Since $x^2 n_0$ is integrable, $v_0(s)$ is continuous in $\bar{\mathbb{C}}_+$ and analytic for $\operatorname{Re} s > 0$. It follows by a standard dominated convergence argument that u_0 is C^1 and φ_0 is C^2 in $\bar{\mathbb{C}}_+$, and these functions are analytic in $\mathbb{C}_+$. From (3.19) we see that the map $s_0 \mapsto s(t;0,s_0)$ is analytic in $\mathbb{C}_+$ and C^2 on $\bar{\mathbb{C}}_+$ (meaning derivatives up to second order extend continuously to $\bar{\mathbb{C}}_+$).

We next claim that this map is one to one. The proof relies on the fact that φ_0 is contractive, with

$$|\varphi_0(\tilde{s}_0) - \varphi_0(s_0)| \le |\tilde{s}_0 - s_0|, \quad \tilde{s}_0, s_0, \in \bar{\mathbb{C}}_+. \tag{3.31}$$

This holds because $|\partial_s \varphi_0(s)| \le 1$ for $s \in \bar{\mathbb{C}}_+$ as an immediate consequence of (3.7) and (3.8). Now suppose $s(t;0,\tilde{s}_0) = s(t;0,s_0)$, where $\tilde{s}_0, s_0 \in \bar{\mathbb{C}}_+$. Then (3.19) implies

$$\tilde{s}_0 - s_0 = \left(1 - e^{-t}\right)\left(\varphi_0(\tilde{s}_0) - \varphi_0(s_0)\right).$$

From this and (3.31) we infer $|\tilde{s}_0 - s_0| \le (1 - e^{-t})|\tilde{s}_0 - s_0|$, whence $\tilde{s}_0 = s_0$. So $s_0 \mapsto s(t;0,s_0)$ is one to one.

We observe that the derivative of this map is uniformly bounded away from zero. Indeed, (3.19) and (3.24) yield

$$\left|\frac{ds}{ds_0}\right| \ge e^{2t}\left(1 - |u_0(s_0)|(1 - e^{-t})\right) \ge e^t.$$

It follows by the inverse function theorem that Ω_t is an open set, and by continuity the image of $\bar{\mathbb{C}}_+$ is $\bar{\Omega}_t$. The inverse map from $\bar{\Omega}_t$ to $\bar{\mathbb{C}}_+$ is analytic in Ω_t, and C^2 on $\bar{\Omega}_t$.

For $t_1 > 0$, the inverse of the map $s_0 \mapsto s_1 = s(t_1;0,s_0)$ may be obtained by solving the characteristic equation in (3.16) backward from time t_1 to $t_0 = 0$, so that we have $s_0 = s(0;t_1,s_1)$. Now whenever $t_1 \ge t_0 \ge 0$ in general, we may follow any characteristic curve back from a point in $\bar{\Omega}_{t_1}$ at time t_1 to a point in $\bar{\mathbb{C}}_+$ at time 0 and then forward to a point in $\bar{\Omega}_{t_0}$ at time t_0. This means that $s(t_1;t_0,s_0) = s(t_1;0,s(0;t_0,s_0))$. Part (iii) of the lemma now follows from the properties established in the case $t_0 = 0$.

Next we prove part (i). For $t > 0$, Γ_t is the image of the map $k \mapsto s(t;0,ik) = e^{2t}(ik - \varphi_0(ik)(1-e^{-t}))$, $k \in \mathbb{R}$, and this is a C^2 function of k. We have $s(t;0,0) = 0$, but $\operatorname{Re} s < 0$ for $k \ne 0$. This is so because $\operatorname{Re} s$ and $\operatorname{Re}\varphi_0(ik)$ have opposite signs, and

$$\operatorname{Re}\varphi_0(ik) = \int_0^\infty (1 - \cos kx) n_0(x)\,dx > 0, \quad k \ne 0,$$

since n_0 is continuous. Finally, we find that

$$\operatorname{Im}\frac{d}{dk} s(t;0,ik) \ge e^{2t}(1 - |u_0(ik)|(1 - e^{-t})) > 0$$

using (3.24). Hence $\operatorname{Re} s$ is a function of $\operatorname{Im} s$ on Γ_t.

Now we establish part (ii). By (3.30) we have that as $|s_0| \to \infty$ with $s_0 \in \bar{\mathbb{C}}_+$, $|\varphi_0(s_0)/s_0| \to 0$, so $s = s_0 e^{2t}(1 + o(1))$ by (3.19). Let $s_1 \in \mathbb{C}$ lie to the right of Γ_t, and put $f(s_0) = s(t;0,s_0) - s_1$. It follows by applying the argument principle to large semicircles that the analytic function f has a single zero at some point $s_0 \in \mathbb{C}_+$. Indeed, $\arg f(re^{i\theta}) \to \theta$ as $r \to \infty$ for $-\frac{\pi}{2} \le \theta \le \frac{\pi}{2}$, and as k goes from ∞ to $-\infty$, $f(ik)$ does not cross the positive real axis, so $\arg f(ik)$ changes from $\frac{\pi}{2}$ to $\frac{3\pi}{2}$. Thus, f maps a large semicircle to a curve that winds exactly once about 0. Hence $s_1 \in \Omega_t$.

Finally, part (iv) follows by a change of variables, replacing $t - t_0$ by t, and applying parts (i)–(iii). □

3.4. Proof of Theorem 3.1. 1. By the Fourier–Laplace inversion formula, it suffices to prove

$$\lim_{t\to\infty} \sup_{x>0} \left| \int_{\mathbb{R}} e^{ikx}\left[v(t,ik) - v_{*,1}(ik)\right] dk \right| = 0. \tag{3.32}$$

2. Let $\varepsilon \in (0, \frac{1}{8})$, and put $R = \frac{1}{2}\varepsilon^{-2}$. We will prove (3.32) by estimating the integral for $t \geq T$ separately in three regions: $|k| \leq R$, $R \leq |k| \leq \tilde{R}e^{2t}$, and $\tilde{R}e^{2t} \leq |k|$, where $\tilde{R} = Re^{-2T}$ and T depends only on ε and the initial data v_0. This is the same decomposition used in the proof of Theorem 2.1, and convergence in the region $|k| \leq R$ will follow as before. However, estimates for $|k| \geq R$ are more subtle and use the analyticity and geometry of the characteristic map.

3. $|k| \leq R$: Theorem 7.1 in [15] implies that $\hat{x}\hat{n}(\tau, \hat{x})\, d\hat{x} \to \hat{x}\hat{n}_{*,0}(\hat{x})\, d\hat{x}$ in the sense of weak convergence of measures. Combined with (3.7) this also implies that the measures $\hat{x}^2\hat{n}(\tau, \hat{x})\, d\hat{x}$ converge weakly to $\hat{x}^2\hat{n}_{*,1}(\hat{x})\, d\hat{x}$ as $t \to \infty$. But this implies $v(t, ik)$ converges to $v_{*,1}(ik)$ uniformly on compact subsets of $\bar{\mathbb{C}}_+$, and in particular on compact subsets of the imaginary axis [7, Theorem XV.3.2]. Thus,

$$\lim_{t\to\infty} \int_{-R}^{R} |v(t, ik) - v_{*,1}(ik)|\, dk = 0. \tag{3.33}$$

4. $|k| \geq R$: It is sufficient to consider only $k \geq R$, since $|v(t, ik)| = |v(t, -ik)|$. We will control $v(t, ik)$ and $v_{*,1}$ separately:

$$\int_R^\infty |v(t, ik) - v_{*,1}(ik)|\, dk \leq \int_R^\infty |v(t, ik)|\, dk + \int_R^\infty |v_{*,1}(ik)|\, dk.$$

But $|v_{*,1}(ik)| \leq (2k)^{-3/2}$ by (3.13). Thus,

$$\int_R^\infty |v_{*,1}(ik)|\, dk \leq \int_R^\infty (2k)^{-3/2}\, dk = (2R)^{-1/2} = \varepsilon.$$

5. In the rest of the proof we estimate $\int_R^\infty |v(t, ik)| dk$. In order to aid the reader, we state the main estimates as two distinct lemmas.

LEMMA 3.4. *Let $\varepsilon \in (0, \frac{1}{8})$. There exists $T > 0$ depending on ε and the initial data, and a universal constant C, such that if $t \geq T$ then*

$$\int_R^{Re^{2(t-T)}} |v(t, ik)|\, dk \leq C\varepsilon. \tag{3.34}$$

LEMMA 3.5. *Let $\tilde{R} > 0$. There exists $\tilde{C}$ depending on $\tilde{R}$ and the initial data such that for all $t \geq 0$ we have*

$$\int_{\tilde{R}e^{2t}}^\infty |v(t, ik)|\, dk \leq \tilde{C}e^{-t}. \tag{3.35}$$

6. We now prove (3.32). We choose T as in Lemma 3.4, and then $\tilde{R} = Re^{-2T}$ in Lemma 3.5. Choose $T_* \geq T$ such that for $t \geq T_*$

$$\int_{-R}^{R} |v(t, ik) - v_{*,1}(ik)|\, dk < \varepsilon, \qquad \tilde{C}e^{-t} \leq \tilde{C}e^{-T_*} < \varepsilon.$$

Thus, for $t \geq T_*$ we have

$$\begin{aligned}
&\int_{\mathbb{R}} |v(t, ik) - v_{*,1}(ik)|\, dk \leq \int_{-R}^{R} |v(t, ik) - v_{*,1}(ik)|\, dk \\
&+2\left(\int_R^\infty |v_{*,1}(ik)|\, dk + \int_R^{\tilde{R}e^{2t}} |v(t, ik)|\, dk + \int_{\tilde{R}e^{2t}}^\infty |v(t, ik)|\, dk \right) \\
&\leq \varepsilon + 2\left(\varepsilon + C\varepsilon + \varepsilon\right).
\end{aligned}$$

Since $\varepsilon \in (0, \frac{1}{8})$ may be chosen arbitrarily small, this completes the proof.

3.5. Proof of Lemma 3.4. In this subsection we will always suppose $s \in \bar{\mathbb{C}}_+$. In a manner similar to step 6 of the proof of Theorem 2.1, the idea is to get estimates on the semicircle $C_R := \{s \in \bar{\mathbb{C}}_+ \mid |s| = R\}$ valid for large time and propagate these estimates outward along characteristics. We first use (3.10) and (3.13) to obtain the following estimates for $s \in \bar{\mathbb{C}}_+$:

$$|\varphi_{*,1}(s)| < |2s|^{1/2}, \quad |u_{*,1}(s)| < |2s|^{-1/2}, \quad |v_{*,1}(s)| < |2s|^{-3/2}. \tag{3.36}$$

Next, we use the uniform convergence on compact sets and (3.36) to see that there exists T_0 (depending on ε and the initial data) such that for all $s_0 \in C_R$ and $t_0 \geq T_0$ we have

$$|\varphi(t_0, s_0)/s_0| \leq 2(2R)^{-1/2} = 2\varepsilon \leq 1/4, \tag{3.37}$$

$$|u(t_0, s_0)| \leq (2R)^{-1/2} = \varepsilon, \tag{3.38}$$

$$|v(t_0, s_0)| \leq (2R)^{-3/2} = \varepsilon^3. \tag{3.39}$$

We first extend (3.37) to a larger domain in s.

Claim 1. There exists $T_1 \geq T_0$ such that

$$\left|\frac{\varphi(t,s)}{s}\right| \leq 1/3, \quad t \geq T_1,\ s \in \bar{\mathbb{C}}_+,\ |s| \geq R. \tag{3.40}$$

Proof of Claim 1. Observe that by using (3.27) and (3.30) in (3.21), we have

$$a := \sup\{|\varphi(T_0, s)/s| \mid s \in \bar{\mathbb{C}}_+,\ |s| \geq R\} < 1.$$

Fix $t_1 \geq T_0$, $s_1 \in \bar{\mathbb{C}}_+$ with $|s_1| \geq R$. Either the characteristic curve $s(t; t_1, s_1)$ that passes through s_1 at time t_1 intersects C_R at some time $t_0 \in [T_0, t_1]$, or not. If so, then $s_1 = s(t_1; t_0, s_0)$ for some $s_0 \in C_R$, and (3.21) and (3.37) directly yield

$$\left|\frac{\varphi(t_1, s_1)}{s_1}\right| \leq \frac{1/4}{1 - 1/4} = \frac{1}{3}.$$

If not, then $|s(t; t_1, s_1)| > R$ for all $t \in [T_0, t_1]$, by continuity and the fact that $s(t; t_1, s_1) \in \bar{\mathbb{C}}_+$ for all $t \in [0, t_1]$ by part (iv) of Lemma 3.3. Then taking $t_0 = T_0$, $s_0 = s(T_0; t_1, s_1)$ in (3.21) yields

$$\left|\frac{\varphi(t_1, s_1)}{s_1}\right| \leq \frac{ae^{-(t_1 - T_0)}}{1 - a} \leq \frac{1}{3},$$

provided $t_1 \geq T_1$ with T_1 sufficiently large. This proves the claim.

Claim 2. Let $T = T_1 + \frac{1}{2}\ln 2$. Suppose $t_1 \geq T$ and $R \leq |s_1| \leq Re^{2(t_1 - T)}$. Then the characteristic curve $s(t; t_1, s_1)$ that passes through s_1 at time t_1 intersects C_R at some time $t_0 \in [T_1, t_1]$.

Proof of Claim 2. Suppose the claim were false. Then the continuity of $|s(t; t_1, s_1)|$ and part (iv) of Lemma 3.3 imply $R < |s(t_0; t_1, s_1)|$ for all $t_0 \in [T_1, t_1]$. But now, by (3.20) with $s_0 = s(t_0; t_1, s_1)$ we have

$$s_0\left(1 - \frac{\varphi(t_0, s_0)}{s_0}\right) = e^{-2(t_1 - t_0)} s_1 \left(1 - \frac{\varphi(t_1, s_1)}{s_1}\right). \tag{3.41}$$

We take $t_0 = T_1$ and apply (3.40) and the hypothesis $|s_1| \leq Re^{2(t_1 - T)} = \frac{1}{2}Re^{2(t_1 - T_1)}$ to deduce

$$R < |s_0| \leq |s_1| e^{-2(t_1 - T_1)} \frac{1 + 1/3}{1 - 1/3} \leq R,$$

a contradiction. This proves the claim.

We now apply these claims to propagate the decay estimate (3.39). From Claim 2, for any $t = t_1 \geq T$, $R \leq k \leq Re^{2(t-T)}$, with $s_1 = ik$, we obtain $t_0 \in [T_1, t]$ and $s_0 \in C_R$ and substitute (3.20), (3.39), and (3.40) in the decay estimate (3.26) to obtain

$$\begin{aligned}|v(t,ik)| &\leq \frac{|v(t_0,s_0)|}{(1-|u(t_0,s_0)|)^3}\left|\frac{s_0-\varphi(t_0,s_0)}{ik-\varphi(t,ik)}\right|^{3/2}\\ &\leq (1-\varepsilon)^{-3}\ |v(t_0,s_0)|\left|\frac{2s_0}{k}\right|^{3/2}\\ &\leq (1-\varepsilon)^{-3}(2R)^{-3/2}\left(\frac{2R}{k}\right)^{3/2} = (1-\varepsilon)^{-3}k^{-3/2}.\end{aligned}$$

Therefore,

$$\int_R^{Re^{2(t-T)}} |v(t,ik)|\,dk \leq (1-\varepsilon)^{-3}\int_R^\infty k^{-3/2}\,dk = \frac{2R^{-1/2}}{(1-\varepsilon)^3} \leq C\varepsilon, \tag{3.42}$$

with $C = 2(8/7)^3 2^{1/2}$. This completes the proof of Lemma 3.4.

3.6. Proof of Lemma 3.5. We consider the initial time $t_0 = 0$ and the following special case of (3.19):

$$s = s(t;0,s_0) = e^{2t}\left[s_0 - \varphi_0(s_0)(1-e^{-t})\right]. \tag{3.43}$$

For any $t \geq 0$, the map $s_0 \mapsto s(t;0,s_0)$ is analytic for $\mathrm{Re}(s_0) > 0$, and

$$\frac{ds}{ds_0} = e^{2t}\left(1 - u_0(s_0)(1-e^{-t})\right), \qquad u_0(s_0) = u(0,s_0). \tag{3.44}$$

Recall that Ω_t denotes the image of $\mathbb{C}_+$ under $s_0 \mapsto s(t;0,s_0)$, and Γ_t denotes the image of the imaginary axis; we let Γ_{-t} denote its preimage. As was observed in Lemma 3.3, Γ_t is a graph over the imaginary axis, contained in the left half plane.

We will use the analyticity of $v(t,s)$ in Ω_t and contour deformation. For large finite $R_2 < \infty$, consider the domain $ABCD$ shown in Figure 3.1. The path AB is chosen so that $A'B'$ is a straight line. CD is parallel to the real axis and lies in Ω_t since Γ_t is a graph over the imaginary axis. Then by Cauchy's theorem,

$$\begin{aligned}\int_{\tilde{R}e^{2t}}^{R_2} e^{ikx}v(t,ik)\,dk &= \int_{BC} e^{ikx}v(t,ik)\,dk\\ &= \int_{DA} e^{sx}v(t,s)\,ds + \int_{AB} e^{sx}v(t,s)\,ds + \int_{CD} e^{sx}v(t,s)\,ds.\end{aligned}$$

Let σ denote $\mathrm{Re}\,s$. Since $\sigma < 0$ in Ω_t for $s \in CD$ we see that the last integral is estimated by

$$\left|\int_{CD} e^{sx}v(t,s)\,ds\right| \leq \sup_{s\in CD}|v(t,s)|\int_{-\infty}^0 e^{\sigma x}d\sigma = \frac{\sup_{s\in CD}|v(t,s)|}{x}.$$

By the decay estimate (3.26) we have

$$\sup_{s\in CD}|v(t,s)| \leq \sup_{s_1\in CD}\frac{|v_0(s_0)|e^{-3t}}{(1-|u_0(s_0)|)^3}, \quad s_0 = s(0;t,s_1).$$

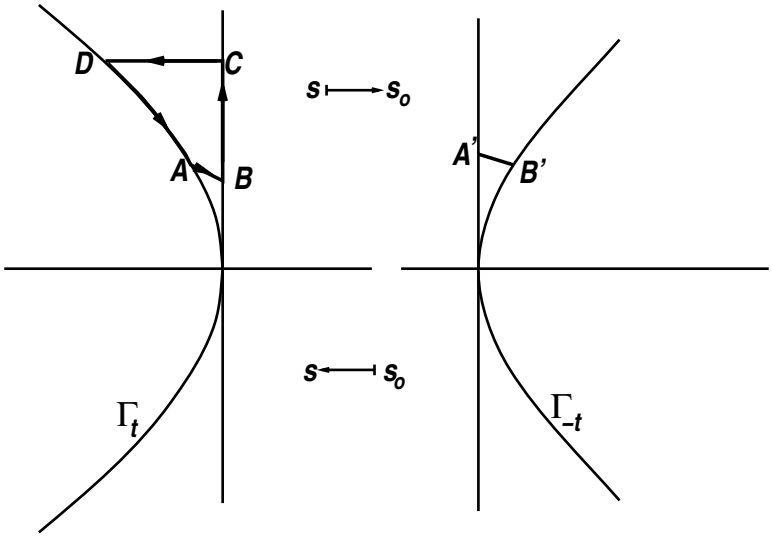

FIG. 3.1. *The s-plane is on the left, the s_0-plane on the right. Ω_t is the region to the right of Γ_t. $A = s(t;0,i\tilde{R})$, $B = i\tilde{R}e^{2t}$, $C = iR_2$, $\mathrm{Im}(D) = R_2$, $A' = i\tilde{R}$, $B' = s(0;t,i\tilde{R}e^{2t})$.*

It follows from (3.30) and the fact that $|s_0| = |s_1|e^{-2t}(1+o(1)) \to \infty$ as $R_2 \to \infty$ that $\sup_{s_1 \in CD} |v_0(s_0)| \to 0$. We thus let $R_2 \to \infty$ to conclude that

$$\int_{\tilde{R}e^{2t}}^{\infty} e^{ikx} v(t,ik)\, dk = \int_{\Gamma_{t,A}} e^{sx} v(t,s)\, ds + \int_{AB} e^{sx} v(t,s)\, ds, \tag{3.45}$$

where $\Gamma_{t,A}$ denotes the path from ∞ to A on Γ_t. Notice that (3.45) holds independent of x.

The virtue of deforming the contour is that the integrals may now be estimated by changing variables from s to s_0. We use the solution formula (3.23) together with the change of variables $s = s(t;0,ik)$ and (3.44) to obtain

$$\int_{\Gamma_{t,A}} e^{sx} v(t,s)\, ds = ie^{-t} \int_{\tilde{R}}^{\infty} e^{s(t;0,ik)x} \frac{v_0(ik)}{\left(1 - u_0(ik)(1-e^{-t})\right)^2}\, dk.$$

Since $\mathrm{Re}\, s(t;0,ik) \le 0$ and $\sup_{|k| \ge \tilde{R}} |u_0(ik)| < 1$, this yields the estimate

$$\left| \int_{\Gamma_{t,A}} e^{sx} v(t,s)\, ds \right| \le C_1 e^{-t} \|v_0\|_{L^1}. \tag{3.46}$$

Similarly, we have by (3.23) and (3.44)

$$\begin{aligned} \left| \int_{AB} e^{sx} v(t,s)\, ds \right| &= e^{-t} \left| \int_{A'B'} e^{s(t;0,s_0)x} \frac{v_0(s_0)}{\left(1 - u_0(s_0)(1-e^{-t})\right)^2}\, ds_0 \right| \\ &\le e^{-t} |A'B'| \sup_{s_0 \in A'B'} \left| 1 - u_0(s_0)(1-e^{-t}) \right|^{-2}. \end{aligned}$$

The point $A' = i\tilde{R}$ is independent of t. It also follows from (3.43) that $B' = s(0;t,i\tilde{R}e^{2t})$ converges to the point $s_0 \in \bar{\mathbb{C}}_+$ that solves $i\tilde{R} = s_0 - \varphi_0(s_0)$. Thus,

we have the exponential decay estimate

$$\left| \int_{AB} e^{sx} v(t,s)\, ds \right| \leq C_2 e^{-t}. \tag{3.47}$$

The constants C_i in (3.46) and (3.47) depend only on $\tilde{R}$ and the initial data u_0. To be explicit, we set $\tilde{C} = C_1 \|v_0\|_{L^1} + C_2$. This completes the proof.

3.7. The discrete Smoluchowski equations. We now use the proof of Theorem 3.1 to obtain a uniform convergence theorem for the discrete Smoluchowski equations with additive kernel. The proof is simpler and we do not need the contour deformation argument.

Let $\nu_t = \sum_{l=1}^{\infty} n_l(t)\delta_{hl}(x)$ denote a measure-valued solution to (1.1). We first adapt the rescaling (3.4) and (3.5) to similarity variables. Let

$$\hat{l} = lhe^{-2t}, \quad \hat{n}_l(t) = h^{-1}e^{4t} n_l(t). \tag{3.48}$$

Then the discrete Fourier inversion formula analogous to (2.32) is

$$\hat{l}^2 \hat{n}_l(t) = \frac{1}{2\pi} \int_{-\pi e^{2t}/h}^{\pi e^{2t}/h} e^{i\hat{l}k} v(t, ik)\, dk. \tag{3.49}$$

THEOREM 3.6. *Let $\nu_0 \geq 0$ be a lattice measure with span h such that $\int_0^\infty x\nu_0(dx) = \int_0^\infty x^2 \nu_0(dx) = 1$. Then with the scaling* (3.48) *we have*

$$\lim_{t\to\infty} \sup_{l\in\mathbb{N}} \hat{l}^2 \left| \hat{n}_l(t) - \hat{n}_{*,1}(\hat{l}) \right| = 0.$$

Proof. By (3.49) and the continuous Fourier inversion formulas it suffices to show that

$$\lim_{t\to\infty} \sup_{\hat{l}\geq 0} \left| \int_{-\pi e^{2t}/h}^{\pi e^{2t}/h} e^{i\hat{l}hk} v(t,ik)\, dk - \int_{\mathbb{R}} e^{i\hat{l}hk} v_{*,1}(ik)\, dk \right| = 0. \tag{3.50}$$

Let $\varepsilon \in (0, \frac{1}{8})$ and choose $R = \frac{1}{2}\varepsilon^{-2}$. The integrals over $[-R, R]$ and $R < |k| < \tilde{R}e^{2t}$ with $\tilde{R} = e^{-2T}$ are controlled as in the proof of Theorem 3.1, and it only remains to control the integral of $|v(t,ik)|$ over $\tilde{R}e^{2t} < k < \pi e^{2t}/h$. This is considerably simpler than in the previous proof. We use the solution formula (3.23) and change variables via $ik = s(t;0,s_0)$, then use (3.44) to obtain

$$\int_{\tilde{R}e^{2t}}^{\pi e^{2t}/h} e^{ikx} v(t,ik)\, dk = ie^{-t} \int_{\Gamma_{-t}(\tilde{R},\pi/h)} \frac{e^{xs(t;0,s_0)} v_0(s_0)}{\left(1 - u_0(s_0)(1-e^{-t})\right)^2}\, ds_0.$$

Here $\Gamma_{-t}(\tilde{R}, \pi/h)$ denotes the segment along the curve Γ_{-t} from $s(0;t,i\tilde{R}e^{2t})$ to $s(0;t,i\pi e^{2t}/h)$. The formula (3.19) shows that $\Gamma_{-t}(\tilde{R},\pi/h)$ converges to a compact C^2 curve defined implicitly by $ik = s_0 - \varphi_0(s_0), \tilde{R} \leq k \leq \pi/h$. Thus, for $t \geq T$ we have

$$e^{-t} \left| \int_{\Gamma_{-t}(\tilde{R},\pi/h)} \frac{e^{xs(t;0,s_0)} v_0(s_0)}{\left(1 - u_0(s_0)(1-e^{-t})\right)^2}\, ds_0 \right| \leq C(T, \tilde{R}, u_0, v_0) e^{-t}.$$

Thus, this term is less than ε for all t large enough. ∎

4. Self-similar gelation for the multiplicative kernel. For $K = xy$, McLeod solved the coagulation equation explicitly for monodisperse initial data and showed that a mass-conserving solution failed to exist for $t > 1$. The second moment satisfies $m_2(t) = (1-t)^{-1}$. The divergence of the second moment indicates that breakdown is associated with an explosive flux of mass toward large clusters. A rescaled limit of McLeod's solution is the following self-similar solution for $K = xy$ [1]:

$$n(t,x) = \frac{1}{\sqrt{2\pi}} x^{-5/2} e^{-(1-t)^2 x/2}, \quad x > 0, \quad t < 1. \tag{4.1}$$

Evidently this solution has infinite mass (first moment). This should not be thought unnatural, however, since it was shown in [15] that (1.1) has a unique weak solution for any initial distribution with finite second moment.

The problem of solving Smoluchowski's equation with multiplicative kernel can be reduced to that for the additive kernel by a change of variables [4]. Let us briefly review this. In unscaled variables we define

$$\Psi(t,z) = \int_0^\infty (1 - e^{-zx}) x n(t,x)\, dx. \tag{4.2}$$

Then Ψ solves the inviscid Burgers equation:

$$\partial_t \Psi - \Psi \partial_z \Psi = 0, \tag{4.3}$$

with initial data

$$\Psi_0(z) = \int_0^\infty (1 - e^{-zx}) x n_0(x)\, dx. \tag{4.4}$$

The gelation time for initial data with finite second moment is $T_{\text{gel}} = (\int_0^\infty x^2 \nu_0(dx))^{-1}$, and this is exactly the time for the first intersection of characteristics [15]. We presume that the initial data is scaled to ensure

$$\int_0^\infty x^2 n_0(x)\, dx = \int_0^\infty x^3 n_0(x)\, dx = 1. \tag{4.5}$$

Then the gelation time is $T_{\text{gel}} = 1$. The connection between the additive and multiplicative kernels is that Ψ solves (4.3) with initial data Ψ_0 if and only if $\Phi(\tau, z)$ is a solution to (3.3) with the same initial data, where

$$\Psi(t,z) = e^\tau \Phi(\tau, z), \quad \text{with } \tau = \log(1-t)^{-1}. \tag{4.6}$$

For solutions $n^{\text{mul}}(t,x)$ and $n^{\text{add}}(\tau,x)$ to Smoluchowski's equation with multiplicative and additive kernels, respectively, this means that

$$x n^{\text{mul}}(t,x) = (1-t)^{-1} n^{\text{add}}(\tau, x) \tag{4.7}$$

for all $t \in (0,1)$ if and only if the same holds at $t = 0$. We thus obtain a scaling limit as $t \to T_{\text{gel}}$ directly from Theorem 3.1. The similarity variables for the multiplicative kernel are

$$\hat{x} = (1-t)^2 x, \quad \hat{n}(t,\hat{x}) = \frac{n(t, \hat{x}(1-t)^{-2})}{(1-t)^5} = \frac{n(t,x)}{(1-t)^5}, \tag{4.8}$$

and the self-similar profile is

$$\hat{n}_{*,2}(\hat{x}) = \frac{1}{\sqrt{2\pi\hat{x}^5}} e^{-\hat{x}/2}. \tag{4.9}$$

THEOREM 4.1. *Suppose* $n_0(x) \geq 0$, $\int_0^\infty x^2 n_0(x)\,dx = \int_0^\infty x^3 n_0(x)\,dx = 1$. *Suppose also that the Fourier transform of* $x^3 n_0$ *is integrable. Then in terms of the rescaling* (4.8) *we have*

$$\lim_{t\to 1} \sup_{\hat{x}>0} \hat{x}^3 |\hat{n}(t,\hat{x}) - \hat{n}_{*,2}(\hat{x})| = 0, \tag{4.10}$$

where $\hat{n}_{*,2}(\hat{x})$ *is the self-similar density in* (4.9).

Notice that (4.8) is *not* a mass-preserving rescaling; indeed, the rescaled mass diverges:

$$\int_0^\infty \hat{x}\hat{n}(t,\hat{x})d\hat{x} = \frac{1}{1-t}\int_0^\infty xn(t,x)\,dx = \frac{1}{1-t} \to \infty.$$

Instead, (4.8) preserves the second moment:

$$\int_0^\infty \hat{x}^2\hat{n}(t,\hat{x})d\hat{x} = (1-t)\int_0^\infty x^2 n(t,x)\,dx = 1, \quad t \in [0,1).$$

The explanation is that the scaling in (4.8) is designed to capture the behavior of the distribution of large clusters as t approaches T_{gel}—the average cluster size is $(1-t)^{-1}$. Correspondingly, the mass of the self-similar solution is infinite.

Theorem 3.6 may be similarly adapted to $K = xy$. In the discrete case, the correspondence (4.7) between solutions of Smoluchowski's equations with multiplicative and additive kernels becomes

$$hln_l^{\text{mul}}(t) = (1-t)^{-1} n_l^{\text{add}}(\log(1-t)^{-1}) \tag{4.11}$$

We introduce similarity variables via

$$\hat{l} = lh(1-t)^2, \quad \hat{n}_l(t) = h^{-1}(1-t)^{-5} n_l(t). \tag{4.12}$$

Then directly from Theorem 3.6 we obtain the following.

THEOREM 4.2. *Let* $\nu_0 \geq 0$ *be a lattice measure with span* h *such that* $\int_0^\infty x^2\nu_0(dx) = \int_0^\infty x^3\nu_0(dx) = 1$. *Then with the rescaling* (4.12) *we have*

$$\lim_{t\to 1} \sup_{l\in\mathbb{N}} \hat{l}^3 \left|\hat{n}_l(t) - \hat{n}_{*,2}(\hat{l})\right| = 0. \tag{4.13}$$

CONVERGENCE TO GLOBAL EQUILIBRIUM FOR A KINETIC FERMION MODEL*

LUKAS NEUMANN† AND CHRISTIAN SCHMEISER‡

Abstract. We study the long-time asymptotics of a kinetic model for fermions in a box with periodic boundary conditions. An entropy dissipation approach is used to prove decay to the global equilibrium for this nonlinear equation, that lacks dissipation in the position variable. We prove convergence at an algebraic rate depending on the smoothness of the solution. The result relies on some initial bounds and a uniform boundedness assumption for spatial derivatives of the solution.

Key words. kinetic equations, fermions, Fermi–Dirac distribution, semiconductors, H-theorem, relative entropy, entropy dissipation, long-time asymptotics

1. Introduction.

We investigate the initial value problem

$$\partial_t f + v \cdot \nabla_x f = Q(f), \quad f(0,x,v) = f_0(x,v), \tag{1}$$

where $f = f(t,x,v) \geq 0$ denotes a particle distribution function, depending on time $t \geq 0$, position $x \in \mathbb{T}^d$ (where $\mathbb{T}^d$ is a d-dimensional torus, i.e., a rectangular box with periodic boundary conditions), and velocity $v \in \mathbb{R}^d$.

The particles are fermions and the scattering operator Q (acting only in the v-direction) is a simple model for the interaction of the particles with a nonmoving background medium with constant temperature

$$Q(f) = \int_{\mathbb{R}^d} [M(1-f)f' - M'(1-f')f] \mathrm{d}v'. \tag{2}$$

Here $f' = f(t,x,v')$, and $M(v) = (2\pi)^{-d/2} e^{-|v|^2/2}$ is the normalized Maxwellian. The factors $(1-f)$ and $(1-f')$ take into account the Pauli exclusion principle. The values of the distribution function have to respect the bounds $0 \leq f \leq 1$.

A kinetic equation with the same scattering operator, but also including acceleration of the particles by a given electric field, has been considered in [12]. Existence and uniqueness for initial value problems with $x \in \mathbb{R}^d$ (nonperiodic) have been proven and the macroscopic (diffusion) limit has been carried out.

A fermion Boltzmann equation modeling elastic particle-particle collisions has been studied by Dolbeault [8]. More elaborate models than (2) for the scattering of fermions due to a background medium or a different species of particles have been considered in the modeling of charge transport in semiconductors (see [10], [11], [4]). Existence and uniqueness and/or macroscopic limits are the subject of these studies.

Here we are interested in the long-time behavior of solutions of (1). It is characterized by two properties: conservation of total mass and entropy dissipation. The first is a consequence of the conservation property $\int_{\mathbb{R}^d} Q(f)\mathrm{d}v = 0$ of the scattering operator and of the periodic boundary conditions in position space:

$$\int_{\mathbb{T}^d}\int_{\mathbb{R}^d} f(t,x,v)\mathrm{d}v\mathrm{d}x = \int_{\mathbb{T}^d}\int_{\mathbb{R}^d} f_0(x,v)\mathrm{d}v\mathrm{d}x.$$

Before stating the entropy dissipation property, we write the collision operator in the form

$$Q(f) = \int_{\mathbb{R}^d} MM'(1-f)(1-f')(F'-F)\mathrm{d}v'$$

with

$$F = \frac{f}{M(1-f)}\,.$$

Then, by the antisymmetry of the integrand with respect to v and v', it is easily shown that

$$\begin{aligned}\int_{\mathbb{R}^d} Q(f)\chi(F)\mathrm{d}v&\\ &= -\frac{1}{2}\int_{\mathbb{R}^d}\int_{\mathbb{R}^d} MM'(1-f)(1-f')(F-F')(\chi(F)-\chi(F'))\mathrm{d}v'\mathrm{d}v \le 0\end{aligned} \tag{3}$$

for arbitrary increasing functions χ. As a consequence, if an entropy is defined by $H_\infty = \int_{\mathbb{T}^d}\int_{\mathbb{R}^d} S_\infty(f,v)\mathrm{d}v\mathrm{d}x$ with

$$\frac{\partial S_\infty}{\partial f} = \chi\left(\frac{f}{M(v)(1-f)}\right),$$

then the entropy dissipation equality

$$\frac{\mathrm{d}H_\infty}{\mathrm{d}t} = \int_{\mathbb{T}^d}\int_{\mathbb{R}^d} Q(f)\chi(F)\mathrm{d}v\mathrm{d}x \tag{4}$$

follows. If χ is chosen strictly increasing, then (by (3)) the entropy dissipation rate on the right-hand side of (4) vanishes only if the (local) equilibrium condition $F = \kappa(t,x)$ is satisfied and the distribution function is the Fermi–Dirac distribution:

$$f(t,x,v) = f_l(t,x,v) = \frac{\kappa(t,x)M(v)}{1+\kappa(t,x)M(v)}\,. \tag{5}$$

Note that in this statement, $\kappa(t,x)$ can be chosen arbitrarily. In the following, however, we shall denote by f_l defined by (5) the local equilibrium distribution associated with an arbitrary (nonequilibrium) distribution f, where κ is chosen by fixing the position density

$$\int_{\mathbb{R}^d} f_l(t,x,v)\mathrm{d}v = \rho(t,x) := \int_{\mathbb{R}^d} f(t,x,v)\mathrm{d}v. \tag{6}$$

Continuing our argument, we expect (because of the entropy dissipation equation) that for large times f approaches an equilibrium distribution, thus making the right-hand side of the transport equation (1) vanish. The left-hand side then vanishes only for constant κ. Thus, we expect f to converge to the global equilibrium

$$f_\infty(v) = \frac{\kappa_\infty M(v)}{1 + \kappa_\infty M(v)},$$

where κ_∞ is determined by mass conservation

$$|\mathbb{T}^d| \int_{\mathbb{R}^d} f_\infty(v)\mathrm{d}v = \int_{\mathbb{T}^d} \int_{\mathbb{R}^d} f_0(x,v)\mathrm{d}v\mathrm{d}x.$$

From (4) a weak version of this statement can be proven (see, e.g., [5], [1]).

Recently, Desvillettes and Villani have developed a strategy for proving strong convergence to equilibrium for nonhomogeneous (in position) kinetic equations. It includes quantitative estimates on convergence rates. They have applied their approach to linear equations with a Fokker–Planck scattering operator and a confining potential [6] as well as, in a monumental work [7], to the Boltzmann equation of gas dynamics. Linear models have also been considered in [9] and [2].

In this work, the method of Desvillettes and Villani is applied to (1) and (2). Its main point is to overcome the following difficulty: the right-hand side of the entropy dissipation equation vanishes when the distribution is in local equilibrium. Thus, the entropy might stop decaying without f having reached the global equilibrium f_∞. As an input, the method requires certain bounds (uniform in time) on the distribution function and on its derivatives with respect to position. Whereas these could be proved for the linear problems in [6], [9], and [2], they have to be assumed for the Boltzmann equation. For the nonlinear problem (1), methods from [12] can be used to prove the propagation of bounds for the initial conditions in terms of Fermi–Dirac distributions. The boundedness of x-derivatives—at least in the perturbative setting—has recently been proved in [3] for a class of problems including (1) and (2).

In the following section, the boundedness result is proved, the method is outlined, and the main result is stated. The detailed (rather involved) computations and estimates are collected in section 3.

2. Preliminaries and main result.

THEOREM 2.1. *Assume there exist constants $\kappa_-, \kappa_+ > 0$ such that*

$$f_-(v) \le f_0(x,v) \le f_+(v) \qquad \text{with } f_\pm(v) = \frac{\kappa_\pm M(v)}{1 + \kappa_\pm M(v)}$$

for all $x \in \mathbb{T}^d$ and $v \in \mathbb{R}^d$. Then there is a unique solution $f(t,x,v)$ of (1) and (2) satisfying the same bounds

$$f_-(v) \le f(t,x,v) \le f_+(v) \tag{7}$$

for all $t > 0$, $x \in \mathbb{T}^d$ and $v \in \mathbb{R}^d$.

Proof. For details we refer the reader to [12]. We only outline the proof of the bounds (7). The existence proof is based on a fixed point iteration on the set $\mathcal{V}$ of distribution functions satisfying (7). For $f \in \mathcal{V}$, we define the next iterate g by solving

$$\partial_t g + v \cdot \nabla_x g = M \int_{\mathbb{R}^d} f' \mathrm{d}v' - g \int_{\mathbb{R}^d} (Mf' + M'(1 - f'))\, \mathrm{d}v',$$

$$g(0,x,v) = f_0(x,v).$$

The difference $r = g - f_-$ satisfies

$$r(0,x,v) = f_0(x,v) - f_-(v) \geq 0$$

and

$$\begin{aligned}&\partial_t r + v\cdot\nabla_x r + r\int_{\mathbb{R}^d}(Mf' + M'(1-f'))\mathrm{d}v'\\ &= (1-f_-)M\int_{\mathbb{R}^d} f'\mathrm{d}v' - f_-\int_{\mathbb{R}^d} M'(1-f')\mathrm{d}v' \geq Q(f_-) = 0.\end{aligned}$$

Nonnegativity of r and, thus, the lower bound $g \geq f_-$ follows. Analogously, $g \leq f_+$ and, therefore, $g \in \mathcal{V}$ is shown. □

Note that this ensures that $(1-f)$ is bounded away from zero, which we will make use of frequently.

In the following, relative entropies will be used for measuring the distance between distributions. Some arbitrariness comes from the freedom to choose the function χ in (4). We define the relative entropy of f with respect to g by

$$H(f|g) := \int_{\mathbb{T}^d}\int_{\mathbb{R}^d} S(f,g)\mathrm{d}v\mathrm{d}x$$

with

$$S(f,g) = \int_g^f \ln\frac{z(1-g)}{g(1-z)}\mathrm{d}z = f\ln\frac{f(1-g)}{g(1-f)} + \ln\frac{1-f}{1-g}. \tag{8}$$

With this choice the relative entropy $H(f|f_\infty)$ coincides with the total entropy H_∞ defined in the introduction for $\chi(z) = \ln(z/\kappa_\infty)$. Until now this choice seems somewhat artificial, but we will further comment on it after explaining the strategy to derive the convergence result. We shall need the derivatives

$$\frac{\partial S}{\partial f} = \ln\frac{f(1-g)}{g(1-f)}, \qquad \frac{\partial^2 S}{\partial f^2} = \frac{1}{f(1-f)}. \tag{9}$$

By $S(f,f) = \frac{\partial S}{\partial f}(f,f) = 0$ and $\frac{\partial^2 S}{\partial f^2} > 0$, the relative entropy has the desired property to measure the distance between f and g. Actually, the following stronger statement is true.

LEMMA 2.2. *Let f and g satisfy* (7). *Then there exist constants $c_1, c_2 > 0$ such that*

$$c_1\|f-g\|_M^2 \leq H(f|g) \leq c_2\|f-g\|_M^2$$

with the weighted L^2-norm

$$\|f\|_M^2 := \int_{\mathbb{T}^d}\int_{\mathbb{R}^d}\frac{f^2}{M}\,\mathrm{d}v\mathrm{d}x.$$

Proof. By (9) and the mean value theorem,

$$S(f,g) = \frac{(f-g)^2}{2\phi(1-\phi)}$$

with ϕ lying between f and g. In particular, ϕ also satisfies (7). As a consequence

$$\frac{M}{c_2} \le 2\phi(1-\phi) \le \frac{M}{c_1}$$

holds with appropriate constants c_1, c_2, completing the proof. ∎

A second important property is what we would call a nonlinear version of the Pythagorean theorem.

LEMMA 2.3. *The relative entropy is additive with respect to the local equilibrium,*

$$H(f|f_l) + H(f_l|f_\infty) = H(f|f_\infty)\,.$$

Proof. A straightforward computation gives

$$H(f|f_l) + H(f_l|f_\infty) = H(f|f_\infty) + \int_{\mathbb{T}^d}\int_{\mathbb{R}^d} (f - f_l)\mathrm{d}v\, \ln\frac{\kappa_\infty}{\kappa}\,\mathrm{d}x.$$

The integral with respect to velocity vanishes because of (6). ∎

Also since

$$\frac{\partial S}{\partial f}(f, f_\infty) = \ln\frac{f}{\kappa_\infty M(1-f)}\,,$$

we can use (4) and (3) with $\chi(z) = \ln(z/\kappa_\infty)$ to obtain

$$\frac{\mathrm{d}}{\mathrm{d}t}H(f|f_\infty) = -\frac{1}{2}\int_{\mathbb{T}^d}\int_{\mathbb{R}^d}\int_{\mathbb{R}^d} MM'(1-f)(1-f')(F-F')\ln\frac{F}{F'}\,\mathrm{d}v'\mathrm{d}v\mathrm{d}x. \tag{10}$$

As mentioned above, the right-hand side vanishes when f is a Fermi–Dirac distribution (such that F is independent of v). The basic idea of the Desvillettes–Villani approach is to show that in such a situation the entropy dissipation cannot remain zero as long as $f \neq f_\infty$. This is done by estimating the entropy dissipation in terms of the relative entropy of f with respect to the local equilibrium f_l and by deriving a second-order differential inequality for $H(f|f_l)$:

$$\begin{aligned} &\frac{\mathrm{d}}{\mathrm{d}t}H(f|f_\infty) \le -c_3 H(f|f_l), \\ &\frac{\mathrm{d}^2}{\mathrm{d}t^2}H(f|f_l) \ge c_4 H(f|f_\infty) - c_5 H(f|f_l)^{1-1/n}. \end{aligned} \tag{11}$$

It is the main contribution of this work to prove that these inequalities hold for appropriate $c_3, c_4, c_5 > 0$ and a positive integer n. This will be done in the following section. The proof requires the estimates from Theorem 2.1 and additional smoothness assumptions on the solution.

A result from [6] for systems of differential inequalities of the form (11) can then be used to get the following convergence theorem.

THEOREM 2.4. *Let the assumptions of Theorem* 2.1 *hold and let the solution* f *of* (1) *satisfy*

$$\left\| \frac{\partial^{k_1+\cdots+k_d} f}{\partial x_1^{k_1}\cdots\partial x_d^{k_d}}(t,\cdot,\cdot)\right\|_M \le c_6, \qquad \forall\, k_1+\cdots+k_d \le n \quad \textit{and} \quad \forall\, t>0, \tag{12}$$

for a constant c_6 and a positive integer n. Then there exists a constant $c_7 > 0$ such that

$$H(f|f_\infty) \le c_7 t^{1-n}.$$

Remark 1. For the Fokker–Planck collision operator, a smoothness result like (12) was proven in [6] even for nonsmooth initial conditions by exploiting a hypoellipticity property. Here, one can hope only for propagation of regularity as in [9], assuming smoothness of the initial data. This question is dealt with in [3], where (12) is derived from the corresponding bound for the initial data if the initial data is close to the equilibrium in a suitable sense.

Remark 2. In principle we have the freedom to choose in (8) any entropy of the type

$$S_\chi(f,g) = \int_g^f \chi\left(\frac{z(1-g)}{g(1-z)}\right) \mathrm{d}z$$

with an arbitrary monotone increasing function χ. Since the biggest difficulty is to deduce the second inequality in the system (11), we choose the relative entropy such that the expression for the derivative $\frac{\mathrm{d}}{\mathrm{d}t}H(f|f_l)$ becomes as simple as possible (see (14) below), leading to the choice $\chi = \ln(\cdot/\kappa_\infty)$, which corresponds to (8).

COROLLARY 2.5. *With the assumptions of Theorem* 2.4 *there exists $c_8 > 0$, such that*

$$\|f(t,\cdot,\cdot) - f_\infty\|_{L^1(\mathbb{T}^d\times\mathbb{R}^d)} \le c_8 t^{(1-n)/2}.$$

Proof. The Cauchy–Schwarz inequality implies

$$\|g\|_{L^1(\mathbb{T}^d\times\mathbb{R}^d)} = \int_{\mathbb{T}^d}\int_{\mathbb{R}^d} \frac{|g|}{\sqrt{M}}\sqrt{M}\,\mathrm{d}v\mathrm{d}x \le \sqrt{|\mathbb{T}^d|}\,\|g\|_M.$$

The result now follows from Lemma 2.2 and Theorem 2.4. ∎

3. Derivation of differential inequalities. Throughout this section c will be a positive real constant that may change from line to line.

LEMMA 3.1. *Let the assumptions of Theorem* 2.4 *hold. Then there is a constant $c_3 > 0$ such that*

$$\frac{\mathrm{d}}{\mathrm{d}t}H(f|f_\infty) \le -c_3 H(f|f_l).$$

Proof. We have to estimate the entropy production (10). Note that by the mean value theorem,

$$\ln\frac{F}{F'} = \frac{F-F'}{\Phi}$$

holds, with Φ between F and F'. Also, by (7), we have $\kappa_- \le \Phi \le \kappa_+$. This gives

$$\begin{aligned}\frac{\mathrm{d}}{\mathrm{d}t}H(f|f_\infty) &\le -\frac{1}{2\kappa_+}\int_{\mathbb{T}^d}\int_{\mathbb{R}^d}\int_{\mathbb{R}^d} MM'(1-f)(1-f')(F-F')^2\mathrm{d}v'\mathrm{d}v\mathrm{d}x\\ &\le -\frac{1}{2\kappa_+}\int_{\mathbb{T}^d}\int_{\mathbb{R}^d}\int_{\mathbb{R}^d} MM'(1-f)(1-f')(1-f_l)(1-f_l')\\ &\qquad\times(F-F_l-(F'-F_l'))^2\mathrm{d}v'\mathrm{d}v\mathrm{d}x,\end{aligned}$$

where we have used $F_l = \frac{f_l}{M(1-f_l)} = \kappa = F_l'$. Expanding the square and using

$$F - F_l = \frac{f - f_l}{M(1-f)(1-f_l)}, \tag{13}$$

gives

$$\begin{aligned}\frac{\mathrm{d}}{\mathrm{d}t}H(f|f_\infty) \leq &-\frac{1}{\kappa_+}\int_{\mathbb{T}^d}\int_{\mathbb{R}^d} M(1-f)(1-f_l)\mathrm{d}v\int_{\mathbb{R}^d}\frac{(f-f_l)^2}{M(1-f)(1-f_l)}\mathrm{d}v\mathrm{d}x\\ &+\frac{1}{\kappa_+}\int_{\mathbb{T}^d}\left(\int_{\mathbb{R}^d}(f-f_l)\mathrm{d}v\right)^2\mathrm{d}x.\end{aligned}$$

The last term vanishes by the requirement (6) on the local equilibrium. From (7),

$$0 < 1 - f_+(0) \leq 1 - f, 1 - f_l \leq 1$$

follows and, therefore,

$$\frac{\mathrm{d}}{\mathrm{d}t}H(f|f_\infty) \leq -c\|f - f_l\|_M^2 .$$

An application of Lemma 2.2 completes the proof. ∎

Now we shall prove the second inequality in (11). A straightforward computation gives

$$\begin{aligned}\frac{\mathrm{d}}{\mathrm{d}t}H(f|f_l) &= \int_{\mathbb{T}^d}\int_{\mathbb{R}^d}\left(\partial_t f\ln\frac{F}{F_l} - \partial_t f_l\frac{f-f_l}{f_l(1-f_l)}\right)\mathrm{d}v\mathrm{d}x\\ &= \int_{\mathbb{T}^d}\int_{\mathbb{R}^d}\left(-v\cdot\nabla_x f\ln F + v\cdot\nabla_x f\ln\kappa + Q(f)\ln F - \frac{\partial_t\kappa}{\kappa}(f-f_l)\right)\mathrm{d}v\mathrm{d}x.\end{aligned}$$

The first term on the right-hand side vanishes by the divergence theorem (with respect to the x-variable) and the last one by (6), leaving

$$\frac{\mathrm{d}}{\mathrm{d}t}H(f|f_l) = \int_{\mathbb{T}^d}\nabla_x\cdot J\,\ln\kappa\,\mathrm{d}x + \int_{\mathbb{T}^d}\int_{\mathbb{R}^d}Q(f)\ln F\,\mathrm{d}v\mathrm{d}x = A + B \tag{14}$$

with the flux density $J = \int_{\mathbb{R}^d} vf\,\mathrm{d}v$ (which vanishes for $f = f_l$).

For the computation of the time derivative of A we need the momentum balance equation

$$\partial_t J + \nabla_x\cdot P = \int_{\mathbb{R}^d} vQ(f)\mathrm{d}v,$$

where we shall split the pressure tensor into a local equilibrium part and a remainder:

$$P = \int_{\mathbb{R}^d} v\otimes vf\,\mathrm{d}v = \int_{\mathbb{R}^d} v\otimes vf_l\,\mathrm{d}v + \int_{\mathbb{R}^d} v\otimes v(f-f_l)\,\mathrm{d}v = P_l + \tilde{P}.$$

Differentiating (6) with respect to time, and the continuity equation $\partial_t\rho + \nabla_x\cdot J = 0$ lead to

$$\frac{\partial_t\kappa}{\kappa} = \frac{-\nabla_x\cdot J}{\int_{\mathbb{R}^d} f_l(1-f_l)\mathrm{d}v}.$$

With these preparations we obtain

$$\begin{aligned}\frac{\mathrm{d}A}{\mathrm{d}t} &= \int_{\mathbb{T}^d} \frac{\nabla_x \kappa}{\kappa} \cdot (\nabla_x \cdot P_l)\mathrm{d}x + \int_{\mathbb{T}^d} \frac{\nabla_x \kappa}{\kappa} \cdot (\nabla_x \cdot \tilde{P})\mathrm{d}x \\ &\quad - \int_{\mathbb{T}^d} \frac{\nabla_x \kappa}{\kappa} \cdot \int_{\mathbb{R}^d} vQ(f)\mathrm{d}v\,\mathrm{d}x - \int_{\mathbb{T}^d} \frac{(\nabla_x \cdot J)^2}{\int_{\mathbb{R}^d} f_l(1-f_l)\mathrm{d}v}\,\mathrm{d}x. \end{aligned} \tag{15}$$

Note that for $f = f_l$ all terms on the right-hand side except the first vanish. This term is responsible for moving f out of local equilibrium as long as it is not in global equilibrium. For estimating it we need

$$\nabla_x \cdot P_l = \int_{\mathbb{R}^d} v \otimes v\, f_l(1-f_l)\mathrm{d}v\, \frac{\nabla_x \kappa}{\kappa}. \tag{16}$$

The integral is an isotropic tensor which is positive definite since f_l satisfies (7):

$$\int_{\mathbb{R}^d} v \otimes v\, f_l(1-f_l)\mathrm{d}v \geq \mathrm{Id} \int_{\mathbb{R}^d} v_i^2 f_-(1-f_+)\mathrm{d}v. \tag{17}$$

The first term on the right-hand side of (15) can, thus, be estimated by

$$\int_{\mathbb{T}^d} \frac{\nabla_x \kappa}{\kappa} \cdot (\nabla_x \cdot P_l)\mathrm{d}x \geq c\|\nabla_x \kappa\|^2_{L^2(\mathbb{T}^d)}.$$

Now we estimate the remaining three terms in (15) one by one. First,

$$\begin{aligned}\left|\int_{\mathbb{T}^d} \frac{\nabla_x \kappa}{\kappa} \cdot (\nabla_x \cdot \tilde{P})\mathrm{d}x\right| &\leq c \int_{\mathbb{T}^d} |\nabla_x \kappa| \int_{\mathbb{R}^d} |v|^2 |\nabla_x (f - f_l)|\mathrm{d}v\,\mathrm{d}x \\ &\leq c \int_{\mathbb{T}^d} |\nabla_x \kappa| \sqrt{\int_{\mathbb{R}^d} |v|^4 M\,\mathrm{d}v \int_{\mathbb{R}^d} \frac{|\nabla_x (f-f_l)|^2}{M}\mathrm{d}v}\,\mathrm{d}x \\ &\leq c\|\nabla_x \kappa\|_{L^2(\mathbb{T}^d)} \|\nabla_x (f - f_l)\|_M. \end{aligned}$$

Second (similarly),

$$\left|\int_{\mathbb{T}^d} \frac{\nabla_x \kappa}{\kappa} \cdot \int_{\mathbb{R}^d} vQ(f)\mathrm{d}v\,\mathrm{d}x\right| \leq c\|\nabla_x \kappa\|_{L^2(\mathbb{T}^d)} \|Q(f)\|_M.$$

Now we need to quantify the behavior of $Q(f)$ near f_l.

LEMMA 3.2. *Q is a bounded operator and moreover*

$$\|Q(f)\|_M \leq c\|f - f_l\|_M.$$

Proof.

$$\|Q(f)\|^2_M \leq c \int_{\mathbb{T}^d} \int_{\mathbb{R}^d} M \left(\int_{\mathbb{R}^d} M' |F - F'|\mathrm{d}v'\right)^2 \mathrm{d}v\,\mathrm{d}x.$$

The integral in parentheses can be estimated by

$$\begin{aligned}\int_{\mathbb{R}^d} M'|F - F'|\mathrm{d}v' &\leq |F - F_l| + \int_{\mathbb{R}^d} M'|F' - F_l'|\mathrm{d}v' \\ &\leq |F - F_l| + \sqrt{\int_{\mathbb{R}^d} M(F - F_l)^2 \mathrm{d}v}. \end{aligned}$$

Estimating the square of the sum by the sum of the squares we get

$$\|Q(f)\|_M^2 \le c\int_{\mathbb{T}^d}\int_{\mathbb{R}^d} M(F-F_l)^2 \mathrm{d}v\,\mathrm{d}x.$$

Now the result of the lemma follows from (13) and the boundedness of $(1-f)$ away from zero. ∎

Second, continued,

$$\left|\int_{\mathbb{T}^d} \frac{\nabla_x\kappa}{\kappa}\cdot\int_{\mathbb{R}^d} vQ(f)\mathrm{d}v\,\mathrm{d}x\right| \le c\|\nabla_x\kappa\|_{L^2(\mathbb{T}^d)}\|f-f_l\|_M.$$

Third (last term in (15)),

$$\begin{aligned}\int_{\mathbb{T}^d}\frac{(\nabla_x\cdot J)^2}{\int_{\mathbb{R}^d} f_l(1-f_l)\mathrm{d}v}\,\mathrm{d}x &\le c\int_{\mathbb{T}^d}\left(\int_{\mathbb{R}^d} v\cdot\nabla_x(f-f_l)\mathrm{d}v\right)^2\mathrm{d}x\\ &\le c\int_{\mathbb{T}^d}\int_{\mathbb{R}^d}|v|^2M\mathrm{d}v\int_{\mathbb{R}^d}\frac{|\nabla_x(f-f_l)|^2}{M}\mathrm{d}v\,\mathrm{d}x = c\|\nabla_x(f-f_l)\|^2.\end{aligned}$$

Collecting our results so far, we have proved

$$\begin{aligned}\frac{\mathrm{d}A}{\mathrm{d}t} \ge c\|\nabla_x\kappa\|^2_{L^2(\mathbb{T}^d)} - \tilde{c}\big(&\|\nabla_x\kappa\|_{L^2(\mathbb{T}^d)}\|\nabla_x(f-f_l)\|_M\\ &+\|\nabla_x\kappa\|_{L^2(\mathbb{T}^d)}\|f-f_l\|_M + \|\nabla_x(f-f_l)\|_M^2\big),\end{aligned}$$

implying

$$\frac{\mathrm{d}A}{\mathrm{d}t} \ge c\|\nabla_x\kappa\|^2_{L^2(\mathbb{T}^d)} - \tilde{c}\big(\|f-f_l\|_M^2 + \|\nabla_x(f-f_l)\|_M^2\big). \tag{18}$$

The $\nabla_x\kappa$ term drives the solution out of local equilibria because it remains nonzero as long as κ is different from the constant κ_∞. A Poincaré-type estimate will help us to describe this by means of relative entropy.

LEMMA 3.3. $\|\nabla_x\kappa\|^2_{L^2(\mathbb{T}^d)} \ge cH(f_l|f_\infty)$ *with* $c>0$.

Proof. Since $\frac{\mathrm{d}\rho}{\mathrm{d}\kappa} = \frac{1}{\kappa}\int_{\mathbb{R}^d} f_l(1-f_l)\mathrm{d}v$ is bounded from above and away from zero (by (7)),

$$\|\nabla_x\kappa\|^2_{L^2(\mathbb{T}^d)} \ge c\|\nabla_x\rho\|^2_{L^2(\mathbb{T}^d)}$$

with $c>0$. Introducing $\rho_\infty = \int_{\mathbb{R}^d} f_\infty\mathrm{d}v$ and noting that $\int_{\mathbb{T}^d}(\rho-\rho_\infty)\mathrm{d}x = 0$, a Poincaré estimate gives

$$\|\nabla_x\kappa\|^2_{L^2(\mathbb{T}^d)} \ge c\|\rho-\rho_\infty\|^2_{L^2(\mathbb{T}^d)}\mathrm{d}x$$

with a possibly different, but still positive constant c. On the other hand,

$$|\rho-\rho_\infty| \ge c|\kappa-\kappa_\infty| = c\frac{|f_l-f_\infty|}{M(1-f_l)(1-f_\infty)} \ge c\frac{|f_l-f_\infty|}{M},$$

where the first inequality follows again from the boundedness of $\frac{\mathrm{d}\rho}{\mathrm{d}\kappa}$ and the last from (7). This implies

$$\|\nabla_x\kappa\|^2_{L^2(\mathbb{T}^d)} \ge c\int_{\mathbb{T}^d}\int_{\mathbb{R}^d} M(\kappa-\kappa_\infty)^2\mathrm{d}v\mathrm{d}x \ge c\|f_l-f_\infty\|_M^2.$$

An application of Lemma 2.2 completes the proof. □

It remains to estimate the time derivative of the second term in (14). Using (3), this term can be written as

$$B = -\frac{1}{2}\int_{\mathbb{T}^d}\int_{\mathbb{R}^d}\int_{\mathbb{R}^d} MM'(1-f)(1-f')(F-F')\ln\frac{F}{F'}\,\mathrm{d}v'\mathrm{d}v\mathrm{d}x.$$

The computation of the time derivative is facilitated by the fact that the integrand is symmetric with respect to f and f':

$$\frac{\mathrm{d}B}{\mathrm{d}t} = \int_{\mathbb{T}^d}\int_{\mathbb{R}^d}\int_{\mathbb{R}^d} M'\frac{1-f'}{1-f}\left[M(1-f)(F-F')\ln\frac{F}{F'} - \ln\frac{F}{F'} - (F-F')\frac{1}{F}\right]\partial_t f\,\mathrm{d}v'\mathrm{d}v\mathrm{d}x.$$

The term multiplying $\partial_t f$ in the integrand can by estimated (using (7)) by $cM'|F-F'|$. As a consequence,

$$\left|\frac{\mathrm{d}B}{\mathrm{d}t}\right| \le c\int_{\mathbb{T}^d}\int_{\mathbb{R}^d}\int_{\mathbb{R}^d} M'|F-F'|(|v|\,|\nabla_x f| + |Q(f)|)\mathrm{d}v'\mathrm{d}v\mathrm{d}x$$

holds. With $|F-F'| \le |f-f_l|/M + |f'-f_l'|/M'$, the right-hand side is bounded by the sum of four terms, which we estimate one by one. First,

$$\int_{\mathbb{T}^d}\int_{\mathbb{R}^d}\int_{\mathbb{R}^d} M'\frac{|f-f_l|\,|Q(f)|}{M}\,\mathrm{d}v'\mathrm{d}v\mathrm{d}x \le \|f-f_l\|_M\|Q(f)\|_M.$$

Second,

$$\int_{\mathbb{T}^d}\int_{\mathbb{R}^d}\int_{\mathbb{R}^d} |f'-f_l'|\,|Q(f)|\,\mathrm{d}v'\mathrm{d}v\mathrm{d}x \le \|f-f_l\|_M\|Q(f)\|_M.$$

Third,

$$\int_{\mathbb{T}^d}\int_{\mathbb{R}^d}\int_{\mathbb{R}^d} |f'-f_l'|\,|v|\,|\nabla_x f|\,\mathrm{d}v'\mathrm{d}v\mathrm{d}x \le \int_{\mathbb{R}^d}|v|^2 M\,\mathrm{d}v\,\|f-f_l\|_M\|\nabla_x(f-f_\infty)\|_M.$$

The fourth term is the most difficult to estimate. Here we have to make a small concession on the exponent. We use $|f-f_l| \le cM$:

$$\int_{\mathbb{T}^d}\int_{\mathbb{R}^d}\int_{\mathbb{R}^d} M'|v|\frac{|f-f_l|\,|\nabla_x f|}{M}\,\mathrm{d}v'\mathrm{d}v\mathrm{d}x \le c\int_{\mathbb{T}^d}\int_{\mathbb{R}^d}\left|\frac{f-f_l}{\sqrt{M}}\right|^{1-\varepsilon}\frac{|\nabla_x f|}{\sqrt{M}}|v|M^{\varepsilon/2}\mathrm{d}v\mathrm{d}x$$
$$\le c\left(\int_{\mathbb{R}^d}|v|^{2/\varepsilon}M\,\mathrm{d}v\right)^{\varepsilon/2}\|f-f_l\|_M^{1-\varepsilon}\|\nabla_x(f-f_\infty)\|_M.$$

Since the Maxwellian has finite moments of arbitrary order, ε can be made arbitrarily small. Collecting the four estimates, using Lemma 3.2 and the fact that $\|f-f_l\|_M$ is bounded, we have

$$\left|\frac{\mathrm{d}B}{\mathrm{d}t}\right| \le c\left(\|f-f_l\|_M^2 + \|\nabla_x(f-f_\infty)\|_M\|f-f_l\|_M^{1-\varepsilon}\right).$$

This implies together with (14), (18), and Lemma 3.3 that

$$\frac{\mathrm{d}^2}{\mathrm{d}t^2}H(f|f_l) \geq cH(f_l|f_\infty) - \tilde{c}\big(\|\nabla_x(f-f_l)\|_M^2 + \|f-f_l\|_M^2 + \|\nabla_x(f-f_\infty)\|_M\|f-f_l\|_M^{1-\varepsilon}\big). \tag{19}$$

The next step is the derivation of bounds for the norms of the gradients. The interpolation inequality

$$\|\nabla_x u\|_{L^2(\mathbb{T}^d)} \leq c\|u\|_{L^2(\mathbb{T}^d)}^{1-1/n}\|u\|_{H^n(\mathbb{T}^d)}^{1/n}$$

and the Hölder inequality imply

$$\begin{aligned}\|\nabla_x g\|_M^2 = \int_{\mathbb{R}^d}\frac{1}{M}\|\nabla_x g\|_{L^2(\mathbb{T}^d)}^2\mathrm{d}v &\leq c\int_{\mathbb{R}^d}\left(\frac{1}{M}\|g\|_{L^2(\mathbb{T}^d)}^2\right)^{1-1/n}\left(\frac{1}{M}\|g\|_{H^n(\mathbb{T}^d)}^2\right)^{1/n}\mathrm{d}v\\ &\leq c\|g\|_M^{2(1-1/n)}\left(\int_{\mathbb{R}^d}\frac{1}{M}\|g\|_{H^n(\mathbb{T}^d)}^2\mathrm{d}v\right)^{1/n}.\end{aligned}$$

By assumption (12) of Theorem 2.4 the last factor is bounded uniformly in time for $g = f - f_l$ and $g = f - f_\infty$. This gives

$$\|\nabla_x(f-f_l)\|_M^2 \leq c\|f-f_l\|_M^{2(1-1/n)}$$

and, with the Young inequality,

$$\begin{aligned}\|\nabla_x(f-f_\infty)\|_M\|f-f_l\|_M^{1-\varepsilon} &\leq c\|f-f_\infty\|_M^{1-1/n}\|f-f_l\|_M^{1-\varepsilon}\\ &\leq \delta\|f-f_\infty\|_M^2 + c_\delta\|f-f_l\|_M^{2(1-\varepsilon)n/(n+1)}.\end{aligned}$$

Now we choose $\varepsilon = n^{-2}$ (such that $(1-\varepsilon)n/(n+1) = 1-1/n$) and we use the above inequalities and Lemmas 2.2 and 2.3 in (19) to obtain the desired results

$$\frac{\mathrm{d}^2}{\mathrm{d}t^2}H(f|f_l) \geq c_4 H(f|f_\infty) - c_5 H(f|f_l)^{1-1/n}.$$

This completes the derivation of the differential inequalities (11) and, thus, the proof of Theorem 2.4.

INTERMEDIATE MODELS IN NONLINEAR OPTICS*

THIERRY COLIN†, GÉRARD GALLICE‡, AND KAREN LAURIOUX‡

Abstract. In this paper, new models are derived for laser propagation in a nonlinear medium. These models are intermediate between nonlinear Maxwell systems and nonlinear Schrödinger equations and are exact in linear cases. We prove rigorous error estimates for a generic class of systems. In the last section, we perform numerical tests in order to investigate the numerical effectivity of the bounds given by the theorem. We compare for a particular nonlinear system the exact solutions and the approximate solutions given by our new model. It is shown that the new models behave as predicted by the theorem but are even better in some cases.

Key words. nonlinear optics, WKB expansions, nonlinear hyperbolic systems, Schrödinger equations

1. Introduction.

1.1. Motivations. The aim of this paper is to propose new models for the simulation of the propagation of laser pulses in a nonlinear medium. The wavelength associated with a pulse is usually near the micrometer (10^{-6} m) while the length of the pulse can be of order 100 micrometers for ultrashort pulses (10^{-4} m) or of the order of the meter. We are concerned with propagation on distances of order of the millimeter (for crystals) or of hundred of meters (for propagation in gas). From the temporal point of view, the frequency of a pulse is $10^{15}\,\mathrm{s}^{-1}$, its duration can be of the order of the picoseconds (10^{-12} s) or of 10 nanoseconds (10^{-8} s). The duration of propagation can be 10^{-11} s for crystals or 10^{-6} s for gas. The width of the beam can be of order of a fraction of millimeter to a few centimeters. Therefore, one has to handle three-dimensional processes involving several orders of magnitude. It is not possible to propose direct simulations for all these situations. Usually, the so-called paraxial approximation or envelope approximation are used. This approximation relies on the fact that the electric field has the form of a plane wave multiplied by an envelope, namely $e^{i(kz-\omega t)}\mathcal{E}(t,x,y,z)$ where $t \geq 0$ is the time, $(x,y,z) \in \mathbb{R}^3$ are the spatial variables, k is the wave number, and ω is the frequency. With this notation, the slowly varying envelope approximation can be expressed by the following set of inequalities:

$$|\partial_t \mathcal{E}| \ll \omega|\mathcal{E}|, \qquad |\partial_x \mathcal{E}| \ll k|\mathcal{E}|, \qquad |\partial_y \mathcal{E}| \ll k|\mathcal{E}|, \qquad |\partial_z \mathcal{E}| \ll k|\mathcal{E}|.$$

Using these inequalities, one obtains approximate equations satisfied by $\mathcal{E}$. These equations can be nonlinear transport equations at the group velocity (for frequency doubling in the phase-matching case in a crystal) or nonlinear Schrödinger equations (in a Kerr medium) or Schrödinger–Bloch equations (in a gas) etc. We refer the reader to general textbook of physics (see [8], [18], for instance) for a precise physical

description. Here, we will address cases where the validity of the paraxial approximation is not so clear. Physically, this can occur when the pulse goes through a diffraction web or when the pulse is "chirped" in order to have a large spectral width. We want to propose alternative intermediate models that are more precise than the usual Schrödinger-like equation but less expensive to compute numerically than the full Maxwell equations. These intermediate models are obtained in the same spirit as the long wave systems for water waves of [6] or [7]. For direct simulations on nonlinear Maxwell systems, see [5] and the references therein. See also [3] for cases with nonplanar phases. In order to introduce our notations, let us recall that a standard model for propagation of a beam in a Kerr medium is the Maxwell–Lorentz system which has the nondimensional form

$$\begin{cases} \partial_t B + \operatorname{curl} E = 0, \\ \partial_t E - \operatorname{curl} B = -\partial_t P, \\ \partial_t^2 P - \dfrac{1}{\varepsilon^2}(E - P) = \dfrac{1}{\varepsilon}|P|^2 P, \end{cases} \tag{1.1}$$

where (E, B) is the electromagnetic field and P is the polarization. Introducing $Q = \varepsilon \partial_t P$, this system becomes

$$\begin{cases} \partial_t B + \operatorname{curl} E = 0, \\ \partial_t E - \operatorname{curl} B = -\dfrac{Q}{\varepsilon}, \\ \partial_t Q - \dfrac{1}{\varepsilon}(E - P) = |P|^2 P, \\ \partial_t P - \dfrac{1}{\varepsilon} Q = 0. \end{cases} \tag{1.2}$$

For propagation in gas, one can use the two-level Maxwell–Bloch system

$$\begin{cases} \partial_t E - \operatorname{curl} B + \partial_t P = 0, \\ \partial_t B + \operatorname{curl} E = 0, \\ P = \operatorname{Re}(c_1 c_2^*) u, \end{cases} \tag{1.3}$$

where c_1 and c_2 are the complex representations of the populations in each level (c_2^* denotes the complex conjugate of c_2) and u is a fixed vector corresponding to the direction of propagation. Level 1 corresponds to the fundamental state, while level 2 corresponds to the excited state. The evolution of c_1 and c_2 is given by the following set of ordinary differential equations which is derived from the Schrödinger equation of quantum mechanics [18]:

$$\begin{cases} i\partial_t c_1 = -\dfrac{E \cdot u c_2}{\varepsilon}, \\ i\partial_t c_2 = \dfrac{1}{\varepsilon} c_2 - \dfrac{E \cdot u c_1}{\varepsilon}. \end{cases} \tag{1.4}$$

Introducing $\Lambda = c_1 c_2^*$ and $\tilde{N} = |c_1|^2 - |c_2|^2$ yields

$$\begin{cases} \partial_t \Lambda = \dfrac{i\Lambda}{\varepsilon} - \dfrac{iE \cdot u \tilde{N}}{\varepsilon}, \\ \partial_t \tilde{N} = -\dfrac{2iE \cdot u(\Lambda - \Lambda^*)}{\varepsilon}. \end{cases} \tag{1.5}$$

Let $P = \mathrm{Re}(\Lambda)$, $Q = \mathrm{Im}(\Lambda)$, and $\tilde{N} = 1 - N$, we obtain

$$\begin{cases} \partial_t P = -\dfrac{1}{\varepsilon} Q, \\ \partial_t Q = \dfrac{1}{\varepsilon} P - \dfrac{E \cdot u(1-N)}{\varepsilon}, \\ \partial_t N = -\dfrac{4E \cdot uQ}{\varepsilon}. \end{cases} \tag{1.6}$$

Now we change all the unknowns by a scaling factor $\sqrt{\varepsilon}$ and we consider a vectorial form of (1.6) without assuming that the electric filed is polarized along the unit vector u:

$$\begin{cases} \partial_t B + \mathrm{curl}\ E = 0, \\ \partial_t E - \mathrm{curl}\ B = \dfrac{Q}{\varepsilon}, \\ \partial_t Q + \dfrac{1}{\varepsilon}(E - P) = EN, \\ \partial_t P + \dfrac{1}{\varepsilon} Q = 0, \\ \partial_t N = -4E \cdot Q. \end{cases} \tag{1.7}$$

See [11] for a precise description of these models and the derivation of the nondimensional forms. See also [10] for the use of Maxwell–Bloch system in a gas. Since the solutions are expected under the form of a plane wave multiplied by an envelope, usually the initial data is taken as being equal to

$$(E, B, P, Q)(t = 0, X) = e^{i\frac{k \cdot X}{\varepsilon}} (E_0, B_0, P_0, Q_0)(X) + c.c.$$

with $X = (x, y, z)$ and $k \in \mathbb{R}^3$. The notation *c.c.* means "complex conjugate." For (1.7), one has, moreover, to take $N(t = 0, X) = 0$ since at the state of rest, all atoms are at level 1 and $c_1 = 1$ and $c_2 = 0$ which implies $N = 0$. Therefore the difficulties concerning the presence of different length scales for the propagation of the beam appears in (1.2) and (1.7) through the presence of terms of size $\frac{1}{\varepsilon}$ in the equations and also in the $e^{i\frac{k \cdot X}{\varepsilon}}$ in the initial data. These terms will create high frequencies (of order $\frac{1}{\varepsilon}$) in time. Moreover, we will need to characterize the solution on short-time scale ($O(1)$) or on long-time scale ($O(\frac{1}{\varepsilon})$), that is, on long or short distance. In order to give a synthetic presentation of these phenomena, we introduce the following general class of systems (including (1.1) and (1.3)) that has been used in several works (see [16], [15], [14], [9], ...):

$$\left(\partial_t + \sum_{j=1}^{n} A_j \partial_{x_j} + \frac{L_0}{\varepsilon} \right) u = f(u), \tag{1.8}$$

where matrices A_j are real symmetric, L_0 is skew-symmetric, f is a smooth nonlinear mapping, and

$$u(t, X) : [0, T] \times \mathbb{R}^n \to \mathbb{R}^p, \quad X = (x_1, \ldots, x_n).$$

For the sake of simplicity, in this paper we will restrict ourselves to the case where $f(u)$ is a homogeneous polynomial of degree q. Of course all of the results can be extended to more general cases.

1.2. Some classical results of nonlinear geometrical optics. We recall some tools of geometrical optics (see [14] for a more complete description). First we seek for plane wave solutions to the linear part of (3.1), that is,

$$u = Fe^{\frac{i(k\cdot X-\omega t)}{\varepsilon}}, \tag{1.9}$$

where $F \in \mathbb{C}^p$ is a constant and $k = (k_1, \dots, k_n) \in \mathbb{R}^n$. Such a plane wave is a solution to

$$\left(\partial_t + \sum_{j=1}^{n} A_j \partial_{x_j} + \frac{L_0}{\varepsilon}\right) u = 0 \tag{1.10}$$

if and only if

$$\left(-i\omega I_d + i\sum_{j=1}^{n} A_j k_j + L_0\right) F = 0, \tag{1.11}$$

where I_d denotes the identity matrix.

System (1.11) has a nontrivial solution if and only if

$$\det\left(-i\omega I_d + i\sum_{j=1}^{n} A_j k_j + L_0\right) = 0, \tag{1.12}$$

which is the dispersion relation. Note that the matrix $i\sum_{j=1}^{n} A_j k_j + L_0$ is skew-adjoint; therefore, the solutions ω are real and the solutions $i\omega$ are the eigenvalues of $i\sum_{j=1}^{n} A_j k_j + L_0$. Moreover the eigenspaces are orthogonal. We denote by $\Pi(\omega, k)$ (or simply by $\Pi(k)$ if no confusion is possible) the orthogonal projector onto $\mathrm{Ker}(-i\omega I_d + i\sum_{j=1}^{n} A_j k_j + L_0)$. We also give the following definition.

DEFINITION 1.1. *The characteristic variety $\mathcal{C}_{\mathcal{L}}$ of the operator $\mathcal{L}(\partial_t, \partial_X) = \partial_t + A(\partial_X) + L_0 := \partial_t + \sum_{j=1}^{n} A_j \partial_{x_j} + L_0$ is the set*

$$\mathcal{C}_{\mathcal{L}} = \{(\tau, \xi) \in \mathbb{R} \times \mathbb{R}^n \text{ such that } \det(-i\tau I_d + iA(\xi) + L_0) = 0\}.$$

Now, coming back to the nonlinear system (1.8), one tries to solve

$$\left(\partial_t + \sum_{j=1}^{n} A_j \partial_{x_j} + \frac{L_0}{\varepsilon}\right) u = f(u).$$

For a given $k \in \mathbb{R}^n$, we select a frequency ω. The way we solve this problem is the following one. We look for u in the form

$$u(t, X) = \mathcal{U}\left(\frac{k\cdot X - \omega t}{\varepsilon}, t, X\right),$$

where $\theta \mapsto \mathcal{U}(\theta, t, X)$ is 2π-periodic. Of course this is not enough in order to define completely function $\mathcal{U}$. We see that $\mathcal{U}$ satisfies the following singular equation:

$$\left(\partial_t + A(\partial_X) + \frac{1}{\varepsilon}\left(-\omega\partial_\theta + A(k)\partial_\theta + L_0\right)\right)\mathcal{U} = f(\mathcal{U}) \quad \text{for all } t \in [0, T], \tag{1.13}$$

for all $X \in \mathbb{R}^n$, and for $\theta = \frac{k\cdot X-\omega t}{\varepsilon}$. At this stage, the function $\mathcal{U}$ is not well defined since it satisfies (1.13) only for $\theta = \frac{k\cdot X-\omega t}{\varepsilon}$. In order to give a correct definition, we impose that $\mathcal{U}$ satisfies (1.13) for all $t \in [0,T]$, $X \in \mathbb{R}^N$, and for $\theta \in \mathbb{T}$ where $\mathbb{T}$ denotes the usual one-dimensional torus. We make the following generic hypothesis.

Hypothesis 1. (k,ω) is a regular point of $\mathcal{C}_L$ (that is, the multiplicity of the eigenvalue $\lambda_j(\xi)$ such that $\lambda_j(k) = \omega$ is constant in a neighborhood of $\xi = k$).

Hypothesis 2. $(pk, p\omega) \notin \mathcal{C}_L$ for all integer $p \le q$, where q is the degree of the nonlinearity f.

Note that Hypothesis 2 is not necessary; we could replace it by the strong finiteness hypothesis as in [12]. One then can construct an approximate solution for u as follows. Let $\mathcal{U}_0$ be the solution to

$$\begin{cases} \partial_t \mathcal{U}_0 + \omega'(k)\cdot\partial_X \mathcal{U}_0 = \Pi(k) C_1(f(\Pi(k)\mathcal{U}_0 e^{i\theta} + c.c.)), \\ \qquad\qquad \mathcal{U}_0(t=0,X) = \mathcal{U}_0(X), \end{cases} \tag{1.14}$$

where $C_q(F(\theta))$ denotes the qth Fourier coefficient of $\theta \mapsto F(\theta)$:

$$C_q(F(\theta)) = \frac{1}{2\pi}\int_0^{2\pi} F(\theta) e^{iq\theta} d\theta.$$

One then shows the following theorem.

THEOREM 1.2. *Let $u_0 \in H^s(\mathbb{R}^n)$ (for s large enough) such that $\Pi(k)u_0 = u_0$. There exists a unique $\mathcal{U}^\varepsilon(\theta,t,X)$ solution to the singular equation* (1.13) *such that $\mathcal{U}^\varepsilon(\theta,0,X) = (e^{i\theta}u_0 + c.c.)$ is defined on $[0,T]$ and*

$$|\mathcal{U}^\varepsilon(\theta,t,X) - (\mathcal{U}_0(t,X)e^{i\theta} + c.c.)|_{L^\infty_t(0,T;H^s_{\theta,X})} \le C_0\varepsilon.$$

It follows that there exists a solution $u^\varepsilon(t,X)$ to (1.8) such that $u^\varepsilon(0,X) = (e^{\frac{ik\cdot X}{\varepsilon}}u_0(X) + c.c.)$ and

$$\left| u^\varepsilon(t,X) - \left(\mathcal{U}_0(t,X)e^{i\frac{k\cdot X-\omega t}{\varepsilon}} + c.c.\right)\right|_{L^\infty([0,T]\times\mathbb{R}^n)} \le C_0\varepsilon.$$

This regime is called geometrical optics. For solutions on long-time scale of size $O(\frac{1}{\varepsilon})$, diffractive effects are important and we have to give another expansion. We look for a solution of (1.8) satisfying

$$u(t=0,X) = \varepsilon^{1/(q-1)}\left(e^{\frac{ik\cdot X}{\varepsilon}}u_0(X) + c.c.\right).$$

Let us recall that q is the order of the nonlinearity. In order to explain briefly why this scaling, $\varepsilon^{1/(q-1)}$, is relevant, let us consider the ordinary differential equation $y' = y^q$. An initial data of size $\varepsilon^{1/(q-1)}$ will lead to a solution of the same size $y(t) = \varepsilon^{1/(q-1)}z(t)$. Then the function $z(t)$ satisfies

$$z'(t) = \varepsilon^{q/(q-1)}\varepsilon^{-1/(q-1)}z^q = \varepsilon z(t)^q,$$

and $z(t)$ is therefore defined on a time interval of size $O(\frac{1}{\varepsilon})$.

The solution u is sought in the form

$$u(t,X) = \mathcal{U}\left(\frac{k\cdot X-\omega t}{\varepsilon}, X - \omega'(k)t, \varepsilon t\right),$$

where $\theta \mapsto \mathcal{U}(\theta, X, \tau)$ is defined on $\mathbb{T} \times \mathbb{R}^n \times [0, T]$. This will lead to a solution to (1.8) defined on $[0, \frac{T}{\varepsilon}]$. $\mathcal{U}$ then satisfies

$$\left(\varepsilon\partial_\tau + (-\omega'(k)\partial_X + A(\partial_X)) + \frac{1}{\varepsilon}(-\omega\partial_\theta + A(k)\partial_\theta + L_0)\right)\mathcal{U} = f(\mathcal{U}) \tag{1.15}$$

with

$$\mathcal{U}(\theta, t = 0, X) = \varepsilon^{1/(q-1)}(e^{i\theta}u_0(x) + c.c.).$$

Let $\mathcal{V}_0$ be the solution to the following nonlinear Schrödinger equation:

$$\partial_\tau \mathcal{V}_0 + i\frac{\omega''(k)}{2}(\partial_X, \partial_X)\mathcal{V}_0 = \Pi(k)C_1(f(\Pi(k)\mathcal{V}_0 e^{i\theta} + c.c.)) \tag{1.16}$$

with $\mathcal{V}_0(\tau = 0, X) = u_0(X)$.

THEOREM 1.3. *Let $u_0 \in H^s(\mathbb{R}^n)$ (for s large enough) such that $\Pi(k)u_0 = u_0$. There exists a unique $\mathcal{V}^\varepsilon(\theta, X, \tau)$ solution to the singular equation* (1.15) *such that $\mathcal{V}^\varepsilon(\theta, X, 0) = \varepsilon^{1/(q-1)}(e^{i\theta}u_0 + c.c.)$ defined on $[0, T]$ and*

$$\left|\frac{1}{\varepsilon^{1/(q-1)}}\mathcal{V}^\varepsilon(\theta, X, \tau) - (\mathcal{V}_0(\tau, X)e^{i\theta} + c.c.)\right|_{L^\infty_\tau(0,T;H^s_{\theta,X})} \leq C_1\varepsilon.$$

As before, it follows that

$$\left|\frac{1}{\varepsilon^{1/(q-1)}}u^\varepsilon(t, X) - \left(\mathcal{V}_0(\varepsilon t, X - \omega'(k)t)e^{i\frac{k\cdot X - \omega t}{\varepsilon}} + c.c.\right)\right|_{L^\infty([0,T]\times\mathbb{R}^n)} \leq C\varepsilon.$$

Of course, from the computational point of view, it is much easier to find low-frequency solutions to (1.14) or (1.16) on $[0, T] \times \mathbb{R}^n$ than oscillatory solutions of (1.8) on $[0, \frac{T}{\varepsilon}] \times \mathbb{R}^n$. Indeed the frequencies in time and space that are relevant for the solution of (1.8) are of size $O(\frac{1}{\varepsilon})$. Therefore, the time and space steps used in any numerical method have to be small compared to ε. This gives a number of points (in space) that has to be large compared to $O(\frac{1}{\varepsilon})$ and a number of time steps large compared to $O(\frac{1}{\varepsilon})$. For (1.14) or (1.16), the frequencies are $O(1)$ and the time or space steps have only to be small with respect to 1. Moreover, while (1.8) has to be solved in the diffractive regime on long-time intervals $[0, \frac{T}{\varepsilon}]$, (1.16) has to be solved on $[0, T]$ only, which decreases the number of time steps. This is why (1.14) or (1.16) are used in practical applications [17].

1.3. Limitations of the models. In some applications (ultrashort pulses), one can have to handle cases where ε is small, but not very small ($\varepsilon \sim 10^{-2}$). The error estimates given by the above results are not very precise especially when the constants C_0 and C_1 (depending at least on the H^s-norm of the initial data) are large. These constants can be large when the initial data has rapid variations and this is the case for short pulses or pulses with a quite large spectrum. This configuration arises when the laser beam propagates through a diffraction web. We give a numerical example below. Let us consider the simplified system

$$\partial_t \begin{pmatrix} u \\ v \end{pmatrix} + \partial_x \begin{pmatrix} v \\ u \end{pmatrix} + \frac{1}{\varepsilon}\begin{pmatrix} -v \\ u \end{pmatrix} = \begin{pmatrix} -(u^2 + v^2)v \\ (u^2 + v^2)u \end{pmatrix} \tag{1.17}$$

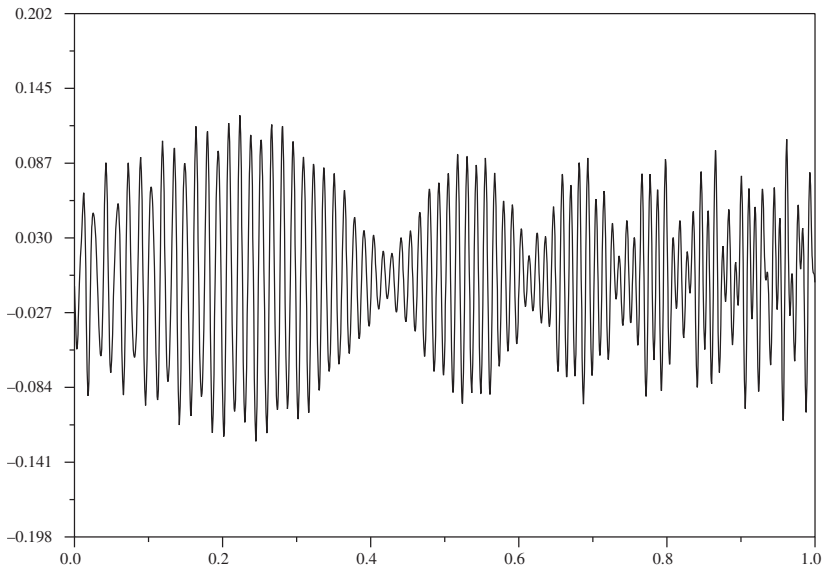

FIG. 1. *Real part of the first component of the solution of system* (1.17) *with* $\varepsilon = 0.01$ *at time* $T = 50$*, with chirped initial data, Case* 6.

with

$$\begin{pmatrix} u_0 \\ v_0 \end{pmatrix} = \varepsilon^{1/2} e^{i\frac{kx}{\varepsilon}} \begin{pmatrix} 1 \\ \frac{-ik+1}{i\omega} \end{pmatrix} a(x) + c.c., \quad x \in [0,1],$$

where $\omega = \sqrt{1+k^2}$. The function $a(x)$ is given by

$$a(x) = e^{-75(x-1/2)^2} e^{i15\cos(15x)}.$$

We make a simulation as described in the last section with $\varepsilon = 10^{-2}$ on $t \in [0, 50]$. The solution to (1.17) at time $t = 50$ is given on Figure 1 and the solution given by the nonlinear Schrödinger equation (1.16) is given on Figure 2. They have nothing in common and the relative error in L^2-norm is 1.4 as indicated in section 3.3.2. For practical use, Morice [17] has already introduced some modification of the linear Schrödinger equation in order to take into account higher-order diffraction effects. Other tentative modifications have been made by Alterman and Rauch [1], Schäfer and Wayne [19], and Barrailh and Lannes [2] for ultrashort pulses. In all these contributions, the authors obtain linear equation, because in a context of pulses with large spectrum it can be shown that the nonlinear effects are less important than usually (see [1] and [2]). Nevertheless, from the physical point of view, it is impossible to neglect nonlinear effects. We therefore need to construct new models that will be exact in the linear case, but that take into account the nonlinear effects and that are not numerically stiff.

This paper is organized as follows. In section 2, we introduce our new models and prove the main result. In section 3, we present some numerical results in order to illustrate our error bounds and also to investigate the numerical effectivity of our model.

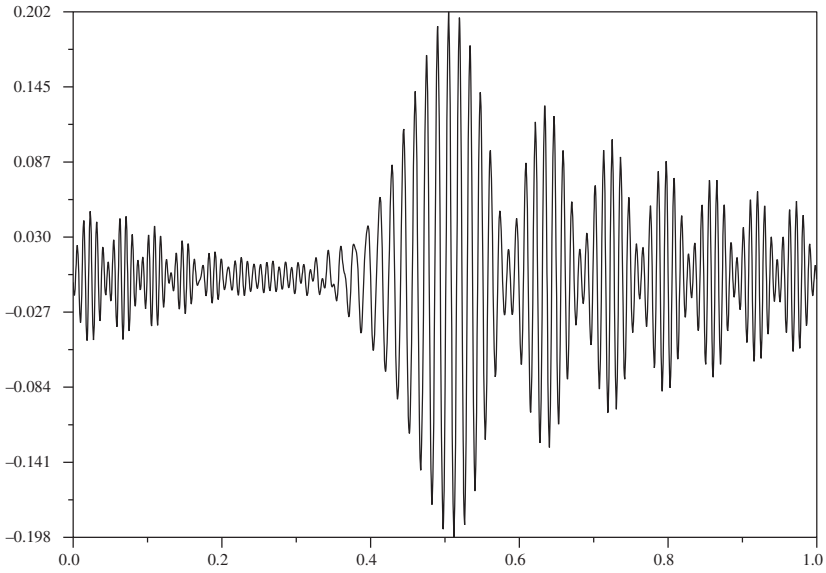

FIG. 2. *Real part of the approximate solution of the first component of system* (1.17) *with* $\varepsilon = 0.01$ *given by the nonlinear Schrödinger equation* (3.5) *at time* $T = 50$*, with chirped initial data, Case* 6.

2. New intermediate models.

2.1. Formal obtaining of the models. We restrict ourselves to geometrical optics regime. We go back to the singular equation (1.13). For $\xi \in \mathbb{R}^n$, let us introduce the following spectral decomposition of the matrix $iA(\xi) + L_0$:

$$iA(\xi) + L_0 = \sum_{j=1}^{m} i\lambda_j(\xi)\Pi_j(\xi), \tag{2.1}$$

where m denotes the number of distinct eigenvalues of $iA(\xi) + L_0$. We have implicitly used the following assumption.

Hypothesis 3. There exist m continuous functions $\xi \mapsto \lambda_j(\xi)$ defining a global parametrization of the characteristic variety C_L.

Of course the functions $\xi \mapsto \Pi_j(\xi)$ are not necessary continuous at the points ξ_0 where there exist j_1 and j_2 such that $\lambda_{j_1}(\xi_0) = \lambda_{j_2}(\xi_0)$. However, since the projector $\Pi_j(\xi)$ are orthogonal projectors, the functions $\xi \mapsto \Pi_j(\xi)$ are bounded. Let us now fix a vector $k \in \mathbb{R}^n$ and take $\omega = \lambda_{l_0}(k)$ one eigenvalue of $iA(\xi) + L_0$ for some $l_0 \in \{1, \ldots, m\}$. In order to simplify the notations, we take $l_0 = 1$. (k, ω) will be the main frequencies of the solution described in the introduction.

Hypothesis 4. There exists a neighborhood V of k such that for all $\xi \in V$ and for all integers $j \geq 2$,

$$\lambda_j(\xi) \neq \lambda_1(\xi).$$

From now on, we use the usual notations $D_\theta = \frac{\partial_\theta}{i}$ and $D_X = \frac{\partial_X}{i}$. Then, (1.13) reads

$$\left(\partial_t + \frac{1}{\varepsilon}(-i\omega D_\theta + iA(kD_\theta + \varepsilon D_X) + L_0)\right)\mathcal{U}^\varepsilon = f(\mathcal{U}^\varepsilon).$$

Using (2.1), we get

$$\left(\partial_t + \frac{1}{\varepsilon}(-i\omega D_\theta + i\lambda_j(kD_\theta + \varepsilon D_X))\right)\Pi_j(kD_\theta + \varepsilon D_X)\mathcal{U}^\varepsilon = \Pi_j(kD_\theta + \varepsilon D_X)f(\mathcal{U}^\varepsilon), \quad j = 1, \dots, m. \tag{2.2}$$

The first model that we introduce relies on the following idea: we want to obtain a model that is exact for the linear regime ($f \equiv 0$) and the best possible for the nonlinear one. Moreover, one starts with initial data that are polarized on the first eigenspace, that is,

$$\Pi_1(kD_\theta + \varepsilon D_X)\mathcal{U}^\varepsilon(t=0) = \mathcal{U}^\varepsilon(t=0).$$

We now make the following hypothesis.

Hypothesis 5. If $m \in \mathbb{Z}$, $j = 1, \dots, m$, then

$$\lambda_j(mk) = m\omega \Rightarrow j = 1 \text{ and } m = \pm 1.$$

One can modify the model obtained below if this assumption is not satisfied. In fact a generalized assumption is the following strong finiteness hypothesis introduced in [12].

Hypothesis 5′. The set $\{m \in \mathbb{Z}$ such that there exists j satisfying $\lambda_j(mk) = m\omega\}$ is finite.

However, for the sake of simplicity, we will restrict ourselves in this work to Hypothesis 5. Under Hypothesis 5, the spectrum of the solution will be mainly supported by the first sheet of the characteristic variety. That is, for all time, we will have $\Pi_1(kD_\theta + \varepsilon D_X)\mathcal{U}^\varepsilon(t) \approx \mathcal{U}^\varepsilon(t)$. We therefore introduce $\mathcal{V}^\varepsilon$ the solution to

$$\left(\partial_t + \frac{1}{\varepsilon}(-i\omega D_\theta + i\lambda_1(kD_\theta + \varepsilon D_X))\right)\Pi_1(kD_\theta + \varepsilon D_X)\mathcal{V}^\varepsilon = \Pi_1(kD_\theta + \varepsilon D_X)f(\mathcal{V}^\varepsilon), \tag{2.3}$$

and

$$\Pi_j(kD_\theta + \varepsilon D_X)\mathcal{V}^\varepsilon = 0 \quad \text{for } j \geq 2. \tag{2.4}$$

We expect $\mathcal{V}^\varepsilon$ to be a good approximation of $\mathcal{U}^\varepsilon$. For $s \in \mathbb{R}$ and $T > 0$ we denote $X_T = L^\infty(0, T; H^s(\mathbb{R}^n_X \times \mathbb{T}_\theta))$. Our first result reads as follows.

THEOREM 2.1. *Let us assume Hypotheses* 3, 4, *and* 5, *and let* $s > \frac{n+1}{2}$, $\alpha > 0$. *Let* $u_0(X) \in H^\sigma(\mathbb{R}^n)$ *(for* σ *large enough) satisfy*

$$\Pi_1(k + \varepsilon D_X)u_0(X) = u_0(X).$$

Then there exists $T > 0$ *(independent of* ε*) and there exist solution* $\mathcal{U}^\varepsilon$ *and* $\mathcal{V}^\varepsilon$, *respectively, to* (2.2), (2.3), and (2.4) *such that*

$$\mathcal{U}^\varepsilon(t=0) = \mathcal{V}^\varepsilon(t=0) = \varepsilon^\alpha(e^{i\theta}u_0 + c.c.).$$

Moreover,

$$\frac{1}{\varepsilon^\alpha}|\Pi_1(kD_\theta + \varepsilon D_X)(\mathcal{U}^\varepsilon - \mathcal{V}^\varepsilon)|_{X_T} = O(\varepsilon^{2\alpha(q-1)+1})$$

and

$$\frac{1}{\varepsilon^\alpha}|\Pi_j(kD_\theta+\varepsilon D_X)\mathcal{U}^\varepsilon|_{X_T}=O(\varepsilon^{\alpha(q-1)+1})\quad \textit{for } j\geq 2.$$

Remark 2.2. The scaling ε^α allows us to see how the error estimate evolves when the nonlinear effects decrease. Indeed, for large α, the nonlinear estimate is better than for small α. The case $\alpha=\infty$ corresponds to the linear regime and the solution is then exact.

Remark 2.3. As usual for the proofs using WKB-type method, we need a lot of regularity on the approximate solution $\mathcal{V}^\varepsilon$. Therefore, we will impose the initial data u_0 to be more regular than the space in which we want the error estimates [14].

Now, we can introduce a second model as follows. Thanks to Hypothesis 5, we expect the Fourier coefficients of order different from ± 1 of $\mathcal{V}^\varepsilon$ to be small. We therefore expect $\mathcal{V}^\varepsilon\approx\mathcal{V}_1^\varepsilon(t,X)e^{i\theta}+c.c.$. We therefore introduce the function $H^\varepsilon(t,X)$ solution to

$$\begin{aligned}\left(\partial_t+\frac{1}{\varepsilon}(-i\omega+i\lambda_1(k+\varepsilon D_X))\right)\Pi_1(k+\varepsilon D_X)H^\varepsilon\\ =\Pi_1(k+\varepsilon D_X)C_1(f(H^\varepsilon e^{i\theta}+c.c.))\end{aligned}\tag{2.5}$$

and we expect $H^\varepsilon e^{i\theta}+c.c.$ to be a good approximation of $\mathcal{V}^\varepsilon$ and hence of $\mathcal{U}^\varepsilon$. Our second result reads as follows.

THEOREM 2.4. *Under the same hypothesis for Theorem* 2.1*, there exist* T_0 *independent of* ε *such that* $T\geq T_0>0$*, a unique solution* $H^\varepsilon(t,X)\in L^\infty(0,T_0;H^s_X(\mathbb{R}^n))$ *to* (2.5) *satisfying* $H^\varepsilon(0,X)=\varepsilon^\alpha u_0(x)$*, and moreover*

$$\frac{1}{\varepsilon^\alpha}|C_1(\mathcal{V}^\varepsilon)-H^\varepsilon(t,X)|_{L^\infty(0,T_0;H^s_X(\mathbb{R}^n))}=O(\varepsilon^{2\alpha(q-1)+1})$$

and

$$\frac{1}{\varepsilon^\alpha}|\mathcal{V}^\varepsilon-(H^\varepsilon e^{i\theta}+c.c.)|_{X_T}=O(\varepsilon^{\alpha(q-1)+1}).$$

Remark 2.5. • The error estimate between $\mathcal{V}^\varepsilon$ and $H^\varepsilon e^{i\theta}+c.c.$ is of the same type as that between $\mathcal{V}^\varepsilon$ and $\mathcal{U}^\varepsilon$.

• The equation satisfied by H^ε is not stiff anymore since $\lambda_1(k)=\omega$.

2.2. Proofs of the theorems. We begin with the proof of Theorem 2.1. One first has an obvious existence result for (2.2) and (2.3).

PROPOSITION 2.6. *Let* $u_0(X)\in H^\sigma(\mathbb{R}^n)$ *(for* σ *large enough) and* $s>\frac{n+1}{2}$*. There exists* $T>0$ *(independent of* ε*) such that there exists a unique solution* $\mathcal{U}^\varepsilon$ *to* (2.2) *and there exists a unique solution* $\mathcal{V}^\varepsilon$ *to* (2.3) *satisfying*

$$\mathcal{U}^\varepsilon\in\mathcal{C}([0,T];H^s(\mathbb{R}^n_X\times\mathbb{T}_\theta)),\qquad \mathcal{V}^\varepsilon\in\mathcal{C}([0,T];H^s(\mathbb{R}^n_X\times\mathbb{T}_\theta)),$$

and

$$\mathcal{U}^\varepsilon(t=0,\theta,X)=\mathcal{V}^\varepsilon(t=0,\theta,X)=\varepsilon^\alpha(e^{i\theta}u_0(X)+c.c.).$$

Moreover, there exists C *independent of* ε *such that*

$$\frac{1}{\varepsilon^\alpha}|\mathcal{U}^\varepsilon|_{X_T}+\frac{1}{\varepsilon^\alpha}|\mathcal{V}^\varepsilon|_{X_T}\leq C.$$

This proposition is obtained by usual energy estimates. It is of course not sufficient in order to prove Theorem 2.1. Let us introduce

$$\mathcal{W}^\varepsilon = \frac{1}{\varepsilon^\alpha}(\mathcal{U}^\varepsilon - \mathcal{V}^\varepsilon), \tag{2.6}$$

and we consider the following decomposition of $\mathcal{W}^\varepsilon$:

$$\begin{aligned}\mathcal{W}^\varepsilon &:= \Pi_1(kD_\theta + \varepsilon D_X)\mathcal{W}^\varepsilon + \sum_{j=2}^{m} \Pi_j(kD_\theta + \varepsilon D_X)\mathcal{W}^\varepsilon \\ &:= \varepsilon^{2\alpha(q-1)+1}a + \sum_{j=2}^{m} \varepsilon^{\alpha(q-1)+1}b_j.\end{aligned} \tag{2.7}$$

In order to prove Theorem 2.1, it is enough to show that the functions a and b_j are bounded in $X_T = L^\infty([0,T]; H^s(\mathbb{R}^n_X \times \mathbb{T}_\theta))$. Let us now write the equations satisfied respectively by a and b_j. Let us form the difference of (2.3) from (2.2) and then apply the projector Π_j. Decomposition of (2.1) yields (using the fact that f is a homogeneous polynomial of degree q)

$$\begin{aligned}&\left(\partial_t + \frac{1}{\varepsilon}(-i\omega D_\theta + i\lambda_1(kD_\theta + \varepsilon D_X))\right) a = \frac{1}{\varepsilon^{\alpha(q-1)+1}}\Pi_1(kD_\theta + \varepsilon D_X) \\ &\cdot \left[f\left(\varepsilon^{2\alpha(q-1)+1}a + \sum_{j=2}^{m} \varepsilon^{\alpha(q-1)+1}b_j + \frac{1}{\varepsilon^\alpha}\mathcal{V}^\varepsilon\right) - f\left(\frac{1}{\varepsilon^\alpha}\mathcal{V}^\varepsilon\right)\right]\end{aligned} \tag{2.8}$$

and

$$\begin{aligned}&\left(\partial_t + \frac{1}{\varepsilon}(-i\omega D_\theta + i\lambda_j(kD_\theta + \varepsilon D_X))\right) b_j \\ &= \frac{1}{\varepsilon}\Pi_j(kD_\theta + \varepsilon D_X)\left[f\left(\varepsilon^{2\alpha(q-1)+1}a + \sum_{j=2}^{m} \varepsilon^{\alpha(q-1)+1}b_j + \frac{1}{\varepsilon^\alpha}\mathcal{V}^\varepsilon\right)\right]\end{aligned} \tag{2.9}$$

for $j = 2, \dots, m$. We start with (2.8). We first use Taylor's formula in the right-hand side of (2.8):

$$\begin{aligned}&f\left(\varepsilon^{2\alpha(q-1)+1}a + \sum_{j=2}^{m} \varepsilon^{\alpha(q-1)+1}b_j + \frac{1}{\varepsilon^\alpha}\mathcal{V}^\varepsilon\right) - f\left(\frac{1}{\varepsilon^\alpha}\mathcal{V}^\varepsilon\right) \\ &= \int_0^1 f'\left(\frac{1}{\varepsilon^\alpha}\mathcal{V}^\varepsilon + \nu\left(\varepsilon^{2\alpha(q-1)+1}a + \sum_{j=2}^{m} \varepsilon^{\alpha(q-1)+1}b_j\right)\right) \\ &\cdot \left(\varepsilon^{2\alpha(q-1)+1}a + \sum_{j=2}^{m} \varepsilon^{\alpha(q-1)+1}b_j\right) d\nu.\end{aligned}$$

f is a homogeneous polynomial of degree q since H^s is an algebra for s large enough, hence this quantity can be estimated in $H^s_{\theta,X}$-norm by

$$\Delta_1(t)= \left| f\left(\varepsilon^{2\alpha(q-1)+1}a+\sum_{j=2}^m \varepsilon^{\alpha(q-1)+1}b_j+\frac{1}{\varepsilon^\alpha}\mathcal{V}^\varepsilon\right)-f\left(\frac{1}{\varepsilon^\alpha}\mathcal{V}^\varepsilon\right)\right|_{H^s}$$

$$\leq C\varepsilon^{\alpha(q-1)+1}\left(\left|\frac{\mathcal{V}^\varepsilon}{\varepsilon^\alpha}\right|^{q-1}_{H^s}+|a|^{q-1}_{H^s}+\sum_{j=2}^m|b_j|^{q-1}_{H^s}\right)\cdot\left(|a|_{H^s}+\sum_{j=2}^m|b_j|_{H^s}\right). \tag{2.10}$$

We now use an integral formulation of (2.8)

$$a=e^{-\frac{1}{\varepsilon}(-i\omega D_\theta+i\lambda_1(kD_\theta+\varepsilon D_X))t}a(t=0)$$

$$+\int_0^t\frac{1}{\varepsilon^{\alpha(q-1)+1}}e^{-\frac{1}{\varepsilon}(-i\omega D_\theta+i\lambda_1(kD_\theta+\varepsilon D_X))(t-\tau)}\Pi_1(kD_\theta+\varepsilon D_X)$$

$$\cdot\left[f\left(\varepsilon^{2\alpha(q-1)+1}a(\tau)+\sum_{j=2}^m\varepsilon^{\alpha(q-1)+1}b_j(\tau)+\frac{1}{\varepsilon^\alpha}\mathcal{V}^\varepsilon(\tau)\right)-f\left(\frac{1}{\varepsilon^\alpha}\mathcal{V}^\varepsilon(\tau)\right)\right]d\tau,$$

and using (2.10),

$$|a|_{H^s}(t)\leq|a(0)|_{H^s}+C\int_0^t\left(\left|\frac{\mathcal{V}^\varepsilon}{\varepsilon^\alpha}\right|^{q-1}_{H^s}+|a|^{q-1}_{H^s}+\sum_{j=2}^m|b_j|^{q-1}_{H^s}\right)\cdot\left(|a|_{H^s}+\sum_{j=2}^m|b_j|_{H^s}\right)d\tau.$$

Using the fact that $\frac{1}{\varepsilon^\alpha}|\mathcal{V}^\varepsilon|_{H^s}$ is bounded, thanks to Proposition 2.6, and that $a(t=0)=0$, one gets

$$|a|_{H^s}(t)\leq C\int_0^t\left(1+|a|_{H^s}+\sum_{j=2}^m|b_j|_{H^s}\right)^q(\tau)d\tau. \tag{2.11}$$

We now deal with (2.9). The main point is to recover one power of ε with respect to the right-hand side using the "elliptic inversion" corresponding to the operator $-i\omega D_\theta+i\lambda_j(kD_\theta+\varepsilon D_X)$. We first rewrite (2.9) as follows:

$$\left(\partial_t+\frac{1}{\varepsilon}\left(-i\omega D_\theta+i\lambda_j(kD_\theta+\varepsilon D_X)\right)\right)b_j$$

$$=\frac{1}{\varepsilon}\Pi_j(kD_\theta+\varepsilon D_X)\left[f\left(\varepsilon^{2\alpha(q-1)+1}a+\sum_{j=2}^m\varepsilon^{\alpha(q-1)+1}b_j+\frac{1}{\varepsilon^\alpha}\mathcal{V}^\varepsilon\right)\right], \tag{2.12}$$

we write the nonlinear term in the form

$$f\left(\varepsilon^{2\alpha(q-1)+1}a+\sum_{j=2}^m\varepsilon^{\alpha(q-1)+1}b_j+\frac{1}{\varepsilon^\alpha}\mathcal{V}^\varepsilon\right)-f\left(\frac{\mathcal{V}^\varepsilon}{\varepsilon^\alpha}\right)+f\left(\frac{\mathcal{V}^\varepsilon}{\varepsilon^\alpha}\right).$$

An integral formula for (2.12) gives

$$
\begin{aligned}
b_j = \frac{1}{\varepsilon}\int_0^t e^{-\frac{1}{\varepsilon}(-i\omega D_\theta + i\lambda_j(kD_\theta+\varepsilon D_X))(t-\tau)}\Pi_j(kD_\theta+\varepsilon D_X)\\
\cdot\left[f\left(\varepsilon^{2\alpha(q-1)+1}a+\sum_{j=2}^m \varepsilon^{\alpha(q-1)+1}b_j+\frac{\mathcal{V}^\varepsilon}{\varepsilon^\alpha}\right)-f\left(\frac{\mathcal{V}^\varepsilon}{\varepsilon^\alpha}\right)\right](\tau)d\tau \qquad (2.13)\\
+\frac{1}{\varepsilon}\int_0^t e^{-\frac{1}{\varepsilon}(-i\omega D_\theta + i\lambda_j(kD_\theta+\varepsilon D_X))(t-\tau)}\Pi_j(kD_\theta+\varepsilon D_X)f\left(\frac{\mathcal{V}^\varepsilon}{\varepsilon^\alpha}\right)(\tau)d\tau\\
:= c_j + d_j.
\end{aligned}
$$

Obviously, one has in the same way that for the estimate of a

$$
|c_j|_{H^s}(t) \le C\int_0^t\left(1+|a|_{H^s}+\sum_{j=2}^m |b_j|_{H^s}\right)^q(\tau)d\tau. \qquad (2.14)
$$

We still have to estimate the term d_j. The idea is to perform the elliptic inversion on the nonlinear term associated with $\mathcal{V}^\varepsilon$ (that is, $f(\mathcal{V}^\varepsilon)$ which is relatively well known (at least asymptotically)). We introduce $\beta_j(D) = -\omega D_\theta + \lambda_j(kD_\theta+\varepsilon D_X)$ and the term d_j can be therefore written as

$$
d_j = \frac{1}{\varepsilon}\int_0^t \Pi_j(kD_\theta+\varepsilon D_X)e^{-\frac{i}{\varepsilon}\beta_j(D)(t-\tau)}f\left(\frac{\mathcal{V}^\varepsilon}{\varepsilon^\alpha}\right)(\tau)d\tau. \qquad (2.15)
$$

In order to use the oscillatory behavior of the exponential, we split the function $\mathcal{V}^\varepsilon$ into low-frequency and high-frequency parts

$$
\begin{aligned}
\mathcal{V}^\varepsilon &= \mathbf{1}_{\{|D_X|\le\frac{1}{\sqrt{\varepsilon}}\}}\mathcal{V}^\varepsilon + \mathbf{1}_{\{|D_X|>\frac{1}{\sqrt{\varepsilon}}\}}\mathcal{V}^\varepsilon\\
&:= \mathcal{V}_1^\varepsilon + \mathcal{V}_2^\varepsilon.
\end{aligned}
$$

Again, we write d_j as follows:

$$
\begin{aligned}
d_j = \frac{1}{\varepsilon}\int_0^t \Pi_j(kD_\theta+\varepsilon D_X)e^{-\frac{i}{\varepsilon}\beta_j(D)(t-\tau)}\left[f\left(\frac{\mathcal{V}^\varepsilon(\tau)}{\varepsilon^\alpha}\right)-f\left(\frac{\mathcal{V}_1^\varepsilon(\tau)}{\varepsilon^\alpha}\right)\right]d\tau\\
+\frac{1}{\varepsilon}\int_0^t \Pi_j(kD_\theta+\varepsilon D_X)e^{-\frac{i}{\varepsilon}\beta_j(D)(t-\tau)}f\left(\frac{\mathcal{V}_1^\varepsilon(\tau)}{\varepsilon^\alpha}\right)d\tau \qquad (2.16)\\
:= e_j + f_j.
\end{aligned}
$$

We begin by estimating e_j

$$
e_j = \frac{1}{\varepsilon}\int_0^t \Pi_j(kD_\theta+\varepsilon D_X)e^{-\frac{i}{\varepsilon}\beta_j(D)(t-\tau)}\int_0^1 f'\left(\frac{\mathcal{V}_1^\varepsilon+\alpha\mathcal{V}_2^\varepsilon}{\varepsilon^\alpha}\right)\cdot\frac{\mathcal{V}_2^\varepsilon}{\varepsilon^\alpha}\,d\alpha d\tau
$$

and

$$
|e_j|_{H^s} \le \frac{1}{\varepsilon}\int_0^t\left(\left|\frac{\mathcal{V}_1^\varepsilon}{\varepsilon^\alpha}\right|_{H^s}^{q-1}+\left|\frac{\mathcal{V}_2^\varepsilon}{\varepsilon^\alpha}\right|_{H^s}^{q-1}\right)\frac{|\mathcal{V}_2^\varepsilon|_{H^s}}{\varepsilon^\alpha}\,d\tau.
$$

Now since

$$\frac{|\mathcal{V}_i^\varepsilon|_{H^s}}{\varepsilon^\alpha} \leq \frac{|\mathcal{V}^\varepsilon|_{H^s}}{\varepsilon^\alpha}$$

for $i = 1, 2$ and thanks to Proposition 2.6, $\frac{|\mathcal{V}^\varepsilon|_{H^s}}{\varepsilon^\alpha}$ is bounded, one has

$$\left|\frac{\mathcal{V}_1^\varepsilon}{\varepsilon^\alpha}\right|_{H^s}^{q-1} + \left|\frac{\mathcal{V}_2^\varepsilon}{\varepsilon^\alpha}\right|_{H^s}^{q-1} \leq C$$

and gets

$$|e_j|_{H^s} \leq \frac{C}{\varepsilon}\int_0^t \frac{|\mathcal{V}_2^\varepsilon(\tau)|_{H^s}}{\varepsilon^\alpha}\, d\tau.$$

Moreover, for all $N \in \mathbb{N}$ and for all $s \in \mathbb{R}$

$$\left|\mathcal{V}^\varepsilon \mathbf{1}_{\{|D_X|>\frac{1}{\sqrt{\varepsilon}}\}}\right|_{H^s} \leq C\varepsilon^N\, |\mathcal{V}^\varepsilon|_{H^{s+2N}}$$

and therefore

$$|e_j|_{H^s}(t) \leq Ct. \tag{2.17}$$

We now deal with the term f_j:

$$f_j = \frac{1}{\varepsilon}\int_0^t \Pi_j(kD_\theta + \varepsilon D_X)e^{-\frac{i}{\varepsilon}\beta_j(D)(t-\sigma)} f\left(\frac{\mathcal{V}_1^\varepsilon(\sigma)}{\varepsilon^\alpha}\right).$$

Now thanks to Hypothesis 4, one can apply the following result of nonlinear geometrical optics (see [14]): there exists a regular function $F(t, X)$ (independent of ε) such that

$$\frac{\mathcal{V}^\varepsilon}{\varepsilon^\alpha} = F(t, X)e^{i\theta} + c.c. + O(\varepsilon),$$

the $O(\varepsilon)$ being for example in $L^\infty(0, T; H^s_{\theta,X}(\mathbb{R}^n \times \mathbb{T}))$-norm. Plugging this expression into the expression of f_j yields

$$\begin{aligned} f_j = \frac{1}{\varepsilon}\int_0^t \Pi_j(kD_\theta + \varepsilon D_X)e^{-\frac{i}{\varepsilon}\beta_j(D)(t-\sigma)} f\left(\mathbf{1}_{\{|D_X|\leq\frac{1}{\sqrt{\varepsilon}}\}}(F(t, X)e^{i\theta} + c.c.)\right) d\sigma \\ + tO(1) := h_j + O(t). \end{aligned}$$

Now, since f is a homogeneous polynomial of degree q,

$$f\left(\mathbf{1}_{\{|D_X|\leq\frac{1}{\sqrt{\varepsilon}}\}}(F(t, X)e^{i\theta} + c.c.)\right)$$

has the form

$$f\left(\mathbf{1}_{\{|D_X|\leq\frac{1}{\sqrt{\varepsilon}}\}}(F(t, X)e^{i\theta} + c.c.)\right) = \sum_{\beta=-q}^{q} a_\beta^\varepsilon(t, X)e^{i\beta\theta},$$

where $a_\beta^\varepsilon(t, X)$ are regular functions, bounded independently of ε in spaces like $W^{k,\infty}(0, T; H^s_X(\mathbb{R}^n))$ for k large enough. Moreover, since the a_β^ε are products of

components of $\mathbf{1}_{\{|D_X|\leq\frac{1}{\sqrt{\varepsilon}}\}}F$ and $\mathbf{1}_{\{|D_X|\leq\frac{1}{\sqrt{\varepsilon}}\}}\bar{F}$, the support of the Fourier transform of a^ε_β is included in $\{\xi||\xi|\leq\frac{q}{\sqrt{\varepsilon}}\}$. Taking the Fourier transform of h_j with respect to θ and X (denoting by $l\in\mathbb{Z}$ and $\xi\in\mathbb{R}^n$ the dual variables of θ and X) gives

$$\hat{h}_j(l,\xi,t)=\frac{1}{\varepsilon}\int_0^t \Pi_j(kl+\varepsilon\xi)e^{-\frac{i}{\varepsilon}[-l\omega+\lambda_j(kl+\varepsilon\xi)](t-\tau)}\hat{a}^\varepsilon_l(\tau,\xi)d\tau \tag{2.18}$$

for $l=-q,\dots,q$. Now thanks to Hypothesis 5, for all l, $l\omega\neq\lambda_j(kl)$ since $j>1$. Moreover, since the support of $\xi\mapsto\hat{a}^\varepsilon_l(s,\xi)$ is included in $\{\xi/\quad|\xi|\leq\frac{q}{\sqrt{\varepsilon}}\}$, it follows that there exist $\varepsilon_0>0$ and $\delta>0$ such that for all $\varepsilon\leq\varepsilon_0$, for all $l=-q$ to q, and for all $\xi\in\{\xi/\quad|\xi|\leq\frac{q}{\sqrt{\varepsilon}}\}$,

$$|-l\omega+\lambda_j(kl+\varepsilon\xi)|\geq\delta. \tag{2.19}$$

We perform an integration by parts in time on (2.18) and get

$$\begin{aligned}\hat{h}_j(l,\xi,t)=\frac{1}{\varepsilon}&\left[\frac{-i\varepsilon}{-l\omega+\lambda_j(kl+\varepsilon\xi)}e^{-\frac{i}{\varepsilon}[-l\omega+\lambda_j(kl+\varepsilon\xi)](t-\tau)}\Pi_j(kj+\varepsilon\xi)\hat{a}^\varepsilon_l(\tau,\xi)\right]_0^t\\&+\frac{1}{\varepsilon}\int_0^t\frac{i\varepsilon}{-l\omega+\lambda_j(kl+\varepsilon\xi)}e^{-\frac{i}{\varepsilon}[-l\omega+\lambda_j(kl+\varepsilon\xi)](t-\tau)}\Pi_j(kj+\varepsilon\xi)\partial_s\hat{a}^\varepsilon_l(\tau,\xi)d\tau.\end{aligned}$$

Therefore using (2.19),

$$|\hat{h}_j(l,\xi,t)|\leq\frac{1}{\delta}\left(|\hat{a}^\varepsilon_l(t,\xi)|+|\hat{a}^\varepsilon_l(0,\xi)|\right)+\frac{1}{\delta}\int_0^t|\partial_\tau\hat{a}^\varepsilon_l(\tau,\xi)|d\tau$$

for all $l=-q,\dots,q$. It follows that

$$|h_j|_{H^s}(t)\leq C(1+t). \tag{2.20}$$

One deduces that

$$|f_j|_{H^s}(t)\leq C(1+t),$$

and with (2.16) and (2.17) we get

$$|d_j|_{H^s}(t)\leq C(1+t).$$

Equality (2.13) and estimate (2.14) give together with the above control of d_j

$$|b_j|_{H^s}\leq C\int_0^t\left(1+|a|_{H^s}+\sum_{j=2}^m|b_j|_{H^s}\right)^q(\tau)d\tau+C(1+t). \tag{2.21}$$

Now we recall the estimate (2.11) of a:

$$|a|_{H^s}(t)\leq C\int_0^t\left(1+|a|_{H^s}+\sum_{j=2}^m|b_j|_{H^s}\right)^q(\tau)d\tau.$$

Introducing $y=1+|a|_{H^s}+\sum_{j=2}^m|b_j|_{H^s}$, one gets using (2.21)

$$y\leq c\int_0^t y^q(\sigma)d\sigma+C(1+t)$$

which implies that there exist $T_0>0$ and $C_0>0$ such that y is defined on $[0,T_0]$ and $|y|_{L^\infty(0,T_0)}\leq C_0$. This ends the proof of Theorem 2.1.

2.3. Proof of Theorem 2.4. We will now compare the solution $\mathcal{V}^\varepsilon$ given by (2.3) and (2.4) and H^ε given by (2.5). The proof is mainly the same as that for the previous result, we only sketch it. Introduce

$$\mathcal{V}^\varepsilon = \sum_{\beta\in\mathbb{Z}} \mathcal{V}^\varepsilon_\beta(t,X)e^{i\beta\theta}.$$

The equation satisfied by $\mathcal{V}^\varepsilon_\beta$ is

$$\left(\partial_t + \frac{1}{\varepsilon}\left(-i\omega\beta + i\lambda_1(k\beta+\varepsilon D_X)\right)\right)\Pi_1(k\beta+\varepsilon D_X)\mathcal{V}^\varepsilon_\beta = \Pi_1(k\beta+\varepsilon D_X)C_\beta\left(f(\mathcal{V}^\varepsilon)\right).$$

Introduce $X^\varepsilon = \frac{1}{\varepsilon^\alpha}[\mathcal{V}^\varepsilon_1 - H^\varepsilon]$ where H^ε is the solution to (2.5). The equation satisfied by $\frac{\mathcal{V}^\varepsilon_\beta}{\varepsilon^\alpha}$ for $\beta \neq \pm 1$ is

$$\begin{aligned}&\left(\partial_t + \frac{1}{\varepsilon}\left(-i\omega\beta + i\lambda_1(k\beta+\varepsilon D_X)\right)\right)\Pi_1(k\beta+\varepsilon D_X)\frac{\mathcal{V}^\varepsilon_\beta}{\varepsilon^\alpha}\\ &\qquad = \Pi_1(k\beta+\varepsilon D_X)\varepsilon^{\alpha(q-1)}C_\beta f\left(\frac{\mathcal{V}^\varepsilon_\beta}{\varepsilon^\alpha}\right).\end{aligned}$$

An elliptic inversion on $\frac{\mathcal{V}^\varepsilon_\beta}{\varepsilon^\alpha}$ gives an estimate of $\frac{\mathcal{V}^\varepsilon_\beta}{\varepsilon^\alpha}$ of size $\varepsilon^{\alpha(q-1)+1}$ for $\beta \neq \pm 1$. Now the equation satisfied by X^ε is

$$\begin{aligned}&\left(\partial_t + \frac{1}{\varepsilon}\left(-i\omega + i\lambda_1(k+\varepsilon D_X)\right)\right)\Pi_1(k+\varepsilon D_X)X^\varepsilon\\ &\qquad = \Pi_1(k+\varepsilon D_X)\varepsilon^{\alpha(q-1)}\left[C_1\left(f\left(\frac{\mathcal{V}^\varepsilon_\beta}{\varepsilon^\alpha}\right)\right) - C_1\left(f\left(\frac{H^\varepsilon e^{i\theta}+c.c.}{\varepsilon^\alpha}\right)\right)\right].\end{aligned} \tag{2.22}$$

Now write $\mathcal{V}^\varepsilon = \mathcal{V}^\varepsilon_1 e^{i\theta} + c.c. + \tilde{\mathcal{V}}^\varepsilon$. Then the right-hand side of (2.22) reads

$$\begin{aligned}&C_1\left(f\left(\frac{\mathcal{V}^\varepsilon_\beta}{\varepsilon^\alpha}\right)\right) - C_1\left(f\left(\frac{H^\varepsilon e^{i\theta}+c.c.}{\varepsilon^\alpha}\right)\right)\\ &\quad = C_1\left(f\left(\frac{H^\varepsilon e^{i\theta}+c.c.}{\varepsilon^\alpha} + X^\varepsilon e^{i\theta} + c.c. + \frac{\tilde{\mathcal{V}}^\varepsilon}{\varepsilon^\alpha}\right) - f\left(\frac{H^\varepsilon e^{i\theta}+c.c.}{\varepsilon^\alpha}\right)\right)\\ &\quad \approx C_1\left(f'\left(\frac{H^\varepsilon e^{i\theta}+c.c.}{\varepsilon^\alpha}\right)\left[X^\varepsilon e^{i\theta} + c.c. + \frac{\tilde{\mathcal{V}}^\varepsilon}{\varepsilon^\alpha}\right]\right).\end{aligned}$$

Integrating (2.22) in time gives

$$|X^\varepsilon|_{H^s}(t) \le \int_0^t \varepsilon^{\alpha(q-1)}C|X^\varepsilon|_{H^s}(\sigma)d\sigma + \int_0^t C\varepsilon^{\alpha(q-1)}\left|\frac{\tilde{\mathcal{V}}^\varepsilon}{\varepsilon^\alpha}\right|_{H^s} d\sigma.$$

But $\frac{\tilde{\mathcal{V}}^\varepsilon}{\varepsilon^\alpha} = O(\varepsilon^{\alpha(q-1)+1})$. It follows that

$$|X|_{L^\infty(0,T;H^s)} = O(\varepsilon^{2\alpha(q-1)+1})$$

which is the desired result.

2.4. Some extensions. Note that if $\alpha = 0$, that is, for $O(1)$ solutions the error estimate is the same as that for usual geometrical optics. The estimate is in fact better for $\alpha > 0$. Recall that ε^α is the size of the initial data and hence of the solution. But if $\alpha > 0$, then standard techniques on (1.13) ensures existence of time of size $\frac{1}{\varepsilon^{\alpha(q-1)}}$. The natural question is then to know if our estimates are valid on such time interval. The answer is affirmative and one has the following theorem.

THEOREM 2.7. *Under the same hypothesis as that for Theorem* 2.1*, there exist* $T_1 > 0$ *and* $C_1 > 0$ *(independent of* ε*) such that*

$$\frac{1}{\varepsilon^\alpha} \left|\Pi_1(kD_\theta + \varepsilon D_X)\left(\mathcal{U}^\varepsilon - \mathcal{V}^\varepsilon\right)\right|_{L^\infty(0,t;H^s_{\theta,X}(\mathbb{T}\times\mathbb{R}^n))} \leq C_1 \varepsilon^{\alpha(q-1)+1}\left(e^{C_1\varepsilon^{\alpha(q-1)}t} - 1\right)$$

and

$$\frac{1}{\varepsilon^\alpha} \left|\Pi_1(kD_\theta + \varepsilon D_X)\mathcal{U}^\varepsilon\right|_{L^\infty(0,t;H^s_{\theta,X}(\mathbb{T}\times\mathbb{R}^n))} \leq C_1 \varepsilon^{\alpha(q-1)+1} t$$

as long as $t \leq \frac{T_1}{\varepsilon^{\alpha(q-1)}}$*. Moreover,*

$$\frac{1}{\varepsilon^\alpha} |C_1(\mathcal{V}^\varepsilon(t,X,\theta)) - H^\varepsilon(t,X)|_{L^\infty(0,t;H^s_X(\mathbb{R}^n))} \leq C_1 \varepsilon^{\alpha(q-1)+1}\left(e_1^{C_1\varepsilon^{\alpha(q-1)}} - 1\right)$$

and

$$\frac{1}{\varepsilon^\alpha} |\mathcal{V}^\varepsilon(t,X,\theta) - (H^\varepsilon(t,X)e^{i\theta} + c.c.)|_{L^\infty(0,t;H^s_{\theta,X}(\mathbb{T}\times\mathbb{R}^n))} \leq C_1 \varepsilon^{\alpha(q-1)+1} t$$

as long $t \leq \frac{T_1}{\varepsilon^{\alpha(q-1)}}$.

That means that our asymptotics are uniform on long-time interval. See the next section for numerical illustrations of these results.

Remark 2.8. Suppose that for all $X \in \mathbb{R}^n$, $f(X) \cdot X = 0$, then for any solution $\mathcal{V}^\varepsilon$ to (2.3) one has

$$\int |\mathcal{V}^\varepsilon|^2(t)\, dX d\theta = \int |\mathcal{V}^\varepsilon|^2(0)\, dX d\theta$$

and for any solution H^ε to (2.5),

$$\int |H^\varepsilon|(t)\, dX = \int |H^\varepsilon|(0)\, dX.$$

That means that if the initial model is conservative, then the asymptotic one is conservative as well.

3. Some numerical results.

3.1. An example. In this section, we want to compare numerically the solutions of the different asymptotic regimes and we want to see to which extent the error estimates that we have proved in the previous section are effective. We choose to make the computations on a simplified system which is dispersive, nonlinear, and preserves the L^2-norm. This system is

$$\begin{cases} \partial_t u + \partial_x v - \dfrac{v}{\varepsilon} = -(u^2+v^2)v, \\ \partial_t v + \partial_x u + \dfrac{u}{\varepsilon} = (u^2+v^2)u. \end{cases} \tag{3.1}$$

The characteristic variety of this system is the set

$$\{(\omega,k)\in\mathbb{R}^2|\omega^2=1+k^2\}.$$

Hypotheses 3 and 4 are therefore satisfied. For Hypothesis 5, suppose that $\omega^2=1+k^2$ and that for $m\in\mathbb{Z}$ one has $m^2\omega^2=1+m^2k^2$. It then follows that $m=\pm1$ and Hypothesis 5 is satisfied.

We now derive the asymptotic models corresponding to (3.1) in the geometrical and diffractive regimes. We refer the reader, for example, to [13] for the case of diffractive optics.

3.1.1. The geometrical optics regime. One searches an approximate solution in the form

$$\begin{pmatrix}u_0(t,x)\\v_0(t,x)\end{pmatrix}e^{i\frac{kx-\omega t}{\varepsilon}}+c.c.$$

Then one obtains

$$u_0=\frac{ik-1}{i\omega}v_0 \tag{3.2}$$

and

$$\partial_t u_0+\frac{k}{\omega}\partial_x u_0=\frac{4i}{\omega}|u_0|^2u_0\quad\text{for } t\in[0,T_0]. \tag{3.3}$$

3.1.2. Diffractive optics. One search an approximate solution in the form

$$\begin{pmatrix}u_1(t,x)\\v_1(t,x)\end{pmatrix}e^{i\frac{kx-\omega t}{\varepsilon}}+c.c.,$$

but on long time-scale with $u_1(0,x)=O(\sqrt{\varepsilon})$ and $v_1(0,x)=O(\sqrt{\varepsilon})$. One gets

$$u_1=\frac{ik-1}{i\omega}v_1 \tag{3.4}$$

and

$$\partial_t u_1+\frac{k}{\omega}\partial_x u_1-\frac{i\varepsilon}{\omega^3}\partial_x^2u_1=\frac{4i}{\omega}|u_1|^2u_1\quad\text{for } t\in\left[0,\frac{T_1}{\varepsilon}\right]. \tag{3.5}$$

3.1.3. The new model. One searches for a solution in the form

$$\begin{pmatrix}u_2(t,x)\\v_2(t,x)\end{pmatrix}e^{i\frac{kx-\omega t}{\varepsilon}}+c.c.$$

and one gets

$$u_2=\frac{i(k+\varepsilon D_x)-1}{i\sqrt{1+(k+\varepsilon D_x)^2}}v_2 \tag{3.6}$$

and

$$\begin{aligned}&\partial_t\begin{pmatrix}u_2\\v_2\end{pmatrix}+\frac{i}{\varepsilon}\left(\sqrt{1+(k+\varepsilon D_x)^2}-\sqrt{1+k^2}\right)\begin{pmatrix}u_2\\v_2\end{pmatrix}\\&=\begin{pmatrix}\frac{1}{2}&\frac{i(k+\varepsilon D_x)-1}{2i\sqrt{1+(k+\varepsilon D_x)^2}}\\\frac{i(k+\varepsilon D_x)+1}{2i\sqrt{1+(k+\varepsilon D_x)^2}}&\frac{1}{2}\end{pmatrix}\begin{pmatrix}-2(|u_2|^2+|v_2|^2)v_2-(u_2^2+v_2^2)\bar{v}_2\\-2(|u_2|^2+|v_2|^2)u_2-(u_2^2+v_2^2)\bar{u}_2\end{pmatrix}.\end{aligned} \tag{3.7}$$

Of course, thanks to (3.6), we can restrict ourselves to the first equation of (3.7) and setting

$$\mu^\varepsilon(D_x) = \frac{i(k+\varepsilon D_x)-1}{i\sqrt{1+(k+\varepsilon D_x)^2}},$$

one obtains

$$\partial_t u_2 + \frac{k\partial_x - i\varepsilon\partial_x^2}{\sqrt{1+(k+\varepsilon D_x)^2}+\sqrt{1+k^2}}u_2 = -(|u_2|^2+|v_2|^2)v_2 - 2(u_2^2+v_2^2)\bar{v}_2 + \mu^\varepsilon(D_x)\left[(|u_2|^2+|v_2|^2)u_2 + 2(u_2^2+v_2^2)\bar{u}_2\right] \tag{3.8}$$

with

$$v_2 = \frac{1}{\mu^\varepsilon(D_x)}u_2, \tag{3.9}$$

which is the complete system.

Finally, the same system with the Kerr nonlinearity is used in practical applications in [17] and reads

$$\partial_t u_3 + \frac{k\partial_x - i\varepsilon\partial_x^2}{\sqrt{1+(k+\varepsilon D_x)^2}+\sqrt{1+k^2}}u_3 = \frac{4i}{\omega}|u_3|^2u_3. \tag{3.10}$$

We will also compare our system with that one.

3.2. The numerical method. We restrict ourselves to the case $x \in [0,1]$ with periodic boundary conditions and we use a spectral method in the space variable x. For time discretization, we adopt a splitting technique.

• For system (3.1), suppose we have built an approximate solution $(u(n\delta t), v(n\delta t))$ at time $n\delta t$; one first integrates the linear part explicitly in Fourier variables with initial data $(u(n\delta t), v(n\delta t))$ over one time step. This gives an indermediate value (u_i, v_i). Then one integrates the nonlinear part

$$\partial_t \begin{pmatrix} u \\ v \end{pmatrix} = \begin{pmatrix} -\big(|u|^2+|v|^2\big)v \\ \big(|u|^2+|v|^2\big)u \end{pmatrix}$$

with initial value (u_i, v_i) explicitly over one time step. This gives $(u((n+1)\delta t), v((n+1)\delta t)$.

• For the geometrical optics (3.3) one has the exact solution

$$u_0(t,x) = A\left(x - \frac{k}{\omega}t\right)e^{\frac{4i}{\omega}|A(x-\frac{k}{\omega}t)|^2 t}, \tag{3.11}$$

where $A(x) = u_0(0,x)$.

• For the diffractive regime (3.5) we use the same strategy as that for (3.1). We omit the details since it is a standard procedure for the nonlinear Schrödinger equation (see [4] and the references therein for a more detailed study).

For the new model (3.8), suppose that one has the Fourier transform of $u_2(n\delta t)$: $\hat{u}_2(n\delta t)$. One solves the linear part of (3.8):

$$\partial_t \hat{u}_2 + \frac{ik\xi + \varepsilon\xi^2}{\sqrt{1+(k+\varepsilon\xi)^2}+\sqrt{1+k^2}}\hat{u}_2 = 0$$

with initial value $\hat{u}_2(n\delta t, \xi)$ on one time step. One gets an intermediate value $\hat{u}_{2i}$. One then obtains an intermediate value of $\hat{v}_2$ called $\hat{v}_{2i}$ using (3.9). We then perform an inverse Fourier transform of $\hat{u}_{2i}$ and $\hat{v}_{2i}$ in order to obtain u_{2i} and v_{2i} and then one constructs the nonlinear terms

$$NL1 := -(|u_{2i}|^2 + |v_{2i}|^2)v_{2i} - 2(u_{2i}^2 + v_{2i}^2)\bar{v}_{2i}$$

and

$$NL2 := (|u_{2i}|^2 + |v_{2i}|^2)u_{2i} + 2(u_{2i}^2 + v_{2i}^2)\bar{u}_{2i}.$$

Next we perform a Fourier transform of $NL1$ and $NL2$ and compute $\hat{NL}1+\mu^\varepsilon(\xi)\hat{NL}2$. The value of $\hat{u}_2((n+1)\delta t)$ is obtained by the explicit Euler scheme

$$\hat{u}_2((n+1)\delta t) = \hat{u}_{2i} + \delta t[\hat{NL}1 + \mu^\varepsilon(\xi)\hat{NL}2].$$

• For the modified system (3.10) the nonlinear step is explicit just like for (3.5) or (3.1).

All these schemes are of order 1 in time.

3.3. Numerical results. We have performed simulations with $\varepsilon = 10^{-2}$ or $\varepsilon = 10^{-3}$. All the results are given in the case where the numerical solution has converged, that is, a division of the time step by 2 and a multiplication by 2 of the number of points for the spatial discretization do not change the result. We use L^2-norms in order to compare the solutions. We take an initial value for u in the form

$$u(t=0,x) = \varepsilon^\alpha \left(e^{i\frac{kx}{\varepsilon}} \varphi(x) + c.c. \right)$$

for $\alpha \geq 0$. All the simulations are done with $k = 2\pi$ and $\omega = \sqrt{1 + (2\pi)^2}$. The initial value for v is obtained by using (3.9). That means that one takes $\psi(x) = \frac{1}{\mu^\varepsilon(D_x)}\varphi(x)$ and

$$v(t=0,x) = \varepsilon^\alpha \left(e^{i\frac{kx}{\varepsilon}} \psi(x) + c.c. \right).$$

The initial data for u_0, u_1, u_2, and u_3 is of course $\varphi(x)$. We call

$$e_{geo} = \max_{t\in[0,T]} \frac{|u(t,\cdot) - \varepsilon^\alpha (u_0(t,\cdot)e^{i\frac{kx-\omega t}{\varepsilon}} + c.c.)|_2}{|u(t,\cdot)|_2},$$

that is the maximum of the error between the exact solution of (3.1) and the approximate solution given by the geometrical optics approximation (3.3) on the time interval $[0,T]$. Here $|f|_2$ denotes the L^2-norm on $[0,1]$ of the function f. We also introduce

$$e_{diff} = \max_{t\in[0,T]} \frac{|u(t,\cdot) - \varepsilon^\alpha (u_1(t,\cdot)e^{i\frac{kx-\omega t}{\varepsilon}} + c.c.)|_2}{|u(t,\cdot)|_2},$$

that is the maximum of the error between the exact solution of (3.1) and the approximate solution given by the diffractive optics approximation (3.5) on the time interval $[0,T]$,

$$e_{new} = \max_{t\in[0,T]} \frac{|u(t,\cdot) - \varepsilon^\alpha (u_2(t,\cdot)e^{i\frac{kx-\omega t}{\varepsilon}} + c.c.)|_2}{|u(t,\cdot)|_2},$$

that is the maximum of the error between the exact solution of (3.1) and the approximate solution given by the new model on the time interval $[0,T]$, and

$$e_{newkerr} = \max_{t\in[0,T]} \frac{|u(t,\cdot) - \varepsilon^\alpha (u_3(t,\cdot)e^{i\frac{kx-\omega t}{\varepsilon}} + c.c.)|_2}{|u(t,\cdot)|_2},$$

that is the maximum of th error between the exact solution of (3.1) and the approximate solution given by the new model with Kerr nonlinearity given by (3.10) on the time interval $[0,T]$. We denote by N the number of Fourier modes in space and N_t the number of time steps.

3.3.1. Time of order 1.

Case 1. We begin with $\varphi(x) = e^{-75(x-\frac{1}{2})^2} e^{i10\cos(x)}$ with $\alpha = 0$ and we compute for $x \in [0,1]$ and $t \in [0,1]$. The errors at $T = 1$ are as follows.

	$\varepsilon = 10^{-2}$	$\varepsilon = 10^{-3}$
e_{geo}	2×10^{-2}	2.3×10^{-3}
e_{diff}	2×10^{-2}	2.3×10^{-3}
e_{new}	1.9×10^{-2}	2×10^{-3}
$e_{newkerr}$	2×10^{-2}	2.3×10^{-3}

For $\varepsilon = 10^{-2}$, the convergence on the errors is reached with $N = 1024$ and $N_t = 1600$. For $\varepsilon = 10^{-3}$ the convergence is reached with $N = 16384$ and $N_t = 12800$. For all cases, the error is of order ε as predicted by the theory. The simplest model (geometrical optics) is precise enough.

Case 2. We made a test for smaller solutions, namelly $\alpha = \frac{1}{2}$. The error at $T = 1$ are as follows.

	$\varepsilon = 10^{-2}$	$\varepsilon = 10^{-3}$
e_{geo}	3.3×10^{-3}	3.2×10^{-4}
e_{diff}	1.7×10^{-4}	1.8×10^{-6}
e_{new}	1.6×10^{-4}	1.9×10^{-6}
e_{newker}	1.9×10^{-4}	2×10^{-6}

For $\varepsilon = 10^{-2}$, the convergence on the errors is reached with $N = 1024$ and $N_t = 1600$. For $\varepsilon = 10^{-3}$, the convergence is reached with $N = 16384$ and $N_t = 12800$. Basically, the error for geometrical optics is the worst (of order ε), however, it remains very satisfactory. The others are of order ε^2 as predicted by the theory.

Case 3. For chirped initial data,

$$u(t=0,x) = \left(e^{-75(x-1/2)^2} e^{i15\cos(15x)} e^{i\frac{kx}{\varepsilon}} + c.c.\right),$$

$x \in [0,1]$. Such kind of solution can occur after diffraction webs for example or for laser with large spectrum. The errors at $T = 1$ are as follows.

	$\varepsilon = 10^{-2}$	$\varepsilon = 10^{-3}$
e_{geo}	0.8	5.7×10^{-2}
e_{diff}	0.17	1.2×10^{-2}
e_{new}	0.023	1.9×10^{-3}
$e_{newkerr}$	0.21	1.4×10^{-2}

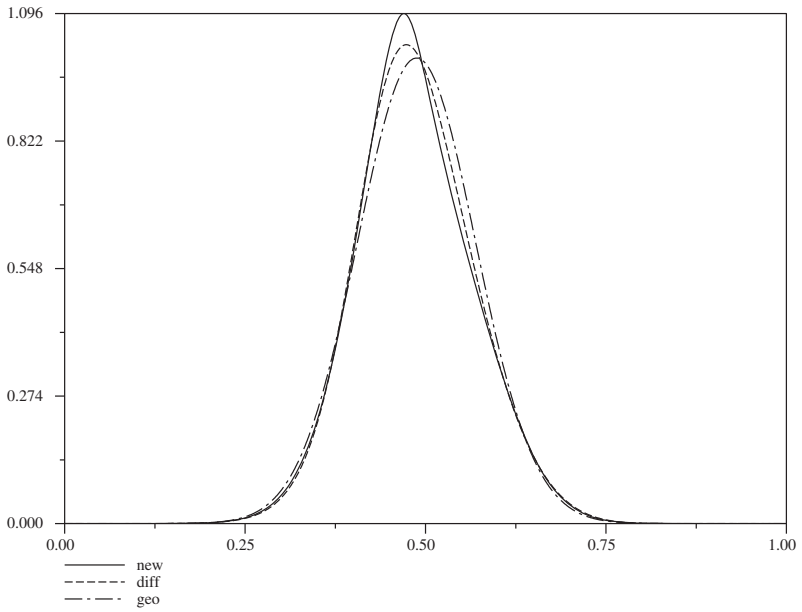

FIG. 3. *Amplitude of the first component of the approximate solution of* (3.1) *at the final time with chirped initial data,* $\alpha = 0$*, given by the geometrical optics, diffractive optics, and new approximations, Case* 3.

For $\varepsilon = 10^{-2}$, the convergence on the errors is reached with $N = 1024$ and $N_t = 1600$. For $\varepsilon = 10^{-3}$, the convergence is reached with $N = 16384$ and $N_t = 12800$. For $\varepsilon = 10^{-2}$, the error for the complete new model is 2.3%, the other errors are above 15%. Such errors are not acceptable in practical applications. As an illustration, one can find on Figure 3 the modulus of the amplitude (that is, without the phase factor $e^{i\frac{(kx-\omega t)}{\varepsilon}}$) of the first component for the three models: the new model, the geometrical optics, and the diffractive optics at the final time. As seen on the figure, the amplitude as well as the positions are false for the diffractive and geometrical optics regimes.

For $\varepsilon = 10^{-3}$, the result given by Shrödinger equation and the new model with the Kerr nonlinearity are correct. The geometrical optics give the worst error and the complete new model the smallest one.

Case 4. For smaller solutions, we made the same test but with $\alpha = \frac{1}{2}$. The errors are as follows.

	$\varepsilon = 10^{-2}$	$\varepsilon = 10^{-3}$
e_{geo}	0.91	6.9×10^{-2}
e_{diff}	0.32	2.3×10^{-3}
e_{new}	1.7×10^{-4}	1.7×10^{-6}
$e_{newkerr}$	2.1×10^{-3}	1.5×10^{-5}

For $\varepsilon = 10^{-2}$, the convergence on the errors is reached with $N = 1024$ and $N_t = 1600$. For $\varepsilon = 10^{-3}$, the convergence is reached with $N = 16384$ and $N_t = 12800$. As in the previous case, geometrical optics and the Schrödinger models give high errors for

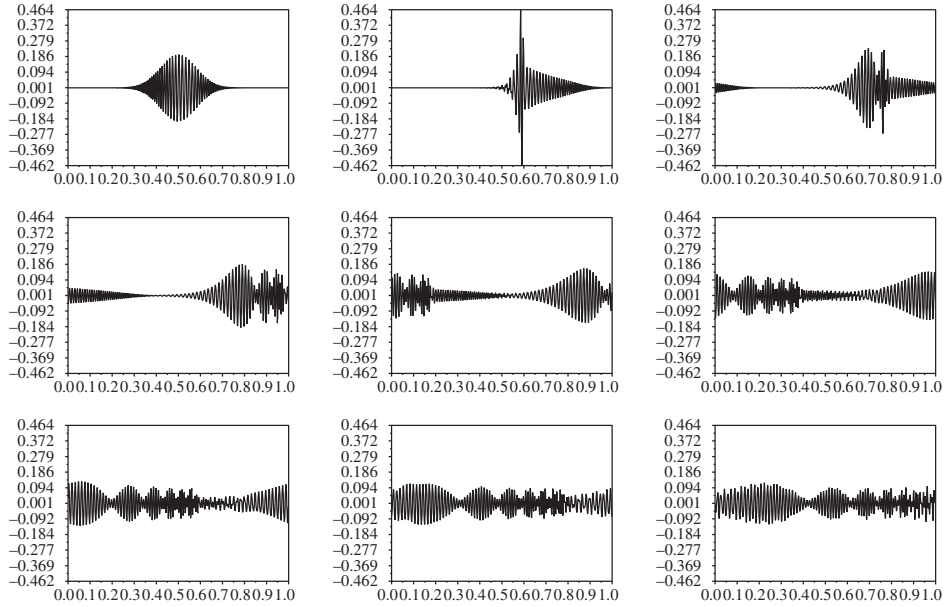

FIG. 4. *Real part of the first component of the solution of system* (3.1) *with* $\varepsilon = 0.01$ *at time* $t = n\frac{50}{8}$ *for* $n = 0, \ldots, 8$ *with chirped initial data and* $\alpha = 1/2$. *First line, from left to right,* $n = 0, 1, 2$, *second line, from left to right,* $n = 3, 4, 5$, *third line, from left to right,* $n = 6, 7, 8$, *Case* 6.

$\varepsilon = 0.01$. Both new models are correct however. For $\varepsilon = 10^{-3}$, the conclusions are the same as in the previous cases.

3.3.2. Diffractive time. We now consider long-time behavior: $T = 50$.

Case 5. We begin by a regular initial data and we take $\varphi(x) = e^{-75(x-\frac{1}{2})^2} e^{i\cos(x)}$ and $\alpha = \frac{1}{2}$. One gets the following errors.

	$\varepsilon = 10^{-2}$	$\varepsilon = 10^{-3}$
e_{geo}	0.13	1.3×10^{-2}
e_{diff}	2.4×10^{-3}	2×10^{-5}
e_{new}	1.7×10^{-4}	3×10^{-6}
$e_{newkerr}$	5.6×10^{-3}	5×10^{-5}

For $\varepsilon = 10^{-2}$, the convergence on the errors is reached with $N = 2048$ and $N_t = 80000$. For $\varepsilon = 10^{-3}$, the convergence is reached with $N = 8192$ and $N_t = 320000$. The geometrical optics gives of course a false result since diffractive effects are important. The result given by the new models are better than that of diffractive optics that is, however, perfectly correct. Any of the three models can be used in practical applications.

Case 6. For chirped initial data, we take

$$\varphi(x) = \left(e^{-75(x-1/2)^2} e^{i15\cos(15x)} + c.c. \right),$$

$x \in [0, 1]$ and $\alpha = \frac{1}{2}$ for $T = 50$. One gets the following errors.

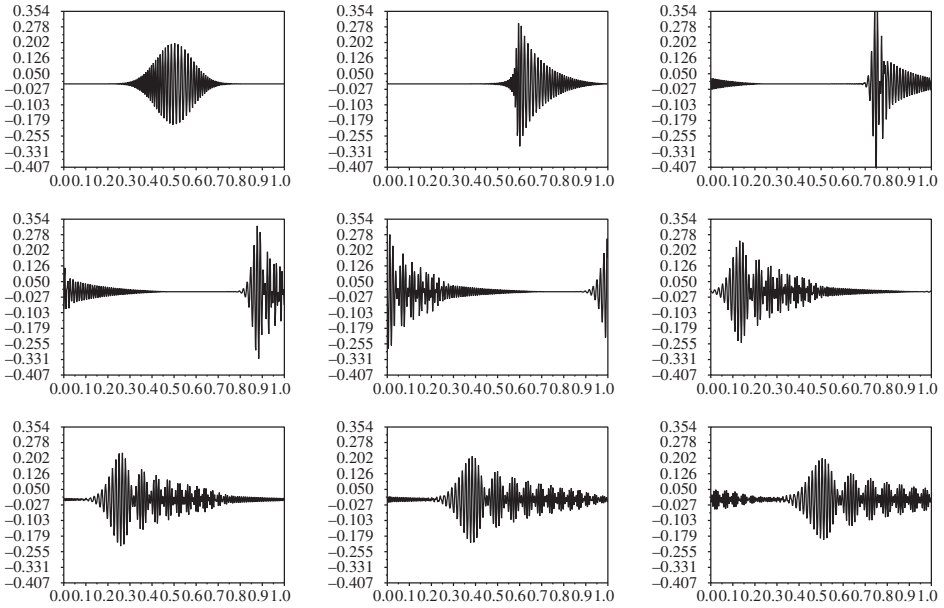

FIG. 5. *Real part of the approximate solution of system* (3.1) *with* $\varepsilon = 0.01$ *at time* $t = n\frac{50}{8}$ *for* $n = 0, \ldots, 8$ *with chirped initial data and* $\alpha = 1/2$ *given by diffractive optics approximation. First line, from left to right,* $n = 0, 1, 2$*, second line, from left to right,* $n = 3, 4, 5$*, third line, from left to right,* $n = 6, 7, 8$*, Case* 6.

	$\varepsilon = 10^{-2}$	$\varepsilon = 10^{-3}$
e_{geo}	1.5	1.6
e_{diff}	1.4	0.11
e_{new}	5×10^{-4}	3×10^{-6}
$e_{newkerr}$	0.08	8×10^{-4}

For $\varepsilon = 10^{-2}$, the convergence on the errors is reached with $N = 2048$ and $N_t = 80000$. For $\varepsilon = 10^{-3}$, the convergence is reached with $N = 8192$ and $N_t = 320000$. Only the complete new model gives an acceptable error. All the others give bad result. The new model with Kerr nonlinearity gives a satisfactory result for small ε but not for $\varepsilon = 0.01$. One can see the evolution of the solution at time $n\frac{50}{8}$ on Figure 4, and on Figure 5 the same but with the solution given by the Schrödinger equation which is far away from the reality.

3.3.3. Conclusion. For small times, chirped initial data or not, the diffractive model is satisfactory. For diffractive times and not chirped initial data, the diffractive model is satisfactory. The geometrical optics regime (that is the explicit solution) is valid on short times.

For diffractive times with chirped initial data, the new model is very useful. The new model with Kerr nonlinearity is intermediate in terms of quality. In any case the solution given by the new system cannot be distinguished from the exact one and will be therefore very useful in practical applications. We postpone the application of this theory to physical cases with more numerical tests to further work.

The main problem of our theory is the boundary conditions. Clearly, because of the pseudodifferential nature of the new model, it is not easy to take into account

nonperiodic boundary conditions. One of the possibility in this direction is to take one space variable as a variable of evolution. This process is under investigation.

INVARIANT MEASURES FOR THE STOCHASTIC VON KARMAN PLATE EQUATION*

JONG UHN KIM†

Abstract. We prove the existence of an invariant measure for the von Karman plate equation with random noise. The nonlinear term which symbolizes the von Karman equation inhibits the standard procedure for the existence of an invariant measure. We propose a technically different approach to handle such intricate nonlinear equations.

Key words. von Karman plate equation, Brownian motion, stopping time, existence of a solution, invariant measure, probability distribution, tightness

1. Introduction.

In this paper, we will establish the existence of an invariant measure for a certain class of stochastic evolution equations with application to the stochastic von Karman plate equation. An invariant measure is an important object in stochastic dynamics. If the initial condition has the probability distribution equal to an invariant measure, then the probability distribution of the evolving solution is invariant in time. Some general results on the existence of invariant measures for stochastic evolution equations are presented in [6] and [7]. The basic method for the existence of invariant measures is due to Krylov and Bogolyubov [12]. However, there are some important equations which are not covered by the known theorems. Here we still follow the Krylov–Bogolyubov method, but with technically different adaptation, which has been motivated by the von Karman equation. For our method, we assume that the stochastic process associated with solutions has the Markov property with mean energy bounded uniformly in time, and that the probability distribution of the process is locally continuous with respect to a weaker norm. Typically, the first assumption is satisfied by a wide class of stochastic evolution equations with suitable dissipation. However, we need an additional condition for tightness of a family of probability measures which will yield an invariant measure. For parabolic equations, the regularizing property is crucially used to obtain tightness of a sequence of probability measures whose weak limit is an invariant measure; see [2]. Hyperbolic equations do not possess the regularizing property. But if the noise term has additional regularity in space variables and if more regular initial data can generate more regular solutions with a higher-order norm bounded uniformly in time, tightness of probability measures can be obtained in the same manner. There are equations which belong to neither case. The von Karman plate equation is a typical example. The advantage of this proposed approach lies in the second assumption, which is fairly mild and can be satisfied by equations such as the von Karman equation. We will highlight the utility of this procedure through the specific example of the von Karman equation.

The initial-boundary value problem for the von Karman plate is formulated as

follows:

$$u_{tt} + \alpha u_t + \Delta^2 u - [u, v] = \sum_{j=1}^{\infty} g_j \frac{dB_j}{dt} \quad \text{in } (0,T) \times G, \tag{1.1}$$

$$\Delta^2 v + [u, u] = 0 \quad \text{in } (0,T) \times G, \tag{1.2}$$

$$u = \frac{\partial u}{\partial \nu} = 0, \quad v = \frac{\partial v}{\partial \nu} = 0 \quad \text{on } [0,T] \times \partial G, \tag{1.3}$$

$$u = u_0(x), \qquad u_t = u_1(x) \quad \text{at } t = 0. \tag{1.4}$$

Here G is a bounded domain in R^2 with smooth boundary ∂G, Δ is the Laplacian in R^2, $\frac{\partial}{\partial \nu}$ is the normal derivative on ∂G, and the bracket $[\cdot, \cdot]$ is defined by

$$[u, v] = \frac{\partial^2 u}{\partial x^2} \frac{\partial^2 v}{\partial y^2} + \frac{\partial^2 v}{\partial x^2} \frac{\partial^2 u}{\partial y^2} - 2 \frac{\partial^2 u}{\partial x \partial y} \frac{\partial^2 v}{\partial x \partial y}. \tag{1.5}$$

Viscous damping is represented by a positive constant α, and B_j's are mutually independent standard Brownian motions over a given stochastic basis. When the right-hand side of (1.1) is replaced by a deterministic term, the existence of a weak solution to (1.1)–(1.4) was proved in [15], and more regular solutions were obtained in [4] and [8]. In fact, the weak solution belongs to the natural function class. Nevertheless, the uniqueness of the weak solution had been an open problem until the work of [1] and [8]. The existence and uniqueness of a solution to the stochastic problem (1.1)–(1.4) can be proved through a standard procedure based upon the known results from the deterministic case. The existence of statistical solutions was established in [3] and [10]. At present, the significant issue is the existence of an invariant measure.

Plate equations are neither hyperbolic nor parabolic while there is no regularizing property. In [4], it was shown that for large $\alpha > 0$ depending on the magnitudes of the given data, the bound of the global solution in a stronger norm is uniform in time. However, for small $\alpha > 0$, it is not known whether such an estimate is valid. Probably, it may not be true. This feature puts the above problem in a new category, which necessitates a technically different approach. Here we proceed in the opposite direction. Instead of trying to find uniform estimates in a stronger norm, we imbed the natural energy space into a larger function class, and obtain a probability measure on this larger space as a limit of a tight family of probability measures. We then prove that this is in fact an invariant measure on the original smaller space. For this, we need to show that the probability distribution of the solution depends continuously on initial data in a weaker norm for fixed time on each closed ball in the natural energy space. The main advantage of this procedure is that we do not need any additional estimates uniform in time other than uniform estimates in the natural energy space. Hence, we do not need either the assumption that $\alpha > 0$ is large or additional regularity of the noise term. We expect this procedure to be applied to other equations which behave like (1.1). Finally, the anonymous referee has informed the author that the idea of using a weaker topology was already used for interacting diffusions in [14] and for stochastic parabolic equations in [16] and [17].

2. Existence of invariant measures. Let $\{\Omega, \mathcal{F}_t, \mathcal{F}, P\}$ be a given stochastic basis and let $E(\cdot)$ denote the expectation with respect to P. Suppose that $X(t, s; z)$, $0 \le s \le t < \infty$ is a pathwise unique solution of a certain stochastic evolution equation such that $X(s, s; z) = z$. We assume

(I) $X(\cdot, s; z)$ is a Ξ-valued continuous process adapted to $\{\mathcal{F}_t\}_{t \ge s}$ for each $z \in \Xi$ and $s \ge 0$, where Ξ is a separable Banach space.

We define a function

$$\mathcal{P}(s,z;t,\Gamma) = P(X(t,s;z)\in\Gamma) \quad \text{for each } \Gamma\in\mathcal{B}(\Xi),\ 0\le s\le t<\infty,\ z\in\Xi, \tag{2.1}$$

where $\mathcal{B}(\Xi)$ is the Borel σ-algebra of Ξ. We assume

(II) $\mathcal{P}(\cdot,\cdot;\cdot,\cdot)$ is a time-homogeneous transition probability function. In other words, it satisfies the following conditions:

(i) $\mathcal{P}(s,z;t,\cdot)$ is a probability measure over $\{\Xi,\mathcal{B}(\Xi)\}$ for all $z\in\Xi$ and $0\le s<t<\infty$;

(ii) $\mathcal{P}(s,\cdot;t,\Gamma)$ is $\mathcal{B}(\Xi)$-measurable for all $0\le s<t<\infty$ and $\Gamma\in\mathcal{B}(\Xi)$;

(iii) for all $0\le s<t<\xi<\infty$ and $\Gamma\in\mathcal{B}(\Xi)$,

$$\mathcal{P}(s,z;\xi,\Gamma) = \int_\Xi \mathcal{P}(s,z;t,dy)\mathcal{P}(t,y;\xi,\Gamma);$$

(iv) $\mathcal{P}(s,\cdot;t,\cdot) = \mathcal{P}(s+h,\cdot;t+h,\cdot)$ for all $0\le s<t<\infty$ and $h>0$.

(III) There is some $z\in\Xi$ such that

$$E(\|X(t,0;z)\|_\Xi)\le M \quad \text{for all } t\ge 0 \tag{2.2}$$

for some positive constant M.

(IV) There is a Banach space Υ such that $\Xi\subset\Upsilon$, the imbedding $\Xi\to\Upsilon$ is continuous, and each closed ball of finite radius in Ξ is a compact subset of Υ. Furthermore, for each bounded continuous function ψ on Ξ, there is a sequence of continuous functions $\{\psi_k\}_{k=1}^\infty$ on Υ such that ψ_k is bounded uniformly in k and

$$\lim_{k\to\infty}\psi_k(y) = \psi(y) \quad \text{for each } y\in\Xi. \tag{2.3}$$

(V) For each fixed $0\le t<\infty$, and each fixed closed ball S of finite radius in Ξ, if $\{z_n\}_{n=1}^\infty$ is a sequence in S such that

$$z_n\to z \quad \text{in } \Upsilon, \tag{2.4}$$

then

$$E(\phi(X(t,0;z_n)))\to E(\phi(X(t,0;z))) \tag{2.5}$$

for every bounded continuous function ϕ on Υ.

Remark. If Ξ has a Schauder basis, the second part of assumption (IV) is automatically satisfied by using the continuous projection onto finite-dimensional subspaces. In fact, this is the case when we consider application to the von Karman plate equation.

THEOREM 2.1. *Under the assumptions* (I)–(V), *there is an invariant measure for the above process* $X(\cdot)$. *In other words, there is a probability measure* μ *on* Ξ *such that*

$$\int_\Xi E(\psi(X(t,0;y)))\mu(dy) = \int_\Xi \psi(y)\mu(dy) \tag{2.6}$$

for all $t\ge 0$ *and every bounded continuous function* ψ *on* Ξ.

Proof. Choose $z\in\Xi$ in the above assumption (III), and define a probability measure μ_T for each $T>0$ by

$$\mu_T(\Gamma) = \frac{1}{T}\int_0^T P(X(t,0;z)\in\Gamma)dt \tag{2.7}$$

for each $\Gamma \in \mathcal{B}(\Xi)$. This is well defined because $P(X(\cdot,0;z) \in \Gamma)$ is $\mathcal{B}([0,\infty))$-measurable. For this measurability, we argue as follows. For each bounded continuous function ϕ on Ξ, $E(\phi(X(t,0;z)))$ is continuous in t by assumption (I). Let Γ be a closed subset of Ξ and $\chi_\Gamma(\cdot)$ be the characteristic function of Γ. Then, there is a sequence of nonnegative bounded continuous functions $\{\phi_k\}_{k=1}^\infty$ on Ξ such that $\phi_k(y) \downarrow \chi_\Gamma(y)$ as $k \to \infty$ for each $y \in \Xi$. Hence, $E(\phi_k(X(t,0;z)))$ converges to $E(\chi_\Gamma(X(t,0;z)))$ as $k \to \infty$ for each t. Hence, $P(X(\cdot,0;z) \in \Gamma)$ is $\mathcal{B}([0,\infty))$-measurable. Let $\mathcal{S}$ be the collection of all subsets Γ such that $P(X(\cdot,0;z) \in \Gamma)$ is $\mathcal{B}([0,\infty))$-measurable. Then, $\mathcal{S}$ is a Dynkin system which includes all closed subsets of Ξ. Thus, $\mathcal{S}$ contains $\mathcal{B}(\Xi)$.

We now proceed to define

$$\tilde{\mu}_T(\Gamma) = \mu_T(\Gamma \cap \Xi) \tag{2.8}$$

for each $\Gamma \in \mathcal{B}(\Upsilon)$. Since the imbedding $\Xi \to \Upsilon$ is continuous, $\Gamma \cap \Xi$ is a Borel subset of Ξ for each $\Gamma \in \mathcal{B}(\Upsilon)$. Hence, $\tilde{\mu}_T$ is well defined and is a probability measure over $\{\Upsilon, \mathcal{B}(\Upsilon)\}$. For any $\epsilon > 0$, there is a positive number r_ϵ such that

$$P(\|X(t,0;z)\|_\Xi \le r_\epsilon) > 1 - \epsilon \quad \text{for all } t \ge 0 \tag{2.9}$$

which follows from assumption (III). Since the ball

$$S_{r_\epsilon} = \{y \in \Xi \mid \|y\|_\Xi \le r_\epsilon\} \tag{2.10}$$

is a compact subset of Υ by assumption (IV), the family of probability measures $\{\tilde{\mu}_T\}_{T>0}$ is tight. Hence, there is a sequence $\{\tilde{\mu}_{T_k}\}_{k=1}^\infty$ and a probability measure $\tilde{\mu}$ over $\{\Upsilon, \mathcal{B}(\Upsilon)\}$ such that $T_k \uparrow \infty$ as $k \to \infty$, and

$$\int_\Upsilon \phi(y)\tilde{\mu}_{T_k}(dy) \to \int_\Upsilon \phi(y)\tilde{\mu}(dy) \quad \text{as } k \to \infty \tag{2.11}$$

for every bounded continuous function ϕ on Υ. Since S_{r_ϵ} is a closed subset of Υ, it follows from (2.9) that

$$1 - \epsilon \le \limsup_{k\to\infty} \tilde{\mu}_{T_k}(S_{r_\epsilon}) \le \tilde{\mu}(S_{r_\epsilon}). \tag{2.12}$$

Since $\epsilon > 0$ is arbitrary and each Borel subset of Ξ is also a Borel subset of Υ, $\tilde{\mu}(\Xi) = 1$ and the restriction of $\tilde{\mu}$ to $\mathcal{B}(\Xi)$, written as μ, is a probability measure over $\{\Xi, \mathcal{B}(\Xi)\}$. Choose any bounded continuous function ϕ on Υ, and fix any $\epsilon > 0$. Then, there is $r > 0$ such that

$$\tilde{\mu}_{T_k}(S_r) = \mu_{T_k}(S_r) > 1 - \epsilon \quad \text{for all } k \ge 1. \tag{2.13}$$

Fix $t > 0$, and let

$$f(y) = E(\phi(X(t,0;y))) = \int_\Xi \mathcal{P}(0,y;t,dw)\phi(w). \tag{2.14}$$

Then, by assumption (V), $f(y)$ is continuous on S_r with respect to the norm of Υ. Since S_r is a closed subset of Υ, we can extend f to $\tilde{f}$ on Υ with the same bound such that $f(y) = \tilde{f}(y)$ for every $y \in S_r$. This follows from the Tietze extension theorem.

It is easy to see that

$$\begin{aligned}\int_\Upsilon \tilde{f}(y)\tilde{\mu}_{T_k}(dy) = &\int_{\Upsilon\setminus S_r} \tilde{f}(y)\tilde{\mu}_{T_k}(dy) \\ &+ \int_{S_r} \tilde{\mu}_{T_k}(dy) \int_\Xi \mathcal{P}(0,y;t,dw)\phi(w)\end{aligned} \tag{2.15}$$

and, by (2.13),

$$\left|\int_{S_r}\tilde{\mu}_{T_k}(dy)\int_{\Xi}\mathcal{P}(0,y;t,dw)\phi(w)-\int_{\Xi}\tilde{\mu}_{T_k}(dy)\int_{\Xi}\mathcal{P}(0,y;t,dw)\phi(w)\right|<M\epsilon, \tag{2.16}$$

where M is a positive constant such that $|\phi(y)|\le M$, for all $y\in\Upsilon$. Here we note that ϕ is also a continuous function on Ξ with respect to the norm of Ξ. It follows from assumption (II) that

$$\begin{aligned}\int_{\Xi}\mu_{T_k}(dy)&\int_{\Xi}\mathcal{P}(0,y;t,dw)\phi(w)\\ &=\frac{1}{T_k}\int_0^{T_k}\left(\int_{\Xi}\mathcal{P}(0,z;s,dy)\int_{\Xi}\mathcal{P}(0,y;t,dw)\phi(w)\right)ds\\ &=\frac{1}{T_k}\int_0^{T_k}\left(\int_{\Xi}\mathcal{P}(0,z;s+t,dy)\phi(y)\right)ds\\ &=\frac{1}{T_k}\int_t^{T_k+t}\left(\int_{\Xi}\mathcal{P}(0,z;\eta,dy)\phi(y)\right)d\eta.\end{aligned} \tag{2.17}$$

But we have

$$\lim_{k\to\infty}\left|\frac{1}{T_k}\int_t^{T_k+t}\left(\int_{\Xi}\mathcal{P}(0,z;\eta,dy)\phi(y)\right)d\eta-\int_{\Xi}\mu_{T_k}(dy)\phi(y)\right|=0, \tag{2.18}$$

$$\int_{\Xi}\mu_{T_k}(dy)\phi(y)=\int_{\Upsilon}\tilde{\mu}_{T_k}(dy)\phi(y), \tag{2.19}$$

and

$$\lim_{k\to\infty}\int_{\Upsilon}\tilde{\mu}_{T_k}(dy)\phi(y)=\int_{\Upsilon}\tilde{\mu}(dy)\phi(y)=\int_{\Xi}\mu(dy)\phi(y). \tag{2.20}$$

In the meantime, it holds that

$$\lim_{k\to\infty}\int_{\Upsilon}\tilde{f}(y)\tilde{\mu}_{T_k}(dy)=\int_{\Upsilon}\tilde{f}(y)\tilde{\mu}(dy), \tag{2.21}$$

$$\left|\int_{\Upsilon}\tilde{f}(y)\tilde{\mu}(dy)-\int_{S_r}f(y)\mu(dy)\right|<M\epsilon, \tag{2.22}$$

$$\int_{S_r}f(y)\mu(dy)=\int_{S_r}\mu(dy)E(\phi(X(t,0;y))), \tag{2.23}$$

and

$$\left|\int_{S_r}\mu(dy)E(\phi(X(t,0;y)))-\int_{\Xi}\mu(dy)E(\phi(X(t,0;y)))\right|<M\epsilon. \tag{2.24}$$

Thus, it follows from (2.15)–(2.24) that

$$\left|\int_{\Xi}\mu(dy)E(\phi(X(t,0;y)))-\int_{\Xi}\mu(dy)\phi(y)\right|<4M\epsilon. \tag{2.25}$$

Since $\epsilon>0$ is arbitrary, we have

$$\int_{\Xi}\mu(dy)E(\phi(X(t,0;y)))=\int_{\Xi}\mu(dy)\phi(y) \tag{2.26}$$

for all bounded continuous function ϕ on Υ for each $t > 0$. Next choose any bounded continuous function ψ on Ξ, and let $\{\psi_k\}_{k=1}^{\infty}$ be the sequence in assumption (IV). Then, for each $k \geq 1$, we have

$$\int_{\Xi} \mu(dy) E(\psi_k(X(t,0;y))) = \int_{\Xi} \mu(dy)\psi_k(y). \tag{2.27}$$

By passing $k \to \infty$, we have

$$\int_{\Xi} \mu(dy) E(\psi(X(t,0;y))) = \int_{\Xi} \mu(dy)\psi(y). \tag{2.28}$$

This completes the proof. □

3. Application to the stochastic von Karman equation. In this section, we present technical preliminaries to apply Theorem 2.1 to (1.1)–(1.4) and formulate the results.

Let $\{\phi_k\}_{k=1}^{\infty}$ be a complete orthonormal basis for $L^2(G)$ where each ϕ_k is an eigenfunction of

$$\begin{cases} \Delta^2 \phi_k = \lambda_k \phi_k & \text{in } G, \\ \phi_k = \dfrac{\partial \phi_k}{\partial \nu} = 0 & \text{on } \partial G. \end{cases} \tag{3.1}$$

Throughout this paper, $\langle \cdot, \cdot \rangle$ stands for the inner product of $L^2(G)$. It is easy to see that

$$\langle \Delta^2 \phi_j, \phi_k \rangle = \langle \Delta \phi_j, \Delta \phi_k \rangle = \lambda_j \delta_{jk} \quad \text{for all } j, k \geq 1. \tag{3.2}$$

$W^{m,p}(G)$, $H^m(G)$, and $H_0^m(G)$ denote the usual Sobolev spaces. Some of them can be characterized in terms of $\{\phi_k\}_{k=1}^{\infty}$:

$$H_0^2(G) \cap H^4(G) = \left\{ f = \sum_{k=1}^{\infty} a_k \phi_k \mid \sum_{k=1}^{\infty} \lambda_k^2 |a_k|^2 < \infty \right\}, \tag{3.3}$$

$$H_0^s(G) = \left\{ f = \sum_{k=1}^{\infty} a_k \phi_k \mid \sum_{k=1}^{\infty} \lambda_k^{s/2} |a_k|^2 < \infty \right\}, \quad 0 \leq s \leq 2, \ s \neq \frac{1}{2}, \frac{3}{2}, \tag{3.4}$$

$$H^{-s}(G) = \left\{ f = \sum_{k=1}^{\infty} a_k \phi_k \mid \sum_{k=1}^{\infty} \frac{1}{\lambda_k^{s/2}} |a_k|^2 < \infty \right\}, \quad 0 \leq s \leq 2, \ s \neq \frac{1}{2}, \frac{3}{2}. \tag{3.5}$$

We define the operator $\mathcal{G}$ on $H^{-2}(G)$ by

$$\mathcal{G}h = \sum_{k=1}^{\infty} \frac{1}{\lambda_k} a_k \phi_k \tag{3.6}$$

for $h = \sum_{k=1}^{\infty} a_k \phi_k \in H^{-2}(G)$. Obviously, $\mathcal{G}$ is the inverse of Δ^2 with the clamped boundary conditions. It is easy to see that for all $f, g \in L^2(G)$,

$$|\langle f, \mathcal{G} g \rangle| \leq \|f\|_{H^{-2}(G)} \|g\|_{H^{-2}(G)} \tag{3.7}$$

and

$$\langle f, \mathcal{G} f \rangle = \|f\|_{H^{-2}(G)}^2. \tag{3.8}$$

The following estimate was proved in [5] and [9]:

$$\|\mathcal{G}[f,g]\|_{W^{2,\infty}(G)} \le C\|f\|_{H^2(G)}\|g\|_{H^2(G)} \tag{3.9}$$

for all $f, g \in H^2(G)$.

Throughout this paper, $\{B_j\}_{j=1}^{\infty}$ is a sequence of mutually independent standard Brownian motions over the stochastic basis $\{\Omega, \mathcal{F}, \mathcal{F}_t, P\}$, where P is a probability measure over the σ-algebra $\mathcal{F}$, $\{\mathcal{F}_t\}$ is a right-continuous filtration over $\mathcal{F}$, and $\mathcal{F}_0$ contains all P-negligible sets. $E(\cdot)$ denotes the expectation with respect to P. When $\mathcal{X}$ is a Banach space, $\mathcal{B}(\mathcal{X})$ denotes the set of all Borel subsets of $\mathcal{X}$. An $\mathcal{X}$-valued function h is said to be $\mathcal{F}$-measurable if $h^{-1}(\mathcal{O}) \in \mathcal{F}$ for all $\mathcal{O} \in \mathcal{B}(\mathcal{X})$. This coincides with strong measurability for Bochner integrals when the range of h is separable. For $1 \le p < \infty$, $L^p(\Omega; \mathcal{X})$ denotes the set of all functions h which are $\mathcal{X}$-valued and strongly measurable with respect to $\mathcal{F}$ such that

$$\int_{\Omega} \|h\|_{\mathcal{X}}^p \, dP < \infty.$$

For general information on stochastic processes, see [11].

We assume the following condition on the noise term in (1.1). Each g_j depends only on the space variables, and

$$\sum_{j=1}^{\infty} \|g_j\|_{L^2(G)}^2 < \infty. \tag{3.10}$$

Under this assumption, we have the following existence result.

THEOREM 3.1. *For each $T > 0$ and $(u_0, u_1) \in H_0^2(G) \times L^2(G)$, there is a unique solution u of (1.1)–(1.4) such that (u, u_t) is adapted to $\{\mathcal{F}_t\}$, and*

$$(u, u_t) \in L^2(\Omega; C([0,T]; H_0^2(G) \times L^2(G))). \tag{3.11}$$

Here u satisfies (1.1) in the following sense. For almost all $\omega \in \Omega$, it holds that

$$\begin{aligned} &\langle u_t(t_2), \psi\rangle - \langle u_t(t_1), \psi\rangle + \int_{t_1}^{t_2} \langle \Delta u, \Delta\psi\rangle \, dt \\ &\quad + \alpha \int_{t_1}^{t_2} \langle u_t, \psi\rangle \, dt + \int_{t_1}^{t_2} \langle [u, \mathcal{G}[u,u]], \psi\rangle \, dt = \sum_{j=1}^{\infty} \int_{t_1}^{t_2} \langle g_j, \psi\rangle \, dB_j \end{aligned} \tag{3.12}$$

for all $\psi \in H_0^2(G)$ and all $0 \le t_1 < t_2 \le T$.

THEOREM 3.2. *There is an invariant measure on $H_0^2(G) \times L^2(G)$ for (1.1)–(1.4).*

4. Proof of Theorems 3.1 and 3.2. Let us define $\chi_N \in C_0^{\infty}(R)$ for each $N \ge 1$ by

$$\chi_N(y) = \begin{cases} 1 & \text{for } |y| \le 2N, \\ 0 & \text{for } |y| \ge 3N. \end{cases} \tag{4.1}$$

Then, it follows from (3.9) that

$$\begin{aligned} &\|\chi_N(\|u\|_{H^2(G)})[u, \mathcal{G}[u,u]] - \chi_N(\|w\|_{H^2(G)})[w, \mathcal{G}[w,w]]\|_{L^2(G)} \\ &\quad \le C_N \|u - w\|_{H^2(G)} \end{aligned} \tag{4.2}$$

for all $u, w \in H^2(G)$ and for some positive constant C_N. We now fix $N \geq 1$ and consider the modified problem

$$u_{tt} + \alpha u_t + \Delta^2 u + \chi_N(\|u\|_{H_0^2(G)})[u, \mathcal{G}[u,u]] = \sum_{j=1}^{\infty} g_j \frac{dB_j}{dt} \quad \text{in } (0,T)\times G, \tag{4.3}$$

$$u = \frac{\partial u}{\partial \nu} = 0 \quad \text{on } [0,T]\times \partial G, \tag{4.4}$$

$$u = u_0(x), \qquad u_t = u_1(x) \quad \text{at } t = 0. \tag{4.5}$$

By the general existence theorem in [6], for each $T > 0$ and $(u_0, u_1) \in H_0^2(G)\times L^2(G)$, there is a pathwise unique solution u of (4.3)–(4.5) such that (u, u_t) is adapted to $\{\mathcal{F}_t\}$, and

$$(u, u_t) \in L^2(\Omega; C([0,T]; H_0^2(G)\times L^2(G))). \tag{4.6}$$

This is still true when (u_0, u_1) is $\mathcal{F}_0$-measurable and $(u_0, u_1) \in L^2(\Omega; H_0^2(G)\times L^2(G))$, which follows from Kotelenez [13].

We introduce the projection P_m of $L^2(G)$ onto the subspace that is spanned by $\{\phi_1, \ldots, \phi_m\}$, and set

$$u_m = P_m u. \tag{4.7}$$

By taking the nonlinear term as a given function, we use the argument in [6, pp. 121–123] to obtain the following representation formula. For almost all $\omega \in \Omega$,

$$\begin{aligned} &\langle u_t(t_2), \psi\rangle - \langle u_t(t_1), \psi\rangle + \int_{t_1}^{t_2} \langle \Delta u, \Delta\psi\rangle\, dt + \alpha \int_{t_1}^{t_2} \langle u_t, \psi\rangle\, dt \\ &\quad + \int_{t_1}^{t_2} \langle \chi_N(\|u\|_{H_0^2(G)})[u, \mathcal{G}[u,u]], \psi\rangle\, dt = \sum_{j=1}^{\infty} \int_{t_1}^{t_2} \langle g_j, \psi\rangle\, dB_j \end{aligned} \tag{4.8}$$

for all $\psi \in H_0^2(G)$ and all $0 \leq t_1 < t_2 \leq T$. Thus, it follows that

$$\begin{aligned} d(u_{mt}) = {} & (-\Delta^2 u_m - \alpha u_{mt} - \chi_N(\|u\|_{H_0^2(G)}) P_m[u, \mathcal{G}[u,u]])dt \\ & + \sum_{j=1}^{\infty} P_m g_j\, dB_j \quad \text{for each } m \geq 1. \end{aligned} \tag{4.9}$$

By Ito's rule, we have, for all $0 \leq t_1 < t_2 \leq T$ and $m \geq 1$,

$$\begin{aligned} &\|u_{mt}(t_2)\|_{L^2(G)}^2 + \|\Delta u_m(t_2)\|_{L^2(G)}^2 \\ &\quad = \|u_{mt}(t_1)\|_{L^2(G)}^2 + \|\Delta u_m(t_1)\|_{L^2(G)}^2 - 2\alpha \int_{t_1}^{t_2} \|u_{mt}\|_{L^2(G)}^2\, dt \\ &\qquad - 2\int_{t_1}^{t_2} \langle \chi_N(\|u\|_{H_0^2(G)}) P_m[u, \mathcal{G}[u,u]], u_{mt}\rangle\, dt \\ &\qquad + 2\sum_{j=1}^{\infty} \int_{t_1}^{t_2} \langle P_m g_j, u_{mt}\rangle\, dB_j + \sum_{j=1}^{\infty} \int_{t_1}^{t_2} \|P_m g_j\|_{L^2(G)}^2 dt. \end{aligned} \tag{4.10}$$

It follows from (3.9) that

$$\begin{aligned} &\|\chi_N(\|u\|_{H_0^2(G)}) P_m[u, \mathcal{G}[u,u]] - \chi_N(\|u\|_{H_0^2(G)})[u_m, \mathcal{G}[u_m, u_m]]\|_{L^2(G)} \\ &\quad \leq \|\chi_N(\|u\|_{H_0^2(G)})(P_m[u, \mathcal{G}[u,u]] - [u, \mathcal{G}[u,u]])\|_{L^2(G)} \\ &\qquad + C_N \|u - u_m\|_{H_0^2(G)} \end{aligned} \tag{4.11}$$

and

$$\int_{t_1}^{t_2} 2\langle [u_m, \mathcal{G}[u_m, u_m]], u_{mt}\rangle dt = \|\Delta v_m(t_2)\|^2_{L^2(G)} - \|\Delta v_m(t_1)\|^2_{L^2(G)}, \tag{4.12}$$

where $v_m = \mathcal{G}[u_m, u_m]$. We now define a stopping time

$$\tau_N = \inf\{t > 0 \mid \|u(t)\|_{H_0^2(G)} \geq N\}. \tag{4.13}$$

By combining these and passing $m \to \infty$, we arrive at

$$\begin{aligned} &\|u_t(t_2)\|^2_{L^2(G)} + \|\Delta u(t_2)\|^2_{L^2(G)} + \|\Delta v(t_2)\|^2_{L^2(G)} \\ &\quad = \|u_t(t_1)\|^2_{L^2(G)} + \|\Delta u(t_1)\|^2_{L^2(G)} + \|\Delta v(t_1)\|^2_{L^2(G)} \\ &\qquad - 2\alpha \int_{t_1}^{t_2} \|u_t\|^2_{L^2(G)} dt + 2\sum_{j=1}^{\infty} \int_{t_1}^{t_2} \langle g_j, u_t\rangle \, dB_j + \sum_{j=1}^{\infty} \int_{t_1}^{t_2} \|g_j\|^2_{L^2(G)} dt \end{aligned} \tag{4.14}$$

for all $0 \leq t_1 \leq t_2 \leq \tau_N$ and for almost all $\omega \in \Omega$, where $v = \mathcal{G}[u, u]$. In the same way, we can also derive

$$\begin{aligned} &\langle u_t(t_2), u(t_2)\rangle + \frac{\alpha}{2}\|u(t_2)\|^2_{L^2(G)} \\ &\quad = \langle u_t(t_1), u(t_1)\rangle + \frac{\alpha}{2}\|u(t_1)\|^2_{L^2(G)} \\ &\qquad - \int_{t_1}^{t_2} (\|\Delta u\|^2_{L^2(G)} + \|\Delta v\|^2_{L^2(G)} - \|u_t\|^2_{L^2(G)}) dt + \sum_{j=1}^{\infty} \int_{t_1}^{t_2} \langle g_j, u\rangle dB_j \end{aligned} \tag{4.15}$$

for all $0 \leq t_1 \leq t_2 \leq \tau_N$ and for almost all $\omega \in \Omega$. We now write $u_N = u$ to signify the dependence of u on $\chi_N(\cdot)$. It follows from the Burkholder–Davis–Gundy inequality that

$$\begin{aligned} &E\left(\sup_{0\leq t\leq \tau_N \wedge T} \left| \sum_{j=1}^{\infty} \int_0^t \langle g_j, u_{Nt}\rangle \, dB_j \right| \right) \\ &\quad \leq ME\left(\sum_{j=1}^{\infty} \int_0^{\tau_N \wedge T} \|g_j\|^2_{L^2(G)} \|u_{Nt}\|^2_{L^2(G)} \, dt \right)^{1/2} \\ &\quad \leq \delta E\left(\sup_{0\leq t\leq \tau_N \wedge T} \|u_{Nt}\|^2_{L^2(G)} \right) + \frac{M^2 T}{4\delta} \sum_{j=1}^{\infty} \|g_j\|^2_{L^2(G)} \end{aligned} \tag{4.16}$$

for all $\delta > 0$ and for some positive constant M independent of N and T. Thus, we can derive from (4.14)

$$\begin{aligned} &E\left(\sup_{0\leq t\leq \tau_N \wedge T} (\|u_{Nt}(t)\|^2_{L^2(G)} + \|\Delta u_N(t)\|^2_{L^2(G)} + \|\Delta v_N(t)\|^2_{L^2(G)}) \right) \\ &\quad \leq C(\|u_0\|^2_{H_0^2(G)} + \|u_1\|^2_{L^2(G)} + \|\mathcal{G}[u_0, u_0]\|^2_{H_0^2(G)}) + CT\sum_{j=1}^{\infty} \|g_j\|^2_{L^2(G)} \end{aligned} \tag{4.17}$$

for some constant C independent of N and $T > 0$. Thus, we find that

$$P(\tau_N \leq T) \leq C_T/N^2 \to 0 \quad \text{as } N \to \infty. \tag{4.18}$$

Since $\tau_{N_1} \le \tau_{N_2}$ for $N_1 < N_2$, it follows that

$$\lim_{N\to\infty} \tau_N = \tau_\infty \ge T \quad \text{for almost all } \omega \in \Omega. \tag{4.19}$$

Since T is arbitrary,

$$\tau_N \uparrow \infty \quad \text{as } N \to \infty \tag{4.20}$$

for almost all $\omega \in \Omega$. By the pathwise uniqueness of u_N, we have $u_{N_1} = u_{N_2}$ on $[0, \tau_{N_1} \wedge \tau_{N_2}]$ for almost all $\omega \in \Omega$, and we can define

$$u(t) = u_N(t) \quad \text{for } t \in [0, \tau_N]. \tag{4.21}$$

Then, this u is the desired solution. Now (4.8) implies (3.12). Since each (u_N, u_{Nt}) is adapted to $\{\mathcal{F}_t\}$, (u, u_t) is adapted to $\{\mathcal{F}_t\}$. By Fatou's lemma, we derive from (4.17) and (4.20) that

$$\begin{aligned} &E\bigg(\sup_{0\le t\le T}(\|u_t(t)\|^2_{L^2(G)} + \|\Delta u(t)\|^2_{L^2(G)} + \|\Delta v(t)\|^2_{L^2(G)})\bigg) \\ &\qquad \le C(\|u_0\|^2_{H_0^2(G)} + \|u_1\|^2_{L^2(G)} + \|\mathcal{G}[u_0,u_0]\|^2_{H_0^2(G)}) + CT\sum_{j=1}^{\infty}\|g_j\|^2_{L^2(G)} \end{aligned} \tag{4.22}$$

for all $T > 0$, where $v = \mathcal{G}[u, u]$.

For the proof of pathwise uniqueness, we suppose that $(\tilde{u}, \tilde{u}_t)$ is another solution of (1.1)–(1.4) in $L^2(\Omega; C([0,T]; H_0^2(G) \times L^2(G)))$. Then, $u - \tilde{u}$ satisfies

$$u_{tt} - \tilde{u}_{tt} + \alpha(u_t - \tilde{u}_t) + \Delta^2(u - \tilde{u}) + [u, \mathcal{G}[u,u]] - [\tilde{u}, \mathcal{G}[\tilde{u}, \tilde{u}]] = 0 \tag{4.23}$$

for almost all $\omega \in \Omega$. Since (u, u_t) and $(\tilde{u}, \tilde{u}_t)$ belong to $C([0,T]; H_0^2(G) \times L^2(G))$ for almost all ω, we can apply the same argument as for the deterministic case to conclude that $u \equiv \tilde{u}$ for almost all $\omega \in \Omega$. This completes the proof of Theorem 3.1.

Next we will obtain uniform estimates. Fix any λ such that

$$0 < \lambda < \min(1, \alpha, \lambda_1), \tag{4.24}$$

where λ_1 is the first eigenvalue of (3.1), and define

$$\begin{aligned} Q(t) = {} & \|u_t(t)\|^2_{L^2(G)} + \|\Delta u(t)\|^2_{L^2(G)} + \|\Delta v(t)\|^2_{L^2(G)} \\ & + \lambda\langle u_t(t), u(t)\rangle + \frac{\alpha}{2}\lambda\|u(t)\|^2_{L^2(G)}. \end{aligned} \tag{4.25}$$

By virtue of (4.20) and (4.21), u satisfies (4.14) and (4.15) for all $0 \le t_1 < t_2 < \infty$ and for almost all ω. Since integrability is guaranteed by (4.22), it follows from (4.14) and (4.15) that

$$\begin{aligned} E(Q(t_2)) - E(Q(t_1)) = {} & -\lambda\int_{t_1}^{t_2} E(\|\Delta u\|^2_{L^2(G)} + \|\Delta v\|^2_{L^2(G)})dt \\ & - (2\alpha - \lambda)\int_{t_1}^{t_2} E(\|u_t\|^2_{L^2(G)})\,dt + \int_{t_1}^{t_2}\sum_{j=1}^{\infty}\|g_j\|^2_{L^2(G)}dt \end{aligned} \tag{4.26}$$

for all $0 \le t_1 < t_2 < \infty$. We can derive

$$\frac{d}{dt}E(Q(t)) \le -cE(Q(t)) + \sum_{j=1}^{\infty} \|g_j\|^2_{L^2(G)} \tag{4.27}$$

for all $t > 0$, where c is a positive constant depending on α, λ_1, and λ. This yields

$$E(Q(t)) \le C_M \quad \text{for all } t \ge 0, \tag{4.28}$$

where M is a constant such that $Q(0) \le M$, and C_M is a constant depending on M and the last term of (4.27). By virtue of (4.24), this yields (2.2).

According to the above argument for the existence of solutions, we could take any $s \ge 0$ as the initial time and $\zeta = (\zeta_0, \zeta_1)$ as the initial value for the Cauchy problem (1.1)–(1.3) if ζ is $H_0^2(G) \times L^2(G)$-valued $\mathcal{F}_s$-measurable such that $\zeta \in L^2(\Omega; H_0^2(G) \times L^2(G))$, and $\mathcal{G}[\zeta_0, \zeta_0] \in L^2(\Omega; H_0^2(G))$. We now write $X(t, s; \zeta) = (u, u_t)$, where u is the solution of (1.1)–(1.3) for $t \ge s$ satisfying $(u(s), u_t(s)) = \zeta$. Then, $X(\cdot, s; \zeta) \in L^2(\Omega; C([s, T]; H_0^2(G) \times L^2(G)))$ for all $T > s$, and (4.28) holds for all $t \ge s$. For each $0 \le s < t$, $z \in H_0^2(G) \times L^2(G)$, and $\Gamma \in \mathcal{B}(H_0^2(G) \times L^2(G))$, we set as in (2.1)

$$\mathcal{P}(s, z; t, \Gamma) = P(X(t, s; z) \in \Gamma).$$

LEMMA 4.1. *Choose any bounded continuous function ψ on $H_0^2(G) \times L^2(G)$, $t > s \ge 0$. Then,*

$$E(\psi(X(t, s; z))) = \int_{H_0^2(G) \times L^2(G)} \mathcal{P}(s, z; t, dy)\psi(y) \tag{4.29}$$

is continuous in $z \in H_0^2(G) \times L^2(G)$.

Proof. Let $\{z_n\}_{n=1}^{\infty}$ be a sequence in $H_0^2(G) \times L^2(G)$ such that $z_n \to z$ in $H_0^2(G) \times L^2(G)$. Let us fix any $t > s \ge 0$. By (4.22), we have

$$\begin{cases} E\left(\sup\limits_{s \le \eta \le t} \|X(\eta, s; z)\|_{H_0^2(G) \times L^2(G)} \right) \le M, \\ E\left(\sup\limits_{s \le \eta \le t} \|X(\eta, s; z_n)\|_{H_0^2(G) \times L^2(G)} \right) \le M \quad \text{for all } n \ge 1 \end{cases} \tag{4.30}$$

for some positive constant M. Let us fix any $\epsilon > 0$ and any bounded continuous function ψ on $H_0^2(G) \times L^2(G)$. Since $H_0^2(G) \times L^2(G)$ is a Polish space and $P(X(t, s; z) \in \cdot)$ is a probability measure over $\{H_0^2(G) \times L^2(G), \mathcal{B}(H_0^2(G) \times L^2(G))\}$, there is a compact subset $\mathcal{K}$ of $H_0^2(G) \times L^2(G)$ such that

$$P(X(t, s; z) \in \mathcal{K}) > 1 - \epsilon. \tag{4.31}$$

By virtue of (4.30), there is some $R > 0$ such that

$$\begin{cases} P\left(\sup\limits_{s \le \eta \le t} \|X(\eta, s; z_n)\|_{H_0^2(G) \times L^2(G)} \le R \right) > 1 - \epsilon \quad \text{for all } n \ge 1, \\ P\left(\sup\limits_{s \le \eta \le t} \|X(\eta, s; z)\|_{H_0^2(G) \times L^2(G)} \le R \right) > 1 - \epsilon. \end{cases} \tag{4.32}$$

By taking R larger, we also have

$$\mathcal{K} \subset \{y \in H_0^2(G) \times L^2(G) \mid \|y\|_{H_0^2(G) \times L^2(G)} \le R\}. \tag{4.33}$$

Let us fix such R and write for each n

$$A_n = \left\{ \sup_{s\le\eta\le t} \|X(\eta,s;z_n)\|_{H_0^2(G)\times L^2(G)} \le R \right\} \bigcap \left\{ \sup_{s\le\eta\le t} \|X(\eta,s;z)\|_{H_0^2(G)\times L^2(G)} \le R \right\} \bigcap \{X(t,s;z)\in\mathcal{K}\}. \tag{4.34}$$

We will estimate the integral on the right-hand side of

$$\begin{aligned} &|E(\psi(X(t,s;z))) - E(\psi(X(t,s;z_n)))| \\ &\quad \le \int_{A_n} |\psi(X(t,s;z)) - \psi(X(t,s;z_n))|\, dP + 6M\epsilon, \end{aligned} \tag{4.35}$$

where M is a positive constant such that $|\psi(y)| \le M$ for all y. By means of (3.9), we can derive from (4.23) that

$$\|X(t,s;z) - X(t,s;z_n)\|^2_{H_0^2(G)\times L^2(G)} \le C_R \|z_n - z\|^2_{H_0^2(G)\times L^2(G)} \tag{4.36}$$

for all $\omega \in \tilde{A}_n$, where $\tilde{A}_n \subset A_n$ and $P(A_n \setminus \tilde{A}_n) = 0$, and C_R is a constant independent of n. Since ψ is continuous on $H_0^2(G)\times L^2(G)$ and $\mathcal{K}$ is compact, there is $\delta > 0$ such that

$$|\psi(x) - \psi(y)| < \epsilon \tag{4.37}$$

for every $x \in \mathcal{K}$, $y \in H_0^2(G)\times L^2(G)$ satisfying $\|x-y\|_{H_0^2(G)\times L^2(G)} < \delta$. Hence, it follows from (4.36) that there is $N \ge 1$ such that for all $n \ge N$,

$$\int_{A_n} |\psi(X(t,s;z)) - \psi(X(t,s;z_n))|\, dP < \epsilon, \tag{4.38}$$

which yields

$$|E(\psi(X(t,s;z))) - E(\psi(X(t,s;z_n)))| < \epsilon + 6M\epsilon \tag{4.39}$$

for all $n \ge N$. Thus, $E(\psi(X(t,s;z)))$ is continuous in z. □

This implies that $\mathcal{P}(s,\cdot;t,\Gamma)$ is $\mathcal{B}(\Xi)$-measurable for all $0 \le s < t < \infty$ and $\Gamma \in \mathcal{B}(\Xi)$. This can be seen by the same argument as in the previous proof of the measurability of $P(X(\cdot,0;z))$.

LEMMA 4.2. *$X(\cdot)$ has the Markov property, and its transition probability function is time-homogeneous.*

Proof. By the uniqueness of solution, it holds that for any $0 \le r < s < t$ and $z \in H_0^2(G)\times L^2(G)$,

$$X(t,r;z) = X(t,s;X(s,r;z)) \tag{4.40}$$

for almost all ω. We have to show that

$$E(\psi(X(t,s;X(s,r;z))) \mid \mathcal{F}_s) = \mathcal{P}_{s,t}(\psi)(X(s,r;z)) \tag{4.41}$$

for almost all ω, for each bounded continuous function ψ on $H_0^2(G)\times L^2(G)$, where

$$\mathcal{P}_{s,t}\psi(y) = E(\psi(X(t,s;y))).$$

According to the proof of Theorem 3.1, the solution was obtained by the truncation method. Let $X_N = X_N(t,s;\zeta)$ denote the solution $(u_N, \partial_t u_N)$ of (4.3)–(4.4) satisfying $(u_N(s), \partial_t u_N(s)) = \zeta$, where $\zeta = (\zeta_0, \zeta_1)$ is $H_0^2(G)\times L^2(G)$-valued $\mathcal{F}_s$-measurable such that $\zeta \in L^2(\Omega; H_0^2(G)\times L^2(G))$ and $\mathcal{G}[\zeta_0,\zeta_0] \in L^2(\Omega; H_0^2(G))$. Then, we know that for each $T > s$,

$$X(t,s;\zeta) = \lim_{N\to\infty} X_N(t,s;\zeta) \quad \text{in } C([s,T]; H_0^2(G)\times L^2(G)) \tag{4.42}$$

for almost all ω. For each $N \geq 1$ and each bounded continuous function ψ on $H_0^2(G)\times L^2(G)$, it holds that

$$E(\psi(X_N(t,s;\zeta)) \mid \mathcal{F}_s) = \mathcal{P}_{s,t}^N(\psi)(\zeta) \tag{4.43}$$

for almost all ω, which follows directly from the argument in [6, p. 250]. Here $\mathcal{P}_{s,t}^N$ is defined by

$$\mathcal{P}_{s,t}^N\psi(y) = E(\psi(X_N(t,s;y))).$$

Since ψ is a bounded continuous function, we pass $N\to\infty$ to arrive at

$$E(\psi(X(t,s;\zeta)) \mid \mathcal{F}_s) = P_{s,t}(\psi)(\zeta) \tag{4.44}$$

for almost all ω. Hence $X(\cdot)$ has the Markov property.

Since g_j's are independent of time, we can apply the result in [6, p. 251] to see that the transition probability function is time-homogeneous. ∎

LEMMA 4.3. *Let $S_L = \{y \in H_0^2(G)\times L^2(G) \mid \|y\|_{H_0^2(G)\times L^2(G)} \leq L\}$, and let $\{z_n\}_{n=1}^\infty$ be a sequence in S_L such that $z_n \to z$ in $H_0^1(G)\times H^{-1}(G)$. If ϕ is a bounded continuous function on $H_0^1(G)\times H^{-1}(G)$, then for each $t > 0$,*

$$E(\phi(X(t,0;z_n))) \to E(\phi(X(t,0;z))) \tag{4.45}$$

as $z_n \to z$ in $H_0^1(G)\times H^{-1}(G)$.

Proof. Let us fix any $t^* > 0$, and write

$$Y_n(t) = X(t,0;z_n) - X(t,0;z). \tag{4.46}$$

Suppose that

$$\|X(t,0;z_n)\|_{H_0^2(G)\times L^2(G)} \leq R, \qquad \|X(t,0;z)\|_{H_0^2(G)\times L^2(G)} \leq R \tag{4.47}$$

for all $0 \leq t \leq t^*$ for some constant R. It follows from (4.23) and the basic inequality established in [1] that

$$\begin{aligned} &\|Y_n(t_2)\|^2_{H_0^1(G)\times H^{-1}(G)} - \|Y_n(t_1)\|^2_{H_0^1(G)\times H^{-1}(G)} \\ &\qquad \leq C_1 \log(1+\lambda_N) \int_{t_1}^{t_2} \|Y_n(s)\|^2_{H_0^1(G)\times H^{-1}(G)}\, ds + C_2 t^* \lambda_{N+1}^{-\beta} \end{aligned} \tag{4.48}$$

for all $0 \leq t_1 < t_2 \leq t^*$, all $N \geq N_0$, for some constant $0 < \beta < 1$, and for positive integer N_0. Here λ_N is the Nth eigenvalue of (3.1), and C_1 and C_2 are positive constants depending only on β and R. We partition $[0,t^*]$ such that

$$0 = t_0 < t_1 < \cdots < t_K = t^*, \quad t_k - t_{k-1} = t^*/K < \beta/C_1, \quad 1 \leq k \leq K. \tag{4.49}$$

By the Gronwall inequality, we can derive from (4.48) that

$$\|Y_n(t)\|^2_{H_0^1(G)\times H^{-1}(G)} \le (\|Y_n(t_k)\|^2_{H_0^1(G)\times H^{-1}(G)} + C_2 t^* \lambda_{N+1}^{-\beta})(1+\lambda_N)^{C_1(t-t_k)} \tag{4.50}$$

for all $t \in [t_k, t_{k+1}]$, all $N \ge N_0$, and for each $k = 0, \dots, K-1$. Since $\lambda_N \uparrow \infty$ as $N \to \infty$, we use (4.49) to infer from (4.50) that for given $\epsilon > 0$, there is $\epsilon_K > 0$ such that if $\|Y_n(t_{K-1})\|_{H_0^1(G)\times H^{-1}(G)} < \epsilon_K$,

$$\|Y_n(t_K)\|_{H_0^1(G)\times H^{-1}(G)} < \epsilon. \tag{4.51}$$

By iteration, we find that there is $\epsilon_1 > 0$ such that if $\|z_n - z\|_{H_0^1(G)\times H^{-1}(G)} < \epsilon_1$, (4.51) holds. By the same argument as in the proof of Lemma 4.1, we arrive at (4.45). □

LEMMA 4.4. *Let ψ be a bounded continuous function on $H_0^2(G) \times L^2(G)$. Then, there is a sequence $\{\psi_k\}_{k=1}^{\infty}$ such that each ψ_k is a continuous function on $H_0^1(G) \times H^{-1}(G)$ bounded uniformly in k, and*

$$\psi_k(y) \to \psi(y) \quad \text{as } k \to \infty \tag{4.52}$$

for each $y \in H_0^2(G) \times L^2(G)$.

Proof. It is enough to set

$$\psi_k(y) = \psi((P_k y_1, P_k y_2)) \quad \text{for } y = (y_1, y_2) \in H_0^1(G) \times H^{-1}(G),\ k = 1, 2, \dots, \tag{4.53}$$

where P_k is the projection onto the subspace spanned by $\{\phi_1, \dots, \phi_k\}$. □

Finally, we set

$$\Xi = H_0^2(G) \times L^2(G), \qquad \Upsilon = H_0^1(G) \times H^{-1}(G).$$

Then, assumptions (I)–(V) follow from the above lemmas, and the proof of Theorem 3.2 is complete.

ERRATUM: ON THE HÖLDER CONTINUITY OF SOLUTIONS OF A CERTAIN SYSTEM RELATED TO MAXWELL'S EQUATIONS*

KYUNGKEUN KANG† AND SEICK KIM‡

Abstract. The main purpose of this erratum is to correct Lemmas 2.4 and 2.5 in [K. Kang and S. Kim, *SIAM J. Math. Anal.*, 34 (2002), pp. 87–100] and present their proofs. We also take this opportunity to rectify some flaws caused by those incorrectly stated lemmas.

AMS subject classifications. 35B45, 35J60, 35Q60

DOI. 10.1137/040612907

First we make a correction to the definition of $\mathcal{D}(\Omega)$ [2, p. 88, line 25] as follows:

$$\mathcal{D}(\Omega) = \mathcal{D}(\Omega;\mathbb{R}^3) = \left\{ f \in C^\infty(\Omega;\mathbb{R}^3) : f \text{ is compactly supported }, \nabla \cdot f = 0 \right\}.$$

In Theorems 2.1 and 2.2 and the other related parts of the article, $f \in \mathcal{H}^q_{\mathrm{loc}}(\Omega)$ should read $f \in \mathcal{H}^q(\Omega)$, and $\|f\|_{L^q(B)}$ should read $\|f\|_{L^q(\Omega)}$.

Then, Lemmas 2.4 and 2.5 should be corrected as follows.

LEMMA 2.4. *Let $\Omega \subset \mathbb{R}^3$ be an open set and assume $f \in \mathcal{D}(\Omega)$. Then there exists $g \in C^\infty(\Omega)$ such that $\nabla \times g = f$ and $\nabla \cdot g = 0$ in Ω. Moreover, we have $\|\nabla g\|_{L^p(\Omega)} \le C(p)\,\|f\|_{L^p(\Omega)}$ for $1 < p < \infty$.*

Proof. We define $g := -\nabla \times N(f)$, where $N(f)$ is the Newtonian potential of f over Ω (see, e.g., [1, p. 51] for the definition). Then from the vector identity

$$\nabla \times (\nabla \times F) = \nabla(\nabla \cdot F) - \Delta F, \tag{2.4}$$

we find

$$\nabla \times g = -\nabla \times (\nabla \times N(f)) = \Delta N(f) - \nabla(\nabla \cdot N(f)) = f - \nabla(N(\nabla \cdot f)) = f.$$

Also, by the Calderón–Zygmund theory (see, e.g., [1, Theorem 9.9]), we find $\|\nabla g\|_{L^p(\Omega)} \le C\,\|f\|_{L^p(\Omega)}$. Clearly, we have $\nabla \cdot g = 0$. ∎

LEMMA 2.5. *Suppose $F \in C^\infty(\overline{B};\mathbb{R}^3)$ satisfies $\nabla \times F = 0$ in B. Then there exists $\varphi \in C^\infty(B)$ such that $\nabla\varphi = F$ and $\int_B \varphi = 0$. Moreover, we have $\|\varphi\|_{L^2(B)} \le C\,\|F\|_{L^2(B)}$.*

Proof. Let φ be a solution to

$$\begin{cases} \Delta\varphi = \nabla \cdot F & \text{in} \quad B, \\ \frac{\partial\varphi}{\partial n} = F \cdot n & \text{on} \quad \partial B. \end{cases}$$

By subtracting a constant, we may assume $\int_B \varphi = 0$.

Denote $\omega := \nabla\varphi - F$. We have $\nabla \cdot \omega = 0$, $\nabla \times \omega = 0$ in B, and $\omega \cdot n = 0$ on ∂B. Therefore $\omega \equiv 0$ in B. We have thus shown that $\nabla\varphi = F$ in B. Since $\int_B \varphi = 0$, the Poincaré inequality implies $\|\varphi\|_{L^2(B)} \le C\,\|F\|_{L^2(B)}$. ∎

‡Mathematics Department, University of Missouri, Columbia, MO 65211 (seick@math.missouri.edu).

Finally, we should make a slight change in the proof of Theorem 2.1.

On page 91, line 2, $f \in \mathcal{H}^q_{\mathrm{loc}}(\Omega) \cap C^\infty(\Omega)$ should read $f \in \mathcal{D}(\Omega)$.

On page 91, lines 7–10 should be replaced as follows:

Since $f \in \mathcal{D}(\Omega)$, we conclude from Lemma 2.4 that there exists a smooth vector g such that $f = \nabla \times g$ in Ω. By subtracting a constant vector, we may assume that $\int_{B_8} g = 0$. Then the Sobolev–Poincaré inequality implies

$$\|g\|_{L^{q^*}(B_8)} \le C \|\nabla g\|_{L^q(B_8)} \le C \|f\|_{L^q(\Omega)}, \quad q^* = nq/(n-q) > n. \tag{2.5}$$

Acknowledgment. We thank Professor Marius Mitrea for bringing these errors to our attention.

PERIODIC MOTIONS OF LINEAR IMPACT OSCILLATORS VIA THE SUCCESSOR MAP*

DINGBIAN QIAN† AND PEDRO J. TORRES‡

Abstract. We investigate the existence and multiplicity of nontrivial periodic bouncing solutions for linear and asymptotically linear impact oscillators by applying a generalized version of the Poincaré–Birkhoff theorem to an adequate Poincaré section called the successor map. The main theorem includes a generalization of a related result by Bonheure and Fabry and provides a sufficient condition for the existence of periodic bouncing solutions for Hill's equation with obstacle at $x \neq 0$.

Key words. impact oscillator, Hill's equation, periodic solution, successor map, Poincaré–Birkhoff twist theorem

1. Introduction and main results.

In this paper, we study the existence of $2m\pi$-periodic bouncing solutions for the following linear impact oscillator:

$$\begin{cases} x'' + a(t)x = p(t) \quad \text{for } x(t) > 0; \\ x(t) \geq 0; \\ x(t_0) = 0 \ \Rightarrow x'(t_0+) = -x'(t_0-), \end{cases} \tag{1.1}$$

where $a(t),\ p(t)$ are 2π-periodic continuous functions and $p(t)$ satisfies

$$p(t) \leq 0 \quad \text{and} \quad \overline{p} = \frac{1}{2\pi}\int_0^{2\pi} p(t)dt < 0. \tag{1.2}$$

This system is included in a larger family of impact oscillators given by

$$\begin{cases} x'' + f(t,x,x') = 0 \quad \text{for } x(t) > q(t); \\ x(t) \geq q(t); \\ x(t_0) = q(t_0) \ \Rightarrow x'(t_0+) = -x'(t_0-) + 2q'(t_0), \end{cases} \tag{1.3}$$

where f is continuous and 2π-periodic with respect to t and $q \in C^2(\mathbb{R})$ is also 2π-periodic. From the viewpoint of mechanics this equation models the motion of a particle attached to a nonlinear spring and bouncing elastically against the barrier described by $q(t)$. Thus (1.3) is a model of dynamical system with discontinuity [23] that can be included in the wide family of *vibro-impact systems* [3]. Because of the range of applications in physics and engineering, vibro-impact systems have attracted the attention of a lot of researchers and in consequence the number of papers related to this topic is huge; see [4, 8, 10, 21, 22, 14] and their bibliographies only to mention

some of them. There are also interesting relations with Fermi accelerator [15, 35], dual billiards [7], and celestial mechanics [9].

In spite of this, even for the simple case of a one-degree-of-freedom linear oscillator with impacts, the dynamics is far from being understood, although some results are known [6, 24, 25, 33]. Our purpose in this paper is to investigate the existence of nontrivial periodic bouncing solutions with prescribed number of impacts for linear and asymptotically linear impact oscillators. As it is known, the existence of subharmonics of arbitrary order is usually a hint of a complex dynamics. The following definition clarifies the concept of bouncing solution we mean here.

DEFINITION 1.1. *A continuous function $x : \mathbb{R} \to \mathbb{R}$ is a* bouncing solution *for problem* (1.3) *if the following conditions hold:*

1. $x(t) \geq q(t)$ *for all* $t \in \mathbb{R}$*;*
2. *the set* $W = \{t : x(t) = q(t)\}$ *is discrete and not empty;*
3. $x'(t_0+) = -x'(t_0-) + 2q'(t_0)$ *for any* $t_0 \in W$*;*
4. *given an interval* I*, if* $I \cap W = \emptyset$*, then* $x \in C^2(I, \mathbb{R}^+)$ *and it is a classical solution of* (1.3)*.*

Note that the change of variables $y(t) = x(t) - q(t)$ enables to assume without loss of generality that the barrier is fixed at zero. In this context, Lazer and McKenna [25] proved the existence of 2π-periodic bouncing solution for a linear oscillator with small amplitude forcing term and small viscous damping. Recently, Bonheure and Fabry [6] proved the existence of a 2π-periodic bouncing solution for the linear oscillator

$$x'' + \lambda x = p(t), \tag{1.4}$$

where $\lambda > 0$ is a constant and $p(t) < 0$. They also introduced the concept of *admissible* solution in [6] to treat the case where $p(t)$ changes its sign and showed some existence results for perturbations of a linear oscillator. The main feature of an admissible solution is that it can vanish on a whole interval. This is physically equivalent to an attachment of the particle to the barrier $x = 0$ during a whole interval of time. Due to the condition (1.2), we are able to work directly with the more specific concept of bouncing solution, which constitutes a particular class of admissible solutions.

Obviously, our model (1.1) includes (1.4) and also the bouncing problem for the Hill's equation

$$x'' + a(t)x = 0 \tag{1.5}$$

with obstacle $q(t) = d > 0$. Note that $x(t)$ is a bouncing solution of the problem

$$\begin{cases} x'' + a(t)x = 0 \quad \text{for } x(t) > d; \\ x(t) \geq d; \\ x(t_0) = d \ \Rightarrow x'(t_0+) = -x'(t_0-) \end{cases} \tag{1.6}$$

if and only if $y(t)$ is a solution of (1.1) with $p(t) = -a(t)d$ by means of the change $y(t) = x(t) - d$.

The approach of this paper is different from that in [25, 6]. We apply a new generalized version of Poincaré–Birkhoff twist theorem to the so-called successor map, defined as follows. For a given $\tau \in \mathbb{R}$ and $v \in \mathbb{R}^+$, let us denote by $x(t; \tau, v)$ the unique solution of the bouncing problem (1.1) with initial conditions $x(\tau; \tau, v) = 0$, $x'(\tau; \tau, v) = v > 0$. We assume conditions such that this solution is well defined and vanishes at some time $\hat{\tau} > \tau$. Thus $\hat{\tau}$ is the time of the next impact. As the bouncing is elastic, the velocity after this impact is

$$\hat{v} = -x'(\hat{\tau}; \tau, v).$$

If $\hat{v}$ is finite and positive, then the map

$$\mathcal{S} : \mathbb{R} \times \mathbb{R}^+ \to \mathbb{R} \times \mathbb{R}^+,$$
$$\mathcal{S}(\tau, v) = (\hat{\tau}, \hat{v})$$

is well defined, continuous, and one to one. Following [1, 31, 32, 33], this function is called *successor map*, although in this context "impact map" would be also adequate.

Let us state some notation to be used in the rest of the paper: given a 2π-periodic function $p(t)$, $\bar{p} = \frac{1}{2\pi}\int_0^{2\pi} p(t)\mathrm{d}t$ is the mean value of p and $\|p\|_\infty = \max_{0\le t\le 2\pi} |p(t)|$. The projection for the component i of a given vector is denoted by Π_i. All along the paper, the iteration of the successor map is denoted by $\mathcal{S}^n(\tau, v) = (\hat{\tau}^n(\tau, v),\ \hat{v}^n(\tau, v))$ and we will use $\hat{\tau}^n = \hat{\tau}^n(\tau, v),\ \hat{v}^n = \hat{v}^n(\tau, v)$ for short. Therefore, $\Pi_1(\mathcal{S}^n(\tau, v)) = \hat{\tau}^n,\ \Pi_2(\mathcal{S}^n(\tau, v)) = \hat{v}^n$. Both notations are used without distinction.

Our main result is the following.

THEOREM 1.2. *Assume that the successor map $\mathcal{S}$ is well defined for all $(\tau, v) \in \mathbb{R} \times \mathbb{R}^+$ and $p(t) \le 0$ for all t, $\bar{p} < 0$. Then for any $m, n \in \mathbb{N}$ such that $n > 2m(\sqrt{\|a\|_\infty})$, there exists at least one $2m\pi$-periodic bouncing solution of* (1.1) *with exactly n impacts in each period. Moreover, for any $m \in \mathbb{N}$ such that $2m(\sqrt{\|a\|_\infty}) < 1$, there exist at least two $2m\pi$-periodic solutions with one bouncing in each period.*

The following corollaries present two concrete situations where the successor map is well defined and the previous result applies.

COROLLARY 1.3. *Assume that $p(t) \le 0$ for all t, $\bar{p} < 0$, and $\bar{a} > 0$. Then, the conclusion of Theorem* 1.2 *holds.*

COROLLARY 1.4. *Assume that $p(t) \le 0$ for all t, $\bar{p} < 0$, and $a(t) \equiv 0$. Then for any $m, n \in \mathbb{N},\ n \ge 2$, there exists at least one $2m\pi$-periodic bouncing solution of* (1.1) *with exactly n impacts in each period. Moreover, for any $m \in \mathbb{N}$, there exist at least two $2m\pi$-periodic solutions with one bouncing in each period.*

Remark 1.5. In our opinion, the application of the Poincaré–Birkhoff twist theorem to the successor map instead of the Poincaré map (as it is done in [6]) is more natural and direct. For the linear impact oscillator (1.4) we can obtain at least two $2m\pi$-periodic bouncing solutions for (1.4) with exactly 1 impact in each period if $2m\sqrt{\lambda} < 1$, whereas in [6] only one solution is found. Moreover, we can deal with a nonconstant coefficient $a(t)$, in contrast with [6].

In order to understand some of the new phenomena arising in vibro-impact systems, it is interesting to consider in detail the Hill's equation with impacts (1.6) as a particular case. Note that if the obstacle is placed at $d = 0$, then a classical solution x of Hill's equation generates a bouncing solution $|x|$ of (1.6). Hence, in this case (1.6) inherits the dynamics of Hill's equation without impacts and in consequence its resonant or nonresonant character. However, if the obstacle is $d > 0$, the situation is different. Physically, this model corresponds to a kind of offset impact oscillator [18], consisting of a linear spring-mass system with a displaced wall with respect to the origin (see Figure 1(a)). The time-dependence of the stiffness coefficient $a(t)$ of the spring can be produced by periodic changes of the temperature or other physical variables. A periodic bouncing solution corresponds to a nontrivial periodic motion with prescribed impacts in one period. The following result holds.

COROLLARY 1.6. *Assume that $d > 0$, $a(t) \ge 0$ for all t, and $\bar{a} > 0$. Then for any $m, n \in \mathbb{N}$ such that $n > 2m(\sqrt{\|a\|_\infty})$, there exists at least one $2m\pi$-periodic bouncing solution of* (1.6) *with exactly n impacts in each period.*

The proof follows from Corollary 1.3 by means of the change of variables $y = x - d$. Thus, the Hill's equation could be unstable (equivalently, all nontrivial solutions are

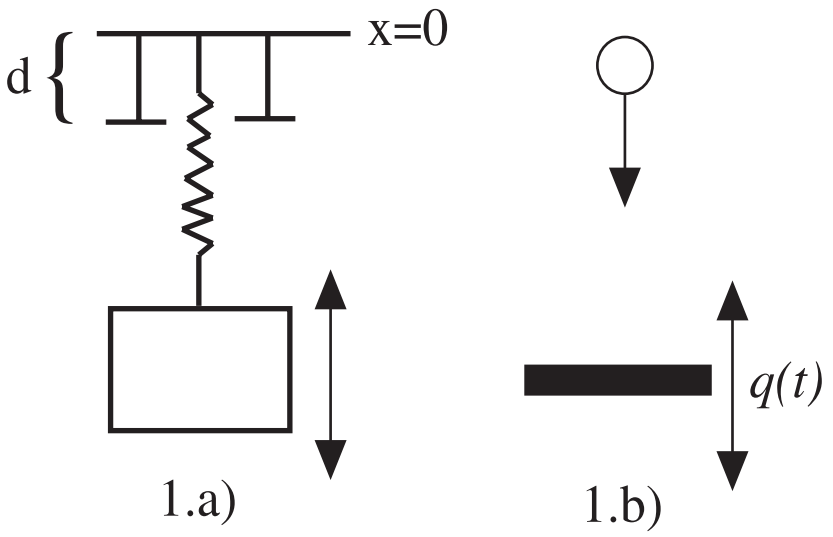

FIG. 1. (a) *The offset oscillator.* (b) *The "ping-pong" model.*

unbounded [26]) but nevertheless (1.6) has periodic bouncing solutions. In other words, possible parametric resonances are killed by the presence of an obstacle. This fact is a good example of the obstacle's influence in the dynamics of a given system.

Another simple but physically interesting model is the *"ping-pong" problem*, that is, a free ball moving in a vertical line subjected to gravity force and bouncing against a barrier or racket describing a periodic movement $q(t)$ (see Figure 1(b)). If G is the acceleration of gravity, the motion of the ball is described by

$$\begin{cases} x'' + G = 0 \quad \text{for } x(t) > q(t); \\ x(t) \geq q(t); \\ x(t_0) = q(t_0) \ \Rightarrow x'(t_0+) = -x'(t_0-) + 2q'(t_0). \end{cases}$$

This is a simple variation of Fermi's model that have deserved the attention of many researchers (see [19, 5, 13] and their references). After the change $y(t) = x(t) - q(t)$, the problem is transformed in (1.1) with $a(t) \equiv 0$ and $p(t) = -G - q''(t)$. Then, if $q''(t) > -G$ for any t, the ball experiences a diversity of periodic motions with a prescribed number of impacts as a consequence of Corollary 1.4.

Remark 1.7. The concept of bouncing solution could involve other new features and strong differences with the situation when working with differential equations without impacts. An interesting open problem is to prove or disprove the validity of Massera's theorem for impact oscillators. Massera's theorem asserts that in the framework of periodic differential equations the existence of a bounded solution implies the existence of a periodic solution [28]. This classical result is false in the context of equations with impacts in the sense that a bounded bouncing solution (using the definition in this paper) does not imply a periodic bouncing solution. To prove this, consider the Mathieu equation $a(t) = \gamma + \delta \cos t$ with obstacle $d = 0$ and parameters γ, δ placed in a stability region with irrational rotation number. Then any nontrivial solution of (1.5) is quasi-periodic (but not periodic) and in consequence every bouncing solution of (1.5) is bounded but there are no periodic bouncing solutions. Of course,

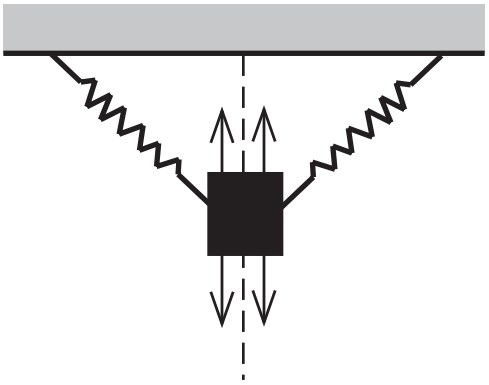

FIG. 2. *A spring-mass impact system.*

this is just an effect of the definition chosen here, since the trivial solution is excluded. Note that the trivial solution is not a bouncing solution but it is an admissible solution in the sense of [6]. So the exciting question of the validity of Massera's theorem for impact oscillators is still open: does the existence of a bounded bouncing solution imply the existence of a periodic admissible solution (including trivial solution)? We do not know the answer.

Our successor map approach is also suitable for use in nonlinear impact oscillators, as it is done in [34] for a singular equation. Here we include a result about the asymptotically linear impact oscillator.

THEOREM 1.8. *Let us assume that $g(t,x)$ is continuous, 2π-periodic with respect to t, and satisfies*

$$\limsup_{x\to 0^+}\left|\frac{g(t,x)}{x}\right| < +\infty, \qquad \lim_{x\to+\infty}\frac{g(t,x)}{x} = 0. \tag{1.7}$$

Besides, let us suppose that the successor map $\mathcal{S}$ of the bouncing problem

$$\begin{cases} x'' + a(t)x + g(t,x) = p(t) \quad \text{for } x(t) > 0; \\ x(t) \geq 0; \\ x(t_0) = 0 \ \Rightarrow x'(t_0+) = -x'(t_0-) \end{cases} \tag{1.8}$$

is well defined for all $(\tau, v) \in \mathbb{R}\times\mathbb{R}^+$ and $p(t) \leq 0$ for all t, $\bar{p} < 0$. Then, the conclusion of Theorem 1.2 *holds.*

A corollary of the previous result is the following.

COROLLARY 1.9. *Assume that $p(t) \leq 0$ for all t, $\bar{p} < 0$, $g(t,x)$ satisfies* (1.7) *and $a(t)x + g(t,x) \geq 0$ for any $x \geq 0$. Then, the conclusion of Theorem* 1.2 *holds.*

This result can be illustrated by a simple physical model presented in Figure 2. This mechanical system is a modification of the model presented in [2, 17] and consists of a single mass moving in a straight line, attached to the wall by two linear springs of constant k and natural length L and perturbed periodically by an external force $p(t)$. If it is assumed that the impacts between the mass and the wall are perfectly elastic, then the motion of the mass is governed by

$$\begin{cases} mx'' + 2k\left[x - \dfrac{Lx}{(c^2+x^2)^{1/2}}\right] = p(t) \quad \text{for } x(t) > 0; \\ x(t) \geq 0; \\ x(t_0) = 0 \ \Rightarrow x'(t_0+) = -x'(t_0-), \end{cases}$$

where $c > 0$ is the distance between the point of impact and the attachments of the springs (see [2, 17] for more details). If $p(t) \leq 0$ for all t, $\bar{p} < 0$, it is easy to verify that this problem is under the assumptions of Corollary 1.9 when $c > L$.

The rest of the paper is organized as follows. In section 2, the proof of Theorem 1.2 is given. It relies on a generalized version of Poincaré–Birkhoff theorem. Section 3 collects some auxiliary lemmas which are needed in the mentioned proof, more specifically the twist property of some iteration of the successor map is proved. Finally, section 4 is devoted to the study of the asymptotically linear impact oscillator.

2. Existence of periodic bouncing solutions. We will apply the Poincaré–Birkhoff twist theorem to the successor map $\mathcal{S}$ for proving the existence of 2π-periodic bouncing solutions for impact oscillators (1.1). The successor map was used recently by Ortega [33] for investigation of the boundedness of all the solutions for a linear impact oscillator by using Moser's twist theorem and the authors [34] for investigation of the periodic bouncing solutions for some singular impact oscillator. As a general idea, this successor map is just a different section of the flux and it goes back at least to Alekseev [1] and Moser [30].

The following generalized version of Poincaré–Birkhoff twist theorem is based on the theorems of Franks [16] and Ding [11] and is slightly different from the version used by others (see, for example, [20], [6], and [27]).

Let A and B be two annuli

$$A := \mathbf{S}^1 \times [a_1, a_2], \qquad B := \mathbf{S}^1 \times [b_1, b_2]$$

with $0 < b_1 < a_1 < a_2 < b_2 < +\infty$. A map $f : A \to B$ possesses a lift $\tilde{f} : \mathbb{R}\times[a_1, a_2] \to \mathbb{R} \times [b_1, b_2]$ with the form

$$\theta' = \theta + h(\theta, \rho), \quad \rho' = g(\theta, \rho),$$

where $h,\ g$ are continuous and 2π-periodic in θ. We say that $\tilde{f}$ satisfies the boundary twist condition if

$$h(\theta, a_1) \cdot h(\theta, a_2) < 0 \quad \text{for } \theta \in [0,\ 2\pi].$$

THEOREM 2.1. *Assume that $f : A \to B$ is an area-preserving homeomorphism homotopic to the inclusion such that $f(A) \cap \partial B = \emptyset$. Moreover, f possesses a lift $\tilde{f}$ satisfying the boundary twist condition and the area of the two connected components of the complement of $f(A)$ in B is the same as the area of the corresponding connected components of the complement of A in B. Then, f has at least two geometrically distinct fixed points (θ_i, ρ_i), $(i = 1, 2)$ satisfying $h(\theta_i, \rho_i) = 0$ for $i = 1, 2$.*

Proof. The proof basically combines the proofs from Franks [16] and Ding [11]. In [16], Franks showed that by using a result from Oxtoby and Ulam, one can extend f to an area-preserving homeomorphism $F : B \to B$ such that F is the identity on the boundary of B (see the proof and the remark of Theorem 4.2 in [16]). Then, we can assume further that F is an area-preserving homeomorphism of $D := \{(\theta, \rho) : \rho \leq b_2\}$ to its image such that $O \in F(D\backslash B)$. Now we meet all the assumptions of the argument in [11]. According to the argument of [11], we can prove that F, and then f, has at least two fixed points in A. Moreover, the fixed points (θ_i, ρ_i) satisfy $h(\theta_i, \rho_i) = 0$ for $i = 1, 2$ (see [11] and [12] for more details). Figure 3 illustrates the geometrical meaning of the hypotheses. □

Now, we apply the above Poincaré–Birkhoff theorem to the successor map $\mathcal{S}$. From the discussion in the next section we know that our successor map $\mathcal{S}$

$$\mathcal{S} : (\tau,\ v) \mapsto (\hat{\tau},\ \hat{v})$$

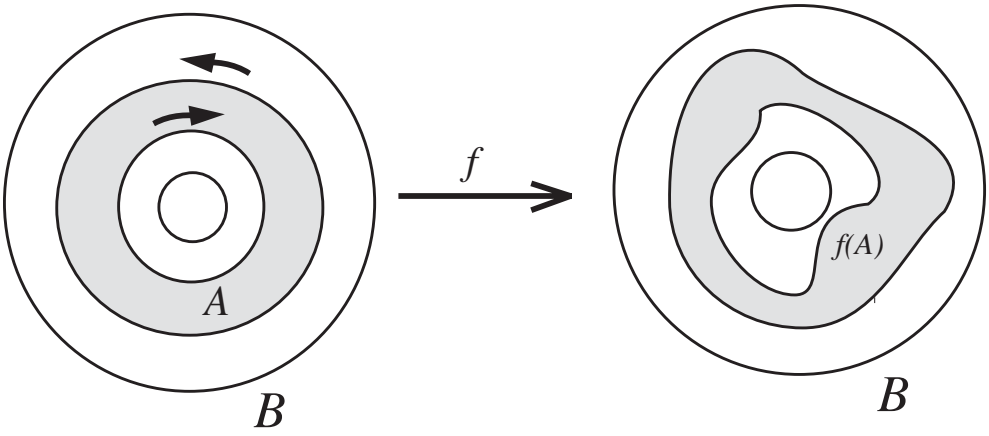

FIG. 3. *The Poincaré–Birkhoff theorem.*

is well defined, one to one, and continuous in its domain $\mathbb{R}\times\mathbb{R}^+$. Moreover, it satisfies

$$\mathcal{S}(\tau+2\pi,v)=\mathcal{S}(\tau,v)+(2\pi,0).$$

Thus, we can interpret τ and v as polar coordinates and $\mathcal{S}$ is an embedding homeomorphism on $\mathbf{S}^1\times\mathbb{R}^+$. It is easy to show that for any $n,m\in\mathbb{N}$, a fixed point of the map $\mathcal{S}^n(\tau,v)-(2m\pi,0)$ corresponds a $2m\pi$-periodic bouncing solution of the equation with n impacts in each period. We have the following lemma.

LEMMA 2.2. *$\mathcal{S}$ is an area-preserving map with the area element $vdvd\tau$. Moreover, $\mathcal{S}$ is area-preserving homotopic to the inclusion, and for any annuli $A\subset B\subset\mathbf{S}^1\times\mathbb{R}^+$ with $\mathcal{S}(A)\subset\overset{\circ}{B}$, the area of the two connected components of the complement of $\mathcal{S}(A)$ in B is the same as the area of the corresponding components of the complement of A in B.*

The proof of this lemma is similar to the proof of Lemma 1 in [20] and the proof of Proposition 2.3 in [31]. At first we can prove, under the assumption of the C^1-smoothness of a and p which implies the C^1-smoothness of $\mathcal{S}$, that $\mathcal{S}$ is an exact symplectic map in its domain; that is, for any C^1-closed path γ in its domain

$$\int_\gamma \frac{v^2}{2}d\tau=\int_{S\circ\gamma}\frac{v^2}{2}d\tau. \tag{2.1}$$

Moreover, note that $\mathcal{S}$ is an embedding homeomorphism on $\mathbf{S}^1\times\mathbb{R}^+$, then from Jordan separation theorem (see, for instance, [29]), we know that for any annuli $A\subset B\subset\mathbf{S}^1\times\mathbb{R}^+$ with $\mathcal{S}(A)\subset\overset{\circ}{B}$, there are two connected components of the complement of $\mathcal{S}(A)$ in B. Such components are the images of the two components of the complement of A in B. Hence, the geometric meaning of (2.1) is that the area of the components of the complement of $\mathcal{S}(A)$ in B are the same as the area of the corresponding components of the complement of A in B. The conclusion for the case of continuous functions a and p follows from an approximation argument.

Moreover, Lemmas 3.4 and 3.6 (see section 3) imply that, under the assumptions of Theorem 1.2, we can choose $v_-^{(n)}<v_+^{(n)}$ such that

$$\Pi_1(\mathcal{S}^n(\tau,v_-^{(n)}))-\tau<2m\pi,$$
$$\Pi_1(\mathcal{S}^n(\tau,v_+^{(n)}))-\tau>2m\pi\quad\text{for }\tau\in[0,2\pi].$$

Hence, let A be the annulus bounded by $\mathbf{S}^1 \times \{v_-^{(n)}\}$ and $\mathbf{S}^1 \times \{v_+^{(n)}\}$ and let B be the annulus bounded by $\mathbf{S}^1 \times \{v_*\}$ and $\mathbf{S}^1 \times \{v^*\}$. We can prove, as showed in section 3, that $f(A) \subset \overset{\circ}{B}$ for $v_* > 0$ sufficiently small and v^* sufficiently large, where $f : A \to B$ is defined by

$$f(\tau, v) = \mathcal{S}^n(\tau, v) - (2m\pi, 0).$$

It is easy to see that f is an area-preserving homeomorphism homotopic to the inclusion and $\tilde{f}$ satisfies the boundary twist condition. Thus the conclusion of Theorem 1.2 follows by a direct application of Theorem 2.1. Note that in any case we get two fixed points of $\mathcal{S}^n(\tau, v) - (2m\pi, 0)$. However, if the number of bouncings n is greater than or equal to 2, these two fixed points provided by Theorem 2.1 may correspond to the same bouncing solution, so we can only assure the existence of two different $2m\pi$-periodic bouncing solutions when there is only one impact in each period.

3. Twist property for the successor map. The aim of this section is to provide the necessary properties for the application of the Poincaré–Birkhoff theorem yet done in section 2. Basically, our goal is to prove that the rotation for some iteration of the successor map is *slow* for small velocities and *fast* for large velocities. This will be done through some auxiliary lemmas concerning the asymptotic dynamics of the solutions for (1.1). Lemma 3.1 gives a second-order differential inequality to be used later. Lemma 3.2 shows that $\mathcal{S}$ is well defined for $v \ll 1$, Lemma 3.3 shows that the impact velocity $\hat{v}$ is small if the initial velocity v is small enough and in consequence, Lemma 3.4 gives the slow rotation for some iteration of $\mathcal{S}$ for small initial velocities. Lemma 3.5 discusses, under the assumption that the successor map is well defined, the fast rotation of $\mathcal{S}$ for large velocities by using the Sturm comparison theorem. This fact implies (Lemma 3.6) the fast rotation for some iteration of $\mathcal{S}$ for large initial velocities. At the end of this section, we discuss, in Lemmas 3.7 and 3.8, when the successor map $\mathcal{S}$ is well defined by using some oscillatory properties of the solutions of the Hill's equation.

LEMMA 3.1. *Suppose that $x_1(t)$ is a solution of the equation $x'' = Mx$ for $t \in I$, where $M > 0$, and $x_2(t)$ satisfies the differential inequality $x'' \le Mx$ for $t \in I$, with the same initial conditions $x_1(\tau) = x_2(\tau)$, $x_1'(\tau) = x_2'(\tau)$. Then $x_1(t) \ge x_2(t)$ for $t \in I$.*

Proof. Let $z_n(t) = x_n(t) - x_2(t)$, where $x_n(t)$ is the solution of $x'' = Mx$ with the initial condition $x_n(\tau) = x_2(\tau)$, $x_n'(\tau) = x_2'(\tau) + \frac{1}{n}$. Then $z_n(\tau) = 0$, $z_n'(\tau) = \frac{1}{n} > 0$ which implies that $z_n(t) > 0$ for $t > \tau$ and t close to τ. Moreover, $z_n''(t) \ge M z_n(t)$ for $t > \tau$. Thus $z_n'(t) > z_n'(\tau) > 0$ and $z_n(t)$ increases strictly for $t > \tau$. Hence $x_n(t) > x_2(t)$ for $t > \tau$. Let $n \to \infty$. Then $x_n(t) \to x_1(t)$ in any compact interval by using the continuous dependence on initial values. Therefore, $x_1(t) \ge x_2(t)$ for $t \in I$. □

LEMMA 3.2. *If $p(t) \le 0$ and $\overline{p} = \frac{1}{2\pi}\int_0^{2\pi} p(t)dt < 0$, then every solution $x(t; \tau, v)$ of (1.1) starting from $x(\tau; \tau, v) = 0$, $x'(\tau; \tau, v) = v > 0$ does not satisfy $x(t; \tau, v) = x'(t; \tau, v) = 0$ for any t in its domain. Moreover, $\mathcal{S}$ is well defined and one to one for $v \ll 1$.*

Proof. Note that every solution of (1.1) starting from $x(\tau; \tau, v) = 0$, $x'(\tau; \tau, v) = v > 0$ satisfies

$$x' = y, \quad y' = -a(t)x + p(t)$$

in (x, y)-plane before it meets $x = 0$ again. Then $x'(t; \tau, v) > 0$ when it is in the half-plane $y > 0$ which implies that $x(t; \tau, v) > 0$ for $t > \tau$ and close to τ. Moreover,

if there are $\tau_1,\ \tau_2$ such that

$$x'(\tau_1;\tau,v)=x'(\tau_2;\tau,v)=0,\qquad x'(s;\tau,v)>0\quad \text{for } s\in(\tau_1,\tau_2),$$

then

$$x(\tau_2;\tau,v)>x(\tau_1;\tau,v). \tag{3.1}$$

If $x'(\tau_3;\tau,v)=0$ and $x'(s;\tau,v)<0$ for $s\in(\tau_3,t)$, then by using polar coordinates

$$x=r\cos\theta,\qquad y=r\sin\theta$$

in the half-plane $y\le 0$ we get

$$r'=(1-a(t))r\cos\theta\sin\theta+p(t)\sin\theta\ge -Kr,$$

where $K=\max_{0\le t\le 2\pi}|1-a(t)|$. Thus

$$r(t)\ge r(\tau_3)\exp(-K(t-\tau_3)). \tag{3.2}$$

Therefore, either $x(t;\tau,v)$ has no any impact in $t>\tau$ or $x(t;\tau,v)$ has its next impact at $t=\hat\tau$. In this case, (3.1), (3.2) imply that

$$x'(\hat\tau;\tau,v)\le -x(\tilde\tau;\tau,v)\exp(-K(\hat\tau-\tau))<0,$$

where $t=\tilde\tau$ is the first time $x(t;\tau,v)$ meets $y=0$ after τ. The conclusion of the first part of the lemma is thus proved.

Next, note that when $x(t;\tau,v)$ is remaining in half-plane $x>0$,

$$x''(t;\tau,v)=-a(t)x(t;\tau,v)+p(t)\le Mx(t;\tau,v),$$

where $M=\max_{0\le t\le 2\pi}|a(t)|$. Then Lemma 3.1 implies that

$$x(t;\tau,v)\le M_0=\frac{v}{2\sqrt{M}}(\exp(2\pi\sqrt{M})-\exp(-2\pi\sqrt{M})) \tag{3.3}$$

for $t\in(\tau,\tau+2\pi)$. Thus,

$$x'(t;\tau,v)=v-\int_\tau^t(a(s)x(s;\tau,v)-p(s))ds\le O(v)+\int_\tau^t p(s)ds.$$

Because $\bar p<0$, there must be $\tilde\tau\in(\tau,\tau+2\pi)$ such that

$$x(\tilde\tau;\tau,v)>0,\qquad x'(\tilde\tau;\tau,v)=0,\qquad x'(s;\tau,v)>0\quad \text{for } s\in(\tau,\tilde\tau),$$

provided that $v\ll 1$. Moreover, for $t\in(\tilde\tau,\tau+2\pi)$, we have

$$x(t;\tau,v)=x(\tilde\tau;\tau,v)-\int_{\tilde\tau}^t\int_{\tilde\tau}^w(a(s)x(s;\tau,v)-p(s))dsdw=O(v)+\int_{\tilde\tau}^t\int_{\tilde\tau}^w p(s)dsdw$$

from which it follows that there exists $\hat\tau\in(\tilde\tau,\tau+2\pi)$ such that

$$x(\hat\tau;\tau,v)=0,\qquad x'(\hat\tau;\tau,v)<0,\qquad x(t;\tau,v)>0\quad \text{for } t\in[\tilde\tau,\hat\tau),$$

provided that $v\ll 1$ and $\bar p<0$. The lemma is thus proved. □

The next lemma clarifies the behavior of the next impact velocity $\hat{v}$ for small v.

LEMMA 3.3. *If $p(t) \le 0$ and $\overline{p} < 0$, then the next velocity $\hat{v}$ of the successor map satisfies*

$$\lim_{v \to 0^+} \hat{v}(\tau, v) = 0$$

uniformly for $\tau \in [0, 2\pi)$.

Proof. As it is shown in Lemma 3.2, for $v > 0$ small enough, we have a well-defined $\hat{\tau} \in (\tau, \tau + 4\pi)$. Moreover,

$$\max_{\tau \le t \le \hat{\tau}} x(t; \tau, v) = O(v) \quad \text{as } v \to 0^+. \tag{3.4}$$

By contradiction, let us assume that there exist $\{\tau_n\}$ belonging to $[0, 2\pi)$ and $\{v_n\}$ with $v_n \to 0^+$ as $n \to \infty$, such that $\hat{v}(\tau_n, v_n) \le -\delta < 0$. Then there exist $t_n \in (\tau_n, \hat{\tau}(\tau_n, v_n))$ satisfying

$$x'(t_n; \tau_n, v_n) = -\frac{\delta}{2}, \qquad x'(s; \tau_n, v_n) \le -\frac{\delta}{2} \quad \text{for } s \in [t_n, \hat{\tau}(\tau_n, v)].$$

Denote by $P = \|p\|_\infty$, then

$$\begin{aligned} -\frac{\delta}{2} &\ge \hat{v}(\tau_n, v_n) - x'(t_n; \tau_n, v_n) = -\int_{t_n}^{\hat{\tau}(\tau_n, v_n)} (a(s)x(s; \tau_n, v_n) - p(s))ds \\ &\ge -(M + P)(\hat{\tau}(\tau_n, v_n) - t_n), \end{aligned}$$

provided that $\max_{t_n \le t \le \hat{\tau}(\tau_n, v_n)} x(t; \tau_n, v_n) \le 1$ (this is guaranteed for v_n small by (3.4)). Thus we can estimate

$$\begin{aligned} \max_{\tau_n \le t \le \hat{\tau}_n} x(t; \tau_n, v_n) &\ge x(t_n; \tau_n, v_n) - x(\hat{\tau}(\tau_n, v_n); \tau_n, v_n) \\ &= -\int_{t_n}^{\hat{\tau}(\tau_n, v_n)} x'(s; \tau_n, v_n) \mathrm{d}s \ge \frac{\delta}{2} \cdot (\hat{\tau}(\tau_n, v_n) - t_n) \ge \frac{\delta^2}{4(M + P)}, \end{aligned}$$

which contradicts (3.4). The result is thus proved. ∎

Let us recall that we write $\mathcal{S}^n(\tau, v) = (\hat{\tau}^n(\tau, v),\ \hat{v}^n(\tau, v))$ and we will use the abbreviation $\hat{\tau}^n = \hat{\tau}^n(\tau, v)$, $\hat{v}^n = \hat{v}^n(\tau, v)$. Then, it is deduced from Lemma 3.3 that for all $n \in \mathbb{N}$ and $v_n > 0$, there exists $v_0 > 0$, such that

$$|x'(t; \tau, v)| \le v_n \quad \text{for } v \in (0, v_0],\ t \in [\tau, \hat{\tau}^n].$$

Now, suppose that there are $c > 0$ and $\delta > 0$ such that $p(t) \le -c$ for $t \in [\tau_0 - 2\delta, \tau_0 + 2\delta]$. Then,

$$\hat{\tau}^n - \tau < \delta \quad \text{for } v \ll 1 \text{ and } \tau \in [\tau_0 - \delta, \tau_0 + \delta]. \tag{3.5}$$

Actually,

$$|\hat{v}^j + \hat{v}^{j-1}| = |x'(\hat{\tau}^j; \tau, v) - x'(\hat{\tau}^{j-1}; \tau, v)| = \int_{\hat{\tau}^{j-1}}^{\hat{\tau}^j} (a(t)x(t; \tau, v) - p(t))dt \ge \frac{c}{2}(\hat{\tau}^j - \hat{\tau}^{j-1}),$$

provided that (3.4) and $[\hat{\tau}^{j-1}, \hat{\tau}^j] \subset [\tau_0 - 2\delta, \tau_0 + 2\delta]$. Then

$$\hat{\tau}^n - \tau \le \frac{4}{c} \sum_{j=1}^{n} \hat{v}^j < \delta \tag{3.6}$$

if we choose $v \ll 1$ and $\tau \in [\tau_0 - \delta, \tau_0 + \delta]$.

Now, we can prove the twist property of the successor map for $v \ll 1$.

LEMMA 3.4. *Let us suppose that $p(t) \leq 0$ and $\bar{p} < 0$. Then, for all $n, m \in \mathbb{N}$, there exists $v_n > 0$ such that*

$$\Pi_1(\mathcal{S}^n(\tau, v)) - \tau < 2m\pi \quad \text{for } v \in (0, v_n] \text{ and } \tau \in [0, 2\pi].$$

Proof. Since $p(\cdot)$ is continuous and $\bar{p} < 0$, there are $c > 0$, $\delta > 0$, and $\tau_0 \in [0, 2\pi]$ such that $p(t) \leq -c$ for $t \in [\tau_0 - 2\delta, \tau_0 + 2\delta]$. Then, there exists $v \ll 1$ such that

$$\hat{\tau}^n(\tau, v) - \tau < \delta \quad \text{for } \tau \in [\tau_0 - \delta, \tau_0 + \delta]. \tag{3.7}$$

For $\tau \in (\tau_0 + \delta, 2\pi + \tau_0 - \delta)$ either $\hat{\tau}^n(\tau, v) \leq 2\pi + \tau_0 - \delta$ which implies that

$$\hat{\tau}^n - \tau < 2\pi - 2\delta, \tag{3.8}$$

or there exists $t \in (\hat{\tau}^{j-1}, \hat{\tau}^j) \cap [2\pi + \tau_0 - \delta, 2\pi + \tau_0]$ for some $j \in \{1, 2, \ldots, n\}$. Then, by estimating like in (3.6) it is proved that, if v small enough, $\hat{\tau}^j - t \leq \frac{\delta}{n}$. From here it is deduced that

$$\hat{\tau}^j \in \left(2\pi + \tau_0 - \delta, 2\pi + \tau_0 + \frac{\delta}{n}\right] \tag{3.9}$$

and then $\hat{\tau}^n - \hat{\tau}^j < \frac{n-1}{n}\delta$ which implies that

$$\hat{\tau}^n - \tau = \hat{\tau}^n - \hat{\tau}^j + \hat{\tau}^j - t + t - \tau < \frac{n-1}{n}\delta + \frac{\delta}{n} + 2\pi + \tau_0 - (\tau_0 + \delta) = 2\pi. \tag{3.10}$$

Since $\mathcal{S}$ is continuous on $\mathbb{R} \times \mathbb{R}^+$ (this is a consequence of the uniqueness of the solution for the initial value problem for linear equation), the above estimations are uniform for the compact interval $[0, 2\pi]$. Therefore, (3.7)–(3.10) complete the proof of the lemma. ∎

Under the assumption that the successor map $\mathcal{S}$ is well defined, our next result proves the twist property for large velocities.

LEMMA 3.5. *Assume that $\mathcal{S} : (\tau, v) \mapsto (\hat{\tau}, \hat{v})$ for $(\tau, v) \in \mathbb{R} \times \mathbb{R}^+$ is well defined and $p(t) \leq 0$, $\bar{p} < 0$. Then*

$$\liminf_{v \to +\infty} [\hat{\tau}(\tau, v) - \tau] \geq \frac{\pi}{\sqrt{\|a\|_\infty}} \tag{3.11}$$

uniformly for $\tau \in [0, 2\pi)$. If $a(t) \equiv 0$, then

$$\lim_{v \to +\infty} [\hat{\tau}(\tau, v) - \tau] = +\infty \tag{3.12}$$

uniformly for $\tau \in [0, 2\pi)$.

Proof. Suppose firstly that $\|a\|_\infty > 0$ and there are $\tau_n \in [0, 2\pi)$ and $v_n > 0$ with $v_n \to +\infty$ as $n \to \infty$ such that $\hat{\tau}(\tau_n, v_n) - \tau_n \leq \pi/\sqrt{\|a\|_\infty} - \gamma$ with $\gamma > 0$. Then there are $\tau_* \in [0, 2\pi]$ and $\hat{\tau}_* \in (\tau_*, \tau_* + \pi/\sqrt{\|a\|_\infty} - \gamma]$ such that $\tau_n \to \tau_*$ and $\hat{\tau}(\tau_n, v_n) \to \hat{\tau}_*$ as $n \to \infty$. Moreover, $y_n(t) = x(t; \tau_n, v_n)/v_n$ is the solution of the equation

$$x'' + a(t)x = \frac{1}{v_n}p(t)$$

with the initial conditions $y_n(\tau_n) = 0,\ y_n'(\tau_n) = 1$. By continuous dependence of the solutions with respect to initial value and parameters we have that

$$\lim_{n\to\infty} y_n(t) = y_0(t) \quad \text{and} \quad \lim_{n\to\infty} y_n'(t) = y_0'(t) \tag{3.13}$$

uniformly on compact intervals, where $y_0(t)$ is the solution of Hill's equation (1.5) with the initial condition $y_0(\tau_*) = 0,\ y_0'(\tau_*) = 1$. Thus $y_0(\hat{\tau}_*) = 0$ due to the continuous dependence of the solutions with respect to initial values and parameters. On the other hand, by using Sturm comparison theorem, it is proved that

$$\tau' - \tau \geq \frac{\pi}{\sqrt{\|a\|_\infty}},$$

where τ' and τ are two consecutive zeros of $y_0(t)$, so in consequence $\hat{\tau}_* - \tau_* \geq \pi/\sqrt{\|a\|_\infty}$. This is a contradiction. If $a(t) \equiv 0$, then any solution $x(t;\tau,v)$ of the equation $x'' = p(t)$ has the derivative $x'(t;\tau,v) = v + \int_\tau^t p(s)\mathrm{d}s$. Hence, for any fixed $v > 0$ there exists a $\hat{\tau} > \tau$ such that $x(\hat{\tau};\tau,v) = \int_\tau^{\hat{\tau}}(v + \int_\tau^t p(s)\mathrm{d}s)\mathrm{d}t = 0$ and $\lim_{v\to+\infty}(\hat{\tau} - \tau) = +\infty$. Therefore, the lemma is proved. □

From the above estimation we can prove the twist property of successor map for $v \gg 1$. Recall that $r(t) = (x^2(t;\tau,v) + (x'(t;\tau,v))^2)^{1/2}$ satisfies

$$-Kr(t) - P \leq r'(t) \leq Kr(t) + P \quad \text{for } t \in (\tau, \hat{\tau}),$$

where $K = \max_{0\leq t\leq 2\pi} |1 - a(t)|$ and $P = \max_{0\leq t\leq 2\pi} |p(t)|$. Then, by using Gronwall inequality,

$$\left(v + \frac{P}{K}\right)\exp(-KT) \leq \hat{v} + \frac{P}{K} \leq \left(v + \frac{P}{K}\right)\exp(KT), \tag{3.14}$$

provided that $\hat{\tau} - \tau \leq T$. Suppose that $\Pi_1(\mathcal{S}^n(\tau,v)) - \tau \leq 2m\pi$, then

$$\Pi_1(\mathcal{S}^{i+1}(\tau,v)) - \Pi_1(\mathcal{S}^i(\tau,v)) \leq 2m\pi \quad \text{for } i = 0, 1, \ldots, n-1.$$

This implies that

$$\begin{aligned}\left(\Pi_2(\mathcal{S}^i(\tau,v)) + \frac{P}{K}\right)\exp(-2m\pi K) &\leq \Pi_2(\mathcal{S}^{i+1}(\tau,v)) + \frac{P}{K} \\ &\leq \left(\Pi_2(\mathcal{S}^i(\tau,v)) + \frac{P}{K}\right)\exp(2m\pi K)\end{aligned}$$

for $i = 0, 1, \ldots, n-1$. Thus for a given $v_0^+ > 0$ we have $v_{n,m}^+ > 0$ such that

$$\text{if } v > v_{n,m}^+ \text{ and } \Pi_1(\mathcal{S}^n(\tau,v)) - \tau \leq 2m\pi, \text{ then } \Pi_2(\mathcal{S}^i(\tau,v)) > v_0^+ \tag{3.15}$$

for $i = 0, 1, \ldots, n-1$. Hence, the following result is obtained.

LEMMA 3.6. *Let us suppose that $p(t) \leq 0$ and $\bar{p} < 0$. Let $n, m \in \mathbb{N}$ be such that $n > 2m(\sqrt{\|a\|_\infty})$. Then, there exists $v_{n,m}^+ > 0$ such that*

$$\Pi_1(\mathcal{S}^n(\tau,v)) - \tau > 2m\pi \quad \textit{for } v \geq v_{n,m}^+ \textit{ and } \tau \in [0, 2\pi].$$

Proof. From Lemma 3.5 we know that there exists $v_0^+ > 0$ such that

$$\Pi_1(\mathcal{S}(\tau,v)) - \tau \geq \frac{\pi}{\sqrt{\|a\|_\infty}} \quad \text{for } v \geq v_0^+ \text{ and } \tau \in [0, 2\pi). \tag{3.16}$$

By the periodicity of the equation, it is verified that

$$\mathcal{S}(\tau + 2\pi, v) = \mathcal{S}(\tau, v) + (2\pi, 0).$$

This means that the function $f(\tau) = \Pi_1(\mathcal{S}(\tau, v)) - \tau$ is 2π-periodic. Therefore, (3.16) holds for all $\tau \in \mathbb{R}$. Taking $v^+_{n,m}$ as in (3.15), if $v > v^+_{n,m}$ then either $\Pi_1(\mathcal{S}^n(\tau, v)) - \tau > 2m\pi$ or $\Pi_1(\mathcal{S}^n(\tau, v)) - \tau \leq 2m\pi$. In the second case, it follows from (3.15) that $\Pi_2(\mathcal{S}^i(\tau, v)) > v_0^+$ for $i = 0, 1, \ldots, n-1$, and in consequence for every $i = 1, \ldots, n-1$ we have

$$\Pi_1(\mathcal{S}^{i+1}(\tau, v)) - \Pi_1(\mathcal{S}^i(\tau, v)) \geq \frac{\pi}{\sqrt{\|a\|_\infty}} \quad \text{for } v \geq v^+_{n,m} \text{ and } \tau \in [0, 2\pi).$$

Adding the previous inequalities for $i = 1, \ldots, n-1$ with (3.16),

$$\Pi_1(\mathcal{S}^n(\tau, v)) - \tau \geq n\frac{\pi}{\sqrt{\|a\|_\infty}}.$$

Now, taking into account that $n > 2m(\sqrt{\|a\|_\infty})$, the result is done. □

The rest of this section is devoted to the discussion of the conditions implying that the successor map is well defined. At first we can prove as in the proof of Lemma 3.2 that successor map is well defined if $p(t) \leq 0$ for all t, $\bar{p} < 0$ and $a(t) \equiv 0$. We will prove in the following that $\bar{a} > 0$ is also enough to assure that the successor map is well defined. With this, the proofs of Corollaries 1.3 and 1.4 are completed.

Consider the solution $x(t; \tau, v)$ of the impact oscillator (1.1) starting from

$$x(\tau; \tau, v) = 0, x'(\tau; \tau, v) = v > 0.$$

Lemma 3.2 implies that either there exists $\hat{\tau} > \tau$ such that $x(\hat{\tau}; \tau, v) = 0$ and $x(t; \tau, v) > 0$ for $t \in (\tau, \hat{\tau})$, or

$$x(t; \tau, v) > 0 \quad \text{for all } t > \tau, \tag{3.17}$$

and in consequence $x(t; \tau, v)$ is a (classical) solution of the equation $x'' + a(t)x = p(t)$, with $t > \tau$. If (3.17) holds, we will show that there is a constant $\delta > 0$ such that $x(t; \tau, v) \geq \delta$ for sufficiently large $t > \tau$. Actually, we will show firstly that (3.17) implies that

$$|x(t; \tau, v)| + |x'(t; \tau, v)| \geq 2\delta. \tag{3.18}$$

By contradiction, let us suppose that there exists $\tau_1 > \tau$ such that $x(\tau_1; \tau, v) = \alpha \geq 0$, $x'(\tau_1; \tau, v) = \beta$ with $|\alpha| + |\beta| < 2\delta$. Then as in Lemma 3.2 it is shown that

$$x(t; \tau, v) \leq \frac{1}{2\sqrt{M}}((\sqrt{M}\alpha + \beta)\exp(2\pi\sqrt{M}) + (\sqrt{M}\alpha - \beta)\exp(-2\pi\sqrt{M}))$$

for $t \in (\tau_1, \tau_1 + 2\pi)$, being $M = \|a\|_\infty$. Thus,

$$\begin{aligned} x(t; \tau, v) &= \alpha + \int_{\tau_1}^t \left(\beta + \int_{\tau_1}^s (-a(\xi)x(\xi; \tau_1, v) + p(\xi)\mathrm{d}\xi)\mathrm{d}s\right) \\ &= O(|\alpha| + |\beta|) + \int_{\tau_1}^t \int_{\tau_1}^s (p(\xi))\mathrm{d}\xi\mathrm{d}s. \end{aligned}$$

This implies that, using $\bar{p} < 0$, if δ is small enough, then there must be some $\hat{\tau} \in (\tau_1, \tau_1 + 2\pi)$ such that $x(\hat{\tau}; \tau, v) = 0$. This contradicts (3.17).

Note that (3.18) implies that $v \geq 2\delta$. Moreover, there exists $t_1 > \tau$ such that $x(t_1; \tau, v) \geq \delta$. We claim that

$$x(t; \tau, v) \geq \delta \quad \text{for } t \geq t_1. \tag{3.19}$$

If (3.19) is not true, let $t_2 = \inf\{t : t \geq t_1,\ x(t; \tau, v) < \delta\}$. Then $x'(t_2; \tau, v) \leq 0$. If $x'(t; \tau, v) \leq 0$ for $t \geq t_2$, then $x(t; \tau, v) \leq x(t_2; \tau, v) \leq \delta$ for $t \geq t_2$, and (3.18) implies that $x'(t; \tau, v) < -\delta$ for $t \geq t_2$. Thus

$$x(t; \tau, v) = x(t_2; \tau, v) + \int_{t_2}^{t} x'(s; \tau, v)\mathrm{d}s \leq -\delta(t - t_2) + \delta < 0$$

for $t > t_2 + 1$ which contradicts (3.17). Hence, we can define $t_3 = \inf\{t : t \geq t_2,\ x'(t; \tau, v) > 0\}$. Clearly, $x'(t_3; \tau, v) = 0$ and

$$x(t_3; \tau, v) = x(t_2; \tau, v) + \int_{t_2}^{t_3} x'(s; \tau, v)\mathrm{d}s \leq x(t_2; \tau, v) \leq \delta$$

which contradicts (3.18). Therefore, we have proved the following result.

LEMMA 3.7. *There exists $\delta > 0$ independent of (τ, v) such that if $\mathcal{S}$ is not defined for some $(\tau, v) \in \mathbb{R} \times \mathbb{R}^+$, then $x(t; \tau, v) \geq \delta$ for $t \gg 1$.*

Now we assume that Hill's equation is oscillatory, that is, all nonzero solution of Hill's equation have infinitely many zeros. It is a known fact (see [26]) that these zeros correspond to a sequence tending to $+\infty$.

LEMMA 3.8. *Let us assume that Hill's equation* (1.5) *is oscillatory. Then there exist $\beta_0 > 0$ and $\varepsilon_0 > 0$ such that any solution $x(t; \tau, v)$ of* (1.1) *such that $x(\tau_1; \tau, v) = \alpha,\ x'(\tau_1; \tau, v) = \beta$ with $\beta \geq \beta_0$ and $0 \leq \alpha \leq \varepsilon_0\beta$ will have a next zero $\hat{\tau} > \tau_1$.*

Proof. Let $y_\beta(t) := \frac{1}{\beta}x(t; \tau, v)$. Then, $y_\beta(t)$ is a solution of the equation

$$x'' + a(t)x = \frac{1}{\beta}p(t)$$

for $t > \tau_1$ and $y_\beta(s) > 0$ for $s \in (\tau_1, t)$ with initial conditions

$$y_\beta(\tau_1) = \frac{\alpha}{\beta}, \qquad y'_\beta(\tau_1) = 1.$$

If $y_0(t)$ is the solution of the Hill's equation $x'' + a(t)x = 0$ with initial conditions $y_0(\tau_1) = 0,\ y'_0(\tau_1) = 1$, by continuous dependence of the solutions with respect to initial value and parameters we have that

$$\lim_{\beta \to +\infty} y_\beta(t) = y_0(t) \quad \text{and} \quad \lim_{\beta \to +\infty} y'_\beta(t) = y'_0(t) \tag{3.20}$$

uniformly on compact interval. Let $\hat{\tau}_0(\tau_1)$ be the next zero of $y_0(t)$ after τ_1 (that is, $y_0(\hat{\tau}_0) = 0$ and $y_0(t) > 0$ for all $\tau_1 < t < \hat{\tau}_0$). Then, $\hat{\tau}_0(\tau_1)$ is a simple zero with $y'_0(\hat{\tau}_0) < 0$ independent of β. Thus (3.20) implies that for β large enough and $\frac{\alpha}{\beta}$ small enough there exists $\hat{\tau}(\tau_1)$ such that $y_\beta(\hat{\tau}) = 0$. The lemma is thus proved. ∎

A direct consequence of the above lemma is that the successor map $\mathcal{S}$ for the impact oscillator (1.1) is well defined for $v \gg 1$. As shown in [26], the condition $\bar{a} > 0$ implies that Hill's equation (1.5) is oscillatory. This condition is also enough to

assure that our successor map is well defined. Actually, if $\mathcal{S}$ is not defined for some (τ, v) with $v > 0$, then by using Lemmas 3.7 and 3.8, the solution $x(t;\tau,v)$ will satisfy $x(t;\tau,v) \geq \delta$ and $|\frac{x'(t;\tau,v)}{x(t;\tau,v)}| < \max\{\frac{\beta_0}{\delta}, \frac{1}{\varepsilon_0}\}$ for t large enough. Now, by integrating (1.1) in $[2l\pi, 2k\pi]$ for $l, k \in \mathbb{N}$ we have

$$\int_{2l\pi}^{2k\pi} \left(\frac{x''}{x}\right) \mathrm{d}t + 2\pi(k-l)\bar{a} \leq 0,$$

but this implies that

$$2\pi(k-l)\bar{a} + \int_{2l\pi}^{2k\pi} \frac{(x')^2}{x^2} \mathrm{d}t - 2\max\left\{\frac{\beta_0}{\delta}, \frac{1}{\varepsilon_0}\right\} \leq 0.$$

It is clear that this is not possible if k is large enough. Therefore the successor map $\mathcal{S}$ is well defined for all (τ, v) with $v > 0$, provided that $p(t) \leq 0$ for all $t, \bar{p} < 0$ and $\bar{a} > 0$.

4. Asymptotically linear impact oscillators. Finally, we discuss the case of the asymptotically linear impact oscillator (1.8). Throughout this section, it is understood that the assumptions of Theorem 1.8 hold. Such assumptions imply that there exist $M, P > 0$ such that $|a(t)x + g(t,x) - p(t)| \leq Mx + P$ for $x \geq 0$ and for all t. Moreover, the successor map $\mathcal{S}$ of the problem (1.8) is well defined for all $(\tau, v) \in \mathbb{R} \times \mathbb{R}^+$ and $p(t) \leq 0$ for all t, $\bar{p} < 0$. Then, by using similar arguments as in Lemmas 3.2 and 3.3, it is easy to prove that the conclusions of Lemma 3.4 are still valid for the successor map of problem (1.8). Roughly speaking, Lemma 3.4 means that the rotation of some iteration of the successor map is slow for small velocities. On the other hand, it is necessary to control the behavior of the successor map for large velocities (that is, an analogous to Lemma 3.6). To this purpose, some lemmas are needed. For the moment, let us assume that $\|a\|_\infty > 0$.

LEMMA 4.1. *The solution $x(t;\tau,v)$ of problem (1.8) with initial conditions $x(\tau;\tau,v) = 0$, $x'(\tau;\tau,v) = v > 0$ satisfies*

$$\left(r(\tau_1) + \frac{P}{M+1}\right)\exp(-(M+1)(\tau_2 - \tau_1)) \leq r(\tau_2) + \frac{P}{M+1} \leq \left(r(\tau_1) + \frac{P}{M+1}\right)\exp((M+1)(\tau_2 - \tau_1)) \tag{4.1}$$

for $\tau_2 - \tau_1 \geq 0$, where $r(t) = ((x(t;\tau,v))^2 + (x'(t;\tau,v))^2)^{1/2}$.

Proof. This inequality is proved by using the Gronwall lemma as in (3.14). ∎

Let $n, m \in \mathbb{N}$ be such that $n > 2m(\sqrt{\|a\|_\infty})$. Then, there exists $\sigma > 0$, such that $n > 2m(\sqrt{\|a\|_\infty} + 2\sigma)$. Let us fix the positive numbers $T = \frac{n\pi}{\sqrt{\|a\|_\infty}}$ and

$$\delta = \frac{1}{2}\left|\frac{\pi}{\sqrt{\|a\|_\infty + 2\sigma}} - \frac{\pi}{\sqrt{\|a\|_\infty + \sigma}}\right|.$$

Note that σ (and in consequence δ) can be chosen arbitrarily small. By using the assumption (1.7), it is possible to take $d > 0$ (depending on σ) such that

$$\max_{0 \leq t \leq 2\pi} |a(t)x + g(t,x) - p(t)| \leq (\|a\|_\infty + \sigma)x \quad \text{for } x \geq d.$$

The following estimation is obtained by using the previous lemma.

LEMMA 4.2. *Let $x(t;\tau,v)$ be the solution of* (1.8) *with initial conditions*

$$x(\tau;\tau,v)=0,\quad x'(\tau;\tau,v)=v>0.$$

Then for d, δ, and $T>0$ as given before, there exists $v_\delta>0$ such that if $v\geq v_\delta$, then there exists $\tau_d^+>\tau$ such that $x(\tau_d^+;\tau,v)=d$ and $x(t;\tau,v)<d$ for $t\in(\tau,\tau_d^+)$, and moreover $|\tau_d^+-\tau|<\delta$. Besides, if there exists $\tau_d^->\tau_d^+$ such that $x(\tau_d^-;\tau,v)=d$, $x'(\tau_d^-;\tau,v)<0$, and $|\tau_d^--\tau|<T$, then there exists $\hat\tau>\tau_d^+$ such that $x(\hat\tau;\tau,v)=0$ and $|\hat\tau-\tau_d^-|<\delta$. Moreover, if δ is small enough, then

$$\frac{v_d^+}{2}\leq v\leq 2v_d^+. \tag{4.2}$$

Proof. Firstly, the global existence of $x(t;\tau,v)$ right to τ is assured from the assumptions. Suppose there is no time $t\in(\tau,\tau+1)$ such that $x(t;\tau,v)=d$, that is, $0<x(t;\tau,v)<d$ for $t\in(\tau,\tau+1)$. Then

$$x'(t;\tau,v)>\left(v+\frac{P}{M+1}\right)\exp(-(M+1))-d-\frac{P}{M+1},$$

so an integration gives

$$x(\tau+1;\tau,v)>\left(v+\frac{P}{M+1}\right)\exp(-(M+1))-d-\frac{P}{M+1}>d$$

if v is large enough. Thus we have proved the existence of τ_d^+. Moreover,

$$v_d^+=x'(\tau_d^+;\tau,v)>\left(v+\frac{P}{M+1}\right)\exp(-(M+1)(\tau_d^+-\tau))-d-\frac{P}{M+1}.$$

Hence

$$\begin{aligned}d&=\int_\tau^{\tau_d^+}x'(s;\tau,v)\mathrm{d}s\\&\geq\left[\left(v+\frac{P}{M+1}\right)\exp(-(M+1)(\tau_d^+-\tau))-d-\frac{P}{M+1}\right](\tau_d^+-\tau)\end{aligned}$$

and in consequence for a given δ we get $|\tau_d^+-\tau|<\delta$ by taking v large enough. The discussion for $\hat\tau$ is similar. Finally, if δ is small enough, then

$$\left(v_d^++\frac{P}{M+1}\right)\exp(-(M+1)\delta)-\frac{P}{M+1}\geq\frac{v_d^+}{2}$$

and

$$\left(v_d^++d+\frac{P}{M+1}\right)\exp(-(M+1)\delta)-\frac{P}{M+1}\leq 2v_d^+.$$

Now, the estimation (4.2) follows easily from (4.1). ∎

Define now

$$h(t,x)=\begin{cases}\dfrac{a(t)x+g(t,x)-p(t)}{x},&x\geq d;\\[2ex]\dfrac{a(t)d+g(t,d)-p(t)}{d},&x<d.\end{cases}$$

Then $h(t,x)$ is continuous and 2π-periodic with respect to t and verifies $|h(t,x)| \leq \|a\|_\infty + \sigma$ for $x \geq 0$ and for all t. Let $x(t;\tau,v)$ be the solution of the equation $x''+h(t,x)x = 0$ satisfying initial conditions $x(\tau;\tau,v) = 0$, $x'(\tau;\tau,v) = v > 0$. On the other hand, let $y_0(t;\tau,v)$ be the solution of the equation $x''+(\|a\|_\infty+\sigma)x = 0$ satisfying the same initial conditions as $x(t;\tau,v)$. By using Sturm comparison theorem,

$$\hat{\tau}(h) - \tau \geq \frac{\pi}{\sqrt{\|a\|_\infty + \sigma}},$$

where $\hat{\tau}(h)$ is the next zero of $x(t;\tau,v)$ right to τ. Moreover, we have the following lemma.

LEMMA 4.3. *Let $x(t;\tau,v)$ be the solution of the equation $x'' + h(t,x)x = 0$ satisfying the initial conditions*

$$x(\tau;\tau,v) = 0, \quad x'(\tau;\tau,v) = v > 0.$$

Then, there is $v_\delta > 0$ such that if $v \geq v_\delta$, then there exist τ_d^+, τ_d^- such that $x(\tau_d^+;\tau,v) = d$, $x'(\tau_d^+;\tau,v) = v_d^+ > 0$, $x(t;\tau,v) < d$ for $t \in (\tau,\tau_d^+)$ and $x(\tau_d^-;\tau,v) = d$, $x'(\tau_d^-;\tau,v) = v_d^- < 0$, $x(t;\tau,v) > 0$ for $t \in (\tau,\tau_d^-)$, respectively. Moreover,

$$\tau_d^- - \tau_d^+ > \frac{\pi}{\sqrt{\|a\|_\infty + 2\sigma}}.$$

Proof. Recall that $|h(t,x)x| \leq (\|a\|_\infty + \sigma)x$ for $x \geq 0$ and for all t, so the conclusion of Lemmas 4.1 and 4.2 are valid for $x(t;\tau,v)$ if $v > 0$ is sufficiently large, thus we have $\tau_d^+ - \tau < \delta$. Note that $h(t,x)x = a(t)x + g(t,x) - p(t)$ for $x \geq d$ and for all t. This implies, under the assumption of Theorem 1.8, that there exists $\tau_d^- > \tau_d^+$ such that $x(\tau_d^-;\tau,v) = d$, $x'(\tau_d^-;\tau,v) = v_d^- < 0$, and $x(t;\tau,v) > 0$ for $t \in (\tau,\tau_d^-)$. By contradiction, if

$$\tau_d^- - \tau_d^+ \leq \frac{\pi}{\sqrt{\|a\|_\infty + 2\sigma}},$$

then $\tau_d^- - \tau < \tau_d^- - \tau_d^+ + \delta < T$, and Lemma 4.2 implies that the zero $\hat{\tau}(h)$ right to τ exists and $\hat{\tau}(h) - \tau_d^- < \delta$. Hence,

$$\tau_d^- - \tau_d^+ > \hat{\tau}(h) - \tau - 2\delta \geq \frac{\pi}{\sqrt{\|a\|_\infty + \sigma}} - 2\delta = \frac{\pi}{\sqrt{\|a\|_\infty + 2\sigma}}.$$

This contradiction completes the proof of Lemma 4.3. ∎

Finally, let us consider $x(t;\tau,v)$ the solution of (1.8) with initial conditions

$$x(\tau;\tau,v) = 0, \quad x'(\tau;\tau,v) = v > 0.$$

Let $\hat{\tau}$ be the first zero right to τ. If v is large enough, then there exist τ_d^-, $\tau_d^+ \in (\tau,\hat{\tau})$ such that $x(\tau_d^\pm;\tau,v) = d$, $v_d^+ = x'(\tau_d^+;\tau,v) > 0$, $v_d^- = x'(\tau_d^-;\tau,v) < 0$, and $x(t;\tau,v) < d$ for $t \in (\tau,\tau_d^+) \cup (\tau_d^-,\hat{\tau})$. Moreover, $|\tau_d^+ - \tau| < \delta$ and v_d^+ is arbitrarily large by using the estimation (4.2). On the other hand, let $x_h(t)$ be the solution of the equation $x'' + h(t,x)x = 0$ satisfying $x_h(\tau_d^+) = d$, $x_h'(\tau_d^+) = v_d^+ > 0$. If τ_h is such that $x_h(\tau_h) = 0$, $x_h(t) > 0$ for $t \in (t_h,\tau_d^+)$, then the estimation (4.2) implies that the initial velocity $v_h = x_h'(\tau_h)$ is arbitrarily large. Taking into account that $h(t,x)x = a(t)x + g(t,x) - p(t)$ for $x \geq d$ and for all t, Lemma 4.2 implies that the time in which the solution $x(t;\tau,v)$ of the equation $x'' + a(t)x + g(t,x) = p(t)$ moves

from (d_σ, v_d^+) to (d_σ, v_d^-) is larger than $\frac{\pi}{\sqrt{\|a\|_\infty+2\sigma}}$. In consequence, if v large enough (more explicitly, $v \geq v_\delta$), then we have

$$\hat{\tau} - \tau \geq \frac{\pi}{\sqrt{\|a\|_\infty + 2\sigma}}. \tag{4.3}$$

Looking for the estimation of $\Pi_1(\mathcal{S}^n(\tau, v)) - \tau$, note that by using the argument leading to (3.15), it results that for a given $v_\delta > 0$ there is $v_{n,m}^+(\delta) > 0$ such that

$$\text{if } v > v_{n,m}^+(\delta) \quad \text{and} \quad \Pi_1(\mathcal{S}^n(\tau, v)) - \tau \leq 2m\pi, \text{ then } \Pi_2(\mathcal{S}^i(\tau, v)) > v_\delta \tag{4.4}$$

for $i = 0, 1, \ldots, n-1$. Hence, following the arguments of section 3, we can prove that the conclusions of Lemma 3.6 are true for the successor map of the problem (1.8) under the assumptions of Theorem 1.8. Note that if $a(t) \equiv 0$, then T is not well defined, but it is easy to prove, by using similar arguments as before, that $\Pi_1(\mathcal{S}(\tau, v)) - \tau \geq 2m\pi$ for v sufficiently large. Now, Theorem 1.8 can be proved by mimicking the arguments of sections 2 and 3 with minor modifications.

The property that the successor map $\mathcal{S}$ is well defined is not easy to check. For example, consider the equation $x'' - x = -1$. It has a singular point $(1, 0)$ in $x - x'$ phase plane and the solution $x(t; \tau, 1)$ starting from $x(\tau; \tau, 1) = 0$, $x'(\tau; \tau, 1) = 1$ will tend to $(1, 0)$ in $x - x'$ phase plane as $t \to +\infty$. Thus we can construct an equation by modifying the above equation such that the new equation is asymptotically linear and the successor map $\mathcal{S}$ of this equation is well defined for v sufficiently small and sufficiently large but $\mathcal{S}$ is not well defined for $v = 1$. In spite of that, in the following we show that $a(t)x + g(t, x) \geq 0$ is a sufficient condition to have $\mathcal{S}$ well defined. Actually, let us note that

$$\begin{aligned} x'(t; \tau, v) &= v - \int_\tau^t (a(s)x + g(s, x))\mathrm{d}s + \int_\tau^t p(s)\mathrm{d}s \\ &\leq v + \int_\tau^t p(s)\mathrm{d}s \to -\infty \quad \text{as } t \to +\infty. \end{aligned}$$

Thus, for any fixed $v > 0$, there exists a $\hat{\tau} > \tau$ such that $x(\hat{\tau}; \tau, v) = 0$ which implies that $\mathcal{S}$ is well defined for (τ, v). Hence Corollary 1.9 is proved.

Acknowledgments. The authors thank Prof. R. Ortega for his help in understanding the bouncing problem. Finally, they thank the referees for their help and valuable suggestions.

SPECTRAL STABILITY OF LOCAL DEFORMATIONS OF AN ELASTIC ROD: HAMILTONIAN FORMALISM*

S. LAFORTUNE† AND J. LEGA‡

Abstract. Hamiltonian methods are used to obtain a necessary and sufficient condition for the spectral stability of pulse solutions to two coupled nonlinear Klein–Gordon equations. These equations describe the near-threshold dynamics of an elastic rod with circular cross section. The present work completes and extends a recent analysis of the authors' [*Phys. D*, 182 (2003), pp. 103–124], in which a sufficient condition for the instability of "nonrotating" pulses was found by means of Evans function techniques.

Key words. spectral stability, Hamiltonian methods, elastic filament

1. Introduction.

Coherent structures, such as fronts, pulses, defects, or solitons, play an important role in the dynamics of many physical, optical, or biological systems (see for instance [1]). When such systems are modeled in terms of partial differential equations, a coherent structure is often described as one or a family of solutions, which asymptotically connects simple plane waves or stationary states of the system. Numerous numerical and analytical techniques have been developed to study the stability of coherent structures. In particular, the Evans function [2, 3, 4, 5, 6, 7, 8, 9] can be used to obtain information on the point spectrum of one-dimensional linear operators. This approach is very general [9], but only a sufficient condition for the instability of a solution is typically found analytically. A numerical investigation of the number of zeros of the Evans function in the right half complex plane is therefore often necessary to obtain complete spectral stability results (see for instance [10] and the references therein). On the other hand, in the case of Hamiltonian systems with symmetries, global techniques are available, which give sufficient conditions for orbital stability (or instability) [11, 12].

In this paper, we apply and also extend such techniques to obtain a necessary and sufficient criterion for the spectral stability of a family of pulse solutions of two coupled nonlinear Klein–Gordon equations. These equations describe the near-threshold dynamics of an elastic filament with circular cross section [13]. The family of coherent structures we are interested in has two parameters, the speed c at which each pulse travels, and the frequency ω at which the filament rotates about its axis. In a recent paper [14], we used Evans function techniques to obtain a criterion that guarantees the instability of "nonrotating" ($\omega = 0$) pulses. Because the nonlinear Klein–Gordon equations are Hamiltonian and invariant under space translations as well as gauge invariant [15], we show here that one can take advantage of these properties to obtain spectral stability results for both "rotating" ($\omega \neq 0$) as well as nonrotating pulses.

The Hamiltonian formalism we use below is described in [12], and is a generalization to systems whose symmetry group has a dimension larger than 1, of the technique discussed in [11]. For the purpose of this study, the method can be simplified and summarized as follows. Consider a Hamiltonian system of the form

$$\frac{\partial \mathbf{u}}{\partial t} = JE'(\mathbf{u}), \tag{1.1}$$

where $\mathbf{u}(x,t) \in X$ is an n-dimensional vector which depends on the space coordinate x and on time t, X is a real Hilbert space with inner product denoted by $(\cdot\,,\cdot)$, J is an invertible $n \times n$ skew-symmetric matrix, E is a functional of $\mathbf{u}$, and E' is its Fréchet derivative. Assume that this Hamiltonian system is invariant under a one-parameter group T of unitary transformations on X which commute with J, and that there exists a one-parameter family of solutions $\mathbf{u}(x,t)$ to (1.1) which can be written as

$$\mathbf{u}(x,t) = T(st)\ \mathbf{u}_s(x), \tag{1.2}$$

where $\mathbf{u}_s(x)$ only depends on space and is parametrized by the one-dimensional parameter s. In order to study the linear stability of $\mathbf{u}(x,t)$, one first linearizes (1.1) about this one-parameter family of solutions. As shown in Appendix A, the linearized system reads

$$\frac{\partial \mathbf{w}}{\partial t} = J\, H_s\, \mathbf{w}, \tag{1.3}$$

where the perturbation to $\mathbf{u}(x,t)$ is $T(st)\mathbf{w}(x,t)$, H_s is the self-adjoint operator given by

$$H_s = E''(\mathbf{u}_s) - s\, Q''(\mathbf{u}_s),$$

and Q is the conserved quantity associated with the invariance T. It can be found from T by means of an infinite-dimensional version of Noether's theorem [11, 12, 16], and is given by $Q(\mathbf{u}) = \frac{1}{2}\,\langle \mathcal{B}\mathbf{u}\,, \mathbf{u}\rangle$, where $\langle \mathbf{u}^*, \mathbf{v}\rangle \equiv (\mathbf{u}, \mathbf{v})$ for all $\mathbf{u}$, $\mathbf{v} \in X$ (X^* is the dual of X and X is identified with X^{**}), and the linear operator $\mathcal{B}$ is such that $J\,\mathcal{B}$ is an extension of $T'(0)$.

The method described in [11, 12] takes advantage of the fact that H_s is self-adjoint and therefore relatively simple to analyze, to obtain information on the spectrum of JH_s, which is the linearization of (1.1) about the coherent structure (1.2). More precisely, it is shown in [11] that if H_s has exactly one negative eigenvalue, the convexity requirement

$$\frac{d^2}{ds^2}\, d(s) > 0,$$

where the scalar function $d(s)$ is given by

$$d(s) = E(\mathbf{u}_s) - s\, Q(\mathbf{u}_s),$$

is a necessary and sufficient condition for the stability of (1.2), provided the continuous spectrum of H_s is positive and bounded away from the origin. By stability, we mean (nonlinear) orbital stability: by starting close enough to a solution (1.2), $\mathbf{u}_0(x,t)$, with say $s = s_0$, one can guarantee that at each time the system will remain close to the orbit of $\mathbf{u}_0$ under changes in the parameter s; i.e., at each time t the solution will

be arbitrarily close to some $T(st)\mathbf{u}_s(x)$ where s may depend on t and is of course not necessarily equal to s_0.

This approach can be extended [12] to the case where the symmetry group of the Hamiltonian system is m-dimensional ($1 < m < \infty$). Then, H_s and $d(s)$ are replaced by

$$H_{\mathbf{s}} = E''(\mathbf{u}_{\mathbf{s}}) - \sum_{i=1}^{m} s_i\, Q_i''(\mathbf{u}_{\mathbf{s}}), \qquad d(\mathbf{s}) = E(\mathbf{u}_{\mathbf{s}}) - \sum_{i=1}^{m} s_i\, Q_i(\mathbf{u}_{\mathbf{s}}),$$

where $\{Q_i\}_{i=1,\dots,m}$ is the set of conserved quantities associated with the unitary representation T of the m-dimensional symmetry group, and $\mathbf{s}$ is the vector with components s_i. In this case, it is shown in [12] that if $H_{\mathbf{s}}$ has an appropriate spectral decomposition, if the scalar function $d(\mathbf{s})$ is nondegenerate at $\mathbf{s}$, and if the number of negative eigenvalues of $H_{\mathbf{s}}$ is equal to the number of positive eigenvalues of the Hessian of $d(\mathbf{s})$ at $\mathbf{s}$, then the coherent structure is stable.

This paper is organized as follows. In section 2, we introduce the coupled nonlinear Klein–Gordon equations as well as the family of pulses, the stability of which we want to analyze. In section 3, we rewrite the Klein–Gordon equations in their Hamiltonian form, define the symmetries of this system and the associated conserved quantities, as well as $H_{\mathbf{s}}$. We then show that the self-adjoint operator $H_{\mathbf{s}}$ has exactly one negative eigenvalue, and that its continuous spectrum is positive but touches the origin. As a consequence, one of the hypotheses of [12], which says that $H_{\mathbf{s}}$ has a closed positive subspace, is not satisfied. This implies that it is difficult to prove orbital stability in X. Indeed, the continuous spectrum of JH_s is not bounded away from the origin and in such a case one typically resorts to the introduction of weighted spaces in order to obtain nonlinear stability results. The goal of this paper is to consider spectral stability instead. In section 4, we point out that only nonnegativity of the bilinear form $\langle H_{\mathbf{s}}\,\mathbf{u}, \mathbf{u}\rangle$ on the closure of the positive subspace of $H_{\mathbf{s}}$ is in fact needed to obtain spectral stability. We then show that, under this less restrictive assumption, the results of [12] can be extended to give a necessary and sufficient condition for the nonexistence of positive point spectrum of the linearization $J\,H_s$ about the two-parameter family of pulses. Since the continuous spectrum of $J\,H_s$ is on the imaginary axis, this is equivalent to the spectral stability of these solutions. Finally, we derive an explicit expression for this stability condition, and we show that it is consistent with the criterion found in [14] in the case of nonrotating pulses. In section 5, we summarize our results and mention possible extensions of this work to more complex models for the dynamics of elastic filaments.

2. The coupled nonlinear Klein–Gordon equations. We consider the following dimensionless coupled nonlinear Klein–Gordon equations, which describe the near-threshold dynamics of an elastic rod with circular cross section, subject to constant twist:

$$\begin{aligned} &\frac{\partial^2 A}{\partial t^2} - c_0^2 \frac{\partial^2 A}{\partial x^2} = \mu A - A|A|^2 + A\frac{\partial B}{\partial x}, \\ &\frac{\partial^2 B}{\partial t^2} - \frac{\partial^2 B}{\partial x^2} = -\frac{\partial |A|^2}{\partial x}, \end{aligned} \tag{2.1}$$

where $A(x,t)$ denotes the (scaled) slowly varying complex amplitude of the helical mode which grows above the bifurcation threshold, $B(x,t)$ is the (scaled) real axial

twist, c_0 is the group velocity of amplitude deformations, relative to the group velocity of twist deformations, and μ measures the distance from the threshold above which filaments subject to increasing constant twist tend to assume a helical shape [13]. Both c_0 and μ are real parameters. We are interested in pulse solutions [15, 17] of (2.1) of the form

$$A = a_0(\xi)e^{i\omega t}, \qquad B = b_0(\xi), \qquad \xi = x - ct, \tag{2.2}$$

where

$$a_0(\xi) = \alpha\ \mathrm{sech}(\beta\xi)\exp\left(i\frac{\omega c}{c^2 - c_0^2}\,\xi\right), \qquad b_0(\xi) = \frac{\alpha^2}{\beta(1-c^2)}\tanh(\beta\xi), \tag{2.3}$$

and

$$\alpha^2 = \frac{2\beta^2}{c^2}(c^2-1)(c^2-c_0^2), \qquad \beta^2 = \frac{\mu(c^2-c_0^2) - \omega^2 c_0^2}{(c^2-c_0^2)^2}. \tag{2.4}$$

As in [14], we only consider the case $\mu < 0$, since the continuous spectrum of the linearization of (2.1) about any pulse solution (2.2–2.4) would otherwise intersect the right half complex plane. As a consequence, α^2 and β^2 in (2.4) are positive if and only if

$$c^2 < c_0^2\left(1 + \frac{\omega^2}{\mu}\right) \ \text{ and } \ c^2 - 1 < 0. \tag{2.5}$$

We also note for later reference that a_0 and b_0 in (2.3) satisfy the following ordinary differential equations in ξ:

$$\begin{aligned}(c^2 - c_0^2)\,\frac{d^2a_0}{d\xi^2} - 2\,i\,c\,\omega\frac{da_0}{d\xi} &= a_0\left(\omega^2 + \mu - |a_0|^2 + \frac{db_0}{d\xi}\right),\\ (c^2-1)\frac{d^2b_0}{d\xi^2} &= -\frac{d}{d\xi}(|a_0|^2).\end{aligned} \tag{2.6}$$

As indicated in [15], system (2.1) may be written in Hamiltonian form. To this end, we first introduce the real variables P, Q, R, S, and U such that

$$A = P + iQ, \qquad A_t = R + iS, \qquad U = B_t. \tag{2.7}$$

Then (2.1) reads

$$\frac{\partial\,\mathbf{v}}{\partial t} = J\ E'(\mathbf{v}), \tag{2.8}$$

where $\mathbf{v} = [R, S, U, P, Q, B]^T$, the energy E is given by

$$E(\mathbf{v}) = \int_{-\infty}^{\infty} h\,\mathrm{d}x, \tag{2.9}$$

where

$$\begin{aligned}h = c_0^2\left(P_x^2 + Q_x^2\right) - \mu\left(P^2+Q^2\right) + \frac{1}{2}\left(P^2+Q^2\right)^2 - \left(P^2+Q^2\right)B_x\\ +\ R^2 + S^2 + \frac{1}{2}B_x^2 + \frac{1}{2}U^2,\end{aligned} \tag{2.10}$$

and the invertible, skew-symmetric matrix J reads

$$J = \begin{pmatrix} 0 & 0 & 0 & -1/2 & 0 & 0 \\ 0 & 0 & 0 & 0 & -1/2 & 0 \\ 0 & 0 & 0 & 0 & 0 & -1 \\ 1/2 & 0 & 0 & 0 & 0 & 0 \\ 0 & 1/2 & 0 & 0 & 0 & 0 \\ 0 & 0 & 1 & 0 & 0 & 0 \end{pmatrix}. \tag{2.11}$$

3. Hamiltonian formalism. As indicated in the introduction, we first look for the group of unitary transformations which leave the Hamiltonian system invariant [18] and define the corresponding conserved quantities. Let $\mathbf{v}_0 = [r_0, s_0, u_0, p_0, q_0, b_0]^T$ be the six-dimensional vector corresponding to the solution of (2.6), with a_0 and b_0 given in (2.3) and

$$a_0 = p_0 + i\,q_0, \quad r_0 = -c\,p_0' - \omega\,q_0, \quad s_0 = -c\,q_0' + \omega\,p_0, \quad u_0 = -c\,b_0'. \tag{3.1}$$

We require perturbations of $\mathbf{v}_0$ to be in $X = L^2 \times L^2 \times L^2 \times H^1 \times H^1 \times H^1$, even though the last component b_0 of $\mathbf{v}_0$ is nondecaying at infinity.

3.1. Symmetries. There are two unitary transformations that preserve the Hamiltonian structure (2.8) and which are elements of the symmetry group of (2.1) [14]. They are

1. The translational invariance, denoted by T_1 and such that

$$T_1(x_0)\,A(x,t) = A(x - x_0, t), \quad T_1(x_0)\,B(x,t) = B(x - x_0, t), \tag{3.2}$$

   where x_0 is a real arbitrary constant.
2. The gauge invariance, T_2, such that

$$T_2(\theta)\,A(x,t) = A(x,t)\,e^{i\theta}, \quad T_2(\theta)\,B(x,t) = B(x,t), \tag{3.3}$$

   where θ is a real arbitrary constant.

Using these definitions, the pulse solution given in (2.2) and (2.3) can be written as a function of x and t whose temporal dependence is generated by the action of these transformations. In other words, any pulse solution of (2.1) reads

$$[A(x,t), B(x,t)] = T_1(ct) \circ T_2(\omega t)\,[a_0(x), b_0(x)], \tag{3.4}$$

where a_0 and b_0 are defined in (2.3) and depend on c and ω.

The conserved quantities corresponding to the symmetries T_1 in (3.2) and T_2 in (3.3) are, respectively,

$$Q_1(\mathbf{v}) = -\int_{-\infty}^{\infty} \left(2\,(RP_x + SQ_x) + UB_x\right) dx, \tag{3.5}$$

$$Q_2(\mathbf{v}) = 2\int_{-\infty}^{\infty} (SP - QR)\,dx, \tag{3.6}$$

and any pulse solution defined in (2.2) and (2.3) is a critical point of the functional

$$I(\mathbf{v}) = E(\mathbf{v}) - c\,Q_1(\mathbf{v}) - \omega\,Q_2(\mathbf{v}). \tag{3.7}$$

Indeed, the system of equations given by

$$I'(\mathbf{v}) = \begin{pmatrix} 2(R + cP_x + \omega Q) \\ 2(S + cQ_x - \omega P) \\ U + cB_x \\ 2(-c_0^2 P_{xx} + P(-\mu + P^2 + Q^2 - B_x) - cR_x - \omega S) \\ 2(-c_0^2 Q_{xx} + Q(-\mu + P^2 + Q^2 - B_x) - cS_x + \omega R) \\ -B_{xx} + (P^2 + Q^2)_x - cU_x \end{pmatrix} = 0 \tag{3.8}$$

is equivalent to (2.6) with the first equation split into its real and imaginary parts. Equation (3.8) can be rewritten as

$$E'(\mathbf{v}) = Q'(\mathbf{v})\ \kappa, \tag{3.9}$$

where $\kappa = [c, \omega]^T$ and $Q'(\mathbf{v})$ is the 6×2 matrix $[Q_1'(\mathbf{v})\ Q_2'(\mathbf{v})]$. By taking the directional derivative of (3.9) in the direction $\sigma = [c_1, \omega_1]^T$ and evaluating it at $\mathbf{v} = \mathbf{v_0}$, we obtain

$$I''(\mathbf{v_0})\ \partial_\sigma \mathbf{v_0} = Q'(\mathbf{v_0})\ \sigma, \tag{3.10}$$

which is equation (3.3) of [12]. Here $\partial_\sigma \mathbf{v_0}$ denotes the directional derivative of $\mathbf{v_0}$, which depends on κ, in the direction σ. In what follows, we denote $I''(\mathbf{v_0})$ by $H_{c,\omega}$, and the linearization of (2.1) about the pulse solution $\mathbf{v_0}$ reads

$$\frac{\partial \mathbf{w}}{\partial t} = J\, H_{c,\omega}\ \mathbf{w},$$

where the perturbation to $[A, B]$ is $[(p(\xi, t) + iq(\xi, t)) \exp(i\omega t), b(\xi, t)]$ and where $\mathbf{w} = [r, s, u, p, q, b]^T$ is such that

$$r = p_t - c\, p_\xi - \omega\, q, \qquad s = q_t - c\, q_\xi + \omega\, p, \qquad u = b_t - c\, b_\xi.$$

Below, we show that the self-adjoint operator $H_{c,\omega}$ has a two-dimensional kernel, has only one negative eigenvalue, and is such that its continuous spectrum is nonnegative.

3.2. Kernel of $H_{c,\omega}$. In [14], it is shown that the kernel of $J\, H_{c,\omega}$ is two-dimensional and generated by

$$-T_1'(0)\mathbf{v}_0 = \mathbf{v}_0' \qquad \text{and} \qquad T_2'(0)\mathbf{v}_0 = \begin{pmatrix} -s_0 \\ r_0 \\ 0 \\ -q_0 \\ p_0 \\ 0 \end{pmatrix}, \tag{3.11}$$

where T_1 and T_2 are the Hamiltonian symmetries defined in (3.2) and (3.3) and $\mathbf{v}_0$ is the six-dimensional pulse solution defined at the beginning of section 3. Since J is invertible, $\mathrm{Ker}(J\, H_{c,\omega}) = \mathrm{Ker}(H_{c,\omega})$.

3.3. Negative subspace of $H_{c,\omega}$. In what follows, we show that the dimension of the negative subspace of $H_{c,\omega}$ is equal to 1. To do so, we first rewrite the quadratic form $\langle H_{c,\omega}\mathbf{w},\mathbf{w}\rangle$, where $\mathbf{w}\in X$, as a sum of squares plus terms of the form $\langle\tilde{\mathcal{L}}_i\, z_i, z_i\rangle$, $i=1,2$, where the $\tilde{\mathcal{L}}_i$ are second-order differential operators. We then find the number of negative eigenvalues of these two operators, using results from Sturm–Liouville theory. Finally, we use this information together with the min-max principle, to find the sign of the two lowest eigenvalues of $H_{c,\omega}$.

The linear operator $H_{c,\omega}$ reads

$$H_{c,\omega}\equiv I''(\mathbf{v}_0)=E''(\mathbf{v}_0)-c\,Q_1''(\mathbf{v}_0)-\omega\,Q_2''(\mathbf{v}_0)=\begin{pmatrix} D^2 & C\\ C^* & L\end{pmatrix}, \tag{3.12}$$

where

$$D^2=\begin{pmatrix}2&0&0\\0&2&0\\0&0&1\end{pmatrix},\quad C=\begin{pmatrix}2c\partial_x & 2\omega & 0\\ -2\omega & 2c\partial_x & 0\\ 0&0&c\partial_x\end{pmatrix},$$

$$C^*=\begin{pmatrix}-2c\partial_x & -2\omega & 0\\ 2\omega & -2c\partial_x & 0\\ 0&0&-c\partial_x\end{pmatrix}=-C, \tag{3.13}$$

and

$$L=\begin{pmatrix} 2\left(-c_0^2\,\partial_{xx}-\partial_x\,b_0-\mu+q_0^2+3p_0^2\right) & 4p_0\,q_0 & -2p_0\,\partial_x\\ 4p_0\,q_0 & 2\left(-c_0^2\partial_{xx}-\partial_x\,b_0-\mu+p_0^2+3q_0^2\right) & -2q_0\,\partial_x\\ 2\left(p_0\,\partial_x+\partial_x\,p_0\right) & 2\left(q_0\,\partial_x+\partial_x\,q_0\right) & -\partial_{xx}\end{pmatrix}. \tag{3.14}$$

Here ∂_x and ∂_{xx} refer to first and second partial derivatives with respect to x. We denote a six-dimensional vector in X by $\mathbf{w}=[w_1,w_2]^T$, where $i=1,2$ and the w_i are three-dimensional. Then,

$$\begin{aligned}\langle H_{c,\omega}\mathbf{w},\mathbf{w}\rangle &= \langle D^2\,w_1,w_1\rangle+\langle C\,w_2,w_1\rangle+\langle C^*\,w_1,w_2\rangle+\langle L\,w_2,w_2\rangle\\ &= (D\,w_1,D\,w_1)+2\langle C\,w_2,w_1\rangle+\langle L\,w_2,w_2\rangle\\ &= \left|\left|D\,w_1+D^{-1}C\,w_2\right|\right|^2+\langle(L+C^2D^{-2})\,w_2,w_2\rangle. \end{aligned}\tag{3.15}$$

The linear operator $L_1=L+C^2D^{-2}$ is such that

$$L_1=\begin{pmatrix} & L_2 & \begin{matrix}-2p_0\,\partial_x\\ -2q_0\,\partial_x\end{matrix}\\ 2\left(p_0\,\partial_x+\partial_x\,p_0\right) & 2\left(q_0\,\partial_x+\partial_x\,q_0\right) & -(1-c^2)\,\partial_{xx}\end{pmatrix}, \tag{3.16}$$

where

$$L_2=\begin{pmatrix} 2\left((c^2-c_0^2)\partial_{xx}-\partial_x\,b_0-\mu-\omega^2+q_0^2+3p_0^2\right) & 4\left(p_0\,q_0+c\,\omega\,\partial_x\right)\\ 4\left(p_0\,q_0-c\,\omega\,\partial_x\right) & 2\left((c^2-c_0^2)\partial_{xx}-\partial_x\,b_0-\mu-\omega^2+p_0^2+3q_0^2\right)\end{pmatrix}. \tag{3.17}$$

With $\mathbf{y} = [y_1, y_2, y_3]^T$, we have

$$\begin{aligned}\langle L_1\,\mathbf{y},\mathbf{y}\rangle &= \left\langle L_2 \begin{pmatrix} y_1 \\ y_2 \end{pmatrix}, \begin{pmatrix} y_1 \\ y_2 \end{pmatrix} \right\rangle \\ &\quad + (1-c^2)\,(\partial_x y_3, \partial_x y_3) + 2\sqrt{1-c^2}\,\left(K^T\,\partial_x y_3, \begin{pmatrix} y_1 \\ y_2 \end{pmatrix}\right) \\ &= \left\langle \left(L_2 - K^T K\right) \begin{pmatrix} y_1 \\ y_2 \end{pmatrix}, \begin{pmatrix} y_1 \\ y_2 \end{pmatrix} \right\rangle + \left\| \sqrt{1-c^2}\,\partial_x y_3 + K \begin{pmatrix} y_1 \\ y_2 \end{pmatrix} \right\|^2,\end{aligned} \tag{3.18}$$

where

$$K = -\frac{2}{\sqrt{1-c^2}}\,(p_0, q_0)\,.$$

Finally, let

$$\mathcal{L} \equiv L_2 - K^T K \tag{3.19}$$

and introduce the change of variable

$$\begin{pmatrix} z_1 \\ z_2 \end{pmatrix} = \begin{pmatrix} \cos\left(\frac{\omega c x}{c^2-c_0^2}\right) & \sin\left(\frac{\omega c x}{c^2-c_0^2}\right) \\ -\sin\left(\frac{\omega c x}{c^2-c_0^2}\right) & \cos\left(\frac{\omega c x}{c^2-c_0^2}\right) \end{pmatrix} \begin{pmatrix} y_1 \\ y_2 \end{pmatrix} \equiv M \begin{pmatrix} y_1 \\ y_2 \end{pmatrix}. \tag{3.20}$$

Then

$$\left\langle \mathcal{L} \begin{pmatrix} y_1 \\ y_2 \end{pmatrix}, \begin{pmatrix} y_1 \\ y_2 \end{pmatrix} \right\rangle = \left\langle \tilde{\mathcal{L}} \begin{pmatrix} z_1 \\ z_2 \end{pmatrix}, \begin{pmatrix} z_1 \\ z_2 \end{pmatrix} \right\rangle, \tag{3.21}$$

where

$$\tilde{\mathcal{L}} = \begin{pmatrix} \tilde{\mathcal{L}}_1 & 0 \\ 0 & \tilde{\mathcal{L}}_2 \end{pmatrix} \tag{3.22}$$

and

$$\begin{aligned}\tilde{\mathcal{L}}_1 &= \tilde{\mathcal{L}}_2 - \frac{4c^2}{1-c^2}(p_0^2 + q_0^2), \\ \tilde{\mathcal{L}}_2 &= 2\left((c^2 - c_0^2)\,\partial_{xx} + \frac{\omega^2\,c_0^2}{c^2-c_0^2} + p_0^2 + q_0^2 - \partial_x\,b_0 - \mu\right).\end{aligned} \tag{3.23}$$

The operator $\tilde{\mathcal{L}}_2$ has 0 as an eigenvalue since, from (2.6), one can show that

$$\tilde{\mathcal{L}}_2\,|a_0| = 0, \tag{3.24}$$

where a_0 is given in (2.3). Since the pulse has no zero, Sturm–Liouville theory (see, for instance, [19, p. 104]) indicates that $\tilde{\mathcal{L}}_2$ does not have any negative eigenvalue. By taking the derivative of (3.24) with respect to x we obtain

$$\tilde{\mathcal{L}}_1\,|a_0|' = 0. \tag{3.25}$$

Since $|a_0|'$ has exactly one zero, $\tilde{\mathcal{L}}_1$ has one negative eigenvalue.

We now use the above information together with the min-max principle (see for instance, Theorem XIII.1, page 76 [20]; see pages 87–90 [21], for a discussion in the finite-dimensional case), to prove that $H_{c,\omega}$ has exactly one negative eigenvalue. We have shown that

$$\begin{aligned}\langle H_{c,\omega}\,\mathbf{w},\mathbf{w}\rangle = \left|\left|D\,w_1 + D^{-1}C\,w_2\right|\right|^2 + \left|\left|\sqrt{1-c^2}\,\partial_x y_3 + K\begin{pmatrix} y_1 \\ y_2\end{pmatrix}\right|\right|^2 \\ +\langle\tilde{\mathcal{L}}_1\,z_1,z_1\rangle + \langle\tilde{\mathcal{L}}_2\,z_2,z_2\rangle,\end{aligned}$$

where $\mathbf{w} = [w_1,w_2]^T$, $w_2 = [y_1,y_2,y_3]$, $[z_1,z_2]^T = M\,[y_1,y_2]^T$, and M is defined in (3.20). Let $\tilde{\mathbf{w}} = [\tilde{w}_1,\tilde{w}_2]^T$, $||\tilde{\mathbf{w}}|| = 1$, be such that

$$\begin{aligned}\tilde{w}_1 &= -D^{-2}C\,\tilde{w}_2, \quad \tilde{w}_2 = [\tilde{y}_1,\tilde{y}_2,\tilde{y}_3], \\ \partial_x\,\tilde{y}_3 &= \frac{-1}{\sqrt{1-c^2}}\,K\begin{pmatrix}\tilde{y}_1\\ \tilde{y}_2\end{pmatrix}, \quad \begin{pmatrix}\tilde{y}_1\\ \tilde{y}_2\end{pmatrix} = M^{-1}\begin{pmatrix}\tilde{z}_1\\ 0\end{pmatrix},\end{aligned}$$

with $\tilde{z}_1$ chosen to be an eigenvector of $\tilde{\mathcal{L}}_1$ with eigenvalue $\kappa < 0$. Note that the $\tilde{z}_2$ variable associated with $\tilde{\mathbf{w}}$ is zero. By the min-max principle, the smallest eigenvalue $\mu_1(H_{c,\omega})$ of $H_{c,\omega}$ is such that

$$\mu_1(H_{c,\omega}) = \inf_{\mathbf{w}\in X,||\mathbf{w}||=1}\langle H_{c,\omega}\,\mathbf{w},\mathbf{w}\rangle.$$

Thus,

$$\mu_1(H_{c,\omega}) \le \langle H_{c,\omega}\,\tilde{\mathbf{w}},\tilde{\mathbf{w}}\rangle = \langle\tilde{\mathcal{L}}_1\tilde{z}_1,\tilde{z}_1\rangle = \kappa\langle\tilde{z}_1,\tilde{z}_1\rangle < 0;$$

i.e., $H_{c,\omega}$ has at least one negative eigenvalue. Similarly, the second smallest eigenvalue $\mu_2(H_{c,\omega})$ of $H_{c,\omega}$ is given by

$$\mu_2(H_{c,\omega}) = \sup_{\phi_1\in X}\ \inf_{\mathbf{w}\in X,||\mathbf{w}||=1,\mathbf{w}\perp\phi_1}\langle H_{c,\omega}\,\mathbf{w},\mathbf{w}\rangle.$$

Choose $\tilde{\phi}_1 \neq \mathbf{0}$ such that $\tilde{\phi}_1 = [0,0,0,\tilde{\varphi}_1,\tilde{\varphi}_2,0]^T$ with $[\tilde{\varphi}_1,\tilde{\varphi}_2]^T = M^{-1}\,[1,0]^T \perp M^{-1}\,[0,1]^T$. Then, $\mathbf{w}\perp\tilde{\phi}_1$ is equivalent to having the z_1 variable associated with $\mathbf{w}$ equal to zero, the other variables being arbitrary. Thus,

$$\begin{aligned}&\mu_2(H_{c,\omega}) \\ &\ge \inf_{\mathbf{w}\in X,||\mathbf{w}||=1,\mathbf{w}\perp\tilde{\phi}_1}\langle H_{c,\omega}\,\mathbf{w},\mathbf{w}\rangle \\ &= \inf_{\substack{\mathbf{w}\in X,\\ ||\mathbf{w}||=1,\\ z_1=0}}\left[\left|\left|D\,w_1 + D^{-1}C\,w_2\right|\right|^2 + \left|\left|\sqrt{1-c^2}\,\partial_x y_3 + K\begin{pmatrix}y_1\\ y_2\end{pmatrix}\right|\right|^2 + \langle\tilde{\mathcal{L}}_2\,z_2,z_2\rangle\right] \\ &\ge \inf_{\mathbf{w}\in X,||\mathbf{w}||=1,z_1=0}\langle\tilde{\mathcal{L}}_2\,z_2,z_2\rangle = 0,\end{aligned}$$

the last equality being a consequence of the fact that $\tilde{\mathcal{L}}_2$ has the bottom of its point spectrum at zero. Thus, $H_{c,\omega}$ has at most one negative eigenvalue. Since it also has at least one negative eigenvalue, $H_{c,\omega}$ has exactly one negative eigenvalue.

3.4. Continuous spectrum of $H_{c,\omega}$. To find the continuous spectrum of $H_{c,\omega}$, we define

$$H^{\infty}_{c,\omega} \equiv \lim_{x\to\infty} H_{c,\omega} = \begin{pmatrix} D^2 & C \\ C^* & L^{\infty} \end{pmatrix}, \tag{3.26}$$

where C and D are given in (3.13) and

$$L^{\infty} = \begin{pmatrix} 2\left(-c_0^2\,\partial_{xx} - \mu\right) & 0 & 0 \\ 0 & 2\left(-c_0^2\partial_{xx} - \mu\right) & 0 \\ 0 & 0 & -\partial_{xx} \end{pmatrix}. \tag{3.27}$$

The continuous spectrum of $H_{c,\omega}$ is then given [22, Theorem A.2, p. 140] by the set

$$S = \left\{\lambda \in \mathbb{C} \,:\, \det\left(H^{\infty}_{c,\omega}(k) - \lambda\, I_6\right) = 0 \ \text{ for some } \ k \in \mathbb{R}\right\}, \tag{3.28}$$

where $H^{\infty}_{c,\omega}(k)$ is obtained from $H^{\infty}_{c,\omega}$ by replacing ∂_x with $i\,k$. The six eigenvalues of $H^{\infty}_{c,\omega}(k)$ are

$$\begin{aligned} \lambda_1^{\pm}(k) &= \frac{1}{2}\left(1 + k^2 \pm \sqrt{(1-k^2) + 4k^2c^2}\right), \\ \lambda_2^{\pm}(k) &= -\mu + c_0^2k^2 + 1 \pm \sqrt{(\mu + 1 - c_0^2k^2)^2 + 4(\omega - kc)^2}, \\ \lambda_3^{\pm}(k) &= -\mu + c_0^2k^2 + 1 \pm \sqrt{(\mu + 1 - c_0^2k^2)^2 + 4(\omega + kc)^2}. \end{aligned}$$

We now show that $\lambda_1^{\pm}(k) \geq 0$ and that $\lambda_{2,3}^{\pm}(k) > 0$ for all k's. First, the condition $\lambda_1^{\pm}(k) \geq 0$ is equivalent to $4k^2(1-c^2) \geq 0$, which is always satisfied since $c^2 < 1$, by the second inequality of (2.5). Since $\lambda_1^{-}(0) = 0$, the set $\{\lambda_1^{\pm}(k),\ k \in \mathbb{R}\}$ is in fact equal to $[0, +\infty)$. Second, the condition $\lambda_2^{\pm}(k) > 0$ is equivalent to $P(k) \equiv \omega^2 - 2\,k\,c\,\omega + \mu + (c^2 - c_0^2)\,k^2 < 0$. To see that this condition is satisfied for all k's, we proceed as follows. Note that as $k \to \pm\infty$, $P(k)$ is negative since $c^2 < c_0^2$ by the first inequality of (2.5). The derivative of P vanishes at $k = k_0 \equiv c\,\omega/(c^2 - c_0^2)$, and P reaches its maximum at that point. Substitution of the expression of k_0 into the formula for $P(k)$ gives

$$P(k_0) = \frac{\mu}{c^2 - c_0^2}\left[c^2 - c_0^2\left(1 + \frac{\omega^2}{\mu}\right)\right],$$

which is strictly negative since $\mu < 0$ by hypothesis and since $c^2 - c_0^2(1 + \omega^2/\mu) < 0$, whence $c^2 - c_0^2 < 0$, by the first inequality of (2.5). Thus, $\lambda_2^{\pm}(k) > 0$ for all k's. Finally, since the above argument does not depend on the sign of ω and since $\lambda_3^{\pm}(k)$ can be obtained from $\lambda_2^{\pm}(k)$ by changing ω into $-\omega$, we also have that $\lambda_3^{\pm}(k) > 0$ for all k's. Therefore, S is the whole nonnegative real axis.

A similar calculation shows that the continuous spectrum of $J\,H_{c,\omega}$ is the whole imaginary axis, and therefore contains the origin. This was to be expected since the symmetry $B \to B + \text{constant}$ of (2.1) indicates that the origin is in the continuous spectrum of the linearization of (2.1) about any solution whose B-component converges to a constant as ξ goes to infinity. Given this, it is also not surprising that the continuous spectrum of $H_{c,\omega}$ touches the origin, as shown above.

An important consequence of this discussion is that the stability theorems of [12] are not directly applicable, since the hypothesis that the positive subspace of $H_{c,\omega}$

be closed is not satisfied. As already mentioned in the introduction, the presence of continuous spectrum of $H_{c,\omega}$ all the way to the origin—or, as exemplified by the above calculations, the fact that the continuous spectrum of $J\,H_{c,\omega}$ includes the origin—typically rules out the possibility of having nonlinear stability results for perturbations $\mathbf{w} \in X$. In the next section, we thus restrict ourselves to the question of the spectral stability of pulse solutions. We show that the theorems of [12] can be adapted to the present situation, and obtain a necessary and sufficient condition for the spectral stability of the family of pulses.

4. Spectral stability criterion. Consider the scalar function of c and ω given by

$$d(c,\omega) = E(\mathbf{v}_0) - c\,Q_1(\mathbf{v}_0) - \omega\,Q_2(\mathbf{v}_0), \tag{4.1}$$

where E, Q_1, and Q_2 are defined in (2.9), (3.5), and (3.6) and $\mathbf{v}_0 = [r_0, s_0, u_0, p_0, q_0, b_0]^T$ is, as before, the six-dimensional solution of (3.8) defined by (3.1) with a_0 and b_0 given in (2.3). Note that d defined in (4.1) depends on c and ω both explicitly and implicitly through the dependence of $\mathbf{v}_0$ on c and ω.

Even though Assumption 3 of [12] is not satisfied here since the positive subspace of $H_{c,\omega}$ is not closed (in other words, since the continuous spectrum of $H_{c,\omega}$ is not bounded away from zero), the following theorems carry through.

THEOREM 1 (from Theorem 3.1 of [12]). *Let* $X_1 = \{\mathbf{u} \in X | \langle Q_i'(\mathbf{v_0}), \mathbf{u}\rangle = 0,\ i = 1, 2\}$, *and* Π_1 *be the orthogonal projection of* X *onto* X_1. *If* d *is nondegenerate, the reduced Hamiltonian* $H_1 = \Pi_1^*\,H_{c,\omega}\,\Pi_1$ *has the negative index (i.e., a negative subspace of dimension)*

$$n(H_1) = n(H_{c,\omega}) - p\,(d''), \tag{4.2}$$

where $p\,(d'')$ *is the number of positive eigenvalues of the Hessian* d'' *of* d, *and* $n(H_{c,\omega})$ *is the dimension of the negative subspace of* $H_{c,\omega}$.

In our case, $n(H_{c,\omega}) = 1$, and (4.2) therefore implies that

$$p\,(d'') \leq 1. \tag{4.3}$$

THEOREM 2 (from Theorem 5.1 of [12]). *Let* d'' *be nonsingular,* $n(H_{c,\omega}) - p\,(d'')$ *be odd, and* X *be separable. Then* $J\,H_{c,\omega}$ *has at least one pair of real nonzero eigenvalues.*

Note that only nonnegativity of the bilinear form $\langle H_{c,\omega}\,\mathbf{u}, \mathbf{u}\rangle$ on the closure of the positive subspace of $H_{c,\omega}$ is needed in the proof of this theorem given in [12].

Therefore, if

$$\det\,(d'') = d_{cc}\,d_{\omega\omega} - d_{c\omega}^2 > 0, \tag{4.4}$$

the number of positive eigenvalues of d'' is even, and by (4.3), it is equal to zero. Equation (4.2) of Theorem 1 then implies that $n(H_1) = n(H_{c,\omega}) = 1$, and by Theorem 2, the linearization $J\,H_{c,\omega}$ has at least one pair $(\lambda, -\lambda)$, $\lambda \in \mathbb{R}$, of real nonzero eigenvalues. Thus, the linearization of (2.1) about a pulse solution has positive point spectrum, and the pulse solution is dynamically unstable (section VI of [12]). Condition (4.4) reads

$$\begin{aligned} &-12\,c^2{c_0}^4\left(c_0^2-1\right)\left(-3\,{c_0}^2+2\,c^2+c^4\right)\omega^4 \\ &-18\,\mu\,{c_0}^2\left(c^4-3\,c^2{c_0}^2+c^2+{c_0}^2\right)\left(c^2-c_0^2\right)^2\omega^2 \\ &+3\,\left(c^2-1\right)\mu^2\left(c^4{c_0}^2+2\,c^4-9\,c^2{c_0}^2+6\,{c_0}^4\right)\left(c^2-c_0^2\right)^2 > 0. \end{aligned} \tag{4.5}$$

In the case $\omega = 0$, we see that pulses are thus unstable if

$$T \equiv 3c_0^2\left(3c^2 - 2c_0^2\right) - c^4\left(c_0^2 + 2\right) > 0, \tag{4.6}$$

since $c^2 - 1 < 0$. This is exactly the condition found in [14] by means of Evans function techniques. As discussed in [14], the condition $T > 0$ defines a nonempty set of speeds c. There also exists values of c such that $T < 0$. For instance, the stable propagation of a pulse solution with $\omega = 0$, and for which $T = -27.078$, is illustrated in the numerical simulation of Figure 11 of [15] (or equivalently Figure 1 of [14]).

We now show that if $\det(d'') < 0$, $J\,H_{c,\omega}$ has no positive point spectrum. In this case, since the continuous spectrum of the linearization $J\,H_{c,\omega}$ is on the imaginary axis, this operator has no positive spectrum, and the corresponding pulse solution is therefore spectrally stable. First note that if $\det(d'') < 0$, then $p\,(d'') = 1$ and $n(H_1) = 0$ by Theorem 1 above. We now prove that $n(H_1) = 0$ implies that it is not possible for $J\,H_{c,\omega}$ to have any nonzero eigenvalue. Suppose that $\mathbf{y}$ is an eigenvector of $J\,H_{c,\omega}$ with nonzero eigenvalue a. Then $\mathbf{y} \in X_1$, where X_1 is defined in Theorem 1. Indeed, for $i = 1, 2$, we have

$$\begin{aligned}
\langle Q_i'(\mathbf{v_0}), \mathbf{y}\rangle &= \langle \mathcal{B}_i\,\mathbf{v_0}, \mathbf{y}\rangle \qquad \text{by (A.6)} \\
&= \langle J^{-1}\,T_i'(0)\,\mathbf{v_0}, \mathbf{y}\rangle \qquad \text{since } J\,\mathcal{B}_i \text{ is an extension of } T_i'(0) \\
&= \langle J^{-1}\,T_i'(0)\,\mathbf{v_0}, a^{-1}JH_{c,\omega}\,\mathbf{y}\rangle \\
&= -\langle a^{-1}H_{c,\omega}\,\mathbf{y}, T_i'(0)\,\mathbf{v_0}\rangle \qquad \text{since } J \text{ is skew} \\
&= -\langle H_{c,\omega}\,T_i'(0)\,\mathbf{v_0}, a^{-1}\,\mathbf{y}\rangle = 0,
\end{aligned}$$

since $T_i'(0)\,\mathbf{v_0}$ is in the kernel Z of $H_{c,\omega}$ by (A.11) with T replaced by T_i. Note that X_1 contains Z, since (see [12, p. 316]) if $\mathbf{z} \in Z$, then

$$\forall \sigma = [c_1, \omega_1]^T, \qquad 0 = \langle H_{c,\omega}\,\mathbf{z}, \partial_\sigma \mathbf{v_0}\rangle = \langle H_{c,\omega}\,\partial_\sigma \mathbf{v_0}, \mathbf{z}\rangle = \langle Q'(\mathbf{v_0})\;\sigma, \mathbf{z}\rangle,$$

where $Q'(\mathbf{v_0})$ is defined at the end of section 3.1, and we made use of (3.10). Then, let (see equation (5.1) of [12])

$$X_2 = \left\{\mathbf{u} \in X \middle| \langle Q_i'(\mathbf{v_0}), \mathbf{u}\rangle = 0 = (T_i'(0)\,\mathbf{v_0}, \mathbf{u}),\ i = 1, 2\right\}.$$

From the definition of X_2, one has the orthogonal decomposition $X_1 = X_2 + Z$, and $\mathbf{y} \in X_1$ can therefore be written as $\mathbf{y} = \mathbf{x_2} + \mathbf{z}$ with $\mathbf{x_2} \in X_2$ and $\mathbf{z} \in Z$. Then,

$$\langle H_{c,\omega}\,\mathbf{y}, \mathbf{y}\rangle = \langle a\,J^{-1}\,\mathbf{y}, \mathbf{y}\rangle = 0$$

since J^{-1} is skew. This implies that $\langle H_{c,\omega}\,\mathbf{x_2}, \mathbf{x_2}\rangle = \mathbf{0}$ since

$$\langle H_{c,\omega}\,\mathbf{y}, \mathbf{y}\rangle = \langle H_{c,\omega}\,\mathbf{x_2}, \mathbf{x_2}\rangle + \langle H_{c,\omega}\,\mathbf{x_2}, \mathbf{z}\rangle = \langle H_{c,\omega}\,\mathbf{x_2}, \mathbf{x_2}\rangle.$$

As a consequence, $\langle H_1\,\mathbf{x_2}, \mathbf{x_2}\rangle = 0$. Finally, since $n(H_1) = 0$, H_1 is a nonnegative self-adjoint operator on X_1. By the spectral decomposition theorem, $\langle H_1\,\mathbf{x_2}, \mathbf{x_2}\rangle = 0$ implies $\mathbf{x_2} = \mathbf{0}$, whence $\mathbf{y} \in Z = \operatorname{Ker} H_{c,\omega}$. This contradicts the hypothesis that $\mathbf{y}$ is an eigenvector of $J\,H_{c,\omega}$ with nonzero eigenvalue a. Therefore, we have the following theorem.

THEOREM 3. *Let d'' be nonsingular. Then, pulse solutions of* (2.1) *given by* (2.2) *and* (2.3) *are spectrally stable if and only if $n(H_1) = 0$, i.e., if and only if* $\det(d'') < 0$.

In other words, pulses are unstable if condition (4.5) is satisfied, and they are spectrally stable if the left-hand side of (4.5) is negative. More generally, if $n(H_1) = 0$, i.e., if $n(H_{c,\omega}) = p(d'')$, and if d'' is nonsingular, then pulse solutions are spectrally stable.

5. Conclusion. We have obtained a necessary and sufficient condition for the spectral stability of a family of pulse solutions to two coupled Klein–Gordon equations. This analysis, based on Hamiltonian methods [11, 12], confirms and extends the results of [14] obtained by means of Evans functions techniques for nonrotating pulses, and also applies to the case of rotating pulses. As discussed in the introduction and in sections 3 and 4, the theorems of [12] do not directly apply here because the continuous spectrum of the linearization of the coupled Klein–Gordon equations about the family of pulse solutions contains the origin. As a consequence, one cannot use these results to establish orbital stability of the solutions. However, we have shown that one can modify the results of [12] in order to obtain spectral stability. The system of partial differential equations considered here models the near-threshold dynamics of an elastic rod with circular cross section. More general envelope equations taking into account other physical properties of elastic filaments, such as extensibility, the existence of a tension mode, or the presence of a noncircular cross section, can be found in the literature (see for example [23]). All of these equations can be written in Hamiltonian form and it should be possible to extend the analysis presented in this paper to these more general models.

Appendix A. Linearization about a coherent structure. This discussion is entirely based on Section II of [11], and is presented here to make this paper self-contained. Consider the following Hamiltonian system:

$$\frac{\partial \mathbf{u}}{\partial t} = J E'(\mathbf{u}), \tag{A.1}$$

where $\mathbf{u} \in X$, X is a real Hilbert space with inner product denoted by $(\cdot\,,\cdot)$, $J : X^* \to X$ is invertible and skew-symmetric (X^* is the dual of X), E is a functional of $\mathbf{u}$, and $E' : X \to X^*$ is its Fréchet derivative. Assume that $\mathbf{U}_s(x,t) = T(st)\ \mathbf{u}_s(x)$ is a solution of this system, where $T \equiv \{T(s) : X \to X,\ s \in \mathbb{R}\}$, is a one-parameter group of unitary transformations, which has the following properties:

1. T commutes with J, i.e.,

$$T(s)\, J = J\, T^*(-s), \tag{A.2}$$

   where $T^*(s)$ is the adjoint of $T(s)$.
2. E is invariant under T, i.e.,

$$E\,(T(s)\mathbf{u}) = E(\mathbf{u}) \tag{A.3}$$

   for all $\mathbf{u} \in X$ and for all $s \in \mathbb{R}$.

By taking the Fréchet derivative of (A.3) with respect to $\mathbf{u}$, one obtains

$$E'(\mathbf{u}) = T^*(s)\, E'(T(s)\mathbf{u}). \tag{A.4}$$

The conserved quantity associated with the invariance T is given by

$$Q(\mathbf{u}) = \frac{1}{2}\langle \mathcal{B}\mathbf{u}\,, \mathbf{u}\rangle, \tag{A.5}$$

where $\langle \mathbf{u}^*, \mathbf{v}\rangle \equiv (\mathbf{u}, \mathbf{v})$ for all $\mathbf{u}$, $\mathbf{v} \in X$ (and X is identified with X^{**}), and the linear operator $\mathcal{B} : X \to X^*$ is such that $J\,\mathcal{B}$ is an extension of $T'(0) : X \to X$ [11, 12, 16]. By differentiating (A.5), one obtains

$$Q'(\mathbf{u}) = \mathcal{B}\,\mathbf{u} \qquad \text{and} \qquad \mathcal{B} = Q''(\mathbf{u}), \qquad \forall\ \mathbf{u} \in X. \tag{A.6}$$

Since T is a representation of a one-parameter group of operators, we have $T(s+\epsilon) = T(s)\,T(\epsilon),\ \forall\,(s,\epsilon) \in \mathbb{R}^2$, which implies

$$T'(s) = T'(0)\,T(s). \tag{A.7}$$

To see that Q is invariant under T, calculate

$$\begin{aligned}
\frac{d}{ds}\left[Q(T(s)\mathbf{u})\right] &\equiv \langle Q'(T(s)\,\mathbf{u}), T'(s)\,\mathbf{u}\rangle \\
&= \langle Q'(T(s)\,\mathbf{u}), T'(0)\,T(s)\,\mathbf{u}\rangle \qquad \text{by (A.7)} \\
&= \langle Q'(T(s)\,\mathbf{u}), J\,\mathcal{B}\,T(s)\,\mathbf{u}\rangle \qquad \text{since } J\,\mathcal{B} \text{ extends } T'(0) \\
&= \langle B\,T(s)\,\mathbf{u}, J\,\mathcal{B}\,T(s)\,\mathbf{u}\rangle \qquad \text{by (A.6)} \\
&= 0 \qquad \text{since } \langle \mathbf{u}^*, J\,\mathbf{u}^*\rangle = 0,\ \forall\,\mathbf{u}^* \in X^*.
\end{aligned}$$

Thus, $Q(T(s)\,\mathbf{u}) = Q(\mathbf{u})$ and by differentiation

$$T^*(s)\ Q'(T(s)\,\mathbf{u}) = Q'(\mathbf{u}), \tag{A.8}$$

which, together with the first equation of (A.6), implies

$$T^*(s)\,\mathcal{B}\,T(s) = \mathcal{B}. \tag{A.9}$$

To perform a linear stability analysis of the coherent structure, let

$$\mathbf{u}(x,t) = T(st)\left(\mathbf{u}_s(x) + \mathbf{w}(x,t)\right),$$

and substitute into (A.1). We have

$$\begin{aligned}
\frac{\partial \mathbf{u}}{\partial t} &= \frac{\partial}{\partial t}\left[T(st)\left(\mathbf{u}_s(x) + \mathbf{w}(x,t)\right)\right] = s\,T'(st)\left(\mathbf{u}_s(x) + \mathbf{w}(x,t)\right) + T(st)\frac{\partial \mathbf{w}}{\partial t} \\
&= s\,T'(0)\,T(st)\left(\mathbf{u}_s(x) + \mathbf{w}(x,t)\right) + T(st)\frac{\partial \mathbf{w}}{\partial t} \qquad \text{by (A.7)} \\
&= s\,J\,\mathcal{B}\,T(st)\left(\mathbf{u}_s(x) + \mathbf{w}(x,t)\right) + T(st)\frac{\partial \mathbf{w}}{\partial t} \qquad \text{since } J\mathcal{B} \text{ is an extension of } T'(0) \\
&= s\,J\,T^*(-st)\,\mathcal{B}\left(\mathbf{u}_s(x) + \mathbf{w}(x,t)\right) + T(st)\frac{\partial \mathbf{w}}{\partial t} \qquad \text{by } (A.9) \\
&= s\,J\,T^*(-st)\,Q'(\mathbf{u}_s) + s\,J\,T^*(-st)\,Q''(\mathbf{u}_s)\,\mathbf{w} + T(st)\frac{\partial \mathbf{w}}{\partial t} \qquad \text{by } (A.6).
\end{aligned}$$

On the other hand,

$$\begin{aligned}
J\,E'(T(st)\left(\mathbf{u}_s + \mathbf{w}\right)) &= J\,T^*(-st)\,E'(\mathbf{u}_s + \mathbf{w}) \qquad \text{by (A.4)} \\
&= J\,T^*(-st)\,E'(\mathbf{u}_s) + J\,T^*(-st)\,E''(\mathbf{u}_s)\,\mathbf{w} + O\left(||\mathbf{w}||^2\right).
\end{aligned}$$

Since $T(st)\,\mathbf{u}_s$ is a solution of the Hamiltonian system, the terms which do not depend on $\mathbf{w}$ on each side of (A.1) written as

$$\frac{\partial}{\partial t}\left[T(st)\left(\mathbf{u}_s(x) + \mathbf{w}(x,t)\right)\right] = J\,E'(T(st)\left(\mathbf{u}_s + \mathbf{w}\right))$$

balance out, which implies

$$E'(\mathbf{u}_s) = s\,Q'(\mathbf{u}_s). \tag{A.10}$$

The rest of the equation reads, to first order in $\mathbf{w}$,

$$\begin{aligned} T(st)\frac{\partial \mathbf{w}}{\partial t} &= J\,T^*(-st)\,E''(\mathbf{u}_s)\,\mathbf{w} - s\,J\,T^*(-st)\,Q''(\mathbf{u}_s)\,\mathbf{w} \\ &= T(st)\,J\,(E''(\mathbf{u}_s) - s\,Q''(\mathbf{u}_s))\,\mathbf{w} \qquad \text{by (A.2).} \end{aligned}$$

By multiplying both sides of this equation by $T(-st)$, we obtain

$$\frac{\partial \mathbf{w}}{\partial t} = J\,(E''(\mathbf{u}_s) - s\,Q''(\mathbf{u}_s))\,\mathbf{w} \equiv J\,H_s\,\mathbf{w},$$

which is (1.3).

Finally, note that

$$E'(T(s)\,\mathbf{u}_s) - s\,Q'(T(s)\,\mathbf{u}_s) = T^*(-s)\,E'(\mathbf{u}_s) - T^*(-s)\,s\,Q'(\mathbf{u}_s) = 0$$

by (A.4), (A.8), and (A.10). Differentiation with respect to s at $s = 0$ gives

$$[E''(\mathbf{u}_s) - s\,Q''(\mathbf{u}_s)]\;T'(0)\,\mathbf{u}_s = 0,$$

i.e.,

$$H_s T'(0)\,\mathbf{u}_s = 0. \tag{A.11}$$

A REACTION DISPERSION SYSTEM AND RAMAN INTERACTIONS*

MICHAEL I. WEINSTEIN† AND VADIM ZHARNITSKY‡

Abstract. We consider the problem of amplification of an optical signal wave with an optical pump wave when both are propagating in the fundamental mode of a single mode optical waveguide. We introduce a system of Ginzburg–Landau type and study the radiation loss due to the nonlinear interaction between the signal and the pump waves. The linear dynamics are dispersive, while nonlinearity governs the transfer of energy from the pump wave to the signal wave. The strength of the effect is shown to depend on a dimensionless parameter, which is given by the ratio of the diffraction length and amplification length. If this parameter is small, then the radiation loss is small. This result is established by (i) verifying the absence of resonant terms that can potentially drive the growth of radiative components and (ii) then by estimating the oscillatory (nonresonant) terms by proving the relevant PDE a priori estimates. These estimates require appropriate bounds on the solutions of the PDE, whose only conserved integral is the L^2 norm. However, the special structure of the nonlinear term, dictated by the physics of the Raman effect, implies a weak space-time bound involving the signal and pump intensities. This bound and L^2 conservation are used together with Strichartz (space-time) estimates for the Schrödinger equation to obtain control of stronger classical norms of the signal and pump fields.

1. Introduction.

In this paper we study a system of nonlinear and dispersive partial differential equations, where nonlinearity is of "reaction" type, i.e., in the absence of dispersion it induces pure energy exchange between the fields. Such systems are reminiscent of reaction-diffusion systems; here the diffusive mechanism is replaced by dispersion. While the latter has been widely studied, the former has received very little attention.

Our reaction-dispersion system arises naturally in mathematical modeling of the stimulated Raman process, but will also arise in other systems (perhaps in somewhat modified form), where two dispersive waves interact nonlinearly, while other nonlinear effects (such as self-phase modulation) and diffusion are negligible. This system can be also considered as a special case of complex Ginzburg–Landau (CGL) system, which has been studied in a different parameter regime [2]. We will often refer to the systems (1.1) and (1.2) as the Raman model, due to their relation to the motivating physical context.

The Raman effect is one where light of one frequency, ω_s ("signal"), is amplified by light of a down shifted frequency, ω_p ("pump"). Taking the energy transfer characteristics of the Raman process into account as well as diffraction leads to the system

of nonlinear evolution equations, discussed in greater detail in Appendix A:

$$\begin{aligned} i\partial_t u_s &= -\Delta u_s + i\epsilon|u_p|^2 u_s, \\ i\partial_t u_p &= -\Delta u_p - i\epsilon|u_s|^2 u_p. \end{aligned} \tag{1.1}$$

More generally, we must include the Kerr effect in (1.1). This would introduce cross-phase and self-phase modulation terms of the types $\alpha_s|u_p|^2u_s + \beta_s|u_s|^2u_s$ and $\alpha_p|u_s|^2u_s+\beta_p|u_p|^2u_p$ with $\alpha_{s,p}$, $\beta_{s,p}$ real on the right-hand side of (1.1). We remark on the analysis of this more complete model at the end of this section; see Remark 1.1. In a waveguide setting, which is of importance in optical communications, the equations take the form

$$\begin{aligned} i\partial_t u_s &= Hu_s + i\epsilon|u_p|^2 u_s, \\ i\partial_t u_p &= Hu_p - i\epsilon|u_s|^2 u_p, \end{aligned} \tag{1.2}$$

where

$$H = -\Delta + V.$$

Here, $u_s = u_s(x,t)$ and $u_p = u_p(x,t)$ denote, respectively, the signal and pump complex electric field envelopes. Systems (1.1) and (1.2) are valid, assuming the *paraxial approximation*. Δ denotes the Laplace operator with respect to x ($x \in \mathbb{R}^1$ or $x \in \mathbb{R}^2$). The longitudinal coordinate (z), a *time-like* variable with which propagation distance is measured, is denoted by t. In the waveguide setting, the "potential" $V(x)$ is determined by the transverse refractive index profile of the waveguide. The parameter ϵ measures the size of the nonlinear effects relative to the linear effects (e.g., diffraction, dispersion). The particular application to optical communications is discussed in Appendix A.

Our study of systems (1.2) and (1.1) is motivated by a fundamental issue arising in the modeling of the Raman interaction in a waveguide setting. In optical communication applications, the weak signal field whose envelope encodes bits of information is amplified by the strong pump field. This process takes place in an optical fiber waveguide, with one transverse localized state or "guided mode" and radiation modes. Raman amplification of the signal is based on the intended net transfer of energy from the pump to the signal. Physicists have found that good agreement with experiment is achieved by an ODE model, in which one neglects the effect of nonlinear coupling of bound states to radiation modes:

$$\begin{aligned} &\partial_t I_s = \epsilon g_s I_s I_p, \\ &\partial_t I_p = -\epsilon g_p I_s I_p, \\ &I_s \sim |u_s|^2,\ I_p \sim |u_p|^2, \end{aligned} \tag{1.3}$$

where $g_{s,p}$ are coefficients depending on the properties of the fundamental modes, e.g., on frequency and the so-called effective area.

A satisfactory explanation for the above approximation has been lacking; see, for example, [3]. This motivated us to consider the Raman energy transfer problem in the context of the model (1.2). We have found an explanation for the above statement about energy transfer using ideas and methods of resonance and averaging. In particular, in Theorem 3.1 we establish that if the initial field energy, which is not small, is in the guided mode, then this property persists with negligible error on the

length scale of physical interest, $\mathcal{O}(\epsilon^{-1})$, and therefore the model (1.3) applies. Note that on the time interval of order ϵ^{-1}, the radiation of size ϵ can grow to become of order $\mathcal{O}(1)$ (since the rate of radiation change is of order $\mathcal{O}(\epsilon)$).

The proof of Theorem 3.1 requires a good understanding of the large time dynamics of the flow defined by (1.2). Thus we consider the question of global existence of the initial value problem for such systems and we have derived results of independent interest. The standard approach to controlling the large time dynamics is to first prove local in time existence of the solutions to the initial value problem in a "natural" Banach space. A "natural" space is often one in which the physically relevant conserved integrals are defined. We formulate initial value problem for system (1.2) as a system of integral equations and prove that there are local solutions using fixed point argument; see sections 2 and 4. Global existence in time then follows from an appropriate a priori bound on the norm of this Banach space. If this norm remains bounded in terms of conserved integrals of the flow, global existence holds.

The ideas we use to prove global existence apply to both systems (1.1) and (1.2). Equations (1.1) and (1.2) have the L^2 (energy) conservation law

$$\mathcal{P}[u_s(t), u_p(t)] \equiv \int_{-\infty}^{+\infty} (|u_s|^2 + |u_p|^2)\, dx = \mathcal{P}[u_s(0), u_p(0)] \equiv \mathcal{P}_0. \tag{1.4}$$

Unfortunately, L^2 is a very weak space in which to control the nonlinear flow. Unlike the nonlinear Schrödinger equation, a Hamiltonian system, (1.2) and (1.1) do not have a second conserved integral (Hamiltonian), which controls $\|\nabla u_{s,p}\|_{L^2}$, and from which sufficient a priori control follows for global existence to hold.

We find that the key to a global existence theory is the following space-time integral a priori bound, which is a consequence of the form of the nonlinear Raman interaction terms:

$$\int_0^T dt \int |u_s|^2 |u_p|^2\, dx \le \frac{1}{2}\mathcal{P}_0. \tag{1.5}$$

Remark 1.1. We believe our theory can be extended to system (1.1) with Kerr effect included. An essential ingredient is the space-time estimate (1.5), which holds for the more general system. However, a more technical analysis is required to obtain closed space-time estimates in the presence of Kerr effect terms. This is work in progress.

Outline of the paper. The paper is structured as follows. We first consider system (1.2) in one space dimension and one time dimension. In section 2 we prove global well-posedness for the solution of the initial value problem. The key to this result are certain a priori estimates, whose point of departure is the L^2 conservation law (1.4) and the space-time a priori bound (1.5). This space-time estimate implies that (1.2) may be viewed as an inhomogeneous system of equations for u_s and u_p, with a source term, which is bounded in a space-time norm. Strichartz estimates [8] are then used to bound u_s and u_p individually in space-time norms and then finally in classical Sobolev norms. In section 3 the energy transfer from the bound mode of a single mode waveguide to radiation modes is studied by estimating nonresonant oscillating terms. Section 4 contains a theory of well-posedness in the case of two transverse dimensions. Finally, there are three appendices: one with a detailed discussion of the motivating application to optical communications, the second one in which we prove the normal form result, based on the symmetries of the system, and the third one describing numerical simulations.

2. Existence theory on $\mathbb{R}^1$. In this section we prove that system (1.2) has a unique global solution in an appropriate (physical) function space. In subsection 2.1 we provide the required operator estimates we shall require. In subsection 2.2 we derive certain a priori bounds which are satisfied by solutions of (1.2). In subsection 2.3 existence in a "weak" space is proved. In section 2.4 it is shown how to extend these results to H^s.

2.1. Estimates for the linear flow. We first introduce the fundamental solution of the Schrödinger equation.

(1) The solution of the initial value problem

$$i\partial_t u = -\partial_x^2 u, \quad u(0,x) = f \tag{2.1}$$

is denoted by $U_0(t)f$ and $U_0(t)$ is called the free propagator.

(2) The solution of the initial value problem

$$i\partial_t u = (-\partial_x^2 + V(x))u = Hu, \quad u(0,x) = f \tag{2.2}$$

is denoted by $U(t)f$.

The operator, H, may have spectrum consisting of continuous and discrete parts, with associated spectral projections P_c and $P_b = I - P_c$. We shall assume that H has finitely many point eigenvalues. Intuitively, on the range of P_c we expect $U(t)$ to behave dispersively in a manner similar to $U_0(t)$. We use dispersive estimates which involve space-time integrals, often referred to as estimates of Strichartz type; see [8] and [9]. The proofs of the space-time estimates for the free Schrödinger equation in the form we use are due to Ginibre and Velo [12] and, in the inhomogeneous case, to Yajima [10] and Cazenave and Weissler [11]. For complete proofs see, for example, Theorems 3.3 and 3.4 of [4].

We now introduce the function spaces and the notation of an *admissible pair* in terms of which the space-time estimates are expressed.

(3) For a real interval I and a Banach space X, we denote by $L^p(I,X)$ the Banach space of functions $u : I \to X$ for which $\int_I \|u(t)\|_X^p \, dt$ is finite.

(4) A pair of real numbers (q,r) is called *admissible* (for dimension $n = 1$) if

$$\frac{2}{q} = \frac{1}{2} - \frac{1}{r}, \quad r \in [2,\infty]. \tag{2.3}$$

We now state Strichartz-type estimates for $U(t)$ for the initial value problem (2.2) and the inhomogeneous problem

$$i\partial_t u = Hu + P_c g. \tag{2.4}$$

THEOREM 2.1. *Assume that V satisfies*

$$\int_{-\infty}^{+\infty} |V(x)|(1+|x|)^{5/2} \, dx < \infty. \tag{2.5}$$

Thus, H has finitely many negative eigenvalues and continuous spectrum extending from 0 to $+\infty$, with associated spectral projections P_b and P_c.[1]

[1] Finiteness of negative discrete spectrum and continuity of spectrum from $[0,\infty)$ follows from sufficient decay of the potential.

Let (q,r) be an admissible pair. For any $f \in L^2$, $U_0(t)f$ and $U(t)P_cf$ are of class $L^q(\mathbb{R}, L^r)$ and satisfy the estimates

$$\begin{aligned} \|U_0(\cdot)f\|_{L^q([0,T],L^r)} &\le C\|f\|_{L^2}, \\ \|U(\cdot)P_cf\|_{L^q([0,T],L^r)} &\le C\|f\|_{L^2}, \end{aligned} \tag{2.6}$$

where C depends only on q.

THEOREM 2.2. *Let V satisfy* (2.5) *and let (γ,ρ) be an admissible pair $(2/\gamma = 1/2 - 1/\rho)$, $f \in L^{\gamma'}([0,T], L^{\rho'})$, where (γ',ρ') is conjugate to (γ,ρ). Then for any admissible pair (q,r) $(2/q = 1/2 - 1/r)$*

$$\begin{aligned} \left\| \int_0^t U_0(t-\tau)f(\tau)d\tau \right\|_{L^q([0,T],L^r)} &\le C\|f\|_{L^{\gamma'}([0,T],L^{\rho'})}, \\ \left\| \int_0^t U(t-\tau)P_cf(\tau)d\tau \right\|_{L^q([0,T],L^r)} &\le C\|f\|_{L^{\gamma'}([0,T],L^{\rho'})}, \end{aligned} \tag{2.7}$$

where C depends only on q, γ.

The proofs rely on the $L^p - L^{p'}$ estimates for the free Schrödinger equation

$$\|U_0(t)f\|_{L^p} \le (4\pi|t|)^{-\frac{1}{2}+\frac{1}{p}} \|f\|_{L^{p'}}. \tag{2.8}$$

In the case of a Schrödinger equation with a potential in one space dimension the analogous estimate for $U(t)P_c$ was established by Weder [5]. Adapting the proofs in [4], for the free propagator $U_0(t)$, and using Weder's estimate, one obtains the Strichartz-type estimates for Schrödinger equation with a potential.

The following corollary, easily derived from the previous estimates by a change of variables, concerns the dependence of space-time estimates on a parameter, which arises when we rescale (1.2).

COROLLARY 2.3. *Consider a one-parameter family of Schrödinger initial value problems*

$$\begin{aligned} i\partial_t u &= \beta H u, \\ u(x,0) &= f(x), \end{aligned} \tag{2.9}$$

where $\beta \in [\beta_0, \infty)$ with $\beta_0 > 0$. Assume that the potential, $V(x)$, satisfies (2.5). *Then, the conclusions of Theorems* 2.1 *and* 2.2 *hold with β-dependent constants. In particular, if $U_\beta(t)f = U(\beta t)f$ denotes the solution of the initial value problem* (2.9), *then*

$$\|U_\beta(\cdot)P_cf\|_{L^q([0,T],L^r)} \le C_1(\beta,q)\|f\|_{L^2}, \tag{2.10}$$

$$\left\| \int_0^t U_\beta(t-\tau)P_cf(\tau)d\tau \right\|_{L^q([0,T],L^r)} \le C_2(\beta,q,\gamma')\|f\|_{L^{\gamma'}([0,T],L^{\rho'})}, \tag{2.11}$$

where

$$C_1(\beta,q) = C_{11}(q)\beta^{-\frac{1}{q}}, \qquad C_2(\beta,q,\gamma') = C_{22}(q,\gamma')\beta^{-1-\frac{1}{q}+\frac{1}{\gamma'}}. \tag{2.12}$$

In [6], Weder proves continuity of wave operators for (2.2). We use a special case of the main theorem from [6].

PROPOSITION 2.4. *Let V satisfy* (2.5). *Then, there exist wave operators Ω and Ω^* satisfying*

$$\Omega(I-\Delta)\Omega^* = (I+H)P_c. \tag{2.13}$$

These operators are continuous in H^1:

$$\|\Omega f\|_{H^1} \le C\|f\|_{H^1}, \qquad \|\Omega^* f\|_{H^1} \le C\|f\|_{H^1}. \tag{2.14}$$

2.2. A priori space-time estimates. Essential in the proof that system (1.2) defines the solution globally in time and that the solution does not develop singularities are a priori estimates which we now derive. For convenience, we rescale the time $\epsilon t = t_{\text{new}}$, so the uniform bound on the interval $t_{\text{new}} \in [0,T]$ will correspond to the interval $[0,T/\epsilon]$ in old time. We will continue to use t as the time variable

$$\partial_t u_s + i\beta H u_s = |u_p|^2 u_s, \tag{2.15}$$

$$\partial_t u_p + i\beta H u_p = -|u_s|^2 u_p, \tag{2.16}$$

where $\beta := \epsilon^{-1}$ is a dispersion/diffraction parameter and $\beta \in [\beta_0, \infty]$.

Multiplication of (2.15) by $\overline{u_s}$, taking the real part of the resulting equation and integrating over all gives

$$\frac{d}{dt}\int |u_s|^2\,dx = 2\int |u_s|^2|u_p|^2\,dx. \tag{2.17}$$

Similarly, multiplication of (2.16) by $\overline{u_p}$ yields

$$\frac{d}{dt}\int |u_p|^2\,dx = -2\int |u_s|^2|u_p|^2\,dx. \tag{2.18}$$

Equations (2.17) and (2.18) express the gain of signal energy at the expense of pump energy and the depletion of pump energy at the expense of signal energy; see (1.2).

Addition of (2.17) and (2.18) yields the conservation law

$$\frac{d}{dt}\int |u_s|^2 + |u_p|^2\,dx = 0 \tag{2.19}$$

or

$$\int |u_s|^2 + |u_p|^2\,dx = \int |u_s(0)|^2 + |u_p(0)|^2\,dx \equiv \mathcal{P}_0. \tag{2.20}$$

An important step in our analysis is to use the *energy dissipation identity* (2.18). Integration of (2.18) over time interval $[0,T]$ yields

$$2\int_0^T \int |u_s(x,t)|^2|u_p(x,t)|^2\,dx\,dt = \int |u_p(x,0)|^2\,dx - \int |u_p(x,t)|^2\,dx. \tag{2.21}$$

A simple consequence of (2.21) is the following *space-time bound.*

PROPOSITION 2.5 (a priori space-time estimate). *Let (u_s,u_p) denote a solution of* (2.15)–(2.16) *in the sense of Theorem* 2.9. *Then,*

$$\int_0^T \int |u_s|^2|u_p|^2\,dx\,dt \le \frac{1}{2}\mathcal{P}_0. \tag{2.22}$$

Remark 2.6. Since in Theorem 2.9 we assume that the initial conditions are merely L^2, strictly speaking the above derivation of the bound (2.22) is not valid, since the manipulations require that the solution is a classical solution of the PDE, i.e., pointwise differentiable in space and time. At the end of section 2.3, we sketch a proof of (2.22) for the case of L^2 initial data.

Equations (2.16) and (2.15) can both be viewed as inhomogeneous Schrödinger equations of the form

$$i\partial_t U = \beta H U + g \tag{2.23}$$

with a source term g given by

$$g = |u_p|^2 u_s \quad \text{or} \quad g = -|u_s|^2 u_p. \tag{2.24}$$

We next show that the a priori estimate (2.22) implies bounds on the source terms (2.24) which are suitable for application of the inhomogeneous Strichartz estimate of Theorem 2.2.

PROPOSITION 2.7. *Let g denote either term in* (2.24). *Then, for any $T > 0$ and any $\kappa \in [0, 2]$,*

$$\int_0^T \left| \int |g|\, dx \right|^\kappa \, dt \le 2^{-\frac{\kappa}{2}} \mathcal{P}_0^\kappa T^{\frac{2-\kappa}{2}}. \tag{2.25}$$

In particular, for $\kappa \in [1, 2]$ and $g \in L^\kappa([0, T], L^1)$,

$$\|g\|_{L^\kappa([0,T],L^1)} \le 2^{-\frac{1}{2}} \mathcal{P}_0 T^{\frac{2-\kappa}{2k}}. \tag{2.26}$$

To prove Proposition 2.7, let $g = -|u_s|^2 u_p$. The proof for $g = |u_p|^2 u_s$ is analogous. By the Cauchy–Schwarz inequality,

$$\left| \int |u_s|^2 |u_p|\, dx \right| \le \left(\int |u_s|^2\, dx \right)^{\frac{1}{2}} \left(\int |u_s|^2 |u_p|^2\, dx \right)^{\frac{1}{2}}. \tag{2.27}$$

Squaring this inequality and integrating the result over the time interval $[0, T]$ yields, after using that the L^2 norm of u_s is bounded by $\mathcal{P}_0$, that

$$\int_0^T \left| \int |u_s|^2 |u_p|\, dx \right|^2 \, dt \le \frac{1}{2} \mathcal{P}_0^2. \tag{2.28}$$

This handles the case $\kappa = 2$. For $\kappa = 0$ the trivial bound of T holds. The result follows by interpolation.

Using the a priori bounds of Proposition 2.7 we can now estimate the solution in $L^q([0, T], L^r)$ spaces, for admissible (q, r).

THEOREM 2.8 (a priori bounds in $L^q([0, T], L^r)$). *Let (q, r) be an admissible pair; see* (2.3). *Then, any solution (u_s, u_p) of system* (2.15)–(2.16) *for $0 \le t \le T$ satisfies the bounds*

$$\begin{aligned} \|u_s\|_{L^q([0,T],L^r)} &\le C \left(\mathcal{P}_0 + \mathcal{P}_0^{\frac{1}{2}} \right) (T + 1), \\ \|u_p\|_{L^q([0,T],L^r)} &\le C \left(\mathcal{P}_0 + \mathcal{P}_0^{\frac{1}{2}} \right) (T + 1), \end{aligned} \tag{2.29}$$

where C depends only on q, γ, and β_0.

Proof of Theorem 2.8. We estimate $\|u_s\|_{L^q([0,T],L^r)}$. The corresponding estimate for u_p is similar. Equation (2.15) can be rewritten as an equivalent integral equation:

$$u_s(t) = U_\beta(t)u_s(0) + \int_0^t U_\beta(t-\tau)|u_p(\tau)|^2 u_s(\tau)d\tau. \tag{2.30}$$

To estimate the space-time norm of u_s, we apply Corollary 2.3 to the continuous spectral part and estimate the finite-dimensional (bound state) part of u_s separately. For ease of presentation we assume that H has only one spatial localized bound state solution, $\phi(x)$; the proof is the same for any finite number of bound states. Estimation of (2.30) using Corollary 2.3 gives

$$\begin{aligned}
&\|u_s\|_{L^q([0,T],L^r)} \\
&\quad\le C\left\|U_\beta(t)u_s(0) + \int_0^t U_\beta(t-\tau)|u_p(\tau)|^2 u_s(\tau)d\tau\right\|_{L^q([0,T],L^r)} \\
&\quad\le C_1(\|u_s(0)\|_{L^2} + \langle u_s(0),\phi\rangle\|\phi\|_{L^q([0,T],L^r)}) + C_2\|u_p^2 u_s\|_{L^{\gamma'}([0,T],L^{\rho'})} \\
&\qquad + \left\|\int_0^t U_\beta(t-\tau)\langle|u_p(\tau)|^2 u_s(\tau),\phi\rangle\phi d\tau\right\|_{L^q([0,T],L^r)} \\
&\quad\le C_1(1+T^{q^{-1}}\|\phi\|_{L^2}\|\phi\|_{L^r})\|u_s(0)\|_{L^2} + C_2\|u_p^2 u_s\|_{L^{\gamma'}([0,T],L^{\rho'})} \\
&\qquad + \left\|\int_0^t e^{-i\lambda(t-\tau)}\langle|u_p(\tau)|^2 u_s(\tau),\phi\rangle\phi d\tau\right\|_{L^q([0,T],L^r)}.
\end{aligned} \tag{2.31}$$

The last integral is estimated as follows: using that

$$\begin{aligned}
\left|\int_0^t \langle|u_p(\tau)|^2 u_s(\tau),\phi\rangle\phi d\tau\right| &\le \left|\int_0^t |\phi(x)|\int|\phi(x)|\cdot|u_p^2(x,\tau)u_s(x,\tau)|\,dxd\tau\right| \\
&\le |\phi(x)|\int_0^t \|\phi\|_{L^\rho}\cdot\|u_p^2 u_s\|_{L^{\rho'}}d\tau \\
&\le |\phi(x)|\cdot\|\phi\|_{L^\gamma([0,T],L^\rho)}\cdot\|u_p^2 u_s\|_{L^{\gamma'}([0,T],L^{\rho'})}
\end{aligned}$$

we have

$$\begin{aligned}
&\left\|\int_0^t e^{-i\lambda(t-\tau)}\langle|u_p(\tau)|^2 u_s(\tau),\phi\rangle\phi d\tau\right\|_{L^q([0,T],L^r)} \\
&\quad\le \|\phi\|_{L^\gamma([0,T],L^\rho)}\cdot\|\phi\|_{L^q([0,T],L^r)}\cdot\|u_p^2 u_s\|_{L^{\gamma'}([0,T],L^{\rho'})} \\
&\quad= \|\phi\|_{L^\rho}\cdot\|\phi\|_{L^r}\cdot\|u_p^2 u_s\|_{L^{\gamma'}([0,T],L^{\rho'})}\cdot T^{\gamma^{-1}+q^{-1}}.
\end{aligned}$$

Now Proposition 2.7 implies a bound on $\|u_p^2 u_s\|_{L^{\gamma'}([0,T],L^{\rho'})}$, where $\rho' = 1$ and $\gamma' \in [0,2]$. Note that the exponents γ and ρ, dual to γ' and $\rho' = 1$, form an admissible pair provided $\gamma = 4$ and $\gamma' = 4/3$.[2]

Setting $\gamma' = 4/3$ and $\rho' = 1$ in (2.31) and applying Proposition 2.7 with $\kappa = \gamma' = 4/3$ implies

$$\begin{aligned}
\|u_s\|_{L^q([0,T],L^r)} &\le C_1(1+T^{1/q}\|\phi\|_{L^2}\|\phi\|_{L^r})\|u_s(0)\|_{L^2} \\
&\quad + C_2\|u_p^2 u_s\|_{L^{\frac{4}{3}}([0,T],L^1)} + T^{1/4+1/q}\|\phi\|_{L^\infty}\|\phi\|_{L^r}\|u_p^2 u_s\|_{L^{\frac{4}{3}}([0,T],L^1)} \\
&\le C_1(1+T^{\frac{1}{q}})\mathcal{P}_0^{\frac{1}{2}} + C_2\mathcal{P}_0 T^{\frac{1}{4}} + C_3\mathcal{P}_0 T^{\frac{1}{2}+\frac{1}{q}} \le C(\mathcal{P}_0+\mathcal{P}_0^{\frac{1}{2}})(T+1),
\end{aligned} \tag{2.32}$$

[2]Indeed, since $1/\rho' + 1/\rho = 1$, $1/\gamma + 1/\gamma' = 1$, and $2/\gamma = 1/2 - 1/\rho$, we have $\rho = \infty$, $\gamma = 4$, and $\gamma' = 4/3$.

where C_1, C_2, C_3 depend on the corresponding norms of ϕ and we used that $4 \le q \le \infty$. This completes the proof of Theorem 2.8. □

2.3. Existence in $L^8(\mathbb{R}_+, L^4) \cap L^\infty(\mathbb{R}_+, L^2)$. In this subsection we prove existence of solutions in a function space $\mathcal{X}(T)$ defined by

$$\mathcal{X}(T) = L^8([0,T], L^4) \cap L^\infty([0,T], L^2) \tag{2.33}$$

with the norm

$$\|u\|_{\mathcal{X}(T)} = \|u\|_{L^8([0,T],L^4)} + \|u\|_{L^\infty([0,T],L^2)} \tag{2.34}$$

$$= \|u\|_{8,4} + \|u\|_{\infty,2}, \tag{2.35}$$

the latter being written when there is no ambiguity. For the two-dimensional field (u_s, u_p), we naturally define the norm

$$\|u_s, u_p\|_{\mathcal{X}(T)} = \|u_s\|_{\mathcal{X}(T)} + \|u_p\|_{\mathcal{X}(T)} = \|u_s\|_{8,4} + \|u_s\|_{\infty,2} + \|u_p\|_{8,4} + \|u_p\|_{\infty,2}. \tag{2.36}$$

Since Theorem 2.8 gives a priori control of solutions in $L^q([0,T], L^r)$ spaces for any admissible pairs (q,r), it is natural to obtain a local existence theorem in a space, where the maximal time of existence depends only on $L^q([0,T], L^r)$ bounds. Then, global existence follows from Theorem 2.8; see the discussion below.

Define the mapping

$$(u_s, u_p) \mapsto A_\beta(u_s, u_p) \equiv \left(A_\beta^{(s)}(u_s, u_p), A_\beta^{(p)}(u_s, u_p) \right), \tag{2.37}$$

where

$$A_\beta^{(s)}(u_s, u_p) = U_\beta(t) u_s(0) + \int_0^t U_\beta(t-\tau) |u_p(\tau)|^2 u_s(\tau) d\tau, \tag{2.38}$$

$$A_\beta^{(p)}(u_s, u_p) = U_\beta(t) u_p(0) - \int_0^t U_\beta(t-\tau) |u_s(\tau)|^2 u_p(\tau) d\tau. \tag{2.39}$$

Then, the above evolution equation has the equivalent formulation as a fixed point problem.

For initial data $(u_s(0), u_p(0)) \in L^2$, find $(u_s, u_p) \in \mathcal{X}(T)$ for some $T > 0$ such that

$$(u_s, u_p) = A_\beta(u_s, u_p). \tag{2.40}$$

Our local existence theorem is the following.

THEOREM 2.9 (local existence).

(1) *Given initial data $(u_s(0), u_p(0)) \in L^2$, there exist a $T > 0$ and a unique solution $(u_s, u_p) \in \mathcal{X}(T)$ of* (2.40). *This local solution satisfies the a priori estimate* (2.22).

(2) *Let $T_{\max} > 0$ denote the maximal time of existence. Either $T_{\max} = \infty$ (global existence in time) or*

$$T_{\max} < \infty \quad \text{and} \quad \limsup_{T \to T_{\max}} \|(u_s, u_p)\|_{\mathcal{X}(T)} = \infty. \tag{2.41}$$

Using the local existence theory of Theorem 2.9 and the a priori bounds of Theorem 2.8, we have $T_{\max} = \infty$. Therefore, the following result holds.

THEOREM 2.10 (global existence). *For any initial data* $(u_s(0), u_p(0))$ *in* L^2, (2.40) *has a unique global solution of class* $L^8(\mathbb{R}_+, L^4) \cap L^\infty(\mathbb{R}_+, L^2)$.

We need only prove the local existence Theorem 2.9. The proof follows from the next two propositions in which we establish that for L^2 initial conditions and T sufficiently small,

(i) the transformation A_β maps a specified ball $\mathcal{B}(T)$ in $\mathcal{X}(T)$ into itself and that

(ii) A_β is a contraction mapping on $\mathcal{B}(T)$.

PROPOSITION 2.11. *Let* $(u_s(0), u_p(0))$ *be in* L^2. *Define the ball in* $\mathcal{X}(T)$

$$\mathcal{B}(T) = \{(u_s, u_p) \in \mathcal{X}(T) : \|(u_s, u_p)\|_{\mathcal{X}(T)} \le 2C(\|u_s(0)\|_2 + \|u_p(0)\|_2)\}, \tag{2.42}$$

where C *is found in the proof below. There exists* $T_0 > 0$ *such that for any* $T < T_0$, *the ball is mapped into itself, i.e.,* $A_\beta(\mathcal{B}(T)) \subset \mathcal{B}(T)$ *for any* $\beta \in [\beta_0, \infty]$, *with* T_0 *depending on* β_0.

Proof of Proposition 2.11. We estimate the action of $A_\beta^{(s)}$. The estimation for $A_\beta^{(p)}$ is similar.

Following the proof of Theorem 2.8, we obtain a similar inequality

$$\begin{aligned}\|A_\beta^{(s)}(u_s, u_p)\|_{q,r} &\le \|U_\beta(t)u_s(0)\|_{q,r} + \left\|\int_0^t U_\beta(t-\tau)|u_p|^2 u_s\right\|_{q,r} \\ &\le C_1(1+T)\|u_s(0)\|_2 + C_2(1+T)\|u_p^2 u_s\|_{\gamma',\rho'},\end{aligned}$$

where C_1, C_2 depend on ϕ.

Estimation of the cubic term proceeds as follows. By the Cauchy–Schwarz inequality,

$$\begin{aligned}\|u_p^2 u_s\|_{\gamma',\rho'} &= \left[\int_0^T \left(\int |u_p^2 u_s|^{\rho'}\,dx\right)^{\gamma'/\rho'} dt\right]^{1/\gamma'} \\ &\le \left[\int_0^T \left(\int |u_p|^{4\rho'}\,dx\right)^{\gamma'/\rho'} dt\right]^{1/2\gamma'} \left[\int_0^T \left(\int |u_s|^{2\rho'}\,dx\right)^{\gamma'/\rho'} dt\right]^{1/2\gamma'}.\end{aligned}$$

Set $\rho' = 1$ and therefore $\gamma' = 4/3$. Then the last expression becomes

$$= \left[\int_0^T \left(\int |u_p|^4\,dx\right)^{4/3} dt\right]^{3/8} \left[\int_0^T \left(\int |u_s|^2\,dx\right)^{4/3} dt\right]^{3/8} \tag{2.43}$$

and by Hölder's inequality, applied to each factor, we have the bound

$$\begin{aligned}&\le \left[\left[\int_0^T \left(\int |u_p|^4\,dx\right)^2 dt\right]^{(2/3)\cdot(3/8)} \left[\int_0^T 1^3\,dt\right]^{(1/3)}\right]^{3/8} \left[\sup_t \|u_s(t)\|_2^{2\cdot(4/3)} T\right]^{3/8} \\ &\quad \le \|u_p\|_{8,4}^2 \|u_s\|_{\infty,2} T^{1/2}.\end{aligned}$$

Adding up all the terms, we obtain

$$\begin{aligned}\left\|A_\beta^{(s)}(u_s, u_p)\right\|_{\mathcal{X}(T)} &\le C(\|u_s(0)\|_2 + \|u_p\|_{8,4}^2 \|u_s\|_{\infty,2} T^{\frac{1}{2}})(1+T), \\ \left\|A_\beta^{(p)}(u_s, u_p)\right\|_{\mathcal{X}(T)} &\le C(\|u_p(0)\|_2 + \|u_s\|_{8,4}^2 \|u_p\|_{\infty,2} T^{\frac{1}{2}})(1+T),\end{aligned}$$

where $C = \max\{C_1, C_2\}$. Finally, combining the last two terms, we have

$$\|A_\beta(u_s, u_p)\|_{\mathcal{X}(T)} \le C(\|u_s(0)\|_2 + \|u_p(0)\|_2 + \|(u_s, u_p)\|^3_{\mathcal{X}(T)} T^{\frac{1}{2}})(1+T). \tag{2.44}$$

Assume now that $\|(u_s, u_p)\|_{\mathcal{X}(T)} \le 2C(\|u_s(0)\|_2 + \|u_p(0)\|_2)$ and that T is sufficiently small; then A_β maps $\mathcal{B}(T)$ into itself. This completes the proof of Proposition 2.11. ∎

PROPOSITION 2.12. *For $T < T_1 \le T_0$ sufficiently small, the transformation, A_β, is a contraction on $\mathcal{B}(T)$. That is,*

$$\|A_\beta(u_s, u_p) - A_\beta(v_s, v_p)\|_{\mathcal{X}(T)} \le q\|(u_s - v_s, u_p - v_p)\|_{\mathcal{X}(T)}, \tag{2.45}$$

where $0 < q < 1$.

Proof of Proposition 2.12. Consider the first component of the map. By Corollary 2.3,

$$\begin{aligned}\|A^{(s)}_\beta(u_s, u_p) - A^{(s)}_\beta(v_s, v_p)\|_{q,r} &\le C_2\||u_p|^2 u_s - |v_p|^2 v_s\|_{\frac{4}{3},1} \\ &\le \|u_p^2(u_s - v_s)\|_{\frac{4}{3},1} + \|u_p v_s(u_p - v_p)\|_{\frac{4}{3},1} \\ &\quad + \|v_p v_s(u_p - v_p)\|_{\frac{4}{3},1}.\end{aligned}$$

These terms are all estimated in a similar manner. We focus on the second term. First, by the Cauchy–Schwarz inequality,

$$\begin{aligned}\|u_p v_s(u_p - v_p)\|_{\frac{4}{3},1} &\le \left[\int_0^T \left(\int |u_p|^2 |v_s|^2\, dx\right)^{4/3} dt\right]^{3/8} \left[\int_0^T \left(\int |u_p - v_p|^2 dx\right)^{4/3} dt\right]^{3/8} \\ &\le \left[\int_0^T \left(\int |u_p|^2 |v_s|^2\, dx\right)^{4/3} dt\right]^{3/8} T^{3/8}\|u_p - v_p\|_{\infty,2}.\end{aligned}$$

Another application of the Cauchy–Schwarz inequality to the spatial integral in the first factor in the previous expression and then Hölder's inequality to the time integral gives

$$\begin{aligned}&\left[\int_0^T \left(\int |u_p|^4\, dx\right)^{4/3} dt\right]^{3/16} \left[\int_0^T \left(\int |v_s|^4\, dx\right)^{4/3} dt\right]^{3/16} T^{3/8}\|u_p - v_p\|_{\infty,2} \\ &\quad \le \|u_p\|_{8,4}\|v_s\|_{8,4} T^{\frac{2}{16}} T^{\frac{3}{8}} \|u_p - v_p\|_{\infty,2} = \|u_p\|_{8,4}\|v_s\|_{8,4} T^{1/2}\|u_p - v_p\|_{\infty,2} \\ &\quad \le \|u_p\|_{8,4}\|v_s\|_{8,4} T^{1/2}\|(u_s - v_s, u_p - v_p)\|_{\mathcal{X}(T)}.\end{aligned}$$

Adding the estimates for

$$\left\|A^{(s)}_\beta(u_s, u_p) - A^{(s)}_\beta(v_s, v_p)\right\|_{\mathcal{X}(T)} \quad \text{and} \quad \left\|A^{(p)}_\beta(u_s, u_p) - A^{(p)}_\beta(v_s, v_p)\right\|_{\mathcal{X}(T)} \tag{2.46}$$

and choosing, if necessary, $T_1 < T_0$, we obtain the contraction estimate. This completes the proof. ∎

Remark 2.13. Finally, we give a proof of the space-time bound for solutions with data in L^2.

(1) *Existence of solutions for very regular data.* Using that H^s is an algebra for $s > \frac{1}{2}$, it is standard to prove, by a contraction mapping argument, that for

data in H^s with $s \geq s_0 \geq 2$ there is a unique classical solution. However, this argument requires differentiation of the original system and as a consequence $V(x)$. This requires imposing unnecessary smoothness assumptions on V. To avoid such restrictions on V, we observe that the norms $\|\cdot\|_{H^2} = \|(I+H)P_c\cdot\|_{L^2}$ and $\|(I-\Delta)\cdot\|_{L^2}$ are equivalent, by Proposition 2.4; see also Proposition 2.15. Therefore, applying $(I + H)P_c$, which commutes with $U_\beta(\cdot)$, to the integral equation for (u_s, u_p), we can use standard estimates to obtain a classical solution. An argument of this type is implemented in section 2.4. Therefore, by the computation of section 2.2, this classical solution satisfies (2.22).

(2) *Continuity of solutions with respect to variations in the initial data.* Let (u_s, u_p) denote the solution corresponding to data $(u_s(0), u_p(0))$ and (v_s, v_p) denote the solution corresponding to data $(v_s(0), v_p(0))$. Both of these are fixed points of the operator A_β (see (2.37)) with the corresponding data. By the same estimate as in the proof of Proposition 2.12 we have (2.45) plus an additional data term on the right-hand side: $\|(u_s(0) - v_s(0), u_p(0) - v_p(0))\|_{L^2}$, where the Strichartz estimate for the free propagator is applied to the difference of initial conditions. In other words,

$$\|(u_s, u_p) - (v_s, v_p)\|_{q,r} \leq C\|(u_s(0) - v_s(0), u_p(0) - v_p(0))\|_{L^2}. \tag{2.47}$$

(3) *Convergence.* Finally, take a sequence of initial data in $H^s, s \geq s_0 \geq 2$, which converges in L^2 to a limit. For each member of this sequence, the solution satisfies the space-time bound (2.22). The right-hand side of (2.22) converges by convergence in L^2 of the data and the left-hand side of (2.22) converges by (2.47). Therefore, (2.22) holds on the interval of existence for any solution with L^2 data.

2.4. Existence in $H^1(\mathbb{R}^1_+)$. We consider the existence theory in H^1. In this section we prove the following theorem.

THEOREM 2.14. *Let $(u_s(0), u_p(0))$ be in H^1 and let the potential V satisfy* (2.5). *Then there exists a unique global solution for system* (1.2) *in $L^\infty(\mathbb{R}^1_+, H^1)$.*

We first observe that our proof of local existence, via the contraction mapping principle, extends to the space

$$\mathcal{X}_1(T) \equiv C([0,T], H^1) \cap \mathcal{X}(T). \tag{2.48}$$

In particular, one needs only to prove that A_β maps a ball to a ball in this smaller space and it is a contraction mapping there, for $T < T_2$, where $T_2 \leq T_1 \leq T_0$. This can be proven by applying $(H+I)^{\frac{1}{2}}P_c$ to the equations, using equivalence of norms (in the appropriate spaces): $\|(H+I)^{\frac{1}{2}}P_c\cdot\|_{L^2}$ and $\|\cdot\|_{H^1}$ and carrying out the standard energy estimates. We use $(H+I)P_c$ rather than $I-\Delta$ because functions of H commute with H and thus we avoid differentiation of the potential $V(x)$. Otherwise, we would require bounds on norms of $\partial_x V$.

If $T^*_{\max}$ denotes the maximal time of existence for the solution in $\mathcal{X}_1(T)$, then in view of the a priori estimates in $\mathcal{X}(T)$, global existence ($T^*_{\max} = \infty$) will follow from a priori bounds on (u_s, u_p) in H^1.

Let

$$\mathcal{A}_c \equiv (I + H)P_c. \tag{2.49}$$

Applying to system (2.15)–(2.16) operator $\mathcal{A}_c^{1/2}$, we obtain the inequality

$$\frac{\partial}{\partial t}\int (|\mathcal{A}_c^{1/2}u_s|^2 + |\mathcal{A}_c^{1/2}u_s|^2)dx \tag{2.50}$$

$$\leq 2\left|\int \left(\overline{\mathcal{A}_c^{1/2}u_s}\mathcal{A}_c^{1/2}(|u_p|^2u_s) - \overline{\mathcal{A}_c^{1/2}u_p}\mathcal{A}_c^{1/2}(|u_s|^2u_p)\right)dx\right|. \tag{2.51}$$

PROPOSITION 2.15. *Assume that V satisfies condition* (2.5). *Then the operator $\mathcal{A}_c^{1/2}(I-\Delta)^{-1/2}$ and its inverse are bounded in L^2; that is, for any $f \in L^2$ both $\mathcal{A}_c^{1/2}(I-\Delta)^{-1/2}f$ and $(I-\Delta)^{1/2}\mathcal{A}_c^{-1/2}f$ are bounded in L^2 and*

$$\|\mathcal{A}_c^{1/2}(I-\Delta)^{-1/2}f\|_{L^2} \le C\|f\|_{L^2}, \tag{2.52}$$

$$\|(I-\Delta)^{1/2}\mathcal{A}_c^{-1/2}f\|_{L^2} \le C\|f\|_{L^2}. \tag{2.53}$$

Proof. This proposition states that the $\|(I-\Delta)^{\frac{1}{2}}\|_{L^2}$ norm and $\|\mathcal{A}_c^{1/2}\cdot\|_{L^2}$ are equivalent. Then our strategy will be similar to the proof in the potential-free case (as if $\mathcal{A}_c^{1/2}$ were ∂_x).

We prove the proposition using Weder's result on the continuity of wave operators [6]. Under the conditions stated above, Weder proves that there exists wave operator Ω such that

$$\Omega(I-\Delta)\Omega^* = \mathcal{A}_c,$$

where Ω is a bounded continuous operator on H^1. Then, taking the square root, we obtain

$$\Omega(I-\Delta)^{-1/2}\Omega^* = \mathcal{A}_c^{-1/2}. \tag{2.54}$$

The square root exists since $\mathcal{A}_c = (I+H)P_c$ is a positive operator on the subspace corresponding to the continuous spectrum.

Now it is easy to verify (2.52):

$$\begin{aligned}\|\mathcal{A}_c^{1/2}(I-\Delta)^{-1/2}f\|_{L^2} &= \|\Omega(I-\Delta)^{1/2}\Omega^*(I-\Delta)^{-1/2}f\|_{L^2}\\ &= \|(I-\Delta)^{1/2}\Omega^*(I-\Delta)^{-1/2}f\|_{L^2} \le C\|\Omega^*(I-\Delta)^{-1/2}f\|_{H^1}\\ &\le C\|(I-\Delta)^{-1/2}f\|_{H^1} \le C\|f\|_{L^2},\end{aligned}$$

where we have used that Ω, Ω^* are isometries in L^2 and continuous in H^1. The other inequality (2.53) can be proved similarly. □

COROLLARY 2.16. *Let $f \in H^1 \cap \mathrm{Range}(P_c)$. Then*

$$\|\mathcal{A}_c^{1/2}f\|_2 \le C\|(I-\Delta)^{1/2}f\|_2, \tag{2.55}$$

$$\|(I-\Delta)^{1/2}f\|_2 \le \|\mathcal{A}_c^{1/2}f\|_2. \tag{2.56}$$

Proof. Let $f = (I-\Delta)^{1/2}g$ in (2.52), with $g \in H^1 \cap \mathrm{Range}(P_c)$. Then we have

$$\|\mathcal{A}_c^{1/2}g\|_{L^2} \le \|(I-\Delta)^{1/2}g\|_{L^2}.$$

To prove the other inequality (2.56), we write

$$\|(I-\Delta)^{1/2}f\|_{L^2} = \|(I-\Delta)^{1/2}\mathcal{A}_c^{-1/2}\mathcal{A}_c^{1/2}f\|_{L^2} \le \|\mathcal{A}_c^{1/2}f\|_{L^2}. \qquad \square$$

Proof of Theorem 2.14. First, using the above proposition, we estimate

$$\begin{aligned}\left|\int \left(\overline{\mathcal{A}_c^{1/2}u_s}\mathcal{A}_c^{1/2}(|u_p|^2u_s)\right)dx\right| &\le \|\mathcal{A}_c^{1/2}u_s\|_2 \cdot \|\mathcal{A}_c^{1/2}(|u_p|^2u_s)\|_2\\ &= \|\mathcal{A}_c^{1/2}u_s\|_2 \cdot \|\mathcal{A}_c^{1/2}(I-\Delta)^{-1/2}(I-\Delta)^{1/2}(|u_p|^2u_s)\|_2\\ &\le \|\mathcal{A}_c^{1/2}u_s\|_2 \cdot \|\mathcal{A}_c^{1/2}(I-\Delta)^{-1/2}\|_{\mathcal{B}(L^2,L^2)} \cdot \|(I-\Delta)^{1/2}(|u_p|^2u_s)\|_2.\end{aligned}$$

Using Leibnitz formula for the fraction, see [7],

$$\|(I-\Delta)^{1/2}(fg)\|_2 \le \|f\|_\infty \cdot \|(I-\Delta)^{1/2}g\|_2 + \|(I-\Delta)^{1/2}f\|_2 \cdot \|g\|_\infty,$$

we obtain

$$\|(I-\Delta)^{1/2}(|u_p|^2u_s)\|_2 \le \|u_p\|_\infty^2\|(I-\Delta)^{1/2}u_s\|_2 + 2\|u_p\|_\infty\|u_s\|_\infty\|(I-\Delta)^{1/2}u_p\|_2.$$

Combining the last two estimates, we obtain

$$\begin{aligned}
&\left|\int \left(\overline{\mathcal{A}_c^{1/2}u_s}\mathcal{A}_c^{1/2}(|u_p|^2u_s)\right)\,dx\right| \\
&\quad\le C\|\mathcal{A}_c^{1/2}u_s\|_2 \cdot (\|u_p\|_\infty^2 + \|u_s\|_\infty^2)(\|(I-\Delta)^{1/2}u_p\|_2 + \|(I-\Delta)^{1/2}u_s\|_2) \\
&\quad\le C\|\mathcal{A}_c^{1/2}u_s\|_2 \cdot (\|u_p\|_\infty^2 + \|u_s\|_\infty^2)(\|(I-\Delta)^{1/2}P_cu_p\|_2 + \|(I-\Delta)^{1/2}\langle u_p,\phi\rangle\phi\|_2 \\
&\qquad\qquad +\|(I-\Delta)^{1/2}P_cu_s\|_2 + \|(I-\Delta)^{1/2}\langle u_s,\phi\rangle\phi\|_2) \\
&\quad\le C(\|\mathcal{A}_c^{1/2}u_s\|_2^2 + \|\mathcal{A}_c^{1/2}u_p\|_2^2 + 1)\cdot(\|u_p\|_\infty^2 + \|u_s\|_\infty^2).
\end{aligned}$$

Finally, adding the s and p components of the differential inequalities, we obtain

$$\partial_t(\|\mathcal{A}_c^{1/2}u_s\|_2^2 + \|\mathcal{A}_c^{1/2}u_p\|_2^2) \le C(\|u_p\|_\infty^2 + \|u_s\|_\infty^2)\cdot(\|\mathcal{A}_c^{1/2}u_s\|_2^2 + \|\mathcal{A}_c^{1/2}u_p\|_2^2 + 1)$$

which implies that

$$\begin{aligned}
&\|\mathcal{A}_c^{1/2}u_s\|_2^2 + \|\mathcal{A}_c^{1/2}u_p\|_2^2 \\
&\qquad\le \exp\left(C\int_0^T [\|u_s\|_{L^\infty}^2 + \|u_p\|_{L^\infty}^2]\right)(\|\mathcal{A}_c^{1/2}u_s(0)\|_2^2 + \|\mathcal{A}_c^{1/2}u_p(0)\|_2^2 + 1).
\end{aligned}$$

Applying Hölder's inequality to the time integral in the exponent we have

$$\begin{aligned}
\int_0^T [\|u_s\|_{L^\infty}^2 + \|u_p\|_{L^\infty}^2]\,dt &\le C\|u_s\|_{L^4([0,T],L^\infty)}^2T^{\frac12} + C\|u_p\|_{L^4([0,T],L^\infty)}^2T^{\frac12} \\
&= C(\|u_s\|_{L^4([0,T],L^\infty)}^2 + \|u_p\|_{L^4([0,T],L^\infty)}^2)T^{\frac12} \\
&\le C(\mathcal{P}_0 + \mathcal{P}_0^{\frac12})(T^{\frac14} + T^{\frac34})T^{\frac12}.
\end{aligned}$$

The last inequality follows from the a priori space-time estimate of Theorem 2.8 and the fact that $(4,\infty)$ is an admissible pair. We, thus, establish the boundedness of (u_s,u_p) in $\|\mathcal{A}_c(\cdot)\|_2$ norm:

$$\|\mathcal{A}_c^{1/2}u_s\|_2^2 + \|\mathcal{A}_c^{1/2}u_p\|_2^2 \le K_1e^{K_2(\mathcal{P}_0+1)(T^2+1)}(\|\mathcal{A}_c^{1/2}u_s(0)\|_2^2 + \|\mathcal{A}_c^{1/2}u_p(0)\|_2^2 + 1).$$

Therefore, using the equivalence of norms, see Corollary 2.16, we obtain

$$\|u_s(t)\|_{H^1} + \|u_p(t)\|_{H^1} \le \tilde{K}_1e^{K_2(\mathcal{P}_0+1)(T^2+1)}(\|u_s(0)\|_{H^1} + \|u_p(0)\|_{H^1} + 1) \tag{2.57}$$

for some $K_1, K_2 > 0$. This completes the proof of global existence in H^1. ∎

3. Energy transfer from the guided mode to radiation modes. In this section, we prove that, over time scales of interest ($t \leq \mathcal{O}(\epsilon^{-1})$), radiation terms remain small during the amplification process and the finite-dimensional model (1.3) is a valid approximation. In the discussion of this section we return to the time-scale, where nonlinear terms are of order ϵ:

$$i\partial_t u_s - Hu_s = i\epsilon|u_p|^2 u_s, \tag{3.1}$$

$$i\partial_t u_p - Hu_p = -i\epsilon|u_s|^2 u_p. \tag{3.2}$$

For this system, we are going to show that radiation is indeed bounded by $C\epsilon$ on a time scale of order $1/\epsilon$.

To proceed, we first orthogonally decompose a solution of (3.1)–(3.2) into its bound state and continuous spectral (radiative) parts:

$$u_s(x,t) = a_s(t)\phi(x) + U_s(x,t), \tag{3.3}$$

$$u_p(x,t) = a_p(t)\phi(x) + U_p(x,t). \tag{3.4}$$

We prove the following theorem.

THEOREM 3.1. *Let $(u_s(0), u_p(0)) \in H^1$ and $P_c u_s(0) = P_c u_p(0) = 0$. Assume that $0 < \epsilon < \epsilon_0 < \infty$ and that V satisfies (2.5). Then, for any $T > 0$ there exists $C(T, \epsilon_0)$ so that*

$$\max\{\|U_s(t)\|_{H^1}, \|U_p(t)\|_{H^1}\} \leq C(T,\epsilon_0)\epsilon \tag{3.5}$$

on the interval $t \in [0, T/\epsilon]$.

We begin the proof with the following proposition, which follows from the ϵ-independent bounds $\|u_{s,p}\|_{H^1} \leq C(T,\epsilon_0)$, (2.57).

PROPOSITION 3.2. *Let $0 < \epsilon < \epsilon_0 < \infty$. Then for any $T > 0$ there exists $C(T,\epsilon_0)$ such that*

$$\|U_s\|_{H^1}, \|U_p\|_{H^1}, |a_s|, |a_p| \leq C \tag{3.6}$$

on the interval $t \in [0, T/\epsilon]$.

Substitution of (3.3)–(3.4) into (3.1)–(3.2) and projection onto ϕ and the range of P_c gives

$$\begin{aligned} i\partial_t a_s - \lambda a_s = i\epsilon[&|a_p|^2 a_s\langle\phi^3|\phi\rangle + \overline{a_p}a_s\langle\phi^3|U_p\rangle + a_p a_s\langle\phi^3|\overline{U_p}\rangle \\ &+ |a_p|^2\langle\phi^3|U_s\rangle + \cdots + \langle|U_p|^2 U_s|\phi\rangle], \end{aligned} \tag{3.7}$$

$$\begin{aligned} i\partial_t a_p - \lambda a_p = -i\epsilon[&|a_s|^2 a_p\langle\phi^3|\phi\rangle + \overline{a_s}a_p\langle\phi^3|U_s\rangle + a_p a_s\langle\phi^3|\overline{U_s}\rangle \\ &+ |a_s|^2\langle\phi^3|U_p\rangle + \cdots + \langle|U_s|^2 U_p|\phi\rangle], \end{aligned} \tag{3.8}$$

$$\begin{aligned} i\partial_t U_s - HU_s = i\epsilon[&|a_s||a_p|^2 P_c\phi^3 + \overline{a_p}a_s P_c\phi^2 U_p + a_p a_s P_c\phi^2\overline{U_p} \\ &+ |a_p|^2 P_c\phi^2 U_s + \cdots + P_c|U_p|^2 U_s], \end{aligned} \tag{3.9}$$

$$\begin{aligned} i\partial_t U_p - HU_p = -i\epsilon[&a_p|a_s|^2 P_c\phi^3 + \overline{a_s}a_p P_c\phi^2 U_s + a_p a_s P_c\phi^2\overline{U_s} \\ &+ |a_s|^2 P_c\phi^2 U_p + \cdots + P_c|U_s|^2 U_p], \end{aligned} \tag{3.10}$$

where $H = -\partial_x^2 + V(x)$ and $H\phi = \lambda\phi$.

COROLLARY 3.3. *The fundamental modes are slowly varying with the rate ϵ*

$$|\partial_t|a_s\||, |\partial_t|a_p\|| \leq C(T,\epsilon_0)\epsilon.$$

Proof. This follows from Proposition 3.2 and (3.7)-(3.8). Indeed,

$$|\partial_t|a_s\|| = |\partial_t|ia_s e^{it\lambda}\|| \le |\partial_t i(a_s e^{it\lambda})| = |(i\partial_t - \lambda)a_s| \le C(T,\epsilon_0)\epsilon.$$

The same argument leads to a similar estimate for $|\partial_t|a_p\||$. This ends the proof of the corollary. □

The following estimates are used in the proof of the theorem and can be easily verified.

LEMMA 3.4.

$$\begin{aligned}
&\|P_c f\|_2 \le \|f\|_2,\\
&\|P_c f\|_\infty \le \|f\|_\infty(1+\|\phi\|_1\cdot\|\phi\|_\infty),\\
&\|(H-\lambda)^{-1}e^{i(H-\lambda)t}P_c f\|_2 \le C\|f\|_2,\\
&\|(H-\lambda)^{-1}P_c\|_{H^1} \le \frac{C}{\operatorname{dist}(H_c,\lambda)} \le \frac{C}{|\lambda|}.
\end{aligned} \tag{3.11}$$

Proof of Theorem 3.1. We now make transformations $a_s = e^{-i\lambda t}A_s$ and $U_s = \epsilon e^{-iHt}W_s$ to remove rapid oscillations and explicitly show the smallness of radiation. By hypothesis of Theorem 3.1, we have $\|W_{s,p}(0)\|_{H^1} \le C$. Note that by the bounds of Proposition 3.2 we have $\|W_{s,p}\|_{H^1} \le C(T,\epsilon_0)/\epsilon$ and $|A_{s,p}| \le C(T,\epsilon_0)$.

The slowly varying amplitudes A_s, A_p satisfy

$$\begin{aligned}
\partial_t A_s = {}& \epsilon|A_p|^2 A_s\langle\phi^3|\phi\rangle + \epsilon^2\overline{A_p}A_s\langle\phi^3|e^{-i(H-\lambda)t}W_p\rangle + \epsilon^2 A_p A_s\langle\phi^3|e^{i(H-\lambda)t}\overline{W_p}\rangle\\
&+\epsilon^2|A_p|^2\langle\phi^3|e^{-i(H-\lambda)t}W_s|\phi\rangle + \cdots + \epsilon^4\langle|e^{-iHt}W_p|^2 e^{-i(H-\lambda)t}W_s\rangle,
\end{aligned} \tag{3.12}$$

$$\begin{aligned}
\partial_t A_p = {}& -\epsilon|A_s|^2 A_p\langle\phi^3|\phi\rangle - \epsilon^2\overline{A_s}A_p\langle\phi^3|e^{-i(H-\lambda)t}W_s\rangle - \epsilon^2 A_p A_s\langle\phi^3|e^{i(H-\lambda)t}\overline{W_s}\rangle\\
&-\epsilon^2|A_s|^2\langle\phi^3|e^{-i(H-\lambda)t}W_p\rangle - \cdots - \epsilon^4\langle|e^{-iHt}W_s|^2 e^{-i(H-\lambda)t}W_p|\phi\rangle.
\end{aligned} \tag{3.13}$$

Further, $W_{s,p}$ satisfy

$$\begin{aligned}
\partial_t W_s = {}& e^{i(H-\lambda)t}A_s|A_p|^2 P_c\phi^3\\
&+e^{iHt}[\epsilon\overline{A_p}A_s P_c\phi^2 e^{-iHt}W_p + \epsilon A_p A_s P_c\phi^2 e^{iHt}\overline{W_p}\\
&\quad+\epsilon|A_p|^2 P_c\phi^2 e^{-iHt}W_s + \cdots + \epsilon^3 P_c|e^{-iHt}W_p|^2 e^{-iHt}W_s],
\end{aligned} \tag{3.14}$$

$$\begin{aligned}
\partial_t W_p = {}& e^{i(H-\lambda)t}A_p|A_s|^2 P_c\phi^3\\
&+e^{iHt}[\epsilon\overline{A_s}A_p P_c\phi^2 e^{-iHt}W_s + \epsilon A_p A_s P_c\phi^2 e^{iHt}\overline{W_s}\\
&\quad+\epsilon|A_s|^2 P_c\phi^2 e^{-iHt}W_p + \cdots + \epsilon^3 P_c|e^{-iHt}W_s|^2 e^{-iHt}W_p].
\end{aligned} \tag{3.15}$$

The goal is now to show that given initial data where W is $\mathcal{O}(1)$ (which corresponds to radiation $\mathcal{O}(\epsilon)$) during the evolution W will remain $\mathcal{O}(1)$ on time interval $\mathcal{O}(1/\epsilon)$.

In order to do this we integrate the above equations:

$$W_s(t) = W_s(0) + \int_0^t e^{i(H-\lambda)s}A_s|A_p|^2 P_c\phi^3 ds + \epsilon\int_0^t R_s ds, \tag{3.16}$$

where ϵR_s is the ϵ-order part in (3.14), i.e., the second and the third lines. Integrating by parts

$$\begin{aligned}
W_s(t) = {}& W_s(0) + \frac{e^{i(H-\lambda)t}-1}{i(H-\lambda)}A_s|A_p|^2 P_c\phi^3\\
&-\int_0^t \frac{e^{i(H-\lambda)s}}{i(H-\lambda)}\partial_s(A_s|A_p|^2)P_c\phi^3 ds + \epsilon\int_0^t R_s ds
\end{aligned} \tag{3.17}$$

and applying $\|\mathcal{A}_c^{\frac{1}{2}} \cdot\|_{L^2}$, we obtain

$$\|\mathcal{A}_c^{\frac{1}{2}} W_s(t)\|_{L^2} \le \|\mathcal{A}_c^{\frac{1}{2}} W_s(0)\|_{L^2} + \left\| \frac{e^{i(H-\lambda)t}-1}{i(H-\lambda)} A_s |A_p|^2 \mathcal{A}_c^{\frac{1}{2}} P_c \phi^3 \right\|_{L^2} \tag{3.18}$$

$$+ C(T,\epsilon_0)\epsilon \int_0^t \left\| \frac{e^{i(H-\lambda)t}-1}{i(H-\lambda)} \mathcal{A}_c^{\frac{1}{2}} P_c \phi^3 \right\|_{L^2} \tag{3.19}$$

$$+ \epsilon \int_0^t \|\mathcal{A}_c^{\frac{1}{2}} R_s\|_{L^2} ds.$$

Therefore, we have

$$\|\mathcal{A}_c^{\frac{1}{2}} W_s(t)\|_{L^2} \le \|\mathcal{A}_c^{\frac{1}{2}} W_s(0)\|_{L^2} + C\|(H-\lambda)^{-1} \mathcal{A}_c^{\frac{1}{2}} P_c \phi^3\|_{L^2} \tag{3.20}$$

$$+ \epsilon \int_0^t \Big(\|\mathcal{A}_c^{\frac{1}{2}} P_c \phi^2 W_p\|_{L^2} \tag{3.21}$$

$$+ \cdots + \epsilon^2 \|\mathcal{A}_c^{\frac{1}{2}} P_c |e^{-iHt} W_p|^2 e^{-iHt} W_s\|_{L^2} \Big) ds.$$

The terms on the right-hand side in the first line are bounded by a constant. To estimate the other terms we use the above properties of $\mathcal{A}_c$, $(H-\lambda)^{-1}$, etc. We illustrate how one proceeds with the estimates using the last term:

$$\epsilon^2 \|\mathcal{A}_c^{\frac{1}{2}} P_c |e^{-iHt} W_p|^2 e^{-iHt} W_s\|_{L^2} \tag{3.22}$$

$$\le \epsilon^2 \|(I-\Delta)^{\frac{1}{2}} |e^{-iHt} W_p|^2 e^{-iHt} W_s\|_{L^2}$$

$$\le \epsilon^2 \|(I-\Delta)^{\frac{1}{2}} e^{-iHt} W_p\|_{L^2}^2 \cdot \|(I-\Delta)^{\frac{1}{2}} e^{-iHt} W_s\|_{L^2} \tag{3.23}$$

$$\le \epsilon^2 \|\mathcal{A}_c^{\frac{1}{2}} e^{-iHt} W_p\|_{L^2}^2 \cdot \|\mathcal{A}_c^{\frac{1}{2}} e^{-iHt} W_s\|_{L^2}$$

$$\le \epsilon^2 \|\mathcal{A}_c^{\frac{1}{2}} W_p\|_{L^2}^2 \cdot \|\mathcal{A}_c^{\frac{1}{2}} W_s\|_{L^2} \tag{3.24}$$

$$\le \epsilon^2 \|W_p\|_{H^1}^2 \cdot \|\mathcal{A}_c^{\frac{1}{2}} W_s\|_{L^2} \le C \|\mathcal{A}_c^{\frac{1}{2}} W_s\|_{L^2},$$

where we used equivalence of norms, Leibnitz rule, and the uniform bound $\|W_{s,p}\|_{H^1} \le C/\epsilon$. Thus, the inequality takes the form

$$\|\mathcal{A}_c^{\frac{1}{2}} W_s(t)\|_{L^2} \le B + \epsilon K \int_0^t (\|\mathcal{A}_c^{\frac{1}{2}} W_p\|_{L^2} + \cdots + \|\mathcal{A}_c^{\frac{1}{2}} W_s\|_{L^2}) ds, \tag{3.25}$$

where B and K do not depend on $\epsilon < \epsilon_0$. Adding the last inequality with the similar one for the p-component, and then using the notation $z(t) = \|\mathcal{A}_c^{\frac{1}{2}} W_s(t)\|_{L^2} + \|\mathcal{A}_c^{\frac{1}{2}} W_p(t)\|_{L^2}$, we obtain the inequality with modified B and K (but still independent of ϵ):

$$z(t) \le B + \epsilon K \int_0^t z(s) ds. \tag{3.26}$$

Using the standard Gronwall's result, we find

$$z(t) \le B e^{\epsilon K t} \Rightarrow z(t) \le B e^{KT}, \tag{3.27}$$

which proves the bound $\|W_s\|_{H^1} \le C(T,\epsilon_0)$. □

Remark 3.5. Using dispersive properties of e^{itH}, it is possible to establish smallness of radiation in weaker spaces, namely, in $\|\cdot\|_{L^\infty}$ norm. Taking (3.9)–(3.10) for $U_{s,p}$ and rewriting them in the integral form, we are led to estimate the terms

$$\epsilon \int_0^t e^{itH} a_s |a_p|^2 P_c \phi^3 ds \tag{3.28}$$

and

$$\epsilon \int_0^t e^{itH} R_s ds. \tag{3.29}$$

After some changes of variables with the aid of standard L^∞ decay estimates for the Schrödinger evolution, one obtains that

$$\|U_{s,p}\|_{L^\infty} \le C\sqrt{\epsilon}. \tag{3.30}$$

This argument also extends to the two-dimensional case with even better decay in ϵ (see the end of section 4.4).

4. Two-dimensional problem. We now consider the Raman system in the case of two transverse spatial dimensions

$$i\partial_t u_s - \beta H u_s = i|u_p|^2 u_s, \tag{4.1}$$

$$i\partial_t u_p - \beta H u_p = -i|u_s|^2 u_p, \tag{4.2}$$

where $H = -\Delta + V(x,y)$ and we prove analogous existence results and energy transfer estimates. Our strategy in the two-dimensional case is similar to the one-dimensional case; therefore, we omit some calculations which can be found in the previous sections.

In the two-dimensional case we require stronger conditions on the potential.

Assumption 4.1. The potential $V(x,y)$ is twice differentiable and

$$|D^\alpha V| \le C_\alpha (1 + x^2 + y^2)^{-a},$$

where $a > 6$ and $|\alpha| \le 2$.

Assumption 4.2. We assume that potential $V(x,y)$ has no zero energy eigenvalues or resonances.[3]

These assumptions are required to obtain space-time estimates in the next section.

4.1. Space-time estimates for the propagator. The definition of admissible pair is modified: (q,r) is admissible (in dimension $n=2$) if

$$\frac{1}{q} = \frac{1}{2} - \frac{1}{r}, \quad r \in [2,\infty].$$

THEOREM 4.3. *Assume that the potential V satisfies both assumptions and let (q,r) be an admissible pair. Then for any $f \in L^2$ we have that $U_0(t)f$ and $U(t)P_c f$ are in $L^q(\mathbb{R}, L^r)$ and*

$$\|U_0(\cdot)f\|_{L^q([0,T],L^r)} \le C\|f\|_{L^2}, \tag{4.3}$$
$$\|U(\cdot)P_c f\|_{L^q([0,T],L^r)} \le C\|f\|_{L^2},$$

[3]Zero eigenvalues and resonances are obstructions to the optimal time-decay estimates for e^{-iHt}. Their absence holds generically; see, for example, [10].

where C depends only on q.

THEOREM 4.4. *Assume that the potential V satisfies both assumptions, let (γ, ρ) be an admissible pair, and let $f \in L^{\gamma'}([0,T], L^{\rho'})$, where (γ', ρ') is conjugate to (γ, ρ). Then for any admissible pair (q, r)*

$$\left\| \int_0^t U_0(t-\tau) f(\tau) d\tau \right\|_{L^q([0,T],L^r)} \le C \|f\|_{L^{\gamma'}([0,T],L^{\rho'})},$$

$$\left\| \int_0^t U(t-\tau) P_c f(\tau) d\tau \right\|_{L^q([0,T],L^r)} \le C \|f\|_{L^{\gamma'}([0,T],L^{\rho'})}, \tag{4.4}$$

where C depends only on q, γ.

Both Theorems 4.3 and 4.4 are proven by using Yajima's results [10] on $W^{k,p}$ continuity of wave operators. The argument follows the proof of Proposition 2.15 and is omitted here. Finally, Corollary 2.3 is valid in the current setting without any changes as the scaling is independent of the space dimension.

Remark 4.5. The application of Yajima's results on $W^{k,p}$ continuity of wave operators is the origin of the more restrictive smoothness assumptions on the potential $V(x)$. In one space dimension smoothness of $V(x)$ is not required [6].

4.2. A priori space-time estimates. The same argument as in the one-dimensional case applies here and we obtain the a priori bound of Proposition 2.5, as well as the bound (2.28) on nonlinear terms.

THEOREM 4.6 (a priori bounds in $L^q([0,T], L^r)$). *Let (q, r) be an admissible pair. Then any solution (u_s, u_p) satisfies the bounds*

$$\|u_s\|_{L^q([0,T],L^r)} \le C(\mathcal{P}_0 + 1)(T+1), \tag{4.5}$$

$$\|u_p\|_{L^q([0,T],L^r)} \le C(\mathcal{P}_0 + 1)(T+1). \tag{4.6}$$

Proof. As in the one-dimensional case, this estimate is proved by a straightforward application of space-time estimate for Schrödinger equation with a potential and using a priori estimate on nonlinear terms. Following the proof of Theorem 2.8, we obtain the same bounds with different ρ, ρ', γ, γ'. We must impose $\rho' = 1$ with $\rho = \infty$, but $\gamma = 2$ (since in $1/\gamma = 1/2 - 1/\rho$) with $\gamma' = 2$. This results in

$$\begin{aligned} \|u_s\|_{L^q([0,T],L^r)} &\le C_1 \|u_s(0)\|_{L^2} + C_2 \|u_p^2 u_s\|_{L^2([0,T],L^1)} \\ &\quad + \|\phi\|_{L^\infty} \|\phi\|_{L^r} T^{1/2+1/q} \|u_p^2 u_s\|_{L^2([0,T],L^1)} \\ &\le C_1 \mathcal{P}_0^{\frac{1}{2}} + C_2 \mathcal{P}_0 + C_3 \mathcal{P}_0 (T + T^{\frac{1}{2}}), \end{aligned}$$

since $q \ge 2$. ∎

4.3. Local existence in $H^2(\mathbb{R}^2)$. We now prove local existence of solutions in H^2 and will extend it to a global solution using our space-time estimates.

THEOREM 4.7 (local existence).

(1) *Given initial data $(u_s(0), u_p(0)) \in H^2(\mathbb{R}^2)$, there exist $T > 0$ and a unique solution $(u_s, u_p) \in L^\infty([0,T], H^2(\mathbb{R}^2))$.*

(2) *Let $T_{\max} > 0$ denote the maximal time of existence. Then, either $T_{\max} = \infty$ (global existence in time) or*

$$T_{\max} < \infty \quad \text{and} \quad \limsup_{t \to T_{\max}} \|(u_s, u_p)\|_{L^\infty([0,T],H^2(\mathbb{R}^2))} = \infty.$$

To prove the local existence theorem we have to show that a ball in H^2 is mapped into itself and that the mapping is a contraction.

Consider the same mapping as in the one-dimensional case (2.38)–(2.39). We will first show that it maps a ball into a ball:

$$\|A_\beta^{(s)}(u_s,u_p)\|_{H^2} \le \|U_\beta(t)u_s(0)\|_{H^2} + \left\|\int_0^t U_\beta(t-\tau)|u_p|^2u_s\right\|_{H^2}. \tag{4.7}$$

The first term is estimated as follows:

$$\begin{aligned}\|U_\beta(t)u_s(0)\|_{H^2} &= \|(I-\Delta)U_\beta(t)u_s(0)\|_{L^2} = \|(I-\Delta)(H+i)(H+i)^{-1}U_\beta(t)u_s(0)\|_{L^2}\\ &\le \|(I-\Delta)(H+i)^{-1}\|_{\mathcal{B}(L^2,L^2)}\|(H+i)U_\beta(t)u_s(0)\|_{L^2}.\end{aligned}$$

Note that the operator $(I-\Delta)(H+i)^{-1}$ is bounded in L^2-operator norm. This follows from the identity

$$(I-\Delta)(H+i)^{-1} = -I + (I+i-V)(H+i)^{-1}$$

and the boundedness of V in L^∞ and of $(H+i)^{-1}$ in L^2.

Next, we have to establish the bound for

$$\begin{aligned}\|(H+i)U_\beta(t)u_s(0)\|_{L^2} &= \|(H+i)u_s(0)\|_{L^2} = \|(H+i)(I-\Delta)^{-1}(I-\Delta)u_s(0)\|_{L^2}\\ &\le \|(H+i)(I-\Delta)^{-1}\|_{\mathcal{B}(L^2,L^2)}\|(I-\Delta)u_s(0)\|_{L^2} \le C\|u_s(0)\|_{H^2},\end{aligned}$$

where the operator $(H+i)(I-\Delta)^{-1}$ is bounded by similar calculations as for $(I-\Delta)(H+i)^{-1}$.

Now, we estimate the second term in (4.7):

$$\left\|\int_0^t U_\beta(t-\tau)|u_p|^2u_s\,d\tau\right\|_{H^2} \le C\left\|\int_0^t (H+i)U_\beta(t-\tau)|u_p|^2u_s\,d\tau\right\|_{L^2}.$$

To bound this term we write it in the form

$$\int dx\left\{\int_0^t\int_0^t (H+i)U_\beta(t-\tau_1)|u_p(\tau_1)|^2u_s(\tau_1)(H-i)\overline{U_\beta}(t-\tau_2)|u_p(\tau_2)|^2\overline{u_s}(\tau_2)d\tau_1d\tau_2\right\}$$

(using Hölder inequality and isometry of U_β in L^2)

$$\begin{aligned}&\le \int_0^t\int_0^t d\tau_1d\tau_2\left|\int |(H+i)|u_p(\tau_1)|^2u_s(\tau_1)|^2\,dx\right|^{\frac12}\left|\int |(H+i)|u_p(\tau_2)|^2u_s(\tau_2)|^2\,dx\right|^{\frac12}\\ &\quad\le t^2\sup_{\tau\in[0,t]}\|(H+i)u_p^2(\tau)u_s(\tau)\|_2 \le Ct^2\sup_{\tau\in[0,t]}\|u_p^2(\tau)u_s(\tau)\|_{H^2}^2\\ &\quad\le Ct^2\sup_{\tau\in[0,t]}\|u_p(\tau)\|_{H^2}^4\|u_s(\tau)\|_{H^2}^2.\end{aligned}$$

Therefore, we finally obtain the bound on the s-part of the map

$$\|A_\beta^{(s)}(u_s,u_p)\|_{H_2} \le C\|u_s(0)\|_{H^2} + Ct\sup_{\tau\in[0,t]}\|u_p(\tau)\|_{H^2}^2\|u_s(\tau)\|_{H^2}$$

and the full map

$$\begin{aligned}\|A_\beta(u_s,u_p)\|_{L^\infty([0,t],H^2)} &\le C\left(\|u_s(0)\|_{H^2} + \|u_p(0)\|_{H^2}\right)\\ &\quad + Ct\big(\|u_p\|_{L^\infty([0,t],H^2)}^2\|u_s\|_{L^\infty([0,t],H^2)}\\ &\qquad + \|u_p\|_{L^\infty([0,t],H^2)}\|u_s\|_{L^\infty([0,t],H^2)}^2\big).\end{aligned}$$

With the obtained inequality it is easy to establish the following proposition.

PROPOSITION 4.8. *Let $(u_s(0), u_p(0))$ be in H^2. Define the ball in $L^\infty([0,T], H^2)$ as*

$$\mathcal{B}(T) = \big\{(u_s, u_p) \in L^\infty([0,T], H^2) : \|(u_s, u_p)\|_{L^\infty([0,T],H^2)} \\ \le 2C(\|u_s(0)\|_{H^2} + \|u_p(0)\|_{H^2})\big\}.$$

Then there exists $T_0 > 0$ such that for any $T < T_0$, the ball is mapped into itself, i.e., $A_\beta(\mathcal{B}(T)) \subset \mathcal{B}(T)$ with T_0 independent of β.

Next, we have to show that the mapping is a contraction in $L^\infty([0,T], H^2)$. Consider the first component of the map applied to two different pairs (u_s, u_p) and (v_s, v_p) with the same initial data $(u_s(0), u_p(0)) = (v_s(0), v_p(0))$:

$$\begin{aligned}
&\|A^{(s)}_\beta(u_s, u_p) - A^{(s)}_\beta(v_s, v_p)\|_{L^\infty([0,t],H^2)} \\
&\quad \le CT \sup_{t\in[0,T]} \||u_p(t)|^2 u_s(t) - |v_p(t)|^2 v_s(t)\|_{H^2} \\
&\quad \le CT \sup_{t\in[0,T]} (\|u_p^2(u_s - v_s)\|_{H^2} + \|u_p v_s(u_p - v_p)\|_{H^2} + \|v_p v_s(u_p - v_p)\|_{H^2}) \\
&\quad \le C(\|u_p, u_s, v_p, v_s\|_{L^\infty([0,T],H^2)})T\|(u_p - v_p, u_s - v_s)\|_{L^\infty([0,T],H^2)}.
\end{aligned}$$

Adding both s and p components of the map we obtain

$$\begin{aligned}
&\|A_\beta(u_p, u_s) - A_\beta(v_p, v_s)\|_{L^\infty([0,T],H^2)} \\
&\qquad \le TC(\|u_p, u_s, v_p, v_s\|_{L^\infty([0,T],H^2)})\|(u_p - v_p, u_s - v_s)\|_{L^\infty([0,T],H^2)}.
\end{aligned}$$

This inequality implies the following proposition.

PROPOSITION 4.9. *There exists $T_1 : 0 < T_1 < T_0$ sufficiently small such that the map A_β is a contraction in the ball $\mathcal{B}(T)$ for any $T : 0 < T < T_1$:*

$$\|A_\beta(u_p, u_s) - A_\beta(v_p, v_s)\|_{L^\infty([0,T],H^2)} \le q\|(u_p - v_p, u_s - v_s)\|_{L^\infty([0,T],H^2)},$$

where $q < 1$.

Remark 4.10. Whenever there exists a local solution on $t \in [0,T]$, it is bounded in $L^q([0,T], L^r(\mathbb{R}^2))$. Indeed, a solution in $L^\infty([0,T], H^2)$ is also in $L^q([0,T], L^r(\mathbb{R}^2))$ and the earlier obtained a priori bounds apply.

4.4. Global existence in $H^2(\mathbb{R}^2)$. In this section we will show that the local solution obtained via the contraction mapping principle in the previous section can be extended to a global solution using space-time estimates. We start with establishing uniform bound in H^1 space.

A priori estimates in H^1. Proceeding as in the one-dimensional problem (2.4), we obtain H^1 bound. Since $(\infty, 2)$ is an admissible pair, we obtain that the solutions are even uniformly bounded in time on the interval of existence of a local solution:

$$\|(u_s, u_p)\|_{L^\infty([0,T],H^1)} \le C(\mathcal{P}_0, T)\|(u_s(0), u_p(0))\|_{H^1}. \tag{4.8}$$

Continuation to a global solution using Theorem 4.7 requires an H^2 estimate, which we now derive.

Global existence in H^2. Having established uniform bound in H^1, we are ready to obtain a bound in H^2, which will rule out the first alternative in Theorem 4.7 (on local existence) and, thus, leave the global existence as the only possibility.

Applying $H+I$ to the s component of (4.2) and using energy estimates, we obtain

$$\begin{aligned}\partial_t \int |(H+I)u_s|^2 &\le \int |(H+I)u_s| \cdot |(H+I)(|u_p|^2 u_s)| \\ &\le \|(H+I)u_s\|_2 \|(H+I)(|u_p|^2 u_s)\|_2. \end{aligned} \tag{4.9}$$

To estimate the last term, we write

$$\begin{aligned}\int |\Delta(|u_p|^2 u_s)|^2 &= \int |u_p|^4 |\Delta u_s|^2 + 2\int |\nabla u_p|^2 |\nabla u_s|^2 |u_p|^2 + \int |\nabla u_p|^4 |u_s|^2 \\ &\le C(\|u_p\|_\infty^4 \cdot \|u_s\|_{H^2}^2 + \|u_s\|_\infty^2 \cdot \|u_p\|_{H^2}^2 \cdot \|u_p\|_{H^1}^2 \\ &\quad + \|u_p\|_\infty^2 \cdot \|u_s\|_{H^2}^2 \cdot \|u_s\|_{H^1}^2 + \|u_p\|_\infty^2 \cdot \|u_p\|_{H^2}^2 \cdot \|u_p\|_{H^1}^2)\end{aligned}$$

and therefore we have

$$\int |\Delta(|u_p|^2 u_s)|^2 \le C\left(1 + \|u_p\|_\infty^4 + \|u_s\|_\infty^4\right) \|(u_s, u_p)\|_{H^1}^2 \cdot \|(u_s, u_p)\|_{H^2}^2.$$

Now, adding the s and p components, we obtain

$$\begin{aligned}&\partial_t \int (|(H+I)u_s|^2 + |(H+I)u_s|^2) \\ &\quad \le C(1 + \|u_p\|_\infty^2 + \|u_s\|_\infty^2)(\|(H+I)u_s\|_{H^2}^2 + \|(H+I)u_p\|_{H^2}^2),\end{aligned}$$

where we have used that $\|(u_s, u_p)\|_{H^1}$ is bounded (see previous paragraph on H^1 estimates).

Since $(2, \infty)$ is an admissible pair, both $\int \|u_p\|_\infty^2 \, dt$ and $\int \|u_s\|_\infty^2 \, dt$ are bounded, and we obtain the required bound:

$$\|(H+I)u_s\|_2^2 + \|(H+I)u_p\|_2^2 \le C(\mathcal{P}_0, T) e^{kT} (\|(H+I)u_s(0)\|_2^2 + \|(H+I)u_p(0)\|_2^2)$$

on the interval $t \in [0, T]$. Because of the norm equivalence, we also obtain

$$\|u_s(t)\|_{H^2}^2 + \|u_p(t)\|_{H^2}^2 \le C(\mathcal{P}_0, T) e^{kT} (\|u_s(0)\|_{H^2}^2 + \|u_p(0)\|_{H^2}^2).$$

This bound implies the global existence of solutions in H^2.

Radiation losses in two-dimensional amplification model. The analogue of Theorem 3.1 on the boundedness of radiation in H^2 holds with the proof carrying over from the one-dimensional case. One can also obtain boundedness in L^∞ as described in Remark 3.5 with even faster decay: $\epsilon \log \epsilon$ rather than $\sqrt{\epsilon}$.

Appendix A. Application to optical communications. In this section we provide the details on the Raman model in optical communication systems as well as the derivation of the reaction-dispersion system. In modern long-haul optical communication systems the signal propagates in the fundamental mode of a single mode fiber. In an "ideal" lossless optical fiber waveguide the transverse shape of the wave envelope does not change and there is no transfer of energy from the fundamental mode to radiation modes. However, in the real systems Rayleigh scattering causes

attenuation of signal power, thus requiring periodic amplification [1]. A current strategy for amplification of a signal is based on the stimulated Raman effect. Here, light of a second *pump* wavelength is co- or counter-propagated in the medium. The stimulated Raman effect is a parametric process in which light of the pump frequency is transferred to that of the signal frequency. This amplification process is inherently nonlinear and therefore is expected to cause deformation of the transverse mode shape. There are other linear and nonlinear effects which may need to be taken into account such as group velocity dispersion, self-phase modulation, and four wave mixing. Also, refractive index depends on the frequency shift between the pump and signal frequencies.

Regarding linear effects, like group velocity dispersion, in practice they are weaker compared to the Raman effect assuming that pulses are not too short. However, in our case, we consider a model problem with both pump and signal being continuous (constant amplitude) waves. Then dispersion just vanishes.

The refractive index depends on the light frequency. As a result fundamental modes would be slightly different for pump and signal waves. Here, we assume that the modes are the same as it simplifies the exposition. All our results can be obtained for the frequency-dependent dispersion/diffraction coefficients with minimal modifications.

Approximate equations for the Raman interaction of signal and pump in the waveguide have been derived in [3]. These authors derived a pair of coupled ODEs for the signal and pump intensities, based on the assumption that all energy is contained in the fundamental modes. This model compares well with experiment [3] (see also [1] and the references therein). The authors [3] also discussed why the approximation was so accurate. They suggested that radiative losses (energy transfer from bound to radiation modes) is negligible due to the fact that "the wave-guiding action of the fiber reforms the pump and Stokes waves so that they always have intensities distributions which are close approximations to those which would exist in the absence of Raman interaction." However, this explanation has some limitations as the energy transfer could occur adiabatically (e.g., like the ionization of an atom). In other words, a weak process may lead to non-negligible changes after sufficiently long time. In particular, one might expect that the modes would undergo continuous deformation while also shedding radiation, so that after the full energy exchange a non-negligible amount of energy would accumulate in radiative modes and would constitute a significant loss.

To understand these effects, equations which take into account the effects of diffraction, wave-guiding and amplification should be studied. Naturally, the model will contain a small parameter: the ratio of diffraction and amplification lengths.

Raman stimulated emission describes the amplification of signal photons (with frequency ω_s) with Stokes down shifted pump photons (with frequency ω_p) and is governed by [3]

$$\frac{\partial n_s}{\partial z} = g(\omega_p - \omega_s) n_s n_p, \tag{A.1}$$

$$\frac{\partial n_p}{\partial z} = -g(\omega_p - \omega_s) n_s n_p, \tag{A.2}$$

where n_s, n_p are the number densities of signal and pump photons, respectively, and the total number of photons per unit volume is conserved $n_s + n_p = N$. Since we wish to focus on the effects due to the resonant coupling of the two wave fields (pump and signal), we ignore other effects, such as amplified spontaneous emission [1] which is always present, though a small effect.

Introducing the intensities

$$I_s = h\omega_s n_s, \qquad I_p = h\omega_p n_p, \tag{A.3}$$

where h denotes Planck's constant, we obtain the corresponding equations

$$\frac{\partial I_s}{\partial z} = \frac{g(\omega_p - \omega_s)}{h\omega_p} I_s I_p, \tag{A.4}$$

$$\frac{\partial I_p}{\partial z} = -\frac{g(\omega_p - \omega_s)}{h\omega_s} I_s I_p. \tag{A.5}$$

These equations satisfy the photon number conservation relation

$$\frac{I_s}{\omega_s} + \frac{I_p}{\omega_p} = \text{constant}. \tag{A.6}$$

In the case of radiative loss, this conservation law would be violated, since some photons would be lost from the bound waveguide mode to radiation modes. Equations (A.4)–(A.5) describe the plane wave Raman interaction.

Consider now the propagation of light in a dielectric cylinder waveguide with longitudinal coordinate, z. Maxwell's equations [1] imply

$$\Delta \mathbf{E} - \frac{1}{c^2}\mathbf{E}_{tt} - \nabla(\nabla \cdot \mathbf{E}) = \frac{1}{c^2}[\chi^{(1)}(\mathbf{r}, t) * \mathbf{E}_{tt}]_{tt} = 0,$$

where $\mathbf{E} \in \mathbb{R}^3$ is the electric field and $\chi^{(1)}(\mathbf{r}, t)$ is the linear susceptibility. Neglecting vector effects (see, e.g., [1]), we find that the time Fourier transform of $\mathbf{E}$, $\hat{\mathbf{E}}$, satisfies

$$\Delta \hat{\mathbf{E}} + \frac{\omega^2 n^2(\mathbf{x}_\perp, \omega)}{c^2}\hat{\mathbf{E}} = 0.$$

Each component of $\mathbf{E}$ satisfies

$$E_{zz} + \Delta_\perp E + \frac{\omega^2 n^2(\mathbf{x}_\perp, \omega)}{c^2} E = 0. \tag{A.7}$$

Next, we introduce the paraxial approximation. Let δ be a small parameter, and assume the following structure for the refraction index dependence on $\mathbf{x}_\perp$:

$$n^2(\mathbf{x}_\perp, \omega) = n_0^2(\omega) + \delta^2 n_1^2(\delta \mathbf{x}_\perp/\lambda_0, \omega). \tag{A.8}$$

We also seek E, in the form

$$E = A((\delta/\lambda_0)\mathbf{x}_\perp, (\delta^2/\lambda_0)z)e^{ikz}, \tag{A.9}$$

where λ_0 is the light wavelength and

$$\frac{2\pi}{\lambda_0} = k = \omega n_0(\omega)/c.$$

Thus, E varies more rapidly in the transverse than longitudinal directions.

Substituting (A.8), (A.9) into (A.7) and multiplying by $\lambda_0^2 \delta^{-4}$ we obtain

$$A_{ZZ} + 2ik\lambda_0\delta^{-2}A_Z + \delta^{-2}\Delta_\perp A + \delta^{-2}\lambda_0^2(\omega^2/c^2)n_1^2(\mathbf{X}_\perp) = 0,$$

where $Z = (\delta^2/\lambda_0)z$, $\mathbf{X}_\perp = (\delta/\lambda_0)\mathbf{x}_\perp$, and $(*)_\perp$ denotes differentiation with respect to $\mathbf{X}_\perp$. For δ small, we keep the dominant terms, those of order δ^{-2} and obtain, after using the relation between k and λ_0,

$$i4\pi A_Z + \Delta_\perp A + \frac{4\pi^2 n_1(\mathbf{X}_\perp, \omega)}{n_0^2} A = 0. \tag{A.10}$$

Equation (A.10) governs the linear propagation of any light field (signal or pump) in the paraxial approximation. To obtain a model governing the Raman interaction of signal and pump fields, u_s and u_p, we argue as follows. The signal field envelope propagates through a medium with refractive index (A.8) corrected by an imaginary term proportional to $i|u_p|^2$ corresponding to the Raman amplification by pump. The pump field envelope, u_p, propagates through a medium with refractive index (A.8) corrected by an imaginary term proportional to $-i|u_s|^2$ corresponding to pump depletion by the signal. The coupled signal and pump envelopes are then taken to satisfy the system

$$i\partial_z u_s + \Delta_\perp u_s - V(\omega_s, \mathbf{x}_\perp)u_s = i\epsilon_s|u_p|^2 u_s, \tag{A.11}$$

$$i\partial_z u_p + \Delta_\perp u_p - V(\omega_p, \mathbf{x}_\perp)u_p = -i\epsilon_p|u_s|^2 u_p, \tag{A.12}$$

where $\epsilon_{p,s}$ is the parameter which measures the ratio of the diffraction and nonlinear lengths. Usually, $\epsilon_{p,s}$ is very small [1]. We further assume[4] $\epsilon = \epsilon_s = \epsilon_p$ and neglect the dependence of the refractive index on frequency, i.e., $V(x_\perp, \omega) = V(x_\perp)$.

System (A.12) models the Raman energy exchange between the two continuous waves. We have not included the effects of losses due to the Rayleigh scattering in order not to burden the exposition. In reality, the Raman amplification length might be comparable to the effective (loss) length (20 km).

Thus, we have

$$\begin{aligned} i\partial_t u_s - Hu_s &= i\epsilon|u_p|^2 u_s, \\ i\partial_t u_p - Hu_p &= -i\epsilon|u_s|^2 u_p, \end{aligned} \tag{A.13}$$

where we use "t" to denote the "time-like" direction, z, $x_\perp = x$, and

$$H = -\Delta + V(x). \tag{A.14}$$

We study system (A.13) in the case where H has spectrum consisting of one point eigenvalue, $\lambda < 0$, with corresponding eigenfunction ϕ, $\|\phi\|_{L^2} = 1$. The components of u_s and u_p, which are orthogonal to ϕ, are called radiative components. Our goal is to prove if for $t = 0$ the order-one energy is concentrated in ϕ alone, then on time scales of order ϵ^{-1} the energy in radiative components is at most of order ϵ.

Appendix B. Normal form theorem. In this section we state a normal form result on the absence of the terms driving the radiation to any order of the perturbation theory. While in the main part of the paper we have used only the fact that these terms can be removed at the first order, we find this result important and potentially useful in the search for sharper estimates of radiation growth. The results in this section are formal in the sense that we do not verify the validity of transformations and of obtained systems.

[4]Nonlinear coefficient ϵ is then the same for both fields. Therefore, in this system the energy is conserved rather than photon number. This is done to simplify the presentation. All results hold for the "true" model as well.

For the Raman energy exchange system

$$i\partial_t u_s - Hu_s = i\epsilon|u_p|^2 u_s, \tag{B.1}$$

$$i\partial_t u_p - Hu_p = -i\epsilon|u_s|^2 u_p, \tag{B.2}$$

we now use representation

$$u_s = u_0^s\phi_0^s(x) + \int_0^\infty u_\lambda^s\phi_\lambda^s(x)d\lambda,$$
$$u_p = u_0^p\phi_0^p(x) + \int_0^\infty u_\lambda^p\phi_\lambda^p(x)d\lambda,$$

where H becomes diagonal

$$H\phi_0 = \lambda_0\phi_0,$$
$$H\phi_\lambda = \lambda\phi_\lambda, \qquad \langle u_\lambda, \phi_\lambda\rangle = u_\lambda,$$

where $\lambda_0 < 0$ corresponds to the fundamental mode and the remaining part of the spectrum ($\lambda > 0$) corresponds to the continuous spectrum. In this representation the equations take the form

$$\begin{aligned}
i\partial_t u_0^s - \lambda_0 u_0^s &= i\epsilon C_{00}^{00} u_0^p\overline{u}_0^p u_0^s + i\epsilon\int_0^\infty C_{\lambda_1 0}^{00} u_0^p\overline{u}_0^p u_{\lambda_1}^s d\lambda_1 \\
&\quad + \cdots + i\epsilon\int_0^\infty\int_0^\infty\int_0^\infty C_{\lambda_1 0}^{\mu_1\mu_2} u_{\mu_1}^p\overline{u}_{\mu_2}^p u_{\lambda_1}^s d\mu_1 d\mu_2 d\lambda_1, \\
i\partial_t u_0^p - \mu_0 u_0^p &= i\epsilon C_{00}^{00} u_0^s\overline{u}_0^s u_0^p + i\epsilon\int_0^\infty C_{00}^{\mu_1 0} u_0^s\overline{u}_0^s u_{\mu_1}^p d\mu_1 \\
&\quad + \cdots + i\epsilon\int_0^\infty\int_0^\infty\int_0^\infty C_{\lambda_1\lambda_2}^{\mu_1 0} u_{\lambda_1}^s\overline{u}_{\lambda_2}^s u_{\mu_1}^p d\lambda_1 d\lambda_2 d\mu_1, \\
i\partial_t u_\lambda^s - \lambda u_\lambda^s &= i\epsilon C_{0\lambda}^{00} u_0^p\overline{u}_0^p u_0^s + i\epsilon\int_0^\infty C_{\lambda_1\lambda}^{00} u_0^p\overline{u}_0^p u_{\lambda_1}^s d\lambda_1 \\
&\quad + \cdots + i\epsilon\int_0^\infty\int_0^\infty\int_0^\infty C_{\lambda_1\lambda}^{\mu_1\mu_2} u_{\mu_1}^p\overline{u}_{\mu_2}^p u_{\lambda_1}^s d\mu_1 d\mu_2 d\lambda_1, \\
i\partial_t u_\mu^p - \mu u_\mu^p &= i\epsilon C_{00}^{0\mu} u_0^s\overline{u}_0^s u_0^p + i\epsilon\int_0^\infty C_{00}^{\mu_1\mu} u_0^s\overline{u}_0^s u_{\mu_1}^p d\mu_1 \\
&\quad + \cdots + i\epsilon\int_0^\infty\int_0^\infty\int_0^\infty C_{\lambda_1\lambda_2}^{\mu_1\mu} u_{\lambda_1}^s\overline{u}_{\lambda_2}^s u_{\mu_1}^p d\lambda_1 d\lambda_2 d\mu_1,
\end{aligned}$$

where

$$C_{\lambda_1\lambda_2}^{\mu_1\mu_2} = \int_{-\infty}^{+\infty}\phi_{\mu_1}^p\overline{\phi}_{\mu_2}^p\phi_{\lambda_1}^s\overline{\phi}_{\lambda_2}^s\,dx.$$

The natural consequence of the stimulated emission process is the invariance with respect to the phase shifts of both the signal and the pump modes:

$$u_{\lambda_i}^s, u_{\mu_j}^p \to u_{\lambda_i}^s e^{i\psi_s}, u_{\mu_j}^p e^{i\psi_p}.$$

This torus action will be called G_{sp}-action below.

Consider the class of polynomial vector fields which stay invariant under this group action. We are going to consider near-identity transformations, which commute with the torus action. Therefore these transformations map a G_{sp}-invariant vector field to another G_{sp}-invariant vector field. We will now invoke these transformations to remove nonresonant terms from the equations. We first observe that a polynomial vector field that is invariant with respect to the G_{sp}-action is generated by the monomials of this form

$$\mathbf{e}^{\mathbf{s}}_{\lambda} u^p_{\mu_1} \overline{u}^p_{\mu_2} \cdots u^p_{\mu_{m-1}} \overline{u}^p_{\mu_m} u^s_{\lambda_1} \overline{u}^s_{\lambda_2} \cdots u^s_{\lambda_{k-1}} \overline{u}^s_{\lambda_k} u^s_{\lambda_{k+1}}, \tag{B.3}$$

$$\mathbf{e}^{\mathbf{p}}_{\mu} u^s_{\lambda_1} \overline{u}^s_{\lambda_2} \cdots u^s_{\lambda_{m-1}} \overline{u}^s_{\lambda_m} u^p_{\mu_1} \overline{u}^p_{\mu_2} \cdots u^p_{\mu_{k-1}} \overline{u}^p_{\mu_k} u^p_{\mu_{k+1}}, \tag{B.4}$$

where m and k are even numbers.

DEFINITION. *The monomial of type* (B.3) *is called resonant if*

$$\mu_1 - \mu_2 + \cdots + \mu_{m-1} - \mu_m + \lambda_1 - \lambda_2 + \cdots + \lambda_{k-1} - \lambda_k + \lambda_{k+1} - \lambda = 0$$

and the monomial of type (B.4) *is called resonant if*

$$\lambda_1 - \lambda_2 + \cdots + \lambda_{m-1} - \lambda_m + \mu_1 - \mu_2 + \cdots + \mu_{k-1} - \mu_k + \mu_{k+1} - \mu = 0.$$

If in a G_{sp}-invariant vector field initially all the energy is concentrated in fundamental modes, then the radiative modes can be excited only through the terms

$$\mathbf{e}^{\mathbf{s}}_{\lambda} |u^p_0|^k |u^s_0|^l u^s_0 \quad \text{and} \quad \mathbf{e}^{\mathbf{p}}_{\mu} |u^s_0|^k |u^p_0|^l u^p_0,$$

while no other radiation driving terms can appear after application of a G_{sp}-invariant transformation. These terms are nonresonant, since the corresponding arithmetic combinations are $\lambda - \lambda_0$ and $\mu - \lambda_0$, where $\lambda, \mu > 0$ and $\lambda_0 < 0$. Therefore, $|\lambda - \lambda_0| > |\lambda_0| > 0$ and $|\mu - \lambda_0| > |\lambda_0| > 0$.

According to the standard normal form procedure, these terms can be removed by employing the transformations of the form[5]

$$u^s_{\lambda} = U^s_{\lambda} + \epsilon^{\frac{k+l}{2}} C^s_{\lambda} |U^p_0|^k |U^s_0|^l U^s_0, \tag{B.5}$$

$$u^p_{\mu} = U^p_{\mu} + \epsilon^{\frac{k+l}{2}} C^p_{\mu} |U^s_0|^k |U^p_0|^l U^p_0. \tag{B.6}$$

Now we formulate the normal form theorem.

THEOREM B.1. *For any $N \geq 1$ there exists a sequence of transformations of the form* (B.5)–(B.6)*, which bring the system to the form*

$$\begin{aligned}
i\partial_t U^s_0 - \lambda_0 U^s_0 &= i \left[\epsilon C^{00}_{00} U^p_0 \overline{U}^p_0 U^s_0 + \sum_{n_1,n_2>0}^{n_1+n_2<N+1} \epsilon^{\frac{n_1+n_2}{2}} C^s_{n1,n_2} |U^p_0|^{n_1} |U^s_0|^{n_2} U^s_0 \right] \\
&\quad + \epsilon R^s_0(U,\epsilon) + O(\epsilon^{N+1}), \\
i\partial_t U^p_0 - \lambda_0 U^p_0 &= -i \left[\epsilon C^{00}_{00} U^s_0 \overline{U}^s_0 U^p_0 + \sum_{n_1,n_2>0}^{n_1+n_2<N+1} \epsilon^{\frac{n_1+n_2}{2}} C^p_{n1,n_2} |U^p_0|^{n_1} |U^s_0|^{n_2} U^p_0 \right] \\
&\quad + \epsilon R^p_0(U,\epsilon) + O(\epsilon^{N+1}), \\
i\partial_t U^s_{\lambda} - \lambda U^s_{\lambda} &= \epsilon R^s_{\lambda}(U,\epsilon) + O(\epsilon^{N+1}), \\
i\partial_t U^p_{\mu} - \mu U^p_{\mu} &= \epsilon R^p_{\mu}(U,\epsilon) + O(\epsilon^{N+1}),
\end{aligned}$$

[5]Capitals denote new variables while small ones denote old variables.

where $R_*^{s,p}(U,\epsilon)$ are the terms which vanish if there is no energy in radiative modes ($U_\lambda^s = U_\mu^p = 0$ for all $\lambda, \mu > 0 \Rightarrow R = 0$).

Proof. We will prove the theorem by applying a series of nearly identical transformations. We start with the transformation

$$u_\lambda^s = U_\lambda^s + \epsilon C_\lambda^s U_0^p \overline{U_0^p} U_0^s.$$

Straightforward calculations show that in order to remove the corresponding radiation driving terms, the coefficient C_λ^s must be of the form

$$C_\lambda^s = \frac{C_{0\lambda}^{00}}{i(\lambda_0 - \lambda)}$$

and similarly to remove pump radiation driving terms, we apply

$$u_\mu^p = U_\mu^p + \epsilon C_\mu^p U_0^s \overline{U_0^s} U_0^p$$

with

$$C_\mu^p = \frac{C_{0\mu}^{00}}{i(\mu_0 - \mu)}.$$

Our results from the previous sections indicate that the transformations are valid and the new system is well defined. Indeed, with the first-order radiation driving terms removed, the obtained system is equivalent to (3.14)–(3.15).

Next, we formally remove quadratic radiation driving terms. We observe that all transformations are near-identity ones differing only by fundamental mode amplitudes. No small denominators arise due to the gap in the spectrum (between the eigenvalue and the continuum spectrum). Continuing these transformations, we remove higher-order radiation driving terms to order N. ∎

Appendix C. Numerical simulations. We verify some of the results obtained in this paper by carrying out numerical simulations. We simulate system (1.2) in one dimension, where the potential is chosen to be $V = \mathrm{sech}^2(x)$, so that the fundamental mode can be explicitly calculated. We use the initial data with all the power (L^2 norm) contained in fundamental modes.

The numerical simulation uses a Fourier split-step scheme, where evolutions due to dispersive, potential, and nonlinear interactions are calculated separately. Nonlinear interaction is solved exactly using the standard solution of the corresponding ODE [1]. Time step is chosen to be $\Delta t = 0.01$ and there are 2^{12} Fourier modes. In Figure 1, the L^2 norm of total radiation is calculated after sufficiently long evolution, so that power exchange between the fields is almost complete. This is done for $\epsilon \in [0.005, 0.05]$. One can see that the time interval is sufficiently long from Figure 2, where for the smallest $\epsilon = 0.005$, the power of both fields contained in the fundamental modes is computed. Even in this case with the smallest ϵ (so that the energy exchange takes longer) there is enough time for the pump field to transfer almost all the power to the signal field. It appears from Figure 1 that losses due to radiation (L^2 norm) scale linearly with nonlinearity strength ϵ, as predicted by our analysis.

Acknowledgment. Part of this research was carried out while V. Zharnitsky was visiting the Program in Applied and Computational Mathematics at Princeton University. He would like to thank Ingrid Daubechies for her hospitality and for providing stimulating research environment.

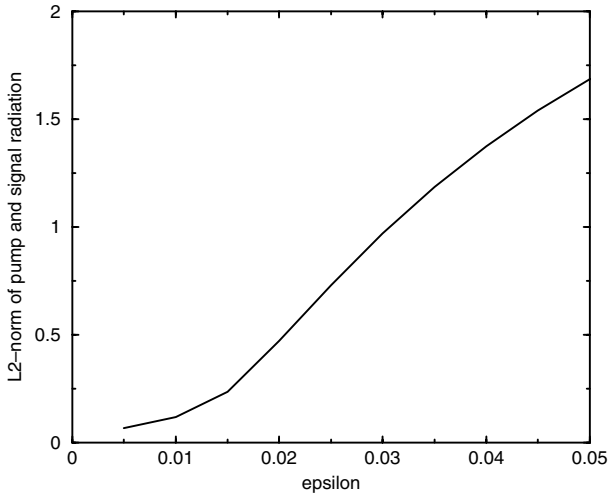

FIG. 1. *Dependence of radiation power on time. The radiation is "measured" after the evolution for* 75 *units of dimensionless time.*

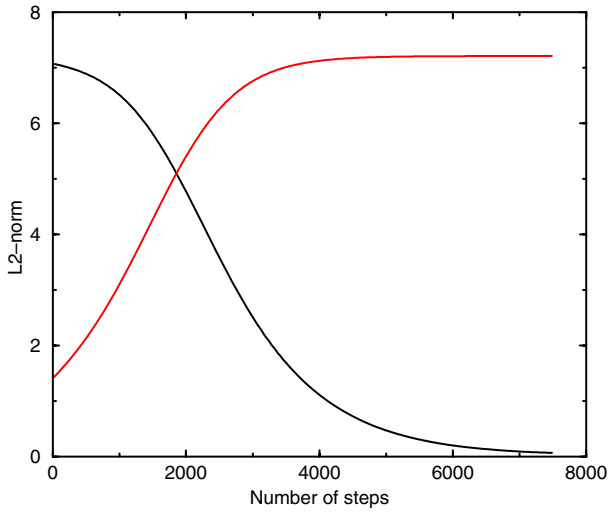

FIG. 2. *Power exchange between fundamental modes for the smallest* $\epsilon = 0.005$ *after the evolution for the same time* $T = 75$ *(it corresponds to* 7500 *steps). Note that the pump field is almost completely "depleted." This indicates that time interval* $T = 75$ *is of sufficient length for the power exchange to take place.*

BLOW-UP BEHAVIOR OF PLANAR HARMONIC FUNCTIONS SATISFYING A CERTAIN EXPONENTIAL NEUMANN BOUNDARY CONDITION*

KAI MEDVILLE† AND MICHAEL S. VOGELIUS†

Abstract. In this paper we provide a detailed analysis of the limiting behavior of some very general families of solutions to the boundary value problem $\Delta v = 0$ in Ω, $\partial v/\partial \mathbf{n} = \lambda \sinh(v)$ on $\partial\Omega$, as $\lambda \to 0^+$. The existence of countably many of these families has already been established in [*Quart. Appl. Math.*, 60 (2002), pp. 675–694] and [*Proc. Roy. Soc. Edinburgh Sect. A*, 133 (2003), pp. 119–149].

Key words. harmonic functions, exponential boundary conditions, blow-up

1. Introduction.

In this paper we give a detailed analysis of the limiting "blow-up" behavior of certain solutions to the two-dimensional, nonlinear elliptic boundary value problem

$$\begin{aligned} &\Delta v_\lambda = 0 \quad \text{in } \Omega, \\ &\frac{\partial v_\lambda}{\partial \mathbf{n}} = \lambda \sinh(v_\lambda) \quad \text{on } \partial\Omega. \end{aligned} \tag{1.1}$$

This is a simplified model problem, the likes of which frequently show up in connection with corrosion/oxidation modeling. For a brief discussion of some practical aspects of this problem, and some references to the applied literature, we refer the reader to [5] and [12]. For $\lambda < 0$ the solution structure of (1.1) is trivial: zero is the only solution. For $\lambda = 0$ the only solutions are constants. Our focus is thus on certain nontrivial (nonzero) solutions corresponding to $\lambda > 0$, and in particular on the asymptotic behavior of these solutions as λ approaches zero. In the case when $\Omega = D$ is a disk (e.g., the unit disk) it is possible to find explicit formulas for a countable set of families of solutions to the problem (1.1) (cf. [4]). To be precise, let $\{\mathbf{x}_i\}_{i=0}^{2k-1}$ be a set of $2k$ equispaced points on the unit circle, and set

$$v_{2k,\lambda}(x) = \sum_{i=0}^{2k-1} (-1)^i K(x - \mu_k(\lambda)\mathbf{x}_i),$$

with $K(x) = \log|x|^2$ and $\mu_k(\lambda) = [(k+\lambda)/(k-\lambda)]^{1/2k}$. For any positive integer k and any $0 < \lambda < k$ the functions $v_{2k,\lambda}$ are solutions to (1.1). A simple computation shows that

$$\|\nabla v_{2k,\lambda}\|^2_{L^2(D)} = 8k\pi \log(1/\lambda) + O(1),$$

as $\lambda \to 0^+$. It is also easy to see that

$$\frac{\partial v_{2k,\lambda}}{\partial \mathbf{n}} \to 2\pi \sum_{i=0}^{2k-1} (-1)^{i+1} \delta_{\mathbf{x}_i}$$

in the sense of measures on ∂D, as $\lambda \to 0^+$.

In [6] it was shown that similar families of solutions whose gradient L^2 norms blow up like $\sqrt{\log(1/\lambda)}$, as $\lambda \to 0^+$, continue to exist for arbitrary smooth domains, Ω. These solutions were characterized variationally, and it was also shown that the corresponding boundary currents, $\partial v_\lambda/\partial \mathbf{n} = \lambda \sinh(v_\lambda)$, stay bounded in $L^1(\partial\Omega)$ (the bound depending on the particular family). We were thus able to conclude that there exist appropriately normalized convergent subsequences of solutions, and we showed that each subsequence has a finite, nonempty set of "blow-up" points, which also happen to be the points at which the limit of the absolute value of the flux, $|\partial v_\lambda/\partial \mathbf{n}|$, has nonzero point masses. As was pointed out in [6] these solutions do not necessarily represent all solutions. For instance, for certain nonsimply connected domains it is not hard to construct additional families of solutions whose gradient L^2 norms blow up faster than $\sqrt{\log(1/\lambda)}$ (and which themselves blow up everywhere, except on a set of measure 0).

In this paper we provide a detailed characterization of the elliptic boundary value problem satisfied by an arbitrary ($\lambda \to 0^+$) limit point v_0, of the normalized functions $v_\lambda^0 = v_\lambda - \int_{\partial\Omega} v_\lambda/|\partial\Omega|$, coming from a family of solutions to (1.1) whose boundary currents stay bounded in $L^1(\partial\Omega)$. In particular we show (Theorem 3.1) that the limiting boundary flux, in addition to a nontrivial finite sum of point masses, may contain a regular part that is proportional to e^{v_0} or e^{-v_0}. The possible presence of a regular part of the limiting boundary flux represents a sharp contrast to the corresponding situation for the problem $\Delta v_\lambda = -\lambda e^{v_\lambda}$ (with Dirichlet boundary conditions) where only a pure sum of (negative) point masses occur. It will frequently happen that the constant in front of the exponential term is zero (so that the regular part vanishes)—this is, for instance, the case whenever the solutions have an odd symmetry, or in general whenever the boundary averages of the solutions are small in the sense that $\lambda \exp[|\int_{\partial\Omega} v_\lambda|/|\partial\Omega|] \to 0$. We do, however, also provide very convincing numerical evidence that nonvanishing regular parts do indeed occur: For a family of domains that are simple conformal images (using the maps $z \to e^{\gamma z}$) of the unit disk, our computations clearly document how, for certain values of the parameter γ, a regular part seems to emerge.

For simply connected domains, we derive necessary conditions for the weights and locations of the point masses. The weights are always larger than or equal to 2π in absolute value, and generically take values $\pm 2\pi$ (Theorem 4.1). The conditions concerning locations are derived under the assumption that the limit flux be a pure sum of point masses (no regular part). These conditions express the fact that the tangential derivative of the regular part of the limiting solution, v_0, vanishes at all potential point mass locations (Theorem 4.6). They may be seen as the analogues of the conditions derived in [11] (see also [10] and [13]) for the weights and the singularity locations of limits of solutions to the equation $\Delta v_\lambda = -\lambda e^{v_\lambda}$, with Dirichlet boundary conditions.

2. The particular solutions. Let $\lambda_n \to 0$ be a sequence of positive real numbers, and let v_{λ_n} be solutions of

$$\begin{aligned} &\Delta v_{\lambda_n} = 0 \quad \text{in } \Omega, \\ &\frac{\partial v_{\lambda_n}}{\partial \mathbf{n}} = \lambda_n \sinh(v_{\lambda_n}) \quad \text{on } \partial\Omega, \end{aligned} \tag{2.1}$$

where Ω is a bounded, smooth (C^∞) domain in $\mathbb{R}^2$. Whenever in this paper we talk about solutions to (2.1), we mean $v_{\lambda_n} \in H^1(\Omega)$ that satisfy the standard weak formulation of this nonlinear Neumann problem. Due to elliptic regularity theory it is well known that any such solution is also a classical $C^\infty(\overline{\Omega})$ solution. Let $E_\lambda(\cdot)$ denote the energy

$$E_\lambda(v) = \frac{1}{2}\int_\Omega |\nabla v|^2 \, dx - \lambda \int_{\partial\Omega} (\cosh(v) - 1) \, d\sigma.$$

Suppose that, for some positive constants a_i, b_i, $i = 0, 1$,

$$a_0 \log\left(\frac{1}{\lambda_n}\right) - b_0 \le E_{\lambda_n}(v_{\lambda_n}) \le a_1 \log\left(\frac{1}{\lambda_n}\right) + b_1. \tag{2.2}$$

Since $\cosh(x) - 1 \le \epsilon x \sinh(x) + C_\epsilon$ (for any $0 < \epsilon$), it follows that, for solutions to (2.1),

$$\begin{aligned} E_{\lambda_n}(v_{\lambda_n}) &\le \frac{1}{2}\int_\Omega |\nabla v_{\lambda_n}|^2 \, dx \\ &= E_{\lambda_n}(v_{\lambda_n}) + \lambda_n \int_{\partial\Omega} (\cosh(v_{\lambda_n}) - 1) \, d\sigma \\ &\le E_{\lambda_n}(v_{\lambda_n}) + \epsilon\lambda_n \int_{\partial\Omega} v_{\lambda_n} \sinh(v_{\lambda_n}) \, d\sigma + C_\epsilon \lambda_n \\ &= E_{\lambda_n}(v_{\lambda_n}) + \epsilon \int_\Omega |\nabla v_{\lambda_n}|^2 \, dx + C_\epsilon \lambda_n, \end{aligned}$$

and so the assumption (2.2) is also (for $0 < \lambda_n < C$) equivalent to

$$a_0 \log\left(\frac{1}{\lambda_n}\right) - b_0 \le \int_\Omega |\nabla v_{\lambda_n}|^2 \, dx \le a_1 \log\left(\frac{1}{\lambda_n}\right) + b_1 \tag{2.3}$$

for some positive constants a_i, b_i, $i = 0, 1$. The existence of infinitely (countably) many families of solutions to (2.1), that satisfy (2.2) (or (2.3)), was already established in [6]. These solutions were characterized variationally. To be more precise, the upper bound in (2.2) (or (2.3)) is a consequence of the particular construction we perform in [6]. The lower bounds, however, hold for any nontrivial solution, as asserted by the following lemma.

LEMMA 2.1. *Suppose v_λ, $0 < \lambda$, is a solution to* (1.1) *which is not identically zero. There exist constants $a, b > 0$, independent of λ and v_λ such that*

$$a \log\left(\frac{1}{\lambda}\right) - b \le E_\lambda(v_\lambda) \quad \textit{and} \quad a \log\left(\frac{1}{\lambda}\right) - b \le \int_\Omega |\nabla v_\lambda|^2 \, dx.$$

Proof. This is a restatement of Lemma 3.2 in [6]. We refer to that paper for the proof. ∎

A consequence of the upper bound in (2.2) (or (2.3)) is that

$$\|\lambda_n \sinh(v_{\lambda_n})\|_{L^1(\partial\Omega)} = \lambda_n \int_{\partial\Omega} |\sinh(v_{\lambda_n})|\, d\sigma \le C. \tag{2.4}$$

The verification of this relies on the following real analysis lemma.

LEMMA 2.2. *Let a and b be two given positive constants, and let w be a continuous function such that for a certain $\lambda \in (0,1)$, one has*

$$\int_{\partial\Omega} |w| e^{|w|}\, d\sigma \le \frac{a}{\lambda} \log\left(\frac{1}{\lambda}\right) + b.$$

There exists a positive constant C, depending only on a, b, and $|\partial\Omega|$ such that

$$\int_{\partial\Omega} e^{|w|}\, dx \le \frac{C}{\lambda}.$$

Proof. Let f denote the function $f(x) = x \log x$. A simple computation shows that f is convex and monotonically increasing on the half-line $[1,\infty)$. An application of Jensen's inequality gives

$$\begin{aligned} f\left(\int_{\partial\Omega} e^{|w|} \frac{d\sigma}{|\partial\Omega|}\right) &\le \int_{\partial\Omega} f\big(e^{|w|}\big) \frac{d\sigma}{|\partial\Omega|} \\ &= \int_{\partial\Omega} e^{|w|} |w| \frac{d\sigma}{|\partial\Omega|} \\ &\le \frac{a}{|\partial\Omega|\lambda} \log\left(\frac{1}{\lambda}\right) + \frac{b}{|\partial\Omega|} \\ &\le \frac{C}{\lambda} \log \frac{C}{\lambda} = f\left(\frac{C}{\lambda}\right), \end{aligned}$$

with $C \ge 1$ depending only on a, b, and $|\partial\Omega|$. The monotonicity of f now yields the desired estimate. ∎

To arrive at (2.4) from the upper bound in (2.3), simply note that

$$\begin{aligned} \int_{\partial\Omega} |v_{\lambda_n}| e^{|v_{\lambda_n}|}\, d\sigma &\le 2 \int_{\partial\Omega} v_{\lambda_n} \sinh(v_{\lambda_n})\, d\sigma + |\partial\Omega| e^{-1} \\ &= 2\lambda_n^{-1} \int_{\Omega} |\nabla v_{\lambda_n}|^2\, dx + |\partial\Omega| e^{-1} \\ &\le \frac{a}{\lambda_n} \log\left(\frac{1}{\lambda_n}\right) + b, \end{aligned}$$

and then use Lemma 2.2.

We shall also make use of the decomposition $v_{\lambda_n} = v^0_{\lambda_n} + s_{\lambda_n}$, with $s_{\lambda_n} = \int_{\partial\Omega} v_{\lambda_n}\, d\sigma/|\partial\Omega|$ (and thus $\int_{\partial\Omega} v^0_{\lambda_n}\, d\sigma = 0$). By a combination of Jensen's inequality for the exponential function and the estimate (2.4), it follows immediately that

$$\begin{aligned} |s_{\lambda_n}| &\le \log\left(\exp\left(\int_{\partial\Omega} |v_{\lambda_n}| \frac{d\sigma}{|\partial\Omega|}\right)\right) \le \log\left(\int_{\partial\Omega} \exp(|v_{\lambda_n}|) \frac{d\sigma}{|\partial\Omega|}\right) \\ &\le \log\left(\int_{\partial\Omega} \frac{2}{|\partial\Omega|} |\sinh(v_{\lambda_n})|\, d\sigma + 1\right) \le \log\left(\frac{C}{\lambda_n} + 1\right) \\ &\le \log \frac{1}{\lambda_n} + D. \end{aligned} \tag{2.5}$$

This estimate was used in the "blow-up" analysis in [6]. We note that as an immediate consequence of (2.5) we get the estimate $\lambda_n e^{|s_{\lambda_n}|} \le e^D$.

3. The limiting behavior. We shall now study in more detail the limiting behavior of solutions v_{λ_n} to (2.1) that satisfy the L^1 boundary flux estimate (2.4). For that purpose it is useful to introduce the Neumann function $N(x,y)$. For fixed $y \in \Omega$ this solves

$$\begin{aligned} \Delta_x N(x,y) &= \delta_y \quad \text{in } \Omega, \\ \frac{\partial N}{\partial \mathbf{n}_x}(x,y) &= \frac{1}{|\partial\Omega|}, \end{aligned}$$

with the normalization $\int_{\partial\Omega} N(x,y)\, d\sigma_x = 0$. It is well known that $N(x,y)$ may be smoothly extended to $\overline{\Omega \times \Omega} \setminus \{x = y\}$ and that $N(x,y) = N(y,x)$. For fixed $y \in \partial\Omega$ the function $N(x,y)$ satisfies

$$\begin{aligned} \Delta_x N(x,y) &= 0 \quad \text{in } \Omega, \\ \frac{\partial N}{\partial \mathbf{n}_x}(x,y) &= -\delta_y + \frac{1}{|\partial\Omega|}. \end{aligned}$$

For fixed $y \in \partial\Omega$, $N(x,y)$ therefore allows the decomposition

$$N(y,x) = N(x,y) = \frac{1}{\pi} \log|x-y| + H_y(x), \tag{3.1}$$

where the function $H_y(\cdot) \in C^\infty(\overline{\Omega})$ is the classical solution to

$$\begin{aligned} &\Delta_x H_y(x) = 0 \quad \text{in } \Omega, \qquad \frac{\partial H_y}{\partial \mathbf{n}_x} = -\frac{1}{\pi} \frac{(x-y)\cdot \mathbf{n}_x}{|x-y|^2} + \frac{1}{|\partial\Omega|} \quad \text{on } \partial\Omega, \\ &\qquad \text{with } \int_{\partial\Omega} H_y \, d\sigma_x = -\int_{\partial\Omega} \frac{1}{\pi} \log|x-y| \, d\sigma_x. \end{aligned} \tag{3.2}$$

In terms of $N(x,y)$ the functions $v^0_{\lambda_n}$ may be represented as follows:

$$v^0_{\lambda_n}(y) = -\int_{\partial\Omega} N(x,y) \frac{\partial v_{\lambda_n}}{\partial \mathbf{n}} \, d\sigma_x = -\int_{\partial\Omega} N(x,y) \lambda_n \sinh(v_{\lambda_n}) \, d\sigma_x. \tag{3.3}$$

Given any function f, let $f^+ \geq 0$ and $f^- \geq 0$ denote its positive and negative part, respectively, i.e., let $f^+ = \max\{f, 0\}$ and $f^- = -\min\{f, 0\}$. With this definition $f = f^+ - f^-$ and $|f| = f^+ + f^-$. Some of our main results are contained in the following theorem.

THEOREM 3.1. *Let $\Omega \subset \mathbb{R}^2$ be a bounded smooth (C^∞) domain, and let $v_{\lambda_n} \in H^1(\Omega)$, $\lambda_n \to 0^+$, be a sequence of nontrivial, i.e., not identically vanishing, solutions to the nonlinear elliptic Neumann problem* (2.1) *that additionally satisfy the boundary flux estimate* (2.4). *Decompose v_{λ_n} as $v_{\lambda_n} = v^0_{\lambda_n} + s_{\lambda_n}$, with $s_{\lambda_n} = \int_{\partial\Omega} v_{\lambda_n} \, d\sigma / |\partial\Omega|$. There exists a subsequence, for simplicity also denoted v_{λ_n}; two positive, regular Borel measures μ_+ and μ_-; and two nonnegative constants d_+ and d_- such that*

$$\lambda_n \sinh(v^+_{\lambda_n}) = \lambda_n \sinh(v_{\lambda_n})^+ \to \mu_+, \qquad \lambda_n \sinh(v^-_{\lambda_n}) = \lambda_n \sinh(v_{\lambda_n})^- \to \mu_-$$

in the sense of measures on $\partial\Omega$ (i.e., in the weak* topology of the dual of $C^0(\partial\Omega)$) and

$$\lambda_n e^{s_{\lambda_n}} \to d_+, \qquad \lambda_n e^{-s_{\lambda_n}} \to d_-.$$

At least one of the constants d_+ and d_- is zero, i.e., there are two possible scenarios:

$$(d_+, d_-) = (d_+, 0) \quad or \quad (d_+, d_-) = (0, d_-).$$

The subsequence $v^0_{\lambda_n}$ converges in $H^t(\Omega)$ for any $t < 1$; the limit, v_0, is the solution to

$$\Delta v_0 = 0 \quad in\ \Omega, \qquad \frac{\partial v_0}{\partial \mathbf{n}} = \mu_+ - \mu_- \quad on\ \partial\Omega, \quad \int_{\partial\Omega} v_0\ d\sigma = 0,$$

in the sense that

$$v_0(y) = -\int_{\partial\Omega} N(x,y)\ d(\mu_+ - \mu_-)_x, \quad y \in \Omega.$$

There exist two finite sets of points $\{\mathbf{x}_i^+\}_{i=1}^M$ and $\{\mathbf{x}_i^-\}_{i=1}^N \subset \partial\Omega$, and two sets of positive weights $\{\alpha_i^+\}_{i=1}^M$ and $\{\alpha_i^-\}_{i=1}^N$ such that

$$\mu_+ = \sum_{i=1}^M \alpha_i^+ \delta_{\mathbf{x}_i^+} + \frac{d_+}{2} e^{v_0}, \qquad \mu_- = \sum_{i=1}^N \alpha_i^- \delta_{\mathbf{x}_i^-} + \frac{d_-}{2} e^{-v_0}. \tag{3.4}$$

The combined set $S = \{\mathbf{x}_i^+\}_{i=1}^M \cup \{\mathbf{x}_i^-\}_{i=1}^N$ is nonempty. The function v_0 is infinitely smooth away from S, i.e., $v_0 \in C^\infty(\overline{\Omega}\backslash S)$, and the convergence of $v^0_{\lambda_n}$ toward v_0 takes place in $C^\infty(K)$ for any compact set $K \subset \overline{\Omega}\backslash S$. The functions $\frac{d_\pm}{2} e^{\pm v_0}$ of the limiting boundary fluxes (3.4) *are in $L^1(\partial\Omega)$. The set $S = \{\mathbf{x}_i^+\}_{i=1}^M \cup \{\mathbf{x}_i^-\}_{i=1}^N$ represents exactly the locations of the point masses of the measure $\mu_+ + \mu_- = \lim_{\lambda_n \to 0^+} \lambda_n |\sinh(v_{\lambda_n})|$. Furthermore, this set also represents the "blow-up" points for the subsequence $v^0_{\lambda_n}$, in the sense that*

$$S = \{x \in \bar{\Omega} : \exists x_n \in \bar{\Omega},\ with\ x_n \to x,\ such\ that\ |v^0_{\lambda_n}(x_n)| \to \infty\}.$$

Remark 3.2. As stated in the theorem, the locations of the point masses for the measure $\lim_{\lambda_n \to 0^+} \lambda_n |\sinh(v_{\lambda_n})| = \mu_+ + \mu_-$ are exactly the set $\{\mathbf{x}_i^+\}_{i=1}^M \cup \{\mathbf{x}_i^-\}_{i=1}^N$. We cannot exclude some overlap between the points $\mathbf{x}_i^+$ of the measure μ_+ and the points $\mathbf{x}_i^-$ of the measure μ_-. In the case of common points it might at first seem possible that the corresponding coefficients α^+ and α^- are equal. In other words it might at first seem possible that the locations of the nonzero point masses for the measure $\lim_{\lambda_n \to 0^+} \lambda_n \sinh(v_{\lambda_n}) = \mu_+ - \mu_-$ are a strict subset of $\{\mathbf{x}_i^+\}_{i=1}^M \cup \{\mathbf{x}_i^-\}_{i=1}^N$. However, a closer analysis shows that this is never the case; in Theorem 4.1 we prove that for Ω simply connected $|\alpha^+ - \alpha^-|$ (as well as $\alpha^+ + \alpha^-$) is always greater than or equal to 2π. In particular, it follows that $\mu_+ - \mu_-$ and $\mu_+ + \mu_-$ have the exact same nonzero point mass locations. See also Remark 4.2, following the statement of Theorem 4.1.

Remark 3.3. In the case when Ω is a disk we have constructed countably many families of explicit solutions satisfying boundary flux bound (2.4) (cf. [4]). These solutions all have $s_\lambda = \int_{\partial\Omega} v_\lambda\ d\sigma/|\partial\Omega| = 0$, so that $d_+ = d_- = 0$, and thus the corresponding limiting problems have boundary fluxes consisting of point masses only. In section 5 of this paper we provide numerical examples of families of solutions for which the limiting boundary fluxes have point masses, as well as nonzero regular parts. For these examples the domain, Ω, is an exponential image of a disk.

Remark 3.4. If v_{λ_n}, $\lambda_n \to 0^+$, is a sequence of solutions for which the boundary flux estimate (2.4) does not hold, then we may extract a subsequence such that

$$\alpha_n = \|\lambda_n \sinh(v_{\lambda_n})\|_{L^1(\partial\Omega)} \to \infty.$$

Consider now $w_{\lambda_n} = v_{\lambda_n}/\alpha_n$. By extraction of a subsequence we may obtain that

$$\frac{\partial w_{\lambda_n}}{\partial \mathbf{n}} = \lambda_n \sinh(v_{\lambda_n})/\alpha_n \to \tilde{\mu},$$

in the sense of measures on $\partial\Omega$. If we *assume* that the limiting measure $\tilde{\mu}$ is *not* identically zero, then it is easy to show that

$$w^0_{\lambda_n}(y) = -\int_{\partial\Omega} N(x,y)\frac{\partial w_{\lambda_n}}{\partial \mathbf{n}}\, d\sigma_x \to -\int_{\partial\Omega} N(x,y)\, d\tilde{\mu}_x = w_0(y), \quad y \in \Omega,$$

with $w_0(y)$ being different from zero almost everywhere in Ω. It follows immediately that $v^0_{\lambda_n} = \alpha_n w^0_{\lambda_n}$ converges to $\pm\infty$ almost everywhere in Ω. As indicated by this simple argument, "blow-up" almost everywhere in Ω appears as a highly probable alternative to the finite (boundary) point "blow-up" described by Theorem 3.1. However, we do want to emphasize that here, unlike in the case of the boundary value problem $\Delta u_\lambda = -\lambda e^{u_\lambda}$ in Ω, $u_\lambda = 0$ on $\partial\Omega$ (cf. [11]), this is *not* the only alternative for a sequence v_{λ_n}, with $\|\lambda_n \sinh(v_{\lambda_n})\|_{L^1(\partial\Omega)} \to \infty$. For instance, it is very easy to select, among the explicit solutions we constructed in [4], a sequence whose elements (as $\lambda_n \to 0^+$) come from "higher and higher" branches in such a way that $\|\lambda_n \sinh(v_{\lambda_n})\|_{L^1(\partial\Omega)} \to \infty$, but at the same time $v^0_{\lambda_n}(y) = v_{\lambda_n}(y)$ has a finite limit (zero) at any point y inside the unit disk.

Proof of Theorem 3.1. Due to the L^1 bound (2.4) on $\lambda_n \sinh(v_{\lambda_n})$ it follows that $\lambda_n \sinh(v_{\lambda_n})^{\pm}$ are bounded in $L^1(\partial\Omega)$, and therefore norm bounded in the dual of $C^0(\partial\Omega)$. From the bound $|s_{\lambda_n}| \le \log\frac{1}{\lambda_n} + D$ (see (2.5)) we get that $\lambda_n e^{|s_{\lambda_n}|} \le e^D$. These bounds (and the compactness) imply the existence of a subsequence (also denoted λ_n) two nonnegative, regular Borel measures μ_+, μ_- and two nonnegative constants d_+, d_-, so that

$$\lambda_n \sinh(v_{\lambda_n})^+ \to \mu_+, \qquad \lambda_n \sinh(v_{\lambda_n})^- \to \mu_- \tag{3.5}$$

in the sense of measures—that is, in the weak* topology on the dual of $C^0(\partial\Omega)$—and

$$\lambda_n e^{s_{\lambda_n}} \to d_+, \qquad \lambda_n e^{-s_{\lambda_n}} \to d_-.$$

If $d_+ > 0$, then $e^{s_{\lambda_n}} \to \infty$, and thus $e^{-s_{\lambda_n}} \to 0$, so that $d_- = 0$; similarly, if $d_- > 0$, then we may conclude that $d_+ = 0$. In summary, at least one of the constants d_+ and d_- is zero.

Due to the fact that $\int_{\partial\Omega} \lambda_n \sinh(v_{\lambda_n})\, d\sigma = 0$ we conclude that $(\mu_+ - \mu_-)(\partial\Omega) = \lim_{\lambda_n\to 0}\int_{\partial\Omega} \lambda_n \sinh(v_{\lambda_n})\, d\sigma = 0$, or $\mu_+(\partial\Omega) = \mu_-(\partial\Omega)$. The $L^1(\partial\Omega)$ bound on $\lambda_n \sinh(v_{\lambda_n})$ in combination with Sobolev's imbedding theorem implies that

$$\begin{aligned}\|\lambda_n \sinh(v_{\lambda_n})\|_{H^{-s}(\partial\Omega)} &= \sup_{\|w\|_{H^s(\partial\Omega)}\le 1}\int_{\partial\Omega} \lambda_n \sinh(v_{\lambda_n}) w\, d\sigma \\ &\le \|\lambda_n \sinh(v_{\lambda_n})\|_{L^1(\partial\Omega)} \sup_{\|w\|_{H^s(\partial\Omega)}\le 1} \|w\|_{L^\infty(\partial\Omega)} \le C\end{aligned}$$

for any $s > 1/2$. Duality and elliptic estimates for solutions to the boundary value problem $\Delta w = f$ in Ω, $\partial w/\partial\mathbf{n} = \text{const}$ on $\partial\Omega$ now yield

$$\|v^0_{\lambda_n}\|_{H^{\frac{3}{2}-s}(\Omega)} \le C\|\lambda_n \sinh(v_{\lambda_n})\|_{H^{-s}(\partial\Omega)} \le C \tag{3.6}$$

for arbitrary $\frac{3}{2} - s < 1$. By compactness we may extract a subsequence, also referred to as $v^0_{\lambda_n}$, so that $v^0_{\lambda_n}$ converges, in say $L^2(\Omega)$, to a limit v_0. By compactness (and uniqueness of the limit) this subsequence will now actually converge to v_0 in $H^t(\Omega)$ for any $t < 1$. Since

$$v^0_{\lambda_n}(y) = -\int_{\partial\Omega} N(x,y)\frac{\partial v_{\lambda_n}}{\partial \mathbf{n}}\, d\sigma_x = -\int_{\partial\Omega} N(x,y)\lambda_n \sinh(v_{\lambda_n})\, d\sigma_x, \quad y \in \Omega,$$

it follows immediately from (3.5) that $v^0_{\lambda_n}$ converges to $-\int_{\partial\Omega} N(x,y)\ d(\mu_+ - \mu_-)_x$ pointwise in Ω. By uniqueness of the limit we thus get

$$v_0(y) = -\int_{\partial\Omega} N(x,y)\ d(\mu_+ - \mu_-)_x. \tag{3.7}$$

Let ν denote the nonnegative measure $\nu = \mu_+ + \mu_-$. Following [6] (and [3]) we call a point $x_0 \in \partial\Omega$ *regular* if there exists a continuous function $0 \le \psi \le 1$, with $\psi \equiv 1$ in a neighborhood of x_0 such that $\int_{\partial\Omega} \psi d\nu < \pi/2$. Lemma 4.5 of [6] shows that given any regular point x_0 there exists a neighborhood $B_{r_0}(x_0) \cap \partial\Omega$ of x_0, and a constant C such that

$$\|v^0_{\lambda_n}\|_{L^\infty(B_{r_0}(x_0)\cap\partial\Omega)} \le C.$$

The proof of this estimate relies crucially on (an appropriate adaptation of) an inequality due to Brezis and Merle (cf. [3] and [6]). Following [6] we call a point $x_0 \in \partial\Omega$ *singular* if it is not regular in the above sense. A point $x_0 \in \partial\Omega$ is thus singular if for any continuous $0 \le \psi \le 1$, with $\psi \equiv 1$ in a neighborhood of x_0, we have $\int_{\partial\Omega} \psi d\nu \ge \pi/2$; as a consequence, $\nu(\{x_0\}) \ge \pi/2$ for any singular point x_0. Let S denote the set of singular points. We immediately conclude that S must consist of finitely many points and that

$$\#S \le \frac{\int_{\partial\Omega} d\nu}{\inf_{x_0\in S}\ \nu(\{x_0\})} \le 2\frac{\int_{\partial\Omega} d\nu}{\pi}.$$

This estimate is part of Lemma 4.7 of [6]. That same lemma further establishes that S is nonempty by showing that otherwise $E_{\lambda_n}(v_{\lambda_n}) \to 0$ as $\lambda_n \to 0^+$, which obviously contradicts the lower bound for nontrivial solutions (cf. Lemma 2.1). Thus $\pi/2 \le \nu(\partial\Omega) = \mu_+(\partial\Omega) + \mu_-(\partial\Omega)$, and so μ_+, μ_-, and ν are indeed positive measures.

Since $v^0_{\lambda_n}|_{\partial\Omega}$ is bounded in L^∞ near any regular point it follows that

$$\frac{\partial v^0_{\lambda_n}}{\partial \mathbf{n}} = \frac{\lambda_n}{2}e^{v_{\lambda_n}} - \frac{\lambda_n}{2}e^{-v_{\lambda_n}} = \frac{\lambda_n}{2}e^{s_{\lambda_n}}e^{v^0_{\lambda_n}} - \frac{\lambda_n}{2}e^{-s_{\lambda_n}}e^{-v^0_{\lambda_n}}$$

is bounded in L^∞, and thus in L^2, near any regular point. By elliptic regularity (and the estimate (3.6)) it now follows that for any regular point, x_0,

$$\|v^0_{\lambda_n}\|_{H^{3/2}(B_{r_1}(x_0)\cap\Omega)} \le C$$

for some $r_1 > 0$. Consequently

$$\|v^0_{\lambda_n}\|_{H^1(B_{r_1}(x_0)\cap\partial\Omega)} \le C, \qquad \|e^{\pm v^0_{\lambda_n}}\|_{H^1(B_{r_1}(x_0)\cap\partial\Omega)} \le C,$$
$$\text{and} \quad \left\|\frac{\partial v^0_{\lambda_n}}{\partial \mathbf{n}}\right\|_{H^1(B_{r_1}(x_0)\cap\partial\Omega)} \le C.$$

By repeated use of elliptic estimates (induction) we may conclude that there exists $r_1 > 0$ such that

$$\|v^0_{\lambda_n}\|_{H^k(B_{r_1}(x_0)\cap\partial\Omega)} \le C_k, \qquad \|e^{\pm v^0_{\lambda_n}}\|_{H^k(B_{r_1}(x_0)\cap\partial\Omega)} \le C_k,$$
$$\text{and} \quad \left\| \frac{\partial v^0_{\lambda_n}}{\partial \mathbf{n}} \right\|_{H^k(B_{r_1}(x_0)\cap\partial\Omega)} \le C_k \quad \text{for any } k \ge 1.$$

Therefore

$$\|v^0_{\lambda_n}\|_{H^s(B_{r_1}(x_0)\cap\Omega)} \le C_s \quad \text{for any } s \ge 1.$$

In combination with a compactness argument and interior elliptic regularity results this yields

$$\|v^0_{\lambda_n}\|_{H^s(K)} \le C_{s,K} \quad \text{for any index } s \tag{3.8}$$

and any compact set $K \subset \overline{\Omega} \setminus S$. Since we already know that $v^0_{\lambda_n}$ converges to v_0 in $H^t(\Omega)$, $t < 1$, it follows from (3.8), compactness, and the uniqueness of the limit that v_0 lies in $C^\infty(\overline{\Omega} \setminus S)$ and that $v^0_{\lambda_n}$ converges to v_0 in $C^\infty(K)$ for any compact set $K \subset \overline{\Omega} \setminus S$ (i.e., $v^0_{\lambda_n}$ converges to v_0 in $C^\infty(\overline{\Omega} \setminus S)$). In particular,

$$\begin{aligned} &v^0_{\lambda_n} \text{ converges to } v_0 \text{ uniformly with all derivatives} \\ &\text{in a neighborhood of any regular point } x_0 \in \partial\Omega. \end{aligned}$$

It follows immediately that

$$\begin{aligned} &\lambda_n \sinh(v_{\lambda_n}) = \frac{\lambda_n}{2}\left(e^{s_{\lambda_n}} e^{v^0_{\lambda_n}} - e^{-s_{\lambda_n}} e^{-v^0_{\lambda_n}}\right) \text{ converges to} \\ &\frac{d_+}{2} e^{v_0} - \frac{d_-}{2} e^{-v_0} \text{ uniformly with all derivatives in a} \\ &\text{neighborhood of any regular point } x_0 \in \partial\Omega \end{aligned}$$

and that

$$\begin{aligned} &\lambda_n |\sinh(v_{\lambda_n})| = \left| \frac{\lambda_n}{2}\left(e^{s_{\lambda_n}} e^{v^0_{\lambda_n}} - e^{-s_{\lambda_n}} e^{-v^0_{\lambda_n}}\right) \right| \text{ converges to} \\ &\left| \frac{d_+}{2} e^{v_0} - \frac{d_-}{2} e^{-v_0} \right| = \frac{d_+}{2} e^{v_0} + \frac{d_-}{2} e^{-v_0} \text{ uniformly in a} \\ &\text{neighborhood of any regular point } x_0 \in \partial\Omega. \end{aligned}$$

For the last identity we used the fact that $d_\pm$ are nonnegative, with at least one being zero. As a consequence

$$\begin{aligned} &\lambda_n \sinh(v_{\lambda_n})^+ = \frac{\lambda_n}{2}(|\sinh(v_{\lambda_n})| + \sinh(v_{\lambda_n})) \text{ converges to } \frac{d_+}{2} e^{v_0} \\ &\text{uniformly in a neighborhood of any regular point } x_0 \in \partial\Omega \end{aligned} \tag{3.9}$$

and

$$\begin{aligned} &\lambda_n \sinh(v_{\lambda_n})^- = \frac{\lambda_n}{2}(|\sinh(v_{\lambda_n})| - \sinh(v_{\lambda_n})) \text{ converges to } \frac{d_-}{2} e^{-v_0} \\ &\text{uniformly in a neighborhood of any regular point } x_0 \in \partial\Omega. \end{aligned} \tag{3.10}$$

From the representation formula (3.7) and the just-established regularity of the measures $\mu_\pm$ at regular points, we conclude that v_0 satisfies the boundary condition

$$\frac{\partial v_0}{\partial \mathbf{n}}(y) = \frac{d_+}{2} e^{v_0(y)} - \frac{d_-}{2} e^{-v_0(y)}$$

in a classical sense at points $y \in \partial\Omega \setminus S$. For any compact set $K \subset \partial\Omega \setminus S$

$$\begin{aligned}\frac{d_\pm}{2} \int_K e^{\pm v_0}\, d\sigma &= \lim_{\lambda_n \to 0} \int_K \lambda_n \sinh(v_{\lambda_n})^\pm \, d\sigma \\ &\le \lim_{\lambda_n \to 0} \int_{\partial\Omega} \lambda_n |\sinh(v_{\lambda_n})| \, d\sigma \\ &= (\mu_+ + \mu_-)(\Omega) = \nu(\Omega).\end{aligned}$$

From Lebesgue's monotone convergence theorem it therefore follows that $\frac{d_\pm}{2} e^{\pm v_0}$ are in $L^1(\partial\Omega)$ with

$$\left\| \frac{d_\pm}{2} e^{\pm v_0} \right\|_{L^1(\partial\Omega)} \le \nu(\Omega).$$

Suppose $S = \cup_{i=1}^L \{\mathbf{x}_i\}$ and let $\phi_i \in C^0(\partial\Omega)$, $i = 1, \dots, L$, be a fixed set of functions with $0 \le \phi_i \le 1$, with $\phi_i(\mathbf{x}_j) = 0$, $j \ne i$, and with $\phi_i \equiv 1$ in a neighborhood of $\mathbf{x}_i$. Given any $\phi \in C^0(\partial\Omega)$ we may now write

$$\phi = \phi_0 + \sum_{i=1}^L \phi(\mathbf{x}_i)\phi_i,$$

where $\phi_0 \in C^0(\partial\Omega)$ vanishes at all points of S. Given any $\epsilon > 0$ we may find $\phi_{0,\epsilon} \in C^0(\partial\Omega)$, with compact support $K \subset \partial\Omega \setminus S$, such that

$$\|\phi_0 - \phi_{0,\epsilon}\|_{C^0(\partial\Omega)} \le \epsilon. \tag{3.11}$$

Using (3.9), (3.10), and compactness we obtain

$$\int_{\partial\Omega} \lambda_n \sinh(v_{\lambda_n})^\pm \phi_{0,\epsilon} \, d\sigma \to \frac{d_\pm}{2} \int_{\partial\Omega} e^{\pm v_0} \phi_{0,\epsilon} \, d\sigma \tag{3.12}$$

as $\lambda_n \to 0$. We also have

$$\begin{aligned}&\left| \int_{\partial\Omega} \lambda_n \sinh(v_{\lambda_n})^\pm \phi \, d\sigma - \sum_{i=1}^L \phi(\mathbf{x}_i) \int_{\partial\Omega} \lambda_n \sinh(v_{\lambda_n})^\pm \phi_i \, d\sigma \right. \\ &\qquad \left. - \int_{\partial\Omega} \lambda_n \sinh(v_{\lambda_n})^\pm \phi_{0,\epsilon} \, d\sigma \right| \\ &= \left| \int_{\partial\Omega} \lambda_n \sinh(v_{\lambda_n})^\pm (\phi_0 - \phi_{0,\epsilon}) \, d\sigma \right| \\ &\le \epsilon \|\lambda_n \sinh(v_{\lambda_n})\|_{L^1(\partial\Omega)}.\end{aligned}$$

After passage to the limit $\lambda_n \to 0$, and combination with (3.12), this yields

$$\left| \int_{\partial\Omega} \phi \, d\mu_\pm - \sum_{i=1}^L \beta_i^\pm \phi(\mathbf{x}_i) - \frac{d_\pm}{2} \int_{\partial\Omega} e^{\pm v_0} \phi_{0,\epsilon} \, d\sigma \right| \le \epsilon \nu(\partial\Omega),$$

with

$$\beta_i^{\pm} = \lim_{\lambda_n \to 0} \int_{\partial\Omega} \lambda_n \sinh(v_{\lambda_n})^{\pm} \phi_i \, d\sigma = \int_{\partial\Omega} \phi_i \, d\mu_{\pm}.$$

Thus

$$\begin{aligned}
&\left| \int_{\partial\Omega} \phi \, d\mu_{\pm} - \sum_{i=1}^{L} \beta_i^{\pm} \phi(\mathbf{x}_i) - \frac{d_{\pm}}{2} \int_{\partial\Omega} e^{\pm v_0} \phi_0 \, d\sigma \right| \\
&\quad \leq \epsilon \nu(\partial\Omega) + \left| \int_{\partial\Omega} \frac{d_{\pm}}{2} e^{\pm v_0} (\phi_0 - \phi_{0,\epsilon}) \, d\sigma \right| \\
&\quad \leq \epsilon \nu(\partial\Omega) + \epsilon \left\| \frac{d_{\pm}}{2} e^{\pm v_0} \right\|_{L^1(\partial\Omega)} \\
&\quad \leq 2\epsilon \nu(\partial\Omega).
\end{aligned}$$

By introducing

$$\alpha_i^{\pm} = \beta_i^{\pm} - \frac{d_{\pm}}{2} \int_{\partial\Omega} e^{\pm v_0} \phi_i \, d\sigma,$$

we may rewrite this latter inequality as

$$\left| \int_{\partial\Omega} \phi \, d\mu_{\pm} - \sum_{i=1}^{L} \alpha_i^{\pm} \phi(\mathbf{x}_i) - \frac{d_{\pm}}{2} \int_{\partial\Omega} e^{\pm v_0} \phi \, d\sigma \right| \leq 2\epsilon \nu(\partial\Omega) \quad \text{for any } \epsilon > 0.$$

We therefore conclude that

$$\int_{\partial\Omega} \phi \, d\mu_{\pm} = \sum_{i=1}^{L} \alpha_i^{\pm} \phi(\mathbf{x}_i) + \frac{d_{\pm}}{2} \int_{\partial\Omega} e^{\pm v_0} \phi \, d\sigma$$

or

$$\mu_{\pm} = \sum_{i=1}^{L} \alpha_i^{\pm} \delta_{\mathbf{x}_i} + \frac{d_{\pm}}{2} e^{\pm v_0}. \tag{3.13}$$

Since $\mu_{\pm}$ are positive it follows that $\alpha_i^{\pm} \geq 0$, $1 \leq i \leq L$. We now let $\{\mathbf{x}_i^+\}_{i=1}^M \subset \{\mathbf{x}_i\}_{i=1}^L$ denote those points for which the corresponding coefficients α_i^+ are strictly positive, and similarly we let $\{\mathbf{x}_i^-\}_{i=1}^N \subset \{\mathbf{x}_i\}_{i=1}^L$ denote those points for which the corresponding coefficients α_i^- are strictly positive. It is obvious that $\{\mathbf{x}_i^+\}_{i=1}^M \cup \{\mathbf{x}_i^-\}_{i=1}^N$ are exactly the locations at which the measure $\nu = \mu_+ + \mu_-$ has nonzero point masses. According to Lemma 4.8 of [6] (see also the corrigendum [7]) the set of singular points, S, is likewise characterized as the set of points at which the measure $\nu = \mu_+ + \mu_-$ has point masses. Consequently $S = \{\mathbf{x}_i\}_{i=1}^L = \{\mathbf{x}_i^+\}_{i=1}^M \cup \{\mathbf{x}_i^-\}_{i=1}^N$ and $N + M \geq L$. Since S is nonempty (i.e., $L \geq 1$) at least one of the sets $\{\mathbf{x}_i^+\}_{i=1}^M$ and $\{\mathbf{x}_i^-\}_{i=1}^N$ must be nonempty (i.e., $M \geq 1$ or $N \geq 1$). From (3.13) and the definition of the points $\{\mathbf{x}_i^+\}_{i=1}^M$ and $\{\mathbf{x}_i^-\}_{i=1}^N$ it now follows (after renumbering the $\alpha_i^{\pm}$) that

$$\mu_+ = \sum_{i=1}^{M} \alpha_i^+ \delta_{\mathbf{x}_i^+} + \frac{d_+}{2} e^{v_0} \quad \text{and} \quad \mu_- = \sum_{i=1}^{N} \alpha_i^- \delta_{\mathbf{x}_i^-} + \frac{d_-}{2} e^{-v_0},$$

with $\alpha_i^{\pm} > 0$, and $d_{\pm} \geq 0$. We recall that at least one of the coefficients d_+ or d_- is zero. This is exactly the desired representation formula. Finally, Lemma 4.8 of [6] asserts that S also equals the set of "blow-up" points for the subsequence $v_{\lambda_n}^0$ in the sense introduced here. This completes the proof of Theorem 3.1. ∎

4. Singularity weights and locations. The aim of this section is to deduce more specific information about the "blow-up" behavior of the subsequence of solutions to (2.1), extracted in Theorem 3.1. We shall do this by uncovering more specific information about the form of the limiting measures μ_+ and μ_-.

THEOREM 4.1. *Suppose the domain $\Omega \subset \mathbb{R}^2$ is smooth, bounded, and simply connected. Let μ_+ and μ_- be the limiting measures from Theorem* 3.1*, i.e.,*

$$\mu_+ = \lim \lambda_n \sinh(v_{\lambda_n})^+ \quad \textit{and} \quad \mu_- = \lim \lambda_n \sinh(v_{\lambda_n})^-.$$

Let $\{\mathbf{x}_i^+\}_{i=1}^M$ and $\{\mathbf{x}_i^-\}_{i=1}^N$ be the locations of the nonzero point masses of μ_+ and μ_-, respectively, and let $S = \{\mathbf{x}_i^+\}_{i=1}^M \cup \{\mathbf{x}_i^-\}_{i=1}^N$. Then

$$(\mu_+ + \mu_-)(\{\mathbf{x}^*\}) \geq |(\mu_+ - \mu_-)(\{\mathbf{x}^*\})| \geq 2\pi \quad \forall \mathbf{x}^* \in S,$$

with

$$(\mu_+ + \mu_-)(\{\mathbf{x}^*\}) = |(\mu_+ - \mu_-)(\{\mathbf{x}^*\})| = 2\pi$$

for all $\mathbf{x}^* \in S \setminus (\{\mathbf{x}_i^+\}_{i=1}^M \cap \{\mathbf{x}_i^-\}_{i=1}^N)$. Furthermore, if the regular part of $\mu_+ - \mu_-$ is strictly positive, i.e., if $d_+ > 0$, then $(\mu_+ - \mu_-)(\{\mathbf{x}^*\})$ is negative for all $\mathbf{x}^* \in S$, whereas if the regular part of $\mu_+ - \mu_-$ is strictly negative, i.e., if $d_- > 0$, then $(\mu_+ - \mu_-)(\{\mathbf{x}^*\})$ is positive for all $\mathbf{x}^* \in S$. In particular, the measures $\mu_+ + \mu_-$ and $\mu_+ - \mu_-$ have the exact same set of locations with nonzero point masses. This set coincides with the "blow-up" points for the sequence $v_{\lambda_n}^0$.

Remark 4.2. In Theorem 4.1 of [6] it is stated that the set of point mass locations of $\mu = \mu_+ - \mu_-$ is finite and nonempty and that it equals the set of "blow-up" points for the sequence $v_{\lambda_n}^0$. As pointed out in the subsequent corrigendum this is not quite the statement proven in [6]. What was indeed proven was that the set of point mass locations of $\nu = \mu_+ + \mu_-$ is finite and nonempty and that this set equals the set of "blow-up" points for the sequence $v_{\lambda_n}^0$ (this statement is also included as part of Theorem 3.1 of the present paper). By showing, as we have done here, that the point mass locations of the measures $\mu_+ + \mu_-$ and $\mu_+ - \mu_-$ agree, we have indeed established the validity of the original formulation of Theorem 4.1 in [6] for simply connected domains.

Before proceeding to the proof of Theorem 4.1, we establish three lemmas which will be used in that proof as well as in the proof of our second theorem in this section (Theorem 4.6).

LEMMA 4.3. *Let v_{λ_n} be the subsequence extracted in Theorem* 3.1*. Then*

$$\lambda_n e^{v_{\lambda_n}} \to 2\mu_+ \quad \textit{and} \quad \lambda_n e^{-v_{\lambda_n}} \to 2\mu_-$$

in the sense of measures on $\partial\Omega$. The convergence takes place in $L^\infty(K)$ for any compact set $K \subset \partial\Omega \setminus S = \partial\Omega \setminus (\{\mathbf{x}_i^+\}_{i=1}^M \cup \{\mathbf{x}_i^-\}_{i=1}^N)$.

Proof. From Theorem 3.1 we know that

$$\lambda_n \sinh(v_{\lambda_n}) \to \mu_+ - \mu_- \quad \text{and} \quad \lambda_n |\sinh(v_{\lambda_n})| \to \mu_+ + \mu_- \tag{4.1}$$

in the sense of measures on $\partial\Omega$. From Theorem 3.1 we also know that the convergence takes place in $L^\infty(K)$ for any compact set $K \subset \partial\Omega \setminus S$. The identity $\cosh(x) = |\sinh(x)| + e^{-|x|}$ and the fact that $|\lambda_n e^{-|v_{\lambda_n}|}| \leq \lambda_n$ now imply that

$$\lambda_n \cosh(v_{\lambda_n}) = \lambda_n |\sinh(v_{\lambda_n})| + \lambda_n e^{-|v_{\lambda_n}|} \to \mu_+ + \mu_- \tag{4.2}$$

in the sense of measures on $\partial\Omega$. It also follows that this convergence takes place in $L^\infty(K)$ for any compact set $K \subset \partial\Omega \setminus S$. A combination of the first statement in (4.1) and the statement (4.2) immediately leads to the conclusion of this lemma. ∎

LEMMA 4.4. *Let $\mathbb{H}$ denote the half-plane $\mathbb{H} = \{(y_1, y_2) : y_2 > 0\}$, and for fixed real $\gamma \neq 0$ and β, let $l_{\gamma,\beta}$ denote the half-line $l_{\gamma,\beta} = \{y_2 = \gamma y_1 + \beta\} \cap \mathbb{H}$. Suppose F is Lebesgue integrable on $\mathbb{R}$, that is, suppose F is in $L^1(\mathbb{R})$. Then we have the following asymptotic statements:*

$$\int_{\mathbb{R}} F(z_1) \frac{y_1 - z_1}{(y_1 - z_1)^2 + y_2^2}\, dz_1 = o(1/y_2), \qquad \int_{\mathbb{R}} F(z_1) \frac{y_2}{(y_1 - z_1)^2 + y_2^2}\, dz_1 = o(1/y_2),$$
$$\text{and} \qquad \int_{\mathbb{R}} F(z_1) \frac{(y_1 - z_1) y_2}{[(y_1 - z_1)^2 + y_2^2]^2}\, dz_1 = o(1/y_2^2)$$

as $(y_1, y_2) \in \mathbb{H}$ approaches the point $(-\beta/\gamma, 0) \in \partial\mathbb{H}$ along the half-line $l_{\gamma,\beta}$.

Proof. We shall prove the first of these three statements. The proof of the other two proceed in a similar fashion but are left to the reader. Simple calculations give that for $(y_1, y_2) \in l_{\gamma,\beta}$

$$\begin{aligned}
\int_{\mathbb{R}} F(z_1) \frac{y_1 - z_1}{(y_1 - z_1)^2 + y_2^2}\, dz_1 &= \int_{\mathbb{R}} F(z_1) \frac{\frac{y_2}{\gamma} - \left(z_1 + \frac{\beta}{\gamma}\right)}{\left(\frac{y_2}{\gamma} - \left(z_1 + \frac{\beta}{\gamma}\right)\right)^2 + y_2^2}\, dz_1 \\
&= \int_{\mathbb{R}} F\left(z_1 - \frac{\beta}{\gamma}\right) \frac{\frac{y_2}{\gamma} - z_1}{\left(\frac{y_2}{\gamma} - z_1\right)^2 + y_2^2}\, dz_1 \\
&= \frac{\gamma}{y_2} \int_{\mathbb{R}} F\left(z_1 - \frac{\beta}{\gamma}\right) \frac{1 - \frac{\gamma z_1}{y_2}}{\left(1 - \frac{\gamma z_1}{y_2}\right)^2 + \gamma^2}\, dz_1.
\end{aligned} \tag{4.3}$$

From the inequality $|s/(s^2 + \gamma^2)| \leq 1/2\gamma$ it follows that

$$\left| F\left(z_1 - \frac{\beta}{\gamma}\right) \frac{1 - \frac{\gamma z_1}{y_2}}{\left(1 - \frac{\gamma z_1}{y_2}\right)^2 + \gamma^2} \right| \leq \frac{1}{2\gamma} \left| F\left(z_1 - \frac{\beta}{\gamma}\right) \right|.$$

Since the right-hand side is an integrable function, and since

$$F\left(z_1 - \frac{\beta}{\gamma}\right) \frac{1 - \frac{\gamma z_1}{y_2}}{\left(1 - \frac{\gamma z_1}{y_2}\right)^2 + \gamma^2} \to 0 \quad \text{a.e. in } z_1$$

as $y_2 \to 0$, it now follows from Lebesgue's dominated convergence theorem that

$$\int_{\mathbb{R}} F\left(z_1 - \frac{\beta}{\gamma}\right) \frac{1 - \frac{\gamma z_1}{y_2}}{\left(1 - \frac{\gamma z_1}{y_2}\right)^2 + \gamma^2}\, dz_1 \to 0 \quad \text{as } y_2 \to 0.$$

By a combination with (4.3) we immediately get the first asymptotic statement of this lemma. ∎

At several points in this section we shall use the notion of conformal equivalence. We shall call a smooth mapping $\Phi : \Omega \to \mathbb{R}^2$ a conformal equivalence if and only if the following four conditions are satisfied:

(a) $D\Phi(x)$ is a similarity, i.e., $|D\Phi(x)\xi| = k(x)|\xi|$, $k(x) > 0$, $\forall\, \xi \in \mathbb{R}^2$, and $x \in \Omega$,
(b) $k(x) = |\det(D\Phi(x))|^{1/2} \geq k_0 > 0\ \forall x \in \Omega$,
(c) the mapping Φ is injective and may be extended as an injective mapping: $\overline{\Omega} \to \mathbb{R}^2 \cup \{\infty\}$, and
(d) the extended mapping Φ is either smooth or there exists a point z^* (in $\mathbb{R}^2 \setminus \Phi(\overline{\Omega})$) such that the mapping $\frac{(\cdot - z^*)}{|\cdot - z^*|^2} \circ \Phi(x)$ has a smooth extension to $\overline{\Omega}$.

We note that conditions (a)–(d) imply that $\langle D\Phi(x)\xi, D\Phi(x)\eta\rangle = k^2(x)\langle\xi,\eta\rangle = |\det(D\Phi(x))|\langle\xi,\eta\rangle\ \forall\, \xi,\ \eta$ in $\mathbb{R}^2$ and all x in $\overline{\Omega} \setminus \{\Phi^{-1}(\infty)\}$. We also note that for any smooth, bounded, simply connected domain we may construct a conformal equivalence of Ω onto the upper half-plane. The point $\Phi^{-1}(\infty)$ may be picked arbitrarily on $\partial\Omega$. This follows from Riemann's mapping theorem and subsequent composition with a linear fractional transformation.

The following representation result will prove extremely useful.

LEMMA 4.5. *Let Φ be a conformal equivalence of the smooth, bounded, simply connected domain Ω onto the half-plane $\mathbb{H} = \{(y_1, y_2) : y_2 > 0\}$, constructed so that the point $\Phi^{-1}(\infty)$ lies in $\partial\Omega \setminus (\{\mathbf{x}_i^+\}_{i=1}^M \cup \{\mathbf{x}_i^-\}_{i=1}^N)$, where $\mathbf{x}_i^\pm$ are the "blow-up" points from Theorem* 3.1. *Let v_0 denote the limit from Theorem* 3.1, *i.e.,*

$$v_0 = \lim v_{\lambda_n}^0 = \lim \left(v_{\lambda_n} - \frac{1}{|\partial\Omega|} \int_{\partial\Omega} v_{\lambda_n}\ d\sigma \right),$$

and define $u_0 := v_0 \circ \Phi^{-1}$. Let F denote the function

$$F(y_1) = \left(\frac{d_+}{2} e^{u_0(y_1,0)} - \frac{d_-}{2} e^{-u_0(y_1,0)} \right) h(y_1, 0),$$

with

$$h(y) = |\det(D\Phi(\Phi^{-1}(y)))|^{-1/2}$$

and $d_\pm$ as in Theorem 3.1. *Then $F \in L^1(\mathbb{R}, \log(|x|+2)dx)$, and the function u_0 and its derivatives have the representation formulas*

$$\begin{aligned} u_0(y) = v_0(\Phi^{-1}(\infty)) &- \frac{1}{\pi} \sum_{i=1}^M \alpha_i^+ \log|y - \mathbf{y}_i^+| + \frac{1}{\pi} \sum_{i=1}^N \alpha_i^- \log|y - \mathbf{y}_i^-| \\ &- \frac{1}{\pi} \int_{\mathbb{R}} F(z_1) \log|y - (z_1, 0)|\ dz_1, \quad y \in \mathbb{H}, \\ \frac{\partial u_0}{\partial y_j}(y) = &- \frac{1}{\pi} \sum_{i=1}^M \alpha_i^+ \frac{(y - \mathbf{y}_i^+)_j}{|y - \mathbf{y}_i^+|^2} + \frac{1}{\pi} \sum_{i=1}^N \alpha_i^- \frac{(y - \mathbf{y}_i^-)_j}{|y - \mathbf{y}_i^-|^2} \\ &- \frac{1}{\pi} \int_{\mathbb{R}} F(z_1) \frac{(y - (z_1, 0))_j}{|y - (z_1, 0)|^2}\ dz_1, \quad y \in \mathbb{H},\ j = 1, 2. \end{aligned}$$

The coefficients $\alpha_i^\pm$ are as in Theorem 3.1, *and $\mathbf{y}_i^\pm = \Phi(\mathbf{x}_i^\pm)$.*

Proof. For any $z \in \mathbb{H}$ let $\overline{z}$ denote the "reflection in $\partial\mathbb{H}$," i.e., $\overline{z} = \overline{(z_1, z_2)} = (z_1, -z_2)$. A simple calculation shows that the function $G(x, w)$, $x, w \in \Omega$, defined by

$$G(x, w) = \frac{1}{2\pi} \log|\Phi(x) - \Phi(w)| + \frac{1}{2\pi} \log|\Phi(x) - \overline{\Phi(w)}|$$

is indeed the solution to

$$\Delta_x G(x,w) = \delta_w \quad \text{in } \Omega, \qquad \frac{\partial}{\partial \mathbf{n}_x} G(x,w) = \delta_{w^*} \quad \text{on } \partial\Omega,$$

with $w^* = \Phi^{-1}(\infty)$. Using the representation formula for v_0 from Theorem 3.1 we get

$$\int_{\partial\Omega} G(x,w)\, d(\mu_+ - \mu_-)_x = \int_{\partial\Omega} (N(x,w) - N(x,w^*))\, d(\mu_+ - \mu_-)_x = -v_0(w) + v_0(w^*).$$

For the identity $v_0(w^*) = -\int_{\partial\Omega} N(x,w^*)\, d(\mu_+ - \mu_-)_x$ we rely on the boundary limit of the representation formula from Theorem 3.1, which remains valid due to the fact that the measure $\mu_+ - \mu_-$ is given by a C^∞ density near the point w^*. By rearrangement of the above formula,

$$\begin{aligned} v_0(w) &= v_0(w^*) - \int_{\partial\Omega} G(x,w)\, d(\mu_+ - \mu_-)_x \\ &= v_0(w^*) - \sum_{i=1}^{M} \alpha_i^+ G(\mathbf{x}_i^+, w) + \sum_{i=1}^{N} \alpha_i^- G(\mathbf{x}_i^-, w) \\ &\quad - \int_{\partial\Omega} \left(\frac{d_+}{2} e^{v_0} - \frac{d_-}{2} e^{-v_0} \right) G(x,w)\, d\sigma_x. \end{aligned}$$

Introducing $y = \Phi(w)$ and $z = \Phi(x)$ and changing variable of integration (from x to z) we immediately obtain the first representation formula of this lemma. The second formula follows by differentiation. The fact that $F \in L^1(\mathbb{R}, \log(|z|+2)dz)$ follows immediately from the finiteness of the last integral in the above integral identity. ∎

Proof of Theorem 4.1. Let Φ be a conformal equivalence of Ω onto the half-plane $\mathbb{H}$ such that the point $\Phi^{-1}(\infty)$ lies in $\partial\Omega \setminus (\{\mathbf{x}_i^+\}_{i=1}^M \cup \{\mathbf{x}_i^-\}_{i=1}^N)$. Setting $u_{\lambda_n} = v_{\lambda_2} \circ \Phi^{-1}$, we have a family of solutions to

$$\begin{cases} \Delta u_{\lambda_n} = 0 & \text{in } \mathbb{H}, \\ \dfrac{\partial u_{\lambda_n}}{\partial y_2} = -\lambda_n h(y) \sinh(u_{\lambda_n}) & \text{on } \partial\mathbb{H}, \end{cases} \tag{4.4}$$

with $h(y) = |\det(D\Phi(\Phi^{-1}(y)))|^{-1/2}$. The sequence

$$u_{\lambda_n} - s_{\lambda_n}, \quad \text{with } s_{\lambda_n} = \int_{\partial\Omega} v_{\lambda_n}\, d\sigma/|\partial\Omega|,$$

converges to $u_0 = v_0 \circ \Phi^{-1}$ in $H^t(\mathbb{H} \cap \{|y| \le R\})$ for any $t < 1$ and any R; the convergence also takes place in $C^\infty(\overline{\mathbb{H}} \setminus (\{\mathbf{y}_i^+\}_{i=1}^M \cup \{\mathbf{y}_i^-\}_{i=1}^N))$, i.e., in $C^\infty(K)$ for any compact set $K \subset \overline{\mathbb{H}} \setminus (\{\mathbf{y}_i^+\}_{i=1}^M \cup \{\mathbf{y}_i^-\}_{i=1}^N)$. We now introduce functions w_{λ_n} and w_0 by

$$w_{\lambda_n} := \partial_{y_1} u_{\lambda_n} \partial_{y_2} u_{\lambda_n} \quad \text{and} \quad w_0 := \partial_{y_1} u_0 \partial_{y_2} u_0,$$

respectively. Due to the $C^\infty(\overline{\mathbb{H}} \setminus \{\mathbf{y}_i^\pm\})$ convergence of $u_{\lambda_n} - s_{\lambda_n}$ toward u_0, the sequence w_{λ_n} converges in $C^\infty(\overline{\mathbb{H}} \setminus (\{\mathbf{y}_i^+\}_{i=1}^M \cup \{\mathbf{y}_i^-\}_{i=1}^N))$ toward w_0.

Let $\mathbf{y}^* = (y_1^*, 0)$ be one of the points from $\{\mathbf{y}_i^+\}_{i=1}^M \cup \{\mathbf{y}_i^-\}_{i=1}^N$, and given any $\gamma \neq 0$, let $l_{\mathbf{y}^*}$ denote the half-line $l_{\mathbf{y}^*} = \{(y_1, y_2) : y_2 = \gamma y_1 - \gamma y_1^*\} \cap \mathbb{H}$. Suppose there is a point mass contribution $\alpha_*^+ \delta_{\mathbf{x}^*}$ to μ_+ and point mass contribution $\alpha_*^- \delta_{\mathbf{x}^*}$

to μ_- from the point $\mathbf{x}^* = \Phi^{-1}(\mathbf{y}^*)$. This includes the possibility that one of the $\alpha_*^{\pm}$ could be zero, corresponding to $\mathbf{y}^* \notin \{\mathbf{y}_i^+\}_{i=1}^M \cap \{\mathbf{y}_i^-\}_{i=1}^N$. From a combination of Lemmas 4.4 and 4.5 we conclude that

$$\begin{aligned}\frac{\partial u_0}{\partial y_1}(y) &= \frac{1}{\pi}(-\alpha_*^+ + \alpha_*^-)\frac{y_1 - y_1^*}{|y - \mathbf{y}^*|^2} + o(1/y_2)\\ &= \frac{1}{\pi}(-\alpha_*^+ + \alpha_*^-)\frac{\gamma}{1+\gamma^2}\frac{1}{y_2} + o(1/y_2) \quad \text{and}\\ \frac{\partial u_0}{\partial y_2}(y) &= \frac{1}{\pi}(-\alpha_*^+ + \alpha_*^-)\frac{y_2}{|y - \mathbf{y}^*|^2} + o(1/y_2)\\ &= \frac{1}{\pi}(-\alpha_*^+ + \alpha_*^-)\frac{\gamma^2}{1+\gamma^2}\frac{1}{y_2} + o(1/y_2)\end{aligned}$$

as y approaches the point $\mathbf{y}^*$ along the half-line $l_{\mathbf{y}^*}$. As a consequence,

$$w_0(y) = \frac{(\alpha_*^+ - \alpha_*^-)^2}{\pi^2}\frac{\gamma^3}{(1+\gamma^2)^2}\frac{1}{y_2^2} + o(1/y_2^2) \tag{4.5}$$

as y approaches the point $\mathbf{y}^*$ along the half-line $l_{\mathbf{y}^*}$ (and so y_2 approaches 0).

We now proceed to analyze the same asymptotic scenario, using the relationship $w_0(y) = \lim w_{\lambda_n}(y)$, which holds for any point $y \in l_{\mathbf{y}^*}$. Simple calculations yield

$$\Delta w_{\lambda_n} = 0 \quad \text{in } \mathbb{H}$$

and

$$w_{\lambda_n} = -\lambda_n h(y_1,0)\sinh(u_{\lambda_n})\partial_{y_1}u_{\lambda_n} = -\lambda_n h(y_1,0)\partial_{y_1}\left(\cosh(u_{\lambda_n})\right) \quad \text{on } \partial\mathbb{H}, \tag{4.6}$$

with $h(y) = |\det(D\Phi(\Phi^{-1}(y)))|^{-1/2}$. Let $D \subset \mathbb{H}$ be a bounded, smooth domain with $\Gamma_0 = \partial D \cap \partial\mathbb{H} = [-R,R]\times\{0\}$ (for instance, take D to be the half-disk $B_R(0)\cap\mathbb{H}$ with the two corners "smoothed out"). Choose R sufficiently large that all the points $\mathbf{y}_i^{\pm}$ lie strictly inside $\frac{1}{2}\Gamma_0$. Let $G_D(y,z)$ denote the Green's function for the domain D, i.e., the solution to

$$\begin{cases}\Delta G_D(\cdot,z) = \delta_z & \text{in } D,\\ G_D(\cdot,z) = 0 & \text{on } \partial D.\end{cases} \tag{4.7}$$

For any fixed $z \in D$ the harmonic function w_{λ_n} may now be represented as

$$w_{\lambda_n}(z) = \int_{\partial D} w_{\lambda_n}(y)\frac{\partial G_D}{\partial \mathbf{n}_y}(y,z)\, d\sigma_y.$$

We decompose the boundary of D as follows: $\partial D = \Gamma_0 \cup \Gamma_1$, with $\Gamma_0 = \partial D \cap \partial\mathbb{H}$ and $\Gamma_1 = \partial D \cap \mathbb{H}$. In light of (4.6), the above integral representation for w_{λ_n} reads

$$\begin{aligned}w_{\lambda_n}(z) &= \int_{\Gamma_1} w_{\lambda_n}(y)\frac{\partial G_D}{\partial \mathbf{n}_y}(y,z)d\sigma_y\\ &\quad + \int_{\Gamma_0}\lambda_n h(y_1,0)\partial_{y_1}\left(\cosh(u_{\lambda_n}(y_1,0))\right)\frac{\partial G_D}{\partial y_2}((y_1,0),z)dy_1\\ &= I_{1,\lambda_n}(z) + I_{2,\lambda_n}(z).\end{aligned} \tag{4.8}$$

Since the sequence w_{λ_n} converges in $C^\infty(\overline{\mathbb{H}} \setminus (\{\mathbf{y}_i^+\}_{i=1}^M \cup \{\mathbf{y}_i^-\}_{i=1}^N))$ toward w_0

$$\lim_{\lambda_n \to 0} I_{1,\lambda_n}(z) = \int_{\Gamma_1} w_0(y) \frac{\partial G}{\partial \mathbf{n}_y}(y,z) d\sigma_y \quad \forall z \in D. \tag{4.9}$$

Integration by parts yields

$$\begin{aligned} I_{2,\lambda_n}(z) = &- \int_{\Gamma_0} \lambda_n \cosh(u_{\lambda_n}(y_1,0)) h(y_1,0) \partial_{y_1} \left(\frac{\partial G_D}{\partial y_2}((y_1,0),z) \right) dy_1 \\ &- \int_{\Gamma_0} \lambda_n \cosh(u_{\lambda_n}(y_1,0)) \partial_{y_1} h(y_1,0) \frac{\partial G_D}{\partial y_2}((y_1,0),z) dy_1 \\ &+ \left(\lambda_n \cosh(u_{\lambda_n}(y_1,0)) h(y_1,0) \frac{\partial G_D}{\partial y_2}((y_1,0),z) \right) \Bigg|_{y_1=-R}^{y_1=R}. \end{aligned} \tag{4.10}$$

From Lemma 4.3 we know that

$$\lambda_n e^{v_{\lambda_n}} \to 2\mu_+ \quad \text{and} \quad \lambda_n e^{-v_{\lambda_n}} \to 2\mu_-,$$

in the sense of measures on $\partial\Omega$, and so

$$\begin{aligned} \lambda_n \cosh(v_{\lambda_n}) &\to \mu_+ + \mu_- \\ &= \sum_{i=1}^M \alpha_i^+ \delta_{\mathbf{x}_i^+} + \sum_{i=1}^N \alpha_i^- \delta_{\mathbf{x}_i^-} + \frac{d_+}{2} e^{v_0} + \frac{d_-}{2} e^{-v_0}, \end{aligned}$$

in the sense of measures on $\partial\Omega$. In the last case, the left-hand side converges uniformly to the C^∞ function $\frac{d_+}{2} e^{v_0} + \frac{d_-}{2} e^{-v_0}$ away from the points $\mathbf{x}_i^\pm$. When "pushed forward" by the conformal map Φ this last convergence statement translates into

$$\lambda_n h(y_1,0) \cosh(u_{\lambda_n}(y_1,0)) \to \sum_{i=1}^M \alpha_i^+ \delta_{\mathbf{y}_i^+} + \sum_{i=1}^N \alpha_i^- \delta_{\mathbf{y}_i^-} + E(y_1) \tag{4.11}$$

in the sense of measures on $\Gamma_0 = [-R,R] \times \{0\}$, with E given by

$$E(y_1) = \left(\frac{d_+}{2} e^{u_0(y_1,0)} + \frac{d_-}{2} e^{-u_0(y_1,0)} \right) h(y_1,0).$$

As a consequence of (4.10) and (4.11) we immediately obtain the following limit for the integrals I_{2,λ_n}:

$$\begin{aligned} &\lim_{\lambda_n \to 0} I_{2,\lambda_n}(z) \\ &\quad = - \sum_{i=1}^M \alpha_i^+ \frac{\partial^2 G_D}{\partial y_1 \partial y_2}(\mathbf{y}_i^+, z) - \sum_{i=1}^N \alpha_i^- \frac{\partial^2 G_D}{\partial y_1 \partial y_2}(\mathbf{y}_i^-, z) \\ &\qquad - \sum_{i=1}^M \alpha_i^+ \frac{\partial_{y_1} h(\mathbf{y}_i^+)}{h(\mathbf{y}_i^+)} \frac{\partial G_D}{\partial y_2}(\mathbf{y}_i^+, z) - \sum_{i=1}^N \alpha_i^- \frac{\partial_{y_1} h(\mathbf{y}_i^-)}{h(\mathbf{y}_i^-)} \frac{\partial G_D}{\partial y_2}(\mathbf{y}_i^-, z) \\ &\qquad - \int_{\Gamma_0} E(y_1) \left(\frac{\partial^2 G_D}{\partial y_1 \partial y_2}((y_1,0),z) + \frac{\partial_{y_1} h(y_1,0)}{h(y_1,0)} \frac{\partial G_D}{\partial y_2}((y_1,0),z) \right) dy_1 \\ &\qquad + E(y_1) \frac{\partial G_D}{\partial y_2}((y_1,0),z) \Bigg|_{y_1=-R}^{y_1=R} \quad \forall z \in D. \end{aligned} \tag{4.12}$$

Here we also used the fact that $\lambda_n \cosh(u_{\lambda_n}(y_1,0))h(y_1,0)$ converges pointwise to E away from the points $\mathbf{y}_i^{\pm}$, in order to treat the boundary term in (4.10). A combination of (4.9) and (4.12) with (4.8) now yields

$$\begin{aligned} w_0(z) &= \lim_{\lambda_n \to 0} w_{\lambda_n}(z) \\ &= \int_{\Gamma_1} w_0(y) \frac{\partial G_D}{\partial \mathbf{n}_y}(y,z) d\sigma_y \\ &\quad - \sum_{i=1}^{M} \alpha_i^+ \frac{\partial^2 G_D}{\partial y_1 \partial y_2}(\mathbf{y}_i^+, z) - \sum_{i=1}^{N} \alpha_i^- \frac{\partial^2 G_D}{\partial y_1 \partial y_2}(\mathbf{y}_i^-, z) \\ &\quad - \sum_{i=1}^{M} \alpha_i^+ \frac{\partial_{y_1} h(\mathbf{y}_i^+)}{h(\mathbf{y}_i^+)} \frac{\partial G_D}{\partial y_2}(\mathbf{y}_i^+, z) - \sum_{i=1}^{N} \alpha_i^- \frac{\partial_{y_1} h(\mathbf{y}_i^-)}{h(\mathbf{y}_i^-)} \frac{\partial G_D}{\partial y_2}(\mathbf{y}_i^-, z) \\ &\quad - \int_{\Gamma_0} E(y_1) \left(\frac{\partial^2 G_D}{\partial y_1 \partial y_2}((y_1,0),z) + \frac{\partial_{y_1} h(y_1,0)}{h(y_1,0)} \frac{\partial G_D}{\partial y_2}((y_1,0),z) \right) dy_1 \\ &\quad + E(y_1) \frac{\partial G_D}{\partial y_2}((y_1,0),z) \Big|_{y_1=-R}^{y_1=R} \qquad \forall z \in D. \end{aligned} \tag{4.13}$$

Set $\omega = \{z \in D : |z_1| < R/2 \text{ and } 0 < z_2 < \epsilon\}$ for ϵ fixed, but sufficiently small. The Green's function $G_D(y,z)$, $(y,z) \in \overline{D \times \omega} \setminus \{y = z\}$, may now be written

$$G_D(y,z) = \frac{1}{2\pi} \log|y - z| - \frac{1}{2\pi} \log|y - \overline{z}| + g(y,z),$$

where $\overline{z} = \overline{(z_1, z_2)} = (z_1, -z_2)$ and where the function g is in $C^\infty(\overline{D \times \omega})$. We thus compute

$$\begin{aligned} \frac{\partial G_D}{\partial y_2}(y,z) &= -\frac{1}{\pi} \frac{z_2}{|y-z|^2} + \partial_{y_2} g(y,z) \quad \text{and} \\ \frac{\partial^2 G_D}{\partial y_1 \partial y_2}(y,z) &= \frac{2}{\pi} \frac{(y-z)_1 z_2}{|y-z|^4} + \partial_{y_1} \partial_{y_2} g(y,z) \end{aligned} \tag{4.14}$$

for $(y,z) \in \Gamma_0 \times \overline{\omega} \setminus \{y = z\}$. Substituting (4.14) into (4.13) we arrive at

$$\begin{aligned} w_0(z) &= \frac{2}{\pi} \sum_{i=1}^{M} \alpha_i^+ \frac{(z - \mathbf{y}_i^+)_1 z_2}{|z - \mathbf{y}_i^+|^4} + \frac{2}{\pi} \sum_{i=1}^{N} \alpha_i^- \frac{(z - \mathbf{y}_i^-)_1 z_2}{|z - \mathbf{y}_i^-|^4} \\ &\quad + \frac{1}{\pi} \sum_{i=1}^{M} \alpha_i^+ \frac{\partial_{y_1} h(\mathbf{y}_i^+)}{h(\mathbf{y}_i^+)} \frac{z_2}{|z - \mathbf{y}_i^+|^2} + \frac{1}{\pi} \sum_{i=1}^{N} \alpha_i^- \frac{\partial_{y_1} h(\mathbf{y}_i^-)}{h(\mathbf{y}_i^-)} \frac{z_2}{|z - \mathbf{y}_i^-|^2} \\ &\quad + \frac{1}{\pi} \int_{\Gamma_0} E(y_1) \left(2 \frac{(z_1 - y_1) z_2}{|z - (y_1,0)|^4} + \frac{\partial_{y_1} h(y_1,0)}{h(y_1,0)} \frac{z_2}{|z - (y_1,0)|^2} \right) dy_1 \\ &\quad + R(z), \end{aligned} \tag{4.15}$$

where R is in $C^\infty(\overline{\omega})$. Let $\mathbf{y}^* = (y_1^*, 0)$ be one of the points from $\{\mathbf{y}_i^+\}_{i=1}^M \cup \{\mathbf{y}_i^-\}_{i=1}^N$ (the same as before) and let $l_{\mathbf{y}^*}$ denote the half-line $l_{\mathbf{y}^*} = \{(z_1, z_2) : z_2 = \gamma z_1 - \gamma y_1^*\} \cap \mathbb{H}$. Suppose (as before) that there is a point mass contribution $\alpha_*^+ \delta_{\mathbf{x}^*}$ to μ_+ and point mass contribution $\alpha_*^- \delta_{\mathbf{x}^*}$ to μ_- from the point $\mathbf{x}^* = \Phi^{-1}(\mathbf{y}^*)$ (so there are terms with

coefficients α_*^+ and α_*^- corresponding to $\mathbf{y}^*$ in the respective sums above). From a combination of Lemma 4.4 with (4.15) we conclude that

$$\begin{aligned} w_0(z) &= \frac{2}{\pi}(\alpha_*^+ + \alpha_*^-)\frac{(z_1 - y_1^*)z_2}{|z - y^*|^4} + o(1/z_2^2) \\ &= \frac{2}{\pi}(\alpha_*^+ + \alpha_*^-)\frac{\gamma^3}{(1+\gamma^2)^2}\frac{1}{z_2^2} + o(1/z_2^2) \end{aligned} \tag{4.16}$$

as z approaches $\mathbf{y}^*$ along the half-line $l_{\mathbf{y}^*}$ (and therefore z_2 approaches 0). By comparison of the two alternate asymptotic representations, (4.5) and (4.16), for w_0, we infer that

$$\frac{(\alpha_*^+ - \alpha_*^-)^2}{\pi^2} = \frac{2}{\pi}(\alpha_*^+ + \alpha_*^-), \tag{4.17}$$

which immediately yields

$$\alpha_*^+ + \alpha_*^- \geq |\alpha_*^+ - \alpha_*^-| = 2\pi\frac{\alpha_*^+ + \alpha_*^-}{|\alpha_*^+ - \alpha_*^-|} \geq 2\pi$$

or

$$(\mu_+ + \mu_-)(\{\mathbf{x}^*\}) \geq |(\mu_+ - \mu_-)(\{\mathbf{x}^*\})| \geq 2\pi, \tag{4.18}$$

as stated in the formulation of this theorem. If $\mathbf{x}^* \in S \setminus (\{\mathbf{x}_i^+\}_{i=1}^M \cap \{\mathbf{x}_i^-\}_{i=1}^N)$, so that either α_*^+ or α_*^- is zero, then it follows from (4.17) that

$$(\mu_+ + \mu_-)(\{\mathbf{x}^*\}) = |(\mu_+ - \mu_-)(\{\mathbf{x}^*\})| = 2\pi.$$

The statement about the coincidence of the point mass locations of the measures $\mu_+ + \mu_-$ and $\mu_+ - \mu_-$ is a direct consequence of the inequalities (4.18), valid for all $\mathbf{x}^* \in S$.

Let us go back to the representation formula for u_0 from Lemma 4.5,

$$\begin{aligned} u_0(y) = &-\frac{1}{\pi}\sum_{i=1}^M \alpha_i^+ \log|y - \mathbf{y}_i^+| + \frac{1}{\pi}\sum_{i=1}^N \alpha_i^- \log|y - \mathbf{y}_i^-| \\ &-\frac{1}{\pi}\int_{\mathbb{R}} F(z_1)\log|y - (z_1,0)|\, dz_1 + v_0(\Phi^{-1}(\infty)), \quad y \in \mathbb{H}, \end{aligned}$$

with $F(z_1) = (\frac{d_+}{2}e^{u_0(z_1,0)} - \frac{d_-}{2}e^{-u_0(z_1,0)})h(z_1,0)$. By taking the limit as y approaches points $(y_1,0) \in \partial\mathbb{H} \setminus (\{\mathbf{y}_i^+\}_{i=1}^M \cup \{\mathbf{y}_i^-\}_{i=1}^N)$ we obtain

$$\begin{aligned} u_0(y_1,0) = &-\frac{1}{\pi}\sum_{i=1}^M \alpha_i^+ \log|(y_1,0) - \mathbf{y}_i^+| + \frac{1}{\pi}\sum_{i=1}^N \alpha_i^- \log|(y_1,0) - \mathbf{y}_i^-| \\ &-\frac{1}{\pi}\int_{\mathbb{R}} F(z_1)\log|y_1 - z_1|\, dz_1 + v_0(\Phi^{-1}(\infty)). \end{aligned}$$

Let $\mathbf{y}^* = (y_1^*, 0)$ be one of the points of $S = \{\mathbf{y}_i^+\}_{i=1}^M \cup \{\mathbf{y}_i^-\}_{i=1}^N$, and define $d_0 = \min\{\mathrm{dist}(\mathbf{y}^*, S \setminus \mathbf{y}^*), 1\}$. The above representation formula now yields

$$\begin{aligned} u_0(y_1,0) = &-\frac{1}{\pi}(\alpha_*^+ - \alpha_*^-)\log|y_1 - y_1^*| \\ &-\frac{1}{\pi}\int_{|z_1 - y_1^*| < d_0/2} F(z_1)\log|y_1 - z_1|\, dz_1 + O(1) \end{aligned} \tag{4.19}$$

for $0 < |y_1 - y_1^*| < d_0/4$. Recall that $F \in L^1(\mathbb{R}, \log(|x|+2)dx)$.

Now let us consider the case $d_+ > 0$. In that case $d_- = 0$, and so

$$F(z_1) = \frac{d_+}{2} e^{u_0(z_1,0)} |\det(D\Phi(\Phi^{-1}(z_1,0)))|^{-1/2} > 0.$$

Since $\log|y_1 - z_1| < 0$ whenever $|z_1 - y_1^*| < d_0/2$ and $|y_1 - y_1^*| < d_0/4$, we then obtain

$$-\frac{1}{\pi}\int_{|z_1 - y_1^*| < d_0/2} F(z_1) \log|y_1 - z_1| \, dz_1 > 0 \quad \text{for } 0 < |y_1 - y_1^*| < d_0/4.$$

By insertion into (4.19) this yields

$$u_0(y_1,0) \geq \frac{1}{\pi}(\alpha_*^+ - \alpha_*^-) \log|y_1 - y_1^*|^{-1} - C$$

for $0 < |y_1 - y_1^*| < d_0/4$. Now suppose $(\mu_+ - \mu_-)(\{\mathbf{x}^*\}) = \alpha_*^+ - \alpha_*^- \geq 2\pi$. Then it follows immediately that

$$u_0(y_1,0) \geq \log|y_1 - y_1^*|^{-2} - C \quad \text{for } 0 < |y_1 - y_1^*| < d_0/4.$$

As a consequence,

$$e^{u_0(y_1,0)} \geq c|y_1 - y_1^*|^{-2} \quad \text{for } 0 < |y_1 - y_1^*| < d_0/4.$$

However, this contradicts the fact that $e^{u_0(\cdot,0)} \in L^1_{loc}(\mathbb{R})$ ($e^{v_0} \in L^1(\partial\Omega)$). Since we already know that $|\alpha_*^+ - \alpha_*^-| \geq 2\pi$, we may thus conclude that

$$(\mu_+ - \mu_-)(\{\mathbf{x}^*\}) = \alpha_*^+ - \alpha_*^- \leq -2\pi$$

if d_+ is positive. The argument to show that

$$(\mu_+ - \mu_-)(\{\mathbf{x}^*\}) = \alpha_*^+ - \alpha_*^- \geq 2\pi$$

if d_- is positive proceeds similarly. □

As our last result in this paper, we establish a theorem which provides more precise information about the location of the point masses in the case when the limiting measures are "pure" sums of such point masses, i.e., when $d_+ = d_- = 0$. An extension of the proof used to verify this result may be used to derive more precise information about the point mass locations also in the case when either d_+ or d_- is nonzero (see [9]). Since the results obtained are most complete if there is assumed to be no overlap between the points $\{\mathbf{x}_i^+\}$ and $\{\mathbf{x}_i^-\}$, we formulate only the theorem under this assumption. In Remark 4.10 we describe what the corresponding results are without this assumption.

THEOREM 4.6. *Suppose the domain $\Omega \subset \mathbb{R}^2$ is smooth, bounded, and simply connected. Let v_{λ_n}, $\lambda_n \to 0^+$, be the subsequence of solutions to the nonlinear elliptic Neumann problem* (2.1) *extracted in Theorem* 3.1, *for which*

$$\lambda_n \sinh(v_{\lambda_n}^+) = \lambda_n \sinh(v_{\lambda_n})^+ \to \mu_+, \qquad \lambda_n \sinh(v_{\lambda_n}^-) = \lambda_n \sinh(v_{\lambda_n})^- \to \mu_-$$

in the sense of measures on $\partial\Omega$. Suppose that $d_+ = d_- = 0$, i.e., suppose

$$\mu_+ = \sum_{i=1}^M \alpha_i^+ \delta_{\mathbf{x}_i^+}, \qquad \mu_- = \sum_{i=1}^N \alpha_i^- \delta_{\mathbf{x}_i^-}, \tag{4.20}$$

and furthermore, suppose $\{\mathbf{x}_i^+\} \cap \{\mathbf{x}_i^-\} = \emptyset$. *Then*

$$M = N(\geq 1), \quad \alpha_i^+ = \alpha_i^- = 2\pi, \quad 1 \leq i \leq M, \quad \textit{and}$$
$$\lim_{\lambda_n \to 0} \lambda_n \int_{\partial\Omega} |\sinh(v_{\lambda_n})| \, d\sigma = 4M\pi.$$

Set $v^0_{\lambda_n} = v_{\lambda_n} - \frac{1}{|\partial\Omega|}\int_{\partial\Omega} v_{\lambda_n} \, d\sigma$ *and let* v_0 *denote the limit* $v_0 = \lim_{\lambda_n \to 0} v^0_{\lambda_n}$, *whose existence is guaranteed by Theorem* 3.1. *The function* v_0 *satisfies*

$$\Delta v_0 = 0 \quad \textit{in } \Omega, \qquad \frac{\partial v_0}{\partial \mathbf{n}} = 2\pi \sum_{i=1}^M \delta_{\mathbf{x}_i^+} - 2\pi \sum_{i=1}^M \delta_{\mathbf{x}_i^-} \quad \textit{on } \partial\Omega, \quad \int_{\partial\Omega} v_0 \, d\sigma = 0$$

in the sense that

$$v_0(x) = H(x) - 2\sum_{i=1}^M \log|x - \mathbf{x}_i^+| + 2\sum_{i=1}^M \log|x - \mathbf{x}_i^-|,$$

where $H \in C^\infty(\overline{\Omega})$ *is the classical solution to*

$$\Delta H = 0 \quad \textit{in } \Omega, \qquad \frac{\partial H}{\partial \mathbf{n}} = 2\sum_{i=1}^M \frac{(x - \mathbf{x}_i^+)\cdot \mathbf{n}}{|x - \mathbf{x}_i^+|^2} - 2\sum_{i=1}^M \frac{(x - \mathbf{x}_i^-)\cdot \mathbf{n}}{|x - \mathbf{x}_i^-|^2} \quad \textit{on } \partial\Omega,$$
$$\int_{\partial\Omega} H \, d\sigma = 2\sum_{i=1}^M \int_{\partial\Omega} \log|x - \mathbf{x_i}^+| \, d\sigma_x - 2\sum_{i=1}^M \int_{\partial\Omega} \log|x - \mathbf{x}_i^-| \, d\sigma_x.$$

The $2M$ *points* $\{\mathbf{x}_i^+\}_{i=1}^M \cup \{\mathbf{x}_i^-\}_{i=1}^M \subset \partial\Omega$ *satisfy the equations*

$$\begin{aligned} &\frac{\partial}{\partial \tau_x}(v_0(x) + 2\log|x - \mathbf{x}_i^+|)|_{x=\mathbf{x}_i^+} = 0, \quad i = 1, \dots, M, \quad \textit{and} \\ &\frac{\partial}{\partial \tau_x}(v_0(x) - 2\log|x - \mathbf{x}_i^-|)|_{x=\mathbf{x}_i^-} = 0, \quad i = 1, \dots, M, \end{aligned} \tag{4.21}$$

where $\frac{\partial}{\partial \tau_x}$ *denotes a tangential derivative to* $\partial\Omega$.

Remark 4.7. Since $\frac{\partial v_0}{\partial \mathbf{n}} = 2\pi\sum_{i=1}^M \delta_{\mathbf{x}_i^+} - 2\pi\sum_{i=1}^M \delta_{\mathbf{x}_i^-}$ on $\partial\Omega$ we easily calculate that

$$\frac{\partial}{\partial \mathbf{n}_x}(v_0 \pm 2\log|x - \mathbf{x}_i^\pm|)_{x=\mathbf{x}_i^\pm} = \lim_{\substack{x \in \partial\Omega \\ x \to \mathbf{x}_i^\pm}} \pm \frac{2(x - \mathbf{x}_i^\pm)\cdot \mathbf{n}(x)}{|x - \mathbf{x}_i^\pm|^2} = \pm\kappa(\mathbf{x}_i^\pm),$$

where $\kappa(x)$ is the (signed) curvature of $\partial\Omega$ at the point x. If we supplement the identities (4.21) with these identities we obtain

$$\nabla(v_0(x) \pm 2\log|x - \mathbf{x}_i^\pm|)|_{x=\mathbf{x}_i^\pm} = \pm\kappa(\mathbf{x}_i^\pm)\mathbf{n}(\mathbf{x}_i^\pm). \tag{4.22}$$

This is the complete analog of the identities derived in [11] for the singularity locations for the somewhat related problem $\Delta v_\lambda = -\lambda e^{v_\lambda}$.

Remark 4.8. If we apply Theorem 4.6 to the case when Ω is a disk, then $H(x) = 0$, and so

$$v_0(x) = -2\sum_{i=1}^M \log|x - \mathbf{x}_i^+| + 2\sum_{i=1}^M \log|x - \mathbf{x}_i^-|.$$

The equations (4.21) become

$$-\sum_{j=1,\,j\neq i}^{M}\frac{(\mathbf{x}_i^+-\mathbf{x}_j^+)\cdot\tau(\mathbf{x}_i^+)}{|\mathbf{x}_i^+-\mathbf{x}_j^+|^2}+\sum_{j=1}^{M}\frac{(\mathbf{x}_i^+-\mathbf{x}_j^-)\cdot\tau(\mathbf{x}_i^+)}{|\mathbf{x}_i^+-\mathbf{x}_j^-|^2}=0,\quad i=1,\dots,M,$$

and

$$-\sum_{j=1}^{M}\frac{(\mathbf{x}_i^--\mathbf{x}_j^+)\cdot\tau(\mathbf{x}_i^-)}{|\mathbf{x}_i^--\mathbf{x}_j^+|^2}+\sum_{j=1,\,j\neq i}^{M}\frac{(\mathbf{x}_i^--\mathbf{x}_j^-)\cdot\tau(\mathbf{x}_i^-)}{|\mathbf{x}_i^--\mathbf{x}_j^-|^2}=0,\quad i=1,\dots,M,$$

or in terms of the angles θ_j^+ and θ_j^- associated with the points $\mathbf{x}_j^+$ and $\mathbf{x}_j^-$,

$$-\sum_{j=1,\,j\neq i}^{M}\frac{\sin(\theta_i^+-\theta_j^+)}{1-\cos(\theta_i^+-\theta_j^+)}+\sum_{j=1}^{M}\frac{\sin(\theta_i^+-\theta_j^-)}{1-\cos(\theta_i^+-\theta_j^-)}=0,\quad i=1,\dots,M,$$

and

$$-\sum_{j=1}^{M}\frac{\sin(\theta_i^--\theta_j^+)}{1-\cos(\theta_i^--\theta_j^+)}+\sum_{j=1,\,j\neq i}^{M}\frac{\sin(\theta_i^--\theta_j^-)}{1-\cos(\theta_i^--\theta_j^-)}=0,\quad i=1,\dots,M.$$

It is clear that $\theta_j^+=\frac{2j\pi}{M}$, $\theta_j^-=\frac{(2j-1)\pi}{M}$, $j=1,\dots,M$, (and any fixed rotation of this set of angles) is a solution to these equations. This is consistent with the fact that all the explicit solution families constructed in [4] blow up, with alternating signs, at an even number of equidistant points.

The following lemma will be used for the proof of Theorem 4.6.

LEMMA 4.9. *Let Φ be a conformal equivalence on $\overline{\Omega}$, and let $\mathbf{x}^*$ be an arbitrary point on $\partial\Omega\setminus\{\Phi^{-1}(\infty)\}$; then*

$$\frac{\partial}{\partial\tau_x}\left(\log|\Phi(x)-\Phi(\mathbf{x}^*)|-\log|x-\mathbf{x}^*|\right)|_{x=\mathbf{x}^*}=\frac{\frac{\partial}{\partial\tau_x}|\det(D\Phi(x))|_{x=\mathbf{x}^*}}{4|\det(D\Phi(\mathbf{x}^*))|}.$$

Proof. In the following proof we use the Einstein summation convention: Repeated indices indicate summation. We immediately calculate

$$\begin{aligned}
&\frac{\partial}{\partial\tau_x}\left(\log|\Phi(x)-\Phi(\mathbf{x}^*)|-\log|x-\mathbf{x}^*|\right)|_{x=\mathbf{x}^*}\\
&\quad=\lim_{\substack{x\in\partial\Omega\\ x\to\mathbf{x}^*}}\left[\frac{(\Phi(x)-\Phi(\mathbf{x}^*))_k\partial_{x_j}\Phi_k(x)\tau_j(x)}{|\Phi(x)-\Phi(\mathbf{x}^*)|^2}-\frac{(x-\mathbf{x}^*)_j\tau_j(x)}{|x-\mathbf{x}^*|^2}\right]\\
&\quad=\lim_{\substack{x\in\partial\Omega\\ x\to\mathbf{x}^*}}\frac{(\Phi(x)-\Phi(\mathbf{x}^*))_k\partial_{x_j}\Phi_k(x)\tau_j(x)|x-\mathbf{x}^*|^2-(x-\mathbf{x}^*)_j\tau_j(x)|\Phi(x)-\Phi(\mathbf{x}^*)|^2}{|\Phi(x)-\Phi(\mathbf{x}^*)|^2|x-\mathbf{x}^*|^2}.
\end{aligned}$$

The numerator in this last expression may be expanded as follows:

$$\begin{aligned}
&(\Phi(x)-\Phi(\mathbf{x}^*))_k\partial_{x_j}\Phi_k(x)\tau_j(x)|x-\mathbf{x}^*|^2-(x-\mathbf{x}^*)_j\tau_j(x)|\Phi(x)-\Phi(\mathbf{x}^*)|^2\\
&\quad=\frac{1}{2}\partial_{x_l}\partial_{x_m}\Phi_k(\mathbf{x}^*)(x-\mathbf{x}^*)_l(x-\mathbf{x}^*)_m\partial_{x_j}\Phi_k(\mathbf{x}^*)\tau_j(\mathbf{x}^*)|x-\mathbf{x}^*|^2\\
&\qquad+\partial_{x_m}\Phi_k(\mathbf{x}^*)(x-\mathbf{x}^*)_m\partial_{x_l}\partial_{x_j}\Phi_k(\mathbf{x}^*)(x-\mathbf{x}^*)_l\tau_j(\mathbf{x}^*)|x-\mathbf{x}^*|^2\\
&\qquad-(x-\mathbf{x}^*)_j\tau_j(\mathbf{x}^*)\partial_{x_n}\Phi_k(\mathbf{x}^*)(x-\mathbf{x}^*)_n\partial_{x_l}\partial_{x_m}\Phi_k(\mathbf{x}^*)(x-\mathbf{x}^*)_l(x-\mathbf{x}^*)_m\\
&\qquad+O(|x-\mathbf{x}^*|^5)\\
&\quad=|x-\mathbf{x}^*|^4\left(\frac{1}{2}\partial_{x_l}\partial_{x_m}\Phi_k(\mathbf{x}^*)\tau_l(\mathbf{x}^*)\tau_m(\mathbf{x}^*)\partial_{x_j}\Phi_k(\mathbf{x}^*)\tau_j(\mathbf{x}^*)+O(|x-\mathbf{x}^*|)\right),
\end{aligned}\tag{4.23}$$

and the denominator may be expanded as follows:

$$|\Phi(x)-\Phi(\mathbf{x}^*)|^2|x-\mathbf{x}^*|^2 = |x-\mathbf{x}^*|^4\left[|\det(D\Phi(\mathbf{x}^*))| + O(|x-\mathbf{x}^*|)\right]. \tag{4.24}$$

Here we have on several occasions used that Φ is conformal on $\overline{\Omega}\backslash\{\Phi^{-1}(\infty)\}$. Insertion of these new expressions, (4.23) and (4.24), immediately yields

$$\begin{aligned}&\frac{\partial}{\partial\tau_x}\left(\log|\Phi(x)-\Phi(\mathbf{x}^*)| - \log|x-\mathbf{x}^*|\right)|_{x=\mathbf{x}^*}\\ &\quad= \frac{\partial_{x_l}\partial_{x_m}\Phi_k(\mathbf{x}^*)\tau_l(\mathbf{x}^*)\tau_m(\mathbf{x}^*)\partial_{x_j}\Phi_k(\mathbf{x}^*)\tau_j(\mathbf{x}^*)}{2|\det(D\Phi(\mathbf{x}^*))|}.\end{aligned} \tag{4.25}$$

Now

$$\begin{aligned}\frac{\partial}{\partial\tau_x}|\det(D\Phi(x))| &= \frac{\partial}{\partial\tau_x}\sum_{k=1}^{2}(\partial_{x_j}\Phi_k(x)\tau_j(x))^2\\ &= 2\partial_{x_j}\Phi_k(x)\tau_j(x)\partial_{x_m}\left(\partial_{x_l}\Phi_k(x)\tau_l(x)\right)\tau_m(x)\\ &= 2\partial_{x_j}\Phi_k(x)\tau_j(x)\partial_{x_m}\partial_{x_l}\Phi_k(x)\tau_l(x)\tau_m(x)\\ &\quad + 2\partial_{x_j}\Phi_k(x)\tau_j(x)\partial_{x_l}\Phi_k(x)\partial_{x_m}\tau_l(x)\tau_m(x)\\ &= 2\partial_{x_j}\Phi_k(x)\tau_j(x)\partial_{x_m}\partial_{x_l}\Phi_k(x)\tau_l(x)\tau_m(x).\end{aligned} \tag{4.26}$$

For the last identity we used that

$$\left\langle D\Phi(x)\tau(x), D\Phi(x)\frac{\partial}{\partial\tau_x}\tau(x)\right\rangle = -\kappa(x)\langle D\Phi(x)\tau(x), D\Phi(x)\mathbf{n}(x)\rangle = 0.$$

Insertion of (4.26) into (4.25) finally gives

$$\frac{\partial}{\partial\tau_x}\left(\log|\Phi(x)-\Phi(\mathbf{x}^*)| - \log|x-\mathbf{x}^*|\right)|_{x=\mathbf{x}^*} = \frac{\frac{\partial}{\partial\tau_x}|\det(D\Phi(x))|_{x=\mathbf{x}^*}}{4|\det(D\Phi(\mathbf{x}^*))|},$$

exactly as desired. ∎

Proof of Theorem 4.6. The statement about the convergence of $v^0_{\lambda_n} = v_{\lambda_n} - \int_{\partial\Omega} v_{\lambda_n}\, d\sigma/|\partial\Omega|$ follows directly from Theorem 3.1. The limit v_0 has the form

$$\begin{aligned}v_0(x) &= -\int_{\partial\Omega} N(z,x)\; d(\mu_+-\mu_-)_z = -\sum_{i=1}^{M}\alpha_i^+ N(\mathbf{x}_i^+,x) + \sum_{i=1}^{N}\alpha_i^- N(\mathbf{x}_i^-,x)\\ &= H^\alpha(x) - \sum_{i=1}^{M}\frac{\alpha_i^+}{\pi}\log|x-\mathbf{x}_i^+| + \sum_{i=1}^{N}\frac{\alpha_i^-}{\pi}\log|x-\mathbf{x}_i^-|,\end{aligned} \tag{4.27}$$

where H^α is the $C^\infty(\overline{\Omega})$ solution to

$$\Delta H^\alpha = 0 \quad \text{in } \Omega, \qquad \frac{\partial H^\alpha}{\partial\mathbf{n}} = \sum_{i=1}^{M}\frac{\alpha_i^+}{\pi}\frac{(x-\mathbf{x}_i^+)\cdot\mathbf{n}}{|x-\mathbf{x}_i^+|^2} - \sum_{i=1}^{N}\frac{\alpha_i^-}{\pi}\frac{(x-\mathbf{x}_i^-)\cdot\mathbf{n}}{|x-\mathbf{x}_i^-|^2} \quad \text{on } \partial\Omega,$$

$$\int_{\partial\Omega} H^\alpha\, d\sigma = \sum_{i=1}^{M}\frac{\alpha_i^+}{\pi}\int_{\partial\Omega}\log|x-\mathbf{x}_i^+|\, d\sigma_x - \sum_{i=1}^{N}\frac{\alpha_i^-}{\pi}\int_{\partial\Omega}\log|x-\mathbf{x}_i^-|\, d\sigma_x.$$

The form of H^α and the last identity in (4.27) are consequences of (3.1) and (3.2). We introduce a convenient renaming of the points $\mathbf{x}_i^\pm$ and the weights $\alpha_i^\pm$. Define points $\mathbf{x}_i$, $1 \le i \le M+N$, by

$$\mathbf{x}_i = \mathbf{x}_i^+, \quad 1 \le i \le M, \qquad \mathbf{x}_{i+M} = \mathbf{x}_i^-, \quad 1 \le i \le N,$$

and weights $\beta_i^\pm$, $1 \le i \le M+N$, by

$$\begin{aligned} &\beta_i^+ = \alpha_i^+ > 0, \quad 1 \le i \le M, \qquad \beta_{i+M}^+ = 0, \quad 1 \le i \le N, \\ &\beta_i^- = 0, \quad 1 \le i \le M, \qquad \beta_{i+M}^- = \alpha_i^- > 0, \quad 1 \le i \le N. \end{aligned}$$

The points $\mathbf{x}_i$ are distinct, and the product of β_i^+ and β_i^- is zero, since there is, by assumption, no overlap between $\{\mathbf{x}_i^+\}_{i=1}^M$ and $\{\mathbf{x}_i^-\}_{i=1}^N$. With this notation,

$$\mu_\pm = \sum_{i=1}^{M+N} \beta_i^\pm \delta_{\mathbf{x}_i}. \tag{4.28}$$

A part of the following argument is similar to that given in the proof of Theorem 4.1. At this point we need a refined version in order to treat asymptotically smaller terms, and for ease of comprehension we have decided to give the argument in its entirety. Let $x \to y = \Phi(x)$ be a conformal equivalence of Ω onto the upper half-plane $\mathbb{H} = \{(y_1, y_2) : y_2 > 0\}$ with the property that none of the points $\mathbf{y}_i = \Phi(\mathbf{x}_i)$, $1 \le i \le M+N$ are mapped to infinity. Setting $u_{\lambda_n} = v_{\lambda_n} \circ \Phi^{-1}$, we now have a family of solutions to

$$\begin{cases} \Delta u_{\lambda_n} = 0 & \text{in } \mathbb{H}, \\ \dfrac{\partial u_{\lambda_n}}{\partial y_2} = -\lambda_n h(y) \sinh(u_{\lambda_n}) & \text{on } \partial\mathbb{H}, \end{cases} \tag{4.29}$$

with $h(y) = |\det(D\Phi(\Phi^{-1}(y)))|^{-1/2}$. The sequence

$$u_{\lambda_n} - s_{\lambda_n}, \quad \text{with } s_{\lambda_n} = \int_{\partial\Omega} v_{\lambda_n}\, d\sigma/|\partial\Omega|,$$

converges to $u_0 = v_0 \circ \Phi^{-1}$ in $H^t(\mathbb{H} \cap \{|y| \le R\})$ for any $t < 1$ and any R; the convergence also takes place in $C^\infty(\overline{\mathbb{H}} \setminus \{\mathbf{y}_i\}_{i=1}^{M+N})$, i.e., in $C^\infty(K)$ for any compact set $K \subset \overline{\mathbb{H}} \setminus \{\mathbf{y}_i\}_{i=1}^{M+N}$. The function u_0 satisfies

$$\begin{cases} \Delta u_0 = 0 & \text{in } \mathbb{H}, \\ \dfrac{\partial u_0}{\partial y_2} = -\displaystyle\sum_{i=1}^{M+N} (\beta_i^+ - \beta_i^-)\delta_{\mathbf{y}_i} & \text{on } \partial\mathbb{H}. \end{cases} \tag{4.30}$$

We now introduce functions w_{λ_n} and w_0 by

$$w_{\lambda_n} := \partial_{y_1} u_{\lambda_n} \partial_{y_2} u_{\lambda_n} \quad \text{and} \quad w_0 := \partial_{y_1} u_0 \partial_{y_2} u_0,$$

respectively. Due to the $C^\infty(\overline{\mathbb{H}} \setminus \{\mathbf{y}_i\}_{i=1}^{M+N})$ convergence of $u_{\lambda_n} - s_{\lambda_n}$ toward u_0, the sequence w_{λ_n} converges in $C^\infty(\overline{\mathbb{H}} \setminus \{\mathbf{y}_i\}_{i=1}^{M+N})$ toward w_0. Simple calculations yield

$$\Delta w_{\lambda_n} = 0 \quad \text{in } \mathbb{H}$$

and

$$w_{\lambda_n} = -\lambda_n h(y_1,0)\sinh(u_{\lambda_n})\partial_{y_1}u_{\lambda_n} = -\lambda_n h(y_1,0)\partial_{y_1}\left(\cosh(u_{\lambda_n})\right) \quad \text{on } \partial\mathbb{H}. \tag{4.31}$$

From (4.30) and the fact that $u_0 = v_0 \circ \Phi^{-1}$, it follows that u_0 has the form

$$u_0(y) = c_0 - \sum_{i=1}^{M+N} \frac{(\beta_i^+ - \beta_i^-)}{\pi}\log|y - \mathbf{y}_i|, \tag{4.32}$$

where the constant c_0 is given by $c_0 = v_0(\Phi^{-1}(\infty))$. This is a simplified version of Lemma 4.5, corresponding to $F = 0$. We may thus calculate

$$\begin{aligned} w_0(y) &= \partial_{y_1}u_0\partial_{y_2}u_0(y) \\ &= \sum_{i,j}\frac{(\beta_j^+ - \beta_j^-)(\beta_i^+ - \beta_i^-)}{\pi^2}\frac{(y-\mathbf{y}_j)_1 y_2}{|y-\mathbf{y}_j|^2|y-\mathbf{y}_i|^2} \end{aligned}$$

or by a slight regrouping

$$\begin{aligned} w_0(y) = &\sum_i \frac{(\beta_i^+ - \beta_i^-)^2}{\pi^2}\frac{(y-\mathbf{y}_i)_1 y_2}{|y-\mathbf{y}_i|^4} \\ &+ \sum_{i,j,\, i\neq j}\frac{(\beta_j^+ - \beta_j^-)(\beta_i^+ - \beta_i^-)}{\pi^2}\frac{(y-\mathbf{y}_j)_1 y_2}{|y-\mathbf{y}_j|^2|y-\mathbf{y}_i|^2}. \end{aligned} \tag{4.33}$$

We now derive an alternate representation for the function w_0 by use of the relationship $w_0 = \lim_{\lambda_n\to 0} w_{\lambda_n}$. Let $D \subset \mathbb{H}$ be a bounded, smooth domain with $\Gamma_0 = \partial D \cap \partial\mathbb{H} = [-R,R]\times\{0\}$ (for instance, take D to be the half-disk $B_R(0)\cap\mathbb{H}$ with the two corners "smoothed out"). Choose R sufficiently large that all the points $\mathbf{y}_i^{\pm}$ lie inside $\frac{1}{2}\Gamma_0$. Let $G_D(y,z)$ denote the Green's function for the domain D, i.e., the solution to

$$\begin{cases} \Delta G_D(\cdot,z) = \delta_z & \text{in } D, \\ G_D(\cdot,z) = 0 & \text{on } \partial D. \end{cases} \tag{4.34}$$

For any fixed $z \in D$ the harmonic function w_{λ_n} may now be represented as

$$w_{\lambda_n}(z) = \int_{\partial D} w_{\lambda_n}(y)\frac{\partial G_D}{\partial \mathbf{n}_y}(y,z)\, d\sigma_y.$$

We decompose the boundary of D as follows: $\partial D = \Gamma_0 \cup \Gamma_1$, with $\Gamma_0 = \partial D \cap \partial\mathbb{H}$ and $\Gamma_1 = \partial D \cap \mathbb{H}$. In light of (4.31), the above integral representation for w_{λ_n} reads

$$\begin{aligned} w_{\lambda_n}(z) = &\int_{\Gamma_1} w_{\lambda_n}(y)\frac{\partial G_D}{\partial \mathbf{n}_y}(y,z)d\sigma_y \\ &+ \int_{\Gamma_0}\lambda_n h(y_1,0)\partial_{y_1}(\cosh(u_{\lambda_n}(y_1,0)))\frac{\partial G_D}{\partial y_2}((y_1,0),z)dy_1 \\ &= I_{1,\lambda_n}(z) + I_{2,\lambda_n}(z). \end{aligned} \tag{4.35}$$

As a consequence of the $C^\infty(\overline{\mathbb{H}}\setminus\{\mathbf{y}_i\}_{i=1}^{M+N})$ convergence of w_{λ_n} toward w_0

$$\lim_{\lambda_n\to 0} I_{1,\lambda_n}(z) = \int_{\Gamma_1} w_0(y)\frac{\partial G_D}{\partial \mathbf{n}_y}(y,z)d\sigma_y \quad \forall z \in D. \tag{4.36}$$

Integration by parts yields

$$
\begin{aligned}
I_{2,\lambda_n}(z) = &- \int_{\Gamma_0} \lambda_n \cosh(u_{\lambda_n}(y_1,0)) h(y_1,0) \partial_{y_1} \left(\frac{\partial G_D}{\partial y_2}((y_1,0),z) \right) dy_1 \\
&- \int_{\Gamma_0} \lambda_n \cosh(u_{\lambda_n}(y_1,0)) \partial_{y_1} h(y_1,0) \frac{\partial G_D}{\partial y_2}((y_1,0),z) dy_1 \\
&+ \left(\lambda_n \cosh(u_{\lambda_n}(y_1,0)) h(y_1,0) \frac{\partial G_D}{\partial y_2}((y_1,0),z) \right) \Bigg|_{y_1=-R}^{y_1=R}.
\end{aligned} \tag{4.37}
$$

From Lemma 4.3 we know that

$$
\lambda_n e^{v_{\lambda_n}} \to 2\mu_+ = 2 \sum_{i=1}^{M+N} \beta_i^+ \delta_{\mathbf{x}_i} \quad \text{and} \quad \lambda_n e^{-v_{\lambda_n}} \to 2\mu_- = 2 \sum_{i=1}^{M+N} \beta_i^- \delta_{\mathbf{x}_i}
$$

in the sense of measures on $\partial\Omega$, and so

$$
\lambda_n \cosh(v_{\lambda_n}) \to \sum_{i=1}^{M+N} (\beta_i^+ + \beta_i^-) \delta_{\mathbf{x}_i}
$$

in the sense of measures on $\partial\Omega$. The left-hand sides also converge uniformly to zero away from the points $\mathbf{x}_i$. When "pushed forward" by the conformal map Φ, the convergence implies that

$$
\lambda_n h(y_1,0) \cosh(u_{\lambda_n}(y_1,0)) \to \sum_{i=1}^{M+N} (\beta_i^+ + \beta_i^-) \delta_{\mathbf{y}_i} \tag{4.38}
$$

in the sense of measures on $\Gamma_0 = [-R,R] \times \{0\}$. As a consequence of (4.37) and (4.38) we immediately obtain the following limit for the integrals I_{2,λ_n}:

$$
\begin{aligned}
\lim_{\lambda_n \to 0} I_{2,\lambda_n}(z) = &- \sum_{i=1}^{M+N} (\beta_i^+ + \beta_i^-) \frac{\partial^2 G_D}{\partial y_1 \partial y_2}(\mathbf{y}_i, z) \\
&- \sum_{i=1}^{M+N} (\beta_i^+ + \beta_i^-) \frac{\partial_{y_1} h(\mathbf{y}_i)}{h(\mathbf{y}_i)} \frac{\partial G_D}{\partial y_2}(\mathbf{y}_i, z) \quad \forall z \in D.
\end{aligned} \tag{4.39}
$$

Here we also used the fact that $\lambda_n \cosh(u_{\lambda_n}(y_1,0)) h(y_1,0)$ converges pointwise to zero away from the points $\mathbf{y}_i$ to eliminate the boundary term in (4.37). A combination of (4.36) and (4.39) with (4.35) now yields

$$
\begin{aligned}
w_0(z) = \lim_{\lambda_n \to 0} w_{\lambda_n}(z) = &\int_{\Gamma_1} w_0(y) \frac{\partial G_D}{\partial \mathbf{n}_y}(y,z) d\sigma_y \\
&- \sum_{i=1}^{M+N} (\beta_i^+ + \beta_i^-) \frac{\partial^2 G_D}{\partial y_1 \partial y_2}(\mathbf{y}_i, z) \\
&- \sum_{i=1}^{M+N} (\beta_i^+ + \beta_i^-) \frac{\partial_{y_1} h(\mathbf{y}_i)}{h(\mathbf{y}_i)} \frac{\partial G_D}{\partial y_2}(\mathbf{y}_i, z) \quad \forall z \in D.
\end{aligned} \tag{4.40}
$$

Set $\omega = \{z \in D : |z_1| < R/2 \text{ and } 0 < z_2 < \epsilon\}$ for ϵ fixed but sufficiently small. The Green's function $G(y,z)$, $(y,z) \in \overline{D \times \omega} \setminus \{y = z\}$, may now be written

$$
G_D(y,z) = \frac{1}{2\pi} \log|y - z| - \frac{1}{2\pi} \log|y - \overline{z}| + g(y,z),
$$

where $\overline{z} = \overline{(z_1, z_2)} = (z_1, -z_2)$ and where the function g is in $C^\infty(\overline{D \times \omega})$. Since $\mathbf{y}_i \in \Gamma_0 = \partial D \cap \partial \mathbb{H}$, $1 \le i \le M+N$, we thus compute

$$\begin{aligned} \frac{\partial G_D}{\partial y_2}(\mathbf{y}_i, z) &= -\frac{1}{\pi}\frac{z_2}{|\mathbf{y}_i - z|^2} + \partial_{y_2} g(\mathbf{y}_i, z) \quad z \in \overline{\omega} \setminus \{\mathbf{y}_i\} \quad \text{and} \\ \frac{\partial^2 G_D}{\partial y_1 \partial y_2}(\mathbf{y}_i, z) &= \frac{2}{\pi}\frac{(\mathbf{y}_i - z)_1 z_2}{|\mathbf{y}_i - z|^4} + \partial_{y_1}\partial_{y_2} g(\mathbf{y}_i, z) \quad z \in \overline{\omega} \setminus \{\mathbf{y}_i\}. \end{aligned} \tag{4.41}$$

Substituting (4.41) into (4.40) we arrive at

$$\begin{aligned} w_0(z) = \frac{2}{\pi}\sum_{i=1}^{M+N} (\beta_i^+ + \beta_i^-)\frac{(z - \mathbf{y}_i)_1 z_2}{|z - \mathbf{y}_i|^4} \\ + \frac{1}{\pi}\sum_{i=1}^{M+N} (\beta_i^+ + \beta_i^-)\frac{\partial_{y_1} h(\mathbf{y}_i)}{h(\mathbf{y}_i)}\frac{z_2}{|z - \mathbf{y}_i|^2} + R(z), \end{aligned} \tag{4.42}$$

where R is in $C^\infty(\overline{\omega})$. By comparing the two representations (4.33) and (4.42) for w_0, and using the fact that the singular terms of same type (near $\mathbf{y}_i$) must coincide, we now obtain equations for the weights $\{\beta_i^\pm\}_{i=1}^{M+N}$ and the points $\{\mathbf{y}_i\}_{i=1}^{M+N}$. From the terms of type $(\cdot - \mathbf{y}_i)_1(\cdot)_2/|\cdot - \mathbf{y}_i|^4$,

$$\frac{(\beta_i^+ - \beta_i^-)^2}{\pi^2} = \frac{2}{\pi}(\beta_i^+ + \beta_i^-), \quad 1 \le i \le N + M. \tag{4.43}$$

From the terms of type $(\cdot)_2/|\cdot - \mathbf{y}_i|^2$,

$$\begin{aligned} \frac{(\beta_i^+ - \beta_i^-)}{\pi^2}\sum_{j=1,\, j\neq i}^{M+N} (\beta_j^+ - \beta_j^-)\frac{(\mathbf{y}_i - \mathbf{y}_j)_1}{|\mathbf{y}_i - \mathbf{y}_j|^2} \\ = \frac{1}{\pi}(\beta_i^+ + \beta_i^-)\frac{\partial_{y_1} h(\mathbf{y}_i)}{h(\mathbf{y}_i)}, \quad 1 \le i \le N + M. \end{aligned} \tag{4.44}$$

Recall that, by assumption, the two set of points $\{\mathbf{x}_i^+\}_{i=1}^M$ and $\{\mathbf{x}_i^-\}_{i=1}^N$ are disjoint, and $0 < \beta_i^+ = \alpha_i^+$, $1 \le i \le M$, $0 < \beta_{i+M}^- = \alpha_i^-$, $1 \le i \le N$, with $\beta_i^\pm = 0$ otherwise. In terms of the points $\mathbf{y}_i^\pm = \Phi(\mathbf{x}_i^\pm)$ and the weights $\alpha_i^\pm$, the identities (4.43) and (4.44) now reduce to

$$\alpha_i^+ = 2\pi, \quad 1 \le i \le M, \qquad \alpha_i^- = 2\pi, \quad 1 \le i \le N,$$

$$2\sum_{j=1,\, j\neq i}^{M} \frac{(\mathbf{y}_i^+ - \mathbf{y}_j^+)_1}{|\mathbf{y}_i^+ - \mathbf{y}_j^+|^2} - 2\sum_{j=1}^{N} \frac{(\mathbf{y}_i^+ - \mathbf{y}_j^-)_1}{|\mathbf{y}_i^+ - \mathbf{y}_j^-|^2} = \frac{\partial_{y_1} h(\mathbf{y}_i^+)}{h(\mathbf{y}_i^+)}, \quad 1 \le i \le M, \quad \text{and} \tag{4.45}$$

$$-2\sum_{j=1}^{M} \frac{(\mathbf{y}_i^- - \mathbf{y}_j^+)_1}{|\mathbf{y}_i^- - \mathbf{y}_j^+|^2} + 2\sum_{j=1,\, j\neq i}^{N} \frac{(\mathbf{y}_i^- - \mathbf{y}_j^-)_1}{|\mathbf{y}_i^- - \mathbf{y}_j^-|^2} = \frac{\partial_{y_1} h(\mathbf{y}_i^-)}{h(\mathbf{y}_i^-)}, \quad 1 \le i \le N. \tag{4.46}$$

Since all the $\alpha_i^\pm$ have the same value (2π) and since $\sum_{i=1}^M \alpha_i^+ = \mu_+(\partial\Omega) = \mu_-(\partial\Omega) = \sum_{i=1}^N \alpha_i^-$, it follows that $M = N (\ge 1)$. From the definition of h we calculate

$$\frac{\partial h}{\partial y_1}(\mathbf{y}_i^\pm) = -\frac{1}{2}|\det(D\Phi(\mathbf{x}_i^\pm)|^{-2}\frac{\partial}{\partial \tau_x}|\det(D\Phi(x))|_{x=\mathbf{x}_i^\pm},$$

so that

$$\frac{\partial_{y_1} h(\mathbf{y}_i^{\pm})}{h(\mathbf{y}_i^{\pm})^2} = -\frac{1}{2}\frac{\frac{\partial}{\partial\tau_x}\left|\det(D\Phi(x))\right|_{x=\mathbf{x}_i^{\pm}}}{|\det(D\Phi(\mathbf{x}_i^{\pm})|}. \tag{4.47}$$

We have that

$$\begin{aligned} v_0(x) + 2\log|x-\mathbf{x}_i^+| &= v_0(x) + 2\log|\Phi(x)-\Phi(\mathbf{x}_i^+)| \\ &\quad + 2(\log|x-\mathbf{x}_i^+| - \log|\Phi(x)-\Phi(\mathbf{x}_i^+)|) \\ &= [u_0(y) + 2\log|y-\mathbf{y}_i^+|]_{y=\Phi(x)} \\ &\quad + 2(\log|x-\mathbf{x}_i^+| - \log|\Phi(x)-\Phi(\mathbf{x}_i^+)|) \\ &= \left[c_0 - 2\sum_{j=1,\, j\neq i}^{M}\log|y-\mathbf{y}_j^+| + 2\sum_{j=1}^{M}\log|y-\mathbf{y}_j^-|\right]_{y=\Phi(x)} \\ &\quad + 2(\log|x-\mathbf{x}_i^+| - \log|\Phi(x)-\Phi(\mathbf{x}_i^+)|). \end{aligned}$$

For the last identity we used the representation formula (4.32) for u_0 and the facts that $M = N$ and $\beta_i^+ - \beta_i^- = 2\pi$, $1 \le i \le M$, $\beta_i^+ - \beta_i^- = -2\pi$, $M+1 \le i \le 2M$. By differentiation and use of Lemma 4.9 we now get that

$$\begin{aligned} &\frac{\partial}{\partial\tau_x}(v_0(x) + 2\log|x-\mathbf{x}_i^+|)_{x=\mathbf{x}_i^+} \\ &\quad = \frac{1}{h(\mathbf{y}_i^+)}\frac{\partial}{\partial y_1}\left[c_0 - 2\sum_{j=1,\, j\neq i}^{M}\log|y-\mathbf{y}_j^+| + 2\sum_{j=1}^{M}\log|y-\mathbf{y}_j^-|\right]_{y=\mathbf{y}_i^+} \\ &\qquad -\frac{1}{2}\frac{\frac{\partial}{\partial\tau_x}|\det(D\Phi(x))|_{x=\mathbf{x}_i^+}}{|\det(D\Phi(\mathbf{x}_i^+))|}. \end{aligned}$$

In combination with (4.45) and (4.47) this immediately yields

$$\frac{\partial}{\partial\tau_x}(v_0(x) + 2\log|x-\mathbf{x}_i^+|)_{x=\mathbf{x}_i^+} = 0, \quad 1 \le i \le M.$$

A similar approach, based on (4.46), leads to the identities

$$\frac{\partial}{\partial\tau_x}(v_0(x) - 2\log|x-\mathbf{x}_i^-|)_{x=\mathbf{x}_i^-} = 0, \quad 1 \le i \le M.$$

Finally

$$\lim_{\lambda_n\to 0}\lambda_n\int_{\partial\Omega}|\sinh(v_{\lambda_n})|\,d\sigma = (\mu_+ + \mu_-)(\partial\Omega) = \sum_{i=1}^{M}\alpha_i^+ + \sum_{i=1}^{M}\alpha_i^- = 4M\pi.$$

This completes the proof of Theorem 4.6. □

Remark 4.10. If we drop the assumption that $\{\mathbf{x}_i^+\} \cap \{\mathbf{x}_i^-\} = \emptyset$, then the same techniques that were used for the proof of Theorem 4.6 still lead to some interesting conclusions. Let $\mathbf{x}^*$ be any point in $\{\mathbf{x}_i^+\} \cup \{\mathbf{x}_i^-\} = S \subset \partial\Omega$ and suppose μ_+ and μ_- have contributions $\alpha_*^+\delta_{\mathbf{x}^*}$ and $\alpha_*^-\delta_{\mathbf{x}^*}$, respectively (included here is the possibility

that α_*^+ or α_*^- is zero). From (4.43) in the proof of Theorem 4.6 we immediately obtain the identity

$$\frac{(\alpha_*^+ - \alpha_*^-)^2}{\pi^2} = \frac{2}{\pi}(\alpha_*^+ + \alpha_*^-).$$

For points that are in only one of the sets $\{\mathbf{x}_i^+\}$ or $\{\mathbf{x}_i^-\}$ (but not in $\{\mathbf{x}_i^+\} \cap \{\mathbf{x}_i^-\}$) this still asserts that the nonzero weight (α_*^+ or α_*^-) is 2π, but for potential $\mathbf{x}_*$ in $\{\mathbf{x}_i^+\} \cap \{\mathbf{x}_i^-\}$ this identity implies only that

$$\alpha_*^+ + \alpha_*^- > |\alpha_*^+ - \alpha_*^-| > 2\pi,$$

so that the contribution to $\frac{\partial v_0}{\partial \mathbf{n}} = \mu_+ - \mu_-$ and to $\mu_+ + \mu_-$ is of greater magnitude than $2\pi\delta_{\mathbf{x}^*}$. This result was already derived in the proof of Theorem 4.1 in the most general setting, without any assumptions about $d_\pm$.

The equation analogous to (4.21) becomes

$$\frac{\partial}{\partial \tau_x}\left(v_0(x) + \frac{(\alpha_*^+ - \alpha_*^-)}{\pi}\log|x - \mathbf{x}^*|\right)\Big|_{x=\mathbf{x}^*} = 0,$$

or in terms of the full gradient

$$\begin{aligned}\nabla_x\left(v_0(x) + \frac{(\alpha_*^+ - \alpha_*^-)}{\pi}\log|x - \mathbf{x}^*|\right)\Big|_{x=\mathbf{x}^*} &= \frac{(\alpha_*^+ - \alpha_*^-)}{2\pi}\kappa(\mathbf{x}^*)\mathbf{n}(\mathbf{x}^*) \\ &= \frac{(\alpha_*^+ + \alpha_*^-)}{(\alpha_*^+ - \alpha_*^-)}\kappa(\mathbf{x}^*)\mathbf{n}(\mathbf{x}^*).\end{aligned}$$

For points that are in only one of the sets $\{\mathbf{x}_i^+\}$ or $\{\mathbf{x}_i^-\}$ (but not in $\{\mathbf{x}_i^+\} \cap \{\mathbf{x}_i^-\}$) these are exactly the same equations as in Theorem 4.6. We are not at the moment able to derive equations analogous to (4.21) (or (4.22)) for the case when either d_+ or d_- is nonzero.

5. Computational examples. In this section we present some results of numerical calculations of solutions to the boundary value problem (1.1) on two different simply connected domains. As $\lambda \to 0^+$ the solutions we calculate all appear to have boundary fluxes that are bounded in L^1, i.e., they appear to satisfy $\|\lambda \sinh(v_\lambda)\|_{L^1(\partial\Omega)} \leq C$, and as predicted by Theorems 3.1 and 4.1 the limiting fluxes thus all contain at least one nonzero point mass. In section 2 we showed that such solutions also necessarily satisfy

$$|s_\lambda| = \left|\frac{1}{|\partial\Omega|}\int_{\partial\Omega} v_\lambda \, d\sigma\right| \leq \log\frac{1}{\lambda} + D.$$

The second of our numerical experiments gives strong evidence that asymptotic equality is indeed attained for certain solutions. This again implies that one of the expressions,

$$\lambda e^{\pm s_\lambda} = \lambda \exp\left(\pm\frac{1}{|\partial\Omega|}\int_{\partial\Omega} v_\lambda \, d\sigma\right),$$

has a nonzero limit point as $\lambda \to 0^+$. As seen in Theorem 3.1 (and Theorem 4.1), such a nonzero limit point gives rise to a subsequence of solutions with a limiting

boundary flux that contains point masses as well as a regular part. It is therefore not surprising that some of the limiting boundary fluxes arising in the second experiment show strong evidence of the presence of a nonzero regular part. Due to the emergence of nonzero regular parts in some of the limiting boundary fluxes (and the corresponding elimination of some potential point masses) our second experiment also provides potential evidence that the identities (4.21) (or (4.22)), derived in Theorem 4.6 for the locations of point masses, are necessary but not sufficient.

For the purpose of our computations we reformulate the problem (1.1) as a nonlinear boundary integral equation, which we then approximate using a Nyström collocation method and finally solve by means of a Newton iteration scheme [1], [8]. In order to achieve high numerical accuracy in the presence of the points of "blow-up," we first calculate the potential "blow-up" locations (by the approximate solution of the equations from Theorem 4.6) and then use a mesh for the Nyström collocation that is refined appropriately near these points. For more details about these and other Matlab computations, see [9]. Nyström's method is known to achieve exceptional (exponential) accuracy for "uniform" meshes and smooth solutions. Since our solutions develop very strong singularities as $\lambda \to 0^+$, the accuracy using a "uniform" mesh is completely unsatisfactory for small λ. We believe our mesh-refinement strategy provides much higher (though, far from exponential) accuracy. However, we should point out that, due to the fact that even the L^∞ norm of the solution blows up, we do not have any good a priori estimate of the accuracy associated with a particular mesh, valid uniformly in λ. Part of the challenge (short of rigorously developing a posteriori error estimators) is to find decent ways to gauge the accuracy of the computations.

5.1. Pure sums of point masses. The domains we consider are conformal images of the unit disk by the (complex-valued) exponential map, $\Phi(z) = e^{\gamma z}$ with $0 < \gamma < \pi$. For small values of γ, the image of this map is very close to a disk, so we expect the solutions to behave like the solutions on a disk. Indeed, this is the case when we choose $\gamma = 0.5$. We compute the two "first" nontrivial solution families, i.e., the solution families branching off at the first two nonzero Steklov eigenvalues of the linearized problem $\Delta w = 0$ in Ω, $\frac{\partial w}{\partial n} = \lambda w$ on $\partial\Omega$. Since these two eigenvalues represent the "split" of the first nonzero (double) eigenvalue for a disk, we expect to see two distinct families of solutions whose boundary fluxes each develop two point masses of opposite strength. Graphical output from our computations is shown in Figure 1. The first two frames show the normal fluxes plotted against the arclength for the two families of solutions. Arclength = 0 corresponds to the rightmost intersection of the domain with the x-axis (the point $(e^{0.5}, 0)$). In each frame we plot the boundary fluxes $\frac{\partial u_\lambda}{\partial n}$, for a collection of λ ranging between 0.24 and 10^{-3}. We clearly see two point masses develop as λ decreases. There are no nonzero regular parts in the limiting fluxes. The two families have different locations for the point masses. In the third frame we show the mesh grading function used for the computation of the first family of solutions. The horizontal axis represents the node number (from 1 to 512) and the vertical axis represents (the arclength to) the corresponding node location on $\partial\Omega$. There are "exponential-type" refinements near the two potential point mass locations, the kind of refinements that appear well suited to the expected logarithmic near-singularities of the solutions. For more details, see [9]. The fourth frame shows the two potential pairs of point mass locations as computed from the necessary conditions of Theorem 4.6 (with $M = 1$). Each potential pair is in total agreement with the approximate point mass locations observed in exactly one of the first two frames. The locations marked by $\circ$ correspond to the first family of solutions,

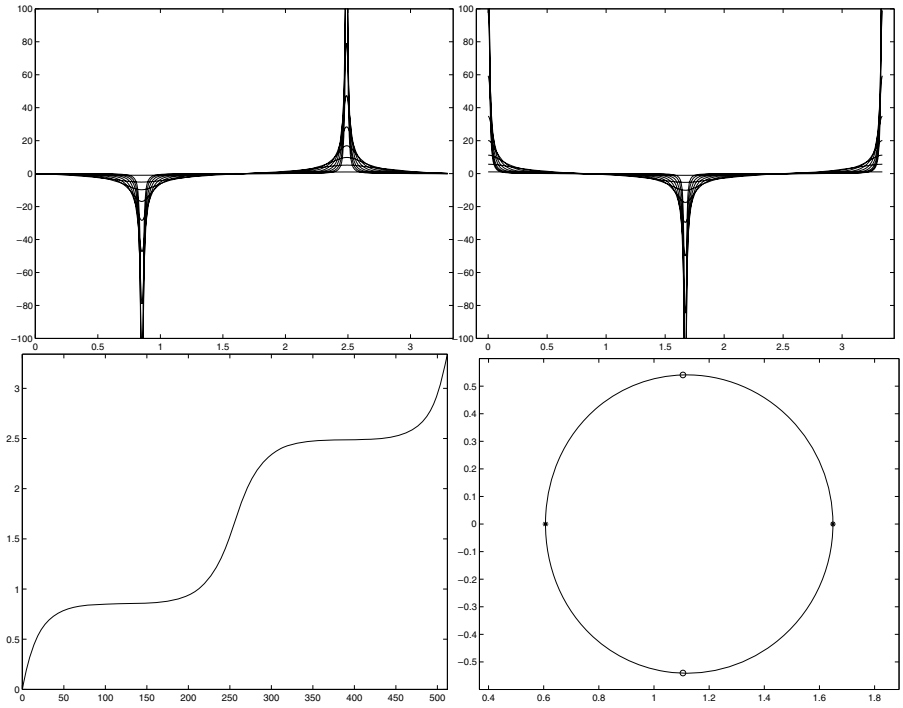

FIG. 1. *The case $\gamma = 0.5$. The two top frames show boundary fluxes for the two first solution families as a function of arclength. The third frame shows the mesh grading function used for the computation of the first solution family. The fourth frame shows the domain with marked point mass locations: $\circ$'s correspond to the first family, *'s to the second.*

the locations marked by * to the second family.

5.2. A regular part. At the other end of the spectrum, for clarity, we look at the case of $\gamma = 2.0$. Figure 2 shows a collection of boundary fluxes of solutions, for λ as small as 10^{-3}, using a mesh that is "exponentially" refined near the two potential "blow-up" points. On this domain (the shape of which is shown in the insert of Figure 2) we see very strong evidence of a positive regular part and a single negative point mass in the limiting boundary flux.

For some of the first uniform (and coarser) meshes we used in our computations, we initially saw behavior like the one showed in Figure 2, but at a certain point in λ, depending on the mesh, the positive part of the boundary flux would accelerate its growth as λ approached 0. In all the meshes we tried it has always been clear that the negative part of the boundary flux converges to a single point mass. A vast difference in scale made it plausible that the negative part was the only point mass to develop in the limit and that the positive part would converge to some smooth function. However, the accelerated growth in the positive part of the flux could indicate some additional point masses. In order to effectively rule this out we need some simple a posteriori tests to indicate, for a certain mesh, what values of λ are simply too small to allow accurate computational results.

To illustrate this point we choose $\lambda = 10^{-2}$ and $\lambda = 10^{-3}$ and compute the approximate boundary fluxes for the same three meshes. The first frame in Figure 3

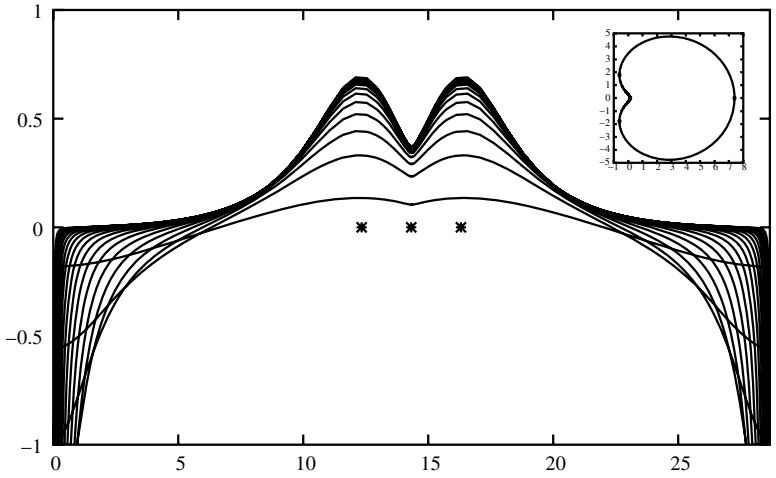

FIG. 2. *An example of a limiting boundary flux with a nonzero regular part. The domain* Ω *(insert) corresponds to* $\gamma = 2$*. The three locations indicated by *'s (below the graphs) correspond to the three marked points on the leftmost part of the boundary of* Ω*.*

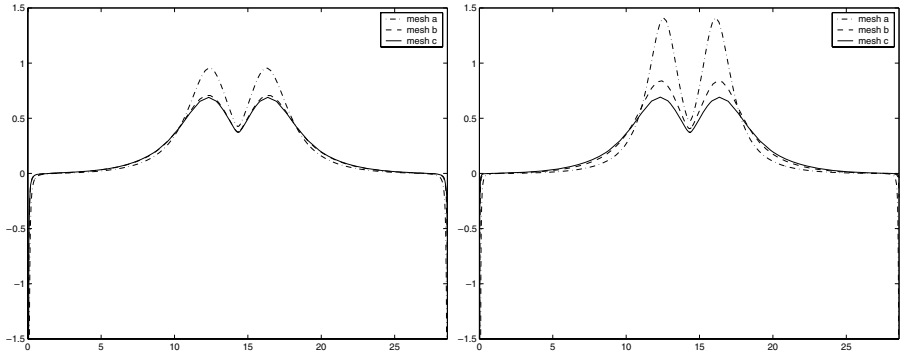

FIG. 3. *Left frame: Boundary fluxes for* $\lambda = 10^{-2}$ *computed using three different meshes. Right frame: Boundary fluxes for* $\lambda = 10^{-3}$ *computed using the same three meshes. The domain in both cases corresponds to* $\gamma = 2$*.*

displays the computed fluxes for $\lambda = 10^{-2}$; the second frame, those for $\lambda = 10^{-3}$. The three meshes we use are "exponentially" refined at the "blow-up" points. They differ by the size of the smallest mesh width near "blow-up" points. Mesh **a** is the coarsest near these points, and mesh **c** is the finest. Using the exact same three meshes, we have computed the integrals of the positive part of the approximate boundary flux and the boundary averages of the approximate solution. These results are displayed in Figure 4. Since it is quite clear (from all three meshes) that a single, isolated negative point mass develops, Theorem 4.1 asserts that this must have a mass of -2π. Correspondingly, the integral of $(\frac{\partial v_\lambda}{\partial n})^+$ should approach 2π. The left frame in Figure 4 clearly indicates that meshes **a** and **b** lack sufficient accuracy for $\lambda = 10^{-3}$, whereas mesh **c** achieves an integral very close to 2π even for $\lambda = 10^{-3}$. According to the same test mesh **b** seems adequate for $\lambda = 10^{-2}$, but mesh **a** already lacks sufficient

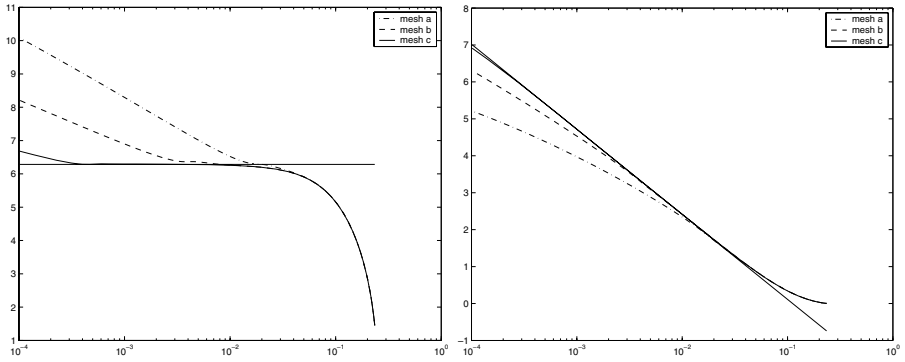

FIG. 4. *Two gauges of accuracy, as explained in text. Left frame: The integrals of the positive part of the approximate boundary flux. Right frame: The boundary averages of the approximate solution. The three meshes are the same as in Figure* 3.

accuracy for this value of λ. Comparing with Figure 3 we are thus inclined to believe the results of meshes **b** and **c** for $\lambda = 10^{-2}$ and those of mesh **c** for $\lambda = 10^{-3}$. These results predict the presence of a nonzero regular part in the limiting boundary flux. The growing "modes" we see in the other results can all be attributed to numerical inaccuracy. The right frame in Figure 4 gives a positive confirmation of the accuracy associated with mesh **c** all the way down to $\lambda = 10^{-3}$ (and the accuracy associated with mesh **b** down to 10^{-2}). In this frame we plot the boundary averages of the approximate solution versus λ. For comparison we also plot the line corresponding to the function $\log(\frac{1}{\lambda}) + D$. D is chosen by fitting the results from the "finest" mesh (mesh **c**) to this logarithmic line. From Theorem 3.1 we know that a nonzero regular part of the limiting boundary flux exists if and only if the boundary averages of the solution behave like $\pm\log(\frac{1}{\lambda}) + D$. The computations corresponding to mesh **c** shown in Figure 3 and in the right frame of Figure 4 are completely consistent with this equivalence, as are the computations corresponding to mesh **b** shown in the left frame of Figure 3 and in the right frame of Figure 4.

Based on these additional computations we believe that the limiting boundary flux for this second family of solutions, in case $\gamma = 2$, does indeed exhibit a nonzero regular part as shown in Figure 2. The equations derived in Theorem 4.6 for the potential locations of two point masses ($M = 1$) continue to have as a solution the pair of points lying at the intersection of Ω and the horizontal coordinate axis (as these equations did in the case of $\gamma = 0.5$). The fact that none of the first two computed solution families (or for that matter none of the first four solution families, as seen in the next figure) develops a pair of singularities at these two points gives some indication that our "location conditions" are necessary but not sufficient.

So far we have considered only the first two nontrivial solution families, but we have in many cases computed solution families branching off at much "higher" Steklov eigenvalues. Figure 5 shows the results of such a computation on the domain corresponding to $\gamma = 2$. The first frame shows the bifurcation diagram for the first six nontrivial solution families. We plot $\|\nabla v_\lambda\|_{L^2(\Omega)}$ versus λ. In the following four frames we show a sequence of eight boundary fluxes corresponding to each of the first four solution branches. The number m is a counter for the Steklov eigenvalues; $m = 1$ corresponds to the eigenvalue 0, $m = 2$ is the first nonzero eigenvalue, etc. The

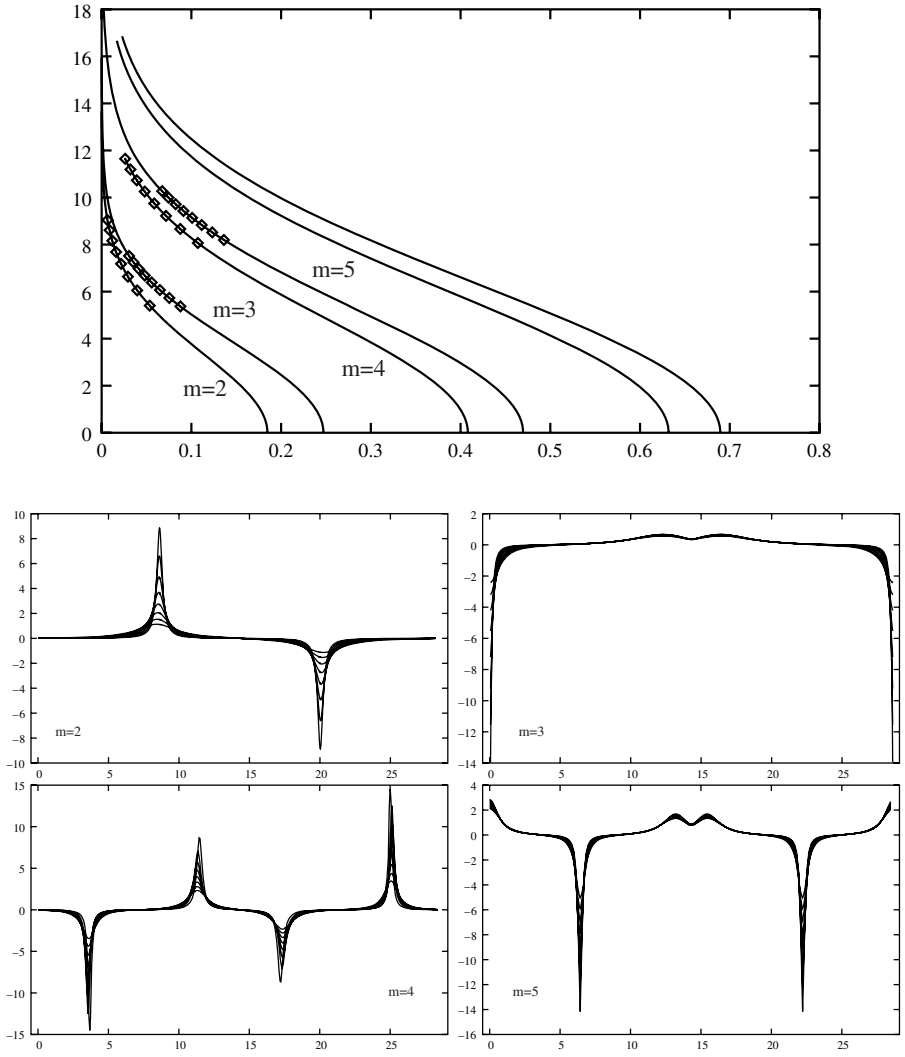

FIG. 5. *A bifurcation diagram showing* $\|\nabla v_\lambda\|_{L^2(\Omega)}$ *as a function of* λ*, and the boundary fluxes at selected points on the first four solution branches. The domain* Ω *corresponds to* $\gamma = 2$.

points in the bifurcation diagram that correspond to the shown boundary fluxes have been marked with squares. As seen in Figure 5, the boundary fluxes corresponding to $m = 2$ and $m = 4$ appear to converge to pure sums of alternating point masses (the computations also confirm that each point mass is of strength $\pm 2\pi$), whereas the limiting boundary fluxes for $m = 3$ and $m = 5$ appear to contain a nonzero regular part as well. The situation $m = 3$ has already been discussed. For $m = 5$ the limiting boundary flux appears to have two negative point masses (each of mass -2π) balanced by a positive regular part, in complete agreement with Theorem 4.1.

Acknowledgments. Part of this work was carried out during a stay at Université de Versailles. The authors thank O. Kavian and J.-P. Puel for their hospitality and

for many interesting discussions.

FROM KINETIC EQUATIONS TO MULTIDIMENSIONAL ISENTROPIC GAS DYNAMICS BEFORE SHOCKS*

F. BERTHELIN† AND A. VASSEUR†

Abstract. This article is devoted to the proof of the hydrodynamical limit from kinetic equations (including BGK-like equations) to multidimensional isentropic gas dynamics. It is based on a relative entropy method; hence the derivation is valid only before shocks appear on the limit system solution. However, no a priori knowledge on high velocity distributions for kinetic functions is needed. The case of the Saint–Venant system with topography (where a source term is added) is included.

Key words. hydrodynamic limit, entropy method, BGK equation, isentropic gas dynamics, Saint–Venant system

DOI. 10.1137/S0036141003431554

1. Introduction.

1.1. Context and results. This article is devoted to the study of the hydrodynamical limit of kinetic equations to the multidimensional system of isentropic gas dynamics:

$$\begin{cases} \partial_t \rho + \operatorname{div}_x(\rho u) = 0, \quad t \in \mathbb{R}^+,\ x \in \mathbb{R}^n, \\ \partial_t(\rho u) + \operatorname{div}_x(\rho u \otimes u + I\rho^\gamma) = \rho F, \quad t \in \mathbb{R}^+,\ x \in \mathbb{R}^n, \end{cases} \tag{1.1}$$

for $1 \le \gamma \le \frac{n+2}{n}$ and a given external force field F.

This is a simplified situation of the long-term problem concerning the compressible limit of the Boltzmann equation. In this case, the hydrodynamical limit has been performed by Caflisch [9] only for smooth data during a small time. The asymptotic limit of the Boltzmann equation in low Mach number towards incompressible Euler (or Navier–Stokes) systems has been achieved recently by Saint-Raymond [26] and Lions and Masmoudi [22] following the pioneering work of Bardos, Golse, and Levermore [1]. As for our work, they are still local time results, since it is valid in the lapse of time in which the limit solution remains smooth. However, at the kinetic level, no strong smoothness property is needed. Notice that in our case we deal with compressible gases, and even the existence of a solution to (1.1) after shocks appear is not known in the multidimensional situation.

At the kinetic level, we consider a Fokker–Planck equation for the isothermal case ($\gamma = 1$) and a BGK-like equation for the other values of γ. Originally, BGK equations have been introduced by Bathnagar, Gross, and Krook as a simplification of the Boltzmann equation. This model has been extended in order to construct kinetic equations associated with different hydrodynamical systems (see the book of Perthame [24] for a survey of this field). In our particular case, the BGK model we use has been introduced for the full range of γ by Bouchut [5]. Our main result is the following.

THEOREM 1.1. *Let F be in $C^2(\mathbb{R}^n) \cap L^\infty(\mathbb{R}^n)$. Let $(\rho^0, \rho^0 u^0) \in L^1(\mathbb{R}^n)$ be the initial data of a solution $U = (\rho, \rho u) \in C^1([0,T[\times\mathbb{R}^n) \cap L^1([0,T[\times\mathbb{R}^n)$ to (1.1) such that $\rho > 0$; ρ, u, $\partial_x \rho$, $\partial_x u$ are bounded with respect to (t,x); and ρu^2, $h(\rho)$ are integrable with respect to (t,x), where $h(\rho) = \rho^\gamma/(\gamma-1)$ for $\gamma > 1$ and $h(\rho) = \rho \ln \rho$ for $\gamma = 1$. Consider a family of kinetic initial values f_ε^0 verifying $f_\varepsilon^0 \in L^1(\mathbb{R}^{2n})$, $H(f_\varepsilon^0, v) \in L^1(\mathbb{R}^{2n})$ (where H is the kinetic entropy associated with the system (1.1); see section 4). We assume that it verifies*

$$\int_{\mathbb{R}^n} (f_\varepsilon^0, v f_\varepsilon^0, H(f_\varepsilon^0, v))\, dv \underset{\varepsilon\to 0}{\longrightarrow} (\rho^0, \rho^0 u^0, \rho^0 (u^0)^2/2 + h(\rho^0)) \quad \text{in } L^1(\mathbb{R}^n).$$

Let f_ε be the solution to the BGK equation (4.1) for $1 < \gamma \le n/(n+2)$ or the solution to the Fokker–Planck equation (4.5) for the isotherm case ($\gamma = 1$). We denote

$$(\rho_\varepsilon, \rho_\varepsilon u_\varepsilon) = \left(\int_{\mathbb{R}^n} f_\varepsilon\, dv, \int_{\mathbb{R}^n} v f_\varepsilon\, dv \right).$$

Then ρ_ε converges strongly in $C^0(0,T; L^p_{\mathrm{loc}}(\mathbb{R}^n))$ to ρ for every $1 \le p < \gamma$ and $\rho_\varepsilon u_\varepsilon$ converges strongly to ρu in $C^0(0,T; L^q_{\mathrm{loc}}(\mathbb{R}^n))$ for every $1 \le q < 2\gamma/(\gamma+1)$.

In the monodimensional case ($n = 1$) a stronger result has been achieved by Berthelin and Bouchut [3] in the similar situation where we have only one entropy. This result is valid even when shocks appear. The simpler case dealing with the complete family of entropies has been performed by Berthelin and Bouchut [2] (see also Serre [27] for regular systems). However, notice that in our case, no a priori assumption on the support of f_ε in v is needed. Everything is controlled by the energy bound. (We also refer the reader to [28], [17] for the convergence of discrete kinetic models to the Lagrangian version of the p-system in the one-dimensional case but even after the appearance of shocks.)

The main tool is a relative entropy method. It relies on the "weak-strong" uniqueness principle, established by Dafermos for multidimensional systems of hyperbolic conservation laws admitting a convex entropy functional [10]. It is close to the concept of dissipative solutions for the Euler equations of Lions [21]. It has been frequently used for systems of particles and rarefied gas dynamics; see Yau [29] and Golse, Levermore, and Saint-Raymond [14] (see also Goudon, Jabin, and Vasseur [18]). For different asymptotic problems it is called the "modulated energy" method (Brenier [7], Masmoudi [23], and Brenier [8]).

1.2. Numerical motivation. The kinetic structure of hyperbolic conservation laws have been used for a long time to construct entropic numerical schemes (see Kaniel [20], Giga and Miyakawa [13], the "transport-collapse" method of Brenier [6], etc.). This method has been intensively developed by the group of Perthame (see [24] for a review). In this framework, study of hydrodynamical limits of BGK-like equations can give a first step for the proof of the convergence of those schemes.

Recently an intense activity has been produced to solve numerically hyperbolic conservation laws with source terms. As a test, the Saint–Venant system with bottom topography is often proposed:

$$\begin{cases} \partial_t h + \mathrm{div}_x(hu) = 0, \quad t > 0,\ x \in \mathbb{R}^2, \\ \partial_t (hu) + \mathrm{div}_x(hu \otimes u) + \nabla_x h^2 + Z'(x) h = 0, \quad t > 0,\ x \in \mathbb{R}^2, \\ (h, hu)|_{t=0} = (h^0, h^0 u^0), \quad x \in \mathbb{R}^2, \end{cases} \tag{1.2}$$

where Z is the given bottom topography, h is the unknown depth of the water, and u is the unknown velocity of the water. This system models the evolution of a river.

Different numerical methods have been proposed to solve such problems (see Gosse [16], [15], Jin [19], Gallouët, Hérard, and Seguin [12], etc.). Botchorishvili, Perthame, and Vasseur [4] developed a kinetic procedure to construct numerical schemes and showed the convergence in the scalar case. This method has been successfully implemented by Perthame and Simeoni [25] for the Saint–Venant system. Notice that the Saint–Venant system corresponds exactly to the sytem (1.1) with $\gamma = 2$ and $Z' = F$. Our result can be seen as a first attempt to show the convergence of kinetic schemes in this framework.

1.3. Idea of the proof. As mentioned above, the proof relies on a relative entropy method. We consider the following abstract conservation law:

$$\partial_t U + \operatorname{div}_x A(U) = Q(U, x), \tag{1.3}$$

with $U(t,x) \in \mathcal{U} \subset \mathbb{R}^p$ for $t \in \mathbb{R}^+$, $x \in \mathbb{R}^n$, $A : \mathcal{U} \to \mathbb{R}^p$, and $Q : \mathcal{U} \times \mathbb{R}^n \to \mathbb{R}^p$. We assume that there exists an entropy, entropy flux couple (η, G) with $\eta \in C^2(\mathcal{U}, \mathbb{R})$ convex such that

$$\partial_i G_k(W) = \sum_j \partial_j \eta(W)\, \partial_i A_{jk}(W) \quad \forall k, i, \ \forall W. \tag{1.4}$$

For smooth solutions of this system, we have the entropy equality

$$\partial_t \eta(U) + \partial_x G(U) = \eta'(U) Q(U, x). \tag{1.5}$$

Following the notations of Dafermos, for every function $\Phi \in C^1(\mathbb{R}^p)$ of U we introduce the associated related quantity $\Phi(\cdot|\cdot) \in C^0(\mathbb{R}^p \times \mathbb{R}^p)$:

$$\Phi(U_1|U_2) = \Phi(U_1) - \Phi(U_2) - \nabla\Phi(U_2)(U_1 - U_2). \tag{1.6}$$

For example, the relative entropy is defined by

$$\eta(U_1|U_2) = \eta(U_1) - \eta(U_2) - \eta'(U_2) \cdot (U_1 - U_2), \tag{1.7}$$

and the entropy flux by

$$A(U_1|U_2) = A(U_1) - A(U_2) - A'(U_2) \cdot (U_1 - U_2). \tag{1.8}$$

We notice that if Φ is convex, then $\Phi(U_1|U_2) \geq 0$. Moreover, if it is strictly convex, then $\Phi(U_1|U_2) = 0$ if and only if $U_1 = U_2$.

We consider in the same way an abstract kinetic equation

$$\partial_t f_\varepsilon + v \cdot \nabla_x f_\varepsilon + q(f_\varepsilon) = \frac{\mathcal{Q}(f_\varepsilon, v)}{\varepsilon}, \tag{1.9}$$

where $f_\varepsilon = f_\varepsilon(t, x, v) \in \mathbb{R}$ with $t \in \mathbb{R}^+$, $x, v \in \mathbb{R}^n$, and q a linear operator, $\mathcal{Q} : \mathbb{R} \times \mathbb{R}^n \to \mathbb{R}$ and with $a : \mathbb{R}^n \to \mathbb{R}^p$, where the collision term $\mathcal{Q}$ satisfies

$$\int_{\mathbb{R}^n} a(v) \mathcal{Q}(f, v)\, dv = 0 \quad \text{for any } f \in \mathbb{R}. \tag{1.10}$$

We assume the existence of a kinetic entropy $H : \mathbb{R} \times \mathbb{R}^n \to \mathbb{R}$ which is well related to the entropy η of the hyperbolic system we want to relax. In more precise words, we need that the following nonincrease is checked for the solution of the kinetic equation,

$$\frac{d}{dt} \iint_{\mathbb{R}^{2n}} H(f_\varepsilon, v)\, dv\, dx \leq \int_{\mathbb{R}^n} \eta'(U_\varepsilon) Q(U_\varepsilon)\, dx, \tag{1.11}$$

where

$$U_\varepsilon(t,x) = \int_{\mathbb{R}^n} a(v) f_\varepsilon(t,x,v)\, dv, \tag{1.12}$$

and that the following compatibility between the entropy η and the kinetic entropy H is satisfied:

$$\eta(U_\varepsilon) \le \int_{\mathbb{R}^n} H(f_\varepsilon, v)\, dv. \tag{1.13}$$

In addition we assume that

$$\begin{aligned} &\left| \int_{\mathbb{R}^n} (|a(v)| + |a(v)\otimes v|) f_\varepsilon\, dv + \int_{\mathbb{R}^n} a(v) q(f_\varepsilon)\, dv \right| \\ &\qquad \le \int_{\mathbb{R}^n} (f_\varepsilon + H(f_\varepsilon, v))\, dv. \end{aligned} \tag{1.14}$$

Then we have the following abstract theorem.

THEOREM 1.2. *Let $U \in [C^1([0,T]\times\mathbb{R}^n)]^p$ be a strong solution on $[0,T]$ of the multidimensional hyperbolic system* (1.3)*, a system with a convex, C^2 entropy, for an initial data U^0. We assume in addition that U, $\eta'(U)$, and $\partial_x \eta'(U)$ are bounded and that U and $\eta(U)$ are integrable with respect to x. Let f_ε be a solution to the kinetic equation* (1.9)*, satisfying* (1.10)–(1.14) *and $f_\varepsilon + H(f_\varepsilon, v)$ integrable with respect to x and v for every t. We set*

$$U_\varepsilon(t,x) = \int_{\mathbb{R}^n} a(v) f_\varepsilon(t,x,v)\, dv.$$

We assume the convergence of initial data

$$\int_{\mathbb{R}^n} \eta(U_\varepsilon^0 | U^0)\, dx \le C_0 \sqrt{\varepsilon}, \tag{1.15}$$

and the following compatibility for the initial data

$$\left| \int_{\mathbb{R}^n} H(f_\varepsilon^0, v)\, dv - \eta(U_\varepsilon^0) \right| \le C_0 \sqrt{\varepsilon}. \tag{1.16}$$

If we have the control of the kinetic quantities

$$\int_0^T \int_{\mathbb{R}^n} \left| A(U_\varepsilon) - \int_{\mathbb{R}^n} v \otimes a(v) f_\varepsilon\, dv \right| dx\, dt \le C_1 \sqrt{\varepsilon}, \tag{1.17}$$

$$\int_0^T \int_{\mathbb{R}^n} \left| Q(U_\varepsilon, x) + \int_{\mathbb{R}^n} a(v) q(f_\varepsilon)\, dv \right| dx\, dt \le C_1 \sqrt{\varepsilon}, \tag{1.18}$$

and the control of the relative flux and the source terms by the relative entropy as

$$|A(U_\varepsilon | U)| \le C_2\ \eta(U_\varepsilon | U), \tag{1.19}$$

$$|Q(U)\eta'(U_\varepsilon | U) + [Q(U_\varepsilon) - Q(U)](\eta'(U_\varepsilon) - \eta'(U))| \le C_2\ \eta(U_\varepsilon | U), \tag{1.20}$$

where C_1 and C_2 are positive constants, then we get, for a constant C,

$$\int_{\mathbb{R}^n} \eta(U_\varepsilon | U)(t,x)\, dx \le C\sqrt{\varepsilon} \quad \text{for any } t \in [0,T]. \tag{1.21}$$

Hypothesis (1.15) and (1.16) are compatibility conditions on the initial data. Hypothesis (1.19) and (1.20) are structure conditions on the system (1.3). This theorem shows that if (1.17) and (1.18) are fulfilled (which will be derived from kinetic dissipation), and the system (1.3) has a good structure, then the total relative entropy of U_ε with respect to U converges to 0. This applies to the convergence of U_ε to U. Notice that this presentation splits nicely the kinetic dissipation effect from the control of the nonlinearities. The kinetic dissipation is needed in order to fulfill the consistency (1.17) and (1.18). The nonlinearity is driven by the relative entropy method which can be applied if (1.3) verifies (1.19) and (1.20). Notice that the method depends only on the structure of the system whatever the kinetic equation is.

Then we show that the isentropic system (1.1) verifies the structure compatibility and that the involved kinetic equations verify the dissipation properties needed. Notice that the full Euler system (with the added energy equation) does not verify (1.19). Hence this method cannot be applied directly to the convergence from the Boltzmann equation to the Euler system, for instance (see the appendix). The problem relies already on the structure itself of the system (the relative flux cannot be controlled by the relative entropy because of the high macroscopic velocities). Of course an additional difficulty lies in the kinetic level to control high velocities to obtain (1.17) and (1.18).

2. Study of the abstract problem. We consider the abstract equation (1.3) and abstract kinetic equation (1.9). This section is devoted to the proof of Theorem 1.2.

2.1. The key estimate. In the following proposition, we describe the evolution of the relative entropy using canonical quantities associated with the system (1.3) and entropy equation (1.5). We do not claim any originality in this result. It can be found in [10], except for the slight generalization concerning the source term Q. However, we give the proof for the sake of completeness.

PROPOSITION 2.1. *For the entropy $\eta \in C^2(\mathbb{R}^p)$ and for any $U, V \in [C^1(\mathbb{R}^n)]^p$, we have*

$$\begin{aligned}
\partial_t \eta(V|U) = {} & [\partial_t \eta(V) + \operatorname{div}_x G(V) - \eta'(V)Q(V)] \\
& - [\partial_t \eta(U) + \operatorname{div}_x G(U) - \eta'(U)Q(U)] \\
& - \eta''(U) \cdot [\partial_t U + \operatorname{div}_x A(U) - Q(U))] \cdot (V - U) \\
& - \eta'(U) \cdot [\partial_t V + \operatorname{div}_x A(V) - Q(V)] \\
& + \eta'(U) \cdot [\partial_t U + \operatorname{div}_x A(U) - Q(U))] \\
& + \operatorname{div}_x [G(U) - G(V)] + \sum_{ik} \partial_{x_k} [\partial_i G_k(U)(V_i - U_i)] \\
& + \sum_{jk} \partial_j \eta(U) \partial_{x_k} [A(V|U)] \\
& + Q(U)\eta'(V|U) + [Q(V) - Q(U)](\eta'(V) - \eta'(U)).
\end{aligned}$$

Remark 2.2. Notice that if U and V are regular solutions to (1.3), the first five lines vanish. The sixth line has a divergence form, hence its integral is vanishing. Finally, the two last terms are quadratic with respect to $V-U$ (at least when $|V-U| \leq R$) as η is. Hence, from this proposition, we can expect to have a good structure to use Gronwall's lemma on $\int \eta(V|U)\, dx$.

Proof. From the definition of relative quantity (1.6), we have

$$\begin{aligned}\partial_t\eta(V|U) &= \partial_t\eta(V) - \partial_t\eta(U) - \partial_t\left[\eta'(U)\right]\cdot(V-U) - \eta'(U)\cdot\partial_t(V-U)\\ &= \left[\partial_t\eta(V) + \operatorname{div}_x G(V) - \eta'(V)Q(V)\right]\\ &\quad - \left[\partial_t\eta(U) + \operatorname{div}_x G(U) - \eta'(U)Q(U)\right]\\ &\quad - \eta''(U)\cdot\left[\partial_t U + \operatorname{div}_x A(U) - Q(U)\right]\cdot(V-U)\\ &\quad - \eta'(U)\cdot\left[\partial_t V + \operatorname{div}_x A(V) - Q(V)\right]\\ &\quad + \eta'(U)\cdot\left[\partial_t U + \operatorname{div}_x A(U) - Q(U)\right] + R_1 + R_2,\end{aligned} \tag{2.1}$$

where

$$\begin{aligned}R_1 &= \eta'(V)Q(V) - \eta'(U)Q(U) - \eta''(U)\cdot Q(U)\cdot(V-U)\\ &\quad - \eta'(U)\cdot Q(V) + \eta'(U)\cdot Q(U)\\ &= Q(U)\eta'(V|U) + \left[\eta'(U) - \eta'(V)\right]\cdot\left[Q(U) - Q(V)\right]\end{aligned} \tag{2.2}$$

and

$$\begin{aligned}R_2 &= \operatorname{div}_x\left[G(U) - G(V)\right]\\ &\quad + \eta''(U)\cdot\operatorname{div}_x A(U)\cdot(V-U)\\ &\quad + \eta'(U)\cdot\operatorname{div}_x\left[A(V) - A(U)\right].\end{aligned}$$

The existence of the associated entropy flux G gives the relation (see (1.4))

$$\partial_i G_k(W) = \sum_j \partial_j\eta(W)\,\partial_i A_{jk}(W) \quad \forall k, i,\ \forall W.$$

A derivation of this relation with respect to W_l gives

$$\sum_j \partial_{lj}\eta(W)\partial_i A_{jk}(W) = \partial_{il}G_k(W) - \sum_j \partial_j\eta(W)\partial_{il}A_{jk}(W).$$

We use this relation with $W = U$ and get

$$\begin{aligned}&\eta''(U)\cdot\operatorname{div}_x A(U)\cdot(V-U)\\ &\quad = \sum \partial_{lj}\eta(U)\partial_{x_k}[A_{jk}(U)](V_l - U_l)\\ &\quad = \sum \partial_{lj}\eta(U)\partial_i A_{jk}(U)\partial_{x_k}U_i(V_l - U_l)\\ &\quad = \sum \partial_{il}G_k(U)\partial_{x_k}U_i(V_l - U_l) - \sum \partial_j\eta(U)\partial_{il}A_{jk}(U)\partial_{x_k}U_i(V_l - U_l),\end{aligned}$$

and now

$$\begin{aligned}&-\partial_j\eta(U)\partial_{il}A_{jk}(U)\partial_{x_k}U_i(V_l - U_l)\\ &\quad = \partial_j\eta(U)\left[-\partial_{x_k}\left[\partial_l A_{jk}(U)\right](V_l - U_l)\right]\\ &\quad = \partial_j\eta(U)\left[-\partial_{x_k}\left[\partial_l A_{jk}(U)(V_l - U_l)\right] + \partial_l A_{jk}(U)\partial_{x_k}(V_l - U_l)\right];\end{aligned}$$

therefore, we obtain

$$\begin{aligned}
R_2 &= \operatorname{div}_x [G(U) - G(V)] + \sum \partial_{il} G_k(U) \partial_{x_k} U_i (V_l - U_l) \\
&\quad + \sum \partial_j \eta(U) \left[-\partial_{x_k} \left[\partial_l A_{jk}(U)(V_l - U_l) \right] + \partial_l A_{jk}(U) \partial_{x_k} (V_l - U_l) \right] \\
&\quad + \eta'(U) \cdot \operatorname{div}_x [a(V) - A(U)] \\
&= \operatorname{div}_x [G(U) - G(V)] + \sum \partial_{x_k} [\partial_l G_k(U)](V_l - U_l) \\
&\quad - \sum \partial_j \eta(U) \partial_{x_k} \left[\partial_l A_{jk}(U)(V_l - U_l) \right] \\
&\quad + \sum \partial_j \eta(U) \partial_l A_{jk}(U) \partial_{x_k} (V_l - U_l) \\
&\quad + \sum \partial_j \eta(U) \partial_{x_k} [A_{jk}(V) - A_{jk}(U)].
\end{aligned}$$

Permuting indexes i and l, we can rewrite (1.4) in the following way:

$$\sum_j \partial_j \eta(U) \partial_l A_{jk}(U) = \partial_l G_k(U).$$

Thus we find

$$\begin{aligned}
R_2 &= \operatorname{div}_x [G(U) - G(V)] + \sum \partial_{x_k} [\partial_i G_k(U)(V_i - U_i)] \\
&\quad + \sum \partial_j \eta(U) \partial_{x_k} [A(V|U)].
\end{aligned} \tag{2.3}$$

Equation (2.1), with (2.2) and (2.3), gives the desired relation. □

Remark 2.3. We notice that in particular, the term R_2 of the proof satisfies

$$\begin{aligned}
\int_{\mathbb{R}^n} R_2 \, dx &= \int_{\mathbb{R}^n} \sum_{jk} \partial_j \eta(U) \partial_{x_k} \left[A(V|U) \right] \, dx \\
&= - \int_{\mathbb{R}^n} \sum_{jk} \partial_{x_k} \left[\partial_j \eta(U) \right] A_{jk}(V|U) \, dx.
\end{aligned}$$

This result is now used to obtain information if one deals with weak, strong, or/and approximated solutions.

2.2. Weak and strong solutions. This subsection is completely imbedded in Dafermos [10] (except for the slight generalization of the source term). Moreover, it is completely independent of the remainder of the paper. We give it since it clarifies the structure conditions (1.19) and (1.20) needed to use the relative entropy method without a priori condition on V in L^∞ for instance. We assume here that U is a strong solution of (1.3) (and as a consequence (1.5) is satisfied), and that V is a weak solution of (1.3) satisfying the entropy inequality

$$\partial_t \eta(V) + \partial_x G(V) \leq \eta'(V) Q(V). \tag{2.4}$$

Thus applying Proposition 2.1 (on a regularization of V and passing to the limit in the regularization), we get with the notations (2.2) and (2.3)

$$\partial_t \eta(V|U) \leq R_1 + R_2, \tag{2.5}$$

and using Remark 2.3, it leads to the following result.

COROLLARY 2.4. *Let $U \in [C^1([0,T]\times\mathbb{R}^n)]^p$ be a strong solution of* (1.3) *such that U, $\eta'(U)$, $\partial_x\eta'(U)$ are bounded and U, $\eta(U)$ are integrable. Let V be an entropy weak solution of* (1.3). *Then we have*

$$\begin{aligned}\frac{d}{dt}\int_{\mathbb{R}^n}\eta(V|U)\,dx \le &-\int_{\mathbb{R}^n}\sum_{jk}\partial_{x_k}\left[\partial_j\eta(U)\right]A_{jk}(V|U)\,dx\\ &+\int_{\mathbb{R}^n}Q(U)\eta'(V|U)\,dx\\ &+\int_{\mathbb{R}^n}[Q(V)-Q(U)](\eta'(V)-\eta'(U))\,dx.\end{aligned}\tag{2.6}$$

This result clarifies necessary information needed on the structure of the system (1.3). If we have for every $V,U\in\mathbb{R}^p$

$$|A(V|U)| \le C\eta(V|U)\tag{2.7}$$

and

$$|Q(U)\eta'(V|U)+[Q(V)-Q(U)](\eta'(V)-\eta'(U))| \le C\eta(V|U),\tag{2.8}$$

then we get

$$\frac{d}{dt}\int_{\mathbb{R}^n}\eta(V|U)\,dx \le (C(U)+1)C\int_{\mathbb{R}^n}\eta(V|U)\,dx,$$

and by a Gronwall's argument, it gives

$$\int_{\mathbb{R}^n}\eta(V|U)(t,x)\,dx \le \int_{\mathbb{R}^n}\eta(V|U)(0,x)\,dx\ e^{(C(U)+1)Ct}.$$

Thus if $U^0=V^0$, then

$$\eta(V|U)(t,x)=0\quad\forall t\in[0,T],\ \text{a.e. } x\in\mathbb{R}^n.$$

It gives $V=U$ if η is strictly convex. We recover here part of the classical results for weak = strong solutions. In fact, estimates as (2.7)–(2.8) are the important point to perform our entropy method. If we do not have a source term, it says that we need a control of the relative flux of the system by the relative entropy. This was already the case in Brenier [8]. We want now to extend the possible applications by studying the link between a strong solution and some approximations of it.

2.3. Strong and approximated solutions. We now assume that U is a strong solution of (1.3), and U_ε is any approximation of a solution, coming for example from a kinetic model. We get the following corollary from Proposition 2.1.

COROLLARY 2.5. *Let $U\in[C^1([0,T]\times\mathbb{R}^n)]^p$ be a strong solution of* (1.3) *such that U, $\eta'(U)$, $\partial_x\eta'(U)$ are bounded and U, $\eta(U)$ are integrable. Then we have, for any function $U_\varepsilon\in[C^1([0,T]\times\mathbb{R}^n)]^p$,*

$$\begin{aligned}\partial_t\eta(U_\varepsilon|U) = &\left[\partial_t\eta(U_\varepsilon)+\operatorname{div}_x G(U_\varepsilon)-\eta'(U_\varepsilon)Q(U_\varepsilon)\right]\\ &-\eta'(U)\cdot\left[\partial_t U_\varepsilon+\operatorname{div}_x A(U_\varepsilon)-Q(U_\varepsilon)\right]\\ &+\operatorname{div}_x\left[G(U)-G(U_\varepsilon)\right]+\sum\partial_{x_k}[\partial_i G_k(U)((U_\varepsilon)_i-U_i)]\\ &+\sum_{jk}\partial_j\eta(U)\partial_{x_k}\left[A(U_\varepsilon|U)\right]\\ &+Q(U)\eta'(U_\varepsilon|U)+[Q(U_\varepsilon)-Q(U)](\eta'(U_\varepsilon)-\eta'(U)).\end{aligned}$$

In this situation we have

$$\begin{aligned}\frac{d}{dt}\int_{\mathbb{R}^n}[\eta(U_\varepsilon|U)-\eta(U_\varepsilon)]\,dx &= -\int_{\mathbb{R}^n}\eta'(U_\varepsilon)Q(U_\varepsilon)\,dx\\ &\quad -\int_{\mathbb{R}^n}\eta'(U)\cdot\left[\partial_t U_\varepsilon+\operatorname{div}_x A(U_\varepsilon)-Q(U_\varepsilon)\right]\,dx\\ &\quad -\int_{\mathbb{R}^n}\sum_{jk}\partial_{x_k}\left[\partial_j\eta(U)\right]A_{jk}(U_\varepsilon|U)\,dx\\ &\quad +\int_{\mathbb{R}^n}Q(U)\eta'(U_\varepsilon|U)\,dx\\ &\quad +\int_{\mathbb{R}^n}[Q(U_\varepsilon)-Q(U)](\eta'(U_\varepsilon)-\eta'(U))\,dx.\end{aligned}$$

We use now this relation in the case where U_ε comes from a kinetic equation.

2.4. Approximation from a kinetic equation. We consider f_ε a solution to the kinetic model (1.9) which satisfies (1.10)–(1.14) with $f_\varepsilon+H(f_\varepsilon,v)$ integrable with respect to x and v for every t. Let U_ε be the moments of f_ε defined by (1.12). We set

$$\Delta_\varepsilon=\eta(U_\varepsilon|U)+\int_{\mathbb{R}^n}H(f_\varepsilon,v)\,dv-\eta(U_\varepsilon). \tag{2.9}$$

From (1.13) and the convexity of η, we have

$$\Delta_\varepsilon\geq 0. \tag{2.10}$$

Using (1.11) and the relation of the previous section, we obtain (again after a regularization)

$$\begin{aligned}\frac{d}{dt}\int_{\mathbb{R}^n}\Delta_\varepsilon\,dx &\leq -\int_{\mathbb{R}^n}\eta'(U)\cdot\left[\partial_t U_\varepsilon+\operatorname{div}_x A(U_\varepsilon)-Q(U_\varepsilon)\right]\,dx\\ &\quad -\int_{\mathbb{R}^n}\sum_{jk}\partial_{x_k}\left[\partial_j\eta(U)\right]A_{jk}(U_\varepsilon|U)\,dx\\ &\quad +\int_{\mathbb{R}^n}Q(U)\eta'(U_\varepsilon|U)\,dx\\ &\quad +\int_{\mathbb{R}^n}[Q(U_\varepsilon)-Q(U)](\eta'(U_\varepsilon)-\eta'(U))\,dx.\end{aligned}$$

Now multiplying the kinetic equation (1.9) by $a(v)$ and then integrating it with respect to v and using (1.10), we have

$$\partial_t U_\varepsilon+\operatorname{div}_x\int_{\mathbb{R}^n}v\otimes a(v)f_\varepsilon\,dv+\int_{\mathbb{R}^n}a(v)q(f_\varepsilon)\,dv=0.$$

It gives

$$\begin{aligned}\partial_t U_\varepsilon+\operatorname{div}_x A(U_\varepsilon)-Q(U_\varepsilon) &= \operatorname{div}_x\left(A(U_\varepsilon)-\int_{\mathbb{R}^n}v\otimes a(v)f_\varepsilon\,dv\right)\\ &\quad -\left[\int_{\mathbb{R}^n}a(v)q(f_\varepsilon)\,dv+Q(U_\varepsilon)\right].\end{aligned}$$

Therefore we get the following result.

PROPOSITION 2.6. *We assume that the system* (1.3) *admits a strictly convex entropy* $\eta \in C^2(\mathbb{R}^p)$. *Let* $U \in [C^1([0,T]\times\mathbb{R}^n)]^p$ *be a strong solution of* (1.3) *such that* U, $\eta'(U)$, $\partial_x\eta'(U)$ *are bounded and* U, $\eta(U)$ *are integrable. Let* f_ε *be a solution of* (1.9) *such that* (1.10)–(1.14) *are satisfied and* $f_\varepsilon + H(f_\varepsilon, v)$ *are integrable with respect to* x *and* v *for every time* t. *We set*

$$U_\varepsilon(t,x) = \int_{\mathbb{R}^n} a(v) f_\varepsilon(t,x,v)\, dv.$$

Then there exists a constant $C(U)$ *such that*

$$\begin{aligned}
&\frac{d}{dt}\int_{\mathbb{R}^n}\left[\eta(U_\varepsilon|U) + \int_{\mathbb{R}^n} H(f_\varepsilon)\, dv - \eta(U_\varepsilon)\right] dx \\
&\le C(U)\left(\int_{\mathbb{R}^n}\left|A(U_\varepsilon) - \int_{\mathbb{R}^n} v\otimes a(v) f_\varepsilon\, dv\right| dx \right. \qquad (2.11)\\
&\qquad + \int_{\mathbb{R}^n}\left|Q(U_\varepsilon) + \int_{\mathbb{R}^n} a(v) q(f_\varepsilon)\, dv\right| dx \qquad (2.12)\\
&\qquad + \int_{\mathbb{R}^n} |\, Q(U)\eta'(U_\varepsilon|U) + [Q(U_\varepsilon) - Q(U)](\eta'(U_\varepsilon) - \eta'(U))\,|\, dx \qquad (2.13)\\
&\qquad \left. + \int_{\mathbb{R}^n} |A(U_\varepsilon|U)|\, dx\right). \qquad (2.14)
\end{aligned}$$

Remark 2.7. This inequality uncouples the various structures which come into play. The term (2.11) is related to the kinetic approximation, the term (2.14) is related to the structure of the system, the term (2.12) is related to the kinetic structure of the source term, and the term (2.13) is related to the structure of the source term with respect to the hyperbolic system.

We use this majoration to get the convergence result from a solution of a kinetic equation to a strong solution of a multidimensional hyperbolic system, that is, Theorem 1.2.

2.5. Proof of Theorem 1.2. We use again the notation Δ_ε given by (2.9). From Proposition 2.6, we get

$$\begin{aligned}
\frac{d}{dt}\int_{\mathbb{R}^n}\Delta_\varepsilon(t,x)\, dx \le C(U)\left(\int_{\mathbb{R}^n}\left|A(U_\varepsilon) - \int_{\mathbb{R}^n} v\otimes a(v) f_\varepsilon\, dv\right| dx\right.\\
+ \int_{\mathbb{R}^n}\left|Q(U_\varepsilon) + \int_{\mathbb{R}^n} a(v) q(f_\varepsilon)\, dv\right| dx\\
\left. + 2C_2\int_{\mathbb{R}^n}\eta(U_\varepsilon|U)\, dx\right),
\end{aligned}$$

and thus, for $t \in [0,T]$,

$$\begin{aligned}
&\int_{\mathbb{R}^n}\Delta_\varepsilon(t,x)\, dx\\
&\quad \le \int_{\mathbb{R}^n}\Delta_\varepsilon(0,x)\, dx + 2C(U)C_1\sqrt{\varepsilon} + 2C(U)C_2\int_0^t\int_{\mathbb{R}^n}\Delta_\varepsilon(s,x)\, dx\, ds.
\end{aligned}$$

By Gronwall's argument, it gives

$$\int_{\mathbb{R}^n}\Delta_\varepsilon(t,x)\, dx \le \left(\int_{\mathbb{R}^n}\Delta_\varepsilon(0,x)\, dx + 2C(U)C_1\sqrt{\varepsilon}\right) e^{2C(U)C_2 t}.$$

From (1.15)–(1.16), we have

$$\left| \int_{\mathbb{R}^n} \Delta_\varepsilon(0,x)\,dx \right| \leq C\sqrt{\varepsilon},$$

and consequently, since $0 \leq \eta(U_\varepsilon|U) \leq \Delta_\varepsilon$, we obtain the result. □

Two independant studies to apply this result for a given example are thus necessary: the study of the system structure and the study of the dissipation of the kinetic model.

3. Study of the system structure. We consider here the case of the multidimensional isentropic gas dynamics system (1.1) avoiding the appearance of the vacuum. The associated entropy is

$$\eta(\rho,\rho u) = \rho\frac{u^2}{2} + h(\rho), \tag{3.1}$$

where $h(\rho) = \frac{1}{\gamma-1}\rho^\gamma$ for $\gamma > 1$ and $h(\rho) = \rho\ln\rho$ for the isotherm case $\gamma = 1$. The existence of strong solution for this problem is related to the classical result for regular solution for hyperbolic systems endowed with a strong entropy (see for instance [11]). In order to apply the convergence result of the previous section, we require that the structure of the system and the source terms be controllable by the relative entropy. For the system (1.1), the relative entropy is given by

$$\eta(U_1|U_2) = \frac{\rho_1}{2}|u_1-u_2|^2 + h(\rho_1|\rho_2). \tag{3.2}$$

The relative flux of the system is

$$A(U_1|U_2) = (0, \rho_1(u_1-u_2)\otimes(u_1-u_2) + h(\rho_1|\rho_2)I). \tag{3.3}$$

We clearly have the existence of a constant C such that

$$|A(U_1|U_2)| \leq C\eta(U_1|U_2) \tag{3.4}$$

for every $U_1, U_2 \in \mathbb{R}^{n+1}$. This fulfills estimate (1.19).

For the system (1.1), the source terms reads

$$Q(\rho,\rho u,x) = (0,\rho F(x)). \tag{3.5}$$

This gives

$$Q(U_2)\eta'(U_1|U_2) = -(u_2-u_1)(\rho_2-\rho_1)F \tag{3.6}$$

and

$$[Q(U_1)-Q(U_2)](\eta'(U_1)-\eta'(U_2)) = (u_2-u_1)(\rho_2-\rho_1)F, \tag{3.7}$$

and finally

$$Q(U_2)\eta'(U_1|U_2) + [Q(U_1)-Q(U_2)](\eta'(U_1)-\eta'(U_2)) = 0. \tag{3.8}$$

Thus the term (1.20) associated with the system (1.1) does not appear in the system structure study.

We turn now to the study of the terms related to the kinetic structure.

4. Study of the kinetic structure. We begin introducing the kinetic model we are dealing with. For $\gamma > 1$ we consider the following BGK kinetic equation:

$$\partial_t f_\varepsilon + v \cdot \nabla_x f_\varepsilon + F(x) \cdot \nabla_v f_\varepsilon = \frac{M f_\varepsilon - f_\varepsilon}{\varepsilon}, \tag{4.1}$$

where the unknown is $f_\varepsilon = f_\varepsilon(t,x,v) \in \mathbb{R}$ with $t \in \mathbb{R}^+$, $x, v \in \mathbb{R}^n$. The force term $F : \mathbb{R}^n \to \mathbb{R}^n$ is given. The equilibrium function $M f_\varepsilon$ is defined in the following way:

$$M f_\varepsilon(t,x,v) = M(\rho_\varepsilon(t,x), \rho_\varepsilon u_\varepsilon(t,x), v) \tag{4.2}$$

with

$$\rho_\varepsilon(t,x) = \int_{\mathbb{R}^n} f_\varepsilon(t,x,v)\, dv,$$
$$\rho_\varepsilon u_\varepsilon(t,x) = \int_{\mathbb{R}^n} v f_\varepsilon(t,x,v)\, dv,$$

where the Maxwellian $M : \mathbb{R}^p \times \mathbb{R}^n \to \mathbb{R}$ is given by

$$M(\rho, \rho u, v) = \mathbf{1}_{|u-v|^n \le c_n \rho} \quad \text{for } \gamma = \frac{n+2}{n}, \tag{4.3}$$

$$M(\rho, \rho u, v) = c \left(\frac{2\gamma}{\gamma - 1} \rho^{\gamma - 1} - |v-u|^2 \right)_+^{d/2} \quad \text{else.} \tag{4.4}$$

The constants are given by

$$c_n = n/|\mathbb{S}_n|,$$
$$d = \frac{2}{\gamma - 1} - n,$$
$$c = \left(\frac{2\gamma}{\gamma - 1} \right)^{-1/(\gamma-1)} \frac{\Gamma(\frac{\gamma}{\gamma-1})}{\pi^{n/2} \Gamma(d/2+1)}.$$

In the isothermal case $\gamma = 1$ we consider the following Fokker–Planck equation:

$$\partial_t f_\varepsilon + v \cdot \nabla_x f_\varepsilon + F(x) \cdot \nabla_v f_\varepsilon = \frac{1}{\varepsilon} \operatorname{div}_v((v - u_\varepsilon) f_\varepsilon + \nabla_v f_\varepsilon), \tag{4.5}$$

where

$$\rho_\varepsilon = \int_{\mathbb{R}^n} f_\varepsilon\, dv, \qquad \rho_\varepsilon u_\varepsilon = \int_{\mathbb{R}^n} v f_\varepsilon\, dv. \tag{4.6}$$

This section is devoted to the proof of the estimates needed to apply Theorem 1.2 for each model. For each case, we will first show that it verifies (1.10)–(1.14), and in the second step that it verifies the more difficult estimates (1.17) and (1.18).

4.1. BGK structure for isentropic gas with $1 < \gamma \le (n+2)/n$. In this section, we start by the study of kinetic BGK equations whose hydrodynamic limit is the isentropic system with an external force field.

We denote

$$U_\varepsilon = (\rho_\varepsilon, \rho_\varepsilon u_\varepsilon),$$
$$U = (\rho, \rho u),$$
$$a(v) = (1, v),$$
$$q(f) = F(x) \cdot \nabla_v f,$$
$$\mathcal{Q}(f, v) = Mf - f.$$

The Maxwellian M satisfies (see Bouchut [5])

$$\int_{\mathbb{R}^n} a(v)M(U,v)\,dv = U \qquad \forall U \in \mathbb{R}^p, \tag{4.7}$$

$$\int_{\mathbb{R}^n} v \otimes a(v)M(U,v)\,dv = A(U) \qquad \forall U \in \mathbb{R}^p, \tag{4.8}$$

$$\int_{\mathbb{R}^n} a(v)q(M(U,v))\,dv = -Q(U,x) \quad \forall U \in \mathbb{R}^p, \quad x \in \mathbb{R}^n. \tag{4.9}$$

This is the classical compatibility conditions required for the kinetic equation to be related to the system. Notice that thanks to (4.7), we have (1.10).

The kinetic entropy is the following:

$$H(f,v) = \frac{|v|^2}{2} f \quad \text{for } \gamma = \frac{n+2}{n},$$
$$H(f,v) = \frac{|v|^2}{2} f + \frac{1}{2c^{2/d}} \frac{f^{1+2/d}}{1+2/d} \quad \text{else.}$$

We have (see Bouchut [5]) that, for any f satisfying $\int_{\mathbb{R}^n} (f + H(f,v))\,dv < \infty$, and denoting $U = \int_{\mathbb{R}^n} a(v)f(v)\,dv$, the following minimization principle holds:

$$\int_{\mathbb{R}^n} H(M(U,v),v)\,dv \le \int_{\mathbb{R}^n} H(f)\,dv, \tag{4.10}$$

and a compatibility between the entropy η and the kinetic entropy H is satisfied as

$$\int_{\mathbb{R}^n} H(M(U,v),v)\,dv = \eta(U) \quad \text{for any } U \in \mathbb{R}^p. \tag{4.11}$$

First notice that (1.14) is verified. As a consequence of (4.10) and (4.11), we get

$$\eta(U) = \int_{\mathbb{R}^n} H(M(U,v),v)\,dv \le \int_{\mathbb{R}^n} H(f,v)\,dv,$$

which in particular gives (1.13). We prove now the decrease (1.11). We give it for $\gamma = (n+2)/n$. The other case is similar. Multiplying (4.1) by $|v|^2/2$ and then integrating in (v,x), we get

$$\begin{aligned} \frac{d}{dt} \iint_{\mathbb{R}^{2n}} \frac{|v|^2}{2} f_\varepsilon\,dv\,dx &= \iint_{\mathbb{R}^{2n}} F(x) \cdot v f_\varepsilon\,dv\,dx \\ &\quad + \frac{1}{\varepsilon} \iint_{\mathbb{R}^{2n}} \frac{|v|^2}{2} (M f_\varepsilon - f_\varepsilon)\,dv\,dx, \end{aligned} \tag{4.12}$$

since

$$\iint_{\mathbb{R}^{2n}} \frac{|v|^2}{2} F(x) \cdot \nabla_v f_\varepsilon\,dv\,dx = -\iint_{\mathbb{R}^{2n}} F(x) \cdot v f_\varepsilon\,dv\,dx.$$

In particular, from (4.10), it gives

$$\begin{aligned} \frac{d}{dt} \iint_{\mathbb{R}^{2n}} H(f_\varepsilon,v)\,dv\,dx &\le \int_{\mathbb{R}^n} F(x) \cdot \left(\int_{\mathbb{R}^n} v f_\varepsilon\,dv \right) dx \\ &\le \int_{\mathbb{R}^n} F(x) \cdot \rho_\varepsilon u_\varepsilon\,dx. \end{aligned} \tag{4.13}$$

Since

$$\int_{\mathbb{R}^n} \eta'(U_\varepsilon) Q(U_\varepsilon)\, dx = \int_{\mathbb{R}^n} F(x) \cdot \rho_\varepsilon u_\varepsilon\, dx,$$

this leads to (1.11).

We want now to prove (1.17)–(1.18). Since

$$A(U_\varepsilon) = \int_{\mathbb{R}^n} v \otimes a(v) M f_\varepsilon\, dv$$

and

$$Q(U_\varepsilon) = \sum_j \int_{\mathbb{R}^n} F_j(x) \partial_{v_j} a(v) M f_\varepsilon\, dv,$$

it gives

$$\begin{aligned} &\int_0^T \int_{\mathbb{R}^n} \left| A(U_\varepsilon) - \int_{\mathbb{R}^n} v \otimes a(v) f_\varepsilon\, dv \right| dx\, dt \\ &\quad = \int_0^T \int_{\mathbb{R}^n} \left| \int_{\mathbb{R}^n} v \otimes a(v)(M f_\varepsilon - f_\varepsilon)\, dv \right| dx\, dt \end{aligned} \tag{4.14}$$

and

$$\begin{aligned} &\int_0^T \int_{\mathbb{R}^n} \left| Q(U_\varepsilon, x) - \int_{\mathbb{R}^n} F(x) \nabla_v a(v) f_\varepsilon\, dv \right| dx\, dt \\ &\quad = \int_0^T \int_{\mathbb{R}^n} \left| \int_{\mathbb{R}^n} F(x) \nabla_v a(v)(f_\varepsilon - M f_\varepsilon)\, dv \right| dx\, dt. \end{aligned} \tag{4.15}$$

We have

$$\int_{\mathbb{R}^n} \partial_{v_i} a_j(v)(f_\varepsilon - M f_\varepsilon)\, dv = \delta_{i+1,j} \int_{\mathbb{R}^n} (f_\varepsilon - M f_\varepsilon)\, dv = 0;$$

thus the kinetic structure of the source term (1.18) vanishes. In order to apply the convergence result for this kinetic model, it only remains to control the entropy dissipation (1.17). It is the technical point of this example.

4.1.1. Control of the entropy dissipation. This subsection is devoted to the proof of the following proposition.

PROPOSITION 4.1. *Let f_ε be a solution to the BGK equation of the previous section with initial value f_ε^0 bounded in $L^1(\mathbb{R}^{2n})$ verifying (finite energy)*

$$\iint_{\mathbb{R}^{2n}} |v|^2 f_\varepsilon^0(x,v)\, dv\, dx \le C^0 < \infty, \tag{4.16}$$

and with $\gamma = (n+2)/n$. Then there exists C_n such that for every $\varepsilon < 1$, we have

$$\int_0^T \int_{\mathbb{R}^n} \left| \int_{\mathbb{R}^n} v \otimes a(v)(M f_\varepsilon - f_\varepsilon)\, dv \right| dx\, dt \le C_n \sqrt{\varepsilon}.$$

We define

$$D_\varepsilon(t,x)=\int_{\mathbb{R}^n}|v|^2(f_\varepsilon(t,x,v)-Mf_\varepsilon(t,x,v))\,dv.$$

From (4.13), we have

$$\begin{aligned}\frac{d}{dt}\iint_{\mathbb{R}^{2n}}H(f_\varepsilon,v)\,dv\,dx&\le\|F\|_{L^\infty}\iint_{\mathbb{R}^{2n}}|v|f_\varepsilon\,dx\,dv\\&\le\|F\|_{L^\infty}\iint_{\mathbb{R}^{2n}}(1+|v|^2)f_\varepsilon\,dx\,dv\\&\le\|F\|_{L^\infty}\left(\|\rho_\varepsilon\|_{L^1}+2\iint_{\mathbb{R}^{2n}}H(f_\varepsilon,v)\,dx\,dv\right);\end{aligned}$$

thus by Gronwall's argument, we obtain

$$\iint_{\mathbb{R}^{2n}}|v|^2f_\varepsilon(t,x,v)\,dv\,dx\le C,\quad 0\le t\le T. \tag{4.17}$$

Integrating now (4.13) with respect to t leads to

$$\begin{aligned}&\int_0^T\int_{\mathbb{R}^n}D_\varepsilon(t,x)\,dx\,dt\\&\quad\le\varepsilon\left(\iint_{\mathbb{R}^{2n}}|v|^2f^0(x,v)\,dv\,dx-2\iiint_{[0,T]\times\mathbb{R}^{2n}}F(x)vf_\varepsilon\,dv\,dx\,dt\right)\\&\quad\le\varepsilon\left(C^0+2\|F\|_{L^\infty}\iiint_{[0,T]\times\mathbb{R}^{2n}}|v|f_\varepsilon\,dv\,dx\,dt\right)\\&\quad\le\varepsilon\left(C^0+2\|F\|_{L^\infty}\iiint_{[0,T]\times\mathbb{R}^{2n}}(1+|v|^2)f_\varepsilon\,dv\,dx\,dt\right)\\&\quad\le\varepsilon(C^0+2\|F\|_{L^\infty}T\|f_\varepsilon^0\|_{L^1}+2\|F\|_{L^\infty}C)\\&\quad\le\varepsilon\,\tilde{C}.\end{aligned}\tag{4.18}$$

This gives a bound in ε for

$$\int_0^T\iint_{\mathbb{R}^{2n}}|v|^2(f_\varepsilon-Mf_\varepsilon)\,dv\,dx\,dt,$$

but we need to control

$$\int_0^T\int_{\mathbb{R}^n}\left|\int_{\mathbb{R}^n}v\otimes a(v)(Mf_\varepsilon-f_\varepsilon)\,dv\right|dx\,dt,$$

which is more delicate.

We set $a_1(v)=1$ and $a_2(v)=v$ such that $a=(a_1,a_2)$. Similarly, we define $A_1(U)=\rho u$ and $A_2(U)=\rho u\otimes u+I\rho^\gamma$.

Since

$$A(U_\varepsilon)=\int_{\mathbb{R}^n}v\otimes a(v)Mf_\varepsilon\,dv,$$

the first component of $\left|\int_{\mathbb{R}^n} v\otimes a(v)(Mf_\varepsilon - f_\varepsilon)\,dv\right|$ is still zero here. Now we have

$$\left|A_2(U_\varepsilon) - \int_{\mathbb{R}^n} v\otimes v f_\varepsilon\,dv\right| = \left|\int_{\mathbb{R}^n} (v-u)\otimes(v-u)(Mf_\varepsilon - f_\varepsilon)\,dv\right| \le \int_{\mathbb{R}^n} |v-u|^2 |Mf_\varepsilon - f_\varepsilon|\,dv.$$

The first equality uses (4.7). Thus to control the second component, we want to show that

$$\int_{\mathbb{R}^n} |v-u|^2 |Mf_\varepsilon - f_\varepsilon|\,dv$$

can be controlled (at least for bounded mass ρ) by the dissipation of entropy

$$\int_{\mathbb{R}^n} |v|^2 (f_\varepsilon - Mf_\varepsilon)\,dv.$$

It is the aim of the following proposition.

PROPOSITION 4.2. *For every $f\in L^1(\mathbb{R}^n)$ verifying $0\le f\le 1$, and every $u\in\mathbb{R}^n$ we denote*

$$\rho = \int_{\mathbb{R}^n} f(v)\,dv,$$
$$F = \int_{\mathbb{R}^n} |v-u|^2 |f(v) - M(\rho,u,v)|\,dv,$$
$$D = \int_{\mathbb{R}^n} |v|^2 (f(v) - M(\rho,u,v))\,dv.$$

Then there exists a constant C_n such that, for every $f\in L^1(\mathbb{R}^n)$ verifying $0\le f\le 1$,

$$F \le C_n(\rho^{\frac{n+2}{2n}}\sqrt{D} + D).$$

To prove this result, we first introduce some notations and prove preliminary results. Notice that, thanks to (4.7),

$$D = \int_{\mathbb{R}^n} |v-u|^2 (f(v) - M(\rho,u,v))\,dv.$$

Then changing v by $v+u$ if necessary, we see that we can restrict ourselves to the case $u=0$. We first reduce the problem to a one-dimensional problem. We introduce the following quantities:

$$\overline{f}(r) = \frac{1}{|\mathbb{S}_n|}\int_{\mathbb{S}_n} f(r\sigma)\,d\sigma,$$
$$\overline{M}(r) = \frac{1}{|\mathbb{S}_n|}\int_{\mathbb{S}_n} M(\rho,0,r\sigma)\,d\sigma = \mathbb{1}_{\{r^n\le c_n\rho\}}(r).$$

Since the integral of f is equal to the integral of $M(\rho,0,\cdot)$, we have

$$\int_0^\infty r^{n-1}\overline{f}(r)\,dr = \int_0^\infty r^{n-1}\overline{M}(r)\,dr. \tag{4.19}$$

We denote $r_1 = (c_n\rho)^{\frac{1}{n}}$, and we have

$$\begin{aligned}
F &= |\mathbb{S}_n| \int_0^\infty r^{n+1} |\overline{f}(r) - \overline{M}(r)|\, dr \\
&= |\mathbb{S}_n| \left(\int_0^{r_1} r^{n+1} (1 - \overline{f}(r))\, dr + \int_{r_1}^\infty r^{n+1} \overline{f}(r)\, dr \right), \\
D &= |\mathbb{S}_n| \int_0^\infty r^{n+1} (\overline{f}(r) - \overline{M}(r))\, dr \\
&= |\mathbb{S}_n| \left(- \int_0^{r_1} r^{n+1} (1 - \overline{f}(r))\, dr + \int_{r_1}^\infty r^{n+1} \overline{f}(r)\, dr \right).
\end{aligned}$$

We define in addition

$$M = \int_0^{r_1} r^{n-1} (1 - \overline{f}(r))\, dr = \int_{r_1}^\infty r^{n-1} \overline{f}(r)\, dr;$$

the last equality comes from (4.19) and $\overline{M}(r) = \mathbb{1}_{\{r \le r_1\}}(r)$. We have to do a different treatment for values close to r_1 and far from this value. For this purpose we consider $r_2 > r_1$ a new number which will be fixed later on. Then we denote

$$\begin{aligned}
M_1 &= \int_{r_1}^{r_2} r^{n-1} \overline{f}(r)\, dr, \\
M_2 &= \int_{r_2}^\infty r^{n-1} \overline{f}(r)\, dr.
\end{aligned}$$

We have $M = M_1 + M_2$. Then we define $0 < r_0 < r_1$ (in a unique way when r_2 is chosen) in the following way:

$$M_1 = \int_{r_0}^{r_1} r^{n-1} (1 - \overline{f}(r))\, dr.$$

Then, from the definition of M and since M is the sum of M_1 and M_2, we have

$$M_2 = \int_0^{r_0} r^{n-1} (1 - \overline{f}(r))\, dr.$$

In the same way we define F_1, F_2, D_1, D_2 in the following way:

$$\begin{aligned}
F_1 &= \int_{r_0}^{r_2} r^{n+1} |\overline{f}(r) - \overline{M}(r)|\, dr \\
&= \int_{r_0}^{r_1} r^{n+1} (1 - \overline{f}(r))\, dr + \int_{r_1}^{r_2} r^{n+1} \overline{f}(r)\, dr, \\
F_2 &= \int_0^{r_0} r^{n+1} |\overline{f}(r) - \overline{M}(r)|\, dr + \int_{r_2}^\infty r^{n+1} |\overline{f}(r) - \overline{M}(r)|\, dr \\
&= \int_0^{r_0} r^{n+1} (1 - \overline{f}(r))\, dr + \int_{r_2}^\infty r^{n+1} \overline{f}(r)\, dr,
\end{aligned}$$

$$
\begin{aligned}
D_1 &= \int_{r_0}^{r_2} r^{n+1}(\overline{f}(r) - \overline{M}(r))\,dr \\
&= -\int_{r_0}^{r_1} r^{n+1}(1-\overline{f}(r))\,dr + \int_{r_1}^{r_2} r^{n+1}\overline{f}(r)\,dr, \\
D_2 &= \int_{0}^{r_0} r^{n+1}(\overline{f}(r) - \overline{M}(r))\,dr + \int_{r_2}^{\infty} r^{n+1}(\overline{f}(r) - \overline{M}(r))\,dr \\
&= -\int_{0}^{r_0} r^{n+1}(1-\overline{f}(r))\,dr + \int_{r_2}^{\infty} r^{n+1}\overline{f}(r)\,dr.
\end{aligned}
$$

Notice that F_1, F_2, M_1, M_2 are nonnegative (as integrals of nonnegative functions) and verify

$$
\begin{aligned}
M &= M_1 + M_2, \\
F &= F_1 + F_2, \\
D &= D_1 + D_2.
\end{aligned}
$$

We can show, in addition, that D_1 and D_2 are nonnegative too.

LEMMA 4.3. *We have*

$$D_1 \geq 0, \qquad D_2 \geq 0.$$

Proof. We show the result for D_1 (the proof is similar for D_2). We have

$$
\begin{aligned}
\int_{r_1}^{r_2} r^{n+1}\overline{f}(r)\,dr &= \int_{r_1}^{r_2} r^2(r^{n-1}\overline{f}(r))\,dr \geq r_1^2 M_1, \\
\int_{r_0}^{r_1} r^{n+1}\overline{f}(r)\,dr &= \int_{r_0}^{r_1} r^2(r^{n-1}\overline{f}(r))\,dr \leq r_1^2 M_1.
\end{aligned}
$$

Since D_1 is the difference of those two terms, we find that D_1 is nonnegative. ∎

We first consider the values far from r_1.

LEMMA 4.4. *We can dominate F_2 by D_2 in the following way:*

$$F_2 \leq D_2 \left(\frac{r_1^2 + r_2^2}{r_2^2 - r_1^2} \right).$$

Proof. We have

$$
\begin{aligned}
\int_{r_2}^{\infty} r^{n+1}\overline{f}(r)\,dr &\geq r_2^2 M_2 \\
&\geq r_2^2 \frac{1}{r_0^2} \int_0^{r_0} r^{n+1}(1-\overline{f}(r))\,dr \\
&\geq \frac{r_2^2}{r_1^2} \int_0^{r_0} r^{n+1}(1-\overline{f}(r))\,dr.
\end{aligned}
$$

Hence we have

$$D_2 \geq \left(\frac{r_2^2}{r_1^2} - 1 \right) \int_0^{r_0} r^{n+1}(1-\overline{f}(r))\,dr.$$

But F_2 can be expressed in the following way:

$$F_2 = D_2 + 2\int_0^{r_0} r^{n+1}(1-\overline{f}(r))\,dr.$$

Those two expressions lead to

$$F_2 \le D_2 \left(\frac{r_1^2 + r_2^2}{r_2^2 - r_1^2} \right). \qquad \square$$

We consider now the values close to r_1.

LEMMA 4.5. *There exist $a > 0$ and a constant C_n depending only on n such that if $|r_2 - r_1| \le a r_1$, then*

$$F_1 \le C_n a^2 \rho^{\frac{n-2}{2n}} \sqrt{D_1}.$$

Proof. We split the proof in several parts.

(i) *Minimization of the entropy dissipation.* We define α and β such that

$$M_1 = \int_{r_1}^{\beta} r^{n-1}\, dr = \int_{\alpha}^{r_1} r^{n-1}\, dr.$$

From the definition of M_1, notice that $\beta \le r_2$. In the same way we have $\alpha \ge r_0$. We want to show that

$$D_1 \ge \int_{r_1}^{\beta} r^{n+1}\, dr - \int_{\alpha}^{r_1} r^{n+1}\, dr.$$

First we calculate

$$\begin{aligned}
&\int_{r_1}^{r_2} r^{n+1} \overline{f}(r)\, dr - \int_{r_1}^{\beta} r^{n+1}\, dr \\
&\quad = \int_{r_1}^{\beta} r^2 [r^{n-1}(\overline{f}(r) - 1)]\, dr + \int_{\beta}^{r_2} r^2 [r^{n-1} \overline{f}(r)]\, dr \\
&\quad = \int_{\beta}^{r_2} r^2 [r^{n-1} \overline{f}(r)]\, dr - \int_{r_1}^{\beta} r^2 [r^{n-1}(1 - \overline{f}(r))]\, dr \\
&\quad \ge \beta^2 \left[\int_{\beta}^{r_2} r^{n-1} \overline{f}(r)\, dr - \int_{r_1}^{\beta} r^{n-1}(1 - \overline{f}(r))\, dr \right] \\
&\quad \ge \beta^2 (M_1 - M_1) = 0.
\end{aligned}$$

In the same way we calculate

$$\begin{aligned}
&\int_{r_0}^{r_1} r^{n+1} (\overline{f}(r) - 1)\, dr + \int_{\alpha}^{r_1} r^{n+1}\, dr \\
&\quad = \int_{r_0}^{\alpha} r^{n+1} (\overline{f}(r) - 1)\, dr + \int_{\alpha}^{r_1} r^{n+1} \overline{f}(r)\, dr \\
&\quad \ge \alpha^2 \left[\int_{r_0}^{\alpha} r^{n-1} (\overline{f}(r) - 1)\, dr + \int_{\alpha}^{r_1} r^{n-1} \overline{f}(r)\, dr \right] \\
&\quad \ge 0.
\end{aligned}$$

Summing those two last inequalities gives the desired result.

(ii) *Taylor expansion of the critical entropy dissipation.* We call critical entropy dissipation the function defined by

$$D^c = \left(\int_{r_1}^{\beta} r^{n+1}\, dr - \int_{\alpha}^{r_1} r^{n+1}\, dr \right),$$

where α and β are defined in (i). Then we have

$$\begin{aligned} nM_1 &= \beta^n - r_1^n, \\ nM_1 &= r_1^n - \alpha^n, \\ (n+2)D^c &= \beta^{n+2} - 2r_1^{n+2} + \alpha^{n+2}, \end{aligned}$$

and therefore

$$\begin{aligned} \frac{D^c}{r_1^{n+2}} = \frac{\alpha+\beta-2r_1}{r_1} + \frac{n+1}{2}\left(\left(\frac{\beta-r_1}{r_1}\right)^2 + \left(\frac{\alpha-r_1}{r_1}\right)^2\right) \\ + O\left(\left(\frac{\beta-r_1}{r_1}\right)^3 + \left(\frac{\alpha-r_1}{r_1}\right)^3\right). \end{aligned}$$

Now

$$\begin{aligned} \frac{M_1}{r_1^n} &= \frac{\beta-r_1}{r_1} + \frac{n-1}{2}\left(\frac{\beta-r_1}{r_1}\right)^2 + O\left(\frac{\beta-r_1}{r_1}\right)^3 \\ &= \frac{r_1-\alpha}{r_1} - \frac{n-1}{2}\left(\frac{r_1-\alpha}{r_1}\right)^2 + O\left(\frac{r_1-\alpha}{r_1}\right)^3, \end{aligned}$$

and hence

$$\begin{aligned} 0 = \frac{\beta+\alpha-2r_1}{r_1} + \frac{n-1}{2}\left[\left(\frac{\beta-r_1}{r_1}\right)^2 + \left(\frac{r_1-\alpha}{r_1}\right)^2\right] \\ + O\left(\left(\frac{\beta-r_1}{r_1}\right)^3 + \left(\frac{r_1-\alpha}{r_1}\right)^3\right). \end{aligned}$$

Finally, we obtain

$$\begin{aligned} \frac{D^c}{r_1^{n+2}} &= \left[\left(\frac{\beta-r_1}{r_1}\right)^2 + \left(\frac{r_1-\alpha}{r_1}\right)^2\right] + O\left(\left(\frac{\beta-r_1}{r_1}\right)^3 + \left(\frac{r_1-\alpha}{r_1}\right)^3\right) \\ &= 2\left(\frac{M_1}{r_1^n}\right)^2 + O\left(\left(\frac{\beta-r_1}{r_1}\right)^3 + \left(\frac{r_1-\alpha}{r_1}\right)^3\right). \end{aligned}$$

Hence, there exist $\eta > 0$ and $\delta > 0$ such that

$$D^c \geq \frac{\delta}{r_1^{n-2}} M_1^2$$

whenever

$$\left|\frac{\beta-r_1}{r_1}\right| + \left|\frac{r_1-\alpha}{r_1}\right| \leq \eta.$$

(iii) *Final estimation.* From the definition of α, there exists $a > 0$ such that $|\frac{r_1-\alpha}{r_1}| \leq \eta$ whenever $|\frac{\beta-r_1}{r_1}| \leq a$. Remember that $r_2 \leq \beta$. Hence if $|r_2 - r_1| \leq ar_1$, then

$$\left|\frac{\beta-r_1}{r_1}\right| + \left|\frac{r_1-\alpha}{r_1}\right| \leq \eta$$

and

$$\begin{aligned} F_1 &\le r_2^2 M_1 \le a^2 \delta \sqrt{D^c} r_1^{\frac{n+2}{2}} \\ &\le C_n a^2 \sqrt{D_1} \rho^{\frac{n+2}{2n}}. \end{aligned}$$

The first inequality uses the definition of F_1, the second one uses the result of (ii), and the third one uses the definition of r_1 and the result of (i). ∎

Now we are able to prove the estimate of Proposition 4.2.

Proof of Proposition 4.2. We fix a and r_2 verifying the properties of Lemma 4.5. Thanks to Lemmas 4.4 and 4.5, we have

$$\begin{aligned} F \le F_1 + F_2 &\le D_2 \left(\frac{1+a}{a} \right) + C_n \rho^{\frac{n+2}{2n}} \sqrt{D_1} \\ &\le C_n'(D + \rho^{\frac{n+2}{2n}} \sqrt{D}). \end{aligned}$$ ∎

We are now able to prove the announced result.

Proof of Proposition 4.1. Thanks to Proposition 4.2, we have

$$\begin{aligned} &\int_0^T \int_{\mathbb{R}^n} \left| \int_{\mathbb{R}^n} v \otimes a(v)(M f_\varepsilon - f_\varepsilon)\, dv \right| dx\, dt \\ &\le C_n \sqrt{\left(\int_0^T \int_{\mathbb{R}^n} \rho_\varepsilon^{\frac{n+2}{n}}(t,x,v)\, dx\, dt \right) \left(\int_0^T \iint_{\mathbb{R}^{2n}} D_\varepsilon(t,x)\, dx\, dt \right)} \\ &\quad + C_n \int_0^T \iint_{\mathbb{R}^{2n}} D_\varepsilon(t,x)\, dx\, dt. \end{aligned}$$

From (4.17) and

$$\begin{aligned} \rho_\varepsilon |u_\varepsilon|^2 + n \rho_\varepsilon^{\frac{n+2}{n}} &= \int_{\mathbb{R}^n} |v|^2 M f_\varepsilon(t,x,v)\, dv \\ &\le \int_{\mathbb{R}^n} |v|^2 f_\varepsilon(t,x,v)\, dv, \end{aligned} \tag{4.20}$$

we have

$$\int_0^T \int_{\mathbb{R}^n} \rho_\varepsilon^{\frac{n+2}{n}}(t,x,v)\, dx\, dt \le \frac{T}{n} C.$$

Using (4.18), those lead to

$$\begin{aligned} &\int_0^T \int_{\mathbb{R}^n} \left| \int_{\mathbb{R}^n} v \otimes a(v)(M f_\varepsilon - f_\varepsilon)\, dv \right| dx\, dt \\ &\le C_n \sqrt{\frac{\varepsilon T}{n}} \tilde{C}^{1/2} + C_n \varepsilon \tilde{C}. \end{aligned}$$ ∎

We can then conclude the convergence result for $\gamma = (n+2)/n$.

Proof of Theorem 1.1. We apply Theorem 1.2 to get

$$\int_{\mathbb{R}^n} \eta(U_\varepsilon | U)(t,x)\, dx \to 0 \quad \text{for } t \in [0,T], \text{ as } \varepsilon \to 0. \tag{4.21}$$

Now

$$\eta(U_\varepsilon|U) = \int_0^1 \eta''(U + \vartheta(U_\varepsilon - U)) \cdot (U_\varepsilon - U)^2 \vartheta \, d\vartheta$$

with

$$\eta''(\rho, \rho u) \cdot (X_0, X_1)^2 = \gamma \rho^{\gamma-2} X_0^2 + \frac{1}{\rho}(X_1 - u X_0)^2,$$

and thus we have

$$\int_{\mathbb{R}^n} \int_0^1 \vartheta(\rho + \vartheta(\rho_\varepsilon - \rho))^{\gamma-2}(\rho_\varepsilon - \rho)^2 \, d\vartheta \, dx \to 0 \quad \text{for } t \in [0,T], \text{ as } \varepsilon \to 0 \tag{4.22}$$

and

$$\int_{\mathbb{R}^n} \int_0^1 \frac{\vartheta \rho^2}{(\rho + \vartheta(\rho_\varepsilon - \rho))^3}(\rho_\varepsilon(u_\varepsilon - u))^2 \, d\vartheta \, dx \to 0 \quad \text{for } t \in [0,T], \text{ as } \varepsilon \to 0. \tag{4.23}$$

For $\gamma \geq 2$, (4.22) gives that, up to a subsequence, $\rho_\varepsilon \to \rho$ a.e. as $\varepsilon \to 0$ since $\rho > 0$. For $\gamma < 2$, it gives this result except at the points where $\rho_\varepsilon \to +\infty$, but in this case, as ρ stays bounded,

$$(\rho + \vartheta(\rho_\varepsilon - \rho))^{\gamma-2}(\rho_\varepsilon - \rho)^2 \underset{\varepsilon \to 0}{\sim} \vartheta^{\gamma-2}\rho_\varepsilon^\gamma \to 0 \text{ a.e.},$$

and thus this case is impossible. Now (4.23) gives that, up to a subsequence, $\rho_\varepsilon(u_\varepsilon - u) \to 0$ a.e. as $\varepsilon \to 0$ and therefore $\rho_\varepsilon u_\varepsilon \to \rho u$ a.e. as $\varepsilon \to 0$. But from (4.17) and (4.20), we have that ρ_ε is bounded in $L^\infty(0,T;L^\gamma(\mathbb{R}^n))$ and that $\sqrt{\rho_\varepsilon}u_\varepsilon$ is bounded in $L^\infty(0,T;L^2(\mathbb{R}^n))$. Hence, the whole family ρ_ε converges strongly in $L^\infty(0,T;L^p(\mathbb{R}^n))$ to ρ for every $1 \leq p < \gamma$ and $\sqrt{\rho_\varepsilon}u_\varepsilon$ converges strongly to $\sqrt{\rho}u$ in $L^\infty(0,T;L^q(\mathbb{R}^n))$ for every $1 \leq q < 2$. In particular, $\rho_\varepsilon u_\varepsilon$ converges strongly to ρu in $L^\infty(0,T;L^q(\mathbb{R}^n))$ for every $1 \leq q < 2\gamma/(\gamma+1)$. □

4.1.2. Extension to every γ. The previous model works for $\gamma = (n+2)/n$. In order to deal with the values of $\gamma \in]1,(n+2)/n[$, we use an other model which was introduced in [5] and is written as follows.

We consider the BGK equation

$$\partial_t f_\varepsilon + \xi \cdot \nabla_x f_\varepsilon + F(x) \cdot \nabla_\xi f_\varepsilon = \frac{M f_\varepsilon - f_\varepsilon}{\varepsilon}, \tag{4.24}$$

where $f_\varepsilon = f_\varepsilon(t,x,v) \in \mathbb{R}$ with $t \in \mathbb{R}^+$, $x \in \mathbb{R}^n$, $v = (\xi, I) \in \mathbb{R}^n \times \mathbb{R}^+$, and $F : \mathbb{R}^n \to \mathbb{R}^n$, with

$$M f_\varepsilon(t,x,v) = M(U_\varepsilon(t,x), v), \qquad U_\varepsilon(t,x) = \int_{\mathbb{R}^{n+1}} a(v) f_\varepsilon(t,x,v) \, dv \tag{4.25}$$

with $a : \mathbb{R}^{n+1} \to \mathbb{R}^p$, $a(v) = (1, \xi)$, $p = n+1$, and

$$dv = b_1 I^{d-1} \, dI \, d\xi, \qquad b_1 = 2\,\pi^{d/2}/\Gamma(d/2),$$

where d is the number of degrees of freedom satisfying

$$n + d = \frac{2}{\gamma - 1}. \tag{4.26}$$

We notice that the function f_ε takes its values in $[0, b_2]$, and the Maxwellian M is defined by

$$M(U,v) = b_2 \mathbb{1}_{|\xi-u|^2+I^2<b_3\rho^{\gamma-1}}, \quad U=(\rho,\rho u), \tag{4.27}$$

where

$$b_2 = \left(\frac{2\pi\gamma}{\gamma-1}\right)^{-1/(\gamma-1)} \Gamma\left(\frac{\gamma}{\gamma-1}\right), \qquad b_3 = \frac{2\gamma}{\gamma-1},$$

and satisfies (4.7)–(4.8). It satisfies also (4.9) with $\partial_{\xi_j} a(v)$ instead of $\partial_{v_j} a(v)$. The kinetic entropy is

$$H(f,v) = \frac{1}{2}|v|^2 f = \frac{1}{2}(|\xi|^2 + I^2) f, \tag{4.28}$$

and satisfies (4.10)–(4.11). We get, as in the previous kinetic model, (1.11) and (1.18).

We recover the BGK model introduced previously integrating (4.24) (and the function f_ε) with respect to I with the measure $b_1 I^{d-1} dI$ [5].

Now for the control of the dissipation, we set

$$\overline{f}(r) = \frac{1}{s_n}\int_{\mathbb{S}^+_{n+1}} f(r\sigma)(\cos\theta)^{d-1}\, d\sigma,$$
$$\overline{M}(r) = \frac{1}{s_n}\int_{\mathbb{S}^+_{n+1}} M(\rho,0,r\sigma)(\cos\theta)^{d-1}\, d\sigma = b_2 \mathbb{1}_{\{r^2\le b_3\rho^{\gamma-1}\}}(r),$$

where $\mathbb{S}^+_{n+1} = \{(\xi, I) \in \mathbb{S}_{n+1};\ I \ge 0\}$, $I = r\cos\theta$ and $s_n = \int_{\mathbb{S}^+_{n+1}} (\cos\theta)^{d-1}\, d\sigma$. Then, we get from the mass conservation

$$\int_0^\infty r^{n+d-1}\overline{f}(r)\, dr = \int_0^\infty r^{n+d-1}\overline{M}(r)\, dr. \tag{4.29}$$

By similar techniques to those in the previous section, we get the following estimate.

PROPOSITION 4.6. *For every $f \in L^1_{dv}(\mathbb{R}^{n+1})$ verifying $0 \le f \le b_2$ and every $u \in \mathbb{R}^n$ we denote*

$$\rho = \int_{\mathbb{R}^{n+1}} f(v)\, dv,$$
$$F = \int_{\mathbb{R}^{n+1}} |v-u|^2 |f(v) - M(\rho,u,v)|\, dv,$$
$$D = \int_{\mathbb{R}^{n+1}} |v|^2 (f(v) - M(\rho,u,v))\, dv.$$

Then there exists a constant C_n such that, for every $f \in L^1_{dv}(\mathbb{R}^{n+1})$ verifying $0 \le f \le b_2$,

$$F \le C_n(\rho^{\frac{n+d+2}{2(n+d)}}\sqrt{D} + D).$$

Now since

$$\frac{n+d+2}{n+d} = \gamma,$$

we get a similar dissipation result to that in Proposition 4.1, and we can conclude the convergence in this case for every γ such that (4.26) is satisfied with $d > 0$; that is to say,

$$1 < \gamma < \frac{n+2}{n}.$$

We then obtain Theorem 1.1 in the same way as in the previous case.

We thank Bouchut for noticing that the proof of the case $\gamma = (n+2)/n$ (of the previous subsection) is also valid for every $1 < \gamma < (n+2)/n$ using this model.

4.2. Fokker–Planck. In this subsection, we study the convergence from the Fokker–Planck kinetic equation to the isothermal system, that is, the case $\gamma = 1$.

4.2.1. The kinetic model. The Fokker–Planck equation on $f_\varepsilon = f_\varepsilon(t,x,v) \in \mathbb{R}$, with $t \in \mathbb{R}^+$ and $x, v \in \mathbb{R}^n$, is given by

$$\partial_t f_\varepsilon + v \cdot \nabla_x f_\varepsilon + F(x) \cdot \nabla_v f_\varepsilon = \frac{1}{\varepsilon} \operatorname{div}_v((v - u_\varepsilon) f_\varepsilon + \nabla_v f_\varepsilon), \tag{4.30}$$

where

$$\rho_\varepsilon = \int_{\mathbb{R}^n} f_\varepsilon \, dv, \qquad \rho_\varepsilon u_\varepsilon = \int_{\mathbb{R}^n} v f_\varepsilon \, dv, \tag{4.31}$$

with the kinetic entropy

$$H(f,v) = \left(\frac{1}{2}|v|^2 + \ln f \right) f. \tag{4.32}$$

Here, we have $q(f) = F(x) \cdot \nabla_v f$, $a(v) = (1, v)$, and

$$\mathcal{Q}(f,v) = \operatorname{div}_v((v-u)f + \nabla_v f), \qquad (\rho, \rho u) = \int_{\mathbb{R}^n} a(v) f \, dv.$$

The property (1.10) is clear, and the property (1.13) comes from the following majorations: for $f \in L^1(\mathbb{R}^n)$ such that $\int_{\mathbb{R}^n} H(f,v)\, dv < \infty$, denoting $(\rho, \rho u) = \int_{\mathbb{R}^n} a(v) f(v)\, dv$, we have

$$\rho u^2 = \frac{(\int_{\mathbb{R}^n} v f \, dv)^2}{\int_{\mathbb{R}^n} f(v)\, dv} \le \int_{\mathbb{R}^n} |v|^2 f(v)\, dv,$$
$$\rho \ln \rho = \left(\int_{\mathbb{R}^n} f(v)\, dv \right) \ln \left(\int_{\mathbb{R}^n} f(v)\, dv \right) \le \int_{\mathbb{R}^n} f(v) \ln f(v)\, dv,$$

by Cauchy–Schwarz and by Jensen's inequality. As in the previous section we can check that

$$Q(\rho_\varepsilon, \rho_\varepsilon u_\varepsilon) = (0, F\rho_\varepsilon) = -\int_{\mathbb{R}^n} a(v) q(f_\varepsilon)\, dv,$$

so (1.18) is verified. It remains to verify (1.11) and (1.17).

4.2.2. Control of the entropy estimate and convergence result. We have the following estimate.

PROPOSITION 4.7. *Let f_ε be a solution to the kinetic equation* (4.5) *with initial value f_ε^0 bounded in $L^1(\mathbb{R}^{2n})$ verifying (finite energy)*

$$\iint_{\mathbb{R}^{2n}} H(f_\varepsilon^0(x,v),v)\,dv\,dx \le C^0 < \infty. \tag{4.33}$$

Then f_ε satisfies (1.11) *and*

$$\int_0^T \int_{\mathbb{R}^n} \left| A(U_\varepsilon) - \int_{\mathbb{R}^n} v \otimes a(v) f_\varepsilon\,dv \right| dx\,dt \le C\sqrt{\varepsilon}, \tag{4.34}$$

where A is the flux of the isothermal system.

Proof. We have

$$\partial_f H(f_\varepsilon, v) = \frac{|v|^2}{2} + 1 + \ln f_\varepsilon.$$

So

$$\begin{aligned}\int_{\mathbb{R}^n} \partial_f H(f_\varepsilon,v) F(x)\cdot\nabla_v f_\varepsilon\,dv &= -\rho_\varepsilon u_\varepsilon F(x)\\ &= -\eta'(\rho_\varepsilon,\rho_\varepsilon u_\varepsilon) Q(\rho_\varepsilon,\rho_\varepsilon u_\varepsilon)\end{aligned}$$

and

$$\begin{aligned}&\int_{\mathbb{R}^n} \partial_f H(f_\varepsilon,v)\,\mathrm{div}_v((v-u_\varepsilon)f_\varepsilon + \nabla_v f_\varepsilon)\,dv\\ &\quad= -\int_{\mathbb{R}^n} (v(v-u_\varepsilon)f_\varepsilon + v\nabla_v f_\varepsilon)\,dv - \int_{\mathbb{R}^n}\left(\frac{\nabla_v f_\varepsilon}{f_\varepsilon}(v-u_\varepsilon)f_\varepsilon + \frac{(\nabla_v f_\varepsilon)^2}{f_\varepsilon}\right) dv\\ &\quad= -\int_{\mathbb{R}^n} \frac{((v-u_\varepsilon)f_\varepsilon + \nabla_v f_\varepsilon)^2}{f_\varepsilon}\,dv - \int_{\mathbb{R}^n} u_\varepsilon(\nabla_v f_\varepsilon + (v-u_\varepsilon)f_\varepsilon)\,dv\\ &\quad= -\int_{\mathbb{R}^n} \frac{((v-u_\varepsilon)f_\varepsilon + \nabla_v f_\varepsilon)^2}{f_\varepsilon}\,dv.\end{aligned}$$

That is to say,

$$\begin{aligned}&\partial_t \int_{\mathbb{R}^n} H(f_\varepsilon,v)\,dv + \int_{\mathbb{R}^n} v\cdot\nabla_x H(f_\varepsilon,v)\,dv\\ &\quad= \int_{\mathbb{R}^n} \partial_f H(f_\varepsilon,v)(\partial_t f_\varepsilon + v\cdot\nabla_x f_\varepsilon)\,dv\\ &\quad= F(x)\rho_\varepsilon u_\varepsilon - \frac{1}{\varepsilon}\int_{\mathbb{R}^n} \frac{((v-u_\varepsilon)f_\varepsilon + \nabla_v f_\varepsilon)^2}{f_\varepsilon}\,dv.\end{aligned}$$

The first consequence of this relation is

$$\frac{d}{dt}\iint_{\mathbb{R}^{2n}} H(f_\varepsilon,v)\,dv\,dx \le \int_{\mathbb{R}^n} \eta'(\rho_\varepsilon,\rho_\varepsilon u_\varepsilon) Q(\rho_\varepsilon,\rho_\varepsilon u_\varepsilon)\,dx.$$

In particular this implies property (1.11). Moreover,

$$\begin{aligned}\frac{d}{dt}\iint_{\mathbb{R}^{2n}} H(f_\varepsilon, v)\,dv\,dx &\le F(x)\iint_{\mathbb{R}^{2n}} v f_\varepsilon\,dv\,dx\\ &\le \|F\|_{L^\infty}\iint_{\mathbb{R}^{2n}} (|v|^2+1) f_\varepsilon\,dv\,dx\\ &\le C_1\left(\|\rho_\varepsilon^0\|_{L^1} + \iint_{\mathbb{R}^{2n}} H(f_\varepsilon, v)\,dv\,dx\right),\end{aligned}$$

since the quantity $\iint |v|^2 f_\varepsilon\,dx\,dv$ is controlled in a classical way by $\iint H(f_\varepsilon, v)\,dx\,dv$. Using Gronwall's lemma, we deduce that there exists a constant C depending on T and f_ε^0 such that, for every $0 \le t \le T$,

$$\iint_{\mathbb{R}^{2n}} H(f_\varepsilon(t,x,v), v)\,dv\,dx \le C. \tag{4.35}$$

The second consequence is

$$\begin{aligned}&\left|\iiint_{[0,T]\times\mathbb{R}^{2n}} \frac{((v-u_\varepsilon)f_\varepsilon + \nabla_v f_\varepsilon)^2}{f_\varepsilon}\,dv\,dx\,dt\right|\\ &\quad\le \varepsilon\left(\iint_{\mathbb{R}^{2n}} H(f_\varepsilon^0)\,dv\,dx + \iint_{[0,T]\times\mathbb{R}^n} F(x)\rho_\varepsilon u_\varepsilon\,dx\,dt\right)\\ &\quad\le \varepsilon\left(C^0 + \|F\|_{L^\infty}\iiint_{[0,T]\times\mathbb{R}^{2n}} |v| f_\varepsilon\,dv\,dx\,dt\right)\\ &\quad\le \varepsilon\left(C^0 + \|F\|_{L^\infty}\iiint_{[0,T]\times\mathbb{R}^{2n}} (|v|^2+1) f_\varepsilon\,dv\,dx\,dt\right)\\ &\quad\le \varepsilon\left(C^0 + \|F\|_{L^\infty}\left(C' + T\iint_{[0,T]\times\mathbb{R}^n} f_\varepsilon^0\,dv\,dx\right)\right)\\ &\quad\le \varepsilon\, C_2.\end{aligned}$$

We have to estimate

$$\int_{\mathbb{R}^n}\left|A(U_\varepsilon) - \int_{\mathbb{R}^n} v\otimes a(v) f_\varepsilon\,dv\right|\,dx.$$

The first componant is zero. The second one is

$$E_2 = \int_{\mathbb{R}^n}\left|\rho_\varepsilon u_\varepsilon\otimes u_\varepsilon + \rho_\varepsilon I - \int_{\mathbb{R}^n} v\otimes v f_\varepsilon\,dv\right|\,dx,$$

which can be rewritten as

$$E_2 = \iint_{\mathbb{R}^{2n}} |v\otimes[(u_\varepsilon - v)f_\varepsilon - \nabla_v f_\varepsilon]|\,dv\,dx,$$

since

$$\int_{\mathbb{R}^n} v\otimes\nabla_v f_\varepsilon\,dv = -\int_{\mathbb{R}^n} f_\varepsilon\,dv I.$$

Thus we get

$$\int_0^T\!\!\int_{\mathbb{R}^{2n}} \left| A_2(U_\varepsilon) - \int_{\mathbb{R}^n} v \otimes a_2(v) f_\varepsilon \, dv \right| dx\, dt$$
$$\leq \left(\int_0^T\!\!\iint_{\mathbb{R}^{2n}} |v|^2 f_\varepsilon \, dv\, dx\, dt \right)^{1/2} \left(\int_0^T\!\!\iint_{\mathbb{R}^{2n}} \frac{((v-u_\varepsilon) f_\varepsilon + \nabla_v f_\varepsilon)^2}{f_\varepsilon} \, dv\, dx\, dt \right)^{1/2},$$

which concludes the proof. □

We can then apply the convergence result (Theorem 1.2). As in the previous section, this leads to Theorem 1.1 for the isothermal case.

Appendix. Euler. In this appendix, we calculate the various quantities which appear in our study in the case of the Euler system in order to see what prevents us from applying the method. For the full gas dynamics of Euler, the conservative variables are

$$U = (\rho, q, E) = \left(\rho, \rho u, \rho \frac{|u|^2}{2} + \frac{n}{2} \rho T \right),$$

and the flux is

$$A(U) = \left(\rho u, \rho u \otimes u + \rho T I, \rho u \frac{|u|^2}{2} + \frac{n+2}{2} \rho T u \right).$$

The entropy is

$$\eta(U) = \rho \ln \left(\frac{\rho}{(2\pi T)^{n/2}} \right) - \frac{n}{2} \rho,$$

and the associated flux is $G(U) = \eta(U) u$. The expression of the flux A in conservative variables is

$$A(U) = \left(q, \frac{1}{\rho} q \otimes q + \frac{2E}{n} I - \frac{1}{n\rho} |q|^2 I, \frac{n+2}{n} \frac{q}{\rho} E - \frac{1}{n} \frac{q}{\rho^2} |q|^2 \right).$$

Then we get

$$\begin{aligned}
\partial_\rho A_q(U) &= -u \otimes u + \frac{1}{n} |u|^2 I, \\
\partial_{q_i} (A_q)_{jk}(U) &= \delta_{ij} u_k + \delta_{ik} u_j - \delta_{jk} \frac{2u_i}{n}, \\
\partial_E A_q(U) &= \frac{2}{n} I, \\
\partial_\rho A_E(U) &= -\frac{n-2}{2} u \frac{|u|^2}{2} - \frac{n+2}{2} u T, \\
\partial_{q_i} (A_E)_j(U) &= \delta_{ij} \left(\frac{|u|^2}{2} + \frac{n+2}{2} T \right) - \frac{2}{n} u_i u_j, \\
\partial_E A_E(U) &= \frac{n+2}{n} u,
\end{aligned}$$

and the relative flux is

$$A_\rho(U_1|U_2) = 0, \tag{A.1}$$

$$A_q(U_1|U_2) = \rho_1(u_1-u_2)\otimes(u_1-u_2) - \frac{1}{n}\rho_1|u_1-u_2|^2 I, \tag{A.2}$$

$$A_E(U_1|U_2) = \frac{1}{2}\rho_1(|u_1|^2-|u_2|^2)(u_1-u_2) + \frac{n+2}{2}\rho_1(u_1-u_2)(T_1-T_2) - \frac{1}{n}\rho_1 u_2|u_1-u_2|^2. \tag{A.3}$$

We compute now the relative entropy. Since the linear part in a function disappeared in any relative quantity, we have to compute the flux of

$$\tilde\eta(U) = \left(1+\frac{n}{2}\right)\rho\ln\rho - \frac{n}{2}\rho\ln\left(\frac{2E}{n}-\frac{|q|^2}{n\rho}\right),$$

which satisfies

$$\partial_\rho\tilde\eta(U) = 1+\ln\rho+\frac{n}{2}-\frac{n}{2}\ln T - \frac{|u|^2}{2T}, \qquad \partial_q\tilde\eta = \frac{u}{T}, \qquad \partial_E\tilde\eta = -\frac{1}{T},$$

and thus we get

$$\eta(U_1|U_2) = h(\rho_1|\rho_2) + \frac{n\rho_1}{2T_2}h(T_2|T_1) + \frac{\rho_1}{2T_2}|u_1-u_2|^2, \tag{A.4}$$

where $h(x) = x\ln x$.

We see that we cannot apply our method in this case because of the cubic power in velocity in $A_E(U_1|U_2)$ since such a term does not appear in $\eta(U_1|U_2)$.

EXPANDING LORENZ ATTRACTORS THROUGH RESONANT DOUBLE HOMOCLINIC LOOPS*

C. A. MORALES†, M. J. PACIFICO†, AND B. SAN MARTIN‡

Abstract. In this paper we study the existence of Lorenz attractors in the unfolding of resonant double homoclinic loops in dimension three. Our results generalize the ones obtained in [C. Robinson, *SIAM J. Math. Anal.*, 32 (2000), pp. 119–141] in two ways. First, we obtain *attractors* instead of *weak attractors* obtained there. Second, we enlarge considerably the region in the parameter space corresponding to flows presenting expanding Lorenz attractors. The proof is based on rescaling techniques [J. Palis and F. Takens, *Hyperbolicity and Sensitive Choatic Dynamics at Homoclinic Bifurcations. Fractal Dimensions and Infinitely Many Attractors*, Cambridge University Press, Cambridge, UK, 1993] to obtain convergence to noncontinuous maps.

Key words. Lorenz attractors, resonant double homoclinic loops

1. Introduction. In the series of papers [Rob1, Rob2, Rob3] Robinson studied the existence of transitive attractors of Lorenz type in generic unfoldings of resonant double homoclinic loops in dimension three. For instance, [Rob1, Theorem 3.1, p. 130] says that under certain conditions such unfoldings produce transitive weak attractors containing the singularity. In this paper we improve this result in two ways. First, we obtain expanding Lorenz attractors instead of weak attractors as defined in [Rob1, p. 120]. Second, we enlarge considerably the region in the parameter space which corresponds to flows presenting expanding Lorenz attractors. By *attractor* we mean a transitive set which is maximal invariant in a positively invariant open set. A set is *transitive* if it is the omega-limit set of one of its orbits. An attractor of a three-dimensional vector field is *expanding Lorenz* if it contains a unique singularity whose eigenvalues $\lambda_1, \lambda_2, \lambda_3$ are real and satisfy $\lambda_2 < \lambda_3 < 0 < -\lambda_3 < \lambda_1$. The classical example of an expanding Lorenz attractor is the geometric Lorenz attractor in [GW, ABS]. We shall consider parametrized families of vector fields unfolding a resonant double homoclinic loop at $\eta = \eta_0$ as in [Rob1]. We assume the same hypotheses (A1)–(A7) of [Rob1], except for (A5) that we replace with

$$B = \frac{C^+_{\eta_0} + C^-_{\eta_0}}{C^+_{\eta_0} C^-_{\eta_0}} > 1,$$

where $C^\pm_{\eta_0}$ are defined as in that paper: the constants $C^\pm_{\eta_0}$ measure the change in area within a certain bundle over Γ, the resonant double homoclinic loop. Note that (A5) in [Rob1] implies $B > 1$ but not conversely. The proof is based on rescaling techniques [PT] to obtain convergence to noncontinuous maps. In a forthcoming paper we use

the rescaling techniques developed here to study the existence of contracting Lorenz attractors (Rovella attractors) in the unfolding of resonant double homoclinic loops. This will answer a question posed in [Rob1, Remark 5.1, p. 138].

Before we announce in a precise way our results, let us comment on some other results concerning Lorenz attractors and its bifurcations.

1.1. Related results and comments.

1.1.1. Lorenz equations and the geometrical model. The main motivation for all these results is the Lorenz attractor [Lo], given by the solutions of the polynomial vector field in $\mathbb{R}^3$:

$$X(x,y,z) = \begin{cases} \dot{x} = -\alpha x + \alpha y, \\ \dot{y} = \beta x - y - xz, \\ \dot{z} = -\gamma z + xy, \end{cases} \tag{1.1}$$

where α, β, γ are real parameters. Numerical experiments performed by Lorenz (for $\alpha = 10, \beta = 28,$ and $\gamma = 8/3$) suggested the existence of a strange attractor toward which tends a full neighborhood of positive trajectories of the above system. Moreover, the strange attractor seemed to be robust: it cannot be destroyed by any perturbation of the parameters. On the other hand, this attractor contains an equilibrium point $(0,0,0)$, and periodic points accumulating on it, and hence cannot be hyperbolic. The book [Sp] contains an extensive presentation of analytical and numerical facts about the original Lorenz equations. We point out that it was proved [Tu1, Tu2] that the solutions of (1.1) satisfy such a property for values α, β, γ near the ones considered by Lorenz. See the feature review [Tu2, V] for a survey and a discussion of Tucker's proof.

However, already in the mid-seventies, the existence of robust nonhyperbolic attractors was proved for flows introduced in [ABS, GW], which we now call geometrical models for Lorenz attractors. At the same time the theory of uniformly hyperbolic systems was being developed, and it was increasingly clear that such systems are not dense. One of those examples was precisely the geometrical Lorenz attractor.

Although geometrical Lorenz attractors fail to be uniformly hyperbolic, they do exhibit a certain amount of hyperbolicity (called singular hyperbolicity in [MPP2, MPP3]), which has been exploited to understand their structure. The bifurcations of these attractors and their relations to homoclinic bifurcations of codimensions 2 and 3 have also been intensively studied by several authors, both theoretically and with a view toward applications. This included great interest in the so-called Lorenz maps, one-dimensional models to which the dynamics of a geometrical Lorenz attractor can be reduced. In addition a number of bifurcation mechanisms have been found which yield attractors with similar properties. In what follows we give an overview of the literature, without trying to be exhaustive.

1.1.2. Attractors that resemble a Lorenz attractor. First, let us list some papers about the existence of chaotic attractors that resemble geometrical Lorenz models. We start with [MPP2, MPP3] where it is proved that any robust attractor of a flow in three manifolds containing equilibria looks like a geometric Lorenz attractor. In [BPV] the authors construct a multidimensional Lorenz-like attractor that is C^r-robust (r large) and contains a singularity with at least two positive eigenvalues. They also investigate the Sinai–Bowen–Ruelle (SBR) measures of these attractors. Their construction works in dimension greater than or equal to 5. In [ST] the authors present an example of a four-dimensional quasi-attractor and study its perturbations. The

quasi-attractor is pseudohyperbolic, contains a singularity with a complex eigenvalue, and cannot be destroyed by small perturbations of the system. In [Lo84] the author reports a careful numerical study of what seems to be a strange (chaotic) attractor in four dimensions for a system of 2-degree polynomial equations. In [Rov] the author proves existence and persistence of contracting Lorenz attractors, that is, with the contracting eigenvalue condition $-\lambda_3 > \lambda_1$.

In [PRV] the authors prove that certain parametrized families of one-dimensional maps with infinitely many critical points exhibit global chaotic behavior in a persistent way. An application of the methods developed there yields a proof of existence and even persistence of global spiral attractors for smooth flows in three dimensions, to be given in [CPRV].

In [P, S] the authors propose abstract models for attractors with singularities, called generalized hyperbolic attractors, and study their properties.

1.1.3. Topological dynamics. Some aspects of the topological dynamics of the geometric model was studied in [Ko1, Ko2], where it was proved that most geometrical Lorenz attractors do not have the shadowing property, and their expansive properties are investigated. In [Kl] the author finds a topological invariant for the Lorenz attractor allowing him to exhibit an uncountable number of nonhomeomorphic Lorenz attractors in the unfolding of a certain homoclinic loop. In [Ya] the author shows that the geometrical Lorenz attractor can be approximated by horseshoes with entropy close to that of the Lorenz attractor. In [BW] the knot type of the geometric model is analyzed, and in [GH] the Lorenz attractor is used to investigate the existence of flows realizing all links and knots as periodic orbits in 3-manifolds and an explicit ODE with such properties is exhibited. One can also see the survey [PS].

1.1.4. Dimension theory, ergodic and statistical properties. Concerning fractal dimensions of Lorenz attractors we mention the results in [Le1, Le2] and [BL]. The first contains an explicit formula for the Liapunov dimension of the Lorenz attractor and in the second a simple upper bound on the Hausdorff dimension of Lorenz attractors is given in terms of parameters σ, α, β in (1.1).

Statistical and ergodic properties of the geometrical model were investigated in [Bu]. In [Me1, Me2] the existence of SBR measures and the stochastic stability for the contracting model are proved.

1.1.5. Lorenz maps of the interval. Lorenz-like maps of the interval and their bifurcations have been studied in [LM1, LM2]. See also the references therein. In [AL] the authors describe the use of kneading theory to study the dynamics of Lorenz maps. In [HS] the Lorenz maps are classified, up to topological conjugacy, by their kneading invariants. In [MdeM] the notion of monotone Lorenz families is introduced, and the authors prove that all possible topological dynamics behavior of Lorenz maps is realized within every monotone Lorenz family. In [KS] the authors study the case where the Lorenz map has negative Schwarzian derivative and the derivative vanishes at both sides of the discontinuity point. The paper has both a survey and a research flavor. Among other results they characterize the global attractor associated in terms of renormalization properties of the Lorenz map. A modified Lorenz interval map is studied in [LV], combining a finite number of critical points and a finite number of discontinuities with infinite derivative. The authors prove that the associated attractor is nonuniformly hyperbolic. In [DY] the authors study the asymptotic periodicity of a Lorenz interval map. They prove that a Lorenz-like map is asymptotically periodic if the derivative set of the pre-image set of the discontinuity point is countable. See

also the book [AH] and the references therein for more about this topic.

1.1.6. Bifurcations. An extensive series of works have been dedicated to the bifurcations of systems leading to the appearance of Lorenz attractors, contracting or not, besides the papers by Robinson quoted before. We start with the Shimizu–Morioka model, a three-dimensional system of first-order ODEs which depend on two parameters. It has been derived to study the Lorenz system for large Rayleigh number. In [SM] the authors proved that there are two types of Lorenz-like attractors in this model. In [Sh], bifurcations near two codimension-two points in the parameter plane are analyzed in great detail. These points lie on the boundary of the region of existence of the Lorenz-like attractors. In [MPP1] a bifurcation of hyperbolic vector fields on three-dimensional manifolds leading to robust strange attractors with singularities is studied. In [DKO] the authors prove that bifurcations of a certain double homoclinic loop associated with a degenerated singularity can produce geometrical Lorenz attractors, and they also exhibit an explicit ODE presenting such attractors. [Ry] gives sufficient conditions for a butterfly inclination-flip loop to generate geometrical Lorenz attractors. In [ACL] the authors investigate the existence of Lorenz attractors in the unfolding of a certain singular cycle involving a saddle-node periodic orbit and a Lorenz-like singularity. In [MPu] the authors show the appearance of Lorenz attractors in the unfolding of a cycle formed by a Lorenz-like singularity and a saddle-node periodic orbit, and in [Mo] the appearance of Lorenz attractors through a saddle-node bifurcation is shown. See also [KKO] and the references therein for more about bifurcations generating geometrical Lorenz attractors.

1.2. Our hypotheses. Let us state our hypotheses in a precise way. In what follows X_η is a family of C^r, $r \geq 1$, vector fields on $\mathbb{R}^3$ satisfying the following conditions.

(A1) *For every η, X_η has a hyperbolic singularity Q_η such that the eigenvalues of $DX_\eta(Q_\eta)$ are real with $\lambda_{ss}(\eta) < \lambda_s(\eta) < 0 < \lambda_u(\eta)$, and with eigenvectors v^{ss}, v^s, and v^u, respectively.*

With this assumption, there are several invariant manifolds for the singularity Q_η. We denote the one-dimensional unstable manifold tangent to v^u by $W^u(Q_\eta, \eta)$, and the two-dimensional stable manifold tangent to v^{ss} and v^s by $W^s(Q_\eta, \eta)$. Next, there is a one-dimensional strong stable manifold $W^{ss}(Q_\eta, \eta)$. This latter manifold is made of points which converge to Q_η at an asymptotic rate determined by the eigenvalue λ_{ss}. All these manifolds are C^r if the vector field is C^r. Finally, there is a two-dimensional extended stable manifold tangent to v^s and v^u, which we denote by $W^{cu}(Q_\eta, \eta)$. The later manifold is at least C^1. With this notation we can make the second assumption about the existence of a double homoclinic connection.

(A2) *For the bifurcation value η_0, there is a double homoclinic connection with the unstable manifold of Q_{η_0} contained in the stable manifold but outside the strong stable manifold, that is,*

$$\Gamma = W^u(Q_{\eta_0}, \eta_0) \subset W^s(Q_{\eta_0}, \eta_0) \setminus W^{ss}(Q_{\eta_0}, \eta_0).$$

In fact, we assume that the two branches $\Gamma^\pm$ of $\Gamma \setminus \{Q_{\eta_0}\}$ are contained in the same component of $W^s(Q_{\eta_0}, \eta_0) \setminus W^{ss}(Q_{\eta_0}, \eta_0)$. Note that $\Gamma = \{Q_{\eta_0}\} \cup \Gamma^+ \cup \Gamma^-$.

(A3) *For η_0, the central manifold $W^{cu}(Q_{\eta_0}, \eta_0)$ is transverse to the stable manifold $W^s(Q_{\eta_0}, \eta_0)$ along Γ.*

Let

$$P(q) = T_q W^{cu}(Q_{\eta_0}, \eta_0) \quad \text{for } q \in \Gamma.$$

The transversality condition in (A3) with the condition

$$W^u(Q_{\eta_0}, \eta_0) \cap W^{ss}(Q_{\eta_0}, \eta_0) = Q_{\eta_0}$$

in assumption (A2) implies that $P(q)$ converges to $P(Q_{\eta_0})$ as q converges to Q_{η_0} along Γ (by the inclination lemma [dMP]). Therefore, $\{P(q) : q \in \Gamma\}$ is a continuous bundle over Γ. Considering one half of the homoclinic connection $\Gamma^+ \cup Q_{\eta_0}$, let $\nu^+ = 1$ if the bundle $\{P(q) : q \in \Gamma^+ \cup Q_{\eta_0}\}$ is orientable and $\nu^+ = -1$ if the bundle is nonorientable. In the same way, considering the other half of the homoclinic connection $\Gamma^- \cup Q_{\eta_0}$, let $\nu^- = \pm 1$ whenever the bundle $\{P(q) : q \in \Gamma^- \cup Q_{\eta_0}\}$ is orientable or nonorientable, respectively.

(A4) *We assume that*

$$\lambda_{ss}(\eta_0) - \lambda_s(\eta_0) + \lambda_u(\eta_0) < 0 \quad \textit{and} \quad \lambda_{ss}(\eta_0) < 2\lambda_s(\eta_0).$$

We shall use the notation $\alpha(\eta) = -\frac{\lambda_s(\eta)}{\lambda_u(\eta)}$ and $\beta(\eta) = -\frac{\lambda_{ss}(\eta)}{\lambda_u(\eta)}$.

These are open conditions and so do not add a codimension to the bifurcation. The second inequality in (A4) assures that $W^{cu}(Q_{\eta_0}, \eta_0)$ is C^2.

Let $q^{\pm}(t)$ be a parametrization of the solution along $\Gamma^{\pm}$ and $\operatorname{div}_2(q^{\pm}(t))$ the Jacobian of X_{η_0} at t restricted to $T_{\Gamma^{\pm}} W^{cu}$. Define $C^{\pm}_{\eta_0}$ by

$$C^{\pm}_{\eta_0} = \exp\left(\int_{-\infty}^{\infty} \operatorname{div}_2(q^{\pm}(t)) dt \right).$$

The quantity $C^{\pm}_{\eta_0}$ is the change in area within the planes $P(q)$ along the whole length of $\Gamma^{\pm}$.

(A5) $B > 1$, *where*

$$B = \frac{C^+_{\eta_0} + C^-_{\eta_0}}{C^+_{\eta_0} C^-_{\eta_0}}.$$

We observe that condition (A5) in [Rob1] requires either $0 < C^{\pm}_{\eta_0} < 1$ or $0 < C^{\pm}_{\eta_0} < 2$ and $\frac{C^+_{\eta_0}}{C^-_{\eta_0}} \in [(1+\sqrt{2})^{-1}, 1+\sqrt{2}]$. Robinson also has a polynomial vector field realizing such conditions.

We, on the contrary, do not make such assumptions on $C^{\pm}_{\eta_0}$. See Figure 1.1. On the other hand, we are still working on the problem of finding a polynomial vector field realizing the unfolding described in this paper.

Note that (A5) in [Rob1] implies $B > 1$ but not conversely. Assumption (A5) is open.

(A6) *There is a one-to-one resonance between the unstable and weak stable eigenvalue for η_0:*

$$\lambda_u(\eta_0) + \lambda_s(\eta_0) = 0.$$

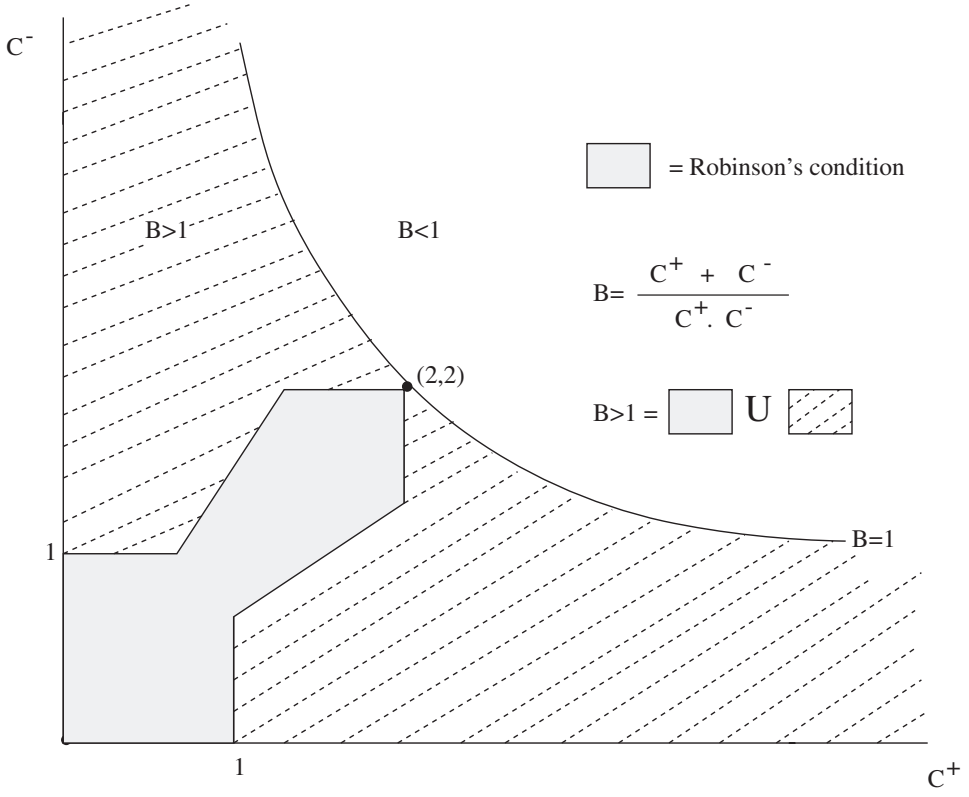

FIG. 1.1.

Observe that condition (A6) means $\alpha(\eta) = 1$. This condition is needed to have (A5) satisfied; see [Rob1]. This resonance condition is a codimension-one condition; in total, the conditions on η_0 are codimension three. (Two conditions are from the double homoclinic connection and resonance gives the third and final codimension.)

The final assumption is related to the unfolding of the bifurcation. We assume that the parameter space is large enough in order to break the double homoclinic loop in a correct way.

(A7) *Let $\mathcal{N} \subset \mathcal{X}^1(\mathbb{R}^3)$ be the 3-submanifold defined by conditions* (A1)–(A6). *We assume that the family $\{X_\eta\}$ is transverse to $\mathcal{N}$ at η_0.*

1.3. The main result. It is now possible to announce our main result. Given an A, a subset in the parameter space, we set $Cl(A)$ for the closure of A.

THEOREM 1.1. *Let $\{X_\eta\}$ be a C^k-parametrized family of C^r-vector fields (where $r, k \geq 3$) satisfying* (A1)–(A7). *Then, there is an open set $\mathcal{O}$ in the parameter space with $\eta_0 \in Cl(\mathcal{O})$ such that X_η has an expanding Lorenz attractor for all $\eta \in \mathcal{O}$.*

The tools used in the proof are reduction of the dynamics to a one-dimensional Poincaré map and the existence of a suitable rescaling for such maps with a well-defined limit dynamics. Rescaling techniques in the unfolding of homoclinic loops were used in [N] to obtain convergence to the Henon map. Here we use such techniques to obtain convergence to noncontinuous maps. Convergence to noncontinuous maps via rescaling was already considered in [MPu] for the study of certain heteroclinic

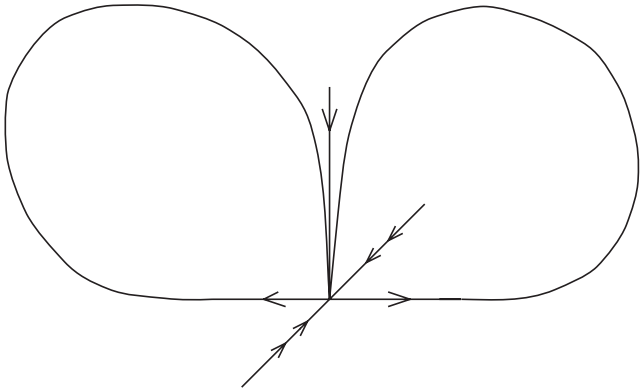

FIG. 1.2. *Vector field* X_{η_0}.

connections involving saddle-node periodic orbits. See [MSV] for more about rescaling techniques for singular cycles. Figure 1.2 displays a double homoclinic loop for the vector field X_{η_0}.

1.4. Sketch of the proof. Let us present the idea of the proofs. As in [Rob1], we observe that (A1)–(A3) imply the existence of a strong stable invariant foliation close to the loop. By (A4), the C^r-section theorem [S] implies that such a foliation is C^1 and varies C^1 with the parameters. As usual we consider the Poincaré map along the homoclinic loop. Using the strong stable foliation we reduce the dynamics of the return map to a one-dimensional map $f_\eta(\tau)$. Following [Rob2] we denote by α the order of $f_\eta(\tau)$. Clearly α depends on η. At this point the proof in [Rob1] requires solving certain inequalities allowing trapping regions for suitable parameter values. Recall that a compact interval J is a trapping region for f_η if $f_\eta(J) \subset \text{int}(J)$, where $\text{int}(J)$ means the interior of J. Instead, we use a different approach in which we consider α as a parameter. In Lemma 2.2 we fix α and prove the existence of *good parameters values*, i.e., parameters for which the critical values $f_\eta(0^\pm)$ of f_η are either fixed or pre-fixed or periodic (with period 2) expanding points. Such parameters are solutions of certain equations that can be solved only for $\alpha < 1$ because of (A5). Using the critical values we construct, for those good parameters, an f_η-invariant closed interval $[p, q]$ containing $\tau = 0$. We also get $|f'_\eta(\tau)| > 1$ uniformly for $\tau \in [p, q]$. Afterward we use rescaling techniques [PT]: we take a suitable parameter-depending change of coordinates in a neighborhood of $[p, q]$ and, at the same time, we normalize the parameter space in a small neighborhood of those good parameters. This yields a new family $g_\alpha(\mu, \nu, \cdot)$ and new good parameters $(\mu(\alpha), \nu(\alpha))$. In Lemma 3.3 we show the existence of bounds for the derivative of $g_\alpha(\nu, \mu, \cdot)$. This is used to prove that $g_\alpha(\mu, \nu, \cdot)$ converges (in a C^1-sense to be defined below) to a map $g(\mu, \nu, \cdot)$ as $\alpha \to 1^-$. The limit map $g(\mu, \nu, \cdot)$ is piecewise linear expanding that looks like the one in Figure 3.1 in section 3. In the same lemma we show that $\lim_{\alpha \to 1^\pm}(\mu(\alpha), \nu(\alpha)) = (\mu(1), \nu(1))$ exists.

The maps $g(\mu, \nu, \cdot)$ above do not have trapping regions, but they can be approximated in our family by ones having them. Indeed, by Theorem 4.1, we have that $g_\alpha(\mu, \nu, \cdot)$ has trapping regions for $\alpha < 1$ close to 1 and for (μ, ν) close to $(\mu(\alpha), \nu(\alpha))$. That is, for each $\alpha < 1$ close to 1 there is a compact interval J_α such that $g_\alpha(\mu, \nu, J_\alpha) \subset \text{int}(J_\alpha)$. Then for all $\alpha < 1$ and close to 1 the flow associated

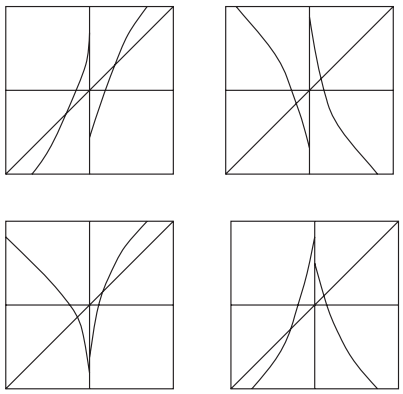

FIG. 2.1. *Possible* f_η.

with $g_\alpha(\mu,\nu,\cdot)$ has a trapping region. Thus a trapping region for the flow does exist in an open set $\mathcal{O}$ of parameters accumulating $\eta = 0$. To prove Theorem 1.1 we use the closeness of $g_\alpha(\mu,\nu,\cdot)$ to $g(\mu(1),\nu(1),\cdot)$. Such a closeness and Theorem 5.1 imply both transitiveness and expansiveness of $g_\alpha(\mu,\nu,\cdot)$ for the parameters with trapping regions; see also [Rob4, Theorem A].

2. One-dimensional reduction and good parameters. To start with, consider a cross section Σ of X_{η_0} close to Q_{η_0} transversal $W^s(Q_{\eta_0})$ intersecting both branches of $W^u(Q_{\eta_0})$. There is a neighborhood V of $\Sigma \cap W^s(Q_{\eta_0})$ in Σ such that the positive orbit of every point at $V \setminus W^s(Q_{\eta_0})$ intersects Σ for every parameter η near enough to η_0, defining in this way a Poincaré map $F_\eta : V \setminus W^s(Q_{\eta_0}) \subset \Sigma \to \Sigma$.

As X_{η_0} satisfies conditions (A1)–(A4), the standard stable manifold theory applies to show the existence of a C^1 stable foliation in a small neighborhood (that for convenience we assume equals to V) of $W^s(Q_\eta)$ varying C^1 with the parameter. As in [Rob2] the existence of a C^r stable foliation ($r \geq 1$) depends on the relation

$$C_3 e^{T(\lambda_{ss}(\eta_0)-\lambda_s(\eta_0))}(e^{T\lambda_u(\eta_0)})^r < 1\,.$$

By the first eigenvalue inequality in (A4) we have the above relation for $r = 1$. Then, we can use the C^r-section theorem (see [S, Theorem 5.18]) in the same way as in [Rob2]. Thus, via projection along the leaves of the strong stable foliation, the problem can be reduced to a one-dimensional Poincaré map $f_\eta : V' \setminus \{c_\eta\} \subset [-1,1] \to [-1,1]$. Here c_η is the projection of $W^s(Q_{\eta_0}) \cap V$ onto V'. We assume $c_\eta = 0$ for every η. Denote $a_\eta^\pm = \lim_{\tau\to\pm 0} f_\eta(\tau)$, $\tau \in [-1,1]$. Recall the description of the coefficients $\nu^\pm$ in assumption (A3).

LEMMA 2.1. *There is an interval J, $0 \in J$, such that for every η sufficiently near to η_0, the map $f_\eta : J \subset [-1,1] \to [-1,1]$ has the following form:*

$$f_\eta(\tau) = \begin{cases} a_\eta^+ + \nu^+ C_\eta^+ |\tau|^{\alpha_\eta} + O_{\eta,1}(|\tau|^{\alpha_\eta}) & \text{if } \tau > 0, \\ a_\eta^- - \nu^- C_\eta^- |\tau|^{\alpha_\eta} + O_{\eta,2}(|\tau|^{\alpha_\eta}) & \text{if } \tau < 0, \end{cases}$$

where $O_{\eta,i}$ are C^1, varying C^1 with respect to η, and $\lim_{x\to 0} \frac{O_{\eta,i}(x)}{x} = 0$ uniformly on η. Moreover, $C_\eta^\pm$ depends C^1 on η.

This result was proved in [Rob2]. See Figure 2.1.

From now on we assume that X_η is a three-parameter family for which there is an open set $U \subset \mathbb{R}^3$ such that for $\eta \in U$, X_η satisfies conditions (A1)–(A7).

It follows from (A7) that the map $\eta \mapsto (\alpha_\eta, a^+_\eta, a^-_\eta)$ is a diffeomorphism from a neighborhood of η_0 onto a neighborhood of $(1,0,0)$. So, we can reparametrize η by $(\alpha, a^+, a^-) \mapsto \eta(\alpha, a^+, a^-)$ in such a way that $\alpha_{\eta(\alpha,a^+,a^-)} = \alpha$, $a^+_{\eta(\alpha,a^+,a^-)} = a^+$ and $a^-_{\eta(\alpha,a^+,a^-)} = a^-$.

LEMMA 2.2. *There are $\Lambda > 0$, an open dense set $O \subset (1-\Lambda, 1)$, and C^1 maps $a^+(\cdot), a^-(\cdot), p(\cdot), q(\cdot) : O \to \mathbb{R}$ such that $p(\alpha) < 0 < q(\alpha)$ and for $\eta = \eta(\alpha, a^+(\alpha), a^-(\alpha))$ the following hold:*

(a) *if $\nu^+ = \nu^- = 1$, then $f_\eta(p(\alpha)) = p(\alpha)$, $f_\eta(q(\alpha)) = q(\alpha)$, $f_\eta(0^+) = p(\alpha)$, and $f_\eta(0^-) = q(\alpha)$;*

(b) *if $\nu^+ = \nu^- = -1$, then $f_\eta(p(\alpha)) = q(\alpha)$, $f_\eta(q(\alpha)) = p(\alpha)$, $f_\eta(0^+) = q(\alpha)$, and $f_\eta(0^-) = p(\alpha)$;*

(c) *if $\nu^+ = -\nu^- = 1$, then $f_\eta(p(\alpha)) = q(\alpha)$, $f_\eta(q(\alpha)) = q(\alpha)$, and $f_\eta(0^+) = f_\eta(0^-) = p(\alpha)$;*

(d) *if $\nu^+ = -\nu^- = -1$, then $f_\eta(p(\alpha)) = p(\alpha)$, $f_\eta(q(\alpha)) = p(\alpha)$, and $f_\eta(0^+) = f_\eta(0^-) = q(\alpha)$.*

In any case, $\lim_{\alpha\to 1^-} |p(\alpha)|/q(\alpha) = C^+_{\eta_0}/C^-_{\eta_0}$, $\lim_{\alpha\to 1^-} q(\alpha) = 0 = \lim_{\alpha\to 1} p(\alpha)$, and $\lim_{\alpha\to 1^-} q(\alpha)^{\alpha-1} = \lim_{\alpha\to 1^-} |p(\alpha)|^{\alpha-1} = B$, where B is the number given in (A5).

Proof. We prove (a). Define, for $\alpha < 1$, $p < 0$, and $q > 0$, the functions h, $\tilde{h}$, ℓ, and $\tilde{\ell}$ by

$$h(\alpha,p,q) = q^\alpha \left(\frac{1 + \left(\frac{C^+_\eta q^\alpha + O_{\eta,1}(|q|^\alpha)}{C^-_\eta |p|^\alpha - O_{\eta,2}(|p|^\alpha)} \frac{|p|^\alpha}{|q|^\alpha} \right)^{\frac{1}{\alpha}}}{C^+_\eta q^\alpha + O_{\eta,1}(|q|^\alpha)} \right),$$

$$\tilde{h}(\alpha,p,q) = |p|^\alpha \left(\frac{1 + \left(\frac{C^-_\eta |p|^\alpha - O_{\eta,2}(|p|^\alpha)}{C^+_\eta |q|^\alpha + O_{\eta,1}(|q|^\alpha)} \frac{|q|^\alpha}{|p|^\alpha} \right)^{\frac{1}{\alpha}}}{C^-_\eta |p|^\alpha - O_{\eta,2}(|p|^\alpha)} \right),$$

$$\ell(\alpha,p,q) = q^{\alpha-1}, \quad \tilde{\ell}(\alpha,p,q) = |p|^{\alpha-1},$$

where $\eta = \eta(\alpha,p,q)$.

Observe that h and $\tilde{h}$ are differentiable except for $D = \{(1,p,0), (1,0,q), \forall p,q\}$, and they extend continuously to D. Indeed,

$$\lim_{(\alpha,p,q)\to(1,0,0)} h(\alpha,p,q) = B = \lim_{(\alpha,p,q)\to(1,0,0)} \tilde{h}(\alpha,p,q),$$

and so we define $h(1,0,0) = B = \tilde{h}(1,0,0)$. Furthermore,

$$h(\alpha,p,q) \left(\frac{C^+_\eta q^\alpha + O_{\eta,1}(|q|^\alpha)}{q^\alpha} \right)^{\frac{\alpha-1}{\alpha}} = \tilde{h}(\alpha,p,q) \left(\frac{C^-_\eta |p|^\alpha - O_{\eta,2}(|p|^\alpha)}{|p|^\alpha} \right)^{\frac{\alpha-1}{\alpha}}. \tag{2.1}$$

Let us choose $\Lambda > 0$. As $B > 1$, by (A5) there is $\epsilon > 0$ such that $1 \notin [B-\epsilon, B+\epsilon]$. Fix δ_0 and Λ such that if $q, |p| \in (0, \delta_0)$ and $\alpha \in (1-\Lambda, 1)$, then

$$B - \epsilon < h(\alpha,p,q), \tilde{h}(\alpha,p,q) < B + \epsilon\,. \tag{2.2}$$

Shrinking Λ if necessary, we can further assume $\delta_0^{\alpha-1} < B - \epsilon$.

For the proof of Lemma 2.2(a) we shall use the following result which states that for all $\alpha \in (1-\Lambda, 1)$, the projection on the plane $p\,q$ of $graph(h(\alpha,\cdot,\cdot))\cap graph(\ell(\alpha,\cdot,\cdot))$ contains a regular curve C_α joining the vertical sides of $[-\delta_0, 0] \times [0, \delta_0]$.

Let $\mathcal{C}^1([0,1])$ be the set of C^1 maps $\gamma : [0,1] \to [-\delta_0, 0] \times [0, \delta_0]$ endowed with the C^1 topology.

LEMMA 2.3. *There are an open dense set $O \subset (1-\Lambda, 1)$ and a C^1 map*

$$\Gamma : O \times [0,1] \mapsto \mathcal{C}^1([0,1]), \quad (\alpha, t) \mapsto C_\alpha(t),$$

where

$$C_\alpha(t) = (p_\alpha(t), q_\alpha(t))$$

is such that $p_\alpha(0) = 0$, $p_\alpha(1) = -\delta_0$, $h(\alpha, p_\alpha(t), q_\alpha(t)) = [q_\alpha(t)]^{\alpha-1}$, and $0 < q_\alpha(t) < \delta_0$ for all $t \in (0,1)$.

Proof. We first prove that for all α small enough, $graph(h(\alpha,\cdot,\cdot))\cap graph(\ell(\alpha,\cdot,\cdot))$ is transversal. For this we proceed as follows.

By the definition of $h(\alpha, p, q)$ above we have

$$h(\alpha,p,q) = \frac{1 + \left(\frac{C_\eta^+ + O_{\eta,1}(|q|^\alpha)/q^\alpha}{C_\eta^- - O_{\eta,2}(|p|^\alpha)} / \mid p \mid^\alpha\right)^{\frac{1}{\alpha}}}{C_\eta^+ q^\alpha + O_{\eta,1}(|q|^\alpha)}.$$

Recall that $\eta = \eta(\alpha, p, q)$.

Assume that $O_{\eta,i} = 0$ for $i = 1, 2$. Taking the derivative of h with respect to q we obtain

$$\partial_q h(\alpha,p,q) = \frac{(1/\alpha)(C_\eta^+/C_\eta^-)^{1/\alpha-1} \cdot (\partial(C_\eta^+) \cdot C_\eta^- - C_\eta^+ \partial_q(C_\eta^-)) \cdot (C_\eta^-)^{-2} \cdot C_\eta^+}{(C_\eta^+)^2}.$$

From this we have that $\lim_{(\alpha,p,q)\to(1,0,0)} \partial_q h(\alpha,p,q)$ exists, and so $\partial_q h(\alpha,p,q)$ has a lower bound $K > -\infty$. By the definition of $\ell(\alpha,p,q)$ one has

$$\partial_q \ell(\alpha,p,q) = (\alpha-1) q^{(\alpha-2)}.$$

If (α,p,q) satisfies $h(\alpha,p,q) = l(\alpha,p,q)$, then the definition of $\ell(\alpha,\cdot,\cdot)$ with (2.2) imply that

$$q^{\alpha-1} > B - \epsilon.$$

So, for such points (α,p,q) one has

$$\partial_q h(\alpha,p,q) - \partial_q l(\alpha,p,q) > K - (\alpha-1) q^{\alpha-2} > K + \frac{\ln(B-\epsilon)\cdot(B-\epsilon)}{|\ln(q)|\cdot q}. \tag{2.3}$$

Because $B - \epsilon > 1$ it follows that the right-hand term of (2.3) goes to ∞ as $q \to 0^+$. In particular, the left-hand term of (2.3) is nonzero and so $graph(h(\alpha,\cdot,\cdot)) \cap graph(\ell(\alpha,\cdot,\cdot))$ is transversal.

The general case follows from similar computations using that for (α,p,q) such that $h(\alpha,p,q) = l(\alpha,p,q)$ we have $B - \epsilon < q^{(\alpha-1)} < B + \epsilon$ and

$$\lim_{(\alpha,p,q)\to(1,0,0)} \frac{O_{\eta,1}(q^\alpha)}{q^\alpha} = \lim_{(\alpha,p,q)\to(1,0,0)} \partial_q \left(\frac{O_{\eta,1}(q^\alpha)}{q^\alpha}\right) = 0.$$

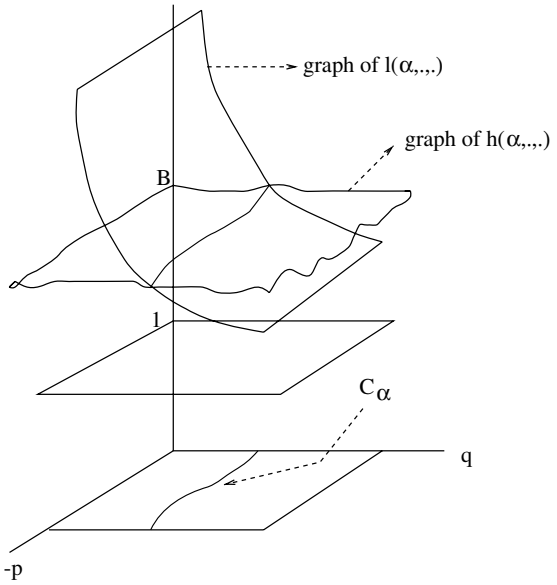

FIG. 2.2. *graph* $(h(\alpha,\cdot,\cdot)) \cap$ *graph* $(l(\alpha,\cdot,\cdot))$.

Returning to the proof of Lemma 2.3, since $graph(h(\alpha,\cdot,\cdot)) \cap graph(\ell(\alpha,\cdot,\cdot))$ is transversal, we have that this intersection is a compact 1-manifold; see Figure 2.2. Although $graph(h(\alpha,\cdot,\cdot)) \cap graph(\ell(\alpha,\cdot,\cdot))$ may be nonconnected, the number of connected components of this intersection is finite. On the other hand, it follows from the intermediate value theorem that $graph(\ell(\alpha,\cdot,\cdot))$ intersects $h(\alpha,\ p(q),q)$ for any curve $q \to p(q)$ with $p(-\delta) = \delta$, $p(0) = 0$. Then, for all $\alpha \in (1-\Lambda, 1)$, the projection onto the plane $p\,q$ of one of the connected components of $graph(h(\alpha,\cdot,\cdot)) \cap graph(\ell(\alpha,\cdot,\cdot))$ is a regular curve C_α joining the vertical sides of $[-\delta_0, 0] \times [0, \delta_0]$. That is,

$$C_\alpha : [0,1] \to [-\delta_0, 0] \times [0, \delta_0], \quad t \mapsto (p_\alpha(t), q_\alpha(t))$$

such that $p_\alpha(0) = 0$, $p_\alpha(1) = -\delta_0$, $h(\alpha, p_\alpha(t), q_\alpha(t)) = [q_\alpha(t)]^{\alpha-1}$, and $0 < q_\alpha(t) < \delta_0$ for all $t \in (0,1)$.

Now observe that by usual transversality arguments, for all α' there is $I_{\alpha'}$ such that for all $\alpha \in I_{\alpha'}$ the curve C_α obtained above can be chosen in such way that the map $(\alpha, t) \in I_{\alpha'} \times [0,1] \mapsto C_\alpha(t) \in [-\delta_0, 0] \times [0, \delta_0]$ is C^1. Hence we can choose an open dense set O in $(1-\Lambda, 1)$ such that the map $(\alpha, t) \in O \times [0,1] \mapsto C_\alpha(t)$ is C^1. All of this together concludes the proof of Lemma 2.3. □

Returning to the proof of Lemma 2.2, observe that we have the following inequalities:

$$\lim_{t\to 0} |p_\alpha(t)|^{\alpha-1} > B + \epsilon \geq \tilde{h}(\alpha, p_\alpha(t), q_\alpha(t)) \geq B - \epsilon > \delta_0^{\alpha-1} = |p_\alpha(1)|^{\alpha-1}.$$

These inequalities and the intermediate value theorem imply that there is $t = t(\alpha)$ such that

$$\tilde{h}(\alpha, p_\alpha(t), q_\alpha(t)) = |p_\alpha(t)|^{\alpha-1}.$$

By Lemma 2.3, $C_\alpha(t) = (p_\alpha(t), q_\alpha(t))$ depends C^1 on (α, t) and so, by the implicit function theorem we get that the map $\alpha \mapsto t(\alpha)$ is C^1.

From now on O is the open dense set given by Lemma 2.3.

Let $a^+(\cdot)$, $a^-(\cdot)$, $p(\cdot)$, $q(\cdot) : O \to \mathbb{R}$ be given by $p(\alpha) = p_\alpha(t_0(\alpha))$, $q(\alpha) = q_\alpha(t_0(\alpha))$, $a^+(\alpha) = p(\alpha)$, and $a^-(\alpha) = q(\alpha)$. These maps are C^1 and satisfy

$$h(\alpha, p(\alpha), q(\alpha)) = (q(\alpha))^{\alpha-1}, \quad \tilde{h}(\alpha, p(\alpha), q(\alpha)) = |p(\alpha)|^{\alpha-1}. \tag{2.4}$$

From this it follows that $(B-\epsilon)^{\frac{1}{\alpha-1}} < q(\alpha) < (B+\epsilon)^{\frac{1}{\alpha-1}}$, and hence we obtain $\lim_{\alpha\to 1^-} q(\alpha) = 0$. Similarly for $p(\alpha)$. Applying these facts in (2.4) we get $\lim_{\alpha\to 1^-} q(\alpha)^{\alpha-1} = B$ and $\lim_{\alpha\to 1^-} |p(\alpha)|^{\alpha-1} = B$.

We claim that $p = p(\alpha)$, $q = q(\alpha)$, $a^+ = a^+(\alpha)$, and $a^- = a^-(\alpha)$ chosen as above satisfy (a) in Lemma 2.2.

Indeed, since $h(\alpha, p, q) = q^{\alpha-1}$ and $\tilde{h}(\alpha, p, q) = |p|^{\alpha-1}$, (2.1) implies that

$$q^{\alpha-1}\left(\frac{C_\eta^+ q^\alpha + O_{\eta,1}(q^\alpha)}{q^\alpha}\right)^{\frac{\alpha-1}{\alpha}} = |p|^{\alpha-1}\left(\frac{C_\eta^- |p|^\alpha - O_{\eta,2}(|p|^\alpha)}{|p|^\alpha}\right)^{\frac{\alpha-1}{\alpha}}.$$

Hence

$$C_\eta^+ q^\alpha + O_{\eta,1}(q^\alpha) = C_\eta^- |p|^\alpha - O_{\eta,2}(|p|^\alpha). \tag{2.5}$$

On the other hand, from the definition of h we get

$$q^{\alpha-1} = q^\alpha \left(\frac{1 + \left(\frac{C_\eta^+ q^\alpha + O_{\eta,1}(q^\alpha)}{C_\eta^- |p|^\alpha - O_{\eta,2}(|p|^\alpha)} \frac{|p|^\alpha}{q^\alpha}\right)^{\frac{1}{\alpha}}}{C_\eta^+ q^\alpha + O_{\eta,1}(q^\alpha)}\right). \tag{2.6}$$

From (2.5) and (2.6) we get $C_\eta^+ q^\alpha + O_{\eta,1}(q^\alpha) = q - p$, implying that $f_\eta(q) = q$ and $f_\eta(p) = p$.

Note that (2.5) implies

$$q^\alpha\left(C_\eta^+ + \frac{O_{\eta,1}(q^\alpha)}{q^\alpha}\right) = |p|^\alpha\left(C_\eta^- - \frac{O_{\eta,2}(|p|^\alpha)}{|p|^\alpha}\right)$$

and so $\lim_{\alpha\to 1^-} \frac{|p(\alpha)|}{q(\alpha)} = \frac{C_{\eta_0}^+}{C_{\eta_0}^-}$.

All of this together finishes the proof of Lemma 2.2(a). The remaining cases are similar and are left to the reader. □

Note 1. Let O be as in Lemma 2.2 and for $\alpha \in O$, let $a^+(\alpha)$ and $a^-(\alpha)$ be the functions defined above. We shall call $\eta = \eta(\alpha, a^+(\alpha), a^-(\alpha))$ for $\alpha \in O$ the *good parameters* of X_η.

3. Rescaling. In this section we perform rescaling techniques [PT]. Keeping the notation p, q in Lemma 2.2 we take suitable parameter-depending change of coordinates in a neighborhood of $[p, q]$ and, at the same time, we normalize the parameter space in a small neighborhood of the good parameters in Notation 2. This yields a new family $g_\alpha(\mu, \nu, \cdot)$ and new good parameters $(\mu(\alpha), \nu(\alpha))$. The goal of this section is to prove that $g_\alpha(\mu, \nu, \cdot)$ converges to a map $g(\mu, \nu, \cdot)$ in the sense to be described below.

To start we consider the parametrized family $\{X_\eta\}$ as in section 2. Recall the notation in that section.

Given $\alpha \in O$ let $a^-(\alpha)$, $a^+(\alpha)$, $p(\alpha)$, and $q(\alpha)$ be as in Lemma 2.2. Define $(\mu(\alpha), \nu(\alpha)) = (\frac{a^+(\alpha)}{q(\alpha)}, \frac{a^-(\alpha)}{q(\alpha)})$ and $(\mu, \nu) = (\frac{a^+}{q(\alpha)}, \frac{a^-}{q(\alpha)})$ in a neighborhood of $(a^+(\alpha), a^-(\alpha))$ onto a neighborhood of $(\mu(\alpha), \nu(\alpha))$, and the family of maps

$$g_\alpha(\mu, \nu, x) = \frac{1}{q(\alpha)} f_\eta(q(\alpha)x), \tag{3.1}$$

where $\eta = \eta(\alpha, q(\alpha)\mu, q(\alpha)\nu)$. We set $\mathrm{Dom}(g_\alpha)$ for the domain of g_α.

Note 2. Observe that for each fixed α, this change of variables renormalizes the parameters $a^\pm$ with $a^+ = q(\alpha)\mu$ and $a^- = q(\alpha)\nu$. Moreover, by Lemma 2.2, $\lim_{\alpha\to 1^-} \mu(\alpha)$ and $\lim_{\alpha\to 1^-} \nu(\alpha)$ exist and we denote them by $\mu(1)$ and $\nu(1)$, respectively.

DEFINITION 3.1. *Let $g : \mathbb{R}^2 \times (\mathbb{R} \setminus \{0\}) \to \mathbb{R}$. We say that $g_\alpha \to g$ in the C^0 topology in compact sets of $\mathbb{R}^3$ as $\alpha \to 1^-$ if*

(a) $\mathrm{Dom}(g_\alpha) \to \mathbb{R}^2 \times (\mathbb{R} \setminus \{0\})$ *as $\alpha \to 1^-$, that is, for all $R > 0$ there is $0 < \alpha_0 < 1$ such that if $\alpha_0 < \alpha < 1$, then $B_R(0) \cap (\mathbb{R}^2 \times (\mathbb{R} \setminus \{0\}) \subset \mathrm{Dom}(g_\alpha)$, where $B_R(0)$ is the ball of radius R centered at $(0, 0, 0)$,*

(b) *for every compact set $K \subset \mathbb{R}^3$ and every $\epsilon > 0$ there is $\delta > 0$ such that if $|\alpha - 1| < \delta$, then*

$$\sup_{y \in K \cap (\mathbb{R}^2 \times (\mathbb{R}\setminus\{0\}))} |g_\alpha(y) - g(y)| < \epsilon.$$

DEFINITION 3.2. *Let $g : \mathbb{R}^2 \times (\mathbb{R} \setminus \{0\}) \to \mathbb{R}$. We say that $g_\alpha \to g$ in the C^1 topology in compact sets of $\mathbb{R}^2 \times (\mathbb{R} \setminus \{0\})$ if*

(a) $\mathrm{Dom}(g_\alpha) \to \mathbb{R}^2 \times (\mathbb{R} \setminus \{0\})$ *as $\alpha \to 1^-$,*

(b) *for every compact set $K \subset \mathbb{R}^2 \times (\mathbb{R} \setminus \{0\})$ and every $\epsilon > 0$ there is $\delta > 0$ such that if $|\alpha - 1| < \delta$, then*

$$\sup_{i \in \{0,1\}, y \in K} |D^i g_\alpha(y) - D^i g(y)| < \epsilon.$$

Note that with these notions, C^1 convergence does not imply C^0 convergence.

We have the following result.

LEMMA 3.3. *Let g_α be as in* (3.1) *and define*

$$g(\mu, \nu, x) = \begin{cases} \mu + \nu^+ C^+_{\eta_0} Bx & \text{if } x > 0, \\ \nu + \nu^- C^-_{\eta_0} Bx & \text{if } x < 0, \end{cases}$$

where $\eta_0 = \eta(1, 0, 0)$. Then

(i) *$g_\alpha \to g$ in the C^0 topology in compact sets of $\mathbb{R}^3$ as $\alpha \to 1^-$, $\alpha \in O$,*

(ii) *$g_\alpha \to g$ in the C^1 topology in compact sets of $\mathbb{R}^2 \times (\mathbb{R} \setminus \{0\})$ as $\alpha \to 1^-$, $\alpha \in O$.*

Moreover, for any $c > \max\{1, C^+_{\eta_0}/C^-_{\eta_0}\}$, there are constants $\Delta_0 > 0$, $0 < K_1 < K_2$ such that for $\alpha \in O \cap [1 - \Delta_0, 1]$ we have

(a) $[-c, c]^2 \times ([-c, c] \setminus \{0\}) \subset \mathrm{Dom}(g_\alpha)$,

(b) $K_1|x|^{\alpha-1} \le \left|\frac{\partial}{\partial x} g_\alpha(\mu, \nu; x)\right| \le K_2|x|^{\alpha-1}$ *for all* $(\mu, \nu, x) \in [-c, c]^2 \times ([-c, c] \setminus \{0\})$.

Proof. First, let us prove that $\mathrm{Dom}(g_\alpha) \to \mathbb{R}^2 \times (\mathbb{R} \setminus \{0\})$. For this, fix $R > 0$. We shall prove that

$$B_R(0) \cap (\mathbb{R}^2 \times (\mathbb{R} \setminus \{0\})) \subset \mathrm{Dom}(g_\alpha)$$

for all α close to 1.

For simplicity set $k = q(\alpha)$, where $q(\alpha)$ is given by Lemma 2.3. Recall $k \to 0$ as $\alpha \to 1^-$.

Let $0 < \epsilon_0$, ϵ_1 so that $(1-\epsilon_1, 1+\epsilon_1) \times (-\epsilon_0, \epsilon_0) \times (-\epsilon_0, \epsilon_0) \subset \mathrm{Dom}(\eta)$.

Given $(\mu, \nu, x) \in B_R(0)$ and α with $|\alpha - 1| < \epsilon_1$, we have $|k\mu|, |k\nu| \le kR < \epsilon_0$ for ϵ_1 small enough. Thus, $(\alpha, k\mu, k\nu) \in \mathrm{Dom}(\eta)$. In a similar way we have that $kx \in \mathrm{Dom} f_{\eta(\alpha,k\mu,k\nu)}$. This proves (a) of Definitions 3.1 and 3.2.

To verify (b) we proceed as follows. First observe that, by definition, see Lemma 2.1, we have

$$g_\alpha(\mu,\nu,x) = k^{-1} f_\eta(kx) = \begin{cases} k^{-1}[k\mu + \nu^+ C_\eta^+ |kx|^\alpha + O_{\eta,1}(|k_\alpha x|^\alpha)], & x > 0, \\ k^{-1}[k\nu - \nu^- C_\eta^- |kx|^\alpha + O_{\eta,2}(|kx|^\alpha)], & x < 0 \end{cases}$$

$$= \begin{cases} \mu + \nu^+ C_\eta^+ k^{\alpha-1}|x|^\alpha + \frac{O_{\eta,1}(|kx|^\alpha)}{k}, & x > 0, \\ \nu - \nu^- C_\eta^- k^{\alpha-1}|x|^\alpha + \frac{O_{\eta,2}(|kx|^\alpha)}{k}, & x < 0. \end{cases} \tag{3.2}$$

As $k^{\alpha-1} \to B$, $k \to 0$, and $\eta \to \eta_0$ when $\alpha \to 1$, we obtain $\nu^\pm C_\eta^\pm k^{\alpha-1}|x|^\alpha \to \nu^\pm C_{\eta_0}^\pm B|x|$ as $\alpha \to 1^-$. On the other hand, by Lemma 2.1 we have $\lim_{x\to 0} \frac{O_{\eta,i}(x)}{|x|} = 0$ uniformly on η. So, $\frac{O_{\eta,i}(|kx|^\alpha)}{k} = \frac{\mathcal{O}_{\eta,i}(|kx|^\alpha)}{|kx|^\alpha} k^{\alpha-1}|x|^\alpha \to 0$ as $\alpha \to 1^-$ for $|x| < R$. All of this together imply (b) of Definition 3.1. So we finish the proof of (i).

To prove (ii) we proceed as follows. We have, for $x \neq 0$,

$$\partial_x g_\alpha(\mu,\nu,x) = \begin{cases} \nu^+ C_\eta^+ \alpha k^{\alpha-1}|x|^{\alpha-1} + O'_{\eta,1}(|kx|^\alpha)\alpha|kx|^{\alpha-1}, & x > 0, \\ \nu^- C_\eta^- \alpha k^{\alpha-1}|x|^{\alpha-1} + O'_{\eta,2}(|kx|^\alpha)\alpha|kx|^{\alpha-1}, & x < 0. \end{cases} \tag{3.3}$$

Now fix a compact set $K \subset \mathbb{R}^2 \times (\mathbb{R} \setminus \{0\})$. Then there are $0 < C_1 = C_1(K) < C_2 = C_2(K)$ such that for all $(\mu, \nu, x) \in K$ we have $C_1 < |x| < C_2$, implying that $|x|^{\alpha-1} \to 1$ as $\alpha \to 1^-$. On the other hand, by Lemma 2.1, $O'_{\eta,i}(0) = 0$ for $i = 1, 2$. Since $k \to 0$ as $\alpha \to 1^-$, $C_1 < |x| < C_2$, we get $kx \to 0$ as $\alpha \to 1$. So, $O'_{\eta,i}(|kx|^\alpha)\alpha|x|^{\alpha-1} \to 0$ as $\alpha \to 1$. Thus $\partial_x g_\alpha(\mu,\nu,x) \to \partial_x g(\mu,\nu,x)$ as $\alpha \to 1^-$ in compact sets of $\mathbb{R}^2 \times (\mathbb{R} \setminus \{0\})$.

On the other hand, since $k = q(\alpha)$, we have $a^+ = k\mu$ and $a^- = k\nu$, see Note 2, and so

$$\partial_\mu g_\alpha(\mu,\nu,x) = \begin{cases} 1 + \nu^+ \partial_{a^+} C_\eta^+ k^\alpha |x|^\alpha + \partial_{a^+} \mathcal{O}_{\eta,1}(|kx|^\alpha), & x > 0, \\ -\nu^- \partial_{a^+} C_\eta^- k^\alpha |x|^\alpha + \partial_{a^+} \mathcal{O}_{\eta,2}(|kx|^\alpha), & x < 0, \end{cases} \tag{3.4}$$

$$\partial_\nu g_\alpha(\mu,\nu,x) = \begin{cases} \nu^+ \partial_{a^-} C_\eta^+ k^\alpha |x|^\alpha + \partial_{a^-} \mathcal{O}_{\eta,1}(|kx|^\alpha), & x > 0, \\ 1 - \nu^- \partial_{a^-} C_\eta^- k^\alpha |x|^\alpha + \partial_{a^-} \mathcal{O}_{\eta,2}(|kx|^\alpha), & x < 0. \end{cases} \tag{3.5}$$

As $C_\eta^\pm$ is C^1, we obtain that $|\partial_{a^+} C_\eta^\pm|$ is uniformly bounded on K. Since $k^{\alpha-1} \to B$ and $k \to 0$ as $\alpha \to 1^-$ we get $k^\alpha |x|^\alpha = k^{\alpha-1} k|x| \to 0$ as $\alpha \to 1^-$ on K. Moreover, $\mathcal{O}_{\eta,i}(0) = 0$ and so $\partial_{a^+} \mathcal{O}_{\eta,i}(|kx|^\alpha) \to 0$ as $\alpha \to 1^-$. Replacing these bounds on (3.4) and (3.5), respectively, we obtain that $\partial_\mu g_\alpha(\mu,\nu,x) \to \partial_\mu g(\mu,\nu,x)$ and $\partial_\nu g_\alpha(\mu,\nu,x) \to \partial_\nu g(\mu,\nu,x)$ for $(\mu,\nu,x) \in K$. This finishes the proof. □

Note 3. Observe that $|g'| = |C_{\eta_0}^\pm B|$. Since $|\nu^\pm C_{\eta_0}^\pm B| > 1$ we obtain that g is an expanding map. Figure 3.1 displays the possible graphics for the map g.

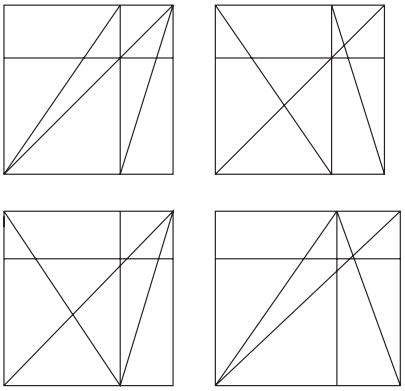

FIG. 3.1. *Possible* $g(\mu(1),\nu(1),.)$.

4. Trapping region. The main goal of this section is to prove Theorem 4.1, which asserts the existence of trapping regions for $g_\alpha(\mu,\nu,\cdot)$, for $\alpha \in O$ close to 1 and (μ,ν) close to $(\mu(\alpha),\nu(\alpha))$ (recall the notation in section 3). A trapping region for $g_\alpha(\mu,\nu,.)$ is a closed interval J such that $g_\alpha(\mu,\nu,J) \subset \mathrm{Int}(J)$, where $\mathrm{Int}(J)$ stands for the interior of J. To prove the existence of such a trapping region we define an auxiliary function $F_\alpha : \mathbb{R}^2 \to \mathbb{R}^2$, which will be used to find them. This function involves the critical and the fixed points of $g_\alpha(\mu,\nu,\cdot)$. We shall prove that F_α is locally one-to-one, i.e., $\det(DF_\alpha(\mu(\alpha),\nu(\alpha))) \neq 0$. Once we have that, the parameters corresponding to maps with trapping regions will be the ones in the inverse image $F_\alpha^{-1}(W_\alpha)$ for certain open set W_α to be defined below, proving Theorem 4.1.

THEOREM 4.1. *There is an open set* $\mathcal{O}^- \subset \mathbb{R}^3$ *such that the following properties hold:*

1. $(\alpha,\mu(\alpha),\nu(\alpha)) \in Cl(\mathcal{O}^-)$ *for all* $\alpha \in O$*;*
2. *if* $\theta = (\alpha,\mu,\nu) \in \mathcal{O}^-$*, then there is a closed interval* $I_\theta \subset \mathbb{R}$ *with* $0 \in \mathrm{Int}\,(I_\theta)$ *such that* $g_\alpha(\mu,\nu,x) \subset \mathrm{Int}\,(I_\theta)$ *for all* $x \in I_\theta$*.*

To prove the theorem we need some terminology. Let O be the set given in the last section. For $\alpha \in O$ let $\mu(\alpha) = \frac{a^+(\alpha)}{q(\alpha)}$, $\nu(\alpha) = \frac{a^-(\alpha)}{q(\alpha)}$, $x(\alpha) = \frac{p(\alpha)}{q(\alpha)}$, and $y(\alpha) = \frac{q(\alpha)}{q(\alpha)} = 1$. Fix $c > \max\{1, C^+_{\eta_0}/C^-_{\eta_0}\}$. Recall that Lemma 2.2 gives us $\lim_{\alpha\to 1} \frac{|p(\alpha|}{q(\alpha)} = \frac{C^+_{\eta_0}}{C^-_{\eta_0}}$. Again, by Lemma 2.2, we have that if $\nu^+ = \nu^- = 1$, then $a^+(\alpha) = p(\alpha)$, $a^-(\alpha) = q(\alpha)$ and so $\mu(\alpha) = \frac{p(\alpha)}{q(\alpha)}$, $\nu(\alpha) = 1$. Then $\lim_{\alpha\to 1} \mu(\alpha) = \lim_{\alpha\to 1} x(\alpha) = \frac{-C^+_{\eta_0}}{C^-_{\eta_0}}$. This implies that $(\mu(\alpha),\nu(\alpha),x(\alpha))$ and $(\mu(\alpha),\nu(\alpha),1)$ belong to $[-c,c]^2 \times ([-c,c] \setminus \{0\})$ and we conclude, by Lemma 3.3(a), that $(\mu(\alpha),\nu(\alpha),x(\alpha))$ and $(\mu(\alpha),\nu(\alpha),1) \in \mathrm{Dom}(g_\alpha)$ for all α close to 1.

In a similar way, for the remaining cases $\nu^+ = \nu^- = -1$, $\nu^+ = -\nu^- = 1$, and $\nu^+ = -\nu^- = -1$, we also obtain $(\mu(\alpha),\nu(\alpha),x(\alpha))$ and $(\mu(\alpha),\nu(\alpha),1) \in \mathrm{Dom}(g_\alpha)$ for all α close to 1.

From now on we assume that $\nu^+ = \nu^- = 1$. In this case

$$g_\alpha(\mu(\alpha),\nu(\alpha),x(\alpha)) = x(\alpha), \quad g_\alpha(\mu(\alpha),\nu(\alpha),1) = 1,$$

$$\partial_x g_\alpha(\mu(\alpha),\nu(\alpha),x(\alpha)) > 1, \quad \partial_x g_\alpha(\mu(\alpha),\nu(\alpha),1) > 1.$$

Next, set $x(\alpha,\mu,\nu)$ and $y(\alpha,\mu,\nu)$ for the C^1 continuations of $x(\alpha)$ and $y(\alpha)$ for (μ,ν) close to $(\mu(\alpha),\nu(\alpha))$ in the (μ,ν) parameter space, i.e., $g_\alpha(x(\alpha,\mu,\nu)) = x(\alpha,\mu,\nu)$

and $g_\alpha(y(\alpha,\mu,\nu)) = y(\alpha,\mu,\nu)$. Observe that $x(\alpha,\mu(\alpha),\nu(\alpha)) = x(\alpha)$ and $y(\alpha,\mu(\alpha),\nu(\alpha)) = y(\alpha) = 1$ for all $\alpha \in O$. As before, set $k = q(\alpha)$.

Define

$$F_\alpha(\mu,\nu) = (\mu - x(\alpha,\mu,\nu), \nu - y(\alpha,\mu,\nu)).$$

We shall prove the following theorem.

THEOREM 4.2. $\det DF_\alpha(u(\alpha),\nu(\alpha)) \neq 0$ *for all* $\alpha \in O$ *close to* 1.

Assuming Theorem 4.2, let us show how to obtain Theorem 4.1.

Observe that Theorem 4.2 implies that F_α is a local diffeomorphism in a neighborhood V_α of $(\mu(\alpha),\nu(\alpha))$ onto a neighborhood of $F_\alpha(\mu(\alpha),\nu(\alpha)) = (0,0)$. Let $W_\alpha = F_\alpha(V_\alpha) \cap A$ where $A = \{(x,y), x > 0, y < 0\}$.

Consider $\theta = (\alpha,\mu,\nu)$ such that $\alpha \in O$ and $(\mu,\nu) \in F_\alpha^{-1}(W_\alpha)$.

We claim that there is a closed interval I_θ satisfying (2) in Theorem 4.1. Indeed, we have the following inequalities:

$$x(\alpha,\mu,\nu) < \mu \quad \text{and} \quad \nu < y(\alpha,\mu,\nu), \text{ since } (\mu,\nu) \in F_\alpha^{-1}(W_\alpha). \tag{4.1}$$

Moreover, by (3.2),

$$\nu = g_\alpha(\mu,\nu,0^-) \quad \text{and} \quad \mu = g_\alpha(\mu,\nu,0^+).$$

Furthermore, since $\nu^+ = \nu^- = 1$, we have that

$$g_\alpha(\mu,\nu,.) \text{ is monotonic in } [x(\alpha,\mu,\nu),0) \text{ and in } (0,y(\alpha,\mu,\nu)], \tag{4.2}$$

and

$$\partial_x g_\alpha(\mu,\nu,\sigma) > 1, \quad \sigma \in \{x(\alpha,\mu,\nu), y(\alpha,\mu,\nu)\}. \tag{4.3}$$

Now, (4.1) and (4.3) imply that there is $\epsilon > 0$ (depending on μ and ν), small such that

$$\nu < y(\alpha,\mu,\nu) - \epsilon \quad \text{and} \quad g_\alpha(\mu,\nu,x(\alpha,\mu,\nu)+\epsilon) > x(\alpha,\mu,\nu) + \epsilon, \tag{4.4}$$

$$x(\alpha,\mu,\nu) + \epsilon < \mu \quad \text{and} \quad g_\alpha(\mu,\nu,y(\alpha,\mu,\nu)-\epsilon) < y(\alpha,\mu,\nu) - \epsilon. \tag{4.5}$$

Define $I_\theta^-(\epsilon) = [x(\alpha,\mu,\nu)+\epsilon, 0)$, $I_\theta^+(\epsilon) = (0, y(\alpha,\mu,\nu)-\epsilon]$, and $I_\theta(\epsilon) = I_\theta^- \cup I_\theta^+$.

On one hand, (4.4) together with (4.2) imply that $g_\alpha(\mu,\nu,I_\theta^-(\epsilon)) \subset \mathrm{Int}(I_\theta(\epsilon))$. On the other hand, (4.5) together with (4.2) imply $g_\alpha(\mu,\nu,I_\theta^+(\epsilon)) \subset \mathrm{Int}(I_\theta(\epsilon))$. Thus, $g_\alpha(\mu,\nu,I_\theta(\epsilon)) \subset \mathrm{Int}(I_\theta(\epsilon))$, proving the claim with $I_\theta = I_\theta(\epsilon)$.

The proof for the remaining cases is similar.

As the existence of a trapping region is an open condition, we conclude that there is $\delta_\theta > 0$ such that if $\|\zeta - \theta\| < \delta_\theta$, then $I_\zeta = I_\theta$ is such that $g_\alpha(I_\zeta) \subset \mathrm{Int}(I_\zeta)$.

Now define

$$\mathcal{O}_0^- = \{\theta = (\alpha,\mu,\nu); \alpha \in O,\ (\mu,\nu) \in F_\alpha^{-1}(W_\alpha)\}$$

and

$$\mathcal{O}^- = \cup_{\theta \in \mathcal{O}_0^-} B(\theta,\delta_\theta),$$

where $B(\theta,\delta_\theta)$ is the ball centered at θ with radius δ_θ. Clearly, $\mathcal{O}^-$ satisfies the required properties. This finishes the proof of Theorem 4.1. □

To prove Theorem 4.2 we shall use the following lemmas.

LEMMA 4.3.
(a) $\lim_{\alpha\to 1^-} \frac{q(\alpha)}{\alpha-1} = \lim_{\alpha\to 1^-} \frac{p(\alpha)}{\alpha-1} = 0.$
(b) $\lim_{\alpha\to 1^-} \frac{q(\alpha)^\alpha}{\alpha-1} = \lim_{\alpha\to 1^-} \frac{|p(\alpha)|^\alpha}{\alpha-1} = 0.$

Proof. (a) As part of the proof of the existence of $q(\alpha)$ and $p(\alpha)$, we obtain that

$$B-\varepsilon < q(\alpha)^{\alpha-1} < B+\varepsilon\,,$$

and from this it follows that

$$\frac{(B-\varepsilon)^{\frac{1}{\alpha-1}}}{|\alpha-1|} < \frac{q(\alpha)}{|\alpha-1|} < \frac{(B+\varepsilon)^{\frac{1}{\alpha-1}}}{|\alpha-1|}\,.$$

Now recall that $q(\alpha)$ and $p(\alpha)$ are defined for $\alpha < 1$. Moreover, since $B-\epsilon > 1$, we get

$$\lim_{\alpha\to 1^-} \frac{(B-\varepsilon)^{\frac{1}{\alpha-1}}}{|\alpha-1|} = \lim_{\alpha\to 1^-} \frac{(B+\varepsilon)^{\frac{1}{\alpha-1}}}{|\alpha-1|} = 0\,.$$

So $\lim_{\alpha\to 1^-} \frac{q(\alpha)}{|\alpha-1|} = 0\,.$

The same argument implies $\lim_{\alpha\to 1^-} \frac{p(\alpha)}{|\alpha-1|} = 0.$

(b) $\lim_{\alpha\to 1^-} \frac{q(\alpha)^\alpha}{|\alpha-1|} = \lim_{\alpha\to 1^-} \frac{q(\alpha)}{|\alpha-1|}\cdot q(\alpha)^{\alpha-1} = 0\cdot B = 0.$ □

LEMMA 4.4. *Set $\eta = \eta(\alpha, p(\alpha), q(\alpha))$. Then*

$$\lim_{\alpha\to 1^-} \frac{1}{\alpha-1}\left[C_\eta^+ C_\eta^- \cdot |p(\alpha)|^{\alpha-1}\cdot q(\alpha)^{\alpha-1} - C_\eta^-\ |p(\alpha)|^{\alpha-1} - C_\eta^+\ q(\alpha)^{\alpha-1}\right] = 0.$$

Proof. Equation (2.6) in Lemma 2.2 implies

$$q(\alpha)^{\alpha-1} = \frac{1+\sqrt[\alpha]{\frac{C_\eta^+ + \frac{O_{n,1}(q(\alpha)^\alpha)}{q(\alpha)^\alpha}}{C_\eta^- - \frac{O_{n,2}(|p(\alpha)|^\alpha)}{|p(\alpha)|^\alpha}}}}{C_\eta^+ + \frac{O_{n,1}(q(\alpha)^\alpha)}{q(\alpha)^\alpha}}.$$

In a similar way we obtain

$$|p(\alpha)|^{\alpha-1} = \frac{1+\sqrt[\alpha]{\frac{C_\eta^- - \frac{O_{n,2}(|p(\alpha)|^\alpha)}{|p(\alpha)|^\alpha}}{C_\eta^+ + \frac{O_{n,1}(q(\alpha)^\alpha)}{q(\alpha)^\alpha}}}}{C_\eta^- - \frac{O_{n,2}(|p(\alpha)|^\alpha)}{|p(\alpha)|^\alpha}}.$$

From these equalities it follows that

$$C_\eta^+ q(\alpha)^{\alpha-1} = 1 + \sqrt[\alpha]{\frac{C_\eta^+ + \frac{O_{n,1}(q(\alpha)^\alpha)}{q(\alpha)^\alpha}}{C_\eta^- - \frac{O_{n,2}(|p(\alpha)|^\alpha)}{|p(\alpha)|^\alpha}}} - \frac{O_{n,1}(q(\alpha)^\alpha)}{q(\alpha)}$$

and

$$C_\eta^- |p(\alpha)|^{\alpha-1} = 1 + \sqrt[\alpha]{\frac{C_\eta^- - \frac{O_{n,2}(|p(\alpha)|^\alpha)}{|p(\alpha)|^\alpha}}{C_\eta^+ + \frac{O_{n,1}(q(\alpha)^\alpha)}{q(\alpha)^\alpha}}} + \frac{O_{n,2}(|p(\alpha)|^\alpha)}{|p(\alpha)|}.$$

In this way we obtain that

$$
\begin{aligned}
(4.6)\qquad & C_\eta^+\, C_\eta^-\ |p(\alpha)|^{\alpha-1}\, q(\alpha)^{\alpha-1} - C_\eta^-\, |p(\alpha)|^{\alpha-1} - C_\eta^+ q(\alpha)^{\alpha-1} \\
&= -\sqrt[\alpha]{\frac{C_\eta^- - \frac{O_{n,2}(|p(\alpha)|^\alpha)}{|p(\alpha)|^\alpha}}{C_\eta^+ + \frac{O_{n,1}(q(\alpha)^\alpha)}{q(\alpha)^\alpha}}} \cdot \frac{O_{n,1}\left(q(\alpha)^\alpha\right)}{q(\alpha)} \\
&\quad + \sqrt[\alpha]{\frac{C_\eta^+ + \frac{O_{n,1}(q(\alpha)^\alpha)}{q(\alpha)^\alpha}}{C_\eta^- - \frac{O_{n,2}(|p(\alpha)|^\alpha)}{|p(\alpha)|^\alpha}}} \cdot \frac{O_{n,2}\left(|p(\alpha)|^\alpha\right)}{p(\alpha)} \\
&\quad - \frac{O_{n,1}\left(q(\alpha)^\alpha\right)}{q(\alpha)} \cdot \frac{O_{n,2}\left(|p(\alpha)|\right)^\alpha}{|p(\alpha)|}\,.
\end{aligned}
$$

But

$$
\left|\frac{O_{n,1}\left(q(\alpha)^\alpha\right)}{q(\alpha)}\right| = \left|O'_{n,1}(x)\right| \cdot q(\alpha)^{\alpha-1}\ C \cdot |x| \cdot q(\alpha)^{\alpha-1}\ ,
$$

where $0 < x < q(\alpha)^\alpha$ and C is a positive constant (mean value theorem).

Thus, by Lemma 4.3

$$
(4.7)\qquad \lim_{\alpha\to 1^-} \left|\frac{O_{n,1}\left(q(\alpha)^\alpha\right)}{(\alpha-1)\cdot q(\alpha)}\right| C \cdot \lim_{\alpha\to 1^-} \frac{q(\alpha)^\alpha}{\alpha-1} \cdot \lim_{\alpha\to 1} q(\alpha)^{\alpha-1} = 0\,.
$$

In the same way we obtain

$$
(4.8)\qquad \lim_{\alpha\to 1^-} \left|\frac{O_{n,2}\left(\left|p_{(\alpha)}\right|^\alpha\right)}{(\alpha-1)\cdot p(\alpha)}\right| = 0\,.
$$

In addition,

$$
\lim_{\alpha\to 1^-} \sqrt[\alpha]{\frac{C_\eta^- - \frac{O_{n,2}(|p(\alpha)|^\alpha)}{|p(\alpha)|^\alpha}}{C_\eta^+ + \frac{O_{n,1}(q(\alpha)^\alpha)}{q(\alpha)^\alpha}}} = \frac{C_{\eta_0}^-}{C_{\eta_0}^+}
$$

and

$$
\lim_{\alpha\to 1^-} \sqrt[\alpha]{\frac{C_\eta^+ + \frac{O_{n,1}(q(\alpha)^\alpha)}{q(\alpha)^\alpha}}{C_\eta^- - \frac{O_{n,2}(|p(\alpha)|^\alpha)}{|p(\alpha)|^\alpha}}} = \frac{C_{\eta_0}^+}{C_{\eta_0}^-}.
$$

Now, taking limit as $\alpha \to 1^-$ and replacing (4.7) and (4.8) in (4.6) we conclude the proof of Lemma 4.4. □

Now we prove Theorem 4.2. For this, recall that $x(\alpha,\mu,\nu)$ and $y(\alpha,\mu,\nu)$ are the continuations of $x(\alpha)$ and $y(\alpha)$ for (μ,ν) close to $(\mu(\alpha),\nu(\alpha))$ in the (μ,ν)-parameter space. Observe that $x(\alpha,\mu(\alpha),\nu(\alpha)) = x(\alpha)$ and $y(\alpha,\mu(\alpha),\nu(\alpha)) = y(\alpha)$.

Since $F_\alpha(\mu,\nu) = (\mu - x(\alpha,\mu,\nu), \nu - y(\alpha,\mu,\nu))$ we have that

$$
DF_\alpha(u(\alpha),\nu(\alpha)) = \begin{pmatrix} 1-\partial_\mu x(\alpha,\mu,\nu) & -\partial_\nu x(\alpha,\mu,\nu) \\ -\partial_\mu y(\alpha,\mu,\nu) & 1-\partial_\nu y(\alpha,\mu,\nu) \end{pmatrix}.
$$

So,

$$\begin{aligned}\det DF_\alpha\left(u\left(\alpha\right),\nu\left(\alpha\right)\right) = &\left(1-\partial_\mu x\left(\alpha,\mu\left(\alpha\right),\nu\left(\alpha\right)\right)\right)\cdot\left(1-\partial_\nu y\left(\alpha,\mu\left(\alpha\right),\nu\left(\alpha\right)\right)\right)\\ &-\partial_\mu y\left(\alpha,\mu\left(\alpha\right),\nu\left(\alpha\right)\right)\cdot\partial_\nu x\left(\alpha,\mu\left(\alpha\right),\nu\left(\alpha\right)\right).\end{aligned}$$

By definition $g_\alpha\left(\mu,\nu,x\left(\alpha,\mu,\nu\right)\right) = x\left(\alpha,\mu,\nu\right)$ and $g_\alpha\left(\mu,\nu,y\left(\alpha,\mu,\nu\right)\right) = y\left(\alpha,\mu,\nu\right)$. Then, by the implicit function theorem we get

$$\partial_\mu x\left(\alpha,\mu\left(\alpha\right),\nu\left(\alpha\right)\right) = \frac{\partial_\mu g_\alpha\left(u\left(\alpha\right),\nu\left(\alpha\right),x\left(\alpha\right)\right)}{1-\partial_x g_\alpha\left(\mu\left(\alpha\right),\nu\left(\alpha\right),x\left(\alpha\right)\right)},$$

$$\partial_\nu x\left(\alpha,\mu\left(\alpha\right),\nu\left(\alpha\right)\right) = \frac{\partial_\nu g_\alpha\left(u\left(\alpha\right),\nu\left(\alpha\right),x\left(\alpha\right)\right)}{1-\partial_x g_\alpha\left(\mu\left(\alpha\right),\nu\left(\alpha\right),x\left(\alpha\right)\right)},$$

$$\partial_\mu y\left(\alpha,\mu\left(\alpha\right),\nu\left(\alpha\right)\right) = \frac{\partial_\mu g_\alpha\left(u\left(\alpha\right),\nu\left(\alpha\right),y\left(\alpha\right)\right)}{1-\partial_x g_\alpha\left(\mu\left(\alpha\right),\nu\left(\alpha\right),y\left(\alpha\right)\right)},$$

$$\partial_\nu y\left(\alpha,\mu\left(\alpha\right),\nu\left(\alpha\right)\right) = \frac{\partial_\nu g_\alpha\left(u\left(\alpha\right),\nu\left(\alpha\right),y\left(\alpha\right)\right)}{1-\partial_x g_\alpha\left(\mu\left(\alpha\right),\nu\left(\alpha\right),y\left(\alpha\right)\right)}.$$

Thus,

$$\begin{aligned}&\det DF_\alpha\left(u\left(\alpha\right),\nu\left(\alpha\right)\right)\\ &= \frac{1-\partial_x g_\alpha\left(u\left(\alpha\right),\nu\left(\alpha\right),x\left(\alpha\right)\right)-\partial_\mu g_\alpha\left(u\left(\alpha\right),\nu\left(\alpha\right),x\left(\alpha\right)\right)}{1-\partial_x g_\alpha\left(u\left(\alpha\right),\nu\left(\alpha\right),x\left(\alpha\right)\right)}\\ &\quad\cdot\frac{\left(1-\partial_x g_\alpha\left(u\left(\alpha\right),\nu\left(\alpha\right),y\left(\alpha\right)\right)-\partial_\nu g_\alpha\left(u\left(\alpha\right),\nu\left(\alpha\right),y\left(\alpha\right)\right)\right)}{1-\partial_x g_\alpha\left(\mu\left(\alpha\right),\nu\left(\alpha\right),y\left(\alpha\right)\right)}\\ &\quad-\frac{\partial_\mu g_\alpha\left(u\left(\alpha\right),\nu\left(\alpha\right),y\left(\alpha\right)\right)}{1-\partial_x g_\alpha\left(u\left(\alpha\right),\nu\left(\alpha\right),x\left(\alpha\right)\right)}\cdot\frac{\partial_\nu g_\alpha\left(u\left(\alpha\right),\nu\left(\alpha\right),y\left(\alpha\right)\right)}{1-\partial_x g_\alpha\left(u\left(\alpha\right),\nu\left(\alpha\right),y\left(\alpha\right)\right)}.\end{aligned}$$

Now we will prove that

$$\lim_{\alpha\to 1^-}\frac{\det DF_\alpha\left(\mu(\alpha),\nu(\alpha)\right)}{\alpha-1} = 2+\frac{C^+_{\eta_0}}{C^-_{\eta_0}}+\frac{C^-_{\eta_0}}{C^+_{\eta_0}}.$$

In fact, note that

$$\begin{aligned}&\det DF_\alpha\left(u\left(\alpha\right),\nu\left(\alpha\right)\right)\\ &= \frac{E}{\left(1-\partial_x g_\alpha\left(u\left(\alpha\right),\nu\left(\alpha\right),x\left(\alpha\right)\right)\right)\left(1-\partial_x g_\alpha\left(u\left(\alpha\right),\nu\left(\alpha\right),y\left(\alpha\right)\right)\right)},\end{aligned}\tag{4.9}$$

where

$$\begin{aligned}E = &\left[1-\partial_x g_\alpha\left(u\left(\alpha\right),\nu\left(\alpha\right),y\left(\alpha\right)\right)-\partial_\mu g_\alpha\left(u\left(\alpha\right),\nu\left(\alpha\right),y\left(\alpha\right)\right)\right]\\ &\cdot\left[1-\partial_x g_\alpha\left(u\left(\alpha\right),\nu\left(\alpha\right),y\left(\alpha\right)\right)-\partial_\nu g_\alpha\left(\partial_x g_\alpha\left(u\left(\alpha\right),\nu\left(\alpha\right),y\left(\alpha\right)\right)\right)\right]\\ &-\partial_\mu g_\alpha\left(u\left(\alpha\right),\nu\left(\alpha\right),y\left(\alpha\right)\right)\cdot\partial_\nu g_\alpha\left(u\left(\alpha\right),\nu\left(\alpha\right),y\left(\alpha\right)\right).\end{aligned}$$

Using the definitions of g_α we obtain

$$\begin{aligned}E = &\Big[1-\alpha C_\eta^- k^{\alpha-1}\left|x\left(\alpha\right)\right|^{\alpha-1}+O_{n,2}^{'}\left(\left|kx\left(\alpha\right)\right|^{\alpha}\right)\left|kx\left(\alpha\right)\right|^{\alpha-1}\\ &+\partial_{a^+}\ C_\eta^-\ \left|kx\left(\alpha\right)\right|^{\alpha}-\partial_{a^+}O_{n,2}\left(\left|kx\left(\alpha\right)\right|^{\alpha}\right)\Big]\\ &\cdot\Big[1-\alpha C_\eta^+ k^{\alpha-1}y\left(\alpha\right)^{\alpha-1}-O_{n,1}^{'}\left(\left|ky\left(\alpha\right)\right|^{\alpha}\right)\left|ky\left(\alpha\right)\right|^{\alpha-1}\\ &-\partial_{a^-}C_\eta^-\left|ky\left(\alpha\right)\right|^{\alpha}-\partial_{a^-}O_{n,1}\left(\left|ky\left(\alpha\right)\right|^{\alpha}\right)\Big]\\ &-\left[1+\partial_{a^+}C_\eta^+\ \left|ky\left(\alpha\right)\right|^{\alpha}+\partial_{a^+}O_{n,1}\left(\left|ky\left(\alpha\right)\right|^{\alpha}\right)\right]\\ &\cdot\left[1-\partial_{a^-}C_\eta^-\left|kx\left(\alpha\right)\right|^{\alpha}+\partial_{a_-}\ O_{n,2}\left(\left|kx\left(\alpha\right)\right|^{\alpha}\right)\right]\ .\end{aligned}$$

Arranging terms we get

$$\begin{aligned}E = &\left[1-\alpha C_\eta^-\left|kx\left(\alpha\right)\right|^{\alpha-1}+A_1\ \left|kx\left(\alpha\right)\right|^{\alpha}\right]\cdot\left[1-\alpha C_\eta^+\left|ky\left(\alpha\right)\right|^{\alpha-1}+A_2\left|ky\left(\alpha\right)\right|^{\alpha}\right]\\ &-\left[1+\partial_{a^+}C_\eta^+\left|ky\left(\alpha\right)\right|^{\alpha-1}+A_3\right]\cdot\left[1-\partial_{a^-}C_\eta'\left|kx\left(\alpha\right)\right|^{\alpha}+A_4\right],\end{aligned}$$

where

$$\begin{aligned}A_1 &= \frac{O_{n,2}'\left(\left|kx\left(\alpha\right)\right|^{\alpha}\right)}{\left|kx\left(\alpha\right)\right|}+\partial_{a^+}C_\eta^- -\frac{\partial_{a^+}O_{n,2}\left(\left|kx\left(\alpha\right)\right|^{\alpha}\right)}{\left|kx\left(\alpha\right)\right|^{\alpha}},\\ A_2 &= -\frac{O_{n,1}'\left(\left|ky\left(\alpha\right)\right|^{\alpha}\right)}{\left|ky\left(\alpha\right)\right|}+\partial_{a-}C_\eta^+ -\frac{\partial_{a^+}O_{n,1}\left(\left|ky\left(\alpha\right)\right|^{\alpha}\right)}{\left|ky\left(\alpha\right)\right|^{\alpha}},\\ A_3 &= \partial_{a^+}\ O_{n,1}\left(\left|ky\left(\alpha\right)\right|^{\alpha}\right),\end{aligned}$$

and $A_4 = \partial_{a^-}\ O_{n,2}\left(\left|kx\left(\alpha\right)\right|^{\alpha}\right)$.

Note that $\lim_{\alpha\to 1^-}A_i$ exists and is a finite number for $1\le i\le 4$.

Recall that $k\,x\left(\alpha\right)=p\left(\alpha\right)$ and $k\,y\left(\alpha\right)=q\left(\alpha\right)$, then

$$\begin{aligned}E = &\left(1-\alpha C_\eta^-\left|p\left(\alpha\right)\right|^{\alpha-1}\right)\cdot\left(1-\alpha C_\eta^+ q\left(\alpha\right)^{\alpha-1}\right)\\ &+\left(1-\alpha C_\eta^-\left|p\left(\alpha\right)\right|^{\alpha-1}\right)A_2\ q\left(\alpha\right)^{\alpha}\\ &+\left(1-\alpha C_\eta^+ q\left(\alpha\right)^{\alpha-1}\right)A_1\ \left|p\left(\alpha\right)\right|^{\alpha}+A_1\ A_2\ q\left(\alpha\right)^{\alpha}\ \left|p\left(\alpha\right)\right|^{\alpha}\\ &-1\ -\ \partial_{a^+}C_\eta^+\ q\left(\alpha\right)^{\alpha}-\ A_3\ +\ \partial_{a^-}\ C_\eta^-\left|p\left(\alpha\right)\right|^{\alpha}-\partial_{a^+}C_\eta^+\ q\left(\alpha\right)^{\alpha}\ \partial_{a^-}C_\eta^-\left|p\left(\alpha\right)\right|^{\alpha}\\ &-A_3\ \partial_{a^-}C_\eta^-\left|p\left(\alpha\right)\right|^{\alpha}-A_4-\partial_{a^+}C_\eta^+\ q\left(\alpha\right)^{\alpha}\ A_4-A_3\ A_4.\end{aligned}$$

So,

$$\begin{aligned}E = &-\alpha\ C_\eta^-\left|p\left(\alpha\right)\right|^{\alpha-1}-\alpha\ C_\eta^+\ q\left(\alpha\right)^{\alpha-1}+\alpha^2\ C_\eta^-\ C_\eta^+\ \left|p\left(\alpha\right)\right|^{\alpha-1}\ q\left(\alpha\right)^{\alpha-1}\\ &+A_5\ q\left(\alpha\right)^{\alpha}+A_6\ \left|p\left(\alpha\right)\right|^{\alpha}+A_7\ q\left(\alpha\right)^{\alpha}\ \left|p\left(\alpha\right)\right|^{\alpha},\end{aligned}$$

where

$$\begin{aligned}A_5 &= \left(1-\alpha\ C_\eta^-\ \left|p\left(\alpha\right)\right|^{\alpha-1}\right)A_2-\partial_{a^+}\ C_\eta^+-\frac{A_3}{q\left(\alpha\right)^{\alpha}}-\partial_{a^+}\ C_\eta^+\ A_4,\\ A_6 &= \left(1-\alpha\ C_\eta^+\ q\left(\alpha\right)^{\alpha-1}\right)A_1+\partial_{a^-}\ C_\eta^- -A_3\ \partial_{a^-}\ C_\eta^- -\frac{A_4}{\left|p\left(\alpha\right)\right|^{\alpha}},\end{aligned}$$

and $A_7 = A_1\, A_2 - \partial_{a^+}\, C_\eta^+\, \partial_{a^-}\, C_\eta^- - \frac{A_3\, A_4}{q(\alpha)^\alpha\, |p(\alpha)|^\alpha}$.

Note that $\lim_{\alpha\to 1^-} A_i$ exists and is a finite number for $5 \le i \le 7$.

Thus,

$$\begin{aligned} E = {} & \left(\alpha^2 - \alpha\right)\left[C_\eta^-\ |p\,(\alpha)|^{\alpha-1} + C_\eta^+\ q\,(\alpha)^{\alpha-1}\right] \\ & + \alpha^2\left[C_\eta^+\ C_\eta^-\ |p\,(\alpha)|^{\alpha-1}\, q\,(\alpha)^{\alpha-1} - C_\eta^-\, |p\,(\alpha)|^{\alpha-1} - C_\eta^+ q\,(\alpha)^{\alpha-1}\right] \\ & + A_5\, q\,(\alpha)^\alpha + A_6\, |p\,(\alpha)|^\alpha + A_7\, q\,(\alpha)^\alpha\, |p\,(\alpha)|^\alpha\,. \end{aligned}$$

Now, taking limits and using Lemmas 4.3 and 4.4 we obtain that

$$\begin{aligned} \lim_{\alpha\to 1^-} \frac{E}{\alpha - 1} = {} & \lim_{\alpha\to 1} \alpha\left[C_\eta^-\ |p\,(\alpha)|^{\alpha-1} + C_\eta^+\ q\,(\alpha)^{\alpha-1}\right] \\ & + \lim_{\alpha\to 1^-} \frac{\alpha^2}{\alpha - 1}\left[C_\eta^+\ C_\eta^-\ |p\,(\alpha)|^{\alpha-1}\ q\,(\alpha)^{\alpha-1} - C_\eta^-\ |p\,(\alpha)|^{\alpha-1} + C_\eta^+\ q\,(\alpha)^{\alpha-1}\right] \\ & + \lim_{\alpha\to 1^-}\left[A_5\, \frac{q\,(\alpha)^\alpha}{\alpha - 1} + A_6\, \frac{|p\,(\alpha)|^\alpha}{\alpha - 1} + A_7\, \frac{q\,(\alpha)^\alpha}{\alpha - 1}\ |p\,(\alpha)|^\alpha\right] \\ & = C_{\eta_0}^-\, B + C_{\eta_0}^+\, B = 2 + \frac{C_{\eta_0}^+}{C_{\eta_0}^-} + \frac{C_{\eta_0}^-}{C_{\eta_0}^+}. \end{aligned}$$

To finish, we have that

$$\begin{aligned} & \lim_{\alpha\to 1^-} \left(1 - \partial_x g_\alpha\left(\mu\,(\alpha), \nu\,(\alpha), x\,(\alpha)\right)\right) \cdot \left(1 - \partial_x g_\alpha\left(\mu\,(\alpha), \nu\,(\alpha), y\,(\alpha)\right)\right) \\ & \qquad = \left(1 - C_{\eta_0}^- B\right)\left(1 - C_{\eta_0}^+ B\right) = 1\,. \end{aligned}$$

So, replacing this last equality in (4.9) we get

$$\lim_{\alpha\to 1^-} \frac{\det DF_\alpha\left(\mu_{(\alpha)}, \nu_{(\alpha)}\right)}{\alpha - 1} = 2 + \frac{C_{\eta_0}^+}{C_{\eta_0}^-} + \frac{C_{\eta_0}^-}{C_{\eta_0}^+}.$$

All of these facts together conclude the proof of Theorem 4.2. □

5. One-dimensional analysis. In this section we will prove that the trapping region obtained in the previous section is contained in the basin of a transitive attractor of $g_\alpha(\mu, \nu)$. Depending on the geometry of the original vector field we can obtain a different kind of such attractor. When $\nu^+ = \nu^- = 1$, the attractor is the interval $[\mu, \nu]$. If $\nu^+ = \nu^- = -1$ we have three alternatives: (1) the attractor is given by the interval $[\nu, g_\alpha(\mu, \nu, \mu)]$, (2) $[\nu, \mu]$, or (3) $[g_\alpha(\mu, \nu, \mu), \mu]$, depending on $\nu < g_\alpha(\mu, \nu, \mu) < \mu \le g_\alpha(\mu, \nu, \nu)$, $\nu < g_\alpha(\mu, \nu, \mu) < g_\alpha(\mu, \nu, \nu) < \mu$, or $g_\alpha(\mu, \nu, \mu) \le \nu < g_\alpha(\mu, \nu, \nu) < \mu$, respectively. For $\nu^+ = -\nu^- = 1$ we have two possibilities: (1) $[\mu, g_\alpha(\mu, \nu, \mu)]$ when $\mu \le \nu$ and (2) $[\nu, g_\alpha(\mu, \nu, \nu)]$ when $\nu < \mu$. In the same way, for $\nu^+ = -\nu^- = -1$, we have (1) $[g_\alpha(\mu, \nu, \mu), \nu]$ or (2) $[g_\alpha(\mu, \nu, \nu), \mu]$, when $\mu \le \nu$ or $\nu < \mu$, respectively (see Figure 5.1).

The proof below is similar to the one given in [Rob4, Theorem A] and we are including it here for completeness.

THEOREM 5.1. *Fix $\lambda > 1$ and let $n_0 \in \mathbb{N}$ be such that*

$$\frac{\lambda^{n_0}}{2} > 1.$$

Let $a < 0 < b$ and $f : [a, b]^* \to [a, b]$, $[a, b]^* = [a, b] \setminus \{0\}$ a map such that $f(0_-) = \mu$, $f(0_+) = \nu$. Assume also that the following conditions hold:

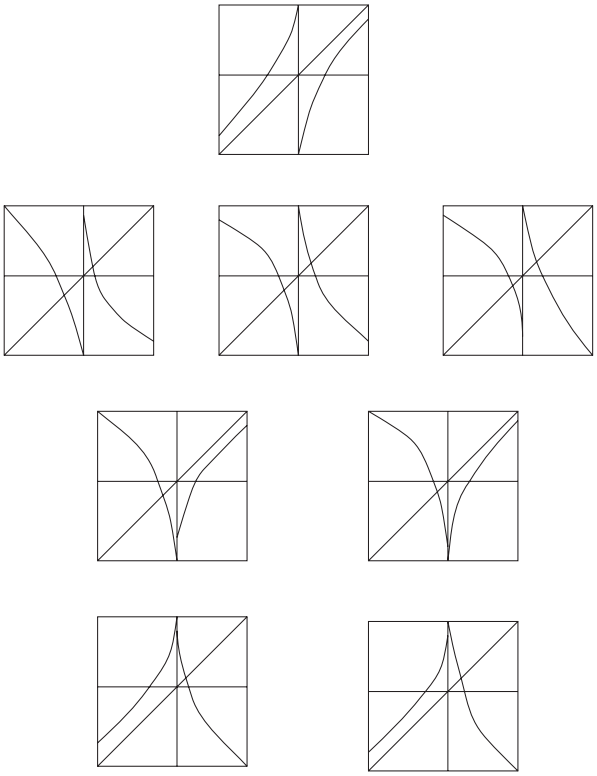

FIG. 5.1. *Possible attractors for* $g_\alpha(\mu,\nu,.)$.

(H0) $[a,b] = convexhull\{\mu,\nu,f(\mu),f(\nu)\}$,
(H1) f *has a single singularity at* $x=0$,
(H2) f *is differentiable in* $[a,b]^*$ *and* $|f'(x)| \geq \lambda$ *for all* $x \in [a,b]^*$,
(H3) *there are* $x<0<y$ *such that* $f(x)=f(y)=0$,
(H4) *there is* $\epsilon>0$ *such that if* $f(0_+)=\nu$ *and* $f(0_-)=\mu$, *then* $\{f^i(\mu), f^i(\nu), f^i(a), f^i(b) : 0 \leq i \leq n_0\} \subset [a,a+\epsilon] \cup [b-\epsilon,b]$ *for all* $1 \leq i \leq n_0$.

Then, for ϵ *sufficiently small* f *is transitive.*

Note 4. For $n_0=2$ this lemma reduces to a well-known result in [W].

Proof. First of all, hypothesis (H0) shows that $f([x,0))$ or $f((0,y])$ must contain $(a,0]$ or $[0,b)$. Now, fix and open interval $I \subset [a,b]$. We claim that one of the following alternatives hold:

(A) $f(I)$ is an interval and $|f(I)| \geq \lambda |I|$,
(B) there is $n \in \mathbb{N}$ such that $f^n(I)$ contains $(a,0]$ or $[0,b)$,
(C) there is an interval $J \subset f^{n_0}(I)$ such that $|J| > \frac{\lambda^{n_0}}{2}|I|$.

Indeed, if $0 \notin I$, then (A) holds. Thus, we can assume that $0 \in I$. Then $I^* = I \setminus \{0\}$ splits into $I^* = I^+ \cup I^-$ where $I^+ = I \cap (0,b]$ and $I^- = I \cap [a,0)$.

Let $\tilde{I} = I^+$ or I^- such that $|f(\tilde{I}| \geq \lambda/2\ |I|$.

We have either
(a) $f(\tilde{I}) \supset (a,0]$,
(b) $f(\tilde{I}) \supset [0,b)$,
(c) $f(\tilde{I}) = (x,\delta)$ with $0<x<\delta$ where $\delta \in \{\mu,\nu\}$, or
(d) $f(\tilde{I}) = (\delta,x)$ with $\delta<x<0$ where $\delta \in \{\mu,\nu\}$.

In cases (a) and (b) we have (B) for I with $n = 1$.

Assume case (c).

In this case we have two possibilities, namely,

(c1) there is $1 \leq i = i(I) < n_0$ such that i is the first iterate such that $0 \in f^i(f(\tilde{I}))$,

(c2) $0 \notin f^i(f(\tilde{I}))$ for all $1 \leq i \leq n_0$.

If (c2) holds, then

$$|f^{n_0}(\tilde{I})| = |f^{n_0-1}(f(\tilde{I}))| \geq \lambda^{n_0-1} \ |f(\tilde{I})| \geq \lambda^{n_0-1} \ \lambda/2 \ |I| \geq \lambda^{n_0}/2 \ |I|.$$

If (c1) holds, then $f^i(f(\tilde{I}))$ is an interval containing both 0 and $f^i(\delta)$.

As $f^i(f(\tilde{I}))$ is an interval we conclude that $f^i(f(\tilde{I}))$ contains an interval containing 0 and $f^i(\delta)$, and this implies that it contains one of the intervals $[x, 0]$ or $[0, y]$. From here, $f^{i+1}(f(\tilde{I}))$ contains both $[x, 0]$ and $[0, y]$. Hence,

$$f^{i+2}(f(\tilde{I})) = f(f^{i+1}(f(\tilde{I}))) \supset (a, 0]$$

or

$$f^{i+2}(f(\tilde{I})) = f(f^{i+1}(f(\tilde{I}))) \supset [0, b).$$

Thus, (B) holds with $n = i + 2$.

Finally, assume (d). The proof is similar to the previous case.

To finish the proof we proceed as follows.

First we claim that for all open intervals $I \subset [a, b]$ there is $N \in \mathbb{N}$ such that $f^N(I)$ contains either $(a, 0)$ or $(0, b)$.

The proof goes by contradiction. Assume that such an N does not exist. Then, either (A) or (C) holds.

Fix $I_1 = I$. Then there is $N_1 \in \mathbb{N}$ such that $f^{N_1}(I_1)$ contains an interval I_2 such that $|I_2| \geq \min\{\lambda, \frac{\lambda^{n_0}}{2}\} \ |I_1|$. Set $k = \min\{\lambda, \frac{\lambda^{n_0}}{2}\}$. Note that (B) is not true for I_2 (because $I_2 \subset f^{N_1}(I_2)$). Then, there is $N_2 \in \mathbb{N}$ such that $f^{N_2}(I_2)$ contains an interval I_3 such that $|I_3| \geq k \ |I_2| \geq k^2 \ |I_1|$.

In this way we construct a sequence of intervals $I_1, I_2, I_3, \ldots$ such that

$$|I_i| \geq k^i \ |I_1|.$$

This yields a contradiction since $k > 1$. This proves the claim.

Now we finish the proof arguing in the following way.

If $f^N(I) \supset (a, 0)$ or $f^N(I) \supset (0, b)$, then $f^N(I) \cup f^{N+1}(I) \supset (a, b)$. This implies that f is transitive and the theorem follows. □

Note 5. It is not difficult to prove, using (H4), that the map f in Theorem 5.1 is *leo* (locally eventually onto), i.e., for any interval $J \subset I$, there is $n \geq 1$ such that $f^n(J) = I$. Clearly a leo map is transitive.

Proof of Theorem 1.1. Let X_η satisfying (A1)–(A7), and f_η be the one-parameter family associated with X_η given by Lemma 2.1 in section 2. Recall that $\eta = \eta(\alpha, a^+, a^-)$. Next, as in section 3 we obtain $g_\alpha(\mu, \nu, x)$ which is a renormalization of f_η.

From now on we work with $g_\alpha(\mu, \nu, x)$.

By (A5), we can apply Theorem 4.1. Let $\mathcal{O}^- \subset \mathbb{R}^3$ be the open set given by Theorem 4.1. For each $\alpha \in O$ close enough to 1, where O is given by Lemma 2.2, consider $(\alpha, \mu(\alpha), \nu(\alpha))$, with $(\mu(\alpha), \nu(\alpha))$ defined at the beginning of section 3.

By the definition of $\mathcal{O}^-$ we have that $(\alpha, \mu(\alpha), \nu(\alpha)) \in \mathrm{Cl}(\mathcal{O}^-)$.

By Theorem 4.1(2) we have that for all $\theta \in \mathcal{O}^-$ there is I_θ such that $g_\alpha(\mu, \nu, I_\theta) \subset \mathrm{Int}(I_\theta)$. Set $\tilde{I}_\theta \subset I_\theta$ the $convexhull\{\mu, \nu, g_\alpha(\mu, \nu, \mu), g_\alpha(\mu, \nu, \nu)\}$. Taking (μ, ν) close to $(\mu(\alpha), \nu(\alpha))$, the map $g_\alpha(\mu, \nu, \cdot)$ satisfies the hypotheses of Theorem 5.1. Indeed, (H0) follows from the definition of $\tilde{I}_\theta$, (H1) is straightforward by the definition of g_α, and (H2), (H3), and (H4) follow from Lemma 3.3 for (μ, ν) close to $(\mu(\alpha), \nu(\alpha))$. Hence, the restriction of $g_\alpha(\mu, \nu, .)$ to $\tilde{I}_\theta$ is transitive, and thus we conclude that $g_\alpha(\mu, \nu, .)$ is transitive in $\tilde{I}_\theta$. All of these facts together conclude the proof of Theorem 1.1. □

TRAFFIC FLOW ON A ROAD NETWORK*

G. M. COCLITE†, M. GARAVELLO‡, AND B. PICCOLI§

Abstract. This paper is concerned with a fluidodynamic model for traffic flow. More precisely, we consider a single conservation law, deduced from the conservation of the number of cars, defined on a road network that is a collection of roads with junctions. The evolution problem is underdetermined at junctions; hence we choose to have some fixed rules for the distribution of traffic plus optimization criteria for the flux. We prove existence of solutions to the Cauchy problem and we show that the Lipschitz continuous dependence by initial data does not hold in general, but it does hold under special assumptions.

Our method is based on a wave front tracking approach [A. Bressan, *Hyperbolic Systems of Conservation Laws. The One-dimensional Cauchy Problem*, Oxford University Press, Oxford, UK, 2000] and works also for boundary data and time-dependent coefficients of traffic distribution at junctions, including traffic lights.

Key words. scalar conservation laws, traffic flow

1. Introduction.

This paper deals with a fluidodynamic model of heavy traffic on a road network. More precisely, we consider the conservation law formulation proposed by Lighthill and Whitham [14] and Richards [15]. This nonlinear framework is based simply on the conservation of cars and is described by the equation

$$\rho_t + f(\rho)_x = 0, \tag{1.1}$$

where $\rho = \rho(t,x) \in [0, \rho_{max}]$, $(t,x) \in \mathbb{R}_+ \times \mathbb{R}$, is the *density* of cars, $v = v(t,x)$ is the *velocity*, and $f(\rho) = v\,\rho$ is the *flux*. This model is appropriate for revealing shocks formation, as it is natural for conservation laws, whose solutions may develop discontinuities in finite time even for smooth initial data (see [5]). In most cases one assumes that v is a function of ρ only and that the corresponding flux is a concave function. We make this assumption; moreover, we let f have a unique maximum $\sigma \in]0, \rho_{max}[$ and for notational simplicity we assume $\rho_{max} = 1$.

Here we deal with a network of roads, as in [12]. This means that we have a finite number of roads modeled by intervals $[a_i, b_i]$ (with one of the two endpoints possibly infinite) that meet at some junctions. For endpoints that do not touch a junction (and are not infinite), we assume given boundary data and solve the corresponding boundary problem, as in [1, 2, 4]. The key role is played by junctions, at which the system is underdetermined even after prescribing the conservation of cars, that can

be written as the Rankine–Hugoniot relation

$$\sum_{i=1}^{n} f(\rho_i(t,b_i)) = \sum_{j=n+1}^{n+m} f(\rho_j(t,a_j)), \tag{1.2}$$

where ρ_i, $i = 1,\dots,n$, are the car densities on incoming roads, while ρ_j, $j = n+1,\dots,n+m$, are the car densities on outgoing roads. In [12], the Riemann problem, that is, the problem with constant initial data on each road, is solved maximizing a concave function of the fluxes, and existence of weak solutions for Cauchy problems with suitable initial data of bounded variation is proved. In this paper we assume the following:

(A) There are some prescribed preferences of drivers, that is, the traffic from incoming roads is distributed on outgoing roads according to fixed coefficients.

(B) Respecting (A), drivers choose so as to maximize fluxes.

To deal with rule (A), we fix a traffic distribution matrix

$$A \doteq \{\alpha_{ji}\}_{j=n+1,\dots,n+m,\ i=1,\dots,n} \in \mathbb{R}^{m\times n},$$

such that

$$0 < \alpha_{ji} < 1, \qquad \sum_{j=n+1}^{n+m} \alpha_{ji} = 1, \tag{1.3}$$

for each $i = 1,\dots,n$ and $j = n+1,\dots,n+m$, where α_{ji} is the percentage of drivers arriving from the ith incoming road who take the jth outgoing road. Notice that with only the rule (A) Riemann problems are still underdetermined. This choice represents a situation in which drivers have a final destination, and hence distribute on outgoing roads according to a fixed law but maximize the flux whenever possible. We are able to solve uniquely Riemann problems, under suitable conditions on the matrix A, and then to construct solutions to Cauchy problems for networks with simple junctions, i.e., junctions with two incoming roads and two outgoing ones. Our main technique is the use of a front tracking algorithm and the control of the total variation of the flux. We refer the reader to [5] for the general theory of conservation laws and for a discussion of wave front tracking algorithms.

The main difficulty in solving systems of conservation laws is the control of the total variation; see [5]. It is easy to see that for a single conservation law the total variation is decreasing; however, in our case it may increase due to interaction of waves with junctions.

There is a natural lack of symmetry for *big waves* (i.e., waves crossing the value σ; see Definition 5.8) and *bad data* (see Definition 5.8) at junctions, since the role of incoming roads is different from that of outgoing ones. Similarly, for scalar conservation laws with discontinuous coefficients, one has to use a definition of strength for discontinuities of the coefficient, seen as waves, that is not symmetric but depends on the sign of the jump in the solution; see [13, 16, 17]. This is enough to control the total variation in that case; on the contrary, our problem is more delicate. In fact, the variation can still increase due to interactions of waves with junctions (and there is no bound on the number of interactions and of the size of magnification; see Appendix B). The bounded quantity is the total variation of the flux. We prove this fact for junctions with only two incoming roads and two outgoing ones. Unfortunately the total variation of the flux is not equivalent to the total variation of ρ, since $f'(\sigma) = 0$,

and so it is not sufficient to prove existence of solutions. Therefore some compactness argument is used together with a bound of big waves near junctions.

Our techniques are quite flexible, so we can deal with time-dependent coefficients for rule (A). In particular, we can model traffic lights and, in this case, the control of total variation is extremely delicate. An arbitrarily small change in the coefficients can produce waves whose strength is bounded away from zero. Still, it is possible to consider periodic coefficients, a case of particular interest for applications. We can also deal with roads having different fluxes: these can be treated in the same way with the necessary notational modifications.

There is an interesting ongoing discussion on hydrodynamic models for heavy traffic flow. In particular, some models using systems of two conservation laws have been proposed; see [3, 8, 10, 11]. We do no treat this aspect.

The paper is organized as follows. In section 2 we give the definition of weak entropic solution and, following rules (A) and (B), we introduce an admissibility condition at junctions. In section 3 we prove the existence and uniqueness of admissible solutions for the Riemann problem in a junction, then using this we describe the construction of the approximants for the Cauchy problem (see section 4). In section 5 we prove the bound on the total variation of the flux and existence of admissible solutions for the Cauchy problem with suitable initial data. In section 6 we prove with a counterexample that the Lipschitz continuous dependence with respect to initial data does not hold in general, but we also show that this property holds under special assumptions. In section 7 we describe what happens when there are traffic lights and time-dependent coefficients. Appendix A contains an example of flux variation increase that does not occur for junctions with only two incoming and two outgoing roads. Finally, in Appendix B we show that the interaction of a small wave with a junction can produce a uniformly big wave.

2. Basic definitions. We consider a network of roads that is modeled by a finite collection of intervals $I_i = [a_i, b_i] \subset \mathbb{R}$, $i = 1, \dots, N$, $a_i < b_i$, possibly with either $a_i = -\infty$ or $b_i = +\infty$, on which we consider (1.1). Hence the data are given by a finite collection of functions ρ_i defined on $[0, +\infty[\times I_i$.

On each road I_i we want ρ_i to be a weak entropic solution, that is, for every function $\varphi : [0, +\infty[\times I_i \to \mathbb{R}$ smooth with compact support on $]0, +\infty[\times]a_i, b_i[$

$$\int_0^{+\infty} \int_{a_i}^{b_i} \Big(\rho_i \frac{\partial \varphi}{\partial t} + f(\rho_i) \frac{\partial \varphi}{\partial x} \Big) dx dt = 0, \tag{2.1}$$

and for every $k \in \mathbb{R}$ and every $\tilde{\varphi} : [0, +\infty[\times I_i \to \mathbb{R}$ smooth, positive with compact support on $]0, +\infty[\times]a_i, b_i[$

$$\int_0^{+\infty} \int_{a_i}^{b_i} \Big(|\rho_i - k| \frac{\partial \tilde{\varphi}}{\partial t} + \operatorname{sgn}\,(\rho_i - k)(f(\rho_i) - f(k)) \frac{\partial \tilde{\varphi}}{\partial x} \Big) dx dt \geq 0. \tag{2.2}$$

It is well known that, for (1.1) on $\mathbb{R}$ and for all initial data in L^∞, there exists a unique weak entropic solution depending in a continuous way on the initial data in L^1_{loc}.

We assume that the roads are connected by some junctions. Each junction J is given by a finite number of incoming roads and a finite number of outgoing roads; thus we identify J with $((i_1, \dots, i_n), (j_1, \dots, j_m))$, where the first n-tuple indicates the set of incoming roads and the second m-tuple indicates the set of outgoing roads.

We assume that each road can be an incoming road for at most one junction and outgoing for at most one junction.

Hence the complete model is given by a couple $(\mathcal{I}, \mathcal{J})$, where $\mathcal{I} = \{I_i : i = 1, \dots, N\}$ is the collection of roads and $\mathcal{J}$ is the collection of junctions.

Fix a junction J with incoming roads, say $I_1, \dots, I_n$, and outgoing roads, say $I_{n+1}, \dots, I_{n+m}$. A weak solution at J is a collection of functions $\rho_l : [0, +\infty[\times I_l \to \mathbb{R}$, $l = 1, \dots, n+m$, such that

$$\sum_{l=0}^{n+m} \left(\int_0^{+\infty} \int_{a_l}^{b_l} \left(\rho_l \frac{\partial \varphi_l}{\partial t} + f(\rho_l) \frac{\partial \varphi_l}{\partial x} \right) dx dt \right) = 0, \tag{2.3}$$

for every φ_l, $l = 1, \dots, n+m$ smooth having compact support in $]0, +\infty[\times]a_l, b_l]$ for $l = 1, \dots, n$ (incoming roads) and in $]0, +\infty[\times [a_l, b_l[$ for $l = n+1, \dots, n+m$ (outgoing roads) that are also *smooth across the junction*, i.e.,

$$\varphi_i(\cdot, b_i) = \varphi_j(\cdot, a_j), \qquad \frac{\partial \varphi_i}{\partial x}(\cdot, b_i) = \frac{\partial \varphi_j}{\partial x}(\cdot, a_j), \qquad i = 1, \dots, n,\ j = n+1, \dots, n+m.$$

Remark 1. Let $\rho = (\rho_1, \dots, \rho_{n+m})$ be a weak solution at the junction such that each $x \to \rho_i(t, x)$ has bounded variation. We can deduce that ρ satisfies the *Rankine–Hugoniot condition* at the junction J, namely,

$$\sum_{i=1}^{n} f(\rho_i(t, b_i-)) = \sum_{j=n+1}^{n+m} f(\rho_j(t, a_j+)), \tag{2.4}$$

for almost every $t > 0$.

Rules (A) and (B) can be given explicitly only for solutions with bounded variation, as in the next definition.

DEFINITION 2.1. *Let $\rho = (\rho_1, \dots, \rho_{n+m})$ be such that $\rho_i(t, \cdot)$ is of bounded variation for every $t \geq 0$. Then ρ is an admissible weak solution of* (1.1) *related to the matrix A, satisfying* (1.3), *at the junction J if and only if the following properties hold:*

(i) *ρ is a weak solution at the junction J;*
(ii) *$f(\rho_j(\cdot, a_j+)) = \sum_{i=1}^{n} \alpha_{ji} f(\rho_i(\cdot, b_i-))$, for each $j = n+1, \dots, n+m$;*
(iii) *$\sum_{i=1}^{n} f(\rho_i(\cdot, b_i-))$ is maximum subject to* (ii).

For every road $I_i = [a_i, b_i]$, if $a_i > -\infty$ and I_i is not the outgoing road of any junction, or $b_i < +\infty$ and I_i is not the incoming road of any junction, then boundary data $\psi_i : [0, +\infty[\to \mathbb{R}$ are given. In this case we ask ρ_i to satisfy $\rho_i(t, a_i) = \psi_i(t)$ (or $\rho_i(t, b_i) = \psi_i(t)$) in the sense of [4]. The treatment of boundary data in the sense of [4] can be done in the same way as in [1, 2]; thus we treat the case without boundary data. All the stated results hold also for the case with boundary data with obvious modifications.

Our aim is to solve the Cauchy problem on $[0, +\infty[$ for given initial and boundary data as in next definition.

DEFINITION 2.2. *Given $\bar{\rho}_i : I_i \to \mathbb{R}$, $i = 1, \dots, N$, L^∞ functions, a collection of functions $\rho = (\rho_1, \dots, \rho_N)$, with $\rho_i : [0, +\infty[\times I_i \to \mathbb{R}$ continuous as functions from $[0, +\infty[$ into L^1_{loc}, is an admissible solution if ρ_i is a weak entropic solution to* (1.1) *on I_i, $\rho_i(0, x) = \bar{\rho}_i(x)$ a.e., at each junction ρ is a weak solution and is an admissible weak solution in case of bounded variation.*

On the flux f we make the following assumption:

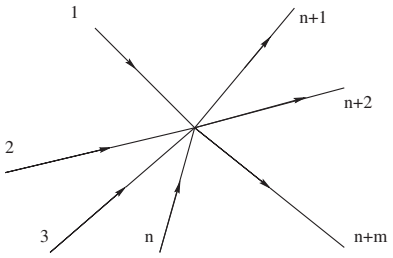

FIG. 1. *A junction.*

($\mathcal{F}$) $f : [0,1] \to \mathbb{R}$ is a smooth strictly concave function (i.e., $f'' \le -c < 0$ for some $c > 0$) such that $f(0) = f(1) = 0$. Therefore there exists a unique $\sigma \in]0,1[$ such that $f'(\sigma) = 0$ (that is, σ is a strict maximum).

3. The Riemann problem. In this section we study Riemann problems. For a scalar conservation law a Riemann problem is a Cauchy problem for initial data of Heaviside type, that is, piecewise constant with only one discontinuity. One looks for centered solutions, i.e., $\rho(t,x) = \phi(\frac{x}{t})$, which are the building blocks of solutions to the Cauchy problem via wave front tracking algorithm. These solutions are formed by continuous waves called rarefactions and by traveling discontinuities called shocks. The speeds of waves are related to the values of f'; see [5].

Analogously, we call the Riemann problem for a junction the Cauchy problem corresponding to an initial datum that is constant on each road. Then, for the whole network, since solutions on each road I_i can be constructed in the same way as for the scalar conservation law, it suffices to describe the solution at junctions. Because of finite propagation speed, it is enough to study the Riemann problem for a single junction.

Consider a junction J in which there are n roads with incoming traffic, m roads with outgoing traffic, and a traffic distribution matrix A. For simplicity we indicate by

$$(t,x) \in \mathbb{R}_+ \times I_i \mapsto \rho_i(t,x) \in [0,1], \quad i = 1, \dots, n, \tag{3.1}$$

the densities of the cars on the roads with incoming traffic and by

$$(t,x) \in \mathbb{R}_+ \times I_j \mapsto \rho_j(t,x) \in [0,1], \quad j = n+1, \dots, n+m \tag{3.2}$$

those on the roads with outgoing traffic; see Figure 1.

We need the following notation.

DEFINITION 3.1. *Let $\tau : [0,1] \to [0,1]$ be the map such that*

1. *$f(\tau(\rho)) = f(\rho)$ for every $\rho \in [0,1]$;*
2. *$\tau(\rho) \neq \rho$ for every $\rho \in [0,1] \setminus \{\sigma\}$.*

Clearly, τ is well defined and satisfies

$$0 \le \rho \le \sigma \Longleftrightarrow \sigma \le \tau(\rho) \le 1, \qquad \sigma \le \rho \le 1 \Longleftrightarrow 0 \le \tau(\rho) \le \sigma.$$

To state the main result of this section we need some assumption on the matrix A satisfied under generic conditions. Let $\{e_1, \dots, e_n\}$ be the canonical basis of $\mathbb{R}^n$ and, for every subset $V \subset \mathbb{R}^n$, indicate by $V^\perp$ its orthogonal. Define for every $i = 1, \dots, n$, $H_i = \{e_i\}^\perp$, i.e., the coordinate hyperplane orthogonal to e_i, and for

every $j = n+1, \dots, n+m$ let $\alpha_j = (\alpha_{j1}, \dots, \alpha_{jn}) \in \mathbb{R}^n$ and define $H_j = \{\alpha_j\}^\perp$. Let $\mathcal{K}$ be the set of indices $k = (k_1, \dots, k_\ell)$, $1 \le \ell \le n-1$, such that $0 \le k_1 < k_2 < \cdots < k_\ell \le n+m$, and for every $k \in \mathcal{K}$ set

$$H_k = \bigcap_{h=1}^{\ell} H_{k_h}.$$

Letting $\mathbf{1} = (1, \dots, 1) \in \mathbb{R}^n$, we assume

(C) for every $k \in \mathcal{K}$, $\mathbf{1} \notin H_k^\perp$.

Remark 2. Condition (C) is a technical condition, which allows us to have uniqueness in the maximization problem described in Theorem 3.2. From (C) we immediately derive $m \ge n$. Otherwise, since by definition, $\mathbf{1} = \sum_{j=n+1}^{n+m} \alpha_j$, we get $\mathbf{1} \in H_k^\perp$, where

$$H_k = \bigcap_{j=n+1}^{n+m} H_j.$$

Moreover if $n \ge 2$, then (C) implies that, for every $j \in \{n+1, \dots, n+m\}$ and for all distinct elements $i, i' \in \{1, \dots, n\}$, it holds that $\alpha_{ji} \ne \alpha_{ji'}$. Otherwise, without loss of generality, we may suppose that $\alpha_{n+1,1} = \alpha_{n+1,2}$. If we consider

$$H = \left(\bigcap_{2<j\le n} H_j \right) \bigcap H_{n+1},$$

then, by (C), there exists an element $(x_1, x_2, 0, \dots, 0) \in H$ such that $x_1 + x_2 \ne 0$ and $\alpha_{n+1,1}(x_1 + x_2) = 0$.

In the case of a simple junction J with two incoming roads and two outgoing ones, condition (C) is completely equivalent to the fact that, for every $j \in \{3, 4\}$, $\alpha_{j1} \ne \alpha_{j2}$.

Remark 3. Notice that the matrix A could have identical lines. For example the matrix

$$A = \begin{pmatrix} \frac{1}{3} & \frac{1}{4} & \frac{1}{5} \\ \frac{1}{3} & \frac{1}{4} & \frac{1}{5} \\ \frac{1}{3} & \frac{1}{2} & \frac{3}{5} \end{pmatrix}$$

satisfies condition (C).

THEOREM 3.2. *Consider a junction J, assume that the flux $f : [0,1] \to \mathbb{R}$ satisfies $(\mathcal{F})$, and that the matrix A satisfies condition* (C). *For every $\rho_{1,0}, \dots, \rho_{n+m,0} \in [0,1]$, there exists a unique admissible centered weak solution, in the sense of Definition* 2.1, *$\rho = (\rho_1, \dots, \rho_{n+m})$ of* (1.1) *at the junction J such that*

$$\rho_1(0, \cdot) \equiv \rho_{1,0}, \dots, \rho_{n+m}(0, \cdot) \equiv \rho_{n+m,0}.$$

Moreover, there exists a unique $(n+m)$-tuple $(\hat\rho_1, \dots, \hat\rho_{n+m}) \in [0,1]^{n+m}$ such that

$$\hat\rho_i \in \begin{cases} \{\rho_{i,0}\} \cup \,]\tau(\rho_{i,0}), 1] & \text{if } 0 \le \rho_{i,0} \le \sigma, \\ [\sigma, 1] & \text{if } \sigma \le \rho_{i,0} \le 1, \end{cases} \qquad i = 1, \dots, n, \tag{3.3}$$

and

$$\hat\rho_j \in \begin{cases} [0,\sigma] & \text{if } 0 \le \rho_{j,0} \le \sigma, \\ \{\rho_{j,0}\} \cup [0, \tau(\rho_{j,0})[& \text{if } \sigma \le \rho_{j,0} \le 1, \end{cases} \qquad j = n+1, \dots, n+m. \tag{3.4}$$

By fixed $i \in \{1, \dots, n\}$*, if* $\rho_{i,0} \le \hat\rho_i$*, we have*

$$\rho_i(t,x) = \begin{cases} \rho_{i,0} & \text{if } x < \frac{f(\hat\rho_i) - f(\rho_{i,0})}{\hat\rho_i - \rho_{i,0}} t + b_i,\ t \ge 0, \\ \hat\rho_i & \text{if } x > \frac{f(\hat\rho_i) - f(\rho_{i,0})}{\hat\rho_i - \rho_{i,0}} t + b_i,\ t \ge 0, \end{cases} \tag{3.5}$$

and, if $\hat\rho_i < \rho_{i,0}$*,*

$$\rho_i(t,x) = \begin{cases} \rho_{i,0} & \text{if } x \le f'(\rho_{i,0})t + b_i,\ t \ge 0, \\ \big(f'\big)^{-1}\big((x-b_i)/t\big) & \text{if } f'(\rho_{i,0})t + b_i \le x \le f'(\hat\rho_i)t + b_i,\ t \ge 0, \\ \hat\rho_i & \text{if } x > f'(\hat\rho_i)t + b_i,\ t \ge 0. \end{cases} \tag{3.6}$$

By fixed $j \in \{n+1, \dots, n+m\}$*, if* $\rho_{j,0} \le \hat\rho_j$*, we have*

$$\rho_j(t,x) = \begin{cases} \hat\rho_j & \text{if } x \le f'(\hat\rho_j)t + a_j,\ t \ge 0, \\ \big(f'\big)^{-1}\big((x-a_j)/t\big) & \text{if } f'(\hat\rho_j)t + a_j \le x \le f'(\rho_{j,0})t + a_j,\ t \ge 0, \\ \rho_{j,0} & \text{if } x > f'(\rho_{j,0})t + a_j,\ t \ge 0, \end{cases} \tag{3.7}$$

and, if $\hat\rho_j < \rho_{j,0}$*,*

$$\rho_j(t,x) = \begin{cases} \hat\rho_j & \text{if } x < \frac{f(\rho_{j,0}) - f(\hat\rho_j)}{\rho_{j,0} - \hat\rho_j} t + a_j,\ t \ge 0, \\ \rho_{j,0} & \text{if } x > \frac{f(\rho_{j,0}) - f(\hat\rho_j)}{\rho_{j,0} - \hat\rho_j} t + a_j,\ t \ge 0. \end{cases} \tag{3.8}$$

Proof. Define the map

$$E : (\gamma_1, \dots, \gamma_n) \in \mathbb{R}^n \longmapsto \sum_{i=1}^{n} \gamma_i$$

and the sets

$$\Omega_i \doteq \begin{cases} [0, f(\rho_{i,0})] & \text{if } 0 \le \rho_{i,0} \le \sigma, \\ [0, f(\sigma)] & \text{if } \sigma \le \rho_{i,0} \le 1, \end{cases} \qquad i = 1, \dots, n,$$

$$\Omega_j \doteq \begin{cases} [0, f(\sigma)] & \text{if } 0 \le \rho_{j,0} \le \sigma, \\ [0, f(\rho_{j,0})] & \text{if } \sigma \le \rho_{j,0} \le 1, \end{cases} \qquad j = n+1, \dots, n+m,$$

$$\Omega \doteq \Big\{ (\gamma_1, \dots, \gamma_n) \in \Omega_1 \times \cdots \times \Omega_n \big| A \cdot (\gamma_1, \dots, \gamma_n)^T \in \Omega_{n+1} \times \cdots \times \Omega_{n+m} \Big\}.$$

The set Ω is closed, convex, and not empty. Moreover, by (C), $\nabla E = \mathbf{1}$ is not orthogonal to any nontrivial subspace contained in a supporting hyperplane of Ω; hence there exists a unique vector $(\hat\gamma_1, \dots, \hat\gamma_n) \in \Omega$ such that

$$E(\hat\gamma_1, \dots, \hat\gamma_n) = \max_{(\gamma_1, \dots, \gamma_n) \in \Omega} E(\gamma_1, \dots, \gamma_n).$$

For every $i \in \{1, \dots, n\}$, we choose $\hat{\rho}_i \in [0,1]$ such that

$$f(\hat{\rho}_i) = \hat{\gamma}_i, \quad \hat{\rho}_i \in \begin{cases} \{\rho_{i,0}\} \cup]\tau(\rho_{i,0}), 1] & \text{if } 0 \le \rho_{i,0} \le \sigma, \\ [\sigma, 1] & \text{if } \sigma \le \rho_{i,0} \le 1. \end{cases}$$

By $(\mathcal{F})$, $\hat{\rho}_i$ exists and is unique. Let

$$\hat{\gamma}_j \doteq \sum_{i=1}^{n} \alpha_{ji} \hat{\gamma}_i, \qquad j = n+1, \dots, n+m,$$

and $\hat{\rho}_j \in [0,1]$ be such that

$$f(\hat{\rho}_j) = \hat{\gamma}_j, \quad \hat{\rho}_j \in \begin{cases} [0, \sigma] & \text{if } 0 \le \rho_{j,0} \le \sigma, \\ \{\rho_{j,0}\} \cup [0, \tau(\rho_{j,0})[& \text{if } \sigma \le \rho_{j,0} \le 1. \end{cases}$$

Since $(\hat{\gamma}_1, \dots, \hat{\gamma}_n) \in \Omega$, $\hat{\rho}_j$ exists and is unique for every $j \in \{n+1, \dots, n+m\}$. Solving the Riemann problem (see [5, Chap. 6]) on each road, the claim is proved. ∎

4. The wave front tracking algorithm. Once the solution to a Riemann problem is provided, we are able to construct piecewise constant approximations via a wave front tracking algorithm. The construction is very similar to that for scalar conservation laws (see [5]); hence we briefly describe it.

Let $\bar{\rho} = (\rho_1, \dots, \rho_N)$ be a piecewise constant map defined on the road network. We want to construct a weak solution of (1.1) with initial condition $\rho(0, \cdot) \equiv \bar{\rho}$. We begin by solving the Riemann problems on each road in correspondence to the jumps of $\bar{\rho}$ and the Riemann problems at junctions determined by the values of $\bar{\rho}$ (see Theorem 3.2). We split each rarefaction wave into a rarefaction fan formed by rarefaction shocks that are discontinuities traveling with the Rankine–Hugoniot speed. We always split rarefaction waves, inserting the value σ (if it is in the range of the rarefaction). Moreover, we let any rarefaction shock with endpoint σ have velocity zero.

When a wave interacts with another we simply solve the new Riemann problem. Instead, when a wave reaches a junction, we solve the Riemann problem at the junction. The number of waves may increase only for interactions of waves at junctions. Since the speeds of waves are bounded, there are finitely many waves on the network at each time $t \ge 0$. We call the obtained function *an approximate wave front tracking solution*. Given a general initial data, we approximate it by a sequence of piecewise constant functions and construct the corresponding approximate solutions. If they converge in L^1_{loc}, then the limit is a weak entropic solution on each road; see [5] for a proof.

5. Estimates on flux variation and existence of solutions. This section is devoted to the estimation of the total variation of the flux along an approximate wave front tracking solution and to the construction of solutions to the Cauchy problem. From now on, we assume that every junction has exactly two incoming roads and two outgoing ones. This hypothesis is crucial because, as shown in Appendix A, the presence of more complicated junctions causes additional increases in the total variation of the flux. The case where junctions have at most two incoming roads and at most two outgoing roads can be treated in the same way. So, for each junction J, the matrix A, defined in the introduction, takes the form

$$A = \begin{pmatrix} \alpha & \beta \\ 1-\alpha & 1-\beta \end{pmatrix}, \tag{5.1}$$

where $\alpha, \beta \in]0,1[$ and $\alpha \neq \beta$, so that (C) is satisfied.

From now on we fix an approximate wave front tracking solution ρ, defined on the road network.

DEFINITION 5.1. *For every road I_i, $i = 1, \dots, N$, we indicate by*

$$(\rho^\theta_-, \rho^\theta_+), \quad \theta \in \Theta = \Theta(\rho, t, i), \quad \Theta \text{ finite set},$$

the discontinuities on road I_i at time t, and by $x^\theta(t)$, $\lambda^\theta(t)$, $\theta \in \Theta$, respectively, their positions and velocities at time t. We also refer to the wave θ to indicate the discontinuity $(\rho^\theta_-, \rho^\theta_+)$.

For each discontinuity $(\rho^\theta_-, \rho^\theta_+)$ at time $\bar t$ on road I_i, we call $y^\theta(t)$, $t \in [\bar t, t_\theta]$, the trace of the wave so defined. We start with $y^\theta(\bar t) = x^\theta(\bar t)$ and we continue up to the first interaction with another wave or a junction. If at time $\tilde t$ an interaction with a wave or a junction occurs, then either a single new wave $(\rho^{\tilde\theta}_-, \rho^{\tilde\theta}_+)$ on road I_i is produced or no wave is produced. In the latter case we set $t_\theta = \tilde t$; otherwise we set $y^\theta(\tilde t) = x^{\tilde\theta}(\tilde t)$ and follow $x^{\tilde\theta}(t)$ for $t \geq t^{\tilde\theta}$ up to the next interaction, and so on.

We start by proving some technical lemmas.

LEMMA 5.2. *Fix a junction J and an incoming road I_i. Let θ be a wave on road I_i, originated at time $\bar t$ from J with a flux decrease, i.e., $x^\theta(\bar t) = b_i$, $\lambda^\theta(\bar t) < 0$, and $f(\rho^\theta_+) < f(\rho^\theta_-)$. Let y^θ be the traced wave and assume that there exists $\tilde t$, the first time y^θ interacts with J after $\bar t$. Then either y^θ interacts with another junction on $]\bar t, \tilde t[$ or, letting $\theta_1, \dots, \theta_l$ be the waves interacting with y^θ at times $t_m \in]\bar t, \tilde t[$, $m = 1, \dots, l$ $(t_1 < t_2 < \dots < t_l)$, we have*

$$\begin{aligned}&\left|f(\rho(\tilde t - \varepsilon, y^\theta(\tilde t - \varepsilon)+)) - f(\rho(\tilde t - \varepsilon, y^\theta(\tilde t - \varepsilon)-))\right| \\ &\leq \sum_{m=1}^{l} \left|f(\rho(t_m - \varepsilon, x^{\theta_m}(t_m - \varepsilon)+)) - f(\rho(t_m - \varepsilon, x^{\theta_m}(t_m - \varepsilon)-))\right| - \left|f(\rho^\theta_-) - f(\rho^\theta_+)\right|\end{aligned}$$

for $\varepsilon > 0$ small enough. This means that the initial flux variation along y^θ is canceled. The same conclusion holds for an outcoming road I_j.

Proof. Consider the wave $(\rho^\theta_-, \rho^\theta_+)$ as in the statement. Then it is a shock with negative velocity and $\rho^\theta_+ > \max\{\rho^\theta_-, \tau(\rho^\theta_-)\}$. If y^θ interacts with another junction, then there is nothing to prove. So, we assume that y^θ does not interact with another junction. At time t_1, the wave θ_1 interacts with y^θ. We analyze first the case of interaction from the left of y^θ. We have the following two possibilities:

1. $\rho^{\theta_1}_- \in [0, \tau(\rho^\theta_+)]$. In this case we have total cancellation of the flux variation and so
$$\left|f(\rho^\theta_+) - f(\rho^{\theta_1}_-)\right| = \left|f(\rho^{\theta_1}_-) - f(\rho^\theta_-)\right| - \left|f(\rho^\theta_-) - f(\rho^\theta_+)\right|.$$
Therefore the claim easily follows.
2. $\rho^{\theta_1}_- \in]\tau(\rho^\theta_+), \rho^\theta_+]$. In this case the wave y^θ after the time interaction t_1 is of the same type of y^θ before t_1, i.e.,
$$\max\{\rho(t_1, y^\theta(t_1)-), \tau(\rho(t_1, y^\theta(t_1)-))\} < \rho(t_1, y^\theta(t_1)+).$$

We consider now the case of interaction from the right of y^θ. It is clear that $\rho^{\theta_1}_+ \in]\rho^\theta_-, 1]$. If, moreover, $f(\rho^{\theta_1}_+) \geq f(\rho^\theta_-)$, then we have total cancellation of the flux and we conclude as before. If instead $f(\rho^{\theta_1}_+) < f(\rho^\theta_-)$, then the wave y^θ after the time t_1 is of the same type of y^θ before t_1.

We repeat this argument at each interaction time t_m. If at some t_m we have total cancellation of the flux, then we are done. Therefore we may suppose that at each t_m total cancellation of the flux does not occur. Since the type of the wave y^θ does not change, we have

$$\max\{\rho(\tilde{t}-\tilde{\varepsilon}, y^\theta(\tilde{t}-\tilde{\varepsilon})-), \tau(\rho(\tilde{t}-\tilde{\varepsilon}, y^\theta(\tilde{t}-\tilde{\varepsilon})-))\} < \rho(\tilde{t}-\tilde{\varepsilon}, y^\theta(\tilde{t}-\tilde{\varepsilon})+)$$

for $\tilde{\varepsilon} > 0$ small enough, and hence the speed $\lambda^\theta(\tilde{t}-\tilde{\varepsilon})$ is negative, which contradicts the fact that y^θ interacts with J at time $\tilde{t}$. □

LEMMA 5.3. *Fix a junction J and an incoming road I_i. Let θ be a wave on road I_i, originated at time $\bar{t}$ from J by a flux increase, i.e., $x^\theta(\bar{t}) = b_i$, $\lambda^\theta(\bar{t}) < 0$, and $f(\rho^\theta_+) > f(\rho^\theta_-)$. Let y^θ be the traced wave and assume that there exists $\tilde{t}$, the first time y^θ interacts with J after $\bar{t}$. Then y^θ interacts with other junctions in $]\bar{t}, \tilde{t}[$, or cancels the flux variation, or produces a flux decrease at J at $\tilde{t}$, i.e.,*

$$f(\rho(\tilde{t}-\varepsilon, y^\theta(\tilde{t}-\varepsilon)-)) < f(\rho(\tilde{t}-\varepsilon, y^\theta(\tilde{t}-\varepsilon)+)),$$

for $\varepsilon > 0$ small enough. The same holds for outgoing roads.

Proof. Since $\lambda^\theta(\bar{t}) < 0$ and $f(\rho^\theta_+) > f(\rho^\theta_-)$, then $\rho^\theta_- > \sigma$. Moreover, the wave $(\rho^\theta_-, \rho^\theta_+)$ is a rarefaction fan; hence $\sigma < \rho^\theta_+ < \rho^\theta_-$.

If an interaction on the right with a wave θ_1 occurs, then $\rho^{\theta_1}_+ \in]\rho^\theta_-, 1]$ and we have total cancellation of the flux variation. Therefore we may suppose that an interaction on the left with a wave θ_1 occurs. In this case we have two possibilities:

1. $\rho^{\theta_1}_- \in [0, \tau(\rho^\theta_+)[$;
2. $\rho^{\theta_1}_- \in [\tau(\rho^\theta_+), \rho^\theta_+[$.

In the latter case we have total cancellation of the flux variation and so we are done. In the first case, instead, the type of the wave changes, since

$$0 < \rho^{\theta_1}_- < \tau(\rho^\theta_+) \le \sigma \le \rho^\theta_+ < 1.$$

The speed of the wave y^θ after this interaction is positive and if there are no more interactions, then we have the claim since $f(\rho^{\theta_1}_-) < f(\rho^\theta_+)$. Thus we suppose that an interaction with a wave θ_2 occurs. If it is an interaction from the left, then the possibilities are as follows:

1. $\rho^{\theta_2}_- \in [0, \tau(\rho^\theta_+)[$. We do not have total cancellation of the flux variation, but the type of the wave does not change and the situation is identical to the previous one.
2. $\rho^{\theta_2}_- \in [\tau(\rho^\theta_+), \sigma[$. We have total cancellation of the flux variation and so we are done.

If it is an interaction from the right, then the possibilities are as follows:

1. $\rho^{\theta_2}_+ \in [\sigma, \tau(\rho^{\theta_1}_-)[$. We do not have total cancellation of the flux variation, but the type of the wave does not change.
2. $\rho^{\theta_2}_+ \in [\tau(\rho^{\theta_1}_-), 1]$. We have total cancellation of the flux variation and so we are done.

The conclusion now easily follows repeating this argument. If at each interaction we do not have total cancellation of the flux variation, then we necessarily have that

$$f(\rho(\tilde{t}-\varepsilon, y^\theta(\tilde{t}-\varepsilon)-)) < f(\rho(\tilde{t}-\varepsilon, y^\theta(\tilde{t}-\varepsilon)+))$$

for $\varepsilon > 0$ small enough, which concludes the proof. □

LEMMA 5.4. *Fix a junction J. If a wave interacts with the junction J from an incoming road at time $\bar t$, then*

$$\mathit{Tot.Var.}\big(f(\rho(\bar t+,\cdot))\big) = \mathit{Tot.Var.}\big(f(\rho(\bar t-,\cdot))\big). \tag{5.2}$$

Proof. For simplicity let us assume that I_1, I_2 are the incoming roads and I_3, I_4 are the outgoing ones. Let $(\rho_{1,0},\dots,\rho_{4,0})$ be an equilibrium configuration at the junction J. We assume that the wave is coming from the first road and that it is given by the values $(\rho_1,\rho_{1,0})$. Let us define the incoming flux

$$f^{in}(y) \doteq \begin{cases} f(y) & \text{if } 0 \le y \le \sigma, \\ f(\sigma) & \text{if } \sigma \le y \le 1, \end{cases} \tag{5.3}$$

and the outgoing flux

$$f^{out}(y) \doteq \begin{cases} f(\sigma) & \text{if } 0 \le y \le \sigma, \\ f(y) & \text{if } \sigma \le y \le 1. \end{cases} \tag{5.4}$$

Clearly, since the wave on the first road has positive velocity, we have

$$0 \le \rho_1 < \sigma. \tag{5.5}$$

Let $(\hat\rho_1,\dots,\hat\rho_4)$ be the solution of the Riemann problem in the junction J with initial data $(\rho_1,\rho_{2,0},\rho_{3,0},\rho_{4,0})$ (see Theorem 3.2). By definition, $\big(f(\rho_{1,0}),f(\rho_{2,0})\big)$ is the maximum point of the map E on the domain

$$\Omega_0 \doteq \Big\{(\gamma_1,\gamma_2) \in \Omega_{1,0}\times\Omega_{2,0}\big| A\cdot(\gamma_1,\gamma_2)^T \in \Omega_{3,0}\times\Omega_{4,0}\Big\},$$

and $\big(f(\hat\rho_1),f(\hat\rho_2)\big)$ is the maximum point of the map E on the domain

$$\hat\Omega \doteq \Big\{(\gamma_1,\gamma_2) \in \Omega_{1}\times\Omega_{2,0}\big| A\cdot(\gamma_1,\gamma_2)^T \in \Omega_{3,0}\times\Omega_{4,0}\Big\},$$

where

$$\Omega_{j,0} \doteq \begin{cases} [0,f^{in}(\rho_{j,0})] & \text{if } j=1,2, \\ [0,f^{out}(\rho_{j,0})] & \text{if } j=3,4, \end{cases}$$

and, by (5.5),

$$\Omega_1 \doteq [0,f^{in}(\rho_1)] = [0,f(\rho_1)].$$

It is also clear that

$$\big(f(\rho_{1,0}),f(\rho_{2,0})\big) \in \partial\Omega_0, \qquad \big(f(\hat\rho_1),f(\hat\rho_2)\big) \in \partial\hat\Omega.$$

For simplicity we use the notation (5.1).

We distinguish two cases. First we suppose that

$$f(\rho_1) < f(\rho_{1,0}) \tag{5.6}$$

(equality cannot happen in the previous equation because the wave would have velocity zero). Then $\hat\Omega \subset \Omega_0$ and

$$f(\hat\rho_1) \le f(\rho_1), \qquad f(\hat\rho_1)+f(\hat\rho_2) \le f(\rho_{1,0})+f(\rho_{2,0}). \tag{5.7}$$

We claim that

$$f(\rho_{2,0}) \le f(\hat\rho_2), \quad f(\hat\rho_3) \le f(\rho_{3,0}), \quad f(\hat\rho_4) \le f(\rho_{4,0}). \tag{5.8}$$

The points $\big(f(\rho_{1,0}), f(\rho_{2,0})\big)$, $\big(f(\hat\rho_1), f(\hat\rho_2)\big)$ are on the boundaries of Ω_0, $\hat\Omega$, respectively, where the function E attains the maximum; hence each one is at least on one of the curves

$$\alpha\gamma_1 + \beta\gamma_2 = f^{out}(\rho_{3,0}), \qquad (1-\alpha)\gamma_1 + (1-\beta)\gamma_2 = f^{out}(\rho_{4,0}), \qquad \gamma_2 = f^{in}(\rho_{2,0}).$$

Let us assume that the two points are on the same curve, with the other cases being similar:

$$\alpha\gamma_1 + \beta\gamma_2 = f^{out}(\rho_{3,0}). \tag{5.9}$$

Observe that the map E is increasing on the curve

$$\gamma_1 \mapsto \left(\gamma_1, \frac{f^{out}(\rho_{3,0})}{\beta} - \frac{\alpha}{\beta}\gamma_1\right);$$

otherwise we contradict the maximality of E at $\big(f(\rho_{1,0}), f(\rho_{2,0})\big)$. Thus $\alpha < \beta$, $\hat\rho_1 = \rho_1$, the first two inequalities in (5.8) hold, and

$$f(\hat\rho_1) = f(\rho_1), \qquad f(\hat\rho_2) > f(\rho_{2,0}), \qquad f(\hat\rho_3) = f(\rho_{3,0}) = f^{out}(\rho_{3,0}). \tag{5.10}$$

On the other hand, by (5.7), we have

$$\begin{aligned} f(\hat\rho_4) &= (1-\alpha)f(\hat\rho_1) + (1-\beta)f(\hat\rho_2) \\ &\le (1-\alpha)\big(f(\rho_{1,0}) + f(\rho_{2,0}) - f(\hat\rho_2)\big) + (1-\beta)f(\hat\rho_2) \\ &= (1-\alpha)\big(f(\rho_{1,0}) + f(\rho_{2,0})\big) + \big(\alpha-\beta\big)f(\hat\rho_2) \\ &\le (1-\alpha)\big(f(\rho_{1,0}) + f(\rho_{2,0})\big) + \big(\alpha-\beta\big)f(\rho_{2,0}) = f(\rho_{4,0}). \end{aligned}$$

Thus (5.8) holds. Using the Rankine–Hugoniot condition (2.4) at the junction J, and using (5.8) and (5.10), we get

$$\begin{aligned} &\text{Tot.Var.}\big(f(\rho(\bar t+,\cdot))\big) \\ &= |f(\hat\rho_1) - f(\rho_1)| + |f(\hat\rho_2) - f(\rho_{2,0})| + |f(\hat\rho_3) - f(\rho_{3,0})| + |f(\hat\rho_4) - f(\rho_{4,0})| \\ &= \big(f(\hat\rho_2) - f(\rho_{2,0})\big) + \big(f(\rho_{3,0}) - f(\hat\rho_3)\big) + \big(f(\rho_{4,0}) - f(\hat\rho_4)\big) \\ &= f(\rho_{1,0}) - f(\hat\rho_1) = f(\rho_{1,0}) - f(\rho_1) = \text{Tot.Var.}\big(f(\rho(\bar t-,\cdot))\big). \end{aligned}$$

Suppose now that

$$f(\rho_{1,0}) < f(\rho_1);$$

then $\rho_{1,0} < \rho_1 < \sigma$ and $\Omega_0 \subset \hat\Omega$. Assuming again that both maximum points of the function E are on the curve (5.9), we have

$$f(\hat\rho_1) = f(\rho_1), \quad f(\hat\rho_2) \le f(\rho_{2,0}), \quad f(\rho_{3,0}) = f(\hat\rho_3), \quad f(\rho_{4,0}) \le f(\hat\rho_4).$$

By the Rankine–Hugoniot condition at the junction J (see (2.4)), we have

$$\begin{aligned}&\text{Tot.Var.}\big(f(\rho(\bar{t}+,\cdot))\big)\\ &= |f(\hat{\rho}_1) - f(\rho_1)| + |f(\hat{\rho}_2) - f(\rho_{2,0})| + |f(\hat{\rho}_3) - f(\rho_{3,0})| + |f(\hat{\rho}_4) - f(\rho_{4,0})|\\ &= \big(f(\rho_{2,0}) - f(\hat{\rho}_2)\big) + \big(f(\hat{\rho}_3) - f(\rho_{3,0})\big) + \big(f(\hat{\rho}_4) - f(\rho_{4,0})\big)\\ &= f(\hat{\rho}_1) - f(\rho_{1,0}) = f(\rho_1) - f(\rho_{1,0}) = \text{Tot.Var.}\big(f(\rho(\bar{t}-,\cdot))\big).\end{aligned}$$

This concludes the proof. ∎

LEMMA 5.5. *Consider a network $(\mathcal{I},\mathcal{J})$. We have*

$$\textit{Tot. Var.}\big(f(\rho(0+,\cdot))\big) \le \textit{Tot. Var.}\big(f(\rho(0,\cdot))\big) + 2Rf(\sigma),$$

where R is the total number of roads of the network.

Proof. At time $t = 0$ we can have an instantaneous increase of the total variation of the flux due to the waves generated by the Riemann problems in the junctions. Clearly, this increase can be estimated by the maximum number of waves generated in the junctions ($\le 2R$) times the maximum variation of the flux on each road ($\le f(\sigma)$). ∎

We are now ready to prove the following.

LEMMA 5.6. *Consider a road network $(\mathcal{I},\mathcal{J})$. For some $K > 0$, we have*

$$\begin{aligned}\textit{Tot. Var.}\big(f(\rho(t+,\cdot))\big) &\le e^{Kt}\,\textit{Tot. Var.}\big(f(\rho(0+,\cdot))\big)\\ &\le e^{Kt}\big(\textit{Tot. Var.}\big(f(\rho(0,\cdot))\big) + 2Rf(\sigma)\big),\end{aligned}$$

for each $t \ge 0$.

Proof. Fix a junction J. Notice that there exists a constant C_J, depending on the coefficients of the matrix A at J, so that each interaction of a wave with J causes an increase in the flux variation by at most a factor of C_J. More precisely, if $\text{Tot.Var.}_f^{\pm}$ is the flux variation of waves before and after the interaction, then $\text{Tot.Var.}_f^{+} \le C_J \text{Tot.Var.}_f^{-}$.

Consider a wave θ interacting with the junction J. Then from Lemma 5.4 the flux variation can increase only if the wave is coming from an outgoing road. Let $\theta_1,\dots,\theta_4$ be the waves so produced. Thanks to Lemma 5.2, waves produced by a flux decrease cannot interact with the junction J without canceling the flux variation or reaching another junction. Moreover, by Lemma 5.3, every θ_i can return to junction J (without interacting with other junctions) only with a decrease of the flux. Now notice that a wave with decreasing flux interacting with J always produces a flux decrease on outgoing roads. Hence, waves θ_i may return to the junction only with decreasing flux, thus, by Lemma 5.2, producing other waves that cannot return to the junction, unless they cancel their flux variation or interact with other junctions. Finally, each wave flux variation can be magnified at most twice by a factor C_J interacting only with junction J and not with other junctions.

Now let δ be the minimum length of a road, i.e., $\delta = \min_{i\in\mathcal{I}}(b_i - a_i)$, and $\hat{\lambda}$ be the maximum speed of a wave, i.e., $\hat{\lambda} = \max\{f'(0), |f'(1)|\}$. Then each wave takes at least time $\delta/\hat{\lambda}$ to go from one junction to another.

Finally, recalling that the total variation of the flux may only decrease for interactions on roads, we get that a magnification of flux variation of a factor $C_{\mathcal{J}} = \max_{J\in\mathcal{J}} C_J^2$ may occur only once on each time interval of length $\delta/\hat{\lambda}$. We thus get

$$\begin{aligned}\text{Tot.Var.}\big(f(\rho(t+,\cdot))\big) &\le C_{\mathcal{J}}^{\frac{t\hat{\lambda}}{\delta}}\,\text{Tot.Var.}\big(f(\rho(0+,\cdot)\big)\\ &= e^{Kt}\text{Tot.Var.}\big(f(\rho(0+,\cdot))\big),\end{aligned}$$

where $K = \hat{\lambda}\log(C_{\mathcal{J}})/\delta$. ∎

DEFINITION 5.7. *Consider a road network $(\mathcal{I},\mathcal{J})$ and an approximate wave front tracking solution ρ. For every road I_i, we define two curves $Y_-^{i,\rho}(t)$, $Y_+^{i,\rho}(t)$, called* boundary of external flux (BEF)*, in the following way. We set the initial condition $Y_-^{i,\rho}(0) = a_i$, $Y_+^{i,\rho}(0) = b_i$ (if $a_i = -\infty$, then $Y_-^{i,\rho} \equiv -\infty$ and if $b_i = +\infty$, then $Y_+^{i,\rho} \equiv +\infty$). We let $Y_\pm^{i,\rho}(t)$ follow the generalized characteristic as defined in* [9]*, letting $Y_-^{i,\rho}(t) = a_i$ (resp., $Y_+^{i,\rho}(t) = b_i$) if the generalized characteristic reaches the boundary and $f'(\rho(t,a_i)) < 0$ (resp., $f'(\rho(t,b_i)) > 0$). (In this way $Y_\pm^{i,\rho}(t)$ may coincide with a_i or b_i for some time intervals.) Let $\bar{t}$ be the first time $\bar{t}$ such that $Y_-^{i,\rho}(\bar{t}) = Y_+^{i,\rho}(\bar{t})$ (possibly $\bar{t} = +\infty$); then we let $Y_\pm^{i,\rho}$ be defined on $[0,\bar{t}]$. Finally, we define the sets*

$$D_1^i(\rho) = \Big\{(t,x) : t \in [0,\bar{t}) : Y_-^{i,\rho}(t) \le x \le Y_+^{i,\rho}(t)\Big\}$$

and

$$D_2^i(\rho) = [0,+\infty) \times [a_i,b_i] \setminus D_1^i(\rho).$$

Clearly, $Y_\pm^i(t)$ bounds the set on which the data are not influenced by the other roads through the junctions.

DEFINITION 5.8. *Fix an approximate wave front tracking solution ρ, a road I_i, $i = 1,\dots,N$, and a junction J. A wave θ in I_i is said to be a big wave if*

$$sgn(\rho_-^\theta - \sigma)\cdot sgn(\rho_+^\theta - \sigma) \le 0,$$

where $sgn(0) = 0$.

We say that an incoming road I_i has a bad datum at J at time $t > 0$ if

$$\rho_i(t,b_i-) \in [0,\sigma[.$$

We say that an outgoing road I_j has a bad datum at J at time $t > 0$ if

$$\rho_j(t,a_j+) \in]\sigma,1].$$

LEMMA 5.9. *For every $t \ge 0$, there exist at most two big waves on*

$$\big\{x : (t,x) \in D_2^i(\rho)\big\} \subseteq [a_i,b_i].$$

Proof. A big wave can originate at time t on road I_i from J only if road I_i has a bad datum at J at time t. If this happens, then road I_i does not have a bad datum at J up to the time in which a big wave is absorbed from I_i. Then we reach the conclusion. ∎

THEOREM 5.10. *Fix a road network $(\mathcal{I},\mathcal{J})$. Given $C > 0$ and $T > 0$, there exists an admissible solution defined on $[0,T]$ for all initial data $\bar{\rho} \in \mathrm{cl}\{\rho : TV(\rho) \le C\}$, where* cl *indicates the closure in L^1_{loc}.*

Proof. We fix a sequence of initial data $\bar{\rho}_\nu$ piecewise constant such that $TV(\bar{\rho}_\nu) \le C$ for every $\nu \ge 0$ and $\bar{\rho}_\nu \to \bar{\rho}$ in L^1_{loc} as $\nu \to +\infty$. For each $\bar{\rho}_\nu$ we consider an approximate wave front tracking solution ρ_ν such that $\rho_\nu(0,x) = \bar{\rho}_\nu(x)$ and rarefactions are split in rarefaction shocks of size $\frac{1}{\nu}$.

For every road I_i, we notice that on $D_1^i(\rho_\nu)$, ρ_ν is not influenced by other roads and so the estimates of [5] hold. Since the curves $Y_\pm^{i,\rho_\nu}$ are uniformly Lipschitz continuous,

they converge, up to a subsequence, to a limit curve, and hence the regions $D_1^i(\rho_\nu)$ "converge" to a limit region D_1^i. Then $\rho_\nu \to \rho$ in L^1_{loc} on D_1^i with ρ an admissible solution to the Cauchy problem.

On $D_2^i := [0, +\infty[\times [a_i, b_i] \setminus D_1^i$, we have that, up to a subsequence, $\rho_\nu \rightharpoonup^* \rho$ weak* on L^1 and, using Theorem 2.4 of [5] and Lemma 5.6, $f(\rho_\nu) \to \bar{f}$ in L^1 for some $\bar{f}$. By Lemma 5.9, there are at most two big waves on D_2^i for every time, hence splitting the domain D_2^i in a finite number of pieces, where we can invert the function f, getting $\rho_\nu \to f^{-1}(\bar{f})$ in L^1. Together with $\rho_\nu \rightharpoonup^* \rho$ weak* on L^1, we conclude that $\rho_\nu \to \rho$ strongly in L^1.

The other requirements of the definition of admissible solution are clearly satisfied. □

6. Lipschitz continuous dependence: A counterexample and two special cases. In this section we assume that every junction has exactly two incoming roads and two outgoing ones and for every junction we follow the notation (5.1). We present a counterexample to the Lipschitz continuous dependence by initial data with respect to the L^1-norm. The continuous dependence by initial data with respect the L^1-norm remains an open problem. The counterexample is constructed using shifts of waves as in the spirit of [6, 7], to which we refer the reader for general theory.

We show that, for every $C > 0$, it is possible to choose two piecewise constant initial data, which are exactly the same except for a shift ξ of a discontinuity, such that the L^1-distance of the two corresponding solutions increases by the multiplicative factor C. Obviously, the L^1-distance of the initial data is finite and given by $|\xi\, \Delta\rho|$, where ξ is the shift and $\Delta\rho$ is the jump across the corresponding discontinuity. From now on, we consider a junction J, satisfying condition (C), with I_1, I_2 as incoming roads and I_3, I_4 as outgoing ones. Moreover, we suppose that the entries of the matrix A satisfy $\alpha < \beta$.

First we need some technical lemmas. The first one is well known; we report the proof for the reader's convenience.

LEMMA 6.1. *Let us consider in a road two waves, with speeds λ_1 and λ_2, respectively, that interact together at a certain time $\bar{t}$ producing a wave with speed λ_3. If the first wave is shifted by ξ_1 and the second wave by ξ_2, then the shift of the resulting wave is given by*

$$\xi_3 = \frac{\lambda_3 - \lambda_2}{\lambda_1 - \lambda_2}\xi_1 + \frac{\lambda_1 - \lambda_3}{\lambda_1 - \lambda_2}\xi_2. \tag{6.1}$$

Moreover, we have that

$$\Delta\rho_3\, \xi_3 = \Delta\rho_1\, \xi_1 + \Delta\rho_2\, \xi_2, \tag{6.2}$$

where $\Delta\rho_i$ are the signed strengths of the corresponding waves.

Proof. We suppose that ρ_l and ρ_m are the left and right values of the wave with speed λ_1 and ρ_m and ρ_r are the left and right values of the wave with speed λ_2; see Figure 2.

So $\Delta\rho_1 = \rho_m - \rho_l$, $\Delta\rho_2 = \rho_r - \rho_m$, and $\Delta\rho_3 = \rho_r - \rho_l$. The two wave fronts have, respectively,

$$x = \lambda_1 t + x_{1,0}, \qquad x = \lambda_2 t + x_{2,0},$$

where $x_{1,0}$ and $x_{2,0}$ are the initial positions of the wave fronts with speed λ_1 and λ_2,

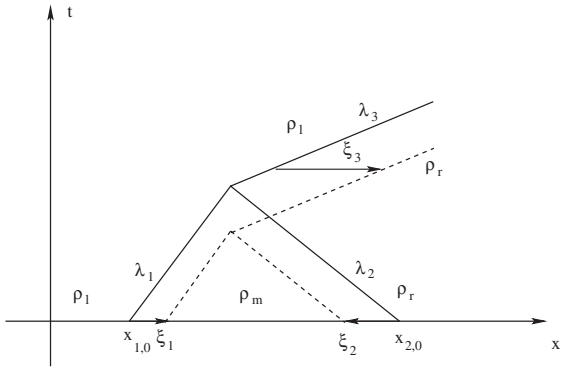

FIG. 2. *Shifts of waves.*

respectively. Therefore they interact at the point

$$(\bar{x},\bar{t}) = \left(\lambda_1 \frac{x_{1,0}-x_{2,0}}{\lambda_2-\lambda_1} + x_{1,0}, \frac{x_{1,0}-x_{2,0}}{\lambda_2-\lambda_1}\right).$$

If we consider the shifts, then the two wave fronts interact at the point

$$(\tilde{x},\tilde{t}) = \left(x_{1,0}+\xi_1+\lambda_1\frac{(x_{2,0}+\xi_2)-(x_{1,0}+\xi_1)}{\lambda_1-\lambda_2}, \frac{(x_{2,0}+\xi_2)-(x_{1,0}+\xi_1)}{\lambda_1-\lambda_2}\right),$$

and consequently (6.1) holds. Multiplying equation (6.1) by $\Delta\rho_3 = \Delta\rho_1 + \Delta\rho_2$, we easily deduce (6.2). ∎

LEMMA 6.2. *Let us consider a junction J with incoming roads I_1 and I_2 and outgoing roads I_3 and I_4. If a wave on a road I_i ($i \in \{1,\dots,4\}$) interacts with J without producing waves in the same road I_i and if ξ_i is the shift of the wave in I_i, then the shift ξ_j produced in a different road I_j ($j \in \{1,\dots,4\}\setminus\{i\}$) satisfies*

$$\xi_j\left(\rho_j^+ - \rho_j^-\right) = \frac{\Delta\gamma_j}{\Delta\gamma_i}\xi_i\left(\rho_i^+ - \rho_i^-\right), \tag{6.3}$$

where $\Delta\gamma_l$ ($l \in \{i,j\}$) represents the variation of the flux in the road I_l and ρ_l^-, ρ_l^+ ($l \in \{i,j\}$) are the states at J in the road I_l, respectively, before and after the interaction.

Proof. For simplicity let us consider the case $i = 1$ and $j = 3$, with the other cases being identical. Applying the shift ξ_1 to the wave (ρ_1^+, ρ_1^-), the interaction of the wave with J is shifted in time by

$$-\xi_1\frac{\rho_1^+-\rho_1^-}{f(\rho_1^+)-f(\rho_1^-)} = -\xi_1\frac{\rho_1^+-\rho_1^-}{\Delta\gamma_1}.$$

The shift in time in I_3 must be the same and so

$$\xi_1\frac{\rho_1^+-\rho_1^-}{\Delta\gamma_1} = \xi_3\frac{\rho_3^+-\rho_3^-}{\Delta\gamma_3},$$

which concludes the lemma. ∎

Remark 4. It is easy to understand that the coefficient of multiplication $\Delta\gamma_j/\Delta\gamma_i$ in the previous lemma depends by the entries of the matrix A. For example, under the same hypotheses of the previous lemma, if a wave in the I_1 road interacts with J producing a variation of the flux $\Delta\gamma_1$, and if no wave is produced in I_1 and I_2, then

$$\Delta\gamma_3 = \alpha\Delta\gamma_1, \qquad \Delta\gamma_4 = (1-\alpha)\Delta\gamma_1.$$

Consequently, in this case

$$\frac{\Delta\gamma_3}{\Delta\gamma_1} = \alpha, \quad \frac{\Delta\gamma_4}{\Delta\gamma_1} = 1-\alpha.$$

The following lemma is the first step needed to show that the Lipschitz dependence by initial data does not hold in our setting. More precisely, we show that there exists a simple configuration of waves and of shifts, which, after some interactions with J, produces an increase in the L^1-distance and takes a similar configuration.

LEMMA 6.3. *There exists an initial datum given by* $(\rho_{1,0}, \rho_{2,0}, \rho_{3,0}, \rho_{4,0})$ *that is an equilibrium configuration at* J*, a wave* $(\bar\rho_2, \rho_{2,0})$ *on road* I_2*, waves* $(\rho_{3,0}, \rho_3^*)$ *with shift* $\xi_{3,0}$*, and* $(\rho_3^*, \bar\rho_3)$ *on road* I_3 *such that the following occur in chronological order:*

1. *The initial distance in* L^1 *is* $\xi_{3,0}\,|\rho_{3,0} - \rho_3^*|$;
2. *the wave* $(\rho_{3,0}, \rho_3^*)$ *in* I_3 *with shift* $\xi_{3,0}$ *interacts with* J;
3. *waves are produced only in* I_2 *and* I_4;
4. *the wave on road* I_2 *interacts with* $(\bar\rho_2, \rho_{2,0})$ *producing a new wave*;
5. *the new wave from road* I_2 *interacts with* J;
6. *waves are produced only in* I_3 *and* I_4;
7. *in* I_4 *the* L^1*-distance after the interactions is equal to*

$$2\frac{1-\beta}{\beta}\,|\xi_{3,0}\,(\rho_3^* - \rho_{3,0})|\,,$$

and the L^1*-distance on road* I_3 *is equal to* $\xi_{3,0}\,|\rho_{3,0} - \rho_3^*|$.

Proof. Let $(\rho_{1,0}, \rho_{2,0}, \rho_{3,0}, \rho_{4,0})$ be an equilibrium configuration in J such that

$$0 < \rho_{1,0} < \sigma, \quad 0 < \rho_{2,0} < \sigma, \quad 0 < \rho_{3,0} < \sigma, \quad 0 < \rho_{4,0} < \sigma.$$

In road I_3, we consider a wave with negative speed $(\rho_{3,0}, \rho_3^*)$ with shift $\xi_{3,0}$. Since $(\rho_{3,0}, \rho_3^*)$ has negative speed, then $\rho_3^* > \tau(\rho_{3,0})$. Initially the L^1-distance of the two solutions is given by $|\xi_{3,0}(\rho_{3,0} - \rho_3^*)|$. When this wave interacts with J, new waves are produced in I_2 and I_4, which is possible, since $\alpha < \beta$. Therefore the new solution to the Riemann problem at J is given by

$$(\rho_{1,0}, \hat\rho_2, \hat\rho_3, \hat\rho_4)\,,$$

where $\tau(\rho_{2,0}) < \hat\rho_2 < 1$, $0 < \hat\rho_4 < \rho_{4,0}$. Moreover, some shifts $\hat\xi_2$ and $\hat\xi_4$ are produced in roads I_2 and I_4, respectively, where obviously $\hat\xi_2$ has the same sign of $\xi_{3,0}$ while $\hat\xi_4$ has opposite sign. By Lemma 6.2, we have

$$\begin{cases} \hat\xi_2(\hat\rho_2 - \rho_{2,0}) = \frac{1}{\beta}\xi_{3,0}(\rho_3^* - \rho_{3,0}), \\ \hat\xi_4(\hat\rho_4 - \rho_{4,0}) = \frac{1-\beta}{\beta}\xi_{3,0}(\rho_3^* - \rho_{3,0}). \end{cases}$$

If $0 < \bar\rho_2 < \tau(\hat\rho_2)$, then the wave $(\bar\rho_2, \rho_{2,0})$ in the road I_2 with shift $\bar\xi_2 = 0$ interacts with the wave $(\rho_{2,0}, \hat\rho_2)$ producing a wave $(\bar\rho_2, \hat\rho_2)$ with positive speed and with shift $\tilde\xi_2$. In this case,

$$\tilde\xi_2(\hat\rho_2 - \bar\rho_2) = \hat\xi_2(\hat\rho_2 - \rho_{2,0}) = \frac{1}{\beta}\xi_{3,0}(\rho_3^* - \rho_{3,0}).$$

Then, after the interaction of the wave $(\bar\rho_2, \hat\rho_2)$ with J, the new solution of the Riemann problem at J is given by

$$(\rho_{1,0}, \bar\rho_2, \hat\rho_3, \bar\rho_4)\,,$$

where $0 < \hat\rho_3 < \tau(\rho_3^*)$ and $0 < \bar\rho_4 < \hat\rho_4$. So in the roads I_3 and I_4 new shifts $\hat\xi_3$ and $\bar\xi_4$ are created, where

$$\begin{cases} \hat\xi_3(\rho_3^* - \hat\rho_3) = \beta\tilde\xi_2(\hat\rho_2 - \bar\rho_2) = \xi_{3,0}(\rho_3^* - \rho_{3,0}), \\ \bar\xi_4(\hat\rho_4 - \bar\rho_4) = (1-\beta)\tilde\xi_2(\hat\rho_2 - \bar\rho_2) = \frac{1-\beta}{\beta}\xi_{3,0}(\rho_3^* - \rho_{3,0}). \end{cases}$$

Now, if $\tau(\hat\rho_3) < \bar\rho_3 < 1$, then the wave $(\rho_3^*, \bar\rho_3)$ with shift $\bar\xi_3 = 0$ interacts in I_3 with the wave $(\hat\rho_3, \rho_3^*)$ producing a wave $(\hat\rho_3, \bar\rho_3)$ with negative speed and with shift $\tilde\xi_3$ such that

$$\tilde\xi_3(\bar\rho_3 - \hat\rho_3) = \hat\xi_3(\rho_3^* - \hat\rho_3) = \xi_{3,0}(\rho_3^* - \rho_{3,0}).$$

If the two waves on road I_4 do not interact, and this occurs when choosing appropriately the position of waves, then in the road I_4 the L^1-distance is

$$2\frac{1-\beta}{\beta}\left|\xi_{3,0}(\rho_3^* - \rho_{3,0})\right|,$$

and so the lemma is proved. □

Applying repeatedly Lemma 6.3, we produce a counterexample to the Lipschitz continuous dependence by initial data, as the next proposition shows.

PROPOSITION 6.4. *Let $C > 0$, J be a junction, and $(\rho_{1,0}, \dots, \rho_{4,0})$ be an equilibrium configuration as in Lemma* 6.3. *There exist two piecewise constant initial data satisfying the equilibrium configuration at J such that the L^1-distance between the corresponding two solutions increases by the multiplication factor C.*

Proof. Let n be big enough so that

$$\left(1 + 2n\frac{1-\beta}{\beta}\right) > C.$$

We want to define an initial data that provides the desired increase. We choose ρ_3^* and two finite sequences $(\bar\rho_2^i)$, $(\bar\rho_3^i)$, $i = 1, \dots, n$, so that, letting $\hat\rho_2^i$, $\hat\rho_3^i$ be the states determined as in Lemma 6.3, we have

$$\begin{cases} \rho_3^* \in\,]\tau(\rho_{3,0}), 1], \\ \bar\rho_2^i \in [0, \tau(\hat\rho_2^i)[, \qquad i = 1, \dots, n, \\ \bar\rho_3^i \in\,]\tau(\hat\rho_3^i), 1], \qquad i = 1, \dots, n. \end{cases}$$

It is easy to check that these sequences can be defined by induction.

The piecewise constant initial data in I_3 are given by

$$\begin{cases} \rho_{3,0} & \text{if } 0 < x < x^*, \\ \rho_3^* & \text{if } x^* < x < \hat{x}_1, \\ \hat{\rho}_3^1 & \text{if } \hat{x}_1 < x < \hat{x}_2, \\ \vdots & \dots \\ \bar{\rho}_3^n & \text{if } \tilde{x}_n < x, \end{cases}$$

where the values x^*, $\hat{x}_1, \dots, \hat{x}_n$ are to be determined in what follows. If $\xi_{3,0}$ denotes the shift of the wave $(\rho_{3,0}, \rho_3^*)$ and if no more shifts are present, then the L^1-distance of initial data are given by

$$|\xi_{3,0}| \, (\rho_3^* - \rho_{3,0}) \, .$$

The initial data on I_2 are

$$\begin{cases} \rho_{2,0} & \text{if } \tilde{x}_1 < x < 0, \\ \hat{\rho}_2^1 & \text{if } \tilde{x}_2 < x < \tilde{x}_1, \\ \vdots & \dots \\ \hat{\rho}_2^n & \text{if } x < \tilde{x}_n, \\ \vdots & \dots, \end{cases}$$

where $\tilde{x}_1, \dots, \tilde{x}_n$ are to be chosen appropriately.

The speed of the wave $(\rho_{3,0}, \rho_3^*)$ is given by the Rankine–Hugoniot condition

$$\frac{f(\rho_{3,0}) - f(\rho_3^*)}{\rho_{3,0} - \rho_3^*},$$

and consequently the time needed to go to junction J is

$$\bar{T} = -\frac{(\rho_{3,0} - \rho_3^*) \, x^*}{f(\rho_{3,0}) - f(\rho_3^*)}.$$

Clearly we adjust $\bar{T}$, choosing x^*. Applying n times Lemma 6.3 and adjusting the interaction times by choosing appropriately $\bar{x}_i$, $\tilde{x}_i$, $i \in \{1, \dots, n\}$, we can create $2n$ waves on road I_4 that do not interact together before the end of these n cycles and so we deduce that, at the end, the L^1-distance of the two solutions is given by

$$\left(1 + 2n \frac{1-\beta}{\beta}\right) |\xi_{3,0}(\rho_3^* - \rho_{3,0})| \, ,$$

which concludes the proof. □

Remark 5. The process described in the proof of Proposition 6.4 cannot be infinitely repeated. In fact, the sequences $\bar{\rho}_2^i$, $\bar{\rho}_3^i$ are monotonic and so $\bar{\rho}_3^{i+1} - \bar{\rho}_3^i \sim \frac{\bar{\rho}_3^1}{n}$ as n goes to infinity. Then the corresponding shifts on I_3 tend to infinity, letting waves interact with each other on road I_4. Therefore, with this method, it is not possible to produce a blow-up of the L^1-distance in finite time.

In some special cases the Lipschitz continuous dependence holds, as we show in the next subsections.

6.1. Network with only one junction. We consider a road network with only one junction J and with I_1, I_2 incoming roads and I_3, I_4 outgoing roads. We define

$$\mathcal{D} := \left\{ \bar\rho = (\bar\rho_1, \dots, \bar\rho_4) \in L^\infty(I_1 \times \cdots \times I_4) \cap L^1(I_1 \times \cdots \times I_4) : \bar\rho_j \in [0, \sigma], j = 3, 4 \right\}.$$

The following theorem holds.

THEOREM 6.5. *There exists a Lipschitz continuous semigroup $S : [0, +\infty[\times \mathcal{D} \to \mathcal{D}$ so that, for every $\bar\rho \in \mathcal{D}$, $\rho(t, x) = S(t, \bar\rho)(x)$ is an admissible solution with $\rho(0, x) = \bar\rho(x)$.*

Before proving the theorem, we consider the following lemma.

LEMMA 6.6. *Let $T > 0$ and let $\rho, \tilde\rho$ be two approximate wave front tracking solutions (AWFTS) connected by shifts such that $\rho(0, \cdot) \in \mathcal{D}$ and $\tilde\rho(0, \cdot) \in \mathcal{D}$. Then, for every $t \in [0, T]$, we have*

$$\|\rho(t, \cdot) - \tilde\rho(t, \cdot)\|_{L^1} = \sum_{\theta \in \Theta(t)} \left|\xi^\theta \Delta\rho^\theta\right| = \|\rho(0, \cdot) - \tilde\rho(0, \cdot)\|_{L^1},$$

where $\Theta(t)$ denotes the set of the jumps $\Delta\rho^\theta$ of $\rho(t, \cdot)$ with shifts ξ^θ.

Proof. We note first that $\mathcal{D}$ is invariant with respect to approximate wave front tracking solutions. Since $\rho_j \in [0, \sigma]$ for every $j \in \{3, 4\}$, each wave on I_3 and I_4 has positive speed and so shifts on outgoing roads cannot propagate themselves on other roads. The conclusion easily follows from Lemmas 6.2 and 5.4. ∎

Proof of Theorem 6.5. For every $T > 0$, by Theorem 5.10, a solution exists for every initial data in $\mathcal{D}$. By fixed $\rho, \tilde\rho \in \mathcal{D}$, we denote by $\rho_\nu, \tilde\rho_\nu$ two approximate wave front tracking solutions. As in [5, 6], to control the norm $\|\rho_\nu(t, \cdot) - \tilde\rho_\nu(t, \cdot)\|_{L^1}$, $t \in [0, T]$, it is enough to control the lengths of the shifts. Therefore, by Lemma 6.6, we obtain

$$\|\rho_\nu(t, \cdot) - \tilde\rho_\nu(t, \cdot)\|_{L^1} \le \|\rho_\nu(0, \cdot) - \tilde\rho_\nu(0, \cdot)\|_{L^1}$$

for every $t \in [0, T]$. Passing to the limit in the last expression, we finish the proof. ∎

6.2. Finite number of big waves, bad data, and interactions. Here we want to show a more general result about the Lipschitz continuity with respect to initial data. We omit the proof of this result, since it can be done with the same techniques as in the last subsection.

Let us consider a road network $(\mathcal{I}, \mathcal{J})$.

DEFINITION 6.7. *Let us fix an approximate wave front tracking solution ρ. For every junction J and for every incoming road I_i, the function $b_\rho(J, i, \cdot)$ is defined on $[0, T]$ by*

$$b_\rho(J, i, t) = \begin{cases} 0 & \text{if } \rho_i(t, b_i-) \in [\sigma, 1], \\ 1 & \text{if } \rho_i(t, b_i-) \in [0, \sigma[. \end{cases}$$

If ρ_ν is a sequence of AWFTS, then we say that the sequence ρ_ν has the property (H) if the following hold:

H1. There exists $M \in \mathbb{N}$ such that the function $b_{\rho_\nu}(J, i, \cdot)$ has at most M discontinuities for every $J \in \mathcal{J}$, for every $i \in \{1, \dots, N\}$, and for every $\nu \ge 0$.

H2. There exists $\delta > 0$ such that

$$|\rho_\nu(t, a_i+) - \sigma| > \delta$$

and

$$|\rho_\nu(t,b_i-)-\sigma|>\delta$$

for every $J\in\mathcal{J}$, for every $i\in\{1,\dots,N\}$, for every $\nu\geq 0$, and for every $t\in[0,T]$.

The following proposition holds.

PROPOSITION 6.8. *By fixed $T>0$, we consider a solution ρ defined on $[0,T]$ such that, for every $t\in[0,T]$, $\rho(t,\cdot)$ is a bounded variation function. Given $\eta>0$, $\delta>0$, and $M\in\mathbb{N}$, we define*

$$\begin{aligned}\mathcal{D}_\rho^\eta(\delta,M):=\{\bar\rho\in L^1_{loc}:\ &\exists(\rho_\nu)_{\nu\in\mathbb{N}}\ \textit{sequence of AWFTS satisfying (H)}\\ &\textit{with parameters } \delta \textit{ and } M,\\ &\rho_\nu(0,\cdot)\to\bar\rho(\cdot)\ \textit{in } L^1_{loc},\ \textit{Tot.Var.}(\rho_\nu(0,\cdot)-\rho(0,\cdot))<\eta\}.\end{aligned}$$

If there exist $0<\eta'<\eta$, $\delta>0$ and $M\in\mathbb{N}$ such that

$$\mathcal{D}:=\operatorname{cl}\{\tilde\rho:Tot.Var.(\rho-\tilde\rho)<\eta'\}\subseteq\mathcal{D}_\rho^\eta(\delta,M),$$

then there exists a Lipschitz continuous semigroup S of solutions defined on $[0,T]\times\mathcal{D}$.

Remark 6. We expect the existence of η,η',δ,M, as in Proposition 6.8, if we have $\eta<\delta$ and if we assume that big waves of ρ have velocity bounded away from zero.

7. Time-dependent traffic. In this section we consider a model of traffic including traffic lights and time-dependent traffic. The latter means that the choice of drivers at junctions may depend on the period of the day; for instance, during the morning the traffic flows toward some specific parts of the network and during the evening it may flow back. This means that the matrix A may depend on time t.

Consider a single junction J as in section 3 with two incoming roads I_1, I_2 and two outgoing ones I_3 and I_4. Let $\alpha=\alpha(t)$, $\beta=\beta(t)$ be two piecewise constant functions such that

$$0<\alpha(t)<1,\qquad 0<\beta(t)<1,\qquad \alpha(t)\neq\beta(t) \tag{7.1}$$

for each $t\geq 0$. Moreover, let $\chi_1=\chi_1(t),\chi_2=\chi_2(t)$ be piecewise constant maps such that

$$\chi_1(t)+\chi_2(t)=1,\qquad \chi_i(t)\in\{0,1\},\qquad i=1,2,$$

for each $t\geq 0$. The two maps represent traffic lights, with the value 0 corresponding to the red light and the value 1 to the green light.

DEFINITION 7.1. *Consider $\rho=\big(\rho_1,\dots,\rho_4\big)$ with bounded variation. We say that ρ is a solution at junction J if it satisfies* (i), (iii) *of Definition* 2.1 *and if the following property holds:*

(iv) $f(\rho_3(t,a_3+))=\alpha(t)\chi_1(t)f(\rho_1(t,b_1-))+\beta(t)\chi_2(t)f(\rho_2(t,b_2-))$ *and* $f(\rho_4(t,a_4+))=\big(1-\alpha(t)\big)\chi_1(t)f(\rho_1(t,b_1+))+\big(1-\beta(t)\big)\chi_2(t)f(\rho_2(t,b_2+))$ *for each $t>0$.*

The construction of the solution can be done as in section 5. However, the total variation of $f(\rho)$ does not depend continuously on the total variation of the maps $\alpha(\cdot)$, $\beta(\cdot)$. Indeed, let us suppose that there are no traffic lights, i.e., $\chi_i\equiv 1$, and let

$$\alpha(t)=\begin{cases}\eta_1 & \text{if } 0\leq t\leq\bar t,\\ \eta_2 & \text{if } \bar t\leq t\leq T,\end{cases}\qquad \beta(t)=\begin{cases}\eta_2 & \text{if } 0\leq t\leq\bar t,\\ \eta_1 & \text{if } \bar t\leq t\leq T,\end{cases}$$

where $0 < \eta_2 < \eta_1 < \frac{1}{2}$ and $0 < \bar{t} < T$. Consider the initial data $(\rho_{1,0}, \rho_{2,0}, \rho_{3,0}, \rho_{4,0})$, where

$$f(\rho_{1,0}) = f(\rho_{4,0}) = f(\sigma), \qquad f(\rho_{2,0}) = f(\rho_{3,0}) = \frac{\eta_1}{1-\eta_2} f(\sigma),$$

and

$$\sigma < \rho_{2,0} < 1, \qquad 0 < \rho_{3,0} < \sigma.$$

This is an equilibrium configuration and hence the solution of the Riemann problem for $0 \le t \le \bar{t}$. At time $t = \bar{t}$ we have to solve a new Riemann problem. Let $(\hat{\rho}_1, \hat{\rho}_2, \hat{\rho}_3, \hat{\rho}_4)$ be the new solution. We have

$$f(\hat{\rho}_2) = f(\hat{\rho}_4) = f(\sigma), \qquad f(\hat{\rho}_1) = f(\hat{\rho}_3) = \frac{\eta_1}{1-\eta_2} f(\sigma).$$

Now, if $\eta_1 \to \eta_2$, then

$$\text{Tot.Var.}\big(\alpha; [0,T]\big) \longrightarrow 0, \qquad \text{Tot.Var.}\big(\beta; [0,T]\big) \longrightarrow 0,$$

but

$$(f(\rho_{1,0}),\ f(\rho_{2,0})) \to \left(f(\sigma),\ \frac{\eta_2}{1-\eta_2} f(\sigma)\right), (f(\hat{\rho}_1),\ f(\hat{\rho}_2)) \to \left(\frac{\eta_2}{1-\eta_2} f(\sigma),\ f(\sigma)\right),$$

and hence $\text{Tot.Var.}\big(f(\rho); [0,T]\big)$ is bounded away from zero.

Appendix A. Total variation of the fluxes. Let J be a junction with three incoming roads and three outgoing ones. We show with an example that the total variation of the flux may increase if a wave arrives at J from an incoming road. Let us suppose that the matrix A is given by

$$A \doteq \begin{pmatrix} \frac{1}{2} - \varepsilon & \frac{1}{2} & \frac{1}{3} \\ \frac{1}{3} & \frac{1}{2} & \frac{1}{2} + \varepsilon \\ \frac{1}{6} + \varepsilon & 0 & \frac{1}{6} - \varepsilon \end{pmatrix}, \tag{A.1}$$

with $\varepsilon > 0$. Notice that the matrix A satisfies condition (C) for every $\varepsilon > 0$ small enough.

Let us choose $\rho_1,\ \rho_{1,0}, \ldots,\ \rho_{6,0} \in [0,1]$ such that

$$\rho_{1,0} = \rho_{4,0} = \rho_{5,0} = \sigma, \quad \sigma < \rho_{2,0} < 1, \quad \sigma < \rho_{3,0} < 1, \quad 0 < \rho_{6,0} < \sigma, \quad 0 < \rho_1 < \sigma,$$

$$f(\rho_{2,0}) = \frac{1 + 36\varepsilon + 36\varepsilon^2}{3(1+6\varepsilon)}, \qquad f(\rho_{3,0}) = \frac{1-6\varepsilon}{1+6\varepsilon}, \qquad f(\rho_{6,0}) = \frac{1}{6} + \varepsilon + \frac{(1-6\varepsilon)^2}{6(1+6\varepsilon)}.$$

We assume $f(\sigma) = 1$. Then $(\rho_{1,0}, \ldots,\ \rho_{6,0})$ is an equilibrium configuration and ρ, given by

$$\rho_1(0,x) = \begin{cases} \rho_{1,0} & \text{if } x_1 \le x \le b_1, \\ \rho_1 & \text{if } x < x_1, \end{cases} \qquad \rho_i(0,\cdot) \equiv \rho_{i,0}, \quad i = 2, \ldots, 6,$$

is a solution (see Figure 3). Moreover the point $\big(f(\rho_{1,0}), f(\rho_{2,0}), f(\rho_{3,0})\big)$ is given by the intersection of the planes

$$\left(\frac{1}{2} - \varepsilon\right)\gamma_1 + \frac{1}{2}\gamma_2 + \frac{1}{3}\gamma_3 = 1, \qquad \frac{1}{3}\gamma_1 + \frac{1}{2}\gamma_2 + \left(\frac{1}{2} + \varepsilon\right)\gamma_3 = 1, \qquad \gamma_1 = 1.$$

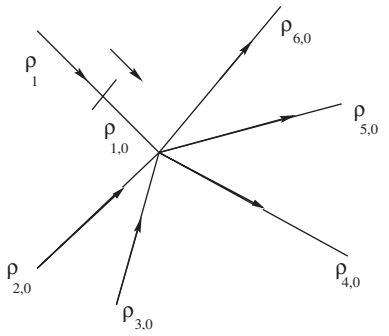

FIG. 3. *Configuration at J.*

At some time, say $\bar{t}$, the wave $(\rho_1, \rho_{1,0})$ interacts with the junction. Let $(\hat{\rho}_1, \dots, \hat{\rho}_6)$ be the solution of the Riemann problem at the junction for the data $(\rho_1, \rho_{2,0}, \dots, \rho_{6,0})$. If $f(\rho_1)$ is sufficiently near 1, then we have

$$\begin{aligned} f(\hat{\rho}_1) &= f(\rho_1), & f(\hat{\rho}_2) &= 2 - \frac{5 - 36\varepsilon^2}{3(1+6\varepsilon)} f(\rho_1), \\ f(\hat{\rho}_3) &= \frac{1-6\varepsilon}{1+6\varepsilon} f(\rho_1), & f(\hat{\rho}_4) &= f(\hat{\rho}_5) = 1, \\ f(\hat{\rho}_6) &= \frac{1+36\varepsilon^2}{3(1+6\varepsilon)} f(\rho_1). \end{aligned}$$

Therefore

$$\text{Tot.Var.}\big(f(\rho(\bar{t}-,\cdot))\big) = 1 - f(\rho_1)$$

and

$$\text{Tot.Var.}\big(f(\rho(\bar{t}+,\cdot))\big) = \frac{3(1-2\varepsilon)}{1+6\varepsilon}\big(1 - f(\rho_1)\big) > 2\,\text{Tot.Var.}\big(f(\rho(\bar{t}-,\cdot))\big).$$

Appendix B. Total variation of the densities. Consider a junction J with two incoming roads and two outgoing ones that we parameterize with the intervals $]-\infty, b_1]$, $]-\infty, b_2]$, $[a_3, +\infty[$, $[a_4, +\infty[$, respectively. We suppose that $0 < \beta < \alpha < 1/2$, where α and β are the entries of the matrix A as in (5.1).

Define a solution ρ by

(B.1)
$$\rho_1(0,x) = \begin{cases} \rho_{1,0} & \text{if } x_1 \le x \le b_1, \\ \rho_1 & \text{if } x < x_1, \end{cases} \quad \rho_2(0,x) = \rho_{2,0},\ \rho_3(0,x) = \rho_{3,0},\ \rho_4(0,x) = \rho_{4,0},$$

where ρ_1, $\rho_{1,0}$, $\rho_{2,0}$, $\rho_{3,0}$, $\rho_{4,0}$ are constants such that

(B.2)
$$\sigma < \rho_{2,0} < 1, \quad \sigma < \rho_{3,0} < 1, \quad 0 \le \rho_1 < \sigma, \quad \rho_{1,0} = \rho_{4,0} = \sigma,$$

$$f(\rho_{1,0}) = f(\rho_{4,0}) = f(\sigma), \quad f(\rho_{2,0}) = f(\rho_{3,0}) = \frac{\alpha}{1-\beta} f(\sigma),$$

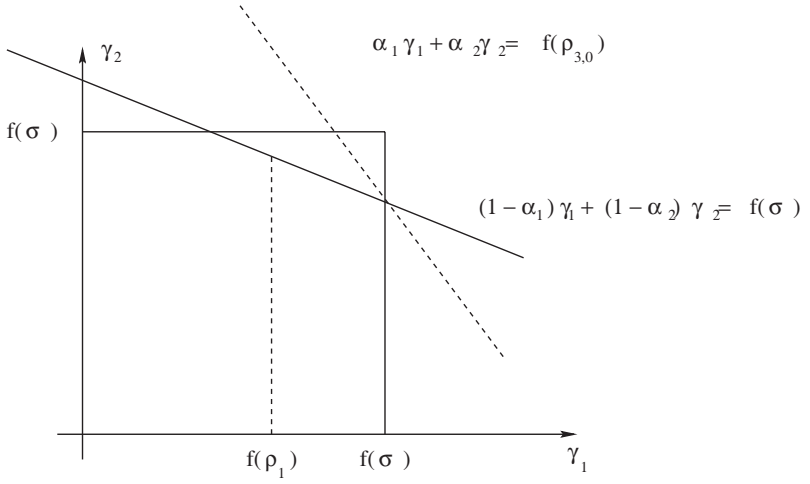

FIG. 4. *Solution to the Riemann problem at J.*

so $(\rho_{1,0},\ \rho_{2,0},\ \rho_{3,0},\ \rho_{4,0})$ is an equilibrium configuration.

After some time the wave $(\rho_1, \rho_{1,0})$ interacts with the junction. Let $(\hat{\rho}_1, \hat{\rho}_2, \hat{\rho}_3, \hat{\rho}_4)$ be the solution of the Riemann problem in the junction for the data $(\rho_1, \rho_{2,0}, \rho_{3,0}, \rho_{4,0})$; see Figure 4. By (B.1) and (B.2),

$$f(\hat{\rho}_1) = f(\rho_1), \quad f(\hat{\rho}_2) = \frac{f(\sigma) - (1-\alpha) f(\rho_1)}{1-\beta},$$

$$f(\hat{\rho}_3) = \frac{\alpha - \beta}{1-\beta} f(\rho_1) + \frac{\beta}{1-\beta} f(\sigma), \quad f(\hat{\rho}_4) = f(\sigma),$$

and

$$0 < \hat{\rho}_3 < \sigma \leq \hat{\rho}_2 < 1. \tag{B.3}$$

Therefore, if $\rho_1 \to \rho_{1,0} = \sigma$, then

$$f(\hat{\rho}_3) \longrightarrow \frac{\alpha}{1-\beta} f(\sigma) = f(\rho_{3,0}),$$

and, by (B.3) and (B.2), we have $\hat{\rho}_3 \to \tau(\rho_{3,0})$. Then, we are able to create on the third road a wave with strength bounded away from zero using an arbitrarily small wave on the first one.

Acknowledgments. The authors would like to thank Prof. Rinaldo M. Colombo for useful discussions.

SIZE EFFECTS ON QUASI-STATIC GROWTH OF CRACKS*

ALESSANDRO GIACOMINI†

Abstract. We perform an analysis of the size effect for quasi-static growth of cracks in isotropic linearly elastic bodies under antiplanar shear. In the framework of the variational model proposed by Francfort and Marigo in [*J. Mech. Phys. Solids*, 46 (1998), pp. 1319–1342], we prove that if the size of the body tends to infinity, and even if the surface energy is of cohesive form, under suitable boundary displacements the crack propagates following the Griffith's functional.

Key words. variational models, energy minimization, free discontinuity problems, crack propagation, quasi-static evolution, brittle fracture

1. Introduction.

A well-known fact in fracture mechanics is that *ductility* is also influenced by the size of the structure, and in particular the structure tends to become brittle if its size increases (see, for example, [8] and the references therein). The aim of this paper is to capture this fact for the problem of quasi-static growth of cracks in linearly elastic bodies in the framework of the variational theory of crack propagation formulated by Francfort and Marigo in [14].

The model proposed in [14] is inspired by the classical Griffith's criterion (see [16], [17], [18]) and it determines the evolution of the crack through a competition between volume and surface energies. Let us illustrate the theory and the variant we investigate in the case of *generalized antiplanar shear*.

Let $\Omega \subseteq \mathbb{R}^N$ be open, connected, bounded, and with Lipschitz boundary. A crack $\Gamma \subseteq \overline{\Omega}$ is any rectifiable set, and a displacement u is any function defined almost everywhere in Ω whose set of discontinuities $S(u)$ is contained in Γ (we will make precise the functional setting later). The total energy of the configuration (u, Γ) is given by

$$\int_{\Omega\setminus\Gamma} |\nabla u|^2 \, dx + \mathcal{H}^{N-1}(\Gamma). \tag{1.1}$$

The first term in (1.1) implies that we assume to apply linearized elasticity in the unbroken part of Ω. The second term can be considered as the work done to create Γ.

As suggested in [14], more general surface energies can be considered in (1.1), especially those of Barenblatt's type [5], and here we consider energies of the form

$$\int_{\Gamma} \varphi(|[u]|(x)) \, d\mathcal{H}^{N-1}(x), \tag{1.2}$$

where $[u](x) := u^+(x) - u^-(x)$ is the difference of the traces of u on both sides of Γ, and $\varphi : [0, +\infty[\to [0, +\infty[$ (which depends on the material) is such that $\varphi(0) = 0$.

In order to get a physical interpretation of (1.2), let us set $\sigma := \varphi'$: we interpret $\sigma(|[u]|(x))$ as density of forces in x that act between the two lips of the crack Γ whose displacements are $u^+(x)$ and $u^-(x)$, respectively. Typically σ is decreasing, and $\sigma(s) = 0$ for $s \geq \bar{s}$: this means that the interaction between the two lips of the crack decreases as the opening increases, and disappears when the opening is greater than a critical length $\bar{s}$. As a consequence, φ is increasing and concave, and $\varphi(s)$ is constant for $s \geq \bar{s}$. We will then consider φ increasing, concave, with $\varphi(0) = 0$, $a = \varphi'(0) < +\infty$, and $\lim_{s\to+\infty} \varphi(s) = 1$. We can interpret

$$\int_\Gamma \varphi(|[u]|(x))\, d\mathcal{H}^{N-1}(x)$$

as the work made to create Γ with an opening given by $[u]$. Assuming linearized elasticity to hold in $\Omega \setminus \Gamma$, we consider a total energy of the form

$$\|\nabla u\|^2 + \int_\Gamma \varphi(|[u]|)\, d\mathcal{H}^{N-1}, \tag{1.3}$$

where $\|\cdot\|$ denotes the L^2 norm. The problem of irreversible quasi-static growth of cracks in the cohesive case can be addressed through a *time discretization process* in analogy to what is proposed in [14] for the energy (1.1).

Let $g(t)$ be a time-dependent boundary displacement defined on $\partial_D\Omega \subseteq \partial\Omega$ with $t \in [0,T]$. Let $\delta > 0$ and let $I_\delta := \{0 = t_0^\delta < t_1^\delta < \cdots < t_{N_\delta}^\delta = T\}$ be a subdivision of $[0,T]$ with $\max(t_{i+1}^\delta - t_i^\delta) < \delta$, and let $g_i^\delta := g(t_i^\delta)$. At time $t = 0$ we consider u_0^δ as a minimum of

$$\|\nabla u\|^2 + \int_{S^{g(0)}(u)} \varphi(|[u]|)\, d\mathcal{H}^{N-1}. \tag{1.4}$$

Here $S^{g(0)}(u) := S(u) \cup \{x \in \partial_D\Omega : u(x) \neq g(0)(x)\}$, and for all $x \in \partial_D\Omega$ we consider $[u](x) := g(x) - \tilde{u}(x)$, where $\tilde{u}$ is the trace of u on $\partial\Omega$. We define the crack Γ_0^δ at time $t = 0$ as $S^{g(0)}(u_0^\delta)$. We also set $\psi_0^\delta := |[u_0^\delta]|$ on Γ_0^δ. The presence of $S^{g(0)}(u)$ in (1.4) indicates that the points at which the boundary displacement is not attained are considered as a part of the crack.

Supposing to have constructed Γ_i^δ and ψ_i^δ at time t_i^δ, we consider a minimum u_{i+1}^δ of the problem

$$\|\nabla u\|^2 + \int_{S^{g_{i+1}^\delta}(u)\cup\Gamma_i^\delta} \varphi(|[u]| \vee \psi_i^\delta)\, d\mathcal{H}^{N-1}, \tag{1.5}$$

where $|[u]| \vee \psi_i^\delta := \max\{|[u]|, \psi_i^\delta\}$, and define $\Gamma_{i+1}^\delta := \Gamma_i^\delta \cup S^{g_{i+1}^\delta}(u_{i+1}^\delta)$ and $\psi_{i+1}^\delta := \psi_i^\delta \vee |[u_{i+1}^\delta]|$ on Γ_{i+1}^δ.

Notice that problem (1.5) takes into account an *irreversibility condition* in the growth of the crack. Indeed, while on $S^{g_{i+1}^\delta}(u) \setminus \Gamma_i^\delta$ the surface energy which comes in minimization of (1.5) is exactly as in (1.2), on $S^{g_{i+1}^\delta}(u) \cap \Gamma_i^\delta$ the surface energy involved takes into account the previous work made on Γ_i^δ. The surface energy is of the form of (1.2) only if $|[u]| > \psi_i^\delta$, that is, only if the opening is increased. If $|[u]| \leq \psi_i^\delta$, no energy is gained, that is, displacements of this form along the crack are in a sense surface-energy-free. Notice finally that the irreversibility condition involves only the modulus of $[u]$: this is an assumption which is reasonable since we are considering only antiplanar displacements. Clearly more complex irreversibility conditions can be

formulated, involving, for example, a partial release of energy: the one we study is the first straightforward extension of the irreversibility condition given in [14] for the energy (1.1).

The *discrete-in-time evolution* of the crack relative to the subdivision I_δ, and the boundary datum $g(t)$ is given by $\{(u_i^\delta, \Gamma_i^\delta, \psi_i^\delta) : i = 0, \dots, N_\delta\}$.

The *irreversible quasi-static evolution* of the crack relative to the boundary datum $g(t)$ is obtained as a limit for $\delta \to 0$ of $(u^\delta(t), \Gamma^\delta(t), \psi^\delta(t))$, where $u^\delta(t) := u_i^\delta$, $\Gamma^\delta(t) := \Gamma_i^\delta$, and $\psi^\delta(t) := \psi_i^\delta$ for $t_i^\delta \le t < t_{i+1}^\delta$.

This program has been studied in detail in several papers in the case $\varphi \equiv 1$, that is, for energy of the form (1.1). A first mathematical formulation has been given by Dal Maso and Toader in [12], where the authors consider the case of dimension $N = 2$ and cracks which are compact and with a uniform bound on the number of connected components. This analysis has been extended to the case of plane elasticity by Chambolle in [9]. In [13] Francfort and Larsen consider the general N-dimensional case, and remove the bound on the number of the connected components of the cracks: the key point is to introduce a weak formulation of the problem considering displacements in the space SBV (see section 2). Finally Dal Maso, Francfort, and Toader [11] treat the case of finite elasticity not restricted to antiplanar shear, with volume energy depending on the full gradient under suitable growth conditions, and in presence of body and traction forces: the appropriate functional space for the displacements is now $GSBV$ (see, for example, [4] for a precise definition).

In all these papers (see [12], [9], [13], [11]), the analysis of the limit reveals three basic properties (irreversibility, static equilibrium, and nondissipativity; see Theorem 2.2) which are taken as definition of irreversible quasi-static growth in brittle fractures: the time discretization procedure is considered as a privileged way to get an existence result.

In the case of energy (1.3), several difficulties arise in the analysis of the discrete-in-time evolution, and in the analysis as $\delta \to 0$. In section 3, we prove that the functional space we need in order to apply the direct method of the Calculus of Variations in the step-by-step minimizations (1.4), (1.5) is the space of functions with bounded variation BV (see section 2): we thus consider a relaxed version of the problems, namely,

$$\int_\Omega f(\nabla u)\, dx + \int_\Gamma \varphi(|[u]| \vee \psi)\, d\mathcal{H}^{N-1} + a|D^c u|(\Omega),$$

where $a = \varphi'(0)$, f is defined in (3.3), and $D^c u$ indicates the Cantorian part of the derivative of u. An existence result for *discrete-in-time evolution* in this context of BV space is given in Proposition 3.1.

The analysis for $\delta \to 0$ presents several difficulties, the main one being the stability of the minimality property of the discrete-in-time evolutions. The main purpose of this paper is to prove that these difficulties disappear as the size of the reference configuration increases, thanks to the fact that the body response tends to become more and more brittle in spite of the presence of cohesive forces on the cracks. More precisely, we prove this fact for the discrete evolutions in $\Omega_h := h\Omega$ for h large and under suitable boundary displacements. The idea is to rescale displacements and cracks to the fixed configuration Ω, and take advantage from the form of the problem in this new setting. The boundary displacements on $\partial_D \Omega_h := h\partial_D \Omega$ will be taken of the form

$$g_h(t,x) := h^\alpha g\left(t, \frac{x}{h}\right), \qquad g \in AC([0,T]; H^1(\Omega)),$$
$$\|g(t)\|_\infty \le C, \qquad t \in [0,T],\ x \in \Omega_h,$$

where $\alpha > 0$ and $C > 0$. We indicate by $(u^{\delta,h}(t), \Gamma^{\delta,h}(t), \psi^{\delta,h}(t))$ the piecewise constant interpolation of the discrete-in-time evolution of the crack in Ω_h relative to the boundary displacement g_h. Let us moreover set for every $t \in [0,T]$

$$\mathcal{E}^{\delta,h}(t) := \int_{h\Omega} f(\nabla u^{\delta,h}(t))\,dx + \int_{\Gamma^{\delta,h}(t)} \varphi(\psi^{\delta,h}(t))\,d\mathcal{H}^{N-1} + a|D^c u^{\delta,h}(t)|(\Omega_h).$$

In the case $\alpha = \frac{1}{2}$, we make the following rescaling:

$$v^{\delta,h}(t,x) := \frac{1}{\sqrt{h}} u^{\delta,h}(t,hx), \qquad K^{\delta,h}(t) := \frac{1}{h}\Gamma^{\delta,h}(t), \qquad \gamma^{\delta,h}(t) := \frac{1}{\sqrt{h}}\psi^{\delta,h}(t,hx),$$

where $t \in [0,T]$ and $x \in \Omega$. The main result of the paper is the following (see Theorem 4.1 for a more precise statement).

THEOREM 1.1. *If $\delta \to 0$ and $h \to +\infty$, there exists a quasi-static crack evolution $\{t \to (v(t), K(t))\}$ in Ω relative to the boundary displacement g in the sense of* [13] *(see Theorem* 2.2*) such that for all $t \in [0,T]$ we have*

$$\nabla v^{\delta,h}(t) \rightharpoonup \nabla v(t) \qquad \text{weakly in } L^1(\Omega; \mathbb{R}^N).$$

Moreover, for all $t \in [0,T]$ we have

$$\frac{1}{h^{N-1}}\mathcal{E}^{\delta,h}(t) \to \|\nabla v(t)\|^2 + \mathcal{H}^{N-1}(K(t));$$

in particular $h^{-N+1}|D^c u^{\delta,h}(t)|(\Omega_h) \to 0$,

$$\frac{1}{h^{N-1}}\int_{\Omega_h} f(\nabla u^{\delta,h}(t))\,dx \to \|\nabla v(t)\|^2,$$

and

$$\frac{1}{h^{N-1}}\int_{\Gamma^{\delta,h}(t)} \varphi(\psi^{\delta,h}(t))\,d\mathcal{H}^{N-1} \to \mathcal{H}^{N-1}(K(t)).$$

Theorem 1.1 proves that as the size of the reference configuration increases, the response of the body in the problem of quasi-static growth of cracks tends to become brittle, so that energy (1.1) can be considered. Moreover, we have convergence results for the volume and surface energies involved.

The particular value $\alpha = \frac{1}{2}$ comes out because a problem of quasi-static evolution has been considered. In fact if we consider an infinite plane with a crack segment of length l and subject to a uniform stress σ at infinity, following Griffith's theory, the crack propagates quasi-statically if $\sigma = \frac{K_{IC}}{\sqrt{\pi l}}$, where K_{IC} is the critical *stress intensity factor* (depending on the material). So if the crack has length hl, the stress rescales as $\frac{1}{\sqrt{h}}$. This is precisely what we are prescribing in the case $\alpha = \frac{1}{2}$: in fact the stress that intuitively we prescribe at the boundary can be reconstructed from ∇u_h and rescales precisely as $\frac{1}{\sqrt{h}}$.

For the proof of Theorem 1.1, the first step is to recognize that

$$(v^{\delta,h}(t), K^{\delta,h}(t), \gamma^{\delta,h}(t))$$

is a discrete-in-time evolution relative to the boundary displacement g for a total energy of the form

$$\int_\Omega f_h(\nabla u)\,dx + \int_\Gamma \varphi_h(|[u]| \vee \gamma)\,d\mathcal{H}^{N-1} + a\sqrt{h}|D^c u|(\Omega),$$

where $\varphi_h(s) \nearrow 1$ for all $s \in [0, +\infty[$, and $f_h(\xi) \nearrow |\xi|^2$ for all $\xi \in \mathbb{R}^N$. From the fact that $\varphi_h \nearrow 1$ we recognize that the structure tends to become brittle. Bound on total energy for the discrete-in-time evolution is available, so that compactness in the space BV can be applied: it turns out that the limits of the displacements are of class SBV with gradient in $L^2(\Omega; \mathbb{R}^N)$. Limits for the cracks are constructed through a Γ-convergence procedure (see Proposition 5.2). The main point in order to see that $(v(t), K(t))$ is a quasi-static crack growth is to recover the static equilibrium condition (see point (c) of Theorem 2.2)

$$\|\nabla v(t)\|^2 \le \|\nabla v\|^2 + \mathcal{H}^{N-1}(S^{g(t)}(v) \setminus K(t)), \qquad v \in SBV(\Omega)$$

from the minimality properties satisfied by $(v^{\delta,h}(t), K^{\delta,h}(t), \gamma^{\delta,h}(t))$. This is done in Proposition 5.5 by means of a refined version of the Transfer of Jump of [13]: the main difference here is that we have to deal with BV functions and we have to transfer the jump on the part of $K^{\delta,h}(t)$ where $\psi^{\delta,h}(t)$ is greater than a given small constant.

We also consider the cases $\alpha \in]0, \frac{1}{2}[$ and $\alpha > \frac{1}{2}$. It turns out that in the case $\alpha \in]0, \frac{1}{2}[$, the body is not solicited enough to create a crack, that is, Ω_h tends to behave elastically: more precisely we prove (Theorem 4.2) that setting

$$v^{\delta,h}(t,x) := \frac{1}{h^\alpha} u^{\delta,h}(t, hx) \tag{1.6}$$

for all $t \in [0,T]$, we have that $v^{\delta,h}(t)$ converges to the displacement of the elastic problem in Ω under boundary displacement given by $g(t)$.

In the case $\alpha > \frac{1}{2}$ we have that the body tends brutally toward *rupture*: in fact in Theorem 4.3 we prove that $v^{\delta,h}(0)$ given by (1.6) converges to a piecewise constant function v in Ω, so that $S^{g(0)}(v)$ disconnects Ω. This phenomenon is a consequence of the variational approach based on the search for global minimizers: as the size of Ω_h increases, cracks carry an energy of order h^{N-1}, while nonrigid displacements carry an energy of greater order: in this way crack is preferred to deformation.

The paper is organized as follows. In section 2 we recall some basic definitions and introduce the functional setting for the problem. In section 3 we deal with the problem of discrete-in-time evolutions for cracks in the cohesive case. The main theorems are listed in section 4, while in section 5 we prove some results which will be employed in their proofs to which sections 6, 7, and 8 are devoted. In the appendix we prove a relaxation result which is used in the problem of the discrete-in-time evolution of cracks.

2. Preliminaries. In this section we state the notation and recall the preliminary results employed in the rest of the paper.

2.1. Basic notation. We will employ the following basic notation:

- Ω is an open, connected, and bounded subset of $\mathbb{R}^N$ with Lipschitz boundary;
- $\partial_D\Omega$ is a subset of $\partial\Omega$ open in the relative topology;
- $\mathcal{H}^{N-1}$ is the $(N-1)$-dimensional Hausdorff measure;
- we say that $A \tilde{\subseteq} B$ if $A \subseteq B$ up to a set of $\mathcal{H}^{N-1}$-measure zero; similarly we say that $A \tilde{=} B$ if $A = B$ up to a set of $\mathcal{H}^{N-1}$-measure zero;

- $\Gamma \subseteq \Omega$ is rectifiable if there exists a sequence of C^1 manifolds $(M_i)_{i\in\mathbb{N}}$ such that $\Gamma \tilde{\subseteq} \cup_i M_i$;
- for all $A \subseteq \mathbb{R}^N$, $|A|$ denotes the Lebesgue measure of A;
- for all $A \subseteq \mathbb{R}^N$, 1_A denotes the characteristic function of A;
- if μ is a Borel measure on $\mathbb{R}^N$ and A is a Borel subset of $\mathbb{R}^N$, $\mu \llcorner A$ denotes the restriction of μ to A, i.e., $(\mu \llcorner A)(B) := \mu(B \cap A)$ for all Borel sets $B \subseteq \mathbb{R}^N$;
- $\|u\|_\infty$ and $\|u\|$ denote the sup-norm and the L^2 norm of u, respectively;
- if $u, g \in BV(\Omega;\mathbb{R}^m)$, $S^g(u) := S(u) \cup \{x \in \partial_D\Omega : u(x) \neq g(x)\}$;
- if $x, y \in \mathbb{R}$, $x \vee y := \max\{x, y\}$ and $x \wedge y := \min\{x, y\}$.

2.2. Functions of bounded variation. For the general theory of functions of bounded variation, we refer the reader to [4]; here we recall some basic definitions and theorems we need in what follows. We say that $u \in BV(A)$ if $u \in L^1(A)$, and its distributional derivative Du is a bounded vector-valued Radon measure on A. In this case it turns out that the set $S(u)$ of points $x \in A$ which are not Lebesgue points of u is rectifiable, that is, there exists a sequence of C^1 manifolds $(M_i)_{i\in\mathbb{N}}$ such that $S(u) \subseteq \cup_i M_i$ up to a set of $\mathcal{H}^{N-1}$-measure zero. As a consequence $S(u)$ admits a normal $\nu_u(x)$ at $\mathcal{H}^{N-1}$-a.e. $x \in S(u)$. Moreover, for $\mathcal{H}^{N-1}$-a.e. $x \in S(u)$, there exist $u^+(x), u^-(x) \in \mathbb{R}$ such that

$$\lim_{r\to 0} \frac{1}{|B_r^\pm(x)|} \int_{B_r^\pm(x)} |u(y) - u^\pm(x)|\, dy = 0,$$

where $B_r^+(x) := \{y \in B_r(x) : (y-x)\cdot\nu_u(x) > 0\}$ (similarly for $B_r^-(x)$), and $B_r(x)$ is the ball with center x and radius r. It turns out that Du can be represented as

$$Du(A) = \int_A \nabla u(x)\, dx + \int_{A\cap S(u)} (u^+(x) - u^-(x))\nu_u(x)\, d\mathcal{H}^{N-1}(x) + D^c u(A),$$

where ∇u denotes the approximate gradient of u and $D^c u$ is the Cantor part of Du. $BV(A)$ is a Banach space with respect to the norm $\|u\|_{BV(A)} := \|u\|_{L^1(A)} + |Du|(A)$.

We will often use the following result: if A is bounded and Lipschitz, and if $(u_k)_{k\in\mathbb{N}}$ is a bounded sequence in $BV(A)$, then there exist a subsequence $(u_{k_h})_{h\in\mathbb{N}}$ and $u \in BV(A)$ such that

$$\begin{aligned} u_{k_h} &\to u \quad \text{strongly in } L^1(A), \\ Du_{k_h} &\overset{*}{\rightharpoonup} Du \quad \text{weakly* in the sense of measures.} \end{aligned} \tag{2.1}$$

We say that $u_k \overset{*}{\rightharpoonup} u$ weakly* in $BV(A)$ if (2.1) holds.

We say that $u \in SBV(A)$ if $u \in BV(A)$ and $D^c u = 0$. The space $SBV(A)$ is called the space of *special functions of bounded variation*. Note that if $u \in SBV(A)$, then the singular part of Du is concentrated on $S(u)$.

The space SBV is very useful when dealing with variational problems involving volume and surface energies because of the following compactness and lower semicontinuity result due to Ambrosio [1], [2], [3].

THEOREM 2.1. *Let A be an open and bounded subset of $\mathbb{R}^N$, and let $(u_k)_{k\in\mathbb{N}}$ be a sequence in $SBV(A)$. Assume that there exist $q > 1$ and $C \in [0;+\infty[$ such that*

$$\int_A |\nabla u_k|^q\, dx + \mathcal{H}^{N-1}(S(u_k)) + ||u_k||_\infty \leq C$$

for every $k \in \mathbb{N}$. Then there exist a subsequence $(u_{k_h})_{h\in\mathbb{N}}$ and a function $u \in SBV(A)$ such that

$$\begin{aligned} u_{k_h} &\to u \quad \textit{strongly in } L^1(A),\\ \nabla u_{k_h} &\rightharpoonup \nabla u \quad \textit{weakly in } L^1(A;\mathbb{R}^N),\\ \mathcal{H}^{N-1}(S(u)) &\le \liminf_{h\to+\infty} \mathcal{H}^{N-1}(S(u_{k_h})). \end{aligned} \tag{2.2}$$

In the rest of the paper, we will say that $u_k \rightharpoonup u$ weakly in $SBV(A)$ if u_k and u satisfy (2.2). The following fact, which can be derived from Ambrosio's theorem, will also be useful: if $u_k \rightharpoonup u$ weakly in $SBV(A)$ and if $\mathcal{H}^{N-1}\llcorner S(u_k) \overset{*}{\rightharpoonup} \mu$ weakly* in the sense of measures, then $\mathcal{H}^{N-1}\llcorner S(u) \le \mu$ as measures.

Finally in the context of fracture problems we will use the following notation: if A is Lipschitz, and if $\partial_D A \subseteq \partial A$, then for all $u, g \in BV(A)$ we set

$$S^g(u) := S(u) \cup \{x \in \partial_D A \,:\, u(x) \neq g(x)\}, \tag{2.3}$$

where the inequality on $\partial_D A$ is intended in the sense of traces. Moreover, we set for all $x \in S(u)$

$$[u](x) := u^+(x) - u^-(x),$$

and for all $x \in \partial_D A$ we set $[u](x) := u(x) - g(x)$, where the traces of u and g on ∂A are used.

2.3. Quasi-static evolution in brittle fracture. Let Ω be an open bounded subset of $\mathbb{R}^N$ with Lipschitz boundary, and let $\partial_D\Omega$ be a subset of $\partial\Omega$ open in the relative topology. Let $g : [0,T] \to H^1(\Omega)$ be absolutely continuous (see [7] for a precise definition); we indicate the gradient of g at time t by $\nabla g(t)$, and the time derivative of g at time t by $\dot g(t)$. For $u \in SBV(\Omega)$, let $S^{g(t)}(u)$ be defined as in (2.3), and for every $A, B \subseteq \mathbb{R}^N$, let $A \tilde\subseteq B$ mean $A \subseteq B$ up to a set of $\mathcal{H}^{N-1}$-measure zero. The main result of [13] is the following theorem.

THEOREM 2.2. *There exists $\{(u(t), \Gamma(t)) : t \in [0,T]\}$ with $\Gamma(t) \tilde\subseteq \Omega \cup \partial_D\Omega$ rectifiable and $u(t) \in SBV(\Omega)$ such that*

(a) $\Gamma(s) \tilde\subseteq \Gamma(t)$ *for all* $0 \le s \le t \le T$;

(b) $u(0)$ *minimizes*

$$\|\nabla v\|^2 + \mathcal{H}^{N-1}(S^{g(0)}(v))$$

among all $v \in SBV(\Omega)$;

(c) *for $t \in]0,T]$, $u(t)$ minimizes*

$$\|\nabla v\|^2 + \mathcal{H}^{N-1}(S^{g(t)}(v) \setminus \Gamma(t))$$

among all $v \in SBV(\Omega)$;

(d) $S^{g(0)}(u(0)) = \Gamma(0)$, *and* $S^{g(t)}(u(t)) \tilde\subseteq \Gamma(t)$ *for all* $t \in]0,T]$.

Furthermore, the total energy

$$\mathcal{E}(t) := \|\nabla u(t)\|^2 + \mathcal{H}^{N-1}(\Gamma(t))$$

is absolutely continuous and satisfies

$$\mathcal{E}(t) = \mathcal{E}(0) + 2\int_0^t \int_\Omega \nabla u(\tau)\nabla \dot g(\tau)\, dx\, d\tau \tag{2.4}$$

for every $t \in [0,T]$.

Condition (a) stands for the *irreversibility* of the crack propagation, conditions (b) and (c) are *static equilibrium* conditions, while (2.4) stands for the *nondissipativity* of the process.

2.4. Γ-convergence. Let us recall the definition and some basic properties of De Giorgi's Γ-*convergence* in metric spaces. We refer the reader to [10] for an exhaustive treatment of this subject. Let (X,d) be a metric space. We say that a sequence $F_h : X \to [-\infty,+\infty]$ Γ-converges to $F : X \to [-\infty,+\infty]$ (as $h \to +\infty$) if for all $u \in X$ we have

(i) (Γ-*liminf inequality*) for every sequence $(u_h)_{h\in\mathbb{N}}$ converging to u in X,

$$\liminf_{h\to+\infty} F_h(u_h) \geq F(u);$$

(ii) (Γ-*limsup inequality*) there exists a sequence $(u_h)_{h\in\mathbb{N}}$ converging to u in X, such that

$$\limsup_{h\to+\infty} F_h(u_h) \leq F(u).$$

The function F is called the Γ-limit of $(F_h)_{h\in\mathbb{N}}$ (with respect to d). Γ-convergence is a convergence of variational type as explained in the following proposition.

PROPOSITION 2.3. *Assume that the sequence* $(F_h)_{h\in\mathbb{N}}$ Γ-*converges to* F *and that there exists a compact set* $K \subseteq X$ *such that for all* $h \in \mathbb{N}$

$$\inf_{u\in K} F_h(u) = \inf_{u\in X} F_h(u).$$

Then F *admits a minimum on* X, $\inf_X F_h \to \min_X F$, *and any limit point of any sequence* $(u_h)_{h\in\mathbb{N}}$ *such that*

$$\lim_{h\to+\infty} \Big(F_h(u_h) - \inf_{u\in X} F_h(u)\Big) = 0$$

is a minimizer of F.

Moreover, the following compactness result holds.

PROPOSITION 2.4. *If* (X,d) *is separable, and* $(F_h)_{h\in\mathbb{N}}$ *is a sequence of functionals on* X, *then there exist a subsequence* $(F_{h_k})_{k\in\mathbb{N}}$ *and a function* $F : X \to [-\infty;+\infty]$ *such that* $(F_{h_k})_{k\in\mathbb{N}}$ Γ-*converges to* F.

3. Discrete-in-time evolution of cracks in the cohesive case. In this section we are interested in generalized antiplanar shear of an elastic body Ω in the context of linearized elasticity and in presence of cohesive forces on the cracks.

The notion of *discrete-in-time evolution* for cracks relative to time-dependent boundary displacement $g(t)$ has been described in the introduction. It relies on the minimization of functionals of the form

$$\|\nabla u\|^2 + \int_{\Gamma\cup S^{g(t)}(u)} \varphi(|[u]| \vee \psi)\, d\mathcal{H}^{N-1}, \tag{3.1}$$

with ψ a positive function defined on Γ. We now define rigorously the functional space to which the displacements belong, and the properties of Ω, Γ, ψ, and $g(t)$ in order to prove an existence result for the discrete-in-time evolution of cracks.

Let Ω be an open bounded subset of $\mathbb{R}^N$ with Lipschitz boundary. Let $\partial_D\Omega \subseteq \partial\Omega$ be open in the relative topology, and let $\partial_N\Omega := \partial\Omega\setminus\partial_D\Omega$. Let $\varphi : [0,+\infty[\to [0,+\infty[$

be increasing and concave, $\varphi(0) = 0$ and such that $\lim_{s\to+\infty} \varphi(s) = 1$. If $a := \varphi'(0) < +\infty$, we have

$$\varphi(s) \le as \qquad \text{for all } s \in [0, +\infty[.$$

Let $T > 0$, and let us consider a boundary displacement $g \in AC([0,T]; H^1(\Omega))$ such that $\|g(t)\|_\infty \le C$ for all $t \in [0,T]$. We discretize g in the following way. Given $\delta > 0$, let I_δ be a subdivision of $[0,T]$ of the form $0 = t_0^\delta < t_1^\delta < \cdots < t_{N_\delta}^\delta = T$ such that $\max_i(t_i^\delta - t_{i-1}^\delta) < \delta$. For $0 \le i \le N_\delta$ we set $g_i^\delta := g(t_i^\delta)$.

As for the space of the displacements, it would be natural, following [13], to consider $u \in SBV(\Omega)$. Since $a = \varphi'(0) < +\infty$, we have unfortunately that the minimization of (3.1) is not well posed in $SBV(\Omega)$. Let us in fact consider $(u_n)_{n\in\mathbb{N}}$ minimizing sequence for (3.1): it turns out that we may assume $(u_n)_{n\in\mathbb{N}}$ bounded in $BV(\Omega)$. As a consequence $(u_n)_{n\in\mathbb{N}}$ admits a subsequence weakly* convergent in $BV(\Omega)$ to a function $u \in BV(\Omega)$. Then we have that minimizing sequences of (3.1) converge (up to a subsequence) to a minimizer of the relaxation of (3.1) with respect to the weak* topology of $BV(\Omega)$. By Proposition 9.1, the natural domain of this relaxed functional is $BV(\Omega)$, and that its form is

$$\int_\Omega f(\nabla u)\,dx + \int_{\Gamma\cup S^{g(t)}(u)} \varphi(|[u]| \vee \psi)\,d\mathcal{H}^{N-1} + a|D^c u|(\Omega), \tag{3.2}$$

where

$$f(\xi) := \begin{cases} |\xi|^2 & \text{if } |\xi| \le \frac{a}{2}, \\ \\ \frac{a^2}{4} + a(|\xi| - \frac{a}{2}) & \text{if } |\xi| \ge \frac{a}{2}. \end{cases} \tag{3.3}$$

In view of these remarks, we consider $BV(\Omega)$ as the space of displacements u of the body Ω, and a total energy of the form (3.2). The volume part in the energy (3.2) can be interpreted as the contribution of the elastic behavior of the body. The second term represents the work done to create the crack $\Gamma \cup S^{g(t)}(u)$ with opening given by $|[u]| \vee \psi$. The new term $a|D^c u|$ can be interpreted as the contribute of microcracks in the configuration which are considered as reversible.

Let us define the discrete evolution of the crack in this new setting. For $i = 0$, let $u_0^\delta \in BV(\Omega)$ be a minimum of

$$\min_{u\in BV(\Omega)} \left\{ \int_\Omega f(\nabla u)\,dx + \int_{S^{g_0^\delta}(u)} \varphi(|[u]|)\,d\mathcal{H}^{N-1} + a|D^c u| \right\}. \tag{3.4}$$

We set $\Gamma_0^\delta := S^{g_0^\delta}(u_0^\delta)$.

Supposing to have constructed u_j^δ and Γ_j^δ for all $j = 0, \dots, i-1$, let u_i^δ be a minimum of

$$\min_{u\in BV(\Omega)} \left\{ \int_\Omega f(\nabla u)\,dx + \int_{S^{g_i^\delta}(u)\cup\Gamma_{i-1}^\delta} \varphi(|[u]| \vee \psi_{i-1}^\delta)\,d\mathcal{H}^{N-1} + a|D^c u| \right\}, \tag{3.5}$$

where $\psi_{i-1}^\delta := |[u_0^\delta]| \vee \cdots \vee |[u_{i-1}^\delta]|$. We set $\Gamma_i^\delta := \Gamma_{i-1}^\delta \cup S^{g_i^\delta}(u_i^\delta)$.

In the following proposition we establish the existence of this discrete evolution.

PROPOSITION 3.1. *Let $I_\delta = \{0 = t_0^\delta < \cdots < t_{N_\delta}^\delta = T\}$ be a subdivision of $[0,T]$ such that $\max(t_i^\delta - t_{i-1}^\delta) < \delta$. Then for all $i = 0, \dots, N_\delta$ there exists $u_i^\delta \in BV(\Omega)$ such that setting $\Gamma_{-1}^\delta := \emptyset$, $\psi_{-1}^\delta := 0$,*

$$\Gamma_i^\delta := \bigcup_{j=0}^{i} S^{g_j^\delta}(u_j^\delta), \qquad \psi_i^\delta(x) := |[u_0^\delta]|(x) \vee \cdots \vee |[u_i^\delta]|(x),$$

the following holds:

(a) $\|u_i^\delta\|_\infty \le \|g_i^\delta\|_\infty \le C$;

(b) *for all $v \in BV(\Omega)$ we have*

$$\begin{aligned} \int_\Omega f(\nabla u_i^\delta)\,dx + \int_{\Gamma_i^\delta} \varphi(\psi_i^\delta)\,d\mathcal{H}^{N-1} + a|D^c u_i^\delta|(\Omega) \\ \le \int_\Omega f(\nabla v)\,dx + \int_{S^{g_i^\delta}(v)\cup\Gamma_{i-1}^\delta} \varphi(|[v]| \vee \psi_{i-1}^\delta)\,d\mathcal{H}^{N-1} + a|D^c v|(\Omega), \end{aligned} \tag{3.6}$$

where $a = \varphi'(0)$ and f is defined in (3.3);

(c) *we have that*

$$\begin{aligned} &\int_\Omega f(\nabla u_i^\delta)\,dx + \int_{\Gamma_i^\delta} \varphi(\psi_i^\delta)\,d\mathcal{H}^{N-1} + a|D^c u_i^\delta|(\Omega) \\ &\quad = \inf_{v \in SBV(\Omega)} \left\{ \|\nabla v\|^2 + \int_{S^{g_i^\delta}(v)\cup\Gamma_{i-1}^\delta} \varphi(|[v]| \vee \psi_{i-1}^\delta)\,d\mathcal{H}^{N-1} \right\}. \end{aligned}$$

Proof. We have to prove that problems (3.4) and (3.5) admit solutions. Let us consider, for example, problem (3.5), the other being similar. Let $(u_n)_{n\in\mathbb{N}}$ be a minimizing sequence for problem (3.5). By a truncation argument we may assume that $\|u_n\|_\infty \le \|g_i^\delta\|$. Comparing u_n with g_i^δ, we get for n large

$$\begin{aligned} \int_\Omega f(\nabla u_n)\,dx + \int_{S^{g_i^\delta}(u_n)\cup\Gamma_{i-1}^\delta} \varphi(|[u_n]| \vee \psi_{i-1}^\delta)\,d\mathcal{H}^{N-1} + a|D^c u_n|(\Omega) \\ \le \int_\Omega f(\nabla g_0^\delta)\,dx + \int_{\Gamma_{i-1}^\delta} \varphi(\psi_{i-1}^\delta)\,d\mathcal{H}^{N-1} + 1 \le C', \end{aligned}$$

with C' independent of n. Since there exists $d > 0$ such that $a|\xi| - d \le f(\xi)$ for all $\xi \in \mathbb{R}^N$, we deduce that $(\nabla u_n)_{n\in\mathbb{N}}$ is bounded in $L^1(\Omega;\mathbb{R}^N)$. Moreover, if $\bar s$ is such that $\varphi(\bar s) = \frac{1}{2}$ and $\bar a$ is such that $s \le \bar a \varphi(s)$ for all $s \in [0,\bar s]$, we have

$$\begin{aligned} \int_{S(u_n)} |[u_n]|\,d\mathcal{H}^{N-1} &= \int_{\{|[u_n]|\le\bar s\}} |[u_n]|\,d\mathcal{H}^{N-1} + \|g_i^\delta\|_\infty \mathcal{H}^{N-1}(\{|[u_n]| > \bar s\}) \\ &\le \bar a \int_{|[u_n]|\le\bar s} \varphi(|[u_n]|)\,d\mathcal{H}^{N-1} + 2\|g_i^\delta\|_\infty \int_{|[u_n]|>\bar s} \varphi(|[u_n]|)\,d\mathcal{H}^{N-1} \\ &\le (\bar a + 2\|g_i^\delta\|_\infty) C'. \end{aligned}$$

Finally for all n

$$|D^c u_n| \le \frac{C'}{a}.$$

We conclude that $(u_n)_{n\in\mathbb{N}}$ is bounded in $BV(\Omega)$. Then there exists $u \in BV(\Omega)$ such that up to a subsequence $u_n \overset{*}{\rightharpoonup} u$ weakly* in $BV(\Omega)$ and pointwise almost everywhere. Let us set $u_i^\delta := u$. By Lemma 9.2 we deduce that

$$\int_\Omega f(\nabla u)\,dx + \int_{S^{g_i^\delta}(u)\cup\Gamma_{i-1}^\delta} \varphi(|[u]|\vee\psi_{i-1}^\delta)\,d\mathcal{H}^{N-1} + a|D^c u|(\Omega)$$
$$\le \liminf_{n\to+\infty}\int_\Omega f(\nabla u_n)\,dx + \int_{S^{g_i^\delta}(u_n)\cup\Gamma_{i-1}^\delta} \varphi(|[u_n]|\vee\psi_{i-1}^\delta)\,d\mathcal{H}^{N-1} + a|D^c u_n|(\Omega).$$

Setting $\psi_i^\delta := \psi_{i-1}^\delta \vee |[u_i^\delta]|$, we have that point (b) holds. Moreover $\|u_i^\delta\|_\infty \le \|g_0^\delta\|_\infty \le C$, so that point (a) holds. Finally point (c) is a consequence of Proposition 9.1. ∎

Let us consider now the following piecewise constant interpolation in time:

$$u^\delta(t) := u_i^\delta, \qquad \Gamma^\delta(t) := \Gamma_i^\delta, \qquad \psi^\delta(t) := \psi_i^\delta, \qquad g^\delta(t) := g_i^\delta \tag{3.7}$$

for $t_i^\delta \le t < t_{i+1}^\delta$, with $u^\delta(T) := u_{N_\delta}^\delta$, $\Gamma^\delta(T) := \Gamma_{N_\delta}^\delta$, $\psi^\delta(T) := \psi_{N_\delta}^\delta$, and $g^\delta(T) := g(T)$.

For every $v \in BV(\Omega)$ and for every $t \in [0,T]$ let us set

$$\mathcal{E}^\delta(t,v) := \int_\Omega f(\nabla v)\,dx + \int_{S^{g^\delta(t)}(v)\cup\Gamma^\delta(t)} \varphi(|[v]|\vee\psi^\delta(t))\,d\mathcal{H}^{N-1} + a|D^c v|(\Omega). \tag{3.8}$$

Then the following estimate holds.

LEMMA 3.2. *There exists $e_a^\delta \to 0$ for $\delta \to 0$ and $a \to +\infty$ such that for all $t \in [0,T]$ we have*

$$\mathcal{E}^\delta(t,u^\delta(t)) \le \mathcal{E}^\delta(0,u^\delta(0)) + \int_0^{t_i^\delta}\int_\Omega f'(\nabla u^\delta(\tau))\nabla\dot g(\tau)\,dx\,d\tau + e_a^\delta,$$

where t_i^δ is the step discretization point such that $t_i^\delta \le t < t_{i+1}^\delta$.

Proof. Comparing u_i^δ with $u_{i-1}^\delta + g_i^\delta - g_{i-1}^\delta$ by means of (3.6) we obtain

$$\mathcal{E}^\delta(t_i^\delta,u_i^\delta) \le \int_\Omega f(\nabla u_{i-1}^\delta + \nabla g_i^\delta - \nabla g_{i-1}^\delta)\,dx + \int_{\Gamma_{i-1}^\delta}\varphi(\psi_{i-1}^\delta)\,d\mathcal{H}^{N-1} + a|D^c u_{i-1}^\delta|(\Omega).$$

Notice that by the very definition of f the following hold:

(1) if $|\nabla u_{i-1}^\delta + \nabla g_i^\delta - \nabla g_{i-1}^\delta| \ge \frac{a}{2}$ and $|\nabla u_{i-1}^\delta| \ge \frac{a}{2}$,

$$f'(\nabla u_{i-1}^\delta + \nabla g_i^\delta - \nabla g_{i-1}^\delta) = f'(\nabla u_{i-1}^\delta);$$

(2) if $|\nabla u_{i-1}^\delta + \nabla g_i^\delta - \nabla g_{i-1}^\delta| < \frac{a}{2}$ and $|\nabla u_{i-1}^\delta| \ge \frac{a}{2}$,

$$f(\nabla u_{i-1}^\delta + \nabla g_i^\delta - \nabla g_{i-1}^\delta) \le f(\nabla u_{i-1}^\delta);$$

(3) if $|\nabla u_{i-1}^\delta + \nabla g_i^\delta - \nabla g_{i-1}^\delta| \ge \frac{a}{2}$ and $|\nabla u_{i-1}^\delta| < \frac{a}{2}$,

$$f(\nabla u_{i-1}^\delta+\nabla g_i^\delta-\nabla g_{i-1}^\delta) \le f(\nabla u_{i-1}^\delta)+2(\nabla u_{i-1}^\delta, \nabla g_i^\delta-\nabla g_{i-1}^\delta)+|\nabla g_i^\delta-\nabla g_{i-1}^\delta|^2;$$

(4) if $|\nabla u_{i-1}^\delta + \nabla g_i^\delta - \nabla g_{i-1}^\delta| < \frac{a}{2}$ and $|\nabla u_{i-1}^\delta| < \frac{a}{2}$,

$$f(\nabla u_{i-1}^\delta+\nabla g_i^\delta-\nabla g_{i-1}^\delta) = f(\nabla u_{i-1}^\delta)+2(\nabla u_{i-1}^\delta, \nabla g_i^\delta-\nabla g_{i-1}^\delta)+|\nabla g_i^\delta-\nabla g_{i-1}^\delta|^2.$$

Then by convexity of f we deduce

$$\mathcal{E}^\delta(t_i^\delta, u_i^\delta) \le \mathcal{E}^\delta(t_{i-1}^\delta, u_{i-1}^\delta) + \int_\Omega f'(\nabla u_{i-1}^\delta)(\nabla g_i^\delta - \nabla g_{i-1}^\delta)\,dx + R_{i-1}^{\delta,a},$$

where

$$R_{i-1}^{\delta,a} := \int_\Omega |\nabla g_i^\delta - \nabla g_{i-1}^\delta|^2\,dx + \int_{\{|\nabla u_{i-1}^\delta| \ge \frac{a}{2}\}} |f'(\nabla u_{i-1}^\delta)|\,|\nabla g_i^\delta - \nabla g_{i-1}^\delta|\,dx.$$

Then summing up from t_i^δ to t_0^δ, and taking into account (3.7) we get

$$\mathcal{E}^\delta(t, u^\delta(t)) \le \mathcal{E}^\delta(0, u^\delta(0)) + \int_0^{t_i^\delta}\int_\Omega f'(\nabla u^\delta(\tau))\nabla \dot g(\tau)\,dx\,d\tau + \int_0^{t_i^\delta} R^{\delta,a}(\tau)\,d\tau,$$

where

$$R^{\delta,a}(\tau) := \sigma(\delta)\|\nabla \dot g(\tau)\| + \int_{\{|\nabla u^\delta(\tau)| \ge \frac{a}{2}\}} |f'(\nabla u^\delta(\tau))|\,|\nabla \dot g(\tau)|\,dx$$

and

$$\sigma(\delta) := \max_{i=1,\dots,N_\delta} \int_{t_{i-1}^\delta}^{t_i^\delta} \|\nabla \dot g\|\,d\tau.$$

In order to conclude the proof it is sufficient to see that

$$\int_0^T R^{\delta,a}(\tau)\,d\tau \to 0$$

as $\delta \to 0$ and $a \to +\infty$. Notice that $\sigma(\delta) \to 0$ as $\delta \to 0$ by the absolutely continuity of $\|\nabla \dot g\|$. Let us come to the second term. Note that $|f'(\nabla u^\delta(\tau))| = a$ on $\{|\nabla u^\delta(\tau)| \ge \frac{a}{2}\}$. Then we have to see

$$\int_0^T \int_\Omega a|\nabla \dot g(\tau)| 1_{\{|\nabla u^\delta(\tau)| \ge \frac{a}{2}\}}\,dx\,d\tau \to 0 \tag{3.9}$$

as $\delta \to 0$ and $a \to +\infty$. Setting $A_a^\delta(\tau) := \{x \in \Omega : |\nabla u^\delta(\tau)|(x) \ge \frac{a}{2}\}$ we have by Hölder inequality

$$\int_\Omega a|\nabla \dot g(\tau)| 1_{A_a^\delta(\tau)}\,dx \le a\sqrt{|A_a^\delta(\tau)|}\left(\int_{A_a^\delta(\tau)} |\nabla \dot g(\tau)|^2\,dx\right)^{\frac{1}{2}}.$$

Notice that

$$\frac{a^2}{2}|A_a^\delta(\tau)| \le a\int_{A_a^\delta(\tau)} |\nabla u^\delta(\tau)|\,dx \le 2\int_{A_a^\delta(\tau)} f(\nabla u^\delta(\tau))\,dx \le C', \tag{3.10}$$

where C' depends only on g and is obtained comparing $u^\delta(\tau)$ with $g^\delta(\tau)$ by means of (3.6). We deduce that

$$\int_\Omega a|\nabla \dot g(\tau)| 1_{A_a^\delta(\tau)}\,dx \le \sqrt{2C'}\left(\int_{A_a^\delta(\tau)} |\nabla \dot g(\tau)|^2\,dx\right)^{\frac{1}{2}} \le \sqrt{2C'}\|\nabla \dot g(\tau)\|.$$

As $\delta \to 0$ and $a \to +\infty$, by (3.10) we have that $|A_a^\delta(\tau)| \to 0$. Then by the equicontinuity of $|\nabla \dot g(\tau)|^2$ and by the Dominated Convergence theorem, we deduce that (3.9) holds, and the proof is finished. □

4. The main results. Let Ω be an open, connected, and bounded subset of $\mathbb{R}^N$ with Lipschitz boundary. Let $\partial_D\Omega \subseteq \partial\Omega$ be open in the relative topology, and let $\partial_N\Omega := \partial\Omega \setminus \partial_D\Omega$.

In this section we consider discrete-in-time evolution of cracks in a linearly elastic body whose reference configuration is given by $\Omega_h := h\Omega$, where h is positive and large. Let us assume that the cohesive forces on the cracks of Ω_h are given in the sense of section 3 by a function $\varphi : [0,+\infty[\to [0,1]$ which is increasing, concave, $\varphi(0) = 0$, $\varphi'(0) = a < +\infty$, and such that $\lim_{s\to+\infty} \varphi(s) = 1$. Let us moreover set

$$f(\xi) := \begin{cases} |\xi|^2 & \text{if } |\xi| \le \frac{a}{2}, \\ \\ \frac{a^2}{4} + a(|\xi| - \frac{a}{2}) & \text{if } |\xi| \ge \frac{a}{2}. \end{cases} \tag{4.1}$$

Let us consider on $\partial_D\Omega_h := h\partial_D\Omega$ boundary displacements of the following particular form:

$$g_h(t,x) := h^\alpha g\left(t, \frac{x}{h}\right), \tag{4.2}$$

with $g \in AC([0,T]; H^1(\Omega))$ such that $\|g(t)\|_\infty \le C$ for all $t \in [0,T]$. Given $\delta > 0$, let

$$I_\delta = \{0 = t_0^\delta < \cdots < t_{N_\delta}^\delta = T\}$$

be a subdivision of $[0,T]$ such that $\max(t_i^\delta - t_{i-1}^\delta) < \delta$, and let

$$\{t \to (u^{\delta,h}(t), \Gamma^{\delta,h}(t), \psi^{\delta,h}(t)) \,:\, t \in [0,T]\}$$

be the piecewise constant interpolation in the sense of (3.7) of a discrete-in-time evolution of cracks in Ω_h relative to the boundary datum g_h and the subdivision I_δ given by Proposition 3.1.

Our aim is to study the asymptotic behavior of $\{t \to (u^{\delta,h}(t), \Gamma^{\delta,h}(t), \psi^{\delta,h}(t)) : t \in [0,T]\}$ as $\delta \to 0$ and $h \to +\infty$. Let us consider $h \in \mathbb{N}$ (we can consider any sequence which diverges to $+\infty$), let us fix $\delta_h \to 0$, and let us set for all $t \in [0,T]$

$$u_h(t) := u^{\delta_h,h}(t), \qquad \Gamma_h(t) := \Gamma^{\delta_h,h}(t), \qquad \psi_h(t) := \psi^{\delta_h,h}(t), \tag{4.3}$$

and let $g_h^{\delta_h}(t) := g_h(t_i^{\delta_h})$ where $t_i^{\delta_h} \in I_{\delta_h}$ is such that $t_i^{\delta_h} \le t < t_{i+1}^{\delta_h}$. Let us moreover set for every $v \in BV(\Omega)$ and for every $t \in [0,T]$

$$\begin{aligned} \mathcal{E}_h(t,v) := &\int_{\Omega_h} f(\nabla v)\,dx + \int_{S^{g_h^{\delta_h}(t)}(v)\cup\Gamma_h(t)} \varphi(|[v]| \vee \psi_h(t))\,d\mathcal{H}^{N-1} \\ &+ a|D^c v|(\Omega_h). \end{aligned} \tag{4.4}$$

The asymptotic of (u_h, Γ_h, ψ_h) depends on α, and we have to distinguish three cases. The first case $\alpha = \frac{1}{2}$ was stated in the introduction and reveals the prevalence of brittle effects as the size of the body increases. We give here the precise statement we will prove.

THEOREM 4.1. *Let $g \in AC(0,T;H^1(\Omega))$ be such that $\|g(t)\|_\infty \le C$ for all $t \in [0,T]$. Let $\{t \to (u_h(t), \Gamma_h(t), \psi_h(t)) : t \in [0,T]\}$ be the piecewise constant interpolation given in* (4.3) *of a discrete-in-time evolution of cracks in Ω_h relative to the boundary data*

$$g_h(x,t) := \sqrt{h}\, g\left(\frac{x}{h}, t\right).$$

Then the following facts hold:

(a) *there exists a constant C' dependent only on g such that for all $t \in [0,T]$*

$$\frac{1}{h^{N-1}}\mathcal{E}_h(t,u_h(t)) \le C';$$

(b) *for all $t \in [0,T]$*

$$v_h(t,x) := \frac{1}{\sqrt{h}}u_h(t,hx) \qquad \text{is bounded in } BV(\Omega);$$

(c) *there exists a subsequence independent of t and there exists a quasi-static crack evolution $\{t \to (v(t),K(t)) : t \in [0,T]\}$ in Ω relative to boundary displacement g in the sense of Theorem 2.2 such that for all $t \in [0,T]$ we have*

$$\nabla v_h(t) \rightharpoonup \nabla v(t) \qquad \text{weakly in } L^1(\Omega;\mathbb{R}^N),$$

and every accumulation point v of $(v_h(t))_{h\in\mathbb{N}}$ in the weak topology of $BV(\Omega)$ is such that $v \in SBV(\Omega)$, $S^{g(t)}(v) \tilde{\subseteq} K(t)$, and $\nabla v = \nabla v(t)$. Moreover, for all $t \in [0,T]$ we have*

$$\frac{1}{h^{N-1}}\mathcal{E}_h(t,u_h(t)) \to \|\nabla v(t)\|^2 + \mathcal{H}^{N-1}(K(t)); \tag{4.5}$$

in particular $h^{-N+1}|D^c u_h(t)|(\Omega_h)| \to 0$,

$$\frac{1}{h^{N-1}}\int_{\Omega_h} f(\nabla u_h(t))\,dx \to \|\nabla v(t)\|^2, \tag{4.6}$$

and

$$\frac{1}{h^{N-1}}\int_{\Gamma_h(t)} \varphi(\psi_h(t))\,d\mathcal{H}^{N-1} \to \mathcal{H}^{N-1}(K(t)). \tag{4.7}$$

Notice that in point (c) we cannot assert that the sequence $(v_h(t))_{h\in\mathbb{N}}$ converges to $v(t)$ in the weak* topology of $BV(\Omega)$: this is due to the fact that $K(t)$ could disconnect Ω (in a weak sense), so that $v(t)$ is determined up to a constant on the components of $\Omega \setminus K$ which do not touch $\partial_D\Omega$.

The case $\alpha < \frac{1}{2}$ leads to a problem in elasticity in Ω_h in the sense of the following theorem.

THEOREM 4.2. *Let $g \in AC(0,T;H^1(\Omega))$ be such that $\|g(t)\|_\infty \le C$ for all $t \in [0,T]$. Let $\{t \to (u_h(t),\Gamma_h(t),\psi_h(t)) : t \in [0,T]\}$ be the piecewise constant interpolation given in* (4.3) *of a discrete-in-time evolution of cracks in Ω_h relative to the boundary data*

$$g_h(x,t) := h^\alpha g\left(t,\frac{x}{h}\right)$$

with $\alpha < \frac{1}{2}$. Then the following facts hold:

(a) *for all $t \in [0,T]$*

$$v_h(t,x) := \frac{1}{h^\alpha}u_h(t,hx) \qquad \text{is bounded in } BV(\Omega);$$

(b) *there exists a subsequence independent of* t *such that for all* $t \in [0,T]$ *we have* $v_h(t) \overset{*}{\rightharpoonup} v(t)$ *weakly* in* $BV(\Omega)$ *and*

$$\nabla v_h(t) \rightharpoonup \nabla v(t) \qquad \text{weakly in } L^1(\Omega;\mathbb{R}^N),$$

where $v(t)$ *is the minimizer of*

$$\min\{\|\nabla v\|^2 \,:\, v \in H^1(\Omega), v = g(t) \text{ on } \partial_D\Omega\};$$

moreover for all $t \in [0,T]$ *we have*

$$\frac{1}{h^{N+2\alpha-2}} \int_{\Omega_h} f(\nabla u_h(t))\,dx \to \|\nabla v(t)\|^2.$$

Finally for the case $\alpha > \frac{1}{2}$ the body goes to *rupture* at time $t = 0$, in the sense of the following theorem.

THEOREM 4.3. *Let* $g \in AC(0,T;H^1(\Omega))$ *be such that* $\|g(t)\|_\infty \le C$ *for all* $t \in [0,T]$. *Let* $\{t \to (u_h(t), \Gamma_h(t), \psi_h(t)) \,:\, t \in [0,T]\}$ *be the piecewise constant interpolation given in* (4.3) *of a discrete-in-time evolution of cracks in* Ω_h *relative to the boundary data*

$$g_h(x,t) := h^\alpha g\left(\frac{x}{h}, t\right)$$

with $\alpha > \frac{1}{2}$. *Let us set* $v_h(t,x) := \frac{1}{h^\alpha} u_h(t,hx)$ *for all* $x \in \Omega$ *and for all* $t \in [0,T]$.

Then $(v_h(0))_{h\in\mathbb{N}}$ *is bounded in* $BV(\Omega)$, *and every accumulation point* v *of* $(v_h(0))_{h\in\mathbb{N}}$ *in the weak* topology of* $BV(\Omega)$ *is piecewise constant in* Ω, *i.e.,* $v \in SBV(\Omega)$ *and* $\nabla v = 0$. *Moreover,*

$$\mathcal{H}^{N-1}(S^{g(0)}(v(0))) \le \mathcal{H}^{N-1}(S^{g(0)}(w)) \tag{4.8}$$

for all piecewise constant function $w \in SBV(\Omega)$.

Notice that the minimality property (4.8) can be restated saying that $v(0)$ determines a minimal partition of Ω (in the sense of the perimeter of $S^{g(0)}(w)$).

5. Some tools for the asymptotic analysis. In this section we prove some technical propositions which will be very useful in the proofs of the main results of the paper. More precisely, we will prove compactness results for the displacements and the cracks, and we will prove a generalization of the Transfer of Jump of [13] which will be employed in order to study what the minimality property of the discrete-in-time evolutions imply in the limit.

For all $h \in \mathbb{N}$ let $f_h : \mathbb{R}^N \to [0,+\infty[$ be such that for all $\xi \in \mathbb{R}^N$

$$f_h(\xi) \nearrow |\xi|^2, \qquad f_h(\xi) \ge \min\{|\xi|^2 - 1, b_h|\xi|\} \tag{5.1}$$

with $b_h \to +\infty$ as $h \to +\infty$, and let $\varphi_h : [0,+\infty[\to [0,1]$ be increasing and such that for all $s \in [0,+\infty[$

$$\varphi_h(s) \ge \min\{c_h s, d_h\} \tag{5.2}$$

with $c_h \to +\infty$ and $d_h \nearrow 1$ for $h \to +\infty$.

5.1. Compactness for the displacements. In this subsection we give a compactness and lower semicontinuity result for the displacements whose proof is inspired by the proof of Ambrosio's compactness theorem (see [3]).

PROPOSITION 5.1. *Let us consider the functionals*

$$F_h(u) := \sum_{i=1}^{m} \int_\Omega f_h(\nabla u_i)\,dx + \int_{S(u)} \varphi_h(|[u_1]| \vee \cdots \vee |[u_m]|)\,d\mathcal{H}^{N-1} + a_h|D^c u|(\Omega),$$

where $u = (u_1, \dots, u_m) \in BV(\Omega;\mathbb{R}^m)$ *(with* f_h *and* φ_h *defined in* (5.1) *and* (5.2)*). Let* $a_h \to +\infty$ *for* $h \to +\infty$*, and let* $(u_h)_{h\in\mathbb{N}}$ *be a sequence in* $BV(\Omega)$*. Then the following facts hold.*

(a) *If*

$$F_h(u^h) + \|u^h\|_{L^\infty(\Omega;\mathbb{R}^m)} \le C$$

for some $C \in [0, +\infty[$*, then up to a subsequence*

$$u^h \overset{*}{\rightharpoonup} u \qquad \text{weakly* in } BV(\Omega;\mathbb{R}^m).$$

(b) *If* $F_h(u^h) \le C$ *for some* $C \in [0, +\infty[$ *and* $u^h \overset{*}{\rightharpoonup} u$ *weakly* in* $BV(\Omega;\mathbb{R}^m)$*, then* $u \in SBV(\Omega;\mathbb{R}^m)$*,*

$$\nabla u^h \rightharpoonup \nabla u \qquad \text{weakly in } L^1(\Omega;\mathbb{R}^{m\times N}), \tag{5.3}$$

$$\|\nabla u_i\|^2 \le \liminf_{h\to+\infty} \int_\Omega f_h(\nabla u_i^h)\,dx, \qquad i = 1, \dots, m, \tag{5.4}$$

and

$$\mathcal{H}^{N-1}(S(u)) \le \liminf_{h\to+\infty} \int_{S(u^h)} \varphi_h(|[u_1^h]| \vee \cdots \vee |[u_m^h]|)\,d\mathcal{H}^{N-1}. \tag{5.5}$$

Proof. As for point (a), let us prove that there exists C' independent of h such that we have

$$|Du^h(t)|(\Omega) \le C'. \tag{5.6}$$

In fact, since for h large we have for all $\xi \in \mathbb{R}^N$

$$|\xi| - 1 \le f_h(\xi),$$

we deduce that for all $i = 1, \dots, m$

$$\int_\Omega |\nabla u_i^h|\,dx \le \int_\Omega [f_h(\nabla u_i^h) + 1]\,dx \le C + |\Omega|,$$

where $|\Omega|$ denotes the Lebesgue measure of Ω. Moreover, if h is so large that $s \le 2\varphi_h(s)$ for all $s \in [0, 1]$, we have for all $i = 1, \dots, m$

$$\begin{aligned}\int_{S(u_i^h)} |[u_i^h]|\,d\mathcal{H}^{N-1} &\le \int_{|[u_i^h]|<1} |[u_i^h]|\,d\mathcal{H}^{N-1} + \|u_i^h(t)\|_\infty \mathcal{H}^{N-1}\left(\left\{|[u_i^h]| \ge 1\right\}\right)\\ &\le 2\int_{|[u_i^h]|<1} \varphi_h(|[u_i^h]|)\,d\mathcal{H}^{N-1} + 2C\int_{|[u_i^h]|\ge1} \varphi_h(|[u_i^h]|)\,d\mathcal{H}^{N-1} \le 2(1+C)C.\end{aligned}$$

Finally for all h

$$|D^c u^h|(\Omega) \le \frac{C}{a_h}.$$

We deduce that (5.6) holds, and so up to a subsequence we may suppose that $u_h \overset{*}{\rightharpoonup} u$ weakly* in $BV(\Omega;\mathbb{R}^m)$.

Let us come to point (b). Let us consider $u^h \in BV(\Omega)$ such that $u^h \overset{*}{\rightharpoonup} u$ weakly* in $BV(\Omega;\mathbb{R}^m)$ and $F_h(u^h) \le C$. Notice that $(\nabla u^h)_{h\in\mathbb{N}}$ is equi-integrable. In fact if r_h is such that for all $|\xi| \le r_h$

$$|\xi|^2 - 1 \le b_h|\xi|,$$

we get for all $i = 1,\dots,m$ and for all $E \subseteq \Omega$

$$\begin{aligned}\int_E |\nabla u_i^h|\,dx &\le \int_{\{|\nabla u_i^h|\le r_h\}\cap E} |\nabla u_i^h|\,dx + \int_{\{|\nabla u_i^h|> r_h\}\cap E} |\nabla u_i^h|\,dx\\ &\le \left(\int_{\{|\nabla u_i^h|\le r_h\}\cap E} |\nabla u_i^h|^2\,dx\right)^{\frac12} |E|^{\frac12} + \int_{\{|\nabla u_i^h|> r_h\}\cap E} |\nabla u_i^h|\,dx\\ &\le \left(\int_\Omega (f_h(\nabla u_i^h)+1)\,dx\right)^{\frac12} |E|^{\frac12} + \frac{1}{b_h}\int_\Omega f_h(\nabla u_i^h)\,dx \le \sqrt{(C+|\Omega|)|E|} + \frac{C}{b_h}.\end{aligned}$$

This proves that ∇u_h is equi-integrable. Up to a subsequence we may suppose that for all $i = 1,\dots,m$ we have

$$\nabla u_i^h \rightharpoonup g_i \qquad \text{weakly in } L^1(\Omega;\mathbb{R}^N).$$

Since $a_h \to +\infty$, we get $D^c u^h \to 0$ strongly in the sense of measures.

Let $\psi : \mathbb{R} \to \mathbb{R}$ be bounded, Lipschitz, and C^1, and for all $i = 1,\dots,m$ let us consider the measures

$$\mu_i^h(B) := D\psi(u_i^h)(B) - \int_B \psi'(u_i^h)\nabla u_i^h\,dx, \qquad \lambda_i^h(B) := \int_{S(u_i^h)\cap B} \varphi_h(|[u_i^h]|)\,d\mathcal{H}^{N-1},$$

where B is a Borel set in Ω. Notice that $\psi(u_i^h) \in BV(\Omega)$, and that by chain rule in BV (see [4, Theorem 3.96]) we have

$$D\psi(u_i^h) = \psi'(u_i^h)\nabla u_i^h\,d\mathcal{L}^N + (\psi((u_i^h)^+) - \psi((u_i^h)^-))\nu\mathcal{H}^{N-1}\llcorner S(u_i^h) + \psi'(\tilde u_i^h)D^c u_i^h,$$

where $\tilde u_i^h(x)$ is the Lebesgue value of u_i^h at x. We deduce that

$$|D\psi(u_i^h) - \psi'(u_i^h)\nabla u_i^h\,d\mathcal{L}^N| \le ||\psi||_{\varphi_h}\lambda_i^h + ||\psi'||_\infty |D^c u_i^h|, \tag{5.7}$$

where

$$||\psi||_{\varphi_h} := \sup\left\{\frac{\psi(t)-\psi(s)}{\varphi_h(|t-s|)} \,:\, t \ne s\right\}.$$

Up to a subsequence we have

$$\mu_i^h \overset{*}{\rightharpoonup} D\psi(u_i) - \psi'(u)g_i\,d\mathcal{L}^N, \qquad \lambda_i^h \overset{*}{\rightharpoonup} \lambda_i$$

weakly* in the sense of measures, and so from (5.7), by lower semicontinuity for the variations of measures (see [4, Proposition 1.62]) and since $D^c u^h \to 0$ strongly in the sense of measures we get

$$|D\psi(u_i) - \psi'(u) g_i \, d\mathcal{L}^N| \le (\sup \psi - \inf \psi)\lambda_i.$$

As a consequence of SBV characterization (see [4, Proposition 4.12]), we get that $u_i \in SBV(\Omega)$, $\nabla u_i = g_i$, and $\mathcal{H}^{N-1} \llcorner S(u_i) \le \lambda_i$ for all $i = 1, \dots, m$. We deduce that (5.3) holds.

In order to prove (5.4), for every $M > 0$ let g_i^M be the weak limit in $L^1(\Omega)$ (up to a subsequence) of $|\nabla u_i^h| \wedge M$. Since $f_h(\xi) \to |\xi|^2$ uniformly on $[0, M]$, we have

$$\|g_i^M\|^2 \le \liminf_{h \to +\infty} \int_\Omega f_h(\nabla u_i^h) \, dx.$$

Then letting $M \to +\infty$ we obtain (5.4).

Let us come to (5.5). If λ is the weak limit in the sense of measures of

$$\lambda^h(A) := \int_{S(u^h) \cap A} \varphi_h(|[u_1^h]| \vee \cdots \vee |[u_m^h]|) \, d\mathcal{H}^{N-1},$$

we have that $\lambda_i \le \lambda$ for all $i = 1, \dots, m$. Since we have $\mathcal{H}^{N-1} \llcorner S(u_i) \le \lambda_i$ for all $i = 1, \dots, m$, we deduce that $\mathcal{H}^{N-1} \llcorner S(u) \le \lambda$, so that (5.5) is proved. □

5.2. Compactness for the cracks. This subsection is devoted to the proof of a compactness property for the cracks of the discrete-in-time evolutions, which is closely related to the notion of σ^p-convergence of sets defined in [11].

The convergence we propose is related to the energies which appear in the asymptotic study of the size effects, and so it depends on the cracks, but also on the bulk and surface energies, and on the rate at which the Cantor parts of the derivative of the displacements are disappearing.

Let $(K_h)_{h \in \mathbb{N}}$ be a sequence of rectifiable sets in $\Omega \cup \partial_D \Omega$, and let $f_h : \mathbb{R}^N \to [0, +\infty[$ and $\varphi_h : [0, +\infty[\to [0, 1]$ be such that (5.1) and (5.2) hold. Let γ_h be a positive function on K_h such that for all h

$$\int_{K_h} \varphi_h(\gamma_h) \, d\mathcal{H}^{N-1} < C \tag{5.8}$$

for some $C \in [0, +\infty[$, and let $a_h \to +\infty$. Let $g_h, g \in H^1(\Omega)$ be such that $g_h \to g$ strongly in $H^1(\Omega)$. Let us set for all $u \in BV(\Omega)$

$$\mathcal{E}_h(u) := \int_\Omega f_h(\nabla u) \, dx + \int_{S^{g_h}(u)} \varphi_h(|[u]|) \, d\mathcal{H}^{N-1} + a_h |D^c u|(\Omega).$$

Then the following compactness result holds.

PROPOSITION 5.2. *Up to a subsequence there exists a rectifiable set $K \tilde{\subseteq} \Omega \cup \partial_D \Omega$ such that the following facts hold:*

(a) *for all subsequences $(h_k)_{k \in \mathbb{N}}$ and for all $(u_k)_{k \in \mathbb{N}}$ such that $S^{g_{h_k}}(u_k) \tilde{\subseteq} K_{h_k}$, $|[u_k]| \le \gamma_{h_k}$, $\mathcal{E}_{h_k}(u_{h_k}) \le C'$ for some $C' \in [0, +\infty[$, and $u_k \overset{*}{\rightharpoonup} u$ weakly* in $BV(\Omega)$, we have $u \in SBV(\Omega)$, $\nabla u \in L^2(\Omega; \mathbb{R}^N)$, and $S^g(u) \tilde{\subseteq} K$;*

(b) *there exists a countable set D in $SBV(\Omega)$ such that*

$$K = \bigcup_{u\in D} S^g(u), \tag{5.9}$$

where for every $u \in D$ there exists a sequence $(u_h)_{h\in\mathbb{N}}$ in $BV(\Omega)$ with $S^{g_h}(u_h) \tilde{\subseteq} K_h$, $|[u_h]| \le \gamma_h$, $\mathcal{E}_h(u_h) \le C'$ for some $C' \in [0,+\infty[$, and $u_h \overset{*}{\rightharpoonup} u$ weakly in $BV(\Omega)$;*

(c) *we have*

$$\mathcal{H}^{N-1}(K) \le \liminf_{h\to+\infty} \int_{K_h} \varphi_h(\gamma_h)\, d\mathcal{H}^{N-1}. \tag{5.10}$$

Proof. Our approach is based on Γ-convergence (see section 2). In order to deal with $S^g(u)$ as an internal jump, let us consider $\tilde{\Omega} \subseteq \mathbb{R}^N$ open and bounded, such that $\overline{\Omega} \subseteq \tilde{\Omega}$, and let us set $\Omega' := \tilde{\Omega} \setminus \partial_N\Omega$.

Let us consider the functionals $\mathcal{E}'_h : BV(\Omega') \to [0,+\infty]$,

$$\mathcal{E}'_h(u) := \int_{\Omega'} f_h(\nabla u)\, dx + \int_{S(u)} \varphi_h(|[u]|)\, d\mathcal{H}^{N-1} + a_h|D^c u|(\Omega'),$$

if $u \in BV(\Omega')$, $u = g_h$ on $\Omega' \setminus \Omega$, $S(u) \tilde{\subseteq} K_h$, $|[u]| \le \gamma_h$ on K_h, and $\mathcal{E}'_h(u) = +\infty$ otherwise for $u \in BV(\Omega')$. Let us consider on $BV(\Omega')$ the strong topology of $L^1(\Omega')$. By Proposition 2.4, up to a subsequence, $(\mathcal{E}'_h)_{h\in\mathbb{N}}$ Γ-converges to a functional $\mathcal{E}'$. We denote this subsequence still by $(\mathcal{E}'_h)_{h\in\mathbb{N}}$, and we may suppose that the liminf in (5.10) and the liminf along this subsequence are equal.

Let us consider

$$\mathrm{epi}(\mathcal{E}') := \{(u,s) \in BV(\Omega') \times \mathbb{R} : \mathcal{E}'(u) \le s\},$$

and let $\mathcal{D} \subseteq \mathrm{epi}(\mathcal{E}'(t))$ be countable and dense. If $\pi : BV(\Omega') \times \mathbb{R} \to BV(\Omega')$ denotes the projection on the first factor, let $D := \pi(\mathcal{D})$ and let us set

$$K := \bigcup_{u\in D} S(u).$$

Notice that by a truncation argument we may suppose that each $u \in D$ is bounded in $L^\infty(\Omega)$, and moreover that there exists $u_h \in BV(\Omega')$ such that $u_h \overset{*}{\rightharpoonup} u$ weakly* in $BV(\Omega')$ and $\mathcal{E}'_h(u_h) \le C'$ with $C' \in [0,+\infty[$. By Proposition 5.1 and Γ-liminf inequality we deduce that $u \in SBV(\Omega')$ and

$$\|\nabla u\|^2 + \mathcal{H}^{N-1}(S(u)) \le \mathcal{E}'(u). \tag{5.11}$$

Then K is precisely of the form (5.9) once we consider the restriction of u to Ω and recall that $u = g$ on $\Omega' \setminus \Omega$. Thus point (b) is proved.

Let us prove that (5.10) holds. Let $u_1, \dots, u_k \in D$, and let $u_1^h, \dots, u_k^h \in BV(\Omega')$ be such that $u_i^h \overset{*}{\rightharpoonup} u_i$ weakly* in $BV(\Omega')$ and

$$\lim_{h\to+\infty} \mathcal{E}'_h(u_i^h) = \mathcal{E}'(u_i), \qquad i = 1,\dots,k. \tag{5.12}$$

Setting $u^h := (u_1^h, \dots, u_k^h)$, by (5.12) we have

$$\sum_{i=1}^k \int_{\Omega'} f_h(\nabla u_i^h)\, dx + \int_{S(u^h)} \varphi_h(|[u_1^h]| \vee \cdots \vee |[u_k^h]|)\, d\mathcal{H}^{N-1} + a_h|D^c u^h|(\Omega') \le \tilde{C}$$

with $\tilde{C}$ independent of h. By Proposition 5.1 we deduce

$$\mathcal{H}^{N-1}\left(\bigcup_{i=1}^{k} S(u_i)\right) \leq \liminf_{h\to+\infty} \int_{S(u^h)} \varphi_h(|[u_1^h]| \vee \cdots \vee |[u_k^h]|)\, d\mathcal{H}^{N-1}$$
$$\leq \liminf_{h\to+\infty} \int_{K_h} \varphi_h(\gamma_h)\, d\mathcal{H}^{N-1}.$$

Taking the sup over all possible $u_1, \ldots, u_k$ we get

$$\mathcal{H}^{N-1}(K) \leq \liminf_{h\to+\infty} \int_{K_h(t)} \varphi_h(\gamma_h(t))\, d\mathcal{H}^{N-1},$$

so that (5.10) is proved. In particular, by (5.8) we have that $\mathcal{H}^{N-1}(K) < +\infty$.

Let us come to point (a). Let us extend u_k and u to Ω' setting $u_k = g_{h_k}$ and $u = g$ on $\Omega' \setminus \overline{\Omega}$. By Proposition 5.1 we get $u \in SBV(\Omega')$ and $\nabla u \in L^2(\Omega'; \mathbb{R}^N)$. Let us see that $S(u) \tilde{\subseteq} K$. Notice that by Γ-liminf inequality we have

$$\mathcal{E}'(u) \leq \liminf_{k\to+\infty} \mathcal{E}'_{h_k}(u_k) < +\infty,$$

so that $(u, \mathcal{E}'(u)) \in \mathrm{epi}(\mathcal{E}')$. Let $(v_j, s_j) \in \mathcal{D}$ be such that $v_j \to u$ strongly in $L^1(\Omega')$ and $s_j \to \mathcal{E}'(u)$. By truncation, we may assume that u and v_j are uniformly bounded in L^∞. We know that $v_j \in SBV(\Omega')$ for all j, and that by (5.11)

$$\|\nabla v_j\|^2 + \mathcal{H}^{N-1}(S(v_j)) \leq \mathcal{E}'(v_j). \tag{5.13}$$

By lower semicontinuity of $\mathcal{E}'$ we have

$$\mathcal{E}'(u) \leq \liminf_{j\to+\infty} \mathcal{E}'(v_j).$$

Moreover, since $\mathcal{E}'(v_j) \leq s_j$, we deduce

$$\limsup_{j\to+\infty} \mathcal{E}'(v_j) \leq \lim_{j\to+\infty} s_j = \mathcal{E}'(u),$$

so that we have $\mathcal{E}'(v_j) \to \mathcal{E}'(u) < +\infty$. By (5.13) we conclude that $v_j \rightharpoonup u$ weakly in $SBV(\Omega')$: since $S(v_j) \tilde{\subseteq} K$ for all j, and $\mathcal{H}^{N-1}(K) < +\infty$, by Ambrosio's theorem we get $S(u) \tilde{\subseteq} K$. The proof is now complete. □

Remark 5.3. Notice that in the case $f_h(\xi) = |\xi|^p$ ($p \in]1, +\infty[$) and $\varphi_h = 1$, and no Cantor part is considered (i.e., $a_h = +\infty$), Proposition 5.2 gives an alternative proof of the compactness and lower semicontinuity properties of σ^p-convergence of sets formulated in [11].

Notice moreover that the limit set of Proposition 5.2 is contained (up to negligible $\mathcal{H}^{N-1}$ set) in $\Omega \cup \partial_D\Omega$, so that $\partial_N\Omega$ is not involved: this is done in view of the concrete application to quasi-static crack growth, where convergence for the surface energy holds, and so a crack would never approach $\partial_N\Omega$ otherwise but transversally. This can be seen also from an energetic point of view, since the displacement can choose the more convenient boundary datum on $\partial_N\Omega$ without creating a crack on this part of the boundary.

5.3. A generalization of the Transfer of Jump. In this subsection we prove a generalization of the Transfer of Jump theorem of Francfort–Larsen [13] which will be useful in the proof of Theorem 4.1.

Let $f_h : \mathbb{R}^N \to [0,+\infty[$ and $\varphi_h : [0,+\infty[\to [0,1]$ be such that (5.1) and (5.2) hold. Then the following proposition holds.

PROPOSITION 5.4. *Let $(u_h)_{h\in\mathbb{N}}$ be a sequence in $BV(\Omega)$ such that $(\nabla u_h)_{h\in\mathbb{N}}$ is equi-integrable,*

$$\sup_h \int_{S(u_h)} \varphi_h(|[u_h]|)\, d\mathcal{H}^{N-1} \le C, \quad \text{and} \qquad |D^c u_h|(\Omega) \to 0. \tag{5.14}$$

Let $u \in SBV(\Omega)$ be such that $u_h \overset{*}{\rightharpoonup} u$ weakly in $BV(\Omega)$, and let $g_h, g \in H^1(\Omega)$ be such that $g_h \to g$ strongly in $H^1(\Omega)$. Then for all $v \in SBV(\Omega)$ with $\nabla v \in L^2(\Omega;\mathbb{R}^N)$ there exists $v_h \in SBV(\Omega)$ such that $\nabla v_h \to \nabla v$ strongly in $L^2(\Omega;\mathbb{R}^N)$ and*

$$\limsup_{h\to+\infty} \left[\int_{S^{g_h}(v_h)\cup S^{g_h}(u_h)} \varphi_h(|[v_h]| \vee |[u_h]|)\, d\mathcal{H}^{N-1} - \int_{S^{g_h}(u_h)} \varphi_h(|[u_h]|)\, d\mathcal{H}^{N-1} \right] \le \mathcal{H}^{N-1}(S^g(v) \setminus S^g(u)).$$

Proof. In order to deal with $S^g(u)$ as an internal jump, let us consider $\tilde\Omega \subseteq \mathbb{R}^N$ open and bounded, and such that $\overline\Omega \subseteq \tilde\Omega$. Let us set $\Omega' := \tilde\Omega \setminus \partial_N\Omega$. Let $v \in SBV(\Omega)$ with $\nabla v \in L^2(\Omega;\mathbb{R}^N)$ and $\mathcal{H}^{N-1}(S^g(v)) < +\infty$. Let us consider

$$w := v - g, \qquad z := u - g, \qquad z_h := u_h - g_h,$$

and let us extend w, z, z_h to Ω' setting $w = z = z_h = 0$ on $\Omega' \setminus \Omega$. In this setting, we have to find $w_h \in SBV(\Omega')$ such that $w_h \equiv 0$ on $\Omega' \setminus \Omega$, $\nabla w_h \to \nabla w$ strongly in $L^2(\Omega';\mathbb{R}^N)$, and such that

$$\limsup_{h\to+\infty} \left[\int_{S(w_h)\cup S(z_h)} \varphi_h(|[w_h]| \vee |[z_h]|)\, d\mathcal{H}^{N-1} - \int_{S(z_h)} \varphi_h(|[z_h]|)\, d\mathcal{H}^{N-1} \right] \le \mathcal{H}^{N-1}(S(w) \setminus S(z)).$$

Then the result follows considering the restriction of w_h to Ω, and setting $v_h := w_h + g_h$.

The key point in the proof is the following: for all $\varepsilon > 0$ find $\delta > 0$ and $w_h \in SBV(\Omega')$ such that $w_h \equiv 0$ on $\Omega' \setminus \Omega$,

$$\limsup_{h\to+\infty} \|\nabla w_h - \nabla w\|_{L^2(\Omega';\mathbb{R}^N)} \le \varepsilon, \tag{5.15}$$

and

$$\limsup_{h\to+\infty} \mathcal{H}^{N-1}(S(w_h) \setminus K_h^\delta) \le \mathcal{H}^{N-1}(S(w) \setminus S(z)) + \varepsilon, \tag{5.16}$$

where $K_h^\delta := \{x \in S(z_h) : |[z_h]| \ge \delta\}$. In fact if (5.16) holds, noting that by (5.14) we get $\mathcal{H}^{N-1}(K_h^\delta) \le C + 1$ for h large enough, following the decomposition

$$\begin{aligned} S(w_h) \cup S(z_h) &= (S(w_h) \setminus K_h^\delta) \cup (S(w_h) \cap K_h^\delta) \\ &\qquad \cup (K_h^\delta \setminus S(w_h)) \cup [S(z_h) \setminus (S(w_h) \cup K_h^\delta)], \\ S(z_h) &= (K_h^\delta \cap S(w_h)) \cup (K_h^\delta \setminus S(w_h)) \cup (S(z_h) \setminus K_h^\delta), \end{aligned}$$

we have (d_h is defined in (5.2))

$$\begin{aligned}
&\limsup_{h\to+\infty}\left[\int_{S(w_h)\cup S(z_h)}\varphi_h(|[w_h]|\vee|[z_h]|)\,d\mathcal{H}^{N-1}-\int_{S(z_h)}\varphi_h(|[z_h]|)\,d\mathcal{H}^{N-1}\right]\\
&\qquad\le\mathcal{H}^{N-1}(S(w)\setminus S(z))+\varepsilon\\
+&\limsup_{h\to+\infty}\left[\int_{S(w_h)\cap K_h^\delta}\varphi_h(|[w_h]|\vee|[z_h]|)\,d\mathcal{H}^{N-1}-\int_{S(w_h)\cap K_h^\delta}\varphi_h(|[z_h]|)\,d\mathcal{H}^{N-1}\right]\\
&\qquad\le\mathcal{H}^{N-1}(S(w)\setminus S(z))+\varepsilon+\limsup_{h\to+\infty}(1-d_h)\mathcal{H}^{N-1}(S(w_h)\cap K_h^\delta)\\
&\qquad\le\mathcal{H}^{N-1}(S(w)\setminus S(z))+\varepsilon.
\end{aligned}$$

Letting now $\varepsilon\to 0$, and using a diagonal argument we obtain the result.

Let $\varepsilon>0$, and let us prove that we can find $\delta>0$ and $(w_h)_{h\in\mathbb{N}}$ such that (5.15) and (5.16) hold. Following the Transfer of Jump [13, Theorem 2.1], let us fix $G\subseteq\mathbb{R}$ countable and dense: we recall that we have up to a set of $\mathcal{H}^{N-1}$-measure zero

$$S(z)=\bigcup_{c_1,c_2\in G}\partial^*E_{c_1}(z)\cap\partial^*E_{c_2}(z),$$

where $E_c(z):=\{x\in\Omega'\,:\,x\text{ is a Lebesgue point for }z,\ z(x)>c\}$ and ∂^* denotes the essential boundary (see [4, Definition 3.60]). Let us orient ν_z in such a way that $z^-(x)<z^+(x)$ for all $x\in S(z)$, and let us consider

$$J_j:=\left\{x\in S(z)\,:\,z^+(x)-z^-(x)>\frac{1}{j}\right\},$$

with j so large that

$$\mathcal{H}^{N-1}\left(S(z)\setminus J_j\right)<\sigma,$$

where $\sigma>0$. Let U be a neighborhood of $S(z)$ such that

$$|U|<\frac{\sigma}{j^2},\qquad\int_U|\nabla w|^2\,dx<\sigma.$$

Following [13, Theorem 2.1], we can find a finite disjoint collection of closed cubes $\{Q_k\}_{k=1,\dots,n}$ with edge of length $2r_k$, with center $x_k\in S(z)$, and oriented as the normal $\nu(x_k)$ to $S(z)$ at x_k, such that $\bigcup_{k=1}^n Q_k\subseteq U$ and $\mathcal{H}^{N-1}(J_j\setminus\bigcup_{k=1}^n Q_k)\le\sigma$. Let H_k denote the intersection of Q_k with the hyperplane through x_k orthogonal to $\nu(x_k)$. Following [13] we can suppose that the following facts hold:

(a) if $x_k\in\Omega$, then $Q_k\subseteq\Omega$, and if $x_k\in\partial_D\Omega$, then $\partial\Omega\cap Q_k\subseteq\{y+s\nu(x_k)\,:\,y\in H_k,\ s\in[-\frac{\sigma r_k}{2},\frac{\sigma r_k}{2}]\}$;
(b) $\mathcal{H}^{N-1}(S(z)\cap\partial Q_k)=0$;
(c) $r_k^{N-1}<2\mathcal{H}^{N-1}(S(z)\cap Q_k)$;
(d) $z^-(x_k)<c_k^1<c_k^2<z^+(x_k)$ and $c_k^2-c_k^1>\frac{1}{2j}$;
(e) $\mathcal{H}^{N-1}([S(z)\setminus\partial^*E_{c_k^s}(z)]\cap Q_k)<\sigma r_k^{N-1}$ for $s=1,2$;
(f) $\mathcal{H}^{N-1}(\{y\in\partial^*E_{c_k^s}(z)\cap Q_k\,:\,\operatorname{dist}(y,H_k)\ge\frac{\sigma}{2}r_k\})<\sigma r_k^{N-1}$ for $s=1,2$;

(g) if $Q_k^+ := \{x \in Q_k \,|\, (x - x_k) \cdot \nu(x_k) > 0\}$ and $s = 1, 2$,

$$\|1_{E_{c_k^s}(z))\cap Q_k} - 1_{Q_k^+}\|_{L^1(\Omega')} < \sigma^2 r_k^N;$$

(h) $\mathcal{H}^{N-1}\left(\big(S(w) \setminus S(z)\big) \cap Q_k\right) < \sigma r_k^{N-1}$ and $\mathcal{H}^{N-1}(S(w) \cap \partial Q_k) = 0$.

Since $(\nabla z_h)_{h\in\mathbb{N}}$ is equi-integrable, we may assume that U is chosen so that for h large

$$\sum_{k=1}^n \int_{Q_k} |\nabla z_h|\, dx < \frac{\sigma}{j^2}. \tag{5.17}$$

Let $\eta \in]0, 1[$: we claim that there exists $\delta > 0$ such that for all $k = 1, \dots, n$

$$\limsup_{h\to+\infty} |Dz_h|(\{0 < |[z_h]| < \delta\} \cap Q_k) \le \eta |Q_k|. \tag{5.18}$$

Let $M > 0$: by (5.2) there exists $s_h \to 0$ with $\varphi_h(s_h) \to 1$ such that for h large enough

$$Ms \le \varphi_h(s) \qquad \text{for all } s \in [0, s_h].$$

Then we have

$$\begin{aligned} |Dz_h|\left(\{0 < |[z_h]| < s_h\} \cap Q_k\right) &= \int_{\{0<|[z_h]|<s_h\}\cap Q_k} |[z_h]|\, d\mathcal{H}^{N-1} \\ &\le \frac{1}{M} \int_{\{0<|[z_h]|<s_h\}\cap Q_k} \varphi_h(|[z_h]|)\, d\mathcal{H}^{N-1}, \end{aligned}$$

so that we conclude for h large

$$\begin{aligned} |Dz_h|\left(\{0 < |[z_h]| < \delta\} \cap Q_k\right) &\le \frac{1}{M} \int_{\{0<|[z_h]|<s_h\}\cap Q_k} \varphi_h(|[z_h]|)\, d\mathcal{H}^{N-1} \\ &+ \frac{\delta}{\varphi_h(s_h)} \int_{\{s_h\le|[z_h]|<\delta\}\cap Q_k} \varphi_h(|[z_h]|)\, d\mathcal{H}^{N-1} \le \left(\frac{1}{M} + \frac{\delta}{\varphi_h(s_h)}\right) C, \end{aligned}$$

where C is defined in (5.14). Taking the limsup in h and choosing δ small enough and M large enough, we have that (5.18) holds.

Let δ be as in (5.18), and let us set

$$K_h^\delta := \{x \in S(z_h) \,:\, |[z_h]|(x) \ge \delta\}.$$

Then in view of (5.17) and (5.18), since $|D^c z_h|(\Omega') \to 0$, by the Coarea formula for BV functions (see [4, Theorem 3.40]) we have for h large enough

$$\begin{aligned} \sum_{k=1}^n \int_{c_k^1}^{c_k^2} \mathcal{H}^{N-1}\left(\partial^* E_c(z_h) \cap (Q_k \setminus K_h^\delta)\right)\, dc &\le \sum_{k=1}^n |Dz_h|(Q_k \setminus K_h^\delta) \\ &= \sum_{k=1}^n \int_{Q_k} |\nabla z_h|\, dx + \sum_{k=1}^n |Dz_h|(Q_k \cap \{0 < |[z_h]| < \delta\}) + |D^c z_h|\left(\bigcup_{k=1}^n Q_k\right) \\ &\le (1+\eta)\frac{\sigma}{j^2}. \end{aligned}$$

By the Mean Value theorem and by property (d) we get that there exist $c_k^1 < c_k^h < c_k^2$, $k = 1, \dots, n$, such that

$$\sum_{k=1}^n \mathcal{H}^{N-1}\left(\partial^* E_{c_k^h}(z_h) \cap (Q_k \setminus K_h^\delta)\right) \le 2(1+\eta)\frac{\sigma}{j}. \tag{5.19}$$

Following [13], by property (g) we have that for h large

$$\|1_{E_{c_k^h}(z_h)\cap Q_k} - 1_{Q_k^+}\|_{L^1(\Omega')} \le \sigma^2 r_k^N.$$

Then by Fubini's theorem and by the Mean Value theorem, we can find $s_k^+ \in [\frac{\sigma r_k}{2}, \sigma r_k]$ and $s_k^- \in [-\sigma r_k, -\frac{\sigma r_k}{2}]$ such that setting $H_k^+ := \{x = y + s_k^+\nu(x_k),\, y \in H_k\}$ and $H_k^- := \{x = y + s_k^-\nu(x_k),\, y \in H_k\}$ we have

$$\mathcal{H}^{N-1}(H_k^+ \setminus (E_{c_k^h}(z_h)\cap Q_k)) + \mathcal{H}^{N-1}(H_k^- \cap (E_{c_k^h}(z_h)\cap Q_k)) \le 2\sigma r_k^{N-1}.$$

Let R_k be the region between H_k^- and H_k^+, i.e.,

$$R_k := \{x \in Q_k \,:\, x = y + s\nu(x_k),\, y \in H_k,\, s_k^2 \le s \le s_k^1\},$$

and let us indicate by $R_k^+ w$ the reflection in Q_k of $w_{|Q_k^+\setminus R_k}$ with respect to H_k^+, and by $R_k^- w$ the reflection in Q_k of $w_{|Q_k^-\setminus R_k}$ with respect to H_k^-. We can now consider w_h defined in the following way:

$$w_h := \begin{cases} w & \text{on } \Omega' \setminus \bigcup_{k=1}^n R_k, \\ R_k^+ w & \text{on } R_k \cap E_{c_k^h}(z_h), \\ R_k^- w & \text{on } R_k \setminus E_{c_k^h}(z_h). \end{cases}$$

w_h is well defined for σ small, and $w_h = 0$ on $\Omega' \setminus \Omega$. Notice that by construction we have that for h large

$$\|\nabla w_h - \nabla w\|_{L^2(\Omega';\mathbb{R}^N)} + \sum_{k=1}^n \mathcal{H}^{N-1}((S(w_h) \setminus K_h^\delta)\cap Q_k) \le e(\sigma),$$

where $e(\sigma) \to 0$ as $\sigma \to 0$: the proof follows analyzing the set $S(w_h)$ inside Q_k, and it is very similar to that contained in [13, Theorem 2.1]. Since

$$S(w_h) \setminus K_h^\delta \tilde{\subseteq} [S(w) \setminus S(z)] \cup \left[S(z) \setminus \bigcup_{k=1}^n Q_k\right] \cup \bigcup_{k=1}^n ((S(w_h) \setminus K_h^\delta)\cap Q_k),$$

we deduce

$$\limsup_{h\to+\infty} \mathcal{H}^{N-1}\left(S(w_h) \setminus K_h^\delta\right) \le \mathcal{H}^{N-1}\left(S(w) \setminus S(z)\right) + e(\sigma),$$

with $e(\sigma) \to 0$ as $\sigma \to 0$. Choosing σ small enough and using a diagonal argument, we obtain that (5.15) and (5.16) hold, and the proof is finished. □

The following proposition extends the Transfer of Jump to the case of cracks converging in the sense of Proposition 5.2.

PROPOSITION 5.5. *Let $(K_h, \gamma_h)_{h\in\mathbb{N}}$ and K be as in Proposition 5.2, and let $g_h, g \in H^1(\Omega)$ be such that $g_h \to g$ strongly in $H^1(\Omega)$. Then for all $v \in SBV(\Omega)$ with $\nabla v \in L^2(\Omega;\mathbb{R}^N)$ there exists $v_h \in SBV(\Omega)$ such that $\nabla v_h \to \nabla v$ strongly in $L^2(\Omega;\mathbb{R}^N)$ and*

$$\limsup_{h\to+\infty} \left[\int_{S^{g_h}(v_h)\cup K_h} \varphi_h(|[v_h]| \vee \gamma_h)\, d\mathcal{H}^{N-1} - \int_{K_h} \varphi_h(\gamma_h)\, d\mathcal{H}^{N-1}\right] \le \mathcal{H}^{N-1}(S^g(v) \setminus K).$$

Proof. We indicate how to modify the proof of Proposition 5.4 in order to get the result for $(K_h, \gamma_h)_{h\in\mathbb{N}}$ and K.

Notice that properties (5.15) and (5.16) can be extended to the case of a finite number of converging sequences: more precisely if $k = 1, \dots, m$, $(u_h^k)_{h\in\mathbb{N}}$ is a sequence in $BV(\Omega)$ such that $u_h^k \overset{*}{\rightharpoonup} u^k$ weakly* in $BV(\Omega)$, $(\nabla u_h^k)_{h\in\mathbb{N}}$ is equi-integrable,

$$\int_{S^{g_h}(u_h^k)} \varphi_h(|[u_h^k]|)\, d\mathcal{H}^{N-1} \le C, \qquad |D^c u_h^k|(\Omega) \to 0,$$

then for every $\varepsilon > 0$ and $v \in SBV(\Omega)$ with $\nabla v \in L^2(\Omega;\mathbb{R}^N)$ there exists $v_h \in SBV(\Omega)$ such that

$$\limsup_{h\to+\infty} \|\nabla v_h - \nabla v\|_{L^2(\Omega;\mathbb{R}^N)} \le \varepsilon \tag{5.20}$$

and

$$\limsup_{h\to+\infty} \mathcal{H}^{N-1}(S^{g_h}(v_h) \setminus \tilde{K}_h^\delta) \le \mathcal{H}^{N-1}\left(S^g(v) \setminus \bigcup_{k=1}^m S^g(u^k)\right) + \varepsilon, \tag{5.21}$$

where $\tilde{K}_h^\delta := \{x \in \bigcup_{k=1}^m S^{g_h}(u_h^k) : |[u_h^k]|(x) \ge \delta \text{ for some } k = 1, \dots, m\}$. This can be done using the localization on the squares already employed in [13, Theorem 2.3]: on each squares Q_j we have that $\bigcup_{k=1}^m S^g(u^k) \cap Q_j$ is essentially given by $S^g(u^{\tau(j)})$ for some $\tau(j) \in \{1, \dots, m\}$.

Let us come to the Transfer of Jump for K. We recall that

$$K = \bigcup_{u\in D} S^g(u)$$

for some countable set D, and that each $u \in D$ is limit in the weak* topology of $BV(\Omega)$ of a function u_h such that $S^{g_h}(u_h) \tilde{\subseteq} K_h$, $|[u_h]| \le \gamma_h$, $\nabla u_h \rightharpoonup \nabla u$ weakly in $L^1(\Omega;\mathbb{R}^N)$,

$$\sup_h \int_{S(u_h)} \varphi_h(|[u_h]|)\, d\mathcal{H}^{N-1} \le C, \quad \text{and} \qquad |D^c u_h|(\Omega) \to 0.$$

Let $\varepsilon > 0$ be fixed: since $\mathcal{H}^{N-1}(K) < +\infty$, we can find m such that

$$\mathcal{H}^{N-1}\left(K \setminus \bigcup_{k=1}^m S^g(u^k)\right) \le \varepsilon \tag{5.22}$$

for some $u^k \in D$, $k = 1, \dots, m$. Let u_h^k be the approximation of u^k for all $k = 1, \dots, m$, and let $v \in SBV(\Omega)$ with $\nabla v \in L^2(\Omega;\mathbb{R}^N)$. Then by (5.20) and (5.21) we can find $(v_h)_{h\in\mathbb{N}}$ such that

$$\limsup_{h\to+\infty} \|\nabla v_h - \nabla v\|_{L^2(\Omega;\mathbb{R}^N)} \le \varepsilon$$

and

$$\limsup_{h\to+\infty} \mathcal{H}^{N-1}(S^{g_h}(v_h) \setminus \tilde{K}_h^\delta) \le \mathcal{H}^{N-1}\left(S^g(v) \setminus \bigcup_k S^g(u^k)\right) + \varepsilon.$$

Setting $K_h^\delta := \{x \in K_h : \gamma_h(x) \geq \delta\}$, recalling that $\tilde{K}_h^\delta \tilde{\subseteq} K_h^\delta$ since $|[u_h^k]| \leq \gamma_h$, by (5.22) we deduce that

$$\limsup_{h\to+\infty} \mathcal{H}^{N-1}\left(S^{g_h}(v_h) \setminus K_h^\delta\right) \leq \mathcal{H}^{N-1}\left(S^g(v) \setminus K\right) + 2\varepsilon.$$

The proof now follows exactly as in Proposition 5.4. □

6. Proof of Theorem 4.1. In this section we will give the proof of Theorem 4.1. Let $\{t \to (u_h(t), \Gamma_h(t), \psi_h(t)) : t \in [0,T]\}$ be the piecewise constant interpolation of a discrete-in-time evolution of cracks in Ω_h relative to the subdivision $I_{\delta_h} := \{0 = t_0^{\delta_h} < \cdots < t_{N_{\delta_h}}^{\delta_h} = T\}$, and the boundary displacement $\sqrt{t}g(t, \frac{x}{h})$ given in (4.3). We divide the proof in several steps.

Step 1: Rescaling. For all $t \in [0,T]$ let $v_h(t) \in BV(\Omega)$ and $K_h(t) \tilde{\subseteq} \Omega \cup \partial_D\Omega$ be defined as

$$v_h(t,x) := \frac{1}{\sqrt{h}} u_h(t, hx), \qquad K_h(t) := \frac{1}{h}\Gamma_h(t). \tag{6.1}$$

Let us moreover set

$$\gamma_h(t,x) := \frac{1}{\sqrt{h}}\psi_h(t,hx) = \max_{0\leq s\leq t} |[v_h(s)](t,x)|, \qquad t \in [0,T], x \in \Omega. \tag{6.2}$$

We notice that $\{t \to (v_h(t), K_h(t), \gamma_h(t)) : t \in [0,T]\}$ is the piecewise constant interpolation of a discrete-in-time evolution of cracks in Ω relative to the subdivision I_{δ_h} and boundary displacement $g(t)$ with respect to the basic total energy

$$\int_\Omega f_h(\nabla v)\, dx + \int_{S^{g^{\delta_h}(t)}(v)\cup K_h(t)} \varphi_h(|[v]| \vee \gamma_h(t))\, d\mathcal{H}^{N-1} + a\sqrt{h}|D^c v|(\Omega),$$

where $g^{\delta_h}(t) := g(t_i^{\delta_h})$ for $t_i^{\delta_h} \leq t < t_{i+1}^{\delta_h}$, $a := \varphi'(0)$,

$$\varphi_h(s) := \varphi(\sqrt{h}s), \qquad s \in [0, +\infty[, \tag{6.3}$$

and

$$f_h(\xi) := \begin{cases} |\xi|^2 & \text{if } |\xi| \leq \frac{a\sqrt{h}}{2}, \\ \frac{a^2 h}{4} + a\sqrt{h}(|\xi| - \frac{a\sqrt{h}}{2}) & \text{if } |\xi| \geq \frac{a\sqrt{h}}{2}. \end{cases} \tag{6.4}$$

Let us recall some properties of the evolution $\{t \to (v_h(t), K_h(t), \gamma_h(t)) : t \in [0,T]\}$ which are derived from Proposition 3.1 and that will be employed in what follows:

(a) for all $t \in [0,T]$

$$\|v_h(t)\|_\infty \leq \|g^{\delta_h}(t)\|_\infty; \tag{6.5}$$

(b) $K_h(0) = S^{g^{\delta_h}(0)}(v_h(0))$ and $S^{g^{\delta_h}(t)}(v_h(t)) \tilde{\subseteq} K_h(t)$ for all $t \in]0,T]$;

(c) for all $w \in BV(\Omega)$ we have

$$\begin{aligned} &\int_\Omega f_h(\nabla v_h(0))\, dx + \int_{S^{g^{\delta_h}(0)}(v_h(0))} \varphi_h(|[v_h(0)]|)\, d\mathcal{H}^{N-1} + a\sqrt{h}|D^c v_h(0)|(\Omega) \\ &\leq \int_\Omega f_h(\nabla w)\, dx + \int_{S^{g^{\delta_h}(0)}(w)} \varphi_h(|[w]|)\, d\mathcal{H}^{N-1} + a\sqrt{h}|D^c w|(\Omega); \end{aligned} \tag{6.6}$$

(d) for all $w \in BV(\Omega)$ and for all $t \in]0,T]$ we have

$$\int_\Omega f_h(\nabla v_h(t))\,dx + \int_{K_h(t)} \varphi_h(\gamma_h(t))\,d\mathcal{H}^{N-1} + a\sqrt{h}|D^c v_h(t)|(\Omega) \leq \int_\Omega f_h(\nabla w)\,dx + \int_{S^{g^{\delta_h}(t)}(w)\cup K_h(t)} \varphi_h(|[w]| \vee \gamma_h(t))\,d\mathcal{H}^{N-1} + a\sqrt{h}|D^c w|(\Omega). \tag{6.7}$$

Let us set for all $w \in BV(\Omega)$ and for all $t \in [0,T]$

$$\mathcal{F}_h(t,w) := \int_\Omega f_h(\nabla w)\,dx + \int_{S^{g^{\delta_h}(t)}(w)\cup K_h(t)} \varphi_h(|[w]| \vee \gamma_h(t))\,d\mathcal{H}^{N-1} + a\sqrt{h}|D^c w|(\Omega). \tag{6.8}$$

Notice that for all $t \in [0,T]$

$$\mathcal{F}_h(t, v_h(t)) = \frac{1}{h^{N-1}}\mathcal{E}_h(t, u_h(t)), \tag{6.9}$$

where $\mathcal{E}_h(t,u)$ is defined in (4.4).

Recalling Lemma 3.2, for all $t \in [0,T]$ we have

$$\mathcal{F}_h(t, v_h(t)) \leq \mathcal{F}_h(0, v_h(0)) + \int_0^{t_h}\int_\Omega f_h'(\nabla v_h(\tau))\nabla \dot g(\tau)\,dx\,d\tau + e(h), \tag{6.10}$$

where $e(h) \to 0$ as $h \to +\infty$, and $t_h := t_{i_h}^{\delta_h}$ is the step discretization point of I_{δ_h} such that $t_{i_h}^{\delta_h} \leq t < t_{i_h+1}^{\delta_h}$.

Step 2: Uniform bound on the energy. There exists a constant C' independent of h such that for all $t \in [0,T]$ we have

$$\mathcal{F}_h(t, v_h(t)) + \|v_h(t)\|_\infty \leq C'. \tag{6.11}$$

In fact by (6.6) we have

$$\mathcal{F}_h(0, u_h(0)) \leq \|\nabla g(0)\|^2,$$

and by (6.7) for all $\tau \in [0,T]$,

$$\int_\Omega f_h(\nabla v_h(\tau))\,dx \leq \|\nabla g^{\delta_h}(\tau)\|^2.$$

Moreover, for all $\tau \in [0,T]$

$$\int_\Omega |f_h'(\nabla v_h(\tau))|^2\,dx \leq 4\int_\Omega f_h(\nabla v_h(\tau))\,dx.$$

Taking into account (6.10) and (6.5) we deduce that (6.11) holds.

Step 3: Compactness. In view of Step 2, by Propositions 5.1 and 5.2 we have that for all $t \in [0,T]$ the displacements $(v_h(t))_{h\in\mathbb{N}}$ are relatively compact with respect to the weak* topology of $BV(\Omega)$, while the cracks $(K_h(t), \gamma_h(t))_{h\in\mathbb{N}}$ are compact in a suitable energetic sense.

Let $B \subseteq [0,T]$ be countable and dense, and such that $0 \in B$. By Propositions 5.1 and 5.2 (with f_h and φ_h defined in (6.4) and (6.3), $a_h := a\sqrt{h}$, $\gamma_h := \gamma_h(t)$, and $g_h := g^{\delta_h}$) up to a subsequence (which we denote by the same symbol) for all $t \in B$ there exists $v(t) \in SBV(\Omega)$ and a rectifiable set $K(t) \tilde\subseteq \Omega \cup \partial_D\Omega$ such that the following facts hold:

(a) $v_h(t) \overset{*}{\rightharpoonup} v(t)$ in the weak* topology of $BV(\Omega)$, $\nabla v_h(t) \rightharpoonup \nabla v(t)$ weakly in $L^1(\Omega;\mathbb{R}^N)$, $\nabla v(t) \in L^2(\Omega;\mathbb{R}^N)$, and

$$S^{g(t)}(v(t)) \tilde{\subseteq} K(t);$$

(b) $K(s) \tilde{\subseteq} K(t)$ for all $s,t \in B$, $s \le t$;

(c) we have

$$\mathcal{H}^{N-1}(K(t)) \le \liminf_{h\to+\infty} \int_{K_h(t)} \varphi_h(\gamma_h(t))\, d\mathcal{H}^{N-1}; \tag{6.12}$$

(d) $K(0) = S^{g(0)}(v(0))$.

Points (a) and (c) comes directly from Propositions 5.1 and 5.2. Let us prove point (b). Let $s,t \in B$ with $s < t$. By Proposition 5.2 we know that there exists a countable set $D(s)$ in $SBV(\Omega)$ such that

$$K(s) = \bigcup_{u\in D} S^{g(s)}(u), \tag{6.13}$$

and such that for every $u \in D(s)$ there exists a sequence $(u_h)_{h\in\mathbb{N}}$ in $BV(\Omega)$ such that $u_h \overset{*}{\rightharpoonup} u$ weakly* in $BV(\Omega)$ with $S^{g^{\delta_h}(s)}(u_h) \tilde{\subseteq} K_h(s)$, $|[u_h]| \le \gamma_h(s)$, and $\mathcal{F}_h(s,u_h) \le C'$ for some $C' \in [0,+\infty[$. Let us set $v_h := u_h - g^{\delta_h}(s) + g^{\delta_h}(t)$. Since $K_h(s) \tilde{\subseteq} K_h(t)$ and $\gamma_h(s) \le \gamma_h(t)$, we have that $S^{g^{\delta_h}(t)}(v_h) \tilde{\subseteq} K_h(t)$, $|[v_h]| \le \gamma_h(t)$,

$$\int_\Omega f_h(\nabla v_h)\, dx + \int_{K_h(t)} \varphi_h(|[v_h]|)\, d\mathcal{H}^{N-1} + a\sqrt{h}|D^c v_h|(\Omega) \le \tilde{C}'$$

with $\tilde{C}'$ independent of h, and $v_h \overset{*}{\rightharpoonup} u - g(s) + g(t)$ weakly* in $BV(\Omega)$. We deduce that $S^{g(t)}(u - g(s) + g(t)) \tilde{\subseteq} K(t)$, that is, $S^{g(s)}(u) \tilde{\subseteq} K(t)$. Then by (6.13) we obtain $K(s) \tilde{\subseteq} K(t)$.

Let us come to point (d). Notice that

$$\begin{aligned} \|\nabla v(0)\|^2 + \mathcal{H}^{N-1}(K(0)) &\le \liminf_{h\to+\infty} \mathcal{F}_h(0, v_h(0)) \\ &\le \|\nabla v(0)\|^2 + \mathcal{H}^{N-1}(S^{g(0)}(v(0))), \end{aligned} \tag{6.14}$$

the first inequality coming from point (c) and Proposition 5.1, the last inequality coming from the minimality property (6.6). Since $S^{g(0)}(v(0)) \tilde{\subseteq} K(0)$, by (6.14) we get that $S^{g(0)}(v(0)) = K(0)$, so that point (d) is proved.

Step 4: Recovering the static equilibrium for $K(t)$, $t \in B$. Let B be the countable and dense set defined in Step 3, and let $K(t)$ be the limit crack associated with $(K_h(t), \gamma_h(t))_{h\in\mathbb{N}}$ for all $t \in B$. In order to prove that $K(t)$ is part of an evolution in the sense of [13] with respect to the boundary data $g(t)$, we have to prove that $K(t)$ satisfies the one-sided minimality property with respect to the Griffith's energy given by point (c) of Theorem 2.2. This is done in this step, where also some useful convergence results for the gradient of the displacements are obtained.

Let $t \in B$, and let us consider the subsequence of $(v_h(t), K_h(t), \gamma_h(t))_{h\in\mathbb{N}}$ (which we indicate with the same symbol), the displacement $v(t)$ and the rectifiable set $K(t)$ given by Step 3. Then for all $v \in SBV(\Omega)$ we have

$$\|\nabla v(0)\|^2 + \mathcal{H}^{N-1}(S^{g(0)}(v(0))) \le \|\nabla v\|^2 + \mathcal{H}^{N-1}(S^{g(0)}(v)), \tag{6.15}$$

and for all $t \in]0,T]$

$$\|\nabla v(t)\|^2 \le \|\nabla v\|^2 + \mathcal{H}^{N-1}(S^{g(t)}(v) \setminus K(t)). \tag{6.16}$$

Moreover,

$$\|\nabla v(0)\|^2 + \mathcal{H}^{N-1}(K(0)) = \lim_{h\to+\infty} \mathcal{F}_h(0, v_h(0)), \tag{6.17}$$

where $\mathcal{F}_h$ is defined in (6.8), and for all $t \in B$

$$\nabla v_h(t) 1_{E_h(t)} \to \nabla v(t) \qquad \text{strongly in } L^2(\Omega;\mathbb{R}^N), \tag{6.18}$$

where

$$E_h(t) := \left\{ x \in \Omega \,:\, |\nabla v_h(t)| \le \frac{a\sqrt{h}}{2} \right\}$$

and

$$\|\nabla v(t)\|^2 = \lim_{h\to+\infty} \int_\Omega f_h(\nabla v_h(t))\, dx. \tag{6.19}$$

In fact (6.15) and (6.17) come from point (d) of Step 3, from the minimality property (6.6), and from Proposition 5.1.

Let us come to (6.16). Let $t \in [0,T]$. By Proposition 5.5 we have that there exists $(v_h)_{h\in\mathbb{N}}$ sequence in $SBV(\Omega)$ such that $\nabla v_h \to \nabla v$ strongly in $L^2(\Omega;\mathbb{R}^N)$ and

$$\limsup_{h\to+\infty} \left[\int_{S^{g^{\delta_h(t)}}(v_h)\cup K_h(t)} \varphi_h(|[v_h]| \vee \gamma_h(t))\, d\mathcal{H}^{N-1} - \int_{K_h(t)} \varphi_h(\gamma_h(t))\, d\mathcal{H}^{N-1} \right] \le \mathcal{H}^{N-1}(S^{g(t)}(v) \setminus K(t)).$$

Then using the minimality property (6.7) we get

$$\limsup_{h\to+\infty} \int_\Omega f_h(\nabla v_h(t))\, dx \le \|\nabla v\|^2 + \mathcal{H}^{N-1}(S^{g(t)}(v) \setminus K(t)). \tag{6.20}$$

By Proposition 5.1 we have that

$$\|\nabla v(t)\|^2 \le \liminf_{h\to+\infty} \int_\Omega f_h(\nabla v_h(t))\, dx, \tag{6.21}$$

and so we obtain that (6.16) holds.

Let us now come to (6.18) and (6.19). Equation (6.19) is a direct consequence of (6.21) and (6.20) with $v = v(t)$. Finally, notice that $(\nabla v_h(t) 1_{E_h(t)})_{h\in\mathbb{N}}$ is bounded in $L^2(\Omega;\mathbb{R}^N)$. Since $\nabla v_h(t) \rightharpoonup \nabla v(t)$ weakly in $L^1(\Omega;\mathbb{R}^N)$ and $\nabla v(t) \in L^2(\Omega;\mathbb{R}^N)$, we get $\nabla v_h(t) 1_{E_h(t)} \rightharpoonup \nabla v(t)$ weakly in $L^2(\Omega;\mathbb{R}^N)$. By (6.20) with $v = v(t)$ we have

$$\limsup_{h\to+\infty} \|\nabla v_h(t) 1_{E_h(t)}\|^2 \le \limsup_{h\to+\infty} \int_\Omega f_h(\nabla v_h(t))\, dx \le \|\nabla v(t)\|^2,$$

so that (6.18) holds.

Step 5: Defining $K(t)$ for all $t \in [0,T]$. Since $\{t \to K(t) : t \in B\}$ is increasing by Step 3, setting

$$K^-(t) := \bigcup_{s\in B, s\le t} K(s), \qquad K^+(t) := \bigcap_{s\in B, s\ge t} K(s),$$

there exists a countable set $B' \subseteq [0,T]\setminus B$ such that we have $K^-(t) \tilde{=} K^+(t)$ for all $t \in [0,T]\setminus B'$. For all such t's let us set $K(t) := K^-(t) \tilde{=} K^+(t)$. Up to a further subsequence relative to the elements of B' (which we indicate still with the same symbol), we find $K(t)$ such that Steps 3 and 4 hold for every $t \in B'$. Notice that

$$\{t \to K(t) : t \in [0,T]\}$$

is increasing, and for all $t \in [0,T]$ we have $\mathcal{H}^{N-1}(K(t)) \le C'$, where C' is given by (6.11).

Let $v(t)$ be a minimum of the following problem:

$$\min\{\|\nabla v\|^2 : v \in SBV(\Omega),\ S^{g(t)}(v) \tilde{\subseteq} K(t)\}. \tag{6.22}$$

Notice that problem (6.22) is well posed since $K(t)$ has finite $\mathcal{H}^{N-1}$-measure, and $g(t)$ is bounded in $L^\infty(\Omega)$: moreover by strict convexity we have that $\nabla v(t)$ is uniquely determined.

Let us prove that $(v(t), K(t))$ satisfies Steps 3 and 4 for every $t \in [0,T]$. Moreover, let us see that

$$\nabla v_h(t) \rightharpoonup \nabla v(t) \qquad \text{weakly in } L^1(\Omega;\mathbb{R}^N), \tag{6.23}$$

and that every accumulation point v of $(v_h(t))_{h\in\mathbb{N}}$ in the weak* topology of $BV(\Omega)$ is such that $v \in SBV(\Omega)$, $S^{g(t)}(v) \tilde{\subseteq} K(t)$, and $\nabla v = \nabla v(t)$.

In fact let $t \notin B \cup B'$ (otherwise the result holds by construction), and let $v_{h_m}(t) \overset{*}{\rightharpoonup} v$ weakly* in $BV(\Omega)$ for some subsequence $(h_m)_{m\in\mathbb{N}}$. By Proposition 5.1 we get that $v \in SBV(\Omega)$, $\nabla v \in L^2(\Omega;\mathbb{R}^N)$, and $\nabla v_{h_m}(t) \rightharpoonup \nabla v$ weakly in $L^1(\Omega;\mathbb{R}^N)$.

Applying Steps 3 and 4 to $B \cup \{t\}$, we can find (up to a further subsequence) $\tilde{K}(t)$ such that $S^{g(t)}(v) \tilde{\subseteq} \tilde{K}(t)$, $\tilde{K}(t)$ satisfies static equilibrium, and

$$K(s_1) \tilde{\subseteq} \tilde{K}(t) \tilde{\subseteq} K(s_2)$$

for all $s_1, s_2 \in B$ with $s_1 < t < s_2$. Then we get $\tilde{K}(t) = K(t)$ up to a set of $\mathcal{H}^{N-1}$-measure zero.

Finally, in order to prove that (6.23) holds, notice that v is a minimum of problem (6.22): by uniqueness we obtain $\nabla v = \nabla v(t)$ so that (6.23) holds along the entire sequence.

Step 6: Recovering the nondissipativity condition. In order to prove that

$$\{t \to (v(t), K(t)),\ t \in [0,T]\}$$

is a quasi-static crack growth in the sense of [13], that is, in the sense of Theorem 2.2, we have just to prove the *nondissipativity* condition, that is,

$$\mathcal{E}(t) = \mathcal{E}(0) + 2\int_0^t (\nabla v(\tau), \nabla \dot{g}(\tau))_{L^2(\Omega;\mathbb{R}^N)}\, d\tau, \tag{6.24}$$

where $\mathcal{E}(t) := \|\nabla v(t)\|^2 + \mathcal{H}^{N-1}(K(t))$ for all $t \in [0,T]$. In fact *irreversibility* and *static equilibrium* are consequences of Steps 3, 4, and 5. First of all, for all $t \in [0,T]$ we have

$$\mathcal{E}(t) \geq \mathcal{E}(0) + 2\int_0^t (\nabla u(\tau), \nabla \dot{g}(\tau))_{L^2(\Omega;\mathbb{R}^N)}\, d\tau. \tag{6.25}$$

In fact as noticed in [15], using the minimality property (6.16), the map $\{t \to \nabla v(t)\}$ is continuous at all the continuity points of $\{t \to \mathcal{H}^{N-1}(K(t))\}$, in particular it is continuous up to a countable set in $[0,T]$. Given $t \in [0,T]$ and $k > 0$, let us set

$$s_i^k := \frac{i}{k}t, \qquad v^k(s) := v(s_{i+1}^k) \quad \text{for } s_i^k < s \leq s_{i+1}^k, \qquad i = 0, 1, \ldots, k.$$

By (6.16), comparing $v(s_i^k)$ with $v(s_{i+1}^k) - g(s_{i+1}^k) + g(s_i^k)$, it is easy to see that

$$\mathcal{E}(t) \geq \mathcal{E}(0) + 2\int_0^t (\nabla v^k(\tau), \nabla \dot{g}(\tau))_{L^2(\Omega;\mathbb{R}^N)}\, d\tau + e(k),$$

where $e(k) \to 0$ as $k \to +\infty$. By the continuity property of ∇v, passing to the limit for $k \to +\infty$ we deduce that (6.25) holds. On the other hand, for all $t \in [0,T]$ we have that

$$\mathcal{E}(t) \leq \mathcal{E}(0) + 2\int_0^t (\nabla u(\tau), \nabla \dot{g}(\tau))_{L^2(\Omega;\mathbb{R}^N)}\, d\tau. \tag{6.26}$$

In fact by Step 4 we have that for all $t \in [0,T]$

$$\nabla v_h(t) 1_{E_h(t)} \to \nabla v(t) \qquad \text{strongly in } L^2(\Omega;\mathbb{R}^N), \tag{6.27}$$

where

$$E_h(t) := \left\{ x \in \Omega \,:\, |\nabla v_h(t)| \leq \frac{a\sqrt{h}}{2} \right\}.$$

By (6.10) and by the very definition of f_h we deduce

$$\begin{aligned} \mathcal{F}_h(t, v_h(t)) \leq \mathcal{F}_h(0, v_h(0)) &+ 2\int_0^t (\nabla v_h(\tau) 1_{E_h(\tau)}, \nabla \dot{g}(\tau))_{L^2(\Omega;\mathbb{R}^N)}\, d\tau \\ &+ a\sqrt{h}\int_0^t \int_{\Omega \setminus E_h(\tau)} |\nabla \dot{g}(\tau)|\, dx\, d\tau + e(h), \end{aligned} \tag{6.28}$$

where $e(h) \to 0$ as $h \to +\infty$. Notice that by (6.11) we have

$$\frac{a}{2} h |\Omega \setminus E_h(\tau)| \leq \sqrt{h} \int_{\Omega \setminus E_h(\tau)} |\nabla v_h(\tau)|\, dx \leq \frac{2}{a} \int_{\Omega \setminus E_h(\tau)} f_h(\nabla v_h(\tau))\, dx \leq \frac{2}{a} C'.$$

We deduce that

$$\begin{aligned} \sqrt{h} \int_{\Omega \setminus E_h(\tau)} |\nabla \dot{g}(\tau)|\, dx &\leq \left(\int_{\Omega \setminus E_h(\tau)} |\nabla \dot{g}(\tau)|^2\, dx \right)^{\frac{1}{2}} \sqrt{h |\Omega \setminus E_h(\tau)|} \\ &\leq \frac{2\sqrt{C'}}{a} \left(\int_{\Omega \setminus E_h(\tau)} |\nabla \dot{g}(\tau)|^2\, dx \right)^{\frac{1}{2}} \to 0 \end{aligned} \tag{6.29}$$

as $h \to +\infty$ by equicontinuity of $\nabla \dot g(\tau)$. Then passing to the limit for $h \to +\infty$ in (6.28), in view of (6.19), (6.12), (6.17), (6.27), and (6.29) we deduce that (6.26) holds. This proves that (6.24) holds, and so $\{t \to (v(t), K(t)) : t \in [0,T]\}$ is a quasi-static crack growth in the sense of [13].

Step 7: Convergence of bulk and surface energies. In order to conclude the proof, let us see that (4.5), (4.6), and (4.7) hold. By (6.28) we deduce that for all $t \in [0,T]$

$$\mathcal{F}_h(t, v_h(t)) \to \mathcal{E}(t),$$

so that by (6.19) and (6.12) we deduce that

$$\mathcal{H}^{N-1}(K(t)) = \lim_{h\to+\infty} \int_{K_h(t)} \varphi_h(\gamma_h(t))\, d\mathcal{H}^{N-1}, \qquad a\sqrt{h}|D^c v_h(t)|(\Omega) \to 0.$$

Theorem 4.1 is now completely proved in view of the rescaling (6.1), of (6.2), (6.3), and (6.9).

7. Proof of Theorem 4.2. In this section we will give the proof of Theorem 4.2. Let $\{t \to (u_h(t), \Gamma_h(t), \psi_h(t)) : t \in [0,T]\}$ be the piecewise constant interpolation given in (4.3) of a discrete-in-time evolution of crack in Ω_h relative to the subdivision $I_{\delta_h} := \{0 = t_0^{\delta_h} < \cdots < t_{N_{\delta_h}}^{\delta_h} = T\}$, and the boundary displacement $h^\alpha g(t, \frac{x}{h})$ with $\alpha \in \,]0, \frac{1}{2}[$. We divide the proof in several steps.

Step 1: Rescaling. We rescale u_h and Γ_h in the following way: for all $t \in [0,T]$ let $v_h(t) \in BV(\Omega)$ and $K_h(t) \tilde\subseteq \Omega \cup \partial_D\Omega$ be given by

$$v_h(t,x) := \frac{1}{h^\alpha} u_h\,(t, hx)\,, \qquad K_h(t) := \frac{1}{h}\Gamma_h(t), \qquad t \in [0,T], x \in \Omega. \tag{7.1}$$

Let us moreover set

$$\gamma_h(t,x) := \frac{1}{h^\alpha}\psi_h(t,hx) = \max_{0\le s\le t} |[v_h(s)](t,x)|, \qquad t \in [0,T], x \in \Omega.$$

It turns out that $\{t \to (v_h(t), K_h(t), \gamma_h(t)) : t \in [0,T]\}$ is the piecewise constant interpolation of a discrete-in-time evolution of cracks in Ω relative to the subdivision I_{δ_h} and boundary displacement $g(t)$ with respect to the basic total energy

$$\int_\Omega f_h(\nabla v)\, dx + h^{1-2\alpha} \int_{S^{g^{\delta_h}(t)}(v)\cup K_h(t)} \varphi_h(|[v]| \vee \gamma_h(t))\, d\mathcal{H}^{N-1} + ah^{1-\alpha}|D^c v|(\Omega),$$

where $g^{\delta_h}(t) := g(t_i^{\delta_h})$ for $t_i^{\delta_h} \le t < t_{i+1}^{\delta_h}$, $a := \varphi'(0)$,

$$\varphi_h(s) := \varphi(h^\alpha s), \qquad s \in [0, +\infty[,$$

and

$$f_h(\xi) := \begin{cases} |\xi|^2 & \text{if } |\xi| \le \frac{ah^{1-\alpha}}{2}, \\ \frac{a^2h^{2(1-\alpha)}}{4} + ah^{1-\alpha}(|\xi| - \frac{ah^{1-\alpha}}{2}) & \text{if } |\xi| \ge \frac{ah^{1-\alpha}}{2}. \end{cases}$$

We have that the following facts hold:

(a) for all $t \in [0,T]$

$$\|v_h(t)\|_\infty \le \|g^{\delta_h}(t)\|_\infty \le C; \tag{7.2}$$

(b) $K_h(0) = S^{g^{\delta_h}(0)}(v_h(0))$, and $S^{g^{\delta_h}(t)}(v_h(t)) \tilde{\subseteq} K_h(t)$ for all $t \in]0,T]$;
(c) for all $w \in BV(\Omega)$ we have

$$\begin{aligned}\int_\Omega f_h(\nabla v_h(0))\,dx + h^{1-2\alpha}\int_{S^{g^{\delta_h}(0)}(v_h(0))}\varphi_h(|[v_h(0)]|)\,d\mathcal{H}^{N-1}\\ + ah^{1-\alpha}|D^c v_h(0)|(\Omega)\\ \le \int_\Omega f_h(\nabla w)\,dx + h^{1-2\alpha}\int_{S^{g^{\delta_h}(0)}(w)}\varphi_h(|[w]|)\,d\mathcal{H}^{N-1} + ah^{1-\alpha}|D^c w|(\Omega);\end{aligned}$$

(d) for all $w \in BV(\Omega)$ and $t \in]0,T]$ we have

$$\begin{aligned}\int_\Omega f_h(\nabla v_h(t))\,dx + h^{1-2\alpha}\int_{K_h(t)}\varphi_h(\gamma_h(t))\,d\mathcal{H}^{N-1} + ah^{1-\alpha}|D^c v_h(t)|(\Omega)\\ \le \int_\Omega f_h(\nabla w)\,dx + h^{1-2\alpha}\int_{S^{g^{\delta_h}(t)}(w)\cup K_h(t)}\varphi_h(|[w]|\vee\gamma_h(t))\,d\mathcal{H}^{N-1}\\ + ah^{1-\alpha}|D^c w|(\Omega).\end{aligned}$$

Let us set for all $v \in BV(\Omega)$ and for all $t \in [0,T]$

$$\begin{aligned}\mathcal{F}_h(t,w) := \int_\Omega f_h(\nabla w)\,dx + h^{1-2\alpha}\int_{S^{g^{\delta_h}(t)}(w)\cup K_h(t)}\varphi_h(|[w]|\vee\gamma_h(t))\,d\mathcal{H}^{N-1}\\ + ah^{1-\alpha}|D^c w|(\Omega).\end{aligned}$$

Notice that

$$\mathcal{F}_h(t,v_h(t)) = \frac{1}{h^{N+2\alpha-2}}\mathcal{E}(t,u_h(t)),$$

where $\mathcal{E}(t,u_h(t))$ is defined in (4.4).

By Lemma 3.2 we obtain for all $t \in [0,T]$

$$\mathcal{F}_h(t,v_h(t)) \le \mathcal{F}_h(0,v_h(0)) + \int_0^{t_h}\int_\Omega f_h'(\nabla v_h(\tau))\nabla\dot{g}(\tau)\,dx\,d\tau + e(h), \tag{7.3}$$

where $e(h) \to 0$ as $h \to +\infty$, and $t_h := t_{i_h}^{\delta_h}$ is the step discretization point of I_{δ_h} such that $t_{i_h}^{\delta_h} \le t < t_{i_h+1}^{\delta_h}$.

Step 2: Uniform bound on the energy. By point (c) comparing $v_h(0)$ and $g(0)$ we have

$$\int_\Omega f_h(\nabla v_h(0))\,dx + h^{1-2\alpha}\int_{S^{g(0)}(v_h(0))}\varphi_h(|[v_h(0)]|) + ah^{1-\alpha}|D^c v_h(0)|(\Omega) \le \|\nabla g(0)\|^2.$$

By point (d) comparing $v_h(t)$ and $g^{\delta_h}(t)$ we obtain

$$\int_\Omega f_h(\nabla v_h(t))\,dx \le \|\nabla g^{\delta_h}(t)\|^2,$$

and since we have

$$\int_\Omega |f_h'(\nabla v_h(\tau))|^2\,dx \le 4\int_\Omega f_h(\nabla v_h(\tau))\,dx,$$

by (7.3) we deduce that

$$\int_\Omega f_h(\nabla v_h(t))\,dx + h^{1-2\alpha}\int_{K_h(t)}\varphi_h(\gamma_h(t))\,d\mathcal{H}^{N-1} + ah^{1-\alpha}|D^c v|(\Omega) \le C'$$

with C' independent of h and of t. By Proposition 5.1 and by (7.2) we deduce that $(v_h(t))_{h\in\mathbb{N}}$ is bounded in $BV(\Omega)$, and this proves point (a).

Step 3: Convergence to the elastic solution. Let $v(t)$ be an accumulation point for $(v_h(t))_{h\in\mathbb{N}}$ in the weak* topology of $BV(\Omega)$, and let us consider $\tilde\Omega \subseteq \mathbb{R}^N$ open and bounded, and such that $\overline\Omega \subseteq \tilde\Omega$. Let us set $\Omega' := \tilde\Omega \setminus \partial_N\Omega$. Then we can extend $v_h(t)$ and $v(t)$ to Ω' setting $v_h(t) = g^{\delta_h}(t)$ and $v(t) = g(t)$ on $\Omega'\setminus\Omega$, respectively. We have $v_{h_j}(t) \overset{*}{\rightharpoonup} v(t)$ weakly* in $BV(\Omega')$ for a suitable $h_j \nearrow +\infty$, and

$$\begin{aligned}(7.4)\qquad &\int_{\Omega'} f_{h_j}(\nabla v_{h_j}(t))\,dx + h_j^{1-2\alpha}\int_{S(v_{h_j}(t))}\varphi_{h_j}(|[v_{h_j}(t)]|)\,d\mathcal{H}^{N-1}\\ &\qquad + ah_j^{1-\alpha}|D^c v_{h_j}(t)|(\Omega') \le \tilde C\end{aligned}$$

with $\tilde C$ independent of j. In particular, we have

$$\int_{\Omega'} f_{h_j}(\nabla v_{h_j}(t))\,dx + \int_{S(v_{h_j}(t))}\varphi_{h_j}(|[v_{h_j}(t)]|)\,d\mathcal{H}^{N-1} + ah_j^{1-\alpha}|D^c v_{h_j}(t)|(\Omega') \le \tilde C'$$

with $\tilde C'$ independent of j. Then by Proposition 5.1 we have that $v(t)\in SBV(\Omega)$,

$$\nabla v_{h_j}(t) \rightharpoonup \nabla v(t) \qquad \text{weakly in } L^1(\Omega;\mathbb{R}^N),$$

and

$$(7.5)\qquad \|\nabla v(t)\|^2 \le \liminf_{j\to+\infty}\int_\Omega f_{h_j}(\nabla v_{h_j}(t))\,dx.$$

Finally, if we consider for all Borel sets $B\subseteq\Omega'$

$$\lambda_j(B) := \int_{B\cap S(v_{h_j}(t))}\varphi_{h_j}(|[v_{h_j}(t)]|)\,d\mathcal{H}^{N-1}$$

and if (up to a subsequence) $\lambda_j \overset{*}{\rightharpoonup} \lambda$ weakly* in the sense of measures, we deduce following Proposition 5.1 that

$$\mathcal{H}^{N-1}\llcorner S(v(t)) \le \lambda \qquad \text{as measures.}$$

Since by (7.4) we have $\lambda = 0$, then we have $S(v(t)) = \emptyset$, that is, $v(t)\in H^1(\Omega)$ and $v(t) = g(t)$ on $\partial_D\Omega$.

Let us consider $v\in H^1(\Omega)$ with $v = g(t)$ on $\partial_D\Omega$. Comparing $v_h(t)$ with $v - g(t) + g^{\delta_h}(t)$ by minimality property of point (d) we obtain

$$\begin{aligned}(7.6)\qquad \int_\Omega f_h(\nabla v_h(t))\,dx + ah^{1-\alpha}|D^c v_h(t)|(\Omega) &\le \int_\Omega f_h(\nabla v - \nabla g(t) + \nabla g^{\delta_h}(t))\,dx\\ &\le \|\nabla v - \nabla g(t) + \nabla g^{\delta_h}(t)\|^2.\end{aligned}$$

In view of (7.5) we deduce that

$$\|\nabla v(t)\|^2 \le \|\nabla v\|^2,$$

so that $v(t)$ is a minimizer of

$$\min\{\|\nabla v\|^2 \,:\, v \in H^1(\Omega),\, v = g(t) \text{ on } \partial_D\Omega\}.$$

By strict convexity and since Ω is connected, we have that $v(t)$ is uniquely determined, and so we deduce that $v_h(t) \overset{*}{\rightharpoonup} v(t)$ weakly* in $BV(\Omega)$ and $\nabla v_h(t) \rightharpoonup \nabla v(t)$ weakly in $L^1(\Omega;\mathbb{R}^N)$.

Choosing $v = v(t)$ in (7.6) and taking the limsup in h we have

$$\limsup_{h\to+\infty} \int_\Omega f_h(\nabla v_h(t))\,dx \le \|\nabla u(t)\|^2,$$

so that

$$\lim_{h\to+\infty} \int_\Omega f_h(\nabla v_h(t))\,dx = \|\nabla u(t)\|^2.$$

The proof of point (b) is now concluded thanks to the rescaling (7.1).

8. Proof of Theorem 4.3. In this section we will give the proof of Theorem 4.3. Let $\{t \to (u_h(t), \Gamma_h(t), \psi_h(t)) \,:\, t \in [0,T]\}$ be the piecewise constant interpolation given in (4.3) of a discrete-in-time evolution of crack in Ω_h relative to the subdivision $I_{\delta_h} := \{0 = t_0^{\delta_h} < \cdots < t_{N_{\delta_h}}^{\delta_h} = T\}$, and the boundary displacement $h^\alpha g(t, \frac{x}{h})$ with $\alpha > \frac{1}{2}$.

We rescale u_h and Γ_h in the following way: for all $t \in [0,T]$ let $v_h(t) \in BV(\Omega)$ and $K_h(t) \tilde{\subseteq} \Omega \cup \partial_D\Omega$ be given by

$$v_h(t,x) := \frac{1}{h^\alpha} u_h\,(t, hx)\,, \qquad K_h(t) := \frac{1}{h}\Gamma_h(t), \qquad t \in [0,T], x \in \Omega.$$

Let us moreover set

$$\gamma_h(t,x) := \frac{1}{h^\alpha}\psi_h(t,hx) = \max_{0\le s\le t} |[v_h(s)](t,x)|, \qquad t \in [0,T], x \in \Omega.$$

It turns out that $\{t \to (v_h(t), K_h(t), \gamma_h(t)) \,:\, t \in [0,T]\}$ is the piecewise constant interpolation of a discrete-in-time evolution of cracks in Ω relative to the subdivision I_{δ_h} and boundary displacement $g(t)$ with respect to the basic total energy

$$h^{2\alpha-1}\int_\Omega f_h(\nabla v)\,dx + \int_{S^{g^{\delta_h}(t)}(v)} \varphi_h(|[v]| \vee \gamma_h(t))\,d\mathcal{H}^{N-1} + ah^\alpha |D^c v|(\Omega),$$

where $g^{\delta_h}(t) := g(t_i^{\delta_h})$ for $t_i^{\delta_h} \le t < t_{i+1}^{\delta_h}$, $a := \varphi'(0)$,

$$\varphi_h(s) := \varphi(h^\alpha s), \qquad s \in [0, +\infty[,$$

and

$$f_h(\xi) := \begin{cases} |\xi|^2 & \text{if } |\xi| \le \frac{ah^{1-\alpha}}{2}, \\ \frac{a^2h^{2(1-\alpha)}}{4} + ah^{1-\alpha}(|\xi| - \frac{ah^{1-\alpha}}{2}) & \text{if } |\xi| \ge \frac{ah^{1-\alpha}}{2}. \end{cases}$$

Notice that by Proposition 3.1 we have

$$\|v_h(0)\|_\infty \le \|g(0)\|_\infty \le C, \tag{8.1}$$

and for all $w \in BV(\Omega)$ we have

$$h^{2\alpha-1}\int_\Omega f_h(\nabla v_h(0))\,dx + \int_{S^{g^{\delta_h(0)}(v_h(0))}} \varphi_h(|[v_h(0)]|)\,d\mathcal{H}^{N-1} + ah^\alpha |D^c v_h(0)|(\Omega)$$
$$\le h^{2\alpha-1}\int_\Omega f_h(\nabla w)\,dx + \int_{S^{g^{\delta_h(0)}(w)}} \varphi_h(|[w]|)\,d\mathcal{H}^{N-1} + ah^\alpha |D^c w|(\Omega). \tag{8.2}$$

Comparing $v_h(0)$ and $w = -C$ by means of (8.2) we have

$$h^{2\alpha-1}\int_\Omega f_h(\nabla v_h(0))\,dx + \int_{S^{g^{\delta_h(0)}(v_h(0))}} \varphi_h(|[v_h(0)]|)\,d\mathcal{H}^{N-1} + ah^\alpha |D^c v_h(0)|(\Omega)$$
$$\le \mathcal{H}^{N-1}(\partial_D\Omega). \tag{8.3}$$

As a consequence, since $\|v_h(0)\|_\infty \le C$ by (8.1), following Proposition 5.1, we deduce that $(v_h(0))_{h\in\mathbb{N}}$ is bounded in $BV(\Omega)$. Let v be an accumulation point for $(v_h(0))_{h\in\mathbb{N}}$ in the weak* topology of $BV(\Omega)$. Let us prove that $v \in SBV(\Omega)$ and that $\nabla v = 0$: in fact we have that for all $\xi \in \mathbb{R}^N$

$$\tilde{f}_h(\xi) \le h^{2\alpha-1} f_h(\xi),$$

where

$$\tilde{f}_h(\xi) := \begin{cases} |\xi|^2 & \text{if } |\xi| \le \frac{ah^\alpha}{2}, \\ \frac{a^2h^{2\alpha}}{4} + ah^\alpha(|\xi| - \frac{ah^\alpha}{2}) & \text{if } |\xi| \ge \frac{ah^\alpha}{2}. \end{cases}$$

We deduce that there exists C'' independent of h such that for all h

$$\int_\Omega \tilde{f}_h(\nabla v_h(0))\,dx + \int_{S(v_h(0))} \varphi_h(|[v_h(0)]|)\,d\mathcal{H}^{N-1} + ch^\alpha |D^c v_h(0)|(\Omega) \le C''.$$

By Proposition 5.1, we obtain that $v \in SBV(\Omega)$ and that $\nabla v_h(0) \rightharpoonup \nabla v$ weakly in $L^1(\Omega;\mathbb{R}^N)$. By (8.3) we obtain that

$$\|\nabla v_h(0)\|_{L^1(\Omega;\mathbb{R}^N)} \le \frac{\mathcal{H}^{N-1}(\partial_D\Omega) + 1}{ah^\alpha},$$

so that we deduce $\nabla v = 0$; that is, v is piecewise constant in Ω. Finally taking the limit in (8.2) with w piecewise constant, by Proposition 5.1 we get exactly (4.8), so that the proof of Theorem 4.3 is concluded.

9. Appendix. In this section, we prove a relaxation result we used in order to study the discrete-in-time evolution of cracks in the cohesive case. It consists of a variant of a result by Bouchitté, Braides, and Buttazzo [6]: the difference here is that we have to take into account the presence of a preexisting crack with a given opening which enters in the surface part of the energy.

Let $f : \mathbb{R} \to [0, +\infty[$ be convex, $f(0) = 0$, and with superlinear growth, i.e.,

$$\limsup_{|\xi|\to+\infty} \frac{f(\xi)}{|\xi|} = +\infty.$$

Let $\varphi : [0,+\infty[\to [0,+\infty[$ be increasing, concave, and such that $\varphi(0) = 0$. Notice that if $a := \varphi'(0) < +\infty$, we have

$$\varphi(s) \le as \qquad \text{for all } s \in [0,+\infty[.$$

Let Ω be a Lipschitz bounded open set in $\mathbb{R}^N$, and let $\partial_D\Omega \subseteq \partial\Omega$ be open in the relative topology. Let Γ be a rectifiable set in $\Omega \cup \partial_D\Omega$, and let ψ be a positive function defined on Γ. Let us extend ψ to $\Omega \cup \partial_D\Omega$ setting $\psi = 0$ outside Γ. Let $g \in W^{1,1}(\Omega)$: we may assume that g is extended to the whole $\mathbb{R}^N$, and we indicate this extension still by g.

We will study the following functional:

$$F(u) := \begin{cases} \int_\Omega f(|\nabla u|)\,dx + \int_{S^g(u)\cup\Gamma} \varphi(|[u]| \vee \psi)\,d\mathcal{H}^{N-1} & \text{if } u \in SBV(\Omega), \\ +\infty & \text{otherwise in } BV(\Omega), \end{cases}$$

where $S^g(u)$ is defined in (2.3), and $a \vee b := \max\{a,b\}$ for all $a,b \in \mathbb{R}$. The functional F naturally appears (see section 3) when dealing with quasi-static growth of cracks in the cohesive case, where one is required to look for its minima. We are led to compute the relaxation of F with respect to the strong topology of $L^1(\Omega)$. The relaxation in the case $\Gamma = \emptyset$ (without boundary conditions but without superlinear growth on f) has been proved in [6]. Let

$$f_1(\xi) := \inf\{f(\xi_1) + a|\xi_2| \,:\, \xi_1 + \xi_2 = \xi\}, \tag{9.1}$$

where $a := \varphi'(0)$. We have that the following result holds.

PROPOSITION 9.1. *The relaxation of the functional F with respect to the weak* topology of $BV(\Omega)$ is given by $\overline{F} : BV(\Omega) \to [0,+\infty]$ defined as*

$$\overline{F}(u) := \int_\Omega f_1(|\nabla u|)\,dx + \int_{S^g(u)\cup\Gamma} \varphi(|[u]| \vee \psi)\,d\mathcal{H}^{N-1} + a|D^c u|,$$

where $a = \varphi'(0)$ and f_1 is defined in (9.1).

In order to prove Proposition 9.1, the first step is the following lemma.

LEMMA 9.2. *Let $\bar{F} : BV(\Omega) \to [0,+\infty]$ be defined by*

$$\overline{F}(u) := \int_\Omega f_1(|\nabla u|)\,dx + \int_{S^g(u)\cup\Gamma} \varphi(|[u]| \vee \psi)\,d\mathcal{H}^{N-1} + a|D^c u|,$$

with $a = \varphi'(0)$ and f_1 as in (9.1). *Then $\bar{F}$ is lower semicontinuous with respect to the weak* topology of $BV(\Omega)$.*

The proof of Lemma 9.2 is obtained by a standard slicing argument (see, for example, [4, Theorem 5.4]) based on the lower semicontinuity result in dimension one. We establish this last one.

Let $I \subseteq \mathbb{R}$ be a finite union of disjoint intervals, and let $J \subseteq I$ be a countable set. Let us consider the functional

$$\begin{aligned} \mathcal{F}(\mu) := \int_I f_1(|\phi_\mu|)\,dx + \sum_{t\in S_\mu\setminus J} \varphi(|\mu(\{t\})|) \\ + \sum_{t\in J} \varphi(|\mu(\{t\})| \vee \psi(t)) + a|\mu^c|(I) \end{aligned} \tag{9.2}$$

defined for all $\mu \in \mathcal{M}_b(I;\mathbb{R}^k)$, i.e., μ is a bounded $\mathbb{R}^k$-valued Radon measure on I. Here ϕ_μ is the density of the absolutely continuous part μ^a of μ, S_μ is the set of atoms

of μ, $\mu^c := \mu - \mu^a - \mu \llcorner S_\mu$, ψ is a strictly positive function defined on J, $a = \varphi'(0)$, and f_1 is defined in (9.1).

LEMMA 9.3. *The functional $\mathcal{F}$ defined in* (9.2) *is lower semicontinuous with respect to the weak* convergence in the sense of measures.*

Proof. Since $\mathcal{F}$ can be obtained as the sup of functionals of the form (9.2) with J finite, we may assume that $J = \{x_1, \dots, x_m\}$. Let $\mu_n \overset{*}{\rightharpoonup} \mu$ weakly* in the sense of measures, and let λ be the weak* limit (up to a subsequence) of $|\mu_n \llcorner J|$. Let $J := J_1 \cup J_2$, with

$$J_1 := \{t \in J \,:\, |\mu(\{t\})| \geq \psi(t)\}, \qquad J_2 := J \setminus J_1.$$

Let $\varepsilon > 0$ be such that

$$\bigcup_{x_i \in J_2} \bar{B}_\varepsilon(x_i) \subseteq I$$

and such that for all n

$$|\mu_n| \left(\bigcup_{x_i \in J_2} \partial \bar{B}_\varepsilon(x_i) \right) = |\mu| \left(\bigcup_{x_i \in J_2} \partial \bar{B}_\varepsilon(x_i) \right) = 0.$$

Let us set

$$I_1 := I \setminus \bigcup_{x_i \in J_2} \bar{B}_\varepsilon(x_i), \qquad I_2 := \bigcup_{x_i \in J_2} B_\varepsilon(x_i).$$

Let $\mathcal{F}_1$ and $\mathcal{F}_2$ denote the restriction of $\mathcal{F}$ to $\mathcal{M}_b(I_1; \mathbb{R}^k)$ and $\mathcal{M}_b(I_2; \mathbb{R}^k)$, respectively. We have

$$\liminf_{n \to +\infty} \mathcal{F}(\mu_n) \geq \liminf_{n \to +\infty} \mathcal{F}_1(\mu_n \llcorner I_1) + \liminf_{n \to +\infty} \mathcal{F}_2(\mu_n \llcorner I_2).$$

We notice that

$$\mathcal{F}_1(\mu_n \llcorner I_1) \geq \mathcal{G}_1(\mu_n \llcorner I_1),$$

where

$$\mathcal{G}_1(\eta) := \int_{I_1} f_1(|\phi_\eta|)\, dx + \sum_{t \in S_\eta} \varphi(|\eta(\{t\})|) + a|\eta^c|(I_1)$$

for all $\eta \in \mathcal{M}_b(I_1; \mathbb{R}^k)$. By [4, Thorem 5.2] we have that

$$\mathcal{G}_1(\mu \llcorner I_1) \leq \liminf_{n \to +\infty} \mathcal{G}_1(\mu_n \llcorner I_1),$$

so that

$$\mathcal{F}_1(\mu \llcorner I_1) = \mathcal{G}_1(\mu \llcorner I_1) \leq \liminf_{n \to +\infty} \mathcal{F}_1(\mu_n \llcorner I_1).$$

On the other hand, we have

$$\mathcal{F}_2(\mu_n \llcorner I_2) = \mathcal{G}_2(\mu_n \llcorner I_2 \setminus J_2) + \sum_{t \in J_2} \varphi(|\mu_n(\{t\})| \vee \psi(t)),$$

where

$$\mathcal{G}_2(\eta) := \int_{I_2} f_1(|\phi_\eta|)\,dx + \sum_{t\in S_\eta} \varphi(|\eta(\{t\})|) + a|\eta^c|(I_2)$$

for all $\eta \in \mathcal{M}_b(I_2;\mathbb{R}^k)$. We have

$$\begin{aligned}\liminf_{n\to+\infty} \mathcal{F}_2(\mu_n \llcorner I_2) &\geq \mathcal{G}_2(\mu \llcorner I_2 \setminus J_2) + \sum_{t\in J_2} \varphi(\lambda(\{t\}) \vee \psi(t)) \\ &\geq \mathcal{G}_2(\mu \llcorner I_2 \setminus J_2) + \sum_{t\in J_2} \varphi(\psi(t)).\end{aligned}$$

We deduce

$$\mathcal{F}_2(\mu \llcorner I_2) = \mathcal{G}_2(\mu \llcorner I_2 \setminus J_2) + \sum_{t\in J_2} \varphi(\psi(t)) \leq \liminf_{n\to+\infty} \mathcal{F}_2(\mu_n \llcorner I_2),$$

and so we get

$$\mathcal{F}(\mu) = \mathcal{F}_1(\mu \llcorner I_1) + \mathcal{F}_2(\mu \llcorner I_2) \leq \liminf_{n\to+\infty} \mathcal{F}(\mu_n).$$

The proof is now concluded. □

Let us now come to the proof of Proposition 9.1.

Proof of Proposition 9.1. We can assume without loss of generality that

$$\int_\Gamma \varphi(\psi)\,d\mathcal{H}^{N-1} < +\infty.$$

Following Lemma 9.2, let us consider $\tilde{\Omega}$ open and bounded in $\mathbb{R}^N$ such that $\overline{\Omega} \subset \tilde{\Omega}$, and let us set $\Omega' := \tilde{\Omega} \setminus \partial_N\Omega$. Let us consider the functional

$$F'(u) := \begin{cases} \int_\Omega f(|\nabla u|)\,dx + \int_{S(u)\cup\Gamma} \varphi(|[u]| \vee \psi)\,d\mathcal{H}^{N-1} & \text{if } u \in SBV(\Omega'), \\ & u = g \text{ on } \Omega' \setminus \Omega, \\ +\infty & \text{otherwise in } BV(\Omega'). \end{cases}$$

The relaxation result of Proposition 9.1 is equivalent to proving that the relaxation of F' under the weak* topology of $BV(\Omega')$ is

$$\overline{F'}(u) := \int_\Omega f_1(|\nabla u|)\,dx + \int_{S(u)\cup\Gamma} \varphi(|[u]| \vee \psi)\,d\mathcal{H}^{N-1} + a|D^c u|(\Omega')$$

if $u \in BV(\Omega')$, $u = g$ on $\Omega' \setminus \Omega$, and $\overline{F'}(u) = +\infty$ otherwise in $BV(\Omega')$.

Following [6], it is useful to introduce the localized version of F'; namely, for all open set $A \subseteq \Omega'$ let us set

$$F'(u,A) := \int_{A\cap\Omega} f(|\nabla u|)\,dx + \int_{A\cap(S(u)\cup\Gamma)} \varphi(|[u]| \vee \psi)\,d\mathcal{H}^{N-1} \tag{9.3}$$

if $u \in SBV(\Omega')$, $u = g$ on $\Omega' \setminus \Omega$, and $F'(u,A) = +\infty$ otherwise in $BV(\Omega')$. Let us indicate by $\overline{F'}(u,A)$ the relaxation of (9.3) under the weak* topology of $BV(\Omega')$.

Arguing as in [6, Proposition 3.3], we have that for every $u \in BV(\Omega')$, $\overline{F'}(u,\cdot)$ is the restriction to the family $\mathcal{A}(\Omega')$ of all open subsets of Ω' of a regular Borel measure. Since for all $u \in SBV(\Omega')$ with $u = g$ on $\Omega' \setminus \Omega$ and for all $A \in \mathcal{A}(\Omega')$ we have

$$\begin{aligned}\int_{A\cap\Omega} f(|\nabla u|)\,dx + \int_{A\cap S(u)} \varphi(|[u]|)\,d\mathcal{H}^{N-1} &\le F'(u,A)\\ &\le \int_{A\cap\Omega} f(|\nabla u|)\,dx + \int_{A\cap S(u)} \varphi(|[u]|)\,d\mathcal{H}^{N-1} + \int_{A\cap\Gamma} \varphi(\psi)\,d\mathcal{H}^{N-1},\end{aligned}$$

by [6, Theorem 3.1] we obtain that for all $u \in BV(\Omega')$ with $u = g$ on $\Omega' \setminus \Omega$ and for all $A \in \mathcal{A}(\Omega')$ with $A \cap \partial_D\Omega = \emptyset$

$$\begin{aligned}\int_{A\cap\Omega} f_1(|\nabla u|)\,dx + \int_{A\cap S(u)} \varphi(|[u]|)\,d\mathcal{H}^{N-1} + a|D^c u|(A) &\le F'(u,A)\\ &\le \int_{A\cap\Omega} f_1(|\nabla u|)\,dx + \int_{A\cap S(u)} \varphi(|[u]|)\,d\mathcal{H}^{N-1} + a|D^c u|(A) + \int_{A\cap\Gamma} \varphi(\psi)\,d\mathcal{H}^{N-1}.\end{aligned} \tag{9.4}$$

As a consequence of (9.4), we deduce that

$$\overline{F'}(u,\cdot)\llcorner(\Omega' \setminus (S(u)\cup\Gamma\cup\partial_D\Omega)) = f_1(|\nabla u|)\,d\mathcal{L}^N\llcorner\Omega + a|D^c u|.$$

In order to evaluate $\overline{F'}(u,\cdot)\llcorner(S(u)\cup\Gamma\cup\partial_D\Omega)$, we notice that for all $A \in \mathcal{A}(\Omega')$ and for all $u \in SBV(\Omega')$ with $u = g$ on $\Omega' \setminus \Omega$

$$\int_{A\cap\Omega} f_1(|\nabla u|)\,dx + \int_{A\cap(S(u)\cup\Gamma)} \varphi(|[u]|\vee\psi)\,d\mathcal{H}^{N-1} + a|D^c u|(A) \le F'(u,A),$$

and since the left-hand side is lower semicontinuous by Lemma 9.2, we get that for all $u \in BV(\Omega')$ with $u = g$ on $\Omega' \setminus \Omega$

$$\int_{A\cap\Omega} f_1(|\nabla u|)\,dx + \int_{A\cap(S(u)\cup\Gamma)} \varphi(|[u]|\vee\psi)\,d\mathcal{H}^{N-1} + a|D^c u|(A) \le \overline{F'}(u,A).$$

By outer regularity of $\overline{F'}(u,\cdot)$ we conclude that

$$\overline{F'}(u,E) \ge \int_E \varphi(|[u]|\vee\psi)\,d\mathcal{H}^{N-1}$$

for all Borel sets $E \subseteq S(u)\cup\Gamma\cup\partial_D\Omega$. We have to prove the opposite inequality, namely,

$$\overline{F'}(u,E) \le \int_E \varphi(|[u]|\vee\psi)\,d\mathcal{H}^{N-1}$$

for all Borel sets $E \subseteq S(u)\cup\Gamma\cup\partial_D\Omega$. Without loss of generality, we may assume that

$$\int_{S(u)} \varphi(|[u]|)\,d\mathcal{H}^{N-1} < +\infty,$$

and by a truncation argument, we can suppose that $u_{|\Omega} \in L^\infty(\Omega)$. Let K be a compact subset of $S(u)\cup\Gamma\cup\partial_D\Omega$, $\varepsilon > 0$, and let A_ε be open with $K \subseteq A_\varepsilon$ and

$$|Du|(A_\varepsilon \setminus K) < \varepsilon, \qquad \int_{(A_\varepsilon\setminus K)\cap\Gamma} \varphi(\psi)\,d\mathcal{H}^{N-1} < \varepsilon.$$

We can find $u_h \in BV(\Omega')$ with $u_h = g$ on $\Omega' \setminus \Omega$ and such that u_h is piecewise constant in Ω (that is $(u_h)_{|\Omega} \in SBV(\Omega)$ with $\nabla u_h = 0$ in Ω), $u_h \to u$ strongly in $L^\infty(\Omega)$, and $|Du_h|(A_\varepsilon \setminus K) < \varepsilon$. Since u_h is piecewise constant in Ω we have for all h

$$\overline{F'}(u_h, A_\varepsilon) \le \int_{A_\varepsilon \cap (S(u_h) \cup \Gamma)} \varphi(|[u_h]| \vee \psi)\, d\mathcal{H}^{N-1}. \tag{9.5}$$

We conclude

$$\begin{aligned}
\overline{F'}(u, A_\varepsilon) &\le \liminf_{h \to +\infty} \overline{F'}(u_h, A_\varepsilon) \le \liminf_{h \to +\infty} \int_{A_\varepsilon \cap (S(u_h) \cup \Gamma)} \varphi(|[u_h]| \vee \psi)\, d\mathcal{H}^{N-1} \\
&\le \int_{K \cap (S(u) \cup \Gamma)} \varphi(|[u]| \vee \psi)\, d\mathcal{H}^{N-1} + a|Du_h|(A_\varepsilon \setminus K) + \int_{(A_\varepsilon \setminus K) \cap \Gamma} \varphi(\psi)\, d\mathcal{H}^{N-1} \\
&\le \int_{K \cap (S(u) \cup \Gamma)} \varphi(|[u]| \vee \psi)\, d\mathcal{H}^{N-1} + (a+1)\varepsilon
\end{aligned}$$

so that, letting $\varepsilon \to 0$ we obtain

$$\overline{F'}(u, K) \le \int_{K \cap (S(u) \cup \Gamma)} \varphi(|[u]| \vee \psi)\, d\mathcal{H}^{N-1}.$$

Since K is arbitrary in $S(u) \cup \Gamma \cup \partial_D \Omega$, the proof is concluded. □

Acknowledgments. The author wishes to thank Gianni Dal Maso for many helpful and interesting discussions, and Gilles Francfort for useful comments on a preliminary version of the paper.

REGULARITY OF SOLUTIONS TO A CLASS OF CROSS DIFFUSION SYSTEMS*

DUNG LE†

Abstract. Regularity of bounded solutions to a class of strongly coupled parabolic systems is investigated. Conditions on the structure of the systems are found to assure that bounded solutions are Hölder continuous. The theory is then applied to the general Shigesada–Kawasaki–Teramoto model in population dynamics.

Key words. cross diffusion systems, Hölder regularity

AMS subject classifications. 35K57, 35B65

DOI. 10.1137/S0036141003428354

1. Introduction. In the last twenty years, cross diffusion systems have attracted great attention in both mathematical analysis and real life modeling. The introduction of cross diffusion terms into regular diffusion systems allows the mathematical models to capture much more important features of phenomena in physics, biology, ecology, and engineering sciences. At the same time, the presence of these terms caused enormous difficulties in the mathematical treatment due to the strong coupling in the diffusion terms. Among unanswered fundamental questions, we face the regularity of bounded weak solutions.

In this work, we study Hölder continuity of a bounded weak solution $\vec{u} = (u_1, \dots, u_m)$ to the following parabolic system:

$$\vec{u}_t = \nabla \cdot (\mathcal{A}(\vec{u})\nabla\vec{u}) + \mathcal{F}(\vec{u}). \tag{1.1}$$

Here, $\mathcal{A}(\vec{u}) = (P_{ij}(\vec{u}))$ is an $m \times m$ matrix, $\mathcal{F}(\vec{u}) = (F_1(\vec{u}), \dots, F_m(\vec{u}))$, and $\nabla\vec{u} = (\nabla_x u_1, \dots, \nabla_x u_m)$.

This system is coupled with certain boundary conditions on the boundary of a bounded domain Ω in $\mathbb{R}^n$. For the sake of simplicity, we will study only interior regularity of solutions although our method can be easily modified to cover the boundary case, given suitable boundary conditions.

Fundamental theory for strongly coupled systems like (1.1) was presented in [1]. The question on the global existence of solutions was also discussed there. For regular reaction diffusion systems, when $\mathcal{A}$ is a diagonal matrix, it is well known that bounded weak solutions are Hölder continuous (see [6]). Moreover, $\vec{u}$ exists globally if its supremum norm $\|\vec{u}(\bullet, t)\|_{\infty,\Omega}$ does not blow up in time. In contrast, things are more complicated if $\mathcal{A}$ is a full matrix. Counterexamples in [4] showed that, in general, a bounded solution to (1.1) can disappear in finite time while staying bounded. Thus, the boundedness of the L^∞ norm of a solution $\vec{u}$ is not sufficient to guarantee its global existence. Fortunately, there is an elaborated theory developed in [1] showing that a solution $\vec{u}$ to (1.1) exists globally (and is classical) if one has controls on both of its L^∞ and Hölder norms. Thus, it is necessary to study the Hölder continuity

of the solutions. Furthermore, estimates on Hölder norms of solutions also provide valuable information on the compactness of the trajectories of solutions if one wishes to study their long time dynamics, such as the existence of global attractors.

Partial regularity results were obtained by Giaquinta and Struwe in [3] for a general class of systems. Everywhere regularity results for bounded solutions were proven only in very few situations assuming restrictive structure conditions. Among these are triangular systems (see [1, 9]) or strongly coupled systems of special form (see [9, 11]). In [9], we had to assume certain structural conditions that prevent the application of our results to many important models. In fact, the strongly coupled parabolic system

$$\begin{cases} \dfrac{\partial u}{\partial t} = \Delta[(d_1 + a_{11}u + a_{12}v)u] + F(u,v), \\ \dfrac{\partial v}{\partial t} = \Delta[(d_2 + a_{21}u + a_{22}v)v] + G(u,v), \end{cases} \tag{1.2}$$

does not satisfy the structures studied in [9, 11]. This system was proposed by Shigesada, Kawasaki and Teramoto in [10] to study spatial segregation of interacting species. Global existence and long time dynamics of solutions were investigated in either triangular cases or under the assumption that the dimension n of the domain Ω is two (see [5, 7] and the reference therein). For $n > 2$, to our best knowledge, the question of whether bounded positive solutions to this model are Hölder continuous (everywhere) remains open.

The aim of this paper is to present certain sufficient conditions on the structure of (1.1) for its bounded weak solutions to be Hölder continuous everywhere (and therefore classical). The dimension n of the domain Ω and the number m of equations in (1.1) can be arbitrary. This will be done in section 2. Our key assumption (see (H.1)) is the existence of a function $H(\vec{u})$, being defined on the range of a solution $\vec{u}$, which links the structures of the equations in a way that we can derive certain regularity information of $H(\vec{u}(x,t))$ in (x,t). To this end, we follow logarithmic function techniques developed in [8] dealing with scalar equations. Such regularity of H will be exploited later to study that of $\vec{u}$.

The condition (H.1) was motivated by a biological model of two equations studied in [10], where the following form of $P_{i,j}$ was considered:

$$P_{ij}(\vec{u}) = a\nabla u_i + c_i \nabla H(x,t,\vec{u}), \text{ with } i,j \in \{1,2\}. \tag{1.3}$$

The function H was a given affine function in $\vec{u}$ and represented the environmental influences on the species $\vec{u}$. Naturally, this influence might depend nonlinearly on $\vec{u}$ itself. For simplicity, let us assume that H depends only on $\vec{u}$, then (H.1) can be fulfilled (see Remark 2.2). Our condition (H.1) generalizes this situation in hope that it can cover more general structure and, in particular, (1.2).

Unless H is described explicitly as in (1.3), the existence of such function H required in (H.1) seems to be unclear and of little use in practice. In particular, we may ask if (H.1) is ever satisfied for (1.2). We take a closer look at these hypotheses in section 3, and try to find sufficient conditions on the parameters defining (1.1). This is not an easy task for systems of more than two equations. We are forced to study the case $m = 2$ (but n is still arbitrary). It turns out that H must be a solution to a first order PDE dictated by the coefficients of the system. This PDE can be solved by elementary methods of characteristics. Sufficient conditions for H to exist

will be formulated in Theorem 3. We will describe a way of constructing such H in Lemma 3.3 of section 3.

The system (1.2) is a test case of the general result in section 2. Since u, v are population densities, only positive solutions are of interest. We then study these solutions in section 4 where we will give the proof of the following theorem.

THEOREM 1. *Assume that $d_i, a_{ij} > 0$, $i, j = 1, 2$. If $(a_{22} - a_{12})(a_{11} - a_{21}) > 0$, then bounded positive weak solutions to* (1.2) *are Hölder continuous everywhere.*

That is, in population dynamics terms, we assumed that self diffusion rates are either stronger or weaker than cross diffusion ones. In fact, our method also works for a more general setting than that of (1.2) as we briefly point out in Theorem 4.

2. The general case. Let $\vec{u} = (u_1, \dots, u_m)$ be a bounded solution to (1.1) that exists on some interval $(0, T)$. We consider the range of $\vec{u}$

$$\Gamma = \{\vec{u}(x,t) \,:\, (x,t) \in \Omega_T = \Omega \times (0,T)\} \subset \mathbb{R}^m. \tag{2.1}$$

Hereafter, we use the summation convention, where the i, j indices run from 1 to m. We set $\mathcal{P}_i = P_{i,j}\nabla u_j = \sum_{j=1}^m P_{i,j}\nabla u_j$.

Our main assumptions are the followings.

(P.1) The functions $P_{i,j}, F_i$ are continuous functions in $\vec{u} \in \mathbb{R}^m$.

(H.1) There exist a C^2 function $H : \mathbb{R}^m \to \mathbb{R}$ defined on a bounded neighborhood Γ_0 of Γ, and positive numbers $\lambda_1, \lambda_2, \lambda_3$ such that

$$\Delta_1 = \nabla H \cdot (H_{u_j}\mathcal{P}_j) = \nabla H \cdot \sum_{j=1}^m H_{u_j}\mathcal{P}_j \geq \lambda_1 |\nabla H|^2, \tag{2.2}$$

$$\Delta_2 = \mathcal{P}_j \cdot \nabla H_{u_j} = \sum_{j=1}^m \mathcal{P}_j \cdot \nabla H_{u_j} \geq \lambda_2 |\nabla \vec{u}|^2, \tag{2.3}$$

$$\Delta_3 = |H_{u_j}\mathcal{P}_j| = |\sum_{j=1}^m H_{u_j}\mathcal{P}_j| \leq \lambda_3 |\nabla H| \tag{2.4}$$

for every C^1 function $\vec{u} : \Omega_T \to \mathbb{R}^m$ whose range is contained in Γ_0.

Here, with a slight abuse of notation, we will write $H_t = \frac{\partial}{\partial t} H(\vec{u}(x,t))$, $H_{u_j} = \frac{\partial}{\partial u_j} H(\vec{u})$, $H_{u_i u_j} = \frac{\partial^2}{\partial u_i \partial u_j} H(\vec{u})$, $\nabla H = \nabla_x H(\vec{u}(x,t))$, and so on.

Our main result of this section is the following theorem.

THEOREM 2. *Assume that Γ is bounded and* (P.1) *and* (H.1) *hold. We assert that $\vec{u}$ belongs to the Hölder class $C^{\alpha,\alpha/2}(\Omega_T)$ for any $\alpha \in (0,1)$. Moreover, the $C^{\alpha,\alpha/2}$ norm of $\vec{u}$ can be estimated in terms of the data of the equation and $\|\vec{u}\|_{\infty,\Omega_T}$.*

Let us fix a point $(x_0, t_0) \in \Omega_T$. For $R, r > 0$, we consider the cylinder $Q(R,r) := Q(x_0, t_0, R, r) := B_{x_0}(R) \times [t_0 - r, t_0]$, and always assume that R, r are sufficiently small such that $Q(R,r) \subset \Omega_T$. For $i = 1, 2, \dots$, we denote $Q_{iR} = Q(iR, iR^2)$.

The key ingredient of our proof is to show that

$$\liminf_{R\to 0} \frac{1}{R^n} \iint_{Q_R} |\nabla \vec{u}|^2 \, dxdt < \varepsilon, \quad Q_R := B(x_0, R) \times [t_0 - R^2, t_0] \quad \forall \varepsilon > 0. \tag{2.5}$$

Once this is proven, thanks to the Poincaré type inequality (see [3, Prop. 3.1])

$$\iint_{Q_R} |\vec{u} - \vec{u}_R|^2 \, dxdt \leq cR^2 \iint_{Q_R} |\nabla \vec{u}|^2 \, dxdt, \tag{2.6}$$

we see that (2.5) implies $\liminf_{R\to 0} \fint\!\!\!\fint_{Q_R} |\vec{u}-\vec{u}_R|^2\, dxdt < \varepsilon$. Since $\varepsilon > 0$ can be arbitrarily small, the Hölder continuity of $\vec{u}$ follows from [3, Theorem 3.1]. Moreover, provided ε is taken sufficiently small, the proof (see [3, pages 445–446]) also shows that $\fint\!\!\!\fint_{Q_R} |\vec{u}-\vec{u}_R|^2\, dxdt \le CR^\alpha$, for *any* $\alpha \in (0,1)$ and $R > 0$ with the constant C depends uniformly on α, ε the data and the supremum norm of $\vec{u}$. By the Campanato imbedding theorem (see [3]), the desired estimate for the $C^{\alpha,\alpha/2}$ norm of $\vec{u}$ is implied and we conclude the proof of Theorem 2.

For $R > 0$, we denote

$$M_i = \sup_{Q_{iR}} H(\vec{u}(x,t)), \quad m_i = \inf_{Q_{iR}} H(\vec{u}(x,t)), \text{ and } \omega_i = M_i - m_i,$$

and, for some positive θ, α to be determined later, define the following function:

$$w(x,t) := \log\left(\frac{\omega_4 + R^\alpha}{N(\vec{u}(x,t))}\right), \text{ with } N(\vec{u}) = \theta(M_4 - H(\vec{u})) + R^\alpha.$$

Let $Q^0 = \{(x,t) \in Q_{2R} : w(x,t)_+ = 0\}$. It is easy to see that Q^0 is the set where $H \le (1-1/\theta)M_4 + m_4$, or $H(\vec{u}(x,t))$ is away from M_4.

We consider the following two alternatives discussing the largeness of the measure $|Q^0|$ of this set Q^0.

(A) There is $R_0 > 0$ such that

$$|Q^0| > \frac{1}{\theta} R^{n+2} \quad \forall R \in (0, R_0). \tag{2.7}$$

(B) There is a sequence $\{R_k\}$, $R_k \to 0$, such that

$$|Q^0| < \frac{1}{\theta} R^{n+2}, \quad \text{for } R = R_k. \tag{2.8}$$

For any given $\varepsilon > 0$, we will try to determine $\theta = \theta(\varepsilon) > 0$ such that (2.5) holds. If (A) holds, the role of θ is not relevant in this case as any positive θ will do. Here, the values of $H(\vec{u}(x,t))$ in Q_{2R} are "evenly" between m_4, M_4, and we will follow the argument in [8] to show that $H(\vec{u}(x,t))$ is Hölder continuous by proving that w is uniformly bounded. On the other hand, if (B) holds for large θ, then H is close to M_4 in a large part of Q_{2R}. We will show that $\vec{u}$ will not oscillate to much by proving that its gradients is averagely small if θ is large.

First, we test the jth equation by $H_{u_j}\eta$, sum the results, and use (2.3) to get

$$\int_\Omega \frac{\partial H}{\partial t}\eta\, dx + \int_\Omega \left[(H_{u_j}\mathcal{P}_j)\nabla\eta + \lambda_2|\nabla\vec{u}|^2\eta\right] dx \le \int_\Omega \Psi\eta\, dx. \tag{2.9}$$

Here we denoted $\Psi = \sum F_j H_{u_j}$.

Proof of (2.5) *given (A).*

Let η be a function with compact support in Q_{2R}. We test the jth equation by $\theta H_{u_j}\eta/N$, and add the results to get

$$\begin{aligned} &\int_\Omega \frac{\partial w}{\partial t}\eta\, dx \qquad + \int_\Omega \theta\left[\frac{(H_{u_j}\mathcal{P}_j)}{N}\nabla\eta + \frac{\mathcal{P}_j\nabla H_{u_j}}{N}\eta\right] dx \\ &\qquad + \int_\Omega \theta^2 \frac{(H_{u_j}\mathcal{P}_j)\nabla H}{N^2}\eta\, dx = \int_\Omega \frac{\theta\Psi}{N}\eta\, dx. \end{aligned} \tag{2.10}$$

If $\eta \geq 0$, then (2.2), (2.3) and the above imply

$$\int_\Omega \frac{\partial w}{\partial t}\eta \, dx + \theta \int_\Omega \frac{(H_{u_j}\mathcal{P}_j)}{N}\nabla\eta \, dx \leq \int_\Omega \frac{\theta\Psi}{N}\eta \, dx. \tag{2.11}$$

We first show that $\|w\|_{\infty,Q_R}$ can be estimated in terms of $\|w\|_{2,Q_{2R}}$. We replace η in (2.11) by $(w-k)_+\eta^2$, with η being a cut-off function in Q_{2R}. Note that $\nabla w = \theta\nabla H/N$. We derive

$$\begin{aligned}\int_\Omega \frac{\partial (w-k)_+^2}{\partial t}\eta^2 \, dx \quad &+ \quad \int_{w\geq k} \frac{\theta^2(H_{u_j}\mathcal{P}_j)\nabla H}{N^2}\eta^2 dx \\ &\leq \int_\Omega \frac{\theta(H_{u_j}\mathcal{P}_j)(w-k)_+}{N}\eta|\nabla\eta| \, dx + \int_\Omega \frac{\theta\Psi(w-k)_+}{N}\eta^2 \, dx.\end{aligned}$$

Integrating with respect to $t \in I := [t_0 - 4R^2, t_0]$ and using the Young inequality and (2.4) to the first term on the right-hand side, we obtain

$$\begin{aligned}&\sup_{t\in[t_0-R^2,t_0]}\int_{B(R)} \frac{\partial (w-k)_+^2}{\partial t}\eta^2 \, dx + \iint_{Q_{2R}} |\nabla(w-k)_+|^2\eta^2 \, dxdt \\ &\leq \theta^2 \iint_{Q_{2R}} (w-k)_+^2 R^{-2} \, dxdt + \theta^2 \int_I \int_{w\geq k} \frac{R^2\Psi^2}{N^2}\eta^2 dxdt.\end{aligned} \tag{2.12}$$

Let $A_k = \{(x,t) \in Q_{2R} : w(x,t) > k\}$. Because Ψ is bounded on Γ_0 and $N \geq R^\alpha \geq C|A_k|^{\frac{\alpha}{n+2}}$, we bound the last term in (2.12) by

$$\int_I \int_{w\geq k} \frac{R^2\Psi^2}{N^2}\eta^2 dxdt \leq C|A_k|^{1-\frac{2\alpha}{n+2}}. \tag{2.13}$$

We now choose $\alpha < 1$ and see that $1 - \frac{2\alpha}{n+2} > \frac{n}{n+2}$. This fact, (2.12), (2.13), and the well known DiGiorgi's method in [6] will give

$$\sup_{B_{x_0}(R)\times[t_0-R^2,t_0]} w \leq \text{Const}\left(1 + \frac{1}{R^{n+2}}\iint_{B_{x_0}(2R)\times[t_0-2R^2,t_0]} (w^+)^2 \, dxdt\right). \tag{2.14}$$

Next, we replace η by η^2 in (2.10) and use (2.2), (2.3), and (2.4) to get

$$\int_\Omega \frac{\partial w}{\partial t}\eta^2 \, dx + \int_\Omega |\nabla w|^2\eta^2 \, dx \leq C\int_\Omega \left(|\nabla w|\eta|\nabla\eta| + \frac{\theta\Psi}{N}\eta^2\right) \, dx.$$

This and the condition on the measure of Q^0 in (2.7) allow us to follow the proof of [8, Lemma 2.4] to show that $\|w\|_{2,Q_{2R}}$, and therefore $\|w\|_{\infty,Q_R}$ (see (2.14)), can be bounded by a constant independent of R. The argument in [8, page 924] then gives a decay estimate for the oscillation of H and then its Hölder continuity.

Moreover, let η be a cutoff function for Q_R and satisfy: $\eta \equiv 1$ in Q_R, $\eta(x,t) \equiv 0$ outside the cylinder Q' given by $B_{x_0}(2R)\times[t_0-2R^2, t_0+R^2]$. In addition, $|D\eta| \leq 1/R$ and $\left|\frac{\partial\eta}{\partial t}\right| \leq 1/R^2$. Replacing η in (2.9) by $(H(\vec{u}) - \inf_{Q_R} H(\vec{u}))\eta^2$, with η is the above cutoff function, and using the fact that for some positive ν, $|H(\vec{u}) - \inf_{Q_R} H(\vec{u})| \leq CR^\nu$ we easily show that $|DH(\vec{u})|^2 \in L^{1,\mu}_{loc}$ for $\mu = n + 2\nu > n$.

Let $\bar{H}(\vec{u}) = H(\vec{u}) - H(\vec{u})_R$, where $H(\vec{u})_R$ denotes the mean value of $H(\vec{u}(x,t))$ over Q_R. We can replace H in (2.9) by $\bar{H}$. We use (2.4) to get

$$\int_\Omega \frac{\partial(\bar{H}\eta)}{\partial t}\, dx + \lambda_2 \int_\Omega |\nabla \vec{u}|^2 \eta\, dx \le C \int_\Omega \left[|\nabla H||\nabla \eta| + |\bar{H}| \frac{\partial \eta}{\partial t} + \Psi \eta \right] dx.$$

We integrate the above inequality with respect to t over the interval $[t_0 - 2R^2, t_0 + R^2]$ and obtain

$$\lambda_2 \iint_{Q'} |\nabla \vec{u}|^2 \eta\, dxdt \le C \iint_{Q'} \left(|\nabla H||\nabla \eta| + |\bar{H}||\frac{\partial \eta}{\partial t}| + |\Psi \eta| \right) dxdt.$$

Using the definition of η and the facts that $|DH(\vec{u})|^2 \in L^{1,\mu}_{loc}$, and that $|\bar{H}| \le CR^\nu$ (since $H(\vec{u}(x,t))$ is Hölder continuous), we can majorize the terms on the right as follows:

$$\iint_{Q'} |\bar{H}| \left| \frac{\partial \eta}{\partial t} \right| dxdt \le CR^{n+\nu},$$

$$\iint_{Q'} |\nabla H||\nabla \eta|\, dxdt \le \frac{|Q'|^{1/2}}{R} \left(\iint_{Q'} |\nabla H|^2\, dxdt \right)^{1/2} \le CR^{(n+\mu)/2}.$$

Since $\mu > n$, we have $(n+\mu)/2 > n$. From these estimates, for some $\gamma > 0$, we obtain

$$\iint_{Q_R} |\nabla \vec{u}|^2\, dxdt \le \iint_{Q'} |\nabla \vec{u}|^2 \eta\, dxdt \le CR^{n+\gamma}.$$

This gives (2.5) and completes this alternative.

Proof of (2.5) *given (B).* Since we can replace H by $H + k$ with k being any constant, we will hereafter assume that $m_4 = 0$ in the definition of w. It is clear that (B) implies

$$|\{(x,t) \in Q_R | H \le (1-\rho) M_4\}| < \rho R^{n+2}, \quad \text{with } \rho = 1/\theta. \tag{2.15}$$

We have the following estimate for the integral of $|\nabla \vec{u}|$.

LEMMA 2.1. *Let $q = 2n/(n+2)$. There exists a constant $C(M_4)$ such that*

$$\left(\fint\!\!\!\fint_{Q_R} |\nabla \vec{u}|^q\, dxdt \right)^{\frac{2}{q}} \le C(M_4) \rho^{\frac{2}{n}} R^{-2} \quad \forall R < \rho M_4. \tag{2.16}$$

Proof. We substitute $(H-k)^+ \eta^2$, with $k \in \mathbb{R}$ and η being a cut-off function on Q_{2R} with respect to Q_R, into the places of η in (2.9). Since we can choose η such that $|D\eta|^2 + |\eta_t| \le cR^{-2}$, standard estimates give

$$\lambda_2 \int \int_{Q_R} |\nabla \vec{u}|^2 (H-k)_+ dxdt + \frac{\lambda_1}{2} \int \int_{Q_R} |\nabla H|^2 \le \int \int_{Q_{2R}} (H-k)_+^2 |\nabla \eta|^2 + CR^{n+2}.$$

By the choice of $k := (1-2\rho)M_4$, $(H-k)^+ \le 2\rho M_4$ on Q_{2R} so that

$$\iint_{Q_R} |\nabla \vec{u}|^2 (H-k)^+\, dxdt \le C(\rho M_4)^2 R^n + CR^{n+2}.$$

Let $A_0 := \{(x,t) \in Q_R | H \geq (1-\rho)M_4\}$. Then $(H-k)^+ \geq \rho M_4$ on A_0. So,

$$\iint_{A_0} |\nabla \vec{u}|^2 \, dxdt \leq CR^n \left(\rho M_4 + \frac{R^2}{\rho M_4}\right) \leq 2\rho M_4 R^n \quad \forall R < \rho M_4. \tag{2.17}$$

Also, by substituting $e^{sH}\eta^2$ into places of η in (2.9) with $s > 0$ sufficiently large, it is standard to show

$$\iint_{Q_R} |\nabla \vec{u}|^2 \, dxdt \leq CR^n. \tag{2.18}$$

For any subset A of Q_R, Hölder's inequality gives

$$\iint_A |\nabla \vec{u}|^q \, dxdt \leq \left(\iint_A |\nabla \vec{u}|^2 \, dxdt\right)^{\frac{n}{n+2}} |A|^{\frac{2}{n+2}}. \tag{2.19}$$

Taking $A = A_0$ and using (2.17), we obtain

$$\iint_{A_0} |\nabla \vec{u}|^q \, dxdt \leq (2\rho M_4 R^n)^{\frac{n}{n+2}} R^2 = (2\rho M_4)^{\frac{n}{n+2}} R^{n+\frac{4}{n+2}} \quad \forall R < \rho M_4.$$

Similarly, we take $A = Q_R \setminus A_0$ in (2.19). Using (2.18) and also the fact that $|A| \leq \rho R^{n+2}$ by (2.15), we have

$$\iint_{Q_R \setminus A_0} |\nabla \vec{u}|^q \, dxdt \leq (CR^n)^{\frac{n}{n+2}} (\rho R^{n+2})^{\frac{2}{n+2}} R^2 = C\rho^{\frac{2}{n+2}} R^{n+\frac{4}{n+2}}.$$

Since $(n + \frac{4}{n+2} - n - 2)\frac{2}{q} = -2$. The above estimates give the lemma. □

From [3, page 443], we have

$$⨍\!\!⨍_{Q_R} |\nabla \vec{u}|^2 \, dxdt \leq C(\varepsilon) \left(⨍\!\!⨍_{Q_{4R}} |\nabla \vec{u}|^q \, dxdt\right)^{\frac{2}{q}} + \varepsilon ⨍\!\!⨍_{Q_{4R}} |\nabla \vec{u}|^2 \, dxdt \quad \forall \varepsilon > 0. \tag{2.20}$$

Using (2.18), (2.16) in (2.20) to estimate the integrals on the right-hand side and multiplying through by R^2, we obtain

$$\frac{1}{R^n} \iint_{Q_{R/4}} |\nabla \vec{u}|^2 \, dxdt \leq C(\varepsilon) C(M_4) \rho^{\frac{2}{n}} + C\varepsilon \quad \forall R < \rho M_4.$$

Obviously, we can make the right-hand side arbitrarily small by choosing ε and then $\rho = \rho(\varepsilon)$ sufficiently small. We have shown (2.5), given (B) with θ being sufficiently large. Our proof is now complete.

Remark 2.2. If (1.3) is considered, then one can easily check that (H.1) is verified if a, c_i are positive constants, and the matrix $(H_{u_i u_j})$ is positive definite (that is, $H_{u_i u_j}\xi_i\xi_j \geq \gamma|\xi|^2$ for some $\gamma > 0$ and $\xi \in \mathbb{R}^{m\times n}$). The conditions (2.2)–(2.4) seem to be technical. They are discovered in the search for an equation satisfied by the influence H. It turns out that these conditions make H a subsolution to some scalar parabolic equation. This information was used in the proof of the alternative (A).

3. Sufficient conditions for the existence of H. In this section we will find sufficient conditions that guarantee the existence of the function H satisfying our main assumptions (2.2)–(2.4). Unless H is explicitly present in systems like (1.3), the question of the existence of H verifying (H.1) is not easy to answer for general $m \geq 2$. Here, we restrict ourself to the case of two equations ($m = 2$). Parts of our calculation can be useful to study the case $m > 2$, but the possibility of formulating a similar sufficient condition, like (H.2) below, is questionable.

From now on, as we will deal with two equations and to simplify our notation, we denote $\vec{u} = (u, v)$, $P_1 = P_{11}$, $P_2 = P_{12}$, $Q_1 = P_{21}$, and $Q_2 = P_{22}$.

We then assume further that

(P.2) P_1, P_2, Q_1, Q_2 are C^1 functions on Γ_0 and are positive on Γ. Moreover, P_1, Q_2 are greater than a positive constant on $\overline{\Gamma}$.

We consider the following equation:

$$-P_2 f^2 + (P_1 - Q_2) f + Q_1 = 0, \tag{3.1}$$

because $P_2 Q_1 > 0$, (3.1) has two solutions $f = f_1, f_2$ with $f_1 f_2 < 0$. In what follows, we denote by $f(u, v)$ the positive solution of (3.1). By (P.2), f is differentiable so that there exists a C^2 solution g (see [2, pages 106–109]) to the following first order equation:

$$g_u - f(u, v) g_v = 0. \tag{3.2}$$

We will impose the following main assumption of this section.

(H.2) Let Γ_0 be connected. Assume that there exists a solution g to (3.2) such that g is defined on Γ_0, and

$$g_v \neq 0, \text{ and } 4(Q_1 P_2 - P_1 Q_2)(f_u - f_v f) \neq 0 \quad \forall (u, v) \in \Gamma_0. \tag{3.3}$$

The existence of H is then given by the following theorem.

THEOREM 3. *Assume* (H.2) *and let* $H(u, v) = K \exp(k g(u, v))$. *There exist* $K > 0$ *and* $k \in \mathbb{R}$ *such that* (H.1) *holds.*

Note also that if $G : \mathbb{R} \to \mathbb{R}$ is a C^2 function, then $H(u, v) = G(g(u, v))$ is also a C^2 solution to (3.2). To prove this theorem, we need only to verify the conditions (2.2)–(2.4) that amount to the positivity of the following quadratics for every $(u, v) \in \overline{\Gamma}$ and $U, V \in \mathbb{R}^n$.

$$\begin{aligned} A_1 \;=\; & \left((P_1 H_u + Q_1 H_v) H_u - \lambda_1 {H_u}^2\right) U^2 + \left((P_2 H_u + Q_2 H_v) H_v - \lambda_1 {H_v}^2\right) V^2 \\ & + \left((P_2 H_u + Q_2 H_v) H_u + (P_1 H_u + Q_1 H_v) H_v - 2\lambda_1 H_v H_u\right) VU, \end{aligned} \tag{3.4}$$

$$\begin{aligned} A_2 \;=\; & (Q_1 H_{uv} + P_1 H_{uu} - \lambda_2) U^2 + (P_2 H_{uv} + Q_2 H_{vv} - \lambda_2) V^2 \\ & + (P_2 H_{uu} + P_1 H_{uv} + Q_2 H_{uv} + Q_1 H_{vv}) VU, \end{aligned} \tag{3.5}$$

and

$$\begin{aligned} A_3 \;=\; & \left(\lambda_3 {H_u}^2 - (P_1 H_u + Q_1 H_v)^2\right) U^2 + \left(\lambda_3 {H_v}^2 - (P_2 H_u + Q_2 H_v)^2\right) V^2 \\ & + \left(2\lambda_3 H_v H_u - 2 (P_2 H_u + Q_2 H_v) (P_1 H_u + Q_1 H_v)\right) VU. \end{aligned} \tag{3.6}$$

To study these quadratics, we will need some lemmas and calculations.

LEMMA 3.1. *If* H *is a solution to* (3.2) *and* (P.2) *holds, then there exist* $\lambda_1, \lambda_3 > 0$ *such that* A_1, A_3 *are positive definite.*

Proof. First, we will prove that the discriminants Θ_1, Θ_3 of A_1, A_3 are nonpositive. However, simple calculation shows that

$$\begin{aligned}\Theta_1 &= \left(\left(P_2H_u + Q_2H_v\right)H_u + \left(P_1H_u + Q_1H_v\right)H_v - 2\lambda_1 H_v H_u\right)^2 \\ &\quad -4\left(\left(P_1H_u + Q_1H_v\right)H_u - \lambda_1 {H_u}^2\right)\left(\left(P_2H_u + Q_2H_v\right)H_v - \lambda_1 {H_v}^2\right) \\ &= \left(H_v P_1 H_u - P_2 {H_u}^2 - H_u Q_2 H_v + Q_1 {H_v}^2\right)^2,\end{aligned}$$

and

$$\Theta_3 = 4\lambda_3\left(P_1 H_u H_v - {H_u}^2 P_2 - H_v H_u Q_2 + Q_1 {H_v}^2\right)^2.$$

Because H satisfies (3.2), it is easy to see that $\Theta_1 = \Theta_3 = 0$. We need only to show that the coefficients of U^2, V^2 in A_1, A_3 are positive. By (3.1), they can be written as

$$H_v^2(P_1 f^2 + Q_1 f - \lambda_1 f^2) = H_v^2 f^2(P_2 f + Q_2 - \lambda_1), \quad H_v^2(P_2 f + Q_2 - \lambda_1),$$

$$H_u^2(\lambda_3 - (P_1 + Q_1/f)^2) = H_u^2(\lambda_3 - (P_2 f + Q_2)^2), \quad H_v^2(\lambda_3 - (P_2 f + Q_2)^2).$$

Since $f > 0$ and because of (P.2), we can take

$$\lambda_1 = \frac{1}{2}\inf_{\Gamma}(P_2 f + Q_2), \quad \lambda_3 = 2\sup_{\Gamma}(P_2 f + Q_2)^2,$$

which are positive thanks to (P.2). The lemma is proven. □

To verify the positivity of A_2 in (2.3), we consider its discriminant Θ_2. Easy computation shows that we can write

$$\Theta_2 = -4\lambda_2^2 + \Theta_{11}\lambda_2 + \Theta_{12},$$

with

$$\Theta_{11} := 4\left(Q_1 H_{uv} + P_1 H_{uu} + P_2 H_{uv} + Q_2 H_{vv}\right),$$

$$\Theta_{12} := \left(P_2 H_{uu} + P_1 H_{uv} + Q_2 H_{uv} + Q_1 H_{vv}\right)^2 - 4\left(Q_1 H_{uv} + P_1 H_{uu}\right)\left(P_2 H_{uv} + Q_2 H_{vv}\right).$$

Differentiating $H_u = f H_v$, we get $H_{uu} = f_u H_v + f H_{uv}$ and $H_{uv} = f_v H_v + f H_{vv}$. Substitute these into Θ_{12} and simplify to obtain

$$\Theta_{12} := \alpha_1 H_{vv}^2 + \alpha_2 H_{vv} H_v + \alpha_3 H_v^2,$$

with

$$\begin{aligned}\alpha_1 &= \left(P_2 f^2 + P_1 f + Q_2 f + Q_1\right)^2 - 4\left(Q_1 f + P_1 f^2\right)\left(P_2 f + Q_2\right), \\ \alpha_2 &= 2\left(P_2\left(f_u + f f_v\right) + P_1 f_v + Q_2 f_v\right)\left(P_2 f^2 + P_1 f + Q_2 f + Q_1\right) \\ &\quad -4\left(Q_1 f_v + P_1\left(f_u + f f_v\right)\right)\left(P_2 f + Q_2\right) - 4\left(Q_1 f + P_1 f^2\right) P_2 f_v, \\ \alpha_3 &= \left(P_2(f_u + f f_v) + P_1 f_v + Q_2 f_v\right)^2 - 4(Q_1 f_v + P_1(f_u + f f_v)) P_2 f_v.\end{aligned}$$

From (3.1), we have $P_2 f^2 + Q_2 f = P_1 f + Q_1$. Hence,

$$\alpha_1 = 4(P_1 f + Q_1)^2 - 4(Q_1 + P_1 f)(P_2 f^2 + Q_2 f) = 0,$$

$$\begin{aligned}\alpha_2 &= 4[(P_2(f_u+ff_v)+P_1f_v+Q_2f_v)(P_1f+Q_1)\\ &\quad -(Q_1f_v+P_1(f_u+ff_v))(P_2f+Q_2)-(Q_1f+P_1f^2)P_2f_v]\\ &= 4[P_2Q_1(f_u-ff_v)-P_1f_v(P_2f^2-P_1f-Q_1)-P_1f_uQ_2]\\ &= 4(Q_1P_2-P_1Q_2)(f_u-f_vf),\end{aligned}$$

$$\begin{aligned}\alpha_3 &= (f_u+ff_v)^2{P_2}^2+(P_1+Q_2)^2f_v^2+2P_2f_v[(f_u+ff_v)(Q_2-P_1)-2Q_1]\\ &= (f_u+ff_v)^2{P_2}^2+(P_1-Q_2)^2f_v^2+2P_2f_v(f_u+ff_v)(Q_2-P_1)\\ &\quad +4(P_1Q_2-Q_1P_2)f_v^2\\ &= [(f_u+ff_v)P_2+f_v(Q_2-P_1)]^2+4(P_1Q_2-Q_1P_2)f_v^2.\end{aligned}$$

Similarly, we also have $\Theta_{11}=\beta_2H_{vv}+\beta_3H_v$, with

$$\beta_2=4(Q_1f+P_1f^2+P_2f+Q_2)=4(f^2+1)(P_2f+Q_2),$$

$$\beta_3=4(Q_1f_v+P_1(f_u+ff_v)+P_2f_v).$$

Proof of Theorem 3. Thanks to Lemma 3.1 and the choice of g, we need only to check the positivity of A_2. We first show that $\Theta_2<0$ on Γ for suitable choice of k. Let $G(x)=\exp(kx)$ and $\widetilde{H}(u,v)=G(g(u,v))$. As $\widetilde{H}_v=G'g_v$, $\widetilde{H}_{vv}=(G''g_v^2+G'g_{vv})$, and $G''/G'=k$, we have

$$\widetilde{\Theta}_{12}=\widetilde{H}_{vv}\widetilde{H}_v\alpha_2+\widetilde{H}_v^2\alpha_3=(G')^2\left[kg_v^3\alpha_2+(g_{vv}g_v\alpha_2+g_v^2\alpha_3)\right].$$

Thanks to our assumption (3.3) and the fact that Γ_0 is connected, the coefficient of k never vanishes on Γ_0. That is, either $\sup_{\overline{\Gamma}}g_v^3\alpha_2<0$ or $\inf_{\overline{\Gamma}}g_v^3\alpha_2>0$. Moreover, $(g_{vv}g_v\alpha_2+g_v^2\alpha_3)$ is bounded on $\overline{\Gamma}$ and $g_v,G'\neq 0$. The above shows that $\widetilde{\Theta}_{12}<0$ on $\overline{\Gamma}$ for suitable choice of k with $|k|$ sufficiently large.

We then choose K sufficiently large in

$$\Theta_2=-4\lambda_2^2+\Theta_{11}\lambda_2+\Theta_{12}=-4\lambda_2^2+K(\beta_2\widetilde{H}_{vv}+\beta_3\widetilde{H}_v)\lambda_2+K^2\widetilde{\Theta}_{12}$$

to see that $\Theta_2<0$, because $\widetilde{\Theta}_{12}<0$ on $\bar{\Gamma}$.

Finally, we need only to check that the coefficients of U^2,V^2 in A_2 are positive. This amounts to show that the quantities

$$\delta_1=(Q_1H_{uv}+P_1H_{uu})\ \text{ and }\ \delta_2=(P_2H_{uv}+Q_2H_{vv})$$

are strictly positive on $\overline{\Gamma}$, and then choose λ_2 sufficiently small. Similar calculation as before yields

$$\delta_1=\left(Q_1f+P_1f^2\right)H_{vv}+Q_1f_vH_v+P_1\left(f_uH_v+ff_vH_v\right)=K\exp(kg)\left[k\delta_{12}+f\delta_{11}k^2\right],$$

$$\delta_2=(P_2f+Q_2)H_{vv}+P_2f_vH_v=K\exp(kg)\left[k\delta_{21}+\frac{\delta_{22}}{f}k^2\right],$$

where $\delta_{12}=\left(Q_1f+P_1f^2\right)g_{vv}+Q_1f_vg_v+P_1\left(f_ug_v+ff_vg_v\right)$, $\delta_{21}=(P_2f+Q_2)g_{vv}+P_2f_vg_v$ and $\delta_{11}=\delta_{22}={g_v}^2(Q_1+P_1f)={g_v}^2(P_2f^2+Q_2f)$.

Since δ_{12},δ_{21} are bounded on $\overline{\Gamma}$, and $\delta_{11}=\delta_{22}>0$, we can choose $|k|$ large to have that $\delta_1,\delta_2>0$ on $\overline{\Gamma}$. □

Remark 3.2. Differentiate (3.1) with respect to u, v, and then solve for f_u, f_v to see that

$$f_u - f_v f = \frac{f\mathcal{F}}{P_2 f^2 + Q_1}, \tag{3.7}$$

with $\mathcal{F} = \partial_v P_v f^3 + (\partial_v Q_2 - \partial_u P_2 - \partial_v P_1) f^2 + (\partial_u P_1 - \partial_u Q_2 - \partial_v Q_1) f + \partial_u Q_1$. Therefore, (3.3) of (H.2) requires that $\mathcal{F} \neq 0$ on $\overline{\Gamma}$.

We conclude this section by discussing the existence of a solution g of (3.2) and the condition $g_v \neq 0$ in (3.3). In applications, see section 4, the function $f(u, v)$ may be singular in u, v so that we will rewrite (3.2) in the form

$$M(u) g_u - N(u, v) g_v = 0 \tag{3.8}$$

for some function M, N such that $f = N/M$, $M \neq 0$. The above equation can be solved by characteristic methods. If g is such a solution, then we know that (see [2, pp 97–99]) $\vec{x}(t) = (u(t), v(t))$, $z(t) = g(\vec{x}(t))$ and $\vec{p}(t) = (p_u(t), p_v(t)) = \nabla g(\vec{x}(t))$ solve the following system:

$$\begin{aligned} \vec{x}'(t) &= (M, -N), \\ \vec{p}'(t) &= (-M_u p_u + N_u p_v, N_v p_v), \\ z'(t) &= M p_u - N p_v. \end{aligned} \tag{3.9}$$

We first observe that the above system is decoupled. In fact, one can solve for $u(t)$ from the first equation $u'(t) = M(u(t))$, and then substitute the result into the second equation $v'(t) = -N(u(t), v(t))$ to get $v(t)$. Once $u(t), v(t)$ are known, we can solve the (linear) equation for $\vec{p}$. Equation (3.8) simply says that g is constant along the characteristic curve $\vec{x}(t)$, which is an integral curve of the planar vector field $(M, -N)$.

Let γ be a smooth curve in $\Gamma_0 \subset \mathbb{R}^2$, which is a diffeomorphic image of an open interval, and assume that γ is noncharacteristic with respect to (3.9). For each $x_0 \in \gamma$, we assume that the first equation of (3.9) has a solution $\vec{x}(t)$ with $\vec{x}(0) = x_0$. This solution is locally defined on certain open interval I_{x_0} containing 0. We then define

$$\Xi = \{(x_0, s) \in \gamma \times I_{x_0} \,:\, \vec{x}(t) \text{ exists on } I_{x_0} \text{ with } \vec{x}(0) = x_0\},$$

and the map $X : \Xi \to \mathbb{R}^2$ by $X(\vec{x}(0), t) = \vec{x}(t)$. The system (3.9) is also supplied with its initial data

$$z(0) = \widetilde{g}(\vec{x}(0)) \quad \text{and} \quad \vec{p}(0) = \vec{p}_0(\vec{x}(0)) \tag{3.10}$$

along γ. Here, the function $\widetilde{g}$ is given in a neighborhood of γ and $\vec{p}_0(\vec{x}_0) = (p_u^0, p_v^0)$ is a vector field defined along γ. The initial data must satisfy the compatibility conditions on γ,

$$\vec{p}_0 = (p_u^0, p_v^0) = \nabla \widetilde{g}, \quad M p_u^0 = N p_v^0. \tag{3.11}$$

Let $\vec{T} = (T_u, T_v)$ be the unit tangent vector along γ. Since γ is a diffeomorphic image of an open interval, we can pick $\widetilde{g}$ such that $\nabla \widetilde{g} \cdot \vec{T} \neq 0$ (see also the proof of Theorem 1 in section 4).

The following lemma concerns the first condition in (3.3) of (H.2).

LEMMA 3.3. *Assume that* $\bar{\Gamma} \subset X(\Xi)$ *and* (3.11). *Then there exists a solution to* (3.2) *with* $g_v \neq 0$ *on* $\bar{\Gamma}$.

Proof. We define g on $\bar{\Gamma}$ by $g(\vec{x}(t)) = \widetilde{g}(\vec{x}(0))$. From the condition (3.11), we have $\vec{p_0} \cdot \vec{T} = \nabla \widetilde{g} \cdot \vec{T}$. Therefore, $p_v^0(NT_u + MT_v) = M \nabla \widetilde{g} \cdot \vec{T}$. Since γ is noncharacteristic, we have $(NT_u + MT_v) \neq 0$. Because $\nabla \widetilde{g} \cdot \vec{T} \neq 0$, $p_v^0 \neq 0$ along γ. From the second equation of (3.9) we have $p_v' = N_v p_v$. This gives

$$p_v(t) = p_v^0(\vec{x}(0)) \exp\left(\int_0^t N_v(\vec{x}(s)) ds \right).$$

Because $g_v(\vec{x}(t)) = p_v(t)$ and $p_v^0(\vec{x}(0)) \neq 0$, we see that $g_v(\vec{x}(t)) \neq 0$ on $I_{\vec{x}(0)}$. Thus, $g_v \neq 0$ on $\bar{\Gamma}$. ∎

In a more special situation, we can explicitly find g.

LEMMA 3.4. *If* $f(u,v) = \hat{f}(v/u)$ *for some function* $\hat{f}$, *then there exists a solution to* (3.2) *defined on the set* $u, v > 0$ *with* $g_v > 0$.

Proof. Set $v = Yu$, we derive

$$\frac{dv}{du} = u\frac{dY}{du} + Y = -\hat{f}(Y) \Rightarrow \frac{dY}{\hat{f}(Y) + Y} = -\frac{du}{u},$$

which has the general solution $g(u,v) = C$ with

$$g(u,v) = \int \frac{dY}{\hat{f}(Y) + Y} + \log(u), \quad Y = \frac{v}{u}.$$

Hence, $g_v = 1/[\hat{f}(\frac{v}{u}) + \frac{v}{u})u] = 1/(f(u,v)u + v)$, which is positive if u, v are positive. ∎

4. Applications. We conclude our paper by giving the proof of Theorem 1. We consider the system (1.2) and let

$$P = d_1 u + a_{12} uv + a_{11} u^2, \quad Q = d_2 v + a_{21} uv + a_{22} v^2.$$

Obviously, (1.2) is a special case of (1.1) with P_1, P_2, Q_1, Q_2 simply the partial derivatives of P, Q with respect to u, v. That is,

$$P_1 = d_1 + a_{12} v + 2a_{11} u, \quad P_2 = a_{12} u, \quad Q_1 = a_{21} v, \quad Q_2 = d_2 + a_{21} u + 2a_{22} v. \tag{4.1}$$

The proof is to verify the assumption (H.2) and that of Lemma 3.3 in the previous section. As we consider bounded positive solutions, the set Γ in (2.1) is a bounded subset of $\mathbb{R}^2_+$. One can see that (P.2) is satisfied.

Proof of Theorem 1. We first look at the condition $\alpha_2 \neq 0$ in (H.2). From Remark 3.2 and (4.1), we have $\mathcal{F} = 2(a_{22} - a_{12}) f^2 + 2(a_{11} - a_{21}) f \neq 0$. This is the case because $f > 0$ and $(a_{22} - a_{12})(a_{11} - a_{21}) > 0$. Calculation also shows that $Q_1 P_2 - P_1 Q_2$ is

$$-(2a_{11}u^2 a_{21} + 4a_{11} u a_{22} v + (d_1 a_{21} + 2a_{11} d_2)\, u + 2a_{12} v^2 a_{22} + (2d_1 a_{22} + a_{12} d_2)\, v + d_1 d_2),$$

which is negative on $\mathbb{R}^2_+$. Therefore, the second condition in (3.3) of (H.2). is verified.

Finally, we show the existence of g solving (3.8) with $g_v \neq 0$. Since Γ is bounded, there exists $L > 0$ such that $\Gamma \subset \Gamma_0 = (0, L) \times (0, L)$. On the other hand, we see that the positive solution to (3.1) is given by

$$f(u,v) = \frac{(P_1 - Q_2) + \sqrt{(P_1 - Q_2)^2 + 4P_2 Q_1}}{2P_2}, \quad u, v > 0.$$

Because $P_2 = a_{12}u$, $f(u,v)$ is singular in u. Therefore, we will take in the equation (3.8),

$$M(u) = u, \quad N(u,v) = ((P_1 - Q_2) + \sqrt{(P_1 - Q_2)^2 + 4P_2Q_1})/(2a_{12}). \tag{4.2}$$

Let $(u_0, v_0) \in \Gamma_0$ be given. The characteristic curves of (3.8), with $u(0) = u_0$ and $v(0) = v_0$, are given by $u(t) = u_0 \exp(t)$ and $v(t)$ being the solution to $\frac{d}{dt}v(t) = -N(u(t), v(t))$. Let $I_0 = (a_0, b_0)$ be the interval on which $u(t), v(t)$ are positive.

From (4.2), the equation for v is sublinear. That is, there are functions $\alpha(t), \beta(t)$ such that $|N(u(t), v(t))| \le \alpha(t)v(t) + \beta(t)$. Using the Gronwall inequality, it is easy to show that $v(t)$ exists for all t in some interval I as long as $N(u,v)$ is defined. In particular, this is the case when $u(t), v(t)$ stay positive. Since $N(u,v) > 0$, $v(t)$ is decreasing so that $v(t) > v_0 > 0$ for all $t < 0$. Of course, $u(t) > 0$, for all t and $\lim_{t\to-\infty} u(t) = 0$. Hence, we can take $I_0 = (-\infty, b_0)$.

We argue that $\lim_{t\to b_0^-} v(t) = 0$. If not, let $v_1 > 0$ be the limit. Continuation arguments allow us to extend u, v, being positive, beyond b_0 if b_0 is finite. Thus $b_0 = \infty$. From the definitions of P, Q, N, we easily see that $N(u(t), v(t)) \ge c_0$ for some $c_0 > 0$ and t sufficiently large. But this implies $v(t) \le -c_0 e^t + v_0$ for some constant v_0, and v can be negative on I_0 as $t \to \infty$, a contradiction. This shows that $\lim_{t\to b_0^-} v(t) = 0$.

The function $u(t) - v(t)$ is increasing on I_0. It is negative when $t \to -\infty$, and positive when $t \to b_0^-$. Thus, there is t_0 such that $u(t_0) = v(t_0) \le \max\{u_0, v_0\}$. So, if we take the curve γ in Lemma 3.3 to be the diagonal $u = v$ of Γ_0, then for every $(u_0, v_0) \in \Gamma_0$ the characteristic curve intersects γ. In other words, Γ is contained in $X(\Xi)$. Moreover, as M, N are positive, we see that γ is noncharacteristic. Finally, we need to define the initial condition $\widetilde{g}(u,v) = \phi(u) + \psi(v)$ on γ to fulfill the assumption (3.11) of Lemma 3.3. For $\gamma = \{u = v\}$, (3.11) reads $M(u)\widetilde{g}_u = N(u,u)\widetilde{g}_v$ Clearly, this holds if we choose $\widetilde{g}$ such that $\widetilde{g}_v = p_v^0 = M(u)$ and $\widetilde{g}_u = p_u^0 = N(u,u)$. That is,

$$\phi(u) = \int_0^u N(s,s)ds, \quad \psi(v) = \int_0^v M(s)ds. \tag{4.3}$$

Since $M, N > 0$, we see that $\nabla\widetilde{g} \cdot \vec{T} \neq 0$. Lemma 3.3 is applicable and our proof is complete. □

Remark 4.1. If $d_1 = d_2$, then $f(u,v) = (Au + Bv + \sqrt{a_1u^2 + a_2v^2 + a_3uv})/(a_{21}u)$ for some constants A, B, a_1, a_2, a_3. If $u, v \ge 0$, then $f(u,v) > 0$. We also see that f can be written as $\hat{f}(v/u)$ for some function $\hat{f}$. Therefore, Lemma 3.4 applies here to give an explicit formula for g.

We conclude this paper by considering a generalized version of (1.2)

$$\begin{aligned} u_t &= \nabla((d_1 + a_{12}v + a_{11}u)\nabla u + (c_1 + b_{12}u)\nabla v) + F(u,v), \\ v_t &= \nabla((c_2 + b_{21}v)\nabla u + (d_2 + a_{21}u + a_{22}v)\nabla v) + G(u,v). \end{aligned} \tag{4.4}$$

The constants d_i, c_i, a_{ij}, b_{ij} are assumed to be positive. With minor modifications in the calculation of the proof of Theorem 1, we can prove the following.

THEOREM 4. *Bounded positive solutions to* (4.4) *are Hölder continuous if*

$$a_{11} > a_{21} + b_{21}, \quad a_{22} > a_{12} + b_{12}, \tag{4.5}$$

$$d_1d_2 > c_1c_2, \quad d_1a_{22} + d_2a_{12} > c_1b_{21}, \quad d_1a_{21} + d_2a_{11} > c_2b_{12}. \tag{4.6}$$

Again, these conditions simply say that the self diffusion dominates the cross diffusion. We only remark here that (4.5) gives $f_u - f_v f > 0$, and (4.6) provides $Q_1P_2 - P_1Q_2 < 0$ so that $\alpha_2 < 0$ as required by (H.2). The proof of the existence of g can be repeated here with $M(u) = c_1 + b_{12}u$ (so that the interval $I_0 = (a_0, b_0)$, on which $u(t), v(t)$ are positive, may not be unbounded as before).

Acknowledgment. We would like to thank the anonymous referees for their invaluable comments that lead to many improvements of this version of the paper.

Γ-LIMIT OF A PHASE-FIELD MODEL OF DISLOCATIONS*

A. GARRONI† AND S. MÜLLER‡

Abstract. We study, by means of Γ-convergence, the asymptotic behavior of a variational problem modeling a dislocation ensemble moving on a slip plane through a discrete array of obstacles. The variational problem is a two-dimensional phase transition-type energy given by a nonlocal term and a nonlinear potential which penalizes noninteger values. In this paper we consider a regime corresponding to a diluted distribution of obstacles. In this case the leading term of the energy can be described by means of a cell problem formula defining an appropriate notion of capacity (that we call dislocation capacity).

Key words. dislocations, phase transitions, capacity, Γ-convergence

1. Introduction.

1.1. Formulation of the problem. In this paper we begin the study of the large body limit of a phase-field model for dislocations, recently introduced by Koslowski, Cuitino, and Ortiz [10]. This model studies a dislocation ensemble moving within a single slip plane through an array of discrete obstacles (e.g., forest dislocations) under the action of an applied shear stress. In this theory, after a suitable rescaling (see the end of this subsection for the details), the slip (measured in units of the Burgers vectors) on the slip plane is represented by a scalar phase field u, which prefers to take integer values. We will consider a periodic setting; i.e., u will be a periodic scalar-valued function defined on the slip plane which is chosen as $T^2 \times \{0\}$. The first contribution to the energy, the so-called Peierls potential, penalizes noninteger values of the slip distribution u and is given by

$$\frac{1}{2\varepsilon} \int_{T^2} \operatorname{dist}^2(u, \mathbf{Z})\, dx\,. \tag{1.1}$$

Here $T^2 = \mathbf{R}^2/\mathbf{Z}^2$ denotes the standard torus; i.e., functions on T^2 are periodic with period one. The small parameter ε is proportional to the ratio between the Burgers vector (or, equivalently, the lattice spacing) and the physical size of the (periodic) domain under consideration. In particular the large body limit is characterized by the limit $\varepsilon \to 0$. The arguments in this paper do not require the special form of (1.1). Instead of the special integrand $\operatorname{dist}^2(u, \mathbf{Z})$ we could consider a general integrand $W(u)$, where W is a $\mathbf{Z}$ periodic C^1 function satisfying $W(u) \geq c \operatorname{dist}^2(u, \mathbf{Z})$, $c > 0$.

The second term in the energy represents the long-range elastic interaction induced by the slip. This can be obtained by considering a field $\widetilde{u}$ on $T^2 \times \mathbf{R}$ which has

a jump of size u across $\{x_3 = 0\}$ and considering its elastic energy

$$\frac{1}{2}\int_{T^2\times\mathbf{R}} |\nabla \widetilde{u}|^2\, dx\,.$$

One can easily verify that the optimal $\widetilde{u}$ (for a given jump u) is antisymmetric in x_3 (up to an irrelevant constant) and the elastic energy is given by the minimizer of the expression

$$\int_{T^2\times(0,+\infty)} |\nabla \widetilde{u}|^2\, dx$$

subject to the boundary condition $\widetilde{u}(x',0) = \frac{1}{2}u(x')$. This energy is nothing but the square of the $H^{\frac{1}{2}}$ seminorm of $\frac{1}{2}u$ which in the Fourier representation is given by

$$\frac{1}{4}[u]^2_{H^{\frac{1}{2}}(T^2)} = \frac{1}{4}\sum_{k\in(2\pi\mathbf{Z})^2} |k||\widehat{u}(k)|^2\,, \tag{1.2}$$

where

$$\widehat{u}(k) = \int_{T^2} \mathrm{e}^{-ikx}u(x)\, dx\,.$$

In real space the energy can be written as

$$\frac{1}{4}[u]^2_{H^{\frac{1}{2}}(T^2)} = \frac{1}{2}\int\!\!\int_{T^2\times T^2} K(x-y)|u(x)-u(y)|^2\, dx\, dy\,, \tag{1.3}$$

where the kernel $K(t)$ has the following properties:

(i) $K(t) = O(|t|^{-3})$ as $|t| \to 0$.

(ii) $K(t)$ is periodic, i.e., is defined in T^2.

In fact, the Fourier coefficients of K are given by $\widehat{K}(k) = -\frac{1}{4}|k|$, so that $K(t) \sim \frac{1}{8\pi}t^{-3}$ as $t \to 0$.

The energy we are really looking at is the isotropic elastic bulk energy given in terms of the symmetrized displacement gradient $e(U) = \frac{1}{2}(\nabla U + \nabla U^T)$ as

$$\int_{T^2\times\mathbf{R}} \mu\,|e(U)|^2 + \frac{\lambda}{2}\,|\mathrm{tr}\, e(U)|^2\; dx'\,,$$

where U is the vector displacement and the jump of U across $\{x_3 = 0\}$ is given by $u\mathbf{e_1}$. Using Fourier variables this leads to the following $H^{\frac{1}{2}}$-like energy:

$$\frac{\mu}{4}\sum_{k\in(2\pi\mathbf{Z})^2} m_\nu(k)|\widehat{u}(k)|^2. \tag{1.4}$$

Here the weight $m_\nu(k)$ is homogeneous of degree 1 and is explicitly given by

$$m_\nu(k) = \frac{k_2^2}{\sqrt{k_1^2+k_2^2}} + \frac{1}{1-\nu}\frac{k_1^2}{\sqrt{k_1^2+k_2^2}}\,,$$

where $\nu < \frac{1}{2}$ is the Poisson ratio (see [10] for a detailed derivation of the above formula). If $\nu = 0$, then $m_\nu(k) = |k|$, and (1.4) reduces to (1.2); we call this the *isotropic case*.

One can also compute the real space version of the energy in (1.4), and this gives the following representation of the elastic energy:

$$\frac{\mu}{2}\iint_{T^2\times T^2} K_\nu(x-y)|u(x)-u(y)|^2\,dx\,dy\,, \tag{1.5}$$

where the kernel $K_\nu(t)$ satisfies conditions (i) and (ii). In fact, K_ν is the Fourier series of $-\frac{1}{4}m_\nu(k)$, and a more explicit formula is given in (2.4) below. It is also clear that this nonlocal energy is controlled from above and below by the $H^{\frac{1}{2}}$-periodic seminorm introduced above; more precisely,

$$[u]^2_{H^{\frac{1}{2}}(T^2)} \le \frac{1}{4}\sum_{k\in(2\pi\mathbf{Z})^2} m_\nu(k)|\widehat{u}(k)|^2 \le \frac{1}{1-\nu}[u]^2_{H^{\frac{1}{2}}(T^2)}. \tag{1.6}$$

We now take $\mu = 1$. Then the total energy is thus given by

$$\frac{1}{2\varepsilon}\int_{T^2}\operatorname{dist}^2(u,\mathbf{Z})\,dx + \frac{1}{2}\iint_{T^2\times T^2} K_\nu(x-y)|u(x)-u(y)|^2\,dx\,dy - \int_{T^2} S^\varepsilon u\,dx. \tag{1.7}$$

The last term of the energy takes into account the interaction with the (nondimensionalized) resolved shear stress S^ε. In this paper we will consider the case that S^ε is of order 1, more precisely that it converges weakly in L^2 as $\varepsilon \to 0$. To study the Γ-limit of the above energy it thus suffices to consider only the first two terms and to regard the third term as a continuous perturbation (see Remark 15). We shall study this energy subject to a pinning condition in order to model, e.g., a forest hardening mechanism by secondary dislocation. For definiteness we focus on the idealization of obstacles with infinitely strong pinning; i.e., we require that u vanishes on the union of discs $B(x_i^\varepsilon, R\varepsilon) = B^i_{R\varepsilon}$ of radius $R\varepsilon$ and centers x_i^ε, $i = 1,\dots,N_\varepsilon$. (The effects of a finite pinning strength are discussed in the appendix.)

To summarize, we will study the asymptotic behavior, in terms of Γ-convergence, of the following functional:

$$E_\varepsilon(u) = \begin{cases} \dfrac{1}{\varepsilon}\displaystyle\int_{T^2}\operatorname{dist}^2(u,\mathbf{Z})\,dx + \iint_{T^2\times T^2} K_\nu(x-y)|u(x)-u(y)|^2\,dx\,dy & \\ \qquad\qquad \text{if } u\in H^{\frac{1}{2}}(T^2)\,, u=0, \text{ on } \bigcup_i B^i_{R\varepsilon}, & \\ +\infty \qquad\qquad \text{otherwise}\,. & \end{cases} \tag{1.8}$$

Before discussing in more detail the relevant limits let us briefly indicate how the above nondimensionalized functional is related to the energy considered in [10]. Passing from the Fourier representation to the real space formulation and directly taking into account the periodicity of the phase field we can write the energy in [10] as follows:

$$\frac{b^2}{2d}\int_{Q_L}\operatorname{dist}^2(v,\mathbf{Z})\,dx' + b^2\iint_{Q_L\times Q_L} L^{-3}K_\nu\left(\frac{x'-y'}{L}\right)|v(x')-v(y')|^2\,dx'\,dy',$$

where Q_L is the square in $\mathbf{R}^2$ of side L, where b is the length of the Burgers vector, and where d is the interplanar spacing (which is of the same order of b). Scaling with $x = \frac{x'}{L}$ and $y = \frac{y'}{L}$ and dividing the energy by b^2L we get (1.8) with ε of order $\frac{b}{L}$.

1.2. Mathematical context and scaling regimes for N_ε. From a mathematical point of view the functional E_ε combines two features: a singular perturbation of Modica–Mortola type and a boundary condition on perforated domains, i.e., domains with many small holes.

If we ignore the boundary condition and also replace the $H^{\frac{1}{2}}$ seminorm by the Dirichlet integral we obtain exactly a version of the Modica–Mortola problem for a potential with infinitely many wells [13, 14]. In this case the typical scaling of the energy is proportional to $1/\sqrt{\varepsilon}$. The situation for the $H^{\frac{1}{2}}$ seminorm is more delicate, and Alberti, Bouchitté, and Seppecher [2] showed (for the case of two wells) that the natural scaling for the energy is $\ln 1/\varepsilon$ and that after rescaling by $1/\ln(1/\varepsilon)$ the Γ-limit of the energy is proportional to the BV-norm $\int |\nabla u|$, i.e., to the length of the jump set of u. (The limiting energy is finite only on functions which take values in the wells.)

If we ignore instead the singular Peierls energy, then our functional falls in the class of variational problems in perforated domains. Again for the Dirichlet integral (and many other local functionals) a large amount of literature is available (see, e.g., [12] and [4], or [6], for a more general approach). The general idea is that in the limit a violation of the boundary condition no longer carries an infinite cost but only a finite cost computed by the integration of a suitable function of u against a suitable measure which captures the local density of holes (in the sense of capacity). At least in terms of scaling, our problem (without the Peierls term) can be reduced to that setting by working with the harmonic extension $\widetilde{u}$ of u. This shows that without Peierls energy, E_ε should scale like the "capacity density" $\varepsilon N_\varepsilon$. Combining these two results we expect two standard scaling regimes.

1. $\varepsilon N_\varepsilon \to 1$. In this case we expect that E_ε is of order 1 and that the limiting energy can be obtained by solving a suitable cell problem which involves one obstacle in an infinite medium with boundary conditions at the obstacle and at infinity. In view of the results of [2] we expect also that the limit energy functional is finite only on constant, integer-valued functions, since a jump would result in an energy cost of order $\ln 1/\varepsilon$. A typical minimizer u_ε of (1.8) looks almost constant with small perturbations (on a length scale ε) near the holes. The shape of these perturbations is essentially determined by the cell problem.
2. $\varepsilon N_\varepsilon/\ln(1/\varepsilon) \to 1$. In this case the contributions of the pinning energy discussed above and the Modica–Mortola-like energy are of the same order. After rescaling by $1/\ln(1/\varepsilon)$ we expect a limiting energy of the form $\int |\nabla u| + \int D(u)$ (subject to the constraint $u(x) \in \mathbf{Z}$ almost everywhere) where, as before, the function $D(a)$ is computed from a cell problem with boundary condition a at infinity. In the physics literature this functional is referred to as a line-tension model because the first term penalizes the length of the jump set of u. In fact, for the anisotropic kernel K_ν above, the term $|\nabla u|$ has to be replaced by an anisotropic line energy of the type $\gamma(\frac{\nabla u}{|\nabla u|})|\nabla u|$.

In this paper we investigate the first regime $\varepsilon N_\varepsilon \sim 1$ (see Theorem 14 below for a precise statement). In fact, it turns out that the regime $\varepsilon N_\varepsilon \to 0$ can be handled in exactly the same way if we scale the energy by $1/(\varepsilon N_\varepsilon)$ (see also Theorem 14). Going back to (1.8) the natural scaling of the resolved shear stress in this regime is $S_\varepsilon \sim \varepsilon N_\varepsilon$. The regimes $\varepsilon N_\varepsilon \sim \ln 1/\varepsilon$ and $\varepsilon N_\varepsilon \gg \ln 1/\varepsilon$ will be discussed in a forthcoming paper [8].

Finally, we remark that while our analysis is phrased in terms of statics the same energy functional arises in the approximation of the evolution through a sequence of

minimization problems at discrete times (see [10, Chapter 4]). Actually in this case it is more natural to consider a "soft" pinning condition which can be treated exactly along the same lines (see the appendix). In this case the "pinning energy" represents the energy dissipated in crossing one of the pinning sites. A full understanding of dislocation dynamics and its macroscopic consequences, such as hysteresis, will of course require a much better understanding of local minimizers (and the energy barriers between them). To do this rigorously seems currently out of reach. Nonetheless we can identify (in this paper and in [8]) in a rigorous way the relevant scaling regimes for the competition of elastic energy, applied stress, pinning energy, dissipation, and line energy of the dislocations, and we believe that this will be helpful for further studies.

2. The nonlocal energy. This section will be devoted to recalling some basic properties of the nonlocal part of the energy. By minimizing an elastic energy on $\mathbf{R}^3_+$ we get, as in the periodic case, a nonlocal energy equivalent to the $H^{\frac{1}{2}}(\mathbf{R}^2)$ seminorm. Indeed, as above, similar considerations give an energy of the form

$$\int_{\mathbf{R}^2} \left(\frac{\lambda_2^2}{|\lambda|} + \frac{1}{1-\nu} \frac{\lambda_1^2}{|\lambda|} \right) |\widehat{u}(\lambda)|^2 d\lambda,$$

which can be written in spatial variables as

$$\frac{1}{2} \iint_{\mathbf{R}^2 \times \mathbf{R}^2} \Gamma_\nu(x-y)|u(x)-u(y)|^2 \, dx \, dy \,, \tag{2.1}$$

where the Fourier transform of the kernel $\Gamma_\nu(t)$, with $t \in \mathbf{R}^2$, is $-\frac{1}{4}(\frac{\lambda_2^2}{|\lambda|} + \frac{1}{1-\nu}\frac{\lambda_1^2}{|\lambda|})$ and it can be computed explicitly, i.e.,

$$\Gamma_\nu(t) = \frac{1}{2\pi(1-\nu)|t|^3} \left(\nu + 1 - 3\nu \frac{t_2^2}{|t|^2} \right) . \tag{2.2}$$

In particular it is homogeneous of degree -3 and is positive if $\nu < \frac{1}{2}$. Clearly we also have

$$[u]^2_{H^{\frac{1}{2}}(\mathbf{R}^2)} \le \frac{1}{2} \iint_{\mathbf{R}^2 \times \mathbf{R}^2} \Gamma_\nu(x-y)|u(x)-u(y)|^2 \, dx \, dy \, \le \frac{1}{1-\nu} [u]^2_{H^{\frac{1}{2}}(\mathbf{R}^2)} \,, \tag{2.3}$$

where

$$[u]_{H^{\frac{1}{2}}(\mathbf{R}^2)} := \left(\frac{1}{4\pi} \iint_{\mathbf{R}^2 \times \mathbf{R}^2} \frac{|u(x)-u(y)|^2}{|x-y|^3} \, dx \, dy \right)^{\frac{1}{2}} = \left(\int_{\mathbf{R}^2} |\lambda| |\widehat{u}(\lambda)|^2 \, d\lambda \right)^{\frac{1}{2}} .$$

PROPOSITION 1. *Let $K_\nu(t)$ be the anisotropic kernel defined above for the periodic case, and let $\Gamma_\nu(t)$ be the corresponding kernel in $\mathbf{R}^2$. Then there exists a constant $C > 0$ such that*

$$|\Gamma_\nu(t) - K_\nu(t)| \le C$$

on $\{t \in \mathbf{R}^2 \,:\, |t_i| \le 3/4\}$.

Proof. By the Poisson summation formula (see, e.g., Stein and Weiss [15, Corollary 2.6]) we have

$$K_\nu(t) = \sum_{z\in\mathbf{Z}^2} \Gamma_\nu(t+z)\,. \tag{2.4}$$

In particular, for any $t \in \mathbf{R}^2$ such that $|t_i| \le 3/4$ we get

$$|K_\nu(t) - \Gamma_\nu(t)| = \sum_{z\in\mathbf{Z}^2\setminus\{0\}} \Gamma_\nu(t+z) \le \sum_{z\in\mathbf{Z}^2\setminus\{0\}} \frac{c}{|z|^3} \le C\,. \qquad \square$$

Remark 2. By Proposition 1, using the homogeneity of Γ_ν we deduce that for every $\delta > 0$

$$\lim_{\varepsilon\to 0} \varepsilon^3 K_\nu(\varepsilon t) = \Gamma_\nu(t)$$

uniformly on $\{t \in \mathbf{R}^2 : |t| \le \delta\}$.

From the definition of $[\cdot]_{H^{\frac12}}$ as a trace seminorm we can deduce a Poincaré-type inequality for functions in $H^{\frac12}(T^2)$. For a given bounded domain $D \subseteq \mathbf{R}^3$ a refinement of the classical Poincaré inequality permits us to estimate the L^2 norm of a function in $H^1(D)$ with the L^2 norm of its gradient, as long as the set where the function is zero is not too small. There exists a constant C such that for every $w \in H^1(D)$

$$\int_D |w|^2 dx' \le \frac{C}{\mathrm{Cap}(N(w))} \int_D |\nabla w|^2 dx'\,, \tag{2.5}$$

where $\mathrm{Cap}(N(w))$ denote the harmonic capacity (with respect to $\mathbf{R}^3$) of the set $N(w) = \{x' \in D : w(x) = 0\}$ (see [16, Corollary 4.5.2] or [7, Theorem 2.9]). (Note that in view of (2.5) the set $N(w)$ is well defined, since the pointwise value of w can be specified up to a set of zero harmonic capacity using its quasi-continuous representative.)

Proposition 3. *There exists a constant C_0 such that for every $u \in H^{\frac12}(T^2)$, with $u = 0$ on $E \subseteq T^2$, we have*

$$\int_{T^2} |u|^2 dx \le C_0 \left(1 + \frac{1}{\mathrm{Cap}(E\times\{0\})}\right) [u]^2_{H^{\frac12}(T^2)}\,, \tag{2.6}$$

where $\mathrm{Cap}(E\times\{0\})$ *denote the harmonic capacity of* $E\times\{0\}$ *as a subset of* $\mathbf{R}^3$.

Proof. The proof follows immediately by applying (2.5) to the harmonic extension $\widetilde{u}$ of u in $D = (0,1)^3$ and by the fact that

$$\int_{T^2} |u|^2 dx \le c\,\|\widetilde{u}\|^2_{H^1(D)}\,. \qquad \square$$

Remark 4. Given an arbitrary $H^{\frac12}(Q)$ function we can extend by reflection to a periodic function on Q_2, and applying the above inequality we get that there exists a constant C_1 such that

$$\int_Q |u|^2 dx \le C_1 \left(1 + \frac{1}{\mathrm{Cap}(E\times\{0\})}\right) \iint_{Q\times Q} \frac{|u(x)-u(y)|^2}{|x-y|^3} dx\,dy\,. \tag{2.7}$$

3. The cell problem. In this section we will define a suitable notion of capacity which will be the natural tool to study the asymptotics of our problem. We call the following set function the "$H^{\frac{1}{2}}$ dislocation capacity of an open set E with respect to Ω at the integer level $a \in \mathbf{Z}$":

(3.1)
$$D^{\nu}_{\frac{1}{2}}(a,E,\Omega) := \inf\Bigg\{ \int_{\mathbf{R}^2} \mathrm{dist}^2(\zeta,\mathbf{Z})\,dx + \iint_{\mathbf{R}^2\times\mathbf{R}^2} \Gamma_\nu(x-y)|\zeta(x)-\zeta(y)|^2\,dx\,dy : \zeta = a \text{ on } E\,,\ \zeta = 0 \text{ on } \mathbf{R}^2\setminus\Omega \Bigg\}.$$

We denote by $D^{\nu}_{\frac{1}{2}}(a,E)$ the "$H^{\frac{1}{2}}$ dislocation capacity of an open set E with respect to $\mathbf{R}^2$ at the integer level $a \in \mathbf{Z}$"; namely,

(3.2)
$$D^{\nu}_{\frac{1}{2}}(a,E) := \inf\Bigg\{ \int_{\mathbf{R}^2} \mathrm{dist}^2(\zeta,\mathbf{Z})\,dx + \iint_{\mathbf{R}^2\times\mathbf{R}^2} \Gamma_\nu(x-y)|\zeta(x)-\zeta(y)|^2\,dx\,dy : \zeta = a \text{ on } E\,,\ \zeta \in L^4(\mathbf{R}^2) \Bigg\}.$$

The condition $\zeta \in L^4(\mathbf{R}^2)$ is the natural condition at ∞, in view of the following Sobolev inequality:

(3.3)
$$\|u\|_{L^4(\mathbf{R}^2)} \le C^*[u]_{H^{\frac{1}{2}}(\mathbf{R}^2)} \qquad \forall\ u \in C_0^\infty(\mathbf{R}^2)\,.$$

Remark 5. Denote

(3.4)
$$I(\zeta) := \int_{\mathbf{R}^2} \mathrm{dist}^2(\zeta,\mathbf{Z})\,dx + \iint_{\mathbf{R}^2\times\mathbf{R}^2} \Gamma_\nu(x-y)|\zeta(x)-\zeta(y)|^2\,dx\,dy\,.$$

Using the fact that the kernel Γ_ν is positive (under the assumption $\nu < \frac{1}{2}$), it is easy to check that both terms in the energy are decreasing under truncations by integers. For every $a, b \in \mathbf{R}$ we set $a \wedge b = \min(a,b)$ and $a \vee b = \max(a,b)$. Then for every $t \in \mathbf{Z}$, we have $I(\zeta \wedge t) \le I(\zeta)$ (and $I(\zeta \vee t) \le I(\zeta)$). Moreover, $I(\zeta \wedge t) < I(\zeta)$ (and $I(\zeta \vee t) < I(\zeta)$) unless $\zeta \wedge t = \zeta$ a.e. (or $\zeta \vee t = \zeta$ a.e.).

PROPOSITION 6. *Let Ω be a bounded open subset of $\mathbf{R}^2$, and let $E \subseteq \Omega$ be an open set such that $D^{\nu}_{\frac{1}{2}}(a,E,\Omega) < +\infty$, with $a \in \mathbf{Z}$. Then there exists a minimum point $\zeta \in H^{\frac{1}{2}}(\Omega)$ for* (3.1) *and it satisfies $0 \le \zeta \le a$. We will call each minimum point a $D^{\nu}_{\frac{1}{2}}$-capacitary potential of E with respect to Ω.*

Proof. In order to obtain the existence let ζ_k be a minimizing sequence for (3.1). By Remark 5 we may assume that $0 \le \zeta_k \le a$. Now let $\xi_k : \mathbf{R}^2 \to \mathbf{Z}$ such that

$$\int_{\mathbf{R}^2} \mathrm{dist}^2(\zeta_k,\mathbf{Z})\,dx = \int_{\mathbf{R}^2} |\zeta_k - \xi_k|^2 dx\,,$$

i.e., $\xi_k = \mathbf{P}_{\mathbf{Z}}\zeta_k$. Clearly $\xi_k = 0$ on $\mathbf{R}^2 \setminus \Omega$, and

$$\lim_{k\to\infty} \int_{\mathbf{R}^2} |\zeta_k - \xi_k|^2\,dx + \iint_{\mathbf{R}^2\times\mathbf{R}^2} \Gamma_\nu(x-y)|\zeta_k(x)-\zeta_k(y)|^2\,dx\,dy = D^{\nu}_{\frac{1}{2}}(a,E,\Omega)\,.$$

By (2.3) and the assumption $D^{\nu}_{\frac12}(a,E,\Omega)<+\infty$, the sequence $\{(\zeta_k,\xi_k)\}$ is bounded in $H^{\frac12}(\mathbf{R}^2)\times L^2(\Omega,\mathbf{Z})$, and we may assume that ζ_k and ξ_k converge weakly to a pair (ζ,ξ). By lower semicontinuity the limiting pair minimizes the energy and clearly satisfies $0\le\zeta\le a$ and $\zeta=0$ on $\mathbf{R}^2\setminus\Omega$. □

Remark 7. If $\Omega=B_R$, $E=B_r$, and $\nu=0$ (in the "isotropic case") the capacitary potential is unique and radially symmetric. This follows immediately by the fact that both terms of the energy defining $D_{\frac12}(a,B_r,B_R)$ are rotation invariant and the $H^{\frac12}$ seminorm is strictly decreasing under radial rearrangements. (For results on rearrangements for nonlocal energies see, e.g., [9] or the review paper [3].)

PROPOSITION 8. *There exists a minimizer for problem* (3.2)*, the $D^{\nu}_{\frac12}$-capacitary potential of E with respect to $\mathbf{R}^2$. If, moreover, E is bounded, then every minimizer converges to zero uniformly at infinity.*

Proof. As above, the existence follows by considering a minimizing sequence and remarking that the "boundary condition" $\zeta-a\in L^4(\mathbf{R}^2)$ is preserved, in view of (3.3).

Let now ζ be a potential of a bounded set E with respect to $\mathbf{R}^2$. In the case $\nu=0$ the decay at infinity follows by a comparison argument with the radially symmetric case (see Remark 7). Let us consider now the general case. Let L be the linear operator representing the quadratic form defined by (2.1), so that

$$I(\zeta)=\langle L\zeta,\zeta\rangle+\int_{\mathbf{R}^2}\mathrm{dist}^2(\zeta,\mathbf{Z})\,dx\,.$$

We will see that there exist a function $\psi\in L^4(\mathbf{R}^2)$ and a measure μ supported on $\overline{E}$ such that ζ is the solution in the sense of distributions of

$$L\zeta=\mu+\psi\,. \tag{3.5}$$

This would follow immediately from the Euler–Lagrange equation if $\mathrm{dist}^2(\cdot,\mathbf{Z}^2)$ was a C^1 function. For the case at hand we can argue as follows.

Fix $\eta\in C_0^\infty(\mathbf{R}^2)$, with $\eta\ge0$ on E, and compute the variation of $I(\zeta)$ in direction η. We have

$$2\langle L\zeta,\eta\rangle+t\langle L\eta,\eta\rangle+\int_{\mathbf{R}^2}\frac{\mathrm{dist}^2(\zeta+t\eta,\mathbf{Z})-\mathrm{dist}^2(\zeta,\mathbf{Z})}{t}\,dx\ge0\,. \tag{3.6}$$

Since $\mathrm{dist}(\cdot,\mathbf{Z})$ is a Lipschitz function,

$$\limsup_{t\to0}\frac{\mathrm{dist}^2(\zeta(x)+t\eta(x),\mathbf{Z})-\mathrm{dist}^2(\zeta(x),\mathbf{Z})}{t}\le2\mathrm{dist}(\zeta(x),\mathbf{Z})\,\eta(x)\qquad\text{a.e. } x\in\mathbf{R}^2,$$

and hence, by Fatou's lemma, we get

$$\langle L\zeta,\eta\rangle+\int_{\mathbf{R}^2}\mathrm{dist}(\zeta,\mathbf{Z})\,\eta\,dx\ge0\qquad\forall\,\eta\in C_0^\infty(\mathbf{R}^2)\,,\quad\eta\ge0\,.$$

Thus there exists a positive measure $\widetilde{\mu}$ such that

$$L\zeta=\widetilde{\mu}-\mathrm{dist}(\zeta,\mathbf{Z}) \tag{3.7}$$

in the sense of distributions. Now consider $\eta\in C_0^\infty(\mathbf{R}^2)$, with $\eta=0$ on E. We can apply the above argument to η and $-\eta$ and get

$$|\langle L\zeta,\eta\rangle|\le\int_{\mathbf{R}^2}\mathrm{dist}(\zeta,\mathbf{Z})|\eta|\,dx\qquad\forall\eta\in C_0^\infty(\mathbf{R}^2\setminus\overline{E})\,.$$

By density this holds also for $\eta \in C_0^0(\mathbf{R}^2 \setminus \overline{E})$, and since $\operatorname{dist}(\zeta, \mathbf{Z}) \in L^4(\mathbf{R}^2)$ we deduce that the restriction of $\widetilde{\mu}$ to $\mathbf{R}^2 \setminus \overline{E}$ is absolutely continuous with respect to the Lebesgue measure and its density is a L^4 function. Thus $\widetilde{\mu}$ can be written as the sum of a measure μ supported on $\overline{E}$ and a function belonging to $L^4(\mathbf{R}^2)$ which together with (3.7) gives (3.5).

Now let G_ν be the Green function of the operator $L+I$. We will need only rather mild decay properties of G_ν at ∞. To verify these it suffices to note that the Fourier transform of G_ν is given by

$$\widehat{G_\nu}(\lambda) = \frac{1}{1 + \frac{\lambda_2^2}{|\lambda|} + \frac{1}{1-\nu}\frac{\lambda_1^2}{|\lambda|}},$$

since $\widehat{L\zeta}(\lambda) = (\frac{\lambda_2^2}{|\lambda|} + \frac{1}{1-\nu}\frac{\lambda_1^2}{|\lambda|})\,\widehat{\zeta}(\lambda)$. One easily sees that $\widehat{G_\nu}$ and its first two derivatives are in $L^1(\mathbf{R}^2)$. Hence G_ν is continuous, and $G_\nu(x) \le C/(1+|x|^2)$. In particular, $G_\nu \in L^{4/3}(\mathbf{R}^2)$.

Since ψ and ζ belong to $L^4(\mathbf{R}^2)$, for every $\varepsilon > 0$ we can write $\psi + \zeta = \psi_1 + \psi_2$, where ψ_1 has compact support and $\|\psi_2\|_4 \le \varepsilon$. Thus we have

$$\zeta(x) = G_\nu * \mu(x) + G_\nu * \psi_1(x) + G_\nu * \psi_2(x) \qquad \text{a.e. } \mathbf{R}^2\,.$$

We can estimate the L^∞ norm of the last term of the right-hand side using the Hölder inequality and get

$$\|G_\nu * \psi_2\|_{L^\infty(\mathbf{R}^2)} \le \|G_\nu\|_{L^{\frac{4}{3}}(\mathbf{R}^2)} \|\psi_2\|_{L^4(\mathbf{R}^2)} \le C\varepsilon\,.$$

On the other hand, the decay of G_ν and the fact that μ and ψ_1 have compact support guarantee that for $|x|$ big enough ζ is uniformly small. This concludes the proof of the proposition. □

The following proposition shows that as $a \to \infty$ the Peierls potential term becomes negligible and the dislocation capacity converges to the $H^{\frac{1}{2}}$-capacity, defined for any open set $E \subseteq \mathbf{R}^2$ as

(3.8)

$$\operatorname{Cap}^\nu_{H^{\frac{1}{2}}}(E) = \inf\left\{ \int\!\!\int_{\mathbf{R}^2\times\mathbf{R}^2} \Gamma_\nu(x-y)|\eta(x)-\eta(y)|^2\,dx\,dy :\ \eta = 1 \text{ on } E\,,\ \eta \in L^4(\mathbf{R}^2) \right\}$$

(see, for instance, [1]).

PROPOSITION 9. *For any bounded open set $E \subseteq \mathbf{R}^2$ there exists a positive constant C_E such that*

$$a^2 \operatorname{Cap}^\nu_{H^{\frac{1}{2}}}(E) \le D^\nu_{\frac{1}{2}}(a,E) \le a^2 \operatorname{Cap}^\nu_{H^{\frac{1}{2}}}(E) + 2a^{3/2} \operatorname{Cap}^\nu_{H^{\frac{1}{2}}}(E) + C_E a \tag{3.9}$$

for every $a \in \mathbb{N}$. In particular,

$$\lim_{a\to\infty} \frac{D^\nu_{\frac{1}{2}}(a,E)}{a^2} = \operatorname{Cap}^\nu_{H^{\frac{1}{2}}}(E)\,. \tag{3.10}$$

Proof. The first inequality in (3.9) is trivial. In order to prove the estimate from above let η_E be the $H^{\frac{1}{2}}$-potential of E, i.e., the minimum point for (3.8). Using the fact that $\widehat{\Gamma_\nu}(\lambda)$ is homogeneous of degree 1, nonvanishing, and smooth on the unit

sphere, one can easily check that η_E decays at infinity as $1/|x|$. Fix $a \in \mathbb{N}$ and define the function

$$v_a(x) = \begin{cases} \frac{a}{a-\sqrt{a}}(a\eta_E(x) - \sqrt{a}) & \text{if } x \in E_a = \{\eta_E > 1/\sqrt{a}\}, \\ 0 & \text{otherwise.} \end{cases}$$

The function v_a is admissible in the definition of $D^\nu_{\frac{1}{2}}(a, E)$; thus

(3.11)
$$D^\nu_{\frac{1}{2}}(a, E) \le \int_{E_a} \operatorname{dist}^2(\tfrac{a}{a-\sqrt{a}}(a\eta_E - \sqrt{a}), \mathbf{Z})\, dx + \iint_{\mathbf{R}^2\times\mathbf{R}^2} \Gamma_\nu(x-y)|v_a(x) - v_a(y)|^2 dx\, dy\,.$$

By the decay of η_E at infinity we have that there exists a constant C_E such that $|E_a| \le C_E a$. Thus

$$\int_{E_a} \operatorname{dist}^2(\tfrac{a}{a-\sqrt{a}}(a\eta_E - \sqrt{a}), \mathbf{Z})\, dx \le C_E a\,.$$

Moreover,

$$\begin{aligned} &\iint_{\mathbf{R}^2\times\mathbf{R}^2} \Gamma_\nu(x-y)|v_a(x) - v_a(y)|^2 dx\, dy \\ &\quad \le \frac{a^2}{(1-\frac{1}{\sqrt{a}})^2} \iint_{\mathbf{R}^2\times\mathbf{R}^2} \Gamma_\nu(x-y)|\eta_E(x) - \eta_E(y)|^2 dx\, dy \\ &\quad = \frac{a^2}{(1-\frac{1}{\sqrt{a}})^2} \mathrm{Cap}^\nu_{H^{\frac{1}{2}}}(E)\,. \end{aligned}$$

After possibly modifying the value of C_E this yields (3.8). □

We can extend the dislocation capacity to the class of all subsets of Ω by setting

$$D^\nu_{\frac{1}{2}}(a, E, \Omega) = \inf\{D^\nu_{\frac{1}{2}}(a, A, \Omega) \,:\, A \text{ open}\,,\ A \supseteq E\} \tag{3.12}$$

for any set $E \subseteq \Omega$.

PROPOSITION 10. *The dislocation capacity satisfies the following properties:*

(1) $D^\nu_{\frac{1}{2}}(a, E, \Omega) \le D^\nu_{\frac{1}{2}}(a, F, \Omega)$ *if* $E \subseteq F \subseteq \Omega$;
(2) $D^\nu_{\frac{1}{2}}(a, E, \Omega) \le D^\nu_{\frac{1}{2}}(a, E, \Omega')$ *if* $E \subseteq \Omega' \subseteq \Omega$;
(3) $D^\nu_{\frac{1}{2}}(a, E, \Omega) = D^\nu_{\frac{1}{2}}(-a, E, \Omega)$ *for every* $a \in \mathbf{Z}$;
(4) *If* $0 \le a \le b$, $a, b \in \mathbf{Z}$, *then* $D^\nu_{\frac{1}{2}}(a, E, \Omega) \le D^\nu_{\frac{1}{2}}(b, E, \Omega)$;
(5) *(Subadditivity). Given two open subsets of* Ω, E_1 *and* E_2,

$$D^\nu_{\frac{1}{2}}(a, E_1 \cup E_2, \Omega) \le D^\nu_{\frac{1}{2}}(a, E_1, \Omega) + D^\nu_{\frac{1}{2}}(a, E_2, \Omega)$$

for every $a \in \mathbf{Z}$;
(6) *(Continuity on increasing sequences of sets). Given a sequence of subsets* $E_n \subseteq \Omega$, *such that* $E_n \subseteq E_{n+1}$, *and letting* $E = \bigcup_n E_n$, *we have*

$$\lim_{n\to\infty} D^\nu_{\frac{1}{2}}(a, E_n, \Omega) = D^\nu_{\frac{1}{2}}(a, E, \Omega)$$

for every $a \in \mathbf{Z}$;

(7) *(Continuity on decreasing sequences of compact sets). Given a sequence of compact subsets of* Ω, K_n, *such that* $K_n \supseteq K_{n+1}$, *and letting* $K = \bigcap_n K_n$, *we have*

$$\lim_{n\to\infty} D^{\nu}_{\frac{1}{2}}(a, K_n, \Omega) = D^{\nu}_{\frac{1}{2}}(a, K, \Omega)$$

for every $a \in \mathbf{Z}$.

Proof. The monotonicity properties (1)–(4) can be checked directly by the definition. In order to prove property (5) let ζ_1 and ζ_2 be capacitary potentials of E_1 and E_2, respectively. Clearly the function $\zeta_1 \vee \zeta_2$ is a good competitor for the $D^{\nu}_{\frac{1}{2}}$-capacity of $E_1 \cup E_2$. The conclusion follows by the explicit computation of the energy, remarking that

$$|\zeta_1(x) - \zeta_2(y)|^2 \le |\zeta_1(x) - \zeta_1(y)|^2 \vee |\zeta_2(x) - \zeta_2(y)|^2$$

if $\zeta_1(x) \ge \zeta_2(x)$ and $\zeta_2(y) \ge \zeta_1(y)$.

Let us prove property (6). By (1) we have

$$\lim_{n\to\infty} D^{\nu}_{\frac{1}{2}}(a, E_n, \Omega) \le D^{\nu}_{\frac{1}{2}}(a, E, \Omega)\,.$$

For the reverse inequality it is enough to consider the case of open sets. Let $\zeta_n \in H^{\frac{1}{2}}(\mathbf{R}^2)$ be a sequence of capacitary potentials, i.e., $\zeta_n = a$ a.e. on E_n and

$$I(\zeta_n) = D^{\nu}_{\frac{1}{2}}(a, E_n, \Omega) \le D^{\nu}_{\frac{1}{2}}(a, E, \Omega)\,.$$

Thus the $H^{\frac{1}{2}}$ seminorm of ζ_n is bounded. In view of (3.3), ζ_n is bounded in L^4, and hence in $H^{\frac{1}{2}}_{\mathrm{loc}}(\mathbf{R}^2)$. Thus (a subsequence of) ζ_n converges strongly in $L^2_{\mathrm{loc}}(\mathbf{R}^2)$. By the lower semicontinuity of $I(\cdot)$ we get

$$I(\zeta) \le \liminf_{n\to\infty} I(\zeta_n) = \liminf_{n\to\infty} D^{\nu}_{\frac{1}{2}}(a, E_n, \Omega)\,.$$

Since $E = \bigcup_n E_n$ is also open, $\zeta = a$ a.e. in E, and hence is a good competitor for the definition of $D^{\nu}_{\frac{1}{2}}(a, E, \Omega)$. Thus

$$D^{\nu}_{\frac{1}{2}}(a, E, \Omega) \le I(\zeta) \le \liminf_{n\to\infty} D^{\nu}_{\frac{1}{2}}(a, E_n, \Omega),$$

which concludes the proof.

Finally, the proof of property (7) follows directly from the definition. In fact, for any fixed $\varepsilon > 0$ there exists an open set $A \supseteq K$ such that $D^{\nu}_{\frac{1}{2}}(a, A, \Omega) \le D^{\nu}_{\frac{1}{2}}(a, K, \Omega) + \varepsilon$. Since the sets K_n are decreasing and compact, there exists an index n_0 such that $K_n \subseteq A$ for every $n \ge n_0$. The conclusion follows by the monotonicity of the dislocation capacity. □

Remark 11. The properties proved above show that the dislocation capacity is a Choquet capacity (see, for instance, [1] or [11] for a general capacity theory). Note, however, that we define the dislocation capacity starting from open sets instead of compact sets, since this is more convenient for the present purpose.

In the following we will mostly consider the dislocation capacity of a ball with respect to either a concentric ball or $\mathbf{R}^2$. In order to simplify the notation we will state and prove some properties of the capacity in this particular case, although most of them hold in a more general situation.

PROPOSITION 12. *Let $a \in \mathbf{Z}$ and $r > 0$. Then*

$$\lim_{R\to\infty} D^\nu_{\frac12}(a, B_r, B_R) = D^\nu_{\frac12}(a, B_r)\,.$$

Proof. By Proposition 10 we know that $D^\nu_{\frac12}(a, B_r, B_R)$ is decreasing in R. Thus the limit always exists, and

$$\lim_{R\to\infty} D^\nu_{\frac12}(a, B_r, B_R) \geq D^\nu_{\frac12}(a, B_r)\,.$$

In order to prove the reverse inequality, fix $a \in \mathbf{Z}$ positive, and let ζ be a capacitary potential of B_r with respect to $\mathbf{R}^2$. We may assume that $0 \leq \zeta \leq a$, and by Proposition 8 we know that ζ decays to zero uniformly at infinity; i.e., for every $\varepsilon > 0$ there exists $R_0 > 0$ such that

$$|\zeta(x)| < \varepsilon \qquad \text{if} \quad |x| \geq R_0\,.$$

Fix $\varepsilon > 0$, and let us define the function ζ_ε as follows:

$$\zeta_\varepsilon(x) = \begin{cases} \zeta(x) & \text{if } x \in \{\zeta \geq 1\},\\ \dfrac{\zeta(x)-\varepsilon}{1-\varepsilon} & \text{if } x \in \{\varepsilon \leq \zeta < 1\},\\ 0 & \text{if } x \in \{\zeta < \varepsilon\}. \end{cases}$$

We can write ζ_ε as $\zeta_\varepsilon(x) = \max\{\min\{\zeta(x), \frac{\zeta(x)-\varepsilon}{1-\varepsilon}\}, 0\}$, and hence $\zeta_\varepsilon \in H^{\frac12}(\mathbf{R}^2)$. Moreover, $\zeta_\varepsilon(x) = a$ on B_r, and $\zeta_\varepsilon(x) = 0$ in $\mathbf{R}^2 \setminus B_{R_0}$. This implies that ζ_ε is an admissible function in the definition of $D^\nu_{\frac12}$ and

(3.13)

$$D^\nu_{\frac12}(a, B_r, B_R) \leq \int_{\mathbf{R}^2} \operatorname{dist}^2(\zeta_\varepsilon, \mathbf{Z})\,dx + \iint_{\mathbf{R}^2\times\mathbf{R}^2} \Gamma_\nu(x-y)|\zeta_\varepsilon(x)-\zeta_\varepsilon(y)|^2\,dx\,dy = I(\zeta_\varepsilon)$$

for every $R \geq R_0$. Let us compute $I(\zeta_\varepsilon)$ and show that $I(\zeta_\varepsilon) \leq I(\zeta) + o(1)$, as $\varepsilon \to 0$. Denote by E_t the level set $\{\zeta \leq t\}$, and let us first estimate the dislocation part of the energy

$$\begin{aligned}\int_{\mathbf{R}^2} \operatorname{dist}^2(\zeta_\varepsilon, \mathbf{Z})\,dx &= \int_{\mathbf{R}^2\setminus E_1} \operatorname{dist}^2(\zeta, \mathbf{Z})\,dx + \frac{1}{(1-\varepsilon)^2}\int_{E_1\setminus E_\varepsilon} \operatorname{dist}^2(\zeta-\varepsilon, (1-\varepsilon)\mathbf{Z})\,dx\\ &= \int_{\mathbf{R}^2\setminus E_1} \operatorname{dist}^2(\zeta, \mathbf{Z})\,dx + \frac{1}{(1-\varepsilon)^2}\int_{E_1\setminus E_{\frac{1+\varepsilon}{2}}} |\zeta-1|^2 dx + \frac{1}{(1-\varepsilon)^2}\int_{E_{\frac{1+\varepsilon}{2}}\setminus E_\varepsilon} |\zeta-\varepsilon|^2 dx\,.\end{aligned}$$

Since

$$\int_{E_{\frac{1+\varepsilon}{2}}\setminus E_\varepsilon} |\zeta-\varepsilon|^2 dx \leq \int_{E_{\frac{1+\varepsilon}{2}}\setminus E_\varepsilon} |\zeta|^2 dx,$$

we have

$$\limsup_{\varepsilon\to0} \int_{\mathbf{R}^2} \operatorname{dist}^2(\zeta_\varepsilon, \mathbf{Z})\,dx \leq \int_{\mathbf{R}^2} \operatorname{dist}^2(\zeta, \mathbf{Z})\,dx\,.$$

To estimate the nonlocal term in $I(\zeta_\varepsilon)$ it suffices to note that $\zeta_\varepsilon = \psi_\varepsilon \circ \zeta$ with $\operatorname{Lip}\psi_\varepsilon \leq \frac{1}{1-\varepsilon}$. Hence $|\zeta_\varepsilon(x)-\zeta_\varepsilon(y)|^2 \leq (1-\varepsilon)^{-2}|\zeta(x)-\zeta(y)|^2$, and we get

$$\limsup_{\varepsilon\to0} \iint_{\mathbf{R}^n\times\mathbf{R}^n} \Gamma_\nu(x-y)|\zeta_\varepsilon(x)-\zeta_\varepsilon(y)|^2\,dx\,dy \leq \iint_{\mathbf{R}^n\times\mathbf{R}^n} \Gamma_\nu(x-y)|\zeta(x)-\zeta(y)|^2\,dx\,dy\,.$$

Thus the conclusion follows from (3.13). ∎

4. Compactness and Γ-convergence result. In this section we will study the Γ-convergence of the functional E_ε defined in (1.8) with a pinning condition on N_ε balls of radius εR and centered in uniformly distributed and well-separated points x_i^ε, $i \in I_\varepsilon \subset \mathbb{N}$, in the regime where $N_\varepsilon \varepsilon$ is bounded.

For every $i \in I_\varepsilon$ and $r > 0$ we denote by B_r^i the ball in $\mathbf{R}^2$ of radius r and center x_i^ε. (B_r always denotes the ball of radius r centered at 0.)

In order to get a nontrivial result we rescale the function E_ε and prove that the functional $F_\varepsilon(u) := E_\varepsilon(u)/N_\varepsilon\varepsilon$, i.e.,

$$F_\varepsilon(u) = \begin{cases} \dfrac{1}{N_\varepsilon \varepsilon^2} \displaystyle\int_{T^2} \operatorname{dist}^2(u, \mathbf{Z})\, dx + \dfrac{1}{N_\varepsilon \varepsilon} \displaystyle\iint_{T^2 \times T^2} K_\nu(x-y)|u(x)-u(y)|^2\, dx\, dy \\ \qquad\qquad \text{if } \ u \in H^{\frac{1}{2}}(T^2)\,, \\ \qquad\qquad u = 0 \text{ on } \bigcup_i B^i_{R\varepsilon}, \\ +\infty \qquad\qquad \text{otherwise}\,, \end{cases}$$

Γ-converges, with respect to the strong L^2 topology, to the functional

$$F(u) = \begin{cases} D^\nu_{\frac{1}{2}}(u, B_R) & \text{if } u = \text{const.} \in \mathbf{Z}\,, \\ +\infty & \text{otherwise}\,. \end{cases} \tag{4.1}$$

For every subset E of $(0,1)^2$ we denote $I_\varepsilon(E) := \{i \in I_\varepsilon \,:\, x_i^\varepsilon \in E\}$. For the centers of the balls we assume the following conditions:

- (*Uniformly distributed*). There exists a constant $L > 0$ such that

$$|\#(I_\varepsilon(Q)) - N_\varepsilon |Q|| \le L \tag{4.2}$$

  for every open square $Q \subset (0,1)^2$.
- (*Well separated*). There exists $\beta < 1$ such that

$$\operatorname{dist}(x_i^\varepsilon, x_j^\varepsilon) > 6\varepsilon^\beta \tag{4.3}$$

  for every $i, j \in I_\varepsilon$, $i \neq j$, and for every $\varepsilon \in (0, \varepsilon_0)$.
- (*Finite capacity density*). There exists a constant $\Lambda \ge 0$ (possibly zero) such that $N_\varepsilon \varepsilon \to \Lambda$.

Remark 13. For brevity we refer to the constant Λ as the *capacity density* of the obstacles. (More correctly $\Lambda \mathrm{Cap}^\nu_{H^{\frac{1}{2}}}(B_R) \sim \Lambda R$ is the capacity density.) Note that in order to get a Γ-convergence result the capacity density does not need to be constant. One could also consider either a case where the obstacles are not uniformly distributed in space or the case where the radii of the obstacles are varying (i.e., $B_\varepsilon^i = B(x_\varepsilon^i, R_\varepsilon^i \varepsilon)$). This would lead in general to a nonconstant capacity density $\Lambda(x)$. In this case, condition (4.2) should be replaced by

$$\left| \sum_{x_\varepsilon^i \in Q} R_\varepsilon^i - \frac{1}{\varepsilon} \int_Q \Lambda(x)\, dx \right| \le L, \tag{4.4}$$

with $\Lambda \in L^\infty$.

THEOREM 14. *Assume that $N_\varepsilon \to +\infty$ and that the balls $B^i_{R\varepsilon}$ are uniformly distributed, are well separated, and have finite capacity density. Then*

(i) *every sequence $\{u_\varepsilon\}$ such that $\sup_\varepsilon F_\varepsilon(u_\varepsilon) < \infty$ is precompact in L^2, and every cluster point is an integer constant;*

(ii) *for every $u \in L^2(\mathbf{R}^2)$ there exists a sequence $\{u_\varepsilon\}$ strongly converging in L^2 to u such that*

$$\lim_{\varepsilon\to 0} F_\varepsilon(u_\varepsilon) = F(u)\,;$$

(iii) *every sequence $\{u_\varepsilon\}$ strongly converging in L^2 to some function u satisfies*

$$\liminf_{\varepsilon\to 0} F_\varepsilon(u_\varepsilon) \geq F(u)\,.$$

Remark 15. As noted in the introduction, by general facts about Γ-convergence (see, e.g., [5, Proposition 6.20]), we can easily include an applied stress S^ε. If S^ε converges to some S strongly in L^2, then the functional

$$F_\varepsilon(u) - \int_{T^2} S^\varepsilon u\, dx$$

Γ-converges to $F(u) - \int_{T^2} S\, u\, dx$.

Proof of (i) *(compactness).* Since $\sup_\varepsilon F_\varepsilon(u_\varepsilon) \leq C < +\infty$, by (1.6) we have

$$[u_\varepsilon]_{H^{\frac12}(T^2)} \leq C N_\varepsilon \varepsilon\,. \tag{4.5}$$

Moreover, $u_\varepsilon = 0$ on $\bigcup_i B^i_{R\varepsilon} = E_\varepsilon$. This obstacle condition is enough to deduce an L^2 estimate via Poincaré's inequality (2.7). Roughly speaking, the idea is the standard fact that the capacity is almost additive on a union of small well-separated sets and the three-dimensional harmonic capacity of a disc is proportional to its radius, i.e.,

$$\mathrm{Cap}(E_\varepsilon \times \{0\}) \approx \sum_i \mathrm{Cap}(B^i_{R\varepsilon} \times \{0\}) \approx N_\varepsilon \varepsilon\,.$$

In order to carry out this argument rigorously we cover the unit square with a lattice of small squares and apply the Poincaré inequality to each of them. The right estimate follows if we choose the side of each square small but big enough to contain at least one obstacle.

Fix $r_\varepsilon = \sqrt{\frac{L+1}{N_\varepsilon}}$. ($L$ is the constant given by (4.2).) With a little abuse of notation we denote by $Q^{r_\varepsilon}_j$ the squares of a lattice on $(0,1)^2$ of size approximatively r_ε. Applying the Poincaré inequality (2.7), scaled to the square $Q^{r_\varepsilon}_j$, we get

$$\int_{Q^{r_\varepsilon}_j} |u_\varepsilon|^2 dx \leq C_0 r_\varepsilon \left(1 + \frac{r_\varepsilon}{\mathrm{Cap}((\{u_\varepsilon = 0\} \cap Q^{r_\varepsilon}_j) \times \{0\})}\right) [u]^2_{H^{\frac12}(Q^{r_\varepsilon}_j)}\,. \tag{4.6}$$

By our choice of r_ε and assumption (4.2) we have

$$1 \leq \#(I_\varepsilon(Q^{r_\varepsilon}_j)) \leq 2L + 1,$$

and thus $\mathrm{Cap}((\{u_\varepsilon = 0\} \cap Q^{r_\varepsilon}_j) \times \{0\}) > CR\varepsilon$. Taking the sum over all j in (4.6), by (4.5), we get

$$\int_{T^2} |u_\varepsilon|^2 dx \leq \sum_j C_0 r_\varepsilon \left(1 + \frac{r_\varepsilon}{CR\varepsilon}\right) [u]^2_{H^{\frac12}(Q^{r_\varepsilon}_j)} \leq C r_\varepsilon \left(1 + \frac{r_\varepsilon}{CR\varepsilon}\right) N_\varepsilon \varepsilon \leq C\,.$$

Thus u_ε is precompact in the weak topology of $H^{\frac12}$ and, by the compact embedding, in the strong topology of L^2.

Finally, let u be a cluster point. Assume for simplicity that the whole sequence u_ε converges to u. In particular, since $\sup_\varepsilon F_\varepsilon(u_\varepsilon) \le C$, we have

$$\lim_{\varepsilon\to 0}\int_{T^2} \operatorname{dist}^2(u_\varepsilon, \mathbf{Z})\,dx = 0\,.$$

This implies that $u \in H^{\frac12}(T^2, \mathbf{Z})$. Then u must be constant. This is obvious in the case when $N_\varepsilon\varepsilon \to 0$ but is true in general for any function in $H^{\frac12}$ taking values in $\mathbf{Z}$. (This fact can be easily checked in one dimension, where jumps are not permitted, and then extended to any dimension by slicing.) □

Proof of (ii) *(the upper bound).* It is clearly enough to prove the result for any constant function $u = a \in \mathbf{Z}$. (Otherwise the upper bound is trivial.) In order to construct a sequence $\{u_\varepsilon\}$ which converges strongly to a in L^2 and satisfies

$$\lim_{\varepsilon\to 0} F_\varepsilon(u_\varepsilon) = D^\nu_{\frac12}(a, B_R),$$

fix $\rho_\varepsilon > 0$ such that $\varepsilon \le \rho_\varepsilon \ll \varepsilon^{(\beta+1)/2}$, and let ζ_ε be a $H^{\frac12}$-dislocation capacitary potential of B_R with respect to $B_{\frac{\rho_\varepsilon}{\varepsilon}}$ at level a. Define

$$u^i_\varepsilon(x) = a - \zeta_\varepsilon\left(\frac{x - x^i_\varepsilon}{\varepsilon}\right)$$

and

$$u_\varepsilon(x) = \begin{cases} \sum_i u^i_\varepsilon(x)\chi_{B^i_{\varepsilon^\beta}}(x) & \text{if } x \in \bigcup_i B^i_{\varepsilon^\beta},\\ a & \text{otherwise.}\end{cases}$$

It is easy to check that the sequence u_ε converges to a in L^2. In order to control the nonlocal term in the energy let us first show that long-range interactions are negligible. Indeed, using the fact that $u^i_\varepsilon = a$ outside $B^i_{\rho_\varepsilon}$ and the properties of the kernel K_ν we have

$$\begin{aligned}\iint_{\substack{T^2\times T^2\\ |x-y|>\varepsilon^\beta}} & K_\nu(x-y)|u_\varepsilon(x) - u_\varepsilon(y)|^2 dx\,dy\\ &\le 2\sum_i \int_{B^i_{\rho_\varepsilon}}\int_{T^2} \chi_{|x-y|>\varepsilon^\beta}\, K_\nu(x-y)\,|u^i_\varepsilon(x) - u_\varepsilon(y)|^2 dx\,dy\\ &\le 2a^2 N_\varepsilon \int_{B_{\rho_\varepsilon}}\int_{T^2} \chi_{|y|>\varepsilon^\beta}\, K_\nu(y)\,dy\,dx \le C\frac{\rho^2_\varepsilon N_\varepsilon}{\varepsilon^\beta}\,.\end{aligned}$$

The constant C depends on a, but since a is fixed we suppress this dependence in the following. Since $(T^2 \setminus \cup_i B^i_{2\varepsilon^\beta}) \times T^2 \subseteq \left[(T^2 \setminus \cup_i B^i_{\varepsilon^\beta}) \times (T^2 \setminus \cup_i B^i_{\varepsilon^\beta})\right] \cup \{|x-y| > \varepsilon^\beta\}$ and $u_\varepsilon(x) = a$ outside $\cup_i B^i_{\varepsilon^\beta}$, by our choice of ρ_ε and (4.3) we have

(4.7)

$$\begin{aligned}F_\varepsilon(u_\varepsilon) &\le \sum_i \frac{1}{N_\varepsilon\varepsilon}\left(\frac1\varepsilon\int_{B^i_{\varepsilon^\beta}} \operatorname{dist}^2(u^i_\varepsilon, \mathbf{Z})\,dx + \iint_{B^i_{3\varepsilon^\beta}\times B^i_{3\varepsilon^\beta}} K_\nu(x-y)\,|u^i_\varepsilon(x) - u^i_\varepsilon(y)|^2 dx\,dy\right) + o(1)\\ &= \frac{1}{\varepsilon^2}\int_{B_{\varepsilon^\beta}} \operatorname{dist}^2\left(\zeta_\varepsilon\left(\frac{x}{\varepsilon}\right), \mathbf{Z}\right) dx + \frac1\varepsilon\iint_{B_{3\varepsilon^\beta}\times B_{3\varepsilon^\beta}} K_\nu(x-y)\left|\zeta_\varepsilon\left(\frac{x}{\varepsilon}\right) - \zeta_\varepsilon\left(\frac{y}{\varepsilon}\right)\right|^2 dx\,dy + o(1)\\ &= \int_{B_{\varepsilon^\beta - 1}} \operatorname{dist}^2(\zeta_\varepsilon(x), \mathbf{Z})\,dx + \iint_{B_{3\varepsilon^\beta-1}\times B_{3\varepsilon^\beta-1}} \varepsilon^3 K_\nu(\varepsilon(x-y))\,|\zeta_\varepsilon(x) - \zeta_\varepsilon(y)|^2\,dx\,dy + o(1).\end{aligned}$$

Now, by Proposition 1, for ε small enough we have

$$|\varepsilon^3 K_\nu(\varepsilon(x-y)) - \Gamma_\nu(x-y)| \le C\varepsilon^3 \qquad \forall\, x\,, y \in B_{3\varepsilon^{\beta-1}}\,,$$

and hence

$$\begin{aligned}(4.8)\quad &\iint_{B_{3\varepsilon^{\beta-1}}\times B_{3\varepsilon^{\beta-1}}} \varepsilon^3 K_\nu(\varepsilon(x-y))\ |\zeta_\varepsilon(x)-\zeta_\varepsilon(y)|^2\,dx\,dy \\ &\qquad \le \iint_{B_{3\varepsilon^{\beta-1}}\times B_{3\varepsilon^{\beta-1}}} \Gamma_\nu(x-y)\ |\zeta_\varepsilon(x)-\zeta_\varepsilon(y)|^2\,dx\,dy + C\varepsilon^3\varepsilon^{4(\beta-1)}\,.\end{aligned}$$

Thus by the definition of ζ_ε we have

$$F_\varepsilon(u_\varepsilon) \le D_\nu^{\frac12}(a, B_R, B_{\frac{\rho_\varepsilon}{\varepsilon}}) + C\varepsilon^{4\beta-1},$$

which for the choice of $\beta > \frac14$ together with Proposition 12 gives

$$\limsup_{\varepsilon\to 0} F_\varepsilon(u_\varepsilon) \le D_\nu^{\frac12}(a, B_R).$$

(Note that if (4.3) holds for some β, it also holds for all larger β.) ∎

The proof of the lower bound is based on the following key lemma.

LEMMA 16. *Given $\mathcal{R} : \mathbf{R}_+ \to \mathbf{R}_+$, with $\mathcal{R}(\varepsilon) \to \infty$ as $\varepsilon \to 0$, there exists a function $\omega : \mathbf{R}_+ \times \mathbf{R}_+ \to \mathbf{R}_+$, with $\omega(\varepsilon,\delta) \to 0$ as $(\varepsilon,\delta) \to (0,0)$, such that the following statement holds. Let $a \in \mathbf{Z}$. If $\zeta \in H^{\frac12}(B_{\mathcal{R}(\varepsilon)})$ satisfies*

$$(4.9)\qquad \fint_{B_{\mathcal{R}(\varepsilon)}} |\zeta - a|dx \le \delta$$

and $\zeta = 0$ on B_R, then

$$\begin{aligned}(4.10)\quad J_\varepsilon(\zeta) &:= \int_{B_{\mathcal{R}(\varepsilon)}} \operatorname{dist}^2(\zeta, \mathbf{Z})\,dx + \iint_{B_{\mathcal{R}(\varepsilon)}\times B_{\mathcal{R}(\varepsilon)}} K^\varepsilon(x-y)|\zeta(x)-\zeta(y)|^2\,dx\,dy \\ &\ge D^\nu_{\frac12}(a, B_R) - \omega(\varepsilon,\delta)\,,\end{aligned}$$

where $K^\varepsilon(t) = \varepsilon^3 K_\nu(\varepsilon t)$.

Proof. Assume for a contradiction that there exist $(\varepsilon_k,\delta_k) \to (0,0)$, $\eta > 0$, and $\zeta_k \in H^{\frac12}(B_{\mathcal{R}(\varepsilon_k)})$, with $\zeta_k = 0$ on B_R such that

$$J_{\varepsilon_k}(\zeta_k) \le D^\nu_{\frac12}(a, B_R) - \eta$$

and

$$(4.11)\qquad \fint_{B_{\mathcal{R}(\varepsilon_k)}} |\zeta_k - a|dx \to 0 \qquad \text{as } k \to \infty\,.$$

Denote $B^k = B_{\mathcal{R}(\varepsilon_k)}$. By the Sobolev embedding there exists a sequence of real numbers a_k such that

$$\left(\int_{B^k} |\zeta_k - a_k|^4 dx\right)^{\frac12} \le C \iint_{B^k\times B^k} K^{\varepsilon_k}(x-y)|\zeta_k(x)-\zeta_k(y)|^2\,dx\,dy \le C\,.$$

Hence by the Hölder inequality we have

$$\fint_{B^k} |\zeta_k - a_k| dx \le \left(\fint_{B^k} |\zeta_k - a_k|^4 dx \right)^{\frac{1}{4}} \to 0,$$

and thus we deduce that $a_k \to a$ as $k \to \infty$. In conclusion there exists a function ζ such that for every $r > 0$ we have that ζ_k converge weakly to ζ in $H^{\frac{1}{2}}(B_r)$ and in $L^4(B_r)$ and strongly in $L^2(B_r)$. Moreover,

$$\int_{B_r} |\zeta - a|^4 dx \le \liminf_{k\to\infty} \int_{B_r} |\zeta_k - a_k|^4 dx \le \liminf_{k\to\infty} \int_{B^k} |\zeta_k - a_k|^4 dx \le C; \tag{4.12}$$

i.e., ζ is a good competitor for the definition of $D^{\nu}_{\frac{1}{2}}(a, B_R)$. In addition we have

$$\lim_{k\to\infty} \int_{B_r} \operatorname{dist}^2(\zeta_k, \mathbf{Z})\, dx = \int_{B_r} \operatorname{dist}^2(\zeta, \mathbf{Z})\, dx$$

and

$$\lim_{k\to\infty} \iint_{B_r\times B_r} \Gamma_\nu(x-y)|\zeta_k(x) - \zeta_k(y)|^2\, dx\, dy = \iint_{B_r\times B_r} \Gamma_\nu(x-y)|\zeta(x) - \zeta(y)|^2\, dx\, dy\,.$$

Finally, by Proposition 1 and the homogeneity of Γ_ν we have

$$|K^\varepsilon(x-y) - \Gamma_\nu(x-y)| \le C_r \frac{\varepsilon^3}{|x-y|^3} \qquad \text{if } |x-y| \le \frac{3}{4\varepsilon},$$

and hence

$$\left| \iint_{B_r\times B_r} \left(K^{\varepsilon_k}(x-y) - \Gamma_\nu(x-y)\right) |\zeta_k(x) - \zeta_k(y)|^2\, dx\, dy \right| \le C_r \varepsilon_k^3 \|\zeta_k\|_{H^{\frac{1}{2}}(B_r)}\,.$$

Thus for every $r > 0$ we get

$$D^{\nu}_{\frac{1}{2}}(a, B_R) - \eta \ge \limsup_{k\to\infty} J_{\varepsilon_k}(\zeta_k) \ge \int_{B_r} \operatorname{dist}^2(\zeta, \mathbf{Z})\, dx + \iint_{B_r\times B_r} \Gamma_\nu(x-y)|\zeta(x) - \zeta(y)|^2\, dx\, dy$$

so that

$$D^{\nu}_{\frac{1}{2}}(a, B_R) - \eta \ge \int_{\mathbf{R}^2} \operatorname{dist}^2(\zeta, \mathbf{Z})\, dx + \iint_{\mathbf{R}^2\times\mathbf{R}^2} \Gamma_\nu(x-y)|\zeta(x) - \zeta(y)|^2\, dx\, dy\,.$$

This is a contradiction, in view of the fact that ζ is a good test function in the definition of $D^{\nu}_{\frac{1}{2}}(a, B_R)$, and the proof is complete. □

A second key point for the proof of the lower bound is to show that if the sequence $u_\varepsilon - a$ is close to zero in some ball B_r, then it is close to zero also at a smaller scale. This is a consequence of the following proposition.

PROPOSITION 17. *There exists a positive constant C such that for every $0 < \rho < r$ the following inequality holds:*

$$\fint_{B_\rho} |u|\, dx \le \fint_{B_r} |u|\, dx + \frac{C}{\sqrt{\rho}} [u]_{H^{\frac{1}{2}}(B_r)} \tag{4.13}$$

for all $u \in H^{\frac{1}{2}}(B_r)$.

Proof. Let us first show that there exists a constant C such that for any $u \in H^{\frac{1}{2}}(B_1)$

$$\fint_{B_\theta} |u|\,dx \le \fint_{B_1} |u|\,dx + C\,[u]_{H^{\frac{1}{2}}(B_1)} \tag{4.14}$$

for every $\theta \in [\frac{1}{2}, 1]$. By the Hölder inequality and the Sobolev embedding there exists a constant c such that

$$\|u-c\|_{L^1(B_\theta)} \le \|u-c\|_{L^1(B_1)} \le C\,[u]_{H^{\frac{1}{2}}(B_1)}\,. \tag{4.15}$$

Moreover, the constant c can be estimated as follows:

$$c = \fint_{B_1} c \le \fint_{B_1} |u|\,dx + \fint_{B_1} |u-c|\,dx \le \fint_{B_1} |u|\,dx + C\,[u]_{H^{\frac{1}{2}}(B_1)}\,,$$

and hence (4.14) follows by (4.15). By a scaling argument we obtain

$$\fint_{B_{\theta r}} |u|\,dx \le \fint_{B_r} |u|\,dx + \frac{C}{\sqrt{r}}[u]_{H^{\frac{1}{2}}(B_r)}$$

for every $r > 0$, $\theta \in [\frac{1}{2}, 1]$, and $u \in H^{\frac{1}{2}}(B_r)$. Finally, any $\rho < r$ can be written as $\rho = \theta 2^{-k} r$ for some $\theta \in (\frac{1}{2}, 1)$ and $k \in \mathbb{N} \cup \{0\}$, so that the conclusion follows by an iteration procedure, with a slightly modified constant C. □

Proof of (iii) *(lower bound).* Let u_ε be a sequence in $H^{\frac{1}{2}}(T^2)$, and assume that u_ε converges to u strongly in L^2. In order to prove the lower bound we may assume that $\liminf_\varepsilon F_\varepsilon(u_\varepsilon) = \lim_\varepsilon F_\varepsilon(u_\varepsilon) < +\infty$. Thus by (i) (compactness) we have that $u = a \in \mathbf{Z}$. Since the energy decreases under truncation we may assume that $0 \le u_\varepsilon \le a$.

Consider a lattice of squares Q_j^ε of size approximatively $1/\sqrt{N_\varepsilon}$. Let $\widehat{Q}_j^\varepsilon$ be concentric squares twice the size. Since each point is contained at most in nine of the squares $\widehat{Q}_j^\varepsilon$, we have

$$\sum_j \iint_{\widehat{Q}_j^\varepsilon \times \widehat{Q}_j^\varepsilon} \frac{|u_\varepsilon(x) - u_\varepsilon(y)|^2}{|x-y|^3}\,dx\,dy \le C N_\varepsilon \varepsilon$$

and

$$\sum_j \int_{\widehat{Q}_j^\varepsilon} |u_\varepsilon - a| dx \le \omega_\varepsilon\,,$$

where $\omega_\varepsilon \to 0$ as $\varepsilon \to 0$. Let $\theta > 0$. Then there exist a set of indices J^ε such that $\frac{1}{N_\varepsilon}\#(J^\varepsilon) \ge 1 - \theta$ and a constant C_θ such that

$$\iint_{\widehat{Q}_j^\varepsilon \times \widehat{Q}_j^\varepsilon} \frac{|u_\varepsilon(x) - u_\varepsilon(y)|^2}{|x-y|^3}\,dx\,dy \le C_\theta \varepsilon \tag{4.16}$$

and

$$\fint_{\widehat{Q}_j^\varepsilon} |u_\varepsilon - a| dx \le C_\theta \omega_\varepsilon \tag{4.17}$$

for all $j \in J^\varepsilon$. Let $0 < \delta < 1$. By applying Proposition 17 with $\rho = \varepsilon^\beta$, with $\frac{1}{2} < \beta < 1$, and $r = \frac{1}{\sqrt{N_\varepsilon}}$, for each $x_\varepsilon^i \in Q_j^\varepsilon$ we also have

$$\fint_{B^i_{\varepsilon^\beta}} |u_\varepsilon - a|^2 dx \le \delta \qquad \text{if } \varepsilon \le \varepsilon_0(\delta, \theta)\,. \tag{4.18}$$

Then by Lemma 16 and the assumption that $\operatorname{dist}(x_i^\varepsilon, x_j^\varepsilon) > 6\varepsilon^\beta$

$$F_\varepsilon(u_\varepsilon) \ge \frac{1}{N_\varepsilon}\left[\sum_{j\in J^\varepsilon} \#(I_\varepsilon(Q_j^\varepsilon))\right]\left(D_\nu^{\frac{1}{2}}(a, B_R) - \omega(\varepsilon,\delta)\right). \tag{4.19}$$

The uniform distribution of the obstacles (see condition (4.2)) implies that

$$\begin{aligned}\sum_{j\in J^\varepsilon} \#(I_\varepsilon(Q_j^\varepsilon)) &= N_\varepsilon - \sum_{j\notin J^\varepsilon} \#(I_\varepsilon(Q_j^\varepsilon)) \ge N_\varepsilon - \sum_{j\notin J^\varepsilon} (N_\varepsilon |Q_j^\varepsilon| + L)\\ &= N_\varepsilon - (L+1)\#(\{j:\ j\notin J^\varepsilon\})\,.\end{aligned}$$

Since $\#(\{j:\ j\notin J^\varepsilon\}) \le N_\varepsilon\theta$, we get

$$F_\varepsilon(u_\varepsilon) \ge (1-\theta(L+1))\left(D_\nu^{\frac{1}{2}}(a, B_R) - \omega(\varepsilon,\delta)\right),$$

and this yields the required lower bound taking the limit as $\varepsilon \to 0$; then $\delta \to 0$, and, finally, $\theta \to 0$. □

Appendix. Finite pinning condition. We can model the hardening mechanism due to obstacles such as secondary dislocations by assuming a weaker pinning condition given by a concentrated force. Namely, we assume that a crossing of an obstacle by a dislocation costs a finite amount of energy, i.e.,

$$\lambda_0 \int_{B^i_{R\varepsilon}} \varepsilon\psi_\varepsilon^i |u|\, dx\,,$$

where $\psi_\varepsilon^i(x) = \varepsilon^{-2}\psi(\frac{x-x_\varepsilon^i}{\varepsilon})$, with $\operatorname{supp}\psi \subseteq B_R(0)$ and $\int_{B_R}\psi\, dx = 1$, and $\lambda_0\varepsilon\psi_\varepsilon^i$ is the force concentrated on each obstacle B_ε^i. Then we can consider the following functional:

$$\widetilde{F}_\varepsilon(u) = \begin{cases} \dfrac{1}{\varepsilon}\displaystyle\int_{T^2} \operatorname{dist}^2(u, \mathbf{Z})\, dx \;+\; \iint_{T^2\times T^2} K_\nu(x-y)|u(x)-u(y)|^2\, dx\, dy \\ \qquad\qquad + \displaystyle\sum_i \lambda_0 \int_{B^i_{R\varepsilon}} \varepsilon\psi_\varepsilon^i |u|\, dx \\ \qquad\qquad\qquad\qquad \text{if } u \in H^{\frac{1}{2}}(T^2)\,, \\ +\infty \qquad\qquad\qquad\qquad \text{otherwise}\,. \end{cases} \tag{A.1}$$

With our scaling assumptions the total force due to the obstacles is finite and is given by

$$\sum_i \lambda_0 \int_{B^i_{R\varepsilon}} \varepsilon\psi_\varepsilon^i\, dx = N_\varepsilon\varepsilon\lambda_0 \approx \Lambda\lambda_0\,.$$

In order to study the Γ-limit of the functional $\widetilde{F}_\varepsilon$, another natural notion of capacity has to be defined, i.e.,

(A.2)
$$\widetilde{D}^\nu_{\frac12}(a,\lambda_0,\psi) := \inf\Bigg\{ \int_{\mathbf{R}^2} \operatorname{dist}^2(\zeta,\mathbf{Z})\,dx + \iint_{\mathbf{R}^2\times\mathbf{R}^2} \Gamma_\nu(x-y)|\zeta(x)-\zeta(y)|^2\,dx\,dy + \\ +\lambda_0 \int_{\mathbf{R}^2} \psi|\zeta|\,dx : \quad \zeta - a \in L^4(\mathbf{R}^2) \Bigg\}.$$

Again one can check that this is a Choquet capacity and satisfies

$$\widetilde{D}^\nu_{\frac12}(a,\lambda_0,\psi) \le D^\nu_{\frac12}(a,B_R)\,.$$

Moreover,

$$\lim_{\lambda_0\to\infty} \widetilde{D}^\nu_{\frac12}(a,\lambda_0,\psi) = D^\nu_{\frac12}(a,B_R)\,. \tag{A.3}$$

Indeed, $\widetilde{D}^\nu_{\frac12}(a,\lambda_0,\psi)$ is increasing in λ_0; thus the limit always exists. If $\widetilde{\zeta}_{\lambda_0}$ is a sequence of potentials for $\widetilde{D}^\nu_{\frac12}(a,\lambda_0,\psi)$, one can check that, up to a subsequence, it converges weakly in $H^{\frac12}$ to a function $\widetilde{\zeta}$ which is a good competitor for $D^\nu_{\frac12}(a,B_R)$.

Using this notion of capacity we can perform the same analysis as above and prove the following theorem.

THEOREM 18. *Assume that $N_\varepsilon \to +\infty$ and that the balls $B^i_{R_\varepsilon}$ are uniformly distributed, are well separated, and have finite capacity density. Denote by $\widetilde{F}$ the functional*

$$\widetilde{F}(u) = \begin{cases} \widetilde{D}^\nu_{\frac12}(u,\lambda_0\psi) & \text{if } u = \text{const.} \in \mathbf{Z}\,, \\ +\infty & \text{otherwise}\,. \end{cases} \tag{A.4}$$

Then

(i) *every sequence $\{u_\varepsilon\}$ such that $\sup_\varepsilon \widetilde{F}_\varepsilon(u_\varepsilon) < \infty$ is precompact in L^2, and every cluster point is an integer constant;*

(ii) *for every $u \in L^2(\mathbf{R}^2)$ there exists a sequence $\{u_\varepsilon\}$ strongly converging in L^2 to u such that*
$$\lim_{\varepsilon\to0} \widetilde{F}_\varepsilon(u_\varepsilon) = \widetilde{F}(u)\,;$$

(iii) *every sequence $\{u_\varepsilon\}$ strongly converging in L^2 to some function u satisfies*
$$\liminf_{\varepsilon\to0} \widetilde{F}_\varepsilon(u_\varepsilon) \ge \widetilde{F}(u)\,.$$

Remark 19. The new dislocation capacity for the weak pinning condition is linear for a big enough. In order to see this we can rewrite it for positive a as follows:

(A.5)
$$\widetilde{D}(a,\lambda_0,\psi) = \inf\Bigg\{ \int_{\mathbf{R}^2} \operatorname{dist}^2(w,\mathbf{Z})\,dx + \iint_{\mathbf{R}^2\times\mathbf{R}^2} \Gamma_\nu(x-y)|w(x)-w(y)|^2\,dx\,dy \\ +\ \lambda_0 \int_{\mathbf{R}^2} \psi(w+a)\,dx : \quad w \in L^4(\mathbf{R}^2) \text{ and } \quad -a \le w \le 0 \Bigg\}.$$

Then consider the following minimum problem:

(A.6)
$$D_0(\lambda_0,\psi) := \inf\Bigg\{\int_{\mathbf{R}^2} \operatorname{dist}^2(w,\mathbf{Z})\,dx + \iint_{\mathbf{R}^2\times\mathbf{R}^2} \Gamma_\nu(x-y)|w(x)-w(y)|^2\,dx\,dy + \lambda_0\int_{\mathbf{R}^2}\psi w\,dx : \quad w\in L^4(\mathbf{R}^2)\Bigg\},$$

and let w_0 be a minimum point. As in the proof of Proposition 8 one can prove that there exists an L^4 function f_0 such that

$$Lw_0 = f_0 - \frac{\lambda_0}{2}\psi$$

in the sense of distributions. Using the Green function G_ν of $L+I$ we show that w_0 is bounded. In fact,

$$w_0(x) = G_\nu * f_0(x) + G_\nu * w_0(x) - \frac{\lambda_0}{2}G_\nu * \psi(x),$$

and the conclusion follows by the Hölder inequality. Now let a_0 the smallest positive integer such that

$$w_0 \geq -a_0\,.$$

Clearly we have

$$\widetilde{D}(a,\lambda_0,\psi) = D_0(\lambda_0,\psi) + \lambda_0 a \qquad \forall a \geq a_0\,.$$

In particular, if we minimize our energy subject to an external force S, i.e.,

$$\min_{a\in\mathbf{Z}}\ \widetilde{F}(a) - a\int_{T^2} S\,dx\,,$$

then the minimum exists if and only if $|\int_{T^2} S\,dx| \leq \lambda_0$. If the force S is greater than the total resistance of the obstacles, then no equilibrium states exist.

Acknowledgment. We would like to thank M. Ortiz for bringing this problem to our attention and for many stimulating discussions.

QUASI-PERIODIC SOLUTIONS FOR 1D SCHRÖDINGER EQUATIONS WITH HIGHER ORDER NONLINEARITY*

ZHENGUO LIANG† AND JIANGONG YOU†

Abstract. In this paper, one-dimensional (1D) nonlinear Schrödinger equations

$$iu_t - u_{xx} + mu + \nu|u|^4u = 0,$$

with Dirichlet boundary conditions are considered. It is proved that for all real parameters m, the above equation admits small-amplitude quasi-periodic solutions corresponding to b-dimensional invariant tori of an associated infinite-dimensional dynamical system. The proof is based on infinite-dimensional KAM theory, partial normal form, and scaling skills.

Key words. quasi-periodic solutions, infinite-dimensional KAM theory, partial normal form

AMS subject classifications. 37K55, 35Q55

DOI. 10.1137/S0036141003435011

1. Introduction and main result. In this paper, we will prove that one-dimensional (1D) nonlinear Schrödinger equation

$$iu_t - u_{xx} + mu + \nu|u|^4u = 0 \tag{1.1}$$

subject to Dirichlet boundary conditions

$$u(0,t) = u(\pi,t) = 0, \tag{1.2}$$

admits small-amplitude quasi-periodic solutions for all m. Equation (1.1) with $m = 0$ and negative ν is called "focusing" while (1.1) with $m = 0$ and positive ν is called "defocusing." Under some initial-boundary conditions they have been considered by many authors (see [2, 3, 4, 11]). Throughout this paper, we suppose $\nu > 0$ in (1.1). As we will see later, the sign of ν is immaterial for our results.

We study the equation (1.1) as a Hamiltonian system on $\mathcal{P} = W_0^1([0,\pi])$, the Sobolev space of all complex valued L^2-functions on $[0,\pi]$ with an L^2-derivative and vanishing boundary values. Let

$$\phi_j(x) = \sqrt{\frac{2}{\pi}}\sin jx, \lambda_j = j^2 + m, j \geq 1$$

be the basic modes and their frequencies for the linear equation $iu_t = u_{xx} - mu$ with Dirichlet boundary conditions. Then every solution is the superposition of oscillations of the basic modes, with the coefficients moving on circles,

$$u(t,x) = \sum_{j\geq 1} q_j(t)\phi_j(x), q_j(t) = q_j^0 e^{i\lambda_j t}.$$

Together they move on a rotational torus of finite or infinite dimension, depending on how many modes are excited. In particular, for every choice

$$J = \{j_1 < j_2 < \cdots < j_b\} \subset \mathbb{N}$$

of b basic modes there is an invariant linear space E_J of complex dimension b which is completely foliated into rotational tori,

$$E_J = \{u = q_1\phi_{j_1} + \cdots + q_b\phi_{j_b} : q \in C^b\} = \bigcup_{I \in \overline{P^b}} \mathcal{T}_J(I),$$

where $P^b = \{I : I_j > 0 \text{ for } 1 \le j \le b\}$ and

$$\mathcal{T}_J(I) = \{u = q_1\phi_{j_1} + \cdots + q_b\phi_{j_b} : |q_j|^2 = 2I_j \text{ for} 1 \le j \le b\}.$$

In addition, each such torus is linearly stable and all solutions have vanishing Lyapunov exponents. This is the linear situation.

Upon restoration of the nonlinearity $\nu|u|^4u$, we show that there exists a Cantor set $\mathcal{C} \subset \mathcal{P}^b$, a specially chosen index set $\mathcal{I} = n_1 < n_2 < \cdots < n_b \subset \mathbb{N}$ (we will call it an admissible set, for more specific see section 3) and a family of b-tori

$$\mathcal{T}_{\mathcal{I}}[\mathcal{C}] = \cup_{I \in \mathcal{C}} \mathcal{T}_{\mathcal{I}}(I) \subset E_{\mathcal{I}}$$

over $\mathcal{C}$, and a Whitney smooth embedding

$$\Phi : \mathcal{T}_{\mathcal{I}}[\mathcal{C}] \hookrightarrow \mathcal{P},$$

such that the restriction of Φ to each $\mathcal{T}_{\mathcal{I}}(I)$ in the family is an embedding of a rotational b-torus for the nonlinear equation. In [10], The image $\mathcal{E}_{\mathcal{I}}$ of $\mathcal{T}_{\mathcal{I}}[\mathcal{C}]$ is called a Cantor manifold of rotational b-tori given by the embedding $\Phi : \mathcal{T}_{\mathcal{I}}[\mathcal{C}] \to \mathcal{E}_{\mathcal{I}}$.

THEOREM 1 (main theorem). *Consider the* 1*D nonlinear Schrödinger equation* (1.1) *with* (1.2). *Then for any admissible index set* $\mathcal{I} = \{n_1 < n_2 < \cdots < n_b\} \subset \mathbb{N}$ *and* $m \in R$, *there exists a positive-measure Cantor manifold* $\mathcal{E}_{\mathcal{I}}$ *of real analytic, linearly stable, Diophantine b-tori for the nonlinear Schrödinger equation given by a Whitney smooth embedding* $\Phi : \mathcal{T}_{\mathcal{I}}[\mathcal{C}] \to \mathcal{E}_{\mathcal{I}}$, *which is a higher order perturbation of the inclusion map* $\Phi_0 : E_{\mathcal{I}} \hookrightarrow \mathcal{P}$ *restricted to* $\mathcal{T}_{\mathcal{I}}[\mathcal{C}]$.

Remark 1. The existence of admissible sets will be proved in the appendix. In fact there exist infinite admissible index sets $\mathcal{I}$.

Remark 2. The result remains true for more general nonlinearities $f(|u|^2)u$, where $f(0) = f'(0) = 0, f''(0) \neq 0$. Our method essentially applies to the nonlinearities $f(|u|^2)u$, where $f(0) = f^{(1)}(0) = \cdots = f^{(k-1)}(0), f^{(k)}(0) \neq 0, k \ge 1$, but the proof would be much more complicated.

Remark 3. The frequencies of the diophantine tori are also under control. They are $\omega(I) = (\lambda_{n_1}, \lambda_{n_2}, \ldots, \lambda_{n_b}) + \frac{1}{\pi^2}(10I_1^2 + 18I_2^2 + \cdots + 18I_b^2 + 36I_1(I_2 + \cdots + I_b) + 48(I_2I_3 + \cdots + I_{b-1}I_b), \ldots, 18I_1^2 + \cdots + 18I_{b-1}^2 + 10I_b^2 + 36I_b(I_1 + \cdots + I_{b-1}) + 48(I_1I_2 + \cdots + I_{b-2}I_{b-1})) + O(||I||^{\frac{13}{6}})$.

Remark 4. The technique of this paper is not restricted to the nonlinear Schrodinger equation. It applies equally well to the nonlinear 1D beam equations

$$u_{tt} + u_{xxxx} = f(u)$$

with hinged boundary conditions, where f is a real analytic, odd function of u of the form $f(u) = au^3 + \sum_{k \ge 5} f_k u^k,\ a \neq 0$. Our result is an improvement on [6]. Details

will be given in another paper. Unfortunately, our technique can't be applied to the complete resonant 1D wave equation

$$u_{tt} + u_{xx} = u^3 \tag{1.3}$$

with Dirichlet boundary conditions. From the proof, one sees that that superlinear growth of the eigenvalues $\lambda_j \sim j^2$ is crucial. For (1.3), the admissible set does not exist and one can't obtain the desired partial Birkhoff normal form by eliminating all the unpleasant terms, which include 2 or 3 tangential coordinates.

The rest of the paper is organized as follows. In section 2 the Hamiltonian function is written in infinitely many coordinates, which is then put into partial normal form in section 3. In section 4 we improve an infinite dimensional KAM theorem, which is developed by many people (see Kuksin [7, 8, 9], Wayne [16], Pöschel [13], Chierchia and You [5]). Measure estimates are given in section 5. Some propositions are proved in the appendix.

2. The Hamiltonian. For simplicity, we choose $\nu = 1$. Other cases can be rescaled into this case. The Hamiltonian of the nonlinear Schrödinger equation is

$$H = \frac{1}{2}\langle Au, u\rangle + \frac{1}{6}\int_0^\pi |u|^6 dx, \tag{2.1}$$

where $A = -d^2/dx^2 + m$. We rewrite H as a Hamiltonian in infinitely many coordinates by making the ansatz

$$u(x) = \sum_{j\geq 1} q_j \phi_j, \quad \phi_j = \sqrt{\frac{2}{\pi}}\sin jx, \quad j \geq 1.$$

The coordinates are taken from the Hilbert spaces $\mathcal{H}^{a,\rho}$ of all complex-valued sequences $q = (q_1, q_2, \ldots)$ with

$$\|q\|^2_{a,\rho} = \sum_{j\geq 1} |q_j|^2 j^{2a} e^{2j\rho} < \infty.$$

Fix $\rho > 0$ and $a \geq 0$ later. One then obtains the Hamiltonian

$$H = \Lambda + G = \frac{1}{2}\sum_{j\geq 1} \lambda_j |q_j|^2 + \frac{1}{6}\int_0^\pi |u|^6 dx \tag{2.2}$$

on the phase space $\mathcal{H}^{a,\rho}$ with symplectic structure $\frac{i}{2}\sum_j dq_j \wedge d\bar{q}_j$. Its equations of motion are

$$\dot{q}_j = 2i\frac{\partial H}{\partial \bar{q}_j}, \quad j \geq 1. \tag{2.3}$$

They are the classical Hamiltonian equations of motion for the real and imaginary parts of $q_j = x_j + iy_j$ written in complex notation. Rather than discussing the above formal validity, we shall, following [10] or [5], use the following elementary observation.

LEMMA 1. *Let I be an interval and let*

$$t \in I \to q(t) \equiv (\{q_j(t)\}_{j\geq 1})$$

be an analytic solution of (2.3) *such that*

$$\sup_{t\in I}\sum_{j\geq 1}|q_j(t)|^2 j^{2a}e^{2j\rho}<\infty \tag{2.4}$$

for some $\rho>0$ *and* $a\geq 0$. *Then*

$$u(t,x)\equiv\sum_{j\geq 1}q_j(t)\phi_j(x),$$

is an analytic solution of (1.1).

For the proof, refer to Lemma 1 in [10].

Next, we consider the regularity of the gradient of G. To this end, let $\mathcal{H}_b^2$ and L^2, respectively, be the Hilbert spaces of all bi-infinite, square summable sequences with complex coefficients and all square-integrable complex valued functions on $[-\pi,\pi]$. Let

$$\mathcal{F}:\mathcal{H}_b^2\to L^2,\quad q\mapsto \mathcal{F}q=\frac{1}{\sqrt{2\pi}}\sum_j q_j e^{\mathrm{i}jx}$$

be the inverse discrete Fourier transform, which defines an isometry between the two spaces. The subspaces $\mathcal{H}_b^{a,\rho}\subset\mathcal{H}_b^2$ consist, by definition, of all bi-infinite sequences with finite norm

$$\|q\|_{a,\rho}^2=|q_0|^2+\sum_j|q_j|^2|j|^{2a}e^{2|j|\rho}.$$

Through $\mathcal{F}$ they define subspaces $W^{a,\rho}\subset L^2$ that are normed by setting $\|\mathcal{F}q\|_{a,\rho}=\|q\|_{a,\rho}$.

LEMMA 2. *For* $a>\frac{1}{2}$ *and* $\rho\geq 0$, *the space* $\mathcal{H}_b^{a,\rho}$ *is a Hilbert algebra with respect to convolution of sequences, and*

$$\|q*p\|_{a,\rho}\leq c\|q\|_{a,\rho}\|p\|_{a,\rho}$$

with a constant c *depending only on* a. *Consequently,* $W^{a,\rho}$ *is a Hilbert algebra with respect to a multiplication of functions.*

For the proof, see [10].

LEMMA 3. *For* $a>\frac{1}{2}$ *and* $\rho\geq 0$, *the gradient* G_q *is real analytic as a map from some neighborhood of the origin in* $\mathcal{H}^{a,\rho}$ *into* $\mathcal{H}^{a,\rho}$, *with*

$$\|G_q\|_{a,\rho}=O(\|q\|_{a,\rho}^5).$$

The proof is similar with Lemma 3 in [10], which we omit.

By the elementary computation, one can get

$$\begin{aligned}G&=\frac{1}{6}\int_0^\pi|u(x)|^6\,dx\\&=\frac{1}{6}\sum_{i,j,k,l,m,n}G_{ijklmn}q_iq_jq_k\bar{q}_l\bar{q}_m\bar{q}_n\end{aligned}$$

with

$$G_{ijklmn}=\int_0^\pi\phi_i\phi_j\phi_k\phi_l\phi_m\phi_n\,dx. \tag{2.5}$$

It is not difficult to verify that $G_{ijklmn} = 0$ unless $i \pm j \pm k \pm l \pm m \pm n = 0$, for some combination of plus and minus signs. For simplicity, we denote $G_{ijk} = G_{iijjkk}, G_i = G_{iiiiii}$. If we choose $n_1, n_2, \ldots, n_b$ satisfying

$$n_i \neq n_j + n_k, \ \forall i, j, k \in \{1, 2, \ldots, b\}, \tag{2.6}$$

one can get

$$G_{n_1} = \cdots = G_{n_b} = \frac{5}{2\pi^2}, \quad G_{n_i n_j n_j} = \frac{3}{2\pi^2}, \quad G_{n_i n_j n_k} = \frac{1}{\pi^2}$$

and

$$G_{n_i n_j l} = \frac{1}{4\pi^2}(4 - \delta^{n_j}_{n_i+l} - \delta^{n_i}_{n_j+l} - \delta^{l}_{n_i+n_j}), \quad G_{n_i n_i l} = \frac{1}{4\pi^2}(6 - \delta^{2n_i}_{l}),$$

where $i \neq j, \ j \neq k, \ k \neq i, \ i, j, k \in \{1, 2, \ldots, b\}, \ l \notin \{n_1, n_2, \ldots, n_b\}$, and for $v \in \mathbb{Z}$

$$\delta^v_i = \begin{cases} 1, & i = v, \\ 0, & \text{otherwise.} \end{cases}$$

3. Partial Birkhoff normal form. We shall use the KAM iteration to get the desired result. Since the quadratic part of the Hamiltonian

$$H = \Lambda + G = \frac{1}{2}\sum_{j\geq 1} \lambda_j |q_j|^2 + \frac{1}{6} \sum_{i\pm j\pm k\pm l\pm m\pm n=0} G_{ijklmn} q_i q_j q_k \bar{q}_l \bar{q}_m \bar{q}_n$$

does not provide any "twist" required by KAM theory, we shall use the normal form technique to get the "twisted" integrable terms from the sixth order terms. To get finite dimensional KAM tori, we shall first fix finite many sites $\{n_1, n_2, \ldots, n_b\}$, and call $q = (q_{n_1}, \ldots, q_{n_b})$ tangential variables. All the other variables, denoted by w, are called normal variables. For our purpose, the sixth order terms with at most two normal variables

$$q_i q_j q_k q_l \bar{q}_m \bar{q}_n, \qquad q_i q_j q_k \bar{q}_l q_m w_n, \qquad q_i q_j q_k q_l w_m w_n$$

must be put into normal form, i.e., the terms that remain after normal form procedure must have the form of $|q_i|^2|q_j|^2|q_k|^2$ or $|q_i|^2|q_j|^2|w_k|^2$. The other sixth order terms are left since they can be scaled into higher perturbations. Such kind of normal form is called a partial Birkhoff normal form since we don't normalize all sixth order terms. In order to get the desired partial Birkhoff normal form, we have to carefully choose $\{n_1, n_2, \ldots, n_b\}$.

For fixed $\{n_1, n_2, \ldots, n_b\}$, we define the index sets $\Delta_*, * = 0, 1, 2$ and Δ_3 in the following way: Δ_* is the set of index (i, j, k, l, m, n) such that there exist right $*$ components not in $\{n_1, n_2, \ldots, n_b\}$. Δ_3 is the set of the index (i, j, k, l, m, n) such that there exist at least three components not in $\{n_1, n_2, \ldots, n_b\}$. Define the resonance sets $\mathcal{N} = \{(i, j, k, i, j, k)\} \cap \Delta_2$ and $\mathcal{M} = \{(i, j, k, i, j, k)\} \cap \Delta_2$. For our convenience, rewrite $G = G^0 + G^1 + G^2 + \hat{G}$, where

$$G^* = \frac{1}{6} \sum_{i\pm j\pm k\pm l\pm m\pm n=0, (i,j,k,l,m,n)\in\Delta_*} G_{ijklmn} q_i q_j q_k \bar{q}_l \bar{q}_m \bar{q}_n, \tag{3.1}$$

and $* = 0, 1, 2$.

DEFINITION 1. *The index set* $\mathcal{I} = \{n_1 < n_2 < \cdots < n_b\}$ *is said to be admissible if and only if* $n_1, n_2, \ldots, n_b$ *satisfy the following Assumptions* A, B, C *and* (2.6).

A. If $i \pm j \pm k \pm l \pm m \pm n = 0, (i, j, k, l, m, n) \in \Delta_0 \setminus \mathcal{N}$, *then*

$$\lambda_i + \lambda_j + \lambda_k - \lambda_l - \lambda_m - \lambda_n \neq 0.$$

B. If $i \pm j \pm k \pm l \pm m \pm n = 0, (i, j, k, l, m, n) \in \Delta_1$, *then*

$$\lambda_i + \lambda_j + \lambda_k - \lambda_l - \lambda_m - \lambda_n \neq 0.$$

C. If $i \pm j \pm k \pm l \pm m \pm n = 0, (i, j, k, l, m, n) \in \Delta_2 \setminus \mathcal{M}$, *then*

$$\lambda_i + \lambda_j + \lambda_k - \lambda_l - \lambda_m - \lambda_n \neq 0.$$

PROPOSITION 1. *There exist infinite many admissible index sets.*

When $b = 2$, we can construct some of the admissible index sets clearly. Denote

$$\mathcal{S} = \{n_1 \leq n_2 | n_1 \equiv 5 \text{ or } 9 (\mathrm{mod} 14),\ n_2 \equiv 8 (\mathrm{mod} 14), n_2 \geq 11 n_1^2\}.$$

PROPOSITION 2. *If* $b = 2$, *any element in* $\mathcal{S}$ *is the admissible index set.*

The proofs of Propositions 1 and 2 are given in the appendix.

Next we transform the Hamiltonian (2.2) into the partial Birkhoff form of order six so that the infinite KAM Theorem (see section 4) can be applied.

LEMMA 4. *For any given admissible index set* $\{n_1 < n_2 < \cdots < n_b\}$, *there exists a real analytic, symplectic change of coordinates* X_F^1 *in some neighborhood of the origin that takes the Hamiltonian* $H = \Lambda + G$ *into*

$$H \circ X_F^1 = \Lambda + \overline{G} + \hat{G} + K,$$

where $X_{\overline{G}}, X_{\hat{G}}$ *and* X_K *are real analytic vector fields in a neighborhood of the origin in* $\mathcal{H}^{a,\rho}$,

$$\begin{aligned}
\overline{G} = {} & \frac{5}{12\pi^2}(|q_{n_1}|^6 + \cdots + |q_{n_b}|^6) \\
& + \frac{9}{4\pi^2}(|q_{n_1}|^4 |q_{n_2}|^2 + \cdots + |q_{n_1}|^4 |q_{n_b}|^2 \\
& + |q_{n_2}|^4 |q_{n_1}|^2 + |q_{n_2}|^4 |q_{n_3}|^2 + \cdots + |q_{n_2}|^4 |q_{n_b}|^2 + \cdots + |q_{n_b}|^4 |q_{n_{b-1}}|^2) \\
& + \frac{6}{\pi^2}(|q_{n_1}|^2 |q_{n_2}|^2 |q_{n_3}|^2 + \cdots + |q_{n_{b-2}}|^2 |q_{n_{b-1}}|^2 |q_{n_b}|^2) \\
& + \frac{3}{2}\left(\sum_{i \neq n_1, n_2, \ldots, n_b} G_{n_1 n_1 i} |q_{n_1}|^4 |q_i|^2 + \cdots + \sum_{i \neq n_1, n_2, \ldots, n_b} G_{n_b n_b i} |q_{n_b}|^4 |q_i|^2\right) \\
& + 6\left(\sum_{i \neq n_1, n_2, \ldots, n_b} G_{n_1 n_2 i} |q_{n_1}|^2 |q_{n_2}|^2 |q_i|^2 + \ldots + \sum_{i \neq n_1, n_2, \ldots, n_b} G_{n_{b-1} n_b i} |q_{n_{b-1}}|^2 |q_{n_b}|^2 |q_i|^2\right),
\end{aligned}$$

$|K| = O(||q||_{a,\rho}^8)$ *and* $\hat{G} = \frac{1}{6} \sum_{i \pm j \pm k \pm l \pm m \pm n = 0, (i,j,k,l,m,n) \in \Delta_3} G_{ijklmn} q_i q_j q_k \bar{q}_l \bar{q}_m \bar{q}_n$.

Proof. Let $\Gamma = X_F^t|_{t=1}$ be the time 1-map of the flow of the Hamiltonian vector field X_F given by the Hamiltonian

$$\begin{aligned} F &= F^0 + F^1 + F^2 \\ &= \frac{1}{6}\Bigg\{ \sum_{i,j,k,l,m,n} F^0_{ijklmn} q_i q_j q_k \bar{q}_l \bar{q}_m \bar{q}_n \\ &\quad + \sum_{i,j,k,l,m,n} F^1_{ijklmn} q_i q_j q_k \bar{q}_l \bar{q}_m \bar{q}_n \\ &\quad + \sum_{i,j,k,l,m,n} F^2_{ijklmn} q_i q_j q_k \bar{q}_l \bar{q}_m \bar{q}_n \Bigg\} \end{aligned}$$

with coefficients

$$\mathrm{i}F^0_{ijklmn} = \begin{cases} \frac{G_{ijklmn}}{\lambda_i+\lambda_j+\lambda_k-\lambda_l-\lambda_m-\lambda_n} & i \pm j \pm k \pm l \pm m \pm n = 0, (i,j,k,l,m,n) \in \Delta_0 \setminus \mathcal{N}, \\ 0 & otherwise, \end{cases}$$

$$\mathrm{i}F^1_{ijklmn} = \begin{cases} \frac{G_{ijklmn}}{\lambda_i+\lambda_j+\lambda_k-\lambda_l-\lambda_m-\lambda_n} & i \pm j \pm k \pm l \pm m \pm n = 0, (i,j,k,l,m,n) \in \Delta_1, \\ 0 & otherwise, \end{cases}$$

$$\mathrm{i}F^2_{ijklmn} = \begin{cases} \frac{G_{ijklmn}}{\lambda_i+\lambda_j+\lambda_k-\lambda_l-\lambda_m-\lambda_n} & i \pm j \pm k \pm l \pm m \pm n = 0, (i,j,k,l,m,n) \in \Delta_2 \setminus \mathcal{M}, \\ 0 & otherwise. \end{cases}$$

Note our Assumptions A, B, C, the remained proof is just a copy of Lemma 4 of [10]. □

Now our Hamiltonian is $H = \Lambda + \overline{G} + \hat{G} + K$. Introduce the symplectic polar and complex coordinates by setting

$$q_j = \begin{cases} \sqrt{2(\xi_j + y_j)} e^{-\mathrm{i}x_j}, & j = n_1, n_2, \ldots, n_b \\ \sqrt{2} z_j, & j \neq n_1, n_2, \ldots, n_b \end{cases}$$

depending on parameters $\xi \in \Pi = [0,1]^b$. The precise domain will be specified later. In order to simplify the expression, we substitute $\xi_{n_j}, j = 1, 2, \ldots, b$ by $\xi_j, j = 1, 2, \ldots, b$. Then one gets

$$\frac{i}{2} \sum_{j \geq 1} dq_j \wedge d\bar{q}_j = \sum_{j = n_1, n_2, \ldots, n_b} dx_j \wedge dy_j + i \sum_{j \neq n_1, n_2, \ldots, n_b} dz_j \wedge d\bar{z}_j.$$

The new Hamiltonian

$$H = \Lambda + \overline{G} + \hat{G} + K = \langle \omega(\xi), y \rangle + \langle \Omega(\xi) z, \bar{z} \rangle + \tilde{G} + \hat{G} + K$$

with frequencies $\omega(\xi) = \alpha' + A(\xi)$, $\Omega(\xi) = \beta' + B(\xi)$, where

$$\alpha' = (\lambda_{n_1}, \lambda_{n_2}, \ldots, \lambda_{n_b}), \beta' = (\lambda_i)_{i \neq n_1, \ldots, n_b},$$

$$\begin{aligned} A(\xi) = \frac{1}{\pi^2} (&10\xi_1^2 + 18\xi_2^2 + \cdots + 18\xi_b^2 + 36\xi_1(\xi_2 + \cdots + \xi_b) + 48(\xi_2\xi_3 + \cdots + \xi_{b-1}\xi_b), \ldots, \\ &18\xi_1^2 + \cdots + 18\xi_{b-1}^2 + 10\xi_b^2 + 36\xi_b(\xi_1 + \cdots + \xi_{b-1}) + 48(\xi_1\xi_2 + \cdots + \xi_{b-2}\xi_{b-1})), \end{aligned}$$

$$B(\xi) = (12G_{n_1 n_1 i}\xi_1^2 + \cdots + 12G_{n_b n_b i}\xi_b^2 + 48G_{n_1 n_2 i}\xi_1\xi_2 + \cdots + 48G_{n_{b-1} n_b i}\xi_{b-1}\xi_b)_{i \neq n_1, \ldots, n_b},$$

and the remainder $\tilde{G} = O(|y|^3) + O(|\xi||y|^2) + O(|\xi||y||z|^2_{a,\rho}) + O(|y|^2|z|^2_{a,\rho}), \hat{G} = O(|\xi|^{\frac{3}{2}}|z|^3_{a,\rho}), K = O(|\xi|^4)$. Rescaling ξ by $\epsilon^6\xi$,$z, \bar{z}$ by $\epsilon^4 z, \epsilon^4\bar{z}$, and y by $\epsilon^8 y$, one obtains a Hamiltonian given by the rescaled Hamiltonian

$$\begin{aligned}\tilde{H}(x, y, z, \bar{z}, \xi) &= \epsilon^{-20} H(x, \epsilon^8 y, \epsilon^4 z, \epsilon^4\bar{z}, \epsilon^6\xi, \epsilon)\\ &= \langle\tilde{\omega}(\xi), y\rangle + \langle\tilde{\Omega}(\xi)z, \bar{z}\rangle + \epsilon\tilde{P}(x, y, z, \bar{z}, \xi, \epsilon),\end{aligned}$$

where $\tilde{\omega}(\xi) = \epsilon^{-12}\alpha' + A(\xi),\ \tilde{\Omega} = \epsilon^{-12}\beta' + B(\xi),\ \xi \in [1, 2]^b$. For simplicity, we rewrite $\tilde{H}$ by H, $\tilde{\omega}$ by ω, $\tilde{\Omega}$ by Ω, and $\tilde{P}$ by P.

In what follows, we use the KAM iteration which involves infinite many steps of coordinate transformations to prove the existence of the KAM tori. To make this quantitative we introduce the following notations and spaces.

Define

$$D(r, s) = \{(x, y, z, \bar{z}) : |Imx| < s, |y| < r^2, ||z||_{a,\rho} < r, ||\bar{z}||_{a,\rho} < r\}$$

a complex neighborhood of $\mathbb{T}^b \times \{y = 0\} \times \{z = 0\} \times \{\bar{z} = 0\}$, where $|\cdot|$ denotes the sup-norm for complex vectors. For a p ($p \geq 1$) order Whitney smooth function $F(\xi)$, define

$$\begin{aligned}||F||^* &= \max\left\{\sup_{\xi\in\Pi}|F|, \ldots, \sup_{\xi\in\Pi}\left|\frac{\partial^p F}{\partial\xi^p}\right|\right\},\\ ||F||_* &= \max\left\{\sup_{\xi\in\Pi}\left|\frac{\partial F}{\partial\xi}\right|, \ldots, \sup_{\xi\in\Pi}\left|\frac{\partial^p F}{\partial\xi^p}\right|\right\}.\end{aligned}$$

If $F(\xi)$ is a vector function from ξ to $\mathcal{H}^{a,\rho}(R^n)$ which is p order Whitney smooth on ξ, define $||F||^*_{a,\rho} = ||(||F_i(\xi)||^*)_i||_{a,\rho}(||F||^*_{R^n} = \max_i(||F_i(\xi)||^*))$. If $F(\eta, \xi)$ is a vector function from $D \times \Pi$ to $\mathcal{H}^{a,\rho}$, define $||F||^*_{a,\rho,D} = \sup_{\eta\in D}||F||^*_{a,\rho}$. We usually omit D for brevity. For functions F, associate a Hamiltonian vector field defined as $X_F = \{F_y, -F_x, iF_{\bar{z}}, -iF_z\}$. Denote the weighted norm for X_F by letting

$$|X_F|^*_{r,D(r,s)} = ||F_y||^* + \frac{1}{r^2}||F_x||^* + \frac{1}{r}\|F_z\|^*_{a,\rho} + \frac{1}{r}\|F_{\bar{z}}\|^*_{a,\rho}.$$

4. An infinite dimensional KAM theorem. Theorem 1 is a direct result of Theorem 2 and measures estimates in section 5. Consider small perturbations of an infinite dimensional Hamiltonian in the parameter dependent normal form

$$N = \langle\omega(\xi), y\rangle + \langle\Omega(\xi)z, \bar{z}\rangle$$

on a phase space

$$\mathcal{P}^{a,\rho} = \mathbb{T}^n \times \mathbb{R}^n \times \mathcal{H}^{a,\rho} \times \mathcal{H}^{a,\rho} \ni (x, y, z, \bar{z}),$$

where

$$\omega_j = \frac{j^d + \cdots}{\epsilon^t} + O(\xi^p)^1, \quad \Omega_j = \frac{j^d + \cdots}{\epsilon^t} + O(\xi^p),$$

$t, p \in \mathbb{N}, \rho > 0, a \geq 0$. Suppose that $||\omega||_* \leq M_1, ||\Omega_j||_* \leq M_2, M_1 + M_2 \geq 1$. Define $M = (M_1 + M_2)^p$. The parameter set Π is $[1, 2]^n$.

[1] $O(\xi^p)$ means pth order terms in $\xi_1, \ldots, \xi_b$

For the Hamiltonian $H = N + P$, there exists n-dimensional, linearly stable torus $\mathcal{T}_0^n = \mathbb{T}^n \times \{0,0,0\}$ with frequencies $\omega(\xi)$ when $P = 0$. Our aim is to prove the persistence of a large portion of this family of linearly stable rotational tori under small perturbations. Suppose that the perturbation P is real analytic in the space variables, C^p in ξ, and for each $\xi \in \Pi$ its Hamiltonian vector field $X_P = (P_y, -P_x, iP_{\bar{z}}, -iP_z)^T$ defines near $\mathcal{T}_0^n$ a real analytic map $X_P : \mathcal{P}^{a,\rho} \to \mathcal{P}^{a,\rho}$. Under the previous assumptions, we have the following theorem.

THEOREM 2. *Suppose that $H = N + P$ satisfies*

$$|X_P|^*_{r,D(s,r)} \le \gamma s^{2(1+\mu)}, \tag{4.1}$$

where γ depends on n, p, τ and M, $\mu = (p+1)\tau + p + \frac{n}{2}$. Then there exists a Cantor set $\Pi_\epsilon \subset \Pi$, a Whitney smooth family of torus embeddings $\Phi : \mathbb{T}^n \times \Pi_\epsilon \to \mathcal{P}^{a,\rho}$, and a Whitney smooth map $\omega_* : \Pi_\epsilon \to \mathbb{R}^n$, such that for each $\xi \in \Pi_\epsilon$, the map Φ restricted to $\mathbb{T}^n \times \{\xi\}$ is a real analytic embedding of a rotational torus with frequencies $\omega_*(\xi)$ for the Hamiltonian H at ξ.

Each embedding is real analytic on $|\mathrm{Im} x| < \frac{s}{2}$, and

$$\|\Phi - \Phi_0\|^*_r \le c\epsilon^{\frac{1}{2}},$$
$$||\omega_* - \omega||^* \le c\epsilon,$$

uniformly on that domain and Π_ϵ, where Φ_0 is the trivial embedding $\mathbb{T}^n \times \Pi \to \mathcal{T}_0^n$. Moreover, there exist Whitney smooth maps ω_m and Ω_m on Π for $m \ge 1$ satisfying $\omega_1 = \omega$, $\Omega_1 = \Omega$ and

$$||\omega_m - \omega||^* \le c\epsilon, \tag{4.2}$$

$$\|\Omega_m - \Omega\|^* \le c\epsilon. \tag{4.3}$$

Remark. Note that in the theorem, we didn't claim that the measure of Π_ϵ is positive. For positive measure, one needs further information of the frequencies $\omega(\xi)$ and $\Omega(\xi)$. We shall come back to this point in section 5.

Since the proof of Theorem 2 is essentially standard, we only state the main step of KAM iteration. The more detailed steps can be found in [13] and other papers.

4.1. Solving the linearized equations and KAM step. At each step of KAM iteration, the symplectic coordinate change Φ is obtained as the time 1-map $X_F^t|_{t=1}$ of the flow of Hamiltonian vector field X_F. Its generating function F and some normal correction $\hat{N}$ to the given normal form N are solutions of the linear equation

$$\{F, N\} + \hat{N} = R, \tag{4.4}$$

where

$$R = \sum_{2m+|q+\bar{q}|\le 2} R_{km q\bar{q}} y^m z^q \bar{z}^{\bar{q}} e^{i\langle k,x\rangle}, R_{km q\bar{q}} = P_{km q\bar{q}},$$

and the coefficients $R_{km q\bar{q}}$ depend on ξ such that $X_R : P^{a,\rho} \to P^{a,\rho}$ is real analytic and Whitney smooth in ξ. Below we solve the linear equation and estimate the generating function F.

LEMMA 5. *Suppose that uniformly on* $\Pi_+ \subset \Pi$,

$$|\langle k,\omega\rangle| \geq \frac{\epsilon^\beta}{A_k} \text{ for } k \neq 0, \tag{4.5}$$

$$|\langle k,\omega\rangle + \Omega_i| \geq \frac{\epsilon^\beta}{A_k}, \tag{4.6}$$

$$|\langle k,\omega\rangle + \Omega_i + \Omega_j| \geq \frac{\epsilon^\beta(|i-j|+1)}{A_k}, \tag{4.7}$$

$$|\langle k,\omega\rangle + \Omega_i - \Omega_j| \geq \frac{\epsilon^\beta(|i-j|+1)}{A_k}, i \neq j. \tag{4.8}$$

Then the linear equation has solution F *and* $\hat{N}$, *which satisfy* $[F] = 0$, $[\hat{N}] = \hat{N}$. *Moreover,*

$$|X_{\hat{N}}|^*_{r,D(s,r)} \leq |X_R|^*_{r,D(s,r)}, |X_F|^*_{r,D(s-\sigma,r)} \leq \frac{cM}{\epsilon^{(p+1)\beta}\sigma^\mu}|X_R|^*_{r,D(s,r)}, \tag{4.9}$$

where $A_k = 1 + |k|^\tau$, β *will be denoted later.*

For the proof, refer to [13].

LEMMA 6. *If* $|X_F|^*_{r,D(s-\sigma,r)} \leq \sigma$, *then for any* $\xi \in \Pi_+$, *the flow* $X_F^t(\cdot,\xi)$ *exists on* $D(s-2\sigma,\frac{r}{2})$ *for* $|t| \leq 1$ *and maps* $D(s-2\sigma,\frac{r}{2})$ *into* $D(s-\sigma,r)$. *Moreover, for* $|t| \leq 1$,

$$|X_F^t - id|^*_{r,D(s-2\sigma,\frac{r}{2})}, \sigma||DX_F^t - Id||^*_{r,r,D(s-3\sigma,\frac{r}{4})} \leq c|X_F|^*_{r,D(s-\sigma,r)},$$

where D *is the differentiation operator with respect to* $(x,y,z,\bar{z})$, id *and* Id *are identity mapping and unit matrix, and the operator norm*

$$||A(\xi,\eta)||_{\bar{r},r,D(s,r)} = \sup_{\eta\in D(s,r)}\sup_{w\neq 0}\frac{||A(\xi,\eta)w||_{a,\bar{r}}}{||w||_{a,r}},$$

$$||A||^*_{r,r} = \max\left\{||A||_{r,r}, \ldots, \left|\left|\frac{\partial^p A}{\partial\xi^p}\right|\right|_{r,r}\right\}.$$

For the proof, see [14].

Below we consider the new perturbation under the sympletic transformation $\Phi = X_F^t|_{t=1}$. Let $|X_P|^*_{r,D(s,r)} \leq \epsilon$. From the above we have

$$R = \sum_{2|m|+|q+\bar{q}|\leq 2} R_{kmq\bar{q}} y^m z^q \bar{z}^{\bar{q}} e^{i\langle k,x\rangle}.$$

Thus $|X_R|^*_{r,D(s,r)} \leq \cdot|X_P|^*_{r,D(s,r)} \leq \cdot\epsilon$, and for $\eta \leq \frac{1}{8}$,

$$|X_{P-R}|^*_{\eta r,D(s,4\eta r)} \leq \cdot\eta|X_P|^*_{r,D(s,r)} \leq \cdot\eta\epsilon. \tag{4.10}$$

Since

$$\hat{N} = \sum_{2|m|+|q+\bar{q}|\leq 2, q=\bar{q}} P_{0mq\bar{q}} y^m z^q \bar{z}^{\bar{q}} e^{i\langle k,x\rangle},$$

the new normal form is

$$N_+ = N + \hat{N} = \langle \omega_+, y\rangle + \langle \Omega_+ z, \bar{z}\rangle.$$

By Lemma 5, one has $|X_{\hat{N}}|^*_{r,D(s,r)} \leq \cdot\epsilon$. Therefore,

$$||\omega_+ - \omega||^*, ||\Omega_+ - \Omega||^* \leq \cdot\epsilon, \tag{4.11}$$

where $||\Omega||^* = \max_{j\geq 1} ||\Omega_j||^*$. If $\frac{cM\epsilon^{1-\beta(p+1)}}{\sigma^{\mu+1}} \leq 1$, by Lemmas 5 and 6, it follows that for $|t| \leq 1$,

$$\frac{1}{\sigma}|X_F^t - id|^*_{r,D(s-2\sigma,\frac{r}{2})}, ||DX_F^t - Id||^*_{r,r,D(s-3\sigma,\frac{r}{4})} \leq \frac{cM\epsilon^{1-(p+1)\beta}}{\sigma^{\mu+1}}. \tag{4.12}$$

Under the transformation $\Phi = X_F^1$, $(N+R)\circ\Phi = N_+ + R_+$, where $R_+ = \int_0^1 \{(1-t)\hat{N} + tR, F\}\circ X_F^t$. Thus, $H\circ\Phi = N_+ + R_+ + (P-R)\circ\Phi = N_+ + P_+$, where the new perturbation

$$P_+ = R_+ + (P-R)\circ\Phi = (P-R)\circ\Phi + \int_0^1 \{\bar{R}(t), F\}\circ X_F^t dt,$$

where $\bar{R}(t) = (1-t)\hat{N} + tR$. Hence, the Hamiltonian vector field of the new perturbation is

$$X_{P_+} = (X_F^1)^*(X_{P-R}) + \int_0^1 (X_F^t)^*[X_{\bar{R}(t)}, X_F]dt.$$

For the estimate of X_{P_+}, we need the following lemma.

LEMMA 7. *If the Hamiltonian vector field $W(\cdot,\xi)$ on $V = D(s-4\sigma, 2\eta r)$ depends on the parameter $\xi \in \Pi_+$ with $||W||^*_{r,V} < +\infty$, and $\Phi = X_F^t : U = D(s-5\sigma,\eta r) \to V$, then $\Phi^* W = (D\Phi)^{-1} W\circ\Phi$ and if $\frac{cM\epsilon^{1-(p+1)\beta}}{n^2\sigma^{\mu+1}} \leq 1$, we have $||\Phi^* W||^*_{\eta r,U} \leq c||W||^*_{\eta r,V}$.*

For the proof, see [14].

Now we estimate X_{P_+}. By Lemma 7, if $\frac{cM\epsilon^{1-(p+1)\beta}}{n^2\sigma^{\mu+1}} \leq 1$,

$$|X_{P_+}|^*_{\eta r,D(s-5\sigma,\eta r)} \leq c|X_{P-R}|^*_{\eta r,D(s-4\sigma,2\eta r)} + c\int_0^1 |[X_{\bar{R}(t)}, X_F]|^*_{\eta r,D(s-4\sigma,2\eta r)}dt.$$

By Cauchy's inequality and Lemma 6, one obtains

$$\begin{aligned}|[X_{\bar{R}(t)}, X_F]|^*_{\eta r,D(s-4\sigma,2\eta r)} &\leq \frac{cM\epsilon^{2-(p+1)\beta}}{\eta^2\sigma^{\mu+1}} \\ &= cM\eta\epsilon,\end{aligned}$$

where one chooses $\eta^3 = \frac{\epsilon^{1-(p+1)\beta}}{\sigma^{\mu+1}}$. Combining (4.10) we have

$$|X_{P_+}|^*_{\eta r,D(s-5\sigma,\eta r)} \leq cM\eta\epsilon.$$

4.2. Iteration and proof of Theorem 2. To iterate the KAM step infinitely we must choose suitable sequences. For $m \geq 1$ set

$$\epsilon_{m+1} = \frac{cM(m)\epsilon_m^{\frac{4}{3}-\frac{1}{3}(p+1)\beta}}{\sigma_m^{\frac{1}{3}(1+\mu)}}, \quad \sigma_{m+1} = \frac{\sigma_m}{2}, \quad \eta_m^3 = \frac{\epsilon_m^{1-(p+1)\beta}}{\sigma_m},$$

where $\beta = \frac{1}{2(p+1)}$. Furthermore, $s_{m+1} = s_m - 5\sigma_m$, $r_{m+1} = \eta_m r_m$, $M(m) = (M_1 + M_2 + 2c(\epsilon_1 + \cdots + \epsilon_{m-1}))^p$, and $D_m = D(s_m, r_m)$. As initial value fix $\sigma_1 = \frac{s_1}{20} \leq \frac{1}{2}$. Choose

$$\epsilon_1 \leq \frac{\gamma_0^6 \sigma_1^{2(\mu+1)}}{c^6 M^{6p}}, \tag{4.13}$$

where $\gamma_0 \leq \frac{1}{c(M+1)^p 2^{6p+4\mu}}$. Finally, let $K_m = K_1 2^{m-1}$ with

$$K_1^{\tau+1} = c^{5-6\beta} M^{6p(1-\beta)} 2^{2(1+\mu)(1-\beta)-3} \gamma_0^{6(\beta-1)}. \tag{4.14}$$

LEMMA 8. *Suppose $H_m = N_m + P_m$ is given on $D_m \times \Pi_m$, where $N_m = \langle \omega_m(\xi), y\rangle + \langle \Omega_m, z\bar{z}\rangle$ is a normal form satisfying*

$$|\langle k, \omega_m\rangle| \geq \frac{\epsilon_m^\beta}{A_k} \text{ for } k \neq 0, \tag{4.15}$$

$$|\langle k, \omega_m\rangle + \Omega_{m,i}| \geq \frac{\epsilon_m^\beta}{A_k}, \tag{4.16}$$

$$|\langle k, \omega_m\rangle + \Omega_{m,i} + \Omega_{m,j}| \geq \frac{\epsilon_m^\beta (|i-j|+1)}{A_k}, \tag{4.17}$$

$$|\langle k, \omega_m\rangle + \Omega_{m,i} - \Omega_{m,j}| \geq \frac{\epsilon_m^\beta (|i-j|+1)}{A_k}, i \neq j, \tag{4.18}$$

for any $\xi \in \Pi_m$, and

$$|X_{P_m}|^*_{r_m, D_m} \leq \epsilon_m.$$

Then there exists a Whitney smooth family of real analytic symplectic coordinate transformations $\Phi_{m+1} : D_{m+1} \times \Pi_m \to D_m$ and a closed subset

$$\Pi_{m+1} = \Pi_m \setminus \bigcup_{|k| > K_m} R_{kl}^{m+1}(\epsilon_{m+1})$$

of Π_m, where

$$R_{kl}^{m+1}(\epsilon_{m+1}) = A_{k1}^{m+1} \cup A_{k2}^{m+1} \cup A_{k3}^{m+1} \cup A_{k4}^{m+1},$$

and

$$A_{k1}^{m+1} = \left\{ \xi \in \Pi_m : |\langle k, \omega_{m+1}\rangle| < \frac{\epsilon_{m+1}^\beta}{A_k} \right\},$$

$$A_{k2}^{m+1} = \bigcup_i B_{ki}^{m+1,1} = \bigcup_i \left\{ \xi \in \Pi_m : |\langle k, \omega_{m+1}\rangle + \Omega_{m+1,i}| < \frac{\epsilon_{m+1}^\beta}{A_k} \right\},$$

$$A_{k3}^{m+1} = \bigcup_{i,j} B_{kij}^{m+1,11} = \bigcup_{i,j} \left\{ \xi \in \Pi_m : |\langle k, \omega_{m+1}\rangle + \Omega_{m+1,i} + \Omega_{m+1,j}| < \frac{\epsilon_{m+1}^\beta (|i-j|+1)}{A_k} \right\},$$

$$A_{k4}^{m+1} = \bigcup_{i \neq j} B_{kij}^{m+1,12} = \bigcup_{i \neq j} \left\{ \xi \in \Pi_m : |\langle k, \omega_{m+1}\rangle + \Omega_{m+1,i} - \Omega_{m+1,j}| < \frac{\epsilon_{m+1}^\beta (|i-j|+1)}{A_k} \right\},$$

such that for $H_{m+1} = H_m \circ \Phi_{m+1} = N_{m+1} + P_{m+1}$ *the same assumptions are satisfied with* $m+1$ *in place of* m.

Proof. Note the value for p_1, ϵ_1, β and σ_1, one verifies that

$$\frac{M_{m+1}\epsilon_{m+1}^{1-(p+1)\beta}}{\sigma_{m+1}^{1+\mu}} \le \frac{1}{2}\frac{M_m\epsilon_m^{1-(p+1)\beta}}{\sigma_m^{1+\mu}} \tag{4.19}$$

for all $m \ge 1$. So the smallness condition of the KAM step is satisfied. For the remained proof, see the iterative lemma in [13]. □

With (4.11) and (4.12), we also obtain the following estimate.

LEMMA 9. *For* $m \ge 1$,

$$\frac{1}{\sigma_m}||\Phi_{m+1} - id||^*_{r_m, D_{m+1}}, ||D\Phi_{m+1} - I||^*_{r_m, r_m, D_{m+1}} \le \frac{cM(m)\epsilon_m^{1-(p+1)\beta}}{\sigma_m^{\mu+1}} \tag{4.20}$$

$$||\omega_{m+1} - \omega_m||^*_{\Pi_m}, ||\Omega_{m+1} - \Omega_m||^*_{\Pi_m} \le c\epsilon_m. \tag{4.21}$$

Proof of Theorem 2. The smallness condition is

$$\epsilon_1 \le \frac{\gamma_0^6}{20^{2(1+\mu)(cM^p)^6}} s_1^{2(1+\mu)}. \tag{4.22}$$

To apply Lemma 8 with $m = 1$, set $s_1 = s$, $r_1 = r, \ldots$, $N_1 = N$, $P_1 = P$,

$$\gamma = \frac{\gamma_0^6}{20^{2(1+\mu)(cM^p)^6}} \text{ and } \epsilon_1 = \gamma s_1^{2(1+\mu)}.$$

The smallness condition is satisfied, because

$$|X_{P_1}|^*_{r_1, D(s_1, r_1)} = |X_P|^*_{r, D(r,s)} \le \gamma s^{2(1+\mu)} = \epsilon_1.$$

The small divisor conditions are satisfied by setting $\Pi_1 = \Pi \setminus \cup_{kl} R^1_{kl}(\epsilon)$, where $k \ne 0$ for A^1_{k1}, and $\Pi_0 = \Pi$. Then the iterative lemma applies. □

Remark. For the rescaled Hamiltonian H, we fix $r = 1$. Then

$$|X_{\epsilon P}|^*_{1, D(s,1)} \le |X_{\epsilon P}|^*_{1, D(1,1)} \le c\epsilon \le \gamma s^{2(1+\mu)},$$

for ϵ small enough. If fix $\rho > 0$ and $a > \frac{1}{2}$ arbitrarily, Theorem 2 can be applied to the rescaled Hamiltonian.

5. Measure estimates. The remaining job is to estimate the measure. We first give the measure estimates for the first step. In our case, the tangent frequencies $\omega_i = \lambda_i + O(\xi^2)(i = n_1, \ldots, n_b)$ and normal frequencies $\Omega_j = \lambda_j + O(\xi^2)(j \ne n_1, \ldots, n_b)$ are second orders in ξ while the ones appeared in the papers such as [10] and [12] are linear in ξ. This is another main difference between our paper and others. To obtain the measure estimates, we have to control the higher order derivatives for $\langle k, \omega\rangle \pm \Omega_i \pm \Omega_j$ etc. One finds that more information from $O(\xi^2)$ is needed to exclude the degenerate cases. The measure estimates in the subsequent steps are based on the techniques developed in [14] and [15].

5.1. Measure estimates in the first step. The thrown parameter sets in the first step are $(\cup_{k\neq 0}A^1_{k1})\bigcup(\cup_k(A^1_{k2}\cup A^1_{k3}\cup A^1_{k4}))$, where

$$A^1_{k1}=\left\{\xi\in\Pi:|\langle k,\omega\rangle|<\frac{\epsilon^\beta}{A_k}\right\}, \tag{5.1}$$

$$A^1_{k2}=\bigcup_i B^{1,1}_{ki}=\bigcup_i\left\{\xi\in\Pi:|\langle k,\omega\rangle+\Omega_i|<\frac{\epsilon^\beta}{A_k}\right\}, \tag{5.2}$$

$$A^1_{k3}=\bigcup_{i,j} B^{1,11}_{kij}=\bigcup_{i,j}\left\{\xi\in\Pi:|\langle k,\omega\rangle+\Omega_i+\Omega_j|<\frac{\epsilon^\beta(|i-j|+1)}{A_k}\right\}, \tag{5.3}$$

$$A^1_{k4}=\bigcup_{i\neq j} B^{1,12}_{kij}=\bigcup_{i\neq j}\left\{\xi\in\Pi:|\langle k,\omega\rangle+\Omega_i-\Omega_j|<\frac{\epsilon^\beta(|i-j|+1)}{A_k}\right\}. \tag{5.4}$$

It is obvious that $|A^1_{02}\cup A^1_{03}\cup A^1_{04}|=0$.

LEMMA 10. *Suppose that $g(x)$ is an* m*th differentiable function on the closure $\bar{I}$ of I, where $I\subset\mathbb{R}$ is an interval. Let $I_h=\{x||g(x)|<h\}, h>0$. If for some constant $d>0$, $|g^m(x)|\geq d$ for any $x\in I$, then $|I_h|\leq ch^{\frac{1}{m}}$, where $|I_h|$ denotes the Lebesgue measure of I_h and $c=2(2+3+\cdots+m+d^{-1})$.*

For the proof, see [15]. The similar method can be found in [1] and [14].

LEMMA 11. *For $\tau>2b+5$, $|\bigcup_{k\neq 0}A^1_{k3}|=O(\epsilon^{\frac{\beta}{2}})$.*

Proof. Suppose $i\geq j$ without losing generalities. When $i\geq c|k|$, one obtains $\frac{|\Omega_i+\Omega_j|}{1+i-j}\geq\frac{c|k|}{8\epsilon^{12}}$. But we know $\frac{|\langle k,\omega\rangle|}{1+(i-j)}\leq\frac{c'|k|}{\epsilon^{12}}$. If c is large enough, then $\frac{|\Omega_i+\Omega_j+\langle k,\omega\rangle|}{1+(i-j)}\geq 1$. This means $A^1_{k3}=\bigcup_{\max\{i,j\}\leq c|k|}B^{1,11}_{kij}$. Define

$$\begin{aligned}f(\xi)=&\frac{k_1}{\pi^2}(10\xi_1^2+18\xi_2^2+\cdots+18\xi_b^2+36\xi_1(\xi_2+\cdots+\xi_b)+48(\xi_2\xi_3+\cdots+\xi_{b-1}\xi_b))+\cdots\\&+\frac{k_b}{\pi^2}(18\xi_1^2+18\xi_2^2+\cdots+10\xi_b^2+36\xi_b(\xi_1+\cdots+\xi_{b-1})+48(\xi_1\xi_2+\cdots+\xi_{b-2}\xi_{b-1}))\\&+(12\xi_1^2G_{n_1n_1i}+\cdots+12\xi_b^2G_{n_bn_bi}+48G_{n_1n_2i}\xi_1\xi_2+\cdots+48G_{n_{b-1}n_bi}\xi_{b-1}\xi_b)\\&+(12\xi_1^2G_{n_1n_1j}+\cdots+12\xi_b^2G_{n_bn_bj}+48G_{n_1n_2j}\xi_1\xi_2+\cdots+48G_{n_{b-1}n_bj}\xi_{b-1}\xi_b).\end{aligned}$$

It follows that

$$\begin{aligned}\frac{\pi^2}{2}\frac{\partial^2 f}{\partial\xi_1^2}&=10k_1+18k_2+\cdots+18k_b+3(c_1+c_1')\\&\vdots\\\frac{\pi^2}{2}\frac{\partial^2 f}{\partial\xi_n^2}&=18k_1+18k_2+\cdots+10k_b+3(c_b+c_b'),\end{aligned}$$

where $c_i,c_i'=5$ or $6, i=1,2,\ldots,b$. We will prove the inequality

$$\max\left(\frac{\pi^2}{2}\left|\frac{\partial^2 f}{\partial\xi_1^2}\right|,\ldots,\frac{\pi^2}{2}\left|\frac{\partial^2 f}{\partial\xi_b^2}\right|\right)\geq 1$$

always holds. If it is not true, one gets that

$$k_1=\frac{-3}{8(9b-4)}((13-9b)(c_1+c_1')+9(c_2+c_2'+\cdots+c_b+c_b')).$$

One can draw the contradictions from the following three cases.

Case 1. Two "5s" in $\{c_1, c_2, \ldots, c_b, c_1', c_2', \ldots, c_b'\}$. In this case, we discuss it from different possibilities.

Subcase a: $c_1 = 5,\ c_1' = 6$. One obtains $k_1 = -\frac{3(9b+26)}{72b-32}$. It is obvious that $k_1 \notin Z$. It is similar for the case $c_1 = 6,\ c_1' = 5$.

Subcase b: $c_1 = c_1' = 6$. One gets $k_1 = -\frac{45}{4(9b-4)}$. It is impossible.

Subcase c: $c_1 = c_1' = 5$. One gets $|k_1| = \frac{3(18b+22)}{8(9b-4)}$. When $b \geq 6$, $0 < |k_1| < 1$. For $b = 2, \ldots, 5$, one can get $k_1 \notin Z$(check directly).

Case 2. Only one "5" in $\{c_1, c_2, \ldots, c_b, c_1', c_2', \ldots, c_b'\}$.

Subcase a: $c_1 = 5$ or $c_1' = 5$. One obtains $|k_1| = \frac{105+27b}{72b-32}$. If $b \geq 4$, then $0 < |k_1| < 1$. It is impossible. If $b = 2, 3$, one has $k_1 \notin Z$(check directly). It also contradicts with the previous assumption.

Subcase b: $c_{k_0} = 5$ or $c_{k_0}' = 5 (k_0 \neq 1)$. One gets $k_1 = -\frac{117}{8(9b-4)}$. It can't happen.

Case 3. No "5s" in $\{c_1, c_2, \ldots, c_b, c_1', c_2', \ldots, c_b'\}$.

One gets $k_1 = -\frac{18}{9b-4}$. If $b \geq 3$, one can get $0 < |k_1| < 1$. When $b = 2$, we obtain $k_1 \notin Z$ directly. It is impossible.

Hence, for any $k \neq 0, i$, there exists some $k_0 \in \{1, 2, \ldots, b\}, s.t., |\frac{\pi^2}{2}\frac{\partial^2 f}{\partial \xi_{k_0}^2}| \geq 1$. Then one obtains

$$\begin{aligned}\left|\bigcup_{k\neq 0} A_{k3}^1\right| &= \left|\bigcup_{k\neq 0}\bigcup_{i,j\leq c|k|} B_{kij}^{1,11}\right|,\\ &\leq \cdot \sum_{k\neq 0}\left(\frac{\epsilon^\beta |k|}{A_k}\right)^{\frac{1}{2}} |k|^2,\\ &\leq \cdot \sum_{l=1}^{+\infty} \frac{1}{l^{\frac{\tau-2b-3}{2}}}\epsilon^{\frac{\beta}{2}},\\ &= O(\epsilon^{\frac{\beta}{2}}). \qquad \square\end{aligned}$$

LEMMA 12. *For* $\tau > 2b + 5$, $|\bigcup_{k\neq 0} A_{k4}^1| = O(\epsilon^{\frac{\beta}{2}})$.

Proof. By the same methods, one obtains that $A_{k4}^1 = \bigcup_{\max\{i,j\}\leq c|k|} B_{kij}^{1,12}$. Following the similar way, we can get

$$k_l = \frac{-3}{8(9b-4)}\left((13-9b)(c_l - c_l') + 9\left(\sum_{m\neq l} c_k - \sum_{m\neq l} c_k'\right)\right),$$

where $l, m \in \{1, \ldots, b\}$.

Case 1. Two "5s" in $\{c_1, c_2, \ldots, c_b, c_1', c_2', \ldots, c_b'\}$.

If for any i, we have $c_i = c_i'$. One gets $k = 0$ in this case. It is impossible. If $\exists i_0, c_{i_0} \neq c_{i_0}'$, there exist two cases. One is $c_{i_0} = 5$, $c_{i_0}' = 6$. The other is $c_{i_0} = 6$, $c_{i_0}' = 5$. In any case, one can get $|k_{i_0}| = \frac{3}{8}$.

Case 2. One "5" in $\{c_1, c_2, \ldots, c_b, c_1', c_2', \ldots, c_b'\}$.

Case 3. No "5s" in $\{c_1, c_2, \ldots, c_b, c_1', c_2', \ldots, c_b'\}$.

We omit the proof for the two cases. The measure estimate is similar as before. We also omit it. $\square$

The following conclusions are obvious according to the above methods.

LEMMA 13. *For $\tau > 2b+2$, $|\bigcup_{k\neq 0} A^1_{k2}| = O(\epsilon^{\frac{\beta}{2}})$.*

LEMMA 14. *For $\tau > 2b$, $|\bigcup_{k\neq 0} A^1_{k1}| = O(\epsilon^{\frac{\beta}{2}})$.*

LEMMA 15. *For $\tau > 2b+5$, $|(\cup_{k\neq 0} A^1_{k1}) \bigcup (\cup_k (A^1_{k2} \cup A^1_{k3} \cup A^1_{k4}))| = O(\epsilon^{\frac{\beta}{2}})$.*

5.2. The total measure. In order to estimate the total measure of the parameter sets Π_ϵ which is thrown in all the steps, we must estimate the measure in the subsequent steps. The thrown parameter set in $m+1$ step is $\bigcup_{|k|>K_m} R^{m+1}_{kl}(\epsilon_{m+1})$, where $\xi \in \Pi_m$. In fact, we may extend ω_m and Ω_m defined in Π_m to Π. The following ω_m and Ω_m are both defined in Π.

LEMMA 16. *For $\tau > 2b+4$ and $K_m \geq \frac{80b}{c_1}$,*

$$\left| \bigcup_{|k|>K_m} A^{m+1}_{k4} \right| = \left| \bigcup_{|k|>K_m} \bigcup_{i\neq j} B^{m+1,12}_{k,ij} \right| = O\left(\epsilon^{\frac{\beta}{2}}_{m+1}\right),$$

where c_1 is a constant which depends on b and will be defined in the following.

Proof. For our convenience, we write ω' and Ω' for ω_{m+1} and Ω_{m+1}. Define $v_1 = (1,0,\ldots,0)^T$ and $v_b = (0,0,\ldots,1)^T$. Define $S = \{(x_1,x_2,\ldots,x_b) \in \mathbb{R}^b : |x_1|+|x_2|+\cdots+|x_b| = 1\}$. Write $A(\xi) = (D^2_{v_1}\omega, D^2_{v_2}\omega, \ldots, D^2_{v_b}\omega)^T$. It is easy to check that $|A(\xi)| = c > 0$, for any $\xi \in \Pi$. For any $(\xi, v) \in \Pi \times S$, $|A(\xi)v|_1 \geq c_1 > 0$. Thus for any $(\xi, v) \in \Pi \times S$, there exists a open neighborhood S_v of v in S, such that for some i, $|\langle D^2_{v_i}\omega, v'\rangle| \geq \frac{c_1}{2b}$, for any $(\xi, v') \in \Pi \times S_v$. Since $\{\Pi \times S_v\}$ covers the compact set $\Pi \times S$, there exist finite covers: $\Pi \times S_1, \ldots, \Pi \times S_{k_0}$ such that $\bigcup_{i=1}^{k_0} \Pi \times S_i \supset \Pi \times S$ and for any $(\xi, v) \in \Pi \times S_i$,

$$|\langle D^2_{\bar{v}}\omega, v\rangle| \geq \frac{c_1}{2b},$$

where $\bar{v} \in \{v_1, v_2, \ldots, v_b\}$.

Now fix $k \neq 0$ and suppose $\frac{k}{|k|} \in S_i$. Then for any $\xi \in \Pi$,

$$\left| \left\langle D^2_{\bar{v}}\omega, \frac{k}{|k|} \right\rangle \right| \geq \frac{c_1}{2b} > 0. \tag{5.5}$$

Define $f(\xi) = \langle k, \omega'\rangle + \Omega'_i - \Omega'_j$. Note

$$\begin{aligned} D^2_{\bar{v}} \frac{f(\xi)}{|k|} = &\left\langle \frac{k}{|k|}, D^2_{\bar{v}}(\omega) \right\rangle + \frac{D^2_{\bar{v}}(\Omega_i - \Omega_j)}{|k|} + \frac{D^2_{\bar{v}}(\Omega'_i - \Omega_i)}{|k|} \\ &+ \frac{D^2_{\bar{v}}(\Omega_j - \Omega'_j)}{|k|} + \left\langle \frac{k}{|k|}, D^2_{\bar{v}}(\omega' - \omega) \right\rangle. \end{aligned} \tag{5.6}$$

We estimate every term in (5.6). From (4.2) and (4.3), one obtains

$$\left| \left\langle \frac{k}{|k|}, D^2_{\bar{v}}(\omega' - \omega) \right\rangle \right| \leq |D^2_{\bar{v}}(\omega' - \omega)| \leq c\epsilon, \tag{5.7}$$

$$\frac{|D^2_{\bar{v}}(\Omega'_i - \Omega_i)|}{|k|} \leq \frac{c\epsilon}{|k|} \leq \frac{1}{|k|}, \tag{5.8}$$

$$\frac{|D^2_{\bar{v}}(\Omega_j - \Omega'_j)|}{|k|} \leq \frac{c\epsilon}{|k|} \leq \frac{1}{|k|}. \tag{5.9}$$

Note $\frac{|D_{\bar v}^2(\Omega_i-\Omega_j)|}{|k|}\le\frac{8}{|k|}$ and (5.7), (5.8), (5.9), (5.5), we arrive at $|D_{\bar v}\frac{f(\xi)}{|k|}|\ge\frac{c_1}{4b}$ when $|k|\ge\frac{80b}{c_1}$. We will show in what follows that when $\max\{i,j\}\ge c|k|$,

$$\frac{|\langle k,\omega'\rangle+\Omega_i'-\Omega_j'|}{|i-j|+1}\ge 1. \tag{5.10}$$

The proof is similar as before. First,

$$\begin{aligned}\frac{|\Omega_i'-\Omega_j'|}{|i-j|+1}&\ge\frac{|\Omega_i-\Omega_j|}{2|i-j|}-\frac{|\Omega_i'-\Omega_i|}{2|i-j|}-\frac{|\Omega_j'-\Omega_j|}{2|i-j|}\\&\ge\frac{c|k|}{2\epsilon^{12}}-M_9-c_*\epsilon\\&\ge\frac{c|k|}{4\epsilon^{12}}.\end{aligned}$$

Moreover,

$$|\langle k,\omega'\rangle|\le|\langle k,\omega\rangle|+|\langle k,\omega'-\omega\rangle|\le\frac{c'|k|}{\epsilon^{12}}.$$

Therefore, when c is large enough and $\max\{i,j\}\ge c|k|$, (5.10) holds. So when $K_m\ge\frac{80b}{c_1}$ and $\tau>2b+4$,

$$\begin{aligned}\left|\bigcup_{|k|>K_m}\bigcup_{i\ne j}B_{k,ij}^{m+1,12}\right|&=\left|\bigcup_{|k|>K_m}\bigcup_{i,j\le c|k|}B_{k,ij}^{m+1,12}\right|\\&\le\sum_{|k|\ge|K_m|}\sum_{i,j\le c|k|}\left(\frac{|i-j|}{A_k|k|}\right)^{\frac12}O(\epsilon_{m+1}^{\frac\beta2}),\\&\le\sum_{l=1}^{+\infty}\frac{1}{l^{\frac\tau2-b-1}}O(\epsilon_{m+1}^{\frac\beta2})\\&=O(\epsilon_{m+1}^{\frac\beta2}).\qquad\square\end{aligned}$$

LEMMA 17. *For $\tau>2b+4$ and $K_m\ge\frac{80b}{c_1}$,*

$$\left|\bigcup_{|k|>K_m}A_{k3}^{m+1}\right|=\left|\bigcup_{|k|>K_m}\bigcup_{i,j}B_{k,ij}^{m+1,11}\right|=O(\epsilon_{m+1}^{\frac\beta2}).$$

LEMMA 18. *For $\tau>2b+1$ and $K_m\ge\frac{80b}{c_1}$,*

$$\left|\bigcup_{|k|>K_m}A_{k2}^{m+1}\right|=\left|\bigcup_{|k|>K_m}\bigcup_{i}B_{k,i}^{m+1,1}\right|=O(\epsilon_{m+1}^{\frac\beta2}).$$

LEMMA 19. *For $\tau>2b-1$,*

$$\left|\bigcup_{k\ne0}A_{k1}^{m+1}\right|=O(\epsilon_{m+1}^{\frac\beta2}).$$

LEMMA 20. *For $\tau > 2b+4$ and $K_m \geq \frac{80b}{c_1}$,*

$$\left| \bigcup_{|k|>K_m} R_{kl}^{m+1}(\epsilon_{m+1}) \right| = O(\epsilon_{m+1}^{\frac{\beta}{2}}).$$

In order to estimate the value for K_1, a series of constants have to be chosen. We know $p = 2$, $\beta = \frac{1}{6}$. One fixes $M, \tau > 2b+5$. It is easy to see that one obtains $K_1 \geq \frac{80b}{c_1}$ when γ_0 is small enough. Now we compute the total measure of the parameter sets Π_ϵ which is thrown in all the steps

$$\begin{aligned} |\Pi_\epsilon| &\leq O(\epsilon_1^{\frac{1}{12}}) + O(\epsilon_2^{\frac{1}{12}}) + \cdots \\ &\leq O(\epsilon_1^{\frac{1}{12}}) = O(\epsilon^{\frac{1}{12}}). \end{aligned}$$

6. Appendix. The existence of infinite admissible index sets isn't obvious since the corresponding tangential frequencies have to satisfy infinite many nonresonance conditions. The main idea of the proof is as follows: Suppose that our conclusions hold when $b = d-1$, we prove that there exists at least one n_d in $[x, x+\sqrt{\frac{x}{9n_{d-1}}}]$($x, n_1$ is large enough) such that $n_1, \ldots, n_{d-1}, n_d$ satisfy all the nonresonance assumptions (see section 3). The idea is to estimate the total number of integers n in $[x, x+\sqrt{\frac{x}{9n_{d-1}}}]$ such that $n_1, n_2, \ldots, n_{d-1}, n$ conflicts with one of our nonresonance assumptions. In fact we can prove that the total number is far less than $\sqrt{\frac{x}{9n_{d-1}}}$. This shows the existence of n_d. In case $d = 2$, we explicitly construct the admissible index sets. The proof of Proposition 1 requires a couple of lemmas. For our convenience, we introduce the set $K^2 = \{k^2 | k \in Z\}$ and define $L = \sqrt{\frac{n_d}{9n_{d-1}}}$.

LEMMA 21. *For any given $n_1, n_2, \ldots, n_{d-1}$ with $n_1 < n_2 < \cdots < n_{d-1}$, $\{n_1, n_2\} \in \mathcal{S}$ and n_d large enough, there exists at most $\frac{L}{8d}$ integers $x_d \in [n_d, n_d+L] \cap Z$ satisfying $5x_d^2 + 2kx_d - 3k^2 \in K^2, k \in \{n_1, n_2, \ldots, n_{d-1}\}$.*

Proof. Note $\sqrt{5} \notin Q$, the conclusion is obvious. □

Similarly, we have the following lemma.

LEMMA 22. *For any given $n_1, n_2, \ldots, n_{d-1}$ with $n_1 < n_2 < \cdots < n_{d-1}$, $\{n_1, n_2\} \in \mathcal{S}$ and n_d large enough, there exist at most $\frac{L}{8d}$ integers $x_d \in [n_d, n_d+L] \cap Z$ satisfying $5x_d^2 - 2kx_d - 3k^2 \in K^2, k \in \{n_1, n_2, \ldots, n_{d-1}\}$.*

For the following two lemmas, it is easy to draw the contradictions from the contrary.

LEMMA 23. *For any given $n_1, n_2, \ldots, n_d$ where $n_1 < n_2 < \cdots < n_{d-1} < n_d$, $n_d >> n_{d-1}^2$ and $\{n_1, n_2\} \in \mathcal{S}$, there exists at most one $x_{ij} \in [n_d, n_d + L] \cap Z$ satisfying*

$$4x_{ij}(n_j + n_i) + (n_j - 3n_i)(n_j + n_i) \in K^2,$$

where $i, j \in \{1, 2, \ldots, d-1\}$.

LEMMA 24. *For any given $n_1, n_2, \ldots, n_d$ with $n_1 < n_2 < \cdots < n_{d-1} < n_d$, $n_d >> n_{d-1}^2$ and $\{n_1, n_2\} \in \mathcal{S}$, there exists at most one $x_{ij} \in [n_d, n_d + L] \cap Z$ satisfying*

$$4x_{ij}(n_j - n_i) + (n_j + 3n_i)(n_j - n_i) \in K^2,$$

where $1 \leq i < j \leq d-1, i, j \in Z$.

LEMMA 25. *For any given $n_1, n_2, \ldots, n_{d-1}, n_d$, where $n_1 < n_2 < \cdots < n_{d-1} < n_d$, $n_d >> n_{d-1}^3$ and $(n_1, n_2) \in \mathcal{S}$, there exists at most $\frac{12L}{\sqrt{n_j - n_i}}$ integers x belonging to $[n_d, n_d + L]$ so that $\frac{x^2 - n_i^2}{n_j - n_i} \in Z$, where $1 \le i < j \le d-1, i, j \in Z$.*

Proof. Rewrite $n_j - n_i = p_1^{k_1} p_2^{k_2} \cdots p_s^{k_s}$, where $p_1, \ldots, p_s$ are different prime numbers, $k_1, k_2, \ldots, k_s \in Z^+$. For $x + n_i, x \in [n_d, n_d + L]$, it is apparent that there exist at most $\frac{L}{p_1^{l_1} p_2^{l_2} \cdots p_s^{l_s}} + 2$ integers including $p_1^{l_1} p_2^{l_2} \cdots p_s^{l_s}$ as factor, where $0 \le l_i \le k_i, i = 1, 2, \ldots, s$. For our convenience, we use $A^{l_1 l_2 \cdots l_s}$ representing the event that $x + n_i$ includes $p_1^{l_1} p_2^{l_2} \cdots p_s^{l_s}$ as factor. Similarly, $B^{l_1 l_2 \cdots l_s}$ represents the event that $x - n_i$ includes $p_1^{k_1 - l_1} p_2^{k_2 - l_2} \cdots p_s^{k_s - l_s}$ as factor. C represents the event $\frac{x^2 - n_i^2}{n_j - n_i} \in Z$. It is apparent that $\cup_{l_1 \cdots l_s} A^{l_1 l_2 \cdots l_s} B^{l_1 l_2 \cdots l_s} = C$. Then the probability of C is

$$\begin{aligned} P(C) &= \sum_{l_1 \cdots l_s} P(A^{l_1 l_2 \cdots l_s} B^{l_1 l_2 \cdots l_s}) \\ &\le \sum_{l_1 \cdots l_s} P(A^{l_1 l_2 \cdots l_s}) P(B^{l_1 l_2 \cdots l_s}) \\ &\le \sum_{l_1 \cdots l_s} \left(\frac{\frac{L}{p_1^{l_1} p_2^{l_2} \cdots p_s^{l_s}} + 2}{L} \right) \left(\frac{\frac{L}{p_1^{k_1 - l_1} p_2^{k_2 - l_2} \cdots p_s^{k_s - l_s}} + 2}{L} \right) \\ &\le 2 \sum_{l_1 \cdots l_s} \frac{1}{p_1^{k_1} p_2^{k_2} \cdots p_s^{k_s}} \\ &\le \frac{2(k_1 + 1) \cdots (k_s + 1)}{p_1^{k_1} p_2^{k_2} \cdots p_s^{k_s}}. \end{aligned}$$

We know that $l + 1 \le p^{\frac{l}{2}} (p \ge 4)$, $l + 1 \le 3^{\frac{l}{2}+1}$, and $l + 1 \le 2^{\frac{l}{2}+1}$, for any $l \ge 1$. Then $P(C) \le \frac{2(k_1+1)\cdots(k_s+1)}{n_j - n_i} \le \frac{12}{\sqrt{n_j - n_i}}$. Now it is easy to see that our conclusion holds. □

Similarly, we have the following lemma.

LEMMA 26. *For any given $n_1, n_2, \ldots, n_d$ where $n_1 < n_2 < \cdots < n_{d-1} < n_d$, $n_d >> n_{d-1}^3$ and $\{n_1, n_2\} \in \mathcal{S}$, there exists at most $\frac{12L}{\sqrt{n_j + n_i}}$ integers x belonging to $[n_d, n_d + L]$ so that $\frac{x^2 - n_i^2}{n_j + n_i} \in Z$, where $L = \sqrt{\frac{n_d}{9 n_{d-1}}}, 1 \le i \le j \le d-1, i, j \in Z$.*

The proof of Proposition 1.

We first admit that Proposition 2 holds (the proof will be delayed to the end). This means that Proposition 1 holds for $b = 2$. Suppose that Proposition 1 holds for $b = d - 1 \ge 2$, we will show that it also holds for d. When $b = d - 1$, one can choose one admissible set made of $n_1, n_2, \ldots, n_{d-1}$. Our aim is to construct n_d so that $\{n_1 < n_2 < \cdots < n_d\}$ is an admissible set for $b = d$. We first construct n_d to satisfy Assumption A. In fact, it is enough when $n_d >> n_i, i \le d-1$. Otherwise one gets

$$\begin{cases} i^2 + j^2 + k^2 = l^2 + m^2 + n^2 \\ i \pm j \pm k \pm l \pm m \pm n = 0, \end{cases}$$

where $i, j, k, l, m, n \in \{n_1, n_2, \ldots, n_d\}$. One can induce the contradictions from different cases. We only prove the case in which there exist two $n_d's$ in $\{i, j, k, l, m, n\}$. For any more or less n_d(at least one n_d), the proof is similar. Note $n_d >> n_i (i \le d-1)$,

one gets $\{i,j,k\}\cap\{l,m,n\}\supset n_d$. Hence, one obtains

$$\begin{cases} j^2+k^2=l^2+m^2 \\ n_d\pm n_d\pm j\pm k\pm l\pm m=0. \end{cases} \tag{6.1}$$

We know that $\pm n_d\pm n_d=0,\pm 2n_d$. For the preceding, from Lemma 5 in [10], it contradicts with our choice of $\{i,j,k,l,m,n\}$. For the last, it is apparent that $|j\pm k\pm l\pm m|<2n_d$. This leads a contradiction to (6.1). If none of $n_d's$ is in $\{i,j,k,l,m,n\}$, this contradicts with the choice of $n_1,n_2,\ldots,n_{d-1}$.

In fact, n_d also satisfies Assumption B under the same condition. If this is not true, then

$$x^2+j^2+k^2-l^2-m^2-n^2=0.$$

The unique index which is different with $n_1,n_2,\ldots,n_d$ is denoted by x. We only prove the case in which there exist three $n_d's$ in $\{j,k,l,m,n\}$. For the other cases (at least one n_d), the method is similar. One can induce the contradictions from the following three cases.

Case 1.

$$\begin{cases} x^2+j^2+k^2=3n_d^2 \\ x\pm j\pm k\pm n_d\pm n_d\pm n_d=0. \end{cases}$$

From $x^2+j^2+k^2=3n_d^2$, we conclude that $x\approx\sqrt{3}n_d$. But from $x\pm j\pm k\pm n_d\pm n_d\pm n_d=0$, we know that $|x|\approx 3n_d$ or n_d. It is impossible.

Case 2.

$$\begin{cases} x^2+n_d^2=m^2+n^2 \\ x\pm n_d\pm n_d\pm n_d\pm m\pm n=0. \end{cases}$$

From $n_d^2>>m^2+n^2$, we know it can't happen.

Case 3.

$$\begin{cases} x^2+j^2=n_d^2+m^2 \\ x\pm j\pm m\pm n_d\pm n_d\pm n_d=0. \end{cases} \tag{6.2}$$

From $x^2+j^2=n_d^2+m^2$, we can get $x\approx n_d$. Hence, (6.2) holds only when $\pm n_d\pm n_d\pm n_d=\pm n_d$. But at this case, from Lemma 5 of [10], one can get $\{x,j\}=\{n_d,m\}$. It can't happen.

If none n_d in $\{j,k,l,m,n\}$, this contradicts with the choice of $n_1,n_2,\ldots,n_{d-1}$.

For Assumption C, one must place much heavier restrictions on n_d. From Lemmas 21–26, we will prove that there exist many integer points x belonging to $[n_d,n_d+\sqrt{\frac{n_d}{9n_{d-1}}}]$ so that $n_1,\ldots,x$ fulfill our Assumption C when n_d and n_1 is large enough. If it isn't true, then

$$i^2+j^2+k^2=l^2+m^2+n^2.$$

The other two indexes different from $n_1,n_2,\ldots,n_d$ are denoted by x,y,

Case 1.

$$\{x,y\}\subset\{i,j,k\} \text{ or } \{x,y\}\subset\{l,m,n\}.$$

Without losing generality, one gets

$$\begin{cases} x^2+y^2=l^2+m^2+n^2-k^2 \\ x\pm y=\pm k\pm l\pm m\pm n. \end{cases}$$

We have to consider several different subcases. For our convenience, we introduce the notation "$|\cdot|$." The equality $|\{k,l,m,n\}|=t, t=1,2,3,4$, means there exist exactly t $n_d's$ in $\{k,l,m,n\}$.

Subcase a.

$$|\{k,l,m,n\}|=1.$$

It is easy to see that the case $x^2+y^2+n_d^2=l^2+m^2+n^2$ can't happen. So only the following case need be considered:

$$\begin{cases} x^2+y^2+k^2=l^2+m^2+n_d^2 \\ x\pm y\pm k\pm l\pm m\pm n_d=0. \end{cases}$$

We only consider the case when

$$x=y\pm k\pm l\pm m\pm n_d. \tag{6.3}$$

For $x=-y\pm k\pm l\pm m\pm n_d$, it is similar. From (6.3), one obtains

$$2y^2+2(\pm k\pm l\pm m\pm n_d)y+(\pm k\pm l\pm m\pm n_d)^2+k^2-l^2-m^2-n_d^2=0.$$

Write $a=\pm k\pm l\pm m$. Note

$$\triangle=4(n_d-a)^2+8(l^2+m^2-a^2-k^2),$$

and $y\in Z$, one gets

$$l^2+m^2=a^2+k^2. \tag{6.4}$$

At the same time, one obtains

$$y=\frac{-(a\pm n_d)\pm(n_d-a)}{2}.$$

By further computations, one knows $|x|=n_d$ or $|y|=n_d$. It is impossible.

Subcase b.

$$|\{k,l,m,n\}|=2.$$

We must consider different cases.

Case I.

$$\begin{cases} x^2+y^2=m^2+n^2 \\ x\pm y\pm m\pm n\pm n_d\pm n_d=0. \end{cases} \tag{6.5}$$

If $\pm n_d\pm n_d=0$, we arrive at $\{x,y\}=\{m,n\}$ from Lemma 5 of [10]. It is impossible. When $\pm n_d\pm n_d=\pm 2n_d$, we get $|x\pm y|<<n_d$ from (6.5). Hence the equality $x\pm y\pm m\pm n\pm 2n_d=0$ can't hold.

Case II.

$$\begin{cases} x^2+y^2+k^2=2n_d^2+n^2 \\ x\pm y\pm k\pm n\pm n_d\pm n_d=0. \end{cases} \tag{6.6}$$

Write $\pm k\pm n=a$. If $\pm n_d\pm n_d=0$, one gets

$$2y^2+2ay+(a^2+k^2-2n_d^2-n^2)=0$$

and

$$\triangle=16n_d^2+8n^2-8k^2-4a^2.$$

From $y\in Z$, one obtains $8n^2-8k^2-4a^2=0$. Then we have $3k^2\pm 2kn-n^2=0$. Hence, $3k=n$ or $k=n$. Only the last case need be considered. But at this case, we get $|y|=n_d$. It is impossible.

If $\pm n_d\pm n_d=2n_d$, from (6.6), one gets $|x|<<\sqrt{3}n_d$. Then the equality $x\pm y\pm k\pm n+2n_d=0$ can't hold. Similarly, the equality $x-y\pm k\pm n-2n_d=0$ can't be true. So the only case need be considered is

$$x+y\pm k\pm n-2n_d=0. \tag{6.7}$$

Denote $\pm k\pm n=a$. From (6.6) and (6.7), one gets

$$2y^2-2y(a+2n_d)+2n_d^2+4an_d+a^2+k^2-n^2=0.$$

If $a=-k-n$, we obtain $\triangle=4(n_i+n_j)(4n_d+n_j-3n_i)=4\triangle_1, i,j\in\{1,2,\ldots,d-1\}$. If $a=-k+n, k\neq n$, we obtain $\triangle=4(n_j-n_i)(4n_d+3n_i+n_j)=4\triangle_2$. Other cases can't happen. In order to draw the contradictions, one removes all the integers belonging to $[n_d,n_d+L]$ which satisfy $\triangle_1\in K^2,\triangle_2\in K^2$. Thanks to Lemmas 23 and 24, we throw at most $2(d-1)^2$ integer points. Then $y\notin Z$.

Subcase c.

$$|\{k,l,m,n\}|=3.$$

Case I.

$$\begin{cases} x^2+y^2=n_d^2+n^2 \\ x\pm y\pm n\pm n_d\pm n_d\pm n_d=0. \end{cases} \tag{6.8}$$

If $\pm n_d\pm n_d\pm n_d=\pm n_d$, from (6.8) and Lemma 5 of [10], one gets $\{x,y\}=\{n_d,n\}$. It is impossible. If $\pm n_d\pm n_d\pm n_d=\pm 3n_d$, from $x^2+y^2=n_d^2+n^2$ one obtains $|\pm x\pm y\pm n|<<\frac{5}{2}n_d$. Hence the equality $x\pm y\pm n\pm 3n_d=0$ can't hold.

Case II.

$$\begin{cases} x^2+y^2+k^2=3n_d^2 \\ x\pm y\pm k\pm n_d\pm n_d\pm n_d=0. \end{cases} \tag{6.9}$$

If $\pm n_d\pm n_d\pm n_d=\pm 3n_d$, from $x^2+y^2+k^2=3n_d^2$, one gets $|x\pm y|^2\le 2(x^2+y^2)\le 6n_d^2$. Hence, one knows $|x\pm y\pm k|<<\sqrt{7}n_d$. The inequality $x\pm y\pm k\pm 3n_d=0$ can't hold. For the case when $\pm n_d\pm n_d\pm n_d=\pm n_d$, we throw all the integers belonging to $[n_d,n_d+L]$ which satisfy $5n_d^2\pm 2kn_d-3k^2\in K^2, k=n_1,\ldots,n_{d-1}$. From Lemmas 21 and 22, the thrown integers are at most $\frac{L}{4}$. Then $y\notin Z$.

Subcase d.

$$|\{k,l,m,n\}| = 4.$$

$$\begin{cases} x^2 + y^2 = 2n_d^2 \\ x \pm y \pm n_d \pm n_d \pm n_d \pm n_d = 0. \end{cases}$$

The discussion is trivial. We omit it.

Subcase e. If which is no n_d in $\{k,l,m,n\}$, this contradicts with the choice of $n_1, n_2, \ldots, n_{d-1}$.

Case 2.

$$\{x,y\} \cap \{i,j,k\} \neq \{x,y\} \text{ and } \{x,y\} \cap \{l,m,n\} \neq \{x,y\}.$$

In this case, one obtains

$$\begin{cases} x^2 - y^2 = m^2 + n^2 - i^2 - j^2 \\ x \pm y \pm i \pm j \pm m \pm n = 0. \end{cases} \tag{6.10}$$

We have to discuss it in several subcases.

Subcase a'.

$$|\{i,j,m,n\}| = 1.$$

In this case, (6.10) is

$$\begin{cases} x^2 - y^2 = m^2 + n_d^2 - i^2 - j^2 \\ x \pm y \pm i \pm j \pm m \pm n_d = 0. \end{cases} \tag{6.11}$$

Without losing generality, we suppose that $x = y \pm i \pm j \pm m \pm n_d$. From (6.11), one gets

$$2y(\pm i \pm j \pm m \pm n_d) + (\pm i \pm j \pm m \pm n_d)^2 + i^2 + j^2 - m^2 - n_d^2 = 0.$$

Write $a = \pm i \pm j \pm m$. If $x = y + a + n_d$, one has

$$y = -a + \frac{a^2 + m^2 - i^2 - j^2}{2(a + n_d)}.$$

If $n_d >> n_{d-1}^2$ and $y \in Z$, one obtains $a^2 + m^2 - i^2 - j^2 = 0$ and $y = -a$. Hence $|x| = n_d$. It is impossible. If $x = y + a - n_d$, the proof is similar.

Subcase b'. $|\{i,j,m,n\}| = 2$.

If $\{x,i,j\} \cap \{y,m,n\} = \{n_d\}$, then

$$\begin{cases} x^2 + i^2 = y^2 + m^2 \\ x \pm y \pm i \pm m \pm n_d \pm n_d = 0. \end{cases} \tag{6.12}$$

When $\pm n_d \pm n_d = 0$, from Lemma 5 of [10], one gets $\{x,i,n_d\} = \{y,m,n_d\}$. It contradicts with our assumptions. When $\pm n_d \pm n_d = \pm 2n_d$, write $a = \pm i \pm m$. Without losing generality, we suppose that

$$x = y - a \pm 2n_d. \tag{6.13}$$

From (6.13) and (6.12), one gets

$$y = \frac{m^2 - i^2 - (-a \pm 2n_d)^2}{2(-a \pm 2n_d)}.$$

Note that $y > 0$, we have

$$y = \frac{1}{2}(a + 2n_d) + \frac{m^2 - i^2}{-2(a + 2n_d)}.$$

If $\{\frac{1}{2}(a + 2n_d)\} = \frac{1}{2}$, one gets $y \notin Z$. It is impossible. If $\{\frac{1}{2}(a + 2n_d)\} = 0$ and $m^2 - i^2 \neq 0$, we know $y \notin Z$. It is also impossible. If $\{\frac{1}{2}(a + 2n_d)\} = 0$ and $m^2 = i^2$, one gets $x = y$. It can't happen.

If $\{x, i, j\} \cap \{y, m, n\} = \emptyset$, we have

$$\begin{cases} x^2 + 2n_d^2 = y^2 + m^2 + n^2 \\ x \pm y \pm m \pm n \pm n_d \pm n_d = 0. \end{cases} \tag{6.14}$$

When $\pm n_d \pm n_d = \pm 2n_d$, write $\pm m \pm n = a$. If $x = y + a \pm 2n_d$, from (6.14) and $y > 0$, we get

$$y = \frac{6n_d - a}{4} + \frac{2m^2 + 2n^2 - a^2}{4(a - 2n_d)}.$$

If $\{\frac{6n_d - a}{4}\} \neq 0$, one gets $y \notin Z$. It is impossible. Only when $\{\frac{6n_d - a}{4}\} = 0$ and $a = 2m$ or $a = -2m$, we gets $y \in Z$. But by further computation, one gets $x < 0$. It is impossible. If $x = -y + a \pm 2n_d$, one get $x < 0$ by similar method. When $\pm n_d \pm n_d = 0$, we throw all the integers x belonging to $[n_d, n_d + L]$ which satisfy $\frac{x^2 - m^2}{n - m} \in Z (1 \leq m < n \leq d - 1)$ or $\frac{x^2 - m^2}{n + m} \in Z (1 \leq m \leq n \leq d - 1)$. From Lemmas 25 and 26, the thrown integers are at most $\frac{24L(d-1)^2}{\sqrt{2n_1}}$. Then $y \notin Z$.

Subcase c′. $|\{i, j, m, n\}| = 3$.

In this case, we get

$$\begin{cases} x^2 + i^2 = y^2 + n_d^2 \\ x \pm y \pm i \pm n_d \pm n_d \pm n_d = 0. \end{cases} \tag{6.15}$$

When $\pm n_d \pm n_d \pm n_d = \pm n_d$, from Lemma 5 of [10], one obtains $\{x, i\} = \{y, n_d\}$. It is impossible. When $\pm n_d \pm n_d \pm n_d = \pm 3n_d$, we suppose $x = y \pm i \pm 3n_d$. For $x = -y \pm i \pm 3n_d$, the method is similar. From (6.15) and $y > 0$, we get

$$y = \frac{4}{9}(3n_d + i) + \frac{4i^2}{9(3n_d - i)} - i,$$

or

$$y = \frac{4}{9}(3n_d - i) + \frac{4i^2}{9(3n_d + i)} + i.$$

Both can't be integers. It is impossible.

Subcase d′. $|\{i, j, m, n\}| = 4$.

We easily get $x = y$. It means $\{x, n_d, n_d\} = \{y, n_d, n_d\}$. It contradicts with our assumptions.

Subcase e'. If there is no n_d in $\{i, j, m, n\}$, this contradicts with the choice of $n_1, n_2, \ldots, n_{d-1}$.

Now we declare that there exist many integers x belonging to $[n_d, n_d + L]$ so that $n_1, \ldots, x$ fulfill our Assumptions A, B, C and (2.6) when n_d is large enough and $n_1 \geq 18432d^2$. In fact the thrown integers are at most

$$\frac{24L(d-1)^2}{\sqrt{2n_1}} + \frac{L}{4} + 2(d-1)^2. \tag{6.16}$$

If $n_1 \geq 18432d^2$, one can get (6.16)$\leq \frac{L}{2}$. Then there exist many x satisfying Assumptions A, B, C and (2.6). From Proposition 2, Proposition 1 is complete. □

The proof of Proposition 2 also requires a couple of lemmas. Since the proof is elementary, we give them without proof as follows.

LEMMA 27. *If* $n_1, n_2 \in \mathbb{N}, n_1 < n_2$, *then* $-7n_2^2 + n_1^2 \pm 6n_1n_2 \notin K^2$.

LEMMA 28. *If* $n_1 \equiv 2$ or $5(mod 7), n_2 \equiv 1(mod 7)$, *then* $-7n_1^2 + n_2^2 \pm 6n_1n_2 \notin K^2$.

LEMMA 29. *If* $n_1, n_2 \in \mathbb{N}, n_2 > 11n_1^2$, *then* $-3n_1 \pm n_2 \dagger n_2^2 - n_1^2, 3n_2 \pm n_1 \dagger n_2^2 - n_1^2$, *where the notation* $a\dagger b$ *means that* a *is not a factor of* b.

LEMMA 30. *If* $n_1 \in 2\mathbb{N} - 1, n_2 \in 2\mathbb{N},$, *then* $5n_1^2 - 3n_2^2 \pm 2n_1n_2 \notin K^2$, $5n_2^2 - 3n_1^2 \pm 2n_1n_2 \notin K^2$, $n_1(2n_2 - n_1) \notin K^2$, $n_2^2 - n_1^2 \notin K^2$.

Since the proof of Proposition 2 is similar with Proposition 1, we omit it. □

Acknowledgments. The authors thank the anonymous referees for several kind suggestions. It is also a pleasure to thank Dr. Jiansheng Geng for many fruitful discussions on this subject.

RENORMALIZED SOLUTIONS TO A NONLINEAR PARABOLIC-ELLIPTIC SYSTEM*

MARÍA TERESA GONZÁLEZ MONTESINOS† AND FRANCISCO ORTEGÓN GALLEGO‡

Abstract. The aim of this paper is to show the existence of renormalized solutions to a parabolic-elliptic system with unbounded diffusion coefficients. This system may be regarded as a modified version of the well-known thermistor problem; in this case, the unknowns are the temperature in a conductor and the electrical potential.

Key words. renormalized solutions, nonlinear elliptic equations, nonlinear parabolic equations, weak solutions, Caratheodory functions, thermistor problem, Sobolev spaces

AMS subject classifications. 35M10, 35J60, 35K65

DOI. 10.1137/S0036141003423041

1. Introduction.

This paper is concerned with the resolution of the nonlinear parabolic-elliptic system

$$
(1)\qquad \begin{cases} \dfrac{\partial u}{\partial t} - \nabla \cdot (a(u)\nabla u) = \sigma(u)|\nabla \varphi|^2 & \text{in } Q = \Omega \times (0,T), \\ -\nabla \cdot (\sigma(u)\nabla \varphi) = \nabla \cdot F(u) & \text{in } Q, \\ u = 0 & \text{on } \partial\Omega \times (0,T), \\ \varphi = 0 & \text{on } \partial\Omega \times (0,T), \\ u(\cdot,0) = u_0 & \text{in } \Omega, \end{cases}
$$

where $\Omega \subset \mathbb{R}^N$ is a bounded domain, $T > 0$, $a(x,t,s)$, $\sigma(x,t,s)$, and $F(x,t,s)$, $F = (F_1, \dots, F_N)'$, are Caratheodory functions defined in $Q \times \mathbb{R}$. This problem has a similar structure to the so-called thermistor problem arising in electromagnetism ([4, 12]); in that particular context, Ω stands for the domain occupied by the thermistor, u is the temperature, u_0 the initial temperature, φ is a shifted electric potential, $F(x,t,s) = \sigma(s)\nabla\varphi_0(x,t)$, φ_0 is a given function, and σ is a continuous and bounded function. Indeed, the actual electric potential is $\psi = \varphi + \varphi_0$, and thus φ_0 is the electric potential Dirichlet boundary data on $\partial\Omega \times (0,T)$. In our analysis, and from a mathematical standpoint, we will consider more general functions $F(x,t,s)$.

A great deal of attention has been paid to the thermistor problem during the last two decades by several authors ([2, 4, 13, 26], etc.). In these works, many situations and different hypotheses have been considered, but both a and σ are assumed to be bounded in all these referred works.

The goal of this paper is to analyze problem (1) in the case of nonbounded diffusion coefficients a and σ. Moreover, no asymptotic behavior on a, σ, and F is assumed.

Under these general assumptions, one readily realizes that weak solutions (in the sense of distributions) are not well suited in this context. Note that even if u or φ

belong to some Banach space of the form $L^q(W^{1,q}(\Omega))$, the terms $a(u)\nabla u$, $\sigma(u)\nabla\varphi$, or $F(u)$ may not belong to any $L^r(Q)$ space, $r \geq 1$. For this reason, we consider the notion of renormalized solutions adapted to our setting. The concept of renormalized solution was fist introduced by DiPerna and Lions ([15, 16]) in the framework of the Fokker–Plank–Boltzmann equations; later on, it was applied to more general situations (for instance, in the resolution of nonlinear elliptic equations ([9, 22, 23]), or in the resolution of nonlinear parabolic equations ([6, 7, 8])).

The fact that a and σ are unbounded is not the only difficulty we may encounter in the resolution of problem (1). Indeed, the parabolic equation needs a special treatment due to the nonlinear right-hand side belonging to $L^1(Q)$.

In order to solve problem (1) under the assumptions stated below, we use truncation and approximate solutions. This work is organized as follows.

In section 2, we set up the notation used in the paper; this leads to the introduction of some functional spaces. We also recall certain compactness results and give an existence theorem for problem (1) in the case of bounded data.

Section 3 enumerates the hypotheses and introduces the concept of renormalized solution adapted to our context. Finally, we give the existence result.

Section 4 develops the proof of the existence result; it is split into three steps, namely: setting of approximate problems, derivation of estimates, and passing to the limit and conclusion.

2. Notation and functional spaces. Let $\Omega \subset \mathbb{R}^N$, $N \geq 1$, be an open bounded domain, and $\partial\Omega$ its boundary. Then we define $\mathcal{D}(\Omega)$ as the space of all C^∞–functions in Ω with compact support.

For $p \in [1, +\infty]$, let $W^{1,p}(\Omega)$ be the first order Sobolev space given as

$$W^{1,p}(\Omega) = \left\{ v \in L^p(\Omega) \,/\, \nabla v \in L^p(\Omega)^N \right\},$$

where the gradient $\nabla v = \left(\frac{\partial v}{\partial x_1}, \ldots, \frac{\partial v}{\partial x_N} \right)'$ is taken in the sense of distributions (here, the prime symbol stands for vector transposition). It is well-known that $W^{1,p}(\Omega)$ is a Banach space with norm

$$\begin{aligned} \|v\|_{W^{1,p}(\Omega)} &= \left(\|v\|^p_{L^p(\Omega)} + \|\nabla v\|^p_{L^p(\Omega)^N} \right)^{1/p}, \quad p \in [1, +\infty), \\ \|v\|_{W^{1,\infty}(\Omega)} &= \|v\|_{L^\infty(\Omega)} + \|\nabla v\|_{L^\infty(\Omega)^N}; \end{aligned}$$

moreover, if $p = 2$, then we write $H^1(\Omega) = W^{1,2}(\Omega)$, which is a Hilbert space.

Since we deal with homogenous Dirichlet boundary conditions, it is interesting to introduce the space $W^{1,p}_0(\Omega)$ defined as the closure of $\mathcal{D}(\Omega)$ with respect to $\|\cdot\|_{W^{1,p}(\Omega)}$, that is,

$$W^{1,p}_0(\Omega) = \overline{\mathcal{D}(\Omega)}^{W^{1,p}(\Omega)}, \quad p \in [1, +\infty).$$

It is known that if $\partial\Omega$ is smooth enough (for instance, Lipschitz continuous), $W^{1,p}_0(\Omega)$ is characterized by the following property:

$$W^{1,p}_0(\Omega) = \{ v \in W^{1,p}(\Omega) \,/\, v_{|\partial\Omega} = 0 \}, \quad p \in [1, +\infty).$$

Also we put $H^1_0(\Omega) = W^{1,2}_0(\Omega)$. $W^{1,p}_0(\Omega)$ and $H^1_0(\Omega)$ are, respectively, Banach and Hilbert spaces. By Poincaré's inequality, the seminorm $|v|_{W^{1,p}(\Omega)} = \|\nabla v\|_{L^p(\Omega)^N}$ is a

norm in $W_0^{1,p}(\Omega)$ equivalent to $\|\cdot\|_{W^{1,p}(\Omega)}$ on $W_0^{1,p}(\Omega)$. The space $W^{-1,p'}(\Omega)$ stands for the dual space of $W_0^{1,p}(\Omega)$, $p \in [1,+\infty)$.

We now introduce some notation according to the parabolic equation of (1). For a Banach space X and $1 \le p \le +\infty$, let $L^p(X)$ denote the space $L^p([0,T];X)$, that is, the set of (equivalence class of) measurable functions $f : [0,T] \to X$ such that $t \in [0,T] \mapsto \|f(t)\|_X$ is in $L^p(0,T)$. If $f \in L^p(X)$, we define

$$\|f\|_{L^p(X)} = \left(\int_0^T \|f(t)\|_X^p \right)^{1/p}, \ 1 \le p < +\infty, \quad \|f\|_{L^\infty(X)} = \operatorname*{ess\,sup}_{t\in[0,T]} \|f(t)\|_X;$$

and thus $\left(L^p(X), \|\cdot\|_{L^p(X)}\right)$ is a Banach space. By Fubini's theorem we can identify the space $L^p(L^p(\Omega))$ with $L^p(Q)$, Q being the cylinder $\Omega \times (0,T)$.

Let X and Y be two Banach spaces, $X \hookrightarrow Y$ with continuous inclusion, and set

$$W = \left\{ v \in L^p(X) \,/\, \frac{\mathrm{d}v}{\mathrm{d}t} \in L^q(Y) \right\}, \ p,q \in [1,+\infty],$$

provided with the standard norm $\|w\|_W = \|w\|_{L^p(X)} + \left\|\frac{\mathrm{d}v}{\mathrm{d}t}\right\|_{L^q(Y)}$. Then $(W, \|\cdot\|_W)$ is a Banach space and the inclusion $W \hookrightarrow C^0([0,T];Y)$ holds and is continuous. However, it will be very interesting and useful to know if a particular compactness embedding involving these spaces holds. The answer is given by the following two lemmas ([24]).

LEMMA 1. *Let X, B, and Y be three Banach spaces such that $X \hookrightarrow B \hookrightarrow Y$, every embedding being continuous and the inclusion $X \hookrightarrow B$ compact. Let $1 \le p < +\infty$ and $1 \le q \le +\infty$. Then, the inclusion $W \hookrightarrow L^p(B)$ holds and is compact.*

LEMMA 2. *Let X, B and Y be as in Lemma 1, and $E \subset L^\infty(X)$ be a bounded set such that*

(i) $\frac{\mathrm{d}v}{\mathrm{d}t} \in L^1(Y)$ *for all $v \in E$, and*

(ii) *there exist $h \in L^1(0,T)$, $s > 1$ and a bounded set $\mathcal{Z} \subset L^s(0,T)$ such that*

$$\left\| \frac{\mathrm{d}v}{\mathrm{d}t} \right\|_Y \le h + z_v, \ \text{for all } v \in E, \ z_v \in \mathcal{Z} \text{ and a.e. in } (0,T).$$

Then, E is relatively compact in $C^0([0,T];B)$.

The approximate problems in section 4.1 are defined via truncation functions. For this purpose, we introduce, for each $j > 0$ in $\mathbb{R}$, the truncation function at height j to be

$$T_j(s) = \operatorname{sign}(s) \min(j, |s|), \quad \operatorname{sign}(s) = \begin{cases} 0 & \text{if } s = 0, \\ s/|s| & \text{if } s \neq 0. \end{cases} \tag{2}$$

We will also make use of the following lemma, due to Boccardo and Gallouët ([10]) and ([19]).

LEMMA 3. *Let (v_n) be a sequence of measurable functions in Q such that*

1. *(v_n) is bounded in $L^\infty(L^1(\Omega))$.*
2. *For all $j > 0$, $n \ge 0$, $T_j(v_n) \in L^2(H_0^1(\Omega))$.*
3. *There exists a constant $C > 0$ such that*

$$\int_{\{m \le |v_n| < m+1\}} |\nabla v_n|^2 \le C \ \text{for all } m, n \ge 0.$$

Then (v_n) is bounded in the space $L^q(W^{1,q}(\Omega))$ for all $q < \frac{N+2}{N+1}$ if $N \geq 2$, and for all $q < 2$ if $N = 1$.

If $g : Q \times \mathbb{R}$ is a Caratheodory function and u is measurable in Q, we write $g(u)$ for the measurable function in Q defined as $(x,t) \in Q \mapsto g(x,t,u(x,t))$.

In what follows, $C > 0$ stands for generic constant values which only depend on initial data.

The introduction of the approximate solutions relies on the following result.

THEOREM 4. *Assume that the Caratheodory functions a, σ and F are such that $a, \sigma \in L^\infty(Q \times \mathbb{R})$, $F \in L^\infty(Q \times \mathbb{R})^N$ and there exist two constant values $a_0 > 0$ and σ_0 satisfying*

$$a(x,t,s) \geq a_0,\ \sigma(x,t,s) \geq \sigma_0,\ \textit{for all } s \in \mathbb{R},\ \text{a.e. } (x,t) \in Q.$$

Finally, let $u_0 \in L^2(\Omega)$. Then, for every $j > 0$, there exists $u \in L^2(H_0^1(\Omega))$ and $\varphi \in L^\infty(H_0^1(\Omega))$ such that

$$\frac{\mathrm{d}u}{\mathrm{d}t} \in L^2(H^{-1}(\Omega)), \quad u(\cdot,0) = u_0 \textit{ in } \Omega,$$

and

$$(3)\quad \begin{cases} \displaystyle\int_0^T \left\langle \frac{\mathrm{d}u}{\mathrm{d}t}, v \right\rangle + \int_Q a(u)\nabla u \nabla v = \int_Q T_j\left(\sigma(u)|\nabla\varphi|^2\right) v,\ \textit{for all } v \in L^2(H_0^1(\Omega)), \\ \displaystyle\int_\Omega \sigma(u)\nabla\varphi\nabla\psi = \int_\Omega F(u)\nabla\psi,\ \textit{for all } \psi \in H_0^1(\Omega),\ \text{a.e. } t \in (0,T). \end{cases}$$

For the proof of this result one may follow the same arguments as in the proof of the existence theorem for the thermistor problem ([4]).

3. The main result. We make the following assumptions:

(H.1) $a, \sigma : Q \times \mathbb{R} \to \mathbb{R}$ and $F : Q \times \mathbb{R} \to \mathbb{R}^N$ are Caratheodory functions and there exists a nondecreasing function $\gamma : \mathbb{R}^+ \to \mathbb{R}^+$ such that

$$\max\left(a(x,t,s), \sigma(x,t,s), |F(x,t,s)|\right) \leq \gamma(|s|),\ \text{for all } s \in \mathbb{R},\ \text{a.e. in } Q.$$

(H.2) There exist two constant values $a_0 > 0$ and $\sigma_0 > 0$ such that

$$a(x,t,s) \geq a_0,\ \sigma(x,t,s) \geq \sigma_0,\ \text{for all } s \in \mathbb{R},\ \text{a.e. in } Q.$$

(H.3) There exists a function $\Gamma \in L^1(Q)$ such that

$$|F(x,t,s)|^2 \leq \Gamma(x,t)\sigma(x,t,s),\ \text{for all } s \in \mathbb{R},\ \text{a.e. in } Q.$$

(H.4) $\displaystyle\max_{k \leq |s| \leq 2k} \operatorname*{ess\,sup}_Q \frac{1}{k}\frac{\sigma(x,t,s)}{a(x,t,s)} = \omega(k)$ as $k \to +\infty$, where $\omega(k)$ stands for a null sequence, that is, $\lim_{k\to\infty} \omega(k) = 0$.

(H.5) $u_0 \in L^1(\Omega)$.

Hypothesis (H.1) is one of the main difficulties in the resolution of problem (1). As it has been stated in section 1, we cannot expect to search for weak solutions. However, assumptions (H.3) and (H.4) give a relation of the asymptotic behavior of $a(s)$, $\sigma(s)$ and $F(s)$ for large values of s.

We introduce now the definition of renormalized solutions to problem (1).

DEFINITION 5. *A couple of functions (u, φ) is called a renormalized solution to problem* (1) *if the following conditions are fulfilled:*

(R.1) $u \in L^1(\Omega)$, $\varphi \in L^2(H_0^1(\Omega))$, *and* $\int_Q \sigma(u)|\nabla\varphi|^2 < +\infty$;
(R.2) $T_M(u) \in L^2(H_0^1(\Omega))$ *for all* $M > 0$;
(R.3) $\lim_{n\to\infty} \int_{\{n\le|u|<n+1\}} a(u)\nabla u\nabla u = 0$;
(R.4) *For all* $S \in C^\infty(\mathbb{R})$ *with* supp S' *compact,*

$$\frac{\partial S(u)}{\partial t} - \nabla\cdot[a(u)\nabla u S'(u)] + S''(u)a(u)\nabla u\nabla u = \sigma(u)|\nabla\varphi|^2 S'(u) \text{ in } \mathcal{D}'(Q),$$
$$S(u(\cdot,0)) = S(u_0) \text{ in } \Omega;$$

(R.5) *For all* $\psi \in L^2(H_0^1(\Omega))$ *such that* $\int_Q \sigma(u)|\nabla\psi|^2 < +\infty$, *we have*

$$\int_Q \sigma(u)\nabla\varphi\nabla\psi = -\int_Q F(u)\nabla\psi.$$

Remark. Properties (R.1)–(R.4) on u are the usual conditions verified by renormalized solutions of parabolic equations ([7]). On the other hand, (R.5) says in particular that the set of test functions in the equation for φ depends upon the solution u.

We can now state the main result of this work.

THEOREM 6. *Under hypotheses* (H.1)–(H.5), *system* (1) *admits a renormalized solution* (u,φ) *in the sense of Definition* 5.

4. Proof of Theorem 6. The proof is divided into three steps: first, we introduce a sequence of approximate problems; then, we derive certain estimates for the approximate solutions; and finally, we pass to the limit and conclude.

4.1. Setting of the approximate problems. For every $j > 0$, we consider the truncation functions defined by

$$a_j(x,t,s) = a(x,t,T_j(s)), \quad \sigma_j(x,t,s) = \sigma(x,t,T_j(s)), \quad F_j(x,t,s) = F(x,t,T_j(s)),$$

where T_j is defined in (2). Thanks to $a_j, \sigma_j \in L^\infty(Q\times\mathbb{R})$ and $F_j \in L^\infty(Q\times\mathbb{R})^N$.

The approximate problems are stated as follows: to find $u_j \in L^2(H_0^1(\Omega))$ and $\varphi_j \in L^\infty(H_0^1(\Omega))$ such that $\frac{\mathrm{d}u_j}{\mathrm{d}t} \in L^2(H^{-1}(\Omega))$, $u_j(\cdot,0) = T_j(u_0)$ in Ω and

$$(4)\quad \begin{cases} \displaystyle\int_0^T \left\langle \frac{\mathrm{d}u_j}{\mathrm{d}t}, v\right\rangle + \int_Q a_j(u_j)\nabla u_j\nabla v = \int_Q T_j\left(\sigma_j(u_j)|\nabla\varphi_j|^2\right) v, \text{ for all } v\in L^2(H_0^1(\Omega)), \\ \displaystyle\int_\Omega \sigma_j(u_j)\nabla\varphi_j\nabla\psi = -\int_\Omega F_j(u_j)\nabla\psi, \text{ for all } \psi\in H_0^1(\Omega), \text{ a.e. } t\in(0,T). \end{cases}$$

By virtue of Theorem 4, we know that for each $j > 0$, there exists (u_j,φ_j) verifying all these conditions.

4.2. Estimates for (u_j) and (φ_j). Choosing $\psi = \varphi_j$ in the equation for φ_j and integrating over Q yields,

$$\int_Q \sigma_j(u_j)|\nabla\varphi_j|^2 = -\int_Q F_j(u_j)\nabla\varphi_j \le \left(\int_Q \sigma_j(u_j)^{-1}|F_j(u_j)|^2\right)^{1/2}\left(\int_Q \sigma_j(u_j)|\nabla\varphi_j|^2\right)^{1/2},$$

hence, using (H.3),

$$(5)\qquad \int_Q \sigma_j(u_j)|\nabla\varphi_j|^2 \le \int_Q \sigma_j(u_j)^{-1}|F_j(u_j)|^2 \le \int_Q \Gamma = C.$$

In this way, the sequence $\left(\sigma_j(u_j)|\nabla\varphi_j|^2\right)$ is bounded in $L^1(Q)$. We may rewrite the parabolic equation of (4) as

$$\left\{ \begin{array}{c} \displaystyle\int_0^T \left\langle \frac{\mathrm{d}u_j}{\mathrm{d}t}, v \right\rangle + \int_Q a_j(u_j)\nabla u_j \nabla v = \int_Q f_j v, \text{ for all } v \in L^2(H_0^1(\Omega)), \\ u_j(\cdot,0) = T_j(u_0), \end{array} \right. \tag{6}$$

where $f_j = T_j\left(\sigma_j(u_j)|\nabla\varphi_j|^2\right)$. Since the sequences (f_j) and $(T_j(u_0))$ are bounded in $L^1(Q)$ and $L^1(\Omega)$, respectively, we may deduce some well-known estimates for the sequence of solutions to (6) (u_j) in suitable Banach spaces ([7, 10]), namely

$$(u_j) \text{ is bounded in } L^\infty(L^1(\Omega)); \tag{7}$$

for all $M > 0$ and $j \geq 1$, there exists a constant $C > 0$, not depending upon M and j, such that

$$\int_Q |\nabla T_M(u_j)|^2 \leq CM, \tag{8}$$

$$\int_{\{M \leq |u_j| < M+1\}} |\nabla u_j|^2 \leq C, \tag{9}$$

and also

$$\int_{\{M \leq |u_j| < M+1\}} a_j(u_j)\,|\nabla u_j|^2 \leq \int_{\{|u_j| > M\}} |f_j| + \int_{\{|u_0| > M\}} |u_0|. \tag{10}$$

Owing to (7), (9), and Lemma 3, we have

$$(u_j) \text{ is bounded in } L^q(W_0^{1,q}(\Omega)), \text{ for all } q < \frac{N+2}{N+1} \text{ if } N \geq 2,\ q < 2 \text{ if } N = 1. \tag{11}$$

As far as the parabolic term $\frac{\mathrm{d}u_j}{\mathrm{d}t}$ is concerned, we proceed as follows. Let $S \in C^\infty(\mathbb{R})$ with supp $S' \subset [-M, M]$. Taking $v = S'(u_j)\phi$, $\phi \in \mathcal{D}(\Omega)$, in (6), it yields

$$\frac{\mathrm{d}S(u_j)}{\mathrm{d}t} - \nabla \cdot [a_j(u_j)\nabla u_j S'(u_j)] + S''(u_j)a_j(u_j)\nabla u_j \nabla u_j = f_j S'(u_j) \text{ in } \mathcal{D}'(\Omega). \tag{12}$$

Thanks to (8) and (H.1) we obtain

$$\left(\frac{\mathrm{d}S(u_j)}{\mathrm{d}t}\right) \text{ is bounded in } L^2(H^{-1}(\Omega)) + L^1(Q).$$

Since $L^2(H^{-1}(\Omega)) + L^1(Q) \hookrightarrow L^1(W^{-1,r}(\Omega))$, $r < \frac{N}{N-1}$, with continuous inclusion, we have

$$\left(\frac{\mathrm{d}S(u_j)}{\mathrm{d}t}\right) \text{ is bounded in } L^1(W^{-1,r}(\Omega)) \text{ for all } r < \frac{N}{N-1}. \tag{13}$$

Furthermore, using (11), we readily have

$$(S(u_j)) \text{ is bounded in } L^q(W_0^{1,q}(\Omega)), \text{ for all } q < \frac{N+2}{N+1}, \text{ if } N \geq 2,\ q < 2 \text{ if } N = 1.$$

Now we apply the compactness result stated in Lemma 1. To do so, we take

$$X = W_0^{1,q}(\Omega), \quad B = L^q(\Omega), \quad Y = W^{-1,r}(\Omega);$$

therefore,

$$(S(u_j)) \text{ is relatively compact in } L^q(Q) \text{ for all } q < \frac{N+2}{N+1}. \tag{14}$$

Property (14) is not enough to deduce the almost everywhere convergence of (u_j) modulo a subsequence. We must also use the estimates derived above. To this end, let $M > 0$ and consider a function $S \in C^\infty(\mathbb{R})$ satisfying

(i) supp S' is compact,
(ii) S is nondecreasing, and
(iii) $S(s) = s$ if $|s| \le M$.

Therefore, we have the identity $T_M(s) = T_M(S(s))$ for all $s \in \mathbb{R}$, and, in particular,

$$T_M(u_j) = T_M(S(u_j)). \tag{15}$$

According to (8), for every $M > 0$ there exist a subsequence, which will be denoted in the same way, and a function $z_M \in L^2(H_0^1(\Omega))$ such that

$$T_M(u_j) \to z_M \text{ weakly in } L^2(H_0^1(\Omega)). \tag{16}$$

On the other hand, from (14), there exist a subsequence, still denoted in the same way, and a function $\varsigma_S \in L^q(Q)$ such that

$$S(u_j) \to \varsigma_S \text{ strongly in } L^q(Q) \text{ and a.e. in } Q. \tag{17}$$

Notice that (15) and (17) imply that $T_M(u_j)$ converges almost everywhere to $T_M(\varsigma_S)$; this fact, together with (16), implies that $z_M = T_M(\varsigma_S)$.

Furthermore, from (11), there exist $u \in L^q(W_0^{1,q}(\Omega))$ and a subsequence of (u_j) such that

$$u_j \to u \text{ weakly in } L^q(W_0^{1,q}(\Omega)), \text{ for all } q < \frac{N+2}{N+1} \text{ if } N \ge 2,\ q < 2 \text{ if } N = 1.$$

All these convergences lead to (modulo a subsequence) the almost everywhere convergence of (u_j). Indeed, this property can be readily derived from the next result ([19]).

LEMMA 7. *Let $q \ge 1$, $A \subset \mathbb{R}^N$ a nonnegligible measurable set, $(w_j) \subset L^q(A)$, $w \in L^q(A)$ be such that*

$$w_j \to w \text{ weakly in } L^q(A).$$

Assume that for every $M > 0$ there exists $v_M \in L^1(A)$ such that

$$T_M(v_j) \to v_M \text{ a.e. in } A,$$

then $T_M(w) = v_M$, for all $M > 0$ (and in particular $w_j \to w$ almost everywhere in A).

Summing up, we have shown the existence of subsequences, still denoted in the same way, (u_j), (φ_j), and functions $u \in L^q(W_0^{1,q}(\Omega))$ and $\varphi \in L^2(H_0^1(\Omega))$ such that

$$u_j \to u \text{ weakly in } L^q(W_0^{1,q}(\Omega)), \text{ for all } q < \frac{N+2}{N+1} \text{ if } N \ge 2,\ q < 2 \text{ if } N = 1, \tag{18}$$

$$T_M(u_j) \to T_M(u) \quad \text{weakly in } L^2(H_0^1(\Omega)), \tag{19}$$

$$u_j \to u \quad \text{a.e. in } Q, \tag{20}$$

$$S(u_j) \to S(u) \quad \text{strongly in } L^r(Q) \text{ for all } r < +\infty, \tag{21}$$

$$\frac{\mathrm{d}S(u_j)}{\mathrm{d}t} \to \frac{\mathrm{d}S(u)}{\mathrm{d}t} \quad \text{in } \mathcal{D}'(Q), \tag{22}$$

$$\varphi_j \to \varphi \quad \text{weakly in } L^2(H_0^1(\Omega)), \tag{23}$$

where (21) and (22) are valid for all $S \in C^\infty(\Omega)$ with supp S' compact, and (23) is obtained from (5) and (H.2).

Now we turn our attention to (φ_j) and φ. First of all, we show that

$$\sigma_j(u_j)^{1/2}\nabla\varphi_j \to \sigma(u)^{1/2}\nabla\varphi \text{ weakly in } L^2(Q)^N. \tag{24}$$

Indeed, from (5), there exist a subsequence and $\Phi \in L^2(Q)^N$ such that

$$\sigma_j(u_j)^{1/2}\nabla\varphi_j \to \Phi \text{ weakly in } L^2(Q)^N. \tag{25}$$

Using (20) and (H.2), it yields

$$\sigma_j(u_j)^{-1/2} \to \sigma(u)^{-1/2} \text{ weakly–}* \text{ in } L^\infty(Q) \text{ and a.e. in } Q. \tag{26}$$

Putting

$$\nabla\varphi_j = \sigma_j(u_j)^{-1/2}\sigma_j(u_j)^{1/2}\nabla\varphi_j, \tag{27}$$

and passing to the limit, gathering (25)–(27), we obtain $\Phi = \sigma(u)^{1/2}\nabla\varphi$, and this shows the statement (24). Notice that, in particular, $\sigma(u)|\nabla\varphi|^2 \in L^1(Q)$.

One of the most delicate parts in the passing to the limit consists in showing the convergence

$$\sigma_j(u_j)^{1/2}\nabla\varphi_j \to \sigma(u)^{1/2}\nabla\varphi \text{ strongly in } L^2(Q)^N. \tag{28}$$

From (24), it is enough to show that

$$\int_Q \sigma_j(u_j)|\nabla\varphi_j|^2 \to \int_Q \sigma(u)|\nabla\varphi|^2. \tag{29}$$

To do this, we first introduce the function $S_k \in W^{1,\infty}(\mathbb{R})$, $k > 0$, defined as

$$S_k(s) = \begin{cases} 1 & \text{if } |s| \le k, \\ (2k - |s|)/k & \text{if } k < |s| \le 2k, \\ 0 & \text{if } |s| > 2k. \end{cases} \tag{30}$$

Note that supp $S_k = [-2k, 2k]$ and $S_k'(s) = \frac{1}{k}\left(\chi_{(-2k,-k)} - \chi_{(k,2k)}\right)$. Then, we take in (4) the test function $\psi = S_k(u_j)T_M(\varphi) \in L^\infty(H_0^1(\Omega))$. The integration over $(0,T)$ leads to

$$\begin{aligned} &\int_Q \sigma_j(u_j)\nabla\varphi_j\nabla T_M(\varphi)S_k(u_j) + \int_Q \sigma_j(u_j)\nabla\varphi_j\nabla u_j S_k'(u_j)T_M(\varphi) \\ &\quad = -\int_Q F_j(u_j)\nabla T_M(\varphi)S_k(u_j) - \int_Q F_j(u_j)\nabla u_j S_k'(u_j)T_M(\varphi); \end{aligned}$$

we call these terms (I)–(IV) and study them separately.
(I). Since $\sigma_j(u_j)S_k(u_j) = \sigma_j(T_{2k}(u_j))S_k(u_j) \in L^\infty(Q)$ and is bounded in this space, using (20) it yields

$$\sigma_j(u_j)S_k(u_j) \to \sigma(u)S_k(u) \text{ weakly–}* \text{ in } L^\infty(Q) \text{ and a.e. in } Q.$$

From (23), making $j \to \infty$, we readily obtain

$$\int_Q \sigma_j(u_j)\nabla\varphi_j\nabla T_M(\varphi)S_k(u_j) \to \int_Q \sigma(u)\nabla\varphi T_M(\varphi)S_k(u).$$

Owing to Lebesgue's theorem, we finally deduce

$$\lim_{M\to\infty}\lim_{k\to\infty}\lim_{j\to\infty}\int_Q \sigma_j(u_j)\nabla\varphi_j\nabla T_M(\varphi)S_k(u_j) = \int_Q \sigma(u)|\nabla\varphi|^2.$$

(II). We first derive another estimate for (u_j). Let $H_k \in W^{1,\infty}(\mathbb{R})$ be the function

$$H_k(s) = \begin{cases} 0 & \text{if } |s| \le k, \\ (|s|-k)/k & \text{if } k < |s| \le 2k, \\ |s|/s & \text{if } |s| > 2k, \end{cases}$$

then put $\tilde{H}_k(s) = \int_0^s H_k(\tau)\mathrm{d}\tau$ and $E_j^k = \{k < |u_j| < 2k\}$. Choosing $v = H_k(u_j)$ in (4) yields

$$\int_\Omega \tilde{H}_k(u_j(T)) + \frac{1}{k}\int_{E_j^k} a_j(u_j)|\nabla u_j|^2 = \int_Q f_j H_k(u_j) + \int_\Omega \tilde{H}_k(T_j(u_0));$$

therefore, for all $j \ge 1$ and $k > 0$, there exists a constant $C > 0$, not depending upon j and k, such that

$$\frac{1}{k}\int_Q a_j(u_j)|\nabla u_j|^2\chi_{E_j^k} \le C,$$

that is,

$$\left(\frac{1}{\sqrt{k}}a_j(u_j)^{1/2}\nabla u_j\chi_{E_j^k}\right) \text{ is bounded (in } j \text{ and } k) \text{ in } L^2(Q)^N. \tag{31}$$

Going back to (II)

$$(II) = \int_Q \sigma_j(u_j)^{1/2}\nabla\varphi_j\sigma_j(u_j)^{1/2}a_j(u_j)^{-1/2}a_j(u_j)^{1/2}\nabla u_j S_k'(u_j)T_M(\varphi),$$

thus

$$\begin{aligned} |(II)| &\le M\int_Q \left|\sigma_j(u_j)^{1/2}\nabla\varphi_j\,\frac{1}{\sqrt{k}}\sigma_j(u_j)^{1/2}a_j(u_j)^{-1/2}\,\frac{1}{\sqrt{k}}a_j(u_j)^{1/2}\nabla u_j\chi_{E_j^k}\right| \\ &\le M\left\|\sigma_j(u_j)^{1/2}\nabla\varphi_j\right\|_{L^2(Q)}\cdot\left\|\frac{1}{\sqrt{k}}a_j(u_j)^{1/2}\nabla u_j\chi_{E_j^k}\right\|_{L^2(Q)} \\ &\qquad\cdot\left\|\frac{1}{\sqrt{k}}\sigma_j(u_j)^{1/2}a_j(u_j)^{-1/2}\chi_{E_j^k}\right\|_{L^\infty(Q)}. \end{aligned}$$

Hence, from (H.4), (5), and (31), we deduce

$$|(II)| \leq C\omega(k),$$

which implies

$$\lim_{k\to\infty} \limsup_{j\to\infty} \int_Q \sigma_j(u_j)\nabla\varphi_j \nabla u_j S_k'(u_j) T_M(\varphi) = 0.$$

(III). Lebesgue's theorem easily shows that

$$\lim_{j\to\infty} \int_Q F_j(u_j)\nabla T_M(\varphi) S_k(u_j) = \int_Q F(u)\nabla T_M(\varphi) S_k(u).$$

We now express this last integral as

$$\int_Q F(u)\sigma(u)^{-1/2}\sigma(u)^{1/2}\nabla T_M(\varphi) S_k(u).$$

Owing to (H.3) and (24) we can apply again Lebesgue's theorem, first in k, then in M, to deduce finally that

$$\lim_{M\to\infty} \lim_{k\to\infty} \lim_{j\to\infty} \int_Q F_j(u_j)\nabla T_M(\varphi) S_k(u_j) = \int_Q F(u)\nabla\varphi. \tag{32}$$

(IV). Following the same techniques as in (II) and (III), it is straightforward that

$$\lim_{k\to\infty} \limsup_{j\to\infty} \int_Q F_j(u_j)\nabla u_j S_k'(u_j) T_M(\varphi) = 0.$$

Gathering (27)–(32),

$$\int_Q \sigma(u)|\nabla\varphi|^2 = -\int_Q F(u)\nabla\varphi. \tag{33}$$

On the other hand, taking $\psi = \varphi_j$ in (4) and integrating over $(0,T)$, we obtain

$$\int_Q \sigma_j(u_j)|\nabla\varphi_j|^2 = -\int_Q F_j(u_j)\nabla\varphi_j;$$

since $F_j(u_j)\nabla\varphi_j = F_j(u_j)\sigma_j(u_j)^{-1/2}\sigma_j(u_j)^{1/2}\nabla\varphi_j$, and bearing in mind (H.3), (20), and (24), we conclude that

$$\int_Q F_j(u_j)\nabla\varphi_j \to \int_Q F(u)\nabla\varphi; \tag{34}$$

putting together (33)–(34) gives directly (29), that is, $\sigma_j(u_j)^{1/2}\nabla\varphi_j \to \sigma(u)^{1/2}\nabla\varphi$ strongly in $L^2(Q)^N$. This also implies that

$$f_j = T_j\left(\sigma_j(u_j)|\nabla\varphi_j|^2\right) \to \sigma(u)|\nabla\varphi|^2 \text{ strongly in } L^1(Q). \tag{35}$$

The last relevant convergence to be shown before passing to the limit in the approximate problems (4) is,

$$T_M(u_j) \to T_M(u) \text{ strongly in } L^2(H_0^1(\Omega)), \text{ for every } M > 0. \tag{36}$$

In fact, this is a consequence of (6), (19), and (35), but it is not an immediate result; for details of the proof of this property the reader is referred to [8].

4.3. Passing to the limit and conclusion. Let u and φ be the limit functions given in (18) and (23). Here we show that both functions verify (R.1)–(R.5) of Definition 5.

In fact, (R.1) and (R.2) have been already obtained.

By virtue of (19), (20), and (35), making $j \to \infty$ in (10) yields

$$\int_{\{M\le|u|<M+1\}} a(u)|\nabla u|^2 \le \int_{\{|u|>M\}} \sigma(u)|\nabla\varphi|^2 + \int_{|u_0|>M} |u_0|;$$

due to hypothesis (H.5) and making $M \to \infty$ in this last expression, we can easily derive (R.3).

In order to obtain (R.4), we just take $v = S(u_j)\phi$ in (4) with $S \in C^\infty(\mathbb{R})$, supp S' compact and $\phi \in \mathcal{D}(\Omega)$. Thanks to the convergence properties derived in the preceding section, we can make $j \to \infty$ and this yields the variational formulation (R.4). Note that the strong convergence of the truncations function $T_M(u_j) \to T_M(u)$ in $L^2(H_0^1(\Omega))$ is essential in this stage. It remains to state the initial condition $S(u(\cdot,0)) = S(u_0)$; to do so, we apply Lemma 2 with the following choices:

$$X = L^\infty(\Omega), \quad B = Y = W^{-1,r}(\Omega), \text{ any } r < \frac{N}{N-1},$$

and put $E = \{S(u_j)\}_{j\ge1}$, supp $S' = [-M, M]$. Obviously, E is bounded in $L^\infty(X)$ and, according to (13), $\frac{\mathrm{d}v}{\mathrm{d}t} \in L^1(Y)$ for all $v \in E$. Also, by virtue of (12), we can write

$$\frac{\mathrm{d}S(u_j)}{\mathrm{d}t} = f_j S'(u_j) - S''(u_j)a_j(T_M(u_j))|\nabla T_M(u_j)|^2 + \nabla\cdot[a_j(T_M(u_j))\nabla T_M(u_j)S'(u_j)]\,.$$

Now, from (20) and (35), $f_jS'(u_j)$ converges strongly in $L^1(Q)$ and from (20) and (36), $S''(u_j)a_j(T_M(u_j))|\nabla T_M(u_j)|^2$ converges strongly in $L^1(Q)$. Owing to Lebesgue's inverse theorem, there exists $\bar h \in L^1(Q)$ such that

$$|\Phi_j| \le \bar h \text{ for all } j \ge 1 \text{ and a.e. in } Q,$$

where $\Phi_j = f_jS'(u_j) - S''(u_j)a_j(u_j)|\nabla u_j|^2$. Consequently,

$$\|\Phi_j\|_{W^{-1,r}(\Omega)} \le C\|\Phi_j\|_{L^1(\Omega)} \le C\|\bar h\|_{L^1(\Omega)}, \text{ for all } r < \frac{N}{N-1},\ j \ge 1, \text{a.e. } t \in (0,T).$$

On the other hand, the last term $\nabla\cdot[a_j(T_M(u_j))\nabla T_M(u_j)S'(u_j)]$ is bounded in $L^2(H^{-1}(\Omega))$, and therefore it is also bounded in $L^2(W^{-1,r}(\Omega))$, for all $r < \frac{N}{N-1}$. Hence, we may take $h = C\|\bar h\|_{L^1(\Omega)} \in L^1(0,T)$ and $s = 2$ to deduce that

$$\left\|\frac{\mathrm{d}S(u_j)}{\mathrm{d}t}\right\|_Y \le h + \|\nabla\cdot[a_j(T_M(u_j))\nabla T_M(u_j)S'(u_j)]\|_Y\,, \text{ for all } j \ge 1, \text{ a.e. } t \in (0,T).$$

By Lemma 2, this means that $(S(u_j))$ is relatively compact in $C^0\left([0,T];W^{-1,r}(\Omega)\right)$ for any $r < \frac{N}{N-1}$ and thus, there exists a subsequence, still denoted in the same way, such that $(S(u_j))$ converges in $C^0\left([0,T];W^{-1,r}(\Omega)\right)$. From (21), this limit must be $S(u)$. In particular,

$$S(u_j(\cdot,0)) \to S(u(0)) \text{ in } W^{-1,r}(\Omega),$$

and since $S(u_j(0)) = S(T_j(u_0)) \to S(u_0)$ in $L^1(\Omega)$-strongly, we deduce the initial condition

$$S(u(\cdot,0)) = S(u_0) \text{ in } W^{-1,r}(\Omega),\ r < \frac{N}{N-1}.$$

Finally, in order to derive (R.5), we just take $\psi = S_k(u_j)T_M(\phi)$ in (3), where S_k is defined in (30) and $\phi \in L^2(H_0^1(\Omega))$ is such that $\int_Q \sigma(u)|\nabla\phi|^2 < +\infty$. In this situation, we can proceed as in (I)–(IV) above: taking the iterate limits, first in j, then in k, then in M, and the last expression becomes (R.5).

This ends the proof of Theorem 6. □

5. Concluding remarks. The diffusion coefficients a and σ are scalar functions in the setting given by hypotheses (H.1)–(H.4). We may consider a more general setting in which a and σ are diffusion matrices of order $N \times N$. The hypotheses on this data read as follows:

(H.1) $a, \sigma : Q \times \mathbb{R} \to \mathbb{R}^{N\times N}$ and $F : Q \times \mathbb{R} \to \mathbb{R}^N$ are Caratheodory functions and there exists a nondecreasing function $\gamma : \mathbb{R}^+ \to \mathbb{R}^+$ such that

$$\max\left(\|a(x,t,s)\|, \|\sigma(x,t,s)\|, |F(x,t,s)|\right) \le \gamma(|s|),\ \text{for all } s \in \mathbb{R}, \text{ a.e. in } Q,$$

where $\|\cdot\|$ stands for the spectral norm.

(H.2) There are two constant values $a_0 > 0$ and $\sigma_0 > 0$ so that

$$a(x,t,s)\xi\xi \ge a_0|\xi|^2,\ \sigma(x,t,s)\xi\xi \ge \sigma_0|\xi|^2,\ \text{for all } s \in \mathbb{R},\ \xi \in \mathbb{R}^N, \text{ a.e. in } Q.$$

(H.3) $\Gamma \in L^1(Q)$ is a function satisfying

$$|\sigma(x,t,s)^{-\mathrm{S}/2}F(x,t,s)|^2 \le \Gamma(x,t),\ \text{for all } s \in \mathbb{R}, \text{ a.e. in } Q.$$

(H.4) $\displaystyle\max_{k\le|s|\le 2k} \operatorname*{ess\,sup}_Q \frac{1}{\sqrt{k}}\|\sigma(x,t,s)^{\mathrm{S}/2}a(x,t,s)^{-\mathrm{S}/2}\| = \omega(k)$ as $k \to +\infty$.

(H.5) $u_0 \in L^1(\Omega)$.

The notation in (H.3) and (H.4) is now explained: for a matrix $B \in \mathbb{R}^{N\times N}$, we denote by B^{S} the symmetric part of B, that is, $B^{\mathrm{S}} = (B + B')/2$. From (H.2), $\sigma(x,t,s)^{\mathrm{S}}$ and $a(x,t,s)^{\mathrm{S}}$ are positive definite; then $\sigma(x,t,s)^{\mathrm{S}/2}$ stands for the unique positive definite square root of $\sigma(x,t,s)$, whereas $a(x,t,s)^{-\mathrm{S}/2}$ represents the inverse matrix of the unique positive definite square root of $a(x,t,s)^{\mathrm{S}}$.

In this situation, the existence result given in Theorem 6 still holds true.

The analysis described in this paper shows that the concept of renormalized solutions may be applied to systems of parabolic-elliptic equations with unbounded diffusion coefficients. The existence result relies on certain assumptions on data, apart from the standard ones, describing the relation of the asymptotic behavior between them.

The uniqueness of renormalized solution to problem (1) is a very complex task to be deduced; this is due to the fact that all known uniqueness results for the thermistor problem are derived from L^∞ estimates verified by u and φ; this regularity may be obtained under certain restrictive assumptions, including for instance $F \in L^\infty$, $a, \sigma \in L^\infty$. In that setting, there is no need to search for renormalized solutions: one reencounters the setting of weak solutions.

Acknowledgment. The authors wish to thanks the referees for useful comments and suggestions which led to improvements in the presentation of this paper.

EXISTENCE OF ENERGY MINIMIZERS FOR MAGNETOSTRICTIVE MATERIALS*

PIOTR RYBKA† AND MITCHELL LUSKIN‡

Abstract. The existence of a deformation and magnetization minimizing the magnetostrictive free energy is given. Mathematical challenges are presented by a free energy that includes elastic contributions defined in the reference configuration and magnetic contributions defined in the spatial frame. The one-to-one a.e. and orientation-preserving property of the deformation is demonstrated, and the satisfaction of the nonconvex saturation constraint for the magnetization is proven.

Key words. calculus of variations, magnetostriction, micromagnetics

1. Introduction.

A mathematical model for magnetostrictive materials, in which the deformation and the magnetization are coupled, has been given in [4, 19, 20, 22, 8]. More significant shape change can be obtained from magnetostrictive materials that also undergo a structural phase transformation since the material can then lower its energy by an increase in the volume fraction of the martensitic variant with magnetic easy axis aligned with the applied magnetic field [11, 21]. This shape change is being utilized in emerging applications in actuators, sensors, and micromachines because they can provide a large *work output*/(*cycle* · *volume*) [25].

In this paper, we prove the existence of a deformation and magnetization minimizing the magnetostrictive free energy [4, 19, 20]. A novel feature of this free energy is that the elastic free energy is given in a reference configuration, as usual for elasticity, but the magnetic energies are given in the spatial frame. This requires that we use a free energy for which the Jacobian of the deformation can be controlled. We also must prove that the deformation is one-to-one a.e. and that the magnetization satisfies the nonconvex saturation constraint.

The existence of low energy phase and variant interfaces in single crystal thin films that do not exist in bulk martensitic crystals offers the possibility to develop thin materials with substantially larger strains than are possible in bulk [2]. Magnetostrictive, shape memory, single crystal, thin films such as Ni_2MnGa have recently been grown [11, 21]. We hope that this work will provide the foundation for our future work on the derivation of a rigorous magnetostrictive thin film energy to extend the results developed for micromagnetics [17] and martensitic deformation [2, 7, 6, 5].

The plan of our work is the following. In section 2, we introduce the magnetostriction model and in particular we present the constitutive assumptions. We shall

seek the minimizers in an admissible set $\mathcal{A}$, described in section 2, that incorporates all of the constraints. To prove the existence of minimizers, we demonstrate in Theorem 3.1 that $\mathcal{A}$ is closed in a weak topology. We then show in section 4 that $\mathcal{E}$ is lower semicontinuous on $\mathcal{A}$, and hence that it attains its minimum. This is the content of Theorem 4.2 and is the main result of this paper.

2. The magnetostriction model. We consider a magnetostrictive crystal that in an undeformed state occupies the Lipschitz domain $\Omega \subset \mathbb{R}^3$. The admissible deformations $\bar{y} : \Omega \to \mathbb{R}^3$ of the crystal will be required to have the regularity $y \in W^{2,2}(\Omega;\mathbb{R}^3)$, to be orientation-preserving ($\det \nabla y > 0$ a.e. [18]), and to be one-to-one a.e., where we recall that a mapping $y : \Omega \to \mathbb{R}^3$ is *one-to-one a.e.* if there is a set $G \subset \Omega$ of full measure (that is, $|G| = |\Omega|$) such that $y(x)$ restricted to G is one-to-one. The one-to-one property everywhere of $y(x)$ would seem more appropriate; however, it is the weaker property that we will prove is preserved under weak convergence in $W^{2,2}(\Omega;\mathbb{R}^3)$.

The demonstration that energy-minimizing deformations obtained from the calculus of variations are one-to-one often requires sophisticated techniques [28], such as for problems with cavitation [27] or other problems with low regularity. Since our problem has higher regularity, simpler methods based on Banach's indicatrix are sufficient.

Because of the continuity of $y \in W^{2,2}(\Omega;\mathbb{R}^3)$, it follows that the sets $y(\bar{\Omega})$ and $y(\partial\bar{\Omega})$ are closed and the deformed domain $\mathcal{O}(y) := y(\bar{\Omega}) \setminus y(\partial\bar{\Omega})$ is open. Here and in what follows the bar over a set denotes its closure. We note that $\mathcal{O}(y)$ differs from $y(\Omega)$ on a set of measure zero [14] and $|\mathcal{O}(y)| = |y(\bar{\Omega})|$.

We wish to model a crystal that is attached on a nonempty, open subset of its boundary, $\Gamma \subset \partial\Omega$, so we will assume that admissible deformations $y(x)$ satisfy the boundary condition

$$y(x) = y_0(x) \qquad \text{for all } x \in \Gamma, \tag{2.1}$$

where $y_0 : \bar{\Omega} \to \mathbb{R}^3$ is a C^2 diffeomorphism with positive Jacobian.

The magnetization $m(z)$ of the crystal is naturally defined in spatial coordinates by $m : \mathcal{O}(y) \to \mathbb{R}^3$ and admissible magnetizations will be required to have the regularity $m \in W^{1,2}(\mathcal{O}(y);\mathbb{R}^3)$ which is equivalent to

$$\int_{\mathcal{O}(y)} \left[|\nabla_z m(z)|^2 + |m(z)|^2\right] dz = \int_\Omega \left[|\nabla_z m(y(x))|^2 + |m(y(x))|^2\right] \det \nabla y(x)\, dx < \infty.$$

We will often find it convenient as above to consider the magnetization $m \circ y : \Omega \to \mathbb{R}^3$ described in material coordinates. We will assume that the crystal is at a fixed temperature below the Curie temperature so that

$$|m(y(x))| \det \nabla y(x) = \tau, \qquad x \in \Omega, \tag{2.2}$$

where τ, the saturation magnetization, is a positive constant depending on the temperature.

The applied magnetic field will be given in spatial coordinates by $h : \mathbb{R}^3 \to \mathbb{R}^3$, and we will assume that $h \in L^2(\mathbb{R}^3;\mathbb{R}^3)$.

The free energy of a magnetostrictive crystal can be modeled by [20, 4],

$$\begin{aligned}\mathcal{E}(y,m) &= \int_\Omega \left\{\kappa \left|D^2 y(x)\right|^2 + \Phi\left(\nabla y(x), m\circ y(x)\right)\right\} dx \\ &\quad + \int_{\mathcal{O}(y)} \left\{\alpha \left|\nabla_z m(z)\right|^2 - h(z)\cdot m(z)\right\} dz + e_{\mathrm{mag}}(y,m) \\ &= \int_\Omega \Big\{\kappa \left|D^2 y(x)\right|^2 + \Phi\left(\nabla y(x), m\circ y(x)\right) \\ &\quad + \Big(\alpha \left|\nabla_z m\left(y(x)\right)\right|^2 - h(y(x))\cdot m(y(x))\Big) \det \nabla y(x)\Big\} dx + e_{\mathrm{mag}}(y,m),\end{aligned} \tag{2.3}$$

where the magnetostatic energy $e_{\mathrm{mag}}(y,m)$ is calculated from the magnetic scalar potential $\zeta : \mathbb{R}^3 \to \mathbb{R}$ by

$$e_{\mathrm{mag}}(y,m) = \frac{1}{2}\int_{\mathbb{R}^3} \left|\nabla_z \zeta(z)\right|^2 dz, \tag{2.4}$$

and where the magnetic scalar potential ζ satisfies

$$\mathrm{div}_z\left(-\nabla_z \zeta + \chi_{\mathcal{O}(y)} m\right) = 0, \qquad z \in \mathbb{R}^3. \tag{2.5}$$

We use the definition

$$\int_\Omega \left|D^2 y(x)\right|^2 dx = \int_\Omega \left[\sum_{i,j=1}^3 \left|\frac{\partial^2 y(x)}{\partial x_i \partial x_j}\right|^2\right] dx,$$

and we recall above that $\chi_{\mathcal{O}(y)}(z)$ is the characteristic function of $\mathcal{O}(y)$. The terms in (2.3) represent, from left to right, the surface energy [2, 26, 23], the anistropy energy, the exchange energy [17, 9], the interaction energy due to the applied magnetic field, and the magnetostatic energy. The parameters α and κ are positive material constants depending on the fixed temperature. The anisotropy energy density $\Phi(F,m)$ is a continuous function of the deformation gradient $F \in \mathbb{R}^{3\times 3}_+$ (where $\mathbb{R}^{3\times 3}_+$ denotes the group of 3×3 matrices with positive determinant) and the magnetization $m \in \mathbb{R}^3$. (Since the temperature is assumed to be fixed, we do not explicitly denote the dependence of the anisotropy energy density $\Phi(F,m)$ on temperature.)

We will assume that the anisotropy free energy density $\Phi \in C^2(\mathbb{R}^{3\times 3}_+ \times \mathbb{R}^3; \mathbb{R})$ is of the form

$$\Phi(F,m) = W(F,m) + \psi(\det F), \tag{2.6}$$

where $\psi : (0,\infty) \to \mathbb{R}$ is continuous, convex, and satisfies for

$$q > 2 \qquad \text{and} \qquad c_L > 0$$

the growth conditions

$$c_L(a^{-q} + a^q) \le \psi(a) \quad \text{for all } 0 < a < +\infty, \tag{2.7}$$

and where $W : \mathbb{R}^{3\times 3}_+ \times \mathbb{R}^3 \to \mathbb{R}$ is continuous and satisfies for

$$2 \le r < 6 \qquad \text{and} \qquad 0 < C_L < C_U$$

the growth conditions

$$C_L(|F|^2-1) \le W(F,m) \le C_U(|F|^r+1) \quad \text{for all } F \in \mathbb{R}^{3\times 3}_+ \text{ and } \ m \in \mathbb{R}^3. \tag{2.8}$$

We shall define the set of admissible functions to be

$$\mathcal{A} = \Big\{ (y,m) \in W^{2,2}(\Omega;\mathbb{R}^3) \times W^{1,2}(\mathcal{O}(y);\mathbb{R}^3) : y(x) = y_0(x) \text{ for all } x \in \Gamma,$$
$$\psi(\det \nabla y) \in L^1(\Omega),\ \det \nabla y > 0 \text{ a.e., and } y \text{ is one-to-one a.e.} \Big\},$$

where the growth properties of ψ were given in (2.7). We note that $\mathcal{A}$ is nonempty since we assumed in (2.1) that $y_0 : \bar{\Omega} \to \mathbb{R}^3$ is a C^2 diffeomorphism with positive Jacobian. We also note that $\mathcal{A}$ is not an affine space.

We shall show under the above assumptions that the problem

$$\min\{\mathcal{E}(y,m) : (y,m) \in \mathcal{A} \text{ and } |m(y(x))| \det \nabla y(x) = \tau \text{ for almost all } x \in \Omega\} \tag{2.9}$$

has a solution. We shall see that the terms

$$\int_{\mathcal{O}(y)} |\nabla_z m(z)|^2 \, dz = \int_\Omega |\nabla_z m|^2 \det \nabla y \, dx \quad \text{and} \quad \int_\Omega \psi(\det \nabla y)\, dx$$

in $\mathcal{E}$ require the most care in the analysis.

The anisotropy energy density for magnetostrictive crystals that undergo a structural phase transformation can have the form (2.6). To see this, we note that the anisotropy energy density for magnetostrictive crystals such as Ni_2MnGa is minimized at temperatures below the martensitic transformation on the wells [20, 21]

$$\mathcal{M} = \mathrm{SO}(3)(U_1,m_1) \cup \mathrm{SO}(3)(U_1,-m_1) \cup \cdots \cup \mathrm{SO}(3)(U_N,m_N) \cup \mathrm{SO}(3)(U_N,-m_N),$$

where $\det U_1 > 0$ and where for the symmetry group $\mathcal{G} \subset \mathrm{SO}(3)$ of the high temperature phase we have

$$\{(U_1,m_1),\dots,(U_N,m_N)\} = \{(QU_1Q^T, Qm_1) : Q \in \mathcal{G}\}. \tag{2.10}$$

We note that SO(3) is the group of proper rotations and

$$\mathrm{SO}(3)(U_k,\pm m_k) \equiv \{(RU_k, \pm Rm_k) : R \in \mathrm{SO}(3)\} \qquad \text{for } k = 1,\dots,N.$$

If $W(F,m)$ satisfies the property of frame indifference

$$W(RF,Rm) = W(F,m) \qquad \text{for all } F \in \mathbb{R}^{3\times 3}_+,\ m \in \mathbb{R}^3,\ R \in \mathrm{SO}(3),$$

and the property of material symmetry for the group, $\mathcal{G}$,

$$W(FQ,m) = W(F,m) \qquad \text{for all } F \in \mathbb{R}^{3\times 3}_+,\ m \in \mathbb{R}^3,\ R \in \mathcal{G},$$

then $\Phi(F,m)$ satisfies the property of frame indifference and material symmetry by the invariance of the determinant function. If $W(F,m)$ is minimized on the wells (2.10), that is,

$$W(\hat{F},\hat{m}) < W(F,m) \qquad \text{for all } (\hat{F},\hat{m}) \in \mathcal{M} \text{ and } (F,m) \in \mathbb{R}^{3\times 3}_+ \times \mathbb{R}^3 \setminus \mathcal{M}$$

and $\psi(a)$ is minimized at $\det U_1$, then $\Phi(F,m)$ is also minimized on the wells (2.10).

By rescaling the crystal domain Ω onto a domain of unit size, we can see that the dimensionless size of the surface energy coefficient (κ) and the exchange energy coefficient (α) become large for small crystals [9, 26, 17]. For the large crystal limit [9], the scaled micromagnetic energy converges to a phase theory which is the relaxation of the micromagnetics energy without exchange energy ($\alpha = 0$).

Since energy-minimizing solutions of (2.3) without surface energy ($\kappa = 0$) and exchange energy ($\alpha = 0$) do not generally exist, microstructures defined by minimizing sequences are studied in [20]. The existence of minimizers for a two-dimensional model without surface energy ($\kappa = 0$) and exchange energy ($\alpha = 0$) when the deformation is constrained on the boundary to be affine, $y(x) = Fx$, for $F \in \mathbb{R}^{2\times 2}_+$ in the lamination convex hull of a $\mathcal{M}$ with two wells ($N = 2$) was given in [10] using the method of convex integration.

3. Compactness and closure in the set of admissible functions. In order to demonstrate the existence of minimizers, we will use the direct method of the calculus of variations. For this purpose, we will show that weak limits of elements of $\mathcal{A}$ belong to $\mathcal{A}$. To be precise, we say that the sequence $\{(y_n, m_n)\} \subset \mathcal{A}$ *converges weakly* to $(y, m) \in \mathcal{A}$ if and only if

$$y_n \rightharpoonup y \quad \text{in } W^{2,2}(\Omega;\mathbb{R}^3),$$

and

$$\begin{aligned} \chi_{\mathcal{O}(y_n)} m_n &\rightharpoonup \chi_{\mathcal{O}(y)} m \qquad \text{in } L^2(\mathbb{R}^3;\mathbb{R}^3),\\ \chi_{\mathcal{O}(y_n)} \nabla_z m_n &\rightharpoonup \chi_{\mathcal{O}(y)} \nabla_z m \quad \text{in } L^2(\mathbb{R}^3;\mathbb{R}^{3\times 3}). \end{aligned}$$

It is possible to explain the weak convergence defined above within the general framework of Cartesian currents (see [15]). However, since y_n, m_n enjoy so much smoothness, we shall be content with easier, more direct methods.

It is convenient to introduce another definition. Namely, we say that a sequence $\{(y_n, m_n)\} \subset \mathcal{A}$ is $\mathcal{A}$-*bounded* if there exists a positive constant K, independent of n, such that

(3.1)
$$\int_\Omega \left\{ |D^2 y_n(x)|^2 + |\nabla y_n(x)|^2 + \psi(\det \nabla y_n(x)) \right\} dx + \int_{\mathcal{O}(y_n)} |\nabla_z m_n(z)|^2 \, dz \le K.$$

We now state the main technical result of this section.

THEOREM 3.1. *If a sequence $\{(y_n, m_n)\} \subset \mathcal{A}$ is $\mathcal{A}$-bounded, then there exists a subsequence (not relabeled) and $(y, m) \in \mathcal{A}$ such that (y_n, m_n) converges weakly to (y, m).*

This result is fundamental for our considerations. It guarantees the existence of candidates for minimizers, which are weak limits of minimizing sequences. We shall divide the proof into a number of tasks. We shall first deal with $\{y_n\}$ prior to discussing $\{m_n\}$.

Our main technical tool will be the distribution function. We define

$$\begin{aligned} A^n_t &= \{x \in \Omega : \det \nabla y_n(x) < t\}, \quad t < 1,\\ B^n_t &= \{x \in \Omega : \det \nabla y_n(x) > t\}, \quad t > 1. \end{aligned}$$

LEMMA 3.2. *If the sequence $\{(y_n, m_n)\} \subset \mathcal{A}$ is $\mathcal{A}$-bounded, then*

$$|A^n_t| \le t^q c_L^{-1} K \quad \textit{and} \quad |B^n_t| \le t^{-q} c_L^{-1} K.$$

Proof. Our starting point is simply

$$|A_t^n| = \int_{A_t^n} 1\,dx = \int_{A_t^n} \frac{t}{t}\,dx$$
$$\leq t \int_{A_t^n} \frac{1}{\det \nabla y_n}\,dx \leq t \left(\int_{A_t^n} \frac{1}{(\det \nabla y_n)^q}\,dx \right)^{\frac{1}{q}} \cdot |A_t^n|^{1-\frac{1}{q}}.$$

Hence, we have by (2.7) that

$$|A_t^n| \leq t^q \int_{A_t^n} (\det \nabla y_n)^{-q}\,dx \leq t^q c_L^{-1} \int_{A_t^n} \psi(\det \nabla y_n)\,dx \leq t^q c_L^{-1} K$$

for $t < 1$.

The argument leading to the second estimate is similarly given by

$$|B_t^n| = \int_{B_t^n} 1\,dx = \int_{B_t^n} \frac{t}{t}\,dx$$
$$\leq t^{-1} \int_{B_t^n} \det \nabla y_n\,dx \leq t^{-1} \left(\int_{B_t^n} (\det \nabla y_n)^q\,dx \right)^{\frac{1}{q}} \cdot |B_t^n|^{1-\frac{1}{q}}.$$

Hence, we have by (2.7) that

$$|B_t^n| \leq t^{-q} \int_{B_t^n} (\det \nabla y_n)^q\,dx \leq t^{-q} c_L^{-1} \int_{B_t^n} \psi(\det \nabla y_n)\,dx \leq t^{-q} c_L^{-1} K$$

for $t > 1$. ∎

We next state and prove a main lemma on the convergence of $\{y_n\}$. We note that the convergence result for $\det \nabla y_n$ below is better than that implied by the Sobolev embedding and compactness theorem [1, 16, 13]. It is due to the growth condition (2.7).

LEMMA 3.3. *If the sequence $\{(y_n, m_n)\} \subset \mathcal{A}$ is $\mathcal{A}$-bounded, then there exists a subsequence (not relabeled) such that*

$$y_n \rightharpoonup y \quad \text{in} \quad W^{2,2}(\Omega; \mathbb{R}^3),$$

and

$$\det \nabla y_n \to \det \nabla y \quad \text{in} \quad L^p(\Omega) \quad \text{for } p < q, \tag{3.2}$$

$$\det \nabla y_n \rightharpoonup \det \nabla y \quad \text{in} \quad L^q(\Omega), \tag{3.3}$$

$$\int_\Omega \psi(\det \nabla y)\,dx < \infty, \tag{3.4}$$

$$\det \nabla y > 0 \quad \text{a.e.} \tag{3.5}$$

Proof. In order to show existence of a subsequence (not relabeled) $\{y_n\}_{n=1}^\infty$, which is weakly convergent in $W^{2,2}(\Omega; \mathbb{R}^3)$, it is sufficient to prove a uniform in n bound on $\|y_n\|_{W^{2,2}}$. Due to the $\mathcal{A}$-boundedness of $\{(y_n, m_n)\}$, it is enough to prove a uniform bound on $\|y_n\|_{L^2}$. This easily follows from the boundary condition (2.1), the Poincaré

inequality [1, 16, 13], and the $\mathcal{A}$-boundedness because we have

$$\begin{aligned}\int_\Omega |y_n(x)|^2\,dx &\le 2\int_\Omega |y_n(x)-y_0(x)|^2\,dx + 2\int_\Omega |y_0(x)|^2\,dx\\ &\le 2C(\Omega)\int_\Omega |\nabla\left(y_n(x)-y_0(x)\right)|^2\,dx + 2\int_\Omega |y_0(x)|^2\,dx\\ &\le C\left(\int_\Omega |\nabla y_n(x)|^2\,dx + 1\right) \le C(K+1).\end{aligned}$$

Since the sequence $\{y_n\}$ converges weakly in $W^{2,2}(\Omega;\mathbb{R}^3)$ it follows from the Sobolev embedding theorem [1] that there exists a subsequence such that $y_n \longrightarrow y$ in $W^{1,p}(\Omega;\mathbb{R}^3)$ for $p<6$ and also in $C^{0,\alpha}(\overline{\Omega};\mathbb{R}^3)$ for $0<\alpha<1-\frac{3}{6}=\frac{1}{2}$. Thus, for another subsequence

$$\begin{aligned}\nabla y_n &\longrightarrow \nabla y \qquad \text{a.e.},\\ \det\nabla y_n &\longrightarrow \det\nabla y \qquad \text{a.e.},\\ \det\nabla y_n &\longrightarrow \det\nabla y \qquad \text{in } L^p(\Omega) \quad \text{for } p<2.\end{aligned} \tag{3.6}$$

We now show that we can improve the convergence in (3.6). For that purpose, we are going to show that $\{(\det\nabla y_n)^p\}$ is equi-integrable for any $p<q$, that is, for any given $\epsilon>0$ there is a $\delta>0$ such that, if $V\subset\Omega$ satisfies $|V|<\delta$, then

$$\int_V (\det\nabla y_n)^p\,dx < \epsilon.$$

Indeed, for any $V\subset\Omega$ and $t>1$ we have that

$$\int_V (\det\nabla y_n)^p\,dx = \left(\int_{V\setminus B_t^n} + \int_{V\cap B_t^n}\right)(\det\nabla y_n)^p\,dx. \tag{3.7}$$

Due to the definition of B_t^n, we can see that

$$\begin{aligned}\int_V (\det\nabla y_n)^p\,dx &\le t^p\,|V\setminus B_t^n| + \left(\int_{V\cap B_t^n}(\det\nabla y_n)^q\,dx\right)^{\frac{p}{q}}\cdot |B_t^n|^{1-\frac{p}{q}}\\ &\le t^p|V| + c_L^{-p/q}\left(\int_{B_t^n}\psi\left(\det\nabla y_n\right)\,dx\right)^{\frac{p}{q}}\cdot\left(t^{-q}c_L^{-1}K\right)^{\left(1-\frac{p}{q}\right)}\\ &\le t^p|V| + c_L^{-1}Kt^{-q+p}.\end{aligned}$$

We can now take $t>1$ so large that the second term is less than $\frac{\varepsilon}{2}$. Then we choose δ so small that $t^p\delta<\frac{\varepsilon}{2}$, and the claim follows since $|V|<\delta$.

After we choose an a.e.-convergent subsequence, we deduce by Vitali's theorem that

$$(\det\nabla y_n)^p \to (\det\nabla y)^p \quad \text{ in } L^1(\Omega) \quad \text{for } p<q.$$

Furthermore, we can infer that for this subsequence [3, Theorem 1],

$$\det\nabla y_n \longrightarrow \det\nabla y \ \text{ in } \ L^p(\Omega) \quad \text{for } p<q.$$

Thus, (3.2) follows.

In order to deduce (3.3), we notice that due to (2.7) the sequence $\det \nabla y_n$ is bounded in $L^q(\Omega)$. Hence, it contains a subsequence converging weakly to g. By uniqueness of the limit it follows that $g = \det \nabla y$.

To prove (3.4), we observe that since $\det \nabla y_n \to \det \nabla y$ in $L^1(\Omega)$, we have that there exists a subsequence (not relabeled) such that $\det \nabla y_n \to \det \nabla y$ a.e. Since ψ is continuous, we have also that $\psi(\det \nabla y_n) \to \psi(\det \nabla y)$ a.e. Thus, since sequence $\{(y_n, m_n)\}$ is $\mathcal{A}$-bounded, we have by Fatou's lemma [12] that

$$\int_\Omega \psi(\det \nabla y)\, dx \le \liminf_{n\to\infty} \int_\Omega \psi(\det \nabla y_n)\, dx \le K < \infty.$$

Our next task is to show that (3.5) holds. For this purpose, we use again the technique of distribution functions. Let us define for $t < 1$ the set

$$A_t = \{x \in \Omega :\ \det \nabla y < t\}.$$

It is clear that (3.5) holds once we establish the estimate

$$|A_t| \le c t^q, \tag{3.8}$$

where c is a positive constant. Since

$$\det \nabla y = \det \nabla y_n + (\det \nabla y - \det \nabla y_n)$$

and $\det \nabla y_n > 0$ a.e., we have for all $n \in \mathbb{N}$ that

$$A_t \subset A^n_{2t} \cup \{x \in \Omega :\ |\det \nabla y(x) - \det \nabla y_n(x)| \ge t\} \equiv A^n_{2t} \cup E^n.$$

By Egorov's theorem, for any $t \in (0,1)$ there is a $V \subset \Omega$ such that $|V| < t^q$ and $\det \nabla y_n$ converges uniformly to $\det \nabla y$ on $\Omega \setminus V$. Hence,

$$\begin{aligned} |A_t| &\le |A^n_{2t}| + |E^n \cap V| + |E^n \setminus V| \\ &\le c_L^{-1} K 2^q t^q + t^q + |E^n \setminus V|. \end{aligned}$$

However, for fixed t and sufficiently large n, the set $E^n \setminus V$ is empty. Thus, (3.8) holds with $c = 1 + c_L^{-1} K 2^q$. Hence, (3.5) follows. ∎

We remark that the methods we have presented and the assumptions on ψ allow us to prove similar convergence statements for $(\det \nabla y_n)^{-1}$. Indeed, we have the following lemma.

LEMMA 3.4. *If $1 \le p < q$, then $(\det \nabla y_n)^{-1}$ converges to $(\det \nabla y)^{-1}$ in $L^p(\Omega)$.*

Proof. By previous results, $\det \nabla y_n$ converges a.e., and the limit $\det \nabla y$ is positive a.e. Hence, $(\det \nabla y_n)^{-1} \to (\det \nabla y)^{-1}$ a.e. Due to Vitali's convergence theorem, it is sufficient to check that the sequence $(\det \nabla y_n)^{-p}$ is equi-integrable. To prove this, we suppose that $\epsilon > 0$ is given. Then for $V \subset \Omega$ with $|V| \le \delta$, similar to argument following (3.7), we have that

$$\begin{aligned} \int_V (\det \nabla y_n)^{-p}\, dx &= \left(\int_{V \setminus A^n_t} + \int_{V \cap A^n_t} \right) (\det \nabla y_n)^{-p}\, dx \\ &\le t^{-p} |V| + \left(\int_{V \cap A^n_t} (\det \nabla y_n)^{-q}\, dx \right)^{\frac{p}{q}} |A^n_t|^{1 - \frac{p}{q}} \\ &\le t^{-p} |V| + c_L^{-1} K t^{q-p} \le \epsilon \end{aligned}$$

for a suitable choice of t and δ. ∎

Finally, we want to make sure that the limit mapping y is indeed one-to-one a.e.

LEMMA 3.5. *Let us suppose that $\Omega \subset \mathbb{R}^3$ is open, the deformations $y_n : \Omega \to \mathbb{R}^3$ are one-to-one a.e., and $\det \nabla y_n > 0$ a.e. We also assume that the sequence y_n converges weakly in $W^{2,2}(\Omega)$ to y, $\det \nabla y_n \to \theta$ in $L^1(\Omega)$, and $\theta > 0$ a.e. Then y is one-to-one a.e. (and obviously $\det \nabla y = \theta$).*

Proof. We need a characterization of invertibility a.e. which is easy to apply to the limit y. Let us recall for that purpose the notion of Banach's indicatrix

$$N(y, \Omega, z) = \#\{x \in \Omega : \ y(x) = z\},$$

where we restrict our attention to the continuous representative of y. Of course, we have that $y(\Omega) = \{z \in \mathbb{R}^3 : \ N(y, \Omega, z) \geq 1\}$.

We claim that y is one-to-one a.e. if and only if

$$|\{z \in \mathbb{R}^3 : \ N(y, \Omega, z) \geq 2\}| = 0.$$

Indeed, let us suppose that $y|_G$ is one-to-one and G is of full measure. Since y has the Lusin property (see [14], section 5.2), we deduce that $E = y(\Omega \setminus G)$ has measure zero. Moreover, $N(y, \Omega, z) \geq 2$ if and only if $z \in E$.

On the other hand, let us suppose that $E = \{z \in \mathbb{R}^3 : \ N(y, \Omega, z) \geq 2\}$ has measure zero. We set $G = \Omega \setminus y^{-1}(E)$. We must show that $|y^{-1}(E)| = 0$. By the area formula (see [14], Theorem 5.11), we can see that

$$\int_{y^{-1}(E)} \det \nabla y(x)\, dx = \int_E N(y, \Omega, z)\, dz = 0.$$

Since $\det \nabla y > 0$ a.e., we deduce that $|y^{-1}(E)| = 0$.

We shall show that

$$N(y, \Omega, z) \leq 1 \quad a.e.$$

Let us take $\phi \in C_0(\mathbb{R}^3)$ such that $\phi \geq 0$. Obviously, we obtain since y_n is one-to-one a.e. that

$$\int_\Omega \phi(y_n(x)) \det \nabla y_n(x)\, dx = \int_{y_n(\Omega)} \phi(z)\, dz \leq \int_{\mathbb{R}^3} \phi(z)\, dz.$$

Hence,

$$\int_\Omega \phi(y(x)) \det \nabla y(x)\, dx \leq \int_{\mathbb{R}^3} \phi(z)\, dz.$$

Furthermore, this inequality implies that $N(y, \Omega, z) \leq 1$ a.e. That is, y is one-to-one a.e. as desired. ∎

Our next task is to prove the convergence of the sequence of magnetization vectors $\{m_n\}$.

LEMMA 3.6. *If $\{y_n, m_n\} \subset \mathcal{A}$ is a $\mathcal{A}$-bounded sequence, then there exists $m \in W^{1,2}(\mathcal{O}(y); \mathbb{R}^3)$ such that a subsequence (not relabeled) converges weakly to (y, m).*

Proof. We shall apply again the technique of distribution functions. We define the set

$$D_t^n = \{x \in \Omega : |\nabla_z m_n \circ y_n(x)| > t\}.$$

We claim that

$$|D_t^n| \leq K c_L^{-\frac{1}{q+1}} t^{-2\frac{q}{q+1}}. \tag{3.9}$$

Indeed, by the Schwartz inequality

$$\begin{aligned}
|D_t^n| &= \int_{D_t^n} 1\,dx = \int_{D_t^n} \left(\frac{|\nabla m_n| \det{}^{\frac{1}{2}} \nabla y_n}{|\nabla m_n| \det{}^{\frac{1}{2}} \nabla y_n} \right) dx \\
&\le \left(\int_{D_t^n} |\nabla m_n|^2 \det \nabla y_n \, dx \right)^{1/2} \left(\int_{D_t^n} |\nabla m_n|^{-2} (\det \nabla y_n)^{-1} \, dx \right)^{1/2} \\
&\le \frac{1}{t} K^{1/2} \left(\int_{D_t^n} \frac{1}{\det \nabla y_n} \, dx \right)^{1/2} \\
&\le \frac{1}{t} K^{1/2} \left(\int_{D_t^n} \frac{1}{(\det \nabla y_n)^q} \, dx \right)^{\frac{1}{2q}} |D_t^n|^{\frac{1}{2}(1-\frac{1}{q})} \\
&\le \frac{1}{t} K^{1/2} \left(\int_{D_t^n} c_L^{-1} \psi \left(\det \nabla y_n \right) \, dx \right)^{\frac{1}{2q}} |D_t^n|^{\frac{1}{2}(1-\frac{1}{q})} \\
&\le \frac{1}{t} c_L^{-\frac{1}{2q}} K^{\frac{1}{2}+\frac{1}{2q}} |D_t^n|^{\frac{1}{2}(1-\frac{1}{q})}.
\end{aligned}$$

Hence, (3.9) follows.

We recall that $\mathcal{O}(y) = y(\bar{\Omega}) \backslash y(\partial \bar{\Omega})$ is open. We define the two families of sets $\mathcal{O}_\varepsilon(y) = \{z \in \mathcal{O}(y) : \operatorname{dist}(z, \partial \mathcal{O}(y)) > \varepsilon\}$ and $\mathcal{O}^\epsilon(y) = \{z \in \mathbb{R}^3 : \ \operatorname{dist}(z, \mathcal{O}(y)) \le \epsilon\}$.

We note that

$$\bigcup_{\varepsilon > 0} \mathcal{O}_\varepsilon(y) = \mathcal{O}(y).$$

For $\varepsilon > 0$ fixed, we have that $\mathcal{O}_\varepsilon(y) \subset \mathcal{O}(y_n)$ for sufficiently large n because of the uniform convergence of y_n to y. We now claim that for any $\varepsilon > 0$ there exists a subsequence (not relabeled) such that

$$m_n \rightharpoonup m \quad \text{in} \quad W^{1,2}(\mathcal{O}_\varepsilon(y); \mathbb{R}^3). \tag{3.10}$$

We have for any $\varepsilon > 0$ that

$$\int_{\mathcal{O}_\varepsilon(y)} |\nabla_z m_n(z)|^2 \, dz \le \int_{\mathcal{O}(y_n)} |\nabla_z m_n(z)|^2 \, dz = \int_\Omega |\nabla_z m_n|^2 \det \nabla y_n \, dx \le K.$$

Due to the constraint (2.2), we can see that

$$\begin{aligned}
\int_{\mathcal{O}(y_n)} |m_n(z)|^2 \, dz &= \int_\Omega |m_n(y_n(x))|^2 \det \nabla y_n(x) \, dx \\
&= \tau^2 \int_\Omega (\det \nabla y_n(x))^{-1} \, dx \\
&\le \tau^2 \left(\int_\Omega (\det \nabla y_n(x))^{-q} \, dx \right)^{\frac{1}{q}} |\Omega|^{1-\frac{1}{q}} \\
&\le \tau^2 c_L^{-\frac{1}{q}} \left(\int_\Omega \psi(\det \nabla y_n(x)) \, dx \right)^{\frac{1}{q}} |\Omega|^{1-\frac{1}{q}} \le K_1.
\end{aligned}$$

This immediately implies that there exists a subsequence (not relabeled) such that

$$m_n \rightharpoonup m \quad \text{in} \quad W^{1,2}(\mathcal{O}_\varepsilon(y);\mathbb{R}^3).$$

It thus follows that there exists a further subsequence (not relabeled) such that

$$m_n \to m \quad \text{in} \quad L^2(\mathcal{O}_\varepsilon(y);\mathbb{R}^3). \tag{3.11}$$

We shall now show that

$$\chi_{\mathcal{O}(y_n)} m_n \to \chi_{\mathcal{O}(y)} m \text{ in } L^2(\mathbb{R}^3;\mathbb{R}^3) \text{ and } \chi_{\mathcal{O}(y_n)} \nabla_z m_n \rightharpoonup \chi_{\mathcal{O}(y)} \nabla_z m \text{ in } L^2(\mathbb{R}^3;\mathbb{R}^{3\times 3}).$$

We first estimate $\chi_{\mathcal{O}(y_n)} m_n - \chi_{\mathcal{O}(y)} m$ in $L^2(\mathbb{R}^3;\mathbb{R}^3)$ by observing that
$\chi_{\mathcal{O}(y_n)} m_n - \chi_{\mathcal{O}(y)} m = (\chi_{\mathcal{O}(y_n)} - \chi_{\mathcal{O}_\epsilon(y)}) m_n + \chi_{\mathcal{O}_\epsilon(y)}(m_n - m) + (\chi_{\mathcal{O}_\epsilon(y)} - \chi_{\mathcal{O}(y)}) m.$

Thus,

$$\begin{aligned}
&\|\chi_{\mathcal{O}(y_n)} m_n - \chi_{\mathcal{O}(y)} m\|_{L^2(\mathbb{R}^3)} \\
&\quad \le \|m_n\|_{L^2(\mathcal{O}(y_n)\Delta\mathcal{O}_\epsilon(y))} + \|m_n - m\|_{L^2(\mathcal{O}_\epsilon)} + \|m\|_{L^2(\mathcal{O}(y)\setminus\mathcal{O}_\epsilon(y))} \\
&\quad = I + II + III.
\end{aligned}$$

To estimate I, we set $\Omega_n^\epsilon := y_n^{-1}(\mathcal{O}_\epsilon(y))$. We can see using (2.2) and (2.7) that for $t < 1$

$$\begin{aligned}
I^2 &= \int_\Omega (1 - \chi_{\Omega_n^\epsilon})^2 |m_n|^2 \det \nabla y_n \, dx \\
&= \left(\int_{A_t^n} + \int_{\Omega \setminus A_t^n} \right) \frac{(1 - \chi_{\Omega_n^\epsilon})^2 \tau^2}{\det \nabla y_n} \, dx \\
&\le \tau^2 \left(\int_{A_t^n} \left(\frac{1}{\det \nabla y_n} \right)^q dx \right)^{\frac{1}{q}} |A_t^n|^{1-\frac{1}{q}} + \frac{\tau^2}{t} |\Omega \setminus (\Omega_n^\epsilon \cup A_t^n)| \\
&\le c t^{q-1} + \frac{\tau^2}{t} |\Omega \setminus (\Omega_n^\epsilon \cup A_t^n)|.
\end{aligned}$$

We first choose $t < 1$ to make the first term small, that is, less than $\frac{1}{2}(\delta/3)^2$. We then show that we can select ϵ so that the second term is less than $\frac{1}{2}(\delta/3)^2$. This would imply that $I < \delta/3$, as desired. We can do so because

$$\begin{aligned}
|\mathcal{O}^\epsilon(y) \setminus \mathcal{O}_\epsilon(y)| &\ge |y_n(\Omega \setminus \Omega_n^\epsilon)| \ge |y_n(\Omega \setminus (\Omega_n^\epsilon \cup A_t^n))| \\
&= \int_{\Omega \setminus (\Omega_n^\epsilon \cup A_t^n)} \det \nabla y_n \ge t |\Omega \setminus (\Omega_n^\epsilon \cup A_t^n)|.
\end{aligned}$$

Our claim follows because $|\mathcal{O}^\epsilon(y) \setminus \mathcal{O}_\epsilon(y)|$ can be made arbitrarily small, for fixed t.

For fixed $\epsilon > 0$ and for sufficiently large n, we have that $II < \delta/3$ because of (3.11). Finally, for given $\delta > 0$ one can find $\epsilon > 0$ for which $III < \delta/3$ because $|\mathcal{O}(y) \setminus \mathcal{O}_\epsilon(y)|$ can be made arbitrarily small, and integration is absolutely continuous with respect to the set of integration.

The weak convergence is slightly easier. For $\varphi \in L^2(\mathbb{R}^3;\mathbb{R}^{3\times 3})$, we consider

$$\begin{aligned}
&\int_{\mathbb{R}^3} (\chi_{\mathcal{O}(y_n)}\nabla_z m_n - \chi_{\mathcal{O}(y)}\nabla_z m)\cdot\varphi\,dz \\
&\quad = \int_{\mathbb{R}^3} \Big[(\chi_{\mathcal{O}(y_n)} - \chi_{\mathcal{O}_\epsilon(y)})\nabla_z m_n\cdot\varphi \\
&\qquad\qquad + \chi_{\mathcal{O}_\epsilon(y)}(\nabla_z m_n - \nabla_z m)\cdot\varphi + (\chi_{\mathcal{O}_\epsilon(y)} - \chi_{\mathcal{O}(y)})\nabla_z m\cdot\varphi\Big]\,dz \\
&\quad = J + JJ + JJJ.
\end{aligned}$$

We can see that

$$|J| \le \|\nabla_z m_n\|_{L^2(\mathcal{O}(y_n))}\|\varphi\|_{L^2(\mathcal{O}_(y_n)\setminus\mathcal{O}_\epsilon(y))}.$$

We can make $|J| < \delta/3$ by taking $\epsilon > 0$ small enough. The second term can be made small due to (3.10). Moreover, it is clear that $|JJJ| < \delta/3$ for sufficiently small $\epsilon > 0$. ∎

Finally, we shall demonstrate that the term $\int_\Omega |\nabla m_n|^2 \det\nabla y_n\,dx$ is lower semicontinuous.

LEMMA 3.7. *If $\{(y_m, m_n)\} \subset \mathcal{A}$ is an $\mathcal{A}$-bounded sequence, then*

$$\int_\Omega |\nabla_z m|^2 \det\nabla y\,dx \le \liminf_{n\to\infty}\int_\Omega |\nabla_z m_n|^2\det\nabla y_n\,dx.$$

Proof. If we take any $\delta > 0$, then there exists $\varepsilon > 0$ such that

$$\int_{\mathcal{O}_\varepsilon(y)} |\nabla_z m|^2\,dz \ge \int_{\mathcal{O}(y)} |\nabla_z m|^2\,dz - \delta.$$

It then follows from (3.10) that

$$\begin{aligned}
&\liminf_{n\to\infty}\int_\Omega |\nabla_z m_n|^2\det\nabla y_n\,dx \\
&\quad = \liminf_{n\to\infty}\int_{\mathcal{O}(y_n)} |\nabla_z m_n|^2\,dz \ge \liminf_{n\to\infty}\int_{\mathcal{O}_\varepsilon(y)} |\nabla_z m_n|^2\,dz \\
&\quad \ge \int_{\mathcal{O}_\varepsilon(y)} |\nabla_z m|^2\,dz \ge \int_{\mathcal{O}(y)} |\nabla_z m|^2\,dz - \delta = \int_\Omega |\nabla_z m|^2\det\nabla y\,dx - \delta.
\end{aligned}$$

The proof follows since δ was arbitrary. ∎

We are now ready for the proof of Theorem 3.1.

Proof of Theorem 3.1. If $\{(y_n, m_n)\} \subset \mathcal{A}$ is an $\mathcal{A}$-bounded sequence (3.1) with bound K, then by Lemmas 3.2–3.7 its subsequence converges weakly to an element (y, m) in $\mathcal{A}$ and

$$\int_\Omega \left\{|D^2 y|^2 + |\nabla y|^2 + \psi(\det\nabla y)\right\}\,dx + \int_{\mathcal{O}(y)} |\nabla_z m|^2\,dz \le K. \qquad ∎$$

4. The existence of an energy minimizer. We are going to demonstrate a lower semicontinuity property for the energy $\mathcal{E}$. We begin with a simple observation on minimizing sequences.

LEMMA 4.1. *If $\{(y_n, m_n)\} \subset \mathcal{A}$ is a minimizing sequence, then it is $\mathcal{A}$-bounded.*

Proof. We can estimate the magnetic interaction energy term, which is the only nonpositive expression in $\mathcal{E}$, by

$$\begin{aligned} J_n &= \left| \int_{\mathcal{O}(y_n)} h(z) \cdot m_n(z)\, dz \right| = \left| \int_\Omega h(y_n(x)) \cdot m_n(y_n(x)) \det \nabla y_n(x)\, dx \right| \\ &\le C_\varepsilon \int_{\mathcal{O}(y_n)} h^2(z)\, dz + \varepsilon \int_\Omega |m_n(y_n(x))|^2 \det \nabla y_n\, dx \\ &\le C_\varepsilon \,\|h\|^2_{L^2(\mathbb{R}^3)} + \varepsilon\tau^2 \int_\Omega (\det \nabla y_n)^{-1}\, dx \\ &\le C_\varepsilon \,\|h\|^2_{L^2(\mathbb{R}^3)} + \varepsilon\tau^2 c_L^{-\frac{1}{q}} \left(\int_\Omega \psi(\det \nabla y_n)\, dx \right)^{\frac{1}{q}} |\Omega|^{\frac{q-1}{q}}. \end{aligned}$$

By Young's inequality, we have that

$$J_n \le C_\varepsilon \,\|h\|^2_{L^2(\mathbb{R}^3)} + \varepsilon\tau^2 c_L^{-\frac{1}{q}} \left(\frac{1}{q} \int_\Omega \psi(\det \nabla y_n)\, dx + \frac{q-1}{q} |\Omega| \right).$$

Hence, due to (2.8) we have that

$$\begin{aligned} &\int_\Omega \left[\kappa |D^2 y_n|^2 + |\nabla y_n|^2 + \psi(\det \nabla y_n) + |\nabla_z m_n \circ y_n|^2 \det \nabla y_n \right] dx \\ &\quad \le \max\left\{1, \frac{1}{C_L}\right\} \mathcal{E}(y_n, m_n) + J_n + |\Omega| \\ &\quad \le K + |\Omega| + C_\varepsilon \,\|h\|^2_{L^2(\mathbb{R}^3)} + \varepsilon\tau^2 c_L^{-\frac{1}{q}} \left(\frac{1}{q} \int_\Omega \psi(\det \nabla y_n)\, dx + \frac{q-1}{q} |\Omega| \right). \end{aligned}$$

Since ε can be made arbitrarily small and since we have assumed that $h \in L^2(\mathbb{R}^3)$, our claim follows. ∎

We are thus ready to prove the main result of this paper, the existence of a solution to (2.9).

THEOREM 4.2. *Suppose that the magnetostrictive free energy $\mathcal{E}$ is given by* (2.3) *and that the growth assumptions* (2.7) *and* (2.8) *hold. Then the minimum free energy satisfying the saturation constraint* (2.2) *is attained.*

Proof. We consider a minimizing sequence $\{(y_n, m_n)\} \subset \mathcal{A}$. By Lemma 4.1, $\{(y_m, m_n)\}$ is an $\mathcal{A}$-bounded sequence. Hence, by Theorem 3.1 there exists $(y, m) \in \mathcal{A}$ such that a subsequence $\{(y_{n_k}, m_{n_k})\}$ converges weakly to (y, m). It is sufficient for us to show that

$$\mathcal{E}(y, m) \le \liminf_{n\to\infty} \mathcal{E}(y_m, m_n).$$

We shall treat each term in $\mathcal{E}$ separately, because after choosing a suitable subsequence we may replace lim inf with lim.

Due to the lower semicontinuity of the norm, we see for the elastic surface energy that

$$\kappa \int_\Omega |D^2 y|^2\, dx \le \liminf_{n\to\infty} \kappa \int_\Omega |D^2 y_n|^2\, dx.$$

We recall from (2.6) that the anisotropy energy density $\Phi(\nabla y, m)$ is the sum $\Phi(\nabla y, m) = W(\nabla y, m) + \psi(\det \nabla y)$. We first show that

$$\lim_{n\to\infty} \int_\Omega W(\nabla y_n, m_n)\, dx = \int_\Omega W(\nabla y, m)\, dx. \tag{4.1}$$

Indeed, we know that $\nabla y_n \to \nabla y$ in $L^p(\Omega : \mathbb{R}^{3\times 3})$ for $p < 6$ and $m_n \circ y_n \to m \circ y$ a.e. Moreover, due to Lemma 3.4 we have that

$$|m_n \circ y_n| = \frac{\tau}{\det \nabla y_n} \to \frac{\tau}{\det \nabla y} = |m \circ y| \quad \text{in } L^1(\Omega).$$

Thus, by [3, Theorem 1], (there is no need to extract another subsequence) we conclude that $m_n \circ y_n \to m \circ y$ in $L^1(\Omega; \mathbb{R}^3)$. Thus, by the continuity of the Nemytskii operator [24]

$$L^r(\Omega) \times L^1(\Omega) \ni (\nabla y, m) \to W(\nabla y, m) \in L^1(\Omega),$$

where $r < 6$ is the growth factor for $W(F, m)$ given by (2.8), we deduce (4.1). We finally recall that we have proved that

$$\int_\Omega \psi(\det \nabla y)\, dx \le \liminf_{n\to\infty} \int_\Omega \psi(\det \nabla y_n)\, dx.$$

For the magnetic exchange energy, we have from Lemma 3.7 that

$$\alpha \int_\Omega |\nabla m|^2 \det \nabla y\, dx \le \liminf_{n\to\infty} \alpha \int_\Omega |\nabla m_n|^2 \det \nabla y_n\, dx.$$

We now turn to the magnetic interaction energy and observe that

$$\lim_{n\to\infty} \int_\Omega (h \circ y_n \cdot m_n \circ y_n) \det \nabla y_n\, dx = \int_\Omega (h \circ y \cdot m \circ y) \det \nabla y\, dx.$$

We recall that

$$\int_\Omega (h \circ y_n \cdot m_n \circ y_n) \det \nabla y_n\, dx = \int_{\mathcal{O}(y_n)} m_n(z) \cdot h(z)\, dz = \int_{\mathbb{R}^3} \chi_{y_n(\Omega)} m_n(z) \cdot h(z)\, dz.$$

Since $\chi_{y_n(\Omega)} m_n$ converges to $\chi_{y(\Omega)} m$ in $L^2(\mathbb{R}^3; \mathbb{R}^3)$, our claim follows.

We finally have to show the convergence of the magnetization energy $e_{mag}(y, m)$ given by (2.4). We note that for given y and m, the weak solution $\zeta \in \mathcal{H}(\mathbb{R}^3)$ of the magnetostatic equation (2.5) satisfies

$$\int_{\mathbb{R}^3} (-\nabla_z \zeta + \chi_{\mathcal{O}(y)} m) \nabla_z \eta\, dz = 0 \quad \text{for all } \eta \in \mathcal{H}(\mathbb{R}^3), \tag{4.2}$$

where

$$\mathcal{H}(\mathbb{R}^3) = \left\{ \zeta \in \mathcal{D}'(\mathbb{R}^3) :\ \nabla \zeta \in L^2,\ \int_{\mathbb{R}^3} \zeta(z)\, dz = 0 \right\}.$$

Since $\nabla_z \zeta$ for $\zeta \in \mathcal{H}(\mathbb{R}^3)$ is an $L^2(\mathbb{R}^3; \mathbb{R}^3)$ projection of $\chi_{\mathcal{O}(y)} m(z)$, we have that

$$\|\nabla_z \zeta\|_{L^2} \le \|\chi_{\mathcal{O}(y)} m\|_{L^2};$$

and since $\chi_{\mathcal{O}(y_n)} m_n \to \chi_{\mathcal{O}(y)} m$ in $L^2(\mathbb{R}^3; \mathbb{R}^3)$, we have

$$\lim_{n\to\infty} \frac{1}{2} \int_{\mathbb{R}^3} |\nabla_z \zeta_n|^2\, dz = \frac{1}{2} \int_{\mathbb{R}^3} |\nabla_z \zeta|^2\, dz.$$

We have to check that weak limits also satisfy the pointwise magnetic saturation constraint (2.2). If $(y_n, m_n) \subset \mathcal{A}$ is a minimizing sequence, then the magnetic saturation constraint (2.2) follows since we showed L^2 convergence of $m_n \circ y_n$ and $\det \nabla y_n$. Namely, we have that

$$\begin{aligned}\int_\Omega \left|(m_n \circ y_n) \det \nabla y_n - (m \circ y) \det \nabla y\right| dx \\ \leq \| m_n - m \|_{L^2} \| \det \nabla y_n \|_{L^2} + \| m \|_{L^2} \| \det \nabla y_n - \det \nabla y \|_{L^2}.\end{aligned}$$

Finally, combining all of the above results we conclude that

$$\mathcal{E}(y, m) \leq \lim_{n \to \infty} \mathcal{E}(y_n, m_n),$$

that is, $(y, m) \in \mathcal{A}$ is the desired minimum of $\mathcal{E}$. □

A PREY-PREDATOR MODEL WITH HYSTERESIS EFFECT*

TOYOHIKO AIKI† AND EMIL MINCHEV‡

Abstract. This paper provides mathematical analysis of a system of nonlinear PDEs which describes a prey-predator model with hysteresis effect. Existence and uniqueness of solutions for the system under consideration are proved.

Key words. hysteresis, nonlinear PDEs, prey-predator model, subdifferential

1. Introduction and biological motivation.

The present paper deals with a class of prey-predator models which could take into account the diffusive as well as the hysteresis effects in the evolution of the populations and is described by the following system of PDEs:

$$\sigma_t - (\lambda(u))_t - \kappa\Delta\sigma + \partial I_{u,v}(\sigma) \ni F(\sigma, u, v) \quad \text{in } Q, \tag{1}$$

$$u_t - \Delta u = h(\sigma, u, v) \quad \text{in } Q, \tag{2}$$

$$v_t - \Delta v = g(\sigma, u, v) \quad \text{in } Q, \tag{3}$$

where $T > 0$, $\Omega \subset R^N$ is a bounded domain with smooth boundary $\partial\Omega$, $Q = (0,T)\times\Omega$; $\kappa \geq 0$ is a constant; $\lambda : R \to R$, $F, h, g : R^3 \to R$, $f_*, f^* : R^2 \to R$ are given functions. We assume that $f_*, f^* \in C^2(R^2)$, $0 \leq f_* \leq f^* \leq 1$ on R^2, and all partial derivatives of first and second order of f_* and f^* are bounded on R^2. We denote by $I_{u,v}(\cdot)$ the indicator function of the interval $[f_*(u,v), f^*(u,v)]$, and $\partial I_{u,v}(\cdot)$ denotes the subdifferential of $I_{u,v}(\cdot)$. The subdifferential $\partial I_{u,v}(\sigma)$ is a set-valued mapping in our statement of the problem

$$\partial I_{u,v}(\sigma) = \begin{cases} \emptyset & \text{if } \sigma > f^*(u,v) \text{ or } \sigma < f_*(u,v), \\ [0, +\infty) & \text{if } \sigma = f^*(u,v) > f_*(u,v), \\ \{0\} & \text{if } f_*(u,v) < \sigma < f^*(u,v), \\ (-\infty, 0] & \text{if } \sigma = f_*(u,v) < f^*(u,v), \\ R & \text{if } \sigma = f^*(u,v) = f_*(u,v). \end{cases} \tag{4}$$

Equation (1) corresponds to the kinetics of the density of the quantity of food σ (for the prey), (2), (3) describe the evolution of the prey and evolution of the predator, respectively; here u and v are the densities of the prey and predator, respectively. A typical example from the population dynamics is the following system:

$$\sigma_t + au_t - \kappa\Delta\sigma + \partial I_{u,v}(\sigma) \ni 0 \quad \text{in } Q, \tag{5}$$

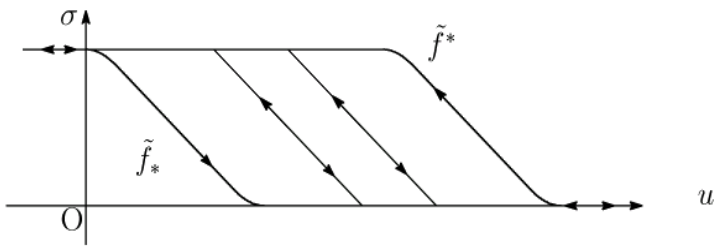

FIG. 1.

$$u_t - \Delta u = a_0 \sigma u - b_0 u v \quad \text{in } Q, \tag{6}$$

$$v_t - \Delta v = -c_0 v + d_0(1-\sigma)v \quad \text{in } Q, \tag{7}$$

where a, a_0, b_0, c_0, d_0 are positive constants. The system (5)–(7) could be considered a generalization of the classical prey-predator model allowing hysteresis relation between the prey/predator densities u, v and the density of the food quantity σ for the prey with vector input (u, v) and output σ. Our model originates from a prey-predator model of the type

$$\sigma = \lambda(u) \quad \text{in } Q, \tag{8}$$

$$u_t - \Delta u = h(\sigma, u, v) \quad \text{in } Q, \tag{9}$$

$$v_t - \Delta v = g(\sigma, u, v) \quad \text{in } Q, \tag{10}$$

in which the density of the food σ is determined by relation (8). We generalize this model in order to allow this relation to possibly depend also on the previous evolution data. More precisely, in our model the speed of change of density of food when the density of the prey decreases is different from the speed when the density of the prey increases. This situation can be described by the generalized stop operator shown in Figure 1, where $\tilde{f}^*$ and $\tilde{f}_*$ are upper and lower curves, respectively, of the hysteresis loop and a is the slope of the line in the loop. As a biologically consistent example for the constraint functions $\tilde{f}_*, \tilde{f}^*$ we can consider, for instance,

$$\tilde{f}^*(u) = \begin{cases} 1 & \text{if } u < 2, \\ -2.5u^2 + 10u - 9 & \text{if } 2 \le u < 2.2, \\ -u + 3.1 & \text{if } 2.2 \le u < 3, \\ 2.5u^2 - 16u + 25.6 & \text{if } 3 \le u < 3.2, \\ 0 & \text{if } 3.2 \le u, \end{cases} \quad \tilde{f}_*(u) = \begin{cases} 1 & \text{if } u < 0, \\ -2.5u^2 + 1 & \text{if } 0 \le u < 0.2, \\ -u + 1.1 & \text{if } 0.2 \le u < 1, \\ 2.5u^2 - 6u + 3.6 & \text{if } 1 \le u < 1.2, \\ 0 & \text{if } 1.2 \le u. \end{cases}$$

The biologically relevant assumption on the constraint functions reflected in the above example is that $\tilde{f}_*(0) = \tilde{f}^*(0)$ $(= 1)$ and $\tilde{f}_* = \tilde{f}^* = 0$ on $[u_c, \infty)$, which is due to the fact that the food σ should be constant $(= 1)$ if $u = 0$, and σ should keep zero value if the density u is bigger than some critical value $u_c > 0$.

Let us note that although there are indications for the existence of hysteresis in various biological problems (see, for example, [10], [13]), the mathematical treatment of biological problems with hysteresis has been considered only in a few papers; see

[7], as well as the survey paper [14]. The paper [7] seems to be the first to treat hysteresis phenomena in a biological problem. The authors of [7] treated bacterial growth in a petri dish modeled by a hysteresis operator of relay type which describes the relation between the rate of the growth of the bacterial population and the pH of the surrounding acid-buffer mix. The survey paper [14] treats applications of hysteresis in various natural phenomena. One of the chapters of [14] is devoted to the applications in biological problems and the authors of [14] also note the necessity of developing new models describing hysteresis effect in biological processes. The lack of papers dealing with hysteresis in biological phenomena could be explained with the diversity of the processes involved in mathematical biology. Let us note that many biological problems involve a fold catastrophe regime which, as is shown in [11], could be replaced by hysteresis model. Also there are various biological processes whose state variables change due to change of parameters in such a way that when the parameters go back to the old values the system does not follow its steps in return and thus a hysteresis loop is formed.

It is known that some types of hysteresis operators can be represented by ordinary differential inclusion containing subdifferential of the indicator function of a closed interval (whose length could possibly depend on the unknown variables). This fact was already pointed out by Visintin in [16]. Now we give a brief explanation of the fact that a function σ is determined by the hysteresis operator in Figure 1 if and only if σ is the solution of the differential inclusion

$$(*) \qquad \sigma_t + au_t + \partial I_u(\sigma) \ni 0 \quad \text{in } Q,$$

where u is some given function, $\tilde{f}_*$ and $\tilde{f}^*$ are Lipschitz continuous functions on R and $0 \le \tilde{f}_* \le \tilde{f}^* \le 1$ on R, and $-a \le \tilde{f}_*' \le 0$ and $-a \le \tilde{f}^{*'} \le 0$ on R. Indeed, since the solution of the inclusion is unique it is sufficient to show that σ defined by Figure 1 is a solution of (*). If $\tilde{f}_* < \sigma < \tilde{f}^*$, then $\sigma_t = au_t$ so that (*) holds. If $\tilde{f}_*(u) = \sigma$, then $u_t \ge 0$ and $\sigma_t = u_t \tilde{f}_*'(u) \ge -au_t$. This implies that $-\sigma_t - au_t \le 0$ and (*) holds. It is easy to see that (*) holds also if $\tilde{f}^*(u) = \sigma$.

This characterization of hysteresis operators was used for analysis of many nonlinear phenomena; for example, a real-time control problem (see [8]), solid-liquid phase transition (see [6], [9]), and shape memory alloy (see [1], [2], [3]). Also, in [9] it is explained that by using the inclusion (*) various types of hysteresis operators can be described. However, to the best of our knowledge this approach to hysteresis phenomena has not been used to problems from population dynamics.

In the model under consideration we allow also a small diffusive effect ($0 \le \kappa \ll 1$) for the food of the prey σ (from a biological point of view the diffusive effect for σ (for example, a plant occupying the domain Ω) is almost negligible with respect to other terms).

In the present paper we obtain results for positivity, boundedness, existence, and uniqueness of solutions of the prey-predator model with hysteresis effect (1)–(3). Using the method of Yosida approximation combined with derivation of appropriate uniform bounds, we prove that there exists at least one solution of the system under consideration (1)–(3). Furthermore, uniqueness of solutions is obtained in the case when $N \le 3$.

2. Preliminary notes. Denote by H the Hilbert space $L^2(\Omega)$ with the usual scalar product $(\cdot, \cdot)$ and norm $|\cdot|_H$. Denote by V the Sobolev space $H^1(\Omega)$ equipped with the norm $|u|_V = (u,u)_V^{1/2}$, where $(u,v)_V = (u,v) + a(u,v)$, $a(u,v) = \int_\Omega \nabla u(x) \cdot \nabla v(x) dx$, $u, v \in V$. Let $A : V \to V'$ be a linear continuous operator defined by

$\langle Au, v\rangle = a(u, v)$, $u, v \in V$, where V' is the dual space of V and $\langle\cdot,\cdot\rangle$ stands for the duality pairing between V' and V. For simplicity, in what follows we will denote the supremum of a bounded function by $|\cdot|_\infty$. Define the operator $-\Delta_N : D(-\Delta_N)(\subset H) \to H$ by the restriction of A to the elements $w \in V$ such that $Aw \in H$, i.e., $D(-\Delta_N) = \{w \in H^2(\Omega) : \ \frac{\partial w}{\partial n} = 0 \text{ in } H^{1/2}(\partial\Omega)\}$ and $-\Delta_N w = -\Delta w$ for all $w \in D(-\Delta_N)$, where $\frac{\partial}{\partial n}$ is the outward normal derivative on $\partial\Omega$.

DEFINITION 2.1. *Let $\kappa \geq 0$. A triplet of functions $\{\sigma, u, v\}$ is called a solution of the system* (1)–(3) *if*

(i) $\sigma \in W^{1,2}(0,T;H)\cap L^\infty(0,T;V)\cap L^2(0,T;H^2(\Omega))$ if $\kappa > 0$ and $\sigma \in W^{1,2}(0,T;H)$ if $\kappa = 0$.

(ii) $u, v \in W^{1,2}(0,T;H) \cap L^\infty(0,T;V) \cap L^2(0,T;H^2(\Omega))$.

(iii) $\sigma' - (\lambda(u))' - \kappa\Delta_N\sigma + \partial I_{u,v}(\sigma) \ni F(\sigma, u, v)$ in H a.e. in $(0,T)$.

(iv) $u' - \Delta_N u = h(\sigma, u, v)$ in H a.e. in $(0,T)$.

(v) $v' - \Delta_N v = g(\sigma, u, v)$ in H a.e. in $(0,T)$.

(vi) $\sigma(0) = \sigma_0, \ \ u(0) = u_0, \ \ v(0) = v_0$.

For simplicity, we denote, respectively, by σ', u', and v' the time-derivatives σ_t, u_t, and v_t of σ, u, and v. Note that the inclusion (iii) implies the following:

(iii)(a) $f_*(u, v) \leq \sigma \leq f^*(u, v)$ a.e. in Q.

(iii)(b) $(\sigma'(t) - (\lambda(u))'(t) - \kappa\Delta\sigma(t) - F(\sigma(t), u(t), v(t)), \sigma(t) - z) \leq 0$ for all $z \in H$ with $f_*(u(t), v(t)) \leq z \leq f^*(u(t), v(t))$ a.e. in Ω for a.e. $t \in (0,T)$.

(iii)(c) $\frac{\partial\sigma(t)}{\partial n} = 0$ a.e. on $\partial\Omega$ for a.e. $t \in (0,T)$ if $\kappa > 0$.

Throughout the paper we suppose that the following assumptions hold:

H1. $\kappa \geq 0$ is a given constant; $\lambda \in C^2(R)$, λ', and λ'' are bounded functions on R.

H2. $f_*, f^* \in C^2(R^2)$, $0 \leq f_* \leq f^* \leq 1$ on R^2, and all partial derivatives of first and second order of f_* and f^* are bounded on R^2. We put $C_0 = \max\{|f_*|_{W^{2,\infty}(R^2)}, |f^*|_{W^{2,\infty}(R^2)}\}$.

H3. F, h, and g are Lipschitz continuous functions on R^3 (with a common Lipschitz constant M), and $h(\sigma, 0, v) = 0$ for $\sigma \in [0,1], v \in R$, $g(\sigma, u, 0) = 0$ for $\sigma \in [0,1], u \in R$.

H4. $\sigma_0, u_0, v_0 \in L^\infty(\Omega) \cap V$ and $u_0 \geq 0$, $v_0 \geq 0$, $f_*(u_0, v_0) \leq \sigma_0 \leq f^*(u_0, v_0)$ a.e. in Ω.

3. Main results.

3.1. Nonnegativity of solutions.

THEOREM 3.1. *Any solution $\{\sigma, u, v\}$ of* (1)–(3) *satisfies the estimate*

$$\sigma \geq 0, \ u \geq 0, \ v \geq 0 \quad \text{a.e. in } Q. \tag{11}$$

Proof. The estimate for σ follows from the constraint $0 \leq f_*(u, v) \leq \sigma \leq f^*(u, v) \leq 1$ a.e. in Q. Now we prove the estimate for u. We multiply both sides of (2) by $[-u]^+$ (the positive part of $-u$) and using the Lipschitz continuity of h, we obtain that

$$\frac{1}{2}\frac{d}{dt}\left|[-u]^+\right|_H^2 + a([-u]^+, [-u]^+) \leq M\left|[-u]^+\right|_H^2 \quad \text{a.e. in } (0,T).$$

Therefore, by integration and application of the Gronwall inequality we conclude that $u(t) \geq 0$ a.e. in Q. Analogously it can be proved that $v(t) \geq 0$ a.e. in Q. ∎

3.2. Boundedness of solutions.

THEOREM 3.2. *Any solution* $\{\sigma, u, v\}$ *of* (1)–(3) *satisfies the estimate*

$$|\sigma|_\infty, |u|_\infty, |v|_\infty \le M_0, \tag{12}$$

where $M_0 = \max\{1, k_1 e^{MT}\}$, $k_1 = \max\{|u_0|_\infty, |v_0|_\infty\}$.

Proof. First let us note that $|\sigma|_\infty \le 1$ by the definition. Now we prove the estimate for u. Define $p(t) = k_1 e^{Mt}$ for $t \in [0,T]$. We have in view of Theorem 3.1 that

$$(u-p)' - \Delta_N(u-p) = h(\sigma,u,v) - Mp \le M(u-p) \text{ a.e. in } (0,T)\times\Omega. \tag{13}$$

Multiplying both sides of inequality (13) by $[u-p]^+$, we obtain that

$$\frac{1}{2}\frac{d}{dt}\left|[u-p]^+\right|_H^2 \le M\left|[u-p]^+\right|_H^2 \quad \text{a.e. in } (0,T).$$

Thus integrating and applying Gronwall inequality, we conclude that $u(t) \le p(t) \le k_1 e^{MT} \le M_0$ a.e. in Q. Similarly, it can be proved that $v \le M_0$, a.e. in $(0,T)\times\Omega$. □

Remark 3.1. From Theorems 3.1 and 3.2 it follows that by restricting ourselves to the set $\{0 \le \sigma \le M_0,\ 0 \le u \le M_0,\ 0 \le v \le M_0\}$ (if necessary), we can assume without loss of generality that the functions F, h, and g are bounded and Lipschitz continuous on R^3.

Remark 3.2. The proofs of Theorems 3.1 and 3.2 could be easily adapted to the system (5)–(7) using the boundedness of σ.

3.3. Existence of solutions.

3.3.1. Approximate solutions. For $\sigma, u, v \in R$ denote by $\partial I^\mu_{u,v}$ the Yosida regularization of the subdifferential graph $\partial I_{u,v}$,

$$\partial I^\mu_{u,v}(\sigma) = \frac{1}{\mu}[\sigma - f^*(u,v)]^+ - \frac{1}{\mu}[f_*(u,v) - \sigma]^+.$$

Consider the following approximate system of PDEs:

$$\sigma_t - (\lambda(u))_t - \kappa\Delta\sigma + \partial I^\mu_{u,v}(\sigma) = F(\sigma,u,v) \quad \text{in } Q, \tag{14}$$

$$u_t - \Delta u = h(\sigma,u,v) \quad \text{in } Q, \tag{15}$$

$$v_t - \Delta v = g(\sigma,u,v) \quad \text{in } Q. \tag{16}$$

DEFINITION 3.3. *Let* $\kappa \ge 0$. *The triplet of functions* $\{\sigma_\mu, u_\mu, v_\mu\}$ *is said to be a solution of the system* (14)–(16) *if*

(i) $\sigma_\mu \in W^{1,2}(0,T;H) \cap L^\infty(0,T;V) \cap L^2(0,T;H^2(\Omega))$ if $\kappa > 0$ and $\sigma_\mu \in W^{1,2}(0,T;H)$ if $\kappa = 0$.

(ii) $u_\mu, v_\mu \in W^{1,2}(0,T;H) \cap L^\infty(0,T;V) \cap L^2(0,T;H^2(\Omega))$.

(iii) $\sigma_\mu' - (\lambda(u_\mu))' - \kappa\Delta_N\sigma_\mu + \partial I^\mu_{u_\mu,v_\mu}(\sigma_\mu) = F(\sigma_\mu,u_\mu,v_\mu)$ in H a.e. in $(0,T)$.

(iv) $u_\mu' - \Delta_N u_\mu = h(\sigma_\mu,u_\mu,v_\mu)$ in H a.e. in $(0,T)$.

(v) $v_\mu' - \Delta_N v_\mu = g(\sigma_\mu,u_\mu,v_\mu)$ in H a.e. in $(0,T)$.

(vi) $\sigma_\mu(0) = \sigma_0$, $u_\mu(0) = u_0$, $v_\mu(0) = v_0$.

LEMMA 3.4. *Let* $\{\sigma_\mu, u_\mu, v_\mu\}$ *be a solution of* (14)–(16). *Then*

$$u_\mu \geq 0,\ v_\mu \geq 0 \quad \textit{a.e. in } Q. \tag{17}$$

The proof of Lemma 3.4 is similar to the proof of Theorem 3.1.

LEMMA 3.5. *Let* $\{\sigma_\mu, u_\mu, v_\mu\}$ *be a solution of* (14)–(16). *Then*

$$|u_\mu|_\infty,\ |v_\mu|_\infty \leq M_0,$$

for the same constant M_0 *as in Theorem* 3.2.

The proof of Lemma 3.5 is similar to the proof of Theorem 3.2.

THEOREM 3.6. *There exists a constant* $\kappa_0 > 0$ *such that for* $0 < \kappa < \kappa_0$ *there exists at least one solution of the system* (1)–(3).

3.3.2. Proof of Theorem 3.6. By a result of Colli and Hoffmann [5], it follows that the approximate system (14)–(16) possesses a unique solution $\{\sigma_\mu, u_\mu, v_\mu\}$ for each $\mu > 0$. Indeed, the function $A(\sigma, u) = \sigma - \lambda(u)$ is Lipschitz continuous as well as the function $F(\sigma, u, v) - \partial I^\mu_{u,v}(\sigma)$ and $(A(\sigma_1, u) - A(\sigma_2, u), \sigma_1 - \sigma_2) \geq |\sigma_1 - \sigma_2|^2$ for all $\sigma_1, \sigma_2, u \in R$. Moreover, define

$$\Phi(\mathbf{U}) = \begin{cases} \frac{1}{2}a(u,u) + \frac{1}{2}a(v,v) & \text{if } u, v \in V, \\ +\infty & \text{otherwise,} \end{cases} \quad \text{for } \mathbf{U} = \begin{pmatrix} u \\ v \end{pmatrix} \in H \times H.$$

We have that Φ is a proper convex l.s.c. function on $H \times H$, and its subdifferential is $\begin{pmatrix} -\Delta_N u \\ -\Delta_N v \end{pmatrix}$. Thus, choosing $X = H \times H$ in Theorem 1 of [5], we conclude that there exists a unique solution of the approximate system (14)–(16).

Now, we will prove some uniform bounds for the triplets $\{\sigma_\mu, u_\mu, v_\mu\},\ \mu > 0$, that solve the equations

$$\sigma'_\mu - (\lambda(u_\mu))' - \kappa\Delta_N\sigma_\mu + \partial I^\mu_{u_\mu, v_\mu}(\sigma_\mu) = F(\sigma_\mu, u_\mu, v_\mu) \quad \text{in } H \text{ a.e. in } (0,T), \tag{18}$$

$$u'_\mu - \Delta_N u_\mu = h(\sigma_\mu, u_\mu, v_\mu) \quad \text{in } H \text{ a.e. in } (0,T), \tag{19}$$

$$v'_\mu - \Delta_N v_\mu = g(\sigma_\mu, u_\mu, v_\mu) \quad \text{in } H \text{ a.e. in } (0,T). \tag{20}$$

To this end we derive certain energy inequalities. Again for simplicity of the notation we will write $\{\sigma, u, v\}$ instead of $\{\sigma_\mu, u_\mu, v_\mu\}$. Now, we multiply (19) by u' and (20) by v'; adding together and applying Young's inequality, we obtain that

$$|u'|^2_H + |v'|^2_H + \frac{d}{dt}|\nabla u|^2_H + \frac{d}{dt}|\nabla v|^2_H \leq C_1 \quad \text{a.e. in } (0,T), \tag{21}$$

where $C_1 = (|h|^2_\infty + |g|^2_\infty)|\Omega|$, $|\Omega|$ denotes the Lebesgue measure of the set Ω. Multiply (19) by $-\Delta u$ and (20) by $-\Delta v$, and adding together, we conclude that

$$\frac{d}{dt}|\nabla u|^2_H + \frac{d}{dt}|\nabla v|^2_H + |\Delta u|^2_H + |\Delta v|^2_H \leq C_1 \quad \text{a.e. in } (0,T). \tag{22}$$

LEMMA 3.7. *Let* $\{\sigma, u, v\}$ *be a solution of* (14)–(16). *Then the function*

$$(I^\mu_{u,v}(\sigma))(t) = \frac{1}{2\mu}\left|[\sigma - f^*(u,v)]^+\right|^2_H + \frac{1}{2\mu}\left|[f_*(u,v) - \sigma]^+\right|^2_H$$

is absolutely continuous on $[0,T]$ *and*

$$\frac{d}{dt}I^{\mu}_{u,v}(\sigma) \le (\partial I^{\mu}_{u,v}(\sigma),\sigma') + C_0|\partial I^{\mu}_{u,v}(\sigma)|_H(|u'|_H+|v'|_H) \quad a.e.\ in\ (0,T).$$

The proof of Lemma 3.7 is similar to the proof of Lemma 4.1 of [6].

Now, we multiply (18) by σ' and using Lemma 3.7, we obtain that

(23)
$$|\sigma'|^2_H + \kappa\frac{d}{dt}|\nabla\sigma|^2_H + 2\frac{d}{dt}I^{\mu}_{u,v}(\sigma) \le C_2\left(|u'|^2_H+|v'|^2_H+\kappa^2|\Delta\sigma|^2_H+1\right) \text{ a.e. in } (0,T),$$

where $C_2=\max\{4C_0^2+C_0+3C(\lambda),2C_0|F|^2_\infty|\Omega|\}$, $C(\lambda)=\max\{|\lambda'|_\infty,|\lambda''|_\infty\}$.
Since $f_*(u,v), f^*(u,v)\in H^2(\Omega)$ a.e. in $(0,T)$, we have that

$$\begin{aligned}
&(\partial I^{\mu}_{u,v}(\sigma),-\Delta\sigma)\\
&=\left(\frac{1}{\mu}[\sigma-f^*(u,v)]^+,-\Delta(\sigma-f^*(u,v))\right)+\left(\frac{1}{\mu}[\sigma-f^*(u,v)]^+,-\Delta f^*(u,v)\right)\\
&+\left(\frac{1}{\mu}[f_*(u,v)-\sigma]^+,-\Delta(f_*(u,v)-\sigma)\right)+\left(\frac{1}{\mu}[f_*(u,v)-\sigma]^+,\Delta f_*(u,v)\right)\\
&=\frac{1}{\mu}|\nabla[\sigma-f^*(u,v)]^+|^2_H+\left(\frac{1}{\mu}[\sigma-f^*(u,v)]^+,-\Delta f^*(u,v)\right)\\
&+\frac{1}{\mu}|\nabla[f_*(u,v)-\sigma]^+|^2_H+\left(\frac{1}{\mu}[f_*(u,v)-\sigma]^+,\Delta f_*(u,v)\right)\\
&\ge -\frac{1}{4\mu^2}\left\{|[\sigma-f^*(u,v)]^+|^2_H+|[f_*(u,v)-\sigma]^+|^2_H\right\}-|\Delta f^*(u,v)|^2_H-|\Delta f_*(u,v)|^2_H
\end{aligned}$$

$$\ge -\frac{1}{4}|\partial I^{\mu}_{u,v}(\sigma)|^2_H-|\Delta f^*(u,v)|^2_H-|\Delta f_*(u,v)|^2_H. \tag{24}$$

Also

$$(F(\sigma,u,v),-\Delta\sigma)\le C^*_F(|\nabla\sigma|^2_H+|\nabla u|^2_H+|\nabla v|^2_H), \tag{25}$$

where $C^*_F=\left|\frac{\partial F}{\partial\sigma}\right|_\infty+\left|\frac{\partial F}{\partial u}\right|_\infty+\left|\frac{\partial F}{\partial v}\right|_\infty$.
Now, multiplying (18) by $-\Delta\sigma$, we get in view of (24) and (25) that

$$\begin{aligned}
&\frac{1}{2}\frac{d}{dt}|\nabla\sigma|^2_H+\kappa|\Delta\sigma|^2_H+((\lambda(u))',\Delta\sigma)\\
&\le\frac{1}{4}|\partial I^{\mu}_{u,v}(\sigma)|^2_H+|\Delta f^*(u,v)|^2_H+|\Delta f_*(u,v)|^2_H+C^*_F(|\nabla\sigma|^2_H+|\nabla u|^2_H+|\nabla v|^2_H).
\end{aligned}$$

Since $((\lambda(u))',\Delta\sigma)=-\frac{d}{dt}(\lambda'(u)\nabla u,\nabla\sigma)-(\Delta\lambda(u),\sigma')$, we conclude that

$$\begin{aligned}
\frac{1}{2}\frac{d}{dt}|\nabla\sigma|^2_H+\kappa|\Delta\sigma|^2_H-\frac{d}{dt}(\lambda'(u)\nabla u,\nabla\sigma)&\le\frac{1}{4}|\partial I^{\mu}_{u,v}(\sigma)|^2_H+|\Delta f^*(u,v)|^2_H+|\Delta f_*(u,v)|^2_H\\
&+\frac{1}{2}|\Delta\lambda(u)|^2_H+\frac{1}{2}|\sigma'|^2_H+C^*_F(|\nabla\sigma|^2_H+|\nabla u|^2_H+|\nabla v|^2_H).
\end{aligned} \tag{26}$$

Note that $\Delta\lambda(u)=\lambda''(u)|\nabla u|^2+\lambda'(u)\Delta u$ and consequently,

$$|\Delta\lambda(u)|^2_H\le 2C(\lambda)^2(|\nabla u|^4_{L^4}+|\Delta u|^2_H).$$

By the Gagliardo–Nirenberg inequality (cf. [17]), we have that

$$|\nabla u|^4_{L^4(\Omega)} \le C(\Omega)|u|^2_{H^2(\Omega)}|u|^2_\infty \le C(\Omega)(|u|^2_H + |\Delta u|^2_H)|u|^2_\infty \le C_3(1+|\Delta u|^2_H), \tag{27}$$

where the constant C_3 depends on M_0 (cf. Lemma 3.5). Thus, we obtain that

$$|\Delta\lambda(u)|^2_H \le C_4(1+|\Delta u|^2_H), \tag{28}$$

with $C_4 = 2C(\lambda)^2(C_3+1)$. Hence we have that

$$\frac{1}{2}\frac{d}{dt}|\nabla\sigma|^2_H + \kappa|\Delta\sigma|^2_H - \frac{d}{dt}(\lambda'(u)\nabla u, \nabla\sigma) \le \frac{1}{4}|\partial I^\mu_{u,v}(\sigma)|^2_H + |\Delta f^*(u,v)|^2_H + |\Delta f_*(u,v)|^2_H$$

$$+ \frac{1}{2}C_4(1+|\Delta u|^2_H) + \frac{1}{2}|\sigma'|^2_H + C^*_F(|\nabla\sigma|^2_H + |\nabla u|^2_H + |\nabla v|^2_H). \tag{29}$$

Now, we multiply (18) by $\partial I^\mu_{u,v}(\sigma)$ and using Lemma 3.7, we obtain the estimate

$$\frac{d}{dt}I^\mu_{u,v}(\sigma) + \frac{1}{2}|\partial I^\mu_{u,v}(\sigma)|^2_H \le C_5(|u'|^2_H + |v'|^2_H)$$

$$+ \frac{\kappa}{4}|\partial I^\mu_{u,v}(\sigma)|^2_H + \kappa|\Delta f^*(u,v)|^2_H + \kappa|\Delta f_*(u,v)|^2_H + C_6, \tag{30}$$

where $C_5 = (C_0+1)(C_0+C(\lambda)^2)$, $C_6 = (C_0+1)|F|^2_\infty|\Omega|$.

Noting that $|\Delta f_*(u,v)|^2_H + |\Delta f^*(u,v)|^2_H \le 2C_7(|\nabla u|^4_{L^4} + |\nabla v|^4_{L^4} + |\Delta u|^2_H + |\Delta v|^2_H)$, where $C_7 = 32C_0^2$, we conclude in view of (27) that

$$|\Delta f_*(u,v)|^2_H + |\Delta f^*(u,v)|^2_H \le C_8(1+|\Delta u|^2_H + |\Delta v|^2_H), \tag{31}$$

with $C_8 = 2C_7(C_3+1)$. Adding (29) and (30), we get in view of (31) that

$$\frac{d}{dt}\left\{I^\mu_{u,v}(\sigma) + \frac{1}{2}|\nabla\sigma|^2_H - (\lambda'(u)\nabla u, \nabla\sigma)\right\} + \kappa|\Delta\sigma|^2_H + \frac{1-\kappa}{4}|\partial I^\mu_{u,v}(\sigma)|^2_H$$

$$\le C_9(1 + |\nabla\sigma|^2_H + |\nabla u|^2_H + |\nabla v|^2_H + |\sigma'|^2_H$$

$$+ |u'|^2_H + |v'|^2_H + (1+\kappa)(1+|\Delta u|^2_H + |\Delta v|^2_H)), \tag{32}$$

where $C_9 = \max\left\{\frac{C_4}{2} + C_6, C^*_F, \frac{1}{2}, C_5, \frac{C_4}{2} + C_8\right\}$.

Let $\varepsilon_1, \varepsilon_2, \varepsilon_3$ be positive numbers to be specified later. Calculate (21) + $\varepsilon_1 \times$ (22) + $\varepsilon_2 \times$ (23) + $\varepsilon_3 \times$ (32). We have that

$$(1-\varepsilon_2C_2-\varepsilon_3C_9)|u'|^2_H + (1-\varepsilon_2C_2-\varepsilon_3C_9)|v'|^2_H$$

$$+ (\varepsilon_2-\varepsilon_3C_9)|\sigma'|^2_H + (\varepsilon_1-\varepsilon_3C_9(1+\kappa))|\Delta u|^2_H + (\varepsilon_1-\varepsilon_3C_9(1+\kappa))|\Delta v|^2_H$$

$$+ \kappa(\varepsilon_3-\varepsilon_2C_2\kappa)|\Delta\sigma|^2_H + \varepsilon_3\frac{1-\kappa}{4}|\partial I^\mu_{u,v}(\sigma)|^2_H$$

$$+ \frac{d}{dt}\{(1+\varepsilon_1)|\nabla u|^2_H + (1+\varepsilon_1)|\nabla v|^2_H + \left(\varepsilon_2\kappa + \frac{\varepsilon_3}{2}\right)|\nabla\sigma|^2_H$$

$$- \varepsilon_3(\lambda'(u)\nabla u, \nabla\sigma) + (2\varepsilon_2 + \varepsilon_3) I^{\mu}_{u,v}(\sigma)\}$$

$$\leq C_{10} + \varepsilon_3 C_9 \left(2 + \kappa + |\nabla u|_H^2 + |\nabla v|_H^2 + |\nabla\sigma|_H^2\right), \tag{33}$$

where $C_{10} = C_1 + \varepsilon_1 C_1 + \varepsilon_2 C_2$. Now, we will fix ε_i, $i = 1, 2, 3$, as well the constant κ_0 in the statement of the theorem, so that the coefficients in the first three lines of (33), i.e., $1 - \varepsilon_2 C_2 - \varepsilon_3 C_9$, $\varepsilon_2 - \varepsilon_3 C_9$, $\varepsilon_1 - \varepsilon_3 C_9(1+\kappa)$, $\kappa(\varepsilon_3 - \varepsilon_2 C_2 \kappa)$, $\varepsilon_3 \frac{1-\kappa}{4}$ will be all positive whenever $\kappa \in (0, \kappa_0)$. For instance, we can take $\varepsilon_2 = \frac{1}{4C_2}$, $\varepsilon_3 = \min\{\frac{1}{4C_9}\min\{1, \frac{1}{2C_2}\}, \frac{1}{C(\lambda)^2}\}$, and then $\varepsilon_1 = \min\{\min\{1, \frac{1}{2C_2}\}, \frac{4C_9}{C(\lambda)^2}\}$ with $\kappa_0 = \min\{\frac{1}{2}, \frac{1}{2C_9}\min\{1, \frac{1}{2C_2}\}, \frac{2}{C(\lambda)^2}\}$. We note that in this case

$$1 - \varepsilon_2 C_2 - \varepsilon_3 C_9 \geq \frac{1}{2}, \tag{34}$$

$$\varepsilon_2 - \varepsilon_3 C_9 \geq \frac{\varepsilon_2}{2} \tag{35}$$

along with

$$\varepsilon_1 - \varepsilon_3 C_9(1+\kappa) \geq \frac{\varepsilon_1}{2} \qquad \text{for all } \kappa \in (0, \kappa_0), \tag{36}$$

so that the above coefficients are all bounded from below uniformly with respect to κ. Moreover, concerning the coefficients in the third line of (33), we have that $\kappa(\varepsilon_3 - \varepsilon_2 C_2 \kappa) \geq \kappa\frac{\varepsilon_3}{2}$, $\varepsilon_3\frac{1-\kappa}{4} \geq \frac{\varepsilon_3}{8}$ for all $\kappa \in (0, \kappa_0)$.

Consequently, from (33) we can deduce uniform estimates for $\sigma_\mu = \sigma$, $u_\mu = u$, and $v_\mu = v$ with respect to the parameter μ. We have that $\{\sigma_\mu\}_\mu, \{u_\mu\}_\mu$, and $\{v_\mu\}_\mu$ are bounded in $W^{1,2}(0,T;H) \cap L^\infty(0,T;V) \cap L^2(0,T;H^2(\Omega))$, $\{\partial I^{\mu}_{u_\mu,v_\mu}(\sigma_\mu)\}_\mu$ is bounded in $L^2(0,T;H)$, and $\{I^{\mu}_{u_\mu,v_\mu}(\sigma_\mu)\}_\mu$ is bounded in $L^\infty(0,T)$.

Therefore (cf. [6], [8]), possibly by extracting a subsequence $\mu_n \searrow 0$, we conclude that $\sigma_{\mu_n} \to \sigma$, $u_{\mu_n} \to u$, and $v_{\mu_n} \to v$ weakly in $W^{1,2}(0,T;H) \cap L^2(0,T;H^2(\Omega))$ and weakly star in $L^\infty(0,T;V)$ to a triplet $\{\sigma, u, v\}$, which is a solution of the system (1)–(3). Let us note also that $f_*(u,v) \leq \sigma \leq f^*(u,v)$ a.e. in Q. □

Remark 3.3. Without loss of generality, in the proof of Theorem 3.6 it could be assumed that σ is also bounded. Thus, in view of Remarks 3.1 and 3.2 it follows that the proof of Theorem 3.6 can be easily adapted to the system (5)–(7) as well.

3.4. Uniqueness of solutions. The purpose of this section is to discuss the uniqueness of solutions. Before the proof of uniqueness we give an estimate for a solution of a parabolic equation. The estimate in the following lemma will play a very important role in the proof of uniqueness.

LEMMA 3.8 (cf. [12, Theorem 3.7.1]). *Let $\mu_0 > 0$ and θ be a solution of the following initial boundary value problem:*

$$\theta' - \mu_0 \Delta\theta = f \quad \text{in } Q, \tag{37}$$

$$\frac{\partial\theta}{\partial n} = 0 \quad \text{on } (0,T)\times\partial\Omega, \quad \theta(0) = \theta_0, \tag{38}$$

where f and θ_0 are given functions. If $f \in L^r(0,T;L^q(\Omega))$ with $\frac{1}{r} + \frac{N}{2q} < 1$ for $q, r \geq 1$ and $\theta_0 \in L^\infty(\Omega)$, then there exists a positive constant C_* depending only on Ω, μ_0, q, r, and N such that

$$|\theta|_{L^\infty(0,t;L^\infty(\Omega))} \leq C_*(|f|_{L^r(0,t;L^q(\Omega))} + |\theta_0|_{L^\infty(\Omega)}) \quad \text{for } 0 \leq t \leq T.$$

Proof. First, we assume that $|f|_{L^r(0,T;L^q(\Omega))} + |\theta_0|_{L^\infty(\Omega)} \le 1$. Let θ be a solution of (37)–(38). Then Theorem 3.7.1 of [12] implies that

$$|\theta|_{L^\infty(0,t;L^\infty(\Omega))} \le C_* \quad \text{for } 0 \le t \le T,$$

where C_* is a positive constant. Next, for general f and θ_0 we put $\hat{\theta} = \frac{\theta}{\ell_0}$, where θ is a solution of (37)–(38) and $\ell_0 = |f|_{L^r(0,t;L^q(\Omega))} + |\theta_0|_{L^\infty(\Omega)}$. Immediately, $\hat{\theta}$ is a solution of (37)–(38) with $\hat{f} = \frac{f}{\ell_0}$ and $\hat{\theta}_0 = \frac{\theta_0}{\ell_0}$ so that $|\hat{\theta}|_{L^\infty(0,t;L^\infty(\Omega))} \le C_*$ for $0 \le t \le T$ because $|\hat{f}|_{L^r(0,T;L^q(\Omega))} + |\hat{\theta}_0|_{L^\infty(\Omega)} \le 1$. Thus we can prove this lemma. □

In order to prove uniqueness we assume that $\Omega \subset R^3$.

THEOREM 3.9. *Let $\Omega \subset R^3$. Then the system* (1)–(3) *admits at most one solution.*

The main idea of the proof is due to Kenmochi, Koyama, and Meyer [8].

Proof. Let $\{\sigma_1, u_1, v_1\}$ and $\{\sigma_2, u_2, v_2\}$ be solutions of (1)–(3) in the sense of Definition 2.1. Also, we put $\sigma = \sigma_1 - \sigma_2$, $u = u_1 - u_2$, $v = v_1 - v_2$. For $s \in (0, T]$ we define

$$L(s) = \max\{|f_*(u_1, v_1) - f_*(u_2, v_2)|_{L^\infty(0,s;L^\infty(\Omega))}, |f^*(u_1, v_1) - f^*(u_2, v_2)|_{L^\infty(0,s;L^\infty(\Omega))}\}.$$

The proof is rather long. So, we divide it into several steps.

1*st step.*

$$\begin{aligned} &|[\sigma(t) - L(s)]^+|_H^2 + |[-\sigma(t) - L(s)]^+|_H^2 \\ &\le K_1 \exp\left\{\int_0^t (3 + |u_1'(\tau)|_H^2 + |u_2'(\tau)|_H^2) d\tau\right\} \\ &\quad \times \int_0^t (|u(\tau)|_H^2 + |v(\tau)|_H^2 + |\sigma(\tau)|_H^2 + |u(\tau)|_{L^\infty(\Omega)}^2 + |u'(\tau)|_H^2) d\tau \text{ for } t \in [0, s], \end{aligned} \tag{39}$$

where K_1 is a positive constant.

Proof of 1*st step.* We put $\tilde{\sigma}_1 = \sigma_1 - [\sigma - L(s)]^+, \tilde{\sigma}_2 = \sigma_2 + [\sigma - L(s)]^+$ a.e. on $(0, s) \times \Omega$. Easily, we have $f_*(u_i, v_i) \le \tilde{\sigma}_i \le f^*(u_i, v_i)$ for $i = 1, 2$, a.e. on $(0, s) \times \Omega$. Then, Definition 2.1(iii)(b) implies that

$$\begin{aligned} &(\sigma_1'(t), [\sigma(t) - L(s)]^+) + \kappa a(\sigma_1(t), [\sigma(t) - L(s)]^+) \\ &\le (F(u_1(t), v_1(t), \sigma_1(t)) + (\lambda(u_1))'(t), [\sigma(t) - L(s)]^+) \quad \text{for a.e. } t \in [0, s]. \end{aligned} \tag{40}$$

Also, we have

$$\begin{aligned} &-(\sigma_2'(t), [\sigma(t) - L(s)]^+) - \kappa a(\sigma_2(t), [\sigma(t) - L(s)]^+) \\ &\le -(F(u_2(t), v_2(t), \sigma_2(t)) + (\lambda(u_2))'(t), [\sigma(t) - L(s)]^+) \quad \text{for a.e. } t \in [0, s]. \end{aligned} \tag{41}$$

By adding (40) and (41), we obtain

$$\begin{aligned} &(\sigma'(t), [\sigma(t) - L(s)]^+) + \kappa a(\sigma(t), [\sigma(t) - L(s)]^+) \\ &\le (F(u_1(t), v_1(t), \sigma_1(t)) - F(u_2(t), v_2(t), \sigma_2(t)), [\sigma(t) - L(s)]^+) \\ &\quad + ((\lambda(u_1))'(t) - (\lambda(u_2))'(t), [\sigma(t) - L(s)]^+) \quad \text{for a.e. } t \in [0, s] \end{aligned}$$

so that

(42)
$$\begin{aligned}
&\frac{d}{dt}|[\sigma(t)-L(s)]^+|_H^2\\
&\le M(|u(t)|_H+|v(t)|_H+|\sigma(t)|_H)|[\sigma(t)-L(s)]^+|_H\\
&\quad+((\lambda'(u_1)(t)-\lambda'(u_2)(t))u_1'(t),[\sigma(t)-L(s)]^+)+(\lambda'(u_2)u'(t),[\sigma(t)-L(s)]^+)\\
&\le K_2(|u(t)|_H^2+|v(t)|_H^2+|\sigma(t)|_H^2+|u(t)|_{L^\infty(\Omega)}^2+|u'(t)|_H^2)\\
&\quad+(3+|u_1'(t)|_H^2)|[\sigma(t)-L(s)]^+|_H^2 \quad \text{for a.e. } t\in[0,s],
\end{aligned}$$

where $C(\lambda)=\max\{|\lambda''|_{L^\infty(R)},|\lambda'|_{L^\infty(R)}\}$ and $K_2=M^2+2C(\lambda)^2$. Applying the Gronwall inequality to (42) it holds that

$$\begin{aligned}
&|[\sigma(t)-L(s)]^+|_H^2\le K_2\exp\left\{\int_0^t(3+|u_1'(\tau)|_H^2)d\tau\right\}\\
&\times\int_0^t(|u(\tau)|_H^2+|v(\tau)|_H^2+|\sigma(\tau)|_H^2+|u(\tau)|_{L^\infty(\Omega)}^2+|u'(\tau)|_H^2)d\tau \quad \text{for } t\in[0,s].
\end{aligned}$$

We can obtain similar estimate for $[-\sigma(t)-L(s)]^+$. Hence, we get (39). □

2nd step. It holds that

$$\frac{1}{2}(|u(t)|_H^2+|v(t)|_H^2)\le 4M\int_0^t(|u(\tau)|_H^2+|v(\tau)|_H^2+|\sigma(\tau)|_H^2)d\tau,\quad t\in[0,T], \tag{43}$$

$$\int_0^t|u'(\tau)|_H^2d\tau\le 4M\int_0^t(|u(\tau)|_H^2+|v(\tau)|_H^2+|\sigma(\tau)|_H^2)d\tau,\quad t\in[0,T]. \tag{44}$$

The proof of this step is omitted since it is quite standard.

3rd step.

$$\begin{aligned}
&|u|_{L^\infty(0,t;L^\infty(\Omega))}\le C_*M(|u|_{L^s(0,t;H)}+|v|_{L^s(0,t;H)}+|\sigma|_{L^s(0,t;H)}),\\
&|v|_{L^\infty(0,t;L^\infty(\Omega))}\le C_*M(|u|_{L^s(0,t;H)}+|v|_{L^s(0,t;H)}+|\sigma|_{L^s(0,t;H)}) \text{ for } 0\le t\le T,
\end{aligned}$$

where C_* is a positive constant given by Lemma 3.8.

Proof of 3rd step. Lemma 3.8 guarantees that

$$|u|_{L^\infty(0,t;L^\infty(\Omega))}\le C_*|h(\sigma_1,u_1,v_1)-h(\sigma_2,u_2,v_2)|_{L^s(0,t;H)} \text{ for } 0\le t\le T.$$

Therefore, by using H3, we conclude that the assertion of the 3rd step is true. □

4th step. There exists a positive constant K_3 such that

$$|\sigma|_{L^\infty(0,s;H)}^2\le K_3s^{1/4}(|u|_{L^\infty(0,s;H)}^2+|v|_{L^\infty(0,s;H)}^2+|\sigma|_{L^\infty(0,s;H)}^2) \text{ for } 0\le s\le T. \tag{45}$$

Proof of 4th step. It is easy to see that

$$\begin{aligned}
&|\sigma|\le|[\sigma-L(s)]^+-[-\sigma-L(s)]^+-\sigma|+|[\sigma-L(s)]^+|+|[-\sigma-L(s)]^+|\\
&\le L(s)+|[\sigma-L(s)]^+|+|[-\sigma-L(s)]^+| \quad \text{a.e. on } (0,s)\times\Omega.
\end{aligned} \tag{46}$$

It follows from the definition of $L(s)$ and the 3rd step that

$$\begin{aligned}
&L(s)^2\le 4M_0^2(|u|_{L^\infty(0,s;L^\infty(\Omega))}^2+|v|_{L^\infty(0,s;L^\infty(\Omega))}^2)\\
&\le 24M_0^2C_*^2M^2s^{1/4}(|u|_{L^\infty(0,s;H)}^2+|v|_{L^\infty(0,s;H)}^2+|\sigma|_{L^\infty(0,s;H)}^2).
\end{aligned} \tag{47}$$

On account of (39), (46), (47), the 3rd step, and (44), we observe that

$$\begin{aligned}
&|\sigma|^2_{L^\infty(0,s;H)} \le K_3 s^{1/4}(|u|^2_{L^\infty(0,s;H)} + |v|^2_{L^\infty(0,s;H)} + |\sigma|^2_{L^\infty(0,s;H)})\\
&+K_4\int_0^s (|u(t)|^2_H + |v(t)|^2_H + |\sigma(t)|^2_H)dt\\
&+K_4\int_0^s (|u(t)|^2_{L^\infty(\Omega)} + |u'(t)|^2_H)dt\\
&\le K_4(1+T^{3/4}+C_*MT+4MT^{3/4})s^{1/4}\\
&\quad\times(|u|^2_{L^\infty(0,s;H)} + |v|^2_{L^\infty(0,s;H)} + |\sigma|^2_{L^\infty(0,s;H)}),
\end{aligned}$$

where $K_4 = 24M_0^2C_*^2M^2 + K_1\exp\{\int_0^T(3+|u_1'(\tau)|^2_H + |u_2'(\tau)|^2_H)d\tau\}$. Thus we have proved the 4th step. □

Proof of the uniqueness. By (43) we have

$$|u|^2_{L^\infty(0,s;H)}+|v|^2_{L^\infty(0,s;H)} \le 8Ms(|u|^2_{L^\infty(0,s;H)}+|v|^2_{L^\infty(0,s;H)}+|\sigma|^2_{L^\infty(0,s;H)}) \text{ for } 0\le s\le T.$$

This inequality together with (45) implies that

$$\begin{aligned}
&|u|^2_{L^\infty(0,s;H)} + |v|^2_{L^\infty(0,s;H)} + |\sigma|^2_{L^\infty(0,s;H)}\\
&\le (8MT^{3/4}+K_3)s^{1/4}(|u|^2_{L^\infty(0,s;H)} + |v|^2_{L^\infty(0,s;H)} + |\sigma|^2_{L^\infty(0,s;H)}) \text{ for } 0\le s\le T.
\end{aligned}$$

Here, we take $s_1 > 0$ satisfying $(8MT^{3/4}+K_3)s_1^{1/4} \le \frac{1}{2}$. Then we see that

$$|u|^2_{L^\infty(0,s_1;H)} + |v|^2_{L^\infty(0,s_1;H)} + |\sigma|^2_{L^\infty(0,s_1;H)} = 0,$$

that is, $u = v = \sigma = 0$ a.e. on $(0,s_1)\times\Omega$. The choice of s_1 is independent of initial values. Therefore, we can obtain the uniqueness of the solution. □

3.5. Existence and uniqueness in the case when $\Omega \subset R^3$. In this section we present an existence and uniqueness result for the case when $\Omega \subset R^3$.

THEOREM 3.10. *Let $\Omega \subset R^3$. Then* (i) *the system* (1)–(3) *with $\kappa = 0$ possesses a unique solution;* (ii) *there exists a constant $\kappa_0 > 0$ such that the system* (1)–(3) *possesses a unique solution for any κ satisfying $0 < \kappa < \kappa_0$.*

Proof. (i) Let us note that the validity of the estimates for the approximate solutions from section 3.3.2 extends to the constructed solution $\{\sigma^{(\kappa)}, u^{(\kappa)}, v^{(\kappa)}\}$ of the system (1)–(3) whenever $0 < \kappa < \kappa_0$ (cf. (33)–(36)). Therefore, in view of Theorem 3.9 and arguing as in [8], it could be shown that $\{\sigma^{(\kappa)}, u^{(\kappa)}, v^{(\kappa)}\}$ converges in a suitable sense to the unique solution $\{\sigma, u, v\}$ of the system (1)–(3) with $\kappa = 0$. Moreover, σ satisfies $\sigma \in L^\infty(0,T;V)$. (ii) is a corollary of Theorems 3.6 and 3.9. □

A UNIFORM ANALYSIS OF NONSYMMETRIC AND COERCIVE LINEAR OPERATORS*

GIANCARLO SANGALLI†

Abstract. In this work, we show how to construct, by means of the function space interpolation theory, a *natural* norm $|\!|\!| \cdot |\!|\!|$ for a generic linear *coercive* and *nonsymmetric* operator $\mathcal{L}$. The natural norm $|\!|\!| \cdot |\!|\!|$ allows for *continuity* and *inf-sup* conditions which hold independently of $\mathcal{L}$. In particular we will consider the convection-diffusion-reaction operator, for which we obtain continuity and inf-sup conditions that are uniform with respect to the operator coefficients. In this case, our results give some insight for the analysis of the singular perturbed behavior of the operator, occurring when the diffusivity coefficient is small. Furthermore, our analysis is preliminary to applying some recent numerical methodologies (such as *least-squares* and *adaptive wavelet* methods) to this class of operators, and more generally to analyzing any numerical method within the classical framework [I. Babuška and A. K. Aziz, in *The Mathematical Foundations of the Finite Element Method with Applications to Partial Differential Equations*, Academic Press, New York, 1972, pp. 1–359].

1. Introduction.

Consider the convection-diffusion-reaction linear operator

$$w \mapsto \mathcal{L}w := -\kappa \Delta w + \beta \cdot \nabla w + \rho w, \tag{1.1}$$

where the argument w is a function on the domain $\Omega \subset \mathbb{R}^n$, κ is a constant positive diffusion coefficient, $\beta : \Omega \to \mathbb{R}^n$ is a velocity field, and $\rho : \Omega \to \mathbb{R}$ is a reaction coefficient. Under suitable assumptions on the coefficients, e.g., $\rho - 1/2\,\mathrm{div}\beta \geq 0$, the operator $\mathcal{L}$ is an isomorphism from $V := H_0^1(\Omega)$ into $V^* := H^{-1}(\Omega)$. In fact, given a source term $f \in V^*$, the boundary value problem

$$\begin{cases} \mathcal{L}u = f & \text{in } \Omega, \\ u = 0 & \text{on } \partial\Omega \end{cases} \tag{1.2}$$

admits a unique solution $u \in V$. Nevertheless, the norm of $\mathcal{L}$, as linear operator from $H_0^1(\Omega)$ into $H^{-1}(\Omega)$,

$$\|\mathcal{L}\|_{H_0^1(\Omega)\to H^{-1}(\Omega)} := \sup_{w\in H_0^1(\Omega)} \frac{\|\mathcal{L}w\|_{H^{-1}(\Omega)}}{\|w\|_{H_0^1(\Omega)}} = \sup_{w\in H_0^1(\Omega)} \sup_{v\in H_0^1(\Omega)} \frac{\langle \mathcal{L}w, v\rangle}{\|w\|_{H_0^1(\Omega)}\|v\|_{H_0^1(\Omega)}},$$

and the norm of its inverse $\mathcal{L}^{-1}$

$$\begin{aligned} \|\mathcal{L}^{-1}\|_{H^{-1}(\Omega)\to H_0^1(\Omega)} &:= \sup_{w\in H_0^1(\Omega)} \frac{\|w\|_{H_0^1(\Omega)}}{\|\mathcal{L}w\|_{H^{-1}(\Omega)}} \\ &= \left(\inf_{w\in H_0^1(\Omega)} \sup_{v\in H_0^1(\Omega)} \frac{\langle \mathcal{L}w, v\rangle}{\|w\|_{H_0^1(\Omega)}\|v\|_{H_0^1(\Omega)}} \right)^{-1} \end{aligned}$$

depend on the coefficients κ, β, and ρ.

Our analysis encompasses any linear and *coercive* operator $\mathcal{L}$, of which (1.1) is a model case. Given such an operator $\mathcal{L}$, we construct a norm $\|\!|\cdot|\!\|$ on its domain V such that the *continuity*

$$\sup_{w\in V}\sup_{v\in V}\frac{\langle \mathcal{L}w, v\rangle}{|\!|\!|w|\!|\!|\,|\!|\!|v|\!|\!|} \leq \mathcal{C}_c < +\infty \tag{1.3}$$

and the *inf-sup* condition

$$\inf_{w\in V}\sup_{v\in V}\frac{\langle \mathcal{L}w, v\rangle}{|\!|\!|w|\!|\!|\,|\!|\!|v|\!|\!|} \geq \mathcal{C}_{is} > 0 \tag{1.4}$$

hold true with constants $\mathcal{C}_c$ and $\mathcal{C}_{is}$ independent of $\mathcal{L}$. Therefore, for the example (1.1), $\mathcal{C}_c$ and $\mathcal{C}_{is}$ will be independent of the coefficients κ, β, and ρ.

If $\mathcal{L}$ were symmetric, besides coercive, then conditions (1.3)–(1.4) would hold true for the so-called energy norm, i.e., by setting $|\!|\!|w|\!|\!| := \langle \mathcal{L}w, w\rangle^{1/2}$, with $\mathcal{C}_c = \mathcal{C}_{is} = 1$. Our aim is to extend this trivial result to the nonsymmetric case, obtaining a suitable $\|\!|\cdot|\!\|$ by means of the function space interpolation.

The norm $\|\!|\cdot|\!\|$, for which (1.3)–(1.4) hold true, depends on $\mathcal{L}$ and gives the *natural* topology for $\mathcal{L}$. For the example (1.1)–(1.2), given a source term f and a perturbed source term $f + \delta f$, denoting by u and $u + \delta u$ the solutions of $\mathcal{L}u = f$ and $\mathcal{L}(u + \delta u) = f + \delta f$, respectively, one easily gets from (1.3)–(1.4)

$$\frac{|\!|\!|\delta u|\!|\!|}{|\!|\!|u|\!|\!|} \leq \frac{\mathcal{C}_c}{\mathcal{C}_{is}}\frac{|\!|\!|\delta f|\!|\!|_*}{|\!|\!|f|\!|\!|_*};$$

i.e., the relative perturbation of the solution of (1.2) is uniformly bounded by the relative perturbation of the source term, $|\!|\!|\cdot|\!|\!|_*$ being the dual of norm of $|\!|\!|\cdot|\!|\!|$. This is the proper framework to understand the behavior of (1.1)–(1.2) for small values of the diffusivity κ, when the higher order term $-\kappa\Delta$ acts as a singular perturbation on the lower order term $\beta\cdot\nabla + \rho\,\mathrm{Id}$.

Conditions (1.3)–(1.4) are also the proper framework for using some recent numerical methodologies for solving (1.1)–(1.2). Particularly, we are thinking of the *least-squares* formulations in the context of finite element methods [6] or in the context of wavelet methods [12], and of *adaptive wavelet methods* [11] (see also [10, 2, 5]).

More generally, (1.3)–(1.4) are the starting point for the classical analysis of numerical methods devoted to (1.1)–(1.2). When the continuity and inf-sup conditions are known for an operator $\mathcal{L}$, then *ideal* numerical methods should preserve them at the discrete level. This happens, for example, with symmetric and coercive operators (see [9]) or with some indefinite problems (as in mixed formulations; see [7]), and it is in general the key property for the classical error theory (see, e.g., [1]). Even though there are very effective numerical methods for solving (1.1)–(1.2), such as the *streamline-upwind Petrov-Galerkin* (SUPG) finite element method (see [8] and [17]), the error analysis of them typically does not follow the classical argument mentioned above and it is not completely satisfactory (see [18]). We hope this paper could give some insights for a deeper theoretical understanding of numerical methods devoted to (1.1)–(1.2) (we refer to [18, section 4], [19], and [3, section 2.1] for a further discussion on the topic).

This work is an extension of our previous analysis proposed in [18], where the convection-diffusion operator, without the reaction term, is considered. Different

estimates for (1.1)–(1.2) have been obtained by other authors; see, for example, the analysis by Bertoluzza, Canuto, and Tabacco in [4, section 2.1] or the paper by Dörfler [13]. The peculiarity of our paper is that both conditions (1.3)–(1.4) are obtained for (1.1)–(1.2).

The outline of this paper is as follows: in section 2 we present our methodology for obtaining (1.3)–(1.4) in the case of a generic nonsymmetric and coercive operator $\mathcal{L}$. Then we apply the theory—first, in section 3.1, to the very simple one-dimensional ($n = 1$) convection-diffusion-reaction model problem, and then, in section 3.2, to the multidimensional ($n > 1$) case—and discuss the results.

2. The abstract framework. In this section, we present our idea for obtaining uniform continuity and inf-sup conditions (1.3)–(1.4).

Let V be a Hilbert space, and let V^* be its dual. In the present section we consider a generic coercive isomorphism $\mathcal{L} : V \to V^*$ and the associated bilinear form

$$a(w, v) := {}_{V^*}\langle \mathcal{L}w, v\rangle_V \quad \forall w, v \in V. \tag{2.1}$$

The abstract variational problem which corresponds to (1.2) is

$$\text{find } u \in V \text{ such that } a(u, v) = {}_{V^*}\langle f, v\rangle_V \quad \forall v \in V. \tag{2.2}$$

We also assume that $\|\cdot\|_V$, the norm of V, is the *energy norm* for $\mathcal{L}$, i.e.,

$$a(w, w) = \|w\|_V^2 \quad \forall w \in V. \tag{2.3}$$

We split $\mathcal{L} = \mathcal{L}_{\text{sym}} + \mathcal{L}_{\text{skew}}$, and introduce the bilinear forms $a_{\text{sym}}(\cdot,\cdot)$ and $a_{\text{skew}}(\cdot,\cdot)$ on $V \times V$ such that

$$\begin{aligned} {}_{V^*}\langle \mathcal{L}_{\text{sym}}w, v\rangle_V &:= a_{\text{sym}}(w, v) := \frac{1}{2}\left(a(w, v) + a(v, w)\right) \quad \forall w, v \in V, \\ {}_{V^*}\langle \mathcal{L}_{\text{skew}}w, v\rangle_V &:= a_{\text{skew}}(w, v) := \frac{1}{2}\left(a(w, v) - a(v, w)\right) \quad \forall w, v \in V. \end{aligned} \tag{2.4}$$

In other words $\mathcal{L}_{\text{sym}}$ is the symmetric part of $\mathcal{L}$ (i.e., $a_{\text{sym}}(w, v) = a_{\text{sym}}(v, w)\ \forall w, v \in V$), and we have

$$\begin{aligned} a_{\text{sym}}(w, w) &= \|w\|_V^2 && \forall w \in V, \\ a_{\text{sym}}(w, v) &\le \|w\|_V \|v\|_V && \forall w, v \in V, \end{aligned} \tag{2.5}$$

while $\mathcal{L}_{\text{skew}}$ is the skew-symmetric part of $\mathcal{L}$ (i.e., $a_{\text{skew}}(w, v) = -a_{\text{skew}}(v, w)\ \forall w, v \in V$).

Finally, we define

$$\begin{aligned} \|w\|_{A_0}^2 &:= \|w\|_V^2 \quad \forall w \in V, \\ \|w\|_{A_1}^2 &:= \|w\|_V^2 + \|\mathcal{L}_{\text{skew}}w\|_{V^*}^2 \quad \forall w \in V, \end{aligned} \tag{2.6}$$

where

$$\|\mathcal{L}_{\text{skew}}w\|_{V^*} = \sup_{v \in V} \frac{a_{\text{skew}}(w, v)}{\|v\|_V}.$$

We also set $A_0 = A_1 = V$ from the algebraic standpoint; in other words A_0 and A_1 are the same space with the same topology, but the two norms $\|\cdot\|_{A_0}$ and $\|\cdot\|_{A_1}$ are different (even though equivalent, up to constants depending on L).

The following lemma states two basic estimates; we explicitly compute the constants appearing in the estimates to highlight their independence of $\mathcal{L}$.

LEMMA 2.1. *We have*

$$a(w,v) \le 2^{1/2}\|w\|_{A_i}\|v\|_{A_{1-i}} \quad \forall w,v \in V, \tag{2.7}$$

$$\sup_{v\in V}\frac{a(w,v)}{\|v\|_{A_{1-i}}} \ge 5^{-1/2}\|w\|_{A_i} \quad \forall w \in V \tag{2.8}$$

for $i=0$ or $i=1$.

Proof. Let v and w be two generic elements of V.

By using the Cauchy–Schwarz inequality we easily get

$$\begin{aligned} a(w,v) &= a_{\mathrm{sym}}(w,v) + a_{\mathrm{skew}}(w,v) \\ &\le \|w\|_V\|v\|_V + \|\mathcal{L}_{\mathrm{skew}}w\|_{V^*}\|v\|_V \\ &\le 2^{1/2}\|w\|_{A_1}\|v\|_{A_0}. \end{aligned}$$

Similarly, since $a_{\mathrm{skew}}(w,v) = -a_{\mathrm{skew}}(v,w)$, we also get $a(w,v) \le 2^{1/2}\|w\|_{A_0}\|v\|_{A_1}$, and then (2.7) follows.

Recalling (2.3) and (2.5), we have

$$\|w\|_V \le \sup_{v\in V}\frac{a(w,v)}{\|v\|_V} \tag{2.9}$$

and

$$\sup_{v\in V}\frac{a_{\mathrm{sym}}(w,v)}{\|v\|_V} = \|w\|_V \le \sup_{v\in V}\frac{a(w,v)}{\|v\|_V}. \tag{2.10}$$

Then, we get

$$\begin{aligned} \|\mathcal{L}_{\mathrm{skew}}w\|_{V^*} &= \sup_{v\in V}\frac{a_{\mathrm{skew}}(w,v)}{\|v\|_V} \\ &\le \sup_{v\in V}\frac{a(w,v)}{\|v\|_V} + \sup_{v\in V}\frac{a_{\mathrm{sym}}(w,v)}{\|v\|_V} \\ &\le 2\sup_{v\in V}\frac{a(w,v)}{\|v\|_V}, \end{aligned} \tag{2.11}$$

and collecting (2.9) and (2.11), we get

$$\|w\|_{A_1} \le 5^{1/2}\sup_{v\in V}\frac{a(w,v)}{\|v\|_{A_0}}, \tag{2.12}$$

which is (2.8) for $i=1$. We are left to show that

$$\|w\|_{A_0} \le 5^{1/2}\sup_{v\in V}\frac{a(w,v)}{\|v\|_{A_1}}; \tag{2.13}$$

for that purpose, we make use of a duality argument. Reasoning as for (2.12) we obtain

$$\|\tilde{w}\|_{A_1} \le 5^{1/2}\sup_{v\in V}\frac{a(v,\tilde{w})}{\|v\|_{A_0}} \tag{2.14}$$

for any $\tilde{w} \in V$. Given a generic $w \in V$, we associate with it $\tilde{w} \in V$ such that $a(v, \tilde{w}) = a_{\mathrm{sym}}(v, w)\ \forall v \in V$; thanks to (2.14) we have

$$\|\tilde{w}\|_{A_1} \leq 5^{1/2} \sup_{v \in V} \frac{a(v, \tilde{w})}{\|v\|_{A_0}} = 5^{1/2} \sup_{v \in V} \frac{a_{\mathrm{sym}}(v, w)}{\|v\|_{A_0}} = 5^{1/2} \|w\|_{A_0},$$

whence

$$\begin{aligned} \|w\|_{A_0}^2 &= a_{\mathrm{sym}}(w, w) = a(w, \tilde{w}) \\ &\leq \sup_{v \in V} \frac{a(w, v)}{\|v\|_{A_1}} \cdot \|\tilde{w}\|_{A_1} \\ &\leq 5^{1/2} \sup_{v \in V} \frac{a(w, v)}{\|v\|_{A_1}} \cdot \|w\|_{A_0}, \end{aligned}$$

which completes the proof. ∎

From Lemma 2.1 we can obtain a family of intermediate estimates by means of the function spaces interpolation. We follow the notation and the definitions of [20]; for the reader's convenience, we recall the fundamental definition of *interpolated norm*, according to the *K-method*: given $0 < \theta < 1$ and $1 \leq p \leq +\infty$, we define

$$\|w\|_{(A_0, A_1)_{\theta, p}} := \left[\int_0^{+\infty} \inf_{\substack{w_0 \in A_0, w_1 \in A_1, \\ w_0 + w_1 = w}} \left(t^{-\theta} \|w_0\|_{A_0} + t^{1-\theta} \|w_1\|_{A_1} \right)^p \frac{dt}{t} \right]^{1/p}. \tag{2.15}$$

Generally $(A_0, A_1)_{\theta,p}$ is the space of functions $w \in A_0 + A_1$ such that $\|w\|_{(A_0,A_1)_{\theta,p}} < +\infty$. In our particular case, A_0 and A_1 are the same space from the algebraic standpoint ($A_0 \equiv A_1 \equiv V$), and $\|\cdot\|_{(A_0,A_1)_{\theta,p}}$ simply is a new norm on V.

LEMMA 2.2. *Given θ, p, and p' such that $0 < \theta < 1$, $1 \leq p \leq +\infty$, and $1/p + 1/p' = 1$, we have*

$$a(w, v) \leq 2^{1/2} \|w\|_{(A_0,A_1)_{\theta,p}} \|v\|_{(A_0,A_1)_{1-\theta,p'}} \quad \forall w, v \in V, \tag{2.16}$$

$$\sup_{v \in V} \frac{a(w, v)}{\|v\|_{(A_0,A_1)_{1-\theta,p'}}} \geq 5^{-1/2} \|w\|_{(A_0,A_1)_{\theta,p}} \quad \forall w \in V. \tag{2.17}$$

Proof. Typically interpolation theorems are stated in terms of linear operators instead of bilinear forms. Then it is more convenient to rephrase (2.7) as

$$\begin{aligned} \|\mathcal{L} w\|_{A_1^*} &\leq 2^{1/2} \|w\|_{A_0}, \\ \|\mathcal{L} w\|_{A_0^*} &\leq 2^{1/2} \|w\|_{A_1} \end{aligned} \tag{2.18}$$

and (2.8) as

$$\begin{aligned} \|w\|_{A_0} &\leq 5^{1/2} \|\mathcal{L} w\|_{A_1^*}, \\ \|w\|_{A_1} &\leq 5^{1/2} \|\mathcal{L} w\|_{A_0^*} \end{aligned} \tag{2.19}$$

$\forall\ w \in V$.

From (2.18) and thanks to the theorems in [20, sections 1.3.3 and 1.11.2], we get (2.16). Proceeding similarly for $\mathcal{L}^{-1}$, from (2.19) we obtain

$$\|\mathcal{L}^{-1} \phi\|_{(A_0,A_1)^*_{1-\theta,p'}} \leq 5^{1/2} \|\phi\|_{(A_0,A_1)_{\theta,p}}$$

for any $\phi \in V^*$, and that gives (2.17). ∎

Thanks to (2.5), $\mathcal{L}_{\rm sym}$ is an isomorphism from V into $V^* \equiv \mathcal{L}_{\rm sym}(V)$; henceforth, we also assume that $\mathcal{L}_{\rm skew}$ is injective. Then we introduce the two Hilbert spaces C_0 and C_1:

$$\begin{aligned} &C_0 := \mathcal{L}_{\rm skew}(V) \quad \text{with } \|\phi\|_{C_0} := \|\mathcal{L}_{\rm skew}^{-1}\phi\|_V, \\ &C_1 := \mathcal{L}_{\rm sym}(V) \quad \text{with } \|\phi\|_{C_1} := \|\mathcal{L}_{\rm sym}^{-1}\phi\|_V = \|\phi\|_{V^*}. \end{aligned} \tag{2.20}$$

In the next lemma we analyze the structure of $\|\cdot\|_{(A_0,A_1)_{\theta,p}}$.

LEMMA 2.3. *Given θ, p, and p' such that $0 < \theta < 1$, $1 \le p \le +\infty$, and $1/p + 1/p' = 1$, we have*

$$1/10\,\|w\|^2_{(A_0,A_1)_{\theta,p}} \le \|w\|^2_V + \|\mathcal{L}_{\rm skew}w\|^2_{(C_0,C_1)_{\theta,p}} \le 2\|w\|^2_{(A_0,A_1)_{\theta,p}} \quad \forall w \in V. \tag{2.21}$$

Proof. Since $\|w\|_V \le \|w\|_{A_i}$ with $i = 0, 1$, then $\|w\|_V \le \|w\|_{(A_0,A_1)_{\theta,p}}$ follows by a straightforward application of the interpolation theorem (e.g., [20, section 1.3.3]). We also have

$$\begin{aligned} &\|\mathcal{L}_{\rm skew}w\|_{C_0} = \|w\|_{A_0}, \\ &\|\mathcal{L}_{\rm skew}w\|_{C_1} \le \|w\|_{A_1}, \end{aligned}$$

which gives $\|\mathcal{L}_{\rm skew}w\|_{(C_0,C_1)_{\theta,p}} \le \mathcal{C}\|w\|_{(A_0,A_1)_{\theta,p}}$, whence $\|w\|^2_V + \|\mathcal{L}_{\rm skew}w\|^2_{(C_0,C_1)_{\theta,p}} \le 2\|w\|^2_{(A_0,A_1)_{\theta,p}}$.

In order to complete the proof, we deal directly with the definition of interpolated norm (2.15). For any $t > 0$ consider the two splittings

$$\begin{aligned} &w = \tilde{w}_0(t) + \tilde{w}_1(t) \text{ with } \tilde{w}_i(t) \in V, \quad i = 1, 2, \\ &w = \hat{w}_0(t) + \hat{w}_1(t) \text{ with } \hat{w}_i(t) \in V, \quad i = 1, 2. \end{aligned} \tag{2.22}$$

Then define $w_0(t) \in V$ and $w_1(t) \in V$ such that $\mathcal{L}w_i(t) = \mathcal{L}_{\rm sym}\tilde{w}_i(t) + \mathcal{L}_{\rm skew}\hat{w}_i(t)$, i.e.,

$$a(w_i(t), v) = a_{\rm sym}(\tilde{w}_i(t), v) + a_{\rm skew}(\hat{w}_i(t), v) \quad \forall v \in V, \quad i = 0, 1, \tag{2.23}$$

whence $w = w_0(t) + w_1(t)$ $\forall t > 0$.

Thanks to (2.8) and to the properties of $a_{\rm sym}(\cdot,\cdot)$ and $a_{\rm skew}(\cdot,\cdot)$ we have

$$\begin{aligned} \|w_0(t)\|_{A_0} &\le 5^{1/2} \sup_{v\in V} \frac{a(w_0(t), v)}{\|v\|_{A_1}} \\ &\le 5^{1/2} \left(\sup_{v\in V} \frac{a_{\rm sym}(\tilde{w}_0(t), v) - a_{\rm skew}(v, \hat{w}_0(t))}{\|v\|_{A_1}} \right) \\ &\le 5^{1/2} \left(\sup_{v\in V} \frac{a_{\rm sym}(\tilde{w}_0(t), v)}{\|v\|_V} + \sup_{v\in V} \frac{a_{\rm skew}(v, \hat{w}_0(t))}{\|\mathcal{L}_{\rm skew}v\|_{V^*}} \right) \\ &\le 5^{1/2} \left(\|\tilde{w}_0(t)\|_V + \|\hat{w}_0(t)\|_V \right). \end{aligned} \tag{2.24}$$

In a similar way, we have

$$
\begin{aligned}
\|w_1(t)\|_{A_1} &\le 5^{1/2} \sup_{v\in V} \frac{a(w_1(t),v)}{\|v\|_{A_0}} \\
&\le 5^{1/2} \left(\sup_{v\in V} \frac{a_{\mathrm{sym}}(\tilde{w}_1(t),v) + a_{\mathrm{skew}}(\hat{w}_1(t),v)}{\|v\|_{A_0}} \right) \\
&\le 5^{1/2} \left(\sup_{v\in V} \frac{a_{\mathrm{sym}}(\tilde{w}_1(t),v)}{\|v\|_V} + \sup_{v\in V} \frac{a_{\mathrm{skew}}(\hat{w}_1(t),v)}{\|v\|_V} \right) \\
&\le 5^{1/2} \left(\|\tilde{w}_1(t)\|_V + \|\mathcal{L}_{\mathrm{skew}} \hat{w}_1(t)\|_{V^*} \right).
\end{aligned} \tag{2.25}
$$

From (2.15), by the triangle inequality and using (2.24)–(2.25), we have

$$
\begin{aligned}
\|w\|_{(A_0,A_1)_{\theta,p}} &\le \left[\int_0^{+\infty} \left(t^{-\theta} \|w_0(t)\|_{A_0} + t^{1-\theta} \|w_1(t)\|_{A_1} \right)^p \frac{dt}{t} \right]^{1/p} \\
&\le 5^{1/2} \Bigg[\int_0^{+\infty} \Big(t^{-\theta} \|\tilde{w}_0(t)\|_V + t^{-\theta} \|\hat{w}_0(t)\|_V \\
&\qquad + t^{1-\theta} \|\tilde{w}_1(t)\|_V + t^{1-\theta} \|\mathcal{L}_{\mathrm{skew}} \hat{w}_1(t)\|_{V^*} \Big)^p \frac{dt}{t} \Bigg]^{1/p} \\
&\le 5^{1/2} \left[\int_0^{+\infty} \left(t^{-\theta} \|\tilde{w}_0(t)\|_V + t^{1-\theta} \|\tilde{w}_1(t)\|_V \right)^p \frac{dt}{t} \right]^{1/p} \\
&\quad + \left[\int_0^{+\infty} \left(t^{-\theta} \|\mathcal{L}_{\mathrm{skew}} \hat{w}_0(t)\|_{C_0} + t^{1-\theta} \|\mathcal{L}_{\mathrm{skew}} \hat{w}_1(t)\|_{C_1} \right)^p \frac{dt}{t} \right]^{1/p}.
\end{aligned}
$$

Finally, taking the infimum over all $\tilde{w}_0 \in V$, and $\tilde{w}_1 = w - \tilde{w}_0 \in V$, $\hat{w}_0 \in V$ and $\hat{w}_1 = w - \hat{w}_0 \in V$, and using [20, 1.3.3.(f)], we finally get $\|w\|_{(A_0,A_1)_{\theta,p}} \le 5^{1/2} \left(\|w\|_V + \|\mathcal{L}_{\mathrm{skew}} w\|_{(C_0,C_1)_{\theta,p}} \right)$, completing the proof of (2.21). ∎

When $p = p' = 2$ and $\theta = 1-\theta = 1/2$, Lemma 2.2 gives the continuity and inf-sup conditions for $\mathcal{L}$, as stated in section 1, where $|\!|\!| \cdot |\!|\!| = \| \cdot \|_{(A_0,A_1)_{1/2,2}}$. In particular, under the hypotheses of Lemma 2.3, we have the following obvious corollary.

COROLLARY 2.4. *Under the assumption of Lemma* 2.3 *and setting*

$$
|\!|\!| \cdot |\!|\!| := \left(\| \cdot \|_V^2 + \| \mathcal{L}_{\mathrm{skew}} \cdot \|^2_{(C_0,C_1)_{1/2,2}} \right)^{1/2}, \tag{2.26}
$$

we have the continuity and inf-sup conditions (1.3)–(1.4) *for* $\mathcal{L}$*, with constants* $\mathcal{C}_c$ *and* $\mathcal{C}_{is}$ *independent of* $\mathcal{L}$*.*

The particular case considered in Corollary 2.4 is of interest from the numerical analysis standpoint, as discussed in [18, section 4].

3. The convection-diffusion-reaction operator. We now apply the results of the previous section to the convection-diffusion-reaction operator. In Lemmas 2.1–2.3 we have explicitly computed the constants involved into the estimates, in order to emphasize that the estimates do not depend on $\mathcal{L}$; henceforth, for the sake of simplicity, we will use generic constants denoted by $\mathcal{C}$, $\mathcal{C}_1$, $\mathcal{C}_2$, which are independent on the operator coefficients κ, β, and ρ and on the domain Ω.

3.1. The one-dimensional case. We start with the analysis of the very simple one-dimensional operator, with constant coefficients $\kappa > 0$ and $\rho \geq 0$ and unitary velocity. Then, for this subsection only, we will consider a special case of (1.1), which is

$$w \mapsto \mathcal{L}w := -\kappa w'' + w' + \rho w, \tag{3.1}$$

where the argument w is a function of the interval $\Omega = [0,1]$.

We consider first, and with particular emphasis, the ordinary differential equation with homogeneous Dirichlet boundary conditions (1.2). The variational formulation (2.2) reads as

$$\text{find } u \in V \text{ such that } a(u,v) = \int_0^1 fv \quad \forall v \in V,$$

where

$$\begin{aligned} V &= H_0^1(0,1) \text{ with } \|\cdot\|_V^2 = \kappa|\cdot|_{H^1}^2 + \rho\|\cdot\|_{L^2}^2, \\ a(w,v) &= \kappa\int_0^1 w'v' + \int_0^1 w'v + \rho\int_0^1 wv. \end{aligned} \tag{3.2}$$

Then $\mathcal{L}_{\text{sym}}w = -\kappa w'' + \rho w$, $\mathcal{L}_{\text{skew}}w = w'$, $a_{\text{sym}}(w,v) = \kappa\int_0^1 w'v' + \rho\int_0^1 wv$, and $a_{\text{skew}}(w,v) = \int_0^1 w'v$. From the algebraic standpoint, $C_0 = L_0^2(0,1)$ and $C_1 = H^{-1}(0,1)$, where L_0^2 is the subspace of L^2 of zero mean value functions, its natural norm is $\|\cdot\|_{L_0^2} := \|\cdot\|_{L^2}$, and H^{-1} is the dual of H_0^1, endowed with the dual norm $\|\cdot\|_{H^{-1}} = \sup_{v\in H_0^1(0,1)} \langle\cdot, v\rangle / |v|_{H^1}$ (we recall that $|\cdot|_{H^1} := [\int_0^1 (w')^2]^{1/2}$ is a norm on H_0^1). It is easy to see that L_0^2 is a dense subspace of H^{-1}. From Corollary 2.4 we immediately have the following result.

THEOREM 3.1. *For the case* (3.1)–(3.2)*, uniform continuity and inf-sup conditions* (1.3)–(1.4) *hold true with respect to the norm*

$$w \mapsto |\!|\!| w |\!|\!| = \left(\kappa|w|_{H^1}^2 + \|w'\|_{(C_0,C_1)_{1/2,2}}^2 + \rho\|w\|_{L^2}^2\right)^{1/2}. \tag{3.3}$$

Now we focus our attention on $|\!|\!|\cdot|\!|\!|$ in (3.3) in order to better understand its structure. Roughly speaking, the term $\|w'\|_{(C_0,C_1)_{1/2,2}}$ is related to the skew-symmetric part of $\mathcal{L}$, which is the *first* order derivative. Then we expect $w \mapsto \|w'\|_{(C_0,C_1)_{1/2,2}}$ to act as a 1/2-order norm uniformly on the operator coefficients κ and ρ. That is in fact stated in the next theorem: we show that $\|w'\|_{(C_0,C_1)_{1/2,2}}$ stays between the $H^{1/2}$-seminorm and $H_{00}^{1/2}$-norm, where $H^{1/2} := (L^2, H^1)_{1/2,2}$ and $H_{00}^{1/2} := (L^2, H_0^1)_{1/2,2}$ are the two usual Hilbert spaces of order 1/2, endowed with the usual norms given by interpolation (see [15]), and $|w|_{H^{1/2}}$ is the seminorm $\|w - \Pi_0 w\|_{H^{1/2}}$, $\Pi_0\cdot$ denoting the mean value of its argument.

THEOREM 3.2. *For the case* (3.1)–(3.2)*, we have*

$$\mathcal{C}_1|w|_{H^{1/2}} \leq \|w'\|_{(C_0,C_1)_{1/2,2}} \leq \mathcal{C}_2\|w\|_{H_{00}^{1/2}} \quad \forall w \in V. \tag{3.4}$$

Proof. When $\rho = 0$, (3.4) follows from (3.18); we assume henceforth that $\rho > 0$.

We consider first the left inequality in (3.4), i.e.,

$$\mathcal{C}|w|_{H^{1/2}} \leq \|w'\|_{(C_0,C_1)_{1/2,2}} \quad \forall w \in V. \tag{3.5}$$

It is easy to see that $\|z'\|_{L^2} \simeq \|z\|_{H^1}$ and $\|z'\|_{H^{-1}} \simeq \|z\|_{L^2}$ for any $z \in H^1 \cap L^2_0$; then, thanks to the theorems in [20, sections 1.3.3, 1.11.2, and 1.17.1], the first order derivative is a topological isomorphism from $H^{1/2} \cap L^2_0$ into $(H^{-1}, L^2)_{1/2,2}$, which means

$$|w|_{H^{1/2}} = \|w - \Pi_0 w\|_{H^{1/2}} \simeq \|w'\|_{(H^{-1},L^2)_{1/2,2}}. \tag{3.6}$$

We introduce now the new space $\widetilde{C}_0$: from the algebraic standpoint we set $\widetilde{C}_0 := L^2$, and we define $\|\cdot\|_{\widetilde{C}_0} := \left(\kappa\|\cdot\|^2_{L^2} + \rho\|\cdot\|^2_{H^{-1}}\right)^{1/2}$. Our next step is to show that

$$\|\phi\|_{(H^{-1},L^2)_{1/2,2}} \le \mathcal{C}\|\phi\|_{(\widetilde{C}_0,C_1)_{1/2,2}} \quad \forall \phi \in L^2. \tag{3.7}$$

For that purpose we split a generic $\phi \in L^2$ into

$$\phi = \phi_{\text{high}} + \phi_{\text{low}}, \tag{3.8}$$

where $\phi_{\text{high}}, \phi_{\text{low}} \in L^2$ are, roughly speaking, the high frequency part and the low frequency part of ϕ, respectively, in such a way that

$$\kappa^{1/2}\|\phi_{\text{high}}\|_{L^2} + \rho^{1/2}\|\phi_{\text{low}}\|_{H^{-1}} \le \mathcal{C}\|\phi\|_{\widetilde{C}_0}, \tag{3.9}$$

$$\kappa^{-1/2}\|\phi_{\text{high}}\|_{H^{-1}} + \rho^{-1/2}\|\phi_{\text{low}}\|_{L^2} \le \mathcal{C}\|\phi\|_{C_1}. \tag{3.10}$$

For that purpose, we introduce an auxiliary problem: let $\psi \in H^1_0$ be the solution of

$$\mathcal{L}_{\text{sym}}\psi = \phi \qquad \text{in } (0,1) \tag{3.11}$$

and let $\phi_{\text{high}} := -\kappa\psi''$ and $\phi_{\text{low}} := \rho\psi$.

Multiplying both members of the differential equation (3.11) by $-\psi''$, integrating over $(0,1)$, and integrating by parts we get

$$\kappa\|\psi''\|^2_{L^2} + \rho\|\psi'\|^2_{L^2} = -\int_0^1 \phi\psi'';$$

then, thanks to the Cauchy–Schwarz inequality, we have

$$\|\phi_{\text{high}}\|_{L^2} = \|\kappa\psi''\|_{L^2} \le \|\phi\|_{L^2}. \tag{3.12}$$

Integrating (3.11) we have

$$-\kappa\psi' + \kappa\psi'(0) + \rho\Psi = \Phi,$$

where $\Psi(x) = \int_0^x \psi(t)\,dt$ and analogously $\Phi(x) = \int_0^x \phi(t)\,dt$. After multiplying both members by $\Psi - \Pi_0\Psi$, integrating over $(0,1)$, and integrating by parts, we obtain

$$\kappa\|\psi\|^2_{L^2} + \rho\|\Psi - \Pi_0\Psi\|^2_{L^2} = \int_0^1 \Phi(\Psi - \Pi_0\Psi),$$

whence now

$$\|\phi_{\text{low}}\|_{H^{-1}} = \rho\|\Psi - \Pi_0\Psi\|_{L^2} \le \|\Phi - \Pi_0\Phi\|_{L^2} = \|\phi\|_{H^{-1}}. \tag{3.13}$$

Collecting (3.12)–(3.13) we obtain (3.9). From (3.11) it is also easy to obtain the estimate $(\kappa\|\psi'\|^2_{L^2} + \rho\|\psi\|^2_{L^2})^{1/2} \le \|\phi\|_{V^*} = \|\phi\|_{C_1}$, which gives (3.10) straightforwardly.

Consider now the linear operator $\phi \mapsto (\phi_{\text{high}}, \phi_{\text{low}})$ from L^2 into $L^2 \times L^2$, with ϕ_{high}, ϕ_{low} as defined earlier: by interpolation from the two continuity estimates (3.9) and (3.10) we get

$$\|\phi_{\text{high}}\|_{(L^2,H^{-1})_{1/2,2}} + \|\phi_{\text{low}}\|_{(H^{-1},L^2)_{1/2,2}} \leq \mathcal{C}\|\phi\|_{(\widetilde{C}_0,C_1)_{1/2,2}}, \tag{3.14}$$

whence, by using the triangle inequality and since $\|\cdot\|_{(L^2,H^{-1})_{1/2,2}} = \|\cdot\|_{(H^{-1},L^2)_{1/2,2}}$, we obtain (3.7). Finally (3.6) and (3.7) gives (3.5).

Now we consider the right equivalence in (3.4), which is

$$\|w'\|_{(C_0,C_1)_{1/2,2}} \leq \mathcal{C}\|w\|_{H^{1/2}_{00}} \quad \forall w \in V. \tag{3.15}$$

Given $w \in H^1_0$ it is easy to see that

$$\|w'\|_{C_0} = \|w\|_V = \|w\|_{C_1^*}$$

and

$$\|w'\|_{C_1} = \|w'\|_{V^*} \leq \|w\|_{\widetilde{C}_0^*},$$

whence (thanks to the theorem in [20, section 1.11.2])

$$\|w'\|_{(C_0,C_1)_{1/2,2}} \leq \|w\|_{(C_1^*,\widetilde{C}_0^*)_{1/2,2}} = \|w\|_{(\widetilde{C}_0,C_1)^*_{1/2,2}}. \tag{3.16}$$

Moreover, passing to the duals in (3.7), still using the theorem in [20, section 1.11.2], we also have

$$\|w\|_{(\widetilde{C}_0,C_1)^*_{1/2,2}} \leq \|w\|_{(H^{-1},L^2)^*_{1/2,2}} = \|w\|_{(H^1_0,L^2)_{1/2,2}} = \|w\|_{(H^{1/2}_{00})}. \tag{3.17}$$

Inequalities (3.16)–(3.17) give (3.15). □

It is worth noting that Theorems 3.1 amd 3.2 allow for $\rho = 0$ as well; in that case we have $\|w'\|_{(C_0,C_1)_{1/2,2}} = \|w'\|_{(H^{-1},L^2_0)_{1/2,2}}$, since the coefficient κ easily cancels when interpolating. Let $H^1_\#$ be the subspace of H^1 of functions w such that $w(0) = w(1)$ endowed with the $\|\cdot\|_{H^1_\#} := \|\cdot\|_{H^1}$, and $H^{1/2}_\# := (L^2, H^1_\#)_{1/2,2}$ endowed with the norm given by interpolation. Given $z \in H^1_\# \cap L^2_0$, one has $\|z'\|_{L^2_0} \simeq \|z\|_{H^1_\#}$ and $\|z'\|_{H^{-1}} \simeq \|z\|_{L^2}$, whence (making use of the theorems in [20, sections 1.3.3, 1.11.2, and 1.17.1], for example) we have $\|z'\|_{(H^{-1},L^2_0)_{1/2,2}} \simeq \|z\|_{(L^2,H^1_\#)_{1/2,2}}$ and therefore $\|w'\|_{(H^{-1},L^2_0)_{1/2,2}} \simeq \|w - \Pi_0 w\|_{(L^2,H^1_\#)_{1/2,2}}$, for any $w \in H^1_0$; this means that we have the following characterization:

$$\rho = 0 \;\Rightarrow\; |w|_{H^{1/2}_\#} := \|w - \Pi_0 w\|_{(L^2,H^1_\#)_{1/2,2}} = \|w'\|_{(C_0,C_1)_{1/2,2}} \quad \forall w \in V. \tag{3.18}$$

We may also deal with different kinds of boundary conditions. Consider the example

$$\begin{cases} \mathcal{L}u = f & \text{in } (0,1), \\ u(0) = u'(1) = 0, \end{cases} \tag{3.19}$$

where $\mathcal{L}$ is still formally given by (3.1). The variational formulation (2.2) now requires

$$V = \left\{ v \in H^1(0,1) \text{ such that } v(0) = 0 \right\},$$
$$a(w,v) = \kappa \int_0^1 w'v' + \int_0^1 w'v + \rho \int_0^1 wv.$$

The key point is that the bilinear form $a(\cdot,\cdot)$ is coercive on V; accordingly, we define $\|\cdot\|_V$ as

$$\|w\|_V^2 := a(w,w) = \kappa|w|_{H^1}^2 + \rho\|w\|_{L^2}^2 + \frac{1}{2}w(1)^2,$$

and we now have

$$a_{\rm sym}(w,v) = \kappa\int_0^1 w'v' + \rho\int_0^1 wv + \frac{1}{2}w(1)v(1),$$
$$a_{\rm skew}(w,v) = \int_0^1 w'v - \frac{1}{2}w(1)v(1).$$

Then we can still make use of the theory of section 2 and obtain uniform inf-sup and continuity conditions from Corollary 2.4.

When the bilinear form $a(\cdot,\cdot)$ is not coercive, we cannot use the results of section 2. This is the case of

$$\begin{cases} -\kappa u'' + u' = f \text{ in } (0,1), \\ u'(0) = u(1) = 0, \end{cases} \tag{3.20}$$

i.e., when $\rho = 0$ and we prescribe a Neumann boundary condition at the *inflow* $x = 0$; then $V = \left\{v \in H^1(0,1) \text{ such that } v(1) = 0\right\}$ and

$$a(w,w) = \kappa|w|_{H^1}^2 + \rho\|w\|_{L^2}^2 - \frac{1}{2}w(1)^2,$$

which is not positive in general, when κ and ρ are small enough. However, when $f = 1$ the solution of (3.20) is $u(x) = \kappa\left(\exp(1/\kappa) - \exp(x/\kappa)\right) + x - 1$; for $\kappa \to 0$ we have $\|u\|_{L^2} \approx \kappa\exp(1/\kappa)$, whence we see that (3.20) is not uniformly well posed with respect to κ.

3.2. The multidimensional case. In this section, we analyze the multidimensional convection-diffusion-reaction operator with Dirichlet homogeneous boundary conditions (1.1)–(1.2), and the associated bilinear form

$$a(w,v) = \kappa\int_\Omega \nabla w\cdot\nabla v + \int_\Omega \beta\cdot\nabla w\, v + \int_\Omega \rho wv,$$

which is defined on $H_0^1(\Omega)\times H_0^1(\Omega)$ (see, e.g., [15]). Under the assumption

$$\rho - \frac{1}{2}{\rm div}(\beta) \geq 0 \tag{3.21}$$

the bilinear form $a(\cdot,\cdot)$ is coercive, whence we set

$$V = H_0^1(\Omega),$$
$$\|w\|_V^2 = a(w,w) = \kappa|w|_{H^1}^2 + \left(\rho - \frac{1}{2}{\rm div}(\beta)\right)\|w\|_{L^2}^2. \tag{3.22}$$

The decomposition (2.4) gives

$$a_{\rm sym}(w,v) = \kappa\int_\Omega \nabla w\cdot\nabla v + \int_\Omega \left(\rho - \frac{1}{2}{\rm div}(\beta)\right)wv,$$
$$a_{\rm skew}(w,v) = \int_\Omega \beta\cdot\nabla w\, v + \frac{1}{2}\int_\Omega {\rm div}(\beta)\, wv. \tag{3.23}$$

For the sake of simplicity, we shall consider henceforth the case

$$\operatorname{div}(\beta) = 0. \tag{3.24}$$

In order to apply Corollary 2.4 to this case, we need $\mathcal{L}_{\text{skew}} = \beta \cdot \nabla$ to be injective on V. This is assured, for example, by the assumption

$$\text{there exists a smooth } \phi : \Omega \to \mathbb{R} \text{ such that } \nabla\phi \cdot \beta \geq \mathcal{C} > 0; \tag{3.25}$$

we refer to [14] for further details. Definition (2.20) says that, from the algebraic standpoint, C_0 is the space of the streamline derivatives $\beta \cdot \nabla w$ of functions $w \in H^1_0$, while C_1 is H^{-1}. Corollary 2.4 then gives the following result.

THEOREM 3.3. *For the case* (3.22), (3.24)–(3.25)*, the uniform continuity and inf-sup conditions* (1.3)–(1.4) *hold true with respect to the norm*

$$w \mapsto |\!|\!| w |\!|\!| = \left(\kappa |w|^2_{H^1} + \|\beta \cdot \nabla w\|^2_{(C_0,C_1)_{1/2,2}} + \rho \|w\|^2_{L^2} \right)^{1/2}. \tag{3.26}$$

Roughly speaking, we expect $\|\beta \cdot \nabla w\|_{(C_0,C_1)_{1/2,2}}$ to be of order $1/2$ in the direction of β and of order 0 in the directions orthogonal to β (this can be more easily seen for the case $\rho = 0$), but a rigorous analysis of the structure of $\|\beta \cdot \nabla w\|_{(C_0,C_1)_{1/2,2}}$ is more difficult now than for the simpler one-dimensional case considered in section 3.1. The next result shows that $\|\beta \cdot \nabla w\|_{(C_0,C_1)_{1/2,1}}$ has some uniform bounds independent of κ and ρ (though the anisotropy is not investigated). Then we end with a comparison between $\|\beta \cdot \nabla w\|_{(C_0,C_1)_{1/2,1}}$ and $\|\beta \cdot \nabla w\|_{(C_0,C_1)_{1/2,2}}$.

PROPOSITION 3.4. *For the case* (3.22), (3.24)–(3.25)*, we have*

$$\begin{aligned} \mathcal{C}_p \|\beta\|^{1/2}_{L^\infty} \mathit{diam}(\Omega)^{-1/2} \|w\|_{L^2} &\leq \|\beta \cdot \nabla w\|_{(C_0,C_1)_{1/2,1}} \\ &\leq \mathcal{C} \|\beta\|^{1/2}_{L^\infty} \|w\|_{(L^2,H^1_0)_{1/2,1}} \quad \forall w \in V, \end{aligned} \tag{3.27}$$

where the constant $\mathcal{C}_p$ of the Poincaré-like inequality depends on $\beta/\|\beta\|_{L^\infty}$ and (the shape of) Ω.

Proof. Let η be the solution of $\beta \cdot \nabla \eta = \|\beta\|_{L^\infty}$ with $\eta = 0$ on $\partial\Omega^- := \{\mathbf{x} \in \partial\Omega | \beta(\mathbf{x}) \cdot \mathbf{n}(\mathbf{x}) < 0\}$, where $\mathbf{n}$ denotes the outward normal unit vector defined on $\partial\Omega$. The existence of η is guaranteed by (3.25). Given $w \in H^1_0$, integrating by parts, and using the Cauchy–Schwarz inequality and (3.24), we have

$$\begin{aligned} \|\beta\|_{L^\infty} \|w\|^2_{L^2} &= \int_\Omega \beta \cdot \nabla \eta \, w^2 \\ &= -2 \int_\Omega \eta w \, \beta \cdot \nabla w \\ &\leq 2 \|\eta w\|_V \|\beta \cdot \nabla w\|_{V^*}. \end{aligned} \tag{3.28}$$

We have

$$\|\eta w\|_{L^2} \leq \|\eta\|_{L^\infty} \|w\|_{L^2}, \tag{3.29}$$

and using the classical Poincaré inequality, it is easy to get

$$\begin{aligned} |\eta w|_{H^1} &\leq \mathcal{C}(\|\eta\|_{L^\infty} |w|_{H^1} + \|\nabla \eta\|_{(L^\infty)^2} \|w\|_{L^2}) \\ &\leq \mathcal{C}(\|\eta\|_{L^\infty} + \operatorname{diam}(\Omega) \|\nabla \eta\|_{(L^\infty)^2}) |w|_{H^1}. \end{aligned} \tag{3.30}$$

Moreover, thanks to (3.25), we have $\widetilde{\mathcal{C}_p} := \mathrm{diam}(\Omega)^{-1}\|\eta\|_{L^\infty} + \|\nabla\eta\|_{(L^\infty)^2} < +\infty$ (e.g., see [14, Theorem 3.2]), where $\widetilde{\mathcal{C}_p}$ depends on η, i.e., on $\beta/\|\beta\|_{L^\infty}$ and on (the shape of) Ω. Then

$$\|\eta w\|_V \le \mathcal{C}\widetilde{\mathcal{C}_p}\mathrm{diam}(\Omega)\|w\|_V; \tag{3.31}$$

substituting back in (3.28),

$$\begin{aligned}\|\beta\|_{L^\infty}\|w\|_{L^2}^2 &\le \mathcal{C}\widetilde{\mathcal{C}_p}\mathrm{diam}(\Omega)\|w\|_V\|\beta\cdot\nabla w\|_{V^*}\\ &= \mathcal{C}\widetilde{\mathcal{C}_p}\mathrm{diam}(\Omega)\|\beta\cdot\nabla w\|_{C_0}\|\beta\cdot\nabla w\|_{C_1}.\end{aligned} \tag{3.32}$$

It has been proven in [16] (see also Lemma (a) in [20, section 1.10.1]) that when a linear operator $L : C_0 \cap C_1 \to E$ satisfies $\|L\phi\|_E \le \|\phi\|_{C_0}^{1/2}\|\phi\|_{C_1}^{1/2}$, for all $\phi \in C_0 \cap C_1$, it also satisfies $\|L\phi\|_E \le \|\phi\|_{(C_0,C_1)_{1/2,1}}$; using this in (3.32), with $L = (\beta\cdot\nabla)^{-1}$ and $\phi = \beta\cdot\nabla w$, we get

$$\mathcal{C}_p\|\beta\|_{L^\infty}^{1/2}\mathrm{diam}(\Omega)^{-1/2}\|w\|_{L^2} \le \|\beta\cdot\nabla w\|_{(C_0,C_1)_{1/2,1}} \quad \forall w \in V, \tag{3.33}$$

which is the left inequality of (3.27).

We have, thanks to the theorem in [20, section 1.3.3],

$$\begin{aligned}\|\beta\cdot\nabla w\|_{(C_0,C_1)_{1/2,1}}^2 &\le \|\beta\cdot\nabla w\|_{C_0}\|\beta\cdot\nabla w\|_{C_1}\\ &\le \kappa^{1/2}|w|_{H^1}\|\beta\cdot\nabla w\|_{V^*}\\ &\quad + \rho^{1/2}\|w\|_{L^2}\|\beta\cdot\nabla w\|_{V^*}\end{aligned} \tag{3.34}$$

and

$$\begin{aligned}\|\beta\cdot\nabla w\|_{V^*} \le \kappa^{-1/2}\|\beta\cdot\nabla w\|_{H^{-1}} \le \kappa^{-1/2}\|\beta\|_{L^\infty}\|w\|_{L^2},\\ \|\beta\cdot\nabla w\|_{V^*} \le \rho^{-1/2}\|\beta\cdot\nabla w\|_{L^2} \le \rho^{-1/2}\|\beta\|_{L^\infty}|w|_{H^1};\end{aligned} \tag{3.35}$$

from (3.34)–(3.35) we get

$$\|\beta\cdot\nabla w\|_{(C_0,C_1)_{1/2,1}}^2 \le 2\|\beta\|_{L^\infty}|w|_{H^1}\|w\|_{L^2}.$$

Still using the result of [16] mentioned above, for (3.32)–(3.33) we get

$$\|\beta\cdot\nabla w\|_{(C_0,C_1)_{1/2,1}} \le \mathcal{C}\|\beta\|_{L^\infty}^{1/2}\|w\|_{(L^2,H_0^1)_{1/2,1}} \quad \forall w \in V,$$

which concludes the proof of (3.27). ∎

In the previous proposition, we have shown uniform bounds (with respect to the operator coefficients) for $\|\beta\cdot\nabla w\|_{(C_0,C_1)_{1/2,1}}$. As a general result of the interpolation theory (see, e.g., [20, 1.3.3.d]), we have

$$\|\beta\cdot\nabla w\|_{(C_0,C_1)_{1/2,2}} \le \|\beta\cdot\nabla w\|_{(C_0,C_1)_{1/2,1}} \quad \forall w \in V, \tag{3.36}$$

and similarly

$$\|w\|_{(A_0,A_1)_{1/2,2}} \le \|w\|_{(A_0,A_1)_{1/2,1}} \quad \forall w \in V. \tag{3.37}$$

The converse inequality of (3.36), that is, $\|\beta\cdot\nabla w\|_{(C_0,C_1)_{1/2,1}} \le \mathcal{C}\|\beta\cdot\nabla w\|_{(C_0,C_1)_{1/2,2}}$, does not hold true; on the other hand the converse of (3.37) holds true, and it is,

roughly speaking, *almost* uniform in the sense that the constant in it only depends on a logarithm of the coefficients, as stated in the next proposition.

PROPOSITION 3.5. *Consider the case* (3.22), (3.24), *and* (3.25)*: let*

$$\alpha := \max\left\{\kappa^{1/2}\rho^{1/2}, \kappa\, diam(\Omega)\right\} / \|\beta\|_{L^\infty}. \tag{3.38}$$

When $\alpha \leq 1$ *we have*

$$\|w\|_{(A_0,A_1)_{1/2,1}} \leq \left(\mathcal{C} - \log^{1/2}(\alpha)\right) \|w\|_{(A_0,A_1)_{1/2,2}} \quad \forall w \in V, \tag{3.39}$$

while for $\alpha > 1$ *we have*

$$\|w\|_{(A_0,A_1)_{1/2,1}} \leq \mathcal{C}\|w\|_{(A_0,A_1)_{1/2,2}} \quad \forall w \in V. \tag{3.40}$$

Proof. We only consider here the case $\alpha \leq 1$, since when $\alpha > 1$ we can set $\alpha := 1$ instead of (3.38) and follow the proof. Recall that from the definition (2.6) we have

$$\begin{aligned} \|w\|_{A_0} &\leq \|w\|_{A_0} \quad \forall w \in V, \\ \|w\|_{A_0} &\leq \|w\|_{A_1} \quad \forall w \in V, \end{aligned} \tag{3.41}$$

and from (3.35) and the Poincaré inequality, we also have

$$\begin{aligned} \|w\|_{A_1} &\leq \|w\|_{A_1} \quad \forall w \in V, \\ \alpha\|w\|_{A_1} &\leq \mathcal{C}\|w\|_{A_0} \quad \forall w \in V. \end{aligned} \tag{3.42}$$

Then, by interpolation we get from (3.41)

$$\|w\|_{A_0} \leq \|w\|_{(A_0,A_1)_{1/2,2}} \quad \forall w \in V, \tag{3.43}$$

and from (3.42)

$$\alpha^{1/2}\|w\|_{A_1} \leq \mathcal{C}\|w\|_{(A_0,A_1)_{1/2,2}} \quad \forall w \in V. \tag{3.44}$$

By the definition (2.15) and by the triangle inequality we get

$$\begin{aligned} \|w\|_{(A_0,A_1)_{1/2,1}} &\leq \int_0^{+\infty} \left(t^{-1/2}\|w_0(t)\|_{A_0} + t^{1/2}\|w_1(t)\|_{A_1}\right) \frac{dt}{t} \\ &\leq \int_0^{\alpha} \left(t^{-1/2}\|w_0(t)\|_{A_0} + t^{1/2}\|w_1(t)\|_{A_1}\right) \frac{dt}{t} \\ &\quad + \int_{\alpha}^{1} \left(t^{-1/2}\|w_0(t)\|_{A_0} + t^{1/2}\|w_1(t)\|_{A_1}\right) \frac{dt}{t} \\ &\quad + \int_{1}^{+\infty} \left(t^{-1/2}\|w_0(t)\|_{A_0} + t^{1/2}\|w_1(t)\|_{A_1}\right) \frac{dt}{t} \\ &= I + II + III \end{aligned}$$

for any $w_0(t)$ and $w_1(t)$ with $w = w_0(t) + w_1(t)$, $w_i(t) \in V, i = 1, 2$ and $0 < t < +\infty$. Taking $w_0(t) = w$ and $w_1(t) = 0$ for $t \geq 1$ and using (3.43) we have

$$\begin{aligned} III &\leq \|w\|_{A_0} \int_1^{\infty} t^{-3/2} dt \\ &\leq 2\|w\|_{A_0} \\ &\leq 2\|w\|_{(A_0,A_1)_{1/2,2}}. \end{aligned}$$

In a very similar way, we deal with the first term, taking $w_1(t) = w$ and $w_0(t) = 0$ for $0 < t < \alpha$; thanks to (3.44) we obtain

$$\begin{aligned} I &\le \|w\|_{A_1} \int_0^\alpha t^{-1/2} dt \\ &\le 2\alpha^{1/2} \|w\|_{A_1} \\ &\le \mathcal{C} \|w\|_{(A_0,A_1)_{1/2,2}}. \end{aligned}$$

Thanks to the Cauchy–Schwarz inequality we have

$$\begin{aligned} &\int_\alpha^1 \left(t^{-1/2} \|w_0(t)\|_{A_0} + t^{1/2} \|w_1(t)\|_{A_1} \right) \frac{dt}{t} \\ &\quad \le \left[\int_\alpha^1 \frac{dt}{t} \right]^{1/2} \\ &\qquad \cdot \left[\int_\alpha^1 \left(t^{-1/2} \|w_0(t)\|_{A_0} + t^{1/2} \|w_1(t)\|_{A_1} \right)^2 \frac{dt}{t} \right]^{1/2} \\ &\quad \le [-\log(\alpha)]^{1/2} \\ &\qquad \cdot \left[\int_\alpha^1 \left(t^{-1/2} \|w_0(t)\|_{A_0} + t^{1/2} \|w_1(t)\|_{A_1} \right)^2 \frac{dt}{t} \right]^{1/2}, \end{aligned} \tag{3.45}$$

which holds true for any choice of $w_0(t)$ and $w_1(t)$ on $\alpha < t < 1$. Taking the infimum on w_0, w_1 we obtain

$$II \le [-\log(\alpha)]^{1/2} \|w\|_{(A_0,A_1)_{1/2,2}}.$$

Finally, (3.39) follows from the previous estimates on I, II, and III. ∎

From Propositions 3.4 and 3.5 we easily derive the next *almost* uniform bounds (up to a $\log(\alpha)^{1/2}$ factor, which is, roughly speaking, a *weak* loss of uniformity).

COROLLARY 3.6. *For the case* (3.22), (3.24)–(3.25), *given* α *from* (3.38), *we have*

$$\mathcal{C}_p \min\left\{1, |\log(\alpha)|^{-1/2}\right\} diam(\Omega)^{-1/2} \|\beta\|_{L^\infty}^{1/2} \|w\|_{L^2} \le |\!|\!| w |\!|\!| \quad \forall w \in V, \tag{3.46}$$

$$\|\beta \cdot \nabla w\|_{(C_0,C_1)_{1/2,2}} \le \mathcal{C} \|\beta\|_{L^\infty}^{1/2} \|w\|_{(L^2,H_0^1)_{1/2,1}} \quad \forall w \in V, \tag{3.47}$$

where $\mathcal{C}_p$ *depends on* $\beta/\|\beta\|_{L^\infty}$ *and (the shape of)* Ω.

Though (3.46)–(3.47) are not as sharp as the estimates we got in section 3.1 for the one-dimensional case, they put in evidence the relationship between the norm $|\!|\!| \cdot |\!|\!|$ defined in (3.26) and the skew-symmetric part $\mathcal{L}_{\text{skew}} = \beta \cdot \nabla$ of (1.1). Recall that $\max\{\kappa^{1/2} \text{diam}(\Omega)^{-1}, \rho^{1/2}\} \|w\|_{L^2} \le \mathcal{C} \|w\|_V \le \mathcal{C} |\!|\!| w |\!|\!|$, while (3.46) states the bound on the L^2-norm which is mainly due to $\|\beta \cdot \nabla w\|_{(C_0,C_1)_{1/2,2}}$. Then (3.46) becomes relevant when κ and ρ are small.
