RESULTS ON PARABOLIC EQUATIONS RELATED TO SOME CAFFARELLI–KOHN–NIRENBERG INEQUALITIES*

ANDREA DALL'AGLIO†, DANIELA GIACHETTI†, AND IRENEO PERAL‡

Abstract. In this paper problem

$$\begin{cases} u_t - \operatorname{div}(|x|^{-p\gamma}|\nabla u|^{p-2}\nabla u) = \lambda \dfrac{u^{p-2}u}{|x|^{p(\gamma+1)}} & \text{in } \Omega \times (0,\infty),\ 0 \in \Omega, \\ u(x,t) = 0 \quad \text{on } \partial\Omega \times (0,\infty), \\ u(x,0) = \psi(x) \geq 0 \end{cases} \tag{0.1}$$

is studied when $1 < p < N$, $-\infty < (\gamma+1) < \frac{N}{p}$, and under hypotheses on the initial data.

Key words. nonlinear parabolic equations, p-laplacian, existence, behavior of solutions, critical problems, Caffarelli–Kohn–Nirenberg inequalities

1. Introduction. The results by Baras and Goldstein in [7] concerning a blow-up for the solution to the heat equation with a critical potential of the type

$$\begin{cases} u_t - \Delta u = \lambda \dfrac{u}{|x|^2} & \text{in } \Omega \times (0,\infty),\ 0 \in \Omega, \\ u(x,t) = 0 \quad \text{on } \partial\Omega \times (0,\infty), \\ u(x,0) = \psi(x) \geq 0 \end{cases} \tag{1.1}$$

have attracted in recent years the interest of research on some related problems. Roughly speaking, apparently, the main ingredient of the problem studied by Baras and Goldstein is a classical Hardy inequality,

$$\int_{\mathbb{R}^n} \frac{|u|^2}{|x|^2}\,dx \leq C_N \int_{\mathbb{R}^n} |\nabla u|^2\,dx, \tag{1.2}$$

where $C_N = (\frac{2}{N-2})^2$ is the optimal constant that is not achieved in the Sobolev space $\mathcal{D}^{1,2}(\mathbb{R}^n)$. For problem (1.1) Baras and Goldstein have proved that if $\lambda \leq C_N^{-1}$, then there exists a global solution if the initial datum is in a convenient class, while if $\lambda > C_N^{-1}$, there is no solution in the sense that if we consider the solutions u_n of the problems with truncated potential $W_n(x) = \min\{n, |x|^{-2}\}$, then

$$\lim_{n\to\infty} u_n(x,t) = +\infty \quad \text{for all } (x,t) \in \Omega \times \mathbb{R}^+.$$

We will call this behavior *spectral instantaneous complete blow-up.* On the other hand, we have the following extension of Hardy's inequality:

$$\int_{\mathbb{R}^n} \frac{|u|^p}{|x|^{(\gamma+1)p}}\,dx \le C_{n,p,\gamma} \int_{\mathbb{R}^n} \frac{|\nabla u|^p}{|x|^{\gamma p}}\,dx, \quad -\infty < \gamma < \frac{N-p}{p}. \tag{1.3}$$

This is a particular limit case of the following Caffarelli–Kohn–Nirenberg inequalities which are proven in [13] (see also [14], [4], and [11]).

PROPOSITION 1.1. *Assume that $1 < p < N$. Then there exists a positive constant $C_{N,p,\gamma,q}$ such that, for every $u \in C_0^\infty(\mathbb{R}^N)$,*

$$\left(\int_{\mathbb{R}^n} \frac{|u|^q}{|x|^{\delta q}}\,dx\right)^{p/q} \le C_{N,p,\gamma,q} \int_{\mathbb{R}^n} \frac{|\nabla u|^p}{|x|^{\gamma p}}\,dx, \tag{1.4}$$

where p, q, γ, δ are related by

$$\frac{1}{q} - \frac{\delta}{N} = \frac{1}{p} - \frac{\gamma+1}{N}, \quad \gamma \le \delta \le \gamma + 1, \tag{1.5}$$

and $\delta q < N$, $\gamma p < N$.

Remark 1.2.

(i) Inequality (1.3) holds a fortiori in every open set Ω.

(ii) One can take

$$C_{n,p,\gamma} = \left(\frac{p}{N - p(\gamma+1)}\right)^p \tag{1.6}$$

in (1.3). This choice of $C_{n,p,\gamma}$ is optimal in every open set Ω containing 0. (The arguments are similar to those in [19] for $\gamma = 0$.)

(iii) If $0 \in \Omega$, the optimal constant is never attained in (1.3).

Remark 1.3. The other limit case for inequality (1.4) is for $\delta = \gamma$, and then one obtains a weighted Sobolev inequality

$$\left(\int_{\mathbb{R}^n} \frac{|u|^{p^*}}{|x|^{\gamma p^*}}\,dx\right)^{p/p^*} \le S_{n,p,\gamma} \int_{\mathbb{R}^n} \frac{|\nabla u|^p}{|x|^{\gamma p}}\,dx, \tag{1.7}$$

where $p^* = \frac{pN}{N-p}$.

It is quite natural to study the parabolic equations associated to inequality (1.3); namely, for the same values of p and γ we consider the problem

$$\text{(P)} \qquad \begin{cases} u_t - \operatorname{div}\left(\dfrac{|\nabla u|^{p-2}\nabla u}{|x|^{\gamma p}}\right) = \lambda \dfrac{|u|^{p-2}u}{|x|^{(\gamma+1)p}}, & (x,t) \in \Omega \times (0,T), \\ u(x,t) = 0, & (x,t) \in \partial\Omega \times (0,T), \\ u(x,0) = \psi(x), & x \in \Omega, \end{cases}$$

where we assume that Ω is a bounded domain in $\mathbb{R}^n$ such that $0 \in \Omega$ and $\partial\Omega$ is a $\mathcal{C}^1$ submanifold.

It is clear that the constant (1.6) will play an essential role in what follows, since the behavior of the problem (P) will deeply depend on whether the parameter λ is smaller or greater than the value

$$\lambda_{n,p,\gamma} = \frac{1}{C_{n,p,\gamma}} = \left(\frac{N - p(\gamma+1)}{p}\right)^p. \tag{1.8}$$

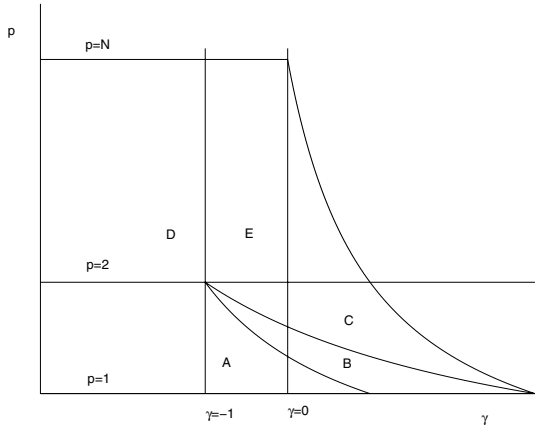

FIG. 1.1. *Summary of the existence and nonexistence results for* $\lambda > \lambda_{N,p,\gamma}$:
Region A: *Global existence of energy solutions.*
Region B: *Global existence of entropy solutions.*
Region C: *Global existence of very weak solutions.*
Region D: *Local existence of solutions.*
Region E: *Instantaneous complete blow-up.*

It could be expected that the behavior for problem (P) should be similar to the one obtained by Baras and Goldstein for (1.1). This conjecture is not completely true. Actually, there is another property which plays an important role in the spectral instantaneous and complete blow-up: a Harnack inequality for the homogeneous parabolic equation. This property is verified if $p \geq 2$ and $(1+\gamma) > 0$. The case $p = 2$ was proved by Chiarenza and Serapioni in [15], while the case $p > 2$ was proved by Abdellaoui and Peral in [1].

The main contribution of this paper is *to show that in the complementary range of the parameters* p *and* γ *we find solutions, even for large values of* λ. The case $p = 2$, $\gamma = 0$ has been studied in [7] and recently in [26]. The case $p \neq 2$, $\gamma = 0$ has been studied in [19] and [5].

The plan of this work is as follows. We begin with section 2, where some notation is provided and appropriate function spaces are defined. Section 3 is devoted to the existence results. In subsection 3.1 we obtain the existence of a global solution in the case $\lambda < \lambda_{N,p,\gamma}$ for all $1 < p < N$. This is the content of Theorem 3.1. In this case the solution belongs to the space $L^p(0,T;\mathcal{D}^{1,p}_{0,\gamma}(\Omega))$, which is naturally related to (P) (see section 2 for the definition). For this reason we will refer to this function u as an *energy solution*. In the proof of Theorem 3.1 we give the details of some convergence results that will be used thereafter. Subsection 3.2 deals with the case $\lambda > \lambda_{N,p,\gamma}$ and $1 < p \leq 2$. The existence of solutions according to the values of γ and p is investigated, and the main results are stated in Theorems 3.3, 3.6, and 3.8. Roughly speaking, as γ and p become larger, we find solutions which are less and less regular. More precisely, we show the following.

1. If $1 < p \leq 2$ and $\gamma + 1 < \frac{N(2-p)}{2p}$ (see region A in Figure 1.1), then we show the existence of energy solutions (see Theorem 3.3).

2. If $1 < p \leq 2$ and $\frac{N(2-p)}{2p} \leq \gamma + 1 < \frac{N(2-p)}{p}$ (see region B), we show the existence of a solution of (P) in the sense of distributions; however, this solution does not belong to the energy space (see Theorem 3.6). We will show that this is an *entropy*

solution in the sense introduced in [8], [22], and [23] for equations with L^1 data (see Definition 3.5 below).

3. If $1 < p \le 2$ and $N(2-p)/(p) < \gamma + 1 < N/p$ (see region C), we show the existence of solutions of (P) in a very weak sense (see Theorem 3.8). We would like to point out that in this case we solve a problem where the right-hand side is not bounded in L^1.

Notice that, comparing the existence results with those contained in [3] for the case $p = 2$, we find that in the nonlinear case (i.e., $p \neq 2$) a very much different behavior of the solutions appears, depending on the parameters; namely, the behavior in cases 2 and 3 above is typical of the nonlinear setting and does not appear in the linear case.

In subsection 3.3, for completeness, we include the elementary local existence result for $p \ge 2$ and $\gamma \le -1$ (see region D in Figure 1.1) in Theorem 3.10, which is also stated in [2].

In section 4 we study the blow-up when $p > 2$, $0 < 1 + \gamma < \frac{N}{p}$, and $\lambda > \lambda_{N,p,\gamma}$ (see region E in Figure 1.1), extending and improving the result of [19] for $\gamma = 0$. (See also [12].)

The case $p = 2$ is obtained in [3] by different kinds of techniques. The main result is Theorem 4.4 and its consequences. The results in Theorems 4.5 and 4.7 have also been stated in [2] and are included here for completeness. With regard to the proof of instantaneous blow-up that we give, it is interesting to point out that for $p > 2$ the blow-up is stronger than that obtained for $p = 2$. Indeed, even the solutions u_n of the problems with truncated potential, $W_n(x) = \min\{n, |x|^{-p(\gamma+1)}\}$, blow up in finite time, and the blow-up time tends to zero as $n \to \infty$.

Finally, in section 5 we study the extinction in finite time of the solution in the case $1 < p < 2$, according to the relation between λ and $\lambda_{N,p,\gamma}$. Roughly speaking, the role that $\lambda_{N,p,\gamma}$ plays in the case $p > 2$ for the blow-up is changed to be a threshold for the finite time extinction property in the case $1 < p < 2$.

2. Notation and function spaces. For $1 < p < \infty$ and $\gamma < \frac{N-p}{p}$, we define the weighted space

$$L^p_\gamma(\Omega) = \left\{ u : \Omega \to \mathbb{R} \text{ measurable, such that } \frac{u(x)}{|x|^\gamma} \in L^p(\Omega) \right\},$$

equipped with the norm

$$\|u\|_{L^p_\gamma(\Omega)} = \left(\int_\Omega \frac{|u(x)|^p}{|x|^{\gamma p}}\, dx \right)^{1/p}.$$

It is easy to check that the dual space $(L^p_\gamma(\Omega))'$ of $L^p_\gamma(\Omega)$ is the space $L^{p'}_{-\gamma}(\Omega)$, where p' is defined by $\frac{1}{p} + \frac{1}{p'} = 1$. Moreover, we define $\mathcal{D}^{1,p}_{0,\gamma}(\Omega)$ as the closure of $C^\infty_0(\Omega)$ in the norm

$$\|u\|_{\mathcal{D}^{1,p}_{0,\gamma}(\Omega)} = \|\nabla u\|_{L^p_\gamma(\Omega)} = \left(\int_\Omega \frac{|\nabla u(x)|^p}{|x|^{\gamma p}}\, dx \right)^{1/p}.$$

As $1 < p < \infty$, $\mathcal{D}^{1,p}_{0,\gamma}(\Omega)$ is reflexive, and we can define the dual space of $\mathcal{D}^{1,p}_{0,\gamma}(\Omega)$, which we will denote by $\mathcal{D}^{-1,p'}_{-\gamma}(\Omega)$, as

$$\mathcal{D}^{-1,p'}_{-\gamma}(\Omega) = \{ G \in \mathcal{D}'(\Omega) : G = \operatorname{div} F,\ F \in L^{p'}_{-\gamma}(\Omega; \mathbb{R}^N) \}.$$

Let us point out that functions in $L^p_\gamma(\Omega)$ do not need to be distributions since they do not belong necessarily to $L^1(\Omega)$. If $\gamma+1 \le -\frac{(p-1)N}{p}$, $\mathcal{D}^{1,p}_{0,\gamma} \not\subset L^1(\Omega)$. The meaning of the gradient in this case is understood as follows. If $u \in \mathcal{D}^{1,p}_{0,\gamma}$ and $\{\phi_n\}_{n\in\mathbb{N}} \subset \mathcal{C}^\infty_0(\Omega)$ is an approximating sequence, then we obtain

$$\nabla\phi_n \to \mathcal{V} \text{ in } L^p_\gamma(\Omega; R^N);$$

in fact, by density and duality we can justify the integration by parts, namely,

$$\int_\Omega \langle \mathcal{V}, \psi\rangle dx = \lim_{n\to\infty} \int_\Omega \langle \nabla\phi_n, \psi\rangle dx = -\int_\Omega u \operatorname{div}(\psi) dx \quad \text{for all } \psi \in \mathcal{D}^{1,p'}_{0,-(\gamma+1)}.$$

As a consequence we define $\operatorname{grad}(u) := \mathcal{V}$. On the other hand, Theorem 1.18 in [20] shows that if $u \in \mathcal{D}^{1,p}_{0,\gamma}$, then the truncature $T_k(u) \in \mathcal{D}^{1,p}_{0,\gamma}(\Omega)$, where $T_k(u)$ is defined by $T_k(u) = u$ if $|u| < k$ and $T_k(u) = k\frac{u}{|u|}$ if $|u| \ge k$. Since $T_k(u) \in L^\infty(\Omega)$, we can define $\nabla T_k(u)$ as a distribution and by Theorem 1.20 in [20] we have

$$\nabla T_k(u) = \operatorname{grad}(u)\chi_{\{|u|<k\}}. \tag{2.1}$$

Hereafter we will denote $\nabla u = \operatorname{grad}(u)$. Notice the relation of this concept of gradient with the one in Lemma 2.1 in [8].

Therefore, inequality (1.4) implies the continuous imbedding

$$\mathcal{D}^{1,p}_{0,\gamma}(\Omega) \subset L^q_\delta(\Omega) \quad \text{for } p, q, \gamma, \delta \text{ satisfying (1.5).} \tag{2.2}$$

This implies, by duality,

$$L^{q'}_{-\delta}(\Omega) \subset \mathcal{D}^{-1,p'}_{-\gamma}(\Omega) \quad \text{for } p, q, \gamma, \delta \text{ satisfying (1.5).} \tag{2.3}$$

We now define the following "evolution" spaces which will be useful in what follows.

$$L^p(0,T;\mathcal{D}^{1,p}_{0,\gamma}(\Omega)) = \{u(x,t) : \Omega\times(0,T) \to \mathbb{R} \text{ measurable}:$$
$$u(\cdot,t) \in \mathcal{D}^{1,p}_{0,\gamma}(\Omega) \text{ for a.e. } t \in (0,T),\ \|u(\cdot,t)\|_{\mathcal{D}^{1,p}_{0,\gamma}(\Omega)} \in L^p(0,T)\},$$

endowed with the norm

$$\|u\|_{L^p(0,T;\mathcal{D}^{1,p}_{0,\gamma}(\Omega))} = \left(\int_0^T \|u(\cdot,t)\|^p_{\mathcal{D}^{1,p}_{0,\gamma}(\Omega)} dt\right)^{1/p} = \left(\iint_{Q_T} \frac{|\nabla u|^p}{|x|^{p\gamma}}\, dx\right)^{1/p}.$$

The dual space of $L^p(0,T;\mathcal{D}^{1,p}_{0,\gamma}(\Omega))$ is $L^{p'}(0,T;\mathcal{D}^{-1,p'}_{-\gamma}(\Omega))$. Let us point out that

$$\mathcal{D}^{1,p}_{0,\gamma}(\Omega) \subset L^q_\delta(\Omega) \quad \text{compactly}$$

for every p, q, γ, δ satisfying $\frac{1}{q} - \frac{\delta}{N} > \frac{1}{p} - \frac{\gamma+1}{N}$ with $\gamma \le \delta \le \gamma+1$ and $\delta q < N$, $\gamma p < N$.

Indeed, a sequence $\{u_n\}$ which is bounded in $\mathcal{D}^{1,p}_{0,\gamma}(\Omega)$ has a subsequence, again denoted by $\{u_n\}$, which converges almost everywhere in Ω to a function $u \in L^q_\delta(\Omega)$. Moreover, by Hölder's inequality and (1.7), for every measurable subset $E \subset \Omega$,

$$\int_E \frac{|u_n-u|^q}{|x|^{\delta q}}\, dx \le \left(\int_\Omega \frac{|u_n-u|^{p^*}}{|x|^{\gamma p^*}}\, dx\right)^{q/p^*} \left(\int_E \frac{1}{|x|^{(\delta-\gamma)\frac{qp^*}{p^*-q}}}\, dx\right)^{(p^*-q)/p^*}$$
$$\le c \left(\int_E \frac{1}{|x|^{(\delta-\gamma)\frac{qp^*}{p^*-q}}}\, dx\right)^{(p^*-q)/p^*}.$$

Since the function in the last integral is an L^1 function, we get the compactness result by Vitali's theorem.

It is easy to see that the operator defined by

$$-\Delta_{p,\gamma}u = -\mathrm{div}\left(\frac{|\nabla u|^{p-2}\nabla u}{|x|^{p\gamma}}\right)$$

maps $\mathcal{D}^{1,p}_{0,\gamma}(\Omega)$ into its dual $\mathcal{D}^{-1,p'}_{-\gamma}(\Omega)$ and is hemicontinuous, coercive, and monotone. (See [21].)

In what follows, we will often use the following result, which is an easy application of Theorem 1.2 of [21] and the reference [24] for the continuity with respect to the time of the L^2-norm.

PROPOSITION 2.1. *If $f \in L^{p'}(0,T;\mathcal{D}^{-1,p'}_{-\gamma}(\Omega))$, $\psi \in L^2(\Omega)$, then there exists a unique solution in the distribution sense, $u \in L^p(0,T;\mathcal{D}^{1,p}_{0,\gamma}(\Omega)) \cap \mathcal{C}^0(0,T;L^2(\Omega))$, of the following problem:*

$$\begin{cases} u_t - \Delta_{p,\gamma}u = f & \text{in } \Omega\times(0,T)\,, \\ u(x,t) = 0 & \text{in } \partial\Omega\times(0,T)\,, \\ u(x,0) = \psi(x) & \text{in } \Omega. \end{cases}$$

We have the following result about the boundedness of the solutions.

LEMMA 2.2. *Let $u \in L^p(0,T;\mathcal{D}^{1,p}_{0,\gamma}(\Omega)) \cap \mathcal{C}^0(0,T;L^2(\Omega))$ be a distributional solution of* (F) *(see section 2), with $\psi \in L^\infty(\Omega)$, and assume that there exist two constants q and β_0 such that*

$$q > \frac{N}{p}, \qquad \beta_0 < p\gamma, \qquad \operatorname*{ess\,sup}_t \int_\Omega |f(x,t)|^q |x|^{\beta_0 q}\,dx < +\infty. \tag{2.4}$$

Then $u \in L^\infty(Q_T)$.

The proof is a slight modification of the classical arguments and is omitted.

3. Existence results. We start with the simpler case $\lambda < \lambda_{N,p,\gamma}$, where $\lambda_{N,p,\gamma}$ is defined by (1.8).

3.1. The case $\boldsymbol{\lambda < \lambda_{N,p,\gamma}}$: Global existence. As usual we denote by $T_n(s)$ the truncation function, i.e., $T_n(s) = s$ if $|s| < n$, $T_n(s) = n\,\mathrm{sign}\,s$ if $|s| > n$. Let us observe that in this range for λ the operator $-\Delta_{p,\gamma} - \lambda\frac{|u|^{p-2}u}{|x|^{p(\gamma+1)}}$ is coercive in the space $\mathcal{D}^{1,p}_{0,\gamma}(\Omega)$. This essentially justifies the following.

THEOREM 3.1. *If $1 < p < N$, $\gamma < \frac{N-p}{p}$, $\lambda < \lambda_{N,p,\gamma}$, $\psi(x) \in L^2(\Omega)$, there exists one distributional solution u for problem* (P). *Moreover, $u \in L^p(0,T;\mathcal{D}^{1,p}_{0,\gamma}(\Omega)) \cap \mathcal{C}^0(0,T;L^2(\Omega))$.*

Proof. Define

$$w_n(x) = \begin{cases} |x|^{-p\gamma} & \text{if } \gamma \geq 0, \\ |x|^{-p\gamma} + \dfrac{1}{n} & \text{if } \gamma < 0, \end{cases}$$

$$f_n(x,u) = \begin{cases} \dfrac{T_n(|u|^{p-2}u)}{|x|^{p(\gamma+1)} + \frac{1}{n}} & \text{if } \gamma \geq 0, \\ \dfrac{T_n(|u|^{p-2}u)}{|x|^{p\gamma}(|x|^p + \frac{1}{n})} & \text{if } \gamma < 0. \end{cases}$$

Let us first consider the following approximate problems:

$$(\mathrm{P}_n)\quad \begin{cases} (u_n)_t - \operatorname{div}\left(w_n(x)|\nabla u_n|^{p-2}\nabla u_n\right) = \lambda f_n(x,u_n), & (x,t)\in\Omega\times(0,T),\\ u_n(x,t)=0, & (x,t)\in\partial\Omega\times(0,T),\\ u_n(x,0)=T_n(\psi(x)), & x\in\Omega. \end{cases}$$

By Proposition 2.1 of section 2 and Schauder's fixed point theorem, it is quite easy to get existence of a solution $u_n \in W_0^{1,p}(\Omega)\cap L^\infty(Q_T)$. Let us multiply (P_n) by $u_n(x,t)$. Using inequality (1.4), one obtains

$$\begin{aligned}\iint_{Q_T}\frac{\partial u_n}{\partial t}u_n + \iint_{Q_T} w_n(x)|\nabla u_n|^p &\le \lambda\iint_{Q_T} f_n(x,u_n)u_n\\ &\le \lambda\iint_{Q_T}\frac{|u_n|^p}{|x|^{p(\gamma+1)}} \le \frac{\lambda}{\lambda_{N,p,\gamma}}\iint_{Q_T}\frac{|\nabla u_n|^p}{|x|^{p\gamma}},\end{aligned}$$

where the first integral is understood as a duality product. Since $\lambda<\lambda_{N,p,\gamma}$, we get the estimates

$$\|u_n\|_{L^\infty(0,T;L^2(\Omega))}\le c_1, \tag{3.1}$$

$$\iint_{Q_T}\frac{|\nabla u_n|^p}{|x|^{p\gamma}}\,dx\,dt\le c_2, \tag{3.2}$$

that is,

$$\|u_n\|_{L^p(0,T;\mathcal{D}^{1,p}_{0,\gamma}(\Omega))}\le c_3. \tag{3.3}$$

Therefore, there exist a function $u\in L^p(0,T;\mathcal{D}^{1,p}_{0,\gamma}(\Omega))\cap L^\infty(0,T;L^2(\Omega))$ and a subsequence (still denoted by u_n) such that $u_n \rightharpoonup u$ weakly in $L^p(0,T;\mathcal{D}^{1,p}_{0,\gamma}(\Omega))$ and $*$-weakly in $L^\infty(0,T;L^2(\Omega))$.

Moreover, if B_ε is the sphere centered in the origin with radius ε, we also have

$$\|u_n\|_{L^p(0,T;W^{1,p}(\Omega\setminus B_\varepsilon))}\le c_4(\varepsilon) \tag{3.4}$$

for every $\varepsilon>0$. By (P_n) we also deduce

$$\left\|\frac{\partial u_n}{\partial t}\right\|_{L^{p'}(0,T;W^{-1,p'}(\Omega\setminus B_\varepsilon))}\le c_5(\varepsilon). \tag{3.5}$$

Using a compactness Aubin-type result (see, for instance, [24]), by (3.4) and (3.5) we can assume that $u_n\to u$ strongly in $L^p((\Omega_\varepsilon)\times(0,T))$ for every $\varepsilon>0$, and therefore, up to a subsequence,

$$u_n\to u \quad \text{a.e. and in measure in } Q_T. \tag{3.6}$$

Let us now prove that, for every $\varepsilon>0$, if we define

$$Q_T^{(\varepsilon)} = (\Omega\setminus B_\varepsilon)\times(0,T),$$

then

$$\nabla u_n\to\nabla u \quad \text{in measure on } Q_T^{(\varepsilon)}. \tag{3.7}$$

To do this, we follow a technique similar to the one introduced by Boccardo and Murat in [10]. Let us define, for $h > 0$, the set

$$H_h = H_{h,m,n} = \{(x,t) \in Q_T^{(\varepsilon)} : |\nabla u_n - \nabla u_m| > h\}.$$

We are going to prove that, for every $\delta > 0$, one has $\operatorname{meas} H_h < \delta$ for m and n large enough. Then, if we set, for positive A, k,

$$\begin{aligned}
\Gamma(n,A) &= \{(x,t) \in Q_T^{(\varepsilon)} : |\nabla u_n| > A\},\\
\Lambda(k) &= \{(x,t) \in Q_T^{(\varepsilon)} : |u_n - u_m| > k\},\\
D(A,k,h) &= \{(x,t) \in Q_T^{(\varepsilon)} : |\nabla u_n - \nabla u_m| > h,\\
&\qquad |\nabla u_n| \le A,\ |\nabla u_m| \le A,\ |u_n - u_m| \le k\},
\end{aligned}$$

then

$$H_h \subset \Gamma(n,A) \cup \Gamma(m,A) \cup \Lambda(k) \cup D(A,k,h).$$

For every $n \in \mathbb{N}$, $\operatorname{meas}\Gamma(n,A)$ is small for A large enough, uniformly in n, since $|\nabla u_n|^q$ is bounded in $L^1(Q_T)$ for every $q < Np/(N-\gamma p)$. Indeed

$$\iint_{Q_T} |\nabla u_n|^q = \iint_{Q_T} \frac{|\nabla u_n|^q}{|x|^{\gamma q}} |x|^{\gamma q} \le \left(\iint_{Q_T} \frac{|\nabla u_n|^p}{|x|^{\gamma p}} |x|^{\gamma q} \right)^{\frac{q}{p}} \left(\iint_{Q_T} |x|^{\frac{\gamma p q}{p-q}} \right)^{\frac{p-q}{p}}, \tag{3.8}$$

and the last integral is finite. Moreover, by (3.6), for every fixed k, $\operatorname{meas}\Lambda(k)$ is small if n, m are large enough. We now consider the set $D(A,k,h)$. By multiplying by $\varphi(x) T_k(u_n - u_m)$ the equations satisfied by u_n and u_m, respectively, where $\varphi(x) \in C_0^\infty(\Omega)$, $\varphi(x) \equiv 0$ for $|x| \le \varepsilon/2$, and $\varphi(x) \equiv 1$ for $|x| \ge \varepsilon$, one obtains, since the integral involving the time-derivative is positive,

$$\begin{aligned}
&\iint_{Q_T^{(\varepsilon/2)}} \frac{|\nabla u_n|^{p-2}\nabla u_n - |\nabla u_m|^{p-2}\nabla u_m}{|x|^{p\gamma}} \nabla T_k(u_n - u_m)\varphi(x)\\
&\qquad \le \lambda k \iint_{Q_T^{(\varepsilon/2)}} \frac{|u_n|^{p-1} + |u_m|^{p-1}}{|x|^{p(\gamma+1)}} + k \iint_{Q_T^{(\varepsilon/2)}} \frac{|\nabla u_n|^{p-1} + |\nabla u_m|^{p-1}}{|x|^{p\gamma}} |\nabla \varphi|.
\end{aligned} \tag{3.9}$$

Using Hölder's inequality, (1.4), and (3.3), one checks that the right-hand side of (3.9) is bounded by $c_6 k$, where c_6 is a constant which only depends on λ, ε, p, N. Since the left-hand side is greater than

$$\varepsilon^{-p\gamma} \iint_{Q_T^{(\varepsilon)} \cap \{|u_n - u_m| \le k\}} \left(|\nabla u_n|^{p-2}\nabla u_n - |\nabla u_m|^{p-2}\nabla u_m\right) \cdot \nabla(u_n - u_m),$$

we have proved that this last integral is small (uniformly in n and m) if k is sufficiently small. Observe now that by the monotonicity and continuity of $|\xi|^{p-2}\xi$, for every $h > 0$, there exists $\mu > 0$ such that

$$\begin{aligned}
D(A,k,h) \subset G(A,k,\mu) = \{(x,t) \in Q_T^{(\varepsilon)} &: |\nabla u_n| \le A,\ |\nabla u_m| \le A,\ |u_n - u_m| \le k,\\
&(|\nabla u_n|^{p-2}\nabla u_n - |\nabla u_m|^{p-2}\nabla u_m) \cdot \nabla(u_n - u_m) > \mu\}.
\end{aligned}$$

It follows that

$$\text{meas}\, D(A,k,h) \le \frac{1}{\mu} \iint_{Q_T^{(\varepsilon)} \cap \{|u_n - u_m| \le k\}} \left(|\nabla u_n|^{p-2}\nabla u_n - |\nabla u_m|^{p-2}\nabla u_m\right) \cdot \nabla(u_n - u_m),$$

so that meas $D(A,k,h)$ is small (uniformly in n and m) if k is sufficiently small. This proves (3.7). We can now pass to the limit in (P_n) in the sense of distributions. Indeed, if we multiply (P_n) by $\varphi(x,t) \in C_0^\infty(Q_T)$, we obtain

$$-\iint_{Q_T} u_n \frac{\partial \varphi}{\partial t} + \iint_{Q_T} \frac{|\nabla u_n|^{p-2}\nabla u_n}{|x|^{p\gamma}} \nabla \varphi = \lambda \iint_{Q_T} T_n\left(\frac{|u_n|^{p-2}u_n}{|x|^{p(\gamma+1)}}\right)\varphi. \tag{3.10}$$

One can easily pass to the limit in each term using the convergences (3.6) and (3.7), the estimates (3.1) and (3.3), the inequality (1.4), and Vitali's theorem. ∎

3.2. The case $\lambda > \lambda_N$, , $p \le 2$: Global existence. In this section we will suppose $\lambda > \lambda_{N,p,\gamma}$ and $p \le 2$. We will show the existence of solutions with different behaviors (see Theorems 3.3, 3.6, and 3.8 in subsections 3.2.1, 3.2.2, and 3.2.3 below), depending on the range for the parameters γ and p.

More precisely, we will find solutions which become weaker and weaker (from the point of view of regularity) as γ and p increase (see Figure 1.1).

First, let us prove the following lemma which will be useful in what follows. It gives the existence of self-similar solutions $S(x,t)$ of the equation in problem (P) for this range of the parameters.

LEMMA 3.2. *If $\lambda > \lambda_{N,p,\gamma}$ and $p < 2$, the function*

$$S(x,t) = A \cdot \left(\frac{t}{|x|^{p(\gamma+1)}}\right)^{\frac{1}{2-p}}, \tag{3.11}$$

where $A = A(\lambda,\gamma) > 0$, is such that

$$A^{p-2} = \frac{1}{(2-p)[(p-1)\delta^p - (N - p(\gamma+1))\delta^{p-1} + \lambda]} \quad \text{and} \quad \delta = \frac{p(\gamma+1)}{2-p} \tag{3.12}$$

satisfy the following:

1. *If $\gamma + 1 < \frac{N(2-p)}{2p}$, then $S(\cdot,t) \in \mathcal{D}^{1,p}_\gamma(\Omega)$ and verifies* (P) *in the sense of distributions.*
2. *If $\frac{N(2-p)}{2p} \le \gamma + 1 < \frac{N(2-p)}{p}$, then*
   - (i) *$S(\cdot,t) \in L^q(\Omega)$ for every q such that $1 < q < \frac{N(2-p)}{p(\gamma+1)}$;*
   - (ii) *$\nabla S(\cdot,t) \in L^{q_1}(\Omega)$ for every q such that $0 < q_1 < \frac{N(2-p)}{2+p\gamma}$;*
   - (iii) *$\nabla S(\cdot,t) \in L^q_\gamma(\Omega)$ for every q such that $0 < q < \frac{N(2-p)}{2(\gamma+1)}$;*
   - (iv) *$\frac{|\nabla S(\cdot,t)|^{p-1}}{|x|^{p\gamma}}$, $\frac{S(\cdot,t)^{p-1}}{|x|^{p(\gamma+1)}} \in L^1(\Omega)$;*
   - (v) *S solves* (P) *in the sense of distributions.*
3. *If $N\frac{(2-p)}{p} \le (\gamma+1) < \frac{N}{p}$, then S solves* (P) *in $\mathcal{D}'(\mathbb{R}^N \setminus \{0\} \times (0,\infty))$ (and in some weighted Sobolev spaces that will be made precise later).*

Proof. We start by looking for solutions of (P) of the form

$$S(x,t) = t^\alpha f(r), \quad \text{with } r = |x|.$$

Choosing the exponent $\alpha = 1/(2-p)$, one can cancel the variable t from the equation, getting the following ordinary differential equation for $f(r)$:

$$\alpha f = (p-1)r^{-p\gamma}|f'|^{p-2}f'' + r^{-(p\gamma+1)}(N - (p\gamma+1))|f'|^{p-2}f' + \lambda r^{-p(\gamma+1)}|f|^{p-2}f. \tag{3.13}$$

Next we look for solutions $f(r)$ of the form

$$f(r) = Ar^{-\delta}, \quad A > 0.$$

It is easy to check that if we choose δ as in (3.12), we can cancel the terms involving powers of r in (3.13), getting solutions of the form (3.11), provided the constant A is defined as in (3.12) and is positive. This last assertion is true if

$$\lambda > \left(\frac{p(\gamma+1)}{2-p}\right)^p (s-1) = \mu_{p,\gamma},$$

where

$$s = \frac{N(2-p)}{p(\gamma+1)}.$$

Let us observe that the critical value $\lambda_{N,p,\gamma}$ can be rewritten as

$$\lambda_{N,p,\gamma} = \left(\frac{p-2+s}{2-p}(\gamma+1)\right)^p.$$

Moreover, if we regard the constants $\lambda_{N,p,\gamma}$ and $\mu_{N,p,\gamma}$ as functions of the variable s,

$$\lambda_{N,p,\gamma}(2) = \mu_{N,p,\gamma}(2), \qquad \lambda'_{N,p,\gamma}(2) = \mu'_{N,p,\gamma}(2), \qquad \lambda''_{N,p,\gamma}(s) > 0 \quad \text{for } s \geq 2-p,$$

which implies $\lambda_{N,p,\gamma} \geq \mu_{N,p,\gamma}$, since $s > 2-p$. Therefore, for $\lambda \geq \lambda_{N,p,\gamma}$ we have $A > 0$, and we obtain the existence of a positive solution $S(x,t)$. The regularity of S stated in the lemma is an easy calculation from the explicit expression of S. It is also easy to see that, if $\gamma + 1 < N(2-p)/p$, then $S(x,t)$ is a solution of (P) in the sense of distributions. □

We can summarize the results about S for $1 < p < 2$ as follows.

(a) If $\gamma+1 < \frac{N(2-p)}{2p}$, $S(x,t)$ is an energy solution; i.e., $S(x,t) \in L^p(0,T;\mathcal{D}^{1,p}_{0,\gamma}(\Omega)) \cap \mathcal{C}^0(0,T;L^2(\Omega))$.

(b) If $\frac{N(2-p)}{2p} \leq \gamma + 1 < \frac{N(2-p)}{p}$, $S(x,t)$ is an *entropy solution* (see Definition 3.5 in subsection 3.2.2).

(c) If $\frac{N(2-p)}{p} \leq \gamma + 1 < \frac{N}{p}$, $S(x,t)$ is a *very weak solution* (see Theorem 3.8, below).

We will prove that the regularity of the self-similar solution gives the behavior of the solutions for the initial value problem in each interval of the parameters. Notice that behavior means that, if $1 < p < 2$, then, for all $\gamma \in (-\infty, \frac{N-p}{p})$, the *spectral instantaneous and complete blow-up* as in Baras–Goldstein does not occur. Namely, there exist solutions with different meanings for all λ.

Let us point out that, if $p = 2$, all the previous critical values collapse to $1+\gamma = 0$, and we will find that for $1 + \gamma \leq 0$ there exist solutions in the energy sense. Note that in this case, by linearity, we obtain *global solutions*. Hence, also in this case, the *spectral instantaneous and complete blow-up* does not occur.

Moreover, if $p > 2$ and $1+\gamma \leq 0$, an argument of comparison allows us to conclude that there exists at least a local (in time) solution.

The remaining question about the behavior in the case $p \geq 2$, $\frac{N}{p} > 1+\gamma > 0$ will be discussed in section 4.

3.2.1. The case $\lambda > \lambda_N$, , , $p \le 2$, $\gamma + 1 < N(2-p)/(2p)$: Global existence of solutions with finite energy.

THEOREM 3.3. *If $\lambda > \lambda_{N,p,\gamma}$, $1 < p \le 2$, $\gamma + 1 < \frac{N(2-p)}{2p}$, $\psi(x) \in L^2(\Omega)$, then there exists a distributional solution u of problem* (P) *such that*

$$u \in L^p(0,T;\mathcal{D}^{1,p}_{0,\gamma}(\Omega)) \cap L^\infty(0,T;L^2(\Omega)).$$

Proof. Let us consider the approximate problems (P_n) defined in the proof of Theorem 3.1. Using $u_n(x,t)$ as test function in (P_n), we get

$$\frac{1}{2}\int_\Omega u_n^2(x,\tau)\,dx + \iint_{Q_\tau} \frac{|\nabla u_n|^p}{|x|^{p\gamma}} \le \lambda \iint_{Q_\tau} \frac{|u_n|^p}{|x|^{p(\gamma+1)}} - \frac{1}{2}\int_\Omega \psi^2(x)\,dx.$$

If $p < 2$, one has

$$\iint_{Q_\tau} \frac{|u_n|^p}{|x|^{p(\gamma+1)}} \le \iint_{Q_\tau} u_n^2 + c_1 T \int_\Omega \frac{dx}{|x|^{2p(\gamma+1)/(2-p)}},$$

where $c_1 = c_1(p)$. The last integral is finite by the hypotheses on γ. If $p = 2$, then necessarily $\gamma + 1 < 0$, and therefore

$$\iint_{Q_\tau} \frac{|u_n|^p}{|x|^{p(\gamma+1)}} \le c_2 \iint_{Q_\tau} u_n^2,$$

with $c_2 = c_2(\Omega,\gamma)$. In both cases, by Gronwall's lemma, we obtain the estimates (3.1)–(3.3), and we can conclude the proof exactly as for Theorem 3.1. ∎

Remark 3.4. Note that actually, in the proof of this theorem, λ can be any real number, since the principal part of the operator is never used to obtain estimates.

3.2.2. The case $\lambda > \lambda_N$, , , $p \le 2$, $N(2-p)/(2p) < \gamma + 1 < N(2-p)/p$: Global existence of entropy solutions. We will specify the sense in which we consider solutions in this case.

DEFINITION 3.5. *Assume that $\psi \in L^1(\Omega)$. We say that $u \in C([0,T];L^1(\Omega))$ is an entropy solution to problem* (P) *if $\frac{|u|^{(p-1)}}{|x|^{p(\gamma+1)}} \in L^1(Q_T)$, $T_k(u) \in L^p(0,T;\mathcal{D}^{1,p}_{0,\gamma}(\Omega))$ for all $k > 0$, and*

$$\int_\Omega \Theta_k(u(T) - v(T))\,dx + \int_0^T \langle v_t, T_k(u-v)\rangle\,dt + \iint_{Q_T} \frac{|\nabla u|^{p-2}}{|x|^{p\gamma}} \nabla u \cdot \nabla(T_k(u-v))$$
$$\le \int_\Omega \Theta_k(\psi - v(0))\,dx + \lambda \iint_{Q_T} \frac{|u|^{p-2}u}{|x|^{p(\gamma+1)}} T_k(u-v) \tag{3.14}$$

for all $k > 0$ and $v \in L^p((0,T),\mathcal{D}^{1,p}_{0,\gamma}(\Omega)) \cap L^\infty(Q_T) \cap C([0,T];L^1(\Omega))$ such that $v_t \in L^{p'}((0,T);\mathcal{D}^{-1,p'}_{-\gamma}(\Omega))$, where Θ_k is given by

$$\Theta_k(s) = \int_0^s T_k(t)dt. \tag{3.15}$$

For a general definition and basic properties of entropy solutions, see, for instance, the references [9], [23], and [22].

THEOREM 3.6. *If $\lambda \geq \lambda_{N,p,\gamma}$, $1 < p < 2$, $\frac{N(2-p)}{2p} \leq \gamma + 1 < \frac{N(2-p)}{p}$, while the initial datum $\psi(x)$ satisfies*

$$\psi \in L^q(\Omega) \quad \text{for every } q \text{ such that } 1 < q < \frac{N(2-p)}{p(\gamma+1)},$$

then there exists a distributional solution u of problem (P) *such that*

$$u \in L^\infty(0,T;L^q(\Omega)) \quad \text{for every } q \text{ such that } 1 < q < \frac{N(2-p)}{p(\gamma+1)}, \tag{3.16}$$

$$\frac{|\nabla u|^{q_1}}{|x|^{\gamma q_1}} \in L^1(Q_T) \quad \text{for every } q_1 \text{ such that } 0 < q_1 < \frac{N(2-p)}{2(\gamma+1)}, \tag{3.17}$$

$$\frac{|\nabla u|^{p-1}}{|x|^{p\gamma}},\ \frac{u^{p-1}}{|x|^{p(\gamma+1)}} \in L^1(Q_T). \tag{3.18}$$

Moreover, u is an entropy solution to problem (P).

Proof. Once again, we consider the approximate problems (P_n), and we multiply them by the test function $\Phi(u_n) = [(1+|u_n|)^{1-\mu} - 1]\operatorname{sign} u_n$, with $\mu \in (0,1)$ to be chosen hereafter. If we define

$$\Psi(s) = \int_0^s \Phi(\sigma)\,d\sigma = \frac{(1+|s|)^{2-\mu}-1}{2-\mu} - |s|,$$

we have

$$\Psi(s) \geq c_1(\mu)|s|^{2-\mu} - c_2(\mu). \tag{3.19}$$

Therefore,

$$\begin{aligned}
&\int_\Omega \Psi(u(x,\tau))\,dx + (1-\mu)\iint_{Q_\tau} \frac{|\nabla u_n|^p}{|x|^{\gamma p}} \frac{1}{(1+|u_n|)^\mu} \\
&\qquad \leq \int_\Omega \Psi(\psi(x))\,dx + \lambda \iint_{Q_\tau} \frac{|u_n|^{p-1}}{|x|^{p(\gamma+1)}} (1+|u_n|)^{1-\mu} \\
&\qquad \leq \int_\Omega \Psi(\psi(x))\,dx + c_3 \iint_{Q_\tau} \frac{|u_n|^{p-\mu}+1}{|x|^{p(\gamma+1)}},
\end{aligned} \tag{3.20}$$

where c_3 depends on λ, μ, p. Note that $\Psi(\psi)$ is integrable by the hypothesis on the initial datum. Since $p < 2$, we can estimate the last integral as

$$\iint_{Q_\tau} \frac{|u_n|^{p-\mu}+1}{|x|^{p(\gamma+1)}} \leq c_4 \iint_{Q_\tau} |u_n|^{2-\mu} + c_5 \iint_{Q_\tau} \frac{1}{|x|^{p(\gamma+1)(2-\mu)/(2-p)}}, \tag{3.21}$$

where c_4 and c_5 depend on μ and p. Now we choose μ in such a way that

$$2 - \frac{(2-p)N}{p(\gamma+1)} < \mu < 1. \tag{3.22}$$

This implies that the last integral in (3.21) converges. Using (3.19)–(3.22) and Gronwall's lemma, we obtain the following estimates:

$$\|u_n\|_{L^\infty(0,T;L^q(\Omega))} \le c_6 \quad \text{for every } q \text{ such that } 1 < q < \frac{(2-p)N}{p(\gamma+1)}, \tag{3.23}$$

$$\iint_{Q_T} \frac{|\nabla u_n|^p}{|x|^{\gamma p}} \frac{1}{(1+|u_n|)^\mu} \le c_7 \quad \text{for every } \mu \text{ such that (3.22) holds}, \tag{3.24}$$

$$\iint_{Q_T} \frac{|\nabla u_n|^{q_1}}{|x|^{\gamma q_1}} \le c_8 \quad \text{for every } q_1 \text{ such that } 0 < q_1 < \frac{(2-p)N}{2(\gamma+1)}, \tag{3.25}$$

$$\iint_{Q_T} \frac{|u_n|^{p-\mu}}{|x|^{p(\gamma+1)}} \le c_9 \quad \text{for every } \mu \text{ such that (3.22) holds}. \tag{3.26}$$

Indeed,

$$\iint_{Q_T} \frac{|\nabla u_n|^{q_1}}{|x|^{\gamma q_1}} \le \left(\iint_{Q_T} \frac{|\nabla u_n|^p}{|x|^{\gamma p}} \frac{1}{(1+|u_n|)^\mu} \right)^{q_1/p} \left(\iint_{Q_T} (1+|u_n|)^{\mu q_1/(p-q_1)} \right)^{(p-q_1)/p}.$$

The estimate (3.25) follows from (3.24) and (3.22).

We now show that the sequence $\{u_n\}$ satisfies

$$\iint_{Q_T} \frac{|u_n|^{(p-1)r}}{|x|^{p(\gamma+1)}} \le c_{10} \quad \text{for all } r \text{ such that } 1 \le r < \frac{2-p}{p-1}\left[\frac{N}{p(\gamma+1)} - 1\right], \tag{3.27}$$

$$\iint_{Q_T} \frac{|\nabla u_n|^{(p-1)s}}{|x|^{p\gamma}} \le c_{11} \quad \text{for all } s \text{ such that } 1 \le s < \frac{(N-p\gamma)(2-p)}{(p-1)(2+p\gamma)}. \tag{3.28}$$

Inequality (3.27) follows from (3.26) and (1.4), while (3.28) follows easily from (3.25). We can now pass to the limit in the distributional formulation, as we have done in the proof of Theorem 3.1, using the estimate in $L^{q_1}(0,T;W^{1,q_1}(\Omega \setminus B_\varepsilon))$, which follows from (3.17), for every $\varepsilon > 0$.

The function u is an entropy solution. Indeed, it is easy to prove (taking $T_k(u_n)$ as test function in (P_n)) that $T_k(u_n)$ is bounded in $L^p(0,T;\mathcal{D}^{1,p}_{0,\gamma}(\Omega))$ and (using Vitali's theorem and (3.28)) that $f_n(x,u_n)$ converges to $\frac{u^{p-1}}{|x|^{p(\gamma+1)}}$ strongly in $L^1(Q_T)$.

Then, if we take $T_k(u_n - v)$ as test function in (P_n), with v as in Definition 3.5, we can easily pass to the limit and get the result with the same techniques as in [22]. □

Remark 3.7. As far as the sharpness of the regularity of the solutions found in Theorem 3.6, let us observe that any function of the form $S_{t_0}(x,t) = S(x,t+t_0)$, where S is defined by (3.11), is a solution in the distribution sense of problem (P), with initial data $\psi(x) = S(x,t_0)$, and its regularity is exactly the one we quoted in Theorem 3.6.

3.2.3. The case $\lambda > \lambda_N$, , $p \le 2$, $N(2-p)/(p) < \gamma+1 < N/p$: Global existence of very weak solutions. We point out that for every $t > 0$ the singular solution $S(x,t)$ is continuous with respect to t with values in $L^2_{-\alpha p/2}(\Omega)$ for every α such that

$$\alpha > \frac{2(\gamma+1)}{2-p} - \frac{N}{p}. \tag{3.29}$$

This, together with the previous estimates on S, suggests the definition of the following space:

(3.30)
$$\mathcal{Y}_\alpha = \{u \in L^p(0,T;\mathcal{D}^{1,p}_{0,\gamma-\alpha}(\Omega)) \cap C^0([0,T];L^2_{-\frac{\alpha p}{2}}(\Omega)) : u' \in L^{p'}(0,T;\mathcal{D}^{-1,p'}_{-\beta}(\Omega))\},$$

where

$$\beta = \gamma + \alpha(p-1). \tag{3.31}$$

The following theorem specifies the meaning of a very weak solution.

THEOREM 3.8. *Assume that $\lambda > \lambda_{N,p,\gamma}$, $1 < p < 2$, $\frac{N(2-p)}{p} \le \gamma + 1 < \frac{N}{p}$, and that the initial data $\psi(x)$ belongs to $L^2_{-\frac{\alpha p}{2}}(\Omega)$ for some α satisfying* (3.29). *Then there exists a function $u \in \mathcal{Y}_\alpha$ which is a distributional solution of* (P) *away from the origin (that is, in $\mathcal{D}'((\Omega \setminus \{0\}) \times (0,T))$). Moreover, u is a solution of* (P) *in the following sense:*

$$\begin{aligned} &-\int_0^\tau \langle v', |x|^{\alpha p}u\rangle\, dt + \int_\Omega u(\tau)v(\tau)|x|^{\alpha p}\,dx - \int_\Omega \psi v(0)|x|^{\alpha p}\,dx \\ &+ \iint_{Q_\tau} \frac{|\nabla u|^{p-2}\nabla u\cdot\nabla(v|x|^{\alpha p})}{|x|^{\gamma p}}\,dx\,dt = \iint_{Q_\tau} \frac{|u|^{p-2}uv|x|^{\alpha p}}{|x|^{(\gamma+1)p}}\,dx\,dt \end{aligned} \tag{3.32}$$

for every $\tau \in [0,T]$ and for every $v \in \mathcal{Y}_\alpha$.

Proof. Step 1: *A priori estimate.* Let u_n be a solution of problem (P_n). We use $|x|^{\alpha p}u_n(x,t)$ as test function in (P_n). Then, by Young's inequality,

$$\begin{aligned} &\int_\Omega u_n^2(x,T)|x|^{\alpha p}\,dx + \iint_{Q_T} |\nabla u_n|^p |x|^{(\alpha-\gamma)p} \\ &\quad\le c_1 \iint_{Q_T} |\nabla u_n|^{p-1}|x|^{(\alpha-\gamma)p-1} + \lambda \iint_{Q_T} \frac{|u_n|^p}{|x|^{p(\gamma+1-\alpha)}} + \frac{1}{2}\int_\Omega \psi^2(x)|x|^{\alpha p}\,dx \\ &\quad\le \frac{1}{2}\iint_{Q_T} |\nabla u_n|^p|x|^{(\alpha-\gamma)p} + c_3 \iint_{Q_T} |u_n|^2|x|^{\alpha p} + c_3\int_\Omega |x|^{p\left(\alpha-\frac{2(\gamma+1)}{2-p}\right)} \\ &\qquad+ \frac{1}{2}\int_\Omega \psi^2(x)|x|^{\alpha p}\,dx. \end{aligned}$$

Under the hypotheses on α and on the initial datum, the last two integrals are finite. Therefore, we can use Gronwall's lemma to conclude that

$$u_n \text{ is bounded in } L^p(0,T;\mathcal{D}^{1,p}_{0,\gamma-\alpha}(\Omega)) \cap C^0([0,T];L^2_{-\frac{\alpha p}{2}}(\Omega)).$$

By (P_n), one can easily check that

$$u_n' \text{ is bounded in } L^{p'}(0,T;\mathcal{D}^{-1,p'}_{-\beta}(\Omega)).$$

Step 2: *Passage to the limit.* By weak convergence, and following the same argument as in the proof of Theorem 3.1 for the pointwise convergence of the gradients, we obtain a function $u \in L^p(0,T;\mathcal{D}^{1,p}_{0,\gamma-\alpha}(\Omega)) \cap L^\infty(0,T;L^2_{-\frac{\alpha p}{2}}(\Omega))$, with

$u' \in L^{p'}(0,T;\mathcal{D}^{-1,p'}_{-\beta}(\Omega))$, such that

$$u_n \rightharpoonup u \quad \text{weakly in } L^p(0,T;\mathcal{D}^{1,p}_{0,\gamma-\alpha}(\Omega)),$$
$$u_n \rightharpoonup u \quad *\text{-weakly in } L^\infty(0,T;L^2_{-\frac{\alpha p}{2}}(\Omega)),$$
$$\nabla u_n \to \nabla u \quad \text{almost everywhere in } Q_T,$$
$$u_n(\cdot,\tau) \to u(\cdot,\tau) \quad \text{a.e. in } \Omega \text{ and weakly in } L^2_{-\frac{\alpha p}{2}}(\Omega) \text{ for every } \tau \in [0,T].$$

Using these convergences, one can take $|x|^{\alpha p}v$ as test function in (P_n) and pass to the limit as $n \to \infty$, obtaining the weak formulation (3.32). Since the functions of the form $|x|^{\alpha p}v$ include smooth test functions in $\mathcal{D}(Q_T)$ which are zero in a neighborhood of the origin, we have also proved that u is a solution in the distributional sense far from the origin.

We now prove that $u \in C^0([0,T];L^2_{-\frac{\alpha p}{2}}(\Omega))$. According to the uniform estimates for the approximate solutions, we find that $u_n(\cdot,t)$ is an equicontinuous sequence in $L^2_{-\frac{\alpha p}{2}}(\Omega))$. By the Ascoli–Arzelà lemma, we conclude. □

Remark 3.9.

(i) The previous result, in the case where $\gamma = 0$, improves the result contained in [19] and specifies the meaning of the solution given in that paper; more precisely, it gives us that the solution is in $L^p(0,T;\mathcal{D}^{1,p}_{-\alpha}(\Omega))$ for some $\alpha > 2/(2-p) - N/p$.

(ii) If we define the operator $\Gamma v = |x|^{\alpha p}v$, then Γ is an isomorphism from $\mathcal{D}^{1,p}_{0,\gamma-\alpha}(\Omega)$ to $\mathcal{D}^{1,p}_{0,\beta}(\Omega)$, where $\beta = (p-1)\alpha + \gamma$. Therefore, the weak formulation (3.32) could be rewritten as

$$-\int_0^\tau \langle w', u\rangle\, dt + \int_\Omega u(\tau)w(\tau)\, dx - \int_\Omega \psi w(0)\, dx + \iint_{Q_\tau} \frac{|\nabla u|^{p-2}\nabla u \cdot \nabla w}{|x|^{\gamma p}}\, dx\, dt = \iint_{Q_\tau} \frac{|u|^{p-2}uw}{|x|^{(\gamma+1)p}}\, dx\, dt$$

for every $\tau \in [0,T]$ and for every $w \in L^p(0,T;\mathcal{D}^{1,p}_{0,\beta}(\Omega)) \cap C^0([0,T];L^2_{\frac{\alpha p}{2}}(\Omega))$ such that $w' \in L^{p'}(0,T;\mathcal{D}^{-1,p'}_{\alpha-\gamma}(\Omega))$.

(iii) In the case where the initial data $\psi(x)$ is nonnegative and satisfies

$$\psi(x) \le S(x,t+t_0) \quad \text{for some positive } t_0,$$

it is possible to obtain an alternative (constructive) proof by a monotone iteration argument, using $S(x,t+t_0)$ as a supersolution and solving, by induction, the sequence of problems

$$(\tilde{\mathrm{P}}_n) \qquad \begin{cases} \dfrac{\partial u_n}{\partial t} - \Delta_{p,\gamma} u_n = \lambda T_n\left(\dfrac{1}{|x|^{p(\gamma+1)}}\right) u_{n-1}^{p-1}, & (x,t) \in \Omega \times (0,T), \\ u_n(x,t) = 0, & (x,t) \in \partial\Omega \times (0,T), \\ u_n(x,0) = \psi(x), & x \in \Omega, \end{cases}$$

with $u_0 \equiv 0$.

(iv) The solution found in Theorem 3.10 satisfies the equation in a very weak sense because the right-hand side of the equation does not even belong to L^1.

3.3. The case $\lambda > \lambda_N$, , , $p \geq 2$, $\gamma \leq -1$: Existence for small times. This subsection deals with existence for small values of t in the case $\lambda > \lambda_{N,p,\gamma}$, $p > 2$, $\gamma \leq -1$. The result of this subsection can be compared with the ones of section 4: an instantaneous blow up will occur for the solutions of the approximate problems for the same values of λ and p when $\gamma > -1$.

THEOREM 3.10. *If $\lambda > \lambda_{N,p,\gamma}$, $p \geq 2$, $\gamma \leq -1$, while the initial data $\psi(x)$ satisfies $\psi(x) \in L^\infty(Q_T)$ and $\psi(x) \geq 0$, then there exist $T^* = T^*(N, p, \gamma, \lambda, \|\psi\|_{L^\infty(\Omega)}) > 0$ and a distributional solution u in Q_{T^*} of our problem with $u \in L^p(0, T; \mathcal{D}^{1,p}_{0,\gamma}(\Omega)) \cap L^\infty(0, T; L^2(\Omega))$ for every $T < T^*$. Moreover, if $p = 2$, T^* is any positive value.*

Proof. Let us define the problems $(\tilde{\mathrm{P}}_n)$ as in the previous subsection and let $y(t)$ be the solution of the ordinary differential equation

$$\begin{cases} y'(t) = d\, y^{p-1}, \\ y(0) = \|\psi\|_{L^\infty(\Omega)}, \end{cases}$$

where

$$d \geq \lambda \sup_{x \in \Omega} |x|^{-p(\gamma+1)}. \tag{3.33}$$

An immediate calculation shows the following.

(α) If $p > 2$, the solution is

$$y(t) = \frac{\|\psi\|_{L^\infty(\Omega)}}{(1 - (p-2)d\|\psi\|^{p-2}_{L^\infty(\Omega)} t)^{1/(p-2)}},$$

which blows up in $t = T^* = \frac{1}{(p-2)d\|\psi\|^{p-2}_{L^\infty(\Omega)}}$.

(β) If $p = 2$, then the global solution is

$$y(t) = \|\psi\|_{L^\infty(\Omega)} e^{dt}.$$

Since $y(t)$ is a supersolution of (P), by the comparison principle we have

$$u_1 \leq u_2 \leq \cdots \leq u_n \leq \cdots \leq y.$$

If we multiply problem $(\tilde{\mathrm{P}}_n)$ by $u_n \chi_{(0,\tau)}$, we obtain

$$\frac{1}{2} \int_\Omega u_n^2(x, \tau)\, dx + \iint_{Q_T} \frac{|\nabla u|^p}{|x|^{p\gamma}} \leq \lambda \iint_{Q_T} |y|^{p-1} |x|^{-p(\gamma+1)} + \frac{1}{2} \int_\Omega \psi^2(x)\, dx.$$

By condition (3.33),

$$\lambda \iint_{Q_T} |y|^{p-1} |x|^{-p(\gamma+1)} \leq \operatorname{meas} \Omega (y(\tau) - \|\psi\|_{L^\infty(\Omega)}).$$

Therefore, we get the estimates

$$\|u_n\|_{L^\infty(0,\tau;L^2(\Omega))} \leq c_1, \quad \|u_n\|_{L^p(0,\tau;\mathcal{D}^{1,p}_{0,\gamma}(\Omega))} \leq c_2 \quad \text{for every } \tau < T^*.$$

In the case $p = 2$, we can fix any $T^* > 0$ to get the same estimates. Now the conclusion follows exactly as in the proof of Theorem 3.1. ∎

4. Blow-up: $p > 2$, $N/p > (1+\gamma) > 0$, and $\lambda > \lambda$, , . We consider in this section the *spectral, instantaneous, and complete blow-up* in the case $p > 2$ and $(1+\gamma) > 0$. The case $p = 2$ has been obtained in [3] and requires a different method. We would like to point out that in the case $p > 2$ a stronger result than in the linear case is obtained. This behavior is given because even the problem with the truncated potential blows up in finite time. We will assume that the initial data verifies that $\psi \in L^2(\Omega)$ and there exists $\delta > 0$ such that $\psi > 0$ in $B_\delta(0)$. Notice that for the equation

$$u_t - \Delta_{p,\gamma} u = 0 \tag{4.1}$$

and by direct calculations we can find Barenblatt-type solutions; precisely,

$$\mathcal{B}(x,t) = t^{-N\beta(N,p,\gamma)} \left[M - \frac{(p-2)\beta(N,p,\gamma)^{\frac{1}{p-1}}}{p(\gamma+1)} \xi^{\frac{p(\gamma+1)}{p-1}} \right]_+^{\frac{(p-2)}{(p-1)}}, \tag{4.2}$$

where M is a positive arbitrary constant,

$$\beta(N,p,\gamma) = \frac{1}{N(p-2)+p(\gamma+1)}, \quad \text{and} \quad \xi = \frac{|x|}{t^{\beta(N,p,\gamma)}}.$$

This property could be understood as some kind of *finite speed of propagation* for the equation with zero right-hand side. It is necessary to point out that if $\gamma \neq 0$, the equation is not invariant by translation, and then the corresponding translated Barenblatt functions are not solutions to the equation.

The lack of homogeneity in (4.1) provides the following weak Harnack inequality.

LEMMA 4.1. *Let u be a nonnegative weak solution to* (4.1)*, and assume that $u(x_0,t_0) > 0$ for some $(x_0,t_0) \in \Omega_T$; then there exists $B(N,p,\gamma) > 1$ such that, for all $\theta, \rho > 0$ satisfying $B_{4\rho}(x_0) \times (t_0 - 4\theta, t_0 + 4\theta) \subset \Omega_T$, we have*

$$\begin{aligned} &\frac{1}{|B_\rho(x_0)|} \int_{B_\rho(x_0)} u(x,t_0)\,dx \\ &\quad \le B \left[\left(\frac{\rho^{p(\gamma+1)}}{\theta} \right)^{\frac{1}{p-2}} + \left(\frac{\theta}{\rho^{p(\gamma+1)}} \right)^{\frac{N}{p(\gamma+1)}} \left(\inf_{B_\rho(x_0)} u(.,t_0+\theta) \right)^{\frac{\lambda_\gamma}{p(\gamma+1)}} \right], \end{aligned} \tag{4.3}$$

where $\lambda_\gamma = N(p-2) + p(\gamma+1) = \frac{1}{\beta(N,p,\gamma)}$.

The proof is similar to the one by DiBenedetto in [17] for the case $\gamma = 0$. The details can be found in [1] in the case $(1+\gamma) > 0$, where some counterexamples to the Harnack inequality if $(1+\gamma) \le 0$ are shown.

We consider problem (P), and we make the following assumptions:

(H1) $p > 2$, $0 < 1 + \gamma < N/p$, and $\lambda > \lambda_{n,p,\gamma}$.

(H2) $\psi \in L^\infty(\Omega)$, $\psi(x) \ge 0$, and moreover, there exists $\rho, \delta > 0$ such that $\psi(x) > \delta$ for every $x \in B_\rho(0)$.

We will prove that problem (P) has no solution. We start by studying, for $n \in \mathbb{N}$, the approximate problems

$$\begin{cases} (u_n)_t - \Delta_{p,\gamma} u_n = \lambda W_n(x) |u_n|^{p-2} u_n & \text{in } Q_T, \\ u(x,t) = 0 & \text{on } \partial\Omega \times (0,T), \\ u(x,0) = \psi(x) & \text{in } \Omega, \end{cases} \tag{4.4}$$

where $W_n(x) = T_n(\frac{1}{|x|^{p(\gamma+1)}})$. Note that for every fixed n, problem (4.4) has a solution at least for small times (depending on n and λ), as one can easily see using a convenient supersolution independent of x.

By separation of variables we look for solutions of (4.4) of the form $\Phi(x,t) = \Theta(t)X(x)$, to use as a subsolution. The equation becomes

$$\Theta' X - \Theta^{p-1}\Delta_{p,\gamma} X = \lambda W_n(x)\Theta^{p-1}X^{p-1}.$$

We take the $\Theta(t)$ solution of

$$\begin{cases} \Theta'(t) = \mu\Theta^{p-1}(t), \\ \Theta(0) = A, \end{cases} \tag{4.5}$$

that is,

$$\Theta(t) = \frac{A}{[1-(p-2)\mu A^{p-2}t]^{1/(p-2)}}$$

with $\mu, A > 0$ to be chosen. Note that $\lim_{t\to\tau}\Theta(t) = \infty$ for $\tau = \frac{1}{\mu(p-2)A^{p-2}}$.

On the other hand, $X(x)$ must solve the elliptic problem

$$\begin{cases} -\Delta_{p,\gamma} X = \lambda W_n(x)X^{p-1} - \mu X & \text{in } \Omega, \\ X(x) = 0 & \text{on } \partial\Omega. \end{cases} \tag{4.6}$$

Defining $\alpha X = Y$ with $\mu\alpha^{p-2} = \lambda$ the problem above becomes

$$\begin{cases} -\Delta_{p,\gamma} Y = \lambda(W_n(x)Y^{p-1} - Y) & \text{in } \Omega, \\ Y(x) = 0 & \text{in } \partial\Omega. \end{cases} \tag{4.7}$$

Problem (4.7) fails in the hypotheses for bifurcation from infinity as in [6]; see [16] for details.

Let $\lambda_1(n)$ be the first eigenvalue for the problem

$$\begin{cases} -\Delta_{p,\gamma}\varphi = \lambda W_n(x)|\varphi|^{p-2}\varphi & \text{in } \Omega, \\ \varphi(x) = 0 & \text{in } \partial\Omega. \end{cases}$$

Then (i) $\lambda_1(n) > 0$; (ii) $\lambda_1(n)$ is isolated and simple; (iii) the first eigenfunction does not change sign; (iv) $\lambda_1(n)$ is decreasing in n, and $\lambda_1(n) \searrow \lambda_{N,p,\gamma}$. The properties (i), (ii), and (iii) are similar to the p-*laplacian* case and are detailed in [16]; (iv) is easily checked following the proof for the p-laplacian in [19].

THEOREM 4.2. *If $\lambda > \lambda_{N,p,\gamma}$, then there exists n_0 such that, for every $n > n_0$, there exists a bounded positive solution $Y(x)$ to* (4.7).

Proof. As $\lambda > \lambda_{N,p,\gamma}$ there exists n_0 such that, for $n > n_0$, $\lambda > \lambda_1(n)$. Now $\lambda_1(n)$ is the unique bifurcation point of positive solutions from infinity for problem (4.7). Moreover, as $(1+\gamma) > 0$, the solutions in the branch are bounded; see [16] and [6]. Moreover, if $Y > 0$ is a solution to (4.7), then $\|Y\|_\infty \geq R_n > 0$ for some constant R_n, because if a positive solution Y is such that $\|Y\|_\infty < \varepsilon$, then we have $-\Delta_{p,\gamma} Y \leq \lambda Y(n\varepsilon^{p-2} - 1) < 0$, and for ε small we reach a contradiction with the maximum principle. □

As a consequence we can find a subsolution to problem (4.4) that shows the finite time blow-up. Precisely, we have the following result.

LEMMA 4.3. *Let u be a solution to problem* (4.4)*, where $\lambda > \lambda_1(n)$ and $\psi(x) > 0$ in every $x \in \Omega$. Then there exists $T > 0$ depending on the data and there exists a subsolution Φ such that $u(x,t) \geq \Phi(x,t)$ and $\lim_{t\to T} \Phi(x,t) = \infty$ for every $x \in \Omega$.*

Proof. The solution u is positive and, by regularity (see [1]), is bounded for small times. Therefore, we fix a small time $\tau > 0$, and we look for a subsolution of the form $\Phi(x,t) = X(x)\Theta(t)$, with $X(x)$ the solution of (4.6), and

$$\Theta(t) = \epsilon(1 - (p-2)\varepsilon^{p-2}(t-\tau))^{-1/(p-2)},$$

with $\varepsilon > 0$ such that $\varepsilon X(x) \leq u(x,\tau)$. By the weak comparison principle we conclude. □

In order to show the instantaneous complete blow-up, we need to rescale the problem, using the following property. Define

$$Z_n(x) = \left(\frac{n_0}{n}\right)^{\frac{1}{p-2}} X\left(\left(\frac{n}{n_0}\right)^{\frac{1}{p(\gamma+1)}} x\right). \tag{4.8}$$

Then Z_n solves

$$\begin{cases} -\Delta_{p,\gamma} Z_n = \lambda W_n(x) Z_n^{p-1} - \mu Z_n & \text{if } |x| < \left(\frac{n_0}{n}\right)^{\frac{1}{p(\gamma+1)}}, \\ Z_n(x) = 0 & \text{if } |x| = \left(\frac{n_0}{n}\right)^{\frac{1}{p(\gamma+1)}} \end{cases}$$

since $(\frac{n}{n_0}) W_{n_0}((\frac{n}{n_0})^{\frac{1}{p(\gamma+1)}} x) = W_n(x)$. Moreover, the radius of the ball goes to zero and $\|Z_n\|_\infty \to 0$ as $n \to \infty$. Therefore, for prescribed $R, \eta > 0$ we can choose n such that

$$\left(\frac{n_0}{n}\right)^{\frac{1}{p(\gamma+1)}} < R, \qquad Z_n(x) \leq \eta \quad \text{on } B_R. \tag{4.9}$$

THEOREM 4.4. *Assume that* (H1), (H2) *hold. Then for every $\varepsilon > 0$ there exist $r(\varepsilon) > 0$ and n_ε such that if u_n is the minimal solution to* (4.4) *$\forall n > n_\varepsilon$*

$$u_n(x,t) \equiv +\infty \quad \textit{for} \quad t > \varepsilon \textit{ and } |x| < r(\varepsilon).$$

Proof. Take n_0 such that $\lambda > \lambda_1(n_0)$. We prescribe the blow-up time $T = \varepsilon$ and choose $\mu = [(p-2)\varepsilon]^{-1}$. For such μ and $n > n_0$, the scaled solution (4.8) to (4.4), X_n, satisfies (4.9) with $R = \rho$ and $\eta = \delta$. Consider $\Theta(t)$ solution to (4.5) with μ as above and A = 1. Then $\phi_n(x,t) = \Theta(t) X_n(x)$ blows up in $T = \varepsilon$. By weak comparison in the ball $|x| < (\frac{n_0}{n})^{\frac{1}{p(\gamma+1)}}$, the minimal solution to (4.4) blows up in $T_0 < \varepsilon$. □

We point out that in order to obtain blow-up in a prescribed small time we have to take the index n large enough. We will use the concept of entropy solution introduced in Definition 3.5 and a straightforward modification of the comparison arguments for entropy solutions (see [23]).

THEOREM 4.5. *Assume that* (H1), (H2) *hold. Then problem* (P) *has no entropy solution, even for small times, and moreover, if $u_n(x,t)$ is the minimal solution to* (4.4)*, we have that $\lim_{n\to\infty} u_n(x,t) = +\infty$ for all $(x,t) \in \Omega \times (0,\infty)$.*

Proof. By contradiction, assume that there exists an entropy solution $u(x,t) > 0$ of problem (P). Then u is a supersolution to problem (4.4) for all n. As a consequence the minimal solution to (4.4) satisfies $u_n(x,t) \leq u(x,t)$; hence $u(x,t)$ blows up at least in the time in which u_n blows up, so we conclude.

By using Theorem 4.4 we obtain a region E_∞ such that

$$E_\infty \supset \{|x| < r(t)\} \times (0, \infty),$$

such that

$$\lim_{n\to\infty} u_n(x,t) = +\infty \quad \text{for all } (x,t) \in E_\infty.$$

Next we use the Harnack inequality (4.3), assume that there exists a point $(x_0, t_0) \in \Omega \times (0,\infty)$ such that $0 \le u_n(x_0,t_0) \le M < \infty$, and call

$$\rho(x_0,t_0) = \operatorname{dist}\{x_0, \partial\Omega\} > 0.$$

Then, if $B_r(x_0) \times \{t = t_1\} \cap E_\infty$ has N-dimensional positive measure for some $r < \rho(x_0,t_0)$ and $t_1 < t_0$, we consider the problem

$$\begin{cases} (v_n)_t - \Delta_{p,\gamma} v_n = 0 & \text{in } B_r(x_0) \times (t_1, t_0), \\ v_n(x,t) = 0 & \text{on } \partial B_r(x_0) \times (t_1, t_0), \\ v_n(x,t_1) = u_n(x,t_1) & \text{in } B_r(x_0); \end{cases} \tag{4.10}$$

then $v_n(x,t) \le u_n(x,t)$, and this is a contradiction to the Harnack inequality (4.3). If for all $r < \rho(x_0)$ and all $t_1 < t_0$, $|B_r(x_0) \times \{t = t_1\} \cap E_\infty| = 0$, then for all $\delta > 0$ we can find in a finite number of steps a point $(x_1, t_0 - \delta) \in \Omega \times (0, t_0)$ such that

$$|B_r(x_0) \times \{t = t_1\} \cap E_\infty| > 0,$$

and then we reach a contradiction as above. ∎

Remark 4.6. Notice that this result is stronger, in some sense, than the result by Baras and Goldstein (see [7]) for the heat equation; if $p > 2$, even the solution to the equation with truncated potential blows up in finite time.

Next we will prove that even if we truncate the whole nonlinearity, we find spectral instantaneous complete blow-up. More precisely, we have the following result.

THEOREM 4.7. *Consider the truncated problem*

$$\begin{cases} (v_n)_t - \Delta_{p,\gamma} v_n = \lambda\, W_n(x)\, T_n(v_n^{p-1}) & \text{in } \Omega \times \mathbb{R}^+, \\ v(x,t) = 0 & \text{on } \partial\Omega \times \mathbb{R}^+, \\ v(x,0) = \psi(x) & \text{in } \Omega, \end{cases} \tag{4.11}$$

where (H1) *and* (H2) *hold. Then*

$$\lim_{n\to\infty} v_n(x,t) = +\infty \quad \text{for every } (x,t) \in \Omega \times \mathbb{R}^+.$$

Proof. Using the same argument as in [2], we find that if $B_{4r}(0) \subset \Omega$, then

$$\lim_{n\to\infty} \int_{B_r(0)} v_n(x,t)\, dx = +\infty \quad \text{for every } t > 0.$$

Then by the Harnack inequality and a strategy which is similar to the one in Theorem 4.5, we obtain the complete blow-up. ∎

Remark 4.8.

(i) An alternative method to the one described above can be seen in [1]. The separation of variables gives a more transparent view of the behavior but uses in a strong way the presence of exactly two homogeneities. In the linear case (see [3]), or if the second member is not eigenvalues-like (see [2]), different arguments are needed.

(ii) If instantaneous and complete blow-up happens without hypothesis (H2), this seems to be an open problem. If $\gamma = 0$, we can take as a subsolution a convenient scaled and translated Barenblatt function that allows us to conclude that there exists a $T^* > 0$ such that for $t > T^*$ the same result as in Theorem 4.7 holds.

5. Behavior of solutions in the case $1 < p < 2$ and $\lambda < \lambda_N$, , . In this section we will try to explain how the optimal constant in the Hardy inequality becomes the threshold for extinction in finite time of the solution.

5.1. Finite time extinction.

THEOREM 5.1. *Assume that*

$$\max\left\{\frac{2N}{N+2}, \frac{2N}{N+2(\gamma+1)}\right\} < p < 2,$$

$\lambda < \lambda_{N,p,\gamma}$, *and* $\psi \in L^2(\Omega)$. *Then there exists a constant*

$$T^* = T^*(N,p,\gamma,\lambda,\Omega) \le c_1(N,p,\gamma,\lambda,\Omega)\|\psi\|_{L^2(\Omega)}^{2-p}$$

such that any solution of problem (P) *satisfies*

$$u(\cdot,t) \equiv 0 \quad \text{for } t \ge T^*. \tag{5.1}$$

Proof. Taking u as a test function in (P), and using inequalities (1.3) and (1.7), we get

$$\frac{1}{2}\frac{d}{dt}\int_\Omega u^2(t)\,dx + \frac{1}{S_{N,p,\gamma}}\left(1 - \frac{\lambda}{\lambda_{N,p,\gamma}}\right)\left[\int_\Omega \frac{|u(t)|^{p^*}}{|x|^{\gamma p^*}}\,dx\right]^{\frac{p}{p^*}} \le 0.$$

Using the assumptions on p and γ, by Hölder's inequality we obtain

$$\int_\Omega u^2(t)\,dx \le \left[\int_\Omega \frac{|u(t)|^{p^*}}{|x|^{\gamma p^*}}\,dx\right]^{\frac{2}{p^*}}\left[\int_\Omega |x|^{\frac{2\gamma p^*}{p^*-2}}\,dx\right]^{\frac{p^*-2}{\gamma p^*}} \le c_1\left[\int_\Omega \frac{|u(t)|^{p^*}}{|x|^{\gamma p^*}}\,dx\right]^{\frac{2}{p^*}},$$

where $c_1 = c_1(N,p,\gamma,\Omega)$ is a positive constant. Therefore, setting

$$\phi(t) = \int_\Omega u^2(t)\,dx,$$

one has

$$\phi'(t) + c_2[\phi(t)]^{\frac{p}{2}} \le 0,$$

with $c_2 > 0$. Since $p < 2$, this implies

$$\phi(t) \le \left([\phi(0)]^{\frac{2-p}{2}} - c_3 t\right)_+^{\frac{2}{2-p}},$$

from which the statement follows. ∎

THEOREM 5.2. *Assume that*

$$\gamma \geq 0, \qquad 1 < p < \frac{2N}{N+2},$$
$$\lambda < \eta_{N,p,\gamma} = \left(\frac{N(2-p)}{p} - 1\right)\left(\frac{[N - p(\gamma+1)]p}{(2-p)(N-p)}\right)^p,$$

and

$$\int_\Omega |\psi|^{\frac{N(2-p)}{p}}\, dx < \infty.$$

Then there exists a constant

$$T^* = T^*(N,p,\gamma,\lambda,\Omega) \leq c_1(N,p,\gamma,\lambda,\Omega)\|\psi\|^{2-p}_{L^{\frac{N}{p}(2-p)}(\Omega)}$$

such that any solution of problem (P) *found by approximation as in Theorem* 3.1 *satisfies*

$$u(\cdot,t) \equiv 0 \quad \text{for } t \geq T^*. \tag{5.2}$$

Proof. We take $v_n = |u_n|^{\alpha-2}u_n$ as test function in (P_n), with $\alpha \geq 2$ to be chosen hereafter. We obtain

$$\frac{1}{\alpha}\frac{d}{dt}\int_\Omega u_n^\alpha(t)\,dx + (\alpha-1)\int_\Omega \frac{|\nabla u_n(t)|^p |u_n(t)|^{\alpha-2}}{|x|^{\gamma p}}\,dx = \lambda\int_\Omega \frac{|u_n(t)|^{\alpha-(2-p)}}{|x|^{(\gamma+1)p}}\,dx.$$

Since

$$\int_\Omega \frac{|\nabla u_n(t)|^p |u_n(t)|^{\alpha-2}}{|x|^{\gamma p}}\,dx = \left(\frac{p}{\alpha-(2-p)}\right)^p \int_\Omega \frac{\left|\nabla\left(|u_n(t)|^{\frac{\alpha-(2-p)}{p}}\right)\right|^p}{|x|^{\gamma p}}\,dx$$

and, by Hardy's inequality,

$$\int_\Omega \frac{|u_n(t)|^{\alpha-(2-p)}}{|x|^{(\gamma+1)p}}\,dx \leq \lambda_{N,p,\gamma}^{-1}\int_\Omega \frac{\left|\nabla\left(|u_n(t)|^{\frac{\alpha-(2-p)}{p}}\right)\right|^p}{|x|^{\gamma p}}\,dx,$$

we obtain

$$\frac{1}{\alpha}\frac{d}{dt}\int_\Omega u_n^\alpha(t)\,dx + c_1\int_\Omega \frac{\left|\nabla\left(|u_n(t)|^{\frac{\alpha-(2-p)}{p}}\right)\right|^p}{|x|^{\gamma p}}\,dx \leq 0,$$

where

$$c_1 = (\alpha-1)\left(\frac{p}{\alpha-(2-p)}\right)^p - \lambda\left(\frac{p}{N-p(\gamma+1)}\right)^p > 0.$$

Therefore, by (1.7),

$$\frac{1}{\alpha}\frac{d}{dt}\int_\Omega u_n^\alpha(t)\,dx + c_1 S_{N,p,\gamma}\left[\int_\Omega \frac{|u_n(t)|^{\frac{[\alpha-(2-p)]p^*}{p}}}{|x|^{\gamma p^*}}\,dx\right]^{\frac{p}{p^*}} \leq 0. \tag{5.3}$$

Choosing

$$\alpha = \frac{N(2-p)}{p},$$

the two powers of u_n become equal. Since $\gamma \geq 0$, if we define

$$\phi(t) = \int_\Omega u_n^\alpha(t)\,dx,$$

we obtain

$$\phi'(t) + c_2[\phi(t)]^{\frac{p}{p^*}} \leq 0,$$

where $c_2 = c_2(N, p, \gamma, \Omega) > 0$, and we obtain the result for the approximate solutions u_n as in the previous theorem. The result on u follows by taking the limit on n. ∎

Remark 5.3. Note that $\eta_{N,p,\gamma} = \lambda_{N,p,\gamma}$ for $p = \frac{2N}{N+2}$.

THEOREM 5.4. *Assume that*

$$\begin{gathered} 0 < \gamma + 1 < \frac{N(2-p)}{2p}, \\ \lambda < \mu_{N,p,\gamma} = \left(\frac{N(2-p)}{p(\gamma+1)} - 1\right)\left(\frac{p(\gamma+1)}{2-p}\right)^p, \end{gathered} \tag{5.4}$$

and that there exists

$$\bar{\alpha} > \frac{(2-p)N}{p(\gamma+1)}$$

such that $\psi \in L^{\bar{\alpha}}(\Omega)$. *Then there exists a constant*

$$T^* = T^*(N, p, \gamma, \lambda, \Omega, \bar{\alpha}, \psi) \leq c_1(N, p, \gamma, \lambda, \Omega, \bar{\alpha})\|\psi\|_{L^\alpha(\Omega)}^{2-p}$$

such that any solution of problem (P) *found by approximation as in Theorem* 3.1 *satisfies*

$$u(\cdot, t) \equiv 0 \quad \text{for } t \geq T^*. \tag{5.5}$$

Proof. We use $|u_n|^{\alpha-2}u_n$ as a test function in (P_n), where α is such that

$$\frac{(2-p)N}{p(\gamma+1)} < \alpha \leq \bar{\alpha} \tag{5.6}$$

and

$$\lambda < (\alpha - 1)\left(\frac{p(\gamma+1)}{\alpha - (2-p)}\right)^p. \tag{5.7}$$

Note that this is always possible, since assumption (5.4) implies that (5.7) is true for $\alpha = \frac{(2-p)N}{p(\gamma+1)}$. As in the previous proof, we obtain inequality (5.3), where the constant c_1 is positive by (5.7). Now observe that condition (5.6) implies

$$\alpha > \frac{N(2-p)}{p}$$

and

$$\frac{\gamma\alpha pp^*}{p^*[\alpha-(2-p)]-\alpha p} > -N;$$

therefore, by Hölder's inequality,

$$\int_\Omega u_n^\alpha(t)\,dx \le \left[\int_\Omega |x|^{\frac{\gamma\alpha pp^*}{p^*[\alpha-(2-p)]-\alpha p}}\,dx\right]^{\frac{p^*[\alpha-(2-p)]-\alpha p}{p^*[\alpha-(2-p)]}} \left[\int_\Omega \frac{|u_n(t)|^{\frac{[\alpha-(2-p)]p^*}{p}}}{|x|^{\gamma p^*}}\,dx\right]^{\frac{\alpha p}{p^*[\alpha-(2-p)]}}$$
$$\le c_2(N,p,\gamma,\alpha,\Omega)\left[\int_\Omega \frac{|u_n(t)|^{\frac{[\alpha-(2-p)]p^*}{p}}}{|x|^{\gamma p^*}}\,dx\right]^{\frac{\alpha p}{p^*[\alpha-(2-p)]}}.$$

Hence one has

$$\frac{d}{dt}\int_\Omega u_n^\alpha(t)\,dx + c_3\left[\int_\Omega u_n^\alpha(t)\,dx\right]^{\frac{\alpha-(2-p)}{\alpha}} \le 0,$$

with $c_3 > 0$. Since $\frac{\alpha-(2-p)}{\alpha} < 1$, we conclude as before. □

Remark 5.5. Note that condition $0 < \gamma + 1 < \frac{N(2-p)}{2p}$ in Theorem 5.4 means that $1 < p < \frac{2N}{N+2(\gamma+1)}$, which implies, for $\gamma \ge 0$, that p also satisfies $1 < p < \frac{2N}{N+2}$. Therefore, we can compare the results of Theorems 5.2 and 5.4 in the region where $1 < p < \frac{2N}{N+2}$ and $\gamma \ge 0$. An easy calculation shows that in that region we have $\eta_{N,p,\gamma} < \mu_{N,p,\gamma}$, where $\eta_{N,p,\gamma}$ and $\mu_{N,p,\gamma}$ are given in the statements of Theorems 5.2 and 5.4, respectively. Since $\frac{N(2-p)}{p} > \frac{N(2-p)}{p(\gamma+1)}$, Theorem 5.4 gives a better result than Theorem 5.2 in the above region. Let us also point out that the value $\mu_{N,p,\gamma}$ is the same value we find in Lemma 3.2, which gives the esistence of self-similar solutions of the equation in problem (P).

5.2. Nonextinction results. If $p > 2$ and ψ verifies the hypothesis (H2), by using the Barenblatt-type functions one can easily prove that there is no extinction in finite time. Indeed, for any fixed time $T > 0$, consider the function $B(x, t+1)$, where B is the function defined in (4.2). One can easily check that, if the constant M in (4.2) is sufficiently small, then this function is a subsolution of problem (P). Since T is arbitrary, the result follows.

In this section we will prove that solutions to problem (P) with $1 < p < 2$, $\gamma + 1 \ge 0$, and $\lambda > \lambda_{n,p,\gamma}$ are nonzero for all time. The key of the proof is the construction of a nonnegative subsolution to the problem

$$\begin{cases} u_t - \Delta_{p,\gamma}(u) = \lambda\dfrac{|u|^{p-2}u}{|x|^{(\gamma+1)p}}, & (x,t) \in \Omega\times(0,T),\\ u(x,t) = 0, & (x,t)\in\partial\Omega\times(0,T),\\ u(x,0) = 0, & x\in\Omega, \end{cases} \tag{5.8}$$

following the ideas in [18] (see also [19]). Consider the eigenvalue problem

$$\begin{cases} -\Delta_{p,\gamma}(\phi_1) = \mu_1(n)W_n(x)\phi_1^{p-1}, & x\in\Omega,\\ u(x) = 0, & x\in\partial\Omega, \end{cases} \tag{5.9}$$

where $W_n(x) = \min\{n, |x|^{-(\gamma+1)p}\}$. The principal eigenvalue is isolated and simple. Moreover, it is easy to check that the sequence of principal eigenvalues, $\{\mu_1(n)\}$, is decreasing, that $\lim_{n\to\infty} \mu_1(n) = \lambda_{n,p,\gamma}$, and that the corresponding eigenfunction ϕ_1 has constant sign (see, for instance, [16]). In this way, if $\lambda > \lambda_{n,p,\gamma}$, there exists n_0 such that for $n > n_0$, one has $\lambda > \mu_1(n)$. Hence, for $n > n_0$, let $\Theta(t)$ be the positive solution to the problem $\Theta'(t) = \Theta^{p-1}(t)$, $\Theta(0) = 0$.

Define

$$v(x,t) = \Theta(\varepsilon t)\phi_1(x),$$

where $\varepsilon > 0$ will be chosen later, and ϕ_1 is a positive eigenfunction of (5.9) such that $\|\phi_1\|_\infty = 1$. We have that

$$\frac{v_t - \Delta_{p,\gamma}(v)}{\lambda v(x,t)^{p-1}} < \frac{\varepsilon \phi_1^{2-p}}{\lambda} + \frac{\mu_1(n)}{\lambda} W_n(x);$$

hence, as $2 - p > 0$, $\gamma + 1 \geq 0$, and $\frac{\mu_1(n)}{\lambda} < 1$, for a suitable $\varepsilon > 0$ we obtain that

$$\frac{v_t - \Delta_{p,\gamma}(v)}{\lambda v(x,t)^{p-1}} < W_n(x).$$

Then $v(x,t)$ is a subsolution to the truncated problem obtained from (5.8) and therefore to problem (5.8) with $1 < p < 2$, $\psi(x) \geq 0$, $(1+\gamma) > 0$, and $\lambda > \lambda_{n,p,\gamma}$. For the truncated equation we obtain a flat supersolution by solving the ordinary differential equation $y'(t) = n\lambda[y(t)]^{p-1}$, $1 < p < 2$, with data $y(0) = a$, whose solution is $y(t) = [a^{2-p} + n\lambda(2-p)t]^{1/(2-p)}$. Given a $T > 0$ we find a value of a for which $v(x,t) < y(t)$ in $\Omega \times (0,T)$ and $y(0) \geq \psi(x)$. Iterating from v, we obtain as a conclusion that in these hypotheses the minimal solution to the truncated equation of (5.8) has no finite time extinction. And therefore the same result holds for (5.8).

Remark 5.6. If $1 + \gamma < 0$, the weights are flat at the origin. If we use the eigenvalue analysis as in [16], i.e., for $\beta_n = (1+\gamma) - \frac{1}{n}$, then we define, for instance,

$$\alpha_n(x) = \begin{cases} |x|^{-p\beta_n} & \text{if } x \in \Omega \cap B_1(0), \\ |x|^{-p(\gamma+1)} & \text{if } x \in \Omega \setminus B_1(0). \end{cases}$$

In this way $\alpha_n(x) \leq |x|^{-p(\gamma+1)}$ for all $x \in \Omega$, and moreover, the eigenvalue problems

$$\begin{cases} -\operatorname{div}\left(\dfrac{|\nabla\psi_1|^{p-2}\nabla\psi_1}{|x|^{\gamma p}}\right) = \nu_1(n)\alpha_n(x)\psi_1^{p-1}, & x \in \Omega, \\ u(x) = 0, & x \in \partial\Omega, \end{cases} \tag{5.10}$$

verify the following:

1. The principal eigenvalue is isolated and simple.
2. We can choose the corresponding eigenfunction ψ_1 positive.
3. The sequence of principal eigenvalues satisfies $\nu_1(n) \searrow \lambda_{N,p,\gamma}$ as $n \to \infty$.

However, the final construction does not work.

INVARIANCE AND NONINVARIANCE OF CENTER MANIFOLDS OF TIME-t MAPS WITH RESPECT TO THE SEMIFLOW*

TIBOR KRISZTIN†

Dedicated to Professors István Győri and László Hatvani for their 60*th birthdays*

Abstract. This paper contains two examples related to the problem of whether the local center manifolds of the time-t maps of a semiflow at an equilibrium point are also invariant under the semiflow itself. An ordinary differential equation in $\mathbb{R}^2$ is given to show that, for almost all choices of the localization functions, the center manifold of the time-1 map at the origin is not locally invariant under the flow. The second example is an abstract functional differential equation. Although a variation-of-constants formula is not known to exist in the phase space, we prove that the classical approach works: The semiflow can be modified outside a neighborhood of the equilibrium point so that the center manifold of the time-t map of the modified semiflow will be locally invariant under the original semiflow.

Key words. invariant manifold, time-t map, smoothness, modification of the nonlinearity, Lyapunov–Perron method, abstract functional differential equation

1. Introduction.

Center manifolds play a fundamental role in the study of dynamical systems near nonhyperbolic equilibrium points. They were discovered by Pliss [25] and Kelley [18] in the 1960s and later developed by many others (e.g., [4, 16, 27, 31]). There are essentially two methods for proving the existence of center manifolds. The Lyapunov–Perron approach obtains the manifold as a fixed point of a certain integral equation for flows, and of a corresponding equation with sums for maps (e.g., [5, 8, 30, 31]). The Hadamard approach is more geometrical; it uses the graph transform technique (see, e.g., [1, 16]). There is a very extensive literature on applications and various generalizations of the theory of center manifolds; see [1, 4, 6, 7, 8, 9, 13, 19, 20, 32] and the references therein. For some interesting properties of center manifolds we refer to [3, 4, 27].

In this paper we consider the time-t, $t > 0$, map of a smooth semiflow on a Banach space with an equilibrium point at zero and study the problem of whether the local center manifolds (i.e., local center-stable, center-unstable, and center manifolds) of the time-t map are invariant with respect to the semiflow. If the answer for a given semiflow were affirmative, then the local center manifolds of the time-t map would also be local center manifolds of the semiflow. In particular, the problem is very important for semiflows, for which smooth local center manifolds are not known to exist because of certain technical difficulties, while for their time-t maps smooth local center manifolds have been constructed (see, e.g., [13]). We note that at a hyperbolic equilibrium point, under natural conditions it is straightforward to show that the stable and unstable manifolds of the time-t maps are invariant with respect to the semiflow.

In section 3, for an ordinary differential equation in $\mathbb{R}^2$, we construct a center manifold of the time-1 map so that it is not locally invariant with respect to the flow. In the example, the noninvariance holds for an open and dense subset of the localization functions. It is expected that the general case is analogous, although the calculations are specific to the example.

There is a classical approach for solving the above invariance problem (see, e.g., [5]): Assume that the semiflow can be extended from a small neighborhood of the equilibrium point to a global semiflow, which is a small and globally Lipschitzian perturbation of the linearized semiflow with a small Lipschitz constant. Then the center manifold (if it exists) of the time-t map of the modified semiflow will be locally positively invariant with respect to the original semiflow. In section 4 we show that the above extendability property holds for the semiflows generated by a class of abstract functional differential equations, for which the existence of C^k-smooth local center-stable, center, and center-unstable manifolds was a problem for a long time since a variation-of-constants formula in the phase space was not known. Namely, we consider the semilinear functional differential equation

$$\dot{u}(t) = A_T u(t) + Bu_t + F(u_t) \tag{1.1}$$

in a Banach space X, where $r \geq 0$, $C = C([-r, 0]; X)$ is the Banach space of continuous mappings from $[-r, 0]$ into X with the supremum norm, $u_t \in C$ is defined by $u_t(\theta) = u(t + \theta)$ for $\theta \in [-r, 0]$, $B : C \to X$ is a bounded linear operator, $A_T : D(A_T) \subset X \to X$ is the infinitesimal generator of a compact C_0-semigroup of linear operators on X, and F is C^k-smooth from an open neighborhood of 0 in C into X with $F(0) = 0$, $DF(0) = 0$. The mild solutions of (1.1) generate a local semiflow Ψ on C. It is shown by Faria, Huang, and Wu [13] that, for $\tau > r$, the time-τ map $\Psi(\tau, \cdot)$ has C^k-smooth local center-stable, center-unstable, and center manifolds at 0. Therefore, (1.1) is a new example for the general method of [5] to construct smooth local center manifolds for semiflows.

Reaction-diffusion equations with time delay are examples for (1.1). These equations have served as models for many ecology, chemistry, and biology problems [32]. A simple yet important equation is Fisher's equation with a delayed logistic type of reaction term

$$\frac{\partial U(t,x)}{\partial t} = \frac{\partial^2 U(t,x)}{\partial x^2} + lU(t,x)[1 - U(t-r,x)], \quad t > 0,\ x \in (0,\pi), \tag{1.2}$$

with the Dirichlet boundary condition

$$U(t,0) = U(t,\pi) = 0, \tag{1.3}$$

where $l > 0$ and $r > 0$. It was shown for $l \leq 1$ that the origin is a global attractor of all positive solutions of (1.2), (1.3). As l exceeds 1, the origin loses its stability, and a unique positive equilibrium $U_l(x)$ bifurcates from the origin. By [17], the spatially nonconstant $U_l(x)$ is locally stable provided $rl \max\{U_l(x) : x \in [0,\pi]\} < \pi/2$. In addition, for $l > 1$ and $l - 1$ small, as the delay increases and crosses some critical values, Hopf bifurcations occur [2]. The stability of the nontrivial periodic solutions on the center manifold arising from the first Hopf bifurcation point was stated without a proof in [2]. Recently, Faria and Huang [12] completed the proof by applying normal form theory from [11, 13] and C^k-smoothness of center manifolds from [13]. However, the C^k-smooth center manifold of a time-τ map as obtained in [13] is not necessarily invariant with respect to the semiflow (see section 3 in this paper), and thus it is not

necessarily a C^k-smooth center manifold of the semiflow. Our result in this paper provides the C^k-smoothness of the center manifold. This fact was used without proof in the papers [11, 12]. We refer to [12, 32] to see how problem (1.2), (1.3) can be written in the abstract form (1.1) with $X = L^2([0,\pi],\mathbb{R})$ after time-scaling and translating the equilibrium U_l to the origin. Of course, the same approach works for more general reaction-diffusion equations and different bifurcation problems.

We conclude this introduction by listing some notation. $\mathbb{N}$, $\mathbb{Z}$, $\mathbb{R}$, and $\mathbb{C}$ denote the set of nonnegative integers, integers, real, and complex numbers, respectively.

Spectra of linear operators in a Banach space E over $\mathbb{R}$ are defined as spectra of complexifications. If a decomposition $E = E_s \oplus E_c \oplus E_u$ into closed linear subspaces is given, then $E_{sc} = E_s \oplus E_c$, $E_{cu} = E_c \oplus E_u$, $E_{su} = E_s \oplus E_u$, and Pr_{E_s} denotes the associated projection along E_{cu} onto E_s, and similarly for $\mathrm{Pr}_{E_{sc}}$, Pr_{E_c}, Pr_{E_u}, $\mathrm{Pr}_{E_{su}}$, and $\mathrm{Pr}_{E_{cu}}$.

By a (local) semiflow Φ on E we mean a continuous semiflow defined on an open subset of $[0,\infty) \times E$. If the domain of Φ is $[0,\infty) \times E$, then Φ is called a global semiflow on E. The semiflow Φ is said to be C^k-smooth on E if, for each $t \geq 0$, $\Phi(t,\cdot)$ is C^k-smooth from its domain into E. If $I \subset \mathbb{R}$ is an interval and $y : I \to E$ is a curve with $y(t+s) = \Phi(t, y(s))$ for all $s \in I$ and for all $t \geq 0$ with $t + s \in I$, then y is called a trajectory of Φ. If $x \in E$, $I \subset (-\infty, 0]$ is an interval with $0 \in I$, and $y : I \to E$ is a trajectory of Φ with $y(0) = x$, then y is called a backward trajectory of Φ through x.

Let $V \subset U \subset E$, and let Φ be a semiflow on E. We say that V is positively invariant with respect to the semiflow Φ relative to U if for each $x \in V$ and for every $t > 0$,

$$\{\Phi(s,x) : s \in [0,t]\} \subset U \quad \text{implies} \quad \{\Phi(s,x) : s \in [0,t]\} \subset V.$$

We say that V is negatively invariant with respect to Φ relative to U if for each $x \in V$ the following holds: If a backward trajectory through x exists, then there exist a $t_x > 0$ and a backward trajectory $y : (-t_x, 0] \to E$ through x, with t_x maximal, so that for every $t \in (0, t_x)$,

$$\{y(s) : s \in [-t,0]\} \subset U \quad \text{implies} \quad \{y(s) : s \in [-t,0]\} \subset V.$$

V is invariant relative to U if it is both positively and negatively invariant relative to U.

The set $V \subset E$ is called locally positively invariant with respect to the semiflow Φ if for each $x \in V$ there exists $t_x > 0$ so that $\Phi(s,x) \in V$ for all $s \in [0, t_x]$. It is easy to see that if $V \subset U \subset E$, U is open, $\{0\} \times U$ belongs to the domain of Φ, and V is positively invariant with respect to Φ relative to U, then V is also locally positively invariant with respect to Φ.

For $\eta > 0$ and a Banach space E with norm $|\cdot|$, let E_η denote the Banach space of all sequences $\chi = (x_n)_0^\infty \in E^{\mathbb{N}}$ with $\sup_{j\in\mathbb{N}} |x_j|\eta^{-j} < \infty$ and norm $||\chi||_{E_\eta} = \sup_{j\in\mathbb{N}} |x_j|\eta^{-j}$.

2. Invariant manifolds for maps. In this section we recall some steps of the construction of invariant manifolds of maps from [13, 19] with a slight modification. It is shown in section 3 that if the map is the time-1 map of a flow, then the construction of [13, 19] may lead to center manifolds of the map which are not locally invariant with respect to the flow. A modified construction is used in section 4 to get smooth invariant manifolds for a semiflow generated by an abstract functional differential equation. This application motivates some of the particular assumptions on the map below.

Let $f : V \to E$ be a C^k-smooth map, $k \in \mathbb{N} \setminus \{0\}$, on an open subset V of a Banach space E over $\mathbb{R}$, with $0 \in V$ and $f(0) = 0$. Let $L = Df(0)$ and assume that E has the decomposition

$$E = E_s \oplus E_c \oplus E_u$$

such that E_s, E_c, and E_u are closed subspaces of E, E_c and E_u are finite-dimensional, $E_c \neq \{0\}$, $L(E_s) \subset E_s$, $L(E_c) \subset E_c$, $L(E_u) \subset E_u$, and the spectra σ_s, σ_c, and σ_u of the induced maps $L_s : E_s \ni x \mapsto Lx \in E_s$, $L_c : E_c \ni x \mapsto Lx \in E_c$, and $L_u : E_u \ni x \mapsto Lx \in E_u$ are contained in compact subsets of $\{z \in \mathbb{C} : |z| < 1\}$, $\{z \in \mathbb{C} : |z| = 1\}$, and $\{z \in \mathbb{C} : |z| > 1\}$, respectively.

Recent works of Faria, Huang, and Wu [13] and Krisztin, Walther, and Wu [19] show that under the above conditions on f, C^k-smooth local center-stable, center-unstable, and center manifolds of the map f can be obtained by using a discrete version of the Lyapunov–Perron method, and by following the approach of Vanderbauwhede and van Gils [31] for flows, and Diekmann et al. [9] for semiflows. The construction of these manifolds starts with an extension and modification of f. As $E_c \oplus E_u$ is finite-dimensional, by applying a suitable cut-off function, it is possible to modify and extend $f - L$ outside a small neighborhood of 0 in E to get a small Lipschitzian $r_\delta : E \to E$ with a small Lipschitz constant such that r_δ is C^k-smooth on small strips containing the center-unstable space $E_c \oplus E_u$. The global center-stable, center-unstable, and center manifolds of the map $g_\delta := L + r_\delta$ are defined as initial points of forward, backward, and global trajectories, respectively, of g_δ having a small exponential growth bound. These global manifolds are graphs of Lipschitz continuous maps from the spaces $E_s \oplus E_c$, $E_c \oplus E_u$, and E_c into their complementary spaces, respectively. Since the global center-unstable and center manifolds are situated in regions where g_δ is C^k-smooth, their C^k-smoothness can be also verified. This is not surprising since analogous results for flows and semiflows were known. The significance of [13, 19] is that the same modification works also for the infinite-dimensional center-stable manifold, although in a different way: Only that part of the global center-stable manifold is C^k-smooth which is in a small strip containing $E_c \oplus E_u$. This is sufficient because the local center-stable, center-unstable, and center manifolds of the map f are obtained as intersections of the corresponding global manifolds of g_δ with suitable small neighborhoods of 0 in E.

We remark that the finite dimensionality of E_c and E_u is made to guarantee the existence of smooth cut-off functions. This restriction is not necessary if E is a Hilbert space, or if it is a Banach space with the "C^k extension property" (see, e.g., [26]). In the example of section 4, $\dim E_c < \infty$ and $\dim E_u < \infty$ hold.

Set $a = \sup_{\lambda \in \sigma_s} |\lambda|$ and $b = \inf_{\lambda \in \sigma_u} |\lambda|$. In case $E_s = \{0\}$ let $a = 1/2$, and in case $E_u = \{0\}$ let $b = 3/2$. Fix an $\epsilon > 0$ with $a + \epsilon < 1$ and $(1 + \epsilon)^k < b - \epsilon$. There exists a norm $|\cdot|$ on E which is equivalent to the one given originally and satisfies $|x| = |\operatorname{Pr}_{E_s} x| + |\operatorname{Pr}_{E_c} x| + |\operatorname{Pr}_{E_u} x|$ and

$$\begin{aligned} |L \operatorname{Pr}_{E_s} x| &\leq (a + \epsilon) |\operatorname{Pr}_{E_s} x|, \\ |L \operatorname{Pr}_{E_c} x| &\leq (1 + \epsilon) |\operatorname{Pr}_{E_c} x|, \\ |L \operatorname{Pr}_{E_u} x| &\geq (b - \epsilon) |\operatorname{Pr}_{E_u} x| \end{aligned} \tag{2.1}$$

for all $x \in E$.

Define $r^* : V \ni x \mapsto f(x) - Lx \in E$, and extend r^* to a map $r : E \to E$ by $r(x) = 0$ for all $x \in E \setminus V$. Let $g = L + r$.

For $q > 0$ let $\mathcal{R}_q$ denote the set of C^∞-smooth functions $\rho : \mathbb{R} \to \mathbb{R}$ satisfying $\rho(t) = 1$ for $t \le 1$, $0 < \rho(t) < 1$ for $1 < t < 2$, $\rho(t) = 0$ for $t \ge 2$, and $|\rho'(t)| < q$ for all $t \ge 0$. Clearly, for a sufficiently large $q > 0$, $\mathcal{R}_q \neq \emptyset$. We fix such a $q > 0$, and set $\mathcal{R} = \mathcal{R}_q$. Let $\mathcal{R}$ be equipped with the metric d defined by $d(\rho, \zeta) = \sup_{t\in\mathbb{R}} |\rho(t)-\zeta(t)|$, $\rho, \zeta \in \mathcal{R}$.

Fix a norm $|\cdot|_{cu}$ on the finite-dimensional E_{cu}, which is C^∞-smooth on $E_{cu} \setminus \{0\}$. Then $||\cdot|| : E \ni x \mapsto \max\{|\operatorname{Pr}_{E_s} x|, |\operatorname{Pr}_{E_{cu}} x|_{cu}\} \in \mathbb{R}$ is a new norm on E which is equivalent to $|\cdot|$. Let $E(\delta) = \{x \in E : ||x|| < \delta\}$ for $\delta > 0$.

In section 3 we shall consider a set of modifications of the nonlinearity r. This motivates the introduction of a parametrized family of modifications $r_{\delta p}$, given below.

Let a $\delta^* > 0$, a set $\mathcal{P}$, and, for each $\delta \in (0, \delta^*]$ and $p \in \mathcal{P}$, a mapping $r_{\delta p} : E \to E$ be given. Assume that the family of mappings $r_{\delta p}$, $\delta \in (0, \delta^*]$, $p \in \mathcal{P}$, satisfies the following two hypotheses:

(R1) $E(\delta^*) \subset V$; $r_{\delta p}|_{E(\delta)} = r|_{E(\delta)}$ for all $\delta \in (0, \delta^*]$ and $p \in \mathcal{P}$; there exists a nondecreasing function $\lambda : [0, \delta^*] \to [0, 1]$ with $\lim_{\delta\to 0^+} \lambda(\delta) = 0 = \lambda(0)$ such that for every $\delta \in (0, \delta^*]$, for every $p \in \mathcal{P}$, and for all x, y in E,

$$|r_{\delta p}(x)| \le \delta\lambda(\delta),$$
$$|r_{\delta p}(x) - r_{\delta p}(y)| \le \lambda(\delta)|x - y|.$$

(R2) For every $\delta \in (0, \delta^*]$ and $p \in \mathcal{P}$ the restriction $r_{\delta p}|_{\{x\in E:|\operatorname{Pr}_{E_s} x|<\delta\}}$ is C^k-smooth, and all lth derivatives, $l \in \{1, \dots, k\}$, of $r_{\delta p}|_{\{x\in E:|\operatorname{Pr}_{E_s} x|<\delta\}}$ are bounded.

For every $\delta > 0$ and $\rho \in \mathcal{R}$, define $\tilde{r}_{\delta\rho} : E \to E$ by

$$\tilde{r}_{\delta\rho}(x) = r(x)\rho\left(\frac{|\operatorname{Pr}_{E_{cu}} x|_{cu}}{\delta}\right)\rho\left(\frac{|\operatorname{Pr}_{E_s} x|}{\delta}\right),$$

and set $\tilde{g}_{\delta\rho} = L + \tilde{r}_{\delta\rho}$. One can fix a $\delta_0 > 0$ so that $\overline{E(3\delta_0)} \subset V$ and that $r|_{E(3\delta_0)}$ is C^k-smooth, and all lth derivatives, $l \in \{1, \dots, k\}$, of $r|_{E(3\delta_0)}$ are bounded. If $\delta > 0$, $\rho \in \mathcal{R}$, and $x \in E$ with $|\operatorname{Pr}_{E_s} x| < \delta$, then

$$\tilde{r}_{\delta\rho}(x) = r(x)\rho\left(\frac{|\operatorname{Pr}_{E_{cu}} x|_{cu}}{\delta}\right).$$

It follows that, for every $\delta \in (0, \delta_0)$ and $\rho \in \mathcal{R}$, the map $\tilde{r}_{\delta\rho}|_{\{x\in E:|\operatorname{Pr}_{E_s} x|<\delta\}}$ is C^k-smooth, and all lth derivatives, $l \in \{1, \dots, k\}$, of $\tilde{r}_\delta|_{\{x\in E:|\operatorname{Pr}_{E_s} x|<\delta\}}$ are bounded. By an argument completely analogous to [19, Proposition II.2] there exist $\delta_1 \in (0, \delta_0)$ and a nondecreasing function $\tilde{\lambda} : [0, \delta_1] \to [0, 1]$ with $\lim_{\delta\to 0^+} \tilde{\lambda}(\delta) = 0 = \tilde{\lambda}(0)$ so that for each $\delta \in (0, \delta_1]$ and $\rho \in \mathcal{R}$, and for all x, y in E,

$$|\tilde{r}_{\delta\rho}(x)| \le \delta\tilde{\lambda}(\delta), \qquad |\tilde{r}_{\delta\rho}(x) - \tilde{r}_{\delta\rho}(y)| \le \tilde{\lambda}(\delta)|x - y|. \tag{2.2}$$

The construction of $\tilde{\lambda}$ (see [19, Proposition II.2]) uses the facts $r(0) = 0$, $Dr(0) = 0$ and that ρ' is bounded on $[0, \infty)$. Since $\sup_{t\ge 0} |\rho'(t)| < q$ for all $\rho \in \mathcal{R}$, a function $\tilde{\lambda}$ can be constructed so that (2.2) is satisfied for all $\rho \in \mathcal{R}$.

The choice $\delta^* = \delta_1$, $\mathcal{P} = \mathcal{R}$ and $r_{\delta\rho} = \tilde{r}_{\delta\rho}$, $\delta \in (0, \delta_1]$, $\rho \in \mathcal{R}$, clearly satisfies hypotheses (R1) and (R2). This case is used in section 3. In section 4, the case $\mathcal{P} = \{\rho\}$ with a fixed $\rho \in \mathcal{R}$ is applied. However, there the mappings $r_{\delta\rho}$ are necessarily different from $\tilde{r}_{\delta\rho}$ in order to guarantee that the local center manifolds of the time-t maps of the semiflow generated by (1.1) are invariant with respect to the semiflow.

Choose the reals η_0 and η_1 so that $1+\epsilon<\eta_0<\eta_0^k<\eta_1<b-\epsilon$, and define

$$c=\max\left\{\frac{1}{s-1-\epsilon}+\frac{1}{b-\epsilon-s}:s\in[\eta_0,\eta_1]\right\}.$$

Assuming that a family of mappings $r_{\delta p}$, $\delta\in(0,\delta^*]$, $p\in\mathcal{P}$, is given with properties (R1) and (R2), we choose $\delta^{**}\in(0,\delta^*)$ so small that $\lambda(\delta^{**})<1/(2c)$ and $\lambda(\delta^{**})<(1-a-\epsilon)^2/2$.

In the following result we state a slightly modified version of Theorem 5.1 in [13].

THEOREM 2.1. *Let E, f, L, and r be defined as above. Let a $\delta^*>0$, a set $\mathcal{P}$, and, for each $\delta\in(0,\delta^*]$ and $p\in\mathcal{P}$, a mapping $r_{\delta p}:E\to E$ be given such that hypotheses* (R1) *and* (R2) *are satisfied. Set $g_{\delta p}=L+r_{\delta p}$ for $\delta\in(0,\delta^*)$ and $p\in\mathcal{P}$.*

Then for all $\delta\in(0,\delta^{**})$ and $p\in\mathcal{P}$ the following holds:

(i) *There is a Lipschitz continuous map $w:E_{sc}\to E_u$ with Lipschitz constant 2 and $w(0)=0$ so that the set*

$$W^{cs}=\{z+w(z):z\in E_{sc}\}$$

is equal to the set

$$\{x\in E:\text{There is }(x_n)_0^\infty\in E_{\eta_0}\text{ with }x_0=x,\text{ and }x_{n+1}=g_{\delta p}(x_n)\text{ for all }n\in\mathbb{N}\}.$$

(ii) *There exist convex open neighborhoods N_{sc} of 0 in E_{sc}, N_u of 0 in E_u, $N\subset V$ of 0 in E such that $N_{sc}+N_u\subset E(\delta)$, $w(N_{sc})\subset N_u$, $w|_{N_{sc}}$ is C^k-smooth, $Dw(0)=0$, and the set*

$$W^{cs}_{loc}=\{z+w(z):z\in N_{sc}\}$$

satisfies $f(W^{cs}_{loc}\cap N)\subset W^{cs}_{loc}$ and $\cap_{n=0}^\infty f^{-n}(N_{sc}+N_u)\subset W^{cs}_{loc}$.

For a proof of Theorem 2.1 we can refer to the proof of Theorem 5.1 in [13] (see also [19, Theorem II.1]). Our observation is that the particular modification used in [13] can be replaced by a parametrized family of mappings. The reason for this is that all the required smallness conditions on δ are expressed by the function λ, and λ is independent of the choice of $p\in\mathcal{P}$.

Remarks. 1. The set $W^{cs}=\{z+w(z):z\in E_{sc}\}$ is called the global center-stable manifold of the map $g_{\delta p}$, while W^{cs}_{loc} is a local center-stable manifold of f. Since, for the fixed η, w depends on the constant δ and on the parameter p, the sets W^{cs} and W^{cs}_{loc} also depend on δ and p. This dependence on δ and p is related also to the nonuniqueness of local center manifolds (see [3, 4]). As the function λ in hypothesis (R1) is independent of $p\in\mathcal{P}$, for a fixed $\delta>0$, the neighborhood N_{sc} of 0 in E_{sc} can be chosen independently of $p\in\mathcal{P}$.

2. Under the same conditions as those in Theorem 2.1, analogous results can be stated for the center-unstable and center manifolds. For the center-unstable case we refer to [19, Theorem III.1]; for the center case we refer to [13]; and for works containing results for semiflows we refer to [5, 9, 30, 31].

3. The proofs of Theorem 5.1 in [13] and Theorem II.1 in [19] fix a $\rho\in\mathcal{R}$ and use the modification $r_\delta=\tilde{r}_{\delta\rho}$, $\delta>0$, of the nonlinearity r.

In the next section we need the dependence of the manifolds obtained in Theorem 2.1 on the parameters in a particular case.

PROPOSITION 2.2. *Let E, f, L, r, η_0, η_1, and c be the same as in Theorem 2.1. Assume that the family of mappings $\tilde{r}_{\delta\rho} : E \to E$, $\delta \in (0, \delta_1]$, $\rho \in \mathcal{R}$, is given as above. Define $\delta^{**} \in (0, \delta_1)$ so that $\tilde{\lambda}(\delta^{**}) < \min\{1/(2c), (1-a-\epsilon)^2/2\}$. Set $r_0 = \sup_{x \in E(2\delta^{**})} |r(x)|$.*

Then for each $\delta \in (0, \delta^{**})$ and for all $\rho, \zeta \in \mathcal{R}$, the mappings $w_{\delta\rho} : E_{sc} \to E_u$ and $w_{\delta\zeta} : E_{sc} \to E_u$, guaranteed by Theorem 2.1, satisfy

$$\sup_{z \in E_{sc}} |w_{\delta\rho}(z) - w_{\delta\zeta}(z)| \le 4cr_0\, d(\rho, \zeta).$$

The proof is omitted since it goes in a standard way.

3. Noninvariance: An example. In this section we consider an ordinary differential equation in $\mathbb{R}^2$ so that the origin is an equilibrium point with a one-dimensional center and unstable subspaces. Fixing a smooth norm $||\cdot||$ in $\mathbb{R}^2$, we modify the nonlinearity r of the time-1 map as

$$\tilde{r}_{\delta\rho} = r(x)\rho\left(\frac{||x||}{\delta}\right), \quad \delta > 0,\ \rho \in \mathcal{R}.$$

For a sufficiently small fixed $\delta > 0$, Theorem 2.1 guarantees local center-stable manifolds $W^{cs}_{loc}(\rho)$ for all $\rho \in \mathcal{R}$, which are center manifolds since the stable subspace is trivial. We show that, for an open and dense subset of $\mathcal{R}$, these local manifolds are not locally positively invariant with respect to the flow.

The idea of the proof is simple. Let $\rho \in \mathcal{R}$ be fixed. The global center-stable manifold W of the modified time-1 map $G = L + \tilde{r}_{\delta\rho}$ consists of those points $z \in \mathbb{R}^2$ for which the trajectories $(G^n(z))_{n=0}^{\infty}$ do not grow faster than $(\eta^n)_{n=0}^{\infty}$ with some fixed η between 1 and the greatest eigenvalue of the linear part L of the time-1 map. There is a smooth function $h : \mathbb{R} \to \mathbb{R}$ with $h(0) = 0$ and $h'(0) = 0$ so that $W = \{(x, h(x)) : x \in \mathbb{R}\}$. If the local center manifold $W(\gamma) = \{(x, h(x)) : |x| < \gamma\}$, with a sufficiently small $\gamma > 0$, is locally positively invariant with respect to the flow, then $W^+(\gamma) = \{(x, h(x)) : 0 < x < \gamma\}$ is a single trajectory of the flow. For another cut-off function $\rho_\kappa \in \mathcal{R}$ the same holds replacing G, h, W, $W(\gamma)$, $W^+(\gamma)$ by G_κ, h_κ, W_κ, $W_\kappa(\gamma)$, $W^+_\kappa(\gamma)$, respectively. Consequently, if both $W(\gamma)$ and $W_\kappa(\gamma)$ are locally positively invariant with respect to the flow, then either $W^+(\gamma) = W^+_\kappa(\gamma)$, or $W^+(\gamma)$ and $W^+_\kappa(\gamma)$ are disjoint sets. If ρ_κ is chosen such that ρ_κ differs from ρ only in a small interval $(c_1, c_2) \subset (1, 2)$, then $G(z) = G_\kappa(z)$ for all z from the set $\mathbb{R}^2 \setminus \{z \in \mathbb{R}^2 : c_1\delta < ||z|| < c_2\delta\}$. This fact allows us to construct a sequence $(u_n)_{n\in\mathbb{Z}}$ in the open right half plane $\mathbb{R}^2_+$ such that $u_n \in W \cap W_\kappa$, and $u_n \to 0$ as $n \to -\infty$. On the other hand, $\rho \ne \rho_\kappa$ makes it possible to find another sequence $(v_n)_{n\in\mathbb{Z}}$ in $\mathbb{R}^2_+$ with $v_n \in W_\kappa \setminus W$ for all integers $n \le 0$, and $v_n \to 0$ as $n \to -\infty$. Thus, for each $\gamma > 0$, $W^+(\gamma) \ne W^+_\kappa(\gamma)$ and $W^+(\gamma) \cap W^+_\kappa(\gamma) \ne \emptyset$. Therefore, both $W(\gamma)$ and $W_\kappa(\gamma)$ cannot be locally positively invariant with respect to the flow. It also follows that the noninvariance holds for a dense subset of $\mathcal{R}$. By using Proposition 2.2, there is an open subset of $\mathcal{R}$ so that the corresponding time-1 maps are noninvariant with respect to the flow.

It is expected that the general case is analogous, although the calculations below are specific to the example.

Now we give the details of the promised example. Consider the two-dimensional system of ordinary differential equations

$$\begin{cases} \dot{x} = x^3, \\ \dot{y} = y - x^2. \end{cases} \tag{3.1}$$

In $\mathbb{R}^2$ the solutions of (3.1) define the flow

$$\Phi(t,x,y)=\begin{pmatrix} \frac{x}{\sqrt{1-2tx^2}} \\ e^t y - e^t \int_0^t \frac{e^{-s}x^2}{1-2sx^2}ds \end{pmatrix},$$

$-\infty < t < 1/(2x^2)$. Let us fix an integer $k \geq 1$. It is clear that, for each $t \in \mathbb{R}$, $\Phi(t,\cdot)$ is C^k-smooth. Set

$$V = \left(-\frac{1}{\sqrt{2}}, \frac{1}{\sqrt{2}}\right) \times \mathbb{R}.$$

The time-1 map $f = \Phi(1,\cdot)$ is defined and C^k-smooth on V, and it is given by

$$f(x,y)=\begin{pmatrix} \frac{x}{\sqrt{1-2x^2}} \\ ey - e\int_0^1 \frac{e^{-s}x^2}{1-2sx^2}ds \end{pmatrix} \qquad ((x,y)\in V).$$

We have

$$Df(0,0)=\begin{pmatrix} 1 & 0 \\ 0 & e \end{pmatrix},$$

and $E=\mathbb{R}^2$ has the decomposition $E = E_s \oplus E_c \oplus E_u$ with $E_s = \{(0,0)\}$, $E_c = \mathbb{R}\times\{0\}$, and $E_u = \{0\}\times\mathbb{R}$. In this case $a = 1/2$, $b = e$. Choose $\epsilon \in (0,1/2)$ so that $(1+\epsilon)^k < e - \epsilon$, and let the norm $|\cdot|$ on $\mathbb{R}^2$ be given by

$$|(x,y)| = |(x,0)| + |(0,y)| = |x| + |y|$$

Then the trichotomy (2.1) holds for $L = Df(0,0)$.

Define $r : \mathbb{R}^2 \to \mathbb{R}^2$ by $r(x,y) = (0,0)$ for $(x,y) \in \mathbb{R}^2 \setminus V$, and

$$r(x,y)=\begin{pmatrix} \frac{x}{\sqrt{1-2x^2}} - x \\ -e\int_0^1 \frac{e^{-s}x^2}{1-2sx^2}\,ds \end{pmatrix} \quad \text{for } (x,y)\in V.$$

In order to make certain estimates simpler, we choose a particular smooth norm in $\mathbb{R}^2$.

PROPOSITION 3.1. *There exists a norm $||\cdot||$ on $\mathbb{R}^2$ which is C^∞-smooth on $\mathbb{R}^2\setminus\{(0,0)\}$ and satisfies the following:*

$$\begin{aligned}
&|x| \leq \frac{3}{4} \text{ and } |y| \leq \frac{3}{4} \quad \text{imply} \quad ||(x,y)|| < 1,\\
&|x| = 1 \text{ and } |y| \leq \frac{3}{4} \quad \text{imply} \quad ||(x,y)|| = 1,\\
&|x| \leq \frac{3}{4} \text{ and } |y| = 1 \quad \text{imply} \quad ||(x,y)|| = 1,\\
&|x| \geq 1 \text{ or } |y| \geq 1 \quad \text{implies} \quad ||(x,y)|| \geq 1.
\end{aligned} \tag{3.2}$$

Proof. Suppose that $\nu : \mathbb{R} \to \mathbb{R}$ is a $\pi/2$-periodic positive C^∞-smooth function. Let $\mathcal{C}$ be the simple closed curve in $\mathbb{R}^2$ given by $r = \nu(\phi)$, $\phi \in [0, 2\pi]$, in polar coordinates $[r,\phi]$. Then $\operatorname{int}\mathcal{C}$, the interior of $\mathcal{C}$, is symmetric about zero. Assume that $\operatorname{int}\mathcal{C}$ is convex. For $(x,y) \in \mathbb{R}^2$ set $s(x,y) = \sqrt{x^2+y^2}$, and let $\phi(x,y)$ denote the

polar angle of the point (x, y). Then, by the symmetry and convexity of $\operatorname{int}\mathcal{C}$, it is not difficult to see that the map

$$\mathbb{R}^2 \ni (x, y) \mapsto \frac{s(x, y)}{\nu(\phi(x, y))} \in \mathbb{R}$$

defines a norm $||\cdot||$ on $\mathbb{R}^2$ which is C^∞-smooth on $\mathbb{R}^2 \setminus \{(0, 0)\}$. In fact, the norm is the Minkowski functional associated to the bounded balanced convex absorbing set $\operatorname{int}\mathcal{C}$. Let $|\mathcal{C}|$ denote the trace of $\mathcal{C}$. If

$$\left\{(x, y) : |x| = 1,\ |y| \le \frac{3}{4}\right\} \bigcup \left\{(x, y) : |x| \le \frac{3}{4}, |y| = 1\right\} \subset |\mathcal{C}| \tag{3.3}$$

also holds, then $||\cdot||$ satisfies (3.2). It is an elementary exercise to find a ν with the above properties. □

For $\rho \in \mathcal{R}$ and $\delta > 0$, define $\tilde{r}_{\delta\rho} : \mathbb{R}^2 \to \mathbb{R}^2$ by

$$\tilde{r}_{\delta\rho}(x, y) = r(x, y)\rho\left(\frac{||(x, y)||}{\delta}\right).$$

Set $\tilde{g}_{\delta\rho} = Df(0, 0) + \tilde{r}_{\delta\rho}$. We have seen in section 2 that there exists $\delta_1 > 0$ so that the family of mappings $r_{\delta\rho} = \tilde{r}_{\delta\rho}$, $\delta \in (0, \delta_1]$, $\rho \in \mathcal{R}$, satisfies hypotheses (R1) and (R2) with $\delta^* = \delta_1$ and $\mathcal{P} = \mathcal{R}$. Therefore, we can fix $\eta_0 \in (1 + \epsilon, e - \epsilon)$ and $\delta^{**} \in (0, \delta^*)$ such that statements (i) and (ii) of Theorem 2.1 are satisfied for all $\delta \in (0, \delta^{**})$ and for all $\rho \in \mathcal{R}$.

Let us fix $\rho \in \mathcal{R}$ and $\delta \in (0, \delta^{**})$ so that

$$\delta < \min\left\{\frac{e - 2}{16e}, \frac{1}{\sqrt{32q}}\right\}, \tag{3.4}$$

where $q > 0$ appears in the definition of $\mathcal{R}$. Set $G = L + \tilde{r}_{\delta\rho}$. We have

$$G(x, y) = \begin{pmatrix} x + \left(\frac{x}{\sqrt{1-2x^2}} - x\right)\ \rho\left(\frac{||(x,y)||}{\delta}\right) \\ ey - e\int_0^1 \frac{e^{-s}x^2}{1-2sx^2} ds\, \rho\left(\frac{||(x,y)||}{\delta}\right) \end{pmatrix} \quad ((x, y) \in \mathbb{R}^2).$$

By Theorem 2.1, the global center-stable manifold W of G exists, and there is a map $w : \mathbb{R} \times \{0\} \to \{0\} \times \mathbb{R}$ such that $w((0, 0)) = (0, 0)$ and

$$\begin{aligned} W &= \{z + w(z) : z \in \mathbb{R} \times \{0\}\} \\ &= \{u \in \mathbb{R}^2 : \text{There is a sequence } (u_n)_0^\infty \text{ in } \mathbb{R}^2_{\eta_0} \\ &\qquad \text{with } u_0 = u, \text{ and } u_{n+1} = G(u_n) \text{ for all } n \in \mathbb{N}\}, \end{aligned}$$

$$|w(x_1, 0) - w(x_2, 0)| \le 2|(x_1, 0) - (x_2, 0)| = 2|x_1 - x_2| \quad (x_1, x_2 \in \mathbb{R}).$$

We shall use the notation

$$((x, y))_1 = x, \quad ((x, y))_2 = y$$

for $(x, y) \in \mathbb{R}^2$.

Define $h : \mathbb{R} \to \mathbb{R}$ by

$$h(x) = \big(w((x, 0))\big)_2.$$

Then $h(0) = 0$,

$$|h(x_1) - h(x_2)| \leq 2|x_1 - x_2| \quad (x_1, x_2 \in \mathbb{R}),$$

and

$$W = \{(x, h(x) : x \in \mathbb{R}\}.$$

PROPOSITION 3.2. *$h(x) = 0$ for $|x| \geq 2\delta$, and $0 < h(x) < \delta/2$ for $0 < |x| < 2\delta$.*

Proof. Assume $|x| \geq 2\delta$. Then $||(x, y)|| \geq 2\delta$ for all $y \in \mathbb{R}$, and $G^n(x, h(x)) = (x, e^n h(x))$ for all $n \in \mathbb{N}$. The fact $(x, h(x)) \in W$ implies $((x, e^n h(x)))_0^\infty \in \mathbb{R}^2_{\eta_0}$. Since $1 < \eta_0 < e$, $h(x) = 0$ follows.

Assume that $|x| < 2\delta$ and $h(x) \geq \delta/2$. By the choice of δ, we have $\delta < (e-2)/(16e)$, and thus

$$e \int_0^1 \frac{e^{-s}x^2}{1 - 2sx^2} ds \leq \frac{ex^2}{1 - 2x^2} < \frac{4e\delta^2}{1 - 8\delta^2} < 8e\delta^2 < \frac{8e(e-2)}{16e}\delta = \frac{e-2}{2}\delta.$$

Then

$$(G(x, h(x)))_2 = eh(x) - e \int_0^1 \frac{e^{-s}x^2}{1 - 2sx^2} ds\, \rho\left(\frac{||(x, h(x))||}{\delta}\right) \geq \frac{e\delta}{2} - \frac{e-2}{2}\delta = \delta.$$

By using the facts $G(x, h(x)) \in W$ and $h(u) = 0$ for $|u| \geq 2\delta$, we conclude

$$|(G(x, h(x)))_1| < 2\delta.$$

Hence

$$(G^2(x, h(x)))_2 \geq e\delta - \frac{e-2}{2}\delta = \left(\frac{e}{2} + 1\right)\delta > 2\delta$$

follows. Then $||G^2(x, h(x))|| \geq 2\delta$ holds. Consequently,

$$G^{n+2}(x, h(x)) = \begin{pmatrix} (G^2(x, h(x)))_1 \\ e^n (G^2(x, h(x)))_2 \end{pmatrix} \quad \text{for all } n \in \mathbb{N}.$$

Clearly, $(G^n(x, h(x)))_0^\infty \notin \mathbb{R}^2_{\eta_0}$ because of $\left(G^2(x, h(x))\right)_2 > 2\delta$. On the other hand, the definition of W yields $(G^n(x, h(x)))_0^\infty \in \mathbb{R}^2_{\eta_0}$, a contradiction. Therefore, $h(x) < \delta/2$.

If $y < 0$ and $x \in \mathbb{R}$, then

$$(G^n(x, y))_2 \leq e^n y \quad \text{for all } n \in \mathbb{N}.$$

Obviously, $(G^n(x, y))_0^\infty \notin \mathbb{R}^2_{\eta_0}$, and $(x, y) \notin W$.

If $0 < |x| < 2\delta$ and $y = 0$, then $||(x, y)|| = |x| < 2\delta$. Then

$$\left(G(x, 0)\right)_2 = -e \int_0^1 \frac{e^{-s}x^2}{1 - 2x^2} ds\, \rho\left(\frac{|x|}{\delta}\right) < 0.$$

Hence $(x, 0) \notin W$ follows as above. Consequently, $h(x) > 0$ for $0 < |x| < 2\delta$. ∎

Define

$$U = (0, 2\delta) \times \left(0, \frac{\delta}{2}\right).$$

If $(x,y) \in U$ and $x \le (3/4)\delta$, then $||(x,y)|| < \delta$, and $\rho(||(x,y)||/\delta) = 1 = \rho(x/\delta)$. If $(x,y) \in U$ and $x > (3/4)\delta$, then $|x| > (3/2)|y|$, and thus $||(x,y)|| = |x| = x$. Consequently,

$$\rho\left(\frac{||(x,y)||}{\delta}\right) = \rho\left(\frac{x}{\delta}\right) \quad \text{for all } (x,y) \in U.$$

Therefore, the first component of G in U is given by the function

$$a : [0, 2\delta] \ni x \mapsto x + \left(\frac{x}{\sqrt{1-2x^2}} - x\right)\rho\left(\frac{x}{\delta}\right) \in \mathbb{R}.$$

The function a is C^∞-smooth, $a(0) = 0$, $a(2\delta) = 2\delta$. Moreover, it has nice properties.

PROPOSITION 3.3. *The function a is strictly increasing on $[0, 2\delta]$. For each $x \in (0, 2\delta)$ there is a unique sequence $(x_n)_{n\in\mathbb{Z}}$ in $(0, 2\delta)$ so that $x_{n+1} = a(x_n)$ for all $n \in \mathbb{Z}$. For the sequence $(x_n)_{n\in\mathbb{Z}}$, $\lim_{n\to-\infty} x_n = 0$ and $\lim_{n\to\infty} x_n = 2\delta$ are satisfied.*

Proof. We have

$$a'(x) = 1 + \left(\frac{1}{(1-2x^2)^{3/2}} - 1\right)\rho\left(\frac{x}{\delta}\right) + \left(\frac{x}{\sqrt{1-2x^2}} - x\right)\rho'\left(\frac{x}{\delta}\right)\frac{1}{\delta}.$$

For the last term

$$\left|\left(\frac{x}{\sqrt{1-2x^2}} - x\right)\rho'\left(\frac{x}{\delta}\right)\frac{1}{\delta}\right| = \frac{2x^3|\rho'(x/\delta)|}{\delta\sqrt{1-2x^2}(1+\sqrt{1-2x^2})} \le \frac{32\delta^3 q}{\delta} = 32q\delta^2 < 1$$

holds because of the choice of δ. Then

$$a'(x) \ge \left(\frac{1}{(1-2x^2)^{3/2}} - 1\right)\rho\left(\frac{x}{\delta}\right) > 0 \quad \text{for all } x \in (0, 2\delta).$$

Consequently, a is strictly increasing. Observe that $a(x) > x$ for all $x \in (0, 2\delta)$. Combining these facts with $a(0) = 0$ and $a(2\delta) = 2\delta$, the last two statements follow immediately. ∎

As a has an inverse, the sequence $(x_n)_{n\in\mathbb{Z}}$ guaranteed by Proposition 3.3 will be denoted also by $(a^n(x))_{n\in\mathbb{Z}}$.

PROPOSITION 3.4. *For each $(u,v) \in U$ there is a unique $(x,y) \in U$ with $G(x,y) = (u,v)$.*

Proof. Let $(u,v) \in U$ be given. Define

$$x = a^{-1}(u), \quad y = \frac{1}{e}v + \int_0^1 \frac{e^{-s}x^2}{1-2sx^2}ds\,\rho\left(\frac{x}{\delta}\right).$$

Clearly, $x \in (0, 2\delta)$ and

$$0 < y < \frac{\delta}{2e} + \frac{4\delta^2}{1-8\delta^2} \le \frac{\delta}{2e} + 8\delta^2 < \frac{\delta}{2e} + 8\delta\frac{e-2}{16e} < \frac{\delta}{e} < \frac{\delta}{2}.$$

Thus $(x,y) \in U$, and then $G(x,y) = (u,v)$. Obviously, x is uniquely determined by u. Hence the uniqueness of y also follows. ∎

By Proposition 3.4, the restriction $G|_U$ has an inverse, denoted by G^{-1}.

PROPOSITION 3.5. *For each $(x,y) \in U$,*

$$G^{-n}(x,y) \to (0,0) \quad \text{as } n \to \infty.$$

Proof. Let $(x, y) \in U$ be given. Set $(x_{-n}, y_{-n}) = G^{-n}(x, y)$, $n \in N$. By Proposition 3.3,

$$x_{-n} = a^{-n}(x) \to 0 \quad \text{as } n \to \infty.$$

Let $\tilde{\epsilon} > 0$ be given. There exists $n_0 \in \mathbb{N}$ such that

$$\int_0^1 \frac{e^{-s}x_{-n}^2}{1 - 2sx_{-n}^2} ds\, \rho\left(\frac{x_{-n}}{\delta}\right) < \frac{\tilde{\epsilon}}{2}$$

for all $n \geq n_0$. For all $k \in \mathbb{N}$, we have

$$y_{-n_0-k} = ey_{-n_0-k-1} - e\int_0^1 \frac{e^{-s}x_{-n_0-k-1}^2}{1 - 2sx_{-n_0-k-1}^2} ds\, \rho\left(\frac{x_{-n_0-k-1}}{\delta}\right),$$

from which

$$|y_{-n_0-k-1}| \leq \frac{1}{e}|y_{-n_0-k}| + \frac{\tilde{\epsilon}}{2} \quad \text{for all } k \in \mathbb{N}.$$

Using $|y_{-n_0}| < \delta/2$, an induction argument yields

$$|y_{-n_0-k-1}| \leq \frac{1}{e^{k+1}}\frac{\delta}{2} + \left(\sum_{j=0}^{k} \frac{1}{e^j}\right)\frac{\tilde{\epsilon}}{2} \quad \text{for all } k \in \mathbb{N}.$$

Hence

$$\limsup_{n\to\infty} |y_{-n}| < \tilde{\epsilon}$$

follows. As $\tilde{\epsilon} > 0$ was arbitrary, we conclude $\lim_{n\to\infty} y_{-n} = 0$. ∎

Define

$$c_1 = \frac{3\delta + a(\delta)}{4\delta}, \quad c_2 = \frac{\delta + 3a(\delta)}{4\delta}$$

and

$$x^* = \frac{\delta + a(\delta)}{2}, \quad I = \left(x^* - \frac{a(\delta) - \delta}{4}, x^* + \frac{a(\delta) - \delta}{4}\right) = (c_1\delta, c_2\delta).$$

Let $\beta : \mathbb{R} \to \mathbb{R}$ be a C^∞-smooth function so that $\beta(t) > 0$ for $c_1 < t < c_2$, and $\beta(t) = 0$ for all $t \in \mathbb{R} \setminus (c_1, c_2)$. Fix $\kappa > 0$ so small that

$$\rho + \kappa\beta \in \mathcal{R}.$$

Set $\rho_\kappa = \rho + \kappa\beta$. If ρ is replaced by ρ_κ, then, with the same fixed $\eta_0 > 0$ and $\delta > 0$, we get G_κ, W_κ, h_κ, a_κ, a_κ^{-1}, and G_κ^{-1} instead of G, W, h, a, a^{-1}, and G^{-1}, respectively, and G_κ, W_κ, h_κ, a_κ, a_κ^{-1}, and G_κ^{-1} have the same properties as obtained above for G, W, h, a, a^{-1}, and G^{-1}, respectively.

We have

$$\rho\left(\frac{x}{\delta}\right) = \rho_\kappa\left(\frac{x}{\delta}\right) \quad \text{for all } x \in (0, 2\delta) \setminus I.$$

As $I \subset (\delta, a(\delta))$ and $(a^n(\delta))_{n\in\mathbb{Z}}$ is increasing, we obtain that

$$G(a^n(\delta), h(a^n(\delta))) = G_\kappa(a^n(\delta), h(a^n(\delta))) \quad \text{for all } n \in \mathbb{Z}.$$

The positive invariance of W with respect to G and

$$\big(G(a^n(\delta), h(a^n(\delta)))\big)_1 = a^{n+1}(\delta)$$

combined yield

$$G(a^n(\delta), h(a^n(\delta))) = \big(a^{n+1}(\delta), h(a^{n+1}(\delta))\big)$$

for all $n \in \mathbb{Z}$. Hence

$$G_\kappa(a^n(\delta), h(a^n(\delta))) = \big(a^{n+1}(\delta), h(a^{n+1}(\delta))\big) \quad \text{for all } n \in \mathbb{Z}$$

follows. From $(a^n(\delta), h(a^n(\delta))) \in W$, $n \in \mathbb{Z}$, we get

$$\big(a^{n+k}(\delta), h(a^{n+k}(\delta))\big)_{k=0}^{\infty} \in \mathbb{R}^2_{\eta_0} \quad \text{for all } n \in \mathbb{Z}.$$

These facts imply

$$(a^n(\delta), h(a^n(\delta))) \in W_\kappa \quad \text{for all } n \in \mathbb{Z}.$$

PROPOSITION 3.6. $G_\kappa(x^*, h(x^*)) \notin W$.

Proof. Assume $G_\kappa(x^*, h(x^*)) \in W$. Clearly, $G(x^*, h(x^*)) \in W$ because of the positive invariance of W with respect to G. We have

$$G(x^*, h(x^*)) = \begin{pmatrix} x^* + \left(\frac{x^*}{\sqrt{1-2x^{*2}}} - x^*\right) \rho\left(\frac{x^*}{\delta}\right) \\ eh(x^*) - e\int_0^1 \frac{e^{-s}x^{*2}}{1-2sx^{*2}} ds\, \rho\left(\frac{x^*}{\delta}\right) \end{pmatrix}$$

and

$$G_\kappa(x^*, h(x^*)) = \begin{pmatrix} x^* + \left(\frac{x^*}{\sqrt{1-2x^{*2}}} - x^*\right) \left(\rho\left(\frac{x^*}{\delta}\right) + \kappa\beta\left(\frac{x^*}{\delta}\right)\right) \\ eh(x^*) - e\int_0^1 \frac{e^{-s}x^{*2}}{1-2sx^{*2}} ds \left(\rho\left(\frac{x^*}{\delta}\right) + \kappa\beta\left(\frac{x^*}{\delta}\right)\right) \end{pmatrix}.$$

Using the fact that W is the graph of h, and h is Lipschitz continuous with Lipschitz constant 2, one gets

$$\left|\big(G(x^*, h(x^*))\big)_2 - \big(G_\kappa(x^*, h(x^*))\big)_2\right| \le 2\left|\big(G(x^*, h(x^*))\big)_1 - \big(G_\kappa(x^*, h(x^*))\big)_1\right|,$$

that is

$$e\int_0^1 \frac{e^{-s}x^{*2}}{1-2x^{*2}} ds\, \kappa\beta\left(\frac{x^*}{\delta}\right) \le 2\left(\frac{x^*}{\sqrt{1-2x^{*2}}} - x^*\right) \kappa\beta\left(\frac{x^*}{\delta}\right).$$

As $x^* > 0$, $\kappa > 0$, and $\beta(x^*/\delta) > 0$, the last inequality is equivalent to

$$e\int_0^1 \frac{e^{-s}}{-2sx^{*2}} ds \le \frac{4x^*}{\sqrt{1-2x^{*2}}(1+\sqrt{1-2x^{*2}})}.$$

By $0 < x* < 2\delta$ and the choice of δ,

$$1 < e\int_0^1 \frac{e^{-s}}{1-2sx^{*2}} ds \le \frac{4x^*}{\sqrt{1-2x^{*2}}(1+\sqrt{1-2x^{*2}})} \le 16\delta < \frac{e-2}{e},$$

a contradiction. Therefore, $G_\kappa(x^*, h(x^*)) \notin W$. ∎

Define $y^* \in (0, \delta/2)$ so that

$$(x^*, y^*) = G_\kappa^{-1}(a_\kappa(x^*), h(a_\kappa(x^*))).$$

Clearly, $G_\kappa(x^*, y^*) = (a_\kappa(x^*), h(a_\kappa(x^*))) \in W$. By Proposition 3.6, $y^* \neq h(x^*)$, that is

$$(x^*, y^*) \notin W.$$

Observe that $a_\kappa(x) \geq a(x)$ for all $x \in [0, 2\delta]$. Hence we get

$$a_\kappa(x^*) \geq a(x^*) > a(\delta),$$

and for each $n \in \mathbb{N}$,

$$a_\kappa^n(a_\kappa(x^*)) = a^n(a_\kappa(x^*)) > a(\delta).$$

This fact and the invariance of W combined give

$$\begin{aligned} G_\kappa^{n+1}(x^*, y^*) &= G_\kappa^n(G_\kappa(x^*, y^*)) = G^n\left(a_\kappa(x^*), h(a_\kappa(x^*))\right) \\ &= (a^n(a_\kappa(x^*)), h(a^n(a_\kappa(x^*)))) \in W \end{aligned}$$

for all $n \in \mathbb{N}$. It follows that

$$(G_\kappa^n(x^*, y^*))_0^\infty \in \mathbb{R}^2_{\eta_0}.$$

By the analogue of Proposition 3.4 for G_κ, $G_\kappa^{-n}(x^*, y^*) \in U$ is well defined for all $n \in \mathbb{N}$. Consequently,

$$G_\kappa^n(x^*, y^*) \in W_\kappa \quad \text{for all } n \in \mathbb{Z}.$$

We have

$$G_\kappa^n(x^*, y^*) = (a_\kappa^n(x^*), h_\kappa(a_\kappa^n(x^*))) \quad \text{for all } n \in \mathbb{Z}.$$

If $x \in [\delta, x^*]$, then $a_\kappa(x) \geq a(x) \geq a(\delta)$. Thus $a_\kappa^{-1}(x^*) < \delta$, and

$$a_\kappa^{-n}(x^*) < \delta \quad \text{for all } n \in \mathbb{N} \setminus \{0\}.$$

Since $\rho(x/\delta) = \rho_\kappa(x/\delta) = 1$ for $0 < x < \delta$, we obtain that

$$G_\kappa^{-n}(x^*, y^*) = G^{-n}(x^*, y^*) \quad \text{for all } n \in \mathbb{N}.$$

This equality, the positive invariance of W with respect to G, and $(x^*, y^*) \notin W$ combined yield

$$G_\kappa^{-n}(x^*, y^*) \notin W \quad \text{for all } n \in \mathbb{N}.$$

By the analogue of Proposition 3.5 for G_κ, $G_\kappa^{-n}(x^*, y^*) \to (0, 0)$ as $n \to \infty$ also holds.

For $\gamma \in (0, \delta)$, the sets

$$W(\gamma) = \{(x, h(x)) : |x| < \gamma\}, \quad W_\kappa(\gamma) = \{(x, h_\kappa(x)) : |x| < \gamma\}$$

are local center-stable manifolds of f. Set

$$W^+(\gamma) = \{(x, h(x)) : 0 < x < \gamma\}, \quad W_\kappa^+(\gamma) = \{(x, h_\kappa(x)) : 0 < x < \gamma\}.$$

PROPOSITION 3.7. *If $W(\gamma)$ and $W_\kappa(\gamma)$ are locally positively invariant with respect to Φ, then*

$$W^+(\gamma) = \{\Phi(t, \gamma, h(\gamma)) : t < 0\},$$
$$W_\kappa^+(\gamma) = \{\Phi(t, \gamma, h_\kappa(\gamma)) : t < 0\}.$$

Proof. We know that

$$G^n(\gamma, h(\gamma)) = (a^n(\gamma), h(a^n(\gamma))) \in W \quad \text{for all } n \in \mathbb{Z},$$

where $(a^n(\gamma))_{n\in\mathbb{Z}}$ is a strictly increasing sequence with $\lim_{n\to-\infty} a^n(\gamma) = 0$. It is also true that

$$G^{-n}(\gamma, h(\gamma)) = f^{-n}(\gamma, h(\gamma)) = \Phi(-n, \gamma, h(\gamma)) \in W(\gamma)$$

for all $n \in \mathbb{N} \setminus \{0\}$. Assume that $t_0 < 0$ and $\Phi(t_0, \gamma, h(\gamma)) \notin W^+(\gamma)$. Choose $n_0 \in \mathbb{N} \setminus \{0\}$ with $-n_0 < t_0 < -n_0 + 1$. Define

$$t_1 = \sup\left\{s \in [-n_0, t_0) : \Phi(s, \gamma, h(\gamma)) \in W^+(\gamma)\right\}.$$

Clearly, $-n_0 \le t_1 < t_0$ and

$$\Phi(t_1, \gamma, h(\gamma)) \in W^+(\gamma).$$

The local positive invariance of $W(\gamma)$ gives $t^* > 0$ so that $\Phi(s, \Phi(t_1, \gamma, h(\gamma))) = \Phi(t_1 + s, \gamma, h(\gamma)) \in W^+(\gamma)$ for all $s \in [0, t^*]$. This contradicts the definition of t_1. Consequently,

$$\{\Phi(t, \gamma, h(\gamma)) : t < 0\} \subset W^+(\gamma).$$

The inclusion $\{\Phi(t, \gamma, h(\gamma)) : t < 0\} \supset W^+(\gamma)$ follows from $\{\big(\Phi(t, \gamma, h(\gamma))\big)_1 : t < 0\} = (0, \gamma)$.

The proof for $W_\kappa^+(\gamma)$ is analogous. □

Finally, we can state the following.

PROPOSITION 3.8. *One of the local manifolds $W(\gamma)$ and $W_\kappa(\gamma)$ is not locally positively invariant with respect to Φ.*

Proof. Assume that both $W(\gamma)$ and $W_\kappa(\gamma)$ are locally positively invariant with respect to Φ. By Proposition 3.7 either

$$W^+(\gamma) = W_\kappa^+(\gamma)$$

or

$$W^+(\gamma) \cap W_\kappa^+(\gamma) = \emptyset$$

holds. On the other hand,

$$(a^n(\delta), h(a^n(\delta))) \in W \cap W_\kappa \quad \text{for all } n \in \mathbb{Z},$$
$$G_\kappa^{-n}(x^*, y^*) \in W_\kappa \setminus W \qquad \text{for all } n \in \mathbb{N},$$

and $\lim_{n\to-\infty} a^n(\delta) = 0$, $\lim_{n\to\infty} G_\kappa^{-n}(x^*, y^*) = (0, 0)$ combined imply

$$W^+(\gamma) \neq W^+_\kappa(\gamma)$$

and

$$W^+(\gamma) \cap W^+_\kappa(\gamma) \neq \emptyset,$$

which is a contradiction. □

We remark that in the above example W and W_κ are in fact the global center manifolds of G and G_κ, respectively, because of $E_s = \{(0,0)\}$. Then $W(\gamma)$ and $W_\kappa(\gamma)$, $\gamma \in (0,\delta)$, are local center manifolds of the time-1 map $\Phi(1,\cdot)$ at $(0,0)$. These local center manifolds depend on δ and ρ, ρ_κ, too. Thus, in the next result, where their dependence on the elements of $\mathcal{R}$ is considered, the notation $W_{\delta\rho}(\gamma)$ will be used instead of $W(\gamma)$.

PROPOSITION 3.9. *Let Φ, r, the norm $||\cdot||$ in $\mathbb{R}^2$, the family of mappings $\tilde{r}_{\delta\rho}$, $0 < \delta \leq \delta_1$, $\rho \in \mathcal{R}$, and the constants η_0, δ^{**} be given as above. Let $\delta \in (0, \delta^{**})$ be fixed so that* (3.4) *holds. Fix a $\gamma \in (0,\delta)$.*

Then the set of those elements $\rho \in \mathcal{R}$, for which the local center manifold $W_{\delta\rho}(\gamma)$ of the time-1 map $\Phi(1,\cdot)$ is not locally positively invariant with respect to Φ, is an open and dense subset of $\mathcal{R}$.

Proof. Let $\mathcal{Q}$ be the set of $\rho \in \mathcal{R}$ such that $W_{\delta\rho}(\gamma)$ is not locally positively invariant with respect to Φ.

If $\rho \in \mathcal{R} \setminus \mathcal{Q}$, then the above construction shows that for all sufficiently small $\kappa > 0$, $W_{\delta\rho_\kappa}(\gamma) \in \mathcal{Q}$. Thus, $\mathcal{Q}$ is dense in $\mathcal{R}$.

If $\rho \in \mathcal{Q}$, then there exist $u_0 \in W_{\delta\rho}(\gamma)$ and a $t_0 > 0$ such that $\Phi(t_0,u_0) \notin W_{\delta\rho}(\gamma)$ and $\left|\left(\Phi(t,u_0)\right)_1\right| < \gamma$ for all $t \in [0,t_0]$. There is an $\epsilon_1 > 0$ so that for every $u_1 \in \mathbb{R}^2$ with $|u_1 - u_0| < \epsilon_1$ we have $\operatorname{dist}(\Phi(t_0,u_1), W_{\delta\rho}(\gamma)) > \epsilon_1$, and $\left|\left(\Phi(t,u_1)\right)_1\right| < \gamma$ for all $t \in [0,t_0]$. By Proposition 2.2, there is $\epsilon_2 > 0$ such that for each $\zeta \in \mathcal{R}$ with $d(\rho,\zeta) < \epsilon_2$, $\operatorname{dist}(u_0, W_{\delta\zeta}(\gamma)) < \epsilon_1$ and $\operatorname{dist}(\Phi(t_0,u_1), W_{\delta\zeta}(\gamma)) > \epsilon_1/2$ for all $u_1 \in \mathbb{R}^2$ with $|u_1 - u_0| < \epsilon_1$. Let $\zeta \in \mathcal{R}$ be given with $d(\rho,\zeta) < \epsilon_2$, and choose $u_1 \in W_{\delta\zeta}(\gamma)$ such that $|u_1 - u_0| < \epsilon_1$. Then $\Phi(t_0,u_1) \notin W_{\delta\zeta}(\gamma)$ and $\left|\left(\Phi(t,u_1)\right)_1\right| < \gamma$ for all $t \in [0,t_0]$. Define

$$t_1 = \sup\{t \in [0,t_0] : \Phi(t,u_1) \in W_{\delta\zeta}(\gamma)\}.$$

It is easy to see that $t_1 < t_0$, $\Phi(t_1,u_1) \in W_{\delta\zeta}(\gamma)$, and $\Phi(t,u_1) \notin W_{\delta\zeta}(\gamma)$ for all $t \in (t_1,t_0]$. It follows that $W_{\delta\zeta}(\gamma)$ is not locally positively invariant under Φ. So, $\zeta \in \mathcal{Q}$. Therefore, $\mathcal{Q}$ is an open subset of $\mathcal{R}$. □

4. Invariance: An abstract functional differential equation. Let Φ be a C^k-smooth semiflow on the Banach space E with $\Phi(t,0) = 0$ for all $t \geq 0$. Fix $\tau > 0$. There exists an open neighborhood V of 0 in E so that the time-τ map $f = \Phi(\tau,\cdot)$ is defined on V. Let $L = Df(0)$, and assume that E has the decomposition and the exponential trichotomy with the norm $|\cdot|$ as described in section 2. Let $r : E \to E$ and the equivalent norm $||\cdot||$ on E also be given as in section 2.

The classical solution to the invariance problem consists in assuming that the semiflow can be modified outside a small neighborhood of the equilibrium point so that the modified semiflow is a small and Lipschitzian perturbation of the linearized semiflow, and taking as a modification of the time-τ map the time-τ map of the modified semiflow [5]. We formulate this as a proposition for the semiflow Φ with the conditions on the time-τ map f given in section 2. The proof is omitted since it is essentially the same as the proof in [5].

PROPOSITION 4.1. *Let Φ, L, and r be given as above. Assume that there is a $\delta^*>0$, and that for each $\delta \in (0,\delta^*]$ there exists a semiflow $\Phi_\delta : [0,\infty)\times E \to E$ such that*

(a) $\Phi_\delta|_{[0,\tau]\times E(\delta)} = \Phi|_{[0,\tau]\times E(\delta)}$ *for all* $\delta \in (0,\delta^*]$;

(b) *the family of mappings* $r_\delta := \Phi_\delta(\tau,\cdot) - L$, $0 < \delta \le \delta^*$, *satisfies hypotheses* (R1) *and* (R2);

(c) *for every* $\delta \in (0,\delta^*]$, *there exists* $K > 0$ *so that* $|\Phi_\delta(t,x)| \le K|x|$ *for all* $(t,x) \in [0,\tau]\times E$.

Then the C^k-smooth local center-stable manifold W^{cs}_{loc} of $\Phi(\tau,\cdot)$, given in Theorem 2.1, *is invariant with respect to Φ relative to $N_{sc}+N_u$.*

Analogous results can be stated for the local center-stable and center manifolds.

The paper [5] by Chen, Hale, and Tan contains several examples where a modification Φ_δ of Φ with the required properties in Theorem 4.1 can be obtained. All of these semiflows are generated by evolutionary equations, and a variation-of-constants formula is valid for the evolutionary equation.

Now we demonstrate the applicability of Proposition 4.1 to (1.1), which does not fall into the class of examples considered in [5] since a suitable variation-of-constants formula in the phase space is not known.

Consider the abstract semilinear functional differential equation

$$\dot u(t) = A_T u(t) + Bu_t + F(u_t) \tag{4.1}$$

in a Banach space X over $\mathbb{R}$, where $r \ge 0$, $C = C([-r,0];X)$ is the Banach space of continuous mappings from $[-r,0]$ into X with the supremum norm $||\cdot||_0$, $u_t \in C$ is defined by $u_t(\theta) = u(t+\theta)$ for $\theta \in [-r,0]$, $B : C \to X$ is a bounded linear operator, $A_T : D(A_T) \subset X \to X$ is the infinitesimal generator of a compact C_0-semigroup $(T(t))_{t\ge 0}$ of linear operators on X, $F : V_1 \to X$ is C^k-smooth, $k \in \mathbb{N}\setminus\{0\}$ on an open neighborhood V_1 of 0 in C, and $F(0) = 0$, $DF(0) = 0$.

The following results on the decomposition of C and on the existence and smoothness of solutions of (4.1) can be found in the works [13, 14, 29, 32]. For other results and applications of (4.1) we refer to [10, 11, 20, 21, 22, 28, 32].

For any $\phi \in C$ there exists a unique continuous function $u = u(\phi) : [-r,\infty) \to X$ such that

$$u(t) = T(t)\phi(0) + \int_0^t T(t-s)Bu_s\,ds, \quad t \ge 0,$$

and $u_0 = \phi$ holds. The operators $U(t) : C \to C$, given by $U(t)\phi = u_t(\phi)$, form a C_0-semigroup of bounded linear operators on C; moreover, $U(t)$ is compact for all $t > r$.

Fix $\tau > r$. Since $U(\tau)$ is compact, its spectrum $\sigma(U(\tau))$ consists of three disjoint compact sets σ_s, σ_c, and σ_u, where σ_s is contained in $\{z \in \mathbb{C} : |z| < 1\}$, and σ_c and σ_u are finite sets in $\{z \in \mathbb{C} : |z| = 1\}$ and $\{z \in \mathbb{C} : |z| > 1\}$, respectively. We assume $\sigma_c \ne \emptyset$. Set $a = \max_{\lambda\in\sigma_s}|\lambda|$ and $b = \min_{\lambda\in\sigma_u}|\lambda|$. As in section 2, $a = 1/2$ if $\sigma_s = \emptyset$, $b = 3/2$ if $\sigma_u = \emptyset$. Choose $\epsilon > 0$ with $a+\epsilon < 1$ and $(1+\epsilon)^k < b - \epsilon$. Let $\alpha = (1/\tau)\log(a+\epsilon)$, $\beta = (1/\tau)\log(b-\epsilon)$, $\kappa = (1/\tau)\log(1+\epsilon)$. The space C has the decomposition

$$C = C_s \oplus C_c \oplus C_u$$

into closed subspaces C_s, C_c, C_u of C so that C_c and C_u are finite-dimensional, the spaces C_s, C_c, and C_u are invariant under $U(t)$ for all $t \ge 0$, and $(U(t))_{t\ge 0}$ can be extended to a group on C_c and C_u. There exists a norm $|\cdot|$ on C which is equivalent to $||\cdot||_0$ and satisfies $|\phi| = |\operatorname{Pr}_{C_s}\phi| + |\operatorname{Pr}_{C_c}\phi| + |\operatorname{Pr}_{C_u}\phi|$ and

$$
\begin{aligned}
&|U(t)\,\mathrm{Pr}_{C_s}\,\phi| \le e^{\alpha t}|\,\mathrm{Pr}_{C_s}\,\phi| \quad (t \ge 0),\\
&|U(t)\,\mathrm{Pr}_{C_c}\,\phi| \le e^{\kappa|t|}|\,\mathrm{Pr}_{C_c}\,\phi| \quad (t \in \mathbb{R}),\\
&|U(t)\,\mathrm{Pr}_{C_u}\,\phi| \le e^{\beta t}|\,\mathrm{Pr}_{C_u}\,\phi| \quad (t \le 0)
\end{aligned} \tag{4.2}
$$

for all $\phi \in C$. In addition, $|\,\mathrm{Pr}_{C_s}\,| = |\,\mathrm{Pr}_{C_c}\,| = |\,\mathrm{Pr}_{C_u}\,| = 1$ also holds.

For any $\phi \in V_1$ there exist a maximal $t_\phi > 0$ and a unique continuous function $u^\phi : [-r, t_\phi) \to X$ such that $u_0^\phi = \phi$ and

$$u^\phi(t) = T(t)\phi(0) + \int_0^t T(t-s)\left[Bu_s^\phi + F(u_s^\phi)\right]\,ds$$

for all $t \in [0, t_\phi)$. The function u^ϕ is called the mild solution of (4.1) through $(0, \phi)$.

There is an open neighborhood $V_2 \subset V_1$ of 0 in C so that Ψ, given by $\Psi(t, \phi) = u_t^\phi$, is a C^k-smooth semiflow on V_2 with $\Psi(t, 0) = 0$ and $D_2\Psi(t, 0) = U(t)$ for all $t \ge 0$.

Let $V \subset V_2$ be an open neighborhood of 0 in C such that $[0, \tau] \times V$ is in the domain of Ψ. Define $R : C \to C$ so that $R(\phi) = \Psi(\tau, \phi) - U(\tau)\phi$ for $\phi \in V$ and $R(\phi) = 0$ for $\phi \in C \setminus V$.

Under the above assumptions, there exist C^k-smooth local center-stable, center-unstable, and center manifolds of the semiflow Ψ at 0. More precisely, we have the following.

THEOREM 4.2.

(i) *There exist convex open neighborhoods N_{sc} of 0 in C_{sc}, N_u of 0 in C_u, and a C^k-smooth map $w_{cs} : N_{sc} \to C_u$ so that $w_{cs}(0) = 0$, $Dw_{cs}(0) = 0$, $w_{cs}(N_{sc}) \subset N_u$, the set $W_{loc}^{cs} = \{z + w_{cs}(z) : z \in N_{sc}\}$ is invariant with respect to Ψ relative to $N_{sc} + N_u$, and*

$$\{\Psi(t, \phi) : t \ge 0\} \subset N_{sc} + N_u \quad \textit{implies} \quad \phi \in W_{loc}^{cs}.$$

(ii) *There exist convex open neighborhoods N_{cu} of 0 in C_{cu}, N_s of 0 in C_s, and a C^k-smooth map $w_{cu} : N_{cu} \to C_s$ so that $w_{cu}(0) = 0$, $Dw_{cu}(0) = 0$, $w_{cu}(N_{cu}) \subset N_s$, the set $W_{loc}^{cu} = \{z + w_{cu}(z) : z \in N_{cu}\}$ is invariant with respect to Ψ relative to $N_{cu} + N_s$, and for every backward trajectory $y : (-\infty, 0] \to C$ of Ψ,*

$$\{y(t) : t \le 0\} \subset N_{cu} + N_s \quad \textit{implies} \quad y(0) \in W_{loc}^{cu}.$$

(iii) *There exist convex open neighborhoods N_c of 0 in C_c, N_{su} of 0 in C_{su}, and a C^k-smooth map $w_c : N_c \to C_{su}$ so that $w_c(0) = 0$, $Dw_c(0) = 0$, $w_c(N_c) \subset N_{su}$, the set $W_{loc}^{c} = \{z + w_c(z) : z \in N_c\}$ is invariant with respect to Ψ relative to $N_c + N_{su}$, and for every trajectory $y : \mathbb{R} \to C$ of Ψ,*

$$\{y(t) : t \in \mathbb{R}\} \subset N_c + N_{su} \quad \textit{implies} \quad y(0) \in W_{loc}^{c}.$$

We show only statement (i) in Theorem 4.2 since the proof of (ii) is analogous, and (iii) is a consequence of (i) and (ii) by the proof of Theorem 5.4 in [13].

The proof of (i) *in Theorem* 4.2. Choose a norm $|\cdot|_{cu}$ on the finite-dimensional C_{cu} so that $|\cdot|_{cu}$ is C^∞-smooth on $C_{cu} \setminus \{0\}$. Then $||\phi|| = \max\{|\,\mathrm{Pr}_{C_s}\,\phi|, |\,\mathrm{Pr}_{C_{cu}}\,|_{cu}\}$, $\phi \in C$, defines a new norm on C which is equivalent to the norms $||\cdot||_0$ and $|\cdot|$ on C. There are positive constants c_1, c_2, c_3, c_4 such that $c_1|\phi| \le ||\phi|| \le c_2|\phi|$ and $c_3|\phi| \le ||\phi||_0 \le c_4|\phi|$ for all $\phi \in C$. For $\delta > 0$ let $C(\delta) = \{\phi \in C : ||\phi|| < \delta\}$.

Let $\rho \in \mathcal{R}$. Fix a $\gamma_0 > 0$ so that $C(2\gamma_0) \subset V$ and all lth derivatives, $l \in \{0, \dots, k\}$, of $F|_{C(2\gamma_0)}$ are bounded. Let $F^* : C \to X$ be an extension of F so that $F^*(\phi) = 0$ for $\phi \in C \setminus V_1$. For each $\gamma \in (0, \gamma_0]$ define $F_\gamma : C \to X$ by

$$F_\gamma(\phi) = F^*(\phi)\rho\left(\frac{|\operatorname{Pr}_{C_{cu}} \phi|_{cu}}{\gamma}\right)\rho\left(\frac{|\operatorname{Pr}_{C_s} \phi|}{\gamma}\right).$$

Then, for every $\gamma \in (0, \gamma_0]$, F_γ is C^k-smooth on the open set $\{\phi \in C : |\operatorname{Pr}_{C_s} \phi| < \gamma\}$, and all lth derivatives, $l \in \{0, \dots, k\}$, of $F_\gamma|_{\{\phi \in C : |\operatorname{Pr}_{C_s} \phi| < \gamma\}}$ are bounded.

There exits $\gamma_1 \in (0, \gamma_0]$ and a nondecreasing function $\mu : [0, \gamma_1] \to [0, 1]$ (the proof is the same as that of Proposition II.2 in [19]) with $\lim_{\gamma \to 0^+} \mu(\gamma) = 0 = \mu(0)$ such that for each $\gamma \in (0, \gamma_1]$ and for all ϕ, ψ in C,

$$||F_\gamma(\phi)||_X \le \gamma\mu(\gamma), \quad ||F_\gamma(\phi) - F_\gamma(\psi)||_X \le \mu(\gamma)||\phi - \psi||_0.$$

There exists a constant $M \ge 1$ so that $||B|| \le M$, and $||T(t)|| \le M$, $||U(t)|| \le M$ for all $t \in [0, \tau]$.

For each $\gamma \in (0, \gamma_1]$, consider the modification

$$\dot{u}(t) = A_T u(t) + Bu_t + F_\gamma(u_t) \tag{4.3}$$

of equation (4.1). By [32], for every $\phi \in C$ there exists a unique continuous function $u = u^{\phi,\gamma} : [-r, \infty) \to X$ so that $u_0 = \phi$ and

$$u(t) = T(t)\phi(0) + \int_0^t T(t-s)\left(Bu_s + F_\gamma(u_s)\right) ds$$

for all $t \ge 0$. The map

$$\Psi_\gamma : [0, \infty) \times C \ni (t, \phi) \mapsto u_t^{\phi,\gamma} \in C$$

is a global semiflow on C.

By the Gronwall inequality, from the integral equation of $u^{\phi,\gamma}$, it is easy to see that there exists $K \ge 1$ such that, for each $\gamma \in (0, \gamma_1]$,

$$|\Psi_\gamma(t, \phi)| \le K|\phi| \quad (t \in [0, \tau],\ \phi \in C). \tag{4.4}$$

Set $c = \max\{2, Kc_2/c_1\}$, and choose $\gamma_2 \in (0, \gamma_1]$ such that

$$\frac{c_4 + c}{c_3}\tau M^2 e^{2\tau M(M+1)}\mu(\gamma_2) < 1.$$

We state that for each $\gamma \in (0, \gamma_2]$,

$$|U(t)\phi - \Psi_\gamma(t, \phi)| < \frac{\gamma}{2} \quad (t \in [0, \tau],\ \phi \in C). \tag{4.5}$$

Set $u_s = U(s)\phi$ and $v_s = \Psi_\gamma(s, \phi)$ for $s \ge 0$. From the integral equations for u and v, we get

$$||u_t - v_t||_0 \le \int_0^t M(M||u_s - v_s||_0 + \gamma\mu(\gamma))\, ds \le \tau M\gamma\mu(\gamma) + \int_0^t M^2||u_s - v_s||_0\, ds$$

for $t \in [0, \tau]$. Gronwall's inequality yields

$$||u_t - v_t||_0 \le \tau M\gamma\mu(\gamma)e^{\tau M^2} < \frac{c_3}{c_4 + c}\gamma < \frac{c_3}{2}\gamma$$

for $t \in [0,\tau]$. Now (4.5) follows by the equivalence of the norms $||\cdot||_0$ and $|\cdot|$.

We claim that for each $\gamma \in (0,\gamma_2]$,

$$|\operatorname{Pr}_{C_s}\phi| < \frac{\gamma}{2} \quad \text{implies} \quad |\operatorname{Pr}_{C_s}\Psi_\gamma(t,\phi)| < \gamma$$

for all $t \in [0,\tau]$ and $\phi \in C$.

Applying (4.5) and the exponential trichotomy (4.2) for U, we get for every $t \in [0,\tau]$ and for all $\phi \in C$ with $|\operatorname{Pr}_{C_s}\phi| < \gamma/2$ that

$$\begin{aligned}|\operatorname{Pr}_{C_s}\Psi_\gamma(t,\phi)| &\le |\operatorname{Pr}_{C_s}(\Psi_\gamma(t,\phi) - U(t)\phi)| + |\operatorname{Pr}_{C_s}U(t)\phi| \\ &\le \frac{\gamma}{2} + e^{\alpha t}|\operatorname{Pr}_{C_s}\phi| < \frac{\gamma}{2} + \frac{\gamma}{2} = \gamma.\end{aligned}$$

The above result and the C^k-smoothness of $F_\gamma|_{\{\phi\in C:|\operatorname{Pr}_{C_s}\phi|<\gamma\}}$ makes it possible to prove, for each $t \in [0,\tau]$, that the map

$$\left\{\phi \in C : |\operatorname{Pr}_{C_s}\phi| < \frac{\gamma}{2}\right\} \ni \psi \mapsto \Psi_\gamma(t,\psi) \in C$$

is C^k-smooth. We omit the proof since it goes as that of Lemma 6.1 in [13].

For $\gamma \in (0,\gamma_2]$, define $R_\gamma : C \to C$ by

$$R_\gamma(\phi) = \Psi_\gamma(\tau,\phi) - U(\tau)\phi.$$

By a standard induction procedure it can be shown that all jth derivatives, $j \in \{0,\dots,k\}$, of R_γ are bounded on the open set $\{\phi \in C : |\operatorname{Pr}_{C_s}\phi| < \gamma/2\}$.

Finally we show that Proposition 4.1 can be applied with $E = C$, $\Phi = \Psi$, $L = U(\tau)$, $r = R$.

By the equivalence of the norms $|\cdot|$ and $||\cdot||$ in C, and by (4.4), the estimate

$$||\Psi_\gamma(t,\phi)|| \le c||\phi|| \quad (\phi \in C,\ t \in [0,\tau]) \tag{4.6}$$

holds with $c = \max\{2, Kc_2/c_1\}$.

Define $\delta^* = \gamma_2/c$, and for $\delta \in (0,\delta^*]$ set $\Phi_\delta = \Psi_{c\delta}$. Then $r_\delta = R_{c\delta}$, $\delta \in (0,\delta^*]$, and obviously $E(\delta^*) \subset V$.

Since $c\delta \le c\delta^* = \gamma_2$, $\Phi_\delta : [0,\infty)\times E \to E$ is a global semiflow for all $\delta \in (0,\delta^*]$. Hypothesis (c) of Proposition 4.1 follows from (4.4).

Let $\delta \in (0,\delta^*]$ be fixed. If $\phi \in C(\delta)$, that is $||\phi|| < \delta$, then by (4.6)

$$||\Phi_\delta(t,\phi)|| = ||\Psi_{c\delta}(t,\phi)|| \le c||\phi|| < c\delta \quad (0 \le t \le \tau).$$

Using $F_{c\delta}|_{C(c\delta)} = F|_{C(c\delta)}$, it follows that $F_{c\delta}(\Psi_{c\delta}(t,\phi)) = F(\Psi(t,\phi))$ for all $\phi \in C(\delta)$ and $t \in [0,\tau]$. Thus, for $\phi \in C(\delta)$, both $\Psi_{c\delta}(t,\phi)$ and $\Psi(t,\phi)$ satisfy the same integral equation on the interval $[0,\tau]$. By uniqueness, $\Psi_{c\delta}(t,\phi) = \Psi(t,\phi)$ follows for $0 \le t \le \tau$. As $\phi \in C(\delta)$ and $\delta \in (0,\delta^*]$ were arbitrary, hypothesis (a) of Proposition 4.1 is also satisfied.

We have $r_\delta = R_{c\delta} = \Psi_{c\delta}(\tau,\cdot) - U(\tau) = \Phi_\delta(\tau,\cdot) - L$, and thus, by using (a), we get $r_\delta|_{C(\delta)} = r|_{C(\delta)}$. For each $\delta \in (0,\delta^*]$, the map $R_{c\delta}|_{\{\phi\in C:|\operatorname{Pr}_{C_s}\phi|<c\delta/2\}}$ is C^k-smooth, and its jth derivatives, $j \in \{1,\dots,k\}$, are bounded. Since $\delta \le c\delta/2$ it follows that $r_\delta|_{\{\phi\in C:|\operatorname{Pr}_{C_s}\phi|<\delta\}}$ is C^k-smooth, and all jth derivatives, $j \in \{1,\dots,k\}$, of $r_\delta|_{\{\phi\in C:|\operatorname{Pr}_{C_s}\phi|<\delta\}}$ are bounded.

Define $\lambda : [0, \delta^*] \to \mathbb{R}$ by

$$\lambda(\delta) = \mu(c\delta)\frac{c_4 + c}{c_3}\tau M^2 e^{2\tau M(M+1)}.$$

Then λ is nondecreasing, $\lim_{\delta \to 0^+} \lambda(\delta) = 0 = \lambda(0)$, and by the choice of γ_2, $\lambda([0, \delta^*]) \subset [0, 1]$.

Above we obtained

$$||r_\delta(\phi)||_0 = ||R_{c\delta}(\phi)||_0 = ||\Psi_{c\delta}(\tau, \phi) - U(\tau)\phi||_0 \le \tau M e^{\tau M^2} c\delta\mu(c\delta) \le c_3\delta\lambda(\delta)$$

for all $\phi \in C$. Therefore, $|r_\delta(\phi)| \le \delta\lambda(\delta)$, $\phi \in C$.

Let $\phi, \psi \in C$, and set $u_t = U(t)\phi$, $\tilde{u}_t = U(t)\psi$, $v_t = \Psi_{c\delta}(t, \phi)$, $\tilde{v}_t = \Psi_{c\delta}(t, \psi)$ for $0 \le t \le \tau$. Then $u_0 = v_0 = \phi$, $\tilde{u}_0 = \tilde{v}_0 = \psi$. Using the integral equations for v and $\tilde{v}$, $v_0 = \phi$, $\tilde{v}_0 = \psi$, the Lipschitz continuity of $F_{c\delta}$, and $\mu(c\delta) \le 1$,

$$||v_t - \tilde{v}_t||_0 \le M||\phi - \psi||_0 + \int_0^t M(M+1)||v_s - \tilde{v}_s||_0\, ds$$

follows for $0 \le t \le \tau$. The Gronwall inequality yields

$$||v_t - \tilde{v}_t||_0 \le Me^{\tau M(M+1)}||\phi - \psi||_0 \quad (0 \le t \le \tau). \tag{4.7}$$

The integral equations for $u, \tilde{u}, v, \tilde{v}$, the Lipschitz continuity of $F_{c\delta}$, and inequality (4.7) combined give

$$\begin{aligned} ||r_\delta(\phi) - r_\delta(\psi)||_0 &= ||v_t - u_t - \tilde{v}_t + \tilde{u}_t||_0 \\ &\le \int_0^t M^2||v_s - u_s - \tilde{v}_s + \tilde{u}_s||_0\, ds + \int_0^t M\mu(c\delta)||v_s - \tilde{v}_s||_0\, ds \\ &\le \tau M^2 e^{\tau M(M+1)}\mu(c\delta)||\phi - \psi||_0 + \int_0^t M^2||v_s - u_s - \tilde{v}_s + \tilde{u}_s||_0\, ds \end{aligned}$$

for $0 \le t \le \tau$. The Gronwall inequality implies

$$||r_\delta(\phi) - r_\delta(\psi)||_0 \le \tau M^2 e^{2\tau M(M+1)}\mu(c\delta)||\phi - \psi||_0,$$

that is

$$|r_\delta(\phi) - r_\delta(\psi)| \le \frac{c_4}{c_3}\tau M^2 e^{2\tau M(M+1)}\mu(c\delta)|\phi - \psi| \le \lambda(\delta)|\phi - \psi|.$$

Therefore, the family of mappings r_δ, $0 < \delta \le \delta^*$, satisfies hypotheses (R1) and (R2), and thus condition (b) in Proposition 4.1 holds.

Clearly, (4.2) implies that (2.1) is satisfied with $E = C$ and $L = U(\tau)$. Consequently, we can apply Theorem 2.1 with some fixed η_0 and $\delta \in (0, \delta^{**})$ to get a center-stable manifold W^{cs}_{loc} of the time-τ map $\Psi(\tau, \cdot)$ at 0 as described in statements (i) and (ii) of Theorem 2.1. The invariance of W^{cs}_{loc} with respect to Ψ relative to $N_{sc} + N_u$ is guaranteed by Proposition 4.1.

Assume that $\{\Psi(t, \phi) : t \ge 0\} \subset N_{sc} + N_u$ for some $\phi \in C$. Then $(\Psi(n\tau, \phi))_0^\infty$ is a trajectory of the time-τ map $\Psi(\tau, \cdot)$ in $N_{sc} + N_u$. Theorem 2.1 implies that $\phi \in W^{cs}_{loc}$. This completes the proof. □

Remarks. 1. Some conditions in Theorem 4.2 could be relaxed—for example, the compactness assumption on the semigroup $T(t)$. However, such a generalization is not necessary for handling the motivating example (1.2), (1.3).

2. Theorem 4.2 shows that a variation-of-constants formula in the space X is sufficient to apply the classical approach of [5]; it is not necessary to have a variation-of-constants formula in the phase space $C([-r,0];X)$.

3. Recently Hino et al. [15] proved a "limiting variation-of-constants formula" for (1.1) in the phase space $C([-r,0];X)$, and Murakami and Minh [23] used it to get some Lipschitz continuous invariant manifolds. However, it is not clear whether the variation-of-constants formula of [15] is suitable for a proof of smooth local center-stable, center-unstable, and center manifolds of (1.1) at 0.

4. The very recent paper of Minh and Wu [24] constructs smooth local center-unstable and center manifolds (but not center-stable manifolds) for (1.1) by using the graph transform method.

Acknowledgment. The author thanks the referees for their useful comments and suggestions.

SUPER-BROWNIAN MOTION WITH EXTRA BIRTH AT ONE POINT*

KLAUS FLEISCHMANN† AND CARL MUELLER‡

Abstract. A super-Brownian motion in two and three dimensions is constructed where "particles" give birth at a higher rate, if they approach the origin. This contradicts the intuition suggested by the fact that in more than one dimension Brownian particles do not hit a given point. Via a log-Laplace approach, the construction is based on the work of Albeverio, Brzeźniak, and Dabrowski [*J. Funct. Anal.*, 130 (1995), pp. 220–254], who calculated the fundamental solutions of the heat equation with one-point potential in dimensions less than four.

Key words. super-Brownian motion, measure-valued process, heat equation, singular potential, one-point potential, $(1+\beta)$-branching, log-Laplace approach

AMS subject classifications. Primary, 60J80; Secondary, 60K35

1. Introduction.

1.1. Motivation and background. Measure-valued branching processes, also called superprocesses, arise naturally as limits of particle branching Markov processes. There is an immense literature on this topic; see any of the expositions [Daw93, Dyn94, LG99, Eth00, Per02], for example. Since these models involve mainly "noninteracting particles," many powerful tools are available, and many detailed properties of these processes are known. Building on this success, many probabilists have turned their attention to more complicated models, many of which are governed by singularities. For example, in two or more dimensions, with probability 1, continuous super-Brownian motion takes values in the space of measures whose closed support has Lebesgue measure 0. Nevertheless, in certain situations, pairs of such processes can kill each other when the corresponding "particles" meet (see, e.g., [EP94]).

Another example of singular behavior is catalytic branching. Here, the branching of the "particles" is controlled by a catalytic measure; the higher the "density" of this measure, the faster the "particles" branch or die. This catalytic measure can be supported on a set of Lebesgue measure 0, as long as it is not a polar set of Brownian motion. In other words, individual "particles" must have a positive probability of "hitting the measure." See, e.g., [DF95, Del96, FK99, Kle00].

A further example of singular behavior is mass creation. One could imagine a "mass creation measure," which would give rise to new "particles" whenever the "particles" of the superprocess hit the support of the measure. For the extreme case of a single point source δ_0 in R, see [EF00, ET02]. In particular, a continuous super-Brownian motion in R with a point source makes sense. In higher dimensions, however,

at first sight one would expect that a super-Brownian motion with single-point mass creation degenerates to ordinary super-Brownian motion, since the Brownian particles do not hit a given point.

Our goal is to disprove this intuition. But first, we mention a deterministic, "one-particle model," which already gives a different picture. This model was developed by mathematical physicists starting in the 1930s; see Albeverio et al. [AGHKH88] for historical background.

Consider the heat equation in R^d with a one-point potential:

$$\frac{\partial u}{\partial t} = \Delta u + \delta_0^{(\alpha)} u =: \Delta^{(\alpha)} u \tag{1.1}$$

(by $f := g$ or $g =: f$, we mean that f is defined to be equal to g). Heuristically, $\Delta^{(\alpha)} = \Delta + \delta_0^{(\alpha)}$ is the limit as $\varepsilon \downarrow 0$ of the operator

$$\Delta_\varepsilon^{(\alpha)} := \Delta + h(d, \alpha, \varepsilon)\varepsilon^{-d} \mathbf{1}_{B_\varepsilon(0)}, \tag{1.2}$$

where $B_\varepsilon(y)$ denotes the open ball around $y \in \mathsf{R}^d$ with radius ε, and $h(d, \alpha, \varepsilon)$ is some additional rescaling factor, depending on a parameter α, at least.

For instance, in dimension $d = 3$,

$$h(3, \alpha, \varepsilon) := \left(k + \frac{1}{2}\right)^2 \pi^2 \varepsilon - 8\pi^2 \alpha \varepsilon^2 - \zeta \varepsilon^3, \quad \alpha \in \mathsf{R},\ \varepsilon > 0, \tag{1.3}$$

where k is any integer and ζ any real number (we rely on [AGHKH88, (H.74)]). Then, in a sense, $\Delta_\varepsilon^{(\alpha)} \to \Delta^{(\alpha)}$ as $\varepsilon \downarrow 0$, where the limit operator $\Delta^{(\alpha)}$ is *independent* of k and ζ (so for simplification one could set $k = 0 = \zeta$).

Actually, in the physics literature, primary attention is paid to the Schrödinger equation, not the heat equation (and the positive definite operator $-\Delta$ is preferred instead of Δ). But note that in the time-stationary case, the Schrödinger and heat equations coincide. So the operators $\Delta^{(\alpha)}$ are relevant in both cases. Physically, the parameter α is related to the "scattering length" $(4\pi\alpha)^{-1}$ (see, for instance, [AGHKH88, p. 13]). In particular, $\Delta^{(\alpha)} \to \Delta$ as $\alpha \uparrow \infty$, giving the "free" case. We understand $\delta_0^{(\alpha)}$ as $\lambda_\alpha \delta_0$. In dimension $d = 3$ the coupling constant λ_α of the point source δ_0 has to be of the form $\lambda_\alpha = \varepsilon - \alpha\varepsilon^2$ with ε "infinitesimal" in a special way.

Even though the number of particles that hit the origin is infinitesimal, one can imagine that they give raise to a positive mass, provided that the birth rate is high enough. This explains why the linear ε-term in (1.3) is not allowed to be too small; in particular, it cannot be negative. In the latter case, particles will simply die, and nothing else will happen. But since there are only infinitesimally many particles hitting the origin, their possible deaths will pass unnoticed.

At this point we would like to understand certain questions from a probabilistic point of view. For instance, in dimensions $d = 3$, why don't all sufficiently high coefficients of the linear ε-term occur, and why is the limit operator $\Delta^{(\alpha)}$ independent of the integer k? Unfortunately, this is outside the scope of the present paper.

Strictly speaking, $\{\Delta^{(\alpha)} : \alpha \in \mathsf{R}\} \cup \{\Delta\}$ is the family of all self-adjoint extensions on $\mathcal{L}^2(\dot{\mathsf{R}}^d, \mathrm{d}x)$, $d = 2, 3$, of the Laplacian Δ acting on $\mathcal{C}_0^{(\infty)}(\dot{\mathsf{R}}^d)$, where $\dot{\mathsf{R}}^d := \mathsf{R}^d \backslash \{0\}$. See, for instance, [AGHKH88, Chapters I.1 and I.5]. We mention that in dimension one there is a 4-parameter family of extensions instead (see [ABD95]), whereas for $d \geq 4$ there is no other extension than the Laplacian Δ.

The *fundamental solutions* P^α to equation

$$\frac{\partial u}{\partial t} = \Delta^{(\alpha)} u \quad \text{on} \quad (0,\infty) \times \dot{\mathsf{R}}^d, \quad d = 2, 3, \tag{1.4}$$

have been computed in [ABD95]. P^α is different from the heat kernel for each $\alpha \in \mathsf{R}$ (only for $\alpha \uparrow \infty$ one gets back the heat kernel; for the case $d = 3$, see subsection 2.4 below). P^α is a basic object in the present paper.

1.2. Sketch of result. Based on the preceding analytical results from [ABD95], the *purpose* of the present paper is to construct a measure-valued super-Brownian motion $X = \{X_t : t \geq 0\}$ in $\dot{\mathsf{R}}^d = \mathsf{R}^d \backslash \{0\}$, $d = 2, 3$,[1] related to the formal log-Laplace equation

$$\begin{cases} \dfrac{\partial v}{\partial t} = \Delta^{(\alpha)} v - \eta v^{1+\beta} \quad \text{on} \quad (0,\infty) \times \dot{\mathsf{R}}^d, \\ \qquad v(0+, x) = \varphi(x) \geq 0, \quad x \in \dot{\mathsf{R}}^d, \end{cases} \tag{1.5}$$

with constants $0 < \beta \leq 1$, $\eta \geq 0$, and where the φ are appropriate test functions. Of course, X is related to (1.5) via the log-Laplace transition functional

$$-\log \mathbf{P}\{\mathrm{e}^{-\langle X_t, \varphi \rangle} \mid X_0\} = \langle X_0, v(t, \cdot) \rangle, \quad t > 0, \tag{1.6}$$

of the Markov process X.

Roughly speaking, we have "many" independent Brownian "particles" which everywhere undergo critical branching with index $1+\beta$ and rate η, but additionally give birth to new particles if they "approach" the origin 0.

Here is a rough formulation of our main result; a more precise statement will be given in Theorem 4.4 in subsection 4.3 below.

THEOREM 1.1 (existence of X). *If $d = 2$, then let $0 < \beta \leq 1$, and if $d = 3$, let $0 < \beta < 1$. Then, for each $\alpha \in \mathsf{R}$, there is a (unique in law) nondegenerate measure-valued (time-homogeneous) Markov process $X = X^\alpha$ having log-Laplace transition functional* (1.6) *with v solving* (1.5).

We call X a *super-Brownian motion in R^d with extra birth at point $x = 0$*. Note that in the case $\eta = 0$, the process degenerates to the deterministic mass flow related to the kernels P^α, the fundamental solutions to (1.4). At the same time, this mass flow is identical to the expectation of X for any η. In particular, $X = X^\alpha$ is different from ordinary super-Brownian motion (corresponding to $\alpha = \infty$).

Remark 1.2 (open problem). The condition $\beta < 1$ in the three-dimensional case, which excludes finite variance branching as in continuous super-Brownian motion, looks a bit strange. We need this condition for technical reasons, to handle some singularities at the point $x = 0$ where extra birth occurs (see Remark 2.8 below).

It would, of course, be interesting to reveal that this superprocess X has strange new properties. However, we leave this task for a future paper (see [FV04]) and present this construction result separately, since it seems to be interesting enough.

[1] Recall that the one-dimensional super-Brownian motion with extra birth at 0, that is, related to the log-Laplace equation

$$\frac{\partial v}{\partial t} = \frac{1}{2}\Delta v + \delta_0 - v^2 \quad \text{on} \quad (0,\infty) \times \mathsf{R},$$

was introduced in [EF00].

1.3. Outline. In section 2 we give some estimates involving the basic solutions P^α and the semigroup related to the linear equation (1.4). This semigroup is not Markovian in the usual sense, since the integral of the kernel P^α is greater than 1. Then, in section 3, we show that the log-Laplace equation (1.5) is well posed. Here we use Picard iteration, but for the nonnegativity of solutions we go back to a linearized equation. For the construction of X in section 4 we use a Trotter product formula, alternating between purely continuous-state branching (Feller's branching diffusion if $\beta = 1$) and deterministic mass flow with single-point mass creation (related to the kernels P^α).

For background from a mathematical physics point of view concerning the operators $\Delta^{(\alpha)}$ we recommend [AGHKH88], and for basic facts on superprocesses we refer to one of the systematic treatments [Daw93, Dyn94, LG99, Eth00, Per02], which we have already mentioned.

2. The heat equation with birth at a single point. After introducing the set Φ of test functions, on which the heat flow acts continuously (Lemma 2.4), we define the kernel P^α in subsection 2.4 and show the strong continuity of the related flow S^α on Φ (Corollary 2.10).

2.1. Preliminaries: Test functions and measures. The letter C denotes a constant which might change its value from occurrence to occurrence. $C_\#$ and $C_{(\#)}$ refer to specific constants which are defined around Lemma #, say, or formula (#), respectively.

Let ϕ denote the *weight and reference function*

$$\phi(x) := |x|^{-(d-1)/2}, \quad x \in \dot{\mathsf{R}}^d = \mathsf{R}^d \backslash \{0\}. \tag{2.1}$$

For each fixed constant $\varrho \geq 1$, we introduce the Lebesgue space $\mathcal{H} = \mathcal{H}^\varrho = \mathcal{L}^\varrho(\dot{\mathsf{R}}^d, \phi(x)\mathrm{d}x)$ of equivalence classes φ of measurable functions on $\dot{\mathsf{R}}^d$ for which $\|\varphi\|_{\mathcal{H}} < \infty$, where[2]

$$\|\varphi\|_{\mathcal{H}} := \left(\int_{\mathsf{R}^d} \mathrm{d}x \phi(x) |\varphi|^\varrho(x) \right)^{1/\varrho}. \tag{2.2}$$

(As usual, we do not distinguish between an equivalence class and its representatives.)

For fixed $\varrho \geq 1$, let $\Phi = \Phi^\varrho$ denote the set of all *continuous* functions $\varphi : \dot{\mathsf{R}}^d \to \mathsf{R}$ such that $\varphi \in \mathcal{H}$ and

$$0 \leq \varphi \leq C_{(2.3)}\phi \quad \text{for some constant } C_{(2.3)} = C_{(2.3)}(\varphi). \tag{2.3}$$

We endow Φ with the topology inherited from $\mathcal{H}$. Note that the set $\mathcal{C}^+_{\mathrm{com}} = \mathcal{C}^+_{\mathrm{com}}(\dot{\mathsf{R}}^d)$ of all nonnegative continuous functions on $\dot{\mathsf{R}}^d$ with compact support is contained in Φ. Note also that $\varphi \in \Phi$ might have a singularity at $x = 0$ of order $|x|^{-\xi}$ with $0 < \xi < \frac{d-1}{2} \wedge \frac{d+1}{2\varrho}$. (Later, in Hypothesis 3.2, we will restrict ϱ to be less than $\frac{d+1}{d-1}$; then at least the singularity orders $\xi < \frac{d-1}{2}$ are allowed.) The functions in Φ will serve as test functions in log-Laplace representations.

Let $\mathcal{M} = \mathcal{M}(\dot{\mathsf{R}}^d)$ denote the set of all measures μ defined on $\dot{\mathsf{R}}^d$ such that $\langle \mu, \varphi \rangle := \int_{\mathsf{R}^d} \mu(\mathrm{d}x)\varphi(x) < \infty$ for all $\varphi \in \Phi$. We equip $\mathcal{M}$ with the vague topology (recall that

[2]Here and in similar cases we use this simplified integration domain R^d, since in the case of integration with respect to Lebesgue measure, including or not including the point $0 \in \mathsf{R}^d$ of singularity makes no difference.

$\mathcal{C}^+_{\rm com} \subset \Phi$). Of course, each measure $\mu \in \mathcal{M}$ can also be considered as a measure on R^d with zero mass at $0 \in \mathsf{R}^d$. But in our pairing $\langle \mu, \varphi \rangle$, $\varphi \in \Phi$, we cannot extend to work with measures μ on R^d allowing positive mass at 0 by the mentioned possible singularities of the $\varphi \in \Phi$.

If μ is a finite measure, we write $\|\mu\|$ for its total mass. The symbol ℓ denotes the Lebesgue measure, $A^{\rm c}$ the complement of A, and $a \vee b$ the maximum of a and b.

2.2. Heat flow estimates on $\mathcal{H}$. In this subsection we fix a dimension $d \geq 1$. Let $P = P(t; x, y)$ refer to the fundamental solution of the heat equation

$$\frac{\partial u}{\partial t} = \Delta u \quad \text{on} \quad (0, \infty) \times \mathsf{R}^d. \tag{2.4}$$

In other words,

$$P(t; x, y) = (4\pi t)^{-d/2} \mathrm{e}^{-|y-x|^2/4t}, \quad t > 0,\ x, y \in \mathsf{R}^d. \tag{2.5}$$

Let $S = \{S_t : t \geq 0\}$ denote the semigroup corresponding to this heat kernel P.

Here is our first estimate (with ϕ the weight and reference function introduced in (2.1)).

LEMMA 2.1 (a heat flow estimate). *There is a constant $C_{2.1} = C_{2.1}(d)$ such that*

$$S_t \phi \leq C_{2.1} \phi, \quad t \geq 0. \tag{2.6}$$

Proof. Without loss of generality, let $t > 0$ and $x \neq 0$. We have to show that

$$\frac{1}{\phi(x)} S_t \phi(x) = \frac{1}{\phi(x)} \int_{\mathsf{R}^d} \mathrm{d}y \phi(y) \frac{1}{(4\pi t)^{d/2}} \mathrm{e}^{-|y-x|^2/4t} \tag{2.7}$$

is bounded in $t > 0$ and $x \neq 0$. By the change of variables $w := t^{-1/2}(y - x)$, and with the notation $z := -t^{-1/2} x$, we get

$$\frac{1}{\phi(x)} S_t \phi(x) = C \int_{\mathsf{R}^d} \mathrm{d}w \phi((w - z)/z) \mathrm{e}^{-|w|^2/4}. \tag{2.8}$$

We have to show that the right-hand side is bounded in $z \neq 0$. If we restrict the integration to $|w| \leq |z|/2$, then $|w - z| \geq |z|/2$, implying $\phi((w - z)/z) \leq 2^{(d-1)/2}$, and the whole restricted integral is bounded by a constant. On the other hand, if we restrict the integration to $|w| > |z|/2$, the exponential expression can be estimated from above by $\mathrm{e}^{-|z|^2/32} \mathrm{e}^{-|w|^2/8}$, and for the restricted integral we get the upper bound

$$C \int_{\mathsf{R}^d} \mathrm{d}w \phi(w - z) \mathrm{e}^{-|w|^2/8}. \tag{2.9}$$

But this integral is bounded in z. To see this, distinguish between $|w - z| \leq 1$ and $|w - z| > 1$. This completes the proof. □

We finish this subsection with a simple maximization result.

LEMMA 2.2 (maximum in the center). *Fix a constant $\varkappa > 0$. Then*

$$S_t \phi^\varkappa(x) \leq S_t \phi^\varkappa(0), \quad t > 0,\ x \in \mathsf{R}^d. \tag{2.10}$$

Proof. We will use the fact that in the integral

$$\int_{\mathsf{R}^d} \mathrm{d}y P(t; x, y) \phi^\varkappa(y) \tag{2.11}$$

the mapping $y \mapsto \phi^{\varkappa}(y)$ is radially symmetric and decreasing in $|y|$. The same is true for $y \mapsto P(t;x,y)$, except for a shift by x.

Step 1 (*simplification*). Let $a,b,c,d \geq 0$. Then, by expanding,

$$(a+b)(c+d)+ac \geq (a+b)c+a(c+d). \tag{2.12}$$

Step 2 (*functions with n steps*). For $n \geq 2$, let

$$f_i := \sum_{j=1}^{n} a_{i,j} 1_{B_j} \geq 0, \quad i=1,2, \tag{2.13}$$

be two step functions defined on $n \geq 2$ cubes $B_1,\dots,B_n$ in R^d of equal volume, say v. For $i=1,2$, let $\bar{f}_i$ be constructed from f_i by rearranging the $a_{i,j}$ to $\bar{a}_{i,1} \geq \cdots \geq \bar{a}_{i,n}$. Then

$$\int_{\mathsf{R}^d} \mathrm{d}x \bar{f}_1(x)\bar{f}_2(x) \geq \int_{\mathsf{R}^d} \mathrm{d}x f_1(x)f_2(x). \tag{2.14}$$

In fact,

$$\int_{\mathsf{R}^d} \mathrm{d}x f_1(x)f_2(x) = \mathrm{v}\sum_{j=1}^{n} a_{1,j}a_{2,j}. \tag{2.15}$$

Rearranging if necessary, we may assume that $f_1 = \bar{f}_1$, that is, $a_{1,j} = \bar{a}_{1,j}$, $1 \leq j \leq n$. Exploiting Step 1, we may switch from f_2 to $\bar{f}_2$ by a sequence of rearrangements which never decrease the integral in (2.15). This then gives the claim (2.14).

Step 3 (*approximation*). We may assume that the right-hand side of (2.10) is finite. Then the "integrals" in (2.10) (recall (2.11)) can be approximated by using step functions as in (2.13). Then (2.10) follows from (2.14) by passing to the limit. □

2.3. Strong continuity of the heat flow on $\mathcal{H}$. Next we will prove the following statement.

LEMMA 2.3 (estimate of S in case of an additional singularity). *Let $d \geq 1$, $0 \leq \beta \leq 1$, and assume that ϱ in* (2.2) *satisfies*

$$\varrho > \frac{1}{1-\beta(d-1)/2d}. \tag{2.16}$$

Then there is a constant $C_{2.3} = C_{2.3}(d,\beta,\varrho)$ such that for all $\varphi \in \mathcal{H} = \mathcal{H}^{\varrho}$,

$$\|S_t(\varphi\phi^{\beta})\|_{\mathcal{H}}^{\varrho} \leq C_{2.3}t^{-\beta\varrho(d-1)/4}\|\varphi\|_{\mathcal{H}}^{\varrho}, \quad t>0. \tag{2.17}$$

Proof. Fix d, β, ϱ as in the lemma. For $t>0$ and $x \in \mathsf{R}^3$, we introduce the measures

$$\mu_{t,x}(\mathrm{d}y) := t^{\kappa}P(t;x,y)\phi^{\lambda}(y)\mathrm{d}y, \tag{2.18}$$

with

$$\kappa := \frac{\beta\varrho(d-1)}{4(\varrho-1)} \quad \text{and} \quad \lambda := \frac{\beta\varrho}{\varrho-1}. \tag{2.19}$$

By Lemma 2.2,

$$\|\mu_{t,x}\| \leq \|\mu_{t,0}\| = \int_{\mathsf{R}^d} \mathrm{d}y P(1;0,y)\phi^{\lambda}(y) =: C_{(2.20)}, \tag{2.20}$$

where in the last step we used Brownian scaling and the identity $\kappa - \lambda(d-1)/4 = 0$. Note that $C_{(2.20)} = C_{(2.20)}(d, \beta, \varrho)$ is finite by our assumption (2.16). Therefore, the measures $\mu_{t,x}$ are finite with total mass at most $C_{(2.20)}$ independent of t and x. Now, for each finite measure μ on R^d, and for measurable φ, by Hölder's inequality,

$$\left[\int_{\mathsf{R}^d} |\varphi|(y)\mu(\mathrm{d}y)\right]^{\varrho} \le \|\mu\|^{\varrho-1} \int_{\mathsf{R}^d} \mu(\mathrm{d}y)|\varphi|^{\varrho}(y). \tag{2.21}$$

Applied to the measures $\mu_{t,x}$ we get

$$\begin{aligned} |S_t(\varphi\phi^\beta)(x)|^\varrho &= t^{-\kappa\varrho}\left|\int_{\mathsf{R}^d} \mu_{t,x}(\mathrm{d}y)\phi^{\beta-\lambda}(y)\varphi(y)\right|^\varrho \\ &\le t^{-\kappa\varrho}\|\mu_{t,x}\|^{\varrho-1}\int_{\mathsf{R}^d} \mu_{t,x}(\mathrm{d}y)\phi^{(\beta-\lambda)\varrho}(y)|\varphi|^\varrho(y) \\ &\le t^{-\kappa(\varrho-1)}C_{(2.20)}^{\varrho-1} S_t|\varphi|^\varrho(x), \end{aligned} \tag{2.22}$$

since $\lambda + (\beta - \lambda)\varrho = 0$ by (2.19). But by Lemma 2.1,

$$\begin{aligned} \int_{\mathsf{R}^d} \mathrm{d}x\phi(x)S_t|\varphi|^\varrho(x) &= \int_{\mathsf{R}^d} \mathrm{d}y|\varphi|^\varrho(y)S_t\phi(y) \\ &\le \int_{\mathsf{R}^d} \mathrm{d}y|\varphi|^\varrho(y)C_{2.1}\phi(y) = C_{2.1}\|\varphi\|_{\mathcal{H}}^\varrho. \end{aligned} \tag{2.23}$$

Hence,

$$\|S_t(\varphi\phi^\beta)\|_{\mathcal{H}}^\varrho \le t^{-\kappa(\varrho-1)}C_{(2.20)}^{\varrho-1}C_{2.1}\|\varphi\|_{\mathcal{H}}^\varrho, \tag{2.24}$$

and the claim follows since $\kappa(\varrho - 1) = \beta\varrho(d-1)/4$. □

Lemma 2.3 with $\beta = 0$ yields the following result.

LEMMA 2.4 (strong continuity of the heat flow on $\mathcal{H}$). *The semigroup S acting on $\mathcal{H} = \mathcal{H}^\varrho$ is strongly continuous.*

Proof. Fix $\varphi \in \mathcal{H}$. By linearity, we may assume that $\varphi \ge 0$. Consider $t \in (0, 1]$.

Step 1 (*reducing to bounded functions on compact sets*). Fix $\varepsilon \in (0, 1]$. We choose a compact set $K \subset \mathsf{R}^d$ so large that $\|\varphi 1_{K^c}\|_{\mathcal{H}} < \varepsilon$, and then a number $N \ge 1$ such that $\|\varphi 1_K 1_{\{\varphi > N\}}\|_{\mathcal{H}} < \varepsilon$. Then

$$\begin{aligned} \|S_t\varphi - \varphi\|_{\mathcal{H}} &\le \|S_t(\varphi 1_{K^c}) - \varphi 1_{K^c}\|_{\mathcal{H}} + \|S_t(\varphi 1_K 1_{\{\varphi>N\}}) - \varphi 1_K 1_{\{\varphi>N\}}\|_{\mathcal{H}} \\ &\quad + \|S_t(\varphi 1_K 1_{\{\varphi\le N\}}) - \varphi 1_K 1_{\{\varphi\le N\}}\|_{\mathcal{H}} \\ &\le C\varepsilon + \|S_t(\varphi 1_K 1_{\{\varphi\le N\}}) - \varphi 1_K 1_{\{\varphi\le N\}}\|_{\mathcal{H}}, \end{aligned} \tag{2.25}$$

where in the last step we used twice Lemma 2.3 with $\beta = 0$. Thus, for the rest of the proof we may assume that φ is bounded by $N \ge 1$ and vanishes outside a compact set $K \subset \mathsf{R}^d$. That is, from now on in this proof we assume that R^d is replaced by K in the definition of $\mathcal{H}$.

Step 2 (*passing to a continuous function*). Fix $\varepsilon \in (0, 1]$. Choose a continuous nonnegative function $f_\varepsilon \le N$ (on K) such that $\varphi = f_\varepsilon$ on a measurable set $A_\varepsilon \subseteq K$ satisfying $\ell(A_\varepsilon^c) \le \varepsilon$. Then, again by twice applying Lemma 2.3 with $\beta = 0$,

$$\begin{aligned} \|S_t\varphi - \varphi\|_{\mathcal{H}} &\le \|S_t(\varphi 1_{A_\varepsilon^c}) - \varphi 1_{A_\varepsilon^c}\|_{\mathcal{H}} + \|S_t(f_\varepsilon 1_{A_\varepsilon}) - f_\varepsilon 1_{A_\varepsilon}\|_{\mathcal{H}} \\ &\le C\|\varphi 1_{A_\varepsilon^c}\|_{\mathcal{H}} + C\|f_\varepsilon 1_{A_\varepsilon^c}\|_{\mathcal{H}} + \|S_t f_\varepsilon - f_\varepsilon\|_{\mathcal{H}}. \end{aligned} \tag{2.26}$$

For $x \in K$ fixed, $S_t f_\varepsilon(x) \to f_\varepsilon(x)$ as $t \downarrow 0$,

$$\sup_{t \geq 0} \|S_t f_\varepsilon\|_\infty \leq \|f_\varepsilon\|_\infty < \infty \tag{2.27}$$

(with $\|\cdot\|_\infty$ denoting the supremum norm), and ϕ is integrable on K. Hence, by dominated convergence, the third term in (2.26) will vanish as $t \downarrow 0$ for fixed ε. On the other hand, $\|\varphi 1_{A_\varepsilon^c}\|_{\mathcal{H}}$ converges to 0 as $\varepsilon \downarrow 0$. Finally, the same is true for $\|f_\varepsilon 1_{A_\varepsilon^c}\|_{\mathcal{H}}$ since $f_\varepsilon \leq N$. This completes the proof. □

2.4. The fundamental solutions P . Fix $\alpha \in \mathsf{R}$. We now introduce the fundamental solutions $P^\alpha = P^\alpha(t; x, y)$ of the heat equation with one-point potential $\delta_0^{(\alpha)}$, that is, of (1.4).

Step 1 ($d = 3$). Based on [ABD95, formula array (3.4)], for $d = 3$, we can *define*

$$\begin{aligned} P^\alpha(t; x, y) &:= P(t; x, y) + \frac{2t}{|x||y|} P(t; |x| + |y|) \\ &\quad - \frac{8\pi\alpha t}{|x||y|} \int_0^\infty \mathrm{d}u \mathrm{e}^{-4\pi\alpha u} P(t; u + |x| + |y|), \end{aligned} \tag{2.28}$$

$t > 0$, $x, y \neq 0$, where with a slight abuse of notation for heat kernel P,

$$P(t; r) := (4\pi t)^{-d/2} \exp(-r^2/4t), \quad t, r > 0. \tag{2.29}$$

Note that the term in (2.28) involving the integral is always finite and that it disappears for $\alpha = 0$. Otherwise, using the substitution $|\alpha|u \to u$ (for $\alpha \neq 0$) one realizes that $P^\alpha(t; x, y)$ is continuous and decreasing in α, and that $P^\alpha \downarrow P$, the heat kernel, pointwise as $\alpha \uparrow \infty$, whereas $P^\alpha \uparrow \infty$ pointwise as $\alpha \downarrow -\infty$.

Step 2 ($d = 2$). On the other hand, by [ABD95, formula (3.15)], for $d = 2$, we may *define*

$$\begin{aligned} P^\alpha(t; x, y) &:= P(t; x, y) + \frac{\sqrt{4\pi t}}{\sqrt{|x||y|}} P(t; |x| + |y|) \\ &\quad \times \int_0^\infty \mathrm{d}u \frac{t^u \mathrm{e}^{-\alpha u}}{\Gamma(u)} \int_0^\infty \mathrm{d}r \frac{r^{u-1} \mathrm{e}^{-(|x|+|y|)^2/4tr}}{(r+1)^{u+1/2}} \tilde{K}_0 \left(\frac{|x||y|}{2t}(r+1) \right), \end{aligned} \tag{2.30}$$

$t > 0$, $x, y \neq 0$, where Γ is the Gamma function,

$$\Gamma(u) := \int_0^\infty \mathrm{d}s s^{u-1} \mathrm{e}^{-s}, \quad u > 0, \tag{2.31}$$

and

$$\tilde{K}_0(z) := \mathrm{e}^z (2z/\pi)^{1/2} K_0(z), \quad z \geq 0, \tag{2.32}$$

with $K_0 \geq 0$ the Macdonald function of order 0. In other words, K_0 is the modified Bessel function of the third kind, of order 0. See [Leb65, p. 109].

Recall that P^α ($d = 2, 3$) is the family of fundamental solutions to (1.4), computed in [ABD95]. Since $\Delta^{(\alpha)}$ is a self-adjoint extension of Δ on $\dot{\mathsf{R}}^d$, the kernel P^α solves the heat equation on $(0, \infty) \times \dot{\mathsf{R}}^d$, as shown in the following corollary.

Corollary 2.5 (solutions of the heat equation). *Let $d = 2, 3$ and $\alpha \in \mathsf{R}$. Then*

$$\frac{\partial}{\partial t} P^\alpha(t; x, y) = \Delta P^\alpha(t; x, y) \quad \textit{on} \quad (0, \infty) \times \dot{\mathsf{R}}^d, \tag{2.33}$$

where the Laplacian acts on x (or y, respectively). In particular, $(t,x,y) \mapsto P^\alpha(t;x,y)$ is jointly continuous on $(0,\infty) \times \dot{\mathsf{R}}^d$.

Let $S^\alpha = \{S^\alpha_t : t \geq 0\}$ denote the semigroup corresponding to the kernel P^α, $\alpha \in \mathsf{R}$. As we noted in subsection 1.3, since $\int_{\mathsf{R}^d} \mathrm{d}y P^\alpha(t;x,y) > 1$, this semigroup is not Markovian in the usual sense.

2.5. Bounds on P . In this subsection we will derive some bounds for the kernels P^α introduced in (2.28) and (2.30), respectively. To this end, we set

$$\bar{P}(t;x,y) := t^{-1/2}\phi(x)\phi(y)\mathrm{e}^{-|x|^2/4t}\mathrm{e}^{-|y|^2/4t} \tag{2.34}$$

for $t > 0$ and $x, y \neq 0$ (recall the weight and reference function ϕ from (2.1)).

LEMMA 2.6 (P^α bound). *Let $d = 2, 3$. For each $\alpha \in \mathsf{R}$ and $T > 0$, there is a constant $C_{2.6} = C_{2.6}(d,\alpha,T)$ such that*

$$P(t;x,y) \leq P^\alpha(t;x,y) \leq P(t;x,y) + C_{2.6}\bar{P}(t;x,y) \tag{2.35}$$

for all $t \in (0,T]$ and $x, y \neq 0$.

Proof.

Step 1 ($d = 3$). By the arguments after (2.29), for $\alpha \geq 0$,

$$P \leq P^\alpha \leq P^0 \leq P + 2(4\pi)^{-3/2}\bar{P}, \tag{2.36}$$

since

$$(|x| + |y|)^2 \geq |x|^2 + |y|^2. \tag{2.37}$$

So we will restrict our attention to $\alpha < 0$. Abbreviating

$$-4\pi\alpha =: \frac{r}{2} > 0 \quad \text{and} \quad |x| + |y| =: R \geq 0 \tag{2.38}$$

and using the last inequality in (2.36) and (2.37), it suffices to verify that

$$\int_0^\infty \mathrm{d}u \frac{r}{2}\,\mathrm{e}^{\frac{r}{2}u} P(t;u+R) \leq C_{(2.39)} P(t;R) \tag{2.39}$$

(recall notation (2.29)), with a positive constant $C_{(2.39)} = C_{(2.39)}(T,r)$ independent of t and R. Fix any

$$u_0 > rT \quad \text{and put} \quad u_1 := u_0 - rT > 0. \tag{2.40}$$

Consider first the integral in (2.39) restricted to $u \in [0,u_0]$. Here we can use $P(t;u+R) \leq P(t;R)$ and the fact that

$$\int_0^{u_0} \mathrm{d}u \frac{r}{2}\,\mathrm{e}^{\frac{r}{2}u} \leq \mathrm{e}^{\frac{r}{2}u_0}, \tag{2.41}$$

resulting in a positive constant independent of t and R. It remains to deal with

$$\int_{u_0}^\infty \mathrm{d}u \frac{r}{2}\,\mathrm{e}^{\frac{r}{2}u}(4\pi t)^{-3/2}\,\mathrm{e}^{-(u+R)^2/4t} \tag{2.42a}$$

$$= \frac{r}{2}(4\pi t)^{-3/2}\,\mathrm{e}^{-(2rRt - r^2t^2)/4t} \int_{u_0}^\infty \mathrm{d}u \mathrm{e}^{-(u+R-rt)^2/4t} \tag{2.42b}$$

for $0 < t \le T$. The exponential factor in front of the integral in (2.42b) is bounded by

$$\mathrm{e}^{r^2T/4} =: C_{(2.43)}, \tag{2.43}$$

which is a positive constant independent of t and R. Substituting $u + R - rt \to u$ and recalling notation (2.40), the integral in (2.42b) can be bounded by

$$\int_{R+u_1}^{\infty} \mathrm{d}u \mathrm{e}^{-u^2/4t} \le \frac{2T}{u_1} \int_R^{\infty} \mathrm{d}u \frac{u}{2t} \mathrm{e}^{-u^2/4t} = \frac{2T}{u_1} \mathrm{e}^{-R^2/4t}. \tag{2.44}$$

Thus for the integral in (2.42a) we found the bound

$$C_{(2.43)} \frac{r}{2} \frac{2T}{u_1} P(t; R), \tag{2.45}$$

which finishes the proof in the case $d = 3$.

Step 2 ($d = 2$). Recall definition (2.32) of $\tilde{K}_0$. According to [ABD95, after (3.14)],

$$\lim_{z \to \infty} \tilde{K}_0(z) = 1. \tag{2.46}$$

Consulting [Tra69, section 1.15, equation (1.66)], we find that

$$K_0(z) \sim -\gamma - \log(z/2) \sim -\log z \quad \text{as } z \downarrow 0, \tag{2.47}$$

where γ is Euler's constant. Therefore,

$$\lim_{z \downarrow 0} \tilde{K}_0(z) = \lim_{z \downarrow 0} [\mathrm{e}^z (2z/\pi)^{1/2} \log z] = 0. \tag{2.48}$$

Since $\tilde{K}_0$ is continuous, relations (2.46) and (2.48) together give

$$\|\tilde{K}_0\|_\infty < \infty. \tag{2.49}$$

Fix $\alpha \in \mathsf{R}$ and consider $0 < t \le T$. We may assume that $T \ge 1$. We start by estimating the inner integral appearing on the right-hand side of definition (2.30) of P^α. For $u > 0$,

$$\begin{aligned} &\int_0^{\infty} \mathrm{d}r \frac{r^{u-1} \mathrm{e}^{-(|x|+|y|)^2/4tr}}{(r+1)^{u+1/2}} \tilde{K}_0 \left(\frac{|x||y|}{2t} (r+1) \right) \\ &\qquad \le \|\tilde{K}_0\|_\infty \int_0^{\infty} \mathrm{d}r \frac{r^{u-1}}{(r+1)^{u+1/2}}. \end{aligned} \tag{2.50}$$

If $r \ge 1$, drop the 1 in the denominator; otherwise drop the r there. Thus, for the inner integral in (2.30) we find the bound

$$\|\tilde{K}_0\|_\infty [2 + 1/u]. \tag{2.51}$$

Using this bound, we turn to the outer integral of (2.30). For the Gamma function Γ of (2.31), Stirling's formula gives

$$\Gamma(u) \sim \sqrt{2\pi} (u-1)^{u-1/2} \mathrm{e}^{-u+1} \quad \text{as } u \uparrow \infty. \tag{2.52}$$

It follows that, for some constant $C_{(2.53)} = C_{(2.53)}(T, \alpha)$,

$$\int_1^\infty \mathrm{d}u \frac{t^u \mathrm{e}^{-\alpha u}}{\Gamma(u)} \le C_{(2.53)}, \quad 0 \le t \le T. \tag{2.53}$$

Next, using integration by parts, we estimate $u\Gamma(u)$ for $u \in (0, 1]$:

$$u\Gamma(u) = \int_0^\infty \mathrm{d}s u s^{u-1} \mathrm{e}^{-s} = \int_0^\infty \mathrm{d}s s^u \mathrm{e}^{-s} \ge \mathrm{e}^{-1} \int_0^1 \mathrm{d}s s =: C_{(2.54)}. \tag{2.54}$$

Finally, for some constant $C_{(2.55)} = C_{(2.55)}(T, \alpha)$, since $T \ge 1$,

$$\int_0^1 \mathrm{d}u \frac{t^u \mathrm{e}^{-\alpha u}}{u\Gamma(u)} \le \frac{1}{C_{(2.54)}} T \mathrm{e}^{|\alpha|} =: C_{(2.55)}. \tag{2.55}$$

Altogether, we found that the double integral appearing on the right-hand side of definition (2.30) of P^α is bounded by a constant depending only on α, T. This gives estimate (2.35) also in the case $d = 2$, since $\tilde{K}_0 \ge 0$, finishing the proof of Lemma 2.6. □

2.6. Strong continuity of S . We abbreviate

$$\bar{S}_t\varphi(x) := \int_{\mathsf{R}^d} \mathrm{d}y \varphi(y) \bar{P}(t; x, y), \quad t > 0, \ x \ne 0, \tag{2.56}$$

with $\bar{P}$ from (2.34), as long as the right-hand side expression makes sense. The estimates (2.35) and Minkowski's inequality then imply that

$$\|S_t\varphi\|_{\mathcal{H}} \le \|S^\alpha_t\varphi\|_{\mathcal{H}} \le \|S_t\varphi\|_{\mathcal{H}} + C_{2.6}\|\bar{S}_t\varphi\|_{\mathcal{H}}, \quad 0 < t \le T, \tag{2.57}$$

for those φ for which the right-hand side of (2.57) is meaningful and finite.

LEMMA 2.7 (estimate of $\bar{S}$ in case of an additional singularity). *Let $d = 2, 3$ as well as $0 \le \beta \le 1$, and assume*

$$\frac{1}{1 - \beta(d-1)/(d+1)} < \varrho < \frac{d+1}{d-1}. \tag{2.58}$$

Then there is a constant $C_{2.7} = C_{2.7}(d, \beta, \varrho)$ such that for all $\varphi \in \mathcal{H} = \mathcal{H}^\varrho$,

$$\|\bar{S}_t(\varphi\phi^\beta)\|^\varrho_{\mathcal{H}} \le C_{2.7}\varepsilon(t, \varphi) t^{-\beta\varrho(d-1)/4} \|\varphi\|^\varrho_{\mathcal{H}}, \quad t > 0, \tag{2.59}$$

where $0 \le \varepsilon(t, \varphi) \le 1$ and $\varepsilon(t, \varphi) \to 0$ as $t \downarrow 0$.

Remark 2.8 (restriction to infinite variance branching if $d = 3$). Note that in dimension $d = 3$ condition (2.58) can only be satisfied for some ϱ if $\beta < 1$ holds.

Proof of Lemma 2.7. This time we work with the measures

$$\mu_t(\mathrm{d}y) := t^{-\kappa} \mathrm{e}^{-|y|^2/4t} \phi^\lambda(y) \, \mathrm{d}y, \quad t > 0, \tag{2.60}$$

on R^d, where

$$\kappa := \frac{d+1}{4} - \frac{(d-1)\beta\varrho}{4(\varrho - 1)} > 0 \quad \text{and} \quad \lambda := 1 + \beta\varrho/(\varrho - 1). \tag{2.61}$$

Note that the measures μ_t have a t-independent total mass

$$\|\mu_t\| = \int_{\mathsf{R}^d} \mathrm{d}y \mathrm{e}^{-|y|^2/4}\phi^\lambda(y) =: C_{(2.62)} = C_{(2.62)}(d,\beta,\varrho), \tag{2.62}$$

which is finite by the left-hand inequality in assumption (2.58). Then, by our definition (2.34) of $\bar{P}$, for $t>0$ and $x\neq 0$,

$$|\bar{S}_t(\varphi\phi^\beta)(x)|^\varrho = t^{-\varrho/2+\kappa\varrho}\phi^\varrho(x)\mathrm{e}^{-\varrho|x|^2/4t}\left|\int_{\mathsf{R}^d}\mu_t(\mathrm{d}y)\phi^{-\lambda+\beta+1}(y)\varphi(y)\right|^\varrho. \tag{2.63}$$

By (2.21) and the definition of μ_t we may continue with

$$|\bar{S}_t(\varphi\phi^\beta)(x)|^\varrho \le t^{-\varrho/2+\kappa\varrho}\phi^\varrho(x)\mathrm{e}^{-\varrho|x|^2/4t}C_{(2.62)}^{\varrho-1}t^{-\kappa}\int_{\mathsf{R}^d}\mathrm{d}y\mathrm{e}^{-|y|^2/4t}\phi(y)|\varphi|^\varrho(y), \tag{2.64}$$

since $(-\lambda+\beta+1)\varrho+\lambda=1$. We may assume that $\varphi\neq 0$. Define

$$\varepsilon(t,\varphi) := \frac{1}{\|\varphi\|_{\mathcal{H}}^\varrho}\int_{\mathsf{R}^d}\mathrm{d}y\phi(y)\mathrm{e}^{-|y|^2/4t}|\varphi|^\varrho(y). \tag{2.65}$$

Note that $0<\varepsilon(t,\varphi)\le 1$ and that $\varepsilon(t,\varphi)\to 0$ as $t\downarrow 0$, by dominated convergence. Consequently,

$$|\bar{S}_t(\varphi\phi^\beta)(x)|^\varrho \le t^{-\varrho/2+\kappa\varrho}\phi^\varrho(x)\mathrm{e}^{-\varrho|x|^2/4t}C_{(2.62)}^{\varrho-1}t^{-\kappa}\varepsilon(t,\varphi)\|\varphi\|_{\mathcal{H}}^\varrho. \tag{2.66}$$

Therefore,

$$\|\bar{S}_t(\varphi\phi^\beta)\|_{\mathcal{H}}^\varrho \le C_{(2.62)}^{\varrho-1}\varepsilon(t,\varphi)t^{-\varrho/2+\kappa\varrho-\kappa}\|\varphi\|_{\mathcal{H}}^\varrho\int_{\mathsf{R}^d}\mathrm{d}x\phi^{\varrho+1}(x)\mathrm{e}^{-\varrho|x|^2/4t}.$$

But the latter integral is finite since $-(\varrho+1)(d-1)/2+d>0$ by the right-hand inequality in assumption (2.58). Moreover, using a change of variables, the integral gives an additional factor $t^{d/2-(\varrho+1)(d-1)/4}$, so that the whole t-term equals $t^{-\beta\varrho(d-1)/4}$. This finishes the proof. □

Since condition (2.58) is stronger than (2.16), combining Lemmas 2.3 and 2.7 with inequality (2.57) gives the following result.

COROLLARY 2.9 (estimate of S^α in case of an additional singularity). *Let $d=2,3$ as well as $0\le\beta\le 1$. Suppose* (2.58). *To each $T>0$ there is a constant $C_{2.9}=C_{2.9}(d,T,\alpha,\beta,\varrho)$ such that for all $\varphi\in\mathcal{H}=\mathcal{H}^\varrho$,*

$$\|S_t^\alpha(\varphi\phi^\beta)\|_{\mathcal{H}} \le C_{2.9}t^{-\beta(d-1)/4}\|\varphi\|_{\mathcal{H}}, \quad 0<t\le T. \tag{2.67}$$

In particular,

$$\sup_{t\le T}\|S_t^\alpha\varphi\|_{\mathcal{H}} \le C_{2.9}\|\varphi\|_{\mathcal{H}} < \infty, \quad \varphi\in\mathcal{H}. \tag{2.68}$$

Another consequence of Lemma 2.7 is shown in the following corollary.

COROLLARY 2.10 (strong continuity of S^α). *Let $d=2,3$. For each $\alpha\in\mathsf{R}$, the semigroup S^α acting on $\mathcal{H}=\mathcal{H}^\varrho$ with $\varrho\in(1,(d+1)/(d-1))$ is strongly continuous.*

Proof. Fix $\varphi\in\mathcal{H}$. By linearity, we may additionally assume that $\varphi\ge 0$. Consider $0<t\le T$. Decompose

$$S_t^\alpha\varphi = S_t\varphi + (S_t^\alpha - S_t)\varphi, \tag{2.69}$$

where by Lemma 2.6,

$$0 \le (S_t^\alpha - S_t)\varphi \le C_{2.6}\bar{S}_t\varphi, \tag{2.70}$$

implying

$$\|(S_t^\alpha - S_t)\varphi\|_{\mathcal{H}} \le C_{2.6}\|\bar{S}_t\varphi\|_{\mathcal{H}}. \tag{2.71}$$

From (2.69) and (2.71)

$$\begin{aligned}\|S_t^\alpha\varphi - \varphi\|_{\mathcal{H}} &\le \|S_t\varphi - \varphi\|_{\mathcal{H}} + \|(S_t^\alpha - S_t)\varphi\|_{\mathcal{H}} \\ &\le \|S_t\varphi - \varphi\|_{\mathcal{H}} + C_{2.6}\|\bar{S}_t\varphi\|_{\mathcal{H}}.\end{aligned} \tag{2.72}$$

But by Lemma 2.7 with $\beta = 0$, the second term in (2.72) goes to 0 as $t \downarrow 0$, whereas the first term does by Lemma 2.4. By (2.68), this finishes the proof. □

2.7. S as a flow on Φ. Recall our set Φ of continuous nonnegative test functions introduced in subsection 2.1. From the proof of Lemma 2.7 we also get the following result.

COROLLARY 2.11 (S^α bound). *Let $d = 2, 3$, assume $\varrho \in (1, (d+1)/(d-1))$, and assume $\varphi \in \mathcal{H}^\varrho$ satisfies*[3] (2.3). *Then, to each $T > 0$, there is a constant $C_{2.11} = C_{2.11}(d, T, \alpha, \varrho, \varphi)$ such that*

$$0 \le S_t^\alpha\varphi \le C_{2.11}(1 + t^{-1/2+(d+1)(\varrho-1)/4\varrho})\phi, \quad 0 < t \le T. \tag{2.73}$$

In particular, $S_t^\alpha\varphi \in \Phi$ for all $t > 0$.

Proof. From Lemma 2.6,

$$0 \le S_t^\alpha\varphi \le S_t\varphi + C_{2.6}\bar{S}_t\varphi. \tag{2.74}$$

Moreover, by assumption (2.3) on φ and by Lemma 2.1,

$$S_t\varphi \le C_{(2.3)}S_t\phi \le C\phi. \tag{2.75}$$

On the other hand, raising estimate (2.66) (with $\beta = 0$ there, implying $\kappa = (d+1)/4$ and $\lambda = 1$) into the power $1/\varrho$ gives

$$\bar{S}_t\varphi \le Ct^{-1/2+(d+1)(\varrho-1)/4\varrho}\phi\|\varphi\|_{\mathcal{H}}. \tag{2.76}$$

Putting together (2.74)–(2.76) yields (2.73). Finally, $(t, x) \mapsto S_t^\alpha\varphi$ is continuous on $(0, \infty) \times \dot{\mathsf{R}}^d$, since it solves the heat equation; recall Corollary 2.5. This finishes the proof. □

Combining Corollaries 2.10 and 2.11, we get the following result.

COROLLARY 2.12 (S^α acting on Φ). *Let $d = 2, 3$ and $\varrho \in (1, (d+1)/(d-1))$. Then S^α is a strongly continuous linear semigroup acting on $\Phi = \Phi^\varrho$.*

3. Analysis of the log-Laplace equation. The main result of this section is the well-posedness of the log-Laplace equation (Theorem 3.3). Uniqueness follows from a contraction argument (Lemma 3.7). Existence is shown via a Picard iteration (Lemmas 3.8, 3.9, and 3.11), whereas nonnegativity follows using a linearized equation (Lemma 3.10).

[3] Of course, an inequality on an element $\varphi \in \mathcal{H}$ means that the inequality holds for each representative in Lebesgue at almost every point.

3.1. Preliminaries and purpose. Formally, we can rewrite the log-Laplace equation (1.5) as the following *integral equation*:[4]

$$v(t,x) = S_t^\alpha \varphi(x) - \eta \int_0^t \mathrm{d}s S_{t-s}^\alpha (v^{1+\beta}(s))(x), \tag{3.1}$$

$t \geq 0$, $x \neq 0$ (with constants $\alpha \in \mathsf{R}$, $\eta \geq 0$, $0 < \beta \leq 1$, and where $\varphi \geq 0$ has yet to be specified). Here in writing $v^{1+\beta}$ we have in mind that $v \geq 0$. Note also that this nonnegativity implies the following *domination:*

$$0 \leq v(t) \leq S_t^\alpha \varphi, \quad t \geq 0. \tag{3.2}$$

The task of this section is to verify that the log-Laplace equation (3.1) is well posed in Φ.

DEFINITION 3.1 (Φ-valued solution). *Let $\varphi \in \Phi$. A measurable map $t \mapsto v(t) = V_t\varphi$ of R_+ into Φ is called a* solution *of* (3.1) *if* (3.1) *is true for all $x \neq 0$ and $t \geq 0$.*

For convenience, we introduce the following hypothesis.

Hypothesis 3.2 (choice of parameters). Let $\alpha \in \mathsf{R}$, $\eta \geq 0$, and

$$d = 2, 3, \quad 0 < \beta \leq 1, \quad \text{and} \quad \frac{1}{1 - \beta(d-1)/(d+1)} < \varrho < \frac{d+1}{d-1}. \tag{3.3}$$

Recall that for $d = 3$ this requires that $\beta < 1$.

Now we are ready to state the main result of this section.

THEOREM 3.3 (well-posedness of the log-Laplace equation). *If Hypothesis* 3.2 *holds, and if $\varphi \in \Phi$, then* (3.1) *has a unique Φ-valued solution $v = V\varphi = \{V_t\varphi : t \geq 0\}$. Moreover, $V = \{V_t : t \geq 0\}$ is a nonlinear strongly continuous semigroup acting on Φ.*

The rest of this section is devoted to the proof of this theorem.

3.2. First properties of solutions. Now we prepare for the uniqueness proof. Impose Hypothesis 3.2. Fix an integer $T > 0$ for a while, and $\varphi \in \Phi$. We will also fix measurable functions ψ_1, ψ_2 on $(0, T] \times \dot{\mathsf{R}}^d$ such that

$$0 \leq \psi_1(t,x) \leq M(1 + t^{-\kappa})\phi^\beta(x), \tag{3.4a}$$

$$0 \leq \psi_2(t,x) \leq S_t^\alpha \varphi(x), \tag{3.4b}$$

with constants $M = M(T, \psi_1) > 0$ and

$$\kappa := \beta/2 - \beta(d+1)(\varrho - 1)/4\varrho \in (0,1). \tag{3.5}$$

LEMMA 3.4 (properties of the nonlinear term). *There is a constant $C_{3.4} = C_{3.4}(d, M, T, \alpha, \beta, \varrho)$ such that*

$$\left\| \int_0^t \mathrm{d}s S_{t-s}^\alpha (\psi_1(s)\psi_2(s)) \right\|_{\mathcal{H}} \leq C_{3.4} \|\varphi\|_{\mathcal{H}} I(t), \quad 0 < t \leq T, \tag{3.6}$$

where

$$\infty > I(t) := \int_0^t \mathrm{d}s (1 + s^{-\kappa})(t-s)^{-\lambda} \underset{t \downarrow 0}{\searrow} 0, \tag{3.7}$$

[4] We often use notation as $v(s) := v(s, \cdot)$.

with

$$\lambda := \beta(d-1)/4. \tag{3.8}$$

Moreover, if for fixed $t \in (0,T]$,

$$N_t(x) := \int_0^t \mathrm{d}s S^\alpha_{t-s}(\psi_1(s)\psi_2(s))(x), \quad x \in \dot{\mathsf{R}}^d, \tag{3.9}$$

satisfies

$$N_t(x) \le S^\alpha_t \varphi(x), \quad x \in \dot{\mathsf{R}}^d, \tag{3.10}$$

then $N_t \in \Phi$.

Proof. First, by Corollary 2.10, we see that

$$\|S^\alpha_s \varphi\|_{\mathcal{H}} \le C\|\varphi\|_{\mathcal{H}}, \quad 0 \le s \le T, \tag{3.11}$$

where $C = C(T)$. Now, Corollary 2.9 states that

$$\|S^\alpha_t(\phi^\beta \varphi)\|_{\mathcal{H}} \le C_{2.9} t^{-\lambda}\|\varphi\|_{\mathcal{H}}, \quad 0 < t \le T. \tag{3.12}$$

Applying first (3.12) and then (3.11), we obtain

$$\|S^\alpha_{t-s}(\phi^\beta S^\alpha_s \varphi)\|_{\mathcal{H}} \le C_{2.9}(t-s)^{-\lambda}\|\varphi\|_{\mathcal{H}}, \quad 0 \le s < t \le T. \tag{3.13}$$

Exploiting assumption (3.4), we find

$$\|S^\alpha_{t-s}(\psi_1(s)\psi_2(s))\|_{\mathcal{H}} \le C(1+s^{-\kappa})(t-s)^{-\lambda}\|\varphi\|_{\mathcal{H}}. \tag{3.14}$$

However, $I(t)$ from (3.7) can be written as

$$I(t) = \frac{t^{1-\lambda}}{1-\lambda} + t^{1-\lambda-\kappa}\int_0^1 \mathrm{d}s s^{-\kappa}(1-s)^{-\lambda}. \tag{3.15}$$

The positive numbers κ and λ defined in (3.5) and (3.8), respectively, satisfy $\kappa+\lambda < 1$, hence (3.6) and (3.7) follow. Thus, the integrals in (3.9) are finite for almost all x. By assumption (3.10), it remains to show that $N_t(x)$ from (3.9) is continuous in x.

Let $\delta \in (0,t)$. Then

$$\int_0^{t-\delta} \mathrm{d}s S^\alpha_{t-s}(\psi_1(s)\psi_2(s))(x) \;=\; S^\alpha_\delta \int_0^{t-\delta} \mathrm{d}s S^\alpha_{t-\delta-s}(\psi_1(s)\psi_2(s))(x). \tag{3.16}$$

We already showed that the latter integral term belongs to $\mathcal{H}_+$. Then by Corollary 2.11, the left-hand side in (3.16) belongs to Φ, and hence is continuous in x for each δ. To complete the proof, it suffices to show that

$$\int_{t-\delta}^t \mathrm{d}s S^\alpha_{t-s}(\psi_1(s)\psi_2(s))(x) \underset{\delta \downarrow 0}{\longrightarrow} 0 \quad \text{uniformly in } x \in K, \tag{3.17}$$

where K is any compact subset of $\dot{\mathsf{R}}^d$ and is fixed from now on. Next apply assumption (3.4b) and Corollary 2.11 to $S^\alpha_s \varphi$ together with the definition (3.5) of κ to get

$$0 \le \psi_2(s) \le S^\alpha_s \varphi \le C_{2.11}(1+s^{-\kappa/\beta})\phi \le C\phi, \tag{3.18}$$

since s in (3.17) is bounded away from 0. Inserting the assumed upper bound (3.4a) on ψ_1, for the integral in (3.17) we find the estimate

$$C\int_{t-\delta}^{t} \mathrm{d}s S^{\alpha}_{t-s}\phi^{\beta+1}(x) = C\int_{0}^{\delta} \mathrm{d}s S^{\alpha}_{s}\phi^{\beta+1}(x). \tag{3.19}$$

Hence, it suffices to show that

$$s \mapsto \max_{x\in K} S^{\alpha}_{s}\phi^{\beta+1}(x) \quad \text{is integrable on } (0,\delta]. \tag{3.20}$$

By Lemma 2.6,

$$S^{\alpha}_{s}\phi^{\beta+1} \le S_s\phi^{\beta+1} + C_{2.6}\bar{S}_s\phi^{\beta+1}, \quad s>0. \tag{3.21}$$

Now, $(s,x)\mapsto S_s\phi^{\beta+1}(x)$ is finite and satisfies the heat equation on $[0,\delta]\times K$, implying

$$\sup_{(s,x)\in[0,\delta]\times K} S_s\phi^{\beta+1}(x) < \infty. \tag{3.22}$$

Turning to the second term in (3.21), by definition (2.34),

$$\bar{S}_s\phi^{\beta+1}(x) = \; s^{-1/2}\phi(x)\mathrm{e}^{-|x|/4s}\int_{\mathsf{R}^d} \mathrm{d}y\, \mathrm{e}^{-|y|/4s}\phi^{\beta+2}(y), \quad s>0. \tag{3.23}$$

By the substitution $y\mapsto y\sqrt{s}$, the latter integral gives an additional power contribution to $s^{-1/2}$. Moreover,

$$\sup_{x\in K} \phi(x)\mathrm{e}^{-|x|/4s} \le C\mathrm{e}^{-C/s}, \tag{3.24}$$

which together with $s^{-\lambda_0}$ is integrable on $(0,\delta]$ for each $\lambda_0\in\mathsf{R}$. This finishes the proof. □

LEMMA 3.5 (continuity at $t=0$). *Let $\varphi\in\Phi=\Phi^{\varrho}$ and let $v=V\varphi$ be a Φ-valued solution to* (3.1). *Under Hypothesis* 3.2, *for $T\ge 0$ fixed, there is a constant $C_{3.5}=C_{3.5}(d,T,\alpha,\varrho)$ such that*

$$\|V_t\varphi\|_{\mathcal{H}} \le C_{3.5}\|\varphi\|_{\mathcal{H}}, \quad 0\le t\le T. \tag{3.25}$$

Moreover, $V\varphi$ is strongly continuous at $t=0$, where $V_0\varphi=\varphi$.

Proof. By domination (3.2),

$$\|V_t\varphi\|_{\mathcal{H}} \le \|S^{\alpha}_t\varphi\|_{\mathcal{H}}. \tag{3.26}$$

Now (3.25) follows from (2.68). It remains to verify the continuity claim. Clearly, for $t\in(0,T]$,

$$|V_t\varphi-\varphi| \le |V_t\varphi - S^{\alpha}_t\varphi| + |S^{\alpha}_t\varphi-\varphi|. \tag{3.27}$$

By Corollary 2.10, it suffices to deal with the first term at the right-hand side. By (3.1), we have to look at

$$\left|\int_0^t \mathrm{d}s S^{\alpha}_{t-s}(v^{\beta}(s)v(s))\right|. \tag{3.28}$$

But from domination (3.2) and Corollary 2.11,

$$0\le v^{\beta}(s)\le C_{(3.29)}(1+s^{-\kappa})\phi^{\beta}, \quad 0<s\le T, \tag{3.29}$$

with κ from (3.5) and a constant $C_{(3.29)}=C_{(3.29)}(T,\varphi)$ (note that other dependencies are not important in the present proof). Thus, we can apply (3.6) and (3.7) from Lemma 3.4 to finish the proof. □

3.3. Uniqueness of solutions. The following lemma will be useful when we estimate the difference of solutions to (3.1).

LEMMA 3.6 (an elementary observation). *Let $\beta > 0$ and $a, b \in \mathsf{R}$. Then*

$$|a(a \vee 0)^\beta - b(b \vee 0)^\beta| \leq (1+\beta)(|a|+|b|)^\beta |a-b|. \tag{3.30}$$

Proof. First assume that $a, b \geq 0$. By the mean value theorem, there exists a number c between a and b such that

$$|a^{1+\beta} - b^{1+\beta}| = (1+\beta)c^\beta |a-b| \leq (1+\beta)(a+b)^\beta |a-b|. \tag{3.31}$$

This proves (3.30) for $a, b \geq 0$.

Now suppose that $a, b < 0$. In that case the left-hand side in (3.30) disappears, and hence (3.30) holds trivially.

Finally, it remains to consider the case $a < 0 \leq b$. Then

$$|a(a \vee 0)^\beta - b(b \vee 0)^\beta| = b^{1+\beta} \leq (1+\beta) b^\beta b \leq (1+\beta)(|a|+|b|)^\beta |a-b|,$$

and the proof is finished. □

We are ready to prove uniqueness for solutions to (3.1).

LEMMA 3.7 (uniqueness). *Impose Hypothesis* 3.2. *Fix $\varphi \in \Phi$. Suppose that u, v are Φ-valued solutions of* (3.1). *Then $u = v$.*

Proof. Fix $T > 0$. It suffices to prove uniqueness on $[0, T]$. Let

$$D(t,x) := u(t,x) - v(t,x), \quad 0 \leq t \leq T, \ x \neq 0. \tag{3.32}$$

Note that by Lemma 3.5,

$$\|D(t)\|_{\mathcal{H}} \leq 2C_{3.5} \|\varphi\|_{\mathcal{H}}, \quad 0 \leq t \leq T. \tag{3.33}$$

By the elementary inequality (3.30),

$$\begin{aligned} |D(t,x)| &= \eta \left| \int_0^t \mathrm{d}s S^\alpha_{t-s}(u^{1+\beta}(s) - v^{1+\beta}(s))(x) \right| \\ &\leq \eta \int_0^t \mathrm{d}s S^\alpha_{t-s} |u^{1+\beta}(s) - v^{1+\beta}(s)|(x) \\ &\leq 2\eta \int_0^t \mathrm{d}s S^\alpha_{t-s}([u^\beta(s) + v^\beta(s)]|D(s)|)(x). \end{aligned} \tag{3.34}$$

From (3.29), we get

$$|D(t,x)| \leq 4\eta\, C_{(3.29)} \int_0^t \mathrm{d}s (1 + s^{-\kappa}) S^\alpha_{t-s}(|D(s)|\phi^\beta)(x). \tag{3.35}$$

Thus

$$\begin{aligned} \|D(t)\|_{\mathcal{H}} &\leq 4\eta\, C_{(3.29)} \int_0^t \mathrm{d}s (1 + s^{-\kappa}) \|S^\alpha_{t-s}(|D(s)|\phi^\beta)\|_{\mathcal{H}} \\ &\leq 4\eta\, C_{(3.29)} \int_0^t \mathrm{d}s (1 + s^{-\kappa}) C_{2.9}(t-s)^{-\lambda} \|D(s)\|_{\mathcal{H}}, \end{aligned} \tag{3.36}$$

$0 < t \leq T$, where we used Corollary 2.9 and notation (3.8). Setting

$$D_t := \sup_{0 < s \leq t} \|D(s)\|_{\mathcal{H}}, \quad 0 < t \leq T \tag{3.37}$$

(for finiteness, recall (3.33)), since $I(t)$ from (3.7) is increasing in t (recall representation (3.15)), we find

$$D_t \le C_{(3.38)} D_t I(t), \quad 0 < t \le T, \tag{3.38}$$

with some constant $C_{(3.38)} = C_{(3.38)}(T, \varphi)$. Therefore, by (3.7), $D_t = 0$ for all sufficiently small t, say $t < \delta(T, \varphi) < T$. Since the model is time-homogeneous, we can repeat the argument finitely often to extend to the whole interval $[0, T]$. In fact, when iterating the argument, we need to use the bound (3.29) with the constant $C_{(3.29)}$ depending on our original φ, not with φ replaced by the new initial condition at the beginning of the new subinterval, since (3.29) holds on the whole $(0, T]$. Thus, the constants $C_{(3.38)}$ will be the same for each subinterval, and thus each subinterval will have the same length. (For a more complicated time-inhomogeneous situation, see the proof of Lemma 3.8 below.) Because u and v are Φ-valued, we found $u = v$ on $[0, T]$, and the proof is complete. □

3.4. Auxiliary functions w_N, . Recall that we fixed T, φ, and ψ_1 satisfying (3.4a). For fixed integer $N \ge 2$ set

$$\psi_N := \psi_1 \wedge N. \tag{3.39}$$

We inductively define functions $w_{N,n}$. First of all,

$$w_{N,0}(t) := S^\alpha_t \varphi \in \Phi, \quad 0 \le t \le T. \tag{3.40}$$

Assuming that we have defined $w_{N,n}$ for some n, let

$$w_{N,n+1}(t,x) := S^\alpha_t \varphi(x) - \int_0^t \mathrm{d}s S^\alpha_{t-s}(\psi_N(s) w_{N,n}(s))(x), \tag{3.41}$$

$0 \le t \le T$, $x \in \dot{\mathsf{R}}^d$, provided the latter integral makes sense.

LEMMA 3.8 (properties of $w_{N,n}$). *For all $n \ge 0$ and $t \in [0, T]$,*

$$0 \le w_{N,n}(t) \le S^\alpha_t \varphi, \quad \textit{and} \quad x \mapsto w_{N,n}(t,x) \textit{ is continuous.} \tag{3.42}$$

Proof. For $n = 0$, the claim is true by (3.40). Suppose that we have verified (3.42) for some $n \ge 0$. Then the integral in (3.41) is nonnegative, and hence

$$w_{N,n+1}(t) \le S^\alpha_t \varphi, \quad t \in [0, T]. \tag{3.43}$$

Assume for the moment that $w_{N,n+1} \ge 0$ under our induction hypothesis. Then by Lemma 3.4,

$$w_{N,n+1}(t) \in \Phi, \quad t \in [0, T], \tag{3.44}$$

and the proof would be finished.

Next we will verify that $w_{N,n+1}$ is nonnegative on $[0, 1/N]$. Since $\psi_N \le N$, and using the induction assumption, it follows that

$$S^\alpha_{t-s}(\psi_N(s) w_{N,n}(s)) \le S^\alpha_{t-s}(N S^\alpha_s \varphi) \le N S^\alpha_t \varphi. \tag{3.45}$$

Therefore, if $0 \le t \le 1/N$,

$$w_{N,n+1}(t) \ge S^\alpha_t \varphi - N \int_0^{1/N} \mathrm{d}s S^\alpha_t \varphi = 0. \tag{3.46}$$

Now we prove that $w_{N,n+1}$ is nonnegative on $[0,T]$. We use induction on the time intervals $[k/N,(k+1)/N]$, $0 \le k < NT$. To begin with, we have already shown that $w_{N,n+1}$ is nonnegative on $[0,1/N]$. Also, we know already that $w_{N,n+1}(1/N) \in \Phi$. Suppose that we have shown $w_{N,n+1}$ is nonnegative on $[(k-1)/N,k/N]$ for some $0 \le k < NT-1$, and that $w_{N,n+1}(k/N) \in \Phi$. We will shift time and define

$$w^{(k)}_{N,n+1}(t) := w_{N,n+1}(t+k/N), \tag{3.47a}$$

$$\varphi^{(k)}_{N,n+1}(t) := w_{N,n+1}(k/N), \tag{3.47b}$$

$$\psi^{(k)}_{N}(t) := \psi_N(t+k/N), \tag{3.47c}$$

$0 \le t \le 1/N$. We claim that

$$w^{(k)}_{N,n+1}(t) := S^\alpha_t \varphi^{(k)}_{N,n+1} - \int_0^t \mathrm{d}s S^\alpha_{t-s}(\psi^{(k)}_N(s) w^{(k)}_{N,n}(s)), \quad 0 \le t \le \frac{1}{N}. \tag{3.48}$$

Assume for the moment that (3.48) is true. Then the proof that $w_{N,n+1} \ge 0$ on $[k/N,(k+1)/N]$ reduces to showing that $w^{(k)}_{N,n+1} \ge 0$ on $[0,1/N]$. But this follows from the step we have already done. We are left with showing (3.48).

Using definition (3.41), we get

$$S^\alpha_t w_{N,n+1}(r) := S^\alpha_{t+r}\varphi - \int_0^r \mathrm{d}s S^\alpha_{t+r-s}(\psi_N(s) w_{N,n}(s)). \tag{3.49}$$

Let $r = k/N$. Then, for $0 \le t \le 1/N$,

$$S^\alpha_t \varphi^{(k)}_{N,n+1} = S^\alpha_{t+k/N}\varphi - \int_0^{k/N} \mathrm{d}s S^\alpha_{t+k/N-s}(\psi_N(s) w_{N,n}(s)). \tag{3.50}$$

Also, by a change of variables, for $0 \le t \le 1/N$, we obtain

$$\int_0^t \mathrm{d}s S^\alpha_{t-s}(\psi^{(k)}_N(s) w^{(k)}_{N,n}(s)) = \int_{k/N}^{t+k/N} \mathrm{d}s S^\alpha_{t+k/N-s}(\psi_N(s) w_{N,n}(s)). \tag{3.51}$$

Inserting (3.50) and (3.51) into the right-hand side of (3.48), and then using (3.41), we get

$$\begin{aligned} &S^\alpha_t \varphi^{(k)}_{N,n+1} - \int_0^t \mathrm{d}s S^\alpha_{t-s}(\psi^{(k)}_N(s) w^{(k)}_{N,n}(s)) \\ &\quad = S^\alpha_{t+k/N}\varphi - \int_0^{t+k/N} \mathrm{d}s S^\alpha_{t+k/N-s}(\psi_N(s) w_{N,n}(s)) \\ &\quad = w_{N,n+1}(t+k/N) = w^{(k)}_{N,n+1}(t), \end{aligned} \tag{3.52}$$

which proves (3.48). This finishes the proof. □

3.5. Auxiliary functions w . Recall that we fixed T, φ, ψ_1 with (3.4a). For $n \ge 0$, we inductively define functions w_n as follows. Let

$$w_0(t) := S^\alpha_t \varphi, \quad 0 \le t \le T, \tag{3.53}$$

and, given w_n, set

$$w_{n+1}(t,x) := S^\alpha_t \varphi(x) - \int_0^t \mathrm{d}s S^\alpha_{t-s}(\psi_1(s) w_n(s))(x), \tag{3.54}$$

$0 \le t \le T$, $x \in \dot{\mathsf{R}}^d$. Recall the functions $w_{N,n}$ as in Lemma 3.8.

LEMMA 3.9 (properties of w_n). *For each $n \geq 0$ and $t \in [0,T]$,*

$$\lim_{N\uparrow\infty} |w_{N,n}(t) - w_n(t)| = 0 \tag{3.55}$$

pointwise on $\dot{\mathsf{R}}^d$. Moreover,

$$0 \leq w_n(t) \leq S_t^\alpha \varphi, \quad \text{and} \quad x \mapsto w_n(t,x) \text{ is continuous.} \tag{3.56}$$

Proof. Again, we use induction on n. The claims are trivially true for $n = 0$. Suppose they hold for n. By definitions (3.41) and (3.54),

$$\begin{aligned} |w_{n+1}(t) - w_{N,n+1}(t)| &= \left| \int_0^t \mathrm{d}s S_{t-s}^\alpha (\psi_1(s) w_n(s) - \psi_N(s) w_{N,n}(s)) \right| \\ &\leq \left| \int_0^t \mathrm{d}s S_{t-s}^\alpha ([\psi_1(s) - \psi_N(s)] w_n(s)) \right| \\ &\quad + \int_0^t \mathrm{d}s S_{t-s}^\alpha (\psi_1(s) |w_n(s) - w_{N,n}(s)|) =: A_{N,n} + B_{N,n}, \end{aligned} \tag{3.57}$$

with the obvious correspondence. We will show that both $A_{N+1,n}$ and $B_{N+1,n}$ tend to 0 as $N \uparrow \infty$, giving (3.55) for $n+1$. This then yields also the remaining claims in Lemma 3.9 for $n+1$. In fact, by Lemma 3.8 then the inequalities hold in (3.56), and Lemma 3.4 gives the continuity claim.

First note that by the induction hypothesis,

$$\begin{aligned} A_{N,n} &\leq \int_0^t \mathrm{d}s S_{t-s}^\alpha ([\psi_1(s) - \psi_N(s)] S_s^\alpha \varphi) \\ &\leq \int_0^t \mathrm{d}s S_{t-s}^\alpha (\psi_1(s) S_s^\alpha \varphi) < \infty \end{aligned} \tag{3.58}$$

by Lemma 3.4. Thus, by monotone convergence,

$$\lim_{N\uparrow\infty} A_{N,n} = 0. \tag{3.59}$$

By Lemma 3.8 and the induction hypothesis,

$$|w_{N,n}(t) - w_n(t)| \leq 2 S_t^\alpha \varphi. \tag{3.60}$$

Moreover, by the induction assumption, (3.55) holds. Then, by Lemma 3.4, the dominated convergence theorem implies that

$$\lim_{N\uparrow\infty} B_{N,n} = 0, \tag{3.61}$$

finishing the proof. □

3.6. A linearized equation. Next we show that w_n converges as $n \uparrow \infty$ to a solution of a linearized equation.

LEMMA 3.10 (linearized equation). *Fix again $T \geq 1$, $\varphi \in \Phi$, and $\psi_1 : \mathsf{R}_+ \times \mathsf{R}^d \to \mathsf{R}_+$ satisfying* (3.4a). *Then, for $0 \leq t \leq T$, in $\mathcal{H}$ the (nonnegative) limit*

$$w(t) := \lim_{n\uparrow\infty} w_n(t) \tag{3.62}$$

exists and is the unique Φ*-valued solution to*

$$w(t) = S_t^\alpha \varphi - \int_0^t \mathrm{d}s S_{t-s}^\alpha(\psi_1(s)w(s)), \quad 0 \le t \le T, \tag{3.63}$$

implying

$$0 \le w(t) \le S_t^\alpha \varphi, \quad 0 \le t \le T. \tag{3.64}$$

Proof. Extending the uniqueness proof (Lemma 3.7) in the obvious way, one can show that

$$\sup_{0<s\le t} \|w_n(s) - w_m(s)\|_{\mathcal{H}} \xrightarrow[n,m\uparrow\infty]{} 0, \tag{3.65}$$

provided that $t < \delta = \delta(T, \varphi) < T$. Hence, there is a measurable mapping $s \mapsto w(s) \in \mathcal{H}$ on $[0, \delta]$ such that

$$\sup_{0<s\le t} \|w_n(s) - w(s)\|_{\mathcal{H}} \xrightarrow[n\uparrow\infty]{} 0. \tag{3.66}$$

Obviously, for each choice of representatives, w satisfies (3.63). By Lemma 3.4, the $w(s)$ belong to Φ, and the proof is finished. □

3.7. Existence of solutions. Our next goal is to use Lemma 3.10 to prove the existence of a Φ-valued solution for (3.1). Hypothesis 3.2 is still in force.

LEMMA 3.11 (existence). *To each* $\varphi \in \Phi$*, there exists a* Φ*-valued solution* $v = V\varphi$ *to the log-Laplace equation* (3.1).

Proof. We want to construct a sequence of Φ-valued functions v_m satisfying

$$v_m(t) \le S_t^\alpha \varphi. \tag{3.67}$$

In fact, if $m = 0$, set $v_0 := S^\alpha \varphi$. Assume that we have already defined v_m for some $m \ge 0$. Note that by Corollary 2.11,

$$|v_m^\beta(t)| \le M(1 + t^{-\kappa})\phi^\beta, \tag{3.68}$$

with κ from (3.5). Let v_{m+1} be the unique Φ-valued solution to

$$v_{m+1}(t,x) = S_t^\alpha \varphi(x) - \int_0^t \mathrm{d}s S_{t-s}^\alpha(v_m^\beta(s) v_{m+1}(s))(x) \tag{3.69}$$

according to Lemma 3.10, implying (3.67) for $m + 1$. Altogether, by induction we defined Φ-valued functions v_m satisfying (3.69), (3.67), and (3.68).

For $m \ge 0$, let

$$D_m := v_{m+1} - v_m. \tag{3.70}$$

Then, as in the proof of Lemma 3.7 (uniqueness), using Lemma 3.6, for fixed $T > 0$, we find

$$|D_{m+1}(t)| \le C \int_0^t \mathrm{d}s (1 + s^{-\kappa}) S_{t-s}^\alpha(|D_m(s)|\phi^\beta), \tag{3.71}$$

$0 \le t \le T$, with a constant $C = C(T)$, and

$$\begin{aligned} \|D_{m+1}(t)\|_{\mathcal{H}} &\le C \int_0^t \mathrm{d}s(1 + s^{-\kappa})\|S^{\alpha}_{t-s}(|D_m(s)|\phi^{\beta})\|_{\mathcal{H}} \\ &\le C \int_0^t \mathrm{d}s(1 + s^{-\kappa})C_{2.9}(t-s)^{-\lambda}\|D_m(s)\|_{\mathcal{H}}. \end{aligned} \tag{3.72}$$

Setting

$$D_{m,t} := \sup_{0\le s\le t} \|D_m(s)\|_{\mathcal{H}}, \quad 0 \le t \le T, \tag{3.73}$$

we found that

$$D_{m+1,t} \le \varepsilon_t D_{m,t}, \tag{3.74}$$

where the ε_t are independent of m, and $\varepsilon_t \to 0$ as $t \downarrow 0$. Thus, if our $T > 0$ is small enough, then there exists a constant $0 < \gamma < 1$ such that if $0 \le t \le T$, then

$$D_{m+1,t} \le \gamma D_{m,t}, \tag{3.75}$$

and so

$$D_{m,t} \le \gamma^m D_{0,t}. \tag{3.76}$$

Therefore, we can define

$$v(t,x) := \sum_{m=0}^{\infty} D_m(t,x) = \lim_{m\uparrow\infty} v_m(t,x), \quad 0 \le t \le T,\ x \ne 0, \tag{3.77}$$

where the limit is taken in $\mathcal{H}_+$.

From our construction, it follows that

$$0 \le v(t) \le S^{\alpha}_t\varphi \quad \text{and} \quad |v^{\beta}(t)| \le M(1 + t^{-\kappa})\phi^{\beta}. \tag{3.78}$$

Now we want to show that v satisfies (3.1) for $0 \le t \le T$. We start from definition (3.69). First, by (3.77),

$$\lim_{m\to\infty} \|v_{m+1}(t) - v(t)\|_{\mathcal{H}} = 0, \quad 0 \le t \le T. \tag{3.79}$$

As for the integral terms, we first note that for $a, b, c \ge 0$, by (3.30) we have

$$\begin{aligned} |ab^{\beta} - c^{1+\beta}| &\le |a^{1+\beta} - c^{1+\beta}| + |b^{1+\beta} - c^{1+\beta}| \\ &\le (1+\beta)(a+c)^{\beta}|a-c| + (1+\beta)(b+c)^{\beta}|b-c|. \end{aligned} \tag{3.80}$$

Therefore, using the second part of (3.78), we have

$$\begin{aligned} &\left\| \int_0^t \mathrm{d}s S^{\alpha}_{t-s}(v_{m+1}(s)v_m^{\beta}(s)) - \int_0^t \mathrm{d}s S^{\alpha}_{t-s} v^{1+\beta}(s) \right\|_{\mathcal{H}} \\ &\quad \le \int_0^t \mathrm{d}s \|S^{\alpha}_{t-s}|v_{m+1}(s)v_m^{\beta}(s) - v^{1+\beta}(s)|\|_{\mathcal{H}} \\ &\quad \le C \int_0^t \mathrm{d}s(1 + s^{-\kappa})\|S^{\alpha}_{t-s}(\phi^{\beta}|v_{m+1}(s) - v(s)| + \phi^{\beta}|v_m(s) - v(s)|)\|_{\mathcal{H}}. \end{aligned} \tag{3.81}$$

By Corollary 2.9, this chain of inequalities can be continued with

$$\begin{aligned} &\leq C\int_0^t \mathrm{d}s(1+s^{-\kappa})(t-s)^{-\lambda}\|v_{m+1}(s)-v(s)\|_{\mathcal{H}} \\ &\quad + C\int_0^t \mathrm{d}s(1+s^{-\kappa})(t-s)^{-\lambda}\|v_m(s)-v(s)\|_{\mathcal{H}}. \end{aligned} \tag{3.82}$$

By dominated convergence, the latter terms converge to 0 as $m \uparrow \infty$. In fact, the norm expressions tend to 0 by (3.79), the v_m and v are dominated by $S^\alpha\varphi$, which are strongly continuous by Corollary 2.10, and hence bounded in norm on the finite time interval, and recall (3.7). Thus, v satisfies (3.1) in $\mathcal{H}_+$ for $t \leq T$ and for sufficiently small T. By induction on intervals, as in the proof of Lemma 3.8, we extend the solution v from $[0,T]$ to all times. By Lemma 3.4, the constructed solution v is Φ-valued. □

Completion of the proof of Theorem 3.3. With Lemmas 3.7 and 3.11, we already proved the uniqueness and existence claims, respectively. The semigroup property of V follows from the uniqueness of solutions, and the strong continuity of V from Lemma 3.5. □

4. Construction of X. Having available the well-posedness of the log-Laplace equation (Theorem 3.3) under Hypothesis 3.2, we now construct the desired process X via a Trotter product approach to the related log-Laplace semigroup. For this purpose, we introduce an approximating log-Laplace equation related to separating critical continuous-state branching with index $1+\beta$, and mass flow according to S^α on alternate small time intervals (Lemma 4.1). The main work consists in showing that its solutions converge to the solutions to the true log-Laplace equation (Proposition 4.3). Then, in the final subsection, all pieces can easily put together to get our main result, the existence theorem, Theorem 4.4.

4.1. Approximating equation. We continue to impose Hypothesis 3.2. Fix $n \geq 1$ and $\varphi \in \Phi$. We inductively define measurable functions $\bar{v}_n$ on $\mathsf{R}_+ \times \dot{\mathsf{R}}^d$. First of all,

$$\bar{v}_n(0) := S^\alpha_{1/n}\varphi. \tag{4.1}$$

Assume for the moment $\bar{v}_n(\frac{k}{n})$ is defined for some $k \geq 0$. For $\frac{k}{n} \leq t < \frac{k+1}{n}$, set

$$\bar{v}_n(t,x) := \frac{\bar{v}_n(\frac{k}{n},x)}{\left[1+\eta\beta\bar{v}_n^\beta(\frac{k}{n},x)(t-\frac{k}{n})\right]^{1/\beta}}, \quad x \neq 0. \tag{4.2}$$

Note that

$$\frac{\partial}{\partial t}\bar{v}_n(t,x) = -\eta\bar{v}_n^{1+\beta}(t,x) \quad \text{on} \quad \left(\frac{k}{n},\frac{k+1}{n}\right)\times\dot{\mathsf{R}}^d, \tag{4.3}$$

that $\bar{v}_n(\frac{k}{n}+,x) = \bar{v}_n(\frac{k}{n},x)$, and that also the limit $\bar{v}_n(\frac{k+1}{n}-,x)$ exists. Note also that for $x \neq 0$ fixed, (4.2) gives the log-Laplace transition function of a critical continuous-state branching process (on R_+) with index $1+\beta$ (see, for instance, [Lam67]). Put

$$\bar{v}_n\left(\frac{k+1}{n},x\right) := S^\alpha_{1/n}\bar{v}_n\left(\frac{k+1}{n}-,\cdot\right)(x), \quad x \neq 0. \tag{4.4}$$

LEMMA 4.1 (approximating log-Laplace equation). *The function $\bar{v}_n \geq 0$ we have just defined satisfies*

$$\bar{v}_n(t,x) = S^\alpha_{(1+[tn])/n}\varphi(x) - \eta\int_0^t \mathrm{d}s S^\alpha_{([tn]-[sn])/n}(\bar{v}_n^{1+\beta}(s))(x) \tag{4.5}$$

on $\mathsf{R}_+ \times \dot{\mathsf{R}}^d$.

Proof. Differentiating equation (4.5) to $t \neq \frac{k}{n}$, $k \geq 0$, gives the true statement (4.3). On the other hand, for $t = \frac{k}{n}$, $k \geq 0$,

$$\bar{v}_n\left(\frac{k}{n}\right) = S^\alpha_{(1+k)/n}\varphi - \eta\sum_{i=1}^k \left[S^\alpha_{(k-(i-1))/n}\int_{(i-1)/n}^{i/n} \mathrm{d}s\bar{v}_n^{1+\beta}(s)\right]. \tag{4.6}$$

By (4.3) and the fundamental theorem of calculus, the right-hand side of the latter equation equals $\bar{v}_n(\frac{k}{n})$, finishing the proof. □

Set

$$t_n := [tn]/n. \tag{4.7}$$

Since $\bar{v}_n$ is nonnegative, from (4.5) we get the *domination*

$$0 \leq \bar{v}_n(t) \leq S^\alpha_{1/n+t_n}\varphi, \quad t \geq 0,\ n \geq 1, \tag{4.8}$$

implying by Corollary 2.9 with $\beta = 0$,

$$\|\bar{v}_n(t)\|_{\mathcal{H}} \leq C_{(4.9)}\|\varphi\|, \quad 0 \leq t \leq T,\ n \geq 1, \tag{4.9}$$

for each $T > 0$, and where $C_{(4.9)} = C_{(4.9)}(T)$. In particular, $\bar{v}_n$ is $\mathcal{H}_+$-valued. Our aim is to show that the $\bar{v}_n$ converge to the unique solution to (3.1). For this purpose, we will need the following estimate.

LEMMA 4.2 (pointwise bound). *Impose Hypothesis* 3.2. *To each $\varphi \in \mathcal{H}_+$ and $T > 0$, there is a $\varphi_0 = \varphi_0(d,T,\alpha,\varphi,\varrho)$ in $\mathcal{H}_+$, such that*

$$\sup_{T/2\leq t\leq T} S^\alpha_t\varphi \leq \varphi_0. \tag{4.10}$$

Proof. Recall from (2.35) that

$$P^\alpha(t;x,y) \leq P(t;x,y) + C_{2.6}\bar{P}(t;x,y). \tag{4.11}$$

Choose a constant $C_{(4.12)} = C_{(4.12)}(d,T)$ such that, for $T/2 \leq t \leq T$,

$$P(t;x,y) \leq C_{(4.12)}P(T;x,y) \tag{4.12}$$

and

$$\bar{P}(t;x,y) = t^{-1/2}\phi(x)\phi(y)\mathrm{e}^{-|x|^2/4t}\mathrm{e}^{-|y|^2/4t} \leq C_{(4.12)}\bar{P}(T;x,y) \tag{4.13}$$

(recall (2.34)). From Lemma 2.3 (with $\beta = 0$) we conclude that $S_T\varphi$ belongs to $\mathcal{H}_+$, whereas Lemma 2.7 (with $\beta = 0$) gives $\bar{S}_T\varphi \in \mathcal{H}_+$. Therefore, we may set

$$\varphi_0 := C_{(4.12)}(S_T\varphi + C_{2.6}\bar{S}_T\varphi) \tag{4.14}$$

to finish the proof. □

4.2. Convergence to the limit equation. With the functions $\bar v_n$ we may pass to the limit.

PROPOSITION 4.3 (convergence to the limit equation). *Fix $\varphi \in \Phi$. Define $\bar v_n$ as in* (4.1)–(4.4). *Let $v = V\varphi$ be the unique Φ-valued solution to* (3.1) *according to Theorem* 3.3. *Then, for each $t \geq 0$,*

$$\lim_{n\uparrow\infty} \|v(t) - \bar v_n(t)\|_{\mathcal H} = 0. \tag{4.15}$$

Proof. We may restrict our attention to $t \in [0,T]$ for any fixed $T > 1$. For $n \geq 1$ and with t_n defined in (4.7), from (3.1) and (4.5) we have

$$\begin{aligned}
\|v(t) - \bar v_n(t)\|_{\mathcal H} \leq\ & \|S^\alpha_t\varphi - S^\alpha_{1/n+t_n}\varphi\|_{\mathcal H} \\
& + \eta \int_0^{t_n} \mathrm{d}s \|S^\alpha_{t-s} v^{1+\beta}(s) - S^\alpha_{t_n - s_n} v^{1+\beta}(s)\|_{\mathcal H} \\
& + \eta \int_0^{t_n} \mathrm{d}s \|S^\alpha_{t_n - s_n} |v^{1+\beta}(s) - \bar v_n^{1+\beta}(s)|\|_{\mathcal H} \\
& + \eta \left\| \int_{t_n}^t \mathrm{d}s S^\alpha_{t-s} v^{1+\beta}(s) \right\|_{\mathcal H} + \eta \left\| \int_{t_n}^t \mathrm{d}s S^\alpha_{t_n - s_n} \bar v_n^{1+\beta}(s) \right\|_{\mathcal H} \\
=:\ & A_n(t) + B_n(t) + C_n(t) + D_n(t) + E_n(t),
\end{aligned} \tag{4.16}$$

with the obvious correspondence. We will deal with each of these terms separately.

Step 1 ($A_n(t)$). From the semigroup property and boundedness (2.68),

$$A_n(t) = \|S^\alpha_t\varphi - S^\alpha_{1/n+t_n}\varphi\|_{\mathcal H} \leq C_{2.9} \|S^\alpha_{|t-1/n-t_n|}\varphi - \varphi\|_{\mathcal H}. \tag{4.17}$$

But

$$\left| t - \frac{1}{n} - t_n \right| \leq \frac{1}{n}, \quad t \geq 0. \tag{4.18}$$

Hence,

$$\sup_{0\leq t\leq T} A_n(t) \leq C_{2.9} \sup_{0\leq s\leq 2/n} \|S^\alpha_s\varphi - \varphi\|_{\mathcal H} \underset{n\uparrow\infty}{\longrightarrow} 0 \tag{4.19}$$

by strong continuity according to Corollary 2.10.

Step 2 ($D_n(t)$). Clearly, by our estimates (recall (3.29) and (2.67)),

$$D_n(t) \leq C(\varphi)\eta \int_{t_n}^t \mathrm{d}s (1 + s^{-\kappa})(t-s)^{-\lambda} \|\varphi\|_{\mathcal H}. \tag{4.20}$$

By scaling, the integral equals

$$t^{1-\lambda} \int_{t_n/t}^1 \mathrm{d}s (1-s)^{-\lambda} + t^{1-\kappa-\lambda} \int_{t_n/t}^1 \mathrm{d}s s^{-\kappa}(1-s)^{-\lambda} =: I_n(t) + I\!I_n(t),$$

with the obvious correspondence. Take $\varepsilon \in (0,T)$ and let $n > 1/\varepsilon$. Since

$$\frac{t_n}{t} \geq 1 - \frac{1}{tn} \geq 1 - \frac{1}{\varepsilon n}, \quad \varepsilon \leq t \leq T, \tag{4.21}$$

we get

$$\sup_{\varepsilon\le t\le T} I_n(t) \le T^{1-\lambda}\int_{1-1/\varepsilon n}^{1} \mathrm{d}s(1-s)^{-\lambda} \underset{n\uparrow\infty}{\longrightarrow} 0, \tag{4.22}$$

whereas

$$\sup_{0\le t\le \varepsilon} I_n(t) \le \varepsilon^{1-\lambda}\int_{0}^{1} \mathrm{d}s(1-s)^{-\lambda} \le\ C\varepsilon^{1-\lambda}. \tag{4.23}$$

Now ε was arbitrary, and consequently,

$$\sup_{0\le t\le T} I_n(t) \underset{n\uparrow\infty}{\longrightarrow} 0, \tag{4.24}$$

and the same reasoning leads to the analogous statement on $I\!I_n(t)$. Summarizing,

$$\sup_{0\le t\le T} D_n(t) \underset{n\uparrow\infty}{\longrightarrow} 0. \tag{4.25}$$

Step 3 ($E_n(t)$). We may assume that $t > t_n$. By (4.5),

$$E_n(t) = \|\bar{v}_n(t) - \bar{v}_n(t_n)\|_{\mathcal{H}}. \tag{4.26}$$

According to the definition (4.2) of $\bar{v}_n(t)$,

$$0 \le \bar{v}_n(t_n,x) - \bar{v}_n(t,x) = \bar{v}_n(t_n,x)\left(1 - \frac{1}{[1+\eta\beta\bar{v}_n^{\beta}(t_n,x)(t-t_n)]^{1/\beta}}\right). \tag{4.27}$$

Since t is fixed, it follows that for n large enough, $t/2 < t_n$. Using domination and Lemma 4.2, there is a $\varphi_0 = \varphi_0(d,t,\alpha,\varphi,\varrho) \in \mathcal{H}_+$ such that

$$\bar{v}_n(t_n,x) \le S^{\alpha}_{1/n+t_n}\varphi(x) \le \varphi_0. \tag{4.28}$$

But (4.27) is increasing in $\bar{v}_n(t_n,x)$, so we may insert (4.28) to obtain

$$0 \le \bar{v}_n(t_n,x) - \bar{v}_n(t,x) \le \varphi_0(x)\left(1 - \frac{1}{[1+\eta\beta\varphi_0^{\beta}(x)/n]^{1/\beta}}\right) \le \varphi_0(x),$$

since $0 \le t - t_n \le 1/n$. Then, from dominated convergence we get

$$\lim_{n\to\infty} E_n(t) = 0 \tag{4.29}$$

for our fixed t.

Step 4 ($B_n(t)$). First of all, we want to deal with $B_n(t)$ for small t. Clearly, for $0 < s < t_n$,

$$\|S^{\alpha}_{t-s}v^{1+\beta}(s)\|_{\mathcal{H}} \le C(1+s^{-\kappa})(t-s)^{-\lambda}\|\varphi\|_{\mathcal{H}} \tag{4.30}$$

and

$$\|S^{\alpha}_{t_n-s_n}v^{1+\beta}(s)\|_{\mathcal{H}} \le C(1+s^{-\kappa})(t_n-s)^{-\lambda}\|\varphi\|_{\mathcal{H}} \tag{4.31}$$

since

$$t_n - s_n \geq t_n - s > 0. \tag{4.32}$$

Let $0 < \varepsilon < T$. Using notation (3.7), from (4.30) and (4.31), for $0 \leq t \leq \varepsilon$,

$$B_n(t) \leq C[I(t) + I(t_n)]. \tag{4.33}$$

Moreover, since I is increasing (recall (3.15)),

$$\sup_{n\geq 1} \sup_{0\leq t\leq \varepsilon} B_n(t) \leq C \sup_{0\leq t\leq \varepsilon} I(t) \underset{\varepsilon\downarrow 0}{\longrightarrow} 0. \tag{4.34}$$

Now we may restrict our attention to $t \in [\varepsilon, T]$. We want to exploit the strong continuity of the semigroup S^α acting on $\mathcal{H}_+$ (Corollary 2.10). To this end, we truncate $v^{1+\beta}$ to a function in $\mathcal{H}_+$, and consider a small time interval around t_n separately to get rid of the varying upper integration bound. Here are the details.

Take $\delta \in (0, \varepsilon)$ and $N \geq 1$. Set

$$v_{1,N}(t) := (v(t) \wedge N)1_{B_N(0)}, \tag{4.35a}$$

$$v_{2,N}(t) := v(t) - v_{1,N}(t). \tag{4.35b}$$

Then for $\varepsilon \leq t \leq T$,

$$\begin{aligned} B_n(t) \leq & \int_0^{t-\delta} \mathrm{d}s \|S^\alpha_{t-s} v^{1+\beta}_{1,N}(s) - S^\alpha_{t_n-s_n} v^{1+\beta}_{1,N}(s)\|_{\mathcal{H}} \\ & + \int_{t-\delta}^{t} \mathrm{d}s \|S^\alpha_{t-s} v^{1+\beta}(s)\|_{\mathcal{H}} + \int_{t-\delta}^{t_n} \mathrm{d}s \|S^\alpha_{t_n-s_n} v^{1+\beta}(s)\|_{\mathcal{H}} \\ & + \int_0^{t-\delta} \mathrm{d}s \|S^\alpha_{t-s} v^{1+\beta}_{2,N}(s)\|_{\mathcal{H}} + \int_0^{t-\delta} \mathrm{d}s \|S^\alpha_{t_n-s_n} v^{1+\beta}_{2,N}(s)\|_{\mathcal{H}} \\ =: & B_n^{(1)}(t) + \cdots + B_n^{(5)}(t) \end{aligned} \tag{4.36}$$

in the obvious correspondence. Again, we deal with all terms separately.

Step 4.1 ($B_n^{(2)}(t)$). From (4.30) and scaling,

$$B_n^{(2)}(t) \leq C \int_{1-\delta/t}^1 \mathrm{d}s (1-s)^{-\lambda} + C \int_{1-\delta/t}^1 \mathrm{d}s s^{-\kappa}(1-s)^{-\lambda}. \tag{4.37}$$

But $1 - \delta/t \geq 1 - \delta/\varepsilon$, and hence

$$\sup_n \sup_{\varepsilon\leq t\leq T} B_n^{(2)}(t) \underset{\delta\downarrow 0}{\longrightarrow} 0. \tag{4.38}$$

Step 4.2 ($B_n^{(3)}(t)$). Similarly, from (4.31) and (4.32),

$$B_n^{(3)}(t) \leq C \int_{t-\delta}^{t_n} \mathrm{d}s (1 + s^{-\kappa})(t_n - s)^{-\lambda}. \tag{4.39}$$

Now

$$t \geq t_n \geq t - \frac{1}{n} \geq \varepsilon - \frac{1}{n} \geq \delta, \tag{4.40}$$

provided that $n \geq 1/(\varepsilon - \delta)$. Thus, the lower integration bound can be replaced by $t_n - \delta$, and by scaling,

$$B_n^{(3)}(t) \leq C \int_{1-\delta/t_n}^1 \mathrm{d}s(1-s)^{-\lambda} + C \int_{1-\delta/t_n}^1 \mathrm{d}s s^{-\kappa}(1-s)^{-\lambda}. \tag{4.41}$$

By (4.40), the lower integration bounds can be changed to $1 - \delta/(\varepsilon - 1/n)$, implying

$$\limsup_{n\uparrow\infty} \sup_{\varepsilon \leq t \leq T} B_n^{(3)}(t) \underset{\delta\downarrow 0}{\longrightarrow} 0. \tag{4.42}$$

Step 4.3 ($B_n^{(4)}(t)$ *and* $B_n^{(5)}(t)$). By domination and Corollary 2.11,

$$v_{2,N}^{\beta}(s) \leq v^{\beta}(s) \leq (S_s^{\alpha}\varphi)^{\beta} \leq C(1+s)^{-\kappa}\phi^{\beta}. \tag{4.43}$$

Note that for $s \in [0, t-\delta]$,

$$t - s \quad \text{and} \quad t_n - s_n \quad \text{belong to } [\delta/2, t] \text{ if } n > 2/\delta \tag{4.44}$$

(for instance, $t_n - s_n \geq t - \frac{1}{n} - s \geq -\frac{1}{n} + \delta \geq \delta$). Then, for $r \in [\delta/2, t]$ and $n > 2/\delta$,

$$\|S_r^{\alpha} v_{2,N}^{1+\beta}(s)\|_{\mathcal{H}} \leq C(1+s)^{-\kappa} \|S_r^{\alpha}(v_{2,N}(s)\phi^{\beta})\|_{\mathcal{H}} \leq C(1+s)^{-\kappa}\|v_{2,N}(s)\|_{\mathcal{H}},$$

where in the last step we used Lemma 2.7 with φ replaced by $v_{2,N}(s)$. Now by domination and boundedness, for $0 \leq s \leq T$,

$$\|v_{2,N}(s)\|_{\mathcal{H}} \leq \|S_s^{\alpha}\varphi\|_{\mathcal{H}} \leq C\|\varphi\|_{\mathcal{H}} \tag{4.45}$$

and

$$\|v_{2,N}(s)\|_{\mathcal{H}} \underset{N\uparrow\infty}{\searrow} 0. \tag{4.46}$$

Therefore,

$$\begin{aligned} &\limsup_{n\uparrow\infty} \sup_{\varepsilon \leq t \leq T} (B_n^{(4)}(t) + B_n^{(5)}(t)) \\ &\qquad \leq C \int_0^T \mathrm{d}s(1+s)^{-\kappa} \|v_{2,N}(s)\|_{\mathcal{H}} \underset{N\uparrow\infty}{\searrow} 0, \end{aligned} \tag{4.47}$$

by monotone convergence, for the fixed ε and δ.

Step 4.4 ($B_n^{(1)}(t)$). It remains to deal with $B_n^{(1)}(t)$. By the semigroup property, boundedness, and strong continuity,

$$\begin{aligned} &\|S_{t-s}^{\alpha} v_{1,N}^{1+\beta}(s) - S_{t_n - s_n}^{\alpha} v_{1,N}^{1+\beta}(s)\|_{\mathcal{H}} \\ &\qquad \leq C \sup_{0 \leq r \leq 2/n} \|S_r^{\alpha} v_{1,N}^{1+\beta}(s) - v_{1,N}^{1+\beta}(s)\|_{\mathcal{H}} \underset{N\uparrow\infty}{\searrow} 0 \end{aligned} \tag{4.48}$$

for all s and N, since by definition

$$v_{1,N}^{1+\beta}(s) \leq N^{1+\beta} 1_{B_N(0)} \in \mathcal{H}_+. \tag{4.49}$$

Moreover, the supremum in (4.48) is bounded from above by

$$2N^{1+\beta}\|1_{B_N(0)}\|_{\mathcal{H}}. \tag{4.50}$$

Therefore,

$$\sup_{\varepsilon\le t\le T} B_n^{(1)}(t) \le \int_0^T \mathrm{d}s \sup_{0\le r\le 2/n} \|S_r^\alpha v_{1,N}^{1+\beta}(s) - v_{1,N}^{1+\beta}(s)\|_{\mathcal{H}} \underset{n\uparrow\infty}{\searrow} 0, \tag{4.51}$$

by monotone convergence, for all our N, ε, δ.

Step 4.5 (*conclusion*). Putting together (4.34), (4.38), (4.42), (4.47), and (4.51),

$$\sup_{0\le t\le T} B_n(t) \underset{n\uparrow\infty}{\longrightarrow} 0. \tag{4.52}$$

Step 5 ($C_n(t)$). First note that

$$C_n(t) = 0 \quad \text{for } t \le 1/n. \tag{4.53}$$

So we may assume that $t \ge 1/n$. Next we apply Lemma 3.6 to get for the term in abstract value sign in the definition of $C_n(t)$ the bound

$$C[|v|^\beta(s) + |\bar v_n|^\beta(s)]|v(s) - \bar v_n(s)|. \tag{4.54}$$

From domination, the expression in square brackets is bounded by

$$(S_s^\alpha\varphi)^\beta + (S_{1/n+s_n}^\alpha\varphi)^\beta \le C(1+s^{-\kappa})\phi^\beta, \tag{4.55}$$

where we used Corollary 2.11 and $1/n + s_n \ge s$. But by Corollary 2.9,

$$\|S_{t_n-s_n}^\alpha |v(s) - \bar v_n(s)|\phi^\beta\|_{\mathcal{H}} \le C(t_n - s_n)^{-\lambda}\|v(s) - \bar v_n(s)\|_{\mathcal{H}}. \tag{4.56}$$

Setting

$$F_n(t) := \sup_{s\le t} \|v(s) - \bar v_n(s)\|_{\mathcal{H}}, \tag{4.57}$$

we found for $\frac{1}{n} \le t \le T$,

$$\begin{aligned} &\int_0^{t_n} \mathrm{d}s \|S_{t_n-s_n}^\alpha |v^{1+\beta}(s) - \bar v_n^{1+\beta}(s)|\|_{\mathcal{H}} \\ &\qquad \le CF_n(t)\int_0^{t_n} \mathrm{d}s(1+s^{-\kappa})(t_n-s)^{-\lambda} \le CF_n(t)I(t) \end{aligned} \tag{4.58}$$

(recall (3.7)).

Step 6 (*completion of the proof*). By (4.19), (4.25), (4.29), (4.52), and (4.58), from estimate (4.16) we obtain

$$\|v(t) - \bar v_n(t)\|_{\mathcal{H}} \le \varepsilon_n + CF_n(t)I(t) \tag{4.59}$$

for the fixed $t \le T$, where $C = C(T)$ and where $\varepsilon_n = \varepsilon_n(t,T)$ tends to 0 as $n \uparrow \infty$. Imposing additionally on t that $CI(t) < \frac{1}{2}$ (recall (3.7)), we get

$$F_n(t) \le \varepsilon_n + \frac{1}{2}F_n(t), \quad \text{that is, } F_n(t) \le 2\varepsilon_n \underset{n\uparrow\infty}{\longrightarrow} 0. \tag{4.60}$$

Consequently,

$$\|v(t) - \bar v_n(t)\|_{\mathcal{H}} \underset{n\uparrow\infty}{\longrightarrow} 0 \quad \text{for all sufficiently small } t. \tag{4.61}$$

Repeating the argument, we can lift up for $t \in [0,T]$. Since T was arbitrary, the proof of Proposition 4.3 is finished altogether. □

4.3. Construction of the process. Here is now the more precise formulation of our main result, announced in Theorem 1.1.

THEOREM 4.4 (existence of X). *Under Hypothesis* 3.2*, there is a (unique in law) nondegenerate $\mathcal{M}(\dot{\mathsf{R}}^d)$-valued (time-homogeneous) Markov process $X = (X, P_\mu,\ \mu \in \mathcal{M})$ with log-Laplace transition functional* (1.6) *using test functions $\varphi \in \Phi$ and where $v = V\varphi$ is the unique Φ-valued solution to* (3.1)*.*

Remark 4.5 (nondegeneracy). It is easy to see that the following expectation formula holds:

$$P_\mu\langle X_t, \varphi\rangle = \langle \mu, S_t^\alpha \varphi\rangle =: \langle S_t^\alpha \mu, \varphi\rangle, \quad \mu \in \mathcal{M},\ t \geq 0,\ \varphi \in \Phi. \tag{4.62}$$

But

$$V_t\varphi \neq S_t^\alpha \varphi, \quad t > 0,\ \varphi \in \Phi,\ \varphi \neq 0. \tag{4.63}$$

Hence, the log-Laplace formula (1.6) shows that X is different from its expectation; that is, it is nondegenerate.

Proof of Theorem 4.4. For the moment, fix $\mu \in \mathcal{M}$ and $n \geq 1$. Our first purpose is, for $t \geq 0$ fixed, to construct a random measure X_t^n in $\mathcal{M}$ with log-Laplace functional

$$-\log \mathbf{P}\mathrm{e}^{-\langle X_t^n, \varphi\rangle} = \langle \mu, \bar{v}_n(t)\rangle, \quad \varphi \in \Phi, \tag{4.64}$$

where $\bar{v}_n =: V^n\varphi$ is taken from definitions (4.1)–(4.4). Then we later let $n \uparrow \infty$ and obtain (for the fixed t) a random measure X_t in $\mathcal{M}$ with log-Laplace functional

$$-\log \mathbf{P}\mathrm{e}^{-\langle X_t, \varphi\rangle} = \langle \mu, v(t)\rangle, \quad \varphi \in \Phi. \tag{4.65}$$

Actually, we will get a probability kernel Q_t, say, in $\mathcal{M}$, which as a function in t turns out to satisfy Chapman–Kolmogorov. Trivially, Q is then the transition kernel of a time-homogeneous Markov process X, say, in $\mathcal{M}$, regardless of its possible path properties (which are not considered in the theorem) and whether, for fixed n, the family of the X_t^n, $t \geq 0$, is defined on a common probability space (which is necessary to form a random process) or not. Now the details will follow.

As the $\bar{v}_n$ had been constructed by alternating operations of mass flow and continuous-state branching on time intervals of length $\frac{1}{n}$, we will construct also the X_t^n by such an alternation procedure. Note, however, since the two alternating operations do not commute, on the dual level of measures we have to interchange the order of operations.

An essential tool in our construction of the X_t^n will be an $\mathcal{M}$-valued process Y that we will introduce next. As already noted in the beginning of subsection 4.1, the unique solutions g to the ordinary differential equation

$$\frac{\mathrm{d}g}{\mathrm{d}t}(t) = -\eta g^{1+\beta}(t) \quad \text{on} \quad \mathsf{R}_+ \quad \text{with } g(0) = \theta \tag{4.66}$$

yield the log-Laplace transition functions of a critical continuous-state branching process, say $y = \{y_t : t \geq 0\}$, with index $1 + \beta$:

$$-\log \mathbf{P}\{\mathrm{e}^{-y_t\theta} \mid y_0 = a\} = ag(t) \tag{4.67}$$

(see [Lam67]). (Clearly, for $\beta = 1$, we have the famous critical Feller's branching diffusion; otherwise the y_t have infinite variance.) We want to let such processes evolve independently at each spatial point $x \neq 0$. More precisely, consider the $\mathcal{M}$-valued

(time-homogeneous) Markov process $\{Y_t : t \geq 0\}$ with càdlàg paths and log-Laplace transition functional

$$-\log \mathbf{P}\{\mathrm{e}^{-\langle Y_t,\varphi\rangle} \mid Y_0 = \mu\} = \langle \mu, G_t\varphi\rangle, \quad t \geq 0,\ \varphi \in \Phi,\ \mu \in \mathcal{M}, \tag{4.68}$$

where

$$G_t\varphi(x) := g(t,x), \quad t \geq 0,\ x \neq 0, \tag{4.69}$$

and for each $x \neq 0$ fixed, $t \mapsto g(t,x)$ solves (4.66) with θ replaced by $\varphi(x)$. This process Y can also be obtained by starting from a critical super-Brownian motion on R^d with $(1+\beta)$-branching and letting the migration constant of the super-Brownian motion tend to zero; see [DF88, Theorem 5.8]. Although started from any measure $Y_0 = \mu \in \mathcal{M}$, at positive times t the random measures Y_t are atomic, where the (closed) support of Y_t forms a Poisson point field on R^d, whereas the weights of the atoms evolve in time independently as critical continuous-state branching processes y of index $1+\beta$ (see [DF88, discussion after Theorem 3.1]).

For fixed $\mu \in \mathcal{M}$, and $n \geq 1$, we now want inductively to introduce the random measures X_t^n satisfying (4.64). First of all, for $t \in [0, \frac{1}{n})$ set

$$X_t^n \ := \ S_{1/n}^\alpha Y_t, \quad \text{where } Y \text{ starts from } Y_0 := \mu. \tag{4.70}$$

Here we used the notation of smearing out measures according to the flow S^α introduced in (4.62), and Lemma 4.2. Then by (4.68),

$$\mathbf{P}\mathrm{e}^{-\langle X_t^n,\varphi\rangle} = \mathbf{P}\mathrm{e}^{-\langle Y_t, S_{1/n}^\alpha\varphi\rangle} = \mathrm{e}^{-\langle \mu, G_t S_{1/n}^\alpha\varphi\rangle}, \quad \varphi \in \Phi. \tag{4.71}$$

But by uniqueness of the solutions to (4.66) and by (4.3) in the case $k = 0$, we get $G_t S_{1/n}^\alpha \varphi = \bar{v}_n(t)$. Consequently, (4.64) is true for $0 \leq t < \frac{1}{n}$.

Assume now that for some $k \geq 0$ the random measures X_t^n, $t \in [\frac{k}{n}, \frac{k+1}{n})$, are defined (not necessarily on a common probability space) and satisfy (4.64). Recall that this is true for $k = 0$. Then, for fixed $t \in [\frac{k+1}{n}, \frac{k+2}{n})$, conditionally on $X_{t-1/n}^n$, we set

$$X_t^n \ := \ S_{1/n}^\alpha Y_{1/n}, \quad \text{where } Y \text{ starts from } Y_0 := X_{t-1/n}^n. \tag{4.72}$$

Now (4.68) implies

$$\mathbf{P}\mathrm{e}^{-\langle X_t^n,\varphi\rangle} = \mathbf{P}\mathbf{P}\{\mathrm{e}^{-\langle Y_{1/n}, S_{1/n}^\alpha\varphi\rangle} \mid Y_0 = X_{t-1/n}^n\} = \mathbf{P}\mathrm{e}^{-\langle X_{t-1/n}^n, G_{1/n} S_{1/n}^\alpha\varphi\rangle}. \tag{4.73}$$

By the induction hypothesis, the chain of equations (4.73) can be continued with

$$= \mathrm{e}^{-\langle \mu, \bar{v}_n(t-1/n)\rangle}, \qquad \varphi \in \Phi, \tag{4.74}$$

but where $\bar{v}_n(0) = S_{1/n}^\alpha G_{1/n} S_{1/n}^\alpha \varphi$ instead of $S_{1/n}^\alpha\varphi$. However, by the constructions in the beginning of subsection 4.1, the new $\bar{v}_n(t - \frac{1}{n})$ coincides with the original $\bar{v}_n(t)$, yielding (4.64). Consequently, by induction we obtained random measures X_t^n satisfying (4.64) for any $t \geq 0$.

Next we want to let $n \uparrow \infty$. According to Proposition 4.3, for $t \geq 0$ fixed, $\bar{v}_n(t) \to v(t)$ as $n \uparrow \infty$, implying that the right-hand sides of (4.64) converge to $\langle \mu, v(t)\rangle$. Therefore, the log-Laplace transforms at the left-hand side of (4.64) converge to $\langle \mu, v(t)\rangle$, too. Now, by domination as in (3.2), we get $\langle \mu, v(t)\rangle \downarrow 0$ as $\varphi \downarrow 0$.

Therefore, the limit of the log-Laplace transforms in (4.64) is again a log-Laplace transform of a random measure in $\mathcal{M}$, say X_t (see, for instance, [Dyn94, section 3.3.4, pp. 50–51]; in other words, there is no loss of probability mass, that is, the laws of the random measures X_t^n are relatively compact). Consequently, for t fixed, $X_t^n \to X_t$ in law as $n \uparrow \infty$. Since the map $\mu \mapsto \langle \mu, V_t\varphi\rangle$ is measurable, via $\mu \mapsto X_t$ we get a probability kernel Q_t in $\mathcal{M}$ for the fixed t. From the semigroup property of $V\varphi$ it follows that the family $Q := \{Q_t : t > 0\}$ satisfies Chapman–Kolmogorov. Hence, Q is the transition kernel of a time-homogeneous Markov process in $\mathcal{M}$, which is the desired superprocess X. This finishes the proof of Theorem 4.4. □

Remark 4.6 (convergence theorem on càdlàg path space). The previous proofs should be modified and refined as the superprocess X is constructed as a Markov process via convergence of the one-, hence finite-dimensional, distributions of approximating processes X^n with càdlàg paths, say. Now the processes X^n and X should have finite moments of all orders $\theta \in (0, 1 + \beta)$. Using martingale methods, via Aldous's criterion it should be possible to prove tightness of the laws of the processes X^n on Skorohod path space, then sharpening Theorem 4.4 to a convergence theorem on path space with a limiting càdlàg superprocess X.

Acknowledgments. We would like to thank Sergio Albeverio, Zdzisław Brzeźniak, Werner Kirsch, and Karl-Theodor Sturm for discussions on the operators $\Delta^{(\alpha)}$. We are also very grateful to an anonymous referee for his very careful reading and suggestions for improving the exposition, in particular concerning the final construction of the superprocess.

RANDOM SAMPLING OF MULTIVARIATE TRIGONOMETRIC POLYNOMIALS*

RICHARD F. BASS† AND KARLHEINZ GRÖCHENIG‡

Abstract. We investigate when a trigonometric polynomial p of degree M in d variables is uniquely determined by its sampled values $p(x_j)$ on a random set of points x_j in the unit cube (the "sampling problem for trigonometric polynomials") and estimate the probability distribution of the condition number for the associated Vandermonde-type and Toeplitz-like matrices. The results provide a solid theoretical foundation for some efficient numerical algorithms that are already in use.

Key words. sampling, band-limited functions, multivariate trigonometric polynomials, random sampling, block Toeplitz matrix, Vandermonde matrix, condition number, metric entropy

1. Introduction.

The reconstruction, interpolation, or approximation of a function (signal, image) from a given data set is a central task in many problems of data processing. The mathematical problem is to find a function $f(x)$ in a suitable function space V that interpolates or approximates the given data $y_j = f(x_j)$. The set $\mathcal{X} = \{x_j : j = 1, \dots, r\} \subseteq \mathbb{R}^d$ is the sampling set, and the function space V comes from the mathematical modeling of signals or images (e.g., band-limitedness, smoothness). The numerical and theoretical analysis of the sampling problem depends, of course, heavily on the signal model V.

In this paper we focus almost exclusively on multivariate trigonometric polynomials as our model. While this is by no means the only possible model, it is convenient, interesting, and occurs in many applications where standard uniform sampling is not possible. Specifically, the model of trigonometric polynomials has been used in cardiology (one-dimensional) [39]; geophysics (two-dimensional) [30]; image processing (two-dimensional) [37]; as a nonuniform discrete Fourier transform (one- and two-dimensional) [8, 14, 15, 29, 35]; and in computer tomography (two- and three-dimensional) [3, 28, 33]. Furthermore the space of trigonometric polynomials of fixed degree is the appropriate finite-dimensional model for the approximation of band-limited functions from a finite number of samples [20, 21].

Clearly, the sampling operator $f \to \{f(x_j) : j = 1, \dots, r\}$ is linear, and, for a finite-dimensional model space, it can therefore be described by a matrix. For the model of trigonometric polynomials of fixed degree, this matrix possesses an additional structure; namely, it is either a rectangular Vandermonde-like matrix or a square Toeplitz-like matrix. This structure is the basis for efficient and fast numerical algorithms. For dimension $d = 1$ we refer to [8, 16, 17, 31, 38], and for higher dimensions to [28, 30, 33, 37]. These algorithms are fast, stable, and robust, but only in dimension $d = 1$ do the numerical algorithms possess a solid theoretical basis

(invertibility, estimates of condition numbers, and rates of convergence for iterative algorithms).

In higher dimensions, there is only numerical evidence that the existing algorithms work; except for some isolated results [19, 23] there has been no theoretical justification for the success of these numerical methods. The main reason for this disparity lies in the nature of zero sets of trigonometric polynomials in one and higher dimensions. In dimension $d = 1$ the zero set of a trigonometric polynomial is finite by the fundamental theorem of algebra, whereas the zero set of a trigonometric polynomial in several variables is an algebraic variety. This difference makes it almost impossible to determine effectively whether the reconstruction problem $\{f(x_j)\} \to f$ is solvable for a fixed multidimensional sampling set $\mathcal{X} \subseteq \mathbb{R}^d$. It seems even more difficult to estimate the condition numbers of the associated matrices. On the other hand, numerical experiments and successful applications make it plausible that for generic sampling sets $\mathcal{X} \subseteq \mathbb{R}^d$ the sampling problem is solvable and well-conditioned.

Our goal is to achieve some understanding for the success of existing numerical methods and to provide more insight into the theoretical issues. To do this we adopt a probabilistic point of view: Instead of seeking analytic statements for a fixed sampling set, we consider the collection of all sampling sets of size r and assume that the *sampling set consists of a finite sequence of independent random variables.* Instead of worst-case estimates, i.e., inequalities within mathematical analysis, we will seek probabilistic estimates (from the realm of probability theory). With this underlying philosophy, we will pursue the following objectives:

(a) We seek to explain and predict the performance of the existing numerical algorithms.

(b) We estimate the distribution of the condition numbers of the associated Vandermonde-like and Toeplitz-like matrices.

(c) We investigate the asymptotic behavior of condition numbers as the number of samples r tends to infinity.

The randomization of the sampling points seems to be a new idea in the investigation of numerical sampling algorithms. So far random sampling has been investigated by Seip and Ulanovskii [32], Chistyakov and Lyubarskii [9], Chistyakov, Lyubarskii, and Pastur [10] for entire functions of exponential type of one complex variable. These results rely on the deep characterization of deterministic sampling sets [26, 27] and, to our knowledge, cannot be extended to higher dimensions. In a different direction, Smale and Zhou [34] have recently used probabilistic methods from learning theory [12] to investigate sampling in reproducing kernel Hilbert spaces.

By contrast, our main contribution is to sampling theory for functions of several variables. In higher dimensions there is currently no satisfactory deterministic theory, and our analysis provides the first clues that existing algorithms and methods do really work. From a more applied point of view, our results suggest that random sampling of images or higher-dimensional objects may be a successful strategy to capture the essential information of multidimensional objects while preserving numerical efficiency and stability.

Description of results. We now describe the main results.

Let $\mathcal{P}_M$ be the space of trigonometric polynomials on $\mathbb{R}^d$ of degree M and period 1, that is, $\mathcal{P}_M$ consists of all functions on $\mathbb{R}^d$ of the form

$$p(x) = \sum_{k \in [-M,M] \cap \mathbb{Z}^d} a_k e^{2\pi i k \cdot x}. \tag{1}$$

Note that the (distributional) Fourier transform of $p \in \mathcal{P}_M$ is $\hat{p} = \sum_{k\in[-M,M]\cap\mathbb{Z}^d} a_k\delta_k$, so supp $\hat{p} \subseteq [-M,M]^d$. The parameter M can be interpreted as the "bandwidth," and indeed trigonometric polynomials have been shown to be the appropriate finite-dimensional model for band-limited functions [20, 21].

Now assume that the samples $p(x_j), j = 1,\dots,r$, of some trigonometric polynomial $p \in \mathcal{P}_M$ are given for some sampling set $\mathcal{X} = \{x_j : j = 1,\dots,r\}$. By our normalization, we may assume that the sampling set $\mathcal{X}$ is contained in the unit cube $[0,1]^d$. Our goal is to reconstruct or to approximate p. Equivalently, we want to determine the coefficients a_k of p from the samples $p(x_j)$. This task can be seen as a nonuniform discrete Fourier transform and is a frequent task in data processing [8, 14, 15, 29, 35].

In its simplest form, the reconstruction of p amounts to solving the r equations

$$\sum_{k\in[-M,M]^d\cap\mathbb{Z}^d} a_k e^{2\pi i k\cdot x_j} = p(x_j) = y_j, \quad j = 1,\dots,r,$$

for the coefficient vector $\mathbf{a} = (a_k)_{k\in\mathbb{Z}^d\cap[-M,M]^d}$. This system of equations can be written in matrix form as

$$\mathcal{U}\mathbf{a} = \mathbf{y}, \tag{2}$$

where $\mathcal{U}$ is the matrix with entries $\mathcal{U}_{jk} = e^{2\pi i k\cdot x_j}, k \in \mathbb{Z}^d \cap [-M,M]^d, j = 1,\dots,r$, and $\mathbf{y}$ is the target vector $\mathbf{y} = (y_j)_{j=1,\dots,r}$. Alternatively, one may try to find $\mathbf{a}$ from the normal equations [18]

$$\mathcal{U}^*\mathcal{U}\mathbf{a} = \mathcal{U}^*\mathbf{y}. \tag{3}$$

In this case the matrix $\mathcal{T} = \mathcal{U}^*\mathcal{U}$ has entries

$$\mathcal{T}_{kl} = \sum_{j=1}^{r} e^{-2\pi i(k-l)\cdot x_j}, \quad k,l \in [-M,M]^d \cap \mathbb{Z}^d.$$

The matrices of these linear systems are highly structured, $\mathcal{U}$ is a *Vandermonde-like matrix*, and $\mathcal{T}$ is a positive semidefinite $D \times D$ matrix with a *block Toeplitz structure*. Both structures have been successfully exploited for fast numerical algorithms [17, 23, 29, 37].

However, before the numerical analysis of the sampling problem can be undertaken, we need to settle a fundamental theoretical issue: Is either of the equations (2) or (3) solvable? Note that both matrices $\mathcal{U}$ and $\mathcal{T}$ depend on the sampling points x_j as parameters. Therefore we ask more precisely, *for which sampling set $\mathcal{X}$ does $\mathcal{U}$ have full rank, or, equivalently, when is $\mathcal{T}$ invertible?*

In dimension $d = 1$, $\mathcal{T}$ is invertible if and only if $r \geq 2M + 1$ (the number of sampling points is greater than the dimension of the space). In higher dimensions no criterion for the invertibility of $\mathcal{T}$ is known, and useful results are sparse. See [23] for a discussion.

In the spirit of probability theory we model the sampling set as a sequence of independent, identically distributed (i.i.d.) random variables in $[0,1]^d$. This means that we treat the sampling points as a sequence of functions $x_j = x_j(\omega)$ on some probability space $(\Omega, \mathbb{P})$. Thus the matrices $\mathcal{U}$ and $\mathcal{T}$ are now random matrices, and their determinants, eigenvalues, and singular values are random variables on $(\Omega, \mathbb{P})$ that depend on the sampling set in a rather complicated way.

The first theorem guarantees the generic invertibility of $\mathcal{T}$.

THEOREM 1.1. *Assume that the finite sequence of random variables $x_1, \dots, x_r$ satisfies the following properties:*

(a) $r \geq (2M+1)^d$.

(b) *The x_j's are independent.*

(c) *The distribution μ_j of each x_j is absolutely continuous with respect to Lebesgue measure on $[0,1]^d$.*

Then with probability one the Toeplitz-like matrix $\mathcal{T}$ is invertible.

Estimates for the condition number. For a stable numerical solution of either of the systems (2) and (3) we need effective invertibility of $\mathcal{T}$. This is usually measured by the condition number $\kappa(\mathcal{T})$ of $\mathcal{T}$. (The condition number $\kappa(M)$ of a rectangular matrix is the ratio of largest to smallest singular value [18]; for a positive-definite square matrix, this is simply the ratio of the largest to the smallest eigenvalue.) To estimate the condition numbers of $\mathcal{U}$ and $\mathcal{T}$ we observe that

$$\sum_{j=1}^{r} |p(x_j)|^2 = \langle \mathbf{y}, \mathbf{y} \rangle = \langle \mathcal{U}\mathbf{a}, \mathcal{U}\mathbf{a} \rangle = \langle \mathcal{U}^*\mathcal{U}\mathbf{a}, \mathbf{a} \rangle = \langle \mathcal{T}\mathbf{a}, \mathbf{a} \rangle. \tag{4}$$

Consequently, if we can prove an inequality of the form

$$A\|p\|_2^2 \leq \sum_{j=1}^{r} |p(x_j)|^2 \leq B\|p\|_2^2 \quad \forall p \in \mathcal{P}_M, \tag{5}$$

then the largest (smallest) eigenvalue of $\mathcal{T}$ is at most B (at least A), since $\|p\|_2 = \|\mathbf{a}\|_2$. Consequently, (5) implies the estimates

$$\kappa(\mathcal{T}) \leq \frac{B}{A} \quad \text{and} \quad \kappa(\mathcal{U}) \leq \Big(\frac{B}{A}\Big)^{1/2}. \tag{6}$$

Our main theorem is the following asymptotic estimate for the condition numbers of $\mathcal{T}$ or $\mathcal{U}$ as $r \to \infty$.

THEOREM 1.2. *Assume that $\mathcal{X} = \{x_j : j \in \mathbb{N}\}$ is a sequence of i.i.d. random variables uniformly distributed over $[0,1]^d$. There exist constants $A, B > 0$ depending only on the bandwidth M and the dimension d such that for any $\mu \in (0,1)$, the sampling inequality*

$$(1-\mu)r\|p\|_2^2 \leq \sum_{j=1}^{r} |p(x_j)|^2 \leq (1+\mu)r\|p\|_2^2 \quad \forall p \in \mathcal{P}_M \tag{7}$$

holds with probability at least

$$1 - Ae^{-Br\frac{\mu^2}{1+\mu}}.$$

Consequently, with the same probability estimate, the Toeplitz-type matrix $\mathcal{T}$ has condition number $\kappa(\mathcal{T}) \leq \frac{1+\mu}{1-\mu}$ and the Vandermonde-like matrix $\mathcal{U}$ has condition number $\kappa(\mathcal{U}) \leq \sqrt{1+\mu}/\sqrt{1-\mu}$.

For a fixed threshold $\theta > 1$, the probability that $\kappa(\mathcal{T}) \leq \theta$ converges to 1 exponentially fast as the number of samples increases. With some poetic license, we may therefore say that *oversampling improves the condition number.*

We will give two proofs of this result. The first proof is by reduction to a deterministic result. We estimate the probability that the conditions of an existing deterministic result from [23] are satisfied. With this approach we obtain explicit estimates for the

constants. The second proof uses a version of the powerful metric entropy method; see [4, 5, 13] for just a few of its applications to probability theory. This approach is genuinely asymptotic and does not yield effective estimates of the constants. The main advantage of this method is its flexibility and generality. To demonstrate the power of this approach we will formulate versions of Theorem 1.2 for ordinary polynomials in several variables, for almost periodic functions, and for spherical harmonics on the sphere (section 6).

As a consequence of Theorem 1.2 we obtain the following law of the iterated logarithm.

COROLLARY 1.3. *If $\{x_j : j \in \mathbb{N}\}$ is a sequence of i.i.d. random variables that are uniformly distributed over $[0,1]^d$, then*

$$\limsup_{r\to\infty} \frac{\sup_{p\in\mathcal{P}} |\sum_{j=1}^{r} [|p(x_j)|^2 - \|p\|_2^2]|}{\sqrt{r \log\log r}\,\|p\|_2^2} = c \quad a.s. \tag{8}$$

for some positive constant c of order $D = (2M+1)^d$.

With less precision, but more intuitively, the corollary says that with probability one, the condition number of the sampling problem is

$$\kappa(\mathcal{T}) \le (r + c\sqrt{r\log\log r})/(r - c\sqrt{r\log\log r}) \approx 1 + 2c\left(\frac{\log\log r}{r}\right)^{1/2},$$

whenever r is large enough.

Our main theorems validate existing numerical algorithms for nonuniform sampling sets in higher dimensions. Furthermore, they make precise in which sense random sampling of multidimensional objects is better than deterministic sampling.

The paper is organized as follows. In section 2 we collect some facts about multivariate trigonometric polynomials and explain the idea of the simplest numerical algorithms. In section 3 we prove Theorem 1.1 about the almost certain solvability of the sampling problem. In section 4 we provide the first proof of Theorem 1.2 and show a probabilistic covering result that may be of independent interest. In section 5 we develop the metric entropy approach and give a second proof of Theorem 1.2 for the asymptotic estimate of the condition number. Furthermore, we develop some consequences of our main theorem. In section 6 we discuss extensions of the metric entropy method to other sampling problems.

2. Sampling of trigonometric polynomials. We first collect the background information on sampling of trigonometric polynomials and some of the numerical aspects that motivated our investigation.

By $\mathcal{X} = \{x_j : j = 1, \dots, r\}$ we denote a sampling set of r (distinct) points in $[0,1]^d$.

The space of trigonometric polynomials on $\mathbb{R}^d$ of degree M and period 1 in each variable is

$$\mathcal{P}_M = \left\{ p : p(x) = \sum_{k\in[-M,M]^d\cap\mathbb{Z}^d} a_k e^{2\pi i k\cdot x} \right\}. \tag{9}$$

Remarks. (1) The vector space $\mathcal{P}_M$ has dimension $D = (2M+1)^d$. This implies that we need at least $(2M+1)^d$ data points in order to recover a polynomial $p \in \mathcal{P}_M$.

(2) The parameter M can be interpreted as the "bandwidth" and measures the permissible amount of oscillation (smoothness). We will assume that M is given, but

note that the determination of the optimal bandwidth is an important step in the practical application of sampling algorithms [38].

(3) On $\mathcal{P}_M$ the following estimates between equivalent norms hold:

$$\|p\|_2^2 = \int_{[0,1]^d} |p(x)|^2 \, dx = \|\mathbf{a}\|_2,$$

$$\|p\|_\infty \le D^{1/2} \, \|\mathbf{a}\|_2 = D^{1/2} \, \|p\|_2, \tag{10}$$

$$\|p\|_4^4 \le \|p\|_\infty^2 \|p\|_2^2 \le D\|p\|_2^4.$$

The reconstruction of $p \in \mathcal{P}_M$ from given samples $\{p(x_j) : j = 1, \dots, r\}$ amounts to solving the following system of r equations:

$$\sum_{k \in [-M,M]^d \cap \mathbb{Z}^d} a_k e^{2\pi i k \cdot x_j} = f(x_j) = y_j, \quad j = 1, \dots, r. \tag{11}$$

Introducing the matrices $\mathcal{U}$ and $\mathcal{T}$ with entries

$$U_{jk} = e^{2\pi i k \cdot x_j}, \quad j = 1, \dots, r, k \in [-M, M]^d \cap \mathbb{Z}^d, \tag{12}$$

$$\mathcal{T}_{kl} = (\mathcal{U}^* \mathcal{U})_{kl} = \sum_{j=1}^{r} e^{-2\pi i (k-l) \cdot x_j}, \quad k, l \in [-M, M]^d \cap \mathbb{Z}^d, \tag{13}$$

we can then formulate the sampling problem for $\mathcal{P}_M$ in several distinct ways.

LEMMA 2.1. *The following are equivalent:*

(i) *The equations* (11) *possess a unique solution in* $\mathcal{P}_M$.

(ii) *The Vandermonde-type matrix has full rank and* $r \ge D$.

(iii) *There exist* $A, B > 0$ *such that*

$$A\|\mathbf{a}\|_2 \le \|\mathcal{U}\mathbf{a}\|_2 \le B\|\mathbf{a}\|_2 \quad \forall \mathbf{a} \in \mathbb{C}^D.$$

(iv) *The* $D \times D$ *Toeplitz-like matrix* $\mathcal{T}$ *is invertible.*

(v) *There exist* $A, B > 0$ *such that*

$$A\|p\|_2 \le \sum_{j=1}^{r} |p(x_j)|^2 \le B\|p\|_2 \quad \forall p \in \mathcal{P}_M. \tag{14}$$

If any of (i)–(v) hold, we say that $\mathcal{X}$ is a *set of stable sampling* for $\mathcal{P}_M$ [25].

Despite its lack of mathematical substance, this lemma is useful because each of the criteria may be used as a starting point for the theoretical or numerical investigation of the sampling problem. For the mathematical analysis the *sampling inequality* (14) is most appropriate, because it invites the use of analytic methods. For the numerical solution of the sampling problem, the linear algebra criteria (ii), (iii), and (iv) are most useful, because the theory of structured matrices offers fast solution techniques.

A numerical algorithm for the solution of (11) could then be based on the following steps.

ALGORITHM.

Input. Given a sampling set $\mathcal{X} = \{x_j : j = 1, \dots, r\} \subseteq [0,1]^d$ and a data vector $\mathbf{y} = \{y_j : j = 1, \dots, r\}$, assume that $\mathcal{T}$ defined in (13) is invertible.

Step 1. Compute $\mathbf{b} = \mathcal{U}^*\mathbf{y}$, i.e.,

$$b_k = \sum_{j=1}^{r} e^{-2\pi i k\cdot x_j}\, y_j \quad \text{for } k \in [-M, M]^d \cap \mathbb{Z}^d. \tag{15}$$

Step 2. Solve the system of equations

$$\mathbf{a} = \mathcal{T}^{-1}\mathbf{b}. \tag{16}$$

Step 3. Compute $p \in \mathcal{P}_M$ by

$$p(x) = \sum_{k\in[-M,M]^d\cap\mathbb{Z}^d} a_k e^{2\pi i k\cdot x}. \tag{17}$$

Then p is the (unique) least squares approximation of the given data vector $\mathbf{y}$ in the sense that

$$\sum_{j=1}^{r} |y_j - p(x_j)|^2 = \min_{q\in\mathcal{P}_M} \sum_{j=1}^{r} |y_j - q(x_j)|^2. \tag{18}$$

If $\mathbf{y}$ arises as the sampled vector of a polynomial $p \in \mathcal{P}_M$, i.e., $y_j = p(x_j)$, then this algorithm provides the exact reconstruction of p.

Remarks. (1) The numerical implementation of this idea is often referred to as the ACT-algorithm. The decisive step is the solution of matrix equation $\mathcal{T}\mathbf{a} = \mathbf{b}$ in Step 2. Since $\mathcal{T}$ is a positive-definite Toeplitz-like matrix, the exploitation of this structure in conjunction with block Toeplitz solvers and conjugate gradient algorithms has led to fast and efficient reconstruction algorithms in higher dimensions [30, 37]. For numerical issues and real applications we refer to [23].

(2) Since the condition numbers of $\mathcal{U}$ and $\mathcal{T}$ are related by $\kappa(\mathcal{T}) = \kappa(\mathcal{U})^2$, it may be better to solve the Vandermonde-type system $\mathcal{U}\mathbf{a} = \mathbf{y}$ directly; see the work of Potts and Steidl [28].

3. Invertibility almost surely. We first establish that the reconstruction algorithm discussed in section 2 works almost surely. In dimension $d = 1$, $\mathcal{T}$ is invertible if and only if $r \geq 2M + 1$. In higher dimensions, a complete and effective characterization of the invertibility seems out of reach. For this reason we use a probabilistic approach.

First we provide a lemma in which λ will denote Lebesgue measure.

LEMMA 3.1. *Let $p \in \mathcal{P}_M$ be a trigonometric polynomial in d variables. Then its zero set $\mathcal{Z}(p) = \{x \in [0,1]^d : p(x) = 0\}$ has Lebesgue measure* 0.

Proof. This fact is well known; we provide its easy proof for the sake of completeness.

Fix $x_1, \ldots, x_{d-1} \in [0,1]^d$; then $P(x_1, \ldots, x_{d-1}, x_d)$ is a trigonometric polynomial in one variable x_d of degree M and thus has at most $2M + 1$ zeros. The set $\{x \in [0,1] : (x_1, \ldots, x_{d-1}, x) \in \mathcal{Z}(p)\}$ has Lebesgue measure 0. This is true for every choice of $x_1, \ldots, x_{d-1}$, so by Fubini's theorem, we obtain that

$$\lambda(\mathcal{Z}(p)) = \int_{[0,1]^{d-1}} \Big(\int_{[0,1]} \chi_{\mathcal{Z}(p)}(x_1, \ldots, x_{d-1}, x)\, dx \Big)\, dx_1 \ldots dx_{d-1} = 0\,,$$

as desired. ∎

The following result is a first indication why in practice no serious problems have occurred in the application of multidimensional sampling algorithms.

THEOREM 3.2. *Assume that the random variables $\{x_1, \dots, x_r\}$ are independent and that the distribution μ_j of each x_j is absolutely continuous with respect to Lebesgue measure on $[0,1]^d$.*

Then the Vandermonde-like matrix $\mathcal{U}$ is of full rank almost surely. If, in addition, $r \geq D = (2M+1)^d$, then the Toeplitz-like matrix $\mathcal{T} = \mathcal{U}^*\mathcal{U}$ is invertible almost surely.

Proof. Let $m_1, \dots, m_D$ be an enumeration of the index set $[-M, M] \cap \mathbb{Z}^d$ over which we are summing, and let C_N be the $N \times N$ matrix with entries

$$C_{\ell j} = e^{im_\ell \cdot x_j}, \quad 1 \leq \ell,\ j \leq N.$$

Then C_N depends on the sampling points $x_1, \dots x_N$, and we may define the "bad" set

$$\mathcal{B}_N = \{(x_1, \dots, x_N) \in ([0,1]^d)^N : \det C_N = 0\}.$$

We claim that $\lambda(\mathcal{B}_N) = 0$ for all $N \leq \min(r, D)$ and prove this by induction over N. This is certainly true for $N = 1$. So assume that $N < \min(r, D)$ and that $(x_1, \dots, x_N) \notin \mathcal{B}_N$.

Let $a_\ell = (C_{\ell,1}, \dots, C_{\ell,N})$, $\ell \leq N$, be the ℓth row of C_N and let $a_{N+1} = (C_{N+1,1}, \dots, C_{N+1,N})$. Since C_N is invertible, there exist coefficients $b_\ell = b_\ell(x_1, \dots, x_N) \in \mathbb{C}$, not all 0, such that

$$a_{N+1} = b_1 a_1 + \cdots + b_N a_N\,.$$

By looking at the $(N+1)$st column of C_{N+1}, we find that C_{N+1} is invertible if and only if $C_{N+1,N+1} \neq b_1 C_{1,N+1} + \cdots + b_N C_{N,N+1}$, or if and only if

$$e^{im_{N+1} \cdot x_{N+1}} \neq b_1 e^{im_1 \cdot x_{N+1}} + \cdots + b_N e^{im_N \cdot x_{N+1}}.$$

In other words, C_{N+1} is invertible if x_{N+1} is *not* in the set

$$D_N = D_N(x_1, \dots, x_N) = \{x \in [0,1]^d : e^{im_{N+1} \cdot x} = b_1 e^{im_1 \cdot x} + \cdots + b_N e^{im_N \cdot x}\}\,.$$

For fixed $(x_1, \dots, x_N) \in ([0,1]^d)^N$, D_N is the zero set of some trigonometric polynomial, and by Lemma 3.1 D_N has Lebesgue measure 0 in $[0,1]^d$.

Since the bad set $\mathcal{B}_{N+1}$ is contained in $\{(x_1, \dots, x_N, x_{N+1}) \in ([0,1]^d)^{N+1} : x_{N+1} \in D_N(x_1, \dots, x_N)\}$, we see by Fubini's theorem that

$$\begin{aligned}\lambda(\mathcal{B}_{N+1}) &= \int_{([0,1]^d)^N} \left(\int_{[0,1]^d} \chi_{B_{N+1}}(x_1, \dots, x_N, x_{N+1})\, dx_{N+1} \right) dx_1, \dots, dx_N \\ &\leq \int_{([0,1]^d)^N} \int_{[0,1]^d} \lambda(D_N(x_1, \dots, x_N)) dx_1, \dots, dx_N = 0.\end{aligned}$$

The induction step is proved.

If $r \leq D$, then C_r is invertible for almost every choice of $x_1, \dots, x_D$, where "almost every" is with respect to Lebesgue measure λ. Consequently, the $r \times D$ matrix $\mathcal{U}$ has full rank. If $r \geq D$, this also implies that the $D \times D$ square matrix $\mathcal{T} = \mathcal{U}^*\mathcal{U}$ is invertible for almost every choice of $x_1, \dots, x_D$.

Since the distribution μ_j of x_j is absolutely continuous with respect to λ, the bad set $\mathcal{B}_D$ also has measure 0 with respect to $\mu_1 \times \cdots \times \mu_D$. ∎

COROLLARY 3.3. *The Toeplitz-like matrix $\mathcal{T}$ is invertible under each of the following hypotheses on the sampling set:*

(a) *The $x_j, j = 1, \dots, r$, are i.i.d. random variables, each of which is uniformly distributed over $[0,1]^d$.*

(b) *The sampling set is a random perturbation of a uniform sampling set, i.e., it is some enumeration of $\{\frac{1}{N}k + \delta_k : k \in \mathbb{Z}^d \cap [0, N-1]^d\}$, where $N \geq 2M+1$ and the δ_k are i.i.d. random variables uniformly distributed over a neighborhood of 0.*

4. A covering results and reduction to deterministic estimates. Theorem 1.1 guarantees that an implementation of the algorithm in section 2 will work in principle. However, numerical invertibility requires a reasonable bound on the condition number of $\mathcal{T}$ or of $\mathcal{U}$.

This is already a serious problem in dimension $d = 1$. It is easy to construct sampling sets in $[0,1]$ for which the corresponding Toeplitz matrix has condition number of the order 10^{15} [17]. While such a matrix is invertible in theory, for practical purposes it may be considered to be noninvertible.

As a next step we therefore turn to estimates for the condition number of the block Toeplitz matrix $\mathcal{T}$. For this we combine a deterministic result with a probabilistic statement on coverings.

We work with the metric $d(x,y) = \min_{k \in \mathbb{Z}^d} \|x - y + k\|_\infty$ on the torus $\mathbb{T}^d \sim [0,1)^d$ and the associated cubes of side-length 2ρ,

$$B(x,\rho) = \{y \in [0,1]^d : d(y,x) \leq \rho\} = x + [-\rho, \rho]^d.$$

To every sequence of sampling points $\{x_j : j \in \mathbb{N}\} \subseteq [0,1]^d$, let $\{V_j\}$ we assign the "distance function"

$$\delta(r) = \inf \left\{ s : \bigcup_{j=1}^{r} B(x_i, s) \supset [0,1]^d \right\}. \tag{19}$$

The quantity $2\delta(r)$ can be interpreted as the maximum distance of any of the first r sampling points x_j to its next neighbor. Let $V_j, j = 1, \dots, r$, be Voronoi regions

$$V_j = \{y \in [0,1]^d : d(y, x_j) \leq d(y, x_k), k \neq j, 1 \leq j, k \leq r\}$$

and $w_j = \lambda(V_j)$ and consider the weighted Toeplitz-like matrix $\mathcal{T}^w$ with entries

$$\mathcal{T}^w_{kl} = (\mathcal{U}^* \mathcal{U})_{kl} = \sum_{j=1}^{r} w_j e^{-2\pi i (k-l)\cdot x_j}, \quad k, l \in [-M, M]^d \cap \mathbb{Z}^d.$$

Then it is possible to show the following deterministic theorem [19, 23].

THEOREM 4.1. *If*

$$\delta(r) < \frac{\log 2}{2\pi M d}, \tag{20}$$

then, for all $p \in \mathcal{P}_M$,

$$(2 - e^{2\pi d M \delta})^2 \|p\|_2^2 \leq \sum_{j=1}^{r} |p(x_j)|^2 w_j = \langle a, \mathcal{T}^w a \rangle \leq 4 \|p\|_2^2. \tag{21}$$

Consequently, the condition number of $\mathcal{T}^w$ can be estimated by

$$\kappa(\mathcal{T}^w) \leq \frac{4}{(2 - e^{2\pi dM\delta})^2}, \tag{22}$$

and both $\mathcal{T}$ and $\mathcal{T}^w$ are invertible.

Remarks. (1) The specific choice of weights w_j is crucial for the explicit estimate (22). In the numerical implementation of the algorithm of section 2, they serve as a simple and cheap preconditioner.

(2) In higher dimensions, (22) is far from being optimal, since it depends on the dimension d. It is an open problem to obtain improvements to this estimate. For a related result for band-limited functions, see [7].

We next suppose that the sampling points form an infinite sequence of i.i.d. independent random variables $x_j, j \in \mathbb{N}$. We first investigate how the distribution of the associated sequence of random variables $\delta(r)$ depends on the number of sampling points r.

THEOREM 4.2. *If $X = \{x_j : j \in \mathbb{N}\}$ is a sequence of i.i.d. random variables uniformly distributed over $[0,1]^d$, then for every $r, N \in \mathbb{N}$*

$$\mathbb{P}(\delta(r) > 1/N) \leq N^d(1 - N^{-d})^r \leq N^d e^{-r/N^d}. \tag{23}$$

Consequently, $\kappa(\mathcal{T}^w) \leq 4(2 - e^{2\pi Md/N})^{-2}$ and both $\mathcal{T}^w$ and $\mathcal{T}$ are invertible with probability at least

$$1 - N^d(1 - N^{-d})^r \geq 1 - N^d e^{-r/N^d}.$$

Proof. Divide $[0,1]^d$ into N^d disjoint subcubes of side-length $1/N$, i.e., $[0,1]^d = \bigcup_{j=1}^r B(c_j, \frac{1}{2N})$, where the c_j are the centers of these subcubes. Note that if a subcube contains a point x_j, then that subcube is contained in $B(x_j, 1/N)$. So if each of these subcubes contains at least one of the x_j, we conclude $\delta(r) \leq 1/N$.

Since the $x_j, j = 1, \ldots, r$, are chosen independently and uniformly, the number of x_j's in any cube is a binomial random variable. Thus the probability that a particular subcube is empty is

$$(1 - N^{-d})^r$$

(since N^{-d} is the probability that any particular x_j is in this subcube and there are r points). Since there are N^d subcubes altogether, the probability that at least one of the subcubes is empty is bounded by

$$N^d(1 - N^{-d})^r. \tag{24}$$

If $\delta(r) > 1/N$, then at least one of the subcubes must be empty, which proves the left-hand inequality of (23). The right-hand side follows from the obvious inequality $(1 - N^{-d})^r = e^{r\log(1-N^{-d})} \leq e^{-r/N^d}$.

The estimate for the condition number of $\mathcal{T}^w$ and the invertibility of $\mathcal{T}$ now follow from Theorem 4.1. □

Remark. For (20) we need that $\frac{1}{N} < \frac{\log 2}{2\pi Md}$; this means that we need at least $r = N^d \geq \left(\frac{2\pi Md}{\log 2}\right)^d \approx \left(\frac{\pi d}{\log 2}\right)^d D$ sampling points before Theorem 4.2 becomes effective.

Next we derive an asymptotic result for $\delta(r)$, which may be of independent interest.

THEOREM 4.3. *Assume that* $\{x_j : j \in \mathbb{N}\}$ *is a sequence of i.i.d. points uniformly distributed in* $[0,1]^d$. *Then*

$$\limsup_{r\to\infty} \frac{\delta(r)}{(\log r/r)^{1/d}} = c \quad \text{a.s.} \tag{25}$$

for some constant $c \in [\frac{1}{4}, 2^{1+1/d}]$.

Thus for r sampling points the maximum distance to the nearest neighbor is roughly $(\log r/r)^{1/d}$. For comparison, for the $r = N^d$ equispaced points $\{\frac{k}{N} : k \in [0,N]\cap\mathbb{Z}^d\}$, we have $\delta(r) = \frac{1}{2N} = \frac{1}{2}r^{-1/d}$. For r randomly distributed points we need an additional logarithmic term.

Proof of Theorem 4.3.

Step 1. We first show that

$$\limsup_{r\to\infty} \frac{\delta(r)}{(\log r/r)^{1/d}} \le 2^{1+1/d} \quad \text{a.s.} \tag{26}$$

Choose $r_k = 2^k$ as the number of points, and let N_k be the greatest integer less than $(\frac{r_k}{2\log r_k})^{1/d}$. We divide $[0,1]^d$ into N_k^d disjoint subcubes of side-length N_k^{-1}. Let A_k be the event that at least one of the subcubes contains none of the $x_j, j = 1,\dots,r_k$. By (24) we have

$$\mathbb{P}(A_k) \le N_k^d e^{-r_k/N_k^d} \le \frac{r_k}{2\log r_k} e^{-2\log r_k} = \frac{1}{2r_k\log r_k} = \frac{1}{2^{k+1}k\log 2}. \tag{27}$$

Therefore $\sum_{k=1}^{\infty}\mathbb{P}(A_k) < \infty$, and so the Borel–Cantelli lemma [11] implies that the probability of A_k infinitely often is 0. This means for almost every $\omega\in\Omega$ there is a k_0 depending on ω such that for $k \ge k_0$, each of the subcubes of side-length N_k^{-1} will contain at least one of the points of $x_1,\dots,x_{r_k}$.

Now for r arbitrary and sufficiently large (depending on ω), choose k such that $r_k \le r < r_{k+1}$. Then each of the subcubes of side-length N_k^{-1} will contain at least one of the points $x_1,\dots,x_{r_k}$, and hence at least one of the points $x_1,\dots,x_r$. Consequently

$$\delta(r) \le \frac{1}{N_k},$$

and thus

$$\left(\frac{r}{\log r}\right)^{1/d}\delta(r) \le \left(\frac{r_{k+1}}{\log r_{k+1}}\right)^{1/d}\delta(r) \le 2^{1/d}(2N_k+1)\delta(r) \le 2^{1/d}\left(2+\frac{1}{N_k}\right).$$

Taking $r\to\infty$ proves (26).

We prove the converse inequality

$$\limsup_{r\to\infty} \frac{\delta(r)}{(\log r/r)^{1/d}} \ge \frac{1}{4} \quad \text{a.s.} \tag{28}$$

in several steps.

Step 2. Assume for the moment that we have already chosen a sequence r_k (number of sampling points) and N_k. Then we divide $[0,1]^d$ into N_k^d subcubes of side-length N_k^{-1}, and we enumerate the cubes as $C_1, C_2, \dots, C_{N_k^d}$. Let D_j be the event that the cube C_j does not contain any of the points $x_{r_{k-1}+1},\dots,x_{r_k}$. As in (24) the probability of D_j is given by

$$\mathbb{P}(D_j) = (1 - N_k^{-d})^{r_k - r_{k-1}}. \tag{29}$$

For $j \neq k$, $D_j \cap D_k$ is the event that the region $C_j \cup C_k$ does not contain any of the points $x_{r_{k-1}+1}, \dots, x_{r_k}$. Therefore as in (24) we obtain that

$$\begin{aligned} \mathbb{P}(D_j \cap D_k) &= (1 - 2N_k^{-d})^{r_k - r_{k-1}} \\ &\leq (1 - N_k^{-d})^{2(r_k - r_{k-1})} = \mathbb{P}(D_j)\mathbb{P}(D_k), \end{aligned} \tag{30}$$

since $1 - 2x \leq (1-x)^2$ for $x \in [0,1]$.

Step 3. Now let B_k be the event that at least one of the first N_k (out of a total of N_k^d) cubes $C_1, \dots, C_{N_k}$ does not contain any of the points $x_{r_{k-1}}, \dots, x_{r_k}$. (In dimension $d = 1$ we take the first N_k^α of N_k cubes for some $\alpha, 1/2 < \alpha < 1 - 1/e$, and modify the following argument slightly.) If we define the random variable Y_k by

$$Y_k = \sum_{j=1}^{N_k} 1_{D_j},$$

then $B_k = \{Y_k > 0\}$. To find a lower estimate for the probability of B_k, we use an argument due to Kochen and Stone [24]. Using Cauchy–Schwarz we find that

$$\begin{aligned} \mathbb{E}\, Y_k &= \sum_{l=1}^{N_k} l\, \mathbb{P}(Y_k = l) \\ &\leq \left(\sum_{l=1}^{N_k} l^2 \mathbb{P}(Y_k = l) \right)^{1/2} \left(\sum_{l=1}^{N_k} \mathbb{P}(Y_k = l) \right)^{1/2} \\ &= (\mathbb{E}\, Y_k^2)^{1/2} (\mathbb{P}(Y_k > 0))^{1/2}, \end{aligned}$$

whence

$$\mathbb{P}(B_k) = \mathbb{P}(Y_k > 0) \geq \frac{(\mathbb{E}\, Y_k)^2}{\mathbb{E}\, Y_k^2}. \tag{31}$$

On the other hand,

$$\mathbb{E}\, Y_k = \sum_{j=1}^{N_k} \mathbb{P}(D_j) = N_k \mathbb{P}(D_j)$$

and by (30)

$$\begin{aligned} \mathbb{E}\, Y_k^2 &= \sum_{j=1}^{N_k} \mathbb{P}(D_j) + \sum_{k \neq j} \mathbb{P}(D_j \cap D_k) \\ &\leq \mathbb{E}\, Y_k + \sum_{k \neq j} \mathbb{P}(D_j)\mathbb{P}(D_k) \\ &\leq \mathbb{E}\, Y_k + (\mathbb{E}\, Y_k)^2. \end{aligned}$$

Substituting into (31), we obtain

$$\mathbb{P}(B_k) \geq \frac{\mathbb{E}\, Y_k}{1 + \mathbb{E}\, Y_k}. \tag{32}$$

Step 4. Finally we choose $r_k = e^{e^k}$ and N_k the least integer $\geq (2^d r_k/\log r_k)^{1/d}$. Then

$$\mathbb{P}(D_j) = (1 - N_k^{-d})^{r_k - r_{k-1}} \geq \left(1 - \frac{\log r_k}{2^d r_k}\right)^{r_k}.$$

Since $\lim_{x\to\infty} x^{1/2^d}\big(1 - \frac{\log x}{2^d x}\big)^x = 1$, we have $\big(1 - \frac{\log x}{2^d x}\big)^x \geq \frac{1}{2}x^{-1/2^d}$ for x sufficiently large, and consequently

$$\mathbb{E}\, Y_k = N_k \mathbb{P}(D_j) \geq \left(\frac{2^d r_k}{\log r_k}\right)^{1/d} \frac{1}{2} r_k^{-1/2^d} = r_k^{\frac{1}{d} - \frac{1}{2^d}} / (\log r_k)^{1/d} \geq 1 \tag{33}$$

for sufficiently large k ($k \geq 3$). Now (32) implies that $\mathbb{P}(B_k) \geq 1/2$ and so $\sum_{k=1}^{\infty} \mathbb{P}(B_k) = \infty$. Finally we observe that the events B_k are independent, because they depend on disjoint segments of the sequence $x_j, j \in \mathbb{N}$. Therefore the second part of the Borel–Cantelli lemma [11] implies that the probability of B_k infinitely often is 1. This means that for almost every ω there is an infinite subsequence of k's (depending on ω) such that $\omega \in B_k$.

Step 5. It remains to consider the event E_k that one of the points $x_1, \ldots, x_{r_{k-1}}$ is in $\bigcup_{j=1}^{N_k} C_j$. Since the volume of $\bigcup_{j=1}^{N_k} C_j$ is $N_k \cdot N_k^{-d}$, the probability that a particular x_j is in this set is N_k^{1-d}. There are r_{k-1} points to consider, so as in (24)

$$\mathbb{P}(E_k) \leq r_{k-1} N_k^{1-d}.$$

By our choices of r_k and N_k, we have $\sum_{k=1}^{\infty} \mathbb{P}(E_k) < \infty$, and so by the Borel–Cantelli lemma once again, the probability of E_k infinitely often is 0.

Combining Steps 4 and 5 we conclude that with probability 1, infinitely often at least one of the C_ℓ with $\ell \leq N_k$ will contain none of the points $x_1, \ldots, x_{r_k}$. Since C_ℓ contains none of these x_j, the center of C_ℓ is not contained in $\bigcup_{j=1}^{r_k} B(x_j, 1/(2N_k))$. Consequently $\delta(r_k) > 1/(2N_k)$ for infinitely many k almost surely. So

$$\delta(r_k) \left(\frac{r_k}{\log r_k}\right)^{1/d} \geq \delta(r_k) N_k/2 \geq 1/4$$

and (28) is proved.

Step 6. It is clear that if we omit the first M points $x_1, \ldots, x_M$ for any fixed integer M, then this will not affect the value of $\limsup \delta(r)/(\log r/r)^{1/d}$. Therefore this random variable is measurable with respect to the tail σ-field of the sequence $x_1, x_2, \ldots$. By the Kolmogorov's 0-1 law, the value of this random variable must be constant almost surely [11, p. 254]. This completes the proof. □

5. Asymptotic estimates of the condition number. In the previous section we have combined a deterministic argument with a covering argument. Essentially we have calculated the probability that a random sampling set satisfies the sufficient condition already known from deterministic sampling theory.

In this section we develop an alternative approach that is based on a metric entropy argument such as the ones used in [13]. This approach does not rely on deterministic sampling results and can therefore be adapted to other sampling models. On the other hand, it is difficult to keep track of the constants involved, and thus the results are only efficient for large sampling sets.

Once again we start with an infinite sequence of i.i.d. random variables $\{x_j : j \in \mathbb{N}\}$, each of which is uniformly distributed over $[0,1]^d$. Our goal is to estimate the

quantity $\sum_{j=1}^r |p(x_j)|^2 - r\|p\|_2^2$ and its distribution as a function of the number of sampling points r.

For every $p \in \mathcal{P}_M$ we introduce the random variable $Y_j(p) = |p(x_j)|^2 - \|p\|_2^2$. To obtain a sampling inequality of the form $A\|p\|_2^2 \le \sum_{j=1}^r |p(x_j)|^2 \le B\|p\|_2^2$, we have to estimate the probability distribution of the random variable

$$\sup_{p\in\mathcal{P}_M, \|p\|_2=1} \sum_{j=1}^r Y_j(p).$$

This is accomplished in the following theorem.

THEOREM 5.1. *If $\{x_j : j \in \mathbb{N}\}$ is a sequence of i.i.d. random variables that are uniformly distributed over $[0,1]^d$, then there exist constants $A, B > 0$ depending on d and M, such that*

$$\mathbb{P}\left(\sup_{p\in\mathcal{P}_M, \|p\|_2=1} \sup_{s\le r} \left| \sum_{j=1}^s Y_j(p) \right| \ge \lambda \right) \le A \exp\left(- B \frac{\lambda^2}{r+\lambda} \right) \tag{34}$$

for $r \in \mathbb{N}$ and $\lambda \ge 0$.

For the distribution of a sum of random variables we use Bernstein's inequality [6] in the following form.

PROPOSITION 5.2. *Let $Y_j, j = 1, \dots, r$, be a sequence of bounded, independent random variables with $\mathbb{E}\, Y_j = 0$, $\operatorname{Var} Y_j = \sigma^2$, and $\|Y_j\|_\infty \le M$ for $j = 1, \dots, r$. Then*

$$\mathbb{P}\left(\left| \sum_{j=1}^r Y_j \right| \ge \lambda \right) \le 2 \exp\left(- \frac{\lambda^2}{2r\sigma^2 + \frac{2}{3}M\lambda} \right). \tag{35}$$

To apply (35) to the $Y_j(p)$, we need several simple estimates. It suffices to work with the unit ball of $\mathcal{P}_M$, which we denote by $\mathcal{P}^0 = \{p \in \mathcal{P}_M : \|p\|_2 \le 1\}$.

LEMMA 5.3. *Let $p, q \in \mathcal{P}^0$ and $j \in \mathbb{N}$. Then the following identities and inequalities hold:*

$$\mathbb{E}\, Y_j(p) = 0, \tag{36}$$

$$\operatorname{Var} Y_j(p) = \|p\|_4^4 - \|p\|_2^4 \le D - 1, \tag{37}$$

$$\operatorname{Var}\left(Y_j(p) - Y_j(q)\right) \le 8\|p-q\|_\infty^2, \tag{38}$$

$$\|Y_j(p)\|_\infty \le \|p\|_\infty^2 - \|p\|_2^2 \le (D-1), \tag{39}$$

$$\|Y_j(p) - Y_j(q)\|_\infty \le 2(D^{1/2}+1)\|p-q\|_\infty. \tag{40}$$

Proof. Since each x_j is uniformly distributed over $[0,1]^d$, we have

$$\mathbb{E}\left(Y_j(p)\right) = \int_{[0,1]^d} \left(|p(x)|^2 - \|p\|_2^2 \right) dx = 0$$

and consequently (also using (10))

$$\begin{aligned} \operatorname{Var} Y_j(p) = \mathbb{E}\left[Y_j(p)^2\right] &= \int_{[0,1]^d} \left(|p(x)|^2 - \|p\|_2^2 \right)^2 dx \\ &= \|p\|_4^4 - \|p\|_2^4 \le D - 1, \end{aligned}$$

since $\|p\|_2 = 1$. Similarly, we obtain

$$\|Y_j(p)\|_\infty = \sup_{\omega\in\Omega} \left| |p(x_j(\omega))|^2 - \|p\|_2^2 \right| \le \left| \|p\|_\infty^2 - \|p\|_2^2 \right| \le D - 1.$$

Next, since $\mathbb{E}\, Y_j(p) = 0$, we obtain

$$\begin{aligned}\operatorname{Var}(Y_j(p) - Y_j(q)) &= \mathbb{E}\left((Y_j(p) - Y_j(q))^2\right)\\ &= \int_{[0,1]^d} \left(|p(x)|^2 - |q(x)|^2\right)^2 dx - (\|p\|_2^2 - \|q\|_2^2)^2\\ &\le \|p-q\|_\infty^2 \,\|\, |p| + |q| \,\|_2^2 + \|p-q\|_2^2\big(\|p\|_2^2 + \|q\|_2^2\big)\\ &\le 8\|p-q\|_\infty^2.\end{aligned}$$

The last estimate follows similarly from

$$\begin{aligned}\|Y_j(p) - Y_j(q)\|_\infty &\le \sup_{\omega\in\Omega}\Big|\, |p(x_j(\omega))|^2 - |q(x_j(\omega))|^2\Big| + \Big|\|q\|_2^2 - \|p\|_2^2\Big|\\ &\le \|p-q\|_\infty\big(\|p\|_\infty + \|q\|_\infty\big) \;+\; \|q-p\|_2\big(\|p\|_2 + \|q\|_2\big)\\ &\le \|p-q\|_\infty\, D^{1/2}\big(\|p\|_2 + \|q\|_2\big) \;+\; \|q-p\|_\infty\big(\|p\|_2 + \|q\|_2\big)\\ &= 2(D^{1/2}+1)\,\|p-q\|_\infty. \qquad \square\end{aligned}$$

Proof of Theorem 5.1.

Step 1: *A metric entropy argument.* For a given $\delta > 0$, we construct a δ-net for $\mathcal{P}^0$ with respect to the L^∞-norm as follows. Given $p \in \mathcal{P}^0$ with coefficients $\mathbf{a} = (a_k)_{k\in\mathbb{Z}^d\cap[-M,M]^d}$ and $\|\mathbf{a}\|_2 \le 1$, we approximate the real and imaginary parts of each a_k by a number $\frac{\delta}{\sqrt{2}D}\ell$, $\ell \in \mathbb{Z}$; in other words, we choose a vector $\mathbf{b}$ of the form $\mathbf{b} = \frac{\delta}{\sqrt{2}D}(\ell + im)$, $\ell, m \in \mathbb{Z}^d$, to approximate $\mathbf{a}$. Then for each coordinate $a_k, k \in [-M,M]^d \cap \mathbb{Z}^d$, we have

$$|a_k - b_k| \le \frac{\delta}{D},$$

and so

$$\|\mathbf{a}-\mathbf{b}\|_2 \le \big(D \max_k |a_k - b_k|^2\big)^{1/2} = \frac{\delta}{\sqrt{D}}\,.$$

Setting $q(x) = \sum_{k\in I_M} b_k e^{2\pi i k\cdot x}$, we obtain

$$\|p-q\|_\infty \le D^{1/2}\|p-q\|_2 \le D^{1/2}\|\mathbf{a}-\mathbf{b}\|_2 = \delta.$$

We denote the δ-net of all $q \in \mathcal{P}^0$ with coefficients of the form $\mathbf{b} = \frac{\delta}{\sqrt{2}D}(\ell + im)$, $\ell, m \in \mathbb{Z}^d, \|\mathbf{b}\|_2 \le 1$, by $\mathcal{A}(\delta)$. The cardinality of $\mathcal{A}(\delta)$ is estimated as follows:

$$\begin{aligned}\operatorname{card}\mathcal{A}(\delta) &= \operatorname{card}\left\{\mathbf{b} = \frac{\delta}{\sqrt{2}D}(\ell + im),\ \ell, m \in \mathbb{Z}^D, \|\mathbf{b}\|_2 \le 1\right\}\\ &= \operatorname{card}\left\{k \in \mathbb{Z}^{2D} : \|k\|_2 \le \frac{\sqrt{2}D}{\delta}\right\}\\ &\le c_1\delta^{-2D},\end{aligned}$$

where the constant $c_1 \approx \frac{(2\pi)^D}{D}D^{2D}$ is roughly the number of integer lattice points in a ball of radius $\sqrt{2}D$ in $\mathbb{R}^{2D}$.

Given $p \in \mathcal{P}^0$, let p_j be the polynomial in $\mathcal{A}(2^{-j})$ that is closest to p in L^∞-norm, with some convention for breaking ties. Since $\|p - p_j\|_2 \to 0$, we can write

$$Y_j(p) = Y_j(p_0) + (Y_j(p_1) - Y_j(p_0)) + (Y_j(p_2) - Y_j(p_1)) + \cdots.$$

If $\sup_{p\in\mathcal{P}^0}\sup_{s\le r}|\sum_{j=1}^s Y_j(p)| \ge \lambda$, then either

(a) $\sup_{s\le r}|\sum_{j=1}^s Y_j(p)|\ge\lambda/2$ for some $p\in\mathcal{A}(1)$; or
(b) for some $\ell\ge 1$, some $p\in\mathcal{A}(2^{-\ell})$, and some $q\in\mathcal{A}(2^{-\ell+1})$ with $\|p-q\|_\infty\le 3\cdot 2^{-\ell}$ we have $\sup_{s\le r}|\sum_{j=1}^s\big(Y_j(p)-Y_j(q)\big)|\ge\lambda/2(\ell+1)^2$.

(Possibly both (a) and (b) hold.)

If this were not the case, then

$$\sup_{s\le r}\left|\sum_{j=1}^s Y_j(p)\right|\le\sup_{s\le r}\left|\sum_{j=1}^s Y_j(p_0)\right|+\sup_{s\le r}\sum_{\ell=1}^\infty\left|\sum_{j=1}^s(Y_j(p_\ell)-Y_j(p_{\ell-1}))\right|$$
$$\le\sum_{\ell=1}^\infty\frac{\lambda}{2\ell^2}=\frac{\pi^2}{12}\lambda<\lambda.$$

So far the construction is purely deterministic. Now we estimate the probability of each of the events in (a) and (b).

Step 2. For fixed $p\in\mathcal{A}(1)$, the probability of the event in (a) is bounded, using Bernstein's inequality (35) and Lemma 5.3, by

$$2\exp\Big(-\frac{\lambda^2}{2r\operatorname{Var}Y_j(p)+\frac{2}{3}\lambda\|Y_j(p)\|_\infty}\Big)$$
$$\le 2\exp\Big(-\frac{\lambda^2}{2r(D-1)+\frac{2}{3}(D-1)\lambda}\Big).$$

There are at most c_1 polynomials in $\mathcal{A}(1)$, so the probability of (a) is bounded by

$$2c_1\exp\Big(-\frac{\lambda^2}{(D-1)(2r+\frac{2}{3}\lambda)}\Big). \tag{41}$$

Step 3. We estimate (b) in a similar fashion using Lemma 5.3, (38), and (40). If $p\in\mathcal{A}(2^{-\ell})$ and $q\in\mathcal{A}(2^{-\ell+1})$ with $\|p-q\|_\infty\le 3\cdot 2^{-\ell}$, we have

$$\mathbb{P}\Big(\sup_{s\le r}\Big|\sum_{j=1}^s(Y_j(p)-Y_j(q))\Big|>\frac{\lambda}{2(\ell+1)^2}\Big)$$
$$\le 2\exp\Big(-\frac{\lambda^2/4(\ell+1)^4}{144r2^{-2\ell}+4\cdot 2^{-\ell}D^{1/2}\lambda/(\ell+1)^2)}\Big)$$
$$\le 2\exp\Big(-2^\ell\frac{\lambda^2}{c_3(r(\ell+1)^4 2^{-\ell}+D^{1/2}\lambda(\ell+1)^2)}\Big).$$

There are $c_1 2^{(2\ell-2)D}$ trigonometric polynomials in $\mathcal{A}(2^{-\ell+1})$, and for each q the number of trigonometric polynomials $p\in\mathcal{A}(2^{-\ell})$ satisfying $\|p-q\|_\infty\le 3\cdot 2^{-\ell}$ is bounded by a constant c_2 independent of q and j. (Similar to the count in Step 1, $c_2\approx\frac{(6\pi)^D}{D}D^{2D}$ is roughly the number of integer lattice points in a ball of radius $3\sqrt{2}D$ in $\mathbb{R}^{2D}$.) Finally, this can happen for any ℓ. So the probability in (b) is bounded by

$$\sum_{\ell=1}^\infty 2c_1c_2 2^{(2\ell-2)D}\exp\Big(-2^\ell\frac{\lambda^2}{c_3(r(\ell+1)^4 2^{-\ell}+D^{1/2}\lambda(\ell+1)^2)}\Big). \tag{42}$$

Step 4. Estimate of the sum (42).

Since $(\ell+1)^4 2^{-\ell}$ is bounded above and $2^{\ell/2}/(\ell+1)^2$ is bounded below, the above sum is bounded by

$$\sum_{\ell=1}^{\infty} c_4 \exp\left(-2^{\ell/2}\frac{\lambda^2}{c_5(r+\lambda)} + (2\ell-2)D\log 2\right) = (\star). \tag{43}$$

We distinguish two cases. In the first,

$$\frac{\lambda^2}{c_5(r+\lambda)} \geq 64D. \tag{44}$$

Then

$$2^{\ell/2}\frac{\lambda^2}{c_5(r+\lambda)} \geq 2(2\ell-2)D\log 2 \quad \forall\, \ell \geq 1,$$

and so

$$(\star) \leq \sum_{\ell=1}^{\infty} c_4 \exp\left(-2^{\ell/2}\frac{\lambda^2}{2c_5(r+\lambda)}\right).$$

Now we use the fact that $\sum_{\ell=1}^{\infty} e^{-a^\ell x} \leq c_6 e^{-x}$ for any $a > 1$ and $x \geq 1$ (with c_6 depending only on a). Consequently the sum in (43) is bounded by

$$(\star) \leq c_7 \exp\left(-\frac{\lambda^2}{c_8(r+\lambda)}\right).$$

In the second case, (44) does not hold. But then the probability of the event in (b) is at most 1, which is certainly less than or equal to

$$e^{64D}\exp\left(-\frac{\lambda^2}{c_8(r+\lambda)}\right).$$

In either case, we have that the probability of the event in (b) is bounded by

$$c_9 \exp\left(-\frac{\lambda^2}{c_8(r+\lambda)}\right).$$

Step 5. The statement now follows by combining the bounds for (a) and (b), and so we have

$$\mathbb{P}\left(\sup_{p\in\mathcal{P}^0}\sup_{s\leq r}\left|\sum_{j=1}^{s} Y_j(p)\right| \geq \lambda\right) \leq A\exp\left(-B\frac{\lambda^2}{r+\lambda}\right). \qquad \square \tag{45}$$

COROLLARY 5.4. *If $\{x_j : j \in \mathbb{N}\}$ is a sequence of i.i.d. random variables that are uniformly distributed over $[0,1]^d$ and $0 < \mu < 1$, then the sampling inequality*

$$(1-\mu)r\|p\|_2^2 \leq \sum_{j=1}^{r} |p(x_j)|^2 \leq (1+\mu)r\|p\|_2^2 \quad \forall p \in \mathcal{P}_M \tag{46}$$

holds with probability at least

$$1 - Ae^{-Br\frac{\mu^2}{1+\mu}}.$$

Consequently with the same probability estimate the Toeplitz-type matrix $\mathcal{T}$ has condition number $\kappa(\mathcal{T}) \le \frac{1+\mu}{1-\mu}$ and also $\kappa(\mathcal{U}) \le (\frac{1+\mu}{1-\mu})^{1/2}$

Proof. Choose $\lambda = r\mu$ in Theorem 5.1 and observe that the inequality

$$\left| \sum_{j=1}^{r} |p(x_j)|^2 - r \right| \le r\mu$$

for all $p \in \mathcal{P}^0$ is equivalent to the sampling inequality (46) for all $p \in \mathcal{P}_M$. □

From Theorem 5.1 it is straightforward to obtain a law of the iterated logarithm.

COROLLARY 5.5. *If $\{x_j : j \in \mathbb{N}\}$ is a sequence of i.i.d. random variables that are uniformly distributed over $[0,1]^d$, then*

$$\limsup_{r\to\infty} \frac{\sup_{p\in\mathcal{P}} |\sum_{j=1}^{r} [|p(x_j)|^2 - \|p\|_2^2]|}{\sqrt{r \log\log r}\, \|p\|_2^2} = c \quad a.s. \tag{47}$$

for some constant $c \in [\left(\frac{2}{\pi}\right)^d D - 1, \infty)$.

Proof. Let $r_k = 2^k$ and $\lambda_k = \frac{2}{\sqrt{B}} \sqrt{r_k \log\log r_k}$, where B is the constant from (34). Let

$$C_k = \left\{ \sup_{p\in\mathcal{P}^0} \sup_{s\le r_k} \left| \sum_{j=1}^{s} Y_j(p) \right| > \lambda_k \right\}.$$

Then for k large enough, we have $r_k > \lambda_k$. So the probability of C_k is bounded by

$$\begin{aligned}
\mathbb{P}(C_k) &\le A \exp\left(- B \frac{\lambda_k^2}{r_k + \lambda_k} \right) \\
&\le A \exp\left(- B \frac{\lambda_k^2}{2r_k} \right) \\
&\le A \exp\left(- B \frac{4}{B} \frac{r_k \log\log r_k}{2r_k} \right) \\
&\le A \exp(-2 \log k) = \frac{A}{k^2}.
\end{aligned}$$

So $\sum_{k=1}^{\infty} \mathbb{P}(C_k) < \infty$, and by the Borel–Cantelli lemma, the probability of C_k happening infinitely often is 0.

If $|\sum_{j=1}^{r} Y_j(p)| > \frac{2}{\sqrt{B}} \sqrt{r \log\log r}$ for some r, we choose k so that $r_{k-1} \le r < r_k$ and observe that C_k holds. (This is the only place where we need the estimate for $\sup_{s\le r} |\sum_{j=1}^{s} Y_j(p)|$ instead of just $|\sum_{j=1}^{r} Y_j(p)|$.) So this inequality cannot happen for infinitely many r and we therefore have

$$\limsup_{r\to\infty} \frac{\sup_{p\in\mathcal{P}^0} |\sum_{j=1}^{r} [|p(x_j)|^2 - r|}{\sqrt{r \log\log r}} \le c' \quad a.s.$$

for some constant $c' > 0$.

For fixed $p \in \mathcal{P}^0$ the classical law of the iterated logarithm [11, p. 232] says that

$$\limsup_{r\to\infty} \frac{\left|\sum_{j=1}^{r} Y_j(p)\right|}{\sqrt{2r \log\log r}} = \sqrt{\operatorname{Var} Y_j(p)} = \|p\|_4^4 - 1 \quad \text{a.s.}$$

Choosing $p(x) = D^{-1/2} \sum_{k\in[-M,M]^d\cap\mathbb{Z}^d} e^{2\pi i k\cdot x}$, we have $\|p\|_2 = 1$ and the elementary estimate $\|p\|_4 \geq \frac{2}{\pi} D^{1/4}$. So

$$\limsup_{r\to\infty} \frac{\sup_{p\in\mathcal{P}^0} |\sum_{j=1}^r [|p(x_j)|^2 - r]|}{\sqrt{r\log\log r}} \geq \left(\frac{2}{\pi}\right)^4 D - 1\,.$$

The conclusion follows as in the proof of Theorem 4.3 by applying Kolmogorov's 0-1 law. □

This result can be summarized by saying that for large enough r (r depending on ω) we always have the sampling inequality

$$(48)\qquad (r - c\sqrt{r\log\log r})\|p\|_2^2 \leq \sum_{j=1}^r |p(x_j)|^2 \leq (r + c\sqrt{r\log\log r})\|p\|_2^2 \quad \forall p\in\mathcal{P}_M.$$

The condition number of the random matrix $\mathcal{T}$ is therefore

$$\kappa \leq (r + c\sqrt{r\log\log r})/(r - c\sqrt{r\log\log r}) \approx 1 + 2c\left(\frac{\log\log r}{\sqrt{r}}\right)^{1/2}$$

almost surely for some constant c of order D.

6. A universal sampling theorem and examples. The main statements (Theorems 4.2 and 5.1 and Corollary 5.4) reach similar conclusions. At first glance, Theorem 4.2 seems preferable because of its elementary proof and the explicit constants. In this section we focus on the merits of the metric entropy method. This method is extremely flexible and works for many other sampling problems. We formulate a general framework for finite-dimensional sampling theorems and derive a universal sampling theorem in the style of Corollary 5.4. We then will discuss several examples of practical interest.

To begin, we note that the proofs of Theorem 5.1 and Corollary 5.4 do not use any specific properties of trigonometric polynomials. In fact, we have used only the following (interrelated) properties of $\mathcal{P}_M$.

(a) The space $\mathcal{P}_M$ is finite-dimensional and possesses a basis of continuous functions.

(b) All norms on $\mathcal{P}_M$ are equivalent; in the proofs we have used the norms $\|p\|_2, \|p\|_4, \|p\|_\infty$, and $\|\mathbf{a}\|_2$ and the associated equivalence constants. As a consequence the random variables related to the samples $|p(x_j)|^2$ satisfy the uniform estimates of Lemma 5.3.

(c) The unit ball of $\mathcal{P}_M$ is compact. This fact enables the construction of the δ-nets $\mathcal{A}(\delta)$ and suitable estimates for their cardinality.

It is evident that Theorem 5.1 and Corollary 5.4 can be obtained under much more general conditions.

A general framework. We make the following assumptions.

1. Let $S \subseteq \mathbb{R}^d$ be a compact set and let ν be a probability measure on S with $\operatorname{supp}\nu = S$.

2. Let $\mathcal{B}$ be a finite-dimensional subspace of $L^2(S,\nu)$ with a basis $\{e_k : k = 1,\dots,D\}$ of continuous functions. Often this basis is chosen as a finite subset of a Riesz basis for $L^2(S,\nu)$ and in this sense $\mathcal{B}$ may be interpreted as a space of band-limited functions in $L^2(S,\nu)$. Since $p = \sum_{k=1}^D a_k e_k$ for every $p\in\mathcal{B}$, all functions in $\mathcal{B}$ are continuous.

The sampling problem in $\mathcal{B}$. The task is now to interpolate or to approximate a given data set $\{(x_j, p(x_j)) : j = 1, \dots, r\}$ by a function in $\mathcal{B}$. As in section 2 this amounts to solving the system of linear equations

$$\sum_{k=1}^{D} a_k e_k(x_j) = p(x_j) = y_j, \quad j = 1, \dots, r.$$

Let $\mathcal{U}_{jk} = e_k(x_j)$ and

$$\mathcal{T}_{kl} = (\mathcal{U}^*\mathcal{U})_{kl} = \sum_{j=1}^{r} \overline{e_k(x_j)} e_l(x_j); \tag{49}$$

then we need to solve either the $r \times D$ system

$$\mathcal{U}\mathbf{a} = \mathbf{y}$$

or the $D \times D$ normal equations

$$\mathcal{T}\mathbf{a} = \mathcal{U}^*\mathcal{U}\mathbf{a} = \mathcal{U}^*\mathbf{y}.$$

Assume that we can prove the sampling inequality

$$A\|p\|_{2,\nu}^2 \le \sum_{j=1}^{r} |p(x_j)|^2 = \langle \mathcal{T}\mathbf{a}, \mathbf{a}\rangle \le B\|p\|_{2,\nu}^2 \quad \forall p \in \mathcal{B}. \tag{50}$$

Inserting the norm equivalence $\alpha\|\mathbf{a}\|_2 \le \|p\|_{2,\nu} \le \beta\|\mathbf{a}\|_2$, (50) then implies the estimates

$$\kappa(\mathcal{T}) \le \frac{\beta^2 B}{\alpha^2 A} \quad \text{and} \quad \kappa(\mathcal{U}) \le \Big(\frac{\beta^2 B}{\alpha^2 A}\Big)^{1/2} \tag{51}$$

for the condition numbers of these matrices. Furthermore, $p \in \mathcal{B}$ is uniquely determined by its samples, if and only if $\mathcal{T}$ is invertible, or if and only if $r \ge D$ and $\mathcal{U}$ has full rank.

We can now formulate our main theorem for random sampling in finite-dimensional spaces of band-limited functions.

THEOREM 6.1. *If $\{x_j : j \in \mathbb{N}\}$ is a sequence of i.i.d. random variables and if each x_j is ν-distributed over S, then there exist constants $A, B > 0$ depending on S, ν, and D, such that for all $\mu \in (0, 1)$, the sampling inequality*

$$(1-\mu) r\|p\|_{2,\nu}^2 \le \sum_{j=1}^{r} |p(x_j)|^2 \le (1+\mu) r\|p\|_{2,\nu}^2 \quad \forall p \in \mathcal{B} \tag{52}$$

holds with probability at least

$$1 - Ae^{-Br\frac{\mu^2}{1+\mu}}.$$

With the same probability estimate the matrix $\mathcal{T}$ has condition number $\kappa(\mathcal{T}) \le \frac{\beta^2(1+\mu)}{\alpha^2(1-\mu)}$ and also $\kappa(\mathcal{U}) \le (\frac{\beta^2(1+\mu)}{\alpha^2(1-\mu)})^{1/2}$

Proof. We have already done all the work when we proved Theorem 5.1 and Corollary 5.4. The only minor modifications occur in the constants in Lemma 5.3 and in Step 1 of the proof. We now use the random variables $Y_j(p) = |p(x_j)|^2 - \|p\|_{2,\nu}^2 = |p(x_j)|^2 - \mathbb{E}\,[|p(x_j)|^2]$. □

We present the following examples where the general hypotheses are satisfied, and so Theorem 6.1 is applicable. Each example yields a new result on random sampling. In some of these examples it seems to be extremely difficult to derive quantitative deterministic results in the style of Theorem 4.1.

Example 1. Trigonometric polynomials revisited. Choose a closed set $S \subseteq [0,1]^d$ of positive Lebesgue measure and a probability measure ν with $\operatorname{supp} \nu = S$ and equivalent to λ on S. If $p \in \mathcal{P}_M$ vanishes on S, then by Lemma 3.1 $p \equiv 0$ and, consequently, $\|p\chi_S\|_{2,\nu} = \left(\int_S |p(x)|^2 \, d\nu(x)\right)^{1/2}$ is equivalent to the L^2-norm on $\mathcal{P}_M$; i.e., there exist constants $\alpha, \beta > 0$ such that

$$\alpha \|p\|_2 \leq \|p\chi_S\|_{2,\nu} \leq \beta \|p\|_2 \quad \forall p \in \mathcal{P}_M.$$

We state the conclusion of Theorem 6.1 explicitly.

THEOREM 6.2. *Suppose that $\{x_j : j \in \mathbb{N}\} \subseteq S$ is a sequence of i.i.d. random variables that are ν-distributed over S. Then there exist constants $A, B > 0$ depending on S, ν, and D, such that for all $\mu \in (0,1)$ the sampling inequality*

$$\alpha^2(1-\mu) r \|p\|_2^2 \leq \sum_{j=1}^{r} |p(x_j)|^2 \leq \beta^2 (1+\mu) r \|p\|_2^2 \quad \forall p \in \mathcal{P}_M \tag{53}$$

holds with probability at least

$$1 - Ae^{-Br\frac{\mu^2}{1+\mu}}.$$

With the same probability estimate we have $\kappa(\mathcal{T}) \leq \frac{\beta^2(1+\mu)}{\alpha^2(1-\mu)}$.

Comparing with Theorem 5.1 we have been able to change the distribution of the random variables x_j and the target set S in which the samples are taken.

Example 2. Almost periodic functions and trigonometric polynomials with arbitrary frequencies. Assume that $S \subseteq \mathbb{R}^d$ is compact and has positive Lebesgue measure and that ν is equivalent to λ on S. Choose exponentials $e^{i\lambda_k \cdot x}$ with arbitrary frequencies $\lambda_k \in \mathbb{R}^d$ ($\lambda_k \in \mathbb{Z}^d$ is the case of trigonometric polynomials) and consider the subspace of almost periodic functions (trigonometric polynomials) on S,

$$\mathcal{B} = \{p \in L^2(S) : p(x) = \sum_{k=1}^{D} a_k e^{i\lambda_k \cdot x} \ \chi_S(x).$$

Then Theorem 6.1 applies.

Example 3. Algebraic polynomials. Again assume that $S \subseteq \mathbb{R}^d$ has positive Lebesgue measure and that ν is equivalent to λ on S. Choose a finite set $F \subseteq (\mathbb{N} \cap \{0\})^d$ and consider the space of algebraic polynomials on a compact set $S \subseteq \mathbb{R}^d$ defined as

$$\mathcal{P}_F = \{p \in L^2(S) : p(x) = \sum_{k \in F} a_k x^\alpha \ \chi_S(x).$$

Thus Theorem 6.1 applies also to algebraic polynomials of several variables.

Example 4. Local shift-invariant spaces. Let ϕ be a continuous function on $\mathbb{R}^d$ with $\operatorname{supp} \phi \subseteq [-\sigma, \sigma]^d \subseteq S$. The local shift-invariant space $V(\phi, S)$ is defined by

$$V(\phi, S) = \left\{ f \in L^2(S) : f(x) = \sum_{k \in (S + [-\sigma,\sigma]^d) \cap \mathbb{Z}^d} a_k \phi(x-k) \right\}.$$

If we assume that $0 < a \le \sum_{k\in\mathbb{Z}^d} |\hat{\phi}(\omega - k)|^2 \le b$ for all $\omega \in \mathbb{R}^d$, then the translates $\phi(x-k), k \in \mathbb{Z}^d$, form a Riesz basis for the generated subspace, and so any finite subset is linearly independent. Thus Theorem 6.1 applies. In dimension $d = 1$ and for certain "generators" ϕ this model is well understood both numerically [22] and theoretically [1]. In dimension $d > 1$, however, there are no quantitative deterministic estimates. Theorem 6.1 gives the first hint that the numerical methods of [22] also work in higher dimensions. See [2] for a survey of sampling in shift-invariant spaces.

Example 5. Sampling on the sphere and spherical harmonics. Let $S_d = \{x \in \mathbb{R}^{d+1} : |x| = 1\}$ be the unit sphere in $\mathbb{R}^{d+1}$ with surface measure ν_d. We choose the sequence J_ℓ of suitably normalized spherical harmonics [36] as an orthonormal basis for $L^2(S_d, \nu_d)$ and consider the space of band-limited functions on the sphere, namely,

$$\mathcal{B} = \left\{ p \in L^2(S_d, \nu_d) : p = \sum_{\ell=1}^{D} a_\ell J_\ell \right\}.$$

Then the conclusions of Theorem 6.1 hold for every sequence of i.i.d. random variables x_j on S_d with x_j being ν_d-distributed.

Remark. Whereas the asymptotic results for the distribution number hold universally in finite-dimensional vector spaces, the generalization of Theorem 3.2 is more subtle and depends on the support properties of the basis functions. The same proof as in section 3 shows that the system matrix $\mathcal{T}$ defined in (49) is invertible with probability 1 in Examples 1, 2, and 3 whenever $r \ge D$. On the other hand, for Example 4 it can be shown that $\mathcal{T}$ is always singular with positive probability. As this probability depends on the number of samples r, this observation does not contradict Theorem 6.1.

ON THE TWO-DIMENSIONAL HYDROSTATIC NAVIER–STOKES EQUATIONS*

DIDIER BRESCH†, ALEXANDRE KAZHIKHOV‡, AND JÉRÔME LEMOINE§

Abstract. This paper concerns some mathematical results on the two-dimensional hydrostatic equations, also called the primitive equations. The uniqueness of weak solutions of the two-dimensional Navier–Stokes equations is well known. Such a result is not known on the two-dimensional hydrostatic equations with Dirichlet boundary condition on the bottom. These equations are derived from the Navier–Stokes equations replacing the vertical component of the momentum equations by the hydrostatic equation on the pressure. We give here some partial answers on the uniqueness, the global strong existence of solutions, and the exponential decay in time of the energy. We assume a basin with a strictly positive depth. The degenerate case, in which the depth vanishes on the shore, remains open.

Key words. thin domains, geophysics, hydrostatic equation, global existence and uniqueness, overdetermined and underdetermined equations

1. Introduction.

The hydrostatic Navier–Stokes equations correspond to the primitive equations used in oceanography that assume the density to be constant; see [10], [11]. They are obtained from the Navier–Stokes equations with anisotropic viscosity by an asymptotic analysis as the aspect ratio of the domain $\delta = \text{depth/width}$ tends to 0. The reader interested in such asymptotic analysis is referred, for example, to [1], [9]. We also mentioned the different works [12], [13], where they study the hydrostatic Navier–Stokes equations in thin rectangular domains and spherical domains. See also [2], [5] for the hydrostatic Euler equations in the two-dimensional case.

The uniqueness of weak solutions of two-dimensional Navier–Stokes equations is well known. See, for instance, [4] for a survey of uniqueness results and related fields on Navier–Stokes equations. This is not the case for the two-dimensional hydrostatic Navier–Stokes equations. Some partial results have been obtained in several recent papers, such as [6], [3].

The first paper [6] concerns the global strong solutions (u, p) of the hydrostatic equations and a weak strong uniqueness result in two and three space dimensions with Dirichlet condition on the bottom. In the two-dimensional case, they prove that if one has two weak solutions $u_1 = (v_1, w_1)$ and $u_2 = (v_2, w_2)$ of the two-dimensional hydrostatic equations such that v_1 satisfies $\partial_z v_1 \in L^4(0, T; L^2(\Omega))$, these solutions coincide. Moreover they prove a global strong existence result, assuming the data are small enough.

The second paper [3] concerns the existence and uniqueness of weak solutions, assuming that the vertical derivative of the initial data is square integrable and using

a Chezye condition on the bottom and on the surface, which means a condition of the type $\partial_z v = \alpha v$ with $u \cdot n = 0$. The domain is assumed to be with a depth vanishing on the shore. Regularity on the pressure has to be derived and Hardy's inequality must be used. Such a Chezye condition is used, for instance, in limnology; see, for instance, [8]. This kind of boundary condition is important in the proof. Let us remark that the problem of global existence and uniqueness with the same assumption as for the Navier–Stokes equations is an open problem.

The reader interested in some regularity results concerning the stationary hydrostatic Stokes equations is referred to [14]. We give here a regularity result on the nonstationary hydrostatic Navier–Stokes equations.

We consider the case with a Dirichlet condition on the bottom. At first, we establish a global existence result on v such that v and $\partial_z v$ have a weak regularity. The key of the proof is to find an appropriate boundary condition for $\partial_z v$ on the bottom using the hydrostatic condition and the fact that the integration of v with respect to the vertical coordinate is equal to 0, and we deduce existence of a global strong solution assuming initial data regular enough but without assuming that the data are small enough, as was done in [6]. In conclusion, we give some results related to the uniqueness of weak solutions. Note that our results remain valid if variable density or temperature is introduced.

2. The model. Let s (the horizontal section) denote an open interval and let $h : [0,1] \to \mathbb{R}_+$ denote a nonnegative continuous function on $[0,1]$ with $h \geq c > 0$. Let us consider the two-dimensional domain Ω defined by

$$\Omega = \{(x,z) : x \in (0,1), -h(x) < z < 0\}.$$

The boundary of the domain is $\partial\Omega = b \cup s \cup \bar{l}$, where the bottom b is defined by

$$b = \{(x, -h(x)) \in \mathbb{R}^2 : x \in (0,1)\}.$$

The surface s and lateral side l are given by

$$s = \{(x,0) : x \in (0,1)\}, \quad l = \{(0,z) : z \in (-h(0),0)\} \cup \{(1,z) : z \in (-h(1),0)\}.$$

Let us consider that the velocity (v,w) and the pressure p satisfy the following problem in Ω:

$$\begin{cases} \partial_t v - \nu\Delta v + v\partial_x v + w\partial_z v + \partial_x p = 0, \\ \partial_z p = 0, \\ \partial_x v + \partial_z w = 0. \end{cases} \tag{1}$$

System (1) is supplemented with the boundary condition on the surface,

$$\partial_z v = 0, \qquad w = 0 \text{ on } s,$$

the Dirichlet condition on the bottom,

$$(v,w) = 0 \text{ on } b,$$

and the following condition on the lateral wall side:

$$v = 0 \text{ on } l.$$

In addition, we consider the initial data $u|_{t=0} = (v_0, w_0)$ with $w_0(x,z) = \int_z^0 \partial_x v_0(x,\xi)\, d\xi$ and $\int_{-h}^0 v_0\, dz = 0$. In fact w is given from v by the relation

$$w = -\int_0^z \partial_x v.$$

This will give a system on (v,p) that we will write, in the next section, in another form (2).

Let us remark that the boundary condition on the lateral-side walls corresponds to a condition on the normal velocity and gives a condition on $\partial_z v$. Indeed $v = 0$ on l implies $\partial_z v = 0$ on the vertical lateral sides l.

Another way to write the system. Throughout the paper, we choose the viscosity ν equal to 1. Then we can write the system (1) as follows. The horizontal velocity v has to satisfy the following system:

$$\text{(2)} \qquad \begin{cases} \partial_t v - \Delta v + v\partial_x v + \left(\displaystyle\int_z^0 \partial_x v\right) \partial_z v + \partial_x p = 0 \text{ in } \Omega, \\ \displaystyle\int_{-h}^0 v\, dz = 0 \text{ in } s, \\ \partial_z v = 0 \text{ on } s, \qquad v = 0 \text{ on } b \cup l, \\ v|_{t=0} = v_0. \end{cases}$$

The vertical velocity w will be given by

$$w = \int_z^0 \partial_x v.$$

We remark that system (2) concerns only the horizontal component of the velocity.

3. Main results. This section is devoted to the functional setting of the hydrostatic equations (2) and to the main results. We introduce the space

$$\mathcal{V} = \left\{ \varphi \in C^\infty_{b,l}(\overline{\Omega}) : \langle \varphi \rangle = 0 \text{ in } s \right\},$$

where $\langle \varphi \rangle = \int_{-h}^0 \varphi\, dz$ and $\mathcal{C}^\infty_{b\,l}(\overline{\Omega})$ denotes the space of all smooth ($\mathcal{C}^\infty$) functions on $\overline{\Omega}$ that vanish in a neighborhood of $l \cup b$. Then the space H (resp., V) is the closure of $\mathcal{V}$ in $L^2(\Omega)$ (resp., $H^1(\Omega)$). We can easily check that

$$H = \left\{ \varphi \in L^2(\Omega) : \langle \varphi \rangle = 0 \text{ in } s \right\}, \quad V = \left\{ \varphi \in H^1(\Omega) : \langle \varphi \rangle = 0 \text{ in } s,\, \varphi = 0 \text{ on } b \cup l \right\}.$$

The goal of this paper is to prove the following theorems.

THEOREM 1. *Let us assume $v_0 \in H$ with $\partial_z v_0 \in L^2(\Omega)$ and $h \in W^{2,\infty}(0,1)$ with $h \geq c > 0$. Then there exists a unique global solution v of system (2) such that*

$$v \in L^2(0,\infty; V) \cap L^\infty(0,\infty; H)$$

and

$$\partial_z v \in L^2(0,\infty; H^1(\Omega)) \cap L^\infty(0,\infty; L^2(\Omega)). \qquad \square$$

The definition of a global solution is a weak solution in the classical way (see, for instance, [6]) such that $\partial_z v$ has a weak regularity.

Remark. It is important to note that, in Theorems 1 and 2, if $h'' < 0$ (which means that Ω is convex), then h'' must not be assumed to be bounded. See the estimate (39) below.

Moreover, we can prove the following regularity result.

THEOREM 2. *Let us assume $v_0 \in V$ and $h \in W^{2,\infty}(0,1)$ with $h \geq c > 0$. Then there exists a unique global strong solution v of system* (2) *such that*

$$\begin{aligned} &v \in L^2(0,\infty; H^2(\Omega) \cap V) \cap L^\infty(0,\infty; V), \\ &\partial_t v \in L^2(0,\infty; H), \\ &\partial_x p \in L^2(0,\infty; L^q(\Omega)) \text{ for all } q < \infty. \end{aligned}$$ ∎

A global strong solution is a weak solution with the previous extra regularities, the pressure being given by the de Rham theorem as usual for the hydrostatic equation; see, for instance, [14].

Using the previous theorem and the energy estimates, we can prove the following exponential decay in time of the solution.

COROLLARY 3. *Let us assume $v_0 \in V$ and $h \in W^{2,\infty}(0,1)$ with $h \geq c > 0$. Then the energy of the unique global strong solution v of system* (2) *decays exponentially fast in time. This means that there exists t_0 such that for all $t \geq t_0$,*

$$\|\nabla v(t)\|_{(L^2(\Omega))^2} \leq c_1 \|\nabla v_0\|_{(L^2(\Omega))^2} \exp(-c_2 t),$$

with c_1 and c_2 two nonnegative constants. ∎

At the end, we consider the domain $\Omega = (0,1) \times (0,\pi)$. We define the space $L^2_x H^\alpha_z$ by

$$L^2_x H^\alpha_z = \left\{ v = \sum_{k=1}^{\infty} a_k(x) \varphi_k(z) : \left(\sum_{k=1}^{\infty} \|\lambda_k^{\alpha/2} a_k(x)\|^2_{L^2(0,1)} \right)^{1/2} < \infty \right\},$$

with $\alpha = \pm 1$ and $\{\varphi_k, \lambda_k\}$ the L^2_z orthogonal basis associated to the Stokes operator

$$\begin{cases} \partial_z^2 \varphi_k - \partial_x p_k + \lambda_k^2 \varphi_k = 0, \qquad \partial_z p_k = 0, \\ \displaystyle\int_0^\pi \varphi_k \, dz = 0, \\ \partial_z \varphi_k|_{z=\pi} = 0, \quad \varphi_k|_{z=0} = 0. \end{cases}$$

We prove the following result.

THEOREM 4. *Let us assume $v_0 \in L^2_x H^{1/2}_z$. Then there exists a unique global weak solution v of the system* (2) *such that*

$$\partial_z v \in L^4(0,\infty; L^2(\Omega)),$$

the boundary condition on $\partial_z v$ being satisfied in a weak sense. ∎

We divide the proofs into three sections. Section 4 is devoted to the case of a domain with constant depth ($h = 1$), for didactic purposes. We will also prove Theorems 1 and 2 and Corollary 3 in this section. Section 5 concerns the case where h is a nonconstant function. We will only prove the compatibility condition and the

energy estimate on $\partial_z v$, the rest being similar to the case of a constant depth. In the last section, we look at the uniqueness result and prove that $v_0 \in L^2_x H^{1/2}_z$ ensures uniqueness.

Remark. We can assume to have a traction condition $\partial_z v = f$ on s, as was done in [6]. Then it is possible to establish the same kind of global existence and uniqueness result with some regularity assumptions on f.

Remark. If we consider the homogeneous Chezye condition $\partial_z v = 0$ on b instead of the Dirichlet condition, all previous results remain true.

It would be interesting to consider a depth vanishing on the shore, i.e., $h(0) = h(1) = 0$. This will be done in a forthcoming work since it seems difficult to control the left-hand side of (39), which gives the weak regularity of $\omega = \partial_z v$.

4. Domain with a constant depth. In this section we consider $h = 1$. The system (2) is equivalent to the systems

$$\begin{cases} \partial_t \omega - \Delta \omega + v \partial_x \omega + w \partial_z \omega = 0, \\ \omega = 0 \text{ on } s \cup l, \\ \omega|_{t=0} = \partial_z v_0 \end{cases} \tag{3}$$

and

$$\begin{cases} \partial_z^2 \Psi = \omega, \\ \Psi|_{\partial\Omega} = 0, \\ \partial_z \Psi|_b = 0, \end{cases} \tag{4}$$

with $v = \partial_z \Psi$. The first system comes from the derivative, with respect to z, of the momentum equation satisfied by v using the fact that $\partial_z p = 0$. The second one comes from the fact that $(v, w) = (\partial_z \Psi, -\partial_x \Psi)$. The boundary condition on Ψ on s and b comes from the fact that $w = 0$ on s and b, $v = 0$ on ℓ, $w = -\partial_x \Psi$, and $v = \partial_z \Psi$.

Remark. We note that normally $\Psi|_{\partial\Omega}$ must be equal to a constant $c(t)$. We choose $c(t) = 0$ since u is defined from Ψ by its derivative with respect to z. We then choose a particular stream function.

The existence proof is classically obtained using a Faedo–Galerkin method on ω after finding an appropriate boundary condition on $\omega = \partial_z v$.

A compatibility condition. The first system is underdetermined and the second one is overdetermined. Let us show how to obtain a compatibility condition between ω and Ψ to ensure existence of global strong solution.

A simple proof. At first, let us integrate the momentum equation $(2)_1$ with respect to z from -1 to 0. We get, using the boundary condition satisfied by v and the fact that $\int_{-1}^{0} \partial_x p dz = \partial_x p$, the following equality:

$$\partial_x p = -\omega|_{z=-1} - \int_{-1}^{0} \partial_x |v|^2 \, dz. \tag{5}$$

Moreover we have $\partial_x p|_{z=-1} = \partial_x p$; therefore by taking the trace on the bottom of equation $(2)_1$, we get

$$\partial_x p = \partial_z \omega|_{z=-1}. \tag{6}$$

Using (5)–(6), this gives

$$\partial_z\omega|_{z=-1} + \omega|_{z=-1} + 2\int_{-1}^{0} w\omega dz = 0.$$

This boundary condition will be used to ensure an energy estimate on the vorticity ω.

Another way to prove the compatibility condition. We integrate equation (4) with respect to z, obtaining

$$\Psi_z = \int_{-1}^{z} \omega(t,x,\xi)\,d\xi$$

since $\Psi_z = 0$ on b. Therefore

$$\Psi = \int_{-1}^{z}\left(\int_{-1}^{y}\omega(t,x,\xi)\,d\xi\right)dy = \int_{-1}^{z}(z-\xi)\omega(t,x,\xi)\,d\xi$$

since $\Psi = 0$ on b. Thus to ensure $\Psi|_{z=0} = 0$, we imply

$$\int_{-1}^{0}\xi\omega(t,x,\xi)\,d\xi = 0.$$

So we have to provide

$$\int_{-1}^{0} z\omega\,dz = 0 \text{ for all } t > 0.$$

This gives

$$\int_{-1}^{0} z\partial_t\omega\,dz = 0$$

and

$$\int_{-1}^{0} z\partial_x^2\omega\,dz = 0.$$

Therefore, using equation $(3)_1$, we find

$$\int_{-1}^{0} z\big(\partial_z^2\omega - \partial_z(\partial_x|v|^2) + \partial_z^2(w\,v)\big)\,dz = 0,$$

and thus, integrating by parts, since

$$\int_{-1}^{0} z\partial_z^2(w\,v)\,dz = 0,$$

we get

$$\partial_z\omega|_{z=-1} + \omega|_{z=-1} + 2\int_{-1}^{0} w\omega\,dz = 0. \tag{7}$$

This gives the result. □

A priori estimates. Let us give the a priori estimates which allow us to prove the global existence result.

Energy estimate on v. Choosing v as a test function in $(2)_1$, we get

$$\frac{1}{2}\frac{d}{dt}\|v\|^2_{L^2(\Omega)} + \|\nabla v\|^2_{(L^2(\Omega))^2} \leq 0. \tag{8}$$

Energy estimate on ω. We choose now ω as a test function in $(3)_1$. Using the compatibility condition (7), we get

$$\frac{d}{dt}\|\omega\|^2_{L^2(\Omega)} + \|\nabla\omega\|^2_{(L^2(\Omega))^2} \leq \int_0^1 |\omega|_{z=-1}|^2\,dx + 2I, \tag{9}$$

with

$$I = \left| \int_0^1 \left(\omega|_{z=-1} \int_{-1}^0 w\omega dz \right) dx \right|. \tag{10}$$

Let us prove that this inequality joint with the weak regularity of v will give the weak estimate on ω. At first we remark that

$$\left(\omega|_{z=-1}\right)^2 = -2\int_{-1}^0 \omega\partial_z\omega\,dz \leq c\|\omega\|_{L^2_z}\,\|\partial_z\omega\|_{L^2_z},$$

so

$$\left|\omega|_{z=-1}\right| \leq c\|\omega\|^{1/2}_{L^2_z}\|\partial_z\omega\|^{1/2}_{L^2_z}. \tag{11}$$

Thus the first term in the right-hand side of (9) is bounded as follows:

$$\int_0^1 |\omega|_{z=-1}|^2\,dx \leq \varepsilon\|\nabla\omega\|^2_{(L^2(\Omega))^2} + c\|\omega\|^2_{L^2(\Omega)}. \tag{12}$$

Moreover we have

$$\|\omega\|^2_{L^\infty_x L^2_z} \leq 2\int_0^1\int_{-1}^0 |\omega\partial_x\omega|dzdx \leq c\|\omega\|_{L^2(\Omega)}\|\partial_x\omega\|_{L^2(\Omega)};$$

then

$$\|\omega\|^{1/2}_{L^\infty_x L^2_z} \leq c\|\omega\|^{1/4}_{L^2(\Omega)}\|\partial_x\omega\|^{1/4}_{L^2(\Omega)}. \tag{13}$$

Therefore, using (10), (11), and (13), we get

$$I \leq c\|\omega\|^{1/4}_{L^2(\Omega)}\|\partial_x\omega\|^{1/4}_{L^2(\Omega)} \int_0^1 \left(\|\partial_z\omega\|^{1/2}_{L^2_z} \left| \int_{-1}^0 w\omega dz \right| \right) dx. \tag{14}$$

Since $\omega = \partial_z v$, we get

$$\left|\int_{-1}^0 w\omega\,dz\right| = \left|\int_{-1}^0 w\partial_z v\,dz\right| = \left|\int_{-1}^0 v\partial_z w\,dz\right| \leq \|v\|_{L^2_z}\|\partial_z w\|_{L^2_z}. \tag{15}$$

Moreover

$$\|\partial_z w\|^2_{L^2_z} = -\int_{-1}^0 w\partial_z^2 w\,dz = \int_{-1}^0 w\partial_x\omega\,dz \leq \|w\|_{L^2_z}\|\partial_x\omega\|_{L^2_z}.$$

So, using (15), we get

$$\left|\int_{-1}^{0} w\omega\right| \le \|v\|_{L_z^2}\|w\|_{L_z^2}^{1/2}\|\partial_x\omega\|_{L_z^2}^{1/2}. \tag{16}$$

This implies, using (14) and (16), that

$$I \le c\|\omega\|_{L^2(\Omega)}^{1/4}\|\partial_x\omega\|_{L^2(\Omega)}^{1/4}\int_0^1 \left(\|\partial_z\omega\|_{L_z^2}^{1/2}\|\partial_x\omega\|_{L_z^2}^{1/2}\|v\|_{L_z^2}\|w\|_{L_z^2}^{1/2}\right) dx$$

and thus

$$I \le c\|\omega\|_{L^2(\Omega)}^{1/4}\|\partial_x\omega\|_{L^2(\Omega)}^{1/4}\int_0^1 \left(\|\nabla\omega\|_{L_z^2}\|v\|_{L_z^2}\|w\|_{L_z^2}^{1/2}\right) dx. \tag{17}$$

Using the Hölder inequality on (17), we find

$$I \le c\|\omega\|_{L^2(\Omega)}^{1/4}\|\nabla\omega\|_{(L^2(\Omega))^2}^{1/4}\|\nabla\omega\|_{(L^2(\Omega))^2}\|w\|_{L^2(\Omega)}^{1/2}\left(\int_0^1 \|v\|_{L_z^2}^4\, dx\right)^{1/4}. \tag{18}$$

Next, we bound

$$\int_0^1 \|v\|_{L_z^2}^4\, dx \le \|v\|_{L^2(\Omega)}^2\|v\|_{L_x^\infty L_z^2}^2$$

and

$$\|v\|_{L_x^\infty L_z^2}^2 \le c\|v\|_{L^2(\Omega)}\|\partial_x v\|_{L^2(\Omega)}.$$

So we get

$$I \le c\|\omega\|_{L^2(\Omega)}^{1/4}\|\nabla\omega\|_{(L^2(\Omega))^2}^{5/4}\|v\|_{L^2(\Omega)}^{1/4}\|\partial_x v\|_{L^2(\Omega)}^{1/4}\|v\|_{L^2(\Omega)}^{1/2}\|w\|_{L^2(\Omega)}^{1/2},$$

which implies

$$I \le \varepsilon\|\nabla\omega\|_{(L^2(\Omega))^2}^2 + c\|v\|_{L^2(\Omega)}^2\|\omega\|_{L^2(\Omega)}^{2/3}\|\partial_x v\|_{L^2(\Omega)}^{2/3}\|w\|_{L^2(\Omega)}^{4/3}.$$

This gives, using inequalities (9) and (12),

$$\frac{d}{dt}\|\omega\|_{L^2(\Omega)}^2 + \frac{1}{2}\|\nabla\omega\|_{(L^2(\Omega))^2}^2 \le c\|v\|_{L^2(\Omega)}^2\|\partial_x v\|_{L^2(\Omega)}^{2/3}\|w\|_{L^2(\Omega)}^{4/3}\|\omega\|_{L^2(\Omega)}^{2/3} + c\|\omega\|_{L^2(\Omega)}^2, \tag{19}$$

with c independent on t.

Weak strong solution. The first inequality, (8), gives, if $v_0 \in H$, that

$$v \in L^2(0,\infty;V) \cap L^\infty(0,\infty;H).$$

Assuming that $v_0 \in L^2(\Omega)$ and $\partial_z v_0 \in L^2(\Omega)$, we see that

$$\|v\|_{L^2(\Omega)}^2\|\partial_x v\|_{L^2(\Omega)}^{2/3}\|w\|_{L^2(\Omega)}^{4/3} \in L^1(0,\infty).$$

Inequality (19) will give the weak regularity on $\partial_z v$, meaning that

$$\partial_z v \in L^\infty(0,\infty;L^2(\Omega)) \cap L^2(0,\infty;H^1(\Omega)).$$

Indeed $\|\omega\|^2_{L^2(\Omega)} = \|\partial_z v\|^2_{L^2(\Omega)} \in L^1(0,\infty)$. The verification is straightforward, using the weak regularity of v, the exponential decaying property of $\|v(t)\|_{L^2(\Omega)}$ (which will be proved later on), and the relation between ω, $\nabla\omega$, and v. Indeed we have $v \in L^\infty(0,\infty;L^2(\Omega))$ and

$$\int_0^\infty \|\partial_x v\|^{2/3}_{L^2(\Omega)} \|w\|^{4/3}_{L^2(\Omega)}\, dt \le \left(\int_0^\infty \|v_x\|^2_{L^2(\Omega)}\, dt\right)^{1/3} \left(\int_0^\infty \|w\|^2_{L^2(\Omega)}\, dt\right)^{2/3}.$$

Remark. Therefore (5) implies that $\partial_x p \in L^2(0,\infty;L^1_x L^\infty_z)$.

Uniqueness. This energy estimate on $\partial_z v$ allows us to prove the existence of a weak strong solution when $v_0 \in H$ and $\partial_z v_0 \in L^2(\Omega)$; this means a solution such that

$$v \in L^2(0,\infty;V) \cap L^\infty(0,\infty;H),$$
$$\partial_z v \in L^2(0,\infty;H^1(\Omega)) \cap L^\infty(0,\infty;L^2(\Omega)).$$

The uniqueness follows from the fact that if we consider two weak solutions, one of which has the regularity $\partial_z v \in L^4(0,T;L^2(\Omega))$, then they coincide; see [6]. Denoting v_1 and v_2 as the two weak solutions, with v_2 satisfying the extra regularity and $w_1 = -\int_0^z v_1$ and $w_2 = -\int_0^z v_2$ making the difference of the two momentum equations, this result is easy to check by classical energy estimates using anisotropic estimates on the nonlinear quantity

$$I_1 = \int_\Omega (v_1 - v_2)^2 \partial_x v_2 + (w_1 - w_2)\partial_z v_2 (v_1 - v_2).$$

More precisely, we use the fact that

$$I_1 \le \|v_1 - v_2\|_{L^2_x L^\infty_z} \|v_1 - v_2\|_{L^\infty_x L^2_z} \|\partial_x v_2\|_{L^2} + \|v_1 - v_2\|_{L^\infty_x L^2_z} \|\partial_z v_2\|_{L^2} \|w_1 - w_2\|_{L^2_x L^\infty_z},$$

and therefore

$$I_1 \le \frac{\nu}{2} \int_\Omega (\partial_x (v_1 - v_2))^2 + c_1 (\|\partial_x v_2\|^2_{L^2(\Omega)} + \|\partial_z v_2\|^4_{L^2(\Omega)}) \|v_1 - v_2\|^2_{L^2(\Omega)}.$$

Therefore we obtain the first global existence and uniqueness result with the Dirichlet boundary condition at the bottom for a domain with a constant depth. We do not have to assume a smallness assumption on the data. We will prove in the next section how to obtain the same result for a domain with $h \ge c > 0$ and $h'' \in W^{2,\infty}(0,1)$.

Exponential decay in time on $\|v\|_{L^2(\Omega)}$ and $\|\omega\|_{L^2(\Omega)}$. Equation (8) gives the exponential decay in time of $\|v\|^2_{L^2(\Omega)}$. Therefore, denoting $y = \|\omega\|^2_{L^2(\Omega)}$ and $f = \|\partial_x v\|^{2/3}_{L^2(\Omega)} \|w\|^{4/3}_{L^2(\Omega)} \in L^1(0,\infty)$, equation (19) gives

$$y' + cy \le c \exp(-ct) f(t) y^{\frac{1}{3}} + c\|\omega\|^2_{L^2(\Omega)}.$$

Now, using the inequality $\|\omega\|^2_{L^2(\Omega)} \le \|v\|_{L^2(\Omega)} \|\partial_z \omega\|_{L^2(\Omega)}$, we obtain

$$c\|\omega\|^2_{L^2(\Omega)} \le c y^{\frac{1}{3}} \exp(-ct) g(t),$$

with $g(t) \in L^1(0,\infty)$ (since for all $\alpha > 0$, $\|v\|^\alpha_{L^2(\Omega)} \in L^1(0,\infty)$ and $\|\partial_z \omega\|_{L^2(\Omega)} \in L^2(0,\infty)$). Thus we have

$$y' + cy \le c \exp(-ct) h(t) y^{\frac{1}{3}},$$

with $h(t) = f(t) + g(t) \in L^1(0,\infty)$, and therefore $y = \|\omega\|^2_{L^2(\Omega)}$ decays exponentially fast in time.

Regularity. We can prove, if we assume $v_0 \in V$, that there exists a unique weak solution such that

$$v \in L^2(0,\infty;H^2(\Omega)\cap V)\cap L^\infty(0,\infty;V), \qquad \partial_t v \in L^2(0,\infty;H),$$
$$\partial_x p \in L^2(0,\infty;L^q(\Omega)) \text{ for all } q<\infty.$$

Let us recall that if $v_0 \in H$ with $\partial_z v_0 \in L^2(\Omega)$, then we have weak estimates on $\omega = \partial_z v$. Using $\partial_t v$ as a test function, we get $\partial_t v \in L^2(0,\infty;L^2(\Omega))$ and $v \in L^\infty(0,\infty;H^1(\Omega))$. Therefore (5) gives $\partial_x p \in L^2(0,\infty;L^2(\Omega))$. Then we obtain by regularity $v \in L^2(0,\infty;H^2(\Omega))$. Now using the regularity on v, this gives the regularity on $\partial_x p$ with the help of (5).

Regularity on $\partial_x p$. Since $v \in L^\infty(0,\infty;V)$, we get $v \in L^\infty(0,\infty;L^\infty_x L^2_z)$. On the one hand, $\partial_x v \in L^2(0,\infty;H^1(\Omega))$, and then $\partial_x v \in L^2(0,\infty;L^\infty_x L^2_z)$. Then $\int_{-1}^0 \partial_x |v|^2\,dz \in L^2(0,\infty;L^\infty_x)$. This gives

$$\int_{-1}^0 \partial_x |v|^2\,dz \in L^2(0,\infty;L^\infty(\Omega)).$$

On the other hand $\omega = \partial_x v \in L^2(0,\infty;H^1(\Omega))$, and then $\omega|_{z=-1} \in L^2(0,\infty;H^{\frac12}(b))$. Since $H^{\frac12}(b) \subset L^q(b)$ for all $q \in [1,+\infty[$ $(d=2)$, this gives, for all $q \in [1,+\infty[$, $\omega|_{z=-1} \in L^2(0,\infty;L^q(b))$; then

$$\omega|_{z=-1} \in L^2(0,\infty;L^q(\Omega)).$$

Therefore, using (5), this ends the proof.

Regularity on $\partial_t v$ and ∇v. For the reader's convenience, let us give the estimate on $\partial_t v$ and on ∇v, for which we will use the regularity obtained on $\partial_z v$. We multiply the momentum equation satisfied by v by $\partial_t v$, giving

$$\int_\Omega |\partial_t v|^2 + \frac12 \frac{d}{dt}\int_\Omega |\nabla v|^2 + \int_\Omega (v\partial_x v\partial_t v + w\partial_z v\partial_t v) = 0. \tag{20}$$

Let us estimate the two last terms. We have

$$\left|\int_\Omega v\partial_x v\partial_t v\right| \le \varepsilon \|\partial_t v\|^2_{L^2(\Omega)} + c\|v\partial_x v\|^2_{L^2(\Omega)}. \tag{21}$$

Since

$$\|v\partial_x v\|^2_{L^2(\Omega)} \le \|\partial_x v\|^2_{L^\infty_z L^2_x}\|v\|^2_{L^2_z L^\infty_x},$$

we get, using (13),

$$\|v\partial_x v\|^2_{L^2(\Omega)} \le c\|\partial_x\omega\|_{L^2(\Omega)}\|v\|_{L^2(\Omega)}\|\partial_x v\|^2_{L^2(\Omega)}. \tag{22}$$

Let us now look at the last term of (20). We have

$$\left|\int_\Omega w\partial_z v\partial_t v\right| \le \varepsilon\|\partial_t v\|^2_{L^2(\Omega)} + c\|w\omega\|^2_{L^2(\Omega)}. \tag{23}$$

Since

$$\|w\omega\|^2_{L^2(\Omega)} \le \int_0^1 \left(\|w\|^2_{L^\infty_z}\int_{-1}^0 |\omega|^2\,dz\right)dx,$$

we get

$$\|w\omega\|^2_{L^2(\Omega)} \le \|\omega\|^2_{L^\infty_x L^2_z}\|\partial_x v\|^2_{L^2(\Omega)},$$

and therefore

$$\|w\omega\|^2_{L^2(\Omega)} \le \|\omega\|_{L^2(\Omega)}\|\partial_x\omega\|_{L^2(\Omega)}\|\partial_x v\|^2_{L^2(\Omega)}. \tag{24}$$

Now using (20)–(24), we find

$$\int_\Omega |\partial_t v|^2 + \frac{d}{dt}\int_\Omega |\nabla v|^2 \le c(t)\int_\Omega |\nabla v|^2, \tag{25}$$

with

$$c(t) = \|\partial_x\omega\|_{L^2(\Omega)}(\|\omega\|_{L^2(\Omega)} + \|v\|_{L^2(\Omega)}) \in L^1(0,\infty).$$

This gives $\partial_t v \in L^2(0,\infty;L^2(\Omega))$ and $v \in L^\infty(0,\infty;H^1(\Omega))$ if $v_0 \in H^1(\Omega)$.

Let us now look at the regularity $v \in L^2(0,\infty;H^2(\Omega))$. We have

$$-\Delta v = -\partial_t v - \partial_x p - v\partial_x v - w\partial_z v.$$

Using the regularity on $\partial_t v$, v, and $\partial_x p$, we get an elliptic equations with a right-hand side in $L^2(0,\infty;L^2(\Omega))$. Therefore, using [14], $v \in L^2(0,\infty;H^2(\Omega))$. Now using the expression (5) of $\partial_x p$, we conclude that $\partial_x p \in L^2(0,\infty;L^q(\Omega))$ for all $q < \infty$.

Exponential decay in time on $\|\nabla v\|_{(L^2(\Omega))^2}$. Using the energy inequalities (19), (25), we can prove the exponential decay in time of $\|\nabla v\|^2_{(L^2(\Omega))^2}$ since $\|v\|^2_{L^2(\Omega)}$ and $\|\omega\|^2_{L^2(\Omega)}$ decay exponentially fast. Let us give the proof for the reader's convenience. We have

$$\int_\Omega |\partial_t v|^2 + \frac{d}{dt}\int_\Omega |\nabla v|^2 \le c(t)\int_\Omega |\nabla v|^2, \tag{dec2}$$

with

$$c(t) = \|\partial_x\omega\|_{L^2(\Omega)}(\|\omega\|_{L^2(\Omega)} + \|v\|_{L^2(\Omega)})$$

and $\|v\|^2_{L^2(\Omega)}$ and $\|\omega\|^2_{L^2(\Omega)}$ with exponential decaying properties. Therefore, there exists $(c_1,c_2) \in (\mathbb{R}_+)^2$ such that

$$\int_\Omega |\partial_t v|^2 + \frac{d}{dt}\int_\Omega |\nabla v|^2 \le c_1 e^{-c_2 t}\|\partial_x\omega\|_{L^2(\Omega)}\int_\Omega |\nabla v|^2. \tag{dec3}$$

On the other hand, we have

$$\frac{d}{dt}\|v\|^2_{L^2(\Omega)} + \|\nabla v\|^2_{(L^2(\Omega))^2} \le 0; \tag{dec4}$$

then

$$\|\nabla v\|^2_{(L^2(\Omega))^2} \le \int_\Omega |\partial_t v|^2 + \int_\Omega |v|^2.$$

By reinjecting in (dec3), we get

$$\int_\Omega |\nabla v|^2 + \frac{d}{dt}\int_\Omega |\nabla v|^2 \le c_1 e^{-c_2 t}\|\partial_x\omega\|_{L^2(\Omega)}\int_\Omega |\nabla v|^2 + \int_\Omega |v|^2.$$

Since $\int_\Omega |v|^2 \le ce^{-c_3 t}$ with $c_3 \le 1$, then

$$B(t)\int_\Omega |\nabla v|^2 + \frac{d}{dt}\int_\Omega |\nabla v|^2 \le ce^{-c_3 t},$$

where $B(t) = 1 - c_1 e^{-c_2 t}\|\partial_x \omega\|_{L^2(\Omega)}$. Then we get

$$\frac{d}{dt}\left(\int_\Omega |\nabla v|^2 e^{\int_0^t B(\tau)\,d\tau}\right) \le ce^{\int_0^t B(\tau)\,d\tau - c_3 t}.$$

Estimation of $\int_0^t B(\tau)\,d\tau$. We have, for all $t > 0$,

$$\begin{aligned}\int_0^t e^{-c_2\tau}\|\partial_x\omega\|_{L^2(\Omega)}\,d\tau &\le \left(\int_0^t e^{-2c_2\tau}\,d\tau\right)^{\frac12}\left(\int_0^t \|\partial_x\omega\|^2_{L^2(\Omega)}\,d\tau\right)^{\frac12}\\ &\le \frac{1}{\sqrt{2c_2}}(1-e^{-2c_2 t})^{\frac12}\left(\int_0^t \|\partial_x\omega\|^2_{L^2(\Omega)}\,d\tau\right)^{\frac12}.\end{aligned}$$

Then for $t \ge 1$,

$$\int_0^t e^{-c_2\tau}\|\partial_x\omega\|_{L^2(\Omega)}\,d\tau \le te^{-c_2\xi}\left(\int_0^\infty \|\partial_x\omega\|^2_{L^2(\Omega)}\,d\tau\right)^{\frac12},$$

with $\lim_{t\to\infty}\xi = +\infty$; and then, for $t \ge t_0$,

$$\int_0^t e^{-c_2\tau}\|\partial_x\omega\|_{L^2(\Omega)}\,d\tau \le \frac{c_3}{2c_1}t.$$

In conclusion we get, for all $t \ge t_0$,

$$\left(1-\frac{c_3}{2}\right)t \le \int_0^t B(\tau)\,d\tau \le t.$$

This gives, for all $t \ge t_0$,

$$\frac{d}{dt}\left(\int_\Omega |\nabla v|^2 e^{\int_0^t B(\tau)\,d\tau}\right) \le ce^{(1-c_3)t};$$

then

$$\int_\Omega |\nabla v|^2(t) \le c\|\nabla v(t_0)\|^2_{L^2(\Omega)^2}(e^{(1-c_3)t}-1)e^{(-1+\frac{c_3}{2})t} \le c\|\nabla v(t_0)\|^2_{L^2(\Omega)^2}e^{-\frac{c_3}{2}t}$$

since $c_3 \le 1$. Using the fact that ∇v is bounded in $(L^2(0,T;L^2(\Omega))^9)$, this ends the proof. ∎

5. A domain with a nonconstant depth. Let us now consider a domain with a nonconstant depth, and let us give the compatibility condition, which will be more complicated than that for a domain with constant depth.

Before beginning to search for such compatibility condition, let us recall for the reader's convenience the definition of the anisotropic spaces $L^\infty_x L^2_z$.

Definition of the anisotropic space. A function belongs to $L^\infty_x L^2_z$ if

$$u(x,.) \in L^2(-h(x),0) \quad \text{and} \quad \|u(x,.)\|_{L^2(-h(x),0)} \in L^\infty.$$

Moreover its norm is given by

$$\|u\|_{L^\infty_x L^2_z} = \sup_{x\in(0,1)}\Big(\|u(x,.)\|_{L^2(-h(x),0)}\Big).$$

The compatibility condition. We will use the first kind of proof given in section 1 in the case of a constant depth. At first, let us integrate the momentum equation on v from $-h$ to 0 with x fixed. We get, using the boundary condition satisfied by v and the fact that $\int_{-h}^{0} \partial_x p \, dz = h\partial_x p$, the following equality:

$$h\partial_x p - \int_{-h}^{0} \partial_x^2 v \, dz + \omega|_{z=-h} + \int_{-h}^{0} (v\partial_x v + w\partial_z v) \, dz = 0. \tag{26}$$

Let us calculate the term on $\partial_x^2 v$. After some calculations and using that

$$\partial_x\big(v(x,-h(x))\big) = \big(\partial_x v\big)(x,-h(x)) - h' \, \big(\partial_z v\big)(x,-h(x)) \tag{27}$$

and $v = 0$ on b, we get

$$\int_{-h}^{0} \partial_x^2 v \, dz = -(h')^2 \, \omega|_b. \tag{28}$$

We have, using the divergence-free condition on $u = (v, w)$ and the boundary condition satisfied by w,

$$\int_{-h}^{0} (v\partial_x v + w\partial_z v) \, dz = \int_{-h}^{0} \partial_x |v|^2 \, dz = 2 \int_{-h}^{0} w\omega \, dz. \tag{29}$$

If we use (26), (28), and (29), we get

$$h\partial_x p + (1 + (h')^2)\omega|_b + 2 \int_{-h}^{0} \omega w \, dz = 0. \tag{30}$$

Let us now take the trace on the bottom of the momentum equation. Since $(v, w) = 0$ on b, we get

$$(\partial_t v + v\partial_x v + w\partial_z v)|_b = 0.$$

It remains that

$$\partial_x p = (\partial_x^2 v + \partial_z^2 v)|_b. \tag{31}$$

Let us calculate the right-hand side in terms of ω. We have by definition of ω

$$(\partial_z^2 v)|_b = (\partial_z \omega)|_b. \tag{32}$$

Let us look at the $\partial_x^2 v$. We have

$$\partial_x\big((\partial_x v)(x,-h(x))\big) = \big(\partial_x^2 v\big)(x,-h(x)) - h'\big(\partial_x \partial_z v\big)(x,-h(x)).$$

Therefore, using (27), we get

$$(\partial_x^2 v)(x,-h(x)) = \partial_x\big(h' \, \omega(x,-h(x))\big) + h'(\partial_x \omega)(x,-h(x)).$$

Thus we get

$$(\partial_x^2 v)|_b = 2h'(\partial_x \omega)|_b - (h')^2(\partial_z \omega)|_b + h''\omega|_b. \tag{33}$$

Thus using (31), (32), and (33), we get

$$\partial_x p = 2h'(\partial_x\omega)|_b + (1-(h')^2)(\partial_z\omega)|_b + h''\omega|_b. \tag{34}$$

Finally, using (26) and (34), we get the following compatibility condition:

$$\big(hh'' + \big(1+(h')^2\big)\big)\omega|_b + 2\int_{-h}^{0}(\omega w)\,dz + 2hh'(\partial_x\omega)|_b + h\big(1-(h')^2\big)(\partial_z\omega)|_b = 0. \tag{35}$$

Let us rewrite this condition in terms of the normal derivative and the tangential derivative of ω. Recall that

$$\partial\omega/\partial n = -\big(h'(\partial_x\omega)|_b + (\partial_z\omega)|_b\big)/\big(1+(h')^2\big)^{1/2}$$

and

$$\partial\omega/\partial\tau = \big((\partial_x\omega)|_b - h'(\partial_z\omega)|_b\big)/\big(1+(h')^2\big)^{1/2}.$$

Then the compatibility condition may be written as

$$-h\partial\omega/\partial n + hh'\partial\omega/\partial\tau + (1+h'^2)^{-1/2}\left(\big(hh'' + \big(1+(h')^2\big)\big)\omega|_b + 2\int_{-h}^{0}(\omega w)\,dz\right) = 0. \tag{36}$$

A priori estimates. Let us give the a priori estimates, which allows us to prove the global existence result.

Energy estimate on v. Taking v as a test function on the momentum equation, we get, as in the constant depth assumption,

$$\frac{d}{dt}\|v\|^2_{L^2(\Omega)} + \|\nabla v\|^2_{(L^2(\Omega))^2} \le 0. \tag{37}$$

Energy estimate on ω. Let us multiply by ω the equation satisfied by ω; we then get

$$\frac{d}{dt}\|\omega\|^2_{L^2(\Omega)} + \|\nabla\omega\|^2_{(L^2(\Omega))^2} = \int_b \frac{\partial\omega}{\partial n}\omega. \tag{38}$$

Let us remark that the compatibility condition (36) allows us to replace the normal derivative by the tangential derivative and $\omega|_b$. We get

$$\begin{aligned}\int_b \frac{\partial\omega}{\partial n}\omega = \int_b h'\frac{\partial\omega}{\partial\tau}\omega + \int_b (1+h'^2)^{-1/2}\left(h'' + \frac{1+(h')^2}{h}\right)|\omega|^2 \\ + 2\int_b \frac{1}{h\sqrt{1+h'^2}}\left(\int_{-h}^{0}(\omega w)\,dz\right)\omega,\end{aligned}$$

and using the fact that

$$\int_b h'\frac{\partial\omega}{\partial\tau}\omega = -\frac{1}{2}\int_b \frac{h''}{(1+h'^2)^{1/2}}|\omega|^2,$$

we finally obtain

$$\frac{d}{dt}\|\omega\|^2_{L^2(\Omega)} + \|\nabla\omega\|^2_{(L^2(\Omega))^2} \le \int_b \left(\frac{\sqrt{1+h'^2}}{h} + \frac{h''}{2\sqrt{1+h'^2}}\right)|\omega|^2 + 2\int_b \frac{1}{h\sqrt{1+h'^2}}\left(\int_{-h}^0 (\omega w)\,dz\right)\omega. \tag{39}$$

Remark. If we choose $h = 1$ in (39), we get exactly inequality (10) found in section 2.

Assuming that $h \in W^{2,\infty}(0,1)$, the first term in the right-hand side of (39) is bounded as follows:

$$\int_b \left(\frac{\sqrt{1+h'^2}}{h} + \frac{h''}{2\sqrt{1+h'^2}}\right)|\omega|^2 \le c\|\omega\|_{L^2(\Omega)}\|\nabla\omega\|_{(L^2(\Omega))^2},$$

with c depending only on h. The second term in the right-hand side of (39) is bounded, as was done in the case of constant depth, assuming that $h \ge c > 0$. This gives the global existence and uniqueness mentioned in Theorem 1.

The regularity and exponential decay in time given in Theorem 2 and Corollary 3 follow as in the case of constant depth. ∎

Remark. If $h'' < 0$, meaning Ω is convex, then we do not have to assume that $h \in W^{2,\infty}(0,1)$ since the term containing h'' in the right-hand side is therefore negative.

6. Some remarks on the uniqueness result. The result in this section is in the same spirit as [7], where they consider u_0 in $(H^{1/2}(\Omega))^3$ for the Navier–Stokes equations in the three-dimensional case.

We have recalled in the previous sections that we have uniqueness if we prove the regularity $\partial_z v \in L^4(0,\infty;L^2(\Omega))$. With $v_0 \in H$, we have a weak solution of system (2),

$$v \in L^2(0,\infty;V) \cap L^\infty(0,\infty;H),$$

and if we assume $v_0 \in H$ with $\partial_z v_0 \in L^2(\Omega)$, we get a weak solution of (2) such that

$$v \in L^2(0,\infty;V) \cap L^\infty(0,\infty;H),$$
$$\partial_z v \in L^2(0,\infty;H^1(\Omega)) \cap L^\infty(0,\infty;L^2(\Omega)).$$

This last regularity result is not optimal but just ensures uniqueness. Studying the linear problem, we see by interpolation that it is enough to suppose $v_0 \in L^2_x H^{1/2}_z$ to prove that $\partial_z v \in L^4(0,\infty;L^2(\Omega))$. This is what we want to prove in this section on the nonlinear system.

For didactic considerations, we begin by study the nonlinear problem with $\partial_z v|_{z=\pi} = 0$ and $\partial_z v|_{z=0} = 0$.

Nonlinear problem with $\partial_z v|_{z=\pi} = 0$ and $\partial_z v|_{z=0} = 0$. We write the initial data v_0 as $v_0 = \sum_{n=1}^\infty b_n(x)\cos(nz)$ and look at a solution v on the form $v = \sum_{n=1}^\infty a_n \cos(nz)$ with $a_n = a_n(x,t)$. Let us multiply equation $(2)_1$ satisfied by v by $\overline{\partial_z v} = \sum_{n=1}^\infty n a_n \cos(nz)$, and let us prove that it will give us the estimate on $\partial_z^{1/2} v$ if $v_0 \in L^2_x H^{1/2}_z$, meaning that

$$\partial_z^{1/2} v \in L^2(0,\infty;H^1(\Omega)) \cap L^\infty(0,\infty;L^2(\Omega)).$$

This will give

$$\partial_z v \in L^2(0,\infty;L^2_x H^{1/2}_z) \cap L^\infty(0,\infty;L^2_x H^{-1/2}_z),$$

and thus, by interpolation,

$$\partial_z v \in L^4(0,\infty;L^2(\Omega)).$$

This ensures the uniqueness.

We multiply equation $(2)_1$ by $\overline{\partial_z v}$ and obtain, since $\int_0^\pi \overline{\partial_z v}\,dz = 0$ and $\partial_z p = 0$,

$$\int_\Omega \partial_t v\overline{\partial_z v} + \int_\Omega \nabla v \cdot \nabla\overline{\partial_z v} + \int_\Omega v\partial_x v\overline{\partial_z v} + \int_\Omega w\partial_z v\overline{\partial_z v} = 0.$$

The third term reads

$$\int_\Omega v\partial_x v\overline{\partial_z v} = \sum_{l,m,n\geq 0}\int_0^1 a_l a'_m n\, a_n \int_0^\pi \cos(lz)\cos(mz)\cos(nz).$$

The only remaining terms are such that $l+m-n=0$, $l-m-n=0$, $l-m+n=0$. Therefore every time we can upperbound n by $n^{1/2}(l^{1/2}+m^{1/2})$. This will give

$$\begin{aligned}\left|\int_\Omega v\partial_x v\overline{\partial_z v}\right| &\leq \|\partial_z^{1/2} v\|_{L^2(\Omega)}\|\nabla\partial_z^{1/2} v\|_{(L^2(\Omega))^2}\|\partial_x v\|_{L^2(\Omega)} \\ &\quad + \|v\|^{1/2}_{L^2(\Omega)}\|\partial_z v\|^{1/2}_{L^2(\Omega)}\|\nabla\partial_z^{1/2} v\|^{3/2}_{(L^2(\Omega))^2}\|\partial_z^{1/2} v\|^{1/2}_{L^2(\Omega)}.\end{aligned} \tag{40}$$

We prove in the same manner that the fourth term is controlled as follows:

$$\begin{aligned}\left|\int_\Omega w\partial_z v\overline{\partial_z v}\right| &\leq \|\partial_x\partial_z^{1/2} v\|^{3/2}_{L^2(\Omega)}\|v\|^{1/2}_{L^2(\Omega)}\|\partial_z v\|^{1/2}_{L^2(\Omega)}\|\partial_z^{1/2} v\|^{1/2}_{L^2(\Omega)} \\ &\quad + \|\partial_x v\|_{L^2(\Omega)}\|\partial_z^{1/2} v\|_{L^2(\Omega)}\|\nabla\partial_z^{1/2} v\|_{(L^2(\Omega))^2}.\end{aligned} \tag{41}$$

These inequalities will provide us with the estimate

$$\frac{d}{dt}\|\partial_z^{1/2} v\|^2_{L^2(\Omega)} + \|\nabla\partial_z^{1/2} v\|^2_{(L^2(\Omega))^2} \leq c(t)\|\partial_z^{1/2} v\|^2_{L^2(\Omega)}, \tag{42}$$

with $c \in L^1(0,\infty)$. Therefore, assuming the regularity $v_0 \in L^2_x H^{1/2}_z$, we get the result.

Proof of estimate (41). We have

$$\int_\Omega w\partial_z v\overline{\partial_z v} = -\sum_{l,m,n\geq 0}\int_0^1 \frac{a'_l}{l} n a_n m\, a_m \int_0^\pi \sin(lz)\sin(nz)\cos(mz).$$

We recall that

$$\begin{aligned}\sin(lz)\sin(nz)\cos(mz) = \frac{1}{4}\big(&\cos\big((l-n-m)z\big) + \cos\big((l-n+m)z\big) \\ &- \cos\big((l+n-m)z\big) - \cos\big((l+n+m)z\big)\big).\end{aligned}$$

The only terms which do not vanish are the ones such that $l-n-m=0$, $l-n+m=0$, $l+n-m=0$. This gives

$$\begin{aligned}\left|\int_\Omega w\partial_z v\overline{\partial_z v}\right| &= \frac{\pi}{4}\sum_{l-n-m=0}\int_0^1 \frac{a_l'}{l}na_nma_m + \frac{\pi}{4}\sum_{l-n+m=0}\int_0^1 \frac{a_l'}{l}na_nma_m \\ &\quad - \frac{\pi}{4}\sum_{l+n-m=0}\int_0^1 \frac{a_l'}{l}na_nma_m \\ &= \frac{\pi}{4}\sum_{l-n-m=0}\int_0^1 \frac{|a_l'|}{l}na_nma_m.\end{aligned}$$

Let us now estimate the right-hand side. We have, since $m \le m^{1/2}(l^{1/2}+n^{1/2})$,

$$\begin{aligned}\sum_{l-n-m=0}\int_0^1 \frac{a_l'}{l}na_nma_m &\le \frac{\pi}{4}\sum_{l-n-m=0}\int_0^1 \frac{|a_l'|}{l^{1/2}}n|a_n|m^{1/2}|a_m| \\ &\quad + \frac{\pi}{4}\sum_{l-n-m=0}\int_0^1 \frac{|a_l'|}{l}n^{3/2}|a_n|m^{1/2}|a_m|.\end{aligned}$$

Moreover, since when $l-n-m=0$, $n\le l$,

$$\begin{aligned}&\frac{\pi}{4}\sum_{l-n-m=0}\int_0^1 \frac{|a_l'|}{l^{1/2}}n|a_n|m^{1/2}|a_m| \le \frac{\pi}{4}\sum_{l-n-m=0}\int_0^1 l^{1/2}|a_l'||a_n|m^{1/2}|a_m| \\ &\le \sum_{l,n,m}\int_0^1\int_0^\pi l^{1/2}|a_l'|\sin(lz)|a_n|\sin(nz)m^{1/2}|a_m|\cos(mz) \\ &\le \left\|\sum_l l^{1/2}|a_l'|\sin lz\right\|_2 \left\|\sum_n |a_n|\sin nz\right\|_{L_x^2L_z^\infty} \left\|\sum_m m^{1/2}|a_m|\cos mz\right\|_{L_x^\infty L_z^2} \\ &\le \|\partial_x\partial_z^{1/2}v\|_2 \left\|\sum_n |a_n|\sin nz\right\|_2^{1/2} \left\|\sum_n n|a_n|\sin nz\right\|_2^{1/2} \\ &\qquad \left\|\sum_m m^{1/2}|a_m|\cos mz\right\|_2^{1/2} \left\|\sum_m m^{1/2}|a_m'|\cos mz\right\|_2^{1/2} \\ &\le \|\partial_x\partial_z^{1/2}v\|_{L^2(\Omega)}^{3/2}\|v\|_{L^2(\Omega)}^{1/2}\|\partial_z v\|_{L^2(\Omega)}^{1/2}\|\partial_z^{1/2}v\|_{L^2(\Omega)}^{1/2}.\end{aligned}$$

Moreover, since if $l-n-m=0$, $n<l$, we have

$$\begin{aligned}&\frac{\pi}{4}\sum_{l-n-m=0}\int_0^1 \frac{|a_l'|}{l}n^{3/2}|a_n|m^{1/2}|a_m| \le \frac{\pi}{4}\sum_{l-n-m=0}\int_0^1 |a_l'|n^{1/2}a_nm^{1/2}a_m \\ &\le \sum_{l,n,m}\int_0^1\int_0^\pi |a_l'|\sin(lz)n^{1/2}|a_n|\sin(nz)m^{1/2}|a_m|\cos(mz) \\ &\le \sum_{l,n,m}\int_0^1\int_0^\pi |a_l'|\sin(lz)n^{1/2}|a_n|\sin(nz)m^{1/2}|a_m|\cos(mz) \\ &\le \|\partial_x v\|_2 \left\|\sum_n n^{1/2}|a_n|\sin nz\right\|_{L_x^2L_z^\infty} \left\|\sum_m m^{1/2}|a_m|\cos mz\right\|_{L_x^\infty L_z^2}\end{aligned}$$

$$\leq \|\partial_x v\|_2 \left\| \sum_n n^{1/2}|a_n| \sin nz \right\|_2^{1/2} \left\| \sum_n n^{3/2}|a_n| \sin nz \right\|_2^{1/2}$$
$$\left\| \sum_m m^{1/2}|a_m| \cos mz \right\|_2^{1/2} \left\| \sum_m m^{1/2}|a'_m| \cos mz \right\|_2^{1/2}$$
$$\leq \|\partial_x v\|_{L^2(\Omega)} \|\partial_z^{1/2} v\|_{L^2(\Omega)} \|\nabla \partial_z^{1/2} v\|_{(L^2(\Omega))^2},$$

and in conclusion,

$$\left| \int_\Omega w \partial_z v \overline{\partial_z v} \right| \leq \|\partial_x \partial_z^{1/2} v\|_{L^2(\Omega)}^{3/2} \|v\|_{L^2(\Omega)}^{1/2} \|\partial_z v\|_{L^2(\Omega)}^{1/2} \|\partial_z^{1/2} v\|_{L^2(\Omega)}^{1/2}$$
$$+ \|\partial_x v\|_{L^2(\Omega)} \|\partial_z^{1/2} v\|_{L^2(\Omega)} \|\nabla \partial_z^{1/2} v\|_{(L^2(\Omega))^2}.$$

Summary. (i) We have

$$\left\| \sum_n |a_n| \sin nz \right\|_2 = \left\| \sum_n |a_n| \cos nz \right\|_2.$$

(ii) If $f(0) = 0$, we have $|f(x)| = \int_0^x \partial_x |f|^2 \leq c \|\partial_x f\|_2^{1/2} \|f\|_2^{1/2}$, and then

$$\|f(x)\|_\infty \leq c \|\partial_x f\|_2^{1/2} \|f\|_2^{1/2}.$$

Let us now look at the Dirichlet boundary condition on the bottom.

Nonlinear problem with $\partial\ v|_{\ =}\ = 0$ and Dirichlet condition $v|_{\ =0} = 0$. Let us look at the following eigenvalues problem:

$$\begin{cases} \partial_z^2 v_k - \partial_x p_k + \lambda_k^2 v_k = 0, \qquad \partial_z p_k = 0, \\ \displaystyle\int_0^\pi v_k \, dz = 0, \\ \partial_z v_k|_{z=\pi} = 0, \quad v_k|_{z=0} = 0. \end{cases}$$

Writing the system on ω_k with the compatibility condition $(\partial_z \omega_k + \frac{1}{\pi}\omega_k)|_{z=0} = 0$, we find (v_k, λ_k) given by

$$v_k = \frac{1}{\sin(\lambda_k \pi)} \Big(\cos\big(\lambda_k (z - \pi)\big) - \cos(\lambda_k \pi) \Big),$$

with λ_k satisfying

$$\tan(\lambda_k \, \pi) = \lambda_k \pi.$$

Let us remark that $(v_k)_k$ is an orthogonal basis of L_z^2. Then we search the weak solution v of system (2) on the form $v = \sum_{n \geq 0} a_n v_n$ with $a_n = a_n(t, x)$, and we multiply the momentum equation by $\overline{\partial_z v} = \sum_{n=1}^\infty \lambda_n a_n(t, x) v_n(z)$. After some computations, we prove similar estimates to (40) and (41). We get an estimate similar to (42). This gives the results on the regularity and therefore the uniqueness. ∎

PERIODIC SOLUTIONS OF THE KORTEWEG–DE VRIES EQUATION DRIVEN BY WHITE NOISE*

A. DE BOUARD†, A. DEBUSSCHE‡, AND Y. TSUTSUMI§

Abstract. We consider a Korteweg–de Vries equation perturbed by a noise term on a bounded interval with periodic boundary conditions. The noise is additive, white in time, and "almost white in space." We get a local existence and uniqueness result for the solutions of this equation. In order to obtain the result, we use the precise regularity of the Brownian motion in Besov spaces, and the method which was introduced by Bourgain, but based here on Besov spaces.

Key words. Korteweg–de Vries equation, stochastic partial differential equations, white noise, Besov spaces

1. Introduction.

The Korteweg–de Vries (KdV) equation, which models the propagation of unidirectional weakly nonlinear waves in an infinite channel, is an ideal model, and it is natural to consider perturbations of this model. In this direction, stochastic perturbations of this equation were introduced in [5], [12], [19] to model the propagation of weakly nonlinear waves in a noisy plasma.

Here, we consider as in [2], [3] a KdV equation with a stochastic perturbation which is Gaussian and of white noise–type in time. Contrary to the previous works [2] and [3], we will set the equation on a bounded space interval with periodic boundary conditions. Although the derivation of the KdV equation is usually done with $x \in \mathbb{R}$, there is no reason to confine oneself to localized solutions. It is also well known that the KdV equation possesses spatially periodic traveling waves solutions. The study of the periodic boundary conditions case is also of importance when dealing with numerical computations, since these are necessarily performed on a bounded interval.

Our aim in the present paper is to study the Cauchy problem for a stochastic KdV equation with an additive noise as previously described, and which has spatial correlations "as rough" as our techniques allow, the aim being to stay as close as possible to the space-time white noise.

The equation is then written as

$$\partial_t u + \partial_x^3 u + u\partial_x u = \phi \frac{\partial^2 B}{\partial t \partial x}, \tag{1.1}$$

where u is a random process defined for $(t, x) \in \mathbb{R}^+ \times \mathbb{T}$, $\mathbb{T}$ being a one-dimensional torus, and ϕ is a bounded linear operator on $L^2(\mathbb{T})$ that will be described in more detail later. Also, B is a two parameter Brownian motion on $\mathbb{R}^+ \times \mathbb{T}$, that is, a zero

mean Gaussian process whose correlation function is given by

$$\mathbb{E}(B(t,x)B(s,y)) = (t \wedge s)(x \wedge y)$$

for $t, s \geq 0$, $x, y \in \mathbb{T}$.

Note that in the case where ϕ is defined by a kernel $k(x,y)$, the correlation function of the noise is

$$\mathbb{E}\left(\phi\frac{\partial^2 B}{\partial t \partial x}(t,x)\phi\frac{\partial^2 B}{\partial t \partial x}(s,y)\right) = c(x,y)\delta_{t-s},$$

with δ the Dirac δ-function and

$$c(x,y) = \int_{\mathbb{T}} k(x,z)k(y,z)dz.$$

In this formalism, the case $\phi = Id$, i.e., $c(x,y) = \delta(x-y)$, corresponds to the space-time white noise. This is the case we would like to treat. However, our result needs a slightly more restrictive assumption, and we are only able to treat a noise which is "almost" delta correlated in space.

Except in [2] and [3], equations of the type (1.1) have essentially been studied by using inverse scattering theory (and only in cases where the noise is space independent) or by perturbation arguments near the integrable case (see [12], [16], [21], [22]).

A great deal of attention has been paid to the (deterministic) KdV equation on the real line (see [1], [4], [13], [18]) and improvements made on the regularity needed on the initial value to get local existence of solutions have occurred step by step. On the other hand, for the periodic case, up to the famous work of Bourgain on the KdV equation (see [4]), existence results in $H^s(\mathbb{T})$ were restricted to the case $s > 3/2$. Then, using functions spaces based on the linear group, Bourgain was able to prove global well-posedness in $L^2(\mathbb{T})$. Making use of the same spaces, and improving the nonlinear estimate, Kenig, Ponce, and Vega (see [15]) proved local well-posedness in $H^s(\mathbb{T})$ for $s > -1/2$ (see Colliander et al. [7] for $s = -1/2$). After that, using a splitting into high and low Fourier frequencies of the solution, together with almost conserved quantities and rescaling arguments, Colliander et al. [7] were able to prove global existence in $H^s(\mathbb{T})$ for $s \geq -1/2$.

Using Bourgain-type spaces, we were able in [3] to prove local existence of solutions for (1.1) in the real line case, when the noise is a "localized space-time white noise," that is, when its correlation function has the form

$$\mathbb{E}\left(\phi\frac{\partial^2 B}{\partial t \partial x}(t,x)\phi\frac{\partial^2 B}{\partial t \partial x}(s,y)\right) = k(x)k(y)\delta_{x-y}\delta_{t-s},$$

k being an L^2 function. It is indeed hopeless in the real line case to be able to get even local existence of solutions in $H^s(\mathbb{R})$, with a pure space-time white noise. The obstruction is not due to the lack of spatial regularity of the noise, but rather to its homogeneity (see [3]). In the periodic case, however, there is no such obstruction, and we are able to treat homogeneous noises, i.e., noises whose spatial correlation function depends only on $x - y$ (or such that ϕ is a convolution operator); also, thanks to the use of Bourgain's method adapted to Besov spaces, we are able to treat noises which have spatial correlations in H^s, $s > -1/2$. The main difficulty encountered in the application of Bourgain's method in our case is that it needs time regularity of order $1/2$. However, it is well known that this regularity does not hold for Brownian motions

unless Besov spaces are considered. This is why we use this method in the context of Besov spaces—see below for details. The problem of global existence of solutions for such noises in spaces with negative regularity is not considered here, but could probably be handled with the use of the method previously mentioned [7].

Before stating our result precisely, we introduce some notation and assumptions.

We consider $\tilde{W}(t) = \frac{\partial B}{\partial x}$ a cylindrical Wiener process on $L^2(\mathbb{T})$ which may be written as $\tilde{W}(t) = \sum_{j\in\mathbb{N}} \beta_j e_j$, where $(e_j)_{j\in\mathbb{N}}$ is a complete orthonormal system in $L^2(\mathbb{T})$, and $(\beta_j)_{j\in\mathbb{N}}$ is a sequence of mutually independent real-valued Brownian motions in a fixed probability space $(\Omega, \mathcal{F}, \mathbb{P})$ associated with a filtration $(\mathcal{F}_t)_{t\geq 0}$.

The process $W = \phi\tilde{W}$ is then a $\phi\phi^*$-Wiener process (recall that ϕ is a linear bounded operator in $L^2(\mathbb{T})$), that is, $(W(t))_{t\geq 0}$ is a Gaussian process with law $(\mathcal{N}(0, t\phi\phi^*)_{t\geq 0})$.

We then consider (1.1) in its Itô form,

$$du + (\partial_x^3 u + u\partial_x u)dt = dW, \quad x \in \mathbb{T},\ t \geq 0, \tag{1.2}$$

supplemented with the initial condition

$$u(0, x) = u_0(x), \quad x \in \mathbb{T}. \tag{1.3}$$

Consider the Fourier transform

$$\hat{f}(n) = \frac{1}{\sqrt{2\pi}} \int_{\mathbb{T}} e^{inx} f(x)dx$$

for functions f defined on $\mathbb{T}$, and for $s \in \mathbb{R}$, let $H^s(\mathbb{T})$ be the Sobolev space of functions f such that the norm

$$|f|_{H^s(\mathbb{T})} := \left(\sum_{n\in\mathbb{Z}} (1 + n^2)^s |\hat{f}(n)|^2 \right)^{1/2}$$

is finite. We also define, for $s \in \mathbb{R}$, the Besov space $B^s_{2,1}(\mathbb{T})$ as the space of functions f defined on $\mathbb{T}$ for which the norm

$$|f|_{B^s_{2,1}(\mathbb{T})} = |\hat{f}(0)| + \sum_{n\in\mathbb{N}} 2^{sn} \left(\sum_{2^{n-1}\leq |n'|\leq 2^{n+1}} |\hat{f}(n')|^2 \right)^{1/2}$$

is finite.

Let $U(t) = e^{-t\partial_x^3}$ be the group associated with the linear equation on $L^2(\mathbb{T})$, that is, $v(t) = U(t)u_0$ satisfies

$$\begin{cases} \partial_t v + \partial_x^3 v = 0, \\ v(0, x) = u_0(x), \quad x \in \mathbb{T}. \end{cases}$$

Then the solution of

$$\begin{cases} dw + \partial_x^3 w\, dt = dW, \\ w(0, x) = 0, \quad x \in \mathbb{T}, \end{cases}$$

is given by the stochastic convolution

$$w(t) = \int_0^t U(t - s)dW(s). \tag{1.4}$$

Note that $U(t)$ is a unitary group on $H^s(\mathbb{T})$ for any $s \in \mathbb{R}$, so that $w(t)$ lies in $H^s(\mathbb{T})$ almost surely if and only if $\phi\phi^*$ has finite trace from $L^2(\mathbb{T})$ into $H^s(\mathbb{T})$. This clearly holds in the case where ϕ is the identical operator on $L^2(\mathbb{T})$ if and only if $s < -1/2$.

The difficulty in the use of Bourgain's spaces here is the smoothness in time. Indeed, let $Y^{s,b}$ be the space of functions f such that $U(-t)f(t,\cdot) \in H^{s,b}$, where $H^{s,b}$ is a space-time Sobolev space, s being the regularity in space, and b the regularity in time (see [15] for a precise definition of $Y^{s,b}$). Then, as was proved in [15], the only possible value of b for which a bilinear estimate holds, which allows us to handle the nonlinear term $\partial_x(u^2)$ in the KdV equation using a straightforward iteration scheme, in the periodic case, is $b = 1/2$. Writing then the expression of $w(t)$ defined by (1.4) as

$$w(t) = \sum_{j\in\mathbb{N}} \int_0^t U(t-s)(\phi e_j) d\beta_j(s),$$

one can compute the spatial Fourier transform of $h(t) = U(-t)w(t)$:

$$\hat{h}(t,n) = \sum_{j\in\mathbb{N}} \int_0^t e^{isn^3} \widehat{\phi e_j}(n) d\beta_j(s).$$

But there is no hope that this term lives in $H^{1/2}[0,T]$ in the time variable, because the Brownian motions β_j do not. Indeed,

$$\begin{aligned}
&\mathbb{E}\left(|\hat{h}(t,n)|^2_{H^{1/2}_t}\right) \\
&\quad = \sum_{j\in\mathbb{N}} |\widehat{\phi e_j}(n)|^2 \mathbb{E}\left|\int_0^t e^{isn^3} d\beta_j(s)\right|^2_{H^{1/2}_t} \\
&\quad = \sum_{j\in\mathbb{N}} |\widehat{\phi e_j}(n)|^2 \left\{ \mathbb{E}\int_0^T \left|\int_0^t e^{isn^3} d\beta_j(s)\right|^2 dt \right. \\
&\qquad\qquad \left. + \mathbb{E}\int\int_{(0,T)^2} \frac{|\int_0^{t_1} e^{isn^3} d\beta_j(s) - \int_0^{t_2} e^{isn^3} d\beta_j(s)|^2}{|t_1 - t_2|^2} dt_1 dt_2 \right\}.
\end{aligned}$$

The first term in the right-hand side above is obviously equal to $\frac{T^2}{2}\sum_{j\in\mathbb{N}} |\widehat{\phi e_j}(n)|^2$, while the contribution of each j to the second term in the right-hand side above is infinite, due to the fact that

$$\mathbb{E}\left|\int_{t_1}^{t_2} e^{isn^3} d\beta_j(s)\right|^2 = |t_2 - t_1|.$$

However, $H^{1/2}$ is a limiting case concerning the regularity of the Brownian motion, as far as Sobolev spaces are concerned. It is then natural to try to replace Sobolev spaces here by other spaces which describe more precisely the regularity in time of the Brownian motions. This is exactly what we will do here, using Besov spaces instead of Sobolev spaces in time. Indeed, it is known (see [6], [17]) that the Brownian motion lies almost surely in $B^{1/2}_{p,q}([0,T])$ if and only if $1 \le p < +\infty$ and $q = +\infty$. Trying to derive some bilinear estimate which would allow us to handle in the same time both $w(t)$ defined by (1.4) and the nonlinear term,

$$\int_0^t U(t-s)(\partial_x(u^2)(s)) ds,$$

we were led to consider also Besov spaces in the space variable.

We now turn to give precise definitions of these spaces. We denote by $\langle \cdot, \cdot \rangle$ the L^2 space-time duality product, that is,

$$\begin{aligned}\langle f, g \rangle &= \int_{\mathbb{T}} \int_{\mathbb{R}} f(t,x)\overline{g(t,x)} dt\, dx \\ &= \sum_{n \in \mathbb{Z}} \int_{\mathbb{R}} \hat{f}(\tau, n)\overline{\hat{g}(\tau, n)} d\tau\end{aligned}$$

by the Plancherel formula; here, and in all that follows, we denote by $\hat{f}$ (resp., $\hat{g}$) the Fourier transform of f (resp., g) with respect to both variables. We also use the notation $\langle \tau \rangle = (1 + |\tau|^2)^{1/2}$ for $\tau \in \mathbb{R}$. The spaces that we will use are defined as follows. Consider first functions f defined on $\mathbb{R} \times \mathbb{T}$ such that $f(\cdot, x) \in \mathcal{S}'(\mathbb{R})$ for any $x \in \mathbb{T}$, and such that $\hat{f}(\tau, 0) = 0$ for any $\tau \in \mathbb{R}$.

We denote by $X^{s,b}_{1,1}$ the space of such functions f for which in addition the norm

$$\begin{aligned}|f|_{X^{s,b}_{1,1}} = &\sum_{n=0}^{\infty} 2^{sn} \sum_{k=0}^{\infty} \left(\sum_{2^{n-1} \le |n'| \le 2^{n+1}} \int_{2^{k-1}}^{2^{k+1}} |\langle \tau - n'^3 \rangle^b \hat{f}(\tau, n')|^2 d\tau \right)^{1/2} \\ &+ \sum_{n=0}^{\infty} 2^{sn} \left(\sum_{2^{n-1} \le |n'| \le 2^{n+1}} \int_{0}^{1} |\langle \tau - n'^3 \rangle^b \hat{f}(\tau, n')|^2 d\tau \right)^{1/2}\end{aligned}$$

is finite. In the same way, we will denote by $X^{s,b}_{1,\infty}$ the space of such functions f for which in addition the norm

$$\begin{aligned}|f|_{X^{s,b}_{1,\infty}} = &\sum_{n=0}^{\infty} 2^{sn} \sup_{k \in \mathbb{N}} \left(\sum_{2^{n-1} \le |n'| \le 2^{n+1}} \int_{2^{k-1}}^{2^{k+1}} |\langle \tau - n'^3 \rangle^b \hat{f}(\tau, n')|^2 d\tau \right)^{1/2} \\ &+ \sum_{n=0}^{\infty} 2^{sn} \left(\sum_{2^{n-1} \le |n'| \le 2^{n+1}} \int_{0}^{1} |\langle \tau - n'^3 \rangle^b \hat{f}(\tau, n')|^2 d\tau \right)^{1/2}\end{aligned}$$

is finite.

The basic space in which we will solve the Cauchy problem for the stochastic KdV equation is $X^{s,b}_{1,1}$. However, we will make use, at intermediate steps, of other spaces of the same type: $\widetilde{X}^{s,b}_{1,1}$ (resp., $\widetilde{X}^{s,b}_{1,\infty}$) is the space of functions f such that $f(t, \cdot) = U(t)g(t, \cdot)$ with g in the "space-time Besov space" $(B^{s,b}_{2,1})_{x,t}$ (resp., $(B^{s}_{2,1})_x(B^{b}_{2,\infty})_t$), where $(B^{s,b}_{2,1})_{x,t}$ is defined by the norm

$$\begin{aligned}|f|_{(B^{s,b}_{2,1})_{x,t}} = &\sum_{n=0}^{\infty} \sum_{k=0}^{\infty} 2^{sn+kb} \left(\sum_{2^{n-1} \le |n'| \le 2^{n+1}} \int_{2^{k-1}}^{2^{k+1}} |\hat{f}(\tau, n')|^2 d\tau \right)^{1/2} \\ &+ \sum_{n=0}^{\infty} 2^{sn} \left(\sum_{2^{n-1} \le |n'| \le 2^{n+1}} \int_{0}^{1} |\hat{f}(\tau, n')|^2 d\tau \right)^{1/2}\end{aligned}$$

and $(B^s_{2,1})_x(B^b_{2,\infty})_t$ is defined by the norm

$$|f|_{(B^s_{2,1})_x(B^b_{2,\infty})_t} = \sum_{n=0}^{\infty} \sup_{k\in\mathbb{N}} 2^{sn+kb} \left(\sum_{2^{n-1}\le|n'|\le 2^{n+1}} \int_{2^{k-1}}^{2^{k+1}} |\hat f(\tau,n')|^2 d\tau \right)^{1/2} + \sum_{n=0}^{\infty} 2^{sn} \left(\sum_{2^{n-1}\le|n'|\le 2^{n+1}} \int_0^1 |\hat f(\tau,n')|^2 d\tau \right)^{1/2}.$$

Remark 1.1. Note that the spaces $X^{s,b}_{1,1}$ and $\widetilde X^{s,b}_{1,1}$ are different and there is no inclusion relation between them: an alternative definition of the norm in $\widetilde X^{s,b}_{1,1}$ is

$$|f|_{\widetilde X^{s,b}_{1,1}} = \sum_{n=0}^{\infty} 2^{sn} \sum_{k=0}^{\infty} \left(\sum_{2^{n-1}\le|n'|\le 2^{n+1}} \int_{2^{k-1}\le|\tau-n'^3|\le 2^{k+1}} |\langle \tau-n'^3\rangle^b \hat f(\tau,n')|^2 d\tau \right)^{1/2} + \sum_{n=0}^{\infty} 2^{sn} \left(\sum_{2^{n-1}\le|n'|\le 2^{n+1}} \int_{|\tau-n'^3|\le 1} |\langle \tau-n'^3\rangle^b \hat f(\tau,n')|^2 d\tau \right)^{1/2};$$

here, the dyadic decomposition is made on $|\tau - n'^3|$ and not on $|\tau|$. However, embeddings do hold between these spaces with some small loss of space regularity, as is stated in Lemma 1.6, at the end of this section.

Since all those definitions have to be used only locally in time, we will actually consider, for $T \ge 0$ fixed, the spaces $X^{s,b,T}_{1,1}$ and $X^{s,b,T}_{1,\infty}$ of restrictions on $[0,T]$ of functions of $X^{s,b}_{1,1}$ (resp., $X^{s,b}_{1,\infty}$). They are endowed with the natural norm

$$|f|_{X^{s,b,T}_{1,1}} = \inf\left\{ |\tilde f|_{X^{s,b}_{1,1}},\ \tilde f \in X^{s,b}_{1,1} \text{ and } f = \tilde f_{|_{[0,T]}} \right\},$$

and the equivalent for $X^{s,b,T}_{1,\infty}$.

To handle the integral estimate in Duhamel's formula, we will need to make use, as is classical, of another space which is defined as the space of zero (spatial) mean functions with finite corresponding norm, where

$$|f|_{Y_s} = \sum_{n=0}^{\infty} 2^{sn} \left(\sum_{2^{n-1}\le|n'|\le 2^{n+1}} \left(\int_{\mathbb{R}} \frac{|\hat f(\tau,n')|}{\langle \tau-n'^3\rangle} d\tau \right)^2 \right)^{1/2}.$$

A local space $Y_{s,T}$ is also defined, in the same way as for $X^{s,1/2,T}_{1,1}$.

Throughout the paper, we will use the notation $|n'| \sim 2^n$ for $2^{n-1} \le |n'| \le 2^{n+1}$, and $|\tau| \sim 2^k$ for $2^{k-1} \le |\tau| \le 2^{k+1}$ if $k \ge 1$ and $|\tau| \le 2$ if $k = 0$.

As previously mentioned, we will be led to assume[1] that the operator ϕ is a Hilbert–Schmidt operator (or equivalently that $\phi\phi^*$ has finite trace) from $L^2(\mathbb{T})$ into $H^s(\mathbb{T})$ for some negative s with $s > -1/2$. We will denote by $L^{0,s}_2$ the space of such operators, which is endowed by its natural norm,

$$\|\phi\|_{L^{0,s}_2} = \left(\sum_{i\in\mathbb{N}} |\phi e_i|^2_{H^s} \right)^{1/2},$$

[1]Note that this assumption excludes the identical operator on $L^2(\mathbb{T})$.

where $(e_i)_{i\in\mathbb{N}}$ is any complete orthonormal system in $L^2(\mathbb{T})$. For convenience, in all that follows, we take as $(e_i)_{i\in\mathbb{N}}$ the usual complete orthonormal system of $L^2(\mathbb{T})$ given by

$$e_{2k}(x) = \frac{1}{\sqrt{\pi}}\cos kx, \quad k \geq 1, \quad e_0(x) = \frac{1}{\sqrt{2\pi}},$$
$$e_{2k+1}(x) = \frac{1}{\sqrt{\pi}}\sin kx.$$

We consider the mild form of (1.2), (1.3), that is,

$$u(t) = U(t)u_0 - \frac{1}{2}\int_0^t U(t-s)\partial_x(u^2(s))ds + \int_0^t U(t-s)dW(s). \tag{1.5}$$

Our main result, which concerns local existence in a situation where W is arbitrarily close to a cylindrical Wiener process, is the following.

THEOREM 1.2. *Assume that* $\operatorname{Im}\phi \subset \operatorname{span}\{e_j,\ j \geq 1\}$ *and that* $\phi \in L_2^{0,s}$ *for some* s *with* $s > -1/2$. *Let* u_0 *be* $\mathcal{F}_0$*-measurable, with* u_0 *in the Besov space* $B^\sigma_{2,1}(\mathbb{T})$ *almost surely for some* σ *with* $-1/2 \leq \sigma < s$; *then there is a stopping time* $T_\omega > 0$ *and a unique process* u *solution of the forced KdV equation* (1.5) *which satisfies*

$$u \in C([0,T_\omega]; B^\sigma_{2,1}(\mathbb{T})) \cap X^{\sigma,1/2,T_\omega}_{1,1} \text{ almost surely.}$$

Remark 1.3. The assumption $\operatorname{Im}\phi \subset \operatorname{span}\{e_j,\ j \geq 1\}$ says that the spatial mean of the noise is zero at any time. This assumption is necessary to perform the fixed point procedure, because we work in a space of functions with zero spatial mean. We will actually remove this assumption at the end of the paper (see Proposition 4.3) by changing the unknown function u and the noise. At that place, we will have to deal with a non-Gaussian noise.

Remark 1.4. One can show by using classical arguments and looking more carefully into the proof of Proposition 3.1 (see section 3) that the regularity is preserved in Theorem 1.2, i.e., if $\phi \in L_2^{0,s}$ and $u_0 \in B^\sigma_{2,1}(\mathbb{T})$ with $-1/2 \leq \sigma' \leq \sigma < s$, then the existence times of the solution in $B^{\sigma'}_{2,1}(\mathbb{T})$ and in $B^\sigma_{2,1}(\mathbb{T})$ are the same.

Naturally, when the noise is such that the Wiener process lies in $L^2(\mathbb{T})$, we get a global existence result thanks to the invariance of the L^2 norm for the deterministic equation and the embedding $L^2(\mathbb{T}) \subset B^\sigma_{2,1}(\mathbb{T})$ for any $\sigma < 0$.

THEOREM 1.5. *Assume that, in addition,* $\phi \in L_2^{0,0}$; *if* $u_0 \in L^2(\Omega; L^2(\mathbb{T}))$, *the solution given by Theorem* 1.2 *is globally defined in time and lies in* $L^2(\Omega; L^\infty(0,T; L^2(\mathbb{T})))$ *and in* $C(\mathbb{R}^+; B^\sigma_{2,1}(\mathbb{T}))$ *almost surely for any* $T > 0$ *and* $\sigma < 0$.

As was previously mentioned, Theorem 1.2 allows us to handle a situation arbitrarily close to the space-time white noise case, since this latter case corresponds to $\phi = \mathrm{id}$, which is a Hilbert–Schmidt operator from $L^2(\mathbb{T})$ into $H^s(\mathbb{T})$ for any $s < -1/2$. Theorem 1.2 will be proved by using a fixed point argument in the space $X^{\sigma,1/2,T}_{1,1}$ for T small enough. We need the assumption $s > -1/2$ because we will need that $s > \sigma \geq -1/2$. Indeed, to show that the fixed point works, we will first prove that the stochastic integral lies almost surely in $X^{\sigma,1/2}_{1,\infty}$. At that point, we have already lost some spatial regularity. We then prove a bilinear estimate, allowing us to handle such a term as $\partial_x(fg)$ with $f \in X^{\sigma,1/2}_{1,1}$ and $g \in X^{\sigma,1/2}_{1,\infty}$. To treat the term $\partial_x(g^2)$ in the same space, we again have to sacrifice an arbitrarily small amount of spatial regularity.

It is not difficult to see that when $\phi = \mathrm{id}$, the stochastic integral $w(t)$ given by (1.4) lies almost surely in $X^{-1/2,1/2}_{\infty,\infty}$, where this latest space is defined by changing the norm in the definition of $X^{-1/2,1/2}_{1,\infty}$ in an obvious way. Unfortunately, a bilinear estimate which would handle terms like $\partial_x(g^2)$ in $X^{-1/2,-1/2}_{\infty,\infty}$ with g in $X^{-1/2,1/2}_{\infty,\infty}$ seems to fail.

The paper is organized as follows. In section 2, we prove an estimate which shows that the stochastic integral lives in $X^{\sigma,1/2}_{1,\infty}$ almost surely when ϕ is in $L^{0,s}_2$ with $\sigma < s$ (we will actually prove that the stochastic integral lies in $\widetilde{X}^{\sigma,1/2}_{1,\infty}$, which is enough, thanks to Lemma 1.6 below). This result is based on the works of Cieselskii [6] and Roynette [17], but we will use a different characterization of Besov spaces than in [17].

In section 3, we prove some bilinear estimates which are needed in the proof of Theorem 1.2. The main one is an estimate of $\partial_x(fg)$ in $X^{\sigma,-1/2}_{1,1}$ when $f \in X^{\sigma,1/2}_{1,1}$ and $g \in X^{\sigma,1/2}_{1,\infty}$. Other easier bilinear estimates are proved in that section too.

Section 4 is devoted to the proofs of Theorems 1.2 and 1.5. Once we have the bilinear estimates in hand, together with the estimate on the stochastic integral, it mainly remains to prove that we gain one degree of regularity in time when passing from $\partial_x(fg)$ to $\int_0^t U(t-s)\partial_x(fg)(s)ds$. The proof of this fact has to be done because we do not stand in the usual context of Sobolev spaces, but we deal with Besov spaces. However, the proof closely follows that of the Sobolev case.

We end the present section by giving the lemma relating the spaces $X^{s,b}_{1,1}$ and $\widetilde{X}^{s,b}_{1,\infty}$.

LEMMA 1.6. *For any $s_1 > s_2 > s_3$,*

$$\widetilde{X}^{s_1,b}_{1,1} \subset X^{s_2,b}_{1,1} \subset \widetilde{X}^{s_3,b}_{1,1} \quad \textit{and} \quad \widetilde{X}^{s_1,b}_{1,\infty} \subset X^{s_2,b}_{1,\infty} \subset \widetilde{X}^{s_3,b}_{1,\infty}.$$

Proof. We show only that $\widetilde{X}^{s_1,b}_{1,\infty} \subset X^{s_2,b}_{1,\infty}$, and all the other embeddings are proved similarly. Let $f \in \widetilde{X}^{s_1,b}_{1,\infty}$ and let us decompose the norm of f in $X^{s_2,b}_{1,\infty}$ as

$$\begin{aligned}
|f|_{X^{s_2,b}_{1,\infty}} \leq{}& \sum_{n\in\mathbb{N}} 2^{s_2 n} \sup_{k<3n-4} \left(\sum_{|n'|\sim 2^n} \int_{|\tau|\sim 2^k} \langle \tau - n'^3\rangle^{2b} |\hat{f}(\tau,n')|^2 \, d\tau \right)^{1/2} \\
&+ \sum_{n\in\mathbb{N}} 2^{s_2 n} \sup_{3n-4\leq k\leq 3n+4} \left(\sum_{|n'|\sim 2^n} \int_{|\tau|\sim 2^k} \langle \tau - n'^3\rangle^{2b} |\hat{f}(\tau,n')|^2 \, d\tau \right)^{1/2} \\
&+ \sum_{n\in\mathbb{N}} 2^{s_2 n} \sup_{k>3n+4} \left(\sum_{|n'|\sim 2^n} \int_{|\tau|\sim 2^k} \langle \tau - n'^3\rangle^{2b} |\hat{f}(\tau,n')|^2 \, d\tau \right)^{1/2} \\
\leq{}& I + II + III.
\end{aligned}$$

If $k > 3n+4$, $|n'| \sim 2^n$ and $|\tau| \sim 2^k$, then $\frac{1}{8}|\tau| \leq |\tau - n'^3| \leq \frac{3}{2}|\tau|$; hence we easily have

$$\begin{aligned}
III \leq{}& C \sum_{n\in\mathbb{N}} 2^{s_2 n} \sup_{k\in\mathbb{N}} \left(\sum_{|n'|\sim 2^n} \int_{|\tau - n'^3|\sim 2^k} \langle \tau - n'^3\rangle^{2b} |\hat{f}(\tau,n')|^2 \, d\tau \right)^{1/2} \\
\leq{}& C|f|_{\widetilde{X}^{s_2,b}_{1,\infty}}.
\end{aligned}$$

On the other hand, if $k < 3n-4$, $|n'| \sim 2^n$ and $|\tau| \sim 2^k$, then $2^{3n-4} \leq |\tau - n'^3| \leq 2^{3n+4}$; hence

$$I \leq \sum_{n\in\mathbb{N}} 2^{s_2 n} \left(\sum_{|n'|\sim 2^n} \int_{2^{3n-4}\leq|\tau-n'^3|\leq 2^{3n+4}} \langle \tau - n'^3\rangle^{2b} |\hat{f}(\tau,n')|^2 \, d\tau \right)^{1/2}$$
$$\leq 8|f|_{\widetilde{X}^{s_2,b}_{1,\infty}}.$$

Finally, if $3n-4 \leq k \leq 3n+4$, $|n'| \sim 2^n$, and $|\tau| \sim 2^k$, then $0 \leq |\tau - n'^3| \leq 2^{3n+6}$; hence

$$II \leq \sum_{n\in\mathbb{N}} 2^{s_2 n} \left(\sum_{|n'|\sim 2^n} \sum_{k=0}^{3n+5} \int_{|\tau-n'^3|\sim 2^k} \langle \tau - n'^3\rangle^{2b} |\hat{f}(\tau,n')|^2 \, d\tau \right)^{1/2}$$
$$\leq \sum_{n\in\mathbb{N}} 2^{s_2 n}(3n+5) \sup_{k\in\mathbb{N}} \left(\sum_{|n'|\sim 2^n} \int_{|\tau-n'^3|\sim 2^k} \langle \tau - n'^3\rangle^{2b} |\hat{f}(\tau,n')|^2 \, d\tau \right)^{1/2}$$
$$\leq C \sum_{n\in\mathbb{N}} 2^{s_1 n} \sup_{k\in\mathbb{N}} \left(\sum_{|n'|\sim 2^n} \int_{|\tau-n'^3|\sim 2^k} \langle \tau - n'^3\rangle^{2b} |\hat{f}(\tau,n')|^2 \, d\tau \right)^{1/2}$$

since $s_2 < s_1$. The result follows. □

2. Estimate on the stochastic integral. In this section, we prove an estimate on the stochastic integral—that is, the last term in (1.5)—which will enable us to use a fixed point procedure to solve (1.5) in an appropriate space of functions of the space and time variables. This latest space will actually be of the form $X^{\sigma,1/2}_{1,1}$ for some well chosen σ.

Although, for the sake of clarity, we did not assume that the covariance operator $\phi\phi^*$ of the noise could be random or could depend on the time variable t in Theorem 1.2, we will state here a proposition where ϕ is allowed to depend on both t and ω, but under the condition that the $L_2^{0,\sigma'}$ norm of $\phi(\cdot)$ is bounded in both t and ω. This will indeed be useful in order to prove that our result generalizes to the case where the noise does not have a zero spatial mean value (see Proposition 4.3).

We need to use a cut-off function in the time variable: we consider a function $\theta : \mathbb{R} \longrightarrow \mathbb{R}^+$ such that $\theta(t) \equiv 0$ for $t \leq -1$, and $t \geq 2$, $\theta(t) \equiv 1$ for $t \in [0,1]$, and $\theta \in C_0^\infty(\mathbb{R})$.

Also, to state precisely our estimate on the stochastic integral, we define, for $n \in \mathbb{N}$, the operator Δ_n acting on $L^2(\mathbb{T})$ by

$$\widehat{\Delta_n u}(n') = \mathbb{1}_{\{2^{n-1}\leq|n'|\leq 2^{n+1}\}} \hat{u}(n')$$

for $u \in L^2(\mathbb{T})$ and for any $n' \in \mathbb{Z}$.

We now state our proposition.

PROPOSITION 2.1. *Let $s' \in \mathbb{R}$, and assume that ϕ is predictable and lies in $L^\infty([0,T]\times\Omega; L_2^{0,s'})$ for some T with $0 < T \leq 1$; let θ and Δ_n be as above; then the stochastic integral $w(t)$ defined by (1.4) satisfies, for any $\sigma' < \sigma < s'$, $\theta w \in$*

$L^1(\Omega; X_{1,\infty}^{\sigma',1/2,T})$ *and*

$$\mathbb{E}\left(|\theta w|_{X_{1,\infty}^{\sigma',1/2,T}}\right) \le C(\theta)\sum_{n\in\mathbb{N}}\|\Delta_n\phi\|_{L^\infty([0,T]\times\Omega;L_2^{0,\sigma})} \le C(\theta,\sigma,s')\|\phi\|_{L^\infty([0,T]\times\Omega;L_2^{0,s'})},$$

where $C(\theta)$ is a constant depending only on the function θ.

Proof. We first prove that $\theta w \in L^1(\Omega;\widetilde{X}_{1,\infty}^{\sigma,1/2,T})$ and that

$$\mathbb{E}\left(|\theta w|_{\widetilde{X}_{1,\infty}^{\sigma,1/2,T}}\right) \le C(\theta)\sum_{n\in\mathbb{N}}\|\Delta_n\phi\|_{L^\infty([0,T]\times\Omega;L_2^{0,\sigma})}$$

and then make use of Lemma 1.6.

Let $g(t,\cdot)=\theta(t)\int_0^t U(-s)dW(s)$ so that $\theta(t)w(t)=U(t)g(t,\cdot)$; we also set, for $s\in\mathbb{R}$, $n\in\mathbb{Z}$, and $\ell\in\mathbb{N}$,

$$\varphi_{n,\ell}(s)=\begin{cases}0 & \text{if } s<0 \quad \text{or} \quad s\ge T,\\ \widehat{\phi(s)e_\ell}(n) & \text{if } s\in[0,T],\end{cases}$$

and we assume that each β_ℓ has been extended to a Brownian motion on $\mathbb{R}$, in such a way that the family $(\beta_\ell)_{\ell\in\mathbb{N}}$ is still an independent family. We then have, for any $t\in[0,T]$ and $n\in\mathbb{Z}$,

$$\mathcal{F}_n g(t)(n)=\sum_{\ell\in\mathbb{N}}\theta(t)I_{n,\ell}(t),$$

with $I_{n,\ell}(t)=\int_{-\infty}^t\theta(s)e^{ins^3}\varphi_{n,\ell}(s)\,d\beta_\ell(s)$, $\mathcal{F}_n$ being the Fourier transform in space.

In view of the equivalent definition of the space $\widetilde{X}_{1,\infty}^{\sigma,1/2}$, we have to show that

$$\begin{aligned}&\mathbb{E}\left(\sum_{n=0}^\infty \sup_{k\in\mathbb{N}} 2^{\sigma n+k/2}\left(\sum_{|n'|\sim 2^n}\int_{|\tau|\sim 2^k}|\hat g(\tau,n')|^2\,d\tau\right)^{1/2}\right)\\ &\quad+\mathbb{E}\left(\sum_{n=0}^\infty 2^{\sigma n}\left(\sum_{|n'|\sim 2^n}\int_{|\tau|\le 1}|\hat g(\tau,n')|^2\,d\tau\right)^{1/2}\right)\\ &\quad\le C(\theta)\sum_{n=0}^\infty\|\Delta_n\phi\|_{L^\infty([0,T]\times\Omega;L_2^{0,\sigma})}.\end{aligned}\tag{2.1}$$

We first estimate the second term in (2.1).

$$\begin{aligned}&\mathbb{E}\left(\sum_{n=0}^\infty 2^{\sigma n}\left(\sum_{|n'|\sim 2^n}\int_{|\tau|\le 1}\left|\sum_{\ell\in\mathbb{N}}\widehat{\theta I_{n',\ell}}(\tau)\right|^2 d\tau\right)^{1/2}\right)\\ &\le\sum_{n=0}^\infty 2^{\sigma n}\left(\sum_{|n'|\sim 2^n}\mathbb{E}\int_{|\tau|\le 1}\left|\sum_{\ell\in\mathbb{N}}\int_{\mathbb{R}}\theta(t)\int_{-\infty}^t\theta(s)e^{isn'^3}\varphi_{n',\ell}(s)\,d\beta_\ell(s)e^{-i\tau t}dt\right|^2 d\tau\right)^{1/2}\\ &\le\sum_{n=0}^\infty 2^{\sigma n}\left(\sum_{|n'|\sim 2^n}\int_{|\tau|\le 1}\mathbb{E}\left|\sum_{\ell\in\mathbb{N}}\int_{\mathbb{R}}\theta(s)\varphi_{n',\ell}(s)e^{isn'^3}\int_s^{+\infty}\theta(t)e^{-i\tau t}\,dt\,d\beta_\ell(s)\right|^2 d\tau\right)^{1/2},\end{aligned}$$

and using the independence of the $(\beta_\ell)_{\ell\in\mathbb{N}}$, the above term is bounded by

$$\begin{aligned}
&\sum_{n=0}^{\infty} 2^{\sigma n}\left(\sum_{|n'|\sim 2^n}\int_{|\tau|\le 1}\sum_{\ell\in\mathbb{N}}\int_{\mathbb{R}}\mathbb{E}(\theta^2(s)|\varphi_{n',\ell}(s)|^2)\left|\int_s^{+\infty}\theta(t)e^{-i\tau t}\,dt\right|^2 ds\,d\tau\right)^{1/2}\\
&\quad\le 2|\theta|^2_{L^1(\mathbb{R})}|\theta|^2_{L^2(\mathbb{R})}\sum_{n=0}^{+\infty}2^{\sigma n}\sup_{s\in\mathbb{R}}\left|\mathbb{E}\left(\sum_{\ell\in\mathbb{N}}\sum_{|n'|\sim 2^n}|\varphi_{n',\ell}(s)|^2\right)\right|^{1/2}\\
&\quad\le C(\theta)\sum_{n=0}^{+\infty}\sup_{s\in\mathbb{R}}\left|\mathbb{E}\left(\|\Delta_n\phi(s)\|^2_{L_2^{0,\sigma}}\right)\right|^{1/2}\\
&\quad\le C(\theta)\sum_{n=0}^{+\infty}\|\Delta_n\phi(\cdot)\|_{L^\infty([0,T]\times\Omega;L_2^{0,\sigma})},
\end{aligned}$$

and this proves the estimate on the second term in (2.1).

In what follows, we assume that $|\tau|\ge 1/2$; by the stochastic Fubini theorem and using an integration by parts, we easily get, for $n\in\mathbb{Z}$, $\ell\in\mathbb{N}$, and $|\tau|\ge 1/2$,

$$\widehat{\theta I_{n,\ell}}(\tau)=A_{n,\ell}(\tau)+B_{n,\ell}(\tau),$$

with

$$A_{n,\ell}(\tau)=\int_{\mathbb{R}}\theta^2(s)e^{isn^3}\varphi_{n,\ell}(s)\frac{e^{-i\tau s}}{i\tau}\,d\beta_\ell(s)$$

and

$$B_{n,\ell}(\tau)=\int_{\mathbb{R}}\theta(s)e^{isn^3}\varphi_{n,\ell}(s)\int_s^{+\infty}\theta'(t)\frac{e^{-i\tau t}}{i\tau}\,dt\,d\beta_\ell(s).$$

Hence, two terms will be involved in the estimate of the second term in (2.1), which are

$$I=\mathbb{E}\left(\sum_{n=0}^{\infty}\sup_{k\in\mathbb{N}}2^{\sigma n+k/2}\left(\sum_{|n'|\sim 2^n}\int_{|\tau|\sim 2^k}\left|\sum_{\ell=0}^{\infty}A_{n',\ell}(\tau)\right|^2 d\tau\right)^{1/2}\right)$$

and

$$II=\mathbb{E}\left(\sum_{n=0}^{\infty}\sup_{k\in\mathbb{N}}2^{\sigma n+k/2}\left(\sum_{|n'|\sim 2^n}\int_{|\tau|\sim 2^k}\left|\sum_{\ell=0}^{\infty}B_{n',\ell}(\tau)\right|^2 d\tau\right)^{1/2}\right).$$

We may assume that $\sigma=0$, replacing $\varphi_{n',\ell}$ by $2^{\sigma n}\varphi_{n',\ell}$ in the estimate we want to prove. We first estimate the second term above. With this aim in view, we first write,

for $k \geq 0$ and $n \geq 0$,

$$\begin{aligned}
&\mathbb{E}\left(2^k \sum_{|n'|\sim 2^n} \int_{|\tau|\sim 2^k} \left|\sum_{\ell=0}^{\infty} B_{n',\ell}(\tau)\right|^2 d\tau\right) \\
&\quad = 2^k \int_{|\tau|\sim 2^k} \sum_{|n'|\sim 2^n} \mathbb{E}\left|\sum_{\ell=0}^{\infty} \int_{\mathbb{R}} \theta(s) e^{isn'^3} \varphi_{n',\ell}(s) \int_s^{+\infty} \theta'(t) \frac{e^{-i\tau t}}{i\tau} dt \, d\beta_\ell(s)\right|^2 d\tau \\
&\quad = 2^k \int_{|\tau|\sim 2^k} \sum_{\ell=0}^{\infty} \sum_{|n'|\sim 2^n} \int_{\mathbb{R}} |\theta(s)|^2 \mathbb{E}(|\varphi_{n',\ell}(s)|^2) \left|\int_s^{+\infty} \theta'(t) \frac{e^{-i\tau t}}{i\tau} dt\right|^2 ds \, d\tau,
\end{aligned}$$

where we have used again the independence of the family $(\beta_\ell)_{\ell \geq 0}$. Now, for $|\tau|$ in $[2^{k-1}, 2^{k+1}]$, we have

$$\left|\int_s^{+\infty} \theta'(t) \frac{e^{-i\tau t}}{i\tau} dt\right| \leq \left|\frac{\theta'(s)}{\tau^2}\right| + \left|\int_s^{+\infty} \theta''(t) \frac{e^{-i\tau t}}{\tau^2} dt\right| \leq \frac{C(\theta)}{2^{2k}};$$

hence we get, for k, $n \geq 0$,

$$\begin{aligned}
&\mathbb{E}\left(2^k \sum_{|n'|\sim 2^n} \int_{|\tau|\sim 2^k} \left|\sum_{\ell=0}^{\infty} B_{n',\ell}(\tau)\right|^2 d\tau\right) \\
&\quad \leq C(\theta) 2^{-3k} \int_{|\tau|\sim 2^k} \left|\mathbb{E}\left(\|\Delta_n \phi(s)\|^2_{L_2^{0,0}}\right)\right|_{L_s^\infty} d\tau \\
&\quad \leq C(\theta) 2^{-2k} \|\Delta_n \phi(\cdot)\|^2_{L^\infty([0,T]\times\Omega; L_2^{0,0})},
\end{aligned}$$

and using the Cauchy–Schwarz inequality, we get

$$\begin{aligned}
II &= \sum_{n=0}^{+\infty} \sup_{k\in\mathbb{N}} \mathbb{E}\left(2^{k/2} \left(\sum_{|n'|\sim 2^n} \int_{|\tau|\sim 2^k} \left|\sum_{\ell=0}^{\infty} B_{n',\ell}(\tau)\right|^2 d\tau\right)^{1/2}\right) \\
&\leq \sum_{n=0}^{\infty} \sum_{k\in\mathbb{N}} \left(\mathbb{E}\left(2^k \sum_{|n'|\sim 2^n} \int_{|\tau|\sim 2^k} \left|\sum_{\ell=0}^{\infty} B_{n',\ell}(\tau)\right|^2 d\tau\right)\right)^{1/2} \qquad (2.2) \\
&\leq C(\theta) \sum_{n=0}^{\infty} \sum_{k\in\mathbb{N}} 2^{-k} \|\Delta_n \phi(\cdot)\|_{L^\infty([0,T]\times\Omega; L_2^{0,0})} \\
&\leq C(\theta) \sum_{n=0}^{\infty} \|\Delta_n \phi(\cdot)\|_{L^\infty([0,T]\times\Omega; L_2^{0,0})}.
\end{aligned}$$

Our aim is now to estimate I. We set

$$A_{n',\ell}(\tau,s)=\int_{-\infty}^{s}\theta^2(t)e^{itn'^3}\varphi_{n',\ell}(t)\frac{e^{-i\tau t}}{i\tau}d\beta_\ell(t)$$

so that

$$A_{n',\ell}(\tau)=\int_{-\infty}^{+\infty}dA_{n',\ell}(\tau,s).$$

Moreover, using the Itô formula, we have

$$\begin{aligned}\left|\sum_{\ell=0}^{+\infty}A_{n',\ell}(\tau)\right|^2&=\int_{\mathbb{R}}d\left|\sum_{\ell\in\mathbb{N}}A_{n',\ell}(\tau,t)\right|^2\\&=2\,\mathrm{Re}\left(\sum_{\ell,m=0}^{\infty}\int_{\mathbb{R}}\int_{-\infty}^{t}\theta^2(s)e^{isn'^3}\varphi_{n',\ell}(s)\frac{e^{-i\tau s}}{i\tau}\,d\beta_\ell(s)\right.\\&\qquad\left.\times\,\theta^2(t)e^{-itn'^3}\varphi_{n',m}(t)\frac{e^{i\tau t}}{-i\tau}d\beta_m(t)\right)+\sum_{\ell\in\mathbb{N}}\int_{\mathbb{R}}\theta^4(t)\frac{\varphi^2_{n',\ell}(t)}{\tau^2}dt\\&=I^1_{n'}(\tau)+I^2_{n'}(\tau).\end{aligned}$$

Hence, again, two terms are involved in the estimate of I. The estimate of the second term is immediate. Indeed, we have

$$\begin{aligned}&\mathbb{E}\left(\sum_{n=0}^{\infty}\sup_{k\in\mathbb{N}}2^{k/2}\left(\sum_{|n'|\sim2^n}\int_{|\tau|\sim2^k}I^2_{n'}(\tau)d\tau\right)^{1/2}\right)\\&\quad=\mathbb{E}\left(\sum_{n=0}^{\infty}\sup_{k\in\mathbb{N}}2^{k/2}\left(\sum_{|n'|\sim2^n}\int_{|\tau|\sim2^k}\sum_{\ell\in\mathbb{N}}\int_{\mathbb{R}}\theta^4(t)\frac{\varphi^2_{n',\ell}(\tau)}{\tau^2}dt\,d\tau\right)^{1/2}\right)\\&\quad\le C(\theta)\sum_{n=0}^{\infty}\sup_{k\in\mathbb{N}}2^{k/2}\left(\int_{|\tau|\sim2^k}\frac{1}{\tau^2}\left|\sum_{|n'|\sim2^n}\sum_{\ell\in\mathbb{N}}\varphi^2_{n',\ell}(\cdot)\right|_{L^\infty([0,T]\times\Omega)}d\tau\right)^{1/2}\\&\quad\le C(\theta)\sum_{n=0}^{\infty}\|\Delta_n\phi(\cdot)\|_{L^\infty([0,T]\times\Omega;L^{0,0}_2)}.\end{aligned}\tag{2.3}$$

In order to estimate the contribution of the stochastic integral, i.e., of $I^1_{n'}(\tau)$ in the bound of I, we start with the estimate

(2.4)

$$\begin{aligned}
&\mathbb{E}\left(\left|\sum_{|n'|\sim 2^n}\int_{|\tau|\sim 2^k} I^1_{n'}(\tau)d\tau\right|^2\right)\\
&\quad=\mathbb{E}\left(\left|\sum_{|n'|\sim 2^n}\int_{|\tau|\sim 2^k} 2\,\mathrm{Re}\left(\sum_{\ell,m=0}^{\infty}\int_{\mathbb{R}}\int_{-\infty}^{t}\theta^2(s)e^{isn'^3}\varphi_{n',\ell}(s)\frac{e^{-i\tau s}}{i\tau}\,d\beta_\ell(s)\right.\right.\right.\\
&\qquad\qquad\left.\left.\left.\times\,\theta^2(t)e^{-itn'^3}\varphi_{n',m}(t)\frac{e^{i\tau t}}{-i\tau}\,d\beta_m(t)\right)d\tau\right|^2\right)\\
&\quad=\mathbb{E}\left(\left|\sum_{m=0}^{\infty}\int_{\mathbb{R}}\sum_{|n'|\sim 2^n}\sum_{\ell=0}^{\infty}\int_{-\infty}^{t}2\,\mathrm{Re}\left(\theta^2(s)e^{-i(t-s)n'^3}\int_{|\tau|\sim 2^k}\frac{e^{i\tau(t-s)}}{\tau^2}d\tau\right.\right.\right.\\
&\qquad\qquad\left.\left.\left.\times\,\theta^2(t)\right)\varphi_{n',\ell}(s)\,d\beta_\ell(s)\varphi_{n',m}(t)\,d\beta_m(t)\right|^2\right)\\
&\quad=\sum_{m=0}^{\infty}\int_{\mathbb{R}}\mathbb{E}\left|\sum_{|n'|\sim 2^n}\sum_{\ell=0}^{\infty}\int_{-\infty}^{t}2\,\mathrm{Re}\left(\theta^2(s)\theta^2(t)e^{-i(t-s)n'^3}\int_{|\tau|\sim 2^k}\frac{e^{i\tau(t-s)}}{\tau^2}d\tau\right)\right.\\
&\qquad\qquad\left.\times\,\varphi_{n',\ell}(s)d\beta_\ell(s)\varphi_{n',m}(t)\right|^2 dt,
\end{aligned}$$

where we have used again the independence of the family $(\beta_m)_{m\in\mathbb{N}}$. Using now the Cauchy–Schwarz inequality in n', the above term is bounded by

(2.5)

$$\begin{aligned}
&\sum_{m=0}^{\infty}\int_{\mathbb{R}}\mathbb{E}\left(\sum_{|n'|\sim 2^n}\left(\sum_{\ell=0}^{\infty}\int_{-\infty}^{t}2\,\mathrm{Re}\left(\theta^2(s)\theta^2(t)e^{-i(t-s)n'^3}\right.\right.\right.\\
&\qquad\qquad\left.\left.\left.\times\int_{|\tau|\sim 2^k}\frac{e^{i\tau(t-s)}}{\tau^2}d\tau\right)\varphi_{n',\ell}(s)d\beta_\ell(s)\right)^2\sum_{|n'|\sim 2^n}\varphi^2_{n',m}(t)\right)dt\\
&\le\left(\sup_{[0,t]\times\Omega}\sum_{|n'|\sim 2^n}\sum_{m=0}^{\infty}|\varphi_{n',m}(t)|^2\right)\\
&\quad\times\int_{\mathbb{R}}\mathbb{E}\sum_{|n'|\sim 2^n}\left(\sum_{\ell=0}^{\infty}\int_{-\infty}^{t}2\,\mathrm{Re}\left(\theta^2(s)\theta^2(t)e^{-i(t-s)n'^3}\int_{|\tau|\sim 2^k}\frac{e^{i\tau(t-s)}}{\tau^2}d\tau\right)\right.\\
&\qquad\qquad\left.\times\,\varphi_{n',\ell}(s)\,d\beta_\ell(s)\right)^2 dt.
\end{aligned}$$

Concerning the first term in the right-hand side above, we have

$$\begin{aligned}
&\sup_{[0,T]\times\Omega} \sum_{|n'|\sim 2^n} \sum_{m=0}^{\infty} |\varphi_{n',m}(t)|^2 \\
&\quad \le \sup_{[0,T]\times\Omega} \sum_{m=0}^{\infty} \sum_{|n'|\sim 2^n} |\phi(t) e_m(n')|^2 \\
&\quad \le \sup_{[0,T]\times\Omega} \sum_{m=0}^{\infty} |\Delta_n \phi(t) e_m|^2_{L^2(\mathbb{T})} = \|\Delta_n \phi(\cdot)\|^2_{L^\infty([0,T]\times\Omega; L_2^{0,0})},
\end{aligned}$$

while the remaining term in (2.5) is bounded above by

$$\begin{aligned}
&\int_{\mathbb{R}} \sum_{|n'|\sim 2^n} \sum_{\ell=0}^{\infty} \int_{-\infty}^{t} \theta^4(t)\theta^4(s) \left| \int_{|\tau|\sim 2^k} \frac{e^{i\tau(t-s)}}{\tau^2} d\tau \right|^2 \mathbb{E}(|\varphi_{n',\ell}(s)|^2) ds\, dt \\
&\quad \le \|\Delta_n \phi(\cdot)\|^2_{L^\infty([0,T]\times\Omega; L_2^{0,0})} \int_{\mathbb{R}} \int_{-\infty}^{t} \theta^4(t)\theta^4(s) \left| \int_{|\tau|\sim 2^k} \frac{e^{i\tau(t-s)}}{\tau^2} d\tau \right|^2 ds\, dt.
\end{aligned}$$

We then notice that, by interpolation between the cases $\alpha = 0$ and $\alpha = 1$, for any $\alpha \in [0,1]$ there is a positive constant C_α such that

$$\left| \int_{|\tau|\sim 2^k} \frac{e^{i\tau(t-s)}}{\tau^2} d\tau \right| \le \frac{C_\alpha}{|t-s|^\alpha} 2^{-(1+\alpha)k}.$$

Applying this with $\alpha = 1/4$, we get that the second term in (2.5) is bounded above by

$$\begin{aligned}
&C 2^{-\frac{5}{2}k} \|\Delta_n \phi(\cdot)\|^2_{L^\infty([0,T]\times\Omega; L_2^{0,0})} \int_{\mathbb{R}} \int_{-\infty}^{t} \frac{\theta^4(t)\theta^4(s)}{\sqrt{t-s}} ds\, dt \\
&\quad \le C(\theta) 2^{-\frac{5}{2}k} \|\Delta_n \phi(\cdot)\|^2_{L^\infty([0,T]\times\Omega; L_2^{0,0})}.
\end{aligned}$$

Collecting all these estimates from (2.4), we get

$$\mathbb{E}\left(\left| \sum_{|n'|\sim 2^n} \int_{|\tau|\sim 2^k} I^1_{n'}(\tau) d\tau \right|^2 \right) \le C(\theta) 2^{-\frac{5}{2}k} \|\Delta_n \phi(\cdot)\|^4_{L^\infty([0,T]\times\Omega; L_2^{0,0})}$$

and we deduce from this latest inequality that

$$
\begin{aligned}
&\mathbb{E}\left(\sum_{n=0}^{\infty}\sup_{k\in\mathbb{N}}2^{k/2}\left(\sum_{|n'|\sim 2^n}\int_{|\tau|\sim 2^k} I^1_{n'}(\tau)d\tau\right)^{1/2}\right)\\
&\quad\le \mathbb{E}\left(\sum_{n=0}^{\infty}\sum_{k=0}^{\infty}2^{k/2}\left(\sum_{|n'|\sim 2^n}\int_{|\tau|\sim 2^k} I^1_{n'}(\tau)d\tau\right)^{1/2}\right)\\
&\quad\le \sum_{n=0}^{\infty}\sum_{k=0}^{\infty}2^{k/2}\left[\mathbb{E}\left(\left(\sum_{|n'|\sim 2^n}\int_{|\tau|\sim 2^k} I^1_{n'}(\tau)d\tau\right)^2\right)\right]^{1/4}\\
&\quad\le C(\theta)\sum_{n=0}^{\infty}\left(\sum_{k=0}^{\infty}2^{-\frac{k}{8}}\right)\|\Delta_n\phi(\cdot)\|_{L^\infty([0,T]\times\Omega;L_2^{0,0})},
\end{aligned}
$$

where we have used Hölder's inequality at the third line; this, together with (2.3), completes the proof of the estimate of I.

In this way, the first inequality in Proposition 2.1 is proved after an application of Lemma 1.6, with $\sigma' < \sigma$. The second inequality follows from the obvious fact that

$$
\begin{aligned}
&\sum_{n=0}^{\infty}\|\Delta_n\phi(\cdot)\|^2_{L^\infty([0,T]\times\Omega;L_2^{0,\sigma})}\\
&\quad=\sum_{n=0}^{\infty}2^{\sigma n}\|\Delta_n\phi(\cdot)\|^2_{L^\infty([0,T]\times\Omega;L_2^{0,0})}\\
&\quad\le\left(\sum_{n=0}^{\infty}2^{-2(s'-\sigma)n}\right)^{1/2}\left(\sum_{n=0}^{\infty}2^{s'n}\|\Delta_n\phi(\cdot)\|^2_{L^\infty([0,T]\times\Omega;L_2^{0,0})}\right)^{1/2}\\
&\quad\le C(s',\sigma)\|\phi(\cdot)\|_{L^\infty([0,T]\times\Omega;L_2^{0,s'})}.\qquad\square
\end{aligned}
$$

3. Bilinear estimates. We now turn to prove some bilinear estimates which will allow us to handle the nonlinear term in (1.5). The next one is the crucial estimate.

PROPOSITION 3.1. *Let $-\frac{1}{2}\le s\le 0$ and $f\in X^{s,1/2}_{1,1}$, $g\in X^{s,1/2}_{1,\infty}$; then $\partial_x(fg)\in X^{s,-1/2}_{1,1}$ and there is a constant $C>0$ such that*

$$
|\partial_x(fg)|_{X^{s,-1/2}_{1,1}}\le C|f|_{X^{s,1/2}_{1,1}}|g|_{X^{s,1/2}_{1,\infty}}.
$$

Proof. Let f and g be as above; using a duality argument, it is sufficient, as usually, to prove that for some constant $C>0$, and for any function h in $X^{-s,1/2}_{\infty,\infty}$—where $X^{-s,1/2}_{\infty,\infty}$ is defined in an obvious way by modifying the definition of $X^{-s,1/2}_{1,1}$—we have

$$
|\langle\partial_x(fg),h\rangle|\le C|f|_{X^{s,1/2}_{1,1}}|g|_{X^{s,1/2}_{1,\infty}}|h|_{X^{-s,1/2}_{\infty,\infty}}.
$$

Using the Plancherel theorem, one has

$$
|\langle\partial_x(fg),h\rangle|=\left|\sum_{n'\neq 0}\sum_{\substack{n'_1\neq 0\\ n'_1\neq n'}}\int_{\tau\in\mathbb{R}}\int_{\tau_1\in\mathbb{R}} n'\bar{\hat{h}}(\tau,n')\hat{g}(\tau_1,n'_1)\hat{f}(\tau-\tau_1,n'-n'_1)d\tau_1\,d\tau\right|.
$$

We will denote $\sigma = \sigma(\tau, n') = \tau - {n'}^3$, $\sigma_1 = \sigma(\tau_1, n_1')$, $\sigma_2 = \sigma(\tau - \tau_1, n' - n_1')$. We also set $\hat{G}(\tau, n') = {n'}^s \langle\sigma\rangle^{1/2} \hat{g}(\tau, n')$, $\hat{F}(\tau, n') = {n'}^s \langle\sigma\rangle^{1/2} \hat{f}(\tau, n')$, and $\hat{H}(\tau, n') = {n'}^{-s} \langle\sigma\rangle^{1/2} \bar{\hat{h}}(\tau, n')$, so that F, G, and H lie, respectively, in $X^{0,0}_{1,1}$, $X^{0,0}_{1,\infty}$, and $X^{0,0}_{\infty,\infty}$. It suffices to prove that

(3.1)
$$\sum_{n' \neq 0} \sum_{\substack{n_1' \neq 0 \\ n_1' \neq n'}} \int_{\tau \in \mathbb{R}} \int_{\tau_1 \in \mathbb{R}} \frac{|n'|^{1+s} |n_1'|^{-s} |n' - n_1'|^{-s} |\hat{H}_{\tau, n'}| \, |\hat{G}_{\tau_1, n_1'}| \, |\hat{F}_{\tau - \tau_1, n' - n_1'}|}{\langle\sigma\rangle^{1/2} \langle\sigma_1\rangle^{1/2} \langle\sigma_2\rangle^{1/2}} d\tau_1 \, d\tau \leq C |H|_{X^{0,0}_{\infty,\infty}} |G|_{X^{0,0}_{1,\infty}} |F|_{X^{0,0}_{1,1}},$$

where we use $\hat{H}_{\tau, n'}$ for $\hat{H}(\tau, n')$ and so on. We divide the region $(n', n_1', \tau, \tau_1) \in (\mathbb{Z} \setminus \{0\})^2 \times \mathbb{R}^2$ arising in the left-hand side of (3.1) into three subregions,

$$\begin{aligned} &\text{(Region I)} && \langle\sigma_1\rangle = \max\{\langle\sigma\rangle, \langle\sigma_1\rangle, \langle\sigma_2\rangle\}, \\ &\text{(Region II)} && \langle\sigma\rangle = \max\{\langle\sigma\rangle, \langle\sigma_1\rangle, \langle\sigma_2\rangle\}, \\ &\text{(Region III)} && \langle\sigma_2\rangle = \max\{\langle\sigma\rangle, \langle\sigma_1\rangle, \langle\sigma_2\rangle\}, \end{aligned}$$

and we estimate separately the contributions of each of these regions to the left-hand side of (3.1).

Region I. From the identity

$$3|n'| \, |n_1'| \, |n' - n_1'| = |\tau - {n'}^3 - (\tau_1 - {n_1'}^3) - ((\tau - \tau_1) - (n' - n_1')^3)|$$

we get as usual that in Region I,

$$\frac{1}{2} |n'|^2 \leq |n'| \, |n_1'| \, |n' - n_1'| \leq \langle\sigma_1\rangle,$$

so that for any $s \in [-\frac{1}{2}, 0]$,

$$|n'|^{1+s} |n_1'|^{-s} |n' - n_1'|^{-s} \leq C \langle\sigma_1\rangle^{1/2}.$$

Hence, it is sufficient to prove that the contribution of Region I to

$$I = \sum_{n' \neq 0} \sum_{\substack{n_1' \neq 0, \\ n_1' \neq n'}} \int_{\tau \in \mathbb{R}} \int_{\tau_1 \in \mathbb{R}} \frac{|\hat{H}_{\tau, n'}| \, |\hat{G}_{\tau_1, n_1'}| \, |\hat{F}_{\tau - \tau_1, n' - n_1'}|}{\langle\sigma\rangle^{1/2} \langle\sigma_2\rangle^{1/2}} d\tau_1 \, d\tau$$

is bounded above by $C|H|_{X^{0,0}_{\infty,\infty}} |G|_{X^{0,0}_{1,\infty}} |F|_{X^{0,0}_{1,1}}$. Again, we will divide Region I into several subregions.

Region I-a. We consider here the subregion for which $\langle\sigma\rangle \geq \frac{1}{4} {n'}^2$.

We then estimate the contribution of this region to I; it is bounded above by its contribution to

$$\sum_{n, n_1 \in \mathbb{N}} \sum_{k, k_1 \in \mathbb{N}} \sum_{\substack{|n'| \sim 2^n \\ |n_1'| \sim 2^{n_1} \\ n' \neq n_1'}} \int_{|\tau| \sim 2^k} \int_{|\tau_1| \sim 2^{k_1}} \frac{|\hat{H}_{\tau, n'}| \, |\hat{G}_{\tau_1, n_1'}| \, |\hat{F}_{\tau - \tau_1, n' - n_1'}|}{\langle\sigma\rangle^{1/2} \langle\sigma_2\rangle^{1/2}} d\tau_1 \, d\tau, \tag{3.2}$$

with the convention that for $k = 0$, $|\tau| \sim 2^k$ means $|\tau| \leq 2$. This latest term is bounded above, using the Cauchy–Schwarz inequality, by

$$\sum_{n,n_1\in\mathbb{N}} \sum_{k,k_1\in\mathbb{N}} \left(\sum_{|n_1'|\sim 2^{n_1}} \int_{|\tau_1|\sim 2^{k_1}} |\hat{G}_{\tau_1,n_1'}|^2 d\tau_1 \right)^{1/2} \times \left(\sum_{|n_1'|\sim 2^{n_1}} \int_{|\tau_1|\sim 2^{k_1}} \left(\sum_{|n'|\sim 2^n} \int_{|\tau|\sim 2^k} \frac{|\hat{H}_{\tau,n'}|\,|\hat{F}_{\tau-\tau_1,n'-n_1'}|}{\langle\sigma\rangle^{1/2}\langle\sigma_2\rangle^{1/2}} d\tau \right)^2 d\tau_1 \right)^{1/2}. \tag{3.3}$$

Now, we use the fact that in Region I-a, we have, for $\varepsilon > 0$ small, which will be chosen more precisely later,

$$\frac{1}{\langle\sigma(\tau,n')\rangle^{1/2}} \leq C|n'|^{-\varepsilon} \frac{1}{\langle\sigma(\tau,n')\rangle^{1/2-\varepsilon/2}},$$

and using the Cauchy–Schwarz inequality in (τ, n') in (3.3), it is bounded above by

(3.4)

$$\begin{aligned} & C \sum_{n,n_1\in\mathbb{N}} \sum_{k,k_1\in\mathbb{N}} \left(\sum_{|n_1'|\sim 2^{n_1}} \int_{|\tau_1|\sim 2^{k_1}} |\hat{G}_{\tau_1,n_1'}|^2 d\tau_1 \right)^{1/2} \\ & \qquad \times \left[\sum_{|n_1'|\sim 2^{n_1}} \int_{|\tau_1|\sim 2^{k_1}} \left(\sum_{|n'|\sim 2^n} \int_{|\tau|\sim 2^k} |n'|^{-2\varepsilon} \langle\sigma_{\tau,n'}\rangle^{-\varepsilon} |\hat{H}_{\tau,n'}|^2 |\hat{F}_{\tau-\tau_1,n'-n_1'}|^2 d\tau \right) \right. \\ & \qquad\qquad \left. \times \left(\sum_{|n'|\sim 2^n} \int_{|\tau\sim 2^k} \frac{d\tau}{\langle\sigma_{\tau,n'}\rangle^{1-2\varepsilon}\langle\sigma_{\tau-\tau_1,n'-n_1'}\rangle} \right) d\tau_1 \right]^{1/2} \\ & \leq C \sum_{n_1\in\mathbb{N}} \left[\sup_{k_1\in\mathbb{N}} \left(\sum_{|n_1'|\sim 2^{n_1}} \int_{|\tau_1|\sim 2^{k_1}} |\hat{G}_{\tau_1,n_1'}|^2 d\tau_1 \right)^{1/2} \right. \\ & \qquad \times \sup_{k_1,n,k\in\mathbb{N}} \sup_{|n_1'|\sim 2^{n_1}} \sup_{|\tau_1|\sim 2^{k_1}} \left(\sum_{|n'|\sim 2^n} \int_{|\tau|\sim 2^k} \frac{d\tau}{\langle\sigma_{\tau,n'}\rangle^{1-2\varepsilon}\langle\sigma_{\tau-\tau_1,n'-n_1'}\rangle} \right)^{1/2} \\ & \qquad \times \sum_{k_1,n,k\in\mathbb{N}} \left(\sum_{|n_1'|\sim 2^{n_1}} \int_{|\tau_1|\sim 2^{k_1}} \sum_{|n'|\sim 2^n} \int_{|\tau|\sim 2^k} |n'|^{-2\varepsilon} \langle\sigma_{\tau,n'}\rangle^{-\varepsilon} |\hat{H}_{\tau,n'}|^2 \right. \\ & \qquad\qquad \left. \left. \times\, |\hat{F}_{\tau-\tau_1,n'-n_1'}|^2 d\tau d\tau_1 \right)^{1/2} \right]. \end{aligned}$$

But now, the fact that

$$\int_{-\infty}^{+\infty} \frac{d\theta}{(1+|\theta|)^{1-2\varepsilon}(1+|\theta-a|)} \leq \frac{C}{(1+|a|)^{1-4\varepsilon}}$$

for $a \in \mathbb{R}$ and the proof of Lemma 5.1 in [15] show that there is a constant $C > 0$ such that

$$\begin{aligned}
&\sup_{n_1\in\mathbb{Z}^*}\sup_{\tau_1\in\mathbb{R}}\sup_{n,k\in\mathbb{N}}\left(\sum_{|n'|\sim 2^n}\int_{|\tau|\sim 2^k}\frac{d\tau}{\langle\sigma_{\tau,n'}\rangle^{1-2\varepsilon}\langle\sigma_{\tau-\tau_1,n'-n_1}\rangle}\right)\\
&\quad\le \sup_{n_1\in\mathbb{Z}^*}\sup_{\tau_1\in\mathbb{R}}\left(\sum_{\substack{n\in\mathbb{Z}\setminus\{0\}\\ n\neq n_1}}\int_{\tau\in\mathbb{R}}\frac{d\tau}{\langle\sigma_{\tau,n}\rangle^{1-2\varepsilon}\langle\sigma_{\tau-\tau_1,n-n_1}\rangle}\right)\\
&\quad\le C
\end{aligned}$$

for any $\varepsilon > 0$ such that $1 - 4\varepsilon \ge 3/4$, i.e., for any $\varepsilon \le 1/16$. On the other hand the last line in (3.4) is bounded above by

$$\begin{aligned}
&\sum_{\substack{n,n_1\in\mathbb{N}\\ k,k_1\in\mathbb{N}}}\left[\left(\sum_{|n'|\sim 2^n}\int_{|\tau|\sim 2^k}|n'|^{-\varepsilon}\langle\sigma\rangle^{-\varepsilon/2}|\hat H_{\tau,n'}|^2d\tau\right)^{1/2}\right.\\
&\qquad\left.\times\sup_{|n'|\sim 2^n}\sup_{|\tau|\sim 2^k}\left(\sum_{|n_1'|\sim 2^{n_1}}\int_{|\tau_1|\sim 2^{k_1}}|n'|^{-\varepsilon}\langle\sigma\rangle^{-\varepsilon/2}|\hat F_{\tau-\tau_1,n'-n_1'}|^2d\tau_1\right)^{1/2}\right]\\
&\le \sup_{n,k\in\mathbb{N}}\sum_{n_1,k_1\in\mathbb{N}}\sup_{\substack{|n'|\sim 2^n\\ |\tau|\sim 2^k}}\left(\sum_{|n_1'|\sim 2^{n_1}}\int_{|\tau_1|\sim 2^{k_1}}|n'|^{-\varepsilon}\langle\sigma\rangle^{-\varepsilon/2}|\hat F_{\tau-\tau_1,n'-n_1'}|^2d\tau_1\right)^{1/2}\\
&\quad\times\sum_{n,k\in\mathbb{N}}\left(\sum_{|n'|\sim 2^n}\int_{|\tau|\sim 2^k}|n'|^{-\varepsilon}\langle\sigma\rangle^{-\varepsilon/2}|\hat H_{\tau,n'}|^2d\tau\right)^{1/2}\\
&\le C_\varepsilon|H|_{X^{0,0}_{\infty,\infty}}\\
&\quad\times\sup_{n,k\in\mathbb{N}}\sum_{n_1,k_1\in\mathbb{N}}\left(\sup_{\substack{|n'|\sim 2^n\\ |\tau|\sim 2^k}}\left(\sum_{|n_1'|\sim 2^{n_1}}\int_{|t_1|\sim 2^{k_1}}|n'|^{-\varepsilon}\langle\sigma\rangle^{-\varepsilon/2}|\hat F_{\tau-\tau_1,n'-n_1'}|^2d\tau_1\right)^{1/2}\right).
\end{aligned}$$

One may then notice that if $|n_1'| \ge 4|n'|$, then $|n' - n_1'| \sim 2^{n_1}$, and if $|\tau_1| \ge 4|\tau|$, then $|\tau - \tau_1| \sim 2^{k_1}$, so that for any $n, k \in \mathbb{N}$,

$$\begin{aligned}
&\sum_{n_1,k_1\in\mathbb{N}}\sup_{\substack{|n'|\sim 2^n\\ |\tau|\sim 2^k}}\left(\sum_{\substack{|n_1'|\sim 2^{n_1}\\ |n_1'|\ge 4|n'|}}\int_{\substack{|\tau_1|\sim 2^{k_1}\\ |\tau_1|\ge 4|\tau|}}|n'|^{-\varepsilon}\langle\sigma\rangle^{-\varepsilon/2}|\hat F_{\tau-\tau_1,n'-n_1'}|^2d\tau_1\right)^{1/2}\\
&\quad\le C\sum_{n_1,k_1\in\mathbb{N}}\left(\sum_{|n_1'|\sim 2^{n_1}}\int_{|\tau_1|\sim 2^{k_1}}|\hat F_{\tau_1,n_1'}|^2d\tau_1\right)^{1/2}\\
&\quad\le C|F|_{X^{0,0}_{1,1}},
\end{aligned}$$

while if $|n_1'| \le 4|n'|$ (still with $|\tau_1| \ge 4|\tau|$), then $|n'|^{-\varepsilon} \le C|n_1'|^{-\varepsilon}$ and for all $n, k, \in \mathbb{N}$,

$$\begin{aligned}
&\sum_{n_1,k_1\in\mathbb{N}} \sup_{\substack{|n'|\sim 2^n\\ |\tau|\sim 2^k}} \left(\sum_{\substack{|n_1'|\sim 2^{n_1}\\ |n_1'|\le 4|n'|}} \int_{\substack{|\tau_1|\sim 2^{k_1}\\ |\tau_1|\ge 4|\tau|}} |n'|^{-\varepsilon}\langle\sigma\rangle^{-\varepsilon/2} |\hat{F}_{\tau-\tau_1,n'-n_1'}|^2 d\tau_1 \right)^{1/2} \\
&\quad \le C \sum_{n_1\in\mathbb{N}} \left(\sup_{|n_1'|\sim 2^{n_1}} |n_1'|^{-\varepsilon} \right) \sum_{k_1\in\mathbb{N}} \sup_{|n'|\sim 2^n} \left(\sum_{|n_1'|\sim 2^{n_1}} \int_{|\tau_1|\sim 2^{k_1}} |\hat{F}_{\tau_1,n'-n_1'}|^2 d\tau_1 \right)^{1/2} \\
&\quad \le C_\varepsilon \sum_{k_1\in\mathbb{N}} \left(\sum_{\ell\in\mathbb{Z}} \int_{|\tau_1|\sim 2^{k_1}} |\hat{F}_{\tau,\ell}|^2 d\tau \right)^{1/2} \\
&\quad \le C_\varepsilon \sum_{k_1\in\mathbb{N}} \sum_{\ell\in\mathbb{N}} \left(\sum_{|\ell'|\sim 2^{\ell}} \int_{|\tau_1|\sim 2^{k_1}} |\hat{F}_{\tau,\ell'}|^2 d\tau \right)^{1/2} \\
&\quad \le C_\varepsilon |F|_{X^{0,0}_{1,1}}.
\end{aligned}$$

The cases for which $|\tau_1| \le 4|\tau|$ are treated in the same way as the latest case above, using the fact that in this case, $\langle\sigma\rangle^{-\varepsilon} \le C\langle\tau_1 - n'^3\rangle^{-\varepsilon}$, so that the sum over k_1 converges.

It follows from these estimates that (3.4) is bounded above by

$$C|G|_{X^{0,0}_{\infty,\infty}} |H|_{X^{0,0}_{\infty,\infty}} |F|_{X^{0,0}_{1,1}} \le C|G|_{X^{0,0}_{1,\infty}} |H|_{X^{0,0}_{\infty,\infty}} |F|_{X^{0,0}_{1,1}},$$

and this achieves the estimate of the contribution of Region I-a.

Region I-b. Assume here that $\langle\sigma_2\rangle \ge \frac{1}{4}n'^2$.

We may then proceed as in Region I-a by noticing that here we have, for $\varepsilon > 0$ small,

$$\frac{1}{\langle\sigma\rangle^{1/2}\langle\sigma_2\rangle^{1/2}} \le C_\varepsilon |n'|^{-\varepsilon}\langle\sigma\rangle^{-\varepsilon/2} \frac{1}{\langle\sigma\rangle^{1/2-\varepsilon/2}\langle\sigma_2\rangle^{1/2-\varepsilon/2}}$$

and that

$$\sup_{\substack{n,k\in\mathbb{N}\\ n_1'\in\mathbb{Z}\setminus\{0\}\\ \tau_1\in\mathbb{R}}} \left(\sum_{|n'|\sim 2^n} \int_{|\tau|\sim 2^k} \frac{d\tau}{\langle\sigma(\tau,n')\rangle^{1-\varepsilon}\langle\sigma(\tau-\tau_1,n'-n_1')\rangle^{1-\varepsilon}} \right) < +\infty$$

for any $\varepsilon \le 1/8$.

Region I-c. We consider now the region where $\langle\sigma\rangle \le \frac{1}{4}n'^2$ and $\langle\sigma_2\rangle \le \frac{1}{4}n'^2$.

The contribution of this region to I will be the most difficult to estimate. Again, we use in (3.2) the Cauchy–Schwarz inequality in (τ, n') to bound the contribution of

Region I-c to (3.2) by its contribution to

$$\sum_{n,n_1\in\mathbb{N}}\sum_{k,k_1\in\mathbb{N}}\Bigg(\sum_{|n_1'|\sim 2^{n_1}}\int_{|\tau_1|\sim 2^{k_1}}|\hat{G}_{\tau_1,n_1'}|^2d\tau_1\Bigg)^{1/2}$$
$$\times\Bigg[\sum_{|n_1'|\sim 2^{n_1}}\int_{|\tau_1|\sim 2^{k_1}}\Bigg(\sum_{|n'|\sim 2^{n}}\int_{|\tau|\sim 2^{k}}|\hat{H}_{\tau,n'}|^2|\hat{F}_{\tau-\tau_1,n'-n_1'}|^2d\tau\Bigg)$$
$$\times\Bigg(\sum_{|n'|\sim 2^{n}}\int_{|\tau|\sim 2^{k}}\frac{d\tau}{\langle\sigma\rangle\langle\sigma_2\rangle}\Bigg)\Bigg]^{1/2}$$
$$\le\sum_{n_1\in\mathbb{N}}\Bigg[\sup_{k_1\in\mathbb{N}}\Bigg(\sum_{|n_1'|\sim 2^{n_1}}\int_{|\tau_1|\sim 2^{k_1}}|\hat{G}_{\tau_1,n_1'}|^2d\tau_1\Bigg)^{1/2}$$
$$\times\sum_{n\in\mathbb{N}}\sum_{k_1\in\mathbb{N}}\sum_{k\in\mathbb{N}}\Bigg\{\sup_{|n_1'|\sim 2^{n_1}}\sup_{|\tau_1|\sim 2^{k_1}}\Bigg(\sum_{|n'|\sim 2^{n}}\int_{|\tau|\sim 2^{k}}\frac{d\tau}{\langle\sigma\rangle\langle\sigma_2\rangle}\Bigg)^{1/2}$$
$$\times\Bigg(\sum_{|n_1'|\sim 2^{n_1}}\int_{|\tau_1|\sim 2^{k_1}}\sum_{|n'|\sim 2^{n}}\int_{|\tau|\sim 2^{k}}|\hat{H}_{\tau,n'}|^2|\hat{F}_{\tau-\tau_1,n'-n_1'}|^2d\tau\,d\tau_1\Bigg)^{1/2}\Bigg\}\Bigg]$$
$$\le\sum_{n_1\in\mathbb{N}}\Bigg[\sup_{k_1\in\mathbb{N}}\Bigg(\sum_{|n_1'|\sim 2^{n_1}}\int_{|\tau_1|\sim 2^{k_1}}|\hat{G}_{\tau_1,n_1'}|^2d\tau_1\Bigg)^{1/2}$$
$$\times\sum_{n\in\mathbb{N}}\sum_{k_1\in\mathbb{N}}\Bigg\{\sum_{k\in\mathbb{N}}\sup_{|n_1'|\sim 2^{n_1}}\sup_{|\tau_1|\sim 2^{k_1}}\Bigg(\sum_{|n'|\sim 2^{n}}\int_{|\tau|\sim 2^{k}}\frac{d\tau}{\langle\sigma\rangle\langle\sigma_2\rangle}\Bigg)^{1/2}$$
$$\times\sup_{k\in\mathbb{N}}\Bigg(\sum_{|n_1'|\sim 2^{n_1}}\int_{|\tau_1|\sim 2^{k_1}}\sum_{|n'|\sim 2^{n}}\int_{|\tau|\sim 2^{k}}|\hat{H}_{\tau,n'}|^2|\hat{F}_{\tau-\tau_1,n'-n_1'}|^2d\tau\,d\tau_1\Bigg)^{1/2}\Bigg\}\Bigg],$$

and using the Cauchy–Schwarz inequality in n, this is bounded above by

(3.5)
$$\sum_{n_1\in\mathbb{N}}\Bigg\{\sup_{k_1\in\mathbb{N}}\Bigg(\sum_{|n_1'|\sim 2^{n_1}}\int_{|\tau_1|\sim 2^{k_1}}|\hat{G}_{\tau_1,n_1'}|^2d\tau_1\Bigg)^{1/2}$$
$$\times\sum_{k_1\in\mathbb{N}}\Bigg[\Bigg(\sum_{n\in\mathbb{N}}\Bigg(\sum_{k\in\mathbb{N}}B(n_1,k_1,n,k)\Bigg)^2\Bigg)^{1/2}$$
$$\times\Bigg(\sum_{n\in\mathbb{N}}\sup_{k\in\mathbb{N}}\sum_{|n_1'|\sim 2^{n_1}}\int_{|\tau_1|\sim 2^{k_1}}\sum_{|n'|\sim 2^{n}}\int_{|\tau|\sim 2^{k}}|\hat{H}_{\tau,n'}|^2|\hat{F}_{\tau-\tau_1,n'-n_1'}|^2d\tau\,d\tau_1\Bigg)^{1/2}\Bigg]\Bigg\},$$

with

$$B(n_1,k_1,n,k)=\sup_{\substack{|n_1'|\sim 2^{n_1}\\ |\tau_1|\sim 2^{k_1}}}\left(\sum_{|n'|\sim 2^n}\int_{|\tau|\sim 2^k}\frac{d\tau}{\langle\sigma\rangle\langle\sigma_2\rangle}\right)^{1/2}. \tag{3.6}$$

We will then make use of the following lemma.

LEMMA 3.2. *Let N be an integer, k_0 a function of $(n_1,k_1,n)\in\mathbb{N}^3$ with values in $\mathbb{N}$, and n_0 a function of $(n_1,k_1)\in\mathbb{N}^2$ with values in $\mathbb{N}$. Denote by $A(N,n_1,k_1)$ the region in $\mathbb{N}^2$ given by*

$$\begin{aligned}A(N,n_1,k_1)=\{(n,k)\in\mathbb{N}^2,\ k_0(n_1,k_1,n)\le k\le k_0(n_1,k_1,n)+N,\\ n_0(n_1,k_1)\le n\le n_0(n_1,k_1)+N\}.\end{aligned}$$

Then there is a constant $C(N)$ depending only on N such that

$$\sup_{n_1,k_1\in\mathbb{N}}\sum_{(n,k)\in A(N,n_1,k_1)}B(n_1,k_1,n,k)\le C(N),$$

where $B(n_1,k_1,n,k)$ is defined by (3.6).

Proof of Lemma 3.2. It follows easily from Lemma 5.1 in [15], since

$$\begin{aligned}&\sup_{k_1,n_1\in\mathbb{N}}\sum_{\substack{(n,k)\\ \in A(N,n_1,k_1)}}B(n_1,k_1,n,k)\\ &\quad\le N^2\sup_{k_1,n_1\in\mathbb{N}}\sup_{n,k\in\mathbb{N}}B(n_1,k_1,n,k)\\ &\quad\le N^2\sup_{k_1,n_1\in\mathbb{N}}\left(\sum_{\substack{n\in\mathbb{Z}\setminus\{0\}\\ n\ne n_1}}\int_{\mathbb{R}}\frac{d\tau}{\langle\sigma(\tau,n)\rangle\langle\sigma(\tau-\tau_1,n-n_1)\rangle}\right)^{1/2}\\ &\quad<+\infty\end{aligned}$$

by Lemma 5.1 in [15]. □

Now, in order to apply Lemma 3.2, we need to show that Region I-c is embedded in a region of the form

$$\{(n,k,n_1,k_1)\in\mathbb{N}^4,\ (n,k)\in A(N,n_1,k_1)\}$$

for some N and for some functions $n_0(n_1,k_1)$ and $k_0(n_1,k_1,n)$.

Note that we have, in Region I-c,

$$|\tau-n'^3|\le\langle\sigma(\tau,n)\rangle\le\frac{1}{4}n'^2\le\frac{1}{4}|n'|^3;$$

hence

$$\frac{3}{4}|n'|^3\le|\tau|\le\frac{5}{4}|n'|^3$$

and the property $3n-4\le k\le 3n+4$ follows easily. Hence, to prove the preceding result, we only have to find $n_0(n_1,k_1)$ and N such that for any (n,k,n_1,k_1) in Region I-c,

$$n_0(n_1,k_1) \le n \le n_0(n_1,k_1)+N.$$

In order to prove this fact, we again use a partition of Region I-c into three subregions.

- *Region* I-c-1: $2^{-12}|n_1'| \le |n'| \le 2^{12}|n_1'|$. In this region, we obviously have the result with $n_0(n_1,k_1) = n_1 - 4$.
- *Region* I-c-2: $|n'| \le 2^{-12}|n_1'|$. We recall that

$$|\sigma - \sigma_1 - \sigma_2| = 3|n'|\,|n_1'|\,|n'-n_1'|,$$

from which it follows that (since $\langle\sigma_1\rangle$ is dominant)

$$|n_1'|\,|n'|\,|n'-n_1'| \le \langle\sigma_1\rangle \le 3|n_1'|\,|n'|\,|n'-n_1'| + \langle\sigma\rangle + \langle\sigma_2\rangle;$$

using the fact that $|n'| \le \frac{1}{2}|n_1'|$ and that $\langle\sigma\rangle \le \frac{1}{4}|n'|^2$ and $\langle\sigma_2\rangle \le \frac{1}{4}|n'|^2$, from the preceding inequality we easily get

$$\frac{1}{2}|n_1'|^2|n'| \le \langle\sigma_1\rangle \le 5|n_1'|^2|n'|,$$

and the property follows easily with

$$n_0(n_1,k_1) = \frac{\ln|2^{k_1} - 2^{3n_1}|}{\ln 2} - \frac{\ln 5}{\ln 2} - 2n_1.$$

- *Region* I-c-3: $|n'| \ge 2^{12}|n_1'|$. We infer here, from the inequality

$$|n'|\,|n_1'|\,|n'-n_1'| \le \langle\sigma_1\rangle \le 3|n'|\,|n_1'|\,|n'-n_1'| + \langle\sigma\rangle + \langle\sigma_2\rangle,$$

that

$$\frac{1}{2}|n'|^2|n_1'| \le \langle\sigma_1\rangle \le 5|n'|^2|n_1'|,$$

and we conclude as in the preceding case.

Now, going back to (3.5), we may use Lemma 3.2 to show that the contribution of Region I-c to

$$\sup_{n_1,k_1\in\mathbb{N}} \left(\sum_{n\in\mathbb{N}} \left(\sum_{k\in\mathbb{N}} B(n_1,k_1,n,k) \right)^2 \right)^{1/2}$$
$$\le \sup_{n_1,k_1\in\mathbb{N}} \sum_{n,k\in\mathbb{N}} B(n_1,k_1,n,k)$$

is bounded above by an absolute constant.

Hence, each of the contributions of Regions I-c-1, I-c-2, and I-c-3 to (3.5) is bounded above by

(3.7)

$$
\begin{aligned}
&C\sum_{n_1\in\mathbb{N}}\Bigg\{\sup_{k_1\in\mathbb{N}}\left(\sum_{|n_1'|\sim 2^{n_1}}\int_{|\tau_1|\sim 2^{k_1}}|\hat{G}_{\tau_1,n_1}|^2d\tau_1\right)^{1/2}\\
&\qquad\times\sum_{k_1\in\mathbb{N}}\Bigg[\sum_{n=n_0(n_1,k_1)}^{n_0+N}\sup_{k_0(n)\le k\le k_0(n)+N}\sum_{|n_1'|\sim 2^{n_1}}\int_{|\tau_1|\sim 2^{k_1}}\sum_{|n'|\sim 2^{n}}\int_{|\tau|\sim 2^{k}}|\hat{H}_{\tau,n'}|^2\\
&\qquad\qquad\times|\hat{F}_{\tau-\tau_1,n'-n_1'}|^2d\tau\,d\tau_1\Bigg]^{1/2}\Bigg\}\\
&\le CN\sum_{n_1\in\mathbb{N}}\sup_{k_1\in\mathbb{N}}\left(\sum_{|n_1'|\sim 2^{n_1}}\int_{|\tau_1|\sim 2^{k_1}}|\hat{G}_{\tau_1,n_1'}|^2d\tau_1\right)^{1/2}\\
&\qquad\times\sup_{\substack{n_1\in\mathbb{N}\\ k_1\in\mathbb{N}}}\sup_{\substack{n_0\le n\le n_0+N\\ k_0\le k\le k_0+N}}\left(\sum_{|n'|\sim 2^{n}}\int_{|\tau|\sim 2^{k}}|\hat{H}_{\tau,n'}|^2d\tau\right)^{1/2}\\
&\qquad\times\sup_{n_1\in\mathbb{N}}\sum_{k_1\in\mathbb{N}}\sup_{\substack{n_0\le n\le n_0+N\\ k_0\le k\le k_0+N}}\sup_{\substack{|n'|\sim 2^{n}\\ |\tau|\sim 2^{k}}}\left(\sum_{|n_1'|\sim 2^{n_1}}\int_{|\tau_1|\sim 2^{k_1}}|\hat{F}_{\tau-\tau_1,n'-n_1'}|^2d\tau_1\right)^{1/2}\\
&\le CN|G|_{X^{0,0}_{1,\infty}}|H|_{X^{0,0}_{\infty,\infty}}\\
&\qquad\times\sup_{n_1\in\mathbb{N}}\sum_{k_1\in\mathbb{N}}\sup_{\substack{n_0\le n\le n_0+N\\ k_0\le k\le k_0+N}}\sup_{\substack{|n'|\sim 2^{n}\\ |\tau|\sim 2^{k}}}\left(\sum_{|n_1'|\sim 2^{n_1}}\int_{|\tau_1|\sim 2^{k_1}}|\hat{F}_{\tau-\tau_1,n'-n_1'}|^2d\tau_1\right)^{1/2}.
\end{aligned}
$$

It remains to bound the last term in the right-hand side above by $C|F|_{X^{0,0}_{1,1}}$. However, this is not completely obvious, and we again have to consider separately each of the Regions I-c-1, I-c-2, and I-c-3.

Region I-c-2. Recall that we have here $|n'|\le 2^{-12}|n_1'|$.

Then the last term in the right-hand side of the above inequality is clearly bounded by

$$
2\sup_{n_1\in\mathbb{N}}\sum_{k_1\in\mathbb{N}}\sum_{\substack{n=n_0(n_1,k_1)\\ n\le n_1-10}}^{n_0+N}\sum_{k=k_0}^{k_0+N}\left(\sum_{|n_1'|\sim 2^{n_1}}\int_{|\tau_1|\sim 2^{k_1}}|\hat{F}_{\tau-\tau_1,n'-n_1'}|^2d\tau_1\right)^{1/2}.
$$

- The contribution to this term of the k and k_1 for which $k\le k_1-4$ or $k\ge k_1+4$ is clearly bounded above by

$$
\begin{aligned}
&2N^2\sup_{n_1\in\mathbb{N}}\sum_{k\in\mathbb{N}}\left(\sum_{|n_1'|\sim 2^{n_1}}\int_{|\tau|\sim 2^{k}}|\hat{F}_{\tau,n_1'}|^2d\tau\right)^{1/2}\\
&\qquad\le 2N^2|F|_{X^{0,0}_{1,1}}.
\end{aligned}
$$

• It remains to consider the sum in k_1 and k, the contribution of the terms for which $k_1 - 4 \le k \le k_1 + 4$. Since for such terms, $\tau - \tau_1$ may stay bounded, we need to show that there are only a finite number of possibilities for k_1. We recall that in Region I-c, $k \le 3n + 4$, while in Region I-c-2, $n \le n_1 - 10$; it follows easily that if in addition $k_1 - 4 \le k \le k_1 + 4$, then $k_1 \le 3n_1 - 4$. Hence, $n_0(n_1, k_1) = \ln \frac{|2^{k_1} - 2^{3n_1}|}{\ln 2} - 2n_1 = n_1 - 1$ and the region is actually empty.

Region I-c-3: $|n'| \ge 2^{12}|n_1'|$. Again, the last term in (3.7) is easily bounded above by

$$2 \sup_{n_1 \in \mathbb{N}} \sum_{k_1 \in \mathbb{N}} \sum_{\substack{n = n_0(n_1,k_1) \\ n \ge n_1 + 3}}^{n_0+N} \sum_{k=k_0}^{k_0+N} \sup_{|\tau| \sim 2^k} \left(\sum_{|n'| \sim 2^n} \int_{|\tau_1| \sim 2^{k_1}} |\hat{F}_{\tau - \tau_1, n'}|^2 d\tau_1 \right)^{1/2}.$$

• In the same way as before, the contribution in this sum of the terms for which $k \le k_1 - 4$ or $k \ge k_1 + 4$ is bounded by

$$2N^2 \sup_{n \in \mathbb{N}} \sum_{k \in \mathbb{N}} \left(\sum_{|n'| \sim 2^n} \int_{|\tau| \sim 2^k} |\hat{F}_{\tau, n'}|^2 d\tau \right)^{1/2} \le 2N^2 |F|_{X^{0,0}_{1,1}}.$$

• In the region where $k_1 - 4 \le k \le k_1 + 4$, we easily get $k_1 \ge 3n_1 + 4$, and from the expression of $n_0(n_1, k_1)$ in Region I-c-3, we get $n_0(n_1, k_1) = \frac{1}{2}(k_1 - n_1)$. Hence, $n \ge \frac{1}{2}(3n - 8) - \frac{1}{2}n_1$, from which it follows that $n_1 \ge n - 8$, and again the region is empty, since $n \ge n_1 + 10$.

Region I-c-1: $2^{-12}|n_1'| \le |n'| \le 2^{12}|n_1'|$. This is the most difficult part; clearly, we can take in this region $n_0(n_1, k_1) = n_1$. Again, we will divide the region into three subregions depending on the size of k and k_1 compared to each other.

• $k \le k_1 - 4$: the contribution of this region to the last term in (3.7) is then bounded above by

$$2 \sup_{n_1 \in \mathbb{N}} \sum_{k_1 \in \mathbb{N}} \sum_{n=n_1}^{n_1+N} \sup_{|n'| \sim 2^n} \left(\sum_{|n_1'| \sim 2^{n_1}} \int_{|\tau_1| \sim 2^{k_1}} |\hat{F}_{\tau_1, n' - n_1'}|^2 d\tau_1 \right)^{1/2}.$$

Now, since, for each n_1, k_1, n, and n' such that $|n'| \sim 2^n$, one has

$$\left(\sum_{|n_1'| \sim 2^{n_1}} \int_{|\tau_1| \sim 2^{k_1}} |\hat{F}_{\tau_1, n' - n_1'}|^2 d\tau_1 \right)^{1/2} \le \sum_{\ell \in \mathbb{N}} \left(\sum_{|\ell'| \sim 2^\ell} \int_{|\tau_1| \sim 2^{k_1}} |\hat{F}_{\tau_1, \ell'}|^2 d\tau_1 \right)^{1/2},$$

the preceding term is easily bounded above by

$$2 \sup_{n_1 \in \mathbb{N}} \sum_{n=n_1}^{n_1+N} \sum_{k_1 \in \mathbb{N}} \sum_{\ell \in \mathbb{N}} \left(\sum_{|\ell'| \sim 2^\ell} \int_{|\tau_1| \sim 2^{k_1}} |\hat{F}_{\tau_1, \ell'}|^2 d\tau_1 \right)^{1/2} \le 2N |F|_{X^{0,0}_{1,1}}.$$

• $k_1 - 4 \le k \le k_1 + 4$: Using again the arguments immediately above, the contribution of this region to the last term in (3.7) may be bounded above by

$$\sup_{n_1\in\mathbb{N}} \sum_{k_1\in\mathbb{N}} \sup_{\substack{n_1\le n\le n_1+N\\ 3n\le k\le 3n+N\\ k_1-4\le k\le k_1+4}} \sup_{|\tau|\sim 2^k} \sum_{\ell\in\mathbb{N}} \left(\sum_{|\ell'|\sim 2^\ell} \int_{|\tau_1|\sim 2^{k_1}} |\hat{F}_{\tau-\tau_1,\ell'}|^2 d\tau_1 \right)^{1/2}$$

$$\le \sup_{n_1\in\mathbb{N}} \sum_{k_1\in\mathbb{N}} \sup_{\substack{3n_1\le k\le 3n_1+4N\\ k_1-4\le k\le k_1+4}} \sup_{|\tau|\sim 2^k} \sum_{\ell\in\mathbb{N}} \left(\sum_{|\ell'|\sim 2^\ell} \int_{|\tau_1|\sim 2^{k_1}} |\hat{F}_{\tau-\tau_1,\ell'}|^2 d\tau_1 \right)^{1/2}.$$

Here again, $\tau - \tau_1$ may stay bounded even for large k and k_1; however, for a fixed n_1, the number of k_1 for which the right-hand side gives a nonzero contribution is bounded by the total number of k_1 for which there exists at least one k such that $3n_1 \le k \le 3n_1 + 4N$ and $k_1 - 4 \le k \le k_1 + 4$. This number is bounded by $4N + 8$. In this way, the term above is bounded by

$$(4N+8) \sup_{n_1\in\mathbb{N}} \sup_{k,k_1\in\mathbb{N}} \sup_{|\tau|\sim 2^k} \sum_{\ell\in\mathbb{N}} \left(\sum_{|\ell'|\sim 2^\ell} \int_{|\tau_1|\sim 2^{k_1}} |\hat{F}_{\tau-\tau_1,\ell'}|^2 d\tau_1 \right)^{1/2}$$

$$\le (4N+8) \sum_{\ell\in\mathbb{N}} \sum_{j\in\mathbb{N}} \left(\sum_{|\ell'|\sim 2^\ell} \int_{|\tau|\sim 2^j} |\hat{F}_{\tau,\ell'}|^2 d\tau \right)^{1/2}$$

$$\le (4N+8) |F|_{X^{0,0}_{1,1}}.$$

• $k \ge k_1 + 4$: This region is a little bit more delicate than the preceding ones to handle. In the same way as before, we may bound above the contribution of the present region to the last term in the right-hand side of (3.7) by

$$\sup_{n_1\in\mathbb{N}} \sum_{k_1\in\mathbb{N}} \sup_{\substack{3n_1\le k\le 3n_1+2N\\ k\ge k_1+4}} \sup_{|\tau|\sim 2^k} \sum_{\ell\in\mathbb{N}} \left(\sum_{|\ell'|\sim 2^\ell} \int_{|\tau_1|\sim 2^{k_1}} |\hat{F}_{\tau-\tau_1,\ell'}|^2 d\tau_1 \right)^{1/2}$$

$$\le 2 \sup_{n_1\in\mathbb{N}} \sum_{k_1\in\mathbb{N}} \sup_{\substack{3n_1\le k\le 3n_1+2N\\ k\ge k_1+4}} \sum_{\ell\in\mathbb{N}} \left(\sum_{|\ell'|\sim 2^\ell} \int_{|\tau|\sim 2^k} |\hat{F}_{\tau,\ell'}|^2 d\tau \right)^{1/2}. \tag{3.8}$$

Again, we have to show that the number of possible k_1 (or n or n_1) in this region is finite. We recall that here, n and n' are of the same order; moreover, since $|\tau - {n'}^3| \le \frac{1}{4}|n'|^2$ and $|\tau - \tau_1 - (n' - n_1')^3| \le \frac{1}{4}|n'|^2$, it follows that $|\tau|$ is of the order of $|n'|^3$; then $|\tau_1|$, which is negligible compared with $|\tau|$, is negligible compared with $|n'|^3$. Hence $\tau_1 - {n_1'}^3 \sim -{n_1'}^3$ for n_1 sufficiently large. Now, we have the relation

$$\tau_1 - {n_1'}^3 - \tau + {n'}^3 + \tau - \tau_1 - (n' - n_1')^3 = 3n'n_1'(n' - n_1'). \tag{3.9}$$

• Consider first the case where n' and n_1' have opposite signs. Then, taking into account the preceding considerations, one may note that the left-hand side in (3.9) is of the order of $-{n_1'}^3$ (for $|n_1'|$ large), while the right-hand side has the sign of ${n_1'}^3$. Hence (3.9) cannot remain true for large $|n_1'|$, which implies that the number of n_1' in this region is finite.

• Now, if n' and n'_1 have the same sign, then comparing the signs of both sides in (3.9) shows that if $|n'_1|$ is large, then necessarily $n' - n'_1$ has a sign opposite to that of n'_1. But then, for $|n'|$ (or equivalently for $|n'_1|$) large, the facts that $\tau \sim n'^3$, $\tau - \tau_1 \sim (n' - n'_1)^3$, and τ_1 is negligible compared with τ lead again to incompatible signs.

This shows that, in any case, the number of possible n_1 (or n, or k_1) in this region is finite. Hence, (3.8) is bounded above by

$$C \sup_{n_1} \sup_{k_1} \sup_{3n_1 \le k \le 3n_1+2N} \sum_{\ell} \left(\sum_{|\ell'|\sim 2^{\ell}} \int_{|\tau|\sim 2^k} |\hat{F}_{\tau,\ell'}|^2 d\tau \right)^{1/2} \le C|F|_{X^{0,0}_{1,1}}.$$

This ends the proof of the required estimate in Region I, that is, when $\langle \sigma_1 \rangle$ dominates.

Region II. Here, we use the fact that

$$\frac{1}{2}|n'|^2 \le |n' n'_1 (n' - n'_1)| \le \langle \sigma \rangle$$

so that for any $s \in [-\frac{1}{2}, 0]$,

$$|n'|^{1+s} |n'_1|^{-s} |n' - n'_1|^{-s} \le C \langle \sigma \rangle^{1/2}.$$

Exchanging then the roles of n' and n'_1—and hence the roles of $\hat{G}$ and $\hat{H}$—we are led back to proving that the contribution of Region I to I is bounded above by $C|H|_{X^{0,0}_{1,\infty}} |G|_{X^{0,0}_{\infty,\infty}} |F|_{X^{0,0}_{1,1}}$.

For Regions I-a and I-b, this was already done, since the contribution of Regions I-a and I-b to I was actually bounded above by $C|H|_{X^{0,0}_{\infty,\infty}} |G|_{X^{0,0}_{\infty,\infty}} |F|_{X^{0,0}_{1,1}}$.

It remains only to consider the case of Region I-c. Again, the same computations as before lead to bounding the contribution of Region I-c to I as in (3.7), except that the sum over n_1 will be supported by $\hat{H}$ or $\hat{F}$, so that this contribution is bounded by (see (3.7))

(3.10)

$$\begin{aligned} &CN \sup_{n_1 \in \mathbb{N}} \sup_{k_1 \in \mathbb{N}} \left(\sum_{|n'_1|\sim 2^{n_1}} \int_{|\tau_1|\sim 2^{k_1}} |\hat{G}_{\tau_1, n'_1}|^2 d\tau_1 \right)^{1/2} \\ &\times \sum_{n_1 \in \mathbb{N}} \left\{ \sup_{k_1 \in \mathbb{N}} \sup_{n_0 \le n \le n_0+N} \sup_{k_0 \le k \le k_0+N} \left(\sum_{|n'|\sim 2^n} \int_{|\tau|\sim 2^k} |\hat{H}_{\tau,n'}|^2 d\tau \right)^{1/2} \right. \\ &\qquad \left. \times \sum_{k_1 \in \mathbb{N}} \sup_{n_0 \le n \le n_0+n} \sup_{k_0 \le k \le k_0+N} \sup_{\substack{|n'|\sim 2^n \\ |\tau|\sim 2^k}} \left(\sum_{|n'_1|\sim 2^{n_1}} \int_{|\tau_1|\sim 2^{k_1}} |\hat{F}_{\tau-\tau_1, n'-n'_1}|^2 d\tau_1 \right)^{1/2} \right\}. \end{aligned}$$

Hence, we have to bound above the last two lines in (3.10) by $C|H|_{X^{0,0}_{1,\infty}} |F|_{X^{0,0}_{1,1}}$.

Considering the way we have estimated the contribution of Regions I-c-2 and I-c-3 to (3.7), it is clear that the sum over k_1 in these regions can be supported by

$|\hat{F}_{\tau-\tau_1,n'-n_1'}|^2$; in Region I-c-1, we have $2^{-12}|n_1'| \le |n'| \le 2^{12}|n_1'|$ so that $n_0(n_1,k_1) = n_1$ and

$$\sum_{n_1\in\mathbb{N}} \sup_{k_1\in\mathbb{N}} \sup_{n_0\le n\le n_0+N} \sup_{k_0\le k\le k_0+N} \left(\sum_{|n'|\sim 2^n} \int_{|\tau|\sim 2^k} |\hat{H}_{\tau,n'}|^2 d\tau \right)^{1/2}$$
$$\le C \sum_{n_1\in\mathbb{N}} \sup_{k_1\in\mathbb{N}} \left(\sum_{|n'|\sim 2^{n_1}} \int_{|\tau_1|\sim 2^{k_1}} |\hat{H}_{\tau_1,n_1'}|^2 d\tau_1 \right)^{1/2}$$
$$\le C|H|_{X^{0,0}_{1,\infty}}.$$

We may conclude as before.

Region III. Again, exchanging the roles of $\hat{G}$ and $\hat{F}$, we are led back to proving that the contribution of Region I to I is bounded above by $C|G|_{X^{0,0}_{1,1}}|H|_{X^{0,0}_{\infty,\infty}}|F|_{X^{0,0}_{1,\infty}}$, but this is easily done by using the same analysis as for Region I. Hence, the proof of Proposition 3.1 is complete. □

We now prove that when local in time spaces are considered, that is, when $X^{s,-1/2}_{1,1}$ is replaced by $X^{s,-1/2,T}_{1,1}$, a small power of T can be recovered in the right-hand side of the estimate in Proposition 3.1. This will be useful in the contraction procedure, since as is now classical, no small power of T is gained, but on the contrary a $\ln T$ factor is lost in the estimate of the integral convolution with the linear semigroup when dealing with spaces of regularity $1/2$ in time.

The argument of the proof of the next proposition relies, as usual, on the fact that we have wasted a small power of $\langle\sigma\rangle$ or $\langle\sigma_2\rangle$ in Lemma 3.2. Actually, looking carefully to the proof shows that Lemma 3.2 is still true with $B(n_1,k_1,n,k)$ replaced by

$$\tilde{B}(n_1,k_1,n,k) = \sup_{\substack{|n_1'|\sim 2^{n_1}\\ |\tau_1|\sim 2^{k_1}}} \left(\sum_{|n'|\sim 2^n} \int_{|\tau|\sim 2^k} \frac{d\tau}{\langle\sigma\rangle^{1-\varepsilon}\langle\sigma_2\rangle^{1-\varepsilon}} \right)^{1/2}$$

for any $\varepsilon < 1/4$.

PROPOSITION 3.3. *Let $-1/2 \le s \le 0$ and $f \in X^{s,1/2,T}_{1,1}$, $g \in X^{s,1/2,T}_{1,\infty}$; then for any $\alpha < 1/16$, there is a constant C_α such that*

$$|\partial_x(fg)|_{X^{s,-1/2,T}_{1,1}} \le C_\alpha T^\alpha |f|_{X^{s,1/2,T}_{1,1}} |g|_{X^{s,1/2,T}_{1,\infty}}.$$

Proof. Let $f \in X^{s,1/2}_{1,1}$, $g \in X^{s,1/2}_{1,\infty}$, $s \ge 1/2$, both with support in $[-2T,2T]$. Using the arguments immediately above shows that we have actually proved, during the course of the proof of Proposition 3.1, that

$$|\partial_x(fg)|_{X^{s,-1/2}_{1,1}} \le C\left(|f|_{X^{s,1/2}_{1,1}} |g|_{X^{s,\delta}_{1,\infty}} + |f|_{X^{s,\delta}_{1,1}} |g|_{X^{s,1/2}_{1,\infty}} \right)$$

for any $\delta > 3/8$. Let $s = 0$ (the arguments are exactly the same if $s < 0$) and let δ be such that $3/8 < \delta < 1/2$. By an obvious interpolation inequality, one gets

$$|g|_{X^{0,\delta}_{1,\infty}} \le C|g|^{1-2\delta}_{X^{0,0}_{1,\infty}} |g|^{2\delta}_{X^{0,1/2}_{1,\infty}}.$$

On the other hand, using the notation introduced at the beginning of section 2, we have

$$\begin{aligned}
|g|_{X^{0,0}_{1,\infty}} &= \sum_{n=0}^{\infty} \sup_{k\in\mathbb{N}} \left(\sum_{n'\in\mathbb{N}\setminus\{0\}} \int_{|\tau|\sim 2^k} |\widehat{\Delta_n g}(\tau,n')|^2 d\tau \right)^{1/2} \\
&\le \sum_{n=0}^{\infty} |\Delta_n g|_{L^2_{x,t}([-2T,2T]\times\mathbb{T})} \\
&\le CT^{1/4} \sum_{n=0}^{\infty} |\Delta_n g|_{L^4_{x,t}([-2T,2T]\times\mathbb{T})} \\
&\le CT^{1/4} \sum_{n=0}^{\infty} \left(\sum_{n'\in\mathbb{N}\setminus\{0\}} \int_{\tau\in\mathbb{R}} \langle\sigma\rangle^{2/3} |\widehat{\Delta_n g}(\tau,n')|^2 d\tau \right)^{1/2},
\end{aligned}$$

where we have used in the last line above the Strichartz estimate proved in [4]. It follows readily that

$$|g|_{X^{0,0}_{1,\infty}} \le CT^{1/4} |g|_{X^{0,1/3}_{1,2}} \le CT^{1/4} |g|_{X^{0,1/2}_{1,\infty}},$$

and from the above interpolation inequality,

$$|g|_{X^{0,\delta}_{1,\infty}} \le CT^{(1-2\delta)/4} |g|_{X^{0,1/2}_{1,\infty}}.$$

In the same way, we estimate f as follows: taking a small positive ε, one has

$$|f|_{X^{0,\delta}_{1,1}} \le C|f|^{(1-2\delta)/(1+2\varepsilon)}_{X^{0,-\varepsilon}_{1,1}} |f|^{2(\varepsilon+\delta)/(1+2\varepsilon)}_{X^{0,1/2}_{1,1}}$$

and

$$|f|_{X^{0,-\varepsilon}_{1,1}} \le C|f|_{X^{0,0}_{1,2}} \le CT^{1/4} |f|_{X^{0,1/3}_{1,2}}$$

by again using the estimate in [4] for $\Delta_n f$; it follows that

$$|f|_{X^{0,-\varepsilon}_{1,1}} \le CT^{1/4} |f|_{X^{0,1/2}_{1,1}}.$$

Finally,

$$|\partial_x(fg)|_{X^{0,-1/2}_{1,1}} \le C_\alpha T^\alpha |f|_{X^{0,1/2}_{1,1}} |g|_{X^{0,1/2}_{1,\infty}},$$

where α is chosen such that $\alpha < (1-2\delta)/4$, with $\delta > 3/8$, so that at the very end, $\alpha < 1/16$, and since f and g have supports in $[-2T, 2T]$, the proof of Proposition 3.3 follows. □

We now prove an estimate of the same type as those in Propositions 3.1 and 3.3, but in Y_s spaces. We recall that the use of these spaces is needed to handle the integral estimate in Duhamel's formula (see Proposition 4.1).

PROPOSITION 3.4. *Let $-1/2 \le s \le 0$, $f \in X^{s,1/2}_{1,1}$, $g \in X^{s,1/2}_{1,\infty}$; then $\partial_x(fg) \in Y_s$. Moreover, for any $\alpha < 1/16$, there is a constant $C_\alpha > 0$ such that*

$$|\partial_x(fg)|_{Y_{s,T}} \le C_\alpha T^\alpha |f|_{X^{s,1/2,T}_{1,1}} |g|_{X^{s,1/2,T}_{1,\infty}}.$$

Proof. We only sketch the proof, since it is a slight modification of the proof of Proposition 3.1, using, e.g., the arguments in [20]. Let $f \in X^{s,1/2}_{1,1}$ and $g \in X^{s,1/2}_{1,\infty}$. We prove only the estimate

$$|\partial_x(fg)|_{Y_s} \leq C|f|_{X^{s,1/2}_{1,1}}|g|_{X^{s,1/2}_{1,\infty}};$$

the T^α factor can indeed be recovered exactly as in the proof of Proposition 3.3.

By a duality argument, the estimate will be proved if we show that there is a constant $C > 0$ such that for any function w (of the space variable x) lying in the Besov space $B^{-s}_{2,\infty}$, one has

$$\left| \sum_{n' \neq 0} |n'| \int_{\mathbb{R}} \frac{\widehat{fg}(\tau, n')}{\langle \sigma(\tau, n') \rangle} d\tau \hat{w}(n') \right| \leq C|f|_{X^{s,1/2}_{1,1}}|g|_{X^{s,1/2}_{1,\infty}}|w|_{B^{-s}_{2,\infty}}.$$

Setting as above $\hat{F}(\tau, n') = n'^s \langle \sigma(\tau, n') \rangle^{1/2} \hat{f}(\tau, n')$, $\hat{G} = n'^s \langle \sigma \rangle^{1/2} \hat{g}$, and $\hat{W} = n'^{-s} \hat{w}$, it suffices to prove that

(3.11)
$$\sum_{n' \neq 0} \sum_{\substack{n'_1 \neq 0 \\ n'_1 \neq n'}} \int_{\tau \in \mathbb{R}} \int_{\tau_1 \in \mathbb{R}} \frac{|n'|^{1+s} |n'_1|^{-s} |n' - n'_1|^{-s} |\hat{F}_{\tau - \tau_1, n' - n'_1}| \, |\hat{G}_{\tau_1, n'_1}| \, |\hat{W}_{n'}|}{\langle \sigma(\tau, n') \rangle \langle \sigma(\tau - \tau_1, n' - n'_1) \rangle^{1/2} \langle \sigma(\tau_1, n'_1) \rangle^{1/2}} d\tau \, d\tau_1$$
$$\leq C|F|_{X^{0,0}_{1,1}}|G|_{X^{0,0}_{1,\infty}}|W|_{B^0_{2,\infty}}.$$

Again, we will consider separately the three regions defined at the beginning of the proof of Proposition 3.1.

Region I: $\langle \sigma_1 \rangle = \max(\langle \sigma \rangle, \langle \sigma_1 \rangle, \langle \sigma_2 \rangle)$. As already noted, we have in this region

$$|n'|^{1+s} |n'_1|^{-s} |n' - n'_1|^{-s} \leq C \langle \sigma(\tau_1, n'_1) \rangle^{1/2}.$$

Hence, taking $\varepsilon > 0$ small, we have

$$\frac{|n'|^{1+s} |n'_1|^{-s} |n' - n'_1|^{-s} |\hat{F}_{\tau - \tau_1, n' - n'_1}| \, |\hat{G}_{\tau_1, n'_1}| \, |\hat{W}_{n'}|}{\langle \sigma(\tau, n') \rangle \langle \sigma(\tau - \tau_1, n' - n'_1) \rangle^{1/2} \langle \sigma(\tau_1, n'_1) \rangle^{1/2}}$$
$$\leq C \frac{|\hat{W}_{n'}|}{\langle \sigma(\tau, n') \rangle^{1/2+\varepsilon}} \frac{|\hat{F}_{\tau - \tau_1, n' - n'_1}| \, |\hat{G}_{\tau_1, n'_1}|}{\langle \sigma(\tau, n') \rangle^{1/2-\varepsilon} \langle \sigma(\tau - \tau_1, n' - n'_1) \rangle^{1/2}},$$

and we conclude as in the proof of Proposition 3.1, using the fact that $\mathcal{F}^{-1}(\frac{\hat{W}}{\langle \sigma \rangle^{1/2+\varepsilon}}) \in X^{0,0}_{\infty,\infty}$, with

$$\left| \mathcal{F}^{-1} \left(\frac{\hat{W}}{\langle \sigma \rangle^{1/2+\varepsilon}} \right) \right|_{X^{0,0}_{\infty,\infty}} \leq C_\varepsilon |W|_{B^0_{2,\infty}}$$

and using again the fact that Lemma 3.2 is still true with a smaller power of $\sigma(\tau, n')$.

Region III, that is, $\langle \sigma_2 \rangle = \max(\langle \sigma \rangle, \langle \sigma_1 \rangle, \langle \sigma_2 \rangle)$, is treated in the same way.

Region II: $\langle \sigma \rangle = \max(\langle \sigma \rangle, \langle \sigma_1 \rangle, \langle \sigma_2 \rangle)$. Here, we have

$$|n'|^{1+s} |n'_1|^{-s} |n' - n'_1|^{-s} \leq C \langle \sigma(\tau, n') \rangle^{1/2}$$

and it follows that

$$\frac{1}{\langle\sigma(\tau,n')\rangle} \le \frac{C}{\langle\sigma(\tau,n')\rangle + |n'|^{2+2s}|n_1'|^{-2s}|n'-n_1'|^{-2s}}.$$

Hence, going back to the way we have proved Proposition 3.1, it suffices to show that for a fixed n_1',

$$\mathcal{F}^{-1}\left(\frac{|n'|^{1+s}|n_1'|^{-s}|n'-n_1'|^{-s}\hat{W}(n')}{\langle\sigma(\tau,n')\rangle + |n'|^{2+2s}|n_1'|^{-2s}|n'-n_1'|^{-2s}}\right) \in X^{0,0}_{\infty,\infty},$$

with

$$\left|\mathcal{F}^{-1}\left(\frac{|n'|^{1+s}|n_1'|^{-s}|n'-n_1'|^{-s}\hat{W}(n')}{\langle\sigma(\tau,n')\rangle + |n'|^{2+2s}|n_1'|^{-2s}|n'-n_1'|^{-2s}}\right)\right|_{X^{0,0}_{\infty,\infty}} \le C|W|_{B^0_{2,\infty}}$$

and a constant C that does not depend on n_1'.

But this follows from the next easy computation, once we have noticed that $\int_{\mathbb{R}} \frac{d\tau}{(\langle\tau\rangle+a^2)^2} \le \frac{C}{a^2}$:

$$\begin{aligned}
&\left|\mathcal{F}^{-1}\left(\frac{|n'|^{1+s}|n_1'|^{-s}|n'-n_1'|^{-s}\hat{W}(n')}{\langle\sigma(\tau,n')\rangle + |n'|^{2+2s}|n_1'|^{-2s}|n'-n_1'|^{-2s}}\right)\right|^2_{X^{0,0}_{\infty,\infty}} \\
&\quad = \sup_{n,k} \sum_{|n'|\sim 2^n} \int_{|\tau|\sim 2^k} \frac{|n'|^{2+2s}|n_1'|^{-2s}|n'-n_1'|^{-2s}|\hat{W}(n')|^2}{(\langle\sigma(\tau,n')\rangle + |n'|^{2+2s}|n_1'|^{-2s}|n'-n_1'|^{-2s})^2} \\
&\quad \le \sup_{n} \left(\sum_{|n'|\sim 2^n} |n'|^{2+2s}|n_1'|^{-2s}|n'-n_1'|^{-2s}|\hat{W}(n')|^2 \right. \\
&\qquad\qquad \left. \times \int_{\mathbb{R}} \frac{d\tau}{(\langle\sigma(\tau,n')\rangle + |n'|^{2+2s}|n_1'|^{-2s}|n'-n_1'|^{-2s})^2} \right) \\
&\quad \le C|W|^2_{B^0_{2,\infty}}.
\end{aligned}$$

This ends the proof of Proposition 3.4. □

As a last, but easy, bilinear estimate, we briefly show that we can handle terms like $\partial_x(g^2)$ in $X^{s,-1/2}_{1,1}$ if g is only in $X^{s+\varepsilon,1/2}_{\infty,\infty}$ (the ε loss of regularity seems to be necessary here). Our motivation to treat such terms arises from the fact that the stochastic convolution which was studied in Proposition 2.1 belongs to such spaces (or even to $X^{s+\varepsilon,1/2}_{1,\infty}$) if sufficient regularity is assumed on the operator ϕ, but never belongs to $X^{s,1/2}_{1,1}$, due to the lack of regularity of the Brownian motion.

PROPOSITION 3.5. *Let $-1/2 \le s \le 0$ and $\varepsilon > 0$; then there is a constant $C > 0$ such that for any $g \in X^{s+\varepsilon,1/2}_{\infty,\infty}$,*

$$|\partial_x(g^2)|_{X^{s,-1/2}_{1,1}} \le C|g|^2_{X^{s+\varepsilon,1/2}_{\infty,\infty}}.$$

If, moreover, g is supported in $[-2T,2T]$ and $\partial_x(g^2)$ is considered in $X^{s,-1/2,T}_{1,1}$, then a factor T^α can be recovered in the right-hand side above for any $\alpha < 1/16$.

Finally, the same estimate holds if in the left-hand side, $X^{s,-1/2}_{1,1}$ (resp., $X^{s,-1/2,T}_{1,1}$) is replaced by Y_s (resp., $Y_{s,T}$).

Proof. Here again, we only sketch the proof, since the arguments are the same as in the easiest cases of the proof of Proposition 3.1, that is, when some small power of $\langle\sigma\rangle$ or $\langle\sigma_1\rangle$ can be lost.

Indeed, taking $f, g \in X^{s+\varepsilon,1/2}_{\infty,\infty}$, $h \in X^{-s,1/2}_{\infty,\infty}$, and setting as before $\hat{F} = n'^{s+\varepsilon}\langle\sigma\rangle^{1/2}\hat{f}$, $\hat{G} = n'^{s+\varepsilon}\langle\sigma\rangle^{1/2}\hat{g}$, and $\hat{H} = n'^{-s}\langle\sigma\rangle^{1/2}\hat{h}$, we need to show that

$$\sum_{n'\neq 0}\sum_{\substack{n'_1\neq 0\\ n'_1\neq n'}}\int_{\tau\in\mathbb{R}}\int_{\tau_1\in\mathbb{R}}\frac{|n'|^{1+s}|n'_1|^{-s-\varepsilon}|n'-n'_1|^{-s-\varepsilon}}{\langle\sigma\rangle^{1/2}\langle\sigma_1\rangle^{1/2}\langle\sigma_2\rangle^{1/2}}|\hat{H}_{\tau,n'}|\,|\hat{G}_{\tau_1,n'_1}|\,|\hat{F}_{\tau-\tau_1,n'-n'_1}|d\tau d\tau_1$$
$$\leq C|H|_{X^{0,0}_{\infty,\infty}}|F|_{X^{0,0}_{\infty,\infty}}|G|_{X^{0,0}_{\infty,\infty}}.$$

Consider, e.g., Region I, where $\langle\sigma_1\rangle$ dominates, and where we have the inequality

$$|n'|^{1+s}|n'_1|^{-s}|n'-n'_1|^{-s} \leq C\langle\sigma_1\rangle^{1/2},$$

so that we are led to estimate

$$\sum_{n'\neq 0}\sum_{\substack{n'_1\neq 0\\ n'_1\neq n'}}\int_{\tau\in\mathbb{R}}\int_{\tau_1\in\mathbb{R}}\frac{|n'_1|^{-\varepsilon}|n'-n'_1|^{-\varepsilon}}{\langle\sigma\rangle^{1/2}\langle\sigma_2\rangle^{1/2}}|\hat{H}_{\tau,n'}|\,|\hat{G}_{\tau_1,n'_1}|\,|\hat{F}_{\tau-\tau_1,n'-n'_1}|d\tau d\tau_1.$$

This latest term is then handled by the same arguments as those used in Region I-a in the proof of Proposition 3.1, keeping in addition a small power of $\langle\sigma_2\rangle$ to be able to sum over k, and hence to replace the norm $|F|_{X^{0,0}_{1,1}}$ by $|F|_{X^{0,0}_{\infty,\infty}}$ (the sum over n being handled by using $|n'-n'_1|^{-\varepsilon}$).

All the other regions are treated in the same way, and the arguments for the other statements of Proposition 3.5 are exactly the same as those of Propositions 3.3 and 3.4. ∎

4. Proofs of Theorems 1.2 and 1.5. As was pointed out in the introduction, it mainly remains to show that we may gain one degree of regularity in time when passing from $\partial_x(gf)$ to $\int_0^t U(t-s)\partial_x(fg)(s)ds$. The result is stated in the next proposition.

PROPOSITION 4.1. *There is a constant $C>0$ such that if $f \in X^{s,-1/2}_{1,1} \cap Y_s$, $s\in\mathbb{R}$, then $t \mapsto \int_0^t U(t-s)f(s)ds \in X^{s,1/2,T}_{1,1}$ and*

$$\left|\int_0^{\cdot} U(\cdot-s)f(s)ds\right|_{X^{s,1/2,T}_{1,1}} \leq C\left(|f|_{X^{s,-1/2}_{1,1}} + |f|_{Y_s}\right)$$

for any $T\leq 1$.

Moreover, for any $f\in Y_s$, the map $t\mapsto\int_0^t U(t-s)f(s)ds$ is continuous with values in $B^s_{2,1}(\mathbb{T})$ and there is a constant $C>0$ such that

$$\sup_{t\in[-T,T]}\left|\int_0^t U(t-s)f(s)ds\right|_{B^s_{2,1}} \leq C|f|_{Y_s}.$$

Proof. The arguments of the proof are similar to those in [14]. We consider a cut-off function ψ with $\psi\equiv 1$ on $[0,1]$ and $\operatorname{supp}\psi\subset[-1,2]$; it is sufficient to prove

that

$$\left|\psi \int_0^{\cdot} U(\cdot - s) f(s) ds\right|_{X_{1,1}^{s,1/2}} \leq C \left(|f|_{X_{1,1}^{s,-1/2}} + |f|_{Y_s} \right).$$

We first write

$$\begin{aligned}
&\psi(t) \int_0^t U(t-s) f(s) ds \\
&\quad = \psi(t) \sum_{n' \in \mathbb{Z}} \int_{|\tau_1 - n'^3| \leq 1} e^{ixn'} \hat{f}(\tau_1, n') \frac{e^{it(\tau_1 - n'^3)} - 1}{\tau_1 - n'^3} e^{itn'^3} d\tau_1 \\
&\qquad + \psi(t) \sum_{n' \in \mathbb{Z}} \int_{|\tau_1 - n'^3| \geq 1} e^{ixn'} \hat{f}(\tau_1, n') \frac{e^{it\tau_1} - e^{itn'^3}}{\tau_1 - n'^3} d\tau_1 \\
&\quad = g_1(t,x) + g_2(t,x).
\end{aligned}$$

To estimate g_1, we expand the exponential as

$$\frac{e^{it(\tau_1 - n'^3)} - 1}{\tau_1 - n'^3} = \sum_{k=1}^{\infty} \frac{i^k t^k (\tau_1 - n'^3)^k}{k!}$$

so that

$$g_1(t,x) = \sum_{k=1}^{\infty} \frac{i^k t^k}{k!} \psi(t) \sum_{n' \in \mathbb{Z}} \int_{|\tau_1 - n'^3| \leq 1} e^{ixn' + itn'^3} \hat{f}(\tau_1, n') (\tau_1 - n'^3)^k d\tau_1.$$

Let $\varphi_k(t) = t^k \psi(t)$; then

$$\hat{g}_1(\tau, n') = \sum_{k=1}^{\infty} \frac{i^k}{k!} \int_{|\tau_1 - n'^3| \leq 1} \hat{\varphi}_k(\tau - n'^3) \hat{f}(\tau_1, n') (\tau_1 - n'^3)^k d\tau_1$$

and it follows that

$$\begin{aligned}
&|g_1|_{X_{1,1}^{s,1/2}} \\
&= \sum_{n \in \mathbb{N}} 2^{sn} \sum_{\ell=0}^{\infty} \left(\sum_{|n'| \sim 2^n} \int_{|\tau| \sim 2^\ell} |\langle \tau - n'^3 \rangle^{1/2} \hat{g}_1(\tau, n')|^2 d\tau \right)^{1/2} \\
&= \sum_{n \in \mathbb{N}} 2^{sn} \sum_{\ell=0}^{\infty} \Bigg(\sum_{|n'| \sim 2^n} \int_{|\tau| \sim 2^\ell} \langle \tau - n'^3 \rangle \\
&\qquad \times \left[\int_{|\tau_1 - n'^3| \leq 1} \sum_{k=1}^{\infty} \frac{i^k}{k!} \hat{\varphi}_k(\tau - n'^3) \hat{f}(\tau_1, n') (\tau_1 - n'^3)^k d\tau_1 \right]^2 d\tau \Bigg)^{1/2}.
\end{aligned}$$

Now,

$$\sum_{|n'|\sim 2^n}\int_{|\tau|\sim 2^\ell}\langle \tau-n'^3\rangle\left[\int_{|\tau_1-n'^3|\le 1}\sum_{k=1}^{\infty}\frac{i^k}{k!}\hat\varphi_k(\tau-n'^3)\hat f(\tau_1,n')(\tau_1-n'^3)^k d\tau_1\right]^2 d\tau$$
$$\le \sum_{|n'|\sim 2^n}\int_{|\tau|\sim 2^\ell}\langle \tau-n'^3\rangle\left(\sum_{k=1}^{\infty}\frac{|\hat\varphi_k(\tau-n'^3)|}{k!}\right)^2 d\tau\left(\int_{|\tau_1-n'^3|\le 1}|\hat f(\tau_1,n')|^2 d\tau_1\right)$$
$$\le \sup_{|n'|\sim 2^n}\int_{|\tau|\sim 2^\ell}\langle \tau-n'^3\rangle\left(\sum_{k=1}^{\infty}\frac{|\hat\varphi_k(\tau-n'^3)|}{k!}\right)^2 d\tau\left(\sum_{|n'|\sim 2^n}\int_{|\tau_1-n'^3|\le 1}|\hat f(\tau_1,n')|^2 d\tau_1\right).$$

We deduce that

$$|g_1|_{X^{s,1/2}_{1,1}} \le \sup_{n\in\mathbb{N}}\sum_{\ell=0}^{\infty}\left(\sup_{|n'|\sim 2^n}\int_{|\tau|\sim 2^\ell}\langle \tau-n'^3\rangle\left(\sum_{k=1}^{\infty}\frac{|\hat\varphi_k(\tau-n'^3)|}{k!}\right)^2 d\tau\right)^{1/2}$$
$$\times\sum_{n\in\mathbb{N}}2^{sn}\left(\sum_{|n'|\sim 2^n}\int_{|\tau_1-n'^3|\le 1}|\hat f(\tau_1,n')|^2 d\tau_1\right)^{1/2}.$$

Now, we have, for $\varepsilon>0$,

$$\sup_{n\in\mathbb{N}}\sum_{\ell=0}^{\infty}\sup_{|n'|\sim 2^n}\int_{|\tau|\sim 2^\ell}\langle \tau-n'^3\rangle\left(\sum_{k=1}^{\infty}\frac{|\hat\varphi_k(\tau-n'^3)|}{k!}\right)^2 d\tau$$
$$\le \sup_{n\in\mathbb{N}}\sum_{\ell\in\mathbb{N}}\sup_{|n'|\sim 2^n}\left(\sup_{|\tau|\sim 2^\ell}\langle \tau-n'^3\rangle^{-\varepsilon}\right)\int_{|\tau|\sim 2^\ell}\langle \tau-n'^3\rangle^{1+\varepsilon}\left(\sum_{k=1}^{\infty}\frac{|\hat\varphi_k(\tau-n'^3)|}{k!}\right)^2 d\tau$$
$$\le C\left(\sup_{n\in\mathbb{N}}\sum_{\ell\in\mathbb{N}}\langle 2^\ell-2^{3n}\rangle^{-\varepsilon}\right)\sup_{n'\in\mathbb{N}}\int_{\mathbb{R}}\langle \tau-n'^3\rangle^{1+\varepsilon}\left(\sum_{k=1}^{\infty}\frac{|\hat\varphi_k(\tau-n'^3)|}{k!}\right)^2 d\tau$$
$$\le C\left|\sum_{k=1}^{\infty}\frac{\varphi_k}{k!}\right|_{H^{1/2+\varepsilon/2}}.$$

Hence

$$|g_1|_{X^{s,1/2}_{1,1}} \le C\left|\sum_{k=1}^{\infty}\frac{\varphi_k}{k!}\right|_{H^{1/2+\varepsilon/2}}|f|_{X^{s,0}_{1,1}}.$$

In order to estimate the norm of g_2, we write

$$g_2(t,x)=g_{2,1}(t,x)+g_{2,2}(t,x),$$

with

$$g_{2,1}(t,x)=\psi(t)\sum_{n'\in\mathbb{Z}}\int_{|\tau_1-n'^3|\ge 1}e^{ixn'}\hat f(\tau_1,n')\frac{e^{it\tau_1}}{\tau_1-n'^3}d\tau_1$$

and

$$g_{2,2}(t,x) = -\psi(t) \sum_{n' \in \mathbb{Z}} \int_{|\tau_1 - n'^3| \geq 1} e^{ixn'} \hat{f}(\tau_1, n') \frac{e^{itn'^3}}{\tau_1 - n'^3} d\tau_1.$$

We have

$$\hat{g}_{2,1}(\tau, n') = \int_{|\tau_1 - n'^3| \geq 1} \hat{\psi}(\tau - \tau_1) \frac{\hat{f}(\tau_1, n')}{\tau_1 - n'^3} d\tau_1,$$

and

$$\begin{aligned}
&\sum_{|n'| \sim 2^n} \int_{|\tau| \sim 2^k} \langle \tau - n'^3 \rangle |\hat{g}_{2,1}(\tau, n')|^2 d\tau \\
&\quad \leq C \sum_{|n'| \sim 2^n} \int_{|\tau| \sim 2^k} \left[\int_{|\tau_1 - n'^3| \geq 1} \langle \tau_1 - n'^3 \rangle^{1/2} |\hat{\psi}(\tau - \tau_1)| \left| \frac{\hat{f}(\tau_1, n')}{\tau_1 - n'^3} \right| d\tau_1 \right]^2 d\tau \\
&\qquad + C \sum_{|n'| \sim 2^n} \int_{|\tau| \sim 2^k} \left[\int_{|\tau_1 - n'^3| \geq 1} \langle \tau - \tau_1 \rangle^{1/2} |\hat{\psi}(\tau - \tau_1)| \left| \frac{\hat{f}(\tau_1, n')}{\tau_1 - n'^3} \right| d\tau_1 \right]^2 d\tau \\
&\quad \leq I + II.
\end{aligned}$$

For the term I, we have

$$I \leq C \sum_{|n'| \sim 2^n} \int_{|\tau| \sim 2^k} \left[\int_{\mathbb{R}} |\hat{\psi}(\tau_1)| \frac{|\hat{f}(\tau - \tau_1, n')|}{\langle \tau - \tau_1 - n'^3 \rangle^{1/2}} d\tau_1 \right]^2 d\tau.$$

Let $\hat{h} \in L^2_{\tau, n'}$; then

$$\begin{aligned}
&\left| \sum_{|n'| \sim 2^n} \int_{|\tau| \sim 2^k} \hat{h}(\tau, n') \int_{\mathbb{R}} |\hat{\psi}(\tau_1)| \frac{|\hat{f}(\tau - \tau_1, n')|}{\langle \tau - \tau_1 - n'^3 \rangle^{1/2}} d\tau_1 d\tau \right| \\
&\qquad \leq \int_{\mathbb{R}} |\hat{\psi}(\tau_1)| \left(\sum_{|n'| \sim 2^n} \int_{|\tau| \sim 2^k} |\hat{h}(\tau, n')|^2 d\tau \right)^{1/2} \\
&\qquad\qquad \times \left(\sum_{|n'| \sim 2^n} \int_{|\tau| \sim 2^k} \frac{|\hat{f}(\tau - \tau_1, n')|^2}{\langle \tau - \tau_1 - n'^3 \rangle} d\tau \right)^{1/2} d\tau_1.
\end{aligned}$$

We deduce from the preceding estimate that

$$I \leq C \left(\int_{\mathbb{R}} |\psi(\tau_1)| \left(\sum_{|n'| \sim 2^n} \int_{|\tilde{\tau} + \tau_1| \sim 2^k} \frac{|\hat{f}(\tilde{\tau}, n')|^2}{\langle \tilde{\tau} - n'^3 \rangle} d\tilde{\tau} \right)^{1/2} d\tau_1 \right)^2.$$

In the same way, we can prove that

$$II \leq C \left(\int_{\mathbb{R}} \langle \tau_1 \rangle^{1/2} |\psi(\tau_1)| \left(\sum_{|n'| \sim 2^n} \int_{|\tilde{\tau} + \tau_1| \sim 2^k} \frac{|\hat{f}(\tilde{\tau}, n')|^2}{\langle \tilde{\tau} - n'^3 \rangle^2} d\tilde{\tau} \right)^{1/2} d\tau_1 \right)^2.$$

Hence we have

$$I+II\leq C\left(\int_{\mathbb{R}}\langle\tau_1\rangle^{1/2}|\psi(\tau_1)|\left(\sum_{|n'|\sim 2^n}\int_{|\tilde\tau+\tau_1|\sim 2^k}\frac{|\hat f(\tilde\tau,n')|^2}{\langle\tilde\tau-n'^3\rangle}d\tilde\tau\right)^{1/2}d\tau_1\right)^2$$

and we deduce that

$$\sum_{k=0}^{\infty}\left(\sum_{|n'|\sim 2^n}\int_{|\tau|\sim 2^k}\langle\tau-n'^3\rangle|\hat g_{2,1}(\tau,n')|^2d\tau\right)^{1/2}$$

$$\leq C\sum_{k=0}^{\infty}\int_{\mathbb{R}}\langle\tau_1\rangle^{1/2}|\hat\psi(\tau_1)|\left(\sum_{|n'|\sim 2^n}\int_{|\tilde\tau+\tau_1|\sim 2^k}\frac{|\hat f(\tilde\tau,n')|^2}{\langle\tilde\tau-n'^3\rangle}d\tilde\tau\right)^{1/2}d\tau_1$$

$$\leq C\sum_{k_1=0}^{\infty}\int_{|\tau_1|\sim 2^{k_1}}\langle\tau_1\rangle^{1/2}|\hat\psi(\tau_1)|$$

$$\times\left(\sum_{k<k_1-4}+\sum_{k_1-4\leq k\leq k_1+4}+\sum_{k>k_1+4}\right)\left(\sum_{|n'|\sim 2^n}\int_{|\tilde\tau+\tau_1|\sim 2^k}\frac{|\hat f(\tilde\tau,n')|^2}{\langle\tilde\tau-n'^3\rangle}d\tilde\tau\right)^{1/2}d\tau_1.$$

Since

$$\left(\sum_{k<k_1-4}+\sum_{k_1-4\leq k\leq k_1+4}+\sum_{k>k_1+4}\right)\left(\sum_{|n'|\sim 2^n}\int_{|\tilde\tau+\tau_1|\sim 2^k}\frac{|\hat f(\tilde\tau,n')|^2}{\langle\tilde\tau-n'^3\rangle}d\tilde\tau\right)^{1/2}$$

$$\leq C(k_1-4)\left(\sum_{|n'|\sim 2^n}\sum_{j=-1}^{+1}\int_{|\tilde\tau|\sim 2^{k_1+j}}\frac{|\hat f(\tilde\tau,n')|^2}{\langle\tilde\tau-n'^3\rangle}d\tilde\tau\right)^{1/2}$$

$$+8\left(\sum_{|n'|\sim 2^n}\int_{|\tilde\tau|\sim 2^{k_1+5}}\frac{|\hat f(\tilde\tau,n')|^2}{\langle\tilde\tau-n'^3\rangle}d\tilde\tau\right)^{1/2}$$

$$+C\sum_{k\in\mathbb{N}}\left(\sum_{|n'|\sim 2^n}\int_{|\tilde\tau|\sim 2^k}\frac{|\hat f(\tilde\tau,n')|^2}{\langle\tilde\tau-n'^3\rangle}d\tilde\tau\right)^{1/2},$$

we may easily bound the preceding term by

$$C\sum_{k_1=0}^{\infty}\int_{|\tau_1|\sim 2^{k_1}}(1+k_1)2^{k_1/2}|\hat\psi(\tau_1)|d\tau_1\sum_{k=0}^{\infty}\left(\sum_{|n'|\sim 2^n}\int_{|\tau|\sim 2^k}\frac{|\hat f(\tilde\tau,n')|^2}{\langle\tilde\tau-n'^3\rangle}d\tilde\tau\right)^{1/2}$$

$$\leq C_\varepsilon|\langle\tau\rangle^{1/2+\varepsilon}\hat\psi|_{L^1(\mathbb{R})}\sum_{k=0}^{\infty}\left(\sum_{|n'|\sim 2^n}\int_{|\tau|\sim 2^k}\frac{|\hat f(\tilde\tau,n')|^2}{\langle\tilde\tau-n'^3\rangle}d\tilde\tau\right)^{1/2},$$

and thus

$$|g_{2,1}|_{X^{s,1/2}_{1,1}}\leq C_\varepsilon|\langle\tau\rangle^{1/2+\varepsilon}\hat\psi|_{L^1(\mathbb{R})}|f|_{X^{s,-1/2}_{1,1}}.$$

At last,

$$\hat{g}_{2,2}(\tau,n')=\hat{\psi}(\tau-n'^3)\int_{|\tau_1-n'^3|\geq 1}\frac{\hat{f}(\tau_1,n')}{\tau_1-n'^3}d\tau_1,$$

and hence

$$\begin{aligned}
&\sum_{n\in\mathbb{N}}2^{sn}\sum_{k\in\mathbb{N}}\left(\int_{|\tau|\sim 2^k}\sum_{|n'|\sim 2^n}\langle\tau-n'^3\rangle|\hat{g}_{2,2}(\tau,n')|^2d\tau\right)^{1/2}\\
&\quad\leq\sum_{n\in\mathbb{N}}2^{sn}\sum_{k\in\mathbb{N}}\left(\sup_{|n'|\sim 2^n}\int_{|\tau|\sim 2^k}\langle\tau-n'^3\rangle|\hat{\psi}(\tau-n'^3)|^2d\tau\right)^{1/2}\\
&\qquad\qquad\times\left(\sum_{|n'|\sim 2^n}\left(\int_{\mathbb{R}}\frac{|\hat{f}(\tau_1,n')|}{\langle\tau_1-n'^3\rangle}d\tau_1\right)^2\right)^{1/2}\\
&\quad\leq C\sum_{n\in\mathbb{N}}2^{sn}\left(\sum_{k\in\mathbb{N}}\langle 2^k-2^{3n}\rangle^{-\varepsilon}\right)\\
&\qquad\qquad\times\left(\sup_{|n'|\sim 2^n}\int_{\mathbb{R}}\langle\tau-n'^3\rangle^{1+\varepsilon}|\hat{\psi}(\tau-n'^3)|^2d\tau\right)^{1/2}\\
&\qquad\qquad\times\left(\sum_{|n'|\sim 2^n}\left(\int_{\mathbb{R}}\frac{|\hat{f}(\tau_1,n')|}{\langle\tau_1-n'^3\rangle}d\tau_1\right)^2\right)^{1/2}\\
&\quad\leq C|\psi|_{H^{1/2+\varepsilon/2}}|f|_{Y_s}.
\end{aligned}$$

This ends the proof of the first estimate in Proposition 4.1. The proof of continuity with values in $B^s_{2,1}$ and the second estimate follow in an obvious way from a slight modification of the proof of Lemma 2.2 in [10]. □

The next lemma shows that the free term in (1.5) belongs to $X^{\sigma,1/2,T}_{1,1}$ if u_0 is in $B^\sigma_{2,1}(\mathbb{T})$.

LEMMA 4.2. *Let $u_0\in B^\sigma_{2,1}(\mathbb{T})$ and $T\leq 1$. Then $U(t)u_0\in X^{\sigma,1/2,T}_{1,1}$ and there is a constant $C>0$ such that*

$$|U(t)u_0|_{X^{\sigma,1/2,T}_{1,1}}\leq C|u_0|_{B^\sigma_{2,1}}.$$

Proof. Let ψ be a cut-off function with $\psi\equiv 1$ on $[0,1]$ and let us prove that $|\psi U(t)u_0|_{X^{\sigma,1/2}_{1,1}}\leq C|u_0|_{B^\sigma_{2,1}}$.

We use the fact that $X^{\sigma,1/2+\varepsilon}_{1,\infty}\subset X^{\sigma,1/2}_{1,1}$ for any $\varepsilon>0$, and that

$$\widehat{\psi U(t)u_0}(\tau,n')=\hat{u}_0(n')\psi(\tau-n'^3)$$

to get the following bound:

$$
\begin{aligned}
&|\psi U(t)u_0|_{X^{\sigma,1/2}_{1,1}} \le C_\varepsilon |\psi U(t)u_0|_{X^{\sigma,1/2+\varepsilon}_{1,\infty}} \\
&\le C_\varepsilon \sum_{n=0}^{\infty} 2^{\sigma n} \sup_{k\ge 0} \left(\sum_{|n'|\sim 2^n} \int_{|\tau|\sim 2^k} \langle \tau - n'^3\rangle^{1+2\varepsilon} |\hat{u}_0(n')|^2 |\hat{\psi}(\tau - n'^3)|^2 d\tau \right)^{1/2} \\
&\le C_\varepsilon \sum_{n=0}^{\infty} 2^{\sigma n} \sup_{k\ge 0} \left(\sum_{|n'|\sim 2^n} \sum_{j=0}^{\infty} \int_{\substack{|\tau|\sim 2^k \\ |\tau - n'^3|\sim 2^j}} \langle \tau - n'^3\rangle^{1+2\varepsilon} |\hat{u}_0(n')|^2 |\hat{\psi}(\tau - n'^3)|^2 d\tau \right)^{1/2} \\
&\le C_\varepsilon \sum_{n=0}^{\infty} 2^{\sigma n} \sum_{j=0}^{\infty} \left(\sum_{|n'|\sim 2^n} \int_{|\tau - n'^3|\sim 2^j} \langle \tau - n'^3\rangle^{1+2\varepsilon} |\hat{u}_0(n')|^2 |\hat{\psi}(\tau - n'^3)|^2 d\tau \right)^{1/2} \\
&\le C_\varepsilon \sum_{n=0}^{\infty} 2^{\sigma n} \left(\sum_{|n'|\sim 2^n} |\hat{u}_0(n')|^2 \right)^{1/2} \sum_{j=0}^{\infty} \left(\int_{|\tau|\sim 2^j} \langle \tau\rangle^{1+2\varepsilon} |\hat{\psi}(\tau)|^2 d\tau \right)^{1/2} \\
&\le C_\varepsilon |u_0|_{B^\sigma_{2,1}} |\psi|_{B^{1/2+\varepsilon}_{2,1}}. \qquad \square
\end{aligned}
$$

Proof of Theorem 1.2. We now have all the estimates in hand, and we proceed exactly as in [3]; we work pathwise on (1.5), using a fixed point argument in the space $X^{\sigma,1/2,T}_{1,1}$ with $-1/2 \le \sigma < s$, s being defined by the assumption on ϕ, and $T \le 1$ sufficiently small.

Let u_0 be $\mathcal{F}_0$-measurable with $u_0 \in B^\sigma_{2,1}(\mathbb{T})$ almost surely, σ as above, and assume first that $\hat{u}_0(0) = 0$ almost surely. We set

$$z(t) = U(t)u_0; \tag{4.1}$$

then by Lemma 4.2, $z \in X^{\sigma,1/2,T}_{1,1}$ for any $T \le 1$ almost surely, and

$$|z|_{X^{\sigma,1/2,T}_{1,1}} \le C|u_0|_{B^\sigma_{2,1}} \text{ almost surely.} \tag{4.2}$$

Let $w(t)$ be defined by (1.4). By Proposition 2.1, $w \in X^{\sigma',1/2,T}_{1,\infty} \subset X^{\sigma',1/2,T}_{\infty,\infty}$ almost surely for any σ' with $\sigma < \sigma' < s$. We fix such a σ' and consider $\omega \in \Omega$ such that $u_0 \in B^\sigma_{2,1}(\mathbb{T})$ and $w \in X^{\sigma',1/2,T}_{1,\infty}$ for any $T \le 1$ almost surely.

In terms of $v(t) = u(t) - z(t) - w(t)$, (1.5) is written as

$$v(t) = \mathcal{T}v(t) := -\frac{1}{2}\int_0^t U(t-s)\partial_x(v^2 + w^2 + z^2 + 2vw + 2vz + 2wz)(s)ds. \tag{4.3}$$

Taking $0 < \alpha < 1/16$ in Propositions 3.3, 3.4, and 3.5, and applying Proposition 4.1, we easily get the existence of a constant $C_\alpha > 0$ such that

$$|\mathcal{T}v|_{X^{\sigma,1/2,T}_{1,1}} \le C_\alpha T^\alpha \Big(|v|^2_{X^{\sigma,1/2,T}_{1,1}} + |w|^2_{X^{\sigma,1/2,T}_{1,\infty}} + |u_0|^2_{B^\sigma_{2,1}} \Big).$$

In the same way, if v_1, $v_2 \in X^{\sigma,1/2,T}_{1,1}$, then

$$
\begin{aligned}
|\mathcal{T}v_1 - \mathcal{T}v_2|_{X^{\sigma,1/2,T}_{1,1}} \le C_\alpha T^\alpha \Big(&|v_1|_{X^{\sigma,1/2,T}_{1,1}} + |v_2|_{X^{\sigma,1/2,T}_{1,1}} \\
&+ |w|_{X^{\sigma,1/2,T}_{1,\infty}} + |u_0|_{B^\sigma_{2,1}} \Big) |v_1 - v_2|_{X^{\sigma,1/2,T}_{1,1}}.
\end{aligned}
$$

Hence, first setting

$$R_\omega^t = |w|_{X_{1,\infty}^{\sigma,1/2,t}} + |u_0|_{B_{2,1}^\sigma}$$

and then defining the stopping time T_ω by

$$T_\omega = \inf\{t > 0,\ 2C_\alpha t^\alpha R_\omega^t \geq 1/2\}$$

it is easily checked that $\mathcal{T}$ maps the ball of radius $R_\omega^{T_\omega}$ in $X_{1,1}^{\sigma,1/2,T_\omega}$ into itself, and that

$$|\mathcal{T}v_1 - \mathcal{T}v_2|_{X_{1,1}^{\sigma,1/2,T_\omega}} \leq \frac{3}{4}|v_1 - v_2|_{X_{1,1}^{\sigma,1/2,T_\omega}}.$$

Hence $\mathcal{T}$ has a unique fixed point, which is the unique solution of (4.3) in $X_{1,1}^{\sigma,1/2,T_\omega}$.

It follows from classical arguments and the second part of Proposition 4.1 that z and v are in $C([0,T_\omega];B_{2,1}^\sigma(\mathbb{T}))$ almost surely. On the other hand, since $\phi \in L_2^{0,s}$ and $U(t)$ is a unitary group in $H^s(\mathbb{T})$, we have $w \in C([0,T_\omega];H^s(\mathbb{T})) \subset C([0,T_\omega];B_{2,1}^\sigma(\mathbb{T}))$ by Theorem 6.10 in [8]. Hence, the solution $u = v + z + w$ of (1.5) is almost surely continuous with values in $B_{2,1}^\sigma(\mathbb{T})$.

One classically gets rid of the condition $\hat{u}_0(0) = 0$ almost surely by considering $v(t,x) = u(t,x+\alpha_0 t) - \alpha_0$ with $\alpha_0 = \int_{\mathbb{T}} u_0(x)dx$; indeed, v then satisfies the KdV equation (1.2) and the condition $\hat{v}_0(0) = 0$.

This ends the proof of Theorem 1.2. □

We now explain how we can get rid of the condition that the spatial mean of the noise is zero almost surely at any time.

PROPOSITION 4.3. *The conclusion of Theorem* 1.2 *is still true without the assumption that* $\operatorname{Im}\phi \subset \operatorname{span}\{e_j,\ j \geq 1\}$.

Proof. Let P be the orthogonal projector on $\operatorname{span}\{e_0\}$ in $L^2(\mathbb{T})$, i.e., $(Pu)(x) = (u,e_0)e_0$ for $u \in L^2(\mathbb{T})$, where $(\cdot,\cdot)$ denotes the inner product in $L^2(\mathbb{T})$. Then, clearly, $\tilde{\phi} = (I-P)\phi$ satisfies $\operatorname{Im}\tilde{\phi} \subset \operatorname{span}\{e_j,\ j \geq 1\}$; on the other hand, $W = P\phi\tilde{W} + \tilde{\phi}\tilde{W}$, and $\tilde{\beta}(t) = P\phi\tilde{W}(t) = \sum_{k\in\mathbb{N}}(\phi e_k, e_0)\beta_k(t)e_0$ is a real-valued Brownian motion since $\sum_{k\in\mathbb{N}}(\phi e_k, e_0)^2 = |\phi^* e_0|^2_{L^2(\mathbb{T})} < +\infty$.

Let $v = u - \tilde{\beta}$; then if u satisfies the KdV equation (1.2), v satisfies

$$\begin{cases} dv + (\partial_x^3 v + (v+\tilde{\beta})\partial_x v)dt = \tilde{\phi}d\tilde{W}, \\ v(0) = u_0, \end{cases}$$

and setting $\tilde{v}(t,x) = v(t, x + \int_0^t \tilde{\beta}(s)ds)$, we get the equation for $\tilde{v}$

$$\begin{cases} d\tilde{v} + (\partial_x^3\tilde{v} + \tilde{v}\partial_x\tilde{v})dt = d\hat{W}, \\ \tilde{v}(0) = u_0, \end{cases} \tag{4.4}$$

with $\hat{W}(t,x) = \sum_{k\in\mathbb{N}}(\tilde{\phi}e_k)(x - \int_0^t \tilde{\beta}(s)ds)\beta_k(t)$, and it is clear that we can apply all the arguments of the proof of Theorem 1.2 to (4.4), leading to the existence and uniqueness of $\tilde{v}$ from which we deduce the existence and uniqueness of u. Indeed, note that in Proposition 2.1, ϕ was allowed to depend on t and ω provided that it was in $L^\infty((0,T)\times\Omega;L_2^{0,s})$, which is obviously the case here. □

Proof of Theorem 1.5. The arguments are exactly the same as in [3]: let $T > 0$ be fixed; under the assumptions of Theorem 1.5, considering a sequence ϕ_n in $L_2^{0,4}$

such that $\phi_n \to \phi$ in $L_2^{0,0}$ and a sequence $u_{0,n}$ in $L^2(\Omega; H^3(\mathbb{T}))$ such that $u_{0,n} \to u_0$ in $L^2(\Omega; L^2(\mathbb{T}))$, one can easily prove (see [2]) the existence of a unique solution u_n in $C([0,T]; H^3(\mathbb{T}))$ of

$$u_n(t) = U(t)u_{0,n} - \frac{1}{2}\int_0^t U(t-s)\partial_x(u_n^2(s))ds + \int_0^t U(t-s)\phi_n d\tilde{W}(s).$$

Using Itô's formula on $|u_n|^2_{L^2(\mathbb{T})}$ and a martingale inequality, one gets as in [3]

$$\mathbb{E}\left(\sup_{t\in[0,T]} |u_n(t)|^2_{L^2(\mathbb{T})}\right) \le \mathbb{E}(|u_{0,n}|^2_{L^2(\mathbb{T})}) + C(T)\|\phi_n\|^2_{L_2^{0,0}};$$

hence, up to a subsequence, u_n converges in $L^2(\Omega; L^\infty(0,T; L^2(\mathbb{T})))$ weak star to some process $\tilde{u}$. Then if $\mathcal{T}_n$ is defined in the same way as $\mathcal{T}$ in the proof of Theorem 1.2, replacing u_0 and ϕ, respectively, by $u_{0,n}$ and ϕ_n, one shows that, given $\sigma < 0$, $\mathcal{T}_n$ is a uniform contraction in the ball of radius $R_\omega^{T_\omega}$ in $X_{1,1}^{\sigma,1/2,T_\omega}$; moreover the unique fixed point of $\mathcal{T}_n$ is equal to u_n, which, as a result, converges to u (the solution given by Theorem 1.2) in $X_{1,1}^{\sigma,1/2,T_\omega}$ for any $\sigma < 0$. It follows that $u = \tilde{u}$ almost surely on $[0, T_\omega]$, and that

$$|u(T_\omega)|_{B^\sigma_{2,1}(\mathbb{T})} \le C_\sigma |u(T_\omega)|_{L^2(\mathbb{T})} \le |\tilde{u}|_{L^\infty(0,T;L^2(\mathbb{T}))} \text{ almost surely.}$$

so that u may be extended to $[0,T]$ almost surely, giving the result. □

Acknowledgment. The authors would like to thank Professor Masayoshi Takeda for mentioning the regularity in Besov spaces of Brownian motion to them.

HOMOGENIZATION OF TRANSPORT EQUATIONS: WEAK MEAN FIELD APPROXIMATION*

THIERRY GOUDON† AND FRÉDÉRIC POUPAUD‡

Abstract. We are interested, with respect to the small parameter ϵ, in the behavior of solutions ρ^ϵ of the conservative advection-diffusion equation $\partial_t\rho^\epsilon + \nabla_x\cdot(\rho^\epsilon u^\epsilon) = \eta\Delta_x\rho^\epsilon$, driven by a large velocity field, $|u^\epsilon| = \mathcal{O}(1/\epsilon)$, which oscillates periodically with respect to time and space variables. The novelty of our approach compared to that of previous works is that we deal with the periodic case in its full generality. In particular, the cell equation which allows us to compute effective coefficients is parabolic and not elliptic. We also derive estimates on the homogenized solution via entropy methods.

Key words. homogenization, advection-diffusion equation, entropy dissipation

1. Introduction.

We consider the evolution of a scalar physical field $\rho(t,x)$ submitted to convection by a velocity field $u(t,x)$ and molecular diffusion with a diffusion coefficient $\eta > 0$. We are led to the classical equation

$$\partial_t\rho + \mathrm{div}_x(\rho u) = \eta\Delta_x\rho. \tag{1.1}$$

For instance, ρ can be the mass density or the temperature in a fluid. We can also interpret (1.1) as the Fokker–Planck equation for the probability density $\rho(t,x)$ of particles whose trajectories obey the differential Langevin equation

$$\mathrm{d}X(t) = u(t,X(t))\,\mathrm{d}t + \sqrt{2\eta}\,\mathrm{d}W(t), \tag{1.2}$$

W being a Brownian motion. We are interested in the effects of microscopic dynamics at large scale: the given velocity field u is an oscillating quantity with a very fast period. The fluctuations of u can be either deterministic or random. Without being more precise for the time being, we suppose that the variation of u depends on a characteristic scale ϵ, small compared to the large (macroscopic) scale of observation of the scalar field ρ. Therefore we are interested in deriving the bulk properties of ρ from the microscopic behavior of u, a homogenization problem.

While the problem (1.1) is linear, determination of the evolution of the average quantity $\langle\rho\rangle$ requires the knowledge of the correlation $\langle\rho u\rangle$. Indeed, averaging (1.1) yields

$$\partial_t\langle\rho\rangle = \mathrm{div}_x\langle\rho u\rangle + \eta\Delta_x\langle\rho\rangle.$$

The "turbulent moment closure problem" consists of looking for a relation between this correlation function and the average quantity $\langle\rho\rangle$. Classically, a simple linear

relation is postulated,

$$\langle \rho u \rangle = \langle u \rangle \ \langle \rho \rangle + \alpha \langle \rho \rangle + \beta \nabla_x \langle \rho \rangle,$$

involving effective tensors α, β. It yields the average (effective) equation

$$\partial_t \langle \rho \rangle = \operatorname{div}_x \big((\langle u \rangle + \alpha) \langle \rho \rangle \big) + \operatorname{div}_x \Big((\eta + \beta) \nabla_x \langle \rho \rangle \Big)$$

with a modification of both convection and diffusion terms by the homogenization process. The aim of this work is to determine the effective coefficients α, β and to prove rigorously (in the mathematical sense) the convergence of average concentrations $\langle \rho \rangle$ towards solutions of the above effective equation.

The question of homogenizing transport equations with highly oscillating coefficients has motivated many works. Such a problem is related to the propagation of oscillations in fluid dynamics equations; see Di Perna and Majda [12]. Clearly limit processes depend strongly on the scaling used in the equation; some examples are provided in McLaughlin, Papanicolaou, and Pironneau [29]. We also mention the very complete and deep presentation of these problems in the recent review paper of Kramer and Majda [24]. We also refer to the classical book of Bensoussan, Lions, and Papanicolaou [6], or more recently Jikov, Kozlov, and Oleinik [22], for a presentation of homogenization problems and of the classical mathematical methods used to solve it.

The modeling of the fast oscillating (turbulent) velocity field u can be done in two different ways. The first consists of considering deterministic fields which are periodic with respect to some fast variables. The second corresponds to random fields. In this paper we focus on the former case (concerning the latter, general situations are treated by Kesten and Papanicolaou [23]; the interested reader will find details and more references, for instance, in [24]). Let us give some of the known results in this field.

The periodic case can induce resonant phenomena which make the problem considerably more difficult when the molecular diffusivity η vanishes. When $\eta = 0$, the problem of determining the limit of the solutions of the transport equation when the periodicity vanishes is a challenging open question. It has been attacked only by considering simplified geometry of the characteristics associated to u. The first studies are concerned essentially with shear flows: oscillations of the velocity field hold in a direction transverse to the variable of derivation of the scalar field. The approach initiated by Tartar [31, 32] has permitted one to bring out memory effects induced by the homogenization procedure as in the papers of Mascarenhas [28], Amirat, Hamdache, and Ziani [2, 3], Hamdache [19, 20] and others. These effects can also be interpreted as an increase in the order of the equation. The second simplified geometry situation which has been studied is the case of divergence free field in 2 space dimensions. The field is then a curl of a potential and the characteristics are level sets of this potential. This situation has been investigated in the works by Brenier [7], Hou and Xin [21], and E [13]. It cannot be generalized in higher dimension. Actually a common mistake is to assume a Fredholm alternative for transport equations with periodic conditions which does not hold in general.

When $\eta \neq 0$, the positive diffusivity changes completely the asymptotic regime. The case which has been the most studied is when the velocity field is divergence free. The divergence-free case is much easier from a mathematical point of view. Indeed we have in this situation L^2 and H^1 estimates which are uniform with respect to u

thanks to the relation

$$\frac{\mathrm{d}}{\mathrm{d}t}\int |\rho(t)|^2\,\mathrm{d}x + 2\eta\int |\nabla\rho(t)|^2\,\mathrm{d}x = 0.$$

The compactness properties induced by this relation help a lot to mathematically justify the homogenized limit (see, for instance, [6]). When dealing with divergence-free velocity fields, the original diffusion is enhanced by the homogenization process. On the contrary, compressible velocity fields can give rise to a diffusion coefficient which can be depleted in the limit. From a physical point of view this role of compressibility has been pointed out recently by Avellaneda and Vergassola [5]. There do not seem to be mathematical results in this case, and the present work is an attempt to fill this gap.

In this work the homogenization of advection-diffusion equations ($\eta \neq 0$) with periodic oscillation situations is investigated. The most general situation is considered. The velocity field depends on fast variables in time and space but depends also on the slow variables. The equation is written in conservative form. The scaling assumption leads to large fluctuations of the velocity field (order $1/\epsilon$, with ϵ the scale of space fluctuations of the velocity). It corresponds to the invariant scaling of the Navier–Stokes equation. Therefore this scaling is particularly relevant for the study of turbulent flows. In such a case, we cannot obtain compactness properties on the solutions ρ, and the only available estimate is in L^1. We use a method of oscillating test functions (in the spirit of Tartar [11, 31] or Evans [14, 15]).

Under the assumption that a certain mean value of the velocity field (the ballistic velocity) vanishes, we prove the convergence of the solutions to those of a drift-diffusion equation. According to [5], the effective diffusion coefficient is positive, but it can be depleted compared to the original one. The concentration is factorized by a bulk concentration times a given fast oscillating function. We also obtain uniform estimates on the bulk component, which allows us to obtain the uniqueness of the limit.

We also give partial answers to the problem when the ballistic velocity does not vanish. Actually when the velocity does not depend on the macroscopic variables we give a complete description of the homogenized limit. To the best of our knowledge this result is new even from a physical viewpoint.

The two main mathematical difficulties in this work are the following:

- The first one is, when considering oscillating in time velocities, that the cell equation is parabolic and not elliptic as usual. However, considering periodic boundary conditions, the corresponding operators are proved to satisfy the Fredholm alternative.
- The second one relies on the lack of regularity of the sequence of solutions. The only available estimate is in L^1. This is not sufficient to guarantee the uniqueness of the limit. To overcome this difficulty we obtain uniform estimates on the bulk component of the solutions by using an entropy method. It allows us to obtain enough regularity on the homogenized limit to justify the uniqueness of this limit.

2. The periodic homogenization problem. In this section we consider a passive scalar field,

$$\rho^\epsilon : (t,x) \in [0,\infty)\times\mathbb{R}^N \longmapsto \rho^\epsilon(t,x) \in \mathbb{R}^+.$$

It represents a physical quantity whose evolution is driven by a fluid flow. The velocity field of the fluid is

$$u^\epsilon : (t,x) \in [0,\infty) \times \mathbb{R}^N \longmapsto u^\epsilon(t,x) \in \mathbb{R}^N,$$

which is parametrized by $\epsilon > 0$. The parameter ϵ represents the length scale of oscillations of the velocity field u^ϵ. The scalar quantity is advected by the fluid and is also possibly subject to a diffusion process with a diffusion coefficient $\eta \geq 0$. Therefore, the scalar field ρ^ϵ is a solution of the following advection-diffusion equation:

$$\partial_t \rho^\epsilon(t,x) + \operatorname{div}_x\big(\rho^\epsilon u^\epsilon\big)(t,x) = \eta\ \Delta_x \rho^\epsilon(t,x) \quad \forall (t,x) \in (0,\infty) \times \mathbb{R}^N, \tag{2.1}$$

$$\rho^\epsilon(0,x) = \rho_I^\epsilon(x) \quad \forall x \in \mathbb{R}^N. \tag{2.2}$$

The scalar field $\rho_I^\epsilon : \mathbb{R}^N \to \mathbb{R}^+$ is a given initial data.

We are interested in situations where the velocity field can be a model for turbulence. In order to obtain in the limit $\epsilon \to 0$ an effective turbulent diffusion coefficient due to the velocity field, the strength of $|u^\epsilon|$ should be large, of order $1/\epsilon$. On the other hand, the velocity field gives rise to an effective drift term $\overline{u}$, which is the mean over fluctuations of u^ϵ. Therefore, the average value of u^ϵ should remain of order 1. Let us make these considerations more precise. We get u^ϵ of the form

$$u^\epsilon(t,x) = \frac{1}{\epsilon}\left(u^0\left(t,x;\frac{t}{\epsilon^2},\frac{x}{\epsilon}\right) + \epsilon\, u^1\left(t,x;\frac{t}{\epsilon^2},\frac{x}{\epsilon}\right)\right). \tag{2.3}$$

The velocity fields

$$u^{0,1} : (t,x;\tau,y) \in [0,\infty) \times \mathbb{R}^N \times \mathbb{R}^{N+1} \longmapsto u^{0,1}(t,x;\tau,y) \in \mathbb{R}^N$$

are periodic with respect to the fast variables $\tau,\ y$:

$$\begin{gathered}\forall (t,x;\tau,y) \in [0,\infty) \times \mathbb{R}^N \times \mathbb{R}^{N+1},\ \forall n = (n_0,n') \in \mathbb{Z} \times \mathbb{Z}^N,\\ u^{0,1}(t,x;\tau+n_0,y+n') = u^{0,1}(t,x;\tau,y).\end{gathered} \tag{2.4}$$

Finally, setting $Y = (0,1)^{N+1}$, the situation is very different if u^0 has a vanishing or not vanishing mean value

$$\forall (t,x) \in [0,\infty) \times \mathbb{R}^N, \quad \int_Y u^0(t,x;\tau,y)\,\mathrm{d}\mu(\tau,y) \tag{2.5}$$

for a measure $\mathrm{d}\mu(\tau,y)$, which will be made more precise later on. This mean value is the so-called ballistic velocity. Hence, in the vanishing ballistic velocity case, the quantity $\overline{u}(t,x) = \int_Y u^1(t,x;\tau,y)\,\mathrm{d}\mu(\tau,y)$ corresponds to the mean value of the velocity field u^ϵ.

Remark 1. The scaling we use in the fast variables, $u \to u^\epsilon = \frac{1}{\epsilon}u(\frac{t}{\epsilon^2},\frac{x}{\epsilon})$, is the invariant scaling of the incompressible Navier–Stokes equation. (If u is a solution of the Navier–Stokes equation, u^ϵ is also a solution of the same equation.) It shows the relevance of this scaling for studying turbulence in fluids.

Remark 2. Actually, we are working with dimensionless equations, obtained from the original variables (t',x') by setting $t = t'/T$, $x = x'/L$, where T and L are characteristic values of time and length, respectively, under which the evolution of ρ is studied. We point out that the choice of T and L is free. Let us denote by ℓ the typical length of microscopic variations of the velocity field and by τ_0 its typical time scale

of variation. The typical value for the mean velocity field is denoted by U_m and for the fluctuations by U_{fl}. We define the parameter ϵ as $\epsilon = \frac{U_m}{U_{fl}}$. It is natural to choose the scale T and L such that $U_m = \frac{L}{T}$. If we want that the fluctuations of the velocity field give rise to a diffusion process, U_{fl} should be scaled as a parabolic scaling. Then L and T are completely determined by the relation $U_{fl} = \frac{L^2}{T}\ \frac{1}{\ell}$. Consequently, we have $\epsilon = \frac{\ell}{L}$.

Up to now there has been no physical assumption. The regime we are studying in this work corresponds to the assumption $U_{fl} \gg U_m$ or, in other words, $\epsilon \ll 1$. It is also natural to assume that the path of a particle with velocity U_{fl} during the microscopic time period τ_0 is of order ℓ. It leads to

$$U_{fl}\,\tau_0 = \frac{L^2}{\ell}\ \frac{\tau_0}{T} = \ell, \quad \frac{\tau_0}{T} = \frac{\ell^2}{L^2} = \epsilon^2.$$

We have also to assume that the molecular diffusivity acts at the macroscopic scale L and T. If η' stands for the diffusion coefficient in the physical variables, it means that η' has the same order as $\frac{L^2}{T} = U_{fl}\ell$, while $\eta = \eta' \frac{T}{L^2}$. This physical situation corresponds to the so-called weak mean field approximation.

Remark 3. The case of a purely periodic and divergence-free velocity field with null average,

$$u^\epsilon(x) = \frac{1}{\epsilon}\ u(x/\epsilon), \qquad \int_Y u(y)\,\mathrm{d}(y) = 0, \qquad \mathrm{div}_y(u) = 0,$$

can actually be recast into a more classical question of homogenization of parabolic equation. Indeed, in such a case, we can associate to u a skew-symmetric matrix B by solving $\Delta_y B = \nabla_y u$. Using Fourier expansion yields

$$B_{ij}(y) = \sum_{n\neq 0} e^{2i\pi n\cdot y}\ \frac{i}{|n|^2}\Big(n_i\widehat{u_j}(n) - n_j\widehat{u_i}(n)\Big).$$

We have $\mathrm{Div}_y(B) = u(y)$ so that

$$\frac{1}{\epsilon}\ u(x/\epsilon)\cdot\nabla_x\rho + \eta\Delta\rho = \nabla_x\cdot((\eta + B(x/\epsilon))\nabla_x\rho).$$

This remark is used, for instance, in [4]. Difficulties arise when $\int_Y u\,\mathrm{d}(y) \neq 0$. This kind of problem arises, for instance, in neutron transport theory; we refer to Capdeboscq [8, 9] for a treatment of the spectral problem.

3. Formal asymptotics. As usual (see [6]), we try to guess the result with a formal double-scale ansatz,

$$\rho^\epsilon(t,x) = R^0(t,x;t/\epsilon^2,x/\epsilon) + \epsilon R^1(t,x;t/\epsilon^2,x/\epsilon) + \epsilon^2 R^2(t,x;t/\epsilon^2,x/\epsilon) + \cdots,$$

where the $R^i(t,x;\tau,y)$'s are Y-periodic. The action of the operator

$$\mathcal{T}_\epsilon = \partial_t(\cdot) + \mathrm{div}_x\big(u^\epsilon\ \cdot\big) - \eta\Delta_x(\cdot)$$

on functions of the form $r^\epsilon(x) = R(t,x;t/\epsilon^2,x/\epsilon)$ reads as

$$\mathcal{T}_\epsilon(r^\epsilon)\left(t,x;\frac{t}{\epsilon^2},\frac{x}{\epsilon}\right) = \epsilon^{-2}\mathcal{T}_0(R)\left(t,x;\frac{t}{\epsilon^2},\frac{x}{\epsilon}\right) + \epsilon^{-1}\mathcal{T}_1(R)\left(t,x;\frac{t}{\epsilon^2},\frac{x}{\epsilon}\right) + \mathcal{T}_2(R)\left(t,x;\frac{t}{\epsilon^2},\frac{x}{\epsilon}\right)$$

with

$$\begin{cases} \mathcal{T}_0(R)(t,x;\tau,y) = \Big(\partial_\tau R + \mathrm{div}_y\big(u^0 R\big) - \eta\Delta_y R\Big)(t,x;\tau,y), \\ \mathcal{T}_1(R)(t,x;\tau,y) = \Big(\mathrm{div}_y\big(u^1 R\big) + \mathrm{div}_x\big(u^0 R\big) - 2\eta\nabla_x\cdot\nabla_y R\Big)(t,x;\tau,y), \\ \mathcal{T}_2(R)(t,x;\tau,y) = \Big(\partial_t R + \mathrm{div}_x\big(u^1 R\big) - \eta\Delta_x R\Big)(t,x;\tau,y). \end{cases}$$

Plugging the double-scale ansatz into (2.1) and identifying the terms with the same power of ϵ yield

$$\begin{aligned} &\epsilon^{-2}\text{term:} && \mathcal{T}_0 R^0 = 0, \\ &\epsilon^{-1}\text{term:} && \mathcal{T}_0 R^1 = -\mathcal{T}_1 R^0, \\ &\epsilon^{-0}\text{term:} && \mathcal{T}_0 R^2 = -\mathcal{T}_2 R^0 - \mathcal{T}_1 R^1. \end{aligned}$$

These relations can be generically written as $\mathcal{T}_0 R^p = S^p$, where S^p depends only on $R^0,\dots,R^{p-1}$. We also remark that the operator $\mathcal{T}_0$ is a differential operator in the variables $\tau,\ y$, parametrized by t and x. Thus, we are dealing with cell equations with variable $(\tau,y)\in Y$ and periodic boundary conditions. At least formally, we aim at solving recursively these cell equations.

However, by integrating over Y, we realize that $\int_Y S\,\mathrm{d}(\tau,y) = 0$ is a necessary condition for the cell problem $\mathcal{T}_0 R = S$ to have a solution. We also note that the kernel of the adjoint operator $\mathcal{T}_0^\star = -\partial_\tau - u^0\cdot\nabla_y - \eta\Delta_y$ contains the constants. Actually it can be shown that $\mathcal{T}_0$ is a Fredholm operator of index 0. Hence, the condition $\int_Y S\,\mathrm{d}(\tau,y) = 0$ is also sufficient, and we will solve the cell equations by means of the Fredholm alternative. At this point a difficulty should be pointed out. When $\eta = 0$ the cell problem is no more of Fredholm type. The ergodic property that the null space of $\mathcal{T}_0^\star$ is spanned by the constants (with respect to y) is not sufficient to guarantee that the problem $\mathcal{T}_0 R = S$ has a solution under the condition $\int_Y S\,\mathrm{d}(\tau,y) = 0$. These facts will be detailed in the following subsection concerning rigorous proofs.

Now let us assume the following facts:

(A) For $(t,x)\in[0,\infty)\times\mathbb{R}^N$ fixed, 0 is a simple eigenvalue of $\mathcal{T}_0$ and the nullspace is spanned by a normalized function

$$\mathrm{Ker}(\mathcal{T}_0) = \mathrm{Span}\{\Theta\}, \qquad \int_Y \Theta\ \mathrm{d}(\tau,y) = 1.$$

(B) The cell problem $\mathcal{T}_0 R = S$ has a unique solution (up to elements of $\mathrm{Ker}(\mathcal{T}_0)$) under the necessary and sufficient condition $\int_Y S\,\mathrm{d}(\tau,y) = 0$.

From the ϵ^{-2} equation and (A), we infer that the leading term $R^0\in\mathrm{Ker}(\mathcal{T}_0)$ reads

$$R^0(t,x;\tau,y) = \rho(t,x)\ \Theta(t,x;\tau,y).$$

Next, the ϵ^{-1} equation becomes

$$\begin{aligned} \mathcal{T}_0 R^1 = -\mathcal{T}_1(R^0) = &-\Big(\mathrm{div}_x(u^0\ \Theta) + \mathrm{div}_y(u^1\ \Theta) - 2\eta\nabla_x\cdot\nabla_y\Theta\Big)\rho \\ &-\Big(\Theta\ u^0 - 2\eta\nabla_y\Theta\Big)\cdot\nabla_x\rho. \end{aligned}$$

Let us define $\chi(t,x;\tau,y) = (\chi_1,\dots,\chi_N)\in\mathbb{R}^N$ as the solution (with zero mean) of the auxiliary cell problem

$$\mathcal{T}_0\chi_j = \Theta\ {u^0}_j - 2\eta\partial_{y_j}\Theta \tag{3.1}$$

and $\kappa(t,x;\tau,y)$ the solution of

$$\mathcal{T}_0\kappa = -\mathrm{div}_x(u^0\ \Theta) - \mathrm{div}_y(u^1\ \Theta) + 2\eta\nabla_x\cdot\nabla_y\Theta.$$

Remark that, in view of (B), these problems can be solved under the condition

$$\int_Y u^0\ \Theta\,\mathrm{d}(\tau,y) = 0. \tag{3.2}$$

Therefore, the measure mentioned in (2.5) is nothing but $\mathrm{d}\mu(\tau,y) = \Theta\,\mathrm{d}(\tau,y)$. This condition is referred to as the "vanishing ballistic velocity condition." From now on we assume this relation holds true. Thus, the ϵ^{-1} equation is solved by

$$R^1(t,x;\tau,y) = -\chi(t,x;\tau,y)\cdot\nabla_x\rho(t,x) + \kappa(t,x;\tau,y)\rho(t,x) + S^1(t,x)\Theta(t,x;\tau,y),$$

where S^1 is an arbitrary function of (t,x). We will see that the choice of S^1 is irrelevant to obtaining the equation on R^0. As usual in two-scale asymptotics, the determination of S^1 is only necessary to obtain the equation for R^1. Now, let us look at the ϵ^0 term, which provides the equation satisfied by ρ. The solvability condition yields

$$\int_Y \mathcal{T}_2R^0\,\mathrm{d}(\tau,y) + \int_Y \mathcal{T}_1R^1\,\mathrm{d}(\tau,y) = 0.$$

Besides, we have

$$\begin{aligned}
\int_Y \mathcal{T}_2R^0\,\mathrm{d}(\tau,y) &= \partial_t\rho(t,x) + \mathrm{div}_x\left(\int_Y u^1\ \Theta(t,x;\tau,y)\,\mathrm{d}(\tau,y)\ \rho(t,x)\right) - \Delta_x\rho(t,x),\\
\int_Y \mathcal{T}_1R^1\,\mathrm{d}(\tau,y) &= \mathrm{div}_x\left(\int_Y u^0R^1\,\mathrm{d}(\tau,y)\right)\\
&= -\,\mathrm{div}_x\left(\int_Y u^0\otimes\chi(t,x;\tau,y)\,\mathrm{d}(\tau,y)\ \cdot\nabla_x\rho(t,x)\right)\\
&\quad + \mathrm{div}_x\left(\int_Y u^0\kappa(t,x;\tau,y)\,\mathrm{d}(\tau,y)\,\rho(t,x)\right).
\end{aligned}$$

Let us define the turbulent diffusion matrix D by

$$D(t,x) = \int_Y u^0(t,x;\tau,y)\otimes\chi(t,x;\tau,y)\,\mathrm{d}(\tau,y) \tag{3.3}$$

and the effective drift term by

$$v(t,x) = \int_Y \big(u^1\ \Theta(t,x;\tau,y) + u^0\ \kappa(t,x;\tau,y)\big)\,\mathrm{d}(\tau,y). \tag{3.4}$$

We are finally led to the following effective equation for $\rho(t,x) = \lim_{\epsilon\to0}\rho^\epsilon(t,x)$:

$$\partial_t\rho(t,x) + \mathrm{div}_x\big(\rho\ v\big)(t,x) - \mathrm{div}_x\left((D+\eta I_N)\cdot\nabla_x\rho\right)(t,x) = 0.$$

The matrix I_N is the $N\times N$ identity matrix. Therefore, the homogenization procedure induces an effective diffusion which is the sum of the original diffusion ηI with the matrix D.

Remark 4. We might wonder if the effects of the turbulent velocity field are to increase the molecular diffusivity and if the (symmetric part of the) matrix D is nonnegative. This is not true in general. Actually, considering potential flow, we will see that D is negative. This fact has been already noticed by Avellaneda and Vergassola [5]. However, we will check that $\eta I_N + D$ remains nonnegative.

Also the above asymptotic is based on the vanishing ballistic velocity assumption (3.2). The problem of what happens when (3.2) does not hold is addressed in subsection 4.5.

4. Rigorous results.

4.1. Functional preliminaries. First, let us introduce some functional spaces.

Let $\Omega \subset \mathbb{R}^D$, and let $p,\ q \in \mathbb{N}$. The set $C^p_\#(\Omega \times \mathbb{R}^{N+1})$ is the set of p-times continuously differentiable functions on $\Omega \times \mathbb{R}^{N+1}$ which are Y-periodic with respect to the last variable. Similarly, $C^p_{b,\#}(\Omega \times \mathbb{R}^{N+1})$ and $C^p_{c,\#}(\Omega \times \mathbb{R}^{N+1})$ are the subspaces of functions having bounded derivatives up to order p, and being supported in $K \times \mathbb{R}^{N+1}$ for some compact subset K of Ω, respectively. We also define anisotropic spaces $C^{[p;q,\alpha]}_\#([0,\infty) \times \mathbb{R}^N \times \mathbb{R}^{N+1})$ to be the spaces of continuous functions $u = u(t,x,\tau,y)$ such that

- $(\partial_t)^r(\partial_x)^s u$ exist and are continuous for $2r + s \le p$, where $(\partial_x)^s$ denotes any partial derivative of order s with respect to $x \in \mathbb{R}^N$, and $(\partial_t)^r$ stands for the rth derivative with respect to $t \ge 0$;
- $(\partial_\tau)^r(\partial_y)^s u$ exist and are continuous for $2r + s \le q$, where $(\partial_y)^s$ denotes any partial derivative of order s with respect to $y \in \mathbb{R}^N$, and $(\partial_\tau)^r$ stands for the rth derivative with respect to $\tau \in \mathbb{R}$;
- $(\partial_\tau)^r(\partial_y)^s u$ for $2r+s = q$ are Hölder continuous with exponent α with respect to y and with exponent $\alpha/2$ with respect to τ.

Finally, we also need $C^{[p;q,\alpha]}_{c,\#}([0,\infty)\times\Omega\times\mathbb{R}^N)$, the subspaces of functions with compact support with respect to the first two variables.

The formal limit obtained in the previous section can be rigorously justified by using the double-scale techniques as developed by Nguetseng [30] and Allaire [1]. This technique is quite equivalent to the method of oscillating test functions of Tartar [11, 31] and Evans [14, 15] and can be seen as a systematic way (but restricted to periodic situations) to choose the "good" test functions. In the present problem there is no a priori L^2-estimates, except if the u^i's are divergence free. Then the natural framework is an L^1-setting. We will adapt the results of [1, 30] to this setting. Now let us introduce some definitions and basic results about the family of parametrized measures.

DEFINITION 4.1. *Let I be an interval of $\mathbb{R}$. A family $\{\mu(t);\ t \in I\}$ of Radon measures on $\mathbb{R}^N$ is said to be vaguely continuous if and only if*

$$\forall \varphi \in C^0_c(\mathbb{R}^N), \qquad t \longmapsto \int_{\mathbb{R}^N} \varphi(x)\ \mu(t,x)\,\mathrm{d}x \quad \text{is a continuous function on } I.$$

DEFINITION 4.2. *A sequence $\{\mu_n(t);\ t \in I,\ n \in \mathbb{N}\}$ is said to be equibounded and vaguely equicontinuous on I if and only if*

(i) *there exists $M > 0$ such that*

$$\sup_{t\in I,\, n\in\mathbb{N}} |\mu_n|(t,\mathbb{R}^N) \le M;$$

(ii) *for any $\varphi \in C^0_c(\mathbb{R}^N)$, the sequence of functions $\left(t \longmapsto \int_{\mathbb{R}^N} \varphi(x)\ \mu_n(t,x)\,\mathrm{d}x\right)_{n\in\mathbb{N}}$ is equicontinuous on I.*

We recall the following classical compactness result.

PROPOSITION 4.3. *Let I be an interval of $\mathbb{R}$. Let $\big(\mu_n(t)\big)_{n\in\mathbb{N}}$ be a sequence of Radon measures on $\mathbb{R}^N$, equibounded and vaguely equicontinuous on I.*

Then there exist a measure $\mu(t)$ vaguely continuous on I and a subsequence $\big(\mu_{n_k}(t)\big)_{k\in\mathbb{N}}$ such that

$$\forall\varphi\in C_c^0(I\times\mathbb{R}^N),\quad \int_{\mathbb{R}^N}\varphi(t,x)\ \mu_{n_k}(t,x)\,\mathrm{d}x\xrightarrow[k\to\infty]{}\int_{\mathbb{R}^N}\varphi(t,x)\ \mu(t,x)\,\mathrm{d}x,$$

uniformly with respect to $t\in I$. We say that sequence $\big(\mu_{n_k}(t)\big)_{k\in\mathbb{N}}$ converges vaguely to $\mu(t)$ locally, uniformly on I.

Then we also have the existence of a double-scale limit, in the spirit of Allaire [1] and Nguetseng [30].

PROPOSITION 4.4. *Let $\big(\epsilon_n\big)_{n\in\mathbb{N}}$ be a sequence of positive numbers converging to 0. Let $\big(\mu_n(t)\big)_{n\in\mathbb{N}}$ be a sequence of measures on $\mathbb{R}^N$, equibounded on an interval $I\subset\mathbb{R}$. Then there exist a subsequence $\big(\mu_{n_k}(t)\big)_{k\in\mathbb{N}}$ and a measure M on $I\times\mathbb{R}\times\mathbb{R}^N\times Y$ such that for any $\varphi\in C^0_{c,\#}(I\times\mathbb{R}^N\times\mathbb{R}^{N+1})$, we have*

$$\int_I\int_{\mathbb{R}^N}\varphi(t,x;t/\epsilon_{n_k}^2,x/\epsilon_{n_k})\ \mu_{n_k}(t,x)\,\mathrm{d}x\,\mathrm{d}t \xrightarrow[k\to\infty]{}\int_I\int_{\mathbb{R}^N}\int_Y\varphi(t,x;\tau,y)\ M(t,x;\tau,y)\,\mathrm{d}(\tau,y)\,\mathrm{d}x\,\mathrm{d}t.$$

We say that the measure M is the double-scale limit of the sequence $\big(\mu_{n_k}(t)\big)_{k\in\mathbb{N}}$.

This proposition is nothing but a consequence of the Banach–Alaoglu theorem applied to the sequence of measures M_n defined by

$$\int_I\int_{\mathbb{R}^N}\int_Y\varphi(t,x;\tau,y)\,M_n(t,x;\tau,y)\,\mathrm{d}(\tau,y)\,\mathrm{d}x\,\mathrm{d}t:=\int_I\int_{\mathbb{R}^N}\varphi(t,x;t/\epsilon_n^2,x/\epsilon_n)\,\mu_n(t,x)\,\mathrm{d}x\,\mathrm{d}t.$$

The double-scale limit captures the periodic oscillations of μ_n with frequency $1/\epsilon_n$ in x and $1/\epsilon_n^2$ in t. By using test functions of the form $\varphi(t,x;\tau,y)=\psi(t,x)$, we also obtain immediately that the vague limit $\mu(t)$ of $\mu_{n_k}(t)\,\mathrm{d}t$ is given by the marginal

$$\mu(t,x)=\int_Y M(t,x;\tau,y)\,\mathrm{d}(\tau,y)\in\mathcal{M}^1(I\times\mathbb{R}^N).$$

4.2. Cell problems. Next, we are concerned with cell problems. In particular we discuss properties (A) and (B) stated in the previous section.

PROPOSITION 4.5. *Let $u^0\in C_\#^{[2;1,\alpha]}([0,\infty)\times\mathbb{R}^N\times\mathbb{R}^{N+1})$. Then the following assertions hold:*

(i) *There exists a unique function $\Theta\in C_\#^{[2;2,\alpha]}([0,\infty)\times\mathbb{R}^N\times\mathbb{R}^{N+1})$ such that*

$$\begin{cases}\mathcal{T}_0(\Theta)=\big(\partial_\tau\Theta+\mathrm{div}_y(u^0\ \Theta)-\eta\ \Delta_y\Theta\big)(t,x;\tau,y)=0\\ \qquad\forall(t,x;\tau,y)\in[0,\infty)\times\mathbb{R}^N\times\mathbb{R}^N,\\ \displaystyle\int_Y\Theta(t,x;\tau,y)\,\mathrm{d}(\tau,y)=1\qquad\forall(t,x)\in[0,\infty)\times\mathbb{R}^N.\end{cases}$$

Furthermore, we have $\Theta(t,x;\tau,y)>0$ for all $(t,x;\tau,y)$.

(ii) *For any* $S \in C_{\#}^{[p;0,\alpha]}([0,\infty)\times\mathbb{R}^N\times\mathbb{R}^{N+1})$ *with* $p=0,1,2$ *the cell problem*

$$\mathcal{T}_0(R) = \partial_\tau R + \operatorname{div}_y(u^0 R) - \eta\Delta_y R = S, \quad \int_Y R\,\mathrm{d}(\tau,y) = 0$$

has a unique solution $R \in C_{\#}^{[p;2,\alpha]}([0,\infty)\times\mathbb{R}^N\times\mathbb{R}^{N+1})$ *under the necessary and sufficient orthogonality condition*

$$\int_Y S(t,x;\tau,y)\,\mathrm{d}(\tau,y) = 0 \quad \forall (t,x)\in[0,\infty)\times\mathbb{R}^N. \tag{4.1}$$

(iii) *For any* $H \in C_{\#}^{[p;0,\alpha]}([0,\infty)\times\mathbb{R}^N\times\mathbb{R}^{N+1})$ *with* $p=0,1,2$ *the cell problem*

$$-\partial_\tau\Phi - u^0\cdot\nabla_y\Phi - \eta\Delta_y\Phi = H, \quad \int_Y \Phi\,\mathrm{d}(\tau,y) = 0$$

has a unique solution $\Phi \in C_{\#}^{[p;2,\alpha]}([0,\infty)\times\mathbb{R}^N\times\mathbb{R}^{N+1})$ *under the necessary and sufficient orthogonality condition*

$$\int_Y H(t,x;\tau,y)\ \Theta(t,x;\tau,y)\,\mathrm{d}(\tau,y) = 0 \quad \forall (t,x)\in[0,\infty)\times\mathbb{R}^N. \tag{4.2}$$

Proof. Let $(t,x)\in[0,\infty)\times\mathbb{R}^N$ be fixed. We denote by

$$\mathcal{T}_0^\star(\Phi) = -\partial_\tau\Phi - u^0\cdot\nabla_y\Phi - \eta\Delta_y\Phi$$

the adjoint operator of $\mathcal{T}_0$. Obviously, constants belong to the kernel of $\mathcal{T}_0^\star$. For $\lambda>0$ large enough we shall see that the resolvant $R_\lambda = (\lambda+\mathcal{T}_0^\star)^{-1}$ (resp., $S_\lambda = (\lambda+\mathcal{T}_0)^{-1}$) is well defined and we rewrite the problems $\mathcal{T}_0^\star(\Phi)=H$ (resp., $\mathcal{T}_0(R)=S$) as

$$(I-\lambda R_\lambda)\Phi = R_\lambda H \tag{4.3}$$

(resp., $(I-\lambda S_\lambda)\Phi = S_\lambda H$). We wish to conclude by applying the Fredholm alternative. We are thus led to investigate compactness and spectral properties of the resolvant operator R_λ (resp., S_λ).

Hence, we are interested in the problem

$$(\mathcal{T}_0^\star+\lambda)\Phi = H \in L^2_{\#}(Y) \tag{4.4}$$

for some $\lambda>0$ and domain $D(\mathcal{T}_0^\star)$, which will be made precise later on. Assuming existence in $H^1_{\#}(Y)$, uniqueness of the solution follows from the positivity of the energy functional

$$\begin{aligned} a_0(\Phi,\Phi) &= \int_Y (\mathcal{T}_0^\star+\lambda)\Phi\ \Phi\,\mathrm{d}(\tau,y) \\ &= \int_Y \left(\lambda + \frac{1}{2}\operatorname{div}_y u^0\right)\Phi^2\,\mathrm{d}(\tau,y) + \eta\int_Y |\nabla_y\Phi|^2\,\mathrm{d}(\tau,y), \end{aligned}$$

provided λ satisfies $\lambda > \max_{(\tau,y)\in Y}\max(0,-\frac{1}{2}\operatorname{div}_y u^0)$. From now on, we fix λ, which fulfills this relation. It remains to justify the existence of a solution of (4.4).

To this end, we introduce an elliptic regularization of $\mathcal{T}_0^\star$. Let ${\mathcal{T}_0^\star}_\mu$, $\mu>0$, be the operator

$${\mathcal{T}_0^\star}_\mu(\Phi) = -\mu\partial^2_{\tau,\tau}\Phi - \partial_\tau\Phi - u^0\cdot\nabla_y\Phi - \eta\Delta\Phi$$

with domain $D({\mathcal{T}_0^\star}_\mu) = H^2_\#(Y)$, the space of functions Y-periodic, belonging to $H^2_{\rm loc}(\mathbb{R}^{N+1})$. For $\lambda > \frac{1}{2}\max_{\tau,y}\{0, -{\rm div}_y u_0\}$, the associated energy functional

$$a_\mu(\Phi,\Phi) = \int_Y \Phi({\mathcal{T}_0^\star}_\mu(\Phi) + \lambda\Phi)\,{\rm d}(\tau,y)$$
$$= \mu\int_Y |\partial_\tau\Phi|^2\,{\rm d}(\tau,y) + \int_Y \left(\lambda + \frac{1}{2}{\rm div}_y(u^0)\right)\,\Phi^2\,{\rm d}(\tau,y) + \eta\int_Y |\nabla_y\Phi|^2\,{\rm d}(\tau,y)$$

is coercive on the space $H^1_\#(Y)$. A direct application of the Lax–Milgram theorem guarantees, for any data $H \in L^2_\#(Y)$, the existence-uniqueness of a solution $\Phi \in H^1_\#(Y)$ of the cell problem ${\mathcal{T}_0^\star}_\mu(\Phi_\mu) + \lambda\Phi_\mu = H$ in $H^1_\#(Y)$. Then $\mu\partial^2_{\tau,\tau}\Phi + \eta\Delta\Phi \in L^2_\#(Y)$, which implies that Φ_μ belongs to $H^2_\#(Y) = D({\mathcal{T}_0^\star}_\mu)$. We also have $\Phi_\mu \geq 0$ when $H \geq 0$ by the maximum principle. Then (4.4) will be solved by passing to the limit $\mu \to 0$.

By using the relation $a_\mu(\Phi_\mu,\Phi_\mu) = \int_Y H\ \Phi_\mu\,{\rm d}(\tau,y)$, we obtain that Φ_μ and $\nabla_y\Phi_\mu$ are uniformly bounded in $L^2_\#(Y)$. Multiplying the equation ${\mathcal{T}_0^\star}_\mu(\Phi_\mu) + \lambda\Phi_\mu = H$ by $\partial_\tau\Phi_\mu$ and integrating by parts give

$$\int_Y |\partial_\tau\Phi_\mu|^2\,{\rm d}(\tau,y) = -\int_Y u_0\cdot\nabla_y\Phi_\mu\partial_\tau\Phi_\mu\,{\rm d}(\tau,y) - \int_Y H\ \partial_\tau\Phi_\mu\,{\rm d}(\tau,y).$$

We deduce that $\partial_\tau\Phi_\mu$ is also uniformly bounded in $L^2_\#(Y)$. Hence, Φ_μ is bounded in $H^1_\#(Y)$. The cluster points of the sequence Φ_μ as $\mu \to 0$ are solutions in $H^1_\#(Y)$ of (4.4). Such a solution satisfies $\Delta_y\Phi \in L^2_\#(Y)$. Defining $D(\mathcal{T}_0^\star) = \{\Phi \in H^1_\#(Y),\ \Delta_y\Phi \in L^2_\#(Y)\}$, we have obtained the existence of a compact resolvant $R_\lambda = (\mathcal{T}_0^\star + \lambda)^{-1}$.

Then, in order to apply the Fredholm alternative for (4.3), it remains to determine the compatibility relation, and in particular the dimension of the eigenspace ${\rm Ker}(\mathcal{T}_0^\star) = {\rm Ker}(R_\lambda - 1/\lambda))$ (resp., ${\rm Ker}(\mathcal{T}_0) = {\rm Ker}(S_\lambda - 1/\lambda)$). We use the fact that R_λ preserves nonnegativity: for $H \geq 0$, $\Phi = R_\lambda(H) \geq 0$. The Krein–Rutman theorem (see [25]) applies and the spectral radius ρ of R_λ is an eigenvalue, associated to a nonnegative eigenfunction. Reasoning similarly for the adjoint operator, we obtain the existence of a function $\Theta \in H^1_\#(Y)$, $\Theta \geq 0$, verifying $S_\lambda\Theta = \rho\Theta$. However, we have remarked that $(1/\lambda, \mathbb{1})$ is an eigenpair for R_λ. Hence, we get

$$\rho\int_Y \Theta\,{\rm d}(\tau,y) = \int_Y \mathbb{1}\ S_\lambda(\Theta)\,{\rm d}(\tau,y) = \int_Y R_\lambda(\mathbb{1})\ \Theta\,{\rm d}(\tau,y) = \frac{1}{\lambda}\int_Y \Theta\,{\rm d}(\tau,y);$$

i.e., $\rho = 1/\lambda$ is the principal eigenvalue of R_λ, S_λ and Θ satisfies $\mathcal{T}_0(\Theta) = 0$.

Then we make use of regularity results and the maximum principle for parabolic equations. We first remark that the functions of $D(\mathcal{T}_0) = D(\mathcal{T}_0^\star)$ are continuous with respect to time τ with value in $L^2_\#([0,1]^N)$, and their first derivatives with respect to y belong to $L^2_\#(Y)$. With the notation of [27], such functions belong to $V_2^{1,0}$. Therefore, since the coefficients are smooth we can apply [27, Theorem 12.1, p. 223]. We deduce that $R_\lambda(H) = \Phi \in C^{[2,\alpha]}_\#(Y)$ ($H^{2+\alpha,1+\alpha/2}(Y)$ in the terminology of [27]) for $H \in C^{[0,\alpha]}_\#(Y)$. Similarly, we have $\Theta \in C^{[2,\alpha]}_\#(Y)$. Thus, the maximum principle applies (see [16, Theorem 5, p. 39]) and we obtain $\Theta > 0$, and $R_\lambda(H) = \Phi > 0$ for $H \geq 0$. Suppose now there exists a $\Phi \in {\rm Ker}(\mathcal{T}_0^\star)$ with $\int_Y \Phi\,{\rm d}(\tau,y) = 0$. Then Φ is also in $C^{[2,\alpha]}_\#(Y)$ and the positive and negative parts $\Phi_\pm$ are continuous functions nonidentically zero. By the maximum principle $R_\lambda\Phi_\pm > 0$. We deduce that $|\Phi| <$

$\lambda R_\lambda(|\Phi|)$. It would imply $\int_Y \Theta|\Phi| \,\mathrm{d}(\tau,y) = \lambda \int_Y \Theta R_\lambda(|\Phi|) \,\mathrm{d}(\tau,y) > \int_Y \Theta|\Phi| \,\mathrm{d}(\tau,y)$, a contradiction. Thus, the kernel of $\mathcal{T}_0^\star$ (resp., $\mathcal{T}_0$) is monodimensional and spanned by $\mathbb{1}$ (resp., $\Theta > 0$).

We conclude by applying the Fredholm alternative. The solution of $\mathcal{T}_0(R) = S$ exists if and only if S is orthogonal to the kernel of the adjoint that is $\int_Y S \,\mathrm{d}(\tau,y) = 0$. The solution is unique if we impose $\int_Y R \;\mathrm{d}(\tau,y) = 0$. The same is true for $\mathcal{T}_0^\star$: the equation $\mathcal{T}_0^\star(\Phi) = S$ has a solution if and only if $\int_Y S\,\Theta \;\mathrm{d}(\tau,y) = 0$ and the uniqueness is assured by the condition $\int_Y R \;\mathrm{d}(\tau,y) = 0$. By applying [27, Theorem 12.1, p. 223], we obtain that Θ, R, and Φ belong to $C_\#^{[2,\alpha]}(Y)$ if S, $H \in C_\#^{[0,\alpha]}(Y)$ for fixed (t,x).

We study now the dependency with respect to these parameters (t,x). Letting δ_h be a finite difference operator in the variables (t,x), we have

$$\mathcal{T}_0^\star(\delta_h(\Phi)) = -\delta_h(u^0)\cdot\nabla_y(\Phi) + \delta_h(H).$$

The right-hand side is bounded in $C_\#^{[0,\alpha]}(Y)$ uniformly with respect to h. Then the sequence $\big(\delta_h(\Phi)\big)_{h>0}$ is bounded in $C_\#^{2,\alpha}(\mathbb{R}^N)$ uniformly with respect to h. This implies that $(t,x) \longmapsto \Phi(t,x,.)$ is differentiable with respect to (t,x) with values in $C_\#^{[2,\alpha]}(Y)$. In particular $\Phi \in C^0([0,\infty)\times\mathbb{R}^N; C_\#^{[2,\alpha]}(Y))$. If $\partial\Phi$ denotes a derivative with respect to t or x, we have, letting $h \to 0$,

$$\mathcal{T}_0^\star(\partial\Phi) = -\partial u^0\cdot\nabla_y(\Phi) + \partial H.$$

Since the right-hand side is continuous with respect to the parameter (t,x), it yields the continuity of $\partial\Phi$. We obtain the same result for the derivatives up to order 2 by repeating the argument once. The regularity of the solution R and of the eigenfunction Θ are obtained in the same way. ∎

Remark 5. Of course, when the velocity field u^0 does not oscillate with respect to time (i.e., $u^{0,\epsilon} = u^0(t,x;x/\epsilon)$), the corresponding solution of the cell problem Θ does not depend on the fast time variable τ.

4.3. Effective coefficients. Our proof of the homogenization result is based on the expansion of the dual equation. Therefore, we obtain the diffusion matrix and the drift velocity, given by (3.3) and (3.4), respectively, by means of dual formulae. Let us introduce $\chi^\star$, solution of the dual problem of (3.1), namely,

$$\mathcal{T}_0^\star(\chi^\star) = -\partial_\tau\chi^\star - u^0\cdot\nabla_y\chi^\star - \eta\Delta_y\chi^\star = u^0, \qquad \int_Y \chi^\star \,\mathrm{d}(\tau,y) = 0. \tag{4.5}$$

We can express D and v with $\chi^\star$ as follows. On the one hand, we have

$$\begin{aligned} D &= \int_Y u^0\otimes\chi \,\mathrm{d}(\tau,y) = \int_Y \mathcal{T}_0^\star(\chi^\star)\otimes\chi \,\mathrm{d}(\tau,y) \\ &= \int_Y \chi^\star\otimes\mathcal{T}_0(\chi) \,\mathrm{d}(\tau,y) = \int_Y \chi^\star\otimes(\Theta u^0 - 2\eta\nabla_y\Theta) \,\mathrm{d}(\tau,y), \end{aligned} \tag{4.6}$$

and on the other hand,

$$\begin{aligned} v - \int_Y u^1\Theta \,\mathrm{d}(\tau,y) &= \int_Y u^0\;\kappa \,\mathrm{d}(\tau,y) = \int_Y \mathcal{T}_0^\star(\chi^\star)\;\kappa \,\mathrm{d}(\tau,y) = \int_Y \chi^\star\mathcal{T}_0(\kappa) \,\mathrm{d}(\tau,y) \\ &= \int_Y \chi^\star\Big(- \mathrm{div}_x(\Theta u^0) - \mathrm{div}_y(\Theta u_1) + 2\eta\nabla_x\cdot\nabla_y\Theta\Big) \,\mathrm{d}(\tau,y). \end{aligned} \tag{4.7}$$

Of course, the crucial question relies on the positiveness of the diffusion coefficient. Actually, we shall see that (the symmetric part of) D can be nonpositive, while the sum $\eta+D$ remains nonnegative. To this end, it is particularly illuminating to consider the following fundamental examples.

The divergence free case. Suppose that $\mathrm{div}_y(u^0)=0$. In this case, $\Theta=1$ and the vanishing ballistic velocity condition is nothing but

$$\int_Y u^0 \,\mathrm{d}(\tau,y)=0.$$

The function χ satisfies

$$\mathcal{T}_0(\chi)=u^0\Theta=u^0.$$

Then, for $\xi\in\mathbb{R}^N\backslash\{0\}$, we have

$$\begin{aligned} D\xi\cdot\xi &= \int_Y u^0\cdot\xi\ \chi\cdot\xi\,\mathrm{d}(\tau,y)=\int_Y \mathcal{T}_0(\chi\cdot\xi)\ \chi\cdot\xi\ \ \mathrm{d}(\tau,y)\\ &= \eta\int_Y |\nabla_y(\chi\cdot\xi)|^2\ \ \mathrm{d}(\tau,y)\geq 0. \end{aligned}$$

The potential case. Suppose that u_0 does not depend on the variable τ and is of the form $u^0(t,x;y)=\nabla_y V(t,x;y)$ for some potential function $V:\mathbb{R}^+\times\mathbb{R}^N\times\mathbb{R}^N\to\mathbb{R}$, $[0,1]^N$-periodic with respect to the last variable. Then the operator $\mathcal{T}_0$ recasts in the symmetric form

$$\mathcal{T}_0(R)=\partial_\tau R-\eta\ \mathrm{div}_y\Big(e^{V/\eta}\ \nabla_y(e^{-V/\eta}\ R)\Big)$$

so that

$$\int_Y \mathcal{T}_0(R)R\ e^{-V/\eta}\,\mathrm{d}(\tau,y)=\eta\int_Y e^{V/\eta}\ |\nabla_y(Re^{-V/\eta})|^2\,\mathrm{d}(\tau,y).$$

We deduce that

$$\mathrm{Ker}(\mathcal{T}_0)=\mathrm{Span}\{e^{V/\eta}\},\qquad \Theta=Ze^{V/\eta},$$

$Z=(\int_Y e^{V/\eta}\,\mathrm{d}(\tau,y))^{-1}$ being a normalization constant. Notice that the vanishing ballistic velocity condition is fulfilled since

$$\int_Y u^0\ \Theta\ \ \mathrm{d}(\tau,y)=\eta Z\int_Y \nabla_y(e^{V/\eta})\ \ \mathrm{d}(\tau,y)=0.$$

Finally, the equation for χ reads

$$\mathcal{T}_0(\chi)=u^0\Theta-2\eta\nabla_y\Theta=-Z\nabla_y V\ e^{V/\eta}=-u^0\Theta.$$

(Notice the change of sign in the right-hand side in comparison to the divergence-free case.) Then, for $\xi\in\mathbb{R}^N\backslash\{0\}$, we have

$$\begin{aligned} D\xi\cdot\xi &= \int_Y u^0\cdot\xi\ \chi\cdot\xi\ \ \mathrm{d}(\tau,y)=-\int_Y(-u^0\Theta\cdot\xi)\ \chi\cdot\xi\ \Theta^{-1}\ \ \mathrm{d}(\tau,y)\\ &= -\int_Y \mathcal{T}_0(\chi\cdot\xi)\ \chi\cdot\xi\ \Theta^{-1}\,\mathrm{d}(\tau,y)=-\eta\int_Y \Theta\ |\nabla_y(\chi\cdot\xi\Theta^{-1})|^2\,\mathrm{d}(\tau,y)\leq 0, \end{aligned}$$

which reveals an antidiffusive effect. However, Avellaneda and Vergassola [5] pointed out that, in this potential case, the total diffusivity remains nonnegative, $(\eta+D)\xi\cdot\xi \geq 0$. Their argument can be generalized, as shown by the following statement.

PROPOSITION 4.6. *Let D be the matrix defined in* (3.3). *Then, for any $\xi \in \mathbb{R}^N\backslash\{0\}$, one has*

$$(\eta + D)\xi \cdot \xi > 0.$$

Proof. The proof starts with the dissipativity property of $\mathcal{T}_0^\star$, using an inner product with weight Θ. It was pointed out to us by Collet [10] that this property is general and applies for any elliptic operator of order 2 and more generally for any operator coming from Markovian processes (see Kubo [26]). We have

$$\begin{aligned}
\int_Y \mathcal{T}_0^\star(\Phi)\ \Phi\ \Theta\,\mathrm{d}(\tau,y) &= \int_Y (-\partial_\tau\Phi - u^0\cdot\nabla_y\Phi - \eta\Delta_y\Phi)\Phi\ \Theta\,\mathrm{d}(\tau,y)\\
&= -\int_Y \left(\partial_\tau\left(\frac{\Phi^2}{2}\right) + u^0\cdot\nabla_y\left(\frac{\Phi^2}{2}\right)\right)\ \Theta\ \mathrm{d}(\tau,y)\\
&\quad + \eta\int_Y \nabla_y\left(\frac{\Phi^2}{2}\right)\cdot\nabla_y\Theta\ \mathrm{d}(\tau,y) + \eta\int_Y |\nabla_y\Phi|^2\ \Theta\ \mathrm{d}(\tau,y)\\
&= \int_Y \frac{\Phi^2}{2}\ \mathcal{T}_0\Theta\,\mathrm{d}(\tau,y) + \eta\int_Y |\nabla_y\Phi|^2\ \Theta\,\mathrm{d}(\tau,y)\\
&= \eta\int_Y |\nabla_y\Phi|^2\ \Theta\,\mathrm{d}(\tau,y) \geq 0.
\end{aligned}$$

Then let us use the expression of D obtained in (4.6). We get

$$\begin{aligned}
D\xi\cdot\xi &= \int_Y \chi^\star\cdot\xi\ u^0\cdot\xi\ \Theta\ \mathrm{d}(\tau,y) - 2\eta\int_Y \chi^\star\cdot\xi\ \nabla_y\Theta\cdot\xi\ \mathrm{d}(\tau,y)\\
&= \int_Y \chi^\star\cdot\xi\ \mathcal{T}_0^\star(\chi^\star\cdot\xi)\ \Theta\ \mathrm{d}(\tau,y) + 2\eta\int_Y \Theta\ \xi\cdot\nabla_y\big(\chi^\star\cdot\xi\big)\,\mathrm{d}(\tau,y)\\
&= \eta\int_Y |\nabla_y(\chi^\star\cdot\xi)|^2\ \Theta\,\mathrm{d}(\tau,y) + 2\eta\int_Y \Theta\ \xi\cdot\nabla_y\big(\chi^\star\cdot\xi\big)\,\mathrm{d}(\tau,y).
\end{aligned}$$

Thus, we obtain

$$\begin{aligned}
(\eta + D)\xi\cdot\xi &= \eta\int_Y |\xi + \nabla_y(\chi^\star\cdot\xi)|^2\Theta\,\mathrm{d}(\tau,y) \geq 0\\
&= \eta\left(\int_Y (I + \nabla_y\chi^\star)\ (I + \nabla_y\chi^\star)^T\ \Theta\,\mathrm{d}(\tau,y)\right)\xi\cdot\xi,
\end{aligned}$$

since $\int_Y \Theta\,\mathrm{d}(\tau,y) = 1$. The above integral vanishes when for a.e. $(\tau,y)\in Y$, $\nabla_y(\chi^\star\cdot\xi) = -\xi$ does not depend on τ, y. By using the periodicity, it follows that $0 = \int_Y \nabla_y(\chi^\star\cdot\xi)\,\mathrm{d}(\tau,y) = -\xi|Y|$; thus $\xi = 0$. We conclude that the symmetric part of D is positive definite. ∎

Remark 6. It should be pointed out that it is crucial to take into account a positive diffusivity coefficient $\eta > 0$, even for the simple divergence-free case. In this case, we have $\Theta = 1$. Suppose there exists a vector-valued function χ solution of $\partial_\tau\chi + u^0\cdot\nabla_y\chi = u^0$. Then if $\eta = 0$, it is readily checked that $D\xi\cdot\xi = 0$, i.e., the "effective diffusion matrix" vanishes! Turbulent diffusivity strongly depends on the molecular diffusivity.

We have two kinds of results depending on whether or not u^0 satisfies the orthogonality relation $\int_Y u^0\ \Theta\,\mathrm{d}(\tau,y)=0$. We have seen that if u^0 is divergence free, this condition is nothing but the fact that u^0 has a zero mean value and that the condition is always satisfied in the potential case. When the orthogonality relation is satisfied, the result is complete. When it is not, the result is not complete in the sense that we do not know if the effective equations we obtain give rise to a well-posed problem.

4.4. Vanishing ballistic velocity. Let us first investigate the case of a vanishing ballistic velocity.

THEOREM 4.7. *Let $\eta>0$. Let $u^0,\ u^1\in C^{[2;1,\alpha]}_{\#}([0,\infty)\times\mathbb{R}^N\times\mathbb{R}^{N+1})$. Let Θ be defined as in Proposition* 4.5 *and suppose that*

$$\int_Y u^0(t,x;\tau,y)\ \Theta(t,x;\tau,y)\ \mathrm{d}(\tau,y)=0\qquad\forall(t,x)\in[0,\infty)\times\mathbb{R}^N \tag{4.8}$$

holds. Let $\left(\rho_I^\epsilon\right)_{\epsilon>0}$ be a bounded sequence of nonnegative measures on $\mathbb{R}^N$. We suppose that $\left(\rho_I^\epsilon\right)_{\epsilon>0}$ converges vaguely to ρ_I. Let $\rho^\epsilon(t)$ be the solutions of the advection diffusion problem (2.1), (2.2) *with*

$$u^\epsilon(t,x)=\frac{1}{\epsilon}\left(u^0\left(t,x,\frac{t}{\epsilon^2},\frac{x}{\epsilon}\right)+\epsilon u^1\left(t,x,\frac{t}{\epsilon^2},\frac{x}{\epsilon}\right)\right).$$

Then, up to the extraction of a subsequence, $\rho^\epsilon(t)\ge 0$ converges vaguely to $\rho(t)\ge 0$ locally and uniformly, and the limit $\rho(t)$ is a solution of

$$\partial_t\rho(t,x)+\mathrm{div}_x\big(\rho\ v\big)(t,x)-\mathrm{div}_x\left((D+\eta I_N)\cdot\nabla_x\rho\right)(t,x)=0 \tag{4.9}$$

in the sense of distributions with the Cauchy data $\rho(0)=\rho_I$. The coefficients are given by

$$\begin{aligned}
v(t,x)&=\int_Y u^1\ \Theta(t,x;\tau,y)\ \mathrm{d}(\tau,y)\\
&\quad-\int_Y\chi^\star\Big(\mathrm{div}_x(\Theta\ u^0)+\mathrm{div}_y(\Theta\ u^1)-2\eta\nabla_x\cdot\nabla_y\Theta\Big)(t,x;\tau,y)\ \mathrm{d}(\tau,y),\\
D(t,x)&=\int_Y\chi^\star\otimes(\Theta\ u^0-2\eta\nabla_y\Theta)(t,x;\tau,y)\ \mathrm{d}(\tau,y),
\end{aligned}$$

and $\chi^\star$ is the solution of

$$-\partial_\tau\chi^\star-u^0\cdot\nabla_y\chi^\star-\eta\Delta_y\chi^\star=u^0,\quad\int_Y\chi^\star\,\mathrm{d}(\tau,y)=0.$$

Remark 7. The statement can be strengthened when the velocity fields satisfy the divergence-free condition $\mathrm{div}_{x,y}u^{0,1}=0$. In this case, recall that $\Theta=1$. Assume the initial condition is converging in $L^2(\mathbb{R}^N)$: $\rho_I^\epsilon\to\rho_I$. Then one has L^2-estimates on both ρ^ϵ and $\nabla_x\rho^\epsilon$. Consequently, one has convergence of the solutions ρ^ϵ to ρ in $L^2(0,T;H^1(\mathbb{R}^N))$ weakly, and in $C^0([0,T];L^2(\mathbb{R}^N)\text{-}weak)$, and for a.e. $t\in[0,T]$, $\rho^\epsilon(t)\to\rho(t)$ strongly in $L^2(K)$ for any compact set $K\subset\mathbb{R}^N$.

Proof. By using standard results for parabolic equations, the solutions ρ^ϵ satisfy

$$\begin{cases}\forall(t,x)\in[0,\infty)\times\mathbb{R}^N,\ \rho^\epsilon(t,x)\ge 0,\\ \forall t\in[0,\infty),\ \displaystyle\int_{\mathbb{R}^N}\rho^\epsilon(t,x)\,\mathrm{d}x\le\int_{\mathbb{R}^N}\rho_I^\epsilon(x)\,\mathrm{d}x\le M,\end{cases} \tag{4.10}$$

where $M = \sup_{\epsilon>0}\ \rho_I^\epsilon(\mathbb{R}^N)$ is finite by assumption. Note that the conservation of mass $\int_{\mathbb{R}^N} \rho^\epsilon(t,x)\,\mathrm{d}x = \int_{\mathbb{R}^N} \rho_I^\epsilon(x)\,\mathrm{d}x$, which can be expected from formal arguments, is not obvious at all. To obtain this conservation law, an additional bound on $|u^\epsilon|$ is necessary. For instance, we have to assume $|u^0(t,x;\tau,y)| + |u^1(t,x;\tau,y)| \le C|x|$ for some constant $C > 0$. We will not address this problem in this work.

We cannot immediately use Proposition 4.3 for $\rho^\epsilon(t)$ since the equicontinuity with respect to time is far from clear: there is no obvious bound for $\partial_t\rho^\epsilon$ because of the singular term $\frac{1}{\epsilon}\mathrm{div}_x(u^0\rho^\epsilon)$. Actually we will use crucially the condition (4.8) to prove that the sequence $\rho^\epsilon(t)$ is equicontinuous. The idea is to recover the formal asymptotics of the previous subsection, but this time working on the test functions for the adjoint equation. Hence, let us define for any $\varphi \in C^2_{\#}(\mathbb{R}^N \times \mathbb{R}^{N+1})$ the following operators:

$$\begin{aligned}
\mathcal{T}_0^\star(\varphi)(t,x;\tau,y) &= -\partial_\tau\varphi(x;\tau,y) - u^0(t,x;\tau,y)\cdot\nabla_y\varphi(x;\tau,y) - \eta\Delta_y\varphi(x;\tau,y),\\
\mathcal{T}_1^\star(\varphi)(t,x;\tau,y) &= -u^1(t,x;\tau,y)\cdot\nabla_y\varphi(x;\tau,y) - u^0(t,x;\tau,y)\cdot\nabla_x\varphi(x;\tau,y)\\
&\quad -2\eta\nabla_x\cdot\nabla_y\varphi(x;\tau,y),\\
\mathcal{T}_2^\star(\varphi)(t,x;\tau,y) &= -u^1(t,x;\tau,y)\cdot\nabla_x\varphi(x;\tau,y) - \eta\Delta_x\varphi(x;\tau,y).
\end{aligned}$$

Step 1. Let $\varphi \in C^2_{c,\#}([0,\infty)\times\mathbb{R}^N\times\mathbb{R}^{N+1})$. By multiplying the equation by $\epsilon^2\,\varphi(t,x;t/\epsilon^2,x/\epsilon)$, we get

(4.11)
$$\int_{\mathbb{R}^N} \mathcal{T}_0^\star(\varphi)(t,x;t/\epsilon^2,x/\epsilon)\ \rho^\epsilon(t,x)\,\mathrm{d}x = -\epsilon\int_{\mathbb{R}^N}(\mathcal{T}_1^\star+\epsilon\mathcal{T}_2^\star)(\varphi)(t,x;t/\epsilon^2,x/\epsilon)\ \rho^\epsilon(t,x)\,\mathrm{d}x$$
$$-\epsilon^2\frac{\mathrm{d}}{\mathrm{d}t}\int_{\mathbb{R}^N}\varphi(t,x;t/\epsilon^2,x/\epsilon)\ \rho^\epsilon(t,x)\,\mathrm{d}x + \epsilon^2\int_{\mathbb{R}^N}\partial_t\varphi(t,x;t/\epsilon^2,x/\epsilon)\ \rho^\epsilon(t,x)\,\mathrm{d}x.$$

Then we obtain

$$\lim_{\epsilon\to0}\left(\int_{\mathbb{R}^N}\mathcal{T}_0^\star(\varphi)(t,x;t/\epsilon^2,x/\epsilon)\ \rho^\epsilon(t,x)\,\mathrm{d}x\right) = 0 \qquad \text{in } \mathcal{D}'(0,\infty) \tag{4.12}$$

for any $\varphi \in C^2_{c,\#}([0,\infty)\times\mathbb{R}^N\times\mathbb{R}^{N+1})$.

Step 2. In order to get rid of the leading term in the dual equation (4.11), we choose the test function of the form $\varphi(t,x;t/\epsilon^2,x/\epsilon) = \psi(x) + \epsilon\ \phi(t,x;t/\epsilon^2,x/\epsilon)$. We obtain

$$\begin{aligned}
&\frac{\mathrm{d}}{\mathrm{d}t}\int_{\mathbb{R}^N}(\psi+\epsilon\ \phi)\,(t,x;t/\epsilon^2,x/\epsilon)\rho^\epsilon(t,x)\,\mathrm{d}x\\
&\qquad = -\frac{1}{\epsilon}\int_{\mathbb{R}^N}\left(\mathcal{T}_1^\star(\psi)+\mathcal{T}_0^\star(\phi)\right)(t,x;t/\epsilon^2,x/\epsilon)\ \rho^\epsilon(t,x)\,\mathrm{d}x\\
&\qquad\quad -\int_{\mathbb{R}^N}\left(\mathcal{T}_2^\star(\psi)+\mathcal{T}_1^\star(\phi)\right)(t,x;t/\epsilon^2,x/\epsilon)\ \rho^\epsilon(t,x)\,\mathrm{d}x\\
&\qquad\quad +\epsilon\int_{\mathbb{R}^N}\left(\partial_t\phi-\mathcal{T}_2^\star(\phi)\right)(t,x;t/\epsilon^2,x/\epsilon)\ \rho^\epsilon(t,x)\,\mathrm{d}x.
\end{aligned} \tag{4.13}$$

Since ψ does not depend on the fast variables (τ,y), we remark that $\mathcal{T}_1^\star(\psi) = -u^0\cdot\nabla_x\psi$. Consequently, multiplying by ϵ, passing to the limit, and using (4.12) yield

$$\begin{aligned}
&\lim_{\epsilon\to0}\left(\int_{\mathbb{R}^N}\left(\mathcal{T}_1^\star(\psi)+\mathcal{T}_0^\star(\phi)(t,x;t/\epsilon^2,x/\epsilon)\right)\ \rho^\epsilon(t,x)\,\mathrm{d}x\right) = 0\\
&\qquad = \lim_{\epsilon\to0}\left(\int_{\mathbb{R}^N}u^0(t,x;t/\epsilon^2,x/\epsilon)\cdot\nabla_x\psi(x)\ \rho^\epsilon(t,x)\,\mathrm{d}x\right).
\end{aligned} \tag{4.14}$$

Up to now, condition (4.8) has not been used. We shall use the condition to write $u^0 \cdot \nabla_x \psi$ as $\mathcal{T}_0^\star(\phi)$ for a convenient choice of the function ϕ. Therefore, we realize that (4.14) is already contained in (4.12).

In order to go further we have to get rid of the term of order $1/\epsilon$ in (4.13). Let us introduce the vector-valued function $\chi^\star(t,x;\tau,y) \in \left(C_\#^{[2;2,\alpha]}([0,\infty)\times\mathbb{R}^N\times\mathbb{R}^{N+1})\right)^N$ as the solution of the adjoint cell problem

$$\mathcal{T}_0^\star(\chi^\star) = -\partial_\tau - u^0\cdot\nabla_y\chi^\star - \eta\Delta_y\chi^\star = u^0, \qquad \int_Y \chi^\star \,\mathrm{d}(\tau,y) = 0.$$

The function $\chi^\star$ is well defined thanks to Proposition 4.5 and to condition (4.8). We choose the test function ϕ depending on ψ as follows:

$$\phi(t,x;\tau,y) = \chi^\star(t,x;\tau,y)\cdot\nabla_x\psi(x).$$

Assuming $\psi \in C_c^3(\mathbb{R}^N)$, we have $\phi \in C_{c,\#}^{[2;2,\alpha]}([0,T]\times\mathbb{R}^N\times\mathbb{R}^{N+1})$ for any $T>0$. The crucial fact is that $\mathcal{T}_0^\star(\phi) = \mathcal{T}_0^\star(\chi^\star)\cdot\nabla_x\psi = u^0\cdot\nabla_x\psi = -\mathcal{T}_1^\star(\psi)$. Consequently, we recover (4.12) from (4.14). Furthermore, the $\frac{1}{\epsilon}$ term in (4.13) vanishes. We deduce the estimate

$$\left|\frac{\mathrm{d}}{\mathrm{d}t}\int_{\mathbb{R}^N}(\psi+\epsilon\,\phi)\,(t,x;t/\epsilon^2,x/\epsilon)\;\rho^\epsilon(t,x)\,\mathrm{d}x\right| \le C(\psi). \tag{4.15}$$

Moreover, passing to the limit $\epsilon\to 0$, we are led to

$$\lim_{\epsilon\to 0}\left(\frac{\mathrm{d}}{\mathrm{d}t}\int_{\mathbb{R}^N}\psi(x)\;\rho^\epsilon(t,x)\,\mathrm{d}x + \int_{\mathbb{R}^N}\left(\mathcal{T}_2^\star(\psi)+\mathcal{T}_1^\star(\phi)\right)(t,x;t/\epsilon^2,x/\epsilon)\;\rho^\epsilon(t,x)\,\mathrm{d}x\right) = 0 \tag{4.16}$$

for any $\psi\in C_c^3(\mathbb{R}^N)$ with $\phi(t,x;\tau,y) = \chi^\star(t,x;\tau,y)\cdot\nabla_x\psi(x)$.

Step 3. We are now ready to obtain the equicontinuity of $\rho^\epsilon(t)$. Indeed, the bound (4.15) shows that for any $\psi\in C_c^3(\mathbb{R}^N)$ the sequence of functions

$$t\longmapsto\int_{\mathbb{R}^N}(\psi+\epsilon\,\phi)\,(t,x;t/\epsilon^2,x/\epsilon)\;\rho^\epsilon(t,x)\,\mathrm{d}x$$

is equicontinuous on $[0,\infty)$. Since the family of functions

$$t\longmapsto\int_{\mathbb{R}^N}\psi(x)\;\rho^\epsilon(t,x)\,\mathrm{d}x$$

is close, up to ϵ, to the previous sequence, it is also equicontinuous. The density of $C_c^3(\mathbb{R}^N)$ in $C_c^0(\mathbb{R}^N)$ allows us to conclude that $\rho^\epsilon(t)$ is vaguely equicontinuous on $[0,\infty)$. Thanks to (4.10) we can apply Propositions 4.3 and 4.4 to the sequence $\rho^\epsilon(t)$.

Step 4. Up to a subsequence there is a double-scale limit R of $\rho^\epsilon(t)$ and the vague limit of $\rho^\epsilon(t)$ is given by the marginal $\rho(t,x) = \int_Y R(t,x;\tau,y)\,\mathrm{d}(\tau,y)$. The limits (4.12) and (4.16) now become

$$\int_0^\infty\int_{\mathbb{R}^N}\int_Y \mathcal{T}_0^\star(\varphi)(t,x;\tau,y)\;R(t,x;\tau,y)\,\mathrm{d}(\tau,y)\,\mathrm{d}x\,\mathrm{d}t = 0 \qquad \forall\varphi\in C_{c,\#}^2([0,\infty)\times\mathbb{R}^N\times\mathbb{R}^{N+1}), \tag{4.17}$$

and, in the distribution sense on $[0,\infty)$,

$$\frac{\mathrm{d}}{\mathrm{d}t}\int_{\mathbb{R}^N}\psi(x)\ \rho(t,x)\,\mathrm{d}x+\int_{\mathbb{R}^N}\int_Y\left(\mathcal{T}_2^\star(\psi)+\mathcal{T}_1^\star(\phi)\right)\ R\ (t,x;\tau,y)\,\mathrm{d}(\tau,y)\,\mathrm{d}x=0$$
$$\forall\psi\in C_c^3(\mathbb{R}^N)\text{ with }\phi=\chi^\star(t,x;\tau,y)\cdot\nabla_x\psi(x), \tag{4.18}$$

respectively. By formally using Proposition 4.5, (4.17) means that the double-scale limit R lies in the orthogonal set of $\mathrm{Ran}(\mathcal{T}_0^\star)=(\mathrm{Ker}(\mathcal{T}_0))^\perp=(\mathrm{Span}\{\Theta\})^\perp$; thus $R\in\mathrm{Span}\{\Theta\}$, which corresponds to the first step of the formal asymptotics. Let us make this argument rigorous (it does not work due to the lack of regularity of the limit R).

Thanks to Proposition 4.5, we obtain from (4.17) that, for any $H\in C_\#^{[0;0,\alpha]}([0,\infty)\times\mathbb{R}^N\times\mathbb{R}^{N+1})$ verifying $\int_Y H\ \Theta\,\mathrm{d}(\tau,y)=0$, we have

$$\int_0^\infty\int_{\mathbb{R}^N}\int_Y H(t,x;\tau,y)\ R(t,x;\tau,y)\,\mathrm{d}(\tau,y)\,\mathrm{d}x\,\mathrm{d}t=0.$$

Let $\varphi\in C_\#^{[0;0,\alpha]}([0,\infty)\times\mathbb{R}^N\times\mathbb{R}^{N+1})$. We write

$$\varphi(t,x;\tau,y)=c_\varphi(t,x)\Theta(t,x;\tau,y)+(\varphi(t,x;\tau,y)-c_\varphi(t,x)\Theta(t,x;\tau,y)),$$

where

$$c_\varphi(t,x)=\left(\int_Y\varphi(t,x;z)\ \Theta(t,x;z)\,\mathrm{d}z\right)\Big/\left(\int_Y\ \Theta(t,x;\tau,y)^2\,\mathrm{d}(\tau,y)\right).$$

Since $\int_Y(\varphi-c_\varphi\Theta)\ R\ \mathrm{d}(\tau,y)=0$, we obtain

$$\begin{aligned}\int_0^\infty\int_{\mathbb{R}^N}\int_Y&\ \varphi\,(t,x;\tau,y)\ R(t,x;\tau,y)\,\mathrm{d}(\tau,y)\,\mathrm{d}x\,\mathrm{d}t\\&=\int_0^\infty\int_{\mathbb{R}^N}c_\varphi(t,x)\left(\int_Y\Theta(t,x;\tau,y)R(t,x;\tau,y)\,\mathrm{d}(\tau,y)\right)\mathrm{d}x\,\mathrm{d}t\\&=\int_0^\infty\int_{\mathbb{R}^N}\int_Y\varphi(t,x;\tau,y)\ \widetilde{\rho}(t,x)\Theta(t,x;\tau,y)\,\mathrm{d}(\tau,y)\,\mathrm{d}x\,\mathrm{d}t,\end{aligned}$$

where $\widetilde{\rho}(t,x)=\int_Y\Theta(t,x;\tau,y)R(t,x;\tau,y)\,\mathrm{d}(\tau,y)\times\big(\int_Y\ \Theta(t,x;\tau,y)^2\,\mathrm{d}(\tau,y)\big)^{-1}$. Hence, it shows that $R(t,x;\tau,y)=\widetilde{\rho}(t,x)\Theta(t,x;\tau,y)$. Furthermore, using $\int_Y\Theta\,\mathrm{d}(\tau,y)=1$, we have $\widetilde{\rho}=\rho$, the weak limit of ρ^ϵ. Plugging this result into (4.18) gives the desired equation for $\rho(t,x)$ and ends the proof of Theorem 4.7. Note that in this way we obtain the diffusion matrix and the drift velocity with the dual formulae (4.6) and (4.7), respectively. ∎

4.5. Nonvanishing ballistic velocity. We can follow step by step the same strategy without assuming condition (4.8). Of course, we cannot define in this situation $\chi^\star$ by (4.5) since the right-hand side does not fulfill the solvability condition. We have to take into account the ballistic velocity

$$c(t,x)=\int_Y u^0\ \Theta(t,x;\tau,y)\,\mathrm{d}(\tau,y)\neq 0.$$

Then we are led to the following statement.

THEOREM 4.8. *Let the assumptions of Theorem* 4.7 *be fulfilled, except for* (4.8). *Then, up to a subsequence,* $\rho^\epsilon \geq 0$ *converges to* ρ *in the vague sense for measures on* $[0,\infty)\times\mathbb{R}^N$. *The limit* ρ *satisfies*

$$\mathrm{div}_x(c\ \rho) = 0$$

in the sense of distributions on $[0,\infty)\times\mathbb{R}^N$. *Moreover, for any* $\psi \in C_c^2([0,\infty)\times\mathbb{R}^N)$ *which satisfies* $c(t,x)\cdot\nabla_x\psi(t,x) = 0$ *for all* $(t,x)\in[0,\infty)\times\mathbb{R}^N$, *we have*

$$\int_{\mathbb{R}^N} \psi(t,x)\ \rho^\epsilon(t,x)\,\mathrm{d}x \xrightarrow[\epsilon\to 0]{} \int_{\mathbb{R}^N} \psi(t,x)\ \rho(t,x)\,\mathrm{d}x,$$

uniformly on any interval $[0,T]$, $0<T<\infty$. *Furthermore, for any such test function* ψ, *the limit satisfies*

$$\frac{\mathrm{d}}{\mathrm{d}t}\int_{\mathbb{R}^N}\psi\rho(t,x)\,\mathrm{d}x = \int_{\mathbb{R}^N}\Big(\partial_t\psi\ + v\cdot\nabla_x\psi + \mathrm{div}_x\big(D^T\cdot\nabla_x\psi\big)\ + \eta\Delta_x\psi\Big)\ \rho\,\mathrm{d}x,$$

$$\int_{\mathbb{R}^N}\psi\rho(0,x)\,\mathrm{d}x = \int_{\mathbb{R}^N}\psi\rho_I(x)\,\mathrm{d}x,$$

where D^T *is the transpose of the matrix* D. *Here* D *and* v *are defined as in Theorem* 4.7 *but with* $\chi^\star$ *as the solution of*

$$\mathcal{T}_0^\star(\chi^\star) = u^0 - c, \qquad \int_Y \chi^\star\,\mathrm{d}(\tau,y) = 0. \tag{4.19}$$

Proof. The $L^\infty(0,T;L^1(\mathbb{R}^N))\subset L^1((0,T)\times\mathbb{R}^N)$ estimate on ρ^ϵ allows us to assume that, for a subsequence, $\rho^\epsilon \rightharpoonup \rho$ vaguely in $\mathcal{M}^1((0,T)\times\mathbb{R}^N)$. In Step 2, we rewrite (4.14) as

$$\int_0^T\int_{\mathbb{R}^N}\Big((c-u^0)\cdot\nabla_x\psi + \mathcal{T}_0^\star(\phi)\Big)(t,x;t/\epsilon^2,x/\epsilon)\ \rho^\epsilon\,\mathrm{d}x\,\mathrm{d}t$$

$$-\int_0^T\int_{\mathbb{R}^N} c\cdot\nabla_x\psi\ \rho^\epsilon\,\mathrm{d}x\,\mathrm{d}t \to 0 \quad \text{as } \epsilon\to 0.$$

For a given function ψ, we choose ϕ such that the first integral in this expression vanishes. Namely, we set $\phi(t,x;\tau,y) = \chi^\star(t,x;\tau,y)\cdot\nabla_x\psi(t,x)$, $\chi^\star$ being defined by (4.19). We deduce that

$$\int_0^T\int_{\mathbb{R}^N} c\cdot\nabla_x\psi\ \rho\,\mathrm{d}x\,\mathrm{d}t = 0$$

for any test function ψ. Then, considering now a test function verifying $c\cdot\nabla_x\psi = 0$, we can reproduce the arguments of the proof of Theorem 4.7. ∎

Let q be a (scalar) distribution on $(0,T)\times\mathbb{R}^N$. Clearly, $T = \mathrm{div}_x(c\ q)$ belongs to the orthogonal of $E = \{\psi : \mathbb{R}\times\mathbb{R}^N\to\mathbb{R}$, such that $c\cdot\nabla_x\psi = 0\}$. At least formally, the elements T of $E^\perp$ always have this form. Indeed, let us introduce the symmetric degenerate elliptic operator $\mathcal{A}(\psi) = -\mathrm{div}_x(c\otimes c\nabla_x\psi)$. Remarking that $\int_{\mathbb{R}^N}\mathcal{A}(\psi)\ \psi\,\mathrm{d}x = \int_{\mathbb{R}^N}|c\cdot\nabla_x\psi|^2\,\mathrm{d}x$, we have $E = \mathrm{Ker}(\mathcal{A})$. Thus, formally, a distribution $T\in E^\perp$ lies in the range of $\mathcal{A}$. This means that $T = \mathcal{A}(p) = \mathrm{div}_x(cq)$, with $q = -c\nabla_x p$. In these conditions the equations for ρ read

$$\begin{cases} \mathrm{div}_x(c\ \rho) = 0, \\ \partial_t\rho + \mathrm{div}_x(v\ \rho) - \mathrm{div}_x\Big((D+\eta I_N)\nabla_x\rho\Big) = \mathrm{div}_x(c\ q) \end{cases}$$

and q appears as a Lagrange multiplier associated to the constraint $\mathrm{div}_x(c\ \rho) = 0$.

Actually it is possible that the second part of the statement is meaningless. For instance, consider the simple case $c = (1, 0, \dots) \in \mathbb{R}^N$. Thus, $\mathrm{div}_x(c\rho) = 0 = \partial_{x_1}\rho = 0$ means that ρ does not depend on the first variable. Since ρ is a bounded measure on $\mathbb{R}^N$, this implies that $\rho = 0$! According to this example, the set of compactly supported test functions verifying $c \cdot \nabla_x \psi = 0$ can be reduced to $\{0\}$ (this is the case in the autonomous case with characteristics curves verifying $|X(s,x)| \to \infty$ as $s \to \infty \dots$).

The simplest way to treat this difficulty consists of changing the time scale. Let us define $s = t/\epsilon$. Then we study

$$\frac{1}{\epsilon}\partial_s \rho^\epsilon(s,x) + \frac{1}{\epsilon}\mathrm{div}_x\big((u^0 + \epsilon u^1)(\epsilon s, x; s/\epsilon, x/\epsilon)\ \rho^\epsilon(s,x)\big) = \eta\ \Delta_x \rho^\epsilon(s,x)$$

instead of (2.1), (2.3). At least formally we can replace $u^i(\epsilon s)$ by $u^i(0)$. In this case we have only to consider velocities fields independent on the time scale s. For the sake of generality we consider the problem

$$\frac{1}{\epsilon}\partial_s \rho^\epsilon(s,x) + \frac{1}{\epsilon}\mathrm{div}_x\big((u^0 + \epsilon u^1)(s, x; s/\epsilon, x/\epsilon)\ \rho^\epsilon(s,x)\big) = \eta\ \Delta_x \rho^\epsilon(s,x) \tag{4.20}$$

$$\forall (s,x) \in (0,\infty) \times \mathbb{R}^N,$$

$$\rho^\epsilon(0,x) = \rho_I^\epsilon(x) \qquad \forall x \in \mathbb{R}^N. \tag{4.21}$$

The initial data ρ_I^ϵ is still assumed to be a bounded sequence of nonnegative measures which converges vaguely to ρ_I. Therefore, the sequence of solution satisfies the uniform estimate (4.10). The behavior as ϵ goes to 0 is then simply described by the transport equation with velocity $c(s,x) = \int_Y u^0\ \Theta\,\mathrm{d}(\tau, y)$.

THEOREM 4.9. *Let ρ^ϵ be the solution of* (4.20), (4.21). *We assume that ρ_I^ϵ is a bounded sequence of nonnegative measures which converges vaguely to ρ_I. Then ρ^ϵ converges vaguely locally, uniformly on $\mathbb{R}^+$ to ρ, the solution of the transport equation*

$$\partial_s \rho + \mathrm{div}_x(c\rho) = 0$$

with initial data ρ_I.

Proof. We still follow the strategy of the proof of Theorem 4.7. Multiplying (4.20) by $\varphi(s,x;s/\epsilon,x/\epsilon)$ yields

$$\int_{\mathbb{R}^N} \mathcal{T}_0^\star(\varphi)(s,x;s/\epsilon,x/\epsilon)\ \rho^\epsilon(s,x)\,\mathrm{d}x = -\epsilon \int_{\mathbb{R}^N} (\mathcal{T}_1^\star + \epsilon \mathcal{T}_2^\star)(\varphi)(s,x;s/\epsilon,x/\epsilon)\ \rho^\epsilon(s,x)\,\mathrm{d}x \tag{4.22}$$
$$-\epsilon\ \frac{\mathrm{d}}{\mathrm{d}s}\int_{\mathbb{R}^N} \varphi(s,x;s/\epsilon,x/\epsilon)\ \rho^\epsilon(s,x)\,\mathrm{d}x + \epsilon\ \int_{\mathbb{R}^N} \partial_s\varphi(s,x;s/\epsilon,x/\epsilon)\ \rho^\epsilon(s,x)\,\mathrm{d}x.$$

Hence, we recover (4.12). Then we use $\varphi(s,x;\tau,y) = \psi(x) + \epsilon\phi(s,x;\tau,y)$ as a test function so that the ϵ^0 term in (4.22) disappears. We get

$$\frac{\mathrm{d}}{\mathrm{d}s}\int_{\mathbb{R}^N} (\psi + \epsilon\phi)(s,x;s/\epsilon,x/\epsilon)\ \rho^\epsilon(s,x)\,\mathrm{d}x - \epsilon\int_{\mathbb{R}^N} \partial_s\phi(s,x;s/\epsilon,x/\epsilon)\ \rho^\epsilon(s,x)\,\mathrm{d}x \tag{4.23}$$
$$= \int_{\mathbb{R}^N} (u^0\cdot\nabla_x\psi - \mathcal{T}_0^\star(\phi))(s,x;s/\epsilon,x/\epsilon)\ \rho^\epsilon(s,x)\,\mathrm{d}x$$
$$+ \epsilon\int_{\mathbb{R}^N} \Big((u^1\cdot\nabla_x\psi + \eta\Delta_x\psi) + (\mathcal{T}_1^\star + \epsilon\mathcal{T}_2^\star)(\phi)\Big)(s,x;s/\epsilon,x/\epsilon)\ \rho^\epsilon(s,x)\,\mathrm{d}x.$$

We deduce that $(s \mapsto \int_{\mathbb{R}^N} \psi \rho^\epsilon \, \mathrm{d}x)_{\epsilon>0}$ is equicontinuous on $\mathbb{R}^+$, and thus we prove the compactness of ρ^ϵ. Next, the last term in (4.23) goes to 0 as $\epsilon \to 0$. The first term in the right-hand side can be recast as

$$\int_{\mathbb{R}^N} \Big((u^0 - c) \cdot \nabla_x \psi - \mathcal{T}_0^\star(\phi) \Big)(s, x; s/\epsilon, x/\epsilon) \ \rho^\epsilon(s, x) \, \mathrm{d}x + \int_{\mathbb{R}^N} c(s, x) \cdot \nabla_x \psi \ \rho^\epsilon(s, x) \, \mathrm{d}x.$$

Hence, we choose ϕ depending on ψ so that the first integral vanishes. Namely, we set $\phi = \chi^\star \cdot \nabla_x \psi$ with $\mathcal{T}_0^\star(\chi^\star) = (u^0 - c)$. Then, letting $\epsilon \to 0$, we obtain the relation

$$\frac{\mathrm{d}}{\mathrm{d}s} \int_{\mathbb{R}^N} \psi \ \rho(s, x) \, \mathrm{d}x - \int_{\mathbb{R}^N} c(s, x) \cdot \nabla_x \psi \ \rho(s, x) \, \mathrm{d}x = 0,$$

which ends the proof. □

Remark 8. The situation we observe is reminiscent to the hydrodynamic limits in kinetic theory. There, the small parameter is related to the Knudsen number, i.e., the ratio of the mean-free path over some characteristic length. When the flux associated to the equilibrium states of the equation vanishes, a parabolic scaling has to be considered. It corresponds to the vanishing ballistic velocity in this work. Conversely, when the flux does not vanish (nonvanishing ballistic velocity), a hyperbolic scaling has to be used which corresponds to a faster time scale. We refer to the lecture notes of Golse [17] for a presentation of these questions.

More precise information can be given when we restrict ourselves to purely periodic velocity fields. Namely, we assume that $u^{0,1}$ do not depend on t, x but only on the fast variables $(\tau, y) \in Y$. Consequently, the ballistic velocity c is constant. In such a case, there is no mixing of the time scales, and we can give a result incorporating both the transport through the ballistic velocity and the diffusion at the parabolic time scale. A similar approach has been introduced by Mellet in kinetic theory; see [18]. We also mention the interesting attempts due to Capdeboscq [8, 9].

THEOREM 4.10. *Let $\eta > 0$ and let $u^0, \ u^1 \in C_\#^{[1,\alpha]}(\mathbb{R}^{N+1})$. Let $\left(\rho_I^\epsilon\right)_{\epsilon>0}$ be a bounded sequence of nonnegative measures on $\mathbb{R}^N$. We suppose that $\left(\rho_I^\epsilon\right)_{\epsilon>0}$ converges vaguely to ρ_I. Let $\rho^\epsilon(t)$ be the solutions of the advection diffusion problem* (2.1), (2.2) *with*

$$u^\epsilon(t, x) = \frac{1}{\epsilon} \left(u^0 \left(\frac{t}{\epsilon^2}, \frac{x}{\epsilon} \right) + \epsilon u^1 \left(\frac{t}{\epsilon^2}, \frac{x}{\epsilon} \right) \right).$$

Then, up to a subsequence, $\widetilde{\rho}^\epsilon(t, x) = \rho^\epsilon(t, x + ct/\epsilon)$ converges vaguely locally, uniformly on $\mathbb{R}^+$ to $\widetilde{\rho}$, the solution of the drift-diffusion equation

$$\partial_t \widetilde{\rho} + \mathrm{div}_x(v\widetilde{\rho} - D\nabla_x \widetilde{\rho}) = 0$$

with initial data ρ_I. The velocity v is defined as in Theorem 4.7, *while*

$$D = \int_Y \chi^\star \otimes \big(\Theta(u^0 - c) - 2\eta \nabla_y \Theta \big) \, \mathrm{d}(\tau, y)$$

with $\chi^\star$ solution of $\mathcal{T}_0^\star(\chi^\star) = u^0 - c$.

Proof. We remark that $\widetilde{\rho}^\epsilon$ is the solution of the advection-diffusion problem (2.1), (2.2), with u^ϵ replaced by

$$\widetilde{u}^\epsilon(t, x) = \frac{1}{\epsilon} \left(\widetilde{u}^0 \left(\frac{t}{\epsilon^2}, \frac{x}{\epsilon} \right) + \epsilon \widetilde{u}^1 \left(\frac{t}{\epsilon^2}, \frac{x}{\epsilon} \right) \right),$$
$$\widetilde{u}^0(\tau, y) = u^0(\tau, y + c\tau) - c, \quad \widetilde{u}^1(\tau, y) = u^1(\tau, y + c\tau).$$

The functions $\widetilde{u}^i,\ i=1,2$, are not Y-periodic. But if $(e_0,e_1,\dots,e_N)$ is the canonical basis of $\mathbb{R}^{N+1}$, the new cell basis is $(e_0-c,e_1,\dots,e_N)$ corresponding to the cell

$$\widetilde{Y}=\{(\tau,y)/\tau\in(0,1),\ y\in -c\,\tau+(0,1)^N\}.$$

The functions $\widetilde{u}^i,\ i=1,2$, are $\widetilde{Y}$-periodic. It is easily checked that the null function of the new cell problem is then $\widetilde{\Theta}(\tau,y)=\Theta(\tau,y+c\tau)$. As a consequence we have

$$\int_{\widetilde{Y}}\widetilde{u}^0\ \widetilde{\Theta}(\tau,y)\ \mathrm{d}(\tau,y)=\int_Y(u^0-c)\Theta(\tau,y)\ \mathrm{d}(\tau,y)=0.$$

Then $\widetilde{u}^0$ satisfies the vanishing ballistic velocity condition and we can apply Theorem 4.7. This leads to the result. Note that it is crucial that $u^{0,1}$ depends only on (τ,y) and c is constant. ∎

5. Dissipation properties. The only immediate estimate on $\rho^\epsilon(t)$ is in the space L^1, by using the conservative form of the equation. The asymptotic behavior stated in Theorem 4.7 is obtained for a limit $\rho(t)$, which is a priori only a measure. In this functional framework, there is no uniqueness of the solution of the limit effective advection-diffusion problem. In this subsection we want to recover uniqueness (and regularity) of the limit. Assuming more bounds on the initial data, it is possible to obtain more involved dissipation properties of the equation. Actually, quantities like

$$\int H(\rho^\epsilon/\Psi^\epsilon)\ \Psi^\epsilon\,\mathrm{d}x$$

can be uniformly bounded for convex functions H and a suitable choice of $\Psi^\epsilon>0$.

As a preliminary, we establish a general dissipation property which is a consequence of dissipativity of Markovian processes (see [26]) as it is explained by Collet in [10].

PROPOSITION 5.1. *Let*

$$\mathcal{T}=\partial_t\cdot+\sum_{i=1}^N\partial_{x_i}(u_i(t,x)\cdot)-\sum_{i,j=1}^N\partial_{x_i}(a_{ij}(t,x)\partial_{x_j}\cdot)$$

with bounded coefficients u_i,a_{ij} verifying $\sum_{ij}a_{ij}\xi_i\xi_j\geq 0$ for any $\xi\in\mathbb{R}^N$. Let $H:\mathbb{R}\to\mathbb{R}$ be a C^2 convex function. Let ρ and Ψ be in $H^1_{\mathrm{loc}}(\mathbb{R}^{N+1})$, with $\Psi>0$. Then we have

$$\begin{aligned}\mathcal{T}\left(H\left(\frac{\rho}{\Psi}\right)\ \Psi\right)-H'\left(\frac{\rho}{\Psi}\right)\mathcal{T}(\rho)-G\left(\frac{\rho}{\Psi}\right)\mathcal{T}(\Psi)\\ =-\sum_{i,j=1}^N H''\left(\frac{\rho}{\Psi}\right)\ \Psi\ a_{ij}\partial_i\left(\frac{\rho}{\Psi}\right)\ \partial_j\left(\frac{\rho}{\Psi}\right)\leq 0,\end{aligned}$$

with $G(s)=H(s)-sH'(s)$.

The assumptions on ρ and Ψ allow us to use the chain rule for the functions $\rho,\ \Psi$, and $\frac{\rho}{\Psi}$. Then the above proposition is a consequence of two computations whose results are given in the following lemma.

LEMMA 5.2. *Let $\rho,\Psi:\mathbb{R}^{N+1}\to\mathbb{R}$ be as in Proposition* 5.1. *Let $a:\mathbb{R}^{N+1}\to\mathbb{R}$ be a bounded coefficient. Let $H:\mathbb{R}\to\mathbb{R}$ be a C^2 function. Denote by ∂ any derivative in $\mathbb{R}^{N+1}$. We have*

$$\partial\left(H\left(\frac{\rho}{\Psi}\right)\ a\ \Psi\right)=G\left(\frac{\rho}{\Psi}\right)\ \partial(a\Psi)+H'\left(\frac{\rho}{\Psi}\right)\ \partial(a\rho)$$

with $G(s)=H(s)-sH'(s)$.

Proof. We compute

$$\begin{aligned}\partial\left(H\left(\frac{\rho}{\Psi}\right)\ a\ \Psi\right) &= H'\left(\frac{\rho}{\Psi}\right)\ \partial\left(\frac{\rho}{\Psi}\right)\ a\ \Psi + H\left(\frac{\rho}{\Psi}\right)\ \partial(a\Psi)\\ &= H'\left(\frac{\rho}{\Psi}\right)\ \left(\partial\left(\frac{\rho}{\Psi}\ a\ \Psi\right) - \frac{\rho}{\Psi}\partial(a\Psi)\right) + H\left(\frac{\rho}{\Psi}\right)\ \partial(a\Psi)\\ &= \left(H\left(\frac{\rho}{\Psi}\right) - \frac{\rho}{\Psi}H'\left(\frac{\rho}{\Psi}\right)\right)\partial(a\Psi) + H'\left(\frac{\rho}{\Psi}\right)\ \partial(a\rho). \qquad \square\end{aligned}$$

LEMMA 5.3. *We keep the notation of Lemma* 5.2. *Denote by* ∂_i, ∂_j *any derivatives in* $\mathbb{R}^{N+1}$. *We have*

$$\begin{aligned}\partial_i\left(a\partial_j\left[H\left(\frac{\rho}{\Psi}\right)\ \Psi\right]\right) &= G\left(\frac{\rho}{\Psi}\right)\ \partial_i(a\partial_j\Psi) + H'\left(\frac{\rho}{\Psi}\right)\ \partial_i(a\partial_j\rho)\\ &\quad + H''\left(\frac{\rho}{\Psi}\right)\ a\Psi\ \partial_i\left(\frac{\rho}{\Psi}\right)\ \partial_j\left(\frac{\rho}{\Psi}\right).\end{aligned}$$

Proof. We compute

$$\begin{aligned}&\partial_i\left(a\partial_j\left[H\left(\frac{\rho}{\Psi}\right)\ \Psi\right]\right) = \partial_i\left(aH'\left(\frac{\rho}{\Psi}\right)\ \partial_j\left(\frac{\rho}{\Psi}\right)\ \Psi + aH\left(\frac{\rho}{\Psi}\right)\partial_j\Psi\right)\\ &= a\Psi\ H''\left(\frac{\rho}{\Psi}\right)\partial_i\left(\frac{\rho}{\Psi}\right)\ \partial_j\left(\frac{\rho}{\Psi}\right) + H'\left(\frac{\rho}{\Psi}\right)\ \left[\partial_i\left(a\partial_j\left(\frac{\rho}{\Psi}\right)\ \Psi\right) + \partial_i\left(\frac{\rho}{\Psi}\right)\ a\partial_j\Psi\right]\\ &\quad + H\left(\frac{\rho}{\Psi}\right)\ \partial_i(a\partial_j\Psi).\end{aligned}$$

Then we observe that

$$\begin{aligned}\partial_i\left(a\partial_j\left(\frac{\rho}{\Psi}\right)\ \Psi\right) &= \partial_i\left(a\partial_j\left(\frac{\rho}{\Psi}\ \Psi\right)\right) - a\frac{\rho}{\Psi}\partial_j\Psi\Big)\\ &= \partial_i(a\partial_j\rho) - \frac{\rho}{\Psi}\partial_i(a\partial_j\Psi) - \partial_i\left(\frac{\rho}{\Psi}\right)\ a\partial_j\Psi.\end{aligned}$$

Hence, we get

$$\begin{aligned}\partial_i\left(a\partial_j\left[H\left(\frac{\rho}{\Psi}\right)\ \Psi\right]\right) &= a\Psi\ H''\left(\frac{\rho}{\Psi}\right)\partial_i\left(\frac{\rho}{\Psi}\right)\ \partial_j\left(\frac{\rho}{\Psi}\right)\\ &\quad + H'\left(\frac{\rho}{\Psi}\right)\ \left[\partial_i(a\partial_j\rho) - \frac{\rho}{\Psi}\partial_i(a\partial_j\Psi)\right] + H\left(\frac{\rho}{\Psi}\right)\ \partial_i(a\partial_j\Psi)\\ &= a\Psi\ H''\left(\frac{\rho}{\Psi}\right)\partial_i\left(\frac{\rho}{\Psi}\right)\ \partial_j\left(\frac{\rho}{\Psi}\right) + H'\left(\frac{\rho}{\Psi}\right)\ \partial_i(a\partial_j\rho)\\ &\quad + \left(H\left(\frac{\rho}{\Psi}\right) - \frac{\rho}{\Psi}H'\left(\frac{\rho}{\Psi}\right)\right)\ \partial_i(a\partial_j\Psi). \qquad \square\end{aligned}$$

Then we apply Proposition 5.1 with the operator $\mathcal{T}_\epsilon$, ρ^ϵ, and $\Psi^\epsilon = (\Theta + \epsilon\kappa)(t, x; t/\epsilon^2, x/\epsilon)$, where we recall that κ is the solution of the cell problem $\mathcal{T}_0(\kappa) = -\mathcal{T}_1(\Theta)$. We know (Proposition 4.5) that Θ and κ are continuous function and that Θ is positive. Therefore on every compact K of $\mathbb{R}^{n+1}$ they are bounded and Θ is bounded from below. It guarantees that on K, for ϵ small enough, Ψ^ϵ is bounded from above and below. Of course, positivity of Ψ^ϵ is not guaranteed in the whole space. For that we have to assume a uniform behavior of $u^{0,1}$ at infinity. This problem disappears if the problem (2.1), (2.2) is posed on a bounded domain with periodic or Dirichlet conditions. We deduce the following corollary.

COROLLARY 5.4. *With the same assumption as in Theorem* 4.7, *let* ρ^ϵ *be the solution of the problem* (2.1), (2.2) *on* $[0,\infty)\times\Omega$. *Let us assume the following:*

- $\Omega=\mathbb{R}^N$, *and the functions* Θ, κ *and their derivatives are bounded and* Θ *is bounded from below; or*
- Ω *is a cell or a smooth bounded domain, and the problem is completed by periodic or Dirichlet conditions.*

Set $\Psi^\epsilon(t,x)=(\Theta+\epsilon\kappa)(t,x;t/\epsilon^2,x/\epsilon)>0$, *which is bounded from above and below for* $t\in(0,T)$, $x\in\mathbb{R}^N$, $\epsilon\in(0,\epsilon_0)$. *Let* H *be a* C^2 *convex function, satisfying, for all* $s\geq 0$, $|sH'(s)|\leq CH(s)$ *for some constant* $C>0$. *Suppose that initially*

$$\sup_{\epsilon>0}\int H\left(\frac{\rho_I^\epsilon}{\Psi^\epsilon}\right)\ \Psi^\epsilon\,\mathrm{d}x\leq C<\infty.$$

Then the quantities

$$\begin{cases}\displaystyle\int H\left(\frac{\rho^\epsilon}{\Psi^\epsilon}\right)\ \Psi^\epsilon\,\mathrm{d}x,\\ \displaystyle\int_0^t\int H''\left(\frac{\rho^\epsilon}{\Psi^\epsilon}\right)\ \left|\nabla_x\left(\frac{\rho^\epsilon}{\Psi^\epsilon}\right)\right|^2\,\mathrm{d}x\,\mathrm{d}s\end{cases}$$

are bounded on $(0,T)$, *uniformly with respect to* $0<\epsilon<\epsilon_0$.

Proof. We integrate with respect to x the relation given by Proposition 5.1 and get

$$\begin{aligned}\frac{\mathrm{d}}{\mathrm{d}t}\int H\left(\frac{\rho^\epsilon}{\Psi^\epsilon}\right)\ \Psi^\epsilon\,\mathrm{d}x+\int H''\left(\frac{\rho^\epsilon}{\Psi^\epsilon}\right)\ \left|\nabla_x\left(\frac{\rho^\epsilon}{\Psi^\epsilon}\right)\right|^2\,\mathrm{d}x&=\int G\left(\frac{\rho^\epsilon}{\Psi^\epsilon}\right)\ \mathcal{T}_\epsilon(\Psi^\epsilon)\,\mathrm{d}x\\ &\leq(1+C)\int H\left(\frac{\rho^\epsilon}{\Psi^\epsilon}\right)\ \Psi^\epsilon\ \left|\frac{\mathcal{T}_\epsilon(\Psi^\epsilon)}{\Psi^\epsilon}\right|\mathrm{d}x.\end{aligned}$$

We have $\mathcal{T}_\epsilon(\Psi^\epsilon)=(\mathcal{T}_2(\Theta+\epsilon\kappa)+\mathcal{T}_1(\kappa))(t,x;\frac{t}{\epsilon^2},\frac{x}{\epsilon})$, which is a bounded function. Then the Gronwall lemma concludes the proof. ∎

This result allows us to improve the regularity of the limit function. Indeed, with $H(s)=s^2/2$, we get that $\mu^\epsilon(t,x)=\rho^\epsilon/\Psi^\epsilon$ is bounded in $L^\infty(0,T;L^2(\Omega))\cap L^2(0,T;H^1(\Omega))$ (actually, we can obtain bound in any L^p). The double-scale limit of μ^ϵ is

$$R(t,x;\tau,y)/\Theta(t,x;\tau,y)=\rho(t,x).$$

Hence μ^ϵ converges to $\rho(t,x)$, which thus belongs to $L^\infty(0,T;L^2(\Omega))\cap L^2(0,T;H^1(\Omega))$ (or $L^2(0,T;H_0^1(\Omega))$). In this class, there is uniqueness of the solution of the effective advection-diffusion problem. As a consequence, we deduce that the whole sequence converges to a unique cluster point. Let us also remark that $\rho^\epsilon=\mu^\epsilon\ \Psi^\epsilon$ is bounded in $L^\infty(0,T;L^2(\Omega))$, which implies as in the proof of Theorem 4.7 the convergence of ρ^ϵ in $C^0([0,T];L^2(\Omega)\text{-}weak)$. We point out that we cannot have a convergence in L^2-strong due to the oscillating factor Ψ^ϵ.

COROLLARY 5.5. *With the same assumption as in Corollary* 5.4, *suppose that the initial data is bounded in* $L^2(\Omega)$. *Then* ρ^ϵ *converges to* ρ *in* $C^0([0,T];L^2(\Omega)\text{-}weak)$, *the unique solution in* $L^\infty(0,T;L^2(\Omega))\cap L^2(0,T;H^1(\Omega))$ *of* (4.9) *with the corresponding boundary conditions and the initial condition* ρ_I.

Acknowledgments. The authors are particularly grateful to Alain Pumir for fruitful discussions and nice comments about this problem. They also thank Grégoire Allaire and Sylvie Méléard for their help during the preparation of the manuscript.

A FREE BOUNDARY PROBLEM WITH UNILATERAL CONSTRAINTS DESCRIBING THE EVOLUTION OF A TUMOR CORD UNDER THE INFLUENCE OF CELL KILLING AGENTS*

ALESSANDRO BERTUZZI†, ANTONIO FASANO‡, AND ALBERTO GANDOLFI†

Abstract. A system of tumor cords is schematized by an array of identical cords, each one having approximately a rotational symmetry around its central blood vessel. A mathematical model for the evolution of the cord is presented, taking into account the influence of a limiting nutrient on the proliferation and death of the cells, the volume reduction of the necrotic material due to fluid loss from the cord, and the influence of chemotherapy or radiation treatment. Both the steady state and the evolution problem are considered, showing existence and uniqueness of the solution. A peculiar feature of the evolution model is that the boundary conditions for nutrient concentration on the interface between viable cord and the necrotic region may change during the response to treatment, depending on whether or not new cells enter the necrotic region.

Key words. tumor growth, cancer treatment, free boundary problems for PDEs

1. Introduction and model formulation.

In some human and experimental tumors, tumor cells appear to be arranged in cylindrical structures around central blood vessels, generally surrounded by necrosis. These structures are named tumor cords [19, 15, 18]. Oxygen and/or nutrient deprivation in cells remote from the central vessel are likely to play a decisive role in the decrease of cell proliferation rate within the cord and in the occurrence of necrosis. Mathematical models, describing the spatial distribution of proliferating and quiescent cells and the outward directed flux of cells induced by proliferation in a tumor cord at the stationary state, have been recently proposed [3, 5, 12]. The authors represented the proliferating cells as an age- or maturity-structured cell population or as discrete maturity compartments. Existence and uniqueness of the steady-state age density of the cell population within the cord have been shown in [20]. The growth of an isolated tumor cord within the normal tissue, when nutrient is supplied by the central vessel and by a distributed peripheral source that mimics surrounding vessels, has been analyzed in [4].

In the present paper we propose a mathematical model that describes, using the continuum approach, the behavior of a fully developed system of tumor cords under the influence of a therapeutic treatment. The existence of a unique stationary state in the absence of therapy will be shown, as well as the existence and uniqueness of the solution of the evolutive problem that arises following the perturbation of the stationary state. This problem is characterized by the presence of free boundaries, the most important being the ones that confine the necrotic zone: the external boundary is

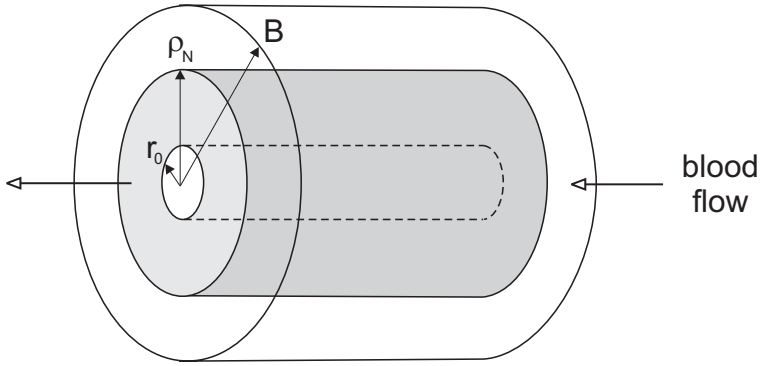

FIG. 1. *Schematic geometry of the tumor cord with the viable region indicated in gray (symbols explained in the text).*

always a no-flux material surface, whereas the internal boundary may be a nonmaterial or a material surface, depending on the evolution of the whole cord.

We concentrate on one cord in the core of the system, supposing that (i) we have symmetry around the axis of the central blood vessel of the cord; (ii) all the quantities describing the cord structure and the concentrations of the various chemical species are independent of the axial coordinate; (iii) there is a cylindrical boundary around the cord where there is no radial exchange of matter (cells, necrotic material, and diffusible chemicals) with the environment. Such a geometry of the outer boundary can be considered a reasonable approximation by viewing the cord inside an array of parallel, identical cords. Figure 1 shows a schematic representation of a tumor cord. As in previous works on the growth of spherical tumors [14, 1, 11, 13] and in [4, 7], we consider for simplicity just one species of "nutrient" with concentration σ. Here we keep the simplified picture in which the system is considered a continuum where we define the concentrations of the various diffusing substances in a global sense, i.e., without distinguishing interstitial and intracellular concentrations. Cells are assumed to die if σ reaches a death threshold σ_N. Moreover, we assume a certain degree of spontaneous cell death within the cord, according to a rate $\mu(\sigma)$, in addition to cell death induced by the treatment. Accordingly, within the cord we have viable cells, dead cells, and extracellular fluids, the respective volume fractions ν_V, ν_N, and ν_E adding to one.

Cells proliferate at the maximum rate χ_0 when $\sigma \geq \sigma_P > \sigma_N$ and ν_E is beyond some threshold $\bar{\nu}_E$. We introduce another threshold $\sigma_Q \in (\sigma_N, \sigma_P)$ below which the progression of cells across cell cycle is arrested and all cells become quiescent, maintaining, however, the capacity to resume the proliferation. The properties of the proliferation rate $\chi(\sigma)$ and of the death rate $\mu(\sigma)$ are stated as follows (see Figure 2):

(H1) $\chi(\sigma), \mu(\sigma)$ continuous and piecewise C^1 functions in $[\sigma_N, \sigma^\star]$, with bounded first derivatives and with $\sigma^\star > \sigma_P$

(H2) $$\chi(\sigma) = \chi_0 \text{ for } \sigma \geq \sigma_P, \text{ and } \chi(\sigma) = 0 \text{ for } \sigma \leq \sigma_Q$$

(H3) $$\chi'(\sigma) > 0 \text{ for } \sigma \in (\sigma_Q, \sigma_P)$$

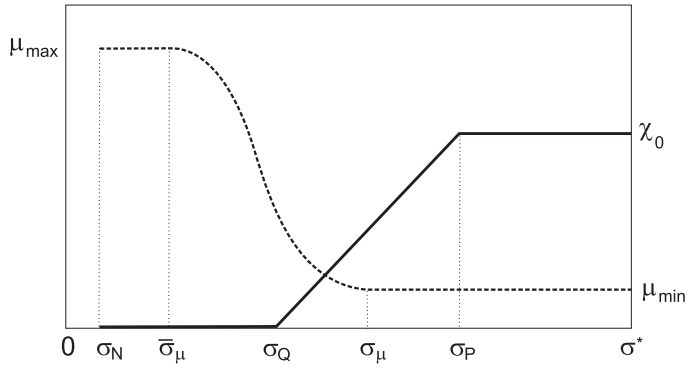

FIG. 2. *Possible graphs of χ (solid line) and μ (dashed line) as functions of σ. For the meaning of the parameters see the text.*

(H4) $$\mu(\sigma)=\mu_{min}\geq 0 \text{ for } \sigma\geq\sigma_\mu, \text{ with } \sigma_\mu\leq\sigma_P$$

(H5) $\mu'(\sigma)\leq 0$; if $\sigma_\mu>\sigma_N$, $\mu'(\sigma)<0$ only in an interval $(\bar\sigma_\mu,\sigma_\mu)$, with $\sigma_\mu>\bar\sigma_\mu\geq\sigma_N$

(H6) $$\chi_0>\mu_{min}\,.$$

Some generalizations are possible, but (H1)–(H6) are physically natural and simplify the exposition. Owing to (i)–(ii) we may consider that the volume fractions and the concentrations of the chemicals depend on the time t and on the radial coordinate r, measured from the axis of the central blood vessel of radius r_0. In the system we distinguish the following regions from inner to outer: P (fully proliferating zone), $\sigma(r,t)\geq\sigma_P$; T (transition zone), $\sigma_P>\sigma(r,t)>\sigma_Q$; Q (quiescent zone), $\sigma_Q\geq\sigma(r,t)>\sigma_N$; and N (purely necrotic zone), $\nu_V=0$. We denote by $\rho_N(t)$ the radius of the interface between the viable cord (the P∪T∪Q region) and the N region, and by $B(t)$ the radius of the exterior boundary of N. The necrotic zone has $\sigma(r,t)=\sigma_N$ in the usually observed conditions, that is, in the steady state of untreated cord, and, as a matter of fact, σ never goes below σ_N if $\sigma(r_0,t)$ remains above σ_N. However, we shall see that during the treatment σ may exceed σ_N in N. Concerning the dead cells, we assume that they decay to a liquid material at a constant rate:

(H7) $$\mu_N>0 \text{ in } \mathrm{P}\cup\mathrm{T}\cup\mathrm{Q},\ \tilde\mu_N>0 \text{ in N.}$$

Such different values reflect the different modes of cell death, i.e., apoptosis within the cord versus necrosis when σ falls to the death threshold. We shall also consider in section 2 the case in which the region N is absent. We denote by $\mathbf{u}$ the velocity field of the cellular component (here assumed to be the same for both living and dead cells) and by $\mathbf{v}$ the velocity of the extracellular fluid. Assuming equal densities for viable cells, dead cells, and extracellular fluid, the increment of cellular volume during proliferation is due to the incorporation of an equal volume of extracellular material. Thus, the governing equations for the three volume fractions in P∪T∪Q are

(1.1) $$\frac{\partial\nu_V}{\partial t}+\nabla\cdot(\mathbf{u}\,\nu_V)=\chi(\sigma)\nu_V-[\mu(\sigma)+\mu_C(c,\sigma)+\mu_R(\sigma,t)]\,\nu_V\,,$$

$$\frac{\partial \nu_N}{\partial t} + \nabla \cdot (\mathbf{u}\, \nu_N) = [\mu(\sigma) + \mu_C(c,\sigma) + \mu_R(\sigma,t)]\, \nu_V - \mu_N \nu_N \,, \tag{1.2}$$

$$\frac{\partial \nu_E}{\partial t} + \nabla \cdot (\mathbf{v}\, \nu_E) = -\chi(\sigma)\nu_V + \mu_N \nu_N \,, \tag{1.3}$$

as long as $\nu_E > \bar{\nu}_E$ (otherwise $\chi(\sigma)$ should be reduced by a factor tending to zero when $\nu_E \to 0$). In (1.1)–(1.3), c is the concentration of a cytotoxic chemical, and $\mu_C(c,\sigma)$ is the chemically induced death rate. The dependence of μ_C on σ allows us to represent the different sensitivity to treatment of cycling cells with respect to quiescent cells. The last term in (1.1) describes the cell killing rate by radiation: the dependence of μ_R on t takes into account the schedule of radiation treatment and the delayed effects following the delivery of a single dose. The death rates μ_C and μ_R are assumed bounded. In the region N, since $\nu_V = 0$, the balance equations reduce to

$$\frac{\partial \nu_N}{\partial t} + \nabla \cdot (\mathbf{u}\, \nu_N) = -\tilde{\mu}_N \nu_N \,, \tag{1.4}$$

$$\frac{\partial \nu_E}{\partial t} + \nabla \cdot (\mathbf{v}\, \nu_E) = \tilde{\mu}_N \nu_N \,. \tag{1.5}$$

Summing up (1.1)–(1.3) and (1.4)–(1.5), and imposing $\nu_V + \nu_N + \nu_E = 1$, we find

$$\nabla \cdot [\mathbf{u}(\nu_V + \nu_N) + \mathbf{v}\nu_E] = 0 \,, \tag{1.6}$$

which expresses total mass conservation. To model the transport of the nutrient we assume, as previously mentioned, a common concentration within the cells and in the extracellular fluid, and uniform diffusivity throughout the system. This proves to be the case for fast diffusing substances like oxygen. In such a way we can write the mass balance equation as follows:

$$\frac{\partial \sigma}{\partial t} - D\Delta\sigma + \nabla \cdot (\sigma[\mathbf{u}(\nu_V + \nu_N) + \mathbf{v}\nu_E]) = -\varphi(\sigma)\nu_V \,, \tag{1.7}$$

where $\varphi(\sigma)$ is the consumption rate of viable cells and D is the diffusion coefficient; $\varphi(\sigma)$ may be assumed to be a function of Michaelis–Menten type. Thus,

(H8) $\varphi(\sigma)$ is a bounded, twice continuously differentiable increasing function for

$$\sigma \geq \sigma_N, \text{ and } \varphi(\sigma_N) > 0.$$

To express the velocity fields in (1.1)–(1.7), one should describe the dynamics of the mixture of cells and extracellular fluids, writing the momentum balance and including the interactions among the components [2]. To avoid new assumptions necessary to express the stress tensor and to take full advantage of the simplified geometry, we decided instead to remain in a purely kinematic framework, introducing the further approximation $\nu_E = \text{constant}$. This assumption appears to be reasonable in view of experimental observations in the untreated cord [18], although ν_E is likely to take different values in P∪T∪Q and in N, and to transiently increase during treatments inducing cell death. Thus we set

$$\nu_E = 1 - \nu^\star, \quad \nu^\star = \text{constant},$$

which amounts to saying that both living and dead cells, despite their volume loss, keep a uniform spatial arrangement. As a result of this simplification, from (1.1), (1.2), and (1.4) we can deduce the following equation for the velocity field $\mathbf{u}$:

$$\nabla \cdot \mathbf{u} = \begin{cases} \chi(\sigma)\dfrac{\nu_V}{\nu^\star} - \mu_N(1 - \dfrac{\nu_V}{\nu^\star}) & \text{in P} \cup \text{T} \cup \text{Q}, \\ -\tilde{\mu}_N \quad \text{in N}. \end{cases} \tag{1.8}$$

From now on, we will set

$$\frac{\nu_V}{\nu^\star} = \nu\,, \quad \nu \in [0,1]\,. \tag{1.9}$$

Moreover, we assume that $\mathbf{u}$ has a negligible component along the axis of the cord (this simplification is justifiable away from the ends of the cord). Thus, denoting by $u(r,t)$ the radial component of $\mathbf{u}$, we write

$$\operatorname{div} u = \frac{1}{r}\frac{\partial}{\partial r}(ru) = \begin{cases} (\chi(\sigma) + \mu_N)\nu - \mu_N & \text{in P} \cup \text{T} \cup \text{Q}, \\ -\tilde{\mu}_N \quad \text{in N}. \end{cases} \tag{1.10}$$

Inserting (1.10) in $\operatorname{div}(\nu u) = \nu \operatorname{div} u + u\partial\nu/\partial r$, we finally get for ν the following equation:

$$\frac{\partial \nu}{\partial t} + u\frac{\partial \nu}{\partial r} + \nu\big[\mu + \mu_C + \mu_R - (\chi + \mu_N)(1-\nu)\big] = 0 \quad \text{in P} \cup \text{T} \cup \text{Q}\,, \tag{1.11}$$

and, integrating (1.10) with the condition $u(r_0,t) = 0$, we find

$$ru = \int_{r_0}^{r} r'[(\chi(\sigma) + \mu_N)\nu - \mu_N]\, dr'\,. \tag{1.12}$$

Since the necrotic material cannot be converted back to living cells, the following condition on $\rho_N(t)$ must be satisfied:

$$u(\rho_N, t) \geq \dot{\rho}_N\,, \tag{1.13}$$

with $u(\rho_N,t) - \dot{\rho}_N$ being the feeding rate per unit surface of the necrotic zone. Condition (1.13) has a central role in the model.

Concerning the equation for σ, by (1.6) and the assumption $\partial\sigma/\partial z = 0$ (z being the axial coordinate) that eliminates from (1.7) the axial component of $\mathbf{v}$, we derive

$$\frac{\partial \sigma}{\partial t} - D\Delta\sigma + \frac{\partial \sigma}{\partial r}[u\nu^\star + \bar{v}(1-\nu^\star)] = -\varphi(\sigma)\nu^\star\nu\,, \tag{1.14}$$

where by $\bar{v}(r,t)$ we denote the average along the axial direction of the radial component of the field $\mathbf{v}$ over the cord length. We may indirectly estimate the value of $\bar{v}$ at the vessel wall from the observation of a fluid loss rate from the vasculature ranging from 0.14 to 0.22 cm^3/h per gram of tissue in experimental tumors [8]. Assuming an overall surface of exchanging vasculature of 20 cm^2/gram, we obtain $(1-\nu^\star)\bar{v} \simeq 70 \div 110$ μm/h, while a typical value for u is of the order of 1 μm/h. Thus we can compare the coefficients of $\partial\sigma/\partial r$ in (1.14), concluding that diffusion with $D > 5{\cdot}10^{-8}$ cm^2/s ($D \simeq 2{\cdot}10^{-5}$ cm^2/s for oxygen [19]) is dominant in cords whose radius is of the order of 100 μm. Moreover, in the typical time scale of cord evolution,

the whole transport process can be considered quasi-stationary. Therefore (1.14) is effectively replaced by

$$\Delta\sigma = f(\sigma)\nu\,, \tag{1.15}$$

where $f(\sigma)=\varphi(\sigma)\nu^\star/D$. The interfaces $r=\rho_P(t)$, $r=\rho_Q(t)$ bounding the zone T are defined implicitly as

$$\sigma(\rho_P(t),t)=\sigma_P\,,\quad \sigma(\rho_Q(t),t)=\sigma_Q\,. \tag{1.16}$$

At the inner boundary, i.e., at the vessel wall, we prescribe

$$\sigma(r_0,t)=\sigma^\star\,. \tag{1.17}$$

When the cells at the boundary $\rho_N(t)$ enter the necrotic zone, that is, when

$$u(\rho_N,t)>\dot\rho_N\,, \tag{1.18}$$

the free boundary between viable cord and N carries the conditions

$$\sigma(\rho_N(t),t)=\sigma_N, \tag{1.19}$$

$$\sigma_r(\rho_N(t),t)=0\,, \tag{1.20}$$

and so the interface is defined implicitly and is not a material surface. We stress that the massive death occurring when the cells cross ρ_N can only be caused by insufficient nutrient, because the treatment was assumed to kill the cells according to bounded rate constants. Thus (1.19) must hold. However, if the treatment kills a sufficiently large number of cells in a sufficiently short time, the sudden decrease of nutrient absorption tends to push outward the free boundary defined by (1.19)–(1.20) with a speed that can easily exceed that of the cells. This possibility cannot be allowed because of (1.13). Therefore, when inequality (1.18) tends to be reversed, we must modify the free boundary conditions, giving up condition (1.19) and replacing it by the equation

$$\dot\rho_N=u(\rho_N,t)\,, \tag{1.21}$$

which expresses that the interface has become a material surface. Condition (1.20) is maintained as the second free boundary condition. When such a switch intervenes, $\sigma(\rho_N,t)$ will rise above σ_N: it is in fact the relative nutrient abundance which is responsible for the switch. Of course, the new constraint

$$\sigma(\rho_N(t),t)\geq\sigma_N \tag{1.22}$$

must be imposed, because no cell can be alive if $\sigma<\sigma_N$, and thus when (1.22) tends to be violated we must revert to the previous formulation. We remark that the possibility for the free boundary $r=\rho_N(t)$ to be nonmaterial or material at different times is a particular feature of this model.

We must also define the exterior boundary, $B(t)$, where there is no exchange of matter. This boundary is defined as

$$\dot B=u(B,t), \tag{1.23}$$

$$B(0) = B_0 \tag{1.24}$$

and is an additional free boundary in the problem.

The discussion about the initial condition for (1.11) and the selection of B_0 is rather delicate (note that (1.11) requires no boundary condition for $r = r_0$, where u vanishes). We denote by $\nu_0(r)$, $\sigma_0(r)$, B_0 the steady-state solution of the system (1.11), (1.12), (1.15), (1.17), (1.19), (1.20), (1.23) in the absence of treatment ($\mu_C = \mu_R = 0$). We will devote section 2 to determining the triple (σ_0, ν_0, B_0). To describe the response to a treatment starting at $t = 0$ of a fully developed tumor cord, we assume

$$\nu(r, 0) = \nu_0(r), \tag{1.25}$$

which implies

$$\sigma(r, 0) = \sigma_0(r)\,. \tag{1.26}$$

The evolution problem must be complemented with the transport equation for the drug concentration c. Also for the cytotoxic chemical we do not distinguish the concentrations inside and outside the cells, and we assume uniform diffusivity. We can thus perform a discussion parallel to the one made for σ. However, we must remark that 1) the boundary condition at r_0 can be rapidly changing due to the pharmacokinetics of the drug (for instance, the half-life in plasma of the drug 5-fluorouracyl is around 10 min), so the process cannot in general be considered quasi-stationary; 2) if the drug diffusivity, D_C, is lower than $5{\cdot}10^{-8}$ cm^2/s, the model should be considerably modified because the field $\bar{v}$ could become important. Neglecting the convective term (as possible, for instance, for the drug tirapazamine, which has $D_C = 7.0 \cdot 10^{-7}$ cm^2/s [16]), we may write for c the following diffusion-absorption equation:

$$\frac{\partial c}{\partial t} - D_C \Delta c = -\varphi_C(c, \sigma)\nu^\star \nu - \lambda c \tag{1.27}$$

with

$$c(r_0, t) = c^\star(t), \tag{1.28}$$

$$c_r(B(t), t) = 0\,, \tag{1.29}$$

$$c(r, 0) = 0\,. \tag{1.30}$$

In (1.27), $\varphi_C(c, \sigma)$ is a continuously differentiable function, positive for $c > 0$ and vanishing for $c = 0$, that represents drug loss by cellular uptake and metabolism. Through the dependence of φ_C on σ it is possible to take into account the different drug uptake into cycling and quiescent cells, whereas the dependence on c accounts for the modality of uptake (for instance, the dependence on c may be of Michaelis–Menten type). The coefficient $\lambda \geq 0$ may be associated with a possible natural decay of c (if the substance is chemically unstable). The function $c^\star(t)$ in (1.28) will represent the pharmacokinetics of the drug in the tumor vasculature.

We summarize here the statement of the evolution problem.

Problem P. Find the following field functions and interfaces with the specified regularity and satisfying the quoted equations:

- $\nu(r,t)$: differential equation (1.11), initial condition (1.25), $\nu(r,t) \in [0,1]$, $\nu \in C^1$ for $r \in [r_0, \rho_N(t)]$ and $t \in [0,T]$;
- $u(r,t)$: integral equation (1.12) for $r_0 \le r \le \rho_N(t)$ and $\mathrm{div} u = -\tilde{\mu}_N$ for $\rho_N(t) < r < B(t)$, continuous across the interface, $\partial u/\partial r$ continuous separately in the two domains;
- $\sigma(r,t)$: differential equation (1.15), condition on the fixed boundary (1.17), either free boundary conditions (1.19)–(1.20) under the constraint (1.18), or (1.20)–(1.21) if the latter is violated, with (1.22) becoming the new constraint; σ, $\partial\sigma/\partial r$, $\partial^2\sigma/\partial r^2$ continuous, and $\partial\sigma/\partial t$ piecewise continuous w.r.t. t, for $r \in [r_0, \rho_N(t)]$ and $t \in [0,T]$;
- $c(r,t)$: satisfies the differential equation (1.27) in the classical sense separately in the N region and its complement, with initial condition (1.30) and boundary conditions (1.28)–(1.29). Moreover, $c \in H^{1+\alpha,(1+\alpha)/2}$ in the whole domain for any $\alpha \in (0,1)$ (the notation of the functional space is taken from [17]);
- $\rho_N(t)$: defined either implicitly through the Cauchy conditions (1.19)–(1.20) or as a material surface by (1.21), continuous and piecewise continuously differentiable;
- $B(t)$: differential equation (1.23), initial condition (1.24), $B(t)$ having Lipschitz continuous first derivative.

The interfaces $\rho_P(t)$, $\rho_Q(t)$ are implicitly defined as the level curves $\sigma = \sigma_P$, $\sigma = \sigma_Q$.

2. The stationary solution. In this section we investigate the stationary solution of the untreated system, to be used as initial data for the evolution problem. For ease of notation in this section we will drop the subscript "0" previously used to denote the stationary solution. Although the typical experimental situation, to which we made specific reference in the formulation of the evolution problem, is characterized by the presence of a necrotic region around viable cells, in the study of the steady state we also envisage the possibility that such a necrotic region may be absent. Both cases may occur, depending on the values of the parameters involved.

Case I*: The stationary problem with a necrotic region.* Find the triple (σ, ν, u) and the boundaries ρ_N, B of the necrotic zone, with $B > \rho_N$, $\sigma(r) > 0$, $\nu(r) \in [0,1]$, and $u(r) > 0$ in (r_0, B), satisfying

$$\Delta\sigma = f(\sigma)\nu\,, \quad r_0 < r < \rho_N\,, \tag{2.1}$$

$$\sigma(r_0) = \sigma^\star\,, \tag{2.2}$$

$$\sigma(\rho_N) = \sigma_N\,, \tag{2.3}$$

$$\sigma_r(\rho_N) = 0\,, \tag{2.4}$$

$$\frac{\partial\nu}{\partial r} + A\nu = 0\,, \quad r_0 < r < \rho_N \tag{2.5}$$

with A given by

$$A = \frac{1}{u}[\mu(\sigma) - (\chi(\sigma) + \mu_N)(1-\nu)]\,, \tag{2.6}$$

$$ru = \begin{cases} \displaystyle\int_{r_0}^{r} r'[(\chi(\sigma)+\mu_N)\nu - \mu_N]\,dr'\,, & r_0 \le r \le \rho_N, \\ \rho_N u(\rho_N) - (\tilde{\mu}_N/2)(r^2 - \rho_N^2)\,, & \rho_N < r \le B\,, \end{cases} \tag{2.7}$$

$$u(B) = 0\,. \tag{2.8}$$

Case II*: The stationary problem without a necrotic region.* The unknowns are (σ, ν, u) and the outer boundary B, again with $\sigma(r) > 0$, $\nu(r) \in [0,1]$, and $u(r) > 0$ in (r_0, B), such that the following equations are satisfied: (2.1), (2.5), (2.6), the first equation in (2.7), all for $r_0 < r < B$, (2.2), (2.8), and

$$\sigma(B) \geq \sigma_N\,, \qquad \sigma > \sigma_N \quad \text{for } r_0 \leq r < B\,, \tag{2.3$'$}$$

$$\sigma_r(B) = 0\,. \tag{2.4$'$}$$

We expect that the latter case occurs when μ_N is sufficiently large and μ is sufficiently large in Q.

We remark that assumption (H8), i.e., $f(\sigma_N) > 0$, is necessary in Case I (otherwise problem (2.1), (2.3), (2.4) for any finite ρ_N can have only the constant solution $\sigma \equiv \sigma_N$). Moreover, in both cases we may say a priori that $\sigma_r < 0$ (in (r_0, ρ_N) or in (r_0, B), respectively) and that, as we shall see very soon, the right derivative of u at r_0 is equal to $\chi_0 - \mu_{min}$, pointing out that $\chi_0 > \mu_{min}$ is a necessary condition for a positive velocity field.

We shall prove an existence and uniqueness theorem treating Cases I and II simultaneously.

THEOREM 2.1. *Under the previously stated assumptions* (H1)–(H8)*, the stationary problem has one unique solution.*

Since u vanishes for $r = r_0$, (2.5) becomes degenerate and we cannot prescribe ν for $r = r_0$. We circumvent this difficulty by noting that when $\sigma > \sigma_P$ equations (2.5)–(2.6) are satisfied by $\nu = \nu_{max}$ with

$$\nu_{max} = 1 - \frac{\mu_{min}}{\chi_0 + \mu_N}\,. \tag{2.9}$$

If $\mu_{min} = 0$, $\nu_{max} = 1$; otherwise $\nu_{max} \in (0,1)$ thanks to (H6). We can state the following lemma that will prove fundamental in establishing uniqueness.

LEMMA 2.2. *When* $\chi(\sigma) = \chi_0$ *and* $\mu(\sigma) = \mu_{min}$, (2.9) *is the only nontrivial bounded solution of* (2.5), (2.6).

Proof. If the limit of ν for $r \to r_0^+$ exists bounded and different from ν_{max} and zero, then the derivative of ν has a nonintegrable singularity near r_0, contradicting the existence of a bounded limit for ν. We can also exclude $\nu \to 0$ because $\partial\nu/\partial r$ and ν would have the opposite sign in a neighborhood of r_0, where $A > 0$. If ν has no limit, ν can oscillate only if all its maxima are equal to ν_{max} and all its minima are equal to zero. However, if $\nu = \nu_{max}$ at any point separated from r_0 (A is then bounded), the only compatible solution of (2.5) is $\nu \equiv \nu_{max}$. Therefore, we must examine only the case in which $\nu \neq \nu_{max}$ for $r > r_0$ and ν tends to ν_{max}. In that case, in the proximity of r_0, $u \simeq (\chi_0 - \mu_{min})(r - r_0)$ and from (2.5) we can see that ν cannot exceed ν_{max}. Setting $\nu = \nu_{max} - \tilde{\nu}$ and using the above first-order approximation for u, we can write a differential equation that describes the behavior of $\tilde{\nu}$ at the leading order in $r - r_0$, on which we impose the condition $\tilde{\nu} \to 0$ as $r \to r_0^+$. Integrating this equation backward from a point $\bar{r}_0 > r_0$, where we suppose $\tilde{\nu}(\bar{r}_0) = \tilde{\nu}_0 < \nu_{max}$ with $\tilde{\nu}_0 > 0$, we obtain

$$\frac{1}{\nu_{max}} \log \left| \frac{\tilde{\nu}(\nu_{max} - \tilde{\nu}_0)}{\tilde{\nu}_0(\nu_{max} - \tilde{\nu})} \right| = -\frac{\chi_0 + \mu_N}{\chi_0 - \mu_{min}} \log \frac{r - r_0}{\bar{r}_0 - r_0}\,,$$

and for any $\tilde{\nu}_0 > 0$ we have a sign incompatibility in the limit $r \to r_0^+$. Hence, it must necessarily be $\tilde{\nu}_0 = 0$ and $\nu \equiv \nu_{max}$. □

Thus we put $\nu \equiv \nu_{max}$ as long as $\sigma \geq \sigma_P$, i.e., for $r \in [r_0, \rho_P]$, and we work with the (nondegenerate) system (2.5), (2.6) for $r > \rho_P$, with the condition

$$\nu(\rho_P) = \nu_{max}\,. \tag{2.10}$$

A useful a priori result concerning the stationary solution is the following.

LEMMA 2.3. *For any solution of the stationary problem, in Case* I ν *is positive, continuously differentiable, and nonincreasing in* $[r_0, \rho_N]$. *More precisely,*

(a) *if* $\mu \equiv 0$, *then* $\nu \equiv 1$ *in* $[r_0, \rho_N]$;
(b) *if* $\mu = 0$ *for* $\sigma \geq \sigma_\mu$, *with* $\sigma_\mu \in (\sigma_N, \sigma_P]$ *and* $\mu > 0$ *for* $\sigma < \sigma_\mu$, *then* $\nu(r) = 1$ *for* $r_0 \leq r \leq \rho_\mu$, *with* ρ_μ *defined by* $\sigma(\rho_\mu) = \sigma_\mu$, *and* $\nu'(r) < 0$ *for* $\rho_\mu < r < \rho_N$;
(c) *if* $\mu = \mu_{min} > 0$ *for* $\sigma \geq \sigma_\mu$, *with* $\sigma_\mu \in (\sigma_N, \sigma_P]$, *then* $\nu'(r) < 0$ *for* $\rho_P < r < \rho_N$.

Moreover, if $\mu_N > \mu_{max}$, *with* μ_{max} *being the maximal value of* $\mu(\sigma)$, *then* $\nu > \nu_{min}$ *with*

$$\nu_{min} = 1 - \frac{\mu_{max}}{\mu_N}\,. \tag{2.11}$$

In Case II, ν *is positive, continuously differentiable, and nonincreasing in* $[r_0, B)$. *Either* (b) *or* (c) *holds after substituting* B *for* ρ_N.

Proof. The continuity of $\nu'(r)$ is an immediate consequence of $\nu = \nu_{max}$ in $[r_0, \rho_P]$ and of (2.5)–(2.7). We start with Case I. First of all, dealing a priori with a solution, we may use the properties $u(r) \geq \hat{u} > 0$ and $\sigma_r < 0$ in (ρ_P, ρ_N). Therefore, the formal integration of (2.5) for $r > \rho_P$ with $\nu(\rho_P) = \nu_{max}$ provides $\nu > 0$ and, in particular, $\nu(\rho_N) > 0$. Case (a) is trivial: since $\chi + \mu_N > 0$, when $\mu \equiv 0$ the only solution of (2.5) with $\nu(\rho_P) = \nu_{max} = 1$ is $\nu \equiv 1$. We note that when $\mu \equiv 0$, only a solution of the type of Case I is possible. To deal with (b) and (c), let us consider the function $\hat{\nu}(r)$ defined by the condition $A(r) = 0$, that is,

$$\hat{\nu}(r) = 1 - \frac{\mu(\sigma(r))}{\chi(\sigma(r)) + \mu_N}\,. \tag{2.12}$$

Since $\mu_N > 0$, $\hat{\nu}(r)$ also is defined in Q.

In case (b) we have $\nu = \hat{\nu} = 1$ up to $r = \rho_\mu$. Computing

$$\hat{\nu}'(r) = \frac{\sigma_r}{\chi + \mu_N}\left[\frac{\mu\,\chi'}{\chi + \mu_N} - \mu'\right],$$

we see that $\hat{\nu}'(r) < 0$ in the union $\mathcal{I}$ of the intervals where $\mu\,\chi' > 0$ and/or $\mu' < 0$, which by (H5) includes a right neighborhood of ρ_μ and is connected. If $\sigma_\mu \in (\sigma_Q, \sigma_P]$, it is indeed $\mathcal{I} = (\rho_\mu, \max[\rho_Q, \bar{\rho}_\mu])$, with $\bar{\rho}_\mu$ being such that $\sigma(\bar{\rho}_\mu) = \bar{\sigma}_\mu$, whereas if $\sigma_\mu \in (\sigma_N, \sigma_Q]$, it is $\mathcal{I} = (\rho_\mu, \bar{\rho}_\mu)$. Now we prove that as long as $\hat{\nu}' < 0$ we must have $\nu > \hat{\nu}$ and consequently $A > 0$, implying $\nu' < 0$. Suppose that for some $\bar{r} \in \mathcal{I}$ we have $\nu(\bar{r}) < \hat{\nu}(\bar{r})$, implying $A(\bar{r}) < 0$ and $\nu'(\bar{r}) > 0$. As a consequence, there must be a point $r^\star \in (\rho_\mu, \bar{r})$ in which ν has a local minimum and thus $A(r^\star) = 0$ and $\nu(r^\star) < \hat{\nu}(r^\star)$, which is impossible. Also, we can exclude that ν equals $\hat{\nu}$ at some point $\bar{r}$ of $\mathcal{I}$, because at such a point $A = 0$ and thus we are back to the previous contradiction in a left neighborhood of $\bar{r}$. Therefore $\nu > \hat{\nu}$ and $\nu' < 0$ in $\mathcal{I}$. If $\bar{\rho}_\mu = \rho_N$, then $\nu' < 0$ for $r \in (\rho_\mu, \rho_N)$. If not, in the interval $[\rho^\star, \rho_N)$, where $\rho^\star = \max[\rho_Q, \bar{\rho}_\mu]$,

we have $\mu = \mu_{max} > 0$ and $\hat{\nu} = 1 - \mu_{max}/\mu_N$. We investigate the behavior of ν in the interval $[\rho^\star, \rho_N)$. If $\mu_N \le \mu_{max}$, it is $\hat{\nu} \le 0$ and necessarily $\nu > \hat{\nu}$ and $\nu' < 0$ in $[\rho^\star, \rho_N)$. If $\mu_N > \mu_{max}$, it is $\hat{\nu} = \nu_{min}$ and, if $\nu(\rho^\star) > \nu_{min}$, we have $\nu > \nu_{min}$ and $\nu' < 0$ in $(\rho^\star, \rho_N)$, because otherwise, integrating (2.5) backward from a point where $\nu = \nu_{min}$, we conclude that $\nu(\rho^\star) = \nu_{min}$ against our assumption. Suppose now that $\nu(\rho^\star) = \nu_{min}$, which would imply $\nu = \nu_{min}$ in $[\rho^\star, \rho_N)$, and take the difference $\tilde{\nu} = \nu - \nu_{min}$. Recalling that $\nu_{min} = 1 - \mu_{max}/\mu_N$, for $r < \rho^\star$ we have

$$\tilde{\nu}' + \tilde{A}\tilde{\nu} = \delta$$

with

$$\tilde{A} = \frac{1}{u}\left[\mu - \chi\left(\frac{\mu_{max}}{\mu_N} - \tilde{\nu} - \nu_{min}\right) - 2\mu_{max} + \mu_N + \mu_N\tilde{\nu}\right],$$

$$\delta = \frac{1}{u}\left(\mu_{max} - \mu + \chi\frac{\mu_{max}}{\mu_N}\right)\nu_{min}\,.$$

For $\rho^\star - r > 0$ sufficiently small, we have $\tilde{A} > 0$, because $\tilde{A}(\rho^\star) > 0$ since $\mu - \mu_{max} = \mu_N\tilde{\nu} = 0$ for $r = \rho^\star$. Also, $\delta > 0$ in the same interval. Therefore, integrating the ODE for $\tilde{\nu}$ backward from $r = \rho^\star$ with $\tilde{\nu}(\rho^\star) = 0$, we obtain $\tilde{\nu} < 0$, contradicting the already established result $\tilde{\nu} > 0$ for $r < \rho^\star$.

In case (c) the set $\mathcal{I}$ is not necessarily connected, but it includes at least the interval (ρ_P, ρ_Q); thus $\nu' < 0$ in the region T. If μ is constant, then $\mathcal{I}$ coincides with T and, to extend the result $\nu' < 0$ to Q, we may argue as in case (b). If there is a gap between T and the set where $\mu' < 0$, the same argument applies there, leading to the same conclusion.

In Case II, as in Case I, since it is a priori known that $u(r) > 0$ for $r_0 < r < B$, the formal integration of (2.5) starting from $r = \rho_P$, where $\nu = \nu_{max}$, gives $\nu > 0$ for $r \in (r_0, B)$. We note preliminarily that in case (b) it is $B > \rho_\mu$, because u is positive for $r_0 < r \le \rho_\mu$. The same cannot be guaranteed in case (c). Following the above arguments with the necessary slight modifications, the stated properties can be demonstrated. □

The proof of Theorem 2.1 is based on the following argument. First we consider the auxiliary problem in which, in place of conditions (2.3), (2.4), we prescribe

$$\sigma_r(r_0) = \Sigma^\star < 0 \tag{2.13}$$

and we look for (σ, ν, u) having the required properties up to $r = \hat{\rho}$, which is the minimum among the points where u or σ_r vanishes for the first time or where σ takes the value σ_N. In such a way σ is never increasing and $\sigma_{rr} > 0$ as long as $\sigma_r < 0$, and $u > 0$ for $r_0 < r < \hat{\rho}$.

A basic property of the auxiliary problem is that, setting $\nu = \nu_{max}$, we can reduce the system (2.1), (2.2), (2.13) for σ to the nonlinear Volterra integral equation

$$\sigma = \sigma^\star + r_0\Sigma^\star\log\frac{r}{r_0} + \nu_{max}\int_{r_0}^{r} r' f(\sigma)\log\frac{r}{r'}\,dr'\,, \tag{2.14}$$

up to the point $\rho_P(\Sigma^\star)$ at which σ takes the value σ_P, which is defined if $\Sigma^\star$ is less than some negative constant. We also find that in the same interval (r_0, ρ_P)

$$\sigma_r = \Sigma^\star\frac{r_0}{r} + \nu_{max}\int_{r_0}^{r} f(\sigma)\frac{r'}{r}\,dr'\,, \tag{2.15}$$

$$ru = \frac{1}{2}(\chi_0 - \mu_{min})(r^2 - r_0^2)\,. \tag{2.16}$$

Therefore, ν and u are independent of $\Sigma^\star$ as long as $\sigma \geq \sigma_P$, and differentiating (2.14) w.r.t. $\Sigma^\star$ we obtain a linear integral equation in $\partial\sigma/\partial\Sigma^\star$:

$$\frac{\partial\sigma}{\partial\Sigma^\star} = r_0 \log\frac{r}{r_0} + \nu_{max}\int_{r_0}^{r} r' f'(\sigma)\frac{\partial\sigma}{\partial\Sigma^\star}\log\frac{r}{r'}\,dr'\,, \tag{2.17}$$

showing that $\partial\sigma/\partial\Sigma^\star > 0$. The fact that $\partial\sigma_r/\partial\Sigma^\star > 0$ in the same interval is now a consequence of (2.15). It is also easy to conclude that $\rho_P(\Sigma^\star)$ is increasing.

Then, we shall go through the following steps:

1) We show that, for $r > \rho_P(\Sigma^\star)$ and $\Sigma^\star$ in a suitable interval, we can continue the solution (σ, ν, u) in a unique way up to $r = \hat{\rho}$.
2) We prove that σ, σ_r, ν, and u depend monotonically on $\Sigma^\star$ also for $r > \rho_P$.
3) We establish that there is a unique choice of $\Sigma^\star$ such that (2.3), (2.4) or (2.3′), (2.4′) are satisfied.

We start by looking for a priori bounds on $\Sigma^\star$.

LEMMA 2.4. *The value of* $\Sigma^\star$ *such that* (2.3), (2.4) *or* (2.3′), (2.4′) *are satisfied lies in a suitable interval* (Σ_1, Σ_2) *which can be computed a priori.*

Proof. If we consider the Cauchy problem

$$\Delta\sigma = f(\sigma)\nu_{max}\,, \qquad \sigma(r_0) = \sigma^\star\,, \quad \sigma_r(r_0) = \Sigma^\star\,,$$

we realize that both σ and σ_r depend monotonically on $\Sigma^\star$ and that we can choose $\Sigma^\star = \Sigma_2$ in such a way that $\partial\sigma/\partial r$ vanishes where σ takes the value σ_P. From (2.16) we note that $u(\rho_P) > 0$. If (2.3), (2.4) or (2.3′), (2.4′) are to be fulfilled, we must necessarily have $\Sigma^\star < \Sigma_2$. We note that, for all $\Sigma^\star < \Sigma_2$, the function $\rho_P(\Sigma^\star)$ is uniquely defined in a monotone fashion.

Let us now establish a lower bound for $\Sigma^\star$. For any fixed $\Sigma^\star < \Sigma_2$, as long as $\sigma > \sigma_P$, the auxiliary problem is reduced to the integral equation (2.14). We also know that beyond ρ_P the volume fraction ν does not exceed ν_{max}. We compare the continuation of $\sigma(r)$ for $r > \rho_P$ with the function $\omega(r)$ satisfying for $r > \rho_P$

$$\Delta\omega = f(\sigma_P)\nu_{max}\,, \qquad \omega(\rho_P) = \sigma_P\,, \quad \omega_r(\rho_P) = \bar{\Sigma} < 0\,, \tag{2.18}$$

with $\bar{\Sigma}$ chosen in such a way that ω_r vanishes where $\omega = \sigma_N$. If $\sigma_r(\rho_P) \leq \bar{\Sigma}$, then $\omega > \sigma$, $\omega_r > \sigma_r$, and therefore $\sigma_r < 0$ where $\sigma = \sigma_N$. If we denote by Σ_1 a Cauchy datum for $\sigma_r(r_0)$ which produces $\sigma_r(\rho_P) = \bar{\Sigma}$, then we have $\Sigma^\star > \Sigma_1$.

To prove the existence of Σ_1 we write explicitly the function ω for any $\rho_P > r_0$ and any $\bar{\Sigma} < 0$:

$$\omega = \sigma_P + \rho_P\bar{\Sigma}\log\frac{r}{\rho_P} + \frac{1}{2}S\left(\frac{r^2 - \rho_P^2}{2} - \rho_P^2\log\frac{r}{\rho_P}\right)$$

with $S = f(\sigma_P)\nu_{max}$. Imposing that ω_r vanishes where $\omega = \sigma_N$, we obtain an algebraic system for the pair $(\bar{\rho}_N, \bar{\Sigma})$, with $\bar{\rho}_N$ being the point such that $\omega(\bar{\rho}_N) = \sigma_N$. Setting $y = \bar{\rho}_N/\rho_P$, $y > 1$, such a system can be written in the following form:

$$\bar{\Sigma} = -\frac{1}{2}S\rho_P(y^2 - 1)\,, \tag{2.19}$$

$$y^2 \log y - \frac{y^2-1}{2} = \frac{2}{S\rho_P^2}(\sigma_P - \sigma_N)\,, \tag{2.20}$$

the derivative of the left-hand side of (2.20) w.r.t. y being positive for $y>1$. Thus for $\rho_P \in (r_0, \rho_P(\Sigma_2))$ there is a one-to-one mapping between ρ_P and y, through which we can define the continuous function $\bar\Sigma = h(\rho_P)$ with range in a finite interval $\bar\Sigma_{min} \le \bar\Sigma \le \bar\Sigma_{max} < 0$. Going back to the determination of Σ_1, we note that it corresponds to finding a value of $\Sigma^\star$ with the property that the function $\Sigma_\star$, defined as $\Sigma_\star(\Sigma^\star) = \sigma_r(\rho_P(\Sigma^\star))$, takes precisely the value of $\bar\Sigma$ corresponding to $\rho_P(\Sigma^\star)$. Since

$$\Sigma_\star = \Sigma^\star \frac{r_0}{\rho_P} + \frac{\nu_{max}}{\rho_P}\int_{r_0}^{\rho_P} f(\sigma) r\, dr < 0$$

for $\Sigma^\star \in (-\infty, \Sigma_2)$, it is easy to see that $d\Sigma_\star/d\Sigma^\star$ is positive, and we conclude that $\Sigma_\star$ grows from $-\infty$ to 0 as $\Sigma^\star$ varies from $-\infty$ to Σ_2. Hence, we can define a C^1 function $\rho_P = g(\Sigma_\star)$, monotonically increasing from r_0 to $\rho_P(\Sigma_2)$, over the interval $(-\infty, 0)$. Therefore, in the plane $(\bar\Sigma, \rho_P)$ the two graphs $\rho_P = g(\bar\Sigma)$ and $\bar\Sigma = h(\rho_P)$ must have at least one intersection. To each intersection we associate a value of Σ_1 via the mapping $\rho_P \to \Sigma^\star$, and our final definition of Σ_1 is the largest in the set of the values above. □

Now we turn our attention to the solution of the auxiliary problem (step 1).

LEMMA 2.5. *The auxiliary problem* (2.1), (2.2), (2.13), (2.5), (2.6), (2.7) *is uniquely solvable for any* $\Sigma^\star \in (\Sigma_1, \Sigma_2)$ *up to* $r = \hat\rho$.

Proof. For each $\Sigma^\star \in (\Sigma_1, \Sigma_2)$, we find $\sigma(r)$ in $(r_0, \rho_P(\Sigma^\star))$, and beyond ρ_P we consider the continuation $\omega(r)$ obtained by solving (2.18) with $\bar\Sigma = \sigma_r(\rho_P^-)$. For any given function $\nu(r)$ taking values in $(0, \nu_{max}]$ the solution of $\Delta\sigma = f(\sigma)\nu$ with the same Cauchy data in ρ_P as for ω is such that $\sigma \le \omega$, $\sigma_r \le \omega_r$. In particular, σ is decreasing as long as ω is decreasing. So we have an estimate (ρ_P, r_1), with r_1 being such that $\omega_r(r_1) = 0$, of the interval in which σ is decreasing. Also, we note that $u(\rho_P) > 0$ can be computed from (2.16), and that for $r > \rho_P$

$$u(r) > \frac{1}{r}\left[\frac{\chi_0 - \mu_{min}}{2}(\rho_P^2 - r_0^2) - \frac{\mu_N}{2}(r^2 - \rho_P^2)\right] = F(r)\,. \tag{2.21}$$

Thus for any $u_m \in (0, u(\rho_P))$ we can define r_2 such that $F(r_2) = u_m$.

At this point we set up a fixed point argument to prove existence in $(\rho_P, \bar r)$, with $\bar r = \min(r_1, r_2)$. Let us introduce the set of functions

$$\mathcal{N} = \left\{\nu \in C([\rho_P, \bar r]) \,|\, \nu(\rho_P) = \nu_{max},\ \nu \text{ nonincreasing},\ \nu \in [0, \nu_{max}], \mathrm{Lip}\,\nu \le \frac{\mu_{max}\nu_{max}}{u_m}\right\},$$

which, if $\mu = 0$, reduces to the only element $\nu = 1$. For ν given in $\mathcal{N}$, solve the problem

$$\Delta\sigma = f(\sigma)\nu\,, \qquad \sigma(\rho_P) = \sigma_P\,, \quad \sigma_r(\rho_P^+) = \sigma_r(\rho_P^-)\,, \quad r > \rho_P \tag{2.22}$$

and define $\tilde\nu(r)$ as the solution of

$$\frac{\partial\tilde\nu}{\partial r} + \tilde A\tilde\nu = 0\,, \quad \tilde A = \frac{1}{u}[\mu(\sigma) - (\chi(\sigma) + \mu_N)(1-\tilde\nu)]/u\,, \qquad \tilde\nu(\rho_P) = \nu_{max} \tag{2.23}$$

with

$$ru = \rho_P u(\rho_P) + \int_{\rho_P}^{r} r'[(\chi(\sigma) + \mu_N)\nu - \mu_N]\, dr'\,, \tag{2.24}$$

where σ is the solution of (2.22) and ν is the chosen element of $\mathcal{N}$. If $\mu = 0$, the trivial fixed point is $\nu = 1$. We know that in $(\rho_P, \bar{r})$ σ is decreasing and $u > u_m > 0$. Rereading the proof of Lemma 2.2, we see that this is all we need to conclude that $\tilde{\nu}$ is nonincreasing and with range in $(0, \nu_{max}]$. In addition, since $\tilde{A} \geq 0$, we can say that $\tilde{A} \leq \mu_{max}/u_m$ and therefore $\tilde{\nu} \in \mathcal{N}$.

Now take ν_1, $\nu_2 \in \mathcal{N}$ and consider the corresponding functions $\tilde{\nu}_1$, $\tilde{\nu}_2$ as well as $\tilde{A}_1$, $\tilde{A}_2$, σ_1, σ_2, u_1, u_2. We set $\delta = \nu_1 - \nu_2$, $\tilde{\delta} = \tilde{\nu}_1 - \tilde{\nu}_2$. It is not difficult to show that $\tilde{\delta}$ satisfies

$$\frac{\partial \tilde{\delta}}{\partial r} + \left[\tilde{A}_1 + \frac{\tilde{\nu}_2}{u_2}(\chi_2 + \mu_N)\right]\tilde{\delta} = \frac{\tilde{\nu}_2}{u_2}\Big[\overline{\chi}'(\sigma_1 - \sigma_2)(1 - \tilde{\nu}_1) + (u_1 - u_2)\tilde{A}_1 - \overline{\mu}'(\sigma_1 - \sigma_2)\Big], \tag{2.25}$$

with $\overline{\chi}'$ and $\overline{\mu}'$ evaluated at values between σ_1 and σ_2 and $\tilde{\delta}(\rho_P) = 0$, and that the estimates

$$\sup_{(\rho_P, r)} |\sigma_1 - \sigma_2| \leq C_1(r) \int_{\rho_P}^{r} \delta(r')\, dr', \tag{2.26}$$

$$\sup_{(\rho_P, r)} |u_1 - u_2| \leq C_2(r) \int_{\rho_P}^{r} \delta(r')\, dr', \tag{2.27}$$

where $C_1(r)$ and $C_2(r)$ are known increasing functions of r vanishing for $r = \rho_P$, can be obtained by standard arguments. Thus we obtain the inequality

$$|\tilde{\delta}(r)| \leq \int_{\rho_P}^{r} C_3(r') \int_{\rho_P}^{r'} \delta(r'')\, dr''\, dr', \tag{2.28}$$

concluding that the mapping $\nu \to \tilde{\nu}$ is continuous in the sup-norm and contractive for r close enough to ρ_P, which provides existence and uniqueness up to $\bar{r}$. To conclude the proof, we apply the same procedure for $r > \bar{r}$, redefining $\omega(r)$ as the solution of

$$\Delta\omega = f(\sigma(\bar{r}))\nu(\bar{r}), \qquad \omega(\bar{r}^+) = \sigma(\bar{r}^-), \quad \omega_r(\bar{r}^+) = \sigma_r(\bar{r}^-), \tag{2.29}$$

thus shifting r_1 to the right, and redefining $F(r)$ as $F(r) = [\bar{r}u(\bar{r}) - \frac{\mu_N}{2}(r^2 - \bar{r}^2)]/r$, which provides a new value of r_2 through $F(r_2) = u_m$, $u_m \in (0, u(\bar{r}))$. Since we can take u_m arbitrarily close to zero, by repeating this procedure we obtain precisely the desired result. □

We remark that the function $\nu(r)$ obtained as the solution of the auxiliary problem is positive and nonincreasing in $(r_0, \hat{\rho})$. Moreover, if $\mu_{min} > 0$, it is $\nu' < 0$ in $(\rho_P, \hat{\rho})$, whereas if $\mu_{min} = 0$, it is $\nu' < 0$ in $(\rho_\mu, \hat{\rho})$ for the values of $\Sigma^\star$ such that $\sigma(\hat{\rho}) < \sigma_\mu$. These properties can be checked following the argument of Lemma 2.2.

The monotonicity result (step 2) is now stated by the following lemma.

LEMMA 2.6. *The functions σ, ν, and u solving the auxiliary problem depend monotonically on $\Sigma^\star$. Indeed, $\partial\sigma/\partial\Sigma^\star > 0$, $\partial\sigma_r/\partial\Sigma^\star > 0$, $\partial\nu/\partial\Sigma^\star \geq 0$ ($\partial\nu/\partial\Sigma^\star > 0$ in the interval in which ν is decreasing), and $\partial u/\partial\Sigma^\star \geq 0$.*

Proof. The auxiliary problem is equivalently rewritten as

$$\sigma = \sigma^\star + r_0\Sigma^\star \log\frac{r}{r_0} + \int_{r_0}^{r} r' f(\sigma)\nu \log\frac{r}{r'}\, dr', \quad r_0 \leq r \leq \hat{\rho}(\Sigma^\star), \tag{2.30}$$

$$\nu = \nu_{max} \exp\left(- \int_{\rho_P}^{r} A \, dr' \right), \quad \rho_P \le r \le \hat{\rho}(\Sigma^\star), \tag{2.31}$$

together with the expression (2.7) for u. We recall that A contains u, σ and ν, so that (2.31) is just a formal way of representing ν. Differentiating (2.30), (2.7), and (2.31) with respect to $\Sigma^\star$, we obtain

$$\frac{\partial \sigma}{\partial \Sigma^\star} = r_0 \log \frac{r}{r_0} + \int_{r_0}^{r} r' \left[f'(\sigma) \frac{\partial \sigma}{\partial \Sigma^\star} \nu + f(\sigma) \frac{\partial \nu}{\partial \Sigma^\star} \right] \log \frac{r}{r'} \, dr' \,, \tag{2.32}$$

$$r \frac{\partial u}{\partial \Sigma^\star} = \int_{r_0}^{r} r' \left[\chi' \frac{\partial \sigma}{\partial \Sigma^\star} \nu + (\chi + \mu_N) \frac{\partial \nu}{\partial \Sigma^\star} \right] dr' \,, \tag{2.33}$$

$$\frac{\partial \nu}{\partial \Sigma^\star} = -\nu \int_{\rho_P}^{r} \frac{\partial A}{\partial \Sigma^\star} \, dr' \,, \tag{2.34}$$

where we have used $A(\rho_P) = 0$. Next we compute

$$\frac{\partial A}{\partial \Sigma^\star} = -\frac{A}{u} \frac{\partial u}{\partial \Sigma^\star} - \frac{1}{u} \left[\chi' \frac{\partial \sigma}{\partial \Sigma^\star} (1 - \nu) - (\chi + \mu_N) \frac{\partial \nu}{\partial \Sigma^\star} - \mu' \frac{\partial \sigma}{\partial \Sigma^\star} \right] \tag{2.35}$$

in which we may eliminate $\partial u / \partial \Sigma^\star$ making use of (2.33). We recall that the problem for σ is uncoupled up to $r = \rho_P$ (because $\nu = \nu_{max}$) and that $\partial \sigma / \partial \Sigma^\star > 0$ in that interval, as it is easily deduced from (2.32) itself and as it was already mentioned. Thus the monotone dependence must in fact be shown for $r > \rho_P(\Sigma^\star)$ (ρ_P is an increasing function of $\Sigma^\star$). For this reason, for $r > \rho_P$ we rewrite (2.32) in the form

$$\frac{\partial \sigma}{\partial \Sigma^\star} = \left. \frac{\partial \sigma}{\partial \Sigma^\star} \right|_{r = \rho_P(\Sigma^\star)} + r_0 \log \frac{r}{\rho_P} + \int_{\rho_P}^{r} r' \log \frac{r}{r'} f' \nu \frac{\partial \sigma}{\partial \Sigma^\star} \, dr' + \int_{\rho_P}^{r} r' \log \frac{r}{r'} f \frac{\partial \nu}{\partial \Sigma^\star} \, dr' \,, \tag{2.36}$$

while (2.34) becomes, using (2.35) and after some algebra,

$$\frac{1}{\nu} \frac{\partial \nu}{\partial \Sigma^\star} = \int_{\rho_P}^{r} \left[\left(r' F(r', r) \nu + \frac{1}{u} (1 - \nu) \right) \chi' - \frac{\mu'}{u} \right] \frac{\partial \sigma}{\partial \Sigma^\star} \, dr'$$

$$+ \int_{\rho_P}^{r} \left[r' F(r', r) - \frac{1}{u} \right] (\chi + \mu_N) \frac{\partial \nu}{\partial \Sigma^\star} \, dr' \tag{2.37}$$

with

$$F(r', r) = \int_{r'}^{r} \frac{1}{r''} \frac{A}{u} \, dr'' \,, \quad r > r' \,. \tag{2.38}$$

As we said, the term $\partial \sigma / \partial \Sigma^\star |_{r = \rho_P(\Sigma^\star)}$ in (2.36) is strictly positive, while $\partial \nu / \partial \Sigma^\star$ is zero at the same point. We have obtained a system of linear Volterra integral equations for the pair $\partial \sigma / \partial \Sigma^\star$, $\partial \nu / \partial \Sigma^\star$ and we restrict r to staying far from the possible singularity of $1/u$. Let us distinguish the same three cases (a), (b), and (c)

as in the proof of Lemma 2.2. Case (a): $\mu \equiv 0$ implies $\partial\nu/\partial\Sigma^\star \equiv 0$, implying also that $\partial\sigma/\partial\Sigma^\star > 0$. Case (b): $\partial\nu/\partial\Sigma^\star = 0$ up to $r = \rho_\mu$, and we may rewrite (2.37) replacing ρ_P by ρ_μ. Note that the problem for σ is uncoupled in (r_0, ρ_μ), where we can easily see that $\partial\sigma/\partial\Sigma^\star > 0$. We consider the modified version of (2.37) for $r > \rho_\mu$ and sufficiently close to ρ_μ, so that $\partial\sigma/\partial\Sigma^\star > 0$. If $(1-\nu)\chi' - \mu' = -\mu' > 0$ for $r = \rho_\mu^+$, then $\int_{\rho_\mu}^r (1/u)[(1-\nu)\chi' - \mu'](\partial\sigma/\partial\Sigma^\star)\, dr' > 0$ is the only term of order $r - \rho_\mu$, all the remaining ones being at least $O[(r-\rho_\mu)^2]$. Thus $\partial\nu/\partial\Sigma^\star > 0$ for a sufficiently small interval on the right of ρ_μ. If $\mu' = 0$ at $r = \rho_\mu^+$, we rewrite (2.37) in the form

$$Y(r) = \Theta(r) + \Xi(r) - \int_{\rho_\mu}^r \frac{1}{u}\nu(\chi + \mu_N) Y\, dr' , \tag{2.39}$$

having defined

$$Y(r) = \frac{1}{\nu}\frac{\partial\nu}{\partial\Sigma^\star} , \qquad \Theta(r) = \int_{\rho_\mu}^r \frac{1}{u}[(1-\nu)\chi' - \mu']\frac{\partial\sigma}{\partial\Sigma^\star}\, dr' ,$$

$$\Xi(r) = \int_{\rho_\mu}^r r' F(r', r)\nu\left[\frac{\partial\sigma}{\partial\Sigma^\star} + (\chi + \mu_N)Y\right] dr' .$$

We note that $\Theta(r) > 0$, at least as long as $\partial\sigma/\partial\Sigma^\star > 0$, and $\Xi(r) > 0$ for r not too far from ρ_μ (note that $A > 0$ for $r > \rho_\mu$ (see Lemma 2.2), implying $F > 0$, and $Y(\rho_\mu) = 0$). Hence (2.39) can be written as

$$Y(r) + \int_{\rho_\mu}^r a(r') Y(r')\, dr' = Z(r) \tag{2.40}$$

with $Z = \Theta + \Xi > 0$, $a = \nu(\chi + \mu_N)/u \geq 0$. From (2.40) we conclude that Y has the same sign as Z in a neighborhood of ρ_μ. In case (c), either $(1-\nu)\chi' - \mu'$ is positive for $r = \rho_P$, or it is positive in a right neighborhood of it and we can repeat the argument above. Clearly $\partial\sigma/\partial\Sigma^\star$ remains positive if $\partial\nu/\partial\Sigma^\star > 0$ and even in a larger interval beyond the possible sign inversion of $\partial\nu/\partial\Sigma^\star$.

Let us now suppose that $\partial\nu/\partial\Sigma^\star$ vanishes for the first time in some $r = \hat{r}$ after it has become positive. Consider first the case (c) with $\hat{r} \in (\rho_P, \rho_Q]$. From (2.37) we have

$$\int_{\rho_P}^{\hat{r}} \left[\left(r' F(r', \hat{r})\nu + \frac{1}{u}(1-\nu)\right)\chi' - \frac{\mu'}{u}\right]\frac{\partial\sigma}{\partial\Sigma^\star}\, dr' + \int_{\rho_P}^{\hat{r}} \left[r' F(r', \hat{r}) - \frac{1}{u}\right](\chi + \mu_N)\frac{\partial\nu}{\partial\Sigma^\star}\, dr' = 0$$

and for $r > \hat{r}$ we can write

$$\frac{1}{\nu}\frac{\partial\nu}{\partial\Sigma^\star} = \int_{\rho_P}^{\hat{r}} r'\Phi(r, \hat{r})\nu\chi'\frac{\partial\sigma}{\partial\Sigma^\star}\, dr' + \int_{\rho_P}^{\hat{r}} r'\Phi(r, \hat{r})(\chi + \mu_N)\frac{\partial\nu}{\partial\Sigma^\star}\, dr'$$

$$+ \int_{\hat{r}}^r \left[\left(r' F(r', r)\nu + \frac{1}{u}(1-\nu)\right)\chi' - \frac{\mu'}{u}\right]\frac{\partial\sigma}{\partial\Sigma^\star}\, dr' + \int_{\hat{r}}^r \left[r' F(r', r) - \frac{1}{u}\right](\chi + \mu_N)\frac{\partial\nu}{\partial\Sigma^\star}\, dr' \tag{2.41}$$

with

$$\Phi(r,\hat r)=F(r',r)-F(r',\hat r)=\int_{\hat r}^{r}\frac{1}{r''}\frac{A}{u}\,dr''>0\,.$$

The first three terms are positive. Since $\chi'>0$ in some interval and $\Phi(r,\hat r)=O(r-\hat r)$ (remember that A is strictly positive near $\hat r$), we can say that the first and the third terms are $O(r-\hat r)$, thus dominating the last term, whose sign is uncertain. In other words, we have proved that $\partial(\partial\log\nu/\partial\Sigma^\star)/\partial r$ is positive in $\hat r$, contradicting the fact that $\partial\nu/\partial\Sigma^\star$ has attained a minimum there in $[\rho_P,\hat r]$. If we are still in case (c), but $\hat r>\rho_Q$, (2.41) can be simplified, taking into account that $\chi=\chi'=0$ for $\rho_Q<r<\hat r$, and a similar conclusion can be reached. Passing to case (b), we can argue in the same way if $\rho_\mu\in(\rho_P,\rho_Q)$. If instead $\rho_\mu\ge\rho_Q$, we have to modify (2.41) to

$$\frac{1}{\nu}\frac{\partial\nu}{\partial\Sigma^\star}=\int_{\rho_\mu}^{\hat r}r'\Phi(r,\hat r)\mu_N\frac{\partial\nu}{\partial\Sigma^\star}\,dr'+\int_{\hat r}^{r}\left[r'F(r',r)-\frac{1}{u}\right]\mu_N\frac{\partial\nu}{\partial\Sigma^\star}\,dr'-\int_{\hat r}^{r}\frac{\mu'}{u}\frac{\partial\sigma}{\partial\Sigma^\star}\,dr'\,,$$

and we infer the desired conclusion since $\mu_N>0$.

Once we have seen that $\partial\sigma/\partial\Sigma^\star>0$, $\partial\nu/\partial\Sigma^\star>0$, it is straightforward to check that $\partial\sigma_r/\partial\Sigma^\star>0$ by differentiating $r\sigma_r=r_0\Sigma^\star+\int_{r_0}^{r}r'f(\sigma)\nu\,dr'$ w.r.t. $\Sigma^\star$. □

Now we can complete the proof of Theorem 2.1, on the basis of the monotonicity results obtained in the previous lemma.

Proof of Theorem 2.1. In view of Lemma 2.4, we have obtained a one-parameter family of solutions of the auxiliary problem, including all possible solutions of the original problem. The reason why a solution of that family is not a solution of the original problem is related to its behavior at the terminal radial coordinate $\hat\rho$. Namely, we may distinguish the following three disjoint classes of solutions of the auxiliary problem not solving the original problem:

(α) $\sigma_r(\hat\rho)=0$, $\sigma(\hat\rho)>\sigma_N$, $u(\hat\rho)>0$;
(β) $\sigma_r(\hat\rho)<0$, $\sigma(\hat\rho)=\sigma_N$, $u(\hat\rho)>0$;
(γ) $\sigma_r(\hat\rho)<0$, $u(\hat\rho)=0$.

The class (α) is certainly not empty because it contains all the solutions with $\Sigma^\star$ sufficiently close to Σ_2. One of the classes (β) or (γ) may be empty. The class (α) may confine with (β) or with (γ). In the former case, (α) and (β) are generally separated by a solution of type I. In the latter case, (α) and (γ) are separated by a solution of Case II. Classes (β) and (γ) both may exist, but a boundary element, corresponding to some $\Sigma^\star=\Sigma_{\beta\gamma}$, generally belongs to ($\gamma$) and therefore is not a solution. However, there can be the exceptional case in which such a boundary element is precisely the limit solution of Case II characterized by $\sigma_r(\rho_N)=0$, $\sigma(\rho_N)=\sigma_N$, $u(\rho_N)=0$, and also confining with class (α). We can approach the solution of our problem from above or from below, making $\Sigma^\star$ decrease from Σ_2 or increase from Σ_1, respectively. We recall that $\partial\sigma/\partial\Sigma^\star>0$ and that $\partial\nu/\partial\Sigma^\star\ge0$ is not identically zero in $(r_0,\hat\rho)$, except for the trivial case $\mu\equiv0$. This implies that $\partial u/\partial\Sigma^\star$ (always nonnegative) is also not identically zero and in particular is strictly positive near the end point $\hat\rho$ (see (2.33)).

1) $\Sigma^\star$ *decreasing from* Σ_2. Obviously we are moving through the class (α). Taking into account that $\sigma_r(\hat\rho)=0$ and $\sigma(\hat\rho)$ is strictly decreasing as long as $u(\hat\rho)>0$, two cases are possible: either $u(\hat\rho)$ remains positive until $\sigma(\hat\rho)$ reaches σ_N or $u(\hat\rho)$ vanishes before (or possibly when $\sigma(\hat\rho)$ reaches σ_N). In the first case, for the corresponding value of $\Sigma^\star$, a solution of type I is found; otherwise we have obtained a solution of type II.

2) $\Sigma^\star$ *increasing from* Σ_1. For $\Sigma^\star$ close to Σ_1 we may have solutions in (β) or in (γ). Suppose we start with class (β). Increasing $\Sigma^\star$, either $u(\hat\rho)$ remains positive and then we reach exactly the same solution of type I approached from above, or $u(\hat\rho)$ vanishes for some $\Sigma^\star$, meaning that we are shifting to class (γ), unless $\sigma_r(\hat\rho)$ also vanishes, so that we have recovered the limit solution of type II having $\sigma_r(\hat\rho)=0$, $\sigma(\hat\rho)=\sigma_N$, $u(\hat\rho)=0$. Moving within (γ) (possibly from $\Sigma^\star=\Sigma_1$), an increase of $\Sigma^\star$ produces a positive velocity and $\hat\rho$ is shifted to the right. The procedure stops when we reach a $\hat\rho$ such that not only $u(\hat\rho)=0$, but also $\sigma_r(\hat\rho)=0$, so that (2.3′), (2.4′) are satisfied.

As a result of the discussion above, we can say that the interval (Σ_1,Σ_2) is partitioned in one of the following ways:

$$(\Sigma_1,\Sigma_{\beta\gamma})\cup[\Sigma_{\beta\gamma},\Sigma^{\rm II}_{sol})\cup\{\Sigma^{\rm II}_{sol}\}\cup(\Sigma^{\rm II}_{sol},\Sigma_2)\equiv I_\beta\cup I_\gamma\cup\{\Sigma^{\rm II}_{sol}\}\cup I_\alpha, \tag{2.42}$$

$$(\Sigma_1,\Sigma^{\rm I}_{sol})\cup\{\Sigma^{\rm I}_{sol}\}\cup(\Sigma^{\rm I}_{sol},\Sigma_2)\equiv I_\beta\cup\{\Sigma^{\rm I}_{sol}\}\cup I_\alpha\,. \tag{2.43}$$

In (2.42) the intervals I_β, I_γ, I_α correspond to solutions in the respective classes, and $\Sigma^{\rm II}_{sol}$ is the value of $\Sigma^\star$ providing a solution of type II. The interval I_β is possibly empty. In (2.43) $\Sigma^{\rm I}_{sol}$ is the value of $\Sigma^\star$ providing a solution of type I. It is evident that the monotone structure of the family of solutions has implied the uniqueness of the solution to the original free boundary problem. □

All we need to complete the description of the solution of Case I is to calculate the velocity field in the region N according to (2.7). As $u(B)=0$, this gives the steady-state value of B,

$$B=\left[\rho_N^2+\frac{2}{\tilde\mu_N}\rho_N u(\rho_N)\right]^{1/2}. \tag{2.44}$$

3. Existence and uniqueness for the evolution problem. We suppose that at $t=0$ the system is in equilibrium and a purely necrotic region is present (Case I). In addition to (H1)–(H8), we make the following assumptions:

(H9) $\mu_C(c,\sigma)$ is a nonnegative, twice continuously differentiable, bounded function, increasing with respect to c and vanishing for $c=0$.

(H10) $\mu_R(\sigma,t), t\ge 0$, is a nonnegative, twice continuously differentiable, bounded function, with $\mu_R(\sigma,0)=0$.

(H11) $c^\star(t), t\ge 0$, is a nonnegative, continuously differentiable and bounded function with $c^\star(0)=0$.

For technical reasons, we need to extend the definition of the consumption coefficient $\varphi(\sigma)$ for values of σ less than σ_N:

(H12) $\varphi(\sigma)$ is extended for $0\le\sigma<\sigma_N$ in such a way that it possesses the same regularity stated in (H8) and it remains strictly positive.

The aim of this section is to prove the existence and uniqueness of the solution of Problem P stated at the end of section 1. We have the following theorem.

THEOREM 3.1. *Under the assumptions* (H1)–(H12)*, Problem P has a solution* $(\nu,\sigma,u,\rho_N,B,c)$ *in an arbitrarily large time interval.*

THEOREM 3.2. *Under the assumptions* (H1)–(H12)*, and supposing that*

$$\|f'\|\left[R_2^2\log\frac{R_2}{r_0}-\frac{1}{2}(R_2^2-r_0^2)\right]<1\,, \tag{3.1}$$

where R_2 is an upper bound for $\rho_N(t)$, Problem P has one unique solution.

An upper bound for $\rho_N(t)$ will be found later (Lemma 3.2).

To prove existence, we approximate the solution of the evolution problem using a step-by-step procedure. For a given time interval $[0,T]$ we partition it into n equal parts; to simplify notation, we will omit the index "n" in the variables of the approximation of order n. Let us now describe our approximation scheme, starting from the first interval $[0,\theta]$, with $\theta = T/n$. All the quantities referring to the steady state are denoted with the subscript "0" as in section 1.

1. Compute the curves $\gamma(\hat r) : r = \eta(\hat r, t)$ integrating

$$\dot\eta = u_0(\eta)\,, \qquad \eta(\hat r, 0) = \hat r\,, \quad \hat r \in [r_0, B_0]\,. \tag{3.2}$$

Note that $\eta(B_0,t) = B_0$; that is, $B(t)$ is equal to B_0 in $[0,\theta]$. The characteristic lines do not intersect because (3.2) has a unique solution forward and backward (u_0 is indeed Lipschitz continuous), and the equation $r = \eta(\hat r, t)$ defines $\hat r = \zeta(r,t)$ uniquely. Moreover, $\partial\eta/\partial\hat r > 0$ and, more precisely, from $\partial(\partial\eta/\partial\hat r)/\partial t = u_0'(\eta)(\partial\eta/\partial\hat r)$, $\partial\eta/\partial\hat r|_{t=0} = 1$, we can say that $\partial\eta/\partial\hat r = \exp[\int_0^t u_0'(\eta(\hat r,\tau))\,d\tau]$, giving a positive lower (and upper) bound for $\partial\eta/\partial\hat r$. Also, we write $0 = (\partial\eta/\partial\hat r)(\partial\zeta/\partial t) + \partial\eta/\partial t$, giving $\partial\zeta/\partial t = -u_0/(\partial\eta/\partial\hat r)$, which is obviously a priori bounded. Similarly we have $1 = (\partial\eta/\partial\hat r)(\partial\zeta/\partial r)$, implying $\partial\zeta/\partial r = (\partial\eta/\partial\hat r)^{-1}$, positive and a priori bounded. Moreover, $\partial\zeta/\partial r$ and $\partial\zeta/\partial t$ are continuous.

2. In the domain $[r_0, B_0]\times[0,\theta]$ solve the problem (1.27)–(1.30) for c, with $B = B_0$ and omitting the consumption term because in the first step we put $c \equiv c(r,0) = 0$ in $\varphi_C(c,\sigma)$. This problem is standard, and it is well known that $0 \le c \le \sup_{[0,\theta]} c^\star(t)$ and that $|c_r|$ can be estimated in terms of $\sup_{[0,\theta]} |\dot c^\star(t)|$.

3. Integrate the equation

$$\begin{aligned} D_u\nu &= -\nu\big[\mu(\sigma_0) + \mu_R(\sigma_0,t) + \mu_C(c,\sigma_0) - (\chi(\sigma_0)+\mu_N)(1-\bar\nu^0)\big] \\ &\equiv -\nu H(t,c,\sigma_0,\bar\nu^0) \end{aligned} \tag{3.3}$$

along the curves $\gamma(\hat r)$, where D_u is the derivative along the characteristic lines (in this interval $D_u = \partial/\partial t + u_0\,\partial/\partial r$) and we have denoted $\bar\nu^0(r,t) = \nu_0(\zeta(r,t))$. The initial datum is $\nu(\hat r, 0) = \nu_0(\hat r)$, $\hat r \in [r_0, \rho_{N0}]$, and $\nu(\hat r, 0) = 0$, $\hat r \in (\rho_{N0}, B_0]$, with ρ_{N0} being the stationary value of ρ_N. Setting $\mathcal{H}(\hat r, t) = H|_{r=\eta(\hat r,t)}$, we have

$$\nu(r,t) = \nu_0(\zeta(r,t)) \exp\left(-\int_0^t \mathcal{H}(\zeta(r,t),\tau)\,d\tau\right). \tag{3.4}$$

Since ν_0 is strictly positive for $\hat r \in [r_0, \rho_{N0}]$ and $\mathcal{H}$ is bounded, $\nu(r,t)$ also is strictly positive for $r \le \eta(\rho_{N0}, t)$. From (3.4) we may calculate $\partial\nu/\partial r$ and $\partial\nu/\partial t$ as follows:

$$\frac{\partial\nu}{\partial r} = \nu\frac{\partial\zeta}{\partial r}\left(\frac{\nu_0'}{\nu_0} - \int_0^t \frac{\partial\mathcal{H}}{\partial\hat r}\,d\tau\right), \tag{3.5}$$

$$\frac{\partial\nu}{\partial t} = -\nu H + \nu\frac{\partial\zeta}{\partial t}\left(\frac{\nu_0'}{\nu_0} - \int_0^t \frac{\partial\mathcal{H}}{\partial\hat r}\,d\tau\right). \tag{3.6}$$

The right-hand sides of (3.5)–(3.6) contain σ_0, ν_0, c and their first derivatives w.r.t. r.

4. Find $\sigma(r,t)$ and $\tilde\rho_N(t)$ such that

$$\Delta\sigma = f(\sigma)\nu\,, \quad r_0 < r < \tilde\rho_N(t)\,, \tag{3.7}$$

$$\sigma(r_0,t)=\sigma^\star\,, \tag{3.8}$$

$$\sigma(\tilde\rho_N,t)=\sigma_N\,, \tag{3.9}$$

$$\sigma_r(\tilde\rho_N,t)=0\,. \tag{3.10}$$

Equations (3.7)–(3.10) are equivalent to

$$\sigma-\sigma_N=\int_r^{\tilde\rho_N(t)} r'\log\frac{r'}{r}f(\sigma)\nu\,dr'\,, \tag{3.11}$$

and

$$\sigma^\star-\sigma_N=\int_{r_0}^{\tilde\rho_N(t)} r\log\frac{r}{r_0}f(\sigma)\nu\,dr\,. \tag{3.12}$$

We want to show that the pair $(\sigma,\tilde\rho_N)$ can be found with $\tilde\rho_N(0)=\rho_{N0}$ and $\tilde\rho_N(t)<\eta(\rho_{N0},t)$ in some interval $(0,\hat t\,)$, $\hat t\le\theta$. It is easily seen that (3.7)–(3.10) have a unique solution $(\sigma,\tilde\rho_N)$ provided that ν does not approach zero. To fulfill this condition, for the moment we give ν a positive continuous extension for $r>\eta(\rho_{N0},t)$, setting $\nu(r,t)=\nu(\eta(\rho_{N0},t),t)$. Then we recall that $\nu\to\nu_0$ (provided that ν_0 is extended in the same way) and $\partial\nu/\partial t\to 0$ as $t\to 0$ in view of (1.30) and (H9)–(H11), and because of (3.6) and (2.5)–(2.6). We may also establish the continuity of $\partial\sigma/\partial t$, noting that it satisfies the equation $\Delta(\partial\sigma/\partial t)=f'(\sigma)(\partial\sigma/\partial t)\nu+f(\sigma)(\partial\nu/\partial t)$, $r_0<r<\tilde\rho_N(t)$, with zero boundary values at $r=r_0$, $r=\tilde\rho_N(t)$. In particular, since $\partial\nu/\partial t$ vanishes for $t=0$, so does $\partial\sigma/\partial t$. Now we compute $\dot{\tilde\rho}_N$ by differentiation of (3.12), obtaining

$$\dot{\tilde\rho}_N\,\tilde\rho_N[f(\sigma)\nu]\Big|_{r=\tilde\rho_N(t)}\log\frac{\tilde\rho_N}{r_0}=-\int_{r_0}^{\tilde\rho_N} r\log\frac{r}{r_0}\,\frac{\partial}{\partial t}[f(\sigma)\nu]\,dr\,. \tag{3.13}$$

Owing to the remarks above, (3.13) implies $\dot{\tilde\rho}_N\,(0)=0<u_0(\rho_{N0})$. Therefore, in some time interval $[0,\hat t\,]$, $\hat t\le\theta$, the pair $(\sigma,\tilde\rho_N)$ is actually the solution of (3.11)–(3.12), where no use is made of the extension of ν (in other words, ν is precisely the function calculated in step 3). Moreover, (3.13) shows the continuity of $\dot{\tilde\rho}_N$.

Starting from $t=0$, as long as $u_0(\tilde\rho_N)\ge\dot{\tilde\rho}_N$, we set $\rho_N(t)=\tilde\rho_N(t)$ and accept the solution σ given by (3.11) up to the time $\bar t$ such that either a right neighborhood of $\bar t$ exists in which $u_0(\tilde\rho_N)<\dot{\tilde\rho}_N$, or in any right neighborhood of $\bar t$ the difference $u_0(\tilde\rho_N)-\dot{\tilde\rho}_N$ undergoes infinite sign changes. In the first case, for $t>\bar t$ we force ρ_N to coincide with the characteristic line tangent to $r=\tilde\rho_N(t)$ at $t=\bar t$; that is, we set $\dot\rho_N=u_0(\rho_N)$. In this case ρ_N becomes known and we redefine σ by solving the problem (3.7)–(3.8) and (3.10) (with $\tilde\rho_N$ changed to ρ_N). We have

$$\sigma-\sigma(\rho_N(t),t)=\int_r^{\rho_N(t)} r'\log\frac{r'}{r}f(\sigma)\nu\,dr'\,, \tag{3.14}$$

$$\sigma^\star-\sigma(\rho_N(t),t)=\int_{r_0}^{\rho_N(t)} r\log\frac{r}{r_0}f(\sigma)\nu\,dr\,, \tag{3.15}$$

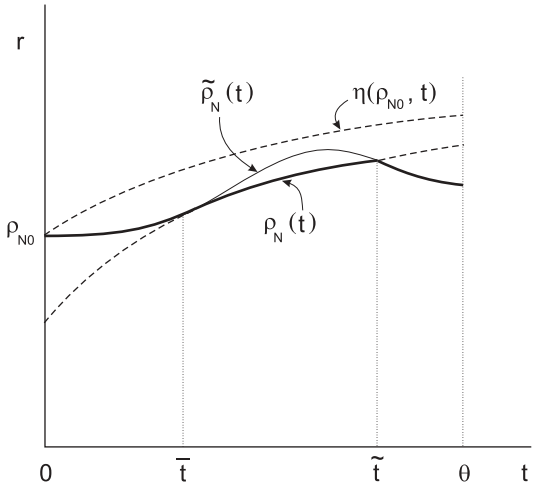

FIG. 3. *The construction of $\rho_N(t)$ (thick line) in the first time step. The characteristic lines are indicated by dashed lines and $\tilde{\rho}_N(t)$ by a thin continuous line. In this example $\hat{t}=\theta$.*

and it can be easily seen that $\sigma(\rho_N(t),t) > \sigma_N$ in an open right neighborhood of $\bar{t}$. In the second case, we must artificially reconstruct the possibility of computing the continuation of the approximate solution over a finite time interval. To this end, we select a velocity u_{tol} as a small fraction of $u_0(\rho_P)$ and we consider the time interval in which $u_0(\tilde{\rho}_N) > \dot{\tilde{\rho}}_N - u_{tol}/n$. Here we choose one of the zeros of the difference $u_0(\tilde{\rho}_N) - \dot{\tilde{\rho}}_N$ beyond which such a quantity becomes negative. At that time we switch to the condition $\dot{\rho}_N = u_0(\rho_N)$, replacing (3.11)–(3.12) with (3.14)–(3.15). Of course, we have to switch back to $\rho_N(t) = \tilde{\rho}_N(t)$ from the possible time $\tilde{t}$ after which (3.15) can be satisfied only with $\sigma(\rho_N(t),t) < \sigma_N$, and we will again have $u_0(\tilde{\rho}_N) > \dot{\tilde{\rho}}_N$ in an open right neighborhood of $\tilde{t}$ with a possible discontinuity of $\dot{\rho}_N$ at $t=\tilde{t}$. If after $\tilde{t}$ the difference $\sigma(\rho_N,t) - \sigma_N$ has infinitely many sign changes in any right neighborhood, after selecting $\sigma_{tol} < \sigma_N$, we consider the time interval in which $\sigma(\rho_N,t) > \sigma_N - \sigma_{tol}/n$, switching to $\rho_N(t) = \tilde{\rho}_N(t)$ at one of the zeros of $\sigma(\rho_N,t) - \sigma_N$ beyond which $\sigma(\rho_N,t) - \sigma_N < 0$.

We remark that if $\hat{t} < \theta$, or $\hat{t} = \theta$ and $\rho_N(\hat{t}) = \eta(\rho_{N0},\theta)$, the time $\bar{t} < \hat{t}$ previously defined will exist. Indeed, in this case we may identify $\hat{t}$ as the time instant such that

$$\sigma^\star - \sigma_N = \int_{r_0}^{\eta(\rho_{N0},\hat{t})} r \log \frac{r}{r_0} f(\sigma)\nu \, dr \,.$$

Therefore, for $t \in (0,\hat{t})$, we have $\eta(\rho_{N0},t) > \tilde{\rho}_N(t)$ and $\eta(\rho_{N0},0) = \tilde{\rho}_N(0)$, $\eta(\rho_{N0},\hat{t}) = \tilde{\rho}_N(\hat{t})$. In this situation the curve $r = \tilde{\rho}_N(t)$ becomes tangent to one of the characteristic lines $\eta(\hat{r},t)$ for some $\hat{r} < \rho_{N0}$ at some time smaller than $\hat{t}$. Since the curve $r = \tilde{\rho}_N(t)$ cannot lie on this characteristic line up to $\hat{t}$, it will leave the characteristic line at some $\bar{t} < \hat{t}$. However, $\bar{t}$ may exist even if $\hat{t} = \theta$ and $\rho_N(\hat{t}) < \eta(\rho_{N0},\theta)$. Figure 3 shows an example of the construction of $\rho_N(t)$.

5. We set ν equal to zero and $\sigma(r,t) = \sigma(\rho_N(t),t)$ for $r > \rho_N(t)$, and this is the final form of ν and σ in the step. Moreover, we continue $c(r,t)$ for $r > B$ by setting

$c(r,t)=c(B(t),t)$.

6. With the new values of σ, ν we compute the new velocity field on the basis of (1.10) as follows:

$$ru=\begin{cases}\displaystyle\int_{r_0}^{r} r'[(\chi(\sigma)+\mu_N)\nu-\mu_N]\,dr', & r_0\le r\le\rho_N(t),\\ \rho_N u(\rho_N)-(\tilde{\mu}_N/2)(r^2-\rho_N^2), & r>\rho_N(t),\end{cases} \tag{3.16}$$

where we have extended the definition of u beyond $r=B(t)$ because we may need it in what follows.

We are now ready to go to the second time step $(\theta,2\theta]$, in which we have

1. Continuation of the characteristic lines $r=\eta(\hat{r},t)$. Starting with the value $\eta(\hat{r},\theta)$ we integrate

$$\dot{\eta}(t)=u(\eta(t),t-\theta),\quad t\in(\theta,2\theta)\,. \tag{3.17}$$

From the continuation of the characteristic line $r=\eta(\hat{r},t)$, the function $\hat{r}=\zeta(r,t)$ is also defined for $t\in(\theta,2\theta]$. Likewise we continue the external boundary as

$$\dot{B}(t)=u(B(t),t-\theta)\,,\quad B(\theta^+)=B(\theta^-)\,. \tag{3.18}$$

2. Computation of c according to

$$\frac{\partial c}{\partial t}-D_C\Delta c=-\varphi_C(c^\theta,\sigma^\theta)\nu^\star\bar{\nu}^\theta-\lambda c\,, \tag{3.19}$$

$$c(r_0,t)=c^\star(t)\,, \tag{3.20}$$

$$c_r(B(t),t)=0\,, \tag{3.21}$$

$$c(r,\theta^+)=c(r,\theta^-)\,,\quad r\in(r_0,B(\theta)]\,. \tag{3.22}$$

Here and in what follows, we denote $c^\theta(r,t)=c(r,t-\theta)$, $\sigma^\theta(r,t)=\sigma(r,t-\theta)$, and $\bar{\nu}^\theta(r,t)=\nu(\eta(\zeta(r,t),t-\theta),t-\theta)$. Note that $\bar{\nu}^\theta(r,t)>0$ if $r\le\eta(\zeta(\rho_N(\theta),\theta),t)$; otherwise $\bar{\nu}^\theta=0$. Therefore, the consumption term in (3.19) is discontinuous. The solution exists in the space $W_q^{2,1}$ (for any $q>1$) and is in fact in the Hölder space $H^{1+\alpha,(1+\alpha)/2}$ for any $\alpha\in(0,1)$ (see [17, Chap. 4]).

3. Computation of ν:

$$D_u\nu=-\nu H(t,c,\sigma^\theta,\bar{\nu}^\theta)\,, \tag{3.23}$$

the initial values for ν being provided by continuity through $t=\theta$. Thus, (3.4) can be extended to the interval $(\theta,2\theta]$.

4. Computation of σ and ρ_N as described in the corresponding point of the first step, the velocity field now being $u(r,t-\theta)$. In the comparison between $u(\tilde{\rho}_N(t),t-\theta)$ and $\dot{\tilde{\rho}}_N(t)$, the expression of $\dot{\tilde{\rho}}_N(t)$ at the general step is still given by (3.13). Note that the existence of $\rho_N(t)$, such that $u(\rho_N,t-\theta)>\dot{\rho}_N(t)$ in a right neighborhood of $t=\theta$, is now not guaranteed.

5. The function ν is set equal to zero and $\sigma \equiv \sigma(\rho_N(t), t)$ for $r > \rho_N(t)$. The function $c(r,t)$ is also continued as in the first step.

6. Computation of u by means of (3.16).

Precisely the same scheme can be iterated up to $t = T$. In the following, when we refer to $\partial\nu/\partial t$, we mean that it is calculated in the positivity set of ν. In particular, the sup-norm $\|\partial\nu/\partial t\|$ is likewise referred to the support of ν.

Remark 3.1. In the approximating solutions constructed above, it is not difficult to see that the function $B(t)$ together with all the characteristic lines is $C^1[0,T]$, whereas the interface $\rho_N(t)$ is not in general continuously differentiable at the switching points. The function $\nu(r,t)$ is C^1 for $r \in [r_0, \rho_N]$ and for $r \in (\rho_N, \infty)$, $t \in [0,T]$. The functions $\sigma(r,t)$, $u(r,t)$, and $c(r,t)$ are continuous in $[r_0,\infty)\times[0,T]$. Moreover, as we shall see, the function c belongs to $H^{1+\alpha,(1+\alpha)/2}$, $\alpha \in (0,1)$. The functions $u(r,t)$ and $\rho_N(t)$ satisfy $u(\rho_N(t), t-\theta) - \dot\rho_N(t) > -u_{tol}/n$ (with $t-\theta$ set to zero for $t<\theta$), so they will not necessarily satisfy inequality (1.13). Also, it may happen that $\sigma < \sigma_N$ and $\nu > 0$ at the same (r,t) point; the approximating solutions may therefore be "nonphysical."

Our aim is now to show that the sequence of approximating solutions so generated defines sets of functions that, when restricted to suitable compact domains, are compact in the sup-norm. First, we establish the following properties.

LEMMA 3.3. *In the family of approximating solutions, the functions ν for $r \in [r_0, \rho_N(t)]$ and $t \in [0,T]$ satisfy the inequalities*

$$0 < N_1 \le \nu(r,t) \le N_2\,, \tag{3.24}$$

where

$$N_1 = \inf_{r\in[r_0,\rho_{N0}]} \nu_0(r)\mathrm{e}^{-\|H\|T}, \qquad N_2 = \sup_{r\in[r_0,\rho_{N0}]} \nu_0(r)\mathrm{e}^{\|H\|T} \tag{3.25}$$

and $\|H\|$ denotes the sup of $|H|$.

Proof. Having defined the characteristic line $r = \eta(\hat r, t)$ in the whole interval $[0,T]$, we can define the function $\hat r = \zeta(r,t)$ for $r \in [r_0, B(t)]$ and $t \in [0,T]$. Thus, we can extend (3.4) for $r \in [r_0, \rho_N(t)]$, $t \in [0,T]$, namely,

$$\nu(r,t) = \nu_0(\zeta(r,t)) \exp\left(-\int_0^t \mathcal{H}(\zeta(r,t),\tau)\, d\tau \right), \tag{3.26}$$

where $\zeta(r,t) \in [r_0, \rho_{N0}]$. From (3.26), the inequalities (3.24) follow immediately considering that $\|H\| \le \max[\max\mu + \max\mu_R + \max\mu_C, \chi_0 + \mu_N]$. □

LEMMA 3.4. *In the family of approximating solutions, $\rho_N(t)$ satisfies the inequalities*

$$r_0 < R_1 < \rho_N(t) < R_2\,, \tag{3.27}$$

where

$$R_1 = \left[r_0^2 + (\hat R_1^2 - r_0^2)\mathrm{e}^{-\mu_{Nmax}T} \right]^{1/2} \tag{3.28}$$

with $\mu_{Nmax} = \max[\mu_N, \tilde\mu_N]$, with $\hat R_1$ being the unique solution larger than r_0 of

$$x^2 \log\frac{x}{r_0} - \frac{1}{2}(x^2 - r_0^2) = 2\frac{\sigma^\star - \sigma_N}{f(\sigma^\star)N_2} \tag{3.29}$$

and R_2 the unique solution larger than r_0 of

$$x^2 \log \frac{x}{r_0} - \frac{1}{2}(x^2 - r_0^2) = 2\frac{\sigma^\star}{f(\sigma_N)N_1}\,. \tag{3.30}$$

Moreover,

$$B(t) > \rho_N(t)\,. \tag{3.31}$$

Proof. Let $\mathcal{T}_1$ be the set of values of $t \in [0,T]$ such that $\sigma(\rho_N(t),t) = \sigma_N$. For $t \in \mathcal{T}_1$, we have from (3.12) that

$$\sigma^\star - \sigma_N \le f(\sigma^\star)\frac{N_2}{2}\left[\rho_N^2 \log \frac{\rho_N}{r_0} - \frac{1}{2}(\rho_N^2 - r_0^2)\right], \tag{3.32}$$

so that $\rho_N(t) \ge \hat{R}_1 > R_1 > r_0$. Recalling the construction of ρ_N, at the time points of the set $\mathcal{T}_2 = [0,T] - \mathcal{T}_1$ (if not empty) the curve $r = \rho_N(t)$ is tangent to a characteristic line. Let us now consider a generic characteristic line $r = \eta(t)$ passing through (t', r'). For $t \ge t'$, $\eta(t)$ satisfies

$$\dot{\eta} = u(\eta(t), t-\theta)\,, \quad \eta(t') = r' \tag{3.33}$$

($t-\theta$ set to zero when $t < \theta$). From (3.16) we have

$$ru(r, t-\theta) > -\frac{\mu_{Nmax}}{2}(r^2 - r_0^2) \tag{3.34}$$

and thus

$$\eta\dot{\eta} > -\frac{\mu_{Nmax}}{2}(\eta^2 - r_0^2)\,, \tag{3.35}$$

which implies

$$\eta(t)^2 - r_0^2 > (r'^2 - r_0^2)\mathrm{e}^{-\mu_{Nmax}(t-t')}\,. \tag{3.36}$$

If $\mathcal{T}_2$ is not empty, for $t \in \mathcal{T}_2$ let $\mathcal{T}_{1t}$ be the subset of $\mathcal{T}_1$ such that $t > \tau$ for each $\tau \in \mathcal{T}_{1t}$, and let $s_t = \sup \mathcal{T}_{1t}$. The characteristic line to which $(t, \rho_N(t))$ belongs will pass through $(s_t, \rho_N(s_t))$, so from (3.36) we have

$$\rho_N(t)^2 - r_0^2 > (\rho_N(s_t)^2 - r_0^2)\mathrm{e}^{-\mu_{Nmax}(t-s_t)}\,. \tag{3.37}$$

Since $\rho_N(s_t) \ge \hat{R}_1$, it follows that $\rho_N(t) > R_1$ also in $\mathcal{T}_2$. Turning now to the upper bound, we have from (3.15) for $t \in [0,T]$

$$\sigma^\star - \sigma(\rho_N(t),t) \ge f(\sigma_N)\frac{N_1}{2}\left[\rho_N^2 \log \frac{\rho_N}{r_0} - \frac{1}{2}(\rho_N^2 - r_0^2)\right], \tag{3.38}$$

so that $\rho_N(t)$ is smaller than the solution larger than r_0 of

$$\frac{1}{2}x^2 \log \frac{x}{r_0} - \frac{1}{4}(x^2 - r_0^2) = \max_{t\in[0,T]} \frac{\sigma^\star - \sigma(\rho_N(t),t)}{f(\sigma_N)N_1}\,, \tag{3.39}$$

which is smaller than the solution R_2 of (3.30).

To prove $B(t) > \rho_N(t)$, it is enough to recognize that for each $t \in [0,T]$ there exists $\hat{r}_t \in (r_0, \rho_{N0}]$ such that $\rho_N(t) = \eta(\hat{r}_t, t)$. Taking into account that $B_0 > r_0$ and that the characteristic lines do not intersect each other, the property (3.31) follows. □

Moreover, we have the following lemma.

LEMMA 3.5. *In the family of approximating solutions, the functions ρ_N, B, and $\dot{B}$ are uniformly bounded and uniformly Lipschitz continuous. The functions σ, u are uniformly bounded and uniformly Lipschitz continuous in $[r_0, M_B] \times [0,T]$, M_B denoting a uniform upper bound of B. The function ν has the same property in $r_0 \le r \le \rho_N(t)$, $t \in [0,T]$. The function c is estimated uniformly in $H^{1+\alpha,(1+\alpha)/2}$, $\alpha \in (0,1)$, for $(r,t) \in [r_0, M_B] \times [0,T]$. In addition, in any domain whose closure has a positive distance from the boundary $r = r_0$ and from the interface $r = \rho_N(t)$, we have uniform estimates of the norm of c in the space $H^{2+\alpha,1+\alpha/2}$.*

Proof. The uniform boundedness of ν and ρ_N is given by Lemmas 3.1 and 3.2, respectively. Moreover, $c(r,t)$ takes values between 0 and $\sup_{[0,T]} c^\star(t)$, owing to the maximum principle. Again from the maximum principle, we can say that $0 < \sigma \le \sigma^\star$. Recalling (3.16) and taking into account the uniform boundedness of ν and ρ_N, the uniform boundedness of u, B, and $\dot{B}$ easily follows. Since H is uniformly bounded, and because of (3.24), $D_u \nu$ is also uniformly bounded.

In order to prove that ν is uniformly Lipschitz in $r_0 \le r \le \rho_N(t)$, $t \in [0,T]$, we note that (3.5)–(3.6) are also valid in the whole domain, with σ^θ, $\bar{\nu}^\theta$ suitably replacing σ_0, $\bar{\nu}^0$ in the expression of $\mathcal{H}$. First we use (3.5), noting that $\partial \mathcal{H}/\partial \hat{r}$ involves the derivatives $\partial \sigma^\theta/\partial r$, $\partial c/\partial r$, and $\partial \bar{\nu}^\theta/\partial r$ multiplied by $\partial \eta/\partial \hat{r}$, which can be easily estimated for each t as done in the first step. The derivatives $\partial \zeta/\partial r$, $\partial \zeta/\partial t$ also are bounded, as explained in the first step. Thus, from (3.5), we can derive a Gronwall-type inequality for $\sup_{[0,t]} |\partial \nu/\partial r|_{\gamma(\hat{r})}$, leading to an estimate of $\sup |\partial \nu/\partial r|$ in terms of ν_0, ν_0' and the sup of $|\partial \sigma^\theta/\partial r|$ and $|\partial c/\partial r|$. Uniform bounds on σ^θ, $|\partial \sigma^\theta/\partial r|$, $|\partial^2 \sigma^\theta/\partial r^2|$ are trivial. To find a bound on $|\partial c/\partial r|$, take the transformation

$$\tilde{r} - r_0 = \frac{R - r_0}{B(t) - r_0}(r - r_0) \tag{3.40}$$

that carries the domain $r_0 < r < B(t)$, $0 < t < T$ into a fixed domain $r_0 < \tilde{r} < R$, $0 < t < T$. Defining $\tilde{c}(\tilde{r}, t) = c(r(\tilde{r}), t)$, the operator $\mathcal{L}c = \partial c/\partial t - D_C \Delta c$ becomes

$$\begin{aligned} \tilde{\mathcal{L}}\tilde{c} = \frac{\partial \tilde{c}}{\partial t} - \frac{\partial \tilde{c}}{\partial \tilde{r}}\left[\frac{\dot{B}(\tilde{r} - r_0)}{B - r_0} + D_C \frac{R - r_0}{B - r_0}\left((\tilde{r} - r_0)\frac{B - r_0}{R - r_0} + r_0\right)^{-1}\right] \\ - D_C \left(\frac{R - r_0}{B - r_0}\right)^2 \frac{\partial^2 \tilde{c}}{\partial \tilde{r}^2}, \end{aligned} \tag{3.41}$$

and the problem (3.19)–(3.22) for c can be rewritten for $\tilde{c}$. Since c, σ, ν are bounded and $\dot{B}/(B - r_0)$, $(R - r_0)/(B - r_0)$, $(B - r_0)/(R - r_0)$ are a priori bounded ($B - r_0$ has indeed a positive lower bound; see Lemma 3.2), we can apply well-known results (see Theorem 9.1 and the remark at the end of section 9 in [17, Chap. 4]) guaranteeing uniform estimates for the norms of $\tilde{c}$ (and hence of c) at least in the spaces $W_q^{2,1}$ (for any $q > 1$) and $H^{1+\alpha,(1+\alpha)/2}$ (for any $\alpha \in (0,1)$). In particular we now have the uniform bound for $|\partial c/\partial r|$, needed to obtain a uniform bound for $|\partial \nu/\partial r|$. Thus, we get a uniform bound for $|\partial \nu/\partial t|$ using just (3.6).

The less trivial step is to establish uniform bounds on $|\partial \sigma/\partial t|$ and $|\dot{\rho}_N|$, needed to complete the proof of compactness. Let $z(r,t) = \partial \sigma/\partial t$. Differentiating $\Delta \sigma = f(\sigma)\nu$

w.r.t. time, we obtain

$$\frac{\partial^2 z}{\partial r^2} + \frac{1}{r}\frac{\partial z}{\partial r} = f'(\sigma) z \nu + f(\sigma)\frac{\partial \nu}{\partial t}\,. \tag{3.42}$$

At a possible maximum of z in (r_0, ρ_N), it must be $\partial z/\partial r = 0$, $\partial^2 z/\partial r^2 \le 0$, so that from (3.42) it follows $f'(\sigma) z\nu \le -f(\sigma)(\partial \nu/\partial t)$. Denoting by $\bar{z}_{max}$ the value of z at such local maximum, and being that $f_{max} = \max_\sigma f(\sigma)$ and $f'_{min} = \min_\sigma f'(\sigma)$, the previous inequality gives

$$\bar{z}_{max} \le -\frac{f(\sigma)}{f'(\sigma)}\frac{1}{\nu}\frac{\partial \nu}{\partial t} \le \frac{f_{max}}{f'_{min}}\frac{1}{N_1}\left\|\frac{\partial \nu}{\partial t}\right\|. \tag{3.43}$$

At a possible minimum of z in (r_0, ρ_N), it must be that

$$\bar{z}_{min} \ge -\frac{f(\sigma)}{f'(\sigma)}\frac{1}{\nu}\frac{\partial \nu}{\partial t} \ge -\frac{f_{max}}{f'_{min}}\frac{1}{N_1}\left\|\frac{\partial \nu}{\partial t}\right\|, \tag{3.44}$$

where $\bar{z}_{min}$ is the value of z at such local minimum.

When $\sigma(\rho_N(t), t) = \sigma_N$, since $z = 0$ for $r = r_0$ and $r = \rho_N(t)$, we can conclude that

$$\left|\frac{\partial \sigma}{\partial t}\right| \le \frac{f_{max}}{f'_{min}}\frac{1}{N_1}\left\|\frac{\partial \nu}{\partial t}\right\|. \tag{3.45}$$

Thus, from (3.13) written for $\rho_N(t)$, we get a uniform bound for $|\dot{\rho}_N|$.

When ρ_N is a material surface, i.e., $\dot{\rho}_N = u(\rho_N, t-\theta)$, the desired estimate for $|\dot{\rho}_N|$ is provided by the uniform boundedness of u. Moreover, since $\partial\sigma/\partial r|_{r=\rho_N(t)} = 0$, differentiating w.r.t. time we obtain

$$\left.\frac{\partial^2 \sigma}{\partial r^2}\right|_{r=\rho_N(t)} \dot{\rho}_N + \left.\frac{\partial^2 \sigma}{\partial r \partial t}\right|_{r=\rho_N(t)} = 0\,. \tag{3.46}$$

Also, we know that

$$\left.\frac{\partial^2 \sigma}{\partial r^2}\right|_{r=\rho_N(t)} = [f(\sigma)\nu]\Big|_{r=\rho_N(t)} \equiv g(t)\,, \tag{3.47}$$

which is positive and bounded. Therefore, at each step, we can construct the solution of the problem

$$\Delta z = \frac{\partial}{\partial t}[f(\sigma)\nu]\,, \qquad z(r_0, t) = 0\,, \quad z_r(\rho_N, t) = -g\dot{\rho}_N\,. \tag{3.48}$$

The solution will satisfy

$$z = -\dot{\rho}_N \rho_N g \log\frac{r}{r_0} - \int_{r_0}^{r} \frac{1}{r'}\left(\int_{r'}^{\rho_N} r''\frac{\partial}{\partial t}[f(\sigma)\nu]\,dr''\right)dr'$$

$$= -\dot{\rho}_N \rho_N g \log\frac{r}{r_0} - \int_{r_0}^{\rho_N} r' \log\frac{\min[r', r]}{r_0}\frac{\partial}{\partial t}[f(\sigma)\nu]\,dr'\,. \tag{3.49}$$

Let us suppose that $\dot\rho_N<0$. Then, from (3.47) and (3.48), $z_r(\rho_N,t)>0$ and z may have an absolute maximum at $r=\rho_N$. If $z_{max}=z(\rho_N)$, from (3.49) and taking into account (3.44) we obtain

$$z_{max}\le -\dot\rho_N\rho_N g\log\frac{\rho_N}{r_0}+f_{max}\left\|\frac{\partial\nu}{\partial t}\right\|\int_{r_0}^{\rho_N} r'\log\frac{r'}{r_0}\,dr'\left(1+\frac{f'_{max}}{f'_{min}}\frac{N_2}{N_1}\right), \tag{3.50}$$

which, together with (3.43)–(3.44), guarantees the uniform boundedness of $|\partial\sigma/\partial t|$. If $\dot\rho_N>0$, $z_r(\rho_N,t)<0$ and z may have an absolute minimum at $r=\rho_N$. If $z_{min}=z(\rho_N)$, we can obtain similarly

$$z_{min}\ge -\dot\rho_N\rho_N g\log\frac{\rho_N}{r_0}-f_{max}\left\|\frac{\partial\nu}{\partial t}\right\|\int_{r_0}^{\rho_N} r'\log\frac{r'}{r_0}\,dr'\left(1+\frac{f'_{max}}{f'_{min}}\frac{N_2}{N_1}\right), \tag{3.51}$$

leading to the parallel conclusion about the lower bound. If $\dot\rho_N=0$, z may have either a maximum or a minimum at $r=\rho_N$. In such cases (3.50) or (3.51) applies, still confirming the boundedness of $|\partial\sigma/\partial t|$.

From the above estimates, it also follows that $u(r,t)$ is uniformly Lipschitz continuous. Finally, concerning $\tilde c$, we can say that we have uniform inner Schauder estimates on both sides of the discontinuity curve of the consumption term (see [17, Chap. 4]). As a matter of fact, the Lipschitz continuity of $\dot B(t)$ allows us to extend such an estimate to the outer boundary $r=B(t)$. Therefore, uniform estimates for c in the norm $H^{2+\alpha,1+\alpha/2}$ are available in all the domains whose closure does not touch $r=r_0$ or the interface $r=\rho_N(t)$. □

Now we can prove Theorem 3.1.

Proof of Theorem 3.1. Let us indicate here by the subscript "n" the approximation of order n. The existence can be established simply thanks to Lemma 3.3, which provides enough compactness of the family of approximating solutions. Indeed, we can select a subsequence of indices, say, $\{n_k\}$, for which we have uniform convergence of $\rho_{N_{n_k}}, B_{n_k}$ to ρ_N, B, and of the functions ν_{n_k} to ν in $r_0\le r\le\rho_N(t)$ and of σ_{n_k}, c_{n_k} to σ, c in $r_0\le r\le B(t)$, $t\in[0,T]$. We notice that the convergence of the approximations ν_{n_k} has to be intended as

$$\lim_{k\to\infty}\sup_{(r,t)\in D_{n_k}\cap D}|\nu_{n_k}(r,t)-\nu(r,t)|=0\,,$$

where $D_n=\{(r,t):\ r\in[r_0,\rho_{N_n}(t)],t\in[0,T]\}$ and $D=\{(r,t):\ r\in[r_0,\rho_N(t)],t\in[0,T]\}$. In turn, through (3.16), this implies the uniform convergence of the corresponding sequence u_{n_k} (and $\partial u_{n_k}/\partial r$). Although the constraints (1.13) and (1.22) in the approximating scheme are not used as written, but rather with a time shift, and moreover they can be applied with the respective tolerances u_{tol}/n and σ_{tol}/n, it is clear that the correct inequalities are obtained in the limit. Similarly we have the uniform convergence of the characteristic lines and we can pass to the limit in equation (3.26). At the same time we can pass to the limit in (3.11)–(3.12) (with $\tilde\rho_N(t)=\rho_N(t)$) or (3.14)–(3.15), showing that the limit functions satisfy the same equations, so that in particular the limit ρ_N preserves the properties characterizing the boundary of the necrotic region. Thus we see that the limit functions ν, σ, u satisfy the governing equations of the model in their integral form. From the integral form we can go back to the original differential statement of the problem, just performing the derivatives and checking that all the governing differential equations, as well as the initial and boundary conditions, are satisfied. Concerning c, the Schauder estimates allow us to

pass to the limit directly in the parabolic differential equation, separately in P∪T∪Q and in N, while the differential equation is satisfied in the whole domain in the sense of $W_q^{2,1}$ for any $q>1$, thus guaranteeing the Hölder continuity of $\partial c/\partial r$. Therefore, any convergent subsequence in the family of approximating solutions provides a solution to the original problem. □

The approximating procedure previously described becomes constructive if we can say that the whole sequence is convergent. In turn, this is guaranteed if we prove uniqueness. First we prove the following property of the solution.

LEMMA 3.6. *The solution ν, for $r\in[r_0,\rho_N(t)]$, satisfies the inequalities*

$$0 < N_1 \le \nu(r,t) \le 1\,, \quad t\in[0,T]\,, \tag{3.52}$$

where N_1 is defined by (3.25).

Proof. We observe preliminarily that, as we did for the approximating solutions, we can also define for the actual solution the function $\hat r=\zeta(r,t)$ for $r\in[r_0,\rho_N(t)]$ and $t\in[0,T]$, such that $r=\eta(\zeta(r,t),t)$, with $\eta(\hat r,t)$ being the characteristic line starting from $\hat r$. In particular, we can interpret (1.11) as $D_u\nu=-\nu H(t,c,\sigma,\nu)$ on the characteristic lines (including $r=r_0$), and we can see that $D_u\nu<0$ at all points where $\nu>1$. Since $\nu_0\le 1$ everywhere, this implies that ν cannot take values greater than 1. Since the lower bound N_1 holds for all the approximations of ν, it will also hold for their limit. □

Let us pass to the following proof of uniqueness.

Proof of Theorem 3.2 We notice that, for a certain time interval starting from $t=0$, the difference $u(\rho_N,t)-\dot\rho_N(t)$ is positive for all possible solutions (the argument is the same one we applied for the approximate solutions during the first time step). Therefore we start comparing two solutions of this type.

Let us consider two possible solutions of type (1.18)–(1.19) in a time interval $(0,\hat t\,)$, $\hat t\le T$, and let us denote by $\delta\nu$, δu, $\delta\sigma$, $\delta\rho_N$, δc, δB the differences of the respective quantities. Using the labels 1 and 2 for the two solutions (so that $\delta\nu(r,t)=\nu_1(r,t)-\nu_2(r,t)$, and so on) and setting $\rho_{min}(t)=\min[\rho_{N_1}(t),\rho_{N_2}(t)]$, $\rho_{max}(t)=\max[\rho_{N_1}(t),\rho_{N_2}(t)]$, we have the following equation (where μ_1, μ_{R_1}, μ_{C_1}, χ_1 mean that the quantities are evaluated for solution 1, and the overbar means that the derivative is computed at a suitable point between the values of the independent variables for solutions 1 and 2):

$$\begin{aligned} &D_{u_1}\delta\nu+\big[\mu_1+\mu_{R_1}+\mu_{C_1}-(\chi_1+\mu_N)+(\chi_1+\mu_N)(\nu_1+\nu_2)\big]\delta\nu+\frac{\partial\nu_2}{\partial r}\delta u\\ &+\nu_2\left[\overline{\frac{\partial\mu}{\partial\sigma}}+\overline{\frac{\partial\mu_R}{\partial\sigma}}+\overline{\frac{\partial\mu_C}{\partial\sigma}}-\overline{\chi}'(1-\nu_2)\right]\delta\sigma+\nu_2\overline{\frac{\partial\mu_C}{\partial c}}\delta c=0 \end{aligned} \tag{3.53}$$

with zero initial condition and with $\delta\nu$ continued in (ρ_{min},ρ_{max}) as $(-1)^{j+1}\nu_j$, with $j=1$ if $\rho_{N_1}\ge\rho_{N_2}$ and $j=2$ otherwise. Of course $\delta\nu=0$ in the intersection of the two regions N_1, N_2. Moreover we have

$$r\delta u=\begin{cases}\displaystyle\int_{r_0}^{r} r'\big[\delta\nu(\chi_1+\mu_N)+\nu_2\overline{\chi}'\delta\sigma\big]\,dr'\,, & r\in[r_0,\rho_{min}],\\ \displaystyle\int_{r_0}^{\rho_{min}} r\big[\delta\nu(\chi_1+\mu_N)+\nu_2\overline{\chi}'\delta\sigma\big]\,dr+(-1)^{j+1}\int_{\rho_{min}}^{r} r'\big[\nu_j(\chi_j+\mu_N)-\mu_N\big]\,dr'\\ \qquad +(-1)^{j+1}\frac{\tilde\mu_N}{2}(r^2-\rho_{min}^2)\,, & r\in(\rho_{min},\rho_{max}]\,.\end{cases} \tag{3.54}$$

Taking into account that for σ_i, $i=1,2$, we have

$$\sigma_i(r,t)-\sigma_N=\int_r^{\rho_{N_i}(t)} r'\log\frac{r'}{r}f(\sigma_i)\nu_i\,dr'\,, \tag{3.55}$$

$$\sigma^\star-\sigma_N=\int_{r_0}^{\rho_{N_i}(t)} r\log\frac{r}{r_0}f(\sigma_i)\nu_i\,dr\,, \tag{3.56}$$

we obtain from (3.56)

$$(-1)^j\int_{\rho_{min}}^{\rho_{max}} r\log\frac{r}{r_0}f(\sigma_j)\nu_j\,dr=\int_{r_0}^{\rho_{min}} r\log\frac{r}{r_0}[f(\sigma_1)\nu_1-f(\sigma_2)\nu_2]\,dr\,. \tag{3.57}$$

From (3.55), for $r\in(r_0,\rho_{min}]$ we have

$$\begin{aligned}\delta\sigma=(-1)^{j+1}&\int_{\rho_{min}}^{\rho_{max}} r'\log\frac{r'}{r}f(\sigma_j)\nu_j\,dr'\\ &+\int_r^{\rho_{min}} r'\log\frac{r'}{r}[f(\sigma_1)\nu_1-f(\sigma_2)\nu_2]\,dr'\,,\end{aligned} \tag{3.58}$$

whereas, for $r\in(\rho_{min},\rho_{max}]$,

$$\delta\sigma=(-1)^{j+1}\int_r^{\rho_{max}} r'\log\frac{r'}{r}f(\sigma_j)\nu_j\,dr'\,. \tag{3.59}$$

Because there exists a positive lower bound of the product $f\nu$, a lower estimate of the left-hand side of (3.57) can be written as $(f\nu)_{min}\,\rho_{min}\log(\rho_{min}/r_0)|\delta\rho_N|$. Since (3.56) gives a lower estimate for ρ_N (as in Lemma 3.2), from (3.57) we get

$$|\delta\rho_N|\le K_1\int_{r_0}^{\rho_{min}} r\big(\|f\|\,|\delta\nu|+\|f'\|\,|\delta\sigma|\big)\log\frac{r}{r_0}\,dr, \tag{3.60}$$

where K_1 is a known constant. From (3.58)–(3.59), we see that for $r\in(r_0,\rho_{max}]$

$$|\delta\sigma|\le\int_{\rho_{min}}^{\rho_{max}} r\log\frac{r}{r_0}f(\sigma_j)\nu_j\,dr+\int_r^{\rho_{min}} r'\log\frac{r'}{r}|f(\sigma_1)\nu_1-f(\sigma_2)\nu_2|\,dr'\,,$$

and, taking into account (3.57) and that $\nu\le1$ (see Lemma 3.4), we obtain

$$|\delta\sigma|\le2\|f'\|\int_{r_0}^{\rho_{min}} r\log\frac{r}{r_0}|\delta\sigma|\,dr+2\|f\|\int_{r_0}^{\rho_{min}} r\log\frac{r}{r_0}|\delta\nu|\,dr\,. \tag{3.61}$$

Provided that

$$2\|f'\|\int_{r_0}^{\rho_{min}} r\log\frac{r}{r_0}\,dr=\|f'\|\left[\rho_{min}^2\log\frac{\rho_{min}}{r_0}-\frac{1}{2}(\rho_{min}^2-r_0^2)\right]<1\,, \tag{3.62}$$

as guaranteed by hypothesis (3.1), from (3.61) we obtain

$$\|\delta\sigma\|_t\le K_2\|\delta\nu\|_t\,, \tag{3.63}$$

where $\|\cdot\|_t$ means the sup w.r.t. r and to time in $[0,t]$. Concerning the equation for δc, to be satisfied in $r_0<r<B_{min}(t)$, $0<t<\hat{t}$, B_{min} denoting $\min[B_1,B_2]$, we have

$$\frac{\partial \delta c}{\partial t} - D_C \Delta \delta c = -\varphi_{C_1} \nu^\star \delta\nu - \left(\overline{\frac{\partial \varphi_C}{\partial c}}\right)\nu^\star \nu_2 \delta c - \left(\overline{\frac{\partial \varphi_C}{\partial \sigma}}\right)\nu^\star \nu_2 \delta\sigma - \lambda \delta c\,, \tag{3.64}$$

$$\delta c(r_0,t) = 0\,, \tag{3.65}$$

$$\delta c(r,0) = 0\,. \tag{3.66}$$

If $\hat{t}$ is sufficiently small to guarantee that the differences $B_i - \rho_{N_j}$, $i=1,2$, $j=1,2$, remain strictly positive, we also have

$$\left.\frac{\partial \delta c}{\partial r}\right|_{r=B_{min}(t)} = (-1)^{k+1} \left.\frac{\partial^2 c_k}{\partial r^2}\right|_{r=\bar{r}(t)} |\delta B|\,, \tag{3.67}$$

where $\bar{r}(t)$ is a suitable point between the boundaries $B_1(t)$, $B_2(t)$, and $k=1$ if $B_1 \geq B_2$ and $k=2$ otherwise. The coefficient of $|\delta B|$ in (3.67) is a priori bounded since c_1,c_2 possess the same properties stated for the approximating functions in Lemma 3.3.

Now we are able to write the following chain of inequalities, starting with

$$\|\delta\nu\|_t \leq \int_0^t \left(k_1 \|\delta u\|_\tau + k_2 \|\delta\sigma\|_\tau + k_3 \|\delta c\|_\tau\right) d\tau, \tag{3.68}$$

that can be obtained from (3.53). From (3.54) we see that $\|\delta u\|_\tau$ can be estimated in terms of $\|\delta\rho_N\|_\tau$, $\|\delta\sigma\|_\tau$, $\|\delta\nu\|_\tau$ and, ultimately, because of (3.60) and (3.63), in terms of $\|\delta\nu\|_\tau$. So (3.68) implies

$$\|\delta\nu\|_t \leq \int_0^t \left(k_3 \|\delta c\|_\tau + k_4 \|\delta\nu\|_\tau\right) d\tau\,. \tag{3.69}$$

Going back to problem (3.64)–(3.67), for which an estimate of $\partial^2 c_k/\partial r^2$ is available in the region between B_{min} and $B_{max}=\max[B_1,B_2]$, taking into account that $|\delta B| \leq \int_0^t \|\delta u\|_\tau \, d\tau$, and exploiting the estimates already used for $\delta\sigma$ and δu, we obtain by classical means the inequality

$$\|\delta c\|_t \leq \int_0^t \left(k_5 \|\delta\nu\|_\tau + k_6 \|\delta c\|_\tau\right) d\tau, \tag{3.70}$$

which, together with (3.69), immediately yields $\|\delta c\|_t = \|\delta\nu\|_t = 0$. Thus we may conclude that the solution is unique in a suitably small time interval, and by extension up to a possible time point $\bar{t}$ such that in any right neighborhood (1.18)–(1.19) cannot hold.

Let us now suppose that after $\bar{t}$ we have in some interval two solutions for which the interface $r=\rho_N(t)$ is a material surface. Arguments similar to those seen above can be repeated, taking into account that in the present case we have ($i=1,2$)

$$\sigma_i(r,t) - \sigma_i(\rho_{N_i}(t),t) = \int_r^{\rho_{N_i}(t)} r' \log\frac{r'}{r} f(\sigma_i)\nu_i \, dr'\,, \tag{3.71}$$

$$\sigma^\star - \sigma_i(\rho_{N_i}(t),t) = \int_{r_0}^{\rho_{N_i}(t)} r \log \frac{r}{r_0} f(\sigma_i)\nu_i \, dr \,, \tag{3.72}$$

implying

$$\sigma_i - \sigma^\star = \int_{r}^{\rho_{N_i}} r' \log \frac{r'}{r} f(\sigma_i)\nu_i \, dr' - \int_{r_0}^{\rho_{N_i}} r \log \frac{r}{r_0} f(\sigma_i)\nu_i \, dr \,. \tag{3.73}$$

Moreover, since $\rho_{N_1}(\bar t)=\rho_{N_2}(\bar t)$, we have for $t>\bar t$

$$\delta\rho_N = \int_{\bar t}^{t} [u_1(\rho_{N_1}(\tau),\tau) - u_2(\rho_{N_2}(\tau),\tau)] \, d\tau \,; \tag{3.74}$$

thus

$$|\delta\rho_N| \le \int_{\bar t}^{t} \left(|\delta u|_{r=\rho_{min}(\tau)} + \left\| \frac{\partial u}{\partial r} \right\| |\delta\rho_N(\tau)| \right) d\tau \,. \tag{3.75}$$

Now, using easy estimates on δu, $\delta\sigma$, $\delta\nu$, and the boundedness of $|\partial u/\partial r|$, we can infer uniqueness until $r=\rho_N(t)$ is a material boundary. The procedures previously described can be applied after each switch to solutions having the interface ρ_N of the same type (both nonmaterial or both material).

We observe now that the evolutive problem in which constraint (1.13) is not imposed, and ρ_N and σ are defined by (1.15), (1.17), (1.19)–(1.20), cannot have more than one solution (the comparison technique is the same as the one used above). The same holds for the evolutive problem in which constraint (1.22) is not imposed, ρ_N is defined by (1.21), and σ is defined by (1.15), (1.17), and (1.20). Therefore, we can exclude that after $\bar t$, or any other switching point, there can be a time interval in which our problem has a solution of one type and another solution of different type. This, in fact, would imply that two different unconstrained solutions exist in a time interval after $\bar t$, since it is the behavior of such unconstrained solutions that governs the switch of ρ_N from one type to the other.

Hence, it remains only to examine the case of two solutions having infinitely many switching points in any right neighborhood of the time $\bar t$ (the reader can observe that the comparison between two solutions of different type after $\bar t$, which we avoided on the basis of the argument above, is de facto included in the analysis that follows). The argument proceeds in a similar way, the main difference occurring in the comparison of σ_1,σ_2 and ρ_{N_1},ρ_{N_2}. Let us consider an interval $(\bar t, \bar t+\varepsilon)$ and its partition in intervals in which the two solutions are both of the same type and in intervals in which they are of different type. We fix our attention on the second class of intervals and, to be specific, let us assume that ρ_N is nonmaterial for solution 1 and material for solution 2. Subtracting (3.72) with $i=2$ from (3.56) with $i=1$, we get

$$\sigma_2(\rho_{N_2}(t),t) - \sigma_N = \int_{r_0}^{\rho_{min}} r \log \frac{r}{r_0} [f(\sigma_1)\nu_1 - f(\sigma_2)\nu_2] \, dr$$

$$+(-1)^{j+1} \int_{\rho_{min}}^{\rho_{max}} r \log \frac{r}{r_0} f(\sigma_j)\nu_j \, dr, \tag{3.76}$$

which replaces (3.57). Thus we may derive an inequality similar to (3.60):

$$|\delta\rho_N| \leq \quad K_1 \int_{r_0}^{\rho_{min}} r\big(\|f\|\,|\delta\nu| + \|f'\|\,|\delta\sigma|\big)\log\frac{r}{r_0}\,dr$$
$$+ K_1|\sigma_2(\rho_{N_2}(t),t)-\sigma_N|\,. \tag{3.77}$$

Now we can write

$$|\sigma_2(\rho_{N_2},t)-\sigma_N| \leq |\delta\sigma(\rho_{N_2},t)| + \sigma_1(\rho_{N_2},t)-\sigma_N\,, \tag{3.78}$$

if, e.g., $\rho_{N_1} > \rho_{N_2}$. Moreover,

$$\sigma_1(\rho_{N_2},t)-\sigma_N = \left|\frac{\partial\sigma_1}{\partial r}(\bar r,t)\right| |\delta\rho_N| \tag{3.79}$$

with $\bar r$ between ρ_{N_2} and ρ_{N_1}. Since $\partial\sigma_1/\partial r$ vanishes for $r=\rho_{N_1}$, we can also say that

$$\left|\frac{\partial\sigma_1}{\partial r}(\bar r,t)\right| \leq \left\|\frac{\partial^2\sigma_1}{\partial r^2}\right\| |\delta\rho_N|\,.$$

If, instead, $\rho_{N_1} < \rho_{N_2}$, we have similar inequalities with the indices interchanged. Thus from (3.78) we deduce

$$|\sigma_2(\rho_{N_2},t)-\sigma_N| \leq |\delta\sigma(\rho_{N_2},t)| + C|\delta\rho_N|^2 \tag{3.80}$$

with $C>0$ known a priori. On the other hand, we may take ε so small that in $(\bar t, \bar t+\varepsilon)$ we have $K_1C|\delta\rho_N|<1/2$, thanks to the fact that for both solutions we know an upper bound for $|\dot\rho_{N_i}|$. Thus, we may rewrite (3.77) in the form

$$|\delta\rho_N| \leq 2K_1 \int_{r_0}^{\rho_{min}} r\big(\|f\|\,|\delta\nu| + \|f'\|\,|\delta\sigma|\big)\log\frac{r}{r_0}\,dr + 2K_1|\delta\sigma(\rho_{N_2}(t),t)|\,. \tag{3.81}$$

We must now replace (3.58) by

$$\delta\sigma + \sigma_2(\rho_{N_2}(t),t)-\sigma_N = (-1)^{j+1}\int_{\rho_{min}}^{\rho_{max}} r'\log\frac{r'}{r} f(\sigma_j)\nu_j\,dr'$$

$$+ \int_r^{\rho_{min}} r'\log\frac{r'}{r}[f(\sigma_1)\nu_1 - f(\sigma_2)\nu_2]\,dr'\,. \tag{3.82}$$

Combining (3.82) and (3.76) we obtain the same inequality (3.61), eventually implying (3.63) with the norm referring to the appropriate time interval.

For the first class of intervals, i.e., the intervals in which the two solutions are both of the same type, the estimates for $|\delta\sigma|$ and $|\delta\rho_N|$ are the same ones we have already used, except for a small change concerning the comparison of solutions which both have a material ρ_N interface. Indeed, in (3.74) the term $\delta\rho_N(\hat t\,)$ (where $\hat t$ now denotes the initial time of the interval we are considering) must be added on the right-hand side. Such a term is inherited from the previous interval in which the solutions are of different type and therefore it is expressed in the way we have just seen, that is, by means of (3.81). Therefore, we can conclude that also in this case the solution is unique. □

4. Concluding comments. As a final comment, we stress that some of the simplifying assumptions made in the development of the present model could be relaxed with some further refinements. For simplicity, we have taken $\sigma^\star$ constant here, but the whole theory can be extended to the case of $\sigma^\star$ variable with the time, provided it remains strictly above σ_P. We could also consider a flux condition instead of (1.17). Similarly, condition (1.28) has no crucial role in the treatment and could be replaced with a flux condition. Finally, a dependence of cell proliferation on treatment could be taken into account by representing the proliferation rate as a function $\chi(\sigma, c, t)$. The numerical solution of the evolutive problem under various therapeutic treatment modalities will be presented in a forthcoming paper [6]. The numerical results show that the switching from a nonmaterial ρ_N interface to a material interface, and vice versa, does occur under usual treatment modalities.

HIGHER DIMENSIONAL SLEP EQUATION AND APPLICATIONS TO MORPHOLOGICAL STABILITY IN POLYMER PROBLEMS*

YASUMASA NISHIURA† AND HIROMASA SUZUKI‡

Dedicated to Professors Masayasu Mimura and Takaaki Nishida on their sixtieth birthdays

Abstract. Existence and stability of stationary internal layered solutions to a rescaled diblock copolymer equation are studied in higher dimensional space. Rescaling is necessary since the characteristic domain size of any stable pattern eventually vanishes in an appropriate singular limit. A general sufficient condition for the existence of singularly perturbed solutions and the associated stability criterion are given in the form of linear operators acting only on the limiting location of the interface. Applying the results to radially symmetric and planar patterns, we can show, for instance, stability of radially symmetric patterns when one of the components of diblock copolymer dominates the other, and that of the long-striped pattern in a long and narrow domain for the planar case. These results are consistent with the experimental ones. The above existence and stability criterion can be easily extended to a class of reaction diffusion systems of activator-inhibitor type.

Key words. singular perturbation, diblock copolymer, reaction diffusion system, pattern formation, matched asymptotic expansion, stability, critical eigenvalues

1. Introduction.

In this paper, we shall discuss two basic problems of singularly perturbed solutions to the fourth order equation (1.1) arising in modelling the dynamics of diblock copolymer melts in higher dimensional space, namely *Under what conditions existence of stationary singularly perturbed solution is guaranteed?* and *How is the stability of it?*. The former is related to the possible morphological forms, and the latter is crucial for observability. We shall see that both problems are eventually reduced to solving the equations on the *interface* in the singular limit. Especially, the spectral problem on the interface called the SLEP equation in higher dimensional space (see (1.13) and (4.22)), is a generalization of a one-dimensional version for reaction diffusion systems discussed in [11] and [10]. The model equation (1.1) below looks very special; however, the method employed here is quite general and can be extended to the activator-inhibitor systems treated in [11] and [10], in fact the mechanisms causing pattern formation have common features in both models. Our model takes the following form:

$$
\begin{cases}
u_t = -\Delta\{d^2\Delta u + f(u) - \sigma(-\Delta_N)^{-1}(u-\overline{u})\} \\
\qquad = -\Delta\{d^2\Delta u + f(u)\} - \sigma(u-\overline{u}), & (X,t) \in \hat{\Omega}\times(0,\infty), \\
\dfrac{\partial u}{\partial n} = \dfrac{\partial(\Delta u)}{\partial n} = 0, & (X,t) \in \partial\hat{\Omega}\times(0,\infty), \\
\dfrac{1}{|\hat{\Omega}|}\displaystyle\int_{\hat{\Omega}} u dX = \overline{u},
\end{cases} \tag{1.1}
$$

where u is the order parameter which represents the ratio of two homopolymers, f is basically a bistable nonlinearity (typically $u-u^3$), d and σ are positive constants, Δ_N is the Laplace operator under the Neumann boundary condition, and $\hat{\Omega}$ is a smooth bounded domain in $\mathbf{R}^N$ ($N \geq 2$). Originally, the model system was given by the energy functional form in [16] (see also [1]), and then reformulated in the above form by [12], which triggered many interesting rigorous works such as [25] and [26]. The associated Euler–Lagrange equation with the functional is given by (1.1). Diblock copolymer is a chain where two different homopolymers are connected, and the connectivity causes a long range interaction. In fact, its effect is reflected by the nonlocal term $\sigma(-\Delta_N)^{-1}(u-\overline{u})$, where σ is proportional to the inverse of the polymerization index (i.e., length of the chain). Due to the nonlocal term $\sigma(-\Delta_N)^{-1}(u-\overline{u})$, (1.1) displays a variety of stationary *mesoscopic* patterns including lamellar, column, spherical, double gyroid morphologies and so on (see, for instance, [24] and the reference therein). Here the mesoscopic means an intermediate scale between micro and macro, and it becomes very fine as d tends to zero as in the following proposition. This makes a sharp contrast with the case $\sigma \equiv 0$, i.e., Cahn–Hilliard equation. For experimental observation, see [6, 7, 8]. Note also that the nonlocal effect is similar to the role of the inhibitor field for activator-inhibitor system, and hence our analysis basically encompasses such a system as we shall see in section 5.

In order to have a reasonable singular limit, some sort of scaling law is necessary and we adopt the following one, which was originally proposed in [12] in the above setting and was proved rigorously by [14] for one-dimensional case and by [2] for higher dimensional case.

PROPOSITION 1.1. *(Theorem* 3.2 in [12]). *In order to have a well-defined limiting stationary problem of* (1.1) *as* $d \downarrow 0$, *which is independent of parameters* d *and* σ, *there exists a unique scaling with respect to space and time given by:* $x := X/(d^{1/3}\sigma^{-1/3})$, $\tau := \sigma t$. *The characteristic domain size is proportional to* $(d/\sigma)^{1/3}$ *and the morphology of pattern is determined by solving* (1.7)–(1.9) (*see assumption* (A4)).

This scaling law is not only a sufficient condition in order to have a well-defined singular limit problem of (1.1) as $d \downarrow 0$ (see [12] for details), but also can be justified from a view point of statistical physics (see [3]). In terms of the new variables x and τ, the equations in (1.1) are recast as

$$
u_\tau = \Delta\left\{-\epsilon\Delta u - \frac{1}{\epsilon}f(u)\right\} - (u-\overline{u}), \quad (x,\tau) \in \Omega\times(0,\infty), \tag{1.2}
$$

where $\epsilon := d^{2/3}\sigma^{1/3}$ and Ω is a magnified unit domain. Here we implicitly assume that the patterns are periodic in space (in the original scaling), and we focus on a unit cell of this periodic structure.

On the other hand, a typical activator-inhibitor system is given by

$$\begin{cases} u_t = d^2\Delta u + f(u) - v, \\ \\ v_t = D\Delta v + g(u,v), \end{cases} \qquad (x,t) \in \hat{\Omega} \times (0,\infty), \tag{1.3}$$

where typically $(f,g) = (u - u^3, u - \gamma v)(\gamma > 0)$. It was proved in [13] that if (1.3) has a d-family of stationary matched asymptotic solutions whose interface is smooth up to $d = 0$, then it must become unstable for small d. It is observed numerically that stable patterns become finer and finer when d becomes small (see also a recent work [15]), which strongly suggests the necessity for rescaling in order to track the stable patterns. It was also shown in [13] that the characteristic size of stable patterns is of order $d^{1/3}$ by formal computation. Magnifying the system (1.3) with this scaling, the rescaled system is given by

$$\begin{cases} u_t = \epsilon^2\Delta u + f(u) - v, \\ \\ \epsilon v_t = D\Delta v + \epsilon g(u,v), \end{cases} \qquad (x,t) \in \Omega \times (0,\infty), \tag{1.4}$$

where $\epsilon = d^{2/3}$. (See [4, 18, 19, 20, 21, 23].)

At first sight there is no resemblance between (1.2) and (1.4); however, rewriting (1.2) by introducing new variable $v := \epsilon^2\Delta u + f(u)$ and new time $\tilde{t} := \tau/\epsilon$, the resulting system becomes

$$\begin{cases} 0 = \epsilon^2\Delta u + f(u) - v, \\ \\ 0 = \Delta v + \epsilon(u - \overline{u}) + u_{\tilde{t}}, \end{cases} \qquad (x,\tilde{t}) \in \Omega \times (0,\infty), \tag{1.5}$$

$$\frac{\partial u}{\partial n} = 0 = \frac{\partial v}{\partial n}, \quad (x,\tilde{t}) \in \partial\Omega \times (0,\infty). \tag{1.6}$$

Now it is clear that (1.2) is similar to (1.4) as far as stationary solutions are concerned. Similarity in fact can be extended to dynamical level (i.e., stability), which will be discussed in section 5.

As a consequence of the above discussion, (1.5) is expected to have a well-defined smooth interface in the singular limit. The next issue is to locate such an interface by solving, what is called, the *reduced problem* of (1.5) (see (1.7)–(1.9)); however, it is in general quite difficult to solve (1.7)–(1.9) and obtain its explicit profile. The results listed below will be, therefore, stated under the assumption that such reduced solutions exist. Nevertheless, this assumption can be checked explicitly for simple but basic cases when Ω has a spherical or planar geometry, which will be shown in later sections.

Now we shall state the assumptions and introduce several key notation and operators for later use.

(A1) f is a smooth bistable nonlinearity. The equation $f(u) - v = 0$ has three sub-branches of solutions

$$\mathcal{C}_+ = \{(u,v) | u = h^+(v), v \in I_+\}, \ \mathcal{C}_- = \{(u,v) | u = h^-(v), v \in I_-\} \quad \text{and}$$

$$\mathcal{C}_0 = \{(u,v) | u = h^0(v), v \in I_+ \cap I_-\}$$

such that $h^-(v) < h^0(v) < h^+(v)$ for $v \in I_+ \cap I_-$.

(A2) $f_u(h^{\pm}(v)) = \frac{d}{du} f(h^{\pm}(v)) < 0$ on $I_{\pm}$.

(A3) $J(v) := \int_{h^-(v)}^{h^+(v)} [f(s) - v] ds$, $v \in I_0$, has an isolated zero $v^* \in I_0$ such that $J'(v^*) < 0$.

(A1)–(A3) with (A4′) and (A7) assumed later are the sufficient conditions for the existence and stability of transition layer solutions to one-dimensional activator-inhibitor system (1.3) (see [10] and [11]).

We assume that the domain Ω is simply connected, and Γ is either one of the following two cases.

Case I. $\Omega \in \mathbf{R}^N$ $(N \geq 2)$ has smooth boundary and define a set $\mathcal{F}$ by

$$\mathcal{F} = \big\{\Gamma \subset \Omega \mid \Gamma \text{ is an } N-1 \text{ dimensional smooth compact connected manifold without boundary}\big\}.$$

Each $\Gamma \in \mathcal{F}$ divides Ω into two connected components. We denote by $\Omega_+(\Gamma)$ the component of $\Omega \backslash \Gamma$ which has $\partial\Omega$ as part of its boundary. The other component is defined by $\Omega_-(\Gamma)$. Therefore we have

$$\partial\Omega_+(\Gamma) = \partial\Omega \cup \Gamma \quad \text{and} \quad \partial\Omega_-(\Gamma) = \Gamma.$$

Case II. $\Omega \in \mathbf{R}^2$ is a rectangle $(0, X) \times (0, Y)$. Then we define $\mathcal{F}$ by

$$\mathcal{F} = \big\{\Gamma \subset \Omega \mid \Gamma \text{ is a line, which is parallel to the } y\text{-axis and touches transversely with the boundary } \partial\Omega\big\}.$$

Then Ω is divided into two connected components $\Omega_-(\Gamma) = (0, x_0) \times (0, Y)$ and $\Omega_+(\Gamma) = (x_0, X) \times (0, Y)$, where $\Gamma = \{(x_0, y) \in \mathbf{R}^2 \mid 0 \leq y \leq Y\}$ for some $x_0 \in (0, X)$. For later use we introduce the *aspect ratio* κ of Ω, i.e., $\kappa := X/Y$.

Let us introduce a local coordinate system in the neighborhood of Γ. By the implicit function theorem there exists a $d_0 > 0$ such that the map $p : [-d_0, d_0] \times \Gamma \to \Gamma_{d_0}$ defined by

$$p(r, y) = y + r\nu(y)$$

is a diffeomorphism, where $\Gamma_{d_0} = \{x \in \Omega | \text{dist}(x, \Gamma) < d_0\}$, $\nu = \nu(y)$ is the unit normal vector on Γ $(y \in \Gamma)$ which points the interior of $\Omega_+(\Gamma)$. Using this diffeomorphism, we identify $x \in \Gamma_{d_0}$ with $(r, y) \in [-d_0, d_0] \times \Gamma_{d_0}$ and write $u(r, y)$ or $u(y + r\nu(y))$ for $u(x)$ $(x \in \Gamma_{d_0})$. We denote by $H(r, y)$ the mean curvature of the manifold

$$\Gamma(r) := \{x \in \Omega | x = y + r\nu(y) \ y \in \Gamma\}$$

at $y \in \Gamma$. Then $H(0, y)$ stands for the mean curvature of the manifold Γ at $y \in \Gamma$.

Such an interface $\Gamma \in \mathcal{F}$ is determined by solving the following equations called the *rescaled reduced problem*:

$$\begin{cases} \Delta V^- + h^-(v^*) - \overline{u} = 0 & \text{in } \Omega_-(\Gamma), \\ V^- = b_1^*(y) & \text{on } \Gamma, \end{cases} \tag{1.7}$$

$$\begin{cases} \Delta V^+ + h^+(v^*) - \overline{u} = 0 & \text{in } \Omega_+(\Gamma), \\ V^+ = b_1^*(y) & \text{on } \Gamma, \\ \dfrac{\partial V^+}{\partial n} = 0 & \text{on } \partial\Omega, \end{cases} \tag{1.8}$$

$$\frac{\partial V^+}{\partial \nu} = \frac{\partial V^-}{\partial \nu} \quad \text{on } \Gamma, \tag{1.9}$$

where

$$b_1^*(y) := \frac{m^2}{[h]}(N-1)H(0,y), \;\; m^2 := \int_{-\infty}^{\infty} [u_\xi^*(\xi)]^2 d\xi$$

and $[h]$ denotes the jump of two branches $u = h^{\pm}(v)$ at $v = v^*$, i.e.,

$$[h] := h^+(v^*) - h^-(v^*).$$

Here $u = u^*(\xi)$ is the unique solution of

$$u_{\xi\xi} + f(u) - v^* = 0, \;\; \xi \in \mathbf{R}, \;\; u(0) = h^0(v^*), \;\; \lim_{\xi \to \pm\infty} u(\xi) = h^{\pm}(v^*).$$

When Γ is a rectangle, we add the boundary condition

$$\frac{\partial V^-}{\partial n} = 0 \quad \text{on } \partial\Omega \cap \partial\Omega_-(\Gamma)$$

to (1.7) and replace the boundary condition for $\frac{\partial V^+}{\partial n}$ in (1.8) by

$$\frac{\partial V^+}{\partial n} = 0 \quad \text{on } \partial\Omega \cap \partial\Omega_+(\Gamma).$$

Roughly speaking, the interface Γ is a set on which the limiting function of the stationary solution u^ϵ as $\epsilon \downarrow 0$ becomes discontinuous in the normal direction. For more discussions on (1.7)–(1.9), see [12]. We assume the existence of a solution (V^*, Γ^*) of (1.7)–(1.9).

(A4) There exists a solution $(V^*, \Gamma^*) \in C^1(\overline{\Omega}) \times \mathcal{F}$ of (1.7)–(1.9), where

$$V^*(x) = \begin{cases} V^-(x), & x \in \Omega_-(\Gamma^*), \\ V^+(x), & x \in \Omega_+(\Gamma^*). \end{cases}$$

$V^{\pm}$ are smooth solutions of (1.7) and (1.8), respectively, satisfying (1.9).

In order to state a sufficient condition for the existence and the SLEP equation, we need to define several operators. Let us consider the following linear boundary value problem:

$$\begin{cases} \Delta Z^- = 0 & \text{in } \Omega_-(\Gamma^*), \\ Z^- = q & \text{on } \Gamma^*, \end{cases} \tag{1.10}$$

$$\begin{cases} \Delta Z^+ = 0 & \text{in } \Omega_+(\Gamma^*), \\ \dfrac{\partial Z^+}{\partial n} = 0 & \text{on } \partial\Omega, \;\; Z^+ = q \quad \text{on } \Gamma^*, \end{cases} \tag{1.11}$$

where $\Gamma^* \in \mathcal{F}$ is a solution of (1.7)–(1.9). When Γ^* is a rectangle, we add the boundary condition

$$\frac{\partial Z^-}{\partial n} = 0 \quad \text{on } \partial\Omega \cap \partial\Omega_-(\Gamma^*)$$

to (1.10) and replace the boundary condition for $\frac{\partial Z^+}{\partial n}$ in (1.11) by

$$\frac{\partial Z^+}{\partial n} = 0 \quad \text{on } \partial\Omega \cap \partial\Omega_+(\Gamma^*).$$

For $q \in C^{2,\alpha}(\Gamma^*)$ $(0 < \alpha < 1)$, the problem (1.10) and (1.11) have a unique solution denoted by $\mathcal{P}^- q$ and $\mathcal{P}^+ q$, respectively, satisfying $\mathcal{P}^\pm q \in C^{2,\alpha}(\overline{\Omega})$, and define normal derivative operator $\Pi_\pm : C^{2,\alpha}(\Gamma^*) \to C^{1,\alpha}(\Gamma^*)$ by

$$\Pi_- q = \frac{\partial}{\partial \nu}(\mathcal{P}^- q)\bigg|_{\Gamma^*}, \quad \Pi_+ q = -\frac{\partial}{\partial \nu}(\mathcal{P}^+ q)\bigg|_{\Gamma^*}.$$

Note that $\Pi := \Pi_- + \Pi_+$ is self-adjoint and the null space $\mathcal{N}(\Pi)$ is one-dimensional spanned by a constant function. Then there is a bounded operator

$$\mathcal{T} : (I - P)C^{1,\alpha}(\Gamma^*) \to (I - P)C^{2,\alpha}(\Gamma^*)$$

satisfying $\Pi\mathcal{T} = I$ on $(I - P)C^{1,\alpha}(\Gamma^*)$ and $\mathcal{T}\Pi = I - P$ on $C^{2,\alpha}(\Gamma^*)$, where P is a projection defined by $P\theta := \frac{1}{|\Gamma^*|}\int_{\Gamma^*} \theta \, dS$ for $\theta \in C^\alpha(\Gamma^*)$ and $|\Gamma^*|$ is surface area of Γ^*.

Concerning the existence of the stationary solution, we have the following theorem.

THEOREM 1.2 (existence). *Assume that* (A1)–(A4) *are satisfied. Moreover, we assume that*

(A5) *There is a bounded linear operator* $L^\dagger : (I - P)C^\alpha(\Gamma^*) \to (I - P)C^{2,\alpha}(\Gamma^*)$ *which is the inverse of the operator*

$$L := \Delta^{\Gamma^*} + H^*(y) - \frac{1}{m^2} J'(v^*) V_r^*(0, y) + \frac{1}{m^2}[h] J'(v^*)\mathcal{T}(\cdot)$$

such that $LL^\dagger = I$ *on* $(I - P)C^\alpha(\Gamma^*)$ *and* $L^\dagger L = I - P$ *on* $(I - P)C^{2,\alpha}(\Gamma^*)$. *Here,* Δ^{Γ^*} *is the Laplace–Beltrami operator on* Γ^*, $H^*(y)$ *the sum of the square of the principal curvature of* Γ^*, $V_r^*(0, y) = \frac{\partial V^*}{\partial \nu}$, *and* $[h]$ *denotes the aforementioned jump at* $v = v^*$.

Then, there is an $\epsilon_0 > 0$ *such that* (1.5)–(1.6) *have an* ϵ*-family of stationary solutions* (u^ϵ, v^ϵ) *for* $\epsilon \in (0, \epsilon_0]$ *satisfying*

(i) $\lim_{\epsilon \to 0} v^\epsilon(x) = v^*$ *uniformly on* $\overline{\Omega}$,

(ii) *for each* $\delta > 0$,

$$\lim_{\epsilon \to 0} u^\epsilon(x) = \begin{cases} h^-(v^*), & x \in \overline{\Omega}_-(\Gamma^*) \backslash \Gamma_\delta^* \\ \\ h^+(v^*), & x \in \overline{\Omega}_+(\Gamma^*) \backslash \Gamma_\delta^* \end{cases} \quad \textit{uniformly,}$$

where Γ_δ^* *is a tubular neighborhood of* Γ^*,

(iii) *for each* $K > 0$,

$$\lim_{\epsilon \to 0} u^\epsilon(y + \epsilon\xi\nu(y)) = u^*(\xi + s^*(y)) \quad \textit{in } C^2[-K, K]$$

uniformly in $y \in \Gamma^*$ *for some* $s^* \in C^{2,\alpha}(\Gamma^*)$.

The stability property of the stationary solutions is determined by the spectrum of the following associated linearized problem:

$$\begin{cases} 0 = \epsilon^2 \Delta w + f_u^\epsilon w - z, \\ \qquad\qquad\qquad\qquad\qquad \text{in } \ \Omega, \\ 0 = \Delta z + \epsilon w + \lambda^\epsilon w, \\ \dfrac{\partial w}{\partial n} = 0 = \dfrac{\partial z}{\partial n} \quad \text{on } \ \partial\Omega, \end{cases} \tag{1.12}$$

where $f_u^\epsilon := \frac{d}{du} f(u^\epsilon)$. We assume the following for (1.12).

(A6) Each eigenvalue λ^ϵ and the associated eigenfunctions (w^ϵ, z^ϵ) of (1.12) have the following asymptotic forms:

$$\begin{cases} \lambda^\epsilon = \epsilon\lambda^* + o(\epsilon), \\ w^\epsilon(x) = \displaystyle\sum_{i=0}^{2} \epsilon^i W^{\pm,i}(x) + \omega(r) \cdot \sum_{i=0}^{2} \epsilon^i w^{\pm,i}(r/\epsilon, y) + o(\epsilon^2), \\ \qquad\qquad\qquad\qquad\qquad\qquad\qquad\qquad \text{in } \ \Omega_\pm(\Gamma^*), \\ z^\epsilon(x) = \displaystyle\sum_{i=0}^{2} \epsilon^i Z^{\pm,i}(x) + \omega(r) \cdot \sum_{j=3}^{5} \epsilon^j z^{\pm,j}(r/\epsilon, y) + o(\epsilon^2), \end{cases}$$

where $W^{\pm,i}(x) \in C^{2,\alpha}(\overline{\Omega}_\pm(\Gamma^*))$ and $Z^{\pm,i}(x) \in C^{2,\alpha}(\overline{\Omega}_\pm(\Gamma^*))$ are outer expansions, $w^{\pm,i}(\xi, y)$ and $z^{\pm,j}(\xi, y)$ are inner expansions bounded for $\pm\xi \in (0, \infty)$, and $y \in \Gamma^*$, $x = (r, y)$ is a local coordinate system in the neighborhood of Γ^*, and $\omega(r)$ is a smooth cutoff function such that

$$\omega(r) = 1, \ \ |r| \le \frac{d_0}{2} \ \ \omega(r) = 0, \ \ |r| \ge d_0.$$

For more details, see section 3.

Here we are interested in only the critical case, i.e., the expansion starts from $\epsilon\lambda^*$, which is justified by Lemma 3.1.

Concerning (1.12), we have the following theorem.

THEOREM 1.3 (SLEP equation). *Suppose the conditions* (A1)–(A6) *are valid. Then the principal part of the critical eigenvalues is given by* $\epsilon\lambda^*$, *where* λ^* *is the eigenvalue of the following problem:*

$$L\theta^* + \frac{1}{m^2}\lambda^*[h]J'(v^*)\mathcal{T}(\theta^*) = 0 \tag{1.13}$$

for $\theta^* \in (I - P)C^{2,\alpha}(\Gamma^*)$. $[h]$ *denotes the aforementioned jump at* $v = v^*$.

Theorem 1.3 gives us a general form which characterizes the asymptotic form of critical eigenvalues. When Γ^* has a special geometry such as spherical or planar shape with $f(u) = u - u^3$, then we can rigorously prove that the critical eigenvalues λ^ϵ given by the form $\lambda^\epsilon = \epsilon\lambda^* + o(1)$, and determine the stability properties. More precisely we have the following results (see section 4 for details).

THEOREM 1.4 (stability of radially symmetric patterns). *Let* Ω *be a ball of radius* R. *Then the following hold:*

(i) *For any fixed* $R \in (0, \infty)$, *there exists* $\overline{u}_0 = \overline{u}_0(R) \in (-1, 1)$ *such that the radially symmetric solution is stable for* $\overline{u} \in (\overline{u}_0, 1)$.

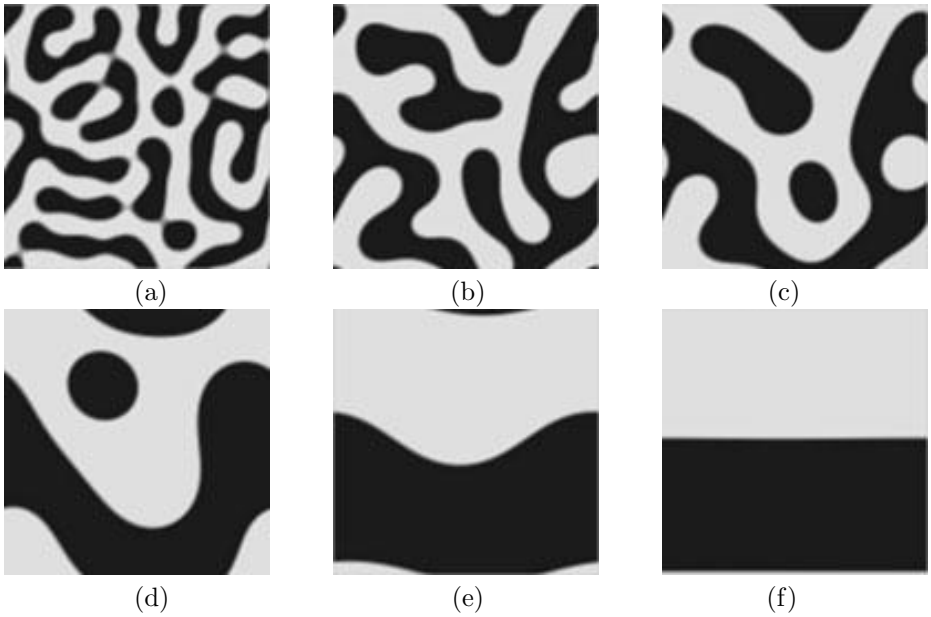

FIG. 1. *Evolution of the interfaces slightly perturbed from the homogeneous state* $u = \overline{u}$*, where* $X = Y = 2.0$*,* $\epsilon = 0.03, \overline{u} = 7.10992 \times 10^{-5}$*. Since* $\overline{u}$ *is very close to 0, lamellar shape is preferable:* (a) $\tilde{t} = 0.05$*,* (b) $\tilde{t} = 0.15$*,* (c) $\tilde{t} = 0.3$*,* (d) $\tilde{t} = 1.5$*,* (e) $\tilde{t} = 6.0$*,* (f) $\tilde{t} = 15.0$*.*

(ii) *For any fixed* $\overline{u} \in (-1, 1)$*, there exists* $R_0 = R_0(\overline{u}) > 0$ *such that the radially symmetric solution is unstable for* $R > R_0$*.*

Note that here the location of interface is given by $\Gamma^* = \{x \in \mathbf{R}^N \mid |x| = r_0\}$, where $r_0 = r_0(\overline{u})$ is a monotone decreasing function of $\overline{u}$, and $\Omega_-(\Gamma^*) = \{x \in \mathbf{R}^N \mid |x| < r_0\}$. See section 4 for details.

THEOREM 1.5 (stability of planar patterns). *Let* Ω *be a rectangle* $(0, X) \times (0, Y)$ *and* $\kappa := X/Y$ *be the aspect ratio defined before. Then the following hold:*

(i) *For any* $\overline{u} \in (-1, 1)$*, there exists* $\underline{X} = \underline{X}(\overline{u}) > 0$ *such that the planar solution is stable for any* $X < \underline{X}$ *and* $\kappa > 0$*.*

(ii) *For any fixed* $\kappa > 0$ *and* $\overline{u} \in (-1, 1)$*, there exists* $\overline{X} = \overline{X}(\kappa, \overline{u}) > 0$ *such that the planar solution is unstable for* $X > \overline{X}$*.*

The results of Theorems 1.4 and 1.5 are useful to understand how the morphology depends on the ratio $\overline{u}$. For instance, Theorem 1.4 (i) implies that the system prefers spherical patterns when either one of the homopolymers dominates the system, which is consistent with the numerics as in Figures 1 and 2. The result of Theorem 1.5 (i) seems against our intuition at first sight; in fact, recalling that the interface is parallel to y-axis, it indicates that very long interface in a slender domain with any small aspect ratio can be stabilized, which makes a sharp contrast to the lamellar patterns arising in activator-inhibitor systems (see [22]). This is, however, consistent with the experimental results as well as numerics, because very fine lamellar structure in the original scaling becomes a long strip after rescaling.

The article is organized as follows. The construction of stationary solution of (1.5) and (1.6) is discussed in section 2 by using the matched asymptotic expansion method. In section 3, the linearized eigenvalue problem (1.12) is reduced to an eigenvalue problem on the interface Γ^*. By using these results, we study the stability properties

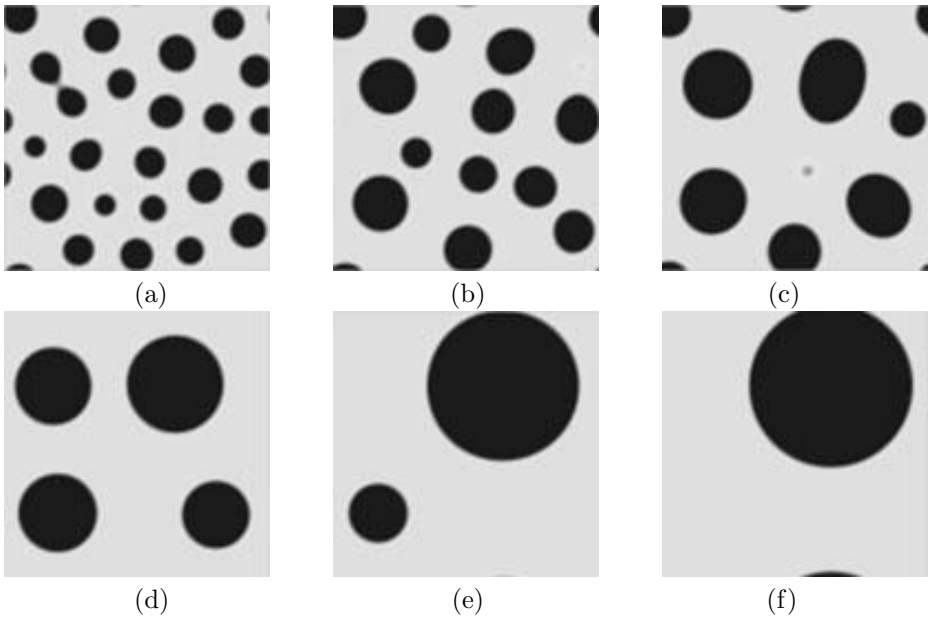

FIG. 2. *Evolution of the interfaces slightly perturbed from the homogeneous state* $u = \overline{u}$*, where* $X = Y = 2.0$*,* $\epsilon = 0.03, \overline{u} = -0.399929$*. Since* $\overline{u}$ *is away from 0, spherical shape is preferable:* (a) $\tilde{t} = 0.15$*,* (b) $\tilde{t} = 0.5$*,* (c) $\tilde{t} = 1.0$*,* (d) $\tilde{t} = 4.0$*,* (e) $\tilde{t} = 12.0$*,* (f) $\tilde{t} = 15.0$*.*

of the lamellar and radially symmetric patterns in section 4. Finally, in section 5, we derive similar results for the activator-inhibitor system (1.4).

2. Construction of stationary solutions by matched asymptotic expansion. In this section, we prove Theorem 1.2. The strategy is as follows. First, we divide the stationary problem for (1.5) and (1.6) into two problems. That is, for $a_0(y), b_0(y), b_1(y), b_2(y) \in C^{2,\alpha}(\Gamma^*)$, consider the following two problems:

$$(2.1)_- \qquad \begin{cases} \epsilon^2 \Delta u^- + f(u^-) - v^- = 0, & \\ \Delta v^- + \epsilon(u^- - \overline{u}) = 0, & \text{in } \Omega_-(\Gamma^*), \\ u^- = a_0(y), \quad v^- = b_0(y) + \epsilon b_1(y) + \epsilon^2 b_2(y) & \text{on } \Gamma^*, \end{cases}$$

$$(2.1)_+ \qquad \begin{cases} \epsilon^2 \Delta u^+ + f(u^+) - v^+ = 0, & \\ \Delta v^+ + \epsilon(u^+ - \overline{u}) = 0, & \text{in } \Omega_+(\Gamma^*), \\ u^+ = a_0(y), \quad v^+ = b_0(y) + \epsilon b_1(y) + \epsilon^2 b_2(y) & \text{on } \Gamma^*, \\ \dfrac{\partial u^+}{\partial n} = 0 = \dfrac{\partial v^+}{\partial n} & \text{on } \partial\Omega. \end{cases}$$

Here, the interface is regarded as the boundary layer at Γ^*.

Let $(u^{\pm,\epsilon}(x), v^{\pm,\epsilon}(x))$ be the solution of $(2.1)_\pm$ and define $(u^\epsilon(x), v^\epsilon(x))$ as

$$(u^\epsilon(x), v^\epsilon(x)) = \begin{cases} (u^{-,\epsilon}(x), v^{-,\epsilon}(x)), & x \in \overline{\Omega}_-(\Gamma^*), \\ (u^{+,\epsilon}(x), v^{+,\epsilon}(x)), & x \in \overline{\Omega}_+(\Gamma^*). \end{cases}$$

Since they are continuous on Γ^* and satisfy $(2.1)_\pm$ in each domain $\overline{\Omega}_\pm(\Gamma^*)$, they become a stationary solution of (1.5) and (1.6) if and only if their normal derivatives are continuous on Γ^*. So we determine $a_0(s)$, $b_0(s)$, $b_1(s)$, and $b_2(s)$ in order that the C^1-matching condition is satisfied in subsection 3.3. In fact, by taking account of the C^1-matching condition of order $O(1)$ and $O(\epsilon)$, we can see that $b_0(y) = v^*$ and $b_1(y) = b_1^*(y)$.

In Theorem 2.1 below, the symbol $C^{2,\alpha}_\epsilon(\overline{\Omega})$ stands for the function space $C^{2,\alpha}(\overline{\Omega})$ endowed with the weighted norm defined by

$$\|u\|_{C^{2,\alpha}_\epsilon(\overline{\Omega})} := \sum_{j=0}^{2} \epsilon^j |u|_{j,\overline{\Omega}} + \epsilon^{2+\alpha} |u|_{2+\alpha,\overline{\Omega}},$$

where

$$|u|_{j,\overline{\Omega}} = \max_{|\sigma|=j} \sup_{x\in\overline{\Omega}} |\partial^\sigma u(x)|, \quad |u|_{k+\alpha,\overline{\Omega}} = \max_{|\sigma|=k} \sup_{x,y\in\overline{\Omega}} \frac{|\partial^\sigma u(x) - \partial^\sigma u(y)|}{|x-y|^\alpha}$$

and σ denote the usual multi-indices.

THEOREM 2.1 (Ikeda [9]). *Suppose the conditions* (A1)–(A4) *are valid and set* $b_0(y) = v^*$ *and* $b_1(y) = b_1^*(y)$. *Then for* $\epsilon \in (0, \epsilon_0]$ *and* $a_0, b_2 \in C^{2,\alpha}(\Gamma^*)$ *satisfying* $a_0(y) \in (h^-(v^*), h^+(v^*))$, *there exist two families of solutions,*

$$(u^{-,\epsilon}, v^{-,\epsilon}) \in C^{2,\alpha}_\epsilon(\overline{\Omega}_-(\Gamma^*)) \times C^{2,\alpha}(\overline{\Omega}_-(\Gamma^*))$$

and

$$(u^{+,\epsilon}, v^{+,\epsilon}) \in C^{2,\alpha}_\epsilon(\overline{\Omega}_+(\Gamma^*)) \times C^{2,\alpha}(\overline{\Omega}_+(\Gamma^*))$$

of $(2.1)_-$ *and* $(2.1)_+$, *respectively, satisfying the following properties:*

(1) $\lim_{\epsilon\to 0} v^{\pm,\epsilon}(x) = v^*$ *uniformly on* $\overline{\Omega}_\pm(\Gamma^*)$.

(2) *For an arbitrary* $\delta > 0$, $\lim_{\epsilon\to 0} u^{\pm,\epsilon}(x) = h^\pm(v^*)$ *uniformly on* $\overline{\Omega}_\pm(\Gamma^*)\backslash\Gamma^*_\delta$.

(3) *The solutions* $(u^{\pm,\epsilon}, v^{\pm,\epsilon})$ *have an asymptotic characterization as follows: There exists a constant such that the estimates below are valid uniformly in* $\epsilon \in (0, \epsilon_0]$:

$$\|u^{\pm,\epsilon} - \mathcal{U}^{\pm,\epsilon}\|_{C^{2,\alpha}_\epsilon(\overline{\Omega}_\pm(\Gamma^*))} \le C\epsilon^{3-\alpha},$$

$$\|v^{\pm,\epsilon} - \mathcal{V}^{\pm,\epsilon}\|_{C^{2,\alpha}(\overline{\Omega}_\pm(\Gamma^*))} \le C\epsilon^{3-\alpha},$$

where $(\mathcal{U}^{\pm,\epsilon}, \mathcal{V}^{\pm,\epsilon})$ *are approximate solutions* (*for more precise information, see* (2.7) *and the subsequent subsections*).

In the next two subsections, we show the procedures of the asymptotic expansion.

2.1. Outer expansion. Substituting the expansion

$$U^{\pm,\epsilon}(x) = U^{\pm,0}(x) + \epsilon U^{\pm,1}(x) + \epsilon^2 U^{\pm,2}(x),$$

$$V^{\pm,\epsilon}(x) = V^{\pm,0}(x) + \epsilon V^{\pm,1}(x) + \epsilon^2 V^{\pm,2}(x)$$

into $(2.1)_\pm$ and equating like powers of ϵ^k, we have the following problem for $(U^{\pm,k}(x), V^{\pm,k}(x))$ $(k = 0, 1, 2)$:

$$\begin{cases} f(U^{\pm,0}) - V^{\pm,0} = 0, \\ \Delta V^{\pm,0} = 0, \end{cases}$$

$$\begin{cases} f_u^{\pm,0} U^{\pm,1} - V^{\pm,1} = 0, \\ \Delta V^{\pm,1} + U^{\pm,0} - \overline{u} = 0, \end{cases}$$

$$\begin{cases} f_u^{\pm,0} U^{\pm,2} - V^{\pm,2} + \dfrac{1}{2} f_{uu}^{\pm,0} (U^{\pm,1})^2 = 0, \\ \Delta V^{\pm,2} + U^{\pm,1} = 0, \end{cases}$$

where $f_u^{\pm,0} = \frac{d}{du} f(U^{\pm,0}(x))$ and others are similarly defined. $V^{-,0}$ and $V^{+,0}$ are uniquely determined under the boundary conditions

$$V^{\pm,0} = b_0 \quad \text{on } \Gamma^*, \quad \frac{\partial V^{+,0}}{\partial n} = 0 \quad \text{on } \partial\Omega,$$

respectively. They are represented as $V^{\pm,0} = \mathcal{P}^\pm b_0$. Then we define $U^{\pm,0}$ as

$$U^{\pm,0} = h^\pm(V^{\pm,0}),$$

where $h^\pm(v)$ is sub-branch of $f(u) - v = 0$ defined in section 1.

The equation for $V^{\pm,1}$ with the boundary conditions is recast as

$$(2.2)_\pm \qquad \begin{cases} \Delta V^{\pm,1} + h^\pm(V^{\pm,0}) - \overline{u} = 0 & \text{in } \Omega_\pm(\Gamma^*), \\ V^{\pm,1} = b_1(y) & \text{on } \Gamma^*, \\ \dfrac{\partial V^{+,1}}{\partial n} = 0 & \text{on } \partial\Omega, \end{cases}$$

respectively. It is not difficult to show that $(2.2)_\pm$ has a unique solution, $V^{\pm,1}$. Then, by using $V^{\pm,1}$, $U^{\pm,1}$ are determined as

$$U^{\pm,1} = h_v^\pm(V^{\pm,0}) V^{\pm,1},$$

where $h_v^\pm(v) = \frac{d}{dv} h^\pm(v)$. As for the equations for $(U^{\pm,2}, V^{\pm,2})$, we obtain the following:

$$U^{\pm,2}(x) = h_v^\pm(V^{\pm,0}) V^{\pm,2} + \frac{1}{2} h_{vv}^\pm(V^{\pm,0})(V^{\pm,1})^2$$

and

$$\begin{cases} 0 = \Delta V^{\pm,2} + h_v^\pm(V^{\pm,0}) V^{\pm,1}(x) & \text{in } \Omega_\pm(\Gamma^*), \\ \dfrac{\partial V^{+,2}}{\partial n} = 0 \quad \text{on } \partial\Omega, \quad V^{\pm,2} = b_2(y) & \text{on } \Gamma^*. \end{cases}$$

The boundary value problems for $V^{\pm,2}$ are uniquely solvable for arbitrary $b_2 \in C^{2,\alpha}(\Gamma^*)$. They are expressed as

$$V^{\pm,2} = \mathcal{P}^\pm b_2 + W^\pm,$$

where $W^{\pm} \in C^{2,\alpha}(\overline{\Omega}_{\pm}(\Gamma^*))$ are solutions of

$$\begin{cases} \Delta W^{\pm} = -h_v^{\pm}(V^{\pm,0}(x))V^{\pm,1}(x) & \text{in } \Omega_{\pm}(\Gamma^*), \\ W^{\pm} = 0 \ \text{ on } \Gamma^*, \quad \dfrac{\partial W^+}{\partial n} = 0 & \text{on } \partial\Omega, \end{cases}$$

respectively. Once $V^{\pm,2}$ is known, $U^{\pm,2}$ is uniquely determined by the expression above.

In this way, we have obtained the following outer expansion:

$$\begin{cases} V^{\pm,\epsilon}(x) = V^{\pm,0}(x) + \epsilon V^{\pm,1}(x) + \epsilon^2(\mathcal{P}^{\pm}b_2 + W^{\pm}), \\ U^{\pm,\epsilon}(x) = h^{\pm}(V^{\pm,0}(x)) + \epsilon h_v^{\pm}(V^{\pm,0}(x))V^{\pm,1}(x) + \epsilon^2 U^{\pm,2}(x), \end{cases} \qquad x \in \overline{\Omega}_{\pm}(\Gamma^*).$$

This expansion is due to the lack of the layer part, in fact, $U^{+,\epsilon}$ and $U^{-,\epsilon}$ are not continuous on Γ^*. So we need a new variable that stretches a neighborhood of the interface.

2.2. Inner expansion. Since the outer expansion $U^{+,\epsilon}$ and $U^{-,\epsilon}$ are not continuous on Γ^*, we need to introduce the stretched variable and make another expansion in the neighborhood of Γ^*.

Let us introduce a local coordinate system in the neighborhood of Γ^*. By the implicit function theorem there exists a $d_0 > 0$ such that the map $p : [-d_0, d_0] \times \Gamma^* \to \Gamma^*_{d_0}$ defined by

$$p(r, y) = y + r\nu(y)$$

is a diffeomorphism, where $\Gamma^*_{d_0} = \{x \in \Omega \mid \operatorname{dist}(x, \Gamma^*) < d_0\}$. Using this diffeomorphism, we identify $x \in \Gamma^*_{d_0}$ with $(r, y) \in [-d_0, d_0] \times \Gamma^*_{d_0}$ and write $u(r, y)$ for $u(x)$ $(x \in \Gamma^*_{d_0})$. With this representation, the suitable magnification of $\Gamma^*_{d_0}$ corresponds to the scaling: $r = \epsilon\xi$. In terms of the variables ξ and $y \in \Gamma^*$, the equations in (1.5) are recast as

$$\begin{cases} 0 = u_{\xi\xi} + \epsilon(N-1)H(\epsilon\xi, y)u_{\xi} + \epsilon^2\Delta(\epsilon\xi)u + f(u) - v, \\ 0 = v_{\xi\xi} + \epsilon(N-1)H(\epsilon\xi, y)v_{\xi} + \epsilon^2\Delta(\epsilon\xi)v + \epsilon^3(u - \overline{u}). \end{cases} \tag{2.3}$$

Here, $H(r, y)$ stands for the mean curvature of the manifold

$$\Gamma^*(r) := \{x \in \Omega | x = y + r\nu(y) \ y \in \Gamma^*\},$$

and $\Delta(r)$ for the Laplace–Beltrami operator on $\Gamma^*(r)$ (for more details, see Sakamoto [17]).

We now determine the functions $u^{\pm,i}$ $(i = 0, 1, 2)$, $v^{\pm,j}$ $(j = 3, 4)$ in the following expressions:

$$\begin{cases} u = U^{\pm,\epsilon}(\epsilon\xi, y) + u^{\pm,0}(\xi, y) + \epsilon u^{\pm,1}(\xi, y) + \epsilon^2 u^{\pm,2}(\xi, y), \\ v = V^{\pm,\epsilon}(\epsilon\xi, y) + \epsilon^3 v^{\pm,3}(\xi, y) + \epsilon^4 v^{\pm,4}(\xi, y). \end{cases} \tag{2.4}$$

The reason why we go to third order $v^{\pm,3}(\xi, y)$ in ϵ is that the inhomogeneous term of the equation for v appears in $O(\epsilon)$-term. We expand the mean curvature $H(\epsilon\xi, y)$

and the Laplace–Beltrami operator $\Delta(\epsilon\xi)$ of manifold $\Gamma^*(\epsilon\xi)$ as

$$H(\epsilon\xi, y) = \sum_{i\geq 0} \epsilon^i \quad H^i(\xi, y), \quad H^i(\xi, y) := \frac{1}{i!}\frac{d^i}{d\epsilon^i} H(\epsilon\xi, y)\Big|_{\epsilon=0},$$

$$\Delta(\epsilon\xi) = \sum_{i\geq 0} \epsilon^i \quad \Delta^i(\xi), \qquad \Delta^i(\xi) := \frac{1}{i!}\frac{d^i}{d\epsilon^i} \Delta(\epsilon\xi)\Big|_{\epsilon=0}.$$

Here we take account of $O(1)$-term of the C^1-matching condition for v. It is given by

$$\frac{\partial V^{-,0}}{\partial \nu} = \frac{\partial V^{+,0}}{\partial \nu} \quad \text{on } \Gamma^*.$$

Combining the result of subsection 2.1, we can see that $V^{\pm,0}$ is a constant function, that is,

$$V^{-,0}(x) = V^{+,0}(x) = \overline{b}_0$$

and $b_0(y) = \overline{b}_0$ for some $\overline{b}_0 \in \mathbf{R}$. In the following, we will use this fact.

Substituting (2.4) and the expansions of $H(\epsilon\xi, y)$ and $\Delta(\epsilon\xi)$ into (2.3), equating like powers of ϵ, we have equations for $u^{\pm,i}$ $(i = 0, 1, 2)$, $v^{\pm,j}$ $(j = 3, 4)$. We present them only for $u^{-,i}$, $v^{-,j}$ below, and omit the superscript "-" of $u^{-,i}$ and $v^{-,j}$.

The equation for u^0 is

$$u^0_{\xi\xi} + f(h^-(\overline{b}_0) + u^0) - \overline{b}_0 = 0, \ \ \xi \in (-\infty, 0).$$

In view of the boundary conditions in $(2.1)_-$, we impose boundary conditions

$$u^0(0, y) + h^-(\overline{b}_0) = a_0(y), \ \ \lim_{\xi\to-\infty} u^0(\xi, y) = 0.$$

Let $u^{\pm,*}(\xi; v)$ be the unique solution of

$$u^{\pm,*}_{\xi\xi} + f(u^{\pm,*}) - v = 0, \ \ \xi \in \pm(0, \infty), \ \ u^{\pm,*}(0; v) = h^0(v), \ \ \lim_{\xi\to\pm\infty} u^{\pm,*}(\xi; v) = h^{\pm}(v).$$

By using these functions, $u^{-,0}(\xi, y)$ is given by

$$u^0(\xi, y) = u^{-,*}(s^-_0(y) + \xi; \overline{b}_0) - h^-(\overline{b}_0),$$

where $s^-_0 \in C^{2,\alpha}(\Gamma^*)$ is related to $a_0 \in C^{2,\alpha}(\Gamma^*)$ via the equation

$$a_0(y) = u^{-,*}(s^-_0(y); \overline{b}_0), \ \ y \in \Gamma^*.$$

The equation for $(u^{-,1}, v^{-,3})$ is

$$\begin{cases} 0 = u^1_{\xi\xi} + \tilde{f}_u u^1 + p_1(\xi, y), \\ 0 = v^3_{\xi\xi} + u^0(\xi, y), \end{cases} \qquad \xi \in (-\infty, 0), \tag{2.5}$$

where

$$p_1(\xi, y) = (N-1)H(0, y)u^0_\xi(\xi, y) + \tilde{f}_u U^1(0, y) - V^1(0, y),$$

$\tilde{f}_u = \frac{d}{du} f(u^{-,*}(s_0(y)+\xi;\bar{b}_0))$ and others are similarly defined. We emphasize the fact $p_1(\xi, y)$ decays exponentially to zero as $\xi \to -\infty$ uniformly in $y \in \Gamma^*$. If we impose the boundary conditions

$$u^1(0,y) = -U^{-,1}(0,y) = -h_v^-(v^*)b_1^*(y), \quad \lim_{\xi\to-\infty} u^1(\xi,y) = 0,$$

then the first equation of (2.5) has a unique solution given by

$$u^1(\xi,y) = -U^1(0,y)\frac{u_\xi^0(\xi,y)}{u_\xi^0(0,y)} - u_\xi^0(\xi,y)\int_0^\xi \frac{1}{[u_\xi^0(\tau,y)]^2}\int_{-\infty}^\tau p_1(s,y)u_\xi^0(s,y)dsd\tau.$$

The boundary conditions for v^3 are

$$v^3(0,y) = 0, \quad \lim_{\xi\to-\infty} v^3(\xi,y) = 0,$$

and v^3 is uniquely determined as

$$v^3(\xi,y) = -\int_{-\infty}^\xi \int_{-\infty}^\tau u^0(s,y)dsd\tau.$$

Finally, we treat the equation for $(u^{-,2}, v^{-,4})$

$$\begin{cases} 0 = u_{\xi\xi}^2 + \tilde{f}_u u^2 + p_2(\xi,y), \\ 0 = v_{\xi\xi}^4 + q_4(\xi,y), \end{cases} \qquad \xi \in (-\infty, 0), \tag{2.6}$$

where

$$\begin{aligned} p_2(\xi,y) &= (N-1)H(0,y)u_\xi^1 + \Delta(0)u^0 + (N-1)H_r(0,y)\xi u_\xi^0 \\ &\quad + \frac{1}{2}\tilde{f}_{uu}[U^1(0,y)+u^1]^2 + \tilde{f}_u[\xi U_r^1(0,y) + U^2(0,y) + u^2] \\ &\quad - [\xi V_r^1(0,y) + V^2(0,y)], \\ q_4(\xi,y) &= (N-1)H(0,y)v_\xi^1 + u^1, \end{aligned}$$

and $U_r^1(0,y) = \frac{\partial}{\partial r}U^1(0,y)$ and others are similarly defined. We note the fact that $p_2(\xi,y)$ and $q_4(\xi,y)$ decay exponentially to zero as $\xi \to -\infty$ uniformly in $y \in \Gamma^*$. If we impose the boundary conditions

$$\begin{aligned} &u^2(0,y) = -U^{-,2}(0,y) = -h_v^-(v^*)b_2(y) - \frac{1}{2}h_{vv}^-(v^*)(b_1(y))^2, \quad \lim_{\xi\to-\infty} u^2(\xi,y) = 0, \\ &v^4(0,y) = 0, \qquad\qquad \lim_{\xi\to-\infty} v^4(\xi,y) = 0, \end{aligned}$$

then the equations in (2.6) have unique solutions given by

$$u^2(\xi,y) = -U^2(0,y)\frac{u_\xi^0(\xi,y)}{u_\xi^0(0,y)} - u_\xi^0(\xi,y)\int_0^\xi \frac{1}{[u_\xi^0(\tau,y)]^2}\int_{-\infty}^\tau p_2(s,y)u_\xi^0(s,y)dsd\tau$$

and

$$v^4(\xi,y) = -\int_{-\infty}^\xi \int_{-\infty}^\tau q_4(s,y)dsd\tau.$$

The same type of arguments can be applied to $u^{+,i}$ $(i=0,1,2)$ and $v^{+,j}$ $(j=3,4)$, which leads to the following approximation:

$$\begin{cases} \mathcal{U}^{\pm,\epsilon}(x) = U^{\pm,\epsilon}(x) + \{u^{\pm,0}(r/\epsilon,y) + \epsilon u^{\pm,1}(r/\epsilon,y) + \epsilon^2 u^{\pm,2}(r/\epsilon,y)\}\cdot\omega(r), \\ \mathcal{V}^{\pm,\epsilon}(x) = V^{\pm,\epsilon}(x) + \{\epsilon^3 v^{\pm,3}(r/\epsilon,y) + \epsilon^4 v^{\pm,4}(r/\epsilon,y)\}\cdot\omega(r), \end{cases} \tag{2.7}$$

where $\omega(r)$ is a smooth cutoff function such that

$$\omega(r)=1, \ \ |r|\le \frac{d_0}{2} \ \ \omega(r)=0, \ \ |r|\ge d_0.$$

2.3. C^1-matching of normal derivatives on Γ^*. In this subsection, we make stationary solutions with the internal transition layer on a whole domain Ω by matching the normal derivatives of $(u^{\pm,\epsilon}(x), v^{\pm,\epsilon}(x))$ on Γ^*.

The normal derivatives $\mathcal{U}^{\pm,\epsilon}$ and $\mathcal{V}^{\pm,\epsilon}$ on Γ^* are computed as

$$\frac{\partial}{\partial\nu}\mathcal{U}^{\pm,\epsilon}\Big|_{\Gamma^*} = \epsilon U_r^{\pm,1}(0,y) + \epsilon^2 U_r^{\pm,2}(0,y) + \frac{1}{\epsilon}u_\xi^{\pm,0}(0,y) + u_\xi^{\pm,1}(0,y) + \epsilon u_\xi^{\pm,2}(0,y),$$

$$\frac{\partial}{\partial\nu}\mathcal{V}^{\pm,\epsilon}\Big|_{\Gamma^*} = \epsilon V_r^{*}(0,y) + \epsilon^2\frac{\partial}{\partial\nu}(\mathcal{P}^{\pm}b_2) + \epsilon^2 W_r^{\pm}(0,y) + \epsilon^2 v_\xi^{\pm,3}(0,y) + \epsilon^3 v_\xi^{\pm,4}(0,y).$$

Then $O(\frac{1}{\epsilon})$ and $O(1)$-term of $u_r^{-,\epsilon}(0,y) - u_r^{+,\epsilon}(0,y)$ are given by

$$u_\xi^{-,0}(0,y) - u_\xi^{+,0}(0,y) \quad \text{and} \quad u_\xi^{-,1}(0,y) - u_\xi^{+,1}(0,y).$$

Multiplying $u_\xi^{\pm,0}$ by the equation of $u^{\pm,0}$ and integrating it from $\pm\infty$ to 0, we have

$$\frac{1}{2}[u_\xi^{\pm,0}(0,y)]^2 + \int_{h^{\pm}(\bar b_0)}^{a_0(y)} [f(u) - \bar b_0]du = 0.$$

Noting that $u^{\pm,0}(\xi,y)$ is a monotonically increasing function with respect to ξ, we can see that $u_\xi^{-,0}(0,y) - u_\xi^{+,0}(0,y) = 0$ is equivalent to

$$J(\bar b_0) = \int_{h^-(\bar b_0)}^{h^+(\bar b_0)} [f(u) - \bar b_0]du = 0.$$

We can conclude from (A3) that

$$b_0(y) \equiv \bar b_0 = v^* = 0.$$

In the following, we set $\bar b_0 = v^*$. Then we can see that $u^{\pm,0}(\xi,y)$ is represented as

$$u^{\pm,0}(\xi,y) = u^*(\xi + s_0(y)) - h^{\pm}(v^*),$$

where $u^*(\xi)$ is the function defined in section 1 and $s_0 \in C^{2,\alpha}(\Gamma^*)$ is a function related to $a_0 \in C^{2,\alpha}(\Gamma^*)$ via the equation

$$a_0(y) = u^*(s_0(y)), \ \ y\in\Gamma^*.$$

Also we obtain $s_0(y) = s_0^-(y) = s_0^+(y)$.

Since $u_\xi^{\pm,1}(0,y)$ is computed as

$$u_\xi^{\pm,1}(0,y) = -\frac{1}{u_\xi^*(s_0)} \int_{\pm\infty}^0 \left[(N-1)H(0,y)u_\xi^*(\xi+s_0(y)) - b_1(y)\right] u_\xi^*(s+s_0)ds,$$

we can see that $u_\xi^{-,1}(0,y) - u_\xi^{+,1}(0,y) = 0$ is equivalent to

$$0 = \frac{1}{u_\xi^*(s_0)} \left[(N-1)H(0,y) \int_{-\infty}^{\infty} [u_\xi^*(\xi)]^2 d\xi - b_1(y)[h]\right].$$

Thus we obtain

$$b_1(y) = b_1^*(y) = \frac{m^2}{[h]}(N-1)H(0,y).$$

Concerning the normal derivatives of $u^{-,\epsilon}(x)$ and $v^{-,\epsilon}(x)$, we have the following proposition.

PROPOSITION 2.2. *Set $b_0(y) = v^*$ and $b_1(y) = b_1^*(y)$. For the derivatives of $(u^{\pm,\epsilon}(x), v^{\pm,\epsilon}(x))$ on Γ^*, we have the following relations:*

$$v_r^{-,\epsilon}(0,y) - v_r^{+,\epsilon}(0,y) = \epsilon^2 \left[\Pi_- b_2 + \Pi_+ b_2 - s_0[h] - \Psi_0^*\right] + \epsilon^{3-\alpha} R_1^\epsilon(s_0,b_2), \tag{2.8}$$

$$\begin{aligned} &u_\xi^*(s_0)[u_r^{-,\epsilon}(0,y) - u_r^{+,\epsilon}(0,y)] \\ &\quad = \epsilon \left[(-m^2\Delta(0) - m^2 H^*(y) + J'(v^*)V_r(0,y))s_0 - J'(v^*)b_2 - \Phi_0^*\right] \\ &\qquad + \epsilon^{2-\alpha} R_2^\epsilon(s_0,b_2), \end{aligned} \tag{2.9}$$

where

$$m^2 = \int_{-\infty}^{\infty} [u_\xi^*(\xi)]^2 d\xi, \quad H^*(y) := -(N-1)\frac{\partial}{\partial r} H(0,y) = \sum_{j=1}^{N-1} \kappa_j^2,$$

$$\Psi_0^* = W_r^+(0,y) - W_r^-(0,y) + \int_{-\infty}^0 [u^*(\xi) - h^-(v^*)]d\xi - \int_{\infty}^0 [u^*(\xi) - h^+(v^*)]d\xi,$$

$$\begin{aligned} \Phi_0^* = &-H^*(y) \int_{-\infty}^{\infty} \xi [u_\xi^*(\xi)]^2 d\xi - V_r^1(0,y) \int_{-\infty}^{\infty} \xi u_\xi^*(\xi) d\xi \\ &+ \int_{-\infty}^{\infty} \xi [(N-1)H(0,y)u_\xi^*(\xi) - b_1^*(y)]u_\xi^*(\xi)d\xi - \frac{1}{2}[b_1^*(y)]^2[h^+(v^*) - h^-(v^*)], \end{aligned}$$

κ_j $(j = 1,2,\ldots,N-1)$ are the principal curvatures of Γ^*. Moreover, $R_1^\epsilon(s_0,b_2)$ and $R_2^\epsilon(s_0,b_2)$ satisfy

$$\|R_1^\epsilon(s_0,b_2)\|_{C^{1,\alpha}(\Gamma^*)} = O(1), \quad \|R_2^\epsilon(s_0,b_2)\|_{C^\alpha(\Gamma^*)} = O(1) \quad as \ \epsilon \to 0.$$

Proof. See Appendix A. □

LEMMA 2.3. *The operators $R_1^\epsilon(s_0,b_2)$ and $R_2^\epsilon(s_0,b_2)$ are Lipschitz continuous in (s_0,b_2). More precisely, there exists a $C > 0$, independent of $\epsilon \in (0,\epsilon_0]$, such that*

$$\|R_1^\epsilon(s^1,b^1) - R_1^\epsilon(s^2,b^2)\|_{C^{1,\alpha}(\Gamma^*)} \le C[\|s^1 - s^2\|_{C^{2,\alpha}(\Gamma^*)} + \|b^1 - b^2\|_{C^{2,\alpha}(\Gamma^*)}],$$

$$\|R_2^\epsilon(s^1,b^1) - R_2^\epsilon(s^2,b^2)\|_{C^{\alpha}(\Gamma^*)} \le C[\|s^1 - s^2\|_{C^{2,\alpha}(\Gamma^*)} + \|b^1 - b^2\|_{C^{2,\alpha}(\Gamma^*)}].$$

Proof of Lemma 2.3. We can prove this lemma in the same manner as the proof of Theorem 3.1 in [17].

Let us solve the following equations for s_0 and b_2 under the conditions $b_0(y) = v^*$ and $b_1(y) = b_1^*(y)$:

$$\begin{cases} \Phi(s_0, b_2, \epsilon) := -\dfrac{1}{m^2\epsilon} u_\xi^*(s_0)[u_r^{-,\epsilon}(0,y) - u_r^{+,\epsilon}(0,y)] = 0, \\ \Psi(s_0, b_2, \epsilon) := \dfrac{1}{\epsilon^2}[v_r^{-,\epsilon}(0,y) - v_r^{+,\epsilon}(0,y)] = 0. \end{cases} \tag{2.10}$$

The next proposition guarantees that the normal derivatives of $u^{\pm,\epsilon}$ and $v^{\pm,\epsilon}$ on Γ^* are matched continuously for an appropriate pair $(s_0^\epsilon, b_2^\epsilon)$.

PROPOSITION 2.4. *Suppose the conditions* (A1)–(A5) *are valid. There exists a pair* $(s_0^\epsilon, b_2^\epsilon) \in C^{2,\alpha}(\Gamma^*) \times C^{2,\alpha}(\Gamma^*)$ *satisfying* (2.10) *for small* $\epsilon > 0$.

Proof. When $\epsilon = 0$, (2.10) can be rewritten as

$$\begin{cases} Ms + \dfrac{1}{m^2} J'(v^*)b + \dfrac{1}{m^2}\Phi_0^* = 0, \\ \Pi b - [h]s - \Psi_0^* = 0, \end{cases} \tag{2.11}$$

where

$$M := \Delta^{\Gamma^*} + H^*(y) - \frac{1}{m^2} J'(v^*) V_r(0,y).$$

Let P be a projection onto the null space $\mathcal{N}(\Pi)$, i.e.,

$$Pa := \frac{1}{|\Gamma^*|} \int_{\Gamma^*} a \, dS \quad \text{for } a \in C^{2,\alpha}(\Gamma^*).$$

Then (2.11) is equivalent to the following system:

$$\begin{cases} PM(s_{\mathcal{N}} + s_\dagger) + \dfrac{1}{m^2} J'(v^*) b_{\mathcal{N}} + \dfrac{1}{m^2} P\Phi_0^* = 0, \\ (I-P)M(s_{\mathcal{N}} + s_\dagger) + \dfrac{1}{m^2} J'(v^*) b_\dagger + \dfrac{1}{m^2}(I-P)\Phi_0^* = 0, \\ -[h]s_{\mathcal{N}} - P\Psi_0^* = 0, \\ \Pi b_\dagger - [h]s_\dagger - (I-P)\Psi_0^* = 0, \end{cases} \tag{2.12}$$

where $s = s_{\mathcal{N}} + s_\dagger$, $b = b_{\mathcal{N}} + b_\dagger$, $s_{\mathcal{N}}, b_{\mathcal{N}} \in PC^{2,\alpha}(\Gamma^*)$, and $s_\dagger, b_\dagger \in (I-P)C^{2,\alpha}(\Gamma^*)$. Solving the third and fourth equations in (2.12) with respect to $s_{\mathcal{N}}$ and $b_\dagger$, respectively, we have

$$\begin{cases} s_{\mathcal{N}}^* = -\dfrac{1}{[h]} P\Psi_0^*, \\ b_\dagger = [h]\mathcal{T} s_\dagger + \mathcal{T}(I-P)\Psi_0^*. \end{cases} \tag{2.13}$$

Substituting (2.13) into the first and second equations in (2.12), we obtain

$$\begin{cases} PM(s_{\mathcal{N}}^* + s_\dagger) + \dfrac{1}{m^2} J'(v^*) b_{\mathcal{N}} + \dfrac{1}{m^2} P\Phi_0^* = 0, \\ (I-P)Ms_\dagger + \dfrac{1}{m^2}[h]J'(v^*)\mathcal{T}s_\dagger + (I-P)Ms_{\mathcal{N}}^* \\ \quad + \dfrac{1}{m^2} J'(v^*)\mathcal{T}(I-P)\Psi_0^* + \dfrac{1}{m^2}(I-P)\Phi_0^* = 0. \end{cases} \tag{2.14}$$

By using the assumption (A5), we can solve the second equation in (2.14) with respect to $s_\dagger$.

$$s_\dagger^* = -L^\dagger \left[(I-P)Ms_{\mathcal{N}}^* + \frac{1}{m^2} J'(v^*)\mathcal{T}(I-P)\Psi_0^* + \frac{1}{m^2}(I-P)\Phi_0^* \right].$$

Then $b_{\mathcal{N}}$ and $b_\dagger$ are determined as

$$b_{\mathcal{N}}^* = -\frac{1}{J'(v^*)}[m^2 PM(s_{\mathcal{N}}^* + s_\dagger^*) - P\Phi_0^*], \;\; b_\dagger^* = [h]\mathcal{T}s_\dagger^* + \mathcal{T}(I-P)\Psi_0^*.$$

Now we find solutions of (2.10). Substituting

$$s_0 = s_{\mathcal{N}}^* + s_\dagger^* + \sigma_{\mathcal{N}} + \sigma_\dagger \quad \text{and} \quad b_2 = b_{\mathcal{N}}^* + b_\dagger^* + \beta_{\mathcal{N}} + \beta_\dagger$$

into (2.10) and operating P and $I-P$ to the equations, we have

$$PM(\sigma_{\mathcal{N}} + \sigma_\dagger) + \frac{1}{m^2} J'(v^*)\beta_{\mathcal{N}} - \epsilon^{1-\alpha} P\hat{R}_2^\epsilon(\sigma_{\mathcal{N}}, \sigma_\dagger, \beta_{\mathcal{N}}, \beta_\dagger) = 0, \tag{2.15}$$

$$(I-P)M(\sigma_{\mathcal{N}} + \sigma_\dagger) + \frac{1}{m^2} J'(v^*)\beta_\dagger - \epsilon^{1-\alpha}(I-P)\hat{R}_2^\epsilon(\sigma_{\mathcal{N}}, \sigma_\dagger, \beta_{\mathcal{N}}, \beta_\dagger) = 0, \tag{2.16}$$

$$-[h]\sigma_{\mathcal{N}} + \epsilon^{1-\alpha} P\hat{R}_1^\epsilon(\sigma_{\mathcal{N}}, \sigma_\dagger, \beta_{\mathcal{N}}, \beta_\dagger) = 0, \tag{2.17}$$

$$\Pi\beta_\dagger - [h]\sigma_\dagger + \epsilon^{1-\alpha}(I-P)\hat{R}_1^\epsilon(\sigma_{\mathcal{N}}, \sigma_\dagger, \beta_{\mathcal{N}}, \beta_\dagger) = 0, \tag{2.18}$$

where

$$\hat{R}_1^\epsilon(\sigma_{\mathcal{N}}, \sigma_\dagger, \beta_{\mathcal{N}}, \beta_\dagger) = R_1^\epsilon(s_{\mathcal{N}}^* + s_\dagger^* + \sigma_{\mathcal{N}} + \sigma_\dagger, b_{\mathcal{N}}^* + b_\dagger^* + \beta_{\mathcal{N}} + \beta_\dagger),$$

$$\hat{R}_2^\epsilon(\sigma_{\mathcal{N}}, \sigma_\dagger, \beta_{\mathcal{N}}, \beta_\dagger) = \frac{1}{m^2} R_2^\epsilon(s_{\mathcal{N}}^* + s_\dagger^* + \sigma_{\mathcal{N}} + \sigma_\dagger, b_{\mathcal{N}}^* + b_\dagger^* + \beta_{\mathcal{N}} + \beta_\dagger).$$

We can solve (2.17) with respect to $\sigma_{\mathcal{N}}$ when $\epsilon > 0$ is small.

$$\sigma_{\mathcal{N}} = \tilde{\sigma}_{\mathcal{N}}^\epsilon(\sigma_\dagger, \beta_{\mathcal{N}}, \beta_\dagger) = \frac{\epsilon^{1-\alpha}}{[h]} P\hat{R}_1^\epsilon(\tilde{\sigma}_{\mathcal{N}}^\epsilon(\sigma_\dagger, \beta_{\mathcal{N}}, \beta_\dagger), \sigma_\dagger, \beta_{\mathcal{N}}, \beta_\dagger). \tag{2.19}$$

Substituting (2.19) into (2.18), we have

$$\Pi\beta_\dagger - [h]\sigma_\dagger + \epsilon^{1-\alpha}(I-P)\hat{R}_1^\epsilon(\tilde{\sigma}_{\mathcal{N}}^\epsilon(\sigma_\dagger, \beta_{\mathcal{N}}, \beta_\dagger), \sigma_\dagger, \beta_{\mathcal{N}}, \beta_\dagger) = 0. \tag{2.20}$$

When $\epsilon > 0$ is small, (2.20) is solvable in $\beta_\dagger$ as

$$\begin{aligned} \beta_\dagger &= \beta_\dagger^\epsilon(\sigma_\dagger, \beta_{\mathcal{N}}) \\ &= [h]\mathcal{T}\sigma_\dagger - \epsilon^{1-\alpha}\mathcal{T}(I-P)\hat{R}_1^\epsilon(\tilde{\sigma}_{\mathcal{N}}(\sigma_\dagger, \beta_{\mathcal{N}}, \beta_\dagger^\epsilon(\sigma_\dagger, \beta_{\mathcal{N}})), \sigma_\dagger, \beta_{\mathcal{N}}, \beta_\dagger^\epsilon(\sigma_\dagger, \beta_{\mathcal{N}})). \end{aligned} \tag{2.21}$$

By using (2.21), $\sigma_{\mathcal{N}}$ is represented as

$$\sigma_{\mathcal{N}} = \sigma_{\mathcal{N}}^\epsilon(\sigma_\dagger, \beta_{\mathcal{N}}) := \tilde{\sigma}_{\mathcal{N}}^\epsilon(\sigma_\dagger, \beta_{\mathcal{N}}, \beta_\dagger^\epsilon(\sigma_\dagger, \beta_{\mathcal{N}})). \tag{2.22}$$

Here note that $\sigma^\epsilon_{\mathcal{N}}(\sigma_\dagger, \beta_{\mathcal{N}})$ and $\beta^\epsilon_\dagger(\sigma_\dagger, \beta_{\mathcal{N}})$ are Lipschitz continuous in $(\sigma_\dagger, \beta_{\mathcal{N}})$ since $R^\epsilon_j(s_0, b_2)$ are Lipschitz continuous in (s_0, b_2). Moreover, they have the following properties:

(2.23)
$$\begin{cases} |\sigma^\epsilon_{\mathcal{N}}(\sigma^1_\dagger, \beta^1_{\mathcal{N}}) - \sigma^\epsilon_{\mathcal{N}}(\sigma^2_\dagger, \beta^2_{\mathcal{N}})| \le \epsilon^{1-\alpha} C[\|\sigma^1_\dagger - \sigma^2_\dagger\|_{C^{2,\alpha}(\Gamma^*)} + \epsilon^{1-\alpha}|\beta^1_{\mathcal{N}} - \beta^2_{\mathcal{N}}|], \\ \|\beta^\epsilon_\dagger(\sigma^1_\dagger, \beta^1_{\mathcal{N}}) - \beta^\epsilon_\dagger(\sigma^2_\dagger, \beta^2_{\mathcal{N}})\|_{C^{2,\alpha}(\Gamma^*)} \le C[\|\sigma^1_\dagger - \sigma^2_\dagger\|_{C^{2,\alpha}(\Gamma^*)} + \epsilon^{1-\alpha}|\beta^1_{\mathcal{N}} - \beta^2_{\mathcal{N}}|], \\ \|B^\epsilon_\dagger(\sigma^1_\dagger, \beta^1_{\mathcal{N}}) - B^\epsilon_\dagger(\sigma^2_\dagger, \beta^2_{\mathcal{N}})\|_{C^{2,\alpha}(\Gamma^*)} \le \epsilon^{1-\alpha} C[\|\sigma^1_\dagger - \sigma^2_\dagger\|_{C^{2,\alpha}(\Gamma^*)} + \epsilon^{1-\alpha}|\beta^1_{\mathcal{N}} - \beta^2_{\mathcal{N}}|], \end{cases}$$

where

$$B^\epsilon_\dagger(\sigma_\dagger, \beta_{\mathcal{N}}) := \beta^\epsilon_\dagger(\sigma_\dagger, \beta_{\mathcal{N}}) - [h]\mathcal{T}\sigma_\dagger,$$
$$|\sigma^\epsilon_{\mathcal{N}}| = O(\epsilon^{1-\alpha}), \quad \|B^\epsilon_\dagger\|_{C^{2,\alpha}(\Gamma^*)} = O(\epsilon^{1-\alpha}) \ \text{ as } \ \epsilon \to 0.$$

Substituting (2.21) and (2.22) into (2.16), we obtain

$$\begin{aligned} (I-P)L\sigma_\dagger = &-(I-P)M\sigma^\epsilon_{\mathcal{N}}(\sigma_\dagger, \beta_{\mathcal{N}}) - \frac{1}{m^2}J'(v^*)B^\epsilon_\dagger(\sigma_\dagger, \beta_{\mathcal{N}}) \\ &+ \epsilon^{1-\alpha}(I-P)\hat{R}^\epsilon_2(\sigma^\epsilon_{\mathcal{N}}(\sigma_\dagger, \beta_{\mathcal{N}}), \sigma_\dagger, \beta_{\mathcal{N}}, \beta^\epsilon_\dagger(\sigma_\dagger, \beta_{\mathcal{N}})). \end{aligned} \tag{2.24}$$

From the assumption (A5), there exists a constant $C_0 > 0$ such that

$$\|L^\dagger\|_{C^\alpha(\Gamma^*) \longrightarrow C^{2,\alpha}(\Gamma^*)} \le C_0, \tag{2.25}$$

and (2.24) is recast as

$$\begin{aligned} \sigma_\dagger = &-L^\dagger(I-P)M\sigma^\epsilon_{\mathcal{N}}(\sigma_\dagger, \beta_{\mathcal{N}}) - \frac{1}{m^2}J'(v^*)L^\dagger B^\epsilon_\dagger(\sigma_\dagger, \beta_{\mathcal{N}}) \\ &+ \epsilon^{1-\alpha}L^\dagger(I-P)\hat{R}^\epsilon_2(\sigma^\epsilon_{\mathcal{N}}(\sigma_\dagger, \beta_{\mathcal{N}}), \sigma_\dagger, \beta_{\mathcal{N}}, \beta^\epsilon_\dagger(\sigma_\dagger, \beta_{\mathcal{N}})). \end{aligned} \tag{2.26}$$

It follows from (2.23) and (2.25) that the right-hand side of (2.26) is a contraction on $\mathbf{B} := \{\sigma_\dagger \in (I-P)C^{2,\alpha}(\Gamma^*) \mid \|\sigma_\dagger\|_{C^{2,\alpha}(\Gamma^*)} \le 1\}$ with Lipschitz constant $O(\epsilon^{1-\alpha})$. Therefore, (2.26) has a unique solution $\sigma_\dagger = \sigma^\epsilon_\dagger(\beta_{\mathcal{N}}) \in \mathbf{B}$ with the property,

$$\|\sigma^\epsilon_\dagger\|_{C^{2,\alpha}(\Gamma^*)} = O(\epsilon^{1-\alpha}) \ \text{ as } \ \epsilon \to 0.$$

Finally, substituting (2.21), (2.22), and $\sigma_\dagger = \sigma^\epsilon_\dagger(\beta_{\mathcal{N}})$ into (2.15), we obtain an equation of $\beta_{\mathcal{N}}$, which is solvable in $\beta_{\mathcal{N}}$. □

Proof of Theorem 1.2. By virtue of Theorem 2.1 and Proposition 2.4, we obtain the statements of Theorem 1.2.

3. Linearized eigenvalue problem. In this section, we study the linearized eigenvalue problem around a stationary solution $(u^\epsilon(x), v^\epsilon(x))$,

$$\begin{cases} 0 = \epsilon^2\Delta w + f^\epsilon_u w - z, & \\ & \text{in } \Omega, \\ 0 = \Delta z + \epsilon w + \lambda^\epsilon w, & \\ \dfrac{\partial w}{\partial n} = 0 = \dfrac{\partial z}{\partial n} & \text{on } \partial\Omega. \end{cases} \tag{3.1}$$

Our goal in this section is to prove Theorem 1.3. Roughly speaking, the SLEP equation (1.13) in Theorem 1.3 becomes a sufficient condition for C^1-matching conditions of the concerning eigenfunctions.

We first divide (3.1) into the following two parts:

$$(3.2)_- \qquad \begin{cases} \epsilon^2 \Delta w^{-,\epsilon} + f_u^\epsilon w^{-,\epsilon} - z^{-,\epsilon} = 0, & \\ & \text{in } \Omega_-(\Gamma^*), \\ \Delta z^{-,\epsilon} + \epsilon w^{-,\epsilon} + \lambda^\epsilon w^{-,\epsilon} = 0, & \\ w^{-,\epsilon}(y) = \Theta^\epsilon(y), \quad z^{-,\epsilon}(y) = q^\epsilon(y), & y \in \Gamma^*, \end{cases}$$

$$(3.2)_+ \qquad \begin{cases} \epsilon^2 \Delta w^{+,\epsilon} + f_u^\epsilon w^{+,\epsilon} - z^{+,\epsilon} = 0, & \\ & \text{in } \Omega_+(\Gamma^*), \\ \Delta z^{+,\epsilon} + \epsilon w^{+,\epsilon} + \lambda^\epsilon w^{+,\epsilon} = 0, & \\ \dfrac{\partial w^{+,\epsilon}}{\partial n} = 0 = \dfrac{\partial z^{+,\epsilon}}{\partial n} & \text{on } \partial\Omega, \\ w^{+,\epsilon}(y) = \Theta^\epsilon(y), \quad z^{+,\epsilon}(y) = q^\epsilon(y), & y \in \Gamma^*, \end{cases}$$

where

$$q^\epsilon(y) = q_0(y) + \epsilon q_1(y) + \epsilon^2 q_2(y), \quad \lambda^\epsilon = \epsilon \lambda_1.$$

$\Theta^\epsilon, q_0, q_1, q_2 \in C^{2,\alpha}(\Gamma^*)$ are unknown boundary data and $\lambda_1 \in \mathbf{C}$ are regarded as parameters. Here we choose $\epsilon\lambda_1$ as the principal term in order that we can successively expand $(3.2)_\pm$ and determine the parameters one after another. In fact, we have the following lemma:

LEMMA 3.1. *Suppose that $\lambda^\epsilon = \lambda_0 + \epsilon\lambda_1$. Then, if we can expand $(3.2)_\pm$ and determine the parameters $\Theta^\epsilon(y)$, $q^\epsilon(y)$ and λ^ϵ one after another, we have either* Re $\lambda_0 < 0$ *or* $\lambda_0 = 0$.

Proof. This result is proved by using the formal matched asymptotic expansions starting from $O(1)$. See Appendix B. ∎

Let us first construct the solutions $(w^{\pm,\epsilon}, z^{\pm,\epsilon})$ of $(3.2)_\pm$, namely, the following.

THEOREM 3.2 (see [9]). *Suppose the conditions* (A1)–(A5) *are valid. Then, for $\epsilon \in (0, \epsilon_0]$, $\lambda_1 \in \mathbf{C}$, $\Theta^\epsilon = \Theta \in C^{2,\alpha}(\Gamma^*)$, $q_0, q_1, q_2 \in C^{2,\alpha}(\Gamma^*)$, there exist two families of solutions*

$$(w^{-,\epsilon}, z^{-,\epsilon}) \in C_\epsilon^{2,\alpha}(\overline{\Omega}_-(\Gamma^*)) \times C^{2,\alpha}(\overline{\Omega}_-(\Gamma^*))$$

and

$$(w^{+,\epsilon}, z^{+,\epsilon}) \in C_\epsilon^{2,\alpha}(\overline{\Omega}_+(\Gamma^*)) \times C^{2,\alpha}(\overline{\Omega}_+(\Gamma^*))$$

of $(3.2)_-$ and $(3.2)_+$, respectively, which have the following asymptotic characterization: There exists a constant $C > 0$ such that the estimates below are valid uniformly in $\epsilon \in (0, \epsilon_0]$:

$$\left\| w^{\pm,\epsilon} - \mathcal{W}_2^{\pm,\epsilon} \right\|_{C_\epsilon^{2,\alpha}(\overline{\Omega}_\pm(\Gamma^*))} \le C\epsilon^{3-\alpha},$$

$$\left\| z^{\pm,\epsilon} - \mathcal{Z}_2^{\pm,\epsilon} \right\|_{C^{2,\alpha}(\overline{\Omega}_\pm(\Gamma^*))} \le C\epsilon^{3-\alpha},$$

where $(\mathcal{W}_2^{\pm,\epsilon}, \mathcal{Z}_2^{\pm,\epsilon})$ are approximate solutions (see (3.18) *for the details). Here $C_\epsilon^{2,\alpha}$ is the same Banach space defined in section* 2.

In the next two subsections, we only construct the approximate solutions of $(3.2)_-$ and omit the superscript (or subscript) + (or −).

3.1. Outer expansion. Let us substitute

$$w(x) = W^0(x) + \epsilon W^1(x) + \epsilon^2 W^2(x), \;\; z(x) = Z^0(x) + \epsilon Z^1(x) + \epsilon^2 Z^2(x)$$

into $(3.2)_-$ and equate like powers of ϵ. Then we have the following problem for $W^{-,i}(x)$ and $Z^{-,j}(x)$ $(i = 0, 1, 2)$:

$$\begin{cases} f_u^0 W^0 - Z^0 = 0, \\ \Delta Z^0 = 0, \end{cases}$$

$$\begin{cases} f_u^0 W^1 + f_u^1 W^0 - Z^1 = 0, \\ \Delta Z^1 + (1+\lambda_1) W^0 = 0, \end{cases} \tag{3.3}$$

$$\begin{cases} f_u^0 W^2 + f_u^1 W^j + f_u^2 W^0 + \Delta W^0 - Z^2 = 0, \\ \Delta Z^2 = -(1+\lambda_1) W^1, \end{cases} \tag{3.4}$$

where

$$f_u^i := \frac{1}{i!} \frac{d^i}{d\epsilon^i} f_u \left(\sum_{i=0}^{2} \epsilon^i U^i(x) \right) \Bigg|_{\epsilon=0}.$$

Z^0 is uniquely determined under the boundary condition

$$Z^0 = q_0 \quad \text{on } \Gamma^*.$$

That is represented as $Z^0 = \mathcal{P}^- q_0$. By using Z^0, W^0 is determined as

$$W^0 = \frac{1}{f_u^0} Z^0 = h_v^-(v^*) Z^0.$$

Here we used the fact that $f(h^-(v)) - v = 0$ and $f_u^0 = f_u(h^-(v^*)) \neq 0$ (see (A1)). Then, (3.3) can be rewritten as

$$\begin{cases} W^1 = \dfrac{1}{f_u^0}[-f_u^1 W^0 + Z^1], \\ \\ \Delta Z^1 = -(1+\lambda_1) h_v^-(v^*) Z^0, \end{cases} \quad \text{in } \Omega_-(\Gamma^*). \tag{3.5}$$

Once W^0 and Z^0 are known, the second equation of (3.5) is Poisson equation associated with Z^1. Therefore, Z^1 is uniquely determined under the boundary conditions

$$Z^1 = q_1 \quad \text{on } \Gamma^*.$$

That is represented as

$$Z^1 = \mathcal{P}^- q_1 + \hat{Z}^1,$$

where $\hat{Z}^1$ is the unique solution of

$$\begin{cases} \Delta \hat{Z}^1 = -(1+\lambda_1) h_v^-(v^*) Z^0 & \text{in } \Omega_-(\Gamma^*), \\ \hat{Z}^1 = 0 & \text{on } \Gamma^*. \end{cases}$$

Once Z^1 is known, W^1 is uniquely determined by the first equation of (3.5).

Noting that the boundary conditions for Z^2 is given by $Z^2 = q_2$ on Γ^*, we can solve Z^2 as

$$Z^2 = \mathcal{P}^- q_2 + \hat{Z}^2,$$

where $\hat{Z}^2$ is the unique solutions of

$$\begin{cases} \Delta \hat{Z}^2 = -(1+\lambda_1) \dfrac{Z^1 - f_u^1 W^0}{f_u^0} & \text{in } \Omega_-(\Gamma^*), \\ \hat{Z}^2 = 0 & \text{on } \Gamma^*. \end{cases}$$

Once Z^2 is known, W^2 is uniquely determined by the first equation of (3.4).

In this way, we have obtained the following outer expansion of order $O(\epsilon^2)$:

$$\begin{cases} Z_2^{-,\epsilon}(x) = \mathcal{P}^- q_0 + \displaystyle\sum_{i=1}^{2} \epsilon^i (\mathcal{P}^- q_i + \hat{Z}^i). \\ \qquad\qquad\qquad\qquad\qquad\qquad\qquad\qquad x \in \overline{\Omega}_-(\Gamma^*). \\ W_2^{-,\epsilon}(x) = \displaystyle\sum_{j=0}^{2} \epsilon^j W^j(x), \end{cases}$$

In the same way as above, we can obtain an outer expansion also for $(3.2)_+$. Since $W_2^{+,\epsilon}$ and $W_2^{-,\epsilon}$ are not continuous on Γ^*, we introduce a new variable $\xi = r/\epsilon$ and construct the inner part.

3.2. Inner expansion. In terms of the variables ξ and $y \in \Gamma^*$, the equations in (3.1) are recast as

$$\begin{cases} w_{\xi\xi} + \epsilon(N-1)H(\epsilon\xi, y) w_\xi + \epsilon^2 \Delta(\epsilon\xi) w + f_u^\epsilon w - z = 0, \\ z_{\xi\xi} + \epsilon(N-1)H(\epsilon\xi, y) z_\xi + \epsilon^2 \Delta(\epsilon\xi) z + \epsilon^3 w + \epsilon^2 \lambda^\epsilon w = 0. \end{cases} \tag{3.6}$$

We now determine the functions $w^{-,i}$ $(i = 0, 1, 2)$, $z^{-,j}$ $(j = 0, 1, \ldots, 5)$ in the following expressions:

$$\begin{aligned} w &= \sum_{i=0}^{2} \epsilon^i W^i(\epsilon\xi, y) + \sum_{i=0}^{2} \epsilon^i w^i(\xi, y) = \sum_{i=0}^{2} \epsilon^i \tilde{W}^i(\xi, y) + \sum_{i=0}^{2} \epsilon^i w^i(\xi, y), \\ z &= \sum_{i=0}^{2} \epsilon^i Z^i(\epsilon\xi, y) + \sum_{i=0}^{5} \epsilon^i z^i(\xi, y) = \sum_{i=0}^{2} \epsilon^i \tilde{Z}^i(\xi, y) + \sum_{i=0}^{5} \epsilon^i z^i(\xi, y), \end{aligned} \tag{3.7}$$

where

$$\tilde{W}^i := \frac{1}{i!} \frac{d^i}{d\epsilon^i} \left(\sum_{k=0}^{2} \epsilon^k W^k(\epsilon\xi, y) \right) \Bigg|_{\epsilon=0}, \quad \tilde{Z}^i := \frac{1}{i!} \frac{d^i}{d\epsilon^i} \left(\sum_{k=0}^{2} \epsilon^k Z^k(\epsilon\xi, y) \right) \Bigg|_{\epsilon=0}.$$

Also we expand the mean curvature $H(\epsilon\xi, y)$ and the Laplace–Beltrami operator $\Delta(\epsilon\xi)$ of manifold $\Gamma^*(\epsilon\xi)$ as in subsection 2.2. Substituting (3.7) into (3.6) and equating like powers of ϵ, we have equations for $w^{-,i}$ $(i = 0, 1, 2)$ and $z^{-,j}$ $(j = 0, 1, \ldots, 5)$ as follows:

$$\begin{cases} w^0_{\xi\xi} + \tilde{f}^0_u w^0 + \tilde{f}^0_u \tilde{W}^0 - (\tilde{Z}^0 + z^0) = 0, & \xi \in (-\infty, 0), \\ w^0(0, y) = \Theta(y) - W^0(0, y), & \lim_{\xi\to-\infty} w^0(\xi, y) = 0, \end{cases}$$

$$\begin{cases} w^1_{\xi\xi} + \tilde{f}^0_u w^1 + (N-1)H(0,y)w^0_\xi + \tilde{f}^0_u \tilde{W}^1 + \tilde{f}^1_u(\tilde{W}^0 + w^0) - (\tilde{Z}^1 + z^1) = 0, \\ \qquad\qquad\qquad\qquad\qquad\qquad\qquad\qquad\qquad\qquad\qquad\qquad \xi \in (-\infty, 0), \\ w^1(0, y) = -W^1(0, y), \quad \lim_{\xi\to-\infty} w^1(\xi, y) = 0, \end{cases}$$

(3.8)
$$\begin{cases} w^2_{\xi\xi} + \tilde{f}^0_u w^2 + (N-1)\displaystyle\sum_{i+j=1} H^i w^j_\xi + \Delta^0 w^0 + (\text{value of } \Delta W^0 \text{ on } \Gamma^*) \\ \quad + \tilde{f}^0_u \tilde{W}^2 + \displaystyle\sum_{i+j=2, i\geq 1} \tilde{f}^i_u(\tilde{W}^j + w^j) - (\tilde{Z}^2 + z^2) = 0, \quad \xi \in (-\infty, 0), \\ w^2(0, y) = -W^2(0, y), \qquad\qquad\qquad\qquad\qquad\qquad \lim_{\xi\to-\infty} w^2(\xi, y) = 0, \end{cases}$$

where

$$\tilde{f}^i_u := \frac{1}{i!}\frac{d^i}{d\epsilon^i} f_u \left(U^{\pm,\epsilon}(\epsilon\xi, y) + \sum_{j=0}^{2} \epsilon^j u^{\pm,j}(\xi, y) \right)\Bigg|_{\epsilon=0} \qquad (i = 0, 1, 2),$$

(3.9)
$$\begin{cases} z^0_{\xi\xi} = 0, & \xi \in (-\infty, 0), \\ z^0(0, y) = 0, & \lim_{\xi\to-\infty} z^0(\xi, y) = 0, \end{cases}$$

(3.10)
$$\begin{cases} z^1_{\xi\xi} + (N-1)H(0,y)z^0_\xi = 0, & \xi \in (-\infty, 0), \\ z^1(0, y) = 0, & \lim_{\xi\to-\infty} z^1(\xi, y) = 0, \end{cases}$$

(3.11)
$$\begin{cases} z^2_{\xi\xi} + (N-1)(H^0 z^1_\xi + H^1 z^0_\xi) + \Delta^0 z^0 = 0, & \xi \in (-\infty, 0), \\ z^2(0, y) = 0, & \lim_{\xi\to-\infty} z^2(\xi, y) = 0, \end{cases}$$

(3.12)
$$\begin{cases} z^n_{\xi\xi} + (N-1)\displaystyle\sum_{i+j=n-1} H^i z^j_\xi + \sum_{i+j=n-2} \Delta^i z^j + (1+\lambda_1) w^{n-3} = 0, \ \xi \in (-\infty, 0), \\ \qquad\qquad\qquad\qquad\qquad\qquad\qquad\qquad\qquad\qquad\qquad\qquad (n = 3, 4, 5), \\ z^n(0, y) = 0, \quad \lim_{\xi\to-\infty} z^n(\xi, y) = 0. \end{cases}$$

The equations (3.9), (3.10), and (3.11) imply that $z^j(\xi, y) \equiv 0$ $(j = 0, 1, 2)$.

The equation for w^0 is recast as

$$w^0_{\xi\xi} + \tilde{f}^0_u w^0 + P_0(\xi, y) = 0, \quad \xi \in (-\infty, 0), \tag{3.13}$$

where

$$P_0(\xi, y) = \tilde{f}^0_u W^0(0, y) - q_0(y), \qquad \tilde{f}^0_u = f_u(u^*(\xi + s_0(y))).$$

In view of the boundary conditions in $(3.2)_-$, we impose boundary conditions

$$w^0(0, y) = \Theta(y) - W^0(0, y), \quad \lim_{\xi \to -\infty} w^0(\xi, y) = 0.$$

By using the fact that $u^*_\xi(\xi + s_0(y))$ is a fundamental solution of (3.13), w^0 is uniquely determined as

$$\begin{aligned} w^0(\xi, y) = {} & [\Theta(y) - W^0(0, y)] \frac{u^*_\xi(\xi + s_0)}{u^*_\xi(s_0)} \\ & - u^*_\xi(\xi + s_0) \int_0^\xi \frac{1}{[u^*_\xi(\tau + s_0)]^2} \int_{-\infty}^\tau P_0(s, y) u^*_\xi(s + s_0) ds d\tau \end{aligned} \tag{3.14}$$

with $s_0 = s_0(y)$. Noting that w^0 decays exponentially to zero as $\xi \to -\infty$, we can solve z^3 as

$$z^3(\xi, y) = -(1 + \lambda_1) \int_{-\infty}^\xi \int_{-\infty}^\tau w^0(s, y) ds d\tau. \tag{3.15}$$

The equations for (w^1, z^4) are

$$\begin{cases} 0 = w^1_{\xi\xi} + \tilde{f}_u w^1 + P_1(\xi, y), \\ \\ 0 = z^4_{\xi\xi} + Q_1(\xi, y), \end{cases} \qquad \xi \in (-\infty, 0), \tag{3.16}$$

where

$$\begin{aligned} P_1(\xi, y) &= (N - 1) H(0, y) w^0_\xi + \tilde{f}^0_u \tilde{W}^1 + \tilde{f}^1_u (\tilde{W}^0 + w^0) - \tilde{Z}^1, \\ Q_1(\xi, y) &= (N - 1) H(0, y) z^3_\xi + (1 + \lambda_1) w^1. \end{aligned}$$

We emphasize the fact $P_1(\xi, y)$ decays exponentially to zero as $\xi \to -\infty$ uniformly in $y \in \Gamma^*$. Therefore, the first equation in (3.16) has a unique solution given by

$$\begin{aligned} w^1(\xi, y) = {} & -W^1(0, y) \frac{u^*_\xi(\xi + s_0)}{u^*_\xi(s_0)} \\ & - u^*_\xi(\xi + s_0) \int_0^\xi \frac{1}{[u^*_\xi(\tau + s_0)]^2} \int_{-\infty}^\tau P_1(s, y) u^*_\xi(s + s_0) ds d\tau \end{aligned}$$

with $s_0 = s_0(y)$. Once z^3 and w^1 are determined, z^4 is uniquely determined as

$$z^4(\xi, y) = - \int_{-\infty}^\xi \int_{-\infty}^\tau Q_1(s, y) ds d\tau.$$

Here we used the fact that $Q_1(\xi, y)$ decays exponentially to zero as $\xi \to -\infty$ uniformly in $y \in \Gamma^*$.

By using the above results, w^2 and z^5 are solved as

$$
\begin{aligned}
w^2(\xi, y) &= -W^2(0, y)\frac{u^*_\xi(\xi + s_0)}{u^*_\xi(s_0)} \\
&\quad - u^*_\xi(\xi + s_0)\int_0^\xi \frac{1}{[u^*_\xi(\tau + s_0)]^2}\int_{-\infty}^\tau P_2(s, y)u^*_\xi(s + s_0)dsd\tau, \\
z^5(\xi, y) &= -\int_{-\infty}^\xi \int_{-\infty}^\tau Q_2(s, y)dsd\tau.
\end{aligned} \tag{3.17}
$$

with $s_0 = s_0(y)$. Here we used the fact $P_2(\xi, y)$ and $Q_5(\xi, y)$ decays exponentially to zero as $\xi \to -\infty$ uniformly in $y \in \Gamma^*$.

The same type of arguments as above apply to $w^{+,i}$ $(i = 0, 1, 2)$ and $z^{+,j}$ $(j = 0, 1, \ldots, 5)$. Now we have obtained the approximation of order $O(\epsilon^2)$,

$$
\begin{cases}
\mathcal{W}_2^{\pm,\epsilon}(x) = W_2^{\pm,\epsilon}(x) + \omega(r)\cdot\displaystyle\sum_{i=0}^{2}\epsilon^i w^{\pm,i}(r/\epsilon, y), \\
\mathcal{Z}_2^{\pm,\epsilon}(x) = Z_2^{\pm,\epsilon}(x) + \omega(r)\cdot\displaystyle\sum_{j=3}^{5}\epsilon^j z^{\pm,j}(r/\epsilon, y),
\end{cases} \tag{3.18}
$$

where $\omega(r)$ is a smooth cutoff function such that

$$
\omega(r) = 1, \ \ |r| \le \frac{d_0}{2}\ \omega(r) = 0, \ \ |r| \ge d_0.
$$

3.3. Matching of normal derivatives on Γ^*. Now we are ready to make the eigenfunctions on a whole domain by matching the normal derivatives of $(w^{\pm,\epsilon}, z^{\pm,\epsilon})$. That is, $\theta(y) := \Theta(y)/u^*_\xi(s_0(y))$, $q_i(y)$ $(i = 0, 1, 2) \in C^{2,\alpha}(\Gamma^*)$, and $\lambda_1 \in \mathbf{C}$ must satisfy the following C^1-matching conditions:

$$
\Phi(\theta, q_0, q_1, q_2, \lambda_1, \epsilon) = 0, \quad \Psi(\theta, q_0, q_1, q_2, \lambda_1, \epsilon) = 0 \quad \text{on } \Gamma^*, \tag{3.19}
$$

where

$$
\begin{aligned}
\Phi(\theta, q_0, q_1, q_2, \lambda_1, \epsilon)(y) &= \epsilon u^*_\xi(s_0(y))[w_r^{-,\epsilon}(0, y) - w_r^{+,\epsilon}(0, y)] \\
&= u^*_\xi(s_0(y))[w_\xi^{-,0}(0, y) - w_\xi^{+,0}(0, y)] \\
&\quad + u^*_\xi(s_0(y))\sum_{i=0}^{1}\epsilon^{i+1}[W_r^{-,i}(0, y) + w_\xi^{-,i+1}(0, y) \\
&\quad - W_r^{+,i}(0, y) - w_\xi^{+,i+1}(0, y)] + \epsilon^{3-\alpha}R_2^\epsilon(\theta, q_0, q_1, q_2, \lambda_1),
\end{aligned}
$$

$$
\begin{aligned}
\Psi(\theta, q_0, q_1, q_2, \lambda_1, \epsilon)(y) &= z_r^{-,\epsilon}(0, y) - z_r^{+,\epsilon}(0, y) \\
&= Z_r^{-,0}(0, y) - Z_r^{+,0}(0, y) + \epsilon[Z_r^{-,1}(0, y) - Z_r^{+,1}(0, y)] \\
&\quad + \epsilon^2[Z_r^{-,2}(0, y) + z_\xi^{-,3}(0, y) - Z_r^{+,2}(0, y) - z_\xi^{+,3}(0, y)] \\
&\quad + \epsilon^{3-\alpha}R_1^\epsilon(\theta, q_0, q_1, q_2, \lambda_1).
\end{aligned}
$$

The crucial part of (3.19) will turn out to be $O(\epsilon^2)$, which leads to the conclusion (1.13). We first compute $O(1)$ and $O(\epsilon)$ terms of (3.19).

LEMMA 3.3. *When* $\epsilon = 0$, (3.19) *is equivalent to*

$$u_\xi^*(s_0(y))[w_\xi^{-,0}(0,y) - w_\xi^{+,0}(0,y)] = q_0(y)[h] = 0, \tag{3.20}$$

$$Z_r^{-,0}(0,y) - Z_r^{+,0}(0,y) = (\Pi_- + \Pi_+)q_0 = 0, \tag{3.21}$$

where $[h] = h^+(v^*) - h^-(v^*)$.

Proof. Differentiating the representation of $w^{\pm,1}(\xi, y)$ at $\xi = 0$,

$$\begin{aligned} u_\xi^*(s_0)w_\xi^{\pm,0}(0,y) &= [\theta(y)u_\xi^*(s_0) - W^{\pm,0}(0,y)]u_{\xi\xi}^*(s_0) \\ &\quad - \int_{\pm\infty}^0 [f_u(u^*(\xi + s_0))W^{\pm,0}(0,y) - q_0(y)]u_\xi^*(\xi + s_0)d\xi \\ &= \theta(y)u_\xi^*(s_0)u_{\xi\xi}^*(s_0) + q_0(y)(u^*(s_0) - h^\pm(v^*)). \end{aligned}$$

Here we used the fact that $u_{\xi\xi\xi}^*(s_0) + f_u(u^*(\xi + s_0))u_\xi^*(\xi + s_0) = 0$. Thus we obtain (3.20). (3.21) is obvious. □

Lemma 3.3 implies that $q_0(y) \equiv 0$. Then we see that

$$W^{\pm,0}(x) \equiv 0 \equiv Z^{\pm,0}(x)$$

and $w^{\pm,0}$ is represented as

$$w^{\pm,0}(\xi, y) = u_\xi^*(\xi + s_0(y))\theta(y). \tag{3.22}$$

In the following, we omit the superscript $\pm$ of $w^{\pm,0}(\xi, y)$.

Next we consider the $O(\epsilon)$-term of (3.19).

LEMMA 3.4. $O(\epsilon)$*-terms of* (3.19) *are equivalent to*

$$u_\xi^*(s_0(y))[W_r^{-,0}(0,y) + w_\xi^{-,1}(0,y) - W_r^{+,0}(0,y) - w_\xi^{+,1}(0,y)] = q_1(y)[h] = 0, \tag{3.23}$$

$$Z_r^{-,1}(0,y) - Z_r^{+,1}(0,y) = (\Pi_- + \Pi_+)q_1 = 0. \tag{3.24}$$

Proof. In view of (3.22), the equation for $w^{\pm,1}$ is recast as

$$\begin{aligned} &w_{\xi\xi}^{\pm,1} + f_u(u^*(\xi + s_0))w^{\pm,1} \\ &\quad + (N-1)H(0,y)w_\xi^0 + f_u(u^*(\xi + s_0))W^{\pm,1}(0,y) + \tilde{f}_u^1 w_\xi^0 - q_1(y) = 0. \end{aligned}$$

Differentiating the representation of $w^{\pm,1}(\xi, y)$ at $\xi = 0$,

$$\begin{aligned} -u_\xi^*(s_0)w_\xi^{\pm,1}(0,y) &= \theta(y)\int_{\pm\infty}^0 [(N-1)H(0,y)u_{\xi\xi}^*(\xi + s_0) + \tilde{f}_u^1 u_\xi^*(\xi + s_0)] \\ &\quad \times u_\xi^*(\xi + s_0)d\xi - q_1(y)\int_{\pm\infty}^0 u_\xi^*(\xi + s_0)d\xi \\ &= \theta(y)[u_\xi^{\pm,1}(0,y)u_{\xi\xi}^*(s_0) - u_\xi^*(s_0)u_{\xi\xi}^{\pm,1}(0,y)] \\ &\quad - q_1(y)\int_{\pm\infty}^0 u_\xi^*(\xi + s_0)d\xi. \end{aligned}$$

Here we used the fact proved in Appendix D that

$$\begin{aligned}(3.25)\qquad &\int_{\pm\infty}^{0}[(N-1)H(0,y)u^*_{\xi\xi}(\xi+s_0)+\tilde{f}^1_u u^*_\xi(\xi+s_0)]u^*_\xi(\xi+s_0)d\xi\\ &\quad=u^{\pm,1}_\xi(0,y)u^*_{\xi\xi}(s_0)-u^*_\xi(s_0)u^{\pm,1}_{\xi\xi}(0,y).\end{aligned}$$

By using the facts that $u^{-,1}_\xi(0,y)=u^{+,1}_\xi(0,y)$ and $u^{-,1}_{\xi\xi}(0,y)=u^{+,1}_{\xi\xi}(0,y)$, we have

$$u^*_\xi(s_0(y))[w^{-,1}_\xi(0,y)-w^{+,1}_\xi(0,y)]=q_1(y)\int_{-\infty}^{\infty}u^*_\xi(\xi)d\xi=q_1(y)[h].$$

Thus we obtain (3.23). Equation (3.24) is obvious. □

Lemma 3.4 implies that $q_1(y)\equiv 0$, and then we see that

$$W^{\pm,1}(x)\equiv 0\equiv Z^{\pm,1}(x).$$

Let us define new functions $\tilde{\Phi}$ and $\tilde{\Psi}$ as follows:

$$\tilde{\Phi}(\theta,q_2,\lambda_1,\epsilon):=\frac{1}{\epsilon^2}\Phi(\theta,0,0,q_2,\lambda_1,\epsilon),\quad \tilde{\Psi}(\theta,q_2,\lambda_1,\epsilon):=\frac{1}{\epsilon^2}\Psi(\theta,0,0,q_2,\lambda_1,\epsilon).$$

LEMMA 3.5. *$\tilde{\Phi}(\theta,q_2,\lambda_1,0)=0$ and $\tilde{\Psi}(\theta,q_2,\lambda_1,0)=0$ are equivalent to*

$$(3.26)\qquad [m^2\Delta^{\Gamma^*}+m^2H^*(y)-V^1_r(0,y)J'(v^*)]\theta+J'(v^*)q_2(y)=0,$$

$$(3.27)\qquad (\Pi_-+\Pi_+)q_2-(1+\lambda_1)[h]\theta=0.$$

Proof. See Appendix C. □

Proof of Theorem 1.3. Using Lemma 3.5, we obtain (1.13).

4. Applications. In this section, we apply the results of the previous sections to the case where the domain Ω is a ball or a rectangle. In the following, we assume that the nonlinearity takes the form

$$f(u)=u-u^3.$$

First we note that the constants appeared in the previous section are computed as follows.

LEMMA 4.1.

$$v^*=0,\quad h^\pm(v^*)=\pm 1,\quad J'(v^*)=-2,\quad [h]=2,\quad m^2=\frac{2\sqrt{2}}{3}=\frac{4}{3\sqrt{2}}.$$

Proof. This is proved by straightforward computation. □

4.1. Stability of radially symmetric solutions. In this subsection, we study the radially symmetric solution when Ω is a ball of radius R. It is convenient to introduce new coordinate system $x=(r,y)$, where $x=ry$ for $r\in[0,R]$ and $y\in\partial\Omega=S^{N-1}$.

Then the rescaled reduced problem (1.7)–(1.9) can be rewritten as

$$(4.1)_+\qquad \begin{cases} V^+_{rr}+\dfrac{N-1}{r}V^+_r+G^+=0, & r_0<r<R,\\ V^+(r_0)=\dfrac{m^2(N-1)}{J'(v^*)r_0}, & V^+_r(1)=0,\end{cases}$$

$$(4.1)_- \qquad \begin{cases} V^-_{rr} + \dfrac{N-1}{r} V^-_r + G^- = 0, & 0 < r < r_0, \\ V^-_r(0) = 0, & V^-(r_0) = \dfrac{m^2(N-1)}{J'(v^*) r_0}, \end{cases}$$

and

$$V^-_r(r_0) = V^+_r(r_0), \tag{4.2}$$

where $G^{\pm} := \pm 1 - \overline{u}$. Here $V^-(r,y)$, $V^+(r,y)$ and r_0 are unknown functions and a parameter, respectively. The solutions of $(4.1)_{\pm}$ have the following expressions:

$$V^+(r) = \frac{m^2(N-1)}{J'(v^*) r_0} + \frac{G^+}{N} \int_{r_0}^{r} (R^N t^{1-N} - t) dt,$$
$$V^-(r) = \frac{m^2(N-1)}{J'(v^*) r_0} + \frac{G^-}{2N} (r_0^2 - r^2).$$

Then, by using the condition (4.2), r_0 is uniquely determined as

$$r_0 = \left(\frac{G^+}{[h]} \right)^{1/N} R,$$

and the interface Γ^* is defined by

$$\Gamma^* = \{ x \in \mathbf{R}^N \mid |x| = r_0 \}.$$

The following existence theorem can be proved in a similar way as in [5], so we omit it (see also [19]).

THEOREM 4.2. *There exists a constant $\epsilon_0 > 0$ such that* (1.5) *and* (1.6) *have an ϵ-family of radially symmetric layer solutions $(u^\epsilon(r), v^\epsilon(r))$ for $\epsilon \in (0, \epsilon_0]$ satisfying the following:*

(i) $\lim_{\epsilon \to 0} v^\epsilon = v^*$ *uniformly on* Ω.

(ii) *For each $\delta > 0$,*

$$\lim_{\epsilon \to 0} u^\epsilon(r) = \begin{cases} -1, & 0 \le r \le r_0 - \delta, \\ 1, & r_0 + \delta \le r \le R. \end{cases}$$

The asymptotic form of $(U^\epsilon(r), v^\epsilon(r))$ is given in section 2.

Using Lemma 4.1 and the above results, we can find that the operator L is recast as

$$L = \frac{1}{r_0^2} \Delta^S + \frac{N-1}{r_0^2} + \frac{3\sqrt{2}}{2} \frac{1+\overline{u}}{N} r_0 - 3\sqrt{2} \mathcal{T}(\cdot).$$

We prepare two lemmas before we state the key proposition.

LEMMA 4.3. *All the eigenvalues of $\mathcal{T}$ and L are real. More precisely,*

(i) *the jth eigenvalue Λ_j of $\mathcal{T}$ is given by*

$$\Lambda_j = \alpha R \hat{\Lambda}(j, \alpha), \tag{4.3}$$

where

$$\hat{\Lambda}(z,\alpha) = \frac{(z+N-2)\alpha^{2z+N-2} + z}{z(2z+N-2)}, \quad r_0 = \alpha R, \quad \alpha = \alpha(\overline{u}) = \left(\frac{1-\overline{u}}{2} \right)^{1/N}. \tag{4.4}$$

Then the associated eigenfunction $\beta_j^m(y)$ is the harmonic function of degree m.

(ii) *The jth eigenvalue L is real and given by $\Sigma_j = \Sigma(j, \alpha, R)$, where*

$$\Sigma(z,\alpha,R) = \frac{1}{\alpha^2 R^2}[-z^2-(N-1)z+N-1] + 3\sqrt{2}\left[\frac{1-\alpha^N}{N} - \hat{\Lambda}(z,\alpha)\right]\alpha R. \tag{4.5}$$

Then the associated eigenfunction is the same as that of $\mathcal{T}$.

Proof. See Appendix E. □

LEMMA 4.4 (properties of $\hat{\Lambda}(z,\alpha)$ and $\Sigma(z,\alpha,R)$).

(i) *For $z \geq 1$ and $\alpha \in (0,1)$,*

$$\frac{\partial}{\partial z}\hat{\Lambda}(z,\alpha) < 0, \quad \frac{\partial^2}{\partial z^2}\hat{\Lambda}(z,\alpha) > 0.$$

(ii)

$$\begin{aligned}\frac{\partial}{\partial z}\Sigma(1,\alpha,R) =& -\frac{N}{\alpha^2R^2}\\ &-\frac{3\sqrt{2}\alpha R}{N^2}[-\alpha^N\{2+4(N-2)+(N-2)^2\}+2(N-1)N\alpha^N\log\alpha-2],\\ \Sigma(1,\alpha,R) =& -3\sqrt{2}\alpha^{N+1}R<0 \quad \textit{for } \alpha\in(0,1),\\ &\frac{\partial^2}{\partial z^2}\Sigma(z,\alpha,R)<0 \quad \textit{for } z\geq 1 \quad \textit{and} \quad \alpha\in(0,1).\end{aligned}$$

Proof. These results can be obtained by direct calculations. □

The following proposition is a key to prove Theorem 1.4.

PROPOSITION 4.5.

(i) *The jth principal eigenvalue λ_j^* of (1.13) is given by the following form.*

$$\lambda_j^* = \lambda_j^*(\alpha,\overline{u}) = \frac{1}{3\sqrt{2}}\cdot\frac{\Sigma(j,\alpha(\overline{u}),R)}{\alpha R\hat{\Lambda}(j,\alpha(\overline{u}),R)}. \tag{4.6}$$

Moreover, it holds that

(ii) *for any fixed $R\in(0,\infty)$, there exists $\overline{u}_0 = \overline{u}_0(R)\in(-1,1)$ such that*

$$\Sigma(z,\alpha(\overline{u}),R)<0 \quad \textit{for} \quad \overline{u}\in(0,\overline{u}_0) \quad \textit{and} \quad z\geq 1.$$

(iii) *For any fixed $\overline{u}\in(-1,1)$, there exist $R_0 = R_0(\overline{u}) > 0$ and integer $z_0 \geq 1$ such that*

$$\Sigma(z_0,\alpha(\overline{u}),R_0) > 0.$$

Proof. (i) Noting that L and $\mathcal{T}$ have the same eigenfunctions $\{\beta_j(y)\}_{j=1}^{\infty}$, we can rewrite (1.13) as

$$L\beta_j = 3\sqrt{2}\lambda^*\mathcal{T}(\beta_j),$$

which leads to (4.6).

(ii) Note that $\alpha(\overline{u})$ is a monotone decreasing function of $\overline{u}$. Since $\frac{\partial}{\partial z}\Sigma(1,\alpha,R)<0$ and $\frac{\partial^2}{\partial z^2}\Sigma(z,\alpha,R)<0$ for sufficiently small α, we obtain (ii).

(iii) For fixed α, we choose z_0 satisfying $\frac{1-\alpha^N}{N} - \hat{\Lambda}(z_0,\alpha) > 0$. Then the sign of the first term of (4.5) is negative and that of the second one is positive. Therefore, for sufficiently large R, it holds that $\Sigma(z_0,\alpha,R) > 0$. □

Proof of Theorem 1.4. It is a direct consequence of Proposition 4.5.

4.2. Stability of planar solutions. Let Ω be a rectangle in (x,y)-plane $\Omega := (0,X)\times(0,Y)$. Then the rescaled reduced problem (1.7)–(1.9) is recast as

$$(4.7)_+ \qquad \begin{cases} V^+_{xx} + G^+ = 0, & x_0 < x < X, \\ V^+(x_0) = 0, & V^+_x(X) = 0, \end{cases}$$

$$(4.7)_- \qquad \begin{cases} V^-_{xx} + G^- = 0, & 0 < x < x_0, \\ V^-_x(0) = 0, & V^-(x_0) = 0, \end{cases}$$

and

$$V^-_x(x_0) = V^+_x(x_0), \tag{4.8}$$

where $G^\pm := \pm 1 - \overline{u}$, $\Omega_+(\Gamma^*) = \{(x,y)\in\mathbf{R}^2 \mid x_0 < x < X,\ 0 < y < Y\}$, $\Omega_-(\Gamma^*) = \{(x,y)\in\mathbf{R}^2 \mid 0 < x < x_0, 0 < y < Y\}$, and $\Gamma^* = \{(x_0,y)\in\mathbf{R}^2 \mid 0 < y < Y\}$. Here we used the fact that $H_1(y) = 0$. We can easily show that $(4.7)_-$ and $(4.7)_+$ have unique solutions given by

$$\begin{aligned} V^-(x) &= -\frac{1}{2}G^-[x^2 - x_0^2], \\ V^+(x) &= -G^+\left[\frac{1}{2}(x^2 - x_0^2) - X(x - x_0)\right]. \end{aligned}$$

Then, by using the C^1-matching condition (4.8), we can uniquely determine x_0 as

$$x_0 = \frac{G^+ X}{[h]},$$

so the derivative $V_x(x_0)$ is given by

$$V_x(x_0) = -\frac{G^+G^-X}{[h]} = \frac{1}{2}X(1-\overline{u})(1+\overline{u}).$$

The existence results of the planar solution to (1.5) and (1.6) is given by Taniguchi and Nishiura [23].

THEOREM 4.6 (see [23]). *There exists a constant $\epsilon_0 > 0$ such that* (1.5) *and* (1.6) *have an ϵ-family of stationary planar solutions $(u^\epsilon(x), v^\epsilon(x))$ independent of $y\in[0,Y]$ for $\epsilon\in(0,\epsilon_0]$ satisfying the following:*

(i) $\lim_{\epsilon\to 0} v^\epsilon = v^*$ *uniformly on* Ω.

(ii) *For each $\delta > 0$,*

$$\lim_{\epsilon\to 0} u^\epsilon(x) = \begin{cases} -1, & 0 \le x \le x_0 - \delta, \\ 1, & x_0 + \delta \le x \le X. \end{cases}$$

Using Lemma 4.1 and the above results, we can find that the operator L is recast as

$$L = \frac{d^2}{dy^2} - \frac{3\sqrt{2}}{2}\left[\frac{1}{2}X(\overline{u}-1)(\overline{u}+1) + 2\mathcal{T}(\cdot)\right].$$

The spectral properties of L and $\mathcal{T}$ are given in the following two lemmas.

LEMMA 4.7. *All the eigenvalues of $\mathcal{T}$ and L are real. More precisely,*

(i) *the jth eigenvalue Λ_j of $\mathcal{T}$ is given by*

$$\Lambda_j = X\Lambda(\kappa\pi j, \overline{u}), \tag{4.9}$$

where

$$\Lambda(z, \overline{u}) := \frac{\cosh z + \cosh \overline{u} z}{2z \sinh z} \tag{4.10}$$

and $\kappa := X/Y$. Then the associated eigenfunction is $\beta_j(y) = \cos(\tau_j y)$, where $\tau_j = \pi j/Y$.

(ii) *The jth eigenvalue of L is real and given by $\Sigma_j = \Sigma(\kappa\pi j, X, \overline{u})$, where*

$$\Sigma(z, X, \overline{u}) := -\left(\frac{z}{X}\right)^2 + \frac{3\sqrt{2}}{2} X \left[\frac{1}{2}(1-\overline{u})(1+\overline{u}) - 2\Lambda(z, \overline{u})\right].$$

Then the associated eigenfunction is the same as that of $\mathcal{T}$.

Proof. See Appendix F. □

LEMMA 4.8 (properties of $\Lambda(z, \overline{u})$). *For $\overline{u} \in (-1, 1)$ and $z > 0$,*

$$\Lambda(z, \overline{u}) > 0, \quad \frac{\partial}{\partial z}\Lambda(z, \overline{u}) < 0, \quad \frac{\partial^2}{\partial z^2}\Lambda(z, \overline{u}) > 0,$$
$$\lim_{z \to +0} \Lambda(z, \overline{u}) = \infty, \quad \lim_{z \to \infty} z\Lambda(z, \overline{u}) = \frac{1}{2}.$$

Proof. These results can be obtained by direct calculations. □

Using the above two lemmas, we can prove the following proposition.

PROPOSITION 4.9. (i) *The jth principal eigenvalue λ_j^* of (1.13) is given by the following form:*

$$\lambda_j^* = \lambda_j^*(\kappa, X, \overline{u}) = \frac{1}{3\sqrt{2}} \cdot \frac{\Sigma(\kappa\pi j, X, \overline{u})}{X\Lambda(\kappa\pi j, \overline{u})}. \tag{4.11}$$

(ii) *The nullcline of $\Sigma(z, X, \overline{u})$ as a function of $z > 0$ and $X > 0$ is given by $\{(z, X(z, \overline{u})) \mid z > z_0\}$, where z_0 is a unique zero of $\frac{1}{2}(1-\overline{u}^2) - 2\Lambda(z, \overline{u}) = 0$ and*

$$X(z; \overline{u}) = \left(\frac{\sqrt{2}}{3}\right)^{1/3} z^{2/3} \left[\frac{1}{2}(1-\overline{u}^2) - 2\Lambda(z, \overline{u})\right]^{-1/3}. \tag{4.12}$$

Moreover, $X(z; \overline{u})$ has the following properties:

$$\lim_{z \to z_0 + 0} X(z; \overline{u}) = \infty, \tag{4.13}$$

$$\lim_{z \to \infty} \left[X(z; \overline{u}) - \left(\frac{2\sqrt{2}}{3}\right)^{1/3} (1-\overline{u}^2)^{-1/3} z^{2/3}\right] = 0, \tag{4.14}$$

$$\frac{dX}{dz} \quad \begin{cases} < 0 & \text{for} \quad z_0 < z < z_1, \\ = 0 & \text{for} \quad z = z_1, \\ > 0 & \text{for} \quad z_1 < z, \end{cases} \tag{4.15}$$

for some $z_1 = z_1(\overline{u})$.

Proof. (i) Noting that L and $\mathcal{T}$ have the same eigenfunctions $\{\beta_j(y)\}_{j=1}^{\infty}$, we can rewrite (1.13) as

$$L\beta_j = 3\sqrt{2}\lambda^*\mathcal{T}(\beta_j),$$

which leads to (4.11).

(ii) We define a function g of z and X on $(0,\infty)\times(0,\infty)$ by

$$g(z,X,\overline{u}) := X^2\Sigma(z,X,\overline{u}) = -z^2 + \frac{3\sqrt{2}}{2}X^3\left[\frac{1}{2}(1-\overline{u}^2) - \Lambda(z,\overline{u})\right].$$

Using Lemma 4.8, we see that $p(z,\overline{u}) := \frac{1}{2}(1-\overline{u}^2)-\Lambda(z,\overline{u})$ has a unique zero $z = z_0(\overline{u})$ and $p(z,\overline{u}) > 0$ for $z > z_0$. Then we can solve $g(z,X,\overline{u}) = 0$ in X as (4.12). Noting the properties of $\Lambda(z,\overline{u})$, we obtain (4.13) and (4.14).

By using the implicit function theorem, we see that

$$\frac{dX}{dz} = -\frac{\partial g}{\partial z}\Big/\frac{\partial g}{\partial X}$$

and $\frac{\partial g}{\partial X} = \frac{9\sqrt{2}}{2}X^2[(1-\overline{u}^2)/2-\Lambda(z,\overline{u})] > 0$. Noting that $\frac{\partial g}{\partial z} = -2z-3\sqrt{2}X^3\Lambda_z$, (4.13) and (4.14), we have

$$\lim_{z\to z_0+0}\frac{\partial g}{\partial z}(z,X(z;\overline{u});\overline{u}) = \infty, \quad \lim_{z\to\infty}\frac{\partial g}{\partial z}(z,X(z;\overline{u});\overline{u}) = -\infty.$$

Combining the above facts and $\frac{\partial^2 g}{\partial z^2} = -2-3\sqrt{2}X^3\Lambda_{zz} < 0$, we can see that $\frac{\partial g}{\partial z}$ has a unique zero $z = z_1$ and $\frac{dX}{dz}$ satisfies (4.15). ∎

Proof of Theorem 1.5. The proof follows from Proposition 4.9. ∎

4.3. Justification of the SLEP equation for the planar case. In subsection 3.3, we derived the SLEP equation for the principal parts of the critical eigenvalues and eigenfunctions. Since our method is constructive, it is not a priori clear that there are no other dangerous eigenvalues. But, fortunately, when the domain Ω is a ball or a rectangle, we can justify our results. Precisely speaking, the principal parts of all dangerous eigenvalues are reduced to the solutions to (1.13).

In this subsection, we outline the justification of (1.13) when Ω is a rectangle $(0,X)\times(0,Y)$. When Ω is a ball, we can justify (1.13) in a parallel way. See [19] and [20] for the activator-inhibitor case.

By using a complete orthonormal system $\{\Phi_j(y)\}_{j=0}^{\infty}$ in $L^2(0,Y)$, where

$$\Phi_j(y) = \begin{cases} 1/\sqrt{Y}, & j = 0, \\ \sqrt{2/Y}\cos(\pi jy/Y), & j > 0, \end{cases}$$

(w,z) is expanded as

$$w(x,y) = \sum_{j=0}^{\infty} w_j(x)\Phi_j(y), \quad z(x,y) = \sum_{j=0}^{\infty} z_j(x)\Phi_j(y),$$

where

$$w_j(x) = \int_0^Y w(x,y)\Phi_j(y)dy, \quad z_j(x) = \int_0^Y z(x,y)\Phi_j(y)dy$$

in $L^2(\Omega)$. By using the above notation, the eigenvalue problem (3.1) is rewritten as

$$\begin{cases} 0 = L^{\epsilon,j} w_j - z_j, \\ 0 = M^j z_j + \epsilon w_j + \lambda w_j, \end{cases} \qquad x \in I := (0, X), \tag{4.16}$$

with the boundary condition

$$\frac{dw_j}{dx}(0) = 0 = \frac{dw_j}{dx}(X), \quad \frac{dz_j}{dx}(0) = 0 = \frac{dz_j}{dx}(X)$$

for $j = 0, 1, \ldots$, where

$$L^{\epsilon,j} := \epsilon^2 \frac{d^2}{dx^2} + f_u^\epsilon - \epsilon^2 \mu_j, \quad M^j := \frac{d^2}{dx^2} - \mu_j, \quad \mu_j = \left(\frac{\pi j}{Y}\right)^2.$$

Then the condition $\iint_\Omega w \, dx \, dy = 0$ is equivalent to either

$$\text{(i)} \qquad \int_0^X w_0(x) \, dx = 0 \quad (w_0(x) \not\equiv 0)$$

or

$$\text{(ii)} \qquad w_0(x) \equiv 0$$

since $\int_0^Y \Phi_j(y) dy = 0$ for $j = 1, 2, \ldots$.

First, we consider the former case. Let $\{\phi_k^{\epsilon,j}\}_{k \geq 0}$ be the complete orthonormal set in $L^2(I)$ consisting of the eigenfunctions of $L^{\epsilon,j}$, and $\{\zeta_k^{\epsilon,j}\}_{k \geq 0}$ the associated eigenvalues. They have the following properties.

LEMMA 4.10 (Nishiura [10] and [11]).

(i) *It holds that*

$$\zeta_0^{\epsilon,j} > 0 > -\delta > \zeta_1^{\epsilon,j} > \zeta_2^{\epsilon,j} > \cdots$$

for sufficiently small $\epsilon > 0$, where δ is a positive constant independent of $j \geq 0$ and $\epsilon > 0$.

(ii) $\lim_{\epsilon \downarrow 0} \frac{\zeta_0^{\epsilon,j}}{\epsilon^2} = \hat{\zeta}_0^* - \mu_j$, *where* $\hat{\zeta}_0^* = -\frac{1}{m^2} J'(v^*) V_x(x_0)$.

(iii) $\lim_{\epsilon \downarrow 0} \frac{\phi_0^{\epsilon,j}}{\sqrt{\epsilon}} = \frac{[h]}{m} \delta_{x_0}$ *in* $H^{-1}(I)$*-sense,*

where δ_{x_0} is a Dirac's δ-function at $x = x_0$.

We decompose w as

$$w = (L^{\epsilon,j})^{-1} z = \frac{\langle z, \ \phi_0^{\epsilon,j} \rangle}{\zeta_0^{\epsilon,j}} \phi_0^{\epsilon,j} + (L^{\epsilon,j})^\dagger(z),$$

where

$$(L^{\epsilon,j})^\dagger := \sum_{n \geq 1} \frac{\langle \ \cdot \ , \ \phi_n^{\epsilon,j} \rangle}{\zeta_n^{\epsilon,j}} \phi_n^{\epsilon,j}.$$

$(L^{\epsilon,j})^\dagger$ has the following properties.

LEMMA 4.11 (Nishiura [10] and [11]). *There exists a constant $\epsilon_0 > 0$ such that $(L^{\epsilon,j})^\dagger$ is a uniformly L^2-bounded operator for $\epsilon \in (0, \epsilon_0)$ and $j \geq 0$. Moreover, the following property holds:*

$$\lim_{\epsilon \to 0} (L^{\epsilon,j})^\dagger p = \frac{p}{f_u^*} \quad \textit{strongly in } L^2 - \textit{sense},$$

where $p \in L^2(I) \cap L^\infty(I)$ and $f_u^* := f_u(h^\pm(v^*))$.

The eigenvalue problem (4.16) and the condition $\iint_\Omega w\, dx\, dy = 0$ with $j = 0$ are recast as

$$z_{xx} + (\epsilon + \lambda) \left[\frac{\langle z,\ \phi_0^{\epsilon,0} \rangle}{\zeta_0^{\epsilon,0}} \phi_0^{\epsilon,0} + (L^{\epsilon,0})^\dagger(z) \right] = 0 \tag{4.17}$$

and

$$\frac{\langle z,\ \phi_0^{\epsilon,0}/\sqrt{\epsilon} \rangle}{\epsilon} \int_0^X \frac{1}{\zeta_0^\epsilon/\epsilon^2} \frac{\phi_0^{\epsilon,0}}{\sqrt{\epsilon}} dx + \int_0^X (L^{\epsilon,0})^\dagger(z) dx = 0.$$

In view of Lemmas 4.10 and 4.11, we see that

$$\lim_{\epsilon \to 0} \int_0^X \frac{1}{\zeta_0^\epsilon/\epsilon^2} \frac{\phi_0^{\epsilon,0}}{\sqrt{\epsilon}} dx = \frac{[h]}{m\hat{\zeta}_0^*}$$

and $\lim_{\epsilon \to 0} \int_0^X (L^{\epsilon,0})^\dagger(z) dx$ is bounded. Consequently, the following limits exist:

$$\hat{z}^* := \frac{m}{[h]} \lim_{\epsilon \downarrow 0} \frac{1}{\epsilon} \langle z,\ \phi_0^{\epsilon,0}/\sqrt{\epsilon} \rangle, \quad 0 = \lim_{\epsilon \downarrow 0} \langle z,\ \phi_0^{\epsilon,0}/\sqrt{\epsilon} \rangle.$$

Now we rewrite (4.17) in a weak form

$$- \langle z_x, \psi_x \rangle + (\epsilon + \lambda) \left[\frac{\langle z,\ \phi_0^{\epsilon,0}/\sqrt{\epsilon} \rangle/\epsilon}{\zeta_0^\epsilon/\epsilon^2} \langle \phi_0^{\epsilon,0}/\sqrt{\epsilon}, \psi \rangle + \langle (L^{\epsilon,0})^\dagger(z), \psi \rangle \right] = 0,$$

$$z \in H_N^1(I),\ \psi \in H^1(I),$$

where $H_N^1(I)$ is the space of closure of $\{\cos(n\pi x/X)\}_{n=0}^\infty$ in $H^1(I)$. Then the limit function $z^* = \lim_{\epsilon \to 0} z$ must exist and satisfy the following limit equation:

$$-\langle z_x^*, \psi_x \rangle + \lambda \left[\frac{[h]^2 \hat{z}^*}{m^2 \hat{\zeta}_0^*} \langle \delta_{x_0}, \psi \rangle + \frac{1}{f_u^*} \langle z^*, \psi \rangle \right] = 0, \quad z^*(x_0) = 0.$$

This is equivalent to the next system:

$$\begin{cases} Z_{xx}^- + \dfrac{\lambda}{f_u^*} Z^- = 0, & x \in (0, x_0), \\ Z_x^-(0) = 0, & Z^-(x_0) = 0, \end{cases} \tag{4.18}$$

$$\begin{cases} Z_{xx}^+ + \dfrac{\lambda}{f_u^*} Z^+ = 0, & x \in (x_0, X), \\ Z^+(x_0) = 0, & Z_x^+(X) = 0, \end{cases} \tag{4.19}$$

$$Z_x^+(x_0) - Z_x^-(x_0) = -\lambda \frac{[h]^2 \hat{z}^*}{m^2 \hat{\zeta}_0^*}. \tag{4.20}$$

LEMMA 4.12. *There exists a constant $\delta > 0$ such that* (4.18)–(4.20) *have no nontrivial solutions for $\lambda > -\delta$ for the case* (i)*, i.e., $\int_0^X w_0(x)\,dx = 0$ ($w_0(x) \not\equiv 0$).*

Proof. When $\lambda = 0$, (4.18)–(4.20) have a unique solution $Z^-(x) \equiv 0$ and $Z^+(x) \equiv 0$.

If $\lambda > 0$, the general solution $Z(x)$ of (4.18) is represented as

$$Z(x) = A \exp(\alpha x) + B \exp(-\alpha x),$$

where $\alpha^2 = -\lambda / f_u^*$, $\alpha > 0$. Then, by using the boundary conditions, we obtain $A = 0$ and $B = 0$. Similarly, we can prove that (4.19) has no nonhomogeneous solutions.

If $-\delta < \lambda < 0$, where $-\delta := \frac{\pi^2}{X^2} f_u^*$, the general solutions $Z^-(x) = C^- \cos \beta x$ and $Z^+(x) = C^+ \cos \beta(X - x)$, where $\beta^2 = \lambda / f_u^*$ and $\beta > 0$, cannot satisfy the boundary conditions $Z^-(x_0) = 0$ and $Z^+(x_0) = 0$ simultaneously. □

Next, we consider the case (ii) $w_0(x) \equiv 0$. The eigenvalue problem (4.16) with $j > 0$ is recast as

$$-\langle z_x, \psi_x \rangle - \mu_j \langle z,\ \psi \rangle + \frac{\epsilon + \lambda}{\epsilon} \left[\frac{\langle z,\ \phi_0^{\epsilon,j}/\sqrt{\epsilon} \rangle}{\zeta_0^{\epsilon,j}/\epsilon^2} \langle \phi_0^{\epsilon,j}/\sqrt{\epsilon}, \psi \rangle + \epsilon \langle (L^{\epsilon,j})^\dagger(z), \psi \rangle \right] = 0,$$

where $z \in H_N^1(I)$, $\psi \in H^1(I)$.

By Lemmas 4.10 and 4.11, we see that $\lambda = O(\epsilon)$ and the limit function $z^* = \lim_{\epsilon \to 0} z$ must exist. Then z^* satisfies the following limit equation:

$$-\langle z_x^*, \psi_x \rangle - \mu_j \langle z^*,\ \psi \rangle + (1 + \hat{\lambda}) \frac{[h]^2}{m^2} \frac{\langle z^*, \delta_{x_0} \rangle}{\hat{\zeta}_0^* - \mu_j} \langle \delta_{x_0}, \psi \rangle = 0, \tag{4.21}$$

where $\hat{\lambda} = \lim_{\epsilon \to 0} \lambda / \epsilon$. Hereafter, we normalize the limit eigenfunction z^* as $\langle z^*, \delta_0 \rangle = 1$. Then (4.21) is equivalent to the next system:

$$\begin{cases} z_{xx}^* - \mu_j z^* = 0, \quad x \in (0, x_0) \cup (x_0, X), \\ \lim\limits_{x \to x_0 + 0} z_x^*(x) - \lim\limits_{x \to x_0 - 0} z_x^*(x) = -(1 + \hat{\lambda}) \dfrac{[h]^2}{m^2 (\hat{\zeta}_0^* - \mu_j)}, \\ z^*(x_0) = 1, \quad z_x^*(0) = 0 = z_x^*(X). \end{cases} \tag{4.22}$$

PROPOSITION 4.13. *The eigenvalue $\hat{\lambda}$ of* (4.22) *is given by* (4.11) *for the case* (ii)*, i.e., $w_0(x) \not\equiv 0$.*

Proof. Note that z^* is determined by the first equation with the third and fourth condition of (4.22). In fact, after simple computations, we have

$$z^*(x) = \begin{cases} \dfrac{\cosh \tau_j x}{\cosh \tau_j x_0}, & 0 < x < x_0, \\ \dfrac{\cosh \tau_j (x - X)}{\cosh \tau_j (X - x_0)}, & x_0 < x < X. \end{cases}$$

Here we used the facts that $\mu_j = \tau_j^2 = (\pi j/Y)^2$. Then

$$\begin{aligned}\lim_{x\to x_0+0} z^*(x) - \lim_{x\to x_0-0} z^*(x) &= \frac{\tau \sinh \tau_j(x-X)}{\cosh \tau_j(X-x_0)} - \frac{\tau \sinh \tau_j x}{\cosh \tau_j x_0} \\ &= -\frac{1}{X}\frac{2\tau_j X \sinh \tau_j X}{\cosh \tau_j X + \cosh \overline{u}\tau_j X} \\ &= -\frac{1}{X\Lambda(\kappa\pi j, \overline{u})}.\end{aligned}$$

Solving the second equation of (4.22) in $\hat{\lambda}$, we have

$$\hat{\lambda} = \frac{m^2}{[h]^2 X\Lambda(\kappa\pi j, \overline{u})}\left[-\mu_j + \hat{\zeta}_0^* - \frac{[h]^2}{m^2} X\Lambda(\kappa\pi j, \overline{u})\right].$$

Noting the facts that

$$\kappa = \frac{X}{Y}, \quad \mu_j = \left(\frac{\kappa\pi j}{X}\right)^2, \quad \hat{\zeta}_0^* = \frac{3\sqrt{2}}{4} X(1-\overline{u})(1+\overline{u}), \quad \frac{[h]^2}{m^2} = 3\sqrt{2},$$

we obtain (4.11). Thus we complete the proof. □

In view of Lemma 4.12 and Proposition 4.13, it is clear that all dangerous eigenvalues to stability are controlled by the SLEP equation (1.13) (or, equivalently, (4.22)).

5. Concluding remarks—activator-inhibitor case. In the preceding sections, we have discussed the stability of mesoscopic patterns in diblock copolymers. Here we show that our approach also works well for the activator-inhibitor system (1.4) under the Neumann boundary condition. We assume the following for the nonlinearity $g(u, v)$:

$$\text{(A7)} \qquad \pm g(h^{\pm}(v^*), v^*) > 0, \quad g_u(h^{\pm}(v^*), v^*) > 0, \quad \frac{d}{dv} g(h^{\pm}(v), v)\Big|_{v=v^*} < 0.$$

In the following, we will use the same notation defined in the previous sections without explanation. The reduced problem to (1.4) is given by

$$\text{(5.1)} \qquad \begin{cases} D\Delta V^- = -g(h^-(v^*), v^*) & \text{in } \Omega_-(\Gamma), \\ V^- = -\dfrac{m^2(N-1)}{J'(v^*)} H(0, y) & \text{on } \Gamma, \\ \dfrac{\partial V^-}{\partial n} = 0 & \text{on } \partial\Omega, \end{cases}$$

$$\text{(5.2)} \qquad \begin{cases} D\Delta V^+ = -g(h^+(v^*), v^*) & \text{in } \Omega_+(\Gamma), \\ V^+ = -\dfrac{m^2(N-1)}{J'(v^*)} H(0, y) & \text{on } \Gamma, \end{cases}$$

$$\text{(5.3)} \qquad \frac{\partial V^+}{\partial \nu} = \frac{\partial V^-}{\partial \nu} \quad \text{on } \Gamma.$$

Concerning the existence of stationary solutions, we have the following corollary.

COROLLARY OF THEOREM 1.2. *Assume that* (A1)–(A3) *in section* 1, (A7)*, and the following* (A4′)–(A5′) *are satisfied:*

(A4′) *There exists a solution* $(V^*, \Gamma^*) \in C^1(\overline{\Omega}) \times \mathcal{F}$ *of* (5.1)–(5.3)*, where*

$$V^*(x) = \begin{cases} V^-(x), & x \in \Omega_-(\Gamma^*), \\ V^+(x), & x \in \Omega_+(\Gamma^*). \end{cases}$$

$V^{\pm}$ *are smooth solutions of* (5.1) *and* (5.2)*, respectively, satisfying* (5.3).

(A5′) *There is a bounded linear operator* $L^\dagger : (I-P)C^\alpha(\Gamma^*) \to (I-P)C^{2,\alpha}(\Gamma^*)$ *called the inverse of the operator*

$$L := \Delta^{\Gamma^*} + H^*(y) - \frac{1}{m^2} J'(v^*) V_r^*(0,y) + \frac{1}{Dm^2}[g] J'(v^*) \mathcal{T}(\cdot)$$

such that $LL^\dagger = I$ *on* $(I-P)C^\alpha(\Gamma^*)$ *and* $L^\dagger L = I - P$ *on* $(I-P)C^{2,\alpha}(\Gamma^*)$. *Here,* Δ^{Γ^*} *is the Laplace–Beltrami operator on* Γ^*, $H^*(y)$ *sum of the square of the principal curvature of* Γ^*, *and* $[g] := g(h^+(v^*), v^*) - g(h^-(v^*), v^*)$.

Then, there is an $\epsilon_0 > 0$ *such that* (1.4) *have an* ϵ*-family of stationary solutions* (u^ϵ, v^ϵ) *for* $\epsilon \in (0, \epsilon_0]$ *satisfying the following:*

(i) $\lim_{\epsilon \to 0} v^\epsilon(x) = v^*$ *uniformly on* $\overline{\Omega}$.

(ii) *For each* $\delta > 0$,

$$\lim_{\epsilon \to 0} u^\epsilon(x) = \begin{cases} h^-(v^*), & x \in \overline{\Omega}_-(\Gamma^*) \backslash \Gamma^*_\delta, \\ h^+(v^*), & x \in \overline{\Omega}_+(\Gamma^*) \backslash \Gamma^*_\delta, \end{cases} \quad \textit{uniformly},$$

where Γ^*_δ *is a tubular neighborhood of* Γ^*.

(iii) *For each* $K > 0$,

$$\lim_{\epsilon \to 0} u^\epsilon(y + \epsilon \xi \nu(y)) = u^*(\xi + s^*(y)) \quad \textit{in } C^2[-K, K],$$

uniformly in $y \in \Gamma^*$ *for some* $s^* \in C^{2,\alpha}(\Gamma^*)$.

The associated linearized problem of (1.4) is of the form

$$\begin{cases} \lambda^\epsilon w = \epsilon^2 \Delta w + f_u^\epsilon w - z, \\ \epsilon \lambda^\epsilon z = D \Delta z + \epsilon g_u^\epsilon w + \epsilon g_v^\epsilon z, & \text{in } \Omega, \\ \dfrac{\partial w}{\partial n} = 0 = \dfrac{\partial z}{\partial n} & \text{on } \partial\Omega. \end{cases} \tag{5.4}$$

Here we focus only on the critical eigenvalues. So we assume the following for (5.4):

(A6′) There exists an integer $m^* \geq 1$ such that each eigenvalue λ^ϵ and the associated eigenfunctions (w^ϵ, z^ϵ) of (5.4) have the following asymptotic forms:

$$\begin{cases} \lambda^\epsilon = \epsilon \lambda_1 + \epsilon^2 \lambda_2 + o(\epsilon^2), \\ w^\epsilon(x) = \displaystyle\sum_{j=0}^{m^*} \epsilon^j W^{\pm,j}(x) + \omega(r) \cdot \sum_{j=0}^{m^*} \epsilon^j w^{\pm,j}(r/\epsilon, y) + o(\epsilon^{m^*}), \\ & \text{in } \Omega_\pm(\Gamma^*), \\ z^\epsilon(x) = \displaystyle\sum_{j=0}^{m^*} \epsilon^j Z^{\pm,j}(x) + \omega(r) \cdot \epsilon^2 \sum_{j=0}^{m^*} \epsilon^j z^{\pm,j}(r/\epsilon, y) + o(\epsilon^{m^*}), \end{cases}$$

where $W^{\pm,i}(x) \in C^{2,\alpha}(\overline{\Omega}_\pm(\Gamma^*))$ and $Z^{\pm,i}(x) \in C^{2,\alpha}(\overline{\Omega}_\pm(\Gamma^*))$ are outer expansions, $w^{\pm,i}(\xi, y)$ and $z^{\pm,j}(\xi, y)$ are inner expansions bounded for $\pm\xi \in (0, \infty)$ and $y \in \Gamma^*$.

In the activator-inhibitor case, the principal parts of C^1-matching conditions to eigenfunctions become

$$u_\xi^*(s_0(y))[w_\xi^{-,0}(0,y) - w_\xi^{+,0}(0,y)] = m^2\lambda_1\theta(y) - J'(v^*)q_0(y) = 0,$$

$$Z_r^{-,0}(0,y) - Z_r^{+,0}(0,y) = (\Pi_- + \Pi_+)q_0 = 0.$$

Then, the following two cases are considered.

Case I. $q_c \neq 0$ and θ is a constant function $\theta(y) = \theta_c(\neq 0)$. Then λ_1 is given by

$$\lambda_1 = \frac{J'(v^*)q_c}{m^2\theta_c}.$$

Case II. $q_c = 0$ and $\lambda_1 = 0$.

Concerning Case I, we have the following a priori estimate for λ_1.

LEMMA 5.1 (a priori estimate for λ_1). *Assume that the principal eigenvalue λ^ϵ and the associated eigenfunctions have the following asymptotic forms:*

$$\lambda^\epsilon = \epsilon\lambda_1(\epsilon) \quad \textit{and} \quad \lim_{\epsilon\downarrow 0}\lambda_1(\epsilon) = \frac{J'(v^*)q_c}{m^2\theta_c},$$

$$w \approx \epsilon h_v^\pm(v^*)q_c + (w^0(r/\epsilon, y) + \epsilon w^{\pm,1}(r/\epsilon, y)) \cdot \omega(r),$$

$$z \approx q_c + \epsilon Z^{\pm,2}(x) + \epsilon^2(z^{\pm,1}(r/\epsilon, y) + \epsilon z^{\pm,2}(r/\epsilon, y)) \cdot \omega(r)$$

on $\Omega_\pm(\Gamma^*)$. Then the real part of $\lambda_1(\epsilon)$ is strictly negative.

Proof. See Appendix G. □

In view of Lemma 5.1, we expand λ^ϵ as $\lambda^\epsilon = \epsilon^2\lambda_2 + o(\epsilon^2)$. For the eigenvalues of (5.4), we have the following result.

COROLLARY OF THEOREM 1.3. *Assume that* (A1)–(A3) *in section* 1, (A4′)–(A6′) *with $\lambda_1 = 0$ and* (A7) *are satisfied. Then the principal part of the critical eigenvalues is given by $\epsilon^2\lambda^*$, where λ^* is the eigenvalue of the following problem:*

$$L\theta^* = \lambda^*\theta^* \tag{5.5}$$

for $\theta^* \in (I - P)C^{2,\alpha}(\Gamma^*)$.

We assume, for simplicity, that the nonlinearity takes the form $(f, g) = (u - u^3, u - \gamma v)$, $\gamma > 3/2$. Then the constants are precisely computed as

$$v^* = 0, \quad h^\pm(v^*) = \pm 1, \quad J'(v^*) = -2, \quad m^2 = \frac{2\sqrt{2}}{3} = \frac{4}{3\sqrt{2}}.$$

For example, when Ω is a rectangle in (x, y)-plane $\Omega = (0, X) \times (0, Y)$, the reduced ploblems (5.1)–(5.3) are recast as

$$(5.6)_+ \qquad \begin{cases} DV_{xx}^+ + G^+ = 0, & x_0 < x < X, \\ V^+(x_0) = 0, \quad V_x^+(X) = 0, \end{cases}$$

$$(5.6)_- \qquad \begin{cases} DV_{xx}^- + G^- = 0, & 0 < x < x_0, \\ V_x^-(0) = 0, \quad V^-(x_0) = 0, \end{cases}$$

$$V_x^-(x_0) = V_x^+(x_0), \tag{5.7}$$

where $G^\pm := g(h^\pm(v^*), v^*) = \pm 1$, $\Omega_+(\Gamma^*) = \{(x,y) \in \mathbf{R}^2 \,|\, x_0 < x < X,\ 0 < y < Y\}$, $\Omega_-(\Gamma^*) = \{(x,y) \in \mathbf{R}^2 \,|\, 0 < x < x_0, 0 < y < Y\}$, and $\Gamma^* = \{(x_0, y) \in \mathbf{R}^2 \,|\, 0 < y < Y\}$. Here we used the fact that $H^*(y) = 0$. We can easily show that $(5.6)_-$ and $(5.6)_+$ have unique solutions given by

$$V^-(x) = -\frac{1}{2D} G^-[x^2 - x_0^2],$$
$$V^+(x) = -\frac{G^+}{D}\left[\frac{1}{2}(x^2 - x_0^2) - X(x - x_0)\right].$$

Then, by using the C^1-matching condition (5.7), we can uniquely determine x_0 and $V_x(x_0)$ as

$$x_0 = \frac{G^+ X}{[g]} \quad \text{and} \quad V_x(x_0) = -\frac{G^+ G^- X}{D[g]},$$

where $[g] = G^+ - G^-$. The existence results of the planar solution to (1.4) is given by Taniguchi and Nishiura [23] (see Theorem 4.6 in section 4).

The jth eigenvalue Λ_j of $\mathcal{T}$ is given by $\Lambda_j = X\Lambda(\kappa\pi j)$, where

$$\Lambda(z) = \frac{\cosh z + \cosh pz}{2z \sinh z}, \quad p = -\frac{G^-}{[g]}, \quad \kappa = \frac{X}{Y}.$$

Then the associated eigenfunction is $\beta_j(y) = \cos(\tau_j y)$, where $\tau_j = \pi j / Y$. Therefore, the jth eigenvalue of L is real and given by $\Sigma_j = \Sigma(\kappa\pi j, X, D)$, where

$$\Sigma(z, X, D) := -\left(\frac{z}{X}\right)^2 - \frac{J'(v^*)X}{Dm^2}\left[-\frac{G^+G^-}{[g]} + [g]\Lambda(z)\right].$$

The associated eigenfunction is the same as that of $\mathcal{T}$. $\Sigma(z, X, D)$ have the following properties.

LEMMA 5.2. *The nullcline of $\Sigma(z, X, D)$ as a function of $z > 0$ and $X > 0$ is given by $\{(z, X(z, D)) \mid z > z_0\}$, where z_0 is a unique zero of $-\frac{G^+G^-}{[g]} + [g]\Lambda(z) = 0$ and*

$$X(z, D) = \left(\frac{Dm^2}{-J'(v^*)}\right)^{1/3}\left[-\frac{G^+G^-}{[g]} + [g]\Lambda(z)\right]^{-1/3} z^{2/3}.$$

Moreover, $X(z, D)$ has the following properties:

$$\lim_{z \to z_0 + 0} X(z, D) = \infty,$$

$$\lim_{z \to \infty}\left[X(z, D) - \left(\frac{Dm^2}{-J'(v^*)}\right)^{1/3}\left(-\frac{G^+G^-}{[g]}\right)^{-1/3} z^{2/3}\right] = 0,$$

$$\frac{dX}{dz} \quad \begin{cases} < 0 & \textit{for} \quad z_0 < z < z_1, \\ = 0 & \textit{for} \quad z = z_1, \\ > 0 & \textit{for} \quad z_1 < z, \end{cases}$$

for some $z_1 = z_1(D)$.

By using Lemma 5.2, we obtain the following corollary.

COROLLARY OF THEOREM 1.5. (i) *For any $D > 0$, there exists $\underline{X} = \underline{X}(D) > 0$ such that the planar solution is stable for $X < \underline{X}$ and $\kappa > 0$.*

(ii) *For any fixed $\kappa > 0$ and $D > 0$, there exists $\overline{X} = \overline{X}(\kappa, D) > 0$ such that the planar solution is unstable for $X > \overline{X}$.*

Note. After finishing our paper, the anonymous referee noted us an interesting preprint, "On the spectra of 3-D lamellar solutions of the diblock copolymer problem," by X. Ren and J. Wei, which now appears in [27]. Their results are consistent with the part of our stability results for the lamellar patterns, although they employed a different Euler–Lagrange equation and methods for stability analysis.

Appendix A. (proof of Proposition 2.2). First we compute $u_\xi^{\pm,2}(0,y)$.

$$
\begin{aligned}
u_\xi^{\pm,2}(0,y) = &- U^{\pm,2}(0,y)\frac{u^*_{\xi\xi}(s_0)}{u^*_\xi(s_0)} \\
&- \frac{1}{u^*_\xi(s_0)}\int_{\pm\infty}^0 \left[p^\pm_{2,1}+p^\pm_{2,2}+p^\pm_{2,3}+p^\pm_{2,4}+p^\pm_{2,5}\right] u^*_\xi(\xi+s_0)d\xi,
\end{aligned} \tag{A.1}
$$

where

$$
\begin{aligned}
p^\pm_{2,1} &= (N-1)H(0,y)u^1_\xi, \\
p^\pm_{2,2} &= \Delta(0)u^0 + (N-1)H_r(0,y)\xi u^0_\xi, \\
p^\pm_{2,3} &= \frac{1}{2}\tilde{f}_{uu}[U^1(0,y)+u^1]^2, \\
p^\pm_{2,4} &= \tilde{f}_u[\xi U^1_r(0,y)+U^2(0,y)], \\
p^\pm_{2,5} &= -[\xi V^1_r(0,y)+V^2(0,y)].
\end{aligned}
$$

In the following, we compute each term of the integral part in (A.1):

$$
\begin{aligned}
&\int_{\pm\infty}^0 p_{2,2}(\xi,y)u^*_\xi(\xi+s_0)d\xi = \Delta(0)s_0\int_{\pm\infty}^{s_0}[u^*_\xi(\xi)]^2d\xi + (N-1)H_r(0,y) \\
&\quad\int_{\pm\infty}^{s_0}(\xi-s_0)[u^*_\xi(\xi)]^2d\xi\int_{\pm\infty}^0 p_{2,3}(\xi,y)u^*_\xi(\xi+s_0)d\xi \\
&\quad= -\frac{1}{2}f^*_u[U^1(0,y)]^2 - \int_{\pm\infty}^0 f_u(u^*(\xi+s_0))[U^1(0,y)+u^1(\xi,y)]u^1_\xi(\xi,y)d\xi \\
&\quad= -\frac{1}{2}f^*_u[U^1(0,y)]^2 + \int_{\pm\infty}^0 [u^1_{\xi\xi}(\xi,y)+(N-1)H(0,y)u^*_\xi(\xi+s_0)]u^1_\xi(\xi,y)d\xi \\
&\quad= \frac{1}{2}U^1(0,y)b^*_1(y) + \frac{1}{2}[u^{1,\pm}_\xi(0,y)]^2 + (N-1)H(0,y)\int_{\pm\infty}^0 u^1_\xi(\xi,y)u^*_\xi(\xi+s_0)d\xi,
\end{aligned}
$$

where $f^*_u = \frac{d}{du}f(h^\pm(v^*))$ and we used the fact that $f^*_uU^1(y,0) - b^*_1(y) = 0$.

$$
\begin{aligned}
\int_{\pm\infty}^0 p_{2,4}(\xi,y)u^*_\xi(\xi+s_0)d\xi &= f(u^*(s_0))U^2(0,y) - U^1_r(0,y)\int_{\pm\infty}^0 f(u^*(\xi+s_0))d\xi \\
&= f(u^*(s_0))U^2(0,y) + U^1_r(0,y)u^*_\xi(s_0) \\
\int_{\pm\infty}^0 p_{2,5}(\xi,y)u^*_\xi(\xi+s_0)d\xi &= -V^1_r(0,y)\int_{\pm\infty}^{s_0}(\xi-s_0)u^*_\xi(\xi)d\xi - b_2(y)[u^*(s_0)-h^\pm(v^*)].
\end{aligned}
$$

Concerning $p_{2,1}$, we have

$$\begin{aligned}
&\int_{\pm\infty}^{0} u_\xi^1(\xi,y)u_\xi^*(\xi+s_0)d\xi = -\frac{U^1(0,y)}{u_\xi^*(s_0)}\int_{\pm\infty}^{0} u_{\xi\xi}^*(\xi+s_0)u_\xi^*(\xi+s_0)d\xi\\
&\quad -\int_{\pm\infty}^{0} u_{\xi\xi}^*(\xi+s_0)u_\xi^*(\xi+s_0)d\xi\int_0^\xi [u_\xi^*(\tau+s_0)]^{-2}\int_{\pm\infty}^{\tau}[***]u_\xi^*(s+s_0)dsd\tau d\xi\\
&\quad -\int_{\pm\infty}^{0}\int_{\pm\infty}^{\xi}[***]u_\xi^*(s+s_0)d\tau d\xi\\
&\qquad = \underline{\frac{1}{2}U^{1,\pm}(0,y)u_\xi^*(s_0)}_A - \frac{1}{2}\int_{\pm\infty}^{0}\int_{\pm\infty}^{\xi}[(N-1)H(0,y)u_\xi^*(\tau+s_0)\\
&\qquad\quad \underline{+f_u(u^*(\tau+s_0))U^1(0,y)}_A - b_1^*(y)]u_\xi^*(\tau+s_0)d\tau d\xi\\
&\qquad = -\frac{1}{2}\int_{\pm\infty}^{0} 1\int_{\pm\infty}^{\xi}[(N-1)H(0,y)u_\xi^*(\tau+s_0)-b_1^*(y)]u_\xi^*(\tau+s_0)d\tau d\xi\\
&\qquad = \frac{1}{2}\int_{\pm\infty}^{s_0}(\xi-s_0)[(N-1)H(0,y)u_\xi^*(\xi)-b_1^*(y)]u_\xi^*(\xi)d\xi.
\end{aligned}$$

The underlined terms cancel pairwise. By using the above expression,

$$\begin{aligned}
&\int_{-\infty}^{0} u_\xi^{-,1}(\xi,y)u_\xi^*(\xi+s_0)d\xi - \int_{\infty}^{0} u_\xi^{+,1}(\xi,y)u_\xi^*(\xi+s_0)d\xi\\
&\qquad = \frac{1}{2}\int_{-\infty}^{\infty}\xi[(N-1)H(0,y)u_\xi^*(\xi)-b_1^*(y)]u_\xi^*(\xi)d\xi.
\end{aligned}$$

Here we used the fact that $b_1^*(y) = -m^2(N-1)H(0,y)/J'(v^*)$.

Combining the above computations, we have

$$\begin{aligned}
&-u_\xi^*(s_0)[u_\xi^{\pm,2}(0,y)+U_r^{\pm,1}(0,y)]\\
&\quad = 2(N-1)H(0,y)\int_{\pm\infty}^{0} u_\xi^{\pm,1}(\xi,y)u_\xi^*(\xi+s_0)d\xi\\
&\qquad + [\Delta(0)s_0-(N-1)H_r(0,y)s_0]\int_{\pm\infty}^{s_0}[u_\xi^*(\xi)]^2d\xi + (N-1)H_r(0,y)\int_{\pm\infty}^{s_0}\xi[u_\xi^*(\xi)]^2d\xi\\
&\qquad + \frac{1}{2}U^{\pm,1}(0,y)b_1^*(y) + \frac{1}{2}[u_\xi^{\pm,1}(0,y)]^2 + s_0V_r^1(0,y)\int_{\pm\infty}^{s_0}u_\xi^*(\xi)d\xi\\
&\qquad - V_r^1(0,y)\int_{\pm\infty}^{s_0}\xi u_\xi^*(\xi)d\xi - b_2(y)\int_{\pm\infty}^{s_0}u_\xi^*(\xi)d\xi,
\end{aligned}$$

$$\begin{aligned}
&u_\xi^*(s_0)[u_\xi^{+,2}(0,y)+U_r^{+,1}(0,y)-u_\xi^{-,2}(0,y)-U_r^{-,1}(0,y)]\\
&= (N-1)\int_{-\infty}^{\infty}\xi[(N-1)H(0,y)u_\xi^*(\xi)-b_1^*(y)]u_\xi^*(\xi)d\xi\\
&+ [\Delta(0)s_0-(N-1)H_r(0,y)s_0]\int_{-\infty}^{\infty}[u_\xi^*(\xi)]^2d\xi + (N-1)H_r(0,y)\int_{-\infty}^{\infty}\xi[u_\xi^*(\xi)]^2d\xi\\
&- \frac{1}{2}b_1^*(y)\left[U^{+,1}(0,y)-U^{-,1}(0,y)\right] + s_0V_r^1(0,y)[h] - V_r^1(0,y)\int_{-\infty}^{\infty}\xi u_\xi^*(\xi)d\xi - b_2(y)[h].
\end{aligned}$$

Substituting the above results into $\frac{\partial}{\partial r}\mathcal{U}^{+,\epsilon}(0,y) - \frac{\partial}{\partial r}\mathcal{U}^{-,\epsilon}(0,y)$, we have (2.9).

Concerning (2.8), we note only the following:

$$\begin{aligned} v_\xi^{\pm,3}(\xi,y) &= -\int_{\pm\infty}^{s_0}[u^*(\tau)-h^\pm(v^*)]d\tau \\ &= -\int_{\pm\infty}^{0}[u^*(\tau)-h^\pm(v^*)]d\tau - \int_0^{s_0} u^*(\tau)d\tau + h^\pm(v^*)s_0, \\ v_\xi^{-,3}(\xi,y) - v_\xi^{+,3}(\xi,y) &= -\int_{-\infty}^{0}[u^*(\tau)-h^-(v^*)]d\tau + \int_{\infty}^{0}[u^*(\tau)-h^+(v^*)]d\tau - [h]s_0. \end{aligned}$$

Appendix B. (proof of Lemma 3.1). We can assume without loss of generality that the $O(1)$-terms W^0, Z^0, w^0 and z^0 are not equivalent to zero at the same time. We note that when $\lambda^\epsilon = \lambda_0 + \epsilon\lambda_1$, the expansions for w and C^1-matching conditions are the same as in subsections 3.1, 3.2, and 3.3. Also, we easily see that $z^0 \equiv 0$ and $z^1 \equiv 0$ (see (3.9) and (3.10)) and the equation for $z^{\pm,2}$ becomes

$$\begin{cases} z_{\xi\xi}^{\pm,2} + \lambda_0 w^{\pm,0} = 0, \\ z^{\pm,2}(0,y) = 0, \quad \lim_{\xi\to\pm\infty} z^{\pm,2}(\xi,y) = 0. \end{cases}$$

If $\lambda^\epsilon = \lambda_0 + \epsilon\lambda_1$, the equations of W^0 and Z^0 become

$$\begin{cases} f_u^0 W^0 - Z^0 = 0, \\ \Delta Z^0 + \lambda_0 W^0 = 0, \end{cases} \qquad \text{in } \Omega_\pm(\Gamma^*),$$

and these equations are rewritten as

$$\Delta Z^0 + \frac{1}{f_u^0}\lambda_0 Z^0 = 0,$$

since $f_u^0 < 0$. On the other hand, we see $Z^0(0,y) = q_0(y) \equiv 0$ from Lemma 3.4. So we conclude (i) $Z^0 \equiv 0$ (hence $W^0 \equiv 0$) and Re $\lambda_0 \geq 0$, or (ii) $Z^0 \neq 0$ and Re $\lambda_0 < 0$. If $Z^0 \equiv 0$, the equation of Z^1 becomes

$$\Delta Z^1 + \frac{1}{f_u^0}\lambda_0 Z^1 = 0.$$

Then the $O(\epsilon)$-term of C^1-matching conditions (3.19) become

$$u_\xi^*(s_0(y))[W_r^{-,0}(0,y) + w_\xi^{-,1}(0,y) - W_r^{+,0}(0,y) - w_\xi^{+,1}(0,y)] = q_1(y)[h] = 0, \tag{B.1}$$

$$\begin{aligned} &Z_r^{-,1}(0,y) + z_\xi^{-,2}(0,y) - Z_r^{+,1}(0,y) - z_\xi^{+,2}(0,y) \\ &\qquad = (\Pi_- + \Pi_+)q_1 - \lambda_0[h]\theta(y) = 0. \end{aligned} \tag{B.2}$$

From (B.1) and (B.2), we have $Z^1(0,y) = q_1(y) \equiv 0$, and (a) $\lambda_0 = 0$ or (b) $\lambda_0 \neq 0$ and $\theta(y) \equiv 0$. In the case (b), we obtain that $w^0 \equiv 0$ since w^0 is given by

$$w^0(\xi,y) = \Theta(y)\frac{u_\xi^*(\xi+s_0)}{u_\xi^*(s_0)} = \theta(y)u_\xi^*(\xi+s_0)$$

(see (3.14)). This contradicts our assumption. Thus we conclude that Re $\lambda_0 < 0$ or $\lambda_0 = 0$.

Appendix C. (proof of Lemma 3.5). $\tilde{\Phi}(\theta, q_2, \lambda_1, 0) = 0$ is equivalent to

$$u_\xi^*(s_0(y))[w_\xi^{-,2}(0,y) - w_\xi^{+,2}(0,y)] = 0.$$

In order to calculate $w_\xi^{\pm,2}(0,y)$, we display the equation and the boundary conditions of $w_\xi^{\pm,2}$ again

$$w_{\xi\xi}^2 + (N-1)H(0,y)w_\xi^1 + [(N-1)H_r(0,y)\xi\partial_\xi + \Delta^\Gamma]w^0$$
$$+\tilde{f}_u^0[w^2 + W^2(0,y)] + \tilde{f}_u^1 w^1 + \tilde{f}_u^2 w^0 - Z^2(0,y) = 0,$$
$$w^{\pm,2}(0,y) = -W^{\pm,2}(0,y), \quad \lim_{\xi\to\pm\infty} w^{\pm,2}(\xi,y) = 0,$$

where

$$\tilde{f}_u^{\pm,2} = \tilde{f}_{uu}[p_{2,1}] + \frac{1}{2}\tilde{f}_{uuu}[p_{2,3}]^2$$
$$p_{2,1} := \xi U_r^1(0,y) + U^2(0,y) + u^2, \quad p_{2,3} := U^1(0,y) + u^1.$$

Using the expression (3.17) for $w^{\pm,2}(\xi,y)$, we have

$$w_\xi^2(0,y) = -\frac{1}{u_\xi^*(s_0)}\int_{\pm\infty}^0 [(N-1)H(0,y)\underbrace{w_\xi^1}_{\text{(i)}} + (N-1)H_r(0,y)\underbrace{\xi\partial_\xi w^0}_{\text{(ii)}}$$
$$+\underbrace{\Delta^{\Gamma^*}w^0}_{\text{(iii)}} + \underbrace{\tilde{f}_u^1 w^1}_{\text{(iv)}} + \underbrace{\tilde{f}_u^2 w^0}_{\text{(v)}} - Z^2(0,y)]u_\xi^*(s+s_0)d\xi. \tag{C.1}$$

In the following, we calculate each term of integral in (C.1):

Computation of (i). By using

$$w^{\pm,1}(\xi,y) = -\theta(y)u_\xi^*(\xi+s_0)\int_0^\xi [u_\xi^*(t+s_0)]^{-2}$$
$$\times\int_{\pm\infty}^t [(N-1)H(0,y)u_{\xi\xi}^*(s+s_0) + \tilde{f}_u^1 u_\xi^*(s+s_0)]u_\xi^*(s+s_0)dsdt,$$

we have

$$\begin{aligned}\int_{\pm\infty}^0 w_\xi^1(\xi,y)u_\xi^*(\xi+s_0)d\xi &= -\int_{\pm\infty}^0 w^1(\xi,y)u_{\xi\xi}^*(\xi+s_0)d\xi \\ &= -\frac{1}{2}\theta(y)\int_{\pm\infty}^0\int_{\pm\infty}^\xi [(N-1)H(0,y)u_{\xi\xi}^*(s+s_0) \\ &\quad +\tilde{f}_u^1 u_\xi^*(s+s_0)]u_\xi^*(s+s_0)dsd\xi \\ &= \frac{1}{2}\theta(y)[u_\xi^{\pm,1}(0,y)u_\xi^*(s_0) - 2I_3^\pm].\end{aligned}$$

Here we used the fact that

$$-\int_{\pm\infty}^0\int_{\pm\infty}^\xi [(N-1)H(0,y)u_{\xi\xi}^*(s+s_0) + \tilde{f}_u^1 u_\xi^*(s+s_0)]u_\xi^*(s+s_0)dsd\xi$$
$$= u_\xi^{\pm,1}(0,y)u_\xi^*(s_0) - 2I_3^\pm, \tag{C.2}$$

where

$$I_3^{\pm} := \int_{\pm\infty}^{0} u_\xi^1(\xi, y) u_{\xi\xi}^*(\xi + s_0) d\xi.$$

Equation (C.2) is proved in Appendix D.

Computation of (ii).

$$\begin{aligned}\int_{\pm\infty}^{0} \xi w_\xi^0(\xi, y) u_\xi^*(\xi + s_0) d\xi &= \theta(y) \int_{\pm\infty}^{0} \xi u_{\xi\xi}^*(\xi + s_0) u_\xi^*(\xi + s_0) d\xi \\ &= -\frac{1}{2}\theta(y) \int_{\pm\infty}^{0} [u_\xi^*(\xi + s_0)]^2 d\xi.\end{aligned}$$

Computation of (iii).

$$\begin{aligned}\Delta^{\Gamma^*} w^0 &= \Delta^{\Gamma^*}(\theta u_\xi^*) \\ &= u_\xi^* \Delta^{\Gamma^*}\theta + 2u_{\xi\xi}^* \nabla^\Gamma \theta \cdot \nabla s_0 + u_{\xi\xi}^* \theta \Delta^{\Gamma^*} s_0 + u_{\xi\xi\xi}^* \theta |\nabla^\Gamma s_0|^2.\end{aligned}$$

Here note that u_ξ^*, $u_{\xi\xi}^*$, etc., are all evaluated at $\xi + s_0$. Then multiplying $\Delta^{\Gamma^*} w^0$ by u_ξ^*, we have

$$\begin{aligned}\int_{\pm\infty}^{0} (\Delta^{\Gamma^*} w^0) u_\xi^* d\xi = \Delta^{\Gamma^*}\theta \int_{\pm\infty}^{0} [u_\xi^*(\xi + s_0)]^2 d\xi + [u_\xi^*(s_0)]^2 \left[\nabla^\Gamma \theta \cdot \nabla s_0 + \frac{1}{2}\theta \Delta^{\Gamma^*} s_0\right] \\ + \left[u_{\xi\xi}^*(s_0) u_\xi^*(s_0) - \int_{\pm\infty}^{0} [u_{\xi\xi}^*(\xi + s_0)]^2 d\xi\right] \theta |\nabla^\Gamma s_0|^2.\end{aligned}$$

Computation of (iv).

$$\begin{aligned}&\int_{\pm\infty}^{0} \tilde{f}_u^1 u_\xi^*(\xi + s_0) w^1(\xi, y) ds d\xi \\ &= -\int_{\pm\infty}^{0} [(N-1)H(0,y) u_{\xi\xi}^*(\xi + s_0) + u_{\xi\xi\xi}^1(\xi, y) + \tilde{f}_u u_\xi^1(\xi, y)] w^1(\xi, y) d\xi \\ &\quad \times (u_{\xi\xi\xi}^1 + \tilde{f}_u u_\xi^1 + (N-1)H(0,y) u_{\xi\xi}^* + \tilde{f}_u^1 u_\xi^* = 0 \ \text{ is used}) \\ &= (N-1)H(0,y) \int_{\pm\infty}^{0} u_\xi^*(\xi + s_0) w_\xi^1(\xi, y) d\xi + u_\xi^{\pm,1}(0,y) w_\xi^{\pm,1}(0,y) \\ &\quad - \int_{\pm\infty}^{0} [w_{\xi\xi}^{\pm,1}(\xi, y) + \tilde{f}_u w^{\pm,1}(\xi, y)] u_\xi^{\pm,1} d\xi \\ &\quad \times (w_{\xi\xi}^1 + \tilde{f}_u w^1 + (N-1)H(0,y) w_\xi^0 + \tilde{f}_u^1 w^0 = 0 \ \text{ and } \ w^0 = \theta u_\xi^* \ \text{ will be used}) \\ &= (N-1)H(0,y) \int_{\pm\infty}^{0} u_\xi^*(\xi + s_0) w_\xi^1(\xi, y) d\xi + u_\xi^{\pm,1}(0,y) w_\xi^{\pm,1}(0,y) \\ &\quad + \theta(y) \int_{\pm\infty}^{0} [(N-1)H(0,y) u_{\xi\xi}^*(\xi + s_0) + \tilde{f}_u^1 u_\xi^*(\xi + s_0)] u_\xi^{\pm,1}(\xi, y) d\xi \\ &= (N-1)H(0,y) \int_{\pm\infty}^{0} u_\xi^*(\xi + s_0) w_\xi^1(\xi, y) d\xi + u_\xi^{\pm,1}(0,y) w_\xi^{\pm,1}(0,y) \\ &\quad + \theta(y)[(N-1)H(0,y) I_3^{\pm} + I_4^{\pm}],\end{aligned}$$

where

$$I_4^{\pm} := \int_{\pm\infty}^{0} \tilde{f}_u^1 u_\xi^*(\xi+s_0) u_\xi^{\pm,1}(\xi,y)d\xi = \int_{\pm\infty}^{0} \tilde{f}_{uu}[U^1(0,y)+u^1]u_\xi^1(\xi,y)u_\xi^*(\xi+s_0)d\xi.$$

Computation of (v).

$$\int_{\pm\infty}^{0} \tilde{f}_u^{\pm,2} w^0 u_\xi^* d\xi = \theta(y)\int_{\pm\infty}^{0} \tilde{f}_u^{\pm,2}[u_\xi^*]^2 d\xi,$$

$$\int_{\pm\infty}^{0} \tilde{f}_u^{\pm,2}[u_\xi^*]^2 d\xi$$

$$= \Big[\tilde{f}_u u_\xi^* p_{2,1}\Big]_{\pm\infty}^{0} - \int_{\pm\infty}^{0} [U_r^1(0,y)+u_\xi^2]\tilde{f}_u u_\xi^* d\xi - \underbrace{\int_{\pm\infty}^{0} \tilde{f}_u p_{2,1} u_{\xi\xi}^* d\xi}_{A}$$

$$+ \left[\frac{1}{2}\tilde{f}_{uu} u_\xi^* [p_{2,3}]^2\right]_{\pm\infty}^{0} \underbrace{-\int_{\pm\infty}^{0} \tilde{f}_{uu}[U^1(0,y)+u^1]u_\xi^1 u_\xi^* d\xi}_{C} \underbrace{-\int_{\pm\infty}^{0} \frac{1}{2}\tilde{f}_{uu}[p_{2,3}]^2 u_{\xi\xi}^* d\xi}_{A}$$

$$= -\int_{\pm\infty}^{0} \left[u_{\xi\xi}^{\pm,2} + \underbrace{\tilde{f}_u p_{2,1} + \frac{1}{2}\tilde{f}_{uu}[p_{2,3}]^2}_{A}\right] u_{\xi\xi}^* d\xi$$

$$+ u_{\xi\xi}^*(s_0)[U_r^{\pm,1}(0,y) + u_\xi^{\pm,2}(0,y)] - \underbrace{\int_{\pm\infty}^{0} \tilde{f}_{uu}[U^1(0,y)+u^1]u_\xi^1 u_\xi^* d\xi}_{C}$$

$$= \int_{\pm\infty}^{0} [(N-1)H(0,y)u_\xi^1 + \Delta(0)u^0 + (N-1)H_r(0,y)\xi u_\xi^0]u_{\xi\xi}^* d\xi + V_r^1(0,y)\int_{\pm\infty}^{0} u_\xi^* d\xi$$

$$+ u_{\xi\xi}^*(s_0)[U_r^{\pm,1}(0,y) + u_\xi^{\pm,2}(0,y)] - I_4^{\pm}.$$

Here we used the equation of $u^{\pm,1}$.

$$\int_{\pm\infty}^{0} [(N-1)H(0,y)u_\xi^1 + \Delta(0)u^0 + (N-1)H_r(0,y)\xi u_\xi^0]u_{\xi\xi}^* d\xi$$

$$= (N-1)H(0,y)I_3^{\pm} + |\nabla^{\Gamma^*} s_0|^2 \int_{\pm\infty}^{0} [u_{\xi\xi}^*(\xi+s_0)]^2 d\xi + \frac{1}{2}[u_\xi^*(s_0)]^2 \Delta^\Gamma s_0$$

$$-\frac{1}{2}(N-1)H_r(0,y)\int_{\pm\infty}^{0} [u_\xi^*(\xi+s_0)]^2 d\xi.$$

Here we used the fact that $\Delta(0)u^0 = |\nabla^{\Gamma^*} s_0|^2 u_{\xi\xi}^* + \Delta^{\Gamma^*} u_\xi^*$.

Combining the above computations, we obtain

$$
\begin{aligned}
-u_\xi^*(s_0)w_\xi^{\pm,2}(0,y) &= \int_\pm^0 P_2(\xi,y)u_\xi^*(\xi+s_0)d\xi \\
&= \frac{1}{2}(N-1)H(0,y)[u_\xi^{\pm,1}(0,y)u_\xi^*(s_0)-2I_3^\pm]\theta \\
&\quad -\frac{1}{2}(N-1)H_r(0,y)[m^\pm]^2\theta \\
&\quad +[m^\pm]^2\Delta^{\Gamma^*}\theta+[u_\xi^*(s_0)]^2\left[\nabla^{\Gamma^*}\theta\cdot\nabla^{\Gamma^*}s_0+\frac{1}{2}\theta\Delta^{\Gamma^*}s_0\right] \\
&\quad +[u_{\xi\xi}^*(s_0)u_\xi^*(s_0)-[n^\pm]^2]|\nabla^{\Gamma^*}s_0|^2\theta \\
&\quad +\frac{1}{2}(N-1)H(0,y)[u_\xi^{\pm,1}(0,y)u_\xi^*(s_0)-2I_3^\pm]\theta+u_\xi^{\pm,1}(0,y)w_\xi^{\pm,1}(0,y) \\
&\quad +[(N-1)H(0,y)I_3^\pm+I_4^\pm]\theta \\
&+\left[(N-1)H(0,y)I_3^\pm+|\nabla^{\Gamma^*}s_0|^2[n^\pm]^2+\frac{1}{2}[u_\xi^*(s_0)]^2\Delta^{\Gamma^*}s_0-\frac{1}{2}(N-1)H_r(0,y)[m^\pm]^2\right. \\
&\quad \left.+u_{\xi\xi}^*(s_0)[U_r^{\pm,1}(0,y)+u_\xi^{\pm,2}(0,y)]-I_4^\pm+V_r^1(0,y)\int_{\pm\infty}^0 u_\xi^*(\xi+s_0)d\xi\right]\theta,
\end{aligned}
$$

$$
\begin{aligned}
&-Z^2(0,y)\int_{\pm\infty}^0 u_\xi^*(\xi+s_0)d\xi \\
&\quad =[m^\pm]^2\Delta^{\Gamma^*}\theta-(N-1)H_r(0,y)[m^\pm]^2\theta+V_r^1(0,y)\theta\int_{\pm\infty}^0 u_\xi^*(\xi+s_0)d\xi \\
&\quad\quad -Z^2(0,y)\int_{\pm\infty}^0 u_\xi^*(\xi+s_0)d\xi+(N-1)H(0,y)u_\xi^{\pm,1}(0,y)u_\xi^*(s_0)\theta \\
&\quad\quad +[u_\xi^*(s_0)]^2[\nabla^{\Gamma^*}\theta\cdot\nabla^{\Gamma^*}s_0+\theta\Delta^{\Gamma^*}s_0]+u_{\xi\xi}^*(s_0)u_\xi^*(s_0)|\nabla^{\Gamma^*}s_0|^2\theta \\
&\quad\quad +u_\xi^{\pm,1}(0,y)w_\xi^{\pm,1}(0,y)+u_{\xi\xi}^*(s_0)[U_r^{\pm,1}(0,y)+u_\xi^{\pm,2}(0,y)],
\end{aligned}
$$

where

$$
m^\pm := \left[\int_{\pm\infty}^0 [u_\xi^*(\xi+s_0)]^2d\xi\right]^{1/2} \quad \text{and} \quad n^\pm := \left[\int_{\pm\infty}^0 [u_{\xi\xi}^*(\xi+s_0)]^2d\xi\right]^{1/2}.
$$

Finally, by using the relations

$$
\begin{aligned}
&u_\xi^{+,1}(0,y)=u_\xi^{-,1}(0,y), \quad w_\xi^{+,1}(0,y)=w_\xi^{-,1}(0,y), \\
&U_r^{+,1}(0,y)+u_\xi^{+,1}(0,y)=U_r^{-,1}(0,y)+u_\xi^{-,1}(0,y),
\end{aligned}
$$

we obtain

$$-u^*_\xi(s_0)[w^{-,2}_\xi(0,y)-w^{+,2}_\xi(0,y)]d = m^2\Delta^{\Gamma^*}\theta + m^2H^*(y)\theta \\ -V^1_r(0,y)J'(v^*)\theta + J'(v^*)Z^2(0,y),$$

where

$$H^*(y) := -(N-1)H_r(0,y) = \sum_{j=1}^{N-1}[\kappa_j]^2,$$

κ_j $(j=1,\dots,N-1)$, are the principal curvatures of Γ^*. Thus we obtain (3.26).

Next we prove (3.27). By using the fact that $W^{\pm,0}(x)\equiv 0\equiv Z^{\pm,0}(x)$ and $W^{\pm,1}(x)\equiv 0\equiv Z^{\pm,1}(x)$, we see that $Z^{\pm,2}$ satisfies the following equation:

$$\begin{cases} \Delta Z^{\pm,2}=0 \quad \text{in } \ \Omega_\pm(\Gamma^*), \\ \\ Z^{\pm,2}=q_2 \quad \text{on } \ \Gamma^*, \ \ \dfrac{\partial Z^{-,2}}{\partial n}=0 \quad \text{on } \ \partial\Omega. \end{cases}$$

Then we have

$$Z^{-,2}_r(0,y)-Z^{+,2}_r(0,y) = \frac{\partial}{\partial\nu}(\mathcal{P}^-q_2)\Big|_{\Gamma^*} + \frac{\partial}{\partial\nu}(\mathcal{P}^+q_2)\Big|_{\Gamma^*} = (\Pi_-+\Pi_+)q_2. \tag{C.3}$$

In view of (3.15) and (3.22), we have

$$z^{-,3}_\xi(0,y)-z^{+,3}_\xi(0,y) = (1+\lambda_1)[h]\theta(y). \tag{C.4}$$

Combining (C.3) and (C.4), we obtain

$$Z^{-,2}_r(0,y)-Z^{+,2}_r(0,y)+z^{-,3}_\xi(0,y)-z^{+,3}_\xi(0,y) = (\Pi_-+\Pi_+)q_2-(1+\lambda_1)[h]\theta(y).$$

Appendix D. (proof of (3.25) and (C.2)). By using

$$u^1_{\xi\xi\xi}+\tilde f_u u^1_\xi + (N-1)H(0,y)u^*_{\xi\xi}+\tilde f^1_u u^*_\xi = 0 \ \text{ and } \ u^*_{\xi\xi\xi}+\tilde f_u u^*_\xi = 0,$$

we have

$$\int_{\pm\infty}^0 \left[(N-1)H(0,y)u^*_{\xi\xi}(\xi+s_0)+\tilde f^1_u u^*_\xi(\xi+s_0)\right]u^*_\xi(\xi+s_0)d\xi \\ = u^{\pm,1}_\xi(0,y)u^*_{\xi\xi}(s_0)-u^*_\xi(s_0)u^{\pm,1}_{\xi\xi}(0,y)$$

and

$$-\int_{\pm\infty}^0\int_{\pm\infty}^\xi [(N-1)H(0,y)u^*_{\xi\xi}(s+s_0)+\tilde f^1_u u^*_\xi(s+s_0)]u^*_\xi(s+s_0)dsd\xi$$

$$= \int_{\pm\infty}^0 [u^1_{\xi\xi}(\xi,y)u^*_\xi(\xi+s_0)-u^1_\xi(\xi,y)u^*_{\xi\xi}(\xi+s_0)]d\xi$$

$$= u^{\pm,1}_\xi(0,y)u^*_\xi(s_0)-2I^\pm_3.$$

Appendix E. (proof of Lemma 4.3). (i) We study the operator $\Pi_- + \Pi_+$ instead of $\mathcal{T}$. The problems (1.11) and (1.10) are rewritten as

$$(\mathrm{E}.1)_+ \qquad \begin{cases} Z^+_{rr} + \dfrac{N-1}{r} Z^+_r + \dfrac{1}{r^2}\Delta^S Z^+ = 0, & r_0 < r < R, \\ Z^+(r_0, y) = q, \quad Z^+_r(R, y) = 0, & y \in S, \end{cases}$$

$$(\mathrm{E}.1)_- \qquad \begin{cases} Z^-_{rr} + \dfrac{N-1}{r} Z^-_r + \dfrac{1}{r^2}\Delta^S Z^- = 0, & 0 < r < r_0, \\ Z^-_r(0, y) = 0, \quad Z^-(r_0, y) = q, & y \in S, \end{cases}$$

where Δ^S is the Laplacian on $S = S^{N-1}$. Note that $\Pi_\pm$ have the same complete system of eigenfunctions as that of Δ^S.

Let $\{\ell_j, \beta^m_j(y)\}_{j=1}^\infty$ be the complete system of an eigenpair for $-\Delta^S$, where $\ell_j = j(j+N-2)$, $j = 1, 2, \ldots$. If we take $q = \beta_j$, then the solutions of $(E.1)_\pm$ separate as $Z^\pm(r, y) = R^{\pm,j}(r)\beta_j(y)$. The equations for $R^{\pm,j}(r)$ are, respectively,

$$\begin{cases} R^{+,j}_{rr} + \dfrac{N-1}{r} R^{+,j}_r - \dfrac{l_j}{r^2} R^{+,j} = 0, & r_0 < r < R, \\ R^{+,j}(r_0) = 1, \quad R^{+,j}_r(R) = 0, & y \in S, \end{cases}$$

$$\begin{cases} R^{-,j}_{rr} + \dfrac{N-1}{r} R^{-,j}_r - \dfrac{l_j}{r^2} R^{-,j} = 0, & 0 < r < r_0, \\ R^{-,j}_r(0) = 0, \quad R^{-,j}(r_0) = 1, & y \in S. \end{cases}$$

In terms of the solutions $R^{\pm,j}$, the operator $\Pi_- + \Pi_+$ acting on β_j are expressed as

$$(\Pi_- + \Pi_+)\beta_j = (R^{-,j}_r(r_0) - R^{+,j}_r(r_0)) \cdot \beta_j.$$

By using the fundamental solutions r^j and $r^{-(j+N-2)}$, we have

$$R^{-,j}(r) = \frac{1}{r_0^j} r^j, \quad R^{+,j}(r) = A^{+,j} r^j + B^{+,j} r^{-(j+N-2)},$$

where

$$A^{+,j} = \frac{(j+N-2)R^{-(j+N-1)}}{\Delta}, \quad B^{+,j} = \frac{jR^{j-1}}{\Delta},$$
$$\Delta = (j+N-2) r_0^j R^{-(j+N-1)} + j r_0^{-(j+N-2)} R^{j-1}.$$

Then, we have

$$R^{-,j}_r(r_0) - R^{+,j}_r(r_0) = \frac{j(2j+N-2)}{\Delta r_0^{j+N-1} R^{-(j-1)}} \tag{E.2}$$

for $j \geq 1$. Therefore, the eigenvalue of $\mathcal{T}$ is given by (4.3) and (4.4) since it is defined by the inverse of the right-hand side of (E.2).

(ii) This can be shown by simple computation so we omit the proof.

Appendix F. (proof of Lemma 4.7). (i) We study the operator $\Pi_- + \Pi_+$ instead of $\mathcal{T}$. The problems (1.11) and (1.10) are recast as

$$(\mathrm{F.1})_+ \qquad \begin{cases} Z^+_{xx} + Z^+_{yy} = 0, & (x,y) \in (x_0, X) \times (0, Y), \\ Z^+(x_0, y) = q, \quad Z^+_r(X, y) = 0, & y \in (0, Y), \end{cases}$$

$$(\mathrm{F.1})_- \qquad \begin{cases} Z^-_{xx} + Z^-_{yy} = 0, & (x,y) \in (0, x_0) \times (0, Y), \\ Z^-_r(0, y) = 0, \quad Z^-(x_0, y) = q, & y \in (0, Y). \end{cases}$$

Note that $\Pi_\pm$ have the same complete system of eigenfunctions as that of $-\frac{d^2}{dy^2}$ under the Neumann boundary condition.

Let $\{\tau_j^2, \beta_j(y)\}_{j=1}^\infty$ be the complete system of an eigenpair for $-\frac{d^2}{dy^2}$, where

$$\beta_j(y) = \cos(\tau_j y), \quad \tau_j := \frac{\pi j}{Y}.$$

If we take $q = \beta_j$, then the solutions of $(F.1)_\pm$ separate as $Z^\pm(x,y) = \zeta^{\pm,j}(x)\beta_j(y)$. The equations for $\zeta^{\pm,j}(x)$ are, respectively,

$$\begin{cases} \zeta^{+,j}_{xx} - \tau_j^2 \zeta^{+,j} = 0, & x_0 < x < X, \\ \zeta^{+,j}(x_0) = 1, & \zeta^{+,j}_x(X) = 0, \end{cases}$$

$$\begin{cases} \zeta^{-,j}_{xx} - \tau_j^2 \zeta^{-,j} = 0, & 0 < x < x_0, \\ \zeta^{-,j}_x(0) = 0, & \zeta^{-,j}(x_0) = 1. \end{cases}$$

In terms of the solutions $\zeta^{\pm,j}$, the operator $\Pi_- + \Pi_+$ acting on β_j are expressed as,

$$(\Pi_- + \Pi_+)\beta_j = (\zeta^{-,j}_x(x_0) - \zeta^{+,j}_x(x_0)) \cdot \beta_j.$$

By using the fundamental solutions $e^{\tau_j x}$ and $e^{-\tau_j x}$, we have

$$\zeta^{\pm,j}(x) = c_1^\pm e^{\tau_j x} + c_2^\pm e^{-\tau_j x},$$

where

$$\begin{bmatrix} c_1^- \\ c_2^- \end{bmatrix} = \frac{1}{\Delta^-} \begin{bmatrix} 1 \\ 1 \end{bmatrix}, \quad \begin{bmatrix} c_1^+ \\ c_2^+ \end{bmatrix} = \frac{1}{\Delta^+} \begin{bmatrix} e^{-\tau_j X} \\ e^{\tau_j X} \end{bmatrix},$$

$$\Delta^- := e^{x_0\tau_j} + e^{-x_0\tau_j}, \quad \Delta^+ := e^{(X-x_0)\tau_j} + e^{-(X-x_0)\tau_j}.$$

Then, we have

$$\zeta^{-,j}_x(x_0) - \zeta^{+,j}_x(x_0) = \frac{2\tau_j \sinh X\tau_j}{\cosh X\tau_j + \cosh \overline{u} X\tau_j} \tag{F.2}$$

for $j \geq 1$. Therefore, the eigenvalue of $\mathcal{T}$ is given by (4.9) and (4.10) since it is defined by the inverse of the right-hand side of (F.2).

(ii) This can be shown by simple computation so we omit the proof.

Appendix G. (proof of Lemma 5.1). Without loss of generality, we can normalize θ_c as $\theta_c = 1$. Multiplying $\overline{z}$ (complex conjugate of z) to the second equation of (5.4) and integrating by parts, we obtain

$$-D\int_\Omega |\nabla z|^2 dx + \int_\Omega g_u w\overline{z} dx + \epsilon\int_\Omega g_v |z|^2 dx = \epsilon^2\lambda_1(\epsilon)\int_\Omega |z|^2 dx, \tag{G.1}$$

where

$$|\nabla z|^2 := \sum_{i=1}^N \frac{\partial z}{\partial x^i}\frac{\partial \overline{z}}{\partial x^i}, \quad |z|^2 := z\overline{z}.$$

Noting that $w^{\pm,i}(\xi, y)$ (i = 0, 1) decays exponentially as $|\xi| \to \infty$, we have

$$\begin{aligned}
\int_\Omega g_u w\overline{z} dx &= \int_{\Omega_+(\Gamma^*)} g_u w^+\overline{z^+} dx + \int_{\Omega_-(\Gamma^*)} g_u w^-\overline{z^-} dx \\
&= g_u^{*,+}\int_{\Omega_+(\Gamma^*)} [\epsilon h_v^+(v^*)q_c + w^0(r,y)\omega(r)]\overline{q_c} dx \\
&\quad + g_u^{*,-}\int_{\Omega_-(\Gamma^*)} [\epsilon h_v^-(v^*)q_c + w^0(r,y)\omega(r)]\overline{q_c} dx + O(\epsilon^2) \\
&= \epsilon[g_u^{*,+}h_v^+(v^*)|\Omega_+(\Gamma^*)| + g_u^{*,-}h_v^-(v^*)|\Omega_-(\Gamma^*)|]|q_c|^2 \\
&\quad + \epsilon[C^+(\epsilon) + C^-(\epsilon)]\overline{q_c} + O(\epsilon^2),
\end{aligned}$$

where $|\Omega_\pm(\Gamma^*)|$ is volume of domain $\Omega_\pm(\Gamma^*)$,

$$C^\pm(\epsilon) := \frac{g_u^{*,\pm}}{\epsilon}\int_{\Omega_\pm(\Gamma^*)} w^0(r/\epsilon, y)\omega(r) dx = \frac{g_u^{*,\pm}}{\epsilon}\int_{\Omega_\pm(\Gamma^*)} u_\xi^*(r/\epsilon)\omega(r) dx > 0$$

for small $\epsilon > 0$ and $g_u^{*,\pm} = g_u(h^\pm(v^*), v^*)$. Using the fact that

$$\sup_{x\in\Omega} |\nabla z| = O(\epsilon) \ \text{ and } \ \int_\Omega |z|^2 dx = O(1) \quad \text{as} \ \ \epsilon \downarrow 0,$$

and dividing (G.1) by ϵ, we have

$$\begin{aligned}
(C^+(\epsilon) + C^-(\epsilon))\overline{q_c} = &-(g_u^{*,+}h_v^+(v^*)|\Omega_+(\Gamma^*)| + g_u^{*,-}h_v^-(v^*)|\Omega_-(\Gamma^*)|)|q_c|^2 \\
&+(g_u^{*,+}|\Omega_+(\Gamma^*)| + g_u^{*,-}|\Omega_-(\Gamma^*)|)|q_c|^2 + O(\epsilon).
\end{aligned}$$

This implies Re $q_c < 0$ since $g_u^{*,\pm} > 0$, $g_v^{*,\pm} = g_v(h^\pm(v^*), v^*) < 0$, and $h_v^\pm(v^*) = 1/f_u(h^\pm(v^*), v^*) < 0$. Then we conclude that

$$\text{Re } \lambda_1^* = \text{Re } \frac{J'(v^*)q_c}{m^2} < 0.$$

ON THE EXISTENCE OF INFINITELY MANY MODES OF A NONLOCAL NONLINEAR SCHRÖDINGER EQUATION RELATED TO DISPERSION-MANAGED SOLITONS*

MICHAEL KURTH†

Abstract. We present a comprehensive study of a nonlinear Schrödinger equation with additional quadratic potential and general, possibly highly nonlocal, cubic nonlinearity. In particular, this equation arises in a variety of applications and is known as the Gross–Pitaevskii equation in the context of Bose–Einstein condensates with parabolic traps or as a model equation describing average pulse propagation in dispersion-managed fibers. Both global and local bifurcation behavior is determined showing the existence of infinitely many symmetric modes of the equation. In particular, our theory provides a strict theoretical proof of the existence of a symmetric bi-soliton which recently was found by numerical simulations.

Key words. nonlinear Schrödinger equation, harmonic potential, dispersion management, global bifurcation theorem

1. Introduction and main results.

In this paper we consider the nonlinear Schrödinger equation (NLS) with additional quadratic potential

$$iu_t + u_{xx} - x^2 u = F(u), \qquad x \in \mathbb{R},\ t \geq 0, \tag{1.1}$$

where $F(u)$ is a cubic, possibly nonlocal, nonlinearity satisfying some assumptions given later in this paper. Nonlocality of the nonlinearity is an important factor in many applications, often approximated by a simpler local nonlinearity. In this paper we will explain that it is possible to determine the full bifurcation behavior without the assumption that F is local.

Equation (1.3) models a variety of phenomena and is known as the Gross–Pitaevskii (GP) equation in context of Bose–Einstein condensates (BEC) with parabolic traps. Assuming a highly anisotropic trap Kivshar, Alexander, and Turitsyn [10] derived the one-dimensional GP-equation (1.1) with $F(u) = \pm|u|^2 u$ as model equation for the macroscopic dynamics of cooled atoms confined in a three-dimensional parabolic potential created by a magnetic trap. Using an approximation technique they explain the existence of infinitely many nonlinear modes of the equation. In the present paper we rigorously prove the existence of such modes identifying them as bifurcating solutions from the eigenvalues of the linear harmonic oscillator. Moreover, the shape of the mode is determined by the corresponding Gauss–Hermite eigenfunctions.

In most applications, including BEC with ultracold atomic gases, the origin of the nonlinearity is nonlocal; cf. [2, 5] and references therein. Usually the nonlocal nonlinearity is assumed to be of Hartree type, i.e.,

$$F(u) = (K * |u|^2)u,$$

where the kernel K is in some L^p-space and $*$ denotes evolution. The standard local GP-equation is an approximation of the nonlocal model in the sense that it arises by approximating the kernel with a δ-function. Thus, the NLS with local nonlinearity can be considered as a simplified model and is of interest to understand the original nonlocal problem, although in most applications it is hard to get a clue on properties of the kernel. It should be mentioned that the analysis given in this paper also includes the Hartree-type nonlinearity; for details we refer to [1].

Our main interest, however, lies in the context of nonlinear fiber optics. Modern optical transmission systems successfully use the so-called dispersion management (DM) technique. The idea of DM is to use a dispersion-compensating fiber to overcome the dispersion of the standard monomode fiber which causes dispersive broadening of a pulse. If the residual dispersion is small the signal should evolve nearly periodical, this situation is called strong DM. Numerical and experimental results show that the corresponding pulse is stable over hundreds of periods; analogous to the traditional NLS, it is called the DM-soliton. Using the so-called lens transformation and an averaging technique developed by Zharnitsky et al. [26] we have shown in [13] that the master equation can be transformed into (1.1) with nonlocal nonlinearity of the following form (after normalization):

$$F(u) := -\int_0^1 S^{-1}(z)\left(\frac{1}{T(z)}|S(z)u|^2 S(z)u\right)dz, \tag{1.2}$$

with $S(z) := U(R^{\mathrm{eff}}(z))$, where $U(z)$ denotes the group generated by the harmonic oscillator, $T(z)$ is a characteristic pulse width, and $R^{\mathrm{eff}}(z)$ is the effective residual dispersion (for details see section 2 below).

Regarding (1.1) we notice that the linear part is nothing other than the harmonic oscillator which has the well-known basis of Gauss–Hermite eigenfunctions. The presence of the quadratic potential helps us to overcome the problems due to the unboundedness of the underlying spatial domain such as the noncompactness or the continuous spectrum of the original problem.

In this paper we are interested in the existence of nonlinear bound states; the corresponding ansatz $u(t,x) = \exp(-\lambda t)v(x)$ results in the nonlinear eigenvalue problem

$$-u_{xx} + x^2 u + F(u) = \lambda u, \tag{1.3}$$

where we have required $F(\exp(i\theta)u) = \exp(i\theta)F(u)$ to derive the equation. The natural space to consider (1.3) is the weighted Hilbert space [9, 12]

$$X := \left\{ u \in H^1(\mathbb{R}) \,\middle|\, \int_{\mathbb{R}} x^2|u|^2 dx < \infty \right\} \tag{1.4}$$

with inner product $\langle u, v\rangle_X := (u_x, v_x) + (xu, xv)$, where $(\cdot,\cdot)$ denotes the standard inner product in $L^2(\mathbb{R})$ and corresponding energy norm

$$\|u\|_X^2 = \int_{\mathbb{R}} |u_x|^2 + x^2|u|^2 dx = \|u_x\|_2^2 + \|xu\|_2^2. \tag{1.5}$$

The main conditions on the nonlinearity are the following.

($\mathcal{F}_1$) $F : X \to L^2(\mathbb{R}) : F(\exp(i\theta)u) = \exp(i\theta)F(u)$ and $u : \mathbb{R} \to \mathbb{R} \Rightarrow F \circ u : \mathbb{R} \to \mathbb{R}$.

($\mathcal{F}_2$) There exist $0 < \alpha < 7/2, \beta \geq 4 - \alpha$ such that

$$\|F(u) - F(v)\|_2^2 \leq C(\|u\|_X^\alpha \|u\|_2^\beta + \|v\|_X^\alpha \|v\|_2^\beta)\|u - v\|_X^{1/2}\|u - v\|_2^{3/2} \ \forall u, v \in X.$$

($\mathcal{F}_3$) F is sufficiently smooth, i.e., $F \in C^1(X, L^2)$.

By virtue of assumption $(\mathcal{F}_1)$ we have

$$\langle F(u), u\rangle \in \mathbb{R}\ \forall u \in X_{\mathcal{C}} = \left\{ u \in H^1(\mathbb{R}, \mathcal{C}) \;\middle|\; \int_{\mathbb{R}} x^2 |u|^2 dx < \infty \right\}$$

and hence we consider throughout the paper only real-valued functions and consequently X instead of $X_{\mathbb{C}}$. Assumption $(\mathcal{F}_2)$ is a general growth condition for a cubic nonlinearity which appears quite natural, resulting in $F(u) = \mathcal{O}(\|u\|_2^3)$ for $u \to 0$. $(\mathcal{F}_3)$ is a minimum smoothness condition which will later be replaced by some stronger condition in order to determine the local bifurcation behavior. Necessary for the validity of the variational approach is the potential property of F, that is, the following assumption:

$(\mathcal{F}_4)$ There exists $G \in \mathcal{C}^1(X, \mathbb{R})$ with $G(0) = 0$ such that
$$G'(u)v = (F(u), v) \quad \forall u, v \in X.$$

Later we will restrict ourselves to the practical relevant case, where ground states exist. In order to determine the direction of bifurcation one has to fix the sign of the nonlinearity, that is to consider only "focusing" nonlinearities with an additional technical assumption, i.e.,

$(\mathcal{F}_5)$ $G(u) < 0\ \forall u \in X \setminus \{0\}$ and $(F(su), u) \geq s^\delta (F(u), u)$ for $0 < s < 1$ and $\delta > 1$.

Moreover, we are interested in the symmetry of the solutions. Thus we consider at some stage only symmetric potentials

$(\mathcal{F}_6)$ $$G(u(x)) = G(u(-x)) \text{ and } G(u(x)) = G(-u(-x)).$$

The above assumptions allow us to determine the direction of bifurcation and orbital stability of the solution. It should be noted that in our applications $G(u)$ is only $(F(u), u)/4$ which is typically of one sign, but much more general nonlinearities can be treated as well.

Note that the nonlinearity $F(u) = \sigma|u|^2 u$ with $\sigma < 0$ satisfies assumptions $(\mathcal{F}_1)$–$(\mathcal{F}_6)$. Equation (1.3) with standard cubic nonlinearity was investigated by several authors in the past: Existence and stability of the solutions of (1.3) was discussed by Fukuizumi [4], Oh [17], and Zhang [28]. Kivshar, Alexander, and Turitsyn [10] observe the existence of infinitely many nonlinear modes of (1.3), but they did not give a theoretical explanation. The NLS with quadratic potential is also discussed in section 9.3 in the book by Cazenave [1]. Both global and local bifurcation results are obtained by Kunze et al. [12]. Moreover, the corresponding solutions decay very fast, i.e., Gaussian-like, and there exists a positive solution [6, 9].

Allowing the nonlinearity to be nonlocal, we will explain in this paper that some results and methods can be adapted, whereas other properties of the solutions are lost, e.g., the Gaussian decay. The main result of this paper can be summarized as follows: In each eigenvalue of the harmonic oscillator bifurcates an unbounded branch of nonlinear bound states in the sense of the global bifurcation theorem of Rabinowitz which give rise to the existence of infinitely many nonlinear modes. Under slightly more restrictive conditions on the nonlinearity, the bifurcating solutions can be characterized as minimizers (resp., saddle points) of the corresponding energy functional. Moreover, there exist infinitely many even (resp., odd solutions). Furthermore, stability and decay properties of the solutions are discussed. These assertions

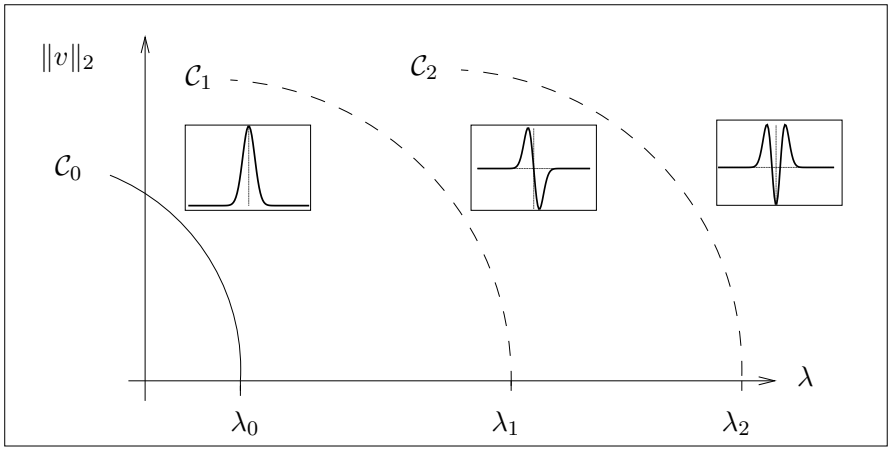

FIG. 1.1. *Bifurcation diagram of* $-v_{xx} + x^2 v + F(v) = \lambda v$.

can be visualized in a bifurcation diagram as shown in Figure 1.1, the direction of bifurcation depends on the sign of the nonlinearity.

In the context of fiber optics the ground state of the corresponding energy functional is close to the true DM-soliton in the sense of the averaging procedure, whereas the other branches correspond to modes of arbitrary order. Our method guarantees the uniqueness (up to a phase factor) of the ground state close to the bifurcation point for fixed energy and shows that it is even. This is a new theoretical result, well supported by numerical simulations. The DM-soliton as a ground state of a macroscopic quantum oscillator as (1.3) has recently been studied by Schäfer et al. [24], but they consider only reduced models and consequently our results are a verification of their approximation method.

Of great practical interest is the theoretical verification that DM-systems support the bi-soliton in addition to the well-known single-soliton. The bi-soliton was recently numerically observed by Maruta et al. [15]; see also the paper of Pare and Belanger [21]. It is a promising candidate for the improvement of today's systems and will help to increase transmission rates by using new encoding schemes.

2. Derivation of the main equation in the case of strong DM. In this section a brief motivation of the nonlinear eigenvalue problem (1.1) with nonlinearity (2.7) for the application of dispersion-managed optical fibers is given. For a more detailed derivation we refer to [13]. From a mathematical point of view the model equation describing pulse propagation in optical fibers with dispersion management is given by the cubic nonlinear Schrödinger equation (DM-NLS) with periodically varying coefficients

$$iA_z(z,t) + D(z)A_{tt}(z,t) + c|A(z,t)|^2 A(z,t) = 0. \tag{2.1}$$

Here, A is the complex envelope of the electric field, t is retarded time, z is propagation distance, D is the dispersion coefficient, and $c > 0$ represents loss and influence of the amplifiers and is assumed to be constant (loss-less model). The dispersion profile D is periodic with normalized period one. In the case of strong dispersion management the residual dispersion $\langle D \rangle$ is small compared to local dispersion, i.e., $\langle D \rangle \ll D$, where $\langle \cdot \rangle$ denotes averaging over one period. Equation (2.1) is mostly

studied for dispersion profiles having the form of a symmetric two-step map:

$$D(z) = D_{\mathrm{loc}} + \langle D\rangle = \begin{cases} d + \langle D\rangle : 0 \le z \le L, 1-L \le z \le 1, \\ -d + \langle D\rangle : L < z < 1-L \end{cases} \tag{2.2}$$

with $\langle D_{\mathrm{loc}}\rangle = 0$. Throughout the paper we restrict ourselves to the case of positive residual dispersion, i.e., we require $\langle D\rangle > 0$. In a series of papers Turitsyn and Gabitov (cf. [25]) suggest applying the following transformation to (2.1), which is known as lens transformation or pseudo-conformal transformation:

$$A(z,t) = N\frac{Q(z, t/T(z))}{\sqrt{T(z)}} \exp\left(it^2 \frac{M(z)}{T(z)}\right). \tag{2.3}$$

Here (T, M) is a periodic solution of the so-called nonlinear TM-equations which arise in the context of lens transformation (see [13, 25] for details):

$$T'(z) = 4D(z)M(z), \qquad T(0) = T_0 > 0, \tag{2.4}$$

$$M'(z) = \frac{D(z)}{T(z)^3} - \frac{N^2}{T(z)^2}, \quad M(0) = 0. \tag{2.5}$$

Thereby, T_0 has to be determined in such a way that for a given N^2 the corresponding solution is periodic or vice versa. T and M have the physical meaning of pulse width and chirp, N^2 is the pulse energy. In [13] it was shown that after applying lens transformation to the (strong) dispersion managed NLS (2.1) with a two-step map as in (2.2) and averaging of the resulting equation one arrives at a Schrödinger-type equation with additional quadratic potential, i.e.,

$$iu_z + au_{xx} - bx^2u + \int_0^1 S^{-1}(z)\left(\frac{N^2}{T(z)}|S(z)u|^2 S(z)u\right) dz = 0, \quad z \ge 0, \quad x \in \mathbb{R}, \tag{2.6}$$

where

$$a = \left\langle \frac{D}{T^2} \right\rangle - N^2 \left\langle \frac{1-\cos(4R^{\mathrm{eff}})}{2T} \right\rangle,$$
$$b = \left\langle \frac{D}{T^2} \right\rangle - N^2 \left\langle \frac{1+\cos(4R^{\mathrm{eff}})}{2T} \right\rangle.$$

In (2.6), $S(z)$ is defined as $S(z) = U(R^{\mathrm{eff}}(z))$, where R^{eff} has the physical meaning of accumulative effective dispersion, i.e., $R^{\mathrm{eff}}(z) = \int_0^z D_{\mathrm{loc}}/T_{\mathrm{lin}}^2$. Furthermore, T_{lin} is the periodic solution of the linear TM-equations

$$T'_{\mathrm{lin}}(z) = 4D_{\mathrm{loc}}(z)M_{\mathrm{lin}}(z), \quad T_{\mathrm{lin}}(0) = T_0 > 0,$$
$$M'_{\mathrm{lin}}(z) = \frac{D_{\mathrm{loc}}(z)}{T_{\mathrm{lin}}(z)^3}, \qquad M_{\mathrm{lin}}(0) = 0,$$

which is explicitly known. $U(z)$ denotes the group generated by the harmonic oscillator, i.e., $U(z) = \exp(iAz)$ with $Au = \triangle u - x^2u$. It is essential for the whole approach that $S(z)$ is 1-periodic since $\langle D_{\mathrm{loc}}/T_{\mathrm{lin}}^2\rangle = 0$. Equation (2.6) describes averaged pulse propagation in a strong dispersion-managed system after lens transformation. In the

region of moderate energy values $N^2 < \overline{N^2}(\langle D \rangle)$ we have shown by numerical simulations in [13] that

$$a, b > 0$$

in contrast to former discussions of the problem (see [25] for details), and hence the potential is attracting. In order to transform (2.6) to the standard bifurcation problem (1.3) we consider steady-state solutions of the following form:

$$u(x,z) = \phi(\gamma x)\exp(-i\sqrt{ab}\lambda z), \quad \text{with } \gamma = \left(\frac{b}{a}\right)^{1/4}.$$

In the new variable $\xi = \gamma x$ we have $-\phi_{\xi\xi} + \xi^2\phi + F(\phi) = \lambda\phi$ with

$$F(\phi) := -\frac{N^2}{\sqrt{ab}} \int_0^1 S^{-1}(z) \left(\frac{1}{T(z)} |S(z)\phi|^2 S(z)\phi \right) dz. \tag{2.7}$$

Writing again u instead of ϕ and x instead of ξ we end up at (1.3) with a highly nonlocal nonlinearity which can be expressed in terms of Mehler's kernel and satisfies all the assumptions $(\mathcal{F}_1)$ throughout $(\mathcal{F}_6)$; see the appendix.

3. Analysis of the nonlinear eigenvalue problem. In this section we present the analysis of the nonlinear eigenvalue problem (1.3) and state our main results. Thereby the developed theory is sufficiently general to cover both applications, BEC and dispersion-managed optical fibers. However, our main goals are to generalize the bifurcation result of Kunze et al. [12] to nonlocal nonlinearities and to characterize the bifurcating solutions more precisely by variational arguments.

3.1. Bifurcation analysis. In this subsection we investigate the bifurcation behavior of (1.3). We strongly rely on the paper by Kunze et al. [12].

3.1.1. Preliminaries. The key property of the space X is the following [28].

LEMMA 3.1. *The embedding $X \hookrightarrow L^q(\mathbb{R})$ is compact for $2 \le q < \infty$.*

Next we consider the linear problem corresponding to (1.3), i.e.,

$$-u_{xx} + x^2 u - \lambda u = 0. \tag{3.1}$$

The following properties of the linear harmonic oscillator are well known [12].

LEMMA 3.2. *Let $\lambda_n = 2n+1, n \in \mathbb{N}_0$, and*

$$u_n(x) := \frac{1}{\sqrt{2^n n! \sqrt{\pi}}} \exp(-x^2/2) H_n(x),$$

where H_n is the nth Hermite polynomial

$$H_n(x) := (-1)^n \exp(x^2) \frac{d^n}{dx^n} \exp(-x^2).$$

(i) *λ_n are exactly the eigenvalues of (3.1). They are simple and the corresponding eigenfunctions are given by $u_n \in X$.*
(ii) *The eigenfunctions u_n of (3.1) form a complete orthonormal system of $L^2(\mathbb{R})$.*

3.1.2. Global bifurcation behavior. In this section we apply the global bifurcation theorem of Rabinowitz [22] to (1.3). The proof is similar to the one by Kunze et al. [12]. Due to the potential property of F we can define a weak solution. Let

$$S_0 := \{(\lambda, u) \in \mathbb{R} \times X : u \neq 0 \text{ is a weak solution of } -u_{xx} + x^2 u + F(u) = \lambda u\}$$

denote the set of all nontrivial solutions of (1.3) and $S = \overline{S_0}^{\mathbb{R}\times X}$ denote its closure. It is clear that $u \in X \subset H^1(\mathbb{R})$ implies $u \in C_0^0(\mathbb{R})$, the set of continuous functions on $\mathbb{R}$ vanishing for $x \pm \infty$. Using a bootstrapping argument it follows then that $u \in C^\infty(\mathbb{R})$, cf. [26], and consequently a weak solution is a classical solution. Our global bifurcation result then reads as follows

THEOREM 3.3. *Let F satisfy assumptions $(\mathcal{F}_1)$–$(\mathcal{F}_3)$. Then for all $n \in \mathbb{N}_0$, $(\lambda_n, 0)$ is a bifurcation point. Let $\mathcal{C}_n$ denote the component of $\mathcal{S}$ with $(\lambda_n, 0) \in \mathcal{C}_n$. Then the following alternative holds: Either*

(i) *$\mathcal{C}_n$ is unbounded in $\mathbb{R} \times X$ or*

(ii) *$\mathcal{C}_n$ is compact and there exists $m \neq n$ such that $(\lambda_m, 0) \in \mathcal{C}_n$.*

Proof. Using the Green's function $g(x, \xi)$ the problem is transformed to an integral problem; see [12] for details. To apply the global bifurcation theorem of Rabinowitz the resulting nonlinearity should be compact and of higher order. Roughly speaking, this is guaranteed by the growth condition together with the compact embedding. In particular, assumptions $(\mathcal{F}_2)$, $(\mathcal{F}_3)$ yield the assertions of Lemma 5 in [12]; the proof then is along the lines of [12]. ∎

Usually the second alternative is ruled out by nodal arguments; see [12] for details. These arguments are no longer valid for nonlocal nonlinearities. However, in section 3.2 we will show by variational arguments that the bifurcating branches are unbounded.

3.1.3. Local bifurcation behavior and orbital stability. In order to determine the local behavior in the vicinity of $(\lambda_n, 0)$ we introduce a nondegeneracy condition on the nonlinearity

$$(\mathcal{F}_3^n) \qquad F \in C^3(X, L^2) \text{ with } \langle \delta^3 F(0)[u_n]^3, u_n\rangle \neq 0.$$

Note that by virtue of $(\mathcal{F}_2)$, $(\mathcal{F}_3)$ the first derivatives of F vanish, i.e., $\delta F(0)[u_n] = 0$ and $\delta^2 F(0)[u_n]^2 = 0$. The local bifurcation behavior then can be determined as follows.

LEMMA 3.4. *Let F satisfy $(\mathcal{F}_1)$, $(\mathcal{F}_2)$, $(\mathcal{F}_3^n)$. Then there exists $\epsilon > 0$ such that $(\lambda, u) \in \mathcal{C}_n \cap U_\epsilon(\lambda_n, 0)$ implies*

$$\lambda = \lambda_n + \lambda(s), \quad u = s u_n + s v_n(s),$$

where $0 < |s| < \epsilon$ and $\lambda(0) = 0$, $\lambda'(0) = 0$, and

$$\operatorname{sgn}(\lambda''(0)) = \operatorname{sgn}\big(\langle \delta^3 F(0)[u_n]^3, u_n\rangle\big). \tag{3.2}$$

Moreover, $v_n(0) = 0$ with $(v_n(s), u_n)_X = 0$.

Proof. The assertions follow by standard Lyapunov–Schmidt theory since the eigenvalues are simple. ∎

Thus, the direction of bifurcation is determined by the sign of $\lambda''(0)$. In the case of negative sign the bifurcating solutions from the smallest eigenvalue λ_0 are orbitally stable by the method of Rose and Weinstein [23]; otherwise they are unstable. Instead of discussing this in detail we refer to the next section where the solutions are characterized as ground states of the energy functional in the situation where the nonlinearity is focusing.

3.2. Variational calculus. In this section we characterize the bifurcating solutions by variational arguments and identify them as minimizers or saddle points of the corresponding energy functional. Throughout the section we assume that F has the potential property.

Considering the energy functional corresponding to (1.3)

$$J(u) = \frac{1}{2}\|u\|_X^2 + G(u), \tag{3.3}$$

it is easy to observe that critical points of J correspond to nonlinear bound states of (1.3). Now we are in a position to state our main theorem, which characterizes the bifurcating solutions. In particular, it shows the existence of infinitely many nonlinear modes of arbitrary energy.

THEOREM 3.5. *Suppose $(\mathcal{F}_1)$–$(\mathcal{F}_6)$ are satisfied and $\omega > 0$ is given. Then there exists an unbounded sequence $\{u_n^\omega\}_{n\in\mathbb{N}_0} \subset X$ of critical points of J with $\|u\|_2^2 = \omega$ and corresponding Lagrange multipliers $\lambda_n^\omega \leq \lambda_n$ with the following properties:*

(i) *u_0^ω is the ground state of the energy functional, and it is even and orbitally stable. Moreover, $(\lambda_0^\omega, u_0^\omega) \in \mathcal{C}_0$.*

(ii) *u_1^ω is odd and minimizes J among all odd functions. Furthermore, we have $(\lambda_1^\omega, u_1^\omega) \in \mathcal{C}_1$.*

(iii) *The u_n^ω with $n > 1$ are saddle points with $(\lambda_n^\omega, u_n^\omega) \in \mathcal{C}_n$. Moreover, u_{2k}^ω is even and u_{2k+1}^ω is odd.*

In the case of a simple nonlinearity $F(u) = -|u|^2u$, it is shown that the ground states are positive [6], using Kato's inequality and maximum principle. Moreover, the solutions of the simpler equation decay like a Gaussian and are unique. However, all these arguments need information about nodal properties of the solutions, which are not at hand for the nonlocal nonlinearity we have in mind.

In particular the second alternative of the global bifurcation theorem can be ruled out by Theorem 3.5.

COROLLARY 3.6.

1. *$\mathcal{C}_n$ is unbounded in both u and λ.*
2. *$\mathcal{C}_n \cap \mathcal{C}_m = \emptyset$ for $n \neq m$.*

Proof of Theorem 3.5. In order to increase the clarity and due to the practical importance of the first two modes, the proof is divided into three parts.

Since the ground states of the equation are of fundamental importance, we discuss them first. Define Γu as $\Gamma u(x) = u(-x)$. Due to assumption $(\mathcal{F}_6)$ the functional J is invariant under Γ. With $X_\Gamma := \{u \in X | \Gamma u = u\}$ the following lemma holds.

LEMMA 3.7 (characterization of the ground state). *For all $\omega > 0$ the minimization problem*

$$J_\Gamma^\omega = \min\{J(u) | u \in X_\Gamma, \|u\|_2^2 = \omega\} \tag{3.4}$$

has a nontrivial solution $u^\omega \in X_\Gamma$ which corresponds to a weak solution of (1.3). *Moreover, u^ω is orbitally stable as the ground state of the equation, that is,*

$$J(u^\omega) = \min\{J(u) | u \in X, \|u\|_2^2 = \omega\}. \tag{3.5}$$

Furthermore, $\{(\lambda^\omega, u^\omega) | \omega \in (0, \infty)\} \subset \mathcal{C}_0$.

Proof. The proof relies on the principle of symmetric criticality [18], which allows us to reduce the problem to even functions, i.e., a minimizer of problem (3.4) is a critical point for the whole problem; see [11] for a similar result. The following lemma is essential to show that J is bounded from below.

LEMMA 3.8. *For $u, v \in X$ the following estimate holds with $\alpha' := \alpha/2 + 1/4 < 2$ and $\beta' = \beta/2 + 3/4$:*

$$|G(u) - G(v)| \le C(\|u\|_X^{\alpha'} + \|v\|_X^{\alpha'})(\|u\|_2^{\beta'} + \|v\|_2^{\beta'})\|u - v\|_2. \tag{3.6}$$

Proof. We calculate as follows:

$$\begin{aligned}
|G(u) - G(v)| &= \left| \int_0^1 \frac{d}{ds} G(su + (1-s)v) ds \right| = \left| \int_0^1 G'(su + (1-s)v)(u - v) ds \right| \\
&= \int_0^1 |(F(su + (1-s)v), u)| ds \le C \int_0^1 \|F(su + (1-s)v)\|_2 \|u - v\|_2 ds \\
&\le C \int_0^1 \|su + (1-s)v\|_X^{\alpha/2+1/4} \|su + (1-s)v\|_2^{\beta/2+3/4} \|u - v\|_2 ds \\
&\le C(\|u\|_X^{\alpha'} + \|v\|_X^{\alpha'})(\|u\|_2^{\beta'} + \|v\|_2^{\beta'})\|u - v\|_2
\end{aligned}$$

which is the assertion of the lemma. ∎

The above lemma together with assumption $(\mathcal{F}_2)$ shows

$$J(u) = \frac{1}{2}\|u\|_X^2 + G(u) \ge \frac{1}{2}\|u\|_X^2 - C\|u\|_X^{\alpha'} \omega^{(\beta'+1)/2} \tag{3.7}$$

which is bounded from below since $\alpha' < 2$. Making use of the fact that the embedding $X_\Gamma \subset\subset L^p(\mathbb{R})$ is compact for $p \ge 2$ we are able to show that a minimizer on X_Γ exists. Let $\{u_n\}$ be a minimizing sequence; that is, $\|u_n\|_2^2 = \omega$ and $J(u_n) \to J_\Gamma^\omega$, which implies that $J(u_n)$ is bounded, say $J(u_n) \le M$, and using (3.7) we conclude that u_n is bounded in X. Passing to a subsequence we may assume that $u_n \rightharpoonup u$ weakly in X and $u_n \to u$ strongly in $L^2(\mathbb{R})$, which yields $\|u\|_2^2 = \omega$. From (3.6) we obtain

$$|G(u_n) - G(u)| \le C\|u - v\|_2 \tag{3.8}$$

since u_n, u are bounded in X. Finally, it follows that $J(u) \le \lim_{n\to\infty} J(u_n) = J_\Gamma^\omega$, and accordingly $u \in X_\Gamma$ is the desired minimizer. The principle of symmetric criticality then reveals that u is a critical point of J and, consequently, a weak solution of (1.3) with Lagrange-multiplier λ^ω.

$$-u_{xx}^\omega + x^2 u^\omega + F(u^\omega) = \lambda^\omega u. \tag{3.9}$$

Next we show $\lim_{\omega\to 0} \lambda^\omega = \lambda_0$, where λ_0 is the eigenvalue of the harmonic oscillator corresponding to u_0.

Therefore, we take the inner product of the Euler–Lagrange equation (3.9) with u^ω to obtain

$$\|u^\omega\|_X^2 + (F(u^\omega), \omega) = \lambda^\omega \omega; \quad \text{hence } \lambda^\omega = \frac{\|u^\omega\|_X^2}{\omega} + \frac{(F(u^\omega), u^\omega)}{\omega}. \tag{3.10}$$

Note that λ_0 can be characterized by the Rayleigh quotient as follows [3]:

$$\lambda_0 = \|u_0\|_X^2 = \inf\left\{ \frac{\|u\|_X^2}{\|u\|_2^2} \middle| u \in X, u \ne 0 \right\} = \inf\left\{ \frac{\|u\|_X^2}{\|u\|_2^2} \middle| u \in X_\Gamma, u \ne 0 \right\},$$

where the last equality holds since u_0 is even. Accordingly, since $\beta' > 3/4$

$$\begin{aligned}\lambda^\omega &\geq \lambda_0 + \frac{(F(u^\omega), u^\omega)}{\omega} \geq \lambda_0 - \frac{\|F(u^\omega)\|_2}{\sqrt{\omega}} \\ &\geq \lambda_0 - \|u^\omega\|_X^{\alpha'} \|u^\omega\|_2^{\beta'-1/2} \geq \lambda_0 - \omega^{\beta'/2-1/4} \to \lambda_0 \quad \text{for } \omega \to 0.\end{aligned}$$

On the other hand G can be written as

$$0 > G(u) = \int_0^1 (F(su), u) ds \geq \int_0^1 s^\delta ds (F(u), u) = \frac{1}{\delta+1}(F(u), u)$$

which shows, in particular, $(F(u), u) < 0$. By definition of J^ω we can write

$$\begin{aligned}\lambda^\omega &= 2\frac{J(u^\omega) - G(u^\omega)}{\omega} + \frac{(F(u^\omega), \omega)}{\omega} \leq 2\frac{J(\sqrt{\omega}u_0)}{\omega} + \frac{(F(u^\omega), \omega) - 2G(u^\omega)}{\omega} \\ &= \lambda_0 + \frac{2G(\sqrt{\omega}u_0) - 2G(u^\omega) + (F(u^\omega), u^\omega)}{\omega} \qquad (3.11) \\ &\leq \lambda_0 + \frac{2G(\sqrt{\omega}u_0)}{\omega} + \left(1 - \frac{2}{\delta+1}\right)(F(u^\omega), u^\omega) \leq \lambda_0.\end{aligned}$$

Thus we have shown $\lambda^\omega \to \lambda_0$ for $\omega \to 0$ which implies that the u^ω are bifurcating from the first eigenvalue. Moreover, due to $\lambda^\omega \leq \lambda_0$ the direction of bifurcation is determined. In a similar way to the argument of Zhang [28] it follows that the bifurcating solutions are orbitally stable.

The uniqueness of the bifurcating solutions from the global bifurcation theorem (up to phase translation) and the fact that the same arguments apply for the (possibly nonsymmetric) ground state $\tilde{u}^\omega$ lead to $u^\omega = \tilde{u}^\omega$ at least for small ω and hence the ground states are even. In addition the solutions u^ω exist for arbitrary $\omega > 0$, and consequently the branch is unbounded in $L^2(\mathbb{R})$ and hence also in X which rules out the second alternative of the global bifurcation theorem.

Next we will show that the solutions bifurcating in the second eigenvalue λ_1 are odd. It should be noted that these modes are somewhat orbitally stable among all odd functions which yields their practical relevance. In order to find odd solutions we introduce the action $\Gamma_2 u(x) = -u(-x)$ and the corresponding space X_{Γ_2} of fixed points of Γ_2 and apply the principle of symmetric criticality again to obtain the following lemma.

LEMMA 3.9. *For all $\omega > 0$ the minimization problem*

$$J^\omega_{\Gamma_2} = \min\{J(u) | u \in X_{\Gamma_2}, \|u\|_2^2 = \omega\} \qquad (3.12)$$

has a nontrivial solution $u^\omega \in X_{\Gamma_2}$, which corresponds to a weak solution of (1.3). *Furthermore, $\{(\lambda^\omega, u^\omega,) | \omega \in (0, \infty)\} \subset \mathcal{C}_1$.*

Proof. The proof of the existence of a minimizer can be adapted by replacing X_Γ with X_{Γ_2} from Lemma 3.7. It remains to verify the behavior for $\omega \to 0$. Note that λ_1 can be characterized as

$$\lambda_1 = \|u_1\|_X^2 = \inf\left\{ \frac{\|u\|_X^2}{\|u\|_2^2} \middle| u \in X_{\Gamma_2}, u \neq 0 \right\}.$$

and using (3.10) it follows that

$$\lambda^\omega \geq \lambda_1 - \|u^\omega\|_X^{\alpha'} \|u^\omega\|_2^{\beta'-1/2} \geq \lambda_1 - \omega^{\beta'/2-1/4} \to \lambda_1 \quad \text{for } \omega \to 0.$$

In the same way as in (3.11) we then can verify the direction of bifurcation, i.e., $\lambda^\omega \leq \lambda_1$. Hence $\lambda^\omega \to \lambda_1$. ∎

Next we show the existence of infinitely many modes of the equation which correspond to saddle points of the energy functional J. Obviously this includes the previously discussed situations, but the proof is more technical and we have therefore discussed the previous cases separately.

LEMMA 3.10. *For arbitrary $\omega > 0$ there exists an unbounded sequence of even (odd) solutions $u_n \in X$ of (1.3) with $\|u\|_2^2 = \omega$.*

The proof relies on the following result [8] which is a generalization of the theorem of Ljusternik–Schnirelmann for infinite-dimensional Hilbert spaces.

THEOREM 3.11. *Let X be an infinite-dimensional Hilbert space, $J, K \in C^1(X, \mathbb{R})$ with $K'(v) \neq 0$ for all $v \in X - \{0\}$ and $S := \{v \in X : K(v) = 0\}$. If $J|_S$ is even and bounded from below and satisfies the Palais–Smale condition on S, then there exist infinitely many critical values, that is, $c_k \in \mathbb{R}$ with $\lim_{k\to\infty} c_k = \infty$ and for all $k \in \mathbb{N}$ there exists a pair $(\lambda_k, v_k) \in \mathbb{R} \times S$ with $J(v_k) = c_k$ and $J'(v_k) - \lambda_k K'(u_k) = 0$. Moreover, $c_k \to \infty$.*

Proof of Lemma 3.10. We apply the theorem with $K(u) = \|u\|_2^2 - \omega$ and $J(u)$ defined as in (3.3) for $X = X_\Gamma$ (resp., $X = X_{\Gamma_2}$) separately. It suffices to show that J satisfies the Palais–Smale condition on S. Let (u_n, λ_n) be a Palais–Smale sequence, that is,

$$J(u_n) \to c \in \mathbb{R}, \qquad J'(u_n) - \lambda_n K'(u_n) \to 0 \quad \text{in } X',$$

where X' denotes the dual space of X. We have to show the existence of a strongly convergent subsequence. As in the proof of Lemma 3.7 we can extract a subsequence still denoted as (u_n, λ_n) with $u_n \rightharpoonup u$ weakly in X and $u_n \to u$ strongly in X. It remains to show $u_n \to u$ strongly in X. Therefore we calculate

$$\begin{aligned}\|u_n - u\|_X^2 &= (J'(u_n) - J'(u))(u_n - u) - (F(u_n) - F(u), u_n - u)\\ &\le C\|J'(u_n)\|_{X'} + |J'(u)(u_n - u)| + \|F(u_n) - F(u)\|_2 \|u_n - u\|_2\\ &\le C\|J'(u_n)\|_{X'} + |J'(u)(u_n - u)| + C\|u_n - u\|_X^{1/4} \|u_n - u\|_2^{7/4}.\end{aligned}$$

Thus, it follows that $u_n \to u$ in X, and from (3.10) it follows that

$$\begin{aligned}|\lambda_n - \lambda| &\le \big|\|u_n\|_X^2 - \|u\|_X^2\big| + \|(F(u_n), u_n) - (F(u), u)\|\\ &\le \big|\|u_n\|_X^2 - \|u\|_X^2\big| + |(F(u_n) - F(u), u_n)| + |(F(u), u_n - u)|\end{aligned}$$

which together with $(\mathcal{F}_2)$ and $u_n \to u \in X$ yields the desired convergence. ∎

We still have to show $(\lambda_n^\omega, u_n^\omega) \in \mathcal{C}_n$. Instead of discussing this in detail we refer to the characterization of the critical values in [8],

$$c_n^\omega = \inf_{A \in \mathcal{B}_n} \max_{u \in A} \frac{J(u)}{\omega}, \quad \text{where } \mathcal{B}_n := \{A \in s(X) : A \subset S, \text{compact with } \gamma(A) \ge k\},$$

and $s(X)$ denotes the set of all nonempty, closed subsets S of X which are symmetric to the origin and satisfy $0 \notin S$. Moreover, $\gamma(A)$ denotes the genus of A, i.e.,

$$\gamma(A) := \inf\{n \ge 1 : \exists \phi : A \to \mathbb{R}^n - \{0\} \text{ continuous and odd}\}.$$

Using (3.10) and calculating as in (3.11) give $\lambda_n^\omega \le 2c_n^\omega$. The assertion then again follows from $G(u) < 0$ combined with the min-max characterization of the eigenvalues, i.e.,

$$\inf_{A \in \mathcal{B}_n} \max_{v \in A} \frac{\|u\|_X^2}{\|u\|_2^2} = \min_{X_n \subset X} \max_{u \in X_n} \frac{\|u\|_X^2}{\|u\|_2^2} = \max_{X_{n-1} \subset X} \min_{u \in X_{n-1}^\perp} \frac{\|u\|_X^2}{\|u\|_2^2} = \lambda_n, \tag{3.13}$$

where X_n denotes a subspace of X of dimension n. Thereby, the first equation can be found in [9], while the second holds due to the equivalence of the principle of Courant–Fischer and the characterization of the nth eigenvalue by Poincare; cf. [3]. Again, (3.13) implies $\lambda_0 \leq \lim_{\omega\to 0} \lambda_n^\omega \leq \lambda_n$. Hence λ_n^ω must converge to an eigenvalue which must be λ_n by induction. ∎

Thus, all statements of the theorem are proven. ∎

For some applications it may be of interest to fix the wave-number. Due to the direction of bifurcation we have the following corollary.

COROLLARY 3.12. *For all* $\lambda \in \mathbb{R}$ (1.3) *has infinitely many solutions* $\{u_n^\lambda\}_{n\in\mathbb{N}_0}$.

Proof. Since all the branches are unbounded in both u and λ, the existence of infinitely many solutions u_n with fixed wave-number λ is obvious. Note that due to $\lambda_n^\omega \leq \lambda_n$ we have $\lambda_n^\omega \to -\infty$ for $\omega \to \infty$. ∎

Remark 3.13. Requiring $\|u\|_p \leq |G(u)|$ for some $p \geq 2$ one can verify that the sequence $\{u_n^\lambda\}$ is unbounded in X [14].

4. Exponential decay of the bound states. In this section it is shown that in case of the nonlinearity (2.7) arising from the context of fiber optics all solutions decay exponentially fast as $x \to \infty$.

THEOREM 4.1. *Let* (λ, u) *be a solution of the nonlinear eigenvalue problem* (1.3) *with nonlinearity* (2.7). *Then there exists* $C > 0$ *such that*

$$|u(x)| + |u_x(x)| \leq C \exp(-|x|/2).$$

Remark 4.2. It is not clear to us whether the decay rate is sharp or not in a rigorous mathematical way. But regarding numerical results or reduced models it turns out that the solution indeed decays only exponentially fast. In fact it is well known that the DM-soliton has a Gaussian kernel and the envelope of its oscillating tails decays exponentially; cf. ([24, 25]). Thus, the above decay rate is the best that one can expect. In conclusion, the Gaussian decay which occurs for simpler nonlinearities is lost due to the nonlocal properties of F.

Proof. The proof is similar to Theorem 8.1.1 in [1], where exponential decay is verified without potential. For $\epsilon > 0$ define the function

$$f^\epsilon(x) := \exp\left(\frac{x}{1+\epsilon x}\right)$$

which has the following properties [1]:

- f^ϵ is bounded for all $\epsilon > 0$,
- $f_x^\epsilon(x) \leq f^\epsilon(x)$,
- $\lim_{\epsilon\to 0} f^\epsilon(x) = \exp(x)$.

Multiplication of (1.3) with $f^\epsilon \overline{u}$ and integration give in the real part

$$\int_{\mathbb{R}} (x^2 - \lambda) f^\epsilon |u|^2 dx = I - \Re\left(\int_{\mathbb{R}} u_x (f^\epsilon \overline{u})_x dx\right), \tag{4.1}$$

$$I := \Re\left(\int_0^1 \int_{\mathbb{R}} S^{-1}(z)\left(\frac{1}{T(z)}|S(z)u|^2 S(z)u\right) f^\epsilon \overline{u} dz dx\right). \tag{4.2}$$

At first we bound the left-hand side from below. Defining $R_1 := \sqrt{|\lambda|+1}$ we find

$$\int_{\mathbb{R}} (x^2-\lambda) f^\epsilon |u|^2 dx \geq \int_{|x|\leq R_1} (x^2-\lambda) f^\epsilon |u|^2 dx + (R_1^2 - \lambda) \int_{|x|>R_1} f^\epsilon |u|^2 dx \tag{4.3}$$

which due to $R_1^2 - \lambda \geq 1$ implies the inequality

$$\int_{|x|>R_1} f^\epsilon |u|^2 dx \leq \int_{\mathbb{R}} (x^2 - \lambda) f^\epsilon |u|^2 dx - \int_{|x|\leq R_1} f^\epsilon |u|^2 dx. \tag{4.4}$$

Next we estimate the right-hand side: The second term is bounded in ϵ, whereas for the first term, regarding (4.1) and using $f_x^\epsilon \leq f^\epsilon$,

$$\begin{aligned}
\Re\left(\int_{\mathbb{R}} u_x (f^\epsilon u)_x dx\right) &= \Re\left(\int_{\mathbb{R}} f^\epsilon |u_x|^2 + f_x^\epsilon u_x \overline{u} dx\right) \geq \int_{\mathbb{R}} f^\epsilon |u_x|^2 - f^\epsilon |u||u_x| dx \\
&\geq \int_{\mathbb{R}} f^\epsilon |u_x|^2 dx - \left(\int_{\mathbb{R}} f^\epsilon |u_x|^2 dx\right)^{1/2} \left(\int_{\mathbb{R}} f^\epsilon |u|^2 dx\right)^{1/2} \\
&\geq \int_{\mathbb{R}} f^\epsilon |u_x|^2 dx - \frac{1}{2}\left(\int_{\mathbb{R}} f^\epsilon |u|^2 dx + \int_{\mathbb{R}} f^\epsilon |u_x|^2 dx\right).
\end{aligned}$$

Hence, by collecting all the terms and splitting the last integral we can conclude that

$$\frac{1}{2}\left(\int_{\mathbb{R}} f^\epsilon |u_x|^2 dx + \int_{|x|>R_1} f^\epsilon |u|^2 dx\right) \leq I - \int_{|x|\leq R_1} (x^2 - \lambda) f^\epsilon |u|^2 dx + \frac{1}{2}\int_{|x|\leq R_1} f^\epsilon |u|^2 dx$$

and it remains to estimate I. Splitting the integral into $|x| \leq R$ and $|x| > R$ with $R > R_1$ to be determined later, the following is true due to $f^\epsilon u \in X$ for all $\epsilon > 0$:

$$\begin{aligned}
&\left|\int_0^1 \int_{|x|>R} S^{-1}(z)\left(\frac{1}{T(z)}|S(z)u|^2 S(z)u\right) f^\epsilon \overline{u} dx dz\right| \\
&\quad \leq \max_{z\in[0,1]}\left(\left\|\frac{1}{T(z)} S(z)u\right\|^2_{L^\infty(x>R)}\right)\left|\int_0^1 \int_{x>R} S(z)u\overline{S(z)\,(f^\epsilon u)} dx dz\right| \\
&\quad = \max_{z\in[0,1]}\left(\frac{1}{T(z)}\|S(z)u\|^2_{L^\infty(x>R)}\right)\int_{|x|>R} f^\epsilon |u|^2 dx.
\end{aligned}$$

Since $S(z)u \in L^2(\mathbb{R})$ in particular $S(z)u(x) \to 0$ for $x \to \pm\infty$. Accordingly there exists $R_2 > R_1$ with

$$\max_{z\in[0,1]}\left(\frac{1}{T(z)}\|S(z)u\|^2_{L^\infty(x>R_2)}\right) < \frac{1}{4}.$$

Using

$$\frac{1}{4}\int_{|x|>R_2} f^\epsilon |u|^2 dx \leq \frac{1}{2}\int_{|x|>R_1} f^\epsilon |u|^2 dx - \frac{1}{4}\int_{|x|>R_2} f^\epsilon |u|^2 dx$$

the following estimate holds:

$$\begin{aligned}
\frac{1}{2}\int_{\mathbb{R}} f^\epsilon |u_x|^2 dx + \frac{1}{4}\int_{|x|>R_2} f^\epsilon |u|^2 dx \leq &-\int_{|x|\leq R_1} (x^2 - \lambda) f^\epsilon |u|^2 dx + \frac{1}{2}\int_{|x|\leq R_1} f^\epsilon |u|^2 dx \\
&+ \left|\int_0^1 \int_{|x|\leq R_2} S^{-1}(z)\left(\frac{1}{T(z)}|S(z)u|^2 S(z)u\right) dz f^\epsilon \overline{u} dx\right|.
\end{aligned}$$

On the right-hand side the limit $\epsilon \to 0$ is finite due to the boundedness of the domain of integration. Hence

$$\int_{x>R_2} \exp(|x|)|u(x)|^2 dx < \infty \quad \text{and} \quad \int_{\mathbb{R}} \exp(|x|)|u_x|^2 dx < \infty,$$

which implies

$$\int_{\mathbb{R}} \exp(|x|)(|u(x)|^2 + |u_x(x)|^2) dx < \infty. \tag{4.5}$$

Using the Lipschitz continuity of u, we are then able to derive exactly as in [1] the existence of a $C > 0$ with

$$\exp(|x|)(|u(x)|^2 + |u_x(x)|^2) < C \quad \forall x \in \mathbb{R},$$

which gives the desired decay estimate. □

5. Conclusion. In this section we explain the meaning of the derived results in the context of dispersion-managed optical fibers and discuss their practical relevance.

Since N^2 in the nonlinear TM-equations has the physical meaning of pulse energy, we are interested in unit-norm solutions of the DM-NLS after lens tranformation. Accordingly we apply our main theorem with $\omega = 1$ to obtain the following.

THEOREM 5.1. *There exists a sequence* $\{\lambda_n, u_n\}$ *of solutions of the averaged equation* (2.6) *having the form*

$$u_n(x,z) = \phi_n(\gamma x)\exp(-i\sqrt{ab}\lambda z), \quad \gamma = \left(\frac{b}{a}\right)^{1/4},$$

where ϕ_{2k} *is even and* ϕ_{2k+1} *is odd. Moreover, there exists* $C > 0$ *such that*

$$|\phi_n(x)| + |\phi_n'(x)| < C\exp\left(-\gamma\frac{|x|}{3}\right).$$

Thereby, the well-known Gaussian decay [9] which occurs for $F(u) = -|u|^2u$ is lost due to the nonlocal properties of F which prevents nodal arguments or a maximum principle. Thus we have shown the existence of infinitely many even (resp., odd) solutions of (1.3). Note that symmetry of the DM-soliton was not rigorously proven up to now. Kunze [11] considered only the case of two spatial dimensions, but in the context of nonlinear optics space and time variables are interchanged and hence the one-dimensional case is of practical interest.

It should be noted that a rigorous averaging theorem as in [26] is not at hand due to the problem of expanding the parameters a and b in powers of $\epsilon = \langle D \rangle$. However, heuristically it is clear that a similar averaging theorem is valid, i.e., the solution of the averaged equation is ϵ-close to the solution of the original (lens transformed) problem on the time scale $1/\epsilon$ in some H^s-space. Consequently, we expect the periodic solution of the averaged problem to be close to the original pulse and the approximation to be accurate if z is not too large.

Before discussing the relevance of our results to dispersion-managed solitons, we compare them to the relevant publications and add some comments on the differences.

(i) In recent publications (cf. [19, 20, 27]), it is explained that DM-solitons do not exist as an exactly periodic solution of the original DM-NLS (2.1) due to parametric

resonance. Using a perturbation series expansion, a coupling between bound states and linear Bloch waves is observed which results in a decay of the DM pulse for $z \to \infty$. In contrast, the averaged equation possesses a true periodic solution which is close to the solution of the original problem in terms of the averaging procedure.

(ii) Due to the lens transformation the continuous spectrum of the DM-NLS becomes discrete due to the parabolic potential and the parametric resonance is destroyed. Therefore, we have been able to apply standard bifurcation theory to our problem in contrast to the equation considered by Zharnitsky et al. [26].

This can be understood as follows: Since the lens transformation makes use of some well-known properties of the DM-soliton some resonant terms in the leading order are removed. Of course the problems with and without lens transformation are equivalent before averaging, but regarding the averaged variational principle it turns out that we reduce the problem to particular solutions, i.e., bound states. Nevertheless, both averaged models give raise to solutions close to the real DM pulse but they describe different problems; i.e., they lead to different approximations for the solution. Hence, it is not surprising that the spectrum has changed. Another way to understand the discrepancy is that some characteristic features of the DM-soliton as the existence of a pulse chirp are implemented in the lens transformation, and consequently, the equation studied in our paper is a better approximation from a practical point of view. However, in a rigorous mathematical way both are just first order approximations of the same equation.

Finally, we discuss the relevance of our result to the original problem. We have shown the existence of infinitely many solutions of the original problem which are close

$$A(z,t) = \frac{N^2}{T(z)} U(R^{\text{eff}}(z)) \left\{ \exp(i\lambda z) u_n(t/T(z)) \right\} \exp\left(i t^2 \frac{M(z)}{T(z)} \right),$$

where u_n decays exponentially fast. Note that the ground state obtained by Zharnitsky et al. [26] was only shown to be in $L^2(\mathbb{R})$. The relevance of our theoretical results can be summarized as follows:

- The ground state ϕ_0 corresponds to the DM-soliton; we have shown that it is an even function at least for small input energies. This is a new theoretical result already known from numerical simulations.
- Moreover, it is shown that the DM-soliton decays exponentially fast and has a Gaussian core. Numerical simulations show the existence of an "optimal" energy N^2, where γ and, accordingly, the decay rate is maximized [14].
- Uniqueness of the DM-soliton is still an open question, reduced models indicate that the DM-solitons form a one-parameter family. We have shown in the present paper the uniqueness of the DM-soliton close to the bifurcation point (that is for small energies), but there could exist a secondary (symmetry-breaking) bifurcation.
- The odd solution ϕ_1 corresponds to the bi-soliton which was first observed by Maruta, Nonaka, and Yoshika [16] by numerical simulations; see also the work of Pare and Belanger [21]. It minimizes the energy functional with respect to all odd functions and is hence stable against odd perturbations. It is a promising candidate for the reduction of intrachannel interactions which play an important role in todays multichannel systems. Numerical simulations [15] show that the bi-soliton propagates stable over long distances and the bit rate is increased significantly by a new encoding scheme.

- Furthermore, we have verified the existence of modes of arbitrary order, a fact which was unknown up to now. Similar to the basis of Gauss–Hermite functions for the linear oscillator there exists a family of nonlinear modes with shape close to the corresponding eigenfunction. Maruta et al. [15] also observed a tri-soliton which corresponds to solutions on the third branch in the bifurcation diagram. They conjectured the existence of a periodic pulse of arbitrary order which is guaranteed by our result.
- A very effective way to derive approxmiations of the DM-soliton is to use a Hermite–Gaussian ansatz in the lens transformed equation; cf. [24]. From the results derived in this paper it is now clear why this method gives reasonable results. We have shown that the DM-soliton in the averaged equation is close to the first eigenmode. In [24], u is expanded in terms of the Gauss–Hermite eigenfunctions, the expansion is truncated after a few modes. Bearing the bifurcation result in mind it is now obvious that the error is small although infinitely many modes are omitted. With this method it should also be possible to obtain approximations for the solutions bifurcating from the other eigenvalues by considering the corresponding eigenfunction and its neighbors as perturbations.

In conclusion we have explained various facts on the DM-soliton which were only known from numerical simulations in an analytical way.

Appendix: Verification of assumptions. In this section we show that F as in (1.2) satisfies assumptions $(\mathcal{F}_1)$ to $(\mathcal{F}_6)$. The same holds obviously for the nonlinearity $F(u) = \sigma|u|^2u$ with $\sigma < 0$.

$(\mathcal{F}_1)$: By definition we have $S(z) = U(R^{\text{eff}}(z))$, where $U(t)$ denotes the group of the harmonic oscillator. Using

$$\overline{U(-t)u} = U(t)\overline{u}$$

together with $-R^{\text{eff}}(z) = R^{\text{eff}}(z + 1/2)$ implies

$$S(z)\overline{u} = U(R^{\text{eff}}(z))\overline{u} = \overline{U(-R^{\text{eff}}(z))u} = \overline{U(R^{\text{eff}}(z + 1/2))u}.$$

Hence, by $S^{-1}(z) = U(-R^{\text{eff}}(z))$,

$$\begin{aligned} &S^{-1}(z)\left(\frac{1}{T(z)}|S(z)\overline{u}|^2S(z)\overline{u}\right) \\ &\quad = \overline{S^{-1}\left(z+\frac{1}{2}\right)\left(\frac{1}{T(z)}\left|S\left(z+\frac{1}{2}\right)u\right|^2 S\left(z+\frac{1}{2}\right)u\right)}. \end{aligned}$$

Due to symmetry $T(z) = T(z + 1/2)$ we can conclude

$$\begin{aligned} F(\overline{u}) &= -\int_0^1 \overline{S^{-1}(z+1/2)\left(\frac{1}{T(z+1/2)}|S(z+1/2)u|^2S(z+1/2)u\right)}dz \\ &= \overline{-\int_{1/2}^{3/2} S^{-1}(z)\left(\frac{1}{T(z)}|S(z)u|^2S(z)u\right)dz} = \overline{F(u)}, \end{aligned}$$

where the last equality holds due to the 1-periodicity of S and T which gives the assertion for real-valued u.

($\mathcal{F}_2$): Due to $\|u\|_{L^1(0,1)} \le \|u\|_{L^2(0,1)}$ we can estimate in the following way:

$$\begin{aligned}\|F(u)-F(v)\|_2^2 &\le C\int_{\mathbb{R}}\left(\int_0^1 |S^{-1}(z)\big(|S(z)u|^2S(z)u-|S(z)v|^2S(z)v\big)\,|dz\right)^2 dx\\ &\le \int_{\mathbb{R}}\left(\int_0^1 \big|S^{-1}(z)\left(|S(z)u|^2S(z)u-|S(z)v|^2S(z)v\right)\big|^2 dz\right)dx\\ &= \int_0^1 \||S(z)u|^2S(z)u-|S(z)v|^2S(z)v\|_2^2\;dz.\end{aligned}$$

Making use of the inequality $\big||a|^2a-|b|^2b\big| \le \frac{3}{2}(|a|^2+|b|^2)|a-b|$ which holds for $a,b\in\mathbb{C}$ and the Cauchy–Schwarz inequality we conclude

$$\begin{aligned}&\||S(z)u|^2S(z)u-|S(z)v|^2S(z)v\|_2^2\\ &\le\ C\ \|\big(|S(z)u|^2+|S(z)v|^2\big)\,|S(z)u-S(z)v|\,\|_2^2\\ &\le\ C\ \|(|S(z)u|^2+|S(z)v|^2)^2\|_2\||S(z)(u-v)|^2\|_2\\ &\le\ C\ \left(\|\,|S(z)u|^4\|_2+\||S(z)v|^4\|_2\right)\||S(z)(u-v)|^2\|_2\\ &=\ C\ \left(\|S(z)u\|_8^4+\|S(z)v\|_8^4\right)\|S(z)(u-v)\|_4^2.\end{aligned}$$

From Oh [17] it is known that $S(z)$ is a bounded operator from $L^p(\mathbb{R})$ to $L^q(\mathbb{R})$, where $q=p/(p-1)$. Since X is compactly embedded in $L^p(\mathbb{R})$ for all $p\ge 2$ we have $S(z)u\in L^q(\mathbb{R})$ for all $q\ge 2$. Estimating the terms separately we interpolate

$$\|S(z)u\|_8 \le \|S(z)u\|_4^{\lambda}\|S(z)u\|_q^{1-\lambda},$$

where

$$\lambda=\frac{1/8-1/q}{1/4-1/q}.$$

Using the estimate of Sobolev type $\|v\|_4^4\le C\|v_x\|_2\|v\|_2^3$ we obtain

$$\begin{aligned}\|S(z)u\|_8 &\le C(\|S(z)u_x\|_2\|S(z)u\|_2^3)^{\lambda/4}\|S(z)u\|_X^{1-\lambda}\\ &\le C\|u\|_X^{\lambda/4}\|u\|_X^{1-\lambda}\|u\|_2^{3\lambda/4}=C\|u\|_X^{1-3\lambda/4}\|u\|_2^{3\lambda/4}.\end{aligned}$$

In the same way it follows that

$$\|S(z)(u-v)\|_4^2\le C\|u-v\|_X^{1/2}\|u-v\|_2^{3/2}.$$

Hence, by collecting all the terms,

$$\|F(u)-F(v)\|_2^2\le C\left(\|u\|_X^{4-3\lambda}\|u\|_2^{3\lambda}+\|v\|_X^{4-3\lambda}\|v\|_2^{3\lambda}\right)\|u-v\|_X^{1/2}\|u-v\|_2^{3/2}.$$

We still have the freedom to choose q. In order to satisfy $\alpha=4-3\lambda<7/2$ we need $\lambda>1/6$ which holds for $q>10$. Note that a choice $q=16$ would give $\alpha=3,\beta=1$.

($\mathcal{F}_3$): It is easy to observe that $F\in C^3(X,L^2)$ with $\delta F(0)[u_n]=0$, $\delta^2F(0)[u_n]^2=0$ and

$$\delta^3F(0)[u_n]^3=-6\int_0^1 S^{-1}(z)\left(\frac{1}{T(z)}|S(z)u_n|^2S(z)u_n\right)dz. \tag{5.1}$$

For a normalized eigenfunction ($\|u_n\|_2 = 1$) we have

$$(\delta^3 F(0)[u_n]^3, u_n)_{L^2} = -6 \int_0^1 \left(S^{-1}(z) \left(\frac{1}{T(z)} |S(z)u_n|^2 S(z)u_n \right), u_n \right)_{L^2} dz$$
$$= -6 \int_0^1 \frac{1}{T(z)} \|S(z)u_n\|_4^4 \, dz < 0.$$

($\mathcal{F}_4$): Defining $G(u) = (F(u), u)/4$ gives

$$G(u) = -\frac{1}{4} \int_0^1 \frac{1}{T(z)} \|S(z)u\|_4^4 dz$$

with $G'(u)v = (F(u), v)$.

($\mathcal{F}_5$): This assumption is fulfilled with $\delta = 3$.

($\mathcal{F}_6$): With $\Gamma u(x) = u(-x)$ we have to show $G(u) = G(\Gamma u)$. This is true since $S(z)$ and Γ commute which is shown as follows: Let $v(z) := \Gamma S(z)u$, then $v(0) = \Gamma u$ holds and with $Au = u_{xx} - x^2 u$ one can observe that

$$iv_z = i\Gamma \left(iR^{\text{eff}}(z) A S(z)u \right) = -R^{\text{eff}}(z) A \Gamma S(z)u,$$

which gives the assertion for Γ, and the same arguments apply for Γ_2.

Acknowledgments. The author thanks Tassilo Küpper for his support and discussions and C. K. R. T. Jones for valuable suggestions.

ADIABATIC APPROXIMATION OF THE SCHRÖDINGER–POISSON SYSTEM WITH A PARTIAL CONFINEMENT*

NAOUFEL BEN ABDALLAH†, FLORIAN MÉHATS†, AND OLIVIER PINAUD†

Abstract. Asymptotic quantum transport models of a two-dimensional electron gas are presented. The starting point is a singular perturbation of the three-dimensional Schrödinger–Poisson system. The small parameter ε is the scaled width of the electron gas and appears as the lengthscale on which a one-dimensional confining potential varies. The rigorous $\epsilon \to 0$ limit is performed by projecting the three-dimensional wavefunction on the eigenfunctions corresponding to the confining potential. This leads to a two-dimensional Schrödinger–Poisson system with a modified Poisson equation keeping track of the third dimension. This limit model is proven to be a first-order approximation of the initial model. An intermediate model, called the "2.5D adiabatic model" is then introduced. It shares the same structure as the limit model but is shown to be a second-order approximation of the three-dimensional model.

Key words. adiabatic approximation, energy estimates, Strichartz estimates, error estimates, nonlinear analysis, two-dimensional electron gas

1. Introduction.

Systems with reduced dimensionality are the basis of operation of most of nanoscale electronic devices. Among them is the two-dimensional electron gas (2DEG) [1, 2, 9], in which the electrons are strongly confined in one direction so that collisionless transport is allowed in the two remaining ones. Although the transport is quasi bidimensional, the Coulomb interaction results in a fully three-dimensional structure. Indeed, the particle density is a sheet density concentrated on the two-dimensional electron gas plane, which generates through mean field interaction a fully three-dimensional potential. In [17], an approximate Schrödinger–Poisson model taking into account the quasi-bidimensional nature of electron transport, while maintaining a three-dimensional description of the electrostatic potential, was proposed and numerically implemented in the stationary framework for electron waveguide structures. The model has been shown to be numerically in very good agreement with the fully three-dimensional Schrödinger–Poisson system, while having a much lower numerical complexity. The aim of this paper is to prove by a rigorous asymptotic analysis that the model introduced in [17] is a good approximation of the fully three-dimensional model and quantify the discrepancy between the two models. In order to simplify the setting and to avoid additional technicalities induced by stationarity and by boundary effects, we shall consider the time-dependent problem in the whole space. The case of stationary boundary value problems will be the subject of a forthcoming work by the third author of this paper [16].

Denoting by z the confined direction, we shall consider the following singularly

perturbed Schrödinger–Poisson system:

$$i\partial_t \psi^\varepsilon = -\frac{1}{2}\Delta_{x,z}\,\psi^\varepsilon + \frac{1}{\varepsilon^2}V_c\left(\frac{z}{\varepsilon}\right)\psi^\varepsilon + V^\varepsilon\psi^\varepsilon, \tag{1.1}$$

$$\psi^\varepsilon(0,x,z) = \psi_0^\varepsilon(x,z), \tag{1.2}$$

$$V^\varepsilon = \frac{1}{4\pi r} * \left(|\psi^\varepsilon|^2\right), \tag{1.3}$$

where $x \in \mathbb{R}^2$, $z \in \mathbb{R}$, $r = \sqrt{|x|^2 + z^2}$, the potential V^ε is the self-consistent potential due to space charge effects, and the external confinement potential $V_c^\varepsilon(z) = \frac{1}{\varepsilon^2}V_c\left(\frac{z}{\varepsilon}\right)$ is given. In this work, the asymptotic behavior of the solution of this nonlinear system is studied when ε goes to 0. Two approximate models are exhibited: the limit model (*2D surface density model*) and an intermediate ε-dependent model (*2.5D adiabatic model*), which is shown to be a more accurate approximation of the initial model.

Quantum systems confined on a surface have been studied previously in [8, 10, 15, 21]. Starting from a similar scaling on the transverse Hamiltonian, these authors consider the linear Schrödinger equation with a confinement on a general surface and derive an effective Hamiltonian which locally depends on the curvature properties of the surface. In our case, the effective Hamiltonian at the leading order is trivial since the surface is the plane $z = 0$. The main difficulty here stems from the nonlinear character of the problem due to the self-consistent potential.

As remarked in [21], quantum constrained systems can be linked to the Born–Oppenheimer approximation in molecular dynamics [12, 19, 21]. In order to analyze this link, let us rescale the variables z, t by setting $\tilde{z} = \frac{z}{\varepsilon}$, $\tilde{t} = \frac{t}{\varepsilon}$ and let $\tilde{x} = x$. To keep densities of order $\mathcal{O}(1)$, we also need to rescale ψ by a factor $\frac{1}{\sqrt{\varepsilon}}$; hence the self-consistent potential is rescaled by $\frac{1}{\varepsilon}$. Denoting again (with an abuse of notation) by ψ^ε and V^ε the functions of the new variables, the system takes the form

$$i\varepsilon\partial_{\tilde{t}}\psi^\varepsilon = -\frac{\varepsilon^2}{2}\Delta_{\tilde{x}}\psi^\varepsilon - \frac{1}{2}\partial_{\tilde{z}}^2\psi^\varepsilon + (V_c + \varepsilon V^\varepsilon)\psi^\varepsilon. \tag{1.4}$$

The above problem (in the linear case) has been studied in particular in [3, 19]. However, the problem (1.1)–(1.3) is not just a rescaling of the Born–Oppenheimer asymptotics for two reasons. The first reason is, again, the nonlinear character of this system, which might induce rapid time oscillations of V^ε. The second reason is the time scale. Indeed, if the asymptotics is done for times $\tilde{t}$ of order 1 for the Born–Oppenheimer problem (1.4), then t is of order ε in the initial problem (1.1)–(1.3). Therefore, since we are here interested in time intervals of order 1 for the variable t, working in the variable $\tilde{t}$ would necessitate longer time intervals (of the order of $1/\varepsilon$) which is more difficult. The two problems, however, share similar properties of adiabatic decoupling. The systems can be diagonalized by using the eigenspaces of the transverse Hamiltonian $-\frac{1}{2}\partial_z^2 + V$ (in which t and x are frozen). Within each eigenspace the dynamics is governed by an effective potential and is quantum in our case, wheras semiclassical behavior is expected in the Born–Oppenheimer approximation.

The paper is organized as follows. In section 2, we first make precise the properties of the confinement operator and define the two approximate models (namely, the two-dimensional and 2.5D models). Then we state the main results of this paper, namely Theorems 2.5, 2.6, and 2.7. Section 3 is devoted to the proof of ε-independent

estimates for (1.1)–(1.3). In section 4, we put both approximate models into a more general framework allowing us to prove existence and uniqueness of their solutions. The 2.5D adiabatic model is shown to be a second-order approximation in section 5, while in section 6 the 2D surface density model is proven to be only a first-order approximation. Finally, the appendices contains some basic results on the Schrödinger equation and the Poisson equation which are used throughout the paper.

Remark on the scaling. Before going further, and in order to make clear the physical assumptions made here, let us show how the system (1.1)–(1.3) can be obtained by a rescaling of the Schrödinger–Poisson system written in the physical dimensional variables. Let $\Psi(T,X,Z)$, $\mathcal{V}(T,X,Z)$ be the solution of

$$i\hbar\partial_T\Psi = -\frac{\hbar^2}{2m}\Delta_{X,Z}\,\Psi + (\mathcal{V}_c+\mathcal{V})\Psi, \tag{1.5}$$

$$\mathcal{V} = \frac{e^2}{4\pi\varepsilon_M}\,\frac{1}{\sqrt{|X|^2+Z^2}} * \left(|\Psi|^2\right), \tag{1.6}$$

where m is the effective mass, e is the elementary charge of the electrons, and ε_M is the electric permittivity of the material. We introduce two characteristic energies, E_c and E, which are, respectively, the typical energy of the confinement and the typical kinetic energy of the electrons. The assumption of a strong confinement is

$$\varepsilon^2 = \frac{E}{E_c} \ll 1. \tag{1.7}$$

The confinement operator is the partial Hamiltonian defined on $\mathbb{R}$ by $-\frac{\hbar^2}{2m}\frac{\partial^2}{\partial Z^2}+\mathcal{V}_c$. Hence we deduce that the typical length L_c of the confinement, defined as the spatial extension of the eigenvalues of this operator, satisfies $\frac{\hbar^2}{2mL_c^2} = E_c$, and the confinement potential takes the form $\mathcal{V}_c(Z) = E_c V_c(\frac{Z}{L_c})$, where V_c denotes a dimensionless potential. Since we are interested in quantum models for the transport of the electrons, the typical space length L and the typical time $\mathcal{T}$ are deduced from the kinetic energy (this crucial assumption says that the initial data are not oscillating): $\frac{\hbar}{\mathcal{T}} = \frac{\hbar^2}{2mL^2} = E$; thus (1.7) gives $\frac{L_c}{L} = \varepsilon$. Finally, we assume that the self-consistent potential is of the same order of magnitude as the kinetic energy, which means that if N_0 is the typical density (the scale of $|\Psi|^2$), we have

$$\frac{e^2N_0L^2}{\varepsilon_M} = E.$$

With these assumptions, setting

$$t = \frac{T}{\mathcal{T}}, \qquad (x,z) = \left(\frac{X}{L},\frac{Z}{L}\right), \qquad \psi^\varepsilon = \frac{\Psi}{\sqrt{N_0}}, \qquad V^\varepsilon = \frac{\mathcal{V}}{E},$$

the system (1.5)–(1.6) is written (1.1)–(1.3) in the dimensionless variables.

2. Notation and main results. Throughout this paper, for any $q\in[1,\infty]$, we shall denote by q' its conjugate, and for any $q\in[2,\infty]$ we denote by q^* its 2-conjugate, respectively, defined by

$$q' = \frac{q}{q-1}; \qquad q^* = \frac{2q}{q-2}.$$

We define the following functional spaces.

DEFINITION 2.1. *Let $1 \le p, q, r \le +\infty$. The spaces $L^p_x L^q_z$ and $L^r_t L^p_x L^q_z$ are defined by*

$$L^p_x L^q_z(\mathbb{R}^3) = \left\{ u \in L^1_{loc}(\mathbb{R}^3), \quad \|u\|_{L^p_x L^q_z(\mathbb{R}^3)} = \left(\int_{\mathbb{R}^2} \|u(x,\cdot)\|^p_{L^q(\mathbb{R})}\, dx \right)^{1/p} < +\infty \right\}$$

(with an obvious generalization of this definition for $p = +\infty$),

$$L^r_t L^p_x L^q_z((0,T)\times\mathbb{R}^3) = L^r((0,T), L^p_x L^q_z(\mathbb{R}^3)).$$

When there is no ambiguity, we shall simply denote these spaces by $L^p_x L^q_z$ and $L^r_t L^p_x L^q_z$ and the corresponding norms by $\|\cdot\|_{p,q}$ and $\|\cdot\|_{r,p,q}$ (when there are two indices, the variables are (x,z); when there are three indices, the variables are (t,x,z)).

For a function $f = f(z)$ belonging to $L^1(\mathbb{R})$, we denote $\langle f \rangle = \int_{\mathbb{R}} f(z)dz$. In particular, if $n(t,x,z)$ is the particle density, the surface particle density is defined by $n_s(t,x) = \langle n(t,x,\cdot)\rangle = \int_{\mathbb{R}} n(t,x,z)\, dz$.

The symbol $*$ denotes a convolution with respect to all the variables $(x,z) \in \mathbb{R}^3$; partial convolutions are denoted by $*_x$ and $*_z$.

2.1. Properties of the confinement operator. Let us now introduce the basic assumptions made on the confining potential.

ASSUMPTION 2.2. (i) *The rescaled confining potential $V_c = V_c(z)$ is a nonnegative real-valued function in $L^2_{loc}(\mathbb{R})$.*

(ii) *The operator $A = -\frac{1}{2}\frac{d^2}{dz^2} + V_c$ defined on $L^2(\mathbb{R})$ with the domain*

$$\mathcal{D}(A) = \left\{ u \in H^2(\mathbb{R}) \text{ such that } V_c\, u \in L^2(\mathbb{R}) \right\}$$

admits a nondegenerate eigenvalue E associated to an eigenfunction $\chi(z)$ such that $z\chi \in L^2(\mathbb{R})$.

The first part of this assumption implies that the operator A is self-adjoint and nonnegative (see, e.g., [18]). The partial Hamiltonian involved in (1.1) is obtained by rescaling the operator A:

$$A^\varepsilon = -\frac{1}{2}\frac{d^2}{dz^2} + V_c^\varepsilon = -\frac{1}{2}\frac{d^2}{dz^2} + \frac{1}{\varepsilon^2} V_c\left(\frac{z}{\varepsilon}\right)$$

and we obtain an eigenfunction/eigenvalue pair of A^ε by setting

$$\chi^\varepsilon(z) = \frac{1}{\sqrt{\varepsilon}}\,\chi\left(\frac{z}{\varepsilon}\right); \quad E^\varepsilon = \frac{E}{\varepsilon^2}.$$

Note that the assumption on the eigenfunction given in Assumption 2.2 implies that

$$\forall \beta \in [0,1], \qquad \|z^\beta\, \chi^\varepsilon\|_{L^2(\mathbb{R})} = \mathcal{O}(\varepsilon^\beta). \tag{2.1}$$

We shall denote by $X^\varepsilon = \mathit{span}(\chi^\varepsilon)$ the corresponding eigenspace and by Π^ε the orthogonal projector on this eigenspace. Following the physical literature [1, 2], we shall refer to the *subband of energy level E^ε* as the space $L^2(\mathbb{R}^2, X^\varepsilon)$. With an abuse of notation, we shall also denote by Π^ε the orthogonal projector $\mathbb{I} \otimes \Pi^\varepsilon$ of $L^2(\mathbb{R}^3)$ on $L^2(\mathbb{R}^2, X^\varepsilon)$.

The following technical lemma will be used several times.

LEMMA 2.3. *Let $V^\varepsilon \in W^{1,\alpha}(\mathbb{R})$ with $\alpha \in [1,+\infty]$. Then there exists a constant $C>0$ such that*

$$\|[\Pi^\varepsilon, V^\varepsilon]\|_{\mathcal{L}(L^2(\mathbb{R}))} \leq C\,\varepsilon^{1-1/\alpha}\,\|\partial_z V^\varepsilon\|_{L^\alpha(\mathbb{R})},$$

where $[\cdot,\cdot]$ denotes the commutator between the two operators.

Proof. Noting that

$$[\Pi^\varepsilon, V^\varepsilon] = \Pi^\varepsilon\, V^\varepsilon\,(\mathbb{I}-\Pi^\varepsilon) - (\mathbb{I}-\Pi^\varepsilon)\,V^\varepsilon\,\Pi^\varepsilon$$

and that in this difference the second operator is the adjoint of the first one, one can see that the lemma stems from

$$\|\Pi^\varepsilon\, V^\varepsilon\,(\mathbb{I}-\Pi^\varepsilon)\|_{\mathcal{L}(L^2(\mathbb{R}))} \leq C\,\varepsilon^{1-1/\alpha}\,\|\partial_z V^\varepsilon\|_{L^\alpha(\mathbb{R})}.$$

In order to prove the above estimate, let $U^\varepsilon(z) = V^\varepsilon(z) - V^\varepsilon(0)$. By orthogonality of Π^ε and $\mathbb{I}-\Pi^\varepsilon$, we have, clearly,

$$\Pi^\varepsilon\, V^\varepsilon\,(\mathbb{I}-\Pi^\varepsilon) = \Pi^\varepsilon\, U^\varepsilon\,(\mathbb{I}-\Pi^\varepsilon).$$

Therefore

$$\|\Pi^\varepsilon\, V^\varepsilon\,(\mathbb{I}-\Pi^\varepsilon)\|_{\mathcal{L}(L^2(\mathbb{R}))} \leq \|\Pi^\varepsilon\, U^\varepsilon\|_{\mathcal{L}(L^2(\mathbb{R}))} \leq \|\chi^\varepsilon\, U^\varepsilon\|_{L^2(\mathbb{R})},$$

where a Cauchy–Schwarz inequality was used. Additionally, we have

$$|U^\varepsilon(z)| = \left|\int_0^z \partial_z V^\varepsilon(y)\,dy\right| \leq |z|^{1-1/\alpha}\,\|\partial_z V^\varepsilon\|_{L^\alpha(\mathbb{R})}.$$

Thus we conclude the proof, thanks to

$$\begin{aligned}\|\chi^\varepsilon\, U^\varepsilon\|^2_{L^2(\mathbb{R})} &\leq \|\partial_z V^\varepsilon\|^2_{L^\alpha(\mathbb{R})}\left\|z^{1-1/\alpha}\chi^\varepsilon\right\|^2_{L^2(\mathbb{R})}\\ &\leq C\,\varepsilon^{2-2/\alpha}\,\|\partial_z V^\varepsilon\|^2_{L^\alpha(\mathbb{R})},\end{aligned}$$

where we used (2.1). ∎

2.2. Definitions of the approximate models and main results. We shall assume that the initial wavefunction belongs to the subband of energy level E^ε.

ASSUMPTION 2.4 (well-prepared data). *The initial data ψ_0^ε of the three-dimensional Schrödinger–Poisson problem* (1.1)–(1.3) *satisfies*

$$\psi_0^\varepsilon = \phi_0\,\chi^\varepsilon \in H^1(\mathbb{R}^2, X^\varepsilon).$$

Let us now write the two approximate models for the three-dimensional Schrödinger–Poisson system (1.1)–(1.3).

The 2D surface density model. The 2D surface density model is obtained by coupling a two-dimensional Schrödinger equation and the Poisson equation with a modified Green function. It is given by

$$i\partial_t\phi = -\frac{1}{2}\Delta_x\,\phi + W\phi, \tag{2.2}$$

$$W = \frac{1}{4\pi|x|} *_x \left(|\phi|^2\right), \tag{2.3}$$

with the initial data $\phi(0,x)=\phi_0(x)=\langle\psi_0^\varepsilon(x,\cdot)\chi^\varepsilon\rangle$. The unknowns are $\phi(t,x)$, $W(t,x)$ and the surface density $n_s(t,x)=|\phi|^2(t,x)$, where $x\in\mathbb{R}^2$. Note that $W(t,x)=V(t,x,0)$, where V is the Coulomb potential generated by the sheet density supported in the plane $z=0$ with a surface density n_s:

$$n(t,x,z)=n_s(t,x)\delta(z);\quad V=\frac{1}{4\pi r}*n. \tag{2.4}$$

The 2.5D adiabatic model. The 2.5D adiabatic model is an intermediate model between the fully three-dimensional model and the 2D surface density model. It takes into account the small thickness of the electron gas and consists in coupling a two-dimensional Schrödinger equation and the three-dimensional Poisson equation. The unknowns are $\phi^\varepsilon(t,x)$, $V^\varepsilon(t,x,z)$ and the density $n^\varepsilon(t,x,z)$, where $x\in\mathbb{R}^2$ and $z\in\mathbb{R}$. This system is written

$$i\partial_t\phi^\varepsilon=-\frac{1}{2}\Delta_x\,\phi^\varepsilon+\left\langle V^\varepsilon|\chi^\varepsilon|^2\right\rangle\phi^\varepsilon, \tag{2.5}$$

$$V^\varepsilon=\frac{1}{4\pi r}*\left(|\phi^\varepsilon|^2\,|\chi^\varepsilon|^2\right), \tag{2.6}$$

with the initial data $\phi^\varepsilon(0,x)=\phi_0(x)=\langle\psi_0^\varepsilon(x,\cdot)\chi^\varepsilon\rangle$ and where the function $\chi^\varepsilon(z)$ is defined as in section 2.1. The population of electrons is described by a pure quantum state which belongs at any time to the subband of energy level E. One can see that in the 2.5D adiabatic model the dynamics on the subband is induced by the effective potential $\left\langle V^\varepsilon|\chi^\varepsilon|^2\right\rangle$, which is the potential "modulated" by the wavefunction χ^ε. Moreover, applying formally the standard perturbation theory (see [14]), the transverse Hamiltonian $-\frac{1}{2}\frac{d^2}{dz^2}+V_c^\varepsilon+V^\varepsilon$ admits an eigenvalue $\epsilon(t,x)$ given by

$$\epsilon=\frac{E}{\varepsilon^2}+\left\langle V^\varepsilon|\chi|^2\right\rangle+\mathcal{O}(\varepsilon^2).$$

Thus, the above 2.5D adiabatic model can be seen—at least formally—as an ε^2-perturbation of the model given by the adiabatic quantum theory [19] (the constant E/ε^2 can be forgotten in (2.5) since it only induces a phase factor).

The main results of the paper, summarized in the three following theorems, state that the 2.5D adiabatic model is (almost) a second-order approximation of the three-dimensional model, while the 2D surface density model is exactly a first-order approximation.

THEOREM 2.5. *Suppose that Assumptions* 2.2 *and* 2.4 *are satisfied. Then the three-dimensional Schrödinger–Poisson system* (1.1)–(1.3) *and the* 2.5*D adiabatic model* (2.5), (2.6) *admit unique global weak solutions denoted by* (ψ^{3D}, V^{3D}) *and* ($\phi^{2.5D}$, $V^{2.5D}$), *respectively. Moreover, for any* T *we have*

$$\|\psi^{3D}-\phi^{2.5D}\chi^\varepsilon\,e^{-itE/\varepsilon^2}\|_{q^*,q,2}=\mathcal{O}(\varepsilon)\qquad\forall q\in[2,\infty), \tag{2.7}$$

$$\|V^{3D}-V^{2.5D}\|_{L^1((0,T),L^\infty(\mathbb{R}^3))}=\mathcal{O}(\varepsilon^{2-\alpha})\qquad\forall\alpha>0. \tag{2.8}$$

Furthermore, the surface densities defined by $n_s^{3D}=\langle|\psi^{3D}|^2\rangle$ *and* $n_s^{2.5D}=|\phi^{2.5D}|^2$ *satisfy*

$$\|n_s^{3D}-n_s^{2.5D}\|_{L^1((0,T),L^q(\mathbb{R}^2))}=\mathcal{O}(\varepsilon^{2-\alpha})\qquad\forall\alpha>0,\qquad\forall q\in[1,\infty). \tag{2.9}$$

THEOREM 2.6. *Suppose that Assumptions* 2.2 *and* 2.4 *are satisfied. Then as* $\varepsilon \to 0$ *and for any* $T > 0$ *the solution* $(\phi^{2.5D},\, n^{2.5D},\, V^{2.5D})$ *of the* $2.5D$ *adiabatic model converges to the unique solution* $(\phi^{2D},\, n_s^{2D},\, V^{2D})$ *of the* $2D$ *surface density model* (2.2), (2.4) *in the following sense:*

$$\|\phi^{2.5D} - \phi^{2D}\|_{L^{q^*}((0,T),W^{1,q}(\mathbb{R}^2))} = \mathcal{O}(\varepsilon) \qquad \forall q \in [2,\infty), \tag{2.10}$$

$$\|V^{2.5D} - V^{2D}\|_{L^q((0,T),L^\infty(\mathbb{R}^3))} = \mathcal{O}(\varepsilon) \qquad \forall q \in [1,\infty), \tag{2.11}$$

$$\|n_s^{2.5D} - n_s^{2D}\|_{L^q((0,T),L^\infty(\mathbb{R}^2))} = \mathcal{O}(\varepsilon) \qquad \forall q \in [1,\infty). \tag{2.12}$$

THEOREM 2.7. *Suppose that Assumptions* 2.2 *and* 2.4 *are satisfied. If, moreover, we have*

$$0 < \|x\phi_0\|_{L^2(\mathbb{R}^2)} < +\infty \quad \textit{and} \quad \phi_0 \in H^2(\mathbb{R}^2), \tag{2.13}$$

then for any $T > 0$ *there exists a constant* $C > 0$ *such that the solutions of the* $2.5D$ *adiabatic model and the* $2D$ *surface density model satisfy*

$$\|(V^{2.5D} - V^{2D})(t,\cdot,0)\|_{L^\infty(\mathbb{R}^2)} + \|(n_s^{2.5D} - n_s^{2D})(t,\cdot)\|_{L^q(\mathbb{R}^2)} \geq C\,\varepsilon \tag{2.14}$$

for any $t \in [0,T]$, $q \in [1,\infty)$, *where* C *depends on* T *and* q *but not on* ε.

An immediate consequence of these theorems is the following.

COROLLARY 2.8. *Under Assumptions* 2.2 *and* 2.4, *the three-dimensional Schrödinger–Poisson system converges as* $\varepsilon \to 0$ *to the* $2D$ *surface density model. Moreover, if in addition* (2.13) *is satisfied, we have for any* $T > 0$ *and* $q \in [1,\infty)$,

$$C_1\,\varepsilon \leq \|V^{3D} - V^{2D}\|_{L^1((0,T),L^\infty(\mathbb{R}^3))} + \|n_s^{3D} - n_s^{2D}\|_{L^1((0,T),L^q(\mathbb{R}^2))} \leq C_2\,\varepsilon,$$

where the notations of Theorems 2.5 *and* 2.6 *were used.*

3. Estimates for the three-dimensional model. In this section we prove some ε-independent estimates for the three-dimensional Schrödinger-Poisson problem (1.1)–(1.3). We first claim that a straightforward adaptation of the proofs of [4, 13] allows us to show that for any initial data

$$\psi_0^\varepsilon \in \mathcal{H} := \{\phi \in H^1(\mathbb{R}^3) \,:\, \sqrt{V_c^\varepsilon}\,\psi \in L^2(\mathbb{R}^3)\}, \tag{3.1}$$

(which may depend on ε) and for an arbitrary $T > 0$, this system admits a unique weak solution ψ^ε, V^ε, such that

$$\psi^\varepsilon \in C([0,T],\mathcal{H}),$$

$$V^\varepsilon \in L^\infty((0,T)\times\mathbb{R}^3); \qquad \nabla_{x,z} V^\varepsilon \in L^\infty((0,T),L^q(\mathbb{R}^3)) \quad \forall q \in (3/2,\infty).$$

Let us define the kinetic energy along the x direction and along the z direction, respectively, by

$$\mathcal{E}^\varepsilon_{kin,x}(t) = \iint_{\mathbb{R}^3} \frac{1}{2}\,|\nabla_x \psi^\varepsilon(t,x,z)|^2\,dx\,dz; \quad \mathcal{E}^\varepsilon_{kin,z}(t) = \iint_{\mathbb{R}^3} \frac{1}{2}\,|\partial_z \psi^\varepsilon(t,x,z)|^2\,dx\,dz.$$

The self-consistent potential energy and the external potential energy are then, respectively, defined by

$$\mathcal{E}^\varepsilon_{pot}(t) = \iint_{\mathbb{R}^3} \frac{1}{2} |\nabla_{x,z} V^\varepsilon|^2 \, dx \, dz; \quad \mathcal{E}^\varepsilon_{ext}(t) = \iint_{\mathbb{R}^3} V^\varepsilon_c(z) |\psi^\varepsilon(t,x,z)|^2 \, dx \, dz$$

and the total energy of the system is

$$\mathcal{E}^\varepsilon_{tot}(t) = \mathcal{E}^\varepsilon_{kin,x}(t) + \mathcal{E}^\varepsilon_{kin,z}(t) + \mathcal{E}^\varepsilon_{pot}(t) + \mathcal{E}^\varepsilon_{ext}(t).$$

The standard energy estimate for the Schrödinger–Poisson system [4] gives the conservation of the total energy:

$$\forall t \geq 0 \qquad \mathcal{E}^\varepsilon_{tot}(t) = \mathcal{E}^\varepsilon_{tot}(0). \tag{3.2}$$

Unfortunately, due to the strong confinement potential V^ε_c, the external energy $\mathcal{E}^\varepsilon_{ext}$ is of order $\mathcal{O}(1/\varepsilon^2)$. Therefore, (3.2) does not provide directly a bound for the kinetic energy (except for the special case where the initial data is concentrated on the ground state). Nevertheless the Strichartz estimates of Appendix A enable us to obtain some estimates independent of ε, without using the energy conservation. The first step is the following lemma.

LEMMA 3.1. *Let $\psi^\varepsilon_0 \in L^2(\mathbb{R}^3)$ and let ψ^ε, V^ε be a solution of* (1.1)–(1.3). *If Assumption* 2.2(i) *is satisfied, then for any $T > 0$ we have*

$$\forall q \in [2, \infty) \qquad \|\psi^\varepsilon\|_{q^*,q,2} \leq C(\psi_0), \tag{3.3}$$

$$\forall q \in [1, 3) \qquad \|V^\varepsilon\|_{L^q((0,T),L^\infty(\mathbb{R}^3))} \leq C(\psi_0), \tag{3.4}$$

where $C(\psi_0)$ denotes a generic constant, which depends only on $\|\psi^\varepsilon_0\|_{L^2(\mathbb{R}^3)}$ (and q), and $q^* = 2q/(q-2)$.

Proof. This proof relies on the Strichartz estimates and on the properties of the Poisson equation studied in Appendices A and B. Let us first recall that the L^2 estimate for the Schrödinger equation gives

$$\forall t \in [0, T] \qquad \|\psi(t)\|_{2,2} \leq \|\psi^\varepsilon_0\|_{L^2(\mathbb{R}^3)}.$$

Additionally, from (B.3) and a Hölder inequality, we deduce that

$$\forall q \in (2, \infty) \qquad \left\| \frac{1}{r} * (fg) \right\|_{q,\infty} \leq C \, \|f\|_{q,2} \, \|g\|_{2,2};$$

thus for all $t \in (0, T)$ we have

$$\forall q \in (2, \infty) \qquad \|V^\varepsilon(t)\|_{q,\infty} \leq C(\psi_0) \, \|\psi^\varepsilon(t)\|_{q,2} \, .$$

Hence

$$\|V^\varepsilon(t) \, \psi^\varepsilon(t)\|_{2,2} \leq \|V^\varepsilon(t)\|_{q,\infty} \, \|\psi^\varepsilon(t)\|_{q^*,2} \leq C(\psi_0) \, \|\psi^\varepsilon(t)\|_{q,2} \, \|\psi^\varepsilon(t)\|_{q^*,2} \, .$$

Let q be fixed such that $q \in [4, \infty)$. It is readily seen that

$$\|\psi^\varepsilon\|_{q^*,2} \leq \|\psi^\varepsilon\|^{2/(q-2)}_{q,2} \, \|\psi^\varepsilon\|^{(q-4)/(q-2)}_{2,2} \, ,$$

which leads to

$$\|V^\varepsilon(t)\,\psi^\varepsilon(t)\|_{2,2} \le C(\psi_0)\,\|\psi^\varepsilon(t)\|_{q,2}^{q^*/2}. \tag{3.5}$$

For any $t \ge 0$, let

$$Y(t) := \|\psi^\varepsilon\|_{L^{q^*}((0,t),L^q_x L^2_z)}.$$

By using (3.5) and a Hölder inequality, we get

$$\|V^\varepsilon\,\psi^\varepsilon\|_{L^1((0,t),L^2(\mathbb{R}^3))} \le C(\psi_0)\,\sqrt{t}\,(Y(t))^{q^*/2}.$$

Consequently the Strichartz inequality stated in Lemma A.2 gives

$$Y(t) \le C(\psi_0)\left(1 + \sqrt{t}\,(Y(t))^{q^*/2}\right).$$

Since $Y(0) = 0$, this is enough to conclude by continuity that there exists $\widetilde{T}$ and C_0 depending only on $\|\psi_0^\varepsilon\|_{L^2(\mathbb{R}^3)}$ and q such that $Y(\widetilde{T}) \le C_0$. We deduce (3.3) for $q \ge 4$ by iterating this procedure on the interval $(\widetilde{T}, 2\widetilde{T})$, then on $(2\widetilde{T}, 3\widetilde{T})$, etc. By interpolation, we also deduce that (3.3) holds true for $q \in (2,4)$. To obtain (3.4), it is enough to apply (B.5) with p close to 2 and to use (3.3) with q close to 4. ∎

From this lemma, one can deduce the main result of this section as follows.

PROPOSITION 3.2. *Assume that the initial data $\psi_0^\varepsilon \in \mathcal{H}$ (defined by* (3.1)*) satisfies*

$$\|\psi_0^\varepsilon\|_{L^2(\mathbb{R}^3)} + \|\nabla_x \psi_0^\varepsilon\|_{L^2(\mathbb{R}^3)} \le C \tag{3.6}$$

and let ψ^ε, V^ε be the solution of (1.1)–(1.3)*. Then, if Assumption* 2.2(i) *is satisfied, we have the following estimates:*

$$\forall q \in [2,\infty) \qquad \|\psi^\varepsilon\|_{q^*,q,2} + \|\nabla_x \psi^\varepsilon\|_{q^*,q,2} \le C, \tag{3.7}$$

$$\|V^\varepsilon\|_{L^\infty((0,T)\times\mathbb{R}^3)} \le C, \tag{3.8}$$

$$\forall q \in (2,\infty) \qquad \|\nabla_{x,z} V^\varepsilon\|_{\infty,q,\infty} \le C. \tag{3.9}$$

Here C denotes a generic constant independent of ε.

Proof. We first remark is that, thanks to (3.6), the estimates (3.3) and (3.4) given in the previous lemma are independent of ε. Differentiating (1.1) with respect to x leads to

$$i\partial_t \nabla_x \psi^\varepsilon = -\frac{1}{2}\Delta_x\,\nabla_x \psi^\varepsilon + A^\varepsilon \nabla_x \psi^\varepsilon + V^\varepsilon \nabla_x \psi^\varepsilon + \nabla_x V^\varepsilon \psi^\varepsilon. \tag{3.10}$$

From (B.4), we deduce that for all $t \in (0,T)$ we have

$$\begin{aligned} \forall q \in (2,\infty) \qquad \|\nabla_x V^\varepsilon(t)\|_{q,\infty} &\le C\,\|\nabla_x(|\psi^\varepsilon(t)|^2)\|_{2q/(2+q),1} \\ &\le C\,\|\nabla_x \psi^\varepsilon(t)\|_{L^2(\mathbb{R}^3)}\,\|\psi^\varepsilon(t)\|_{q,2}\,. \end{aligned}$$

Hence we get, for any $q \in (2,\infty)$,

$$\|\nabla_x V^\varepsilon\|_{q',q,\infty} \le C\,\|\nabla_x \psi^\varepsilon\|_{2,2,2}\,\|\psi^\varepsilon\|_{q^*,q,2}\,, \tag{3.11}$$

since $\frac{1}{q^*}+\frac{1}{2}=\frac{1}{q'}$. Therefore we have

$$\|\nabla_x V^\varepsilon\psi^\varepsilon\|_{1,2,2} \le \|\nabla_x V^\varepsilon\|_{q',q,\infty}\,\|\psi^\varepsilon\|_{q,q^*,2} \le C\,\|\nabla_x\psi^\varepsilon\|_{2,2,2}\,\|\psi^\varepsilon\|_{q^*,q,2}\,\|\psi^\varepsilon\|_{q,q^*,2}\,.$$

Since for any $q\in(2,\infty)$ we have $(q^*)^*=q$, by using (3.3) we obtain

$$\|\nabla_x V^\varepsilon\psi^\varepsilon\|_{1,2,2} \le C\|\nabla_x\psi^\varepsilon\|_{2,2,2}\,.$$

This inequality, combined with the L^2 estimate for (3.10), gives

$$\begin{aligned}\|\nabla_x\psi^\varepsilon\|_{\infty,2,2} &\le \|\nabla_x\psi_0^\varepsilon\|_{L^2(\mathbb{R}^3)} + \|\nabla_x V^\varepsilon\psi^\varepsilon\|_{1,2,2}\\ &\le \|\nabla_x\psi_0^\varepsilon\|_{L^2(\mathbb{R}^3)} + C\,\|\nabla_x\psi^\varepsilon\|_{2,2,2}\,,\end{aligned}$$

which leads, thanks to a Gronwall argument, to

$$\|\nabla_x\psi^\varepsilon\|_{\infty,2,2} + \|\nabla_x V^\varepsilon\psi^\varepsilon\|_{1,2,2} \le C\,. \tag{3.12}$$

In a second step, we apply the Strichartz estimate (A.5) to (3.10) and obtain

$$\forall q\in[2,\infty)\qquad \|\nabla_x\psi^\varepsilon\|_{q^*,q,2} \le C\|\nabla_x\psi_0^\varepsilon\|_{L^2(\mathbb{R}^3)} + C\|V^\varepsilon\nabla_x\psi^\varepsilon\|_{1,2,2} + C\|\nabla_x V^\varepsilon\psi^\varepsilon\|_{1,2,2}\,.$$

Since (3.4) implies

$$\|V^\varepsilon\nabla_x\psi^\varepsilon\|_{1,2,2} \le \|V^\varepsilon\|_{1,\infty,\infty}\,\|\nabla_x\psi^\varepsilon\|_{\infty,2,2} \le C\|\nabla_x\psi^\varepsilon\|_{\infty,2,2}\,,$$

we deduce the estimate (3.7) from (3.6) and (3.12).

For the last step of this proof, we apply a Sobolev estimate pointwise in time to the function

$$u(t,x) = \|\psi^\varepsilon(t,x,\cdot)\|_{L^2(\mathbb{R})}\,.$$

To this aim, by using the Cauchy–Schwarz inequality, we first get

$$|\nabla_x u(t,x)| \le \left(\int |\nabla_x\psi^\varepsilon(t,x,z)|^2\,dz\right)^{1/2},$$

which yields

$$\|u(t,\cdot)\|_{H^1(\mathbb{R}^2)} \le C\|\psi^\varepsilon\|_{\infty,2,2} + C\|\nabla_x\psi^\varepsilon\|_{\infty,2,2} \le C$$

(apply (3.7) with $q=2$ for the last inequality). By Sobolev embeddings, we have

$$\forall p\in[2,\infty)\qquad \|\psi^\varepsilon\|_{\infty,p,2} = \|u\|_{L^\infty_t L^p_x} \le C, \tag{3.13}$$

which can be rewritten

$$\forall q\in[1,\infty)\qquad \left\||\psi^\varepsilon|^2\right\|_{\infty,q,1} \le C\,.$$

From (B.5) we deduce the $L^\infty((0,T)\times\mathbb{R}^3)$ estimate (3.8). Finally, by combining (3.13) and (3.7), we deduce that

$$\forall q\in(1,2)\qquad \left\|\nabla_x\left(|\psi^\varepsilon|^2\right)\right\|_{\infty,q,1} \le \|\psi^\varepsilon\|_{\infty,2q/(2-q),2}\,\|\nabla_x\psi^\varepsilon\|_{\infty,2,2} \le C,$$

and (3.9) is obtained by applying (B.4). ∎

We end this section with a useful lemma concerning the linear Schrödinger equation with a strong confining potential. It states that, up to—at least—the first order in ε, the subspace X^ε is stable under the action of the Schrödinger group.

LEMMA 3.3. *Let $\psi_0^\varepsilon \in L^2(\mathbb{R}^2, X^\varepsilon)$. Assume that $V^\varepsilon \in L^1((0,T), L^\infty(\mathbb{R}^3))$ and that $\partial_z V^\varepsilon \in L^{r',r,\infty}((0,T)\times(\mathbb{R}^3))$ for some $r \in (2,\infty]$. Then any solution ψ^ε of (1.1) satisfies, for all $s \in [2,\infty)$,*

$$\|(\mathbb{I}-\Pi^\varepsilon)\psi^\varepsilon\|_{s^*,s,2} \le C\,\varepsilon\,\|\partial_z V^\varepsilon\|_{r',r,\infty}\,\|\psi_0^\varepsilon\|_{L^2(\mathbb{R}^3)}\,,$$

where C depends only on $\|V^\varepsilon\|_{1,\infty,\infty}$.

Proof. Thanks to the conservation of the L^2 norm for the Schrödinger equation, a solution ψ^ε of (1.1) satisfies

$$\|\psi^\varepsilon\|_{\infty,2,2} \le \|\psi_0^\varepsilon\|_{L^2(\mathbb{R}^3)}.$$

By using (A.5), we get for any $q \in [2,\infty)$

$$\|\psi^\varepsilon\|_{q^*,q,2} \le C\|\psi_0^\varepsilon\|_{L^2(\mathbb{R}^3)} + C\|V^\varepsilon\,\psi^\varepsilon\|_{1,2,2} \le C\|\psi_0^\varepsilon\|_{L^2(\mathbb{R}^3)} \tag{3.14}$$

(in this lemma, C is a generic constant depending only on $\|V^\varepsilon\|_{1,\infty,\infty}$).

Denote $\omega^\varepsilon = (\mathbb{I}-\Pi^\varepsilon)\psi^\varepsilon$. The assumption on ψ_0^ε implies $\omega^\varepsilon(0,x,z) = 0$ for $(x,z)\in\mathbb{R}^3$. Additionally, the operator $\mathbb{I}-\Pi^\varepsilon$ commutes with ∂_t, with Δ_x, and with A^ε (since Π^ε is a spectral projector of A^ε). Hence (1.1) gives, after direct calculations,

$$\begin{cases} i\partial_t\omega^\varepsilon = -\dfrac{1}{2}\Delta_x\omega^\varepsilon + A^\varepsilon\omega^\varepsilon + V^\varepsilon\omega^\varepsilon - [\Pi^\varepsilon, V^\varepsilon]\psi^\varepsilon, \\ \omega^\varepsilon(0,x,z) = 0. \end{cases} \tag{3.15}$$

Because of source terms, the L^2 conservation becomes

$$\|\omega^\varepsilon\|_{\infty,2,2} \le C\,\|[\Pi^\varepsilon, V^\varepsilon]\psi^\varepsilon\|_{1,2,2};$$

thus from (A.5) with $\sigma \in [2,\infty)$ we deduce

$$\|\omega^\varepsilon\|_{\sigma^*,\sigma,2} \le C\,\|[\Pi^\varepsilon, V^\varepsilon]\psi^\varepsilon\|_{1,2,2}\,. \tag{3.16}$$

Additionally, Lemma 2.3 yields

$$\|[\Pi^\varepsilon, V^\varepsilon]\psi^\varepsilon(t,x,\cdot)\|_{L^2(\mathbb{R})} \le C\,\varepsilon\,\|\partial_z V^\varepsilon(t,x,\cdot)\|_{L^\infty(\mathbb{R})}\,\|\psi^\varepsilon(t,x,\cdot)\|_{L^2(\mathbb{R})}.$$

Hence

$$\|[\Pi^\varepsilon, V^\varepsilon]\psi^\varepsilon\|_{1,2,2} \le C\,\varepsilon\,\|\partial_z V^\varepsilon\|_{r',r,\infty}\,\|\psi^\varepsilon\|_{r,r^*,2}.$$

An application of (3.14) with $q = r^*$ gives

$$\|[\Pi^\varepsilon, V^\varepsilon]\psi^\varepsilon\|_{1,2,2} \le C\,\varepsilon\,\|\partial_z V^\varepsilon\|_{r',r,\infty}\,\|\psi_0^\varepsilon\|_{L^2(\mathbb{R}^3)}\,.$$

Therefore we deduce the result from this estimate and (3.16). ∎

4. Existence results for the approximate models. In this section we show that the two approximate models (2.5), (2.6) and (2.2), (2.3) presented in section 2 are well-posed. Let us first remark that the 2.5D adiabatic model can be rewritten as a two-dimensional Schrödinger–Poisson system with a modified Green function. Indeed, denoting $W^\varepsilon(x) = \langle V^\varepsilon | \chi^\varepsilon|^2 \rangle$, (2.5), (2.6) is equivalent to

$$i\partial_t \phi^\varepsilon = -\frac{1}{2}\Delta_x \phi^\varepsilon + W^\varepsilon \phi^\varepsilon, \tag{4.1}$$

$$W^\varepsilon(x) = G^{2.5D} *_x \left(|\phi^\varepsilon|^2\right), \tag{4.2}$$

where

$$G^{2.5D}(x) = \int_{\mathbb{R}}\int_{\mathbb{R}} \frac{1}{4\pi\left(|x|^2 + (z-z')^2\right)^{1/2}} |\chi^\varepsilon(z')|^2 |\chi^\varepsilon(z)|^2 \, dz' \, dz. \tag{4.3}$$

With this formulation, both approximate systems have the same structure; they differ by the kernel of the "Poisson" equation, respectively, $G^{2.5D}(x)$ for (4.1), (4.2) and $G^{2D}(x) = \frac{1}{4\pi|x|}$ for (2.2), (2.3). We shall see below that these kernels share the same properties and that their difference is small (see the proof of Theorem 2.6 in section 4.2).

4.1. A Schrödinger–Poisson system with a general kernel. Let $G^\varepsilon(x)$ be a general convolution kernel such that $G^\varepsilon \in L^1_{loc}(\mathbb{R}^2)$. Consider the system

$$i\partial_t \phi^\varepsilon = -\frac{1}{2}\Delta_x \phi^\varepsilon + W^\varepsilon \phi^\varepsilon, \tag{4.4}$$

$$W^\varepsilon = G^\varepsilon * |\phi^\varepsilon|^2, \tag{4.5}$$

with the initial data $\phi^\varepsilon(0,\cdot) = \phi_0$. In this problem, the dependency of the functions in ε comes from the dependency of G^ε in this parameter. The energy of this system has two terms: the kinetic energy along x and the potential energy, respectively, defined by

$$\mathcal{E}^\varepsilon_{kin}(t) = \frac{1}{2}\int_{\mathbb{R}^2} |\nabla_x \phi^\varepsilon(t,x)|^2 \, dx,$$

$$\mathcal{E}^\varepsilon_{pot}(t) = \frac{1}{2}\int_{\mathbb{R}^2} W^\varepsilon \, n^\varepsilon_s \, dx = \frac{1}{2}\iint_{\mathbb{R}^4} G^\varepsilon(x-x') n^\varepsilon_s(x) n^\varepsilon_s(x') \, dx dx'.$$

By analogy with the function $\frac{1}{|x|}$ (see Lemma B.1), we assume that the kernel G^ε satisfies the following property.

ASSUMPTION 4.1. *The kernel G^ε is a nonnegative, even function which belongs to $L^1_{loc}(\mathbb{R}^2)$. Moreover, we assume the following estimates:*

(i) *For $f \in L^q(\mathbb{R}^2)$ with $1 < q < 2$, we have*

$$\|G^\varepsilon * f\|_{L^{q^\#}(\mathbb{R}^2)} \le C \|f\|_{L^q(\mathbb{R}^2)}, \tag{4.6}$$

where $q^\# = \frac{2q}{2-q}$.

(ii) *For $f \in L^q(\mathbb{R}^2) \cap L^1(\mathbb{R}^2)$ with $2 < q \le +\infty$, the following estimate holds:*

$$\|G^\varepsilon * f\|_{L^\infty(\mathbb{R}^2)} \le C \|f\|^\theta_{L^q(\mathbb{R}^2)} \|f\|^{1-\theta}_{L^1(\mathbb{R}^2)}, \tag{4.7}$$

where $\theta = \frac{q}{2q-2}$. *The constants* C *are assumed independent of* ε *and* f.

Remark. Any kernel of the type $G^\varepsilon(x) = g^\varepsilon(|x|)$, with $g^\varepsilon(|x|)$ satisfying $g^\varepsilon(t) < C/t$, verifies Assumption 4.1.

The following proposition shows that system (4.4), (4.5) is well-posed and gives some ε-independent estimates.

PROPOSITION 4.2. *Under Assumption* 4.1 *and for* $\phi_0 \in H^1(\mathbb{R}^2)$, *system* (4.4), (4.5) *admits a unique global weak solution. Moreover, the total energy of the system is conserved:*

$$\mathcal{E}^\varepsilon_{kin}(t) + \mathcal{E}^\varepsilon_{pot}(t) = \mathcal{E}^\varepsilon_{kin}(0) + \mathcal{E}^\varepsilon_{pot}(0), \tag{4.8}$$

and for any $T > 0$ *the following estimates hold independently of* ε:

$$\|\phi^\varepsilon\|_{L^{q^*}((0,T),W^{1,q}(\mathbb{R}^2))} \le C \qquad \forall q \in [2,\infty), \tag{4.9}$$

$$\|W^\varepsilon\|_{L^\infty((0,T),W^{1,q}(\mathbb{R}^2))} \le C \qquad \forall q \in (2,\infty). \tag{4.10}$$

Proof. The local-in-time existence of a unique weak solution is obtained via a standard fixed point procedure and is only sketched here. For more details we refer to [4, 13]. Denoting $W^\varepsilon(\psi) = G^\varepsilon * |\psi|^2$, it is enough to show that the application $\mathcal{F} : \psi \mapsto W^\varepsilon(\psi)\psi$ is locally Lipschitz in $H^1(\mathbb{R}^2)$ uniformly in time. To this aim, we shall use the following inequalities obtained by simple arguments such as Sobolev embeddings and Cauchy–Schwarz inequalities:

(4.11)
$$\|fg\|_{H^1(\mathbb{R}^2)} \le C\|f\|_{W^{1,4}(\mathbb{R}^2)}\|g\|_{H^1(\mathbb{R}^2)}; \quad \|fg\|_{W^{1,4/3}(\mathbb{R}^2)} \le C\|f\|_{H^1(\mathbb{R}^2)}\|g\|_{H^1(\mathbb{R}^2)}.$$

Let Φ and Ψ be two functions in $H^1(\mathbb{R}^2)$. We have

$$\|\mathcal{F}(\Psi) - \mathcal{F}(\Phi)\|_{H^1(\mathbb{R}^2)} \le \|W^\varepsilon(\Psi)\,(\Psi - \Phi)\,\|_{H^1(\mathbb{R}^2)} + \|\,(W^\varepsilon(\Psi) - W^\varepsilon(\Phi))\,\Phi\|_{H^1(\mathbb{R}^2)}.$$

Using the first inequality of (4.11), the right-hand side is controlled by

$$\|W^\varepsilon(\Psi)\|_{W^{1,4}(\mathbb{R}^2)}\|\Psi - \Phi\|_{H^1(\mathbb{R}^2)} + \|W^\varepsilon(\Psi) - W^\varepsilon(\Phi)\|_{W^{1,4}(\mathbb{R}^2)}\|\Phi\|_{H^1(\mathbb{R}^2)}.$$

Additionally,

$$\begin{aligned}\|W^\varepsilon(\Psi) - W^\varepsilon(\Phi)\|_{W^{1,4}(\mathbb{R}^2)} &\le \left\|G^\varepsilon * \left(|\Psi|^2 - |\Phi|^2\right)\right\|_{W^{1,4}(\mathbb{R}^2)} \\ &\le C\left\||\Psi|^2 - |\Phi|^2|\right\|_{W^{1,4/3}(\mathbb{R}^2)} \\ &\le C\|\Psi - \Phi\|_{H^1(\mathbb{R}^2)}\|\Psi + \Phi\|_{H^1(\mathbb{R}^2)},\end{aligned}$$

where (4.6) is used as well as the second inequality of (4.11). By noticing that $W^\varepsilon(0) = 0$, we conclude that

$$\begin{aligned}\|\mathcal{F}(\Psi) - \mathcal{F}(\Phi)\|_{H^1(\mathbb{R}^2)} \le{}& C\|\Psi\|^2_{H^1(\mathbb{R}^2)}\|\Psi - \Phi\|_{H^1(\mathbb{R}^2)} \\ &+ C\|\Psi - \Phi\|_{H^1(\mathbb{R}^2)}\|\Psi + \Phi\|_{H^1(\mathbb{R}^2)}\|\Phi\|_{H^1(\mathbb{R}^2)},\end{aligned}$$

which proves that $\mathcal{F}$ is locally Lipschitz on $H^1(\mathbb{R}^2)$.

The energy estimate (4.8) shows that the solution is global in time. It can be obtained in a standard manner by multiplying (4.4) by $\partial_t\overline{\phi^\varepsilon}$, integrating on $\mathbb{R}^2$, and

taking the real part. The key point is that the nonlinear term can be written as follows:

$$\begin{aligned}\mathcal{R}e\int_{\mathbb{R}^2} W^\varepsilon\phi^\varepsilon\,\partial_t\overline{\phi}^\varepsilon\,dx &= \int_{\mathbb{R}^2} G^\varepsilon * |\phi^\varepsilon|^2(x)\partial_t|\phi^\varepsilon(x)|^2\,dx\\ &= \frac{1}{4}\frac{d}{dt}\iint_{\mathbb{R}^4} G^\varepsilon(x-x')\,|\phi^\varepsilon(x')|^2\,|\phi^\varepsilon(x)|^2\,dx = \frac{1}{2}\frac{d}{dt}\mathcal{E}^\varepsilon_{pot}(t),\end{aligned}$$

where we have symmetrized the formula by using the properties of G^ε. The proof of (4.9) and (4.10) can be done without any difficulty by an adaptation of Lemma 3.1 and Proposition 3.2. The starting point is the $L^\infty((0,T),H^1(\mathbb{R}^2))$ bound of ϕ^ε given by the energy estimate and the conservation of charge density. Then we use successively Assumption 4.1 and standard Strichartz estimates in dimension 2 (see, for instance, [7]). □

The following proposition shows the Lipschitz dependency of the solution of (4.4), (4.5) with respect to the kernel.

PROPOSITION 4.3. *Let G^ε and $\widetilde{G^\varepsilon}$ satisfy Assumption* 4.1 *such that $G^\varepsilon - \widetilde{G^\varepsilon} \in L^1(\mathbb{R}^2)$. Let $\phi_0 \in H^1(\mathbb{R}^2)$ and denote by $(\phi^\varepsilon, W^\varepsilon)$ and $(\widetilde{\phi^\varepsilon}, \widetilde{W^\varepsilon})$, respectively, the solutions of* (4.4), (4.5) *corresponding to these kernels. Then we have*

$$\|\phi^\varepsilon - \widetilde{\phi^\varepsilon}\|_{L^{q^*}((0,T),W^{1,q}(\mathbb{R}^2))} \le C\|G^\varepsilon - \widetilde{G^\varepsilon}\|_{L^1(\mathbb{R}^2)} \qquad \forall q\in[2,\infty), \tag{4.12}$$

$$\|W^\varepsilon - \widetilde{W^\varepsilon}\|_{L^q((0,T),L^\infty(\mathbb{R}^2))} \le C\|G^\varepsilon - \widetilde{G^\varepsilon}\|_{L^1(\mathbb{R}^2)} \qquad \forall q\in[1,\infty), \tag{4.13}$$

where C is independent of ε.

Proof. Let us denote $\eta = \|G^\varepsilon - \widetilde{G^\varepsilon}\|_{L^1(\mathbb{R}^2)}$. For any function $f \in L^p(\mathbb{R}^2)$, $p \in [1,+\infty]$, we have

$$\left\|(G^\varepsilon - \widetilde{G^\varepsilon}) * f\right\|_{L^p(\mathbb{R}^2)} \le \eta\,\|f\|_{L^p(\mathbb{R}^2)}. \tag{4.14}$$

Setting

$$R^\varepsilon(x) = (G^\varepsilon - \widetilde{G^\varepsilon}) * |\widetilde{\phi}^\varepsilon|^2,$$

we have

$$W^\varepsilon - \widetilde{W}^\varepsilon = G^\varepsilon * \left(|\phi^\varepsilon|^2 - |\widetilde{\phi}^\varepsilon|^2\right) + R^\varepsilon. \tag{4.15}$$

By applying (4.9) and the Sobolev embeddings $W^{1,2}(\mathbb{R}^2) \hookrightarrow L^q(\mathbb{R}^2)$ for all $q \in [2,+\infty)$, and $W^{1,p}(\mathbb{R}^2) \hookrightarrow L^\infty(\mathbb{R}^2)$ for all $p > 2$, we have

$$\|\widetilde{\phi}^\varepsilon\|_{L^\infty((0,T),L^q(\mathbb{R}^2))} + \|\widetilde{\phi}^\varepsilon\|_{L^q((0,T),L^\infty(\mathbb{R}^2))} \le C \qquad \forall q\in[2,\infty). \tag{4.16}$$

Therefore (4.14) yields, for any $q \in [2,\infty)$,

$$\|R^\varepsilon\|_{L^\infty((0,T),L^q(\mathbb{R}^2))} + \|R^\varepsilon\|_{L^q((0,T),L^\infty(\mathbb{R}^2))} \le C\eta. \tag{4.17}$$

In order to estimate the difference $W^\varepsilon - \widetilde{W}^\varepsilon$, we set $u^\varepsilon := \phi^\varepsilon - \widetilde{\phi}^\varepsilon$. This function solves

$$\begin{cases} i\partial_t u^\varepsilon = -\dfrac{1}{2}\Delta_x u^\varepsilon + W^\varepsilon u^\varepsilon + (W^\varepsilon - \widetilde{W}^\varepsilon)\widetilde{\phi}^\varepsilon,\\ u^\varepsilon(0,\cdot) \equiv 0. \end{cases} \tag{4.18}$$

Thanks to (4.16) we deduce that for any $p \in (2,\infty]$ and any $t \in [0,T]$

$$\|u^\varepsilon\|_{L^\infty((0,t),L^2(\mathbb{R}^2))} \leq C\|W^\varepsilon - \widetilde{W}^\varepsilon\|_{L^1((0,t),L^p(\mathbb{R}^2))}, \tag{4.19}$$

and, by using (4.10) and Strichartz estimates in dimension 2 [7], we deduce that for any $s \in [2,\infty)$ and $q \in (2,\infty]$ we have

$$\|u^\varepsilon\|_{L^{s^*}((0,t),L^s(\mathbb{R}^2))} \leq C\|W^\varepsilon - \widetilde{W}^\varepsilon\|_{L^1((0,t),L^q(\mathbb{R}^2))}. \tag{4.20}$$

Let $q \in (2,+\infty)$. By using (4.16) (and the same estimate for ϕ^ε) and (4.19), we obtain

$$\left\||\phi^\varepsilon|^2 - |\widetilde{\phi}^\varepsilon|^2\right\|_{L^\infty((0,t),L^s(\mathbb{R}^2))} \leq C\|W^\varepsilon - \widetilde{W}^\varepsilon\|_{L^1((0,t),L^q(\mathbb{R}^2))}, \tag{4.21}$$

where $s = \frac{2q}{2+q}$. By (4.6), we deduce

$$\left\|G^\varepsilon * \left(|\phi^\varepsilon|^2 - |\widetilde{\phi}^\varepsilon|^2\right)\right\|_{L^q(\mathbb{R}^2)}(t) \leq C\int_0^t \|W^\varepsilon - \widetilde{W}^\varepsilon\|_{L^q(\mathbb{R}^2)}(\tau)\,d\tau.$$

Consequently (4.15) yields

$$\|W^\varepsilon - \widetilde{W}^\varepsilon\|_{L^q(\mathbb{R}^2)}(t) \leq C\int_0^t \|W^\varepsilon - \widetilde{W}^\varepsilon\|_{L^q(\mathbb{R}^2)}(\tau)\,d\tau + \|R^\varepsilon\|_{L^q(\mathbb{R}^2)}(t).$$

Thanks to (4.17), we deduce from a Gronwall argument applied to the above inequality that

$$\|W^\varepsilon - \widetilde{W}^\varepsilon\|_{L^\infty((0,T),L^q(\mathbb{R}^2))} \leq C\eta \qquad \forall q \in (2,\infty). \tag{4.22}$$

From this estimate together with (4.20), (4.16), and (4.19), we deduce that for any $r \in (2,\infty)$, $s \in (2,r^*)$, we have

$$\left\||\phi^\varepsilon|^2 - |\widetilde{\phi}^\varepsilon|^2\right\|_{L^r((0,T),L^s(\mathbb{R}^2))} + \left\||\phi^\varepsilon|^2 - |\widetilde{\phi}^\varepsilon|^2\right\|_{L^\infty((0,T),L^1(\mathbb{R}^2))} < C\eta,$$

which leads to (4.13) in view of (4.15), (4.7), and (4.17).

Let us now improve the estimate on $\phi^\varepsilon - \widetilde{\phi}^\varepsilon$ and show that (4.12) holds. To this aim, we first differentiate (4.18) with respect to x and obtain

$$\begin{cases} i\partial_t v^\varepsilon = -\dfrac{1}{2}\Delta_x v^\varepsilon + W^\varepsilon v^\varepsilon + (\nabla_x W^\varepsilon)u^\varepsilon, + (\nabla_x W^\varepsilon - \nabla_x \widetilde{W}^\varepsilon)\widetilde{\phi}^\varepsilon + (W^\varepsilon - \widetilde{W}^\varepsilon)\nabla_x\widetilde{\phi}^\varepsilon, \\ v^\varepsilon(0,\cdot) \equiv 0, \end{cases} \tag{4.23}$$

where we have denoted $v^\varepsilon = \nabla_x u^\varepsilon$. By combining (4.9), (4.10), (4.20), and (4.22), we get

$$\|(\nabla_x W^\varepsilon)u^\varepsilon + (W^\varepsilon - \widetilde{W}^\varepsilon)\nabla_x\widetilde{\phi}^\varepsilon\|_{L^1((0,T),L^2(\mathbb{R}^2))} \leq C\eta;$$

thus, for any $q \in (2,\infty]$ and $t \in [0,T]$, we have

$$\|v^\varepsilon\|_{L^2(\mathbb{R}^2)}(t) \leq C\eta + C\|\nabla_x W^\varepsilon - \nabla_x\widetilde{W}^\varepsilon\|_{L^1((0,t),L^q(\mathbb{R}^2))}. \tag{4.24}$$

Additionally, by (4.9) and (4.16) and Young's inequality (4.14), we get

$$\left\|(G^\varepsilon - \widetilde{G^\varepsilon}) * \nabla_x |\widetilde{\phi}^\varepsilon|^2\right\|_{L^r((0,t),L^q(\mathbb{R}^2))} \leq C\eta \qquad \forall q \in (2,\infty), \quad \forall r \in [1,q^*).$$

Moreover, using (4.16), (4.9), and (4.20), we have for any $s \in (1,2)$

$$\left\|\nabla_x \left(|\phi^\varepsilon|^2 - |\widetilde{\phi}^\varepsilon|^2\right)\right\|_{L^1((0,t),L^s(\mathbb{R}^2))} \leq C\eta + C\|v^\varepsilon\|_{L^1((0,T),L^2(\mathbb{R}^2))}.$$

Thus, writing

$$\nabla_x W^\varepsilon - \nabla_x \widetilde{W}^\varepsilon = G^\varepsilon * \nabla_x \left(|\phi^\varepsilon|^2 - |\widetilde{\phi}^\varepsilon|^2\right) + (G^\varepsilon - \widetilde{G^\varepsilon}) * \nabla_x |\widetilde{\phi}^\varepsilon|^2 \tag{4.25}$$

and using (4.6), we deduce that for any $q \in (2,\infty)$

$$\left\|\nabla_x W^\varepsilon - \nabla_x \widetilde{W}^\varepsilon\right\|_{L^1((0,t),L^q(\mathbb{R}^2))} \leq C\eta + C\|v^\varepsilon\|_{L^1((0,t),L^2(\mathbb{R}^2))}.$$

Inserting this inequality in (4.24) leads, through a Gronwall argument, to

$$\|v^\varepsilon\|_{L^\infty((0,T),L^2(\mathbb{R}^2))} \leq C\eta.$$

Going back to (4.23), it is readily seen from the above two estimates and from Proposition 4.2 that

$$\left\|i\partial_t v^\varepsilon + \frac{1}{2}\Delta v^\varepsilon\right\|_{L^1((0,T),L^2(\mathbb{R}^2))} \leq C\eta,$$

which leads to (4.12) through a Strichartz estimate. ∎

In section 6, in order to get estimate (2.14), we will need to deal with strong solutions.

LEMMA 4.4. *Under Assumption* 4.1, *let* $\phi_0 \in H^2(\mathbb{R}^2)$. *Then for any* $T > 0$ *the solution* ϕ^ε *of* (4.4), (4.5) *belongs to* $L^\infty((0,T),H^2(\mathbb{R}^2))$ *and its norm is bounded independently of* ε.

Proof. Denote $u^\varepsilon = \Delta_x \phi^\varepsilon$. By differentiating twice (4.4) with respect to x, we get

$$i\partial_t u^\varepsilon = -\frac{1}{2}\Delta_x u^\varepsilon + W^\varepsilon u^\varepsilon + 2\nabla_x W^\varepsilon \cdot \nabla_x \phi^\varepsilon + \Delta_x W^\varepsilon \phi^\varepsilon.$$

The source term in this Schrödinger equation on u^ε is written as

$$2\nabla_x W^\varepsilon \cdot \nabla_x \phi^\varepsilon + \phi^\varepsilon G^\varepsilon * \left(2|\nabla_x \phi^\varepsilon|^2\right) + 2\phi^\varepsilon \, \mathcal{R}e\, G^\varepsilon * \left(\overline{\phi^\varepsilon} u^\varepsilon\right).$$

The first term $\nabla_x W^\varepsilon \cdot \nabla_x \phi^\varepsilon$ can be estimated thanks to (4.9) and (4.10):

$$\|\nabla_x W^\varepsilon \cdot \nabla_x \phi^\varepsilon\|_{L^1((0,t),L^2(\mathbb{R}^2))} \leq \|\nabla_x W^\varepsilon\|_{L^{4/3}((0,t),L^4(\mathbb{R}^2))} \|\nabla_x \phi^\varepsilon\|_{L^4((0,t),L^4(\mathbb{R}^2))} \leq C.$$

The second term can be estimated thanks to (4.6):

$$\begin{aligned}
&\left\|\phi^\varepsilon G^\varepsilon * \left(2|\nabla_x \phi^\varepsilon|^2\right)\right\|_{L^1((0,t),L^2(\mathbb{R}^2))} \\
&\qquad \leq \|\phi^\varepsilon\|_{L^{3/2}((0,t),L^3(\mathbb{R}^2))} \left\|G^\varepsilon * \left(2|\nabla_x \phi^\varepsilon|^2\right)\right\|_{L^3((0,t),L^6(\mathbb{R}^2))} \\
&\qquad \leq C\|\phi^\varepsilon\|_{L^{3/2}((0,t),L^3(\mathbb{R}^2))} \|\nabla_x \phi^\varepsilon\|^2_{L^6((0,t),L^3(\mathbb{R}^2))} \leq C.
\end{aligned}$$

To treat the third term, we also apply (4.6), (4.9), and (4.10):

$$\begin{aligned}
&\|\phi^\varepsilon G^\varepsilon * (2\phi^\varepsilon u^\varepsilon)\|_{L^1((0,t),L^2(\mathbb{R}^2))} \\
&\qquad \le C\|\phi^\varepsilon\|_{L^\infty((0,t),L^3(\mathbb{R}^2))}\ \|G^\varepsilon * (2\phi^\varepsilon u^\varepsilon)\|_{L^1((0,t),L^6(\mathbb{R}^2))} \\
&\qquad \le C\|\phi^\varepsilon\|_{L^\infty((0,t),L^3(\mathbb{R}^2))}\ \|\phi^\varepsilon\|_{L^\infty((0,t),L^6(\mathbb{R}^2)}\ \|u^\varepsilon\|_{L^1((0,t),L^2(\mathbb{R}^2))} \\
&\qquad \le C\,\|u^\varepsilon\|_{L^1((0,t),L^2(\mathbb{R}^2))}\,.
\end{aligned}$$

Hence, for any $t \le T$,

$$\|u^\varepsilon(t)\|_{L^2(\mathbb{R}^2)} \le C + C\int_0^t \|u^\varepsilon(\tau)\|_{L^2(\mathbb{R}^2)}\ d\tau,$$

which leads to the result thanks to a Gronwall argument. ∎

4.2. Application: Proof of Theorem 2.6. Thanks to Lemma B.1 given in Appendix B, the kernel

$$G^{2D}(x) = \frac{1}{4\pi|x|}$$

of the 2D surface density model (2.2)–(2.3) clearly satisfies Assumption 4.1. Moreover, by using Lemma B.2 and the fact that $\int_{\mathbb{R}} |\chi^\varepsilon|^2 dz = 1$, it is readily seen that the kernel of the 2.5D adiabatic model given by

$$G^{2.5D}(x) = \iint_{\mathbb{R}^2} \frac{1}{4\pi\left(|x|^2 + (z-z')^2\right)^{1/2}} |\chi^\varepsilon(z')|^2\, |\chi^\varepsilon(z)|^2\, dz'\, dz$$

also satisfies Assumption 4.1. Therefore an application of Proposition 4.2 gives the existence of unique weak solutions and estimates independent of ε for the two approximate models. The first parts of Theorems 2.5 and 2.6 are thus proved.

To conclude the proof of Theorem 2.6, it suffices to apply Proposition 4.3. Indeed, setting

$$\begin{aligned}
H^\varepsilon(x) &= \frac{1}{4\pi|x|} - G^{2.5D}(x) \\
&= \frac{1}{4\pi|x|} - \iint_{\mathbb{R}^2} \frac{1}{4\pi\left(|x|^2 + (z-z')^2\right)^{1/2}} |\chi^\varepsilon(z')|^2\, |\chi^\varepsilon(z)|^2\, dz\, dz' \\
&= \frac{1}{4\pi} \iint_{\mathbb{R}^2} \int_0^{\varepsilon|z-z'|} \frac{\xi}{(|x|^2+\xi^2)^{3/2}} |\chi(z)|^2\, |\chi(z')|^2\, d\xi\, dz\, dz',
\end{aligned}$$

and noticing that

$$\int_{\mathbb{R}^2} \frac{\xi}{(|x|^2+\xi^2)^{3/2}}\, dx = 2\pi \quad \text{for } \xi > 0,$$

we deduce from (2.1) that

$$\|H^\varepsilon\|_{L^1(\mathbb{R}^2)} = \frac{\varepsilon}{2} \iint_{\mathbb{R}^2} |z-z'|\, |\chi(z)|^2\, |\chi(z')|^2\, dz\, dz' = C\varepsilon.$$

This leads to (2.10), from which we deduce (2.12). In order to prove (2.11), we write

$$V^{2.5D} - V^{2D} = \frac{1}{4\pi r} *_x \left(n_s^{2.5D} - n_s^{2D}\right) + \widetilde{H^\varepsilon} *_x n_s^{2.5D},$$

where

$$\widetilde{H^\varepsilon}(x,z) = -\frac{1}{4\pi r} + \frac{1}{4\pi r} *_z |\chi^\varepsilon|^2. \tag{4.26}$$

It is then enough to remark that

$$\begin{aligned}\left\| \frac{1}{4\pi r} *_x \left(n_s^{2.5D} - n_s^{2D}\right)\right\|_{L^q((0,T),L^\infty(\mathbb{R}^3))} &\le \left\| \frac{1}{4\pi|x|} *_x \left(n_s^{2.5D} - n_s^{2D}\right)\right\|_{L^q((0,T),L^\infty(\mathbb{R}^2))} \\ &\le C\varepsilon\end{aligned}$$

and that

$$\widetilde{H^\varepsilon}(x,z) = \int_{\mathbb{R}} \int_{(z-z')} \frac{\xi}{(|x|^2+\xi^2)^{3/2}} |\chi^\varepsilon(z')|^2 \, d\xi \, dz',$$

which implies

$$\begin{aligned}&|\widetilde{H^\varepsilon} *_x n_s^{2.5D}|(t,x,z) \\ &\quad \le \|n_s^{2.5D}(t,\cdot)\|_{L^\infty(\mathbb{R}^2)} \int_{\mathbb{R}} \int_{min(z,z-z')}^{max(z,z-z')} \int_{\mathbb{R}^2} \frac{|\xi|}{(|x|^2+\xi^2)^{3/2}} |\chi^\varepsilon(z')|^2 \, dx d\xi dz', \\ &\quad = 2\pi \|n_s^{2.5D}(t,\cdot)\|_{L^\infty(\mathbb{R}^2)} \int_{\mathbb{R}} |z'| \, |\chi^\varepsilon(z')|^2 \, dz' = C\varepsilon \|n_s^{2.5D}(t,\cdot)\|_{L^\infty(\mathbb{R}^2)},\end{aligned}$$

and the right-hand side is an $O(\varepsilon)$ is view of (2.12).

5. The 2.5D adiabatic model is a second-order approximation. In this section we end the proof of Theorem 2.5 initiated in section 4.2. Consider the solution ψ^{3D}, V^{3D} of (1.1)–(1.3) with the initial data $\psi_0^\varepsilon = \phi_0 \, \chi^\varepsilon$ and the solution $\phi^{2.5D}$, $V^{2.5D}$ of (2.5), (2.6) corresponding to the initial data ϕ_0. Assumption 2.4 leads in particular to the uniform-in-ε estimate

$$\|\psi_0^\varepsilon\|_{L^2(\mathbb{R}^3)} + \|\nabla_x \psi_0^\varepsilon\|_{L^2(\mathbb{R}^3)} \le C.$$

Proposition 3.2 then implies the following uniform bounds:

$$\|V^{3D}\|_{L^\infty((0,T)\times\mathbb{R}^3)} + \|\nabla_{x,z} V^{3D}\|_{\infty,q,\infty} \le C, \qquad 2 < q < \infty, \tag{5.1}$$

$$\|\psi^{3D}\|_{q^*,q,2} + \|\nabla_x \psi^{3D}\|_{q^*,q,2} \le C, \qquad 2 \le q < \infty. \tag{5.2}$$

Furthermore, Lemma 3.3 implies

$$\left\|(\mathbb{I} - \Pi^\varepsilon)\, \psi^{3D}\right\|_{q^*,q,2} = \mathcal{O}(\varepsilon), \qquad 2 \le q < \infty. \tag{5.3}$$

We start by proving (2.8). To this aim, we write

$$\begin{aligned} V^{3D} - V^{2.5D} &= \frac{1}{4\pi r} * \left(n^{3D} - n^{2.5D}\right) \\ &= \frac{1}{4\pi r} * \left(|\Pi^\varepsilon \psi^{3D}|^2 - |\chi^\varepsilon \phi^{2.5D}|^2\right) + R_a^\varepsilon + R_b^\varepsilon, \end{aligned} \tag{5.4}$$

where the remainder terms are

$$R_a^\varepsilon = \frac{1}{4\pi r} * |\left(\mathbb{I} - \Pi^\varepsilon\right)\psi^{3D}|^2; \quad R_b^\varepsilon = \frac{2}{4\pi r} * \mathcal{R}e\left(\overline{\Pi^\varepsilon \psi^{3D}}\left(\mathbb{I} - \Pi^\varepsilon\right)\psi^{3D}\right).$$

Estimating the remainders R^ε and R^ε. On the one hand, estimates (5.3), (B.3), and (B.5) lead to

$$\|R_a^\varepsilon\|_{1,q,\infty} \leq C\varepsilon^2 \qquad \forall q \in (2,\infty]. \tag{5.5}$$

On the other hand, by orthogonality we have $\langle \overline{\Pi^\varepsilon \psi^{3D}}\left(\mathbb{I} - \Pi^\varepsilon\right)\psi^{3D}\rangle = 0$. Consequently, (B.9) implies for any $q \in (2,\infty)$ and pointwise in time

$$\|R_b^\varepsilon\|_{L^\infty(\mathbb{R}^3)} \leq C\,\|z\chi^\varepsilon\|_{L^2(\mathbb{R})}^{1-2/q}\,\left\|\psi^{3D}\right\|_{2q,2}\left\|\left(\mathbb{I} - \Pi^\varepsilon\right)\psi^{3D}\right\|_{2q,2}.$$

Additionally, we deduce from (5.2) and the Sobolev embedding $H^1(\mathbb{R}^2) \hookrightarrow L^q(\mathbb{R}^2)$ that

$$\left\|\psi^{3D}\right\|_{\infty,q,2} \leq \left\|\psi^{3D}\right\|_{L^\infty((0,T),H^1(\mathbb{R}^2,L^2(\mathbb{R})))} \leq C. \tag{5.6}$$

Moreover, by (2.1) we have $\|z\chi^\varepsilon\|_{L^2(\mathbb{R})}^{1-2/q} = \mathcal{O}(\varepsilon^{1-2/q})$; therefore

$$\|R_b^\varepsilon\|_{L^\infty(\mathbb{R}^3)}(t) \leq C\varepsilon^{1-2/q}\left\|\left(\mathbb{I} - \Pi^\varepsilon\right)\psi^{3D}\right\|_{2q,2}(t).$$

Similarly, by (B.8), we have for any $\alpha \in (0,1)$ and $q \in [2,\infty)$

$$\begin{aligned}\|R_b^\varepsilon\|_{q,\infty}(t) &\leq C\,\|z\chi^\varepsilon\|_{L^2(\mathbb{R})}^{1-\alpha}\,\left\|\psi^{3D}\right\|_{\frac{4q}{2+\alpha q},2}(t)\left\|\left(\mathbb{I} - \Pi^\varepsilon\right)\psi^{3D}\right\|_{\frac{4q}{2+\alpha q},2}(t)\\ &\leq C\varepsilon^{1-\alpha}\,\left\|\left(\mathbb{I} - \Pi^\varepsilon\right)\psi^{3D}\right\|_{\frac{4q}{2+\alpha q},2}(t).\end{aligned}$$

By (5.3), we finally get

$$\forall \alpha \in (0,1), \quad \forall q \in [2,\infty], \qquad \|R_b^\varepsilon\|_{1,q,\infty} \leq C\varepsilon^{2-\alpha}, \tag{5.7}$$

where the constant C depends only on α.

Estimating the first term in the right-hand side of (5.4). We shall estimate the difference

$$w^\varepsilon := \Pi^\varepsilon\psi^{3D} - \chi^\varepsilon\phi^{2.5D}e^{-iE^\varepsilon t}.$$

To this aim, we notice that

$$\begin{cases} i\partial_t w^\varepsilon = -\dfrac{1}{2}\Delta_x w^\varepsilon + A^\varepsilon w^\varepsilon + \langle V^{3D}|\chi^\varepsilon|^2\rangle w^\varepsilon + f^\varepsilon + g^\varepsilon, \\ \omega^\varepsilon(0,x,z) = 0, \end{cases} \tag{5.8}$$

where

$$f^\varepsilon = \langle\left(V^{3D} - V^{2.5D}\right)|\chi^\varepsilon|^2\rangle\chi^\varepsilon\phi^{2.5D}e^{-iE^\varepsilon t}; \quad g^\varepsilon = \Pi^\varepsilon V^{3D}(\mathbb{I} - \Pi^\varepsilon)\psi^{3D}.$$

Standard L^2 estimates for a Schrödinger equation with a source term then imply

$$\|w^\varepsilon\|_{\infty,2,2} \leq \|f^\varepsilon\|_{1,2,2} + \|g^\varepsilon\|_{1,2,2}.$$

Remarking that

$$\Pi^\varepsilon V^{3D}(\mathbb{I}-\Pi^\varepsilon)=\Pi^\varepsilon[\Pi^\varepsilon,V^{3D}](\mathbb{I}-\Pi^\varepsilon),$$

we deduce from Lemma 2.3, (5.1), and (5.3) that

$$\|g^\varepsilon\|_{1,2,2}\le C\varepsilon\|\partial_z V^{3D}\|_{4/3,4,\infty}\|(\mathbb{I}-\Pi^\varepsilon)\psi^{3D}\|_{4,4,2}=\mathcal{O}(\varepsilon^2).$$

Additionally, in the same spirit as the proof of (5.6), by applying (4.9) and standard Sobolev embeddings, we get

$$\left\|\phi^{2.5D}\right\|_{L^\infty((0,T),L^q(\mathbb{R}^2))}\le C\qquad\forall q\in[2,\infty). \tag{5.9}$$

Therefore, it can be easily seen that for any $q\in(2,\infty]$ we have

$$\|f^\varepsilon\|_{1,2,2}\le C\|V^{3D}-V^{2.5D}\|_{1,q,\infty},$$

and we finally obtain

$$\|w^\varepsilon\|_{\infty,2,2}\le C\|V^{3D}-V^{2.5D}\|_{1,q,\infty}+\mathcal{O}(\varepsilon^2). \tag{5.10}$$

Applying the Strichartz inequality (A.5) to (5.8) after having noticed estimate (5.1), we obtain for any $q\in(2,\infty]$, $s\in[2,\infty)$,

$$\|w^\varepsilon\|_{s^*,s,2}\le C\|V^{3D}-V^{2.5D}\|_{1,q,\infty}+\mathcal{O}(\varepsilon^2). \tag{5.11}$$

This gives the following estimate for the first term of the right-hand side of (5.4), for any $q\in(2,\infty)$:

$$\begin{aligned}\left\||\Pi^\varepsilon\psi^{3D}|^2-|\chi^\varepsilon\phi^{2.5D}|^2\right\|_{\frac{2q}{2+q},1}(t)&\le\left(\|\psi^{3D}\|_{\infty,q,2}+\|\phi^{2.5D}\|_{L^\infty((0,t),L^q(\mathbb{R}^2))}\right)\|w^\varepsilon\|_{\infty,2,2}\\&\le C\int_0^t\|V^{3D}-V^{2.5D}\|_{q,\infty}(\tau)\,d\tau+\mathcal{O}(\varepsilon^2),\end{aligned}$$

where we used (5.6), (5.9), and (5.10).

End of the proof. By applying (B.3), we deduce

$$\left\|\frac{1}{r}*\left(|\Pi^\varepsilon\psi^{3D}|^2-|\chi^\varepsilon\phi^{2.5D}|^2\right)\right\|_{q,\infty}(t)\le C\int_0^t\|V^{3D}-V^{2.5D}\|_{q,\infty}(\tau)\,d\tau+\mathcal{O}(\varepsilon^2),$$

where $q\in(2,\infty)$. Consequently, (5.4) yields

$$\begin{aligned}\|(V^{3D}-V^{2.5D})\|_{q,\infty}(t)\le\;& C\int_0^t\|(V^{3D}-V^{2.5D})\|_{q,\infty}(\tau)\,d\tau\\&+\|R_a^\varepsilon\|_{q,\infty}(t)+\|R_b^\varepsilon\|_{q,\infty}(t)+O(\varepsilon^2).\end{aligned}$$

Recalling estimates (5.5) and (5.7) for the remainders, a Gronwall argument leads to the bound

$$\|(V^{3D}-V^{2.5D})\|_{\infty,q,\infty}\le C\varepsilon^{2-\alpha}\qquad\forall q\in(2,\infty),\quad\forall\alpha\in(0,1).$$

To conclude the proof, we insert this estimate into (5.11) and obtain

$$\|w^\varepsilon\|_{s^*,s,2}\le C\varepsilon^{2-\alpha}\qquad\forall s\in[2,\infty),\quad\forall\alpha\in(0,1).$$

Then we now have, for any $q \in [2,\infty)$ and $s < q^*$,

$$\left\| |\Pi^\varepsilon \psi^{3D}|^2 - |\chi^\varepsilon \phi^{2.5D}|^2 \right\|_{s,q,1} \leq C\varepsilon^{2-\alpha} \qquad \forall \alpha \in (0,1)$$

and we apply (B.5). By using again (5.4), (5.5), and (5.7), we find (2.8).

In order to prove (2.7), we simply remark that

$$\|\psi^{3D} - \phi^{2.5D}\chi^\varepsilon\, e^{-itE/\varepsilon^2}\|_{q^*,q,2} \leq \|w_\varepsilon\|_{q^*,q,2} + \|(\mathbb{I} - \Pi^\varepsilon)\psi^{3D}\|_{q^*,q,2},$$

then use (5.3) and (5.11). To prove (2.9), we remark that

$$n_s^{3D} - n_s^{2.5D} = |\Pi^\varepsilon \psi^{3D}|^2 - |\chi^\varepsilon \phi^{2.5D}|^2 + |\left(\mathbb{I} - \Pi^\varepsilon\right)\psi^{3D}|^2.$$

6. The 2D surface density model is a first-order approximation. In this section we prove Theorem 2.7, which gives estimates from below, showing that the accuracy of the limit model is exactly $\mathcal{O}(\varepsilon)$. We denote by $\phi^{2.5D}$, $V^{2.5D}$ and by ϕ^{2D}, V^{2D}, respectively, the solutions of (2.5), (2.6) and (2.2), (2.4). For notational simplicity, we denote

$$V_0^{2.5D}(t,x) = V^{2.5D}(t,x,0); \quad V_0^{2D} = V^{2D}(t,x,0).$$

Since we assume that the initial data ϕ_0 belongs to $H^2(\mathbb{R}^2)$, an application of Lemma 4.4 gives

$$\|\phi^{2.5D}\|_{L^\infty((0,T),H^2(\mathbb{R}^2))} + \|\phi^{2D}\|_{L^\infty((0,T),H^2(\mathbb{R}^2))} \leq C. \tag{6.1}$$

Moreover, with (2.10) and the Sobolev embedding $H^1(\mathbb{R}^2) \hookrightarrow L^{2q}(\mathbb{R}^2)$, we obtain

$$\|n_s^{2.5D} - n_s^{2D}\|_{L^\infty((0,T),L^q(\mathbb{R}^2))} \leq C\varepsilon \qquad \forall q \in [1,\infty). \tag{6.2}$$

Now we recall that

$$V_0^{2.5D} - V_0^{2D} = \frac{1}{4\pi|x|} *_x \left(n_s^{2.5D} - n_s^{2D}\right) + \widetilde{H^\varepsilon}(\cdot,0) *_x |\phi^{2.5D}|^2,$$

where $\widetilde{H^\varepsilon}$ is defined in (4.26). Hence, pointwise in time we get

$$\begin{aligned} \|V_0^{2.5D} - V_0^{2D}\|_{L^\infty(\mathbb{R}^2)} + \left\| \frac{1}{4\pi|x|} *_x \left(n_s^{2.5D} - n_s^{2D}\right)\right\|_{L^\infty(\mathbb{R}^2)} \\ \geq \left\| \widetilde{H^\varepsilon}(\cdot,0) *_x |\phi^{2.5D}|^2 \right\|_{L^\infty(\mathbb{R}^2)}. \end{aligned} \tag{6.3}$$

Additionally, a straightforward calculation leads to

$$i\partial_t(x\phi^{2.5D}) = -\frac{1}{2}\Delta_x(x\phi^{2.5D}) + V^{2.5D}(x\phi^{2.5D}) + \nabla_x \phi^{2.5D};$$

thus

$$\|x\phi^{2.5D}\|_{L^\infty((0,T),L^2(\mathbb{R}^2))} \leq \|x\phi_0\|_{L^2(\mathbb{R}^2)} + \|\nabla_x \phi^{2.5D}\|_{L^1((0,T),L^2(\mathbb{R}^2))} \leq C,$$

where we used (4.9). For any $R > 0$, let us denote $\mathcal{B}_R = \{x \in \mathbb{R}^2, |x| < R\}$. We have

$$\begin{aligned} \|\phi^{2.5D}\|^2_{L^\infty((0,T),L^2(\mathcal{B}_R))} &\geq \|\phi_0\|^2_{L^2(\mathbb{R}^2)} - \frac{1}{R^2}\|x\phi^{2.5D}\|^2_{L^\infty((0,T),L^2(\mathbb{R}^2)} \\ &\geq \|\phi_0\|^2_{L^2(\mathbb{R}^2)} - \frac{C}{R^2}. \end{aligned}$$

Since by assumption we have $\|\phi_0\|_{L^2(\mathbb{R}^2))} = 2\eta > 0$, by choosing R large enough we have

$$\|\phi^{2.5D}\|_{L^\infty((0,T),L^2(\mathcal{B}_R))} > \eta;$$

then

$$\forall t \in [0,T], \qquad \max_{\mathcal{B}_R} |\phi^{2.5D}(t,\cdot)|^2 > \frac{\eta^2}{\pi R^2}.$$

By using (6.1) and the Sobolev embedding $H^2(\mathbb{R}^2) \hookrightarrow C^{0,1/2}(\mathbb{R}^2)$, we deduce finally that there exists $r_0 > 0$, $\alpha > 0$ and $x_0(t) \in \mathbb{R}^2$ defined almost everywhere such that, for a.e. $t \in [0,T]$, we have

$$|\phi^{2.5D}|^2(t,x) > \alpha \quad \forall x \in \mathbb{R}^2 \quad \text{such that } |x - x_0(t)| < r_0. \tag{6.4}$$

For $t \in [0,T]$, we have

$$\begin{aligned}
&\left|\widetilde{H^\varepsilon}(\cdot,0) *_x |\phi^{2.5D}|^2\right|(x_0(t)) \\
&= \int_{\mathbb{R}^2}\int_{\mathbb{R}}\int_0^{\varepsilon|z'|} \frac{\xi}{(|x'|^2+\xi^2)^{3/2}} |\chi(z')|^2 |\phi^{2.5D}(x_0(t)-x')|^2 \, d\xi dz' dx' \\
&\geq 2\pi\alpha \int_{\mathbb{R}}\int_0^{\varepsilon|z'|}\int_{r=0}^{r_0} \frac{r\xi}{(r^2+\xi^2)^{3/2}} |\chi(z')|^2 \, dr d\xi dz' \\
&= 2\pi\alpha \int_{\mathbb{R}} \varepsilon|z'| \left(1 - \frac{\varepsilon|z'|}{r_0^2 + (r_0^2+\varepsilon^2|z'|^2)^{1/2}}\right) |\chi(z')|^2 \, dz' \\
&\geq C_1\varepsilon - C_2\varepsilon^2 \geq C_0\varepsilon,
\end{aligned}$$

where $C_0 > 0$ and ε is small enough. Therefore, by applying (6.3) and using (B.2), we have for $t \in [0,T]$,

$$\|V_0^{2.5D} - V_0^{2D}\|_{L^\infty(\mathbb{R}^2)} + \left\|n_s^{2.5D} - n_s^{2D}\right\|_{L^q(\mathbb{R}^2)}^{\theta} \left\|n_s^{2.5D} - n_s^{2D}\right\|_{L^1(\mathbb{R}^2)}^{1-\theta} \geq C\varepsilon,$$

with any $2 < q < \infty$ and $\theta = \frac{q}{2q-2}$. Bounding $\left\|n_s^{2.5D} - n_s^{2D}\right\|_{L^1(\mathbb{R}^2)}$ by $C\varepsilon$ in view of (6.2), one deduces for any $q \in (2,\infty)$

$$\frac{\|V_0^{2.5D} - V_0^{2D}\|_{L^\infty(\mathbb{R}^2)}}{\varepsilon} + \left(\frac{\left\|n_s^{2.5D} - n_s^{2D}\right\|_{L^q(\mathbb{R}^2)}}{\varepsilon}\right)^{\theta} \geq C_0'.$$

Proceeding analogously, we obtain

$$\frac{\|V_0^{2.5D} - V_0^{2D}\|_{L^\infty(\mathbb{R}^2)}}{\varepsilon} + \left(\frac{\left\|n_s^{2.5D} - n_s^{2D}\right\|_{L^1(\mathbb{R}^2)}}{\varepsilon}\right)^{1-\theta} \geq C_0'.$$

Consequently, we deduce that

$$\|V_0^{2.5D} - V_0^{2D}\|_{L^\infty(\mathbb{R}^2)} + \left\|n_s^{2.5D} - n_s^{2D}\right\|_{L^q(\mathbb{R}^2)} \geq C\varepsilon \quad \forall q \in (2,+\infty) \tag{6.5}$$

and

$$\|V_0^{2.5D} - V_0^{2D}\|_{L^\infty(\mathbb{R}^2)} + \left\|n_s^{2.5D} - n_s^{2D}\right\|_{L^1(\mathbb{R}^2)} \geq C\varepsilon.$$

The last inequality implies, by a simple interpolation argument, that (6.5) actually holds for $q \in [1, +\infty)$, which finishes the proof.

Appendix A. Strichartz estimates in $L^{q^*}L^q_xL^2_z$. For any $q \in [2, \infty)$ we recall the notation $q^* = 2q/(q-2)$: in the usual terminology for the Strichartz estimates, the pair (q^*, q) is said to be admissible. The space $L^{q^*}_t L^q_x L^2_z$ was defined in section 2. Let us first state an extension of the standard Strichartz estimate for Schrödinger equations on $\mathbb{R}^2$ with values in a Hilbert space [6, 7, 11, 20, 22].

LEMMA A.1. *Let $T > 0$ and let $\mathcal{H}$ be a separable Hilbert space. For $\psi_0 \in L^2(\mathbb{R}^2, \mathcal{H})$ and $g \in L^1((0,T), L^2(\mathbb{R}^2, \mathcal{H}))$, we consider the solution $\psi(t,x) \in L^\infty((0,T), L^2(\mathbb{R}^2, \mathcal{H}))$ of*

$$\text{(A.1)} \qquad \begin{cases} i\partial_t \psi = -\dfrac{1}{2}\Delta_x \psi + g, \\ \psi(0,\cdot) = \psi_0\,. \end{cases}$$

Then for any $q \in [2, \infty)$, the function ψ belongs to $L^{q^*}((0,T), L^q(\mathbb{R}^2, \mathcal{H}))$ and satisfies

$$\text{(A.2)} \qquad \|\psi\|_{L^{q^*}((0,T),L^q(\mathbb{R}^2,\mathcal{H}))} \leq C\|\psi_0\|_{L^2(\mathbb{R}^2,\mathcal{H})} + C\|g\|_{L^1((0,T),L^2(\mathbb{R}^2,\mathcal{H}))},$$

where $C > 0$ denotes a constant.

Proof. Let $(\cdot,\cdot)_{\mathcal{H}}$ denote the scalar product on $\mathcal{H}$ and let $(\chi_p)_{p\in\mathbb{N}^*}$ be a Hilbertian basis of $\mathcal{H}$. We shall use the Strichartz estimate for mixed quantum states proved in [5]. For this, let us introduce the following functional space:

$$\widetilde{L^q}(\mathbb{R}^2, \mathcal{H}) = \left\{ \psi \in L^q(\mathbb{R}^2, \mathcal{H}) \,:\quad \|\psi\|^2_{\widetilde{L^q}(\mathbb{R}^2,\mathcal{H})} = \sum_{p\geq 1} \|\psi_p\|^2_{L^q(\mathbb{R}^2)} < +\infty \right\},$$

where we have denoted $\psi_p = (\psi, \chi_p)_{\mathcal{H}}$ (note that this functional space a priori depends on the choice of the Hilbertian basis χ_p). This space is continuously embedded in $L^q(\mathbb{R}^2, \mathcal{H})$; indeed we have

$$\text{(A.3)} \qquad \|\psi\|_{L^q(\mathbb{R}^2,\mathcal{H})} = \left\| \sum_{p\geq 1} |\psi_p|^2 \right\|^{1/2}_{L^{q/2}(\mathbb{R}^2)} \leq \left(\sum_{p\geq 1} \left\| |\psi_p|^2 \right\|_{L^{q/2}(\mathbb{R}^2)} \right)^{1/2} = \|\psi\|_{\widetilde{L^q}(\mathbb{R}^2,\mathcal{H})}.$$

This inequality becomes an equality in the special case $q = 2$ and we have the identification $\widetilde{L^2}(\mathbb{R}^2, \mathcal{H}) = L^2(\mathbb{R}^2, \mathcal{H})$.

This functional space $\widetilde{L^q}(\mathbb{R}^2, \mathcal{H})$ can be identified with the space $L^q(\lambda)$ introduced in [5, Definition 2.1] (in dimension 2 instead of dimension 3), with the choice $\lambda = (1, 1, 1, \ldots)$ and if ψ is identified with the sequence of its components $(\psi_p)_{p\in\mathbb{N}^*}$.

Each component ψ_p satisfies the equation

$$\begin{cases} i\partial_t \psi_p = -\dfrac{1}{2}\Delta_x \psi_p + g_p, \\ \psi_p(0,\cdot) = \psi_{0,p}, \end{cases}$$

where $g_p = (g, \chi_p)_{\mathcal{H}}$ and $\psi_{0,p} = (\psi_0, \chi_p)_{\mathcal{H}}$. Therefore, an application of [5, Theorem 2.1] (adapted to dimension 2) gives

$$\begin{aligned}\|\psi\|_{L^{q^*}((0,T),\widetilde{L^q}(\mathbb{R}^2,\mathcal{H}))} &\le C\|\psi_0\|_{\widetilde{L^2}(\mathbb{R}^2,\mathcal{H})} + C\|g\|_{L^1((0,T),\widetilde{L^2}(\mathbb{R}^2,\mathcal{H}))}\\ &= C\|\psi_0\|_{L^2(\mathbb{R}^2,\mathcal{H})} + C\|g\|_{L^1((0,T),L^2(\mathbb{R}^2,\mathcal{H}))}.\end{aligned}$$

We conclude the proof by using (A.3). ∎

Now let $\mathbb{A}$ be an unbounded operator on $\mathcal{H} = L^2(\mathbb{R})$ with the domain $\mathcal{D}(\mathbb{A})$. We assume that the operator $\mathbb{A}$ is self-adjoint and denote by $e^{it\mathbb{A}}$ the unitary group generated by $i\mathbb{A}$ on $\mathcal{H}$. Throughout this paper, the results of the appendix are applied to the operator $\mathbb{A} = -\frac{1}{2}\frac{d^2}{dz^2} + V_c^\varepsilon$. The operator $i(\frac{1}{2}\Delta_x - \mathbb{A})$, defined with an abuse of notation as $i(\frac{1}{2}\Delta_x \otimes \mathbb{I}_{\mathcal{H}} - \mathbb{I}_{L^2(\mathbb{R}^2)} \otimes \mathbb{A})$ on $H^2(\mathbb{R}^2,\mathcal{H}) \cap L^2(\mathbb{R}^2,\mathcal{D}(\mathbb{A}))$, generates a group of isometries on $L^2(\mathbb{R}^2,\mathcal{H}) = L^2(\mathbb{R}^3)$. Let us now consider the problem

$$\text{(A.4)}\qquad \begin{cases} i\partial_t\psi = -\dfrac{1}{2}\Delta_x\psi + \mathbb{A}\psi + f,\\ \psi(0,x,z) = \psi_0, \end{cases}$$

where the source term $f(t,x,z)$ is given. The following result holds.

LEMMA A.2. *Let $\psi_0 \in L^2(\mathbb{R}^3)$ and $f \in L^1((0,T),L^2(\mathbb{R}^3))$. Then for any $q \in [2,\infty)$, the solution ψ of the Schrödinger equation* (A.4) *belongs to $L_t^{q^*}L_x^qL_z^2((0,T)\times\mathbb{R}^3)$ and satisfies*

$$\text{(A.5)}\qquad \|\psi\|_{q^*,q,2} \le C\|\psi_0\|_{L^2(\mathbb{R}^3)} + C\|f\|_{L^1((0,T),L^2(\mathbb{R}^3))},$$

where C denotes a constant independent of the operator $\mathbb{A}$.

Proof. This lemma is a consequence of Lemma A.1 above. Let us denote $\phi(t,x,z) = e^{i\mathbb{A}t}\,\psi(t,x;z)$. Since $\mathbb{A}$ commutes with ∂_t and Δ_x, we clearly have

$$\begin{cases} i\partial_t\phi = -\Delta_x\phi + e^{i\mathbb{A}t}\,f,\\ \phi(0,x,z) = \psi_0. \end{cases}$$

Therefore ϕ satisfies (A.1) with $g = e^{i\mathbb{A}t}\,f$. We conclude the proof by using (A.2) since $e^{i\mathbb{A}t}$ is an isometry on $L^2(\mathbb{R})$. ∎

Appendix B. The Poisson equation with L^1 densities. This section deals with the convolution product

$$u = \frac{1}{r} * f,$$

where, $r = \sqrt{|x|^2+z^2}$ and $f \in L_x^pL_z^1$. We recall that throughout this paper $x \in \mathbb{R}^2$, $z \in \mathbb{R}$, and $L_x^pL_z^q = L^p(\mathbb{R}^2,L^q(\mathbb{R}))$. We first prove the following result in $\mathbb{R}^2$ with a convolution kernel more singular than the kernel of the Poisson equation.

LEMMA B.1. (i) *Let $f \in L^p(\mathbb{R}^2)$ with $1 < p < 2$. Then*

$$\text{(B.1)}\qquad \left\| \frac{1}{|x|} *_x f \right\|_{L^{p^\#}(\mathbb{R}^2)} \le C_p\,\|f\|_{L^p(\mathbb{R}^2)},$$

where $p^\# = \frac{2p}{2-p}$.

(ii) *Let $f \in L^p(\mathbb{R}^2) \cap L^1(\mathbb{R}^2)$ with $2 < p \le +\infty$. Then*

$$\text{(B.2)}\qquad \left\| \frac{1}{|x|} *_x f \right\|_{L^\infty(\mathbb{R}^2)} \le C_p\,\|f\|_{L^p(\mathbb{R}^2)}^{\theta}\|f\|_{L^1(\mathbb{R}^2)}^{1-\theta},$$

where $\theta = \frac{p}{2p-2}$.

Proof. The first part of the lemma is a straightforward consequence of the generalized Young's formula [18]. Indeed, the function $x \mapsto \frac{1}{|x|}$ belongs to $L^2_w(\mathbb{R}^2)$, and the function f is in $L^p(\mathbb{R}^2)$; thus $\frac{1}{|x|} *_x f$ belongs to $L^{p^\#}(\mathbb{R}^2)$, with $\frac{1}{p} + \frac{1}{2} = 1 + \frac{1}{p^\#}$.

In order to prove item (ii), for any $R > 0$ we separate the integral into two parts:

$$\begin{aligned}\left|\frac{1}{|x|} *_x f\right| &\leq \int_{|x-x'|<R} \frac{|f(x')|}{|x-x'|}dx' + \frac{1}{R}\|f\|_{L^1(\mathbb{R}^2)} \\ &\leq CR^{\frac{p-2}{p}}\|f\|_{L^p(\mathbb{R}^2)} + \frac{1}{R}\|f\|_{L^1(\mathbb{R}^2)},\end{aligned}$$

where we used the Hölder's inequality to estimate the first integral. The value of θ is obtained after optimization of R. ∎

LEMMA B.2. (i) *Let* $f \in L^p_x L^1_z$ *with* $1 < p < 2$. *Then we have*

$$\left\|\frac{1}{r} * f\right\|_{p^\#,\infty} + \left\|\nabla_{x,z}\left(\frac{1}{r} * f\right)\right\|_{p^\#,1} \leq C_p \|f\|_{p,1}, \tag{B.3}$$

where $p^\# = \frac{2p}{2-p}$. *If in addition* $\nabla_x f \in L^p_x L^1_z$, *then*

$$\left\|\nabla_{x,z}\left(\frac{1}{r} * f\right)\right\|_{p^\#,\infty} \leq C_p \|\nabla_x f\|_{p,1}. \tag{B.4}$$

(ii) *Let* $f \in L^p_x L^1_z \cap L^1(\mathbb{R}^3)$ *with* $2 < p \leq +\infty$. *Then we have*

$$\left\|\frac{1}{r} * f\right\|_{L^\infty(\mathbb{R}^3)} + \left\|\nabla_{x,z}\left(\frac{1}{r} * f\right)\right\|_{\infty,1} \leq C_p \|f\|^\theta_{p,1} \|f\|^{1-\theta}_{L^1(\mathbb{R}^3)}, \tag{B.5}$$

where $\theta = \frac{p}{2p-2}$. *If in addition* $\nabla_x f \in L^p_x L^1_z \cap L^1(\mathbb{R}^3)$, *then*

$$\left\|\nabla_{x,z}\left(\frac{1}{r} * f\right)\right\|_{L^\infty(\mathbb{R}^3)} \leq C_p \|\nabla_x f\|^\theta_{p,1} \|\nabla_x f\|^{1-\theta}_{L^1(\mathbb{R}^3)}. \tag{B.6}$$

Proof. Items (i) and (ii) can be proved similarly by using, respectively, items (i) and (ii) of Lemma B.1. We shall only prove here item (i). Denoting $u = \frac{1}{r} * f$, we have

$$\|u(x,\cdot)\|_{L^\infty(\mathbb{R})} \leq \frac{1}{|x|} *_x \|f(x,\cdot)\|_{L^1(\mathbb{R})},$$

and the first part of (B.3) is a consequence of (B.1) since $x \mapsto \|f(x,\cdot)\|_{L^1(\mathbb{R})}$ belongs to $L^p(\mathbb{R}^2)$. Now we have

$$\begin{aligned}\int_{\mathbb{R}} |\nabla_x u(x,z)|\, dz &\leq \iiint_{\mathbb{R}^4} \frac{|x-x'|}{(|x-x'|^2 + (z-z')^2)^{3/2}} |f(x',z')|\, dx'\, dz'\, dz. \\ &= 2\int_{\mathbb{R}^2} \frac{1}{|x-x'|}\|f(x',\cdot)\|_{L^1(\mathbb{R})}\, dx' \\ &= \frac{2}{|x|} *_x \|f(x,\cdot)\|_{L^1(\mathbb{R})},\end{aligned}$$

where we have just evaluated the integral

$$\int_{\mathbb{R}} \frac{|x-x'|}{\left(|x-x'|^2+(z-z')^2\right)^{3/2}}\,dz = \frac{2}{|x-x'|}.$$

Then by again using (B.1) we conclude with the estimate of $\|\nabla_x u\|_{p^\#,1}$. We estimate $\|\partial_z u\|_{p^\#,1}$ similarly:

$$\begin{aligned}\int_{\mathbb{R}} |\partial_z u(x,z)|\,dz &\le \iiint_{\mathbb{R}^4} \frac{|z-z'|}{\left(|x-x'|^2+(z-z')^2\right)^{3/2}} |f(x',z')|\,dx'\,dz'\,dz. \\ &= 2\int_{\mathbb{R}^2} \frac{1}{|x-x'|}\|f(x',\cdot)\|_{L^1(\mathbb{R})}\,dx'.\end{aligned}$$

This proves (B.3). Next, for $i=1,2$ and to prove (B.4) we write

$$\|\nabla_{x,z}\,\partial_{x_i} u\|_{p^\#,1} \le \left\|\nabla_{x,z}\left(\frac{1}{r} * (\partial_{x_i} f)\right)\right\|_{p^\#,1} \le C_p\,\|\partial_{x_i} f\|_{p,1}. \tag{B.7}$$

Together with (B.3) this implies that $\partial_{x_i} u$ belongs to $L^{p^\#}(\mathbb{R}^2, W^{1,1}(\mathbb{R}))$. Note that $W^{1,1}(\mathbb{R}) \hookrightarrow L^\infty(\mathbb{R})$. Therefore, $\partial_{x_i} u$ is in $L_x^{p^\#} L_z^\infty$ and satisfies

$$\|\partial_{x_i} u\|_{p^\#,\infty} \le C\|\partial_z \partial_{x_i} u\|_{p^\#,1} \le C_p\,\|\partial_{x_i} f\|_{p,1}.$$

To prove (B.4), it remains to estimate $\partial_z u$. We recall that $-\Delta_{x,z} u = f$. Additionally, we remark that

$$x \mapsto \|f(x,\cdot)\|_{L^1(\mathbb{R})}$$

belongs to $W^{1,p}(\mathbb{R}^2) \hookrightarrow L^{p^\#}(\mathbb{R}^2)$. Consequently,

$$\|f\|_{p^\#,1} \le C_p \|\nabla_x f\|_{p,1},$$

and applying (B.7) we get

$$\|\partial_{zz} u\|_{p^\#,1} \le \|f\|_{p^\#,1} + \|\Delta_x u\|_{p^\#,1} \le C_p\,\|\nabla_x f\|_{p,1}.$$

Therefore, as above, $\partial_z u$ is bounded in $L^{p^\#}(\mathbb{R}^2, W^{1,1}(\mathbb{R}))$, and thus in $L_x^{p^\#} L_z^\infty$. ∎

LEMMA B.3. (i) *Let $f \in L_x^p L_z^1$, with $1 < p < \infty$ be such that $\int_{\mathbb{R}} f(x,z)dz = 0$, x a.e., and $z\,f \in L_x^p L_z^1$. Then for any $\alpha \in (0, \min(1, 2/p))$ we have*

$$\left\|\frac{1}{r} * f\right\|_{q,\infty} \le C\,\|zf\|_{p,1}^{1-\alpha}\|f\|_{p,1}^{\alpha}, \tag{B.8}$$

where $q = \frac{2p}{2-\alpha p}$.

(ii) *Let $f \in L_x^p L_z^1$, with $2 < p < \infty$ be such that $\int_{\mathbb{R}} f(x,z)dz = 0$, x a.e. and $z\,f \in L_x^p L_z^1$. Then*

$$\left\|\frac{1}{r} * f\right\|_{L^\infty(\mathbb{R}^3)} \le C\,\|zf\|_{p,1}^{1-2/p}\|f\|_{p,1}^{2/p}. \tag{B.9}$$

Proof. Denote $u = \frac{1}{r} * f$. Since $\int_{\mathbb{R}} f(x,z)dz = 0$, we have

$$u(x,z) = \iint_{\mathbb{R}^3} \left(\frac{1}{\left(|x-x'|^2 + (z-z')^2\right)^{1/2}} - \frac{1}{\left(|x-x'|^2 + z^2\right)^{1/2}} \right) f(x',z')\, dx'dz'$$

$$= \iint_{\mathbb{R}^3} \int_0^{z'} \left(\frac{z-\xi}{\left(|x-x'|^2 + (z-\xi)^2\right)^{3/2}} \right) f(x',z')\, d\xi dx'dz'. \tag{B.10}$$

Then we remark that for any z, ξ, and $x \neq x'$, we have

$$\frac{|z-\xi|}{\left(|x-x'|^2 + (z-\xi)^2\right)^{3/2}} \leq \frac{2}{3\sqrt{3}} \frac{1}{|x-x'|^2} \tag{B.11}$$

and that

$$\int_0^{z'} \frac{|z-\xi|}{\left(|x-x'|^2 + (z-\xi)^2\right)^{3/2}} d\xi \leq \int_{\mathbb{R}} \frac{|z-\xi|}{\left(|x-x'|^2 + (z-\xi)^2\right)^{3/2}} d\xi = \frac{2}{|x-x'|}. \tag{B.12}$$

Let us first prove (B.8). By (B.11) and (B.12) we have for any $0 \leq \alpha \leq 1$

$$\begin{aligned} \int_{\mathbb{R}} \int_0^{z'} \frac{|z-\xi|}{\left(|x-x'|^2 + (z-\xi)^2\right)^{3/2}} |f(x',z')| d\xi dz' &\leq C \int_{\mathbb{R}} \frac{|z' f(x',z')|^{1-\alpha}}{|x-x'|^{2(1-\alpha)}} \frac{|f(x',z')|^{\alpha}}{|x-x'|^{\alpha}} dz' \\ &\leq \frac{C}{|x-x'|^{2-\alpha}}\, g(x), \end{aligned}$$

where

$$g(x) = \left(\int |z f(x,z)| dz \right)^{1-\alpha} \left(\int |f(x,z)| dz \right)^{\alpha}.$$

Hence from (B.10) we deduce that

$$\|u(x,\cdot)\|_{L^\infty(\mathbb{R})} \leq C \left(\frac{1}{|x|^{2-\alpha}} * g \right)(x).$$

From the assumptions on f, we deduce that g belongs to $L^p(\mathbb{R}^2)$. Since the function $x \mapsto \frac{1}{|x|^{2-\alpha}}$ belongs to $L_w^{2/(2-\alpha)}(\mathbb{R}^2)$, the generalized Young's inequality gives (B.8).

In order to prove (B.9), the right-hand side of (B.10) is separated into two parts:

$$\int_{\mathbb{R}^3} = \int_{|x-x'|>R} + \int_{|x-x'|<R}.$$

By (B.11), the first part is controlled by

$$C \int_{|x-x'|>R} \frac{\|z' f(x',\cdot)\|_{L^1(\mathbb{R})}}{|x-x'|^2} dx' \leq \frac{C}{R^{2/p}} \|z' f\|_{p,1},$$

while the second integral is estimated, through (B.12), by

$$C \int_{|x-x'|<R} \frac{\|f(x',\cdot)\|_{L^1(\mathbb{R})}}{|x-x'|} dx' \leq R^{1-2/p} \|f\|_{p,1}.$$

Optimization of R leads to (B.9). ∎

GLOBAL SOLUTIONS OF THE 2D DISSIPATIVE QUASI-GEOSTROPHIC EQUATION IN BESOV SPACES*

JIAHONG WU†

Abstract. The two-dimensional (2D) quasi-geostrophic (QG) equation is a 2D model of the 3D incompressible Euler equations, and its dissipative version includes an extra term bearing the operator $(-\Delta)^\alpha$ with $\alpha \in [0,1]$. Existing research appears to indicate the criticality of $\alpha = \frac{1}{2}$ in the sense that the issue of global existence for the 2D dissipative QG equation becomes extremely difficult when $\alpha \le \frac{1}{2}$. It is shown here that for any $\alpha \le \frac{1}{2}$ the 2D dissipative QG equation with an initial datum in the Besov space $B^r_{2,\infty}$ or $B^r_{p,\infty}$ $(p > 2)$ possesses a unique global solution if the norm of the datum in these spaces is comparable to κ, the diffusion coefficient. Since the Sobolev space H^r is embedded in $B^r_{2,\infty}$, a special consequence is the global existence of small data solutions in H^r for any $r > 2 - 2\alpha$.

1. Introduction.

This paper is concerned with global existence results for the two-dimensional (2D) dissipative quasi-geostrophic (QG) equation

$$\begin{cases} \partial_t \theta + u \cdot \nabla \theta + \kappa(-\Delta)^\alpha \theta = 0, \\ u = (u_1, u_2) = \nabla^\perp \psi, \quad (-\Delta)^{\frac{1}{2}} \psi = \theta \end{cases} \tag{1.1}$$

supplemented with the initial condition

$$\theta(x,0) = \theta_0(x). \tag{1.2}$$

In (1.1), $x \in \mathbb{R}^2$, $t \ge 0$, $\kappa > 0$ is the diffusion coefficient and $\alpha \in [0,1]$ is a parameter, $\theta = \theta(x,t)$ is a scalar representing the temperature, u is the velocity field, and ψ is the usual stream function. Besides its geophysical applications [11], [12], the 2D dissipative QG equation serves as a 2D model of the 3D Navier–Stokes equations and has recently been extensively investigated (see [1], [2], [3], [5], [6], [7], [8], [9], [10], [13], [14], [15], [16]).

Prior work on the issue of global existence concerning the 2D dissipative QG equation (1.1) appears to indicate that $\alpha = \frac{1}{2}$ is a critical index. In the subcritical case, namely, $\alpha > \frac{1}{2}$, solutions at several regularity levels, including solutions in the classical sense, have been shown to be global in time [7], [13], [16]. The theory of global existence and regularity for this case is thus in a satisfactory state. In the critical case $\alpha = \frac{1}{2}$, classical solutions are known to be global if their initial L^∞-norms are comparable to κ [6]. For initial data of arbitrary size, the global existence of classical solutions has not been established. It is hoped that the resolution of this problem will shed light on the millennium prize problem on the 3D Navier–Stokes equations. The supercritical case $\alpha < \frac{1}{2}$ seems even harder to deal with, and work on this case has just started to appear. For $\alpha \le \frac{1}{2}$, Chae and Lee [3] established a global existence

result under the assumption that θ_0 is small in the Besov space $B^{2-2\alpha}_{2,1}$. In a recent work [9], A Córdoba and D. Córdoba obtained for any $\alpha \in [0,1]$ a local existence result for $\theta_0 \in H^s$ with $s+\alpha > 2$ and a global result for small θ_0 in H^s with $s > 2$ or in $H^{3/2}$ in the case of $\alpha = \frac{1}{2}$.

This paper is devoted to establishing global existence results for (1.1) with θ_0 in the Besov space $B^r_{2,\infty}$ or in $B^r_{p,\infty}$ with $p > 2$. For any $\alpha \le \frac{1}{2}$ and $\theta_0 \in B^r_{2,\infty}$ with $r > 2-2\alpha$, we prove that the 2D QG equation (1.1) has a unique global solution provided that the norm of θ_0 in $B^r_{2,\infty}$ is comparable to κ. Because of the embeddings $B^r_{2,1} \hookrightarrow H^r \hookrightarrow B^r_{2,\infty}$, a special consequence is the global existence result for small data in $B^r_{2,1}$ or H^r with $r > 2-2\alpha$. We defer the precise statement and many more details to section 3.

The situation for $\theta_0 \in B^r_{p,\infty}$ with $p > 2$ is more sophisticated and the major difficulty lies in how to obtain suitable lower bounds for terms generated from the dissipative part. Thanks to the L^p-decay estimate of A. Córdoba and D. Córdoba [9], we are able to establish a global existence result for solutions in the Besov space $B^r_{p,\infty}$ with $r > 1 + \frac{2}{p}$. Appropriate smallness conditions are imposed on the initial datum θ_0 here. This is accomplished in section 4, which consists of two subsections. The first subsection provides an a priori bound and the second proves the global existence result.

2. Preliminaries. This section provides a precise characterization of the Besov space $B^r_{p,q}$ through the Littlewood–Paley decomposition and gathers several important estimates involving $B^r_{p,\infty}$. First, we recall two commutator estimates established in a previous work [17]. Then follows the tame estimate for the usual product of two functions. Finally, a logarithmic bound for the L^∞-norm of a function in terms of its norms in Besov spaces is stated and proven. We shall also reproduce here the L^p-decay estimate of A. Córdoba and D. Córdoba for the dissipative QG equation [9].

We start with a dyadic decomposition of $\mathbb{R}^d$, where $d > 0$ is an integer. It is a classical result that there exist two radial functions $\chi \in C_0^\infty(\mathbb{R}^d)$ and $\phi \in C_0^\infty(\mathbb{R}^d \backslash \{0\})$ satisfying

$$\operatorname{supp}\chi \subset \{\xi : |\xi| \le 4/3\}, \qquad \operatorname{supp}\phi \subset \{\xi : 3/4 < |\xi| < 8/3\},$$

$$\chi(\xi) + \sum_{j\ge 0} \phi(2^{-j}\xi) = 1 \quad \text{for all } \xi \in \mathbb{R}^d.$$

For the purpose of isolating different Fourier frequencies, define the operators Δ_i for $i \in \mathbb{Z}$ as follows:

$$\Delta_i u = \begin{cases} 0 & \text{if } i \le -2, \\ \chi(D)u = \int h(y)u(x-y)dy & \text{if } i = -1, \\ \phi(2^{-i}D)u = 2^{id}\int g(2^i y)u(x-y)dy & \text{if } i \ge 0, \end{cases} \tag{2.1}$$

where $h = \chi^\vee$ and $g = \phi^\vee$ are the inverse Fourier transforms of χ and ϕ, respectively. We note that Δ_i in (2.1) can be defined in other ways. For example, by further requiring $\chi(\xi) = 1$ for $|\xi| \le \frac{3}{8}$ and writing

$$g(x) = 2^d h(2x) - h(x), \quad g_j(x) = 2^{dj} g(2^j x),$$

one can define $\Delta_{-1} = h*$ and $\Delta_j = g_j*$ for $j \ge 0$.

For $i \in \mathbb{Z}$, S_i is the sum of Δ_j with $j \le i-1$, i.e.,

$$S_i u = \Delta_{-1}u + \Delta_0 u + \Delta_1 u + \cdots + \Delta_{i-1}u = \int_{\mathbb{R}^d} h(2^i y)u(x-y)dy.$$

It can be shown for any tempered distribution f that $S_i f \to f$ in the distributional sense, as $i \to \infty$.

For any $r \in \mathbb{R}$ and $p, q \in [1, \infty]$, the Besov space $B^r_{p,q}$ consists of all tempered distributions f such that the sequence $\{2^{jr}\|\Delta_j f\|_{L^p}\}_{j\in\mathbb{Z}}$ belongs to $L^q(\mathbb{Z})$. In particular, $B^r_{p,\infty}$ contains any function f satisfying

$$\|f\|_{B^r_{p,\infty}} \equiv \sup_{j\in\mathbb{Z}} 2^{jr}\|\Delta_j f\|_{L^p} < \infty. \tag{2.2}$$

It is easy to check that $B^r_{p,\infty}$ endowed with the norm (2.2) is a Banach space.

The following version of Bernstein's lemma can be found in [4].

LEMMA 2.1 (Bernstein's lemma). *Let $d > 0$ be an integer and $R_2 > R_1 > 0$ be two real numbers. If $p \in [1, \infty]$ and $\operatorname{supp}\widehat{f} \subset \{\xi \in \mathbb{R}^d : R_1 2^j \le |\xi| \le R_2 2^j\}$, then*

$$C^{-1}2^{jk}\|f\|_{L^p(\mathbb{R}^d)} \le \max_{|\alpha|=k} \|\partial^\alpha f\|_{L^p(\mathbb{R}^d)} \le C2^{jk}\|f\|_{L^p(\mathbb{R}^d)},$$

where $C > 0$ is a constant depending on k, R_1, and R_2 only.

We now recall two commutator estimates previously established in [17].

PROPOSITION 2.2. *Let $j \ge -1$ be an integer, let $r \in \mathbb{R}$, and let $p \in [1, \infty]$. Then,*

$$\|[u\cdot\nabla, \Delta_j]\theta\|_{L^p} \le C2^{-jr}\left(\|\nabla\theta\|_{L^\infty}\|u\|_{B^r_{p,\infty}} + \|\nabla u\|_{L^\infty}\|\theta\|_{B^r_{p,\infty}}\right), \tag{2.3}$$

where C is a pure constant and the brackets $[\,,\,]$ represent the commutator, namely,

$$[u\cdot\nabla, \Delta_j]\theta = u\cdot\nabla(\Delta_j\theta) - \Delta_j(u\cdot\nabla\theta).$$

Inequality (2.3) is suitable for situations when u and θ are equally regular. If $\nabla\theta$ is not known to be bounded in L^∞, then (2.3) fails. The following proposition provides a new estimate which needs no information about $\nabla\theta$. As a trade-off, u is required to be in $B^{r+1}_{p,\infty}$. The importance of this estimate will be seen in the proofs of Theorems 3.1 and 4.1.

PROPOSITION 2.3. *Let $j \ge -1$, let $r \in \mathbb{R}$, and let $p \in [1, \infty]$. Then, for some pure constant C,*

$$\|[u\cdot\nabla, \Delta_j]\theta\|_{L^p} \le C2^{-jr}\left(\|\nabla u\|_{L^\infty}\|\theta\|_{B^r_{p,\infty}} + \|\theta\|_{L^\infty}\|u\|_{B^{r+1}_{p,\infty}}\right). \tag{2.4}$$

Estimates for the product uv of two functions u and v are handy in dealing with the quadratic nonlinear term in many partial differential equations. In the context of Besov spaces, we have the following estimate.

PROPOSITION 2.4. *Let $r > 0$ be a real number and let $p \in [1, \infty]$. Then*

$$\|u\,v\|_{B^r_{p,\infty}} \le C\big(\|u\|_{L^\infty}\|v\|_{B^r_{p,\infty}} + \|u\|_{B^r_{p,\infty}}\|v\|_{L^\infty}\big),$$

where C is constant depending on r and p only.

In the course of establishing existence results for the QG equation, very often we need to bound the L^∞-norm of a function in terms of its norm in $B^r_{p,\infty}$. The following logarithmic estimate is very helpful.

PROPOSITION 2.5. *Let $p \in [1,\infty]$, let $r_c = \frac{d}{p}$, and let $r > \frac{d}{p}$. Then there exists a constant C depending on p and r only such that*

$$\|f\|_{L^\infty(\mathbb{R}^d)} \le C\|f\|_{B^{r_c}_{p,\infty}(\mathbb{R}^d)} \log_2\left(e + \frac{\|f\|_{B^r_{p,\infty}(\mathbb{R}^d)}}{\|f\|_{B^{r_c}_{p,\infty}(\mathbb{R}^d)}}\right), \tag{2.5}$$

which, in particular, implies

$$\|f\|_{L^\infty(\mathbb{R}^d)} \le C\|f\|_{B^r_{p,\infty}(\mathbb{R}^d)}. \tag{2.6}$$

Proof. According to the definition of Δ_i's in (2.1), $\Delta_k\Delta_j = 0$ if $|k-j| \ge 2$. For $j \ge 0$,

$$\begin{aligned}\|\Delta_j f\|_{L^\infty} &\le \sum_{|k-j|\le 1} \|\Delta_k\Delta_j f\|_{L^\infty} = \sum_{|k-j|\le 1} \|2^{kd} g(2^k\cdot) * (\Delta_j f)\|_{L^\infty} \\ &\le \sum_{|k-j|\le 1} \|2^{kd} g(2^k\cdot)\|_{L^q} \|\Delta_j f\|_{L^p} = \sum_{|k-j|\le 1} 2^{kd\,\frac{1}{p}} \|g\|_{L^q}\, \|\Delta_j f\|_{L^p},\end{aligned}$$

where q is the conjugate of p, or $1/p + 1/q = 1$. Thus,

$$\|\Delta_j f\|_{L^\infty} \le C\, 2^{jr_c}\, \|\Delta_j f\|_{L^p}$$

for a pure constant C. A similar estimate for the case $j = -1$ leads to the same bound. Using this bound, we have

$$\begin{aligned}\|f\|_{L^\infty} &\le \sum_{j\ge -1} \|\Delta_j f\|_{L^\infty} = \sum_{j=-1}^{N-1} \|\Delta_j f\|_{L^\infty} + \sum_{j\ge N} \|\Delta_j f\|_{L^\infty} \\ &\le C\,(N+1)\|f\|_{B^{r_c}_{p,\infty}} + C\,\|f\|_{B^r_{p,\infty}} \sum_{j\ge N} 2^{-j(r-r_c)} \\ &= C(N+1)\|f\|_{B^{r_c}_{p,\infty}} + C\,\frac{2^{-N(r-r_c)}}{1-2^{-(r-r_c)}}\,\|f\|_{B^r_{p,\infty}}.\end{aligned}$$

The desired inequality (2.5) is then obtained by letting

$$N = 1 + \left[\frac{1}{r-r_c}\log_2 \frac{\|f\|_{B^r_{p,\infty}}}{\|f\|_{B^{r_c}_{p,\infty}}}\right].$$

Inequality (2.6) is true because of (2.5) and the fact that $x \to x\log_2(e + M/x)$ with a fixed constant M is an increasing function for $x > 0$. This completes the proof. ∎

As seen in (1.1) of the introduction, the components of the velocity field u are Riesz transforms of θ, namely,

$$u = \mathcal{R}^\perp(\theta) \equiv (-\mathcal{R}_2(\theta), \mathcal{R}_1(\theta)),$$

where $\mathcal{R}_k = \partial_{x_k}\Lambda^{-1}$ for $k = 1, 2$ and $\Lambda \equiv (-\Delta)^{1/2}$. It is a classical result in the Calderon–Zygmund theory that for any $p \in (1,\infty)$ and $r \in \mathbb{R}$

$$\|u\|_{B^r_{p,\infty}} \le C\|\theta\|_{B^r_{p,\infty}}, \tag{2.7}$$

where C is a constant depending only on p and r.

Finally, we recall the L^p-decay result of A. Córdoba and D. Córdoba. In a recent work [9], A. Córdoba and D. Córdoba skillfully proved a pointwise inequality involving the operator $\Lambda^{2\alpha}$ with $\alpha \in [0,1]$ and then derived the L^p-decay result as a special consequence.

PROPOSITION 2.6. *Let $\alpha \in [0,1]$ and let $\theta \in \mathbb{S}$, the Schwartz class. Then,*

$$2\theta\,\Lambda^{2\alpha}\theta(x) \geq \Lambda^{2\alpha}\,\theta^2(x)$$

for any $x \in \mathbb{R}^2$.

The estimate in the following proposition is slightly different from the corresponding L^p-decay result derived in [9].

PROPOSITION 2.7. *Let $p = 2^k$ for an integer $k \geq 1$. If θ solves (1.1) with an initial data $\theta_0 \in L^p$, then the L^p-norm of θ decays algebraically in time. More precisely,*

$$\|\theta(\cdot,t)\|_{L^p} \leq \frac{\|\theta_0\|_{L^p}}{\left(1+\kappa C_p \gamma t \|\theta_0\|_{L^2}^{-\gamma p}\|\theta_0\|_{L^p}^{\gamma p}\right)^{\frac{1}{\gamma p}}},$$

where $\gamma = \frac{\alpha}{p-2}$ and C_p is a constant depending on p and α only.

3. Global existence in $B_{2,\infty}^r$. We shall assume in this section that θ_0 is in the Besov space $B^r_{2,\infty}$. Consider the solution of the 2D dissipative QG equation

$$\partial_t\theta + u\cdot\nabla\theta + \kappa\Lambda^{2\alpha}\theta = 0, \quad u = \mathcal{R}^{\perp}(\theta) \tag{3.1}$$

with $\theta(x,0) = \theta_0(x)$. Assuming $r > 2-2\alpha$, our major result states that (3.1) has a unique global solution if the norm of θ_0 in $B^r_{2,\infty}$ is comparable to κ.

THEOREM 3.1. *Let $\kappa > 0$ and let $0 \leq \alpha \leq \frac{1}{2}$. Assume the initial datum θ_0 is in the Besov space $B^r_{2,\infty}$ with $r > 2-2\alpha$. There exists a constant C_0 depending on α and r only such that if*

$$\|\theta_0\|_{B^r_{2,\infty}} \leq C_0\kappa, \tag{3.2}$$

then the 2D dissipative QG equation (3.1) with $\theta(x,0) = \theta_0(x)$ has a unique global solution θ satisfying

$$\theta \in L^\infty([0,\infty); B^r_{2,\infty}) \cap L^1([0,\infty); B^{r+2\alpha}_{2,\infty}) \cap \mathrm{Lip}([0,\infty); B^{r-1}_{2,\infty}) \cap C([0,\infty); B^{\delta}_{2,\infty})$$

for any $\delta \in [r-1, r)$, and

$$\|\theta(\cdot,t)\|_{B^r_{2,\infty}} \leq C_0\kappa \quad \text{for any } t \geq 0.$$

Remark. Because of the embeddings

$$B^s_{2,1} \hookrightarrow H^s_2 \hookrightarrow B^s_{2,\infty},$$

this theorem also implies that (3.1) has global solutions for small data in $B^s_{2,1}$ or H^s with any $s > 2-2\alpha$.

Before proving Theorem 3.1, we first establish an a priori estimate.

PROPOSITION 3.2. *Assume that θ solves the 2D dissipative QG equation (3.1) with $\kappa > 0$ and $0 \leq \alpha \leq 1$. Let $r \in \mathbb{R}$ and let $s > 2$. Then*

$$\frac{d}{dt}\|\theta\|_{B^r_{2,\infty}} + C_1\,\kappa\|\theta\|_{B^{r+2\alpha}_{2,\infty}} \leq C_2\,\|\theta\|_{B^s_{2,\infty}}\|\theta\|_{B^r_{2,\infty}}, \tag{3.3}$$

where C_1 and C_2 are constants depending on r only.

If $r > 2 - 2\alpha$, we can choose $s = r + 2\alpha$. Then, (3.3) reduces to

$$\frac{d}{dt}\|\theta\|_{B^r_{2,\infty}} + C_1\,\kappa\|\theta\|_{B^{r+2\alpha}_{2,\infty}} \le C_2\,\|\theta\|_{B^{r+2\alpha}_{2,\infty}}\|\theta\|_{B^r_{2,\infty}}.$$

This inequality bears two consequences, which we state as a corollary.

COROLLARY 3.3. *Assume that θ solves the 2D dissipative QG equation* (3.1) *with $\kappa > 0$ and $0 \le \alpha \le 1$. Let $r > 2 - 2\alpha$ be a real number. There exists a constant C_0 depending on α and r only such that if*

$$\|\theta_0\|_{B^r_{2,\infty}} \le C_0\kappa,$$

then, for any $t \ge 0$,

$$\|\theta(\cdot,t)\|_{B^r_{2,\infty}} \le \|\theta_0\|_{B^r_{2,\infty}} \le C_0\kappa.$$

In addition, θ also satisfies the inequality

$$\|\theta(\cdot,t)\|_{B^r_{2,\infty}} + C_1\,\kappa\int_0^t \|\theta(\cdot,\tau)\|_{B^{r+2\alpha}_{2,\infty}}d\tau \le \|\theta_0\|_{B^r_{2,\infty}}\exp\left(C_2\int_0^t \|\theta(\cdot,\tau)\|_{B^{r+2\alpha}_{2,\infty}}d\tau\right).$$

Proof of Proposition 3.2. Let $j \ge -1$. Applying Δ_j to (3.1), we obtain

$$\partial_t\Delta_j\theta + u\cdot\nabla\Delta_j\theta + \kappa\,\Lambda^{2\alpha}\Delta_j\theta = [u\cdot\nabla,\Delta_j]\theta.$$

Multiplying both sides by $2\Delta_j\theta$ and integrating over $\mathbb{R}^2$ yields

$$\frac{d}{dt}\int|\Delta_j\theta|^2dx + 2\kappa\int|\Lambda^\alpha\Delta_j\theta|^2dx = 2\int\Delta_j\theta\,[u\cdot\nabla,\Delta_j]\theta\,dx.$$

Applying Lemma 2.1 to the dissipative term and Hölder's inequality to the right-hand side, we find that

$$\frac{d}{dt}\|\Delta_j\theta\|_{L^2} + C\kappa 2^{2\alpha j}\|\Delta_j\theta\|_{L^2} \le \|[u\cdot\nabla,\Delta_j]\theta\|_{L^2}.$$

In the above inequality, we have used the fact that Lemma 2.1 is valid for fractional derivatives when $p = 2$. For any $r \in \mathbb{R}$, Proposition 2.2 applied to the term on the right-hand side yields

$$\frac{d}{dt}\|\theta\|_{B^r_{2,\infty}} + C\kappa\|\theta\|_{B^{r+2\alpha}_{2,\infty}} \le C\big(\|\nabla u\|_{L^\infty}\|\theta\|_{B^r_{2,\infty}} + \|\nabla\theta\|_{L^\infty}\|u\|_{B^r_{2,\infty}}\big). \tag{3.4}$$

Furthermore, Proposition 2.5 applied to ∇u and $\nabla\theta$ asserts that for any $s > 2$,

$$\|\nabla u\|_{L^\infty} \le C\|u\|_{B^s_{2,\infty}}, \quad \|\nabla\theta\|_{L^\infty} \le C\|\theta\|_{B^s_{2,\infty}}.$$

Inserting these estimates in (3.4) and noticing (2.7), we obtain

$$\frac{d}{dt}\|\theta\|_{B^r_{2,\infty}} + C_1\,\kappa\|\theta\|_{B^{r+2\alpha}_{2,\infty}} \le C_2\,\|\theta\|_{B^s_{2,\infty}}\|\theta\|_{B^r_{2,\infty}}. \qquad \square$$

Proof of Theorem 3.1. We start with a successive approximation sequence $\{\theta^{(n)}\}$ satisfying

$$\begin{cases} \theta^{(1)} = S_2\theta_0, \\ \partial_t\theta^{(n+1)} + u^{(n)}\cdot\nabla\theta^{(n+1)} + \kappa\Lambda^{2\alpha}\theta^{(n+1)} = 0, \\ u^{(n)} = \mathcal{R}^{\perp}(\theta^{(n)}), \\ \theta^{(n+1)}(x,0) = \theta_0^{(n+1)}(x) = S_{n+2}\theta_0. \end{cases}$$

The rest of the proof is divided into two major parts. The first part establishes that $\{\theta^{(n)}\}$ is bounded uniformly in $L^\infty([0,\infty); B^r_{2,\infty})$. The second part verifies that $\{\theta^{(n)}\}$ is a Cauchy sequence in $L^\infty([0,\infty); B^{r-1}_{2,\infty})$.

Noticing that $r > 2-2\alpha$, we proceed as in the proof of Proposition 3.2 to obtain

$$\begin{aligned} \frac{d}{dt}\|\theta^{(n+1)}\|_{B^r_{2,\infty}} &+ C_1\kappa\|\theta^{(n+1)}\|_{B^{r+2\alpha}_{2,\infty}} \\ &\le C\big(\|\nabla u^{(n)}\|_{L^\infty}\|\theta^{(n+1)}\|_{B^r_{2,\infty}} + \|\nabla\theta^{(n+1)}\|_{L^\infty}\|u^{(n)}\|_{B^r_{2,\infty}}\big) \\ &\le C\big(\|u^{(n)}\|_{B^{r+2\alpha}_{2,\infty}}\|\theta^{(n+1)}\|_{B^r_{2,\infty}} + \|\theta^{(n+1)}\|_{B^{r+2\alpha}_{2,\infty}}\|u^{(n)}\|_{B^r_{2,\infty}}\big) \\ &\le C_2\big(\|\theta^{(n)}\|_{B^{r+2\alpha}_{2,\infty}}\|\theta^{(n+1)}\|_{B^r_{2,\infty}} + \|\theta^{(n+1)}\|_{B^{r+2\alpha}_{2,\infty}}\|\theta^{(n)}\|_{B^r_{2,\infty}}\big), \end{aligned} \tag{3.5}$$

where C_1 and C_2 are constants with dependence on α and r only. Now, we choose $C_0 < C_1/(4C_2)$. Further restrictions will be imposed on C_0 in the second part. We show that if

$$\|\theta_0\|_{B^r_{2,\infty}} \le C_0\,\kappa,$$

then for any integer n and any $t \ge 0$,

$$\sup_{\tau\in[0,t]}\|\theta^{(n)}(\cdot,\tau)\|_{B^r_{2,\infty}} + C_1\,\kappa\int_0^t\|\theta^{(n)}(\cdot,\tau)\|_{B^{r+2\alpha}_{2,\infty}}d\tau \le 2C_0\,\kappa. \tag{3.6}$$

We proceed by induction. If (3.6) holds for $n = k$, namely,

$$\|\theta^{(k)}(\cdot,t)\|_{B^r_{2,\infty}} + C_1\,\kappa\int_0^t\|\theta^{(k)}(\cdot,\tau)\|_{B^{r+2\alpha}_{2,\infty}}d\tau \le 2C_0\,\kappa,$$

then, according to (3.5),

$$\begin{aligned} &\sup_{\tau\in[0,t]}\|\theta^{(k+1)}(\cdot,\tau)\|_{B^r_{2,\infty}} + C_1\,\kappa\int_0^t\|\theta^{(k+1)}(\cdot,\tau)\|_{B^{r+2\alpha}_{2,\infty}}d\tau \\ &\quad\le \|\theta_0^{(k+1)}\|_{B^r_{2,\infty}} + C_2\sup_{\tau\in[0,t]}\|\theta^{(k+1)}(\cdot,\tau)\|_{B^r_{2,\infty}}\int_0^t\|\theta^{(k)}(\cdot,\tau)\|_{B^{r+2\alpha}_{2,\infty}}d\tau \\ &\qquad + C_2\sup_{\tau\in[0,t]}\|\theta^{(k)}(\cdot,\tau)\|_{B^r_{2,\infty}}\int_0^t\|\theta^{(k+1)}(\cdot,\tau)\|_{B^{r+2\alpha}_{2,\infty}}d\tau \\ &\quad\le \|\theta_0\|_{B^r_{2,\infty}} + \frac{2C_0C_2}{C_1}\sup_{\tau\in[0,t]}\|\theta^{(k+1)}(\cdot,\tau)\|_{B^r_{2,\infty}} \\ &\qquad + 2C_0C_2\kappa\int_0^t\|\theta^{(k+1)}(\cdot,\tau)\|_{B^{r+2\alpha}_{2,\infty}}d\tau. \end{aligned}$$

Since $2C_0C_2 \le \frac{1}{2}C_1$, the inequality above becomes

$$\sup_{\tau\in[0,t]} \|\theta^{(k+1)}(\cdot,\tau)\|_{B^r_{2,\infty}} + C_1\,\kappa \int_0^t \|\theta^{(k+1)}(\cdot,\tau)\|_{B^{r+2\alpha}_{2,\infty}} d\tau \le 2\|\theta_0\|_{B^r_{2,\infty}} \le 2C_0\kappa.$$

Thus, (3.6) is verified. This completes the first part of the proof.

Next, we consider the difference

$$\eta^{(n+1)} = \theta^{(n+1)} - \theta^{(n)}.$$

The sequence $\{\eta^{(n)}\}$ satisfies

$$\begin{cases} \eta^{(1)} = S_2\theta_0 - \theta_0, \\ \partial_t\eta^{(n+1)} + u^{(n)}\cdot\nabla\eta^{(n+1)} + \kappa\Lambda^{2\alpha}\eta^{(n+1)} = w^{(n)}\cdot\nabla\theta^{(n)}, \\ w^{(n)} = \mathcal{R}^{\perp}(\eta^{(n)}), \\ \eta^{(n+1)}(x,0) = \eta_0^{(n+1)}(x) = \Delta_{n+1}\theta_0. \end{cases}$$

Starting with the equation for $\eta^{(n+1)}$ and proceeding as above, we are led to the following inequality:

$$\begin{aligned} &\frac{d}{dt}\|\eta^{(n+1)}\|_{B^{r-1}_{2,\infty}} + \ C_1\kappa\|\eta^{(n+1)}\|_{B^{r-1+2\alpha}_{2,\infty}} \\ &\quad \le 2^{(r-1)j}\|[u^{(n)}\cdot\nabla,\Delta_j]\eta^{(n+1)}\|_{L^2} + \|w^{(n)}\cdot\nabla\theta^{(n)}\|_{B^{r-1}_{2,\infty}}. \end{aligned} \tag{3.7}$$

Applying Propositions 2.3 and 2.5 to the first term on the right leads to

$$\begin{aligned} &2^{(r-1)j}\|[u^{(n)}\cdot\nabla,\Delta_j]\eta^{(n+1)}\|_{L^2} \\ &\quad \le C\big(\|\nabla u^{(n)}\|_{L^\infty}\|\eta^{(n+1)}\|_{B^{r-1}_{2,\infty}} + \|\eta^{(n+1)}\|_{L^\infty}\|u^{(n)}\|_{B^r_{2,\infty}}\big) \\ &\quad \le C\left(\|u^{(n)}\|_{B^{r+2\alpha}_{2,\infty}}\|\eta^{(n+1)}\|_{B^{r-1}_{2,\infty}} + \|\eta^{(n+1)}\|_{B^{r-1+2\alpha}_{2,\infty}}\|u^{(n)}\|_{B^r_{2,\infty}}\right) \\ &\quad \le C\left(\|\theta^{(n)}\|_{B^{r+2\alpha}_{2,\infty}}\|\eta^{(n+1)}\|_{B^{r-1}_{2,\infty}} + \|\eta^{(n+1)}\|_{B^{r-1+2\alpha}_{2,\infty}}\|\theta^{(n)}\|_{B^r_{2,\infty}}\right). \end{aligned}$$

Since $\alpha \le \frac{1}{2},\ r-1 > 1-2\alpha > 0$ and the same estimate in Proposition 2.4 applies. Consequently,

$$\begin{aligned} \|w^{(n)}\cdot\nabla\theta^{(n)}\|_{B^{r-1}_{2,\infty}} &\le C\big(\|w^{(n)}\|_{L^\infty}\|\nabla\theta^{(n)}\|_{B^{r-1}_{2,\infty}} + \|w^{(n)}\|_{B^{r-1}_{2,\infty}}\|\nabla\theta^{(n)}\|_{L^\infty}\big) \\ &\le C\big(\|w^{(n)}\|_{B^{r-1+2\alpha}_{2,\infty}}\|\theta^{(n)}\|_{B^r_{2,\infty}} + \|w^{(n)}\|_{B^{r-1}_{2,\infty}}\|\theta^{(n)}\|_{B^{r+2\alpha}_{2,\infty}}\big) \\ &\le C\big(\|\eta^{(n)}\|_{B^{r-1+2\alpha}_{2,\infty}}\|\theta^{(n)}\|_{B^r_{2,\infty}} + \|\eta^{(n)}\|_{B^{r-1}_{2,\infty}}\|\theta^{(n)}\|_{B^{r+2\alpha}_{2,\infty}}\big). \end{aligned}$$

Inserting these estimates in (3.7) yields

$$\begin{aligned} &\frac{d}{dt}\|\eta^{(n+1)}\|_{B^{r-1}_{2,\infty}} + C_1\kappa\|\eta^{(n+1)}\|_{B^{r-1+2\alpha}_{2,\infty}} \\ &\quad \le C_3\big(\|\theta^{(n)}\|_{B^{r+2\alpha}_{2,\infty}}\|\eta^{(n+1)}\|_{B^{r-1}_{2,\infty}} + \|\eta^{(n+1)}\|_{B^{r-1+2\alpha}_{2,\infty}}\|\theta^{(n)}\|_{B^r_{2,\infty}}\big) \\ &\qquad + C_3\big(\|\eta^{(n)}\|_{B^{r-1+2\alpha}_{2,\infty}}\|\theta^{(n)}\|_{B^r_{2,\infty}} + \|\eta^{(n)}\|_{B^{r-1}_{2,\infty}}\|\theta^{(n)}\|_{B^{r+2\alpha}_{2,\infty}}\big). \end{aligned}$$

Integrating over $[0,t]$, we obtain

$$\sup_{\tau\in[0,t]}\|\eta^{(n+1)}(\cdot,\tau)\|_{B^{r-1}_{2,\infty}}+C_1\kappa\int_0^t\|\eta^{(n+1)}(\cdot,\tau)\|_{B^{r-1+2\alpha}_{2,\infty}}\,d\tau$$

$$\le\|\theta_0^{(n+1)}\|_{B^{r-1}_{2,\infty}}+C_3\left(\sup_{\tau\in[0,t]}\|\eta^{(n+1)}\|_{B^{r-1}_{2,\infty}}+\sup_{\tau\in[0,t]}\|\eta^{(n)}\|_{B^{r-1}_{2,\infty}}\right)\int_0^t\|\theta^{(n)}\|_{B^{r+2\alpha}_{2,\infty}}d\tau$$

$$+C_3\sup_{\tau\in[0,t]}\|\theta^{(n)}\|_{B^r_{2,\infty}}\int_0^t\left(\|\eta^{(n)}\|_{B^{r-1+2\alpha}_{2,\infty}}+\|\eta^{(n+1)}\|_{B^{r-1+2\alpha}_{2,\infty}}\right)d\tau. \tag{3.8}$$

We now show by induction that for any $t\ge 0$,

$$\sup_{\tau\in[0,t]}\|\eta^{(n)}(\cdot,\tau)\|_{B^{r-1}_{2,\infty}}+C_1\kappa\int_0^t\|\eta^{(n)}(\cdot,\tau)\|_{B^{r-1+2\alpha}_{2,\infty}}\,d\tau\le\|\theta_0\|_{B^r_{2,\infty}}\,2^{-(n-3)}. \tag{3.9}$$

First, we notice that

$$\|\theta_0^{(n+1)}\|_{B^{r-1}_{2,\infty}}=\|\Delta_{n+1}\theta_0\|_{B^{r-1}_{2,\infty}}\le\|\theta_0\|_{B^r_{2,\infty}}\,2^{-n}.$$

Now, we require that C_0 further satisfy

$$2C_0C_3/C_1\le 1/4.$$

According to (3.6), we have the uniform bounds

$$C_3\sup_{\tau\in[0,t]}\|\theta^{(n)}(\cdot,\tau)\|_{B^r_{2,\infty}}\le 2C_0C_3\kappa,\quad C_3\int_0^t\|\theta^{(n)}(\cdot,\tau)\|_{B^{r+2\alpha}_{2,\infty}}\,d\tau\le 2C_0C_3/C_1.$$

If (3.9) is satisfied by $n=k$, then it follows from (3.8) that

$$\begin{aligned}&\frac{3}{4}\left(\max_{\tau\in[0,t]}\|\eta^{(k+1)}(\cdot,\tau)\|_{B^{r-1}_{2,\infty}}+C_1\kappa\int_0^t\|\eta^{(k+1)}(\cdot,\tau)\|_{B^{r-1+2\alpha}_{2,\infty}}\,d\tau\right)\\&\le\|\theta_0\|_{B^r_{2,\infty}}\,2^{-k}+\frac{1}{4}\left(\max_{\tau\in[0,t]}\|\eta^{(k)}(\cdot,\tau)\|_{B^{r-1}_{2,\infty}}+C_1\kappa\int_0^t\|\eta^{(k)}(\cdot,\tau)\|_{B^{r-1+2\alpha}_{2,\infty}}\,d\tau\right)\\&\le 3\|\theta_0\|_{B^r_{2,\infty}}\,2^{-k}.\end{aligned}$$

Thus, (3.9) is true for $n=k+1$. In other words, $\{\eta^{(n)}\}=\{\theta^{(n)}-\theta^{(n-1)}\}$ is a Cauchy sequence in $L^\infty([0,\infty);B^{r-1}_{2,\infty})$.

Therefore, there exists a $\theta\in L^\infty([0,\infty);B^r_{2,\infty})\cap L^1([0,\infty);B^{r+2\alpha}_{2,\infty})$ such that

$$\theta^{(n)}\to\theta\quad\text{in}\quad L^\infty([0,\infty);B^{r-1}_{2,\infty})\cap L^1([0,\infty);B^{r-1+2\alpha}_{2,\infty}).$$

Furthermore, for $0\le\alpha\le\frac{1}{2}$,

$$\begin{aligned}\|\partial_t\theta^{(n)}(\cdot,t)\|_{B^{r-1}_{2,\infty}}&\le\|u^{(n-1)}\cdot\nabla\theta^{(n)}(\cdot,t)\|_{B^{r-1}_{2,\infty}}+\kappa\|\Lambda^{2\alpha}\theta^{(n)}(\cdot,t)\|_{B^{r-1}_{2,\infty}}\\&\le C_3\|\theta^{(n)}(\cdot,t)\|_{B^r_{2,\infty}}\|\theta^{(n-1)}(\cdot,t)\|_{B^{r-1}_{2,\infty}}+\kappa\|\theta^{(n)}(\cdot,t)\|_{B^r_{2,\infty}}\\&\le C_3(C_0\kappa)^2+C_0\kappa^2=(C_3C_0+1)C_0\kappa^2.\end{aligned}$$

Therefore, $\theta \in \mathrm{Lip}([0,\infty); B^{r-1}_{2,\infty})$. Another consequence is $\theta \in C([0,\infty); B^{\delta}_{2,\infty})$ for any $\delta \in [r-1, r)$. Finally, the a priori estimates in Proposition 3.2 and Corollary 3.3 allow us to conclude that

$$\|\theta(\cdot,t)\|_{B^r_{2,\infty}} \le C_0\kappa.$$

This completes the proof. □

4. Global existence in $B_{,\infty}$ with $p > 2$. Attention is now turned to the 2D dissipative QG equation

$$\partial_t\theta + u\cdot\nabla\theta + \kappa\Lambda^{2\alpha}\theta = 0 \tag{4.1}$$

with $\theta(x,0) = \theta_0(x)$ in the Besov space $B^r_{p,\infty}$. We have the following theorem.

THEOREM 4.1. *Let $\kappa > 0$ and let $0 \le \alpha \le \frac{1}{2}$. Consider the solution of the dissipative QG equation* (4.1) *corresponding to $\theta_0 \in B^r_{2,\infty} \cap B^r_{p,\infty}$ with $p = 2^N (N > 1)$. Assume that*

$$\begin{cases} r > 1 + \frac{2}{p} \text{ and } \|\theta_0\|_{B^r_{2,\infty}} \le C_0\kappa \quad \text{if } (1-2\alpha)p \le 2, \\ r > 2 - 2\alpha,\ \|\theta_0\|_{B^r_{2,\infty}} \le C_0\kappa, \text{ and } \|\theta_0\|_{B^r_{p,\infty}} \le C_0\kappa \quad \text{if } (1-2\alpha)p > 2, \end{cases} \tag{4.2}$$

where C_0 is a suitably chosen constant with dependence on α, r, and p only. Then the 2D QG equation (4.1) *has a unique global solution θ satisfying*

$$\theta \in L^\infty([0,\infty); B^r_{p,\infty}) \cap L^1([0,\infty); B^{r+2\alpha}_{p,\infty}) \cap \mathrm{Lip}([0,\infty); B^{r-1}_{p,\infty}) \cap C([0,\infty); B^{\delta}_{p,\infty})$$

for any $\delta \in [r-1, r)$, and

$$\|\theta(\cdot,t)\|_{B^r_{p,\infty}} \le \max\{\|\theta_0\|_{B^r_{p,\infty}}, \tilde{C}_0\kappa\}$$

for any $t \ge 0$ and some constant $\tilde{C}_0$ depending on α, r, and p only.

The rest of this section revolves around the proof of Theorem 4.1 and is divided into two subsections. The first subsection presents an a priori estimate and the second subsection proves Theorem 4.1.

4.1. An a priori bound. We state and prove a global a priori bound.

PROPOSITION 4.2. *Assume that θ solves the 2D dissipative QG equation* (4.1) *with $\kappa > 0$ and $0 \le \alpha \le 1$. Let $r \in \mathbb{R}$, let $p = 2^N$ for an integer $N > 1$, and let $s > 1 + \frac{2}{p}$. Then*

$$\frac{d}{dt}\|\theta\|_{B^r_{p,\infty}} + C_4\, p^{-1}\,\kappa\,\|\theta\|^{1+\beta p}_{B^r_{p,\infty}}\,\|\theta\|^{-\beta p}_{B^r_{2,\infty}} \le C_5\,\|\theta\|_{B^r_{p,\infty}}\,\|\theta\|_{B^s_{p,\infty}}, \tag{4.3}$$

where $\beta = \frac{2\alpha}{p-2}$, and C_4 and C_5 are constants with possible dependence on α and p only.

Remark. The case $p = 2$ is excluded here since this case has been dealt with in the previous section. The assumption $p = 2^N$ is made in order to use Proposition 2.7.

Proof of Proposition 4.2. Applying Δ_j to (4.1), multiplying by $p|\Delta_j\theta|^{p-2}\Delta_j\theta$, and integrating over $\mathbb{R}^2$, we obtain

$$\frac{d}{dt}\|\Delta_j\theta\|^p_{L^p} + I = II, \tag{4.4}$$

where I and II represent the terms

$$I = \kappa p \int |\Delta_j\theta|^{p-2}(\Delta_j\theta)\Lambda^{2\alpha}\Delta_j\theta\, dx,$$

$$II = p \int |\Delta_j\theta|^{p-2}(\Delta_j\theta)\,[u\cdot\nabla, \Delta_j]\theta dx.$$

To estimate II, we first apply Hölder's inequality and then Proposition 2.2 to obtain

$$\begin{aligned} |II| &\le p\,\|\Delta_j\theta\|_{L^p}^{p-1}\,\|[u\cdot\nabla,\Delta_j]\theta\|_{L^p} \\ &\le p\,\|\Delta_j\theta\|_{L^p}^{p-1}\,\big[2^{-jr}\big(\|\nabla u\|_{L^\infty}\|\theta\|_{B^r_{p,\infty}} + \|\nabla\theta\|_{L^\infty}\,\|u\|_{B^r_{p,\infty}}\big)\big]. \end{aligned}$$

For $s > 1+\frac{2}{p}$, Proposition 2.5 asserts that

$$\|\nabla\theta\|_{L^\infty} \le C\,\|\theta\|_{B^s_{p,\infty}}, \quad \|\nabla u\|_{L^\infty} \le C\,\|u\|_{B^s_{p,\infty}} \le C\,\|\theta\|_{B^s_{p,\infty}}.$$

Therefore, for some constant C,

$$|II| \le C\,p\,2^{-jr}\,\|\Delta_j\theta\|_{L^p}^{p-1}\,\|\theta\|_{B^r_{p,\infty}}\,\|\theta\|_{B^s_{p,\infty}}. \tag{4.5}$$

To obtain a lower bound for I, we use Proposition 2.6 and a basic embedding inequality,

$$I \ge C\,\kappa\int\left|\Lambda^\alpha\left(|\Delta_j\theta|^{\frac{p}{2}}\right)\right|^2 dx \ge C\,\kappa\left(\int|\Delta_j\theta|^{\frac{p}{1-\alpha}}dx\right)^{1-\alpha} = C\,\kappa\|\Delta_j\theta\|^p_{L^{\frac{p}{1-\alpha}}},$$

where the assumption $p = 2^N$ is used in the first inequality. Applying the interpolation inequality

$$\|f\|_{L^p} \le C\,\|f\|_{L^2}^{\frac{2\alpha}{p+2\alpha-2}}\,\|f\|_{L^{\frac{p}{1-\alpha}}}^{\frac{p-2}{p+2\alpha-2}}$$

with $f = \Delta_j\theta$, we finally obtain the lower bound

$$I \ge C\,\kappa\|\Delta_j\theta\|_{L^p}^{(1+\beta)p}\,\|\Delta_j\theta\|_{L^2}^{-\beta p}, \tag{4.6}$$

where we have set $\beta = \frac{2\alpha}{p-2}$. Combining (4.4), (4.5), and (4.6) yields

$$\frac{d}{dt}\|\theta\|_{B^r_{p,\infty}} + C\,p^{-1}\,\kappa\,2^{jr}\,\|\Delta_j\theta\|_{L^p}^{1+\beta\,p}\,\|\Delta_j\theta\|_{L^2}^{-\beta p} \le C\,\|\theta\|_{B^r_{p,\infty}}\,\|\theta\|_{B^s_{p,\infty}}$$

or, equivalently,

$$\frac{d}{dt}\|\theta\|_{B^r_{p,\infty}} + C\,p^{-1}\,\kappa\,\|\theta\|_{B^r_{p,\infty}}^{1+\beta\,p}\,\|\theta\|_{B^r_{2,\infty}}^{-\beta\,p} \le C\,\|\theta\|_{B^r_{p,\infty}}\,\|\theta\|_{B^s_{p,\infty}}. \qquad \square$$

We now explore several consequences of Proposition 4.2. If $(1-2\alpha)p \le 2$, then $2\alpha + 2/p \ge 1$ or $\beta p \ge 1$. In addition, $r > 1 + 2/p$ implies $r > 2 - 2\alpha$. It thus follows from Corollary 3.3 that $\|\theta_0\|_{B^r_{2,\infty}} \le C_0\kappa$ implies

$$\|\theta(\cdot,t)\|_{B^r_{2,\infty}} \le C_0\kappa$$

for all $t > 0$. Consequently, (4.3) can be reduced to

$$\frac{d}{dt}\|\theta\|_{B^r_{p,\infty}} \le C_5\,\|\theta\|^2_{B^r_{p,\infty}}\big(1 - C_5^{-1}\,C_4\,(p\,C_0^{\beta p})^{-1}\,\kappa^{1-\beta p}\,\|\theta\|^{\beta\,p-1}_{B^r_{p,\infty}}\big). \tag{4.7}$$

For $\beta p > 1$, (4.7) indicates that

$$\begin{cases} \|\theta(\cdot,t)\|_{B^r_{p,\infty}} \text{ decreases as a function of } t \text{ for a big initial norm } \|\theta_0\|_{B^r_{p,\infty}}, \\ \|\theta(\cdot,t)\|_{B^r_{p,\infty}} \text{ increases up to } \big(C_4/(p\,C_5\,C_0^{\beta\,p})\big)^{\frac{1}{\beta p-1}}\,\kappa \text{ for small } \|\theta_0\|_{B^r_{p,\infty}}. \end{cases}$$

In other words,

$$\|\theta(\cdot,t)\|_{B^r_{p,\infty}} \le \max\Big\{\|\theta_0\|_{B^r_{p,\infty}},\,\big(C_4/(p\,C_5\,C_0^{\beta\,p})\big)^{\frac{1}{\beta p-1}}\,\kappa\Big\}.$$

For $\beta p = 1$ and $C_0 \le C_4/(pC_5)$, (4.7) indicates that $\|\theta(\cdot,t)\|_{B^r_{p,\infty}}$ is a decreasing function of t and thus

$$\|\theta(\cdot,t)\|_{B^r_{p,\infty}} \le \|\theta_0\|_{B^r_{p,\infty}}$$

for any $t \ge 0$.

If $(1-2\alpha)p > 2$, then $1 + \beta p < 2$ and $r > 2 - 2\alpha$ implies that $r > 1 + \frac{2}{p}$. In this case, (4.3) becomes

$$\frac{d}{dt}\|\theta\|_{B^r_{p,\infty}} \le \|\theta\|^{1+\beta\,p}_{B^r_{p,\infty}}\big(C_5\|\theta\|^{1-\beta\,p}_{B^r_{p,\infty}} - C_4\,(p\,C_0^{\beta p})^{-1}\,\kappa^{1-\beta p}\big).$$

If θ_0 satisfies

$$\|\theta_0\|_{B^r_{p,\infty}} \le \big(C_4/(p\,C_5\,C_0^{\beta\,p})\big)^{\frac{1}{1-\beta p}}\,\kappa, \tag{4.8}$$

then $\|\theta(\cdot,t)\|_{B^r_{p,\infty}}$ decreases as a function of t and thus

$$\|\theta(\cdot,t)\|_{B^r_{p,\infty}} \le \|\theta_0\|_{B^r_{p,\infty}}$$

for any $t \ge 0$.

In summary, we have established the following corollary.

COROLLARY 4.3. *Let $\kappa > 0$ and let $0 \le \alpha \le 1$. Assume that θ solves the 2D dissipative QG equation* (4.1) *corresponding to θ_0 in $B^r_{2,\infty} \cap B^r_{p,\infty}$ with $p = 2^N (N > 1)$. If r and θ_0 satisfy* (4.2)*, then we have the global bounds*

$$\|\theta(\cdot,t)\|_{B^r_{2,\infty}} \le \tilde{C}_0\kappa \quad \textit{and} \quad \|\theta(\cdot,t)\|_{B^r_{p,\infty}} \le \max\{\|\theta_0\|_{B^r_{p,\infty}}, \tilde{C}_0\kappa\}$$

for some constant $\tilde{C}_0$ depending on α, r, and p only.

It is worth mentioning that the argument leading to the above corollary can be replaced by utilizing explicit formulas given in the following lemma.

LEMMA 4.4. *Let $\sigma > 0$. Assume that $y = y(t)$ satisfies*

$$\frac{d}{dt}y + g(t)y^{1+\sigma} \le h(t)y \tag{4.9}$$

for real-valued functions g and h. Then $y = y(t)$ is bounded pointwise according to

$$y(t) \le \frac{y(0)\,\exp\left(\int_0^t h(\tau)d\tau\right)}{\left(1+\sigma\, y^\sigma(0)\,\int_0^t g(\tau)\exp\left(\sigma\int_0^\tau h(s)ds\right)d\tau\right)^{\frac{1}{\sigma}}}. \tag{4.10}$$

Proof. It follows easily from (4.9) that $z = y\,\exp\left(-\int_0^t h(\tau)d\tau\right)$ satisfies

$$\frac{d}{dt}z \le -g(t)\,\exp\left(\sigma\int_0^t h(\tau)d\tau\right)\,z^{1+\sigma}.$$

Dividing both sides by $z^{1+\sigma}$ and integrating over $[0,t]$, we obtain

$$z^{-\sigma}(t) \ge z^{-\sigma}(0) + \sigma\int_0^t g(\tau)\exp\left(\sigma\int_0^\tau h(s)ds\right)d\tau,$$

which can be converted into the following inequality for y:

$$y^\sigma \le \frac{y^\sigma(0)\,\exp\left(\sigma\int_0^t h(\tau)d\tau\right)}{1+\sigma y^\sigma(0)\,\int_0^t g(\tau)\exp\left(\sigma\int_0^\tau h(s)ds\right)d\tau}.$$

Raising both sides to $\frac{1}{\sigma}$ yields (4.10). ∎

When an extra term $f(t)$ is added to (4.9), the method of variation of constants still allows us to obtain a formal bound involving a function $C(t)$, which satisfies an additional ordinary differential equation.

LEMMA 4.5. *Let $\sigma > 0$. Assume that $y = y(t)$ satisfies*

$$\frac{d}{dt}y + g(t)y^{1+\sigma} \le h(t)y + f(t) \tag{4.11}$$

for real-valued functions g, h, and f. Then y obeys the bound

$$y(t) \le \frac{\exp\left(\int_0^t h(\tau)d\tau\right)}{\left(-\sigma C(t)+\sigma\,\int_0^t g(\tau)\exp\left(\sigma\int_0^\tau h(s)ds\right)d\tau\right)^{\frac{1}{\sigma}}}, \tag{4.12}$$

where $C(t)$ satisfies the following ordinary differential equation:

$$\begin{aligned}\frac{d}{dt}C(t) &= f(t)\,\exp\left(-\int_0^t h(\tau)d\tau\right)\\ &\quad\times\left(-\sigma C(t)+\sigma\,\int_0^t g(\tau)\exp\left(\sigma\int_0^\tau h(s)ds\right)d\tau\right)^{1+\frac{1}{\sigma}}\end{aligned} \tag{4.13}$$

with the initial datum $C(0) = -1/(\sigma y^\sigma(0))$.

Remark. When $f = 0$, $C(t) = C(0) = -1/(\sigma y^\sigma(0))$ and (4.12) becomes (4.10).

4.2. Proof of Theorem 4.1. Assume that $\{\theta^{(n)}\}$ is a successive approximation sequence satisfying the equations

$$\begin{cases} \theta^{(1)} = S_2\theta_0, \\ \partial_t\theta^{(n+1)} + u^{(n)}\cdot\nabla\theta^{(n+1)} + \kappa\Lambda^{2\alpha}\theta^{(n+1)} = 0, \\ u^{(n)} = \mathcal{R}^{\perp}(\theta^{(n)}), \\ \theta^{(n+1)}(x,0) = \theta_0^{(n+1)}(x) = S_{n+2}\theta_0. \end{cases}$$

Following the same procedure as in the proof of Proposition 4.2 leads to

$$\frac{d}{dt}\|\theta^{(n+1)}\|_{B^r_{p,\infty}} + C_4\, p^{-1}\,\kappa\,\|\theta^{(n+1)}\|^{1+\beta\,p}_{B^r_{p,\infty}}\,\|\theta^{(n+1)}\|^{-\beta\,p}_{B^r_{2,\infty}} \le C_5\,\|\theta^{(n)}\|_{B^r_{p,\infty}}\,\|\theta^{(n+1)}\|_{B^r_{p,\infty}}. \tag{4.14}$$

If the conditions in (4.2) are met, we know from the proof of Theorem 3.1 that

$$\|\theta^{(n)}(\cdot,t)\|_{B^r_{2,\infty}} \le C_0\kappa$$

for any integer n and any $t \ge 0$. Inequality (4.14) can then be rewritten as

$$\frac{d}{dt}\|\theta^{(n+1)}\|_{B^r_{p,\infty}} \le \|\theta^{(n+1)}\|_{B^r_{p,\infty}}\left(C_5\,\|\theta^{(n)}\|_{B^r_{p,\infty}} - C_4(pC_0^{\beta p})^{-1}\kappa^{1-\beta p}\,\|\theta^{(n+1)}\|^{\beta\,p}_{B^r_{p,\infty}}\right).$$

When (4.2) is satisfied, we can argue similarly as in the previous subsection and conclude that

$$\|\theta^{(n)}(\cdot,t)\|_{B^r_{p,\infty}} \le \begin{cases} \|\theta_0\|_{B^r_{p,\infty}} & \text{if } \beta p \le 1, \\ \max\left\{\|\theta_0\|_{B^r_{p,\infty}},\ \left(C_4/(p\,C_5\,C_0^{\beta\,p})\right)^{\frac{1}{\beta p-1}}\ \kappa\right\} & \text{if } \beta p > 1. \end{cases} \tag{4.15}$$

An alternative argument using the explicit formula in Lemma 4.9 also leads to the same bound.

We now show that $\{\eta^{(n)}\} = \{\theta^{(n)} - \theta^{(n-1)}\}$ is a Cauchy sequence in $C([0,\infty); B^{r-1}_{p,\infty})$. The sequence $\{\eta^{(n)}\}$ satisfies

$$\begin{cases} \eta^{(1)} = S_2\theta_0 - \theta_0, \\ \partial_t\eta^{(n+1)} + u^{(n)}\cdot\nabla\eta^{(n+1)} + \kappa\Lambda^{2\alpha}\eta^{(n+1)} = w^{(n)}\cdot\nabla\theta^{(n)}, \\ w^{(n)} = \mathcal{R}^{\perp}(\eta^{(n)}), \\ \eta^{(n+1)}(x,0) = \eta_0^{(n+1)}(x) = \Delta_{n+1}\theta_0. \end{cases}$$

Following the procedures as in the proof of Theorem 3.1 as well as in the first part of this proof, we obtain

$$\frac{d}{dt}\|\eta^{(n+1)}\|_{B^{r-1}_{p,\infty}} + C_4\,p^{-1}\,\kappa\,\|\eta^{(n+1)}\|^{1+\beta\,p}_{B^{r-1}_{p,\infty}}\,\|\eta^{(n+1)}\|^{-\beta\,p}_{B^{r-1}_{2,\infty}} \le K_1 + K_2, \tag{4.16}$$

where K_1 and K_2 represent

$$K_1 = 2^{(r-1)j}\|[u^{(n)}\cdot\nabla, \Delta_j]\eta^{(n+1)}\|_{L^p}, \quad K_2 = \|w^{(n)}\cdot\nabla\theta^{(n)}\|_{B^{r-1}_{p,\infty}}.$$

To estimate K_1 and K_2, we assume that (4.2) is satisfied. By Proposition 2.3,

$$\begin{aligned} K_1 &\le C\left(\|\nabla u^{(n)}\|_{L^\infty}\|\eta^{(n+1)}\|_{B^{r-1}_{p,\infty}} + \|\eta^{(n+1)}\|_{L^\infty}\|u^{(n)}\|_{B^r_{p,\infty}}\right) \\ &\le 2C\,\|u^{(n)}\|_{B^r_{p,\infty}}\,\|\eta^{(n+1)}\|_{B^{r-1}_{2,\infty}} \\ &\le 2C\,\|\theta^{(n)}\|_{B^r_{p,\infty}}\,\|\eta^{(n+1)}\|_{B^{r-1}_{p,\infty}}. \end{aligned} \tag{4.17}$$

By Proposition 2.4,

$$\begin{aligned} K_2 &\le C\left(\|w^{(n)}\|_{L^\infty}\|\nabla\theta^{(n)}\|_{B^{r-1}_{p,\infty}} + \|w^{(n)}\|_{B^{r-1}_{p,\infty}}\|\nabla\theta^{(n)}\|_{L^\infty}\right) \\ &\le 2C\|\theta^{(n)}\|_{B^r_{p,\infty}}\|w^{(n)}\|_{B^{r-1}_{p,\infty}} \\ &\le 2C\|\theta^{(n)}\|_{B^r_{p,\infty}}\|\eta^{(n)}\|_{B^{r-1}_{p,\infty}}. \end{aligned} \tag{4.18}$$

Inserting (4.17) and (4.18) in (4.16), we obtain

$$\begin{aligned} &\frac{d}{dt}\|\eta^{(n+1)}\|_{B^{r-1}_{p,\infty}} + C_4\,p^{-1}\,\kappa\,\|\eta^{(n+1)}\|^{1+\beta\,p}_{B^{r-1}_{p,\infty}}\,\|\eta^{(n+1)}\|^{-\beta\,p}_{B^{r-1}_{2,\infty}} \\ &\quad\le C_7\,\|\theta^{(n)}\|_{B^r_{p,\infty}}\,\left(\|\eta^{(n+1)}\|_{B^{r-1}_{p,\infty}} + \|\eta^{(n)}\|_{B^{r-1}_{p,\infty}}\right). \end{aligned} \tag{4.19}$$

According to the proof of Theorem 3.1 and the first part of this proof,

$$\|\eta^{(n+1)}\|_{B^{r-1}_{2,\infty}} \le \|\theta_0\|_{B^{r-1}_{2,\infty}}\,2^{-(n-2)}, \qquad \|\theta^{(n)}\|_{B^r_{p,\infty}} \le \max\{\|\theta_0\|_{B^r_{p,\infty}},\,\tilde{C}\kappa\},$$

where $\tilde{C}$ is a constant. We are now ready to show that

$$\|\eta^{(n+1)}(\cdot,t)\|_{B^{r-1}_{p,\infty}} \le \bar{C}\,2^{-(n-2-1/(\beta p))},$$

where $\bar{C}$ is given explicitly by

$$\bar{C} = \max\left\{\frac{1}{2},\ \left(2C_7\,\max\{\|\theta_0\|_{B^r_{p,\infty}},\tilde{C}\kappa\}/(C_4 p^{-1}\kappa)\right)^{1/\sigma}\right\}\,\|\theta_0\|_{B^r_{p,\infty}}.$$

To simplify the notation, we set

$$\sigma = \beta p, \quad y(t) = \|\eta^{(n+1)}(\cdot,t)\|_{B^{r-1}_{p,\infty}}, \quad g = C_4 p^{-1}\,\kappa\,2^{(n-1)}\,\|\theta_0\|^{-\sigma}_{B^{r-1}_{2,\infty}},$$

$$h = C_7\,\max\{\|\theta_0\|_{B^r_{p,\infty}},\,\tilde{C}\kappa\}, \quad f = C_7\,\max\{\|\theta_0\|_{B^r_{p,\infty}},\,\tilde{C}\kappa\}\,\bar{C}\,2^{-(n-3-1/(\beta p))}.$$

Inequality (4.19) then becomes

$$\frac{d}{dt}y \le -g\,y^{\sigma+1} + h\,y + f.$$

We further write $z(t)$ for the right-hand side of the inequality above. If $y(0)$ is sufficiently large such that $z(0) \le 0$, then

$$N \equiv \sup_{t\ge 0} y(t) \le y(0).$$

If, on the other hand, $y(0)$ is small and $z(0) \geq 0$, then $y(t)$ initially grows as t increases. But its growth stops as soon as $z(t)$ becomes zero. Therefore, N obeys

$$-g\,N^{1+\sigma} + h\,N + f = 0 \quad \text{or} \quad N^{1+\sigma} - \frac{h}{g}\,N = \frac{f}{g}. \tag{4.20}$$

The discussion is then divided into two cases: i) $N^\sigma \leq 2h/g$ and ii) $N^\sigma > 2h/g$. In the first case,

$$N \leq \left(\frac{2h}{g}\right)^{\frac{1}{\sigma}}.$$

In the second case, (4.20) implies that

$$N^{1+\sigma} < \frac{2f}{g} \quad \text{or} \quad N \leq \left(\frac{2f}{g}\right)^{\frac{1}{1+\sigma}}.$$

In summary, we have obtained

$$\sup_{t\geq 0} y(t) \leq \max\left\{y(0),\, \left(\frac{2h}{g}\right)^{\frac{1}{\sigma}},\, \left(\frac{2f}{g}\right)^{\frac{1}{1+\sigma}}\right\}. \tag{4.21}$$

Returning to the original variable, we find

$$y(0) = \|\Delta_{n+1}\theta_0\|_{B^{r-1}_{p,\infty}} \leq \|\theta_0\|_{B^r_{p,\infty}}\, 2^{-n}, \quad \left(\frac{2h}{g}\right)^{\frac{1}{\sigma}} \leq \bar{C}\, 2^{-n+2},$$

$$\left(\frac{2f}{g}\right)^{\frac{1}{1+\sigma}} \leq \bar{C}\left(2^{-n+3+1/\sigma}\; 2^{-\sigma(n-2)}\right)^{\frac{1}{1+\sigma}} \leq \bar{C}\, 2^{-(n-2-1/\sigma)}.$$

As a consequence, (4.21) yields the desired bound

$$\sup_{t\geq 0} \|\eta^{(n+1)}(\cdot,t)\|_{B^{r-1}_{p,\infty}} \leq \bar{C}\, 2^{-(n-2-1/(\beta p))}.$$

After a similar argument as in the proof of Theorem 3.1, the proof of Theorem 4.1 is then completed. □

LINEARIZED STABILITY ANALYSIS OF STATIONARY SOLUTIONS FOR SURFACE DIFFUSION WITH BOUNDARY CONDITIONS*

HARALD GARCKE†, KAZUO ITO‡, AND YOSHIHITO KOHSAKA§

Abstract. The linearized stability of stationary solutions to the surface diffusion flow with angle conditions and no-flux conditions as boundary conditions is studied. We perform a linearized stability analysis in which the H^{-1}-gradient flow structure plays a key role. As a byproduct our analysis also gives a criterion for the stability of critical points of the length functional of curves which come into contact with the outer boundary. Finally, we study the linearized stability of several examples.

Key words. surface diffusion, gradient flow, stability of stationary solutions, eigenvalues, isoperimetric problems

1. Introduction.

The geometrical evolution law

$$V = -\Delta\kappa$$

was derived by Mullins [20] to model the motion of interfaces in the case that the motion of interfaces is governed purely by mass diffusion within the interfaces (for simplicity we set the diffusion constant to 1). Here V is the normal velocity of the evolving interface, Δ is the Laplace–Beltrami operator, and κ is the mean curvature of the interface where we use the sign convention that a sphere with the normal pointing to the inside has positive curvature. We also refer to work by Davi and Gurtin [7], who derived the above law from balance laws in conjunction with an appropriate version of the second law of thermodynamics, and to work by Cahn, Elliott, and Novick-Cohen [4], who derived this evolution law as the sharp interface limit of a Cahn–Hilliard equation with degenerate mobility. This evolution law has the property that for closed embedded hypersurfaces the enclosed volume is preserved and the surface area decreases in time (see, e.g., [10], [11]). An existence result for curves in the plane and stability of spheres—which are stationary under the flow—has been shown by Elliott and Garcke [10]. This result was generalized to the higher-dimensional case by Escher, Mayer, and Simonett [11].

In general, interfaces will meet an outer boundary or they might intersect at triple or multiple junctions. In this case boundary conditions have to hold, and they were derived by Garcke and Novick-Cohen [14] as the asymptotic limit of a Cahn–Hilliard system with a degenerate mobility matrix. At the outer boundary and at triple junctions, angle conditions and a balance condition for the mass fluxes have to

hold. In addition, at triple junctions a continuity condition for chemical potentials has to hold. Numerical simulations for the degenerate Cahn–Hilliard systems have been performed by Barrett, Blowey, and Garcke [2]. An existence result for surface diffusion of curves that intersect the outer boundary and meet at triple junctions has been given by Garcke and Novick-Cohen [14]. The stability problem for stationary solutions for the surface diffusion flow with triple junctions was addressed by Ito and Kohsaka [18], by Escher, Garcke, and Ito [12] in the case of a geometry with a mirror symmetry, and by Ito and Kohsaka [19] in a triangular domain. The general case is still open. This is partly due to the fact that the stability depends in a nontrivial way on the geometry of the boundary.

For motion by mean curvature, which is given by the law

$$V = \kappa, \tag{1.1}$$

the stability of stationary interfaces with boundaries was studied by Rubinstein, Sternberg, and Keller [21] in the case where the evolving curves intersect an outer boundary with a 90° angle. For stability results for the stationary solutions of (1.1) in the presence of triple junctions, we refer to Sternberg and Ziemer [22] and Ikota and Yanagida [16]. The last authors developed a linear stability criterion that is based on ideas of Ei and Yanagida [9] and Ei, Sato, and Yanagida [8].

One main difference between motion by mean curvature and motion by surface diffusion is that the former does not preserve volume, whereas the latter does. This implies that the stationary solutions are different. For motion by surface diffusion, spherical arcs that intersect the outer boundary perpendicular are stationary. It is the goal of this paper to study the stability of such stationary solutions under surface diffusion. More precisely we study the following problem. Given an open bounded domain Ω, we look for evolving curves $\Gamma = (\Gamma_t)_{t>0}$ (for a definition see Gurtin [15]) lying in Ω with the following properties (for a precise definition of the flow see section 2):

$$\begin{cases} V = -\kappa_{ss} & \text{for all points on the curve,} \\ \partial\Gamma_t \subset \partial\Omega & \text{at all times,} \\ \sphericalangle(\partial\Omega, \Gamma) = \pi/2 & \text{at the boundary,} \\ \kappa_s = 0 & \text{at the boundary.} \end{cases} \tag{1.2}$$

Here a subscript s denotes differentiation with respect to arc-length. The second and third conditions imply that the boundary of the curves at all times intersects the outer boundary perpendicularly. The last condition says that there is no mass flux at the outer boundary (see [14]). It is not difficult to show that (see [14])

$$\frac{d}{dt}\mathrm{Area}_\Gamma(t) = 0, \qquad \frac{d}{dt}\mathrm{Length}_\Gamma(t) \le 0$$

under surface diffusion with the above boundary conditions. Here we denote by $\mathrm{Area}_\Gamma(t)$ the area enclosed by the curve and $\partial\Omega$ at time t (for definiteness we take the side of Γ toward which the normal points) and by $\mathrm{Length}_\Gamma(t)$ the length of Γ at time t.

We will introduce a linear stability criterion based on the work of [9], [8], [16], which studied the mean curvature flow. The analysis in the case of surface diffusion is more difficult because the surface diffusion flow is the gradient flow with respect to the H^{-1} inner product (see [5], [13], [23]) in contrast to the case of motion by mean curvature, which is a gradient flow with respect to the L^2 inner product. We

want to emphasize that the observation that also the linearized problem is an H^{-1}-gradient flow of the bilinearized area functional is an important ingredient of our analysis (see section 4). Indeed, the zero solution is an asymptotically stable solution of the linearized equation $\rho_t = \mathcal{A}\rho$ ($\mathcal{A}$ being the linearized operator) if and only if all eigenvalues of $\mathcal{A}$ are negative, and it will turn out that this is equivalent to the fact that the bilinearized area functional is positive definite. We refer to Bates and Fife [3], who studied a linearized stability analysis for the Cahn–Hilliard equation, and also to Alikakos et al. [1], who considered the Mullins–Sekerka motion—which is also volume conserving—of small droplets on a fixed boundary.

The stability of stationary arcs that are attached perpendicular to the outer boundary depends on their curvature, their length, and the curvature of the outer boundary in a nontrivial way. The reader is advised to have a look at section 7, where we illustrate the stability behavior with the help of several examples. Taking advantage of the gradient flow property of the evolution and using variational arguments, we are able to analyze the linear stability behavior, i.e., the stability of the zero solution of the linearized operator (see section 6).

It would remain to show that the principle of linearized stability holds, which means, except for the critical (or neutral) case of stability, the zero solution of the linearized problem has the same stability as the stationary solution of the nonlinear problem around which we linearized the equation. For the nonlinear boundary conditions appearing in our problem, abstract semigroup theory cannot be applied directly. However, we refer to [12] for a result in this direction. Note that the principle of linearized stability in [12] is shown in spaces consisting of functions which are $(4+\gamma)$-Hölder continuous with respect to the space variable for $\gamma \in (0,1)$. We remark that it is a nontrivial task to apply the method of [12] to our problem. Indeed, in the setting in [12] the boundary conditions are simpler and the difficulties arising from the nonlinear boundary conditions could be resolved. But in our case the boundary conditions keep a highly nonlinear form, which makes the analysis of the principle of linearized stability more difficult. Furthermore, the area-preserving property leads to additional difficulties. In the linearization, a zero eigenvalue appears if we do not take the area-preserving property into account. The zero eigenvalue corresponds to equilibria of (1.2), which in general enclose a different area. In conclusion, if we do not take the mass conservation into account, none of the equilibria is isolated, which further complicates the nonlinear stability analysis (see [11], [12] for similar difficulties arising from an area-preserving property). Nonlinear stability analysis is the topic of ongoing research.

Finally, we remark that our results also have some relevance for isoperimetric problems, as they give stability results for critical points of the length functional, which is restricted to curves that enclose a fixed area. Since the surface diffusion flow reduces length conserving area at the same time, the study of critical points of the length functional (given an area constraint) is what the stability analysis for the evolution problem can be reduced to.

2. Parameterization. In this section we give a precise definition of the flow (1.2), and in particular we introduce a parameterization of an evolving curve that will be convenient for our analysis. For a smooth function $\psi : \mathbb{R}^2 \to \mathbb{R}$ with $\nabla\psi(x) \neq 0$, if $\psi(x) = 0$, set

$$\Omega = \{x \in \mathbb{R}^2 \mid \psi(x) < 0\}, \quad \partial\Omega = \{x \in \mathbb{R}^2 \mid \psi(x) = 0\}.$$

Let Γ_* be a stationary solution and let σ be the arc-length parameter of Γ_*. Then we denote an arc-length parameterization of Γ_* as

$$\Gamma_* = \{\Phi_*(\sigma) \mid \sigma \in [-l, l]\}.$$

Note that we can extend Γ_* naturally either to the full circle when Γ_* is a part of the circle or to the straight line when Γ_* is a line segment. Also note that the curvature κ_* of Γ_* is a constant. We denote

$$\bar{l} := \begin{cases} \pi/|\kappa_*|, & \kappa_* \neq 0, \\ +\infty, & \kappa_* = 0; \end{cases}$$

i.e., $\bar{l}$ is the length of the extension of Γ_* to a full circle (if $\kappa_* \neq 0$). Define

$$\begin{cases} \xi_+(q) = \max\{\sigma \in (-\bar{l}, \bar{l}) \mid \Phi_*(\sigma) + qN_*(\sigma) \in \Omega\}, \\ \xi_-(q) = \min\{\sigma \in (-\bar{l}, \bar{l}) \mid \Phi_*(\sigma) + qN_*(\sigma) \in \Omega\}, \end{cases}$$

where $q \in [-d, d]$ for a small $d > 0$, and $N_*(\sigma)$ is a unit normal vector of Γ_* at σ and is obtained by rotating the unit tangent vector $T_*(\sigma)$ of Γ_* with $\pi/2$. Then it holds that $\psi(\Phi_*(\xi_\pm(q)) + qN_*(\xi_\pm(q))) = 0$. In addition, we have $\xi_\pm(0) = \pm l$. Using the implicit function theorem, we see that $\xi_+(q)$ and $\xi_-(q)$ are smooth. Let

$$\Psi(\sigma, q) := \Phi_*(\xi(\sigma, q)) + qN_*(\xi(\sigma, q))$$

with

$$\xi(\sigma, q) := \xi_-(q) + \frac{\sigma + l}{2l}(\xi_+(q) - \xi_-(q)).$$

Note that $\xi(\pm l, q) = \xi_\pm(q)$ and $\xi(\sigma, 0) = \sigma$.

Let Γ be curves in the neighborhood of Γ_*, which touch the boundary $\partial\Omega$ and are contained in Ω. For some functions $\rho : [-l, l] \to [-d, d]$, we define $\Phi(\sigma) := \Psi(\sigma, \rho(\sigma))$ for $\sigma \in [-l, l]$, which denotes a parameterization of such curves Γ. Thus we set

$$\Gamma(t) := \{\Phi(\sigma, t) \mid \sigma \in [-l, l]\} \tag{2.1}$$

with $\Phi(\sigma, t) := \Psi(\sigma, \rho(\sigma, t))$ for a function ρ depending on σ and t. We remark that $\rho \equiv 0$ means that curves Γ coincide with a stationary curve Γ_*.

Let us derive the representation of (1.2) to the parameterization (2.1). For the arc-length parameter s of Γ, we have

$$\frac{ds}{d\sigma} = |\Phi_\sigma| = \sqrt{|\Psi_\sigma|^2 + 2(\Psi_\sigma, \Psi_q)_{\mathbb{R}^2}\rho_\sigma + |\Psi_q|^2\rho_\sigma^2} \ (=: J(\rho)). \tag{2.2}$$

Here and hereafter $(\cdot, \cdot)_{\mathbb{R}^2}$ denotes the inner product in $\mathbb{R}^2$. Then we find

$$T = \frac{1}{J(\rho)}\Phi_\sigma, \quad N = \frac{1}{J(\rho)}R\Phi_\sigma,$$

where T and N are the unit tangent and normal vector of Γ, respectively, and R is the rotation matrix with $\pi/2$. The normal velocity V of $\Gamma(t)$ is denoted by

$$V = (\Phi_t, N)_{\mathbb{R}^2} = \frac{1}{J(\rho)}(\Phi_t, R\Phi_\sigma)_{\mathbb{R}^2} = \frac{1}{J(\rho)}(\Psi_q, R\Psi_\sigma)_{\mathbb{R}^2}\rho_t.$$

Moreover, since (2.2) gives

$$\partial_s^2 = \frac{1}{J(\rho)}\partial_\sigma\left(\frac{1}{J(\rho)}\partial_\sigma\right) = \frac{1}{(J(\rho))^2}\partial_\sigma^2 + \frac{1}{J(\rho)}\left(\partial_\sigma\frac{1}{J(\rho)}\right)\partial_\sigma \ (=: \Delta(\rho)), \tag{2.3}$$

the curvature κ of $\Gamma(t)$ is written by

$$\begin{aligned}\kappa(\rho) &= (\Delta(\rho)\Phi, N)_{\mathbb{R}^2}\\ &= \frac{1}{(J(\rho))^3}(\Phi_{\sigma\sigma}, R\Phi_\sigma)_{\mathbb{R}^2}\\ &= \frac{1}{(J(\rho))^3}\Big[(\Psi_q, R\Psi_\sigma)_{\mathbb{R}^2}\rho_{\sigma\sigma} + \big\{2(\Psi_{\sigma q}, R\Psi_\sigma)_{\mathbb{R}^2} + (\Psi_{\sigma\sigma}, R\Psi_q)_{\mathbb{R}^2}\big\}\rho_\sigma\\ &\quad + \big\{(\Psi_{qq}, R\Psi_\sigma)_{\mathbb{R}^2} + 2(\Psi_{\sigma q}, R\Psi_q)_{\mathbb{R}^2} + (\Psi_{qq}, R\Psi_q)_{\mathbb{R}^2}\rho_\sigma\big\}\rho_\sigma^2\\ &\quad + (\Psi_{\sigma\sigma}, R\Psi_\sigma)_{\mathbb{R}^2}\Big].\end{aligned} \tag{2.4}$$

Thus the surface diffusion flow equation is described by

$$\rho_t = -L(\rho)\Delta(\rho)\kappa(\rho), \tag{2.5}$$

where

$$L(\rho) := \frac{1}{(\Psi_q, R\Psi_\sigma)_{\mathbb{R}^2}}J(\rho). \tag{2.6}$$

Let us derive the representation of the boundary conditions, which are the Neumann boundary condition and the no-flux condition $\kappa_s = 0$ on $\partial\Omega$ (the second condition in (1.2) is automatically fulfilled). Since the Neumann boundary condition $(\Phi_\sigma, T_{\partial\Omega})_{\mathbb{R}^2} = 0$ on $\partial\Omega$ is equivalent to $(R\Phi_\sigma, \nabla\psi(\Phi))_{\mathbb{R}^2} = 0$ on $\partial\Omega$, we have

$$(R\Psi_\sigma + R\Psi_q\rho_\sigma, \nabla\psi(\Psi))_{\mathbb{R}^2} = 0 \quad \text{at} \ \ \sigma = \pm l.$$

By (2.2) and (2.4) the no-flux condition $\kappa_s = 0$ on $\partial\Omega$ is denoted by

$$\partial_\sigma\kappa(\rho) = 0 \quad \text{at} \ \ \sigma = \pm l.$$

Consequently we have the following proposition.

PROPOSITION 2.1. *For a parameterization* (2.1)*, problem* (1.2) *is represented by*

$$\begin{cases} \rho_t = -L(\rho)\Delta(\rho)\kappa(\rho) & \text{for} \quad \sigma \in (-l, l), \ t > 0,\\ (R\Psi_\sigma + R\Psi_q\rho_\sigma, \nabla\psi(\Psi))_{\mathbb{R}^2} = 0 & \text{at} \quad \sigma = \pm l,\\ \partial_\sigma\kappa(\rho) = 0 & \text{at} \quad \sigma = \pm l, \end{cases} \tag{2.7}$$

where $L(\rho)$*,* $\Delta(\rho)$*, and* $\kappa(\rho)$ *are defined by* (2.6)*,* (2.3)*, and* (2.4)*, respectively.*

3. Linearization. To study the linearized stability of a stationary solution Γ_*, the curvature κ_* of which is a constant, we linearize (2.7) around $\rho \equiv 0$. For this purpose we need the following properties of Ψ at $q = 0$.

LEMMA 3.1. *For the parameterization of section* 2*, the following hold:*

(i) $\Psi(\sigma, 0) = \Phi_*(\sigma)$.

(ii) $\Psi_\sigma(\sigma, 0) = T_*(\sigma)$ *and* $\Psi_q(\sigma, 0) = N_*(\sigma)$.

(iii) $\Psi_{\sigma\sigma}(\sigma, 0) = \kappa_* N_*(\sigma)$ *and* $\Psi_{\sigma q}(\sigma, 0) = -\kappa_* T_*(\sigma)$.

(iv) $\Psi_{\sigma\sigma q}(\sigma,0) = -\kappa_*^2 N_*(\sigma)$.

Proof. By the definition of Ψ, (i) is obvious. Using (i), we readily derive $\Psi_\sigma(\sigma,0) = T_*(\sigma)$. To derive $\Psi_q(\sigma,0) = N_*(\sigma)$, we first prove $\xi_+'(0) = \xi_-'(0) = 0$. Note that $\xi(\pm l, q) = \xi_\pm(q)$ and $\xi_q(\pm l, q) = \xi_\pm'(q)$. Since it follows from the Frenet–Serret formula that

$$\Psi_q(\sigma,q) = \xi_q(\sigma,q)(1-q\kappa_*)T_*(\xi(\sigma,q)) + N_*(\xi(\sigma,q)), \tag{3.1}$$

we are led to

$$\begin{aligned} 0 &= \frac{d}{dq}\psi(\Psi(\pm l,q)) \\ &= (1-q\kappa_*)(\nabla\psi(\Psi(\pm l,q)), T_*(\xi_\pm(q)))_{\mathbb{R}^2}\xi_\pm'(q) + (\nabla\psi(\Psi(\pm l,q)), N_*(\xi_\pm(q)))_{\mathbb{R}^2}. \end{aligned}$$

Putting $q=0$, we have $(\nabla\psi(\Phi_*(\pm l)), T_*(\pm l))_{\mathbb{R}^2}\xi_\pm'(0) = 0$, so that $\xi_+'(0) = \xi_-'(0) = 0$. Then this implies

$$\xi_q(\sigma,0) = \xi_-'(0) + \frac{\sigma+l}{2l}(\xi_+'(0) - \xi_-'(0)) = 0.$$

Putting $q=0$ in (3.1), we derive $\Psi_q(\sigma,0) = N_*(\sigma)$. By virtue of (ii) and the Frenet–Serret formula, we readily derive (iii). Finally, by differentiating $\Psi_{\sigma q}(\sigma,0) = -\kappa_* T_*(\sigma)$ with respect to σ and applying the Frenet–Serret formula, we are led to (iv). ∎

We define the operator $G(\rho) := -L(\rho)\Delta(\rho)\kappa(\rho)$, which maps a function $\rho \in C^4[-l,l]$ to a function in $C^0[-l,l]$. Then we can compute this Fréchet derivative as follows.

LEMMA 3.2. *The operator $G : C^4[-l,l] \to C^0[-l,l]$ is Fréchet differentiable with derivative $\mathcal{A}_0 := \partial G(0)$, where*

$$\mathcal{A}_0\rho = -\partial_\sigma^2(\partial_\sigma^2 + \kappa_*^2)\rho.$$

Proof. Since $G(\rho) = -L(\rho)\Delta(\rho)\kappa(\rho)$, we have

$$\mathcal{A}_0\rho = \partial G(0)\rho = -(\partial L(0)\rho)\Delta(0)\kappa(0) - L(0)(\partial\Delta(0)\rho)\kappa(0) - L(0)\Delta(0)\partial\kappa(0)\rho. \tag{3.2}$$

By virtue of Lemma 3.1 and the definition of $L(\rho)$, $\Delta(\rho)$, and $\kappa(\rho)$, we observe

$$L(0) \equiv 1, \quad \Delta(0) = \partial_\sigma^2, \quad \kappa(0) \equiv \kappa_*. \tag{3.3}$$

Then, since κ_* is a constant, we have $\Delta(0)\kappa(0) = 0$ and

$$\begin{aligned} &(\partial\Delta(0)\rho)\kappa(0) \\ &\quad = \left(\frac{d}{d\varepsilon}(J(\varepsilon\rho))^{-2}\Big|_{\varepsilon=0}\right)\partial_\sigma^2\kappa(0) + \left(\frac{d}{d\varepsilon}(J(\varepsilon\rho))^{-1}\partial_\sigma(J(\varepsilon\rho))^{-1}\Big|_{\varepsilon=0}\right)\partial_\sigma\kappa(0) = 0. \end{aligned}$$

Let us derive $\partial\kappa(0)\rho$. Set

$$\begin{cases} a_1(\rho) = (\Psi_q, R\Psi_\sigma)_{\mathbb{R}^2}, \\ a_2(\rho) = 2(\Psi_{\sigma q}, R\Psi_\sigma)_{\mathbb{R}^2} + (\Psi_{\sigma\sigma}, R\Psi_q)_{\mathbb{R}^2}, \\ a_3(\rho) = (\Psi_{qq}, R\Psi_\sigma)_{\mathbb{R}^2} + 2(\Psi_{\sigma q}, R\Psi_q)_{\mathbb{R}^2} + (\Psi_{qq}, R\Psi_q)_{\mathbb{R}^2}\rho_\sigma, \\ a_4(\rho) = (\Psi_{\sigma\sigma}, R\Psi_\sigma)_{\mathbb{R}^2}. \end{cases}$$

Then $\kappa(\rho)$ is written by

$$\kappa(\rho) = (J(\rho))^{-3} a(\rho),$$

where

$$a(\rho) := a_1(\rho)\rho_{\sigma\sigma} + a_2(\rho)\rho_\sigma + a_3(\rho)\rho_\sigma^2 + a_4(\rho).$$

Thus we have

$$\begin{aligned}\partial\kappa(0)\rho &= \frac{d}{d\varepsilon}\kappa(\varepsilon\rho)\bigg|_{\varepsilon=0} \\ &= (J(0))^{-3}\frac{d}{d\varepsilon}a(\varepsilon\rho)\bigg|_{\varepsilon=0} + \left(\frac{d}{d\varepsilon}(J(\varepsilon\rho))^{-3}\bigg|_{\varepsilon=0}\right) a(0).\end{aligned}$$

By virtue of Lemma 3.1, we observe $J(0) = 1$ and $a(0) = a_4(0) = \kappa_*$. In addition, it holds that

$$\begin{aligned}&\frac{d}{d\varepsilon}a(\varepsilon\rho)\bigg|_{\varepsilon=0} = a_1(0)\rho_{\sigma\sigma} + a_2(0)\rho_\sigma + \partial a_4(0)\rho = \partial_\sigma^2\rho - 2\kappa_*^2\rho, \\ &\frac{d}{d\varepsilon}(J(\varepsilon\rho))^{-3}\bigg|_{\varepsilon=0} = -3(J(0))^{-4}\frac{d}{d\varepsilon}J(\varepsilon\rho)\bigg|_{\varepsilon=0} = 3\kappa_*\rho.\end{aligned}$$

Consequently, we are led to

$$\partial\kappa(0)\rho = (\partial_\sigma^2 + \kappa_*^2)\rho. \tag{3.4}$$

The assertion follows from (3.2)–(3.4). □

Let us consider the boundary condition. Set

$$\begin{cases} B_1(\rho) := (R\Psi_\sigma, \nabla\psi(\Psi))_{\mathbb{R}^2} + (R\Psi_q, \nabla\psi(\Psi))_{\mathbb{R}^2}\rho_\sigma, \\ B_2(\rho) := \partial_\sigma\kappa(\rho) \end{cases}$$

for $\rho \in C^3[-l, l]$, i.e., the operator B_i $(i = 1, 2)$ maps $C^3[-l, l]$ to $C^0[-l, l]$. Define

$$\mathcal{B}_0 := \begin{pmatrix} \partial B_1(0)/(\mp|\nabla\psi(x_*^\pm)|) \\ \partial B_2(0) \end{pmatrix} \quad \text{at} \quad \sigma = \pm l,$$

where $x_*^\pm := \Phi_*(\pm l) \in \partial\Omega$ and $\partial B_i(0)$ $(i = 1, 2)$ is the Fréchet derivatives of B_i at 0. Then we have the following representation of $\mathcal{B}_0$.

LEMMA 3.3. *Let ρ belong to $C^3[-l, l]$ and let $h_\pm$ be the curvatures of $\partial\Omega$ at $x_*^\pm \in \Gamma_* \cap \partial\Omega$, respectively (where we use the sign convention that $h_\pm < 0$ if Ω is convex). Then*

$$\mathcal{B}_0\rho = \begin{pmatrix} \partial_\sigma \pm h_\pm \\ \partial_\sigma(\partial_\sigma^2 + \kappa_*^2) \end{pmatrix}\rho \quad \text{at} \quad \sigma = \pm l.$$

Proof. First we derive $\partial B_1(0)$. Set

$$b_1(\rho) = (R\Psi_\sigma, \nabla\psi(\Psi))_{\mathbb{R}^2}, \quad b_2(\rho) = (R\Psi_q, \nabla\psi(\Psi))_{\mathbb{R}^2}.$$

Then we have $B_1(\rho) = b_1(\rho) + b_2(\rho)\rho_\sigma$, so that

$$\partial B_1(0)\rho = \frac{d}{d\varepsilon}B_1(\varepsilon\rho)\bigg|_{\varepsilon=0} = \frac{d}{d\varepsilon}b_1(\varepsilon\rho)\bigg|_{\varepsilon=0} + b_2(0)\rho_\sigma.$$

It follows from Lemma 3.1 that

$$\frac{d}{d\varepsilon} R\Psi_\sigma(\sigma, \varepsilon\rho)\Big|_{\varepsilon=0} = -\kappa_* N_*(\sigma)\rho,$$
$$\frac{d}{d\varepsilon} \nabla\psi(\Psi(\sigma, \varepsilon\rho))\Big|_{\varepsilon=0} = [D^2\psi(\Phi_*(\sigma))]N_*(\sigma)\rho,$$

where $D^2\psi$ is the Hessian matrix of ψ. Since $(N_*(\sigma), \nabla\psi(\Phi_*(\sigma)))_{\mathbb{R}^2} = 0$ at $\sigma = \pm l$, we are led to

$$\frac{d}{d\varepsilon} b_1(\varepsilon\rho)\Big|_{\varepsilon=0} = (N_*(\sigma), [D^2\psi(\Phi_*(\sigma))]N_*(\sigma))_{\mathbb{R}^2}\rho \quad \text{at} \quad \sigma = \pm l.$$

This implies that for $\sigma = \pm l$

$$\partial B_1(0)\rho = -(T_*(\sigma), \nabla\psi(\Phi_*(\sigma)))_{\mathbb{R}^2}\rho_\sigma + (N_*(\sigma), [D^2\psi(\Phi_*(\sigma))]N_*(\sigma))_{\mathbb{R}^2}\rho.$$

Let the arc-length parameter of $\partial\Omega$ run clockwise. Here we have

$$\kappa_{\partial\Omega} = -\frac{1}{|\nabla\psi|}([D^2\psi]T_{\partial\Omega}, T_{\partial\Omega})_{\mathbb{R}^2},$$

where $T_{\partial\Omega}$ is the unit tangent vector of $\partial\Omega$ and $\kappa_{\partial\Omega}$ is computed in the direction of the unit normal vector $N_{\partial\Omega}$ of $\partial\Omega$, which is obtained by rotating $T_{\partial\Omega}$ with $\pi/2$. Note that $h_\pm = \kappa_{\partial\Omega}(x_*^\pm)$, and denote $T_{\partial\Omega}^\pm := T_{\partial\Omega}(x_*^\pm)$ and $N_{\partial\Omega}^\pm := N_{\partial\Omega}(x_*^\pm)$. At $\sigma = \pm l$, we observe $T_*(\pm l) = \pm N_{\partial\Omega}^\pm$ and $N_*(\pm l) = \mp T_{\partial\Omega}^\pm$. This implies that for $\sigma = l$

$$\begin{aligned}
\partial B_1(0)\rho &= -(N_{\partial\Omega}^+, \nabla\psi(x_*^+))_{\mathbb{R}^2}\rho_\sigma + (-T_{\partial\Omega}^+, [D^2\psi(x_*^+)](-T_{\partial\Omega}^+))_{\mathbb{R}^2}\rho \\
&= -|\nabla\psi(x_*^+)|\left\{\rho_\sigma + \left(-\frac{1}{|\nabla\psi(x_*^+)|}(T_{\partial\Omega}^+, [D^2\psi(x_*^+)]T_{\partial\Omega}^+)_{\mathbb{R}^2}\right)\rho\right\} \\
&= -|\nabla\psi(x_*^+)|(\rho_\sigma + h_+\rho),
\end{aligned}$$

and that for $\sigma = -l$

$$\begin{aligned}
\partial B_1(0)\rho &= -(-N_{\partial\Omega}^-, \nabla\psi(x_*^-))_{\mathbb{R}^2}\rho_\sigma + (T_{\partial\Omega}^-, [D^2\psi(x_*^-)]T_{\partial\Omega}^-)_{\mathbb{R}^2}\rho \\
&= |\nabla\psi(x_*^-)|\left\{\rho_\sigma - \left(-\frac{1}{|\nabla\psi(x_*^-)|}(T_{\partial\Omega}^-, [D^2\psi(x_*^-)]T_{\partial\Omega}^-)_{\mathbb{R}^2}\right)\rho\right\} \\
&= |\nabla\psi(x_*^-)|(\rho_\sigma - h_-\rho).
\end{aligned}$$

Consequently, we have

$$\mp\frac{1}{|\nabla\psi(x_*^\pm)|}\partial B_1(0)\rho = (\partial_\sigma \pm h_\pm)\rho \quad \text{at} \quad \sigma = \pm l.$$

Let us also derive $\partial B_2(0)$. From (3.4) we have

$$\partial B_2(0)\rho = \partial_\sigma[\partial\kappa(0)\rho] = \partial_\sigma(\partial_\sigma^2 + \kappa_*^2)\rho \quad \text{at} \quad \sigma = \pm l.$$

This completes the proof. □

By Lemmas 3.2 and 3.3 we have derived the linearization of (2.7) around $\rho \equiv 0$.

THEOREM 3.4. *The linearization of* (2.7) *around* $\rho \equiv 0$ *is as follows:*

$$\begin{cases} \rho_t = -\partial_\sigma^2(\partial_\sigma^2 + \kappa_*^2)\rho & \text{for} \quad \sigma \in (-l,l),\ t>0\,, \\ (\partial_\sigma \pm h_\pm)\rho = 0 & \text{at} \quad \sigma = \pm l, \\ \partial_\sigma(\partial_\sigma^2 + \kappa_*^2)\rho = 0 & \text{at} \quad \sigma = \pm l. \end{cases} \tag{3.5}$$

Remark 3.5. The flow (1.2) has the property that the area enclosed by the curve Γ and $\partial\Omega$ is preserved. A constraint of fixed area leads to a nonlinear constraint for ρ. If we linearize this constraint, we obtain

$$\int_{-l}^{l} \rho \, d\sigma = 0. \tag{3.6}$$

Since the original problem (1.2) has the area-preserving property, we will analyze the linearized problem (3.5) for functions ρ satisfying (3.6). In fact, the linearized operator will have one eigenvalue zero if we do not take the constraint (3.6) into account. But the eigenfunction related to the eigenvalue zero corresponds to solutions with a different mean value and is therefore not relevant for the stability (see [11], [12] for similar difficulties arising from an area constraint).

4. Gradient flow structure. The surface diffusion flow can be interpreted as the H^{-1}-gradient flow of the area functional (see [5], [13], [23]). In this section we demonstrate that the linearization (3.5) derived in section 3 can also be interpreted as a gradient flow. This observation will be important for our stability analysis.

In what follows we will need the duality pairing $\langle \cdot, \cdot \rangle$ between $(H^1(-l,l))'$ and $(H^1(-l,l))$, and we will need the following weak formulation. We denote by $\| \cdot \|_s$ the norm on $H^s(-l,l)$ where $H^0(-l,l) = L^2(-l,l)$.

DEFINITION 4.1. *We say that* $u_v \in H^1(-l,l)$ *for a given* $v \in (H^1(-l,l))'$ *with* $\langle v, 1\rangle = 0$ *is a weak solution of*

$$\begin{cases} -\partial_\sigma^2 u_v = v & \text{for} \quad \sigma \in (-l,l)\,, \\ \partial_\sigma u_v = 0 & \text{at} \quad \sigma = \pm l \end{cases} \tag{4.1}$$

if u_v *satisfies*

$$\langle v, \xi \rangle = \int_{-l}^{l} \partial_\sigma u_v \partial_\sigma \xi$$

for all $\xi \in H^1(-l,l)$.

DEFINITION 4.2. *For a given* $v \in (H^1(-l,l))'$ *with* $\langle v, 1\rangle = 0$, *we say that* $\rho \in H^3(-l,l)$ *with* $\int_{-l}^{l} \rho = 0$ *is a weak solution of the boundary value problem*

$$\begin{cases} v = -\partial_\sigma^2(\partial_\sigma^2 + \kappa_*^2)\rho & \text{for} \quad \sigma \in (-l,l)\,, \\ (\partial_\sigma \pm h_\pm)\rho = 0 & \text{at} \quad \sigma = \pm l\,, \\ \partial_\sigma(\partial_\sigma^2 + \kappa_*^2)\rho = 0 & \text{at} \quad \sigma = \pm l \end{cases} \tag{4.2}$$

if ρ *satisfies*

$$\langle v, \xi \rangle = \int_{-l}^{l} \partial_\sigma(\partial_\sigma^2 + \kappa_*^2)\rho \, \partial_\sigma \xi \quad \text{and} \quad (\partial_\sigma \pm h_\pm)\rho = 0 \ \text{ at } \ \sigma = \pm l$$

for all $\xi \in H^1(-l,l)$.

In the case that $v \in L^2(-l,l)$ we obtain that $v = -\partial_\sigma^2(\partial_\sigma^2 + \kappa_*^2)\rho$ is fulfilled almost everywhere in $(-l,l)$ and $\partial_\sigma(\partial_\sigma^2 + \kappa_*^2)\rho = 0$ is fulfilled for $\sigma = \pm l$.

In addition we also need the symmetric bilinear form on $H^1(-l,l)$,

$$I(\rho_1,\rho_2) := \int_{-l}^{l} \{\partial_\sigma\rho_1\partial_\sigma\rho_2 - \kappa_*^2\rho_1\rho_2\}d\sigma + h_+\rho_1(l)\rho_2(l) + h_-\rho_1(-l)\rho_2(-l),$$

and the inner product

$$(\rho_1,\rho_2)_{-1} := \int_{-l}^{l} \partial_\sigma u_{\rho_1}\partial_\sigma u_{\rho_2},$$

where $u_{\rho_i} \in H^1(-l,l)$ for a given $\rho_i \in (H^1(-l,l))'$ with $\langle \rho_i, 1\rangle = 0$ is defined as the weak solution of (4.1). The bilinear form I is defined on $H^1(-l,l)$ and the inner product $(\cdot\,,\cdot)_{-1}$ is defined for all pairs of elements in $(H^1(-l,l))'$ with $\langle \rho_i, 1\rangle = 0$. We remark that by Definition 4.1

$$(\rho_1,\rho_2)_{-1} = \langle \rho_1, u_{\rho_2}\rangle \tag{4.3}$$

holds for $\rho_i \in (H^1(-l,l))'$ with $\langle \rho_i, 1\rangle = 0$.

Now we are going to show that the linearized problem (3.5) is the gradient flow of $E(\rho) := I(\rho,\rho)/2$ with respect to the H^{-1} inner product $(\cdot,\cdot)_{-1}$. Let us review the concept of gradient flows. For a given functional E on a linear space X and an inner product $(\cdot,\cdot)_X$ on X, we say that a time-dependent function ρ with values in X is a solution of the gradient flow equation to E and $(\cdot,\cdot)_X$ if and only if

$$(\rho_t(t),\xi)_X = -\partial E(\rho(t))(\xi)$$

holds for all $\xi \in X$ and all t. Here $\partial E(\rho(t))(\xi)$ denotes the derivative of E at the point $\rho(t)$ in the direction ξ. The fact that the linearized problem (3.5) is the gradient flow of $I(\rho,\rho)/2$ with respect to the $(\cdot,\cdot)_{-1}$ inner product follows from the following lemma. This is true since the derivative of $E(\rho) = I(\rho,\rho)/2$ in a direction ξ is given by $I(\rho,\xi)$.

LEMMA 4.3. *Let* $v \in (H^1(-l,l))'$ *with* $\langle v, 1\rangle = 0$ *be given. Then a function* $\rho \in H^3(-l,l)$ *with* $\int_{-l}^{l}\rho = 0$ *is a weak solution of* (4.2) *if and only if*

$$(v,\xi)_{-1} = -I(\rho,\xi)$$

holds for all $\xi \in H^1(-l,l)$ *with* $\int_{-l}^{l}\xi = 0$.

Proof. Let $\rho \in H^3(-l,l)$ be a weak solution of (4.2). By (4.3) and Definition 4.2, we have

$$(v,\xi)_{-1} = \langle v, u_\xi\rangle = \int_{-l}^{l} \partial_\sigma(\partial_\sigma^2 + \kappa_*^2)\rho\,\partial_\sigma u_\xi$$

for all $\xi \in H^1(-l,l)$ with $\int_{-l}^{l}\xi = 0$. Note that $u_\xi \in H^1(-l,l)$ is a weak solution of (4.1) with $\xi \in H^1(-l,l)$. Then, by virtue of $(\partial_\sigma^2 + \kappa_*^2)\rho \in H^1(-l,l)$, we see

$$\int_{-l}^{l} \partial_\sigma(\partial_\sigma^2 + \kappa_*^2)\rho\,\partial_\sigma u_\xi = \int_{-l}^{l} (\partial_\sigma^2 + \kappa_*^2)\rho\,\xi.$$

This implies that

$$\begin{aligned}(v,\xi)_{-1} &= \int_{-l}^{l} (\partial_\sigma^2 + \kappa_*^2)\rho\,\xi \\ &= -\int_{-l}^{l} (\partial_\sigma \rho\,\partial_\sigma \xi - \kappa_*^2 \rho\,\xi) + [\partial_\sigma \rho\,\xi]_{\sigma=-l}^{\sigma=l} \\ &= -I(\rho,\xi)\,.\end{aligned}$$

The last equality is shown by using $(\partial_\sigma \pm h_\pm)\rho = 0$ at $\sigma = \pm l$.

Conversely, assume that $\rho \in H^1(-l,l)$ with $\int_{-l}^{l} \rho = 0$ satisfies

$$(v,\xi)_{-1} = -I(\rho,\xi) \tag{4.4}$$

for all $\xi \in H^1(-l,l)$ with $\int_{-l}^{l} \xi = 0$. Choose $\xi = -\partial_\sigma^2 \eta$ in (4.4) for a given function $\eta \in H^3(-l,l)$ with $\partial_\sigma \eta = 0$ at $\sigma = \pm l$. Then it holds that

$$\begin{aligned}\langle v,\eta\rangle &= (v,\xi)_{-1} \\ &= -I(\rho,\xi) \\ &= -\int_{-l}^{l} (\partial_\sigma \rho\,\partial_\sigma \xi - \kappa_*^2 \rho\,\xi) - \{h_+\rho(l)\xi(l) + h_-\rho(-l)\xi(-l)\} \\ &= -\int_{-l}^{l} (-\partial_\sigma \rho\,\partial_\sigma^3 \eta + \kappa_*^2 \rho\,\partial_\sigma^2 \eta) + \{h_+\rho(l)\partial_\sigma^2\eta(l) + h_-\rho(-l)\partial_\sigma^2\eta(-l)\}\,.\end{aligned}$$

Since $v \in (H^1(-l,l))'$, we deduce from the above identity that $\rho \in H^3(-l,l)$. Integration by parts gives

$$\begin{aligned}\langle v,\eta\rangle &= \int_{-l}^{l} (-\partial_\sigma^2 \rho\,\partial_\sigma^2 \eta + \kappa_*^2 \partial_\sigma \rho\,\partial_\sigma \eta) + [(\partial_\sigma \rho \pm h_\pm \rho)\partial_\sigma^2 \eta]_{\sigma=-l}^{\sigma=l} \\ &= \int_{-l}^{l} \partial_\sigma(\partial_\sigma^2 + \kappa_*^2)\rho\,\partial_\sigma \eta + [(\partial_\sigma \rho \pm h_\pm \rho)\partial_\sigma^2 \eta]_{\sigma=-l}^{\sigma=l}\,,\end{aligned} \tag{4.5}$$

where $[(\partial_\sigma \rho \pm h_\pm \rho)\partial_\sigma^2 \eta]_{\sigma=-l}^{\sigma=l} = (\partial_\sigma \rho + h_+\rho)\partial_\sigma^2\eta|_{\sigma=l} - (\partial_\sigma \rho - h_-\rho)\partial_\sigma^2\eta|_{\sigma=-l}$. Since $\partial_\sigma^2 \eta$ can be chosen arbitrarily at $\sigma = \pm l$ and v is a bounded linear functional on $H^1(-l,l)$, we can deduce that the first boundary condition $(\partial_\sigma \pm h_\pm)\rho = 0$ at $\sigma = \pm l$ holds. The remaining identity in (4.5) then is a weak formulation of $v = -\partial_\sigma^2(\partial_\sigma^2 + \kappa_*^2)\rho$ for $\sigma \in (-l,l)$ together with $\partial_\sigma(\partial_\sigma^2 + \kappa_*^2)\rho = 0$ at $\sigma = \pm l$ (see Definition 4.2). ∎

5. Self-adjointness of the linearized operator. It is the aim of this section to show that the linearized operator is self-adjoint and to study its spectrum. A nonlinear stability analysis will most likely involve spaces of functions that are differentiable in a classical sense. For analyzing the spectrum it will be more appropriate to use spaces involving functions that are differentiable in a weak sense. Since eigenfunctions will be smooth, the spectrum will not depend on the domain of definition as long as the boundary conditions are incorporated correctly. Therefore, choosing an appropriate domain of definition, the linearized operator of (3.5) is given by

$$\mathcal{A} : \mathcal{D}(\mathcal{A}) \to H$$

with

$$\begin{cases} \mathcal{D}(\mathcal{A}) = \left\{ \rho \in H^3(-l,l) \mid (\partial_\sigma \pm h_\pm)\rho = 0 \ \text{ at } \ \sigma = \pm l \ \text{ and } \ \displaystyle\int_{-l}^{l} \rho = 0 \right\}, \\ H = \{\rho \in (H^1(-l,l))' \mid \langle \rho, 1 \rangle = 0\} \end{cases}$$

and

$$\langle \mathcal{A}\rho, \xi \rangle := \int_{-l}^{l} \partial_\sigma (\partial_\sigma^2 + \kappa_*^2)\rho \, \partial_\sigma \xi \, . \tag{5.1}$$

Then the boundary value problem (4.2) corresponds to the problem of finding a $\rho \in \mathcal{D}(\mathcal{A})$ with

$$\mathcal{A}\rho = v \, .$$

We also remark that this definition gives, for all $\xi \in H^1(-l,l)$ with $\int_{-l}^{l} \xi = 0$,

$$(\mathcal{A}\rho, \xi)_{-1} = -I(\rho, \xi).$$

For this operator $\mathcal{A}$, we have the following lemma.

LEMMA 5.1. *The operator $\mathcal{A}$ is symmetric with respect to the inner product $(\cdot,\cdot)_{-1}$.*

Proof. For all $\rho, \xi \in \mathcal{D}(\mathcal{A})$ we have

$$(\mathcal{A}\rho, \xi)_{-1} = -I(\rho, \xi) = -I(\xi, \rho) = (\mathcal{A}\xi, \rho)_{-1} = (\rho, \mathcal{A}\xi)_{-1},$$

so that $\mathcal{A}$ is symmetric. ∎

We need to analyze the spectrum of $\mathcal{A}$ in order to decide on the stability behavior of the linearized problem (3.5). Using classical principles of the variational calculus, we can describe the spectrum of $\mathcal{A}$ with the help of the inner product $(\cdot\,,\cdot)_{-1}$ and I. In fact, if ρ is an eigenfunction to the eigenvalue λ, it holds that

$$\lambda(\rho, \xi)_{-1} = (\mathcal{A}\rho, \xi)_{-1} = -I(\rho, \xi) \, .$$

We remark that eigenvalues $\lambda \neq 0$ always correspond to eigenfunctions that have the mean value zero. This follows by integrating the identity

$$-\partial_\sigma^2(\partial_\sigma^2 + \kappa_*^2)\rho = \lambda\rho$$

and using the boundary conditions. In what follows we will study only eigenvalues which have eigenfunctions with mean value zero. This is a natural request for the linearized problem. It follows when we take the mass constraint in the nonlinear problem into account. This makes sense because the surface diffusion flow is mass preserving (cf. [14]).

Therefore we define $V = \{\rho \in H^1(-l,l) \mid \int_{-l}^{l} \rho = 0\}$. The following two lemmas will be needed to show the boundness of the eigenvalue from above.

LEMMA 5.2. *For all $\delta > 0$ there exists a C_δ such that for all functions $\rho \in V$ the inequality*

$$\rho(l)^2 \leq \delta \|\partial_\sigma \rho\|_0^2 + C_\delta \|\rho\|_{-1}^2$$

holds. The same inequality holds for $\rho(-l)^2$ instead of $\rho(l)^2$.

Proof. We prove the assertion by contradiction. Assume that there exists a $\delta > 0$ such that for all $n \in \mathbb{N}$, $\rho_n \in V$ with $\rho_n(l)^2 = 1$ satisfy

$$1 = \rho_n(l)^2 > \delta \|\partial_\sigma \rho_n\|_0^2 + n\|\rho_n\|_{-1}^2 .$$

This implies

$$\|\rho_n\|_{-1}^2 < \frac{1}{n} \to 0 \qquad \text{as } n \to \infty$$

and

$$\|\partial_\sigma \rho_n\|_0^2 < \frac{1}{\delta} .$$

Since $\int_{-l}^{l} \rho_n = 0$, we conclude from Poincaré's inequality that ρ_n is bounded uniformly in $H^1(-l, l)$. This gives

$$\rho_n \to 0 \quad \text{weakly in } H^1(-l, l)$$

and therefore (since the embedding $H^1(-l, l)$ into $C^0([-l, l])$ is compact)

$$\rho_n(l) \to 0 .$$

This is a contradiction, and therefore the lemma is shown. □

LEMMA 5.3. *There exist positive constants c_1 and c_2 such that*

$$\|\rho\|_1^2 \le c_1 \|\rho\|_{-1}^2 + c_2 I(\rho, \rho) \ \textit{for all } \rho \in V .$$

Proof. Since the embedding $H^1(-l, l) \hookrightarrow L^2(-l, l)$ is compact, we obtain that for all $\delta > 0$ there exists a $\hat{C}_\delta > 0$ such that

$$\|\rho\|_0^2 \le \delta \|\partial_\sigma \rho\|_0^2 + \hat{C}_\delta \|\rho\|_{-1}^2 .$$

This can, for example, be shown in exactly the same manner as in the proof of the preceding lemma. Therefore we obtain, with the help of Lemma 5.2 and the above inequality,

$$\begin{aligned} I(\rho, \rho) &= \int_{-l}^{l} |\partial_\sigma \rho|^2 - \kappa_*^2 \int_{-l}^{l} \rho^2 + h_+ \rho(l)^2 + h_- \rho(-l)^2 \\ &\ge \int_{-l}^{l} |\partial_\sigma \rho|^2 - \kappa_*^2 \int_{-l}^{l} \rho^2 - |h_+| \rho(l)^2 - |h_-| \rho(-l)^2 \\ &\ge (1 - \varepsilon) \int_{-l}^{l} |\partial_\sigma \rho|^2 - C_\varepsilon \|\rho\|_{-1}, \end{aligned}$$

which holds for suitable ε and C_ε. The above inequality proves the lemma. □

COROLLARY 5.4. *The largest eigenvalue of $\mathcal{A}$ is bounded from above by c_1/c_2.*

Proof. Let λ be an eigenvalue of $\mathcal{A}$. Then there exists a $\rho \neq 0$ such that

$$\lambda(\rho, \rho)_{-1} = -I(\rho, \rho) .$$

Assume $\lambda > c_1/c_2$. This implies

$$0 = I(\rho, \rho) + \lambda(\rho, \rho)_{-1} > I(\rho, \rho) + c_1/c_2 (\rho, \rho)_{-1} \ge 1/c_2 \|\rho\|_1^2 > 0,$$

which is a contradiction. □

By virtue of Lemma 5.1 and Corollary 5.4, we have following theorem.

THEOREM 5.5. (i) *The operator $\mathcal{A}$ is self-adjoint with respect to the inner product $(\cdot,\cdot)_{-1}$.*

(ii) *The spectrum of $\mathcal{A}$ contains a countable system of real eigenvalues.*

(iii) *The initial value problem* (3.5) *is solvable for initial data in H.*

(iv) *The zero solution is an asymptotically stable solution of* (3.5) *if and only if the largest eigenvalue of $\mathcal{A}$ is negative.*

Proof. First we show that the resolvent $(\mathcal{A}-\omega)^{-1}$ exists for some $\omega \in \mathbb{R}$. Choosing $\omega > c_1/c_2$ and using Corollary 5.4, we know that $\mathcal{A}-\omega$ is injective. It remains to show that $\mathcal{A}-\omega$ is surjective. For a given $f \in H$ we need to prove that there exists a weak solution ρ of the boundary value problem

$$\left\{\begin{array}{lll} -\partial_\sigma^2\{-(\partial_\sigma^2+\kappa_*^2)\}\rho+\omega\rho=f & \text{for} & \sigma\in(-l,l),\\ (\partial_\sigma \pm h_\pm)\rho=0 & \text{at} & \sigma=\pm l,\\ \partial_\sigma(\partial_\sigma^2+\kappa_*^2)\rho=0 & \text{at} & \sigma=\pm l. \end{array}\right. \tag{5.2}$$

To obtain a solution to (5.2) we use the fact that the minimizing problem

$$F(\rho) := \int_{-l}^{l}\Big(\frac{1}{2}|\partial_\sigma\rho|^2-\frac{1}{2}\kappa_*^2\rho^2\Big)+\frac{1}{2}h_+\rho^2(l)+\frac{1}{2}h_-\rho^2(-l)+\frac{\omega}{2}\|\rho\|_{-1}^2-\int_{-l}^{l}u_f\rho\to\min$$

under all $\rho\in H^1(-l,l)$ with $\int_{-l}^{l}\rho=0$ admits as solutions $\tilde\rho$. This holds since F is coercive, which follows from Lemmas 5.2 and 5.3. Taking the first variation of F, we observe that

$$\left\{\begin{array}{lll} -(\partial_\sigma^2+\kappa_*^2)\tilde\rho+\omega u_{\tilde\rho}=u_f & \text{for} & \sigma\in(-l,l),\\ (\partial_\sigma\pm h_\pm)\tilde\rho=0 & \text{at} & \sigma=\pm l \end{array}\right. \tag{5.3}$$

holds in a weak sense. Since $u_{\tilde\rho}$, $u_f\in H^1(-l,l)$, we have $\tilde\rho\in H^3(-l,l)$. Furthermore, it follows from $\partial_\sigma u_{\tilde\rho}=\partial_\sigma u_f=0$ at $\sigma=\pm l$ that $\partial_\sigma(\partial_\sigma^2+\kappa_*^2)\bar\rho=0$ at $\sigma=\pm l$. Taking second derivatives of (5.3) in a weak sense, we derive that $\tilde\rho$ solves (5.2). This shows that $\mathcal{A}-\omega$ is surjective and hence $(\mathcal{A}-\omega)^{-1}$ exists.

Let us prove (i). We already know from Lemma 5.1 that $\mathcal{A}$ is symmetric. Since the self-adjointness of $\mathcal{A}$ follows from the self-adjointness of $\mathcal{A}-\omega$ for some $\omega\in\mathbb{R}$, we show the self-adjointness of $\mathcal{A}-\omega$. Suppose that there are v, $w\in H$ such that

$$((\mathcal{A}-\omega)\rho,v)_{-1}=(\rho,w)_{-1} \tag{5.4}$$

for all $\rho\in D(\mathcal{A}-\omega)$. By the above argument $\mathcal{A}-\omega$ is invertible if ω is large enough. Then there exists a $z\in D(\mathcal{A}-\omega)$ such that

$$(\mathcal{A}-\omega)z=w \tag{5.5}$$

for sufficiently large ω. By (5.4), (5.5), and Lemma 5.1, we have

$$((\mathcal{A}-\omega)\rho,v)_{-1}=(\rho,(\mathcal{A}-\omega)z)_{-1}=((\mathcal{A}-\omega)\rho,z)_{-1}.$$

Since $\mathcal{A}-\omega$ is surjective, we obtain $v=z$. This implies that $v\in D(\mathcal{A}-\omega)$ and

$$(\mathcal{A}-\omega)v=w,$$

so that $\mathcal{A}-\omega$ is self-adjoint.

Since $(\mathcal{A}-\omega)^{-1}$ exists and is compact, (ii) follows from [14, Theorem 6.29, Chapter 3] and the fact that $\mathcal{A}$ is self-adjoint.

Using the fact that $\mathcal{A}$ is a self-adjoint operator on H, the theory of semigroups is applicable to show (iii) (see, e.g., the functional calculus in sections 5.8–5.10 of [24]). Semigroup theory also gives (iv). ∎

To decide on the linearized stability, it will be important to know that the eigenvalues of $\mathcal{A}$ depend continuously on h_+, h_-, and κ_*^2 and are also monotone in each of these parameters. The following lemma ensures these properties.

LEMMA 5.6. *Let*

$$\lambda_1 \geq \lambda_2 \geq \lambda_3 \geq \cdots$$

be the eigenvalues of $\mathcal{A}$ (taking the multiplicity into account).

(i) *Then it holds for all $n \in \mathbf{N}$ that*

$$-\lambda_n = \inf_{W\in\Sigma_n} \sup_{u\in W\setminus\{0\}} \frac{I(u,u)}{(u,u)_{-1}},$$

$$-\lambda_n = \sup_{W\in\Sigma_{n-1}} \inf_{u\in W^\perp\setminus\{0\}} \frac{I(u,u)}{(u,u)_{-1}}.$$

Here Σ_n is the collection of n-dimensional subspaces of V and $W^\perp$ is the orthogonal complement with respect to the $(\cdot\,,\cdot)_{-1}$-scalar product.

(ii) *The eigenvalues λ_n depend continuously on h_+, h_-, and κ_*^2 and are monotone decreasing in each of the parameters h_+, h_-, and $(-\kappa_*^2)$.*

Proof. The lemma follows with the help of Courant's maximum-minimum principle, together with the fact that I depends in a monotone and continuous way on h_+, h_-, and $(-\kappa_*^2)$. The proof follows the lines of Courant and Hilbert [4, section VI.2]. ∎

6. Stability analysis. To obtain a linearized stability result for stationary solutions of (2.7), it is enough to show that $I(\rho,\rho)$ is positive for all $\rho \in V\setminus\{0\}$. Then $\lambda_1 < 0$, which implies stability. This is true since λ_1 allows the characterization

$$-\lambda_1 = \inf_{\rho\in V\setminus\{0\}} \frac{I(\rho,\rho)}{(\rho,\rho)_{-1}},$$

and the infimum is in fact a minimum; therefore it is enough to show the positivity of I pointwise.

In the following arguments we consider only the case $\kappa_* > 0$ (or $\kappa_* = 0$). We remark that the same result is derived for $\kappa_* < 0$. Also note that the stationary solution is a part of a circle with radius κ_*. The length of the stationary solution is $2l$, and therefore the restriction

$$2l < \frac{2\pi}{\kappa_*},$$

which gives $\kappa_* l < \pi$, has to hold.

Now the following lemma shows that for given κ_* the stationary solution is always stable, provided h_+, h_- are large enough.

LEMMA 6.1. *Let $\kappa_* l < \pi$. Then there exists a constant $K > 0$, such that*

$$I(\rho,\rho) > 0 \quad \textit{for all} \quad \rho \in V\setminus\{0\},$$

provided that $h_+, h_- > K$.

Proof. Using the transformation

$$u(s) = \rho\Big(\frac{2l}{\pi}s - l\Big)$$

and the fact that $\kappa_* l < \pi$, it is enough to show that there exists a constant $\overline{c} > 0$ such that

$$\|u'\|_0^2 - 4\|u\|_0^2 + \overline{c}(u(0)^2 + u(\pi)^2) \geq 0$$

for all $u \in H^1(0,\pi)$ with $\int_0^\pi u = 0$. Assume that such a constant $\overline{c}$ does not exist. Then there exists a sequence u_n (without loss of generality we assume $\|u_n\|_0^2 = 1$) such that

$$\|u_n'\|_0^2 - 4\|u_n\|_0^2 + n(u_n^2(0) + u_n^2(\pi)) < 0\,.$$

This implies

$$\|u_n'\|_0^2 \leq 4,$$

and we deduce the existence of a subsequence (which we also label by $\{u_n\}_{n\in\mathbf{N}}$) such that

$$\begin{array}{lcll} u_n' & \to & u' & \text{weakly in } L^2(0,\pi)\,, \\ u_n & \to & u & \text{strongly in } L^2(0,\pi)\,, \\ u_n & \to & u & \text{strongly in } C^0([0,\pi])\,. \end{array}$$

Then

$$u_n^2(0) + u_n^2(\pi) \leq \frac{4}{n}$$

implies

$$u(0) = u(\pi) = 0\,.$$

The lower semicontinuity of the L^2-norm under weak convergence implies

$$\|u'\|_0^2 < 4\|u\|_0^2\,,$$

which contradicts the facts that $u \in \overset{\circ}{H}{}^1(0,\pi)$ and $\int_0^\pi u = 0$ (see the following lemma). This proves the lemma. □

LEMMA 6.2. *For all* $u \in \overset{\circ}{H}{}^1(0,\pi)$ *with* $\int_0^\pi u(s)ds = 0$, *it holds that*

$$\|u\|_0^2 \leq \frac{1}{4}\|u'\|_2^2\,.$$

Proof. Each $u \in \overset{\circ}{H}{}^1(0,\pi)$ has a representation

$$u(s) = \sum_{k=1}^{\infty} a_k \sin ks\,.$$

Then we have

$$\|u\|_0^2 = \frac{\pi}{2}\sum_{k=1}^{\infty} a_k^2\,, \quad \|u'\|_0^2 = \frac{\pi}{2}\sum_{k=1}^{\infty} k^2 a_k^2.$$

In addition, the assumption $\int_0^\pi u(s)ds = 0$ implies

$$\sum_{\substack{k=1\\ k\,\text{odd}}}^{\infty} \frac{2}{k} a_k = 0\,. \tag{6.1}$$

Now we readily see

$$\sum_{\substack{k=1\\ k\,\text{even}}}^{\infty} a_k^2 \le \frac{1}{4}\sum_{\substack{k=1\\ k\,\text{even}}}^{\infty} k^2 a_k^2\,.$$

It remains to estimate the sum over all odd k, which would follow from

$$3a_1^2 \le \sum_{\substack{k=3\\ k\,\text{odd}}}^{\infty} (k^2-4) a_k^2\,. \tag{6.2}$$

The mean value constraint (6.1) implies

$$a_1 = -\sum_{\substack{k=3\\ k\,\text{odd}}}^{\infty} \frac{1}{k} a_k,$$

which gives

$$3a_1^2 \le 3\Big(\sum_{\substack{k=3\\ k\,\text{odd}}}^{\infty} \frac{1}{k} a_k\Big)^2 \le 3\Big(\sum_{\substack{k=3\\ k\,\text{odd}}}^{\infty} a_k^2\Big)\Big(\sum_{\substack{k=3\\ k\,\text{odd}}}^{\infty} \frac{1}{k^2}\Big) = 3\sum_{\substack{k=3\\ k\,\text{odd}}}^{\infty} a_k^2 \cdot \Big(\frac{\pi^2}{8} - 1\Big)\,.$$

Since $3(\pi^2/8 - 1) < k^2 - 4$ $(k = 3, 5, \dots)$, the inequality (6.2) is derived. Thus the lemma follows. □

The strategy now is as follows. We know that for large h_+ and h_- we have stability. In addition we know that the eigenvalues depend in a monotone and continuous way on h_+ and h_-. If we start with a stable situation $(h_+, h_- \gg 1)$ and decrease h_+ and, respectively, h_-, a loss of stability can therefore occur only in the case that the largest eigenvalue λ_1 passes through zero. For that reason we analyze for which values of h_+, h_-, and κ_* a zero eigenvalue is possible. To obtain a complete picture about the dimension of the unstable manifold, we also determine the multiplicity of a possible zero eigenvalue.

LEMMA 6.3. (i) *Assume that $\kappa_* \neq 0$ and $\kappa_* l < \pi$. Then the operator $\mathcal{A}$ has a zero eigenvalue if and only if*

$$\frac{a}{c} + \frac{b}{c}(h_+ + h_-) + h_+ h_- = 0, \tag{6.3}$$

where

$$\begin{aligned} a &= -2\kappa_*^2 l \sin(\kappa_* l)\cos(\kappa_* l)\,,\\ b &= \kappa_* l(\cos^2(\kappa_* l) - \sin^2(\kappa_* l)) - \sin(\kappa_* l)\cos(k_* l)\,,\\ c &= 2\Big\{-\frac{1}{\kappa_*}\sin^2(\kappa_* l) + l\sin(\kappa_* l)\cos(\kappa_* l)\Big\}\,. \end{aligned}$$

Furthermore, the following inequality holds:

$$\frac{b^2}{c^2} - \frac{a}{c} > 0\,. \tag{6.4}$$

(ii) *If $\kappa_* = 0$, then the operator $\mathcal{A}$ has a zero eigenvalue if and only if*

$$\frac{3}{l^2} + \frac{2}{l}(h_+ + h_-) + h_+h_- = 0\,. \tag{6.5}$$

(iii) *If we interpret a, b, and c as functions of κ_*, we obtain*

$$\frac{a}{c} \to \frac{3}{l^2} \quad \textit{and} \quad \frac{b}{c} \to \frac{2}{l} \quad \textit{as} \quad \kappa_* \to 0\,.$$

(iv) *The multiplicity of a possible zero eigenvalue is equal to one for all h_+, h_-, and κ_*.*

In what follows we set

$$\mathcal{D}(h_+, h_-, \kappa_*) = \frac{a}{c} + \frac{b}{c}(h_+ + h_-) + h_+h_-$$

for all h_+, h_-, and κ_*. The extension to $\kappa_* = 0$ is well defined by the preceding lemma.

Remark 6.4. (a) The equations (6.3) and (6.5) define hyperbolas in the (h_-, h_+)-plane (see Figures 1–5). The hyperbolas are symmetric with respect to the $h_- = h_+$ line, and the inequality (6.4) implies that the line defined by $h_+ = h_-$ always has two intersection points with the hyperbolas.

(b) From (iii) in the preceding lemma we can conclude that the hyperbolas obtained for the case $\kappa_* > 0$ tend to the one for $\kappa_* = 0$.

Proof of Lemma 6.3. (i) Assume that $-\partial_\sigma^2(\partial_\sigma^2 + \kappa_*^2)\rho = 0$. Then the function ρ can be denoted by

$$\rho(\sigma) = \alpha_1\sigma + \alpha_0 + \alpha_c\cos(\kappa_*\sigma) + \alpha_s\sin(\kappa_*\sigma)$$

for constants $(\alpha_1, \alpha_0, \alpha_c, \alpha_s)$. By the boundary conditions $\partial_\sigma(\partial_\sigma^2+\kappa_*^2)\rho = 0$ at $\sigma = \pm l$, we have

$$\pm\alpha_c\kappa_*^3\sin(\kappa_* l) - \alpha_s\kappa_*^3\cos(\kappa_* l) + \kappa_*^2\{\alpha_1 \mp \alpha_c\kappa_*\sin(\kappa_* l) + \alpha_s\kappa_*\cos(\kappa_* l)\} = 0.$$

This implies that $\kappa_*^2\alpha_1 = 0$, so that $\alpha_1 = 0$. Using the boundary conditions $(\partial_\sigma \pm h_\pm)\rho = 0$ at $\sigma = \pm l$, we derive

$$\begin{cases} h_+\alpha_0 + (-\kappa_*\sin(\kappa_* l) + h_+\cos(\kappa_* l))\alpha_c + (\kappa_*\cos(\kappa_* l) + h_+\sin(\kappa_* l))\alpha_s = 0, \\ -h_-\alpha_0 + (\kappa_*\sin(\kappa_* l) - h_-\cos(\kappa_* l))\alpha_c + (\kappa_*\cos(\kappa_* l) + h_-\sin(\kappa_* l))\alpha_s = 0. \end{cases}$$

Moreover, it follows from $\int_{-l}^{l}\rho = 0$ that

$$2l\alpha_0 + \Big\{\frac{2}{\kappa_*}\sin(\kappa_* l)\Big\}\alpha_c = 0.$$

Let us define the 3×3-matrix $M(h_+, h_-, \kappa_*)$ as

$$M(h_+, h_-, \kappa_*) := \begin{pmatrix} h_+ & -\kappa_*\sin(\kappa_* l) + h_+\cos(\kappa_* l) & \kappa_*\cos(\kappa_* l) + h_+\sin(\kappa_* l) \\ -h_- & \kappa_*\sin(\kappa_* l) - h_-\cos(\kappa_* l) & \kappa_*\cos(\kappa_* l) + h_-\sin(\kappa_* l) \\ l & \{\sin(\kappa_* l)\}/\kappa_* & 0 \end{pmatrix}.$$

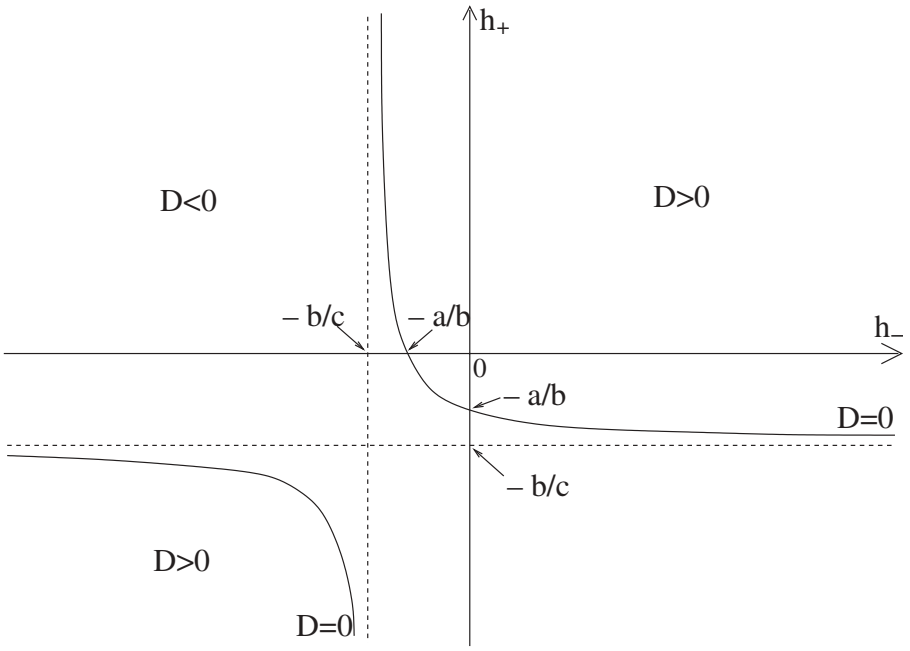

FIG. 1. $\kappa_* l < \pi/2, a < 0, b < 0, c < 0.$

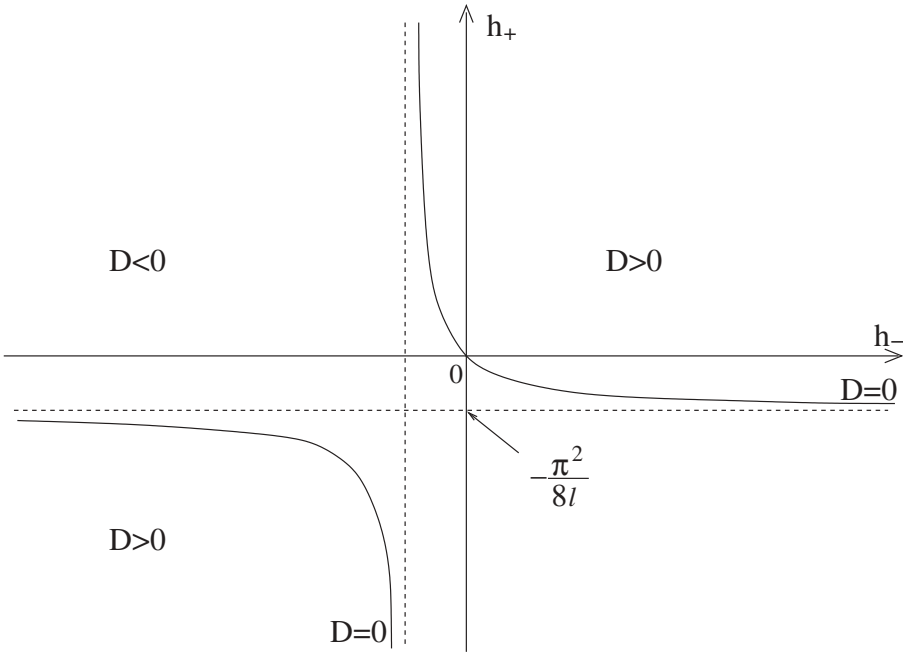

FIG. 2. $\kappa_* l = \pi/2, a = 0, b = -\kappa_* l, c = -2/\kappa_*.$

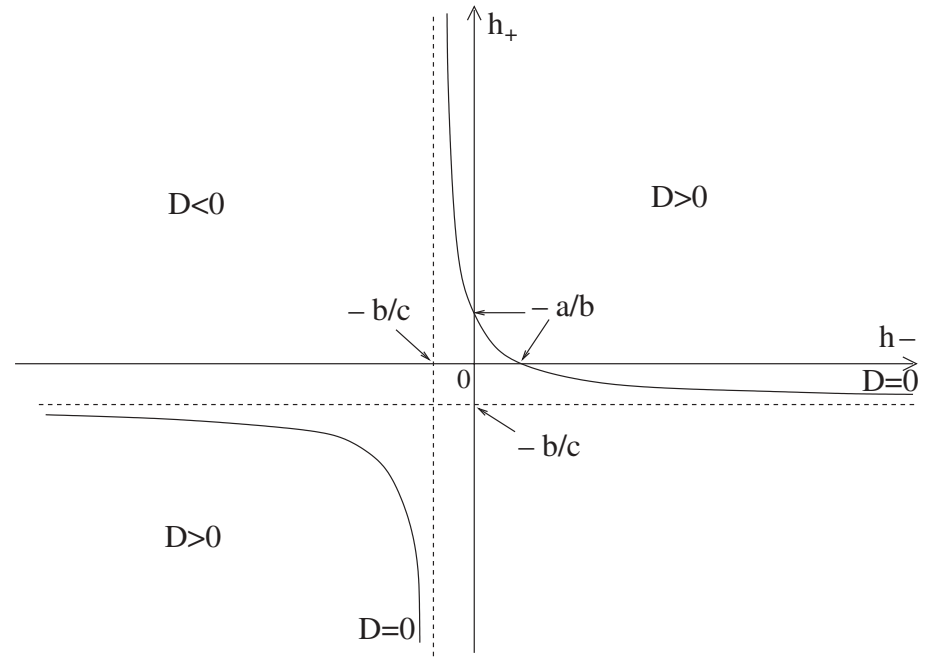

FIG. 3. $\kappa_* l > \pi/2, a > 0, b < 0, c < 0$.

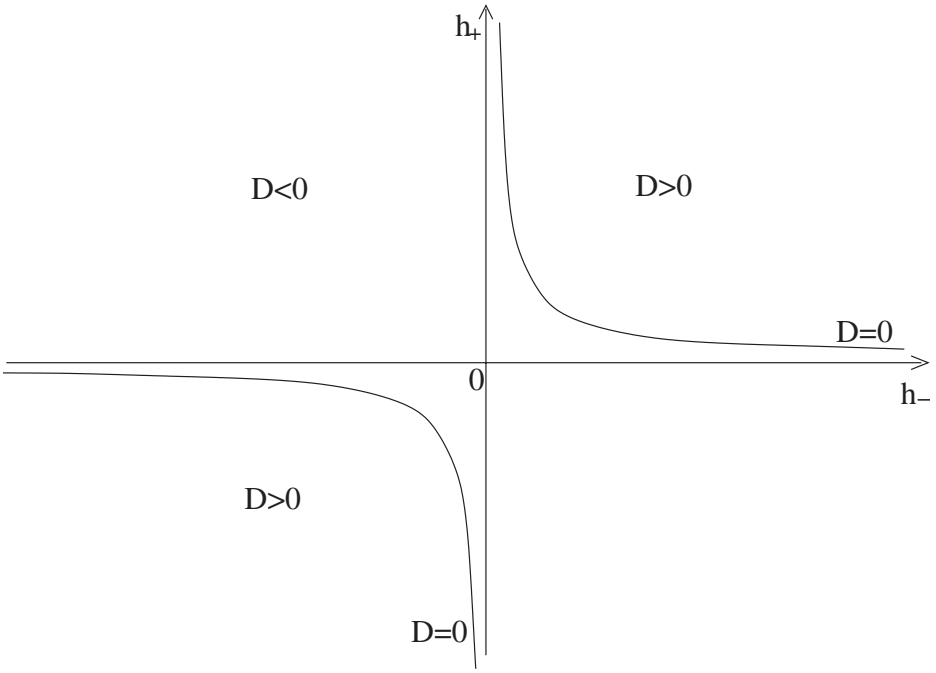

FIG. 4. $\kappa_* l > \pi/2, a > 0, b = 0, c < 0$.

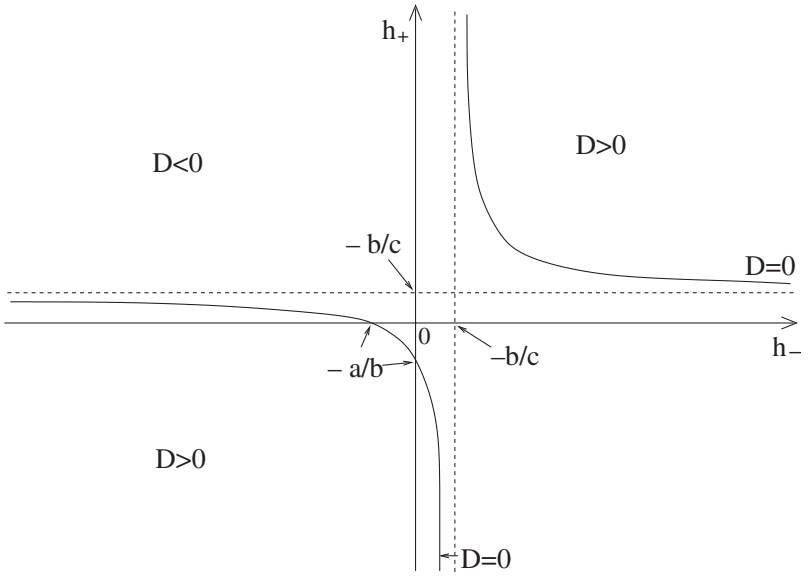

FIG. 5. $\kappa_* l > \pi/2, a > 0, b > 0, c < 0$.

Then the operator $\mathcal{A}$ has a zero eigenvalue if and only if the equation

$$M(h_+, h_-, \kappa_*)\, {}^t(\alpha_0, \alpha_c, \alpha_s) = {}^t(0, 0, 0) \tag{6.6}$$

has nonzero solutions ${}^t(\alpha_0, \alpha_c, \alpha_s)$. Nonzero solutions of (6.6) are derived when

$$\det M(h_+, h_-, \kappa_*) = 0,$$

which implies (6.3). Furthermore, by the definition of a, b, c, we have

$$b^2 - ac = \{\kappa_* l - \sin(\kappa_* l)\cos(\kappa_* l)\}^2 = \frac{1}{4}\{2\kappa_* l - \sin(2\kappa_* l)\}^2 \geq 0.$$

It follows from $\kappa_* l \neq 0$ that $2\kappa_* l - \sin(2\kappa_* l) \neq 0$. This implies (6.4).

(ii) Assume that $-\partial_\sigma^4 \rho = 0$. Then the function ρ can be denoted by

$$\rho(\sigma) = \alpha_3 \sigma^3 + \alpha_2 \sigma^2 + \alpha_1 \sigma + \alpha_0$$

for constants $(\alpha_3, \alpha_2, \alpha_1, \alpha_0)$. By the boundary conditions $\partial_\sigma^3 \rho = 0$ at $\sigma = \pm l$, we have $\alpha_3 = 0$. In addition, the conditions $(\partial_\sigma \pm h_\pm)\rho = 0$ at $\sigma = \pm l$ and $\int_{-l}^{l} \rho = 0$ give the equation

$$M_0(h_+, h_-)\, {}^t(\alpha_2, \alpha_1, \alpha_0) = {}^t(0, 0, 0), \tag{6.7}$$

where the 3×3-matrix $M_0(h_+, h_-)$ is defined as

$$M_0(h_+, h_-) := \begin{pmatrix} 2l + h_+ l^2 & 1 + h_+ l & h_+ \\ -2l - h_- l^2 & 1 + h_- l & -h_- \\ l^2/3 & 0 & 1 \end{pmatrix}.$$

Applying an argument similar to that of the proof of (i), we find that the operator $\mathcal{A}$ with $\kappa_* = 0$ has a zero eigenvalue if and only if $\det M_0(h_+, h_-) = 0$, which implies (6.5).

(iii) This follows readily from the expressions for a/c and b/c with the help of L'Hospital's rule.

(iv) In the case $\kappa_* = 0$, we needed to find nonzero solutions of (6.7) in order to derive a zero eigenvalue of $\mathcal{A}$. Each of the solutions to the linear systems (6.7) corresponds one eigenfunction to the eigenvalue zero. Assume that the multiplicity of an eigenvalue zero is larger than one. This implies that the matrix $M_0(h_+, h_-)$ has rank 1 (less is not possible). This implies

$$1 + h_+ l = 1 + h_- l = 0\,.$$

Hence

$$h_+ = h_- = -\frac{1}{l}\,.$$

But then the first and third columns are not linear dependent. This is a contradiction and shows the assertion for $\kappa_* = 0$. A similar argument works in the case $\kappa_* \neq 0$. ∎

We denote by N_U and N_N the number of unstable and zero eigenvalues of $\mathcal{A}$ (counting the multiplicity). Then we obtain the following theorem.

THEOREM 6.5. *Case* A: *If* $\mathcal{D}(h_-, h_+, \kappa_*) > 0$ *and if* $h_- > -b/c$, *then*

$$N_U = N_N = 0\,.$$

Case B: *If* $\mathcal{D}(h_-, h_+, \kappa_*) = 0$ *and if* $h_- > -b/c$, *then*

$$N_U = 0\,,\ N_N = 1\,.$$

Case C: *If* $\mathcal{D}(h_-, h_+, \kappa_*) < 0$, *then*

$$N_U = 1\,,\ N_N = 0\,.$$

Case D: *If* $\mathcal{D}(h_-, h_+, \kappa_*) = 0$ *and if* $h_- < -b/c$, *then*

$$N_U = 1\,,\ N_N = 1\,.$$

Case E: *If* $\mathcal{D}(h_-, h_+, \kappa_*) > 0$ *and if* $h_- < -b/c$, *then*

$$N_U = 2\,,\ N_N = 0\,.$$

Remark 6.6. (a) In Cases A, B, D, and E the condition $h_- > -b/c$ ($h_- < -b/c$, respectively) can be replaced by $h_+ > -b/c$ ($h_+ < -b/c$, respectively).

(b) Theorem 6.5 says that we have stability above the upper arc of the hyperbola (see Figures 1–5). Underneath it we have instability where the number of instable modes is one when we are above the lower arc of the hyperbola and two when we are underneath of it.

Proof of Theorem 6.5. The proof is a simple consequence of Lemmas 5.6, 6.1, and 6.3. For large h_+ and h_- we have stability. If we decrease h_+ or h_-, the stability behavior changes only on the curves defined by $\mathcal{D}(h_-, h_+, \kappa_*) = 0$. By virtue of (iv) in Lemma 6.3, only one eigenvalue can pass through zero when crossing the curves $\mathcal{D}(h_-, h_+, \kappa_*) = 0$. The monotonicity of the eigenvalues with respect to h_+ and h_- implies that the number of unstable modes can increase only if we further decrease h_+ or h_-. This proves the theorem. ∎

Let us discuss the signs of a, b, and c, which depend on $\kappa_* l$. It is easy to see

$$\begin{cases} a < 0 & \text{for} \quad \kappa_* l < \pi/2, \\ a = 0 & \text{for} \quad \kappa_* l = \pi/2, \\ a > 0 & \text{for} \quad \kappa_* l > \pi/2. \end{cases}$$

To derive the signs of b, we rewrite b as

$$\begin{aligned} b &= \frac{1}{2}\{2\kappa_* l \cos(2\kappa_* l) - \sin(2\kappa_* l)\} \\ &= \frac{1}{2}\cos(2\kappa_* l)\{2\kappa_* l - \tan(2\kappa_* l)\} \quad \text{if} \quad 2\kappa_* l \neq \pi/2, 3\pi/2. \end{aligned}$$

It follows from the relations between $2\kappa_* l$ and $\tan(2\kappa_* l)$ in $0 < 2\kappa_* l < 2\pi$ that

$$\begin{cases} b < 0 & \text{for} \quad \kappa_* l < \theta_0, \\ b = 0 & \text{for} \quad \kappa_* l = \theta_0, \\ b > 0 & \text{for} \quad \kappa_* l > \theta_0 \end{cases}$$

for some $\theta_0 \in (\pi/2, \pi)$. Finally, we investigate the sign of c. If $\kappa_* l \geq \pi/2$, we can easily derive $c < 0$. If $\kappa_* l < \pi/2$, we rewrite c as

$$c = \frac{2}{\kappa_*}\sin(\kappa_* l)\cos(\kappa_* l)\{\kappa_* l - \tan(\kappa_* l)\}.$$

Then $\kappa_* l < \pi/2$ implies that $\sin(\kappa_* l) > 0$, $\cos(\kappa_* l) > 0$, and $\kappa_* l - \tan(\kappa_* l) < 0$, so that $c < 0$. Thus we see $c < 0$ in all cases. Consequently the behavior illustrated in Figures 1–5 follows.

7. Examples. Finally we want to discuss how the linearized stability of equilibria depends on the parameters l, κ_*, h_+, and h_-. In the following the expressions "stable" and "unstable" are to be understood in the linearized sense.

If κ_* is zero and h_+ and h_- are negative, then the stability depends crucially on the length of Γ_*. For fixed h_+ and h_- equilibria with a small length are stable and equilibria with a large length are unstable. They are separated by a case which is neutral in the sense that the linearized evolution operator has, besides negative eigenvalues, one zero eigenvalue. This is, for example, the case when Ω is a ball and Γ_* is a segment intersection $\partial\Omega$ perpendicular (see Figure 6). In this case a nonlinear analysis has to decide on the stability.

If κ_* is nonzero, then the linearized stability behavior depends on the curvature of the outer boundary, roughly speaking, in the following sense. Cases with large positive outer curvatures h_+ and h_- are stable, and cases with large negative outer curvatures are unstable. In Figure 7 we demonstrate this stability behavior for a case where we fix κ_* and l. An equilibrium Γ_* is stable for $h > 0$ and unstable for $h < 0$. The case $h = 0$ is neutral and again a nonlinear analysis has to decide on stability. An interesting special case is when the outer boundary has constant curvature. This case is illustrated in Figure 8 and is always neutral. Indeed, let h be a constant curvature of the outer boundary, which implies $h_+ = h_- = h$. For the case $h = 0$, see the above explanation. If $h \neq 0$, then h is represented as

$$h = -\frac{\kappa_*}{\tan(\kappa_* l)}.$$

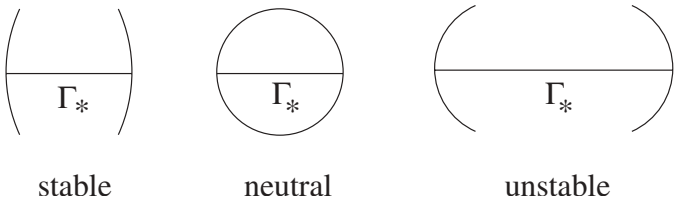

FIG. 6. *Three equilibria with $h_+ = h_-$ and $\kappa_* = 0$. (The stability depends on the length of Γ_*.)*

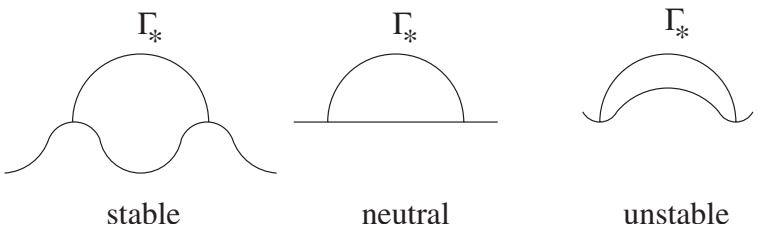

FIG. 7. *Three cases with κ_* and l fixed.*

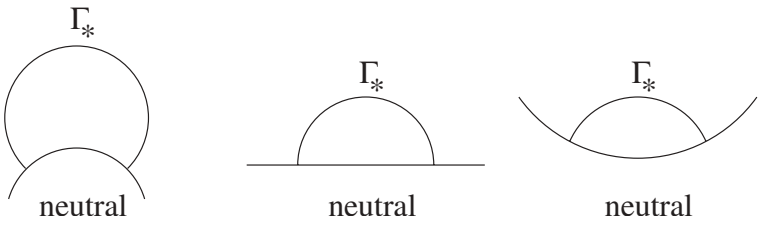

FIG. 8. *Three cases with the same κ_* and with constant curvature of $\partial\Omega$.*

By the definition of a, b, c, we derive

$$\frac{a}{c} = -\frac{\kappa_*^3 l}{\kappa_* l - \tan(\kappa_* l)}, \quad \frac{b}{c} = -\frac{h}{2}\left\{1 - \frac{\kappa_* l \tan^2(\kappa_* l)}{\kappa_* l - \tan(\kappa_* l)}\right\}.$$

This implies that

$$D(h, h, \kappa_*) = \frac{a}{c} + \frac{b}{c} \cdot 2h + h^2 = 0.$$

In addition, $h > -b/c$ for $0 < \kappa_* l < \pi/2$ follows from

$$1 - \frac{\kappa_* l \tan^2(\kappa_* l)}{\kappa_* l - \tan(\kappa_* l)} > 2 \quad \text{for} \quad 0 < \kappa_* l < \pi/2,$$

and we also find $h > 0$ for $\pi/2 < \kappa_* l < \pi$. This means that this case is included in the line $D = 0$ on the right-hand side of Figure 1 and Figures 3–5, so that this case is neutral.

Choosing, for example, $h_+ = h_- = 0$, we observe that $\kappa_* l$, is an important quantity (see Figure 9). As long as $\kappa_* l < \pi/2$ (i.e., Γ_* is less than a half circle) we

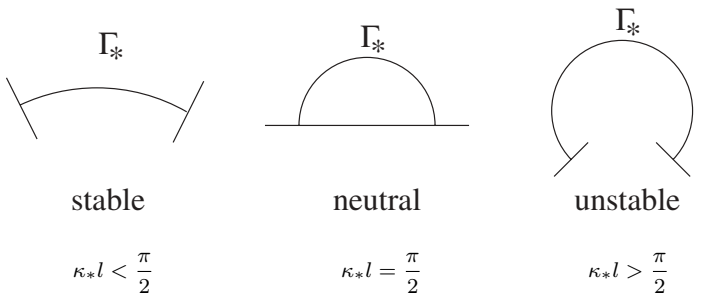

FIG. 9. *Three cases with* $h_+ = h_- = 0$.

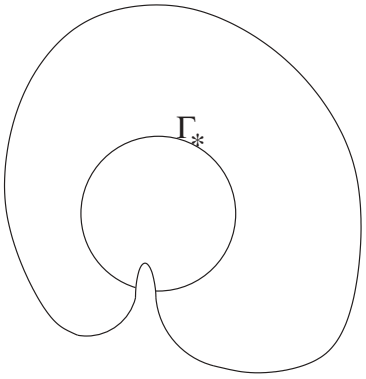

FIG. 10. *Instability for the case* $h_+, h_- > 0$.

have stability, the case $\kappa_* l = \pi/2$ is neutral (i.e., Γ_* is a half circle), and the case $\kappa_* l > \pi/2$ is unstable (i.e., Γ_* is more than a half circle).

Finally, we remark that instability for h_+, h_- positive and large is also possible. In this case $\kappa_* l$ has to be close to π, i.e., Γ_* has to be close to a full circle (see Figure 10).

Acknowledgments. The second author would like to express his special gratitude to Professor J. Escher for helpful discussions and warm hospitality during his stay at the Universität Hannover. Also the third author is grateful to the Universität Regensburg for the kind hospitality during his stay.

DENSITY ESTIMATES FOR A DEGENERATE/SINGULAR PHASE-TRANSITION MODEL*

ARSHAK PETROSYAN† AND ENRICO VALDINOCI‡

Abstract. We consider a Ginzburg–Landau type phase-transition model driven by a p-Laplacian type equation. We prove density estimates for absolute minimizers and we deduce the uniform convergence of level sets and the existence of plane-like minimizers in periodic media.

Key words. density estimates, p-Laplacian equation, phase-transition models, Ginzburg–Landau models, uniform convergence of level sets, plane-like minimizers

1. Introduction.

For a bounded domain Ω in $\mathbb{R}^n$ and $\varepsilon > 0$ consider an energy functional

$$\mathcal{J}_\varepsilon(u;\Omega) = \int_\Omega [A(x,\varepsilon\nabla u) + F(x,u)]\,dx, \tag{1.1}$$

where $A(x,\eta) \simeq |\eta|^p$, $1 < p < \infty$, and $F(x,u) \simeq |1-u^2|^\alpha$, $0 < \alpha \le p$ (see below for precise assumptions). Functionals of this type appear in the context of minimal surfaces, and it has been shown by Γ-convergence methods that sequences of minimizers converge in L^1_{loc} to suitable step functions satisfying a minimal interface property, as $\varepsilon \to 0+$ (see [MM77] for $p = 2$ and [Bou90] for the general case). Functionals of type (1.1) also have a physical relevance, since they appear in the study of the equilibrium of elastic rods under tension (see [Ant73]), in the context of fluid jets (see [AC81] and [ACF84]), and in the van der Waals–Cahn–Hilliard and Ginzburg–Landau theories of phase transition (see, for instance, [Row79]). In the phase-transition setting, the term $A(x,\varepsilon\nabla u)$ in the energy functional (1.1) can be seen as an interfacial energy contribution to the total energy, which penalizes the formation of interfaces (see [Gur85] for details).

The main purpose of this paper is to obtain Caffarelli–Córdoba [CC95] type density estimates for the absolute minimizers of the normalized functional

$$\mathcal{J}(u;\Omega) = \int_\Omega [A(x,\nabla u) + F(x,u)]\,dx. \tag{1.2}$$

Roughly speaking, such density estimates state that, if u is an absolute minimizer of $\mathcal{J}$, then the set $\{|u| < 1/2\}$ behaves in measure as an $(n-1)$-dimensional set, while $\{u > 1/2\}$ and $\{u < -1/2\}$ behave in measure as n-dimensional sets (a precise statement will be given in Theorem 1.1 below). As a consequence, we obtain the uniform convergence of the level sets of minimizers of $\mathcal{J}_\varepsilon$ to a surface of minimal

"area" as $\varepsilon \to 0+$; see Theorem 7.1. Another application of the density estimates is the existence of plane-like minimizers of $\mathcal{J}$ in periodic media; see Theorem 7.3.

We now state in detail the assumptions required in this paper. We assume that $A : \Omega \times \mathbb{R}^n \ni (x, \eta) \longrightarrow \mathbb{R}$ is in $C^1(\Omega \times \mathbb{R}^n)$ and that

$$a(x, \eta) := D_\eta A(x, \eta)$$

is in $C(\Omega \times \mathbb{R}^n) \cap C^1(\Omega \times \mathbb{R}^n - \{0\})$. We require that

$$A(x, 0) = 0, \quad a(x, 0) = 0, \tag{1.3}$$

for every $x \in \Omega$ and that there exists $\Lambda > 0$ such that

$$\zeta \cdot D_\eta a(x, \eta)\, \zeta \geq \Lambda^{-1} |\zeta|^2\, |\eta|^{p-2} \text{ for any } \zeta \in \mathbb{R}^n, \tag{1.4}$$

$$|D_\eta a(x, \eta)| \leq \Lambda\, |\eta|^{p-2} \qquad \text{and} \tag{1.5}$$

$$|D_x a(x, \eta)| \leq \Lambda\, |\eta|^{p-1}\,, \tag{1.6}$$

$$\eta \cdot a(x, \eta) \geq \Lambda^{-1}\, |\eta|^p \tag{1.7}$$

for every $x \in \Omega$ and $\eta \in \mathbb{R}^n$.

Next, we assume that $F : \Omega \times \mathbb{R} \ni (x, u) \longrightarrow \mathbb{R}$ is a Carathéodory function, i.e., continuous in u for a.e. $x \in \Omega$ and measurable in x for every $u \in \mathbb{R}$, and satisfies

$$0 \leq F \leq M, \qquad F(x, \pm 1) = 0, \qquad \inf_{|u| \leq \theta} F(x, u) \geq \gamma(\theta) \tag{1.8}$$

for every $0 \leq \theta < 1$, where $\gamma(\theta)$ and M are positive constants. Here and below all structural inequalities on F are assumed to be uniform for a.e. $x \in \Omega$. Further, we assume that the partial derivative $F_u(x, u)$ exists for every $u \in (-1, 1)$ for a.e. $x \in \Omega$ and that

$$\sup_{|u| \leq \theta} |F_u(x, u)| \leq M(\theta) \tag{1.9}$$

for every $0 \leq \theta < 1$. We also assume the following growth condition near $u = \pm 1$: there exists $s_0 > 0$ and $d \leq p$ such that

$$F_u(x, -1 + s) \geq C s^{d-1}, \qquad F_u(x, 1 - s) \leq -C s^{d-1} \tag{1.10}$$

for every $s \in (0, s_0)$. Without loss of generality, we may and do assume $1 \leq d \leq p$. In the case $d = p$ we additionally require that

$$F_u \text{ is monotone increasing in } u \text{ for } u \in (-1, -1 + s_0) \text{ and } u \in (1 - s_0, 1). \tag{1.11}$$

Finally, if $1 < p \leq 2n/(n+2)$, we require F to be uniformly Lipschitz in $u \in (-1, 1)$. More precisely, we assume that

$$\sup_{|u| < 1} |F_u(x, u)| \leq M \tag{1.12}$$

for a certain constant M.

We will refer to the constants that appear in (1.3)–(1.12), including n and p, as the *structural constants*. Quantities depending only on structural constants will be called *universal constants*.

A "typical" example of the functional $\mathcal{J}$, which satisfies the assumptions above, is given by

$$\int \Big(a_{i,j}(x)\,\partial_i u\,\partial_j u\Big)^{p/2} + Q(x)\,|1-u^2|^\alpha,$$

where $a_{i,j}$ is a C^1 symmetric positive definite matrix, $0 < Q_{\min} \le Q(x) \le Q_{\max}$ and $0 < \alpha \le p$. (The case $\alpha = 0$, which corresponds to $F(x,u) = Q(x)\chi_{(-1,1)}(u)$, has been treated recently in [PV03].)

We say that $u \in W^{1,p}(\Omega)$ is an *absolute minimizer* for $\mathcal{J}$ in Ω if $\mathcal{J}(u;\Omega) \le \mathcal{J}(u+\phi;\Omega)$ for any $\phi \in W_0^{1,p}(\Omega)$. In this paper, we will be concerned only with absolute minimizers u that satisfy $|u| \le 1$. Conditions (1.3)–(1.12) that we impose on $\mathcal{J}$ make it possible to apply the regularity results of Giaquinta and Giusti [GG82]. In particular, by Theorem 3.1 there, we will have that u is locally uniformly Hölder continuous in Ω. Moreover, in the region $\{|u| < 1\}$, the standard variational arguments show that u satisfies the Euler–Lagrange equation

$$\operatorname{div} a(x,\nabla u) = F_u(x,u)$$

in the weak sense. Then u is also $C^{1,\alpha}$ regular in $\{|u| < 1\}$ for some $0 < \alpha < 1$; see, e.g., [Tol84].

We will also denote by $\mathcal{L}^n$ the standard Lebesgue measure on $\mathbb{R}^n$.

The main result of this paper is as follows.

THEOREM 1.1. *For $1 < p < \infty$ assume that the hypotheses* (1.3)–(1.12) *hold. Fix $\theta \in (0,1)$ and let $|u| \le 1$ be an absolute minimizer for $\mathcal{J}$ in a bounded domain Ω, $x \in \{-\theta < u < \theta\}$ and $y \in \Omega$. Then, for every $\delta > 0$, there exist positive r_0, c, and C depending only on θ, on the structural constants, and on δ such that*

$$\mathcal{L}^n\big(B_r(x) \cap \{u > \theta\}\big) \ge c\,r^n \quad \text{and} \quad \mathcal{L}^n\big(B_r(x) \cap \{u < -\theta\}\big) \ge c\,r^n, \tag{1.13}$$

$$\mathcal{L}^n\big(B_r(x) \cap \{|u| < \theta\}\big) \ge c\,r^{n-1} \text{ and } \mathcal{L}^n\big(B_r(y) \cap \{|u| < \theta\}\big) \le C\,r^{n-1} \tag{1.14}$$

for any $r \ge r_0$, provided $B_{r+\delta}(x)$, $B_{r+\delta}(y) \subset\subset \Omega$.

The density estimates of this type have been obtained originally in [CC95] for $p = 2$ and $A(x,\nabla u) = |\nabla u|^2$ and generalized in [Val04] to $A(x,\nabla u) = a_{i,j}\partial_i u\,\partial_j u$. The case of a general $p \in (1,\infty)$ with $A(x,\nabla u)$ satisfying the hypotheses above and $F(x,u) = Q(x)\,\chi_{(-1,1)}(u)$ has been considered in [PV03] as a model for non-Newtonian power-law fluid jets. The case treated here can be seen as a degenerate/singular phase-transition model driven by a p-Laplacian type equation.

We explicitly point out here that there is a restriction in Theorem 1.1 on the decay rate of the "double-well" potential $F(x,u)$ near $u = \pm 1$. In particular, for $F(x,u) = |1-u^2|^\alpha$ for some $\alpha > 0$, we must have $\alpha \le p$ by (1.10). The density estimates as in Theorem 1.1 are not known for $\alpha > p$. Thus, the larger we take p, the wider is the class of admissible potentials $F(x,u)$ for which the density estimates are known. In that sense, the perturbations with $A(x,\eta) \simeq |\eta|^p$ behave better for larger values of p.

We also note that additional difficulties appear in the case $1 < p < 2$. We need to require uniform Lipschitz continuity of the double-well potential $F(x,u)$ in $u \in (-1,1)$ in order to obtain the desired density estimates. This excludes the potentials $F(x,u) = |1-u^2|^\alpha$ with $0 < \alpha < 1$. However, we show that *at least* for the range

of the exponents $2n/(n+2) < p < 2$, one can drop this uniform Lipschitz continuity assumption; see section 6.2.

The paper is organized as follows. In section 2 we collect some short-proof lemmas that will be of use in what follows. A Caccioppoli-type inequality is stated and proved in section 3. The proof of Theorem 1.1 is dealt with in section 4, and it makes use of an auxiliary result, namely, Lemma 4.1 below, which is interesting in itself and which roughly says that as soon as the density of sublevels of minimizers is positive in some ball, it must grow as r^n in balls of bigger radius r. We devote sections 5 and 6 to the proof of such an auxiliary result, considering the cases $p \geq 2$ and $1 < p \leq 2$ separately. In section 7 we point out some consequences that can be derived from Theorem 1.1, such as the uniform convergence of level sets of absolute minima to minimal interfaces and the existence of plane-like minimizers in periodic media.

2. Technical and elementary lemmas. We start this section with a recursive lemma.

LEMMA 2.1. *Let $v_k \geq 0$ and $a_k \geq 0$ be two nondecreasing sequences such that $v_1 + a_1 \geq c_0$,*

$$v_k^{(n-1)/n} \leq C_0 \left(v_{k+1} + a_{k+1} - v_k - a_k - c_1 a_k\right)^{1-\alpha} k^{\alpha(n-1)}$$

for any $k \in \mathbb{N}$ and some positive constants c_0, c_1, C_0, and $0 \leq \alpha < 1/n$. Then there exists $\gamma = \gamma(c_0, c_1, C_0, \alpha) > 0$ such that

$$v_k + a_k \geq \gamma\, k^n$$

for any $k \in \mathbb{N}$.

Proof. We start with an observation that it is enough to prove the estimate for $k \geq k_0$, since

$$v_k + a_k \geq v_1 + a_1 \geq c_0 \geq (c_0/k_0^n)k^n \quad \text{for } k \leq k_0.$$

The proof is by induction. Assume that $v_k + a_k \geq \gamma\, k^n$. Then either $v_k \geq (\gamma/2)k^n$ or $a_k \geq (\gamma/2)k^n$.

1. Assume first $v_k \geq (\gamma/2)k^n$. Then, using the recurrence relationship, we have

$$C_0 \left(v_{k+1} + a_{k+1} - v_k - a_k - c_1 a_k\right)^{1-\alpha} \geq (\gamma/2)^{(n-1)/n}\, k^{(1-\alpha)(n-1)}$$

and consequently

$$v_{k+1} + a_{k+1} \geq \gamma\, k^n + C\gamma^{\frac{1}{1-\alpha}\cdot\frac{n-1}{n}} k^{n-1}.$$

By our assumption, $\alpha < 1/n$, which implies that $\frac{1}{1-\alpha} \cdot \frac{n-1}{n} < 1$. Hence, if γ is sufficiently small,

$$v_{k+1} + a_{k+1} \geq \gamma(k^n + C_* k^{n-1})$$

for C_* as large as we wish. On the other hand, if we choose $C_* \geq 2^n$,

$$k^n + C_* k^{n-1} \geq (k+1)^n$$

and we obtain

$$v_{k+1} + a_{k+1} \geq \gamma(k+1)^n.$$

2. Assume now that $a_k \geq (\gamma/2)k^n$. Then

$$v_{k+1} + a_{k+1} \geq v_k + a_k + c_1 a_k \geq \gamma(k^n + (ck)k^{n-1}) \geq \gamma(k+1)^n$$

for sufficiently large k.

The proof is complete. □

The next lemma is similar in spirit. Its proof can be found on page 10 in [CC95] and is omitted here.

LEMMA 2.2. *Let $a_k \geq 0$ be a sequence such that $a_1 \geq c_0$, $a_k \leq C_0 L^n k^{n-1}$,*

$$\left(\sum_{1\leq j\leq k} a_j\right)^{(n-1)/n} \leq C_0 \left(a_{k+1} + \sum_{1\leq j\leq k} e^{-L(k+1-j)} a_j\right)$$

for any $k \in \mathbb{N}$ and some positive constants L, c_0, and C_0. Then, if $L = L(c_0, C_0)$ is suitably large, there exists $\gamma = \gamma(c_0, C_0) > 0$ such that

$$a_k \geq \gamma\, k^{n-1}$$

for any $k \in \mathbb{N}$. □

The next several lemmas are direct consequences of the structural hypotheses on $A(x,\eta)$ and $F(x,u)$.

LEMMA 2.3. *There exists a universal constant $\gamma > 0$ such that*

$$(a(x,\xi') - a(x,\xi)) \cdot (\xi' - \xi) \geq \gamma \cdot \begin{cases} (|\xi'| + |\xi|)^{p-2}|\xi' - \xi|^2 & \text{if } 1 < p \leq 2, \\ |\xi' - \xi|^p & \text{if } p \geq 2 \end{cases}$$

for every $\xi, \xi' \in \mathbb{R}^n$ and $x \in \Omega$.

Proof. For the reader's convenience we include a standard proof of this lemma. Set

$$\xi^s = s\,\xi' + (1-s)\,\xi, \quad 0 \leq s \leq 1. \tag{2.1}$$

Then $\xi^0 = \xi$ and $\xi^1 = \xi'$ and we have

$$a(x,\xi') - a(x,\xi) = \int_0^1 D_\eta a(x,\xi^s)(\xi' - \xi)ds.$$

By the hypothesis (1.4) we obtain

$$(a(x,\xi') - a(x,\xi)) \cdot (\xi' - \xi) \geq \Lambda^{-1}|\xi' - \xi|^2 \int_0^1 |\xi^s|^{p-2} ds.$$

Without loss of generality we may assume that $|\xi'| \leq |\xi|$. Then

$$(1/4)|\xi' - \xi| \leq |\xi^s| \leq |\xi'| + |\xi| \quad \text{for } 0 \leq s \leq 1/4.$$

Using the left-hand inequality for $p \geq 2$ and the right-hand inequality for $1 < p \leq 2$, we conclude the proof of the lemma. □

LEMMA 2.4. *For any $p \geq 2$ there exists a universal constant $c > 0$ such that*

$$c\,|\xi' - \xi|^p \leq A(x,\xi') - A(x,\xi) - a(x,\xi)\cdot(\xi' - \xi) \tag{2.2}$$

for every $\xi, \xi' \in \mathbb{R}^n$ and $x \in \Omega$.

Proof. Let ξ^s be as in (2.1). Then

$$\begin{aligned} A(x,\xi') - A(x,\xi) &= \int_0^1 a(x,\xi^s)\cdot(\xi' - \xi)ds \\ &= \int_0^1 (a(x,\xi^s) - a(x,\xi))\cdot(\xi' - \xi)ds + a(x,\xi)\cdot(\xi' - \xi) \\ &= \int_0^1 (a(x,\xi^s) - a(x,\xi))\cdot(\xi^s - \xi)\frac{ds}{s} + a(x,\xi)\cdot(\xi' - \xi). \end{aligned}$$

From Lemma 2.3 for $p \geq 2$ we have that

$$(a(x,\xi^s) - a(x,\xi))\cdot(\xi^s - \xi) \geq \gamma\,|\xi^s - \xi|^p.$$

Hence

$$\begin{aligned} A(x,\xi') - A(x,\xi) &\geq \gamma \int_0^1 |\xi^s - \xi|^p \frac{ds}{s} + a(x,\xi)\cdot(\xi' - \xi) \\ &= \gamma\,|\xi' - \xi|^p \int_0^1 s^{p-1}ds + a(x,\xi)\cdot(\xi' - \xi) \\ &= c\,|\xi' - \xi|^p + a(x,\xi)\cdot(\xi' - \xi). \qquad \square \end{aligned}$$

The analogue of the preceding Lemma 2.4 for $1 < p \leq 2$ is as follows.

LEMMA 2.5. *For any $1 < p \leq 2$ and $M \geq 0$ there exists a universal constant $c > 0$ such that*

$$c\,M^{p-2}\,|\xi' - \xi|^2 \leq A(x,\xi') - A(x,\xi) - a(x,\xi)\cdot(\xi' - \xi) \tag{2.3}$$

for every $\xi, \xi' \in \mathbb{R}^n$ with $|\xi| + |\xi'| \leq M$ and $x \in \Omega$.

Proof. The proof repeats the one for Lemma 2.4, except that we have to use the counterpart of Lemma 2.3 for $1 \leq p \leq 2$:

$$(a(x,\xi^s) - a(x,\xi))\cdot(\xi^s - \xi) \geq \gamma\,(|\xi^s| + |\xi|)^{p-2}|\xi^s - \xi|^2.$$

Then, also using $|\xi^s| + |\xi| \leq 2(|\xi'| + |\xi|)$, we will obtain

$$c\,(|\xi| + |\xi'|)^{p-2}|\xi' - \xi|^2 \leq A(x,\xi') - A(x,\xi) - a(x,\xi)\cdot(\xi' - \xi),$$

which implies (2.3) if $|\xi| + |\xi'| \leq M$. $\square$

The following result is elementary, and we omit the proof.

LEMMA 2.6. *Let $d \geq 1$. There exists $c_d > 0$ such that*

$$(u+1)^d - (u'+1)^d \geq c_d\,(u - u')^d$$

for any $u \geq u' \geq -1$.

Next, we deduce an estimate on the double-well potential.

LEMMA 2.7. *There exists $c > 0$ such that, for any $-1 \le u' \le u \le \theta$,*

$$F(x,u) - F(x,u') \ge c\,(u-u')^d\,,$$

provided $1+\theta > 0$ is small enough.

We omit the proof of Lemma 2.7, which easily follows from (1.10) and Lemma 2.6. The proof of the next two lemmas is also elementary.

LEMMA 2.8. *Let us assume (1.11). Then, there exists $c > 0$ so that, for any $-1 \le u' \le u \le \theta$, $F(x,u) - F(x,u') \ge c\,(u'+1)^{d-1}\,(u-u')$, provided $1+\theta > 0$ is small enough.*

LEMMA 2.9. *Let us assume that F is uniformly Lipschitz continuous in u. Then, there exists $c > 0$ so that, for any $u \in [-1,1]$, $F(x,u) \le c(1+u)$.*

We now construct a barrier that will be of use during the proof of the main result.

LEMMA 2.10. *Fix $T \ge 1$, $\Theta \in (0,1]$, and $k \in \mathbb{N}$. Then, there exists a function $h \in C^2(B_{(k+1)T})$ so that $-1 \le h \le 1$, $h = 1$ on $\partial B_{(k+1)T}$,*

$$(h+1) + |\nabla h| + |D^2 h| \le C(h+1) \le Ce^{-\Theta T(k+1-j)} \tag{2.4}$$

in $B_{jT} - B_{(j-1)T}$ for $j = 1,\dots,k$, and

$$|\nabla h| + |D^2 h| \le C\Theta(h+1) \tag{2.5}$$

in $B_{(k+1)T}$.

Proof. Define the following functions $\Phi : [0,1] \longrightarrow \mathbb{R}$, $\Psi : [1,(k+1)T] \longrightarrow \mathbb{R}$:

$$\Phi(t) = 2e^{\Theta[\frac{3}{8}t^6 - \frac{10}{8}t^4 + \frac{15}{8}t^2 - (k+1)T]} - 1 \quad \text{and}$$
$$\Psi(t) = 2e^{\Theta[t-(k+1)T]} - 1\,.$$

By explicit computations,

$$\Phi(1) = \Psi(1)\,, \quad \Phi'(1) = \Psi'(1), \quad \text{and} \quad \Phi''(1) = \Psi''(1)\,.$$

Thus, the function $\bar h$ agreeing with Φ in $[0,1]$ and with Ψ in $[1,(k+1)T]$ belongs to $C^2([0,(k+1)T])$. Define $h(x) = \bar h(|x|)$. Notice that $h \in C^2(B_{(k+1)T})$, since $\bar h'(0) = \Phi'(0) = 0$. Furthermore,

$$|\Phi'(t)| \le C\Theta t(\Phi+1)\,, \qquad |\Phi''(t)| \le C\Theta(\Phi+1) \tag{2.6}$$

in $[0,1]$ and

$$|\Psi'(t)| + |\Psi''(t)| \le C\Theta(\Psi+1) \tag{2.7}$$

in $[1,(k+1)T]$. Moreover,

$$(h+1) + |\nabla h| + |D^2 h| \le (\bar h + 1) + \left(1 + \frac{2}{|x|}\right)|\bar h'| + |\bar h''|\,. \tag{2.8}$$

By means of (2.6), we bound the right-hand side of (2.8) in B_1 by

$$C(\Phi+1) \le Ce^{\Theta(C-(k+1)T)} \le Ce^{-\Theta Tk}\,.$$

Similarly, using (2.7), we bound (2.8) by

$$C(\Psi+1) \le Ce^{-\Theta[(k+1)T-j]} \le Ce^{-\Theta T(k+1-j)}$$

in $B_{jT} - B_{(j-1)T}$ for $j = 2,\dots,k$. This proves (2.4). In a similar way, one can prove (2.5). ∎

3. A Caccioppoli-type inequality. We now state and prove a weaker version of the Caccioppoli inequality.

LEMMA 3.1. *Fix $\delta > 0$. Let $|u| \le 1$ be an absolute minimizer for $\mathcal{J}$ in a domain Ω. Then, there exists $C > 0$, depending only on δ and on the structural constants, such that*

$$\int_{B_r(x_0)} |\nabla u|^p \le C\,(r+\delta)^n$$

for any $r > 0$ and any $x_0 \in \Omega$, provided $B_{r+\delta}(x_0) \subset \Omega$.

Proof. We start with a claim that

$$\int_\Omega a(x,\nabla u)\cdot\nabla\phi + \int_{\Omega\cap\{|u|\neq 1\}} F_u(x,u)\,\phi\,dx \ge 0 \tag{3.1}$$

for any nonnegative $\phi \in C_0^\infty(\Omega\cap\{u > -1\})$ and

$$\int_\Omega a(x,\nabla u)\cdot\nabla\psi + \int_{\Omega\cap\{|u|\neq 1\}} F_u(x,u)\,\psi\,dx \le 0 \tag{3.2}$$

for any nonnegative $\psi \in C_0^\infty(\Omega\cap\{u < 1\})$. Let us show (3.2), the proof of (3.1) being analogous. For ψ as above and a small $\varepsilon > 0$, let

$$\psi_\varepsilon(x) = \psi(x)\chi_\varepsilon(u(x)),$$

where

$$\chi_\varepsilon(u) = \begin{cases} 0 & \text{if } u \le -1+\varepsilon,\\ (u+1)/\varepsilon - 1 & \text{if } -1+\varepsilon < u < -1+2\varepsilon,\\ 1 & \text{if } 1+u \ge 2\varepsilon. \end{cases}$$

Then $\psi_\varepsilon \in W^{1,p}(\Omega)$, $\operatorname{supp}\psi_\varepsilon \subset \Omega\cap\{|u|<1\}$, and therefore

$$\int_\Omega a(x,\nabla u)\cdot\nabla\psi_\varepsilon + F_u(x,u)\,\psi_\varepsilon = 0.$$

On the other hand,

$$\begin{aligned}&\int_\Omega a(x,\nabla u)\cdot\nabla\psi_\varepsilon\\ &= \int_\Omega [a(x,\nabla u)\cdot\nabla\psi]\chi_\varepsilon(u) + \frac{1}{\varepsilon}\int_{\Omega\cap\{\varepsilon<u+1<2\varepsilon\}} [a(x,\nabla u)\cdot\nabla u]\psi\\ &\ge \int_\Omega [a(x,\nabla u)\cdot\nabla\psi]\chi_\varepsilon(u) \to \int_\Omega a(x,\nabla u)\cdot\nabla\psi\end{aligned}$$

as $\varepsilon \to 0+$ and

$$\int_\Omega F_u(x,u)\psi_\varepsilon \to \int_{\Omega\cap\{u>-1\}} F_u(x,u)\psi.$$

The passage to the limit is legitimate, since

$$\int_\Omega |a(x,\nabla u)\cdot\nabla\psi| < \infty,$$

$\psi_\varepsilon \nearrow \psi\chi_{\{u>-1\}}$, and $F_u(x,u) \geq 0$ by (1.10) for u close to -1. Collecting the estimates above, we obtain (3.2).

Now fix $0 < \theta < 1$. If θ is sufficiently close to 1, the assumptions (1.9)–(1.10) and (3.1)–(3.2) above imply that

$$\int_\Omega a(x,\nabla u)\cdot\nabla\phi + K\,\phi \geq 0 \quad \text{and} \quad \int_\Omega a(x,\nabla u)\cdot\nabla\psi - K\,\psi \leq 0 \tag{3.3}$$

for any nonnegative $\phi \in C_0^\infty(\Omega\cap\{u > -\theta\})$ and $\psi \in C_0^\infty(\Omega\cap\{u<\theta\})$ with $K = M(\theta)$ as in (1.9). By standard density arguments, (3.3) also holds for nonnegative $\phi \in W_0^{1,p}(\Omega\cap\{u>-\theta\})$ and $\psi \in W_0^{1,p}(\Omega\cap\{u<\theta\})$.

Next, we observe that in light of Theorem 3.1 in [GG82], the distance between the level sets $\{u=-\theta\}$ and $\{u=\theta\}$ in $B_{r+\delta/2}(x_0)$ is bounded from below by some universal constant (depending only on θ, δ, and the structural constants). Therefore, by partition of unity, there exist two smooth functions η_- and η_+, supported in $B_{r+\delta/2}(x_0)$, so that $0 \leq \eta_-(x), \eta_+(x) \leq 1$ for any $x \in \Omega$, whose gradients are uniformly bounded by a universal constant and which satisfy

$$\begin{aligned} \eta_-(x)+\eta_+(x) \;&=\; 1 \quad \forall x \in B_r(x_0)\,,\\ \operatorname{supp}\eta_- &\subseteq \{-1 \leq u < \theta\}\,,\\ \operatorname{supp}\eta_+ &\subseteq \{-\theta < u \leq 1\}\,,\\ \eta_-(x)+\eta_+(x) &\leq 1 \quad \forall x\in\Omega\,. \end{aligned}$$

We set $\phi := (1-u)\,\eta_+^p$ and $\psi := (1+u)\,\eta_-^p$. By repeating the standard arguments in the proof of the Caccioppoli inequality (e.g., see Lemma 3.27 in [HKM93]), one infers that

$$\int_\Omega |\nabla u|^p\eta_-^p \;\leq\; C\,(r+\delta)^n \qquad \text{and} \qquad \int_\Omega |\nabla u|^p\eta_+^p \;\leq\; C\,(r+\delta)^n. \tag{3.4}$$

For the reader's convenience, we sketch the details of the proof of the second inequality in (3.4), the first being analogous. From (3.3),

$$0 \leq \int_\Omega -a(x,\nabla u)\cdot\nabla u\eta_+^p + p\,a(x,\nabla u)\,(1-u)\,\eta_+^{p-1}\nabla\eta_+ + K(1-u)\eta_+^p\,.$$

Therefore, introducing a parameter $\varepsilon \in (0,1)$, to be chosen suitably small in what follows, and using Young's inequality, we have

$$\begin{aligned} \int_\Omega |\nabla u|^p\eta_+^p &\leq C\left(\int_\Omega (|\nabla u|\eta_+)^{p-1}|\nabla\eta_+| + \eta_+^p\right)\\ &= C\left(\int_\Omega (\varepsilon|\nabla u|\eta_+)^{p-1}\frac{|\nabla\eta_+|}{\varepsilon^{p-1}} + \eta_+^p\right)\\ &\leq C\left(\int_\Omega (\varepsilon|\nabla u|\eta_+)^p + \frac{|\nabla\eta_+|^p}{\varepsilon^{p(p-1)}} + \eta_+^p\right)\\ &\leq C\varepsilon^p\int_\Omega (|\nabla u|\eta_+)^p + \frac{C}{\varepsilon^{p(p-1)}}\int_{B_{r+\delta}}(|\nabla\eta_+|^p + \eta_+^p)\\ &\leq C\varepsilon^p\int_\Omega |\nabla u|^p\eta_+^p + \frac{C}{\varepsilon^{p(p-1)}}(r+\delta)^n\,. \end{aligned}$$

Thus, the second inequality in (3.4) follows by choosing ε suitably small.

Using (3.4), we easily conclude the proof of the lemma:

$$\int_{B_r(x_0)} |\nabla u|^p \,=\, \int_{B_r(x_0)} |\nabla u|^p (\eta_- + \eta_+)^p$$
$$\le C \int_{B_r(x_0)} |\nabla u|^p \eta_-^p + C \int_{B_r(x_0)} |\nabla u|^p \eta_+^p \,\le\, C\,(r+\delta)^n\,. \qquad \square$$

4. Proof of Theorem 1.1. First, we point out that, since u is an absolute minimizer,

$$\mathcal{J}(u; B_r(y)) \le C\, r^{n-1} \tag{4.1}$$

for any $r \ge r_0$, for a suitable universal r_0, provided $B_{r+\delta}(y) \subset \Omega$. To prove (4.1), with no loss of generality assume $y = 0$ and proceed as follows. Let h be a smooth function such that $h\big|_{B_{r-1}} = -1$ and $h\big|_{\partial B_r} = 1$. Let $u^* = \min\{u, h\}$. Then,

$$\begin{aligned}\mathcal{J}(u; B_r) &\le \mathcal{J}(u^*; B_r)\\ &\le C \int_{B_r - B_{r-1}} (|\nabla u|^p + |\nabla h|^p) + r^{n-1}\\ &\le C \int_{B_r - B_{r-1}} |\nabla u|^p + r^{n-1}.\end{aligned}$$

Covering $B_r - B_{r-1}$ with balls of radius $\delta/2$, $\mathcal{B}_1, \dots, \mathcal{B}_N$, with $N \le C\, r^{n-1}$ and applying Lemma 3.1, we obtain

$$\int_{B_r - B_{r-1}} |\nabla u|^p \le \sum_{i=1}^{N} \int_{\mathcal{B}_i} |\nabla u|^p \le C\, r^{n-1}\,.$$

This completes the proof of (4.1).

We now focus our attention on the proof of (1.13). We will deal only with the first inequality in (1.13), the proof of the second one being analogous. To this end, we state the following result, the proof of which is deferred to sections 5 and 6.

LEMMA 4.1. *Let us assume the same hypotheses on A and F as in Theorem* 1.1. *Fix $\theta \in (-1, 1)$ and let u be an absolute minimizer for $\mathcal{J}$ in a domain Ω. Assume that there exist $\mu_1, \mu_2 > 0$ so that $B_{\mu_1}(x) \subset \Omega$ and $\mathcal{L}^n\big(B_{\mu_1}(x) \cap \{u > \theta\}\big) \ge \mu_2$. Then, for fixed $\delta > 0$, there exist positive r_0 and c depending only on θ, μ_1, μ_2, δ, and on the structural constants, such that $\mathcal{L}^n\big(B_r(x) \cap \{u > \theta\}\big) \ge c\, r^n$, for any $r \ge r_0$, provided $B_{r+\delta}(x) \subset\subset \Omega$.*

Analogously, if $\mathcal{L}^n\big(B_{\mu_1}(x) \cap \{u < \theta\}\big) \ge \mu_2$, then $\mathcal{L}^n\big(B_r(x) \cap \{u < \theta\}\big) \ge c\, r^n$ for any $r \ge r_0$, provided $B_{r+\delta}(x) \subset\subset \Omega$.

We now use the above result to prove (1.13). Let $\theta^\star = (1+\theta)/2 \in (\theta, 1)$. Since u is uniformly continuous (with a modulus of continuity depending only on the structural constants; see Theorem 3.1 in [GG82]) and $|u(x)| < \theta$, we have that $|u(x')| < \theta^\star$ for any $x' \in B_{\mu^\star}(x)$, for a suitable universal $\mu^\star > 0$. Hence, in view of Lemma 4.1, $\mathcal{L}^n\big(B_r(x) \cap \{u > -\theta^\star\}\big) \ge c\, r^n$ and $\mathcal{L}^n\big(B_r(x) \cap \{u < \theta^\star\}\big) \ge c\, r^n$. Therefore, by (1.8) and (4.1),

$$\begin{aligned}&c\, r^n - \mathcal{L}^n\big(B_r(x) \cap \{u > \theta\}\big)\\ &\le \mathcal{L}^n\big(B_r(x) \cap \{u > -\theta^\star\}\big) - \mathcal{L}^n\big(B_r(x) \cap \{u > \theta\}\big)\\ &\le \mathcal{L}^n\big(B_r(x) \cap \{-\theta^\star < u \le \theta\}\big)\\ &\le C \int_{\{-\theta^\star < u \le \theta\} \cap B_r(x)} F\\ &\le C\, \mathcal{J}(u; B_r(x)) \,\le\, C\, r^{n-1}\,.\end{aligned}$$

Hence, if r is suitably large, $\mathcal{L}^n\big(B_r(x)\cap\{u>\theta\}\big)\geq c\,r^n$, thus proving (1.13).

We now deal with the proof of (1.14). The second inequality follows from (4.1); hence we focus on the proof of the first one. Let

$$u^\star(x)=\begin{cases} u(x) & \text{if} \quad |u(x)|<\theta\,,\\ \theta & \text{if} \quad u(x)\geq\theta\,,\\ -\theta & \text{if} \quad u(x)\leq-\theta. \end{cases}$$

Using a standard notation in geometric measure theory, we denote by $\mathcal{P}(E;U)$ the perimeter of the Borel set E in an open set U. Then, using the coarea formula, the isoperimetric inequality, and (1.13), we have

$$\begin{aligned}
&\int_{B_r(x)}|\nabla u^\star|\\
&\geq\int_{-\theta}^{\theta}\mathcal{P}\Big(\{u^\star<s\};\,B_r(x)\Big)\,ds\\
&\geq c\int_{-\theta}^{\theta}\min\Big\{\mathcal{L}^n\left(B_r(x)\cap\{u^\star<s\}\right),\,\mathcal{L}^n\left(B_r(x)\cap\{u^\star\geq s\}\right)\Big\}^{\frac{n-1}{n}}\,ds\\
&=c\int_{-\theta}^{\theta}\min\Big\{\mathcal{L}^n\left(B_r(x)\cap\{u<s\}\right),\,\mathcal{L}^n\left(B_r(x)\cap\{u\geq s\}\right)\Big\}^{\frac{n-1}{n}}\,ds\\
&\geq c\int_{-\theta}^{\theta}\min\Big\{\mathcal{L}^n\left(B_r(x)\cap\{u<-\theta\}\right),\,\mathcal{L}^n\left(B_r(x)\cap\{u\geq\theta\}\right)\Big\}^{\frac{n-1}{n}}\,ds\\
&\geq c\,r^{n-1}\,.
\end{aligned}$$

Let us now fix a suitably large parameter $K>0$. In view of the above estimate, denoting by p' the conjugated exponent of p, using Young's inequality and (4.1), we deduce that

$$\begin{aligned}
c\,r^{n-1}&\leq\frac{1}{K^p}\int_{B_r(x)}|\nabla u|^p+K^{p'}\,\mathcal{L}^n\left(B_r(x)\cap\{|u|<\theta\}\right)\\
&\leq\frac{C}{K^p}\mathcal{J}(u;B_r(x))\,+\,K^{p'}\,\mathcal{L}^n\left(B_r(x)\cap\{|u|<\theta\}\right)\\
&\leq\frac{C}{K^p}\,r^{n-1}\,+\,K^{p'}\,\mathcal{L}^n\left(B_r(x)\cap\{|u|<\theta\}\right)\,.
\end{aligned}$$

Then, (1.14) follows by choosing K large enough here above. ∎

5. Proof of Lemma 4.1. The case $p\geq 2$. We will prove the first claim in Lemma 4.1, the second claim being analogous. We point out that it is enough to show the validity of the first claim of Lemma 4.1 for θ as close to -1 as we wish. Indeed, let us assume that the claim holds true for $\theta_\star$ and $-1<\theta_\star<\theta<1$. Then, if $\mathcal{L}^n\left(B_{\mu_1}(x)\cap\{u>\theta\}\right)\geq\mu_2$, then of course $\mathcal{L}^n\left(B_{\mu_1}(x)\cap\{u>\theta_\star\}\right)\geq\mu_2$, and so, since the claim holds for $\theta_\star$, $\mathcal{L}^n\left(B_r(x)\cap\{u>\theta_\star\}\right)\geq c\,r^n$. Thus, using the second part of (1.14) (which has already been proved via (4.1)),

$$\begin{aligned}
&\mathcal{L}^n\left(B_r(x)\cap\{u>\theta\}\right)\\
&\geq\mathcal{L}^n\left(B_r(x)\cap\{u>\theta_\star\}\right)\,-\,\mathcal{L}^n\left(B_r(x)\cap\{\theta_\star<u\leq\theta\}\right)\\
&\geq c\,r^n\,-\,C\,r^{n-1}\,\geq\,\tilde{c}\,r^n
\end{aligned}$$

if r is sufficiently big. This shows that we need only to prove the first claim of Lemma 4.1 for θ close to -1. Thus, we may assume that (1.10) is satisfied for $0<s\leq\theta+1$.

In this section we will assume $p \geq 2$. We will distinguish the cases $d < p$ and $d = p$, where d is the exponent that appears in (1.10).

5.1. The case $d < p$. For θ close to -1 let

$$\mathcal{V}_r = \mathcal{L}^n(\{u \geq \theta\} \cap B_r), \qquad \mathcal{A}_r = \int_{B_r} F(x,u)dx\,, \tag{5.1}$$

where B_r is short for $B_r(x)$. Then, we claim that

$$\mathcal{V}_r^{(n-1)/n} + \mathcal{A}_r \leq C_0\,(\mathcal{V}_{r+1} + \mathcal{A}_{r+1} - \mathcal{V}_r - \mathcal{A}_r)\,. \tag{5.2}$$

With no loss of generality, we can take $r_0 \geq \mu_1$ and $\delta \geq 2$. Thus, by assumption, $\mathcal{V}_{r_0} \geq \mu_2 > 0$. Therefore, by means of Lemma 2.1, the above inequality implies that

$$\mathcal{V}_r \geq c\, r^n$$

for $r \geq 1$.

We now prove (5.2). We use a barrier function $h \in C^2(B_{r+1})$ such that

$$h\big|_{\partial B_{r+1}} = 1, \qquad h\big|_{B_r} = -1.$$

Let $\varepsilon = 1 + \theta$ and define $u^* = \min(u, h)$ and $\beta = \min(u - u^*, \varepsilon)$. Using the Sobolev inequality applied to β^p and then Young's inequality, we have

$$\begin{aligned}
&\left(\int_{B_{r+1}} |\beta|^{pn/(n-1)}\right)^{(n-1)/n} \\
&\leq C \int_{B_{r+1}\cap\{u-u^*<\varepsilon\}} |\beta|^{p-1}|\nabla\beta| \\
&\leq C\,K^p \int_{B_{r+1}\cap\{u-u^*<\varepsilon\}} |\nabla(u-u^*)|^p \\
&\quad + \frac{C}{K^{p'}} \int_{B_{r+1}\cap\{u-u^*<\varepsilon\}} (u-u^*)^p\,.
\end{aligned} \tag{5.3}$$

Here, $K > 0$ is a free parameter that will be conveniently chosen in what follows. As customary, we also denoted the conjugated exponent of p by p'. Since $u^* = -1$ in B_r, $u - u^* \geq \varepsilon$ in $B_r \cap \{u \geq \theta\}$, the left-hand side of the inequality above is bounded from below by

$$c\,\mathcal{L}^n(\{u \geq \theta\} \cap B_r)^{(n-1)/n} = c\,\mathcal{V}_r^{(n-1)/n}.$$

Next, we apply (2.2) with $\xi = \nabla u^*$ and $\xi' = \nabla u$ to estimate $|\nabla(u - u^*)|^p$ in the right-hand side of (5.3). Thus, we obtain

$$\begin{aligned}
\mathcal{V}_r^{(n-1)/n} &\leq C\,K^p \int_{B_{r+1}} A(x,\nabla u) - A(x,\nabla u^*) \\
&\quad - C\,K^p \int_{B_{r+1}} a(x,\nabla u^*)\cdot\nabla(u-u^*) \\
&\quad + \frac{C}{K^{p'}} \int_{B_{r+1}\cap\{u-u^*<\varepsilon\}} (u-u^*)^p.
\end{aligned} \tag{5.4}$$

Since $\operatorname{supp}(u-u^*) \subset B_{r+1} \subset\subset \Omega$, the minimality of u implies that $\mathcal{J}(u;\Omega) \leq \mathcal{J}(u^*;\Omega)$ or, equivalently,

$$\int_{B_{r+1}} A(x,\nabla u) - A(x,\nabla u^*) \leq \int_{B_{r+1}} F(x,u^*) - F(x,u).$$

Using this, and integrating by parts the term $a(x,\nabla u^*)\cdot\nabla(u-u^*)$ in the right-hand side of (5.4), we obtain

$$\begin{aligned} \mathcal{V}_r^{(n-1)/n} &\leq C\,K^p \int_{B_{r+1}} F(x,u^*) - F(x,u) \\ &\quad + C\,K^p \int_{B_{r+1}} \operatorname{div} a(x,\nabla u^*)(u-u^*) \\ &\quad + \frac{C}{K^{p'}} \int_{B_{r+1}\cap\{u-u^*<\varepsilon\}} (u-u^*)^p. \end{aligned} \tag{5.5}$$

Notice also that, by definition of u^*,

$$\int_{B_{r+1}} \operatorname{div} a(x,\nabla u^*)(u-u^*) = \int_{B_{r+1}} \operatorname{div} a(x,\nabla h)(u-u^*).$$

Thus, to proceed, we recall that by (1.5) and (1.6) we have

$$\operatorname{div} a(x,\nabla h) \leq C|\nabla h|^{p-2}(|\nabla h| + |D^2 h|). \tag{5.6}$$

Now let h be a C^2 radial function, defined by

$$h(x) = -1 + 2(|x| - r)_+^\alpha,$$

with some fixed

$$\alpha > \max\left\{\frac{p}{p-d}, 2\right\}.$$

Then

$$|\nabla h| \leq C(h+1)^{(\alpha-1)/\alpha}, \qquad |D^2 h| \leq C(h+1)^{(\alpha-2)/\alpha}.$$

Hence,

$$\operatorname{div} a(x,\nabla h) \leq C(h+1)^{(p-2)(\alpha-1)/\alpha + (\alpha-2)/\alpha} \leq C(h+1)^{d-1} \tag{5.7}$$

and consequently

$$\begin{aligned} \mathcal{V}_r^{(n-1)/n} &\leq C\,K^p \int_{B_{r+1}} [F(x,u^*) - F(x,u)] \\ &\quad + C\,K^p \int_{B_{r+1}} (u^*+1)^{d-1}\,(u-u^*) \\ &\quad + \frac{C}{K^{p'}} \int_{B_{r+1}\cap\{u-u^*<\varepsilon\}} (u-u^*)^p. \end{aligned} \tag{5.8}$$

We now split the right-hand side of the above inequality into three parts, namely, the contribution in B_r, the one in $\{u<\theta\}\cap(B_{r+1}-B_r)$, and the one in $\{u\geq\theta\}\cap(B_{r+1}-B_r)$.

1. The contribution in B_r. Here the second integrand in the right-hand side of (5.8) vanishes, as well as the term $F(x,u^*)$ of the first integrand. Besides, the third integral is taken over the region, where $u-u^*<\varepsilon$. In B_r, the latter condition is equivalent to $u<\theta$, since $u^*=-1$. Furthermore, if K is sufficiently large, for $u<\theta$ we have

$$-C\,K^p F(x,u)+C\,K^{-p'}(u+1)^p\le -c\,F(x,u),$$

since by our assumption $F(x,u)\ge c(u+1)^d\ge c(u+1)^p$ for $-1\le u<\theta$. Hence, the contribution of the right-hand side of (5.8) in B_r is bounded from above by $-c\mathcal{A}_r$.

2. The contribution in $\{u<\theta\}\cap(B_{r+1}-B_r)$. Since $-1\le u^*\le u<\theta$, from Lemma 2.7 we have that

$$F(x,u^*)-F(x,u)\le -c\,(u-u^*)^d.$$

Since both $u^*+1\le u+1$ and $u-u^*\le u+1$, we also have

$$(u^*+1)^{d-1}(u-u^*)\le (u+1)^d\le C\,F(x,u).$$

Thus,

$$K^p[F(x,u^*)-F(x,u)+(u^*+1)^{d-1}(u-u^*)]+K^{-p'}(u-u^*)^p\le C\,F(x,u),$$

and the total contribution of the right-hand side of (5.8) in $\{u<\theta\}\cap(B_{r+1}-B_r)$ is bounded from above by $C(\mathcal{A}_{r+1}-\mathcal{A}_r)$.

3. Finally, the contribution in $\{u\ge\theta\}\cap(B_{r+1}-B_r)$ is easily estimated by

$$C\,\mathcal{L}^n(\{u\ge\theta\}\cap(B_{r+1}-B_r))=C(\mathcal{V}_{r+1}-\mathcal{V}_r),$$

since the terms inside the integrals are bounded.

Collecting the estimates from 1–3, we obtain (5.2), which completes the proof of Lemma 4.1 in the case $p\ge 2$, $d<p$. □

5.2. The case $d=p$. The proof is a refinement of the one in the case $d<p$. Here we use suitable positive parameters Θ and T: we will fix Θ small enough and then choose T suitably large (and in fact ΘT suitably large).

We define $\mathcal{V}_r$ as in (5.1) and set $a_k=\mathcal{V}_{kT}-\mathcal{V}_{(k-1)T}$. Then, we claim that

$$\left(\sum_{1\le j\le k}a_j\right)^{(n-1)/n}\le C\left(a_{k+1}+\sum_{1\le j\le k}e^{-L(k+1-j)}a_j\right),\tag{5.9}$$

with $L=\Theta T$ as large as we wish. With no loss of generality, we can take $r_0\ge\mu_1$. Thus, by assumption, $\mathcal{V}_{r_0}\ge\mu_2>0$. Therefore, by means of Lemma 2.2, the above inequality implies that

$$\mathcal{V}_r\ge c\,r^n$$

for $r\ge 1$.

We now prove (5.9). We use the barrier function $h=h_k\in C^2(B_{(k+1)T})$ introduced in Lemma 2.10. Then, $-1\le h\le 1$, $h=1$, on $\partial B_{(k+1)T}$,

$$(h+1)+|\nabla h|+|D^2h|\le C(h+1)\le Ce^{-\Theta T(k+1-j)}\tag{5.10}$$

in $B_{jT} - B_{(j-1)T}$, and

$$|\nabla h| + |D^2 h| \le C\Theta(h+1) \tag{5.11}$$

in $B_{(k+1)T}$.

Fix $\varepsilon \in (0, 1+\theta)$. Define $u^* = \min(u, h)$ and $\beta = \min(u - u^*, \varepsilon)$. Using the Sobolev inequality applied to β^p and then Young's inequality, we have

$$\begin{aligned}\left(\int_{B_{(k+1)T}} |\beta|^{pn/(n-1)}\right)^{(n-1)/n} \\ \le C\,K^p \int_{B_{(k+1)T}\cap\{u-u^*<\varepsilon\}} |\nabla(u-u^*)|^p \\ + \frac{C}{K^{p'}} \int_{B_{(k+1)T}\cap\{u-u^*<\varepsilon\}} (u-u^*)^p\end{aligned} \tag{5.12}$$

with the parameter $K > 0$ to be chosen later. From (5.10),

$$u - u^* \ge \theta + 1 - Ce^{-\Theta T} > \varepsilon \tag{5.13}$$

in $B_{kT} \cap \{u \ge \theta\}$, provided ΘT is conveniently large; hence the left-hand side of the inequality above is bounded from below by

$$c\,\mathcal{L}^n(\{u \ge \theta\} \cap B_{kT})^{(n-1)/n} = c\,\mathcal{V}_{kT}^{(n-1)/n}.$$

Now, combining (5.12) and (2.2), using the minimality of u, and integrating by parts the term $a(x, \nabla u^*)\cdot\nabla(u-u^*)$ (for more details, see the respective part in section 5.1), we obtain

$$\begin{aligned}\mathcal{V}_{kT}^{(n-1)/n} &\le C\,K^p \int_{B_{(k+1)T}} F(x,u^*) - F(x,u) \\ &\quad + C\,K^p \int_{B_{(k+1)T}} \operatorname{div} a(x,\nabla u^*)(u-u^*) \\ &\quad + \frac{C}{K^{p'}} \int_{B_{(k+1)T}\cap\{u-u^*<\varepsilon\}} (u-u^*)^p.\end{aligned}$$

Recalling (1.5) and (1.6), we have that

$$\operatorname{div} a(x,\nabla h) \le C|\nabla h|^{p-2}(|\nabla h| + |D^2 h|). \tag{5.14}$$

Hence,

$$\begin{aligned}\mathcal{V}_{kT}^{(n-1)/n} &\le C\,K^p \int_{B_{(k+1)T}} F(x,u^*) - F(x,u) \\ &\quad + C\,K^p \int_{B_{(k+1)T}} |\nabla u^*|^{p-2}\,(|\nabla u^*| + |D^2 u^*|)\,(u-u^*) \\ &\quad + \frac{C}{K^{p'}} \int_{B_{(k+1)T}\cap\{u-u^*<\varepsilon\}} (u-u^*)^p\,.\end{aligned}$$

Thanks to the definition of u^*, we may replace u^* with h in the second integral in the previous inequality in order to gather

$$\begin{aligned}\mathcal{V}_{kT}^{(n-1)/n} &\le C\,K^p \int_{B_{(k+1)T}} F(x,u^*) - F(x,u)\\ &\quad + C\,K^p \int_{B_{(k+1)T}} |\nabla h|^{p-2}\,(|\nabla h| + |D^2 h|)\,(u-u^*)\\ &\quad + \frac{C}{K^{p'}} \int_{B_{(k+1)T}\cap\{u-u^*<\varepsilon\}} (u-u^*)^p.\end{aligned} \tag{5.15}$$

We now split the right-hand side of the above inequality into three parts, namely, the contribution in $\{u<\theta\}$, the one in $\{u\ge\theta\}\cap(B_{(k+1)T}-B_{kT})$, and the one in $\{u\ge\theta\}\cap B_{kT}$.

1. The contribution in $\{u<\theta\}$ is estimated using (5.11) and Lemmas 2.7 and 2.8. We actually show that such contribution is negative. Indeed, using the above mentioned results and taking K suitably big (so as to kill the last term with the first one) and Θ suitably small (so as to kill the constant c in Lemma 2.8), the contribution in $\{u<\theta\}$ is bounded by

$$C\int_{B_{(k+1)T}\cap\{u<\theta\}} F(x,u^*) - F(x,u) + C\Theta(u^*+1)^{d-1}(u-u^*) \le 0\,.$$

2. The contribution in $\{u\ge\theta\}\cap(B_{(k+1)T}-B_{kT})$ of the right-hand side of (5.15) can be easily bounded by $C\,a_{k+1}$, since the terms inside the integrals are bounded.

3. We now estimate the contribution of the right-hand side of (5.15) in $\{u\ge\theta\}\cap B_{kT}$. First, notice that, by (5.13),

$$\int_{B_{kT}\cap\{u-u^*<\varepsilon\}\cap\{u\ge\theta\}} (u-u^*)^p = \int_{\emptyset}(u-u^*)^p = 0\,.$$

Also, from (1.9) and (1.11), it follows that F is uniformly Lipschitz continuous in u; thus, from Lemma 2.9, $F(x,h)\le c\,(1+h)$. Therefore, by (5.10), we bound the contribution in $\{u\ge\theta\}\cap B_{kT}$ by

$$\begin{aligned}&C\left(\sum_{j=1}^{k}\int_{(B_{jT}-B_{(j-1)T})\cap\{u\ge\theta\}} F(x,h) + |\nabla h| + |D^2 h|\right)\\ &\le C\left(\sum_{j=1}^{k} e^{-\Theta T(k+1-j)}\,\mathcal{L}^n((B_{jT}-B_{(j-1)T})\cap\{u\ge\theta\})\right).\end{aligned}$$

In light of 1–3, we bound the right-hand side of (5.15) by

$$C\left(a_{k+1} + \sum_{1\le j\le k} e^{-L(k+1-j)}a_j\right).$$

This proves (5.9) and completes the proof of Theorem 1.1 in the case $p\ge 2$.

6. Proof of Lemma 4.1. The case $1 < p < 2$.

6.1. The case of uniformly Lipschitz F. Under the assumption (1.12) of the uniform Lipschitz continuity of the double-well potential F, every absolute minimizer u of $\mathcal{J}$ with $|u| \le 1$ will satisfy an equation

$$\operatorname{div} a(x, \nabla u) = g(x), \tag{6.1}$$

weakly in Ω for some $g \in L^\infty(\Omega)$. Indeed, if M is as in (1.12) and $\psi \in C_0^\infty(\{u < 1\})$ is nonnegative, using that $\mathcal{J}(u + \varepsilon\psi; \Omega) \ge \mathcal{J}(u; \Omega)$, we will easily obtain

$$\int_\Omega a(x, \nabla u) \cdot \nabla\psi + M\,\psi \ge 0.$$

On the other hand, by (3.2), we also have

$$\int_\Omega a(x, \nabla u) \cdot \nabla\psi - M\,\psi \le 0.$$

Hence (6.1) is satisfied with $|g| \le M$ in $\{u < 1\}$. Similarly, we prove (6.1) in $\{u > -1\}$ and consequently in Ω.

Note that $g(x) = F_u(x, u)$ a.e. in $\{|u| < 1\}$ and $g(x) = 0$ in $\Omega \setminus \overline{\{|u| < 1\}}$, but we have no information on $g(x)$ on the "free boundary" $\partial\{|u| < 1\} \cap \Omega$, except that it is bounded. However, that is sufficient for our purposes.

The equation (6.1) implies that u is locally uniformly $C^{1,\alpha}$ regular in Ω; see [Tol84]. Then the proof of Lemma 4.1 in the case $1 < p \le 2$ is a slight variation of the one for $p \ge 2$. The main difference is that we use Lemma 2.5 instead of Lemma 2.4. Technically, we should separately consider the cases $d < p$ and $d = p$. However, since the changes from the case $p \ge 2$ are similar in both cases, we sketch only the proof for the more subtle case $d = p$.

We consider suitable positive parameters Θ, T, and K (playing the same role as in section 5.2) and we define h, u^*, and β as we did in section 5.2 above. In analogy with (5.12), using the Sobolev inequality applied to β^2 and then Young's inequality, we have

$$\begin{aligned} &\left(\int_{B_{(k+1)T}} |\beta|^{2n/(n-1)} \right)^{(n-1)/n} \\ &\le C\,K^2 \int_{B_{(k+1)T} \cap \{u - u^* < \varepsilon\}} |\nabla(u - u^*)|^2 \\ &\quad + \frac{C}{K^2} \int_{B_{(k+1)T} \cap \{u - u^* < \varepsilon\}} (u - u^*)^2 \,. \end{aligned} \tag{6.2}$$

Arguing as in (5.13), we get that the left-hand side of the inequality above is estimated from below by

$$c\,\mathcal{L}^n(\{u \ge \theta\} \cap B_{kT})^{(n-1)/n} = c\,\mathcal{V}_{kT}^{(n-1)/n}.$$

Notice that $|\nabla u|$ is uniformly bounded by means of Theorem 1 in [Tol84] (and, indeed, u is $C^{1,\alpha}$ with uniform estimates in the interior of Ω). Thus, using (2.3), the

minimality of u, and an integration by parts, we infer from (6.2) the following inequality:

$$\begin{aligned}\mathcal{V}_{kT}^{(n-1)/n} &\le C\,K^2 \int_{B_{(k+1)T}} F(x,u^*) - F(x,u)\\ &\quad + C\,K^2 \int_{B_{(k+1)T}} \operatorname{div} a(x,\nabla u^*)(u-u^*)\\ &\quad + \frac{C}{K^2}\int_{B_{(k+1)T}\cap\{u-u^*<\varepsilon\}} (u-u^*)^2.\end{aligned}$$

In light of (5.14), we deduce that

$$\begin{aligned}\mathcal{V}_{kT}^{(n-1)/n} &\le C\,K^2 \int_{B_{(k+1)T}} F(x,u^*) - F(x,u)\\ &\quad + C\,K^2 \int_{B_{(k+1)T}} |\nabla u^*|^{p-2}\,(|\nabla u^*| + |D^2 u^*|)\,(u-u^*)\\ &\quad + \frac{C}{K^2}\int_{B_{(k+1)T}\cap\{u-u^*<\varepsilon\}} (u-u^*)^2.\end{aligned}$$

By the definition of u^*, we may replace u^* with h in the second integral in the previous inequality, obtaining

$$\begin{aligned}\mathcal{V}_{kT}^{(n-1)/n} &\le C\,K^2 \int_{B_{(k+1)T}} F(x,u^*) - F(x,u)\\ &\quad + C\,K^2 \int_{B_{(k+1)T}} |\nabla h|^{p-2}\,(|\nabla h| + |D^2 h|)\,(u-u^*)\\ &\quad + \frac{C}{K^2}\int_{B_{(k+1)T}\cap\{u-u^*<\varepsilon\}} (u-u^*)^2.\end{aligned} \tag{6.3}$$

As done in section 5.2, one splits the right-hand side of the above inequality into three parts, namely, the contribution in $\{u<\theta\}$, the one in $\{u\ge\theta\}\cap(B_{(k+1)T}-B_{kT})$, and the one in $\{u\ge\theta\}\cap B_{kT}$. Such estimates follow the lines of section 5.2. Namely, the contribution in $\{u\le\theta\}$ is estimated by using (5.11) and Lemmas 2.7 and 2.8, obtaining, for big K and small $\Theta>0$, the bound

$$C\int_{B_{(k+1)T}\cap\{u<\theta\}} F(x,u^*) - F(x,u) + C\Theta^{p-1}(u^*+1)^{d-1}(u-u^*) \le 0\,,$$

which is negative. The contribution in $\{u\ge\theta\}\cap(B_{(k+1)T}-B_{kT})$ of the right-hand side of (5.15) can be easily bounded by $C\,a_{k+1}$. As above, the contribution in $\{u\ge\theta\}\cap B_{kT}$ is bounded by using Lemma 2.9 and (5.10), obtaining

$$C\left(\sum_{j=1}^{k} e^{-(p-1)\Theta T(k+1-j)}\,\mathcal{L}^n((B_{jT}-B_{(j-1)T})\cap\{u\ge\theta\})\right).$$

This proves (5.9) and hence completes the proof of Theorem 1.1 in the case $1<p\le 2$ for potentials F satisfying (1.12). □

6.2. The case $2n/(n+2) < p < 2$. We now show that the density estimate in Lemma 4.1 can be obtained at least for $2n/(n+2) < p < 2$ without the technical assumption (1.12) of uniform Lipschitz continuity of the double-well potential F in $u \in (-1,1)$. This will be achieved with a more effective use of the inequality

$$c(|\xi'|+|\xi|)^{p-2}|\xi'-\xi|^2 \le A(x,\xi') - A(x,\xi) - a(x,\xi)\cdot(\xi'-\xi) \tag{6.4}$$

for $1 < p < 2$; see the proof of Lemma 2.5.

Without loss of generality we may assume that $d < p$. Indeed, the additional hypothesis (1.11) in the case $d = p$ implies (1.12), contrary to our assumption.

We revisit the proof of Lemma 4.1 in section 5.1, now with $1 < p < 2$, and let h, u^*, and β be the same as there. We also introduce the weight

$$\omega = (|\nabla u| + |\nabla u^*|)^{1-p/2}.$$

Integrating (6.4) over B_r with $\xi' = \nabla u$ and $\xi = \nabla u^*$, we obtain that

$$c\int_{B_r} \frac{|\nabla\beta|^2}{\omega^2} \le \int_{B_r} A(x,\nabla u) - A(x,\nabla u^*) - a(x,\nabla u^*)\cdot\nabla(u-u^*). \tag{6.5}$$

To avoid complications, related to the vanishing of ω, we also introduce its "regularization"

$$\omega_\varepsilon = (|\nabla u| + |\nabla u^*| + \varepsilon)^{1-p/2}, \quad \varepsilon > 0.$$

Observe that we always have $\omega_\varepsilon > \omega$ and $\omega_\varepsilon \searrow \omega$ as $\varepsilon \searrow 0$.

Analyzing the proof in section 5.1, we realize that one can improve the step when the Sobolev and Young inequalities are applied to the function β^p; see (5.3). Indeed, let κ and $\lambda(x)$ be a certain positive number and a function, to be chosen later. Then

$$c\left(\int_{B_r} \beta^{\kappa\frac{n}{n-1}}\right)^{\frac{n-1}{n}} \le \int_{B_r} \beta^{\kappa-1}|\nabla\beta| = \int_{B_r} \left(\frac{|\nabla\beta|}{\omega_\varepsilon}\lambda\right)\left(\beta^{\kappa-1}\frac{\omega_\varepsilon}{\lambda}\right),$$

where in the first step we have applied the Sobolev inequality to the function β^κ. Now we use Young's inequality, with a certain parameter q, $1 < q < 2$, and its conjugate $q' = q/(q-1)$. We obtain

$$c\int_{B_r} \left(\frac{|\nabla\beta|}{\omega_\varepsilon}\lambda\right)\left(\beta^{\kappa-1}\frac{\omega_\varepsilon}{\lambda}\right) \le K^q \int_{B_r} \frac{|\nabla\beta|^q}{\omega_\varepsilon^q}\lambda^q + K^{-q'}\int_{B_r} \beta^{(\kappa-1)q'}\frac{\omega_\varepsilon^{q'}}{\lambda^{q'}}.$$

Applying the Hölder inequality with exponents $2/q$ and $2/(2-q)$ in both integrals on the right-hand side of the inequality above, we estimate it by

$$\begin{aligned} &K^q\left(\int_{B_r}\frac{|\nabla\beta|^2}{\omega_\varepsilon^2}\right)^{q/2}\left(\int_{B_r}\lambda^{2q/(2-q)}\right)^{1-q/2} \\ &+K^{-q'}\left(\int_{B_r}\beta^{(\kappa-1)q'(2/q)}\right)^{q/2}\left(\int_{B_r}\left(\frac{\omega_\varepsilon}{\lambda}\right)^{2q'/(2-q)}\right)^{1-q/2}. \end{aligned}$$

Let us now choose λ so that

$$\lambda^{2q/(2-q)} = \left(\frac{\omega_\varepsilon}{\lambda}\right)^{2q'/(2-q)}.$$

A simple computation shows that

$$\lambda = \omega_\varepsilon^{q'/(q+q')} = \omega_\varepsilon^{1/q}.$$

Then the expression above transforms to

$$\left[K^q \left(\int_{B_r} \frac{|\nabla\beta|^2}{\omega_\varepsilon^2}\right)^{q/2} + K^{-q'} \left(\int_{B_r} \beta^{(\kappa-1)q'(2/q)}\right)^{q/2}\right] \left(\int_{B_r} \omega_\varepsilon^{1/(1-q/2)}\right)^{1-q/2},$$

which is bounded from above by

$$C\left[K^2 \int_{B_r} \frac{|\nabla\beta|^2}{\omega_\varepsilon^2} + K^{-2q'/q} \int_{B_r} \beta^{(\kappa-1)q'(2/q)}\right]^{q/2} \left(\int_{B_r} \omega_\varepsilon^{1/(1-q/2)}\right)^{1-q/2}.$$

Collecting the estimates above and then letting $\varepsilon \to 0$, we will arrive at the inequality

$$\left(\int_{B_r} \beta^{\kappa\frac{n}{n-1}}\right)^{\frac{n-1}{n}} \leq$$
$$C\left[K^2 \int_{B_r} \frac{|\nabla\beta|^2}{\omega^2} + K^{-2q'/q} \int_{B_r} \beta^{(\kappa-1)q'(2/q)}\right]^{q/2} \left(\int_{B_r} \omega^{1/(1-q/2)}\right)^{1-q/2}.$$

Now observe that the term inside square brackets can be estimated similarly as in section 5.1, recalling also (6.5). We now have arrived at a point when we have to choose q. For that purpose we turn our attention to the term $\omega^{1/(1-q/2)}$. If we knew that ω is bounded, we could let $q \nearrow 2$. This is so, for instance, when F is uniformly Lipschitz in u, and we recover the proof in section 6.1 above. However, for non-Lipschitz F, we a priori know only the L^p integrability of $|\nabla u|$ and $|\nabla u^*|$. Moreover, we have

$$\int_{B_r} |\nabla u|^p + |\nabla u^*|^p \leq \int_{B_r} 2|\nabla u|^p + |\nabla h|^p \leq C\, r^{n-1},$$

by (4.1), for sufficiently large r. Thus, in order to obtain the desired density estimate, we choose q so that $\omega^{1/(1-q/2)} \simeq (|\nabla u|^p + |\nabla u^*|^p)$. Since $\omega = (|\nabla u| + |\nabla u^*|)^{1-p/2}$, we require

$$(1-p/2)/(1-q/2) = p \quad \Longleftrightarrow \quad q = 3 - \frac{2}{p}.$$

Observe that the condition $1 < q < 2$ is satisfied for $1 < p < 2$. As for the value of κ, we choose it to have

$$(\kappa-1)q'(2/q) = p \quad \Longleftrightarrow \quad \kappa = p.$$

Thus, with this choice of constants we obtain

$$\left(\int_{B_r} \beta^{p\frac{n}{n-1}}\right)^{\frac{n-1}{n}} \leq C\left[K^2 \int_{B_r} \frac{|\nabla\beta|^2}{\omega^2} + K^{-p'} \int_{B_r} \beta^p\right]^{q/2} \left(r^{n-1}\right)^{1-q/2}.$$

Now, using (6.5) and repeating the arguments as in section 5.1, we can deduce the following recursive inequality:

$$c\,\mathcal{V}_r^{\frac{n-1}{n}} \leq [\mathcal{V}_{r+1} - \mathcal{V}_r + \mathcal{A}_{r+1} - \mathcal{A}_r - c\mathcal{A}_r]^{q/2}\,(r^{n-1})^{1-q/2}. \tag{6.6}$$

Now the question is whether we can infer from (6.6) that

$$\mathcal{V}_r \geq c\, r^n$$

for $r \geq 1$ if $\mathcal{V}_1 \geq \mu > 0$. The answer is affirmative when

$$\frac{n-1}{n} \cdot \frac{2}{q} < 1 \quad \Longleftrightarrow \quad p > \frac{2n}{n+2}.$$

This follows from Lemma 2.1 with $\alpha = 1 - q/2$. (Unfortunately, (6.6) alone does not imply the density estimate for $p \leq 2n/(n+2)$, since we do need $\alpha < 1/n$ in Lemma 2.1.)

Summarizing, we obtain that for the range of the exponents $2n/(n+2) < p < 2$, one can drop the assumption (1.12) to prove Lemma 4.1. This completes the proof of Theorem 1.1.

7. Consequences of the density estimates. We briefly show in this section two consequences that can be easily derived from Theorem 1.1, thanks to the techniques developed in the last years.

The first consequence is that level sets of absolute minimizers converge, up to subsequence, to minimal interfaces in $L^\infty_{\rm loc}$. More precisely, it has been proved in [Bou90] that minimizers u_ε of

$$\mathcal{J}_\varepsilon(u;\Omega) = \int_\Omega A(x, \varepsilon\,\nabla u) + F(x,u) \tag{7.1}$$

converge, up to subsequence, in $L^1_{\rm loc}$ to a step function u_0 which has a minimal interface with respect to a suitably weighted area. Indeed, from the above density estimates we have that level sets converge in $L^\infty_{\rm loc}$.

THEOREM 7.1. *Fix $\theta \in (0,1)$. Let $|u_\varepsilon| \leq 1$ be an absolute minimizer of (7.1) in a bounded domain Ω. Assume that, as ε tends to zero, u_ε converges in $L^1_{\rm loc}$ to*

$$u_0 := \chi_E - \chi_{\Omega - E}$$

for a suitable $E \subset \Omega$. Then, $\{|u_\varepsilon| \leq \theta\}$ converges locally uniformly to ∂E.

The latter convergence is understood in the sense that $\operatorname{dist}(x, \partial E) \to 0$ uniformly for $x \in \{|u_\varepsilon| \leq \theta\} \cap K$ for any $K \subset\subset \Omega$.

Proof. The proof repeats the one of Theorem 2 in [CC95]. Assume that the claim of the theorem is not correct. Then there is $\delta > 0$, $K \subset\subset \Omega$, and $\varepsilon_n \to 0$, such that there exist $x_n \in \{|u_{\varepsilon_n}| < \theta\}$ with, say, $B_\delta(x_n) \subset E \cap K$. Since the rescalings $\tilde{u}_\varepsilon(x) := u_\varepsilon(\varepsilon x)$ are absolute minimizers of the normalized functional $\mathcal{J}$, applying the density estimates in Theorem 1.1 to $\tilde{u}_\varepsilon$ and then scaling back to u_ε, we will obtain that

$$\mathcal{L}^n(B_{\delta/2}(x_n) \cap \{u_{\varepsilon_n} < \theta\}) \geq c\,\delta^n$$

for some $c > 0$. But then,

$$\int_{B_{\delta/2}(x_n)} |u_{\varepsilon_n} - u_0| \geq c(1-\theta)\,\delta^n,$$

in contradiction with the hypothesis. This proves Theorem 7.1. ∎

Remark 7.2. We point out the following particular case of the above theorem. Let $F(x,u) = |1-u^2|^\alpha$ with $\alpha > 2$. Then it is unknown whether there is a uniform convergence of the level sets of minimizers in the singular perturbation problem

$$\int \varepsilon^2 |\nabla u|^2 + |1-u^2|^\alpha, \qquad \varepsilon \to 0+ .$$

However, if one perturbs with $\varepsilon^p |\nabla u|^p$ with $p \geq \alpha$, the uniform convergence follows from Theorem 7.1.

The second consequence of the density estimates is the existence of plane-like minimizers in the periodic setting. We say that u is a class A minimizer for $\mathcal{J}$ if it is an absolute minimizer for $\mathcal{J}$ in any ball B. With this setting, we can prove the following theorem.

THEOREM 7.3. *Assume that $A(x+e,\eta) = A(x,\eta)$ and $F(x+e,\eta) = F(x,\eta)$ for any $e \in \mathbb{Z}^n$. Fix $\theta \in (0,1)$. Then, there exists a positive constant M_0, depending only on θ and on the structural constants, such that, given any $\omega \in \mathbb{R}^n - \{0\}$, there exists a class A minimizer $u = u_\omega$ for the functional $\mathcal{J}$ for which the set $\{|u| \leq \theta\}$ is constrained in the strip $\{x \cdot \omega \in [0, M_0|\omega|]\}$.*

Furthermore, such u enjoys the following property of "quasi periodicity": if $\omega \in \mathbb{Q}^n - \{0\}$, then u is periodic (with respect to the identification induced by ω, i.e., $u(x+k) = u(x)$ for any $k \in \mathbb{Z}^n \cap \omega^\perp$); if $\omega \in \mathbb{R}^n - \mathbb{Q}^n$, then u can be approximated uniformly on compact sets by periodic class A minimizers.

Notice that M_0 above is *independent* of the frequency ω. These kinds of plane-like structures have been considered in [CdlL01] in the minimal surfaces case, and generalized to fluid jets and Ginzburg–Landau models in [Val04] and [PV03]. See also [Tor04] for a case with a degenerate metric. The proof of Theorem 7.3 is analogous to the one presented in section 8 of [PV03], with minor obvious changes, and we therefore omit the details.

MINIMIZATION METHODS FOR QUASI-LINEAR PROBLEMS WITH AN APPLICATION TO PERIODIC WATER WAVES*

B. BUFFONI†, É. SÉRÉ‡, AND J. F. TOLAND§

Abstract. Penalization and minimization methods are used to give an abstract "semiglobal" result on the existence of nontrivial solutions of parameter-dependent quasi-linear differential equations in variational form. A consequence is a proof of existence, by infinite-dimensional variational means, of bifurcation points for quasi-linear equations which have a line of trivial solutions.

The approach is to penalize the functional twice. Minimization gives the existence of critical points of the resulting problem, and a priori estimates show that the critical points lie in a region unaffected by the leading penalization. The other penalization contributes to the value of the parameter.

As applications we prove the existence of periodic water waves, with and without surface tension.

Key words. variational method, critical-point theory, minimization, quasi-linear elliptic problems, periodic water waves, free boundaries

1. Introduction.

Using local finite-dimensional reduction followed by a constrained minimization argument, Stuart [20], following Krasnosel'skii [15], gave a bifurcation theory for variational problems which was applied in [6] to Babenko's [2] quasi-linear equation for Stokes waves. But how to deal with such problems directly, using variational methods in infinite dimensions, remained unclear. In [8] we took a step in this direction by adapting some ideas of Turner [22] and the mountain-pass lemma in infinite dimensions to obtain an existence theory which was "semiglobal," in the sense that parameter values were quantifiably not infinitesimally small, and finite-dimensional reduction was not involved.

Now, in section 2, we present an abstract result that covers a general class of quasi-linear problems. In section 3 we show that the existence problem for two-dimensional capillary-gravity waves on a flow of infinite depth, with its curvature term that represents surface tension effects, is a special case. Our method should give explicit (and hopefully good) lower bounds on the size of the periodic capillary-gravity waves so obtained, but here the aim is merely to illustrate the generality of the abstract result. Moreover, our abstract method, based on a direct minimization, could probably be enriched to encompass the various kinds of two-dimensional periodic capillary-gravity waves found in [10, 14, 17] by extending it to more involved minimax principles. In section 4, we apply the present method to the Stokes-wave problem (steady periodic water waves without surface tension). As in [8], we obtain the existence of a nonzero symmetric Stokes wave which is not a consequence of local existence theories [1, 6, 20].

In contrast to [8], we no longer appeal to the mountain-pass principle or to Morse theory, and therefore the present proof is simpler.

The vast literature on steady two-dimensional water waves, with or without surface tension, which has been developed since the work of Stokes [19] in the middle of the nineteenth century, is surveyed from various viewpoints in [12, 13, 18, 23]. A great deal is now known about existence theory using global continuation methods [5, 6, 7], numerical investigations [9, 16], and computer assisted proofs [3, 4]. But the need for a global or "semiglobal" variational theory of these and similarly degenerate variational problems, including Morse indices of solutions, remains our focus. An extension of such "semiglobal" methods to cover the three-dimensional waves considered in [10] would be most interesting but is beyond the scope of the present work.

2. Abstract setting. Consider a real Hilbert space X_0 with inner-product $\langle\cdot,\cdot\rangle_0$ and norm $\|\cdot\|_0$, and suppose that A is a (possibly unbounded) positive-definite self-adjoint operator on X_0 such that $A^{-1} : X_0 \to X_0$ exists and is continuous. For $k \geq 1$ let X_k denote the domain of $A^{k/2}$, which is dense in X_0. Then X_k is a Hilbert space with inner-product and norm defined by $\langle u, v\rangle_k = \langle A^{k/2}u, A^{k/2}v\rangle_0$ and $\|u\|_k = \|A^{k/2}u\|_0$ for u, $v \in X_k$, and

$$\|u\|_k \leq \|A^{-1/2}\|\,\|u\|_{k+1} \quad \text{for all} \quad u \in X_{k+1}.$$

For $R_2 > 0$, let $U \subset X_2$ be the open ball $\{u \in X_2 : \|u\|_2 < R_2\}$, and suppose that $\mathcal{K}$, $\mathcal{L} \in C^1(U;\mathbb{R})$ are functionals with Fréchet derivatives at u denoted by $\partial\mathcal{K}(u)$ and $\partial\mathcal{L}(u)$. We are interested in the equation

$$(\star) \qquad \gamma\partial\mathcal{K}(w) + \partial\mathcal{L}(w) = 0, \quad w \in U \setminus \{0\}, \quad \gamma \geq \gamma_0 \geq 0,$$

when the following inequalities hold for constants $C_1\,, C_2 > 0$ and for a continuous function $\psi : [0,\infty)^2 \to \mathbb{R}$, the precise form of which depends on the problem:

$$\text{for} \quad u \in U : \quad \mathcal{K}(u) \geq C_1\|u\|_1^2 \quad \text{and } \mathcal{K}(0) = 0, \tag{2.1a}$$

$$\text{for} \quad u \in U : \quad \mathcal{L}(u) \geq -C_2\|u\|_1^2 \text{ and } \mathcal{L}(0) = 0, \tag{2.1b}$$

$$\text{for} \quad u \in U \cap X_4 : \partial\mathcal{K}(u)Au \geq 0 \quad \text{and} \tag{2.1c}$$

$$\gamma_0\partial\mathcal{K}(u)Au + \partial\mathcal{L}(u)Au \geq \psi(\|u\|_1\,, \|u\|_2). \tag{2.1d}$$

Observe that $\partial\mathcal{K}(0) = \partial\mathcal{L}(0) = 0$ so that $w = 0$ is a trivial solution of $(\star)$.

Roughly speaking, the function ψ takes positive and negative values and will be such that $\psi(s,t) > 0$ when s is "not too large" and t is "not small" (see assumption (2.2) below). In the existence proof, we construct a functional $\mathcal{J}$ on U, whose minimizer w satisfies $\gamma_0\partial\mathcal{K}(w)Aw + \partial\mathcal{L}(w)Aw \leq 0$ with $s = \|w\|_1$ "not too large." This yields an upper bound, better than R_2, on $t = \|w\|_2$ which ensures that w is solution of our problem. To verify the assumptions in practice, it will often be necessary to choose U small enough, whence the term "semiglobal" in the abstract.

The next hypothesis is about weak solutions of a regularized problem: for all $\gamma \geq \gamma_0$, $\epsilon > 0$, and $w \in U$,

$$\text{if} \quad \gamma\partial\mathcal{K}(w) + \partial\mathcal{L}(w) + \epsilon A^2 w = 0 \quad \text{in } X_2^*\,, \text{ then } w \in X_4. \tag{2.1e}$$

Finally, we make the following assumptions:

$$\mathcal{K} \text{ and } \mathcal{L} \quad \text{are weakly lower semicontinuous on } U \subset X_2. \tag{2.1f}$$

$$\text{There exists } u_* \in U \text{ with } \gamma_0\mathcal{K}(u_*) + \mathcal{L}(u_*) < 0 = \gamma_0\mathcal{K}(0) + \mathcal{L}(0). \tag{2.1g}$$

THEOREM 1. *Suppose that hypotheses* (2.1) *hold and that*

$$\psi(s, R_2) > 0 \quad \text{for all} \quad s \in \left[0,\, \sqrt{\mathcal{K}(u_*)/C_1}\right]. \tag{2.2}$$

Then there exist $w \in U\backslash\{0\}$ *and* $\gamma \geq \gamma_0$ *such that*

$$\begin{gathered} \gamma \partial \mathcal{K}(w) + \partial \mathcal{L}(w) = 0, \\ \gamma_0 \mathcal{K}(w) + \mathcal{L}(w) \leq \gamma_0 \mathcal{K}(u_*) + \mathcal{L}(u_*) < 0, \end{gathered} \tag{$\star$}$$

and, as a consequence of (2.1a) *and* (2.1b),

$$\|w\|_1^2 \geq \frac{\gamma_0 \mathcal{K}(u_*) + \mathcal{L}(u_*)}{\gamma_0 C_1 - C_2} > 0.$$

Remarks.

1. Note that in (2.1a) and (2.1b), $\gamma_0 C_1 - C_2 < 0$; otherwise u_* would not exist.
2. A typical form of the function ψ is $\alpha t^2 - \varphi(s,t)$, where $\alpha > 0$, φ is continuous from $[0,\infty)^2$ to $\mathbb{R}$, and $\varphi(0, R_2) = 0$. Then condition (2.2) becomes

$$\varphi(s, R_2) \,<\, \alpha R_2^2 \quad \text{for all} \quad s \in \left[0,\, \sqrt{\mathcal{K}(u_*)/C_1}\right]. \tag{2.3a}$$

This condition is satisfied for $\mathcal{K}(u_*)$ small enough, by continuity of φ at $(0, R_2)$. Note that α may depend on R_2.

3. In the examples of sections 3 and 4 the function ψ is constructed in two steps. First we establish an inequality

$$\partial \mathcal{K}(u) Au \geq C_3 \|u\|_2^2 \quad \text{for all} \quad u \in U \cap X_4, \tag{2.3b}$$

for some constant $C_3(R_2) > 0$. Then we find a function $\varphi(s,t)$ and a constant $C_4 \in \mathbb{R}$ such that

$$\partial \mathcal{L}(u) Au \geq -\varphi(\|u\|_1, \|u\|_2) - C_4 \|u\|_2^2 \quad \text{for all} \quad u \in U \cap X_4. \tag{2.3c}$$

If $\gamma_0 > C_4/C_3$, the estimate (2.1d) will follow for $\psi(s,t) := \alpha t^2 - \varphi(s,t)$, with $\alpha := \gamma_0 C_3 - C_4 > 0$.

Proof of Theorem 1. Let $R_1, R_{\min} > 0$ be finite numbers such that

$$\mathcal{K}(u_*) < R_1^2, \quad \|u_*\|_2 \leq R_{\min} < R_2$$

and

$$\psi(s,t) > 0 \quad \text{for all} \quad s \in \left[0,\, R_1/\sqrt{C_1}\right] \quad \text{and} \quad t \in \left[R_{\min}, R_2\right]. \tag{2.4}$$

These numbers exist because of assumption (2.2) and the uniform continuity of ψ on $\left[0\,,\, 2\sqrt{\mathcal{K}(u_*)/C_1}\right] \times \left[0\,,\, R_2\right]$. We define two smooth, nondecreasing *penalization* functions $\rho_i : [0, R_i^2) \to \mathbb{R}$ such that

$$\begin{gathered} \rho_i(s) \to \infty \text{ as } s \nearrow R_i^2, \quad i = 1,\, 2, \\ 0 \leq s \leq \mathcal{K}(u_*) \Rightarrow \rho_1(s) = 0, \quad 0 \leq s \leq R_{\min}^2 \Rightarrow \rho_2(s) = 0, \end{gathered}$$

and consider the real-valued functional defined for $u \in U$ with $\mathcal{K}(u) < R_1^2$ by

$$\mathcal{J}(u) = \gamma_0 \mathcal{K}(u) + \mathcal{L}(u) + \rho_2(\|u\|_2^2) + \rho_1(\mathcal{K}(u)).$$

The indices denote the facts that ρ_2 and ρ_1 control, respectively, the norms in X_2 and X_1 (through the constant C_1). We refer to ρ_2 as the *leading penalization*. Together they allow us to work in the domain $V := \{u \in U : \mathcal{K}(u) < R_1^2\}$. The inequalities (2.1a), (2.1d), (2.2) will ensure that critical points w of $\mathcal{J}$ in this domain satisfy $\|w\|_2 \le R_{\min}$ and are thus unaffected by the leading penalization. At critical points the other penalization may be nonzero, which leads to the loss of control of the value of the parameter γ in the statement of the theorem.

We must now find a critical point of $\mathcal{J}$, and a natural idea is to look for a minimizer. Note that $\mathcal{J}$ is bounded from below on V, with $\mathcal{J}(u) \to \infty$ as $\|u\|_2 \nearrow R_2$ and $\mathcal{J}(u) \to \infty$ as $\mathcal{K}(u) \nearrow R_1^2$, by the existence of the constants C_1 and C_2. From (2.1f) it follows that $\mathcal{J}$ has a minimizer $w \in V$. We have $\mathcal{K}(w) < R_1^2$, $\|w\|_2 < R_2$, and w is a weak solution of the Euler equation

$$\{\gamma_0 + \rho_1'(\mathcal{K}(w))\}\partial\mathcal{K}(w) + \partial\mathcal{L}(w) + 2\rho_2'(\|w\|_2^2)A^2w = 0. \tag{2.5}$$

Seeking a contradiction, assume that $\epsilon := 2\rho_2'(\|w\|_2^2) > 0$. Then, by (2.1e), $w \in X_4$. Hence $Aw \in X_2$, and we have $\partial\mathcal{J}(w)Aw = 0$. From (2.1c) and (2.1d) it follows that

$$\psi(\|w\|_1, \|w\|_2) \le -\rho_1'(\mathcal{K}(w))\partial\mathcal{K}(w)Aw - 2\rho_2'(\|w\|_2^2)\|w\|_3^2 < 0.$$

Since $\mathcal{K}(w) < R_1^2$, (2.1a) gives the estimate $\|w\|_1 \le R_1/\sqrt{C_1}$. Therefore, by (2.4), $\|w\|_2 < R_{\min}$. This shows that $\rho_2'(\|w\|_2^2) = 0$, which is the required contradiction.

Hence, we have proved that $w \in U$ satisfies (2.5), with $\rho_2'(\|w\|_2^2) = 0$. Therefore

$$\gamma\partial\mathcal{K}(w) + \partial\mathcal{L}(w) = 0 \text{ with } \gamma := \gamma_0 + \rho_1'(\mathcal{K}(w)).$$

Since w is a minimizer of $\mathcal{J}$ and $\rho_1(\mathcal{K}(u_*)) = \rho_2(\|u_*\|_2^2) = 0$, we have

$$\gamma_0\mathcal{K}(w) + \mathcal{L}(w) \le \mathcal{J}(w) \le \mathcal{J}(u_*) = \gamma_0\mathcal{K}(u_*) + \mathcal{L}(u_*) < 0.$$

The critical point w is thus nonzero, and we have the estimate

$$(\gamma_0 C_1 - C_2)\|w\|_1^2 \le \gamma_0\mathcal{K}(u_*) + \mathcal{L}(u_*) < 0. \qquad \square$$

Additional hypotheses yield more information on the critical point w.

THEOREM 2. *Suppose that* (2.1) *holds and*

$$\partial\mathcal{K}(u) + \mu A^2 u \ne 0 \quad \textit{for all} \quad u \in U \setminus \{0\} \quad \textit{and} \quad \mu \ge 0. \tag{2.6}$$

Let the two constants $\underline{R}, \overline{R}$ *satisfy* $\|u_*\|_2 \le \overline{R} < R_2$, $\underline{R} \ge \sqrt{\mathcal{K}(u_*)}$, *and (instead of* (2.2)*) suppose that*

$$\psi(s, \overline{R}) \ge 0 \quad \textit{for all} \quad s \in \big[0, \underline{R}/\sqrt{C_1}\big]. \tag{2.7}$$

Then there exists $w \in U\setminus\{0\}$ *such that* $\|w\|_2 \le \overline{R}$, $\mathcal{K}(w) \le \underline{R}^2$,

$$\gamma_0\mathcal{K}(w) + \mathcal{L}(w) = \min\{\gamma_0\mathcal{K}(u) + \mathcal{L}(u) : \ u \in U, \ \|u\|_2 \le \overline{R}, \ \mathcal{K}(u) \le \underline{R}^2\},$$

and the following hold:

(i) *if* $\mathcal{K}(w) < \underline{R}^2$, *then* $\gamma_0\partial\mathcal{K}(w) + \partial\mathcal{L}(w) = 0$;

(ii) *if* $\mathcal{K}(w) = \underline{R}^2$, *then* $\gamma\partial\mathcal{K}(w) + \partial\mathcal{L}(w) = 0$ *for some* $\gamma \ge \gamma_0$.

Moreover, as a consequence of properties (2.1a), (2.1b),

$$\|w\|_1^2 \geq \frac{\gamma_0 \mathcal{K}(u_*) + \mathcal{L}(u_*)}{\gamma_0 C_1 - C_2} > 0.$$

Proof. By assumptions (2.1a) and (2.1b), the functional $\mathcal{I}(u) := \gamma_0 \mathcal{K}(u) + \mathcal{L}(u)$ is bounded from below on the set $C := \{u \in X_2 : \mathcal{K}(u) \leq \underline{R}^2, \|u\|_2 \leq \overline{R}\}$. By assumption (2.1f), the set C is weakly closed in X_2, and $\mathcal{I}$ is weakly lower semicontinuous. So there exists a minimizer w of $\mathcal{I}$ on C. Since $u_* \in C$,

$$\mathcal{I}(w) \leq \mathcal{I}(u_*) < 0.$$

Hence $(\gamma_0 C_1 - C_2)\|w\|_1^2 \leq \mathcal{I}(u_*) < 0$. By assumption (2.6) and the general theorem on Lagrange multipliers, w is a weak solution of

$$\epsilon A^2 w + \gamma \partial \mathcal{K}(w) + \partial \mathcal{L}(w) = 0$$

for some $\gamma \geq \gamma_0$ and $\epsilon \geq 0$ and

$$(\gamma - \gamma_0)(\underline{R}^2 - \mathcal{K}(w)) = 0 = \epsilon\,(\overline{R} - \|w\|_2).$$

It follows by contradiction, as in the proof of Theorem 1, that $\epsilon = 0$ (this follows from (2.1a), (2.1d), (2.7)). The alternative (i)–(ii) is thus satisfied. ∎

3. Gravity-capillary water waves. Let $L^2_{2\pi}$ denote the usual real Banach space of 2π-periodic, real-valued, square-integrable measurable "functions" on $\mathbb{R}$, and let $L^\infty_{2\pi}$ denote the analogous space of essentially bounded functions. We denote by $C^n_{2\pi}$ (resp., $C^\infty_{2\pi}$) the space of 2π-periodic functions u which are n times continuously differentiable (resp., infinitely differentiable).

With respect to the orthonormal basis $\{(2\pi)^{-\frac{1}{2}} e^{ikt} : k \in \mathbb{Z}\}$, let the Fourier coefficients of $u \in L^2_{2\pi}$ be denoted by $\hat{u}_k$, $k \in \mathbb{Z}$. Then $\hat{u}_{-k} = \overline{\hat{u}_k}$, since u is real, and $L^2_{2\pi}$ is a real Hilbert space with inner-product

$$\langle u, v \rangle = \sum_{k \in \mathbb{Z}} \hat{u}_k \overline{\hat{v}_k}.$$

For $u \in L^2_{2\pi}$ let

$$[u] = \frac{1}{2\pi} \int_{-\pi}^{\pi} u(t)\, dt = \frac{\hat{u}_0}{\sqrt{2\pi}}.$$

The fractional order Sobolev space $H^s_{2\pi}$, $s \geq 0$, is the Hilbert space of functions $u \in L^2_{2\pi}$ with norm given by

$$\|u\|_s^2 = \hat{u}_0^2 + \sum_{k \in \mathbb{Z}} |k|^{2s} |\hat{u}_k|^2 < \infty.$$

Note that if $u \in C^n_{2\pi}$, $k \in \mathbb{N} \cup 0$, then

$$\|u\|_n^2 = 2\pi [u]^2 + \|u^{(n)}\|^2_{L^2_{2\pi}},$$

where $u^{(n)}$ denotes the nth derivative of u. The conjugation operation [24] on $L^2_{2\pi}$ is defined by

$$(\widehat{\mathcal{C}u})_0 = 0 \text{ and } (\widehat{\mathcal{C}u})_k = -i \operatorname{sgn}(k) \hat{u}_k \text{ for } k \in \mathbb{Z} \setminus \{0\}, \text{ when } u \in L^2_{2\pi};$$

equivalently, $\mathcal{C}(\cos kt) = \sin kt, k \geq 0$, and $\mathcal{C}(\sin kt) = -\cos kt, k \geq 1$. Clearly $\mathcal{C} : L^2_{2\pi} \to L^2_{2\pi}$ is a bounded linear operator and $u \mapsto \mathcal{C}u'$ is nonnegative and symmetric in the sense that

$$0 \leq \langle u, \mathcal{C}u' \rangle \text{ and } \langle u, \mathcal{C}v' \rangle = \langle \mathcal{C}u', v \rangle \text{ for all } u,\, v \in C^\infty_{2\pi}.$$

For any function $w \in H^1_{2\pi}$ with $[w] = 0$, writing $w + i\mathcal{C}w = \sqrt{\frac{2}{\pi}} \sum_{k>0} \hat{w}_k e^{ikt}$, one gets

$$\begin{aligned} \|w + i\mathcal{C}w\|_\infty &\leq \frac{1}{\sqrt{2\pi}} \sum_{k \neq 0} |\hat{w}_k| \leq \frac{1}{\sqrt{2\pi}} \left(\sum_{k \neq 0} k^2 |\hat{w}_k|^2 \right)^{1/2} \left(\sum_{k \neq 0} \frac{1}{k^2} \right)^{1/2} \\ &= \sqrt{\frac{\pi}{6}} \left(\sum_{k \neq 0} k^2 |\hat{w}_k|^2 \right)^{1/2} = \sqrt{\frac{\pi}{6}} \|w\|_1 = \sqrt{\frac{\pi}{6}} \|w'\|_{L^2_{2\pi}}. \end{aligned} \tag{3.1}$$

When surface-tension effects are included, the steady water-wave problem can be formulated as follows [6]: find w such that

$$\frac{\nu^2}{2} \{w'^2 + (1 + \mathcal{C}w')^2\}^{-1} + \lambda w - \beta \frac{(1 + \mathcal{C}w')w'' - w'(1 + \mathcal{C}w')'}{\{w'^2 + (1 + \mathcal{C}w')^2\}^{3/2}} = \frac{1}{2}\nu^2, \tag{3.2a}$$

$$w'^2 + (1 + \mathcal{C}w')^2 > 0, \quad w \in H^2_{2\pi} \setminus \{0\}, \quad \lambda \geq 0, \quad \beta, \nu > 0. \tag{3.2b}$$

Here β is the coefficient of surface tension and the parameters λ and ν^2 are defined in terms of the wavelength 2Λ, the wave speed c, the gravitational acceleration g, and the density d by

$$\lambda = \frac{g\Lambda^2 d}{\pi^2}, \quad \nu^2 = \frac{\Lambda c^2 d}{\pi}.$$

Note that (3.2) is not a variational problem as it stands. However, it is known [6] that (3.2) is satisfied by any $w \in H^2_{2\pi}$ such that $w'^2 + (1 + \mathcal{C}w')^2 > 0$ and such that, almost everywhere,

$$\begin{aligned} 0 = {} & -\nu^2 \mathcal{C}w' + \lambda \{w + w\mathcal{C}w' + \mathcal{C}(ww')\} \\ & - \beta \left\{ \frac{w'}{\sqrt{w'^2 + (1 + \mathcal{C}w')^2}} \right\}' + \beta \mathcal{C} \left\{ \frac{1 + \mathcal{C}w'}{\sqrt{w'^2 + (1 + \mathcal{C}w')^2}} \right\}'. \end{aligned} \tag{3.3}$$

Equation (3.3) is the Euler equation of the functional

$$\begin{aligned} J(w) = \int_{-\pi}^{\pi} \Big\{ & -\frac{1}{2}\nu^2 w \mathcal{C}w' + \frac{1}{2}\lambda w^2 (1 + \mathcal{C}w') \\ & + \beta \sqrt{w'^2 + (1 + \mathcal{C}w')^2} - \beta(1 + \mathcal{C}w') \Big\} dt. \end{aligned}$$

For all w, the integral of the last term is $-2\beta\pi$, and it does not contribute to the variational principle (it is a null Lagrangian). It is included here only to ensure that the constant and linear parts of the integrand vanish when $w = 0$.

Observe that, when $\lambda = 0$, every constant function w is a solution of (3.3) and any translate of a solution is also a solution. These superfluous solutions complicate

the problem unnecessarily, and, to eliminate them, we work in the subspace X_2 of $H^2_{2\pi}$ consisting of even functions of zero mean with norm given by

$$\|w\|^2_{X_2} = \int_{-\pi}^{\pi} |w''(t)|^2\, dt = \|w\|_2^2.$$

The critical points of J under the constraint $[w] = 0$ satisfy (3.3) almost everywhere, but with 0 on the left-hand side replaced by the constant $\lambda[w\mathcal{C}w']$. So instead we consider the functional $\widetilde{J}$ defined on X_2 by

$$\widetilde{J}(w) := J(w) - \frac{\lambda}{4\pi}\left\{\int_{-\pi}^{\pi} w\mathcal{C}w'\,dt\right\}^2.$$

Critical points $w \in X_2$ of $\widetilde{J}$ satisfy

$$\frac{\lambda}{2\pi}\int_{-\pi}^{\pi} w\mathcal{C}w'\,dt = -\left(\nu^2 + \frac{\lambda}{\pi}\int_{-\pi}^{\pi} w\mathcal{C}w'\,dt\right)\mathcal{C}w' + \lambda(w + w\mathcal{C}w' + \mathcal{C}(ww')) + \beta\left\{\frac{-w'}{\sqrt{w'^2 + (1+\mathcal{C}w')^2}} + \mathcal{C}\frac{1+\mathcal{C}w'}{\sqrt{w'^2 + (1+\mathcal{C}w')^2}}\right\}', \tag{3.4}$$

and $\widetilde{w} := w - [w\mathcal{C}w']$ satisfies (3.3), from which (3.2a) follows.

Since we can divide (3.2) by any one of the parameters ν^2, λ, and β, there are effectively only two dimensionless parameters in the problem. Now divide J, $\widetilde{J}$, and (3.3) by ν^2 so that, in the remainder of section 3,

$$\lambda = \frac{g\Lambda}{\pi c^2}, \quad \nu^2 = 1, \tag{3.5a}$$

and β has been replaced by the dimensionless parameter

$$\gamma = \frac{\beta\pi}{\Lambda c^2 d}. \tag{3.5b}$$

We now apply the abstract result of section 1 to $\widetilde{J}$. To put the functional $\widetilde{J}$ in the context of section 2, let

$$\begin{aligned} &X_0 = \{w \in L^2_{2\pi} : [w] = 0,\ w \text{ is even}\},\\ &Aw = -w'',\\ &X_k = \{w \in H^k_{2\pi} : [w] = 0,\ w \text{ is even}\} \quad (k \geq 1). \end{aligned}$$

If $R_2 < \sqrt{6/\pi}$, then (3.1) implies that

$$\|w' + i\mathcal{C}w'\|_\infty \leq \sqrt{\pi/6}R_2 < 1 \text{ when } \|w\|_{X_2} < R_2\ . \tag{3.6}$$

For $w \in U$, the ball of radius R_2 centered at the origin in X_2, let

$$\begin{aligned} \mathcal{K}(w) &= \int_{-\pi}^{\pi} \sqrt{w'^2 + (1+\mathcal{C}w')^2} - (1+\mathcal{C}w')\ dt\\ &= \int_{-\pi}^{\pi} \frac{w'^2 dt}{|1+\mathcal{C}w' - iw'| + (1+\mathcal{C}w')}\ ,\\ \mathcal{L}(w) &= -\frac{1}{2}\int_{-\pi}^{\pi} w\mathcal{C}w'dt - \frac{\lambda}{4\pi}\left\{\int_{-\pi}^{\pi} w\mathcal{C}w'dt\right\}^2 + \frac{\lambda}{2}\int_{-\pi}^{\pi} w^2(1+\mathcal{C}w')dt. \end{aligned}$$

With β in (3.4) replaced by γ and ν^2 by 1, we check the hypotheses of Theorem 1 for $0 < R_2 < \sqrt{6/\pi}$ small enough. Obviously, $\mathcal{L}$ is of class C^1 on X_2. Since (3.6) holds, we have

$$0 < 2(1 - \sqrt{\pi/6}R_2) \le |1 + \mathcal{C}w' - iw'| + (1 + \mathcal{C}w') \le 2(1 + \sqrt{\pi/6}R_2). \tag{3.7}$$

So $\mathcal{K}$ is of class C^1 on U. Moreover, if we define

$$C_1(R_2) := \frac{1}{2(1 + \sqrt{\pi/6}R_2)}, \tag{3.8}$$

then

$$C_1\|w'\|^2_{L^2_{2\pi}} \le \int_{-\pi}^{\pi} \frac{w'^2 dt}{|1 + \mathcal{C}w' - iw'| + (1 + \mathcal{C}w')} = \mathcal{K}(w).$$

So (2.1a) is satisfied.

Now to check (2.1b) for all $w \in U$ and $\lambda > 0$, note that

$$\begin{aligned}
\mathcal{L}(w) &= \int_{-\pi}^{\pi} \left\{ -\frac{1}{2} w\mathcal{C}w' + \frac{\lambda}{2} w^2(1 + \mathcal{C}w') \right\} dt - \frac{\lambda}{4\pi} \left\{ \int_{-\pi}^{\pi} w\mathcal{C}w' dt \right\}^2 \\
&\ge -\frac{1}{2}\|w\|_1^2 + \frac{\lambda}{2}(1 - \sqrt{\pi/6}\|w\|_2)\|w\|_0^2 - \frac{\lambda}{4\pi}\|w\|_2^2\|w\|_0^2 \\
&\ge \frac{\lambda}{2}\left(1 - \sqrt{\pi/6}R_2 - \frac{1}{2\pi}R_2^2\right)\|w\|_0^2 - \frac{1}{2}\|w\|_1^2 \\
&\ge -\frac{1}{2}\|w\|_1^2
\end{aligned}$$

under the condition $\sqrt{\pi/6}R_2 + \frac{1}{2\pi}R_2^2 \le 1$, which is satisfied, for instance, when $R_2 < 1$. So, under this restriction on R_2, (2.1b) holds for $C_2 := 1/2$.

Next we show the existence of $C_3(R_2) > 0$ satisfying (2.3b) for R_2 small enough.

LEMMA 3. *If $w \in X_4$ is such that $\|w\|_{X_2} < R_2$ with $0 < R_2 < \sqrt{3/4\pi}$, then*

$$\partial\mathcal{K}(w)\, Aw \ge C_3(R_2)\|w\|^2_{X_2},$$

where

$$C_3(R_2) := \frac{1 - 2\sqrt{\pi/3}R_2}{(1 + \sqrt{\pi/6}R_2)^3}. \tag{3.9}$$

Proof. The product $\partial\mathcal{K}(w)Aw$ is the directional derivative of the functional $\mathcal{K}$ at w in the direction $-w''$. It is also the derivative of the length of the parametrized curve $\{c(t) = (t + \mathcal{C}w(t), w(t)), 0 \le t \le 2\pi\}$ in the direction $\{\delta(t) = (-\mathcal{C}w''(t), -w''(t)),$

$0 \le t \le 2\pi\}$. Using this interpretation, one easily gets the formula

$$\begin{aligned}
\partial\mathcal{K}(w)Aw &= \int_{-\pi}^{\pi} \frac{\{(1+\mathcal{C}w')w'' - w'\mathcal{C}w''\}^2}{\{(1+\mathcal{C}w')^2 + w'^2\}^{3/2}}dt \\
&= \int_{-\pi}^{\pi} \frac{|w'' + \mathcal{R}e\{(\mathcal{C}w' + iw')(w'' + i\mathcal{C}w'')\}|^2}{|1+\mathcal{C}w' + iw'|^3}dt \\
&\ge \int_{-\pi}^{\pi} \frac{|w''|^2 - 2|\mathcal{C}w' + iw'|\,|w'' + i\mathcal{C}w''|\,|w''|}{(1+\sqrt{\pi/6}R_2)^3}dt \\
&\ge \int_{-\pi}^{\pi} \frac{|w''|^2 - 2\sqrt{\pi/6}R_2\,|w'' + i\mathcal{C}w''|\,|w''|}{(1+\sqrt{\pi/6}R_2)^3}dt \\
&\ge \frac{1 - 2\sqrt{\pi/3}R_2}{(1+\sqrt{\pi/6}R_2)^3}\int_{-\pi}^{\pi} |w''|^2\,dt
\end{aligned}$$

since (3.6) holds. □

We now construct a function φ such that (2.3c) is true when $C_4 = 0$. For $\lambda \ge 0$ and $w \in U \cap X_4$, we have

$$\begin{aligned}
\partial\mathcal{L}(w)(-w'') &= -\int_{-\pi}^{\pi} w'\mathcal{C}w''dt - \frac{\lambda}{\pi}\left(\int_{-\pi}^{\pi} w\mathcal{C}w'dt\right)\left(\int_{-\pi}^{\pi} w'\mathcal{C}w''dt\right) \\
&\quad - \lambda\int_{-\pi}^{\pi} \big(w + w\mathcal{C}w' + \mathcal{C}(ww')\big)w''dt \\
&= -\int_{-\pi}^{\pi} w'\mathcal{C}w''dt + \lambda\int_{-\pi}^{\pi} w'^2dt - \lambda\int_{-\pi}^{\pi} w\big(w''\mathcal{C}w' - w'\mathcal{C}w''\big)dt \\
&\quad - \frac{\lambda}{\pi}\left(\int_{-\pi}^{\pi} w\mathcal{C}w'dt\right)\left(\int_{-\pi}^{\pi} w'\mathcal{C}w''dt\right) \\
&\ge -\|w\|_2\|w\|_1 + \lambda\|w\|_1^2 - 2\lambda\|w\|_\infty\|w\|_2\|w\|_1 - \frac{\lambda}{\pi}\|w\|_1^2\|w\|_2^2 \\
&\ge -\varphi(\|w\|_1, \|w\|_2),
\end{aligned}$$

where

$$\varphi(s,t) := ts - \lambda\big(1 - \sqrt{2\pi/3}\,t - t^2/\pi\big)s^2.$$

Let $\gamma_0 > 0$ be given. Then, in (2.1d), we can choose

$$\psi(s,t) := \gamma_0 C_3(R_2)t^2 - \varphi(s,t).$$

If $w \in U$ is a weak solution of $\partial\widetilde{J}(w) + \epsilon A^2 w = 0$, with $\nu^2 = 1$ and $\beta = \gamma$,

$$\begin{aligned}
\frac{\lambda}{2\pi}\int_{-\pi}^{\pi} w\mathcal{C}w'dt = &-\left(1 + \frac{\lambda}{\pi}\int_{-\pi}^{\pi} w\mathcal{C}w'dt\right)\mathcal{C}w' + \lambda(w + w\mathcal{C}w' + \mathcal{C}(ww')) \\
&+ \gamma\left\{\frac{-w'}{\sqrt{w'^2 + (1+\mathcal{C}w')^2}} + \mathcal{C}\frac{1+\mathcal{C}w'}{\sqrt{w'^2 + (1+\mathcal{C}w')^2}}\right\}' + \epsilon w^{iv}
\end{aligned}$$

with $\epsilon > 0$, a standard regularity argument shows that $w \in H^4_{2\pi}$ and thus hypothesis (2.1e) is verified. Hypothesis (2.1f) is a consequence of the compact Sobolev embedding $X_2 \subset C^1_{2\pi}$.

THEOREM 4. *Let $\lambda \geq 0, \gamma_0 > 0$, $0 < R_2 < \sqrt{3/4\pi}$, and suppose that there exists $u_* \in U$ such that*

$$\widetilde{J}(u_*) < 0, \tag{3.10}$$

$$\varphi(s, R_2) < \gamma_0 C_3 R_2^2 \ \text{ for all } \ s \in \big[0\,,\, \sqrt{\mathcal{K}(u_*)/C_1}\,\big]. \tag{3.11}$$

Then there exists $w \in U\backslash\{0\}$ such that $\widetilde{J}(w) \leq \widetilde{J}(u_*)$ and (3.4) holds with $\nu^2 = 1$ and $\beta = \gamma \geq \gamma_0$. Hence (3.2) and (3.3) are satisfied for the same parameters if w is replaced by $\widetilde{w} := w - [w\mathcal{C}w']$.

Proof. This is a consequence of Theorem 1, since its hypotheses have been verified for this example. □

Now we must confirm the existence of u_* satisfying (3.10) and (3.11). The choice of u_* is motivated by a power-series expansion of solutions of the nonlinear problem which bifurcate from the trivial solution. From now on, $\lambda \in (0,1)$ is fixed, and we impose $\gamma_0 > 1 - \lambda$. For u_*, we try $u_*(t) = a\big(\cos t + k\cos 2t\big)$, where $a > 0$ and $k \in \mathbb{R}$ are small. Then $\|u_*\|^2_{L^2_{2\pi}} = \pi a^2(1 + 4k^2)$, $\|u_*''\|^2_{L^2_{2\pi}} = \pi a^2(1 + 16k^2)$, and

$$\int_{-\pi}^{\pi} u_* \mathcal{C}u_*' dt = \pi a^2(1 + 2k^2),$$

which yields

$$\widetilde{J}(u_*) = -\frac{\pi}{2}a^2\big\{1 + 2k^2 - \lambda(1 + k^2 + 2ak)\big\} - \frac{\lambda}{4\pi}\{\pi a^2(1 + 2k^2)\}^2 + \gamma_0\mathcal{K}(u_*).$$

To evaluate $\widetilde{J}(u_*)$, we choose $k = pa$, $\gamma_0 - 1 + \lambda = Ba^2$, where p, $B \in \mathbb{R}$ are yet to be determined, and consider only the terms of order at most 4 in a. Recall that, for $|s| < 1$,

$$\sqrt{1+s} = 1 + \frac{1}{2}s - \frac{1}{8}s^2 + \frac{1}{16}s^3 - \frac{5}{128}s^4 + \cdots.$$

Hence

$$\begin{aligned}
&\sqrt{{u_*'}^2 + (1 + \mathcal{C}u_*')^2} - (1 + \mathcal{C}u_*') \\
&= \sqrt{1 + 2\mathcal{C}u_*' + (\mathcal{C}u_*')^2 + (u_*')^2} - (1 + \mathcal{C}u_*') \\
&= \frac{1}{2}(u_*')^2 - \frac{1}{2}(u_*')^2\mathcal{C}u_*' - \frac{1}{8}(u_*')^4 + \frac{1}{2}(u_*')^2(\mathcal{C}u_*')^2 + \cdots \\
&= \frac{1}{2}a^2\left(\frac{1 - \cos 2t}{2} + 2k^2(1 - \cos 4t) + 2k(\cos t - \cos 3t)\right) \\
&\quad -\frac{1}{2}a^3\left(\frac{\cos t}{2} - \frac{\cos t + \cos 3t}{4} + 2k\sin^2 2t + k\sin 4t\right) \\
&\quad -\frac{1}{8}a^4\sin^2 t + \frac{5}{32}a^4\sin^2 2t + \cdots
\end{aligned}$$

and

$$\begin{aligned}\widetilde{J}(u_*) &= -\frac{\pi}{2}a^2\big\{1+2k^2-\lambda(1+k^2+2ak)\big\} - \frac{\lambda}{4\pi}\{\pi a^2(1+2k^2)\}^2 \\ &\quad +\pi\gamma_0\left\{\frac{a^2}{2}+2a^2k^2-a^3k+\frac{a^4}{32}\right\}+\cdots \\ &= \pi a^4\left\{\frac{B}{2}+\big(1-(3/2)\lambda\big)p^2+\big(2\lambda-1\big)p+(1-9\lambda)/32\big)\right\}+\cdots .\end{aligned}$$

Our aim is to get $\widetilde{\mathcal{J}}(u_*)<0$ for small enough $a>0$. If $\lambda\in[2/3,1)$, we can choose

$$p=-\frac{1-9\lambda}{32(2\lambda-1)}-1 \text{ and } B=2\lambda-1>0.$$

On the other hand, if $\lambda\in(0,2/3)$, then we can choose for p the value at which the following minimum is attained:

$$\min_{p\in\mathbb{R}}\Big\{\big(1-(3/2)\lambda\big)p^2+\big(2\lambda-1\big)p+(1-9\lambda)/32\Big\}=\frac{-74\lambda^2+86\lambda-28}{64(2-3\lambda)}<0.$$

Hence we can choose in this case

$$p=-\frac{2\lambda-1}{2-3\lambda} \text{ and } B=-\frac{-74\lambda^2+86\lambda-28}{64(2-3\lambda)}>0.$$

We can now check the other hypotheses of Theorem 4 for $\lambda>0$ fixed. If R_2 is fixed small enough, then $\varphi(s,R_2)\le R_2\,s$ and $C_1\ge 1/4$, $C_2=1/2$, $C_3\ge 1/2$. If $a>0$ is small, then $\|u_*\|_2^2=\pi a^2(1+16k^2)<R_2^2$. Since $\mathcal{K}(u_*)=\frac{\pi a^2}{2}+O(a^4)$ and $\gamma_0>1-\lambda$, it is clear that $R_2\sqrt{\mathcal{K}(u_*)/C_1}<\gamma_0 C_3R_2^2$ for a small, and (3.11) is satisfied.

To sum up, we have proved the following result that is a particular case of those in [10, 14, 17].

THEOREM 5. *Let λ and γ be given by* (3.5). *Then for all $\lambda\in(0,1)$ and all $\delta>0$, there exist $\gamma>1-\lambda$ and $w\in U\backslash\{0\}$ such that $0<\|w''\|_{L^2_{2\pi}}<\delta$ and* (3.4) *holds. Hence* (3.3) *and* (3.2) *with $\nu=1$ and $\beta=\gamma$ are satisfied if w is replaced by $\widetilde{w}:=w-[w\mathcal{C}w']$.*

By refining the method, it should be possible to obtain explicit lower bounds on the size of w for not too small δ. But the choice of our test function u_*, based on local arguments, is probably not optimal for this purpose. Note that in the case of pure capillary waves ($\lambda=0$), explicit large amplitude solutions have been obtained by Crapper [11]. In the general capillary-gravity case, this could help in the search for better test functions u_* more adapted to the global nature of the problem.

4. Stokes waves. We turn to the case of pure gravity waves. Divide by λ so that, in the abstract theory,

$$\gamma=\frac{\nu^2}{\lambda}=\frac{\pi c^2}{g\Lambda}. \tag{4.1}$$

In (3.2), (3.3), (3.4), J, and $\widetilde{J}$, let $\beta=0$ and $\lambda=1$. Having done so, $w\in H^1_{2\pi}$ in (3.2), (3.3) and we apply the abstract result of section 1 with $\gamma:=\nu^2$,

$$\begin{aligned}&X_0=\{w\in L^2_{2\pi}:[w]=0,\ w \text{ is even}\},\\ &Aw=\mathcal{C}w',\\ &X_k=\{w\in H^{k/2}_{2\pi}:[w]=0,\ w \text{ is even}\} \ \text{ for } \ k\in\{1,2,4\}.\end{aligned}$$

The radius $R_2 > 0$ will be specified later. For $w \in U$ (the ball in X_2 of radius R_2 centered at the origin) let

$$\mathcal{K}(w) = \int_{-\pi}^{\pi} w\mathcal{C}w'dt,$$
$$\mathcal{L}(w) = \frac{1}{2\pi}\left\{\int_{-\pi}^{\pi} w\mathcal{C}w'dt\right\}^2 - \int_{-\pi}^{\pi} w^2(1+\mathcal{C}w')dt.$$

Assumption (2.1a) is satisfied for $C_1 := 1$, and in (2.3b) we can take $C_3 := 2$, since

$$\partial\mathcal{K}(w)\mathcal{C}w' = 2\int_{-\pi}^{\pi} \mathcal{C}w'\mathcal{C}w'dt = 2\|w\|_2^2.$$

The following lemma from [21] is useful for finding the constant C_2 of (2.1b) and the function φ of (2.3c).

LEMMA 6. *If $w \in H^1_{2\pi}$ and if $h \in C^\infty(\mathbb{R})$ is convex on the range of w, then*

$$h'\big(w(t)\big)\mathcal{C}w'(t) - \mathcal{C}\big(h'(w)w'\big)(t) \geq 0$$

almost everywhere, and therefore

$$\int_{-\pi}^{\pi} h'\big(w(t)\big)\mathcal{C}w'(t)dt \geq 0.$$

Now

$$\int_{-\pi}^{\pi} w^2\mathcal{C}w'dt = \int_{-\pi}^{\pi} w\big(w\mathcal{C}w' - \mathcal{C}(ww')\big)dt + \frac{1}{2}\int_{-\pi}^{\pi} w^2\mathcal{C}w'dt,$$

which, with Lemma 6, gives

$$\left|\int_{-\pi}^{\pi} w^2\mathcal{C}w'dt\right| \leq 2\{\sup|w|\}\int_{-\pi}^{\pi}\{w\mathcal{C}w' - \mathcal{C}(ww')\}dt$$
$$= 2\{\sup|w|\}\int_{-\pi}^{\pi} w\mathcal{C}w'dt.$$

Thus

$$\mathcal{L}(w) \geq -(1+2\{\sup|w|\})\|w\|_1^2$$

and we can choose $C_2 := 1 + \sqrt{2\pi/3}R_2$ in (2.1b). We also have

$$\partial\mathcal{L}(w)\mathcal{C}w' = \frac{2}{\pi}\mathcal{K}(w)\int_{-\pi}^{\pi}\mathcal{C}w'\mathcal{C}w'dt - 2\int_{-\pi}^{\pi} w\mathcal{C}w'dt$$
$$- 2\int_{-\pi}^{\pi} w\mathcal{C}w'\mathcal{C}w'dt - \int_{-\pi}^{\pi}\mathcal{C}(w^2)'\mathcal{C}w'dt$$
$$\geq \frac{2}{\pi}\mathcal{K}(w)\int_{-\pi}^{\pi}\mathcal{C}w'\mathcal{C}w'dt - 2\mathcal{K}(w)$$
$$- 2\{\sup|w|\}\int_{-\pi}^{\pi}(\mathcal{C}w')^2 + (w')^2dt$$
$$\geq -\varphi(\|w\|_1, \|w\|_2) - C_4\|w\|_2^2$$

with $\varphi(s,t) := \frac{2}{\pi}s^2t^2 - 2s$ and $C_4 := 4\sqrt{\pi/6}R_2$. This gives (2.3c).

Now $A^2w = -w''$ and so, if $w \in H^1_{2\pi}$ is a weak solution of

$$-\frac{1}{2\pi}\int_{-\pi}^{\pi} w\mathcal{C}w'dt = \left(\nu^2 + \int_{-\pi}^{\pi} w\mathcal{C}w'dt/\pi\right)\mathcal{C}w' - w - w\mathcal{C}w' - \mathcal{C}(ww') + \epsilon A^2 w$$

with $\epsilon > 0$, a standard regularity argument shows that $w \in W^{2,2}_{2\pi}$, and thus hypothesis (2.1e) is verified.

To check assumption (2.1f), note that if $w_n \rightharpoonup w$ weakly in $L^2_{2\pi}$, then $\mathcal{C}w_n' \rightharpoonup \mathcal{C}w'$ weakly in $H^1_{2\pi}$ and $w_n \to w$ uniformly on $[-\pi,\pi]$. It follows that $\mathcal{K}(w_n) \to \mathcal{K}(w)$, $\mathcal{L}(w_n) \to \mathcal{L}(w)$.

THEOREM 7. *Let $\gamma > 0$ and $R_2 < \gamma\sqrt{3/(2\pi)}$. Assume that there exists $u_* \in U$ such that*

$$\gamma\mathcal{K}(u_*) + \mathcal{L}(u_*) < 0$$

and

$$\frac{\mathcal{K}(u_*)}{\gamma - \sqrt{2\pi/3}R_2 + \pi^{-1}\mathcal{K}(u_*)} < R_2^2. \tag{4.2}$$

Then there exist $w \in U\backslash\{0\}$ and $\widetilde{\gamma} \geq \gamma$ such that

$$\widetilde{\gamma}\partial\mathcal{K}(w) + \partial\mathcal{L}(w) = 0 \text{ and } \gamma\mathcal{K}(w) + \mathcal{L}(w) \leq \gamma\mathcal{K}(u_*) + \mathcal{L}(u_*).$$

Proof. This theorem follows from Theorem 1 and the particular form of ψ. Indeed, the inequality (4.2) is equivalent to (2.3a). □

Let $u_*(t) = a\big(\cos t + k\cos 2t\big)$, where $a,\ k > 0$. Then $\|u\|^2_{L^2_{2\pi}} = \pi a^2(1+4k^2)$,

$$\int_{-\pi}^{\pi} u_*\mathcal{C}u_*'dt = \pi a^2(1+2k^2), \quad \text{and} \quad \int_{-\pi}^{\pi} u_*^2\mathcal{C}u_*'dt = 2\pi a^3 k.$$

Moreover, setting $r = \sqrt{\pi a^2(1+2k^2)}$, we get

$$\nu^2\mathcal{K}(u_*) + \mathcal{L}(u_*) = \pi a^2\left\{\nu^2 - 1 + (2\nu^2-1)k^2 - \frac{2rk}{\sqrt{\pi(1+2k^2)}} + \frac{r^2(1+2k^2)}{2\pi}\right\}.$$

All hypotheses of Theorem 7 are verified if

$$r\frac{\sqrt{1+4k^2}}{\sqrt{1+2k^2}} < R_2 < \frac{\sqrt{3}\,\gamma}{\sqrt{2\pi}}, \tag{4.3}$$

$$R_2^2 > \frac{r^2}{\gamma - \sqrt{2\pi/3}R_2 + r^2/\pi},$$

$$\gamma - 1 + (2\gamma-1)k^2 - \frac{2rk}{\sqrt{\pi(1+2k^2)}} + \frac{r^2(1+2k^2)}{2\pi} \;<\; 0. \tag{4.4}$$

Then Theorem 4 provides us with a nontrivial solution w. Take $R_2 = 0.477$, $r = 0.28$, $k = 0.142$, $\gamma = 1/0.99$. Conditions (4.3) to (4.4) above are fulfilled, and we get a solution of (3.2) with $\beta = 0$ and $\lambda = 1$ in which w and ν are replaced by

$$w_* = w - \frac{1}{2\pi} \int_{-\pi}^{\pi} w\mathcal{C}w' dt$$

and $\nu_* \geq 0.99^{-1/2}$. Alternatively, we can fix $\nu = 1$ and let λ be the parameter, in which case the corresponding λ_* is in $(0, 0.99]$. The same result has been obtained in [8] via the mountain-pass theorem, but the present proof is simpler.

Acknowledgment. The authors wish to thank the referees for valuable comments and suggestions.

EXPLICIT SOLUTIONS OF THE EIGENVALUE PROBLEM $-\mathbf{div}\left(\frac{D}{|D|}\right) = u$ IN R^2 *

GIOVANNI BELLETTINI†, VICENT CASELLES‡, AND MATTEO NOVAGA§

Abstract. In this paper we compute explicit solutions of the eigenvalue problem $-\mathrm{div}(Du/|Du|) = u$ in R^2, in particular explicit solutions whose truncatures are in $W^{1,1}_{\mathrm{loc}}(R^2)$, and piecewise constant ones which are sums of characteristic functions of convex sets. The solutions of the above eigenvalue problem describe the asymptotic behavior of solutions of the minimizing total variation flow. As an application, we also construct explicit solutions of the denoising problem in image processing.

Key words. eigenvalue problem, total variation flow, finite perimeter sets, denoising problem

1. Introduction. The main aim of this paper is to compute explicit solutions of the following eigenvalue problem:

$$-\mathrm{div}\left(\frac{Du}{|Du|}\right) = u, \quad u \in L^1_{\mathrm{loc}}(R^2). \tag{1.1}$$

Solutions to (1.1) describe the asymptotic behavior, as $t \to +\infty$, of solutions of the minimizing total variation flow in R^2 given by the equation

$$\frac{\partial u}{\partial t} = \mathrm{div}\left(\frac{Du}{|Du|}\right) \quad \text{in } Q_T := \,]0,T[\times R^2, \tag{1.2}$$

coupled with the initial condition

$$u(0) = u_0 \in L^2(R^2). \tag{1.3}$$

Indeed, as was proved in [9], if $u_0 \in L^2(R^2)$, then the solution $u(t)$ vanishes in finite time $T(u_0)$ and the rescaled function $\frac{u(t)}{T(u_0)-t}$ converges along subsequences to a solution of (1.1) as $t \to T(u_0)$; see Theorem 2.8 below. Thus, solutions of (1.1) describe the profiles of extinction of solutions of (1.2). We also notice that a solution u of (1.1) allows us to construct a solution of (1.2) of the form $v(t,x) = (1-t)^+ u(x)$.

One of the main motivations of our study comes from the total variation approach to the problems of image denoising and restoration. Indeed, as was shown in [12], solutions of (1.1) allow us to construct explicit solutions of the total variation formulation of the denoising problem [33]. Assuming that our observed image (or data) f

comes from noisy observations of an ideal undistorted image u, the image model can be written as

$$f = u + n, \tag{1.4}$$

where n represents the noise, typically assumed to be Gaussian. In [33], Rudin, Osher, and Fatemi proposed obtaining the denoised image u by solving the constrained minimization problem

$$\text{Minimize} \int_D |Du| \quad \text{with} \int_D (u-f)^2\,dx = \sigma^2|D|, \tag{1.5}$$

where D is the image domain, typically a rectangle in R^2, and the constraint incorporates the image acquisition model given by (1.4) in terms of the variance of the noise σ^2. Let us stress here that even if three-dimensional images occur, for instance, a medical image (or video data), the case of R^2, being the case of photographs and satellite or medical images, plays an important role in image processing. In practice, problem (1.5) is solved via the unconstrained minimization problem

$$\min\left\{\int_D |Du| + \frac{1}{2\lambda}\int_D (u-f)^2\,dx : u \in BV(D)\right\} \tag{1.6}$$

for some Lagrange multiplier $\lambda > 0$ [17]. The constraint has been introduced as a penalization term. The regularization parameter λ controls the trade-off between the goodness of fit of the constraint and the smoothness term given by the total variation. This formulation of the denoising problem pioneered the use of total variation as a regularization term and the use of bounded variation functions in image processing. The first regularization methods used the Sobolev (semi)norm $\int_D |Du|^2$ and proposed denoising the data f by solving

$$\min\left\{\int_D |Du|^2 + \frac{1}{2\lambda}\int_D (u-f)^2\,dx : u \in W^{1,2}(D)\right\}. \tag{1.7}$$

In case $D = R^2$, the solution of (1.7) in the Fourier domain is given by

$$\hat{u}(\xi) = \frac{\hat{f}(\xi)}{1 + 4\gamma\pi^2|\xi|^2}, \quad \xi \in R^2$$

(the constants appearing in the denominator being dependent on the form of the Fourier transform). From the above formula we see that high frequencies of f (hence, the noise) are attenuated by the smoothness constraint. This was an important step, but the results were not satisfactory, mainly due to the inability of the previous functional to resolve discontinuities (edges) and oscillatory textured patterns. The smoothness constraint is too restrictive. Indeed, functions in $W^{1,2}(D)$ cannot have discontinuities along rectifiable curves. These observations motivated the introduction of total variation in image restoration models by Rudin, Osher, and Fatemi in their seminal work [33]. The a priori hypothesis is that functions of bounded variation (the BV model) [6, 24, 36] are a reasonable functional model for many problems in image processing, in particular, for restoration problems [33]. Typically, functions of bounded variation have discontinuities along rectifiable curves, being continuous in the measure theoretic sense away from discontinuities. The discontinuities could be identified with edges. The ability of this functional to describe textures is less clear;

some textures can be recovered, but up to a certain scale of oscillation. An interesting experimental discussion of the adequacy of the BV model to describe real images can be seen in [3, 29].

The analysis of problem (1.5) has been the subject of much work in the last ten years, both numerical and theoretical. It will not be our purpose to review it here, and we refer the interested reader to [10] for an account of it. Let us mention only that the existence of solutions of (1.5) for any $f \in L^2(R^N)$ follows easily from the convexity of the functional and the properties of bounded variation functions; that the equivalence between (1.5) and (1.6) was proved in [17]; and that the characterization of the Euler–Lagrange equation in distributional terms was done in [8, 12] (see [10]). To describe the behavior of solutions of (1.6), the authors started in [12] the search for explicit solutions for some particular kind of functions $f \in L^2(R^2)$. Since, when $\lambda = \Delta t$, (1.6) corresponds to the implicit in time discretization of (1.2) (also called the Crandall–Liggett scheme in semigroup theory [19]), the behavior of solutions of one of them is analogous to those of the other. This has been exploited in the papers [8, 12] (see also [10] for a full account).

In particular, in [12] we showed how the explicit solutions of (1.1) could be used to construct data $f \in L^2(R^2)$ for which we could compute the explicit solution of (1.6) in R^2. In the most simple case, if $\overline{u} \in BV(R^2)$ is a solution of (1.1) and $b \in R$, then the function $a\overline{u}$ with $a = \operatorname{sign}(b)(|b| - \lambda)^+$ is the solution of the variational problem (1.6) when $f = b\overline{u}$. In other words, the solution of (1.6) is given by the soft-thresholding rule applied to b. Other more general results were also exhibited. In particular, this established a connection with the wavelet approach to denoising given by the soft-thresholding rule applied to the wavelet coefficients of a noisy function (the uncorrupted function being in some Besov space) [20, 21, 22, 23]. In this direction, let us recall the result of Meyer [31], which proves that by applying a soft-thresholding to the coefficients of the wavelet expansion of f with respect to some orthonormal wavelet basis, one obtains a quasi-optimal solution of (1.6) in the sense that its energy is bounded by a universal constant times the actual minimum energy. Further work exploring the connection between both approaches, variational and wavelet-based, to the denoising problem can be found in [35].

Our purpose in this paper will be to make progress in the study of the solutions of the eigenvalue problem (1.1) and to derive, as a consequence, other explicit solutions of the denoising problem

$$\min\left\{\int_{R^2} |Du| + \frac{1}{2\lambda}\int_{R^2} (u-f)^2\,dx : u \in BV(R^2)\right\} \tag{1.8}$$

for some data $f \in L^2(R^2)$, $\lambda > 0$. For that, in section 2 we shall begin by recalling some preliminary facts about functions of bounded variation, a generalized Green's formula [11], and the notion of solution for the evolution equation (1.2) and for the eigenvalue problem (1.1).

In section 3 we describe the regularity properties of the level lines of the solutions of (1.1). In section 4 we study the solutions of (1.1) which are in $W^{1,1}(R^2)$, and hence do not possess discontinuities along rectifiable curves. Indeed, we compute the explicit solutions u of (1.1) whose truncatures $T_k(u) := (-k) \vee u \wedge k$ are in $W^{1,1}_{\mathrm{loc}}(R^2)$ for any $k > 0$, and we prove that the level sets $\{u > t\}$, $t > 0$ (resp., $\{u < t\}$, $t < 0$), of the nonzero solutions are balls of radius $\frac{1}{t}$ (resp., $-\frac{1}{t}$).

Then we turn our attention to the consideration of piecewise constant solutions of (1.1) which can be described as sums of characteristic functions of convex sets forming

towers (or oscillating towers). As we shall prove, there are geometric restrictions on the curvature of the convex sets, as well as restrictions on their relative position to be able to combine them in towers which are solutions of (1.1). In some particular cases, this kind of geometric condition already appeared in the study of capillarity problems in domains of R^2 [18, 25, 26, 27, 28], and its analogues have also appeared in the case of crystalline variational problems [13, 14, 15]. Let us mention that consideration of convex sets is justified by the results in [12]. The analysis of piecewise constant solutions of (1.1) leads to the study of solutions of $\operatorname{div} z =$ constant in bounded and unbounded domains delimited by convex sets. Section 5 is devoted to solving the equation $\operatorname{div} z =$ constant in a bounded domain F of R^2 determined by an exterior Jordan curve ∂C_0 of class $\mathcal{C}^{1,1}$ and a finite number m of interior Jordan curves, also of class $\mathcal{C}^{1,1}$, where the unknown is a vector field $z \in L^\infty(F; R^2)$, $\|z\|_\infty \leq 1$, whose trace at the boundary is the inner or outer unit normal, depending on the Jordan curve. This is one of the basic building blocks in constructing piecewise constant explicit solutions of (1.1), the other being the solution of the equation $\operatorname{div} z = 0$ in the complement of a bounded domain made by a finite number of connected components whose boundary is a convex curve of class $\mathcal{C}^{1,1}$. This will be the purpose of section 6. By pasting together these solutions one can construct explicit piecewise constant solutions of (1.1). We shall call these solutions oscillating tower solutions of (1.1). We shall use them to construct some data $f \in L^2(R^2)$ for which the explicit solutions of (1.8) can be computed (with a soft-thresholding rule). This will be the purpose of section 8.

The solutions constructed here illustrate the behavior of solutions of (1.8), but do not exhibit all its features. The behavior of (1.8) for characteristic functions of general convex sets in R^2 (together with explicit solutions of (1.2)) was described in [1], where it was shown that the sets are eroded at high curvature points of its boundary. By the way, the extension of the above results to characteristic functions of convex sets in R^N has been started in [2]. The explicit behavior of (1.8) and (1.2) when the initial condition is the characteristic function of a general set in R^2 with smooth or piecewise smooth boundary is still to be described. We believe that with these elements on hand, one would be able to add them and produce a description of a more general class of piecewise constant solutions of (1.2). There is still a long way to go, but our explicit solutions are a first step in this direction and illustrate the behavior of soft-thresholding in some geometrically simple cases, exhibiting the role of the parameter λ in the elimination of small localized perturbations of the image (which could be assimilated to a multiple of a characteristic function of some small ball).

2. Some notation.

2.1. Functions of bounded variation and sets of finite perimeter. Let Q be an open subset of R^N. By $C_0^\infty(Q)$ (resp., $C_0^\infty(Q; R^N)$) we denote the space of functions (resp., vector fields with values in R^N) which are C^∞ and have compact support in Q.

A function $u \in L^1(Q)$ whose gradient Du in the sense of distributions is a (vector-valued) Radon measure with finite total variation in Q is called a function of bounded variation. The class of such functions will be denoted by $BV(Q)$. The total variation of Du on Q turns out to be

$$\sup\left\{\int_Q u \operatorname{div} z \, dx : z \in C_0^\infty(Q; R^N), \|z\|_{L^\infty(Q)} := \operatorname*{ess\,sup}_{x \in Q} |z(x)| \leq 1\right\} \tag{2.1}$$

(where for a vector $v = (v_1, \dots, v_N) \in R^N$ we set $|v|^2 := \sum_{i=1}^N v_i^2$) and will be denoted by $|Du|(Q)$ or by $\int_Q |Du|$. It turns out that the map $u \to |Du|(Q)$ is $L^1_{\rm loc}(Q)$-lower semicontinuous. $BV(Q)$ is a Banach space when endowed with the norm $\int_Q |u|\, dx + |Du|(Q)$. We recall that $BV(R^N) \subseteq L^{N/(N-1)}(R^N)$. The total variation of u on a Borel set $B \subseteq Q$ is defined as $\inf\{|Du|(A)\colon A \text{ open}, B \subseteq A \subseteq Q\}$. We denote by $BV_{\rm loc}(Q)$ the space of functions $w \in L^1_{\rm loc}(Q)$ such that $w\varphi \in BV(Q)$ for all $\varphi \in C_0^\infty(Q)$. For results and information on functions of bounded variation, we refer to [6, 24].

A measurable set $E \subseteq R^N$ is said to be of finite perimeter in Q if (2.1) is finite when u is substituted with the characteristic function χ_E of E. The perimeter of E in Q is defined as $P(E,Q) := |D\chi_E|(Q)$, and $P(E,Q) = P(R^N \setminus E, Q)$. We shall use the notation $P(E) := P(E, R^N)$. For sets of finite perimeter E one can define the essential boundary $\partial^* E$, which is countably $(N-1)$ rectifiable with finite $\mathcal{H}^{N-1}$ measure, and compute the outer unit normal $\nu^E(x)$ at $\mathcal{H}^{N-1}$ almost all points x of $\partial^* E$, where $\mathcal{H}^{N-1}$ is the $(N-1)$-dimensional Hausdorff measure. Moreover, $|D\chi_E|$ coincides with the restriction of $\mathcal{H}^{N-1}$ to $\partial^* E$.

For a Lebesgue measurable subset $E \subseteq R^N$ and a point $x \in R^N$, the upper and lower densities of E at x are, respectively, defined by

$$\overline{D}(x,E) := \limsup_{r \to 0^+} \frac{|E \cap B_r(x)|}{|B_r(x)|}, \quad \underline{D}(x,E) := \liminf_{r \to 0^+} \frac{|E \cap B_r(x)|}{|B_r(x)|}.$$

Here $B_r(x)$ denotes the open ball of radius r centered at x and $|\cdot|$ stands for the Lebesgue measure. If the upper and lower densities are equal, their common value will be called the density of E at x, and it will be denoted by $D(x,E)$. Each set E of finite perimeter will be identified with the representative (in its Lebesgue class) given by the set of all points $x \in R^N$ such that $D(x,E) = 1$. It is clear that if ∂E is Lipschitz continuous, then the precise representative we are choosing is an open set.

If μ is a (possibly vector-valued) Radon measure and f is a Borel function, the integration of f with respect to μ will be denoted by $\int f d\mu$. When μ is the Lebesgue measure, the symbol dx will be often omitted.

By $L^1_w(]0,T[; BV(R^N))$ we denote the space of functions $v :]0,T[\to BV(R^N)$ such that $v \in L^1\left(]0,T[\times R^N\right)$, the maps $t \in]0,T[\to \int_{R^N} \phi\, dDv(t)$ are measurable for every $\phi \in C_0^1(R^N; R^N)$, and $\int_0^T |Dv(t)|(R^N)\, dt < \infty$. By $L^1_w(]0,T[; BV_{\rm loc}(R^N))$ we denote the space of functions $v :]0,T[\to BV_{\rm loc}(R^N)$ such that $v\varphi \in L^1_w(]0,T[; BV(R^N))$ for all $\varphi \in C_0^\infty(R^N)$.

If E is a subset of R^N of class $\mathcal{C}^{1,1}$, we denote by $\kappa_{\partial E}$ the ($\mathcal{H}^{N-1}$-almost everywhere defined) curvature of ∂E, nonnegative for convex sets. The following result can be proved as in [32].

PROPOSITION 2.1. *Let $\mu \in R$ and E be a set of class $\mathcal{C}^{1,1}$. Assume that there exists an open set A such that $A \cap \partial E$ is the graph of a $\mathcal{C}^{1,1}$ function, and*

$$P(E,A) - \mu|E \cap A| \le P(E \cup B, A) - \mu|(E \cup B) \cap A| \tag{2.2}$$

for any bounded measurable set B with $\overline{B} \subset A$. Then $\kappa_{\partial E}(x) \ge \mu$ for $\mathcal{H}^{N-1}$-almost every $x \in A \cap \partial E$. Similarly, if in place of (2.2) *there holds the inequality*

$$P(E,A) - \mu|E \cap A| \le P(E \setminus B, A) - \mu|(E \setminus B) \cap A|,$$

then $\kappa_{\partial E}(x) \le \mu$ for $\mathcal{H}^{N-1}$-almost every $x \in A \cap \partial E$.

The following lemma will be used in several places. Let us include its proof for the sake of completeness.

LEMMA 2.2. *Let $A, B \subseteq R^N$ be two sets of finite perimeter such that $|A \cap B| = 0$. Then, up to a set of $\mathcal{H}^{N-1}$-measure zero, we have*

$$\partial^*(A \cup B) = (\partial^* A \setminus \partial^* B) \cup (\partial^* B \setminus \partial^* A).$$

In particular, we have

$$P(A \cup B) = P(A) + P(B) - 2\mathcal{H}^{N-1}(\partial^* A \cap \partial^* B).$$

Proof. Recall that if $E \subseteq R^N$ has finite perimeter, the essential boundary $\partial^* E$ is contained in the measure theoretic boundary $\partial^M E$ (i.e., the set of points $x \in R^N$ such that $\overline{D}(x, E) > 0$ and $\overline{D}(x, R^N \setminus E) > 0$) of E, and $\mathcal{H}^{N-1}(\partial^M E \setminus \partial^* E) = 0$ [6, 24, 36]. Let $p \in \partial^*(A \cup B)$. Then $\overline{D}(p, A \cup B) > 0$ and $\overline{D}(p, R^N \setminus (A \cup B)) > 0$. Since $R^N \setminus (A \cup B) \subseteq R^N \setminus A$ we have $\overline{D}(p, R^N \setminus A) > 0$. Similarly $\overline{D}(p, R^N \setminus B) > 0$. From $\overline{D}(p, A \cup B) > 0$, we have either $\overline{D}(p, A) > 0$ or $\overline{D}(p, B) > 0$. If $\overline{D}(p, A) > 0$ (resp., $\overline{D}(p, B) > 0$), we have $p \in \partial^* A$ (resp., $p \in \partial^* B$). Now, if $p \in \partial^* A \cap \partial^* B$, $\mathcal{H}^{N-1}$-almost everywhere, we have $D(p, A) = D(p, R^N \setminus A) = D(p, B) = D(p, R^N \setminus B) = \frac{1}{2}$. Since $|A \cap B| = 0$, we conclude

$$D(p, A \cup B) = D(p, A) + D(p, B) = \frac{1}{2} + \frac{1}{2} = 1.$$

This implies that $p \notin \partial^*(A \cup B)$, a contradiction. We conclude that $p \notin \partial^* A \cap \partial^* B$. We have proved that

$$\partial^*(A \cup B) \subseteq (\partial^* A \setminus \partial^* B) \cup (\partial^* B \setminus \partial^* A) \pmod{\mathcal{H}^{N-1}}.$$

To prove the opposite inclusion, assume that $p \in \partial^* A \setminus \partial^* B$. Then for $\mathcal{H}^{N-1}$-almost every p we may assume that

$$D(p, A) = D(p, R^N \setminus A) = \frac{1}{2}. \tag{2.3}$$

In particular, we have that $\overline{D}(p, A \cup B) > 0$. Assume that $\overline{D}(p, R^N \setminus (A \cup B)) = 0$. In this case, $D(p, A \cup B) = 1$. Using (2.3), we obtain $D(p, B) = \frac{1}{2}$. Hence, $p \in \partial^* B$, a contradiction. Thus, we also have $\overline{D}(p, R^N \setminus (A \cup B)) > 0$, and therefore $p \in \partial^*(A \cup B)$ for $\mathcal{H}^{N-1}$-almost every $p \in \partial^* A \setminus \partial^* B$. We conclude that $\partial^* A \setminus \partial^* B \subseteq \partial^*(A \cup B)$. Similarly we have that $\partial^* B \setminus \partial^* A \subseteq \partial^*(A \cup B)$. ∎

2.2. A generalized Green's formula. Let Ω be an open set in R^N. Following [11], let

$$X_2(\Omega) := \{z \in L^\infty(\Omega; R^N) : \operatorname{div} z \in L^2(\Omega)\},$$
$$X_{2,\mathrm{loc}}(\Omega) := \{z \in L^\infty(\Omega; R^N) : \operatorname{div} z \in L^2_{\mathrm{loc}}(\Omega)\}.$$

If $z \in X_{2,\mathrm{loc}}(\Omega)$ and $w \in L^2_{\mathrm{loc}}(\Omega) \cap BV_{\mathrm{loc}}(\Omega)$, we define the functional (z, Dw): $C_0^\infty(\Omega) \to R$ by the formula

$$\langle (z, Dw), \varphi \rangle := -\int_\Omega w\, \varphi \operatorname{div} z\, dx - \int_\Omega w\, z \cdot \nabla \varphi\, dx \qquad \forall \varphi \in C_0^\infty(\Omega). \tag{2.4}$$

Notice that

$$\langle (z, Dw), \varphi \rangle = \int_\Omega z \cdot \nabla w \, \varphi \, dx \qquad \forall w \in L^2_{\rm loc}(\Omega) \cap W^{1,1}_{\rm loc}(\Omega).$$

If $z \in X_2(\Omega)$ and $w \in L^2(\Omega) \cap BV(\Omega)$, then (z, Dw) is a Radon measure in Ω, and

$$\left| \int_B (z, Dw) \right| \le \int_B |(z, Dw)| \le \|z\|_\infty \int_B |Dw| \qquad \forall \text{ Borel set } B \subseteq \Omega.$$

We denote by $\theta(z, Dw) \in L^\infty_{|Dw|}(\Omega)$ the density of (z, Dw) with respect to $|Dw|$, that is,

$$(z, Dw)(B) = \int_B \theta(z, Dw) \, d|Dw| \qquad \forall \text{ Borel set } B \subseteq \Omega. \tag{2.5}$$

If $\Omega = R^N$, we have the following integration-by-parts formula [11] for $z \in X_2(R^N)$ and $w \in L^2(R^N) \cap BV(R^N)$:

$$\int_{R^N} w \, \text{div } z \, dx + \int_{R^N} (z, Dw) = 0. \tag{2.6}$$

In particular, if B is bounded and has finite perimeter in R^N, from (2.6) and (2.5) it follows that

$$\int_B \text{div } z \, dx = \int_{R^N} (z, -D\chi_B) = \int_{\partial^* B} \theta(z, -D\chi_B) \, d\mathcal{H}^{N-1}. \tag{2.7}$$

Notice also that if $z_1, z_2 \in X_2(R^N)$ and $z_1 = z_2$ almost everywhere on B, then $\theta(z_1, -D\chi_B)(x) = \theta(z_2, -D\chi_B)(x)$ for $\mathcal{H}^{N-1}$-almost every $x \in \partial^* B$.

We recall the following result proved in [11].

THEOREM 2.3. *Let $\Omega \subset R^N$ be a open set with Lipschitz boundary, $1 \le p \le N$, $p' = \frac{p}{p-1}$. Assume that either Ω or $R^N \setminus \overline{\Omega}$ is bounded. Let $u \in BV(\Omega) \cap L^{p'}(\Omega)$ and $z \in L^\infty(\Omega; R^N)$ with* div $z \in L^p(\Omega)$. *Then, using test functions $\varphi \in C^\infty_0(\Omega)$, (2.4) defines a Radon measure (z, Du) in Ω, there exists a function $[z \cdot \nu^\Omega] \in L^\infty(\partial\Omega)$ such that $\|[z \cdot \nu^\Omega]\|_{L^\infty(\partial\Omega)} \le \|z\|_{L^\infty(\Omega; R^N)}$, and*

$$\int_\Omega u \, \text{div} z \, dx + \int_\Omega (z, Du) = \int_{\partial\Omega} [z \cdot \nu^\Omega] u \, d\mathcal{H}^{N-1}.$$

In particular, if Ω or $R^N \setminus \overline{\Omega}$ is a bounded open set with Lipschitz boundary, then (2.7) has a meaning also if z is defined only on Ω and not on the whole of R^N, precisely when $z \in L^\infty(\Omega; R^N)$ with div $z \in L^1(\Omega)$. In this case we mean that $\theta(z, -D\chi_\Omega)$ coincides with $[z \cdot \nu^\Omega]$.

Remark 1. Let $\Omega \subset R^2$ be a bounded Lipschitz open set, and let $z_{\rm inn} \in L^\infty(\Omega; R^2)$ with $\text{div} z_{\rm inn} \in L^2(\Omega)$, and $z_{\rm out} \in L^\infty(R^2 \setminus \overline{\Omega}; R^2)$ with $\text{div} z_{\rm out} \in L^2(R^2 \setminus \overline{\Omega})$. Assume that

$$[z_{\rm inn} \cdot \nu^\Omega](x) = -[z_{\rm out} \cdot \nu^{R^2 \setminus \overline{\Omega}}](x) \qquad \text{for } \mathcal{H}^1\text{-a.e. } x \in \partial\Omega.$$

Then if we define $z := z_{\rm inn}$ on Ω and $z := z_{\rm out}$ on $R^2 \setminus \overline{\Omega}$, we have $z \in L^\infty(R^2; R^2)$ and $\text{div} z \in L^2(R^2)$.

2.3. The notion of solution, and existence and uniqueness results. Consider the energy functional $\Psi : L^2(R^N) \to (-\infty, +\infty]$ defined by

$$\Psi(u) := \begin{cases} \int_{R^N} |Du| & \text{if} \quad u \in L^2(R^N) \cap BV(R^N), \\ +\infty & \text{if} \quad u \in L^2(R^N) \setminus BV(R^N). \end{cases} \tag{2.8}$$

Since the functional Ψ is convex, lower semicontinuous, and proper, then $\partial\Psi$ is a maximal monotone operator with dense domain, generating a contraction semigroup in $L^2(R^N)$ (see [16]). Therefore, we have the following result.

THEOREM 2.4. *Let $u_0 \in L^2(R^N)$. Then there exists a unique strong solution in the semigroup sense u of* (1.2), (1.3) *in $[0,T]$ for every $T > 0$, i.e., $u \in C([0,T]; L^2(R^N)) \cap W^{1,2}_{\rm loc}(0,T; L^2(R^N))$, $u(0) = u_0$, $u(t) \in D(\partial\Psi)$ for almost every $t \in [0,T]$, and*

$$-u'(t) \in \partial\Psi(u(t)) \quad \text{for a.e. } t \in [0,T]. \tag{2.9}$$

Moreover, if u and v are the strong solutions of (1.2) *corresponding to the initial conditions $u_0, v_0 \in L^2(\Omega)$, respectively, then*

$$\|u(t) - v(t)\|_2 \le \|u_0 - v_0\|_2 \quad \text{for any } t > 0.$$

The semigroup theory immediately provides us with existence and uniqueness results for (1.2). The characterization of $\partial\Psi$ given in Lemma 2.5 below (see [8, 9, 12] for a proof) allows us to write Theorem 2.4 in more classical terms.

LEMMA 2.5. *The following assertions are equivalent:*

(a) $(u, v) \in \partial\Psi$*;*

(b)

$$u \in L^2(R^N) \cap BV(R^N),\ v \in L^2(R^N), \tag{2.10}$$

$$\exists z \in X_2(R^N) \text{ with } \|z\|_\infty \le 1, \text{ such that } v = -\mathrm{div} z \quad \text{in } \mathcal{D}'(R^N),$$

and

$$\int_{R^N} (z, Du) = \int_{R^N} |Du|. \tag{2.11}$$

Let us now give a more classical definition of solution for problem (1.2). As we shall notice below, this notion coincides with the notion of a strong solution in the sense of semigroups defined above.

DEFINITION 2.6. *A function $u \in C([0,T]; L^2(R^N))$ is called a strong solution of* (1.2) *if*

$$u \in W^{1,2}_{\rm loc}(0,T; L^2(R^N)) \cap L^1_w(]0,T[; BV(R^N)),$$

and there exists $z \in L^\infty\left(]0,T[\times R^N; R^N\right)$ with $\|z\|_\infty \le 1$ such that

$$u_t = \mathrm{div}\ z \qquad \text{in } \mathcal{D}'(]0,T[\times R^N)$$

and

$$\int_{R^N} (z(t), Du(t)) = \int_{R^N} |Du(t)| \quad \text{for a.e. } t > 0. \tag{2.12}$$

We have the following result [8, 9, 12].

THEOREM 2.7. *Let $u_0 \in L^2(R^N)$. A function $u \in C([0,T]; L^2(R^N))$ is a strong solution of* (1.2) *with $u(0) = u_0$ if and only if it is a strong solution of it in the semigroup sense. Hence there exists a unique strong solution u of* (1.2), (1.3) *in $[0,T] \times R^N$ for every $T > 0$. Moreover, if u and v are the strong solutions of* (1.2) *corresponding to the initial conditions $u_0, v_0 \in L^2(R^N)$, respectively, then*

$$\|(u(t) - v(t))^+\|_2 \le \|(u_0 - v_0)^+\|_2 \quad \text{for any } t > 0. \tag{2.13}$$

Obviously, using Lemma 2.5, a strong solution of (1.2) is a strong solution in the sense of semigroups. The converse implication would follow along the same lines, except for the measurability of $z(t,x)$. To ensure the joint measurability of z, one takes into account that, by the Crandall–Liggett theorem [19], semigroup solutions can be approximated by implicit-in-time discretizations of (2.9), and one constructs a function $z(t,x) \in L^\infty(]0,T[\times R^N)$ satisfying the requirements contained in Definition 2.6. For details we refer to [8, 10]. Let us finally recall that, by a suitable extension of the notion of solution, we have existence, uniqueness, and stability results with respect to convergence in $L^1_{\rm loc}(R^N)$ for initial conditions in $L^1_{\rm loc}(R^N)$ [12].

Theorem 2.7 can be complemented with the following result.

THEOREM 2.8. *Let $u_0 \in L^2(R^N) \cap L^N(R^N)$ with support contained in a ball B of radius $R > 0$, and let $u(t,x)$ be the unique solution of problem* (1.2). *Then* $\mathrm{supp}(u) \subseteq B$. *If $T^*(u_0) = \inf\{t > 0 \colon u(t) = 0\}$, then*

$$T^*(u_0) \le \frac{R\|u_0\|_\infty}{N}. \tag{2.14}$$

Let

$$w(t,x) := \begin{cases} \dfrac{u(t,x)}{T^*(u_0) - t} & \text{if} \quad 0 \le t < T^*(u_0), \\ 0 & \text{if} \quad t \ge T^*(u_0). \end{cases}$$

Then there exists an increasing sequence $t_n \to T^*(u_0)$ and a solution $v^* \ne 0$ of the eigenvalue problem

$$v \in \partial\Psi(v) \tag{2.15}$$

such that

$$\lim_{n\to\infty} w(t_n) = v^* \quad \text{in} \quad L^p(R^N)$$

for all $1 \le p < \infty$.

By Lemma 2.5, equation (1.1) can be understood in more classical terms. Let us write this definition in a more general context. We shall use the truncatures $T_k(r) := (-k) \wedge r \vee k$, $r \in R$, $k > 0$.

DEFINITION 2.9. *Let Ω be an open set in R^N and let $f \in L^2_{\rm loc}(\Omega)$. We say that a function $u \in L^1_{\rm loc}(\Omega)$ is a solution of*

$$-\mathrm{div}\left(\frac{Du}{|Du|}\right) = f \quad \text{in } \Omega \tag{2.16}$$

if

$$T_k(u) \in BV_{\rm loc}(\Omega) \qquad \forall k > 0, \tag{2.17}$$

$$\exists z \in L^\infty(\Omega; R^N) \text{ with } \|z\|_\infty \le 1, \text{ such that } -\mathrm{div} z = f \quad \text{in } \mathcal{D}'(\Omega),$$

and

$$\langle (z, DT_k(u)), \varphi \rangle = \int_\Omega |DT_k(u)|\, \varphi \quad \textit{for any } \varphi \in C_0^\infty(\Omega), \tag{2.18}$$

where the left-hand side is defined as in (2.4).

The above definition also makes sense if we assume that $f \in L^1_{\rm loc}(R^N)$. Since this will not be needed in what follows, and to avoid cumbersome statements in subsection 2.2, we have assumed that $L^1_{\rm loc}(R^N)$.

Remark 2. If u is a solution of (2.16) and $f \in L^p_{\rm loc}(\Omega)$ with $p \geq 2$, then $(z, D\chi_{\{u>t\}}) = |D\chi_{\{u>t\}}|$ (in the sense that $\langle (z, D\chi_{\{u>t\}}), \varphi \rangle = \langle |D\chi_{\{u>t\}}|, \varphi \rangle$ for any $\varphi \in C_0^\infty(\Omega)$) for almost any $t \in R$. Indeed, by [11, Proposition 2.7], we have

$$\langle (z, DT_k(u)), \varphi \rangle = \int_{-k}^{k} \langle (z, D\chi_{\{u>t\}}), \varphi \rangle \, dt, \qquad \varphi \in C_0^\infty(\Omega),\ k > 0.$$

Since $|DT_k(u)|(\varphi) = \int_{-k}^{k} |D\chi_{\{u>t\}}|(\varphi)$, we may write (2.18) as

$$\int_{-k}^{k} \langle (z, D\chi_{\{u>t\}}), \varphi \rangle \, dt = \int_{-k}^{k} |D\chi_{\{u>t\}}|(\varphi)\, dt, \qquad \varphi \in C_0^\infty(\Omega),\ k > 0,$$

and this implies our claim.

Remark 3. If $u \in L^\infty(\Omega)$, condition (2.18) can be replaced by $(z, Du) = |Du|$.

3. Properties of $L_{\rm loc}$-solutions. Throughout the paper, from now on we shall assume that $N = 2$.

PROPOSITION 3.1. *Let Ω be an open set in R^2, and let $u \in L^p_{\rm loc}(\Omega)$ for some $p \in]2, +\infty]$. Let u be a solution of* (1.1) *in Ω. The following assertions hold.*

(a) *If $p < +\infty$ (resp., $p = +\infty$), then for any $t \in R$ the sets $\{u > t\}$ and $\{u \geq t\}$ have boundary of class $C^{1,\alpha}$ in Ω for some $\alpha \in]0, 1[$ (resp., $\mathcal{C}^{1,1}$). Similar assertions hold for $\{u < t\}$ and $\{u \leq t\}$.*

(b) *If $u \geq a$ in Ω (resp., $u \leq a$ in Ω) for some $a \in R$, then $\kappa_{\Omega \cap \partial\{u>t\}} \geq a$ and $\kappa_{\Omega \cap \partial\{u \geq t\}} \geq a$ in the sense of distributions.*

Proof. Let us prove (a). Let t be such that $\{u > t\}$ is nonempty and has locally finite perimeter in Ω and $(z, D\chi_{\{u>t\}}) = |D\chi_{\{u>t\}}|$ (in particular, by Remark 2, for almost every t). Let E be a set of finite perimeter in R^2 such that $E \triangle \{u > t\} \subset\subset \Omega$. Take a bounded Lipschitz set Ω' with $E \triangle \{u > t\} \subset\subset \Omega' \subset \Omega$. Then, using (1.1), we have

$$\int_{\{u>t\} \cap \Omega'} {\rm div} z \, dx - \int_{E \cap \Omega'} {\rm div} z \, dx \leq P(E, \Omega') - P(\{u > t\}, \Omega'). \tag{3.1}$$

It follows that $\{u > t\}$ is a minimizer of the functional

$$P(E, \Omega) + \int_{E \cap \Omega} {\rm div}\ z \, dx, \qquad E \subseteq R^2, \tag{3.2}$$

with respect to perturbations with compact support in Ω. Since by assumption $-{\rm div} z = u \in L^p_{\rm loc}(\Omega)$ for some $p \in]2, +\infty]$, using the regularity results for prescribed curvature problems (see [7, 30]), it follows that $\Omega \cap \partial\{u > t\}$ is of class $C^{1,\alpha}$ for some $\alpha \in]0, 1[$ if $p < +\infty$, and of class $\mathcal{C}^{1,1}$ if $p = +\infty$. By the compactness property of minimizers for problem (3.2) (see, for instance, [4]) the above assertion holds for any t, and (a) follows for $\{u > t\}$.

Let us prove (b). Assume that $u \geq a$ in Ω (the case $u \leq a$ is analogous). Let $t \in R$ be such that $\{u > t\}$ is nonempty and has locally finite perimeter in Ω and $(z, D\chi_{\{u>t\}}) = |D\chi_{\{u>t\}}|$ as in Remark 2 (hence, for almost every t). Let E be a set of finite perimeter in R^2 such that $E \supseteq \{u > t\}$ and $E \setminus \{u > t\} \subset\subset \Omega' \subset \Omega$, Ω' being a bounded set with Lipschitz boundary. Then from (3.1) it follows that

$$\begin{aligned} P(\{u > t\}, \Omega') &\leq P(E, \Omega') + \int_{(E\setminus\{u>t\})\cap\Omega'} \mathrm{div} z \; dx \\ &\leq P(E, \Omega') - a(|E \cap \Omega'| - |\{u > t\} \cap \Omega'|). \end{aligned}$$

It follows that $\{u > t\}$ is a minimizer of the functional

$$P(E, \Omega) - a|E \cap \Omega|, \qquad \{u > t\} \subseteq E \subseteq R^2,$$

with respect to perturbations with compact support in Ω. This concludes the proof of (b) [7, 30].

The corresponding assertions for the sets $\{u \geq t\}$ can be proved in a similar way. □

In what follows, given a function u as in Proposition 3.1 and $t \in R$, we always identify the set $\{u > t\}$ (resp., $\{u < t\}$) with its points of density one, which is an open set. We accordingly define $\{u \geq t\}$ as the complement of $\{u < t\}$.

4. Properties of $W^{1,1}_{\mathrm{loc}}$-solutions.

PROPOSITION 4.1. *Let u be a solution of* (1.1). *Assume that $u \in W^{1,1}_{\mathrm{loc}}(\Omega) \cap L^\infty_{\mathrm{loc}}(\Omega)$ for some open set $\Omega \subseteq R^2$. Then for any $t \in R$ every connected component of $\Omega \cap \partial\{u > t\}$ is contained in the boundary of a ball of radius $1/t$.*

Proof. Let $t \in R$, $\gamma := \Omega \cap \partial\{u > t\}$, and $\epsilon > 0$. By Proposition 3.1 the curve γ and the two curves $\gamma^-_\epsilon := \Omega \cap \partial\{u > t - \epsilon\}$, $\gamma^+_\epsilon := \Omega \cap \partial\{u < t + \epsilon\}$ are of class $\mathcal{C}^{1,1}$. Moreover, since $u \in W^{1,1}_{\mathrm{loc}}(\Omega)$, the two sets $\gamma^-_\epsilon \cap \gamma$ and $\gamma^+_\epsilon \cap \gamma$ are closed sets of zero $\mathcal{H}^1$-measure. Then the curve $\gamma \setminus (\gamma^-_\epsilon \cup \gamma^-_\epsilon)$ is contained in $\Omega \cap \{|u - t| < \epsilon\}$. Since γ is of class $\mathcal{C}^{1,1}$, by (b) of Proposition 3.1 it follows that γ has curvature belonging to $(t - \epsilon, t + \epsilon)$. The thesis follows by letting $\epsilon \to 0^+$. □

Note that if u is as in Proposition 4.1, then the set $\{u > t\}$ is a disjoint union of balls of radius $\frac{1}{t}$ for any $t \in R$ such that the boundary of $\{u > t\}$ is contained in Ω.

LEMMA 4.2. *Let $u \in W^{1,1}_{\mathrm{loc}}(R^2) \cap L^\infty_{\mathrm{loc}}(R^2)$ be a solution of* (1.1). *Then $u \equiv 0$.*

Proof. Assume by contradiction that $\lambda := \operatorname{ess\,sup}_{R^2} u > 0$ (the case $\operatorname{ess\,inf} u_{R^2} < 0$ can be treated in a similar way). Using Proposition 4.1 it follows that the set $\{u > t\}$ contains an open ball B_t of radius $\frac{1}{t}$ for any $t \in (0, \lambda)$. Fix $t \in (0, \lambda)$ and let $t^* := \operatorname{ess\,sup}_{B_t} u > t$. Then the closure of a connected component of the set $B_t \cap \{u = t^*\} = B_t \cap \{u \geq t^*\}$ is a closed ball $D_{t^*} \subset B_t$ of radius $\frac{1}{t^*}$. Using (1.1) we get

$$t^* = \frac{(t^*)^2}{\pi} \int_{D_{t^*}} u \; dx = -\frac{(t^*)^2}{\pi} \int_{D_{t^*}} \mathrm{div} z \; dx = 2t^*,$$

which is a contradiction. □

Loosely speaking, the following proposition classifies solutions with no jumps.

PROPOSITION 4.3. *Assume that u is a solution of* (1.1) *satisfying the following assumption:*

$$\forall t \in R \;\; \exists \text{ an open set } U_t \supset \partial\{u > t\} \text{ such that } u \in L^\infty_{\mathrm{loc}}(U_t).$$

Assume also that $T_k(u) \in W^{1,1}_{\rm loc}(R^2)$ for any $k > 0$. Then one of the following possibilities holds:

- *$u \equiv 0$;*
- *u is positive and the set $\{u > t\}$ is a ball of radius $\frac{1}{t}$ for any $t > 0$;*
- *u is negative and the set $\{u < t\}$ is a ball of radius $-\frac{1}{t}$ for any $t < 0$;*
- *u is nonnegative, $\{u > 0\}$ is a halfspace, and the set $\{u > t\}$ is a ball of radius $\frac{1}{t}$ for any $t > 0$;*
- *u is nonpositive, $\{u < 0\}$ is a halfspace, and the set $\{u < t\}$ is a ball of radius $-\frac{1}{t}$ for any $t < 0$;*
- *both $\{u > 0\}$ and $\{u < 0\}$ are halfspaces, the set $\{u > t\}$ is a ball of radius $\frac{1}{t}$ for any $t > 0$, and the set $\{u < \tau\}$ is a ball of radius $-\frac{1}{\tau}$ for any $\tau < 0$.*

Proof. Assume that $\lambda := \operatorname{ess\,sup} u > 0$ (the case $\operatorname{ess\,inf} u < 0$ being similar). From Proposition 4.1 we get that $\{u > t\}$ is the disjoint union of balls of radius $\frac{1}{t}$ for any $t \in (0, \lambda)$. Reasoning as in the proof of Lemma 4.2 we deduce that $\lambda = +\infty$. Observe that, given $0 < t_1 < t_2$, to each ball $B_1 \subseteq \{u > t_1\}$ (of radius $1/t_1$) there corresponds one and only one ball $B_2 \subseteq \{u > t_2\}$ (of radius $1/t_2$) such that $B_2 \subset B_1$, and vice versa. Hence there is a pairwise correspondence between the balls of $\{u > t_1\}$ and those of $\{u > t_2\}$. Letting $t \to 0^+$, $\{u > t\}$ consists of at most two balls, since given any three disjoint balls whose radius goes to infinity, at least one of them has a distance from a fixed point which goes to infinity. Hence $u > 0$ may consist of either one halfspace, two halfspaces, or the whole of R^2.

Claim. The set $\{u > t\}$ consists of exactly one ball of radius $\frac{1}{t}$ for any $t > 0$.

Observe that, once the claim is proved, all assertions of the proposition follow, since $\{u > 0\} = \bigcup_{t>0}\{u > t\}$ can only be a halfspace or the whole of R^2. Assume by contradiction that $\{u > t\}$ is the union of two balls (of radius $\frac{1}{t}$); hence $u \geq 0$ is the union of two halfspaces of R^2. Given $\tau < 0$, the set $\{u < \tau\}$ is either empty or contains a ball of radius $-\frac{1}{\tau}$; however, by the above argument there is no place for such a ball. Hence $u \geq 0$. Then $\{u = 0\}$ is either a line or a stripe. Without loss of generality, we may assume that $\{u = 0\} = [-l, l] \times R$ for some $l \geq 0$. Let $L > l$ and, for $t > 0$ small enough and such that $(z, D\chi_{\{u>t\}}) = |D\chi_{\{u>t\}}|$, set $S_{t,L} := \{u < t\} \cap]-L, L[^2$. Since $-\mathrm{div} z = u$ is bounded in $S_{t,L}$, we have

$$
\begin{aligned}
0 \geq -\int_{S_{t,L}} u \, dx = \int_{S_{t,L}} \mathrm{div}\, z \, dx = \int_{\partial S_{t,L}} [z, \nu^{S_{t,L}}] \, d\mathcal{H}^1 \\
\geq \mathcal{H}^1(\partial S_{t,L} \cap \partial\{u < t\}) - \mathcal{H}^1(\partial S_{t,L} \cap \{u < t\}) \geq 4L - \mathcal{H}^1(\partial S_{t,L} \cap \{u < t\}).
\end{aligned}
$$

Letting $t \to 0^+$ and using the fact that $\{u > t\}$ is the union of two balls of radius $1/t$, we obtain $4L - 4l \leq 0$, a contradiction. Our claim is proved and the proposition follows. ∎

5. Solutions of div z = constant in bounded domains. In the following, $m \geq 1$ is an integer, and we denote by $C_0, C_1, \ldots, C_m$ bounded open sets of R^2 with boundary of class $\mathcal{C}^{1,1}$ having the following properties:

- $\overline{C_l} \subset C_0$ for any $l \in \{1, \ldots, m\}$;
- $\overline{C_l} \cap \overline{C_h} = \emptyset$ for any $l, h \in \{1, \ldots, m\}$, $l \neq h$.

We define

$$
F := C_0 \setminus \bigcup_{l=1}^{m} \overline{C_l},
$$

$$J_0 := \frac{1}{|F|}\left(\sum_{i=0}^{k} P(C_i) - \sum_{j=k+1}^{m} P(C_j)\right), \tag{5.1}$$

where $0 \le k < m$ is a fixed integer.

Given a set $E \subseteq F$ of finite perimeter in F, we also let

$$\mathcal{F}_F(E) := P(E,F) + \sum_{i=0}^{k} \mathcal{H}^1(\partial^* E \cap \partial C_i) - \sum_{j=k+1}^{m} \mathcal{H}^1(\partial^* E \cap \partial C_j) - J_0|E|.$$

Remark 4. It is clear that $\mathcal{F}_F(\emptyset) = 0$. Observe also that, thanks to the definition of J_0, $\mathcal{F}_F(F) = 0$.

We now define a class $\mathcal{A}$ of subsets of F.

DEFINITION 5.1. *Let $E \subseteq F$ be a finite perimeter set and let $J_0 > 0$. We say that $E \in \mathcal{A}$ if either $E \in \{\emptyset, F\}$ or the following conditions hold: $F \cap \partial^* E$ consists of disjoint arcs Γ of circles of radius $1/J_0$, with $\partial F \cap \overline{\Gamma} \neq \emptyset$, and*

$$\nu^E = \nu^{C_0} \quad \text{on } \overline{\Gamma} \cap \partial C_0, \tag{5.2}$$

$$\nu^E = -\nu^{C_i} \quad \text{on } \overline{\Gamma} \cap \partial C_i,\ i \in \{1,\dots,k\}, \tag{5.3}$$

$$\nu^E = \nu^{C_j} \quad \text{on } \overline{\Gamma} \cap \partial C_j,\ j \in \{k+1,\dots,m\}. \tag{5.4}$$

In (5.2), (5.3), and (5.4) we keep the notation ν^E to indicate the extension of the outer unit normal vector to ∂E at the points of $\overline{\Gamma}$.

The following result can be essentially found in [25, Theorem 1] and [26, Theorem 6.10]. Indeed, the results in [25, 26] cover the case of equalities (5.2) and (5.3), but they can be adapted to prove (5.4).

THEOREM 5.2. *Let $E \subseteq F$ be a finite perimeter set and assume that $\mathcal{F}_F(E) = \min\{\mathcal{F}_F(B) : B \subseteq F\}$. Then $E \in \mathcal{A}$.*

The equivalence (a) $\Longleftrightarrow$ (c) of the next theorem in the crystalline case has been investigated in [13].

THEOREM 5.3. *The following conditions are equivalent:*

(a) *There exists a vector field $z : F \to R^2$ satisfying*

$$z \in L^\infty(F;R^2), \quad \begin{cases} -\operatorname{div} z = J_0 & \text{in } \mathcal{D}'(F), \\ \|z\|_\infty \le 1, & \\ [z,\nu^F] = -1 & \mathcal{H}^1\text{-a.e. on } \partial C_i,\ i \in \{0,\dots,k\}, \\ [z,\nu^F] = 1 & \mathcal{H}^1\text{-a.e. on } \partial C_j,\ j \in \{k+1,\dots,m\}. \end{cases} \tag{5.5}$$

(b) *We have*

$$J_0 \int_F w \le \int_F |Dw| + \sum_{i=0}^{k} \int_{\partial C_i} w - \sum_{j=k+1}^{m} \int_{\partial C_j} w \qquad \forall w \in BV(F). \tag{5.6}$$

(c) *For any set $E \subseteq F$ of finite perimeter in F we have $\mathcal{F}_F(E) \ge 0$.*

(d) *We have*

$$\min_{E \in \mathcal{A}} \mathcal{F}_F(E) = 0. \tag{5.7}$$

Proof. We divide the proof into several steps.

Step 1. Let Ω be an open bounded connected subset of R^2 with $\mathcal{C}^{1,1}$ boundary, $f \in L^2(\Omega)$, $g \in L^\infty(\partial\Omega)$, and $\lambda > 0$. Assume that $\|g\|_\infty < 1$. A function $u \in BV(\Omega) \subset L^2(\Omega)$ is a solution of

$$\min_{w\in BV(\Omega)} \mathcal{E}(w), \qquad \mathcal{E}(w) := \int_\Omega |Dw| + \frac{1}{2\lambda}\int_\Omega (w-f)^2\,dx - \int_{\partial\Omega} gw \tag{5.8}$$

if and only if there exists $z \in X_2(\Omega)$, with $\|z\|_\infty \le 1$, satisfying $(z, Du) = |Du|$ as measures in Ω, $[z, \nu^\Omega] = g\,\mathcal{H}^1$-almost everywhere on $\partial\Omega$ and $-\lambda \mathrm{div} z = f - u$ in $\mathcal{D}'(\Omega)$.

We observe that the functional $\mathcal{E}$ is convex and L^1-lower semicontinuous. Moreover, since $\|g\|_\infty < 1$ and $\partial\Omega$ is of class $\mathcal{C}^{1,1}$, using the results of Giusti [28] we get that $\mathcal{E}$ is coercive. Therefore it attains its minimum, which is also unique. Hence $u = \mathrm{argmin}\,\mathcal{E}$ if and only if $0 \in \partial\mathcal{E}(u)$, where ∂ denotes the subdifferential in L^2.

We now define the operator $\mathcal{A}_g$ in $L^2(\Omega)\times L^2(\Omega)$ as follows: $(w, v) \in \mathcal{A}_g$ if and only if $w \in BV(\Omega)$, $v \in L^2(\Omega)$, and there is a vector field $z \in L^\infty(\Omega, R^2)$ with $\|z\|_\infty \le 1$ such that $(z, Dw) = |Dw|$, $-\mathrm{div}\, z = v$ in $\mathcal{D}'(\Omega)$, and $[z, \nu^\Omega] = g\,\mathcal{H}^1$-almost everywhere on $\partial\Omega$. Let us prove that the operator $\mathcal{A}_g$ is maximal monotone. As a consequence, since $\mathcal{A}_g \subseteq \partial\mathcal{E}$ and both are maximal monotone, we conclude that $\mathcal{A}_g = \partial\mathcal{E}$. This will prove Step 1.

The monotonicity of $\mathcal{A}_g$ follows by an integration by parts. To prove the maximal monotonicity, we have to solve

$$f \in u + \mathcal{A}_g u \qquad \forall f \in L^2(\Omega). \tag{5.9}$$

First, we assume that $f \in L^\infty(\Omega)$. Let us approximate (5.9) by

$$\begin{cases} u - \mathrm{div}(\mathcal{T}_\epsilon u) = f & \text{in } \Omega, \\ [\mathcal{T}_\epsilon u, \nu^\Omega] = g & \text{in } \partial\Omega, \end{cases} \qquad \mathcal{T}_\epsilon u := \frac{Du}{\sqrt{\epsilon^2 + |Du|^2}}. \tag{5.10}$$

Following [28], we have that (5.10) has a unique solution $u_\epsilon \in BV(\Omega)$. If we further assume that $f \in W^{1,\infty}(\Omega)$, we have $u_\epsilon \in W^{1,1}(\Omega)$ (actually $u_\epsilon \in C^{2,\alpha}(\overline{\Omega})$; see [28]).

Let us prove the basic estimates required to pass to the limit as $\epsilon \to 0$.

(i) L^2 and bounded variation estimates on u_ϵ when $f \in L^\infty(\Omega)$: multiplying (5.10) by u_ϵ, after integration by parts, we get

$$\int_\Omega u_\epsilon^2 + \int_\Omega \mathcal{T}_\epsilon u_\epsilon \cdot Du_\epsilon = \int_\Omega f u_\epsilon + \int_{\partial\Omega} g u_\epsilon.$$

Since $\frac{x^2}{\sqrt{\epsilon^2+x^2}} \ge |x| - \epsilon$ for all $x \in R$, from the above estimate we have

$$\int_\Omega u_\epsilon^2 + \int_\Omega |Du_\epsilon| \le \epsilon|\Omega| + \int_\Omega f u_\epsilon + \int_{\partial\Omega} g u_\epsilon. \tag{5.11}$$

Now, using [28, Lemma 1.2] and $\|g\|_\infty =: 1 - 2\sigma < 1$, there is a constant c depending on σ, g, Ω, such that

$$\left|\int_{\partial\Omega} gw\right| \le (1-\sigma)\int_\Omega |Dw| + c\int_\Omega |w| \qquad \forall w \in BV(\Omega). \tag{5.12}$$

Inserting (5.12) in (5.11) we obtain the estimate

$$\frac{1}{2}\int_\Omega u_\epsilon^2 + \sigma\int_\Omega |Du_\epsilon| \le (\epsilon + c^2)|\Omega| + \|f\|_2^2.$$

Thus, by extracting a subsequence, if necessary, we may assume that $u_\epsilon \to u$ in $L^p(\Omega)$ for any $1 \le p < 2$ and weakly in $L^2(\Omega)$, where $u \in BV(\Omega)$.

(ii) L^3 estimate on u_ϵ when $f \in W^{1,\infty}(\Omega)$. We multiply (5.10) by $|T_k(u_\epsilon)|u_\epsilon$. After integrating by parts we obtain

$$\int_\Omega u_\epsilon^2 |T_k(u_\epsilon)| + \int_\Omega \mathcal{T}_\epsilon u_\epsilon \cdot D(|T_k(u_\epsilon)|u_\epsilon) = \int_\Omega f|T_k(u_\epsilon)|u_\epsilon + \int_{\partial\Omega} g|T_k(u_\epsilon)|u_\epsilon.$$

Using (5.12) and

$$\int_\Omega \mathcal{T}_\epsilon u_\epsilon \cdot D(|T_k(u_\epsilon)|u_\epsilon) \geq \int_\Omega |D(|T_k(u_\epsilon)|u_\epsilon)| - \epsilon \int_\Omega [|u_\epsilon| + |T_k(u_\epsilon)|]$$

we obtain

$$\int_\Omega u_\epsilon^2 |T_k(u_\epsilon)| + \sigma \int_\Omega |D(|T_k(u_\epsilon)|u_\epsilon| \leq (\|f\|_\infty + c) \int_\Omega |T_k(u_\epsilon)||u_\epsilon| + \epsilon \int_\Omega |u_\epsilon| + \epsilon \int_\Omega |T_k(u_\epsilon)|.$$

Since u_ϵ is bounded in $L^2(\Omega)$, letting $k \to \infty$, we deduce that u_ϵ is bounded in $L^3(\Omega)$. Thus also $u \in L^3(\Omega)$.

Now,

$$\int_\Omega (u_\epsilon - u)^2\, dx \leq \left(\int_\Omega |u_\epsilon - u|^3\, dx\right)^{1/2} \left(\int_\Omega |u_\epsilon - u|\, dx\right)^{1/2} \to 0 \quad \text{as } \epsilon \to 0.$$

Thus we may extract a sequence u_ϵ converging in $L^2(\Omega)$ to some function $u \in BV(\Omega)$. Moreover, we may assume that $\mathcal{T}_\epsilon u_\epsilon \to z$ weakly* in $L^\infty(\Omega, R^2)$. Letting $\epsilon \to 0$ in (5.10) we have

$$u - \operatorname{div} z = f \quad \text{in } \mathcal{D}'(\Omega). \tag{5.13}$$

Still we have to prove that $(z, Du) = |Du|$ and $[z, \nu^\Omega] = g$.

Let φ be a smooth function in Ω, continuous up to $\partial\Omega$. We multiply (5.10) by φ and integrate by parts to obtain

$$\int_\Omega u_\epsilon \varphi + \int_\Omega \mathcal{T}_\epsilon u_\epsilon \cdot \nabla\varphi - \int_{\partial\Omega} [\mathcal{T}_\epsilon u_\epsilon, \nu^\Omega]\varphi = \int_\Omega f\varphi. \tag{5.14}$$

Letting $\epsilon \to 0$ and using that $[\mathcal{T}_\epsilon u_\epsilon, \nu^\Omega] = g$, we obtain

$$\int_\Omega u\varphi + \int_\Omega z \cdot \nabla\varphi - \int_{\partial\Omega} g\varphi = \int_\Omega f\varphi. \tag{5.15}$$

Integrating by parts the second term of the above equality, we get

$$\int_\Omega u\varphi - \int_\Omega \operatorname{div} z\, \varphi + \int_{\partial\Omega} ([z, \nu^\Omega] - g)\varphi = \int_\Omega f\varphi. \tag{5.16}$$

Now, using (5.13) it follows that $\int_{\partial\Omega}([z, \nu^\Omega] - g)\varphi = 0$ for all test functions φ. This implies that $[z, \nu^\Omega] = g$ on $\partial\Omega$.

To prove that $(z, Du) = |Du|$, we observe that from the lower semicontinuity of $\mathcal{E}$ and the convergence $\int_\Omega (u_\epsilon - f)^2\, dx \to \int_\Omega (u - f)^2\, dx$ as $\epsilon \to 0$, we have

$$\begin{aligned}\int_\Omega |Du| - \int_{\partial\Omega} gu &\leq \liminf_\epsilon \left(\int_\Omega |Du_\epsilon| - \int_{\partial\Omega} gu_\epsilon\right) = \liminf_\epsilon \left(\int_\Omega (\mathcal{T}_\epsilon u_\epsilon, Du_\epsilon) - \int_{\partial\Omega} gu_\epsilon\right) \\ &= \liminf_\epsilon - \int_\Omega \operatorname{div} \mathcal{T}_\epsilon u_\epsilon\, u_\epsilon = - \int_\Omega \operatorname{div} z\, u \\ &= \int_\Omega (z, Du) - \int_{\partial\Omega} gu \leq \int_\Omega |Du| - \int_{\partial\Omega} gu.\end{aligned}$$

We conclude that $\int_\Omega (z, Du) = \int_\Omega |Du|$.

We have proved that there is a solution of (5.9) for each $f \in W^{1,\infty}(\Omega)$. Our next goal is to prove that the operator $\mathcal{A}_g$ is closed. As a consequence we obtain that (5.9) has a solution for each $f \in L^2(\Omega)$. To prove the closedness of $\mathcal{A}_g$, let $(u_n, v_n) \in \mathcal{A}_g$ be such that $(u_n, v_n) \to (u, v)$ in $L^2(\Omega) \times L^2(\Omega)$. Then there is a vector field $z_n \in L^\infty(\Omega, R^2)$ with $\|z_n\|_\infty \le 1$ such that $v_n = -\mathrm{div}\, z_n$, $(z_n, Du_n) = |Du_n|$ and $[z_n, \nu^\Omega] = g$. Modulo a subsequence, we may assume that $z_n \to z$ weakly* in $L^\infty(\Omega, R^2)$ with $\|z\|_\infty \le 1$. Since $v_n = -\mathrm{div}\, z_n \to -\mathrm{div}\, z$ in $\mathcal{D}'(\Omega)$, we have $v = -\mathrm{div}\, z$. The proofs of the facts $[z, \nu^\Omega] = g$ and $(z, Du) = |Du|$ follow the same arguments as those in the corresponding proofs above, and we shall omit the details. We conclude that $\mathcal{A}_g$ is closed in $L^2(\Omega)$. This ends the proof that $\mathcal{A}_g$ is maximal monotone and $\partial\mathcal{E} = \mathcal{A}_g$.

Step 2. The function $u \equiv 0$ is the solution of (5.8) if and only if f and g satisfy

$$\int_\Omega |Dw| \ge \frac{1}{\lambda} \int_\Omega wf\, dx + \int_{\partial\Omega} gw \qquad \forall w \in BV(\Omega). \tag{5.17}$$

The proof follows along the same lines as the proof of [12, Lemma 1]. Clearly $u \equiv 0$ is the solution of (5.8) if and only if

$$\int_\Omega |Dw| + \frac{1}{2\lambda} \int_\Omega (w - f)^2\, dx - \int_{\partial\Omega} gw \ge \frac{1}{2\lambda} \int_\Omega f^2\, dx \qquad \forall w \in BV(\Omega). \tag{5.18}$$

Replacing w by ϵw (where $\epsilon > 0$), expanding the L^2-norm, dividing by $\epsilon > 0$, and letting $\epsilon \to 0^+$, we have (5.17).

On the other hand, if (5.17) holds, (5.18) also holds. Finally note that, replacing w by $-w$, we see that we may replace the right-hand side of (5.17) by its absolute value.

Step 3. Problem (5.5) has a solution if and only if (5.6) holds.

Note that it is enough to prove inequality (5.6) only for functions $w \in BV(F)$, which do not change sign, i.e., $w \ge 0$ or $w \le 0$.

Suppose that (5.5) has a solution z. Let $w \in BV(F)$. Multiplying $-\mathrm{div} z = J_0$ on F by w and integrating by parts, we obtain that (5.6) holds.

Assume now that (5.6) holds. Multiplying (5.6) by $1 - \epsilon > 0$ we deduce that

$$(1-\epsilon)J_0 \int_F w \le \int_F |Dw| + (1-\epsilon) \sum_{i=0}^{k} \int_{\partial C_i} w - (1-\epsilon) \sum_{j=k+1}^{m} \int_{\partial C_j} w$$
$$\forall w \in BV(F).$$

Thus, by Step 2 with $\lambda = 1$ we deduce that $u = 0$ is a solution of (5.8) with $f = (1-\epsilon)J_0\chi_F$, and $g \equiv -(1-\epsilon)$ in ∂C_i, $i \in \{0, \dots, k\}$, and $g \equiv 1 - \epsilon$ in ∂C_j, $j \in \{k+1, \dots, m\}$, for all $\epsilon \in]0, 1[$. Then by Step 1, we know that there exists a solution $\xi_\epsilon \in L^\infty(F, R^2)$ such that $\|\xi_\epsilon\|_\infty \le 1$, $-\mathrm{div}\xi_\epsilon = (1-\epsilon)J_0\chi_F$, $[\xi_\epsilon, \nu^F] = g$. Letting $\epsilon \to 0$, we find a vector field z satisfying (5.5).

Step 4. Conditions (b) and (c) are equivalent.

(c) follows from (b) by taking $w = \chi_E$ in (5.6) for any set of finite perimeter $E \subseteq F$. (b) follows from (c) by means of the coarea formula. Indeed, let $w \in BV(F)$, $w \ge 0$. We have

$$J_0\int_F w\,dx = J_0\int_0^\infty\int_F \chi_{\{w\ge t\}}\chi_F\,dx\,dt = J_0\int_0^\infty |\{w\ge t\}\cap F|\,dt$$
$$\le \int_0^\infty P(\{w\ge t\},F)\,dt + \sum_{i=0}^{k}\int_0^\infty \mathcal{H}^1(\partial^*\{w\ge t\}\cap \partial C_i)\,dt$$
$$- \sum_{j=k+1}^{m}\int_0^\infty \mathcal{H}^1(\partial^*\{w\ge t\}\cap \partial C_j)\,dt$$
$$= \int_F |Dw| + \sum_{i=0}^{k}\int_{\partial C_i} w - \sum_{j=k+1}^{m}\int_{\partial C_j} w.$$

Let us prove the corresponding inequality for $w\in BV(F)$, $w\le 0$. First, we observe that, writing $F\setminus E$ instead of E in (c), we obtain

$$P(F\setminus E,F) + \sum_{i=0}^{k}\mathcal{H}^1(\partial^*(F\setminus E)\cap\partial C_i) - \sum_{j=k+1}^{m}\mathcal{H}^1(\partial^*(F\setminus E)\cap\partial C_j) - J_0|F\setminus E|\ge 0.$$

Since $P(F\setminus E,F) = P(E,F)$ and $\mathcal{H}^1(\partial^*(F\setminus E)\cap\partial C_l) = P(C_l) - \mathcal{H}^1(\partial^* E\cap\partial C_l)$, using (5.1), we may write the last equation as

$$P(E,F) + \sum_{j=k+1}^{m}\mathcal{H}^1(\partial^*E\cap\partial C_j) - \sum_{i=0}^{k}\mathcal{H}^1(\partial^*E\cap\partial C_i) + J_0|E|\ge 0. \tag{5.19}$$

Now, we may proceed as in the case where $w\ge 0$ but using (5.19) instead of (c). Indeed,

$$J_0\int_F w\,dx = -J_0\int_{-\infty}^0\int_F \chi_{\{w\le t\}}\chi_F\,dx\,dt = -J_0\int_{-\infty}^0 |\{w\le t\}\cap F|\,dt$$
$$\le \int_{-\infty}^0 P(\{w\le t\},F)\,dt - \sum_{i=0}^{k}\int_{-\infty}^0 \mathcal{H}^1(\partial^*\{w\le t\}\cap\partial C_i)\,dt$$
$$+ \sum_{j=k+1}^{m}\int_{-\infty}^0 \mathcal{H}^1(\partial^*\{w\le t\}\cap\partial C_j)\,dt$$
$$= \int_F |Dw| + \sum_{i=0}^{k}\int_{\partial C_i} w - \sum_{j=k+1}^{m}\int_{\partial C_j} w.$$

Finally, if $w\in BV(F)$, we decompose $w = w^+ + w^-$, write the corresponding inequalities (5.6) for w^+ and w^-, and add them to obtain that (5.6) holds for w.

Step 5. Condition (c) is equivalent to

$$\min_{E\subseteq F}\mathcal{F}_F(E) = \mathcal{F}_F(\emptyset) = \mathcal{F}_F(F) = 0, \tag{5.20}$$

where the minimum is taken on the sets $E\subseteq F$ of finite perimeter. Moreover, any set $E\subseteq F$ of finite perimeter minimizing the left-hand side of (5.20) belongs to $\mathcal{A}$ by Theorem 5.2; therefore condition (c) is equivalent to condition (d). □

Given a set $E\subseteq R^2$, of finite perimeter in R^2, we define the functional $\mathcal{G}$ as

$$\mathcal{G}(E) := P(E) - \sum_{j=k+1}^{m} P(C_j) - J_0|E\cap F|.$$

Remark 5. Recalling the definition of J_0, we have $\mathcal{G}(F \cup (\bigcup_{j=k+1}^m C_j)) = 0$.

PROPOSITION 5.4. *The following conditions are equivalent:*

(a) *The set* $F \cup (\bigcup_{j=k+1}^m C_j)$ *is a solution of the variational problem*

$$\min\left\{\mathcal{G}(E) : \bigcup_{j=k+1}^m C_j \subseteq E \subseteq C_0 \setminus \bigcup_{i=1}^k \overline{C}_i\right\}. \tag{5.21}$$

(b) *There exists a vector field* z *satisfying* (5.5).

Remark 6. If $k = 0$ in Proposition 5.4, the last inclusion in (5.21) must be understood as $E \subseteq C_0$.

Proof of Proposition 5.4. Assume that there exists a vector field z satisfying (5.5). Given a finite perimeter set $E \subset R^2$ such that $\bigcup_{j=k+1}^m C_j \subseteq E \subseteq C_0 \setminus \bigcup_{i=1}^k \overline{C}_i$, we integrate the divergence of z on $E \cap F$ and obtain

$$\begin{aligned} J_0|E \cap F| &= -\int_{E\cap F} \operatorname{div} z \, dx \\ &\le P(E \cap F, F) + \sum_{i=0}^k \mathcal{H}^1(\partial^*(E \cap F) \cap \partial C_i) - \mathcal{H}^1\left(\partial^*(E \cap F) \cap \left(\bigcup_{j=k+1}^m C_j\right)\right) \\ &= P(E) - \sum_{j=k+1}^m P(C_j). \end{aligned}$$

It follows that $\mathcal{G}(E) \ge 0$, and (a) follows.

Let us now assume that (a) holds. Let $D \subset F$ be a set of finite perimeter. By Theorem 5.3 (see condition (c)), to obtain a vector field satisfying (5.5) it is enough to prove that

$$P(D) - 2\sum_{j=k+1}^m \mathcal{H}^1(\partial^* D \cap \partial C_j) \ge J_0|D|. \tag{5.22}$$

Set $A := D \cup \bigcup_{j=k+1}^m C_j$. By assumption we have

$$\begin{aligned} 0 \le \mathcal{G}(A) &= P(A) - \sum_{j=k+1}^m P(C_j) - J_0|D| \\ &= P(D) - 2\sum_{j=k+1}^m \mathcal{H}^1(\partial^* D \cap \partial C_j) + \sum_{j=k+1}^m P(C_j) - \sum_{j=k+1}^m P(C_j) - J_0|D|, \end{aligned}$$

which is (5.22). □

Remark 7. If we consider the case in which $k = 0$, then J_0 tends to zero as C_0 tends to R^2; in this case, the minimum problem (5.21) reduces to the problem considered in [12, Theorem 6].

5.1. Characterization through the curvature of the boundaries. The aim of this subsection is to prove Theorem 5.10, which is a characterization of the solvability of problem (5.5) through pointwise curvature conditions on the boundaries of the sets C_i. We begin with some preliminaries. The next definition is taken from [18, Theorem 4.1].

DEFINITION 5.5. *Let $\Omega \subseteq R^2$ be an open set with boundary of class $\mathcal{C}^{1,1}$ and $\rho > 0$. We say that Ω satisfies the ρ-ball condition if an open ball of radius ρ can be rotated along $\partial\Omega$ in Ω in such a way that no antipods of the ball lie on $\partial\Omega$.*

It is clear that if Ω satisfies the ρ-ball condition, then it satisfies the σ-ball condition for any $\sigma \in]0, \rho]$.

LEMMA 5.6. *Let $\Omega \subseteq R^2$ be an open set satisfying the ρ-ball condition for some $\rho > 0$. Then $\operatorname{ess\,sup}_{\partial\Omega} \kappa_{\partial\Omega} \leq \frac{1}{\rho}$. Moreover, given an open ball $B_\rho \subset \Omega$ of radius ρ and tangent to $\partial\Omega$, the set $\gamma \cap \partial B_\rho$ is connected for any connected component γ of $\partial\Omega$ and spans an angle strictly less than π.*

Proof. The inequality $\operatorname{ess\,sup}_{\partial\Omega} \kappa_{\partial\Omega} \leq \frac{1}{\rho}$ is immediate. Now let $p, q \in \partial B_\rho \cap \partial\Omega$, and denote by $\gamma \subset \partial B_\rho$ the shortest of the two circular arcs in ∂B_ρ having p and q as boundary points (such a γ is uniquely determined since p and q cannot be antipodal by the ρ-ball condition). If $\gamma \not\subset \partial\Omega$, we slightly rotate B_ρ along $\partial\Omega$ around p towards q, and denoting by B' such a rotated ball, one verifies that q belongs to the interior of B', thus violating the ρ-ball condition. Hence $\gamma \subseteq \partial B_\rho \cap \partial\Omega$, and γ spans an angle strictly less than π. □

Remark 8. In general, the inequality $\operatorname{ess\,sup}_{\partial\Omega} \kappa_{\partial\Omega} \leq \frac{1}{\rho}$ does not imply the ρ-ball condition for the set Ω. However, if Ω is a convex set with boundary of class $\mathcal{C}^{1,1}$ such that $\operatorname{ess\,sup}_{\partial\Omega} \kappa_{\partial\Omega} < \frac{1}{\rho}$, then Ω satisfies the ρ-ball condition.

Remark 9. If C_l is convex for any $l \in \{0, \dots, m\}$, $\operatorname{ess\,sup}_{\partial C_0} \kappa_{\partial C_0} < J_0$ (in particular $J_0 > 0$), and

$$\operatorname{dist}(\partial C_l, \partial C_h) > \frac{2}{J_0} \qquad \forall (l, h) \in \{0, \dots, m\},\ l \neq h,$$

then F satisfies the $\frac{1}{J_0}$-ball condition.

Given a function $f \in W^{1,1}(]a, b[) \cap C^{1,1}(]a, b[)$, we denote by $\kappa(x, f(x))$ the curvature of the graph of f at the point $(x, f(x))$, i.e.,

$$\kappa(x, f(x)) := -\frac{f''(x)}{(1 + f'^2(x))^{3/2}} \quad \text{for a.e. } x \in\ ]a, b[.$$

LEMMA 5.7. *Let $f, g \in W^{1,1}(]a, b[) \cap C^{1,1}(]a, b[)$ be such that $f \leq g$ on $[a, b]$, and $f(a) = g(a)$, $f(b) = g(b)$. Assume that $\operatorname{ess\,inf}_{]a,b[} \kappa(x, f(x)) \geq \operatorname{ess\,sup}_{]a,b[} \kappa(x, g(x)) \geq 0$. Then $f = g$.*

Proof. By a smoothing argument we can assume that $f, g \in C^2(]a, b[)$. Suppose by contradiction that $f \neq g$, and let $c := \max_{[a,b]}(g - f) > 0$. Let us fix $\epsilon > 0$ and consider the function $f_\epsilon(x) := (1 - \epsilon) f(x/(1 - \epsilon))$, $x \in [(1 - \epsilon)a, (1 - \epsilon)b]$. Then, for ϵ small enough, the function $g - f_\epsilon$ attains its maximum at a point $\overline{x} \in]a, b[\cap](1 - \epsilon)a, (1 - \epsilon)b[$. Hence $g'(\overline{x}) = f'_\epsilon(\overline{x})$, $g''(\overline{x}) \leq f''_\epsilon(\overline{x})$. It follows that

$$\kappa(\overline{x}, g(\overline{x})) \geq \kappa(\overline{x}, f_\epsilon(\overline{x})) = \frac{1}{1 - \epsilon} \kappa\left(\frac{\overline{x}}{1 - \epsilon}, f\left(\frac{\overline{x}}{1 - \epsilon}\right)\right) > \kappa\left(\frac{\overline{x}}{1 - \epsilon}, f\left(\frac{\overline{x}}{1 - \epsilon}\right)\right),$$

which gives a contradiction. □

LEMMA 5.8. *Let K_0 and K_1 be two bounded strictly convex sets of class $\mathcal{C}^{1,1}$ in the plane, with $K_1 \subseteq K_0$ and $K_1 \neq K_0$. Assume that $\operatorname{ess\,sup}_{\partial K_0} \kappa_{\partial K_0} \leq \operatorname{ess\,inf}_{\partial K_1} \kappa_{\partial K_1}$. Then either $\partial K_0 \cap \partial K_1 = \emptyset$ or $\partial K_0 \cap \partial K_1$ is a connected arc which spans an angle strictly less than π.*

Proof. Let Γ be a connected component of $\partial K_0 \setminus \partial K_1$, and assume that $\Gamma \neq \partial K_0$. It is enough to prove that Γ spans an angle strictly greater than π. Assume by

contradiction that Γ spans an angle less than or equal to π. Then there exists an arc $\Gamma' \subset \partial K_1 \setminus \partial K_0$ which also spans an angle less than or equal to π and has the same endpoints as Γ. By the strict convexity of K_0 and K_1, and with a proper choice of a coordinate system, we may assume that Γ' and Γ are, respectively, the graphs of two functions f and g, which satisfy the assumptions of Lemma 5.7. We get a contradiction from that lemma. □

We recall the following result, which follows from [34, (6.52)].

PROPOSITION 5.9. *Let K_0 and K_1 be two bounded convex sets of class $\mathcal{C}^{1,1}$ in the plane, with $K_1 \subseteq K_0$. Assume that* $\operatorname{ess\,sup}_{\partial K_0} \kappa_{\partial K_0} \leq \operatorname{ess\,inf}_{\partial K_1} \kappa_{\partial K_1}$. *Then*

$$2\pi(|K_0| + |K_1|) - P(K_0)P(K_1) \geq 0.$$

Moreover the inequality is strict if $K_1 \subset\subset K_0$.

Remark 10. Let $\lambda > 0$. Then the function

$$\rho \to P(B_\rho) - \lambda |B_\rho| = \pi(2\rho - \lambda\rho^2)$$

attains its maximum at $\rho = 1/\lambda$.

We are now in a position to prove the main result of this section.

THEOREM 5.10. *Assume that there exists a vector field $z : F \to R^2$ satisfying* (5.5). *Then*

$$\operatorname*{ess\,sup}_{\partial C_0} \kappa_{\partial C_0} \leq J_0, \tag{5.23}$$

$$\operatorname*{ess\,inf}_{\partial C_i} \kappa_{\partial C_i} \geq -J_0, \qquad i \in \{1, \dots, k\}, \tag{5.24}$$

$$\operatorname*{ess\,inf}_{\partial C_j} \kappa_{\partial C_j} \geq J_0, \qquad j \in \{k+1, \dots, m\}. \tag{5.25}$$

Conversely, assume that

(a) *the inequality* (5.25) *holds;*

(b) *$F \cup (\bigcup_{j=k+1}^m C_j)$ satisfies the $\frac{1}{J_0}$-ball condition;*

(c) $\operatorname{dist}(\partial C_l, \partial C_h) > \frac{2}{J_0}$ *for all $(l,h) \in \{0, \dots, k\}^2 \cup \{k+1, \dots, m\}^2$, $l \neq h$.*

Then there exists a vector field $z : F \to R^2$ satisfying (5.5).

Remark 11. If $k = 0$ in Theorem 5.10, then condition (5.24) does not appear.

Proof of Theorem 5.10. Assume that problem (5.5) has a solution. Fix $j \in \{k+1, \dots, m\}$ and $x \in \partial C_j$. Let A be an open neighborhood of x where ∂C_j can be written as a graph; we can assume that $\overline{A} \subset C_0$ and $\overline{A} \cap (\cup_{l \in \{1,\dots,m,\}, l \neq j} C_l) = \emptyset$. We claim that

$$P(C_j) - J_0|C_j| \leq P(C_j \cup B) - J_0|C_j \cup B| \qquad \forall B \text{ Borel}, \ \overline{B} \subset A. \tag{5.26}$$

Let B be a Borel set with $\overline{B} \subseteq A$. We can assume that $P(B) < +\infty$. Define $E := B \cup \bigcup_{l=k+1}^m C_l$. Using Proposition 5.4 we have

$$0 \leq \mathcal{G}(E) = P(E) - \sum_{l=k+1}^m P(C_l) - J_0|E \cap F|.$$

Since $E \cap F = B \setminus C_j$ and $P(E) = P(C_j \cup B) + \sum_{l=k+1, l\neq j}^m P(C_l)$, we have

$$P(C_j \cup B) - J_0|B \setminus C_j| \geq P(C_j). \tag{5.27}$$

By substracting $J_0|C_j|$ to (5.27) we obtain (5.26). Then (5.25) is a consequence of Proposition 2.1.

Similarly, fix $x \in \partial C_0$ (resp., $x \in \partial C_i$ for some $i \in \{1, \dots, k\}$), and let A be an open neighborhood of x where ∂C_0 (resp., ∂C_i) can be written as a graph; we can assume that $\overline{A} \cap (\cup_{l \in \{1,\dots,m\}} C_l) = \emptyset$ (resp., $\overline{A} \subset C_0$, $\overline{A} \cap (\cup_{l \in \{1,\dots,m\}, l \neq i} C_i) = \emptyset$). Then

$$P(C_0) - J_0|C_0| \leq P(C_0 \setminus B) - J_0|C_0 \setminus B| \tag{5.28}$$

$$\text{(resp., } P(C_i) + J_0|C_i| \leq P(C_i \cup B) + J_0|C_i \cup B|) \tag{5.29}$$

for any Borel set B with $\overline{B} \subset A$. Indeed, define $E := (F \setminus B) \cup \bigcup_{j=k+1}^{m} C_j$. Using Proposition 5.4 and the equality $P(E) = P(C_0 \setminus B) + \sum_{i=1}^{k} P(C_i)$, we have

$$\begin{aligned} 0 \leq \mathcal{G}(E) &= P(E) - \sum_{j=k+1}^{m} P(C_j) - J_0|E \cap F| \\ &= P(C_0 \setminus B) - P(C_0) + \sum_{i=0}^{k} P(C_i) - \sum_{j=k+1}^{m} P(C_j) - J_0|E \cap F| \\ &= P(C_0 \setminus B) - P(C_0) + J_0|F| - J_0|E \cap F|, \end{aligned}$$

where in the last equality we have used the definition of J_0. We then get

$$P(C_0) - J_0|C_0| \leq P(C_0 \setminus B) - J_0(|E \cap F| + |C_0| - |F|) = P(C_0 \setminus B) - J_0|C_0 \setminus B|,$$

which is (5.28). Then (5.23) is a consequence of Proposition 2.1.

Eventually, in the case where $x \in \partial C_i$ for some $i \in \{1, \dots, k\}$, and A has been chosen as described above, we define again $E := (F \setminus B) \cup \left(\bigcup_{l=k+1}^{m} C_l\right)$. Then

$$\begin{aligned} 0 \leq \mathcal{G}(E) &= P(E) - \sum_{l=k+1}^{m} P(C_l) - J_0|E \cap F| \\ &= P(C_i \cup B) - P(C_i) + \sum_{l=0}^{k} P(C_l) - \sum_{l=k+1}^{m} P(C_l) - J_0|E \cap F| \\ &= P(C_i \cup B) - P(C_i) + J_0|F| - J_0|E \cap F|, \end{aligned}$$

which implies

$$\begin{aligned} P(C_i) + J_0|C_i| &\leq P(C_i \cup B) + J_0(|F| - |E \cap F| + |C_i|) \\ &= P(C_i \cup B) + J_0|C_i \cup B|, \end{aligned} \tag{5.30}$$

and, by Proposition 2.1, (5.24) follows.

Assume now that (a)–(c) hold. Notice that condition (b) implies (5.23), which, in turn, implies $J_0 > 0$. Observe also that, by (5.25), the sets $C_{k+1}, \dots, C_m$ are strictly convex.

Denote by $E_{\min} \in \mathcal{A}$ a solution of the minimum problem (5.7), with $E_{\min} \notin \{\emptyset, F\}$. By Theorem 5.3 and Remark 4, it is enough to prove that

$$\mathcal{F}_F(E_{\min}) \geq 0. \tag{5.31}$$

We can assume that $E_{\min}$ is connected, since the functional $\mathcal{F}_F$ is additive on connected components [5]. Recall that, by the definition of $\mathcal{A}$, the closure of (any connected component of) $E_{\min}$ must intersect ∂F.

Let Γ be a connected component of $F \cap \partial E_{\min}$, and let p, q be the endpoints of Γ, with $p \in \partial C_j$ and $q \in \partial C_i$, for some $i, j \in \{0, \dots, m\}$ (p not necessarily different from q). We recall that Γ meets tangentially ∂F (see conditions (5.2)–(5.4)) and, by assumption (b), Γ is contained in the boundary of an open ball $B \subseteq F \cup (\bigcup_{n=k+1}^{m} C_n)$ of radius $\frac{1}{J_0}$. We now divide the proof into three steps. We first show that p and q cannot belong both to the same ∂C_i when $i \le k$.

Step 1. If $i \le k$, then $i \neq j$.

Assume by contradiction that $i = j \le k$. Using assumption (b), by Lemma 5.6 (applied with $\Omega := F \cup (\bigcup_{l=k+1}^{m} C_l)$) it follows that p and q are the extrema of an arc $\gamma \subseteq \partial B \cap \partial C_i$ which spans an angle strictly less than π. Notice that $\partial B = \gamma \cup \Gamma$; moreover, recalling that the curvature (which is equal to $1/J_0$) of $E_{\min}$ inside F is positive, either $E_{\min} = B$ or $E_{\min} = B \setminus C_{\bar{j}}$ for some index $\bar{j} \ge k+1$. Observe that, in the latter case, $C_{\bar{j}} \subset\subset B$ and, by condition (c), there cannot be any other C_l, with $l \ge k+1$ and $l \neq \bar{j}$, with $C_l \subseteq B$. Let us consider a new set $E' := B' \setminus B$ if $E_{\min} = B$ (resp., $E' := B' \setminus C_{\bar{j}}$ if $E_{\min} = B \setminus C_{\bar{j}}$), where B' is a ball obtained by slightly translating B towards the interior of F, and slightly modifying its radius. By Remark 10 we have $\mathcal{F}_F(E') < \mathcal{F}_F(E_{\min})$, which contradicts the minimality of $E_{\min}$. We now show that either $i \le k$ and $j \ge k+1$ or vice versa.

Step 2. The cases $i, j \le k$ and $i, j \ge k+1$ cannot happen.

By assumption (c) and Step 1 it is clear that the case $i, j \le k$ cannot happen, nor can the case $i, j \ge k+1$ with $i \neq j$. We have to exclude the case $i = j \ge k+1$. Recalling that (5.25) implies the strict convexity of C_j, using (a) and (5.4), we have that $C_j \subseteq B$. Using again the strict convexity of C_j, Lemma 5.8 implies that $\partial C_j \cap \partial B$ is a connected arc which spans an angle strictly less than π. Hence we get a contradiction by slightly modifying $E_{\min}$ as in Step 1.

By Steps 1 and 2 we conclude that there exists an arc Γ of $F \cap \partial E_{\min}$ whose endpoints p, q satisfy $p \in \partial C_j$, $q \in \partial C_i$, and $i \in \{0, \dots, k\}$, $j \in \{k+1, \dots, m\}$.

In the following, we write C_i for $i \le k$, but we mean $R^2 \setminus \overline{C_0}$ when $i = 0$.

Let us call the inner (resp., outer) side of Γ the side of Γ inside (resp., outside) $E_{\min}$. Notice that from conditions (5.2)–(5.4) C_i cannot lie in the inner side of Γ and C_j cannot lie in the outer side of Γ. Moreover, since $J_0 > 0$ the inner (resp., outer) side of Γ is also the side of Γ inside (resp., outside) B.

Step 3. We have $B = E_{\min} \cup C_j$.

Let $p' \in \partial C_j$ be the endpoint of an arc $\Gamma' \subseteq F \cap \partial E_{\min}$. Then Γ' is contained in the boundary of an open ball $B' \subseteq F \cup \left(\bigcup_{l=k+1}^{m} C_l\right)$ of radius $\frac{1}{J_0}$. By assumption (c) Γ' cannot meet another set $C_{j'}$ with $j' \ge k+1$, $j' \neq j$. On the other hand, the above discussion implies $C_j \subseteq B'$. Let us suppose that the other endpoint q' of Γ' (different from p') belongs to $\partial C_{i'}$ for some $i' \le k$. Observe that $B' \cap C_{i'} = \emptyset$. If $i \neq i'$, then $B \neq B'$ (if $B = B' \ni \{q, q'\}$, then $\operatorname{dist}(C_i, C_{i'}) \le \frac{2}{J_0}$, a contradiction with assumption (c)). Since B and B' contain C_j, we have $B \cap B' \neq \emptyset$. Now, Γ is an arc of ∂B joining $p \in \overline{B} \cap \overline{B'}$ to $q \in \partial C_i \cap \overline{B}$, $q \notin \overline{B'}$, whereas Γ' is joining $p' \in \overline{B} \cap \overline{B'}$ to $q' \in \partial C_{i'} \cap \overline{B'}$, $q \notin \overline{B}$. It follows that either $\Gamma \cap \Gamma' \neq \emptyset$ or there exists another arc of $\partial B \cap \partial E_{\min} \cap F$ different from Γ intersecting Γ'; see Figure 5.1. Since these arcs intersect transversally, this contradicts the fact that $\partial E_{\min}$ is smooth. It follows that $i = i'$. Moreover, since $(B \cup B') \cap C_i = \emptyset$, for the same reason (i.e., the fact that $\partial E_{\min}$ is smooth) we also get $B = B'$.

The ball B cannot meet, nor contain, any other set $C_{i'}$ with $i' \le k$, $i \neq i'$, nor any other set $C_{j'}$ with $j' \ge k+1$, $j' \neq j$. Thus $B = E_{\min} \cup C_j$ (see Figure 5.2) and Step 3 is proved.

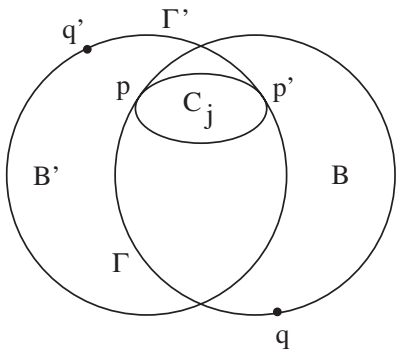

FIG. 5.1. *The two intersecting balls B and B'.*

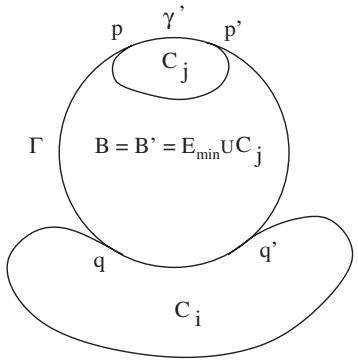

FIG. 5.2. *The minimizing set $E_{\min}$ $(i \geq 1)$.*

We now conclude the proof. Applying Proposition 5.9 with $K_1 = C_j$ and $K_0 = B$, we compute (see Figure 5.2)

$$\begin{aligned}\mathcal{F}_F(E_{\min}) &= P(E_{\min}, F) + \mathcal{H}^1(\partial C_i \cap \partial E_{\min}) - \mathcal{H}^1(\partial C_j \cap \partial E_{\min}) - J_0|E_{\min}| \\ &= \frac{2\pi}{J_0} - P(C_j) - J_0\left(\frac{\pi}{J_0^2} - |C_j|\right) = \frac{\pi}{J_0} - P(C_j) + J_0|C_j| \geq 0,\end{aligned}$$

which gives (5.31) and hence the thesis. □

PROPOSITION 5.11. *Let K_0, K_1 be two bounded open convex sets of R^2 with boundary of class $\mathcal{C}^{1,1}$ such that $\overline{K_1} \subseteq K_0$. Let $F := K_0 \setminus \overline{K_1}$. Let*

$$J := \frac{P(K_0) - P(K_1)}{|F|} > 0.$$

If

$$\operatorname{ess\,sup}_{\partial K_0} \kappa_{\partial K_0} \leq J, \tag{5.32}$$

$$\operatorname{ess\,inf}_{\partial K_1} \kappa_{\partial K_1} \geq J, \tag{5.33}$$

then there exists a vector field $z \in L^\infty(F, R^2)$ *with* $\|z\|_\infty \le 1$ *such that*

$$\begin{cases} -\operatorname{div} z = J & \text{in } \mathcal{D}'(F), \\ [z, \nu^F] = -1 & \mathcal{H}^1\text{-a.e. on } \partial K_0, \\ [z, \nu^F] = 1 & \mathcal{H}^1\text{-a.e. on } \partial K_1. \end{cases} \tag{5.34}$$

Remark 12. Proposition 5.11 admits a direct proof along the lines of [27]. Notice also that, thanks to Remark 9, Proposition 5.11 would be a consequence of Theorem 5.10 (in the case $k = 0$ and $m = 1$) if the strict inequality in (5.32) were valid.

Proof of Proposition 5.11. Let us prove that assumptions (a) and (b) of Theorem 5.10 hold for $F_\lambda := K_{0\lambda} \setminus \overline{K_{1\lambda}}$, where $K_{0\lambda} := (1+\lambda)K_0$, $K_{1\lambda} := (1-\lambda)K_1$, $\lambda > 0$ being small enough. We observe that $P(K_{0\lambda}) = (1+\lambda)P(K_0)$, $P(K_{1\lambda}) = (1-\lambda)P(K_1)$, $|K_{0\lambda}| = (1+\lambda)^2|K_0|$, and $|K_{1\lambda}| = (1-\lambda)^2|K_1|$; hence

$$J_\lambda := \frac{P(K_{0\lambda}) - P(K_{1\lambda})}{|F_\lambda|} = J + \frac{\lambda}{|F|}(P(K_0) + P(K_1) - 2J(|K_0| + |K_1|)) + o(\lambda).$$

Since

$$\operatorname*{ess\,sup}_{\partial K_{0\lambda}} \kappa_{\partial K_{0\lambda}} = \frac{1}{1+\lambda} \operatorname*{ess\,sup}_{\partial K_0} \kappa_{\partial K_0} \le \frac{1}{1+\lambda} J,$$

it suffices to prove that $\frac{1}{1+\lambda} J < J_\lambda$ to conclude that

$$\operatorname*{ess\,sup}_{\partial K_{0\lambda}} \kappa_{\partial K_{0\lambda}} < J_\lambda. \tag{5.35}$$

By Remark 8, this implies that $K_{0\lambda}$ satisfies the $\frac{1}{J_\lambda}$-ball condition. Now, $\frac{1}{1+\lambda} J < J_\lambda$ for λ small enough if and only if

$$2P(K_0)|K_1| < P(K_1)(|K_0| + |K_1|). \tag{5.36}$$

Since $\overline{K_1} \subset K_0$, using Proposition 5.9 and the isoperimetric inequality, we deduce

$$|K_0| + |K_1| > \frac{1}{2\pi} P(K_0)P(K_1) \ge 2\frac{P(K_0)|K_1|}{P(K_1)},$$

and we obtain (5.36), and therefore also (5.35).

Let us prove that condition (b) of Theorem 5.10 holds. Since

$$\operatorname*{ess\,inf}_{\partial K_{1\lambda}} \kappa_{\partial K_{1\lambda}} = \frac{1}{1-\lambda} \operatorname*{ess\,inf}_{\partial K_1} \kappa_{\partial K_1} \le \frac{1}{1-\lambda} J,$$

to conclude that

$$\operatorname*{ess\,sup}_{\partial K_{1\lambda}} \kappa_{\partial K_{1\lambda}} \ge J_\lambda, \tag{5.37}$$

it suffices to prove that $\frac{1}{1-\lambda} J \ge J_\lambda$. Now, $\frac{1}{1-\lambda} J > J_\lambda$ for λ small enough if and only if

$$2P(K_1)|K_0| < P(K_0)(|K_0| + |K_1|). \tag{5.38}$$

Again, since $\overline{K_1} \subseteq K_0$, using Proposition 5.9 and the isoperimetric inequality, we deduce

$$|K_0| + |K_1| > \frac{1}{2\pi} P(K_0)P(K_1) \ge 2\frac{P(K_1)|K_0|}{P(K_0)},$$

and we conclude that (5.38), and therefore also (5.37), holds.

By Theorem 5.10, there exists a vector field $z_\lambda \in L^\infty(F_\lambda, R^2)$ such that $\|z_\lambda\|_\infty \le 1$, satisfying

$$\begin{cases} -\operatorname{div} z_\lambda = J_\lambda & \text{in } \mathcal{D}'(F_\lambda), \\ [z_\lambda, \nu^{F_\lambda}] = -1 & \mathcal{H}^1\text{-a.e. on } \partial K_{0\lambda}, \\ [z_\lambda, \nu^{F_\lambda}] = 1 & \mathcal{H}^1\text{-a.e. on } \partial K_{1\lambda}. \end{cases}$$

Letting $\lambda \to 0^+$ we obtain a solution of (5.34). ∎

6. Solutions of div $z = 0$ in an unbounded domain. In this section we assume that $C_0 = R^2$, $k \ge 1$, we let $C_1, \dots, C_m$ be as in section 5, and we let $F := R^2 \setminus \bigcup_{i=1}^m \overline{C}_i$. We are concerned with the existence of a vector field $z : F \to R^2$ such that

$$(6.1)\quad z \in L^\infty(F, R^2), \quad \begin{cases} -\operatorname{div} z = 0 & \text{in } \mathcal{D}'(F), \\ \|z\|_\infty \le 1, & \\ [z, \nu^F] = -1 & \mathcal{H}^1\text{-a.e. on } \partial C_i,\ i \in \{1, \dots, k\}, \\ [z, \nu^F] = 1 & \mathcal{H}^1\text{-a.e. on } \partial C_j,\ j \in \{k+1, \dots, m\}. \end{cases}$$

THEOREM 6.1. *The following conditions are equivalent:*

(i) *Problem* (6.1) *has a solution.*

(ii) *We have*

$$(6.2)\qquad 0 \le \int_F |Dw| + \sum_{i=1}^k \int_{\partial C_i} w - \sum_{j=k+1}^m \int_{\partial C_j} w \qquad \forall w \in BV(F).$$

(iii) *For any $E \subseteq F$ of finite perimeter, we have*

$$(6.3)\qquad P(E, F) \ge \left| \sum_{j=k+1}^m \mathcal{H}^1(\partial^* E \cap \partial C_j) - \sum_{i=1}^k \mathcal{H}^1(\partial^* E \cap \partial C_i) \right|.$$

(iv) *Let E_1 be a solution of the variational problem*

$$(6.4)\qquad \min \left\{ P(E) : \bigcup_{j=k+1}^m C_j \subseteq E \subseteq R^2 \setminus \bigcup_{i=1}^k C_i \right\}.$$

Then we have

$$(6.5)\qquad P(E_1) = \sum_{j=k+1}^m P(C_j).$$

Let E_2 be a solution of the variational problem

$$(6.6)\qquad \min \left\{ P(E) : \bigcup_{i=1}^k C_i \subseteq E \subseteq R^2 \setminus \bigcup_{j=k+1}^m C_j \right\}.$$

Then we have

$$(6.7)\qquad P(E_2) = \sum_{i=1}^k P(C_i).$$

Remark 13. Notice that (iv) implies that each C_l is a convex set. Moreover, since any minimizer of problems (6.4) and (6.6) has boundary (lying inside F) made of a finite number of segments which intersect tangentially ∂F (and there are only a finite number of such segments), the number of such minimizers is finite. Finally, conditions (6.5) and (6.7) are essentially distance conditions between sets C_i of the same type; for example, they are satisfied if $\mathrm{dist}(\partial C_i, \partial C_j) > P(C_l)$ for any $(i,j,l) \in \{1,\dots,k\}^3 \cup \{k+1,\dots,m\}^3$, $i \neq j$.

Proof. We divide the proof into four steps.

Step 1. Let $f \in L^2(F)$, $g \in L^\infty(\partial F)$, $\lambda > 0$. The following hold:

(a) Assume that $\|g\|_\infty < 1$. The function u is the solution of

$$\min_{w \in BV(F)} Q(w), \qquad Q(w) := \int_F |Dw| + \frac{1}{2\lambda} \int_F (w-f)^2 \, dx - \int_{\partial F} gw \, d\mathcal{H}^1 \tag{6.8}$$

if and only if there exists $z \in X_2(F)$ with $\|z\|_\infty \leq 1$ satisfying $(z, Du) = |Du|$ as measures in F, $[z, \nu^F] = g$ $\mathcal{H}^1$-almost everywhere on ∂F and $-\lambda \mathrm{div} z = f - u$ in $\mathcal{D}'(F)$.

(b) The function $u \equiv 0$ is the solution of (6.8) if and only if

$$\int_F |Dw| \geq \frac{1}{\lambda} \int_F wf \, dx - \int_{\partial F} gw \qquad \forall w \in BV(F).$$

Let us prove both assertions. Let $R > 0$ be such that $R^2 \setminus F \subset\subset B_R = B_R(0)$. We consider the functional

$$Q_R(w) := \int_{B_R \cap F} |Dw| + \frac{1}{2\lambda} \int_{B_R \cap F} (w-f)^2 \, dx - \int_{\partial F} gw \, d\mathcal{H}^1 \tag{6.9}$$

defined for $w \in BV(B_R \cap F)$. Now, since $\|g\|_\infty < 1$ and ∂F is of class $\mathcal{C}^{1,1}$, using the results of Giusti [28], we know that the convex functional Q_R is lower semicontinuous and proper, and it attains its infimum in $BV(B_R \cap F)$. Let $w_n \to w$ in $L^2(B_R \cap F)$. Then $Q_R(w) \leq \liminf_n Q_R(w_n) \leq \liminf_n Q(w_n)$. Since this is true for all $R > 0$, we deduce that $Q(w) \leq \liminf_n Q(w_n)$. Thus, Q is convex, lower semicontinuous, and proper. As we shall note below, Q attains its infimum in $BV(F)$. Hence $u = \mathrm{argmin}\, Q$ if and only if $0 \in \partial Q(u)$.

Now, we define the operator $\mathcal{A}'_g$ in $L^2(F) \times L^2(F)$ as follows: $(w,v) \in \mathcal{A}'_g$ if and only if $w \in BV(F)$, $v \in L^2(F)$, and there is a vector field $z \in L^\infty(F, R^2)$ with $\|z\|_\infty \leq 1$ such that $(z, Dw) = |Dw|$ and $-\mathrm{div}\, z = v$ in $\mathcal{D}'(F)$, $[z, \nu^F] = g$ $\mathcal{H}^1$-almost everywhere on ∂F. We claim that the operator $\mathcal{A}'_g$ is maximal monotone. The monotonicity of $\mathcal{A}'_g$ follows by an integration by parts. To prove the maximal monotonicity we have to solve the equation

$$f \in u + \mathcal{A}'_g u \qquad \forall f \in L^2(F). \tag{6.10}$$

First, we assume that $f \in L^p(F)$ for any $p \in [1, \infty]$. Let us approximate (6.10) by

$$\begin{cases} u - \mathrm{div}\, z = f & \text{in } \mathcal{D}'(B_R \cap F), \\ [z, \nu^{B_R \cap F}] = g & \mathcal{H}^1\text{-a.e. in } \partial F, \\ [z, \nu^{B_R \cap F}] = 0 & \mathcal{H}^1\text{-a.e. in } \partial B_R, \end{cases} \tag{6.11}$$

where $z \in L^\infty(B_R \cap F, R^2)$ is such that $\|z\|_\infty \leq 1$ and $(z, Du) = |Du|$. Then, by Step 1 of the proof of Theorem 5.3, equation (6.11) has a unique solution u_R. Let z_R

denote the associated vector field. Let us comment on the basic estimates required to pass to the limit as $R \to \infty$.

(i) L^2 and bounded variation estimates on u_R: multiplying (6.11) by u_R, after integration by parts, we get

$$\int_{B_R\cap F} u_R^2 + \int_{B_R\cap F} |Du_R| = \int_{B_R\cap F} f u_R + \int_{\partial F} g u_R. \tag{6.12}$$

Now, using [28, Lemma 2.2], there exists $\epsilon_0 > 0$ such that, for each $\delta > 0$, there is $c(\delta) > 0$ such that

$$\left|\int_{\partial F} gw\right| \le \Big(1 - \frac{\epsilon_0}{2}\Big) \int_{S_\delta} |Dw| + c(\delta) \int_{S_\delta} |w| \qquad \forall w \in BV(B_R \cap F), \tag{6.13}$$

where $S_\delta := \{x \in B_R \cap F : \operatorname{dist}(x, \partial F) < \delta\}$, where the constant $c(\delta)$ does not depend on $R > 0$. Using (6.13) in (6.12) we obtain the estimate

$$\frac{1}{4} \int_{B_R\cap F} u_R^2 + \epsilon_0 \int_{B_R\cap F} |Du_R| \le \frac{1}{2}\|f\|_2^2 + C|S_\delta|.$$

Thus, by extracting a subsequence, if necessary, we may assume that $u_R \to u$ in $L^p_{\rm loc}$ for any $1 \le p < 2$ and weakly in $L^2(F)$ where $u \in L^2(F)$ and $\int_F |Du| < \infty$.

Let us mention that, as a consequence of (6.13), if $Q(u_n)$ is bounded, we obtain that $\int_F |u_n|^2$ and $\int_F |Du_n|$ are bounded and, therefore, Q attains its infimum.

(ii) L^p estimate on u_R: let $\eta_p : R \to R$ be a smooth function such that $\eta_p'(r) > 0$ for all $r \in R$, $\eta_p(0) = 0$, and $\operatorname{sign}(r)\eta_p(r)$ behaves as $|r|^{p-1}$ as $r \to \infty$. We multiply (6.11) by $\eta_p(u_R)$. Integrating by parts and using (6.13), we obtain

$$\int_{B_R\cap F} u_R \eta_p(u_R) \le \int_{B_R\cap F} |f||\eta_p(u_R)| + c(\delta) \int_{S_\delta} |\eta_p(u_R)|. \tag{6.14}$$

Let $p = 1$, and assume that $|\eta_1(r)| \le 1$ for any $r \in R$. We obtain

$$\int_{B_R\cap F} u_R \eta_1(u_R) \le \int_{B_R\cap F} |f| + c(\delta)|S_\delta|. \tag{6.15}$$

Take a sequence $\eta_{1,n}(r)$ such that $\eta_{1,n}(r) \to \operatorname{sign}(r)$ for any $r \ne 0$. Using Fatou's theorem we deduce that

$$\int_{B_R\cap F} |u_R| \le \int_{B_R\cap F} |f| + c(\delta)|S_\delta|.$$

Assume that u_R is bounded in L^q. Using $p = q$ in (6.14) and proceeding in the same way, we deduce that u_R is bounded in L^{q+1}. This implies that u_R is bounded in L^p for all $p < \infty$. Thus $u \in L^p(F)$ for any $1 \le p < \infty$.

Now, let $R > M > 0$, where M is such that all sets C_i are contained in $B_{M/4}(0)$. Let $\varphi \in W^{1,\infty}(R^2)$ be such that $\varphi = 0$ on $B_{M/2}(0)$, $\varphi = 1$ outside $B_M(0)$, and it increases linearly along the rays from 0 to 1 in $B_M(0) \setminus B_{M/2}(0)$. We multiply (6.11) by $u_R\varphi^2$ and integrate by parts to obtain

$$\int_{B_R\cap F} u_R^2\varphi^2 + \int_{B_R\cap F} |Du_R|\varphi^2 = \int_{B_R\cap F} f u_R\varphi^2 - \int_{B_R\cap F} u_R z_R \cdot \nabla(\varphi^2).$$

Hence

$$\int_{B_R\cap F} u_R^2\varphi^2 \le \int_{B_R\cap F} |f||u_R|\varphi^2 + \int_{B_R\cap F} |u_R|\varphi|\nabla\varphi| \le \frac{1}{2}\int_{B_R\cap F} |f|^2\varphi^2 + \frac{1}{2}\int_{B_R\cap F} |u_R|^2\varphi^2 + \|u_R\varphi\|_{3/2}\|\nabla\varphi\|_3.$$

As $|\nabla\varphi| \le \frac{2}{M}$ we have

$$\|\nabla\varphi\|_3 \le \frac{2}{M}\left(\frac{3}{4}\pi M^2\right)^{1/3} \le \frac{C}{M^{1/3}}.$$

Since $\|u_R\varphi\|_{3/2}$ is bounded independently of R and M, we have

$$\int_{B_R\cap F} u_R^2\varphi^2 \le C\int_{B_R\cap F} |f|^2\varphi^2 + \frac{C}{M^{1/3}}.$$

Thus, given $\epsilon > 0$ we find M large enough so that

$$\int_{B_R\cap F} u_R^2\varphi^2 \le \epsilon$$

for any $R > M$. Assume that u_R is extended by 0 outside B_R. Thus u_R is equi-integrable near infinity. Thus, to prove that $u_R \to u$ in $L^2(F)$ it is sufficient to prove that $u_R \to u$ in $L^2_{\rm loc}(F)$. For that, let $\varphi \in C_0^\infty(R^2)$. Then

$$\int_F |u_R - u|^2\varphi^2 \le \left(\int_F |u_R-u|^3\varphi^2\right)^{1/2}\left(\int_F |u_R-u|\varphi^2\right)^{1/2} \to 0 \quad \text{as } R\to\infty,$$

since the first integral is bounded independently of R and the second tends to 0 as $R\to\infty$.

The two previous estimates imply that we may extract a subsequence u_R converging in $L^2(F)$ to some function $u \in BV(F)$. Moreover, we may assume that $z_R \to z$ weakly* in $L^\infty(F, R^2)$. Letting $R\to\infty$ in (6.11) we have

$$u - \operatorname{div} z = f \quad \text{in } \mathcal{D}'(F). \tag{6.16}$$

We still have to prove that $(z, Du) = |Du|$ and $[z, \nu^F] = g$.

Let φ be a smooth function in F, continuous up to ∂F and vanishing for large values of $|x|$. We multiply (6.11) by φ and integrate by parts to obtain

$$\int_{B_R\cap F} u_R\varphi + \int_{B_R\cap F} z_R\cdot\nabla\varphi - \int_{\partial F}[z_R, \nu^{B_R\cap F}]\varphi = \int_{B_R\cap F} f\varphi. \tag{6.17}$$

Letting $R\to\infty$ and using that $[z_R, \nu^{B_R\cap F}] = g$, we obtain

$$\int_F u\varphi + \int_F z\cdot\nabla\varphi - \int_F g\varphi = \int_F f\varphi. \tag{6.18}$$

Integrating by parts the second term of the above equality, we get

$$\int_F u\varphi - \int_F \operatorname{div} z\,\varphi + \int_{\partial F}([z,\nu^F] - g)\varphi = \int_F f\varphi. \tag{6.19}$$

Using (6.16) it follows that $\int_{\partial F}([z,\nu^F]-g)\varphi = 0$ for any φ. This implies that $[z,\nu^F]=g$ on ∂F. To prove that $(z,Du)=|Du|$, we observe that from the lower semicontinuity of Q and the convergence $\int_{B_R\cap F}(u_R-f)^2\,dx \to \int_F (u-f)^2\,dx$ as $R\to\infty$, we have

$$\begin{aligned}\int_F |Du| - \int_{\partial F} gu &\le \liminf_R \left(\int_{B_R\cap F}|Du_R| - \int_{\partial F} gu_R\right)\\ &= \liminf_R\left(\int_{B_R\cap F}(z_R,Du_R) - \int_{\partial F} gu_R\right) = \liminf_R -\int_{B_R\cap F}\operatorname{div} z_R\, u_R = -\int_F \operatorname{div} z\, u\\ &= \int_F (z,Du) - \int_{\partial F} gu \le \int_F |Du| - \int_{\partial F} gu.\end{aligned}$$

We conclude that $\int_F (z,Du) = \int_F |Du|$.

We have proved that there is a solution of (6.10) for each $f\in L^\infty(F)\cap L^2(F)$. Our next purpose is to prove that the operator $\mathcal{A}'_g$ is closed. As a consequence we obtain that (6.10) has a solution for any $f\in L^2(B_R\cap F)$. To prove the closedness of $\mathcal{A}'_g$, let $(u_n,v_n)\in\mathcal{A}'_g$ be such that $(u_n,v_n)\to(u,v)$ in $L^2(F)\times L^2(F)$. Then there is a vector field $z_n\in L^\infty(F,R^2)$ with $\|z_n\|_\infty\le 1$ such that $v_n=-\operatorname{div} z_n$, $(z_n,Du_n)=|Du_n|$ and $[z_n,\nu^F]=g$. Up to a subsequence, we may assume that $z_n\to z$ weakly* in $L^\infty(F,R^2)$ with $\|z\|_\infty\le 1$. Since $v_n=-\operatorname{div} z_n\to -\operatorname{div} z$ in $\mathcal{D}'(F)$, we have $v=-\operatorname{div} z$. The proofs of the facts $[z,\nu^F]=g$ and $(z,Du)=|Du|$ follow the same arguments as the corresponding proofs in Theorem 5.3, and we shall omit the details. We conclude that $\mathcal{A}'_g$ is closed.

Since $\mathcal{A}'_g\subseteq\partial Q$ and both are maximal monotone, we conclude that $\mathcal{A}'_g=\partial Q$. This proves (a).

The proof of (b) follows along the same lines as the proof of Step 2 in Theorem 5.3.

Step 2. (i) $\Longleftrightarrow$ (ii). Note that, as before, we may replace the condition "$\forall w\in BV(F)$" by "$\forall w\in BV(F)$ such that $w\ge 0$ or $w\le 0$."

Suppose that (6.1) has a solution z. Let $w\in BV(F)$. Multiplying (6.1) by w and integrating by parts, we obtain (6.2).

Assume now that (6.2) holds for any $w\in BV(F)$. Multiplying (6.2) by $(1-\epsilon)$, we deduce that

$$0\le \int_F |Dw| + (1-\epsilon)\sum_{i=1}^k \int_{\partial C_i} w - (1-\epsilon)\sum_{j=k+1}^m \int_{\partial C_j} w \qquad \forall w\in BV(F).$$

Using Step 1(b), we deduce that $u\equiv 0$ is a solution of (6.8) with $f=0$, and $g\equiv 1-\epsilon$ on ∂C_j and $g\equiv -(1-\epsilon)$ on ∂C_i for all $\epsilon>0$. Then by Step 2(a), we know that there exists a solution $\xi_\epsilon\in L^\infty(F,R^2)$ such that $\|\xi_\epsilon\|_\infty\le 1$, $-\operatorname{div}\xi_\epsilon=0$, $[\xi_\epsilon,\nu^F]=g$. Letting $\epsilon\to 0$, we find a vector field z satisfying (6.1).

The equivalence between (ii) and (iii) can be proved in the same manner as the equivalence between (b) and (c) in Theorem 5.3 was, and we shall omit the details.

Step 3. (iii)$\Rightarrow$(iv). Let $X:=E_1\setminus\bigcup_{j=k+1}^m C_j$. Using (iii) we have

$$\sum_{j=k+1}^m \mathcal{H}^1(\partial^* X\cap\partial C_j) - \sum_{i=1}^k \mathcal{H}^1(\partial^* X\cap\partial C_i)\le P(X,F). \tag{6.20}$$

Using Lemma 2.2, we have

$$P(E_1)=P\left(X\cup\bigcup_{j=k+1}^m C_j\right)=P(X)+\sum_{j=k+1}^m P(C_j)-2\mathcal{H}^1\left(\partial^* X\cap\left(\bigcup_{j=k+1}^m \partial C_j\right)\right).$$

Then, using (6.20), we have

$$\begin{aligned}
P(E_1) &= P(X) + \sum_{j=k+1}^{m} P(C_j) - 2 \sum_{j=k+1}^{m} \mathcal{H}^1(\partial^* X \cap \partial C_j) \\
&= P(X,F) + \sum_{j=k+1}^{m} \mathcal{H}^1(\partial^* X \cap \partial C_j) + \sum_{i=1}^{k} \mathcal{H}^1(\partial^* X \cap \partial C_i) \\
&\quad + \sum_{j=k+1}^{m} P(C_j) - 2 \sum_{j=k+1}^{m} \mathcal{H}^1(\partial^* X \cap \partial C_j) \\
&= P(X,F) + \sum_{i=1}^{k} \mathcal{H}^1(\partial^* X \cap \partial C_i) + \sum_{j=k+1}^{m} P(C_j) - \sum_{j=k+1}^{m} \mathcal{H}^1(\partial^* X \cap \partial C_j) \\
&\geq \sum_{j=k+1}^{m} P(C_j).
\end{aligned}$$

The proof for the set E_2 is analogous.

Step 4. (iv)⇒(iii). Let $X \subseteq F$ be a set of finite perimeter. Let E_1 be a minimizer of (6.4) and set $D := \bigcup_{j=k+1}^{m} C_j$. Using (6.5) and the minimality of E_1, we have

$$\sum_{j=k+1}^{m} P(C_j) = P(E_1) \leq P\left(X \cup D\right). \tag{6.21}$$

Using Lemma 2.2 and (6.21), we have

$$\begin{aligned}
P\left(X \cup D\right) &= P(X) + P(D) - 2\mathcal{H}^1(\partial D \cap \partial^* X) \\
&\leq P(X) + P(X \cup D) - 2\mathcal{H}^1(\partial D \cap \partial^* X).
\end{aligned}$$

Hence

$$\begin{aligned}
2 \sum_{j=k+1}^{m} \mathcal{H}^1(\partial^* X \cap \partial C_j) \leq P(X) = P(X,F) &+ \sum_{i=1}^{k} \mathcal{H}^1(\partial^* X \cap \partial C_i) \\
&+ \sum_{j=k+1}^{m} \mathcal{H}^1(\partial^* X \cap \partial C_j).
\end{aligned}$$

We then have

$$\sum_{j=k+1}^{m} \mathcal{H}^1(\partial^* X \cap \partial C_j) \leq P(X,F) + \sum_{i=1}^{k} \mathcal{H}^1(\partial^* X \cap \partial C_i).$$

The other inequality follows by considering the set E_2 and using condition (6.6) instead of (6.4). □

7. Examples of solutions of the eigenvalue problem (1.1). Let us give an example of how, by pasting the solutions of problems (5.5) and (6.1), we can construct solutions of the eigenvalue problem (1.1).

Let C_i, $i = 1, \dots, m$, $1 \le k \le m$, be a family of convex sets of class $\mathcal{C}^{1,1}$ satisfying the conditions in section 5. For each $i \in \{1, \dots, m\}$ let us consider $C_{i1}, C_{i2}, \dots, C_{im_i}$ open bounded sets with boundary of class $\mathcal{C}^{1,1}$ with the following properties:

- $\overline{C_{ij}} \subset C_i$ for any $j \in \{1, \dots, m_i\}$;
- $\overline{C_{ij}} \cap \overline{C_{ij'}} = \emptyset$ for any $j, j' \in \{1, \dots, m_i\}$, $j \neq j'$.

For $i \in \{1, \dots, m\}$ we define

$$F_i := C_i \setminus \bigcup_{j=1}^{m_i} \overline{C_{ij}}, \qquad J_i := \frac{\sum_{j=0}^{k_i} P(C_{ij}) - \sum_{j=k_i+1}^{m_i} P(C_{ij})}{|F_i|},$$

where $k_i \in \{1, \dots, m_i\}$ are given. Assume that

(a) $\operatorname{ess\,inf}_{\partial C_{ij}} \kappa_{\partial C_{ij}} \ge J_i$, $i \in \{1, \dots, m\}$, $\quad j \in \{k_i + 1, \dots, m_i\}$;

(b) $F_i \cup (\bigcup_{j=k_i+1}^{m_i} \overline{C_{ij}})$ satisfies the $\frac{1}{J_i}$-ball condition for any $i \in \{1, \dots, m\}$;

(c) $\operatorname{dist}(\partial C_{ij}, \partial C_{ij'}) > \frac{2}{J_i}$, $i \in \{1, \dots, m\}$, $(j, j') \in \{0, \dots, k_i\}^2 \cup \{k_i+1, \dots, m_i\}^2$, $j \neq j'$, where we have denoted $C_{i0} = C_i$;

(d)

$$\operatorname*{ess\,sup}_{\partial C_{ij}} \kappa_{\partial C_{ij}} \le \frac{P(C_{ij})}{|C_{ij}|} =: J_{ij}, \qquad i \in \{1, \dots, m\},\ j \in \{1, \dots, m_i\}.$$

Notice that $J_i > 0$, since (b) implies $\operatorname{ess\,sup}_{\partial C_{i0}} \kappa_{\partial C_{i0}} \le J_i$, and also

$$\operatorname*{ess\,inf}_{\partial C_{ij}} \kappa_{\partial C_{ij}} \ge -J_i, \qquad j \in \{1, \dots, k_i\}.$$

Using Theorems 5.10 and 6.1, together with [12, Theorem 4], we have the existence of vector fields $\xi_{\text{ext}} \in L^\infty(R^2 \setminus \bigcup_{i=1}^m C_i)$, $\xi_i \in L^\infty(F_i)$, $\xi_{ij} \in L^\infty(C_{ij})$, such that $\|\xi_{\text{ext}}\|_\infty \le 1$, $\|\xi_i\|_\infty \le 1$, $\|\xi_{ij}\|_\infty \le 1$, $i = 1, \dots, m$, $j = 1, \dots, m_i$, satisfying

$$\text{(7.1)} \qquad \begin{cases} -\operatorname{div} \xi_{\text{ext}} = 0 & \text{on } R^2 \setminus \bigcup_{i=1}^m C_i, \\ [\xi_{\text{ext}}, \nu^{R^2 \setminus \cup_{i=1}^m C_i}] = -1 & \mathcal{H}^1\text{-a.e. on } \partial C_i,\ i \in \{1, \dots, k\}, \\ [\xi_{\text{ext}}, \nu^{R^2 \setminus \cup_{i=1}^m C_i}] = 1 & \mathcal{H}^1\text{-a.e. on } \partial C_j,\ j \in \{k+1, \dots, m\}, \end{cases}$$

$$\text{(7.2)} \qquad \begin{cases} -\operatorname{div} \xi_i = J_i & \text{on } F_i, \\ [\xi_i, \nu^{F_i}] = -1 & \mathcal{H}^1\text{-a.e. on } \partial C_{ij},\ j \in \{0, \dots, k_i\}, \\ [\xi_i, \nu^{F_i}] = 1 & \mathcal{H}^1\text{-a.e. on } \partial C_{ij},\ j \in \{k_i + 1, \dots, m_i\}, \end{cases} \qquad i \in \{1, \dots, m\},$$

$$\text{(7.3)} \qquad \begin{cases} -\operatorname{div} \xi_{ij} = \dfrac{P(C_{ij})}{|C_{ij}|} & \text{on } C_{ij}, \\ [\xi_{ij}, \nu^{C_{ij}}] = -1 & \mathcal{H}^1\text{-a.e. on } \partial C_{ij}, \end{cases} \qquad i \in \{1, \dots, m\},\ j \in \{1, \dots, m_i\}.$$

Now, we may paste together these vector fields to define $\xi \in L^\infty(R^2, R^2)$, $\|\xi\|_\infty \le 1$, by

$$\xi := \begin{cases} \xi_{\text{ext}} & \text{on } R^2 \setminus \bigcup_{i=1}^m C_i, \\ -\xi_i & \text{on } F_i,\ i = 1, \dots, k, \\ \xi_i & \text{on } F_i,\ i = k+1, \dots, m, \\ \xi_{ij} & \text{on } C_{ij},\ i = 1, \dots, k,\ j = 1, \dots, k_i, \\ -\xi_{ij} & \text{on } C_{ij},\ i = 1, \dots, k,\ j = k_i + 1, \dots, m_i, \\ -\xi_{ij} & \text{on } C_{ij},\ i = k+1, \dots, m,\ j = 1, \dots, k_i, \\ \xi_{ij} & \text{on } C_{ij},\ i = k+1, \dots, m,\ j = k_i + 1, \dots, m_i, \end{cases}$$

satisfying

$$-\operatorname{div}\xi = \begin{cases} 0 & \text{on } R^2 \setminus \bigcup_{i=1}^m C_i, \\ -J_i & \text{on } F_i,\ i=1,\dots,k, \\ J_i & \text{on } F_i,\ i=k+1,\dots,m, \\ J_{ij} & \text{on } C_{ij},\ i=1,\dots,k,\ j=1,\dots,k_i, \\ -J_{ij} & \text{on } C_{ij},\ i=1,\dots,k,\ j=k_i+1,\dots,m_i, \\ -J_{ij} & \text{on } C_{ij},\ i=k+1,\dots,m,\ j=1,\dots,k_i, \\ J_{ij} & \text{on } C_{ij},\ i=k+1,\dots,m,\ j=k_i+1,\dots,m_i. \end{cases}$$

Thus, if we define

$$\begin{aligned} u := &-\sum_{i=1}^k J_i\chi_{F_i} + \sum_{i=k+1}^m J_i\chi_{F_i} + \sum_{i=1}^k\sum_{j=1}^{k_i} J_{ij}\chi_{C_{ij}} - \sum_{i=1}^k\sum_{j=k_i+1}^{m_i} J_{ij}\chi_{C_{ij}} \\ &- \sum_{i=k+1}^m\sum_{j=1}^{k_i} J_{ij}\chi_{C_{ij}} + \sum_{i=k+1}^m\sum_{j=k_i+1}^{m_i} J_{ij}\chi_{C_{ij}}, \end{aligned}$$

then u is a solution of (1.1). Therefore, by pasting solutions of problems like (7.1), (7.2), (7.3), we may construct solutions of (1.1).

8. Some explicit solutions of the denoising problem. The previous results allow us to explicitly compute the minimum of the denoising problem (1.8) for some data $f \in L^2(R^2)$. Let us recall that a vector field $z \in X_2(R^2)$ with $\|z\|_\infty \le 1$ satisfying

$$-\operatorname{div} z = F \in L^2(R^2)$$

exists if and only if [31, 12]

$$\|F\|_* := \sup\left\{\left|\int_{R^2} Fv\ dx\right| : v \in BV(R^2),\ \int_{R^2}|Dv| \le 1\right\} \le 1.$$

PROPOSITION 8.1. *Let $u_i \in BV(R^2)$, $u_i \ge 0$, be such that $u_i \wedge u_j = 0$, $i,j \in \{1,\dots,m\}$, $i \ne j$. Assume that u_i and $\sum_{i=1}^m u_i$ are solutions of the eigenvalue problem (1.1), $i \in \{1,\dots,m\}$. Let $b_i \in R$, $i=1,\dots,m$, and $f := \sum_{i=1}^m b_i u_i$. Also let $\lambda > 0$. Then the solution u of the variational problem (1.8) is $u := \sum_{i=1}^m \operatorname{sign}(b_i)(|b_i|-\lambda)^+ u_i$.*

Observe that if (*) $\sum_{i=1}^m u_i$ is a solution of (1.1), then (**) $\|\sum_{i=1}^m u_i\|_* \le 1$. Notice that, using (8.2) below, it is easy to prove that both conditions (*) and (**) are, indeed, equivalent.

Proof. Under our assumptions we have $u_i \in BV(R^2) \subset L^2(R^2)$, $i=1,\dots,m$, and hence $f \in L^2(R^2)$. Recall that a function $u \in BV(R^2)$ is the solution of (1.8) if and only if u is the solution of

$$u - \lambda\operatorname{div}\left(\frac{Du}{|Du|}\right) = f. \tag{8.1}$$

Observe that since each u_i is a solution of (1.1), multiplying (1.1) by u_i and integrating by parts, we obtain

$$\int_{R^2} u_i^2\,dx = \int_{R^2}|Du_i|. \tag{8.2}$$

Let us prove that $u = \sum_{i=1}^m \operatorname{sign}(b_i)(|b_i| - \lambda)^+ u_i$ is the solution of (8.1). Let $I_\lambda := \{i \in \{1, \dots, m\} : |b_i| \geq \lambda\}$, $H_\lambda := \{i \in \{1, \dots, m\} : |b_i| < \lambda\}$. Since, in this case,

$$f - u = \lambda \sum_{i \in I_\lambda} \operatorname{sign}(b_i) u_i + \sum_{i \in H_\lambda} b_i u_i,$$

to prove that u is a solution of (8.1) we have to construct a vector field $\xi \in L^\infty(R^2; R^2)$ with $\|\xi\|_\infty \leq 1$, such that

$$-\operatorname{div} \xi = \sum_{i \in I_\lambda} \operatorname{sign}(b_i) u_i + \sum_{i \in H_\lambda} \frac{b_i}{\lambda} u_i \tag{8.3}$$

and $(\xi, Du) = |Du|$. Let $F \in L^2(R^2)$ denote the right-hand side of (8.3), and let $F^+ := \sup(F, 0)$, $F^- := \sup(-F, 0)$. Let us prove that $\|F\|_* \leq 1$. In order to prove this, we let $v \in BV(R^2)$. Since

$$\int_{R^2} Fv \, dx \leq \int_{R^2} (F^+ v^+ + F^- v^-) \, dx$$

and $\int_{R^2} |Dv| = \int_{R^2} |Dv^+| + \int_{R^2} |Dv^-|$, the inequality $\int_{R^2} Fv \, dx \leq \int_{R^2} |Dv|$ follows if we prove that

$$\int_{R^2} F^+ v^+ \, dx \leq \int_{R^2} |Dv^+| \quad \text{and} \quad \int_{R^2} F^- v^- \, dx \leq \int_{R^2} |Dv^-|.$$

Thus, without loss of generality, we may assume that $F \geq 0$ (i.e., all b_i appearing in the definition of F are nonnegative) and $v \geq 0$. Then, using that $\frac{b_i}{\lambda} \leq 1$ for any $i \in H_\lambda$, we have that

$$0 \leq F \leq \sum_{i=1}^m u_i.$$

Since, by assumption, $\| \sum_{i=1}^m u_i \|_* \leq 1$, we have

$$\int_{R^2} Fv \, dx \leq \int_{R^2} \sum_{i=1}^m u_i v \, dx \leq \int_{R^2} |Dv|.$$

Therefore $\|F\|_* \leq 1$. Thus, there is a vector field $\xi \in L^\infty(R^2; R^2)$ such that $\|\xi\|_\infty \leq 1$, satisfying (8.3).

As $(|b_i| - \lambda)^+ = 0$ for all $i \in H_\lambda$, we have

$$\int_{R^2} |Du| = \sum_{i \in I_\lambda} (|b_i| - \lambda) \int_{R^2} |Du_i|.$$

Since $u_i \wedge u_j = 0$ for any $i, j \in \{1, \dots, m\}$, $i \neq j$, then $Fu = \sum_{i \in I_\lambda} (|b_i| - \lambda) u_i^2$, and we have

$$\int_{R^2} (\xi, Du) = -\int_{R^2} \operatorname{div} \xi \, u \, dx = \int_{R^2} Fu \, dx = \sum_{i \in I_\lambda} (|b_i| - \lambda) \int_{R^2} u_i^2 \, dx;$$

applying (8.2) we obtain

$$\int_{R^2} (\xi, Du) = \sum_{i \in I_\lambda} (|b_i| - \lambda) \int_{R^2} |Du_i| \, dx = \int_{R^2} |Du|,$$

which in turn implies that $(\xi, Du) = |Du|$, since $\|\xi\|_\infty \leq 1$. □

Acknowledgment. We would like to thank the anonymous reviewers for pointing out the necessity to assume strict convexity in Lemma 5.8.

ON THE INVISCID LIMIT FOR TWO-DIMENSIONAL INCOMPRESSIBLE FLOW WITH NAVIER FRICTION CONDITION*

M. C. LOPES FILHO†, H. J. NUSSENZVEIG LOPES†, AND G. PLANAS‡

Abstract. In [*Nonlinearity*, 11 (1998), pp. 1625–1636], Clopeau, Mikelić, and Robert studied the inviscid limit of the two-dimensional incompressible Navier–Stokes equations in a bounded domain subject to Navier friction–type boundary conditions. They proved that the inviscid limit satisfies the incompressible Euler equations, and their result ultimately includes flows generated by bounded initial vorticities. Our purpose in this article is to adapt and, to some extent, simplify their argument in order to include pth power integrable initial vorticities, with $p > 2$.

Key words. Navier–Stokes, boundary layers, vanishing viscosity

1. Introduction. In a recent paper [1], Clopeau, Mikelić, and Robert studied the inviscid limit of solutions of the two-dimensional (2D) incompressible Navier–Stokes equations in a bounded domain with Navier friction–type boundary conditions. They proved that the inviscid limit is a weak solution of the Euler equations, and their results include flows generated by bounded initial vorticities. The purpose of the present work is to extend their argument in order to include flows with initial vorticities in L^p, $p > 2$. Technically this work involves many of the same tools that were used in [1] and relies in an essential manner on the smooth data result of that work.

The main motivation for studying the vanishing viscosity limit for incompressible 2D flow is the problem of boundary layers. This motivation, together with the issue of the physical meaning of the Navier friction condition, was well explored in the introduction to [1]. We will not repeat that discussion here, referring the reader to that article and the references therein for this part of our introduction. We would like to mention that in a pair of recent papers, Jäger and Mikelić rigorously justified the Navier friction condition as a homogenization of the no-slip condition on a rough boundary [5, 6]. Furthermore, 2D boundary layers have been a very active field of inquiry recently, so in addition to [1, 5, 6] we also refer the reader to [3, 14] for other recent developments. Beyond these issues, there is additional background which is specifically related to irregular flows which we must address here.

Existence of weak solutions to the incompressible 2D Euler equations has been established for rather singular initial data, more precisely, initial velocities in L^2_{loc} such that the corresponding vorticity lies in $\mathcal{BM}^+_c + L^1_c$, i.e., nonnegative bounded measures with compact support plus an arbitrary compactly supported integrable function. This result is due primarily to Delort [2]; we refer the reader also to [15]. In both of these papers the weak solutions are obtained by compactness arguments in which the initial data is mollified and the equations are subsequently exactly solved with this

smooth data. Uniqueness has only been established if the initial vorticity is bounded or nearly so [16, 17, 18], so that the issue of selection principles for singular flows is wide open. It makes sense in this case to investigate whether other approximation schemes also yield weak solutions. For example, this has been established for certain numerical schemes; see [10, 13]. It is natural, from a physical point of view, to investigate the vanishing viscosity limit as well. It is possible to adapt Delort's arguments to study the inviscid limit in the absence of boundaries, and this has been done for full plane flow; see [11]. The problem of studying the existence of viscosity solutions in domains with boundary runs into the classical problem of boundary layers if one supplements the viscous approximations with the no-slip boundary condition. The work of Clopeau, Mikelić, and Robert shows that the boundary layer arising from the inviscid limit with Navier friction condition can be treated, while retaining some physical meaning. In fact, the Navier friction condition still allows for vorticity production at the boundary, but in a controlled fashion. It is therefore natural to investigate the existence of viscosity solutions by considering viscous approximations satisfying the Navier friction condition, searching for critical regularity on the initial data that guarantees the existence of such solutions. This is the main point behind the present work.

The remainder of this article is divided into five sections: the next section contains the basic notation and setup of the problem; the third section investigates approximation of initial data that satisfy the Navier friction condition; the fourth section contains the a priori estimate on the L^p-norm of vorticity which is the heart of this work; the fifth section contains a well-posedness result for the viscous approximations with L^p initial vorticity; the last section contains the passage to the inviscid limit and conclusions.

2. Preliminaries. Let $\Omega \subseteq \mathbb{R}^2$ denote a bounded simply connected domain with smooth boundary. Our point of departure is the incompressible Navier–Stokes equations in Ω. We are interested in the initial-boundary value problem where the velocity satisfies the Navier friction condition with friction coefficient $\alpha = \alpha(x) \in C^2(\partial\Omega)$, $\alpha \geq 0$. More precisely, the initial-boundary value problem is given by

$$\begin{cases} u_t + u \cdot \nabla u = -\nabla p + \nu \Delta u & \text{in } \Omega \times (0,T), \\ \operatorname{div} u = 0 & \text{in } \Omega \times [0,T), \\ u \cdot \mathbf{n} = 0 & \text{on } \partial\Omega \times [0,T), \\ 2(Du)_S \mathbf{n} \cdot \tau + \alpha u \cdot \tau = 0 & \text{on } \partial\Omega \times (0,T), \\ u(x,0) = u_0(x) & \text{in } \Omega, \end{cases} \tag{1}$$

where $\nu > 0$ is the viscosity, $\mathbf{n}$ and τ are the unit outwards normal and counterclockwise tangent vectors to $\partial\Omega$, respectively; u is the fluid velocity; p is the scalar pressure; and $(Du)_S$ is the symmetric part of the Jacobian matrix of u, i.e. $(Du)_S = \frac{1}{2}(Du + (Du)^t)$.

The well-posedness of this initial-boundary value problem was established by Clopeau, Mikelić, and Robert in [1]. More precisely, given a divergence-free initial velocity field $u_0 \in H^2(\Omega)$, tangent to the boundary, and satisfying the Navier friction condition $2(Du)_S \mathbf{n} \cdot \tau + \alpha u \cdot \tau = 0$ on $\partial\Omega$ in the trace sense, they showed that there exists a unique weak solution $u^\nu \in L^2((0,T); H^1(\Omega)) \cap L^\infty((0,T); L^2(\Omega))$ satisfying

$$\begin{aligned} &\frac{d}{dt}\int_\Omega \varphi u^\nu + \int_\Omega \varphi \cdot (u^\nu \cdot \nabla) u^\nu dx \\ &+ 2\nu \int_\Omega (D\varphi)_S : (Du^\nu)_S dx + \nu \int_{\partial\Omega} \alpha (\varphi \cdot \tau)(u^\nu \cdot \tau) dS = 0 \end{aligned} \tag{2}$$

for every divergence-free test vector field $\varphi \in H^1(\Omega)$, tangent to $\partial\Omega$. Here the matrix product $A : B$ means $\sum_{i,j} A_{ij}B_{ij}$ and is called the trace product.

We note that the initial condition is not included in this weak formulation. In fact, Clopeau, Mikelić, and Robert also showed that $u^\nu_t \in L^2((0,T); H^1(\Omega))$, from which it follows by integration that $u^\nu \in C([0,T]; H^1(\Omega))$. Therefore the initial condition $u^\nu(\cdot, 0) = u_0$ can be meaningfully imposed. Furthermore, if one assumes that the initial vorticity curl u_0 is bounded, then $u^\nu \in C([0,T); H^2(\Omega))$.

The Navier friction condition can be formulated in terms of vorticity. In order to do so, a calculus identity was established in [1], which we reproduce in the lemma below.

LEMMA 1. *Let $v \in H^2(\Omega)$ be a vector field which is tangent to $\partial\Omega$. Then*

$$(Dv)_S \mathbf{n} \cdot \tau - \frac{\omega}{2} + \kappa(v \cdot \tau) = 0 \quad \text{on } \partial\Omega,$$

where $\omega = \operatorname{curl} v$ and κ is the curvature of $\partial\Omega$.

One of the main difficulties in addressing the classical vanishing viscosity limit in domains with boundary resides in writing useful boundary conditions for the vorticity formulation of the 2D Navier–Stokes equations. It is through the use of the vorticity formulation that one finds higher order estimates for velocity that are independent of viscosity. The inviscid limit for 2D Navier–Stokes with friction condition is more tractable than the classical problem precisely because the friction boundary condition translates into a useful boundary condition for vorticity. We introduce $\omega_0 = \operatorname{curl} u_0$, the initial vorticity, and $\omega^\nu = \operatorname{curl} u^\nu$, the time-dependent vorticity associated to the weak solution u^ν of (1) with initial data u_0. For each fixed time, the velocity u^ν can be recovered from vorticity by means of the Biot–Savart law. We make this explicit by writing

$$u^\nu = K_\Omega(\omega^\nu),$$

where K_Ω is an integral operator of order -1, with kernel given by $\nabla^\perp G_\Omega$, where G_Ω is the Green's function for the Dirichlet Laplacian in Ω. Using Lemma 1 above, it is a standard calculation to show that ω^ν, u^ν satisfies, in a weak sense, the following parabolic initial-boundary value problem, which is the vorticity formulation of (1):

$$\begin{cases} \omega^\nu_t + u^\nu \cdot \nabla\omega^\nu = \nu\Delta\omega^\nu & \text{in } \Omega \times (0,T), \\ u^\nu = K_\Omega[\omega^\nu] & \text{in } \Omega \times [0,T), \\ \omega^\nu = (2\kappa - \alpha)u^\nu \cdot \tau & \text{on } \partial\Omega \times [0,T) \\ \omega^\nu(\cdot, 0) = \omega_0 & \text{on } \Omega \times \{t = 0\}. \end{cases} \tag{3}$$

3. Approximating nonsmooth initial data. The problem we wish to address in this article is the inviscid limit for (1) with initial velocity $u_0 = K_\Omega[\omega_0]$, and $\omega_0 \in L^p(\Omega)$ for some $p > 2$. We must first discuss this initial-boundary value problem for fixed viscosity, as this initial condition does not satisfy the conditions for the well-posedness mentioned in the previous section. It can be easily seen that this initial velocity u_0 is divergence free, tangent to the boundary, and it belongs to $W^{1,p}(\Omega)$ (by elliptic regularity; see [9]). This means that there is not enough regularity to impose the Navier friction condition on the initial data, so that this initial-boundary value problem is subject to an initial layer.

DEFINITION 1. *We will call a function $\omega \in H^1(\Omega) \cap L^\infty(\Omega)$ compatible if the associated velocity $u = K_\Omega[\omega] \in H^2(\Omega)$ satisfies the Navier condition $\omega = (2\kappa - \alpha)u \cdot \tau$ on the boundary in the trace sense.*

The first issue we need to address is how to approximate an arbitrary function in $L^p(\Omega)$ by compatible functions. This issue was addressed by Clopeau, Mikelić, and Robert for $\omega \in L^\infty(\Omega)$, using a fixed point argument. We will state and prove an extension of their result that applies to functions $\omega \in L^p(\Omega)$, $p > 1$. The proof is a reasonably straightforward adaptation of their argument, which we include for the sake of completeness.

LEMMA 2. *Let $\omega \in L^p(\Omega)$ for some $p > 1$. Then there exists a sequence $\{\omega_n\}$ of compatible functions which converges to ω strongly in L^p.*

Proof. Recall the notation introduced in the proof of Lemma 4.2 of [1]. For $x \in \overline{\Omega}$, let $d = d(x)$ be the distance of x to $\partial\Omega$ and let $U_n \equiv \{x \in \overline{\Omega} : d(x) < 1/n\}$. Let $r = r(x)$ denote the orthogonal projection of U_n onto $\partial\Omega$, defined for n sufficiently large. Let ζ_n be a smooth cutoff for a neighborhood of $\Omega \setminus U_n$, so that $\zeta_n \equiv 0$ in U_{n+1} and $\zeta_n \equiv 1$ outside U_n. Let η_n be a standard Friedrichs mollifier. As in Lemma 4.2 we extend ω to vanish outside of Ω. First, assume that $p < 2$ and let $\widehat{p} = p/(2-p)$. For any $G \in L^{\widehat{p}}(\partial\Omega)$ set

$$\beta \equiv \zeta_n(x)\eta_n * \omega(x) + (1 - \zeta_n(x))e^{-nd(x)}G(r(x)). \tag{4}$$

As $G(r(\cdot))$ appears multiplied by a function which vanishes outside U_n we may assume that $G(r(\cdot))$ vanishes outside U_n. Thus (the extended) $G(r(\cdot))$ is defined on all of Ω. Observe also that, by construction, $\beta|_{\partial\Omega} = G$.

Let

$$v = K_\Omega[\beta]$$

and introduce

$$\Psi(G) = (2\kappa - \alpha)v \cdot \tau.$$

We note that Ψ maps $L^{\widehat{p}}(\partial\Omega)$ into itself. To see this, we begin by observing that $\beta \in L^p(\Omega)$. This follows since $G \in L^{\widehat{p}}(\partial\Omega)$, which implies, by a simple change of variables, that $G(r(\cdot)) \in L^{\widehat{p}}(\Omega)$. Since $\widehat{p} > p$, because $p > 1$, we obtain $\beta \in L^p(\Omega)$. Therefore $v \in W^{1,p}(\Omega)$, so that $v \cdot \tau \in W^{1-1/p,p}(\partial\Omega)$. We conclude using the Sobolev imbedding $W^{1-1/p,p}(\partial\Omega) \subset L^{\widehat{p}}(\partial\Omega)$.

Next we show that Ψ is a contraction mapping if n is sufficiently large. Let $G_1, G_2 \in L^{\widehat{p}}(\partial\Omega)$. Then

$$\|\Psi(G_1) - \Psi(G_2)\|_{L^{\widehat{p}}(\partial\Omega)} \le \|2\kappa - \alpha\|_{L^\infty}\|v_1 - v_2\|_{L^{\widehat{p}}(\partial\Omega)} \le C_p\|\beta_1 - \beta_2\|_{L^p(\Omega)}$$

$$\le C_p\|G_1(r(\cdot)) - G_2(r(\cdot))\|_{L^p(U_n)} \le C_p\frac{1}{n^{1/p}}\|G_1 - G_2\|_{L^{\widehat{p}}(\partial\Omega)}.$$

Therefore, for n sufficiently large, Ψ has a unique fixed point, which we denote by $G^n \in L^{\widehat{p}}(\partial\Omega)$. We denote the corresponding β by ω_n, so that

$$\omega_n \equiv \zeta_n\eta_n * \omega + (1 - \zeta_n)e^{-nd}G^n \circ r.$$

We need to verify that ω_n is compatible. We begin by observing that the fact that G^n is a fixed point for Ψ implies that ω_n satisfies the Navier friction condition. Next we show the required regularity for ω_n. A standard bootstrap argument on identity (4), involving Sobolev imbeddings and elliptic regularity, gains $1 - 1/\widehat{p}$ derivatives on ω_n at each step. Indeed, $G^n \in L^{\widehat{p}}(\partial\Omega)$ implies that $G^n \circ r \in L^{\widehat{p}}(\Omega)$

since $\partial\Omega$ is smooth. Hence $\omega_n \in L^{\widehat{p}}(\Omega)$ because $\zeta_n \eta_n * \omega$ is smooth and compactly supported in the interior of Ω. From this it follows that $v_n = K_\Omega[\omega_n] \in W^{1,\widehat{p}}(\Omega)$, so that $v_n|_{\partial\Omega} \in W^{1-1/\widehat{p},\widehat{p}}(\partial\Omega)$. Thus $\Psi(G_n) = (2\kappa - \alpha) v_n \cdot \tau \in W^{1-1/\widehat{p},\widehat{p}}(\partial\Omega)$. But G_n is a fixed point for Ψ, so we conclude that $G_n \in W^{1-1/\widehat{p},\widehat{p}}(\partial\Omega)$. From this last step it follows that $\omega_n \in W^{1-1/\widehat{p},\widehat{p}}(\Omega)$. We may repeat this argument and gain $1 - 1/\widehat{p}$ derivatives at each step. After a finite number of steps we reach $\omega_n \in H^1 \cap L^\infty$.

Finally, we argue that ω_n converges strongly to ω in L^p. Since the first term on the right-hand side of (4) clearly converges strongly to ω in L^p, all we need to show is that the remaining term converges to zero in L^p. First note that

$$\|(1-\zeta_n)e^{-nd(x)}G^n(r(x))\|_{L^p(\Omega)} \le \|G^n(r(x))\|_{L^p(U_n)} \le \frac{C}{n^{1/p}}\|G^n\|_{L^p(\partial\Omega)}$$

$$\le o(1)\|G^n\|_{L^{\widehat{p}}(\partial\Omega)}.$$

Now we estimate $\|G^n\|_{L^{\widehat{p}}(\partial\Omega)}$:

$$\|G^n\|_{L^{\widehat{p}}(\partial\Omega)} \le \|2\kappa - \alpha\|_{L^\infty}\|K_\Omega[\omega_n]\|_{L^{\widehat{p}}(\partial\Omega)}$$

$$\le C(p,\alpha,\kappa)\|\omega_n\|_{L^p(\Omega)} \le C(\|\omega\|_{L^p(\Omega)} + \|G^n(r(x))\|_{L^p(U_n)})$$

$$\le C_p\|\omega\|_{L^p(\Omega)} + \frac{1}{2}\|G^n\|_{L^{\widehat{p}}(\partial\Omega)}$$

for n sufficiently large, which implies the required bound.

For $p = 2$ one repeats the argument above with an arbitrary $\widehat{p}$, and for $p > 2$ one just takes $\widehat{p} = \infty$. □

Remark 1. The result presented is actually more general than what we require. It applies to initial vorticities in L^p, $p > 1$, when we are only going to use it for $p > 2$. It is worth remarking that it is only for the cases $1 < p \le 2$ that we needed to use a fixed point argument in $L^{\widehat{p}}$. We could have written an argument that works for the case $p > 2$ using the fixed point argument in L^∞, as was done in [1], and the proof would really be a very minor adaptation of the proof in [1], not deserving repetition even for the sake of completeness. One of the points of the present work is to clarify the criticality of this problem. This is the main reason to present the approximation result in this generality. The way it is formulated implies that this approximation issue is not part of the $p > 2$ limitation.

Remark 2. There is no asymptotic description of the structure of the boundary layer for the present problem that would be the adaptation of Prandtl's description of the classical boundary layer. We point out that the small viscosity regime does not appear to be physically meaningful under Navier friction conditions, so that there has been no compelling reason to obtain such a description. However, an account of the structure of the boundary layer under Navier friction conditions would certainly be of mathematical interest. In the absence of such an account, the proof above gives at least a clue as to the nature of this boundary layer, embodied in the structure of the correction term. One key issue in the classical boundary layer is that such a correction term would have, at best, a uniform L^1 estimate, leading to a boundary vortex sheet perturbation in the limit. This is apparent in the explicitly computable flow generated by an impulsively started plate, known as the Rayleigh problem; see, for example, [12]. This vortex sheet at the boundary is present in the inviscid limit even for smooth initial vorticities. Now, vortex sheet–type regularity is critical for passing to the weak limit in approximations of the incompressible 2D Euler equations; see [2]. In some sense, it

is this fact that is the heart of the difficulty in the classical boundary layer problem. The correction term in the proof above suggests that the boundary layer associated to the Navier friction condition would correspond to uniformly bounded vorticity near the boundary for $p > 2$, and $L^{\widehat{p}}$ vorticity near the boundary for $1 < p \leq 2$, so that one would expect criticality only at $p = 1$.

Remark 3. The argument presented breaks down when $p = 1$, mainly because elliptic regularity breaks down, so that one cannot guarantee that Ψ maps L^1 to itself.

4. A priori estimate on vorticity. The purpose of this section is to derive an a priori estimate for vorticity on solutions of (1). We begin with a compatible initial vorticity ω_0, as defined in the previous section. We use $u_0 = K_\Omega[\omega_0]$ as initial data. The well-posedness of the initial-boundary value problem (1) for such initial data was established in [1], as previously mentioned. Let $u = u(x,t)$ be the unique weak solution of (1) with data u_0. The vector field u belongs to $C([0,\infty); H^2(\Omega))$ and satisfies the weak formulation (2) of the Navier–Stokes equation with Navier friction condition. The vorticity $\omega = \operatorname{curl} u$ satisfies the parabolic equation (3) in a weak sense.

LEMMA 3. *Fix $p > 2$. There exists a constant $C > 0$, depending only on p, Ω, and the friction coefficient α such that the vorticity satisfies*

$$\|\omega(\cdot,t)\|_{L^p} \leq C(\|\omega_0\|_{L^p} + \|u_0\|_{L^2}).$$

Proof. The proof involves applying a maximum principle to two auxiliary problems. First observe that $u \cdot \tau \in L^\infty(\partial\Omega \times (0,T))$ since $u \in C([0,T); H^2(\Omega))$. Set

$$\Lambda = \|(2\kappa - \alpha) u \cdot \tau\|_{L^\infty(\partial\Omega \times (0,T))}.$$

Consider the initial-boundary value problem for the Fokker–Planck equation

$$\begin{cases} \widetilde{\omega}_t - \nu\Delta\widetilde{\omega} + u \cdot \nabla\widetilde{\omega} = 0 & \text{in } \Omega \times (0,T), \\ \widetilde{\omega}(\cdot,0) = |\omega_0| & \text{in } \Omega, \\ \widetilde{\omega} = \Lambda & \text{on } \partial\Omega \times (0,T). \end{cases} \tag{5}$$

This problem has a unique weak solution $\widetilde{\omega} \in L^2((0,T); H^1(\Omega))$ by Theorems 6.1 and 6.2 in [7]. Then $\omega_1 = \omega - \widetilde{\omega}$ is a weak solution for the following initial-boundary value problem:

$$\begin{cases} (\omega_1)_t - \nu\Delta\omega_1 + u \cdot \nabla\omega_1 = 0 & \text{in } \Omega \times (0,T), \\ \omega_1(\cdot,0) = \omega_0 - |\omega_0| & \text{in } \Omega, \\ \omega_1 = (2\kappa - \alpha) u \cdot \tau - \Lambda & \text{on } \partial\Omega \times (0,T). \end{cases} \tag{6}$$

The coefficients of the Fokker–Planck operator $\partial_t - \nu\Delta + u \cdot \nabla$ are such that the maximum principle for weak solutions, given in Corollary 6.26 of [7], is valid. Therefore, as $\omega_1 \leq 0$ on the parabolic boundary $\partial\Omega \times (0,T) \cup \Omega \times \{t = 0\}$, it follows that $\omega_1 \leq 0$ a.e. in $\Omega \times [0,T)$. Analogously, we prove that $\omega_2 = -\omega - \widetilde{\omega}$ is nonpositive. We thus obtain

$$|\omega| \leq \widetilde{\omega} \text{ a.e. in } \Omega \times [0,T). \tag{7}$$

Moreover, as ω_0 is compatible, it is bounded. Hence Corollary 6.26 of [7] may also be applied to (5), yielding that $\widetilde{\omega} \in L^\infty((0,T) \times \Omega)$.

Next we obtain an estimate for $\widetilde{\omega}$. Let $\widehat{\omega} = \widetilde{\omega} - \Lambda$. This is a solution of the following problem:

$$\begin{cases} \widehat{\omega}_t - \nu\Delta\widehat{\omega} + u\cdot\nabla\widehat{\omega} = 0 & \text{in } \Omega\times(0,T), \\ \widehat{\omega}(\cdot,0) = |\omega_0| - \Lambda & \text{in } \Omega, \\ \widehat{\omega} = 0 & \text{on } \partial\Omega\times(0,T). \end{cases} \tag{8}$$

We formally multiply (8) by $\widehat{\omega}|\widehat{\omega}|^{p-2}$, where $p>2$, we integrate by parts and use the incompressibility of the flow u to obtain

$$\frac{1}{p}\frac{d}{dt}\int_\Omega |\widehat{\omega}|^p + (p-1)\nu\int_\Omega ||\nabla\widehat{\omega}||\widehat{\omega}|^{(p-2)/2}|^2 dx = 0. \tag{9}$$

Then

$$\|\widehat{\omega}(\cdot,t)\|_{L^p(\Omega)} \le \|\widehat{\omega}(\cdot,0)\|_{L^p(\Omega)} \le \|\omega_0\|_{L^p(\Omega)} + \Lambda|\Omega|^{1/p}.$$

Therefore,

$$\|\widetilde{\omega}\|_{L^p(\Omega)} \le \|\widehat{\omega}\|_{L^p(\Omega)} + \Lambda|\Omega|^{1/p} \le \|\omega_0\|_{L^p(\Omega)} + 2\Lambda|\Omega|^{1/p}. \tag{10}$$

This formal calculation can be made rigorous by using the weak formulation of (8) given in [7]. We begin by observing that $\widehat{\omega}_t \in L^2((0,T);H^{-1}(\Omega))$ and $\widehat{\omega}\in L^2((0,T);H^1_0(\Omega))\cap L^\infty((0,T)\times\Omega)$. This implies that $\widehat{\omega}|\widehat{\omega}|^{p-2}\in L^2((0,T);H^1_0(\Omega))$. Therefore we can multiply (8) by $\widehat{\omega}|\widehat{\omega}|^{p-2}$ if we understand the product with $\widehat{\omega}_t$ and with $\Delta\widehat{\omega}$ as duality pairings. Finally, in order to justify (9) one still needs to approximate $\widehat{\omega}$ by suitable smooth functions and pass to the limit in each term of the weak formulation so as to obtain

$$\frac{1}{p}\frac{d}{dt}\int_\Omega |\widehat{\omega}|^p = \langle\widehat{\omega}_t, \widehat{\omega}|\widehat{\omega}|^{p-2}\rangle$$

$$= \nu\langle\Delta\widehat{\omega}, \widehat{\omega}|\widehat{\omega}|^{p-2}\rangle = -(p-1)\nu\int_\Omega ||\nabla\widehat{\omega}||\widehat{\omega}|^{(p-2)/2}|^2 dx.$$

This can be easily accomplished using mollification in time together with the Dirichlet heat semigroup for Ω, thus generating a family of smooth functions $\widehat{\omega}_\varepsilon$ such that $\partial_t\widehat{\omega}_\varepsilon\to\widehat{\omega}_t$ strongly in $L^2((0,T);H^{-1}(\Omega))$, while $\widehat{\omega}_\varepsilon|\widehat{\omega}_\varepsilon|^{p-2}\rightharpoonup\widehat{\omega}|\widehat{\omega}|^{p-2}$ weakly in $L^2((0,T);H^1_0(\Omega))$ and $\widehat{\omega}_\varepsilon$ is uniformly bounded in $\Omega\times(0,T)$.

Given (10) we now turn to the estimate of Λ. Using Sobolev imbedding and interpolating between $W^{1,p}$ and L^2, we find

$$\|u(\cdot,t)\cdot\tau\|_{L^\infty(\partial\Omega)} \le C\|u(\cdot,t)\|_{C(\bar\Omega)} \le C\|u(\cdot,t)\|^\theta_{L^2(\Omega)}\|u(\cdot,t)\|^{1-\theta}_{W^{1,p}(\Omega)}$$

$$\le C\|u(\cdot,t)\|^\theta_{L^2(\Omega)}\|\omega(\cdot,t)\|^{1-\theta}_{L^p(\Omega)},$$

where $\theta = (p-2)/(2p-2)$.

Let ε be an arbitrary positive number. We now use Young's inequality together with the fact that κ and α are bounded to conclude that

$$\Lambda \le C_\varepsilon\|u\|_{L^\infty((0,T);L^2(\Omega)} + \varepsilon\|\omega\|_{L^\infty((0,T);L^p(\Omega))} \tag{11}$$

for some $C_\varepsilon>0$. Taking ε small enough, from (7)–(11) we obtain

$$\|\omega\|_{L^\infty(0,T;L^p(\Omega))} \le C(\|\omega_0\|_{L^p(\Omega)} + \|u\|_{L^\infty(0,T;L^2(\Omega))}) \tag{12}$$

for any $p > 2$, where $C = C(p, \Omega, \|\kappa\|_{L^\infty(\partial\Omega)}, \|\alpha\|_{L^\infty(\partial\Omega)})$. Finally, a standard energy estimate, such as the one carried out in [1] (see estimate (2.16)), yields $\|u\|_{L^\infty(0,T;L^2(\Omega))} \leq \|u_0\|_{L^2(\Omega)}$, thereby concluding the proof. ∎

Remark 4. This lemma is the heart of this article. Note that the restriction $p > 2$ comes into the proof above because of the need to produce a uniform bound on the velocity at the boundary. It would be interesting to know if this is a physically meaningful restriction. This would mean that the problem of controlling the generation of vorticity by the interaction of incompressible flow with a "Navier condition" boundary is critical at $p = 2$. However, this criticality at $p = 2$ seems unlikely. The limitation on the integrability of vorticity in the proof above appears to reflect a limitation on the maximum principle technique employed rather than an essential feature of this problem. In contrast, the exponent $p = 1$ found to be critical in the proof of Lemma 2 seems much more essential and is already known to be critical in terms of passage to weak limits on the nonlinearity of the incompressible 2D Euler and Navier–Stokes equations.

Remark 5. The natural way to extend this vorticity estimate to $p \leq 2$ would be to derive an L^p energy estimate on the vorticity equation. Multiplying the vorticity equation (3) by $p\omega|\omega|^{p-2}$, integrating in space, and performing the usual integration by parts yields

$$\frac{d}{dt}\int_\Omega |\omega|^p dx = -\nu p(p-1)\int_\Omega |\omega|^{p-2}|\nabla\omega|^2 dx + \nu p\int_{\partial\Omega} |\omega|^{p-2}\omega\nabla\omega\cdot\mathbf{n}dS.$$

We note that the boundary term is the flux of $|\omega|^p$ through the boundary, over which we have no control. One special case for which this simple estimate does provide an improvement over Lemma 3 is the case of $\alpha = 2\kappa$, because then the troublesome boundary term vanishes. This corresponds to the so-called free boundary condition $\omega = 0$ on $\partial\Omega$. It is a well-known fact that one can handle the inviscid asymptotics in this case, as one is imposing that the boundary does not generate vorticity and thus there are no boundary layers. For details, see [8] and the special case of time-dependent domain in [4].

5. Well-posedness for the viscous problem. In this section we observe that the initial-boundary value problem for the Navier–Stokes equations with friction-type boundary condition is well-posed even if the initial vorticity is not compatible. This was already done in [1] for bounded initial vorticity.

We begin by showing that if u^ν is a weak solution of (1), then u^ν satisfies an integrated version of relation (2).

LEMMA 4. *Let $u^\nu \in L^2((0,T);H^1(\Omega)) \cap L^\infty((0,T);L^2(\Omega))$ be a weak solution of (1). Then for any test vector field $\varphi \in C_c^\infty([0,T)\times\overline{\Omega})$, divergence free and tangent to $\partial\Omega$, we have*

$$\begin{aligned}\int_0^T\int_\Omega u^\nu\varphi_t + u^\nu(u^\nu\cdot\nabla)\varphi dxdt + \int_\Omega u_0\varphi(\cdot,0)dx \\ = 2\nu\int_0^T\int_\Omega (D\varphi)_S : (Du)_S dxdt + \nu\int_0^T\int_{\partial\Omega}\alpha(\varphi\cdot\tau)(u^\nu\cdot\tau)dSdt.\end{aligned} \tag{13}$$

Proof. Let φ be a test vector field. For each $s \in [0,T)$, define

$$g(t,s) \equiv \int_\Omega u^\nu(x,t)\varphi(x,s)dx.$$

Then by (2) we have

$$\frac{\partial g}{\partial t} = -\int_\Omega \varphi \cdot (u^\nu \cdot \nabla) u^\nu dx$$

$$- 2\nu \int_\Omega (D\varphi)_S : (Du^\nu)_S dx - \nu \int_{\partial\Omega} \alpha(\varphi \cdot \tau)(u^\nu \cdot \tau) dS$$

$$= \int_\Omega u^\nu (u^\nu \cdot \nabla)\varphi dx - 2\nu \int_\Omega (D\varphi)_S : (Du^\nu)_S dx - \nu \int_{\partial\Omega} \alpha(\varphi \cdot \tau)(u^\nu \cdot \tau) dS,$$

using integration by parts and the fact that u^ν is divergence free. On the other hand, we also have

$$\frac{\partial g}{\partial s} = \int_\Omega u^\nu(x,t)\varphi_s(x,s) dx.$$

Therefore, it follows that

$$\frac{d}{dt}(g(t,t)) = \int_\Omega u^\nu(x,t)\varphi_t(x,t) dx$$

$$+ \int_\Omega u^\nu (u^\nu \cdot \nabla)\varphi dx - 2\nu \int_\Omega (D\varphi)_S : (Du^\nu)_S dx - \nu \int_{\partial\Omega} \alpha(\varphi \cdot \tau)(u^\nu \cdot \tau) dS.$$

Integrating this last identity in time and identifying the initial data yields the desired result. □

We now state and prove the main result in this section.

PROPOSITION 1. *Let $\omega_0 \in L^p(\Omega)$ for some $p > 2$ and $u_0 = K_\Omega[\omega_0]$. Fix $\nu > 0$. Then there exists a unique vector field $u^\nu = u^\nu(x,t) \in C([0,T); L^2(\Omega)) \cap L^2((0,T); H^1(\Omega))$ satisfying the weak formulation* (2) *of the* 2*D incompressible Navier–Stokes system* (1) *with initial data u_0. Moreover, the associated vorticity $\omega^\nu = \operatorname{curl} u^\nu$ satisfies the estimate*

$$\|\omega^\nu(\cdot,t)\|_{L^p(\Omega)} \le C$$

a.e. in time, with constant $C > 0$ independent of viscosity.

Proof. Let $\omega_{0,n}$ be a sequence of compatible functions approximating ω_0 strongly in L^p, as constructed in Lemma 2, and let $u_{0,n} = K_\Omega[\omega_{0,n}]$. Let u_n^ν be the weak solution of system (1) given by the well-posedness result of [1], and let $\omega_n^\nu = \operatorname{curl} u_n^\nu$ be the corresponding vorticity. We begin by observing that Lemma 3 gives the uniform estimate

$$\|\omega_n^\nu\|_{L^\infty((0,T);L^p(\Omega))} \le C(\|\omega_0\|_{L^p(\Omega)} + \|u_0\|_{L^2(\Omega)}) \tag{14}$$

for some $C > 0$. By the Poincaré and Calderón–Zygmund inequalities, it follows that

$$\|u_n^\nu\|_{L^\infty((0,T);W^{1,p}(\Omega))} \le C(\|\omega_0\|_{L^p(\Omega)} + \|u_0\|_{L^2(\Omega)}). \tag{15}$$

Let $\varphi \in C_c^\infty((0,T) \times \overline{\Omega})$ be a divergence-free test vector field which is tangent to the boundary of Ω. We compute the time-derivative of u_n^ν in the sense of distributions. We have, using (13),

$$\langle \varphi, \partial_t u_n^\nu \rangle = -\int_0^T \int_\Omega (\partial_t \varphi) u_n^\nu$$

$$= \int_0^T \int_\Omega u_n^\nu (u_n^\nu \cdot \nabla)\varphi - 2\nu (D\varphi)_S : (Du_n^\nu)_S dx dt - \nu \int_0^T \int_{\partial\Omega} \alpha(\varphi \cdot \tau)(u_n^\nu \cdot \tau) dS.$$

Recall that $p > 2$, so that (15) implies that $\|u_n^\nu\|_{L^\infty((0,T)\times\Omega)} \leq C$ for some constant $C > 0$ depending only on the initial data. Similarly, $\|Du_n^\nu\|_{L^2((0,T)\times\Omega)}$ is bounded uniformly by a positive constant depending only on initial data. We use these facts to estimate $\partial_t u_n^\nu$. Let φ be a test vector field, which we first assume to be divergence free as above. We have

$$|\langle \varphi, \partial_t u_n^\nu \rangle| \leq \big(\|u_n^\nu\|_{L^\infty((0,T)\times\Omega)} \|u_n^\nu\|_{L^2((0,T)\times\Omega)} + 2\nu \|Du_n^\nu\|_{L^2((0,T)\times\Omega)}$$

$$+ \nu C \|\alpha u_n^\nu\|_{L^2((0,T);H^1(\Omega))} \big) \|\varphi\|_{L^2((0,T);H^1(\Omega))} \leq C \|\varphi\|_{L^2((0,T);H^1(\Omega))},$$

where we have used the continuity of the trace operator from $H^1(\Omega)$ onto $L^2(\partial\Omega)$ to estimate the boundary term. Now, if the test vector field φ is not divergence free, we use standard properties of the Leray projector P to obtain the estimate

$$\|P\varphi\|_{L^2((0,T);H^1(\Omega))} \leq C \|\varphi\|_{L^2((0,T);H^1(\Omega))},$$

and we repeat the argument above with $P\varphi$ in place of φ. Note that

$$\langle \varphi, \partial_t u_n^\nu \rangle = \langle P\varphi, \partial_t u_n^\nu \rangle$$

as $\partial_t u_n^\nu$ is divergence free and tangent to the boundary. By duality this implies the estimate

$$\|\partial_t u_n^\nu\|_{L^2((0,T);H^{-1}(\Omega))} \leq C, \tag{16}$$

with $C > 0$ depending only on the initial data. Thus u_n^ν is equicontinuous from $(0,T)$ to $H^{-1}(\Omega)$, and we can use the Aubin–Lions lemma to obtain a subsequence, which we will not relabel, converging strongly in $C([0,T]; L^2(\Omega))$. Without loss of generality this subsequence also converges weakly in $L^2((0,T); H^1(\Omega))$ to a limit u^ν. It is now easy to see that we can pass to the limit in each term in the weak formulation (2) of the Navier–Stokes equations, thereby concluding the proof of existence for the initial-boundary value problem (1). Furthermore, from the estimate on vorticity (14) it follows that

$$\|\omega^\nu(\cdot, t)\|_{L^p(\Omega)} \leq C$$

a.e. in time, for some constant $C > 0$ depending only on the initial data.

The uniqueness portion of this result is standard and may be obtained by adapting the classical argument using an energy estimate on the difference of two solutions with the same data. We conclude that there exists at most one weak solution $u \in C([0,T]; L^2(\Omega)) \cap L^2((0,T); H^1(\Omega))$ of (1). □

Remark 6. The proof above can be adapted for $1 < p \leq 2$, assuming of course that Lemma 3 could be proved in that case. The main steps in this adaptation would be the following:

- Substitute the L^∞ estimate on u_n^ν by an $L^\infty((0,T); L^{p^*})$ estimate, with p^* either the critical Sobolev exponent if $p < 2$ or an arbitrary number $1 < q < \infty$ if $p = 2$.
- Use the fact that $\sqrt{\nu}\|u_n^\nu\|_{L^2((0,T);H^1(\Omega))}$ is bounded uniformly in n and ν by the L^2-norm of the initial velocity. This is a consequence of standard energy estimates for the Navier–Stokes equations.

6. Inviscid limit and conclusions. Let $\omega_0 \in L^p(\Omega)$ for some $p > 2$ and let $u_0 = K_\Omega[\omega_0]$. In this last section we show that the sequence of solutions of the Navier–Stokes equations with initial velocity u_0 and with Navier friction conditions possesses a converging subsequence to a solution of the Euler equations with the same initial velocity as viscosity vanishes. The proof is very similar to the existence part of the proof of Proposition 1.

THEOREM 1. *Let $u^\nu = u^\nu(x,t)$ be the solution of (1) such that $u^\nu(\cdot,0) = u_0$. Then there exists a sequence $\nu_k \to 0$ such that $u^{\nu_k} \to u$ strongly in $C([0,T];L^2(\Omega))$ as $k \to \infty$ and u is a weak solution of the incompressible 2D Euler equations in the sense that*

$$\int_0^T \int_\Omega u\varphi_t + u(u\cdot\nabla)\varphi dxdt + \int_\Omega u_0\varphi(\cdot,0)dx = 0 \tag{17}$$

for any test vector field $\varphi \in C_c^\infty([0,T)\times\overline{\Omega})$ which is divergence free and tangent to the boundary.

Proof. We recall from the proof of Proposition 1 that the following uniform estimates hold for u^ν:

$$\|u^\nu\|_{L^\infty((0,T);W^{1,p}(\Omega))} \le C$$

and

$$\|\partial_t u^\nu\|_{L^2((0,T);H^{-1}(\Omega))} \le C,$$

where $C > 0$ depends only on the initial velocity u_0 and initial vorticity ω_0 and is independent of viscosity (see the proof of (15) and (16)). From these estimates it is possible to extract a subsequence u^{ν_k} which converges strongly in $C([0,T];L^2(\Omega))$ and weakly in $L^2((0,T);H^1(\Omega))$. It is easy to see that these modes of convergence are sufficient to pass to the limit in each term of (13) and guarantee that the limit function u satisfies the identity

$$\int_0^T \int_\Omega u\varphi_t + u(u\cdot\nabla)\varphi dxdt + \int_\Omega u_0\varphi(\cdot,0)dx = 0$$

for any test vector field $\varphi \in C_c^\infty([0,T)\times\overline{\Omega})$ which is divergence free and tangent to $\partial\Omega$. This is precisely the standard formulation of a weak solution of the Euler equations, and hence we conclude the proof. ∎

Remark 7. We note that relation (13) is the natural identity to try to pass to the limit in order to obtain (17). Furthermore, all the derivatives which appear in (13) either are applied to the test function or have a factor of ν, so that, in the limit $\nu \to 0$, there are no derivatives applied to the limit flow. This is relevant since solutions of Euler equations are less regular than solutions of Navier–Stokes equations.

We conclude this article with a few final observations. First, we call attention once more to the fact that the authors are not convinced of the criticality of $p = 2$, so the critical p remains an open problem. Second, as mentioned in section 3, there is no asymptotic description in the fluid mechanics literature of the boundary layer associated with the Navier friction condition, something which would clarify the issues raised here, irrespective of physical relevance. Finally, an interesting question which we have not explored is whether the viscosity weak solution of the incompressible 2D Euler equations obtained above conserves the L^p-norm of vorticity. Conservation

of the L^p-norm of vorticity holds both for weak solutions in the full plane, as a consequence of DiPerna–Lions theory (see [9]), and for strong solutions, as one can ascertain directly from the vorticity equation. In the viscous approximation, vorticity can be generated at the boundary, so that the question is whether this possibility disappears in the vanishing viscosity regime.

Acknowledgments. The authors would like to thank D. Iftimie and M. O. Souza for enlightening discussions. We would also like to thank the referees for several comments which improved the presentation and for pointing out the references [5, 6].

THE CONVEX SCATTERING SUPPORT IN A BACKGROUND MEDIUM*

STEVEN KUSIAK† AND JOHN SYLVESTER‡

Abstract. We discuss inverse problems for the Helmholtz equation at fixed energy, specifically the inverse source problem and the inverse scattering problem from a medium or an obstacle. In [S. Kusiak and J. Sylvester, *Comm. Pure Appl. Math.*, 56 (2003), pp. 1525–1548], we introduced the *convex scattering support* of a far field, a set which will be a subset of the convex hull of the support of any source or scattering inhomogeneity which can produce it.

We extend these results and modify the methods to locate a source within a known inhomogeneous background medium, or a deviation from that medium, using observations of a single far field. We also describe some numerical examples that illustrate the robustness of the method.

Key words. inverse scattering, Helmholtz equation, partial differential equations

DOI. 10.1137/S0036141003433577

1. Introduction.

We study an inverse problem for the Helmholtz equation at fixed energy. Our aim is to deduce the location of the source or scatterer from observations of scattered waves made at a distance, which are called *far fields*. Typically, one has access to several far fields. For the inverse medium problem, the index of refraction is uniquely determined by the full scattering kernel, i.e., the observed scattered field for every possible incident wave. In special cases [9, 5, 6], substantial information about the support of the scatterer has been obtained from the scattered field of a few, or even only one, incident wave.

In [8], we showed that, in a homogeneous background medium, we could associate the *convex scattering support* with a single far field. This set is the smallest convex set which supports a source that can produce that far field. We also produced a test, *the circular Paley–Wiener theorem*, for computing the convex scattering support in two dimensions. In [10], we introduced a different numerical method, called the *range test*, for computing this support in a two-dimensional homogeneous medium.

Our work was motivated by the linear sampling method of Colton and Kirsch (see [2]). They first developed a *Picard test*, which determines whether a far field belongs to the range of the (compact) scattering operator, as a tool for inverse scattering. This method, and the subsequent factorization method of Kirsch [7], differ from what we present here in that they require much more data (the full scattering map) and compute much more (the exact support of the scatterer).

In section 2 of this paper, we introduce the necessary scattering formalism and restate the circular Paley–Wiener theorem as a *Picard test*. This restatement, though less explicit, generalizes directly to inhomogeneous media and higher dimensions.

In section 3 we produce this general test. The general test tells us if a far field could have been produced by a source or a scatterer located within a specific domain,

but not whether the true source was located there. Section 4 addresses this issue by extending the concept of convex scattering support to inhomogeneous media. The conclusion is that we can locate a smallest convex set, which must be contained in the convex hull of the support of any source which radiates that far field. Conversely, we produce a source, supported in any neighborhood of the convex scattering support which does radiate that far field.

Section 5 discusses the relationship between the support of a scatterer, rather than a source, and the convex scattering support. In this case we show that the convex scattering support provides a lower bound for the convex hull of the scatterer. Unlike the source case, we don't expect this lower bound to be optimal.

Section 6 contains a description of an explicit algorithm and some numerical results. Maybe the most important observation in this section is that the practical implementation of the algorithm is much simpler and more robust than the theorem guarantees.

2. Far fields in a homogeneous medium. We model the time harmonic wave radiated by a source in a homogeneous medium as a solution to the inhomogeneous Helmholtz equation:

$$(\Delta + k^2)u(x) = f(x), \quad x \in \mathbb{R}^n. \tag{2.1}$$

Equation (2.1) has a unique *outgoing solution*, $u = G_0^+ f$, which can be computed by the limiting absorption principle (see, e.g., [11, p. 147]).

$$\begin{aligned} G_0^+ f &= \lim_{\epsilon \downarrow 0} (\Delta + (k - i\epsilon)^2)^{-1} f \\ &= -\lim_{\epsilon \downarrow 0} \int_{\mathbb{R}^n} \frac{e^{i\langle x,\xi\rangle} \widehat{f}(\xi)}{|\xi|^2 - (k - i\epsilon)^2} d\xi. \end{aligned} \tag{2.2}$$

The limiting absorption principle chooses the unique solution u of (2.1) which extends to be holomorphic in $\{\mathrm{Im}(k) \le 0\}$ and is continuous up to the boundary. According to (one of the many theorems called) the Paley–Wiener theorem, this solution is the Fourier transform of the unique solution $\tilde{u}$ of the wave equation which is zero in the past. That is,

$$u(k, x) = \int_0^\infty e^{-ikt} \tilde{u}(x, t) dt.$$

We call a function in the range of G_0^+ outgoing. We shall refer to a function as incoming if $v = G_0^- f$, where

$$G_0^- f = \lim_{\epsilon \downarrow 0} (\Delta + (k + i\epsilon)^2)^{-1} f.$$

Alternatively, $u = G_0^+ f$ may be characterized as the unique solution of (2.1) satisfying the Sommerfeld radiation condition:

$$\lim_{r \to \infty} r^{\frac{n-1}{2}} (\partial_r u - iku) = 0, \quad r = |x|.$$

Inverting the Fourier transform in (2.2), we may also represent $u = G_0^+ f$ (cf. [4]) as

$$(G_0^+ f)(x) := -\frac{i}{4} \left(\frac{k}{2\pi} \right)^{\frac{n-2}{2}} \int_{\mathbb{R}^n} |x - y|^{\frac{2-n}{2}} H^{(1)}_{\frac{n-2}{2}}(k|x - y|) f(y) dy. \tag{2.3}$$

Here, $H^{(1)}_{(n-2)/2}$ is the Hankel function of the first kind. The representation of G_0^- uses the other Hankel function; i.e., its kernel is the complex conjugate of the kernel of G_0^+.

The simplest estimate for the solution operators $G_0^\pm$ is on the weighted L^2 spaces, $\mathrm{H}^s_\delta(\mathbb{R}^n)$. For $\delta = 0$, $\mathrm{H}^s_0(\mathbb{R}^n)$ is the Sobolev space, $\mathrm{H}^s(\mathbb{R}^n)$. For $\delta > 0$,

$$\|f\|_{s,\delta} = \|(1+|x|^2)^{\delta/2} f\|_{s,0}.$$

PROPOSITION 2.1. *The operators $G_0^\pm$ are bounded as maps between the weighted L^2 spaces*

$$G_0^\pm : \mathrm{H}^s_\delta(\mathbb{R}^n) \longrightarrow \mathrm{H}^{s+2}_{-\delta}(\mathbb{R}^n) \tag{2.4}$$

for any real s and any $\delta > \frac{1}{2}$. Moreover, G_0^- is the Hilbert space adjoint of G_0^+ on L^2 (i.e., $s = 0$ in (2.4)). That is,

$$G_0^{+\,*} = G_0^-.$$

Proof. The estimate was first proved in [1]. Once we have it, it is a simple matter to interchange the order of integration in the L^2 pairing to check that the two operators are adjoints. □

The far field describes the asymptotics of u as $|x| \to \infty$. Stationary phase applied to (2.2) or Hankel function asymptotics applied to (2.3) yields

$$u(x) \sim \frac{e^{ik|x|}}{|x|^{(n-1)/2}} C_{n,k} \int_{\mathbb{R}^n} e^{-ik\langle \Theta, y\rangle} f(y)dy, \quad |x| \to \infty, \tag{2.5}$$

where $\Theta = \frac{x}{|x|}$ is a unit vector on the $n-1$-dimensional sphere S^{n-1} and

$$C_{n,k} = \frac{-i}{\sqrt{8\pi}} \left(\frac{k}{2\pi}\right)^{\frac{n-2}{2}} e^{-i(n-1)\pi/4}.$$

Hence, given a source f we define the far field, $u_\infty = F_0 f$, by

$$(F_0 f)(\Theta) = \int_{\mathbb{R}^n} e^{-ik\langle \Theta, y\rangle} f(y)dy \tag{2.6}$$

$$= \hat{f}(k\Theta). \tag{2.7}$$

The mapping properties of F_0^+ are important for us.

PROPOSITION 2.2. *F_0^+ is a compact linear map*

$$F_0^+ : \mathrm{H}^s_\delta(\mathbb{R}^n) \longrightarrow L^2(S^{n-1}).$$

Its adjoint with respect to the distributional (not the Hilbert space) pairing

$$F_0^{+\,\dagger} : L^2(S^{n-1}) \longrightarrow \mathrm{H}^{-s}_{-\delta}(\mathbb{R}^n)$$

is the Herglotz operator

$$(F_0^{+\,\dagger}\alpha)(x) = (\mathcal{H}f)(x) \tag{2.8}$$

$$= \int_{S^{n-1}} e^{ik\langle \Theta, x\rangle} \alpha(\Theta) dS(\Theta).$$

Remark 2.3. Functions in the range of the Herglotz operator are usually referred to as incident fields. They are the $\mathrm{H}^s_{-\delta}$ solutions of the homogeneous (or free) Helmholtz equation for all real s and any $\delta > \frac{1}{2}$. The Herglotz operator represents these free solutions as superpositions of plane waves.

Proof. The boundedness of F_0^+ follows easily from the representation (2.7). We need only note that if $f \in \mathrm{H}^s_\delta$, then $\hat{f} \in \mathrm{H}^\delta_s$. As $\delta > \frac{1}{2}$, the restriction map from $\mathrm{H}^\delta_s(\mathbb{R}^n)$ to L^2 of the codimension one sphere, S^{n-1}, is a compact operator.

The boundedness of $F_0^\dagger$ follows from the boundedness of F_0. The equality (2.8) can be seen by using formula (2.6), pairing with an L^2 far field, and interchanging the order of integration. Nevertheless, we give a proof that relies more on scattering.

Let $u = G_0^+ f$ and $v = \mathcal{H}\alpha$. Stationary phase shows that v has the asymptotics

$$v(x) \sim C_{n,k} \frac{e^{ik|x|}}{|x|^{(n-1)/2}} \alpha(\theta) + C_{n,k} \frac{e^{-ik|x|}}{|x|^{(n-1)/2}} \alpha(-\theta), \quad |x| \to \infty. \tag{2.9}$$

Applying Green's theorem on the ball of radius R gives

$$\int_{\partial B_R} v \frac{\partial u}{\partial \nu} - \frac{\partial v}{\partial \nu} u = \int_{B_R} v(\Delta + k^2)u - (\Delta + k^2)vu. \tag{2.10}$$

Letting $R \to \infty$ and making use of (2.5) and (2.9) allows us to evaluate the left-hand side of (2.10). Recalling that v is a free solution of the Helmholtz equation removes the second term from the left-hand side so that

$$\int_{S^{n-1}} \alpha(\theta)(F_0 f)(\theta) dS(\theta) = \int_{B_R} vf$$
$$\langle \alpha, F_0 f \rangle = \langle \mathcal{H}\alpha, f \rangle. \qquad \square$$

Proposition 2.2 has a more general statement which will prove convenient in the next section.

THEOREM 2.4. *Suppose that $s_1 + s_2 > -2$, $\delta > \frac{1}{2}$, and that u and v satisfy*

$$u \in \mathrm{H}^{s_1+2}_{-\delta}(\mathbb{R}^n) \quad \textit{and} \quad (\Delta + k^2)u \in \mathrm{H}^{s_1}_\delta(\mathbb{R}^n), \tag{2.11}$$

$$v \in \mathrm{H}^{s_2+2}_{-\delta}(\mathbb{R}^n) \quad \textit{and} \quad (\Delta + k^2)v \in \mathrm{H}^{s_2}_\delta(\mathbb{R}^n); \tag{2.12}$$

then as $|x| \to \infty$,

$$u(x) \sim \frac{e^{ik|x|}}{|x|^{(n-1)/2}} u^+_\infty(\theta) + \frac{e^{-ik|x|}}{|x|^{(n-1)/2}} u^-_\infty(\theta),$$
$$v(x) \sim \frac{e^{ik|x|}}{|x|^{(n-1)/2}} v^+_\infty(\theta) + \frac{e^{-ik|x|}}{|x|^{(n-1)/2}} v^-_\infty(\theta), \tag{2.13}$$

and

$$\langle u^+_\infty, v^-_\infty \rangle - \langle u^-_\infty, v^+_\infty \rangle = \langle u, (\Delta + k^2)v \rangle - \langle (\Delta + k^2)u, v \rangle. \tag{2.14}$$

Remark 2.5. When we write "$\sim$" meaning "asymptotic to," we mean classical asymptotics only in the case that u happens to be smooth near infinity. This is always the case if $(\Delta + k^2)u$ has compact support. In the more general setting, the space of functions that satisfy (2.11) (or (2.12)) form a Hilbert space, and we are asserting that the mappings

$$u \mapsto u^\pm_\infty$$

extend by continuity as mappings from that Hilbert space into $L^2(S^{n-1})$.

Proof. Suppose first that u and v are compactly supported and smooth. Then every such u (and v) is a linear combination of an outgoing function and a solution of the homogeneous Helmholtz equation, i.e., an outgoing wave plus a Herglotz function. Each of these has the asymptotics asserted in (2.5) and in (2.9), and therefore their sum had these asymptotics as well. Now apply Green's formula as in (2.10) to obtain (2.14).

Finally, notice that the left-hand side of (2.14) is a continuous bilinear functional with respect to L^2 convergence and the right-hand side is continuous when $u_n \to u$ and $v_n \to v$ in the topologies of (2.11). □

DEFINITION 2.6. *We shall refer to u^+_∞ as the outgoing far field of u and u^-_∞ as its incoming far field. An outgoing function has zero incoming far field, i.e., $u^-_\infty = 0$. A Herglotz function has outgoing and incoming far fields related by the antipodal map* (2.9)*. Intuitively, one can see this by thinking about a spherical incoming wave passing through the origin to become an outgoing wave.*

In [8], we began to study the *scattering support* of a far field. The first step is to ask whether a far field could have been produced by a source which is a distribution supported in a closed set. We recall that the restricting of a distribution to an open set means restricting it to act on the subspace $C_0^\infty(\Omega)$ of $C_0^\infty(\mathbb{R}^n)$. The support of a distribution is the closed set defined below.

DEFINITION 2.7. *A point x belongs to the support of a distribution f if there exists no open neighborhood, O_x, such that $f|_{O_x} = 0$.*

Distributions supported on a closed set form natural subspaces of $\mathrm{H}^s_\delta(\mathbb{R}^n)$.

DEFINITION 2.8. *$\mathrm{H}^s_0(\Omega)$ is the closed subspace of $\mathrm{H}^s_\delta(\mathbb{R}^n)$ consisting of those distributions which are supported in $\overline{\Omega}$.*

The definition is independent of δ as long as Ω is bounded.

We point out that this is different from $H^s(\Omega)$, which denotes the restrictions of distributions to a bounded open set, and is not a subspace of any $\mathrm{H}^s_\delta(\mathbb{R}^n)$. In fact, $\mathrm{H}^{-s}(\Omega)$ is the natural dual to $\mathrm{H}^s_0(\Omega)$ for all real s. For bounded open sets Ω and positive s, our definition of $\mathrm{H}^s_0(\Omega)$ coincides with the common definition, i.e., the closure of $C_0^\infty(\Omega)$ in the H^s norm. In [8], we proved the following theorem.

THEOREM 2.9. *Let $\alpha \in L^2(S^1)$ represent a far field. There exists $f \in \mathrm{H}^s_0(B_R)$ such that*

$$F_0^+ f = \alpha = \sum_{n=-\infty}^{\infty} \alpha_n e^{in\theta} \tag{2.15}$$

if and only if

$$\sum_{n=-\infty}^{\infty} \left| \frac{\alpha_n n^s}{\sigma_n(R)} \right|^2 < \infty, \tag{2.16}$$

where

$$\sigma_n(R) = \left(\int_0^R |J_n(kr)|^2 r\,dr \right)^{\frac{1}{2}}.$$

In section 3 of this paper, we will prove a generalization of this result to variable index of refraction, higher dimensions, and more general domains. We close this section with a restatement of this theorem which anticipates the generalization to follow.

We don't give the proof here, as it will follow as a corollary of the more general Theorem 3.6 in section 3.

THEOREM 2.10. *Let $\alpha \in L^2(S^{n-1})$ represent a far field. Let $F_0^+|_{\mathrm{H}_0^s(\Omega)}$ represent the restriction of the compact operator F_0^+ to $\mathrm{H}_0^s(\Omega)$ and let*

$$F_0^+|_{\mathrm{H}_0^s(\Omega)} = \sum \sigma_n \psi_n \otimes \overline{\phi_n}$$

be its singular value decomposition. Then

$$\alpha \in \mathrm{Range}(F_0^+|_{\mathrm{H}_0^s(\Omega)})$$

if and only if

$$\sum \left| \frac{(\alpha, \psi_n)}{\sigma_n} \right|^2 < \infty. \tag{2.17}$$

To facilitate the comparison of Theorems 2.9 and 2.10, we describe two examples with Ω equal to $B_R \in \mathbb{R}^2$, the ball of radius R centered at the origin. We can separate variables in this case, representing the operator F_0^+ in terms of complex exponentials, Bessel functions, and the characteristic function of the ball, χ_{B_R}.

$$F_0^+|_{L^2(B_R)} = \sum_{n=-\infty}^{\infty} \mathrm{e}^{in(\theta - \frac{\pi}{2})} \otimes \chi_{B_R} \mathrm{e}^{-in(\phi - \frac{\pi}{2})} J_n(kr). \tag{2.18}$$

Because we are in L^2, its Hilbert space adjoint is

$$(F_0^+|_{L^2(B_R)})^* = \sum_{n=-\infty}^{\infty} \chi_{B_R} \mathrm{e}^{in(\phi - \frac{\pi}{2})} J_n(kr) \otimes \mathrm{e}^{-in(\theta - \frac{\pi}{2})}$$

and its singular values are the eigenvalues of $(F_0^+|_{L^2(B_R)} F_0^+|^*_{L^2(B_R)})$

$$\sigma_n^2 = 4\pi^2 \int_0^R J_n^2(ks) s ds,$$

so we see that (2.16) and (2.17) agree in the case $s = 0$.

Next, we consider $F_0^+|_{\mathrm{H}_0^1(B_R)}$. The operator itself has the same representation as in (2.18); we are just considering it on a smaller subspace. A bit of a calculation shows that the Hilbert space adjoint is now

$$(F_0^+|_{\mathrm{H}_0^1(B_R)})^* = \sum_{n=-\infty}^{\infty} \chi_{B_R} \mathrm{e}^{in(\phi - \frac{\pi}{2})} \left(J_n(kr) - \left(\frac{r}{R}\right)^{|n|} J_n(kR) \right) \otimes \mathrm{e}^{-in(\theta - \frac{\pi}{2})}$$

with singular values (we'll call them $\tilde{\sigma}_n$'s)

$$\tilde{\sigma}_n^2 = 4\pi^2 \left[\int_0^R J_n^2(ks) s ds - \frac{J_n(kR)}{R^n} \int_0^R J_n(ks) s^{n+1} ds \right]. \tag{2.19}$$

Now, the large n asymptotics of the Bessel function is

$$J_n(kr) \sim \frac{1}{\sqrt{\pi n}} \left(\frac{ekr}{2n} \right)^n \quad \text{for } n \gg kr.$$

Integrating with respect to r then gives

$$\sigma_n^2 \sim \frac{8\pi}{(ek)^2}\left(\frac{ekR}{2n}\right)^{2n+2}\left(1+O\left(\frac{1}{n}\right)\right), \quad n\to\infty,$$

while the leading order asymptotics of the two terms in (2.19) cancel, so that

$$\tilde{\sigma}_n^2 = O\left(\frac{\sigma_n^2}{n^2}\right),$$

which agrees with (2.16) in the case $s=1$.

3. Far fields in an inhomogeneous medium. If the medium is inhomogeneous, (2.1) is replaced by

$$(\Delta + k^2 n(x))u(x) = f(x), \quad x\in\mathbb{R}^n. \tag{3.1}$$

The coefficient $n(x)$ is the index of refraction and is the square of the reciprocal of the wave speed at x. We will assume that n has positive imaginary part, that $n-1$ is compactly supported, and that $n\in L^p(\mathbb{R}^n)$ for $p>\max(n-2,n/2)$. The unique continuation principle holds for this is the class of n's.

It will be convenient to rewrite (3.1) as

$$(\Delta + k^2 - q(x))u = f$$

with $q=k^2(n-1)$. Because q is not necessarily smooth, we must restrict the regularity of the Sobolev spaces. We want to allow single and double layer potentials as sources, so that the application of our results to active scattering will include scattering from an obstacle. We will treat $f\in \mathrm{H}_\delta^{s-2}(\mathbb{R}^n)$ with $0\le s\le n/p$ and $\delta>\frac{1}{2}$.

We will standardize the notation used in this section. We will use η and σ to denote unrestricted real numbers. The symbols δ, p, and s will always satisfy the inequalities

$$\begin{gathered}\delta > 1/2,\\ p>\max(2,n/2),\\ 0\le s\le n/p.\end{gathered} \tag{3.2}$$

Our next theorem asserts the existence of the analogues of G_0 and F_0.

THEOREM 3.1. *Let $q\in L^p(\mathbb{R}^n)$ and have compact support. Let $f\in \mathrm{H}_\delta^{s-2}(\mathbb{R}^n)$ with p, s, δ satisfying* (3.2). *Then there exists a unique outgoing (resp., incoming) solution of*

$$(\Delta + k^2 - q(x))u = f$$

which has the asymptotic behavior

$$u(x)\sim \frac{e^{ik|x|}}{|x|^{(n-1)/2}}u_\infty^\pm(\Theta), \quad |x|\to\infty.$$

Moreover, the unique solution u is computed by the operator

$$\begin{aligned} u(x) &= (G_q^\pm f)(x)\\ &:= (I-G_0^\pm q)^{-1}G_0^\pm f \qquad (3.3)\\ &= G_0^\pm(I-qG_0^\pm)^{-1}f \qquad (3.4)\end{aligned}$$

and

$$\begin{aligned} u_\infty^\pm(\Theta) &= (F_q^\pm f)(\Theta) \\ &:= F_0^\pm (I - qG_0^\pm)^{-1} f. \end{aligned} \tag{3.5}$$

Additionally, both $G_q^\pm$ and $F_q^\pm$ are compact operators:

$$G_q^\pm : \mathrm{H}_\delta^{s-2}(\mathbb{R}^n) \to \mathrm{H}_{-\delta}^{s-n/p}(\mathbb{R}^n), \tag{3.6}$$

$$F_q^\pm : \mathrm{H}_\delta^{s-2}(\mathbb{R}^n) \to L^2(S^{n-1}). \tag{3.7}$$

The proof requires that we show that $(I - G_0^\pm q)$ is invertible. Let M_q denote the operator of multiplication by q. Then we have the following lemma.

LEMMA 3.2. *Let q be a compactly supported function on $\mathbb{R}^n$. For any real $p \geq 2$, any real δ and η, and any $0 \leq s \leq \frac{n}{p}$,*

$$M_q : \mathrm{H}_{\eta_1}^s(\mathbb{R}^n) \to \mathrm{H}_{\eta_2}^{s-\frac{n}{p}}(\mathbb{R}^n) \tag{3.8}$$

is bounded.

Proof. According to Hölder's inequality,

$$\begin{aligned} \|qu\|_{L^2(\mathbb{R}^n)} &\leq \|q\|_{L^p(\mathbb{R}^n)} \|u\|_{L^{\frac{2p}{p-2}}(\mathbb{R}^n)} \\ &\leq \|q\|_{L^p(\mathbb{R}^n)} \|u\|_{\mathrm{H}^{\frac{n}{p}}(\mathbb{R}^n)}, \end{aligned}$$

with the second line a consequence of the Sobolev inequality. Thus

$$M_q : \mathrm{H}_0^{\frac{n}{p}}(\mathbb{R}^n) \to L^2(\mathbb{R}^n)$$

is bounded. Duality implies that

$$M_q : L^2(\mathbb{R}^n) \to \mathrm{H}_0^{-\frac{n}{p}}(\mathbb{R}^n)$$

is also bounded. Interpolation then gives (3.8) in the case that $\delta = \eta = 0$. However, because q is compactly supported,

$$\left\| (1 + |x|^2)^{\frac{\eta - \delta}{2}} q \right\|_{L^p(\mathbb{R}^n)} \leq C \|q\|_{L^p(\mathbb{R}^n)},$$

which implies (3.8) for any δ and any η. ∎

As a consequence, we have the following corollary.

COROLLARY 3.3. *Let $p \geq 2$, $0 \leq s \leq \frac{n}{p}$, and $\delta > \frac{1}{2}$. Then*

$$G_0^+ q : \mathrm{H}_\eta^s(\mathbb{R}^n) \to \mathrm{H}_{-\delta}^{s+2-\frac{n}{p}}(\mathbb{R}^n), \tag{3.9}$$

and

$$qG_0^+ : \mathrm{H}_\delta^{s-2}(\mathbb{R}^n) \to \mathrm{H}_\eta^{s-\frac{n}{p}}(\mathbb{R}^n)$$

is bounded. If, in addition, $p > \frac{n}{2}$, then

$$G_0^\pm q : \mathrm{H}_{-\delta}^s(\mathbb{R}^n) \to \mathrm{H}_{-\delta}^s(\mathbb{R}^n)$$

are compact.

Proof. The first statement is a direct consequence of Proposition 2.1 and Lemma 3.2, while the second follows from the compact embedding of $\mathrm{H}^{s_1}_{\eta}$ in $\mathrm{H}^{s_2}_{\delta}$ whenever $\eta > \delta$ and $s_1 > s_2$. ∎

COROLLARY 3.4. *Let $q \in L^p(\mathbb{R}^n)$ with compact support and let p, s, δ satisfy* (3.2). *Then $(I - G_0^+ q)^{-1}$ exists as a bounded linear operator from $\mathrm{H}^s_{-\delta}(\mathbb{R}^n)$ to $\mathrm{H}^s_{-\delta}(\mathbb{R}^n)$.*

Proof. Corollary 3.3 implies that $(I - G_0^+ q)$ is Fredholm, so we only need to show uniqueness. Suppose that $u \in \mathrm{H}^s_{-\delta}(\mathbb{R}^n)$ satisfies

$$(I - G_0^+ q)u = 0. \tag{3.10}$$

Repeated application of (3.9) shows us that $u \in \mathrm{H}^2_{-\delta}(\mathbb{R}^n)$ and satisfies

$$(\Delta + k^2)u = qu.$$

Since u is outgoing, $\overline{u}$ is incoming and satisfies

$$(\Delta + k^2)\overline{u} = \overline{qu}$$

so that we may apply (2.14) to obtain the identities

$$2ik \left\langle \overline{u^+_\infty}, u_\infty \right\rangle = \langle \overline{qu}, u\rangle - \langle \overline{u}, qu\rangle,$$
$$2ik\|u^+_\infty\|^2_{L^2} = 2i \int \operatorname{Im} q|u|^2,$$

which implies

$$\|u^+_\infty\|^2_{L^2} \le 0.$$

Thus, u is an outgoing function with no far field. Rellich's lemma [3] implies that u vanishes outside the support of q, and unique continuation then implies that $u = 0$ everywhere. ∎

COROLLARY 3.5. *Let $q \in L^p(\mathbb{R}^n)$ with compact support and let p, s, δ satisfy* (3.2). *Then $(I - qG_0^+)^{-1}$ exists as a bounded linear operator from $\mathrm{H}^{s-2}_{\delta}(\mathbb{R}^n)$ to $\mathrm{H}^{s-2}_{\delta}(\mathbb{R}^n)$.*

Proof. $(I - qG_0^+)^{-1}$ is also Fredholm, so only uniqueness need be checked. Suppose $f = qG_0^+ f$. Then $u = G_0^+ f$ satisfies (3.10), and therefore it must be zero. However, $f = (\Delta + k^2)u$, so f must also vanish. ∎

Proof of Theorem 3.1. We have shown that formulas (3.3), (3.4), and (3.5) make sense. Both (3.6) and (3.7) follow from the previous corollaries and the mapping properties of F_0 and G_0. To verify that (3.3) and (3.4) are equal, we start with the factorization

$$(I - G_0^\pm q)G_0^\pm = G_0^\pm(I - qG_0^\pm).$$

Now, both $(I - G_0^\pm q)$ and $(I - qG_0^\pm)$ are invertible, so that

$$(I - G_0^\pm q)^{-1}(I - G_0^\pm q)G_0^\pm(I - qG_0^\pm)^{-1} = (I - G_0^\pm q)^{-1}G_0^\pm(I - qG_0^\pm)(I - qG_0^\pm)^{-1},$$

which implies

$$G_0^\pm(I - qG_0^\pm)^{-1} = (I - G_0^\pm q)^{-1}G_0^\pm. \qquad ∎$$

With Theorem 3.1 in place, we may extend the Picard test (2.17) to the inhomogeneous equation.

THEOREM 3.6. *Let $\alpha \in L^2(S^{n-1})$ represent a far field and let $F_q^+|_{\mathrm{H}_0^s(\Omega)}$ represent the restriction of the compact operator F_q^+ to $\mathrm{H}_0^s(\Omega)$. Then*

$$\alpha \in \mathrm{Range}(F_q^+|_{\mathrm{H}_0^s(\Omega)})$$

if and only if

$$\sum \left| \frac{(\alpha_n, \psi_n)}{\sigma_n} \right|^2 < \infty,$$

where

$$F_q^+|_{\mathrm{H}_0^s(\Omega)} = \sum \sigma_n \psi_n \otimes \overline{\phi_n}$$

is the singular value decomposition of $F_q^+|_{\mathrm{H}_0^s(\Omega)}$.

This theorem tells us that we can look for a source in a known inhomogeneous background by simply replacing F_0 by F_q in the convergence test given in Theorem 2.10. Of course, to apply it we must numerically or analytically compute the singular value decomposition of $F_q^+|_{\mathrm{H}_0^s(\Omega)}$.

4. The convex scattering support. We are ready to use Theorem 3.6 to locate the support of a source in an inhomogeneous medium. In Theorem 5.2 of section 5, we will locate the region where a medium differs from a known background by applying this test. In both cases our data will be a single far field.

As we pointed out in [8], a single far field is not enough information to uniquely determine the support of a source. For example, if ϕ has compact support, then $f_\phi = (\Delta + k^2)\phi$ will always have zero far field. We can always add f_ϕ to a source to produce a new one with bigger support which produces the same far field. Thus we cannot associate with a far field a set which contains the support of any source which produces it.

However, we can determine a unique smallest convex set which must be a subset of the convex hull of the support of any source which produces that far field. We refer to this set as the *convex scattering support* of a far field. We will show below that the convex scattering support of any nonzero far field is a nonempty closed set, and that there always exists an L^2 source, supported in an arbitrarily small neighborhood of the convex scattering support, which will reproduce the far field.

We begin with the definition.

DEFINITION 4.1. *The convex scattering support of the far field u_∞, with respect to the background q, is*

$$\mathrm{cS}_k\mathrm{supp}_q u_\infty = \bigcap_{\substack{F_q f = u_\infty \\ f \in \mathrm{H}_\delta^s(\mathbb{R}^n)}} \mathrm{ch}(\mathrm{supp}\, f). \tag{4.1}$$

Here, $\mathrm{ch}(\mathrm{supp}\, f)$ *denotes the convex hull of the support of f.*

We must take $s > -2$ because F_q is only defined for such sources. The next lemma asserts that the $\mathrm{cS}_k\mathrm{supp}_q u_\infty$ doesn't depend on s for $-2 < s \leq 0$. It doesn't depend on s at all if q is smooth. We will use the notation $N_\epsilon(\Omega)$ to denote an open epsilon neighborhood of a set Ω.

LEMMA 4.2. *For any $f \in \mathrm{H}_0^s(\Omega)$ and any $\varepsilon > 0$, there exists $\tilde{f} \in L^2(N_\varepsilon(\Omega))$ such that*

$$F_q^+ \tilde{f} = F_q^+ f.$$

Proof. Let $u = G_q^+ f$ and let $\phi \in C^\infty(\mathbb{R}^n)$ satisfy

$$\phi = \begin{cases} 1, & x \in \mathbb{R}^n \backslash N_\varepsilon(\Omega), \\ 0, & x \in N_\varepsilon(\Omega), \end{cases}$$

and set

$$\tilde{f} = (\Delta + k^2 - q(x))\phi u.$$

Now, $G_q^+ f = u$ outside $N_\varepsilon(\Omega)$ and therefore has the same far field. Note that ϕu is supported outside $\operatorname{supp} f$ so that u is H^2 there, and thus $\tilde{f} \in L^2$. ∎

THEOREM 4.3. *For any far field $\alpha \in L^2(S^{n-1})$ with a compactly supported source, and any $\varepsilon > 0$, there exists an L^2 source f_ε such that $G_q^+ f_\varepsilon = \alpha$ and*

$$\operatorname{ch}(\operatorname{supp} f_\epsilon) \subset N_\epsilon(\mathrm{cS}_k \operatorname{supp}_q \alpha).$$

We shall need two lemmas for the proof.

LEMMA 4.4. *Suppose $\operatorname{supp} f_1 \subset \Omega_1$, $\operatorname{supp} f_2 \subset \Omega_2$, and that $\mathbb{R}^n \setminus (\Omega_1 \bigcup \Omega_2)$ is connected and contains a neighborhood of ∞. If*

$$F_q^+ f_1 = F_q^+ f_2 = \alpha,$$

then, for any $\varepsilon > 0$, there exists an $f_3 \in C^\infty(\mathbb{R}^n)$ with

$$\operatorname{supp} f_3 \subset N_\varepsilon(\Omega_1 \cap \Omega_2)$$

and

$$F_q^+ f_3 = \alpha.$$

Proof. According to Rellich's lemma and unique continuation [3], $u_1 = G_q^+ f_1$ and $u_2 = G_q^+ f_2$ agree on the $\mathbb{R}^n \setminus (\Omega_1 \bigcup \Omega_2)$.

Let $\phi \in C^\infty(\mathbb{R}^n)$ satisfy

$$\phi = \begin{cases} 1, & x \in \mathbb{R}^n \backslash N_\varepsilon(\Omega_1 \cap \Omega_2), \\ 0, & x \in N_{\frac{\varepsilon}{2}}(\Omega_1 \cap \Omega_2); \end{cases}$$

then

$$v = \begin{cases} \phi u_1, & x \in \mathbb{R}^n \backslash \Omega_1, \\ \phi u_2, & x \in \mathbb{R}^n \backslash \Omega_2, \\ 0, & x \in \Omega_1 \cap \Omega_2 \end{cases}$$

is a well-defined C^∞ function and $v = u_1 = u_2$ outside a compact set, so that

$$f_3 = (\Delta + k^2 - q(x))v$$

must also have far field α. ∎

LEMMA 4.5. *For any $\epsilon > 0$ and any far field α with a compactly supported source, there exists an integer N and a sequence of sources f_n such that*

$$N_\epsilon(\mathrm{cS}_k\mathrm{supp}_q\alpha) \supset \bigcap_{n=1}^{N} \mathrm{ch\,supp}(f_n). \tag{4.2}$$

Proof. Let B denote the complement of $\mathrm{cS}_k\mathrm{supp}_q\alpha$, let B_ϵ denote the complement of $N_\epsilon(\mathrm{cS}_k\mathrm{supp}_q\alpha)$, and let A_f denote the complement of $\mathrm{ch\,supp}(f)$. The A_f's are open and B_ϵ is closed. Taking complements in the definition (4.1) tells us that

$$B = \bigcup_{F_q^+ f = \alpha} A_f.$$

We will prove the theorem by showing that we may choose f_n such that

$$B_\epsilon \subset \bigcup_{n=1}^{N} A_{f_n}.$$

Let f_1 be a compactly supported source which radiates α. Now $B_\epsilon \backslash A_{f_1}$ is compact and the A_f's provide an open cover of that compact set, so a finite subcover exists. Numbering that finite subcover A_{f_2} through A_{f_N} establishes (4.2) and proves the theorem. □

Proof of Theorem 4.3. Lemma 4.5 implies that $N_\epsilon(\mathrm{cS}_k\mathrm{supp}_q\alpha)$ is contained in the intersection of finitely many sources. We may take Ω_1 and Ω_2 in Lemma 4.4 to be the convex hulls of the supports of two of the sources, so that the hypothesis that $\mathbb{R}^n \backslash (\Omega_1 \bigcup \Omega_2)$ is connected is automatic. Thus we can produce a source supported on a neighborhood of the intersection of the convex hulls of the supports of any two sources, and we complete the proof by induction. □

5. Active sensing: Finding the support of a scatterer. The convex scattering support of a far field which was not radiated by a source, but rather scattered by an inhomogeneity in a homogeneous medium, detects the deviation of the index of refraction from that of the homogeneous background medium. That is, when we illuminate the medium with an incoming wave, the inhomogeneity becomes a secondary, or induced, source, and our test can be applied to locate that source.

Similarly, we can apply the Picard test in an inhomogeneous background if we wish to locate the deviation of the index of refraction from that known background. In both cases, we apply the test to the deviation of the measured outgoing far field from the outgoing far field that we should have measured if no deviation were present. If the background is homogeneous, the test is applied to the *scattered wave*, the outgoing far field minus the antipodal map of the incoming field, which is the outgoing far field of the free solution with the same incoming far field. In the case of an inhomogeneous background, we subtract the wave scattered by the background.

In order to be mathematically precise we need to recall the scattering operator. We may formulate the scattering problem as

$$(\Delta + k^2 - q(x))u = 0,$$
$$u_\infty^-(\Theta) = \beta(\Theta),$$

where $\beta \in L^2(S^{n-1})$ parameterizes the incoming far field (recall (2.13)). It is customary to seek the total wave u as the sum of an incident wave and a scattered wave:

$$\begin{aligned} u &= u_{inc} + u_{sc} \\ &= \mathcal{H}\beta + u_{sc}. \end{aligned}$$

In our notation, the incident wave is just the Herglotz operator (2.8) acting on β. Because $\mathcal{H}\beta$ has incoming far field equal to β, the scattered wave is outgoing and satisfies

$$\begin{aligned} (\Delta + k^2 - q(x))u_{sc} &= q\mathcal{H}\beta, \\ (u_{sc})^-_\infty &= 0. \end{aligned} \tag{5.1}$$

Thus,

$$u_{sc} = G^+_q q\mathcal{H}\beta$$

and has far field

$$(u_{sc})^+_\infty = F^+_q q\mathcal{H}\beta.$$

The scattering operator, which maps the incoming far field to the scattered far field, is given by

$$\begin{aligned} S_q &= F^+_q q\mathcal{H} \\ &= F^+_0 q(I - G^+_0 q)^{-1}\mathcal{H}. \end{aligned}$$

If we can measure the far field $S_q\beta$ for a single incoming wave β, we may apply the Picard test to $S_q\beta$ to find what must be a subset of the convex hull of the support of the *induced source*

$$\begin{aligned} f &= q(I - G^+_0 q)^{-1}\mathcal{H}\beta \\ &= qu. \end{aligned}$$

Because the unique continuation principle guarantees that u cannot vanish on an open set, we can be certain that we are truly estimating the support of q, i.e., we have the following lemma.

LEMMA 5.1.

$$\operatorname{supp} qu = \operatorname{supp} q.$$

Suppose now that we are looking to locate not the support of q, but the support of $q - q_{bg}$. That is, we want to find the places where the medium deviates from the known inhomogeneous background q_{bg}. We rewrite (5.1) as

$$\begin{aligned} (\Delta + k^2 - q_{bg})u_{sc} &= q_{bg}\mathcal{H}\beta + (q - q_{bg})u, \\ (u_{sc})^-_\infty &= 0, \end{aligned}$$

which shows that

$$u_{sc} = G^+_{q_{bg}}\mathcal{H}\beta + G^+_{q_{bg}}(q - q_{bg})u$$

with outgoing far field

$$S_q\beta = S_{q_{bg}}\beta + F^+_{q_{bg}}(q - q_{bg})u.$$

Thus, if we apply the Picard test to the far field

$$S_q\beta - S_{q_{bg}}\beta,$$

we obtain an estimate of the support of the induced source $(q-q_{bg})u$, which, according to Lemma 5.1, is a lower bound on the support of $q-q_{bg}$. We state this as a corollary of Theorem 3.6.

THEOREM 5.2. *For every incident field α,*

$$\mathrm{cS}_k\mathrm{supp}_q(S^+_{q_{bg}} - S^+_q)\alpha \subset \mathrm{ch}\,\mathrm{supp}(q - q_{bg}),$$

i.e., if $q = q_{bg}$ in $\mathbb{R}^n \setminus \Omega$,

$$(S^+_{q_{bg}} - S^+_q)\alpha \in \mathrm{Range}(F^+_{q_{bg}}|_{L^2(\Omega)})$$

for every incident field α.

6. Computing the convex scattering support. In the previous section, we have shown how to unambiguously associate a closed convex set, the convex scattering support, with a far field; we showed that any source which produces that far field must contain that set in the convex hull of its support, and that there always exists a source supported in any neighborhood of the convex scattering support which radiates that far field.

Theorem 3.6 tests whether that set is contained in a test region Ω. In this section we describe a simple algorithm to make use of Theorem 3.6 to find the convex scattering support and show a numerical result for a homogeneous background in two dimensions to illustrate how the method works. We do not intend to suggest that what we present below is careful numerical study. It is meant to be illustrative. We do, however, view it as strong evidence that this provides a stable numerical method.

ALGORITHM. We will choose as test domain, $\Omega = B_R(c)$, the ball of radius R with center c.

1. *Choose the center $c = 0$ and find the smallest R such that $B_R(0)$ contains the scattering support.* For a homogeneous background medium this is easily seen by simply plotting the modulus of the Fourier coefficients of the far field and looking for the place they become effectively zero (i.e., uniformly small). In the plot on the bottom left in Figure 1, the modulus of the Fourier coefficients are effectively zero for $|n|$ a little bigger than 50. The wavenumber in this example is $k = 50$, so the radius R of the circle about zero is one ($\frac{50}{50}$).
   This succeeds because the decomposition of $F^+_0|_{L^2(B_c(R))}$ is exactly

$$F^+_0|_{L^2(B_0(R))} = \sum_{n=-\infty}^{\infty} \mathrm{e}^{in(\theta-\frac{\pi}{2})} \otimes \chi_{B_0(R)}(r) J_n(kr) \mathrm{e}^{-in(\phi-\frac{\pi}{2})}$$

   (here $\chi_{B_0(R)}(r)$ is the characteristic function of the ball) so that its singular

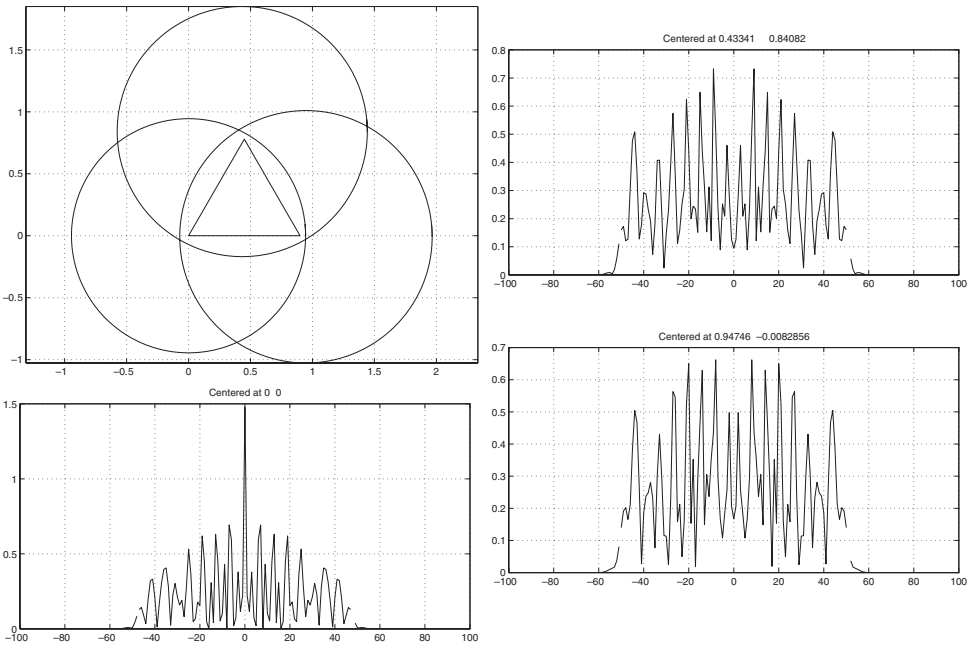

FIG. 1. *Estimating the convex scattering support of a triangular source.*

values are

$$\sigma_n = \left(\int_0^R J_n^2(ks) s ds \right)^{\frac{1}{2}} \sim \begin{cases} (R^2 - n^2)^{\frac{1}{4}} & \text{for } n < kR, \\ \dfrac{1}{\sqrt{n}} \left(\dfrac{eR}{2n} \right)^n & \text{for } n > kR, \end{cases} \tag{6.1}$$

which means that the σ_n are uniformly large for $n < kR$ and decay rapidly to zero as soon as $n > kR$.

2. *Choose another center and repeat.* In the homogeneous case, we compute the far field of the translated source instead of translating the test region. We use the formula

$$F_0^+ f(x - c) = e^{ik|c| \cos(\theta - \theta_c)} F_0^+ f \tag{6.2}$$

and then apply the test from the previous step to the new far field given by the left-hand side of (6.2). The plots on the left-hand sides of Figures 1 and 2 are the results of translating the far fields to the centers indicated in the figures.

We don't suggest a specific algorithm for choosing the centers here. In the first example, we chose a new center to be on the intersection of previous circles. In the second, we needed to choose centers far from the line source to see that it was flat. One expensive alternative is just to grid space and then choose centers at each grid point.

3. Our estimate of the convex scattering support is the intersection of these balls as in the large plots at the top left of Figures 1 and 2).

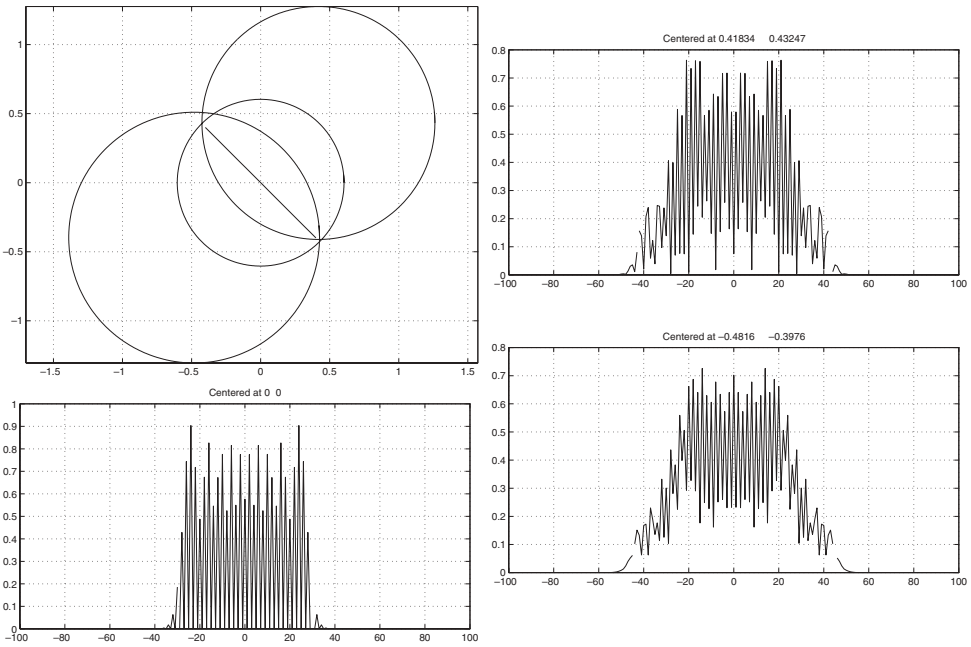

FIG. 2. *Estimating the convex scattering support of a line source.*

7. Conclusions. We have shown that the notion of the convex scattering support extends to scattering in an inhomogeneous background. Theoretically, the notion is actually quite general, relying only on unique continuation, and we expect it to hold in a very general mathematical setting. The observation of a far field can easily be replaced by the observation of a set of Cauchy data on all or part of the boundary of a region.

From a practical point of view, it is the *threshold behavior* of the σ_n's in (6.1) that is the most encouraging and intriguing. Equation (6.1) tells us not only that the Fourier coefficients of a far field produced in the ball of radius R will go to zero rapidly when n becomes greater than kR, but that they can, in general,[1] be expected to be uniformly large for n even slightly less than kR. This means that we need only look for this transition to zero, which is much less sensitive to noise than any sort of convergence or ratio test.

This threshold is intimately associated with wave propagation, and not merely a consequence of unique continuation. While the convex scattering support can easily be defined for Laplace's equation (the Helmholtz equation with $\omega = 0$), the corresponding σ_n's exhibit no such behavior.

From our point of view, one very relevant question is whether this thresholding behavior occurs for other test domains and for Helmholtz equations with inhomogeneous backgrounds. If it does, we can expect these tests to be robust in the presence of noise as well.

[1] Theorem 3.6 itself guarantees that we can always artificially choose examples where the first 1000 Fourier coefficients are zero, and only after that do the hypotheses of the theorem hold. Nevertheless, we expect that, for a broad class of sources, this won't be the case.

ON PRESSURELESS GASES DRIVEN BY A STRONG INHOMOGENEOUS MAGNETIC FIELD*

ISABELLE GALLAGHER† AND LAURE SAINT-RAYMOND‡

Abstract. We are interested in the life span and the asymptotic behavior of the solutions to a system governing the motion of a pressureless gas that is submitted to a strong, inhomogeneous magnetic field $\varepsilon^{-1}B(x)$ of variable amplitude but fixed direction; this is a first step in the direction of the study of rotating Euler equations. This leads to the study of a multidimensional Burgers-type system on the velocity field u_ε, penalized by a rotating term $\varepsilon^{-1}u_\varepsilon \wedge B(x)$. We prove that the unique, smooth solution of this Burgers system exists on a uniform time interval $[0,T]$. We also prove that the phase of oscillation of u_ε is an order one perturbation of the phase obtained in the case of a pure rotation (with no nonlinear transport term), $\varepsilon^{-1}B(x)t$. Finally, going back to the pressureless gas system, we obtain the asymptotics of the density as ε goes to zero.

Key words. rotating pressureless gas, asymptotic behavior, oscillations

1. Introduction.

The aim of this paper is to study the asymptotic behavior of a fluid submitted to a strong external inhomogeneous magnetic field.

The case when the field is constant has been studied by a number of authors, both for compressible and incompressible models of fluids (see, for instance, [1], [3], or [7] for incompressible fluids, and [4] or [6] for rarefied plasmas). In that case, one cannot only derive the asymptotic average motion (which is given by the weak limit of the velocity field), but one can also describe all the oscillations in the system and possibly their coupling: the filtering techniques used for that rely on explicit computations in Fourier space.

In the case when the magnetic field is inhomogeneous, those methods are not relevant anymore. Weak compactness and compensated compactness arguments nevertheless allow us to determine the average motion (see [6] in the case of a rarefied plasma governed by the Vlasov–Poisson system, and [5] in the case of a viscous incompressible fluid). In order to describe the oscillating component of the motion, one has to understand the interaction between the penalization and the nonlinear term of transport: indeed one expects that the flow modifies substantially the phase of oscillation (which is of course inhomogeneous).

We propose here to analyze this interaction for a simplified model of magnetohydrodynamics, the so-called Euler system of pressureless gas dynamics.

1.1. A simple model for magnetohydrodynamics.

We consider the following system of partial differential equations:

$$\begin{aligned} &\partial_t \rho + \nabla\cdot(\rho u) = 0, \quad x \in \mathbf{R}^3, t > 0, \\ &\partial_t(\rho u) + \nabla\cdot(\rho u \otimes u) = \rho u \wedge B, \quad x \in \mathbf{R}^3, t > 0, \\ &\rho(t=0) \equiv \rho_0, \quad u(t=0) \equiv u_0, \quad x \in \mathbf{R}^3, \end{aligned} \tag{1.1}$$

*Received by the editors October 1, 2003; accepted for publication (in revised form) May 21, 2004; published electronically January 27, 2005.

where ρ denotes the density of the fluid, u its mean velocity, and B the external magnetic field ($\nabla\cdot B = 0$). The first equation expresses the local conservation of mass, while the second one gives the local conservation of momentum provided that there is no internal force (no pressure). This assumption is relevant only in some particular regimes (corresponding to sticky particles [2]). From a physical point of view, this may seem a strong restriction, but it allows us to perform a first mathematical study of that type of inhomogeneous singular perturbation problem: indeed in this special case a major simplification arises since the equation on the mean velocity can be (at least formally) decoupled from the rest of the system:

$$\partial_t u + (u\cdot\nabla)u = u\wedge B, \quad x\in\mathbf{R}^3, t>0.$$

We then obtain a system of Burgers type that is a prototype of hyperbolic system. A work in progress should extend the present results to more realistic models, in particular to the three-dimensional incompressible Euler system.

In order to further simplify the analysis, we assume that the direction of the field B is constant,

$$B(x) \equiv \frac{1}{\varepsilon} b(x_1,x_2)e_3, \quad (x_1,x_2)\in\mathbf{R}^2 \text{ and } e_3 = {}^t(0,0,1),$$

which allows us to get rid of the geometry of the field lines (for detailed comments on this subject, see, for instance, [5, Remark 1.4]). Any solution to the system (1.1) has then uniform regularity with respect to the variable x_3. To isolate the phenomenon of inhomogeneous oscillations with instantaneous loss of regularity, we restrict therefore our attention to the two-dimensional singular perturbation problem in the plane orthogonal to the magnetic field. We finally have

$$\begin{aligned} &\partial_t\rho + \nabla\cdot(\rho u) = 0, \quad x\in\mathbf{R}^2, t>0,\\ &\partial_t(\rho u) + \nabla\cdot(\rho u\otimes u) = \frac{b}{\varepsilon}\rho u^\perp, \quad x\in\mathbf{R}^2, t>0,\\ &\rho(t=0)\equiv\rho_0, \quad u(t=0)\equiv u_0, \quad x\in\mathbf{R}^2, \end{aligned} \tag{1.2}$$

where $u^\perp$ denotes the vector field with components $(u_2,-u_1)$, and the intensity b of the magnetic field satisfies the following assumptions:

$$b\in C^\infty(\mathbf{R}^2)\cap W^{2,\infty}(\mathbf{R}^2), \tag{H0}$$

$$\inf_{x\in\mathbf{R}^2} b(x) = b_- > 0. \tag{H1}$$

A standard fixed point argument then allows us to prove the local well-posedness of (1.2). The result is the following.

THEOREM 1. *Consider a function b satisfying assumptions* (H0) *and* (H1). *Let ρ_0 be a nonnegative function and let u_0 be a vector field in $H^s(\mathbf{R}^2)$ ($s>2$). Then, for all $\varepsilon>0$, there exist $T_\varepsilon\in\,]0,+\infty]$ and a unique solution of* (1.2), *$(\rho_\varepsilon,u_\varepsilon)\in L^\infty_{loc}([0,T_\varepsilon[,H^s(\mathbf{R}^2))$.*

Note that the lifespan T_ε of the solution depends on ε, and that the lower bound on T_ε coming from the Duhamel formula goes to zero as $\varepsilon\to 0$. The first difficulty in studying the asymptotics $\varepsilon\to 0$ consists then in understanding why the magnetic penalization does not destabilize the system, and in proving that the solution $(\rho_\varepsilon,u_\varepsilon)$ exists on a uniform interval of time.

1.2. Formal analysis. Before stating more precise results on the life span of the solutions and on the asymptotics $\varepsilon \to 0$, we have chosen to give some simple observations about the problem to guide intuition. In this first approach we restrict our attention to the analysis of the equation governing the velocity.

The first step of the formal analysis consists in determining the mean behavior of the velocity field, that is, the weak limit of u_ε. We have

$$u_\varepsilon = \frac{\varepsilon}{b} \left(\partial_t u_\varepsilon + (u_\varepsilon \cdot \nabla) u_\varepsilon\right)^\perp .$$

As b is bounded from below, if we are able to establish convenient a priori bounds on u_ε, this will imply

$$u_\varepsilon \rightharpoonup 0$$

in some weak sense. This means that we expect the velocity to oscillate at high frequency (on vanishing temporal or spatial scales).

Another way to get an idea of the asymptotic behavior of the velocity is to study the simple case when b is constant. The group of oscillations generated by the magnetic penalization is then homogeneous,

$$R\left(\frac{t}{\varepsilon}\right) u = u \cos\left(\frac{bt}{\varepsilon}\right) - u^\perp \sin\left(\frac{bt}{\varepsilon}\right) ,$$

which corresponds to the rotation with frequency $2\pi b/\varepsilon$. As the coefficients are constant, this group is not perturbed by the transport. Classical filtering methods (see namely [7], [8]) can then be applied: setting

$$v_\varepsilon \stackrel{\text{def}}{=} R\left(-\frac{t}{\varepsilon}\right) u_\varepsilon$$

leads to

$$\partial_t v_\varepsilon + Q\left(\frac{t}{\varepsilon}, v_\varepsilon, v_\varepsilon\right) = 0,$$

where $Q\left(\frac{t}{\varepsilon}, ., .\right)$ is a quadratic form with bounded coefficients depending on t/ε. As there is only one oscillation frequency, there is no resonance, which implies that

$$v_\varepsilon \to u_0$$

in some strong sense, provided that convenient a priori bounds on u_ε (and consequently on v_ε) hold. This means that we can describe completely the oscillations and get a strong convergence result. Of course, we get as a corollary that the life span T_ε is uniformly bounded from below, and we even expect that $T_\varepsilon \to +\infty$ as $\varepsilon \to 0$.

The case we consider here is much more complicated. The group of oscillations generated by the magnetic penalization is again very easy to describe,

$$R\left(\frac{t}{\varepsilon}, x\right) u = u \cos\left(\frac{b(x)t}{\varepsilon}\right) - u^\perp \sin\left(\frac{b(x)t}{\varepsilon}\right) ,$$

but it is nonhomogeneous, which entails

- a loss of regularity ($R\left(\frac{t}{\varepsilon}, x\right) u$ blows up in all Sobolev norms $H^s(\mathbf{R}^2)$ for $s > 0$);
- an interaction with the transport operator (with the same definition of $v_\varepsilon = R\left(-\frac{t}{\varepsilon}, x\right) u_\varepsilon$ as previously, we do not expect $\partial_t v_\varepsilon$ to be bounded in any space of distributions).

The purpose behind this model problem is to understand how to overcome these difficulties. The first step is to explain how the phase of oscillations is modified by the flow: note that even a small correction on the phase changes strongly the vector field. Then we have to establish a strong convergence result using a new method: classical energy methods fail because of the lack of regularity on approximate solutions. Here an appropriate rewriting of the system by means of characteristics associated with the flow allows us to understand the underlying structure and to answer both questions: in particular we will see that the spaces which are well adapted for this type of study are constructed on $L^\infty(\mathbf{R}^2)$. In the case of incompressible dynamics, the analysis will be therefore much more difficult since the transport is replaced by a nonlocal pseudodifferential operator.

1.3. Main results. As long as the solution $(\rho_\varepsilon, u_\varepsilon)$ of system (1.2) is smooth, the velocity u_ε satisfies the following equation of Burgers type:

$$\begin{aligned} \partial_t u_\varepsilon + (u_\varepsilon \cdot \nabla) u_\varepsilon + \frac{b}{\varepsilon} u_\varepsilon^\perp = 0, \quad x \in \mathbf{R}^2, t > 0, \\ u_\varepsilon(t=0) = u^0, \quad x \in \mathbf{R}^2. \end{aligned} \tag{1.3}$$

Using refined a priori estimates on this last equation, we can prove that for all $\varepsilon > 0$ it admits a smooth solution on a uniform time $T > 0$. We will prove the following result.

THEOREM 2. *Consider a function b satisfying assumptions* (H0) *and* (H1). *Let ρ_0 be a nonnegative function in $W^{s-1,\infty}(\mathbf{R}^2)$, and let u_0 be a vector field in $W^{s,\infty}(\mathbf{R}^2)$ ($s \geq 1$). Then there exists $T^* \in]0, +\infty]$ such that, for all $T < T^*$ and all $\varepsilon \leq \varepsilon_T$, there is a unique $(\rho_\varepsilon, u_\varepsilon) \in L^\infty([0,T], W^{s-1,\infty}(\mathbf{R}^2) \times W^{s,\infty}(\mathbf{R}^2))$ solution of* (1.2) *(which is nevertheless not uniformly bounded in $L^\infty([0,T], W^{s-1,\infty}(\mathbf{R}^2) \times W^{s,\infty}(\mathbf{R}^2))$ for $s > 0$).*

Remark 1. The proof of Theorem 2 shows actually that the supremum lifetime T_ε^* of the solution $(\rho_\varepsilon, u_\varepsilon)$ (corresponding to the first crossing of characteristics) converges to T^{**} as ε goes to 0 with

$$T^{**} = C \|u_0\|_{L^\infty}^{-1} \|\nabla b\|_{L^\infty}^{-1}.$$

In this framework, it is relevant to consider the asymptotics $\varepsilon \to 0$ on the time interval $[0,T]$. The same type of computations as used previously allows us to prove that the velocity field behaves almost as in the constant case (with slight modifications of the phase of oscillations).

THEOREM 3. *Consider a function b satisfying assumptions* (H0) *and* (H1). *Let u_0 be a vector field in $W^{s,\infty}(\mathbf{R}^2)$ ($s \geq 1$). For all $T \leq T^*$ as in Theorem* 2 *and all $\varepsilon \leq \varepsilon_T$, denote by u_ε the solution of* (1.3) *in $L^\infty([0,T], W^{s,\infty}(\mathbf{R}^2))$. Then*

$$u_\varepsilon(t,x) - \big(u_0(x) \cos\theta_\varepsilon(t,x) - u_0^\perp(x) \sin\theta_\varepsilon(t,x)\big)$$

converges strongly to 0 in $L^\infty([0,T] \times \mathbf{R}^2)$, where the phase θ_ε is defined by the equation

$$\begin{aligned} \theta_\varepsilon(t,x) = \frac{b(x)t}{\varepsilon} - t u_0(x) \cdot \nabla \log b(x) \sin\theta_\varepsilon(t,x) \\ + \ t u_0^\perp(x) \cdot \nabla \log b(x) \cos\theta_\varepsilon(t,x). \end{aligned} \tag{1.4}$$

Rewriting the equation on the density ρ_ε with a transport term and a penalization term (coming from the divergence of u_ε which is of order $1/\varepsilon$)

$$\begin{aligned} \partial_t \rho_\varepsilon + (u_\varepsilon \cdot \nabla)\rho_\varepsilon + \rho_\varepsilon \nabla \cdot u_\varepsilon = 0, \quad x \in \mathbf{R}^2, t > 0, \\ \rho_\varepsilon(t=0) = \rho^0, \quad x \in \mathbf{R}^2, \end{aligned} \tag{1.5}$$

we can then determine the global asymptotics of the Euler system of pressureless gases (1.2).

THEOREM 4. *Consider a function b satisfying assumptions* (H0) *and* (H1). *Let* ρ_0 *be a nonnegative function in* $W^{s-1,\infty}(\mathbf{R}^2)$, *and let* u_0 *be a vector field in* $W^{s,\infty}(\mathbf{R}^2)$ *(*$s \geq 1$*). For all* $T \leq T^*$ *as in Theorem* 2 *and all* $\varepsilon \leq \varepsilon_T$, *denote by* $(\rho_\varepsilon, u_\varepsilon)$ *the solution of* (1.2) *in* $L^\infty([0,T], W^{s-1,\infty}(\mathbf{R}^2) \times W^{s,\infty}(\mathbf{R}^2))$. *Then*

$$\rho_\varepsilon(t,x) - \rho_0(x)\left(1 + tu_0 \cdot \nabla \log(x) \cos\theta_\varepsilon(t,x) - tu_0^\perp \cdot \nabla \log b(x) \sin\theta_\varepsilon(t,x)\right)$$

converges strongly to 0 *in* $L^\infty([0,T] \times \mathbf{R}^2)$, *where the phase* θ_ε *is defined as in equation* (1.4).

Remark 2. It should be noted that assumption (H1) is not merely a technical artifact which could be removed with some work. In fact all the uniform estimates in this paper blow up if the field B is allowed to have a level curve where $B = 0$—which could occur in many physical cases—and new mathematical difficulties arise in that case.

Let us comment a little on the proof of those theorems and give the structure of the paper.

It is quite clear that energy methods will not enable us to have a good control on the asymptotics of $(\rho_\varepsilon, u_\varepsilon)$, since as soon as we want a control on derivatives of u_ε, unbounded terms will appear. So the most appropriate way to study system (1.2) is to rewrite it using the characteristics of the flow and to study those characteristics precisely.

Section 2 is therefore devoted to rewriting system (1.2) in characteristic form, and in the derivation of a few a priori estimates.

In order to establish the existence of a solution $(\rho_\varepsilon, u_\varepsilon)$ to system (1.2) on a uniform time interval $[0,T]$, it is enough to see that the solution is well-defined (and smooth) as long as the flow generates a diffeomorphism $X_\varepsilon(t,.)$,

$$\frac{dX_\varepsilon}{dt}(t,x) = u_\varepsilon(t, X_\varepsilon(t,x)),$$

and hence to prove that the characteristics cannot cross before time T. The precise estimates on DX_ε leading to Theorem 2 are performed in section 3; they use in a crucial way some results of nonstationary phase type.

The asymptotic behavior of $u_\varepsilon(t, X_\varepsilon(t,.))$ and $\rho_\varepsilon(t, X_\varepsilon(t,.))$ is then simply obtained from the explicit approximation of the characteristics X_ε, using Taylor expansions for the various fields. In order to establish the convergence results stated in Theorems 3 and 4, the main difficulty lies therefore in getting a precise description of the inverse characteristics $X_\varepsilon^{-1}(t,.)$, which is done in section 4.

2. Appropriate formulation of the system. As pointed out in the introduction, energy estimates do not seem to be the right angle of attack for our problem. We shall therefore in this short section present a new formulation of system (1.2), by means of characteristics (subsection 2.1). In that way some a priori estimates can be deduced immediately (see subsection 2.2).

To simplify notation, from now on we shall drop the index ε in u_ε and simply write u (and similarly for any other ε-dependent function).

2.1. Trajectories associated with the flow. Let us write system (1.2) in the following form:

$$\begin{aligned} &\frac{dX}{dt} = u(t,X), \quad X_{|t=0} = x, \\ &\frac{d}{dt}(\rho(t,X)) + \rho\nabla\cdot u(t,X) = 0, \quad \rho_{|t=0} = \rho_0, \\ &\frac{d}{dt}(u(t,X)) + \frac{b(X)}{\varepsilon}u^\perp(t,X) = 0, \quad u_{|t=0} = u_0. \end{aligned} \tag{2.1}$$

As seen in Theorem 1, there is a solution to system (1.2) for a time depending on ε, and as long as the trajectories do not intersect we can write in particular

$$u(t,X(t,x)) = u_0(x)\cos\left(\frac{\phi(t,x)}{\varepsilon}\right) - u_0^\perp(x)\sin\left(\frac{\phi(t,x)}{\varepsilon}\right), \tag{2.2}$$

where we have defined the functions

$$\phi(t,x) = \int_0^t \beta(s,x)\,ds, \quad \beta(t,x) \stackrel{\text{def}}{=} b(X(t,x))$$

(these functions are well-defined as long as the characteristics do not cross each other).

If u is smooth enough, then ρ is uniquely defined by the transport equation it satisfies. So from now on we can concentrate on u (and X). As one of the aims of this article is to prove Theorem 2 (which will be achieved in the next section), we shall from now on call T^ε the largest time before which no characteristics intersect; one of our goals is to prove that T^ε is uniformly bounded from below as ε goes to zero.

In the next subsection we are going to derive from (2.1) and (2.2) some easy a priori estimates for times $0 \le t \le T^\varepsilon$, which will help us prove Theorem 2 in section 3, and Theorems 3 and 4 in section 4.

2.2. A priori estimates. Formula (2.2) immediately enables us to deduce the a priori estimate

$$\|u\|_{L^\infty([0,T^\varepsilon[\times\mathbf{R}^2)} \le 2\|u_0\|_{L^\infty}\,, \tag{2.3}$$

which implies that

$$\left\|\frac{dX}{dt}\right\|_{L^\infty([0,T^\varepsilon[\times\mathbf{R}^2)} \le 2\|u_0\|_{L^\infty}. \tag{2.4}$$

In particular $X - x$ remains bounded in space for all times $0 \le t < T^\varepsilon$, and we have

$$\forall t \in [0,T^\varepsilon[, \quad \|X(t,\cdot) - x\|_{L^\infty(\mathbf{R}^2)} \le 2t\|u_0\|_{L^\infty(\mathbf{R}^2)}. \tag{2.5}$$

Since $\beta(t,x) = b(X(t,x))$, we have

$$\begin{aligned} \|\partial_t\beta\|_{L^\infty([0,T^\varepsilon[\times\mathbf{R}^2)} &\le \|\nabla b\|_{L^\infty(\mathbf{R}^2)}\left\|\frac{dX}{dt}\right\|_{L^\infty([0,T^\varepsilon[\times\mathbf{R}^2)} \\ &\le 2\|\nabla b\|_{L^\infty(\mathbf{R}^2)}\|u_0\|_{L^\infty}, \end{aligned} \tag{2.6}$$

as well as

$$\forall t \in [0,T^\varepsilon[, \quad \forall x \in \mathbf{R}^2, \quad b_- \le \beta(t,x) \le \|b\|_{L^\infty(\mathbf{R}^2)} \tag{2.7}$$

with b_- defined in (H1).

Now we are going to look for an approximation of X: integrating formula (2.2) in time yields

$$X(t,x) = x + u_0(x)\int_0^t \cos\left(\frac{\phi(s,x)}{\varepsilon}\right)\,ds - u_0^\perp(x)\int_0^t \sin\left(\frac{\phi(s,x)}{\varepsilon}\right)\,ds, \tag{2.8}$$

recalling that $\phi(t,x) = \int_0^t b(X(s,x))\,ds$. The following section will be devoted to a precise study of the trajectories X, which will enable us to infer Theorem 2.

3. Study of the trajectories. Formulation (2.1) of system (1.3) shows that the study of the Euler system of pressureless gases with magnetic penalization comes down to a precise analysis of the characteristics, and in particular of their invertibility.

In this section we will establish that the trajectories defined by (2.8) are invertible on a time interval $[0, T^\varepsilon[$ with

$$\lim_{\varepsilon\to 0} T^\varepsilon = T^* > 0,$$

where T^* depends on the magnetic field b and on the initial velocity field u_0. This result is based on an asymptotic expansion of the Jacobian

$$J(t,x) \overset{\text{def}}{=} |\det(DX(t,x))|,$$

which implies that

$$\forall t \in [0,T^*[, \quad \liminf_{\varepsilon\to 0} J(t,x) > 0.$$

The asymptotic expansions of X and DX (subsections 3.2 and 3.4) are obtained using some results of nonstationary phase type and the L^∞-bounds established in subsections 3.1 and 3.3.

3.1. Bounds on $X(t,\cdot)$. The first step of the analysis consists in showing that for any point $x \in \mathbf{R}^2$, the characteristic stemming from x stays in a ball of size $O(\varepsilon)$ around x. This shows that the rotation has a drastic influence over the transport by u.

We have the following proposition.

PROPOSITION 1. *Let $x \in \mathbf{R}^2$ be given, and let $X(\cdot,x)$ be the trajectory starting from x at time 0, defined by (2.8). As long as it is defined, it satisfies*

$$\forall t < \min(T, T^\varepsilon), \quad |X(t,x) - x| \le 4\frac{\varepsilon}{b_-}\|u_0\|_{L^\infty}\left(1 + T\frac{\|\nabla b\|_{L^\infty}\|u_0\|_{L^\infty}}{b_-}\right).$$

Proof of Proposition 1. The proof is an immediate application of the nonstationary phase theorem. As we will be using such arguments many times in the following, let us state and prove the following lemma, which will be invoked systematically in the following sections.

LEMMA 1. *Let T be a given real number, possibly depending on ε. Let F be a function uniformly bounded in $W^{1,\infty}([0,T], L^\infty(\mathbf{R}^2))$, and let β be a positive function, also uniformly bounded in $W^{1,\infty}([0,T], L^\infty(\mathbf{R}^2))$, and bounded from below by b_-. Then for all $t \in [0,T]$ and all $x \in \mathbf{R}^2$, the following bounds hold:*

$$\left|\int_0^t F(s,x)\cos\left(\int_0^s \frac{\beta(s',x)}{\varepsilon}\,ds'\right)\,ds\right| \le \varepsilon\left(\frac{\|F(t,\cdot)\|_{L^\infty(\mathbf{R}^2)}}{b_-} + t\left\|\partial_s\frac{F(s,\cdot)}{\beta(s,\cdot)}\right\|_{L^\infty([0,t]\times\mathbf{R}^2)}\right)$$

and

$$\left|\int_0^t F(s,x)\sin\left(\int_0^s \frac{\beta(s',x)}{\varepsilon}\,ds'\right)\,ds\right| \leq \varepsilon\left(\frac{\|F(t,\cdot)\|_{L^\infty(\mathbf{R}^2)}+\|F(0,\cdot)\|_{L^\infty(\mathbf{R}^2)}}{b_-}+t\left\|\partial_s\frac{F(s,\cdot)}{\beta(s,\cdot)}\right\|_{L^\infty([0,t]\times\mathbf{R}^2)}\right).$$

Proof of Lemma 1. The proof is a simple application of the nonstationary phase theorem: an integration by parts leads to

$$\int_0^t F(s,x)\cos\left(\int_0^s \frac{\beta(s',x)}{\varepsilon}\,ds'\right)\,ds = \varepsilon\frac{F(t,x)}{\beta(t,x)}\sin\left(\int_0^t\frac{\beta(s,x)}{\varepsilon}\,ds\right) - \varepsilon\int_0^t\partial_s\left(\frac{F(s,x)}{\beta(s,x)}\right)\sin\left(\int_0^s\frac{\beta(s',x)}{\varepsilon}\,ds'\right)\,ds,$$

and similarly

$$\int_0^t F(s,x)\sin\left(\int_0^s \frac{\beta(s',x)}{\varepsilon}\,ds'\right)\,ds = \varepsilon\frac{F(0,x)}{\beta(0,x)}-\varepsilon\frac{F(t,x)}{\beta(t,x)}\cos\left(\int_0^t\frac{\beta(s,x)}{\varepsilon}\,ds\right) + \varepsilon\int_0^t\partial_s\left(\frac{F(s,x)}{\beta(s,x)}\right)\cos\left(\int_0^s\frac{\beta(s',x)}{\varepsilon}\,ds'\right)\,ds.$$

The result follows immediately.

Now let us go back to the proof of Proposition 1. Recalling formula (2.8), we simply apply Lemma 1 to the case $F(t,x)=u_0(x)$ to get

$$|X(t,x)-x|\leq 4\varepsilon\frac{\|u_0\|_{L^\infty}}{b_-}+2\varepsilon t\left\|u_0\frac{\partial_s\beta(s,\cdot)}{\beta^2(s,\cdot)}\right\|_{L^\infty([0,t]\times\mathbf{R}^2)}.$$

Estimates (2.6) and (2.7) immediately yield Proposition 1.

3.2. Asymptotics of $X(t,\cdot)$. The same type of computations based on the nonstationary phase theorem allows us actually to obtain an explicit approximation of the characteristic X at any order with respect to ε (in fact we will stop at order 2, but the argument can be pushed as far as wanted if necessary).

LEMMA 2. *For any point $x\in\mathbf{R}^2$ and any time $t\leq\min(T,T^\varepsilon)$, the following approximation of the trajectories defined in* (2.8) *holds:*

$$\left|X(t,x)-x-\varepsilon\frac{u_0(x)}{b(x)}\sin\left(\frac{\phi(t,x)}{\varepsilon}\right)+\varepsilon\frac{u_0^\perp(x)}{b(x)}\left(1-\cos\left(\frac{\phi(t,x)}{\varepsilon}\right)\right)+\varepsilon t v(x)\right|\leq C_T\varepsilon^2,$$

where the drift velocity is given by

$$v(x)=\frac{1}{2b^2(x)}\left((u_0^\perp\cdot\nabla b)u_0(x)-(u_0\cdot\nabla b)u_0^\perp(x)\right),$$

and C_T denotes a constant depending only on T, u_0, and b.

Proof of Lemma 2. Let us write the following expression for $X(t,x)$, obtained from (2.8): we have

$$X(t,x)=x+R^\varepsilon(t,x),$$

with

$$R^\varepsilon(t,x) \stackrel{\text{def}}{=} u_0(x)\int_0^t \cos\left(\frac{\phi(s,x)}{\varepsilon}\right)\,ds - u_0^\perp(x)\int_0^t \sin\left(\frac{\phi(s,x)}{\varepsilon}\right)\,ds \tag{3.1}$$
$$= R_1^\varepsilon(t,x) + R_2^\varepsilon(t,x).$$

We shall compute only the approximation for $R_1^\varepsilon(t,x)$, and we leave $R_2^\varepsilon(t,x)$ to the reader. By an integration by parts we have

$$R_1^\varepsilon(t,x) = \varepsilon\frac{u_0(x)}{\beta(t,x)}\sin\left(\frac{\phi(t,x)}{\varepsilon}\right) - \varepsilon u_0(x)\int_0^t \partial_s\left(\frac{1}{\beta(s,x)}\right)\sin\left(\frac{\phi(s,x)}{\varepsilon}\right)\,ds. \tag{3.2}$$

The first term is easy to approximate: we have, due to Proposition 1,

$$\begin{aligned}\left|\frac{1}{\beta(t,x)} - \frac{1}{b(x)}\right| &\le \frac{\|\nabla b\|_{L^\infty}}{b_-^2}|X(t,x)-x| \\ &\le \frac{4\|\nabla b\|_{L^\infty}\|u_0\|_{L^\infty}}{b_-^3}\left(1+T\frac{\|\nabla b\|_{L^\infty}\|u_0\|_{L^\infty}}{b_-}\right)\end{aligned} \tag{3.3}$$

for all $t \le \min(T, T^\varepsilon)$ and all $x \in \mathbf{R}^2$. So $\beta(t,x)$ can be replaced by $b(x)$ in the first term of R_1^ε in (3.2), up to a remainder $\varepsilon\mathcal{R}^\varepsilon$ with $\|\mathcal{R}^\varepsilon\|_{L^\infty([0,T]\times\mathbf{R}^2)} \le C_T$.

Now we need to approximate the second term. Using the fact that

$$\partial_s\beta(s,x) = (u\cdot\nabla b)(s,X(s,x))$$

with

$$u(s,X(s,x)) = u_0(x)\cos\left(\frac{\phi(s,x)}{\varepsilon}\right) - u_0^\perp(x)\sin\left(\frac{\phi(s,x)}{\varepsilon}\right),$$

we can therefore write

$$-\int_0^t \partial_s\left(\frac{1}{\beta(s,x)}\right)\sin\left(\frac{\phi(s,x)}{\varepsilon}\right)\,ds = \int_0^t u_0(x)\cdot\frac{\nabla b(X(s,x))}{2b^2(X(s,x))}\sin\left(\frac{2\phi(s,x)}{\varepsilon}\right)\,ds$$

$$-\int_0^t u_0^\perp(x)\cdot\frac{\nabla b(X(s,x))}{2b^2(X(s,x))}\left(1-\cos\left(\frac{2\phi(s,x)}{\varepsilon}\right)\right)\,ds. \tag{3.4}$$

Note that similar computations lead to the following formula, which is useful to estimate R_2^ε:

$$\int_0^t \partial_s\left(\frac{1}{\beta(s,x)}\right)\cos\left(\frac{\phi(s,x)}{\varepsilon}\right)\,ds = \int_0^t u_0^\perp(x)\cdot\frac{\nabla b(X(s,x))}{2b^2(X(s,x))}\sin\left(\frac{2\phi(s,x)}{\varepsilon}\right)\,ds$$

$$-\int_0^t u_0(x)\cdot\frac{\nabla b(X(s,x))}{2b^2(X(s,x))}\left(1+\cos\left(\frac{2\phi(s,x)}{\varepsilon}\right)\right)\,ds. \tag{3.5}$$

Both formulas (3.4) and (3.5) show that new harmonics have been created by the coupling in the equation.

Let us go back to the estimate of the right-hand side in (3.4). To estimate the oscillating terms, we use Lemma 1 with

$$F_1(s,x) = u_0(x)\cdot\frac{\nabla b(X(s,x))}{2b^2(X(s,x))} \quad\text{and}\quad F_2(s,x) = u_0^\perp(x)\cdot\frac{\nabla b(X(s,x))}{2b^2(X(s,x))}.$$

We get

$$\Big|\int_0^t F_1(s,x)\sin\left(\frac{2\phi(s,x)}{\varepsilon}\right)\,ds\Big| \leq 2\varepsilon\|u_0\|_{L^\infty}\frac{\|\nabla b\|_{L^\infty}}{b_-^3} + \varepsilon t\|u_0\|_{L^\infty}\left\|\partial_s\frac{\nabla b(X(s,\cdot))}{b^2(X(s,\cdot))}\right\|_{L^\infty([0,t]\times\mathbf{R}^2)},$$

and similarly

$$\Big|\int_0^t F_2(s,x)\cos\left(\frac{2\phi(s,x)}{\varepsilon}\right)\,ds\Big| \leq \varepsilon\|u_0\|_{L^\infty}\frac{\|\nabla b\|_{L^\infty}}{b_-^3} + \varepsilon t\|u_0\|_{L^\infty}\left\|\partial_s\frac{\nabla b(X(s,\cdot))}{b^2(X(s,\cdot))}\right\|_{L^\infty([0,t]\times\mathbf{R}^2)}.$$

By (2.4) and (2.6) we have

$$\left\|\partial_s\frac{\nabla b(X(s,\cdot))}{b^2(X(s,\cdot))}\right\|_{L^\infty([0,t]\times\mathbf{R}^2)} \leq 2\|D^2b\|_{L^\infty}\frac{\|u_0\|_{L^\infty}}{b_-^2} + 4\|\nabla b\|_{L^\infty}^2\frac{\|u_0\|_{L^\infty}}{b_-^3}.$$

Plugging that estimate along with (3.3) into the definition of R_1^ε in (3.2), we finally get

$$R_1^\varepsilon(t,x) = \varepsilon\frac{u_0(x)}{b(x)}\sin\left(\int_0^t\frac{\beta(s,x)}{\varepsilon}\,ds\right) + \varepsilon^2\mathcal{R}^\varepsilon(t,x) - \varepsilon u_0(x)\int_0^t\frac{u_0^\perp(x)\cdot\nabla b(X(s,x))}{2b^2(X(s,x))}ds.$$

Since the trajectories lie in balls of size ε,

$$|\nabla b(X(\tau,x)) - \nabla b(x)| \leq C_T\|D^2b\|_{L^\infty}\varepsilon \tag{3.6}$$

for all $x\in\mathbf{R}^2$ and all $\tau\leq t\leq\min(T^\varepsilon,T)$. So we can approximate $\frac{\nabla b(X(s,x))}{b^2(X(s,x))}$ by $\frac{\nabla b(x)}{b(x)}$ up to a remainder $\varepsilon\mathcal{R}^\varepsilon$, and we have

$$-\varepsilon u_0(x)\int_0^t\frac{u_0^\perp(x)\cdot\nabla b(X(s,x))}{2b^2(X(s,x))}\,ds = -\varepsilon t\frac{u_0^\perp(x)\cdot\nabla b(x)}{2b^2(x)}u_0(x) + \varepsilon^2\mathcal{R}^\varepsilon.$$

The estimate of $R_2^\varepsilon(t,x)$ is similar and left to the reader. This ends the proof of Lemma 2.

3.3. A priori estimates on $DX(t,\cdot)$. A necessary and sufficient condition for $X(t,\cdot)$ to be invertible is that

$$J(t,x)\stackrel{\text{def}}{=}|\det(DX(t,x))|$$

does not cancel. In order to obtain a lower bound on the time T^ε (before which the characteristics do no cross each other), we therefore need to study the behavior of the derivatives $DX(t,\cdot)$. First of all we derive a uniform L^∞-bound which will allow us to neglect some terms in the asymptotic expansion.

LEMMA 3. *Let $x\in\mathbf{R}^2$ be given, and let $X(\cdot,x)$ be the trajectory starting from x at time 0, defined by (2.8). As long as it is defined, it satisfies*

$$\forall t<\min(T,T^\varepsilon),\quad \forall x\in\mathbf{R}^2,\quad \|DX(t,x)\|\leq C_T,$$

where C_T denotes a constant depending only on b, u_0, and T.

Proof of Lemma 3. Differentiating (2.8) leads to

$$DX(t,x) - Id = Du_0(x)\int_0^t \cos\left(\frac{\phi(s,x)}{\varepsilon}\right)\,ds - Du_0^\perp(x)\int_0^t \sin\left(\frac{\phi(s,x)}{\varepsilon}\right)\,ds$$
$$-\frac{1}{\varepsilon}u_0(x)\int_0^t D\phi(s,x)\sin\left(\frac{\phi(s,x)}{\varepsilon}\right)\,ds - \frac{1}{\varepsilon}u_0^\perp(x)\int_0^t D\phi(s,x)\cos\left(\frac{\phi(s,x)}{\varepsilon}\right)\,ds,$$

with

$$D\phi(s,x) \overset{\text{def}}{=} \int_0^s DX(\tau,x)\cdot\nabla b(X(\tau,x))d\tau.$$

Applying the Fubini theorem to both last terms, we can set this identity in a suitable form to get a Gronwall estimate

$$\begin{aligned} DX(t,x) - Id = {} & Du_0(x)\int_0^t \cos\left(\frac{\phi(s,x)}{\varepsilon}\right)\,ds - Du_0^\perp(x)\int_0^t \sin\left(\frac{\phi(s,x)}{\varepsilon}\right)\,ds \\ & - \frac{1}{\varepsilon}u_0(x)\int_0^t (DX(\tau,x)\cdot\nabla)b(X(\tau,x))\int_\tau^t \sin\left(\frac{\phi(s,x)}{\varepsilon}\right)\,ds\,d\tau \\ & - \frac{1}{\varepsilon}u_0^\perp(x)\int_0^t (DX(\tau,x)\cdot\nabla)b(X(\tau,x))\int_\tau^t \cos\left(\frac{\phi(s,x)}{\varepsilon}\right)\,ds\,d\tau. \end{aligned} \tag{3.7}$$

From formula (2.8) we deduce that

$$u_0(x)\int_\tau^t \sin\left(\frac{\phi(s,x)}{\varepsilon}\right)\,ds + u_0^\perp(x)\int_\tau^t \cos\left(\frac{\phi(s,x)}{\varepsilon}\right)\,ds = (X(t,x)-X(\tau,x))^\perp.$$

Plugging this identity back into (3.7) leads to

$$\begin{aligned} DX(t,x) - Id = {} & Du_0(x)\int_0^t \cos\left(\frac{\phi(s,x)}{\varepsilon}\right)\,ds - Du_0^\perp(x)\int_0^t \sin\left(\frac{\phi(s,x)}{\varepsilon}\right)\,ds \\ & - \frac{1}{\varepsilon}\int_0^t (X(t,x)-X(\tau,x))^\perp \otimes (DX(\tau,x)\cdot\nabla)b(X(\tau,x))\,d\tau. \end{aligned} \tag{3.8}$$

As in the proof of Proposition 1, Lemma 1 yields the following estimate: for all $t \le \min(T, T^\varepsilon)$,

$$\left|Du_0(x)\int_0^t \cos\left(\frac{\phi(s,x)}{\varepsilon}\right)\,ds - Du_0^\perp(x)\int_0^t \sin\left(\frac{\phi(s,x)}{\varepsilon}\right)\,ds\right| \le C_T\varepsilon\|\nabla u_0\|_{L^\infty}, \tag{3.9}$$

with

$$C_T = \frac{4}{b_-}\left(1 + T\frac{\|\nabla b\|_{L^\infty}\|u_0\|_{L^\infty}}{b_-}\right).$$

From (3.8) we then deduce an inequality of Gronwall type:

$$\begin{aligned} \|DX(t,\cdot)\|_{L^\infty} \le {} & 1 + C_T\varepsilon\|\nabla u_0\|_{L^\infty} \\ & + \int_0^t \|DX(\tau,\cdot)\|_{L^\infty}\|\nabla b\|_{L^\infty}\left\|\frac{1}{\varepsilon}(X(\tau,x)-X(t,x))\right\|_{L^\infty} d\tau. \end{aligned} \tag{3.10}$$

By Proposition 1,

$$\forall t \leq \min(T, T^\varepsilon), \quad \left\| \frac{1}{\varepsilon}(X(t,\cdot) - X(\tau,\cdot)) \right\|_{L^\infty} \leq 2C_T \|u_0\|_{L^\infty},$$

and hence

$$\|DX(t,\cdot)\|_{L^\infty} \leq (1 + C_T\varepsilon \|\nabla u_0\|_{L^\infty}) \exp\left(2C_T \|\nabla b\|_{L^\infty} \|u_0\|_{L^\infty} t\right),$$

which is the expected estimate, proving Lemma 3.

3.4. Asymptotics of DX. In view of the results established in Lemma 2, we expect actually the derivatives $\partial_i X(t,x)$ to behave asymptotically as

$$\lambda(t,x) + \mu(t,x)\cos\left(\frac{\phi(t,x)}{\varepsilon}\right) + \nu(t,x)\sin\left(\frac{\phi(t,x)}{\varepsilon}\right),$$

where λ, μ, and ν denote some functions which do not depend on ε. Such asymptotics can be justified using the same techniques as in the previous subsection: let us prove the following lemma.

LEMMA 4. *Let $x \in \mathbf{R}^2$ be given, and let $X(\cdot,x)$ be the trajectory starting from x at time 0, defined by* (2.8). *Then, for all $t \leq \min(T^\varepsilon, T)$ and for all $x \in \mathbf{R}^2$,*

$$\left\| DX(t,x) - Id - tu_0 \otimes \nabla \log b \cos\left(\frac{\phi(t,x)}{\varepsilon}\right) + tu_0^\perp \otimes \nabla \log b \sin\left(\frac{\phi(t,x)}{\varepsilon}\right) \right\| \leq C_T\varepsilon,$$

where C_T denotes a constant depending only on b, u_0, and T.

Proof of Lemma 4. Denote by g the function defined on $[0,T] \times \mathbf{R}^2$ by

$$g(t,x) \stackrel{\text{def}}{=} DX(t,x) - Id - tu_0 \otimes \nabla \log b \cos\left(\frac{\phi(t,x)}{\varepsilon}\right) + tu_0^\perp \otimes \nabla \log b \sin\left(\frac{\phi(t,x)}{\varepsilon}\right).$$

In view of (3.10), we expect g to satisfy a Gronwall inequality of the type

$$\|g(t,x)\| \leq \int_0^t \|g(\tau,x)\| \left\| \frac{1}{\varepsilon}(X(t,\cdot) - X(\tau,\cdot)) \right\|_{L^\infty} \|\nabla b\|_{L^\infty} d\tau + C_T\varepsilon \tag{3.11}$$

for all $t \leq \min(T^\varepsilon, T)$, where C_T denotes a constant depending only on T, u_0, and b.

Let us postpone the proof of this inequality for a while and show how it enables us to infer Lemma 4. It is easy to see that

$$g(0,x) = 0.$$

Applying the Gronwall lemma and using Proposition 1 as in (3.10) leads to

$$\forall t \leq \min(T^\varepsilon, T), \quad \forall x \in \mathbf{R}^2, \quad \|g(t,x)\| \leq C_T\varepsilon.$$

Now let us go back to the proof of (3.11). We first compute

$$A(t,x) \stackrel{\text{def}}{=} \int_0^t \left(\frac{1}{\varepsilon}(X(t,x) - X(\tau,x))\right)^\perp \otimes (g(\tau,x) \cdot \nabla b(X(\tau,x)))\, d\tau. \tag{3.12}$$

By Lemma 2,

$$\begin{aligned}\frac{1}{\varepsilon}(X(t,x)-X(\tau,x))^{\perp} = {}& \frac{u_0^{\perp}}{b}(x)\left(\sin\left(\frac{\phi(t,x)}{\varepsilon}\right)-\sin\left(\frac{\phi(\tau,x)}{\varepsilon}\right)\right)\\ & -\frac{u_0}{b}(x)\left(\cos\left(\frac{\phi(t,x)}{\varepsilon}\right)-\cos\left(\frac{\phi(\tau,x)}{\varepsilon}\right)\right)\\ & -\frac{t-\tau}{2b^2(x)}\left((u_0^{\perp}\cdot\nabla b)u_0^{\perp}(x)+(u_0\cdot\nabla b)u_0(x)\right)+\varepsilon\mathcal{R}^{\varepsilon}(t,\tau,x),\end{aligned}$$

where $\mathcal{R}^{\varepsilon}$ is uniformly bounded in $L^{\infty}([0,T]^2\times\mathbf{R}^2)$. Plugging this formula back into the integral (3.12) leads to

$$\int_0^t\left(\frac{1}{\varepsilon}(X(t,x)-X(\tau,x))\right)^{\perp}\otimes(g(\tau,x)\cdot\nabla b(X(\tau,x)))\,d\tau = A_1(t,x)-A_2(t,x), \tag{3.13}$$

with

$$A_1(t,x)\overset{\text{def}}{=}\int_0^t\left(\frac{1}{\varepsilon}(X(t,x)-X(\tau,x))\right)^{\perp}\otimes(DX(\tau,x)\cdot\nabla b)(X(\tau,x))d\tau$$

and

$$\begin{aligned}A_2(t,x)\overset{\text{def}}{=}\int_0^t & \left[\frac{u_0^{\perp}}{b}(x)\left(\sin\left(\frac{\phi(t,x)}{\varepsilon}\right)-\sin\left(\frac{\phi(\tau,x)}{\varepsilon}\right)\right)\right.\\ & -\frac{u_0}{b}(x)\left(\cos\left(\frac{\phi(t,x)}{\varepsilon}\right)-\cos\left(\frac{\phi(\tau,x)}{\varepsilon}\right)\right)\\ & \left.-\frac{1}{2b^2(x)}(t-\tau)\left((u_0^{\perp}\cdot\nabla b)u_0^{\perp}(x)+(u_0\cdot\nabla b)u_0(x)\right)+\varepsilon\mathcal{R}^{\varepsilon}(t,\tau,x)\right]\\ & \otimes\left[\nabla b(X(\tau,x))+(u_0(x)\cdot\nabla b(X(\tau,x)))\nabla\log b(x)\tau\cos\left(\frac{\phi(\tau,x)}{\varepsilon}\right)\right.\\ & \left.-(u_0^{\perp}(x)\cdot\nabla b(X(\tau,x)))\nabla\log b(x)\tau\sin\left(\frac{\phi(\tau,x)}{\varepsilon}\right)\right]d\tau.\end{aligned}$$

From (3.8) and (3.9) we deduce that

$$A_1(t,x)=Id-DX(t,x)$$

up to terms of order ε.

In order to estimate the second term $A_2(t,x)$, we again use a nonstationary phase theorem. We can use (3.6) again, and as $\partial_s\beta$ is uniformly bounded according to (2.6), Lemma 1 shows that

$$\begin{aligned}A_2(t,x)= {}& \left[t\frac{u_0^{\perp}}{b}(x)\sin\left(\frac{\phi(t,x)}{\varepsilon}\right)-t\frac{u_0}{b}(x)\cos\left(\frac{\phi(t,x)}{\varepsilon}\right)-\frac{t^2}{2}v^{\perp}(x)\right]\otimes\nabla b(x)\\ & +\int_0^t\left(\frac{u_0^{\perp}}{b}(x)\sin\left(\frac{\phi(\tau,x)}{\varepsilon}\right)\right)\\ & \qquad\otimes\left((\tau u_0^{\perp}(x)\cdot\nabla b(x))\nabla\log b(x)\sin\left(\frac{\phi(\tau,x)}{\varepsilon}\right)\right)d\tau\\ & +\int_0^t\left(\frac{u_0}{b}(x)\cos\left(\frac{\phi(\tau,x)}{\varepsilon}\right)\right)\\ & \qquad\otimes\left((\tau u_0(x)\cdot\nabla b(x))\nabla\log b(x)\cos\left(\frac{\phi(\tau,x)}{\varepsilon}\right)\right)d\tau+\varepsilon\mathcal{R}^{\varepsilon}(t,x).\end{aligned}$$

Using the identities

$$\cos^2\phi = \frac{1}{2}(1+\cos(2\phi)), \quad \sin^2\phi = \frac{1}{2}(1-\cos(2\phi)),$$

we then obtain that

$$A_2(t,x) = \left(t\frac{u_0^\perp}{b}(x)\sin\left(\frac{\phi(t,x)}{\varepsilon}\right) - t\frac{u_0}{b}(x)\cos\left(\frac{\phi(t,x)}{\varepsilon}\right)\right) \otimes \nabla b(x)$$

up to terms of order ε.

Then (3.13) can be rewritten

$$\int_0^t \left(\frac{1}{\varepsilon}(X(t,x)-X(\tau,x))\right)^\perp \otimes (g(\tau,x)\cdot\nabla b(X(\tau,x)))\,d\tau = -g(t,x)+\varepsilon\mathcal{R}^\varepsilon(t,x),$$

which implies immediately (3.11) and yields Lemma 4 as explained above.

3.5. Existence on a uniform time interval. As an immediate corollary of Lemma 4, we obtain that $X(t,\cdot)$ is a diffeomorphism of $\mathbf{R}^2$ on a uniform time interval. Indeed, DX is invertible as long as

$$\|DX - Id\|_{L^\infty} < 1.$$

COROLLARY 1. *Consider a function b satisfying assumptions* (H0) *and* (H1). *Let (ρ_0,u_0) be, respectively, a nonnegative function of $W^{s-1,\infty}(\mathbf{R}^2)$ and a vector field of $W^{s,\infty}(\mathbf{R}^2)$ ($s\geq 1$). Then, for all $T < \|u_0\|_{L^\infty}^{-1}\|\nabla b\|_{L^\infty}^{-1}$, there exists $\varepsilon_T>0$ such that system* (1.2) *admits a unique solution $(\rho_\varepsilon,u_\varepsilon)\in L^\infty([0,T],W^{s-1,\infty}(\mathbf{R}^2)\times W^{s,\infty}(\mathbf{R}^2))$ for all $\varepsilon\leq\varepsilon_T$.*

Proof of Corollary 1. By Lemma 4, the trajectories defined by (2.8) are continuously differentiable and satisfy, for all $t\leq T$ and all $x\in\mathbf{R}^2$,

$$\left\| DX(t,x) - Id - tu_0\otimes\nabla\log b\cos\left(\frac{\phi(t,x)}{\varepsilon}\right) + tu_0^\perp\otimes\nabla\log b\sin\left(\frac{\phi(t,x)}{\varepsilon}\right)\right\| \leq C_T\varepsilon.$$

This implies in particular the following estimate on the Jacobian $J(t,x) \stackrel{\text{def}}{=} |\det(DX(t,x))|$:

$$\left| J(t,x) - 1 - tu_0\cdot\nabla\log b\cos\left(\frac{\phi(t,x)}{\varepsilon}\right) + tu_0^\perp\cdot\nabla\log b\sin\left(\frac{\phi(t,x)}{\varepsilon}\right)\right| \leq C_T\varepsilon.$$

Then for $T<\|u_0\|_{L^\infty}^{-1}\|\nabla b\|_{L^\infty}^{-1}$, there exists ε_T such that

$$\forall\varepsilon\leq\varepsilon_T,\quad \forall t\in[0,T],\quad \sup_{x\in\mathbf{R}^2}|J(t,x)-1|<1,$$

which means that X is a C^1-diffeomorphism of $\mathbf{R}^2$.

Moreover, from formula (2.8) we can deduce by induction that $X(t,.)$ (and consequently its inverse $X^{-1}(t,\cdot)$) is smooth, its regularity being the same as the regularity of the initial velocity field u_0. Then the vector field u given by

$$u(t,x) = u_0(X^{-1}(t,x))\cos\left(\frac{\phi(t,X^{-1}(t,x))}{\varepsilon}\right) - u_0^\perp(X^{-1}(t,x))\cos\left(\frac{\phi(t,X^{-1}(t,x))}{\varepsilon}\right)$$

belongs to $L^\infty([0,T],W^{s,\infty}(\mathbf{R}^2))$, and it is easy to check that it satisfies system (1.3) in a strong sense.

The density ρ is then obtained as the strong solution of the linear transport equation

$$\partial_t\rho + u\cdot\nabla\rho + \rho\nabla\cdot u = 0$$

whose coefficients belong to $L^\infty([0,T],W^{s-1,\infty}(\mathbf{R}^2))$, with initial data in $W^{s-1,\infty}(\mathbf{R}^2)$. It therefore stays in $L^\infty([0,T],W^{s-1,\infty}(\mathbf{R}^2))$. We emphasize once again that no uniform bound on (ρ,u) is available in $L^\infty([0,T],W^{s-1,\infty}(\mathbf{R}^2)\times W^{s,\infty}(\mathbf{R}^2))$.

Theorem 2 is proved.

Remark 3. The supremum of the life span of the solutions corresponds to a crossing phenomenon, to be compared with the caustic in geometrical optics. Beyond this time, the differential system

$$\left\{\begin{array}{l}\dot X = \xi,\\ \dot\xi = \xi\wedge b\end{array}\right.$$

with initial data $(x,u_0(x))_{x\in\mathbf{R}^2}$ still admits a unique smooth solution, but the application $(X(t,x),\xi(t,x))\mapsto X(t,x)$ is no longer injective, and it cannot be lifted. The hyperbolic system (1.3) no longer has a solution.

4. Study of the asymptotics of u_ε and ρ_ε. Let $T<T^*=\|u_0\|_{L^\infty}^{-1}\|\nabla b\|_{L^\infty}^{-1}$ be fixed. Then, for any $\varepsilon\le\varepsilon_T$ as in Corollary 1, the solution (ρ,u) of system (1.2) with initial data $(\rho_0,u_0)\in W^{s-1,\infty}(\mathbf{R}^2)\times W^{s,\infty}(\mathbf{R}^2)$ belongs to $L^\infty([0,T],W^{s-1,\infty}(\mathbf{R}^2)\times W^{s,\infty}(\mathbf{R}^2))$. Then it makes sense to study their asymptotic behavior as $\varepsilon\to 0$, and the aim of this section is to prove Theorems 3 and 4.

Subsection 4.1 is devoted to the asymptotics of $u(t,X(t,x))$ and $\rho(t,X(t,x))$. Subsection 4.2 consists in inverting the characteristics in order to infer Theorems 3 and 4.

4.1. Asymptotics of $u(t,X)$ and $\rho(t,X)$. From the characteristic formulation of system (1.2) and the asymptotic expansion of $X(t,\cdot)$, we immediately deduce the asymptotic behavior of $u(t,X(t,\cdot))$ and $\rho(t,X(t,\cdot))$.

PROPOSITION 2. *Consider a function b satisfying assumptions* (H0) *and* (H1). *Let u_0 be a vector field in $W^{s,\infty}(\mathbf{R}^2)$ ($s\ge 1$). For all $T<T^*$ and $\varepsilon\le\varepsilon_T$ as in Theorem* 2, *denote by u the solution of* (1.3) *in $L^\infty([0,T],W^{s,\infty}(\mathbf{R}^2))$. Then*

$$u(t,X(t,x)) - \Big(u_0(x)\cos(\widetilde\phi_\varepsilon(t,x)) - u_0^\perp(x)\sin(\widetilde\phi_\varepsilon(t,x))\Big)$$

converges strongly to 0 *in $L^\infty([0,T]\times\mathbf{R}^2)$, at speed $O(\varepsilon)$, where the phase $\widetilde\phi_\varepsilon$ is defined by*

$$\widetilde\phi_\varepsilon(t,x) = \frac{b(x)t}{\varepsilon} - t\left(u_0^\perp(x)\cdot\nabla\right)\log b(x). \tag{4.1}$$

Proof of Proposition 2. Let us first recall that

$$u(t,X(t,x)) = u_0(x)\cos\left(\frac{\phi(t,x)}{\varepsilon}\right) - u_0^\perp(x)\sin\left(\frac{\phi(t,x)}{\varepsilon}\right),$$

where the phase ϕ is given by

$$\phi(t,x) = \int_0^t b(X(s,x))ds.$$

Then in order to establish Proposition 2, we have to approximate the phase. By Lemma 2,

$$b(X(t,x)) = b(x) + \frac{\varepsilon u_0(x)}{b(x)} \sin\left(\frac{\phi(t,x)}{\varepsilon}\right) \cdot \nabla b(x) - \frac{\varepsilon u_0^\perp(x)}{b(x)} \left(1 - \cos\left(\frac{\phi(t,x)}{\varepsilon}\right)\right) \cdot \nabla b(x) + \varepsilon^2 \mathcal{R}^\varepsilon(t,x),$$

noticing that $v \cdot \nabla b = 0$. It follows that

$$\begin{aligned} u(t, X(t,x)) = u_0(x) \cos\Bigg(& \frac{b(x)t}{\varepsilon} + \frac{u_0(x)\cdot\nabla b(x)}{b(x)} \int_0^t \sin\left(\frac{\phi(s,x)}{\varepsilon}\right) ds \\ & - \frac{u_0^\perp(x)\cdot\nabla b(x)}{b(x)} \int_0^t \left(1 - \cos\left(\frac{\phi(s,x)}{\varepsilon}\right)\right) ds + \varepsilon \mathcal{R}^\varepsilon(t,x)\Bigg) \\ - u_0^\perp(x) \sin\Bigg(& \frac{b(x)t}{\varepsilon} + \frac{u_0(x)\cdot\nabla b(x)}{b(x)} \int_0^t \sin\left(\frac{\phi(s,x)}{\varepsilon}\right) ds \\ & - \frac{u_0^\perp(x)\cdot\nabla b(x)}{b(x)} \int_0^t \left(1 - \cos\left(\frac{\phi(s,x)}{\varepsilon}\right)\right) ds + \varepsilon \mathcal{R}^\varepsilon(t,x)\Bigg). \end{aligned}$$

Finally, remembering that due to Lemma 1

$$\left| \int_0^t \sin\left(\frac{\phi(s,x)}{\varepsilon}\right) ds \right| + \left| \int_0^t \cos\left(\frac{\phi(s,x)}{\varepsilon}\right) ds \right| \leq \varepsilon \mathcal{R}^\varepsilon(t,x),$$

with the usual uniform bounds on $\mathcal{R}^\varepsilon$, this yields Proposition 2.

The asymptotic behavior of ρ is obtained in a similar way using the fact that ρ is proportional to the Jacobian $J(t,x) = |\det DX(t,x)|$.

PROPOSITION 3. *Consider a function b satisfying assumptions* (H0) *and* (H1). *Let ρ_0 be a nonnegative function in $W^{s-1,\infty}(\mathbf{R}^2)$, and let u_0 be a vector field in $W^{s,\infty}(\mathbf{R}^2)$ ($s \geq 1$). For all $T < T^*$ and $\varepsilon \leq \varepsilon_T$ as in Theorem* 2, *denote by (ρ, u) the solution of* (1.2) *in $L^\infty([0,T], W^{s-1,\infty}(\mathbf{R}^2))$ and $L^\infty([0,T], W^{s,\infty}(\mathbf{R}^2))$, respectively. Then*

$$\rho(t, X(t,x)) - \rho_0(x) \left(1 + t u_0 \cdot \nabla \log b(x) \sin(\widetilde{\phi}_\varepsilon(t,x)) - t u_0^\perp \cdot \nabla \log b(x) \cos(\widetilde{\phi}_\varepsilon(t,x))\right)$$

converges strongly to 0 *in $L^\infty([0,T] \times \mathbf{R}^2)$, where the phase $\widetilde{\phi}_\varepsilon$ is defined as in* (4.1).

Proof of Proposition 3. As long as the solution of (1.2) is regular, the equation governing ρ can be rewritten

$$\frac{d}{dt}(\log \rho) = \nabla \cdot u,$$

where $\frac{d}{dt}$ denotes as usual the derivative along the trajectories associated with the flow. Of course, the Liouville theorem implies that the equation on the Jacobian of the flow states

$$\frac{d}{dt}(J) = \nabla \cdot u.$$

Then, for all $\varepsilon \leq \varepsilon_T$, all $t \in [0,T]$, and all $x \in \mathbf{R}^2$,

$$\rho(t, X(t,x)) = \rho_0(x) J(t,x),$$

since $J_0(t,x) = \det(Id) = 1$.

From Lemma 4 we then deduce that

$$\left|\rho(t,X(t,x)) - \rho_0(x)\left(1 + tu_0\cdot\nabla\log b(x)\sin\left(\frac{\phi(t,x)}{\varepsilon}\right) - tu_0^\perp\cdot\nabla\log b(x)\left(\frac{\phi(t,x)}{\varepsilon}\right)\right)\right| \leq C_T\varepsilon. \tag{4.2}$$

Plugging back into formula (4.2) the approximation of the phase obtained previously,

$$\frac{\phi(t,x)}{\varepsilon} = \widetilde{\phi}_\varepsilon + \varepsilon\mathcal{R}^\varepsilon(t,x), \tag{4.3}$$

then leads to the expected asymptotics.

4.2. Inversion of the characteristics. In this section we shall prove Theorems 3 and 4. From now on T^* is the time given by Theorem 2, and we will call T any time smaller than T^* (in the following we will also suppose $\varepsilon \leq \varepsilon_T$ as given in Theorem 2).

Let $X^{-1}(t,x)$ be the point at time 0 of the trajectory reaching x at time t. By Proposition 2, we have

$$u(t,x) = u_0(X^{-1}(t,x))\cos\left(\widetilde{\phi}_\varepsilon(t,X^{-1}(t,x))\right) - u_0^\perp(X^{-1}(t,x))\sin\left(\widetilde{\phi}_\varepsilon(t,X^{-1}(t,x))\right) + \varepsilon\mathcal{R}^\varepsilon(t,x)$$

with the usual uniform bounds on $\mathcal{R}^\varepsilon$. That remainder function $\mathcal{R}^\varepsilon(t,x)$ is liable to change from line to line in this subsection.

By Proposition 1 there is a constant C_T (depending on T, u_0, and b), such that

$$\forall x\in\mathbf{R}^2,\quad \forall t\in[0,T],\quad |X^{-1}(t,x) - x| \leq C_T\varepsilon, \tag{4.4}$$

so we can write rather

$$u(t,x) = u_0(x)\cos\left(\widetilde{\phi}_\varepsilon(t,X^{-1}(t,x))\right) - u_0^\perp(x)\sin\left(\widetilde{\phi}_\varepsilon(t,X^{-1}(t,x))\right) + \varepsilon\mathcal{R}^\varepsilon(t,x).$$

By definition of $\widetilde{\phi}_\varepsilon$ in (4.1), we have, using again (4.4),

$$\widetilde{\phi}_\varepsilon(t,X^{-1}(t,x)) = \frac{b(x)t}{\varepsilon} + \frac{t}{\varepsilon}(X^{-1}(t,x)-x)\cdot\nabla b(x) - tu_0^\perp(x)\cdot\nabla\log b(x) + \varepsilon\mathcal{R}^\varepsilon(t,x),$$

and hence, defining

$$\widetilde{\theta}_\varepsilon(t,x) \stackrel{\text{def}}{=} \frac{t}{\varepsilon}(X^{-1}(t,x)-x)\cdot\nabla b(x) - tu_0^\perp(x)\cdot\nabla\log b(x),$$

we have

$$\widetilde{\phi}_\varepsilon(t,X^{-1}(t,x)) = \frac{b(x)t}{\varepsilon} + \widetilde{\theta}_\varepsilon(t,x) + \varepsilon\mathcal{R}^\varepsilon(t,x). \tag{4.5}$$

Now we shall try to make $\widetilde{\theta}_\varepsilon$ more precise. According to Lemma 2 and the approximation for the phase derived in the previous paragraph, we have

$$x - X^{-1}(t,x) = \varepsilon\frac{u_0(x)}{b(x)}\sin\left(\widetilde{\phi}_\varepsilon(t,X^{-1}(t,x)) + \varepsilon\mathcal{R}^\varepsilon(t,x)\right) - \varepsilon\frac{u_0^\perp(x)}{b(x)}\left(1-\cos\left(\widetilde{\phi}_\varepsilon(t,X^{-1}(t,x)) + \varepsilon\mathcal{R}^\varepsilon(t,x)\right)\right) - \varepsilon tv(x) + \varepsilon^2\mathcal{R}^\varepsilon(t,x),$$

where again we have used (4.4). So we obtain, using the fact that $v \cdot \nabla b = 0$,

$$\widetilde{\theta}_\varepsilon(t,x) = -tu_0(x)\cdot\nabla \log b(x) \sin\left(\widetilde{\phi}_\varepsilon(t,X^{-1}(t,x)) + \varepsilon\mathcal{R}^\varepsilon(t,x)\right) + tu_0^\perp(x)\cdot\nabla\log b(x)\cos\left(\widetilde{\phi}_\varepsilon(t,X^{-1}(t,x)) + \varepsilon\mathcal{R}^\varepsilon(t,x)\right) + \varepsilon\mathcal{R}^\varepsilon(t,x),$$

which by (4.5) yields directly the result (1.4), defining $\theta_\varepsilon(t,x) = \widetilde{\theta}_\varepsilon(t,x) + \frac{b(x)t}{\varepsilon}$.

Theorem 3 is proved.

The proof of Theorem 4 is now immediate: we use the formula obtained in Proposition 3 and replace $\rho_\varepsilon(t,X(t,x))$ by $\rho_\varepsilon(t,x)$ using the above formulation of $X^{-1}(t,x)$. The result follows.

GLOBAL SOLUTIONS OF NONLINEAR TRANSPORT EQUATIONS FOR CHEMOSENSITIVE MOVEMENT*

HYUNG JU HWANG†‡, KYUNGKEUN KANG†§, AND ANGELA STEVENS†

Abstract. A widespread phenomenon in moving microorganisms and cells is their ability to reorient themselves depending on changes of concentrations of certain chemical signals. In this paper we discuss kinetic models for chemosensitive movement, which also takes into account evaluations of gradient fields of chemical stimuli which subsequently influence the motion of the respective microbiological species. The basic type of model was discussed by Alt [*J. Math. Biol.*, 9 (1980), pp. 147–177], [*J. Reine Angew. Math.*, 322 (1981), pp. 15–41] and by Othmer, Dunbar, and Alt [*J. Math. Biol.*, 26 (1988), pp. 263–298]. Chalub et al. rigorously proved that, in three dimensions, these kinds of kinetic models lead to the classical Keller–Segel model as its drift-diffusion limit when the equation for the chemo-attractant is of elliptic type [*Monatsh. Math.*, 142 (2004), pp. 123–141], [*On the Derivation of Drift-Diffusion Model for Chemotaxis from Kinetic Equations*, ANUM preprint 14/02, Vienna Technical University, 2002]. In [H. Hwang, K. Kang, and A. Stevens, *Drift-diffusion limits of kinetic models for chemotaxis: A generalization*, Discrete Contin. Dyn. Syst. Ser. B., to appear] it was proved that the macroscopic diffusion limit exists in both two and three dimensions also when the equation of the chemo-attractant is of parabolic type. So far in the rigorous derivations, only the density of the chemo-attractant was supposed to influence the motion of the chemosensitive species. Here we show that in the macroscopic limit some types of evaluations of gradient fields of the chemical stimulus result in a change of the classical parabolic Keller–Segel model for chemotaxis. Under suitable structure conditions, global solutions for the kinetic models can be shown.

1. Introduction.

The starting point of our considerations is the classical chemotaxis model as discussed by Keller and Segel (see [14] and [15]). This system is of advection-diffusion type and consists of two coupled parabolic equations:

$$\frac{\partial \rho}{\partial t} = \nabla \cdot (D(\rho, S)\nabla\rho - \chi(\rho, S)\rho\nabla S), \tag{1.1}$$

$$\tau\frac{\partial S}{\partial t} = D_0\Delta S + \alpha\rho - \beta S, \quad \alpha, \beta, \tau \geq 0. \tag{1.2}$$

Here $\rho = \rho(x,t)$ denotes the density of chemotactic cells and $S = S(x,t)$ is the density of the chemo-attractant. The cells are attracted by the chemical, and χ denotes their chemotactic sensitivity. The first rigorous derivation of the macroscopic chemotaxis equations from microscopic models, namely, interacting stochastic many particle systems, was given in [21]. In [11] a survey about known results on existence of global solutions and finite time blowup for this type of model was given.

In [3] a kinetic model for (1.1) was discussed coupled with the Poisson equation without decay term

$$-\Delta S = \alpha\rho. \tag{1.3}$$

In [3, p. 3] the following kinetic equation for the oriented cell density $f = f(x, v, t) \geq 0$ was considered:

$$\frac{\partial f}{\partial t} + v \cdot \nabla_x f = \int_V (T[S]f' - T^*[S]f)dv', \tag{1.4}$$

where x, v, and t indicate position, velocity, and time, respectively. Here the abbreviations $f' = f(x, v', t)$, $T[S] = T[S](x, v, v', t)$, and $T^*[S] = T[S](x, v', v, t)$ are used. The first term on the right-hand side of (1.4) describes the turning into direction v, and the second term the turning away from v. The cell density ρ fulfills

$$\rho(x, t) = \int_V f(x, v, t)dv,$$

where V is the set of admissible velocities which is assumed to be compact.

Using stochastic models for the motion of bacteria and leukocytes, Alt derived (1.1) from a transport equation similar to (1.4) [1, section 8], [2, section 3]. Later a general formulation of this velocity-jump process was presented and studied in [18, section 3]. In [10] and [19] Othmer and Hillen studied the formal diffusion limit of a transport equation of (1.4) by moment expansions, which generalizes parts of Alt's earlier works [1], [2]. A hyperbolic scaling and its formal limit were discussed in [6].

Based on [19] a rigorous proof of the macroscopic limit was given in [3]. After using diffusive scaling of time and space, the nondimensional form of (1.4) leads to [3, p. 4]

$$\epsilon^2 \frac{\partial f_\epsilon}{\partial t} + \epsilon v \cdot \nabla_x f_\epsilon = -\mathcal{T}_\epsilon[S_\epsilon](f_\epsilon), \quad x \in \mathbb{R}^n,\ v \in V,\ t > 0, \tag{1.5}$$

where

$$\mathcal{T}_\epsilon[Z](g) = \int_V (T^*_\epsilon[Z]g - T_\epsilon[Z]g')dv'.$$

The diffusion limit $\epsilon \to 0$ was studied for initial conditions

$$f_\epsilon(x, v, 0) \equiv f_0(x, v), \quad x \in \mathbb{R}^n,\ v \in V, \tag{1.6}$$

with (1.5) coupled to (1.3) for the chemo-attractant. In [3] it was shown that the coupled nonlinear system (1.5), (1.6), and (1.3) resulted in Keller–Segel-type equations for chemotaxis as its macroscopic drift-diffusion limit under suitable conditions on the turning kernel in three dimensions (compare, e.g., [3, Theorem 5] and [4, Theorem 2]). In [3] and [4] also global solutions were proved for suitable turning kernels for fixed $\epsilon > 0$.

In [12], as an extension of [3], the authors proved that such kinetic models have a macroscopic diffusion limit in both two and three dimensions also when the equation of the chemo-attractant is of parabolic type, i.e., $\tau > 0$, which is the original version of the chemotaxis model. An independent related result was given in [5].

In this article, we consider turning kernels depending not only on S but also on ∇S, as formally discussed, among others, in [22] and [19], i.e.,

$$\epsilon^2 \frac{\partial f_\epsilon}{\partial t} + \epsilon v \cdot \nabla_x f_\epsilon = -\mathcal{T}_\epsilon[S_\epsilon, \nabla S_\epsilon](f_\epsilon), \quad x \in \mathbb{R}^n,\ v \in V,\ t > 0, \tag{1.7}$$

with initial condition (1.6) coupled to

$$\tau \frac{\partial S_\epsilon}{\partial t} = \Delta S_\epsilon + \alpha \rho_\epsilon - \beta S_\epsilon, \quad \tau \geq 0,\ \alpha > 0,\ \beta \geq 0, \tag{1.8}$$

where

$$\rho_\epsilon = \int_V f_\epsilon dv. \tag{1.9}$$

In what follows, for notational convenience, we write $\mathcal{T}_\epsilon[S_\epsilon]$ instead of $\mathcal{T}_\epsilon[S_\epsilon, \nabla S_\epsilon]$, unless any confusion is to be expected. Here we emphasize that the conditions on the turning kernel include also detection of spatial gradients of the chemo-attractant by the chemotactic cells. This behavior results under certain conditions in a macroscopic model which varies from the classical Keller–Segel system by additional higher order terms.

Our main result is that for suitable turning kernels which take into account the effects of gradient measurements of the chemical, global solutions exist also in two dimensions, and thus blowup of the solutions does not happen in finite time (compare Theorems 3.6 and 3.12 for the elliptic and parabolic cases, respectively).

The result is extended to three dimensions under some restrictions on the turning kernels. We also show the existence of a macroscopic diffusion limit of the kinetic model in two and three dimensions. More precisely, under similar assumptions on the turning kernel $T[S]$ as given in [3], we prove that the coupled nonlinear system (1.6), (1.7), and (1.8) converges to Keller–Segel-type equations and their variants for $\epsilon \to 0$ (compare Theorem 4.4). Our main tool is the potential estimate for S. In particular, in case the chemo-attractant equation is of elliptic type, i.e., $\tau = 0$ and in two dimensions, log-type estimates for the chemical S are used to obtain global existence for the kinetic model (similar techniques were used in [13, Lemma 4]).

The plan of this paper is as follows: In section 2, we introduce some notation used and briefly review the derivation of the macroscopic equation as presented in [3] and [12]. In section 3, we prove that the kinetic model (1.7)–(1.9) has a global solution for "suitable" turning kernels. In section 4, we prove the existence of the diffusion limit for a short time interval. In section 5 we give concrete examples on how the specific dependencies of the turning kernel result in different types of macroscopic equations.

2. Preliminaries. We first introduce some notation which will be used throughout this article and recall some of the observations presented in [3].

• By G we denote the Bessel potential, which is the fundamental solution of the differential operator $1 - \Delta$ in $\mathbb{R}^n$ (see [20, pp. 130–132]):

$$G(x) = \frac{1}{4\pi} \int_0^\infty e^{-\pi \frac{|x|^2}{4s} - \frac{s}{4\pi}} s^{\frac{-n+2}{2}} \frac{ds}{s}. \tag{2.1}$$

• By Γ we denote the fundamental solution of the differential operator $\partial_t - \Delta_x + \beta$ in $\mathbb{R}^n \times \mathbb{R}_+$:

$$\Gamma(x,t) = \frac{1}{(4\pi t)^{\frac{n}{2}}} \exp\left(-\frac{|x|^2}{4t} - \beta t\right). \tag{2.2}$$

• By $C = C(\alpha, \beta, \dots)$ we denote a constant depending on the prescribed quantities $\alpha, \beta, \dots$. The domain Ω considered in this article is $\mathbb{R}^n$, $n = 2, 3$.

To make this note self-contained, we review the formal derivation of the macroscopic equation from the kinetic model presented in [3] (compare the details in [3, pp. 5–7]). For simplicity we assume for a moment that $\tau = 1$, $\alpha = 1$, and $\beta = 1$ (other cases can be formally derived in a similar way without any difficulty). Since the integral of $\mathcal{T}_\epsilon[S](f)$ with respect to the velocity vanishes, we obtain the macroscopic conservation equation

$$\frac{\partial \rho_\epsilon}{\partial t} + \nabla \cdot J_\epsilon = 0, \tag{2.3}$$

where $J_\epsilon(x,t) = \epsilon^{-1} \int_V v f_\epsilon(x,v,t) dv$ is the flux density. The turning kernel is assumed to have the following asymptotic expansion: $T_\epsilon[S] = T_0[S] + \epsilon T_1[S] + O(\epsilon^2)$. Then the turning operator can be expanded in a similar way and

$$\mathcal{T}_\epsilon[S](f) = \int_V (T_\epsilon^*[S] f - T_\epsilon[S] f') dv'.$$

By asymptotic expansion of $f_\epsilon = f_0 + \epsilon f_1 + O(\epsilon^2)$ and $S_\epsilon = S_0 + \epsilon S_1 + O(\epsilon^2)$, the equation for the leading order terms can be obtained from (1.7):

$$\mathcal{T}_0[S_0](f_0) = 0, \quad S_0 = \rho_0 * \Gamma, \quad \rho_0 = \int_V f_0 dv. \tag{2.4}$$

Comparing coefficients in (1.7) results in

$$v \cdot \nabla_x f_0 = -\mathcal{T}_0[S_0](f_1) - \mathcal{T}_1[S_0](f_0) - \mathcal{T}_{0S}[S_0, S_1](f_0),$$

where $\mathcal{T}_{0S}[S_0, S_1]$ is part of the turning operator $\mathcal{T}$ and its kernel is the Fréchet derivative of T_0 with respect to S, evaluated at S_0 in the direction S_1. Here, we recall the assumptions on the leading order terms of the turning operator and two useful lemmas presented in [3, (A0), Lemma 1, Lemma 2, pp. 6–7].

Assumption 2.1. There exists a bounded velocity distribution $F(v) > 0$, such that $T_0^*[S]F = T_0[S]F'$ and

$$\int_V vF(v) dv = 0, \qquad \int_V F(v) dv = 1.$$

The turning rate $T_0[S]$ is bounded, and there exists a constant $\gamma = \gamma[S] > 0$ such that $T_0[S]/F \geq \gamma$ for all $(v, v') \in V \times V$, $x \in \mathbb{R}^n$, and $t > 0$.

LEMMA 2.2. *Let $\zeta : \mathbb{R} \to \mathbb{R}$, $g : V \to \mathbb{R}$, and let*

$$\phi_\epsilon^S[S] = \frac{T_\epsilon[S]F' + T_\epsilon^*[S]F}{2}, \qquad \phi_\epsilon^A[S] = \frac{T_\epsilon[S]F' - T_\epsilon^*[S]F}{2}$$

denote, respectively, the symmetric and antisymmetric parts of $T_\epsilon[S]F'$. Then

$$\begin{aligned}\int_V \int_V \mathcal{T}_\epsilon(Fg)\zeta(g) dv = &\frac{1}{2} \int_V \int_V \phi_\epsilon^S[S](g - g')(\zeta(g) - \zeta(g')) dv' dv \\ &+ \frac{1}{2} \int_V \int_V \phi_\epsilon^A[S](g + g')(\zeta(g) - \zeta(g')) dv' dv.\end{aligned}$$

The same holds for $\mathcal{T}_\epsilon[S]$ with analogous definitions of $\phi_\epsilon^S[S]$ and $\phi_\epsilon^A[S]$.

Proof. See Lemma 1 in [3] for the proof. ∎

With $g = f/F$ and $\zeta = \mathrm{id}$ one obtains the following.

LEMMA 2.3. *Let Assumption* 2.1 *hold. Then the entropy equality*

$$\int_V \mathcal{T}_0[S](f)\frac{f}{F}dv = \frac{1}{2}\int_V\int_V \phi_0^S[S]\left(\frac{f}{F} - \frac{f'}{F'}\right)^2 dv'dv \geq 0$$

holds. For $g \in L^2(V; dv/F)$*, the equation* $\mathcal{T}_0[S](f) = g$ *has a unique solution* $f \in L^2(V; dv/F)$ *satisfying* $\int_V f dv = 0$ *if and only if* $\int_V g dv = 0$.

Proof. See Lemma 2 in [3] for the proof. ∎

From the entropy equality, we deduce that

$$f_0(x, v, t) = \rho_0(x, t)F(v).$$

Since $\mathcal{T}_{0S}[S_0, S_1](f_0) = 0$, we obtain

$$\mathcal{T}_0[S](f_1) = -vF \cdot \nabla\rho_0 - \rho_0\mathcal{T}_1[S_0](F).$$

The right-hand side satisfies the solvability condition from Lemma 2.3, and therefore the solution can be written as

$$f_1 = -\kappa(x, v, t) \cdot \nabla\rho_0(x, t) - \Theta(x, v, t)\rho_0(x, t) + \rho_1(x, t)F(v),$$

where $\kappa = \kappa[S_0]$ and $\Theta = \Theta[S_0]$ are the solutions of

$$\mathcal{T}_0[S_0](\kappa) = vF, \qquad \mathcal{T}_0[S_0](\Theta) = \mathcal{T}_1[S_0](F),$$

and ρ_1 is the macroscopic density of f_1, which is a new unknown. By passing to the limit $\epsilon \to 0$ in (2.3), the convection-diffusion equation reads

$$\partial_t\rho_0 - \nabla \cdot (D[S_0]\nabla\rho_0 - \rho_0 H[S_0]) = 0,$$

where

$$D[S_0](x, t) = \int_V v \otimes \kappa[S_0](x, v, t)dv, \qquad H[S_0] = -\int_V v\Theta[S_0](x, v, t)dv,$$

together with

$$\frac{\partial S_0}{\partial t} = \Delta S_0 + \rho_0 - S_0.$$

The specific form of $D[S_0]$ and $H[S_0]$ will depend on the choice of the turning kernels and will be discussed later.

3. Global solution of the kinetic model. In this section we show that solutions of the coupled system (1.6)–(1.9) in two and three dimensions do not blow up in finite time for fixed $\epsilon > 0$ if the turning kernel satisfies a certain structure condition. Without loss of generality we set $\epsilon = 1$ in (1.6) and $\alpha = 1$ in (1.8). We consider two problems, namely, the elliptic and the parabolic equations for the chemo-attractant.

We start with an inequality of Gronwall type in the next lemma. Since it is of the nonstandard form among the Gronwall-type inequalities, we present its proof for clarity, although the proof is similar to that of the usual one.

LEMMA 3.1. *Let a and b be positive constants. Let $y(t)$ and $y'(t)$ be positive and differentiable in t and satisfy*

$$y' \le ay \ln y' + by. \tag{3.1}$$

Then

$$y(t) \le \left[y(0) \exp\left(2b \int_0^t e^{-2as} ds \right) \right]^{\exp(2at)}.$$

Proof. We subtract and add $\ln y$ from the right-hand side of (3.1) to get $y' \le ay \ln y + ay \ln (\ln y)' + by$. Dividing both sides of the above inequality by y, we get $(\ln y)' \le a \ln y + a \ln (\ln y)' + b$. Set $z = \ln y$ to get $z' \le az + a \ln z' + b$. Since we may assume $\ln z' \le (1/2a)z'$ (otherwise, $\ln z' \le C$ and the above inequality reduces to a standard Gronwall inequality), we have $z' \le az + \frac{1}{2} z' + b$. We get $z' \le 2az + 2b$, where $z = \ln y$. Using a standard Gronwall argument, we deduce the lemma. ∎

The structure condition on the turning kernel $T[S]$ is assumed to be as follows.

Assumption 3.2 (structure condition). There exist nonnegative constants $C_i \ge 0$, $i = 1, 2, \ldots, 5$, such that for all $x \in \mathbb{R}^n$, $n = 2, 3$, $v, v' \in V$, $t \in \mathbb{R}^+$, and $S \in W^{1,\infty}(\mathbb{R}^n)$, the turning kernel T satisfies

$$\begin{aligned} 0 \le T_\epsilon[S](x, v, v', t) &\le C_1 + C_2 S(x + \epsilon v, t) + C_3 S(x - \epsilon v', t) \\ &\quad + C_4 |\nabla S(x + \epsilon v, t)| + C_5 |\nabla S(x - \epsilon v', t)|, \end{aligned} \tag{3.2}$$

$$\begin{aligned} |\nabla T_\epsilon[S](x, v, v', t)| &\le C_2 |\nabla S(x + \epsilon v, t)| + C_3 |\nabla S(x - \epsilon v', t)| \\ &\quad + C_4 |\nabla^2 S(x + \epsilon v, t)| + C_5 |\nabla^2 S(x - \epsilon v', t)|. \end{aligned} \tag{3.3}$$

This means that the cells can measure the concentration and the spatial gradient of the chemo-attractant up to a distance ϵ from their position, and this may affect the movement of the cells.

Remark 3.3. The turning kernel, as given above, describes the turning from direction v' into direction v. This means that the actual or "old" direction is evaluated by checking backwards, whereas the evaluation of possible new directions are checked forwards (e.g., by lamelliopodial protrusion). Checking the possible new directions backwards if compared to the actual direction of motion is also possible and could have been taken into account in the following considerations. Nevertheless, it is important to note that a forward evaluation of the actual direction v' causes a technical problem in our approach so far.

We first consider the case that the chemo-attractant equation is of elliptic type.

3.1. Elliptic case: $\tau = 0$. In this part, we consider the elliptic equation for the chemo-attractant S for two cases: $\beta > 0$ and $\beta = 0$. When $\beta > 0$ we may set $\beta = 1$ without loss of generality. So

$$-\Delta S = \rho - \beta S, \quad \beta \in \{0, 1\}, \quad n = 2, 3. \tag{3.4}$$

For $n = 2$ we need some preliminaries and start with elementary properties of the Bessel potential G in two dimensions.

LEMMA 3.4. *Let G be the Bessel potential in $\mathbb{R}^2$. Then $G \in L^p(\mathbb{R}^2)$ for any p with $1 \le p < \infty$ and $\nabla G \in L^p(\mathbb{R}^2)$ for any p with $1 \le p < 2$. Furthermore,*

$$\|G\|_{L^p(\mathbb{R}^2)} \le Cp, \quad 1 \le p < \infty, \tag{3.5}$$

$$\|\nabla G\|_{L^p(\mathbb{R}^2)} \le C \frac{2p}{2 - p}, \quad 1 \le p < 2. \tag{3.6}$$

Proof. For $n = 2$, the Bessel potential is (cf. (2.1))

$$G(x) = \frac{1}{4\pi}\int_0^\infty e^{-\pi\frac{|x|^2}{4s}-\frac{s}{4\pi}}\frac{ds}{s}.$$

Using a change of variables, we have

$$\|G\|_{L^p(\mathbb{R}^2)} \le C\int_0^\infty \frac{e^{-s}}{s}\big\|e^{-\frac{|x|^2}{4s}}\big\|_{L^p(\mathbb{R}^2)}ds \le C\int_0^\infty e^{-s}s^{-1+1/p}ds \le Cp.$$

We thus obtain (3.5). In a similar way we get

$$\|\nabla G\|^p_{L^p(\mathbb{R}^2)} \le C\int_0^\infty \frac{e^{-s}}{s^2}\big\|xe^{-\frac{|x|^2}{4s}}\big\|_{L^p(\mathbb{R}^2)}ds \le C\int_0^\infty e^{-s}s^{-\frac{3}{2}+\frac{1}{p}}ds \le C\frac{2p}{2-p},$$

as long as $1 \le p < 2$. Therefore we deduce (3.6). ∎

The next lemma shows various estimates for the chemo-attractant S.

LEMMA 3.5. *Let S be a solution of* (3.4) *in* $\mathbb{R}^2$. *Then S satisfies the following estimates:*

$$\|S(t)\|_{L^p(\mathbb{R}^2)} + \|\nabla S(t)\|_{L^q(\mathbb{R}^2)} \le C(p,q)\|\rho_0\|_{L^1(\mathbb{R}^2)}, \quad 1 \le p < \infty,\ 1 \le q < 2, \tag{3.7}$$

$$\|\nabla S(t)\|_{L^2(\mathbb{R}^2)} \le C\|\rho_0\|_{L^1(\mathbb{R}^2)}\big[\ln\big(\|\rho(t)\|^2_{L^2(\mathbb{R}^2)}+1\big)\big]^{1/2}. \tag{3.8}$$

Proof. The first estimate (3.7) is an easy consequence of mass conservation, Lemma 3.4, and Young's inequality (see, e.g., [7, pp. 624–625]). Thus it suffices to show the estimate (3.8).

From (3.4) we obtain the Fourier transform $\hat{S}(\xi) = \hat{\rho}(\xi)/(|\xi|^2+1)$, and thus

$$\|\nabla S(t)\|_{L^2(\mathbb{R}^2)} = \|\xi\hat{S}(t)\|_{L^2(\mathbb{R}^2)} = \left\|\frac{|\xi|\hat{\rho}(t)}{|\xi|^2+1}\right\|_{L^2(\mathbb{R}^2)},$$

where Plancherel's equality is used. The above integral can be estimated by splitting $\mathbb{R}^2$ of the ξ-space into two parts:

$$\int_{\mathbb{R}^2}\frac{|\xi\hat{\rho}(t)|^2}{(|\xi|^2+1)^2}d\xi = \int_{|\xi|<R}+\cdots+\int_{|\xi|>R}+\cdots = I_1+I_2,$$

where $R > 0$ will be chosen later. Using Hölder's inequality and Plancherel's equality we have

$$I_1 \le \|\hat{\rho}(t)\|^2_{L^\infty(\mathbb{R}^2)}\int_{|\xi|<R}\frac{|\xi|^2}{(|\xi|^2+1)^2}d\xi \le C\|\rho(t)\|^2_{L^1(\mathbb{R}^2)}\ln(R^2+1),$$

$$I_2 \le \left\|\frac{|\xi|}{|\xi|^2+1}\right\|^2_{L^\infty(|\xi|>R)}\|\hat{\rho}(t)\|^2_{L^2(\mathbb{R}^2)} \le CR^{-2}\|\rho(t)\|^2_{L^2(\mathbb{R}^2)}.$$

Therefore, by choosing $R = \|\rho(t)\|_{L^2(\mathbb{R}^2)}$, we obtain

$$\begin{aligned}\|\nabla S(t)\|_{L^2(\mathbb{R}^2)} &\le C\|\rho(t)\|_{L^1(\mathbb{R}^2)}\{\ln(R^2+1)\}^{1/2} + CR^{-1}\|\rho(t)\|_{L^2(\mathbb{R}^2)}\\ &\le C\left[1+\|\rho(t)\|_{L^1(\mathbb{R}^2)}\big\{\ln\big(\|\rho(t)\|^2_{L^2(\mathbb{R}^2)}+1\big)\big\}^{1/2}\right].\end{aligned}$$

Since $\|\rho\|_{L^1(\mathbb{R}^2)} = \|f_0\|_{L^1(\mathbb{R}^2\times V)}$, we deduce (3.8) and our lemma. ∎

The next theorem shows global existence of solutions for system (1.6)–(1.9) with $\tau = 0$, namely, blowup does not happen in finite time.

THEOREM 3.6. *Suppose the chemo-attractant equation is of elliptic type ($\tau = 0$). Assume that $f_0, \nabla f_0 \in (L^1 \cap L^\infty)(\mathbb{R}^n \times V)$, with $n = 2, 3$.*

1. *Case $n = 2$, $\beta > 0$: Let Assumption* 3.2 *hold. Then there exist global solutions $f, \nabla f \in L^\infty_{\mathrm{loc}}((0,\infty); L^1 \cap L^\infty(\mathbb{R}^2 \times V))$ and $S \in L^\infty_{\mathrm{loc}}((0,\infty); W^{1,p}(\mathbb{R}^2))$ for all $1 \le p \le +\infty$ of the system* (1.6)–(1.9) *with $\epsilon > 0$ fixed but arbitrary.*

2. *Case $n = 2$, $\beta = 0$: Let Assumption* 3.2 *hold with $C_2 = C_3 = C_5 = 0$. Then there exist global solutions $f, \nabla f \in L^\infty_{\mathrm{loc}}((0,\infty); L^1 \cap L^\infty(\mathbb{R}^2 \times V))$ and $\nabla S \in L^\infty_{\mathrm{loc}}((0,\infty); L^p(\mathbb{R}^2))$ for all $2 < p \le \infty$ of the system* (1.6)–(1.9) *with $\epsilon > 0$ fixed but arbitrary.*

3. *Case $n = 3$, $\beta > 0$: Let Assumption* 3.2 *hold with $C_3 = C_5 = 0$. Then there exist global solutions $f, \nabla f \in L^\infty_{\mathrm{loc}}((0,\infty); L^1 \cap L^\infty(\mathbb{R}^3 \times V))$ and $S \in L^\infty_{\mathrm{loc}}((0,\infty); W^{1,p}(\mathbb{R}^3))$ for all $1 \le p \le +\infty$ of the system* (1.6)–(1.9) *with $\epsilon > 0$ fixed but arbitrary.*

4. *Case $n = 3$, $\beta = 0$: Let Assumption* 3.2 *hold with $C_3 = C_5 = 0$. Then there exist global solutions $f, \nabla f \in L^\infty_{\mathrm{loc}}((0,\infty); L^1 \cap L^\infty(\mathbb{R}^3 \times V))$ and $S \in L^\infty_{\mathrm{loc}}((0,\infty); L^p(\mathbb{R}^3))$ for any $3 < p \le \infty$ and $\nabla S \in L^\infty_{\mathrm{loc}}((0,\infty); L^p(\mathbb{R}^3))$ for any $3/2 < p \le \infty$ of the system* (1.6)–(1.9) *with $\epsilon > 0$ fixed but arbitrary.*

Proof. (a) We first consider the case $n = 2$ and $\beta > 0$. Without loss of generality, we assume $\epsilon = 1$. Mass is conserved for ρ, and thus $\|\rho(\cdot,t)\|_{L^1(\mathbb{R}^2)} = \|f_0\|_{L^1(\mathbb{R}^2 \times V)}$.

$$\partial_t f(x,v,t) + v \cdot \nabla_x f(x,v,t) = \int_V T[S](x,v,v',t) f(x,v',t) dv' - \int_V T[S](x,v',v,t) f(x,v,t) dv'.$$

Using Assumption 3.2, we get

$$f(x,v,t) \le f_0(x - vt, v) + C \int_0^t \rho(x - vs, t - s) ds + C f_1(x,v,t) + C f_2(x,v,t),$$

where f_1 and f_2 satisfy

$$\partial_t f_1(x,v,t) + v \cdot \nabla_x f_1(x,v,t) = \int_V [S(x+v,t) + |\nabla S(x+v,t)|] f(x,v',t) dv',$$
$$\partial_t f_2(x,v,t) + v \cdot \nabla_x f_2(x,v,t) = \int_V [S(x-v',t) + |\nabla S(x-v',t)|] f(x,v',t) dv',$$

with initial conditions $f_i(x,v,0) = 0$ for $i = 1, 2$. We first consider f_1. One can easily see that

$$f_1(x,v,t) = \int_0^t [S(x - vs + v, t - s) + |\nabla S(x - vs + v, t - s)|] \rho(x - vs, t - s) ds.$$

After simple calculations, we obtain the following estimates:

$$\|f_1(\cdot,\cdot,t)\|_{L^p(\mathbb{R}^2 \times V)} \le C \sup_{0 \le s \le t} \|S(\cdot,s)\|_{W^{1,p}(\mathbb{R}^2)} \int_0^t \|\rho(\cdot, t - s)\|_{L^p(\mathbb{R}^2)} ds.$$

For the term f_2, we have

$$f_2(x,v,t) = \int_0^t \int_V [S(x - vs - v', t - s) + |\nabla S(x - vs - v', t - s)| f(x - vs, v', t - s) dv' ds.$$

Applying Young's inequality, we get

$$\|(S(\cdot, t - s) + |\nabla S(\cdot, t - s)|) * f(x - vs, \cdot, t - s)\|_{L^\infty(V)} \le \sup_{0 < s < t} \|S(\cdot,s)\|_{W^{1,p}(\mathbb{R}^2)} \|f(x - vs, \cdot, t - s)\|_{L^{p'}(V)},$$

where p and p' are conjugate exponents. If $p \geq 2$, then $p' \leq p$, and so we have, by interpolation between p and 1,

$$\|f(x-vs,\cdot,t-s)\|_{L^{p'}(V)} \leq C(V)\|f(x-vs,\cdot,t-s)\|_{L^p(V)}.$$

Hence,

$$\|f_2(\cdot,\cdot,t)\|_{L^p(\mathbb{R}^2\times V)} \leq \sup_{0<s<t}\|S(\cdot,s)\|_{W^{1,p}(\mathbb{R}^2)}\int_0^t \|f(\cdot,\cdot,t-s)\|_{L^p(\mathbb{R}^2\times V)}ds.$$

Therefore, summing up the estimates above, we obtain for $p \geq 2$

$$\begin{aligned}\|f(\cdot,\cdot,t)\|_{L^p(\mathbb{R}^2\times V)} &\leq \|f_0(\cdot,\cdot)\|_{L^p(\mathbb{R}^2\times V)}\\ &\quad + C\left(1+\sup_{0\leq s\leq t}\|S(\cdot,s)\|_{W^{1,p}(\mathbb{R}^2)}\right)\int_0^t \|f(\cdot,\cdot,s)\|_{L^p(\mathbb{R}^2\times V)}.\end{aligned} \tag{3.9}$$

By Lemma 3.5, we have for $p=2$

$$\begin{aligned}\|f(\cdot,\cdot,t)\|_{L^2(\mathbb{R}^2\times V)} &\leq \|f_0(\cdot,\cdot)\|_{L^2(\mathbb{R}^2\times V)}\\ &\quad + C\left(1+\sup_{0\leq s\leq t}\left[\ln\left(\|f\|^2_{L^2(\mathbb{R}^2\times V)}+1\right)\right]^{1/2}\right)\int_0^t \|f(\cdot,\cdot,s)\|_{L^2(\mathbb{R}^2\times V)}.\end{aligned}$$

Then, applying Gronwall's inequality as in Lemma 3.1, we obtain $f \in L^2(\mathbb{R}^2\times V)$. Now, using bootstrap arguments we obtain the L^∞-estimate by applying repeatedly Lemma 3.4, Young's inequality, and Gronwall's inequality. Next we show L^∞-estimates for the derivatives of f. For convenience let $j=1,2$ be arbitrary but fixed, and we denote by $\tilde{f}$ and $\tilde{T}[S]$ the partial derivatives $\partial_{x_j}f$ and $\partial_{x_j}T[S]$, respectively.

$$\begin{aligned}\partial_t\tilde{f}(x,v,t)+v\cdot\nabla_x\tilde{f}(x,v,t) &= \int_V \tilde{T}[S](x,v,v',t)f(x,v',t)dv'\\ &\quad+\int_V T[S](x,v,v',t)\tilde{f}(x,v',t)dv'\\ &\quad-\int_V \tilde{T}[S](x,v',v,t)f(x,v,t)dv'\\ &\quad-\int_V T[S](x,v',v,t)\tilde{f}(x,v,t)dv'.\end{aligned}$$

Then, in the same manner as before, we obtain

$$\tilde{f}(x,v,t) \leq \tilde{f}_0(x-vt,v)+C\tilde{f}_1(x,v,t)+C\tilde{f}_2(x,v,t)+C\tilde{f}_3(x,v,t)+C\tilde{f}_4(x,v,t),$$

where

$$\begin{aligned}\tilde{f}_1(x,v,t) &= \int_0^t\int_V \tilde{T}[S](x-vs,v,v',t-s)f(x-vs,v',t-s)dv'ds,\\ \tilde{f}_2(x,v,t) &= \int_0^t\int_V T[S](x-vs,v,v',t-s)\tilde{f}(x-vs,v',t-s)dv'ds,\\ \tilde{f}_3(x,v,t) &= -\int_0^t\int_V \tilde{T}[S](x-vs,v',v,t-s)f(x-vs,v,t-s)dv'ds,\\ \tilde{f}_4(x,v,t) &= -\int_0^t\int_V T[S](x-vs,v',v,t-s)\tilde{f}(x-vs,v,t-s)dv'ds.\end{aligned}$$

We consider first $\tilde{f}_1(x,v,t)$. Here we use the fact that the L^∞- and L^p-norms of f, depending on t, are bounded, which was shown above. Therefore we have

$$|\tilde{f}_1(x,v,t)| \le \sup_{0<s<t} \|f(\cdot,s)\|_{L^\infty(\mathbb{R}^2\times V)} \int_0^t \int_V |\tilde{T}[S](x-vs,v,v',t-s)|dv'ds.$$

Using Assumption 3.2, one can easily see

$$\begin{aligned}\|\tilde{f}_1(\cdot,\cdot,t)\|_{L^p(\mathbb{R}^2\times V)} &\le C \sup_{0<s<t} \|f(\cdot,s)\|_{L^\infty(\mathbb{R}^2\times V)} \sup_{0<s<t} \|S(\cdot,s)\|_{W^{2,p}(\mathbb{R}^2)} \\ &\le C \sup_{0<s<t} \|f(\cdot,s)\|_{L^\infty(\mathbb{R}^2\times V)} \sup_{0<s<t} \|\rho(\cdot,s)\|_{L^p(\mathbb{R}^2)} \le C = C(t,|V|),\end{aligned}$$

where we used a standard estimate for the chemo-attractant equation. Since $\tilde{f}_3$ has the same structure as $\tilde{f}_1$, $\tilde{f}_3$ satisfies the estimates above. On the other hand, $\tilde{f}_2$ is estimated, due to Assumption 3.2, as follows:

$$|\tilde{f}_2(x,v,t)| \le \sup_{0<s<t} \|S(\cdot,s)\|_{W^{1,\infty}(\mathbb{R}^2)} \int_0^t \int_V \tilde{f}(x-vs,v',t-s)dv'ds.$$

Again, due to a standard estimate for the chemo-attractant equation, we get

$$|\tilde{f}_2(x,v,t)| \le \sup_{0<s<t} \|\tilde{f}\|_{L^q(\mathbb{R}^2)} \int_0^t \int_V \tilde{f}(x-vs,v',t-s)dv'ds,$$

where q is sufficiently large (i.e., $q>2$). Integration over $\mathbb{R}^2\times V$ yields

$$\|\tilde{f}_2(\cdot,\cdot,t)\|_{L^p(\mathbb{R}^2\times V)} \le C\int_0^t \|\tilde{f}(\cdot,\cdot,t-s)\|_{L^p(\mathbb{R}^2)}ds,$$

where we again used the boundedness of the L^p-norm of f and $C=C(|V|,t)$. $\tilde{f}_4$ can be treated in the same manner, so we omit the details. To sum up, we obtain

$$\|\nabla f(\cdot,\cdot,t)\|_{L^p(\mathbb{R}^2\times V)} \le C(|V|,t) + C(|V|,t)\int_0^t \|\nabla f(\cdot,\cdot,t-s)\|_{L^p(\mathbb{R}^2\times V)}ds.$$

Gronwall's inequality justifies our claim. Repeating this process for higher regularity of f and S, we can easily see that this estimate is valid also in case $p=\infty$. This completes the proof of the case $\beta>0$.

(b) Next we consider the case $n=2$, $\beta=0$. Again, for simplicity, we assume $\epsilon=1$. We first decompose ∇S into two parts,

$$\nabla S = \nabla S^L + \nabla S^S = \rho * \left(-\frac{x}{2\pi|x|^2}\mathbf{I}_{|x|\ge 1}\right) + \rho * \left(-\frac{x}{2\pi|x|^2}\mathbf{I}_{|x|\le 1}\right),$$

where $\mathbf{I_A}$ denotes the characteristic function of a set A. By mass conservation and Young's inequality, we have

$$\|\nabla S^L(t)\|_{L^\infty}(\mathbb{R}^2) \le \frac{1}{2\pi}\|f_0\|_{L^1(\mathbb{R}^2\times V)}.$$

Hence the estimate reduces to considering ∇S^S only, and we may replace ∇S by ∇S^S in the assumption on the turning kernel. Following similar procedures to those described in the case $\beta>0$, we obtain for $p\ge 1$

$$f(x,v,t) \le f_0(x-vt,v) + C\int_0^t \rho(x-vs,t-s)ds + Cf_1(x,v,t),$$

where

$$f_1(x,v,t) = \int_0^t |\nabla S^S(x - vs + v, t - s)|\rho(x - vs, t - s)ds.$$

Simple calculations show

$$\|f_1(\cdot,\cdot,t)\|_{L^p(\mathbb{R}^2\times V)} \le C \sup_{0\le s\le t} \|\nabla S^S(\cdot,s)\|_{L^p(\mathbb{R}^2)} \int_0^t \|\rho(\cdot,t-s)\|_{L^p(\mathbb{R}^2)}ds.$$

To sum up, we obtain

$$\begin{aligned}\|f(\cdot,\cdot,t)\|_{L^p(\mathbb{R}^2\times V)} &\le C + C\left(1 + \sup_{0\le s\le t} \|\nabla S^S(\cdot,s)\|_{L^p(\mathbb{R}^2)}\right)\\ &\quad\times \int_0^t \|f(\cdot,\cdot,t-s)\|_{L^p(\mathbb{R}^2\times V)}ds.\end{aligned} \tag{3.10}$$

Here we note that the above a priori estimate (3.10) holds for all $p \ge 1$. First we choose a specific p with $1 < p < 2$, which ensures, due to Young's inequality, that

$$\|\nabla S^S(\cdot,t)\|_{L^p(\mathbb{R}^2)} \le C\|f_0\|_{L^1(\mathbb{R}^2\times V)}.$$

Then by Gronwall's inequality we get a bound, globally in time, for f in $L^p(\mathbb{R}^2)$ for such chosen p. By bootstrap arguments, we obtain $f \in L^\infty_{\mathrm{loc}}([0,\infty); L^\infty(\mathbb{R}^2 \times V))$.

By similar procedures to those given in the proof of Theorem 3.6, an L^∞-estimate for ∇f can be obtained. $\nabla S \in L^\infty((0,\infty); L^p(\mathbb{R}^2))$, $2 < p \le \infty$, is due to the Hardy–Littlewood–Sobolev theorem (see [20, pp. 119–120]). Since this is also verified by embedding arguments for general elliptic equations, we skip the details.

Remark 3.7. Although similar results, in the theorem above, are expected for nonzero C_2, C_3, C_5 also in case $\beta = 0$, there are some technical difficulties in proving global existence when the chemo-attractant equation is of elliptic type. Indeed, the chemo-attractant equation becomes the Poisson equation without decay term $-\Delta S = \rho$, and thus S has the Newtonian potential representation, i.e., $S = \Gamma * \rho$, where $\Gamma(x) = 1/2\pi \log|x|$. Due to the behavior of Γ at infinity, we cannot, in general, control S in terms of ρ. (We do not have these kind of estimates in Lemma 3.5 if $\beta = 0$.) Thus we leave the global existence as an open question for nonzero C_2, C_3, and C_5 in case $\beta = 0$ and $\tau = 0$.

(c) The three-dimensional case: In this situation, unlike the two-dimensional case in Theorem 3.6, it is not necessary to distinguish proofs for $\beta = 0$ and $\beta \ne 0$. We briefly explain why C_3, C_5 are assumed to be zero in three dimensions. Indeed, as seen in the previous calculations, we end up with the following estimate:

$$\begin{aligned}\|f(\cdot,\cdot,t)\|_{L^p(\mathbb{R}^3\times V)} &\le C + C\left(1 + \sup_{0\le s\le t} \|S^S(\cdot,s)\|_{W^{1,p}(\mathbb{R}^3)}\right)\\ &\quad\times \int_0^t \|f(\cdot,\cdot,t-s)\|_{L^p(\mathbb{R}^3\times V)}ds.\end{aligned} \tag{3.11}$$

On the other hand, in three dimensions, due to behavior of the potential, we have

$$\|S^S(\cdot,s)\|_{W^{1,p}(\mathbb{R}^3)} \le C\|\rho_0\|_{L^1(\mathbb{R}^3)} \quad \text{for } 1 \le p < \frac{3}{2}. \tag{3.12}$$

However, in case C_3 or C_5 are nonzero, one can easily show that estimate (3.11) is still valid provided that $p \geq 2$ (compare the estimates for f_2 and f_4 before), but this does not enable us to use bootstrap arguments to get higher regularity for f because of (3.12). Therefore we assume $C_3 = C_5 = 0$. With this assumption the proof for the case $n = 3$ is similar to the case $n = 2$. ∎

Remark 3.8. It is worth mentioning that Theorem 3.6 also holds in case $n = 3$ when the turning kernel satisfies Assumption 3.2 with $C_2 = C_4 = 0$ instead of $C_3 = C_5 = 0$, namely,

$$0 \leq T[S](x, v, v', t) \leq C\left(1 + S(x - \epsilon v', t) + |\nabla S(x - \epsilon v', t)|\right),$$
$$|\nabla T[S](x, v, v', t)| \leq C(|\nabla S(x - \epsilon v', t)| + |\nabla^2 S(x - \epsilon v', t)|).$$

This can be seen by changing the roles of p and p' in the estimate of f_2 and by following a similar procedure to the one given for the proof of Theorem 3.6.

We do not know if the theorem above is also valid if the turning kernel fulfills the structure conditions (3.2) and (3.3) as in the two-dimensional case.

3.2. Parabolic case: $\tau > 0$. In this part, the parabolic equation for the chemoattractant in (1.8) is considered. From now on we let $\tau = 1$ without loss of generality and, for simplicity, we set here $\alpha = 1$. Then (1.8) for S reads

$$\partial_t S - \Delta S = \rho - \beta S, \quad S(x, 0) = S_0(x), \quad \beta \geq 0. \tag{3.13}$$

To make our arguments simpler, from now on we assume $S_0 = 0$ (compare Remark 3.11 in the following for the case $S_0 \neq 0$).

In the next lemma we recall some basic properties of Γ in two dimensions.

LEMMA 3.9. *Let Γ be the fundamental solution for the operator $\partial_t - \Delta_x + \beta$ in $\mathbb{R}^2$. Then $\Gamma \in L^p(\mathbb{R}^2)$ for any p with $1 \leq p < \infty$, and $\nabla\Gamma \in L^p(\mathbb{R}^2)$ for any q with $1 \leq p < 2$, satisfying*

$$\int_0^t \|\Gamma(\cdot, s)\|_{L^p(\mathbb{R}^2)} ds \leq C(\beta)p, \quad 1 \leq p < \infty,$$
$$\int_0^t \|\nabla\Gamma(\cdot, s)\|_{L^p(\mathbb{R}^2)} ds \leq C(\beta)\frac{2p}{2 - p}, \quad 1 \leq p < 2.$$

Proof. The proof is similar to that of Lemma 3.4, so we omit details. ∎

In the next lemma, we show L^p- and L^2-estimates for S and ∇S, respectively.

LEMMA 3.10. *Let S be a solution of* (3.13) *in $\mathbb{R}^2$ and $S_0 = 0$. Then S satisfies the estimates*

$$\|S(t)\|_{L^p(\mathbb{R}^2)} + \|\nabla S(t)\|_{L^q(\mathbb{R}^2)} \leq C(\beta, p, q)\|\rho_0\|_{L^1(\mathbb{R}^2)}, \tag{3.14}$$

where $1 \leq p < \infty$, $1 \leq q < 2$, and

$$\|\nabla S(t)\|^2_{L^2(\mathbb{R}^2)} \leq C\left(1 + \|\rho_0\|_{L^1(\mathbb{R}^2)}\left(1 + (\ln t)_+ + \sup_{0 \leq \tau \leq t}\left|\ln \|\rho(\tau)\|^2_{L^2(\mathbb{R}^2)}\right|\right)\right), \tag{3.15}$$

where $(f)_+$ indicates the positive part of f.

Proof. By Duhamel's principle and using the fundamental solution Γ in (2.2), we have

$$S(x, t) = \int_0^t \Gamma(\cdot, s) * \rho(\cdot, t - s) ds. \tag{3.16}$$

By using Lemma 3.9, mass conservation, and Young's inequality, we easily get (3.14). To estimate $\|\nabla S\|_{L^2(\mathbb{R}^2)}$, we take the Fourier transform of (3.16) and use Plancherel's equality to get

$$\|\nabla S(t)\|_{L^2(\mathbb{R}^2)} = \|\xi \hat{S}(t)\|_{L^2(\mathbb{R}^2)} \le \int_0^t \||\xi|\hat{\Gamma}(\cdot,s)\hat{\rho}(\cdot,t-s)\|_{L^2(\mathbb{R}^2)}ds = \int_0^r + \cdots + \int_r^t + \cdots,$$

where $r > 0$ will be chosen appropriately later. Note that the Fourier transform of Γ is $\hat{\Gamma}(\xi,s) = \exp(-s(4\xi^2+\beta))$. For $0 < s < r$, due to the Hölder's inequality and Plancherel's equality, we have

$$\begin{aligned}\int_0^r \cdots &\le \int_0^r \||\xi|\exp(-s(4\xi^2+\beta))\|_{L^\infty(\mathbb{R}^2)}\|\hat{\rho}(s)\|_{L^2(\mathbb{R}^2)}ds \\ &\le C \sup_{0\le s\le t}\|\rho\|_{L^2(\mathbb{R}^2)}\int_0^r s^{-1/2}ds \le Cr^{1/2}\sup_{0\le s\le t}\|\rho\|_{L^2(\mathbb{R}^2)}.\end{aligned}$$

For $r < s < t$, due to mass conservation and Hölder's inequality, now applied in the opposite way, we have

$$\begin{aligned}\int_r^t \cdots &\le \int_r^t \||\xi|\exp(-s(4\xi^2+\beta))\|_{L^2(\mathbb{R}^2)}\|\hat{\rho}(s)\|_{L^\infty(\mathbb{R}^2)}ds \\ &\le C\|\rho_0\|_{L^1(\mathbb{R}^2)}\int_r^t \frac{1}{s}ds \le C\|\rho_0\|_{L^1(\mathbb{R}^2)}|\ln t - \ln r|,\end{aligned}$$

where we used $\|\hat{\rho}\|_{L^\infty(\mathbb{R}^2)} \le \|\rho\|_{L^1(\mathbb{R}^2)}$. Therefore we obtain

$$\|\nabla S(t)\|_{L^2(\mathbb{R}^2)} \le C\left(r^{1/2}\sup_{0\le s\le t}\|\rho\|_{L^2(\mathbb{R}^2)} + \|\rho_0\|_{L^1(\mathbb{R}^2)}|\ln t - \ln r|\right).$$

By choosing $r = \min\{(\sup_{0\le s\le t}\|\rho\|_{L^2(\mathbb{R}^2)})^{-2}, t\}$ in the above inequality, we deduce our lemma. □

Remark 3.11. For the case $S_0 \neq 0$, which is assumed to be sufficiently smooth, one has

$$S(x,t) = \int_0^t \Gamma(\cdot,s) * \rho(\cdot,t-s)ds + \int_{\mathbb{R}^2}\Gamma(x-y,t)S_0(y)dy.$$

This gives the following variants of the estimates in the above lemma:

$$\|S(t)\|_{L^p(\mathbb{R}^2)} + \|\nabla S(t)\|_{L^q(\mathbb{R}^2)} \le C\big(\|S_0\|_{L^p(\mathbb{R}^2)} + \|\nabla S_0\|_{L^q(\mathbb{R}^2)} + \|\rho_0\|_{L^1(\mathbb{R}^2)}\big),$$

where $1 \le p < \infty$, $1 \le q < 2$ and

$$\begin{aligned}\|\nabla S(t)\|^2_{L^2(\mathbb{R}^2)} \le C\Bigg(&1 + \|\nabla S_0\|_{L^2(\mathbb{R}^2)} \\ &+ \|\rho_0\|_{L^1(\mathbb{R}^2)}\left(1 + (\ln t)_+ + \sup_{0\le\tau\le t}\left|\ln\left(\|\rho(\tau)\|^2_{L^2(\mathbb{R}^2)}\right)\right|\right)\Bigg).\end{aligned}$$

Since computations are straightforward, we omit the details.

As in the previous elliptic case, we can establish global existence for the system (1.6)–(1.9) with $\tau = 1$. To be more precise, once we have the essential estimate (3.15) for $\|\nabla S\|_{L^2(\mathbb{R}^2)}$, its proof is more or less the same as that for the elliptic case with

$\tau = 0$. Regularity of S is due to standard theory of general parabolic equations. For dimension three, under the weaker assumptions of the turning kernel (Assumption 3.2 with $C_3 = C_5 = 0$) than those in the elliptic case, we can also show global existence of solutions. Since the arguments are straightforward if compared to the elliptic case, we just state the results and skip its proof.

THEOREM 3.12. *Suppose the chemo-attractant equation is of parabolic type. Assume that* $f_0, \nabla f_0 \in (L^1 \cap L^\infty)(\mathbb{R}^n \times V)$.

1. *(Case* $n = 2$*.) Let* $\beta \geq 0$ *and Assumption* 3.2 *hold. Then there exist global solutions* $f, \nabla f \in L^\infty_{\mathrm{loc}}((0,\infty); (L^1 \cap L^\infty)(\mathbb{R}^2 \times V))$ *and* $S, \nabla S \in L^\infty_{\mathrm{loc}}((0,\infty); L^p(\mathbb{R}^2))$ *for all* $1 \leq p \leq +\infty$ *of system* (1.6)–(1.9).

2. *(Case* $n = 3$*.) Let* $\beta \geq 0$ *and Assumption* 3.2 *with* $C_3 = C_5 = 0$. *Then there exist global solutions* $f, \nabla f \in L^\infty_{\mathrm{loc}}((0,\infty); (L^1 \cap L^\infty)(\mathbb{R}^3 \times V))$ *and* $S, \nabla S \in L^\infty_{\mathrm{loc}}((0,\infty); L^p(\mathbb{R}^3))$ *for all* $1 \leq p \leq +\infty$ *of system* (1.6)–(1.9).

4. Diffusion limits of the kinetic model. In this section, the diffusion limit for kinetic models of type (1.6)–(1.9) is presented. First, in a lemma, we review estimates for S which satisfies an equation of elliptic type, i.e.,

$$-\Delta S = \rho - \beta S, \quad \beta \geq 0, \quad \text{in } \mathbb{R}^n, \ n = 2, 3.$$

We use standard arguments, which are known as potential theory. Proofs are straightforward (compare, e.g., [9, Chapters 2 and 8] and [20, Chapter V] for the two-dimensional case, and [16, Chapter 4] and [17, Chapters 4 and 6] for the three-dimensional case).

LEMMA 4.1. *Let* $I = [0, T) \subset \mathbb{R}$ *and* $0 < T < \infty$. *Suppose* $\rho \in L^\infty(I; (W^{1,1}(\mathbb{R}^n) \cap W^{1,q}(\mathbb{R}^n)))$, *where* $q > n$. *Let* S *satisfy the chemo-attractant equation of either elliptic or parabolic type with* $\beta \geq 0$.

(i) *In the case either* $n = 2$, $\beta > 0$ *or* $n = 3$, $\beta \geq 0$, *and* S *fullfils the chemo-attractant equation of either elliptic or parabolic type,*

$$S \in L^\infty(I; W^{2,p}(\mathbb{R}^n)) \cap L^\infty(I; \mathcal{C}^{2+\alpha}(\mathbb{R}^n)), \quad 1 \leq p < \infty, \ 0 < \alpha \leq \frac{q-n}{q},$$

and S *satisfies the estimate*

$$\|S\|_{L^\infty(I; W^{2,p}(\mathbb{R}^n))} + \|S\|_{L^\infty(I; \mathcal{C}^{2+\alpha}(\mathbb{R}^n))} \leq C\big(\|\rho\|_{L^\infty(I; W^{1,1}(\mathbb{R}^n))} + \|\rho\|_{L^\infty(I; W^{1,q}(\mathbb{R}^n))}\big).$$

(ii) *The result of* (i) *is true also for* $n = 2$, $\beta = 0$, *when* S *fullfils the chemo-attractant equation of parabolic type.*

(iii) *In the case* $n = 2$ *and* $\beta = 0$ *and* S *fullfils the chemo-attractant equation of elliptic type,*

$$\nabla S \in L^\infty(I; W^{1,p}(\mathbb{R}^2)) \cap L^\infty(I; \mathcal{C}^{1+\alpha}(\mathbb{R}^2)), \quad 1 \leq p < \infty, \ 0 < \alpha \leq \frac{q-2}{q},$$

and S *satisfies the estimate*

$$\|\nabla S\|_{L^\infty(I; W^{1,p}(\mathbb{R}^2))} + \|\nabla S\|_{L^\infty(I; \mathcal{C}^{1+\alpha}(\mathbb{R}^2))} \leq C\big(\|\rho\|_{L^\infty(I; W^{1,1}(\mathbb{R}^2))} + \|\rho\|_{L^\infty(I; W^{1,q}(\mathbb{R}^2))}\big).$$

As in [3] we need similar assumptions on $\phi^S_\epsilon[S]$ and $\phi^A_\epsilon[S]$, which are the symmetric and antisymmetric parts of $T_\epsilon[S]$ (see Lemma 2.2).

Assumption 4.2. There exist $\gamma > 0$ and a nondecreasing function $\Lambda \in L^\infty_{\mathrm{loc}}$, such that

$$\phi^S_\epsilon[S] \geq \gamma \left(1 - \epsilon\Lambda\left(\|\nabla S\|_{W^{1,\infty}(\mathbb{R}^n)}\right)\right) FF',$$
$$\int_V \frac{\phi^A_\epsilon[S]^2}{F\phi^S_\epsilon[S]} dv' \leq \epsilon^2 \Lambda\left(\|\nabla S\|_{W^{1,\infty}(\mathbb{R}^n)}\right),$$

where $F \in L^\infty(V)$ is a positive velocity distribution satisfying Assumption 2.1.

THEOREM 4.3. *Let Assumptions* 2.1 *and* 4.2 *hold and let $q > n$ with $n = 2, 3$. Suppose that the equation for the chemo-attractant S is either of elliptic ($\tau = 0$) or parabolic type ($\tau \neq 0$). Let one of following conditions hold:*

(i) *If $\tau = 0$, $n = 2$, $\beta > 0$ or if $\tau > 0$, $n = 2$, $\beta \geq 0$, the turning kernel satisfies Assumption* 3.2.

(ii) *If $\tau = 0$, $n = 2$, $\beta = 0$, the turning kernel satisfies Assumption* 3.2 *with $C_2 = C_3 = C_5 = 0$.*

(iii) *If $\tau \geq 0$, $n = 3$, $\beta \geq 0$, the turning kernel satisfies Assumption* 3.2 *with $C_3 = C_5 = 0$.*

Assume further that

$$f_0 \in \Upsilon_q \equiv W^{1,1}(\mathbb{R}^n \times V) \cap W^{1,q}\left(\mathbb{R}^n \times V; \frac{dxdv}{F^{q-1}}\right).$$

Then there exists $t^* > 0$, independent of ϵ, such that the solutions f_ϵ, S_ϵ satisfy

$$f_\epsilon \in L^\infty((0,t^*); \Upsilon_q),$$
$$\nabla S_\epsilon \in L^\infty((0,t^*); W^{1,p}(\mathbb{R}^n) \cap \mathcal{C}^{1+\alpha}(\mathbb{R}^n)), \quad 1 \leq p < \infty,\ \alpha = \frac{q-2}{q}$$
$$\text{if } \tau = 0,\ n = 2,\ \beta = 0.$$
$$S_\epsilon \in L^\infty((0,t^*); W^{2,p}(\mathbb{R}^n) \cap \mathcal{C}^{2+\alpha}(\mathbb{R}^n)), \quad 1 \leq p < \infty,\ \alpha = \frac{q-n}{q} \text{ in all other cases,}$$
$$r_\epsilon = \frac{f_\epsilon - \rho_\epsilon F}{\epsilon} \in L^2\left((0,t^*); \mathbb{R}^n \times V : \frac{dxdvdt}{F}\right). \tag{4.1}$$

Proof. This can be shown by following the same procedure as that given in the proof of Theorem 4 in [3], and therefore we present only a brief sketch of this proof. Simple calculations show

$$\frac{d}{dt}\int_{\mathbb{R}^n}\int_V \frac{f^q_\epsilon}{F^{q-1}} dvdx \leq C\Lambda\big(\|\nabla S\|_{W^{1,\infty}(\mathbb{R}^n)}\big)\int_{\mathbb{R}^n}\int_V \frac{f^q_\epsilon}{F^{q-1}} dvdx.$$

The next step is to estimate S_ϵ:

$$\|\nabla S_\epsilon(\cdot,t)\|_{\mathcal{C}^{1,\alpha}(\mathbb{R}^n)} \leq C\big(1 + \|\nabla\rho_\epsilon(\cdot,t)\|_{L^q(\mathbb{R}^n)}\big) \leq \tilde{C}\big(1 + \|\rho_\epsilon(\cdot,t)\|_{L^q(\mathbb{R}^n)}\big).$$

Here we used the estimates in Lemma 4.1.

$$\frac{d}{dt}\int_{\mathbb{R}^n}\int_V \frac{f^q_\epsilon}{F^{q-1}} dvdx \leq C\left[1 + \left(\int_{\mathbb{R}^n}\int_V \frac{f^q_\epsilon}{F^{q-1}} dvdx\right)^{\frac{1}{q}}\right]\int_{\mathbb{R}^n}\int_V \frac{f^q_\epsilon}{F^{q-1}} dvdx.$$

This shows the first two statements. The rest can be done by using the same method as that given in the proof of Theorem 4 in [3], and thus we omit the details. ∎

Now we are ready to prove the existence of the diffusion limit in a short time interval.

THEOREM 4.4. *Let the assumption of Theorem* 4.3 *hold. Suppose that the equation for the chemo-attractant S is of elliptic ($\tau = 0$) or parabolic ($\tau \neq 0$) type. Assume further that for families (S_ϵ), which are uniformly bounded in $L^\infty_{\mathrm{loc}}([0,\infty);\mathcal{C}^{2+\alpha}(\mathbb{R}^n))$ for some α with $0 < \alpha \leq 1$, such that S_ϵ, ∇S_ϵ, and $\nabla^2 S_\epsilon$ converge to $S_0, \nabla S_0$, and $\nabla^2 S_0$ as $\epsilon \to 0$, respectively, in $L^p_{\mathrm{loc}}([0,\infty);\mathbb{R}^n)$ for some $p > n/(n-1)$ with $n = 2, 3$, we have the convergence*

$$T_\epsilon[S_\epsilon] \to T_0[S_0] \quad \text{in } L^p_{\mathrm{loc}}([0,\infty);\mathbb{R}^n \times \bar{V} \times \bar{V}),$$
$$\frac{\mathcal{T}_\epsilon[S_\epsilon](F)}{\epsilon} = \frac{2}{\epsilon}\int_V \phi^A_\epsilon[S_\epsilon]dv' \to \mathcal{T}_1[S_0](F) \quad \text{in } L^p_{\mathrm{loc}}([0,\infty);\mathbb{R}^n \times \bar{V}). \tag{4.2}$$

Then the solutions f_ϵ and S_ϵ of (1.6)–(1.9) *satisfy*

$$f_\epsilon \to \rho_0 F \quad \text{in } L^\infty((0,t^*);\Upsilon_q) \text{ weak } *,$$

and for $\tau = 0$

$$\nabla S_\epsilon \to \nabla S_0 \quad \text{in } W^{1,q}_{\mathrm{loc}}((0,t^*);\mathbb{R}^n), \quad 1 \leq q < \infty \text{ if } n = 2,\ \beta = 0,$$
$$S_\epsilon \to S_0 \quad \text{in } W^{2,q}_{\mathrm{loc}}((0,t^*);\mathbb{R}^n), \quad 1 \leq q < \infty \text{ otherwise},$$

whereas for $\tau \neq 0$

$$S_\epsilon \to S_0 \quad \text{in } L^q_{\mathrm{loc}}((0,t^*);W^{2,q}(\mathbb{R}^n)), \quad 1 \leq q < \infty.$$

Proof. Since the proof is similar to that of Theorem 5 in [3], we again present only a brief sketch of the procedure. First we note, due to (4.1), that

$$J_\epsilon = \frac{1}{\epsilon}\int_V v f_\epsilon dv = \int_V v r_\epsilon dv \in L^2((0,t^*);L^2(\mathbb{R}^n))$$

uniformly in ϵ. From the cell conservation equation $\partial_t \rho_\epsilon + \operatorname{div} \mathrm{J}_\epsilon = 0$, one can easily see that

$$\partial_t(\nabla S_\epsilon) \in L^2((0,t^*);L^2_{\mathrm{loc}}(\mathbb{R}^n))$$

by considering the gradient of the convolution of (1.8). The strong convergence follows combining the above estimate and the parabolic regularity for the convolutions defining S_ϵ and ∇S_ϵ from ρ_ϵ. Therefore, the kinetic equation (1.7) leads to

$$\epsilon\frac{\partial f_\epsilon}{\partial t} + v \cdot \nabla_x f_\epsilon = -\rho_\epsilon \frac{\mathcal{T}[S_\epsilon](F)}{\epsilon} - \mathcal{T}_\epsilon[S_\epsilon](r_\epsilon).$$

By assumption (4.2) and passing to the limit, we obtain

$$\mathcal{T}_0[S_0](r_0) = -vF \cdot \nabla \rho_0 - \rho_0 \mathcal{T}_1[S_0](F).$$

This equation can be solved due to Lemma 2.3. The limit of the cell conservation equation is $\partial_t \rho_0 + \nabla \cdot J_0 = 0$ with $J_0 = \int_V v r_0 dv$. This completes the proof. ∎

5. Examples. When dealing with chemosensitive movement of biological species, questions of major interest are, How do the individuals "measure" the chemical signal? How is this information processed, and what kind of behavior results? The model we have introduced before and its macroscopic limit give a partial answer to this problem.

First we give a short summary of possible evaluations of the chemical signal by the cells as suggested by Tranquillo and Alt [22] and later discuss related examples. The individuals might evaluate the chemical signal

spatially - the signal is evaluated at (at least) two distinct locations around the individual, which are related to its direction (cf. Examples 5.1, 5.3, and 5.4);

temporal(ly) differential - the signal is evaluated at (at least) two different times (cf. Example 5.1);

positionally - the signal is evaluated momentarily (cf. Example 5.4);

directionally - the signal is evaluated along the individual direction or its relation to a directional signal field, e.g., a spatial gradient at its position (cf. Examples 5.1, 5.3, 5.4, 5.5, and 5.6).

Discussions of possible turning rates of the cells which depend on the given chemical signal in this context are also given in [1], [2], [18] and [10], [19].

In [10], [19] the macroscopic limit is formal. It is assumed that the turning kernel has an expansion in ϵ which is supposed to be given. Here the ϵ-expansion is directly related to possible evaluations of the chemo-attractant by the cells, and thus the connection between the micro- and macroparameters can be derived.

To understand the different influences of the evaluations of the chemical signal, our first example is very general and allows also dependencies on time derivatives of the chemo-attractant. Since we did not prove regularity for S_t so far, the macroscopic limit in this case has to be considered only formal. Nevertheless, from this example the other rigorous examples can be extracted later. Below we only consider the two-dimensional case, to keep the computations simple and since this case is the most interesting one biologically.

Example 5.1 (formal for $\alpha > 0$, rigorous for $\alpha = 0$). Let the turning kernel be of general type:

$$\begin{aligned} T_\epsilon[s] = \phi(&S(x+\epsilon v,t), S(x-\epsilon v',t), S(x,t-\epsilon), \nabla S(x+\epsilon v,t), \nabla S(x-\epsilon v',t),\\ &\partial_t S(x+\epsilon v,t), \partial_t S(x-\epsilon v',t), \partial_t S(x,t-\epsilon), v) + \epsilon\psi\left(\frac{v\cdot v'}{|v||v'|}\right), \end{aligned} \tag{5.1}$$

where $\phi : \mathbb{R}^{12} \to \mathbb{R}$ and $\psi : \mathbb{R} \to \mathbb{R}$ are smooth and $\phi + \epsilon\psi$ is strictly positive (∇S contributes two entries, $\partial_{x_1} S$ and $\partial_{x_2} S$). Here S satisfies the chemo-attractant equation either of elliptic type or of parabolic type with $\alpha \geq 0$ and $\beta > 0$ in two dimensions. For $\alpha = 0$ the S-equation is completely decoupled. In this case the derivation given below is rigorous. We do not include direct dependencies such as $S(x,t), S_t(x,t), \nabla S(x,t)$ at this point. These will be discussed later.

We use the following notational abbreviations:

$$\begin{aligned} \phi[S, \nabla S, \partial_t S, v] &:= \phi(S(x,t), S(x,t), S(x,t), \nabla S(x,t),\\ &\qquad \nabla S(x,t), \partial_t S(x,t), \partial_t S(x,t), \partial_t S(x,t), v),\\ \phi_i[S, \nabla S, \partial_t S, v] &:= \phi_i(S(x,t), S(x,t), S(x,t), \nabla S(x,t), \nabla S(x,t),\\ &\qquad \partial_t S(x,t), \partial_t S(x,t), \partial_t S(x,t), v), \end{aligned}$$

where $\phi_i(\cdots)$ indicates the partial derivative of ϕ with respect to the ith argument for $i = 1, 2, \ldots, 12$. By the asymptotic expansion of $T_\epsilon = T_0 + \epsilon T_1 + O(\epsilon^2)$, one can easily see that $T_0 = T_0[S, v] = \phi[S, \nabla S, \partial_t S, v]$ and

$$\begin{aligned} T_1 &= T_1[S, v, v'] \\ &= (\phi_1[S, \nabla S, \partial_t S, v]v - \phi_2[S, \nabla S, \partial_t S, v]v') \cdot \nabla S + \phi_3[S, \nabla S, \partial_t S, v]\partial_t S \\ &\quad + (\phi_{3+i}[S, \nabla S, \partial_t S, v]v - \phi_{5+i}[S, \nabla S, \partial_t S, v]v') \cdot \nabla S_{x_i} \\ &\quad + (\phi_8[S, \nabla S, \partial_t S, v]v - \phi_9[S, \nabla S, \partial_t S, v]v') \cdot \nabla S_t \\ &\quad - \phi_{10}[S, \nabla S, \partial_t S, v]\partial_t^2 S + \psi\left(\frac{v \cdot v'}{|v||v'|}\right), \end{aligned}$$

where we used the summation convention, which is understood over repeated indices running from 1 to 2. Furthermore, we define Φ, $\tilde{\Phi}$, $\hat{\Phi}$, and $\bar{\Phi}$ as follows:

$$\Phi[S_0, \nabla S_0, \partial_t S_0] := \int_V T_0[S_0, v']dv', \qquad \tilde{\Phi}[S_0, \nabla S_0, \partial_t S_0, v] := \int_V T_1[S_0, v', v]dv',$$

$$\hat{\Phi}[S_0, \nabla S_0, \partial_t S_0, v] := \int_V T_1[S_0, v, v']f_0(v', x, t)dv',$$

$$\bar{\Phi}[S_0, \nabla S_0, \partial_t S_0, v] := \frac{1}{\Phi[S_0, \nabla S_0, \partial_t S_0]} \int_V T_0[S_0, v']T_1[S_0, v, v']dv'.$$

From $\mathcal{T}_0[S_0](f_0) = 0$, we have

$$f_0(v, x, t) = \frac{\phi[S_0, \nabla S_0, \partial_t S_0, v]\rho_0(x, t)}{\Phi[S_0, \nabla S_0, \partial_t S_0]},$$

and therefore it is easy to see $\hat{\Phi}(v) = \bar{\Phi}(v)\rho_0$.

Due to $\mathcal{T}_0[S_0](f_1) = -\mathcal{T}_1[S_0](f_0) - v \cdot \nabla f_0$, we have

$$\begin{aligned} f_1(v, x, t) = \frac{1}{\Phi[S_0, \nabla S_0, \partial_t S_0]}(&- v \cdot \nabla f_0(v, x, t) - \tilde{\Phi}[S_0, \nabla S_0, \partial_t S_0, v]f_0(v, x, t) \\ &+ \hat{\Phi}[S_0, \nabla S_0, \partial_t S_0, v]). \end{aligned}$$

Computing $J_\epsilon = \int_V v f_1(v, x, t)dv$, we obtain

$$\begin{aligned} J_\epsilon = &- \int_V \frac{v^i v^j \partial_{x_j} f_0}{\Phi[S_0, \nabla S_0, \partial_t S_0]}dv - \int_V \frac{v^i \tilde{\Phi}[S_0, \nabla S_0, \partial_t S_0, v]f_0}{\Phi[S_0, \nabla S_0, \partial_t S_0]}dv \\ &+ \int_V \frac{v^i \hat{\Phi}[S_0, \nabla S_0, \partial_t S_0, v]\rho_0}{\Phi[S_0, \nabla S_0, \partial_t S_0]}dv. \end{aligned} \tag{5.2}$$

The first integral in (5.2) becomes

$$\begin{aligned} \int_V \frac{v^i v^j \partial_{x_j} f_0}{\Phi[S_0, \nabla S_0, \partial_t S_0]}dv &= \frac{\rho_0}{\Phi[S_0, \nabla S_0, \partial_t S_0]} \int_V \left(v^i v^j \partial_{x_j}\left(\frac{\phi[S_0, \nabla S_0, \partial_t S_0, v]}{\Phi[S_0, \nabla S_0, \partial_t S_0]}\right)\right)dv \\ &\quad + \frac{\partial_{x_j}\rho_0}{\Phi^2[S_0, \nabla S_0, \partial_t S_0]} \int_V v^i v^j \phi[S_0, \nabla S_0, \partial_t S_0, v]dv \\ &= \frac{A_i}{\Phi}\rho_0 + \frac{B_{ij}}{\Phi^2}\partial_{x_j}\rho_0, \end{aligned}$$

where

$$A_i = A_i[S_0, \nabla S_0, \partial_t S_0] = \int_V v^i v^j \partial_{x_j} \left(\frac{\phi[S_0, \nabla S_0, \partial_t S_0, v]}{\Phi[S_0, \nabla S_0, \partial_t S_0]} \right) dv, \tag{5.3}$$

$$B_{ij} = B_{ij}[S_0, \nabla S_0, \partial_t S_0] = \int_V v^i v^j \phi[S_0, \nabla S_0, \partial_t S_0, v] dv. \tag{5.4}$$

The second integral in (5.2) leads to

$$\int_V \frac{v^i \tilde{\Phi}[S_0, \nabla S_0, \partial_t S_0, v] f_0(v)}{\Phi[S_0, \nabla S_0, \partial_t S_0]} dv = \frac{C_i}{\Phi^2(S_0, \nabla S_0, \partial_t S_0)} \rho_0,$$

where

$$C_i = C_i[S_0, \nabla S_0, \partial_t S_0] = \int_V v^i \tilde{\Phi}[S_0, \nabla S_0, \partial_t S_0, v] \phi[S_0, \nabla S_0, \partial_t S_0, v] dv. \tag{5.5}$$

The last integral in (5.2) becomes

$$\int_V \frac{v^i \hat{\Phi}[S_0, \nabla S_0, \partial_t S_0, v]}{\Phi[S_0, \nabla S_0, \partial_t S_0]} dv = \int_V \frac{v^i \bar{\Phi}[S_0, \nabla S_0, \partial_t S_0, v] \rho_0}{\Phi[S_0, \nabla S_0, \partial_t S_0]} dv = \frac{D_i}{\Phi} \rho_0,$$

where

$$D_i = D_i[S_0, \nabla S_0, \partial_t S_0] = \int_V v^i \bar{\Phi}[S_0, \nabla S_0, \partial_t S_0, v] dv. \tag{5.6}$$

Summing up, we obtain the macroscopic equation

$$\partial_t \rho_0 = \partial_{x_i} \left(\frac{A_i}{\Phi} \rho_0 + \frac{B_{ij}}{\Phi^2} \partial_{x_j} \rho_0 + \frac{C_i}{\Phi^2} \rho_0 - \frac{D_i}{\Phi} \rho_0 \right), \quad \Phi = \Phi[S_0, \nabla S_0, \partial_t S_0],$$

where A_i, B_{ij}, C_i, and D_i are defined in (5.3)–(5.6).

Remark 5.2. If we drop out the explicit dependence of the last argument v in the functional ϕ in (5.1), then the term $\psi(v \cdot v'/|v||v'|)$ does not influence the resulting macroscopic equation anymore. This is due to the fact that only C_i and D_i depend on ψ (A_i, B_i do not), and $C_i = D_i = 0$ when ϕ is independent of v. This is to be expected from a biological point of view since reorientations without any bias cannot have a macroscopic effect.

In the following we will see how to evaluate A_i, B_{ij}, C_i, and D_i more specifically.

Example 5.3 (rigorous for $\alpha \geq 0$). Let

$$T_\epsilon[S] = \phi(S(x + \epsilon v, t), S(x - \epsilon v', t), \nabla S(x + \epsilon v, t), \nabla S(x - \epsilon v', t)), \tag{5.7}$$

where S satisfies chemo-attractant equation of elliptic type with $\beta > 0$ in two dimensions. Note that $\phi : \mathbb{R}^2 \times \mathbb{R}^2 \times \mathbb{R}^2 \to \mathbb{R}$ is an even function with respect to the variable ∇S, and increasing and decreasing for the first and second argument, respectively. Also assume the structure condition of Assumptions 2.1 and 3.2, i.e.,

$$|T_\epsilon[S](x, v, v', t)| \leq C(1 + S(x + \epsilon v, t) + S(x - \epsilon v', t) + |\nabla S(x + \epsilon v, t)| + |\nabla S(x - \epsilon v', t)|).$$

Using the asymptotic expansion of the turning kernel, i.e., $T_\epsilon[S] = T_0[S] + \epsilon T_1[S] + O(\epsilon^2)$, we can easily see that $T_0[S] = \phi(S(x,t), S(x,t), \nabla S(x,t), \nabla S(x,t))$, and

$$\begin{aligned} T_1[S] = {} & (\phi_1(S, S, \nabla S, \nabla S) v - \phi_2(S, S, \nabla S, \nabla S) v') \cdot \nabla S \\ & + \sum_{i=1}^{2} (\phi_{2+i}(S, S, \nabla S, \nabla S) v - \phi_{4+i}(S, S, \nabla S, \nabla S) v') \cdot \nabla S_{x_i}. \end{aligned}$$

Here ϕ_k, $k = 1, 2, \ldots, 6$, indicates differentiation of ϕ with respect to the kth argument. The symmetric $\phi_\epsilon^A[S]$ and antisymmetric part $\phi_\epsilon^S[S]$ of the turning kernel satisfy

$$\phi_\epsilon^S[S] \geq \gamma\big(1 - \epsilon\Lambda\big(\|\nabla S\|_{W^{1,\infty}(\mathbb{R}^n)}\big)\big)FF', \quad \int_V \frac{\phi_\epsilon^A[S]^2}{F\phi_\epsilon^S[S]}dv' \leq \epsilon^2\Lambda\left(\|\nabla S\|_{W^{1,\infty}(\mathbb{R}^n)}\right),$$

where $\gamma > 0$ and $\Lambda \in L^\infty_{\mathrm{loc}}$ is a nondecreasing function. By asymptotic expansion of f_ϵ and S_ϵ, the leading order equation becomes $f_0(x, v, t) = \rho_0(x, t)/|V|$. Here f_0 is independent of v. Since the ϵ-order equation is

$$\mathcal{T}_0[S_0](f_1) = -(v \cdot \nabla\rho_0)/|V| - \mathcal{T}_1[S_0](f_0),$$

we have to calculate

$$\mathcal{T}_1[S_0](f_0) = -\rho_0(\phi_1 + \phi_2)\nabla S_0 \cdot v - \sum_{i=1}^{2} \rho_0(\phi_{2+i} + \phi_{4+i})\nabla S_{0,x_i} \cdot v.$$

Therefore,

$$\mathcal{T}_0[S_0](f_1) = -\frac{v \cdot \nabla\rho_0}{|V|} + \rho_0(\phi_1 + \phi_2)\nabla S_0 \cdot v + \sum_{i=1}^{2} \rho_0(\phi_{2+i} + \phi_{4+i})\nabla S_{0,x_i} \cdot v,$$

due to the solvability condition, and thus we get

$$f_1 = -\frac{v \cdot \nabla\rho_0}{|V|^2\phi} + \frac{\rho_0(\phi_1 + \phi_2)\nabla S_0 \cdot v}{|V|\phi} + \frac{\rho_0(\phi_{2+i} + \phi_{4+i})\nabla S_{0,x_i} \cdot v}{|V|\phi}.$$

Let $\mu = \int_V |v|^2 dv$. Using the above results, we obtain the flux density $J_\epsilon = \int_V v f_1 dv + O(\epsilon)$, where

$$J_\epsilon = -\frac{\mu}{2|V|^2}\frac{\nabla\rho_0}{\phi} + \frac{\mu}{2|V|}\frac{(\phi_1 + \phi_2)\rho_0\nabla S_0}{\phi} + \sum_{i=0}^{2}\frac{\mu}{2|V|}\frac{(\phi_{2+i} + \phi_{4+i})\rho_0\nabla S_{0,x_i}}{\phi}.$$

Hence the diffusion limit is

$$\frac{\partial}{\partial t}\rho_0 = \nabla \cdot \left(D\nabla\rho_0 - \chi\rho_0\nabla S_0 - \sum_{i=1}^{2}\tilde{\chi}_i\rho_0\nabla S_{0,x_i}\right) \tag{5.8}$$

with

$$D = \frac{\mu}{2|V|^2\phi}, \quad \chi = \frac{\mu(\phi_1 + \phi_2)}{2|V|\phi}, \quad \tilde{\chi}_i = \frac{\mu(\phi_{2+i} + \phi_{4+i})}{2|V|\phi}, \quad i = 1, 2,$$

coupled to $-\Delta S_0 = \rho_0 - \beta S_0$. It is not known whether solutions for the macroscopic equation (5.8) blow up in finite time or not.

Example 5.4. If we choose an appropriate turning kernel, then the classical Keller–Segel model with constant coefficients can also be obtained. Indeed, if the turning kernel (5.7) is replaced by $T_\epsilon[s] = \phi(S(x,t), S(x+\epsilon v, t), \nabla S(x+\epsilon v, t), \nabla S(x-\epsilon v', t))$, then, by following similar computations to those given above, we have

$$\frac{\partial}{\partial t}\rho_0 = \nabla \cdot \left(\frac{\mu}{2|V|^2\phi}\nabla\rho_0 - \frac{\mu\phi_2}{2|V|\phi}\rho_0\nabla S_0 - \sum_{i=1}^{2}\frac{\mu(\phi_{2+i} + \phi_{4+i})}{2|V|\phi}\rho_0\nabla S_{0,x_i}\right). \tag{5.9}$$

Now let

$$\phi(x_1,x_2,x_3,x_4,x_5,x_6)=\varphi(x_2-x_1)+\varphi(x_5-x_3)+\varphi(x_6-x_4), \tag{5.10}$$

where $\varphi(x)=C_1\sqrt{1+x^2}+C_2x$, $C_1>C_2>0$.

Concerning the gradient terms, this example seems a bit artificial, but it shows how higher order terms might cancel out. Since $\varphi(0)=C_1$, $\varphi'(0)=C_2$, we have $\phi=C_1$, $\phi_2=C_2$, $\phi_3=\phi_4=-C_2$, and $\phi_5=\phi_6=C_2$. Therefore (5.9) leads to

$$\frac{\partial}{\partial t}\rho_0=\nabla\cdot\left(\frac{\mu}{2|V|^2C_1}\nabla\rho_0-\frac{\mu C_2}{2|V|C_1}\rho_0\nabla S_0\right),$$

which is the classical version of the Keller–Segel model. The diffusion coefficient and chemotactic sensitivity, respectively, are $D=\mu/(2|V|^2C_1)$, $\chi=(\mu C_2)/(2|V|C_1)$, which are both constants in this case.

Example 5.5 (rigorous, $\alpha\geq 0$, $\beta>0$). The next example considers time variations of the chemical S.

$$T_\epsilon=\sigma S(x+\epsilon v,t)+h(\partial_t S(x,t),\nabla S(x,t),v)+C_2, \tag{5.11}$$

where $\sigma\geq 0$ is a fixed constant and $h:\mathbb{R}\times\mathbb{R}^n\times\mathbb{R}^n\to\mathbb{R}$, $n=2,3$, is smooth and bounded, say $-C_1\leq h\leq C_1$ with $0<C_1<C_2$. Note that the turning kernel satisfies the structure condition in Assumption 3.2. Skipping the details of the calculations, *the macroscopic equation reads*

$$\begin{aligned}\partial_t\rho_0=\nabla\cdot\Bigg(&\frac{1}{\sigma S_0|V|+H[S_0]}\left[\nabla\left(\frac{\mu(\sigma S_0+C_2)}{\sigma S_0|V|+H[S_0]}\rho_0\right)+(A_{ij}[S_0]\rho_0)_{x_j}\right]\\&-\frac{\sigma\mu}{\sigma S_0|V|+H[S_0]}\rho_0\nabla S_0\Bigg).\end{aligned} \tag{5.12}$$

This equation is rigorously derived with related turning kernel (5.11) since it satisfies Assumption 4.2.

As a specific example, we consider the case

$$h(\partial_t S,\nabla S,v)=C_1\frac{\gamma\partial_t S+v\cdot\nabla S}{\mathcal{N}(S)},\quad \mathcal{N}(S)=\sqrt{1+\gamma^2|\partial_t S|^2+|\nabla S|^2},$$

where γ is a fixed constant. Then one can easily see

$$H[S_0]=\frac{C_1\gamma\partial_t S_0|V|}{\mathcal{N}(S_0)}+C_2|V|,\qquad A_{ij}[S_0]=\frac{C_1\mu\gamma\partial_t S_0}{(\sigma S_0|B_1|+H[S_0])\mathcal{N}(S_0)}.$$

Therefore, *the macroscopic equation* (5.12) can be explicitly calculated, namely, *for* $\gamma=0$ ($H[S_0]=C_2|V|$ and $A_{ij}[S_0]=0$),

$$\partial_t\rho_0=\nabla\cdot\left(\frac{\mu}{(\sigma S_0+C_2)|V|^2}\nabla\rho_0-\frac{\sigma\mu}{(\sigma S_0+C_2)|V|}\rho_0\nabla S_0\right). \tag{5.13}$$

On the other hand, if $\sigma=0$, then the last term in (5.12) vanishes and (5.12) reads

$$\partial_t\rho_0=\nabla\cdot\left(\frac{1}{H[S_0]}\nabla\left(\frac{\mu C_2}{H[S_0]}\rho_0\right)+(A_{ij}[S_0]\rho_0)_{x_j}\right),$$

where $A_{ij}[S_0] = \int_V v^i v^j h(\partial_t S, \nabla S, v)/H[S_0]dv$. In case h is odd with respect to v, then $A_{ij} = 0$ in (5.12).

In the next example we discuss the influence of nonlocal terms in h.

Example 5.6 (formal for $\alpha > 0$, rigorous for $\alpha = 0$). Consider $T_\epsilon = \sigma S(x + \epsilon v, t) + h(\partial_t S(x+\epsilon v, t), v\cdot\nabla S(x+\epsilon v, t)) + C_2$, where $h : \mathbb{R}\times\mathbb{R}\to\mathbb{R}$, $n = 2, 3$, is smooth and bounded, say $-C_1 \le h \le C_1$ with $0 < C_1 < C_2$. The structure condition in Assumption 3.2 is satisfied.

Again, skipping the detailed calculations, *the macroscopic equation reads*

$$\partial_t\rho_0 = -\nabla\cdot J_\epsilon = \nabla\cdot\left(\frac{1}{\sigma S_0|V| + H[S_0]}\left(\int_V v_i v_j \partial_{x_j} f_0 dv + K[S_0]\int_V v_i f_0 dv - \rho_0\int_V v_i T_1[S_0, v]dv\right)\right).$$

Next we consider a specific example of the turning kernel above. Let

$$h = h(\partial_t S(x+\epsilon v, t-\epsilon), v\cdot\nabla S(x+\epsilon v, t)) = \frac{C_1 v\cdot\nabla S(x+\epsilon v, t)}{\sqrt{1 + (v\cdot\nabla S(x+\epsilon v, t))^2}}.$$

Therefore, *the macroscopic equation reads*

$$\partial_t\rho_0 = \nabla\cdot\left(\frac{\mu}{(\sigma S_0 + C)|V|^2}\nabla\rho_0 - \frac{\sigma\mu}{(\sigma S_0 + C)|V|}\rho_0\nabla S_0 + \frac{L[S_0](L[S_0]\Delta S_0 - M[S_0]|\nabla S_0|^2\Delta S_0)}{(\sigma S_0 + C)^2|V|^2}\rho_0\nabla S_0\right),$$

where

$$L[S_0] = \frac{1}{n}\int_V \frac{|v|^2}{\sqrt{1 + (v\cdot\nabla S_0)^2}}dv, \qquad M[S_0] = \frac{1}{n^2}\int_V \frac{|v|^4}{(1 + (v\cdot\nabla S_0)^2)^{\frac{3}{2}}}dv. \tag{5.14}$$

The third term in the macroscopic equation is completely due to the nonlocal dependencies of h. Compare (5.13) for the local formulation.

Acknowledgment. We would like to thank B. Perthame for pointing out Remark 3.8 during his visit at MPI MIS in Leipzig.

GLOBAL EXISTENCE RESULT FOR PAIR DIFFUSION MODELS*

A. GLITZKY† AND R. HÜNLICH†

Abstract. In this paper we prove a global existence result for pair diffusion models in two dimensions. Such models describe the transport of charged particles in semiconductor heterostructures. The underlying model equations are continuity equations for mobile and immobile species coupled with a nonlinear Poisson equation. The continuity equations for the mobile species are nonlinear parabolic PDEs involving drift, diffusion, and reaction terms; the corresponding equations for the immobile species are ODEs containing reaction terms only. Forced by applications to semiconductor technology, these equations have to be considered with nonsmooth data and kinetic coefficients additionally depending on the state variables.

Our proof is based on regularizations, on a priori estimates which are obtained by estimates of the free energy and by Moser iteration, as well as on existence results for the regularized problems. These are obtained by applying the Banach fixed point theorem for the equations of the immobile species, and the Schauder fixed point theorem for the equations of the mobile species.

Key words. reaction-diffusion systems for charged particles, pair diffusion models, global existence, a priori estimates, fixed point theorems

1. The model.

Pair diffusion models describe the transport of charged particles (dopant atoms, point defects, dopant-defect pairs) in semiconductors [4, 7]. In [11] we treated a rather general model of this kind, which we continue to study in this paper. We consider m species X_i. The first $l \le m$ species are mobile, the other ones are immobile. The particle densities u_i of the ith species and some additional potential ψ are the primary unknown functions. They have to satisfy the following initial boundary value problem:

$$
\left\{
\begin{aligned}
&\frac{\partial u_i}{\partial t} + \nabla \cdot j_i + \sum_{(\alpha,\beta)\in\mathcal{R}^\Omega} (\alpha_i - \beta_i)\, R^\Omega_{\alpha\beta} = 0 && \text{on } (0,\infty)\times\Omega,\\
&\nu \cdot j_i - \sum_{(\alpha,\beta)\in\mathcal{R}^\Gamma} (\alpha_i - \beta_i)\, R^\Gamma_{\alpha\beta} = 0 && \text{on } (0,\infty)\times\Gamma,\\
& && i = 1,\dots,l;\\
&\frac{\partial u_i}{\partial t} + \sum_{(\alpha,\beta)\in\mathcal{R}^\Omega} (\alpha_i - \beta_i)\, R^\Omega_{\alpha\beta} = 0 && \text{on } (0,\infty)\times\Omega,\\
& && i = l+1,\dots,m;\\
&-\nabla\cdot(\varepsilon\nabla\psi) + e(\cdot,\psi) - \sum_{i=1}^{m} Q_i(\psi) u_i = f && \text{on } (0,\infty)\times\Omega,\\
&\nu\cdot(\varepsilon\nabla\psi) = 0 && \text{on } (0,\infty)\times\Gamma;\\
&u_i(0) = U_i && \text{on } \Omega,\ i = 1,\dots,m.
\end{aligned}
\right. \tag{1.1}
$$

Here Γ denotes the boundary of the domain $\Omega \subset \mathbb{R}^2$, and ν is the outer unit normal. For specifying the flux densities j_i and the reaction rates $R^{\Omega}_{\alpha\beta}$, $R^{\Gamma}_{\alpha\beta}$ we introduce other functions related to the primary ones, namely, the chemical activities b_i and electrochemical activities a_i,

$$b_i = \frac{u_i}{p_{0i}}, \quad a_i = b_i \mathrm{e}^{P_i(\psi)}, \qquad P_i(\psi) = \int_0^{\psi} Q_i(s)\mathrm{d}s, \quad i = 1, \dots, m, \tag{1.2}$$

where p_{0i} denotes a reference density, and Q_i is the charge number of the ith species which depends on ψ. Then the flux densities of the mobile species are given by

$$j_i = -D_i(\cdot, b, \psi)\, p_{0i} \left(\nabla b_i + Q_i(\psi)\, b_i \nabla \psi\right), \quad i = 1, \dots, l,$$

where D_i is the diffusivity which depends on the state variables $b = (b_1, \dots, b_m)$ and ψ. All m continuity equations contain volume source terms generated by mass action–type reactions of the form

$$\alpha_1 X_1 + \cdots + \alpha_m X_m \rightleftharpoons \beta_1 X_1 + \cdots + \beta_m X_m, \quad (\alpha, \beta) \in \mathcal{R}^{\Omega},$$

where $\alpha, \beta \in \mathbb{Z}^m_+$ are the vectors of stoichiometric coefficients, and $\mathcal{R}^{\Omega}$ describes the set of all reactions under consideration. The corresponding reaction rates are given by

$$R^{\Omega}_{\alpha\beta} = k^{\Omega}_{\alpha\beta}(x, b_1, \dots, b_m, \psi) \left[\prod_{i=1}^{m} a_i^{\alpha_i} - \prod_{i=1}^{m} a_i^{\beta_i}\right], \quad (\alpha, \beta) \in \mathcal{R}^{\Omega}.$$

The continuity equations for the mobile species include additional boundary source terms generated by boundary reactions with reaction rates given by

$$R^{\Gamma}_{\alpha\beta} = k^{\Gamma}_{\alpha\beta}(x, b_1, \dots, b_l, \psi) \left[\prod_{i=1}^{l} a_i^{\alpha_i} - \prod_{i=1}^{l} a_i^{\beta_i}\right], \quad (\alpha, \beta) \in \mathcal{R}^{\Gamma}.$$

Finally, the nonlinear Poisson equation contains various source terms, namely, the fixed charge density f, the charge density e depending on ψ, and the charge density $\sum_{i=1}^{m} Q_i u_i$ of all particles; ε is the dielectric permittivity.

In heterostructures, which we want to include in our considerations, the reference densities p_{0i} (and other quantities such as D_i, $k^{\Omega}_{\alpha\beta}$, $k^{\Gamma}_{\alpha\beta}$, ε, and e) depend on x, and they may jump when crossing interfaces between different materials. The densities u_i may jump, too, but for the chemical activities b_i of the mobile species and for the potential ψ one can assume that $b_1(t, \cdot), \dots, b_l(t, \cdot)$, $\psi(t, \cdot)$ belong to $H^1(\Omega)$. This regularity can be improved slightly. For example, one obtains that $\psi(t, \cdot)$ belongs to $W^{1,2+\delta}(\Omega)$ if ε is an arbitrary element of $L^{\infty}(\Omega)$ (see [14]), but $W^{2,p}$-regularity can not be expected in general.

It is the aim of the present paper to show that the initial boundary value problem (1.1) has a global solution in a sense which is precisely defined in section 2. In that section all needed assumptions are also listed, and they are motivated by considering the special model in [4, 7]. Here let us only observe that the charge numbers Q_i (see (2.8) for the special model) are monotonic decreasing functions of ψ. This property as well as the special structure of the kinetic relations and natural assumptions on the kinetic coefficients ensure that the evolution problem (see $(\mathcal{P})$ later on) as well as needed regularizations of this problem (see $(\mathcal{P}_N)$, $(\mathcal{P}_M)$ later on) have a convex

Lyapunov function, namely, the free energy. Section 3 contains the proof of the existence result and related assertions. Here we make use of some results derived in our earlier papers [11, 16]. There we did not prove any existence result, but we studied qualitative properties of (possible) solutions, especially the long-time behavior. We give a short summary of these properties in section 4 of the present paper.

Let us yet discuss some simplified models for which results are already known. At first we consider the case that each species has a constant charge number, $Q_i(\psi) = q_i = \text{const}$. Then we arrive at a model which we have studied in [13, 8, 9, 10]. There we assumed that all species are mobile, $l = m$, that the diffusivities do not depend on b, and that the initial values are strongly positive, $U_i \geq c > 0$. The continuity equations were reformulated by introducing the electrochemical potentials $\zeta_i = \ln a_i = \ln b_i + q_i\psi$ (defined for $a_i > 0$). Then the kinetic relations were obtained as

$$j_i = -D_i\, u_i\, \nabla\zeta_i,$$

$$R^\Omega_{\alpha\beta} = k^\Omega_{\alpha\beta}\left[\mathrm{e}^{\sum_{i=1}^m \alpha_i\zeta_i} - \mathrm{e}^{\sum_{i=1}^m \beta_i\zeta_i}\right], \quad R^\Gamma_{\alpha\beta} = k^\Gamma_{\alpha\beta}\left[\mathrm{e}^{\sum_{i=1}^l \alpha_i\zeta_i} - \mathrm{e}^{\sum_{i=1}^l \beta_i\zeta_i}\right].$$

We proved the global existence and uniqueness of a solution and studied its asymptotic behavior. The methods developed in the present paper allow us to handle this class of models also in the case that $l < m$, that $D_1, \dots, D_l$ may depend on b, and that only $U_i \geq 0$ is assumed.

At last we consider the case of a homogeneous material where no physical parameter explicitly depends on x. Especially $p_{0i} = \text{const} > 0$ holds, and for the mobile species $u_i(t,\cdot) \in H^1(\Omega)$ follows. Therefore the flux densities can be rewritten as

$$j_i = -D_i\,(\nabla u_i + Q_i(\psi)\, u_i \nabla\psi), \quad i = 1, \dots, l.$$

Under some additional assumptions (two-dimensional domain with smooth boundary, kinetic coefficients depend only on ψ) global existence and uniqueness results were proven in [21] (all species are mobile, $l = m$) and in [12] (some species can be immobile, $l \leq m$). There higher regularity of the solution was obtained. For example, $\psi(t,\cdot)$ belongs to $W^{2,p}(\Omega)$, $p \geq 2$. One may find in [1] a local existence result for the same simplified model, but in arbitrary space dimension. A special pair diffusion model for uncharged species (and without the Poisson equation) was studied in [15]. The case $l < m$ was treated by passing to the limit $D_i \to 0$, $i = l+1, \dots, m$. Several different asymptotic limits for variants of such a model are discussed in [17].

2. Notation, assumptions, and main result.

2.1. Notation. The notation of function spaces corresponds to that in [18]. By $\mathbb{Z}^k_+, \mathbb{R}^k_+, L^p_+, H^1_+$ we denote the cones of nonnegative elements. If $u \in \mathbb{R}^k$, then $u \geq 0$ ($u > 0$) means $u_i \geq 0\ \forall i$ ($u_i > 0\ \forall i$). $\sqrt{u}$ denotes the vector $\{\sqrt{u_i}\}_{i=1,\dots,k}$. For the scalar product in $\mathbb{R}^k$ we use a centered dot. If $u, v \in \mathbb{R}^k$, then $uv = \{u_i v_i\}_{i=1,\dots,k}$, and u/v is to be understood analogously. If $u \in \mathbb{R}^k_+$ and $\alpha \in \mathbb{Z}^k_+$, then u^α means the product $\prod_{i=1}^k u_i^{\alpha_i}$. In our estimates positive constants, which depend at most on the data of the problem, are denoted by c. Some auxiliary results which are relevant for the paper are collected in the appendix. Finally, we make use of the following.

DEFINITION 2.1. *Consider a function $f : (x,y) \in M \times E \to f(x,y) \in \mathbb{R}$, where E is a closed subset of $\mathbb{R}^k$. We say that $f(x,\cdot)$ is locally Lipschitz continuous uniformly with respect to (w.r.t.) x if $f(x,\cdot)$ is Lipschitz continuous on each compact set $K \subset E$ where the Lipschitz constant depends on K, but not on x.*

2.2. Assumptions. Let us summarize all needed assumptions, which we will apply throughout the rest of the paper:

$$\begin{cases} \Omega \subset \mathbb{R}^2 \text{ is a bounded Lipschitzian domain, } \Gamma = \partial\Omega, \\ m, l \in \mathbb{N},\ 1 \le l \le m,\ U \in L^\infty_+(\Omega, \mathbb{R}^m),\ f \in L^2(\Omega); \end{cases} \tag{2.1}$$

$$\begin{cases} \varepsilon \in L^\infty(\Omega),\ \operatorname{ess\,inf}_{x\in\Omega} \varepsilon(x) > 0, \\ e\colon \Omega \times \mathbb{R} \to \mathbb{R} \text{ satisfies the Carathéodory conditions,} \\ e(x,\cdot) \text{ is locally Lipschitz continuous uniformly w.r.t. } x, \\ |e(x,\psi)| \le c\, e^{c|\psi|} \text{ for a.a. } x \in \Omega,\ \forall \psi \in \mathbb{R} \text{ with some } c > 0, \\ e(x,\psi) - e(x,\overline{\psi}) \ge e_0(x)\,(\psi - \overline{\psi}) \text{ for a.a. } x \in \Omega,\ \forall \psi, \overline{\psi} \in \mathbb{R} \text{ with } \psi \ge \overline{\psi}, \\ \text{where } e_0 \in L^\infty_+(\Omega),\ \|e_0\|_{L^1} > 0; \end{cases} \tag{2.2}$$

$$\begin{cases} \text{for } i = 1, \dots, m\colon \\ p_{0i} \in L^\infty(\Omega),\ \operatorname{ess\,inf}_{x\in\Omega} p_{0i}(x) \ge \epsilon_0 > 0, \\ Q_i \in C^1(\mathbb{R}),\ |Q_i(\psi)| \le c,\ Q_i'(\psi) \le 0 \quad \forall \psi \in \mathbb{R}; \end{cases} \tag{2.3}$$

$$\begin{cases} \mathcal{R}^\Sigma \text{ is a finite subset of } \mathbb{Z}^{m_\Sigma}_+ \times \mathbb{Z}^{m_\Sigma}_+,\ \Sigma = \Omega, \Gamma,\ m_\Omega = m,\ m_\Gamma = l; \\ \text{for } \Sigma = \Omega, \Gamma,\ (\alpha,\beta) \in \mathcal{R}^\Sigma : \\ k^\Sigma_{\alpha\beta}\colon \Sigma \times \mathbb{R}^{m_\Sigma}_+ \times \mathbb{R} \to \mathbb{R}_+ \text{ satisfies the Carathéodory conditions,} \\ k^\Sigma_{\alpha\beta}(x,\cdot,\cdot) \text{ is locally Lipschitz continuous uniformly w.r.t. } x, \\ \forall R > 0 \text{ there exists a constant } c_R > 0 \text{ such that} \\ k^\Sigma_{\alpha\beta}(x,b,\psi) \le c_R \text{ for a.a. } x \in \Sigma,\ \forall b \in \mathbb{R}^{m_\Sigma}_+,\ \forall \psi \in [-R,R]; \end{cases} \tag{2.4}$$

$$\begin{cases} (\alpha_{l+1} + \dots + \alpha_m)\,(\beta_{l+1} + \dots + \beta_m) = 0 \quad \forall (\alpha,\beta) \in \mathcal{R}^\Omega, \\ \text{there exists a constant } c > 0 \text{ such that} \\ \max\limits_{k=1,\dots,m} \big\{(a^\alpha - a^\beta)(\beta_k - \alpha_k)\big\} \le c \sum\limits_{k=1}^{m} a_k^2 + c \quad \forall\, a \in \mathbb{R}^m_+,\ (\alpha,\beta) \in \mathcal{R}^\Omega, \\ \max\limits_{k=1,\dots,l} \big\{(a^\alpha - a^\beta)(\beta_k - \alpha_k)\big\} \le c \sum\limits_{k=1}^{l} a_k + c \quad \forall\, a \in \mathbb{R}^l_+,\ (\alpha,\beta) \in \mathcal{R}^\Gamma; \end{cases} \tag{2.5}$$

$$\begin{cases} \text{for } i = 1, \dots, l\colon \\ D_i\colon \Omega \times \mathbb{R}^m_+ \times \mathbb{R} \to \mathbb{R}_+ \text{ satisfies the Carathéodory conditions,} \\ D_i(x,b,\psi) \ge c > 0 \text{ for a.a. } x \in \Omega,\ \forall b \in \mathbb{R}^m_+,\ \forall \psi \in \mathbb{R}, \\ \forall R > 0 \text{ there exists a constant } c_R > 0 \text{ such that} \\ D_i(x,b,\psi) \le c_R \text{ for a.a. } x \in \Omega,\ \forall b \in \mathbb{R}^m_+,\ \forall \psi \in [-R,R]; \end{cases} \tag{2.6}$$

$$(2.7)\quad \begin{cases} \text{for } i = l+1,\dots,m\text{:} \\ \text{there is a reaction of the form} \\ R^{\Omega}_{\alpha_{(i)}\beta_{(i)}}(x,b,\psi) = k^{\Omega}_{\alpha_{(i)}\beta_{(i)}}(x,b,\psi)\left[\prod_{k=1}^{l} a_k^{\alpha_{(i)k}} - a_i^2\right], \\ \forall R>0 \text{ there exists a constant } c_R>0 \text{ such that} \\ k^{\Omega}_{\alpha_{(i)}\beta_{(i)}}(x,b,\psi) \ge c_R \text{ for a.a. } x\in\Omega,\ \forall b\in\mathbb{R}^m_+,\ \forall \psi\in[-R,R]. \end{cases}$$

2.3. Example. We would like to comment on our assumptions by considering the special pair diffusion model in [4, 7]. This example is concerned with the redistribution of a single dopant (phosphorus) in a homogeneous semiconductor (silicon). Here we have to deal with $m = 5$ species, namely, $X_1 = I$ (silicon interstitials), $X_2 = V$ (vacancies in the silicon lattice), $X_3 = PI$ (phosphorus–interstitial pairs), $X_4 = PV$ (phosphorus–vacancy pairs), and $X_5 = P$ (phosphorus atoms on lattice site). The only immobile species is X_5, and hence $l = 4$.

The charge density e (of electrons and holes, except for the sign) is given by $e(\psi) = e_1\mathrm{e}^{\psi} - e_2\mathrm{e}^{-\psi}$, $e_1, e_2 = \text{const} > 0$, and fulfills the properties required in (2.2). The reference densities p_{0i}, the charge numbers Q_i, and the diffusivities D_i (of the mobile species) are expressions of the form

$$(2.8)\quad p_{0i} = \sum_{k=1}^{k_i} K_{ik},\ Q_i(\psi) = \frac{\sum_{k=1}^{k_i} q_{ik}K_{ik}\mathrm{e}^{-q_{ik}\psi}}{\sum_{k=1}^{k_i} K_{ik}\mathrm{e}^{-q_{ik}\psi}},\ D_i(\psi) = \frac{\sum_{k=1}^{k_i} D_{ik}K_{ik}\mathrm{e}^{-q_{ik}\psi}}{\sum_{k=1}^{k_i} K_{ik}\mathrm{e}^{-q_{ik}\psi}},$$

where $k_i \ge 1$, $K_{ik}, D_{ik} = \text{const} > 0$, $q_{ik} = \text{const}$. Obviously, all properties required in (2.3) and (2.6) are fulfilled. Finally, volume reactions as described in Table 2.1 are considered. The set $\mathcal{R}^{\Omega}$ contains the corresponding (α,β)-pairs. The kinetic coefficients $k^{\Omega}_{\alpha\beta}$ are finite sums of the form

$$k^{\Omega}_{\alpha\beta}(\psi) = \sum_{\gamma} k_{\alpha\beta,\gamma}\mathrm{e}^{-q_{\alpha\beta,\gamma}\psi},\ k_{\alpha\beta,\gamma} = \text{const} > 0,\ q_{\alpha\beta,\gamma} = \text{const}$$

and satisfy the requirements in (2.4). All reactions fulfill the first condition in (2.5), namely, $\alpha_5\beta_5 = 0$. Moreover, all reactions are of second order and provide the first growth condition in (2.5). Reaction no. 6 in Table 2.1 is that which fulfills the assumptions in (2.7). Since here boundary reactions do not occur, we set $\mathcal{R}^{\Gamma} = \emptyset$, and the flux boundary conditions in (1.1) result in $\nu \cdot j_i = 0$, $i = 1,\dots,l$. Thus we see that our basic assumptions can be verified when considering this special model.

TABLE 2.1
Volume reactions, stoichiometric coefficients, and reaction rates.

No.	Reaction	α	β	Reaction rate $R^{\Omega}_{\alpha\beta}$
1	$I + P \rightleftharpoons PI$	$(1,0,0,0,1)$	$(0,0,1,0,0)$	$k^{\Omega}_{\alpha\beta}(\psi)\,(a_1a_5 - a_3)$
2	$V + P \rightleftharpoons PV$	$(0,1,0,0,1)$	$(0,0,0,1,0)$	$k^{\Omega}_{\alpha\beta}(\psi)\,(a_2a_5 - a_4)$
3	$I + V \rightleftharpoons 0$	$(1,1,0,0,0)$	$(0,0,0,0,0)$	$k^{\Omega}_{\alpha\beta}(\psi)\,(a_1a_2 - 1)$
4	$I + PV \rightleftharpoons P$	$(1,0,0,1,0)$	$(0,0,0,0,1)$	$k^{\Omega}_{\alpha\beta}(\psi)\,(a_1a_4 - a_5)$
5	$V + PI \rightleftharpoons P$	$(0,1,1,0,0)$	$(0,0,0,0,1)$	$k^{\Omega}_{\alpha\beta}(\psi)\,(a_2a_3 - a_5)$
6	$PI + PV \rightleftharpoons 2P$	$(0,0,1,1,0)$	$(0,0,0,0,2)$	$k^{\Omega}_{\alpha\beta}(\psi)\,(a_3a_4 - a_5^2)$

For various reasons we formulated our assumptions in somewhat more general forms. First, we want to take into account more immobile dopants and corresponding mobile dopant–defect pairs as well as dopant–dopant pairs, if necessary (see, e.g., [20]). Then the number of volume reactions increases. Second, we allow the appearance of boundary reactions of first order (see the second growth condition in (2.5)). Third, the kinetic coefficients D_i, $k^\Sigma_{\alpha\beta}$ should depend on the state variables u_i (or b_i), too. Fourth, we attach importance to the study of heterostructures where physical parameters explicitly depend on x, namely, discontinuously.

Finally, we give reasons for our assumption that the domain Ω should be two-dimensional. In the continuity equations appear quadratic drift terms and quadratic source terms coming from the reactions. We use Gröger's result concerning the $W^{1,2+\delta}$-regularity of the potential ψ, $\delta > 0$ small [14], and the two-dimensional version of the Gagliardo–Nirenberg inequality (5.3) to estimate the $L^\infty(\mathbb{R}_+, L^p(\Omega))$-norms of u_i (or b_i) for $p \geq 2$. In three dimensions the corresponding procedure does not work. Moreover, in two dimensions we can use Trudinger's imbedding result [25] to simplify the investigation of the nonlinear Poisson equation and of the free energy functional.

2.4. Formulation of the problem. We use the function spaces

$$Y = L^2(\Omega, \mathbb{R}^m), \quad X = \big\{b \in Y\colon b_i \in H^1(\Omega),\ i = 1, \dots, l\big\}$$

and define operators

$$B\colon Y \to Y,\ A, R\colon [X \cap L^\infty_+(\Omega, \mathbb{R}^m)] \times [H^1(\Omega) \cap L^\infty(\Omega)] \to X^*,\ E\colon H^1(\Omega) \times Y \to H^1(\Omega)^*$$

by the relations

$$(Bb, \overline{b})_Y = \int_\Omega \sum_{i=1}^m p_{0i}\, b_i\, \overline{b}_i \,\mathrm{d}x, \quad \overline{b} \in Y,$$

$$\langle A(b,\psi), \overline{b}\rangle_X = \int_\Omega \sum_{i=1}^l D_i(\cdot, b, \psi) p_{0i} (\nabla b_i + b_i Q_i(\psi) \nabla\psi) \cdot \nabla \overline{b}_i \,\mathrm{d}x, \quad \overline{b} \in X,$$

$$\begin{aligned}\langle R(b,\psi), \overline{b}\rangle_X = &\int_\Omega \sum_{(\alpha,\beta)\in\mathcal{R}^\Omega} R^\Omega_{\alpha\beta}(\cdot, b_1, \dots, b_m, \psi) \sum_{i=1}^m (\beta_i - \alpha_i)\, \overline{b}_i \,\mathrm{d}x \\ &+ \int_\Gamma \sum_{(\alpha,\beta)\in\mathcal{R}^\Gamma} R^\Gamma_{\alpha\beta}(\cdot, b_1, \dots, b_l, \psi) \sum_{i=1}^l (\beta_i - \alpha_i)\, \overline{b}_i \,\mathrm{d}\Gamma, \quad \overline{b} \in X,\end{aligned}$$

$$\langle E(\psi, u), \overline{\psi}\rangle_{H^1} = \int_\Omega \left\{ \varepsilon \nabla\psi \cdot \nabla\overline{\psi} + e(\cdot,\psi)\overline{\psi} - \sum_{i=1}^m u_i Q_i(\psi)\overline{\psi} - f\overline{\psi} \right\} \mathrm{d}x, \quad \overline{\psi} \in H^1(\Omega).$$

Let us recall that

$$R^\Sigma_{\alpha\beta}(x, b, \psi) = k^\Sigma_{\alpha\beta}(x, b, \psi)\,(a^\alpha - a^\beta),\ x \in \Sigma,\ b \in \mathbb{R}^{m_\Sigma}_+,\ \psi \in \mathbb{R},\ \Sigma = \Omega, \Gamma,$$

where a is related to b and ψ according to (1.2), $a_i = b_i \mathrm{e}^{P_i(\psi)}$, $i = 1, \dots, m_\Sigma$.

The precise formulation of the initial boundary value problem (1.1) reads as follows:

$$(\mathcal{P})\quad \begin{cases} u'(t) + A(b(t),\psi(t)) = R(b(t),\psi(t)), \\ E(\psi(t),u(t)) = 0,\ u(t) = Bb(t) \text{ for a.a. } t>0,\ u(0)=U, \\ u \in H^1_{\mathrm{loc}}(\mathbb{R}_+, X^*) \cap L^2_{\mathrm{loc}}(\mathbb{R}_+, Y),\ b \in L^2_{\mathrm{loc}}(\mathbb{R}_+, X) \cap L^\infty_{\mathrm{loc}}(\mathbb{R}_+, L^\infty_+(\Omega,\mathbb{R}^m)), \\ \psi \in L^2_{\mathrm{loc}}(\mathbb{R}_+, H^1(\Omega)) \cap L^\infty_{\mathrm{loc}}(\mathbb{R}_+, L^\infty(\Omega)). \end{cases}$$

Remark 2.2. Let (u,b,ψ) be a solution of $(\mathcal{P})$. Lemma 5.1(ii), (iii) ensure that $u, b \in C(\mathbb{R}_+, Y)$. Furthermore one easily obtains that $u, b \in C(\mathbb{R}_+, (L^\infty(\Omega,\mathbb{R}^m), w^*))$, and $\psi \in C(\mathbb{R}_+, H^1(\Omega))$; see Lemma 3.1, too. These properties imply that the relations

$$\begin{aligned} E(\psi(t),u(t)) &= 0 \quad \text{in } H^1(\Omega)^*, \\ u(t) = p_0\, b(t) \text{ in } L^\infty(\Omega,\mathbb{R}^m), &\quad u(t),\ b(t) \ge 0 \text{ a.e. on } \Omega \end{aligned} \tag{2.9}$$

are fulfilled not only for a.a. $t \in \mathbb{R}_+$, but also $\forall t \in \mathbb{R}_+$.

2.5. Main result. Now we formulate the main result of the paper.

THEOREM 2.3. *There exists a solution of* $(\mathcal{P})$.

Further qualitative properties of the evolution problem $(\mathcal{P})$ are summarized in section 4.

3. Proofs.

3.1. The nonlinear Poisson equation. We start with some results concerning the Poisson equation which we need in what follows.

LEMMA 3.1. *For any $u \in Y$ there exists a unique solution $\psi \in H^1(\Omega)$ of the equation $E(\psi,u^+)=0$. Moreover, there is an exponent $q>2$, a positive constant c, and a monotonously increasing function $d\colon \mathbb{R}_+ \to \mathbb{R}_+$ such that*

$$\|\psi - \overline{\psi}\|_{H^1} \le c\,\|u-\overline{u}\|_Y \quad \forall u,\overline{u} \in Y,\ E(\psi,u^+) = E(\overline{\psi},\overline{u}^+) = 0, \tag{3.1}$$

$$\|\psi\|_{L^\infty} \le c\left\{1 + \sum_{i=1}^m \|u_i^+ \ln u_i^+\|_{L^1} + d(\|\psi\|_{H^1})\right\} \quad \forall u \in Y,\ E(\psi,u^+)=0, \tag{3.2}$$

$$\|\psi\|_{W^{1,q}} \le c\left\{1 + \sum_{i=1}^m \|u_i\|_{L^{2q/(2+q)}} + d(\|\psi\|_{H^1})\right\} \quad \forall u \in Y,\ E(\psi,u^+)=0, \tag{3.3}$$

$$\|\psi\|_{H^1} \le c(1+\|u\|_Y) \quad \forall u \in Y,\ E(\psi,u^+)=0. \tag{3.4}$$

Finally, let $S=[0,T]$, $T>0$. Then for every $u \in L^2(S,Y)$ there exists a unique $\psi \in L^2(S,H^1(\Omega))$ such that

$$E(\psi(t),u^+(t)) = 0 \text{ for a.a. } t \in S.$$

If $u \in C(S,Y)$, then $\psi \in C(S,H^1(\Omega))$ follows and the last equation holds $\forall t \in S$.

Proof. For the first existence result and the estimates (3.1), (3.2) we refer to [16, Lemma 1]. The estimate (3.3) is a consequence of Gröger's regularity result for elliptic equations [14, Theorem 1] and of Trudinger's imbedding theorem [25]. Moreover, let ψ_0 be the (unique) solution of $E(\psi_0,0)=0$. According to (3.1) we have $\|\psi-\psi_0\|_{H^1} \le c\|u\|_Y$ if $u \in Y$ and $E(\psi,u^+)=0$. Thus (3.4) follows. The last assertions result from the pointwise existence result and (3.1). ∎

3.2. First regularized problem ($\mathcal{P}_N$). In order to prove Theorem 2.3 we shall consider two regularized problems which are defined on an arbitrary given interval $S = [0,T]$. First we introduce a problem $(\mathcal{P}_N)$ as follows. Let $N \in \mathbb{R}$, $N > 0$, be given and let $\rho_N\colon \mathbb{R}^{m+1} \to [0,1]$ be a Lipschitz continuous function with

$$\rho_N(y) = \begin{cases} 0 & \text{if} \quad |y|_\infty \geq N, \\ 1 & \text{if} \quad |y|_\infty \leq N/2, \end{cases} \qquad |y|_\infty = \max\{|y_1|, \dots, |y_{m+1}|\}.$$

We define the functions $r_i^\Sigma\colon \Sigma \times \mathbb{R}_+^{m_\Sigma} \times \mathbb{R} \to \mathbb{R}$, $i = 1, \dots, m_\Sigma$, $\Sigma = \Omega, \Gamma$, by

$$r_i^\Omega(x,b,\psi) = \rho_N(b,\psi) \sum_{(\alpha,\,\beta)\in\mathcal{R}^\Omega} R_{\alpha\beta}^\Omega(x,b,\psi)(\beta_i - \alpha_i),$$

$$r_i^\Gamma(x,b_1,\dots,b_l,\psi) = \rho_N(b_1,\dots,b_l,0,\dots,0,\psi) \sum_{(\alpha,\,\beta)\in\mathcal{R}^\Gamma} R_{\alpha\beta}^\Gamma(x,b_1,\dots,b_l,\psi)(\beta_i - \alpha_i).$$

These functions satisfy the Carathéodory conditions, and the functions $r_i^\Sigma(x,\cdot,\cdot)$ are Lipschitz continuous uniformly w.r.t. x since $R_{\alpha\beta}^\Sigma(x,\cdot,\cdot)$ are locally Lipschitz continuous uniformly w.r.t. x and ρ_N is a Lipschitz continuous function with compact support. Further important properties of these functions are

$$|r_i^\Sigma(x,b,\psi)| \leq c(N) \quad \text{for a.a. } x \in \Sigma,\ \forall (b,\psi) \in \mathbb{R}_+^{m_\Sigma} \times \mathbb{R},\ i = 1, \dots, m_\Sigma, \tag{3.5}$$

$$\sum_{i=1}^{m_\Sigma} r_i^\Sigma(x,b,\psi)\ (\ln b_i + P_i(\psi)) \leq 0 \quad \text{for a.a. } x \in \Sigma,\ \forall (b,\psi) \in \mathbb{R}_+^{m_\Sigma} \times \mathbb{R},\ b > 0. \tag{3.6}$$

We define the operator $R_N\colon X_+ \times H^1(\Omega) \to X^*$ by

$$\begin{aligned} \langle R_N(b,\psi), \overline{b}\rangle_X = &\int_\Omega \sum_{i=1}^m r_i^\Omega(\cdot, b_1, \dots, b_m, \psi)\, \overline{b}_i \,\mathrm{d}x \\ &+ \int_\Gamma \sum_{i=1}^l r_i^\Gamma(\cdot, b_1, \dots, b_l, \psi)\, \overline{b}_i \,\mathrm{d}\Gamma,\ \overline{b} \in X. \end{aligned}$$

Now our first regularized problem is formulated as follows:

$$(\mathcal{P}_N) \qquad \begin{cases} u'(t) + A(b(t),\psi(t)) = R_N(b(t),\psi(t)), \\ E(\psi(t),u(t)) = 0,\ u(t) = Bb(t) \quad \text{for a.a. } t \in S,\ u(0) = U, \\ u \in H^1(S,X^*) \cap L^2(S,Y),\ b \in L^2(S,X) \cap L^\infty(S, L_+^\infty(\Omega,\mathbb{R}^m)), \\ \psi \in L^2(S,H^1(\Omega)) \cap L^\infty(S, L^\infty(\Omega)). \end{cases}$$

3.3. Energy estimates for solutions of ($\mathcal{P}_N$). We summarize some results which can be obtained as in [11, 16]. Let $\widetilde{F}_1, \widetilde{F}_2 : Y \to \overline{\mathbb{R}}$ be given by

$$\widetilde{F}_1(u) = \int_\Omega \left\{ \frac{\varepsilon}{2}|\nabla\psi|^2 + g(\cdot,\psi) - \sum_{i=1}^m u_i h_i(\psi) \right\} \mathrm{d}x, \quad u \in Y_+, \tag{3.7}$$

where the functions g, h_i are defined by

$$g(x,\psi) = e(x,\psi)\psi - \int_0^\psi e(x,z)\,\mathrm{d}z, \quad x \in \Omega,\ \psi \in \mathbb{R},$$
$$h_i(\psi) = Q_i(\psi)\psi - \int_0^\psi Q_i(z)\,\mathrm{d}z = P_i'(\psi)\psi - P_i(\psi),\ \psi \in \mathbb{R}, \quad i = 1,\dots,m,$$

and $\psi \in H^1(\Omega) \cap L^\infty(\Omega)$ is the unique solution of the Poisson equation $E(\psi, u) = 0$,

$$\widetilde{F}_2(u) = \int_\Omega \sum_{i=1}^m \left\{ u_i \left[\ln \frac{u_i}{p_{0i}} - 1 \right] + p_{0i} \right\} \mathrm{d}x, \quad u \in Y_+, \tag{3.8}$$

$$\widetilde{F}_1(u) = +\infty, \quad \widetilde{F}_2(u) = +\infty, \quad u \in Y \setminus Y_+.$$

Finally, we define the functionals

$$F_k = (\widetilde{F}_k^*|_X)^* : X^* \to \overline{\mathbb{R}},\ k = 1,2,\ F = F_1 + F_2 : X^* \to \overline{\mathbb{R}}. \tag{3.9}$$

The value $F(u)$ represents the free energy of the state $u \in X^*$.

LEMMA 3.2. *The functional $F = F_1 + F_2 : X^* \to \overline{\mathbb{R}}$ is proper, convex, and lower semicontinuous. For $u \in Y_+$ it can be evaluated according to* (3.7), (3.8).

For the proof see [11, Lemma 3.2]. Next, we introduce the functional $D : M_D \to \mathbb{R}$ by the formula

$$D(u) = 4 \int_\Omega \sum_{i=1}^l D_i(\cdot, b, \psi) p_i(\cdot, \psi) |\nabla \sqrt{a_i}|^2 \,\mathrm{d}x,\ u \in M_D, \tag{3.10}$$

$$M_D = \Big\{ u \in L^\infty_+(\Omega, \mathbb{R}^m) : \sqrt{a} \in X, \text{ where } a = u/p(\cdot,\psi) \text{ and } E(\psi, u) = 0 \Big\}, \tag{3.11}$$

where $p_i(\cdot,\psi) = p_{0i}\,\mathrm{e}^{-P_i(\psi)}$, $i = 1,\dots,m$. The functional D is a nonnegative lower estimate for the dissipation rate of problem $(\mathcal{P}_N)$ (and also of problem $(\mathcal{P})$; see (4.3)), where the contributions arising from the reactions have been omitted in view of (3.6). Following the ideas in [16, section 5]) and [11] (see also the similar proof of Lemma 3.15) we obtain the following.

LEMMA 3.3. *Along any solution (u, b, ψ) of $(\mathcal{P}_N)$ the free energy $F(u)$ remains bounded from above and decreases monotonously; more precisely,*

$$F(u(t_2)) + \int_{t_1}^{t_2} D(u(t))\,\mathrm{d}t \le F(u(t_1)) \le F(U), \quad 0 \le t_1 \le t_2 \le T, \tag{3.12}$$

holds. Moreover, there exist constants $c, c_{3.13} > 0$ depending only on the data but not on N and T such that

$$\begin{aligned} &\sum_{i=1}^m \|u_i \ln u_i\|_{L^\infty(S,L^1(\Omega))} \le c, \quad \|u\|_{L^\infty(S,L^1(\Omega,\mathbb{R}^m))} \le c, \\ &\|\psi\|_{L^\infty(S,H^1(\Omega))} \le c, \quad \|\psi\|_{L^\infty(S,L^\infty(\Omega))}, \quad \|\psi\|_{L^\infty(S,L^\infty(\Gamma))} \le c_{3.13} \end{aligned} \tag{3.13}$$

for any solution of $(\mathcal{P}_N)$.

Remark 3.4. Note that the last two estimates of Lemma 3.3 together with the assumptions (2.4), (2.6), (2.7) ensure the existence of constants $c, \tilde{\epsilon}, \epsilon > 0$ such that

$$k^{\Sigma}_{\alpha\beta}(\cdot, b_1, \dots, b_{m_\Sigma}, \psi) \le c \text{ a.e. in } S \times \Sigma,\ (\alpha, \beta) \in \mathcal{R}^{\Sigma},\ \Sigma = \Omega, \Gamma,$$
$$\tilde{\epsilon} \le 2k^{\Omega}_{\alpha_{(i)}\beta_{(i)}}(\cdot, b, \psi)\, \mathrm{e}^{P_i(\psi)} \text{ a.e. in } S \times \Omega,\ i = l+1, \dots, m,$$
$$\epsilon \le D_i(\cdot, b, \psi) p_{0i} \le c \text{ a.e. in } S \times \Omega,\ i = 1, \dots, l,$$

for any solution (u, b, ψ) of $(\mathcal{P}_N)$.

3.4. Further a priori estimates for solutions of $(\mathcal{P}_N)$. The constants in the estimates of this subsection will depend on T. Therefore it is not possible to use these results to obtain global (w.r.t. time) bounds for solutions of $(\mathcal{P})$. Such global bounds are derived in [11] by a modified method.

LEMMA 3.5. *There is a constant $c_{3.14} > 0$ not depending on N such that*

$$\|b_i(t)\|_{L^2} \le c_{3.14} \quad \forall t \in S, \quad i = 1, \dots, m, \tag{3.14}$$

for any solution (u, b, ψ) of $(\mathcal{P}_N)$.

Proof. Let (u, b, ψ) be a solution of $(\mathcal{P}_N)$.

1. Choosing q as in Lemma 3.1 we obtain by Lemmas 3.1 and 3.3 that

$$\|\psi(t)\|_{W^{1,q}} \le c \left(1 + \sum_{i=1}^{m} \|b_i(t)\|_{L^{2q/(2+q)}}\right) \text{ for a.a. } t \in S. \tag{3.15}$$

2. We take into account the assumptions (2.5) and (2.7) concerning the order of the source terms of the reactions and the presence of reactions with quadratic sink terms for the immobile species, respectively. Since $\|\psi\|_{L^\infty(S, L^\infty(\Sigma))} \le c_{3.13}$, $\Sigma = \Omega, \Gamma$, and $|\rho_N(b, \psi)| \le 1$ we find that

$$\int_\Omega \sum_{i=1}^{m} r_i^{\Omega}(\cdot, b, \psi)\, b_i \,\mathrm{d}x$$
$$\le \int_\Omega \rho_N(b, \psi) \sum_{k=l+1}^{m} \left\{ c \sum_{i=1}^{l} (b_i^3 + b_i^2 b_k + b_i b_k^2 + b_k^2 + 1) - \tilde{\epsilon}\, b_k^3 \right\} \mathrm{d}x \le c \sum_{i=1}^{l} \|b_i\|_{L^3}^3 + c,$$
$$\int_\Gamma \sum_{i=1}^{l} r_i^{\Gamma}(\cdot, b_1, \dots, b_l, \psi)\, b_i \,\mathrm{d}\Gamma \le c \sum_{i=1}^{l} \|b_i\|_{L^2(\Gamma)}^2 + c.$$

3. Testing the evolution equation in $(\mathcal{P}_N)$ with $2b$, and using the estimates from step 2 as well as (5.1), (5.3), and Young's inequality, we obtain

$$\sum_{i=1}^{m} \left(\epsilon_0 \|b_i(t)\|_{L^2}^2 - c\|U_i\|_{L^2}^2\right)$$
$$\le \int_0^t \sum_{i=1}^{l} \left\{ -2\epsilon \|b_i\|_{H^1}^2 + c(\|b_i\|_{L^r} \|\psi\|_{W^{1,q}} \|b_i\|_{H^1} + \|b_i\|_{L^3}^3 + \|b_i\|_{L^2(\Gamma)}^2 + 1) \right\} \mathrm{d}s$$
$$\le \int_0^t \sum_{i=1}^{l} \left\{ -\epsilon \|b_i\|_{H^1}^2 + \bar{c}(\|b_i\|_{L^r} \|\psi\|_{W^{1,q}} \|b_i\|_{H^1} + \|b_i\|_{L^2}^4 + 1) \right\} \mathrm{d}s \quad \forall t \in S,$$

where $r = 2q/(q-2)$. Using the estimate $\|b_k\|_{L^{2q/(2+q)}} \le \|b_k\|_{L^1}^{(r-2)/r} \|b_k\|_{L^2}^{2/r}$ as well as Lemma 3.3 and (3.15), (5.3) we calculate

$$\overline{c}\|b_i\|_{L^r}\|\psi\|_{W^{1,q}}\|u_i\|_{H^1} \le c\|b_i\|_{L^2}^{2/r}\left(1+\sum_{k=1}^m \|b_k\|_{L^2}^{2/r}\right)\|b_i\|_{H^1}^{2(r-1)/r}$$
$$\le \epsilon\|b_i\|_{H^1}^2 + c\|b_i\|_{L^2}^2\sum_{k=1}^m \|b_k\|_{L^2}^2 + c.$$

Therefore we can continue the first estimate in step 3 as

$$\sum_{k=1}^m \|b_k(t)\|_{L^2}^2 \le c\int_0^t \sum_{k=1}^m\sum_{i=1}^l \|b_i\|_{L^2}^2\|b_k\|_{L^2}^2\,\mathrm{d}s + c \quad \forall t\in S.$$

Let i, $1\le i\le l$, be fixed. By Lemma 3.3 and (3.10) we find that

$$\|\nabla\sqrt{a_i}\|_{L^2(S,L^2)} \le c,\ \|u_i\|_{L^\infty(S,L^1)} \le c,\ \|\psi\|_{L^\infty(S,L^\infty)} \le c$$

and $\|\sqrt{a_i}\|_{L^2(S,H^1)} \le c$, $\|\sqrt{a_i}\|_{L^\infty(S,L^2)} \le c$. Thus interpolation yields $\|\sqrt{a_i}\|_{L^4(S,L^4)} \le c$ and $\|b_i\|_{L^2(S,L^2)} \le c$. A special form of Gronwall's lemma (see [26, pp. 14, 15]) leads to the desired result. □

Again, let q be chosen as in Lemma 3.1. Since $2q/(2+q) < 2$ we obtain from (3.14), (3.15) the estimate $\|\psi\|_{L^\infty(S,W^{1,q})} \le c_q$. We define

$$\kappa = c_q^{2r} + 1, \text{ where } r = 2q/(q-2),\ q \text{ is as in Lemma 3.1.} \tag{3.16}$$

LEMMA 3.6. *There is a constant $c_{3.17} \ge 1$ not depending on N such that*

$$\|b_i(t)\|_{L^4} \le c_{3.17} \quad \forall t\in S,\ i=1,\dots,m, \tag{3.17}$$

for any solution (u,b,ψ) of $(\mathcal{P}_N)$.

Proof. Let (u,b,ψ) be a solution of $(\mathcal{P}_N)$. We use the test function $4(b_1^3,\dots,b_m^3)$. Using an argument similar to that in step 2 of the proof of Lemma 3.5, we find that

$$\int_\Omega \sum_{i=1}^m r_i^\Omega(\cdot,b,\psi)\,b_i^3\,\mathrm{d}x$$
$$\le \int_\Omega \rho_N(b,\psi)\sum_{k=l+1}^m \Big\{ c\sum_{i=1}^l \big((b_i^2+1)b_k^3 + (b_k^2+1)b_i^3 + b_i^5\big) - \tilde{\epsilon}b_k^5\Big\}\mathrm{d}x \le c\sum_{i=1}^l \|b_i\|_{L^5}^5 + c,$$
$$\int_\Gamma \sum_{i=1}^l r_i^\Gamma(\cdot,b_1,\dots,b_l,\psi)\,b_i^3\,\mathrm{d}\Gamma \le c\sum_{i=1}^l \|b_i\|_{L^4(\Gamma)}^4 + c.$$

Therefore we obtain $\forall t\in S$

$$\sum_{i=1}^m \big(\epsilon_0\|b_i(t)\|_{L^4}^4 - c\|U_i\|_{L^4}^4\big)$$
$$\le \int_0^t \sum_{i=1}^l \big\{ -2\epsilon\|b_i^2\|_{H^1}^2 + c(\|\nabla\psi\|_{L^q}\|\nabla(b_i^2)\|_{L^2}\|b_i^2\|_{L^r} + \|b_i\|_{L^5}^5 + \|b_i\|_{L^4(\Gamma)}^4 + 1)\big\}\,\mathrm{d}s.$$

We apply the trace inequality (5.1), Gagliardo–Nirenberg's inequality (5.3), (3.16), and Young's inequality,

$$\epsilon_0 \sum_{i=1}^{m} \|b_i(t)\|_{L^4}^4 \le \int_0^t \sum_{i=1}^{l} \Big\{ -\frac{\epsilon}{2} \|b_i^2\|_{H^1}^2 + c(\|\psi\|_{W^{1,q}} \|b_i^2\|_{L^1}^{1/r} \|b_i^2\|_{H^1}^{2-1/r} + \|b_i^2\|_{L^1} \|b_i^2\|_{H^1}^{3/2} + \|b_i^2\|_{L^1}^{1/2} \|b_i^2\|_{H^1}^{3/2} + 1) \Big\} \, \mathrm{d}s + c$$
$$\le c \int_0^t \sum_{i=1}^{l} \left(\kappa \|b_i^2\|_{L^1}^2 + \|b_i^2\|_{L^1}^4 + \|b_i^2\|_{L^1}^2 + 1 \right) \mathrm{d}s + c \quad \forall t \in S,$$

and the assertion follows from Lemma 3.5. □

THEOREM 3.7. *There exists a constant $c_{3.18} > 0$ not depending on N such that*

$$\begin{aligned} &\|b_i(t)\|_{L^\infty} \le c_{3.18} \quad \forall t \in S, \quad i = 1, \dots, m, \\ &\|b_i\|_{L^\infty(S, L^\infty(\Gamma))} \le c_{3.18}, \quad i = 1, \dots, l, \end{aligned} \tag{3.18}$$

for any solution (u, b, ψ) of $(\mathcal{P}_N)$.

Proof. The proof will be done in two steps. First, by Moser iteration we establish global upper bounds for the mobile species. Then, using these bounds we derive global upper bounds for the immobile species. Let (u, b, ψ) be a solution of $(\mathcal{P}_N)$. Let $K = \max\{1, \max_{i=1,\dots,m} \|U_i/p_{0i}\|_{L^\infty}\}$ and define $z_i = (b_i - K)^+$, $i = 1, \dots, m$.

1. *Bounds for the mobile species.* Let $p \ge 8$. We use $p(z_1^{p-1}, \dots, z_l^{p-1}, 0, \dots, 0)$ as the test function and define $w_i = z_i^{p/2}$, $i = 1, \dots, l$. At first let us remark that

$$\sum_{i=1}^{l} r_i^\Omega(\cdot, b, \psi) \, z_i^{p-1} \le c \sum_{i=1}^{l} \sum_{k=1}^{m} (b_k^2 + 1) z_i^{p-1} \le c \sum_{i=1}^{l} \left(z_i^{p+1} + \sum_{k=l+1}^{m} z_i^{p-1} z_k^2 \right) + c.$$

With Lemma 3.6 and Hölder's inequality we can estimate

$$\int_\Omega z_i^{p-1} z_k^2 \, \mathrm{d}x \le \|z_i\|_{L^{2(p-1)}}^{p-1} \|z_k\|_{L^4}^2 \le c_{3.17}^2 \|w_i\|_{L^{4(p-1)/p}}^{2(p-1)/p}.$$

Therefore we obtain $\forall t \in S$

$$\epsilon_0 \sum_{i=1}^{l} \|w_i(t)\|_{L^2}^2 \le \int_0^t \sum_{i=1}^{l} \{ -2\epsilon \|w_i\|_{H^1}^2 + cp(\|\nabla\psi\|_{L^q} \|\nabla w_i\|_{L^2} (\|w_i\|_{L^r} + 1) + \|w_i\|_{L^{2(p+1)/p}}^{2(p+1)/p} + c_{3.17}^2 \|w_i\|_{L^{4(p-1)/p}}^{2(p-1)/p} + \|w_i\|_{L^2(\Gamma)}^2 + 1) \} \, \mathrm{d}s.$$

We apply for $k = 1$ and $\widetilde{p} = r$, $\widetilde{p} = 2(p+1)/p$, and $\widetilde{p} = 4(p-1)/p$, respectively, Gagliardo–Nirenberg's inequality (5.3) and continue:

$$\begin{aligned} &\epsilon_0 \sum_{i=1}^{l} \|w_i(t)\|_{L^2}^2 \\ &\le \int_0^t \sum_{i=1}^{l} \{ -\epsilon \|w_i\|_{H^1}^2 + cp^{2r} (\|\psi\|_{W^{1,q}}^{2r} + 1)(\|w_i\|_{L^1}^2 + 1) + cp(\|w_i\|_{H^1}^{(p+2)/p} \|w_i\|_{L^1} \\ &\qquad + c_{3.17}^2 \|w_i\|_{H^1}^{(3p-4)/2p} \|w_i\|_{L^1}^{1/2} + \|w_i\|_{H^1}^{3/2} \|w_i\|_{L^1}^{1/2} + 1) \} \mathrm{d}s \\ &\le \int_0^t \sum_{i=1}^{l} c \{ p^{2r} \kappa (\|w_i\|_{L^1}^2 + 1) + p^4 \|w_i\|_{L^1}^{2p/(p-2)} + p^4 c_{3.17}^8 \|w_i\|_{L^1}^{2p/(p+4)} + p^4 \|w_i\|_{L^1}^2 \} \mathrm{d}s \\ &\le cp^{2r} (\kappa + c_{3.17}^8) \int_0^t \sum_{i=1}^{l} \left(\|w_i\|_{L^1}^{2p/(p-2)} + 1 \right) \mathrm{d}s \\ &\le cp^{2r} \left(\kappa + c_{3.17}^8 \right) T \sum_{i=1}^{l} \left(\sup_{s \in S} \|z_i(s)\|_{L^{p/2}}^{p^2/(p-2)} + 1 \right). \end{aligned}$$

Therefore the iteration formula

$$\sum_{i=1}^{l} \|z_i(t)\|_{L^p}^p + 1 \le \overline{c}\, p^{2r} \left(\kappa + c_{3.17}^8\right)\, T \left(\sum_{i=1}^{l} \sup_{s\in S} \|z_i(s)\|_{L^{p/2}}^{p/2} + 1 \right)^{2p/(p-2)} \qquad \forall t \in S$$

results, where $\overline{c} > 1$ depends only on the data, and $\kappa, r, c_{3.17}$ are defined in (3.16) and Lemma 3.6. Now we set $p = 2^k$, $k \in \mathbb{N}$, $k \ge 3$. The iteration formula yields

$$\gamma_k \le \left(2^{4r} \left(\kappa + c_{3.17}^8\right)\, T\, \overline{c}\, \gamma_2\right)^{c_0 2^k}, \quad \gamma_k = \sum_{i=1}^{l} \sup_{s\in S} \|z_i(s)\|_{L^{2^k}}^{2^k} + 1, \quad c_0 = \prod_{j=1}^{\infty} \frac{2^j}{2^j - 1}.$$

Passing to the limit $k \to \infty$ we obtain

$$\sum_{i=1}^{l} \|z_i(t)\|_{L^\infty} \le \sqrt{l} \left(2^{4r} \left(\kappa + c_{3.17}^8\right)\, T\, \overline{c} \left(\sum_{i=1}^{l} \sup_{s\in S} \|z_i(s)\|_{L^4}^4 + 1 \right) \right)^{c_0} \qquad \forall t \in S.$$

With Lemma 3.6 and (5.2) the desired estimates for b_i, $i = 1, \dots, l$, are verified.

2. *Bounds for the immobile species.* Now, let $p \ge 2$. We use the test function $p(0, \dots, 0, z_{l+1}^{p-1}, \dots, z_m^{p-1})$. Taking into account the assumptions (2.7), (2.5), the estimates for b_i, $i = 1, \dots, l$, obtained in step 1, as well as the inequalities $b_k \ge z_k \ge 0$ we find that

$$\begin{aligned} \sum_{k=l+1}^{m} r_k^\Omega(\cdot, b, \psi)\, z_k^{p-1} &\le c \sum_{i=1}^{l} \sum_{k=l+1}^{m} (b_i^2 + b_i + 1) z_k^{p-1} - \tilde{\epsilon} \sum_{k=l+1}^{m} z_k^{p+1} \\ &\le \tilde{c} \sum_{k=l+1}^{m} z_k^{p-1} - \tilde{\epsilon} \sum_{k=l+1}^{m} z_k^{p+1} \le (m-l) \frac{\tilde{c}^{(p+1)/2}}{\tilde{\epsilon}^{(p-1)/2}}. \end{aligned}$$

The last estimate follows from Young's inequality. Therefore we obtain

$$\epsilon_0 \sum_{k=l+1}^{m} \|z_k(t)\|_{L^p}^p \le pT|\Omega|(m-l)\, \frac{\tilde{c}^{(p+1)/2}}{\tilde{\epsilon}^{(p-1)/2}} \quad \forall t \in S.$$

And consequently,

$$\|z_k(t)\|_{L^p} \le \left(pT|\Omega|(m-l)/\epsilon_0\right)^{1/p}\ \frac{\tilde{c}^{(p+1)/2p}}{\tilde{\epsilon}^{(p-1)/2p}} \le c_\infty\ \ \forall t \in S,\ k = l+1, \dots, m.$$

Passing to the limit $p \to \infty$ we get $\|z_k(t)\|_{L^\infty} \le c_\infty$ $\forall t \in S$, $k = l+1, \dots, m$, which leads to the desired estimates for b_k, $k = l+1, \dots, m$. ∎

3.5. Second regularized problem ($\mathcal{P}_M$). We prove the solvability of ($\mathcal{P}_N$) for fixed $N > 0$ by means of a second regularization ($\mathcal{P}_M$). Let

$$M^* = \max\left\{N + 1, \max_{i=1,\dots,m} \|U_i/p_{0i}\|_{L^\infty}\right\}, \tag{3.19}$$

and let $M \ge M^*$. We denote by σ_M the projection from $\mathbb{R}$ onto $[-M, M]$,

$$\sigma_M(y) = \operatorname{sign}(y) \min\{|y|, M\},\ \ y \in \mathbb{R}.$$

Moreover, we introduce the functions

$$D_{iM}(x,b,\psi) = D_i(x,b^+,\sigma_M(\psi)),\ i=1,\dots,l,\ x\in\Omega,\ b\in\mathbb{R}^m,\ \psi\in\mathbb{R},$$

define the operator $A_M\colon X\times H^1(\Omega)\to X^*$,

$$\langle A_M(b,\psi),\overline{b}\rangle_X = \int_\Omega \sum_{i=1}^{l} D_{iM}(\cdot,b,\psi)p_{0i}(\nabla b_i + [\sigma_M(b_i)]^+ Q_i(\psi)\nabla\psi)\cdot\nabla\overline{b}_i\,\mathrm{d}x,\ \overline{b}\in X,$$

and consider the following problem:

$$(\mathcal{P}_M)\qquad \begin{cases} u'(t) + A_M(b(t),\psi(t)) = R_N(b^+(t),\psi(t)), \\ E(\psi(t),u^+(t)) = 0, \quad u(t) = Bb(t) \quad \text{for a.a. } t\in S, \quad u(0) = U, \\ u\in H^1(S,X^*)\cap L^2(S,Y),\ b\in L^2(S,X),\ \psi\in L^2(S,H^1(\Omega)). \end{cases}$$

Let us remark that we have $u,b\in C(S,Y)$, $\psi\in C(S,H^1(\Omega))$ for solutions of $(\mathcal{P}_M)$.

3.6. Existence result for $(\mathcal{P}_M)$. First we derive an equivalent formulation of $(\mathcal{P}_M)$. We write b in the form $b=(v,w)$, where $v=(b_1,\dots,b_l)$ and $w=(b_{l+1},\dots,b_m)$ denote the chemical activities of the mobile and immobile species, respectively. We introduce the spaces

$$Y^l = L^2(\Omega,\mathbb{R}^l),\ Y^{m-l} = L^2(\Omega,\mathbb{R}^{m-l}),\ X^l = H^1(\Omega,\mathbb{R}^l)$$

and the operators $B_{\mathrm{mob}}\colon L^2(S,Y^l)\to L^2(S,Y^l)$, $B_{\mathrm{imm}}\colon L^2(S,Y^{m-l})\to L^2(S,Y^{m-l})$,

$$\langle (B_{\mathrm{mob}}v)(t),\overline{v}\rangle_{Y^l} = \int_\Omega \sum_{i=1}^{l} p_{0i}\, v_i(t)\,\overline{v}_i\,\mathrm{d}x,\quad \overline{v}\in Y^l,$$

$$\langle (B_{\mathrm{imm}}w)(t),\overline{w}\rangle_{Y^{m-l}} = \int_\Omega \sum_{i=1}^{m-l} p_{0(l+i)}\, w_i(t)\,\overline{w}_i\,\mathrm{d}x,\quad \overline{w}\in Y^{m-l},\quad t\in S.$$

Moreover, we define the operators

$$\begin{aligned} &R_{\mathrm{mob}}\colon L^2(S,X^l)\times L^2(S,Y^{m-l})\times L^2(S,H^1(\Omega))\to L^2(S,X^{l*}),\\ &R_{\mathrm{imm}}\colon L^2(S,X^l)\times L^2(S,Y^{m-l})\times L^2(S,H^1(\Omega))\to L^2(S,Y^{m-l}),\\ &A_{\mathrm{mob}}\colon L^2(S,X^l)\times L^2(S,X^l)\times L^2(S,Y^{m-l})\times L^2(S,H^1(\Omega))\to L^2(S,X^{l*}),\\ &A^0_{\mathrm{mob}}\colon L^2(S,X^l)\times L^2(S,Y^{m-l})\times L^2(S,H^1(\Omega))\to L^2(S,X^{l*}) \end{aligned}$$

as follows:

$$\langle R_{\mathrm{mob}}(v,w,\psi),\overline{v}\rangle_{L^2(S,X^l)} = \int_S \langle R_N(v^+,w^+,\psi),(\overline{v},0)\rangle_X\,\mathrm{d}s,\quad \overline{v}\in L^2(S,X^l),$$

$$\langle R_{\mathrm{imm}}(v,w,\psi),\overline{w}\rangle_{L^2(S,Y^{m-l})} = \int_S \langle R_N(v^+,w^+,\psi),(0,\overline{w})\rangle_X\,\mathrm{d}s,\quad \overline{w}\in L^2(S,Y^{m-l}),$$

$$\langle A_{\mathrm{mob}}(v;\widehat{v},w,\psi),\overline{v}\rangle_{L^2(S,X^l)} = \int_S\int_\Omega \sum_{i=1}^{l}(D_{iM}(\cdot,\widehat{v},w,\psi)\,p_{0i}\,\nabla v_i\cdot\nabla\overline{v}_i + v_i\overline{v}_i)\,\mathrm{d}x\,\mathrm{d}s,$$

$$\begin{aligned}\langle A^0_{\mathrm{mob}}(v,w,\psi),\overline{v}\rangle_{L^2(S,X^l)} = \int_S\int_\Omega \sum_{i=1}^{l}(&D_{iM}(\cdot,v,w,\psi)\,p_{0i}\,[\sigma_M(v_i)]^+ Q_i(\psi)\nabla\psi\cdot\nabla\overline{v}_i\\ &- v_i\overline{v}_i)\,\mathrm{d}x\,\mathrm{d}s,\quad \overline{v}\in L^2(S,X^l).\end{aligned}$$

For any given $v \in L^2(S,Y^l)$, $w \in L^2(S,Y^{m-l})$ we have that $(B_{\rm mob}v, B_{\rm imm}w) \in L^2(S,Y)$, and by Lemma 3.1 we find a unique $\psi \in L^2(S,H^1(\Omega)) \cap L^\infty(S,L^\infty(\Omega))$ such that

$$E(\psi(t),((B_{\rm mob}v)^+(t),(B_{\rm imm}w)^+(t))) = 0 \quad \text{for a.a. } t \in S.$$

We denote by $\mathcal{N}\colon L^2(S,Y^l)\times L^2(S,Y^{m-l}) \to L^2(S,H^1(\Omega))$ the corresponding solution operator, $\psi = \mathcal{N}(v,w)$. Problem $(\mathcal{P}_M)$ is obviously equivalent to the system of equations

$$\begin{aligned}(B_{\rm mob}v)' + A_{\rm mob}(v;v,w,\mathcal{N}(v,w)) &= R_{\rm mob}(v,w,\mathcal{N}(v,w))\\ &\quad - A^0_{\rm mob}(v,w,\mathcal{N}(v,w)),\\ (B_{\rm mob}v)(0) = U_{\rm mob} &= (U_1,\dots,U_l), \quad v \in W^l,\end{aligned} \tag{3.20}$$

where $W^l = \{v \in L^2(S,X^l)\colon (B_{\rm mob}v)' \in L^2(S,X^{l*})\} \subset C(S,Y^l)$,

$$\begin{aligned}(B_{\rm imm}w)' &= R_{\rm imm}(v,w,\mathcal{N}(v,w)),\\ (B_{\rm imm}w)(0) = U_{\rm imm} &= (U_{l+1},\dots,U_m), \quad B_{\rm imm}w \in H^1(S,Y^{m-l}).\end{aligned} \tag{3.21}$$

Let us briefly outline how these equations will be solved. We start with some fixed $\widehat{v} \in W^l$. First we solve the initial value problem

$$\begin{aligned}(B_{\rm imm}w)' &= R_{\rm imm}(\widehat{v},w,\mathcal{N}(\widehat{v},w)),\\ (B_{\rm imm}w)(0) &= U_{\rm imm},\ B_{\rm imm}w \in H^1(S,Y^{m-l}).\end{aligned} \tag{3.22}$$

This problem has a unique solution $w = \mathcal{T}\widehat{v}$ (see Lemma 3.8). Next we solve the initial boundary value problem

$$\begin{aligned}(B_{\rm mob}v)' + A_{\rm mob}(v;\widehat{v},\mathcal{T}\widehat{v},\mathcal{N}(\widehat{v},\mathcal{T}\widehat{v})) &= R_{\rm mob}(\widehat{v},\mathcal{T}\widehat{v},\mathcal{N}(\widehat{v},\mathcal{T}\widehat{v}))\\ &\quad - A^0_{\rm mob}(\widehat{v},\mathcal{T}\widehat{v},\mathcal{N}(\widehat{v},\mathcal{T}\widehat{v})),\\ (B_{\rm mob}v)(0) &= U_{\rm mob},\ v \in W^l.\end{aligned} \tag{3.23}$$

Also this problem has a unique solution $v = \mathcal{Q}\widehat{v}$ (see Lemma 5.2). The operator $\mathcal{Q}$ is compact and continuous (see Lemma 3.10). Using Schauder's fixed point theorem we obtain a fixed point v of $\mathcal{Q}$ (see Lemma 3.11). Then $(v,\mathcal{T}v)$ is a solution of (3.20), (3.21).

Now we give the detailed proofs. The constants c in the estimates of this subsection can depend on the data and on M,N,T.

LEMMA 3.8. *For any $\widehat{v} \in W^l$ there exists a unique solution w of problem* (3.22), *and w belongs to $H^1(S,Y^{m-l}) \subset C(S,Y^{m-l})$.*

Proof. Let $\widehat{v} \in W^l$ be fixed. The initial value problem (3.22) is obviously equivalent to the initial value problem

$$w' + G\,w = 0, \quad w(0) = (B_{\rm imm})^{-1}U_{\rm imm}, \quad w \in H^1(S,Y^{m-l}), \tag{3.24}$$

where $G\colon L^2(S,Y^{m-l}) \to L^2(S,Y^{m-l})$ is defined by

$$G\,w = -(B_{\rm imm})^{-1}[R_{\rm imm}(\hat{v},w,\mathcal{N}(\widehat{v},w))], \quad w \in L^2(S,Y^{m-l}).$$

For $\widehat{v} \in L^2(S, Y^l)$, $w \in L^2(S, Y^{m-l})$ we have $\mathcal{N}(\widehat{v}, w) \in L^2(S, H^1(\Omega))$ and

$$\|\mathcal{N}(\widehat{v}, w^1) - \mathcal{N}(\widehat{v}, w^2)\|_{L^2(S,H^1)} \le c\|w^1 - w^2\|_{L^2(S,Y^{m-l})} \quad \forall w^1,\, w^2 \in L^2(S, Y^{m-l}).$$

Since the functions $r_i^\Omega(x, \cdot, \cdot)$ are Lipschitz continuous uniformly w.r.t. x, the estimate

$$\|G\, w^1 - G\, w^2\|_{L^2(S,Y^{m-l})} \le L\|w^1 - w^2\|_{L^2(S,Y^{m-l})} \quad \forall w^1,\, w^2 \in L^2(S, Y^{m-l})$$

follows, and [6, Chapter V, Theorem 1.3] ensures the existence of a unique solution of (3.24). In principle, this result was obtained by means of the Banach fixed point theorem. ∎

We denote by $\mathcal{T}\colon W^l \to H^1(S, Y^{m-l})$ the operator which assigns to $\widehat{v}$ the solution w of (3.22).

LEMMA 3.9. *There exists a constant $c > 0$ such that the following estimates hold:*

$$\|\mathcal{T}\widehat{v}^1 - \mathcal{T}\widehat{v}^2\|_{C(S,Y^{m-l})} \le c\|\widehat{v}^1 - \widehat{v}^2\|_{L^2(S,Y^l)} \quad \forall\, \widehat{v}^1, \widehat{v}^2 \in W^l,$$
$$\|\mathcal{T}\widehat{v}\|_{C(S,Y^{m-l})} \le c \quad \forall\, \widehat{v} \in W^l.$$

Proof. Let $w^k = \mathcal{T}\widehat{v}^k$, $k = 1, 2$. Using the test function $\overline{w} = w^1 - w^2$ for the corresponding problems (3.22), the Lipschitz continuity of r_i^Ω, Hölder's inequality, and Lemma 3.1, we find that

$$\begin{aligned}
\|\overline{w}(t)\|_{Y^{m-l}}^2 &\le c\|(B_{\mathrm{imm}}(\overline{w}(t))\|_{Y^{m-l}}^2 \\
&\le c\int_0^t \left(\|\overline{w}\|_{Y^{m-l}} + \|\widehat{v}^1 - \widehat{v}^2\|_{Y^l} + \|\mathcal{N}(\widehat{v}^1, w^1) - \mathcal{N}(\widehat{v}^2, w^2)\|_{H^1}\right) \|\overline{w}\|_{Y^{m-l}}\, \mathrm{d}s \\
&\le c\int_0^t \left(\|\overline{w}\|_{Y^{m-l}}^2 + \|\widehat{v}^1 - \widehat{v}^2\|_{Y^l}^2\right)\, \mathrm{d}s.
\end{aligned}$$

Gronwall's lemma leads to the first assertion. Next, testing (3.22) with $w = \mathcal{T}\widehat{v}$ and using (3.5), the estimate

$$\|w(t)\|_{Y^{m-l}}^2 \le c + c\int_0^t \|w(s)\|_{Y^{m-l}}\, \mathrm{d}s \le c + \int_0^t \|w(s)\|_{Y^{m-l}}^2 \quad \forall t \in S$$

follows, where c does not depend on $\widehat{v}$. Again applying Gronwall's lemma the second assertion is obtained. ∎

Next we conclude that for given $\widehat{v} \in W^l$ the initial boundary value problem (3.23) has a unique solution. This follows from Lemma 5.2 since B_{mob} and A_{mob} are diagonal and the right-hand side belongs to $L^2(S, X^{l*})$. We denote by $\mathcal{Q}\colon W^l \to W^l$ the operator which assigns to $\widehat{v}$ the solution v of (3.23).

LEMMA 3.10. *The operator $\mathcal{Q}$ is compact and continuous.*

Proof. 1. Let $\{\widehat{v}_n\} \subset W^l$ be bounded. We show that $\{\mathcal{Q}\widehat{v}_n\} \subset W^l$ contains a convergent subsequence. Because of Lemma 5.1(v) we may assume that there exists an element $\widehat{v} \in W^l$ such that $\widehat{v}_n \to \widehat{v}$ in $L^2(S, Y^l)$ as well as in $L^2(S, L^2(\Gamma, \mathbb{R}^l))$. Let

$$v_n = \mathcal{Q}\widehat{v}_n,\ v = \mathcal{Q}\widehat{v},\ w_n = \mathcal{T}\widehat{v}_n,\ w = \mathcal{T}\widehat{v},\ \psi_n = \mathcal{N}(\widehat{v}_n, w_n),\ \psi = \mathcal{N}(\widehat{v}, w).$$

From Lemmas 3.9 and 3.1 it follows that

$$w_n \to w \text{ in } L^2(S, Y^{m-l}), \quad \psi_n \to \psi \text{ in } L^2(S, H^1).$$

Using the test function $v_n - v$ we obtain

$$\begin{aligned}
&\frac{\epsilon_0}{2}\|(v_n-v)(t)\|_{Y^l}^2 + \int_0^t \epsilon\|v_n-v\|_{X^l}^2\,\mathrm{d}s \\
&\quad\le \int_0^t c\Big\{ \big(\|\widehat{v}_n-\widehat{v}\|_{L^2(\Gamma,\mathbb{R}^l)} + \|\psi_n-\psi\|_{L^2(\Gamma)}\big)\,\|v_n-v\|_{L^2(\Gamma,\mathbb{R}^l)} \\
&\qquad + \big(\|\widehat{v}_n-\widehat{v}\|_{Y^l} + \|w_n-w\|_{Y^{m-l}} + \|\psi_n-\psi\|_{L^2}\big)\,\|v_n-v\|_{Y^l} \\
&\qquad + \int_\Omega \sum_{i=1}^{l} \{ (|\nabla v_i| + |\nabla\psi|)\,|D_{iM}(\cdot,\widehat{v}_n,w_n,\psi_n) - D_{iM}(\cdot,\widehat{v},w,\psi)|\,|\nabla(v_{ni}-v_i)| \\
&\qquad\quad + \big(|Q_i(\psi_n)-Q_i(\psi)| + |[\sigma_M(\widehat{v}_{ni})]^+ - [\sigma_M(\widehat{v}_i)]^+|\big)\,|\nabla\psi|\,|\nabla(v_{ni}-v_i)| \\
&\qquad\quad + |\nabla(\psi_n-\psi)|\,|\nabla(v_{ni}-v_i)|\}\,\mathrm{d}x\Big\}\,\mathrm{d}s \quad \forall t\in S.
\end{aligned}$$

Applying Hölder's inequality and Lemma 3.9 we arrive at

$$\begin{aligned}
\|v_n-v\|_{L^2(S,X^l)}^2 \le c\|v_n-v\|_{L^2(S,X^l)}\{&\|\widehat{v}_n-\widehat{v}\|_{L^2(S,Y^l)} + \|\widehat{v}_n-\widehat{v}\|_{L^2(S,L^2(\Gamma,\mathbb{R}^l))} \\
&+ \|\psi_n-\psi\|_{L^2(S,H^1)} + I_n\},
\end{aligned}$$

$$\begin{aligned}
I_n = \sum_{i=1}^{l}\Big\{ &\Big[\int_0^T\int_\Omega |D_{iM}(\cdot,\widehat{v}_n,w_n,\psi_n) - D_{iM}(\cdot,\widehat{v},w,\psi)|^2\,|\nabla v_i|^2\,\mathrm{d}x\mathrm{d}s\Big]^{1/2} \\
&+\Big[\int_0^T\int_\Omega |D_{iM}(\cdot,\widehat{v}_n,w_n,\psi_n) - D_{iM}(\cdot,\widehat{v},w,\psi)|^2\,|\nabla\psi|^2\,\mathrm{d}x\mathrm{d}s\Big]^{1/2} \\
&+\Big[\int_0^T\int_\Omega |Q_i(\psi_n)-Q_i(\psi)|^2\,|\nabla\psi|^2\,\mathrm{d}x\mathrm{d}s\Big]^{1/2} \\
&+\Big[\int_0^T\int_\Omega |[\sigma_M(\widehat{v}_{ni})]^+ - [\sigma_M(\widehat{v}_i)]^+|^2\,|\nabla\psi|^2\,\mathrm{d}x\mathrm{d}s\Big]^{1/2}\Big\}.
\end{aligned}$$

Properties of superposition operators ensure that the last four bracketed terms tend to zero if $n\to\infty$. Thus in summary we find that $v_n\to v$ in $L^2(S,X^l)$. Next we obtain

$$\begin{aligned}
\|(B_{\mathrm{mob}}v_n)'-(B_{\mathrm{mob}}v)'\|_{L^2(S,X^{l*})} \le{}& \|R_{\mathrm{mob}}(\widehat{v}_n,w_n,\psi_n) - R_{\mathrm{mob}}(\widehat{v},w,\psi)\|_{L^2(S,X^{l*})} \\
&+\|A_{\mathrm{mob}}(v_n;\widehat{v}_n,w_n,\psi_n) - A_{\mathrm{mob}}(v;\widehat{v},w,\psi)\|_{L^2(S,X^{l*})} \\
&+\|A^0_{\mathrm{mob}}(\widehat{v}_n,w_n,\psi_n) - A^0_{\mathrm{mob}}(\widehat{v},w,\psi)\|_{L^2(S,X^{l*})} \\
\le{}& c\{\,\|v_n-v\|_{L^2(S,X^l)} + \|\widehat{v}_n-\widehat{v}\|_{L^2(S,Y^l)} \\
&+\|\widehat{v}_n-\widehat{v}\|_{L^2(S,L^2(\Gamma,\mathbb{R}^l))} + \|w_n-w\|_{L^2(S,Y^{m-l})} \\
&+\|\psi_n-\psi\|_{L^2(S,H^1)} + I_n\},
\end{aligned}$$

and we arrive at $v_n\to v$ in W^l.

2. The continuity of the operator $\mathcal{Q}$ can be shown by similar arguments. ∎

LEMMA 3.11. *The operator $\mathcal{Q}$ has a fixed point.*

Proof. Let $\widehat{v} \in W^l$, $\psi = \mathcal{N}(\widehat{v}, \mathcal{T}\widehat{v})$, and $v = \mathcal{Q}\widehat{v}$. We use v as the test function for (3.23), take into account the properties of D_{iM}, Q_i, and apply Lemma 3.1, (5.1), Lemma 3.9, the boundedness of r_i^{Σ}, and Young's inequality. Thus we obtain

$$\begin{aligned}
&\epsilon_0\|v(t)\|^2_{Y^l} - c\|(U_1,\dots,U_l)\|^2_{Y^l} + 2\epsilon\int_0^t \|v\|^2_{X^l}\,\mathrm{d}s \\
&\quad\le c\int_0^t \big(1 + \|v\|^2_{Y^l} + \|\widehat{v}\|^2_{Y^l} + \|\psi\|_{H^1}\|v\|_{X^l} + \|v\|^2_{L^2(\Gamma,\mathbb{R}^l)}\big)\mathrm{d}s \qquad (3.25)\\
&\quad\le \int_0^t \big(\epsilon\|v\|^2_{X^l} + c\,\big(1 + \|v\|^2_{Y^l} + \|\widehat{v}\|^2_{Y^l}\big)\big)\mathrm{d}s \quad \forall t \in S.
\end{aligned}$$

Therefore we find a constant $\overline{c} > 0$ such that $\forall k > 0$

$$\begin{aligned}
&e^{-kt}\left(\|v(t)\|^2_{Y^l} + \int_0^t \|v\|^2_{X^l}\,\mathrm{d}s\right)\\
&\le \overline{c} + \overline{c}e^{-kt}\int_0^t \left\{\left\{\|v\|^2_{Y^l} + \|\widehat{v}\|^2_{Y^l} + \int_0^s \left(\|v\|^2_{X^l} + \|\widehat{v}\|^2_{X^l}\right)\,\mathrm{d}\tau\right\}e^{-ks}e^{ks}\right\}\mathrm{d}s\\
&\le \overline{c} + \overline{c}e^{-kt}\sup_{s\in S}\left\{\left\{\|v(s)\|^2_{Y^l} + \|\widehat{v}(s)\|^2_{Y^l} + \int_0^s \left(\|v\|^2_{X^l} + \|\widehat{v}\|^2_{X^l}\right)\,\mathrm{d}\tau\right\}e^{-ks}\right\}\frac{e^{kt}-1}{k}.
\end{aligned}$$

Choosing now $k \ge 3\overline{c}$ we obtain

$$\begin{aligned}
&\sup_{t\in S} e^{-kt}\left(\|v(t)\|^2_{Y^l} + \int_0^t \|v(s)\|^2_{X^l}\,\mathrm{d}s\right)\\
&\quad\le \frac{3}{2}\overline{c} + \frac{1}{2}\sup_{t\in S}\left\{e^{-kt}\left(\|\widehat{v}(t)\|^2_{Y^l} + \int_0^t \|\widehat{v}(s)\|^2_{X^l}\,\mathrm{d}s\right)\right\}.
\end{aligned}$$

Again using Lemmas 3.1 and 3.9 we estimate

$$\begin{aligned}
&\|(B_{\mathrm{mob}}v)'\|_{L^2(S,X^{l*})}\\
&= \sup_{\|\overline{v}\|_{L^2(S,X^l)}\le 1} \langle R_{\mathrm{mob}}(\widehat{v},\mathcal{T}\widehat{v},\psi) - A_{\mathrm{mob}}(v;\widehat{v},\mathcal{T}\widehat{v},\psi) - A^0_{\mathrm{mob}}(\widehat{v},\mathcal{T}\widehat{v},\psi),\overline{v}\rangle_{L^2(S,X^l)}\\
&\le c\,\left(\|v\|_{L^2(S,X^l)} + \|\psi\|_{L^2(S,H^1)} + 1\right) \le c\,\left(\|v\|_{L^2(S,X^l)} + \|\widehat{v}\|_{L^2(S,Y^l)} + 1\right)\\
&\le \widetilde{c}\left(\|v\|_{L^2(S,X^l)} + \left[\sup_{t\in S}\left\{e^{-kt}\left(\|\widehat{v}(t)\|^2_{Y^l} + \int_0^t \|\widehat{v}(s)\|^2_{X^l}\,\mathrm{d}s\right)\right\}e^{kT}\right]^{1/2} + 1\right).
\end{aligned}$$

Now we define the set

$$\begin{aligned}
\mathcal{B} = \Bigg\{ v \in W^l\colon &\sup_{t\in S}\left\{e^{-kt}\left(\|v(t)\|^2_{Y^l} + \int_0^t \|v\|^2_{X^l}\,\mathrm{d}s\right)\right\} \le 3\overline{c},\\
&\|(B_{\mathrm{mob}}v)'\|_{L^2(S,X^{l*})} \le \widetilde{c}\left(2\sqrt{3\overline{c}e^{kT}} + 1\right)\Bigg\}.
\end{aligned}$$

This set is a nonempty, bounded, closed, and convex subset of W^l with the property that $\mathcal{Q}(\mathcal{B}) \subset \mathcal{B}$. Since the operator $\mathcal{Q}$ is compact and continuous, the assertion follows from the Schauder fixed point theorem. ∎

THEOREM 3.12. *There exists a solution (u,b,ψ) of $(\mathcal{P}_M)$.*

Proof. Because of Lemma 3.11 there exists a solution v of the problem

$$(B_{\mathrm{mob}}v)'+A_{\mathrm{mob}}(v;v,\mathcal{T}v,\mathcal{N}(v,\mathcal{T}v)) = R_{\mathrm{mob}}(v,\mathcal{T}v,\mathcal{N}(v,\mathcal{T}v))-A^0_{\mathrm{mob}}(v,\mathcal{T}v,\mathcal{N}(v,\mathcal{T}v)),$$

$$(B_{\mathrm{mob}}v)(0) = (U_1,\dots,U_l), \quad v \in W^l.$$

We set $w = \mathcal{T}v \in H^1(S,Y^{m-l})$. Then the pair (v,w) fulfills (3.20) and (3.21), which represent an equivalent formulation of problem $(\mathcal{P}_M)$. ∎

3.7. Energy estimates for solutions of $(\mathcal{P}_M)$. First, we prove the following.

LEMMA 3.13. *For any solution (u,b,ψ) of $(\mathcal{P}_M)$ and for every $t \in S$ the inequalities $b(t), u(t) \geq 0$ a.e. on Ω are fulfilled.*

Proof. Let (u,b,ψ) be a solution of $(\mathcal{P}_M)$. We test the evolution equation with the function $-b^-$. Taking into account that

$$(\nabla b_i + [\sigma_M(b_i)]^+ Q_i(\psi)\nabla\psi)\cdot\nabla b_i^- \leq 0, \quad i = 1,\dots,l,$$

$$-r_i^{\Sigma}(\cdot, b_1^+,\dots,b_{m_\Sigma}^+,\psi)\, b_i^- \leq 0, \quad i = 1,\dots,m_\Sigma,\ \Sigma = \Omega,\Gamma,$$

we find that $\|b^-(t)\|_Y^2 \leq 0\ \forall t \in S$. ∎

Next, we introduce a regularized free energy functional F_M, which is adapted to the regularizations in problem $(\mathcal{P}_M)$. We define the function

$$l_M(y) = \begin{cases} \ln y & \text{if} \quad 0 < y \leq M, \\ \ln M - 1 + \dfrac{y}{M} & \text{if} \quad y > M \end{cases}$$

and the functional $\widetilde{F}_{M2} : Y \to \overline{\mathbb{R}}$ by

$$\widetilde{F}_{M2}(u) = \begin{cases} \displaystyle\int_\Omega \sum_{i=1}^m \int_{p_{0i}}^{u_i} l_M(z/p_{0i})\,\mathrm{d}z\,\mathrm{d}x & \text{if} \quad u \in Y_+, \\ +\infty & \text{if} \quad u \in Y \setminus Y_+. \end{cases} \tag{3.26}$$

Moreover, we set

$$F_{M2} = (\widetilde{F}^*_{M2}|_X)^* : X^* \to \overline{\mathbb{R}}, \quad F_M = F_1 + F_{M2} : X^* \to \overline{\mathbb{R}},$$

where F_1 was introduced in subsection 3.3. Since the function l_M has the same essential properties as the function ln which occurs in the definition of the functional F_2, arguments similar to those in [11] give the following results.

LEMMA 3.14. *The functional $F_M = F_1 + F_{M2} : X^* \to \overline{\mathbb{R}}$ is proper, convex, and lower semicontinuous. For $u \in Y_+$ it can be evaluated according to* (3.7), (3.26). *The restriction $F_M|_{Y_+}$ is continuous. If $u \in Y_+$, then $P(\psi) \in \partial F_1(u)$, where ψ is the solution of $E(\psi,u) = 0$. If $u \in Y$, $u \geq \delta > 0$ and $u/p_0 \in X$, then $l_M(u/p_0) \in \partial F_{M2}(u)$, where $l_M(b)$ denotes the vector $\{l_M(b_i)\}_{i=1,\dots,m}$.*

By the definition of l_M the inequality

$$\int_{p_{0i}}^{y} l_{Mi}(z/p_{0i})\,\mathrm{d}z \geq y\ln\frac{y}{p_{0i}} - y + p_{0i} \quad \text{a.e. on } \Omega,\ \forall y \in \mathbb{R}_+$$

holds. Therefore it follows that

$$F_M(u) \geq c_1 \left\{ \|\psi\|_{H^1}^2 + \sum_{i=1}^m \|u_i \ln u_i\|_{L^1} \right\} - c_2, \ u \in Y_+. \tag{3.27}$$

LEMMA 3.15. *Along any solution (u, b, ψ) of $(\mathcal{P}_M)$ the regularized free energy $F_M(u)$ remains bounded by its initial value and decreases monotonously,*

$$F_M(u(t_2)) \leq F_M(u(t_1)) \leq F_M(U) = F(U), \quad 0 \leq t_1 \leq t_2 \leq T.$$

Moreover, there exist positive constants $c, c_{3.28}, c_{3.29}$ not depending on M, such that

$$\sum_{i=1}^m \|u_i \ln u_i\|_{L^\infty(S,L^1(\Omega))} \leq c, \quad \|u\|_{L^\infty(S,L^1(\Omega,\mathbb{R}^m))} \leq c,$$

$$\sum_{i=1}^m \|b_i \ln b_i\|_{L^\infty(S,L^1(\Omega))} \leq c_{3.28}, \tag{3.28}$$

$$\|\psi\|_{L^\infty(S,H^1(\Omega))} \leq c, \quad \|\psi\|_{L^\infty(S,L^\infty(\Omega))}, \quad \|\psi\|_{L^\infty(S,L^\infty(\Gamma))} \leq c_{3.29} \tag{3.29}$$

for any solution of $(\mathcal{P}_M)$.

Proof. Let (u, b, ψ) be a solution of $(\mathcal{P}_M)$.

1. We know that $u \in H^1(S, X^*)$, $\psi \in L^2(S, H^1(\Omega))$, $P(\psi) \in L^2(S, X)$, $\nabla P(\psi) = Q(\psi)\nabla\psi$. By Lemma 3.14 we find that $P(\psi(t)) \in \partial F_1(u(t))$ for a.a. $t \in S$. Thus, the function $t \mapsto F_1(u(t))$ is absolutely continuous on S, and according to the chain rule (see [3, Lemma 3.3]) we obtain

$$\frac{\mathrm{d}}{\mathrm{d}t} F_1(u(t)) = \langle u'(t), P(\psi(t)) \rangle_X \quad \text{for a.a. } t \in S.$$

2. We choose some $\delta \in (0, 1)$ and define $u^\delta = u + \delta p_0$, $b^\delta = u^\delta / p_0 = b + \delta$. Then we find that $u^\delta \in H^1(S, X^*)$, $l_M(b^\delta) \in L^2(S, X)$, $\nabla l_M(b_i^\delta) = \nabla b_i / \sigma_M(b_i^\delta)$, $i = 1, \ldots, l$. Lemma 3.14 ensures that $l_M(b^\delta(t)) \in \partial F_{M2}(u^\delta(t))$ for a.a. $t \in S$. Thus, the function $t \mapsto F_{M2}(u^\delta(t))$ is absolutely continuous on S and

$$\frac{\mathrm{d}}{\mathrm{d}t} F_{M2}(u^\delta(t)) = \big\langle u'(t), l_M(b^\delta(t)) \big\rangle_X \quad \text{for a.a. } t \in S.$$

3. We set $\zeta_M^\delta = l_M(b^\delta) + P(\psi)$ and obtain

$$\begin{aligned} \big[F_1(u(t)) + F_{M2}(u^\delta(t))\big] \Big|_{t_1}^{t_2} &= \int_{t_1}^{t_2} \langle u'(t), \zeta_M^\delta(t) \rangle_X \, \mathrm{d}t \\ &= \int_{t_1}^{t_2} \langle R_N(b(t), \psi(t)) - A_M(b(t), \psi(t)), \zeta_M^\delta(t) \rangle_X \, \mathrm{d}t. \end{aligned}$$

The volume integral in the definition of $\langle R_N(b, \psi), \zeta_M^\delta \rangle_X$, namely,

$$I = \int_\Omega \rho_N(b, \psi) \sum_{(\alpha,\, \beta) \in \mathcal{R}^\Omega} k_{\alpha\beta}^\Omega(\cdot, b, \psi)(a^\alpha - a^\beta) \sum_{i=1}^m (\beta_i - \alpha_i) \zeta_{Mi}^\delta \, \mathrm{d}x, \ a_i = b_i \mathrm{e}^{P_i(\psi)},$$

is estimated as follows. Since for $|(b, \psi)|_\infty > N$ the integrand vanishes we may assume that $|(b, \psi)|_\infty \leq N$ and thus $b_i \leq N$, $b_i^\delta \leq N + 1 \leq M$, $\zeta_{Mi}^\delta = \ln a_i^\delta$ with $a_i^\delta = b_i^\delta \mathrm{e}^{P_i(\psi)}$,

$i = 1, \dots, m$, $|\psi| \le N$. Then we have

$$\big[(a^\delta)^\alpha - (a^\delta)^\beta\big] \sum_{i=1}^m (\beta_i - \alpha_i) \ln a_i^\delta \le 0,$$

$$\left| \big[a^\alpha - a^\beta - (a^\delta)^\alpha + (a^\delta)^\beta\big] \sum_{i=1}^m (\beta_i - \alpha_i) \ln a_i^\delta \right| \le c_N \delta (1 + |\ln \delta|)$$

and $I \le c_N \delta(1 + |\ln \delta|)$. The boundary integral is handled analogously and, in summary, we obtain

$$\langle R_N(b(t), \psi(t)), \zeta_M^\delta(t) \rangle_X \le h_1^\delta = c_N \delta (1 + |\ln \delta|) \quad \text{for a.a. } t \in S.$$

Next we consider the term $-\langle A_M(b, \psi), \zeta_M^\delta \rangle_X$, i.e., the integral

$$-\int_\Omega \sum_{i=1}^l D_{iM}(\cdot, b, \psi) p_{0i} (\nabla b_i + \sigma_M(b_i) Q_i(\psi) \nabla \psi) \cdot \nabla \zeta_{Mi}^\delta \, \mathrm{d}x.$$

Here we write

$$\nabla b_i + \sigma_M(b_i) Q_i(\psi) \nabla \psi = \sigma_M(b_i^\delta) \nabla \zeta_{Mi}^\delta + \big[\sigma_M(b_i) - \sigma_M(b_i^\delta)\big] Q_i(\psi) \nabla \psi,$$

and in view of $D_{iM}(\cdot, b, \psi) \le c_M$ we obtain

$$-\langle A_M(b(t), \psi(t)), \zeta_M^\delta(t) \rangle_X \le h_2^\delta(t) \quad \text{for a.a. } t \in S,$$

$$h_2^\delta(t) = c_M \int_\Omega \sum_{i=1}^l \delta |\nabla \psi(t)| \left[|\nabla \psi(t)| + \frac{1}{\sigma_M(b_i^\delta(t))} |\nabla b_i(t)| \right] \mathrm{d}x.$$

The last estimates ensure that

$$\big[F_1(u(t)) + F_{M2}(u^\delta(t))\big] \big|_{t_1}^{t_2} \le \int_{t_1}^{t_2} \big(h_1^\delta + h_2^\delta(t)\big) \, \mathrm{d}t,$$

and letting $\delta \to 0$, the inequality $F_M(u(t_2)) - F_M(u(t_1)) \le 0$ follows. The choice of M guarantees that $F_M(U) = F(U)$. The remaining assertions of the lemma are a consequence of (3.27), Lemma 3.1, and (5.2). ∎

3.8. Further estimates for solutions of ($\mathcal{P}_M$). We prove the following.

THEOREM 3.16. *There is a constant $c_{3.30} > 0$ not depending on M such that*

$$\|b\|_{L^\infty(S, L^\infty(\Omega, \mathbb{R}^m))} \le c_{3.30}, \quad \|b_i\|_{L^\infty(S, L^\infty(\Gamma))} \le c_{3.30}, \quad i = 1, \dots, l, \tag{3.30}$$

for any solution (u, b, ψ) of $(\mathcal{P}_M)$.

Proof. Let (u, b, ψ) be a solution of $(\mathcal{P}_M)$. Let $q > 2$ be chosen as in Lemma 3.1, $r = 2q/(q-2)$, $r' = 2q/(2+q)$. Other constants in the following estimates can depend on the data and on N, T.

1. Testing $(\mathcal{P}_M)$ with $(0, \dots, 0, b_{l+1}, \dots, b_m)$ we obtain in view of (3.5) that

$$\|b_i(t)\|_{L^2} \le c \quad \forall t \in S, \quad i = l+1, \dots, m, \tag{3.31}$$

which ensures that $\|u_i(t)\|_{L^{r'}} \le c \; \forall t \in S$, $i = l+1, \dots, m$. Hence we get

$$\|\psi(t)\|_{W^{1,q}} \le c \left[1 + \sum_{i=1}^m \|u_i(t)\|_{L^{r'}}\right] \le c \left[1 + \sum_{i=1}^l \|b_i(t)\|_{L^{r'}}\right] \quad \forall t \in S. \tag{3.32}$$

2. Testing $(\mathcal{P}_M)$ with $2(b_1,\dots,b_l,0,\dots,0)$, estimating $[\sigma_M(b_i)]^+$ by b_i, using (3.5), (3.32), (5.1), (5.3), Young's inequality, and Lemma 3.15, we find that

$$\begin{aligned}
&\sum_{i=1}^{l}\left(\epsilon_0\|b_i(t)\|_{L^2}^2 - c\|U_i\|_{L^2}^2\right)\\
&\quad\le \int_0^t \sum_{i=1}^{l}\{-2\epsilon\|b_i\|_{H^1}^2 + c(\|b_i\|_{L^r}\|\psi\|_{W^{1,q}}\|b_i\|_{H^1} + \|b_i\|_{L^2}^2 + \|b_i\|_{L^2(\Gamma)}^2 + 1)\}\mathrm{d}s\\
&\quad\le \int_0^t \sum_{i=1}^{l}\left\{-\epsilon\|b_i\|_{H^1}^2 + \overline{c}\|b_i\|_{L^r}\|b_i\|_{H^1}\sum_{k=1}^{l}\|b_k\|_{L^{r'}} + c\right\}\mathrm{d}s.
\end{aligned}$$

Using the inequality (5.4) for $p=2$ and Lemma 3.15 we have

$$\begin{aligned}
\overline{c}\sum_{i=1}^{l}\|b_i\|_{L^r}\|b_i\|_{H^1}\sum_{k=1}^{l}\|b_k\|_{L^{r'}} &\le \sum_{i=1}^{l}\left\{\frac{\epsilon}{2}\|b_i\|_{H^1}^2 + c\|b_i\|_{L^2}^2\sum_{k=1}^{l}\|b_k\|_{L^2}^2\right\}\\
&\le \sum_{i=1}^{l}\left\{\frac{\epsilon}{2}\|b_i\|_{H^1}^2 + \left[\frac{\sqrt{\epsilon}}{2c_{3.28}}\|b_i\ln b_i\|_{L^1}\|b_i\|_{H^1} + c\|b_i\|_{L^1}\right]^2\right\} \le \sum_{i=1}^{l}\epsilon\|b_i\|_{H^1}^2 + c.
\end{aligned}$$

The previous estimates and the inequalities (3.31), (3.32) ensure the existence of positive constants $c,\widetilde{\kappa}$ not depending on M such that

$$\|b_i(t)\|_{L^2}\le c,\ i=1,\dots,m,\ \|\psi(t)\|_{W^{1,q}}^{2r}+1\le\widetilde{\kappa}\quad\forall t\in S. \tag{3.33}$$

3. Following the estimates in the proofs of Lemma 3.6 and Theorem 3.7, but estimating $[\sigma_M(b_i)]^+$ by b_i and using $\widetilde{\kappa}$ from (3.33) instead of κ, we find that

$$\begin{aligned}
&\|b_i(t)\|_{L^4}\le\widetilde{c},\ i=1,\dots,m,\\
&\sum_{i=1}^{l}\|(b_i-K)^+(t)\|_{L^\infty}\le\sqrt{l}\left(2^{4r}\left(\widetilde{\kappa}+\widetilde{c}^8\right)cT\left(\sum_{i=1}^{l}\sup_{s\in S}\|(b_i-K)^+(s)\|_{L^4}^4+1\right)\right)^{c_0},\\
&\|(b_i-K)^+(t)\|_{L^\infty}\le c,\ i=l+1,\dots,m,\quad\forall t\in S,
\end{aligned}$$

where the constants K, c_0 have the same meaning as in the proof of Theorem 3.7. This provides the desired estimates. ∎

3.9. Existence result for $(\mathcal{P}_N)$.

THEOREM 3.17. *There exists a solution of* $(\mathcal{P}_N)$.

Proof. Let $N>0$ be fixed. We choose $M=\max\{M^*,c_{3.29},c_{3.30}\}$ (see (3.19), Lemma 3.15, and Theorem 3.16). By Theorem 3.12 there is a solution (u,b,ψ) of $(\mathcal{P}_M)$. Since $b\ge 0$ (see Lemma 3.13) and

$$\begin{aligned}
&\|\psi\|_{L^\infty(S,L^\infty(\Omega))},\ \|\psi\|_{L^\infty(S,L^\infty(\Gamma))}\le M,\\
&\|b_i\|_{L^\infty(S,L^\infty)}\le M,\ i=1,\dots,m,\quad \|b_i\|_{L^\infty(S,L^\infty(\Gamma))}\le M,\ i=1,\dots,l
\end{aligned}$$

(see Lemma 3.15 and Theorem 3.16) this solution is a solution of $(\mathcal{P}_N)$, too. ∎

3.10. Existence result for $(\mathcal{P})$.

Proof of Theorem 2.3. It suffices to prove the existence of a solution of $(\mathcal{P})$ on any finite time interval $S=[0,T]$. Such problems are denoted by $(\mathcal{P}_S)$. We choose $N=2\max\{c_{3.13},c_{3.18}\}$ (see Lemma 3.3 and Theorem 3.7). Then according to Theorem 3.17 there is a solution (u,b,ψ) of $(\mathcal{P}_N)$. The choice of N guarantees that $R_N(b,\psi)=R(b,\psi)$. Therefore (u,b,ψ) is a solution of $(\mathcal{P}_S)$, too. ∎

4. Remarks. For the sake of completeness we summarize here some results of our earlier papers [11, 16] concerned with qualitative properties of solutions of $(\mathcal{P})$, the existence of which is now established by the results of the present paper.

4.1. Uniqueness. Under the restrictive assumption that

$$\begin{cases} D_i\colon \Omega \times \mathbb{R} \to \mathbb{R}_+ \text{ does not depend on } b, \\ D_i(x,\cdot) \text{ is locally Lipschitz continuous uniformly w.r.t. } x,\ i = 1,\dots,l, \end{cases} \tag{4.1}$$

the solution of $(\mathcal{P})$ is unique (see [11, Lemma 7.2]).

4.2. Steady states. We regard the set $\mathcal{R}^\Gamma \subset \mathbb{Z}_+^l \times \mathbb{Z}_+^l$ as a subset of $\mathbb{Z}_+^m \times \mathbb{Z}_+^m$ by setting $\alpha_i = \beta_i = 0$, $i = l+1,\dots,m$, $(\alpha,\beta) \in \mathcal{R}^\Gamma$, and introduce the stoichiometric subspace $\mathcal{S}$ belonging to all reactions,

$$\mathcal{S} = \operatorname{span}\{\alpha - \beta : (\alpha,\beta) \in \mathcal{R}^\Omega \cup \mathcal{R}^\Gamma\} \subset \mathbb{R}^m.$$

Every solution of $(\mathcal{P})$ fulfills the invariance property $\int_\Omega \{u(t) - U\}\,\mathrm{d}x \in \mathcal{S}$, $t \in \mathbb{R}_+$. Therefore we consider the following stationary problem:

$$\begin{cases} A(b,\psi) = R(b,\psi),\ E(\psi,u) = 0,\ u = Bb,\ \displaystyle\int_\Omega \{u - U\}\,\mathrm{d}x \in \mathcal{S}, \\ u \in Y, \quad b \in X \cap L^\infty_+(\Omega,\mathbb{R}^m), \quad \psi \in H^1(\Omega) \cap L^\infty(\Omega). \end{cases} \tag{S}$$

In addition to the assumptions in subsection 2.2 we suppose that

$$\begin{cases} \displaystyle\int_\Omega U \cdot \overline{\zeta}\,\mathrm{d}x > 0 \quad \forall \overline{\zeta} \in \mathcal{S}^\perp,\ \overline{\zeta} \ge 0,\ \overline{\zeta} \ne 0; \\ \Big\{ a \in \mathbb{R}^m_+ :\ a^\alpha = a^\beta\ \forall (\alpha,\beta) \in \mathcal{R}^\Omega \cup \mathcal{R}^\Gamma,\ \displaystyle\int_\Omega (u - U)\,\mathrm{d}x \in \mathcal{S},\ \text{where} \\ u = ap(\cdot,\psi) \text{ and } \psi \text{ is the solution of } E(\psi,u) = 0 \Big\} \cap \partial\mathbb{R}^m_+ = \emptyset; \\ k^\Sigma_{\alpha\beta}(x,b,\psi) \ge b^\Sigma_{\alpha\beta,R}(x) \text{ for a.a. } x \in \Sigma,\ \forall b \in \mathbb{R}^{m\Sigma}_+,\ \forall \psi \in [-R,R],\ R > 0, \\ \text{where } b^\Sigma_{\alpha\beta,R} \in L^\infty_+(\Sigma),\ \|b^\Sigma_{\alpha\beta,R}\|_{L^1(\Sigma)} > 0 \quad \forall (\alpha,\beta) \in \mathcal{R}^\Sigma,\ \Sigma = \Omega,\Gamma. \end{cases} \tag{4.2}$$

Here $p(\cdot,\psi)$ denotes the vector $p_i(\cdot,\psi) = p_{0i}\,\mathrm{e}^{-P_i(\psi)}$, $i = 1,\dots,m$. Then the stationary problem (S) has a unique solution (u^*,b^*,ψ^*), which is a thermodynamic equilibrium (see [11, Theorem 3.1]).

4.3. Energy estimates. The free energy functional F related to problem $(\mathcal{P})$ is again given by (3.7)–(3.9), while the dissipation functional D now reads as

$$\begin{aligned} D(u) = {} & 4\int_\Omega \sum_{i=1}^{l} D_i(\cdot,b,\psi) p_i(\cdot,\psi) |\nabla \sqrt{a_i}|^2\,\mathrm{d}x \\ & + 4\int_\Omega \sum_{(\alpha,\beta)\in\mathcal{R}^\Omega} k^\Omega_{\alpha\beta}(\cdot,b_1,\dots,b_m,\psi) |\sqrt{a}^{\,\alpha} - \sqrt{a}^{\,\beta}|^2\,\mathrm{d}x \\ & + 4\int_\Gamma \sum_{(\alpha,\beta)\in\mathcal{R}^\Gamma} k^\Gamma_{\alpha\beta}(\cdot,b_1,\dots,b_l,\psi) |\sqrt{a}^{\,\alpha} - \sqrt{a}^{\,\beta}|^2\,\mathrm{d}\Gamma, \quad u \in M_D, \end{aligned} \tag{4.3}$$

where the set M_D is the same as in (3.11). The free energy F is a Lyapunov function for problem $(\mathcal{P})$; more precisely, the inequality (3.12) holds for any solution of $(\mathcal{P})$ where D has to be replaced by the expression (4.3) (see [11, Theorem 3.2]). Using the additional assumption (4.2) the following estimate of the free energy by the dissipation rate can be derived (see [16, Theorem 3]):

$$F(u)-F(u^*)\le c(R)D(u)\quad \forall u\in\left\{u\in M_D\colon F(u)-F(u^*)\le R,\ \int_\Omega (u-U)\,\mathrm{d}x\in\mathcal{S}\right\}.$$

This is a logarithmic Sobolev inequality adapted to the structure of $(\mathcal{P})$ and guarantees the exponential decay of the free energy along any solution of $(\mathcal{P})$,

$$0\le F(u(t))-F(u^*)\le \mathrm{e}^{-\lambda t}\,(F(U)-F(u^*))\quad \forall t\in\mathbb{R}_+$$

(see [11, Theorem 3.3]).

4.4. Global upper and lower bounds. Again under the additional assumption (4.2) there exists a constant $c>0$ such that

$$\|u_i(t)\|_{L^\infty},\ \|b_i(t)\|_{L^\infty},\ \|\psi(t)\|_{L^\infty}\le c\quad \forall t\in\mathbb{R}_+,\ i=1,\dots,m,$$

if (u,b,ψ) is a solution of $(\mathcal{P})$ (see [11, Theorem 4.1, Theorem 3.2]). Moreover, if the initial densities are strictly positive, $U_i\ge c_0>0$, $i=1,\dots,m$, then we find a constant $c>0$ such that

$$\operatorname{ess\,inf}_{x\in\Omega} u_i(t)\ge c>0\quad \forall t\in\mathbb{R}_+,\ i=1,\dots,m,$$

for any solution of $(\mathcal{P})$ (see [11, Corollary 5.1]).

4.5. Asymptotic behavior. Let q be fixed as in Lemma 3.1, $p\in[1,+\infty)$. Then there exist constants $c,\lambda_p,\lambda>0$ such that

$$\begin{aligned}&\|u(t)-u^*\|_{L^p(\Omega,\mathbb{R}^m)},\ \|b(t)-b^*\|_{L^p(\Omega,\mathbb{R}^m)}\le c\,\mathrm{e}^{-\lambda_p t}\quad \forall\, t\in\mathbb{R}_+,\\ &\|\psi(t)-\psi^*\|_{W^{1,q}},\ \|\psi(t)-\psi^*\|_{L^\infty}\le c\,\mathrm{e}^{-\lambda t}\quad \forall\, t\in\mathbb{R}_+\end{aligned}$$

if (u,b,ψ) is a solution of $(\mathcal{P})$ (see [11, Theorem 6.1]; again (4.2) has to be assumed).

4.6. Example. Let us consider the example in subsection 2.3. Here we have

$$\mathcal{S}^\perp=\operatorname{span}\{(0,0,1,1,1),(1,-1,1,-1,0)\}\subset\mathbb{R}^5,$$

and the first assumption in (4.2) is fulfilled if we require that

$$\int_\Omega (U_3+U_4+U_5)\,\mathrm{d}x>0.$$

Then the second assumption in (4.2) is fulfilled, too. In general, this assumption means that the underlying reaction system has no false equilibria in the sense of [23].

5. Appendix. We assume that $\Omega\subset\mathbb{R}^2$ is a bounded Lipschitzian domain. We apply Sobolev's imbedding theorems (see [18]) and some other imbedding results, especially the trace inequalities

$$\|w\|^q_{L^q(\Gamma)}\le c_\Omega\, q\,\|w\|^{q-1}_{L^{2(q-1)}(\Omega)}\|w\|_{H^1(\Omega)}\quad \forall w\in H^1(\Omega),\ q\ge 2, \tag{5.1}$$

$$\|w\|_{L^\infty(\Gamma)} \le \|w\|_{L^\infty(\Omega)} \quad \forall w \in H^1(\Omega) \cap L^\infty(\Omega), \tag{5.2}$$

and the following version of the Gagliardo–Nirenberg inequality (see [5, 22]):

$$\|w\|_{L^p} \le c_{p,k} \|w\|_{L^k}^{k/p} \|w\|_{H^1}^{1-k/p} \quad \forall w \in H^1(\Omega),\ 1 \le k < p < \infty. \tag{5.3}$$

As an extended form of this inequality one obtains that for any $\delta > 0$ and any $p \in (1, \infty)$ there exists a constant $c_{\delta,p} > 0$ such that

$$\|w\|_{L^p}^p \le \delta \|w \ln |w|\|_{L^1} \|w\|_{H^1}^{p-1} + c_{\delta,p} \|w\|_{L^1} \quad \forall w \in H^1(\Omega). \tag{5.4}$$

This inequality is proven in [2] for bounded domains with smooth boundary and $p = 3$. But (5.4) is valid also for bounded Lipschitzian domains and $p \in (1, \infty)$, since (5.3) is true in this case, too.

Let $p_0 \in L^\infty(\Omega)$, $\operatorname{ess\,inf}_{x\in\Omega} p_0(x) > 0$. We define $B\colon L^2(\Omega) \longrightarrow L^2(\Omega)$ by

$$(Bw, \overline{w})_{L^2} = \int_\Omega p_0\, w\, \overline{w} \mathrm{d}x, \quad \overline{w} \in L^2(\Omega).$$

Let $S = [0, T]$ be a compact interval. The extended operator $B\colon L^2(S, L^2(\Omega)) \longrightarrow L^2(S, L^2(\Omega))$ is defined by $(Bw)(t) = B(w(t))$ for a.a. $t \in S$. Because of properties of p_0 the operator B is linear, continuous, self-adjoint, and positive definite, and there exists the inverse operator $B^{-1}\colon L^2(S, L^2(\Omega)) \longrightarrow L^2(S, L^2(\Omega))$ with the same properties. Let

$$W_B = \{w \in L^2(S, H^1)\colon (Bw)' \in L^2(S, H^{1*})\}.$$

The following assertions can be verified as in [6, 19, 24].

LEMMA 5.1.

(i) *Equipped with the scalar product*

$$(w, \overline{w})_{W_B} = (w, \overline{w})_{L^2(S,H^1)} + ((Bw)', (B\overline{w})')_{L^2(S,H^{1*})},$$

the linear space W_B is a Hilbert space.

(ii) *W_B is continuously embedded in $C(S, L^2(\Omega))$.*

(iii) *The operator $B\colon W_B \to C(S, L^2(\Omega))$ is continuous.*

(iv) *For $w \in W_B$ and $t_1, t_2 \in S$ the formula*

$$\int_{t_1}^{t_2} \big\langle (Bw)'(s), w(s) \big\rangle_{H^1} \mathrm{d}s = \frac{1}{2} \left((Bw)(t_2), w(t_2)\right)_{L^2} - \frac{1}{2} \left((Bw)(t_1), w(t_1)\right)_{L^2}$$

holds.

(v) *The imbeddings of W_B in $L^2(S, L^2(\Omega))$ and in $L^2(S, L^2(\Gamma))$, respectively, are compact.*

Finally, the following existence result can be obtained as in [6, Chapter VI].

LEMMA 5.2. *Let $A\colon L^2(S, H^1(\Omega)) \to L^2(S, H^1(\Omega)^*)$ be the operator*

$$\langle Aw, \overline{w} \rangle_{L^2(S,H^1)} = \int_0^T \int_\Omega (a\, \nabla w \cdot \nabla \overline{w} + d\, w\, \overline{w}) \mathrm{d}x \mathrm{d}s,\ w, \overline{w} \in L^2(S, H^1(\Omega)),$$

where $a, d \in L^\infty(S \times \Omega)$ with $a(t,x), d(t,x) \ge c > 0$ a.e. on $S \times \Omega$. Then for every $f \in L^2(S, H^1(\Omega)^*)$ and every $U \in L^2(\Omega)$ there is a unique solution of the problem

$$(Bw)' + Aw = f, \quad (Bw)(0) = U, \quad w \in W_B.$$

A SEMILINEAR FOURTH ORDER ELLIPTIC PROBLEM WITH EXPONENTIAL NONLINEARITY*

GIANNI ARIOLI†, FILIPPO GAZZOLA†, HANS-CHRISTOPH GRUNAU‡, AND ENZO MITIDIERI§

Abstract. We study a semilinear fourth order elliptic problem with exponential nonlinearity. Motivated by a question raised in [P.-L. Lions, *SIAM Rev.*, 24 (1982), pp. 441–467], we partially extend results known for the corresponding second order problem. Several new difficulties arise and many problems still remain to be solved. We list those of particular interest in the final section.

Key words. biharmonic operator, super-subsolutions, computer assisted proof

1. Introduction. In the last forty years a great deal has been written about existence and multiplicity of solutions to nonlinear second order elliptic problems in bounded and unbounded domains of $\mathbb{R}^n$ ($n \geq 2$). Important achievements on this topic have been made by applying various combinations of analytical techniques, and among all of them we mention only the variational and topological methods. For the latter, especially when the main interest is focused on the existence of positive solutions, the fundamental tool which has been used is the maximum principle [A1] and its consequences [GNN].

For higher order problems, a possible failure of the maximum principle causes several technical difficulties. This fact is very likely the reason why the knowledge on higher order nonlinear problems is far from being reasonably complete, as it is in the second order case.

One of the most interesting and intensively studied second order model problems that exhibits several peculiar features of most nonlinear elliptic equations is the so-called Gel'fand problem [G, section 15],

$$\begin{cases} -\Delta u = \lambda e^u & \text{in } \Omega, \\ u = 0 & \text{on } \partial\Omega. \end{cases} \tag{1}$$

Here Ω is a bounded smooth domain in $\mathbb{R}^n$ ($n \geq 3$) and $\lambda \geq 0$ is a parameter. This problem appears in connection with combustion theory [G, JL] and stellar structure [C]. From a mathematical point of view, one of the main interests is that it may have both unbounded (singular) solutions and bounded (regular) solutions (see [BV, GMP, MP1, MP2]): by the results in [CR, BCMR] it is known that there exists $\lambda^* > 0$ such that if $\lambda > \lambda^*$ there exists no solution of (1) (neither regular nor singular),

while if $0 \le \lambda < \lambda^*$, there exists a minimal regular solution U_λ of (1) and the map $\lambda \mapsto U_\lambda$ is smooth and increasing. In the unit ball B, the bifurcation picture of radial solutions is rather complete. There is always a singular solution $u_\sigma := -2\log|x|$ with corresponding parameter $\lambda_\sigma = 2(n-2)$. If $n \ge 10$, the solution branch consists only of minimal solutions and terminates at $\lambda^* = \lambda_\sigma$ in the singular solution. If $3 \le n \le 9$, then $\lambda^* > \lambda_\sigma$ and the extremal point (λ^*, U_*) is a turning point. The branch bends back and meanders infinitely many times around λ_σ while approaching the singular solution u_σ. We refer to [BV, Figure 1] for the pictures. The interested reader may see also [BE] for an account on motivations and related results.

Some interesting generalizations of (1) have been considered in the framework of second order quasi-linear operators. We refer to [GPP] for equations associated to the p-Laplace operator and to [J, JS] for the case of the k-Hessian operator.

The aim of this paper is to give a contribution to the solution of a special case of a problem formulated in [Li, section 4.2 (c)], namely, *Is it possible to obtain a description of the solution set for higher order semilinear equations associated to exponential nonlinearities?*

Recently, interest in higher order nonlinear problems due to its exciting and promising developments has become increasingly evident especially for fourth order equations [PT]. Following this trend, we shall consider in this paper the fourth order version of (1), a semilinear elliptic problem which involves the biharmonic operator, more precisely,

$$(P_\lambda) \qquad \begin{cases} \Delta^2 u = \lambda e^u & \text{in } B, \\ u = \dfrac{\partial u}{\partial \mathbf{n}} = 0 & \text{on } \partial B. \end{cases}$$

Here B denotes the unit ball in $\mathbb{R}^n$ ($n \ge 5$) centered at the origin and $\frac{\partial}{\partial \mathbf{n}}$ the differentiation with respect to the exterior unit normal, i.e., in radial direction; $\lambda \ge 0$ is a parameter. We are interested in two kinds of solutions of (P_λ), regular solutions and singular solutions; see Definition 1 in the next section. We restrict our attention to the case $n \ge 5$, where the nonlinearity is supercritical. In low dimensions $1 \le n \le 4$ the problem is subcritical and has a different behavior; see Remark 14 at the end of the following section.

Many techniques, familiar from second order equations like the maximum principle, are not available here. But since we restrict ourselves to the ball, at least a comparison principle is available; see Lemma 16 below. Moreover, in fourth order equations, one usually does not succeed in finding suitable nontrivial auxiliary functions satisfying again a differential inequality. This is a serious difficulty in proving Theorem 3 (cf. the proof of [BCMR, Theorem 3]), and it is overcome by carefully exploiting the properties of the exponential nonlinearity and the construction of minimal solutions, based upon the already mentioned comparison principle. Finally, when looking for radial solutions, one may perform a phase space analysis for the corresponding system of ODEs. Here, the phase space is no longer two-dimensional, where the topology is relatively simple and the Poincaré–Bendixson theory is available, but we have to work in a four-dimensional phase space. Some of the resulting difficulties could be overcome only with computer assistance.

This paper is organized as follows: In the next section we state some definitions and the main results contained in this work (see Theorems 3, 4, 6, 7, and 12 below). The content of sections 3 through 7 is devoted to the proofs of these theorems. Section 8 contains some results on the stability of regular solutions of (P_λ) and a list

of open problems that we consider of some interest and related to the main results of this paper. Finally, in section 9 we describe the algorithm used in the *computer assisted proof* of Theorem 7.

2. Main results. We first make precise in which sense we intend a function to solve (P_λ). For this purpose, we fix some exponent p with $p > \frac{n}{4}$ and $p \geq 2$. The definitions and results below do not depend on the special choice of p.

DEFINITION 1. *We say that $u \in L^2(B)$ is a* solution *of (P_λ) if $e^u \in L^1(B)$ and*

$$\int_B u\Delta^2 v = \lambda \int_B e^u v \qquad \text{for all } v \in W^{4,p} \cap H_0^2(B). \tag{2}$$

We say that a solution u of (P_λ) is regular *(resp.,* singular*) if $u \in L^\infty(B)$ (resp., $u \notin L^\infty(B)$).*

Clearly, according to this definition, regular and singular solutions exhaust all possible solutions. Note that by standard regularity theory for the biharmonic operator (see [ADN]), any regular solution u of (P_λ) satisfies $u \in C^\infty(\overline{B})$. Note also that by the positivity preserving property of Δ^2 in the ball [B] any solution of (P_λ) is positive; see also Lemmas 16 and 18 below for a generalized statement. This property is known to fail in general domains. For this reason, we restrict ourselves to balls also in Theorems 3 and 4; cf. also Open Problem 8 in section 8.

We also need the notion of minimal solution, as follows.

DEFINITION 2. *We call a solution U_λ of (P_λ)* minimal *if $U_\lambda \leq u_\lambda$ a.e. in B for any further solution u_λ of (P_λ).*

In order to state our results, we denote by $\lambda_1 > 0$ the first eigenvalue for the biharmonic operator with Dirichlet boundary conditions

$$\begin{cases} \Delta^2 u = \lambda_1 u & \text{in } B, \\ u = \dfrac{\partial u}{\partial \mathbf{n}} = 0 & \text{on } \partial B; \end{cases} \tag{3}$$

it is known from the mentioned positivity preserving property and Jentzsch's (or Krein–Rutman's) theorem that λ_1 is isolated and simple and that the corresponding eigenfunctions do not change sign.

We may now state the following theorem.

THEOREM 3. *There exists*

$$\lambda^* \in \left[14.72(n-1)(n-3), \frac{\lambda_1}{e}\right)$$

such that the following hold:

(i) *(P_λ) admits a minimal regular solution U_λ for all $\lambda < \lambda^*$ and no solutions if $\lambda > \lambda^*$.*

(ii) *The map $\lambda \mapsto U_\lambda(x)$ is strictly increasing for all $x \in B$. Moreover, there exists a solution U_* of (P_{λ^*}) which is the pointwise limit of U_λ as $\lambda \uparrow \lambda^*$.*

(iii) *$U_\lambda \to U_*$ in the norm topology of $H_0^2(B)$ as $\lambda \uparrow \lambda^*$.*

(iv) *The extremal solution U_* and all the minimal solutions U_λ (for $\lambda < \lambda^*$) are radially symmetric and radially decreasing.*

It is remarkable that at λ^* there is an immediate switch from existence of *regular* minimal solutions to nonexistence of *any* (even singular) solution. The only possibly singular minimal solution corresponds to $\lambda = \lambda^*$. This result is known from [BCMR] for the second order problem (1), but the *method* used there may not be carried over

to fourth order problems. Nevertheless, the *result* extends to the biharmonic case. The proof is given in Lemma 20 below.

We may also characterize the uniform convergence to 0 of U_λ as $\lambda \to 0$ by giving the precise rate of its extinction.

THEOREM 4. *For all $\lambda \in (0, \lambda^*)$ let U_λ be the minimal solution of (P_λ) and let*

$$V_\lambda(x) = \frac{\lambda}{8n(n+2)} \left[1 - |x|^2\right]^2.$$

Then $U_\lambda(x) > V_\lambda(x)$ for all $\lambda < \lambda^*$ and all $|x| < 1$, and

$$\lim_{\lambda \to 0} \frac{U_\lambda(x)}{V_\lambda(x)} = 1 \qquad \textit{uniformly with respect to } x \in B.$$

A complete result in the spirit of Gidas, Ni, and Nirenberg [GNN] does not hold for fourth order equations under Dirichlet boundary conditions. It has been recently proved by Sweers in [Sw] that for general semilinear autonomous biharmonic equations in a ball under Dirichlet boundary conditions, we may have positive radially symmetric solutions which are not radially decreasing, provided the right-hand side is *not* positive everywhere. This phenomenon may not occur in our situation; however, it is not known whether any smooth solution of (P_λ) is radially symmetric. Moreover, also in the second order case it is not known whether singular solutions are always radially symmetric. Nevertheless, Theorem 3 suggests that we pay particular attention to radially symmetric solutions. In this context, we put $r = |x|$ and consider the functions $u = u(r)$.

First of all, in the following definition we introduce a new notion of solution which seems to be the natural framework for radially symmetric solutions.

DEFINITION 5. *We say that a radial singular solution $u = u(r)$ of (P_λ) is* weakly singular *if the limit $\lim_{r \to 0} r u'(r)$ exists.*

We do not know whether every singular solution is also weakly singular. In the second order case, Joseph and Lundgren [JL] reduce (1) to a system of two ODEs and study its phase portrait in $\mathbb{R}^2$; using Bendixson's theorem, they show that singular solutions are also weakly singular. For the fourth order equation (P_λ) a similar argument should be carried out in $\mathbb{R}^4$ (see section 3) where a general result of Bendixson's type does not hold. Therefore, the equivalence between singular and weakly singular solutions seems out of reach in our context; see Open Problem 5 in section 8.

If we seek radially symmetric solutions, we rewrite problem (P_λ) as $(0 < r \le 1)$

$$(4) \qquad \begin{cases} \dfrac{d^4u}{dr^4} + \dfrac{2(n-1)}{r}\dfrac{d^3u}{dr^3} + \dfrac{(n-1)(n-3)}{r^2}\dfrac{d^2u}{dr^2} - \dfrac{(n-1)(n-3)}{r^3}\dfrac{du}{dr} = \lambda e^{u(r)}, \\ u(1) = 0, \\ \dfrac{du}{dr}\,|_{r=1} = 0. \end{cases}$$

In [GPP, JL, MP2] the second order equation (1) was reduced to a system of two autonomous ODEs. Here, we reduce (4) to a system of four equations. First, we make the change of variables

$$(5) \qquad s = \log r, \qquad v(s) = u(e^s), \qquad s \in (-\infty, 0]$$

so that (4) becomes

$$\begin{cases} \dfrac{d^4v}{ds^4} + 2(n-4)\dfrac{d^3v}{ds^3} + (n^2-10n+20)\dfrac{d^2v}{ds^2} - 2(n-2)(n-4)\dfrac{dv}{ds} = \lambda e^{4s+v(s)}, \\ v(0) = 0, \\ \dfrac{dv}{ds}\,|_{s=0} = 0; \end{cases} \tag{6}$$

then we set

$$\begin{cases} v_1(s) = v'(s) + 4, \\ v_2(s) = -v''(s) - (n-2)v'(s), \\ v_3(s) = -v'''(s) + (4-n)v''(s) + 2(n-2)v'(s), \\ v_4(s) = -\lambda e^{v(s)+4s}. \end{cases} \tag{7}$$

Finally, we obtain the following (nonlinear) differential system:

$$\begin{cases} v_1'(s) = (2-n)v_1(s) - v_2(s) + 4(n-2), \\ v_2'(s) = 2v_2(s) + v_3(s), \\ v_3'(s) = (4-n)v_3(s) + v_4(s), \\ v_4'(s) = v_1(s)v_4(s) \end{cases} \tag{8}$$

with initial conditions

$$v_1(0) = 4, \qquad v_4(0) = -\lambda. \tag{9}$$

It turns out that (8) admits only the two stationary points $P_1 = (4,0,0,0)$ and $P_2 = (0, 4n-8, 16-8n, -8(n-2)(n-4))$; see section 3.1. Then, in section 3.2, we prove the following result.

THEOREM 6. *Let $u = u(r)$ be a radial solution of (P_λ) and let*

$$V(s) = (v_1(s), v_2(s), v_3(s), v_4(s))$$

be the corresponding trajectory relative to (8). *Then*

(i) *u is regular (i.e. $u \in L^\infty(B)$) if and only if*

$$\lim_{s\to-\infty} V(s) = P_1;$$

(ii) *u is weakly singular if and only if*

$$\lim_{s\to-\infty} V(s) = P_2.$$

Our following results concern the *existence* of weakly singular solutions and a lower bound $\lambda^*_{\min}$ on the value of λ^*. For all $n = 5, \dots, 16$ we prove the existence of λ_σ such that (P_{λ_σ}) admits a weakly singular solution; we provide a lower and upper bound on the value of λ_σ. For all $n = 5, \dots, 16$ let $\lambda_\sigma^{\min}$ and $\lambda_\sigma^{\max}$ be as given in Table 1, and for all $n = 5, \dots, 10$ let $\lambda^*_{\min}$ be as given in Table 1.

THEOREM 7. *For all $n = 5, \dots, 16$ there exists $\lambda_\sigma \in [\lambda_\sigma^{\min}, \lambda_\sigma^{\max}]$ such that (P_{λ_σ}) admits a weakly singular solution U_σ. In particular, $\lambda_\sigma > 8(n-2)(n-4)$.*

For all $n = 5, \dots, 10$ the value of λ^* is larger than $\lambda^*_{\min}$.

In section 6 we use Theorem 6 to show that Theorem 7 is equivalent to some intersection properties of the unstable manifolds of P_1 and P_2 with the hyperplane

TABLE 1

n	λ_σ	λ^*	$\lambda_\sigma^{\min}$	$\lambda_\sigma^{\max}$	$\lambda_{\min}^*$

$v_1 = 4$. The remaining part of the proof of Theorem 7 is divided into two parts. First, in section 6 a rigorous bound on the location of the unstable manifold close to the stationary point is obtained by analytical methods. Then the intersection of the manifold with the hyperplane and its location are proved by a computer assisted algorithm; see section 9. The following definition explains exactly what we mean by a computer assisted proof.

DEFINITION 8. *A proof is called* computer assisted *if it consists in finitely many elementary operations, but their number is so large that, although each step may be written down explicitly, it is only practical to perform such operations with a computer.*

We believe that a weakly singular solution exists in any dimension $n \geq 5$, but since our type of proof requires a finite number of steps for each value of n, we cannot prove this conjecture. We performed the computer assisted proof for $n = 5, \ldots, 16$ because the "interesting" phenomena of (P_λ) arise in these dimensions.

We expect the "singular parameter" λ_σ and the singular solution to be unique. However, also for this statement, we do not yet have a proof. See Open Problem 3 in section 8 below.

Table 1 summarizes our results: λ^* and λ_σ are the best, purely numerical, estimates for the values, up to two decimal places, while the numbers $\lambda_\sigma^{\min}$, $\lambda_\sigma^{\max}$, and $\lambda_{\min}^*$ are rigorously computed values as stated in Theorem 7.

Remark 9. We point out that both the approximate numerical computation and the computation with rigorous estimate on the error for λ^* become very difficult as n increases. For this reason the best rigorous estimate we have on $\lambda_{\min}^*$ for $n \geq 11$ is nothing but for $\lambda_\sigma^{\min}$, while the best numerical estimate we have on λ^* for $n \geq 13$ is λ_σ. These values of n may be improved with a more accurate algorithm, but we do not feel that this would lead to a qualitative improvement of the result.

From Table 1 we immediately get the following.

COROLLARY 10. *For all $n = 5, \ldots, 10$ we have $\lambda_\sigma < \lambda^*$.*

Remark 11. We have numerical evidence that $\lambda_\sigma < \lambda^*$ for $n = 11, 12$ as well, but $\lambda^* - \lambda_\sigma$ is much smaller than the rigorous estimate of the numerical error, and thus we do not have a proof. For $n \geq 13$ the values of λ_σ and λ^* are closer than the numerical error; therefore we cannot even provide a conjecture supported by numerical evidence. If one could show uniqueness of the singular parameter λ_σ and that in fact $\lambda_\sigma < \lambda^*$ in dimensions $n \leq 12$, one could conclude that here the extremal solution U_* is either regular or "strongly singular" (i.e., $\lim_{r \to 0} ru'(r)$ does not exist). For $n \geq 13$ we expect the extremal solution U_* to be weakly singular. See Open Problems 3, 4, and 5 in section 8.

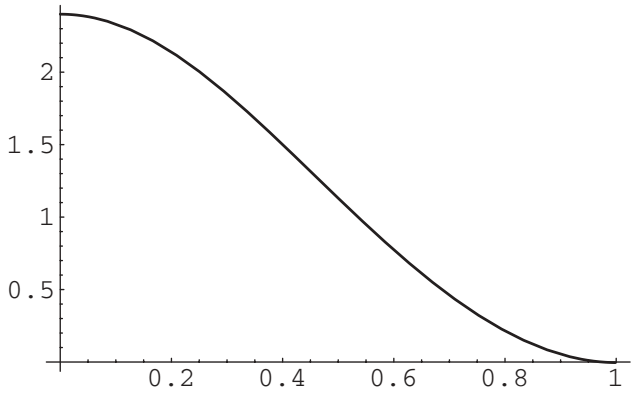

FIG. 1.

To complete the numerical inspection of the problem, we provide Figure 1, which shows the (regular) solution for $n = 5$ and $\lambda = \lambda^*$.

Theorem 6 states that any weakly singular solution $u = u(r)$ of (4) corresponds to a (weakly singular) solution $v = v(s)$ of (6) which satisfies $v(s) \approx -4s$ as $s \to -\infty$: this is because $\overline{v}(s) = -4s$ is precisely the stationary point P_2. Hence, as a further consequence of Theorem 6, we have that any weakly singular solution U_σ behaves asymptotically like $-4 \log r$ as $r \to 0$. Moreover, as may be checked by a simple calculation, the function $r \mapsto -4 \log r$ solves the equation and the first boundary condition in (P_λ) for $\lambda = 8(n-2)(n-4)$ but *not* the second boundary condition (recall also $\lambda_\sigma > 8(n-2)(n-4)$ by Theorem 7). Contrary to what happens for the second order equation (1), the explicit form of the radial weakly singular solution does not seem simple to be determined; see also Proposition 34 below. To this end, we characterize it further by means of the following theorem.

THEOREM 12. *Let U_σ be a weakly singular solution with $\lambda_\sigma > 8(n-2)(n-4)$ as it is obtained in Theorem 7 for $5 \le n \le 16$. Then*

$$U_\sigma(r) = -4 \log r + W(r),$$

where W is a bounded function satisfying

$$\lim_{r \to 0} W(r) = W_0 := \log \frac{8(n-2)(n-4)}{\lambda_\sigma} < 0$$

and (at least) one of the two following facts holds true:

(i) *$W(r) - W_0$ changes sign infinitely many times in any neighborhood of $r = 0$.*

(ii) *$W(r) \ge \max[W_0, 2r^2 - 2]$ for all $r \in (0, 1]$.*

If $n \ge 13$, case (ii) *necessarily occurs.*

Finally, the function $W(r)$ is not analytic, i.e., not a convergent power series in r^2 close to $r_0 = 0$.

Remark 13. It is quite surprising that the asymptotic behavior of weakly singular solutions of (P_λ) is the same as that of the quasi-linear equation $-\Delta_4 u = \lambda e^u$; see [GPP]. Here $-\Delta_p$ denotes the p-Laplace operator.

We conclude this section with a short remark concerning the behavior of (P_λ) in low dimensions.

Remark 14. In dimensions $1 \le n \le 4$ the problem is subcritical and has a different behavior. In particular, there are no singular solutions.

The minimal solution is constructed as in the present paper. There is a parameter $\lambda^* > 0$ such that for any $\lambda \in (0, \lambda^*)$ there is precisely one minimal stable positive solution. Taking this one as a "trivial" solution, with the help of variational techniques (which apply only in a subcritical setting) one finds a second positive "large" solution above the minimal solution and unstable. For $\lambda > \lambda^*$ there is no positive solution. Concerning the bifurcation diagram, one expects a smooth branch emanating from 0, extending until λ^*, where it bends back and approaches $\lambda = 0$, while the L^∞ norm of the solutions blows up. See also [We, Wi].

3. Characterization of regular and weakly singular radial solutions. In this section we perform a phase space analysis for the system (8), which corresponds to the radial version of (P_λ). This gives some insight into which behavior of regular and of weakly singular radial solutions may be expected in dependence on the space dimension. These results are essential for the proofs of Theorems 7 and 12. For the proofs of Theorems 3 and 4 one may skip directly to sections 4 and 5.

3.1. Analysis of the stationary points. It is easy to verify that system (8) has only two stationary points:

$$P_1 = (4, 0, 0, 0) \qquad \text{and} \qquad P_2 = (0, 4n - 8, 16 - 8n, -8(n-2)(n-4)).$$

In order to linearize (8) in a neighborhood of P_1, we must just replace $(8)_4$ with

$$v_4'(s) = 4v_4(s).$$

Then the linearized system has two distinct positive eigenvalues, $\mu_1 = 2$, $\mu_2 = 4$, and two distinct negative ones, $\mu_3 = 2 - n$, $\mu_4 = 4 - n$. We conclude that P_1 is a hyperbolic point independently of the dimension.

Eigenvectors corresponding to the positive eigenvalues μ_1, μ_2 in the neighborhood of P_1 have the form

$$\alpha_1(1, -n, 0, 0) \quad \text{and} \quad \alpha_2(-1, n + 2, 2n + 4, 2n^2 + 4n),$$

where $\alpha_1, \alpha_2 \in \mathbb{R} \setminus \{0\}$. Therefore, the tangent hyperplane to the unstable manifold of P_1 consists of those points in $\mathbb{R}^4$ whose coordinates can be represented as

$$(\alpha_1 - \alpha_2, -n\alpha_1 + (n+2)\alpha_2, (2n+4)\alpha_2, (2n^2+4n)\alpha_2) \tag{10}$$

with $\alpha_1, \alpha_2 \in \mathbb{R}$.

Similarly, the tangent hyperplane to the stable manifold of P_1 is spanned by eigenvectors corresponding to negative eigenvalues of the linearized system, that is,

$$\alpha_3(1, 0, 0, 0) \quad \text{and} \quad \alpha_4(1, -2, 2n - 4, 0),$$

where $\alpha_3, \alpha_4 \in \mathbb{R} \setminus \{0\}$.

Now consider the second critical point P_2 of (8). In its neighborhood the linear approximation of $(8)_4$ (the only nonlinear equation) takes the form

$$v_4'(s) = -8(n-2)(n-4)v_1(s).$$

Therefore, the eigenvalues of the linearized system in the neighborhood of P_2 are the solutions of the fourth order algebraic equation

$$\nu(\nu - 2)(\nu + n - 2)(\nu + n - 4) - 8(n-2)(n-4) = 0;$$

hence,

$$\nu_{1,2,3,4} = \frac{1}{2}\left(4 - n \pm \sqrt{M_1(n) \pm M_2(n)}\right),$$

where $M_1(n) = n^2 - 4n + 8 = (n-2)^2 + 4 > (n-2)^2$ and $M_2(n) = 4\sqrt{68 - 52n + 9n^2}$. Therefore,

$$\nu_1 = \frac{1}{2}\left(4 - n + \sqrt{M_1(n) + M_2(n)}\right) \qquad \text{and} \qquad \nu_2 = \frac{1}{2}\left(4 - n - \sqrt{M_1(n) + M_2(n)}\right)$$

are real numbers. It is easy to see that

$$\nu_2 < 0 < \nu_1 \qquad \text{for all } n \geq 4.$$

Moreover, for $5 \leq n \leq 12$, we have $M_1(n) - M_2(n) < 0$, while for $n \geq 13$ there holds $M_1(n) - M_2(n) > 0$. Therefore, for $5 \leq n \leq 12$ the eigenvalues

$$\nu_3 = \frac{1}{2}\left(4 - n + \sqrt{M_1(n) - M_2(n)}\right) \qquad \text{and} \qquad \nu_4 = \frac{1}{2}\left(4 - n - \sqrt{M_1(n) - M_2(n)}\right)$$

are complex conjugate with the real part

$$\text{Re } \nu_3 = \text{ Re } \nu_4 = \frac{1}{2}(4 - n) < 0,$$

while for $n \geq 13$ both ν_3 and ν_4 are real, $\nu_3 < 0$ and $\nu_4 < 0$.

This analysis implies that for all $n \geq 5$ the critical point P_2 of system (8) is also hyperbolic, but its stable manifold is three-dimensional and the unstable manifold is one-dimensional. Moreover, taking into account that for $5 \leq n \leq 12$ we have $\text{Im}\nu_3 = -\text{Im}\nu_4 \neq 0$, we deduce from the general theory of critical points (see, for example, [A2]) that for these values of n (and only for them) trajectories in the stable manifold of P_2 locally have the form of a spiral.

3.2. Proof of Theorem 6. We first consider regular solutions. It will prove to be useful to have the following meaning of $v_1, \ldots, v_4$ in terms of derivatives of u in mind:

$$\begin{cases} v_1(s) = e^s\, u'\,(e^s) + 4, \\ v_2(s) = -e^{2s} \cdot \Delta u\,(e^s)\,, \\ v_3(s) = -e^{3s}\,(\Delta u)'\,(e^s)\,, \\ v_4(s) = -\lambda e^{4s} e^{u(e^s)}. \end{cases} \tag{11}$$

If u is a regular solution of (P_λ), then $u, u', \Delta u$, and $(\Delta u)'$ stay bounded in particular for $r \searrow 0$, i.e., for $s \to -\infty$. So, we get immediately from (11) the first part of the statement.

To prove the converse, assume that

$$\lim_{s \to -\infty} (v_1(s), v_2(s), v_3(s), v_4(s)) = P_1$$

so that

$$\lim_{r \searrow 0} ru'(r) = \lim_{r \searrow 0} r^2 \Delta u(r) = \lim_{r \searrow 0} r^3 (\Delta u)'(r) = \lim_{r \searrow 0} r^4 e^{u(r)} = 0. \tag{12}$$

The first limit yields particularly, that for $r > 0$ small enough,

$$u(r) \le -\frac{1}{2}\log(r), \qquad e^{u(r)} \le r^{-1/2}.$$

Using the differential equation (P_λ) and the growth conditions (12) (observe $n > 4$), we obtain successively for r close to 0

$$(\Delta u)'(r) = O(r^{1/2}), \quad \Delta u(r) = O(1), \quad u'(r) = O(r), \quad u(r) = O(1).$$

That means that u is regular.

Next, we characterize weakly singular solutions. All the limits are intended as $s \to -\infty$; with c we denote generic constants.

Note first that if $\lim V(s) = P_2$, then the solution is weakly singular.

In order to prove the converse, we claim that

$$v'(s) \to -4. \tag{13}$$

To this end, we exclude all the other cases; recall that $\lim v'(s)$ exists by definition of weakly critical solutions.

(A) It cannot be that $\lim v'(s) = c \in (-\infty, -4)$.

For contradiction, if $\lim v'(s) = c < -4$, then by $(7)_1$ we infer

$$\lim v_1(s) = c + 4 < 0, \tag{14}$$

and by $(7)_4$ we get

$$v_4(s) \to -\infty. \tag{15}$$

Write $(8)_3$ as

$$\frac{d}{ds}[e^{(n-4)s}v_3(s)] = e^{(n-4)s}v_4(s)$$

so that by (15) we infer that the map $s \mapsto e^{(n-4)s}v_3(s)$ is decreasing in a neighborhood of $-\infty$, and therefore it admits a limit. If $e^{(n-4)s}v_3(s) \to c \ge 0$, then by $(8)_3$ and (15) we get $v_3'(s) \to -\infty$ and hence $v_3(s) \to +\infty$. If $e^{(n-4)s}v_3(s) \to c < 0$, then $v_3(s) \to -\infty$. In any case we obtain

$$|v_3(s)| \to +\infty. \tag{16}$$

A completely similar (but slightly more involved) argument shows that $(8)_2$ and (16) entail

$$|v_2(s)| \to +\infty. \tag{17}$$

Finally, $(8)_1$, (14), and (17) furnish $|v_1'(s)| \to +\infty$, which contradicts (14).

(B) It cannot be that $v'(s) \to -\infty$.

For contradiction, assume that $v'(s) \to -\infty$: then by $(7)_1$ we have

$$v_1(s) \to -\infty, \tag{18}$$

and by $(7)_4$ we get

$$v_4(s) \to -\infty; \tag{19}$$

moreover,

$$\frac{v(s)}{s} \to -\infty. \tag{20}$$

We may rewrite $(8)_3$ as

$$\frac{d}{ds}[e^{(n-4)s}v_3(s)] = e^{(n-4)s}v_4(s) = -\lambda e^{ns+v(s)} \to -\infty,$$

where the second equality is just $(7)_4$ and the infinite limit is a consequence of (20): the previous limit yields $e^{(n-4)s}v_3(s) \to +\infty$ and, in turn,

$$v_3(s) \to +\infty. \tag{21}$$

Similarly, we may rewrite $(8)_2$ as

$$\frac{d}{ds}[e^{-2s}v_2(s)] = e^{-2s}v_3(s) \to +\infty,$$

where the infinite limit is a consequence of (21): hence, we deduce that $e^{-2s}v_2(s) \to -\infty$, which, together with $(8)_2$ and (21), shows that $v_2(s) \to -\infty$. Inserting this into $(7)_2$ gives $v''(s)+(n-2)v'(s) \to +\infty$, and therefore $v'(s)+(n-2)v(s) \to -\infty$: hence,

$$\text{there exists } \sigma < 0 \quad \text{such that} \quad v'(s) + (n-2)v(s) < 0 \qquad \text{for all } s \le \sigma.$$

We rewrite this inequality as

$$\frac{d}{ds}[e^{(n-2)s}v(s)] < 0 \qquad \text{for all } s \le \sigma;$$

integrating it over $[s, \sigma]$ and taking into account that $v(\sigma) > 0$, we infer that

$$\text{there exists } K > 0 \quad \text{such that } v(s) \ge Ke^{(2-n)s} \qquad \text{for all } s \le \sigma.$$

Using (5) and returning to the function u (solution of (P_λ) and (4)), this shows that

$$\text{there exists } K > 0 \quad \text{such that } u(r) \ge \frac{K}{r^{n-2}} \qquad \text{for all } r \le e^\sigma;$$

this contradicts $e^u \in L^1(B)$.

(C) It cannot be that $\lim v'(s) = c \in (-4, 0]$.

For contradiction, if $\lim v'(s) = c \in (-4, 0]$, then by $(7)_1$ we infer

$$\lim v_1(s) = c + 4 > 0, \tag{22}$$

and by $(7)_4$ we get

$$v_4(s) \to 0. \tag{23}$$

Then from $(8)_3$ we deduce

$$v_3(s) \to 0, \tag{24}$$

because otherwise we would get a contradiction similar to that of case (A). Next, from $(8)_2$ and (24) we obtain

$$v_2(s) \to 0. \tag{25}$$

Since, by assumption, v_1 has a limit, we deduce that necessarily $v_1(s) \to 4$. This, together with (23), (24), and (25), contradicts part (i) proved above.

By (A), (B), (C), statement (13) is proved. This shows that $v_1(s) \to 0$: inserting this into $(8)_1$ gives $v_2(s) \to 4(n-2)$. Inserting the latter into $(8)_2$ yields $v_3(s) \to -8(n-2)$; finally, inserting this into $(8)_3$ gives $v_4(s) \to -8(n-2)(n-4)$. This completes the proof of (ii). □

Remark 15. If in case (ii) of Theorem 6 we do not assume that $\lim v'(s)$ exists, then we can merely show that $\liminf v'(s) \le -4 \le \limsup v'(s)$. Clearly, if one could prove that both inequalities are in fact equalities, then we would again have (13).

4. Proof of Theorem 3. We denote by $\mathcal{K}$ the cone of nonnegative L^2-functions in B,

$$\mathcal{K} = \{u \in L^2(B);\ u(x) \ge 0 \text{ for almost every } \ x \in B\},$$

and (for the sake of completeness) we prove the following weak formulation of Boggio's positivity preserving property [B], which we extensively use.

LEMMA 16. *Assume that $u \in L^2(B)$ satisfies*

$$\int_B u\Delta^2 v \ge 0 \qquad \textit{for all } v \in \mathcal{K} \cap H^4 \cap H_0^2(B);$$

then $u \in \mathcal{K}$. Moreover, one has either $u \equiv 0$ or $u > 0$ a.e. in B.

Proof. (i) Take any $\varphi \in \mathcal{K} \cap C_c^\infty(B)$ and let v_φ be the unique (classical) solution of

$$\begin{cases} \Delta^2 v_\varphi = \varphi & \text{in } B, \\ v_\varphi = \frac{\partial v_\varphi}{\partial \mathbf{n}} = 0 & \text{on } \partial B. \end{cases}$$

Then, by the classical Boggio principle [B], we infer that $v_\varphi \in \mathcal{K}$. Hence, v_φ is a possible test function for all φ so chosen, and therefore

$$\int_B u\varphi = \int_B u\Delta^2 v_\varphi \ge 0 \qquad \text{for all } \varphi \in \mathcal{K} \cap C_c^\infty(B).$$

This shows that $u \in \mathcal{K}$.

(ii) By (i) we know that $u \in \mathcal{K}$. So, assume that $u \not> 0$ a.e. in B and let ϕ denote the characteristic function of the set $\{x \in B;\ u(x) = 0\}$ so that $\phi \ge 0$, $\phi \not\equiv 0$. Let v_0 be the unique (a.e.) solution of the problem

$$\begin{cases} \Delta^2 v_0 = \phi & \text{in } B, \\ v_0 = \frac{\partial v_0}{\partial \mathbf{n}} = 0 & \text{on } \partial B. \end{cases}$$

Then

$$v_0 \in \left(\bigcap_{q \ge 1} W^{4,q}(B) \right) \subset C^3(\overline{B})$$

and by Boggio's principle [B] we have $v_0 > 0$ in B. By the biharmonic analogue of Hopf's lemma in balls (see [GS, Theorem 3.2], which also holds if $\Delta^2 v_0 \in L^p(B)$ for some $p > n/2$), we necessarily have $\Delta v_0 > 0$ on ∂B. This last inequality allows us to

state that for all $v \in C^4(\overline{B}) \cap H_0^2(B)$ there exists $t_1 \le 0 \le t_0$ such that $v + t_0 v_0 \ge 0$ and $v + t_1 v_0 \le 0$ in B. This, combined with the fact that

$$\int_B u\Delta^2 v_0 = \int_{\{u=0\}} u = 0,$$

enables us to show that both

$$0 \le \int_B u\Delta^2(v + t_0 v_0) = \int_B u\Delta^2 v \qquad \text{and} \qquad 0 \ge \int_B u\Delta^2(v + t_1 v_0) = \int_B u\Delta^2 v.$$

Hence, we have for all $v \in C^4(\overline{B}) \cap H_0^2(B)$

$$\int_B u\Delta^2 v = 0.$$

We need to show that $C^4(\overline{B}) \cap H_0^2(B)$ is dense in $H^4 \cap H_0^2(B)$. For this purpose, take any function $U \in H^4(B) \cap H_0^2(B)$ and put $f := \Delta^2 U$. We approximate f in $L^2(B)$ by $C^\infty(\overline{B})$-functions f_k and solve $\Delta^2 U_k = f_k$ in B under homogeneous Dirichlet boundary conditions. We then even have $U_k \in C^\infty(\overline{B})$, and by L^2-theory there holds $\|U_k - U\|_{H^4(B)} \to 0$ as $k \to \infty$.

By the previous statement we may now conclude that

$$\text{for all } v \in H^4 \cap H_0^2(B): \qquad \int_B u\Delta^2 v = 0.$$

Since $u \in L^2(\Omega)$, we may take as $v \in H^4 \cap H_0^2(B)$ the solution of $\Delta^2 v = u$ under homogeneous Dirichlet boundary conditions. This finally yields $u \equiv 0$. □

In particular, thanks to Lemma 16 we may establish a result in the spirit of [BCMR], as follows.

LEMMA 17. *For all $f \in L^1(B)$ such that $f \ge 0$ a.e. in B there exists a unique $u \in L^1(B)$ such that $u \ge 0$ a.e. in B and which satisfies*

$$\int_B u\Delta^2 v = \int_B fv \qquad \textit{for all } v \in C^4(\overline{B}) \cap H_0^2(B);$$

moreover, there exists $C > 0$ (independent of f) such that $\|u\|_1 \le C\|f\|_1$.

Proof. Uniqueness follows by means of the observation that L^∞-functions may be approximated by a pointwise convergent but uniformly bounded sequence of $C_c^\infty(B)$-functions. This is applied to truncations of u, and suitable test functions v are obtained from approximations of the truncations of u by solving the biharmonic Dirichlet problems.

Existence follows by truncating f and by arguing as in the proof of [BCMR, Lemma 1], the only difference being the positivity preserving property, which is standard for the Laplacian; in our case we invoke Lemma 16. □

Combining the method of proof of Lemmas 16 and 17, one also has the following.

LEMMA 18. *Assume that $u \in L^1(B)$ satisfies*

$$\int_B u\,\Delta^2 v\,dx \ge 0 \qquad \textit{for all } v \in \mathcal{K} \cap C^4(\overline{B}) \cap H_0^2(B);$$

then $u \ge 0$ a.e. in B.

As was pointed out to us by Anna Dall'Acqua (TU Delft), similar techniques and the application of Weierstraß's approximation theorem yield that also for the stronger conclusion of Lemma 16 it is enough to require $u \in L^1(B)$.

The previous lemmas enable us to make use of the super-subsolutions method, as follows.

LEMMA 19. *Let $\lambda > 0$ and assume that there exists $\bar{u} \in \mathcal{K}$ such that $e^{\bar{u}} \in L^1(B)$ and*

$$\int_B \bar{u}\Delta^2 v \geq \lambda \int_B e^{\bar{u}} v \qquad \text{for all } v \in \mathcal{K} \cap W^{4,p} \cap H_0^2(B).$$

Then there exists a solution u of (P_λ) such that $0 \leq u \leq \bar{u}$ a.e. in B.

Proof. Let $u_0 = \bar{u}$, and for all $m \in \mathbb{N}$, define inductively the function u_{m+1} as the unique solution of

$$\int_B u_{m+1}\Delta^2 v = \lambda \int_B e^{u_m} v \qquad \text{for all } v \in W^{4,p} \cap H_0^2(B). \tag{26}$$

Note that by Lemmas 16 to 18 the sequence $\{u_m\}$ is well-defined and

$$u_m \in \mathcal{K}, \quad e^{u_m} \in L^1(B), \quad 0 \leq u_{m+1}(x) \leq u_m(x) \text{ for almost every } x \in B \text{ for all } m \in \mathbb{N}.$$

Since this sequence is pointwise decreasing, there exists $u \in \mathcal{K}$ such that $e^u \in L^1(B)$ and which is the pointwise limit of $\{u_m\}$. Then, letting $m \to \infty$ in (26) and applying Lebesgue's theorem, we obtain the result. ∎

Define $\Lambda := \{\lambda \geq 0;\ (P_\lambda) \text{ admits a solution}\}$ and

$$\lambda^* := \sup \Lambda;$$

clearly $0 \in \Lambda$ and so $\Lambda \neq \emptyset$. Moreover, by the implicit function theorem we know that $\lambda^* > 0$. It follows directly from Lemma 19 that Λ is an interval.

Let $\lambda \in \Lambda$; then there exists u_λ satisfying (2). Taking into account that $e^s \geq es$ for all $s \geq 0$ with strict inequality whenever $s \neq 1$, and choosing $v = \phi_1$ (the normalized positive first eigenfunction of (3)) as a test function in (2), we get

$$\lambda_1 \int_B u_\lambda \phi_1 = \int_B u_\lambda \Delta^2 \phi_1 = \lambda \int_B e^{u_\lambda} \phi_1 > \lambda e \int_B u_\lambda \phi_1,$$

which proves that

$$\lambda < \frac{\lambda_1}{e} \qquad \text{for all } \lambda \in \Lambda. \tag{27}$$

We now prove the most delicate part of Theorem 3, namely, that for any $\lambda < \lambda^*$, there exists a *regular* solution.

LEMMA 20. *Assume that for some $\mu > 0$ there exists a (possibly singular) solution u_0 of (P_μ). Then for all $0 < \lambda < \mu$ there exists a regular solution of (P_λ).*

Proof. Let $0 < \lambda < \mu$ and consider the (unique) functions $u_1, u_2 \in L^1(B)$ satisfying, respectively,

$$\int_B u_1 \Delta^2 v = \lambda \int_B e^{u_0} v \qquad \text{for all } v \in W^{4,p} \cap H_0^2(B),$$

$$\int_B u_2 \Delta^2 v = \lambda \int_B e^{u_1} v \qquad \text{for all } v \in W^{4,p} \cap H_0^2(B). \tag{28}$$

Such functions exist by Lemma 17 and also belong to $L^2(B)$, since by Lemma 18 we have

$$u_0 > \frac{\lambda}{\mu} u_0 = u_1 \geq u_2 \qquad \text{almost everywhere in } B. \tag{29}$$

Let $\varphi(x) = (1 - |x|^2)^2$; it is readily verified that

$$\varphi \in H_0^2(B), \qquad \Delta^2 \varphi = 8n(n+2). \tag{30}$$

We also need the following elementary statement:

$$\begin{aligned} &\text{for all } \vartheta > 1 \text{ and } \delta > 0 \text{ there exists } \gamma > 0 \\ &\text{such that } e^{\vartheta s} + \gamma - (1+\delta)e^s \geq 0 \text{ for all } s \geq 0. \end{aligned} \tag{31}$$

Take $\vartheta = \mu/\lambda$, $\delta = n\lambda/4\mu$ and choose $k > 0$ in such a way that

$$e^{\frac{\mu}{\lambda} s} + \frac{8n(n+2)}{\lambda} k \geq (1+\delta)e^s \quad \text{for all } s \geq 0; \tag{32}$$

this choice is clearly allowed by (31). Thanks to (30) and (32) we find

$$\begin{aligned} \int_B (u_1 + k\varphi)\Delta^2 v = \int_B [\lambda e^{u_0} + 8n(n+2)k]v = \int_B [\lambda e^{\frac{\mu}{\lambda} u_1} + 8n(n+2)k]v \\ \geq \lambda(1+\delta) \int_B e^{u_1} v = (1+\delta) \int_B u_2 \Delta^2 v \\ \text{for all } v \in \mathcal{K} \cap W^{4,p} \cap H_0^2(B). \end{aligned}$$

Hence, by Lemma 16 we infer that $u_2 \leq \frac{u_1 + k\varphi}{1+\delta}$ in B; in particular, we get

$$e^{u_2} \leq e^{\frac{k}{1+\delta}\varphi}\, e^{\frac{\lambda}{\mu(1+\delta)} u_0},$$

from which we get at once that

$$e^{u_2} \in L^{\frac{n}{4} + \frac{\mu}{\lambda}}(B) \tag{33}$$

since $\varphi \in L^\infty(B)$ and $e^{u_0} \in L^1(B)$ (recall also our choice of δ). Finally, consider $u_3 \in L^2(B)$ such that

$$\int_B u_3 \Delta^2 v = \lambda \int_B e^{u_2} v \qquad \text{for all } v \in W^{4,p} \cap H_0^2(B).$$

By (33) and elliptic regularity [ADN], we deduce that

$$u_3 \in W^{4, \frac{n}{4} + \frac{\mu}{\lambda}}(B) \subset L^\infty(B).$$

Moreover, by (28), (29), and Lemma 16 we infer that $u_3 \leq u_2$ and hence

$$\int_B u_3 \Delta^2 v \geq \lambda \int_B e^{u_3} v \qquad \text{for all } v \in \mathcal{K} \cap W^{4,p} \cap H_0^2(B).$$

We have so found a weak bounded supersolution u_3 of (P_λ), and the statement follows from Lemma 19. □

With the help of Lemma 20 we can now show the following.

LEMMA 21. *For all $0 \le \lambda < \lambda^*$, the minimal solution U_λ exists, is regular, and is radially symmetric.*

Proof. By the preceding lemma we have the existence of a regular solution u_λ of (P_λ). This may serve as a (classical) supersolution of (P_λ), while $U_0 \equiv 0$ is a subsolution. Hence, the minimal solution U_λ of (P_λ) may be obtained as the increasing limit of the following sequence $\{U_m\}$:

$$\begin{cases} \Delta^2 U_{m+1} = \lambda e^{U_m} & \text{in } B, \\ U_{m+1} = \dfrac{\partial U_{m+1}}{\partial \mathbf{n}} = 0 & \text{on } \partial B \end{cases} \qquad (m \ge 0).$$

Since U_0 is radially symmetric, so is U_1; similarly, all the functions U_m are radially symmetric: therefore, their (pointwise) limit U_λ is also radially symmetric. □

The previous lemma allows us to show that the interval Λ is closed: we first remark that the map $\lambda \mapsto U_\lambda(x)$ is strictly increasing for all $x \in B$ (in view of Lemma 16). If $0 \le \lambda < \mu < \lambda^*$, the minimal solution U_μ of (P_μ) is a (strict) supersolution for (P_λ). Therefore

$$U_*(x) := \lim_{\lambda \to \lambda^*} U_\lambda(x) \in [0, \infty] \tag{34}$$

exists for all $x \in B$. In fact, more can be said about this limit, as follows.

LEMMA 22. *Let U_* be the function defined in* (34). *Then $U_*(x)$ is finite for almost every $x \in B$ and U_* solves (P_λ) for $\lambda = \lambda^*$. Moreover, $U_\lambda \to U_*$ in $H_0^2(B)$ as $\lambda \uparrow \lambda^*$. Finally, U_* is radially symmetric.*

Proof. By Lemma 21 we have $U_\lambda \in C^\infty(\overline{B})$, and therefore, by using the generalized Pohozaev identity [P] by Pucci and Serrin [PS] and by arguing as in the proof of [GMP, Théorème 2], we obtain that the set $\{U_\lambda;\ \lambda < \lambda^*\}$ is bounded in $H_0^2(B)$, and hence $U_\lambda \rightharpoonup U_*$ in $H_0^2(B)$, up to a subsequence (this follows by uniqueness of the pointwise limit). This shows that U_* is a.e. finite, that U_* solves (P_λ) for $\lambda = \lambda^*$, and also that $U_* e^{U_*} \in L^1(B)$. Finally, since $U_\lambda e^{U_\lambda} \le U_* e^{U_*}$, by Lebesgue's theorem we deduce that

$$\frac{1}{\lambda} \int_B |\Delta U_\lambda|^2 = \int_B U_\lambda e^{U_\lambda} \to \int_B U_* e^{U_*} = \frac{1}{\lambda^*} \int_B |\Delta U_*|^2 \qquad \text{as } \lambda \uparrow \lambda^*,$$

which, together with weak convergence, shows that $U_\lambda \to U_*$ in the norm topology of $H_0^2(B)$; since the above arguments may be repeated for any sequence in $\{U_\lambda;\ \lambda < \lambda^*\}$, the result follows without extracting subsequences.

Finally, by Lemma 21, all the minimal solutions U_λ (for $0 < \lambda < \lambda^*$) are radially symmetric. Then by (34) also U_* is radially symmetric. □

Remark 23. The proof of Lemma 22 may also be obtained by exploiting the stability of the minimal solution U_λ (see Proposition 37(i) below) and by arguing as in [BV, Remark 3.3].

Finally, we claim that

$$\lambda^* \ge 14.72(n-1)(n-3). \tag{35}$$

Indeed, this holds true by Lemma 19 since the function $\bar{u}(x) = 7.36(1-|x|)^2$ is a weak supersolution ($\bar{u} \in C^\infty(\bar{B} \setminus \{0\})$) of (P_λ) for all $\lambda \le 14.72(n-1)(n-3)$.

Proof of Theorem 3. The upper bound for λ^* follows from (27) and from Lemma 22, the latter saying that $\lambda^* \in \Lambda$. The lower bound for λ^* is proved in (35). Statement (i) follows from Lemmas 20 and 21. The map $\lambda \mapsto U_\lambda(x)$ is nondecreasing for all x by Lemma 19 and strictly increasing by Lemma 16; this proves the first part of statement (ii). The second parts of (ii) and (iii) follow from Lemma 22. Finally, the radial symmetry of U_* and of all the minimal solutions U_λ (for $\lambda < \lambda^*$) is obtained in Lemmas 22 and 21, respectively. The regular minimal solutions U_λ (for $\lambda < \lambda^*$) are strictly radially decreasing in view of [So]. Passing to the limit, we also get that U^* is radially decreasing. □

Remark 24. The above analysis does not allow us to establish whether the extremal solution U_* is regular, weakly singular, or singular. However, since it is radially symmetric, in the regular and weakly singular case, Theorem 6 describes the behavior of U_* when studied in the phase space $\mathbb{R}^4$. With our computer assisted proof, we may then find some space dimensions where the first case certainly occurs, provided that we can also show uniqueness of the weakly singular solution and the corresponding parameter λ_σ.

5. Proof of Theorem 4. We first show that

$$U_\lambda \to 0 \qquad \text{uniformly as } \lambda \to 0. \tag{36}$$

Since this is standard, we just briefly sketch its proof. By Theorem 3 we know that

$$0 < \lambda < \mu < \lambda^* \quad \Longrightarrow \quad U_\lambda(x) < U_\mu(x) \qquad \text{if } |x| < 1.$$

Then, by multiplying the equation in (P_λ) by U_λ and by integrating by parts, we obtain that $\|U_\lambda\|_{H_0^2(B)}$ remains bounded. Hence, up to a subsequence, $\{U_\lambda\}$ converges in the weak $H_0^2(B)$ topology to $U_0 \equiv 0$, which is the unique solution of (P_0). By convergence of the norms, we infer that the convergence is in the norm topology. Finally, by pointwise convergence and elliptic regularity, we infer (36).

Next, note that V_λ satisfies

$$\begin{cases} \Delta^2 V_\lambda = \lambda & \text{in } B, \\ V_\lambda = \dfrac{\partial V_\lambda}{\partial \mathbf{n}} = 0 & \text{on } \partial B. \end{cases} \tag{37}$$

Therefore, $\Delta^2 U_\lambda > \Delta^2 V_\lambda$, and the inequality $U_\lambda > V_\lambda$ follows by Lemma 16.

In order to prove the last statement of Theorem 4, note that from (36) we infer

$$\text{for all } \varepsilon > 0 \quad \text{there exists } \lambda_\varepsilon > 0 \quad \text{such that} \qquad \lambda < \lambda_\varepsilon \Longrightarrow \|U_\lambda\|_\infty < \varepsilon.$$

So, fix $\varepsilon > 0$ and let $\lambda < \lambda_\varepsilon$. Then (37) entails

$$\Delta^2 U_\lambda = \lambda e^{U_\lambda} < \lambda e^\varepsilon = e^\varepsilon \Delta^2 V_\lambda \qquad \text{in } B.$$

This shows that $U_\lambda(x) < e^\varepsilon V_\lambda(x)$ for all $x \in B$, and the result follows by arbitrariness of ε.

6. Proof of Theorem 7. The proof of Theorem 7 is obtained with computer assistance. We first describe the numerical procedure used to obtain the approximate values for λ_σ and λ^*; then we show how the algorithm can be made rigorous. We maintain here the same notation as in section 3. The computation of λ_σ is somehow simpler than the computation of λ^*, since the unstable manifold of P_2 is one-dimensional. We

choose a point $\bar{v} = P_2 + re_1$ where e_1 is an eigenvector corresponding to the unstable manifold and r is some small value. We solve system (8) with $\bar{v}$ as the initial condition and look for the intersection of the solution with the hyperplane $v_1 = 4$. The choice of a positive or negative r leads to a different result, since the manifold is made of two branches: it turns out that one branch never appears to intersect the hyperplane, while the other branch always does. If the solution intersects the hyperplane $v_1 = 4$ at some point $\hat{v} = (\hat{v}_1, \hat{v}_2, \hat{v}_3, \hat{v}_4)$ such that $\hat{v}_4 < 0$, by Theorem 6 and by (7) we have numerical evidence of a singular solution at $\lambda = -\hat{v}_4$.

In order to compute the value of λ^*, we have to study the two-dimensional unstable manifold of P_1. The direction on the tangent hyperplane can be parametrized by an angle ϑ. In order to find the largest value for λ, we use a *directional shooting* method; i.e., we choose some value ϑ (the shooting direction) and solve the equation with starting point $\bar{v} = P_1 + r(e_1 \sin\vartheta + e_2 \cos\vartheta)$, where e_1 and e_2 are the orthonormalized eigenvectors corresponding to the (tangent) unstable manifold and $r > 0$ is some small arbitrarily chosen value. If the solution intersects the hyperplane $v_1 = 4$ at some point $\hat{v} = (\hat{v}_1, \hat{v}_2, \hat{v}_3, \hat{v}_4)$ such that $\hat{v}_4 < 0$, then by Theorem 6 and by (7) and (8) we have numerical evidence of a regular solution for $\lambda = -\hat{v}_4$. By varying ϑ we can look for the maximal value of λ.

Of course these procedures do not lead to an exact value for two reasons. First, we can choose only $\bar{v}$ on the unstable manifold of the linearized equation, and although we know that we are close to the manifold of the full equation, we are not exactly on it. Second, the algorithm used to solve the differential equation provides an accurate, but not rigorous, solution. We address the problem of proving that a branch of the unstable manifold of P_2 does intersect the hyperplane $v_1 = 4$ and of computing a rigorous estimate for the values λ_σ and λ^* in the following sections.

6.1. Rigorous bounds for the manifolds. We first address the general problem of computing rigorous bounds for the location of the unstable manifold in the neighborhood of a stationary hyperbolic point of an ODE. The same technique could be applied to the stable manifold as well, but in this paper we are not interested in it.

Let $f \in C^2(\mathbb{R}^d, \mathbb{R}^d)$, $d \geq 2$. We consider the equation $\dot{x} = f(x)$ and assume that 0 is a hyperbolic stationary point. Then

$$\dot{x} = Ax + N(x), \tag{38}$$

where

$$A = \nabla f(0), \quad N(x) = O(|x|^2) \text{ as } x \to 0 \tag{39}$$

and all eigenvalues of A have nonzero real part. Let $\varphi(x,t)$ be the flow induced by (38) and let $\varphi_A(x,t)$ be the flow induced by the linear equation $\dot{x} = Ax$. Let S_0 (resp., U_0) be the span of all eigenvectors corresponding to the eigenvalues with negative (resp., positive) real part. S_0 (resp., U_0) is called the stable (resp., unstable) subspace, and it is characterized as follows: S_0 (resp., U_0) is the set of points $x \in \mathbb{R}^d$ such that $\varphi_A(x,t) \to 0$ as $t \to +\infty$ (resp., $t \to -\infty$). It is well known that the full equation also admits a stable manifold S (resp., an unstable manifold U) still defined as the set of points $x \in \mathbb{R}^d$ such that $\varphi(x,t) \to 0$ as $t \to +\infty$ (resp., $t \to -\infty$). Such a manifold is tangent at the origin to S_0 (resp., U_0). If S_0 (resp., U_0) is empty, then there exists a neighborhood of the origin which is a subset of U (resp., S). We are interested in the case when both manifolds are nontrivial, and we wish to study the intersection of the unstable manifold with some other manifold P. In order to achieve this goal,

we consider a point $\bar{x} \in U \setminus \{0\}$ and study $\varphi(\bar{x}, t)$. If we can prove that $\varphi(\bar{x}, t_0) \in P$ for some positive t_0, then we infer that $U \cap P \neq \emptyset$, and we also know the intersection point. The main problem to address is that the only point of the manifold we know precisely is the origin: the other points lie very close to U_0, at least in a neighborhood of 0, but we do not know their explicit position. We proceed as follows.

There exists an invertible matrix M such that $B := M^{-1}AM$ is block diagonal, i.e., the canonical basis $\{e_i\}$ of $\mathbb{R}^d$ is split in $S_0' \cup U_0'$, where $S_0' = \operatorname{span}\{e_1, \dots, e_m\}$ is the stable eigenspace and $U_0' = \operatorname{span}\{e_{m+1}, \dots, e_d\}$ is the unstable eigenspace. If we let $y = M^{-1}x$, the (38) can be written as

$$\dot{y} = By + M^{-1}N(My) =: g(y). \tag{40}$$

By (39), for all $\varepsilon > 0$ there exists $\beta > 0$ such that $|N(x)| \le \beta |x|^2$ for all $|x| \le \varepsilon$. Let $\alpha < 0$ be the maximum of the real parts of the eigenvalues with negative real parts, $\gamma = -\frac{\alpha}{\beta m_1^2 m_2}$, $m_1 = \|M\|$, and $m_2 = \left\|M^{-1}\right\|$. Choose $\varepsilon > 0$; let $\beta > 0$ as above; choose a vector $\hat{y} \in U_0' \setminus \{0\}$ of norm $r \le \varepsilon$ and $k > 1$. Let P_s be the orthogonal projection onto S_0'; let P_u be the orthogonal projection onto the linear space spanned by $\hat{y}$; and let

$$\Xi = \left\{ y \in \mathbb{R}^d : \frac{\gamma}{k} |P_s y| \le |P_u y|^2 \le r^2 \right\}. \tag{41}$$

We show that, under a suitable choice of $k > 1$ and $0 < r \le \varepsilon$, for all $y \in \partial\Xi$ such that $|P_u y| < r$ the flow is inward; i.e., given $\bar{y} \in \Xi$ we want the solution of the Cauchy problem $\dot{y}(t) = g(y(t))$, $y(0) = \bar{y}$ to leave Ξ only through the set $\{y \in \partial\Xi : |P_u y| = r\}$. If this happens, then for all $\hat{y} \in U_0'$ satisfying $|\hat{y}| = r$ either the unstable manifold intersects the set

$$\kappa := \kappa_{\hat{y}} := \hat{y} + \left\{ \tilde{y} \in S_0' : |\tilde{y}| \le \frac{k}{\gamma} r^2 \right\} \tag{42}$$

or it is entirely contained in Ξ. As a result, to study a branch of the unstable manifold it is sufficient to exclude the second case and consider the initial value problem for all $\bar{y} \in \kappa$.

LEMMA 25. *Choose $\varepsilon > 0$ and $k > 1$. Let α, β, γ, m_1, m_2, and Ξ be as above and let*

$$r = \min\left\{ \frac{\varepsilon\gamma}{m_1\sqrt{\gamma^2 + k^2}}, 1, \frac{\sqrt{k-1}}{k}\gamma, \frac{\gamma}{2} \right\}. \tag{43}$$

For all $\bar{y} \in \partial\Xi$ such that $0 < |P_u \bar{y}| < r$ we have

$$(g(\bar{y}), P_s \bar{y}) < 0. \tag{44}$$

Proof. Let $\hat{y} = P_s\bar{y}$, $\tilde{y} = P_u\bar{y}$, $\hat{r} = |\hat{y}|$, and $\tilde{r} = |\tilde{y}|$. Since $\tilde{r} < r \le \frac{\varepsilon\gamma}{m_1\sqrt{\gamma^2+k^2}}$, then $|M\bar{y}| \le \varepsilon$, and therefore $|N(\bar{y})| \le \beta |\bar{y}|^2$. We have

$$\begin{aligned}(B\bar{y}, \hat{y}) + (M^{-1}N(M\bar{y}), \hat{y}) &= (B\hat{y}, \hat{y}) + (N(M\bar{y}), (M^{-1})^t\hat{y}) \\ &\le \alpha\hat{r}^2 + \beta m_1^2 m_2 (\hat{r}^2 + \tilde{r}^2)\hat{r}.\end{aligned}$$

Then a simple computation shows that (44) is implied by

$$\frac{1}{2}\left(\gamma + \sqrt{\gamma^2 - 4\tilde{r}^2}\right) > \hat{r} > \frac{1}{2}\left(\gamma - \sqrt{\gamma^2 - 4\tilde{r}^2}\right). \tag{45}$$

The first inequality is satisfied because $\tilde{r} < r \le \frac{\gamma}{2}$. For all $\bar{y} \in \partial\Xi$, $0 < |P_u\bar{y}| < r$, by (41), we have $\hat{r} = \frac{k}{\gamma}\tilde{r}^2$ and

$$\frac{1}{2}\left(\gamma - \sqrt{\gamma^2 - 4\tilde{r}^2}\right) < k\frac{\tilde{r}^2}{\gamma} \qquad \text{if} \quad \tilde{r} < \frac{\sqrt{k-1}}{k}\gamma\ .$$

Since $\tilde{r} < r$, then (45) and therefore (44) hold. □

We need a condition which ensures that the invariant manifold is not entirely contained in Ξ, but it intersects κ at some point. Let α' be the minimum of the real parts of the eigenvalues of B with positive real parts.

LEMMA 26. *If r, α, α', k, and Ξ are as above and*

$$\alpha' + \frac{\alpha}{\gamma}\left(r + \frac{k^2}{\gamma^2}r^3\right) > 0, \tag{46}$$

then there exists $\delta > 0$ such that $(g(\bar{y}), P_u\bar{y}) \ge \delta|P_u\bar{y}|^2$ for all $\bar{y} \in \Xi$, and therefore the component of the flow in the direction of the unstable manifold is always increasing in Ξ, together with its first derivative.

Proof. Choose $\delta > 0$ satisfying

$$\beta m_1^2 m_2\left(r + \frac{k^2}{\gamma^2}r^3\right) \le \alpha' - \delta.$$

Fix $\bar{y} \in \Xi$ and let $\hat{y} = P_s\bar{y}$, $\tilde{y} = P_u\bar{y}$, $\hat{r} = |\hat{y}|$, and $\tilde{r} = |\tilde{y}|$. By (46) and the definition of γ, such a δ exists. We have

$$\begin{aligned}(B\bar{y}, \tilde{y}) + (M^{-1}N(M\bar{y}), \tilde{y}) &= (B\tilde{y}, \tilde{y}) + (N(M\bar{y}), (M^{-1})^t\tilde{y}) \\ &\ge \alpha'\tilde{r}^2 - \beta m_1^2 m_2\left(\hat{r}^2 + \tilde{r}^2\right)\tilde{r} \ge \delta\tilde{r}^2,\end{aligned}$$

because $\hat{r} \le \frac{k}{\gamma}\tilde{r}^2$ by the definition of Ξ. □

LEMMA 27. *Let r, α, α', k, $\hat{y}$, and κ be as above. The unstable manifold tangent to $\hat{y}$ intersects κ.*

Proof. By Lemma 26 the unstable manifold cannot be entirely contained in Ξ. By Lemmas 25 and 26 it can only exit through κ. □

In the next subsection we apply these ideas in order to prove Theorem 7.

6.2. The computer assisted proofs. We apply the general result stated in the previous subsection to system (8).

We first consider the point $P_1 = (4, 0, 0, 0)$. Let $x = v - P_1$. System (8) takes the form (38) with

$$A_1 = \begin{bmatrix} 2-n & -1 & 0 & 0 \\ 0 & 2 & 1 & 0 \\ 0 & 0 & 4-n & 1 \\ 0 & 0 & 0 & 4 \end{bmatrix},$$

$N(x) = (0, 0, 0, x_1x_4)$, and $\alpha = 4 - n$.

If we consider the linearization at $P_2 = (0, 4n-8, 16-8n, -8(n-2)(n-4))$ and set $x = v - P_2$, then system (8) can be written as (38) with

$$A_2 = \begin{bmatrix} 2-n & -1 & 0 & 0 \\ 0 & 2 & 1 & 0 \\ 0 & 0 & 4-n & 1 \\ -8(-4+n)(-2+n) & 0 & 0 & 0 \end{bmatrix},$$

and again $N(x) = (0, 0, 0, x_1 x_4)$. From section 3.1 we know that if $n = 5, \dots, 12$, the eigenvalues are $((4-n)/2 + i\sigma, (4-n)/2 - i\sigma, \lambda_1, \lambda_2)$, where $\lambda_1 < (4-n)/2 < 0$ and $\lambda_2 > 0$. It turns out that $\alpha = (4-n)/2$. If $n \geq 13$, all eigenvalues are real and

$$\alpha = 2 - \frac{1}{2}n + \frac{1}{2}\sqrt{8 - 4n + n^2 - 4\sqrt{68 - 52n + 9n^2}}.$$

We remark that since the nonlinear part is very simple, it is possible to obtain a better estimate for the coefficients β, m_1, and m_2 than the one we had in section 6.1.

In the following, let M be the matrix that diagonalizes either A_1 or A_2 and let $|M_i|$ be the (Euclidean) norm of the ith row of M.

LEMMA 28. *For all $y_1, y_2 \in \mathbb{R}^4$ the following inequality holds:*

$$(N(My_1), (M^{-1})^t y_2) \leq |M_1|\,|M_4|\left|(M^{-1})_4^t\right| |y_1|^2 |y_2|.$$

Proof. We have

$$(N(My_1), (M^{-1})^t y_2) = (My_1)_1 (My_1)_4 ((M^{-1})^t y_2)_4,$$

where we denoted by $(Av)_i$ the ith component of the vector (Av), i.e., the scalar product of the ith row of A with the vector v. The conclusion follows by the definition of $|M_i|$. ∎

By the above lemma we infer that γ may be obtained as

$$\gamma = -\frac{\alpha}{|M_1|\,|M_4|\,|(M^{-1})_4^t|} \tag{47}$$

and ε may be chosen arbitrarily.

To compute a rigorous enclosure $[\lambda_\sigma^{\min}, \lambda_\sigma^{\max}]$ for the value of λ_σ, we fix n and compute the value γ in (47). We can choose $k > 1$ and $r > 0$ satisfying (43) and (46). We have some degree of arbitrariness: we prefer a small r in order to have a small set κ, but we also like a large r in order to reach the hyperplane in fewer time steps. It is also convenient to have the smallest possible k, since it also implies a smaller set κ. We have to make an empirical choice by trying different values and selecting the best trade-off. It turns out that it is convenient to choose r first, set

$$k = \frac{\gamma^2 - \sqrt{\gamma^4 - 4r^2\gamma^2}}{2r^2}, \tag{48}$$

and check whether (46) holds. Since the unstable manifold in P_2 is one-dimensional, we have to choose between two possible directions. The numerical experiment gave us the correct direction. Once we choose r and compute k, we have the set κ as given in (42). We should compute the evolution of all points in κ and its intersection with the hyperplane $v_1 = 4$. This would require a very long computer time, but since two solutions of (38) cannot intersect, then it is enough to compute the evolution of the points in the boundary of κ, provided we can prove that the trajectories of all points in the interior of κ also reach the hyperplane $v_1 = 4$. This can be checked by the following lemma.

LEMMA 29. *Set*

$$\kappa' := \kappa'_{\hat{y}} := \hat{y} + \left\{ \tilde{y} \in S_0 : |\tilde{y}| = \frac{k}{\gamma} r^2 \right\}. \tag{49}$$

Assume that the trajectories of all points in κ' intersect the hyperplane $v_1 = 4$ and do not intersect the hyperplane $(2-n)v_1 - v_2 + 4(n-2) = 0$. Let $\hat{\kappa}$ be the intersection of all such trajectories with $v_1 = 4$.

Then the trajectories of all points in κ also intersect the hyperplane $v_1 = 4$, and the intersection takes place in the region bounded by $\hat{\kappa}$.

Proof. Since $v_1' = (2-n)v_1 - v_2 + 4(n-2)$, then v_1' is positive and bounded away from zero for all points of the trajectories starting from κ'. Then, by the uniqueness and continuous dependence on the initial condition of the Cauchy problem, it follows that the union $\tau(\kappa')$ of such trajectories is a "tube" in $\mathbb{R}^4$ and the trajectories of all points in $\kappa \setminus \kappa'$ cannot exit $\tau(\kappa')$. Then v_1' is also positive and bounded away from zero for all points starting in κ, and the trajectory of every point in κ reaches $v_1 = 4$ in a finite time. □

Our strategy is as follows: We compute the intersection of the flow starting from all points in κ' with the hyperplane $v_1 = 4$. If all the trajectories intersect the hyperplane, we have a proof that the singular solution exists; furthermore the envelope in the v_4-direction of all intersections yields the desired λ-interval. Note that the set κ' is the image of S^2 through an invertible affine map, and therefore we need an efficient discretization of a sphere.

LEMMA 30. *For all $n = 5, \dots, 16$, let $r = .001$, let k be as in (48), and, let $\kappa' = \kappa'_{\hat{y}}$ as in (49). For a suitable choice of the direction $\hat{y}$ in the one-dimensional unstable manifold U_0, the following conclusions hold:*

1. *The flow starting in κ' intersects the hyperplane $v_1 = 4$.*
2. *The absolute value of the first coordinate of the intersection point is in the interval set $[\lambda_\sigma^{\min}, \lambda_\sigma^{\max}]$ defined in Table 1.*
3. *The flow starting in κ' and ending on the hyperplane $v_1 = 4$ does not intersect the hyperplane $(2-n)v_1 - v_2 + 4(n-2) = 0$.*

The proof is by computer assistance, as described in section 9.

In order to compute a rigorous lower bound for λ^*, we consider the trajectories of points in the unstable manifold of P_1 and compute the intersection with the hyperplane $v_1 = 4$. Since the manifold is two-dimensional, we have to decide the direction to follow: we use the numerical results presented above to compute the direction that gives the highest possible value for λ. We define κ as above, and we wish to prove that all trajectories starting from κ intersect the hyperplane $v_1 = 4$. We also need to estimate the location of such intersections. It would save some computer time to restrict the computation to the boundary of κ as in the proof of Lemma 30, but we cannot proceed as in Lemma 29 because P_1 lies on the hyperplane $v_1 = 4$ and therefore v_1 cannot be monotone. Furthermore, since the unstable manifold has now dimension 2, we do not have the topological argument (the tube) used before. On the other hand, in this case we only have to consider a region which is the affine image of a disk; therefore it is feasible to compute the trajectory for all point in the disk.

LEMMA 31. *For all $n = 5, \dots, 10$, let $r = .001$ if $n \le 9$ and $r = .0001$ if $n = 10$; let $\hat{y} = P_1 + r(e_1 \sin\vartheta_n + e_2 \cos\vartheta_n)$, where e_1 and e_2 are the eigenvectors of A_1 with unit norm and positive first component corresponding, respectively, to the eigenvalues 2 and 4 and $\vartheta_5 = 6.2829856$, $\vartheta_6 = 6.28298854$, $\vartheta_7 = 6.2829901$, $\vartheta_8 = 6.2829918$, $\vartheta_9 = 6.2829914$, $\vartheta_{10} = 6.28316589$; let k be as in (48) and let κ be as in (42).*

1. *The flow starting at all points of κ intersects the hyperplane $v_1 = 4$.*
2. *The absolute value of the first coordinate of the intersection point is larger than the $\lambda^*_{\min}$ displayed in Table 1.*

We point out that this statement shows only that there exists a regular solution

for some value of λ obtained as the intersection of a one-dimensional submanifold of the unstable manifold with the hyperplane $v_1 = 4$. Since we cannot exclude that there exists a solution for a larger value of λ, we only have a lower bound for λ^*.

The proof of Theorem 7 follows by Lemmas 27–31.

7. Proof of Theorem 12. In this section we use both the PDE notation Δ^2 and the ODE notation with primes denoting differentiation (with respect to r or s, depending on the context).

We assume that U_σ is any radial weakly singular solution of (P_{λ_σ}) with

$$\lambda_\sigma > 8(n-2)(n-4). \tag{50}$$

In particular, we deal with those solutions obtained in Theorem 7; see also Table 1. Then, by Theorem 6(ii), we know that

$$U_\sigma(r) = -4\log r + o(|\log r|) \qquad \text{as } r \to 0.$$

Therefore, we define the function

$$W(r) := U_\sigma(r) + 4\log r$$

and study its behavior. After some calculations, we find that it weakly solves the equation

$$\begin{cases} \Delta^2 W = \dfrac{1}{|x|^4}[\lambda_\sigma e^W - 8(n-2)(n-4)] & \text{in } B, \\ W = 0 & \text{on } \partial B, \\ \dfrac{\partial W}{\partial \mathbf{n}} = 4 & \text{on } \partial B. \end{cases} \tag{51}$$

The proof of Theorem 12 follows from the next two lemmas and Proposition 34 at the end of this section.

LEMMA 32. *Assume* (50) *and assume that* $W \in C^4(0,1]$ *weakly solves* (51) *(*$W = W(r)$*); then*

$$\lim_{r\to 0} W(r) = \log \frac{8(n-2)(n-4)}{\lambda_\sigma} = W_0 < 0. \tag{52}$$

Moreover, at least one of the two following facts holds true:

(i) *The function* $W(r) - W_0$ *changes sign infinitely many times in any neighborhood of* $r = 0$.

(ii) $W(r) \geq \max[W_0, 2r^2 - 2]$ *for all* $r \in (0,1]$.

Proof. The negativity of W_0 follows from (50), while (52) is a consequence of Theorem 6.

Assume that case (i) in the statement does not occur; we first claim that

$$W(r) \geq W_0 \qquad \text{for all } r \in (0,1]. \tag{53}$$

For contradiction, assume that (53) does not hold; then there exists $\bar R \in (0,1)$ such that $W(\bar R) < W_0$ and two cases may occur, as follows.

First case. There exists $R \in (0,1)$ such that $W'(R) = 0$ and $W_0 \leq W(r) < W(R)$ for all $r \in (0,R)$. In this case, let $H(r) = W(r) - W(R)$ so that $H(r) < 0$ for all $r \in (0,R)$; on the other hand, H weakly solves the problem

$$\begin{cases} \Delta^2 H = \Delta^2 W \geq 0 & \text{in } B_R, \\ H = \dfrac{\partial H}{\partial \mathbf{n}} = 0 & \text{on } \partial B_R, \end{cases}$$

so that by Lemma 16, one gets $H(r) \geq 0$ for all $r \in (0, R)$, a contradiction.

Second case. There exists $R \in (0,1)$ such that $W'(R) = 0$ and $W_0 \geq W(r) > W(R)$ for all $r \in (0, R)$. In this case, $H(r) = W(r) - W(R)$ satisfies both $H(r) > 0$ for all $r \in (0, R)$ and

$$\begin{cases} \Delta^2 H = \Delta^2 W \leq 0 & \text{in } B_R, \\ H = \dfrac{\partial H}{\partial \mathbf{n}} = 0 & \text{on } \partial B_R, \end{cases}$$

giving again a contradiction.

We have so proved (53): hence, if we define the function $\phi(r) = W(r) + 2 - 2r^2$, we infer that $\phi = \phi(|x|)$ weakly satisfies

$$\begin{cases} \Delta^2 \phi = \Delta^2 W \geq 0 & \text{in } B, \\ \phi = \dfrac{\partial \phi}{\partial \mathbf{n}} = 0 & \text{on } \partial B; \end{cases}$$

this yields $\phi(r) \geq 0$, namely, $W(r) \geq 2r^2 - 2$ for all $r \in (0, 1]$.

We have so proved that if (i) does not occur, then (ii) holds true, that is, the statement follows. □

In high dimensions the previous alternative breaks down, and we can describe the behavior of weakly singular solutions.

LEMMA 33. *If $n \geq 13$, then case* (i) *of Lemma* 32 *cannot occur.*

Proof. Let $W = W(r)$, let W_0 be as in Lemma 32, and consider the function

$$Z(s) = W(e^s) - W_0, \qquad s \in (-\infty, 0).$$

Then, since W satisfies (51), we deduce that

$$L_4 Z + p(s) Z = 0, \qquad s \in (-\infty, 0), \tag{54}$$

where $L_4 Z = Z'''' + 2(n-4)Z''' + (n^2 - 10n + 20)Z'' - 2(n-2)(n-4)Z'$ and

$$p(s) = -8(n-2)(n-4)\frac{e^{Z(s)} - 1}{Z(s)}.$$

Note that $p(s)$ is well-defined for all $s < 0$ and that, by (52), $p(s) \to -8(n-2)(n-4)$ as $s \to -\infty$. In particular, for all $\varepsilon > 0$ there exists $s_\varepsilon < 0$ such that

$$p(s) \geq -[8(n-2)(n-4) + \varepsilon] \quad \text{for all } s \leq s_\varepsilon. \tag{55}$$

Since $n \geq 13$, for sufficiently small ε, the linear equation

$$L_4 Z - [8(n-2)(n-4) + \varepsilon] Z = 0 \tag{56}$$

admits four linearly independent solutions of "exponential type," namely, $Z_i(s) = e^{\nu_i s}$ for some $\nu_i \in \mathbb{R}$ $(i = 1, \ldots, 4)$; see also the discussion in section 3.1. Hence, (56) is nonoscillatory in $(-\infty, 0)$ according to the definition in [E]. Therefore, by (55) and [E, Corollary 1], also (54) is nonoscillatory in $(-\infty, 0)$ and the statement follows. □

Let us conclude this section with the observation that an explicit form of the weakly singular solution U_σ seems not so easy to be obtained.

PROPOSITION 34. *Assume that the function W is a solution of* (51) *as considered in Lemma* 32. *Then the function $W = W(r)$ is not analytic in r close to* 0.

Proof. For contradiction, let $a_k = W^{(2k)}(0)/(2k)!$ and assume that

$$W(r) = \sum_{k=0}^{\infty} a_k r^{2k}$$

is a convergent power series for r close to 0. Since W is regular, the right-hand side of the equation in (51) is bounded as $r \to 0$, and we necessarily have

$$a_0 = \log \frac{8(n-2)(n-4)}{\lambda_\sigma}\,, \qquad a_1 = \frac{W''(0)}{2} = 0. \tag{57}$$

Then

$$W^{(k)}(r) = \frac{W''''(0)}{(4-k)!}\, r^{4-k} + O\left(r^{5-k}\right) \quad \text{as } r \to 0 \qquad (k = 1, 2, 3),$$

and hence

$$\frac{n(n+2)}{3} W''''(0) = \Delta^2 W|_{r=0} = \frac{\lambda_\sigma e^{a_0} W''''(0)}{24} = \frac{(n-2)(n-4)}{3} W''''(0),$$

where we have used (51) and (57). This shows that $W''''(0) = 0$ and $a_2 = 0$.

We now proceed by induction. Assume that for some $k \geq 2$ we have shown that $a_1 = \cdots = a_k = 0$; we claim that $a_{k+1} = 0$. Once we show this, we achieve a contradiction and the statement follows. Note that $\lambda_\sigma e^W - 8(n-2)(n-4) = 8(n-2)(n-4)[e^{W-a_0} - 1]$ and, by induction assumption,

$$\frac{1}{r^4}\left(e^{W-a_0} - 1\right) = a_{k+1} r^{2k-2} + O\left(r^{2k}\right).$$

Therefore, from (51) we get

$$\left(\frac{d}{dr}\right)^{2k-2} \Delta^2 W\Big|_{r=0} = 8(2k-2)!(n-2)(n-4)a_{k+1}. \tag{58}$$

On the other hand, recalling the radial form of Δ^2 (see the left-hand side of (4)) and taking into account that (as $r \to 0$)

$$W'(r) \sim \frac{W^{(2k+2)}(0)}{(2k+1)!}\, r^{2k+1}\,, \qquad W''(r) \sim \frac{W^{(2k+2)}(0)}{(2k)!}\, r^{2k},$$
$$W'''(r) \sim \frac{W^{(2k+2)}(0)}{(2k-1)!}\, r^{2k-1}\,, \qquad W''''(r) \sim \frac{W^{2k+2}(0)}{(2k-2)!}\, r^{2k-2},$$

we also deduce that

$$\left(\frac{d}{dr}\right)^{2k-2} \Delta^2 W|_{r=0} = 2k(2k+2)(n+2k)(n+2k-2) \cdot (2k-2)!\, a_{k+1}.$$

Combining this with (58), we get

$$a_{k+1}\left\{2k(2k+2)(n+2k)(n+2k-2) - 8(n-2)(n-4)\right\} = 0.$$

Since the term in brackets is strictly positive, this yields $a_{k+1} = 0$. ∎

8. Further results and open problems. First, we discuss the stability of the linearizations around regular solutions of problem (P_λ). For this purpose we observe that the minimal solution depends continuously on λ.

PROPOSITION 35. *As before, let U_λ denote the minimal solution of (P_λ). Then $[0,\lambda^*) \ni \lambda \mapsto U_\lambda \in C^{4,\alpha}(\overline{B})$ is continuous from the left. Moreover, if $\lambda_0 \in [0,\lambda^*)$ is such that the first eigenvalue of the linearization $L_{U_{\lambda_0}} := \Delta^2 - \lambda_0 \exp(U_{\lambda_0})$ is strictly positive, then $\lambda \mapsto U_\lambda$ is also continuous in $\lambda = \lambda_0$.*

Proof. Let $\lambda_k \nearrow \lambda_0$. Since $U_{\lambda_k} \le U_{\lambda_0}$ and since the $(U_{\lambda_k})_k$ are monotonically increasing, we get $\tilde{U} := \lim_{k\to\infty} U_{\lambda_k}$, first in any L^q-space, then by elliptic theory in $W^{4,q}$, and finally in $C^{4,\alpha}(\overline{B})$. Hence, $\tilde{U}$ also solves (P_{λ_0}), and $0 < \tilde{U} \le U_{\lambda_0}$. We conclude that $\tilde{U} = U_{\lambda_0}$ by minimality of U_{λ_0}.

The second statement follows from the implicit function theorem and again the monotonicity of U_λ in λ. □

The next statement extends some results of [CR] to the biharmonic case; see Proposition 2.15 there. In order to show the sign condition of eigenfunctions, we use a decomposition method with respect to pairs of dual cones.

PROPOSITION 36. *Let u be a regular solution for (P_λ), where $\lambda \in (0,\lambda^*]$. Let the first eigenvalue μ_1 of the linearization $L_u := \Delta^2 - \lambda e^u$ under Dirichlet boundary conditions be nonnegative: $\mu_1 \ge 0$. Then every eigenfunction of $L_u\varphi = \mu_1\varphi$ is of fixed sign. Moreover, if $v \in C^4(\bar{B})$ solves $\Delta^2 v \ge \lambda e^v$ in B and $v = \frac{\partial v}{\partial \mathbf{n}} = 0$ on ∂B, then it follows that $v \ge u$. Finally, if $\mu_1 = 0$, then we even have $v = u$.*

Proof. In order to show that the first eigenfunction φ of L_u is of fixed sign, we need to explain a decomposition technique with respect to dual cones, which was found in the abstract setting by Moreau [Mo] and adapted to biharmonic Dirichlet problems in [GG]. As usual we equip $H_0^2(B)$ with the scalar product

$$(u,w)_{H_0^2} := \int_B \Delta u\, \Delta w\, dx.$$

Here, let

$$\mathcal{K} = \left\{ u \in H_0^2(B);\ u \ge 0 \ \text{ a.e. in } B \right\},$$

denote the convex closed cone of nonnegative H_0^2-functions and

$$\mathcal{K}' = \left\{ u \in H_0^2(B); \quad \text{for all } w \in \mathcal{K}: \quad (u,w)_{H_0^2} \le 0 \right\}$$

its dual cone in H_0^2 of weak subsolutions of the clamped plate equation. By Lemma 16 we see that $\mathcal{K}' \subset -\mathcal{K}$. For any $w \in \mathcal{K}'$ we even have that either $w \equiv 0$ or $w < 0$ in B.

Assume now by contradiction that φ is not of fixed sign. Then, according to [Mo], we may decompose

$$\varphi = \varphi_1 + \varphi_2$$

with $\varphi_1 \in \mathcal{K}$, $\varphi_2 \in \mathcal{K}'$, and $\varphi_1 \perp \varphi_2$ in $H_0^2(B)$. By assumption we have that $\varphi_1 \ge 0$, $\varphi_1 \not\equiv 0$, and $\varphi_2 < 0$. But then

$$\begin{aligned} 0 \le \mu_1 &= \inf_{w \in H_0^2(B)\setminus\{0\}} \frac{\int_B \left((\Delta w)^2 - \lambda \exp(u) w^2 \right) dx}{\int_B w^2\, dx} \\ &\le \frac{\int_B \left((\Delta(\varphi_1 - \varphi_2))^2 - \lambda \exp(u)(\varphi_1 - \varphi_2)^2 \right) dx}{\int_B (\varphi_1 - \varphi_2)^2\, dx} \end{aligned}$$

$$< \frac{\int_B \left((\Delta(\varphi_1+\varphi_2))^2 - \lambda \exp(u)(\varphi_1+\varphi_2)^2 \right) dx}{\int_B (\varphi_1+\varphi_2)^2\,dx}$$
$$= \frac{\int_B \left((\Delta\varphi)^2 - \lambda \exp(u)\varphi^2 \right) dx}{\int_B \varphi^2\,dx} = \mu_1,$$

a contradiction. Hence, φ is of fixed sign, say $\varphi \geq 0$, and in a second step we may conclude from the equation and the strict positivity of the biharmonic Green function (in the ball) that $\varphi > 0$.

We consider now u and v as in the statement. For $\tau \in [0,1]$ we look at

$$\begin{aligned} &\Delta^2 \left(u + \tau(v-u)\right) - \lambda \exp\left(u + \tau(v-u)\right) \\ &\geq \Delta^2 \left(u + \tau(v-u)\right) - \lambda \left(\tau \exp(v) + (1-\tau)\exp(u)\right) \geq 0. \end{aligned} \tag{59}$$

Since (59) equals 0 for $\tau = 0$, its first derivative at $\tau = 0$ must be nonnegative:

$$\Delta^2(v-u) - \lambda e^u (v-u) =: f \geq 0. \tag{60}$$

If $\mu_1 > 0$, a decomposition trick as above applied to the functional $w \mapsto \int_B ((\Delta w)^2 - \lambda e^u w^2 - fw)dx$ shows that $v \geq u$.

If $\mu_1 = 0$, we test (60) with the positive first eigenfunction φ and get

$$\Delta^2(v-u) - \lambda e^u (v-u) = 0.$$

That means that also the first derivative of (59) with respect to $\tau = 0$ vanishes, so that the second derivative needs to be nonnegative:

$$-\lambda e^u (v-u)^2 \geq 0.$$

But this immediately yields $v = u$. □

Concerning the stability behavior of the linearizations around regular solutions, we have the following.

PROPOSITION 37. *Let $\lambda > 0$, let u be a regular solution of (P_λ), let $L_u = \Delta^2 - \lambda e^u$ be the linearized operator at u, and let $\mu_1 = \mu_1(L_u)$ be the smallest eigenvalue of L_u; then*

(i) *if $\lambda < \lambda^*$ and u is the minimal solution, then $\mu_1 > 0$;*

(ii) *if $\lambda < \lambda^*$ and u is not the minimal solution, then $\mu_1 < 0$;*

(iii) *if $\lambda = \lambda^*$ and the extremal solution $u = U_*$ is regular, then $\mu_1 = 0$.*

Finally, if U_λ denotes the minimal (regular) solution of (P_λ) and $\mu_1(\lambda) = \mu_1(L_{U_\lambda})$, then the map $\lambda \mapsto \mu_1(\lambda)$ is decreasing.

Proof. (i) The monotonicity of $\mu_1(\lambda)$ follows immediately from the variational characterization

$$\mu_1(\lambda) = \inf_{w \in H_0^2(B)\setminus\{0\}} \frac{\int_B (\Delta w)^2\,dx - \int_B \exp(U_\lambda) w^2\,dx}{\int_B w^2\,dx}$$

and from the monotonicity of U_λ with respect to λ. By Proposition 35 we see that the function $\lambda \mapsto \mu_1(\lambda)$ is continuous from the left on $(0,\lambda^*)$ and even on $(0,\lambda^*]$, provided the extremal solution U_* is regular.

Assume by contradiction that there exists a $\tilde\lambda \in (0,\lambda^*)$ with $\mu_1(\tilde\lambda) \leq 0$. We put

$$\lambda_0 := \sup\{\lambda \geq 0 :\ \mu_1(\lambda) > 0\} \leq \tilde\lambda < \lambda^*.$$

According to the mentioned continuity from the left, we have $\mu_1(\lambda_0) \geq 0$. If we assume $\mu_1(\lambda_0) > 0$, then the second part of Proposition 35 would give $\mu_1(\lambda) > 0$ also for some $\lambda > \lambda_0$, a contradiction. Consequently we have $\mu_1(\lambda_0) = 0$. Let $u = U_{\lambda_0} > 0$ be the corresponding minimal solution:

$$\Delta^2 u = \lambda_0 e^u \text{ in } B, \quad u = \nabla u = 0 \text{ on } \partial B.$$

Consider any $\lambda \in (\lambda_0, \lambda^*)$ with minimal solution $v = U_\lambda > 0$:

$$\Delta^2 v = \lambda e^v \text{ in } B, \quad v = \nabla v = 0 \text{ on } \partial B.$$

Since $\lambda > \lambda_0$, Proposition 36 applies and yields $v = u$ and hence $\lambda = \lambda_0$, a contradiction.

(ii) Let U_λ be the minimal solution for (P_λ) so that $u \geq U_\lambda$. If the linearization around u had nonnegative first eigenvalue, then Proposition 36 would also yield $u \leq U_\lambda$ so that u and U_λ necessarily coincide, a contradiction.

(iii) Assume that the extremal solution $u = U_*$ is regular. By continuity, we have $\mu_1 \geq 0$. If $\mu_1 > 0$, the implicit function theorem would also yield solutions for some $\lambda > \lambda^*$. This is a contradiction, so that $\mu_1 = 0$. □

Open Problem 1. Does (ii) of Proposition 37 extend to weak solutions u as formulated in [BV, Theorem 3.1]?

We now turn to the extremal solution U_*. We first suggest the following open problem.

Open Problem 2. Do we have uniqueness of weak solutions for (P_{λ^*})? By Proposition 37(iii), and arguing as in Lemma 2.6 in [BV], one obtains that if the extremal solution is *regular*, then it is unique even in a weak sense. However, without the regularity assumption on U_*, the proof seems much more difficult; we refer to [Ma] for the corresponding result related to the second order problem (1). In particular, the proof of a result in the spirit of [Ma, Lemma 2.1] requires a new trick, probably of the same kind as the one we used to prove Lemma 20.

Perhaps, the precise characterization of *all* singular solutions U_σ and the corresponding "singular" parameters λ_σ is the most interesting and difficult problem we have to leave open in the present paper.

Open Problem 3. Are the singular parameter and the weakly singular solution unique? In order to construct a weakly singular radial solution, according to Theorem 6, one has to follow the unstable branch arising from P_2. One can do so in two (opposite) exit directions. In one direction we actually find at most (and presumably precisely) one solution by the result of Soranzo [So]: the solution of the PDE has to be strictly decreasing. We emphasize that this result extends to the class of *weakly singular* radial solutions. For the ODE system (8) this means that any "singular" trajectory may intersect the hyperplane $v_1 = 4$ only once and cannot come back to it. But we do not have a proof that the unstable branch leaving P_2 in the other direction will *not* intersect the hyperplane $v_1 = 4$ even if numerical experiments suggest so.

Next, we recall that in [GGM] it was shown that for any open bounded domain $\Omega \subset \mathbb{R}^n$ there exist $C_1, C_2 > 0$ such that the following improved Hardy inequality holds:

(61)
$$\int_\Omega |\Delta u|^2 \, dx \geq \frac{n^2(n-4)^2}{16} \int_\Omega \frac{u^2}{|x|^4} \, dx + C_1 \int_\Omega \frac{u^2}{|x|^2} \, dx + C_2 \int_\Omega u^2 \, dx \quad \text{for all } u \in H_0^2(\Omega).$$

A similar inequality was used in [BV] in order to establish the space dimensions in which the extremal solution for (1) is regular or singular. For (P_λ) this seems more intriguing: it is not clear which is the role of each of the remainder terms in (61). Furthermore, as we have seen in Theorem 12 and Proposition 34, the singular solution is difficult to describe. However, we have a partial result relating Hardy's inequality with extremal solutions: clearly, this statement is weaker than Corollary 10 if $n \le 10$.

PROPOSITION 38. *Let λ_σ and U_σ be as in Theorem 7 and assume that $\lambda_\sigma = \lambda^*$. Then if $n \le 12$, case* (ii) *in Theorem 12 cannot occur.*

Proof. By Proposition 37(i), by Theorem 3(ii)–(iii), and by using the notation of Theorem 12, we infer that

$$\int_B |\Delta\phi|^2 \ge \lambda^* \int_B e^{U_*}\phi^2 = \lambda^* \int_B \frac{e^W}{|x|^4}\phi^2 \qquad \text{for all } \phi \in H_0^2(B). \tag{62}$$

For contradiction, if (ii) in Theorem 12 holds, then

$$\lambda^* \int_B \frac{e^W}{|x|^4}\phi^2 \ge 8(n-2)(n-4)\int_B \frac{\phi^2}{|x|^4} \qquad \text{for all } \phi \in H_0^2(B).$$

Since $8(n-2)(n-4) > \frac{n^2(n-4)^2}{16}$ whenever $n \le 12$, the last inequality, together with (62), would improve the best constant in Hardy's inequality, a contradiction. ∎

Proposition 38 and Corollary 10 suggest the following question and conjecture.

Open Problem 4. Which are all the space dimensions $n \ge 5$ for which $\lambda_\sigma < \lambda^*$? We conjecture that the answer is $n \le 12$. In view of Corollary 10 we know that among these dimensions n, there are at least $5 \le n \le 10$. Moreover, Theorem 12 and Proposition 38 prove "half" of this conjecture when $n = 11, 12$. Maybe the proof relies on the interpretation of the two remainder terms in (61).

Open Problem 5. Show that any radial singular solution is also weakly singular, according to Definition 5. In particular, this would strengthen the statement of Theorem 6.

If the previous three open problems could be solved in the affirmative, then we could also conclude that the extremal solution U_* is singular if and only if $n \ge 13$.

We conclude this paper with some further problems. The next one is not yet completely solved even in the second order case.

Open Problem 6. Do there exist singular *nonradial* solutions to (P_λ) for some $\lambda > 0$? We conjecture that the answer is positive; see also Problem 7 in [BV].

Figure 2 displays the numerically computed value of $-v_4$ of the intersection of a portion of the unstable manifold of P_1 with the hyperplane $v_1 = 4$ in the case $n = 5$.

More precisely, $-v_4$ is displayed as a function of $x := -\log(-\vartheta)$. One may observe the estimated value of λ^* as the maximum value reached by $-v_4$; furthermore, as $\vartheta \to 0^-$ the value of $-v_4$ appears to asymptotically reach λ_σ oscillating around it. This leads us to the following problem.

Open Problem 7. Assume $n \le 12$. Prove that for every $N \in \mathbb{N}$ there exists $\varepsilon = \varepsilon(N) > 0$ such that for $\lambda \in [\lambda_\sigma - \varepsilon, \lambda_\sigma + \varepsilon]$ there exist at least N distinct regular radial solutions. For the second order problem the same statement holds true; see [GPP, Theorem 15].

Open Problem 8. How can one proceed in arbitrary smooth domains where it is known that comparison principles like Lemma 16 become false? How can one construct and *characterize* the *minimal* solution? Does one have similar bifurcation diagrams, where the solutions, however, can no longer be expected to be positive

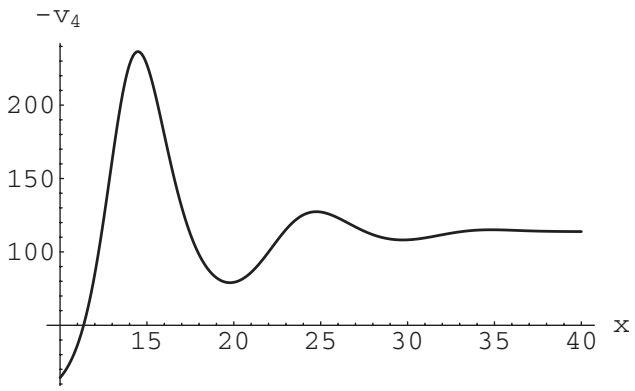

FIG. 2.

everywhere? Or does the lack of comparison principles lead to a completely different behavior, at least in geometrically very complicated domains?

9. Appendix. Computation techniques. We describe here the algorithm used in the computer assisted proofs. In order to prove Theorem 7 we need a rigorous estimate of the intersection of a branch of the unstable manifold with the hyperplane $v_1 = 4$. Since we do not know the exact location of any point of the manifold, except for the stationary point, we compute the trajectory of the whole set κ' as described in section 6. Since no analytical solution of the equation is available, we estimate the trajectories of all points of the set and compute the intersections with the hyperplane $v_1 = 4$ with rigorous error bounds. In order to compute the image of an infinite set of points, we partition it into boxes with small enough sides, which we call *interval sets*, and we compute their trajectories using interval arithmetics. More precisely, we start with a Taylor approximation of order 10; i.e., we estimate the trajectory of an interval by using the Taylor expansion of order 10 and estimate the error by the Lagrange remainder. If h is the time step, we compute a rough but rigorous enclosure D of the trajectory at times $[0, h]$, which is an interval set D such that the solution of the equation lies in D for all times between 0 and h. By Lagrange theorem we estimate the error we make neglecting the remaining terms of the Taylor expansion by computing $x^{(11)}(D)\frac{h^{11}}{11!}$. We compute $x^{(11)}(D)$ (which is an interval enclosing all possible values assumed by the 11th derivative of the trajectory, therefore enclosing the Lagrange remainder) using a recursive algorithm for the time derivatives of the solutions (see section I.8 in [HNW]). We point out that it takes a finite amount of s-time to go from any point in the set κ' (in Lemma 30) or κ (in Lemma 31) to the hyperplane $v_1 = 4$. The actual number and size of the intervals that we used as a partition of the sets κ' and κ can be read directly from the *Mathematica* notebook, together with the time step we used for the integration. We feel that it is pointless to display here the long list of numbers which represents such partitions, but since such a list is an essential part of the proof, we make it available in the *Mathematica* notebook.

The interval arithmetics algorithms address the problem of computing the trajectory of an interval and of keeping track of the errors in an elegant and rigorous way, but they introduce another problem. Indeed, even in the simplest dynamical system, the procedure described above leads to a very rough estimate of trajectories, due to the *wrapping effect* which makes the bounds on the error grow exponentially fast. The wrapping effect is one of the main problems one faces when trying to do

rigorous numerics for ODEs.

We describe it with one example: Consider a square centered at the origin $x = [-\delta, \delta]^2$ and the matrix that represents the rotation in $\mathbb{R}^2$ by an angle α,

$$R(\alpha) = \begin{bmatrix} \cos(\alpha) & -\sin(\alpha) \\ \sin(\alpha) & \cos(\alpha) \end{bmatrix}.$$

Assume for simplicity that $0 < |\alpha| < \pi/2$. If we apply R_α to x and wish to represent the result by another interval (i.e., another rectangle with sides parallel to the coordinate axes), we see that we need $(\cos(\alpha) + |\sin(\alpha)|)[-\delta, \delta]^2$; therefore, although R_α is an isometry, its computer realization has a growth factor $\cos(\alpha) + |\sin(\alpha)| > 1$. When solving the system of equations of the harmonic oscillator

$$\dot{x} = -y, \quad \dot{y} = x, \tag{63}$$

the 2π-shift along the trajectory is an identity map, but when we compute it numerically in interval arithmetics, say with time step $h = 2\pi/N$, we have to compose N times the map induced by $R(h)$. An easy computation shows this computation yields a growth factor $e^{2\pi} \approx 535$ as $h \to 0$.

We substantially reduce the wrapping effect by using the Lohner algorithm. A complete description of interval arithmetics and of the Lohner algorithm is beyond the scope of this paper; we refer to section 6 in [AZ] and the references cited therein for an exhaustive treatment of the topic. More specifically, see [MZ] concerning interval arithmetics and [Lo] for the Lohner algorithm. For the purpose of this description it suffices to consider the Lohner algorithm as a finite number of interval arithmetic operations based on the Taylor expansion which, given (8), an (interval) initial condition $V_0 \subset \mathbb{R}^4$, and a time step h, returns an interval $V_1 \subset \mathbb{R}^4$ such that for all points $v_0 \in V_0$ the solution $v(s)$ of the Cauchy problem with initial condition $v(0) = v_0$ satisfies $v(h) \in V_1$. In other words, the Lohner algorithm provides a rigorous enclosure of the solution at time h of a given Cauchy problem by performing a finite number of operations. The fact that the operations involved are in finite number and purely arithmetical (they are basically sums and multiplications, which can be performed with computer representable numbers with rigorous control on the round-off) makes it suitable for implementation with a computer.

We must determine the intersection of the trajectory with the hyperplane $v_1 = 4$. Since we are computing the trajectory of an interval, it takes a finite (nonzero) amount of "time" to cross the hyperplane; therefore we necessarily introduce another error when estimating the intersection point and have to give a rigorous bound for this error as well. We proceed as follows. We numerically compute the time s_1 required for the flow to reach the intersection. We compute with the Lohner algorithm the solution V_1 of the problem at time s_1. We check if the first component $(V_1)_1$ of V_1 is contained in $(-\infty, 4]$. If $(V_1)_1 \subset (-\infty, 4]$, then no points in V_1 have crossed the hyperplane. If $(V_1)_1 \not\subset (-\infty, 4]$, we choose (arbitrarily) a smaller value of s_1 and repeat the step. Then we roughly compute the time s_2 required for the set V_1 to cross the hyperplane. With the Lohner algorithm we compute the solution V_2 of the problem at time s_2. We check that all points in V_2 have crossed the hyperplane, i.e., $(V_2)_1 \subset [4, +\infty)$. If not, we choose a larger value for s_2 and repeat the step. We are interested only in the value of the fourth component of the solution: since at all points of our interest $v_4' < 0$ (because $v_4' = v_1 v_4$), it suffices to compute the hull of the interval value of v_4 before and after the crossing of the hyperplane. We now have a rigorous proof that the intersection takes place at some $v_4 \in [\min(V_2)_4, \max(V_1)_4]$, and this last interval

(with the left bound rounded down and the right bound rounded up) is the value we display in Table 1. For the λ^* computation we display only $\max(V_1)_4$ rounded down, since the other side of the interval does not have any meaning.

In order to check the third statement in Lemma 30, it is not enough to check that the evolution of all points is in A as defined in subsection 6.2. Indeed, if the time step is large, it may happen that some trajectory leaves A and reenters it in a single integration step. We have therefore to check at every time step that the whole rough enclosure D as defined above is in A and that the part of the set A which is contained in the flow tube has a trivial topology, i.e., it does not have holes. The round-off errors are taken care directly by suitable C++ procedures. Such errors may vary by changing computers and/or operating systems, but since they are usually very small when compared to the wrapping effect, we expect that the proofs can be easily reproduced on any recent computer obtaining very similar bounds.

To perform the proofs, we implemented a version of the whole algorithms in a combination of *Mathematica* 4.0 and C++ (gcc version 2.95.1) under the Linux operating system. More precisely, *Mathematica* was used to handle all the data and to perform a few algorithms which are less demanding for the CPU, but more complicated to implement. Furthermore *Mathematica* was used to make all numerical experiments and to draw the pictures. On the other hand C++ was used for the heavy interval arithmetic computations, where it offered much higher speed and more controllable accuracy. The connection between the two languages was obtained by MathLink. The verification of the whole proof takes a few days of CPU time on a machine equipped with an Athlon XP1700 processor. The computer programs which are part of the proofs can be obtained from the authors upon request, while the interval algorithms are provided by [CAPD].

Acknowledgments. We are grateful to Anna Dall'Acqua (TU Delft) and Elvise Berchio (Università di Torino) for their careful reading and for helpful remarks. We are also grateful to the referees for their careful review of the paper and for some very useful suggestions on the presentation.

ON A STOKES-LIKE SYSTEM FOR MIXTURES OF FLUIDS*

JENS FREHSE†, SONJA GOJ‡, AND JOSEF MÁLEK§

Abstract. We consider a simplified model that describes steady flows of a miscible mixture of fluids. The corresponding system of equations is studied in the whole space $\mathbb{R}^3$. The densities ρ_i of the species and their velocity fields $u^{(i)}$ are prescribed at infinity: $\rho_i|_\infty = \rho_{i\infty} > 0\,, \quad u^{(i)}|_\infty = 0$. We prove the existence of weak solutions to the system under consideration.

Key words. mixtures of fluids, Stokes-like equations, compressible fluid, weak solution

1. Introduction.

1.1. Description of the model. There are various approaches to model the behavior of mixtures. In this paper we deal with a continuum mechanics model describing flows of the mixture of N compressible fluids (we call such a material *N-component* or *multicomponent fluid*) at constant temperature. Based on the assumption that the mixture is sufficiently dense, it is reasonable to assume that at each point of the space occupied by the mixture there are particles belonging to each component.

Following the theory introduced in [24] that generalizes the earlier pioneering works by Fick [10], Darcy [2], and later on by Truesdell [26], isothermal flows of such a material can be fully captured by $2N$ functions $(\rho_i, u^{(i)}), i = 1, \dots, N$, representing the densities ρ_i and the velocities $u^{(i)}$ of the ith component of the mixture, and solving the equations

$$(\rho_i)_t + \operatorname{div}\left(\rho_i u^{(i)}\right) = 0\,, \tag{1.1}$$

$$\left(\rho_i u^{(i)}\right)_t + \operatorname{div}\left(\rho_i u^{(i)} \otimes u^{(i)}\right) - \operatorname{div} T^{(i)} = \rho_i f^{(i)} + J^{(i)}\,, \tag{1.2}$$

where $f^{(i)}$ is a given external force, $T^{(i)}$ represents the partial Cauchy stress, and $J^{(i)}$ is an interaction term (the momentum source); all quantities are associated to the ith constituent. Note that (1.1) and (1.2) follow from the *balance of mass* (no chemical reactions) and the *balance of linear momentum* for each constituent.

Just for simplicity we "restrict" ourselves to a two-component fluid, i.e., $N = 2$. Then the principle of action and reaction implies that

$$J^{(1)} = -J^{(2)}\,. \tag{1.3}$$

Let further ψ_i denote the Helmholtz potential associated to the ith constituent. Then the *balance of entropy* for the total mixture and *the second law of thermodynamics* imply (recall that the temperature is supposed to be constant) that

$$\sum_{i=1}^{2} T^{(i)} \cdot \nabla u^{(i)} + J^{(1)} \cdot \left(u^{(2)} - u^{(1)}\right) - \sum_{i=1}^{2} \left[\rho_i (\psi_i)_t + \rho_i u_k^{(i)} (\psi_i)_{x_k}\right] \geq 0\,, \tag{1.4}$$

where we also used (1.3). Inequality (1.4) helps to identify the structure of the constitutive equations for $T^{(i)}$ and $J^{(i)}$.

We start with the assumption that the energy storage mechanism is the same for each constituent, i.e., $\psi_1 = \psi_2$, and for $i = 1, 2$ we have

$$\psi_i = \Psi(\rho_1 + \rho_2) \quad \text{or more generally} \quad \psi_i = \tilde{\Psi}\left(\frac{\rho_1}{\rho_{1,ref}} + \frac{\rho_2}{\rho_{2,ref}}\right), \tag{1.5}$$

where $\rho_{i,ref}$, $i = 1, 2$, are positive reference densities. Considering the former for simplicity, inserting it into (1.4), using also (1.1), and setting

$$P_i(\rho) = P_i(\,(\rho_1, \rho_2)^T\,) = \rho_i(\rho_1 + \rho_2)\,\Psi'(\rho_1 + \rho_2)\,, \tag{1.6}$$

we eventually arrive at

$$\sum_{i=1}^{2} \left[T^{(i)} + P_i(\rho) I\right] \cdot \nabla u^{(i)} + \left[J^{(1)} + \Psi'(\rho_1 + \rho_2)\,(\rho_1 \nabla \rho_2 - \rho_2 \nabla \rho_1)\right] \cdot (u^{(2)} - u^{(1)}) \geq 0\,, \tag{1.7}$$

where I denotes the identity tensor. Put

$$\sigma^{(i)} := T^{(i)} + P_i(\rho) I \quad \text{and} \quad G := J^{(1)} + \Psi'(\rho_1 + \rho_2)\,(\rho_1 \nabla \rho_2 - \rho_2 \nabla \rho_1)\,. \tag{1.8}$$

Then, denoting $D(w) := \frac{1}{2}\left(\nabla w + (\nabla w)^T\right)$ for $w\colon \mathbb{R}^3 \to \mathbb{R}^3$, we observe that setting

$$\begin{aligned} \sigma^{(i)} &= \mu_{i1} D(u^{(1)}) + \mu_{i2} D(u^{(2)}) + \nu_{i1} \operatorname{div} u^{(1)} I + \nu_{i2} \operatorname{div} u^{(2)} I\,, \\ G &= a(\rho_1, \rho_2, |u^{(1)} - u^{(2)}|)(u^{(2)} - u^{(1)}) \end{aligned}$$

and requiring[1] that for a certain $c_0 > 0$

$$\sum_{i=1}^{2} \sigma^{(i)} \cdot \nabla u^{(i)} \geq c_0 |\nabla u|^2 \qquad \text{and} \qquad a(\rho_1, \rho_2, |u^{(1)} - u^{(2)}|) \geq 0\,, \tag{1.9}$$

(1.7) is automatically fulfilled. This means that the system (1.1)–(1.2) with

$$T^{(i)} = -P_i(\rho) I + \sigma^{(i)}, \tag{1.10}$$

$$J^{(1)} = a(\rho_1, \rho_2, |u^{(1)} - u^{(2)}|)(u^{(2)} - u^{(1)}) - \Psi'(\rho_1 + \rho_2)\,(\rho_1 \nabla \rho_2 - \rho_2 \nabla \rho_1) \tag{1.11}$$

[1] In terms of the viscosities, $(1.9)_1$ is equivalent to

$$\begin{gathered} \mu_{11} > 0\,, \quad \mu_{22} > 0\,, \quad 2\mu_{11} + \nu_{11} > 0\,, \quad 2\mu_{22} + \nu_{22} > 0\,, \\ 4\mu_{11}\mu_{22} - (\mu_{12} + \mu_{21})^2 > 0\,, \\ 4(2\mu_{11} + \nu_{11})(2\mu_{22} + \nu_{22}) - (2\mu_{12} + \nu_{12} + 2\mu_{21} + \nu_{21})^2 > 0\,. \end{gathered}$$

is *thermomechanically consistent*. It means the basic energy estimates are in place.

We, however, consider an approximation of this system neglecting the second term in (1.11). In other words, we assume that the momentum source due to $\rho_1\nabla\rho_2-\rho_2\nabla\rho_1$ is of much lower order than the effects due to the difference between the velocities of the constituents. Numerical simulations of flows in special geometries have also shown that there is no significant difference in the resulting flows regardless of whether the second term in (1.11) is considered or neglected (see also [25]). One may also argue that it is difficult to identify the second term in (1.11) experimentally. Thus, in what follows the interaction terms take the form[2]

$$J^{(1)} = -J^{(2)} = a(\rho_1, \rho_2, |u^{(1)} - u^{(2)}|)\,(u^{(2)} - u^{(1)})\,. \tag{1.12}$$

However, once we accept (1.12) instead of (1.11), the basic energy identity is lost. We will return to this issue in subsection 1.4.

We also restrict ourselves to steady flows, i.e., $(\rho_i)_t = 0$ and $(\rho_i u^{(i)})_t = 0$ in (1.1) and (1.2).

Finally, we neglect the convective term $\operatorname{div}(\rho_i u^{(i)} \otimes u^{(i)})$ in (1.2), which may be justified either geometrically (there are flows in special geometries where $\operatorname{div}(\rho u\otimes u) = 0$) or via a proper scaling that leads to a nondimensional form which allows us to neglect the convective term for slow flows. Since the full system is very complex, our motivation to neglect the convective term has been rather technical: to start with the investigation of a simpler yet interesting system first. Thus, in analogy to the mathematical theory for incompressible fluids, we start with the *Stokes-like system for a mixture of fluids*.

To summarize, we end up with the system ($i = 1, 2$)

$$\operatorname{div}\left(\rho_i u^{(i)}\right) = 0\,, \tag{1.13}$$

$$L^{(i)}u = -\nabla P_i(\rho) + \rho_i f^{(i)} + J^{(i)}, \tag{1.14}$$

where $J^{(i)}$ is of the form (1.12), $L^{(i)}u$ is defined through

$$L^{(i)}u = -\operatorname{div}\sigma^{(i)} = -\sum_{k=1}^{2}(\mu_{ik}\Delta u^{(k)} + (\mu_{ik} + \nu_{ik})\nabla \operatorname{div} u^{(k)})\,, \tag{1.15}$$

and the constant coefficients μ_{ik} and ν_{ik} and the function a fulfill (1.9).

The structure of $P_i(\rho)$ comes from (1.6). To give an example, assuming that $\Psi = (\rho_1 + \rho_2)^{\gamma-1}$ in (1.5) with $\gamma > 1$, we obtain

$$P_i(\rho) = c_i\rho_i\,(\rho_1 + \rho_2)^{\gamma-1} \qquad \text{with} \quad \gamma > 1 \qquad (c_i > 0)\,. \tag{1.16}$$

In this paper we study (1.13)–(1.14) in the whole space $\mathbb{R}^3$, assuming that for given positive $\rho_{i\infty}$, $i = 1, 2$, the following holds:

$$u^{(i)} \to 0 \quad \text{and} \quad \rho_i \to \rho_{i\infty} \qquad \text{as} \quad |x| \to \infty \quad (i = 1, 2)\,. \tag{1.17}$$

We are interested in proving the existence of solutions to (1.13)–(1.14) and (1.17), completed with, say, (1.12), (1.15) with $(1.11)_1$, and (1.16). The precise assumptions on $P_i(\rho)$ and $J^{(i)}$ are given in subsection 1.2. The precise formulation of the main result is postponed to subsection 1.3.

[2]The main reason we prefer (1.12) rather than (1.11) comes of course from the analysis of the system: We have not been able to find sufficient information in order to pass to the limit in the nonlinear terms containing $\nabla\rho_i$.

1.2. Effective viscous flux and assumptions on P_i and $J^{(i)}$. Applying div to (1.14) we obtain

$$(-\Delta)\left(\sum_{k=1}^{2}(2\mu_{ik}+\nu_{ik})\operatorname{div}u^{(k)}-P_i(\rho)\right)=\operatorname{div}\left(\rho_i f^{(i)}+J^{(i)}\right),$$

which can be rewritten as

$$\begin{pmatrix} 2\mu_{11}+\nu_{11} & 2\mu_{12}+\nu_{12} \\ 2\mu_{21}+\nu_{21} & 2\mu_{22}+\nu_{22} \end{pmatrix}\begin{pmatrix} \operatorname{div}u^{(1)} \\ \operatorname{div}u^{(2)} \end{pmatrix}-\begin{pmatrix} P_1(\rho) \\ P_2(\rho) \end{pmatrix}=\begin{pmatrix} F^{(1)} \\ F^{(2)} \end{pmatrix}, \tag{1.18}$$

where

$$F^{(i)}=(-\Delta)^{-1}\operatorname{div}\left(\rho_i f^{(i)}+J^{(i)}\right). \tag{1.19}$$

Alternatively, (1.18) can be viewed as

$$\begin{pmatrix} \operatorname{div}u^{(1)} \\ \operatorname{div}u^{(2)} \end{pmatrix}=\begin{pmatrix} 2\mu_{11}+\nu_{11} & 2\mu_{12}+\nu_{12} \\ 2\mu_{21}+\nu_{21} & 2\mu_{22}+\nu_{22} \end{pmatrix}^{-1}\left[\begin{pmatrix} P_1(\rho) \\ P_2(\rho) \end{pmatrix}+\begin{pmatrix} F^{(1)} \\ F^{(2)} \end{pmatrix}\right]. \tag{1.20}$$

Since the matrix on the right-hand side of (1.20) is not necessarily symmetric, one may choose β_0 such that A_0 defined through

$$A_0=\begin{pmatrix} \beta_0 & 0 \\ 0 & 1 \end{pmatrix}\begin{pmatrix} 2\mu_{11}+\nu_{11} & 2\mu_{12}+\nu_{12} \\ 2\mu_{21}+\nu_{21} & 2\mu_{22}+\nu_{22} \end{pmatrix}^{-1} \tag{1.21}$$

is symmetric, and positive definite if $2\mu_{ik}+\nu_{ik}>0$. With this notation (1.20) results in the form

$$\begin{pmatrix} \beta_0\operatorname{div}u^{(1)} \\ \operatorname{div}u^{(2)} \end{pmatrix}=A_0\left[\begin{pmatrix} P_1(\rho) \\ P_2(\rho) \end{pmatrix}+\begin{pmatrix} F^{(1)} \\ F^{(2)} \end{pmatrix}\right]. \tag{1.22}$$

This equation will play a key role in our analysis. Analogously to the theory of a single compressible fluid we call (1.22) the *equation for the effective viscous flux*.

Now, we can formulate the assumptions on $P_i(\rho)$. We suppose that there are $\gamma>1$ and $\beta_0\neq 0$ such that $P(\rho)=(P_1(\rho),P_2(\rho))^T$ fulfills

(i) *the monotonicity condition*:
there is $\lambda_0>0$ such that for all $\rho=(\rho_1,\rho_2)^T$ and $\hat\rho=(\hat\rho_1,\hat\rho_2)^T$, $\rho_i,\hat\rho_i\geq 0$,

$$(\rho-\hat\rho)^T A_0\left(P(\rho)-P(\hat\rho)\right)\geq\lambda_0\left(|\rho|^{\gamma-1}+|\hat\rho|^{\gamma-1}\right)|\rho-\hat\rho|^2; \tag{1.23}$$

(ii) *the coerciveness condition*:
there are $\lambda_1 > 0, \lambda_2 \in \mathbb{R}$ such that for all $\rho = (\rho_1, \rho_2)^T, \rho_i \geq 0$,

$$(\rho^\gamma - \rho_\infty^\gamma)^T A_0 \left(P(\rho) - P(\rho_\infty)\right) \geq \lambda_1 |\rho - \rho_\infty|^{2\gamma} - \lambda_2 |\rho - \rho_\infty|^2 ; \tag{1.24}$$

(iii) *the growth condition*:
there is $K > 0$ such that for all $\rho = (\rho_1, \rho_2)^T$ and $\hat{\rho} = (\hat{\rho}_1, \hat{\rho}_2)^T$

$$|P(\rho) - P(\hat{\rho})| \leq K \left(|\rho|^{\gamma-1} + |\hat{\rho}|^{\gamma-1}\right) |\rho - \hat{\rho}| . \tag{1.25}$$

In the appendix of [12], we show that $P(\rho)$ of the form (1.16) fulfills the coerciveness condition (1.24). Similarly, one can show that $P(\rho)$ of the form (1.16) fulfills (1.23) under reasonable conditions[3] on γ. Note also that (1.25) is satisfied by (1.16) as well.

Next, we give the assumptions on the interaction terms. We suppose that $J^{(1)}$ and $J^{(2)}$ satisfy (1.12) and

$$\begin{aligned} &\text{there are } \theta \in (0,1) \text{ and } K > 0 \text{ such that} \\ &|J^{(1)}| = |J^{(2)}| = |a(x, \rho, |u^{(1)} - u^{(2)}|)(u^{(2)} - u^{(1)})| \leq K(1 + |u^{(1)} - u^{(2)}|)^\theta \end{aligned} \tag{1.26}$$

and there is $R_0 \gg 1$ such that

$$a \in C(\mathbb{R}^3 \times \mathbb{R}_0^+ \times \mathbb{R}_0^+) \text{ and } a(x, \cdot, \cdot) = 0 \text{ if } |x| \geq R_0 . \tag{1.27}$$

Sublinear growth of $J^{(i)}$, $i = 1, 2$, seems to be crucial in our method in order to deduce estimates for ρ, while the assumption concerning the compact support of a is useful in order to avoid technical difficulties concerning the asymptotic behavior of $u^{(1)}, u^{(2)}$ as $|x| \to \infty$.

We complete this part with two inequalities that follow from (1.23) and (1.25). First of all, taking $\hat{\rho} = \rho_\infty$ in (1.25) and using some elementary considerations, we obtain that there is a $K = K(\rho_\infty) > 0$ such that for all $\rho = (\rho_1, \rho_2)^T$

$$|P(\rho) - P(\rho_\infty)| \leq K(\rho_\infty) \left(|\rho - \rho_\infty|^\gamma + |\rho - \rho_\infty|\right) . \tag{1.28}$$

Also, there is $\hat{\lambda}_0$ such that for all $\rho = (\rho_1, \rho_2)^T$

$$(\rho - \rho_\infty)^T A_0 \left(P(\rho) - P(\rho_\infty)\right) \geq \hat{\lambda}_0 \left(|\rho - \rho_\infty|^{\gamma+1} + |\rho - \rho_\infty|^2\right) , \tag{1.29}$$

which is a consequence of (1.23) and the algebraic inequality

$$(g + h)^{\gamma-1} \geq \frac{1}{2^{\gamma-1}} g^{\gamma-1} - h^{\gamma-1} \qquad (g, h \geq 0) \tag{1.30}$$

---

[3] These conditions will be addressed in [14]. Let us mention two special cases where (1.23) holds.
(i) $\mu_{ij} > 0$ ($\Longrightarrow$ $A_{ij} < 0$, $i \neq j$, where $A_0 = (A_{ij})$) and for all $r \in \mathbb{R}$ with $(B_{ij}) = A_0 \left(\begin{smallmatrix} c_1 & 0 \\ 0 & c_2 \end{smallmatrix}\right)$:

$$\begin{aligned} &(B_{11} + B_{12}(\gamma - 1))r^2 + (B_{21} + \gamma B_{12} + B_{22}(\gamma - 1))r + \gamma B_{22} \geq \lambda_0(1 + r^2) , \\ &(B_{22} + A_{21}(\gamma - 1))r^2 + (B_{12} + \gamma B_{21} + B_{11}(\gamma - 1))r + \gamma B_{11} \geq \lambda_0(1 + r^2) . \end{aligned}$$

These conditions are fulfilled if γ is not too large, say, $\gamma \leq 2$, and the diagonal terms of A_0 dominate the nondiagonal ones.
(ii) $A_{11} = A_{22}$, $A_{12} = A_{21}$, $A_{12}/A_{11} = \chi \leq 0$, and $\gamma(1 + \chi(\gamma - 1)) - 1/4(\chi(\gamma + 1) + \gamma - 1)^2 > 0$.

that follows from $g^{\gamma-1} \le (g+h-h)^{\gamma-1} \le 2^{\gamma-1}\Big((g+h)^{\gamma-1}+h^{\gamma-1}\Big)$. To see that (1.29) holds, we take $\hat\rho = \rho_\infty$ in (1.23) and compute

$$\begin{aligned}(\rho-\rho_\infty)^T A_0\left(P(\rho)-P(\rho_\infty)\right) &\ge \lambda_0\left(|\rho-\rho_\infty+\rho_\infty|^{\gamma-1}+|\rho_\infty|^{\gamma-1}\right)|\rho-\rho_\infty|^2\\ &\ge \frac{\lambda_0}{2}\left(|\rho-\rho_\infty+\rho_\infty|^{\gamma-1}+|\rho_\infty|^{\gamma-1}\right)|\rho-\rho_\infty|^2+\frac{\lambda_0}{2}|\rho_\infty|^{\gamma-1}|\rho-\rho_\infty|^2\\ &\overset{(1.30)}{\ge} \frac{\lambda_0}{2}\left(\frac{1}{2^{\gamma-1}}|\rho-\rho_\infty|^{\gamma-1}\right)|\rho-\rho_\infty|^2+\frac{\lambda_0}{2}|\rho_\infty|^{\gamma-1}|\rho-\rho_\infty|^2,\end{aligned}$$

which implies (1.29) with $\hat\lambda_0 = \min\{\lambda_0/2^\gamma, \lambda_0|\rho_\infty|^{\gamma-1}/2\}$.

1.3. Formulation of the result. First, we fix the notation of the function spaces we will use. The symbols $L^q(\mathbb{R}^3)$, or L^q in short, $1 \le q < \infty$, denote the standard Lebesgue spaces of scalar-valued measurable functions. The space norm is denoted by $\|u\|_{L^q}^q = \int_{\mathbb{R}^3}|u(x)|^q\,dx$. If $X(\mathbb{R}^3)$ is a space of (scalar) functions, then $X(\mathbb{R}^3;\mathbb{R}^3)$ denotes the space of all $w = (w_1,w_2,w_3)^T\colon \mathbb{R}^3 \to \mathbb{R}^3$ such that $w_j \in X(\mathbb{R}^3)$, $j=1,2,3$.

We will further use the space $H_0^1 := H_0^1(\mathbb{R}^3;\mathbb{R}^3)$ defined as the closure of the space of smooth functions with compact support in $\mathbb{R}^3$ with respect to the norm $\|u\|_{H_0^1} = \|\nabla u\|_{L^2}$. Recall that $H_0^1 \hookrightarrow L^6$, but H_0^1 is not embedded into L^2.

We formulate our result.

THEOREM 1.1. *Let $\rho_\infty = (\rho_{1\infty},\rho_{2\infty})^T$, $\rho_{1\infty},\rho_{2\infty} > 0$, be given. Let*

$$f^{(i)} \in L^\infty(\mathbb{R}^3;\mathbb{R}^3) \text{ and have compact support.} \tag{1.31}$$

Assume that ν_{ik},μ_{ik} forming the operators $L^{(i)}$ according to (1.15) *fulfill the condition* $(1.9)_1$. *Assume further that $P(\rho) = (P_1(\rho),P_2(\rho))^T$ satisfies* (1.23)–(1.25) *with $\gamma > 1$. Finally, assume that $J^{(i)}$, $i=1,2$, of the form* (1.12) *fulfill* (1.26)–(1.27). *Then there is a weak solution (ρ,u), $\rho = (\rho_1,\rho_2)^T$, $u = (u^{(1),T},u^{(2),T})^T$, such that for $i=1,2$*

$$\rho_i \ge 0\,, \tag{1.32}$$

$$\rho_i - \rho_{i\infty} \in L^2(\mathbb{R}^3)\cap L^{2\gamma}(\mathbb{R}^3)\,, \tag{1.33}$$

$$u^{(i)} \in H_0^1(\mathbb{R}^3;\mathbb{R}^3)\,, \tag{1.34}$$

solving the equations (1.13)–(1.14) *in a distributional sense.*

The proof of Theorem 1.1 is performed in the consequent sections via the following scale of approximations.

For $\alpha > 0$, $\beta > 0$, $\sigma > 0$, and $s_0 > \max\{4,2\gamma\}$, we consider the system ($i=1,2$)

$$-\sigma\Delta\rho_i + \alpha\left(1+|\rho_i-\rho_{i\infty}|^{s_0-2}\right)(\rho_i-\rho_{i\infty}) + \operatorname{div}\left(\rho_i u^{(i)}\right) = 0, \tag{1.35}$$

$$L^{(i)}u = -\nabla\left(w_\beta(P_i(\rho)-P_i(\rho_\infty))\right) + \rho_i f^{(i)} + (-1)^{i+1}J^{(1)} \quad \text{with } w_\beta = (1+\beta|x|)^{-4}. \tag{1.36}$$

Clearly, if we set $\sigma = 0$, $\alpha = 0$, and $\beta = 0$ in (1.35) and (1.36), we obtain (1.13)–(1.14).

In section 2 we prove the existence of weak solutions to (1.35)–(1.36) in $\mathbb{R}^3$. In section 3, we derive the equation for the effective viscous flux related to this approximation. Using this tool, we can then derive estimates for the densities and the velocities that are uniform with respect to β. This allows us to show not only that there is a weak solution to (1.35) and (1.36) with w_β replaced by 1, but also that this solution satisfies certain types of inequalities, from which estimates uniform with respect to α can be derived. The derivation of these estimates is performed in section 4, together with the passage to the limit as $\alpha \to 0$. Finally, in section 5, we let $\sigma \to 0$.

1.4. Main difficulties. First of all, we would like to point out a remarkable difference between the analysis of the system (1.13)–(1.14) describing the steady flow of two miscible fluids on the one hand and the analysis of the analogous model for a one-constituent compressible fluid on the other hand. This difference manifests itself in the first step, i.e., in the derivation of a priori estimates. To be more precise, consider the equations for one single fluid that are analogous to (1.13)–(1.14):

$$\operatorname{div}(\varrho v) = 0 \quad \text{in } \mathbb{R}^3, \tag{1.37}$$

$$-\mu\Delta v - (\lambda+\mu)\nabla \operatorname{div} v = -\nabla \varrho^\gamma + \varrho f \quad \text{in } \mathbb{R}^3, \tag{1.38}$$

$$v \to 0 \quad \text{and} \quad \varrho \to \varrho_\infty \quad \text{as } |x| \to \infty\,, \tag{1.39}$$

with $\varrho\colon \mathbb{R}^3 \to \mathbb{R}$, $v\colon \mathbb{R}^3 \to \mathbb{R}^3$, and a given $\varrho_\infty > 0$. Multiplying (1.38) by v and integrating by parts, we observe that the left-hand side controls the L^2-norm of the velocity gradient, and the first term on the right-hand side leads to

$$-\int \nabla \varrho^\gamma v\,dx = -\frac{\gamma}{\gamma-1}\int \varrho v\cdot\nabla\varrho^{\gamma-1}\,dx = -\frac{\gamma}{\gamma-1}\int \operatorname{div}(\varrho v)\,\varrho^{\gamma-1}\,dx = 0\,, \tag{1.40}$$

thanks to (1.37). Thus, energy estimates are available once we control the term $\int \varrho f v\,dx$, which is in some sense a lower order term. We will not complete this step.

Rather we wish to emphasize that the cancellation property (1.40) cannot be expected for the model for mixtures (1.13)–(1.14). If we imitate the above outlined procedure and multiply the ith equation in (1.14), where $P_i(\rho)$ is of the form (1.16), by $u^{(i)}$ and sum the resulting equations over $i = 1, 2$, we obtain again with the aid of $(1.9)_1$ the control of the L^2-norm of the velocity gradient on the left-hand side; however, the terms containing the partial pressures on the right-hand side taking the form

$$\sum_{i=1}^{2} c_i \int_{\mathbb{R}^3} (\rho_1+\rho_2)^{\gamma-1}\rho_i \operatorname{div} u^{(i)}\,dx \tag{1.41}$$

are not vanishing, as one can easily check. This means that we have to proceed in a different way.

Our approach is based on the equation for the effective viscous flux (1.22), known from the theory for standard compressible fluid models (see [19, 23, 7, 8]). We multiply this equation gradually by $\rho_i - \rho_{i\infty}$ or $\rho_i^\gamma - \rho_{i\infty}^\gamma$, integrate, and use also the properties of $P_i(\rho)$ and (1.1). Consequently, we succeed in proving estimates on the (approximate) densities.

In this procedure, there arise boundary terms which we are not able to treat up to now for the standard Dirichlet (no-slip) or Neumann-type (no-stick) boundary conditions. Thus, we deal with the problem in $\mathbb{R}^3$, where, however, some additional technical difficulties occur.

Finally, we have to handle the difficulties due to the nonlinearity of the pressure term $P(\rho)$. For this purpose we apply the techniques which were developed to treat the compressible Navier–Stokes equations (see [19, 7]).

1.5. Related results. To our knowledge such systems as (1.13)–(1.14) have not been considered so far for space dimension $d \geq 2$. (The one-dimensional case has been treated, for example, in [17] and [27].) This is in contrast to the successful mathematical theory of "immiscible" mixtures of fluids (cf. [20, 21, 4, 16]), the theory of the density-dependent incompressible Navier–Stokes equations ([18, 1]), and the

compressible Navier–Stokes equations in the steady case (cf. [22, 23, 19]) and in the evolutionary case (cf. [19, 7, 9, 5, 3]).

The result of Theorem 1.1 was announced in [11], where we sketch the limit from σ-approximations to the original problem (cf. section 5 in this paper). In [11], we also show the additional regularity property of the solutions $\rho \in L^q_{loc}$, $\nabla u \in L^q_{loc}$ for all $q < \infty$.

Let us remark that the methods of the present paper can be adapted to treat the stationary case on a bounded domain with Dirichlet boundary conditions in the presence of the convective term, provided that an H^1-estimate for u is available. This is, e.g., possible if $P_i(\rho) \sim |\rho|^{\frac{1}{2}}$, which holds for some examples of mixtures. The quasi-stationary case is studied in [15], where even first derivatives of ρ_i can be estimated. Finally, in [13], the authors show that in the absence of $f^{(i)}$ and interaction terms the only solution to (1.13)–(1.14) is $u^{(i)} = 0$ and $\rho_i = \rho_{i\infty}$. This is a uniqueness type result.

2. Solvability of the $(\boldsymbol{\beta}, \boldsymbol{\alpha}, \boldsymbol{\sigma})$-approximations. The goal of this section is to prove the following statement.

PROPOSITION 2.1. *For each $\alpha > 0$, $\beta > 0$, and $\sigma > 0$, under the assumptions of Theorem* 1.1*, there exists a weak solution $(\rho, u) = (\rho^{\beta,\alpha,\sigma}, u^{\beta,\alpha,\sigma})$, $\rho = (\rho_1, \rho_2)^T$, $u = (u^{(1),T}, u^{(2),T})^T$ solving* (1.35) *and* (1.36) *such that for $i = 1, 2$*

$$\rho_i \geq 0\,, \quad \rho_i - \rho_{i\infty} \in L^2(\mathbb{R}^3) \cap L^{s_0}(\mathbb{R}^3) \cap H^1(\mathbb{R}^3) \qquad \text{and} \qquad u^{(i)} \in H^1_0(\mathbb{R}^3; \mathbb{R}^3).$$

Proof. We consider the system (1.35)–(1.36) in the ball $B_R = \{x \in \mathbb{R}^3; |x| \leq R\}$, where we impose the following boundary conditions:

$$u^{(i)} = 0 \quad \text{and} \quad \nabla \rho_i \cdot n = 0 \text{ on } \partial B_R \qquad (n \text{ being the outer normal to } \partial B_R). \tag{2.1}$$

We focus on only two steps. First, we find energy estimates to (1.35)–(1.36) in B_R that are uniform with respect to R. Note that these estimates are then not only sufficient for the existence of a solution for fixed R, but they also suffice to pass to the limit as $R \to \infty$. We skip these standard arguments based on the compact embeddings. In the second step, we outline that ρ_i are nonnegative.

Step 1. *Energy inequalities.* First, we test (1.36) by $u^{(i)}$ and sum over $i = 1, 2$ (in the next computation, in contrast to the rest of the paper, we use the summation convention over repeated indices i). It leads to (for $q > 2$)

$$\begin{aligned}
c_0 \int_{B_R} |\nabla u|^2 \, dx &\leq \int_{B_R} L^{(i)} u \cdot u^{(i)} \, dx \\
&= \int_{B_R} w_\beta (P_i(\rho) - P_i(\rho_\infty)) \operatorname{div} u^{(i)} \, dx + \int_{B_R} (\rho_i - \rho_{i\infty}) f^{(i)} \cdot u^{(i)} \, dx \\
&\quad + \rho_{i\infty} \int_{B_R} f^{(i)} \cdot u^{(i)} \, dx + (-1)^{i+1} \int_{B_R} a(\rho, |u^{(1)} - u^{(2)}|)(u^{(2)} - u^{(1)}) \cdot u^{(i)} \, dx \\
&\leq \varepsilon \int_{B_R} |\nabla u|^2 \, dx + \delta \int_{B_R} |P(\rho) - P(\rho_\infty)|^q \, dx + K_\delta \int_{B_R} w_\beta^{\frac{2q}{q-2}} \, dx \\
&\quad + 2\varepsilon \int_{B_R} |u|^6 \, dx + \varepsilon \int_{B_R} |\rho - \rho_\infty|^2 \, dx + K_\varepsilon \int_{B_R} |f|^3 \, dx \\
&\quad + K_\varepsilon \int_{B_R} |f|^{6/5} \, dx + \int_{B_{R_0}} (1 + |u^{(1)} - u^{(2)}|)^\theta |u| \, dx\,,
\end{aligned} \tag{2.2}$$

where we used (1.26) and (1.27). Since $0 < \theta < 1$, the last term is bounded (using also Young's inequality) by

$$C \int_{B_{R_0}} \left(|u| + |u|^{1+\theta} \right) dx \le \varepsilon \int_{B_R} |\nabla u|^2 \, dx + K(R_0) \qquad \text{for all } R \ge R_0. \tag{2.3}$$

Note that if θ were greater than or equal to 1, the last estimate would not be available. The sublinear growth of $J^{(1)}$ seems to be important.

Next, since $f \in L^\infty(\mathbb{R}^3)$ and has compact support and $w_\beta^{\frac{2q}{q-2}}$ is integrable over $\mathbb{R}^3$ for any $\beta > 0$, it follows directly from (2.2) and (2.3) and then from (1.28) that

$$\begin{aligned} \int_{B_R} |\nabla u|^2 \, dx &\le \tilde{\varepsilon} \int_{B_R} |P(\rho) - P(\rho_\infty)|^q \, dx + \tilde{\varepsilon} \int_{B_R} |\rho - \rho_\infty|^2 \, dx + K \\ &\le \tilde{\varepsilon} K(\rho_\infty) \int_{B_R} |\rho - \rho_\infty|^{q\gamma} + |\rho - \rho_\infty|^q \, dx + \tilde{\varepsilon} \int_{B_R} |\rho - \rho_\infty|^2 \, dx + K, \end{aligned} \tag{2.4}$$

where $\tilde{\varepsilon}$ is chosen as small as needed and $K = K(\beta^{-1}, \delta^{-1}, R_0)$.

Next, we test (1.35) by $\rho_i - \rho_{i\infty}$. Using inequality (2.4), we obtain

$$\begin{aligned} &\sigma \int_{B_R} |\nabla \rho_i|^2 \, dx + \alpha \int_{B_R} |\rho_i - \rho_{i\infty}|^2 + |\rho_i - \rho_{i\infty}|^{s_0} \, dx = \int_{B_R} \rho_i u^{(i)} \nabla (\rho_i - \rho_{i\infty}) \, dx \\ &= -\frac{1}{2} \int_{B_R} \operatorname{div} u^{(i)} (\rho_i - \rho_{i\infty})^2 \, dx - \rho_{i\infty} \int_{B_R} \operatorname{div} u^{(i)} (\rho_i - \rho_{i\infty}) \, dx \\ &\le \frac{\alpha}{8} \int_{B_R} |\rho_i - \rho_{i\infty}|^4 \, dx + K_\alpha \int_{B_R} |\nabla u|^2 \, dx + \frac{\alpha}{8} \int_{B_R} |\rho_i - \rho_{i\infty}|^2 \, dx \\ &\le \frac{\alpha}{8} \int_{B_R} |\rho_i - \rho_{i\infty}|^4 \, dx + \frac{\alpha}{8} \int_{B_R} |\rho_i - \rho_{i\infty}|^2 \, dx + \tilde{\varepsilon} K(\rho_\infty) \int_{B_R} |\rho - \rho_\infty|^{q\gamma} \, dx \, . \end{aligned}$$

Observing that for $s_0 > 2\gamma$ there is always a $q > 2$ such that $s_0 > q\gamma$, we can (via interpolation) subtract all the terms containing ρ to finally obtain

$$\sigma \int_{B_R} |\nabla \rho_i|^2 \, dx + \alpha \int_{B_R} |\rho_i - \rho_{i\infty}|^2 \, dx + \alpha \int_{B_R} |\rho_i - \rho_{i\infty}|^{s_0} \, dx \le K \, . \tag{2.5}$$

From (2.4) it then follows that

$$\int_{B_R} |\nabla u|^2 \, dx \le K \qquad \text{with } K = K(\alpha^{-1}, \beta^{-1}, R_0) \text{ but independent of } R \, . \tag{2.6}$$

Step 2. *Nonnegativity of the densities.* The proof is performed via standard weak maximum principles. To be more specific, we multiply (1.35) (for fixed $i = 1$ or 2) by a function G solving

$$\begin{aligned} -\sigma \Delta G - u_k^{(i)} \frac{\partial G}{\partial x_k} + \alpha G + \alpha |\rho_i - \rho_{i\infty}|^{s_0 - 2} G = \chi_{\{\rho_i < 0\}} \text{ in } B_R \, , \\ \nabla G \cdot n = 0 \quad \text{ on } \partial B_R \, . \end{aligned}$$

Before doing so, one may prefer to mollify the coefficients $u_k^{(i)}$ and $|\rho_i - \rho_{i\infty}|^{s_0 - 2}$ to construct G smooth enough. Integrating the resulting equation over B_R and using

integration by parts together with the boundary conditions for ρ_i, G and $u^{(i)}$ lead finally to the conclusion that

$$\int_{B_R} \rho_i \chi_{\{\rho_i<0\}}\, dx \geq 0\,,$$

which implies $\rho_i^- = 0$ a.e. in B_R. Thus $\rho_i \geq 0$ a.e. in B_R.

The sketch of the proof of Proposition 2.1 is finished. □

3. Solvability of the (α, σ)-approximations.

3.1. The equation for the effective viscous flux. Let $(\rho, u) = (\rho^{\beta,\alpha,\sigma}, u^{\beta,\alpha,\sigma})$ be solutions of (1.35)–(1.36) constructed above. The aim is to show that (ρ, u) also satisfy (a.e. in $\mathbb{R}^3$) the equation for the effective viscous flux

$$A_0\left(w_\beta\left(P(\rho)-P(\rho_\infty)\right)\right) - \begin{pmatrix} \beta_0 \operatorname{div} u^{(1)} \\ \operatorname{div} u^{(2)} \end{pmatrix} = A_0 \operatorname{div} \Delta^{-1} \begin{pmatrix} \rho_1 f^{(1)} + J^{(1)} \\ \rho_2 f^{(2)} - J^{(1)} \end{pmatrix}. \tag{3.1}$$

Thus, we multiply (1.36) by $\nabla\varphi^{(i)}$, where $\varphi^{(i)}$ is a smooth function with compact support in $\mathbb{R}^3$. In matrix notation, we obtain

$$\begin{aligned} &\int \begin{pmatrix} \Delta\varphi^{(1)} \\ \Delta\varphi^{(2)} \end{pmatrix}^T \begin{pmatrix} 2\mu_{11}+\nu_{11} & 2\mu_{12}+\nu_{12} \\ 2\mu_{21}+\nu_{21} & 2\mu_{22}+\nu_{22} \end{pmatrix} \begin{pmatrix} \operatorname{div} u^{(1)} \\ \operatorname{div} u^{(2)} \end{pmatrix} dx \\ &\quad = \int \begin{pmatrix} \Delta\varphi^{(1)} \\ \Delta\varphi^{(2)} \end{pmatrix}^T \begin{pmatrix} w_\beta\left(P_1(\rho)-P_1(\rho_\infty)\right) - \operatorname{div}\Delta^{-1}\left(\rho_1 f^{(1)} + J^{(1)}\right) \\ w_\beta\left(P_2(\rho)-P_2(\rho_\infty)\right) - \operatorname{div}\Delta^{-1}\left(\rho_2 f^{(2)} - J^{(1)}\right) \end{pmatrix} dx\,, \end{aligned}$$

where we used the identity

$$\int (\rho_i f^{(i)} + J^{(i)})\nabla\varphi^{(i)}\, dx = -\int \operatorname{div}\Delta^{-1}(\rho_i f^{(i)} + J^{(i)})\Delta\varphi^{(i)}\, dx, \tag{3.2}$$

which is valid certainly for smooth functions $\varphi^{(i)}$ with compact support, and by density arguments also for functions such that $\Delta\varphi^{(i)} \in L^2$. To see this, we first denote $h_i = \Delta^{-1}(\rho_i f^{(i)} + J^{(i)})$ so that $\Delta h_i = \rho_i f^{(i)} + (-1)^{i+1} a(\cdot, \rho, |u^{(1)} - u^{(2)}|)(u^{(2)} - u^{(1)})$ in $\mathbb{R}^3$. Then, using (1.26)–(1.27),

$$\begin{aligned} \left|\int \operatorname{div} h_i \Delta\varphi^{(i)}\, dx\right| &\leq \|\Delta\varphi^{(i)}\|_{L^2} \|\operatorname{div} h_i\|_{L^2} \leq c\|\Delta\varphi^{(i)}\|_{L^2}\|\rho_i f^{(i)}\|_{(H_0^1)^*} \\ &\leq c\|\Delta\varphi^{(i)}\|_{L^2}\Big(\|(\rho_i-\rho_{i\infty})f^{(i)}\|_{L^{6/5}} + \rho_{i\infty}\|f^{(i)}\|_{L^{6/5}} \\ &\qquad + \|1+|u^{(1)}-u^{(2)}|\,\|^{2\theta}_{L^{\frac{12\theta}{5}}(B_{R_0})}\Big) \\ &\leq c\|\Delta\varphi^{(i)}\|_{L^2}\left(\|\rho_i-\rho_{i\infty}\|_{L^{s_0}}\|f^{(i)}\|_{L^{\frac{6s_0}{5s_0-6}}} + \|\nabla u\|^{2\theta}_{L^2} + K_f\right) \\ &\leq K\|\Delta\varphi^{(i)}\|_{L^2}\,, \end{aligned} \tag{3.3}$$

as follows from the facts that $\rho_i - \rho_{i\infty} \in L^{s_0}$, $u \in H_0^1$, and $f^{(i)} \in L^\infty$ and a have compact supports. Thus, the validity of (3.2) for $\varphi^{(i)}$ with $\Delta\varphi^{(i)} \in L^2$ is verified.

Choose $\varphi = A_0\tilde{\psi}$, where $\varphi = \left(\varphi^{(1),T}, \varphi^{(2),T}\right)^T$, $\tilde{\psi} = (\tilde{\psi}^{(1),T}, \tilde{\psi}^{(2),T})^T$, and A_0 is introduced in (1.21). Then we obtain

$$\int \begin{pmatrix} \Delta\tilde{\psi}^{(1)} \\ \Delta\tilde{\psi}^{(2)} \end{pmatrix}^T \begin{pmatrix} \beta_0 \operatorname{div} u^{(1)} \\ \operatorname{div} u^{(2)} \end{pmatrix} dx$$
$$= \int \begin{pmatrix} \Delta\tilde{\psi}^{(1)} \\ \Delta\tilde{\psi}^{(2)} \end{pmatrix}^T A_0 \begin{pmatrix} w_\beta \left(P_1(\rho) - P_1(\rho_\infty)\right) - \operatorname{div} \Delta^{-1}\left(\rho_1 f^{(1)} + J^{(1)}\right) \\ w_\beta \left(P_2(\rho) - P_2(\rho_\infty)\right) - \operatorname{div} \Delta^{-1}\left(\rho_2 f^{(2)} - J^{(1)}\right) \end{pmatrix} dx\,.$$

For any $z \in L^2(\mathbb{R}^3)$ solve $-\Delta\tilde{\psi}^{(i)} = z$ in L^2, $i = 1, 2$. Then (3.1) follows.

3.2. Limit $\boldsymbol{\beta \to 0}$. We prove the following statement.

PROPOSITION 3.1. *Let $\alpha > 0$ and $\sigma > 0$ be fixed. Let all assumptions of Theorem* 1.1 *be fulfilled. Then there exists a solution $(\rho, u) = (\rho^{\alpha,\sigma}, u^{\alpha,\sigma}), \rho = (\rho_1, \rho_2)^T, u = (u^{(1),T}, u^{(2),T})^T$, such that (for $i = 1, 2$ and $\varepsilon > 0$ small)*

$$\rho_i \ge 0,\ \rho_i - \rho_{i\infty} \in L^{1+\varepsilon}(\mathbb{R}^3) \cap L^{s_0}(\mathbb{R}^3)\,, \tag{3.4}$$
$$u^{(i)} \in H^1_0(\mathbb{R}^3; \mathbb{R}^3) \tag{3.5}$$

solving weakly (1.35), (1.36), *and* (3.1) *with $\beta = 0$ ($\Longrightarrow w_\beta = 1$).*

In addition, (ρ, u) satisfies

$$\sum_{i=1}^2 \sigma\hat{\beta}_i \int \frac{|\nabla\rho_i|^2}{\rho_i}\,dx + \sum_{i=1}^2 \frac{\alpha\hat{\beta}_i}{2} \int (\rho_i - \rho_{i\infty})(\log\rho_i - \log\rho_{i\infty})\,dx$$
$$+ \sum_{i=1}^2 \frac{\alpha\hat{\beta}_i}{2} \int |\rho_i - \rho_{i\infty}|^{s_0-2}(\rho_i - \rho_{i\infty})(\log\rho_i - \log\rho_{i\infty})\,dx$$
$$+ \int A_0\left(P(\rho) - P(\rho_\infty)\right)\cdot(\rho - \rho_\infty)\,dx \le \int A_0 F\cdot(\rho - \rho_\infty) =: Y_F\,, \tag{3.6}$$

where F is introduced in (1.19), *$\hat{\beta}_1 = \beta_0$ (cf.* (1.21)*), and $\hat{\beta}_2 = 1$.*

Proof. We split the proof into two steps. First, we derive (3.6) for $\left(\rho^{\beta,\alpha,\sigma}, u^{\beta,\alpha,\sigma}\right)$. This means that w_β occurs in the last term of the left-hand side of (3.6). Let us call this inequality $(3.6)_\beta$. To be able to pass to the limit as $\beta \to 0$ we need to find the estimates that are uniform with respect to β. This is done in the second step.

Step 1. *Derivation of* $(3.6)_\beta$. We take the L^2 scalar product of (3.1) with $\tau(\rho - \rho_\infty)$, where τ is the usual cut-off function with $\tau = 1$ on the ball B_R and $\tau = 0$ outside of B_{2R}. We have verified in (3.3) that $F^{(i)}$ is bounded in L^2, which implies that $A_0 F\cdot(\rho - \rho_\infty) \in L^1$. Thus, it is easy to pass to the limit as $R \to \infty$ in all terms except for the terms with $\operatorname{div} u^{(i)}$ that require a detailed investigation. Clearly,

$$-\left(\operatorname{div} u^{(i)}, \tau(\rho_i - \rho_{i\infty})\right) = \left(u^{(i)}, \nabla\tau(\rho_i - \rho_{i\infty})\right) + \left(u^{(i)}, \tau\nabla\rho_i\right) =: H_1 + H_2\,, \tag{3.7}$$

where

$$H_2 = \left((\rho_i + \delta)u^{(i)}\tau, \nabla\log(\rho_i + \delta)\right)$$
$$= -\left(\operatorname{div}\left(\rho_i u^{(i)}\right)\tau, \log(\rho_i + \delta) - \log(\rho_{i\infty} + \delta)\right)$$
$$-\delta\left(\operatorname{div} u^{(i)}\tau, \log(\rho_i + \delta) - \log(\rho_{i\infty} + \delta)\right)$$
$$-\left((\rho_i + \delta)u^{(i)}\nabla\tau, \log(\rho_i + \delta) - \log(\rho_{i\infty} + \delta)\right) =: H_3 + H_4 + H_5\,.$$

First we observe that

$$|H_1| \le \|u^{(i)}\|_{L^6(B_{2R}\setminus B_R)} \|\nabla\tau\|_{L^3} \|\rho_i - \rho_{i\infty}\|_{L^2(B_{2R}\setminus B_R)} \to 0 \text{ as } R\to\infty \tag{3.8}$$

due to the fact that $u \in L^6(\mathbb{R}^3;\mathbb{R}^3)$, $\rho_i - \rho_{i\infty} \in L^2(\mathbb{R}^3)$, and $\|\nabla\tau\|_{L^3} \le C$. Also, since $|\log(\rho_i+\delta) - \log(\rho_{i\infty}+\delta)| \le \delta^{-1}(\rho_i - \rho_{i\infty})$, similar arguments ($\rho_i - \rho_{i\infty} \in L^4(\mathbb{R}^3)$) imply that

$$|H_5| \le \delta^{-1} \int (\rho_i - \rho_{i\infty})^2 |u^{(i)}||\nabla\tau|\, dx + (\rho_{i\infty}+\delta)\delta^{-1}|H_1| \to 0 \text{ as } R\to\infty\,. \tag{3.9}$$

Since $H_4 = -\int \operatorname{div} u^{(i)} \tau(\delta \int_0^1 \frac{1}{\delta + t\rho_i + (1-t)\rho_{i\infty}}\, dt)(\rho_i - \rho_{i\infty})\, dx$ and $\operatorname{div} u^{(i)} \cdot (\rho_i - \rho_{i\infty})$ belongs to L^1, and also

$$\delta \int_0^1 \frac{1}{\delta + t\rho_i + (1-t)\rho_{i\infty}}\, dt \le \delta \int_0^1 \frac{1}{\delta + (1-t)\rho_{i\infty}}\, dt = \frac{2\delta\log\delta}{\rho_{i\infty}} \to 0 \text{ as } \delta\to 0\,,$$

we observe that

$$H_4 \text{ is uniformly bounded with respect to } R \quad \text{and } H_4 \to 0 \text{ as } \delta\to 0\,. \tag{3.10}$$

Finally, inserting (1.35) into H_3 we obtain

$$\begin{aligned} H_3 &= \sigma \int \nabla\rho_i \cdot \nabla\tau \left(\log(\rho_i+\delta) - \log(\rho_{i\infty}+\delta)\right)\, dx \\ &\quad + \sigma \int \frac{|\nabla\rho_i|^2}{\rho_i+\delta}\tau\, dx + \alpha \int (\rho_i - \rho_{i\infty})\tau \left(\log(\rho_i+\delta) - \log(\rho_{i\infty}+\delta)\right)\, dx \\ &\quad + \alpha \int |\rho_i - \rho_{i\infty}|^{s_0-2}(\rho_i - \rho_{i\infty})\tau \left(\log(\rho_i+\delta) - \log(\rho_{i\infty}+\delta)\right)\, dx\,. \end{aligned} \tag{3.11}$$

As $R\to\infty$, the first term on the right-hand side of (3.11) vanishes, arguing as in (3.8) or (3.9). In the remaining terms the cut-off function τ tends to 1. Thus, letting first $R\to\infty$ and then $\delta\to 0$ we obtain inequality $(3.6)_\beta$, using (3.7)–(3.11) and Fatou's lemma.

Step 2. *Estimates uniform with respect to* β. Using the same arguments as in (3.3) to estimate Y_F we conclude that

$$|Y_F| \le \frac{\alpha\hat\beta}{4}\|\rho - \rho_\infty\|_{L^2}^2 + \frac{\alpha\hat\beta}{4}\|\rho - \rho_\infty\|_{L^{s_0}}^{s_0} + K_{R_0}\|\nabla u\|_{L^2}^{2\theta} + K_f\,. \tag{3.12}$$

Thus, the terms including the norms of densities can be absorbed into the left-hand side of $(3.6)_\beta$.

Next, multiplying (1.36) by $u^{(i)}$ (and summing over $i=1,2$) gives similarly[4] as in (2.2) with the help of inequality (1.28) and Hölder's inequality

$$c_0\|\nabla u\|_{L^2}^2 \le K\left(\|\rho_i - \rho_{i\infty}\|_{L^{s_0}}^{s_0} + \|\rho_i - \rho_{i\infty}\|_{L^2}^2\right) + K\,, \tag{3.13}$$

which implies

$$\begin{aligned} \|\nabla u\|_{L^2}^{2\theta} &\le K\left(\|\rho_i - \rho_{i\infty}\|_{L^{s_0}}^{s_0} + \|\rho_i - \rho_{i\infty}\|_{L^2}^2\right)^\theta + K \\ &\le \varepsilon\left(\|\rho_i - \rho_{i\infty}\|_{L^{s_0}}^{s_0} + \|\rho_i - \rho_{i\infty}\|_{L^2}^2\right) + K\,. \end{aligned} \tag{3.14}$$

[4]This time we have to avoid the dependence of the estimates on β. We therefore use the fact that $|w_\beta| \le 1$.

Inserting (3.14) into (3.12) and then into $(3.6)_\beta$, we obtain (first from $(3.6)_\beta$ and then from (3.13))

$$\sum_{i=1}^{2}\left(\int\frac{|\nabla\rho_i|^2}{\rho_i}\,dx+\|\rho-\rho_\infty\|_{L^2}^2+\|\rho-\rho_\infty\|_{L^{s_0}}^{s_0}\right)+\|\nabla u\|_{L^2}^2\le K=K(\alpha^{-1},\sigma^{-1}),$$

where K is independent of β. Since $s_0>4$, this estimate implies that

$$\|\nabla\rho\|_{L^{8/5}}\le K.$$

Letting $\beta\to 0$, it is straightforward to find a subsequence of $(\rho^{\beta,\alpha,\sigma},u^{\beta,\alpha,\sigma})$ weakly converging to $(\rho^{\alpha,\sigma},u^{\alpha,\sigma})$ in $W^{1,8/5}\times H_0^1$, and converging strongly in $(L^{s_0-\varepsilon}\cap L^2)\times L^6$ locally and a.e. in $\mathbb{R}^3$. This is certainly enough to show that $(\rho^{\alpha,\sigma},u^{\alpha,\sigma})$ is a weak solution to (1.35) and (1.36) with $w_\beta=w_0=1$.

What remains is to consider the limit $\beta\to 0$ in $(3.6)_\beta$. Here, we incorporate (in addition to the above mentioned a.e. convergence) lower semicontinuity arguments and Fatou's and Vitali's lemmas in order to obtain (3.6). □

4. Solvability of the σ-approximations. In this section, we prove three assertions. In Proposition 4.1, we find estimates for $(\rho,u)=(\rho^{\alpha,\sigma},u^{\alpha,\sigma})$ that are uniform in *both* α and σ. Then, in Proposition 4.2, we derive estimates involving the gradient of the density. In these estimates, which are uniform with respect to α only, the parameter ε appearing therein is such that $1+\varepsilon\le\gamma$. If we were allowed to take $\varepsilon=1$ in these estimates (which means that γ has to be greater than 2), we could simplify the approximating procedure by setting $\sigma=\alpha$ (however, we want to avoid any bound on γ).

Based on the estimates from Propositions 4.1 and 4.2 we are able to show, in Proposition 4.3, that a suitable weak limit (ρ^σ,u^σ) of $\{(\rho^{\alpha,\sigma},u^{\alpha,\sigma})\}$ is a solution of the σ-approximations. Even more, we show that (ρ^σ,u^σ) fulfills a corresponding equation for the effective viscous flux, and due to weak lower semicontinuity of the norms, the estimates presented in Proposition 4.1 are also valid for (ρ^σ,u^σ) uniformly with respect to σ. These estimates then play a starting role for further consideration regarding the compactness of ρ^σ, which is presented in section 5.

PROPOSITION 4.1. *Let $(\rho^{\alpha,\sigma},u^{\alpha,\sigma})$ be weak solutions to* (1.35)–(1.36) *with $\beta=0$. Then there exists a constant $K>0$ independent of α and σ such that*

$$\|\rho^{\alpha,\sigma}-\rho_\infty\|_{L^2}^2+\|\rho^{\alpha,\sigma}-\rho_\infty\|_{L^{2\gamma}}^{2\gamma}+\|\nabla u^{\alpha,\sigma}\|_{L^2}^2\le K<\infty\,. \tag{4.1}$$

Proof. Step 1. *Derivation of the inequality*

$$\|\rho^{\alpha,\sigma}-\rho_\infty\|_{L^2}^2+\|\rho^{\alpha,\sigma}-\rho_\infty\|_{L^{\gamma+1}}^{\gamma+1}\le K+K\|\nabla u^{\alpha,\sigma}\|_{L^2}^{2\theta}\,. \tag{4.2}$$

Since $(\rho,u)=(\rho^{\alpha,\sigma},u^{\alpha,\sigma})$ fulfills (3.6), neglecting the first three nonnegative terms and using inequality (1.29), we obtain

$$\hat\lambda_0\left(\|\rho-\rho_\infty\|_{L^{\gamma+1}}^{\gamma+1}+\|\rho-\rho_\infty\|_{L^2}^2\right)\le|Y_F|\,.$$

Then $|Y_F|$ is estimated as in (3.12) replacing $\alpha\hat\beta$ by $\hat\lambda_0$ and the L^{s_0}-norm by the $L^{\gamma+1}$-norm. Doing so, we obtain (4.2) (K depends neither on α nor on σ).

Step 2. *Derivation of the inequality*

$$\|\rho^{\alpha,\sigma}-\rho_\infty\|_{L^{2\gamma}}^{2\gamma}\le K+K\|\nabla u^{\alpha,\sigma}\|_{L^2}^{2\theta}\,. \tag{4.3}$$

According to Proposition 3.1, the equation for the effective viscous flux (3.1) with $w_\beta = 1$ holds for $(\rho, u) = (\rho^{\alpha,\sigma}, u^{\alpha,\sigma})$. Multiplying the ith equation by $\tau^2(\rho_i^\gamma - \rho_{i\infty}^\gamma)$, where τ is the standard cut-off function ($\tau = 1$ on B_R and $\tau = 0$ outside of B_{2R}, $|\nabla\tau| \le CR^{-1}$), and integrating it, we end up with[5]

$$\begin{aligned}\left((A_0(P(\rho) - P(\rho_\infty)))_i, (\rho_i^\gamma - \rho_{i\infty}^\gamma)\tau^2\right) &= \hat\beta_i \left(\operatorname{div} u^{(i)}, \tau^2(\rho_i^\gamma - \rho_{i\infty}^\gamma)\right) - Z_F,\\ \text{where } Z_F &:= \left(a_0^{(i)} F^{(i)}, (\rho_i^\gamma - \rho_{i\infty}^\gamma)\tau^2\right).\end{aligned} \tag{4.4}$$

In Step 4 below, we will be able to show that (for α, σ fixed)

$$\limsup_{R\to\infty} \left(\operatorname{div} u^{(i)}, \tau^2(\rho_i^\gamma - \rho_{i\infty}^\gamma)\right) \le 0\,. \tag{4.5}$$

Assuming that (4.5) is valid, it follows from (4.4)–(4.5) and inequality (1.24) that

$$\|\rho - \rho_\infty\|_{L^{2\gamma}}^{2\gamma} \le K\|\rho - \rho_\infty\|_{L^2}^2 + \limsup_{R\to\infty} |Z_F|\,. \tag{4.6}$$

Since, by the mean value theorem ($t \in (0,1)$),

$$|\rho_i^\gamma - \rho_{i\infty}^\gamma| = \gamma|(\rho_{i\infty} + t(\rho_i - \rho_{i\infty}))^{\gamma-1}(\rho_i - \rho_{i\infty})| \le K\left(|\rho_i - \rho_{i\infty}| + |\rho_i - \rho_{i\infty}|^\gamma\right), \tag{4.7}$$

we conclude from (4.6) and (4.7) that

$$\|\rho_i - \rho_{i\infty}\|_{L^{2\gamma}}^{2\gamma} + \|\rho_i^\gamma - \rho_{i\infty}^\gamma\|_{L^2}^2 \le K\left(\|\rho_i - \rho_{i\infty}\|_{L^2}^2 + \limsup_{R\to\infty} |Z_F|\right). \tag{4.8}$$

Next, we estimate $|Z_F|$ using similar arguments as in (3.3) and obtain

$$|Z_F| \le \frac{1}{2}\|\rho_i^\gamma - \rho_{i\infty}^\gamma\|_{L^2}^2 + K\|\nabla u^{(i)}\|_{L^2}^{2\theta} + K\|\rho_i - \rho_{i\infty}\|_{L^2}^2 + K_f\,. \tag{4.9}$$

Taking (4.8)–(4.9) into account together with (4.2) leads to (4.3).

Step 3. *Derivation of* (4.1). We multiply (1.36) (with $\beta = 0$) by $u^{(i)}$. Using standard manipulations we obtain (cf. (3.13))

$$c_0\|\nabla u^{\alpha,\sigma}\|_{L^2}^2 \le K\sum_{i=1}^{2}\left(\|\rho_i^{\alpha,\sigma} - \rho_{i\infty}\|_{L^{2\gamma}}^{2\gamma} + \|\rho_i^{\alpha,\sigma} - \rho_{i\infty}\|_{L^2}^2\right). \tag{4.10}$$

The required energy estimates are thus obtained from (4.2), (4.3), and (4.10).

Step 4. *A proof of* (4.5). We start with observing that

$$\begin{aligned}\left(\operatorname{div} u^{(i)}, \tau^2(\rho_i^\gamma - \rho_{i\infty}^\gamma)\right) &= -\left(u^{(i)}, \nabla\tau^2(\rho_i^\gamma - \rho_{i\infty}^\gamma)\right) - \gamma\left(u^{(i)}, \tau^2\rho_i^{\gamma-1}\nabla\rho_i\right)\\ &= -\left(u^{(i)}, \nabla\tau^2(\rho_i^\gamma - \rho_{i\infty}^\gamma)\right) - \gamma\left(u^{(i)}, \tau^2\nabla\rho_i(\rho_i + \delta)^{\gamma-1}\right)\\ &\quad + \gamma\left(u^{(i)}, \tau^2\nabla\rho_i\Big((\rho_i + \delta)^{\gamma-1} - \rho_i^{\gamma-1}\Big)\right) =: F_1 + F_2 + F_3\,.\end{aligned} \tag{4.11}$$

[5]Recall that $\hat\beta_1 = \beta_0$, $\hat\beta_2 = 1$, and $a_0^{(i)}$ is the ith row of A_0.

Recalling that (cf. (3.4)) $\rho_i - \rho_{i\infty} \in L^{1+\varepsilon} \cap L^{s_0}$ for $\varepsilon > 0$ small and $s_0 > 2\gamma$, we conclude, with the help of (4.7), that (for α, $\sigma > 0$ fixed)

$$|F_1| \le \|\nabla\tau\|_{L^3}\|u^{(i)}\|_{L^6(B_{2R}\setminus B_R)}\|\rho_i^\gamma - \rho_{i\infty}^\gamma\|_{L^2(B_{2R}\setminus B_R)} \to 0 \quad \text{as } R\to\infty\,. \tag{4.12}$$

Also, it is not difficult to see that $F_3 \to 0$ as $\delta \to 0$.

Next, defining $T(\rho_i) := (\rho_i+\delta)^{\gamma-1} - (\rho_{i\infty}+\delta)^{\gamma-1}$, we have

$$\begin{aligned} F_2 &= -\frac{\gamma}{\gamma-1}\left((\rho_i+\delta)u^{(i)}, \tau^2\nabla\left((\rho_i+\delta)^{\gamma-1} - (\rho_{i\infty}+\delta)^{\gamma-1}\right)\right) \\ &= \frac{\gamma}{\gamma-1}\left(\operatorname{div}\left((\rho_i+\delta)u^{(i)}\right), \tau^2 T(\rho_i)\right) + \frac{\gamma}{\gamma-1}\left((\rho_i+\delta)u^{(i)}, \nabla\tau^2 T(\rho_i)\right) := F_4 + F_5\,. \end{aligned}$$

Inserting (1.35) into F_4, we obtain

$$F_4 = \frac{\gamma}{\gamma-1}\big(\sigma\Delta\rho_i, \tau^2 T(\rho_i)\big) - \alpha\big(|\rho_i-\rho_{i\infty}|^{s_0-2}(\rho_i-\rho_{i\infty}) + (\rho_i-\rho_{i\infty}), \tau^2 T(\rho_i)\big)\,.$$

Since the last term is nonpositive (it is a monotone operator), we can neglect it. We integrate the first term by parts. Dropping the term with $-\sigma\int|\nabla\rho_i|^2(\rho_i+\delta)^{\gamma-2}\,dx$, we obtain

$$\begin{aligned} F_4 &\le -\frac{\sigma\gamma}{\gamma-1}\left(\nabla\tau^2\nabla\rho_i, (\rho_i+\delta)^{\gamma-1} - (\rho_{i\infty}+\delta)^{\gamma-1}\right) \\ &= \gamma\sigma\left((\rho_i+\delta)^\gamma - (\rho_{i\infty}+\delta)^\gamma, \Delta\tau^2\right) \end{aligned}$$

and the last term vanishes as $R\to\infty$ since $\|\Delta\tau\|_{L^2}\to 0$ and $(\rho_i+\delta)^\gamma - (\rho_{i\infty}+\delta)^\gamma$ is an L^2-integrable function (α, σ fixed).

Concerning F_5, we first write $\rho_i+\delta = (\rho_i-\rho_{i\infty}) + (\rho_{i\infty}+\delta)$ and consider two cases: $\gamma \ge 2$ and $\gamma \in (1,2)$. If $\gamma \ge 2$, then (4.7) with $\gamma-1$ instead of γ implies

$$\begin{aligned} |F_5| &\le K\gamma\int_{B_{2R}\setminus B_R} |u^{(i)}|\,|\nabla\tau|\Big(|\rho-\rho_\infty|^2 + |\rho-\rho_\infty|^\gamma + |\rho-\rho_\infty|^{\gamma-1} + |\rho_i-\rho_{i\infty}|\Big)\,dx \\ &\le K\|\nabla\tau\|_{L^3}\|\nabla u\|_{L^2(B_{2R})\setminus B_R)}\Big(\|\rho_i-\rho_{i\infty}\|_{L^4} + \|\rho_i-\rho_{i\infty}\|_{L^{2\gamma}} \\ &\qquad + \|\rho_i-\rho_{i\infty}\|_{L^{2(\gamma-1)}} + \|\rho_i-\rho_{i\infty}\|_{L^2}\Big) \to 0 \text{ as } R\to\infty\,. \end{aligned}$$

If $\gamma\in(1,2)$, then $(\rho+\delta)^{\gamma-1} - (\rho_{i\infty}+\delta)^{\gamma-1} \le (\rho_{i\infty})^{\gamma-2}(\rho_i-\rho_{i\infty})$. Then, however, the same arguments complete the proof of the fact that $|F_5|\to 0$ as $\mathbb{R}\to\infty$. ∎

PROPOSITION 4.2. *Let $(\rho^{\alpha,\sigma}, u^{\alpha,\sigma})$ be weak solutions to* (1.35)–(1.36) *with $w_\beta = 1$. For $\varepsilon > 0$ small enough (i.e., $1+\varepsilon \le \gamma$) there is a K, independent of α and σ, such that*

$$\sigma\int|\nabla\rho_i^{\alpha,\sigma}|^2\rho_i^{\varepsilon-1}\,dx + \alpha\int|\rho_i-\rho_{i\infty}|^{s_0-1+\varepsilon}\,dx + \alpha\int|\rho_i-\rho_{i\infty}|^{1+\varepsilon}\,dx \le K\,. \tag{4.13}$$

Proof. We multiply (1.35) by $\varphi^\varepsilon(\rho_i) = \left((\rho_i+\delta)^\varepsilon - (\rho_{i\infty}+\delta)^\varepsilon\right)\tau^2$, where τ is as above. After integrating over $\mathbb{R}^3$ we obtain

$$\begin{aligned} &\varepsilon\sigma\int|\nabla\rho_i|^2(\rho_i+\delta)^{\varepsilon-1}\tau^2\,dx + \sigma\int\left((\rho_i+\delta)^\varepsilon - (\rho_{i\infty}+\delta)^\varepsilon\right)\nabla\rho_i\cdot\nabla\tau^2\,dx \\ &\quad + \int\operatorname{div}\left(\rho_i u^{(i)}\right)\left((\rho_i+\delta)^\varepsilon - (\rho_{i\infty}+\delta)^\varepsilon\right)\tau^2\,dx \\ &\quad + \alpha\int(\rho_i-\rho_{i\infty})\left((\rho_i+\delta)^\varepsilon - (\rho_{i\infty}+\delta)^\varepsilon\right)\tau^2\,dx \\ &\quad + \alpha\int|\rho_i-\rho_{i\infty}|^{s_0-2}(\rho_i-\rho_{i\infty})\left((\rho_i+\delta)^\varepsilon - (\rho_{i\infty}+\delta)^\varepsilon\right)\tau^2\,dx = 0\,. \end{aligned} \tag{4.14}$$

Note that the first, fourth, and fifth terms in (4.14) are nonnegative; in fact, when letting $R \to \infty$ and $\delta \to 0$, these terms provide information on the left-hand side of (4.13). It then remains to estimate the second and third terms in (4.14)—we denote them S and T. Starting with the former, we observe that

$$\begin{aligned} S &= \sigma \int \left(\frac{1}{1+\varepsilon} \nabla(\rho_i+\delta)^{1+\varepsilon} - (\rho_{i\infty}+\delta)^{\varepsilon} \nabla(\rho_i - \rho_{i\infty}) \right) \nabla\tau^2 \, dx \\ &= -\frac{\sigma}{1+\varepsilon} \int \left((\rho_i+\delta)^{1+\varepsilon} - (\rho_{i\infty}+\delta)^{1+\varepsilon} - (1+\varepsilon)(\rho_{i\infty}+\delta)^{\varepsilon}(\rho_i - \rho_{i\infty}) \right) \Delta\tau^2 \, dx \,. \end{aligned}$$

Then the Taylor expansion for $(\delta + x)^{1+\varepsilon}$ and (4.1) imply

$$|S| \le \frac{\sigma\varepsilon}{2\delta} \int |\rho_i - \rho_{i\infty}|^2 \Delta\tau^2 \, dx \le \frac{\sigma\varepsilon}{2\delta R^2} \|\rho_i - \rho_{i\infty}\|_{L^2}^2 \to 0 \quad \text{as } R \to \infty \,.$$

Next,

$$\begin{aligned} -T &= \int \rho_i u^{(i)} \nabla(\rho_i+\delta)^{\varepsilon} \tau^2 \, dx + \int (\rho_i - \rho_{i\infty}) u^{(i)} \big((\rho_i+\delta)^{\varepsilon} - (\rho_{i\infty}+\delta)^{\varepsilon} \big) \nabla\tau^2 \, dx \\ &\quad + \rho_{i\infty} \int u^{(i)} \big((\rho_i+\delta)^{\varepsilon} - (\rho_{i\infty}+\delta)^{\varepsilon} \big) \nabla\tau^2 \, dx =: T_1 + T_2 + T_3 \,. \end{aligned}$$

Recall that

$$\begin{aligned} (\rho_i+\delta)^{\varepsilon} - (\rho_{i\infty}+\delta)^{\varepsilon} &= \varepsilon \int_0^1 (\delta + \rho_{i\infty} + s(\rho_i - \rho_{i\infty}))^{\varepsilon-1} \, ds (\rho_i - \rho_{i\infty}) \\ &\le \varepsilon \int_0^1 (\delta + s(\rho_i - \rho_{i\infty}))^{\varepsilon-1} \, ds (\rho_i - \rho_{i\infty}) \,. \end{aligned} \tag{4.15}$$

Since the right-hand side of (4.15) is bounded by $2\varepsilon(\delta + |\rho_i - \rho_{i\infty}|)^{\varepsilon}$, we see that

$$|T_2| \le K \Big(|T_3| + \|\rho_i - \rho_{i\infty}\|_{L^{2(1+\varepsilon)}(B_{2R}\setminus B_R)}^{1+\varepsilon} \|u^{(i)}\|_{L^6(B_{2R}\setminus B_R)} \|\nabla\tau\|_{L^3} \Big) \,.$$

The right-hand side of (4.15) is also bounded by $\varepsilon\delta^{-1}(\rho_i - \rho_{i\infty})$. This helps to conclude that

$$|T_3| \le \varepsilon\delta^{-1} \rho_{i\infty} \|u^{(i)}\|_{L^6(B_{2R}\setminus B_R)} \|\rho_i - \rho_{i\infty}\|_{L^2(B_{2R}\setminus B_R)} \|\nabla\tau\|_{L^3} \,.$$

Since the L^3-norm of $\nabla\tau$ is bounded, we see that for α and σ fixed and $R \to \infty$ both T_3 and T_2 vanish. (In fact, there is no restriction on ε as we could still use the fact that $\rho_i - \rho_{i\infty}$ belongs to $L^{s_0} \cap L^2$.)

Finally,

$$T_1 = \int \left(\frac{\nabla\big((\rho_i+\delta)^{1+\varepsilon} - (\rho_{i\infty}+\delta)^{1+\varepsilon} \big)}{1+\varepsilon} - \delta \nabla \big((\rho_i+\delta)^{\varepsilon} - (\rho_{i\infty}+\delta)^{\varepsilon} \big) \right) u^{(i)} \tau^2 \, dx \,.$$

The integration by parts leads to four terms. Those with $\nabla\tau^2$ are treated as T_2 and T_3 above. The terms with $\operatorname{div} u^{(i)}$ are estimated in an analogous way; we present the proof of the most difficult one. We have ($t^* \in (0,1)$)

$$\begin{aligned} &\int \big((\rho_i+\delta)^{1+\varepsilon} - (\rho_{i\infty}+\delta)^{1+\varepsilon} \big) \operatorname{div} u^{(i)} \tau^2 \, dx \\ &\qquad = (1+\varepsilon) \int (\delta + \rho_{i\infty} + t^*(\rho_i - \rho_{i\infty}))^{\varepsilon} (\rho_i - \rho_{i\infty}) \operatorname{div} u^{(i)} \tau^2 \, dx \\ &\qquad \le (1+\varepsilon) K \big(\|\rho_i - \rho_{i\infty}\|_{L^2} + \|\rho_i - \rho_{i\infty}\|_{L^{2(1+\varepsilon)}}^{1+\varepsilon} \big) \|\operatorname{div} u^{(i)}\|_{L^2} \,, \end{aligned}$$

which is bounded due to (4.1) provided that $2(1+\varepsilon) \le 2\gamma$.

The proof of Proposition 4.2 is complete. ∎

PROPOSITION 4.3. *Let $\sigma > 0$ be fixed and let all assumptions of Theorem 1.1 be fulfilled. Then there exists a solution $(\rho, u) = (\rho^\sigma, u^\sigma)$ such that (for $i = 1, 2$)*

$$\rho_i \geq 0, \qquad \rho_i^\sigma - \rho_{i\infty} \in L^2(\mathbb{R}^3) \cap L^{2\gamma}(\mathbb{R}^3)\,, \qquad \text{and} \qquad u_\sigma^{(i)} \in H_0^1(\mathbb{R}^3; \mathbb{R}^3),$$

solving weakly

$$-\sigma \Delta \rho_i^\sigma + \operatorname{div}\left(\rho_i^\sigma u_\sigma^{(i)}\right) = 0 \ \text{in } \mathbb{R}^3\,, \tag{4.16}$$

$$L^{(i)} u_\sigma = -\nabla P_i(\rho_i^\sigma) + \rho_i^\sigma f^{(i)} + J_\sigma^{(i)} \ \text{in } \mathbb{R}^3, \tag{4.17}$$

satisfying the equation for the effective viscous flux

$$A_0\left(P(\rho^\sigma) - P(\rho_\infty)\right) - \begin{pmatrix} \beta_0 \operatorname{div} u_\sigma^{(1)} \\ \operatorname{div} u_\sigma^{(2)} \end{pmatrix} = A_0 \operatorname{div} \Delta^{-1} \begin{pmatrix} \rho_1^\sigma f^{(1)} + J_\sigma^{(1)} \\ \rho_2^\sigma f^{(2)} - J_\sigma^{(1)} \end{pmatrix} \tag{4.18}$$

and the estimates

$$\|\rho_i^\sigma - \rho_{i\infty}\|_{L^{2\gamma}}^{2\gamma} + \|\rho_i^\sigma - \rho_{i\infty}\|_{L^2}^2 + \|\nabla u_\sigma^{(i)}\|_{L^2}^2 \leq K, \tag{4.19}$$

where K is independent of σ.

Proof. Letting $\alpha \to 0$, it follows from (4.1) that there is $(\rho, u) = (\rho^\sigma, u^\sigma)$ such that modulo subsequences ($i = 1, 2$)

$$\rho_i^{\alpha,\sigma} - \rho_{i\infty} \rightharpoonup \rho_i^\sigma - \rho_{i\infty} \ \text{ weakly in } L^2(\mathbb{R}^3) \cap L^{2\gamma}(\mathbb{R}^3)\,, \tag{4.20}$$

$$\nabla u_{\alpha,\sigma}^{(i)} \rightharpoonup \nabla u_\sigma^{(i)} \qquad \text{weakly in } L^2(\mathbb{R}^3)\,, \tag{4.21}$$

and due to the weak lower semicontinuity of the norms, (ρ^σ, u^σ) fulfills (4.19).

Even more, for $q \in [1, 6)$,

$$u_{\alpha,\sigma}^{(i)} \to u_\sigma^{(i)} \text{ strongly in } L_{loc}^q \qquad \text{and} \qquad u_{\alpha,\sigma}^{(i)} \to u_\sigma^{(i)} \text{ a.e. in } \mathbb{R}^3. \tag{4.22}$$

We will show below that (4.1) and (4.13) imply

$$\|\nabla \rho^{\alpha,\sigma}\|_{L_{loc}^{2r}} \leq K \qquad \text{with } r = \frac{2\gamma}{2\gamma + 1 - \varepsilon}\,. \tag{4.23}$$

Consequently, for $s \in [1, r^*)$,

$$\rho^{\alpha,\sigma} \to \rho^\sigma \text{ strongly in } L_{loc}^s(\mathbb{R}^3) \qquad \text{and} \qquad \rho^{\alpha,\sigma} \to \rho^\sigma \text{ a.e. in } \mathbb{R}^3. \tag{4.24}$$

Having (4.20)–(4.24), (4.1), and (4.8) in hand, it is straightforward to pass to the limit, as $\alpha \to 0$, in the weak formulations of (1.35), (1.36) and (3.1) with $w_\beta = 1$ and to obtain (4.16)–(4.19).

Thus, the proof of Proposition 4.3 is complete once we verify (4.23). This, however, follows from

$$\int |\nabla \rho^{\alpha,\sigma}|^{2r}\, dx = \int \left(\frac{|\nabla \rho^{\alpha,\sigma}|^2}{(\rho^{\alpha,\sigma})^{1-\varepsilon}}\right)^r (\rho^{\alpha,\sigma})^{(1-\varepsilon)r}\, dx \overset{(4.13)}{\leq} K \left(\int (\rho^{\alpha,\sigma})^{(1-\varepsilon)\frac{r}{r-1}}\, dx\right)^{1-r}$$

if we put $(1-\varepsilon)\frac{r}{r-1} = 2\gamma$, which implies $r = \frac{2\gamma}{2\gamma+1-\varepsilon}$, and use (4.1). ∎

5. Solvability of the original problem. Due to the estimates (4.19), which are uniform with respect to σ, we have, as $\sigma \to 0$,

$$u_\sigma^{(i)} \rightharpoonup u^{(i)} \text{ weakly in } H^1(\mathbb{R}^3;\mathbb{R}^3) \text{ and } \rho_i^\sigma \rightharpoonup \rho_i \text{ weakly in } L^{2\gamma}_{loc}(\mathbb{R}^3) \tag{5.1}$$

and, owing to the compact embedding,

$$u_\sigma^{(i)} \to u^{(i)} \text{ strongly in } L^2_{loc}(\mathbb{R}^3) \text{ and } \rho_i^\sigma \to \rho_i \text{ strongly in } (H^1_{loc}(\mathbb{R}^3))^*\,, \tag{5.2}$$

and we can pass to the limit in the weak formulations of (4.16) and (4.17). The only difficult terms are those including $P_i(\rho)$. Since ρ_i^σ is uniformly bounded in $L^{2\gamma}$, the weak limit $P_i(\rho^\sigma) \rightharpoonup P_i(\rho)$ will follow if we show that (modulo subsequences)

$$\rho_i^\sigma \to \rho_i \quad \text{a.e. in } \mathbb{R}^3\,. \tag{5.3}$$

Let us emphasize that as soon as (5.3) is proved, the proof of Theorem 1.1 is complete. The rest of this section is focused on proving (5.3).

Proof. Let $\tau = \tau_R$ be our usual localization function: $\tau = 1$ on the ball B_R and $\tau = 0$ on $\mathbb{R}^3 \setminus B_{2R}$. We multiply the ith component of (4.18) by $(\rho_i^\sigma - \rho_i)\tau$ and study the limits of particular terms as $\sigma \to 0$. First of all, we observe that

$$(\operatorname{div}\Delta^{-1}(\rho_i^\sigma f^{(i)} + J_\sigma^{(i)}), (\rho_i^\sigma - \rho_i)\tau) \to 0 \quad \text{as} \quad \sigma \to 0\,, \tag{5.4}$$

which follows from (5.2) and the fact that $(\rho_i^\sigma - \rho_{i\infty})f^{(i)} + \rho_{i\infty}f^{(i)} + J_\sigma^{(i)}$ is bounded in $L^2(\mathbb{R}^3;\mathbb{R}^3)$ (implying that $\operatorname{div}\Delta^{-1}(\rho_i f^{(i)} + J_\sigma^{(i)})$ is bounded in H^1_0). Thanks to (5.4), we have

$$\begin{aligned}
&\lim_{\sigma\to 0}\int A_0\,(P(\rho^\sigma) - P(\rho_\infty))\cdot(\rho^\sigma - \rho)\tau\,dx \\
&\qquad = \lim_{\sigma\to 0}\sum_{i=1}^{2}\hat\beta_i\int \rho_i^\sigma \operatorname{div} u_\sigma^{(i)}\tau\,dx - \sum_{i=1}^{2}\hat\beta_i\int \rho_i \operatorname{div} u^{(i)}\,dx \\
&\qquad = \beta_0 \lim_{\sigma\to 0} D_1^\sigma - \beta_0 D_1 + \lim_{\sigma\to 0} D_2^\sigma - D_2.
\end{aligned} \tag{5.5}$$

Next,

$$\begin{aligned}
D_i^\sigma &= \int \rho_i^\sigma \operatorname{div} u_\sigma^{(i)}\tau\,dx = -\int u_\sigma^{(i)}\nabla\rho_i^\sigma\tau\,dx - \int u_\sigma^{(i)}\rho_i^\sigma\nabla\tau\,dx \\
&= -\int (\rho_i^\sigma+\delta)u_\sigma^{(i)}\nabla\log(\rho_i^\sigma+\delta)\tau\,dx - \int u_\sigma^{(i)}\rho_i^\sigma\nabla\tau\,dx \\
&= \int \operatorname{div}\left((\rho_i^\sigma+\delta)u_\sigma^{(i)}\right)\log(\rho_i^\sigma+\delta)\tau\,dx \\
&\quad + \int (\rho_i^\sigma+\delta)u_\sigma^{(i)}\log(\rho_i^\sigma+\delta)\nabla\tau\,dx - \int u_\sigma^{(i)}\rho_i^\sigma\nabla\tau\,dx =: D_{i1}^\sigma + D_{i2}^\sigma - D_{i3}^\sigma.
\end{aligned}$$

Using (4.16), we obtain

$$D_i^\sigma = \sigma\int \Delta\rho_i^\sigma\log(\rho_i^\sigma+\delta)\tau\,dx + \delta\int \operatorname{div} u_\sigma^{(i)}\log(\rho_i^\sigma+\delta)\tau\,dx + D_{i2}^\sigma - D_{i3}^\sigma\,.$$

and with the help of (4.19) ($F(\xi)$ is the primitive function to $\xi\log\xi$)

$$\begin{aligned}
\sigma\int \Delta\rho_i^\sigma\log(\rho_i^\sigma+\delta)\tau\,dx &\le -\sigma\int \nabla\rho_i^\sigma\log(\rho_i^\sigma+\delta)\nabla\tau\,dx \\
&= \sigma\int F(\rho_i^\sigma+\delta)\Delta\tau\,dx \to 0 \text{ as } \sigma\to 0.
\end{aligned}$$

Furthermore, since $\log(\rho_i^\sigma+\delta)\le\log\delta+\rho_i^\sigma$, we have

$$\begin{aligned}\delta\int \operatorname{div} u_\sigma^{(i)}\log(\rho_i^\sigma+\delta)\tau\,dx &\le \delta\int|\rho_i^\sigma|\,|\operatorname{div} u_\sigma^{(i)}|\tau\,dx+\delta|\log\delta|\int\left|\operatorname{div} u_\sigma^{(i)}\right|\tau\,dx\\ &\le \delta|\log\delta|KR^{\frac32}+K\delta\le\delta|\log\delta|KR^{\frac32}.\end{aligned}$$

Applying (5.2) to $\lim_{\sigma\to0}D_{i3}^\sigma$ we conclude that

$$\lim_{\sigma\to0}D_i^\sigma\le\delta|\log\delta|KR^{\frac32}+\lim_{\sigma\to0}D_{i2}^\sigma-\int\rho_iu^{(i)}\nabla\tau\,dx\,.$$

Since

$$\begin{aligned}\lim_{\sigma\to0}D_{i2}^\sigma&=\lim_{\sigma\to0}\int(\rho_i^\sigma+\delta)u_\sigma^{(i)}\log(\rho_i^\sigma+\delta)\nabla\tau\,dx\\ &=\lim_{\sigma\to0}\int\rho_i^\sigma u_\sigma^{(i)}\log(\rho_i^\sigma+\delta)\nabla\tau\,dx+\text{a term smaller than }\delta|\log\delta|KR^{\frac32}\end{aligned}$$

and

$$\begin{aligned}\int\rho_i^\sigma u_\sigma^{(i)}\log(\rho_i^\sigma+\delta)\nabla\tau\,dx&=\int\rho_i^\sigma u_\sigma^{(i)}\log(\rho_{i\infty}+\delta)\nabla\tau\,dx\\ &\quad+\int\rho_i^\sigma u_\sigma^{(i)}\left(\log(\rho_i^\sigma+\delta)-\log(\rho_{i\infty}+\delta)\right)\nabla\tau\,dx\\ &=:D_{i4}^\sigma+D_{i5}^\sigma\,,\end{aligned}$$

we observe first that

$$D_{i4}^\sigma\to\int\rho_iu^{(i)}\log(\rho_{i\infty}+\delta)\nabla\tau\,dx\quad\text{ as }\sigma\to0\,,$$

and then concentrate on D_{i5}^σ. We choose $\varepsilon_0=\frac{\rho_{i\infty}}{2}$ and we split the integral into one over the set $\{\rho_i^\sigma\le\varepsilon_0\}$, denoted $D_{i5}^\sigma(\rho_i^\sigma\le\varepsilon_0)$, and one over the complement $\{\rho_i^\sigma>\varepsilon_0\}$, denoted $D_{i5}^\sigma(\rho_i^\sigma>\varepsilon_0)$. Since $\int|\rho_i^\sigma-\rho_{i\infty}|^2\,dx\le K$, we have $(\rho_{i\infty}/2)^2|\{\rho_i^\sigma\le\varepsilon_0\}|\le K$, which means that the measure of the set where $\rho_i^\sigma\le\varepsilon_0$ is finite. Consequently,

$$\begin{aligned}D_{i5}^\sigma(\rho_i^\sigma\le\varepsilon_0)&\le K_{\varepsilon_0}\int\limits_{\rho_i^\sigma\le\varepsilon_0}|u_\sigma^{(i)}|\,|\nabla\tau|\,dx\\ &\le K_{\varepsilon_0}\|u_\sigma^{(i)}\|_6\,\|\nabla\tau\|_\infty\,|\{\rho_i^\sigma\le\varepsilon_0\}|^{\frac56}\le K_{\varepsilon_0}R^{-1}\,.\end{aligned}$$

The other part is estimated as follows:

$$\begin{aligned}D_{i5}^\sigma(\rho_i^\sigma>\varepsilon_0)&\le\int\limits_{\rho_i^\sigma>\varepsilon_0}|\rho_i^\sigma-\rho_{i\infty}|\,|u_\sigma^{(i)}|\,|\log(\rho_i^\sigma+\delta)-\log(\rho_{i\infty}+\delta)|\,|\nabla\tau|\,dx\\ &\quad+\rho_{i\infty}\int\limits_{\rho_i^\sigma>\varepsilon_0}|u_\sigma^{(i)}|\,|\log(\rho_i^\sigma+\delta)-\log(\rho_{i\infty}+\delta)|\,|\nabla\tau|\,dx\\ &=:E_{0\sigma}+E_{1\sigma}\,.\end{aligned}$$

Since $\log(\xi+\delta)$ is a K_{ε_0}-Lipschitz function on $\{\xi \geq \varepsilon_0\}$, we have

$$E_{1\sigma} \leq K_{\varepsilon_0}\rho_{i\infty}\int_{B_{2R}\setminus B_R} |u_\sigma^{(i)}|\,|\rho_i^\sigma - \rho_{i\infty}|\;|\nabla\tau|\,dx$$

and hence, since $\|\rho_i^\sigma - \rho_{i\infty}\|_{L^2} \leq K$, via Hölder's inequality and with (5.2)

$$\lim_{\sigma\to 0} E_{1\sigma} \leq K_{\varepsilon_0} K\left(\int_{B_{2R}\setminus B_R} |\nabla\tau|^2\,|u^{(i)}|^2\,dx\right)^{\frac{1}{2}}.$$

The other term $E_{0\sigma}$ is split again, with $L := 2\rho_\infty$ this time:

$$\int\limits_{\rho_i^\sigma>\varepsilon_0}\cdots = \int\limits_{L>\rho_i^\sigma>\varepsilon_0}\cdots + \int\limits_{\rho_i^\sigma\geq L}\cdots =: E_{2\sigma} + E_{3\sigma}\,.$$

Since $\int |\rho_i^\sigma - \rho_{i\infty}|^2\,dx \leq K$ uniformly, $|\{\rho_i^\sigma \geq L\}| \leq K$, and we have

$$\int\limits_{\rho_i^\sigma\geq L} |\rho_i^\sigma|^2\,dx \leq K + \int\limits_{\rho_i^\sigma\geq L} |\rho_{i\infty}|^2\,dx \leq K.$$

Similarly, for all $s>1$ we have $\int_{\rho_i^\sigma\geq L} |\log(\rho_i^\sigma+\delta)|^s\,dx \leq K_s$. Thus, we conclude from Hölder's inequality (recalling $\|u_\sigma^{(i)}\|_6 \leq K$) that $|E_{3\sigma}| \leq K\|\nabla\tau\|_\infty \leq KR^{-1}$.

To estimate $E_{2\sigma}$, we use $|\log(\rho_i^\sigma+\delta)| \leq K_{\varepsilon_0,L}$ on $\{L \geq \rho_i^\sigma \geq \varepsilon_0\}$. Thus

$$E_{2\sigma} \leq LK_{\varepsilon_0,L}\int_{\mathbb{R}^3} |u_\sigma^{(i)}|\,|\rho_i^\sigma - \rho_{i\infty}|\,|\nabla\tau|\,dx \leq LK_{\varepsilon_0}K\left(\int_{B_{2R}\setminus B_R} |u_\sigma^{(i)}|^2|\nabla\tau|^2\,dx\right)^{\frac{1}{2}},$$

and thanks to (5.2) we can pass to limit as $\sigma\to 0$.

Collecting our estimates, we obtain

$$\begin{aligned}\lim_{\sigma\to 0} D_i^\sigma \leq{}& \delta|\log\delta|KR^{\frac{3}{2}} - \int \rho_i u^{(i)}\nabla\tau\,dx + \int \rho_i u^{(i)}\log(\rho_{i\infty}+\delta)\nabla\tau\,dx\\ &+ K_{\varepsilon_0}R^{-1} + LK_{\varepsilon_0}K\left(\int_{B_{2R}\setminus B_R} |u^{(i)}|^2\,|\nabla\tau|^2\,dx\right)^{\frac{1}{2}}.\end{aligned}$$

We now analyze the terms D_i introduced in (5.5):

$$D_i = \int \rho_i \operatorname{div} u^{(i)}\tau\,dx = \int (\rho_i * \omega_h)\operatorname{div} u^{(i)}\tau\,dx + \varepsilon_h\,,$$

where ω_h is a mollifier and $\varepsilon_h \to 0$ as the parameter h tends to 0. We have

$$\begin{aligned}
D_i &= -\int \nabla(\rho_i * \omega_h) u^{(i)} \tau \, dx - \int (\rho_i * \omega_h) u^{(i)} \nabla\tau \, dx + \varepsilon_h \\
&= -\int (\rho_i * \omega_h + \delta) u^{(i)} \nabla \log(\rho_i * \omega_h + \delta) \tau \, dx - \int (\rho_i * \omega_h) u^{(i)} \nabla\tau \, dx + \varepsilon_h \\
&= \int \operatorname{div}\left[(\rho_i * \omega_h + \delta) u^{(i)}\right] \log(\rho_i * \omega_h + \delta) \tau \, dx \\
&\quad + \int (\rho_i * \omega_h) u^{(i)} \log(\rho_i * \omega_h + \delta) \nabla\tau \, dx + \delta \int u^{(i)} \log(\rho_i * \omega_h + \delta) \nabla\tau \, dx \\
&\quad - \int (\rho_i * \omega_h) u^{(i)} \nabla\tau \, dx + \varepsilon_h \\
&=: D_{i1} + D_{i2} + \delta \int u^{(i)} \log(\rho_i * \omega_h + \delta) \nabla\tau \, dx - D_{i3} + \varepsilon_h \,,
\end{aligned}$$

where $\delta \int u^{(i)} \log(\rho_i * \omega_h + \delta) \nabla\tau \, dx \le \delta \log \delta \, K$. The terms $\lim_{h\to 0} D_{i3}$ will cancel with the terms $\lim_{\sigma\to 0} D^\sigma_{i3}$. The terms D_{i1} are treated in a way known from the theory of compressible fluids (cf. [19, 7, 9]), namely, with the aid of the lemma of DiPerna and Lions (cf. [6]) we know that

$$\tau \left(\operatorname{div}\left[(\rho_i * \omega_h) u^{(i)}\right] - \operatorname{div}\left[\omega_h * (\rho_i u^{(i)})\right] \right) \rightharpoonup 0 \text{ weakly in } L^{\frac{2\gamma}{\gamma+1}} \quad (h \to 0) \,. \tag{5.6}$$

(In fact, we use $\rho_i \in L^{2\gamma}_{loc}(\mathbb{R}^3), \nabla u^{(i)} \in L^2(\mathbb{R}^3)$, write down the explicit definition of the two mollified terms, and estimate $\nabla\omega_h(r)\rho_i(x+r)\,(u(x) - u(x+r))$ by using Poincaré's inequality for u, which gives the factor $r \sim h$ and the estimate $|\nabla\omega_h(r)| \le \frac{K}{h}$.)

Since $\operatorname{div}\left(\rho_i u^{(i)}\right) = 0$ weakly, we conclude from (5.6) that

$$\tau \operatorname{div}\left[(\rho_i * \omega_h) u^{(i)}\right] \rightharpoonup 0 \text{ weakly in } L^{\frac{2\gamma}{\gamma+1}} \quad (h \to 0) \quad (\delta, R \text{ fixed}) \,.$$

Since $\log(\rho_i * \omega_h + \delta)\tau$ is uniformly bounded in L^q for all q when δ and R are fixed, we conclude that

$$\begin{aligned}
D_{i1} &= \int \operatorname{div}\left[(\rho_i * \omega_h + \delta) u^{(i)}\right] \log(\rho_i * \omega_h + \delta) \tau \, dx \\
&= \varepsilon^1_h + \delta \int \operatorname{div} u^{(i)} \log(\rho_i * \omega_h + \delta) \tau \, dx \to \delta \int \operatorname{div} u^{(i)} \log(\rho_i + \delta) \tau \, dx \quad (h \to 0) \,.
\end{aligned}$$

It remains to treat the term D_{i2}. As $D_{i2} \to \int \rho_i u^{(i)} \log(\rho_i + \delta) \nabla\tau \, dx$ for $h \to 0$, we have

$$\begin{aligned}
\lim_{h\to 0} D_{i2} &= \log(\rho_{i\infty} + \delta) \int \rho_i u^{(i)} \nabla\tau \, dx + \int \rho_i u^{(i)} \left(\log(\rho_i + \delta) - \log(\rho_{i\infty} + \delta)\right) \nabla\tau \, dx \\
&=: D_{i4} + D_{i5} \,.
\end{aligned}$$

The term D_{i4} cancels with the corresponding term $\lim_{\sigma\to 0} D^\sigma_{i4}$ and the term D_{i5} is treated in the same way as D^σ_{i5} above; one obtains

$$D_{i5} \le K R^{-1} + K \int_{B_{2R} \setminus B_R} |u^{(i)}|^2 \, |\nabla\tau|^2 \, dx \,.$$

Bringing all these estimates together, we arrive at the inequality

$$\lim_{\sigma\to 0} D_i^\sigma - D_i \le K\delta|\log\delta|R^{\frac{3}{2}} + KR^{-1} + K\int_{B_{2R}\setminus B_R} |u^{(i)}|^2\,|\nabla\tau|^2\,dx\,.$$

We first let $\delta\to 0$, then let $R\to\infty$. The term $\int_{B_{2R}\setminus B_R} |u^{(i)}|^2\,|\nabla\tau|^2\,dx \to 0$ since $|\nabla\tau|^2 \in L^{\frac{3}{2}}(\mathbb{R}^3)$ and $|u^{(i)}|^2 \in L^3(\mathbb{R}^3)$ (implying that $\|u^{(i)}\|_{L^6(B_{2R}\setminus B_R)} \to 0$). Hence we obtain

$$\lim_{\sigma\to 0}\int A_0 P(\rho^\sigma)\cdot(\rho^\sigma-\rho)\,dx = 0 \text{ in } L^2\,,$$

and the strong convergence $\rho_i^\sigma \to \rho_i$ follows from the monotonicity condition (1.23) and (5.3) follows. □

OPTIMAL STABILITY OF RECONSTRUCTION OF PLANE LIPSCHITZ CRACKS*

LUCA RONDI†

Abstract. We establish an optimal stability estimate for the determination of a finite number of Lipschitz perfectly insulating cracks inside a planar conductor by performing two suitably chosen electrostatic boundary measurements.

Key words. inverse problems, stability, Lipschitz cracks, corkscrew condition

AMS subject classifications. Primary, 35R30; Secondary, 78A30

1. Introduction.

We study the inverse problem of determining a finite number of unknown perfectly insulating cracks σ_j, $j = 1, \dots, N$, whose union is denoted with Σ, inside a known, possibly inhomogeneous and anisotropic, planar conductor Ω, whose known background conductivity is given by A, through voltage and current electrostatic measurements at the boundary.

We prescribe two current densities ψ_1, ψ_2, and we measure on Γ_0, a subarc of the boundary of Ω, $\partial\Omega$, the corresponding electrostatic potentials u_i. We recall that the electrostatic potential u_i satisfies the following Neumann-type boundary value problem:

$$\begin{cases} \operatorname{div}(A\nabla u_i) = 0 & \text{in } \Omega\backslash\Sigma, \\ A\nabla u_i \cdot \nu = 0 & \text{on either side of } \sigma_j,\ j = 1, \dots, N, \\ A\nabla u_i \cdot \nu = \psi_i & \text{on } \partial\Omega, \end{cases} \tag{1.1}$$

where ν denotes the unit normal, with the outward orientation when on $\partial\Omega$.

If ψ_1 and ψ_2 are suitably chosen—for example, they can model a two-electrode configuration where the positive electrode is kept fixed whereas the negative one is moved in a different position as we change the current density from ψ_1 to ψ_2—then the measurements $u_i|_{\Gamma_0}$, $i = 1, 2$, uniquely determine the unknown multiple crack Σ.

This inverse problem was introduced in [8], where the first uniqueness result in two dimensions was proved. Since then, many results concerning uniqueness and stability have been obtained; we refer to [5] and the references therein for a detailed account of these issues in two and three dimensions.

We are interested in estimating the error, in the Hausdorff distance, on the determination of Σ from an estimate of the error on the measurements $u_i|_{\Gamma_0}$. It has already been proven that

(a) if the components of Σ are a priori known to be Lipschitz regular, then the stability estimate is of log-log type (see [12, Theorem 4.1, part (I)]);
(b) if we a priori know either the coordinate system with respect to which the components of Σ are Lipschitz regular, or that the components of Σ are $C^{1,\alpha}$

regular, with $0 < \alpha \leq 1$, then the stability estimate is of log type (see [12, Theorem 4.1, parts (II) and (III)]).

These results were proved first in the case of a single crack. More precisely, part (a) in [3] and part (b), at least for what concerns the $C^{1,\alpha}$ case, in [11]. Their extension to the case of multiple cracks is essentially based on arguments developed in [4] for the treatment of the multiple cavities case.

The aim of the present paper is to fill the gap between cases (a) and (b). In fact, we prove that, under the same assumptions as those of [12, Theorem 4.1, part (I)], Lipschitz regularity is enough to obtain a stability estimate of log type. We remark that single log estimates are usually obtained through a two-step procedure; see [1], where this argument was developed for the first time. For example, the proof of (b) relies on (a), as the first step, and, as the second step, on carefully studying the relation between two unknown multiple cracks Σ and Σ' (corresponding to two different sets of measurements) if they are close enough in the Hausdorff distance, in particular, on proving a uniform interior cone property for the open set $\Omega\backslash(\Sigma \cup \Sigma')$. However, if we consider case (a), it might happen that no kind of uniform interior cone property holds for all the points of $\Sigma \cup \Sigma'$, no matter how close the two multiple cracks are in the Hausdorff distance. On the other hand, if we consider the proof of [12, Theorem 4.1], it is clear that the arguments, at a given stage, in particular in the proof of Proposition 4.9 in [12] (or of Proposition 5.1 in [3] for the case of a single crack), are developed only locally in a suitable neighborhood of the point z where the Hausdorff distance between Σ and Σ' is reached. In this paper we establish that if Σ and Σ' are Lipschitz and close enough, then the points in $\Sigma \cup \Sigma'$ belonging to such a suitable neighborhood of the point z can be reached through a suitable sequence of discs contained in $\Omega\backslash(\Sigma \cup \Sigma')$; see Lemma 3.3. Such a condition, which allows us to carry over the second step of the procedure, is similar to the so-called *corkscrew condition* used in [9] to define nontangentially accessible domains.

We wish to emphasize that logarithmic stability estimates are optimal for this inverse problem. In fact, the abstract method developed in [6] from an idea of Mandache [10] provides the instability character of the problem; see [7], an expanded version of [6], for details.

Finally we wish to remark that, with a completely analogous procedure, we can extend this stability result to the inverse problem of multiple cavities. That is, if we perform two measurements of this kind, corresponding to prescribed current densities ψ_1 and ψ_2 as above, then we can obtain a stability estimate of log type for the determination of Lipschitz multiple cavities. We notice that we have uniqueness and stability results for the determination of multiple cavities with a single measurement, which can be of the most general type; see [3] and the references therein for the two-dimensional case and [2] for the higher-dimensional one. However, in the planar case, with a single measurement the stability estimate is of log-log type if the cavities are assumed to be Lipschitz, and it is of log type if the cavities satisfy the conditions described in case (b) above. Unfortunately, the technique used to prove the stability results with a single measurement is quite different, even if it has many common features with the one used for the inverse crack problem. In particular, in order to exploit the fact that the defects Σ and Σ' are the closures of open sets, we need to study the stability of a Cauchy-type problem up to the whole boundary of $\Omega\backslash(\Sigma \cup \Sigma')$; thus we cannot restrict our analysis to a neighborhood of the point where the Hausdorff distance is reached. This can be clearly observed once we notice that, locally, we are not able to distinguish between a portion of a crack and a portion of the boundary of

a cavity. Therefore the approach developed in this paper cannot be directly applied to improve the stability with a single measurement. It remains an interesting open problem to establish log-type estimates for the determination of Lipschitz multiple cavities by a single measurement.

The plan of the paper is as follows. In section 2 we precisely state the stability result Theorem 2.3 and make some preliminary considerations. In section 3 the proof of Theorem 2.3 is developed.

2. Statement of the stability result. We begin with the definition of a quantitative notion of smoothness for open and closed curves in $\mathbb{R}^2$. The following standard notation will be used. For every $z = x + \mathrm{i}y \in \mathbb{C}$, $x = \Re z$ and $y = \Im z$ being the real and imaginary parts of z, respectively, and for every $r > 0$, we denote with $B_r(z)$ the open disc with center z and radius r. As usual, we shall identify complex numbers $z = x + \mathrm{i}y \in \mathbb{C}$ with points $(x, y) \in \mathbb{R}^2$. We shall use the following notation for complex derivatives:

$$f_{\overline{z}} = (f_x + \mathrm{i}f_y)/2, \quad f_z = (f_x - \mathrm{i}f_y)/2.$$

We denote by $J = \left[\begin{smallmatrix} 0 & -1 \\ 1 & 0 \end{smallmatrix}\right]$ the counterclockwise rotation of 90° and by $(\cdot)^T$ transpose.

DEFINITION 2.1. *Let $\gamma \subset \mathbb{R}^2$ be a bounded, simple curve, either open or closed. Then, with two fixed positive constants δ and M, we say that γ is* Lipschitz *with constants δ, M if for every $z \in \gamma$ there exists a coordinate system (x, y) with origin in z such that with respect to these coordinates $\gamma \cap B_\delta(z)$ is a* Lipschitz graph *with constant M, that is, $\gamma \cap B_\delta(z) = \{y = \phi(x) : a \le x \le b\} \cap B_\delta(z)$, where ϕ is a Lipschitz function on $[-\delta, \delta]$ such that $\|\phi\|_{C^{0,1}[-\delta,\delta]} \le M$, a and b satisfy $-\delta \le a \le 0 \le b \le \delta$, and at least one of them has modulus equal to δ.*

Let $\Omega \subset \mathbb{R}^2$ be a bounded, simply connected domain. We say that $\sigma \subset \Omega$ is a *crack* in Ω if it is a closed set in Ω, which can be represented as the image of a simple open curve. We say that $\Sigma \subset \Omega$ is a *multiple crack* in Ω if it is the finite union of pairwise disjoint cracks in Ω.

We suppose that the following assumptions on the data of the inverse problem and the following a priori information on the unknown multiple crack present in Ω hold. We wish to remark that these assumptions and a priori information are essentially minimal and coincide with those used in previous papers, and we repeat them here for the convenience of the reader.

Assumptions on the domain. Let Ω be a bounded, simply connected domain in $\mathbb{R}^2$. We assume that the diameter of Ω is bounded by a given positive constant L and that its boundary $\partial\Omega$ is a simple closed curve which is Lipschitz with given positive constants δ, M.

From these assumptions we may deduce the following properties of Ω. We may find a constant L_1 depending on δ, M, and L only such that

$$0 < \delta \le \mathrm{length}(\partial\Omega) \le L_1.$$

Furthermore, there exists a constant M_1, depending on δ, M, and L only, such that

$$\mathrm{length}_{\partial\Omega}(z_0, z_1) \le M_1 |z_0 - z_1| \quad \text{for any } z_0, z_1 \in \partial\Omega. \tag{2.1}$$

Here $\mathrm{length}_{\partial\Omega}(z_0, z_1)$ is the length of the smallest arc in $\partial\Omega$ connecting z_0 to z_1. Moreover the measure of Ω, $|\Omega|$, is bounded from below and above by positive constants depending on δ, M, and L only.

Assumptions on the background conductivity. Let $A = A(z)$, $z \in \Omega$, be a conductivity tensor with bounded measurable entries satisfying, for given positive constants λ and Λ,

$$\begin{aligned} &A(z)\xi \cdot \xi \geq \lambda |\xi|^2 \quad \text{for every } \xi \in \mathbb{R}^2 \text{ and for a.e. } z \in \Omega, \\ &|a_{ij}(z)| \leq \Lambda \quad \text{for every } i,j = 1,2 \text{ and for a.e. } z \in \Omega. \end{aligned} \tag{2.2}$$

Assumptions on the boundary data. Let γ_0, γ_1, γ_2 be three fixed simple arcs in $\partial\Omega$, pairwise internally disjoint.

Given $H > 0$, let us fix three functions η_0, η_1, $\eta_2 \in L^2(\partial\Omega)$ such that for every $i = 0, 1, 2$

$$\begin{aligned} &\eta_i \geq 0 \text{ on } \partial\Omega, \quad \operatorname{supp}(\eta_i) \subset \gamma_i, \\ &\int_{\partial\Omega} \eta_i = 1, \quad \|\eta_i\|_{L^2(\partial\Omega)} \leq H. \end{aligned} \tag{2.3}$$

Then we prescribe the current densities on the boundary ψ_1, ψ_2 to be given by

$$\psi_1 = \eta_0 - \eta_1, \quad \psi_2 = \eta_0 - \eta_2. \tag{2.4}$$

We have

$$\int_{\partial\Omega} \psi_i = 0, \quad \|\psi_i\|_{L^2(\partial\Omega)} \leq 2H \quad \text{for every } i = 1, 2. \tag{2.5}$$

We shall consider also the antiderivatives along $\partial\Omega$ of ψ_1, ψ_2,

$$\Psi_i(s) = \int \psi_i(s)\mathrm{d}s, \quad i = 1, 2, \tag{2.6}$$

where the indefinite integral is taken, as usual, with respect to arclength on $\partial\Omega$ in the counterclockwise direction. The functions Ψ_1, Ψ_2 are defined up to an additive constant.

We remark that from the assumptions on Ω, through (2.1), we have that, for every $i = 1, 2$, Ψ_i satisfies the following Hölder continuity property for any z_0, $z_1 \in \partial\Omega$:

$$|\Psi_i(z_0) - \Psi_i(z_1)| \leq 2H(\operatorname{length}_{\partial\Omega}(z_0, z_1))^{1/2} \leq H_1 |z_0 - z_1|^{1/2}, \tag{2.7}$$

where $H_1 = 2HM_1^{1/2}$, M_1 as in (2.1).

Assumptions on the measurements. Let $\Gamma_0 \subset \partial\Omega$ be a subarc whose length is greater than or equal to δ.

A priori information on the multiple interior crack. We assume that an admissible multiple crack $\Sigma \subset \Omega$ is the union of finitely many, pairwise disjoint cracks σ_j, $j = 1, \ldots, N$, $N \geq 1$.

We suppose that each crack σ_j, $j = 1, \ldots, N$, is Lipschitz with constants δ, M. Moreover we suppose that

$$\operatorname{dist}(\Sigma, \partial\Omega) \geq \delta \tag{2.8}$$

and that

$$\operatorname{dist}(\sigma_j, \sigma_l) \geq \delta \quad \text{for any } j \neq l. \tag{2.9}$$

Let us make some remarks about the properties of the admissible multiple cracks. First we notice that Σ is not empty and each component of Σ is a simple open curve whose length is bounded from below and above by positive constants depending on δ, M, and L only.

Let Σ and $\Sigma' = \bigcup_{l=1}^{N'} \sigma'_l$, $N' \geq 1$, be two multiple interior cracks satisfying the a priori information. Then the following lemma is easy to prove. We recall that we denote the Hausdorff distance with d_H and that throughout the paper we set

$$p = \mathrm{d}_H(\Sigma, \Sigma').$$

LEMMA 2.2. *There exists a constant $p_0 > 0$, depending on δ, M, and L only, such that if $p \leq p_0$, then these two properties hold.*

First, the number of connected components of Σ and Σ' is the same, for instance, equal to N, and, up to rearranging their order and swapping Σ with Σ', we can assume that

$$\mathrm{d}_H(\sigma_j, \sigma'_j) \leq \mathrm{d}_H(\Sigma, \Sigma') \quad \textit{for every } j = 1, \dots, N \tag{2.10}$$

and that there exists $z'_0 \in \sigma'_1$ so that

$$\mathrm{dist}(z'_0, \sigma_1) = \mathrm{d}_H(\sigma_1, \sigma'_1) = p. \tag{2.11}$$

Furthermore, $\Sigma \cup \Sigma' \subset \partial G$, where G is the connected component of $\Omega \backslash (\Sigma \cup \Sigma')$ whose boundary contains $\partial\Omega$.

For any $i = 1, 2$, let $u_i \in W^{1,2}(\Omega \backslash \Sigma)$ be the weak solution to (1.1). That is, we understand that u_i satisfies

$$\int_{\Omega \backslash \Sigma} A \nabla u_i \cdot \nabla \varphi = \int_{\partial\Omega} \psi_i \varphi \quad \text{for any } \varphi \in W^{1,2}(\Omega \backslash \Sigma).$$

We remark that u_i is unique up to additive constants. We denote by u'_i the solution to (1.1) when Σ is replaced with Σ'.

The set of constants δ, M, L, λ, Λ, and H will be referred to as the *a priori data*. We are now in position to state the main result.

THEOREM 2.3. *Under the previously stated assumptions, let $\varepsilon > 0$ be such that*

$$\max_{i=1,2} \|u_i - u'_i\|_{L^\infty(\Gamma_0)} \leq \varepsilon. \tag{2.12}$$

Then

$$\mathrm{d}_H(\Sigma, \Sigma') \leq \omega(\varepsilon), \tag{2.13}$$

where $\omega : (0, +\infty) \mapsto (0, +\infty)$ satisfies

$$\omega(\varepsilon) \leq K |\log \varepsilon|^{-\beta} \quad \textit{for every } \varepsilon,\ 0 < \varepsilon < 1/\mathrm{e}, \tag{2.14}$$

and K, $\beta > 0$ depend on the a priori data only.

We conclude this section by describing some properties of the solution to (1.1) and its stream function, assuming that the hypotheses of Theorem 2.3 are satisfied. For details and proofs we refer to [12, Chapter 4].

Let $i = 1, 2$ and let u_i solve (1.1). Then there exists a global single-valued function $v_i \in W^{1,2}(\Omega \backslash \Sigma)$ which satisfies

$$\nabla v_i = JA \nabla u_i \quad \text{almost everywhere in } \Omega \backslash \Sigma. \tag{2.15}$$

Such a function is referred to as the *stream function* associated to u_i. Moreover, letting $f_i = u_i + \mathrm{i}v_i$, we have

$$(f_i)_{\overline{z}} = \mu_1 (f_i)_z + \mu_2 \overline{(f_i)_z} \quad \text{almost everywhere in } \Omega\backslash\Sigma, \tag{2.16}$$

where μ_1 and μ_2 are bounded, measurable, complex-valued coefficients which depend on f_i and satisfy

$$|\mu_1| + |\mu_2| \leq k < 1 \quad \text{almost everywhere in } \Omega\backslash\Sigma, \tag{2.17}$$

where k is a constant depending on λ, Λ only.

Moreover, v_i satisfies in the weak sense the following Dirichlet-type boundary value problem:

$$\begin{cases} \operatorname{div}(B\nabla v_i) = 0 & \text{in } \Omega\backslash\Sigma, \\ v_i = d_j & \text{on } \sigma_j,\ j = 1, \dots, N, \\ v_i = \Psi_i & \text{on } \partial\Omega, \\ \int_\gamma B\nabla v_i \cdot \nu = 0 & \text{for any smooth Jordan curve } \gamma \subset \Omega\backslash\Sigma, \end{cases} \tag{2.18}$$

where $B = (\det A)^{-1} A^T$. We remark that the constants d_j are unknown and depend on $i = 1, 2$.

The weak formulation of (2.18) is the following. We want to find $v_i \in W^{1,2}(\Omega)$ such that v_i is constant in the trace sense on any crack σ_j, its trace on $\partial\Omega$ equals Ψ_i, and it satisfies

$$\int_{\Omega\backslash\Sigma} B\nabla v_i \cdot \nabla\varphi = 0 \quad \text{for any } \varphi \in W_0^{1,2}(\Omega) : \varphi = \text{const. on any crack.}$$

Let us finally remark that the stream function v_i is unique up to additive constants.

For any $i = 1, 2$, the following Hölder estimates hold (see [12, Proposition 4.6]):

$$|v_i(z_1) - v_i(z_2)| \leq C_1 |z_1 - z_2|^{\alpha_1} \quad \text{for every } z_1, z_2 \in \overline{\Omega}, \tag{2.19}$$

$$|u_i(z_1) - u_i(z_2)| \leq C_1 (\tilde{d}(z_1, z_2))^{\alpha_1} \quad \text{for every } z_1, z_2 \in \tilde{\Omega}. \tag{2.20}$$

Here C_1 and $\alpha_1 > 0$ depend on the a priori data only. We denote with $\tilde{\Omega}$ the compact manifold obtained by the appropriate gluing of $\overline{\Omega}\backslash\Sigma$ to the degenerate simple closed curve $\tilde{\sigma}_j$ obtained by overlapping two copies of σ_j, $j = 1, \dots, N$, and with $\tilde{d}$ the geodesic distance on $\tilde{\Omega}$.

It is useful to stress the difference between the estimates (2.19), (2.20). In fact, since v_i is constant on each σ_j, it is expected that v_i is continuous across each σ_j. Instead u_i may have different one-sided limits on σ_j. This is the main motivation for the introduction of the metric $\tilde{d}$.

For any $i = 1, 2$, let v_i' be the stream function associated to u_i' and $f_i' = u_i' + \mathrm{i}v_i'$. In what follows, we shall always normalize v_i and v_i' in such a way that $v_i = v_i'$ on $\partial\Omega$. Then we have that, for any $i = 1, 2$,

$$\|f_i - f_i'\|_{L^\infty(\Gamma_0)} \leq \varepsilon, \tag{2.21}$$

and, by (2.19), (2.20) and by assuming that $\varepsilon \leq 1/\mathrm{e}$,

$$\|f_i - f_i'\|_{L^\infty(\Omega)} \leq C_2, \tag{2.22}$$

where C_2 depends on the a priori data only.

Furthermore (see [12, Proposition 4.11]),

$$|v_i(z) - v_i'(z)| \le \eta(\varepsilon) \quad \text{for any } z \in \overline{\Omega}, \tag{2.23}$$

where η is a positive function defined on $(0, +\infty)$ such that

$$\eta(\varepsilon) \le C_3(\log|\log\varepsilon|)^{-\alpha_2} \quad \text{for every } \varepsilon,\ 0 < \varepsilon < 1/\mathrm{e}. \tag{2.24}$$

Here C_3 and α_2 are positive constants depending on the a priori data only.

3. Proof of Theorem 2.3. We begin with the following two results.

THEOREM 3.1. *Theorem* 2.3 *holds true if we replace* (2.14) *with*

$$\omega(\varepsilon) \le K_1(\log|\log(\varepsilon)|)^{-\beta_1} \quad \textit{for every } \varepsilon,\ 0 < \varepsilon < 1/\mathrm{e}, \tag{3.1}$$

K_1, $\beta_1 > 0$ depending on the a priori data only.

PROPOSITION 3.2. *Suppose that the assumptions of Theorem* 2.3*, with the exception of* (2.12)*, are satisfied. Let us further assume that $p \le p_0$, and hence* (2.10) *and* (2.11) *are satisfied.*

If there exist positive constants c_0 and η such that for every r, $0 \le r \le c_0 p$, there exists $z' \in \sigma_1' \cap \partial B_r(z_0')$ such that

$$|v_i(z') - v_i'(z')| \le \eta \quad \textit{for any } i = 1, 2, \tag{3.2}$$

then we have

$$p \le K_2 \eta^{\beta_2}, \tag{3.3}$$

where K_2 and β_2 are positive constants depending on c_0 and the a priori data only.

Theorem 3.1 is the first part of Theorem 4.1 in [12]. The proof of Proposition 3.2 follows exactly the same argument as that used to prove Proposition 4.9 in [12]. It appears clear that our aim is to improve the estimate (2.23)–(2.24) at least for points which are near to the point where the Hausdorff distance is reached.

The following geometric construction is crucial. Let us recall that G is the connected component of $\Omega\backslash(\Sigma \cup \Sigma')$ whose boundary contains $\partial\Omega$ and that whenever $p \le p_0$, we assume that the conclusions of Lemma 2.2 hold.

LEMMA 3.3. *Let Ω, Σ, and Σ' be as in Theorem* 2.3*. Then there exist positive constants p_1, $0 < p_1 \le p_0$, c_0, δ_0, C_4, and C_5, $0 < C_5 < 1$, depending on δ, M, and L only, such that if $p \le p_1$, then for every r, $0 \le r \le c_0 p$, there exists $z' \in \sigma_1' \cap \partial B_r(z_0')$ satisfying the following condition*

(a) *there exists a sequence of discs $D_n = B_{r_n}(z_n)$ such that, for any $n \in \mathbb{N}$,*

$$\begin{aligned} &\overline{D_n} \cap \overline{D_{n+1}} \ne \emptyset, \quad 2D_n = B_{2r_n}(z_n) \subset G, \\ &|z_n - z'| \le C_4 r_n, \quad r_{n+1} \le C_5 r_n, \end{aligned} \tag{3.4}$$

and, moreover,

$$\operatorname{dist}(D_1, \partial G) \ge \delta_0. \tag{3.5}$$

Let us remark that a point $z \in \Sigma \cup \Sigma'$ satisfies condition (a) provided there exists an open sector of a cone with vertex in z which is contained in G. In fact, in such a case, we can construct the discs satisfying condition (a) as follows. We take discs D_n

centered on the bisecting line of the sector so that $2D_n$ is contained in the sector and D_n is tangent to D_{n+1}, which is obviously chosen to be closer to z; see [1] for details. However, such a cone condition might not be satisfied if Σ and Σ' are only Lipschitz regular, even if they are very close in the Hausdorff distance; see Example 2.14 in [12]. Nevertheless, we show that, roughly speaking, in a neighborhood of the point where the Hausdorff distance is reached, condition (a) is satisfied, even if we might still lack the cone condition.

We begin with some preliminaries and by fixing some notation. Without loss of generality, by (2.8) and (2.9), we can restrict ourselves to the case of single cracks, σ_1 and σ_1', and take as G the unbounded connected component of $\mathbb{R}^2\backslash(\sigma_1 \cup \sigma_1')$.

Let us assume that $p \le \min\{p_0, \delta/4\}$ and that $z_0' \in \sigma_1'$ satisfies $\operatorname{dist}(z_0', \sigma_1) = p$, as in Lemma 2.2. Furthermore, let $z_0 \in \sigma_1$ be the point where this distance is reached, that is, such that $|z_0' - z_0| = p$.

Let us consider the coordinate system (x, y) with origin in z_0' such that with respect to these coordinates $\sigma_1 \cap B_\delta(z_0)$ is a *Lipschitz graph* with constant M and $z_0 = (x_0, y_0)$ with $x_0 \ge 0$ and $y_0 \le 0$. For any $i = 1, 2$, let $z_i = (x_i, y_i) \in \partial B_p(z_0')$ be such that $y_i \le 0$ and the tangent line to $\partial B_p(z_0')$ at the point z_i has slope $(-1)^i M$. Clearly we have $x_2 > 0$, $x_1 = -x_2$, and $y_1 = y_2$.

With the notation $S_r(\theta_1, \theta_2)$, where $r > 0$ and $\theta_1 < \theta_2$, we denote the open sector of a cone so defined:

$$S_r(\theta_1, \theta_2) = \{z = (x, y) : \ |z| < r \text{ and } \theta_1 < \arg z < \theta_2\}.$$

We say that r is the radius and $\theta_2 - \theta_1$ is the amplitude of such a sector. Let θ, $0 < \theta < \pi/2$, be the angle between a line of slope M and the y-axis and let

$$S_0 = S_{\delta/2}(\pi/2 - \theta, \pi/2 + \theta).$$

The proof of Lemma 3.3 is rather technical. Before entering into details, let us sketch its main features. Let us consider, for simplicity, the case in which $x_1 \le x_0 \le x_2$. Let us consider the function

$$f(x) = \begin{cases} -M(x - x_1) + y_1 & \text{if } x \le x_1, \\ -\sqrt{1 - x^2} & \text{if } x_1 \le x \le x_2, \\ M(x - x_2) + y_2 & \text{if } x \ge x_2. \end{cases}$$

We have that since $\sigma_1 \cap B_\delta(z_0)$ is a *Lipschitz graph* with constant M, then σ_1 must be, locally, below the graph of f. In particular, $S_0(z_i) = z_i + S_0$, for any $i = 0, 1, 2$, and $S_0(z_0') = z_0' + S_0$ do not contain points of σ_1. Moreover, by construction, any point z belonging to $S_0(z_0')$ has distance greater than p from the graph of f and, consequently, also from σ_1. Since p is the Hausdorff distance between σ_1 and σ_1', we infer that $S_0(z_0') \cap \sigma_1'$ is empty.

We have shown that there exists an open sector of a cone with vertex in z_0' which is contained in G, and thus condition (a) is satisfied for $r = 0$. For $r > 0$, we proceed as follows. Let $z \in \sigma_1' \cap \partial B_r(z_0')$, and let us consider the two opposite sectors with vertex in z which do not intersect σ_1', which exist by the Lipschitz character of σ_1'. Such sectors, at least for small r and near z, are contained in the epigraph of f, and thus do not intersect σ_1, too. Then the main idea is the following. We proceed from z along the bisecting line of one of these two sectors until we meet the bisecting line of one among the sectors $S_0(z_i)$, $i = 1, 2$, or $S_0(z_0')$. Then we turn and continue along this other bisecting line. This piecewise linear curve will be the direction along which we approach z with the sequence of balls contained in G that provides condition (a).

Proof of Lemma 3.3. Under the previous hypotheses and notation, we have two cases: Either

(i) the tangent line to $\partial B_p(z_0')$ at the point z_0 has slope m less than or equal to M; or

(ii) the tangent line to $\partial B_p(z_0')$ at the point z_0 has slope m greater than M (including the extreme case of a vertical tangent, when $z_0 = (p, 0)$).

If (i) holds, that is, when $x_1 \le x_0 \le x_2$, then $S_0(z_0') = z_0' + S_0$ satisfies $\operatorname{dist}(S_0(z_0'), \sigma_1) \ge p$. Therefore, since $p = \mathrm{d}_H(\sigma_1 \cup \sigma_1')$, we have $S_0(z_0') \cap (\sigma_1 \cup \sigma_1') = \emptyset$.

On the other hand, if (ii) holds, then we pick $\tilde{S}_0(z_0')$ as $\tilde{S}_0(z_0') = z_0' + \tilde{S}_0 = z_0' + S_{\delta/2}(\pi/2, 3\pi/2 - \theta)$, and we still have that $\tilde{S}_0(z_0') \cap (\sigma_1 \cup \sigma_1') = \emptyset$. We wish to remark that (ii) can hold only if z_0 is an endpoint of σ_1.

The construction of $S_0(z_0')$ or $\tilde{S}_0(z_0')$, respectively, already proves that the lemma is true for $r = 0$, that is, for z_0'.

We have that, with respect to a coordinate system which is rotated in the counterclockwise sense of an angle $\tilde{\theta}$, $0 \le \tilde{\theta} < \pi$, with respect to the system (x, y), $\sigma_1' \cap B_\delta(z_0')$ is a Lipschitz graph with constant M, which implies that for any $z' \in \sigma_1' \cap \overline{B}_p(z_0')$, the sectors $S_0'(z')^{\pm} = z' \pm S_{\delta/2}(\pi/2 - \theta + \tilde{\theta}, \pi/2 + \theta + \tilde{\theta})$ do not intersect σ_1'. Furthermore, $S_0(z') = z' + S_0$ does not contain points of σ_1.

If $\tilde{\theta} \in [0, 15\theta/8] \cup [\pi - 15\theta/8, \pi)$, then for any $z' \in \sigma_1' \cap \overline{B}_p(z_0')$, we have that the intersection of $S_0(z')$ either with $S_0'(z')^+$ or with $S_0'(z')^-$ contains a sector of a cone of radius $\delta/2$ and amplitude at least $\theta/8$. Such a sector has empty intersection with $\sigma_1 \cup \sigma_1'$; thus a uniform cone property holds and the lemma easily follows.

We now consider the case in which $\tilde{\theta} \in (15\theta/8, \pi - 15\theta/8)$. We restrict ourselves to the case in which (i) holds; the case in which (ii) holds can be treated in a completely analogous way.

Let us consider the ball $B_{\delta/2}(z_0')$. We have that $B_{\delta/2}(z_0') \setminus (S_0'(z_0')^+ \cup S_0'(z_0')^-)$ consists of two closed sectors $\tilde{S}^+$ and $\tilde{S}^-$, where the first one is the only one whose intersection with $S_0(z_0')$ is not empty. If we further subtract $S_0(z_0')$, then we obtain at most three closed sectors, $\tilde{S}^-$, $\hat{S}_1$, and $\hat{S}_2$, the last ones being contained in $\tilde{S}^+$. We order $\hat{S}_1$ and $\hat{S}_2$ in the counterclockwise direction; that is, we take $\hat{S}_1$ as the one contained in $\{x \ge 0\}$ and $\hat{S}_2$ as the one contained in $\{x \le 0\}$, keeping in mind that one or both of them can be empty or have an empty interior. We observe that at most one between $\hat{S}_1$ and $\hat{S}_2$ contains points of σ_1'.

Assume that $\sigma_1' \cap \hat{S}_1$ is not empty. Then there exist constants c_1, $0 < c_1 < 1$, and $c_2 > 0$, depending on δ and M only, such that for every $z' \in \sigma_1' \cap \hat{S}_1 \cap \overline{B}_{c_1 p}(z_0')$ we have that $S_0'(z')^+ \cap S_0(z_0')$ is not empty, $S_0'(z')^+ \cap S_0(z_0') \subset z_0' + (S_{\delta/4}(\pi/2 - \theta, \pi/2 + \theta) \setminus S_{c_2|z' - z_0'|}(\pi/2 - \theta, \pi/2 + \theta))$, and the angle between the bisecting lines of $S_0'(z')^+$ and $S_0(z_0')$ is greater than a positive constant depending on M only. Then we can prove that for every $z' \in \sigma_1' \cap \hat{S}_1 \cap \overline{B}_{c_1 p}(z_0')$, condition (a) holds. We take a sequence of discs in $S_0(z_0')$, each one so that its center is on the bisecting line of $S_0(z_0')$, it is tangential to the next one, and the disc with double radius and same center is still contained in $S_0(z_0')$, till we reach the intersection of the bisecting lines of $S_0'(z')^+$ and $S_0(z_0')$. From that point on, we continue the construction by taking discs, with analogous properties as before, along the sector $S_0'(z')^+$.

If $\sigma_1' \cap \hat{S}_2$ is not empty, then we can repeat the same reasoning using $S_0'(z')^-$ instead of $S_0'(z')^+$.

It might happen that $\sigma_1' \cap (\hat{S}_1 \cup \hat{S}_2)$ is strictly contained in $B_{c_1 p}(z_0')$, and therefore the proof is not yet concluded. In this case, we can find positive constants p_1, $0 < p_1 \le \min\{p_0, \delta/4\}$, c_3, c_4, and θ_1, $0 < \theta_1 \le \theta$, depending on δ and M only, such that

if $p \le p_1$, then for any r, $0 < r \le c_3 p$, there exists $z' \in \sigma_1' \cap \tilde{S}^-$ such that $|z' - z_0'| = r$ and the following holds. Let $\tilde{S}_0'(z')^{\pm}$ be the sector with vertex in z', radius $\delta/2$, the same bisecting line as $S_0'(z')^{\pm}$, and amplitude $2\theta_1$. Then either (i) $\tilde{S}_0'(z')^+ \cap S_0(z_1)$ is not empty, $\tilde{S}_0'(z')^+ \cap S_0(z_1) \subset z_1 + (S_{\delta/4}(\pi/2-\theta, \pi/2+\theta) \backslash S_{c_4 p}(\pi/2-\theta, \pi/2+\theta))$, the angle between the bisecting lines of $\tilde{S}_0'(z')^+$ and $S_0(z_1)$ is greater than a positive constant depending on M only, and $S_0(z_1) \backslash (z_1 + S_{c_4 p}(\pi/2-\theta, \pi/2+\theta))$ does not contain points of σ_1'; or (ii) the same properties are satisfied by $\tilde{S}_0'(z')^-$ and $S_0(z_2)$. Then we repeat the construction used before using either the two sectors $\tilde{S}_0'(z')^+$ and $S_0(z_1)$ or $\tilde{S}_0'(z')^-$ and $S_0(z_2)$. ∎

We can now conclude the proof of our stability result.

Proof of Theorem 2.3. By Theorem 3.1, we can assume without loss of generality that $p \le p_1$. Then, by Lemma 3.3, we can find c_0, δ_0, C_4, and C_5, $0 < C_5 < 1$, depending on δ, M, and L only, such that for every r, $0 \le r \le c_0 p$, there exists $z' \in \sigma_1' \cap \partial B_r(z_0')$ satisfying condition (a).

Then, for any $i = 1, 2$, and any of these z' satisfying condition (a), we have

$$|v_i(z') - v_i'(z')| \le C_6 |\log \varepsilon|^{-\alpha_3}, \tag{3.6}$$

where C_6 and $\alpha_3 > 0$ depend on the a priori data only.

In fact, let us fix $i \in \{1, 2\}$ and let us call $f = u + \mathrm{i}v = u_i - u_i' + \mathrm{i}(v_i - v_i')$. We have that f is quasiregular inside $\Omega \backslash (\Sigma \cup \Sigma')$; that is, it satisfies a Beltrami-type equation like (2.16)–(2.17).

Let G_{δ_0} be the set of points in G whose distance from $\Sigma \cup \Sigma'$ is greater than or equal to δ_0. We assume, without loss of generality, that $\delta_0 \le \delta/4$; thus a neighborhood of $\partial\Omega$ in G is contained in G_{δ_0}.

Let $\Omega_1 = G_{\delta_0} \cup (\bigcup_{n \in \mathbb{N}} 2D_n)$, with D_n as in condition (a) applied to z'. We have that Ω_1 is a domain contained in G such that $\partial\Omega \subset \partial\Omega_1$.

Let us observe that for any r, $0 < r \le |z_1 - z'|$, with z_1 the center of D_1, there exists $w_r \in \bigcup_{n \in \mathbb{N}} \overline{D_n}$ such that $|w_r - z'| = r$. Furthermore, we can take such a w_r in D_n, where n satisfies $n < C_7(1 + |\log r|)$, with C_7 depending on C_4, C_5, and L only.

Then (3.6) can be obtained as follows. By recalling (2.21) and (2.22), we can estimate, in terms of ε, $|f|$ inside Ω_1 by using the method of harmonic measure, which has been generalized to operators with nonconstant and anisotropic coefficients in [3].

We can estimate $|v(z')|$ using the interior estimate of $|f|$ at the point w_r, $0 < r \le |z_1 - z|$, and (2.19). A precise estimate of $|f(w_r)|$ is obtained through a repeated use of the Harnack inequality along the sequence of discs D_n. We refer to the proof of Proposition 4.12 in [12] for details.

Then the conclusion follows immediately from (3.6) and Proposition 3.2. ∎

CONSERVATION LAWS WITH TIME DEPENDENT DISCONTINUOUS COEFFICIENTS*

GIUSEPPE MARIA COCLITE† AND NILS HENRIK RISEBRO‡

Abstract. We consider scalar conservation laws where the flux function depends discontinuously on both the spatial and temporal locations. Our main results are the existence and well-posedness of an entropy solution to the Cauchy problem. The existence is established by showing that a sequence of front tracking approximations is compact in L^1, and that the limits are entropy solutions. Then, using the definition of an entropy solution taken from [K. H. Karlsen, N. H. Risebro, and J. D. Towers, *Skr. K. Nor. Vidensk. Selsk.*, 3 (2003), pp. 1–49], we show that the solution operator is L^1 contractive. These results generalize the corresponding results from [S. N. Kružkov, *Math. USSR-Sb.*, 10 (1970), pp. 217–243] and also partially those from Karlsen, Risebro, and Towers.

Key words. conservation laws, entropy solutions, discontinuous coefficients

1. Introduction.

In this paper we are concerned with the Cauchy problem for scalar conservation laws where the flux function depends on both the x and t coordinates. We study the case where this dependence takes the form $f(u,x,t) = f(u,a(x),g(t))$ through some functions a and g. Hence, we shall study the initial value problem

$$\begin{cases} u_t + f(u,a(x),g(t))_x = 0, & x \in \mathbf{R}, \quad t > 0, \\ u(x,0) = 0, & x \in \mathbf{R}, \end{cases} \tag{1.1}$$

where $f = f(u,a,g)$ is a smooth function. We regard the function $a(x)$ and $g(t)$ as coefficients, and if these are smooth, the classical results of Kružkov [16] and Oleĭnik [19] state that the above initial value problem is well posed in the class of entropy solutions.

In our case, the coefficients are allowed to be discontinuous, and we cannot apply the techniques of Kružkov and Oleĭnik directly to reach their conclusion. The main obstacle is that of the discontinuity of the spatial coefficient a. The equation where g is constant has recently received considerable attention, beginning with the paper of Temple [23], in which he studied a system of nonstrictly hyperbolic conservation laws. By a Lagrangian transformation, this system is equivalent to a scalar equation with discontinuous coefficients; see Wagner [26]. If one writes the scalar conservation law as a system by introducing a as a new component of the solution, we have

$$\begin{cases} u_t + f(u,a,g(t))_x = 0, \\ a_t = 0. \end{cases}$$

This system has eigenvalues f_u and 0, and if $f_u(u,a,g)=0$ for some (u,a,g), then the system is nonstrictly hyperbolic, and the standard theory for systems (see Glimm [7] and, more recently, [8, 1]) does not apply. In particular, one can show by a concrete example (see, e.g., [23]) that the total variation of the approximate solutions produced by the Glimm scheme (and also by front tracking) is not bounded in terms of the discretization parameters. Such systems are commonly called *resonant*. For resonant systems, one cannot show compactness by the usual method of establishing BV estimates on a sequence of approximate solutions.

To overcome this difficulty, in [23] Temple introduced a nonlinear mapping $\Psi = \Psi(u)$ and used this mapping to prove that the sequence of approximations produced by the Glimm scheme is compact. This approach has since been used in a number of papers for related systems, using other approximations; see Gimse and Risebro [6] and Klingenberg and Risebro [14, 15] for front tracking approximations; Lin, Temple, and Wang [18] for Godunov-type approximations; Towers [24, 25] for monotone difference schemes; and Hong [9] for Godunov schemes for resonant $n \times n$ and for 2×2 systems with inhomogeneous source terms.

As an alternative to the use of Ψ to prove compactness, in [12, 10] Karlsen et al. used the Murat–Tartar compensated compactness approach to prove convergence of numerical approximations.

The conservation law (1.1) is formally equivalent to the Hamilton–Jacobi equation

$$v_t + f(v_x, a(x), g(t)) = 0.$$

In several papers, Ostrov (see, e.g., [20] and [21]) considered this type of equation, and he showed the existence of a viscosity-type solution and discussed the question of uniqueness.

Regarding uniqueness of weak solutions to (1.1) in the case where a and g are not smooth, this was first studied (for the constant g case) in [15] and [13]. In these papers it was shown that the solution is unique if it is the limit of solutions to equations where the coefficients are smoothed. More recently, L^1-contractivity was shown for piecewise smooth solutions in the case of convex flux functions in [25], and in a more general case by Karlsen, Risebro, and Towers [12]. Also, Seguin and Vovelle [22] proved uniqueness for L^∞ solutions for a special case of (1.1) with $g = \text{const.}$ and $a(\cdot)$ taking two values separated by a jump discontinuity. The techniques used in the present paper are heavily inspired by those used in [11], in which Karlsen, Risebro, and Towers show uniqueness of solutions in the case where g is constant, and where $u \mapsto f(u,a)$ is not required to have a single local maximum. The authors of [25, 12, 22, 11] all use a Kružkov-type entropy condition.

The purpose of the present paper is to extend the well-posedness theory for conservation laws with discontinuous coefficients by including a t dependent coefficient.

Conservation laws with discontinuous coefficients, both in x and t, occur in many models. The simplest such model is the hydrodynamic traffic flow model; see Lighthill and Whitham [17]. In this case the x and t dependency model the road conditions, specifically the maximal speed of any vehicle. Both of these dependencies can vary discontinuously—for instance, when modeling a traffic light. Another model in which such conservation laws occur is a clarifier-thickener model of continuous sedimentation; see Bürger et al. [4, 2, 3]. In the papers [2, 3] the actual models were simplified so that $g(t)$ was assumed to be constant.

Now we briefly state our main result and detail our assumptions. In order for the Riemann problem to have a bounded solution, it is convenient to assume that there is

a finite interval $[\alpha,\beta]$ such that $f(\alpha,a,g)=f(\beta,a,g)$ for all a and g, and we can choose $\alpha=0$ and $\beta=1$. This is not necessary for the solution of the Riemann problem to be bounded, but it is certainly sufficient; see [5], however, for less restrictive assumptions that yields the same conclusions.

So therefore we assume that $f:[0,1]\times\mathbf{R}^2\mapsto\mathbf{R}$, $g:\mathbf{R}^+\mapsto\mathbf{R}$ and $a:\mathbf{R}\mapsto\mathbf{R}$ are given functions which satisfy the following:

(A.1) a is piecewise C^1 with finitely many jump discontinuities at $x=x_1,\dots,x_M$.

(A.2) $\|a\|_{L^\infty}<\infty$, $\sup_{x\notin\{x_i\}_1^M}|a'(x)|<\infty$, and $a\in BV(\mathbf{R})$.

(A.3) $f\in C^2([0,1]\times\mathbf{R}^2;\mathbf{R})$, $f_{uu}(u,a,g)\le -c_{uu}<0$ for some positive constant c_{uu} for all a and g.

(A.4) $f(0,\cdot,\cdot)\equiv f(1,\cdot,\cdot)\equiv 0$, and there is a unique value u^* such that $f_u(u^*,\cdot,\cdot)\equiv 0$.

(A.5) $\partial f/\partial g\ge 0$ and $\partial f/\partial a\ge 0$. Furthermore

$$\frac{\partial^2 f}{\partial g\partial a}$$

is bounded.

(A.6) $g\in BV(\mathbf{R}^+)$, and $g(t)>0$ for all $t>0$.

Next, let $\Psi(u,a,g)$ be defined by

$$\Psi(u,g,a)=\operatorname{sign}(u-u^*)\,\frac{f(u^*,a,g)-f(u,a,g)}{f(u^*,a,g)}. \tag{1.2}$$

We demand that the initial data are such that $u_0\in L^1(\mathbf{R};[0,1])$ and

$$|\Psi(u_0,a,g)|_{BV}<\infty. \tag{1.3}$$

We use the following definition of a weak entropy solution of (1.1).

DEFINITION 1.1. *Let $T>0$, and let $u:\Pi_T=\langle 0,T\rangle\times\mathbf{R}\mapsto[0,1]$ be a measurable function. We call u an entropy weak solution of* (1.1) *if the following conditions hold:*

(D.1) *$u\in L^1(\Pi_T)$, and the map $\langle 0,T\rangle\ni t\mapsto u(\cdot,t)\in L^1(\mathbf{R})$ is Lipschitz continuous.*

(D.2) *The following entropy inequality holds for all constants c and all nonnegative test functions φ,*

$$\begin{aligned}\iint_{\Pi_T}&|u-c|\varphi_t+F(u,x,t,c)\varphi_x\,dtdx\\ &-\sum_{m=0}^{M}\int_{x_m}^{x_{m+1}}\int_0^T \operatorname{sign}(u-c)\,f_a(c,a(x),g(t))a'(x)\varphi\,dtdx\\ &+\sum_{m=1}^{M}\int_0^T\left|f(c,a\left(x_m^+\right),g(t))-f(c,a\left(x_m^-\right),g(t))\right|\,dt\ge 0,\end{aligned} \tag{1.4}$$

where we have set $x_0=-\infty$, $x_{M+1}=\infty$ and F is given by

$$F(u,x,t,c)=\operatorname{sign}(u-c)\left[f(u,a(x),g(t))-f(c,a(x),g(t))\right],\quad t>0,\quad x\in\mathbf{R}.$$

(D.3) *$u(\cdot,t)\to u_0$ in $L^1(\mathbf{R})$ as $t\downarrow 0$.*

(D.4) *$|\Psi(u(\cdot,t),a,g(t))|_{BV}<\infty$ for all $t\in\langle 0,T\rangle$.*

The inequality (1.4) implies that any entropy solution is a weak solution, as setting $c = 1$ and $c = 0$ will show. The condition (D.4) implies that the limits

$$\lim_{x \to x_m^{\pm}} \Psi(u, a, g)$$

exist for almost all t. Since $u \mapsto \Psi(u, a, g)$ is invertible, and the inverse is continuous, the limits

$$\lim_{x \to x_m^{\pm}} u(x, t)$$

also exist for almost all t. This will be needed to show uniqueness. Our main result is the following.

MAIN THEOREM. *Assume that f, a, and g satisfy the above assumptions,* (A.1)–(A.6). *If u_0 and v_0 are two functions that satisfy* (1.3), *then there exist corresponding entropy solutions u and v taking initial values u_0 and v_0, respectively. These entropy solutions satisfy*

$$\|u(\cdot, t) - v(\cdot, t)\|_{L^1(\mathbf{R})} \leq \|u_0 - v_0\|_{L^1(\mathbf{R})}.$$

The rest of this paper is organized as follows. In the next section, section 2, we define a sequence of approximate solutions by the front tracking method. This is based on the front tracking method defined in [14]. In section 3 we proceed to establish interaction estimates, which allows us to deduce that the total variation of Ψ is bounded for the front tracking approximations. Then we can use Helly's theorem and show that any limit is an entropy solution in the above sense. Then, using an adaptation of arguments taken from [11], one can show that the entropy solution operator is L^1 contractive. In this way our main theorem is proved. Finally, we conclude with a section showing the front tracking scheme used on a concrete example.

2. The front tracking scheme. We start this section by defining a front tracking scheme for the case where $g(t) \equiv \text{const}$. This scheme is slightly different from the front tracking scheme defined for this case in, e.g., [14]. The reason for this difference is that our front tracking scheme also must work when g is not constant.

Therefore we first consider the initial value problem,

$$\begin{cases} u_t + f(u, a)_x = 0 & \text{for } x \in \mathbf{R},\ t > 0, \\ u(x, 0) = u_0(x) & \text{for } x \in \mathbf{R}, \end{cases} \tag{2.1}$$

where f and a are as described above. The Riemann problem for (2.1) is the initial value problem where

$$u_0(x) = \begin{cases} u_l, & x \leq 0, \\ u_r, & x > 0, \end{cases} \qquad a(x) = \begin{cases} a_l, & x \leq 0, \\ a_r, & x > 0, \end{cases}$$

and its solution is detailed in [14]. This solution consists of at most one u-wave separating the u-values u_l and u_l', followed by a so-called a-wave separating the states (u_l', a_l) and (u_r', a_r). This wave is a contact discontinuity having zero speed. The solution is then completed by a u-wave separating u_r' and u_r. The first u-wave has nonpositive speed, and the second nonnegative. The intermediate states u_l' and u_r' are unique, provided (1.4) holds. Furthermore $u_{l,r}'$ can equal $u_{l,r}$.

Let

$$z(u,a) = \operatorname{sign}(u^* - u)\,(f(u,a) - f(u^*,a)) \quad \text{and} \quad \alpha(a) = f(u^*,a).$$

Since $a \mapsto f(u^*,a)$ is nondecreasing, $a \mapsto \alpha(a)$ is invertible. In the (z,α) plane, a-waves are straight lines of slope ± 1. An a-wave connecting two points (z_1,α_1) and (z_2,α_2) has slope 1 if z_1 and z_2 are nonpositive, and slope -1 if these values are nonnegative. If z_1 and z_2 have different sign, there is no a-wave connecting these points. Since u-waves connect points with the same a-values, these are horizontal lines in the (z,α) plane. Now fix a (small) number $\delta > 0$, and set $\alpha_i = i\delta$ and $z_j = j\delta$ for integers i and j. We define u_0^δ and a^δ as piecewise constant functions, with a finite number of jump discontinuities, such that

$$\left.\begin{aligned} \left\|a - a^\delta\right\|_{L^1(\mathbf{R})} &\to 0 \\ \left\|u_0 - u_0^\delta\right\|_{L^1(\mathbf{R})} &\to 0 \end{aligned}\right\} \quad \text{as } \delta \to 0. \tag{2.2}$$

Label the (finite number of) values of u^δ and a^δ $u_1,\dots,u_M$, and $a_1,\dots,a_N$, respectively. Let α_j be the jth member of the ordered set

$$\{\alpha_k\}_{k=m'}^{M'} \cup \{\alpha(a_k)\}_{k=1}^{M},$$

where m' and M' are chosen such that

$$0 < m' \le \min_x \alpha(a^\delta(x)) < \max_x \alpha(a^\delta(x)) \le M'.$$

For ease of notation, set

$$a_j = \alpha^{-1}(\alpha_j).$$

Next, for each α_j, we define $z_{j,k}$ to be the kth member of the ordered set

$$\{z_i\}_{i=-N'(j)}^{N'(j)} \cup \{z(u_i,a_j)\}_{i=1}^{M},$$

where $N'(j)$ is such that

$$z^{-1}\left(z_{-N'(j)},a_j\right) = 0 \quad \text{and} \quad z^{-1}\left(z_{N'(j)},a_j\right) = 1.$$

We also set

$$u_{j,k} = z^{-1}(z_{j,k},a_j) \quad \text{and} \quad f_{j,k} = f(u_{j,k},a_j).$$

Then, for each j, let the approximate flux function $f^\delta(u,a)$ be the piecewise linear interpolant,

$$f^\delta(u,a_j) = f_{j,k} + (u - u_{j,k})\,\frac{f_{j,k+1} - f_{j,k}}{u_{j,k+1} - u_{j,k}} \quad \text{for } u \in [u_{j,k},u_{j,k+1}]. \tag{2.3}$$

We have chosen the grid so that the entropy solution to the initial value problem

$$\begin{aligned} u_t + f^\delta\left(u,a^\delta\right)_x &= 0, \quad t > 0, \quad x \in \mathbf{R}, \\ u(x,0) &= u_0^\delta(x), \quad x \in \mathbf{R}, \end{aligned} \tag{2.4}$$

can be constructed by front tracking for any time t. We call this front tracking solution u^δ. Furthermore u^δ will take values that are grid points; i.e., for any point (x,t) such that u^δ and a^δ are constant at (x,t),

$$z\left(u^\delta(x,t), a^\delta(x)\right) = z_{j,k} \quad \text{for some } j \text{ and } k.$$

In particular, this means that

$$f^\delta\left(u^\delta, a^\delta\right) = f\left(u^\delta, a^\delta\right) \quad \text{almost everywhere.}$$

For an elaboration and proof of these statements, see [14]. The construction used here differs from the construction in [14] in that we have added grid points corresponding to the discretization of the initial function u_0 and the coefficient a, instead of choosing discretization that takes values on the fixed grid in the (z,α) plane.

Now we can define the front tracking approximation in the case where g is not constant; cf. (1.1). Let g^δ be a piecewise constant approximation to g, such that

$$\begin{aligned} \left\|g^\delta - g\right\|_{L^1(\mathbf{R}^+)} &\to 0 \quad \text{as } \delta \to 0, \\ \left|g^\delta\right|_{BV(\langle 0,T])} &\le |g|_{BV(\langle 0,T])}. \end{aligned} \tag{2.5}$$

Define t^n such that g^δ is constant on each interval $I^n = \langle t^n, t^{n+1}]$. Assuming that we can define front tracking for $t < t^n$, we can then use $u^\delta(\cdot, t^n)$ as initial values for a front tracking approximation defined in $[t^n, t^{n+1}\rangle$. In order to do this we must use a "new" mapping z, since $z = z(u,a,g)$, and redefine the grid on which we operate. However, we keep the grid points corresponding to $u^\delta(\cdot, t^n)$. In this way, the grid used in the interval I^{n+1} will contain more points than the one used in I^n, but since there are only a finite number of intervals I^n such that $t^n \le T$, for a fixed δ, we use a finite number of grid points for $t \le T$. If, for $t \in I^n$, $f^\delta(\cdot,\cdot,g^\delta(t))$ denotes the approximate flux function constructed above using $f(\cdot,\cdot,g^\delta\,\big|_{I^n})$ and $u^\delta(\cdot,t^n)$, then we have that the front tracking construction u^δ will be an entropy solution of

$$\begin{aligned} u^\delta_t + f^\delta\left(u^\delta, a^\delta(x), g^\delta(t)\right)_x &= 0, \quad t > 0, \quad x \in \mathbf{R}, \\ u^\delta(x,0) &= u^\delta_0(x), \quad x \in \mathbf{R}. \end{aligned} \tag{2.6}$$

We call the discontinuities in u^δ *fronts*, and we have three types: u-fronts, a-fronts, and g-fronts (that have infinite speed!).

3. Compactness. In this section we show that the sequence $\left\{u^\delta\right\}_{\delta>0}$ is compact in L^1 by estimating the variation of $\Psi(u^\delta, a^\delta, g^\delta)$. For each time t, such that g^δ is constant at t, we can view u^δ as consisting of a sequence of fronts, u-fronts and a-fronts.

We defined the map Ψ by (1.2), and we define the associated Temple functional of a front w by

$$T(w) = \begin{cases} |\Delta\Psi| & \text{if } w \text{ is a } u\text{-front}, \\ 2\,|\Delta f(u^*,a,g)| & \text{if } w \text{ is an } a\text{-front, and } \Psi_r < \Psi_l, \\ 4\,|\Delta f(u^*,a,g)| & \text{if } w \text{ is an } a\text{-front, and } \Psi_r > \Psi_l. \end{cases} \tag{3.1}$$

If $\Psi_l < \Psi_r$, we call an a-front *counterclockwise*; otherwise we call it *clockwise*. For sequence of fronts, define T additively. Next, for the front tracking approximation u^δ, we define the interaction estimate Q by

$$Q(t) = T(t)\left|g^\delta(\cdot)\right|_{BV([t,T])}, \tag{3.2}$$

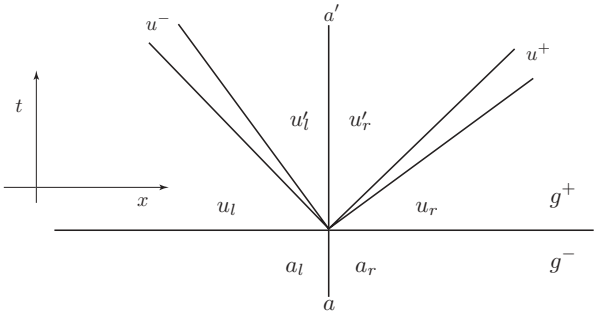

FIG. 1. *The states used in an interaction between an a-wave and a g-wave.*

where with a slight abuse of notation we write $T(t) = T(u^\delta(\cdot, t))$. With these definitions, we can state the following lemma.

LEMMA 3.1. *There exists a positive constant C, depending only on f, a, and g, such that for all $t > 0$, we have that the "Glimm functional"*

$$G(t) = T(t) + CQ(t) \tag{3.3}$$

is nonincreasing in time.

Proof. In each interval I^n, we know from [14] that T is nonincreasing, and the lemma holds. To prove the lemma we must study interactions between u-fronts and g-fronts, and between a-fronts and g-fronts.

We start by considering the interaction between a single a-front and a single g-front. The states involved are depicted in Figure 1. We label the "incoming" a-wave (front) a, the outgoing a-wave a', the left-moving outgoing u-wave u^-, and the right-moving outgoing u-wave u^+. See Figure 1.

In this case we claim that

$$T(u^-) + T(a') + T(u^+) - T(a) \leq C\,|\Delta g|\,|\Delta a| \tag{3.4}$$

for some constant C depending on f and its derivatives, but not on δ. In this case it will follow from the discussion of cases below that if a is (counter)clockwise, then a' is (counter)clockwise. Next, from this it follows that

$$\begin{aligned}
|T(a') - T(a)| &\leq 4\left(\left|f\left(u^*, a_l, g^+\right) - f\left(u^*, a_r, g^+\right)\right| - \left|f\left(u^*, a_l, g^-\right) - f\left(u^*, a_r, g^-\right)\right|\right) \\
&\leq 4\left[\int_{a_l}^{a_r} \left|\frac{\partial f}{\partial a}\right| (u^*, z, g^+)\, dz - \int_{a_l}^{a_r} \left|\frac{\partial f}{\partial a}\right| (u^*, z, g^-)\, dz\right] \\
&\leq 4\int_{a_l}^{a_r}\int_{g^-}^{g^+} \left|\frac{\partial^2 f}{\partial g \partial a}\right| (u^*, z, y)\, dy dz \\
&\leq C\,|\Delta a \Delta g|
\end{aligned}$$

for some C depending on the partial derivatives of f. Therefore it suffices to show that

$$T(u^-) + T(u^+) \leq C\,|\Delta g|\,|\Delta a|\,. \tag{3.5}$$

First observe that since an a-wave cannot cross the line $z = 0$, either both u_l and u_r are less than or equal to u^* or both are greater than or equal to u^*. If this is not so,

then the "a-wave" is in fact a stationary u-wave followed by an a-wave, or vice versa. If this is so, we can perturb u^δ an arbitrarily small amount by shifting the stationary u-wave a small distance and then treat the interaction of the g-wave and the u-wave separately.

We now let

$$G\left(a_l, a_r, g^-, g^+\right) = T\left(u^-\right) + T\left(u^+\right).$$

For simplicity, we regard a_l and g^- as fixed, and the emerging waves as functions of $a = a_r$ and $g = g^+$. Trivially we have that

$$G(a_l, a_l, g^-, g) = G(a_l, a, g^-, g^-) = 0,$$

and (3.5) follows if G is continuous and

$$\frac{\partial^2 G}{\partial a \partial g}$$

is bounded, since

$$G(a_l, a_r, g^-, g^+) = \int_{a_l}^{a_r} \int_{g^-}^{g^+} \frac{\partial^2 G}{\partial a \partial g}(a_l, a, g^-, g)\, dg da.$$

First we assume that both u_l and u_r are less than or equal to u^*. In this case, if

$$f\left(u_l, a_l, g\right) \le f\left(u^*, a, g\right), \tag{3.6}$$

then there are no left-moving waves u^-, while if

$$f\left(u_l, a_l, g\right) > f\left(u^*, a, g\right), \tag{3.7}$$

there will be emerging u-waves of both positive and negative speeds. These two case are depicted in Figure 2. Note that in both cases both a and a' are counterclockwise. So we find that

$$\begin{aligned} G\left(a_l, a, g^-, g\right) = {} & \frac{\operatorname{sign}\left(u_l - u_r\right)}{f\left(u^*, a, g\right)} \left[f\left(u_l, a_l, g\right) - f\left(u_r, a, g\right)\right] \chi_{\{f(u_l,a_l,g) \le f(u^*,a,g)\}} \\ & + \left\{ \frac{1}{f\left(u^*, a_l, g\right)} \left[f\left(u_l, a_l, g\right) - f\left(u^*, a, g\right)\right] \right. \\ & \left. + \frac{1}{f\left(u^*, a, g\right)} \left[f\left(u^*, a, g\right) - f\left(u_r, a, g\right)\right] \right\} \chi_{\{f(u_l,a_l,g) > f(u^*,a,g)\}}. \end{aligned}$$

From this expression it is straightforward to check that G is sufficiently regular, and (3.5) holds.

The case where $u_{l,r} \ge u^*$ is similar: If

$$f\left(u_r, a, g\right) \le f\left(u^*, a_l, g\right), \tag{3.8}$$

there is only one outgoing u-wave, with negative speed. If

$$f\left(u_r, a, g\right) > f\left(u^*, a_l, g\right), \tag{3.9}$$

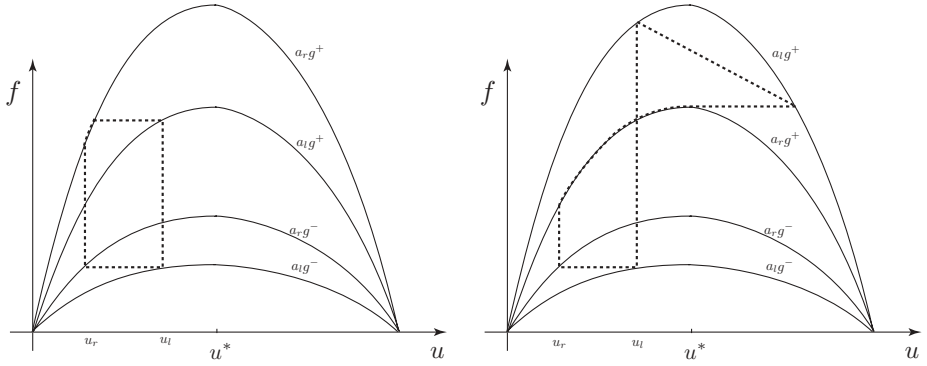

FIG. 2. *The possible results of an interaction if* $u_{l,r} \leq u^*$. *Left:* (3.6) *holds. Right:* (3.7) *holds.*

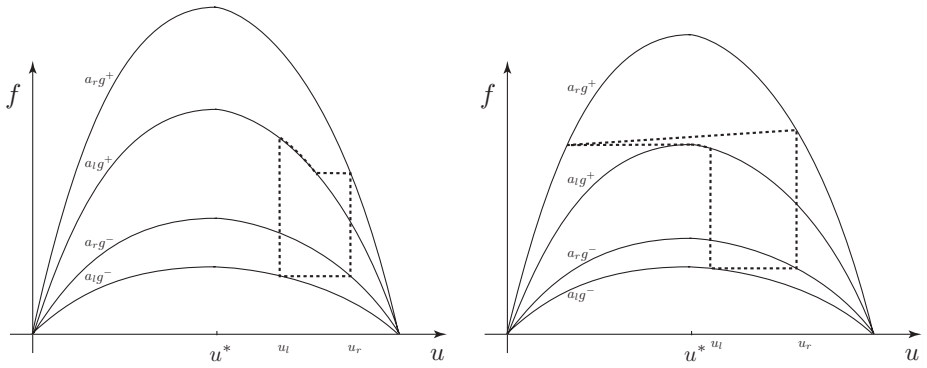

FIG. 3. *The possible results of an interaction if* $u_{l,r} \geq u^*$. *Left:* (3.8) *holds. Right:* (3.9) *holds.*

there are two outgoing u-waves. See Figure 3. Note that in both cases a and a' are clockwise. In this case we have

$$G\left(a_l, a, g^-, g\right) = \frac{\operatorname{sign}\left(u_l - u_r\right)}{f\left(u^*, a_l, g\right)} \left[f\left(u_l, a_l, g\right) - f\left(u_r, a, g\right)\right] \chi_{\{f(u_r,a,g) \leq f(u^*,a_l,g)\}}$$
$$+ \left\{ \frac{1}{f\left(u^*, a, g\right)} \left[f\left(u_r, a, g\right) - f\left(u^*, a_l, g\right)\right] \right.$$
$$\left. + \frac{1}{f\left(u^*, a_l, g\right)} \left[f\left(u^*, a_l, g\right) - f\left(u_l, a_l, g\right)\right] \right\} \chi_{\{f(u_r,a,g) > f(u^*,a_l,g)\}}.$$

Also in this case G is sufficiently regular for (3.5) to hold and thereby (3.4). This finishes the study of the interaction of a- and g-fronts

Now we consider the interaction of a single u-wave and a single g-wave. The situation is depicted in Figure 4. For this interaction we claim that

(3.10)
$$\left|\Psi\left(u_r, a, g^+\right) - \Psi\left(u_l, a, g^+\right)\right| - \left|\Psi\left(u_r, a, g^-\right) - \Psi\left(u_l, a, g^-\right)\right|$$
$$\leq C\left|g^+ - g^-\right| \left|\Psi\left(u_r, a, g^-\right) - \Psi\left(u_l, a, g^-\right)\right|.$$

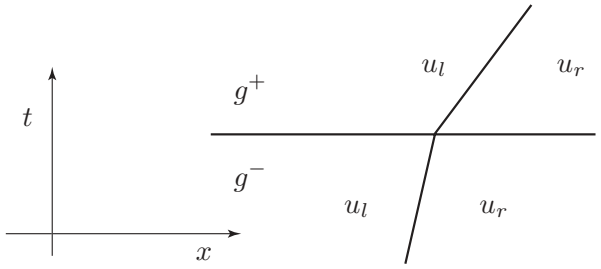

FIG. 4. *The states used in an interaction between a u-wave and a g-wave.*

Since $\Psi(u^*,\cdot,\cdot)=\Psi_u(u^*,\cdot,\cdot)=0$, we can write

$$\begin{aligned}\Psi\left(u_r,a,g^+\right)-\Psi\left(u_l,a,g^+\right)-\Psi\left(u_r,a,g^-\right)+\Psi\left(u_r,a,g^-\right)&\\ =\int_{u_l}^{u_r}\left(\Psi_u\left(\sigma,a,g^+\right)-\Psi_u\left(\sigma,a,g^-\right)\right)\,d\sigma&\\ =\int_{u_l}^{u_r}\int_{u^*}^{\sigma}\left(\Psi_{uu}\left(\eta,a,g^+\right)-\Psi_{uu}\left(\eta,a,g^-\right)\right)\,d\eta\,d\sigma&\\ =\int_{u_l}^{u_r}\int_{u^*}^{\sigma}\int_{g^-}^{g^+}\Psi_{uug}\left(\eta,a,g\right)\,dg\,d\eta\,d\sigma.&\end{aligned}\tag{3.11}$$

We also find that

$$\begin{aligned}\Psi\left(u_r,a,g^-\right)-\Psi\left(u_l,a,g^-\right)&=\int_{u_l}^{u_r}\Psi_u\left(\sigma,a,g^-\right)\,d\sigma\\ &=\int_{u_l}^{u_r}\left(\Psi_u\left(\sigma,a,g^-\right)-\Psi_u\left(u^*,a,g^-\right)\right)\,d\sigma\\ &=\int_{u_l}^{u_r}\int_{u^*}^{\sigma}\Psi_{uu}\left(\eta,a,g^-\right)\,d\eta\,d\sigma.\end{aligned}\tag{3.12}$$

We also have that

$$\Psi_{uu}(u,a,g)=\operatorname{sign}(u-u^*)\,\frac{-f_{uu}(u,a,g)}{f(u^*,a,g)}\geq\frac{c_{uu}}{C_{u^*}},$$
$$|\Psi_{uug}(u,a,g)|=\left|\frac{f_{uu}(u,a,g)f_g(u^*,a,g)-f_{uug}(u,a,g)f(u^*,a,g)}{f^2(u^*,a,g)}\right|\leq C_1$$

for some constant C_1. To fix ideas, assume that $u_l\leq u_r$, so that also

$$\Psi\left(u_l,a,g^\pm\right)\leq\Psi\left(u_r,a,g^\pm\right).$$

To show (3.10), we consider different cases.

Case 1. $u^*\leq u_l\leq u_r$. By (3.11) we have

$$\begin{aligned}\left|\Psi\left(u_r,a,g^+\right)-\Psi\left(u_l,a,g^+\right)\right|-\left|\Psi\left(u_r,a,g^-\right)-\Psi\left(u_l,a,g^-\right)\right|&\\ \leq C'\left|g^+-g^-\right|\int_{u_l}^{u_r}\int_{u^*}^{\sigma}d\eta\,d\sigma&\\ =C'\left|g^+-g^-\right|\left(\frac{\left|u_r^2-u_l^2\right|}{2}-u^*\left(u_r-u_l\right)\right)&\end{aligned}$$

for some constant C' depending on the partial derivatives of f. By (3.12) we also have that

$$\Psi\left(u_r, a, g^-\right) - \Psi\left(u_l, a, g^-\right) \geq \frac{c_{uu}}{C_{u^*}} \int_{u_l}^{u_r} \int_{u^*}^{\sigma} d\eta \, d\sigma,$$

so (3.10) follows with $C = C' C_{u^*}/c_{uu}$.

Case 2. $u_l \leq u_r \leq u^*$. In this case,

$$\begin{aligned} \left|\Psi\left(u_r, a, g^+\right) - \Psi\left(u_l, a, g^+\right)\right| - \left|\Psi\left(u_r, a, g^-\right) - \Psi\left(u_l, a, g^-\right)\right| & \\ \leq \hat{C}\left|g^+ - g^-\right| \int_{u_l}^{u_r} \int_{\sigma}^{u^*} d\eta \, d\sigma & \\ = \hat{C}\left|g^+ - g^-\right| \left[u^*\left(u_r - u_l\right) - \frac{\left|u_r^2 - u_l^2\right|}{2}\right] & \end{aligned}$$

for some constant $\hat{C}$, and also by (3.12)

$$\Psi\left(u_r, a, g^-\right) - \Psi\left(u_l, a, g^-\right) \geq \frac{c_{uu}}{C_{u^*}} \int_{u_l}^{u_r} \int_{\sigma}^{u^*} d\eta \, d\sigma.$$

Hence (3.10) follows as in the first case.

Case 3. $u_l \leq u^* \leq u_r$. Now we write

$$\begin{aligned} \left|\Psi\left(u_r, a, g^+\right) - \Psi\left(u_l, a, g^+\right)\right| - \left|\Psi\left(u_r, a, g^-\right) - \Psi\left(u_l, a, g^-\right)\right| & \\ \leq C_2\left|g^+ - g^-\right| \left[\int_{u_l}^{u^*} \int_{u^*}^{\sigma} d\eta \, d\sigma + \int_{u^*}^{u_r} \int_{\sigma}^{u^*} d\eta \, d\sigma\right] & \\ = C_2\left|g^+ - g^-\right| \left(\frac{u_r^2 - 2\left(u^*\right)^2 + u_l^2}{2} - u^*\left(u_r - 2u^* + u_l\right)\right). & \end{aligned}$$

Also, by (3.12) we can estimate

$$\Psi\left(u_r, a, g^-\right) - \Psi\left(u_l, a, g^-\right) \geq \frac{c_{uu}}{C_{u^*}} \left[\int_{u_l}^{u^*} \int_{u^*}^{\sigma} d\eta \, d\sigma + \int_{u^*}^{u_r} \int_{\sigma}^{u^*} d\eta \, d\sigma\right].$$

So again (3.10) follows.

If $u_l > u_r$, we can use the same arguments as in Cases 1 or 2 above to show (3.10). Since $T(t) \geq \left|a^\delta\right|_{BV}$, the lemma now follows. □

Let $T^n = T\,\big|_{I^n}$ and $g^n = g^\delta\,\big|_{I^n}$. Since T is nonincreasing in each interval I^n, from Lemma 3.1, we have that

$$T^{n+1} \leq T^n\left(1 + C\left|g^{n+1} - g^n\right|\right).$$

By the Grönwall inequality it follows that

$$\begin{aligned} T(t) &\leq T^1(0+) \exp\left(C \sum_n \left|g^n - g^{n-1}\right|\right) \\ &\leq \lim_{s \downarrow 0} T(s) \exp\left(C\left|g\right|_{BV}\right) \\ &\leq \left(\left|\Psi\left(u_0, a, g(0)\right)\right|_{BV} + 4\left|a\right|_{BV}\left|g(0)\right|\right) e^{C|g|_{BV}}, \end{aligned} \tag{3.13}$$

where the sum in the first line above is over those n such that $t_n < t$.

From this it immediately follows that the total variation of $\Psi(u^\delta, a^\delta, g^\delta(t))$ is bounded independently of δ and t. Furthermore

$$-1 \le \Psi\left(u^\delta(x,t), a^\delta(x), g^\delta(t)\right) \le 1.$$

By Helly's theorem, for each fixed $t \in [0,T]$,

$$\Psi\left(u^\delta(\cdot,t), a^\delta, g^\delta(t)\right) \to \psi \quad \text{almost everywhere as } \delta \downarrow 0,$$

and by the Lebesgue dominated convergence theorem also in $L^1(\mathbf{R})$. Furthermore, by a diagonal argument, we can achieve this convergence for a dense countable set $\{t^\gamma\} \subset [0,T]$. For t^γ in this set, define

$$u(\cdot,t^\gamma) = \Psi^{-1}\left(\psi, a, g\left(t^\gamma\right)\right).$$

Hence also $u^\delta(\cdot,t^\gamma) \to u(\cdot,t^\gamma)$. For any $t \in [0,T]$ we have that

$$\begin{aligned}\left\|u^{\delta_1}(\cdot,t) - u^{\delta_2}(\cdot,t)\right\|_{L^1(\mathbf{R})} &\le \left\|u^{\delta_1}(\cdot,t^\gamma) - u^{\delta_1}(\cdot,t)\right\|_{L^1(\mathbf{R})} \\ &\quad + \left\|u^{\delta_1}(\cdot,t^\gamma) - u^{\delta_2}(\cdot,t^\gamma)\right\|_{L^1(\mathbf{R})} + \left\|u^{\delta_2}(\cdot,t^\gamma) - u^{\delta_2}(\cdot,t)\right\|_{L^1(\mathbf{R})},\end{aligned}$$

where t^γ is such that $u^\delta(\cdot,t^\gamma) \to u(\cdot,t^\gamma)$. By Lemma 3.2, $t \mapsto u^\delta(\cdot,t)$ is L^1 Lipschitz continuous, so the first and third terms above can be made arbitrarily small by choosing δ_1 and δ_2 small, and the middle term can be made small by choosing t^γ close to t. Hence we have that u^δ converges to some function u in $L^1(\mathbf{R} \times [0,T])$. For the reader's convenience we show the following.

LEMMA 3.2. *There exists a positive constant C, independent of t, s, and δ, such that*

$$\left\|u^\delta(\cdot,t) - u^\delta(\cdot,s)\right\|_{L^1(\mathbf{R})} \le C\,|t-s|. \tag{3.14}$$

Proof. We start by noting that since

$$\begin{aligned}&\left|\Psi\left(u^\delta(x,t), a^\delta(x), g^\delta(t)\right) - \Psi\left(u^\delta(y,t), a^\delta(y), g^\delta(t)\right)\right| \\ &\qquad \ge \left|f\left(u^\delta(x,t), a^\delta(x), g^\delta(t)\right) - f\left(u^\delta(y,t), a^\delta(y), g^\delta(t)\right)\right|,\end{aligned}$$

it follows that the total variation of f is bounded by some constant C, and C is independent of t and δ. Next, assume that $0 \le s < t \le T$, and let α_h be a smooth approximation to the characteristic function of the interval $[s,t]$, so that

$$\alpha_h \to \chi_{[s,t]} \quad \text{and} \quad \alpha_h' \to \delta_s - \delta_t,$$

as $h \downarrow 0$, where δ_s denotes the Dirac delta function centered at s. Choose a test function $\varphi(x)$ such that $|\varphi| \le 1$, and set $\varphi_h(x,t) = \varphi(x)\alpha_h(t)$. Since u^δ is a weak solution, we have that

$$\iint_{\Pi_T} u^\delta \partial_t \varphi_h + f\left(u^\delta, a^\delta, g^\delta\right) \partial_x \varphi_h \, dtdx = 0,$$

and sending $h \downarrow 0$ we find that

$$\int_{\mathbf{R}} \varphi(x)\left(u^\delta(x,t) - u^\delta(x,s)\right) dx = \int_s^t \int_{\mathbf{R}} \varphi_x(x) f\left(u^\delta, a^\delta, g^\delta\right) dtdx.$$

Now

$$\begin{aligned}\left\|u^\delta(\cdot,t)-u^\delta(\cdot,s)\right\|_{L^1(\mathbf{R})} &= \sup_{|\varphi|\le 1}\int \varphi(x)\left(u^\delta(x,t)-u^\delta(x,s)\right)\,dx\\ &= \sup_{|\varphi|\le 1}\int_s^t\int_{\mathbf{R}} \varphi_x(x) f\left(u^\delta,a^\delta,g^\delta\right)\,dxd\sigma\\ &\le \int_s^t \left|f\left(u^\delta(\cdot,\sigma),a^\delta,g^\delta(\sigma)\right|_{BV}\,d\sigma\\ &\le (t-s)C. \qquad \square\end{aligned}$$

Next, we shall show that the limit u is an entropy solution. First we study how u^δ differs from an entropy solution in each interval $\langle x_m, x_{m+1}\rangle$. Assume that y_k are the discontinuity points of a^δ inside this interval, such that

$$x_m = y_0 < y_1 < \cdots < y_K = x_{m+1},$$

and we have that $a = a_k$ for $x \in \langle y_k, y_{k+1}\rangle$. Since u^δ is an entropy solution inside each interval $\langle y_k, y_{k+1}\rangle$,

(3.15)
$$\int_{y_k}^{y_{k+1}}\int_0^T \left|u^\delta - c\right|\varphi_t + F^\delta(u^\delta,x,t,c)\,dtdx - \int_0^T F^\delta(u^\delta,x,t,c)\Big|_{x=y_k^+}^{x=y_{k+1}^-}\,dt \ge 0,$$

where

$$F^\delta(u,x,t,c) = \operatorname{sign}(u-c)\left(f^\delta(u,a^\delta(x),g^\delta(t)) - f^\delta(c,a^\delta(x),g^\delta(t))\right).$$

If we set $y_k^{l,r} = y_k^{\mp}$, and observe that since u^δ is a weak solution,

$$f\left(u^\delta\left(t,y_k^l\right),a_k,g^\delta\right) = f\left(u^\delta\left(t,y_k^r\right),a_{k+1},g^\delta\right) =: f_k$$

for almost all t. Summing (3.15) for $k = 0,\dots,K-1$, we obtain

(3.16)
$$\int_{x_m}^{x_{m+1}}\int_0^T \left|u^\delta - c\right|\varphi_x + F^\delta\left(u^\delta,x,t,c\right)\varphi_x\,dtdx - \int_0^T \varphi F^\delta(u^\delta,x,t,c)\Big|_{x=x_m^+}^{x=x_{m+1}^-}\,dt$$

(3.17)
$$-\int_0^T\sum_{k=1}^{K-1}\varphi(x_k,t)\left[\operatorname{sign}(u_k^r-c)\left(f_k-f_k^r(c)\right)-\operatorname{sign}\left(u_k^l-c\right)\left(f_k-f_k^l(c)\right)\right]\,dt \ge 0,$$

where we have used the notation

$$u_k^{l,r} = u^\delta(y_k^{\mp},t), \quad f_k^{l,r}(c) = f^\delta(c,a^\delta(y_k^{\mp}),g^\delta).$$

Since at each discontinuity y_k, u^δ is the solution of a Riemann problem, either *both* u_k^l and u_k^r are less than or equal to u^* or both are greater than or equal to u^*. Using this we can label those discontinuities where both u-values are less than or equal to

u^* as L, and the remaining ones as G. Hence we can write the integrand in (3.17) as (for brevity we use a notation where $\varphi(x_k,t)$ is invisible; it will reappear later)

(3.18)
$$-\sum_L \operatorname{sign}\left(u_k^l-c\right)\left(f_k^l(c)-f_k^r(c)\right)+\left[\operatorname{sign}\left(u_k^r-c\right)-\operatorname{sign}\left(u_k^l-c\right)\right]\left(f_k-f_k^r(c)\right)$$

(3.19)
$$-\sum_G \operatorname{sign}\left(u_k^r-c\right)\left(f_k^l(c)-f_k^r(c)\right)+\left[\operatorname{sign}\left(u_k^l-c\right)-\operatorname{sign}\left(u_k^r-c\right)\right]\left(f_k^l(c)-f_k\right).$$

Since $f_u^\delta(u,\cdot,\cdot)>0$ for $u<u^*$, if $u_k^l\le c\le u_k^r$, the second term in (3.18) equals

$$2\left(f_k^r(u_k^r)-f_k^r(c)\right)\ge 0,$$

and if $u_r\le c\le u_l$, the second term equals

$$-2\left(f_k^r(u_k^r)-f_k^r(c)\right)\ge 0.$$

Similarly we find that the second term in (3.19) is always nonnegative. Hence

$$\begin{aligned}(3.17)&\le -\int_0^T\sum_{k=1}^{K-1}\operatorname{sign}\left(u_k^{l,r}-c\right)\left(f^\delta(c,a_{k+1},g^\delta)-f^\delta(c,a_k,g^\delta)\right)\,dt\\&=-\int_0^T\sum_{k=1}^{K-1}\operatorname{sign}\left(u_k^{l,r}-c\right)\frac{f^\delta(c,a_{k+1},g^\delta)-f^\delta(c,a_k,g^\delta)}{\Delta y_k}\,dt\Delta y_k,\end{aligned}$$

where $\Delta y_k=y_{k+1}-y_k$, and we use u_k^l for discontinuities in L, and u_k^r for discontinuities in G. Since a is continuously differentiable in $\langle x_m,x_{m+1}\rangle$ and $a^\delta\to a$, $g^\delta\to g$ and $u^\delta\to u$ as $\delta\downarrow 0$, we find that

$$\lim_{\delta\downarrow 0}(3.17)\ \le -\int_0^T\int_{x_m}^{x_{m+1}}\operatorname{sign}(u-c)\,f(c,a,g)_x\varphi\,dxdt. \tag{3.20}$$

For a rigorous proof of this inequality, see [11, Lemma 4.4]. By the same arguments, we find that for each discontinuity x_m

$$\begin{aligned}&F^\delta\left(u^\delta\left(x_m^+,t\right),x_m^+,t,c\right)-F^\delta\left(u^\delta\left(x_m^-,t\right),x_m^-,t,c\right)\\&\qquad=\operatorname{sign}\left(u_m^r-c\right)\left(f_m-f_m^r(c)\right)-\operatorname{sign}\left(u_m^l-c\right)\left(f_m-f_m^l(c)\right)\\&\qquad\ge\left|f_m^l(c)-f_m^r(c)\right|.\end{aligned}$$

Finally, adding (3.16)–(3.17) for m and using the above, we find that

$$\begin{aligned}&\iint_{\Pi_T}|u-c|\,\varphi_t+F(u,x,t,c)\varphi_x\,dtdx-\sum_m\int_{x_m}^{x_{m+1}}\int_0^T\operatorname{sign}(u-c)\,f_a(u,a,g)a'(x)\varphi\,dtdx\\&\qquad+\sum_m\int_0^T\left|f(c,a(x_m^+,g(t))-f(c,a(x_m^-),g(t))\right|\varphi(x_m,t)\,dt\\&\ge\lim_{\delta\downarrow 0}\sum_m\Big[(3.16)+(3.17)\Big]\\&\ge 0.\end{aligned}$$

Hence the limit u is an entropy solution of (1.1), since by the Lemma 3.2 also $u(\cdot,t) \to u_0$ as $t \downarrow 0$. Summing up, we have shown the following.

THEOREM 3.3. *Assume that the assumptions* (A.1), (A.2), (A.3), (A.4), (A.5), *and* (A.6) *hold. Then the sequence of front tracking solutions defined in section* 2 *converges in* $L^1(\Pi_T)$ *to an entropy weak solution of* (1.1).

Now it is straightforward to use methods from [11] to show that this problem has a unique solution. This is contained in the following theorem.

THEOREM 3.4. *Assume that the assumptions* (A.1), (A.2), (A.3), (A.4), (A.5), *and* (A.6) *hold. Let* $u = u(x,t)$ *and* $v = v(x,t)$ *be two entropy weak solutions of*

$$u_t + f(u,a,g)_x = 0 \quad \textit{in the strip } \Pi_T$$

for some $T > 0$, *satisfying the initial conditions*

$$u(x,0) = u_0(x), \qquad v(x,0) = v_0(x), \qquad x \in \mathbf{R}.$$

Then we have that

$$\|u(t,\cdot) - v(t,\cdot)\|_{L^1(\mathbf{R})} \le \|u(s,\cdot) - v(s,\cdot)\|_{L^1(\mathbf{R})} \tag{3.21}$$

for each $0 \le s \le t < T$.

4. An example. To demonstrate that the front tracking construction also has some potential as a practical numerical method, in this section we show an example of how the front tracking construction works on a concrete example. We use the simple flux function

$$f(u,a,g) = 4agu(1-u), \tag{4.1}$$

and

$$\begin{aligned} a(x) &= \left(1 + 8\chi_{\{x<0.25\}}\,|x|\right) + 2\cos^2(\pi x), \\ g(t) &= 0.6 + 0.55\cos\left(2\pi t\left(\chi_{\{0.15<t<0.65\}} + 1\right)\right), \\ u_0(x) &= 0.5(1 - 0.8\sin(\pi x)). \end{aligned} \tag{4.2}$$

In the example we present, we have used periodic initial data in the interval $x \in [0,1]$, $\delta = 1/20$, and $\Delta t = 0.025$. In Figure 5 we show the initial data u_0^δ and the approximate coefficients a^δ and g^δ. In Figure 6 we show the front tracking solution at $t = 0.5$ and the fronts for $0 \le t \le 0.5$. The a-fronts are depicted as broken horizontal lines, the g-fronts as vertical broken lines, and the u-fronts as solid lines.

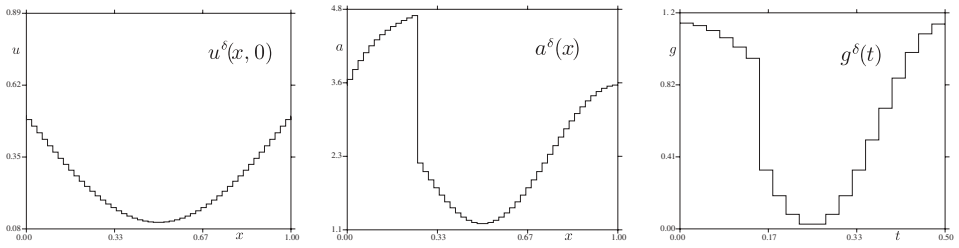

FIG. 5. *The initial function* u_0^δ *(left), the coefficients* a^δ *(middle) and* g^δ *(right).*

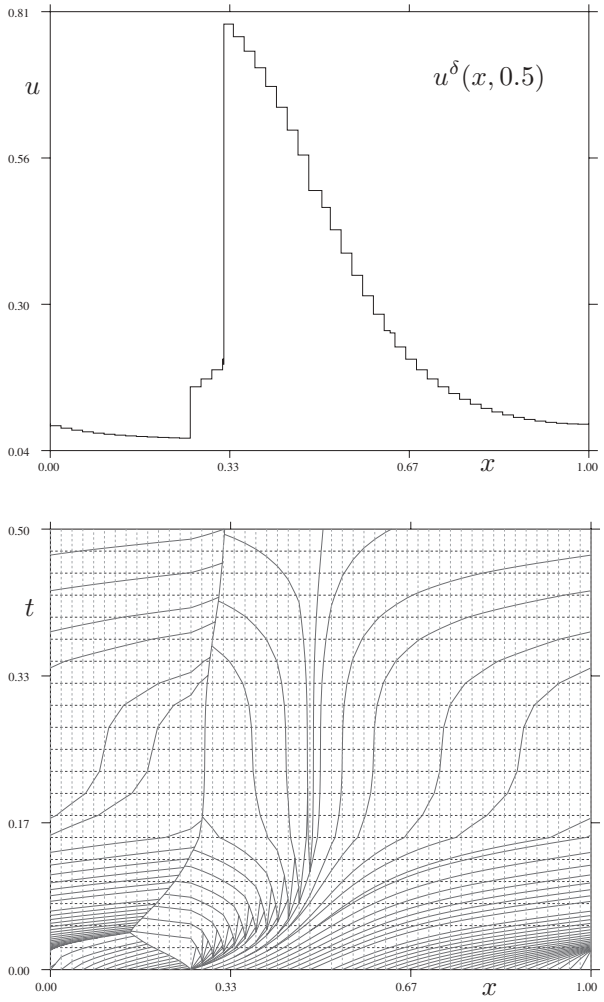

FIG. 6. *The front tracking solution* $u^\delta(x, 0.5)$ *(top) and the fronts (bottom).*

BLOWUP SOLUTIONS FOR A LIOUVILLE EQUATION WITH SINGULAR DATA*

PIERPAOLO ESPOSITO†

Abstract. We study the existence of multiple blowup solutions for a semilinear elliptic equation with homogeneous Dirichlet boundary condition, exponential nonlinearity, and a singular source term given by Dirac masses. In particular, we extend the result of Baraket and Pacard [*Calc. Var. Partial Differential Equations*, 6 (1998), pp. 1–38] by allowing the presence, in the equation, of a weight function possibly vanishing in some points.

Key words. Liouville equation, singular data, exponential nonlinearity, blowup solutions

DOI. 10.1137/S0036141003430548

1. Main results and examples.

Let $\Omega \subset \mathbb{R}^2$ be a smooth bounded open set. We are concerned with the existence of solutions in the distributional sense for the problem

$$\begin{cases} -\triangle u = \rho^2 e^u - 4\pi \sum_{i=1}^N \alpha_i \delta_{p_i} & \text{in } \Omega, \\ u = 0 & \text{on } \partial\Omega \end{cases} \tag{1}$$

with the property that $\rho^2 e^u$ "concentrates" when the parameter $\rho \to 0$. Here $\{\alpha_1, \ldots, \alpha_N\}$ are positive numbers, δ_p defines the Dirac mass at p, and $\Gamma := \{p_1, \ldots, p_N\} \subset \Omega$ is the set of singular sources in (1).

Problem (1) with $\Gamma = \emptyset$ has been largely studied in connection with many physical models such as thermionic emission [21], the theory of the isothermal gas sphere [14], gas combustion [25], and in the context of statistical mechanics in [11], [12], and [23]. The asymptotic analysis for blowup solutions to problem (1) as $\rho \to 0$ is contained in [36] (see also [27]) and alternatively it can be obtained as a by-product of the general blowup analysis of [8]: it leads in the limit to a quantization property of the energy $\rho^2 \int_\Omega e^u$ in terms of the number of blowup points and to a characterization of the location of the blowup points. For the converse question, namely, the construction of solutions to (1) which do blow up at the "admissible" points as $\rho \to 0$, the first result is due to Weston [38] who constructed a sequence of solutions on simply connected domains "concentrating" on a single blowup point according to [36] (see also [26] for more general nonlinearities). The general case of the existence of multiple blowup solutions has been treated only in the beautiful paper [4]. Subsequently Chen and Lin in [17] have given an alternative proof in the special case of an annulus. Thus, perturbative problems with exponential nonlinearities in dimension two seem to be very difficult to handle. So far only a few results have been derived that cover some special cases (beside [4] and its extensions [2], [3], and [5], see also [13] and [29]) in contrast to the vast literature available in higher dimensions; see, for example, [1], [15], [28], and [32].

†Dipartimento di Matematica, Università di Roma "Tor Vergata," Via della Ricerca Scientifica, 00133 Roma, Italy (pesposit@axp.mat.uniroma2.it).

Motivated by some singular elliptic equations arising in the study of Chern–Simons vortex theory (we refer the reader to [39] and the references therein), we are interested in analyzing (1) with $\Gamma \neq \emptyset$. We mention that some of the progress made about condensates in Chern–Simons models is contained in [10], [30], [33], [34], [35], and [37] to quote a few.

Let $G(z, z')$ denote the Green's function of $-\triangle$ on Ω with Dirichlet boundary condition, namely,

$$\begin{cases} -\triangle_z G(z, z') = \delta_{z'} & \text{in } \Omega, \\ G(z, z') = 0 & \text{on } \partial\Omega, \end{cases}$$

and let $H(z, z') = \frac{1}{2\pi} \ln|z - z'| + G(z, z')$ be the regular part of $G(z, z')$. Problem (1) is equivalent to solving for $v = u + 4\pi \sum_{i=1}^{N} \alpha_i G(z, p_i)$, the regular part of u, the equation

$$(2) \qquad \begin{cases} -\triangle v = \rho^2 |z - p_1|^{2\alpha_1} \cdots |z - p_N|^{2\alpha_N} e^{-4\pi \sum_{i=1}^{N} \alpha_i H(z, p_i)} e^v & \text{in } \Omega, \\ v = 0 & \text{on } \partial\Omega. \end{cases}$$

Thus, we may consider the following general model problem:

$$(Q)_\rho \qquad \begin{cases} -\triangle v = \rho^2 |z - p_1|^{2\alpha_1} \cdots |z - p_N|^{2\alpha_N} f(z) e^v & \text{in } \Omega, \\ v = 0 & \text{on } \partial\Omega, \end{cases}$$

where $\Gamma = \{p_1, \ldots, p_N\} \subset \Omega$ and $\{\alpha_1, \ldots, \alpha_N\}$ are positive numbers, $f : \Omega \to \mathbb{R}$ is a smooth function such that $f(p_i) > 0$ for any $i = 1, \ldots, N$. An extension to the singular case of the blowup analysis in [8] is due to [7] (see also [6]). It permits us to perform an asymptotic analysis in the spirit of [36] (see [20] for a proof). To this purpose, set $\Gamma = \{p_1, \ldots, p_N\}$ and $\Omega' = \Omega \cap \{f > 0\}$, and for given $m \in \mathbb{N}$ and $s \in \{1, \ldots, N\}$ define

$$\tilde{\mathcal{F}}(z_1, \ldots, z_m) = \sum_{i=1}^{m} H(z_i, z_i) + \sum_{i \neq j} G(z_i, z_j) + \frac{1}{4\pi} \sum_{i=1}^{m} \ln\left(|z_i - p_1|^{2\alpha_1} \cdots |z_i - p_N|^{2\alpha_N} f(z_i)\right)$$

which is well defined in $(\Omega' \setminus \Gamma)^m$ for $z_i \neq z_j$ whenever $i \neq j$, and let

$$\mathcal{G}(z_1, \ldots, z_m, \omega_1, \ldots, \omega_s) = \frac{1}{4\pi} \left(\sum_{i=1}^{m} \sum_{j=1}^{s} 8\pi(1 + \alpha_j) G(z_i, \omega_j) \right)$$

be well defined for $z_i \neq \omega_j$, with $z_i \in \Omega$, $\omega_j \in \mathbb{C}$, $i = 1, \ldots, m$, $j = 1, \ldots, s$.

THEOREM 1.1. *Let $\Omega \subset \mathbb{R}^2$ be a smooth bounded open set and let f be a smooth positive function. Let v_ρ be a sequence of solutions of $(Q)_\rho$ such that $\sup_\rho T_\rho < +\infty$, $T_\rho = \rho^2 \int_\Omega |z - p_1|^{2\alpha_1} \cdots |z - p_N|^{2\alpha_N} f(z) e^{v_\rho}$. If $T_\rho \to 0$ as $\rho \to 0$, then $v_\rho \to 0$ in $C^{2,\beta}(\Omega)$ and, for ρ small, v_ρ coincides with the unique minimal solution of $(Q)_\rho$. If $T_\rho \to L \neq 0$, then (up to a subsequence) there exists a nonempty finite set $S = \{q_1, \ldots, q_K\} \subset \Omega$ (blowup set) such that $\rho^2 |z - p_1|^{2\alpha_1} \cdots |z - p_N|^{2\alpha_N} f(z) e^{v_\rho} \rightharpoonup \sum_{i=1}^{K} b_i \delta_{q_i}$ in the sense of measures and $v_\rho \to \sum_{i=1}^{K} b_i G(z, q_i)$ in $C^{2,\beta}_{loc}(\Omega \setminus S)$ for some $\beta \in (0, 1)$, with $b_i = 8\pi$ if $q_i \notin \Gamma$, or $b_i = 8\pi(1 + \alpha_j)$ if $q_i = p_j$ for some $j = 1, \ldots, N$.*

Moreover, if $S\cap\Gamma=\emptyset$, *then* $(q_1,\dots,q_K)$ *is a critical point for the function* $\tilde{\mathcal{F}}$; *if* $S\cap\Gamma=\{p_{j_1},\dots,p_{j_s}\}$ *and* $S\setminus\Gamma=\{q_{i_1},\dots,q_{i_m}\}$ *with* $m+s=K$, *then* $(q_{i_1},\dots,q_{i_m})$ *is a critical point for the function* $\tilde{\mathcal{F}}+\mathcal{G}(\cdot,p_{j_1},\dots,p_{j_s})$.

For the existence of a minimal solution of $(Q)_\rho$, we refer the reader to [19]. As a vice versa of Theorem 1.1, we establish the following result.

THEOREM 1.2. *Let* $\Omega\subset\mathbb{R}^2$ *be a smooth bounded open set,* f *be a smooth function, and* $\{\alpha_1,\dots,\alpha_N\}\subset(0,+\infty)\setminus\mathbb{N}$ *be real numbers. We have*

(a) *let* $S=\{p_{j_1},\dots,p_{j_s}\}\subset\Gamma$, *then there exist* $\rho_0>0$ *small and a family* $\{v_\rho\}_{0<\rho<\rho_0}$ *of solutions for equation* $(Q)_\rho$ *such that* $\rho^2|z-p_1|^{2\alpha_1}\cdots|z-p_N|^{2\alpha_N}f(z)e^{v_\rho}\rightharpoonup\sum_{i=1}^s 8\pi(1+\alpha_{j_i})\delta_{p_{j_i}}$ *in the sense of measures and* $v_\rho\to\sum_{i=1}^s 8\pi(1+\alpha_{j_i})G(z,p_{j_i})$ *in* $C^{2,\beta}_{loc}(\Omega\setminus S)$ *for some* $\beta\in(0,1)$;

(b) *let* $S=\{q_1,\dots,q_m\}\subset\Omega'\setminus\Gamma$ *and* $(q_1,\dots,q_m)$ *be a nondegenerate critical point of* $\tilde{\mathcal{F}}$ *such that* $\Delta\ln f(q_1)=\cdots=\Delta\ln f(q_m)=0$, *then there exist* $\rho_0>0$ *small and a family* $\{v_\rho\}_{0<\rho<\rho_0}$ *of solutions for* $(Q)_\rho$ *such that* $\rho^2|z-p_1|^{2\alpha_1}\cdots|z-p_N|^{2\alpha_N}f(z)e^{v_\rho}\rightharpoonup\sum_{i=1}^m 8\pi\delta_{q_i}$ *in the sense of measures and* $v_\rho\to\sum_{i=1}^m 8\pi G(z,q_i)$ *in* $C^{2,\beta}_{loc}(\Omega\setminus S)$ *for some* $\beta\in(0,1)$;

(c) *let* S *be such that* $S\cap\Gamma=\{p_{j_1},\dots,p_{j_s}\}$, $S\setminus\Gamma=\{q_1,\dots,q_m\}$, *and* $(q_1,\dots,q_m)$ *is a critical point of* $\tilde{\mathcal{F}}+\mathcal{G}(\cdot,p_{j_1},\dots,p_{j_s})$ *such that* $\Delta\ln f(q_1)=\cdots=\Delta\ln f(q_m)=0$, *then there exist* $\rho_0>0$ *small and a family* $\{v_\rho\}_{0<\rho<\rho_0}$ *of solutions for* $(Q)_\rho$ *such that* $\rho^2|z-p_1|^{2\alpha_1}\cdots|z-p_N|^{2\alpha_N}f(z)e^{v_\rho}\rightharpoonup\sum_{k=1}^s 8\pi(1+\alpha_{j_k})\delta_{p_{j_k}}+\sum_{j=1}^m 8\pi\delta_{q_j}$ *in the sense of measures and* $v_\rho\to\sum_{k=1}^s 8\pi(1+\alpha_{j_k})G(z,p_{j_k})+\sum_{j=1}^m 8\pi G(z,q_j)$ *in* $C^{2,\beta}_{loc}(\Omega\setminus S)$ *for some* $\beta\in(0,1)$.

Let us point out that the assumption $\Delta\ln f(q_i)=0$ for any $q_i\in S\setminus\Gamma$ is always fulfilled by the original problem (2), so in some sense it seems a "natural" assumption from a physical point of view. In case $\Gamma=\emptyset$, part (b) in Theorem 1.2 gives a direct extension of the result in [4], which has largely motivated our approach. More precisely, it states the following.

COROLLARY 1.3. *Let* $\Omega\subset\mathbb{R}^2$ *be a smooth bounded open set,* f *be a smooth function, and* $S=\{q_1,\dots,q_m\}\subset\Omega'$ *be a nonempty set. Assume that* $(q_1,\dots,q_m)$ *is a nondegenerate critical point of* $\tilde{\mathcal{F}}(z_1,\dots,z_m)=\sum_{i=1}^m H(z_i,z_i)+\sum_{i\neq j}G(z_i,z_j)+\frac{1}{4\pi}\sum_{i=1}^m\ln f(z_i)$ *in* $(\Omega')^m$ *such that* $\Delta\ln f(q_1)=\cdots=\Delta\ln f(q_m)=0$. *There exist* $\rho_0>0$ *small and a family* $\{v_\rho\}_{0<\rho<\rho_0}$ *of solutions for the equation*

$$\begin{cases}-\triangle v=\rho^2 f(z)e^v & \text{in } \Omega,\\ v=0 & \text{on } \partial\Omega,\end{cases}$$

such that $\rho^2 f(z)e^{v_\rho}\rightharpoonup\sum_{i=1}^m 8\pi\delta_{q_i}$ *in the sense of measures and* $v_\rho\to\sum_{i=1}^m 8\pi G(z,q_i)$ *in* $C^{2,\beta}_{loc}(\Omega\setminus S)$ *for some* $\beta\in(0,1)$.

Thus, from Corollary 1.3 the result in [4] is recovered by taking $f=\text{const}>0$.

To avoid technicalities, we derive the proof of Theorem 1.2 only in the following significant cases: (a) holds with $S=\{p\}$ and $p\in\Gamma$, (b) holds with $S=\{q\}$ and $q\notin\Gamma$, and (c) holds with $S=\{p,q\}$, $p\in\Gamma$, and $q\notin\Gamma$. Our approach generalizes to any number of "peaks," the technical details are worked out in [20]. So we restrict our attention to the problem

$$(P)_\rho\qquad\begin{cases}-\triangle v=\rho^2|z-p|^{2\alpha}f(z)e^v & \text{in } \Omega,\\ v=0 & \text{on } \partial\Omega,\end{cases}$$

where $\alpha\in(0,+\infty)\setminus\mathbb{N}$ is a real number and $f:\Omega\to\mathbb{R}$ is a smooth function not necessarily positive. We will prove the following result.

THEOREM 1.4. *Under the above assumptions we have*

(a) *if $p \in \Omega$ with $f(p) > 0$, there exist $\rho_0 > 0$ small and a family $\{v_\rho\}_{0<\rho<\rho_0}$ of solutions for $(P)_\rho$ such that $\rho^2|z-p|^{2\alpha} f(z) e^{v_\rho} \rightharpoonup 8\pi(1+\alpha)\delta_p$ in the sense of measures and $v_\rho \to 8\pi(1+\alpha)G(z,p)$ in $C^{2,\beta}_{loc}(\Omega \setminus \{p\})$ for some $\beta \in (0,1)$;*

(b) *if $q \in \Omega' \setminus \{p\}$ is a nondegenerate critical point of $\mathcal{F}(z) = H(z,z) + \frac{1}{4\pi}\ln[|z-p|^{2\alpha} f(z)]$ in $\Omega' \setminus \{p\}$ such that $\Delta \ln f(q) = 0$, then there exist $\rho_0 > 0$ small and a family $\{v_\rho\}_{0<\rho<\rho_0}$ of solutions for $(P)_\rho$ such that $\rho^2|z-p|^{2\alpha} f(z) e^{v_\rho} \rightharpoonup 8\pi\delta_q$ in the sense of measures and $v_\rho \to 8\pi G(z,q)$ in $C^{2,\beta}_{loc}(\Omega \setminus \{q\})$ for some $\beta \in (0,1)$;*

(c) *if $p \in \Omega$ with $f(p) > 0$ and $q \neq p$ is a nondegenerate critical point of $\mathcal{F}(z) = \tilde{\mathcal{F}}(z) + \mathcal{G}(z,p) = H(z,z) + \frac{1}{4\pi}\ln(|z-p|^{2\alpha} f(z)) + 2(1+\alpha)G(z,p)$ in $\Omega' \setminus \{p\}$ such that $\Delta \ln f(q) = 0$, then there exist $\rho_0 > 0$ small and a family $\{v_\rho\}_{0<\rho<\rho_0}$ of solutions for $(P)_\rho$ such that $\rho^2|z-p|^{2\alpha} f(z) e^{v_\rho} \rightharpoonup 8\pi(1+\alpha)\delta_p + 8\pi\delta_q$ in the sense of measures and $v_\rho \to 8\pi(1+\alpha)G(z,p) + 8\pi G(z,q)$ in $C^{2,\beta}_{loc}(\Omega \setminus \{p,q\})$ for some $\beta \in (0,1)$.*

We now discuss some applications of the results above. As it is well known, for $\alpha \geq 0$, the problem

$$\begin{cases} -\triangle v = \lambda \frac{|z-p|^{2\alpha} f(z) e^v}{\int_\Omega |z-p|^{2\alpha} f(z) e^v} & \text{in } B(0,1), \\ v = 0 & \text{on } \partial B(0,1) \end{cases} \tag{3}$$

with $p = 0$ and $f(z) = 1$ possesses a radial solution for $0 < \lambda < 8\pi(\alpha+1)$ and, as a consequence of a Pohozaev identity, has no solution for $\lambda \geq 8\pi(\alpha+1)$. By means of Theorem 1.4, we can show that such a threshold for existence of (3) is no longer valid if we perturb (3) either by replacing $f = 1$ with a suitable nonconstant function or by moving p close to $\partial B(0,1)$. In fact we will be able to produce solutions v_ρ for (3) with $\lambda_\rho = \rho^2 \int_\Omega |z-p|^{2\alpha} f(z) e^{v_\rho} \to 8\pi(\alpha+1) + 8\pi > 8\pi(\alpha+1)$ concentrating on two points. According to Theorem 1.4, for this purpose we need to exhibit a nondegenerate critical point q for $\mathcal{F}(z) = H(z,z) - \frac{2+\alpha}{2\pi}\ln|z-p| + 2(1+\alpha)H(z,p) + \frac{1}{4\pi}\ln f(z)$ such that $\Delta \ln f(q) = 0$. Let us recall that $H(z,p) = \frac{1}{4\pi}\ln\left(|p|^2|z|^2 - 2\langle p,z\rangle + 1\right)$ and $H(z,z) = \frac{1}{2\pi}\ln\left(1-|z|^2\right)$, where $\langle\cdot,\cdot\rangle$ denotes the inner product in $\mathbb{R}^2$. Hence we obtain for $\mathcal{F}(z)$ the expression

$$\mathcal{F}(z) = \frac{1}{2\pi}\ln\left(1-|z|^2\right) - \frac{2+\alpha}{2\pi}\ln|z-p| + \frac{1+\alpha}{2\pi}\ln\left(|p|^2|z|^2 - 2\langle p,z\rangle + 1\right) + \frac{1}{4\pi}\ln f(z).$$

Example 1.5. We study now the case $p = 0$. For fixed $q \in B(0,1) \setminus \{0\}$, we can define a function $f(z)$ such that in a small neighborhood of q it takes the form

$$f(z) = \exp\left((z_1-q_1)^2 - c_q(z_2-q_2)^2 - 2\ln\left(1-|z|^2\right) + 2(2+\alpha)\ln|z|\right),$$

where $c_q = 1 + \frac{4}{(1-|q|^2)^2} > 0$. For such a function $f(z)$, the function $\mathcal{F}(z)$ near q takes the form $\mathcal{F}(z) = \frac{1}{4\pi}\left[(z_1-q_1)^2 - c_q(z_2-q_2)^2\right]$ and hence q is a nondegenerate critical point of $\mathcal{F}(z)$ such that $\Delta \ln f(q) = 2 - 2c_q + \frac{8}{(1-|q|^2)^2} = 0$. Moreover, if we choose q such that $|q| = r_\alpha$, with $r_\alpha \in (0,1)$ satisfying $r_\alpha^{2+\alpha} + r_\alpha^2 - 1 = 0$, then such an f may be constructed as a small perturbation of the constant function 1. In fact, for ϵ small we can just take f_ϵ of the form

$$f_\epsilon(z) = \left(1 - \chi\left(\frac{z-q}{\epsilon}\right)\right) + \chi\left(\frac{z-q}{\epsilon}\right) \times \exp\left(\epsilon(z_1-q_1)^2 - c_\epsilon(z_2-q_2)^2 - 2\ln\left(1-|z|^2\right) + 2(2+\alpha)\ln|z|\right),$$

where $c_\epsilon = \epsilon + \frac{4}{(1-|q|^2)^2}$ and $0 \le \chi \le 1$ is a smooth cut-off function such that $\chi = 1$ in $B(0,1)$ and $\chi = 0$ in $\mathbb{R}^2 \setminus B(0,2)$.

Example 1.6. We study now the case $f(z) = 1$. The function $\mathcal{F}(z)$ becomes

$$\mathcal{F}(z) = \frac{1}{2\pi} \ln\big(1 - |z|^2\big) - \frac{2+\alpha}{2\pi} \ln|z-p| + \frac{1+\alpha}{2\pi} \ln\big(|p|^2|z|^2 - 2\langle p, z\rangle + 1\big).$$

Let us remark that, according to the nonexistence result stated above, for $p = 0$ the function $\mathcal{F}(z) = \frac{1}{2\pi} \ln\big(1 - |z|^2\big) - \frac{2+\alpha}{2\pi} \ln|z|$ has no critical points in $B(0,1) \setminus \{0\}$ and this remains true for p close to zero. On the other hand, we can take $p \in B(0,1)$ such that $p \to e \in \partial B(0,1)$ along a straight line. We consider a point $q = se$ for $s \in (-1,1)$. We have that

$$\nabla \mathcal{F}(q) = \left(\frac{(\alpha+2)s + \alpha}{2\pi(s^2-1)} + o(1) \right) e \quad \text{as } p \to e$$

for $|s-1|$ bounded away from zero. Let $s_0 = -\frac{\alpha}{\alpha+2}$, for p close to e we find a point s_p such that $\nabla \mathcal{F}(s_p e) = 0$ and $s_p \to s_0$ as $p \to e$. We evaluate now the determinant of $D^2\mathcal{F}(s_p e)$:

$$\det D^2\mathcal{F}(s_p e) = \frac{(\alpha+2)^6}{64\pi^2(\alpha+1)^3} + o(1) \quad \text{as } p \to e.$$

Hence $q_p = s_p e$ is a nondegenerate critical point of $\mathcal{F}(z)$ for p close to e such that $q_p \to -\frac{\alpha}{\alpha+2} e$ as $p \to e$.

As in [4], Theorem 1.4 is based on the construction of a suitable family of approximate solutions $v(\rho, \lambda, a)$ for problem $(P)_\rho$, with (λ, a) a suitable set of parameters, such that the linearized operator about $v(\rho, \lambda, a)$ is invertible. Thus, for ρ small a fixed point argument will provide a solution v_ρ close in some sense to $v(\rho, \lambda, a)$ with the required asymptotic properties.

2. Construction of approximating solutions. As far as part (a) in Theorem 1.4 is concerned, in view of the expected asymptotic behavior, the approximating function $v(\rho, 0, 0)$ will be constructed by gluing in a small neighborhood of p the limit function $8\pi(1+\alpha)G(z,p)$ with a suitable local solution of $-\Delta v = \rho^2|z-p|^{2\alpha} f(p) e^v$. Using the scale invariance $v(z) \to v_t(z) = v(tz) + 2(\alpha+1)\ln t$, $t > 0$, valid for the solutions of the equation

$$-\Delta v = \rho^2 |z|^{2\alpha} e^v, \tag{4}$$

we can construct local solutions which are very concentrated near p in such a way that the gluing with $8\pi(1+\alpha)G(z,p)$ is sufficiently accurate. This is possible in view of the fact that $8\pi(1+\alpha)G(z,p) \to +\infty$ as $z \to p$. For part (b) in Theorem 1.4, we glue in a small neighborhood of q the limit function $8\pi G(z,q)$ with a suitable local solution of $-\Delta v = \rho^2|q-p|^{2\alpha} f(q) e^v$. The scale invariance involved here is $v(z) \to v_t(z) = v(tz) + 2\ln t$, $t > 0$, valid for solutions of

$$-\Delta v = \rho^2 e^v. \tag{5}$$

Finally, for part (c) in Theorem 1.4 we combine the two previous constructions by gluing the limit function $8\pi(1+\alpha)G(z,p) + 8\pi G(z,q)$ with a local solution of $-\Delta v = \rho^2|z-p|^{2\alpha} f(p) e^v$ near p and with a local solution of $-\Delta v = \rho^2|q-p|^{2\alpha} f(q) e^v$ near q.

To this purpose, we recall some known facts. The solutions of $-\Delta u = e^u$ in $\mathbb{R}^2$ have been completely classified by Liouville in [24] and in complex notations they satisfy the so-called Liouville formula

$$\ln \frac{8|F'(z)|^2}{(1+|F(z)|^2)^2} \tag{6}$$

for some meromorphic function F with $F'(z) \neq 0$ whenever defined.

This representation formula generalizes to solutions in the punctured plane $\mathbb{C}\backslash\{0\}$, as proved in [18], by choosing some multivalued meromorphic function $F : \mathbb{C} \to \mathbb{C}$, locally univalent in $\mathbb{C} \setminus \{0\}$, satisfying

$$\text{either} \quad F(z) = G(z)z^\gamma,\ \gamma \in \mathbb{R}, \quad \text{or} \quad F(z) = \Phi(\sqrt{z}),$$

where G and Φ are single-valued holomorphic functions away from the origin and where $\Phi(z)\Phi(-z) = 1$.

A complete classification for solutions of

$$\begin{cases} -\Delta u = e^u & \text{in } \mathbb{R}^2, \\ \int_{\mathbb{R}^2} e^u < +\infty \end{cases} \tag{7}$$

can be performed either by the Liouville formula or via the moving plane method (see [16]) and it leads to the only possible choice of $F(z) = az + b$, with $a, b \in \mathbb{C}$. The complete classification for solutions of

$$\begin{cases} -\Delta u = e^u - 4\pi\alpha\delta_{p=0} & \text{in } \mathbb{R}^2, \\ \int_{\mathbb{R}^2} e^u < +\infty \end{cases} \tag{8}$$

is due to [31] and it corresponds to the choice $F(z) = az^{\alpha+1} + b$, with $a, b \in \mathbb{C}$ and $b = 0$ if $\alpha \notin \mathbb{N}$. By choosing $F(z) = \frac{1}{\tau\rho} z(1+\gamma z^2)$, $\tau > 0$, $\gamma \in \mathbb{C}$ such that $|\gamma| < \frac{1}{3}$, and $F(z) = \frac{1}{\tau\rho} z^{\alpha+1}$, we can provide, respectively, solutions for (7) and (8) in $B(0,1)$. By taking the regular part of this functions and adding a term $2\ln\frac{1}{\rho}$, we obtain a large class of solutions for (4) and (5) in $B(0,1)$, respectively, in the form

$$v_{\rho,\tau} = \ln \frac{8(\alpha+1)^2\tau^2}{(\tau^2\rho^2 + |z|^{2(\alpha+1)})^2}, \qquad v_{\rho,\tau,\gamma} = \ln \frac{8\tau^2|1+3\gamma z^2|^2}{(\tau^2\rho^2 + |z|^2|1+\gamma z^2|^2)^2}. \tag{9}$$

Let $h(z)$ be some smooth function such that $h(0) > 0$. The function $v_{\rho,\tau} - \ln h(0)$ satisfies the equation $-\Delta\left(v_{\rho,\tau} - \ln h(0)\right) = \rho^2 h(0)|z|^{2\alpha} e^{v_{\rho,\tau} - \ln h(0)}$ in $B(0,1)$. Similarly $v_{\rho,\tau,0} - \ln h(0)$ is a solution for $-\Delta\left(v_{\rho,\tau,0} - \ln h(0)\right) = \rho^2 h(0) e^{v_{\rho,\tau,0} - \ln h(0)}$ in $B(0,1)$. For $\rho > 0$ small, they can be viewed as approximating solutions when we replace $h(0)$ by $h(z)$: such an approximation, however, may not be accurate enough to carry out our fixed point argument. In fact, we will need to define the local approximating solution $U_{\rho,\tau}$ as the difference between, respectively, $v_{\rho,\tau}$, $v_{\rho,\tau,0}$ and a Taylor expansion of $\ln h(z)$ at $z = 0$, taking into account two basic facts:

(a) $U_{\rho,\tau}$ must be a "good" local approximating solution;

(b) translating $U_{\rho,\tau}$ at some point $q \in S$, the difference between this local function and the related limit function as $\rho \to 0$ must be small in a small annulus centered at q.

In case $\alpha > 0$, $v_{\rho,\tau} - \ln h(0)$ is satisfactory for (a). For (b), if $p \in S \cap \Gamma$, we choose some $\tau > 0$ such that the Taylor expansion corresponding to the difference function in

a small annulus centered in p contains powers of $z-p$ of degree 1. In case $\alpha=0$ the situation is more delicate as there is more degeneracy. Assuming $\Delta \ln h(0)=0$, for (a) we need to take the local function $U_{\rho,\tau}$ of the form $v_{\rho,\tau,\gamma}-\ln h(0)-2\bar{z}\cdot\partial_z \ln h(0)-\bar{z}^2\cdot\partial_{zz}\ln h(0)$. While for (b) we need the difference function to be an infinitesimal term of order 3 as $z\to q$. This condition will be attained by specifying $\tau>0$ and γ suitably and by the condition $\partial_z \mathcal{F}(q)=0$. The invertibility of $D^2\mathcal{F}(q)$ will guarantee the invertibility of the linearized operator around such an approximating solution at $\rho=0$.

Summarizing, an appropriate approximating solution for our problem near a blowup point should look like

$$U_{\rho,\tau}(z)=\begin{cases} v_{\rho,\tau}(z)-\ln h(0) & \text{if } \alpha>0,\\ v_{\rho,\tau,\gamma}(z)-\ln h(0)-2\bar{z}\cdot\partial_z\ln h(0)-\bar{z}^2\cdot\partial_{zz}\ln h(0) & \text{if } \alpha=0 \end{cases}$$

with τ and γ suitably chosen. Introduce the differential operators $\partial_z=\frac{1}{2}(\partial_1-i\partial_2)$, $\partial_{\bar{z}}=\frac{1}{2}(\partial_1+i\partial_2)$, and the notation $2z\cdot z'=z\overline{z'}+\bar{z}z'=2\mathrm{Re}\,(z\overline{z'})$. Thus $\Delta=4\partial_z\partial_{\bar{z}}$ and the Taylor expansion in 0 for any smooth function $h:\Omega\to\mathbb{R}$ takes the form

$$h(z)=h(0)+2\bar{z}\cdot\partial_z h(0)+\bar{z}^2\cdot\partial_{zz}h(0)+\frac{|z|^2}{4}\Delta h(0)+O(|z|^3).$$

Hence $U_{\rho,\tau}$ is a solution in $B(0,1)$ of

$$-\Delta U_{\rho,\tau}=\begin{cases} \rho^2|z|^{2\alpha}h(0)e^{U_{\rho,\tau}} & \text{if } \alpha>0,\\ \rho^2 e^{\ln h(0)+2\bar{z}\cdot\partial_z\ln h(0)+\bar{z}^2\cdot\partial_{zz}\ln h(0)}e^{U_{\rho,\tau}} & \text{if } \alpha=0, \end{cases} \tag{10}$$

and we see that the right-hand side (RHS) of (10) may be expressed as follows:

$$\mathrm{RHS}=\begin{cases} \rho^2|z|^{2\alpha}h(z)e^{U_{\rho,\tau}}+O\left(\rho^2|z|^{2\alpha+1}e^{U_{\rho,\tau}}\right) & \text{if } \alpha>0,\\ \rho^2 h(z)e^{U_{\rho,\tau}}+O\left(\rho^2|z|^3e^{U_{\rho,\tau}}\right) & \text{if } \alpha=0 \end{cases}$$

provided that when $\alpha=0$ we also satisfy $\Delta\ln h(0)=0$.

By the assumptions in Theorem 1.4, we may translate the function $U_{\rho,\tau}(z)$ around the points p and q by defining

$$\begin{cases} U^1_\rho(z)=v_{\rho,\tau_1}(z-p)-\ln f(p),\\ U^2_\rho(z)=v_{\rho,\tau_2,\gamma}(z-q)-\ln\left(|z-p|^{2\alpha}f\right)(q)-2\overline{z-q}\cdot\partial_z\ln\left(|z-p|^{2\alpha}f\right)(q)\\ \qquad\qquad -\overline{z-q}^2\cdot\partial_{zz}\ln\left(|z-p|^{2\alpha}f\right)(q) \end{cases}$$

with τ_1, τ_2, and γ to be specified below. Thus, we have

$$\Delta U^i_\rho(z)+\rho^2|z-p|^{2\alpha}f(z)e^{U^i_\rho(z)}=\begin{cases} O\left(\rho^2|z-p|^{2\alpha+1}e^{U^1_\rho(z)}\right) & \text{in } B(p,1),\\ O\left(\rho^2|z-q|^3e^{U^2_\rho(z)}\right) & \text{in } B(q,1). \end{cases} \tag{11}$$

Note that the following expansions hold as $\rho\to0$:

$$v_{\rho,\tau}(z-p)=\ln 8(1+\alpha)^2\tau^2-4(1+\alpha)\ln|z-p|+O\left(\frac{\tau^2\rho^2}{|z-p|^{2(\alpha+1)}}\right),$$

$$v_{\rho,\tau,\gamma}(z-q)=\ln 8\tau^2-4\ln|z-q|+2\overline{z-q}^2\cdot\gamma+O\left(|z-q|^4+\frac{\tau^2\rho^2}{|z-q|^2}\right).$$

Let us define the limit function $L(z)$ as

$$L(z)=\begin{cases}8\pi(1+\alpha)G(z,p) & \text{if } S=\{p\},\\ 8\pi G(z,q) & \text{if } S=\{q\},\\ 8\pi(1+\alpha)G(z,p)+8\pi G(z,q) & \text{if } S=\{p,q\}.\end{cases}$$

Hence in $|z-p|<1$ we get

$$U^1_\rho(z)-L(z)=\ln 8(\alpha+1)^2\tau_1^2-\mathcal{F}_1(p)+O\left(\frac{\tau_1^2\rho^2}{|z-p|^{2(1+\alpha)}}+|z-p|\right),$$

while for $|z-q|<1$,

$$U^2_\rho(z)-L(z)=\ln 8\tau_2^2-\mathcal{F}_2(q)-2\overline{z-q}\cdot\partial_z\mathcal{F}_2(q)$$
$$-\overline{z-q}^2\cdot(\partial_{zz}\mathcal{F}_2(q)-2\gamma)+O\left(\frac{\tau_2^2\rho^2}{|z-q|^2}+|z-q|^3\right),$$

where

$$\mathcal{F}_1(z)=\begin{cases}8\pi(1+\alpha)H(z,p)+\ln f(z) & \text{if } S=\{p\},\\ 8\pi(1+\alpha)H(z,p)+8\pi G(z,q)+\ln f(z) & \text{if } S=\{p,q\}\end{cases}$$

and

$$\mathcal{F}_2(z)=\begin{cases}8\pi H(z,q)+\ln\left(|z-p|^{2\alpha}f(z)\right) & \text{if } S=\{q\},\\ 8\pi H(z,q)+\ln\left(|z-p|^{2\alpha}f(z)\right)+8\pi(1+\alpha)G(z,p) & \text{if } S=\{p,q\}.\end{cases}$$

Let us remark that by assumption $\partial_z\mathcal{F}_2(q)=0$. Now we specify the values for τ_1, τ_2, and γ to be fixed as follows:

$$\tau_1=\frac{e^{\frac12\mathcal{F}_1(p)}}{\sqrt{8}(1+\alpha)},\qquad \tau_2=\frac{e^{\frac12\mathcal{F}_2(q)}}{\sqrt{8}},\qquad \gamma=\frac12\partial_{zz}\mathcal{F}_2(q).$$

In such a way we obtain

$$U^1_\rho(z)-L(z)=O\left(\frac{\tau_1^2\rho^2}{|z-p|^{2(1+\alpha)}}+|z-p|\right)\quad\text{in } |z-p|<1 \tag{12}$$

and

$$U^2_\rho(z)-L(z)=O\left(\frac{\tau_2^2\rho^2}{|z-q|^2}+|z-q|^3\right)\quad\text{in } |z-q|<1. \tag{13}$$

By scaling the variables, we can always assume that $\overline{B(p,2)}\cap\overline{B(q,2)}=\emptyset$, $\overline{B(p,2)}\subset\Omega$, $\overline{B(q,2)}\subset\Omega$, and $|\gamma|<\frac13$. For $i=1,2$ let $r_i=r_i(\rho)$ be a positive smooth function such that $\frac{\rho^2}{r_1^{4\alpha+5}}=O(1)$ as $\rho\to0$ and $\frac{\rho^2}{r_2^5}=O(1)$ as $\rho\to0$. Let χ be a radial smooth function such that $0\le\chi\le1$, $\chi=1$ in $B(0,1)$, and $\chi=0$ in $\mathbb{R}^2\setminus B(0,2)$.

To obtain part (a) in Theorem 1.4, for $\lambda_1\in\mathbb{R}$, $|\lambda_1|<\frac12\tau_1$, we consider the approximating function

$$v(\rho,\lambda_1)(z)=\left(1-\chi\left(\frac{z-p}{r_1}\right)\right)8\pi(1+\alpha)G(z,p)$$
$$+\chi\left(\frac{z-p}{r_1}\right)(v_{\rho,\tau_1+\lambda_1}(z-p)-\ln f(p)).$$

So $v(\rho,0)=U^1_\rho$ in $|z-p|<r_1$. For part (b) in Theorem 1.4, we need a three-parameter family of approximating functions and, for $(\lambda_2,a)\in\mathbb{R}\times\mathbb{C}$, $|\lambda_2|<\frac{1}{2}\tau_2$, $|a|<\frac{1}{2}$, and $g(z)=|z-p|^{2\alpha}f(z)$, we consider

$$\begin{aligned} v(\rho,\lambda_2,a)(z) \,=\, & \left(1-\chi\left(\frac{z-q-a}{r_2}\right)\right)8\pi G(z,q+a)\\ & +\chi\left(\frac{z-q-a}{r_2}\right)\left(v_{\rho,\tau_2+\lambda_2,\gamma}(z-q-a)-P_a(z)\right), \end{aligned}$$

where $P_a(z)=\ln g(q+a)+2\overline{z-q-a}\cdot\partial_z\ln g(q+a)+\overline{z-q-a}^2\cdot\partial_{zz}\ln g(q+a)$. So $v(\rho,0,0)=U^2_\rho$ in $|z-q|<r_2$. Finally, for part (c) in Theorem 1.4, we need a four-parameter family of approximating functions and, for $(\lambda,a)\in\mathbb{R}^2\times\mathbb{C}$, $\lambda=(\lambda_1,\lambda_2)$, $|\lambda|<\frac{1}{2}\min\{\tau_1,\tau_2\}$, $|a|<\frac{1}{2}$, and $g(z)=|z-p|^{2\alpha}f(z)$, we take

$$\begin{aligned} v(\rho,\lambda,a)(z) \,=\, & \left(1-\chi\left(\frac{z-p}{r_1}\right)\right)\left(8\pi(1+\alpha)G(z,p)+8\pi G(z,q+a)\right)\\ & +\chi\left(\frac{z-p}{r_1}\right)\left(v_{\rho,\tau_1+\lambda_1}(z-p)-\ln f(p)\right)\quad \text{in } B(p,1), \end{aligned}$$

$$\begin{aligned} v(\rho,\lambda,a)(z) \,=\, & \left(1-\chi\left(\frac{z-q-a}{r_2}\right)\right)\left(8\pi(1+\alpha)G(z,p)+8\pi G(z,q+a)\right)\\ & +\chi\left(\frac{z-q-a}{r_2}\right)\left(v_{\rho,\tau_2+\lambda_2,\gamma}(z-q-a)-P_a(z)\right)\quad \text{in } B(q,1), \end{aligned}$$

and

$$v(\rho,\lambda,a)(z)=8\pi(1+\alpha)G(z,p)+8\pi G(z,q+a)\qquad \text{in } \Omega\setminus(B(p,1)\cup B(q,1)).$$

To unify notation, from now on we will use the convention that

- $\lambda_2=0$, $a=0$ if $S=\{p\}$,
- $\lambda_1=0$ if $S=\{q\}$,
- every expression containing p (or q) does really exist only if $p\in S$ (or $q\in S$).

We remark that in such a way the last definition of $v(\rho,\lambda,a)$ contains the previous ones and (λ,a) always lie in $\mathbb{R}^2\times\mathbb{C}$.

3. A fixed point argument. In this section we obtain the desired existence result by means of a fixed point argument. To this end we have postponed the proof of the most technical aspects necessary to such an approach in the next two sections.

For $a\in\mathbb{C}$, $|a|<\frac{1}{2}$, it is possible to construct a diffeomorphism $\Psi(a,\cdot):\Omega\to\Omega$, smoothly depending on a, such that $\Psi(0,\cdot)=\mathrm{Id}$, $\Psi(a,z)=z-a$ for all $z\in B(q,\frac{3}{2})$, and $\Psi(a,\cdot)=\mathrm{Id}$ for all $z\in\Omega\setminus B(q,2)$. We can suppose that all derivatives of $\Psi(a,z)$ in a, $\bar a$, z, $\bar z$ up to order 3 are bounded in Ω.

We define now suitable function spaces of weighted Hölder type appropriate for our problem, which were introduced for the first time by Caffarelli, Hardt, and Simon in [9].

Definition 3.1. *For any $\nu\in\mathbb{R}$, $k\in\mathbb{N}$, $\beta\in[0,1]$, define the space*

$$C^{k,\beta}_\nu\left(B(0,1)\right):=\left\{w\in C^{k,\beta}\left(B(0,1)\setminus\{0\},\mathbb{R}\right)\,:\,\|w\|_{k,\beta,\nu}<+\infty\right\},$$

where

$$\|w\|_{k,\beta,\nu} := \sup_{r\le 1} r^{-\nu}\left\{\sup_{\{z:\ \frac{r}{2}<|z|<r\}}\left(\sum_{j=0}^{k} r^j|\nabla^j w(z)|\right)\right.$$
$$\left. + r^{k+\beta}\sup_{\{x,y:\ |x|,|y|\in(\frac{r}{2},r)\}}\left(\frac{|\nabla^k w(x)-\nabla^k w(y)|}{|x-y|^\beta}\right)\right\}.$$

Let $\nu_1 \in (0,1)$ and $\nu_2 \in (1,2)$ be two real numbers. Set $\tilde{\Omega} = \Omega \setminus B$, $B = B(p,1)\cup B(q,1)$, and define

$$X = \{w \in C^{2,\beta}(\Omega\setminus S,\mathbb{R}):\ w\equiv 0 \text{ on } \partial\Omega\,,\ \|w\|_X < +\infty\},$$

where $\|w\|_X = \|w\|_{2,\beta,\tilde{\Omega}} + \|w\|_{2,\beta,\nu_1,B(p,1)} + \|w\|_{2,\beta,\nu_2,B(q,1)}$, and

$$Y = \{w \in C^{0,\beta}(\Omega\setminus S,\mathbb{R}):\ \|w\|_Y < +\infty\},$$

where $\|w\|_Y = \|w\|_{0,\beta,\tilde{\Omega}} + \|w\|_{0,\beta,\nu_1-2,B(p,1)} + \|w\|_{0,\beta,\nu_2-2,B(q,1)}$.

We can replace the norm in X with an equivalent one (for ρ fixed) of the form

$$\|w\|_{X'} = \|w\|_{2,\beta,\tilde{\Omega}} + r_1^{\nu_1}\|w\|_{2,\beta,\nu_1,B(p,1)} + r_2^{\nu_2}\|w\|_{2,\beta,\nu_2,B(q,1)}$$

and we will refer to the space X, endowed with the norm $\|\cdot\|_{X'}$, as X'.

Finally, we define

$$\mathcal{E} = \{(w,\lambda,a) : w\in X,\ \lambda\in\mathbb{R}^2,\ a\in\mathbb{C}\}$$

with the norm $\|(w,\lambda,a)\|_{\mathcal{E}} = \|w\|_X + |\lambda| + |a|$, and $\mathcal{E}'$ as the space $\mathcal{E}$ endowed with the equivalent norm $\|(w,\lambda,a)\|_{\mathcal{E}'} = \|w\|_{X'} + |\lambda| + |a|$.

We can produce a solution $v(\rho,\lambda,a)+w\circ\Psi(a,\cdot)$, $(w,\lambda,a)\in\mathcal{E}'$, for problem $(P)_\rho$ if (w,λ,a) is a zero for the nonlinear map

$$N : \mathcal{E}' \to Y$$
$$(w,\lambda,a) \to N(w,\lambda,a) = \Delta\left[v(\rho,\lambda,a)+w\circ\Psi(a,\cdot)\right]\circ\Psi(a,\cdot)^{-1}$$
$$+\rho^2 g\circ\Psi(a,\cdot)^{-1}e^{v(\rho,\lambda,a)\circ\Psi(a,\cdot)^{-1}+w},$$

where $g(z) = |z-p|^{2\alpha}f(z)$. Define $L_{(0,\lambda,a)} : \mathcal{E}' \to Y$ as the linearized operator of N at $(0,\lambda,a)$. Hence,

$$L_{(0,\lambda,a)}(h,\sigma,b) = \Delta\left(h\circ\Psi(a,\cdot)\right)\circ\Psi(a,\cdot)^{-1} + \rho^2 g\circ\Psi(a,\cdot)^{-1}e^{v(\rho,\lambda,a)\circ\Psi(a,\cdot)^{-1}}h$$
$$+\sum_i \sigma_i\left[\Delta\partial_{\lambda_i}v(\rho,\lambda,a) + \rho^2 g(z)e^{v(\rho,\lambda,a)}\partial_{\lambda_i}v(\rho,\lambda,a)\right]\circ\Psi(a,\cdot)^{-1}$$
$$+2b\cdot\left[\Delta\partial_{\overline{a}}v(\rho,\lambda,a) + \rho^2 g(z)e^{v(\rho,\lambda,a)}\partial_{\overline{a}}v(\rho,\lambda,a)\right]\circ\Psi(a,\cdot)^{-1}$$
$$+2\partial_{\bar{z}}\left[\Delta v(\rho,\lambda,a) + \rho^2 g(z)e^{v(\rho,\lambda,a)}\right]|_{\Psi(a,\cdot)^{-1}}\cdot\left[\left(b\partial_a + \overline{b}\partial_{\overline{a}}\right)\Psi(a,\cdot)^{-1}\right].$$

In Theorem 4.13 below, we show that the map $L_{(0,0,0)} : \mathcal{E}' \to Y$ is uniformly invertible for ρ small. We can decompose

$$N(w,\lambda,a) - N(0,0,0) - L_{(0,0,0)}(w,\lambda,a)$$
$$= \left[N(w,\lambda,a) - N(0,\lambda,a) - L_{(0,\lambda,a)}(w,0,0)\right] + \left(L_{(0,\lambda,a)} - L_{(0,0,0)}\right)(w,0,0)$$
$$+\left[N(0,\lambda,a) - N(0,0,0) - L_{(0,0,0)}(0,\lambda,a)\right].$$

In the following three steps we estimate in Y each term above. For simplicity, we show only how to derive the estimates for the L^∞ part in $\|\cdot\|_Y$ since the estimates of the Hölder term can be established in a similar way: all along the paper we will use implicitly this fact to simplify all the computations.

Step 1. Let

$$\begin{aligned} f_1(w,\lambda,a) &= N(w,\lambda,a) - N(0,\lambda,a) - L_{(0,\lambda,a)}(w,0,0) \\ &= \rho^2 g \circ \Psi(a,\cdot)^{-1} e^{v(\rho,\lambda,a)\circ\Psi(a,\cdot)^{-1}} (e^w - 1 - w). \end{aligned}$$

Since

$$\Psi(a,\cdot)^{-1}: \begin{array}{ll} B(q,1) \to B(q+a,1) \\ z \qquad\quad \to z+a, \end{array}$$

we obtain the bounds

(14)
$$|\rho^2 g \circ \Psi(a,\cdot)^{-1} e^{v(\rho,\lambda,a)\circ\Psi(a,\cdot)^{-1}}| = \begin{cases} O\left(\frac{\rho^2|z-p|^{2\alpha}}{(\rho^2+|z-p|^{2\alpha+2})^2}\right) & \text{in } B(p,r_1), \\ O\left(\frac{\rho^2}{|z-p|^{2\alpha+4}}\right) & \text{in } B(p,1)\setminus B(p,r_1), \\ O\left(\frac{\rho^2}{(\rho^2+|z-q|^2)^2}\right) & \text{in } B(q,r_2), \\ O\left(\frac{\rho^2}{|z-q|^4}\right) & \text{in } B(q,1)\setminus B(q,r_2), \\ O(\rho^2) & \text{in } \tilde\Omega, \end{cases}$$

(15)
$$|\partial_{\overline a}\, \rho^2 g \circ \Psi(a,\cdot)^{-1} e^{v(\rho,\lambda,a)\circ\Psi(a,\cdot)^{-1}}| = \begin{cases} O\left(\frac{\rho^2}{(\rho^2+|z-q|^2)^2}\right) & \text{in } B(q,r_2), \\ O\left(\frac{\rho^2}{|z-q|^4}\right) & \text{in } B(q,1)\setminus B(q,r_2), \\ O(\rho^2) & \text{in } \Omega\setminus B(q,1), \end{cases}$$

(16)
$$|\partial_{\lambda_i}\, \rho^2 g \circ \Psi(a,\cdot)^{-1} e^{v(\rho,\lambda,a)\circ\Psi(a,\cdot)^{-1}}| = \begin{cases} O\left(\frac{\rho^2|z-p|^{2\alpha}}{(\rho^2+|z-p|^{2\alpha+2})^2}\right) & \text{in } B(p,2r_1) \text{ if } i=1, \\ O\left(\frac{\rho^2}{(\rho^2+|z-q|^2)^2}\right) & \text{in } B(q,2r_2) \text{ if } i=2, \\ 0 & \text{elsewhere.} \end{cases}$$

Hence, we can derive

$$\begin{aligned} &\|f_1(w_1,\lambda_1,a_1) - f_1(w_2,\lambda_2,a_2)\|_{0,\beta,\tilde\Omega} \\ &\quad = O\Big[\rho^2(\|w_1\|_{2,\beta,\tilde\Omega} + \|w_2\|_{2,\beta,\tilde\Omega})\|(w_1,\lambda_1,a_1) - (w_2,\lambda_2,a_2)\|_{\mathcal E}\Big], \\ &\|f_1(w_1,\lambda_1,a_1) - f_1(w_2,\lambda_2,a_2)\|_{0,\beta,\nu_1-2,B(p,1)} \\ &\quad = O\Big[\rho^{\frac{\nu_1}{\alpha+1}}(\|w_1 - w_2\|_{2,\beta,\nu_1,B(p,1)} \\ &\qquad + |\lambda_1-\lambda_2| + |a_1-a_2|)\left(\|w_1\|_{2,\beta,\nu_1,B(p,1)} + \|w_2\|_{2,\beta,\nu_1,B(p,1)}\right)\Big], \end{aligned}$$

and

$$\begin{aligned}&\|f_1(w_1,\lambda_1,a_1)-f_1(w_2,\lambda_2,a_2)\|_{0,\beta,\nu_2-2,B(q,1)}\\&\quad=O\left[\rho^{\nu_2}\left(\|w_1-w_2\|_{2,\beta,\nu_2,B(q,1)}\right.\right.\\&\qquad\left.\left.+|\lambda_1-\lambda_2|+|a_1-a_2|\right)\left(\|w_1\|_{2,\beta,\nu_2,B(q,1)}+\|w_2\|_{2,\beta,\nu_2,B(q,1)}\right)\right].\end{aligned}$$

Since $\frac{\rho^2}{r_1^{4\alpha+5}}+\frac{\rho^2}{r_2^5}=O(1)$, finally we get

$$\begin{aligned}\|f_1(w_1,\lambda_1,a_1)-f_1(w_2,\lambda_2,a_2)\|_Y=O\left[\|(w_1,\lambda_1,a_1)-(w_2,\lambda_2,a_2)\|_{\mathcal{E}'}\right.\\\left.\times\left(\|(w_1,\lambda_1,a_1)\|_{\mathcal{E}'}+\|(w_2,\lambda_2,a_2)\|_{\mathcal{E}'}\right)\right].\end{aligned}$$

Step 2. Define

$$f_2(w,\lambda,a)=\left(L_{(0,\lambda,a)}-L_{(0,0,0)}\right)(w,0,0)=f_2^1(w,a)+f_2^2(w,\lambda,a),$$

where

$$f_2^1(w,a)=\Delta\left[w\circ\Psi(a,\cdot)\right]\circ\Psi(a,\cdot)^{-1}-\Delta w$$

and

$$f_2^2(w,\lambda,a)=\rho^2 g\circ\Psi(a,\cdot)^{-1}e^{v(\rho,\lambda,a)\circ\Psi(a,\cdot)^{-1}}w-\rho^2 g e^{v(\rho,0,0)}w.$$

Using the identities

$$\begin{aligned}\partial_{\bar z}(w\circ\Psi)&=(\partial_z w\circ\Psi)\,\partial_{\bar z}\Psi+(\partial_{\bar z}w\circ\Psi)\,\partial_{\bar z}\bar\Psi,\\\Delta(w\circ\Psi)&=(\Delta w\circ\Psi)\left[|\partial_z\Psi|^2+|\partial_{\bar z}\Psi|^2\right]+8\mathrm{Re}\left[(\partial_{zz}w\circ\Psi)\,\partial_z\Psi\partial_{\bar z}\Psi\right]\\&\quad+8\mathrm{Re}\left[(\partial_z w\circ\Psi)\,\partial_{z\bar z}\Psi\right],\end{aligned}$$

we obtain

$$\begin{aligned}f_2^1(w_1,a_1)-f_2^1(w_2,a_2)&=\Delta(w_1-w_2)\left(|\partial_z\Psi(a_1,\cdot)|^2+|\partial_{\bar z}\Psi(a_1,\cdot)|^2-1\right)|_{\Psi(a_1,\cdot)^{-1}}\\&\quad+8\mathrm{Re}\left(\partial_{zz}(w_1-w_2)\partial_z\Psi(a_1,\cdot)|_{\Psi(a_1,\cdot)^{-1}}\,\partial_{\bar z}\Psi(a_1,\cdot)\,|_{\Psi(a_1,\cdot)^{-1}}\right)\\&\quad+8\mathrm{Re}\left(\partial_z(w_1-w_2)\partial_{z\bar z}\Psi(a_1,\cdot)\,|_{\Psi(a_1,\cdot)^{-1}}\right)\\&\quad+\Delta\left[w_2\circ\Psi(a_1,\cdot)\right]\circ\Psi(a_1,\cdot)^{-1}-\Delta\left[w_2\circ\Psi(a_2,\cdot)\right]\circ\Psi(a_2,\cdot)^{-1}.\end{aligned}$$

Therefore

$$\begin{aligned}f_2^1(w_1,a_1)-f_2^1(w_2,a_2)&=O\left(|D^2(w_1-w_2)||a_1|+|\nabla(w_1-w_2)||a_1|\right.\\&\quad\left.+|D^2w_2||a_1-a_2|+|\nabla w_2||a_1-a_2|\right)\end{aligned}$$

in $B(q,2)\setminus B(q,1)$ and $f_2^1(w_1,a_1)-f_2^1(w_2,a_2)=0$ outside this region. Hence

$$\begin{aligned}\|f_2^1(w_1,a_1)-f_2^1(w_2,a_2)\|_Y=O\left[\|(w_1,\lambda_1,a_1)-(w_2,\lambda_2,a_2)\|_{\mathcal{E}'}\right.\\\left.\times\left(\|(w_1,\lambda_1,a_1)\|_{\mathcal{E}'}+\|(w_2,\lambda_2,a_2)\|_{\mathcal{E}'}\right)\right].\end{aligned}$$

By (14), (15), and (16), for f_2^2 we get

$$\begin{aligned}&\|f_2^2(w_1,\lambda_1,a_1)-f_2^2(w_2,\lambda_2,a_2)\|_Y\\&\quad=O\left[\left(\|w_1\|_X+\|w_2\|_X\right)\|(w_1,\lambda_1,a_1)-(w_2,\lambda_2,a_2)\|_{\mathcal{E}'}\right.\\&\qquad\left.+\|w_1-w_2\|_X\left(\|(w_1,\lambda_1,a_1)\|_{\mathcal{E}'}+\|(w_2,\lambda_2,a_2)\|_{\mathcal{E}'}\right)\right].\end{aligned}$$

Step 3. Set $f_3(\lambda,a)=N(0,\lambda,a)-N(0,0,0)-L_{(0,0,0)}(0,\lambda,a)$. Let us write explicitly $N(0,\lambda,a)$ in $B(p,1)$,

$$\begin{aligned}N(0,\lambda,a)(z)=&\frac{1}{r_1^2}\Delta\chi\left(\frac{z-p}{r_1}\right)\Delta^1(z)+\frac{8}{r_1}\partial_{\bar z}\chi\left(\frac{z-p}{r_1}\right)\cdot\partial_{\bar z}\Delta^1(z)\\&-\chi\left(\frac{z-p}{r_1}\right)\rho^2|z-p|^{2\alpha}e^{v_{\rho,\tau_1+\lambda_1}(z-p)}\\&+\rho^2|z-p|^{2\alpha}f(z)e^{8\pi(1+\alpha)G(z,p)+8\pi G(z,q+a)+\chi(\frac{z-p}{r_1})\Delta^1(z)}\end{aligned}$$

and in $B(q,1)$

$$\begin{aligned}N(0,\lambda,a)(z)=&\frac{1}{r_2^2}\Delta\chi\left(\frac{z-q}{r_2}\right)\Delta^2(z)+\frac{8}{r_2}\partial_{\bar z}\chi\left(\frac{z-q}{r_2}\right)\cdot\partial_{\bar z}\Delta^2(z)\\&-\chi\left(\frac{z-q}{r_2}\right)\rho^2e^{v_{\rho,\tau_2+\lambda_2,\gamma}(z-q)}\\&+\rho^2g(z+a)e^{8\pi(1+\alpha)G(z+a,p)+8\pi G(z+a,q+a)+\chi(\frac{z-q}{r_2})\Delta^2(z)},\end{aligned}$$

where $g(z)=|z-p|^{2\alpha}f(z)$ and

$$\begin{aligned}&\Delta^1(z):=v_{\rho,\tau_1+\lambda_1}(z-p)-\ln f(p)-8\pi(1+\alpha)G(z,p)-8\pi G(z,q+a)\text{ in }B(p,1),\\&\Delta^2(z):=v_{\rho,\tau_2+\lambda_2,\gamma}(z-q)-P_a(z+a)-8\pi(1+\alpha)G(z+a,p)\\&\qquad\quad-8\pi G(z+a,q+a)\text{ in }B(q,1).\end{aligned}$$

In $B(p,1)$ we get

$$\begin{aligned}\partial_{\lambda_s\lambda_k}N(0,\lambda,a)(z)=&\frac{1}{r_1^2}\Delta\chi\left(\frac{z-p}{r_1}\right)v^1_{sk}(z)\delta_{s1}\delta_{k1}+\frac{8}{r_1}\partial_{\bar z}\chi\left(\frac{z-p}{r_1}\right)\cdot\partial_{\bar z}v^1_{sk}(z)\delta_{s1}\delta_{k1}\\&-\chi\left(\frac{z-p}{r_1}\right)\rho^2|z-p|^{2\alpha}e^{v_{\rho,\tau_1+\lambda_1}(z-p)}\left(v^1_s(z)v^1_k(z)+v^1_{sk}(z)\right)\delta_{s1}\delta_{k1}\\&+\rho^2|z-p|^{2\alpha}f(z)e^{8\pi(1+\alpha)G(z,p)+8\pi G(z,q+a)+\chi(\frac{z-p}{r_1})\Delta^1(z)}\\&\times\chi\left(\frac{z-p}{r_1}\right)\left(v^1_{sk}(z)+\chi\left(\frac{z-p}{r_1}\right)v^1_s(z)v^1_k(z)\right)\delta_{s1}\delta_{k1},\end{aligned}$$

$$\begin{aligned}\partial_{a\lambda_k}N(0,\lambda,a)(z)=&\rho^2|z-p|^{2\alpha}f(z)e^{v_{\rho,\tau_1+\lambda_1}(z-p)-\ln f(p)+(\chi(\frac{z-p}{r_1})-1)\Delta^1(z)}\\&\times\chi\left(\frac{z-p}{r_1}\right)\left(\chi\left(\frac{z-p}{r_1}\right)-1\right)v^1_k(z)\partial_a\Delta^1(z)\delta_{k1},\end{aligned}$$

and

$$\begin{aligned}\partial_{aa}N(0,\lambda,a)(z)=&\frac{1}{r_1^2}\Delta\chi\left(\frac{z-p}{r_1}\right)\partial_{aa}\Delta^1(z)+\frac{8}{r_1}\partial_{\bar z}\chi\left(\frac{z-p}{r_1}\right)\cdot\partial_{aa\bar z}\Delta^1(z)\\&+\rho^2|z-p|^{2\alpha}f(z)e^{v_{\rho,\tau_1+\lambda_1}(z-p)-\ln f(p)+(\chi(\frac{z-p}{r_1})-1)\Delta^1(z)}\\&\times\left\{\left(\chi\left(\frac{z-p}{r_1}\right)-1\right)\partial_{aa}\Delta^1(z)+\left(\chi\left(\frac{z-p}{r_1}\right)-1\right)^2\partial_a\Delta^1(z)\partial_a\Delta^1(z)\right\},\end{aligned}$$

where $v^1_j(z):=\partial_{\lambda_j}v_{\rho,\tau_1+\lambda_1}(z-p)$ and $v^1_{jm}(z):=\partial_{\lambda_j\lambda_m}v_{\rho,\tau_1+\lambda_1}(z-p)$ for any j,m.

Similarly, in $B(q,1)$ we get

$$\begin{aligned}\partial_{\lambda_s\lambda_k}N(0,\lambda,a)(z) &= \frac{1}{r_2^2}\Delta\chi\left(\frac{z-q}{r_2}\right)v_{sk}^2(z)\delta_{s2}\delta_{k2}+\frac{8}{r_2}\partial_{\bar z}\chi\left(\frac{z-q}{r_2}\right)\cdot\partial_{\bar z}v_{sk}^2(z)\delta_{s2}\delta_{k2}\\ &\quad-\chi\left(\frac{z-q}{r_2}\right)\rho^2e^{v_{\rho,\tau_2+\lambda_2,\gamma}(z-q)}\left(v_s^2(z)v_k^2(z)+v_{sk}^2(z)\right)\delta_{s2}\delta_{k2}\\ &\quad+\rho^2g(z+a)e^{8\pi(1+\alpha)G(z+a,p)+8\pi G(z+a,q+a)+\chi(\frac{z-q}{r_2})\Delta^2(z)}\\ &\quad\times\chi\left(\frac{z-q}{r_2}\right)\left(v_{sk}^2(z)+\chi\left(\frac{z-q}{r_2}\right)v_s^2(z)v_k^2(z)\right)\delta_{s2}\delta_{k2},\end{aligned}$$

$$\begin{aligned}\partial_{a\lambda_k}N(0,\lambda,a)(z) &= \rho^2e^{v_{\rho,\tau_2+\lambda_2,\gamma}(z-q)+(\chi(\frac{z-q}{r_2})-1)\Delta^2(z)}\chi\left(\frac{z-q}{r_2}\right)v_k^2(z)\delta_{k2}\\ &\quad\times\Bigg[\left(\chi\left(\frac{z-q}{r_2}\right)-1\right)\partial_a\Delta^2(z)g(z+a)e^{-P_a(z+a)}\\ &\quad+\partial_a\left(g(z+a)e^{-P_a(z+a)}\right)\Bigg],\end{aligned}$$

and

$$\begin{aligned}\partial_{aa}N(0,\lambda,a)(z) &= \frac{1}{r_2^2}\Delta\chi\left(\frac{z-q}{r_2}\right)\partial_{aa}\Delta^2(z)+\frac{8}{r_2}\partial_{\bar z}\chi\left(\frac{z-q}{r_2}\right)\cdot\partial_{aa\bar z}\Delta^2(z)\\ &\quad+\rho^2e^{v_{\rho,\tau_2+\lambda_2,\gamma}(z-q)+(\chi(\frac{z-q}{r_2})-1)\Delta^2(z)}\Bigg\{\partial_{aa}\left(g(z+a)e^{-P_a(z+a)}\right)\\ &\quad+\left(\chi\left(\frac{z-q}{r_2}\right)-1\right)\Big[2\partial_a\Delta^2(z)\partial_a\Big(g(z+a)e^{-P_a(z+a)}\Big)\\ &\qquad+\partial_{aa}\Delta^2(z)g(z+a)e^{-P_a(z+a)}\Big]\\ &\quad+\left(\chi\left(\frac{z-q}{r_2}\right)-1\right)^2(\partial_a\Delta^2(z))^2g(z+a)e^{-P_a(z+a)}\Bigg\},\end{aligned}$$

where $v_j^2(z):=\partial_{\lambda_j}v_{\rho,\tau_2+\lambda_2,\gamma}(z-q)$ and $v_{jm}^2(z):=\partial_{\lambda_j\lambda_m}v_{\rho,\tau_2+\lambda_2,\gamma}(z-q)$ for any j,m.

We have that

$$|\partial_\tau v_{\rho,\tau,\lambda}(z)|+|\partial_{\tau\tau}v_{\rho,\tau,\lambda}(z)|+|z||\nabla\partial_{\tau\tau}v_{\rho,\tau,\lambda}(z)|=O(1)$$

for $\lambda\in\{0,\gamma\}$, $f(z)e^{-\ln f(p)}=1+O(|z-p|)$, $g(z+a)e^{-P_a(z+a)}=1+O(|z-q|^2)$, and

$$|\partial_a\Delta^1(z)|+|\partial_{aa}\Delta^1(z)|+|z-p||\partial_{aa\bar z}\Delta^1(z)|=O(1)\quad\text{ in } B(p,1),$$

$$|\partial_a\Delta^2(z)|+|\partial_{aa}\Delta^2(z)|+|z-q||\partial_{aa\bar z}\Delta^2(z)|=O(1)\quad\text{ in } B(q,1),$$

$$\left|\partial_a\left(g(z+a)e^{-P_a(z+a)}\right)\right|+\left|\partial_{aa}\left(g(z+a)e^{-P_a(z+a)}\right)\right|=O(|z-q|^2).$$

So we can derive $\|\partial^2N(0,\lambda,a)\|_{0,\beta,\nu_1-2,B(p,\frac12)}=O(r_1^{-\nu_1})$, $\|\partial^2N(0,\lambda,a)\|_{0,\beta,\nu_2-2,B(q,\frac12)}=O(r_2^{-\nu_2})$, where ∂^2 denotes some second-order derivative of $N(0,\lambda,a)$ in the variables λ and a. Since $\|\partial^2N(0,\lambda,a)\|_{0,\beta}=O(\rho^2)$ in $\tilde\Omega$, we conclude that $\|\partial^2N(0,\lambda,a)\|_Y=O(\sum_{i=1}^2r_i^{-\nu_i})$. Finally, we obtain

$$\|f_3(\lambda_1,a_1)-f_3(\lambda_2,a_2)\|_Y=O\left(\left(\sum_{i=1}^2r_i^{-\nu_i}\right)\|(w_1,\lambda_1,a_1)-(w_2,\lambda_2,a_2)\|_{\mathcal{E}'}^2\right).$$

Step 4. We define

$$K : \mathcal{E}' \to \mathcal{E}'$$
$$(w, \lambda, a) \to -L^{-1}_{(0,0,0)} \left[N(0,0,0) + \big(N(w,\lambda,a) - N(0,0,0) - L_{(0,0,0)}(w,\lambda,a) \big) \right].$$

Let us remark that (w, λ, a) is a zero for $N \Leftrightarrow (w, \lambda, a)$ is a fixed point for K. Summarizing the previous steps and by means of the uniform estimates derived in Theorem 4.13 below, we have

$$\begin{aligned} &\|K(w_1,\lambda_1,a_1) - K(w_2,\lambda_2,a_2)\|_{\mathcal{E}'} \\ &\quad \le C_0 \left(\sum_{i=1}^{2} r_i^{-\nu_i} \right) (\|(w_1,\lambda_1,a_1)\|_{\mathcal{E}'} + \|(w_2,\lambda_2,a_2)\|_{\mathcal{E}'}) \\ &\quad \times \|(w_1,\lambda_1,a_1) - (w_2,\lambda_2,a_2)\|_{\mathcal{E}'} \end{aligned}$$

for some constant $C_0 > 0$, where we have taken into account that

$$\|w\|_X \le \left(\sum_{i=1}^{2} r_i^{-\nu_i} \right) \cdot \|(w,\lambda,a)\|_{\mathcal{E}'}.$$

We can choose $\nu_1 \in (0,1)$ and $\nu_2 \in (1,2)$ in such a way that $(\nu_1, 1-\nu_1) \cap (\nu_2 - 1, 2-\nu_2) \neq \emptyset$ and let us fix some $\delta > 0$ in this set. Define $\sigma = \frac{4\alpha+5}{2\nu_1} + 1$, $r_i = \rho^{\frac{1}{\sigma\nu_i}}$, and note that $N(0,0,0) = \eta$ where η is the error term defined and estimated in section 5. In fact, from the technical estimates contained in sections 4 and 5 we see that $\|L^{-1}_{(0,0,0)}\eta\|_{\mathcal{E}'} = O(r_1^{1-\delta} + r_2^{2-\delta})$ (see (37) below), and we get

$$\|K(w,\lambda,a)\|_{\mathcal{E}'} \le C_1 \left[\left(\sum_{i=1}^{2} r_i^{-\nu_i} \right) \|(w,\lambda,a)\|^2_{\mathcal{E}'} + r_1^{1-\delta} + r_2^{2-\delta} \right]$$

for some constant $C_1 > 0$, where we have used the fact that $\|K(w,\lambda,a) - K(0,0,0)\|_{\mathcal{E}'} \le C_0(\sum_{i=1}^{2} r_i^{-\nu_i})\|(w,\lambda,a)\|^2_{\mathcal{E}'}$. Thus, the suitable choice of r_1, r_2, as expressed by property (38) below, allows us to conclude that for ρ small the map K is a contraction of the space

$$\mathcal{E}' \cap \left\{ (w,\lambda,a) : \|(w,\lambda,a)\|_{\mathcal{E}'} \le 2C_1 \left(r_1^{1-\delta} + r_2^{2-\delta} \right) \right\}$$

into itself. So there exists a unique fixed point $(w^\rho, \lambda^\rho, a^\rho)$ of the map K for $0 < \rho < \rho_0$, $\rho_0 > 0$ small, such that

$$\|w^\rho\|_{2,\beta,\tilde{\Omega}} + r_1^{\nu_1}\|w^\rho\|_{2,\beta,\nu_1,B(p,1)} + r_2^{\nu_2}\|w^\rho\|_{2,\beta,\nu_2,B(q,1)} + |\lambda^\rho| + |a^\rho| \le 2C_1 \left(r_1^{1-\delta} + r_2^{2-\delta} \right).$$

Hence $v_\rho = v(\rho, \lambda^\rho, a^\rho) + w^\rho \circ \Psi(a^\rho, \cdot)$ is the solution we are looking for in Theorem 1.4. It admits the desired properties in view of the definition of $v(\rho,\lambda,a)$, the fact that $\frac{\rho^2}{r_1^{2\alpha+4}} + \frac{\rho^2}{r_2^4} \to 0$ as $\rho \to 0$ and $w^\rho \to 0$ uniformly in Ω and in $C^{2,\beta}_{loc}(\Omega \setminus S)$, as follows by (38).

4. Invertibility of the linearized operator $L_{(0,0,0)}$.

4.1. Some local operator. The radial case. We are interested in studying the linearized operator of the equation

$$-\Delta v = \rho^2 |z|^{2\alpha} e^v \quad \text{in } B(0,1)\,, \ \alpha \geq 0 \tag{17}$$

about the radial solutions $v_{\rho,\tau}$ defined in (9) in case either $\alpha = 0$ or $\alpha \notin \mathbb{N}$. We define the linearized operator about $v_{\rho,\tau}$ by setting

$$L_{\rho,\tau} w = \Delta w + \rho^2 |z|^{2\alpha} e^{v_{\rho,\tau}} w$$

and we investigate the invertibility of $L_{\rho,\tau}$ under Dirichlet boundary condition. Inspired by the work of Caffarelli, Hardt, and Simon in [9] also used in [4], we have the following result.

PROPOSITION 4.1. *Let $\alpha \notin \mathbb{N}$. For all $\nu \in (0,1)$ and $\tau > 0$, there exist $\rho_0 > 0$, a continuous linear form $H^0_{\rho,\tau} : C^{0,\beta}_{\nu-2}(B(0,1)) \to \mathbb{R}$, and a linear operator $G_{\rho,\tau} : C^{0,\beta}_{\nu-2}(B(0,1)) \to C^{2,\beta}_{\nu}(B(0,1))$, uniformly bounded for $0 < \rho < \rho_0$, such that for all $\rho \in (0,\rho_0)$ and for all $f \in C^{0,\beta}_{\nu-2}(B(0,1))$ there exists a unique bounded solution w of*

$$\begin{cases} L_{\rho,\tau} w = f & \text{in } B(0,1), \\ w = 0 & \text{on } \partial B(0,1) \end{cases} \tag{18}$$

which can be uniquely decomposed as follows:

$$w(z) = G_{\rho,\tau}(f)(z) + H^0_{\rho,\tau}(f) \frac{\tau^2\rho^2 - |z|^{2(\alpha+1)}}{\tau^2\rho^2 + |z|^{2(\alpha+1)}}.$$

Moreover, $H^0_{\rho,\tau}(f) = 0$ for any f such that $\int_0^{2\pi} f(re^{i\theta})d\theta = 0$ for all $r \in (0,1]$.

PROPOSITION 4.2. *Let $\alpha = 0$, $\nu \in (1,2)$, and $\tau > 0$. There exist $\rho_0 > 0$, two continuous linear forms $H^0_{\rho,\tau} : C^{0,\beta}_{\nu-2}(B(0,1)) \to \mathbb{R}$, $H^1_{\rho,\tau} : C^{0,\beta}_{\nu-2}(B(0,1)) \to \mathbb{C}$, and a linear operator $G_{\rho,\tau} : C^{0,\beta}_{\nu-2}(B(0,1)) \to C^{2,\beta}_{\nu}(B(0,1))$, uniformly bounded for $0 < \rho < \rho_0$, such that for all $\rho \in (0,\rho_0)$ and for all $f \in C^{0,\beta}_{\nu-2}(B(0,1))$ there exists a unique bounded solution w of*

$$\begin{cases} L_{\rho,\tau} w = f & \text{in } B(0,1), \\ w = 0 & \text{on } \partial B(0,1) \end{cases}$$

which can be uniquely decomposed as follows:

$$w(z) = G_{\rho,\tau}(f)(z) + H^0_{\rho,\tau}(f) \frac{\tau^2\rho^2 - |z|^2}{\tau^2\rho^2 + |z|^2} + 2H^1_{\rho,\tau}(f) \cdot \frac{z}{\tau^2\rho^2 + |z|^2}.$$

Moreover, $H^0_{\rho,\tau}(f) = 0$, $H^1_{\rho,\tau}(f) = 0$ for any f such that $\int_0^{2\pi} f(re^{i\theta})d\theta = 0$ and $\int_0^{2\pi} f(re^{i\theta})e^{-i\theta}d\theta = 0$ for all $r \in (0,1]$.

By the Liouville formula (6), we get that, for any $j \in \mathbb{Z}$ and $|a| < \frac{\alpha+1}{|j|+\alpha+1}$,

$$\ln \frac{8(\alpha+1)^2\tau^2|1 + \frac{j+\alpha+1}{\alpha+1} a z^j|^2}{(\tau^2\rho^2 + |z|^{2(\alpha+1)}|1 + az^j|^2)^2}$$

solves (17). Hence by taking its derivative with respect to a, evaluated at $a = 0$, we obtain a solution of $L_{\rho,\tau} w = 0$ in the form

$$\frac{1}{\alpha+1} \frac{(j+\alpha+1)\tau^2\rho^2 + (j-\alpha-1)|z|^{2(\alpha+1)}}{\tau^2\rho^2 + |z|^{2(\alpha+1)}} z^j, \quad j \in \mathbb{Z}.$$

Consequently,

$$a_j(r) := \frac{(j+\alpha+1)\tau^2\rho^2 + (j-\alpha-1)r^{2(\alpha+1)}}{\tau^2\rho^2 + r^{2(\alpha+1)}} r^j, \quad j \in \mathbb{Z}$$

is a solution for the ordinary differential equation

$$\ddot{a}_j + \frac{1}{r}\dot{a}_j - \frac{j^2}{r^2} a_j + \frac{8(\alpha+1)^2\tau^2\rho^2 r^{2\alpha}}{(\tau^2\rho^2 + r^{2(\alpha+1)})^2} a_j = 0 \quad \text{in } (0,1).$$

Let us remark that for $j > 0$, $\{a_j(r), a_{-j}(r)\}$ is a set of linearly independent solutions for the same homogeneous equation. Hence any other solution is obtained as a linear combination of $a_j(r)$ and $a_{-j}(r)$. For $j = 0$, another independent solution can be explicitly found and it behaves like $\ln r$ as $r \to 0$. Since $\ln r$ and $a_{-j}(r)$, $j > 0$, are not bounded in a neighborhood of $r = 0$ and $a_j(1) \neq 0$, $j \geq 0$, by means of Fourier decomposition, it is easy to derive the following lemma.

LEMMA 4.3. *Let w be a bounded solution of*

$$\begin{cases} L_{\rho,\tau} w = 0 & \text{in } B(0,1), \\ w = 0 & \text{on } \partial B(0,1). \end{cases}$$

Then $w = 0$.

We decompose w and f into Fourier series:

$$w(z) = w_0(r) + 2\sum_{j=1}^{+\infty} w_j(r) \cdot e^{-ij\theta}, \quad f(z) = f_0(r) + 2\sum_{j=1}^{+\infty} f_j(r) \cdot e^{-ij\theta}.$$

So problem (18) becomes equivalent to

$$\text{(Pj)} \qquad \begin{cases} \ddot{w}_j + \frac{1}{r}\dot{w}_j - \frac{j^2}{r^2} w_j + \frac{8(\alpha+1)^2\tau^2\rho^2 r^{2\alpha}}{(\tau^2\rho^2 + r^{2(\alpha+1)})^2} w_j = f_j, \quad \text{in } (0,1), \\ w_j(1) = 0 \end{cases}$$

for $j \in \mathbb{N}$. Set $j_\alpha = \min\{j \in \mathbb{N} : j > \alpha + 1\}$ and $m_\alpha = \max\{j \in \mathbb{N} : j < \alpha + 1\}$.

Step 1. By the variation of constants formula, for $j \geq j_\alpha$ and $\nu > -j$,

$$w_j(r) = \left(\int_1^r \frac{ds}{s a_j^2(s)} \int_0^s t a_j(t) f_j(t) dt \right) a_j(r), \quad r > 0$$

defines a solution of (Pj). Since $0 < j - \alpha - 1 \leq \frac{(j+\alpha+1)\tau^2\rho^2 + (j-\alpha-1)r^{2(\alpha+1)}}{\tau^2\rho^2 + r^{2(\alpha+1)}} \leq j + \alpha + 1$, we have that for $-j < \nu < j$ $r^{-\nu}|w_j(r)| \leq \frac{(j+\alpha+1)^2}{(j-\alpha-1)^2} \frac{1}{j^2-\nu^2} \|f_j\|_{0,\beta,\nu-2}$ and, by classical rescaled Schauder estimates (see [22]), we find

$$\|w_j\|_{2,\beta,\nu} \leq C \frac{(j+\alpha+1)^2}{(j-\alpha-1)^2} \frac{1}{j^2-\nu^2} \|f_j\|_{0,\beta,\nu-2}$$

for suitable $C > 0$. Finally, for $-j_\alpha < \nu < j_\alpha$, we can define $h(z) = 2\sum_{j=j_\alpha}^{+\infty} w_j(r) \cdot e^{-ij\theta}$ and, since $\|f_j\|_{0,\beta,\nu-2} \le \|f\|_{0,\beta,\nu-2}$, there holds the estimate

$$\sum_{j=j_\alpha}^{+\infty} \|w_j\|_{2,\beta,\nu} \le C \left(\sum_{j=j_\alpha}^{+\infty} \frac{(j+\alpha+1)^2}{(j-\alpha-1)^2} \frac{1}{j^2-\nu^2} \right) \|f\|_{0,\beta,\nu-2}.$$

So $h(z)$ is a well-defined function in $C_\nu^{2,\beta}(B(0,1))$ and satisfies

$$\begin{cases} L_{\rho,\tau} h = 2\sum_{j=j_\alpha}^{+\infty} f_j(r) \cdot e^{-ij\theta} & \text{in } B(0,1), \\ h = 0 & \text{on } \partial B(0,1) \end{cases}$$

together with the estimate $\|h\|_{2,\beta,\nu} \le C\|f\|_{0,\beta,\nu-2}$ for $-j_\alpha < \nu < j_\alpha$.

Step 2. For $0 < j \le m_\alpha$, $\nu > -j$, and $r > \bar r := (\frac{j+\alpha+1}{\alpha+1-j}\tau^2\rho^2)^{\frac{1}{2\alpha+2}}$, it is possible to define

$$\tilde w_j(r) = \left(\int_1^r \frac{ds}{s a_j^2(s)} \int_0^s t a_j(t) f_j(t) dt \right) a_j(r).$$

Note that $a_j(\bar r) = 0$ and hence $\tilde w_j(r)$ is not well defined up to $\bar r$. To be able to obtain an extension of $\tilde w_j$ for $r \le \bar r$, define $\psi_j(s,\rho) = (s-\bar r)^2 \frac{1}{s a_j^2(s)} \int_0^s t a_j(t) f_j(t) dt$ and set

$$w_j(r) = a_j(r) \left[\int_1^r \frac{\psi_j(s,\rho) - \psi_j(\bar r,\rho)}{(s-\bar r)^2} ds - \frac{1-r}{(1-\bar r)(r-\bar r)} \psi_j(\bar r,\rho) \right]. \tag{19}$$

The function w_j is well defined also for $r \le \bar r$ and gives an extension of $\tilde w_j$. We will refer to the first and second terms in the expression of $w_j(r)$ above as $w_j^1(r)$ and $w_j^2(r)$, respectively. Since for $0 < r < \bar r - \delta$, $\delta > 0$, we have

$$\begin{aligned} w_j(r) = a_j(r) \Bigg[& \int_1^{\bar r - \delta} \frac{\psi_j(s,\rho) - \psi_j(\bar r,\rho)}{(s-\bar r)^2} ds \\ & + \int_{\bar r - \delta}^r \frac{ds}{s a_j(s)^2} \int_0^s t a_j(t) f_j(t) dt + \left(\frac{1}{1-\bar r} + \frac{1}{\delta} \right) \psi_j(\bar r,\rho) \Bigg], \end{aligned}$$

the function $w_j(r)$ does solve (Pj) for $r > 0$. Note that for $\nu < j$, we have that $\sup_{r\in(\bar r,1)} r^{-\nu} |w_j(r)| \le C\|f_j\|_{0,\beta,\nu-2}$. In fact, for $r \ge 2\bar r$ we find $|w_j(r)| = |\tilde w_j(r)| \le C\|f_j\|_{0,\beta,\nu-2} r^\nu$ as $\frac{1}{a_j^2(s)} = O(\frac{1}{s^{2j}})$ for $s \ge r$. While for $\bar r \le r \le 2\bar r$ there holds

$$\begin{aligned} |w_j(r)| = |\tilde w_j(r)| &\le C\|f_j\|_{0,\beta,\nu-2} \left(\frac{r}{\bar r} - 1 \right) \bar r^j \int_r^1 \frac{(\tau^2\rho^2 + s^{2(\alpha+1)})^2 s^{\nu-j-1} ds}{[(j+\alpha+1)\tau^2\rho^2 + (j-\alpha-1)s^{2(\alpha+1)}]^2} \\ &\le C\|f_j\|_{0,\beta,\nu-2} \left(\frac{r}{\bar r} - 1 \right) \bar r^\nu \left[\bar r \int_r^{2\bar r} \frac{ds}{(s-\bar r)^2} + 1 \right] \le C\|f_j\|_{0,\beta,\nu-2} \bar r^\nu. \end{aligned}$$

Since $|\psi_j(s,\rho)| \le C\|f_j\|_{0,\beta,\nu-2} \bar r^2 s^{\nu-j-1}$ for $s \le \bar r$, then $|\psi_j(\bar r,\rho)| \le C\|f_j\|_{0,\beta,\nu-2} \bar r^{\nu-j+1}$ and in turn for $s \le \frac{\bar r}{2}$

$$\left| \frac{\psi_j(s,\rho) - \psi_j(\bar r,\rho)}{(s-\bar r)^2} \right| \le C\|f_j\|_{0,\beta,\nu-2} \left(s^{\nu-j-1} + \bar r^{\nu-j-1} \right). \tag{20}$$

For $s \in [\frac{\bar r}{2}, 2\bar r] \setminus \{\bar r\}$, we decompose

$$\frac{\psi_j(s,\rho)-\psi_j(\bar r,\rho)}{(s-\bar r)^2} = \left[\frac{1}{sa_j^2(s)} - \frac{\bar r^{-(2j-1)}(s-\bar r)^{-2}}{[(\alpha+1)^2-j^2]^2}\right]\int_0^{\bar r} ta_j(t)f_j(t)dt + \frac{1}{sa_j^2(s)}\int_{\bar r}^s ta_j(t)f_j(t)dt$$

and hence, using a homogeneity argument, we get

$$\begin{aligned}&\left|\frac{\psi_j(s,\rho)-\psi_j(\bar r,\rho)}{(s-\bar r)^2}\right| \\ \le\ & C\|f_j\|_{0,\beta,\nu-2}\bar r^{\nu-j-1}\left\{\frac{[1+z^{2(\alpha+1)}]^2}{(1-z^{2(\alpha+1)})^2 z^{2j+1}}\left|\int_1^z \frac{1-t^{2(\alpha+1)}}{1+t^{2(\alpha+1)}}t^{\nu+j-1}dt\right|\right. \\ &\left.+\left|\frac{[(\alpha+1-j)+(\alpha+1+j)z^{2(\alpha+1)}]^2}{(1-z^{2(\alpha+1)})^2 z^{2j+1}}-\frac{1}{(z-1)^2}\right|\right\}\Bigg|_{z=\frac{s}{\bar r}\in[\frac12,2]\setminus\{1\}}.\end{aligned}$$

Consequently, for $\frac{\bar r}{2} \le s \le 2\bar r$ we obtain

$$\left|\frac{\psi_j(s,\rho)-\psi_j(\bar r,\rho)}{(s-\bar r)^2}\right| \le C\|f_j\|_{0,\beta,\nu-2}s^{\nu-j-1}. \tag{21}$$

Finally, it is easy to see that for $r \le 2\bar r$ and for w_j^2 there holds

$$\sup_{r\in(0,2\bar r)} r^{-\nu}|w_j^2(r)| \le C\|f_j\|_{0,\beta,\nu-2}\sup_{0\le t\le 2} t^{-\nu+j}\frac{|1-t^{2(\alpha+1)}|}{|1-t|} \le C\|f_j\|_{0,\beta,\nu-2}$$

in view of the estimate available for $\psi_j(\bar r,\rho)$ and $\nu < j$. Since $|w_j^1(2\bar r)| \le |w_j(2\bar r)| + |w_j^2(2\bar r)| \le C\|f_j\|_{0,\beta,\nu-2}\bar r^{\nu}$, then $|\int_1^{2\bar r}\frac{\psi_j(s,\rho)-\psi_j(\bar r,\rho)}{(s-\bar r)^2}ds| \le C\|f_j\|_{0,\beta,\nu-2}\bar r^{\nu-j}$. So we derive, by splitting the integral in (19) as $\int_1^r = \int_1^{2\bar r} + \int_{2\bar r}^r$ and using (20) and (21), the estimate $\sup_{r\in(0,\bar r)} r^{-\nu}|w_j^1(r)| \le C\|f_j\|_{0,\beta,\nu-2}$ for $\nu < j$. Finally, the estimate $\sup_{r\in(0,1)} r^{-\nu}|w_j(r)| \le C\|f_j\|_{0,\beta,\nu-2}$ does hold and, using classical rescaled Schauder estimates, we get the existence of some constant $C > 0$ such that $\|w_j\|_{2,\beta,\nu} \le C\|f\|_{0,\beta,\nu-2}$ for $0 < j \le m_\alpha$ and $-j < \nu < j$.

Step 3. Analogously, for $j = 0$ and $\nu > 0$, it is possible to consider, for $0 < r < \bar r := (\tau\rho)^{\frac{1}{\alpha+1}}$,

$$\tilde w_0(r) = \left(\int_0^r \frac{ds}{sa_0^2(s)}\int_0^s ta_0(t)f_0(t)dt\right)a_0(r).$$

By defining $\psi_0(s,\rho) = (s-\bar r)^2\frac{1}{sa_0^2(s)}\int_0^s ta_0(t)f_0(t)dt$, we can extend $\tilde w_0$ for $r \ge \bar r$ by considering

$$\hat w_0(r) = a_0(r)\left[\int_0^r \frac{\psi_0(s,\rho)-\psi_0(\bar r,\rho)}{(s-\bar r)^2}ds + \frac{r}{\bar r(\bar r-r)}\psi_0(\bar r,\rho)\right]$$

which defines a solution for $(P0)$, with $\hat w_0(1) \ne 0$ in general. We have the estimate $\sup_{r\in(0,\bar r)} r^{-\nu}|\hat w_0(r)| \le C\|f_0\|_{0,\beta,\nu-2}$. In fact, for $r \le \frac{\bar r}{2}$ we see that $|\hat w_0(r)| = |\tilde w_0(r)| \le C\|f_0\|_{0,\beta,\nu-2}r^\nu$ since $\frac{1}{a_0^2(s)} = O(1)$ for $s \le r$. While for $\frac{\bar r}{2} \le r \le \bar r$ there holds

$$|\hat w_0(r)| = |\tilde w_0(r)| \le C\|f_0\|_{0,\beta,\nu-2}\left(1-\frac{r}{\bar r}\right)\bar r^{\nu+1}\int_0^r \frac{ds}{(s-\bar r)^2} \le C\|f_0\|_{0,\beta,\nu-2}\bar r^\nu.$$

Furthermore, since $|\psi_0(s,\rho)| \le C\|f_0\|_{0,\beta,\nu-2}\bar r^2 s^{\nu-1}$ for $s \le \bar r$, as above for $s \le \frac{\bar r}{2}$ we obtain

$$\left|\frac{\psi_0(s,\rho)-\psi_0(\bar r,\rho)}{(s-\bar r)^2}\right| \le C\|f_0\|_{0,\beta,\nu-2}\left(s^{\nu-1}+\bar r^{\nu-1}\right). \tag{22}$$

On the other hand, for $s \ge \frac{\bar r}{2}$ we have

$$\left|\frac{\psi_0(s,\rho)-\psi_0(\bar r,\rho)}{(s-\bar r)^2}\right| \le C\|f_0\|_{0,\beta,\nu-2}s^{\nu-1}. \tag{23}$$

In fact, (23) follows as in (21) when $s \in [\frac{\bar r}{2}, 2\bar r] \setminus \{\bar r\}$. While for $s \ge 2\bar r$, we have

$$\begin{aligned}\left|\frac{\psi_0(s,\rho)-\psi_0(\bar r,\rho)}{(s-\bar r)^2}\right| &= \left[\frac{1}{sa_0^2(s)}-\frac{\bar r}{(\alpha+1)^4(s-\bar r)^2}\right]\int_0^{\bar r} ta_0(t)f_0(t)dt\\ &\quad+\frac{1}{sa_0^2(s)}\int_{\bar r}^{s} ta_0(t)f_0(t)dt\\ &\le C\|f_0\|_{0,\beta,\nu-2}\left(\frac{\bar r^\nu}{s}+\frac{s^{\nu-1}}{(\frac{s}{\bar r})^{\nu-1}(\frac{s}{\bar r}-1)^2}+s^{\nu-1}\right).\end{aligned}$$

Finally, since $\nu > 0$ it is easy to see that $\sup_{r\in(\bar r,1)} r^{-\nu}|a_0(r)\psi_0(\bar r,\rho)\frac{r}{\bar r(r-\bar r)}| \le C\|f_0\|_{0,\beta,\nu-2}$. While by (22) and (23) for $r \ge \bar r$ we get $|a_0(r)\int_0^r \frac{\psi_0(s,\rho)-\psi_0(\bar r,\rho)}{(s-\bar r)^2}ds| \le C\|f_0\|_{0,\beta,\nu-2}r^\nu$. Hence $\sup_{r\in(0,1)} r^{-\nu}|\hat w_0(r)| \le C\|f_0\|_{0,\beta,\nu-2}$. Consequently, by classical rescaled Schauder estimates, we find a suitable constant $C > 0$ such that $\|\hat w_0\|_{2,\beta,\nu} \le C\|f\|_{0,\beta,\nu-2}$. We set now

$$w_0(r) = \hat w_0(r) + H^0_{\rho,\tau}(f)\frac{\tau^2\rho^2 - r^{2(\alpha+1)}}{\tau^2\rho^2 + r^{2(\alpha+1)}}, \tag{24}$$

where $H^0_{\rho,\tau}(f) \in \mathbb{R}$ is such that $w_0(1) = 0$. Hence $w_0(r)$ is a solution for $(P0)$ and for $\nu > 0$,

$$|H^0_{\rho,\tau}(f)| \le C|\hat w_0(1)| \le C\|f\|_{0,\beta,\nu-2}.$$

Notice that for $\alpha > 0$, $\alpha \notin \mathbb{N}$, Steps 1–3 lead to the proof of Proposition 4.1 by choosing $\nu \in (0,1)$ and $G_{\rho,\tau}(f) = \hat w_0(r) + 2\sum_{j=1}^{+\infty} w_j(r)\cdot e^{-ij\theta}$.

Step 4. To obtain Proposition 4.2, it remains for problem $(P1)$ to be considered with $\alpha = 0$ while for the validity of Steps 1–3 we must specify $\nu \in (0,2)$. To account also for $(P1)$ we further specify $1 < \nu < 2$. Then it is possible to define

$$\begin{aligned}\hat w_1(r) &= \left(\int_0^r \frac{ds}{sa_1^2(s)}\int_0^s ta_1(t)f_1(t)dt\right)a_1(r)\\ &= \frac{r}{\tau^2\rho^2+r^2}\int_0^r \frac{(\tau^2\rho^2+s^2)^2}{s^3}ds\int_0^s \frac{t^2}{\tau^2\rho^2+t^2}f_1(t)dt.\end{aligned}$$

To estimate $\|\hat w_1(r)\|_{2,\beta,\nu}$, introduce $z = \frac{r}{\tau\rho}$ and observe that

$$\begin{aligned}\sup_{r\in(0,1)} r^{-\nu}|\hat w_1(r)| &\le \|f_1\|_{0,\beta,\nu-2}\sup_{z\in(0,(\tau\rho)^{-1})}\frac{z^{1-\nu}}{1+z^2}\int_0^z\frac{(1+s^2)^2}{s^3}ds\int_0^s\frac{t^\nu}{1+t^2}dt\\ &\le C\|f\|_{0,\beta,\nu-2}.\end{aligned}$$

Set

$$w_1(r) = \hat{w}_1(r) + \overline{H^1_{\rho,\tau}(f)} \frac{r}{\tau^2\rho^2 + r^2}, \tag{25}$$

where $H^1_{\rho,\tau}(f) \in \mathbb{C}$ is such that $w_1(1) = 0$. Hence $w_1(r)$ is a solution for $(P1)$ and

$$|H^1_{\rho,\tau}(f)| \le C|\hat{w}_1(1)| \le C\|f\|_{0,\beta,\nu-2}.$$

Therefore, for $\alpha = 0$ Proposition 4.2 also follows with

$$G_{\rho,\tau}(f) = \hat{w}_0(r) + 2\hat{w}_1(r) \cdot e^{-i\theta} + 2\sum_{j=2}^{+\infty} w_j(r) \cdot e^{-ij\theta}$$

whenever $\nu \in (1,2)$. Finally, using Lemma 4.3 we can deduce the uniqueness of $w_j(r)$. The uniqueness of the decomposition (24) follows by evaluating $w_0(r)$ at $r = 0$. Similarly, if $\alpha = 0$ the uniqueness of the decomposition (25) follows by evaluating $\frac{w_1(r)}{r}$ at $r = 0$. Hence Propositions 4.1 and 4.2 are completely established.

Remark 4.4. The function $G_{\rho,\tau}(f)$ is the unique solution in $C^{2,\beta}_{\nu}(B(0,1))$ for $L_{\rho,\tau}w = f$ in $B(0,1)$ such that

$$G_{\rho,\tau}(f)|_{\partial B(0,1)} = \begin{cases} \hat{w}_0(1) & \text{if } \alpha \notin \mathbb{N}, \\ \hat{w}_0(1) + 2\hat{w}_1(1) \cdot e^{-i\theta} & \text{if } \alpha = 0. \end{cases}$$

4.2. Some local operator. The nonradial case. In case $\alpha = 0$, we discuss now the invertibility of the operator

$$L_{\rho,\tau,\gamma}w = \Delta w + \rho^2 e^{v_{\rho,\tau,\gamma}} w$$

under Dirichlet boundary condition. The following result holds.

PROPOSITION 4.5. *Let $\alpha = 0$. For all $\nu \in (1,2)$ and $\gamma \in \mathbb{C}$, $|\gamma| < \frac{1}{3}$, $\tau > 0$, there exist $\rho_0 > 0$, two continuous linear forms $H^0_{\rho,\tau,\gamma} : C^{0,\beta}_{\nu-2}(B(0,1)) \to \mathbb{R}$, $H^1_{\rho,\tau,\gamma} : C^{0,\beta}_{\nu-2}(B(0,1)) \to \mathbb{C}$, and a linear operator $G_{\rho,\tau,\gamma} : C^{0,\beta}_{\nu-2}(B(0,1)) \to C^{2,\beta}_{\nu}(B(0,1))$, uniformly bounded for $0 < \rho < \rho_0$, such that for all $\rho \in (0,\rho_0)$ and for all $f \in C^{0,\beta}_{\nu-2}(B(0,1))$ there exists a unique bounded solution w of*

$$\begin{cases} L_{\rho,\tau,\gamma}w = f & \text{in } B(0,1), \\ w = 0 & \text{on } \partial B(0,1) \end{cases}$$

which can be uniquely decomposed as

$$w(z) = G_{\rho,\tau,\gamma}(f)(z) + H^0_{\rho,\tau,\gamma}(f)\partial_\tau v_{\rho,\tau,\gamma} + 2H^1_{\rho,\tau,\gamma}(f) \cdot \partial_{\bar{z}} v_{\rho,\tau,\gamma}.$$

Moreover, the following estimates hold:

$$\|G_{\rho,\tau,\gamma}(f)\|_{2,\beta,\nu} \le C\left(\|G_{\rho,\tau}(f)\|_{2,\beta,\nu} + \rho^2|H^0_{\rho,\tau}(f)| + |H^1_{\rho,\tau}(f)|\right), \tag{26}$$

$$|H^0_{\rho,\tau,\gamma}(f)| \le C\left(\rho^2\|G_{\rho,\tau}(f)\|_{2,\beta,\nu} + |H^0_{\rho,\tau}(f)| + \rho^2|H^1_{\rho,\tau}(f)|\right), \tag{27}$$

$$|H^1_{\rho,\tau,\gamma}(f)| \le C\left(\rho^2\|G_{\rho,\tau}(f)\|_{2,\beta,\nu} + \rho^2|H^0_{\rho,\tau}(f)| + |H^1_{\rho,\tau}(f)|\right), \tag{28}$$

$$\begin{aligned}\|\partial_r G_{\rho,\tau,\gamma}(f)|_{\partial B(0,1)}\|_{1,\beta} \le C\big(&\|\partial_r G_{\rho,\tau}(f)|_{\partial B(0,1)}\|_{1,\beta} + \rho^2\|G_{\rho,\tau}(f)\|_{2,\beta,\nu}\\ &+ \rho^2|H^0_{\rho,\tau}(f)| + |H^1_{\rho,\tau}(f)|\big)\end{aligned} \tag{29}$$

for some constant $C > 0$.

Proof. In case $\alpha = 0$, we compute

$$\begin{aligned}\lim_{\rho\to 0}\partial_\tau v_{\rho,\tau,\gamma}(z) &= \lim_{\rho\to 0}\left(\frac{2}{\tau}\frac{|z|^2|1+\gamma z^2|^2-\tau^2\rho^2}{|z|^2|1+\gamma z^2|^2+\tau^2\rho^2}\right) = \frac{2}{\tau},\\ \lim_{\rho\to 0}\partial_{\bar z} v_{\rho,\tau,\gamma}(z) &= \lim_{\rho\to 0}\left(\frac{6\bar\gamma\bar z}{1+3\bar\gamma\bar z^2} - 2\frac{z(1+\gamma z^2)(1+3\bar\gamma\bar z^2)}{|z|^2|1+\gamma z^2|^2+\tau^2\rho^2}\right)\\ &= 6\bar\gamma\bar z\left(\sum_{k=0}^{+\infty}(-1)^k 3^k\bar\gamma^k\bar z^{2k}\right) - 2(1+3\bar\gamma\bar z^2)\left(\sum_{k=0}^{+\infty}(-1)^k\bar\gamma^k\bar z^{2k-1}\right)\\ &= -\frac{2}{\bar z} + 2\bar\gamma\bar z + \eta^\perp(z)\end{aligned}$$

uniformly on compact sets in $B(0,1)\setminus\{0\}$, where $\eta^\perp(z) = 2\sum_{k=0}^{+\infty}(-1)^{k+1}(3^{k+2}-2)\bar\gamma^{k+2}\bar z^{2k+3}$ is orthogonal to $\{1, e^{\pm i\theta}\}$ (in the sense $\eta^\perp(re^{i\theta})$ is orthogonal to 1 and $e^{\pm i\theta}$ in $L^2([0,2\pi])$ for any $r\in(0,1]$) and it is a harmonic function. Set $\mathrm{Span}\{1, e^{-i\theta}\} = \{a_0 + 2a_1\cdot e^{-i\theta} :\ a_0\in\mathbb{R},\ a_1\in\mathbb{C}\}$ and define π as the orthogonal projection over $\mathrm{Span}\{1, e^{-i\theta}\}$. Define the mapping $\psi_\rho : (h_0,h_1)\in\mathbb{R}\times\mathbb{C}\to(\psi^1_\rho(h_0,h_1),\psi^2_\rho(h_0,h_1))\in\mathbb{R}\times\mathbb{C}$ by setting

$$\psi^1_\rho(h_0,h_1) + 2\psi^2_\rho(h_0,h_1)\cdot e^{-i\theta} = \pi\left(h_0\partial_\tau v_{\rho,\tau,\gamma}(e^{i\theta}) + 2h_1\cdot\partial_{\bar z}v_{\rho,\tau,\gamma}(e^{i\theta})\right).$$

Note that $\psi_\rho\to\psi_0$ as $\rho\to 0$ in the operatorial norm, where $\psi_0(h_0,h_1) = (\frac{2}{\tau}h_0, -2\bar h_1 + 2\gamma h_1)$ is an invertible operator for $|\gamma|<1$ with inverse $\psi_0^{-1}(\tilde h_0,\tilde h_1) = (\frac{\tau}{2}\tilde h_0, -\frac{1}{2(1-|\gamma|^2)}\cdot(\bar\gamma\tilde h_1 + \bar{\tilde h}_1))$. Hence, for ρ small ψ_ρ is invertible with uniformly bounded inverse. Let $f\in C^{0,\beta}_{\nu-2}(B(0,1))$ be a given function and $\nu\in(1,2)$. By Remark 4.4, there exists a unique $w_0\in C^{2,\beta}_\nu(B(0,1))$ such that

$$\begin{cases} L_{\rho,\tau}w_0 = f \quad \text{in } B(0,1),\\ w_0\,|_{\partial B(0,1)} = \tilde h_0 + 2\tilde h_1\cdot e^{-i\theta}\in\mathrm{Span}\{1, e^{-i\theta}\}.\end{cases}$$

Let $(h_0,h_1) = \psi_\rho^{-1}(\tilde h_0,\tilde h_1)$. We define on $\partial B(0,1)$

$$\phi(\theta) := h_0\partial_\tau v_{\rho,\tau,\gamma}(e^{i\theta}) + 2h_1\cdot\partial_{\bar z}v_{\rho,\tau,\gamma}(e^{i\theta}) - \tilde h_0 - 2\tilde h_1\cdot e^{-i\theta}$$

in such a way that $\pi\phi = 0$. We extend ϕ in $B(0,1)$ as $\tilde\phi(z) = \sigma(r)\phi(\theta)$, where $0\le\sigma\le 1$ is a smooth function with $\sigma\equiv 1$ in $[\frac12,1]$ and $\sigma\equiv 0$ in $[0,\frac14]$. Since $L_{\rho,\tau}\tilde\phi\in\mathrm{Span}\{1, e^{-i\theta}\}^\perp$, by Proposition 4.2 we get $H^0_{\rho,\tau}(-L_{\rho,\tau}\tilde\phi) = 0$, $H^1_{\rho,\tau}(-L_{\rho,\tau}\tilde\phi) = 0$ and hence $w_1 := G_{\rho,\tau}(-L_{\rho,\tau}\tilde\phi)$ vanishes on $\partial B(0,1)$. The function $w_2 := w_0 + \tilde\phi + w_1\in C^{2,\beta}_\nu(B(0,1))$ solves

$$\begin{cases} L_{\rho,\tau}w_2 = f \quad \text{in } B(0,1),\\ w_2\,|_{\partial B(0,1)} = h_0\partial_\tau v_{\rho,\tau,\gamma}(e^{i\theta}) + 2h_1\cdot\partial_{\bar z}v_{\rho,\tau,\gamma}(e^{i\theta})\end{cases}$$

with $\|w_2\|_{2,\beta,\nu}\le C\|f\|_{0,\beta,\nu-2}$. Moreover, w_2 is the unique solution in $C^{2,\beta}_\nu(B(0,1))$ for the problem. If w_2' is a solution in $C^{2,\beta}_\nu(B(0,1))$ with

$$w_2'\,|_{\partial B(0,1)} = h_0'\partial_\tau v_{\rho,\tau,\gamma}(e^{i\theta}) + 2h_1'\cdot\partial_{\bar z}v_{\rho,\tau,\gamma}(e^{i\theta}) = \tilde h_0' + 2\tilde h_1'\cdot e^{-i\theta} + \phi',$$

then by the uniqueness part in Proposition 4.2 we derive $w_0 = w_2' - \tilde\phi' - w_1'$, $\tilde h_0' = \tilde h_0$, $\tilde h_1' = \tilde h_1$, where $w_1' = G_{\rho,\tau}(-L_{\rho,\tau}\tilde\phi')$ and $\tilde\phi'$ extends ϕ' as before. Since ψ_ρ is injective, then $h_0' = h_0$, $h_1' = h_1$, $\phi' = \phi$ and hence $\tilde\phi' + w_1' = \tilde\phi + w_1$ and $w_2' = w_2$.

Then $L_{\rho,\tau}$, as an operator between

$$\{w \in C^{2,\beta}_\nu(B(0,1)) : w\,|_{\partial B(0,1)} = h_0\partial_\tau v_{\rho,\tau,\gamma}(e^{i\theta}) + 2h_1\cdot\partial_{\bar z} v_{\rho,\tau,\gamma}(e^{i\theta}),\ (h_0,h_1)\in\mathbb{R}\times\mathbb{C}\}$$

and $C^{0,\beta}_{\nu-2}(B(0,1))$, is an isomorphism with inverse uniformly bounded with respect to $\|\cdot\|_{0,\beta,\nu-2}$ and $\|\cdot\|_{2,\beta,\nu}$. We will denote this inverse operator as $L^{-1}_{\rho,\tau}$. Moreover, we have the estimate $|h_0(f)| + |h_1(f)| \le C\|f\|_{0,\beta,\nu-2}$. We use now a perturbation argument to prove Proposition 4.5. Since for $z, x, y \in B(0,1)$ we have

$$|v_{\rho,\tau,\gamma} - v_{\rho,\tau}|(z) = \left|\ln\frac{(\tau^2\rho^2+|z|^2)^2|1+3\gamma z^2|^2}{(\tau^2\rho^2+|z|^2|1+\gamma z^2|^2)^2}\right| \le C|z|^2,$$

$$\begin{aligned}\left|\frac{(v_{\rho,\tau,\gamma}-v_{\rho,\tau})(x) - (v_{\rho,\tau,\gamma}-v_{\rho,\tau})(y)}{|x-y|^\beta}\right| &\le 2|\partial_z(v_{\rho,\tau,\gamma}-v_{\rho,\tau})(\xi)||x-y|^{1-\beta}\\ &\le C\left(\max\{|x|,|y|\}\right)^{2-\beta}\end{aligned}$$

for some point ξ on the segment joining x and y, we get that $\|v_{\rho,\tau,\gamma} - v_{\rho,\tau}\|_{0,\beta,2} \le C$. Hence, for $w \in C^{2,\beta}_\nu(B(0,1))$ we have the estimate

$$\|(L_{\rho,\tau,\gamma} - L_{\rho,\tau})w\|_{0,\beta,\nu-2} = \rho^2\|(e^{v_{\rho,\tau,\gamma}} - e^{v_{\rho,\tau}})w\|_{0,\beta,\nu-2} \le C\rho^2\|w\|_{2,\beta,\nu}. \tag{30}$$

A solution for the problem

$$\begin{cases} L_{\rho,\tau,\gamma}w = f \quad \text{in } B(0,1),\\ w\,|_{\partial B(0,1)} = -H^0_{\rho,\tau,\gamma}(f)\partial_\tau v_{\rho,\tau,\gamma}(e^{i\theta}) - 2H^1_{\rho,\tau,\gamma}(f)\cdot\partial_{\bar z}v_{\rho,\tau,\gamma}(e^{i\theta})\end{cases}$$

corresponds to a fixed point for the map $w \to L^{-1}_{\rho,\tau}f + L^{-1}_{\rho,\tau}(L_{\rho,\tau} - L_{\rho,\tau,\gamma})w$. By (30) we deduce that this map is a contraction. So it has a unique fixed point $w = G_{\rho,\tau,\gamma}(f)$ which satisfies $\|G_{\rho,\tau,\gamma}(f)\|_{2,\beta,\nu} \le C\|L^{-1}_{\rho,\tau}(f)\|_{2,\beta,\nu}$. At this point, we deduce (26)–(29): since

$$|\partial_\tau v_{\rho,\tau,\gamma}(e^{i\theta}) - \frac{2}{\tau}| + |\partial_{\bar z}v_{\rho,\tau,\gamma}(e^{i\theta}) - \left(-2e^{i\theta} + 2\bar\gamma e^{-i\theta} + \eta^\perp(e^{i\theta})\right)| \le C\rho^2,$$

there holds the estimate $\|\psi_\rho - \psi_0\| + \|\psi_\rho^{-1} - \psi_0^{-1}\| \le C\rho^2$. Therefore

$$\begin{aligned}(h_0,h_1) &= \psi_0^{-1}(\tilde h_0,\tilde h_1) + O\left(\rho^2|H^0_{\rho,\tau}(f)| + \rho^2|H^1_{\rho,\tau}(f)|\right)\\ &= \left(O(|H^0_{\rho,\tau}(f)| + \rho^2|H^1_{\rho,\tau}(f)|), O(\rho^2|H^0_{\rho,\tau}(f)| + |H^1_{\rho,\tau}(f)|)\right)\end{aligned} \tag{31}$$

as $\tilde h_0 = -H^0_{\rho,\tau}(f)\frac{\tau^2\rho^2-1}{\tau^2\rho^2+1}$ and $\tilde h_1 = -\overline{H^1_{\rho,\tau}(f)}\frac{1}{\tau^2\rho^2+1}$. On $\partial B(0,1)$ there holds

$$\begin{aligned}\phi(\theta) &= \frac{2}{\tau}h_0 + 2(-2\bar h_1 + 2\gamma h_1)\cdot e^{-i\theta} - \tilde h_0 - 2\tilde h_1\cdot e^{-i\theta} + 2h_1\cdot\eta^\perp(e^{i\theta})\\ &\quad + O\left(\rho^2|h_0| + \rho^2|h_1|\right) = 2h_1\cdot\eta^\perp(e^{i\theta}) + O\left(\rho^2|H^0_{\rho,\tau}(f)| + \rho^2|H^1_{\rho,\tau}(f)|\right)\\ &= O\left(\rho^2|H^0_{\rho,\tau}(f)| + |H^1_{\rho,\tau}(f)|\right)\end{aligned}$$

and we deduce

$$\|\tilde\phi\|_{2,\beta,\nu} + \|w_1\|_{2,\beta,\nu} = O\left(\rho^2|H^0_{\rho,\tau}(f)| + |H^1_{\rho,\tau}(f)|\right). \tag{32}$$

Since $G_{\rho,\tau,\gamma}(f) = L^{-1}_{\rho,\tau} f + L^{-1}_{\rho,\tau}(L_{\rho,\tau} - L_{\rho,\tau,\gamma})G_{\rho,\tau,\gamma}(f)$ with $L^{-1}_{\rho,\tau} f = G_{\rho,\tau}(f) + \tilde{\phi} + w_1$, we get (26) as follows:

$$\begin{aligned}\|G_{\rho,\tau,\gamma}(f)\|_{2,\beta,\nu} &\le C\left(\|G_{\rho,\tau}(f)\|_{2,\beta,\nu} + \|\tilde{\phi}\|_{2,\beta,\nu} + \|w_1\|_{2,\beta,\nu}\right)\\ &\le C\left(\|G_{\rho,\tau}(f)\|_{2,\beta,\nu} + \rho^2|H^0_{\rho,\tau}(f)| + |H^1_{\rho,\tau}(f)|\right)\end{aligned}$$

and in turn by (32) and (26) we obtain (29).

Letting $S = f + (L_{\rho,\tau} - L_{\rho,\tau,\gamma})G_{\rho,\tau,\gamma}(f)$, by (31) and (26) we find

$$\begin{aligned}|H^0_{\rho,\tau,\gamma}(f)| &= |h_0(S)| = O\left(\rho^2\|G_{\rho,\tau}(f)\|_{2,\beta,\nu} + |H^0_{\rho,\tau}(f)| + \rho^2|H^1_{\rho,\tau}(f)|\right),\\ |H^1_{\rho,\tau,\gamma}(f)| &= |h_1(S)| = O\left(\rho^2\|G_{\rho,\tau}(f)\|_{2,\beta,\nu} + \rho^2|H^0_{\rho,\tau}(f)| + |H^1_{\rho,\tau}(f)|\right),\end{aligned}$$

and the proof of Proposition 4.5 is completed. □

4.3. Some global operator. Let $\alpha \in (0,+\infty)\setminus\mathbb{N}$ be a fixed number. Let χ be a radial smooth function such that $0 \le \chi \le 1$, $\chi = 1$ in $B(0,1)$, $\chi = 0$ in $\mathbb{R}^2 \setminus B(0,2)$. In Theorem 1.4 we are interested in dealing with three possible cases:

(a) the concentration set S is a single point which is a singular source, that is, $S = \{p\}$, and in this case we consider the associated potential as given by $V_\rho(z) = \rho^2\chi(z-p)|z-p|^{2\alpha}e^{v_{\rho,\tau_1}(z-p)}$ where $\tau_1 > 0$ is defined in section 2;

(b) the concentration set S is a single point which is not a singular source, that is, $S = \{q\}$ with $q \ne p$, and the associated potential considered in this case is $V_\rho(z) = \rho^2\chi(z-q)e^{v_{\rho,\tau_2,\gamma}(z-q)}$ where $\tau_2 > 0$ and γ are defined in section 2;

(c) the concentration set $S = \{p,q\}$ and the associated potential is $V_\rho(z) = \rho^2\chi(z-p)|z-p|^{2\alpha}e^{v_{\rho,\tau_1}(z-p)} + \rho^2\chi(z-q)e^{v_{\rho,\tau_2,\gamma}(z-q)}$ where $\tau_1,\tau_2 > 0$ and γ are defined in section 2.

We are assuming that $\overline{B(p,2)} \cap \overline{B(q,2)} = \emptyset$, $\overline{B(p,2)} \subset \Omega$, and $\overline{B(q,2)} \subset \Omega$. Set $B = B(p,1) \cup B(q,1)$ and $\tilde{\Omega} = \Omega \setminus B$.

We introduce the operator $\mathcal{L}_\rho = \Delta + V_\rho$ where the potential V_ρ is defined above according to the cases (a), (b), and (c) we wish to deal with. We investigate the invertibility of $\mathcal{L}_\rho$ between X and Y (see section 3 for the definition of X and Y). We will prove the following result.

THEOREM 4.6. *There exist $\rho_0 > 0$ small, continuous linear forms $\mathcal{H}^0_{\rho,1}, \mathcal{H}^0_{\rho,2} : Y \to \mathbb{R}$ and $\mathcal{H}^1_{\rho,2} : Y \to \mathbb{C}$, a linear operator $\mathcal{G}_\rho : Y \to, X$, uniformly bounded for $\rho \in (0,\rho_0)$, such that for all $f \in Y$ and $\rho \in (0,\rho_0)$ there exists a unique solution $w(z)$ of*

$$\begin{cases}\mathcal{L}_\rho w = f & \text{in } \Omega,\\ w = 0 & \text{on } \partial\Omega\end{cases}$$

which can be decomposed in a unique way in the form

$$w(z) = \mathcal{G}_\rho(f)(z) + \chi(z-p)\mathcal{H}^0_{\rho,1}\partial_\tau v_{\rho,\tau_1}(z-p)$$

in case (a), *in the form*

$$w(z) = \mathcal{G}_\rho(f)(z) + \chi(z-q)\mathcal{H}^0_{\rho,2}\partial_\tau v_{\rho,\tau_2,\gamma}(z-q) + 2\chi(z-q)\mathcal{H}^1_{\rho,2}\cdot\partial_{\bar{z}} v_{\rho,\tau_2,\gamma}(z-q)$$

in case (b), *and in the form*

$$\begin{aligned}w(z) = \mathcal{G}_\rho(f)(z) &+ \chi(z-p)\mathcal{H}^0_{\rho,1}\partial_\tau v_{\rho,\tau_1}(z-p)\\ &+ \chi(z-q)\mathcal{H}^0_{\rho,2}\partial_\tau v_{\rho,\tau_2,\gamma}(z-q) + 2\chi(z-q)\mathcal{H}^1_{\rho,2}\cdot\partial_{\bar{z}} v_{\rho,\tau_2,\gamma}(z-q)\end{aligned}$$

in case (c).

We collect some preliminary results which will be crucial to the proof of Theorem 4.6. Since $|V_\rho| \le C\rho^2$ in $\tilde\Omega$, from classical elliptic theory we have the following lemma.

LEMMA 4.7. *There exists $\rho_0 > 0$ small such that for all $f \in C^{0,\beta}(\tilde\Omega)$ there exists a unique solution $w \in C^{2,\beta}(\tilde\Omega)$ for the problem*

$$\begin{cases} \mathcal{L}_\rho w = f & \text{in } \tilde\Omega, \\ w = 0 & \text{on } \partial\tilde\Omega. \end{cases}$$

Moreover, $\|w\|_{2,\beta,\tilde\Omega} \le C\|f\|_{0,\beta,\tilde\Omega}$.

We introduce now the exterior Dirichlet to Neumann map. Let $\Phi \in C^{2,\beta}(\partial B)$; we can extend Φ inside $\tilde\Omega$ in such a way that $\tilde\Phi \in C^{2,\beta}(\tilde\Omega)$, $\tilde\Phi = 0$ on $\partial\Omega$, and $\|\tilde\Phi\|_{2,\beta,\tilde\Omega} \le C\|\Phi\|_{2,\beta,\partial B}$.

By Lemma 4.7 we can find a solution $\bar w$ for

$$\begin{cases} \mathcal{L}_\rho \bar w = -\mathcal{L}_\rho \tilde\Phi & \text{in } \tilde\Omega, \\ \bar w = 0 & \text{on } \partial\tilde\Omega \end{cases}$$

and hence $w_\Phi = \bar w + \tilde\Phi$ solves

$$\begin{cases} \mathcal{L}_\rho w_\Phi = 0 & \text{in } \tilde\Omega, \\ w_\Phi = 0 & \text{on } \partial\Omega, \\ w_\Phi = \Phi & \text{on } \partial B \end{cases}$$

with $\|w_\Phi\|_{2,\beta,\tilde\Omega} \le C\|\Phi\|_{C^{2,\beta}(\partial B)}$.

Define

$$\begin{aligned} S_\rho : C^{2,\beta}(\partial B) &\to C^{1,\beta}(\partial B) \\ \Phi &\to S_\rho(\Phi) = \frac{\partial w_\Phi}{\partial n} \mid_{\partial B}, \end{aligned}$$

where n is the unit inward normal on ∂B to $\tilde\Omega$. If $\tilde w$ denotes the solution of

$$\begin{cases} \Delta \tilde w = -\Delta \tilde\Phi & \text{in } \tilde\Omega, \\ \tilde w = 0 & \text{on } \partial\tilde\Omega, \end{cases}$$

then

$$\begin{cases} \Delta(\bar w - \tilde w) = -V_\rho w_\Phi & \text{in } \tilde\Omega, \\ \bar w - \tilde w = 0 & \text{on } \partial\tilde\Omega \end{cases}$$

and so, by classical Schauder estimates, $\|\bar w - \tilde w\|_{2,\beta,\tilde\Omega} \le C\rho^2\|\Phi\|_{C^{2,\beta}(\partial B)}$. Hence, if S_0 denotes the Dirichlet to Neumann map corresponding to Δ on $\tilde\Omega$, we have that $S_\rho = S_0 + O(\rho^2)$. Summarizing, we have the following lemma.

LEMMA 4.8. *There exists $\rho_0 > 0$ small such that for $\rho \in (0, \rho_0)$ the map S_ρ is well defined and $S_\rho \to S_0$ as $\rho \to 0$ in the operatorial norm.*

We introduce now the interior Dirichlet to Neumann map. Let $\Phi \in C^{2,\beta}(\partial B)$, which we extend as $\tilde\Phi$ in B in such a way that $\|\tilde\Phi\|_{2,\beta,\nu_1,B(p,1)} + \|\tilde\Phi\|_{2,\beta,\nu_2,B(q,1)} \le$

$C\|\Phi\|_{2,\beta,\partial B}$. By Propositions 4.1 and 4.5, we see that there exists a unique solution $\bar{v}$ of

$$\begin{cases} \mathcal{L}_\rho \bar{v} = -\mathcal{L}_\rho \tilde{\Phi} & \text{in } B, \\ \bar{v} = 0 & \text{on } \partial B \end{cases}$$

and hence $v_\Phi = \bar{v} + \tilde{\Phi}$ uniquely solves

$$\begin{cases} \mathcal{L}_\rho v_\Phi = 0 & \text{in } B, \\ v_\Phi = \Phi & \text{on } \partial B \end{cases}$$

with $\|v_\Phi \mid_{B(p,1)}\|_{\mathcal{E}_1} + \|v_\Phi \mid_{B(q,1)}\|_{\mathcal{E}_2} \le C\|\Phi\|_{2,\beta,\partial B}$.

The space

$$\mathcal{E}_1 = \{w = h + \lambda \partial_\tau v_{\rho,\tau_1}(z-p) : \ h \in C^{2,\beta}_{\nu_1}(B(p,1)), \ \lambda \in \mathbb{R}\}$$

is endowed with the norm $\|w\|_{\mathcal{E}_1} = \|h\|_{2,\beta,\nu_1,B(p,1)} + |\lambda|$, and the space

$$\mathcal{E}_2 = \{w = h + \lambda \partial_\tau v_{\rho,\tau_2,\gamma}(z-q) + 2a\cdot\partial_{\bar{z}} v_{\rho,\tau_2,\gamma}(z-q) : h \in C^{2,\beta}_{\nu_2}(B(q,1)), \lambda \in \mathbb{R}, a \in \mathbb{C}\}$$

with the norm $\|w\|_{\mathcal{E}_2} = \|h\|_{2,\beta,\nu_2,B(q,1)} + |\lambda| + |a|$.

Define

$$\begin{aligned} T^1_\rho : C^{2,\beta}(\partial B(p,1)) &\to C^{1,\beta}(\partial B(p,1)) \\ \phi_1 &\to T^1_\rho(\phi_1) = \partial_{r_1} v_\Phi \mid_{\partial B(p,1)}, \\ T^2_\rho : C^{2,\beta}(\partial B(q,1)) &\to C^{1,\beta}(\partial B(q,1)) \\ \phi_2 &\to T^2_\rho(\phi_2) = \partial_{r_2} v_\Phi \mid_{\partial B(q,1)}, \end{aligned}$$

where $\Phi = (\phi_1, \phi_2)$, $r_1 = |z-p|$, and $r_2 = |z-q|$. T^i_ρ is a uniformly bounded operator such that the following lemma holds.

LEMMA 4.9. *$T^i_\rho \to T^i_0$ as $\rho \to 0$ in the operatorial norm, where*

$$T^1_0 \phi_1 = 2\sum_{n=1}^{+\infty} n a_n \cdot e^{-in\theta}$$

with $\phi_1 = a_0 + 2\sum_{n=1}^{+\infty} a_n \cdot e^{-in\theta}$, while

$$T^2_0 \phi_2 = -2a_1 \cdot (e^{i\theta} + \bar{\gamma} e^{-i\theta}) + 2\sum_{n=2}^{+\infty} n a_n \cdot e^{-in\theta},$$

where $\phi_2 = a_0 + 2a_1 \cdot (e^{i\theta} - \bar{\gamma} e^{-i\theta}) + 2\sum_{n=2}^{+\infty} a_n \cdot e^{-in\theta}$. The variable θ denotes the angular variable of $\frac{z-p}{|z-p|}$ and $\frac{z-q}{|z-q|}$, respectively.

Remark 4.10. (1) The map $a_1 \in \mathbb{C} \to \bar{a}_1 - \gamma a_1 \in \mathbb{C}$ is invertible; see the discussion for the invertibility of ψ_0. Since $a_1 \cdot (e^{i\theta} - \bar{\gamma} e^{-i\theta}) = (\bar{a}_1 - \gamma a_1) \cdot e^{-i\theta}$, the statement of Lemma 4.9 makes good sense.

(2) The operator T^2_0 is the interior Dirichlet to Neumann map associated with Δ on $B(q,1)\setminus\{q\}$ with a first-order singularity in q, since $w = a_0 + 2a_1 \cdot (\frac{z-q}{|z-q|^2} - \bar{\gamma}\overline{z-q}) + 2\sum_{n=2}^{+\infty} a_n \cdot \overline{z-q}^n$ is a harmonic extension of ϕ_2 in $B(q,1)\setminus\{q\}$ with $\partial_{r_2} w \mid_{\partial B(q,1)} = T^2_0 \phi_2$.

Proof. Assume for simplicity that $p = 0$. Write

$$\phi_1(\theta) = a_0 + 2\sum_{n=1}^{+\infty} a_n \cdot e^{-in\theta} = \frac{\tau_1(1+\tau_1^2\rho^2)}{2(1-\tau_1^2\rho^2)} a_0 \partial_\tau v_{\rho,\tau_1}(e^{i\theta}) + 2\sum_{n=1}^{+\infty} a_n \cdot e^{-in\theta}.$$

Then $w = \frac{\tau_1(1+\tau_1^2\rho^2)}{2(1-\tau_1^2\rho^2)} a_0 \partial_\tau v_{\rho,\tau_1}(z) + 2\sum_{n=1}^{+\infty} r^n a_n \cdot e^{-in\theta} + w_1$ solves

$$\begin{cases} L_{\rho,\tau_1} w = 0 & \text{in } B(p,1), \\ w = \phi_1 & \text{on } \partial B(p,1) \end{cases}$$

if and only if w_1 solves

$$\begin{cases} L_{\rho,\tau_1} w_1 = f_1 := -\rho^2 |z-p|^{2\alpha} e^{v_{\rho,\tau_1}} (2\sum_{n=1}^{+\infty} r^n a_n \cdot e^{-in\theta}) & \text{in } B(p,1), \\ w_1 = 0 & \text{on } \partial B(p,1). \end{cases}$$

The well-known estimate $\| \sum_{n=1}^{+\infty} r^n a_n \cdot e^{-in\theta} \|_{2,\beta,1} \le C \|\phi_1\|_{2,\beta}$ implies $\|f_1\|_{0,\beta,\nu_1-2} \le C\rho^{\frac{1-\nu_1}{\alpha+1}} \|\phi_1\|_{2,\beta}$. Since $\int_0^{2\pi} f_1(re^{i\theta}) d\theta = 0$ for all $r \in (0,1]$, by Proposition 4.1 $w_1(z) = G_{\rho,\tau_1}(f_1)(z)$ with $\|G_{\rho,\tau_1}(f_1)\|_{2,\beta,\nu_1} \le C\rho^{\frac{1-\nu_1}{\alpha+1}} \|\phi_1\|_{2,\beta}$. Therefore $\|\partial_r w_1 \mid_{\partial B(p,1)}\|_{1,\beta} \le C\rho^{\frac{1-\nu_1}{\alpha+1}} \|\phi_1\|_{2,\beta}$ and hence

$$\begin{aligned} T_\rho^1 \phi_1 &= \frac{\tau_1(1+\tau_1^2\rho^2)}{2(1-\tau_1^2\rho^2)} a_0 \partial_r \partial_\tau v_{\rho,\tau_1}(z) \mid_{\partial B(p,1)} + 2\sum_{n=1}^{+\infty} n a_n \cdot e^{-in\theta} + O\left(\rho^{\frac{1-\nu_1}{\alpha+1}} \|\phi_1\|_{2,\beta}\right) \\ &= \frac{4(\alpha+1)\tau_1^2\rho^2}{(1+\tau_1^2\rho^2)(1-\tau_1^2\rho^2)} a_0 + 2\sum_{n=1}^{+\infty} n a_n \cdot e^{-in\theta} + O\left(\rho^{\frac{1-\nu_1}{\alpha+1}} \|\phi_1\|_{2,\beta}\right) \\ &= T_0^1 \phi_1 + O\left(\rho^{\frac{1-\nu_1}{\alpha+1}} \|\phi_1\|_{2,\beta}\right). \end{aligned}$$

Assuming for simplicity that $q = 0$, for ϕ_2 as above we can write

$$\begin{aligned} \phi_2(\theta) &= \frac{\tau_2}{2} a_0 \partial_\tau v_{\rho,\tau_2,\gamma}(e^{i\theta}) + \frac{2\tau_2^2\rho^2}{\tau_2^2\rho^2 + |1+\gamma e^{2i\theta}|^2} a_0 - a_1 \cdot \partial_{\bar z} v_{\rho,\tau_2,\gamma}(e^{i\theta}) \\ &\quad + \frac{2\tau_2^2\rho^2}{\tau_2^2\rho^2 + |1+\gamma e^{2i\theta}|^2} a_1 \cdot \frac{1+3\bar\gamma e^{-2i\theta}}{1+\bar\gamma e^{-2i\theta}} e^{i\theta} + a_1 \cdot \eta^\perp(e^{i\theta}) + 2\sum_{n=2}^{+\infty} a_n \cdot e^{-in\theta}. \end{aligned}$$

Let $h(z) := \frac{2\tau_2^2\rho^2|z|^2}{\tau_2^2\rho^2+|1+\gamma z^2|^2} a_0 + \frac{2\tau_2^2\rho^2|z|^2}{\tau_2^2\rho^2+|1+\gamma z^2|^2} a_1 \cdot \frac{1+3\bar\gamma\bar z^2}{1+\bar\gamma\bar z^2} z$, then

$$w(z) = \frac{\tau_2}{2} a_0 \partial_\tau v_{\rho,\tau_2,\gamma}(z) - a_1 \cdot \partial_{\bar z} v_{\rho,\tau_2,\gamma}(z) + h(z) + a_1 \cdot \eta^\perp(z) + 2\sum_{n=2}^{+\infty} a_n \cdot \bar z^n + w_1$$

solves

$$\begin{cases} L_{\rho,\tau_2,\gamma} w = 0 & \text{in } B(q,1), \\ w = \phi_2 & \text{on } \partial B(q,1) \end{cases}$$

if and only if w_1 solves

$$\begin{cases} L_{\rho,\tau_2,\gamma} w_1 = f_2 := -\rho^2 e^{v_{\rho,\tau_2,\gamma}} (2\sum_{n=1}^{+\infty} a_n \cdot \bar z^n + a_1 \cdot \eta^\perp(z)) - L_{\rho,\tau_2,\gamma} h & \text{in } B(q,1), \\ w_1 = 0 & \text{on } \partial B(q,1). \end{cases}$$

Since $\|2\sum_{n=2}^{+\infty} a_n \cdot \bar{z}^n + a_1 \cdot \eta^{\perp}(z)\|_{2,\beta,2} \le C\|\phi_2\|_{2,\beta}$, we get $\|f_2\|_{0,\beta,\nu_2-2} \le C\rho^{2-\nu_2}\|\phi_2\|_{2,\beta}$. By Proposition 4.5,

$$w_1(z) = G_{\rho,\tau_2,\gamma}(f_2)(z) + H^0_{\rho,\tau_2,\gamma}(f_2)\partial_\tau v_{\rho,\tau_2,\gamma}(z) + 2H^1_{\rho,\tau_2,\gamma}(f_2)\cdot\partial_{\bar{z}} v_{\rho,\tau_2,\gamma}(z)$$

with $\|G_{\rho,\tau_2,\gamma}(f_2)\|_{2,\beta,\nu_2} + |H^0_{\rho,\tau_2,\gamma}(f_2)| + |H^1_{\rho,\tau_2,\gamma}(f_2)| \le C\rho^{2-\nu_2}\|\phi_2\|_{2,\beta}$.

Therefore $\|\partial_r w_1 \mid_{\partial B(q,1)}\|_{1,\beta} \le C\rho^{2-\nu_2}\|\phi_2\|_{2,\beta}$, and so

$$\begin{aligned} T^2_\rho\phi_2 = {} & \frac{\tau_2}{2}a_0\partial_r\partial_\tau v_{\rho,\tau_2,\gamma} \mid_{\partial B(q,1)} - a_1\cdot\partial_r\partial_{\bar{z}} v_{\rho,\tau_2,\gamma} \mid_{\partial B(q,1)} + a_1\cdot\partial_r\eta^{\perp} \mid_{\partial B(q,1)} \\ & + 2\sum_{n=2}^{+\infty} n a_n\cdot e^{-in\theta} + O\left(\rho^{2-\nu_2}\|\phi_2\|_{2,\beta}\right). \end{aligned}$$

By direct computation, we find $\partial_r\partial_\tau v_{\rho,\tau_2,\gamma} \mid_{\partial B(q,1)} = O(\rho^2)$ and

$$\begin{aligned} \partial_r\partial_{\bar{z}} v_{\rho,\tau_2,\gamma} \mid_{\partial B(q,1)} &= \partial_r\left(-\frac{2}{r}e^{i\theta} + 2\bar{\gamma}re^{-i\theta} + \eta^{\perp}(re^{i\theta})\right) \mid_{r=1} + O(\rho^2) \\ &= 2(e^{i\theta} + \bar{\gamma}e^{-i\theta}) + \partial_r\eta^{\perp}(re^{i\theta}) \mid_{r=1} + O(\rho^2). \end{aligned}$$

Consequently, $T^2_\rho\phi_2 = T^2_0\phi_2 + O(\rho^{2-\nu_2}\|\phi_2\|_{2,\beta})$ and the proof of the lemma is completed. □

Define

$$\begin{aligned} T_\rho : C^{2,\beta}(\partial B) &\to C^{1,\beta}(\partial B) \\ \Phi = (\phi_1,\phi_2) &\to T_\rho\Phi = (T^1_\rho\phi_1, T^2_\rho\phi_2) \end{aligned}$$

and similarly the operator T_0. We want to prove the following lemma.

LEMMA 4.11. *There exists $\rho_0 > 0$ small such that the operator $S_\rho - T_\rho$ is invertible with uniformly bounded inverse for $\rho \in (0,\rho_0)$.*

Proof. Since $S_\rho - T_\rho \to S_0 - T_0$ as $\rho \to 0$ in the operatorial norm, we want to prove that $S_0 - T_0$ is invertible. By an idea of R. Mazzeo used in [4], we claim that it is enough to prove that $S_0 - T_0$ is injective. Regarding $S_0 - T_0$ as an operator from $H^1(\partial B)$ into $L^2(\partial B)$, it is a self-adjoint first-order pseudodifferential operator. Since S_0 and T_0 are elliptic with principal symbols $-|\xi|$ and $|\xi|$, respectively, the difference $S_0 - T_0$ is also elliptic and semibounded. Hence, $S_0 - T_0$ has a discrete spectrum and the invertibility reduces to prove injectivity. The invertibility in Hölder spaces then will follow by classical regularity theory. Let $\Phi \in H^1(\partial B)$ such that $(S_0 - T_0)\Phi = 0 \in L^2(\partial B)$. In view of (2) in Remark 4.10, by Lemmas 4.8 and 4.9 there exists a solution w_0 for the problem

$$\begin{cases} \Delta w_0 = 0 & \text{in } \Omega\setminus S, \\ w_0 = 0 & \text{on } \partial\Omega, \\ w_0 = \Phi & \text{on } \partial B, \end{cases}$$

such that

$$w(z) = \begin{cases} s_1 + 2q_1\cdot\overline{z-p} + O(|z-p|^2) & \text{as } z\to p, \\ s_2 + 2q_2\cdot\left(\frac{z-q}{|z-q|^2} - \bar{\gamma}\overline{z-q}\right) + O(|z-q|^2) & \text{as } z\to q \end{cases}$$

for some $s_i \in \mathbb{R}$ and $q_i \in \mathbb{C}$. The assumption $(S_0 - T_0)\Phi = 0$ ensures that we are gluing harmonic functions in $\tilde{\Omega}$ and B which coincide with their normal derivative on ∂B. In this way the resulting function is harmonic in $\Omega\setminus S$.

In case $S = \{p\}$, w_0 is bounded near p and it extends to a harmonic function in Ω with homogeneous Dirichlet boundary condition, hence $w_0 = 0$, $\Phi = 0$, and the injectivity of $S_0 - T_0$ is proved. In the remaining cases S contains the point $q \neq p$, the solution w_0 must be equal to $8\pi q_2 \cdot \partial_{\bar{z}'} G(z,q)$ because their difference is a harmonic function in $\Omega \setminus S$ with removable singularities. Moreover, there holds $2\partial_z \left(q_2 \cdot \partial_{\bar{z}'} H(z,q)\right) |_{z=q} = -\frac{q_2\gamma}{4\pi}$ which can be rewritten as follows:

$$q_2 \partial_{zz'} H(q,q) + \bar{q}_2 \partial_{z\bar{z}'} H(q,q) = -\frac{q_2\gamma}{4\pi}. \tag{33}$$

Let us recall that, if $S = \{q\}$, $\mathcal{F}(z) = H(z,z) + \frac{1}{4\pi} \ln \left(|z-p|^{2\alpha} f(z)\right)$ and $\gamma = 4\pi \partial_{zz} H(q,q) + \frac{1}{2}\left[\partial_{zz}\left(|z-p|^{2\alpha} f(z)\right)\right](q)$; while if $S = \{p,q\}$, $\mathcal{F}(z) = H(z,z) + \frac{1}{4\pi} \ln(|z-p|^{2\alpha} f(z)) + 2(1+\alpha) G(z,p)$ and $\gamma = 4\pi \partial_{zz} H(q,q) + \frac{1}{2}\left[\partial_{zz}\left(|z-p|^{2\alpha} f(z)\right)\right](q) + 4\pi(1+\alpha)\partial_{zz} G(q,p)$. Hence (33) is equivalent to $D^2 \mathcal{F}(q)(\frac{q_2}{q_2}) = 0$ when we assume further that $\Delta \ln f(q) = 0$. The assumption that q is a nondegenerate critical point for $\mathcal{F}(z)$ provides $q_2 = 0$. Then w_0 is not singular in the points of S and as before $w_0 = 0$, $\Phi = 0$, and the injectivity of $S_0 - T_0$ follows. □

We are now in position to give the proof of Theorem 4.6.

Proof of Theorem 4.6. By Lemma 4.7 and Propositions 4.1 and 4.5, for any $f \in Y$ we can find $w_{\rm ext} \in C^{2,\beta}(\tilde{\Omega})$ and $w_{{\rm int},i} \in \mathcal{E}_i$, $i = 1,2$, which solve

$$\begin{cases} \mathcal{L}_\rho w_{\rm ext} = f & \text{in } \tilde{\Omega}, \\ w_{\rm ext} = 0 & \text{on } \partial\tilde{\Omega}, \end{cases} \quad \begin{cases} \mathcal{L}_\rho w_{\rm int},1 = f & \text{in } B(p,1), \\ w_{\rm int},1 = 0 & \text{on } \partial B(p,1), \end{cases} \quad \begin{cases} \mathcal{L}_\rho w_{\rm int},2 = f & \text{in } B(q,1), \\ w_{\rm int},2 = 0 & \text{on } \partial B(q,1). \end{cases}$$

Moreover, $\|w_{\rm ext}\|_{2,\beta,\tilde{\Omega}} + \sum_i \|w_{\rm int},i\|_{\mathcal{E}_i} \leq C\|f\|_Y$. By Lemma 4.11, we find $\Phi \in C^{2,\beta} \cdot (\partial B)$ such that

$$(S_\rho - T_\rho)\Phi = \left(-\partial_{r_1}(w_{\rm ext} - w_{\rm int},1) \,|_{\partial B(p,1)}, -\partial_{r_2}(w_{\rm ext} - w_{\rm int},2) \,|_{\partial B(q,1)}\right)$$

with $\|\Phi\|_{C^{2,\beta}(\partial B)} \leq C\|f\|_Y$. At this point, we define $w_{\rm ker} \in C(\Omega \setminus S)$ by solving

$$\begin{cases} \mathcal{L}_\rho w_{\rm ker} = 0 & \text{in } \Omega \setminus \partial B, \\ w_{\rm ker} = 0 & \text{on } \partial\Omega, \\ w_{\rm ker} = \Phi & \text{on } \partial B. \end{cases}$$

Define

$$w(z) = \begin{cases} w_{\rm ext}(z) + w_{\rm ker}(z) & \text{in } \tilde{\Omega}, \\ w_{\rm int},1(z) + w_{\rm ker}(z) & \text{in } B(p,1), \\ w_{\rm int},2(z) + w_{\rm ker}(z) & \text{in } B(q,1). \end{cases}$$

Since the external and internal normal derivative of $w(z)$ on ∂B coincide, we conclude that $w(z)$ is a solution for the problem

$$\begin{cases} \mathcal{L}_\rho w = f & \text{in } \Omega, \\ w = 0 & \text{on } \partial\Omega, \\ w \in C^{2,\beta}(\Omega \setminus S). \end{cases} \tag{34}$$

It remains to discuss the uniqueness of w: let w' be another solution of (34). Set $\Phi' = (w' \,|_{\partial B(p,1)}, w' \,|_{\partial B(q,1)})$. Then $(S_\rho - T_\rho)\Phi' = (S_\rho - T_\rho)\Phi = 0$ and, by injectivity of $S_\rho - T_\rho$, we deduce $\Phi' = \Phi$ and so $w' = w$. □

4.4. The linearized operator. Now we want to pass the information on the invertibility of $\mathcal{L}_\rho$ to $\Lambda_\rho = \Delta + W_\rho$, where $W_\rho(z) = \rho^2|z-p|^{2\alpha} f(z) e^{v(\rho,0,0)(z)}$, and in turn to $L_{(0,0,0)}$. To an element $(h,\lambda,a) \in \mathcal{E}$ we associate in a canonical way the function

$$\begin{aligned} w(z) = h(z) &+ \chi(z-p)\lambda_1 \partial_\tau v_{\rho,\tau_1}(z-p) + \chi(z-q)\lambda_2 \partial_\tau v_{\rho,\tau_2,\gamma}(z-q) \\ &+ \chi(z-q) 2a \cdot \partial_{\bar z} v_{\rho,\tau_2,\gamma}(z-q) \end{aligned}$$

(with the understanding that $\lambda_1 = 0$ if $p \notin S$ and $\lambda_2 = 0$, $a = 0$ if $q \notin S$) and we want to evaluate the difference $\Lambda_\rho - \mathcal{L}_\rho$ on $w(z)$. We have

$$\begin{aligned} \|(\Lambda_\rho - \mathcal{L}_\rho) w\|_Y \le C\rho^2 (\|h\|_{2,\beta,\tilde\Omega} + |\lambda| + |a|) \\ + \|\rho^2 |z-p|^{2\alpha} (f(z) e^{v(\rho,0,0)(z)} - e^{v_{\rho,\tau_1}(z-p)}) w\|_{0,\beta,\nu_1-2,B(p,1)} \\ + \|\rho^2 (|z-p|^{2\alpha} f(z) e^{v(\rho,0,0)(z)} - e^{v_{\rho,\tau_2,\gamma}(z-q)}) w\|_{0,\beta,\nu_2-2,B(q,1)}. \end{aligned}$$

Therefore,

$$(\Lambda_\rho - \mathcal{L}_\rho)(z) = \begin{cases} O\left(\rho^2 |z-p|^{2\alpha+1} e^{v_{\rho,\tau_1}(z-p)}\right) & \text{in } B(p,1), \\ O\left(\rho^2 |z-q|^3 e^{v_{\rho,\tau_2,\gamma}(z-q)}\right) & \text{in } B(q,1) \end{cases}$$

in view of (11), (12), and (13). Since $|\partial_\tau v_{\rho,\tau,\lambda}(z)| + |z||\partial_{\bar z} v_{\rho,\tau,\lambda}(z)| = O(1)$ in $B(0,1)$ when $\lambda \in \{0,\gamma\}$, we deduce $\|(\Lambda_\rho - \mathcal{L}_\rho) w\|_{0,\beta,\nu_1-2,B(p,1)} + \|(\Lambda_\rho - \mathcal{L}_\rho) w\|_{0,\beta,\nu_2-2,B(q,1)} = O\left(r^s \|(h,\lambda,a)\|_{\mathcal{E}'}\right)$, where $r := \max\{r_1, r_2\}$ and $s = \min\{1-\nu_1, 2-\nu_2\} > 0$. This implies $\|(\Lambda_\rho - \mathcal{L}_\rho) w\|_Y \le C r^s \|(h,\lambda,a)\|_{\mathcal{E}'}$. Note that Theorem 4.6 can be restated as follows: for any $f \in Y$ there exists $(h_0,\lambda_0,a_0) = \mathcal{L}_\rho^{-1} f \in \mathcal{E}$ such that

$$\begin{aligned} w_0(z) = h_0(z) &+ \chi(z-p)(\lambda_0)_1 \partial_\tau v_{\rho,\tau_1}(z-p) + \chi(z-q)(\lambda_0)_2 \partial_\tau v_{\rho,\tau_2,\gamma}(z-q) \\ &+ 2\chi(z-q) a_0 \cdot \partial_{\bar z} v_{\rho,\tau_2,\gamma}(z-q) \end{aligned}$$

is a solution for $\mathcal{L}_\rho w_0 = f$ in Ω and $\|(h_0,\lambda_0,a_0)\|_{\mathcal{E}} \le C\|f\|_Y$, provided $\rho > 0$ is small enough.

On the other hand, for given $(h,\lambda,a) \in \mathcal{E}$ the associated $w(z)$ solves $\Lambda_\rho w = f$ in Ω if and only if it corresponds to a fixed point for the map

$$\begin{aligned} &\mathcal{E} \to \mathcal{E} \\ &(h,\lambda,a) \to \mathcal{L}_\rho^{-1} f - \mathcal{L}_\rho^{-1} (\Lambda_\rho - \mathcal{L}_\rho) w. \end{aligned}$$

Since

$$\|\mathcal{L}_\rho^{-1} (\Lambda_\rho - \mathcal{L}_\rho) w\|_{\mathcal{E}} \le C \|(\Lambda_\rho - \mathcal{L}_\rho) w)\|_Y \le C r^s \|(h,\lambda,a)\|_{\mathcal{E}},$$

there exists ρ_0 small such that for $0 < \rho < \rho_0$ such a map defines a contraction. Thus, for any $f \in Y$ there exists a unique $(h,\lambda,a) \in \mathcal{E}$ solving $\Lambda_\rho w = f$ in Ω with $\|(h,\lambda,a)\|_{\mathcal{E}} \le C\|\mathcal{L}_\rho^{-1} f\|_{\mathcal{E}}$.

We rewrite the solution $w(z)$ in the form

$$w(z) = h'(z) + \sum_i \lambda_i \partial_{\lambda_i} v(\rho,0,0)(z) + 2(-a) \cdot \partial_{\overline{a}} v(\rho,0,0)(z)$$

with

$$\begin{aligned} h'(z) = h(z) &+ \chi(z-p)\lambda_1 \left(\partial_\tau v_{\rho,\tau_1}(z-p) - \partial_{\lambda_1} v(\rho,0,0)(z)\right) \\ &+ \chi(z-q)\lambda_2 \left(\partial_\tau v_{\rho,\tau_2,\gamma}(z-q) - \partial_{\lambda_2} v(\rho,0,0)(z)\right) \\ &+ 2\left(1-\chi(z-q)\right) a \cdot \partial_{\overline{a}} v(\rho,0,0)(z) \\ &+ 2\chi(z-q)\, a \cdot \left(\partial_{\bar{z}} v_{\rho,\tau_2,\gamma}(z-q) + \partial_{\overline{a}} v(\rho,0,0)(z)\right), \end{aligned}$$

where we have taken into account that $(1-\chi(z-p))\,\partial_{\lambda_1} v(\rho,0,0)(z)$ and $(1-\chi(z-q))\partial_{\lambda_2} v(\rho,0,0)(z)$ are identically zero. Let us compute the derivatives of $v(\rho,\lambda,a)$:

$$\begin{aligned} \partial_{\lambda_1} v(\rho,0,0)(z) &= \chi\left(\frac{z-p}{r_1}\right) \partial_\tau v_{\rho,\tau_1}(z-p), \\ \partial_{\lambda_2} v(\rho,0,0)(z) &= \chi\left(\frac{z-q}{r_2}\right) \partial_\tau v_{\rho,\tau_2,\gamma}(z-q), \end{aligned}$$

and

$$\partial_{\overline{a}} v(\rho,0,0)(z) = \begin{cases} \left(1-\chi(\frac{z-p}{r_1})\right) 8\pi \partial_{\bar{z}'} G(z,q) & \text{in } B(p,1), \\ -\partial_{\bar{z}} v_{\rho,\tau_2,\gamma}(z-q) - \partial_{\overline{a}} P_0(z) & \\ +\frac{1}{r_2}\partial_{\bar{z}}\chi(\frac{z-q}{r_2}) \left(8\pi(1+\alpha)G(z,p) + 8\pi G(z,q) - U_\rho^2(z)\right) & \\ +\left(1-\chi(\frac{z-q}{r_2})\right)(8\pi \partial_{\bar{z}'} G(z,q) & \\ \qquad +\partial_{\bar{z}} v_{\rho,\tau_2,\gamma}(z-q) + \partial_{\overline{a}} P_0(z)) & \text{in } B(q,1), \\ 8\pi \partial_{\bar{z}'} G(z,q) \quad \text{in } \tilde{\Omega}. & \end{cases}$$

Using again that $\Delta \ln f(q) = 0$, we get $\partial_{\overline{a}} P_0(z) = O(|z-q|^2)$, and so

$$\begin{aligned} \|\chi(z-p)\left(\partial_\tau v_{\rho,\tau_1}(z-p) - \partial_{\lambda_1} v(\rho,0,0)(z)\right)\|_{2,\beta,\nu_1,B(p,1)} &\le C(r_1)^{-\nu_1}, \\ \|\chi(z-q)\left(\partial_\tau v_{\rho,\tau_2,\gamma}(z-q) - \partial_{\lambda_2} v(\rho,0,0)(z)\right)\|_{2,\beta,\nu_2,B(q,1)} &\le C(r_2)^{-\nu_2}, \\ \|\chi(z-q)\left(\partial_{\bar{z}} v_{\rho,\tau_2,\gamma}(z-q) + \partial_{\overline{a}} v(\rho,0,0)(z)\right)\|_{2,\beta,\nu_2,B(q,1)} &\le C(r_2)^{-\nu_2}, \end{aligned}$$

the last estimate being valid in view of the fact that

$$8\pi \partial_{\bar{z}'} G(z,q) + \partial_{\bar{z}} v_{\rho,\tau_2,\gamma}(z-q) = 2\frac{z-q}{|z-q|^2} + O(1) - 2\frac{z-q}{|z-q|^2} + O\left(\frac{\rho^2}{|z-q|^3}\right) = O(1)$$

for any $z \in B(q,1) \setminus B(q,r_2)$. Hence $\|h'\|_{X'} \leq C\|\mathcal{L}_\rho^{-1}(f)\|_{\mathcal{E}}$ for some uniform constant $C > 0$. Thus, we have proved the following result.

THEOREM 4.12. *There exists $\rho_0 > 0$ small such that for any $\rho \in (0, \rho_0)$, we have that for any $f \in Y$ there exists a unique solution $(h, \lambda, a) \in \mathcal{E}'$ satisfying*

$$\begin{cases} \Lambda_\rho w = f \quad \text{in } \Omega, \\ w = 0 \quad \text{on } \partial\Omega, \\ w(z) = h(z) + \sum_i \lambda_i \partial_{\lambda_i} v(\rho,0,0)(z) + 2a \cdot \partial_{\overline{a}} v(\rho,0,0)(z) \end{cases}$$

with $\|(h,\lambda,a)\|_{\mathcal{E}'} \leq C\|\mathcal{L}_\rho^{-1}(f)\|_{\mathcal{E}}$ for some uniform constant $C > 0$.

Let us recall now the definition of $L_{(0,0,0)} : \mathcal{E}' \to Y$ (see section 3): for any $(h,\sigma,b) \in \mathcal{E}'$ we set

$$\begin{aligned} L_{(0,0,0)}(h,\sigma,b) = \Lambda_\rho \Big(h + \sum_i \sigma_i \partial_{\lambda_i} v(\rho,0,0) + 2b \cdot \partial_{\overline{a}} v(\rho,0,0) \Big) \\ + 2\partial_{\overline{z}} \big[\triangle v(\rho,0,0) + \rho^2 |z-p|^{2\alpha} f(z) e^{v(\rho,0,0)} \big] \\ \cdot \big[\big(b\partial_a + \overline{b}\partial_{\overline{a}} \big) \Psi(0,\cdot)^{-1} \big] . \end{aligned}$$

We have to estimate in Y the term

$$\partial_{\overline{z}} \big[\Delta v(\rho,0,0) + \rho^2 |z-p|^{2\alpha} f(z) e^{v(\rho,0,0)} \big] \cdot \big[\big(b\partial_a + \overline{b}\partial_{\overline{a}} \big) \Psi(0,\cdot)^{-1} \big] .$$

Since $\Psi(a,z) \equiv z$ for $z \in \Omega \setminus B(q,2)$, we have that $\big(b\partial_a + \overline{b}\partial_{\overline{a}} \big) \Psi(0,\cdot)^{-1} \equiv 0$ in $\Omega \setminus B(q,2)$. In view of (39) and (40) we get

$$\Big\| \partial_{\overline{z}} \big[\Delta v(\rho,0,0) + \rho^2 |z-p|^{2\alpha} f(z) e^{v(\rho,0,0)} \big] \cdot \big[\big(b\partial_a + \overline{b}\partial_{\overline{a}} \big) \Psi(0,\cdot)^{-1} \big] \Big\|_Y = o(1)|b|,$$

and so using a perturbation argument by Theorem 4.12 we derive the following result.

THEOREM 4.13. *There exists $\rho_0 > 0$ small such that for any $\rho \in (0, \rho_0)$ and $f \in Y$ there exists a unique solution $(h,\sigma,b) \in \mathcal{E}'$ satisfying*

$$\begin{cases} L_{(0,0,0)} w = f \quad \text{in } \Omega, \\ w = 0 \quad \text{on } \partial\Omega, \\ w(z) = h(z) + \sum_i \sigma_i \partial_{\lambda_i} v(\rho,0,0)(z) + 2b \cdot \partial_{\overline{a}} v(\rho,0,0)(z) \end{cases}$$

such that $\|L^{-1}_{(0,0,0)}(f)\|_{\mathcal{E}'} \leq C\|\mathcal{L}_\rho^{-1}(f)\|_{\mathcal{E}}$ for some uniform constant $C > 0$.

5. Some estimates. In order to apply a fixed point argument to K, we used in a crucial way the fact that $K : \mathcal{E}' \to \mathcal{E}'$ maps a suitable small ball into itself; see Step 4 of section 3. To obtain such information we need the estimate contained in (37) below. For this end, first we estimate the preimage through $\mathcal{L}_\rho$ of the error term $\eta = \Delta v(\rho,0,0) + \rho^2 |z-p|^{2\alpha} f(z) e^{v(\rho,0,0)}$. In $\tilde{\Omega} = \Omega \setminus B$, $v(\rho,0,0)$ is a harmonic function and hence

$$|\eta(z)| = |\rho^2 |z-p|^{2\alpha} f(z) \exp\left(8\pi(1+\alpha)G(z,p) + 8\pi G(z,q)\right)| = O(\rho^2)$$

in $\tilde{\Omega}$. In $B(p,1)$ we have that

$$\begin{aligned}\eta(z) = {} & \frac{1}{r_1^2}\Delta\chi\left(\frac{z-p}{r_1}\right)[v_{\rho,\tau_1}(z-p) - \ln f(p) - 8\pi(1+\alpha)G(z,p) - 8\pi G(z,q)] \\ & + \frac{8}{r_1}\partial_{\bar z}\chi\left(\frac{z-p}{r_1}\right)\cdot\partial_{\bar z}\left[v_{\rho,\tau_1}(z-p) - \ln f(p) - 8\pi(1+\alpha)G(z,p) - 8\pi G(z,q)\right] \\ & + \rho^2|z-p|^{2\alpha}e^{v_{\rho,\tau_1}(z-p)}\Big\{ - \chi\left(\frac{z-p}{r_1}\right) + f(z)e^{-\ln f(p)} \\ & \times \exp\left[\left(1-\chi\left(\frac{z-p}{r_1}\right)\right)(8\pi(1+\alpha)G(z,p) + 8\pi G(z,q)\right. \\ & \left. - v_{\rho,\tau_1}(z-p) + \ln f(p))\right]\Big\}\end{aligned}$$

and in $B(q,1)$

$$\begin{aligned}\eta(z) = {} & \frac{1}{r_2^2}\Delta\chi\left(\frac{z-q}{r_2}\right)[v_{\rho,\tau_2,\gamma}(z-q) - P_0(z) - 8\pi(1+\alpha)G(z,p) - 8\pi G(z,q)] \\ & + \frac{8}{r_2}\partial_{\bar z}\chi\left(\frac{z-q}{r_2}\right)\cdot\partial_{\bar z}\left[v_{\rho,\tau_2,\gamma}(z-q) - P_0(z) - 8\pi(1+\alpha)G(z,p) - 8\pi G(z,q)\right] \\ & + \rho^2 e^{v_{\rho,\tau_2,\gamma}(z-q)}\Big\{ - \chi\left(\frac{z-q}{r_2}\right) + |z-p|^{2\alpha}f(z)e^{-P_0(z)} \\ & \times \exp\left[\left(1-\chi\left(\frac{z-q}{r_2}\right)\right)(8\pi(1+\alpha)G(z,p) + 8\pi G(z,q)\right. \\ & \left. - v_{\rho,\tau_2,\gamma}(z-q) + P_0(z))\right]\Big\},\end{aligned}$$

where $P_a(z)$ is defined in section 2. In $B(q,1)$ there holds

$$\partial_{\bar z}\left(v_{\rho,\tau_2,\gamma}(z-q) - P_0(z) - 8\pi(1+\alpha)G(z,p) - 8\pi G(z,q)\right) = -\partial_{\bar z}\mathcal{F}_2(q) \tag{35}$$

$$-\overline{z-q}\,(\partial_{z\bar z}\mathcal{F}_2(q) - 2\overline{\gamma}) + O\left(|z-q|^2 + \frac{\tau_2^2\rho^2}{|z-q|^3}\right) = O\left(|z-q|^2 + \frac{\tau_2^2\rho^2}{|z-q|^3}\right)$$

in view of the fact that $\partial_z\mathcal{F}_2(q) = 0$ and $\gamma = \frac{1}{2}\partial_{zz}\mathcal{F}_2(q)$ (see section 2 for the definitions of $\mathcal{F}_2(z)$ and γ). Similarly, in $B(p,1)$ we get

$$\partial_{\bar z}\left(v_{\rho,\tau_1}(z-p) - \ln f(p) - 8\pi(1+\alpha)G(z,p) - 8\pi G(z,q)\right) = O\left(1 + \frac{\tau_1^2\rho^2}{|z-p|^{2\alpha+3}}\right).$$

As far as second derivatives are concerned, in $B(q,1)$ we have the estimate

$$\partial_{\bar z\bar z}^2\left(v_{\rho,\tau_2,\gamma}(z-q) - P_0(z) - 8\pi(1+\alpha)G(z,p) - 8\pi G(z,q)\right) = O\left(|z-q| + \frac{\tau_2^2\rho^2}{|z-q|^4}\right). \tag{36}$$

Since $\frac{\rho^2}{r_1^{2\alpha+5}} + \frac{\rho^2}{r_2^5} = O(1)$, recalling (11), (12), and (13), for any $\nu \in (0,2)$ we get the estimates

$$\|\eta\|_{0,\beta,\nu-2,B(p,1)} = O\left(r_1^{1-\nu}\right), \qquad \|\eta\|_{0,\beta,\nu-2,B(q,1)} = O\left(r_2^{3-\nu}\right).$$

Fix $0 < \delta < 1$ to be specified below. Following the notations of section 4.1, we find

$$|H^0_{\rho,\tau_1}(\eta\,|_{B(p,1)})| + \|\partial_{r_1} G_{\rho,\tau_1}(\eta\,|_{B(p,1)})\|_{1,\beta,\partial B(p,1)} = O(r_1^{1-\delta})$$

and

$$|H^0_{\rho,\tau_2}(\eta\,|_{B(q,1)})| + |H^1_{\rho,\tau_2}(\eta\,|_{B(q,1)})| + \|\partial_{r_2} G_{\rho,\tau_2}(\eta\,|_{B(q,1)})\|_{1,\beta,\partial B(q,1)} = O(r_2^{3-\delta}).$$

Moreover, choosing $\nu = \nu_1$ in $B(p,1)$ and $\nu = \nu_2$ in $B(q,1)$ we get

$$\|G_{\rho,\tau_1}(\eta\,|_{B(p,1)})\|_{2,\beta,\nu_1,B(p,1)} = O(r_1^{1-\nu_1})\,,\ \|G_{\rho,\tau_2,\gamma}(\eta\,|_{B(q,1)})\|_{2,\beta,\nu_2,B(q,1)} = O(r_2^{3-\nu_2}).$$

By Proposition 4.5 we have

$$|H^0_{\rho,\tau_2,\gamma}(\eta\,|_{B(q,1)})| + |H^1_{\rho,\tau_2,\gamma}(\eta\,|_{B(q,1)})| + \|\partial_{r_2} G_{\rho,\tau_2,\gamma}(\eta\,|_{B(q,1)})\|_{1,\beta,\partial B(q,1)} = O(r_2^{3-\delta}),$$

$$\|G_{\rho,\tau_2,\gamma}(\eta\,|_{B(q,1)})\|_{2,\beta,\nu_2,B(q,1)} = O(\|\eta\|_{0,\beta,\nu_2-2,B(q,1)}) = O(r_2^{3-\nu_2}).$$

Hence, following the notation and the construction of section 4.3, we obtain $\|w_{\rm ext}\|_{2,\beta,\tilde\Omega} \le C\|\eta\|_{0,\beta,\tilde\Omega} = O(\rho^2)$, $\|\partial_{r_1} w_{{\rm int},1}\|_{1,\beta,\partial B(p,1)} = O(r_1^{1-\delta})$, and $\|\partial_{r_2} w_{{\rm int},2}\|_{1,\beta,\partial B(q,1)} = O(r_2^{3-\delta})$.

Let $\Phi = -(S_\rho - T_\rho)^{-1}\left(\partial_{r_1}(w_{\rm ext} - w_{{\rm int},1})\ |_{\partial B(p,1)}, \partial_{r_2}(w_{\rm ext} - w_{{\rm int},2})\ |_{\partial B(q,1)}\right)$. So $\|\Phi\|_{C^{2,\beta}(\partial B)} = O(r_1^{1-\delta} + r_2^{3-\delta})$. Consequently, $\|w_{\rm ker}\|_{2,\beta,\tilde\Omega} + \|w_{\rm ker}\ |_{B(p,1)}\ \|_{\mathcal{E}_1} + \|w_{\rm ker}\ |_{B(q,1)}\ \|_{\mathcal{E}_2} = O(r_1^{1-\delta} + r_2^{3-\delta})$ which in turn implies $\|\mathcal{L}_\rho^{-1}\eta\|_{\mathcal{E}} = O(r_1^{1-\delta} + r_1^{1-\nu_1} + r_2^{3-\delta} + r_2^{3-\nu_2})$. We can choose $\nu_1 \in (0,1)$ and $\nu_2 \in (1,2)$ in such a way that $(\nu_1, 1-\nu_1) \cap (\nu_2 - 1, 2-\nu_2) \neq \emptyset$ and we can suppose that δ is fixed to belong in this set. Hence, by Theorem 4.13 we get

$$\|L^{-1}_{(0,0,0)}\eta\|_{\mathcal{E}'} = O\left(r_1^{1-\delta} + r_2^{2-\delta}\right). \tag{37}$$

Let us define $\sigma = \frac{4\alpha+5}{2\nu_1} + 1$ and choose $r_i = \rho^{\frac{1}{\sigma\nu_i}}$. In this way, we have $\frac{\rho^2}{r_1^{4\alpha+5}} = \rho^{2(1-\frac{4\alpha+5}{2\sigma\nu_1})} \to 0$ as $\rho \to 0$, $\frac{\rho^2}{r_2^5} = \rho^{2(1-\frac{5}{2\sigma\nu_2})} \to 0$ as $\rho \to 0$, and

$$\left(\sum_{i=1}^{2} r_i^{-\nu_i}\right)\left(r_1^{1-\delta} + r_2^{2-\delta}\right) = 2\left(\rho^{\frac{1-\delta-\nu_1}{\sigma\nu_1}} + \rho^{\frac{2-\delta-\nu_2}{\sigma\nu_2}}\right) \to 0 \tag{38}$$

as $\rho \to 0$.

Now, taking the derivative with respect to $\bar z$ in the expression for $\eta = \Delta v(\rho,0,0) + \rho^2|z-p|^{2\alpha} f(z) e^{v(\rho,0,0)}$ and using (13), (35), and (36), we can conclude

$$\left\|\partial_{\bar z}\left(\Delta v(\rho,0,0) + \rho^2|z-p|^{2\alpha} f(z) e^{v(\rho,0,0)}\right)\right\|_{0,\beta,B(q,2)\setminus B(q,1)} = O(\rho^2) \tag{39}$$

and

$$\left\|\partial_{\bar z}\left(\Delta v(\rho,0,0) + \rho^2|z-p|^{2\alpha} f(z) e^{v(\rho,0,0)}\right)\right\|_{0,\beta,\nu_2-2,B(q,1)} = O\left(r_2^{2-\nu_2}\right), \tag{40}$$

where we use in a crucial way the fact that $|z-p|^{2\alpha} f(z) e^{-P_0(z)} - 1 = O(|z-q|^3)$.

Acknowledgment. I express my deep gratitude to Gabriella Tarantello. I am indebted to her for the stimulating discussions and the helpful comments about the manuscript.

STABILITY CONDITIONS FOR STRONG RAREFACTION WAVES*

MARTA LEWICKA†

Abstract. In this paper we study a number of algebraic conditions connected with the stability of strictly hyperbolic $n \times n$ systems of conservation laws in one space dimension:

$$u_t + f(u)_x = 0.$$

Such conditions yield existence and continuity of the flow of solutions in the vicinity of the reference solution. Our main concern is a single rarefaction wave having arbitrarily large strength.

Key words. conservation laws, large data, rarefaction wave, stability conditions

AMS subject classifications. 35L65, 35L45

1. Introduction.

In this paper we study a number of algebraic conditions connected with the stability of strictly hyperbolic $n \times n$ systems of conservation laws in one space dimension:

$$u_t + f(u)_x = 0. \tag{1.1}$$

The well-posedness of (1.1) has been the subject of vast research in recent years; for an overview see [B, D, HR]. While most of the analysis (see [BLY] and more recently [BiB]) has been carried out in the setting of initial data

$$u(0,x) = \bar{u}(x) \tag{1.2}$$

having small total variation, at the same time examples in [BC, J] point out that for the stability of patterns containing large waves, extra assumptions are required, also when the large reference waves do not interact among themselves [BC, Scho, Le1, Le3]. These BV and L^1 stability conditions, in essence, aim at providing an estimate on the distance between a reference solution u_0 and another solution to (1.1) which is viewed as an infinitesimal perturbation of u_0. They refer to the existence of weights with respect to which the flow of the first order perturbation v generated by the linearized system

$$v_t + \mathrm{D}f(u_0)v_x + [\mathrm{D}^2 f(u_0) \cdot v] \cdot (u_0)_x = 0$$

becomes a contraction with respect to the BV or the L^1 norm, respectively, at states attained by u_0. Under these assumptions the existence of global solutions and their continuous dependence on initial data has been proven in the vicinity of patterns containing only noninteracting shocks [Le1] or being a single rarefaction wave [Le3]. The BV stability of general patterns containing shocks, contact discontinuities, and rarefaction waves was established in [Scho].

The objective of this paper is a more detailed study of the stability conditions arising when u_0 contains rarefactions. With respect to the case with only shocks

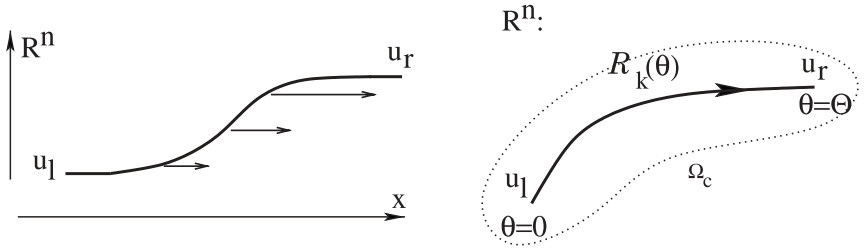

FIG. 1.1.

present [BC, Le2], the main difficulty here stems from the change of weights along rarefaction curves. This accounts for the change of location of perturbation waves of different characteristic families as they pass through each rarefaction fan. Hence we mainly focus on the case when u_0 is a single rarefaction wave of arbitrarily large strength. The stability conditions related to patterns with multiple (noninteracting) shocks and rarefaction waves are presented in section 8.

We now introduce the main hypothesis and set the notation.

(H1) The system (1.1) is strictly hyperbolic in a domain $\Omega \subset \mathbf{R}^n$ to be specified later. More precisely, for each $u \in \Omega$ the Jacobian matrix $\mathrm{D}f(u)$ of the smooth flux $f : \Omega \longrightarrow \mathbf{R}^n$ has n distinct and real eigenvalues: $\lambda_1(u) < \cdots < \lambda_n(u)$.

Let $\{r_i(u)\}_{i=1}^n$ be the basis of right eigenvectors of $\mathrm{D}f$ having unit length:

$$\mathrm{D}f(u)r_i(u) = \lambda_i(u)r_i(u), \quad ||r_i(u)|| = 1.$$

Call $\{l_i(u)\}_{i=1}^n$ the dual basis of left eigenvectors so that $\langle r_i(u), l_j(u)\rangle = \delta_{ij}$ for all $i, j : 1 \dots n$ and all $u \in \Omega$.

Fix $k : 1 \dots n$ and consider an integral curve $\mathcal{R}_k$ of the vector field r_k:

$$\begin{aligned} &\frac{\mathrm{d}}{\mathrm{d}\theta}\mathcal{R}_k(\theta) = r_k(\mathcal{R}_k(\theta)), \\ &u_l = \mathcal{R}_k(0), \quad u_r = \mathcal{R}_k(\Theta), \qquad \Theta > 0. \end{aligned} \tag{1.3}$$

$\mathcal{R}_k$ is called the rarefaction curve joining the left and right states $u_l, u_r \in \Omega$ (see Figure 1.1). For a small $\epsilon > 0$ we define the domain

$$\Omega = \Omega_\epsilon = \{u \in \mathbf{R}^n : \quad ||u - \mathcal{R}_k(\theta)|| < \epsilon \quad \text{for some } \theta \in [0, \Theta]\}. \tag{1.4}$$

We further assume the following:

(H2) In Ω, each characteristic field $i : 1 \dots n$ either is linearly degenerate, $\langle \mathrm{D}\lambda_i, r_i\rangle \equiv 0$, or is genuinely nonlinear, which means that $\langle \mathrm{D}\lambda_i, r_i\rangle > 0$. The kth characteristic field is assumed to be genuinely nonlinear.

The piecewise smooth, self-similar function called the centered rarefaction wave is given by

$$u_0(t,x) = \begin{cases} u_l & \text{if } x < t\lambda_k(u_l), \\ \mathcal{R}_k(\theta) & \text{if } x = t\lambda_k(\mathcal{R}_k(\theta)), \quad \theta \in [0, \Theta], \\ u_r & \text{if } x > t\lambda_k(u_r) \end{cases} \tag{1.5}$$

and provides an entropy admissible solution of (1.1) [Sm, D].

The paper is constructed as follows. In section 2 we present the BV stability condition (BV) and the L^1 stability condition (L1). We also introduce a weaker condition which is sufficient for the solvability of Riemann problems in Ω. In section 3 we prove that our conditions are one stronger than the other, while sections 4, 5, and 6 gather their various properties. In particular, in section 5 we display an interesting connection between the weighted stability conditions and the Riccati equation in case $n = 3$. Section 7 contains examples complementing our work. In section 8 we restate some results of sections 2 and 3, in the context of a general pattern u_0 containing several strong shocks and rarefaction waves.

To appreciate the role of the studied conditions, we end this section by recalling the precise statements of the stability results.

THEOREM 1.1 (see [Le3]). *Assume that* (H1), (H2), *and the BV stability condition* (BV) *hold. For $c, \delta > 0$ let $\mathcal{E}_{c,\delta}$ denote the set of all continuous functions $\bar{u}$ satisfying the following:*

(i) $\bar{u}(x) \in \Omega_c$ *for all* $x \in \mathbf{R}$,
(ii) $\lim_{x\to-\infty} \bar{u}(x) = u_l$ *and* $\lim_{x\to\infty} \bar{u}(x) = u_r$,
(iii) $|TV(\bar{u}) - |\mathcal{R}_k|| < \delta$, *where* $|\mathcal{R}_k|$ *is the arc length of the rarefaction curve* $\mathcal{R}_k(\theta),\ \theta \in [0, \Theta]$.

There exists $c, \delta > 0$ such that for every $\bar{u} \in$ cl $\mathcal{E}_{c,\delta}$, where cl *denotes the closure in L^1_{loc}, the Cauchy problem* (1.1) (1.2) *has a global entropy admissible solution $u(t, x)$.*

THEOREM 1.2 (see [Le3]). *Assume that* (H1), (H2), *and the L^1 stability condition* (L1) *are satisfied. Then there exists a closed domain $\mathcal{D} \subset L^1_{loc}(\mathbf{R}, \Omega)$, containing all continuous functions $\bar{u}$ satisfying* (i), (ii), (iii) *in Theorem* 1.1, *for some $c, \delta > 0$, and there exists a semigroup $S : \mathcal{D} \times [0, \infty) \longrightarrow \mathcal{D}$ such that*

(i) $||S(\bar{u}, t) - S(\bar{v}, s)||_{L^1} \leq L \cdot (|t - s| + ||\bar{u} - \bar{v}||_{L^1})$ *for all $\bar{u}, \bar{v} \in \mathcal{D}$, all $t, s \geq 0$ and a uniform constant L, depending only on the system* (1.1),
(ii) *for all $\bar{u} \in \mathcal{D}$, the trajectory $t \mapsto S(\bar{u}, t)$ is the solution to* (1.1) (1.2) *given in Theorem* 1.1.

2. Stability conditions for strong rarefactions. Define the square $(n-1)$-dimensional production matrix function

$$\mathbf{P}(\theta) = [p_{ij}(\theta)]_{\substack{i,j:1\dots n,\\ i,j\neq k}} \quad \text{for } \theta \in [0, \Theta],$$

$$p_{ij}(\theta) = \begin{cases} |\langle l_j, [r_i, r_k]\rangle(\mathcal{R}_k(\theta))| & \text{if } i \neq j, \\ \operatorname{sgn}(k-i) \cdot \langle l_i, [r_i, r_k]\rangle(\mathcal{R}_k(\theta)) & \text{if } i = j, \end{cases} \tag{2.1}$$

where $[r_i, r_k] = \mathrm{D}r_i \cdot r_k - \mathrm{D}r_k \cdot r_i$ stands for the Lie bracket of the vector fields r_i and r_k. We then have the following:

(BV) *BV stability condition*: There exist positive smooth functions $w_1 \dots w_{k-1}, w_{k+1} \dots w_n : [0, \Theta] \to \mathbf{R}_+$ such that

$$\mathbf{P}(\theta) \cdot \begin{bmatrix} w_1(\theta) \\ \vdots \\ w_{k-1}(\theta) \\ w_{k+1}(\theta) \\ \vdots \\ w_n(\theta) \end{bmatrix} < \begin{bmatrix} w_1'(\theta) \\ \vdots \\ w_{k-1}'(\theta) \\ -w_{k+1}'(\theta) \\ \vdots \\ -w_n'(\theta) \end{bmatrix} \quad \text{for every } \theta \in (0, \Theta).$$

Here $w_i' = \mathrm{d}w_i/\mathrm{d}\theta$ and the above vector inequality holds componentwise.

Define the mass production matrix function

$$\mathbf{M}(\theta) = [m_{ij}(\theta)]_{\substack{i,j:1\dots n,\\ i,j\neq k}} \quad \text{for } \theta \in [0,\Theta],$$

$$m_{ij}(\theta) = \begin{cases} p_{ij}(\theta)\cdot \dfrac{|\lambda_j-\lambda_k|}{|\lambda_i-\lambda_k|}(\mathcal{R}_k(\theta)) & \text{if } i\neq j,\\ p_{ij}(\theta)+\dfrac{\mathrm{D}\lambda_i\cdot r_k}{|\lambda_i-\lambda_k|}(\mathcal{R}_k(\theta)) & \text{if } i=j. \end{cases} \tag{2.2}$$

Then, we have the following:

(L1) L^1 *stability condition*: There exist positive smooth functions $w_1\dots w_{k-1}, w_{k+1}\dots w_n : [0,\Theta]\to \mathbf{R}_+$ such that the inequality in (BV) is satisfied with $\mathbf{M}(\theta)$ replacing the matrix $\mathbf{P}(\theta)$.

A version of (L1), where all weights w_i are linear functions of the parameter θ, was introduced in [BM]. Condition (L1) is more general, as can be seen from Example 7.3; compare also Remark 7.4. On the other hand, (L1) holds if it is satisfied with constant and equal weights, for some rescaling of the coordinate system $\{r_i\}_{i=1}^n$ (see Corollary 4.2).

In section 3 we will prove that (L1) is stronger than the condition (BV). Below we introduce a third stability condition, guaranteeing the existence result of the type of Theorem 1.1, in the context of the Riemann initial data.

Define the $n\times n$ transport matrix function $\mathbf{T}(\theta)$ to be the solution of the following ODE system:

$$\begin{cases} \dfrac{\mathrm{d}}{\mathrm{d}\theta}\mathbf{T}(\theta) = \mathrm{D}r_k(\mathcal{R}_k(\theta))\cdot\mathbf{T}(\theta), \quad \theta\in[0,\Theta],\\ \mathbf{T}(0) = \mathrm{Id}_n. \end{cases} \tag{2.3}$$

Also, for any $\theta_1,\theta_2\in[0,\Theta]$ with $\theta_1\le\theta_2$, let $F(\theta_1,\theta_2)$ be the $n\times n$ matrix whose columns $c_i(\theta_1,\theta_2)\in\mathbf{R}^n,\ i:1\dots n$ are given by

$$\begin{aligned} c_i(\theta_1,\theta_2) &= \mathbf{T}(\theta_2)\cdot\mathbf{T}(\theta_1)^{-1}\cdot r_i(\mathcal{R}_k(\theta_1)) \quad \text{for } i:1\dots k-1,\\ c_i(\theta_1,\theta_2) &= r_i(\mathcal{R}_k(\theta_2)) \quad \text{for } i:k\dots n. \end{aligned} \tag{2.4}$$

We may now set the following:

(F) *Finiteness condition*: For every $\theta_1,\theta_2\in[0,\Theta]$ with $\theta_1\le\theta_2$, the matrix $F(\theta_1,\theta_2)$ is invertible.

THEOREM 2.1. *Assume* (H1), (H2)*, and let the finiteness condition* (F) *hold. There exist* $\epsilon,\delta>0$ *such that for every* $u^-,u^+\in\Omega_\epsilon$ *with* $\lambda_k(u^+)-\lambda_k(u^-)>-\delta$*, the Riemann problem* (1.1) (1.2) *with*

$$\bar u = u(0,x) = \begin{cases} u^-, & x<0,\\ u^+, & x>0, \end{cases} \tag{2.5}$$

has the unique self-similar solution, attaining states inside Ω_ϵ*. The solution is composed of* $n-1$ *weak waves of families* $1\dots k-1, k+1\dots n$*, and a* k*th rarefaction wave or a weak* k*th shock.*

Proof. By a standard argument the assumptions (H1) and (H2) imply the assertion for $u^-,u^+\in\Omega_\epsilon$ such that $|\lambda_k(u^+)-\lambda_k(u^-)|<\delta$, if only δ and ϵ are small

[L, B]. We will prove that the invertibility of $F(0,\Theta)$ is sufficient for the solvability of (1.1) (2.5) whenever $||u^- - u_l|| < \delta$ and $||u^+ - u_r|| < \delta$ with a small $\delta > 0$. By a compactness argument, the proof will then be complete.

For each $i : 1 \dots n$ and $u \in \Omega$, call $\sigma \mapsto \mathcal{S}_i(u,\sigma)$ and $\sigma \mapsto \mathcal{R}_i(u,\sigma)$ the ith shock and the ith rarefaction curves through the point u [L, Sm]. In particular, by (1.3), we have $\mathcal{R}_k(u_l,\theta) = \mathcal{R}_k(\theta)$. Both curves are defined at least locally—that is, for $\sigma \in (-\epsilon,\epsilon)$—and have second order contact at $\sigma = 0$. The ith wave curve $\sigma \mapsto \mathcal{W}_i(u,\sigma)$ is obtained by taking the positive part of $\mathcal{R}_i$ ($\sigma \geq 0$) and the negative part of $\mathcal{S}_i$ ($\sigma < 0$).

Define an auxiliary $\mathcal{C}^2$ function $G(u^-,u^+,\sigma_1 \dots \sigma_n) \in \mathbf{R}^n$, whose arguments stay close to $u_l, u_r, \sigma_i = 0$ for $i \neq k$ and $\sigma_k = \Theta$, respectively:

$$G(u^-,u^+,\sigma_1 \dots \sigma_n) = \mathcal{W}_n(\sigma_n) \dots \circ \mathcal{W}_{k+1}(\sigma_{k+1}) \circ \mathcal{R}_k(\sigma_k) \\ \circ \mathcal{W}_{k-1}(\sigma_{k-1}) \dots \circ \mathcal{W}_1(u^-,\sigma_1) - u^+.$$

Notice that by (1.3) the function $\mathcal{R}_k(u,\sigma)$ is defined on $\Omega_\epsilon \times (-\epsilon, \Theta+\epsilon)$ for a small $\epsilon > 0$. We clearly have

$$\frac{\partial G}{\partial(\sigma_1 \dots \sigma_n)}(u_l, u_r, \sigma_i = 0 \text{ for } i \neq k \text{ and } \sigma_k = \Theta) = F(0,\Theta),$$

as $\mathrm{d}/\mathrm{d}\sigma \mathcal{W}_i(u,0) = r_i(u)$ and $\mathrm{d}/\mathrm{d}\sigma \mathcal{R}_k(u,0) = r_k(u)$ for every $u \in \Omega$. Since $F(0,\Theta)$ is invertible, by implicit function theorem we conclude the result. ∎

Remark 2.2. We have used the following property of the matrix $\mathbf{T}(\theta)$:

$$\mathbf{T}(\theta) \cdot r_i(u_l) = \lim_{\epsilon \to 0} \frac{\mathcal{R}_k(u_l + \epsilon r_i(u_l), \theta) - \mathcal{R}_k(\theta)}{\epsilon}. \tag{2.6}$$

For $i < k$, the left-hand side of (2.6) is equal to $c_i(0,\theta)$. Thus the first $k-1$ columns of the finiteness matrix $F(\theta_1,\theta_2)$ are equal to the eigenvectors at $\mathcal{R}_k(\theta_1)$ corresponding to characteristic families $i < k$ (slow modes), transported by the flow of the ODE (1.3) to the point $\mathcal{R}_k(\theta_2)$. The condition (F) simply says that this set of vectors can be completed by the remaining right eigenvectors at $\mathcal{R}_k(\theta_2)$ (that is, the eigenvectors corresponding to the fast modes $i \geq k$) to form a basis of $\mathbf{R}^n$. Obviously, the kth column c_k in (2.4) can be computed by any of the two formulae because the flow of (1.3) preserves the kth eigenvector: $\mathbf{T}(\theta_2) \cdot \mathbf{T}(\theta_1)^{-1} \cdot r_k(\mathcal{R}_k(\theta_1)) = r_k(\mathcal{R}_k(\theta_2))$.

We have shown that the invertibility of $F(0,\Theta)$ implies the solvability of any Riemann problem (1.1) (2.5) close to the initial data ($u^- = u_l, u^+ = u_r$). This condition is strictly weaker than (F), as shown by the Example 7.1. Also, it follows from Example 7.1 that (F) is a nontrivial condition.

3. A proof of (L1) ⇒ (BV) ⇒ (F). In this section we prove the basic relation among the three stability conditions from section 2. We first establish an abstract lemma on matrix analysis.

LEMMA 3.1. *Let $\tilde{\mathbf{P}}(\theta) = [\tilde{p}_{ij}(\theta)]_{i,j:1\dots n}$ be a continuous $n \times n$ matrix function, defined on an interval $[0,\Theta]$. Fix $k : 1 \dots n$ and define an associated matrix function $\hat{\mathbf{P}}(\theta) = [\hat{p}_{ij}(\theta)]_{i,j:1\dots n}$ by*

$$\hat{p}_{ij}(\theta) = \begin{cases} |\tilde{p}_{ij}(\theta)| & \text{if } i \neq j, \\ (\text{sgn } (i-k)) \cdot \tilde{p}_{ii}(\theta) & \text{if } i = j. \end{cases}$$

Assume that there exist positive smooth functions $w_1 \dots w_n : [0,\Theta] \to \mathbf{R}_+$ *such that the following vector inequality is satisfied componentwise:*

$$\hat{\mathbf{P}}(\theta)\cdot\begin{bmatrix} w_1(\theta)\\ \vdots\\ w_n(\theta)\end{bmatrix} < \begin{bmatrix} w_1'(\theta)\\ \vdots\\ w_{k-1}'(\theta)\\ -w_k'(\theta)\\ \vdots\\ -w_n'(\theta)\end{bmatrix} \quad \text{for every } \theta\in(0,\Theta). \tag{3.1}$$

Then we have the following:

(i) *Let* $b:[0,\Theta]\longrightarrow\mathbf{R}^n$, $b(\theta)=(b_1(\theta)\dots b_n(\theta))$ *satisfy*

$$\frac{\mathrm{d}}{\mathrm{d}\theta}b(\theta) = b(\theta)^t\cdot\tilde{\mathbf{P}}(\theta) \quad \text{for } \theta\in[0,\Theta], \tag{3.2}$$

$$\sum_{i=1}^{n}|b_i(0)|>0. \tag{3.3}$$

The above implies that

$$\sum_{i<k}\Big(|b_i(\Theta)|w_i(\Theta)-|b_i(0)|w_i(0)\Big) > \sum_{i\geq k}\Big(|b_i(\Theta)|w_i(\Theta)-|b_i(0)|w_i(0)\Big). \tag{3.4}$$

(ii) *Calling* B *the solution of the matrix differential equation,*

$$\begin{cases}\dfrac{\mathrm{d}}{\mathrm{d}\theta}B(\theta)=\tilde{\mathbf{P}}(\theta)\cdot B(\theta), \quad \theta\in[0,\Theta],\\ B(0)=\mathrm{Id}_n,\end{cases} \tag{3.5}$$

the $(k-1)\times(k-1)$ *principal minor of* $B(\Theta)$ *is invertible.*

Proof. (i). Using (3.2), (3.3), and (3.1) we obtain the following:

$$\begin{aligned}&\sum_{i<k}(\operatorname{sgn} b_i)\cdot(b_i\cdot w_i)' - \sum_{i\geq k}(\operatorname{sgn} b_i)\cdot(b_i\cdot w_i)'\\ &\quad> \sum_{i=1}^{n}\left((\operatorname{sgn} b_i)\cdot(\operatorname{sgn}(k-i))\cdot w_i\cdot\sum_{j=1}^{n}b_j\tilde{p}_{ji}\right)+\sum_{i=1}^{n}\left(|b_i|\cdot\sum_{j=1}^{n}w_j\hat{p}_{ij}\right)\\ &\quad= \left[\sum_{i\neq j}|b_i|w_j\hat{p}_{ij}+(\operatorname{sgn} b_j)(\operatorname{sgn}(k-j))\cdot b_iw_j\tilde{p}_{ij}\right]\\ &\qquad\qquad+\left[\sum_{i=1}^{n}|b_i|w_i\hat{p}_{ii}+(\operatorname{sgn}(k-i))\cdot|b_i|w_i\tilde{p}_{ii}\right]\\ &\quad\geq \left[\sum_{i\neq j}|b_iw_j\hat{p}_{ij}|-|b_iw_j\tilde{p}_{ij}|\right]+\left[\sum_{i=1}^{n}|b_i|w_i(\hat{p}_{ii}+(\operatorname{sgn}(k-i))\cdot\tilde{p}_{ii})\right].\end{aligned} \tag{3.6}$$

Since $\hat{p}_{ii}=-(\operatorname{sgn}(k-i))\tilde{p}_{ii}$ for every $i:1\dots n$, and $|\tilde{p}_{ij}|=|\hat{p}_{ij}|$ for $i\neq j$, we conclude that the right-hand side of (3.6) is nonnegative, and thus,

$$\forall\,\theta\in[0,\Theta]\quad\sum_{i<k}(\operatorname{sgn} b_i)(\theta)\cdot(b_i\cdot w_i)'(\theta) > \sum_{i\geq k}(\operatorname{sgn} b_i)(\theta)\cdot(b_i\cdot w_i)'(\theta). \tag{3.7}$$

Applying $\int_0^\Theta \mathrm{d}\theta$ to both sides of (3.7) we now arrive at (3.4).

(ii). We fix $k > 1$ and argue by contradiction. If the $(k-1) \times (k-1)$ principal minor of $B(\Theta)$ was singular, then there would exist $b : [0, \Theta] \longrightarrow \mathbf{R}^n$ satisfying (3.2), (3.3) together with

$$\forall\ i \geq k \quad b_i(0) = 0 \quad \text{and} \quad \forall\ i < k \quad b_i(\Theta) = 0. \tag{3.8}$$

In view of (3.4), the condition (3.8) now implies

$$-\sum_{i<k} |b_i(0)| w_i(0) > \sum_{i \geq k} |b_i(\Theta)| w_i(\Theta),$$

which is clearly a contradiction, as the weights $\{w_i\}$ are all positive functions. ∎

THEOREM 3.2. (BV) ⇒ (F).

Proof. It suffices to show that the existence of positive weights in (BV) implies the invertibility of the matrix $F(0, \Theta)$.

For $\theta \in [0, \Theta]$, let $R(\theta)$ denote the $n \times n$ matrix whose columns are the right eigenvectors of the matrix $\mathrm{D}f(\mathcal{R}_k(\theta))$. Obviously $R(\theta)$ is nonsingular and the rows of its inverse $R(\theta)^{-1}$ provide the basis of left eigenvectors $\{l_i(\mathcal{R}_k(\theta))\}$. It is easily seen that the invertibility of $F(0, \Theta)$ is equivalent to the invertibility of the product $R(\Theta)^{-1} \cdot F(0, \Theta)$, which is in turn equivalent to the following condition:

$$\text{The } (k-1)\times(k-1) \text{ principal minor of } R(\Theta)^{-1} \cdot \mathbf{T}(\Theta) \cdot R(0) \text{ is invertible.} \tag{3.9}$$

Recall that the transport matrix function $\mathbf{T}$ is defined in (2.3).

Let $\tilde{\mathbf{P}}(\theta) = [\tilde{p}_{ij}(\theta)]_{i,j:1\ldots n}$ be the $n \times n$ matrix function, with its coefficients given by

$$\tilde{p}_{ij}(\theta) = \langle l_j, [r_k, r_i] \rangle (\mathcal{R}_k(\theta)), \quad \theta \in [0, \Theta].$$

Let

$$B(\theta) = R(\theta)^{-1} \cdot \mathbf{T}(\theta) \cdot R(0). \tag{3.10}$$

We will show that B satisfies (3.5) on $[0, \Theta]$. Indeed, one has

$$B(0) = R(0)^{-1} \cdot \mathbf{T}(0) \cdot R(0) = R(0)^{-1} \cdot R(0) = \mathrm{Id}_n.$$

Using (3.10) and (2.3), we calculate

$$\begin{aligned} \frac{\mathrm{d}}{\mathrm{d}\theta} B(\theta) &= \left\{ \frac{\mathrm{d}}{\mathrm{d}\theta} \left[R(\theta)^{-1} \right] \cdot \mathbf{T}(\theta) + R(\theta)^{-1} \cdot \frac{\mathrm{d}}{\mathrm{d}\theta} \mathbf{T}(\theta) \right\} \cdot R(0) \\ &= \left\{ -R(\theta)^{-1} \cdot \frac{\mathrm{d}}{\mathrm{d}\theta} \left[R(\theta) \right] \cdot R(\theta)^{-1} \cdot \mathbf{T}(\theta) + R(\theta)^{-1} \cdot \mathrm{D}r_k(\theta) \cdot \mathbf{T}(\theta) \right\} \cdot R(0) \\ &= \left\{ -R(\theta)^{-1} \cdot \frac{\mathrm{d}}{\mathrm{d}\theta} \left[R(\theta) \right] + R(\theta)^{-1} \cdot \mathrm{D}r_k(\theta) \cdot R(\theta) \right\} \cdot R(\theta)^{-1} \cdot \mathbf{T}(\theta) \cdot R(0). \end{aligned} \tag{3.11}$$

Since it is clear that

$$\tilde{\mathbf{P}}(\theta) = R(\theta)^{-1} \cdot \left[\mathrm{D}r_k(\theta) \cdot R(\theta) - \frac{\mathrm{d}}{\mathrm{d}\theta} R(\theta) \right],$$

we conclude in view of (3.11) and (3.10) that B satisfies the differential equation in (3.5).

On account of (3.9), it remains thus to prove that the condition (BV) implies the following:

(3.12) The $(k-1)\times(k-1)$ principal minor of $B(\Theta)$ is invertible.

Let $\hat{\mathbf{P}}(\theta) = [\hat{p}_{ij}(\theta)]_{i,j:1\dots n}$ be given by the formula in (2.1) for every $\theta \in [0,\Theta]$. Note that the kth row of $\hat{\mathbf{P}}(\theta)$ contains only zero elements. It is then easy to see that the condition (BV) is equivalent to the existence of positive smooth weights $w_1 \dots w_n : [0,\Theta] \longrightarrow \mathbf{R}_+$ such that (3.1) holds. Indeed, one implication is trivial, and the converse one is obtained by taking

$$w_k(\theta) = \epsilon \cdot (\Theta + 1 - \theta),$$

with $\epsilon > 0$ small enough. Now (3.1) implies (3.12) by Lemma 3.1 and our proof is complete. ∎

Remark 3.3. The implication (F) ⇒ (BV) is not true, as shown by Example 7.5.

We end this section by an easy observation.

THEOREM 3.4. (L1) ⇒ (BV).

Proof. Assume that (L1) holds. For $i \neq k$ define

$$\tilde{w}_i(\theta) = |\lambda_i(\theta) - \lambda_k(\theta)| \cdot w_i(\theta), \quad \theta \in [0,\Theta]. \tag{3.13}$$

We claim that (BV) is satisfied with weights $\{\tilde{w}_i\}_{i\neq k}$ as in (3.13). Indeed, for every $i \neq k$ we have

$$\begin{aligned}
&\left(\sum_{j\neq k} p_{ij}\tilde{w}_j\right) - (\operatorname{sgn}(k-i)) \cdot \tilde{w}_i' \\
&\quad = \left(\sum_{j\neq i,k} p_{ij} \cdot |\lambda_j - \lambda_k| \cdot \tilde{w}_j\right) + p_{ii} \cdot |\lambda_i - \lambda_k| \cdot \tilde{w}_i \\
&\qquad\qquad - \Big(\langle \mathrm{D}\lambda_k, r_k\rangle w_i - \langle \mathrm{D}\lambda_i, r_k\rangle w_i + (\lambda_k - \lambda_i) w_i'\Big) \\
&\quad = |\lambda_i - \lambda_k| \cdot \left\{ \left(\sum_{j\neq i,k} p_{ij} \cdot \frac{|\lambda_j - \lambda_k|}{|\lambda_i - \lambda_k|} \cdot \tilde{w}_j\right) + p_{ii} w_i + \frac{\langle \mathrm{D}\lambda_i, r_k\rangle}{|\lambda_i - \lambda_k|} \cdot w_i \right\} \\
&\qquad\qquad - \langle \mathrm{D}\lambda_k, r_k\rangle w_i \\
&\quad = |\lambda_i - \lambda_k| \cdot \left\{ \left(\sum_{j\neq i,k} m_{ij} w_j\right) + m_{ii} w_i - (\operatorname{sgn}(k-i)) \cdot w_i' \right\} \\
&\qquad\qquad - \langle \mathrm{D}\lambda_k, r_k\rangle w_i,
\end{aligned} \tag{3.14}$$

the last equality being a consequence of (2.2). The right-hand side of (3.14) is clearly negative in view of (L1) and the genuine nonlinearity of the kth characteristic field. This proves the theorem. ∎

4. Miscellaneous properties of (BV) and (L1). In this section we gather several useful properties of the BV and L^1 stability conditions. We mainly focus on (BV) because (L1) has the same structure, and consequently, results on (BV) can be easily translated for (L1) (see Theorem 4.6).

The next theorem states that the condition (BV) is independent of the scaling of eigenvectors $\{r_i\}_{i=1}^n$ in Ω.

THEOREM 4.1. *For every $i : 1 \dots n$ and $u \in \Omega$, define*

$$\tilde{r}_i(u) = \alpha_i(u) \cdot r_i(u),$$

where each rescaling function $\alpha_i : \Omega \longrightarrow \mathbf{R}_+$ is positive and smooth. Call $\{\tilde{l}_i\}_{i=1}^n$ the dual basis to $\{\tilde{r}_i\}_{i=1}^n$ and let $\tilde{\mathcal{R}}_k$ be the corresponding reparametrization of $\mathcal{R}_k$:

$$\begin{aligned} \frac{\mathrm{d}}{\mathrm{d}s}\tilde{\mathcal{R}}_k(s) &= \tilde{r}_k(\tilde{\mathcal{R}}_k(s)), \\ u_l = \tilde{\mathcal{R}}_k(0), \quad u_r &= \tilde{\mathcal{R}}_k(S), \qquad S > 0. \end{aligned}$$

*Then (*BV*) holds iff there exists smooth positive weights $\{\tilde{w}_i(s)\}_{i\neq k}$, defined along the reparametrized rarefaction; $s \in [0, S]$, such that the appropriate vector inequality as in (*BV*) holds.*

Proof. Fix $s \in [0, S]$ and let $\theta \in [0, \Theta]$ be such that $\mathcal{R}_k(\theta) = \tilde{\mathcal{R}}_k(s)$. For every $i, j \neq k$ we have

$$\begin{aligned} \langle \tilde{l}_j, [\tilde{r}_i, \tilde{r}_i]\rangle(\tilde{\mathcal{R}}_k(s)) &= \Big\langle \frac{1}{\alpha_j} l_j,\ \alpha_i\alpha_k \cdot \mathrm{D}r_i \cdot r_k + \alpha_k \cdot \langle \mathrm{D}\alpha_i, r_k\rangle \cdot r_i \\ &\qquad - \alpha_i\alpha_k \cdot \mathrm{D}r_k \cdot r_i - \alpha_i \cdot \langle \mathrm{D}\alpha_k, r_i\rangle \cdot r_k \Big\rangle (\mathcal{R}_k(\theta)) \\ &= \left\{ \frac{\alpha_i}{\alpha_j}\alpha_k \cdot \langle l_j, [r_i, r_i]\rangle + \delta_{ij}\frac{\alpha_k}{\alpha_j} \cdot \langle \mathrm{D}\alpha_i, r_k\rangle \right\} (\mathcal{R}_k(\theta)). \end{aligned} \tag{4.1}$$

Define

$$\tilde{w}_i(s) = \alpha_i(\mathcal{R}_k(\theta)) \cdot w_i(\theta). \tag{4.2}$$

Since $\mathrm{d}\theta/\mathrm{d}s = \alpha_k(\tilde{\mathcal{R}}_k(s))$, by (4.1), (4.2), and (2.1) it follows for every $i \neq k$ that

$$\begin{aligned} &\left(\sum_{j\neq i,k} \tilde{w}_j(s) \cdot |\langle \tilde{l}_j, [\tilde{r}_i, \tilde{r}_k]\rangle(\tilde{\mathcal{R}}_k(s))| \right) \\ &\qquad + \tilde{w}_i(s) \cdot (\mathrm{sgn}\ (k-i)) \cdot \langle \tilde{l}_i, [\tilde{r}_i, \tilde{r}_k]\rangle(\tilde{\mathcal{R}}_k(s)) - (\mathrm{sgn}\ (k-i)) \cdot \tilde{w}_i'(s) \\ &= \left(\sum_{j\neq i,k} w_j(\theta) \cdot |\alpha_i\alpha_k \cdot \langle l_j, [r_i, r_k]\rangle|(\mathcal{R}_k(\theta)) \right) \\ &\qquad\qquad + w_i(\theta) \cdot (\mathrm{sgn}\ (k-i)) \cdot (\alpha_i\alpha_k\langle l_j, [r_i, r_k]\rangle)\,(\mathcal{R}_k(\theta)) \\ &\qquad\qquad + w_i(\theta) \cdot (\mathrm{sgn}\ (k-i)) \cdot (\alpha_k\langle \mathrm{D}\alpha_i, r_k\rangle)\,(\mathcal{R}_k(\theta)) \\ &\qquad - (\mathrm{sgn}\ (k-i)) \cdot \Big\{ w_i'(\theta) \cdot (\alpha_i\alpha_k)(\mathcal{R}_k(\theta)) + w_i(\theta) \cdot (\alpha_k\langle \mathrm{D}\alpha_i, r_k\rangle)(\mathcal{R}_k(\theta)) \Big\} \\ &= (\alpha_i\alpha_k)(\mathcal{R}_k(\theta)) \cdot \left\{ \left(\sum_{j\neq k} p_{ij}(\theta) w_j(\theta) \right) - (\mathrm{sgn}\ (k-i)) \cdot w_i'(\theta) \right\}. \end{aligned} \tag{4.3}$$

Recalling that all the rescalings α_i are positive, we obtain that the negativity of the left-hand side in (4.3) is equivalent to the inequality in (BV). This finishes the proof. ∎

COROLLARY 4.2. *The condition* (BV) *is equivalent to the following one. There exist smooth rescaling of eigenvectors* $\{r_i\}_{i\neq k}$ *along* $\mathcal{R}_k$*, given by functions* $\gamma_i : [0,\Theta] \longrightarrow \mathbf{R}_+$ *such that calling*

$$\tilde{r}_i(\mathcal{R}_k(\theta)) = \gamma_i(\theta)\cdot r_i(\mathcal{R}_k(\theta)) \text{ for } i\neq k \quad \text{and} \quad \tilde{r}_k = r_k,$$

one has for every $i\neq k$ *and every* $\theta\in[0,\Theta]$

$$\left(\sum_{j\neq k,i} |\langle \tilde{l}_j, [\tilde{r}_i,\tilde{r}_k]\rangle(\mathcal{R}_k(\theta))|\right) + (\text{sgn }(k-i))\cdot\langle \tilde{l}_i, [\tilde{r}_i,\tilde{r}_k]\rangle(\mathcal{R}_k(\theta)) < 0. \tag{4.4}$$

Above, the vectors $\{\tilde{l}_i(\mathcal{R}_k(\theta))\}_{i=1}^n$ *are the dual basis to* $\{\tilde{r}_i(\mathcal{R}_k(\theta))\}_{i=1}^n$.

Proof. If (BV) holds, then one may take

$$\gamma_i(\theta) = \frac{1}{w_i(\theta)} \qquad \text{for } i\neq k,\ \theta\in[0,\Theta].$$

On the other hand, if the functions γ_i are given, take $\alpha_i : \Omega \longrightarrow \mathbf{R}_+$ to be any smooth positive reparametrization such that

$$\alpha_i(\mathcal{R}_k(\theta)) = \gamma_i(\theta), \qquad \theta\in[0,\Theta].$$

Since the eigenvectors r_k are not to be rescaled, both implications follow now from Theorem 4.1. ∎

THEOREM 4.3. *The stability condition* (BV) *is satisfied in either of the following cases.*

(i) $k = 1$ *or* n*, that is when the wave in* (1.5) *is of the extreme characteristic field.*

(ii) Θ *is sufficiently small, that is when the wave in* (1.5) *is weak.*

Proof. (i). To fix the ideas, assume that $k = n$. Let Z be any constant $(n-1)\times(n-1)$ matrix whose components are strictly bigger than those of the matrix $\mathbf{P}(\theta)$, for all $\theta\in[0,\Theta]$. Take $w = (w_1\dots w_{k-1}, w_{k+1}\dots w_n)$ to be the solution of

$$w' = Z\cdot w, \qquad w_i(0) = 1 \text{ for } i\neq k. \tag{4.5}$$

Since the fundamental solution of (4.5) has all its components positive, each w_i must be a positive function and consequently the inequality in (BV) holds.

(ii). Define $Z(\theta) = \mathbf{P}(\theta) + \mathrm{Id}_{n-1}$ for $\theta\in[0,\Theta]$. The initial-value problem

$$Z(\theta)\cdot\begin{bmatrix} w_1\\ \vdots\\ w_{k-1}\\ w_{k+1}\\ \vdots\\ w_n\end{bmatrix}(\theta) = \begin{bmatrix} w_1'\\ \vdots\\ w_{k-1}'\\ -w_{k+1}'\\ \vdots\\ -w_n'\end{bmatrix}(\theta), \qquad w_i(0) = 1\,\forall\, i\neq k,$$

has a local solution, remaining positive on some interval $[0,\epsilon]$, and therefore satisfying (BV). ∎

Recall that the system (1.1) is said to have a coordinate system of Riemann invariants [D, Sm, S] if there exist smooth functions $v_1\dots v_n : \Omega\longrightarrow\mathbf{R}$ such that

$$\langle \mathrm{D}v_i, r_j\rangle(u) \quad \begin{cases} = 0 & \text{if } i\neq j,\\ \neq 0 & \text{if } i = j\end{cases} \qquad \text{for every } u\in\Omega. \tag{4.6}$$

Using the Frobenius theorem, one can prove (see [D]) that (4.6) implies

$$[r_i, r_j](u) \in \text{span } \{r_i, r_j\} \qquad \forall\, i,j : 1 \dots n,\ u \in \Omega.$$

Hence the matrix $\mathbf{P}(\theta)$ is diagonal for every $\theta \in [0,\Theta]$ and the inequality in (BV) becomes decoupled. Notice now that for any continuous function $a : [0,\Theta] \longrightarrow \mathbf{R}$, the differential inequality $w'(\theta) \lesseqgtr a(\theta)w(\theta)$ admits a positive solution $w(\theta) = \exp[\int_0^\theta a(s)\mathrm{d}s \mp \theta]$.

We have thus proved the following theorem.

THEOREM 4.4. *If* (1.1) *admits a system of Riemann invariants, then* (BV) *is satisfied, for every* $k : 1 \dots n$.

Remark 4.5. It is well known that every 2×2 hyperbolic system of conservation laws has a coordinate system of Riemann invariants. Therefore any rarefaction wave in such systems satisfies (BV), which is obviously also a consequence of Theorem 4.3(i).

We now restate the results of this section in the context of condition (L1); the detailed verification is left to the reader.

THEOREM 4.6. *The following assertions are true.*

(i) *The* L^1 *stability condition is independent of the scaling of the eigenvectors* $\{r_i\}_{i=1}^n$ *in* Ω. *In particular, it is equivalent to the condition formulated as in Corollary* 4.2 *with the inequality* (4.4) *replaced by*

$$\left(\sum_{j\neq k,i} \Big|(\lambda_j - \lambda_k)\cdot\langle \tilde{l}_j, [\tilde{r}_i, \tilde{r}_k]\rangle\Big|(\mathcal{R}_k(\theta))\right) + \Big((\lambda_k - \lambda_i)\cdot\langle \tilde{l}_i, [\tilde{r}_i, \tilde{r}_k]\rangle\Big)(\mathcal{R}_k(\theta)) + \langle D\lambda_i, r_k\rangle(\mathcal{R}_k(\theta)) < 0.$$

(ii) *Any extreme field* ($k = 1$ *or* n) *rarefaction, or a weak* (Θ *small) rarefaction satisfies* (L1).

(iii) *If* (1.1) *has a coordinate system of Riemann invariants, then* (L1) *holds for every* $k : 1 \dots n$.

In [Le3], the proof of Theorem 1.2 used the form of the mass production coefficients as in (2.2). They may be simplified as follows.

LEMMA 4.7. *For all* $\theta \in [0,\Theta]$ *and all* $i \neq j$ *distinct from* k *there holds*

$$m_{ij}(\theta) = |\langle l_j, \mathrm{D}r_i \cdot r_k\rangle(\mathcal{R}_k(\theta))|, \tag{4.7}$$

$$m_{ii}(\theta) = \text{sgn }(k-i)\cdot\langle l_i, \mathrm{D}r_i \cdot r_k\rangle(\mathcal{R}_k(\theta)). \tag{4.8}$$

Proof. Recall the following useful identity (see [D], pg. 126):

$$\forall j,k \quad \langle \mathrm{D}\lambda_j, r_k\rangle \cdot r_j - \langle \mathrm{D}\lambda_k, r_j\rangle \cdot r_k = \mathrm{D}f\cdot[r_j, r_k] - \lambda_j \mathrm{D}r_j \cdot r_k + \lambda_k \mathrm{D}r_k \cdot r_j. \tag{4.9}$$

Multiplying (4.9) by a left eigenvector l_i we obtain

$$\forall i \notin \{j,k\} \quad (\lambda_i - \lambda_j)\cdot\langle l_i, \mathrm{D}r_j \cdot r_k\rangle = (\lambda_i - \lambda_k)\cdot\langle l_i, \mathrm{D}r_k \cdot r_j\rangle, \tag{4.10}$$

$$\forall j \neq k \quad \langle \mathrm{D}\lambda_j, r_k\rangle = (\lambda_k - \lambda_j)\cdot\langle l_j, \mathrm{D}r_k \cdot r_j\rangle. \tag{4.11}$$

Now (4.7) follows directly from (4.10) and (4.8) is a consequence of (4.11). ∎

5. Discussion of the case $n = 3$, $k = 2$. In view of Theorem 4.3(i), every rarefaction wave (1.3) in a solution to a 2×2 system (1.1), as well as both the slowest and the fastest waves in any $n \times n$ system, is BV (and L^1) stable. In this section

we focus on intermediate field rarefactions in 3×3 systems. In particular, we show the natural correspondence between the conditions in section 2 and the solvability of certain associated Riccati equations. Using this approach we derive several sufficient conditions for (BV) (or (L1)).

Our study relies on a number of abstract matrix analysis results.

LEMMA 5.1. *Let $a, b, c, d : [0, \Theta] \longrightarrow \mathbf{R}$ be continuous functions, b and c nonnegative. Then the vector inequality*

$$\begin{bmatrix} a(\theta) & b(\theta) \\ c(\theta) & d(\theta) \end{bmatrix} \cdot \begin{bmatrix} w_1(\theta) \\ w_2(\theta) \end{bmatrix} < \begin{bmatrix} w_1'(\theta) \\ -w_2'(\theta) \end{bmatrix}, \qquad \theta \in (0, \Theta), \tag{5.1}$$

has a positive solution $w_1, w_2 : [0, \Theta] \longrightarrow \mathbf{R}_+$ iff the Riccati equation

$$v'(\theta) = b(\theta) + [a(\theta) + d(\theta)] \cdot v(\theta) + c(\theta) \cdot v(\theta)^2, \qquad \theta \in (0, \Theta), \tag{5.2}$$

has a positive solution $v : [0, \Theta] \longrightarrow \mathbf{R}_+$.

Proof. 1. If (5.1) holds, then the positive function v can be defined as w_1/w_2. Hence,

$$v' = \frac{w_1'}{w_2} - v \cdot \frac{w_2'}{w_2} > \frac{a \cdot w_1 + b \cdot w_2}{w_2} + v \cdot \frac{c \cdot w_1 + d \cdot w_2}{w_2} = b + [a + d] \cdot v + c \cdot v^2.$$

2. On the other hand, if (5.2) is satisfied for some positive function v, then the inequality

$$w'(\theta) > \epsilon + b(\theta) + [a(\theta) + d(\theta)] \cdot w(\theta) + c(\theta) \cdot w(\theta)^2$$

also has a positive solution $w : [0, \Theta] \longrightarrow \mathbf{R}_+$ if $\epsilon > 0$ is small enough. Define

$$\begin{aligned} w_2(\theta) &= \exp\left(- \int_0^\theta \frac{\epsilon}{w(s)} + d(s) + c(s) w(s) \mathrm{d}s \right), \\ w_1(\theta) &= w(\theta) \cdot w_2(\theta). \end{aligned}$$

It follows that

$$\begin{aligned} w_1' - a w_1 - b w_2 &= w' w_2 + w w_2' - a w w_2 - b w_2 \\ &= w_2 \cdot (w' + w \cdot (\ln w_2)' - a w - b) \\ &= w_2 \cdot (w' - w \cdot (\epsilon / w + d + c w) - a w - b) \\ &= w_2 \cdot \left(w' - \epsilon - b - (a + d) \cdot w - c w^2 \right) > 0 \end{aligned}$$

and

$$w_2' + c w_1 + d w_2 = w_2 \cdot ((\ln w_2)' + c w + d) = - w_2 \cdot \epsilon / w < 0.$$

Therefore, (5.1) holds. ∎

Remark 5.2. In the setting of Lemma 5.1, one can see that $v : [0, \Theta] \longrightarrow \mathbf{R}$ satisfies (5.2) iff the function $w : [0, \Theta] \longrightarrow \mathbf{R}$ defined by

$$w(\theta) = v(\theta) \cdot \exp\left(- \int_0^\theta (a + d)(s) \mathrm{d}s \right)$$

is a solution of the Riccati equation

$$
\begin{aligned}
w'(\theta) =& b(\theta)\cdot\exp\left(-\int_0^\theta (a+d)(s)\mathrm{d}s\right)\\
&+ c(\theta)\cdot\exp\left(\int_0^\theta (a+d)(s)\mathrm{d}s\right)\cdot w(\theta)^2.
\end{aligned}
\tag{5.3}
$$

Thus conditions in Lemma 5.1 are both equivalent to the following one: The initial value problem (5.3) with $w(0)=0$ has the solution defined on $[0,\Theta]$.

LEMMA 5.3. *Let $b,c:[0,\Theta]\longrightarrow \mathbf{R}_+$ be continuous nonnegative functions. Assume that*

$$
\int_0^\Theta c(\theta)\int_0^\theta b(s)\mathrm{d}s\mathrm{d}\theta < 1. \tag{5.4}
$$

Then the initial value problem

$$
\begin{cases} w'(\theta) = b(\theta) + c(\theta)\cdot w(\theta)^2,\\ w(0)=0 \end{cases} \tag{5.5}
$$

has the solution w defined on the entire interval $[0,\Theta]$.

Proof. As in the proof of Lemma 5.1, it is easy to see that the solvability of (5.5) is equivalent to the existence of positive solutions $w_1,w_2:[0,\Theta]\longrightarrow\mathbf{R}_+$ of the following system of two ODEs:

$$
\begin{cases} w_1' = bw_2,\\ w_2' = -cw_1. \end{cases} \tag{5.6}
$$

Indeed, take z to be a positive solution of the equation in (5.5) and define $w_2(\theta)=\int_0^\theta c(s)z(s)\mathrm{d}s$, $w_1(\theta)=z(\theta)w_2(\theta)$. On the other hand, given w_1 and w_2, the function $z=w_1/w_2$ clearly satisfies the ODE in (5.5).

We will prove that assuming (5.4), the solution to (5.6) with initial data

$$
w_1(0)=1, \qquad w_2(0)=C \tag{5.7}
$$

satisfies $w_2(\theta)>0$ for all $\theta\in[0,\Theta]$ if only $C>0$ is large enough. Since, consequently, $w_1>0$, the proof will be complete. We have

$$
\begin{aligned}
w_2(\theta) &= C-\int_0^\theta c(s)w_1(s)\mathrm{d}s = C-\int_0^\theta c(s)\left[1+\int_0^s b(\tau)w_2(\tau)\mathrm{d}\tau\right]\mathrm{d}s\\
&= C-\int_0^\theta c(s)\mathrm{d}s-\int_0^\theta c(s)\int_0^s b(\tau)w_2(\tau)\mathrm{d}\tau\mathrm{d}s.
\end{aligned}
\tag{5.8}
$$

Take $\epsilon\in(0,1)$ and $C>0$ such that

$$
\int_0^\Theta c(\theta)\int_0^\theta b(s)\ \mathrm{d}s\ \mathrm{d}\theta\le\epsilon \quad \text{and} \quad C-\int_0^\Theta c(\theta)\mathrm{d}\theta>\epsilon C.
$$

To obtain a contradiction, suppose that

$$
\min_{[0,\Theta]} w_2 \le 0. \tag{5.9}
$$

Then, by (5.8),

$$\begin{aligned}\max_{[0,\Theta]} w_2 = w_2(\theta_{max}) &\le C - \int_0^{\theta_{max}} c(s)\mathrm{d}s \\ &\quad - \left(\min_{[0,\Theta]} w_2\right) \cdot \int_0^{\theta_{max}} c(s) \int_0^s b(\tau)\mathrm{d}\tau\mathrm{d}s \\ &\le C - \epsilon \cdot \min_{[0,\Theta]} w_2,\end{aligned} \tag{5.10}$$

$$\begin{aligned}\min_{[0,\Theta]} w_2 = w_2(\theta_{min}) &\ge C - \int_0^{\theta_{min}} c(s)\mathrm{d}s \\ &\quad - \left(\max_{[0,\Theta]} w_2\right) \cdot \int_0^{\theta_{min}} c(s) \int_0^s b(\tau)\mathrm{d}\tau\mathrm{d}s \\ &> \epsilon C - \epsilon \cdot \max_{[0,\Theta]} w_2.\end{aligned} \tag{5.11}$$

Combining (5.10) and (5.11) we arrive at

$$\max_{[0,\Theta]} w_2 < C - \epsilon \cdot \left(\epsilon C - \epsilon \cdot \max_{[0,\Theta]} w_2\right),$$

which is equivalent to

$$\max_{[0,\Theta]} w_2 < C.$$

This contradicts (5.7) and thus we see that (5.9) cannot hold, thereby ending the proof. □

By Lemma 5.1, Remark 5.2, and Lemma 5.3, we obtain the following.

THEOREM 5.4. *When $n = 3$ and $k = 2$, then we have the following:*

(i) *The stability condition* (BV) *is equivalent to the existence of a positive solution $v : [0, \Theta] \longrightarrow \mathbf{R}_+$ of the Riccati equation*

$$v'(\theta) = p_{13}(\theta) + (p_{11}(\theta) + p_{33}(\theta)) \cdot v(\theta) + p_{31}(\theta) \cdot v(\theta)^2. \tag{5.12}$$

(ii) *In particular,* (BV) *is satisfied if*

$$\int_0^{\Theta} \int_0^{\theta} e^{\int_s^{\theta} p_{11}+p_{33}} \cdot p_{13}(s) \cdot p_{31}(\theta)\mathrm{d}s\mathrm{d}\theta < 1. \tag{5.13}$$

Remark 5.5. Condition (5.13) is certainly satisfied if p_{13} or p_{31} are equal to 0. We also see that in this case (5.12) becomes the Bernoulli or the linear equation, respectively. On the other hand, in general (5.13) is strictly weaker than the condition postulated in Theorem 5.4(i). Indeed, when $p_{11} = p_{33} = 0$ and $p_{13}(\theta) = b > 0$, $p_{31}(\theta) = c > 0$ are constant functions, then the solution to (5.12) takes the form

$$v(\theta) = \sqrt{b/c} \cdot \mathrm{tg}\left(\sqrt{bc}\theta + \mathrm{arctg}\left(v(0)/\sqrt{b/c}\right)\right).$$

Therefore the condition in (i) is here equivalent to $\Theta\sqrt{bc} < \pi/2$, while (5.13) reduces to: $\Theta^2 \cdot bc/2 < 1$. The former inequality is obviously less restrictive than the latter one.

In view of the above analysis, determining the BV stability of intermediate rarefactions in 3×3 systems of conservation laws reduces to evaluating the position of the blow-up time of the solution to (5.5). In particular the inequality (5.4) provides a sufficient condition for the blow-up to occur after the time Θ. Another proof of this result has been communicated to me by professor Ray Redheffer [R2].

Using the analysis in [R1] one can find other interesting sufficient and necessary conditions in this line. For example [R2], if $c'(0) = 0$, then

$$bc + \frac{1}{2}\left(\frac{c'}{c}\right)' - \frac{1}{4}\left(\frac{c'}{c}\right)^2 < \frac{\pi^2}{4} \qquad \text{on } [0,1] \tag{5.14}$$

implies that the corresponding solution exists on $[0,1]$. On the other hand, if (5.14) holds with a converse inequality, then the blow-up occurs at some point $\theta \leq \Theta = 1$. It can be checked that the conditions (5.14) and (5.13) are independent.

As remarked in section 4, the respective results concerning the L^1 stability condition can be easily recovered. In particular, we have the following theorem.

THEOREM 5.6. *When $n = 3$ and $k = 2$, both assertions of Theorem* 5.4 *remain valid also for the condition* (L1) *if we replace the coefficients p_{ij} in* (5.12) *and* (5.13) *by the mass production matrix coefficients m_{ij} given in* (2.2).

6. A remark for the case $n > 3$. When $n = 3$, the numbers p_{11}, p_{33}, p_{13}, and $p_{31}(\theta)$, playing roles in various conditions derived in the previous section, can be seen (in view of (2.1) and standard Taylor estimates [Sm]) as transmission and reflection coefficients in the interactions of small perturbation of families 1 and 3 with parts of the rarefaction wave $\mathcal{R}_k$ (located at θ). In this section we present a generalization of Theorem 5.4(ii) to a particular case of $n \times n$ systems (1.1) in which both transmission matrices are zero.

LEMMA 6.1. *Let k, n be natural numbers and $1 < k < n$. Let $B(\theta)$ and $C(\theta)$ be two continuous matrix functions defined on $[0, \Theta]$, with all its entries nonnegative, and of dimensions $(n-k) \times (k-1)$ and $(k-1) \times (n-k)$, respectively. Assume that*

$$\left\| \int_0^\Theta \int_0^\theta B^t(s) \cdot C^t(\theta) \mathrm{d}s \mathrm{d}\theta \right\|_1 < 1, \tag{6.1}$$

where the norm of a $m \times m$ matrix $X = [x_{ij}]_{i,j:1\ldots m}$ is defined by

$$\| X \|_1 = \max_{j:1\ldots m} \sum_{i=1}^m |x_{ij}|.$$

Then there exist positive functions $w_1 \ldots w_{k-1}, w_{k+1} \ldots w_n : [0, \Theta] \longrightarrow \mathbf{R}_+$ such that

$$B(\theta) \cdot \begin{bmatrix} w_{k+1} \\ \vdots \\ w_n \end{bmatrix}(\theta) < \begin{bmatrix} w_1' \\ \vdots \\ w_{k-1}' \end{bmatrix}(\theta), \tag{6.2}$$

$$C(\theta) \cdot \begin{bmatrix} w_1 \\ \vdots \\ w_{k-1} \end{bmatrix}(\theta) < -\begin{bmatrix} w_{k+1}' \\ \vdots \\ w_n' \end{bmatrix}(\theta), \tag{6.3}$$

componentwise, for all $\theta \in (0, \Theta)$.

Proof. We will prove that under the condition (6.1), the system of ODEs obtained by replacing the inequalities signs in (6.2) (6.3) by equalities has a positive solution $w_1 \dots w_{k-1}, w_{k+1} \dots w_n$ on $[0, \Theta]$. This will clearly complete the proof since the inequality in (6.1) is strict.

Let $w_i(0) = 1$ for all $i < k$, and $w_i(0) = C$ for all $i > k$ and some constant $C > 0$. Notice that the positivity of $w_1 \dots w_{k-1}$ is now implied by the positivity of $w_{k+1} \dots w_n$. We have, for every $\theta \in [0, \Theta]$,

$$\begin{aligned}\begin{bmatrix} w_{k+1} \\ \vdots \\ w_n \end{bmatrix}(\theta) &= \begin{bmatrix} w_{k+1} \\ \vdots \\ w_n \end{bmatrix}(0) - \int_0^\theta C(s) \cdot \begin{bmatrix} w_1 \\ \vdots \\ w_{k-1} \end{bmatrix}(s)\mathrm{d}s \\ &= \begin{bmatrix} w_{k+1} \\ \vdots \\ w_n \end{bmatrix}(0) - \int_0^\theta C(s)\mathrm{d}s \cdot \begin{bmatrix} w_1 \\ \vdots \\ w_{k-1} \end{bmatrix}(0) \\ &\qquad - \int_0^\theta C(s) \int_0^s B(\tau) \cdot \begin{bmatrix} w_{k+1} \\ \vdots \\ w_n \end{bmatrix}(\tau)\mathrm{d}\tau\mathrm{d}s. \end{aligned} \tag{6.4}$$

To prove that $w_{k+1} \dots w_n$ remain positive we argue by contradiction. Assume there exists $\theta_0 \in [0, \Theta]$ such that

$$\forall \theta \in [0, \theta_0) \quad \forall i > k \quad w_i(\theta) > 0 \quad \text{and} \quad \exists s > k \quad w_s(\theta_0) = 0. \tag{6.5}$$

Then, for every $\theta \in [0, \theta_0)$ and every $i < k$ there holds $w_i(\theta) > 0$. Hence

$$\forall \theta \in [0, \theta_0] \quad \forall i > k \quad w_i(\theta) \le w_i(0) = C.$$

Consequently, by (6.4)

$$\begin{aligned} 0 = w_s(\theta_0) &\ge C - \int_0^\Theta \sum_{j=1}^{k-1} C_{ij}(s)\mathrm{d}s - C \cdot \int_0^{\theta_0} \int_0^s \sum_{j=1}^{k-1} \left(C(s) \cdot B(\tau)\right)_{ij} \mathrm{d}\tau\mathrm{d}s \\ &\ge C - \left|\left| \int_0^\Theta C^t(s)\mathrm{d}s \right|\right|_1 - C \cdot \left|\left| \int_0^\Theta \int_0^\theta B^t(s) \cdot C^t(\theta)\mathrm{d}s\mathrm{d}\theta \right|\right|_1. \end{aligned} \tag{6.6}$$

The right-hand side of (6.6) is strictly positive for a large constant C by (6.1). This contradiction proves that θ_0 in (6.5) does not exist and the lemma follows. ∎

Recall now the definition (2.1) and take

$$\begin{aligned} A &= [p_{ij}]_{i,j:1\dots k-1}, & B &= [p_{ij}]_{\substack{i:1\dots k-1,, \\ j:k+1\dots n}} \\ C &= [p_{ij}]_{\substack{i:k+1\dots n, \\ j:1\dots k-1}} & D &= [p_{ij}]_{i,j:k+1\dots n}. \end{aligned}$$

We see that if A and D are zero matrices, then the condition (6.1) clearly implies (BV). Both this condition and (5.13) were postulated in [Scho] to be sufficient for the existence result as in Theorem 1.1. Using Lemma 6.1 to appropriate blocks of the mass production matrix $\mathbf{M}$, it is also not difficult to find the respective condition implying the L^1 stability.

In the general case, when A and D are not necessarily zero, one expects the following condition to be sufficient for (BV) to hold:

(6.7)
$$\left\| \int_0^{\Theta} \int_0^{\theta} \left[X^D(\theta) \cdot C(\theta) \cdot \left(X^{-A}(\theta)\right)^{-1} \cdot X^{-A}(s) \cdot B(s) \cdot \left(X^D(s)\right)^{-1} \right]^t \mathrm{d}s\mathrm{d}\theta \right\|_1 < 1,$$

where X^{-A} and X^D are the fundamental solutions of the ODEs

$$\begin{cases} \left(X^{-A}\right)' = -X^{-A} \cdot A, \\ X^{-A}(0) = \mathrm{Id}_{k-1} \end{cases} \qquad \begin{cases} \left(X^{D}\right)' = X^{D} \cdot D, \\ X^{D}(0) = \mathrm{Id}_{n-k.} \end{cases}$$

By a change of variables, (6.7) becomes (6.1) (now with different matrices C and B) and Lemma 6.1 can be used to recover (BV) under additional assumptions. Namely, the integrand matrix in (6.7) should have nonnegative components and the fundamental matrix $\left(X^D(\theta)\right)^{-1}$ should have positive diagonal and nonnegative off-diagonal components for each θ. This is the case when, for example, the transmission matrices A and D are diagonal.

7. Examples. In this section we present a number of examples complementing the analysis in sections 2–6. We will usually define a strictly hyperbolic matrix $\mathcal{A}(u)$, for u in a neighborhood of $\mathcal{R}_k$ given by (1.3). We set $\Theta = 1$. The right and left eigenvectors $\{r_i\}_{i=1}^n$, $\{l_i\}_{i=1}^n$ of $\mathcal{A}(u)$ will be used to compute the coefficients in $\mathbf{P}(\theta)$ or $\mathbf{T}(\theta)$. We will not necessarily have $\mathcal{A}(u) = \mathrm{D}f(u)$ for some smooth flux f.

Example 7.1. $F(0,\Theta)$ is invertible but $F(\theta_1,\theta_2)$ is not, for some $0 < \theta_1 < \theta_2 < \Theta$. Thus, in particular, the condition (F) is not satisfied.

Let $n = 3, k = 2$. Set $\mathcal{A}$ to be any strictly hyperbolic 3×3 matrix with the eigenvectors given by

$$r_1(x,y,z) = [\cos 2y,\ 0,\ \sin 2y]^t, \qquad r_2(x,y,z) = [0,\ -1,\ 0]^t,$$
$$r_3(x,y,z) = [-\sin y,\ 0,\ \cos y]^t.$$

Take $\mathcal{R}_2(\theta) = (0, 1-\theta, 0)$. Obviously $\mathbf{T} = \mathrm{Id}_3$. Therefore the matrix $F(0,1) = [r_1(0,1,0), r_2, r_3(0,0,0)]$ is invertible, but $F(1-\pi/4, 1)$ is not as $r_1(0,\pi/4,0) = r_3(0,0,0) = [0,0,1]^t$. □

Remark 7.2. In Example 7.1 take $r_2(x,y,z) = [0,1,0]^t$. Consider the rarefaction $\mathcal{R}_2(\theta) = (0,\theta,0)$ defined on $[0,1]$ and joining the same states as before, but in the reverse order. Using the analysis in section 5 one can prove that the condition (BV) is now equivalent to the existence of the nonnegative solution to the problem

$$\begin{cases} v'(y) = \dfrac{2}{\cos y} - 3(\tan y)v(y) + \dfrac{1}{\cos y}v(y)^2, \qquad y \in [0,1], \\ v(0) = 0. \end{cases}$$

The author used Maple to check that the solution exists on the whole interval $[0,1]$. Thus, in particular, (F) is satisfied along the "inverse rarefaction curve" (with respect to Example 7.1) $\mathcal{R}_2(\theta)$.

Example 7.3. The condition (BV) is satisfied but the weights $\{w_i\}_{i=1}^n$ cannot be taken to be linear.

Indeed, if we requested the weights $\{w_i\}_{i\neq k}$ in (BV) to be linear, then the condition would no longer be invariant under rescalings of the eigenvector basis (compare

Theorem 4.1). Let $n = 2, k = 2$. Take $\mathcal{A}(u)$ to be any smooth strictly hyperbolic 2×2 matrix whose right eigenvectors r_1, r_2 satisfy

$$r_1(\theta, 0) = [\sqrt{1 - \exp(2\theta - 4)},\ \exp(\theta - 2)]^t, \qquad r_2(\theta, 0) = [1\ , 0]^t.$$

By Theorem 4.3 (i), the condition (BV) must be satisfied for any rarefaction in this system. Take $\mathcal{R}_2(\theta) = (\theta, 0)$ and calculate

$$\begin{aligned} p_{11}(\theta) &= \langle \mathrm{D}r_1(\theta, 0) \cdot r_2(\theta, 0), l_1(\theta, 0)\rangle \\ &= \left[\mathrm{d}\sqrt{1 - \exp(2\theta - 4)}/\mathrm{d}\theta,\ \exp(\theta - 2)\right] \cdot \begin{bmatrix} 0 \\ \exp(2 - \theta) \end{bmatrix} = 1. \end{aligned}$$

If $w_1 > 0$ in (BV) could be taken linear, we would then have

$$p_{11} \cdot (w_1(0) + w_1' \cdot \theta) < w_1'.$$

This inequality, however, fails to be true on the interval $[1 - w_1(0)/w_1', 1)$. □

Remark 7.4. Note that all elements of the production matrix in Example 7.3 are nonnegative. This shows that the condition (BV) is indeed stronger than the BV stability version of the L^1 stability condition (3.44) from [BM], where all the second order coefficients p_{ij} (including the diagonal elements p_{ii}) are taken in the absolute value, and the existence of a linear positive solution $\{w_i\}_{i=1}^n$ to the corresponding vector inequality is asked. On the other hand, the existence of linear weights satisfying the inequality in (BV) with a matrix $\mathbf{P}$ with bigger components clearly implies our BV stability condition, which thus can be seen as a generalization of the argument in [BM].

Example 7.5. The condition (F) is satisfied but (BV) is not.

Let $n = 3, k = 2$. Take $\mathcal{A}(u = (x, y, z))$ to be a smooth 3×3 strictly hyperbolic matrix whose eigenvectors are given by

$$r_1(x, y, z) = [1, 0, 0]^t, \quad r_2(x, y, z) = [az, 1, ax]^t, \quad r_3(x, y, z) = [0, 0, 1]^t,$$

with some $a > \pi/2$. Consider the rarefaction curve $\mathcal{R}_2(\theta) = (0, \theta, 0)$. It is easy to calculate that the production matrix $\mathbf{P}$ has the form

$$\mathbf{P}(\theta) = \begin{bmatrix} 0 & a \\ a & 0 \end{bmatrix}.$$

By Remark 5.5, the condition (BV) is thus equivalent to $|a| < \pi/2$ and so it is not satisfied.

We will show that (F) is satisfied, however. Since

$$\mathrm{D}r_2(\mathcal{R}_2(\theta)) = \begin{bmatrix} 0 & 0 & a \\ 0 & 0 & 0 \\ a & 0 & 0 \end{bmatrix},$$

we have

$$\mathbf{T}(\theta) = \exp(\theta \cdot \mathrm{D}r_2) = \begin{bmatrix} \cosh(a\theta) & 0 & \sinh(a\theta) \\ 0 & 1 & 0 \\ \sinh(a\theta) & 0 & \cosh(a\theta) \end{bmatrix}.$$

Fix $0 < \theta_1 < \theta_2 < 1$. Using a version of (3.9), we see that the matrix $F(\theta_1, \theta_2)$ is invertible iff the first row–first column element of $\mathbf{T}(\theta_1)^{-1} \cdot \mathbf{T}(\theta_2)$ is nonzero. Noting that $\det \mathbf{T}(\theta) = 1$, this element can be easily computed as

$$\cosh(a\theta_1)\cosh(a\theta_2) - \sinh(a\theta_1)\sinh(a\theta_2) = \cosh(a\theta_1 - a\theta_2) > 0. \qquad \square$$

Example 7.6. The study of plane waves in a half space occupied by a hyperelastic solid leads to the following 6×6 system of hyperbolic conservation laws [TT]:

$$\begin{cases} S_x - \rho_0 V_t = 0, \\ V_x - G \cdot S_t = 0. \end{cases} \tag{7.1}$$

Here $S = (s_1, s_2, s_3)$ and $V = (v_1, v_2, v_3)$ are unknown quantities whose evolution is governed by a symmetric 3×3 matrix G containing appropriate derivatives of a sufficiently regular constitutive function $W(\sigma = s_1,\ \tau^2 = s_2^2 + s_3^2)$. The constant ρ_0 is positive. The derivation of the system, its physical relevance, and the related details can be found in [TT]. We are merely interested in verifying the BV stability condition for the rarefaction waves generated from the four intermediate characteristic fields of (7.1). Taking

$$W(\sigma, \tau^2) = \frac{\alpha}{2}\sigma^2 + \frac{\beta}{6}\sigma^3 + \frac{\delta}{4}(\tau^2)^2 \tag{7.2}$$

after a number of calculations [Mu] one arrives at explicit forms of the production matrices $\mathbf{P}$, corresponding to different rarefaction curves (which may be bounded or unbounded, depending on the initial data and the parameters of the system). Although the matrices $\mathbf{P}$ are 5×5 and in general with nonconstant coefficients, by their specific structure the inequality in (BV) can be reduced to studying different Riccati equations of the form

$$v'(\theta) = \frac{A}{B \pm \theta} \cdot (a + bv(\theta) + cv^2(\theta)). \tag{7.3}$$

By a change of variable, (7.3) is equivalent to

$$v'(s) = (a + bv(s) + cv^2(s)). \tag{7.4}$$

Since in each case $a, c > 0,\ b < 0$, and $b^2 - 4ac \geq 0$, the right-hand side of (7.4) has a positive root. Thus (7.4) has a (trivial) positive solution existing for all s. Based on this observation one obtains the BV stability of all rarefaction waves in the model (7.1) with the constitutive function (7.2). Incorporating the term $\sigma\tau^2$ in W may lead to a more complicated analysis [Mu]. $\square$

8. Stability conditions for general patterns of noninteracting large waves. In section 2 we have shown that for a single k-rarefaction the invertibility of the matrix $F(0, \Theta)$ implies the assertion of Theorem 2.1 with (u^-, u^+) close to the extreme states of the reference pattern u_0 in (1.5). For a single k-shock the corresponding property follows from the Majda stability condition [M]. It turns out that in case of multiple waves an additional finiteness condition, accounting for the mutual influence of the strong waves in u_0 is required. The analysis related to the case with strong shocks was the contents of [Le1, Le2].

Below we study the similar problem for a general pattern u_0 of M shock and rarefaction waves of different characteristic families. We also state the respective BV stability condition and prove a useful generalization of Theorem 3.2.

Let $M+1$ (with $2 \le M \le n$) distinct states $\{u_0^q\}_{q=0}^M$ in $\mathbf{R}^n$ be given. Assume that the Riemann problem (u_0^0, u_0^M) for (1.1) has a self-similar solution composed of M (large) waves $\{u_0^{q-1}, u_0^q\}_{q=1}^M$. For each $q : 1 \dots M$, the qth wave joining states (u_0^{q-1}, u_0^q) is said to belong to i_qth characteristic family and all families $i_1 < i_2 < \dots < i_M$ are genuinely nonlinear. The waves can be of two types.

(i) Stable rarefaction waves, that is,

$$\begin{aligned} &\frac{\mathrm{d}}{\mathrm{d}\theta}\mathcal{R}_{i_q}(\theta) = r_{i_q}\left(\mathcal{R}_{i_q}(\theta)\right), \\ &u_0^{q-1} = \mathcal{R}_{i_q}(0), \quad u_0^q = \mathcal{R}_{i_q}(\Theta_q), \quad \Theta_q > 0, \end{aligned} \tag{8.1}$$

and the matrix $F_q(0, \Theta_q)$, defined as in (2.4) (2.3) with the field number i_q replacing k, is invertible.

(ii) Lax compressive, Majda stable shocks [L, M]. That is, calling Λ^q the speed of the shock we have

$$\Lambda^q \cdot (u_0^q - u_0^{q-1}) = f(u_0^q) - f(u_0^{q-1}), \tag{8.2}$$

$$\lambda_{i_q-1}(u_0^{q-1}) < \Lambda^q < \lambda_{i_q}(u_0^{q-1}) \quad \text{and} \quad \lambda_{i_q}(u_0^q) < \Lambda^q < \lambda_{i_q+1}(u_0^q), \tag{8.3}$$

$$\det\left[r_1(u_0^{q-1}) \dots r_{i_q-1}(u_0^{q-1}),\ u_0^q - u_0^{q-1},\ r_{i_q+1}(u_0^q) \dots r_n(u_0^q)\right] \neq 0. \tag{8.4}$$

We moreover assume that in a sufficiently small neighborhood of the set of states in $\mathbf{R}^n$ attained by u_0, the system (1.1) is strictly hyperbolic, with each characteristic family genuinely nonlinear or linearly degenerate.

For each $q : 0 \dots M$, let Ω^q be an open neighborhood of the state u_0^q. According to [Le2], for each shock (u_0^{q-1}, u_0^q) conditions (8.2), (8.3), (8.4) imply (and by the shock compressibility are essentially equivalent to) the existence of a constitutive function $\Psi^q : \Omega^{q-1} \times \Omega^q \longrightarrow \mathbf{R}^{n-1}$ whose zero locus is composed of pairs of states that can be joined by a stable i_q shock. Moreover, the following $n-1$ vectors are linearly independent:

$$\left\{ \frac{\partial \Psi^q}{\partial u^{q-1}}(u_0^{q-1}, u_0^q) \cdot r_i(u_0^{q-1}) \right\}_{i=1}^{i_q-1} \cup \left\{ \frac{\partial \Psi^q}{\partial u^q}(u_0^{q-1}, u_0^q) \cdot r_i(u_0^q) \right\}_{i=i_q+1}^{n}. \tag{8.5}$$

In case (u_0^{q-1}, u_0^q) is a stable rarefaction wave as in (i), the corresponding function Ψ^q can be defined as

$$\Psi^q(u^{q-1}, u^q) = (\sigma_1 \dots \sigma_{k-1}, \sigma_{k+1} \dots \sigma_n), \tag{8.6}$$

where $\{\sigma_i\}_{i=1}^n$ stand for the strengths of the waves in the solution of the Riemann problem (u^{q-1}, u^q); compare Theorem 2.1 and its proof.

For each $q : 1 \dots M$ define a $(n-1) \times (n-1)$ matrix C_q whose negative first $i_q - 1$ columns, and last $n - i_q$ columns are the vectors in (8.5). Notice that for rarefactions $C_q = \mathrm{Id}_{n-1}$ and thus C_q is invertible for each q. Call

$$\begin{aligned} F_q^{left} &= -C_q^{-1} \cdot \frac{\partial \Psi^q}{\partial u^{q-1}}(u_0^{q-1}, u_0^q) \cdot \left[r_{i_q}(u_0^{q-1}) \dots r_n(u_0^{q-1})\right], \\ F_q^{right} &= C_q^{-1} \cdot \frac{\partial \Psi^q}{\partial u^q}(u_0^{q-1}, u_0^q) \cdot \left[r_1(u_0^q) \dots r_{i_q}(u_0^q)\right]. \end{aligned} \tag{8.7}$$

By an argument as in the proof of Theorem 2.1, we see that the $(n-1) \times i_q$ matrix F_q^{right} expresses strengths of the weak outgoing waves in terms of strengths of waves

perturbing the right state of the Riemann problem (u_0^{q-1}, u_0^q). Analogously, the $(n-1)\times(n-i_q+1)$ matrix F_q^{left} corresponds to perturbations of u_0^{q-1} in the same Riemann problem.

Now define the square $M\cdot(n-1)$ dimensional finiteness matrix $\mathbf{F}$:

$$\mathbf{F}=\begin{bmatrix} [\Theta] & F_1^{right} & & & \\ F_2^{left} & [\Theta] & F_2^{right} & & \\ & F_3^{left} & [\Theta] & F_3^{right} & \\ & & \ddots & \ddots & \\ & & & F_M^{left} & [\Theta] \end{bmatrix}, \tag{8.8}$$

where $[\Theta]$ stands for the $(n-1)\times(n-1)$ zero matrix. The following is a generalization of Theorem 2.1.

(8.9) *Finiteness condition*: 1 is not an eigenvalue of the matrix $\mathbf{F}$.

THEOREM 8.1. *In the above setting let the condition* (8.9) *hold. Then any Riemann problem* $(u^-, u^+)\in\Omega^0\times\Omega^M$ *for* (1.1) *has a unique self-similar solution attaining* $n+1$ *states, consecutively connected by* $(n-M)$ *weak waves and* M *strong waves (shocks or rarefactions) joining states in different sets* Ω^q.

Proof. Define an auxiliary function

$$\begin{aligned} G:\big(\Omega^0\times\Omega^1\times\ldots\times\Omega^M\big)&\\ \times I^{i_1-1}\times I^{i_2-i_1-1}\times I^{i_3-i_2-1}\times\cdots\times I^{i_M-i_{M-1}-1}\times I^{n-i_M}&\longrightarrow\mathbf{R}^{M\cdot(n-1)}, \end{aligned}$$

$$\begin{aligned} &G((u^-,u^1,u^2\ldots u^{M-1},u^+),\\ &\quad(\sigma_1,\sigma_2\ldots\sigma_{i_1-1}),(\sigma_{i_1+1}\ldots\sigma_{i_2-1})\ldots(\sigma_{i_M+1}\ldots\sigma_n))\\ &\qquad=\Psi^1(\mathcal{W}_{i_1-1}(\sigma_{i_1-1})\ldots\circ\mathcal{W}_1(u^-,\sigma_1),\ u^1),\\ &\qquad\quad\Psi^2(\mathcal{W}_{i_2-1}(\sigma_{i_2-1})\ldots\circ\mathcal{W}_{i_1+1}(u^1,\sigma_{i_1+1}),\ u^2),\\ &\qquad\quad\ldots\\ &\qquad\quad\Psi^M(\mathcal{W}_{i_M-1}(\sigma_{i_M-1})\ldots\circ\mathcal{W}_{i_{M-1}+1}(u^{M-1},\sigma_{i_{M-1}+1}),\ u^M), \end{aligned}$$

where

$$u^+=\mathcal{W}_n(\sigma_n)\ldots\circ\mathcal{W}_{i_M+1}(u^M,\sigma_{i_M+1})$$

and I denotes a small interval in $\mathbf{R}$, containing 0. Call A the $M\cdot(n-1)$ dimensional square matrix, that is, the derivative of G with respect to the variables $(u^1\ldots u^{M-1}),(\sigma_1\ldots\sigma_n)$ at the point $\big((u_0^0\ldots u_0^M),(0\ldots0)\big)$. We will show that A is invertible iff the condition (8.9) holds, which by implicit function theorem will complete the proof.

Note first that the invertibility of A is equivalent to the invertibility of the following matrix (which without loss of generality we also call A), of the same dimension:

$$A=\begin{bmatrix} A_1 & B_1^r & & & & \\ & B_1^l & A_2 & B_2^r & & \\ & & & B_2^l & & \\ & & & \ddots & \ddots & \\ & & & & A_M & \widetilde{A}_M \end{bmatrix}. \tag{8.10}$$

Here

$$A_q = \begin{cases} \dfrac{\partial \Psi^1}{\partial u^0}\ (u_0^0, u_0^1) \cdot \big[r_1(u_0^0) \dots r_{i_1-1}(u_0^0)\big] & \text{for } q = 1, \\ \dfrac{\partial \Psi^q}{\partial u^{q-1}}\ (u_0^{q-1}, u_0^q) \cdot \big[r_{i_{q-1}+1}(u_0^{q-1}) \dots r_{i_q-1}(u_0^{q-1})\big] & \text{for } q : 2 \dots M \end{cases}$$

and

$$\widetilde{A}_M = \frac{\partial \Psi^M}{\partial u^M}\ (u_0^{M-1}, u_0^M) \cdot \big[r_{i_M+1}(u_0^M) \dots r_n(u_0^M)\big],$$

$$B_q^l = \frac{\partial \Psi^q}{\partial u^{q-1}}\ (u_0^{q-1}, u_0^q) \cdot \big[r_1(u_0^{q-1}) \dots r_n(u_0^{q-1})\big],$$

$$B_q^r = \frac{\partial \Psi^q}{\partial u^q}\ (u_0^{q-1}, u_0^q) \cdot \big[r_1(u_0^{q-1}) \dots r_n(u_0^{q-1})\big].$$

Introducing (8.7) in (8.10) and permuting the columns of A we observe that A is invertible iff the following matrix (which we again denote by A) is invertible:

$$A = \begin{bmatrix} -C_1 & C_1 \cdot F_1^{right} & & & \\ C_2 \cdot F_2^{left} & -C_2 & C_2 \cdot F_2^{right} & & \\ & & \ddots & \ddots & \\ & & & C_M \cdot F_M^{left} & -C_M \end{bmatrix}. \tag{8.11}$$

Multiplying A by the square block matrix

$$\begin{bmatrix} C_1^{-1} & & & \\ & C_2^{-1} & & \\ & & \ddots & \\ & & & C_M^{-1} \end{bmatrix},$$

we conclude that the invertibility of A in (8.11) is equivalent to the invertibility of $\mathbf{F} - \mathrm{Id}_{M\cdot(n-1)}$ and hence equivalent to (8.9). □

Remark 8.2. Let (u_0^{q-1}, u_0^q) be a stable i_q- rarefaction wave. After neglecting the i_qth rows of the two matrices

$$\begin{aligned} &F(0, \Theta_q)^{-1} \cdot \mathbf{T}_q(\Theta_q) \cdot \big[r_{i_q}(u_0^{q-1}), r_{i_q+1}(u_0^{q-1}) \dots r_n(u_0^{q-1})\big], \\ &F(0, \Theta_q)^{-1} \cdot \big[r_1(u_0^q) \dots r_{i_q-1}(u_0^q), r_{i_q}(u_0^q)\big], \end{aligned} \tag{8.12}$$

they become, respectively, F_q^{left} and F_q^{right}.

We now formulate the following:

(8.13) *BV stability condition for the wave pattern* u_0.

There exist positive continuous weights $\{w_i(u)\}_{i=1}^n$ defined on the set of states u attained by the reference solution u_0 (that is, at the isolated endpoints of shocks and along the rarefaction curves), such that for every $q : 1 \dots M$ the following holds.

(i) If (u_0^{q-1}, u_0^q) is a shock, then

$$\left|F_q^{left}\right|^t \cdot \begin{bmatrix} w_1(u_0^{q-1}) \\ \vdots \\ w_{i_q-1}(u_0^{q-1}) \\ w_{i_q+1}(u_0^q) \\ \vdots \\ w_n(u_0^q) \end{bmatrix} < \begin{bmatrix} w_{i_q}(u_0^{q-1}) \\ \vdots \\ w_n(u_0^{q-1}) \end{bmatrix}$$

$$\text{and} \quad \left|F_q^{right}\right|^t \cdot \begin{bmatrix} w_1(u_0^{q-1}) \\ \vdots \\ w_{i_q-1}(u_0^{q-1}) \\ w_{i_q+1}(u_0^q) \\ \vdots \\ w_n(u_0^q) \end{bmatrix} < \begin{bmatrix} w_1(u_0^q) \\ \vdots \\ w_{i_q}(u_0^q) \end{bmatrix},$$

where the components of a matrix $|A|$ are meant to be absolute values of the components of A, and the above vector inequality is understood componentwise.

(ii) If (u_0^{q-1}, u_0^q) is a rarefaction, then the corresponding BV stability condition (BV) is satisfied, with the production matrix $\mathbf{P}_q$ defined by (2.1) along the rarefaction curve $\mathcal{R}_q$.

Based on the results of [BM, Le1, Le3], we conjecture that the condition (8.13) implies the BV stability of the pattern u_0, in the sense of Theorem 1.1. Also, a similar weighted L^1 stability condition can be easily formulated and will imply the existence of a continuous flow of solutions, as in Theorem 1.2. Our final result is the following theorem.

THEOREM 8.3. *In the above setting, the condition* (8.13) *implies the solvability of any Riemann problem in the vicinity of* $(u_0(1, x_1), u_0(1, x_2))$ *for any* $x_1 < x_2$.

Proof. In view of Theorem 8.1, it is enough to show that (8.13) implies (8.9). By Lemma 3.3 from [Le2] and Remark 8.2, this will be achieved provided we prove the inequalities in (8.13) (i) for each rarefaction (u_0^{q-1}, u_0^q). But this indeed follows from Lemma 3.1 (i), applied to the matrix $\tilde{\mathbf{P}}$ as in the proof of Theorem 3.2. □

Acknowledgments. I thank my colleagues at the University of Chicago for providing the stimulating atmosphere which enabled me to finish this paper. I thank professor Constantine Dafermos for his encouragement and for bringing to my attention the paper [TT]. Professor Alberto Bressan read the manuscript and pointed out a number of improvements.

LYAPUNOV FUNCTIONAL FOR SOLUTIONS OF SYSTEMS OF CONSERVATION LAWS CONTAINING A STRONG RAREFACTION*

MARTA LEWICKA†

Abstract. We study the Cauchy problem for a strictly hyperbolic $n \times n$ system of conservation laws in one space dimension:

$$u_t + f(u)_x = 0,$$

$$u(0,x) = \bar{u}(x).$$

The initial data $\bar{u}$ is a small BV perturbation of a single rarefaction wave with an arbitrary strength. All characteristic fields are assumed to be genuinely nonlinear or linearly degenerate in the vicinity of the reference rarefaction curve. We prove that a suitable BV stability condition yields uniform bounds on the total variation of perturbation, thus implying the existence of a global admissible solution. On the other hand, a stronger L^1 stability condition guarantees the existence of the Lipschitz continuous flow of solutions. Our proof relies on the construction of a Lyapunov functional which is almost decreasing in time and which is equivalent to the L^1 distance between the two solutions.

Key words. conservation laws, large data, rarefaction wave, stability conditions

1. Introduction and statement of the main results.

The system of conservation laws in one space dimension is the following first order system of nonlinear PDEs:

$$u_t + f(u)_x = 0. \tag{1.1}$$

The well-posedness of (1.1) has been the objective of vast research in recent years; however, at a considerable level of generality it remains an open problem. A complete analysis of the issue has been carried out for strictly hyperbolic flux in (1.1) and initial data $\bar{u} \in BV$ having suitably small total variation:

$$u(0,x) = \bar{u}(x). \tag{1.2}$$

Namely, the entropy solutions to (1.1), (1.2) constitute a flow which is Lipschitz continuous with respect to time and initial data. As shown recently in [BiB], its trajectories are the limits of the solutions to the parabolic regularizations of (1.1), when the viscosity parameter vanishes to zero.

Another approach was implemented in a series of papers [BC, BCP, BLY]. It relies on building piecewise constant approximations of solutions to (1.1), (1.2) and then controlling the evolution of their BV or L^1 norm. The fundamental block in this construction is provided by solutions of the Riemann problems, that is, for initial data $\bar{u}$ consisting of a single discontinuity:

$$u(0,x) = \begin{cases} u^- & x < 0, \\ u^+ & x > 0. \end{cases} \tag{1.3}$$

To analyze how much the condition of the smallness of initial data can be relaxed, one wishes to study the well-posedness of (1.1), (1.2) with $\bar{u}$ being a small perturbation of fixed Riemann data of arbitrarily large strength. We assume that the solution of the latter is given and that it consists of a number of waves of different characteristic families. More generally, we wish to study the stability of a reference pattern containing possibly strong but noninteracting waves. The above mentioned results indicate that the trivial pattern with no waves present is stable, as one can control the amount (measured in TV or in the L^1 norm) of initially small perturbation of this pattern.

An example in [BC] points out that this is no longer true in the presence of strong waves. Indeed, one has to account for the waves' mutual influence as well as for their interaction with the perturbation, and therefore extra stability conditions are necessary. These conditions in essence refer to the existence of weights with respect to which the flow generated by the associated linearized problem is a contraction; the linearization is taken at states attained by the reference solution [BM]. This approach was realized in a series of papers [BC, Scho, BM, LeT, Le1]. All these works, however, concentrate mainly on patterns with strong shocks or deal solely with the BV stability in the presence of rarefactions.

In [BC] the authors study systems of two equations and prove their BV and L^1 stability under the corresponding nonresonance conditions relating to two shocks. The presence of strong rarefaction waves is also admitted; however, their stability follows without any additional restrictions [Le3], since they belong to the extreme characteristic fields. More general $n \times n$ systems of conservation laws are studied in [Scho], and the BV stability of patterns, including strong shocks, rarefactions, and contact discontinuities, is established. In particular this yields the local-in-time existence of solutions to (1.1), (1.2) within the class of initial data with bounded variation. In [Le1] we established both the BV and the L^1 stability of patterns of noninteracting strong classical shocks in $n \times n$ systems. The crucial ingredient for proving the L^1 stability was the Lyapunov functional approach from [BLY]; let us anticipate that the same method will be used in the present article. The role of the stability conditions from [BM, Le1] and their relations to [BC, Scho] were explained in [Le2].

As a next step, this paper studies BV and L^1 stability of solutions to (1.1), (1.2) close to a reference pattern which is a single rarefaction wave of arbitrary strength. The results of this work combined with [Le1] thus yield the well-posedness analysis for patterns of noninteracting shock and rarefaction waves (compare also [Le3]). The stability conditions presented in this paper are studied in a complementary work [Le3].

We now state our basic hypotheses and set the notation:

(H1) The system (1.1) is strictly hyperbolic in a domain $\Omega \subset \mathbf{R}^n$ to be specified later. That is, for each $u \in \Omega$ the Jacobian matrix $\mathrm{D}f(u)$ of the smooth flux $f : \Omega \longrightarrow \mathbf{R}^n$ has n distinct and real eigenvalues: $\lambda_1(u) < \cdots < \lambda_n(u)$.

Let $\{r_i(u)\}_{i=1}^n$ be the basis of right eigenvectors of $\mathrm{D}f$; $\mathrm{D}f(u)r_i(u) = \lambda_i(u)r_i(u)$. Call $\{l_i(u)\}_{i=1}^n$ the dual basis of left eigenvectors so that $\langle r_i(u), l_j(u)\rangle = \delta_{ij}$ for all $i, j : 1 \dots n$ and all $u \in \Omega$.

Fix $k : 1 \dots n$ and consider an integral curve $\mathcal{R}_k$ of the vector field r_k joining states $u_l, u_r \in \Omega$:

$$\begin{aligned} &\frac{\mathrm{d}}{\mathrm{d}\theta}\mathcal{R}_k(\theta) = r_k(\mathcal{R}_k(\theta)), \\ &u_l = \mathcal{R}_k(0), \quad u_r = \mathcal{R}_k(\Theta), \qquad \Theta > 0. \end{aligned} \tag{1.4}$$

$\mathcal{R}_k$ is called the rarefaction curve. For a small $c > 0$ we define the domain

$$\Omega = \Omega_c = \{u \in \mathbf{R}^n : \quad ||u - \mathcal{R}_k(\theta)|| < c \quad \text{for some } \theta \in [0, \Theta]\}; \tag{1.5}$$

all the subsequent reasoning will be restricted to this domain, with the parameter c appropriately small. We further assume that

(H2) In Ω, each characteristic field $i : 1 \dots n$ is either linearly degenerate ($\langle \mathrm{D}\lambda_i, r_i \rangle \equiv 0$), or it is genuinely nonlinear, which means that $\langle \mathrm{D}\lambda_i, r_i \rangle > 0$. The kth characteristic field is assumed to be genuinely nonlinear.

In the case of linearly degenerate fields we set $||r_i(u)|| = 1$, while when the ith field is genuinely nonlinear we choose the normalization of right eigenvectors $r_i(u)$ so that $\langle \mathrm{D}\lambda_i(u), r_i(u) \rangle = 1$ for all $u \in \Omega$. In particular we have

$$\langle \mathrm{D}\lambda_k(u), r_k(u) \rangle = 1 \quad \text{for all } u \in \Omega \tag{1.6}$$

and thus $\Theta = \lambda_k(u_r) - \lambda_k(u_l)$.

The piecewise smooth, self-similar function, called the centered rarefaction wave (see Figure 1.1), is given by

$$u_0(t,x) = \begin{cases} u_l & \text{if } x < t\lambda_k(u_l), \\ \mathcal{R}_k(\theta) & \text{if } x = t\lambda_k(\mathcal{R}_k(\theta)), \quad \theta \in [0, \Theta], \\ u_r & \text{if } x > t\lambda_k(u_r) \end{cases} \tag{1.7}$$

and provides an entropy admissible solution of (1.1) [Sm, D]. The objective of this paper is a study of the stability of u_0. Our main results are expressed in the following theorems.

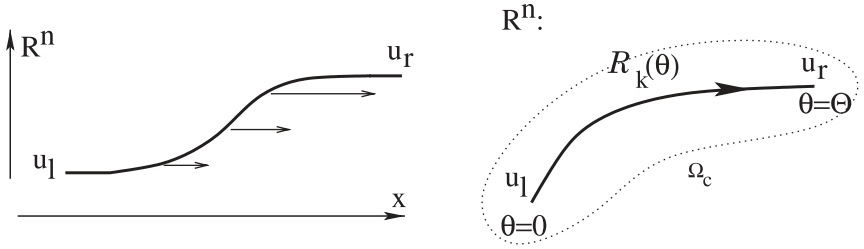

FIG. 1.1.

THEOREM 1. *Assume that* (H1), (H2), *and the BV stability condition* (2.6) *hold. For $c, \delta > 0$ let $\mathcal{E}_{c,\delta}$ denote the set of all continuous functions $\bar{u}$ satisfying*

(i) $\bar{u}(x) \in \Omega_c$ *for all* $x \in \mathbf{R}$,

(ii) $\lim_{x \to -\infty} \bar{u}(x) = u_l$ *and* $\lim_{x \to \infty} \bar{u}(x) = u_r$,

(iii) $|TV(\bar{u}) - |\mathcal{R}_k|| < \delta$, *where* $|\mathcal{R}_k| = TV(\mathcal{R}_k)$ *is the arc-length of the rarefaction curve* $\mathcal{R}_k(\theta)$, $\theta \in [0, \Theta]$.
